Remark 3.1. Consider problem (2.5), (1.2)-(1.4) with $n=m=2$ and $\Omega=[0, U_1]\times[0, U_2]$. Then every optimal pair (x, u) such that $u\in\Omega$, $0=f(x, u)$ must satisfy four equations in the unknowns x_1, x_2, u_1, u_2. In concrete examples, these equations may serve to compute all candidates for optimal equilibria (recall that the maximum principle is only a set of necessary conditions). On the other hand, these equations justify the statement that "in general" there exist at most finitely many optimal equilibria. We shall use this as a hypothesis further below in this section and in § 4.

We proceed to analyze finite-time reachability properties of optimal equilibria in limit sets.

DEFINITION 3.2. An equilibrium e is called strongly optimal if the constant function $x(t)=e$ is the unique optimal trajectory for start in e.

LEMMA 3.3. *Let (x, u) be optimal and suppose that e is a strongly optimal equilibrium in $\omega(x, u)$. Then for every $T>0$ and every neighborhood V of e there exists a neighborhood U of e such that $\varphi(t, x, u)\in U$ implies $\varphi([t, t+T], x, u)\subset V$.*

Proof. Assume, contrary to the assertion, that there exist a neighborhood V of e, $T>0$, and $t_n\to\infty$ with $\varphi(t_n, x, n)\to e$ and $\varphi(t_n+s_n, x, u)\notin V$ for some $s_n\in[0, T]$. Without loss of generality, $s_n\to s\in[0, T]$. We may assume that $\varphi(\cdot, \varphi(t_n, x, u), u(t_n+\cdot))$ converges uniformly on bounded intervals to an optimal $\varphi(\cdot, e, v)$. Since $\varphi(s, e, v)\notin V$ and $\varphi(0, e, v)=e$, this contradicts strong optimality of e.

THEOREM 3.4. *Let $(x, u)\in\mathbb{R}^n_+\times U_{\mathrm{ad}}$ be optimal for* (1.1)-(1.4). *Let $e\in\omega(x, u)$ with the following*:

(i) *e is a strongly optimal equilibrium in* $\operatorname{int}\mathbb{R}^n_+$;

(ii) *There is $u^e\in\operatorname{int}\Omega$ with $f(e, u^e)=0$;*

(iii) *$m\geqq n$ and $f_1(e), \cdots, f_n(e)$ are linearly independent*;

(iv) *R is a C^2-function in a neighborhood of e and $R'(e)=0$, $R''(e)$ is negative definite.*

Then for all $t>0$ sufficiently large $\varphi(t, x, u)=e$.

Proof. (a) Suppose $\psi: V\to\mathbb{R}^n$ is a coordinate change defined on an open neighborhood V of e. If $x(t)$ is in V and satisfies $\dot{x}(t)=f_0(x(t))+\sum_{i=1}^n u_i(t)f_i(x(t))$, then $y(t)=\psi(x(t))$ satisfies $\dot{y}(t)=\dot{\psi}(x(t))(f_0\circ\psi^{-1})y(t)+\sum_{i=1}^n u_i(t)\dot{\psi}(x(t))(f_i\circ\psi^{-1})(y(t))$, which again is a system of equations of the type we are considering. Obviously our assumptions (i)-(iv) carry over. By (iv) and according to the Morse Lemma there is a coordinate change ψ such that $R\circ\psi^{-1}(x)=-\sum_{i=1}^n x_i^2$ for all x in a neighborhood W of $\psi(e)$.

Hence we may without loss of generality assume $R(e+x)=R(e)+\sum_{i=1}^n(x_i-e_i)^2$ in a ball $V(e, r)$ of center e and radius r.

(b) By (ii), (iii) and the implicit function theorem r may be chosen so small that a smooth function $u: V(0, r)\times V(e, r)\to\Omega$ exists such that for all $(y, x)\in V(0, r)\times V(e, r)$ we have $y=f(x, u(x, y))$. In fact, if $F(x)$ is the matrix with columns $f_1(x), \cdots, f_n(x)$ then

$$u(x, y)=F^{-1}(x)(y-f_0(x)).$$

In particular, if $x(t)=a+t(e-a)$, $\dot{x}(t)=e-a=f(x(t), u(x(t), e-a))$ provided $|e-a|<r$. Hence $x(t)=\varphi(t, a, u)$ is an admissible solution of our system at least up to $t=1$ $(u(t)=u(x(t), e-a))$.

(c) We now assume $e\notin\varphi(x, u)$ and try to reach a contradiction to (i). See Fig. 3.1. Choose $T>3$. According to Lemma 3.3 there is by (i) $t>0$ such that $\varphi((t, t+T), x, u)\subset V(e, r)$. By our assumption in (a) there is a first time $s_1\in(0, 1)$ such that for all $s\in(s_1, 1]$

$$R(x_0(s))>R(\varphi(t+s, x, u))$$

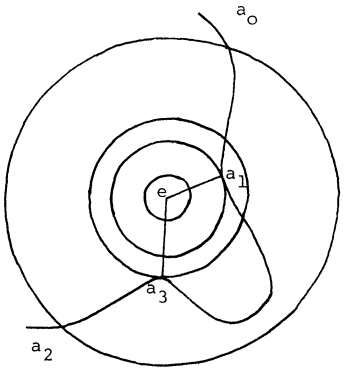

FIG. 3.1. $\hat{\varphi}$ *visits* a_0, a_1, e, a_3, a_2.

where

$$x_0(s) = a_0 + s(e - a_0), \quad a_0 = \varphi(t, x, u).$$

Put

$$a_1 = \varphi(t + s_1, x, u),$$

$$x_1(s) = a_1 + s\frac{|e - a_0|}{|e - a_1|}(e - a_1), \qquad 0 \leqq s \leqq \frac{|e - a_1|}{|e - a_0|} = s_2;$$

then

$$R(x_1(t)) > R(\varphi(t + s_1 + s, x, u)), \qquad 0 \leqq s \leqq s_2.$$

Put

$$a_2 = \varphi(t + T, x, u),$$

$$x_2(s) = e + s(a_2 - e), \qquad 0 \leqq s \leqq 1 = s_3.$$

Note that $s_1 + s_2 + s_3 < 3 < T$.

There is a last time $s_4 \in (0, s_3)$ such that

$$R(x_2(s)) > R(\varphi(t + T - s_3 + s, x, u)), \qquad s \in (0, s_4).$$

Put

$$a_3 = \varphi(t + T - s_3 + s_4, x, u),$$

$$x_3(s) = e + s\frac{|a_2 - e|}{|a_3 - e|}(a_3 - e), \qquad 0 \leqq s \leqq \frac{|a_3 - e|}{|a_2 - e|} = s_4.$$

Then

$$R(x_3(s)) > R(\varphi(t + T - s_3 + s, x, u)), \qquad s \in (0, s_4).$$

Now we combine the x_j's to build a solution that performs better than $\varphi(\cdot, x, u)$. Put

$$\hat{\varphi}(s) = \begin{cases} \varphi(s, x, u), & 0 \leqq s \leqq t + s_1, \\ x_1(s - t - s_2), & t + s_1 \leqq s \leqq t + s_1 + s_2, \\ e, & t + s_1 + s_2 \leqq s \leqq t + T - s_3, \\ x_3(s - t - T + s_3), & t + T - s_3 \leqq s \leqq t + T - s_3 + s_4, \\ \varphi(s, x, u), & t + T - s_3 + s_4 \leqq s. \end{cases}$$

The definition makes sense since $T > s_1 + s_2 + s_3$. Using (b) we may find $v \in U_{\text{ad}}$ such that $\hat{\varphi}(s) = \varphi(s, x, v)$. But

$$\sigma_1 = t + s_1 < t + T - s_3 + s_4 = \sigma_2$$

and

$$R(\varphi(s, x, v)) > R(\varphi(s, x, u)) \quad \text{for } s \in (\sigma_1, \sigma_2),$$
$$R(\varphi(s, x, v)) = R(\varphi(s, x, u)) \quad \text{for } s \notin (\sigma_1, \sigma_2).$$

Therefore $V(x, v) > V(x, u)$ in contradiction to the optimality of (x, u).

Next we give a sufficient condition for optimal solutions to converge to a single optimal equilibrium. This result will be used substantially in the next section.

THEOREM 3.5. *Let* $(x, u) \in \mathbb{R}^n_+ \times U_{\text{ad}}$ *be optimal for* (1.1)-(1.4). *Suppose the following*:

(i) $\omega(x, u)$ *contains at most finitely many optimal equilibria.*

(ii) $\omega(x, u) \subset E = \{y \in \mathbb{R}^n_+ \mid$ *there exists* $v \in \Omega$ *with* $o = f(y, v)\}$.

Then $\omega(x, u)$ *consists of a single optimal equilibrium.*

Proof. Suppose that

$$\# \omega(x, u) \geqq 2.$$

There is $e \in \omega(x, u)$ and a sequence of points $e_n \in \omega(x, u)$ such that $\lim_n e_n = e$ and

$$a = \sup \{R(y) \mid y \in \omega(x, u)\} = \lim_n R(e_n).$$

There is $\tilde{e} \in \omega(x, u)$ such that

$$b = R(\tilde{e}) < a.$$

Otherwise all points in $\omega(x, u)$ would be optimal equilibria and by connectedness $\omega(x, u)$ would contain infinitely many optimal equilibria contrary to (i). We choose numbers b_0, b_1, b_2 with

$$a > b_0 > b_1 > b_2 > b$$

such that there is at most one optimal equilibrium e_1 in $\omega(x, u)$ with $R(e_1) \geqq b_2$.

Choose $(t_k) \subset \mathbb{R}_+$ with $t_k \to \infty$ and $\varphi(t_k, x, u) \to e$. For every $k \in \mathbb{N}$ there are $s_i^k \geqq 0$, $i = 0, 1, 2$, with

$$s_2^k := \inf \{s \geqq 0 \colon R(\varphi(t_k + s, x, u)) < b_2\},$$
$$s_1^k := \sup \{s \leqq s_2^k \colon R(\varphi(t_k + s, x, u)) > b_1\},$$
$$s_0^k := \sup \{s \leqq s_1^k \colon R(\varphi(t_k + s, x, u)) > b_0\}.$$

We may assume that the functions

$$\varphi(t_k + s_0^k + \cdot, x, u)$$

converge uniformly on every bounded interval to an optimal trajectory $\varphi(\cdot, y, v) \subset \omega(x, u)$. Then $y \in E$ and $R(y) = b_0$. Next we show the following: The sequence $t_2^k = s_2^k - s_0^k$, $k \in \mathbb{N}$, is bounded. Otherwise we might assume that $t_2^k < t_2^{k+1}$ and $t_2^k \to \infty$. The functions

$$R(\varphi(t_k + s_0^k + t, x, u)), \qquad t \in [0, t_2^k]$$

have values in

$$V(b_0, b_2) := \{z \colon b_0 \geqq R(z) \geqq b_2\}.$$

Hence also $\varphi(\cdot, y, v)$, $\omega(y, v) \subset V(b_0, b_2)$.

Since $\omega(y, u) \subset E$, Lemma 2.11 implies that $\omega(y, v)$ contains an optimal equilibrium. This contradicts the choice of b_2.

Thus (t_2^k) is bounded and, considering subsequences, we may even assume that $t_2^k \to t_2$ and $t_1^k = s_1^k - s_0^k \to t_1$ with $0 \leqq t_1, t_2 < \infty$. Hence,

$$R(y) = R(\varphi(0, y, v)) = b_0,$$
$$R(\varphi(t, y, v)) \leqq b_0 \quad \text{for } t \in [0, t_1],$$
$$R(\varphi(t, y, v)) \leqq b_1 \quad \text{for } t \in [t_1, t_2],$$
$$R(\varphi(t, y, v)) \leqq a \quad \text{for } t \in [t_2, \infty).$$

We obtain

$$\int_0^\infty e^{-\delta t} R(\varphi(t, y, v))\, dt = \int_0^{t_1} + \int_{t_1}^{t_2} + \int_{t_2}^\infty \leqq \frac{b_0}{\delta}(1 - e^{t_1 \delta}) + \frac{b_1}{\delta}(e^{-t_1\delta} - e^{-t_2\delta}) + \int_{t_2}^\infty.$$

Since $y \in E$ and (y, v) optimal

$$\frac{1}{\delta} R(y) = \frac{b_0}{\delta} \leqq \int_0^\infty e^{-\delta t} R(\varphi(t, y, v))\, dt;$$

hence

$$b_0 \leqq b_0 - b_0\, e^{-t_1\delta} + b_1\, e^{-t_1\delta} - b_1\, e^{-t_2\delta} + \delta \int_{t_2}^\infty,$$

or

$$b_0 \leqq b_1(1 - e^{(t_1 - t_2)\delta}) + \delta\, e^{t_1\delta} \int_{t_2}^\infty R(\varphi(t, y, v))\, dt.$$

Note that the right-hand side is constructed independently of b_0. Hence if $a = +\infty$ we may let b_0 tend to $a = +\infty$, thus obtaining a contradiction since $\int_{t_2}^\infty$ converges to a finite value. Hence we may assume that a is finite and thus

$$b_0 \leqq b_1(1 - e^{(t_1 - t_2)\delta} + a\, e^{(t_1 - t_2)\delta}.$$

Letting b_0 tend to a, we find

$$a(1 - e^{(t_1 - t_2)\delta}) \leqq b_1(1 - e^{(t_1 - t_2)\delta}),$$

leading to the contradiction $a \leqq b_1$ since $\varphi(t_2, y, v) = b_2$, $\varphi(t_1, y, v) = b_1$, and hence $t_1 < t_2$.

Using similar arguments as in the proof above, we can show the analogous result for α-limit sets.

THEOREM 3.6. *Let the assumptions of Theorem* 3.5 *be satisfied for* $\alpha(x, u)$ *instead of* $\omega(x, u)$. *Then* $\alpha(x, u)$ *consists of a single optimal equilibrium.*

Remark 3.7. Let $n = 2$, replace (1.1) by (2.5), and suppose that (2.6) holds. Let $(x, u) \in \mathbb{R}_+^2 \times U_{\text{ad}}$ be optimal. Then when we assume (i), (ii), a slight change in the proof of Theorem 3.5 shows that either $\omega(x, u)$ consists of a single optimal equilibrium or is contained in the boundary of $\mathbb{R}_+^2$. Furthermore the following holds: Let $(y, u) \in \hat{\omega}(x, u)$ with $\omega(y, v) \subset \partial\mathbb{R}_+^2$ such that $\omega(y, v)$ contains only a finite number of optimal equilibria. Then $\omega(y, v)$ consists of a single optimal equilibrium.

Proof. Suppose the assertion is false. Then $\# \omega(y, v) \geqq 2$, and since $\omega(y, v)$ is connected, $\omega(y, v)$ contains infinitely many points. By assumption there is $z = (z_1, z_2) \in \omega(y, v)$, which is not an optimal equilibrium, say with $z_2 = 0$. There is $(z, w) \in \hat{\omega}(x, u)$. Since the first component $\varphi(\cdot, z, w)$ is not constant, it is by Theorem 2.7, say, increasing

(if it is decreasing, analogous arguments will apply). By Remark 2.4, the second component $\varphi_2(t, z, w)$ vanishes for all t. Let $t > 0$ such that the segment between z and $z' = \varphi(t, z, w)$ does not contain an optimal equilibrium. Since $z, z' \in \omega(x, u)$ there are t_n, $s_n \geqq 0$ such that

$$\lim_n t_n = +\infty, \quad \lim_n \varphi(t_n, x, u) = z', \quad \lim_n \varphi(t_n + s_n, x, u) = z$$

and for all $n \in \mathbb{N}$, $t \in [0, s_n]$,

$$z_1 \leqq \varphi_1(t_n + t, x, u) \leqq z_1', \qquad 0 \leqq \varphi_2(t_n + t, x, u) \leqq 1/n.$$

We may assume that the sequence of functions $t \to \varphi(t_n + t, x, u)$ converges locally uniformly to a function $\varphi(\cdot, z', w')$ such that $(z', w') \in \hat{\omega}(x, u)$. If $\lim s_n = +\infty$, then $\omega(z', w') \subset [z_1, z_1'] \times \{0\}$. By Theorem 2.7, $\omega(z', w')$ contains an optimal equilibrium, in contradiction to our assumption.

Therefore a subsequence of (s_n) converges to some $s \in [0, \infty)$. Obviously, $\varphi(s, z', w') = z$. Define

$$w''(\sigma) = w(\sigma) \qquad \text{for } 0 \leqq \sigma \leqq t,$$

$$w''(\sigma) = w'(\sigma - t) \qquad \text{for } t < \sigma \leqq s + t,$$

and extend w'' periodic on $\mathbb{R}_+$ with period $s + t$. Then (z, w'') is optimal and periodic. Now consider (z, w'') as an optimal pair with respect to the restriction of our system to $\mathbb{R}_+ \times \{0\} \simeq \mathbb{R}_+^1$ (Remark 2.4). Since $\varphi(\cdot, z, w'')$ is neither increasing nor decreasing, Theorem 2.7 implies the existence of infinitely many optimal equilibria contrary to the assumption.

4. Poincaré–Bendixson Theorem. The analysis of this section is restricted to two-dimensional systems (i.e., $n = 2$). Our final result, Theorem 4.6, is a generalization of the classical Poincaré-Bendixson Theorem. If we drop the assumption of that theorem that $\varphi(\cdot, x, u)$ is nonself-intersecting, we obtain an optimal periodic solution in a trivial way according to the following proposition.

PROPOSITION 4.1. *Suppose that $(x, u) \in \mathbb{R}_+^n \times U_{\text{ad}}$ is optimal and $\varphi(\cdot, x, u)$ intersects itself, i.e., there are $T_2 > T_1 \geqq 0$ with $\varphi(T_1, x, u) = \varphi(T_2, x, u)$. Then there is $\hat{u} \in U_{\text{ad}}$ such that $(x, \hat{u})$ is optimal and $\varphi(T_1 + s, x, u) = \varphi(T_1 + k(T_2 - T_1) + s, x, \hat{u})$ for $s \in [0, T_2 - T_1]$, $k \in \mathbb{N}$.*

Proof. Define $\hat{u}(t) = u(t)$ for $t \in [0, T_1]$,

$$\hat{u}(T_1 + k(T_2 - T_1) + t) = u(T_1 + t) \quad \text{for } t \in [0, T_2 - T_1], \quad k \in \mathbb{N}.$$

Then the assertion follows since final segments of optimal solutions are optimal.

We call a solution $(x, \hat{u})$ with the property above finally periodic.

For the reader's convenience, we cite the following classical theorem (see, e.g., Beck [3, Cor. C.23]), which will be used frequently.

JORDAN'S CURVE THEOREM. *Let J be a Jordan curve in $\mathbb{R}^2$ (i.e., a homeomorphism from the circle into $\mathbb{R}^2$). Then $\mathbb{R}^2 \setminus \operatorname{Im} J$ has two components, one of which is bounded (called* ins J*) and the other one (called* outs J*) is unbounded. Each one has boundary* Im J *and is simply connected.*

Since the orientation does not concern us, we identify J with its image.

LEMMA 4.2. *Let $(x, u) \in \mathbb{R}_+^2 \times U_{\text{ad}}$ and suppose that the corresponding trajectory $\varphi(\cdot, x, u)$ is nonself-intersecting. Then a local transversal section S has at most one point in common with $\omega(x, u)$. For optimal $\mathbb{R}$-solutions it follows also that S has at most one point in common with $\alpha(x, u)$.*

Proof. As in the theory of uncontrolled differential equations (see, e.g., [1, Lemma 24.1] or [14]) we prove the following: Let (x_i) be a sequence of points in $\varphi(x, u) \cap S$. If (x_i) is increasing on $\varphi(\cdot, x, u)$, then it is also on S. Now suppose that $y_1, y_2 \in \omega(x, u) \cap S$ and $y_1 \neq y_2$. Let U_j be disjoint neighborhoods of y_j, $j = 1, 2$. Then there exists a sequence $t_k \to \infty$ such that

$$\varphi(t_{2k+1}, x, u) \in U_1 \quad \text{and} \quad \varphi(t_{2k}, x, u) \in U_2, \quad k \in \mathbb{N}.$$

By Theorem 2.16, we may choose $U^j = V_1^j$, where (V_0^j, V_1^j, S) are flow boxes around y_j, $j = 1, 2$, and $V_0^1 \cap V_0^2 = \emptyset$. Then there exists a sequence (s_k), $s_k \to \infty$, with

$$\varphi(s_{2k+1}, x, u) \in U_1 \cap S, \qquad \varphi(s_{2k+1}, x, u) \in U_2 \cap S.$$

This contradicts the assertion above.

The same arguments apply to a α-limit sets of optimal $\mathbb{R}$-solutions.

PROPOSITION 4.2. *Let $(x, u) \in \mathbb{R}_+^2 \times U_{\text{ad}}$ be optimal and suppose that $\varphi(\cdot, x, u)$ is nonself-intersecting. Let (y, v) be an optimal $\mathbb{R}$-solution with $\varphi(\mathbb{R}, y, v) \subset \omega(x, u)$. Then $\omega(y, v)$ and $\alpha(y, v)$ consist of equilibria only or $\varphi(\cdot, y, v)$ intersects itself in a point z possessing a local transversal section S.*

Proof. Suppose that $\omega(y, v)$ contains a point z which is not an equilibrium. Then z possesses a local transversal section S by Lemma 2.11. Using a flow box around z we find that $\varphi(y, v) \cap S \neq \emptyset$. Since $\varphi(y, v)$, $\omega(y, v) \subset \omega(x, u)$ and $z \in \omega(y, v) \cap S \subset \omega(x, u) \cap S$ this implies by Lemma 4.2 that $S \cap \omega(x, u) = \{z\}$, and hence $\{z\} = \varphi(y, v) \cap \omega(y, v)$. Thus there is $T_1 \geq 0$ such that $\varphi(T_1, y, v) = z$. Since z is not an equilibrium, there is a neighborhood V_0 of z and $s > T_1$ with $\varphi(s, y, v) \notin V_0$. Using a flow box (V_0, V_1, S) around z, we find a $T_2 > s$ with $\varphi(T_2, y, v) \in S$. Hence $\varphi(T_2, y, v) = \varphi(T_1, y, v) = z$. Thus $\varphi(\cdot, y, v)$ intersects itself in z.

We prepare the proof of the next proposition by the following lemma.

LEMMA 4.4. *Let (C_n) be a decreasing sequence of closed sets in $\mathbb{R}^q$. Define $C := \bigcap_n C_n$, let $n_k \to \infty$, and*

$$D := \{y \in \mathbb{R}^q : \text{there exist } x_{n_k} \text{ with } x_{n_k} \in \partial C_{n_k} \text{ and } x_{n_k} \to y\}.$$

Then $\partial C = D$.

Proof. Suppose $y \in D$, i.e., there are (x_{n_k}) with $x_{n_k} \in \partial C_{n_k}$ and $x_{n_k} \to y$. Let $B(y, \varepsilon)$ be the ball with center y and radius $\varepsilon > 0$. Then for k large enough $x_{n_k} \in B(y, \varepsilon)$. Since $x_{n_k} \in \partial C_{n_k}$ there is $y_{n_k} \in B(y, \varepsilon) \setminus C_{n_k} \subset B(y, \varepsilon) \setminus C$. Since $\varepsilon > 0$ is arbitrary, $y \notin \operatorname{int} C$. Since $C_{n_k} \subset C_{n_l}$ for $k > l$ it follows that $x_{n_k} \in C_{n_l}$ for $k > l$ and, since C_{n_l} is closed, $y \in C_{n_l}$ for all l. Hence $y \in C \setminus \operatorname{int} C = \partial C$.

Conversely suppose that $y \in \partial C$ and note $C = \bigcap_k C_{n_k}$. Then for every $\varepsilon > 0$ there exists $z \in B(y, \varepsilon) \setminus C$. Hence there is n_k such that $y \in B(y, \varepsilon) \setminus C_{n_k}$. Suppose that $B(y, \varepsilon) \cap \partial C_{n_k} = \emptyset$. Then

$$B(y, \varepsilon) = (B(y, \varepsilon) \setminus C_{n_k}) \cup (B(y, \varepsilon) \cap \operatorname{int} C_{n_k}).$$

Since $B(y, \varepsilon)$ is connected and $z \in B(y, \varepsilon) \setminus C_{n_k} \neq \emptyset$ we conclude that $\emptyset = B(y, \varepsilon) \cap \operatorname{int} C_{n_k} = B(y, \varepsilon) \cap C_{n_k} \ni y$. This contradiction shows that there exist $y_{n_k} \in B(y, \varepsilon) \cap \partial C_{n_k}$. Evidently, $\lim y_{n_k} = y$, and hence $y \in D$.

PROPOSITION 4.5. *Let $(x, u) \in \mathbb{R}_+^2 \times U_{\text{ad}}$ be optimal and assume that $\varphi(\cdot, x, u)$ is nonself-intersecting. Suppose that there are $(y, v) \in \hat{\omega}(x, u)$ and $T_2 > T_1$ with*

$$\varphi(T_1, y, v) = \varphi(T_2, y, v) =: z,$$

with z possessing a local transversal section S. Then

$$\omega(x, u) = \varphi([T_1, T_2], y, v).$$

Proof. Since $z \in \omega(x, u)$ we can use a flow box around z to construct inductively a sequence of numbers t_n such that t_{n+1} is the first instant t after t_n with $\varphi(t, x, u) \in S$. Then for all n we have $t_n < t_{n+1}$, $t_n \to \infty$, and $\varphi(t_n, x, n) \to z$. Now define the Jordan arc Γ_n to consist of $\varphi([t_n, t_{n+1}], x, u)$ and the segment on S between $\varphi(t_n, x, n)$ and $\varphi(t_{n+1}, x, u)$. There are two cases.

Case 1. For all n $\operatorname{ins} \Gamma_n \supset \operatorname{ins} \Gamma_{n+1}$.

Case 2. For all n $\operatorname{outs} \Gamma_n \supset \operatorname{outs} \Gamma_{n+1}$.

Let us first consider Case 1. Put $C := \bigcap_n \operatorname{cl} \operatorname{ins} \Gamma_n$. By Lemma 4.4, $\partial C = \omega(x, u)$. Now let $l \in \mathbb{N}$ be arbitrary and consider a flow box (V_0, V_1, S) around z such that V_0 is a ball around z with radius $1/l$. The set V_1 contains a ball around z of positive radius r. Since $(y, v) \in \hat{\omega}(x, u)$, there is $t > 0$ such that

$$|\varphi(t + T_1 + s, x, u) - \varphi(T_1 + s, y, v)| < r, \qquad 0 \leqq s \leqq T_2 - T_1.$$

By the flow box property we may follow $\varphi(t + T_1 + s, x, u)$ starting with $s = 0$ and without leaving V_0 until we reach $t + T_1 + s = t_{l_n}$. Applying the same argument to the instant $t + T_2 - T_1$ we find that the part of $\varphi([t_{n_l}, t_{n_{l+1}}], x, u)$ not contained in $\varphi([t + T_1, t + T_2], x, u)$ is contained in V_0. Hence each $a \in \varphi([t_{n_l}, t_{n_{l+1}}], x, u)$ has a distance less than $1/l$ to some $a' \in \varphi(T_1, T_2], y, v)$. Thus a second application of Lemma 4.4 yields

$$\varphi([T_1, T_2], y, v) = \partial \bigcap_l \operatorname{cl} \operatorname{ins} \Gamma_{n_l} = \partial \bigcap_n \operatorname{cl} \operatorname{ins} \Gamma_n = \omega(x, u).$$

Case 2 can be treated analogously.

The next theorem presents the main result of this paper.

THEOREM 4.6. *Let* $(x, u) \in \mathbb{R}^2_+ \times U_{\text{ad}}$ *be optimal for* (1.1)–(1.4) *with* $\varphi(\cdot, x, u)$ *nonself-intersecting and suppose that* $\omega(x, u)$ *contains only finitely many optimal equilibria. Then one of the following cases occurs*:

(i) *There are* $T > 0$ *and an optimal* $\mathbb{R}$*-solution* $(y, v) \in \hat{\omega}(x, u)$ *such that* $y = \varphi(T, y, v)$ *and* $\omega(x, u) = \varphi([0, T], y, v)$.

(ii) *There are optimal* $\mathbb{R}$*-solutions* $(y_i, v_i) \in \hat{\omega}(x, u)$ *and optimal equilibria* e_i^+, e_i^- *such that for all* i,

$$e_i^- = \lim_{t \to -\infty} \varphi(t, y_i, v_i), \qquad e_i^+ = \lim_{t \to +\infty} \varphi(t, y_i, v_i), \tag{4.1}$$

$$\omega(x, u) = \bigcup_i \varphi(\mathbb{R}, y_i, v_i) \cup \bigcup_i \{e_i^-, e_i^+\}. \tag{4.2}$$

Proof. Let $y \in \omega(x, u)$. By Proposition 2.10 there is $v \in U_{\text{ad}}$ such that $(y, v) \in \hat{\omega}(x, u)$. If either $\alpha(y, v)$ or $\omega(y, v)$ contain a point that is not an equilibrium, then Propositions 4.3 and 4.5 imply that (i) holds (naturally, we may take $T_1 = 0$).

In the other case, $\alpha(y, v)$ and $\omega(y, v)$ consist of equilibria only. Since $\alpha(y, v)$, $\omega(y, v) \subset \omega(x, u)$, Theorems 3.5 and 3.6 imply that there are optimal equilibria e^- and e^+ with

$$e^- = \lim_{t \to -\infty} \varphi(t, y, v), \qquad e^+ = \lim_{t \to +\infty} \varphi(t, y, v).$$

COROLLARY 4.7. *Let* $(x, u) \in \mathbb{R}^2_+ \times U_{\text{ad}}$ *be optimal for* (1.1)–(1.4) *and suppose that* $\omega(x, u)$ *does not contain an optimal equilibrium. Then either there is* $\hat{u} \in U_{\text{ad}}$ *such that* $(x, \hat{u})$ *is optimal, finally periodic and* $\varphi(x, \hat{u}) \subset \varphi(x, u)$ *or there are optimal periodic* $(y, v) \in \mathbb{R}^2_+ \times U_{\text{ad}}$ *with* $\omega(x, u) = \varphi(y, v)$.

Proof. If $\varphi(\cdot, x, u)$ is self-intersecting the assertion follows from Proposition 4.1. Otherwise Proposition 4.5 implies the existence of optimal $(\bar{y}, \bar{v})$ and $T_2 > T_1 \geqq 0$ with $\varphi(T_1, \bar{y}, \bar{v}) = \varphi(T_2, \bar{y}, \bar{v})$ and $\omega(x, u) = \varphi([T_1, T_2], y, v)$. Applying Proposition 4.1 again, we obtain the assertion.

Remark 4.8. By Remarks 2.12 and 3.7, the results above remain true if the performance criterion (1.1) is replaced by (2.5) provided that (2.6) holds.

5. Application to bioeconomic problems. The crucial assumption in the Poincaré-Bendixson Theorem given above is that the integrand of the performance criterion does not depend explicitly on the control u. In this section we show that the weakened form of this assumption specified in (2.6) can be verified in bioeconomic problems.

Furthermore, we present a specific example where the ω-limit set of an optimal solution consists of an optimal periodic trajectory that is not an optimal equilibrium. Feasibility of this case is a specific feature of the two-dimensional problem compared to the one-dimensional problem.

We will have to ensure that the ω-limit set has empty intersection with $\partial\mathbb{R}^2_+$. This deserves special attention also independently of the question considered here. Hence we give the following definition.

DEFINITION 5.1. A pair $(x, u) \in \operatorname{int}\mathbb{R}^n_+ \times U_{\mathrm{ad}}$ leads to extinction if $\omega(x, u) \cap \partial\mathbb{R}^n_+ \neq \emptyset$.

PROPOSITION 5.2. *Let* $(x, u) \in \operatorname{int}\mathbb{R}^n_+ \times U_{\mathrm{ad}}$ *be optimal. If* (x, u) *leads to extinction, then there are optimal* (y_k, v_k) $k = 0, 1, 2, \cdots$, *such that* $y_k \in \operatorname{int}\mathbb{R}^n_+$, $y_k \to y_0 \in \partial\mathbb{R}^n_+$ *and* $\sup\{d(z, \partial\mathbb{R}^n_+), z \in \varphi(y_k, v_k)\} \to 0$ *for* $k \to \infty$.

Proof. In the case $\omega(x, u) \subset \partial\mathbb{R}^n_+$ we may choose $y_k := \varphi(t_k, x, u)$, $v_k := u(t_k + \cdot)$, with $t_k \to \infty$. Now assume that $\omega(x, u) \cap \partial\mathbb{R}^n_+ \neq \emptyset$, but $\omega(x, u) \not\subset \partial\mathbb{R}^n_+$. For $\varepsilon > 0$ let $B_\varepsilon := \{z \in \mathbb{R}^n_+ : d(z, \partial\mathbb{R}^n_+) \leqq \varepsilon\}$. Choose ε small enough such that $\omega(x, u) \not\subset B_\varepsilon$. Then there are $t_l \to \infty$ and $s_l > 0$, $l \in \mathbb{N}$, such that for all l large enough

$$\varphi(t_l, x, u) \in \partial B_\varepsilon, \quad \varphi(t_l + s_l, x, u) \in B_{1/l}, \quad \varphi(t_l + s, x, u) \in B_\varepsilon \quad \text{for } s \in [0, s_l].$$

Without loss of generality we may assume that $t \to \varphi(t_l + t, x, u)$ converges locally uniformly to some $\varphi(\cdot, y, v)$ with $(y, v) \in \hat{\omega}(x, u)$, $y \in \partial B_\varepsilon$. If (s_l) is bounded we may assume that $s_l \to s \in \mathbb{R}_+$. This implies $\varphi(s, y, v) \in \partial\mathbb{R}^n_+$. Hence $\varphi(0, y, v) \subset \partial\mathbb{R}^n_+$. This contradicts $\varphi(t_l, x, u) \in \partial B_\varepsilon$. If (s_l) is unbounded, we may assume that $s_l \to \infty$. This implies $\varphi(y, v) \subset B_\varepsilon$. Choosing a sequence (ε_k) with $\varepsilon_k \to 0$, we obtain (y_k, v_k) satisfying the assertion.

Example 5.3. Maximize

$$V(a, u) = \int_0^\infty e^{-\delta t}\{p_1 x_1(\gamma_{11}u_1 + \gamma_{12}u_2)F^1(x_1) + p_2 x_2(\gamma_{21}u_1 + \gamma_{22}u_2)F^2(x_2) - c_1u_1 - c_2u_2\}\, dt$$

(where dependence on t has been dropped) such that

$$\begin{aligned}
&\dot{x} = x_1(F_0^1(x) - (\gamma_{11}u_1 + \gamma_{12}u_2)F^1(x_1)),\\
&\dot{x}_2 = x_2(F_0^2(x) - (\gamma_{21}u_1 + \gamma_{22}u_2)F^2(x_2)),\\
&(x_1(0), x_2(0)) = (a_1, a_2) \in \mathbb{R}^2_+,\\
&(u_1(t), u_2(t)) \in \Omega = [0, U_1] \times [0, U_2].
\end{aligned}$$

This example is designed to model resource-harvesting of two resources, the stocklevel of which (at time t) is denoted by $x_1(t)$, respectively, $x_2(t)$. There are two technologies available, such that an effort u_j spent applying technology j results in a catch-rate $\gamma_{ij}u_jF^i(x_i)$ with respect to the species i. γ_{ij} are nonnegative efficiency coefficients; $F^i(x_i)$ is a positive locally Lipschitz continuous function $\mathbb{R}^2_+ \to \mathbb{R}$, which relates effort and catch. There is a more detailed discussion of these "density profiles" in Clark [6].

p_1, p_2 are nonnegative constants to be interpreted as prices per unit biomass. c_1, c_2 are nonnegative constants to be interpreted as cost per unit effort spent applying technology one, respectively, two. Therefore $V(a, u)$ represents the "total discounted net revenue."

The rewriting of $V(a, u)$ *in* $\operatorname{int}\mathbb{R}^2_+$. Note first that

$$\gamma_{11}u_1+\gamma_{12}u_2=\frac{x_1F_0^1(x)-\dot{x}_1}{x_1F^1(x_1)},$$

$$\gamma_{21}u_1+\gamma_{22}u_2=\frac{x_2F_0^2(x)-\dot{x}_2}{x_2F^2(x_2)},$$

$$p_1x_1(\gamma_{11}u_1+\gamma_{12}u_2)F^1(x_1)=F_0^1(x)p_1x_1-p_1\dot{x}_1,$$

$$p_2x_2(\gamma_{21}u_1+\gamma_{22}u_2)F^2(x_2)=F_0^2(x)p_2x_2-p_2\dot{x}_2.$$

We assume that the matrix (γ_{ij}) is invertible. For obvious reasons the special case of $\gamma_{12}=\gamma_{21}=0$ is called "*selective harvesting.*" Suppose first $\gamma_{11}\neq 0$. Then

$$\left(\gamma_{22}-\frac{\gamma_{21}\gamma_{12}}{\gamma_{11}}\right)u_2=\frac{F_0^2(x)}{F^2(x_2)}-\frac{\gamma_{21}F_0^1(x)}{\gamma_{11}F^1(x_1)}-\frac{\dot{x}_2}{x_2F^2(x_2)}+\frac{\gamma_{21}}{\gamma_{11}}\frac{\dot{x}_1}{x_1F^1(x_1)},$$

or with $d=\gamma_{11}\gamma_{22}-\gamma_{12}\gamma_{21}$

$$u_2=G^2(x)-\frac{\gamma_{11}}{d}\frac{\dot{x}_2}{x_2F^2(x_2)}+\frac{\gamma_{21}}{d}\frac{\dot{x}_1}{x_1F^1(x_1)},$$

$$\begin{aligned}u_1&=G^1(x)+\frac{\gamma_{12}}{d}\frac{\dot{x}_2}{x_2F^2(x_2)}-\left(\frac{\gamma_{12}\gamma_{21}}{d\gamma_{11}}+\frac{1}{\gamma_{11}}\right)\frac{\dot{x}_1}{x_1F^1(x_1)}-c_1u_1-c_2u_2\\&=G^3(x)+\frac{\dot{x}_1}{x_1F^1(x_1)}\gamma_1+\frac{\dot{x}_2}{x_2F^2(x_2)}\gamma_2\end{aligned}$$

where

$$\gamma_1=\frac{c_1}{\gamma_{11}}+\frac{c_1\gamma_{12}\gamma_{21}}{d\gamma_{11}}-\frac{c_2\gamma_{21}}{d},\qquad \gamma_2=\frac{c_1\gamma_{12}}{d}-\frac{c_2\gamma_{11}}{d},$$

and G^1, G^2, G^3 are locally Lipschitz continuous functions of x. Put $G^4(x)=G^3(x)+F_0^1(x)p_1x_1+F_0^2(x)p_2x_2$. Then

$$V(a,u)=\int_0^\infty e^{-\delta t}G^4(x(t))\,dt+\int_0^\infty e^{-\delta t}\left\{\left[\frac{\gamma_1}{x_1F^1(x_1)}-p_1\right]\dot{x}_1+\left[\frac{\gamma_2}{x_2F^2(x_2)}-p_2\right]\dot{x}_2\right\}dt.$$

Put $g_j(y_j)=\int_{z_j}^{y_j}(\gamma_j/\xi F^j(\xi)-p_j)\,d\xi$, where $z=(z_1, z_2)$ is a pair of positive reals fixed once and for all. Now

$$\begin{aligned}V(a,u)&=\int_0^\infty e^{-\delta t}G^4(x(t))\,dt+\int_0^\infty e^{-\delta t}[g_1'(x_1(t))\dot{x}_1(t)+g_2'(x_2(t))\dot{x}_2(t)]\,dt\\&=\int_0^\infty e^{-\delta t}G^4(x(t))\,dt+\int_0^\infty e^{-\delta t}\frac{d}{dt}[g_1(x_1(t))+g_2(x_2(t))]\,dt\\&=\int_0^\infty e^{-\delta t}G^4(x(t))\,dt+e^{-\delta t}[g_1(x_1(t))+g_2(x_2(t))]\Big|_{t=0}^{\infty}\\&\quad+\int_0^\infty e^{-\delta t}\delta[g_1(x_1(t))+g_2(x_2(t))]\,dt\\&=r(a)+\int_0^\infty e^{-\delta t}R(x(t))\,dt\end{aligned}\tag{5.1}$$

with $r(a) := -g_1(a_1) - g_2(a_2)$, $R(y_1, y_2) = G^4(y) + \delta g_1(y_1) + \delta g_2(y_2)$, provided that

$$\lim_{t\to\infty} e^{\delta t}[g_1(x_1(t)) + g_2(x_2(t))] = 0. \tag{5.2}$$

To establish (5.2) let $c(t) := e^{-\delta t} g_j(x_j(t))$ for $j=1$ or $j=2$. It suffices to show that $\lim_{t\to\infty} c(t) = 0$. Now

$$\begin{aligned}\dot{c}(t) &= -\delta c(t) + e^{-\delta t}\left[\frac{\gamma_j}{x_j(t)F^j(x_j(t))} - p_j\right] x_j(t)[F_0^j(x(t)) - (y_{j1}u_1(t) + \gamma_{j2}u_2(t))F^j(x_j(t))] \\ &= -\delta c(t) + h(t),\end{aligned}$$

where h is a measurable and, since $F^j(0) \neq 0$, also bounded function on $\mathbb{R}_+$. By the variation of constant formula

$$|c(t)| \leqq (|c(0)| + \|h\|_\infty/\delta)\, e^{-\delta t}$$

and (5.2), and hence (5.1), follows.

The definition of R given above implies for $x_1, x_2 > 0$ that

$$\lim_{y\to(x_1,0)} R(y) = \pm\infty \quad \text{if } \gamma_2 \leqq 0,$$

$$\lim_{y\to(0,x_2)} R(y) = \pm\infty \quad \text{if } \gamma_1 \leqq 0.$$

Property (2.6)(α) follows from (5.1) and (5.2).

Analogous arguments can be used if $\gamma_{11} = 0$, and also in the case of nonselective harvesting, where $\gamma_{12} = \gamma_{21} = 0$.

Remark 5.4. We may construct examples of optimal control systems (with $m > n$) where condition (2.6) is not satisfied.

Now we present an example of a predator-prey system where both species are subject to innerspecific competition. Only the predator is harvested and the costs are proportional to the effort. The unharvested system possesses a limit cycle. We will show that there are optimal trajectories tending to an optimal periodic solution as $t \to \infty$. The system equation and the analysis of the uncontrolled system are taken from Sieveking [17].

Example 5.5.

$$\begin{aligned}\text{Maximize} \quad & \int_0^\infty e^{-\delta t}[pqx_2 - c]u\, dt \\ \text{Subject to} \quad & \dot{x}_1 = x_1[\alpha - \gamma x_2 - h(x_1) - \varepsilon x_1], \\ & \dot{x}_2 = x_2[-\beta + \lambda x_1 - \mu x_2 - qu], \qquad t \in \mathbb{R}_+, \\ & (x_1(0), x_2(0)) = x \in \mathbb{R}_+^2, \\ & u \in [0, U^1]\end{aligned}$$

where p, q, c, α, β, γ, δ, λ, μ, U^1 are positive constants, and h is defined by

$$h(x_1) = \begin{cases} (x_1 - \beta/\lambda)^2 & \text{for } 0 \leqq x_1 \leqq \beta/\lambda, \\ 0 & \text{for } \beta/\lambda \leqq x_1. \end{cases}$$

The system above is a special case of Example 5.3, and conditions (2.1), (2.6) are satisfied. First we analyze the uncontrolled equation where $u_1 = u_2 = 0$: All trajectories $\varphi(\cdot, x, 0)$ are bounded and for ε, $\mu > 0$, small, the only equilibria are $(0, 0)$, $(\alpha/\varepsilon, 0)$ and a point e near $e^0 = (\beta/\lambda, \alpha/\gamma)$.

The equilibrium e is (locally) asymptotically stable, the points $(0, 0)$ and $(\alpha/\varepsilon, 0)$ are saddles.

For ε, $\mu > 0$, small enough, the equation possesses a limit cycle (applying the Poincaré-Bendixson Theorem to the time-reversed equation, this implies the existence of another—unstable—periodic solution).

In the following, we assume that ε, μ are small enough such that existence of a limit cycle is guaranteed. There exists an initial value $x \in \operatorname{int} \mathbb{R}^2_+$ on the line $x_2 = -\beta/\mu + \lambda/\mu x_1$ such that $\varphi(\cdot, x, 0)$ spirals outward, i.e., there exists a (minimal) time $T_1 > 0$ such that $\varphi(T_1, x, 0)$ lies on the same line above x. Using continuous dependence of solutions on the right-hand side, this implies that for $U^1 > 0$, small enough, also every trajectory $\varphi(\cdot, x, u)$, $u(t) \in [0, U^1]$ almost everywhere, spirals outward. In particular, this is true for an optimal trajectory $\varphi(\cdot, x, u)$. See Fig. 5.1.

The controlled system has exactly two equilibria on $\partial \mathbb{R}^2_+$, namely $(0, 0)$ and $(\alpha/\varepsilon, 0)$.

Next we show that no optimal pair $(x, u) \in \operatorname{int} \mathbb{R}^2_+ \times U_{\text{ad}}$ leads to extinction. For $\xi > 0$, let $A_\xi := [\xi, \alpha/\varepsilon] \times [0, M]$ where $M := \max z_2(t)$ and $z = (z_1, z_2)$ is the unique trajectory in $\operatorname{int} \mathbb{R}^2_+$ of the uncontrolled system with $\lim_{t \to -\infty} z(t) = (\alpha/\varepsilon, 0)$. Then we can show that there exists $\xi > 0$ with the following property: For all $(y, v) \in \operatorname{int} \mathbb{R}^2_+ \times U_{\text{ad}}$ there is $T > 0$ such that for all $t \geqq T$ it follows that $\varphi(t, y, v) \in A_\xi$; furthermore $\varphi(y, v) \subset A_\xi$ for every $(y, v) \in A_\xi \times U_{\text{ad}}$. Hence $\omega(x, u) \cap \{0\} \times \mathbb{R}_+ = \varnothing$. Now suppose that $\omega(x, u) \cap \mathbb{R}_+ \times \{0\} \neq \varnothing$. Then Proposition 5.2 implies the existence of optimal $(y_k, v_k) \in \operatorname{int} \mathbb{R}^2_+ \times U_{\text{ad}}$ with $y_k \to y_0 \in \mathbb{R}_+ \times \{0\}$ and

$$\max \{d(z, \mathbb{R}_+ \times \{0\}) : z \in \varphi(y_k, v_k)\} \to 0 \quad \text{for } k \to \infty.$$

But for x_2 small, we have $pqx_2 - c < 0$. This contradicts the existence of (y_k, v_k) with the properties indicated above.

Conclusion. Suppose that in Example 5.5 the positive constants ε, μ, U^1 are small enough. No optimal pair $(x, u) \in \operatorname{int} \mathbb{R}^2_+ \times U_{\text{ad}}$ leads to extinction and every trajectory is bounded. There are initial values $x \in \operatorname{int} \mathbb{R}^2_+$ such that corresponding optimal trajectories $\varphi(\cdot, x, u)$ spiral outward. Hence, according to Corollary 4.7, there are optimal finally periodic $(x, \hat{u})$ or $\omega(x, u) = \varphi(y, v)$ with (y, v) optimal periodic.

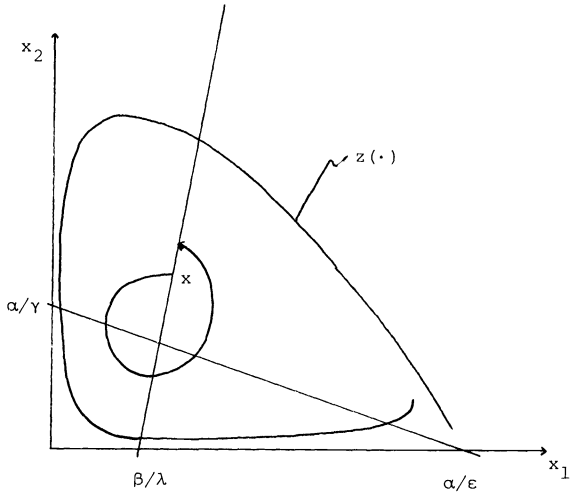

FIG. 5.1.

6. Nonuniqueness. For given initial state, solutions of ordinary differential equations are unique (provided that local Lipschitz continuity prevails). In general, optimal control problems do not share this nice property. In fact in this section we give a nonconstructive criterion implying nonuniqueness for a certain initial value. Furthermore, a simple bioeconomic example is presented with nonunique optimal solutions.

DEFINITION 6.1. An element $x \in \mathbb{R}^n_+$ is called a point of nonuniqueness if there are $u, v \in U_{\text{ad}}$ such that (x, u) and (x, v) are optimal and $\varphi(t, x, u) \neq \varphi(t, x, v)$ for some $t \in \mathbb{R}_+$.

"Nonuniqueness" requires that the trajectories corresponding to u and v do not coincide. Thus "redundancies" in the controls do not lead, in our terminology, to nonuniqueness.

THEOREM 6.2. *Suppose that* $(x, u) \in \mathbb{R}^2_+ \times U_{\text{ad}}$ *are optimal and that there are* $T_2 > T_1 \geqq 0$ *such that* $\varphi(\cdot, x, u)$, $t \in [T_1, T_2]$, *is a Jordan curve. If* $I := \text{cl ins } \Gamma$ *does not contain any optimal equilibrium, then it contains a point of nonuniqueness.*

Proof. Suppose there is no point of nonuniqueness in I and note that I is positively invariant. Hence for every $y \in I$, there is a unique control $u(y) \in U_{\text{ad}}$ such that $(y, u(y))$ is optimal and $\varphi(y, u(y)) \subset I$. Lemma 2.5 implies that $y \to u(y) : I \to U_{\text{ad}}$ is continuous, and hence for every $t \geqq 0$ the map $y \to \varphi(t, y, u(y)) : I \to I$ is continuous. By the Schoenfliess Theorem (Beck [3, p. 22]), I is homeomorphic to the closed unit ball in $\mathbb{R}^2$. Hence, by Brouwer's Fixed Point Theorem, there is for every $t \geqq 0$ a fixed point x_t with

$$\varphi(t, x_t, u(y)) = x_t.$$

Let (t_n) be a sequence of numbers with $t_n > 0$ such that $\lim t_n = 0$ and $\lim x_{t_n} = e \in I$ exists. We claim that e is an optimal equilibrium. In fact, for every $n \in \mathbb{N}$, uniqueness of optimal solutions implies that $\varphi(\cdot, x_n, u(x_n))$ is a periodic solution of period t_n. Without loss of generality we may assume that $\varphi(\cdot, x_n, u(x_n))$ converges uniformly to the constant trajectory e, which therefore is an optimal equilibrium contrary to our assumption.

In the following example, nonuniqueness is shown by a different argument.

Example 6.3.

$$\begin{aligned}
\text{Maximize} \quad & V(x, u) := \int_0^\infty e^{-\delta t}\{[p - c(x_1(t))]u_1(t)x_1(t) \\
& \qquad + [p - c(x_2(t))]u_2(t)x_2(t)\}\, dt \\
\text{Subject to} \quad & \dot{x}_1(t) = x_1(t)[2 - x_1(t) - 2x_2(t) - u_1(t)], \\
& \dot{x}_2(t) = x_2(t)[2 - x_2(t) - 2x_1(t) - u_2(t)], \\
& (u_1(t), u_2(t)) \in \Omega := [0, \tfrac{1}{2}] \times [0, \tfrac{1}{2}], \\
& x_1(0) = x_1, \qquad x_2(0) = x_2,
\end{aligned}$$

where $p > 0$ and $c(\cdot)$ is continuous and strictly decreasing on $\mathbb{R}_+$ with $c(\frac{2}{3}) = p$.

Assertion. For $\delta > 0$ sufficiently small the point $x = (\frac{2}{3}, \frac{2}{3})$ is a point of nonuniqueness.

Proof. (See Fig. 6.1.) First note that existence of an optimal solution follows by uniform boundedness of the trajectories, linearity in u and convexity and compactness of Ω. Define

$$S\begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \begin{pmatrix} y_2 \\ y_1 \end{pmatrix}, \qquad \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \in \mathbb{R}^2_+.$$

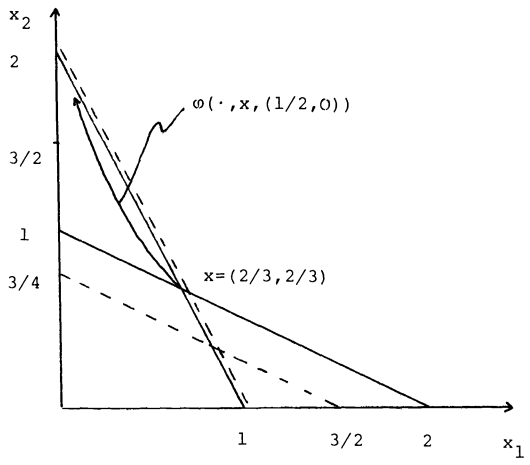

FIG. 6.1. *Illustration of Example* 6.3.

The symmetry of the system equation and $x = Sx$ imply for $u \in U_{ad}$ and $t \geqq 0$

$$S\varphi(t, x, u) = \varphi(t, x, Su).$$

Furthermore,

$$V(x, Su) = V(x, u).$$

Thus, if (x, u) is optimal, also (x, Su) is optimal. If the optimal solution is unique, it follows that

$$\varphi_1(t, x, u) = \varphi_2(t, x, u) \quad \text{for all } t \geqq 0.$$

Looking at the system equation we find that this implies

$$\varphi_1(t, x, u) \leqq \tfrac{2}{3}, \quad \varphi_2(t, x, u) \leqq \tfrac{2}{3} \quad \text{for all } t > 0.$$

Hence

$$p - c(\varphi_1(t, x, u)) \leqq 0, \quad p - c(\varphi_2(t, x, u)) \leqq 0 \quad \text{for all } t > 0$$

and

$$V(x, u) \leqq 0.$$

Thus, in case of uniqueness, the only candidate for an optimal control is $u_1 \equiv u_2 \equiv 0$, which leaves $x = (\frac{2}{3}, \frac{2}{3})$ fixed and

$$V(x, u) = 0.$$

Thus it suffices to construct $v \in U_{ad}$ with

$$V(x, v) > 0.$$

Consider first the control $\bar{v} = (\bar{v}_1, \bar{v}_2)$

$$\bar{v}_1(t) \equiv \tfrac{1}{2}, \qquad \bar{v}_2(t) \equiv 0.$$

A phase plane analysis (cf. Fig. 6.1) yields that for t increasing, $\varphi_1(t, x, \bar{v})$ decreases and $\varphi_2(t, x, \bar{v})$ increases, with

$$\lim_{t \to \infty} \varphi(t, x, \bar{v}) = (0, 2). \tag{6.1}$$

Now consider the system

$$(6.2)\qquad \dot{x}_1(t) = x_1(t)[2 - x_1(t) - 2x_2(t)], \qquad \dot{x}_2(t) = x_2(t)[2 - x_2(t) - 2x_1(t) - \tfrac{1}{2}].$$

For this system the point $(0, \frac{3}{2})$ is (locally) asymptotically stable. In fact, the Jacobian at this point is

$$\begin{pmatrix} -1 & 0 \\ -3 & -\frac{3}{2} \end{pmatrix}.$$

Since the region of attraction of an asymptotically stable point is always open and $(0, 2)$ is attracted by $(0, \frac{3}{2})$, it follows from (6.1) that there is $t_1 > 0$ such that in the system (6.2), $\varphi(t_1, x, \bar{v})$ is attracted by $(0, \frac{3}{2})$. Define

$$v(t) := \begin{cases} \bar{v}(t) = (\frac{1}{2}, 0), & t \in [0, t_1], \\ (0, \frac{1}{2}), & t \in (t_1, \infty). \end{cases}$$

Then

$$\lim_{t \to \infty} \varphi(t, x, v) = (0, \tfrac{3}{2}).$$

By continuity of c, there is $M_1 > 0$ with

$$(p_1 - c(\varphi_1(t, x, \bar{v})))\varphi_1(t, x, \bar{v})\tfrac{1}{2} \geqq -M_1, \qquad 0 \leqq t \leqq t_1.$$

Thus

$$\begin{aligned} \delta V(x, v) &= \delta \int_0^\infty e^{-\delta t}\{[p - c(\varphi_1(t, x, v))]\varphi_1(t, x, v)v_1(t) \\ &\qquad + [p - c(\varphi_2(t, x, v))]\varphi_2(t, x, v)v_2(t)\}\, dt \\ &= \delta \int_0^{t_1} \cdots + \delta \int_{t_1}^\infty \cdots \\ &\geqq -\delta M_1 \frac{1}{2} \int_0^{t_1} e^{-\delta t}\, dt + \delta \int_{t_1}^\infty e^{-\delta t}[p - c(\varphi_2(t, x, \bar{v}))]\frac{1}{2}\, dt; \end{aligned}$$

without loss of generality we may assume

$$\varphi_2(t, x, v) \geqq 1 \quad \text{for all } t \geqq t_1.$$

Since there is $M_2 > 0$ with

$$p - c(y) > M_2 \quad \text{for } y \geqq 1$$

it follows that

$$(p - c(\varphi_2(t, x, v)))\varphi_2(t, x, v)\tfrac{1}{2} \geqq \tfrac{1}{2}M_2 \quad \text{for } t \geqq t_1.$$

Together we get

$$V(x, v) \geqq -\tfrac{1}{2}M_1(1 - e^{-\delta t_1}) + \tfrac{1}{2}M_2\, e^{-\delta t_1}.$$

For $\delta \to 0$, the right-hand side of this inequality tends to $\frac{1}{2}M_2$. Hence $V(x, \bar{v}) > 0$ for $\delta > 0$, sufficiently small. This proves the assertion.

The idea for this example may be sketched as follows. We start in an equilibrium point x, where two competing species coexist, and where the net revenue $p - c(x)$ is zero. Catching *one* of these species we have a temporary loss. On the other hand, the other species increases until it gets into a domain where it can be caught continually, yielding positive net revenue. The initial loss is, for sufficiently small discount rate $\delta > 0$, less than the later revenue.

Acknowledgments. The work of C. W. Clark as well as conversations with him have been a source of motivation and ideas for the present paper. Furthermore, we thank D. Hinrichsen for the support that he provided to our work.

ASYMPTOTIC ADMISSIBILITY OF THE UNIT STEPSIZE IN EXACT PENALTY METHODS*

JOSEPH FRÉDÉRIC BONNANS†

Abstract. Two difficulties arise in the use of optimization algorithms based on an exact penalty function and quadratic subproblems: the possible inconsistency of the quadratic programs and the admissibility of the unit stepsize after a finite number of iterations. In this paper, assuming that no inequality constraint is present, the author devises an algorithm, using a nondifferentiable augmented Lagrangian, that, under convenient hypotheses, solves both problems.

Key words. nonlinear optimization, constrained optimization, Newton's method, successive quadratic programming, optimization algorithms

AMS(MOS) subject classifications. 90C30, 65K05, 49D15

1. Introduction.

We consider a nonlinear programming problem having only equality constraints:

(1.1) Minimize $f(x)$ subject to $g_i(x)=0$, $i=1$ to m,

f and g_i, $i=1$ to m being smooth (C^3) functions from $\mathbb{R}^n$ into $\mathbb{R}$. We suppose that $m \leqq n$. Let $\bar{x}$ be a local solution of (1.1). We suppose that $\bar{x}$ is a regular point, i.e.,

(1.2) $\nabla g_i(\bar{x})$, $i=1$ to m, are linearly independent.

Then there exists a unique $\bar{\lambda} \in \mathbb{R}^m$ satisfying

$$\nabla f(\bar{x}) + \nabla g(\bar{x})\bar{\lambda} = 0, \qquad g(\bar{x}) = 0. \tag{1.3}$$

Equations (1.3) may be solved by a Newton-type method with unknowns (x, λ). This reduces to the computation of a sequence (x^k, λ^k) with $x^{k+1} = x^k + d^k$, where d^k is a solution of the quadratic program

(1.4) Minimize $\nabla f(x^k)'d + \frac{1}{2}d'H^k d$ subject to $g(x^k) + \nabla g(x^k)'d = 0$,

H^k being an approximation to the Hessian of the Lagrangian, and λ^{k+1} being the multiplier associated with d^k. We restrict our analysis to the case when H^k is a positive definite approximation of the Hessian of the Lagrangian. When this approximation is made using the BFGS (Broyden-Fletcher-Goldfarb-Shanno) method, a superlinear convergence rate may be obtained (Powell [15], Boggs, Tolle, and Wang [2]). To globalize this algorithm—i.e., to design some globally convergent algorithm that reduces to a Newton-type method in the neighbourhood of a solution—a key idea is to use the nondifferentiable penalty function

$$\theta_r(x) = f(x) + r\|g(x)\|,$$

where $r>0$ is called the penalty parameter and $\|\cdot\|$ is some norm of $\mathbb{R}^m$; we denote by $\|\cdot\|_D$ the dual norm, i.e.,

$$\|\lambda\|_D = \max\left\{ \sum_{i=1}^{m} \lambda_i \mu_i,\ \|\mu\| = 1 \right\}.$$

† Institut National de Recherche en Informatique et Automatique, Rocquencourt, 78153 Le Chesnay, France.

A key fact is that if (1.4) has a solution d^k associated to a multiplier λ^{k+1}, and if $r > \|\lambda^{k+1}\|_D$, then d^k is a descent direction of $\theta_r(x)$ at x^k. This result is due to Pschenichnyi and Danilin (see [17]) in the case of the L^∞ norm and was rediscovered by Han [10] in the case of the L^1 norm. The general result can be found in Bonnans and Gabay [4]. A difficulty arises if the m vectors $\{\nabla g_i(x^k)\}$ are not everywhere linearly independent; then (1.4) may have no solutions. Some empirical means for taking this into account are given in Powell [14] and Tone [18]. The algorithm of Bonnans and Gabay [4] seems, at least from a theoretical point of view, to give a satisfactory solution to this problem. It is based on the function, defined for each iteration k:

$$\theta_r^k(x) = f(x^k) + \nabla f(x^k)'(x - x^k) + \tfrac{1}{2}(x - x^k)' H^k (x - x^k) + r\|g(x^k) + \nabla g(x^k)'(x - x^k)\|,$$

which is a simple model of $\theta_r(x)$, having the same behaviour around x^k. A direction $\tilde{d}^k$ is computed as the solution of

$$\min\{\theta_r^k(x^k + d);\ d \in \mathbb{R}^n\}. \tag{1.5}$$

Being strictly convex and feasible, problem (1.5) always has a unique solution $\tilde{d}^k$. Then the iteration is

$$x^{k+1} = x^k + \rho^k \tilde{d}^k,$$

where ρ^k is a stepsize computed according to some linesearch rule. Define

$$\tilde{\theta}_r^k(x) = f(x^k) + \nabla f(x^k)'(x - x^k) + r\|g(x^k) + \nabla g(x^k)'(x - x^k)\|.$$

A convenient linesearch rule (see, e.g., Chamberlain et al. [6]) is the following extension of the Armijo rule [1]:

(1.6) Choose $\beta \in]0, 1[$, $\sigma \in]0, \frac{1}{2}[$ (independent of k),
$\rho^k = (\beta)^l$, where l is the smallest nonnegative integer such that
$\theta_r(x^k + (\beta)^l \tilde{d}^k) - \theta_r(x^k) \leqq \sigma(\tilde{\theta}_r^k(x^k + (\beta)^l \tilde{d}^k) - \theta_r(x^k))$.

This means that we reduce the step until the ratio of the achieved decrease on the penalty function divided by the decrease predicted by the local model $\tilde{\theta}_r^k$ is at least σ.

The complexity of problem (1.5) is, at least for the L^1 and L^∞ norms, roughly the same as that of a quadratic program. In addition, if (1.4) has a solution d^k associated with a unique multiplier λ^{k+1}, the solution of (1.5) will be equal to d^k if r^k is greater than $\|\lambda^{k+1}\|_D$. Consequently, when the parameter r^k is iteratively modified in a convenient way, the method leads to a globally convergent algorithm, where computed displacements reduce to the solution of (1.4) near a regular solution of (1.1). This method is related to that of Fletcher [7], [8] who uses a trust region method instead of a linesearch.

One point should be clarified. To compute descent directions, the algorithm described above relaxes the linearized constraints by penalizing them. This is useful when these linearized constraints are not necessarily compatible at any point. However, if it is known a priori that the linearization of some subset of the constraints are compatible, there is no reason to relax the constraints of this subset. A key fact is that this subset must contain the linear constraints (otherwise, the problem has no solution). This means that, in practice, the linear constraints should not be relaxed. To keep the proofs short, in this paper we do not take this remark into account. However, this modification of the algorithm should not essentially change the results.

We now turn to the local convergence analysis. We suppose that a sequence $\{x^k\}$ computed by the preceding algorithm converges to a local solution $\bar{x}$ of (1.1), which is regular point. Let d^k be the solution of (1.4) (well defined for k large enough). Let $\|\cdot\|_U$ be a norm of $\mathbb{R}^n$. We suppose that the vector d^k, which solves (1.4), satisfies

$$\|x^k + d^k - \bar{x}\|_U / \|x^k - \bar{x}\|_U \to 0. \tag{1.7}$$

This hypothesis allows the algorithm to have a superlinear rate of convergence, if $\{\rho^k\}$ converges to 1. However, this does not seem to be the case in general: a counterexample due to Maratos [12] shows that even if (1.7) holds, and if r has the same order of magnitude as $\|\bar{\lambda}\|_D$, $\theta_r(x^k + \rho^k d^k)$ may be greater than $\theta_r(x^k)$ when $\rho^k \to 1$. This may destroy the property of superlinear convergence. Two kind of methods have been proposed to deal with this problem. The first (Mayne and Polak [13]) needs the computation of the constraints at $x^k + d^k$; then a correction term v^k is computed as the solution of

$$\text{Minimize } \sum_{i=1}^{n} (v_i^k)^2 \quad \text{subject to } g(x^k + d^k) + \nabla g(x^k)^t v^k = 0.$$

If a linesearch is used, it can be performed along the arc

$$x^k + \rho d^k + (\rho)^2 v^k.$$

Then it is shown that, under some convenient assumptions, the stepsize $\rho^k = 1$ is admissible if k is great enough. The second method, due to Chamberlain et al. [6], is based on the observation that a sufficient decrease of the exact penalty function is obtained (for k large enough) between the iterations $k-1$ and $k+1$. Consequently, the linesearch criterion at step k should use the information of the iteration $k-1$. However, if the point $x^k + d^k$ is not accepted, we must return to the point x^{k-1} and reduce the stepsize at x^{k-1}; this ensures global convergence. The main drawback of these methods is that, in some situations, they can substantially increase the amount of computations.

In this paper we propose to perform the linesearch, using the following criterion:

$$\theta_{p,r}(x) = f(x) + p^t g(x) + r\|g(x)\|.$$

Here p is an approximation of the optimal Lagrange multiplier $\bar{\lambda}$ and $r > 0$ is a penalty parameter, as before. Choosing p close to $\bar{\lambda}$ allows us to reduce the value of r; we will prove that, if p and r are carefully adapted at each iteration, r being small enough, the unit stepsize is asymptotically admissible. This result allows us to build a "globally convergent" algorithm.

The paper is organized as follows. In § 2 we give a technical result on exact penalty functions that is the basis of the subsequent algorithm. Then in § 3 we use this result to formulate a globally convergent method, based on a linesearch strategy, for which the unit stepsize is, under some convenient hypothesis, asymptotically admissible.

2. Some local properties of a class of exact penalty functions. Let $\bar{x}$ be a local solution of (1.1) satisfying (1.2) and $\bar{\lambda}$ be the element of $\mathbb{R}$ such that (1.3) holds. Define the augmented Lagrangian (for $c \geqq 0$)

$$L_c(x, \lambda) = f(x) + \lambda^t g(x) + c \sum_{i=1}^{m} g_i(x)^2.$$

Denote

$$H_c = \frac{\partial^2 L_c(\bar{x}, \bar{\lambda})}{\partial x^2}.$$

We suppose that the standard second-order sufficiency condition holds at $\bar{x}$ (see, for instance, Fletcher [7]):

(2.1) $d^t H_0 d > 0$ for any d in $\mathbb{R}^n$ satisfying $\nabla g(x)^t d = 0$.

As is well known, (1.3) and (2.1) imply that

(2.2) There exists $\bar{c} > 0$ such that $H_{\bar{c}}$ is positive definite.

We now consider the following class of penalty function that can be viewed as a class of nondifferentiable augmented Lagrangians:

$$\theta_{p,r}(x) = f(x) + p^t g(x) + r\|g(x)\|,$$

where $(p, r) \in \mathbb{R}^m \times \mathbb{R}$ are given parameters with $r > 0$. We recall that $\|\cdot\|$ is a norm of $\mathbb{R}^m$ and $\|\cdot\|_D$ is its dual norm. We give a sufficient condition for these penalty functions to be exact, i.e., to have a (strict) local minimum at $\bar{x}$. This is a variant of results of Han and Mangasarian [11] (see also Bonnans [3]).

PROPOSITION 2.1. *Let $\bar{x}$ be a local minimum of* (1.1) *such that, for some* $\bar{\lambda}$, (1.3) *and* (2.1) *hold. Then if*

(2.3) $$r > \|\bar{\lambda} - p\|_D,$$

$\bar{x}$ is a strict local minimum of $\theta_{p,r}(x)$.

Remark 2.1. As all norms on $\mathbb{R}^m$ are equivalent, there exists $\beta > 0$ satisfying

$$\sum_{i=1}^{m} g_i(x)^2 \leqq \beta \|g(x)\|^2.$$

Proof of Proposition 2.1. We prove that the penalty function $\theta_{p,r}$ dominates the augmented Lagrangian. We have

$$\begin{aligned}\theta_{p,r}(x) - L_{\bar{c}}(x, \bar{\lambda}) &= (p - \bar{\lambda})^t g(x) + r\|g(x)\| - \bar{c} \sum_{i=1}^{m} g_i(x)^2, \\ &\geqq (r - \|p - \bar{\lambda}\|_D)\|g(x)\| \bar{c} \sum_{i=1}^{m} g_i(x)^2, \\ &\geqq (r - \|p - \bar{\lambda}\|_D - \bar{c}\beta\|g(x)\|)\|g(x)\|.\end{aligned}$$

As $g(\bar{x}) = 0$, if (2.3) holds, the right-hand side is nonnegative in a neighbourhood of $\bar{x}$. As $H_{\bar{c}}$ is positive definite, $\bar{x}$ is a strict local minimum of $L_{\bar{c}}(x, \bar{\lambda})$; this proves the proposition. □

Let $\{x^k\}$ be a sequence converging to $\bar{x}$ and $\{p^k\}, \{r^k\}$ be two sequences such that, for k large enough and for some $\gamma > 0$,

(2.4) $$(3 + \gamma)\|p^k - \bar{\lambda}\|_D < r^k,$$

(2.5) $$r^k / \|x^k - \bar{x}\|_U \to +\infty.$$

We define

$$\begin{aligned}\tilde{\theta}^k(x) = f(x^k) + \nabla f(x^k)^t (x - x^k) + (p^k)^t (g(x^k) + \nabla g(x^k)^t (x - x^k)) \\ + r^k \|g(x^k) + \nabla g(x^k)^t (x - x^k)\|.\end{aligned}$$

We recall that the solution d^k of (1.4) is well defined in a neighbourhood of $\bar{x}$ if H^k is positive definite.

THEOREM 2.1. *We suppose that* (1.3), (1.7), (2.1), (2.4), *and* (2.5) *hold. Then for any* ϵ, $0<\varepsilon<\frac{1}{2}$, *there exists* $r_0>0$ *and* k_0 *such that* $k>k_0$ *and* $0<r^k<r_0$ *imply*

$$\theta_{p^k,r^k}(x^k+d^k)-\theta_{p^k,r^k}(x^k)\leqq(\tfrac{1}{2}-\varepsilon)(\tilde{\theta}^k(x^k+d^k)-\theta_{p^k,r^k}(x^k)). \tag{2.6}$$

The proof of the theorem uses two lemmas.

LEMMA 2.1. *We suppose that* (1.3), (1.7), *and* (2.1) *hold. Then, for any* $\varepsilon_1>0$, *there exists* k_1 *such that* $k>k_1$ *implies*

$$\tilde{\theta}^k(x^k+d^k)-\theta_{p^k,r^k}(x^k)\geqq-(1+\varepsilon_1)(x^k-\bar{x})^tH_{\bar{c}}(x^k-\bar{x})-(r^k+\|p^k-\bar{\lambda}\|_D)\|g(x^k)\|.$$

Proof. We have for k large enough

$$\begin{aligned}\Delta&=\tilde{\theta}^k(x^k+d^k)-\theta_{p^k,r^k}(x^k)=\nabla f(x^k)^td^k+(p^k)^t\nabla g(x^k)^td^k-r^k\|g(x^k)\|,\\&=\nabla_xL_0(x^k,\bar{\lambda})^td^k+(p^k-\bar{\lambda})^t\nabla g(x^k)^td^k-r^k\|g(x^k)\|.\end{aligned}$$

From (1.4) it follows that

$$\begin{aligned}\Delta&=\nabla_xL_0(x^k,\bar{\lambda})^td^k-(p^k-\bar{\lambda})^tg(x^k)-r^k\|g(x^k)\|,\\&\geqq\nabla_xL_0(x^k,\bar{\lambda})^td^k-(r^k+\|p^k-\bar{\lambda}\|_D)\|g(x^k)\|.\end{aligned}$$

Now (1.3) and (1.7) imply

$$\begin{aligned}\nabla_xL_0(x^k,\bar{\lambda})&=H_0(x^k-\bar{x})+o(\|x^k-\bar{x}\|_U),\\d^k&=\bar{x}-x^k+o(\|x^k-\bar{x}\|_U),\end{aligned}$$

where the notation $o(\|x^k-\bar{x}\|_U)$ indicates a term whose ratio to $\|x^k-\bar{x}\|_U$ tends to zero as $k\to\infty$. We deduce that

$$\Delta\geqq-(x^k-\bar{x})H_0(x^k-\bar{x})-(r^k+\|p^k-\bar{\lambda}\|_D)\|g(x^k)\|+o(\|x^k-\bar{x}\|_U^2).$$

The result is then a consequence of the inequality

$$d^tH_{\bar{c}}d\geqq d^tH_0d\quad\forall d\in\mathbb{R}^n,$$

and of the positive definiteness of $H_{\bar{c}}$. □

LEMMA 2.2. *If* (1.3), (1.7), *and* (2.1) *hold, for any* $\varepsilon_2>0$, *there exists* k_2 *such that* $k>k_2$ *implies*

$$\begin{aligned}\theta_{p^k,r^k}(x^k+d^k)-\theta_{p^k,r^k}(x^k)\leqq&-\tfrac{1}{2}(1-\varepsilon_2)(x^k-\bar{x})^tH_{\bar{c}}(x^k-\bar{x})\\&+(\|p^k-\bar{\lambda}\|_D+r^k)\|g(x^k+d^k)\|\\&-(r^k-\|p^k-\bar{\lambda}\|_D-\bar{c}\beta\|g(x^k)\|)\|g(x^k)\|.\end{aligned} \tag{2.7}$$

Proof. We have

$$\begin{aligned}\Delta&=\theta_{p^k,r^k}(x^k+d^k)-\theta_{p^k,r^k}(x^k),\\&=L_{\bar{c}}(x^k+d^k)-L_{\bar{c}}(x^k)+(p^k-\bar{\lambda})^t(g(x^k+d^k)-g(x^k))\\&\quad-\bar{c}\left(\sum_{i=1}^m g_i(x^k+d^k)^2-\sum_{i=1}^m g_i(x^k)^2\right)+r^k(\|g(x^k+d^k)\|-\|g(x^k)\|).\end{aligned}$$

Hence, using Remark 2.1, we have

$$\begin{aligned}\Delta\leqq&L_{\bar{c}}(x^k+d^k)-L_{\bar{c}}(x^k)+(\|p^k-\bar{\lambda}\|_D+r^k)\|g(x^k+d^k)\|\\&-(r^k-\|p^k-\bar{\lambda}\|_D-\bar{c}\beta\|g(x^k)\|)\|g(x^k)\|.\end{aligned} \tag{2.8}$$

We focus on the first terms, using (1.3) and (1.7):

$$L_{\bar c}(x^k+d^k)-L_{\bar c}(x^k)=L_{\bar c}(x^k+d^k)-L_{\bar c}(\bar x)+L_{\bar c}(\bar x)-L_{\bar c}(x^k)$$
$$=-\tfrac{1}{2}(x^k-\bar x)^t H_{\bar c}(x^k-\bar x)+o(\|x^k-\bar x\|_U^2).$$

This with (2.8) and the positive definiteness of $H_{\bar c}$ imply (2.7). □

Proof of Theorem 2.1. From the constraints of (1.4) and (1.7) we deduce the existence of some $a_1>0$ such that for k large enough

$$\|g(x^k+d^k)\|\leqq a_1\|x^k-\bar x\|_U^2.$$

From Lemma 2.2 and the positive definiteness of $H_{\bar c}$, it follows that for some $a_2>0$ and k large enough

$$\Delta_1=\theta_{p^k,r^k}(x^k+d^k)-\theta_{p^k,r^k}(x^k)$$
$$\leqq-\tfrac{1}{2}[1-\varepsilon_2-a_2(\|p^k-\bar\lambda\|_D+r^k)](x^k-\bar x)^t H_{\bar c}(x^k-\bar x)$$
$$-(r^k-\|p^k-\bar\lambda\|_D-\bar c\beta\|g(x^k)\|)\|g(x^k)\|.$$

Using (2.4) and (2.5) we deduce that for k large enough, and r_0 small enough,

$$\Delta_1\leqq-\tfrac{1}{2}(1-2\varepsilon_2)(x^k-\bar x)^t H_{\bar c}(x^k-\bar x)-\tfrac{2}{3}r^k\|g(x^k)\|.$$

From Lemma 2.1 and (2.4) we deduce that for k large enough

$$\Delta_2=\tilde\theta^k(x^k+d^k)-\theta_{p^k,r^k}(x^k)\geqq-(1+\varepsilon_1)(x^k-\bar x)^t H_{\bar c}(x^k-\bar x)-\tfrac{4}{3}r^k\|g(x^k)\|.$$

We must prove that $(\frac{1}{2}-\varepsilon)\Delta_2-\Delta_1\geqq 0$. Using the inequalities above, we find (for $0<\varepsilon<\frac{1}{2}$ and k large enough)

$$(\tfrac{1}{2}-\varepsilon)\Delta_2-\Delta_1\geqq\tfrac{1}{2}[1-2\varepsilon_2-(1-2\varepsilon)(1+\varepsilon_1)](x^k-\bar x)^t H_{\bar c}(x^k-\bar x)+\tfrac{4}{3}\varepsilon r^k\|g(x^k)\|,$$
$$\geqq\tfrac{1}{2}(2\varepsilon-2\varepsilon_2-\varepsilon_1)(x^k-\bar x)^t H_{\bar c}(x^k-\bar x).$$

Since ε_1 and ε_2 may be taken arbitrarily small for r_0 small enough and k large enough, we get the result. □

This result suggests building an algorithm, using a penalty function of type $\theta_{p^k,r^k}(x)$, where p^k and r^k are modified at each iteration to ensure a global convergence, which satisfies the hypothesis of Theorem 2.1 after a finite number of iterations. This is the subject of the following section.

3. A globally and superlinearly convergent algorithm. We define a kind of quadratic model of θ_{p^k,r^k} around x^k:

$$\theta^k(x)=\tilde\theta^k(x)+\tfrac{1}{2}(x-x^k)^t H^k(x-x^k). \tag{3.1}$$

We consider the following algorithm.

ALGORITHM 1.

(0) Choose x^1, p^1, r^1, H^1 such that $r^1>0$ and H^1 is positive definite. Set $k=1$. Choose $\beta\in]0,1[$, $\sigma\in]0,\frac{1}{2}[$.

(1) Solve the problem

$$\min\ \theta^k(x^k+d),\qquad d\in\mathbb{R}^n. \tag{3.2}$$

Let $\tilde d^k$ be the unique solution of (3.2). If $\tilde d^k=0$, stop.

(2) Let l be the smallest nonnegative integer such that

$$\theta_{p^k,r^k}(x^k+(\beta)^l\tilde d^k)-\theta_{p^k,r^k}(x^k)\leqq\sigma(\tilde\theta^k(x^k+(\beta)^l\tilde d^k)-\theta_{p^k,r^k}(x^k)), \tag{3.3}$$
$$\rho^k=(\beta)^l,\qquad x^{k+1}=x^k+\rho^k\tilde d^k.$$

(3) $k=k+1$. Set p^k, r^k, H^k with $r^k>0$ and H^k positive definite. Go to (1).

We remark that θ_{p^k,r^k} and $\tilde{\theta}^k$ have the same directional derivatives at x^k and that this derivative in the direction $\tilde{d}^k$ is strictly negative; hence, the integer l of step (2) is well defined.

We now proceed to give an explicit adaptation rule for p^k and r^k. This needs some preliminary considerations. Consider

$$Q^k(\lambda) = \tfrac{1}{2}\lambda^t \nabla g(x^k)^t (H^k)^{-1} \nabla g(x^k)\lambda + \lambda^t (\nabla g(x^k)^t (H^k)^{-1} \nabla f(x^k) - g(x^k)).$$

It is well known that the quadratic program (1.4) is equivalent to

$$\text{(3.4)} \quad \begin{array}{ll} \text{(i)} & \lambda^{k+1} = \arg\min Q^k(\lambda), \qquad \lambda \in \mathbb{R}^m, \\ \text{(ii)} & d^k = -(H^k)^{-1}(\nabla f(x^k) + \nabla g(x^k)\lambda^{k+1}). \end{array}$$

On the other hand, from Bonnans and Gabay [4] we deduce that (3.2) is equivalent to

$$\text{(3.5)} \quad \begin{aligned} &\tilde{\lambda}^{k+1} = \arg\min \{Q^k(\lambda), \|\lambda - p^k\|_D \leqq r^k\}, \\ &\tilde{d}^k = -(H^k)^{-1}(\nabla f(x^k) + \nabla g(x^k)\tilde{\lambda}^{k+1}). \end{aligned}$$

We deduce from (3.4) and (3.5) that

$$\text{(3.6)} \quad \{\|\tilde{\lambda}^{k+1} - p^k\|_D < r^k \Rightarrow \{\text{(1.4) has a solution } (d^k, \lambda^{k+1}) \text{ equal to } (\tilde{d}^k, \tilde{\lambda}^{k+1})\}.$$

We define the sequences

$$D^k = \|\nabla f(x^k) + \nabla g(x^k)\tilde{\lambda}^k\|_U + \|g(x^k)\|,$$

$$S^k = \max\{1/D^l, l = 1 \text{ to } k\}.$$

The monotonically nondecreasing sequence $\{S^k\}$ has the following property.

LEMMA 3.1. *If $\{(x^k, \tilde{\lambda}^k)\}$ is bounded, there exists a subsequence of $\{(x^k, \tilde{\lambda}^k)\}$ converging to some $(\bar{x}, \bar{\lambda})$ satisfying* (1.3) *if and only if $S^k \to +\infty$.*

Let α_i, $i = 1$ to 4, be some positive constants. The adaptation rule for p^k is as follows. An initial value p^1 is chosen; then

(3.7) Let l' be the index of the last iteration at which p^k has been changed ($l' = 1$ if this event never occurred). Then

$$p^k = \begin{cases} \tilde{\lambda}^k & \text{if } S^k > S^{l'} + \alpha_1, \\ p^{k-1} & \text{otherwise.} \end{cases}$$

We need some tools to define the adaptation law on r^k. For any $a > 0$, let

$$s(a) = \min\{10^q;\ a \leqq 10^q,\ q \text{ is an integer}\}.$$

If $\{a^n\}$ is a sequence of positive numbers, the transformed sequence $\{s(a^n)\}$ has the following properties:

$$\text{(3.8)} \quad \{\{a^n\} \to 0\} \Leftrightarrow \{s(a^n) \to 0\},$$

$$\text{(3.9)} \quad \{\limsup a^n = +\infty\} \Leftrightarrow (\limsup s(a^n) = +\infty\},$$

$$\text{(3.10)} \quad \{a^n \uparrow a,\ 0 < a < +\infty\} \Rightarrow \{s(a^n) = s(a) \text{ for } n \text{ large enough}\}.$$

We define the sequence ϕ^k by the following rule:

(0) $\phi^1 = 1$.

(1) Let l'' be the index of the last iteration at which $\phi^{l''}$ was nonnull.
If $S^k - S^{l''} > \alpha_2$ and $\rho^k \neq 1$, $\phi^k = S^k - S^{l''}$.
Else $\phi^k = 0$.

We obviously have

$$\lim S^k = +\infty \Rightarrow \left\{ \sum_k \phi^k = +\infty \text{ or } \rho^k = 1 \text{ for } k \text{ large enough} \right\}, \tag{3.11}$$

$$\lim S^k < +\infty \Rightarrow \phi^k = 0 \text{ for large enough.} \tag{3.12}$$

We suppose that

$$0 < \alpha_4 < 1. \tag{3.13}$$

The adaptation rule for r^k is given by

$$\begin{aligned} &\text{(i)} && r_1^k = (3+\alpha_3)\max\left(\|\tilde{\lambda}^k - p^k\|_D, \min\left(1, (D^k)^{\alpha_4}\right)\right), \\ &\text{(ii)} && r_2^k = \max\left(r_1^k, r_2^{k-1} - \phi^k\right), \\ &\text{(iii)} && r^k = s(r_2^k). \end{aligned} \tag{3.14}$$

The motivation for this rule is as follows. First we compute an estimate r_1^k that satisfies (2.4) if $\tilde{\lambda}^k$ is close to $\bar{\lambda}$; if the convergence occurs in the sense that $x^k \to \bar{x}$ and $D^k \to 0$, then we also have $r_1^k \geqq (D^k)^{\alpha_4}$; since $D^k / \|x^k - \bar{x}\|$ cannot converge to zero, hypothesis (2.5) is satisfied. Then in step (ii) we prevent r_2^k from decreasing if no sufficient progress has been made. Finally, in step (iii) we make a transformation in the hope to get r^k constant for k large enough when the convergence occurs (see case (b) of Theorem 3.1).

Remark 3.1. We may detail step (3) of Algorithm 1 as follows. k is set to $k+1$, then:

- First D^k, S^k, and ϕ^k are computed;
- Then p^k is computed using (3.7);
- Finally r^k is computed using (3.14), and H^k is set.

We now prove that the resulting algorithm is globally and superlinearly convergent.

THEOREM 3.1. *Let $\{x^k\}$ be a sequence computed by Algorithm* 1, *p^k and r^k being given by* (3.7) *and* (3.14). *We suppose that the sequences $\{H^k\}$ and $\{(H^k)^{-1}\}$ are bounded and that $0 < \sigma < \frac{1}{2}$. Then we have the following.*

(a) *One of the following three events occurs*:

(i) $\liminf_{k\to\infty} (\|\nabla f(x^k) + \nabla g(x^k)\tilde{\lambda}^k\|_U + \|g(x^k)\|) = 0$.

(ii) *For k large enough, (p^k, r^k) is equal to some (p, r), $\tilde{\lambda}^k$ is equal to λ^k and $\|\lambda^k - p\|_D < r$, $\theta_{p,r}(x^k) \to -\infty$ or $\{\nabla g(x^k)\}$ is unbounded.*

(iii) *For k large enough, p^k is equal to some p, $r^k \to +\infty$, $\limsup \|\tilde{\lambda}^k\|_D = +\infty$ and either $\{x^k\}$ is unbounded or some limit point $\bar{x}$ of $\{x^k\}$ does not satisfy* (1.2).

(b) *If $x^k \to \bar{x}$ satisfying* (1.2), *then there exists $\bar{\lambda}$ satisfying* (1.3) *and $(\tilde{\lambda}^k, d^k) \to (\bar{\lambda}, 0)$. If in addition $(\bar{x}, \bar{\lambda})$ satisfies* (2.1), *then hypotheses* (2.4) *and* (2.5) *are satisfied, and $\tilde{d}^k = d^k$ for k great enough. If* (1.7) *is also satisfied as well as* (2.1), *then r^k is equal to some $r > 0$ and $\rho^k = 1$ for k great enough, and x^k converges superlinearly to $\bar{x}$.*

Proof. (a) We suppose that (i) does not occur. Then S^k is bounded and ϕ^k is null for k large enough. Hence by (3.7) and (3.14), for k large enough, p^k is equal to some p and r^k is an increasing sequence.

If $\{\tilde{\lambda}^k\}$ is unbounded, (3.14)(i) implies that $r^k \to +\infty$. Then if $\{x^k\}$ is bounded, we deduce from (3.5) that it has a limit point $\bar{x}$ such that $\nabla g_i(\bar{x})$, $i = 1$ to m, are not linearly independent. Hence (iii) is satisfied.

If $\{\tilde{\lambda}^k\}$ is bounded, so is $\{r^k\}$ by (3.14); hence by (3.10), r^k is equal to some r for k large enough such that, by (3.14), $r > \|\tilde{\lambda}^k - p\|_D$. This implies that $\tilde{\lambda}^k = \lambda^k$ and $\tilde{d}^k = d^k$. Let us suppose that $\theta_{p,r}(x^k)$ is bounded from below and that $\{\nabla g(x^k)\}$ is bounded; we

must then get a contradiction to prove that (ii) holds. Let us prove that, for k large enough,

$$\theta_{p,r}(x^k) - \theta_{p,r}(x^k + \rho^k d^k) \geqq \sigma \rho^k (d^k)^t H^k d^k. \tag{3.15}$$

As $d^k = \tilde{d}^k$, we have, using the optimality conditions of (1.4):

$$\begin{aligned}
\theta_{p,r}(x^k) - \tilde{\theta}^k(x^k + d^k) &= -\nabla f(x^k)^t d^k - p^t \nabla g(x^k)^t d^k + r\|g(x^k)\|, \\
&= (d^k)^t H^k d^k + (\lambda^k - p)^t \nabla g(x^k)^t d^k + r\|g(x^k)\|, \\
&\geqq (d^k)^t H^k d^k + (r - \|\lambda^k - p\|_D)\|g(x^k)\|, \\
&\geqq (d^k)^t H^k d^k.
\end{aligned}$$

The convexity of $\tilde{\theta}$ implies

$$\theta_{p,r}(x^k) - \tilde{\theta}^k(x^k + \rho^k d^k) \geqq \rho^k(\tilde{\theta}^k(x^k) - \tilde{\theta}^k(x^k + d^k)) \geqq \rho^k (d^k)^t H^k d^k.$$

Then (3.15) is a consequence of the linesearch rule (3.3). Summing (3.15) over k, we deduce that

$$\sum_k \rho^k (d^k)^t H^k d^k < +\infty.$$

The equality $x^{k+1} - x^k = \rho^k d^k$ and the boundedness of $\{(H^k)^{-1}\}$ imply

$$\sum_k \|x^{k+1} - x^k\|_U \|d^k\|_U < +\infty. \tag{3.16}$$

If $d^k \to 0$ for some subsequence k, then the boundedness of $\{(H^k)\}$ and $\{\nabla g(x^k)\}$, relation (3.4)(ii), and the constraint of (1.4) imply that $S^k \to \infty$, which is impossible. If $\liminf \|d^k\| > 0$, then (3.16) implies the convergence of $\{x^k\}$ toward some $\bar{x}$. From the boundedness of $\{\lambda^k\}$, $\nabla g(x^k)$, and $\{(H^k)^{-1}\}$ and (3.4)(ii), we deduce that $\{d^k\}$ is bounded. As $\|x^{k+1} - x^k\| \to 0$ and $\liminf \|d^k\| > 0$, $\{\rho^k\}$ must converge to zero; this implies that for any integer $l \geqq 0$, the following inequality holds for k large enough:

$$\theta_{p,r}(x^k + (\beta)^l d^k) - \theta_{p,r}(x^k) > \sigma(\tilde{\theta}^k(x^k + (\beta)^l d^k) - \theta_{p,r}(x^k)).$$

Passing to the limit for some sequence K such that $\{d^k\}_{k \in K} \to \bar{d} \neq 0$, we get that, for all integers $l \geqq 0$,

$$\theta_{p,r}(\bar{x} + (\beta)^l \bar{d}) - \theta_{p,r}(\bar{x}) > \sigma(\tilde{\theta}(\bar{x} + (\beta)^l \bar{d}) - \theta_{p,r}(\bar{x})),$$

with $\tilde{\theta}$ defined as $\tilde{\theta}^k$ at point $\bar{x}$. Extracting from K a subsequence if necessary, we may suppose that for k in K, $\lambda^k \to \bar{\lambda}$ and $H^k \to \bar{H}$, with $\bar{H}$ positive definite. Passing to the limit in the constraints of (1.4) and (3.4)(ii), we find that $\bar{d}$ is the unique solution of the quadratic problem

$$\text{Minimize } \nabla f(\bar{x})^t d + \tfrac{1}{2} d^t \bar{H} d \quad \text{subject to } g(\bar{x}) + \nabla g(\bar{x})^t d = 0.$$

Hence the linesearch rule of Algorithm 1 starting at $\bar{x}$ must be satisfied at the first iteration by some $\bar{\rho} = (\beta)^{\bar{l}}$, in contradiction to the inequality above.

(b) If $x^k \to \bar{x}$ satisfying (1.2), then cases (ii) and (iii) of (a) may not occur; hence for some subsequences K, $D^k \to 0$ when $k \to \infty$ in K. As $\lim \nabla g(x^k) = \nabla g(\bar{x})$ has full rank, this implies that $\{\tilde{\lambda}^k\}_{k \in K}$ is bounded; as $\|\nabla f(x^k) + \nabla g(x^k)\tilde{\lambda}^k\|$ vanishes when $k \to \infty$ in K, any limit-point $\bar{\lambda}$ of $\{\tilde{\lambda}^k\}_{k \in K}$ satisfies (1.3); from (1.2) we obtain that $\bar{\lambda}$ is unique and $\{\tilde{\lambda}^k\}_{k \in K} \to \bar{\lambda}$.

By (3.7), p^k is changed only for values of D^k converging to zero, and hence for values of $\tilde{\lambda}^k$ converging to $\bar{\lambda}$; hence $p^k \to \bar{\lambda}$. But (see (3.5)) we obtain that, for all k,

$$\|\tilde{\lambda}^k - \bar{\lambda}\| \leqq \|\tilde{\lambda}^k - p^k\| + \|p^k - \bar{\lambda}\| \leqq \|\lambda^k - p^k\| + \|p^k - \bar{\lambda}\|.$$

Since $\{H^k\}$ and $\{(H^k)^{-1}\}$ are bounded, necessarily $d^k \to 0$ and $\lambda^k \to \bar{\lambda}$; with the above inequality, this implies that all the sequence $\tilde{\lambda}^k$ converges to $\bar{\lambda}$, and hence $D^k \to 0$. Now consider the case when (2.1) is also satisfied. Then the Jacobian of the optimality conditions (1.3) is nondegenerate at $(\bar{x}, \bar{\lambda})$; from it we deduce (see [2]) that there exists $C_1 > 0$ such that for k large enough

$$\|x^k - \bar{x}\| + \|\tilde{\lambda}^k - \bar{\lambda}\| \leqq C_1 D^k.$$

With (3.13) and (3.14), this implies that $r^k / \|x^k - \bar{x}\| \geqq r_1^k / \|x^k - \bar{x}\| > \min(1, (D^k)^{\alpha_4})/(C_1 D^k) \to +\infty$; hence (2.5) holds. Let us prove that (2.4) also holds with $\gamma = \alpha_3/2$; if not, there exists a subsequence K such that (using (3.14) for the left inequality), for k large enough in K,

$$(3+\alpha_3)\|\tilde{\lambda}^k - p^k\|_D \leqq r_1^k \leqq r^k \leqq (3+\alpha_3/2)\|\bar{\lambda} - p^k\|_D;$$

hence

$$(1+\alpha_3/3)\|\tilde{\lambda}^k - p^k\|_D \leqq (1+\alpha_3/6)\|\bar{\lambda} - p^k\|_D.$$

Using this inequality, we get

$$\begin{aligned}\|\bar{\lambda} - p^k\|_D &\leqq \|\bar{\lambda} - \tilde{\lambda}^k\|_D + \|\tilde{\lambda}^k - p^k\|_D, \\ &\leqq \|\bar{\lambda} - \tilde{\lambda}^k\|_D + \frac{1+\alpha_3/6}{1+\alpha_2/3}\|\bar{\lambda} - p^k\|_D.\end{aligned}$$

Hence for k large enough in K and for some $C_2 > 0$

$$\begin{aligned}\|\bar{\lambda} - p^k\|_D &\leqq \frac{1+\alpha_3/3}{\alpha_3/6}\|\bar{\lambda} - \tilde{\lambda}^k\|_D \\ &\leqq \frac{1\alpha_3/3}{\alpha_3/6} C_1 D^k \leqq C_2 (r^k)^{1/\alpha_4}.\end{aligned}$$

Hence for this subsequence $\|\bar{\lambda} - p^k\|_D / r^k$ converges to $+\infty$, contradicting our hypothesis; hence (2.4) holds.

If in addition (1.7) holds, let us prove that $\rho^k = 1$ for k large enough; this will prove that the superlinear convergence holds. If $\rho^k \neq 1$ for some subsequence K, from (3.11) and (3.14) we deduce that $r_1^k \to 0$ and $r_2^k \to 0$ (for all k). As $r^k \leqq 10 r_2^k$, $r^k \to 0$. As (2.4) and (2.5) are satisfied, r^k will be inferior to the value r_0 given by Theorem 2.1 with ε satisfying $\sigma = \frac{1}{2} - \varepsilon$. Then the conclusion of Theorem 2.1 implies that $\rho^k = 1$ for k large enough, in contradiction to our hypothesis. This proves that $\rho^k = 1$ and $\phi^k = 0$ for k large enough; hence by (3.14), as $r_1^k \to 0$, r_2^k and r^k are constant for k large enough. □

We comment on Theorem 3.1. Conclusion (a) is concerned with global convergence. Case (i) is the one in which the global convergence really occurs in a weak sense. Let us assume that $\nabla g(x)$ has full rank for all x. Then if (i) does not occur we deduce that $\{x^k\}$ is unbounded. An extension of the algorithm, including upper and lower bound constraints on all variables, might exclude this case (however, such an extension is not trivial). Conclusion (b) essentially says that when the convergence toward a regular local solution holds, the algorithm reduces to Newton's method (without linesearch) after a finite number of iterations. Our algorithm needs essentially

the computation of one quadratic program at each iteration (the amount of computation needed to update p^k and r^k is negligible). Also, the reduction of the nonsmooth part of the criterion might, even far from the optimum, improve the linesearch. The method is presently being tested on some large-scale network problems; numerical results will appear elsewhere.

Acknowledgments. The author thanks J. C. Dodu of Electricité de France and two referees for valuable suggestions that greatly improved the paper.

CONTROL OF MARKOV CHAINS WITH LONG-RUN AVERAGE COST CRITERION: THE DYNAMIC PROGRAMMING EQUATIONS*

VIVEK S. BORKAR†

Abstract. The long-run average cost control problem for discrete time Markov chains on a countable state space is studied in a very general framework. Necessary and sufficient conditions for optimality in terms of the dynamic programming equations are given when an optimal stable stationary strategy is known to exist (e.g., for the situations studied in [*Stochastic Differential Systems, Stochastic Control Theory and Applications*, IMA Vol. Math. App. 10, Springer-Verlag, New York, Berlin, 1988, pp. 57-77]). A characterization of the desired solution of the dynamic programming equations is given in a special case. Also included is a novel convex analytic argument for deducing the existence of an optimal stable stationary strategy when that of a randomized one is known.

Key words. Markov chains, long-run average cost, optimal control, dynamic programming, stationary strategy

1. Introduction. In [5], the long-run average cost control problem for a Markov chain on a countable state space was studied under a very general setup. The two theoretical issues in this problem are: (i) establishing the existence of an optimal stable stationary strategy; and (ii) characterizing the same via the dynamic programming equations. The main thrust of [5] was (i), whereas (ii) was only cursorily touched on. The present paper has two objectives. One is to provide a more elegant alternative for a part of the argument leading to (i) in [5]. This alternative approach unmasks the underlying convex analytic structure not apparent in the lengthier argument of [5] and reflects the spirit of [6], where other cost criteria have been considered in a similar light. The principal objective of this paper, however, is to give a detailed treatment of the dynamic programming equations, settling (ii) above. The class of cost functions considered here is much more general than that of [5], where the cost functions have been assumed to be bounded.

Although this paper is a sequel to [5] in principle, it can be read independently.

The long-run average cost control problem for Markov chains dates back to [10] for the finite state space case and [7] for the countable state space. In most of its early development, the problem was treated as the "vanishing discount limit" of the discounted cost control problem. This classical approach is by now standard textbook material and the reader is referred to [2] and [13] (among others) for a succinct treatment. The shortcoming of this approach is that it needs a strong uniform stability condition in one of its various garbs [8]. This condition fails in many applications of interest such as controlled queues, as is evidenced in [12]. Motivated by this, in [3] and [4] Borkar has developed an alternative approach for Markov chains exhibiting a "nearest neighbor motion." The latter feature requires that each state have only finitely many neighbors and that the minimum path length from state i to any prescribed finite subset of the state space tend to infinity as i does. The approach was based on a characterization of the almost surely limit points of the empirical process of the joint state and control process. It was this approach that was carried over to a much more general setup in [5]. The present work complements [5] in the sense already described.

The paper is organized as follows. Section 2 is devoted to a recapitulation of the notation introduced in [3] and used throughout [3]–[6]. This notation is not standard, but turns out to be extremely handy for the approach of [3]–[6] and the present paper. Using this notation, § 3 states the principal assumptions under which the dynamic programming equations will be studied and discusses various ramifications thereof. Section 4 treats the necessary conditions for optimality in terms of the dynamic programming equations. The proofs here are very much along the lines of those of [4, § 5] except for the extra work needed to take care of a possibly unbounded cost function and the absence of a "nearest neighbor motion" hypothesis. We include the full details to make this account self-contained. The so-called "value function" appearing in the dynamic programming equations is further studied in § 5. Section 6 establishes sufficient conditions for optimality using the dynamic programming equations. Section 7 concludes with a discussion of the problem of characterizing the desired solution of the dynamic programming equations. The Appendix describes the convex analytic argument mentioned at the beginning of this section.

Note that we develop the dynamic programming formalism given the existence of an optimal stable stationary strategy by independent means, e.g., those of [4] and [5]. This is the opposite of the conventional order of things.

2. Notation and preliminaries. Let X_n, $n = 1, 2, \cdots$, be a controlled Markov chain on state space $S = [1, 2, \cdots]$ with transition matrix $P_u = [[p(i, j, u_i)]]$, $i, j \in S$ indexed by the control vector $u = [u_1, u_2, \cdots]$. Here, $u_i \in D(i)$, $i \in S$, for some prescribed compact metric spaces $D(i)$. The functions $p(i, j, \cdot)$ are assumed to be continuous. By replacing each $D(i)$ by $\Pi D(k)$ and $p(i, j, \cdot)$ by its composition with the projection $\Pi D(k) \to D(i)$, we may assume that all $D(i)$'s are replicas of the same compact metric space D. We do so and then let L denote the countable product of copies of D with the product topology.

For any Polish space Y, $M(Y)$ will denote the space of probability measures on Y with the topology of weak convergence and for $n = 1, 2, \cdots, \infty$, Y^n will denote the n-times product of Y with itself.

A control strategy (CS) is a sequence $\{\xi_n\}$, $\xi_n = [\xi_n(1), \xi_n(2), \cdots]$ of L-valued random variables such that for $i \in S$, $n \geqq 1$,

$$P(X_{n+1} = i / X_m, \xi_m, m \leqq n) = p(X_n, i, \xi_n(X_n)). \tag{2.1}$$

We say that $\{X_n\}$ is governed by $\{\xi_n\}$ whenever (2.1) holds. If $\{\xi_n\}$ are identically distributed and ξ_n is independent of X_m, $m \leqq n$; ξ_m, $m < n$, for each n, we call the control strategy a stationary randomized strategy (SRS). We call it a stationary strategy (SS) if in addition to the above, the law of ξ_n, $n \geqq 1$, is assumed to be a Dirac measure. The motivation for this nomenclature is self-evident.

We assume throughout that S is a single communicating class under any SRS. If $\{X_n\}$ is positive recurrent under an SRS, we call the latter a stable SRS or SSRS. A stable SS (or SSS) is defined analogously.

Let $\{\xi_n\}$ be an SRS. Let $\Phi \in M(L)$ denote the common law of ξ_n, $n \geqq 1$. As we shall be interested only in the law of the process $(X_n, \xi_n(X_n))$, $n \geqq 1$, it suffices to consider Φ of the form $\Phi = \Pi \hat{\Phi}_i$, $\hat{\Phi}_i \in M(D)$ for $i \in S$. We shall denote this SRS by $\gamma[\Phi]$ and the corresponding transition matrix by $P[\Phi] = [[\int p(i, j, u) \hat{\Phi}_i(du)]]$. If the SRS is stable, it will have a unique invariant probability measure denoted by $\pi[\Phi] = [\pi[\Phi](1), \pi[\Phi](2), \cdots] \in M(S)$. For $f: S \to R$ and measurable $g: S \times D \to R$, define

$$C_f[\Phi] = \sum_i f(i) \pi[\Phi](i),$$

$$g_\Phi(i) = \int g(i, u)\hat{\Phi}_i(du), \qquad i \in S,$$

$$C_g[\Phi] = \sum_i g_\Phi(i)\pi[\Phi](i)$$

whenever the quantity on the right is defined. If $\Phi = \delta_\xi$ (i.e., the Dirac measure at ξ) for some $\xi \in L$, $\gamma[\Phi]$ is an SS and will be denoted by $\gamma\{\xi\}$. Correspondingly, we replace $P[\Phi]$, $\pi[\Phi]$, $C_f[\Phi]$, $C_g[\Phi]$ by $P\{\xi\} = P_\xi$, $\pi\{\xi\}$, $C_f\{\xi\}$, $C_g\{\xi\}$, respectively.

For an SSRS $\gamma[\Phi]$, define $\hat{\pi}[\Phi] \in M(S \times D)$ by $\int f d\hat{\pi}[\Phi] = C_f[\Phi]$ for all bounded continuous $f: S \times D \to R$. For an SSS $\gamma\{\xi\}$, define $\hat{\pi}\{\xi\} \in M(S \times D)$ analogously.

Let $k: S \times D \to R^+$ be continuous. Define

$$\psi_n = \frac{1}{n} \sum_{m=1}^{n} k(X_m, \xi_m(X_m)), \tag{2.2}$$

$$\psi_\infty = \liminf_{n \to \infty} \psi_n. \tag{2.3}$$

Our objective is to almost surely minimize ψ_∞ over all CS. If this is achieved for some CS, that CS will be said to be optimal.

Note that under an SSRS $\gamma[\Phi]$ or an SSS $\gamma\{\xi\}$, $\psi_n \to C_k[\Phi]$ almost surely ($\psi_n \to C_k\{\xi\}$ almost surely, respectively) where $+\infty$ is a possible value for $C_k[\Phi]$, $C_k\{\xi\}$. Our aim will be to show the existence of an optimal SSS and characterize the same. Thus it is natural to impose the condition that for at least one SSS $\gamma\{\xi\}$, $C_k\{\xi\} < \infty$. Let

$$\beta = \inf_{\text{SSRS}} C_k[\Phi], \qquad \alpha = \inf_{\text{SSS}} C_k\{\xi\}.$$

Then $\beta \leqq \alpha$.

Finally, let $\tau(i) = \min\{n > 1 | X_n = i\} (= \infty \text{ if } X_n \neq i, n \geqq 2)$, $i \in S$.

3. Stability under local perturbation. Consider the following two sets of assumptions:

(A1) $\liminf_{i \to \infty} \min_u k(i, u) \triangleq \eta > \beta$, (3.1)

(A2) $\sup_{\text{all CS}} E[\tau(1)^2 / X_1 = 1] < \infty$. (3.2)

Remarks. (a) It is not hard to see that in the absence of a blanket stability assumption, something like assumption (A1) would be needed to ensure the existence of an optimal SSS. Intuitively, (A) penalizes unstable behavior. For example, consider the case $k(i, u) = h(i)$ for some $h: S \to (0, \infty)$ satisfying $h(i) \to 0$ as $i \to \infty$. Then any SSS (or SSRS) yields a strictly positive cost while an unstable SS (or SRS) yields zero cost, making the latter optimal.

(b) More directly verifiable conditions that imply (3.2) are given in [5, § IX]. These either are conditions on the graph of the chain or require the existence of a suitable "Lyapunov function" (see [5] for details). An example appears in § 6.

In [5], it was proved that under Assumption (A1) or (A2) and for bounded k:

(1) $\psi_\infty \geqq \beta$ almost surely;

(2) There exists an SSRS $\gamma[\Phi]$ such that $C_k[\Phi] = \beta$;

(3) $\beta = \alpha$;

(4) There exists an SSS $\gamma\{\xi\}$ such that $C_k\{\xi\} = \alpha$.

In the Appendix, we provide an alternative argument to deduce (3) and (4) from (2).

In later sections we give necessary and sufficient conditions for an SSS $\gamma\{\xi\}$ to be optimal, using the "dynamic programming" equations. Some of these were stated without detailed proofs for bounded k in [5]. We make the following two assumptions:

(1) There exists an optimal SSS. (This would be implied, e.g., by Assumption (A1) or (A2).)

(2) (Stability under local perturbation.) If $\gamma\{\xi\}$ is an SSS satisfying $C_k\{\xi\}<\infty$, then for any $\xi' \in L$ such that $\xi'(i) \neq \xi(i)$ for at most one $i \in S$, $\gamma\{\xi'\}$ is an SSS and $C_k\{\xi'\}<\infty$.

In this section we make a few remarks about these conditions.

(i) If k is bounded, (2) is implied by the following condition. For any SSS $\gamma\{\xi\}$, $\gamma\{\xi'\}$ is an SSS whenever $\xi'(i)=\xi(i)$ for all but one $i \in S$.

(ii) If all SS are SSS and k is bounded, (2) holds trivially.

(iii) Condition (2) holds whenever each state in S has only finitely many neighbors, i.e., for each $i \in S$, there is a finite set $R_i \subset S$ such that $p(i, j, \cdot) \equiv 0$ for $j \notin R_i$. To see this, pick $i=1$, for example. If $\gamma\{\xi\}$ is an SSS and $C_k\{\xi\}<\infty$,

$$\infty > E[\tau(1)/X_1=1] \geqq P(\tau(j)<\tau(1)/X_1=1)E[\tau(1)/X_1=j]$$

for each $j \neq 1$. Since $P(\tau(j)<\tau(1)/X_1=1)>0$ for $j \neq 1$ by positive recurrence and single communicating class hypothesis, $a_j = E[\tau(1)/X_1=j]<\infty$ for all $j \neq 1$, and hence for all j. Thus under $\gamma\{\xi'\}$,

$$E[\tau(1)/X_1=1]=1+\sum_{j \in R_1 \setminus \{1\}} P(1, j, \xi'(1))a_j < \infty.$$

A similar argument using the fact that

$$E\left[\sum_{m=1}^{\tau(1)-1} k(X_m, \xi(X_m))/X_1=1\right]<\infty$$

under $\gamma\{\xi\}$ shows that under $\gamma\{\xi'\}$,

$$E\left[\sum_{m=1}^{\tau(1)-1} k(X_m, \xi'(X_m))/X_1=1\right]<\infty.$$

(iv) The following example describes a situation where (2) fails. Relabel S as $\{a_{00}, a_{10}, a_{11}, a_{20}, a_{21}, a_{22}, a_{30}, a_{31}, a_{32}, a_{33}, a_{40}, \cdots\}$. Let $D=[1.5, 3]$. Let $p(i, j, u)=1$, for all $u \in D$, $i=a_{mn}$, $j=a_{m(n+1)}$, $m=1, 2, \cdots$, $n=0, 1, \cdots, m-1$, and for $i=a_{mm}$, $j=a_{00}$, $m=1, 2, \cdots$. Let $f(\alpha)=\sum_n n^{-\alpha}$ for $\alpha \in D$ and $p(a_{00}, a_{m0}, \alpha)=f(\alpha)^{-1}m^{-\alpha}$, $m=1, 2, \cdots$.

Let $\{X_n\}$ be a Markov chain governed by the SS that chooses the control α whenever the chain is in a_{00}. (The transition probabilities for all transitions except those out of a_{00} are control-independent.) Letting $\tau=\inf\{n>1 | X_n=a_{00}\}$, we have

$$E[\tau/X_1=a_{00}]=f(\alpha)^{-1}\sum_{m=1}^{\infty}(m+2)m^{-\alpha},$$

which is finite for $\alpha \in (2, 3]$ and ∞ for $\alpha \in [1.5, 2]$. Changing D to $[2.5, 3]$, we get an example where (2) holds, but a_{00} has infinitely many neighbors. Thus the condition in (iii) above is sufficient but not necessary for (2) to be true.

(v) In what follows, we shall often construct a new SS from a given SSS by changing finitely many of its components. By (2), it will be an SSS and by an assumption already made, S will be a single communicating class under it.

As an immediate consequence of these assumptions, we have the following lemma.

LEMMA 3.1. *Let $\gamma\{\xi\}$ be an* SSS *for which $C_k\{\xi\}<\infty$. Then for any $i \in S$, $u \in D$,*

$$\sum_{j \in S} p(i, j, u)E_\xi\left[\sum_{n=1}^{\tau(1)} k(X_m, \xi(X_m))/X_1=j\right]<\infty, \tag{3.3}$$

$$\sum_{j\in S} p(i,j,u)E_\xi[\tau(1)/X_1=j]<\infty, \tag{3.4}$$

where $E_\xi[\ ]$ *denotes the expectation under* $\gamma\{\xi\}$.

Proof. Note that

$$\infty > E_\xi\left[\sum_{n=1}^{\tau(1)} k(X_n,\xi(X_n))/X_1=1\right] \geqq aE_\xi\left[\sum_{n=1}^{\tau(1)} k(X_n,\xi(X_n))/X_1=j\right]$$

where

$$a = P(\{X_n, n\geqq 2\} \text{ hits } j \text{ before hitting } 1/X_1=1)>0.$$

Thus

$$E_\xi\left[\sum_{n=1}^{\tau(1)} k(X_n,\xi(X_n))/X_1=j\right]<\infty \quad \forall j\in S. \tag{3.5}$$

Similarly,

$$E_\xi[\tau(1)/X_1=j]<\infty \quad \forall j\in S. \tag{3.6}$$

Let $\{\xi'_n\}$ denote a CS such that $\xi'_n=\xi$ for $n\geqq 2$ and $\xi'_1(i)=u$ for some fixed $i\in S$, $u\in D$. Let $\{X'_n\}\{X_n\}$ be the chains governed by $\{\xi'_n\}$, $\gamma\{\xi\}$, respectively, with $X'_1=X_1=i$. Let $\tau'(i)=\inf\{n>1|X'_n=i\}$. Then

$$\begin{aligned}
&k(i,u)+\sum_{j\in S} p(i,j,u)E_\xi\left[\sum_{n=1}^{\tau(1)} k(X_n,\xi(X_n))/X_1=j\right]\\
&\quad=E\left[\sum_{n=1}^{\tau'(1)} k(X'_n,\xi'_n(X'_n))\right]\\
&\quad=E\left[\left(\sum_{n=1}^{\tau'(1)} k(X'_n,\xi'_n(X'_n))\right)I\{\tau'(1)<\tau'(i)\}\right]\\
&\qquad+E\left[\left(\sum_{n=1}^{\tau'(1)} k(X'_n,\xi'_n(X'_n))\right)I\{\tau'(1)>\tau'(i)\}\right].
\end{aligned}$$

When we define $\varphi\in L$ by $\varphi(j)=\xi(j)$ for $i\neq j$ and $\varphi(i)=u$, the above is

$$\begin{aligned}
&\leqq E_\varphi\left[\sum_{n=1}^{\tau(1)} k(X_n,\varphi(X_n))/X_1=i\right]+E_\varphi\left[\sum_{n=1}^{\tau(i)} k(X_n,\varphi(X_n))/X_1=i\right]\\
&\qquad+E_\xi\left[\sum_{n=1}^{\tau(1)} k(X_n,\xi(X_n))/X_1=i\right]<\infty
\end{aligned}$$

by virtue of (3.5). Condition (3.3) follows. Condition (3.4) follows from (3.6) by analogous arguments. □

4. Necessary conditions for optimality. This section proves necessary conditions for the optimality of an SSS in terms of the dynamic programming equations (Theorem 4.1 below). Let $\gamma\{\xi\}$ be an SSS with $C_k\{\xi\}<\infty$. Define $V\{\xi\}=[V\{\xi\}(1), V\{\xi\}(2),\cdots]^T$ by

$$V\{\xi\}(i)=E_\xi\left[\sum_{n=1}^{\tau(1)-1}(k(X_n,\xi(X_n))-C_k\{\xi\})/X_1=i\right], \qquad i\in S.$$

This is well defined by virtue of (3.5), (3.6). By Lemma 3.1,

$$\sum_{j\in S} p(i,j,u)V\{\xi\}(j)$$

is also well defined for $u \in D$. Let $1_c = [1, 1, \cdots]^T$, $U =$ the infinite identity matrix $[[\delta_{ij}]]$ and $Q_\xi = [k(1, \xi(1)), k(2, \xi(2)), \cdots]^T$. The following lemma is recalled from [4].

LEMMA 4.1. *$V\{\xi\}(1) = 0$ and*

$$C_k\{\xi\}1_c = (P\{\xi\} - U)V\{\xi\} + Q_\xi. \tag{4.1}$$

Proof. The first claim follows from the fact that

$$C_k\{\xi\} = \sum_{i \in S} \pi\{\xi\}(i)k(i, \xi(i)) = E_\xi\left[\sum_{n=1}^{\tau(1)-1} k(X_n, \xi(X_n))/X_1 = 1\right] \Big/ E[\tau(1) - 1/X_1 = 1].$$

Since $V\{\xi\}(1) = 0$, we have

$$V\{\xi\}(i) = k(i, \xi(i)) - C_k\{\xi\} + E_\xi\left[\left(\sum_{n=2}^{\tau(1)-1} (k(X_n, \xi(X_n)) - C_k\{\xi\})\right) I\{\tau(1) > 2\}/X_1 = i\right]$$

$$= k(i, \xi(i)) - C_k\{\xi\} + E[V\{\xi\}(X_2) I\{\tau(1) > 2\}/X_1 = i]$$

$$= k(i, \xi(i)) - C_k\{\xi\} + E[V\{\xi\}(X_2)/X_1 = i]$$

$$= k(i, \xi(i)) - C_k\{\xi\} + \sum_{j \in S} p(i, j, \xi(i)) V\{\xi\}(j)$$

for $i \in S$. Equation (4.1) follows. □

Let $A \subset S$ be a finite set containing 1 and $\xi' \in L$ such that $\xi'(i) = \xi(i)$ for $i \notin A$. Let A_n, $n = 1, 2, \cdots$ be an increasing family of finite subsets of S containing A and increasing to S. Define $\sigma_m = \min\{n \geqq 1 | X_n \notin A_m\}$, $m = 1, 2, \cdots$ and $\sigma = \min\{n \geqq 1 | X_n \in A\}$.

Observe that by the assumptions of the previous section, $\gamma\{\xi'\}$ is an SSS with $C_k\{\xi'\} < \infty$.

LEMMA 4.2. $\lim_{n \to \infty} E_{\xi'}[V\{\xi\}(X_{\sigma_n}) I\{\tau(1) \geqq \sigma_n\}/X_1 = 1] = 0$.

Proof. For $i \notin A$,

$$V\{\xi\}(i) = E_\xi\left[\sum_{n=1}^{\sigma-1} (k(X_n, \xi(X_n)) - C_k\{\xi\})/X_1 = i\right] + E_\xi\left[\sum_{n=\sigma}^{\tau(1)-1} (k(X_n, \xi(X_n)) - C_k\{\xi\})/X_1 = i\right],$$

where we use the fact that $V\{\xi\}(1) = 0$. The first term on the right remains unchanged if $E_\xi[\ ]$ is replaced by $E_{\xi'}[\ ]$ and $k(X_n, \xi(X_n))$ by $k(X_n, \xi'(X_n))$. The second term is bounded in absolute value by

$$K = \max_{i \in A} E_\xi\left[\sum_{n=1}^{\tau(1)-1} (k(X_n, \xi(X_n)) + C_k\{\xi\})/X_1 = i\right].$$

Let $c = \max(C_k\{\xi\}, C_k\{\xi'\})$. Then for $i \notin A$,

$$|V\{\xi\}(i)| \leqq E_{\xi'}\left[\sum_{n=1}^{\sigma-1} (k(X_n, \xi'(X_n)) + c)/X_1 = i\right] + K$$

$$\leqq E_{\xi'}\left[\sum_{n=1}^{\tau(1)-1} (k(X_n, \xi'(X_n)) + c)/X_1 = i\right] + K.$$

Hence

$$|E_{\xi'}[V\{\xi\}(X_{\sigma_n})I\{\tau(1)\geqq\sigma_n\}/X_1=1]|$$
$$\leqq E_{\xi'}\left[\left(\sum_{m=\sigma_n}^{\tau(1)-1}(k(X_m,\xi'(X_m))+c)\right)I\{\tau(1)\geqq\sigma_n\}/X_1=1\right]$$
$$+KE_{\xi}[I\{\tau(1)\geqq\sigma_n\}/X_1=1]\to 0 \quad \text{as } n\to\infty. \qquad \square$$

THEOREM 4.1. *If $\gamma\{\xi\}$ is an optimal* SSS, *then*

$$\beta 1_c=\min_{\varphi}((P\{\varphi\}-U)V\{\xi\}+Q_{\varphi}). \tag{4.2}$$

Remark. By (4.1), it follows that the minimum in (4.2) is attained at $\varphi=\xi$.

Proof. Suppose not. Note that the ith component of $(P\{\varphi\}-U)V\{\xi\}+Q_{\varphi}$ depends only on the ith component of φ. Thus there exist $i\in S$, $u\in D$ and $\Delta>0$ such that if $\varphi\in L$ is defined by $\varphi(j)=\xi(j)$ for $j\neq i$ and $\varphi(i)=\mu$, then

$$\beta 1_c=(P\{\varphi\}-U)V\{\xi\}+Q_{\varphi}+J, \tag{4.3}$$

$J=[0,0,\cdots,0,\Delta,0,\cdots,0]$, with Δ in the ith place. Let $\{X_n\}$ be the chain governed by $\gamma\{\varphi\}$ with $X_1=i$. We may take $i=1$ by relabeling S if necessary. By our assumptions of the preceding section, $\gamma\{\varphi\}$ is an SSS with $C_k\{\varphi\}<\infty$. Set $A=\{1\}$ and $\{A_n\}$ as above. By (4.3),

$$\beta=E_{\varphi}[V\{\xi\}(X_{m+1})/X_m]-V\{\xi\}(X_m)+k(X_m,\varphi(X_m))+\Delta I\{X_m=1\}.$$

Thus for $n\geqq 1$,

$$\begin{aligned}\beta(\tau(1)\wedge\sigma_n-1)=&\sum_{m=1}^{\tau(1)\wedge\sigma_n-1}(E_{\varphi}[V\{\xi\}(X_{m+1})/X_m]-V\{\xi\}(X_m))\\&+\sum_{m=1}^{\tau(1)\wedge\sigma_n-1}k(X_m,\varphi(X_m))+\Delta\sum_{m=1}^{\tau(1)\wedge\sigma_n-1}I\{X_m=1\}.\end{aligned} \tag{4.4}$$

Since $V\{\xi\}(X_{\tau(1)})=V\{\xi\}(1)=0$, we have

$$E\left[\sum_{m=1}^{\tau(1)\wedge\sigma_n-1}(E_{\varphi}[V\{\xi\}(X_{m+1})/X_m]-V\{\xi\}(X_m))\right]$$
$$=-E\left[\sum_{m=1}^{\tau(1)\wedge\sigma_n}(V\{\xi\}(X_m)-E_{\varphi}[V\{\xi\}(X_m)/X_{m-1}])\right]$$
$$+E[V\{\xi\}(X_{\sigma_n})I\{\tau(1)\geqq\sigma_n\}]$$
$$=E[V\{\xi\}(X_{\sigma_n})I\{\tau(1)\geqq\sigma_n\}] \quad \text{(by the optional sampling theorem)}$$
$$\to 0 \quad \text{as } n\to\infty,$$

by Lemma 4.2. Taking expectations in (4.4), letting $n\to\infty$, and then dividing by $E_{\varphi}[\tau(1)]-1$, we get

$$\beta=C_k\{\varphi\}+\Delta\pi\{\varphi\}(1)>C_k\{\varphi\},$$

contradicting the definition of β. The claim follows. $\square$

The function $i\to V\{\xi\}(i)$ corresponding to an optimal SSS $\gamma\{\xi\}$ is called the value function and (4.2) the dynamic programming equations.

5. The value function. The definition of the value function in the preceding section depends on our choice of the specific optimal SSS $\gamma\{\xi\}$ and the state "1." In this section, we eliminate this dependence.

LEMMA 5.1. *Suppose* $W=[W(1), W(2), \cdots]^T$ *satisfies*

$$\beta 1_c = \inf_{\varphi}((P\{\varphi\}-U)W+Q_{\varphi}),$$

$$\sup_i |W(i)-V\{\xi\}(i)|<\infty$$

for some optimal SSS $\gamma\{\xi\}$. *Then* $W=V\{\xi\}+$ *constant* $\times 1_c$. *In particular, if* $W(1)=0$, *then* $W=V\{\xi\}$.

Proof. Since

$$\beta 1_c=(P\{\xi\}-U)V\{\xi\}+Q_{\xi}\leqq(P\{\xi\}-U)W+Q_{\xi},$$

we have

$$(P\{\xi\}-U)(W-V\{\xi\})\geqq 0.$$

It follows that under $\gamma\{\xi\}$, $W(X_n)-V\{\xi\}(X_n)$, $n\geqq 1$, is a bounded submartingale with respect to the natural filtration of $\{X_n\}$ and hence converges. Since $\{X_n\}$ visits each $i\in S$ infinitely often, this is possible only if $W(X_n)-V\{\xi\}(X_n)$, $n\geqq 1$, is almost surely a constant sequence. □

LEMMA 5.2. *Let* $\gamma\{\xi\}$, *let* $V\{\xi\}$ *be as above and for some* $i\in S$, *and define* $V'\{\xi\}=[V'\{\xi\}(1), V'\{\xi\}(2), \cdots]^T$ *by*

$$V'\{\xi\}(j)=E_{\xi}\left[\sum_{m=1}^{\tau(i)-1}(k(X_m,\xi(X_m))-\beta)/X_1=j\right].$$

Then

$$V'\{\xi\}=V\{\xi\}+\text{constant}\times 1_c.$$

Remark. Note that (4.2) remains unchanged if we change $V\{\xi\}$ by a constant multiple of 1_c.

Proof. For any $j\in S$,

$$|V\{\xi\}(j)-V'\{\xi\}(j)|\leqq E\left[\sum_{m=\tau(1)\wedge\tau(i)}^{\tau(1)\vee\tau(i)}(k(X_m,\xi(X_m))+\beta)/X_1=j\right]$$

$$\leqq E\left[\sum_{m=1}^{\tau(1)}(k(X_m,\xi(X_m))+\beta)/X_1=i\right] \tag{5.1}$$

$$+E\left[\sum_{m=1}^{\tau(i)}(k(X_m,\xi(X_m))+\beta)/X_1=1\right].$$

Since the choice of state "1" in the preceding section was arbitrary, it is clear that (4.2) also holds with $V'\{\xi\}$ replacing $V\{\xi\}$. The claim now follows from (5.1) and the preceding lemma. □

LEMMA 5.3. *For* $i\in S$, $\gamma\{\xi\}$, $V\{\xi\}$ *as above,*

$$V\{\xi\}(i)=\min E_{\varphi}\left[\sum_{m=1}^{\tau(1)-1}(k(X_m,\varphi(X_m))-\beta)/X_1=i\right],$$

where the minimum is over all SSS $\gamma\{\varphi\}$.

Proof. For $i=1$, the claim follows from the fact that for any SSS $\gamma\{\varphi\}$,

$$E_\varphi\left[\sum_{m=1}^{\tau(1)-1}(k(X_m,\varphi(X_m))-\beta)/X_1=1\right]=E_\varphi[\tau(1)-1](C_k\{\varphi\}-\beta)\geqq 0=V\{\xi\}(1).$$

Take $i\neq 1$. Suppose the claim is false. Then for some SSS $\gamma\{\varphi\}$,

$$E_\varphi\left[\sum_{m=1}^{\tau(1)-1}(k(X_m,\varphi(X_m))-\beta)/X_1=i\right]<V\{\xi\}(i). \tag{5.2}$$

Consider the chain $\{X_n\}$ with $X_1=1$ governed by a CS $\{\xi_n\}$ such that between each successive returns to state 1, $\xi_n=\xi$ until $\{X_n\}$ hits i (if it does) and equals φ from then on until it returns to 1. From (5.2) it follows that under $\{\xi_n\}$,

$$\begin{aligned}
&E\left[\sum_{m=1}^{\tau(1)-1}(k(X_m,\xi_m(X_m))-\beta)\right]\\
&\quad=E\left[\left(\sum_{m=1}^{\tau(1)-1}(k(X_m,\xi(X_m))-\beta)\right)I\{\tau(i)>\tau(1)\}\right]\\
&\qquad+E\left[\left(\sum_{m=1}^{\tau(i)-1}(k(X_m,\xi(X_m))-\beta)\right)I\{\tau(i)<\tau(1)\}\right]\\
&\qquad+E\left[\sum_{m=\tau(i)}^{\tau(1)-1}(k(X_m,\phi(X_m))-\beta)I\{\tau(i)<\tau(1)\}\right]<\text{first two terms}\\
&\qquad+E_\xi\left[\left(\sum_{m=\tau(i)}^{\tau(1)-1}(k(X_m,\xi(X_m))-\beta)\right)I\{\tau(i)<\tau(1)\}\right]\\
&\quad=V\{\xi\}(1)=0,
\end{aligned}$$

where the strict inequality holds because, under the positive recurrence and single communicating class conditions, $P_\xi(\tau(i)<\tau(1)/X_1=1)>0$.

Letting $\{\tau_n\}$ denote the successive return times to 1, we can easily see that

$$\sum_{m=\tau_i}^{\tau_{i+1}-1}(k(X_m,\xi_m(X_m))-\beta),\qquad i\geqq 1,$$

are independently and identically distributed. Thus by the strong law of large numbers,

$$\begin{aligned}
&\left[\sum_{m=1}^{\tau_n}(k(X_m,\xi_m(X_m))-\beta)\right]\Big/\tau_n\\
&\quad\xrightarrow{\text{a.s.}}E\left[\sum_{m=1}^{\tau(1)-1}(k(X_m,\xi_m(X_m))-\beta)/X_1=1\right]\Big/E[\tau(1)-1]<0.
\end{aligned}$$

This contradicts the optimality of $\gamma\{\xi\}$, proving the claim. □

COROLLARY 5.1. *$V\{\xi\}$ above does not depend on our choice of a specific optimal* SSS $\gamma\{\xi\}$.

6. Sufficient conditions for optimality. In this section, we develop sufficient conditions for optimality in terms of the dynamic programming equations. Let $\gamma\{\xi_0\}$ be an optimal SSS and let $V\{\xi_0\}$ be the value function. The traditional form of the sufficient conditions is as follows.

THEOREM 6.1. *Suppose an* SSS $\gamma\{\xi\}$ *satisfies* $C_k\{\xi\}<\infty$ *and*

$$\beta 1_c=(P\{\xi\}-U)V\{\xi_0\}+Q_\xi. \tag{6.1}$$

Then $\gamma\{\xi\}$ is optimal.

Proof. We argue as in the proof of Theorem 4.1 to conclude that

$$\beta E_\xi[\tau(1)\wedge\sigma_n - 1/X_1 = 1] = E_\xi\left[\sum_{m=1}^{\tau(1)\wedge\sigma_n - 1} k(X_m, \xi(X_m))/X_1 = 1\right] + E_\xi[V\{\xi_0\}(X_{\sigma_n})I\{\tau(1) > \sigma_n\}/X_1 = 1].$$

By Lemma 5.3, the last term is dominated by

$$E_\xi\left[E_\xi\left[\sum_{m=0}^{\tau(1)-\sigma_n-1}(k(X_{\sigma_n+m}, \xi(X_{\sigma_n+m})) - \beta)\right]\Big/ X_{\sigma_n}\right] I\{\tau(1) > \sigma_n\}/X_1 = 1\Bigg]$$
$$= E_\xi\left[\left(\sum_{m=0}^{\tau(1)-\sigma_n-1}(k(X_{\sigma_n+m}, \xi(X_{\sigma_n+m})) - \beta)\right) I\{\tau(1) > \sigma_n\}/X_1 = 1\right]$$
$$\to 0 \quad \text{as } n \to \infty.$$

Thus

$$\beta \geqq E_\xi\left[\sum_{m=1}^{\tau(1)-1} k(X_m, \xi(X_m))/X_1 = 1\right]\Big/ E_\xi[\tau(1) - 1/X_1 = 1] = C_k\{\xi\}.$$

Since $\beta \leqq C_k\{\xi\}$ in any case, $\beta = C_k\{\xi\}$ and the claim follows. □

We shall consider another variant of this. Call an SSS $\gamma\{\xi\}$ locally optimal if $C_k\{\xi\} \leqq C_k\{\xi'\}$ for all ξ' for which $\xi(i) \neq \xi'(i)$ for at most finitely many i.

THEOREM 6.2. *Suppose an* SSS $\gamma\{\xi\}$ *satisfies*

$$C_k\{\xi\} < \infty, \qquad C_k\{\xi\}1_c = \min_\varphi ((P\{\varphi\} - U)V\{\xi\} + Q_\varphi). \tag{6.2}$$

Then $\gamma\{\xi\}$ *is locally optimal.*

Proof. Let $\xi' \in L$ be such that $\xi'(i) \neq \xi(i)$ for at most finitely many i. Then $\gamma\{\xi'\}$ is an SSS by our hypothesis (2) of § 3. Let $\{X_n\}$ be a chain governed by $\gamma\{\xi'\}$ with $X_1 = 1$. By (6.2),

$$C_k\{\xi\} \leqq E_{\xi'}[V\{\xi\}(X_{n+1})/X_n] - V\{\xi\}(X_n) + k(X_n, \xi'(X_n))$$

for $n \geqq 1$. As in the proof of Theorem 4.1, we can prove that for $n \geqq 1$,

$$C_k\{\xi\}E_{\xi'}[\tau(1)\wedge\sigma_n - 1] \leqq E_{\xi'}\left[\sum_{m=1}^{\tau(1)\wedge\sigma_n - 1} k(X_m, \xi'_m(X_m))\right] + E_{\xi'}[V\{\xi\}(X_{\sigma_n})I\{\tau(1) \geqq \sigma_n\}].$$

The last term on the right tends to zero as $n \to \infty$ by Lemma 4.2. Thus letting $n \to \infty$ in the above and then dividing through by $E_{\xi'}[\tau(1) - 1]$, we get $C_k\{\xi\} \leqq C_k\{\xi'\}$. □

Remark. The converse can also be proved along the lines of Theorem 4.1.

COROLLARY 6.1. *Suppose all locally optimal* SSS *are optimal. Then an* SSS $\gamma\{\xi\}$ *is optimal if and only if* (6.2) *holds.*

COROLLARY 6.2. *Suppose all* SS *are* SSS *and* $\{\pi\{\xi\} | \xi \in L\}$ *is tight in* $M(S)$. *In addition, suppose that k is bounded. Then an* SSS $\gamma\{\xi\}$ *is optimal if and only if* (6.2) *holds.*

Proof. Let $\gamma\{\xi_0\}$ be an optimal SSS and $\gamma\{\xi\}$ a locally optimal SSS. Define $\xi^n \in L$ by $\xi^n(i) = \xi_0(i)$ for $i \leqq n$, $= \xi(i)$ for $i > n$. Then $P\{\xi^n\} \to P\{\xi_0\}$ termwise. Let $\pi\{\xi^n\} \to \pi \in M(S)$ along a subsequence. By Scheffe's Theorem, this convergence is also in total variation. Thus letting $n \to \infty$ along this subsequence in the equation $\pi\{\xi^n\}P\{\xi^n\} = \pi\{\xi^n\}$, we get $\pi P\{\xi_0\} = \pi$, i.e., $\pi = \pi\{\xi_o\}$. Thus $\hat{\pi}\{\xi^n\} \to \hat{\pi}\{\xi_0\}$ and hence

$$C_k\{\xi^n\} \to C_k\{\xi_o\} \leqq C_k\{\xi\}.$$

But $C_k\{\xi\} \leqq C_k\{\xi^n\}$ by local optimality. Thus $C_k\{\xi\} = C_k\{\xi_o\}$ and $\gamma\{\xi\}$ is optimal. The claim follows from the preceding corollary. □

Clearly, any example that satisfies the hypotheses of Corollary 6.2 will also be an example for Corollary 6.1. One example where the hypotheses of the former are satisfied

is a stable chain where each state has finitely many neighbors as in (iii) of § 4, with the control affecting the transitions out of at most finitely many states. A more serious example can be constructed involving chains that show a strong uniform "drift" toward a finite set when they are sufficiently away from it; the set must be uniform with respect to all the controls. We do this next.

Let $\infty > K > \varepsilon > 0$ be given. Let a_n, $n \geqq 1$, be a sequence in $[2\varepsilon, K]$. Define $W: S \to R_+$ by $W(1) = a_1$, $W(n) = a_1 + \cdots + a_n$, $n \geqq 2$. Consider a controlled Markov chain $\{X_n\}$ whose transition matrix P_u satisfies the following:

(i) $p(i, j, \cdot) \equiv 0$ for $j \neq i+1$ or $i-1$,

> 0 otherwise for $i \in S \backslash \{1\}$,

$p(1, j, \cdot) \equiv 0$ for $j > 2$, > 0 otherwise.

(ii) $p(i, i+1, \cdot) \leqq (a_i - \varepsilon)/(a_{i+1} + a_i)$, $i \geqq 1$.

Letting $\mathcal{F}_n = \sigma(X_m, \xi_m, m \leqq n)$, it is then easy to check that

$$E[(W(X_{n+1}) - W(X_n)) I\{X_n \geqq 2\}/\mathcal{F}_n] < -\varepsilon I\{X_n \geqq 2\}.$$

As observed in [5, pp. 72–73], it then follows from the results of [9, § 2] that the hypotheses of Corollary 6.2 hold.

The proof of Corollary 6.2 indicates that the requirements can be relaxed to the following. For any two SSS $\gamma\{\xi'\}$ and $\gamma\{\xi''\}$, the set $\{\pi\{\xi\} | n \geqq 1$ such that $\xi(i) = \xi'(i)$ for $i \leqq n$ and equals $\xi''(i)$ for $i > n\}$ is tight. This would be true, e.g., if the map $\xi \to \pi\{\xi\}$ from the set $\{\xi \in L | \gamma\{\xi\}$ is an SSS$\}$ to $M(S)$ were continuous. This seems an eminently reasonable thing to expect in "typical" situations. Thus it is tempting to conjecture that local optimality implies optimality, except possibly in some highly pathological situations. Unfortunately, at the moment we are unable to capture the essence of exactly what is involved.

Note that whenever local optimality implies optimality, (6.2) is a much better condition for optimality than (6.1), because all the quantities involved depend only on the SSS $\gamma\{\xi\}$ under scrutiny and no prior knowledge of β or $V\{\xi_0\}$ is needed.

7. Characterizing the solution of the dynamic programming equations. By a solution of the dynamic programming equations, we mean a pair (c, W), $c \in R^+$, $W = [W(1), W(2), \cdots]^T$ an infinite column vector, such that

$$c1_c = \min_{\xi} ((P\{\xi\} - U) W + Q_\xi). \tag{7.1}$$

Clearly, $(\beta, V\{\xi_0\})$ in the foregoing is one solution. Note that if (c, W) is a solution, so is $(c, W + \Delta 1_c)$ for any $\Delta \in R$.

In this section, we shall give a characterization that isolates the distinguished solution $(\beta, V\{\xi_0\})$ from among the solution set for the special case when (A1) holds.

LEMMA 7.1. *Under* (A1), $V\{\xi_0\}(i)$, $i \in S$, *is bounded from below.*

Proof. By (A1), $A = \{i \in S | k(i, u) < \beta$ for some $u \in D(i)\}$ is a finite set. Let $\sigma = \min\{n \geqq 1 | X_n \in A\}$. Then for $i \in S$,

$$V\{\xi_0\}(i) = E_{\xi_0}\left[\sum_{m=1}^{\tau(1)-1} (k(X_m, \xi_0(X_m)) - \beta)/X_1 = i\right]$$

$$\geqq E_{\xi_0}\left[\sum_{m=\sigma}^{\tau(1)-1} (k(X_m, \xi_0(X_m)) - \beta) I\{\tau(1) > \sigma\}/X_1 = i\right]$$

$$\geqq -\beta \sum_{j \in A} E_{\xi_0}[\tau(1)/X_1 = j]. \qquad \square$$

Let $G=\{f\colon S\to R \mid f(1)=0 \text{ and } \inf_i f(i)>-\infty\}$.

LEMMA 7.2. *Let* $(c, W)\in R^+\times G$ *be a solution of* (7.1). *Then* $c\geqq\beta$.

Proof. Let $\varepsilon>0$. Then there exists an SS $\gamma\{\xi\}$ such that

$$(\varepsilon+c)1_c\geqq(P\{\xi\}-U)W+Q_\xi. \tag{7.2}$$

Let $\{X_n\}$ be a chain governed by $\gamma\{\xi\}$ with $X_1=1$. Summing up $X_1, X_2, \cdots, X_n$ rows of (7.2), we have

$$\begin{aligned}(c+\varepsilon)n &\geqq E_\xi[W(X_{n+1})/X_n]\\ &\quad-\sum_{m=2}^{n}(W(X_m)-E_\xi[W(X_m)/X_{m-1}])+\sum_{m=1}^{n}k(X_m,\xi(X_m)).\end{aligned} \tag{7.3}$$

By familiar arguments, we obtain

$$\begin{aligned}(c+\varepsilon)n &\geqq E_\xi[W(X_{n+1})/X_1]+E_\xi\left[\sum_{m=1}^{n}k(X_m,\xi(X_m))/X_1\right]\\ &\geqq K+E_\xi\left[\sum_{m=1}^{n}k(X_m,\xi(X_m))/X_1\right],\end{aligned}$$

where $K>-\infty$ is a lower bound on $W(i)$, $i\in S$. Divide by n and let $n\to\infty$. If $\gamma\{\xi\}$ is not an SSS, then it is not hard to deduce from (A1) that

$$\liminf_{n\to\infty}\frac{1}{n}E_\xi\left[\sum_{m=1}^{n}k(X_m,\xi(X_m))/X_1=1\right]\geqq\eta.$$

Thus

$$c+\varepsilon\geqq\eta\geqq\beta.$$

If $\gamma\{\xi\}$ is an SSS, then

$$\liminf_{n\to\infty}\frac{1}{n}E_\xi\left[\sum_{m=1}^{n}k(X_m,\xi(X_m))/X_1=1\right]\geqq C_k\{\xi\}\geqq\beta.$$

Since $\varepsilon>0$ is arbitrary, the claim follows. □

LEMMA 7.3. *If* (β, W), $W\in G$, *is a solution of* (7.1), *then* $W\geqq V\{\xi_0\}$ *termwise.*

Proof. Let $0<\varepsilon<\eta-\beta$. Then there exists an SS $\gamma\{\xi\}$ such that

$$(\beta+\varepsilon)1_c\geqq(P\{\xi\}-U)W+Q_\xi. \tag{7.4}$$

If $\gamma\{\xi\}$ is not an SSS, we may argue as in the proof of the preceding lemma to conclude that $\beta+\varepsilon\geqq\eta$, a contradiction. Hence $\gamma\{\xi\}$ is an SSS. Let $\{\xi_n\}$ be a chain governed by $\gamma\{\xi\}$ with $X_1=i$ for some $i\in S$. For $\{\sigma_n\}$ as before, we can deduce from (7.4) that

$$\begin{aligned}W(i)\geqq&\sum_{m=1}^{\tau(1)\wedge\sigma_n-1}(k(X_m,\xi(X_m))-(\beta+\varepsilon))\\ &-\sum_{m=2}^{\tau(1)\wedge\sigma_n}(W(X_m)-E_\xi[W(X_m)/X_{m-1}])+W(X_{\tau(1)\wedge\sigma_n}).\end{aligned} \tag{7.5}$$

By Fatou's Lemma,

$$\begin{aligned}\liminf_{n\to\infty}E_\xi[W(X_{\tau(1)\wedge\sigma_n})/X_1=i]&\geqq\liminf_{n\to\infty}E_\xi[W(X_{\sigma_n})I\{\tau(1)>\sigma_n\}/X_1=i]\\ &\geqq 0.\end{aligned}$$

Thus taking expectations in (7.5) and letting $n \to \infty$,

$$W(i) \geqq E_\xi\left[\sum_{m=1}^{\tau(1)-1} (k(X_m, \xi(X_m)) - (\beta+\varepsilon))/X_1 = i\right].$$

Since ε can be made arbitrarily close to zero,

$$\begin{aligned} W(i) &\geqq E_\xi\left[\sum_{m=1}^{\tau(1)-1} (k(X_m, \xi(X_m)) - \beta)/X_1 = i\right], \\ &\geqq V\{\xi_0\}(i) \end{aligned}$$

where the last inequality follows from Lemma 5.3. □

LEMMA 7.4. *For W as above, $W = V\{\xi_0\}$.*

Proof. Let $K > 0$ be a finite number such that $W(i) \geqq -K$ for $i \in S$. Then for each $i \in S$,

$$\sum_{j \in S} p(i, j, u) W(j) + k(i, u) = \sum_{j \in S} p(i, j, u)(W(j) + K) + k(i, u) - K.$$

The first term on the right is a monotone increasing limit of continuous functions in the variable u, and hence is lower semicontinuous in u. Since $k(i, \cdot)$ is continuous, the left-hand side above is lower semicontinuous in u, and hence attains a minimum at some $u_i \in D$. Let $\xi = [u_1, u_2, \cdots] \in L$. Then

$$\beta 1_c = (P\{\xi\} - U) W + Q_\xi.$$

By the arguments used in the proof of Lemma 7.2, $\gamma\{\xi\}$ is an SSS. Since

$$\beta 1_c \leqq (P\{\xi\} - U) V\{\xi_0\} + Q_\xi,$$

we have

$$(P\{\xi\} - U)(W - V\{\xi_0\}) \leqq 0.$$

Letting $\{X_n\}$ be a chain governed by $\gamma\{\xi\}$ with $X_1 = 1$, this and Lemma 7.3 imply that $V = W - V\{\xi_0\}$ satisfies

$$V(X_n) \geqq o = V(X_1), \qquad E_\xi[V(X_{n+1})/X_n] \leqq V(X_n),$$

$n = 1, 2, \cdots$. This is possible only if $V(X_n) = o$ almost surely for each n. Since $\gamma\{\xi\}$ is an SSS, $X_n = i$ infinitely often almost surely for each $i \in S$. Hence $V(i) = 0$ for $i \in S$. The claim follows. □

The following theorem summarizes the above.

THEOREM 7.1. *Among all solutions (c, W) of (7.1) in $R^+ \times G$, $(\beta, V\{\xi_o\})$, is the unique solution corresponding to the least value of c.*

Appendix A. Recall (1)-(4) in the beginning of § 3. Here, we derive (3) and (4) from (2) using a simple convex analytic argument.

LEMMA A.1. *The set $B = \{\hat{\pi}[\Phi] | \gamma[\Phi]$ an SSRS$\}$ is convex and closed in $M(S \times D)$.*

Proof. Let $\gamma[\Phi_1]$, $\gamma[\Phi_2]$ be two SSRS with $\Phi_1 = \Pi_i \hat{\Phi}_{1i}$, $\Phi_2 = \Pi_i \hat{\Phi}_{2i}$. Let $0 \leqq a \leqq 1$ and define $\Phi = \Pi_i \hat{\Phi}_i$ by

$$\hat{\Phi}_i = (a\pi[\Phi_1](i)\hat{\Phi}_{1i} + (1-a)\pi[\Phi_2](i)\hat{\Phi}_{2i})/(a\pi[\Phi_1](i) + (1-a)\pi[\Phi_2](i)), \qquad i \in S.$$

From this definition and the fact that

$$\pi[\Phi_i] P[\Phi_i] = \pi[\Phi_i], \qquad i = 1, 2,$$

it is easily seen that

$$(a\pi[\Phi_1] + (1-a)\pi[\Phi_2]) P[\Phi] = (a\pi[\Phi_1] + (1-a)\pi[\Phi_2]).$$

Thus

$$\pi[\Phi] = a\pi[\Phi_1] + (1-a)\pi[\Phi_2].$$

Hence

$$\pi[\Phi](i)\hat{\Phi}_i = a\pi[\Phi_1](i)\hat{\Phi}_{1i} + (1-a)\pi[\Phi_2](i)\hat{\Phi}_{2i},\ i \in S,$$

implying

$$\hat{\pi}[\Phi] = a\hat{\pi}[\Phi_1] + (1-a)\hat{\pi}[\Phi_2].$$

The convexity follows. Now let $\gamma[\Phi_n]$, $n = 1, 2, \cdots$, be SSRS such that $\hat{\pi}[\Phi_n] \to \hat{\pi}$ for some $\hat{\pi} \in M(S \times D)$. Let $\pi \in M(S)$, $\pi = [\pi(1), \pi(2), \cdots]$, be the image of $\hat{\pi}$ under the projection $S \times D \to S$. Then $\pi[\Phi_n] \to \pi$ in $M(S)$. Disintegrate $\hat{\pi}$ as $\hat{\pi}(\{i\} \times A) = \pi(i)\varphi_i(A)$, $i \in S$, A a Borel subset of D, where $\varphi_i \in M(D)$ for each i. Define $\varphi \in L$ by $\varphi = \Pi_i \varphi_i$. Since $p(\cdot, j, \cdot)$, $j \in S$, are continuous,

$$\int p(\cdot, j, \cdot)\, d\hat{\pi}[\Phi_n] \to \int p(\cdot, j, \cdot)\, d\hat{\pi}, \qquad j \in S.$$

Thus

$$\pi[\Phi_n]P[\Phi_n] \to \pi P[\varphi]$$

termwise. Since $\pi[\Phi_n] \to \pi$ and $\pi[\Phi_n]P[\Phi_n] = \pi[\Phi_n]$, for $n \geqq 1$, we have $\pi P[\varphi] = \pi$, i.e., $\pi = \pi[\varphi]$. Hence $\hat{\pi} = \hat{\pi}[\varphi]$ and we are done. □

Let $\gamma[\Phi]$, $\Phi = \Pi_i \hat{\Phi}_i$ be an SSRS such that for some $i_o \in S$ and $0 < a < 1$, there exist φ_1, φ_2 in $M(D)$ such that

$$\text{(A1)} \quad \begin{aligned} &\int p(i_0, \cdot, u)\hat{\Phi}_{i_0}(du) = a \int p(i_0, \cdot, u)\varphi_1(du) + (1-a) \int p(i_0, \cdot, u)\varphi_2(du), \\ &\int p(i_0, \cdot, u)\varphi_1(du) \neq \int p(i_0, \cdot, u)\varphi_2(du) \end{aligned}$$

as vectors, the integrations being termwise. Without loss of generality, we shall assume that $i_0 = 1$.

LEMMA A.2. *$\hat{\pi}[\Phi]$ is not an extreme point of B.*

Proof. Define $\Phi_i \in M(L)$ by $\Phi_i = \varphi_i \times \Pi_{j=2}^{\infty} \hat{\Phi}_j$, $i = 1, 2$. Let τ, τ_1, τ_2 denote the first return time to 1 under $\gamma[\Phi]$, $\gamma[\Phi_1]$, $\gamma[\Phi_2]$, respectively, when the chain starts at 1. It is easily seen that

$$\begin{aligned} E[\tau] &= 1 + \sum_{j \neq 1} \int p(1, j, u)\hat{\Phi}_1(du)E[\tau / X_1 = j] \\ &= a\left(1 + \sum_{j \neq 1} \int p(1, j, u)\varphi_1(du)E[\tau / X_1 = j]\right) \\ &\qquad + (1-a)\left(1 + \sum_{j \neq 1} \int p(1, j, u)\varphi_2(du)E[\tau / X_1 = j]\right) \\ &= aE[\tau_1] + (1-a)E[\tau_2]. \end{aligned}$$

Since $E[\tau] < \infty$, $E[\tau_i] < \infty$ for $i = 1, 2$, implying that $\gamma[\Phi_i]$, $i = 1, 2$, are SSRS. If $\pi[\Phi] = \pi[\Phi_1] = \pi[\Phi_2]$, the equation

$$\sum_k \pi[\Phi_i](k) \int p(k, j, u)\hat{\Phi}_{ik}(du) = \pi[\Phi_i](j), \qquad i = 1, 2,$$

contradicts (A1) for some j. Hence any two of $\pi[\Phi]$, $\pi[\Phi_1]$, $\pi[\Phi_2]$ are distinct from each other. Let $b \in (0, 1)$ be such that

$$a = b\pi[\Phi_1](1)/(b\pi[\Phi_1](1) + (1-b)\pi[\Phi_2](1)).$$

We argue as in the proof of the preceding lemma to conclude that

$$\hat{\pi}[\Phi] = b\hat{\pi}[\Phi_1] + (1-b)\hat{\pi}[\Phi_2].$$

The claim follows. □

COROLLARY A.1. *The extreme points of B are of the form $\hat{\pi}\{\xi\}$, where $\xi \in L$ satisfies the following*:

(*) *For each $i \in S$, $p(i, \cdot, \xi(i))$ is an extreme point of $\{p(i, \cdot, u) | u \in D\} \subset M(S)$.*

THEOREM A.1. *If an optimal* SSRS *exists, an optimal* SSS *satisfying* (*) *exists. (In particular, $\beta = \alpha$.)*

Proof. Let $\gamma[\Phi]$ be an optimal SSRS. Let $\bar{S} = SU\{\infty\}$ be the one-point compactification of S. We may view B as a subset of $M(\bar{S} \times D)$ by identifying each element of $M(S \times D)$ with that element of $M(\bar{S} \times D)$ that coincides with it when restricted to $S \times D$ and has zero mass at $\{\infty\} \times D$. Let $\bar{B}$ denote the closure of B in $M(\bar{S} \times D)$. Viewing $\hat{\pi}[\Phi]$ as an element of $\bar{B}$, Choquet's Theorem [11] implies that $\hat{\pi}[\Phi]$ is the barycenter of a probability measure ν supported on the set of extreme points of $\bar{B}$. Since $\hat{\pi}[\Phi]$ has no mass at $\{\infty\} \times D$, ν is almost surely supported on the set of extreme points of B itself. Letting E denote the latter set, we have

$$\int_E \left(\int k \, d\hat{\pi} \right) \nu(d\hat{\pi}) = C_k[\Phi].$$

Thus if there is no $\hat{\pi} \in E$ such that $\int k \, d\hat{\pi} = C_k[\Phi]$, there would necessarily exist a $\hat{\pi} \in E$ for which $\int k \, d\hat{\pi} < C_k[\Phi]$. By the preceding corollary, each $\hat{\pi} \in E$ is of the form $\hat{\pi}\{\xi\}$ for some SSS $\gamma\{\xi\}$ satisfying (*). Thus we have a contradiction to the optimality of $\gamma[\Phi]$ unless $C_k[\Phi] = C_k\{\xi\}$ for some SSS $\gamma\{\xi\}$ with $\hat{\pi}\{\xi\} \in E$. □

Remark. As in [5], we can prove that (A1) or (A2) imply (1) and (2) above. (Although k is assumed to be bounded in [5], this part of the arguments of [5] goes through without any difficulty for the more general k's considered here.) The above can then replace the arguments of [5] to deduce (3) and (4) from (1) and (2). This alternative approach is both simpler and says more.

RANK INVARIANTS OF NONLINEAR SYSTEMS*

M. D. DI BENEDETTO†, J. W. GRIZZLE‡, AND C. H. MOOG§

Abstract. A linear algebraic framework for the analysis of rank properties of nonlinear systems is introduced. This framework gives a high-level interpretation of several existing algorithms built around the recursive computation of certain algebraic ranks associated with right-invertibility, left-invertibility, and dynamic decoupling. Furthermore, it can be used to establish links between these algorithms and the differential algebraic approach, as well as to solve some static and dynamic noninteracting control problems.

Key words. invertibility, decoupling, zeros at infinity, differential algebra, nonlinear systems analysis

AMS(MOS) subject classifications. primary 93C10; secondary 93B25

1. Introduction.

Consider a nonlinear control system of the following form:

$$\Sigma: \quad \dot{x} = f(x) + g(x)u, \tag{1.1a}$$

$$y = h(x) \tag{1.1b}$$

where, for simplicity, $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$, $y(t) \in \mathbb{R}^p$, and $f(\cdot)$, the columns of $g(\cdot)$ and the rows of $h(\cdot)$ are *meromorphic* functions of x (on all of $\mathbb{R}^n$); that is, they are elements of the fraction field $\mathcal{F}(x)$ of the ring of analytic functions of x. Our goal is to associate to such a system a chain of (nondifferential) vector spaces and show that it contains a rich amount of structural information about the system. More precisely, the subspaces will recover in a unified way, the inversion algorithm of Singh [1], the generic ranks of Nijmeijer [2], the dynamic decoupling algorithms of Descusse and Moog [3] and Nijmeijer and Respondek [4], and the differential output rank of Fliess [5], [6]. The approach adopted in the paper has been largely inspired by the differential vector spaces considered in [7] by Fliess.

To proceed, suppose that the input function $u(t)$ to the system (1.1) is N times continuously differentiable. Then by Taylor's Theorem,

$$u(t) = \sum_{k=0}^{N} u^{(k)} \frac{(t-t_0)^k}{k!} + R_N(t-t_0),$$

where t_0 is some initial point in time, $u^0 := u(t_0)$, $u^{(i+1)} := d/dt\, u^{(i)}(t)|_{t=t_0}$, and R_N is a remainder term. View $x, u, \cdots, u^{(n-1)}$ as variables and let $\mathcal{K}$ denote the field consisting of the set of rational functions of $(u, \cdots, u^{(n-1)})$ with coefficients that are meromorphic in x. Recall that given such a field, say in the variables $\nu = (\nu_1, \cdots, \nu_j)$, we define $\partial/\partial\nu_i$ acting on a meromorphic function $\eta(\nu) = \pi(\nu)/\theta(\nu)$, where $\pi(\cdot)$ and $\theta(\cdot)$ are analytic, by the usual quotient rule of calculus,

$$\frac{\partial}{\partial \nu_i}\frac{\pi(\nu)}{\theta(\nu)} := \frac{\left(\theta(\nu)\dfrac{\partial}{\partial \nu_i}\pi(\nu) - \pi(\nu)\dfrac{\partial}{\partial \nu_i}\theta(\nu)\right)}{\theta^2(\nu)}. \tag{1.2}$$

The work of this author was performed while he was a NATO visiting professor at the University of Michigan.

Then we define the differential of η by

$$d\eta(\nu) := \sum_{i=1}^{j} \frac{\partial \eta(\nu)}{\partial \nu_i} d\nu_i. \tag{1.3}$$

Returning to the system (1.1), we define in a natural way,

$$\dot{y} = \dot{y}(x, u) = \frac{\partial h}{\partial x}[f(x) + g(x)u], \tag{1.4a}$$

$$\begin{aligned} y^{(k+1)} &= y^{(k+1)}(x, u, \cdots, u^{(k)}) \\ &= \frac{\partial y^{(k)}}{\partial x}[f(x) + g(x)u] + \sum_{i=0}^{k-1} \frac{\partial y^{(k)}}{\partial u^{(i)}} u^{(i+1)}. \end{aligned} \tag{1.4b}$$

Note that $\dot{y}, \cdots, y^{(n)}$ so defined have components in the field $\mathcal{K}$.

Let $\mathcal{E}$ denote the vector space (over $\mathcal{K}$) spanned by $\{dx, du, \cdots, du^{(n-1)}\}$. It is essential to remark that this is an ordinary, nondifferential vector space as opposed to the setting proposed in [7]. Now we introduce the chain of subspaces $\mathcal{E}_0 \subset \cdots \subset \mathcal{E}_n$ of $\mathcal{E}$ by

$$\mathcal{E}_k := \operatorname{span}\{dx, d\dot{y}, \cdots, dy^{(k)}\} \tag{1.5}$$

and define the associated list of dimensions $\rho_0 \leqq \cdots \leqq \rho_n$ by

$$\rho_k := \dim \mathcal{E}_k. \tag{1.6}$$

It is important to note that in (1.5) and (1.6) the span and dimension are both taken with respect to the field $\mathcal{K}$, and *not* the real numbers. Hence ρ_k is a well-defined integer and is not a function of $x, u, \cdots, u^{(n-1)}$. Note also that we abuse notation slightly because $\mathcal{E}_0 := \operatorname{span}\{dx, dy\}$, which is easily seen to be equal to $\operatorname{span}\{dx\}$ since the output y only depends on x. Finally, in the above, as well as in all that follows, "d" of a vector or vector valued function means "d" of each of its components; that is, $\mathcal{E}_0 = \operatorname{span}\{dx_1, \cdots, dx_n\}$, etc.

In the sequel we argue that the chain of subspaces $\mathcal{E}_0 \subset \cdots \subset \mathcal{E}_n$ gives a linear algebraic framework that clarifies many structural properties of nonlinear systems and leads to a synthesis of many previous works on rank invariants of nonlinear systems [1]–[9].

2. Four concepts becomes one. For a linear system, there are many equivalent approaches to defining (or characterizing) its rank. More or less, all possible approaches have been extended to nonlinear systems in an effort to understand such properties as right-invertibility, left-invertibility, dynamic decoupling, etc. In general, these extensions lead to distinct notions when broadened to the class of nonlinear systems [1], [10]. However, we will show that the linear algebraic framework of § 1 can be used to establish the equivalence of four of them. A first attempt at this, using cruder tools, was made in [11].

2.1. Jacobian matrices. In [2], Nijmeijer considers systems of the form (1.1) where $f(\cdot)$, the columns of $g(\cdot)$ and the rows of $h(\cdot)$ are *analytic* functions of x. He defines $\dot{y}, \cdots, y^{(n)}$ as before, and introduces

$$J_k(x, u, \cdots, u^{(k-1)}) := \frac{\partial(\dot{y}, \cdots, y^{(k)})}{\partial(u, \cdots, u^{(k-1)})}. \tag{2.1}$$

J_k is an analytic function of its arguments; hence, we can define

$$R_k := \text{generic rank (over the real numbers) of } J_k(x, u, \cdots, u^{(k-1)}). \tag{2.2}$$

Nijmeijer shows that $R_{k+1} - R_k$ is a nondecreasing sequence of integers and says that (1.1) is right-invertible if $R_n - R_{n-1} = p$, the number of scalar output components. He goes on to relate the integers R_k, for a restricted class of systems, to a set of integer invariants coming from the Δ^*-algorithm; that set, in analogy with results from linear system theory, was termed the "structure at infinity."

We now relate the list of generic ranks $\{R_k\}$ to the list of integers $\{\rho_k\}$ defined in (1.6). The first step is to observe that R_k is equal to the dimension of the row span of J_k, where the field is taken as $\mathcal{K}$. That is, if we define

$$\mathcal{V}_k := \operatorname{span}\left\{\frac{\partial \dot{y}}{\partial u}\, du, \cdots, \sum_{i=0}^{k-1} \frac{\partial y^{(k)}}{\partial u^{(i)}}\, du^{(i)}\right\}, \tag{2.3}$$

then $R_k = \dim \mathcal{V}_k$. It follows immediately that for $k \geqq 1$

$$\mathcal{E}_k = \operatorname{span}\{dx\} \oplus \mathcal{V}_k; \tag{2.4}$$

hence, we have the following theorem.

THEOREM 2.1. $\rho_k = n + R_k$, $1 \leqq k \leqq n$.

This yields the following corollary.

COROLLARY 2.2. *System* (1.1) *is right invertible in the sense of Nijmeijer if and only if* $\dim \mathcal{E}_n - \dim \mathcal{E}_{n-1} = p$, *the number of scalar output components.*

In closing this subsection, we note that the subspaces $\mathcal{V}_k$ give a linear algebraic interpretation of the Jacobian matrices J_k. In the case considered in this section where f, g, and h are analytic, both $\mathcal{E}_k$ and $\mathcal{V}_k$ can be viewed as analytic codistributions on the manifold $M \times T^{(n-1)}U$, where $T^{(n-1)}U$ is the $(n-1)$th order tangent bundle [12, Chap. 1] of the input manifold $U = \mathbb{R}^m$. However, it is easy to see that $\mathcal{E}_k$ is always involutive, whereas $\mathcal{V}_k$, the projection of $\mathcal{E}_k$ along span $\{dx\}$, does not in general enjoy this property. This gives us some reason to believe that the $\mathcal{E}_k$'s are more intrinsic, and certainly indicates that they are more amenable to analysis.

2.2. The inversion algorithm. In [1], Singh introduces an algorithm for calculating the left-inverse of a nonlinear system; his algorithm is in fact a generalization of previous algorithms, due to Silverman [13] and Hirschorn [14], that are only applicable under some restrictive conditions. This algorithm has since been taken up by different authors and has been used to define a finite zero structure for nonlinear systems [15] (important for certain stabilization problems), and a structure at infinity [9] (important for noninteracting control problems and model matching).

In the following, it will be shown that the inversion algorithm actually constructs, step by step, a *basis* for the chain of subspaces $\mathcal{E}_0 \subset \cdots \subset \mathcal{E}_n$. This shows that the chain $\mathcal{E}_0 \subset \cdots \subset \mathcal{E}_n$ contains all of the above-cited structural information yielded by the inversion algorithm, and also confirms the earlier claim that the chain $\mathcal{E}_0 \subset \cdots \subset \mathcal{E}_n$ embodies important structural information on a high level, independently of any particular algorithmic considerations.

The inversion algorithm as detailed in [15] is now given, with the exception that, instead of allowing a large class of analytic transformations, we will use a particular meromorphic transformation. This idea was first sketched in [9].

Step 1. Calculate

$$\dot{y} = \frac{\partial h}{\partial x}[f(x) + g(x)u] \tag{2.5}$$

and write it as

$$\dot{y} =: a_1(x) + b_1(x)u. \tag{2.6}$$

Define

$$s_1 := \operatorname{rank} b_1(x), \tag{2.7}$$

where the rank is taken over the field of meromorphic functions of x. Permute, if necessary, the components of the output so that the first s_1 rows of $b_1(x)$ are linearly independent. Decompose y as

$$\dot{y} = \begin{pmatrix} \dot{\tilde{y}}_1 \\ \dot{\hat{y}}_1 \end{pmatrix}, \tag{2.8}$$

where $\dot{\tilde{y}}_1$ consists of the first s_1 rows of $\dot{y}$. Since the last rows of $b_1(x)$ are linearly dependent upon the first s_1 rows, we can write

$$\dot{\tilde{y}}_1 = \tilde{a}_1(x) + \tilde{b}_1(x)u, \tag{2.9a}$$

$$\dot{\hat{y}}_1 = \hat{y}_1(x, \dot{\tilde{y}}_1), \tag{2.9b}$$

where the last equation is affine in $\dot{\tilde{y}}_1$. Finally, set $\tilde{B}_1(x) := \tilde{b}_1(x)$.

Step $k+1$. Suppose that in Steps 1 through k, $\dot{\tilde{y}}_1, \cdots, \tilde{y}_k^{(k)}, \hat{y}_k^{(k)}$ have been defined so that

$$\begin{aligned} &\dot{\tilde{y}}_1 = \tilde{a}_1(x) + \tilde{b}_1(x)u, \\ &\vdots \\ &\tilde{y}_k^{(k)} = \tilde{a}_k(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k-1,\ i \leqq j \leqq k\}) \\ &\qquad + \tilde{b}_k(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k-1,\ i \leqq j \leqq k-1\})u, \\ &\hat{y}_k^{(k)} = \hat{y}_k^{(k)}(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k,\ i \leqq j \leqq k\}) \end{aligned} \tag{2.10}$$

and so that they are rational functions of $\tilde{y}_i^{(j)}$ with coefficients in the field of meromorphic functions of x. Suppose also that the matrix $\tilde{B}_k := [\tilde{b}_1^T, \cdots, \tilde{b}_k^T]^T$ has full rank equal to s_k. Then calculate

$$\hat{y}_k^{(k+1)} = \frac{\partial}{\partial x}\hat{y}_k^{(k)}[f(x) + g(x)u] + \sum_{i=1}^{k}\sum_{j=i}^{k} \frac{\partial \hat{y}_k^{(k)}}{\partial \tilde{y}_i^{(j)}} \tilde{y}_i^{(j+1)} \tag{2.11}$$

and write it as

$$\hat{y}_k^{(k+1)} = a_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k,\ i \leqq j \leqq k+1\}) + b_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k,\ i \leqq j \leqq k\})u. \tag{2.12}$$

Define $B_{k+1} := [\tilde{B}_k^T, b_{k+1}^T]^T$, and

$$s_{k+1} := \operatorname{rank} B_{k+1}, \tag{2.13}$$

where the rank is taken with respect to the field of rational functions of $\{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k-1,\ i \leqq j \leqq k\}$ with coefficients in the field of meromorphic functions of x. Permute, if necessary, the components of $\hat{y}_k^{(k+1)}$ so that the first s_{k+1} rows of B_{k+1} are linearly independent. Decompose $\hat{y}_k^{(k+1)}$ as

$$\hat{y}_k^{(k+1)} = \begin{pmatrix} \tilde{y}_{k+1}^{(k+1)} \\ \hat{y}_{k+1}^{(k+1)} \end{pmatrix}, \tag{2.14}$$

where $\tilde{y}_{k+1}^{(k+1)}$ consists of the first $(s_{k+1} - s_k)$ rows. Since the last rows of $B_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k,\ i \leqq j \leqq k\})$ are linearly dependent on the first s_{k+1} rows, we can write

$$\begin{aligned} &\dot{\tilde{y}}_1 = \tilde{a}_1(x) + \tilde{b}_1(x)u, \\ &\vdots \\ &\tilde{y}_{k+1}^{(k+1)} = \tilde{a}_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k,\ i \leqq j \leqq k+1\}) \\ &\qquad + \tilde{b}_{k+1}(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k,\ i \leqq j \leqq k\})u, \\ &\hat{y}_{k+1}^{(k+1)} = \hat{y}_{k+1}^{(k+1)}(x, \{\tilde{y}_i^{(j)} \mid 1 \leqq i \leqq k+1,\ i \leqq j \leqq k+1\}), \end{aligned} \tag{2.15}$$

where once again everything is rational in $\tilde{y}_i^{(j)}$. Finally, set $\tilde{B}_{k+1} := [\tilde{B}_k^T, \tilde{b}_{k+1}^T]^T$.

End of Step $k+1$.

It is now possible to state and prove the main result of this subsection.

THEOREM 2.3. *For each* $1 \leqq k \leqq n$:

(a) $\{dx, \{d\tilde{y}_i^{(j)} | 1 \leqq i \leqq k, i \leqq j \leqq k\}\}$ *is a basis for* $\mathscr{E}_k$;

(b) $\dim \mathscr{E}_k = n + s_1 + \cdots + s_k$.

Proof. Part (b) is an immediate consequence of (a), which will be proved by induction. For $k = 1$, the statement is obvious. Suppose that (a) holds at Step k; it will now be shown that it also holds at Step $k+1$. By construction, $\tilde{B}_{k+1}$ is a rational function of $\{\tilde{y}_i^{(j)} | 1 \leqq i \leqq k, i \leqq j \leqq k\}$ with coefficients in the field of meromorphic functions of x. As $\tilde{y}_i^{(j)}$ is a rational function of $(u, \cdots, u^{(n-1)})$ with coefficients in the field of meromorphic functions of x, it therefore follows that $\tilde{B}_{k+1}$ is also. Since from Step k, $\{dx, \{d\tilde{y}_i^{(j)} | 1 \leqq i \leqq k, i \leqq j \leqq k\}\}$ is a linearly independent set over $\mathscr{K}$, it follows easily that $\tilde{B}_{k+1}$, when viewed as a rational function of $(u, \cdots, u^{(n-1)})$, has rank s_{k+1} over the field $\mathscr{K}$. Using (2.15), we show readily that

$$\begin{aligned} &\dim \operatorname{span} \{dx, \{d\tilde{y}_i^{(j)} | 1 \leqq i \leqq k, i \leqq j \leqq k\}\} \\ &\quad = \dim \operatorname{span} \{dx, \{\tilde{B}_\ell \, du^{(k+1-\ell)} | 1 \leqq \ell \leqq k+1\}\}. \end{aligned} \tag{2.16}$$

The dimension on the right-hand side of (2.16) is easily seen to be $n + s_1 + \cdots + s_{k+1}$, showing that, indeed, the vectors on the left-hand side of (2.16) are linearly independent since there are precisely $n + s_1 + \cdots + s_{k+1}$ elements; it only remains to show that they span $\mathscr{E}_{k+1}$. By its definition,

$$\mathscr{E}_{k+1} = \mathscr{E}_k + \operatorname{span} \{dy^{(k+1)}\}. \tag{2.17}$$

Using (2.15) once again, we can write this as follows:

$$\mathscr{E}_{k+1} = \mathscr{E}_k + \operatorname{span} \{d\tilde{y}_i^{(k+1)} | 1 \leqq i \leqq k+1\}, \tag{2.18}$$

which, coupled with the induction hypothesis, completes the proof. □

COROLLARY 2.4. *System* (1.1) *is left-invertible in the sense of Singh if and only if* $\dim \mathscr{E}_n - \dim \mathscr{E}_{n-1} = m$, *the number of scalar input components.*

2.3. The dynamic extension algorithm. The relationship between dynamic input-output decoupling and right invertibility has been clarified recently by Fliess [5], whose work has inspired several authors to develop concrete algorithms for the explicit construction of a dynamic compensator yielding a noninteractive system [3], [4]. Here we will give a simplified version of these algorithms, separating clearly their basic operations of differentiating the outputs, performing static-state feedback, and adding integrators on selected components of the input. This simplified version will still yield a decoupling compensator whenever one exists, but does introduce more integrators than the algorithms previously cited. We will show that it explicitly produces a basis for the chain of subspaces $\mathscr{E}_0 \subset \cdots \subset \mathscr{E}_n$. This shows yet another way in which the chain $\mathscr{E}_0 \subset \cdots \subset \mathscr{E}_n$ incorporates important structural information on a high level—in this case, that information pertraining to dynamic decoupling.

The dynamic extension algorithm is now presented.

Step 1. Let Σ_0 denote the system (1.1). Calculate

$$\dot{y} = \frac{\partial h(x)}{\partial x} [f(x) + g(x)u] \tag{2.19}$$

and write it as

$$\dot{y} = a_1(x) + b_1(x)u. \tag{2.20}$$

Define

$$\sigma_1 = \operatorname{rank} b_1(x), \tag{2.21}$$

where the rank is taken over the field of meromorphic functions of x. Permute, if necessary, the components of the output so that the first σ_1 rows of $b_1(x)$ are linearly independent. Decompose $\dot{y}$ as

$$\dot{y} = \begin{pmatrix} \dot{\bar{y}}_1 \\ \dot{\hat{y}}_1 \end{pmatrix} = \begin{pmatrix} \bar{a}_1(x) + \bar{b}_1(x)u \\ \hat{a}_1(x) + \hat{b}_1(x)u \end{pmatrix}. \tag{2.22}$$

Let

$$u = \alpha_1(x) + \beta_1(x)v_1 \tag{2.23}$$

be any static state feedback such that

(i) $\beta_1(x)$ is invertible over the field of meromorphic functions in x;

(ii) $\dot{\bar{y}}_1 = \bar{v}_1$.

Such a feedback always exists.

For the resulting closed-loop system, we can write

$$\dot{\bar{y}}_1 = \dot{\bar{y}}_1(x, \bar{v}_1), \tag{2.24}$$

since otherwise the rank of $\partial \dot{y}/\partial v_1$ would exceed σ_1. Moreover, $\dot{\bar{y}}_1$ is affine in $\bar{v}_1$. Now introduce a dynamic extension by

$$\dot{\bar{v}}_1 = \bar{u}_1 \tag{2.25a}$$

and rename the remaining components of v_1:

$$\hat{v}_1 = \hat{u}_1. \tag{2.25b}$$

Finally, let Σ_1 denote the system consisting of Σ_0, the static-state feedback (2.23), and the dynamic extension (2.25). Its state is given by $x_1 = \begin{pmatrix} x \\ \bar{v}_1 \end{pmatrix}$, its input is $u_1 = \begin{pmatrix} \bar{u}_1 \\ \hat{u}_1 \end{pmatrix}$, and the output remains $y = h(x)$. We will denote it as

$$\Sigma_1: \begin{aligned} \dot{x}_1 &= f_1(x_1) + g_1(x_1)u_1, \\ y &= h(x). \end{aligned} \tag{2.26}$$

Σ_1 is a dynamic extension of Σ_0 and has the property that $\dot{y} = \dot{y}(x_1)$ is affine in $\bar{v}_1$.

Step $k+1$. Suppose that in Step k the system Σ_k has been constructed such that

$$\Sigma_k: \begin{aligned} \dot{x}_k &= f_k(x_k) + g_k(x_k)u_k, \\ y &= h(x) \end{aligned} \tag{2.27}$$

and $y_k^{(k)} = y_k^{(k)}(x_k)$ is a rational function of $\bar{v}_1, \cdots, \bar{v}_k$ with coefficients in the field of meromorphic functions of x. Then, calculate

$$y^{(k+1)} = \frac{\partial y^{(k)}}{\partial x_k}[f_k(x_k) + g_k(x_k)u_k] \tag{2.28}$$

and rewrite (2.28) as

$$y^{(k+1)} = a_{k+1}(x_k) + b_{k+1}(x_k)u_k. \tag{2.29}$$

Define

$$\sigma_{k+1} = \operatorname{rank} b_{k+1}(x_k), \tag{2.30}$$

where the rank is over the field of rational functions of $\bar{v}_1, \cdots, \bar{v}_k$ with coefficients in the field of meromorphic functions of x. Permute, if necessary, the last $p-\sigma_k$ components of the output so that the first σ_{k+1} rows of $b_{k+1}(x_k)$ are linearly independent. Decompose $y^{(k+1)}$ as

$$y^{(k+1)} = \begin{pmatrix} \bar{y}_{k+1}^{(k+1)} \\ \hat{y}_{k+1}^{(k+1)} \end{pmatrix} = \begin{pmatrix} \bar{a}_{k+1}(x_k) + \bar{b}_{k+1}(x_k)u_k \\ \hat{a}_{k+1}(x_k) + \hat{b}_{k+1}(x_k)u_k \end{pmatrix}. \tag{2.31}$$

Let

$$u_k = \alpha_{k+1}(x_k) + \beta_{k+1}(x_k)v_{k+1} \tag{2.32}$$

be any static-state feedback such that

(i) $\beta_{k+1}(x_k)$ is invertible over the field of rational functions of $\bar{v}_1, \cdots, \bar{v}_k$ with coefficients in the field of meromorphic functions of x.

(ii) $\bar{y}_{k+1}^{(k+1)} = \bar{v}_{k+1}$.

Such a feedback always exists.

For the resulting closed-loop system, we can always write

$$\hat{y}_{k+1}^{(k+1)} = \hat{y}_{k+1}^{(k+1)}(x_k, \bar{v}_{k+1}), \tag{2.33}$$

since otherwise the rank of $\partial y^{(k+1)}/\partial v_{k+1}$ would exceed σ_{k+1}. Moreover, $y^{(k+1)}$ is a rational function of $\bar{v}_1, \cdots, \bar{v}_{k+1}$. Now introduce a dynamic extension by

$$\dot{\bar{v}}_{k+1} = \bar{u}_{k+1} \tag{2.34a}$$

and rename the remaining components of v_{k+1}:

$$\hat{v}_{k+1} = \hat{u}_{k+1}. \tag{2.34b}$$

Finally, let Σ_{k+1} denote the system consisting of Σ_k, the static state feedback (2.32) and the dynamic extension (2.34). Its state is given by $x_{k+1} = \begin{pmatrix} x_k \\ \bar{v}_{k+1} \end{pmatrix}$, its input is $u_{k+1} = \begin{pmatrix} \bar{u}_{k+1} \\ \hat{u}_{k+1} \end{pmatrix}$, and the output remains $y = h(x)$. Σ_{k+1} is then a dynamic extension of Σ_k, has the property that $y^{(k+1)} = y^{(k+1)}(x_{k+1})$, and is a rational function of $\bar{v}_1, \cdots, \bar{v}_{k+1}$.

End of Step $k+1$.

We now have the following theorem.

THEOREM 2.5. *For each* $1 \leqq k \leqq n$:

(a) $\{dx, d\dot{\bar{y}}_1, \cdots, d\bar{y}_k^{(k)}\}$ *is a basis for* $\mathscr{E}_k$.

(b) $\dim \mathscr{E}_k = n + \sigma_1 + \cdots + \sigma_k$.

Proof. Part (b) is an immediate consequence of (a). From (2.33), one has that

$$\mathscr{E}_k = \operatorname{span}\{dx, d\dot{\hat{y}}_1, \cdots, d\bar{y}_k^{(k)}\}, \tag{2.35}$$

which by definition of $\bar{v}_j$ gives

$$\mathscr{E}_k = \operatorname{span}\{dx, d\bar{v}_1, d\bar{v}_2, \cdots, d\bar{v}_k\}. \tag{2.36}$$

Hence, it suffices to show that $\{dx, d\bar{v}_1, \cdots, d\bar{v}_k\}$ is a linearly independent set for each $1 \leqq k \leqq n$. This follows immediately from Lemma 2.6.

LEMMA 2.6. *For each* $1 \leqq k \leqq n-1$,

$$\begin{aligned} &\operatorname{span}\{dx, du, \cdots, du^{(n-1)}\} \\ &\quad = \operatorname{span}\{dx, d\bar{v}_1, \cdots, d\bar{v}_k, du_k, \cdots, du_k^{(n-1-k)}, d\hat{v}_k^{(n-k)}, \cdots, d\hat{v}_1^{(n-1)}\}, \end{aligned} \tag{2.37}$$

where all spans are with respect to the field $\mathscr{K}$.

Proof. Equations (2.23) and (2.25) yield

$$\begin{aligned}&\operatorname{span}\{dx, du, \cdots, du^{(n-1)}\}\\&\quad=\operatorname{span}\{dx, d\bar{v}_1, \{d\hat{v}_1, d\dot{\hat{v}}_1\}, \cdots, \{d\hat{v}_1^{(n-2)}, d\bar{v}_1^{(n-1)}\}, d\hat{v}_1^{(n-1)}\}\\&\quad=\operatorname{span}\{dx, d\bar{v}_1, du_1, \cdots, du_1^{(n-2)}, d\hat{v}_1^{(n-1)}\},\end{aligned}$$

which establishes (2.37) for $k=1$.

Now suppose that (2.37) holds at k. Then, in particular, $\{dx, d\bar{v}_1, \cdots, d\bar{v}_k\}$ is a linearly independent set. After we note that each component of $x_k=(x^T, \bar{v}_1^T, \cdots, \bar{v}_k^T)^T$ is a rational function of $(u, \cdots, u^{(n-1)})$, this gives us that b_{k+1} has full rank over $\mathscr{K}$. Hence, using (2.32) and (2.34), we have

$$\begin{aligned}&\operatorname{span}\{d\bar{x}_k, du_k, \cdots, du_k^{(n-1-k)}\}\\&\quad=\operatorname{span}\{d\bar{x}_k, d\bar{v}_{k+1}, \{d\hat{v}_{k+1}, d\dot{\hat{v}}_{k+1}\}, \cdots, \{d\hat{v}_{k+1}^{(n-k-2)}, d\bar{v}_{k+1}^{(n-1-k)}\}, d\hat{v}_{k+1}^{(n-1-k)}\}\\&\quad=\operatorname{span}\{d\bar{x}_k, d\bar{v}_{k+1}, du_{k+1}, \cdots, du_{k+1}^{(n-k-2)}, d\hat{v}_{k+1}^{(n-1-k)}\},\end{aligned}$$

which establishes (2.37) at $k+1$. □

2.4. Convergence of the chain $\mathscr{E}_0\subset\cdots\subset\mathscr{E}_n$. In a completely analogous fashion to the way the chain $\mathscr{E}_0\subset\cdots\subset\mathscr{E}_n$ is defined in (1.5), we could define an extended chain $\mathscr{E}_0\subset\cdots\subset\mathscr{E}_n\subset\cdots\subset\mathscr{E}_{n+k}$, for any finite integer $k\geqq 1$. The underlying field $\mathscr{K}_{n+k}$ would then consist of the set of rational functions of $(u, \cdots, u^{(n+k-1)})$ with coefficients that are meromorphic in x. We will show, however, that no new structural information is obtained by extending the original chain; hence, we are justified in terminating the chain at n, the dimension of the state space of (1.1).

THEOREM 2.7. *For all finite integers $k\geqq 1$:*

(a) $\{dx, d\dot{y}_1, \cdots, d\bar{y}_n^{(n)}, d\bar{y}_n^{(n+1)}, \cdots, d\bar{y}_n^{(n+\ell)}\}$ *is a basis for* $\mathscr{E}_{n+\ell}$, $1\leqq\ell\leqq k$.

(b) $\dim\mathscr{E}_{n+\ell}=\dim\mathscr{E}_n+\ell\cdot\rho^*$, $1\leqq\ell\leqq k$, *where* $\rho^*=\dim\mathscr{E}_n-\dim\mathscr{E}_{n-1}$.

The proof will be broken down into two lemmas. The functions $(\bar{y}_i^T, \hat{y}_i^T)=y^T$ continue to denote the blocks of the output constructed in the ith step of the dynamic extension algorithm; $\bar{y}_i^{(j)}$, $\hat{y}_i^{(j)}$ denote their jth-order derivatives along the dynamics of the system.

LEMMA 2.8. *There exists an integer $1\leqq N\leqq n$ such that*

$$d\hat{y}_n^{(N)}\in\operatorname{span}_{\mathscr{K}}\{d\hat{y}_n, \cdots, d\hat{y}_n^{(N-1)}, d\dot{\hat{y}}_1, \cdots, d\bar{y}_n^{(N)}\}. \tag{2.38}$$

Proof. From the dynamic extension algorithm, we have that $\hat{y}_k^{(k)}=\hat{y}_k^{(k)}(x, \dot{\hat{y}}_1, \cdots, \bar{y}_k^{(k)})$. Hence, (2.38) holds if

$$\frac{\partial\hat{y}_n^{(N)}}{\partial x}dx\in\operatorname{span}_{\mathscr{K}}\left\{\frac{\partial\hat{y}_n}{\partial x}dx, \cdots, \frac{\partial\hat{y}_n^{(N-1)}}{\partial x}dx\right\}. \tag{2.39}$$

Since the right-hand side of (2.39) can be at most n-dimensional, there must exist $1\leqq N\leqq n$ such that (2.39) holds. Hence, the result is proved. □

For each integer j, $N\leqq j\leqq n+k$, define the field $\mathscr{K}_j$ to be the set of rational functions of $(u, \cdots, u^{(j-1)})$ with coefficients that are meromorphic in x.

LEMMA 2.9. *With N as in Lemma 2.8 and for all integers j, $N\leqq j\leqq n+k$,*

$$d\hat{y}_n^{(j)}\in\operatorname{span}_{\mathscr{K}_j}\{d\hat{y}_n, \cdots, d\hat{y}_n^{(N-1)}, d\dot{\hat{y}}_1, \cdots, d\bar{y}_j^{(j)}\}, \tag{2.40}$$

where, for $j\geqq n$, $\bar{y}_j=\bar{y}_n$.

Proof. Since all the functions appearing in (2.38) are rational functions of $(u, \cdots, u^{(N-1)})$, (2.38) also holds with $\mathscr{K}$ replaced by $\mathscr{K}_N$. Hence there exist coefficients $\alpha_i, \beta_i \in \mathscr{K}_N$ such that

$$d\hat{y}_n^{(N)} = \sum_{i=0}^{N-1} \alpha_i \, d\hat{y}_n^{(i)} + \sum_{i=1}^{N} \beta_i \, d\bar{y}_i^{(i)}. \tag{2.41}$$

Hence,

$$d\hat{y}_n^{(N+1)} = \sum_{i=0}^{N-1} (\dot{\alpha}_i \, d\hat{y}_n^{(i)} + \alpha_i \, d\hat{y}_n^{(i+1)}) + \sum_{i=1}^{N} (\dot{\beta}_i \, d\bar{y}_i^{(i)} + \beta_i \, d\bar{y}_i^{(i+1)}). \tag{2.42}$$

Combining (2.41) with the fact that $\dot{\alpha}_i$, $\dot{\beta}_i$ are in $\mathscr{K}_{N+1}$, we easily see that (2.42) establishes (2.40) for $j = N+1$. In a similar manner we complete the proof of Lemma 2.9. □

To complete the proof of Theorem 2.7, note that Lemma 2.9 establishes that $\mathscr{E}_{n+\ell}$, $1 \leqq \ell \leqq k$ is indeed spanned by the vectors given in (a). We prove that they are independent using the same reasoning employed in the proof of Theorem 2.3. Part (b) follows from (a) by counting the number of basis elements.

Remark 2.10. If we introduce the finite chain of subspaces $\mathscr{F}_0 \subset \cdots \subset \mathscr{F}_n$ of $\mathscr{E}$ by $\mathscr{F}_k = \operatorname{span}\{dy, d\dot{y}, \cdots, dy^{(k)}\}$, then we can show that $\rho^* = \dim \mathscr{F}_n - \dim \mathscr{F}_{n-1}$. However, the inversion algorithm and the dynamic extension algorithm do not calculate bases for this chain.

2.5. Differential output rank. In 1985, Fliess introduced a new approach, centered around differential algebra, to the analysis of nonlinear systems, [5], [16], the proper formalism being perhaps field theoretic [17]. He was the first to define clearly and precisely the fundamental notion of the *rank* of a nonlinear system; he accomplished this by considering the output components to be dependent if they satisfied a nontrivial (nonlinear) differential equation. Fliess' notion of rank generalized to nonlinear systems the usual notion of the rank of a transfer matrix of a linear system, and played the same important role in leading to basic definitions of right invertibility and left invertibility, and important new results on dynamic feedback [5], [16]. All previous attempts in this regard lacked the power and elegance of the differential algebraic approach, being mainly based on algorithmic considerations.

Additional insights on the role of differential algebra in system theory have been contributed by Pommaret [18].

In this section, we will show that the integer $\rho^* = \dim \mathscr{E}_n - \dim \mathscr{E}_{n-1}$ of Theorem 2.7 is actually the differential output rank for those systems that meet the requirements both of § 1 and of the differential algebraic approach. More precisely, we suppose that the system (1.1) satisfies the following assumptions:

(A1) f, g and h are meromorphic;

(A2) f, g and h are differentially algebraic (i.e., elementary transcendental) functions of their arguments [5], [19], [20];

(A3) The set $\mathbb{R}\langle y \rangle$ of all rational functions of $y_i^{(\ell)}$, $1 \leqq i \leqq p$, $\ell \geqq 0$, with coefficients in the field $\mathbb{R}$ is a differential field.

Here, the $y_i^{(\ell)}$ are defined as in (1.4). (It is apparently unknown whether (A1) implies (A3).)

To aid the reader, a few notions from differential algebra are briefly recalled. A finite set of elements $\zeta_1, \cdots, \zeta_k$ of $\mathbb{R}\langle y \rangle$ *is differentially algebraically dependent* if there exists a nonzero differential polynomial $\mathbf{P}$, with coefficients in $\mathbb{R}$, such that

$\mathbf{P}(\zeta_1, \cdots, \zeta_k) = 0$; that is, a nonzero polynomial in $\zeta_1, \cdots, \zeta_k$ and a finite number of their time derivatives. The *differential output rank*, denoted $d^0(\Sigma)$, is the maximum number of differentially algebraically independent elements of $\mathbb{R}\langle y\rangle$. This number is well defined [21].

Our main result relating the $d^0(\Sigma)$ to the chain $\mathscr{E}_0 \subset \cdots \subset \mathscr{E}_n$ will be an easy consequence of the following properties of the differential rank.

LEMMA 2.11 [5]-[7], [16]. (a) $d^0(\Sigma) \leqq \min\{m, p\}$.

(b) *If Σ' is obtained from Σ by applying an invertible static state feedback, whose components are differentially algebraic functions, then $d^0(\Sigma') = d^0(\Sigma)$.*

(c) *If Σ_e is obtained by adding a finite number k_i of integrators on each input channel i of Σ, then $d^0(\Sigma_e) = d^0(\Sigma)$.*

(d) *If for some $1 \leqq i \leqq m$, $\partial y^{(k)}/\partial u_i^{(\ell)} = 0$ for all $k \geqq 0$, $\ell \geqq 0$, then $d^0(\Sigma) \leqq \min\{m-1, p\}$.*

(e) *If for some finite integer k, $y^{(k)} = y^{(k)}(x, u)$, and rank $\partial y^{(k)}/\partial u = r$, then $d^0(\Sigma) \geqq r$.*

Proof. All of these points are essentially contained in [5]-[7], [16]. Part (a) follows from the definition of the differential output rank. Part (b) is true because $d^0(\Sigma') \leqq d^0(\Sigma)$ for any static-state feedback. Thus invertibility gives equality, since the inverse, being a well-defined (differentially algebraic) static-state feedback, yields $d^0(\Sigma) \leqq d^0(\Sigma')$. To prove (c), first note that

$$m = \text{diff. tr. } d^0 \frac{\mathbb{R}\langle u, y\rangle}{\mathbb{R}} = \text{diff. tr. } d^0 \frac{\mathbb{R}\langle u, y\rangle}{\mathbb{R}\langle y\rangle} + \text{diff. tr. } d^0 \frac{\mathbb{R}\langle y\rangle}{\mathbb{R}}, \tag{2.43}$$

which yields

$$d^0(\Sigma) = m - \text{diff. tr. } d^0 \frac{\mathbb{R}\langle u, y\rangle}{\mathbb{R}\langle y\rangle}. \tag{2.44}$$

Similarly,

$$d^0(\Sigma_e) = m - \text{diff. tr. } d^0 \frac{\mathbb{R}\langle v, y\rangle}{\mathbb{R}\langle y\rangle}. \tag{2.45}$$

This establishes the result because the right-hand sides of (2.44) and (2.45) are equal, since v constitutes a differential transcendence basis for $\mathbb{R}\langle u\rangle/\mathbb{R}$. Statement (d) follows from (a) because y is differentially algebraic over $\mathbb{R}\langle u_1, \cdots, u_{i-1}, u_{i+1}, \cdots, u_m\rangle$. Finally, (e) implies that

$$\dim_{\mathscr{K}} \{d\dot{y}, \cdots, dy^{(k)}\} \geqq r, \tag{2.46}$$

which yields

$$\dim_{\mathbb{L}} \{d\dot{y}, \cdots, dy^{(k)}\} \geqq r, \tag{2.47}$$

where $\mathbb{L}$ is the field of rational functions in the indeterminates $\{y, \dot{y}, \cdots, y^{(k)}\}$ with coefficients in $\mathbb{R}$; note that $\mathbb{L} \subset \mathscr{K}$. Hence, by the results in [22], $d^0(\Sigma) \geq r$. □

THEOREM 2.12. *Suppose that system* (1.1) *satisfies Assumptions* (A1)-(A3). Then

$$d^0(\Sigma) = \dim \mathscr{E}_n - \dim \mathscr{E}_{n-1}. \tag{2.48}$$

Proof. Consider the extended system Σ_n constructed at the nth step of the dynamic extension algorithm. From (2.33), Σ_n has the property that rank $\partial y^{(n)}/\partial v_n = \sigma_n$. Hence, by (e) of Lemma 2.11, $d^0(\Sigma_n) \geqq \sigma_n$. By Theorem 2.7, $\sigma_{n+\ell} = \sigma_n$ for all $\ell \geqq 0$; therefore, y satisfies $\partial y^{(k)}/\partial \hat{v}_n^{(\ell)} = 0$ for all $k \geqq 0$, $\ell \geqq 0$. Thus, by (d) of Lemma 2.11, $d^0(\Sigma_n) \leqq \sigma_n$.

Hence, $d^0(\Sigma_n) = \sigma_n$. However, (b) and (c) of Lemma 2.11 then yield that $d^0(\Sigma) = d^0(\Sigma_n) = \sigma_n$, because Σ_n is constructed from Σ by successively applying invertible static feedbacks and finite strings of integrators. Finally, Theorem 2.5 yields $\sigma_n = \dim \mathscr{E}_n - \dim \mathscr{E}_{n-1}$. □

3. Structure at infinity and block decoupling. In this section, the framework of §§ 1 and 2 will be used to give an intrinsic "algebraic" definition of some important integer invariants associated with a nonlinear system, namely the so-called structure at infinity. An alternate approach to defining a structure at infinity has already been carried out in [8], using differential geometric techniques. When specialized to the class of linear systems, the geometric definition and the algebraic approach below both agree with the usual linear notion of the structure at infinity [23]. For general nonlinear systems, both are invariant under regular *static* state feedbacks. However, in contrast to the geometric approach, the algebraically based definition enjoys some additional properties that make it seem closer to the linear situation.

DEFINITION 3.1 [9]. The *number σ_k of zeros at infinity of order less than or equal to k, $k \geqq 1$,* is $\sigma_k = \dim \mathscr{E}_k - \dim \mathscr{E}_{k-1}$. The *structure at infinity* is given by the list $\{\sigma_1, \cdots, \sigma_n\}$.

Note that the total number of zeros at infinity σ_n corresponds precisely to the rank ρ^* of the system (1.1).

The notion of a *regular dynamic feedback* is introduced next. Note that when $q = 0$ in the following definition, we recover the usual definition of a regular static feedback.

DEFINITION 3.2 [24]. The compensator

$$\dot{z} = F(x, z) + G(x, z)v, \qquad u = \alpha(x, z) + \beta(x, z)v, \tag{3.1}$$

where F, G, α, and β are meromorphic, $v \in \mathbb{R}^m$, and $z \in \mathbb{R}^q$ for a given integer q, is said to be *regular* if the composite system (1.1a) and (3.1), with v as the input and u as the output, has rank equal to m.

The structure at infinity of Definition 3.1 enjoys the following properties.

LEMMA 3.3. (a) *The rank ρ^* of the system* (1.1) *is equal to σ_n, the total number of zeros at infinity.*

(b) $\sigma_n \leqq \min\{m, p\}$, *the number of input and output components, respectively.*

(c) *The total number of zeros at infinity is invariant under regular dynamic feedback.*

Proof. Properties (a) and (b) are immediate from the results of § 2. To prove (c), first introduce the field $\mathscr{K}_e$ consisting of the set of rational functions of $(v, \cdots, v^{(n+q-1)})$ with coefficients which are meromorphic in x and z. Assume that for a given l, $0 \leqq l \leqq n+q-1$, there exists i, $1 \leqq i \leqq m$, such that

$$du_i^{(l)} \in \operatorname{span}_{\mathscr{K}_e}\{dx, du, \cdots, du^{(l-1)}, du_j^{(l)}, j \neq i\}.$$

Then, following the calculations involved in the proof of Lemma 2.9, we see that

$$du_i^{(k)} \in \operatorname{span}_{\mathscr{K}_e}\{dx, du, \cdots, du^{(k-1)}, du_j^{(k)}, j \neq i\} \quad \forall k \geqq l,$$

which contradicts the regularity assumption of the dynamic compensator. Hence, for every l, $\{dx, du, \cdots, du^{(l)}\}$ is a linearly independent set. Let $y_e = h(x)$ denote the output of the composite system Σ_e consisting of (1.1) and (3.1), and define

$$\mathscr{G}_k = \operatorname{span}_{\mathscr{K}_e}\{dx, dy_e, \cdots, dy_e^{(k)}\}.$$

By the chain rule,

$$\frac{\partial(x, y_e, \cdots, y_e^{(k)})}{\partial(x, z, v, \cdots, v^{(k-1)})} = \frac{\partial(x, y, \cdots, y^{(k)})}{\partial(x, u, \cdots, u^{(k-1)})} \frac{\partial(x, u, \cdots, u^{(k-1)})}{\partial(x, z, v, \cdots, v^{(k-1)})}. \tag{3.2}$$

Since $\{dx, du, \cdots, du^{(k-1)}\}$ are independent, (3.2) yields that

$$\dim \mathcal{G}_k = \operatorname{rank} \frac{\partial(x, y, \cdots, y^{(k)})}{\partial(x, u, \cdots, u^{(k-1)})},$$

so that

$$\dim \mathcal{G}_k = \dim \mathcal{E}_k. \tag{3.3}$$

Finally, let ρ_e^* denote the rank Σ_e. Then, following the reasoning employed in Lemma 2.8, we show that $\rho_e^* = \dim \mathcal{G}_{n+q} - \dim \mathcal{G}_{n+q-1}$, which yields the result in view of (3.3). □

Now consider a system whose outputs have been grouped into blocks:

$$\dot{x} = f(x) + g(x)u, \tag{1.1a}$$

$$y_i = h_i(x), \qquad 1 \leqq i \leqq \mu, \tag{3.4}$$

where $y_i \in \mathbb{R}^{p_i}$ and h_i is a meromorphic function of x. The system is said to be decoupled with respect to a given partition $u = (u_1^T, \cdots, u_\mu^T)^T$ of the input if u_i affects only y_i, $1 \leqq i \leqq \mu$; that is,

$$dy_i^{(k)} \in \operatorname{span}\{dx, du_i, \cdots, du_i^{(n-1)}\} \tag{3.5}$$

for $0 \leqq k \leqq n$. The decoupling problem is to find, if possible, a regular dynamic compensator and a partition of the new reference input such that the resulting closed-loop system is decoupled. If the compensator has dimension zero, the solution is said to be static; otherwise it is dynamic.

Using (3.5), we immediately obtain the following necessary condition for regular static block decoupling.

PROPOSITION 3.4 (see also [8]). *If the system* (1.1a), (3.4) *with block-partitioned outputs can be decoupled with a regular static state variable feedback, then*

$$\sigma_k = \sum_{i=1}^{\mu} \sigma_k^i, \tag{3.6}$$

where $\{\sigma_1^i, \cdots, \sigma_n^i\}$ *is the structure at infinity of the ith subsystem consisting of the dynamics* (1.1a) *and the output* y_i.

When the outputs y_i are scalar-valued, it is known that (3.6) is also sufficient (see, for example, [9], [25]). This condition is also known to be sufficient for general vector-valued outputs if we restrict our attention to the class of linear systems [26]. Indeed, (3.6) implies that we can perform the inversion algorithm for the overall system (1.1a), (3.4) by applying it to each of the individual subsystems y_i, for $1 \leqq i \leqq \mu$. Then, specializing equation (2.10) to the nth step of the algorithm and invoking linearity, we see that the $\tilde{b}_i$'s are constants, and the $\tilde{a}_i$'s are linear functions of x and various derivatives of y_i. Decoupling is accomplished by cancelling the dependence on x, and diagonalizing the matrix multiplying the inputs, via a static feedback.

The fact that condition (3.6) is not sufficient for general nonlinear systems is illustrated by the following example.

Example 3.5. Consider the system

$$\dot{x} = (u_1, x_4 + x_5 u_1, u_2, x_3 u_1, u_3)^T,$$

$$y_1 = (x_1, x_2)^T, \qquad y_2 = x_3.$$

We easily calculate that $\{\sigma_1, \sigma_2\} = \{2, 3\}$, and for the two subsystems $\{\sigma_1^1, \sigma_2^1\} = \{1, 2\}$ and $\{\sigma_1^2\} = \{1\}$. Thus, (3.6) is fulfilled. Nevertheless, a straightforward application of the results of Nijmeijer and Schumacher [8] shows that the system cannot be decoupled by any regular static-state feedback.

This example underlines the importance of the differential geometric approach in general, and the "geometric" structure at infinity in particular, for the study of static state feedback control problems, since the equivalent of (3.6) for the geometric structure at infinity constitutes a local necessary and sufficient condition (at regular points) [8]. On the other hand, algebraic methods seem to be better when we are studying dynamic feedback problems [3], [4], [27]. In this spirit, we have the following result that does not hold with the geometric version of the structure at infinity because it fails [10] the properties of Lemma 3.3.

THEOREM 3.6. *The system* (1.1a), (3.4) *can be decoupled with regular dynamic state feedback if and only if*

$$\rho = \sum_{i=1}^{\mu} \rho_i, \tag{3.7}$$

where ρ_i *denotes the rank of the subsystem* (1.1a) *with output* y_i.

Proof. Because the necessity is clear, only the sufficiency will be shown. For each block of outputs y_i, permute if necessary the components in such a way that $y_i = (\bar{y}_i^T, \hat{y}_i^T)^T$, $\dim \bar{y}_i = \rho_i$, and on defining

$$\mathscr{E}_k^i = \operatorname{span}\{dx, d\dot{y}_i, \cdots, dy_i^{(k)}\},$$

we have

$$\mathscr{E}_k^i = \operatorname{span}\{dx, d\dot{\bar{y}}_i, \cdots, d\bar{y}_i^{(k)}\}$$

for all k, $1 \leqq k \leqq n$. This can always be accomplished with the help of the inversion algorithm of § 2.2. Then,

$$d\hat{y}_i^{(k)} \in \operatorname{span}\{dx, d\dot{\bar{y}}_i, \cdots, d\bar{y}_i^{(k)}\}$$

and the rank of the subsystem (1.1a) with output $\bar{y}_i$ is equal to ρ_i. Let $\bar{\Sigma}$ denote the subsystem whose output is given by $(\bar{y}_1, \cdots, \bar{y}_\mu)$. We conclude that the rank of $\bar{\Sigma}$ is ρ and the original system (1.1a), (3.4) can be decoupled if and only if $\bar{\Sigma}$ can be. It follows from (3.7) that the rank of $\bar{\Sigma}$ equals the number of its scalar output components; thus, $\bar{\Sigma}$ can be row-wise decoupled [25].

4. Conclusions. In the recent literature, there have been many attempts to extend concepts and tools from the linear setting to the class of nonlinear systems. For example, Nijmeijer extends a definition of right invertibility based on the consideration of the sequence of Toeplitz matrices associated to a linear system. Singh extends the notion of left invertibility based on the input elimination idea of Silverman's algorithm. Descusse and Moog and Nijmeijer and Respondek use the idea of delaying the inputs via the addition of integrators, as does Wang [28], to achieve dynamic decoupling of nonlinear systems. Fliess uses differential algebra to extend the notion of the rank of a transfer matrix, so as to synthesize left invertibility, right invertibility, and dynamic decoupling.

In this paper, we have shown that all of the above extensions can be unified by the study of a particular chain of subspaces naturally associated to the output of a system. As simple corollaries of our analysis, we obtain that right invertibility in the sense of Nijmeijer is the same as in that of Fliess, which in turn is the same as $\rho^* = p$, the number of scalar output components. Left invertibility in the sense of Singh is the

same as in that of Fliess, which is the same as $\rho^* = m$, the number of scalar input components. Moreover, the inversion algorithm has a natural interpretation as a procedure for constructing a basis adapted to the chain of subspaces $\mathscr{E}_0 \subset \cdots \subset \mathscr{E}_n$. In a similar vein, the dynamic extension algorithm, which lies at the heart of dynamic decoupling, also constructs a basis adapted to the chain $\mathscr{E}_0 \subset \cdots \subset \mathscr{E}_n$. The main difficulty in comparing the various algorithms was that each was working over its own unique field. This was overcome by relating each of the fields to a common larger field. In this way, the equivalence of four topics, that previously had only been studied separately, was established.

The search for a nonlinear version of the structure at infinity of a linear system has incited much effort on the part of many researchers [2], [7]-[9], [29], with the goal of finding an appropriate tool for solving such classical synthesis problems as noninteracting control and model matching. One of the first efforts in this regard was perceived to possess certain deficiencies [10], because a system could have more zeros at infinity than input or output components, and also because the number of zeros at infinity could be altered by the addition of integrators on the input channels.

Section 3 takes an algebraic approach to defining a nonlinear structure at infinity [9]. Its number of zeros at infinity is always less than or equal to the number of inputs or outputs, and is invariant under the action of regular dynamic feedback. However, the deficiency of this generalization of the structure at infinity is that it cannot properly address the static block noninteracting control problem. Hence the "right" approach, if it exists [30], is yet to be discovered.

ANALYSE ASYMPTOTIQUE ET PROBLEME HOMOGENEISE EN CONTROLE OPTIMAL AVEC VIBRATIONS RAPIDES*

SHI-GE PENG†

Abstract. Le but de cet article est de discuter un problème de contrôle optimal avec vibrations rapides. Le modèle mathématique est le suivant: pour $\varepsilon > 0$, assez petit, on considère

$$(*)_1 \qquad \frac{dx^\varepsilon}{dt} = g\left(\frac{t}{\varepsilon}, x^\varepsilon(t), v(t)\right), \qquad x^\varepsilon(0) = x_0$$

où $v(\cdot) \in L^2(0, T; \mathbb{R}^k)$ est la fonction de contrôle. $x^\varepsilon(\cdot) \in H^1(0, T; \mathbb{R}^n)$ est la fonction d'état. $g(\tau, x, v)$ est 1-périodique par rapport à $\tau \in \mathbb{R}$. On cherche à minimiser la fonction coût

$$(*)_2 \qquad \int_0^T l\left(\frac{t}{\varepsilon}, x^\varepsilon(t), v(t)\right) dt$$

où $l(\tau, x, v)$ est aussi 1-périodique par rapport à τ.

On s'intéresse tout d'abord au comportement du système quand $\varepsilon \to 0$. On pourrait peut-être croire que ce problème va tendre vers le problème "moyen"

$$\frac{dx}{dt} = \bar{g}(x(t), v(t)), \qquad \min_{v(\cdot)} \int_0^T \bar{l}(x(t), v(t))\, dt$$

où

$$\bar{g}(x, v) = \int_0^1 g(\tau, x, v)\, d\tau, \qquad \bar{l}(x, v) = \int_0^1 l(\tau, x, v)\, d\tau.$$

Mais c'est faux en général. En réalité, le problème de limite de $(*)$ sera

$$(**) \qquad \frac{dx}{dt} = \int_0^1 g(\tau, x(t), v(t, \tau))\, d\tau, \qquad \min_{v(\cdot,\cdot)} \int_0^T \int_0^1 l(\tau, x(t), v(t, \tau))\, d\tau\, dt$$

où

$$v(\cdot, \cdot) \in L^2([0, T] \times [0, 1]; \mathbb{R}^k).$$

C'est donc une sorte de généralisation du problème de contrôle optimal usuel. On va l'appeler le problème homogénéisé du problème $(*)$. Mais on va voir que l'on peut caractériser le problème $(**)$ de façon parallèle au problème classique. On aura le principe de Pontryagin et la méthode de programmation dynamique. On va également établir le développement asymptotique et la convergence des problèmes $(*)$.

AMS(MOS) subject classifications. 49, 93

1. Introduction.

Soit

$$(1) \qquad g(\tau, x, v) : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n, \quad l(\tau, x, v) : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}, \quad h(x) : \mathbb{R}^n \to \mathbb{R}$$

trois fonctions mesurables. On suppose que

$$(2) \qquad \begin{aligned} &g \text{ et } l \text{ sont 1-périodiques par rapport à } \tau, \\ &g(\tau + 1, x, v) = g(\tau, x, v), \\ &l(\tau + 1, x, v) = l(\tau, x, v) \quad \forall \tau, x, v. \end{aligned}$$

* Received by the editors December 29, 1986; accepted for publication (in revised form) September 14, 1988. This work was finished during the author's stay at the U.E.R. de Mathématiques, Université de Provence (Marseille, France) and was supported in part by the Institut National de Recherche en Informatique et en Automatique (INRIA), France.

† Mathematics Department, Shandong University, Jinan, People's Republic of China.

On suppose également que g est Lipschitzien par rapport à x. Pour $\varepsilon > 0$ assez petit, on va chercher le contrôle optimal du problème

$$\begin{aligned} &\frac{dx^\varepsilon}{dt} = g\left(\frac{t}{\varepsilon}, x^\varepsilon(t), v(t)\right), \qquad x^\varepsilon(0) = x_0, \\ &\min_{v(\cdot)} \left[\int_0^T l\left(\frac{t}{\varepsilon}, x^\varepsilon(t), v(t)\right) dt + h(x^\varepsilon(t))\right]. \end{aligned} \tag{3}$$

Formellement on aura les conditions nécessaires d'optimalité (principe de Pontryagin [9])

$$\begin{aligned} &\frac{dx^\varepsilon}{dt} = g\left(\frac{t}{\varepsilon}, x^\varepsilon(t), u^\varepsilon(t)\right), \\ &-\frac{dp^\varepsilon}{dt} = H_x\left(\frac{t}{\varepsilon}, x^\varepsilon(t), u^\varepsilon(t), p^\varepsilon(t)\right), \\ &H_v\left(\frac{t}{\varepsilon}, x^\varepsilon(t), u^\varepsilon(t), p^\varepsilon(t)\right) = 0 \end{aligned} \tag{4}$$

où $H(\tau, x, v, p) = p^* g(\tau, x, v) + l(\tau, x, v)$ est l'Hamiltonien.

On va étudier le comportement du problème de contrôle optimal quand $\varepsilon \to 0$. On va s'apercevoir que ce problème ne tend pas vers le "averaging problem"

$$\frac{dx}{dt} = \bar{g}(x(t), v(t)), \qquad \min_{v(\cdot)} \int_0^T \bar{l}(x(t), v(t))\, dt \tag{5}$$

où

$$\bar{g}(x, v) = \int_0^1 g(\tau, x, v)\, d\tau, \qquad \bar{l}(x, v) = \int_0^1 l(\tau, x, v)\, d\tau.$$

Le problème de limite est en fait une sorte de généralisation du problème de contrôle optimal où l'équation d'état s'écrit:

$$\frac{dx}{dt} = \int_0^1 g(\tau, x(t), v(t, \tau))\, d\tau, \qquad x(0) = x_0 \tag{6}$$

et le contrôle est une fonction de deux variables

$$v : [0, T] \times [0, 1] \to \mathbb{R}^k \quad \text{mesurable.}$$

Ici on souligne que la fonction d'état $x(t)$ est seulement une fonction de $t \in [0, T]$. De la même façon, la fonctionnelle à minimiser est

$$J^0(v(\cdot, \cdot)) = \int_0^1 \int_0^T l(\tau, x(t), v(t, \tau))\, d\tau\, dt + h(x(T)). \tag{7}$$

Ce phénomène peut se comprendre par le développement asymptotique des conditions de Pontryagin (4). On peut écrire formellement les développements de $x^\varepsilon(t)$, $u^\varepsilon(t)$, $p^\varepsilon(t)$ par la technique de changement de l'echelle du temps (voir [5], [6])

$$\begin{aligned} x^\varepsilon(t) &= x(t) + \varepsilon x_1\left(t, \frac{t}{\varepsilon}\right) + \cdots, \\ p^\varepsilon(t) &= p(t) + \varepsilon p_1\left(t, \frac{t}{\varepsilon}\right) + \cdots, \\ u^\varepsilon(t) &= u\left(t, \frac{t}{\varepsilon}\right) + \varepsilon u_1\left(t, \frac{t}{\varepsilon}\right) + \cdots \end{aligned}$$

où $u(t, \tau)$, $x_1(t, \tau)$, $p_1(t, \tau)$ sont 1-périodiques par rapport à τ. La raison pour laquelle le terme $u(t, (t/\varepsilon))$ contient déjà les vibrations rapides est la suivante: le contrôle réagit aux vibrations rapides du système beaucoup plus rapidement que la fonction d'état. En remplaçant x^ε, u^ε, p^ε par leur développement dans (4), pour l'ordre ε^0, on a $(\tau = t/\varepsilon)$

$$\begin{aligned} &\frac{\partial x_1}{\partial \tau} + \frac{dx}{dt} = g(\tau, x(t), u(t, \tau)), \\ &-\frac{\partial p_1}{\partial \tau} - \frac{dp}{dt} = H_x(\tau, x(t), u(t, \tau), p(t)), \\ &H_v(\tau, x(t), u(t, \tau), p(t)) = 0. \end{aligned} \tag{8}$$

On intègre les deux premières équations de (8) par rapport à τ sur $[0, 1]$; donc

$$\begin{aligned} &\frac{dx}{dt} = \int_0^1 g(\tau, x(t), u(t, \tau))\, d\tau, \\ &-\frac{dp}{dt} = \int_0^1 H_x(\tau, x(t), u(t, \tau), p(t))\, d\tau, \\ &H_v(\tau, x(t), u(t, \tau), p(t)) = 0. \end{aligned} \tag{9}$$

Mais on va montrer plus tard que les relations (9) ne sont rien d'autre que les conditions nécessaires d'optimalité du problème (6), (7). On dit que le problème (6), (7) est une sorte de généralisation des problèmes de contrôle optimal, car si l'on fait $\partial g/\partial \tau(\tau, x, v) \equiv 0$, $\partial l/\partial \tau(\tau, x, v) \equiv 0$ (un cas particulier de la fonction périodique), il devient un problème de contrôle optimal classique. On va voir que les méthodes de perturbations singulières jouent un rôle très important dans cet article. Ceci veut dire qu'on va souvent utiliser la technique de changement de l'échelle du temps et les techniques de développements asymptotiques. Pour démontrer le résultat de convergence, l'auteur a beaucoup profité des techniques utilisées initialement par Bensoussan [1], [2]. Le résultat de régularité d'ordre élevé de la fonction du coût (voir Peng [8]) est aussi nécessaire pour traiter la convergence d'ordre élevé de l'équation de Bellman avec vibrations rapides.

Dans § 2, on va traiter le principe du maximum pour le problème homogénéisé. Dans § 3 on va étudier la programmation dynamique du problème homogénéisé. Dans §§ 4 et 5, on va traiter, au point de vue du principe du maximum et de la programmation dynamique, respectivement, le problème de convergence d'ordre élevé en contrôle optimal avec vibrations rapides. On donnera un exemple simple dans § 6.

2. Principe de Pontryagin du problème homogénéisé. On suppose que

(10) g, l, h sont continûment différentiables par rapport à x, v,

$$\begin{aligned} &|g(\tau, x, v)| \leqq C(1+|x|+|v|), \qquad \left|\frac{\partial g}{\partial x}\right|, \left|\frac{\partial g}{\partial v}\right| \leqq C, \\ &|l(\tau, x, v)| \leqq C(1+|x|^2+|v|^2), \quad \left|\frac{\partial l}{\partial x}\right|, \left|\frac{\partial l}{\partial v}\right| \leqq C(1+|x|+|v|), \\ &\left|\frac{\partial h}{\partial x}(x)\right| \leqq C(1+|x|). \end{aligned} \tag{11}$$

Un contrôle admissible du problème homogénéisé est une fonction

(12) $v(\cdot,\cdot)\in L^2([0,T]\times[0,1];\mathbb{R}^k)$ t.q. $v(t,\tau)\in \mathbf{U}_{ad}$ p.p. dans $[0,T]\times[0,1]$

où

$$\mathbf{U}_{ad}\subset\mathbb{R}^k, \quad \text{convexe non vide.}$$

Dans ce chapitre on note que

$$EF(\cdot,x,v(t,\cdot))=\int_0^1 F(\tau,x,v(t,\tau))\,d\tau. \tag{13}$$

Le problème de contrôle optimal homogénéisé est

$$\frac{dx}{dt}=Eg(\cdot,x(t),v(t,\cdot)), \qquad \min_{v(\cdot,\cdot)}\left[E\int_0^T l(\cdot,x(t),v(t,\cdot))\,dt+h(x(T))\right]. \tag{14}$$

On a le principe de Pontryagin (voir le théorème 1).

THEOREME 1. *On fait les hypothèses* (10), (11). *Alors une condition nécessaire pour* $u(t,\tau)$ *soit un contrôle optimal du problème* (14) *est qu'il existe une fonction* $p(\cdot)\in H^1(0,T;\mathbb{R}^n)$, *telle que*

$$\begin{aligned}&\frac{dx}{dt}=Eg(\cdot,x(t),u(t,\cdot)), \qquad -\frac{dp}{dt}=EH_x(\cdot,x(t),u(t,\cdot),p(t)),\\ &H_v(\tau,x(t),u(t,\tau),p(t))(v-u(t,\tau))\geqq 0 \quad \forall t, \text{ p.p. } \forall v\in\mathbf{U}_{ad}.\end{aligned} \tag{15}$$

La démonstration est similaire à la méthode classique (voir, par exemple, Bensoussan [1]).

On aura besoin aussi des conditions du second ordre pour que $u(t,\tau)$ soit un contrôle optimal. On suppose en plus de (11), (12) que

$$g,\ l,\ h\in C^2(\mathbb{R}^n\times\mathbb{R}^k) \tag{16}$$

toutes les dérivées de g et les dérivées secondes de l, h sont supposées bornées.

On a le Théorème 2.

THEOREME 2. *On suppose* (11), (12), (16). *Soit* $(x(t),u(t,\tau),p(t))$, *un triplet vérifiant* (15) *et*

$$H_{vv}(\tau,x,v,p(t))\geqq\beta I, \quad \beta>0 \quad \forall x,\tau,t, \quad \forall v\in\mathbf{U}_{ad}, \tag{17}$$

$$(H_{xx}-H_{xv}H_{vv}^{-1}H_{vx})(\tau,x,v,p_0(t))\geqq 0 \tag{18}$$

pour les mêmes arguments qu'en (17); *alors* $u(t,\tau)$ *est l'unique contrôle optimal du problème* (14).

La démonstration est de nouveau similaire à la méthode classique (voir, par exemple, Bensoussan [1]).

3. Programmation dynamique du problème homogénéisé. On commence par la définition de la fonction de Bellman du problème homogénéisé. On considère pour $t_0\in[0,T]$, $x_0\in\mathbb{R}^n$

$$\frac{dx}{dt}=Eg(\cdot,x(t),v(t,\cdot)), \qquad x(t_0)=x_0. \tag{19}$$

La fonctionnelle à minimiser est donc paramétrée par la donnée initiale (x_0,t_0). La fonction de Bellman est définie par

$$\Phi(x_0,t_0)=\min_{v(\cdot,\cdot)} J^0_{x_0,t_0}(v(\cdot,\cdot)), \tag{20}$$

où

$$J^0_{x_0,t_0}(v(\cdot,\cdot)) = \int_0^T El(\cdot, x(s), v(s,\cdot))\, ds + h(x(T)).$$

On suppose

$$E|g(\cdot, x, v)|,\ E|l(\cdot, x, v)| < +\infty \quad \forall x \in \mathbb{R}^n, \quad v \in \mathbb{R}^k, \tag{21}$$

g, l, h sont continûment différentiable par rapport à x,

$$\mathbf{U}_{\text{ad}} \subset \mathbb{R}^k \text{ mesurable}, \tag{22a}$$

$$|g_x(\tau, x, v)| \leqq C, \tag{22b}$$

$$|h_x(x)| \leqq \bar{h} \cdot (1+|x|), \tag{22c}$$

$$|l_x(\tau, x, v)| \leqq \bar{l}(|l(\tau, 0, v)|^{1/2} + |x| + 1), \tag{22d}$$

$$l(\tau, x, v) \geqq l_0 |g(\tau, x, v) - g(\tau, x, \bar{v})|^2 - C_0, \tag{22e}$$

où

$$\bar{v} \in \mathbb{R}^k \text{ est fixé},$$

$$h(x) \geqq -C_0. \tag{23}$$

Remarque. Quand $\partial g/\partial \tau \equiv 0$, $\partial l/\partial \tau \equiv 0$, on revient au cas classique (voir [4], [1]). Même dans ce cas, les hypothèses (21)-(23) sont plus faibles que ce qu'on suppose souvent: on n'a plus besoin de la continuité par rapport à v, la condition de "quasilinéaire quadratique" de l par rapport à v est remplacée par (22e).

Le lemme suivant donne la régularité de la fonction de Bellman $\Phi(x, t)$.

LEMME 3. *Sous les hypothèses* (21)-(23), *la fonction* $\Phi(x, t)$ *vérifie*

$$|\Phi(x, t)| \leqq C(1+|x|^2), \tag{24}$$

$$|D\Phi(x, t)| \leqq \bar{C}(1+|x|), \tag{25}$$

$$\left|\frac{\partial \Phi}{\partial t}(x, t)\right| \leqq \bar{C}(1+|x|^2). \tag{26}$$

Démonstration. On prend

$$v(s) = \bar{u}, \quad t \leqq s \leqq T, \quad \bar{u} \in \mathbf{U}_{\text{ad}} \quad \text{fixé}$$

comme contrôle et on note $\bar{x}(s)$, la fonction d'état correspondante.

$$\frac{d\bar{x}(s)}{ds} = Eg(\cdot, \bar{x}(s), \bar{u}), \qquad \bar{x}(t) = x. \tag{27}$$

D'après (11) on a

$$|\bar{x}(s)| \leqq C(1+|x|) \quad \forall t \leqq s \leqq T. \tag{28}$$

Donc

$$\begin{aligned}
\Phi(x, t) &\leqq J_{x,t}(\bar{u}) \\
&= E \int_t^T l(\cdot, \bar{x}(s), \bar{u})\, ds + h(\bar{x}(T)) \\
&= E \int_t^T \left[l(\cdot, 0, \bar{u}) + \int_0^1 l_x(\cdot, \lambda \bar{x}(s), \bar{u}) \cdot \bar{x}(s)\, d\lambda \right] ds + h(\bar{x}(T)) \\
&\leqq \int_t^T (E|l(\cdot, 0, \bar{u})|\, ds + E \int_0^1 \bar{l}(|l(\cdot, 0, \bar{u})|^{1/2} + \lambda |\bar{x}(s)| + 1)\, d\lambda \cdot |\bar{x}(s)|)\, ds \\
&\quad + h(\bar{x}(T)) \quad \text{d'après (22d).}
\end{aligned}$$

De (28), (22), on a

$$\Phi(x, t) \leqq \bar{C}(1+|x|^2).$$

Mais d'après (22e) on sait que

$$\Phi(x, t) \geqq -C_0 T.$$

Les deux dernières inégalités impliquent donc l'estimation (24). Cela nous permet de limiter le contrôle admissible par

$$E \int_t^T l(\cdot, x(s), v(s, \cdot))\, ds \leqq C(1+|x|^2). \tag{29}$$

Ce qui avec l'hypothèse (22e) implique

$$l_0 \int_t^r E|g(\cdot, x(s), v(s, \cdot)) - g(\cdot, x(s), \bar{v})|^2\, ds \leqq C(1+|x|^2) \tag{30}$$

donc

$$|y(r)| \leqq C(1+|x|) \tag{31}$$

où on note que

$$y(r) = E \int_t^r (g(\cdot, x(s), v(s, \cdot)) - g(\cdot, x(s), \bar{v}))\, ds.$$

Mais on sait que

$$x(r) - x = y(r) + E \int_t^r g(\cdot, x(s), \bar{v})\, ds;$$

donc

$$|x(r)| \leqq C_1(1+|x|) + C_2 \int_t^r |x(s)|\, ds.$$

Par conséquent

$$|x(r)| \leqq C(1+|x|). \tag{32}$$

Ce qui avec (30) implique

$$E \int_t^T |g(\cdot, x(s), v(\cdot, s))|^2\, ds \leqq C(1+|x|^2). \tag{33}$$

On a aussi

$$E \int_t^T |g(\cdot, 0, v(s, \cdot))|^2\, ds \leqq C(1+|x|^2). \tag{34}$$

On peut montrer également que

$$\int_t^T |El(\cdot, x(s), v(\cdot, s))|\, ds \leqq C(1+|x|^2). \tag{35}$$

$$\int_t^T |El(\cdot, 0, v(\cdot, s))|\, ds \leqq C(1+|x|^2). \tag{36}$$

En effet, si on note

$$\Delta^+ = \{s \in [t, T], El(\cdot, x(s), v(s, \cdot)) > 0\}, \qquad \Delta^- = [t, T] \backslash \Delta^-.$$

On a d'après (29)

$$\int_{\Delta^+} |El(\cdot, x(s), v(s, \cdot))|\, ds - \int_{\Delta^-} |El(\cdot, x(s), v(s, \cdot))|\, ds \leqq C(1+|x|^2). \tag{36}_1$$

Toujours grâce à (22e) on a

$$|El(\cdot, x(s), v(\cdot, s))| \leqq C_0 \quad \forall s \in \Delta^-,$$

ce qui avec $(36)_1$ implique donc (35). On peut déduire (36) de (35) et l'hypothèse (22d).

Avec (32), (36), on peut montrer l'estimation (25). Pour une donnée initiale $\tilde{x} \in \mathbb{R}^n$, on note $\tilde{x}(t)$ la solution de

$$\frac{d\tilde{x}}{ds} = Eg(\cdot, \tilde{x}(s), v(s, \cdot)), \qquad \tilde{x}(t) = \tilde{x}.$$

On peut donc limiter $x(s)$, $\tilde{x}(s)$, $v(s, \tau)$, par

$$(36)_2 \qquad |x(s)|^2, |\tilde{x}(s)|^2, \int_t^T |El(\cdot, 0, v(s, \cdot))|\, ds \leqq C(1+|x|^2+|\tilde{x}|^2).$$

Par ailleurs on a

$$|x(s)-\tilde{x}(s)| \leqq |x-\tilde{x}| + E\int_t^s |g(\cdot, x(r), v(r, \cdot)) - g(\cdot, \tilde{x}(r), v(r, \cdot))|\, dr$$

$$\leqq |x-\tilde{x}| + C\int_t^s |x(r)-\tilde{x}(r)|\, dr.$$

D'après l'inégalité de Gronwall

$$(37) \qquad |x(s)-\tilde{x}(s)| \leqq C_1|x-\tilde{x}|.$$

On a donc

$$|J^0_{x,t}(v(\cdot)) - J^0_{\tilde{x},t}(v(\cdot))|$$

$$= \left| \int_t^T \int_0^1 El_x(\tau, \tilde{x}(s) + \lambda(x(s)-\tilde{x}(s)), v(s, \cdot))\, d\lambda\, (x(s)-\tilde{x}(s))\, ds \right|$$

$$+ \left| \int_0^1 h_x(\tilde{x}(T) + \lambda(x(T)-\tilde{x}(T)))\, d\lambda\, (x(T)-\tilde{x}(T)) \right|.$$

De (37) et les hypothèses (22c), (22d), cela est majoré par $\int_0^1 \int_t^T \bar{l}(|El(\cdot, 0, v(s, \cdot))|^{1/2} + |\tilde{x}(s) + \lambda(x(s)-\tilde{x}(s))| + 1)\, d\lambda\, ds. \quad |x-\tilde{x}| + \bar{h} \cdot |\tilde{x}(T) + \lambda(x(T)-\tilde{x}(T))| \cdot |x(T)-\tilde{x}(T)|$; de $(36)_2$, (37) on a finalement

$$|J^0_{x,t}(v(\cdot)) - J^0_{\tilde{x},t}(v(\cdot))| \leqq C|x-\tilde{x}| \cdot (1+|x|+|\tilde{x}|).$$

On en déduit donc

$$(38) \qquad |\Phi(x, t) - \Phi(\tilde{x}, t)| \leqq C|x-\tilde{x}|(1+|x|+|\tilde{x}|).$$

Cela implique que Φ est presque partout différentiable et que la dérivée $D\Phi(x, t)$ est majorée par (25).

L'estimation (26) est une conséquence du principe d'optimalité de la programmation dynamique homogénéisée.

$$(39) \qquad \Phi(x, t) = \inf_{v(\cdot,\cdot)} \left[\int_t^{t+h} El(\cdot, x(s), v(s, \cdot))\, ds + \Phi(x(t+h), t+h) \right].$$

Si l'on choisit $v(s, \tau) = \bar{u}$, $t \leqq s \leqq t+h$, et note $\bar{x}(t)$ la fonction d'état correspondante, on a d'après (39)

$$\Phi(x, t) \leqq \int_t^{t+h} El(\cdot, \bar{x}(s), \bar{u})\, ds + \Phi(\bar{x}(t+h), t+h). \tag{40}$$

De (28)

$$|\bar{x}(t+h) - x| \leqq C|h|(1+|x|).$$

Compte tenu de l'estimation pour $D\Phi$, on a

$$|\Phi(\bar{x}(t+h), t+h) - \Phi(x, t+h)| \leqq C|h|(1+|x|^2),$$

ce qui avec (40) implique

$$\Phi(x, t) \leqq C|h|(1+|x|^2) + \Phi(x, t+h)$$

donc

$$\frac{\partial \Phi}{\partial t} \geqq -C(1+|x|^2). \tag{41}$$

Par ailleurs on a

$$\begin{aligned} |\Phi(x(t+h), t+h) - \Phi(x, t+h)| &\leqq C|x(t+h) - x|(1+|x|) \\ &= C(1+|x|)|\cdot \left| \int_t^{t+h} Eg(\cdot, x(s), v(s, \cdot))\, ds \right|. \end{aligned}$$

On déduit alors de (39) tenant compte de l'hypothèse (22e)

$$\begin{aligned} \Phi(x, t) &\geqq \inf_{v(\cdot,\cdot)} \left[\int_t^{t+h} E|g(\cdot, x(s), v(s, \cdot)) - g(\cdot, x(s), \bar{v})|^2 \right] ds \\ &\quad - C_0|h| - C(1+|x|) \int_t^{t+h} E|g(\cdot, x(s), v(s, \cdot))|\, ds + \Phi(x, t+h) \\ &\geqq \inf_{v(\cdot,\cdot)} \left[\int_t^{t+h} E(|g(\cdot, x(s), v(s, \cdot))|^2 - C(1+|x|)|g(\cdot, x(s), v(s, \cdot))|) \right] ds \\ &\quad - C_0|h| + \Phi(x, t+h) \\ &\geqq \Phi(x, t+h) - C_1(1+|x|^2)|h| \end{aligned}$$

ce qui avec (41) implique enfin (26). □

L'équation de la programmation dynamique homogénéisée s'écrit

$$\frac{\partial \Phi}{\partial t} + \inf_{u(\cdot) \in \mathbf{U}_{ad}} E[D\Phi \cdot g(\cdot, x, v(\cdot)) + l(\cdot, x, v(\cdot))] = 0, \qquad \Phi(x, T) = h(x) \tag{42}$$

où

$$\mathbf{U}_{ad} = \{v(\cdot), v(\tau) \in L^2([0, T]; \mathbf{U}_{ad})\}. \tag{43}$$

Remarque. L'équation (42) est aussi une équation aux dérivées partielles du premier ordre. Elle peut s'écrire comme

$$\frac{\partial \Phi}{\partial t} + E[D\Phi g(\cdot, x, u(\cdot, x, D\Phi)) + l(\cdot, x, u(\cdot, x, D\Phi))] = 0, \qquad \Phi(x, T) = h(x) \tag{43}_1$$

où

$$(43)_2 \qquad u(\tau, x, D\Phi) = \arg \inf_{u(\cdot)\in U_{ad}} E[D\Phi \cdot g(\cdot, x, u(\cdot)) + l(\cdot, x, u(\cdot))],$$

la fonction $\hat{u}(\tau, x) = u(\tau, x, D\Phi(x))$, s'appelle le contrôle feedback. Si $\hat{u}(\tau, x)$ est Lipschitzien par rapport à x, on peut montrer que $\hat{u}(\tau, x(t))$, $0 \leqq t \leqq \tau$, est exactement le contrôle optimal du problème (6), (7), où $x(t)$ est l'état correspondant

$$(44) \qquad \frac{dx}{dt} = Eg(\cdot, x(t), v(\cdot, x(t))), \qquad x(0) = x_0.$$

Maintenant on peut énoncer le théorème 4.

THEOREME 4. *Sous les hypothèses* (21)-(23). *La fonction* $\Phi(x, t)$ *définie par* (16) *vérifie* (42). *C'est de plus la fonction maximum vérifiant* (42) *et le lemme* 3.

Démonstration. On peut se limiter aux contrôles vérifiant

$$(45) \qquad \int_t^{t+h} E|g(\cdot, 0, v(s, \cdot))|^2 \, ds \leqq Ch(1+|x|^2).$$

En effet on peut considérer seulement les contrôles vérifiant

$$(46) \qquad \int_t^{t+h} El(\cdot, x(s), v(s, \cdot)) \, ds + \Phi(x(t+h), t+h)$$

$$\leqq \int_t^{t+h} El(\cdot, \bar{x}(s), \bar{u}) \, ds + \Phi(\bar{x}(t+h), t+h)$$

où $(\bar{x}(s), \bar{u})$ est le même couple dans (40). D'après le lemme 3 on a

$$|\Phi(x(t+h), t+h) - \Phi(x, t)| \leqq C|x(t+h) - x|(1+|x|) + C(1+|x|^2)h,$$

$$|\Phi(\bar{x}(t+h), t+h) - \Phi(x, t)| \leqq C(1+|x|^2)h.$$

Ce qui avec (46) implique donc

$$\int_t^{t+h} El(\cdot, x(s), v(s, \cdot)) \, ds$$

$$\leqq C|x(t+h) - x|(1+|x|) + C(1+|x|^2)h$$

$$\leqq C_1(1+|x|^2)h + C(1+|x|) \int_t^{t+h} E|g(\cdot, 0, v(s, \cdot))| \, ds$$

$$\leqq C_1(1+|x|^2)h + C(1+|x|)h^{1/2}\left(\int_t^{t+h} E|g(\cdot, 0, v(s, \cdot))|^2 \, ds\right)^{1/2}.$$

D'autre part d'après (22e) on a

$$\int_t^{t+h} l_0 E|g(\cdot, x(s), v(s, \cdot)) - g(\cdot, x(s), \bar{v})|^2 \, ds$$

$$\leqq C_2(1+|x|^2)h + C(1+|x|)h^{1/2}\left(\int_t^{t+h} E|g(\cdot, 0, v(s, \cdot))|^2 \, ds\right)^{1/2}.$$

D'après (32) et l'hypothèse (22b)

$$\int_t^{t+h} l_0 E|g(\cdot, 0, v(s,\cdot))|^2\, ds \leqq C_3(1+|x|^2)h + C(1+|x|)h^{1/2}\left(\int_t^{t+h} E|g(\cdot, 0, v(s,\cdot))|^2\, ds\right)^{1/2};$$

cela implique donc (45).

Pour les contrôles vérifiant (45), on a

$$|x(t+h)-x| \leqq Ch(1+|x|) \tag{47}$$

où C ne dépend pas du contrôle dans la classe (45).

Soit maintenant x, t est un point où Φ est différentiable, on a

$$\left|\Phi(x(t+h), t+h)-\Phi(x,t)-h\frac{\partial\Phi}{\partial t}-\int_t^{t+h} ED\Phi\cdot g(\cdot, x, v(s,\cdot))\, ds\right| \leqq O(h)\cdot h$$

où $O(h)$ tend vers zéro avec h et ne dépend pas du contrôle. Par conséquent de (16) il résulte

$$\inf_{v(\cdot,\cdot)}\left[\frac{1}{h}\int_t^{t+h} E(D\Phi\cdot g(\cdot, x, v(s,\cdot))+l(\cdot, x, v(s,\cdot)))\, ds\right]+\frac{\partial\Phi}{\partial t}\leqq O(h)$$

donc

$$\inf_{v\in \mathbf{U}_{ad}} E[D\Phi g(\cdot, x, v(\cdot))+l(\cdot, x, v(\cdot))]+\frac{\partial\Phi}{\partial t}\leqq O(h).$$

En faisant $h\to 0$

$$\inf_{v\in \mathbf{U}_{ad}} \mathrm{E}[\mathrm{D}\Phi \mathrm{g}(\cdot, \mathrm{x}, \mathrm{v}(\cdot))+\mathrm{l}(\cdot, \mathrm{x}, \mathrm{v}(\cdot))]+\frac{\partial\Phi}{\partial \mathrm{t}}\leqq 0. \tag{48}$$

Comme par ailleurs, toujours d'après (39) on a

$$\Phi(x,t)\leqq \int_t^{t+h} El(\cdot, x(s), v(\cdot))\, ds+\Phi(x(t+h), t+h)$$

$$= El(\cdot, x, v(\cdot))\cdot h+\frac{\partial\Phi}{\partial t}\cdot h+D\Phi Eg(\cdot, x, v(\cdot))h+\Phi(x,t)+O(h).$$

On a

$$\frac{\partial\Phi}{\partial t}+E[D\Phi g(\cdot, x, v(\cdot))+l(\cdot, x, v(\cdot))]\geqq 0$$

d'où

$$\inf_{v(\cdot)\in \mathbf{U}_{ad}} E[D\Phi g(\cdot, x, v(\cdot))+l(\cdot, x, v(\cdot))]+\frac{\partial\Phi}{\partial t}\geqq 0$$

ce qui avec (48) implique (42).

On peut montrer l'affirmation "solution maximum" de façon similaire à Bensoussan [1]. □

On peut traiter la régularité de $\Phi(x, t)$ pour les ordres plus élevés de la même façon qu'en Peng [8, Chap. I] (l'étude de la régularité de l'équation de Bellman par la méthode de perturbation). On énonce ici seulement le résultat.

THEOREME 5. *On fait les hypothèses*

(49) (i) g, l, h *sont* $2p+2$ *fois continûment différentiables*;

(ii) $$\left|\frac{\partial^{(j)} g}{(\partial\beta)^j}(\tau, \beta)\right| \leqq C_j(1+|x|)^{1-j},$$

$$\left|\frac{\partial^{(j)} l}{(\partial\beta)^j}(\tau, \beta)\right|, \left|\frac{\partial^{(j)} h}{(\partial x)^j}(x)\right| \leqq C(1+|x|)^{2-j} \quad \forall 0 \leqq j < 2p+2$$

où on note

$$\beta = (x, v),$$

(iii) $$\frac{\partial^2 h}{\partial x^2} \geqq 0, \qquad h(x) \geqq -C,$$

(iv) $$\frac{\partial^2 l}{\partial \beta^2}(\tau, \beta) \geqq \gamma_0 I$$

où γ_0 *est assez grand par rapport à* C_2,

(v) $\mathbf{U}_{\text{ad}} = \mathbb{R}k$.

On a alors

(50) (i) $\Phi(x, t) \in C^{2p+1}$ *et*

$$\left|D_x^{(j)} \frac{\partial^{(i)}}{\partial t^i} \Phi(x, t)\right| \leqq C(1+|x|)^{2-j}, \qquad i+j \leqq 2p+1,$$

(ii) *le contrôle feedback optimal* $u(x, t, \tau)$ *existe; il est caractérisé par*

$$D\Phi g_v(\tau, x, u(x, t, \tau)) + l_v(\tau, x, u(x, t; \tau)) = 0,$$

(iii) $$\left|\frac{\partial^{(i+j)}}{\partial t^i \partial x^j} u(x, t, \tau)\right| \leqq C(1+|x|)^{1-j}, \qquad i+j \leqq 2p.$$

4. Méthode asymptotique du point de vue du principe maximum.

4.1. Développement asymptotique. On va étudier dans ce paragraphe la méthode des perturbations pour le système d'optimalité, du point de vue du principe de Pontryagin. On va prendre le cas sans contrainte; $\mathbf{U}_{\text{ad}} = \mathbb{R}^K$. Dans ce cas, les conditions nécessaires pour le problème (3) seront

$$\frac{dx^\varepsilon}{dt} = g\left(\frac{t}{\varepsilon}, x^\varepsilon, u^\varepsilon\right), \qquad x^\varepsilon(0) = x_0,$$

(51)
$$-\frac{dp^\varepsilon}{dt} = H_x\left(\frac{t}{\varepsilon}, x^\varepsilon, u^\varepsilon\right), \qquad p^\varepsilon(T) = h(x^\varepsilon(T)),$$

$$H_v\left(\frac{t}{\varepsilon}, x^\varepsilon, u^\varepsilon\right) = 0.$$

On va voir que, quand $\varepsilon \to 0$, ce système tend vers le système d'homogénéisation (6), (7). Pour les développements d'ordre élevé, on utilise naturellement la méthode de changement de l'échelle du temps, $\tau = t/\varepsilon$. Mais on va rencontrer à ce niveau là un

problème. Premièrement, à la différence des perturbations singulières, les vibrations rapides ne disparaissent pas avec le déroulement du temps. De plus, il est évident que $\tau = t/\varepsilon$ ne vérifie pas la condition au bord $t = T$, tandis que $\tau = (T-t)/\varepsilon$ ne la vérifie pas pour $t = 0$. Pour résoudre cette difficulté, on va essayer de développer x^ε, p_ε, u^ε sous la forme suivante

$$
\begin{aligned}
x^\varepsilon(t) &= x_0(t) + \varepsilon x_1\left(t, \frac{t}{\varepsilon}\right) + \cdots, \\
p^\varepsilon(t) &= p_0(t) + \varepsilon p_1\left(t, \frac{t}{\varepsilon}\right) + \cdots, \qquad (52) \\
u^\varepsilon(t) &= u_0\left(t, \frac{t}{\varepsilon}\right) + \varepsilon u_1\left(t, \frac{t}{\varepsilon}\right) + \cdots.
\end{aligned}
$$

On considère $\alpha_0 = T/\varepsilon$ comme un paramètre. En remplaçant x^ε, p^ε, u^ε par (52) dans (51) et en général les termes du même ordre, on a

$$
\begin{aligned}
&\frac{dx_0}{dt} + \frac{dx_1}{d\tau} = g(\tau, x_0(t), u_0(t, \tau)), \\
&\frac{dp_0}{dt} - \frac{\partial x_1}{\partial \tau} = H_x(\tau, x_0(t), u_0(t, \tau), p_0(t)), \qquad (53) \\
&H_v(\tau, x_0(t), u_0(t, \tau), p_0(t)) = 0
\end{aligned}
$$

avec les conditions au bord

$$
x_0(0) = x_0, \qquad p_0(T) = h_x(x_0(T)), \qquad (54)
$$

$$
x_1(0, 0) = 0, \qquad p_1(T, \alpha_0) = h_{xx}(x_0(T))x_1(T, \alpha_0). \qquad (55)
$$

Pour les relations du deuxième ordre on a

$$
\begin{aligned}
&\frac{\partial x_1}{\partial t} + \frac{\partial x_2}{\partial \tau} = g_x(\tau, x_0(t), u_0(t, \tau))x_1 + g_v(\tau, x_0, u_0)u_1, \\
&-\frac{\partial p_1}{\partial t} - \frac{\partial p_2}{\partial \tau} = g_x^*(\cdot)p_1 + H_{xx}(\cdot)x_1 + H_{xv}(\cdot)u_1, \qquad (56) \\
&g_v^*(\cdot)p_1 + H_{vx}(\cdot)x_1 + H_{vv}(\cdot)u_1 = 0
\end{aligned}
$$

avec les conditions au bord

$$
x_2(0, 0) = 0, \qquad p_2(T, \alpha_0) = \tfrac{1}{2}h_x^{(3)}(x_0(T))(x_1(T, \alpha_0))^2 + h_{xx}(\cdot)x_2(T, \alpha_0). \qquad (57)
$$

Généralement, si on note

$$
\beta_i = (x_i, v_i), \qquad \sigma_i = (x_i, v_i, p_i)
$$

pour un nombre entier $l \geqq 1$, on a

$$
\begin{aligned}
&\frac{\partial x_l}{\partial t} + \frac{\partial x_{l+1}}{\partial \tau} = \sum_{(\alpha \cdot l)}^{l} \frac{1}{\alpha_1! \cdots \alpha_l!} g_\beta^{(\alpha_1 + \cdots + \alpha_l)} \beta_1^{\alpha_1} \cdots \beta_l^{\alpha_l}, \\
&-\frac{\partial p_l}{\partial t} - \frac{\partial p_{l+1}}{\partial \tau} = \sum_{(\alpha \cdot l)}^{l} \frac{1}{\alpha_1! \cdots \alpha_l!} D_\sigma^{(\alpha_1 + \cdots + \alpha_l)} H_x(\tau, \sigma_0) \sigma_1^{\alpha_1} \cdots \sigma_l^{\alpha_l}, \qquad (58) \\
&\sum_{(\alpha \cdot l)}^{l} \frac{1}{\alpha_1! \cdots \alpha_l!} D_\sigma^{(\alpha_1 + \cdots + \alpha_l)} H_v(\tau, \sigma_0) \sigma_1^{\alpha_1} \cdots \sigma_l^{\alpha_l} = 0.
\end{aligned}
$$

On peut aussi écrire (58) sous la forme suivante:

$$
\begin{aligned}
&\frac{\partial x_l}{\partial t}+\frac{\partial x_{l+1}}{\partial \tau}=g_x(\cdot)x_l+g_v(\cdot)u_l \\
&\qquad\qquad +\sum_{(\alpha,l-1)}^{l}\frac{1}{\alpha_1!\cdots\alpha_{l-1}!}g_\beta^{(\alpha_1+\cdots+\alpha_{l-1})}\beta_1^{\alpha_1}\cdots\beta_{l-1}^{\alpha_{l-1}}, \\
&-\frac{\partial p_l}{\partial t}-\frac{\partial p_{l+1}}{\partial \tau}=g_x^*(\cdot)p_l+H_{xx}(\cdot)x_l+H_{xv}(\cdot)u_l \\
&\qquad\qquad +\sum_{(\alpha,l-1)}^{l}\frac{1}{\alpha_1!\cdots\alpha_{l-1}!}D_\sigma^{(\alpha_1+\cdots+\alpha_{l-1})}H_x(\cdot)\sigma_1^{\alpha_1}\cdots\sigma_{l-1}^{\alpha_{l-1}}, \\
&0=g_v^{*(\cdot)}p_l+H_{vx}(\cdot)x_l+H_{vv}(\cdot)U_l \\
&\qquad\qquad +\sum_{(\alpha,l-1)r}^{l}\frac{1}{\alpha_1!\cdots\alpha_{l-1}!}D_\sigma^{(\alpha_1+\cdots+\alpha_{l-1})}H_x(\cdot)\sigma_1^{\alpha_1}\cdots\sigma_{l-1}^{\alpha_{l-1}}
\end{aligned}
\tag{59}
$$

avec les conditions au bord

$$
\begin{aligned}
&x_l(0,0)=0, \\
&p_l(T,\alpha_0)=\sum_{(\alpha\cdot l)}^{l}\frac{1}{\alpha_1!\cdots\alpha_l!}D_x^{(1+\alpha_1+\cdots+\alpha_l)}h(x_0(T))x_1^{\alpha_1}(T,\alpha_0)\cdots xl^{\alpha_l}(T,\alpha_0)
\end{aligned}
\tag{60}
$$

où

$$
\sum_{(\alpha,l)}^{j} \text{ désigne la somme } \sum_{\substack{\alpha_1+2\alpha_2+\cdots+l\alpha_l=j,\\ \alpha_1,\cdots,\alpha_l>0}}.
\tag{61}
$$

Remarque 6. Soit $F(\tau)$ une fonction de 1-périodique. On suppose que $\int_0^1|F(\tau)|\,d\tau\leqq C$. Alors, pour que l'équation suivante ait une solution

$$
\frac{dy(\tau)}{d\tau}=F(\tau),\quad y(\tau)\text{: 1-périodique},\quad y(\tau_0)=y_0\in\mathbb{R}^n,
\tag{62}
$$

la condition nécessaire et suffisante est

$$
\int_0^1 F(\tau)\,d\tau=0.
\tag{63}
$$

De plus sous (63), la solution de (62) est unique. □

4.2. Résolution et estimation des termes du développement. On va résoudre progressivement x_i, u_i, p_i, $i=0,1,\cdots$ par (53), (56), (58)-(60). On considère tout d'abord x_0, u_0, p_0.

D'après la remarque 6 pour que $x_1(t,\tau)$, $p_1(t,\tau,\alpha_0)$ soient périodiques par rapport à τ, on doit avoir nécessairement

$$
\begin{aligned}
&\frac{dx_0}{dt}=\int_0^1 g(\tau,x(t),u_0(t,\tau))\,d\tau, \\
&-\frac{dp_0}{dt}=\int_0^1 H_x(\tau,x_0(t),u_0(t,\tau),p_0(t))\,d\tau,\qquad H_v(\tau,x_0(t),u_0(t,\tau),p_0(t))=0
\end{aligned}
\tag{64}
$$

avec les conditions au bord

$$
x_0(0)=x_0,\qquad p_0(T)=h_x(x_0(T)).
\tag{65}
$$

D'après le théorème 1, on sait que (64), (65) sont des conditions nécessaires pour que $u_0(t, \tau)$ soit un contrôle optimal du problème (14) avec $\mathbf{U}_{ad} = \mathbb{R}^k$. Sous les hypothèses du théorème 2, $u_0(t, \tau)$ est l'unique contrôle optimal du problème. Pour l'obtention de l'existence et de la régularité des termes d'ordre plus élevé, on suppose que

(66) $g(\tau, x, v)$, $\mathfrak{L}(\tau, x, v)$, $h(x)$ sont $C^{K+2}(\mathbb{R}^n \times \mathbb{R}^k)$ par rapport à x, v.

On peut vérifier aisément le lemme 7.

LEMME 7. *On suppose les hypothèses du théorème 2 satisfaites et également* (66). *Alors* $(dx_0/dt)(t)$, $(dp_0/dt)(t)$, $u_0(t, \tau)$ *sont de classe* C^{K+1} *par rapport à* t.

Pour trouver x_1, p_1, on les décompose sous la forme

$$x_1(t, \tau) = Y_1(t, \tau) + y_1(t), \qquad p_1(t, \tau) = Q_1(t, \tau) + q_1(t) \tag{67}$$

où, ayant satisfait les conditions au bord (60), on pose

$$Y_1(t, 0) = 0, \qquad y_1(0) = 0, \tag{68}$$

$$Q_1(t, \alpha_0) = 0, \qquad q_1(T, \alpha_0) = h_{xx}(x_0(T))(y_1(T) + Y_1(T, \alpha_0)). \tag{69}$$

Maintenant, on peut résoudre (53) avec les décompositions (67) et les conditions au bord (68), (69). On a

$$Y_1(t, \tau) = -\frac{dx_0}{dt}\tau + \int_0^\tau g(s, \beta_0(t, s))\, ds, \tag{70}$$

$$Q_1(t, \tau, \alpha_0) = -\frac{dp_0}{dt}(\tau - \alpha_0) - \int_{\alpha_0}^\tau H_x(s, \sigma_0(t, s))\, ds. \tag{71}$$

De plus, du lemme 7, on déduit que

$$Y_1(t, \tau),\ Q_1(t, \tau),\ \frac{\partial Y_1}{\partial \tau},\ \frac{\partial Q_1}{\partial \tau} \quad \text{sont de classe } C^{K+1} \text{ par rapport à } t. \tag{72}$$

Maintenant on peut trouver $y_1(t)$, $q_1(t)$ et $u_1(t, \tau)$. En appliquant la remarque 6 à (56), on sait que nécessairement on a

$$\begin{aligned}
\frac{dy_1}{dt} &= \int_0^1 g_x(\tau, x_0(t), u_0(t, \tau))\, dt\, y_1(t) + \int_0^1 g_v(\tau, x_0, u_0) u_1(t, \tau)\, d\tau \\
&\quad + \int_0^1 \left[-\frac{\partial Y_1}{\partial t} g_x(\tau, x_0, u_0)\, Y_1(t, \tau) \right] d\tau, \\
&\qquad\qquad y_1(0) = 0, \\
-\frac{dq_1}{dt} &= \int_0^1 g_x^*(\tau, \beta_0(t, \tau))\, d\tau \cdot q_1(t) + \int_0^1 H_x(\tau, \sigma_0(t, \tau))\, d\tau \cdot y_1(t) \\
&\quad + \int_0^1 H_v(\cdot) u_1(t, \tau)\, d\tau \\
&\quad + \int_0^1 \left[\frac{\partial Q_1}{\partial t} + g_x^*(\cdot) Q_1(t, \tau) + H_{xx}(\cdot)\, Y_1(t, \tau) \right] d\tau, \\
q_1(T) &= h_{xx}(x_0(T))(y_1(T) + Y_1(T, \alpha_0)), \\
g_v^*(\tau, \beta_0(t, \tau)) q_1(t) &+ H_{vx}(\tau, \sigma_0(t, \tau)) y_1(t) \\
&\quad + H_{vv}(\cdot) u_1(t, \tau) + g_v^*(\cdot) Q(t, \tau) + H_{vx}(\cdot)\, Y_1(t, \tau) = 0
\end{aligned} \tag{73}$$

ou

$$\frac{dy_1}{dt} = \int_0^1 (A(t,\tau)y_1(t) + B(t,\tau)u_1(t,\tau) + C(t,\tau))\, d\tau,$$

$$-\frac{dq_1}{dt} = \int_0^1 (A^*(t,\tau)q_1(t) + H_{11}(t,\tau)y_1(t) + H_{12}(t,\tau)u_1(t,\tau) + D(t,\tau))\, d\tau, \tag{74}$$

$$B^*(t,\tau)q_1(t) + H_{21}(t,\tau)y_1(t) + H_{22}(t,\tau)u_1(t,\tau) + E(t,\tau) = 0,$$

$$y_1(0) = 0, \qquad q_1(T) = h_{xx}(x_0(T))(y_1(T) + Y_1(T,\alpha_0))$$

où l'on note

$$A(t,\tau) = g_x(\tau, \beta_0(t,\tau)), \qquad B(t,\tau) = g_v(\tau, \beta_0(t,\tau)),$$

$$\begin{pmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{pmatrix}(t,\tau) = \begin{pmatrix} H_{xx} & H_{xv} \\ H_{vx} & H_{vv} \end{pmatrix}(t, \sigma_0(t,\tau)),$$

$$C(t) = -\frac{\partial Y_1}{\partial t} + A(t,\tau)Y_1(t,\tau),$$

$$D(t) = \frac{\partial Q_1}{\partial t} + A^*(t,\tau)Q_1(t,\tau) + H_{11}(t,\tau)Y_1(t,\tau),$$

$$E(t,\tau) = B^*(t,\tau)Q_1(t,\tau) + H_{21}(t,\tau)Y_1(t,\tau).$$

On peut relier (73) à un problème linéaire quadratique

$$\frac{dy_1}{dt} = \int_0^1 (A(t,\tau)y_1(t) + B(t,\tau)v(t,\tau))\, d\tau$$

$$\min \left[\frac{1}{2} \int_0^T \int_0^1 \begin{pmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{pmatrix} \begin{pmatrix} y_1(t) \\ v_1(t,\tau) \end{pmatrix} + D(t,\tau)y_1(t) \right. \tag{75}$$

$$\left. + (E(t,\tau)v_1(t,\tau))\, d\tau\, dt + \frac{1}{2} h_{xx}(x_0(t))(y_1(T) + Y_1(T,\alpha_0))^2 \right].$$

De la même façon, on peut résoudre $x_2(t,\tau,\alpha_0)$, $p_2(t,\tau,\alpha_0)$, $u_2(t,\tau,\alpha_0)\cdots$, $x_K(t,\tau,\alpha_0)$, $p_K(t,\tau,\alpha_0)$, $u_K(t,\tau,\alpha_0)$ successivement et on a le lemme 8.

LEMME 8. *Sous les mêmes hypothèses que le lemme 7, on peut résoudre* x_i, u_i, p_i, $i = 0, 1, \cdots, K$ *solution de* (59). *De plus on a*

$$\frac{\partial x_i}{\partial t}, \frac{\partial p_i}{\partial t}, \frac{\partial^2 x_i}{\partial \tau\, \partial t}, \frac{\partial^2 p_i}{\partial \tau\, \partial t}, u_i(t,\tau) \quad \textit{sont de classe } C^{K+1-i} \tag{76}$$

par rapport à t.

On peut également définir $Y_{K+1}(t,\tau)$, $Q_{K+1P}(t,\tau)$ par

$$Y_{K+1}(t,\tau) = \int_0^\tau \left(-\frac{\partial x_K}{dt} + \sum_{(\alpha,K)}^{K} \frac{1}{\alpha_1! \cdots \alpha_K!} D_\beta^{\alpha_1+\cdots\alpha_K} g(s,\beta_0)\beta_1^{\alpha_1} \cdots \beta_K^{\alpha_K} \right) ds,$$

$$Q_{K+1}(t,\tau) = \int_0^\tau \left(-\frac{\partial p_K}{dt} + \sum_{(\alpha,K)}^{K} \frac{1}{\alpha_1! \cdots \alpha_K!} D_\sigma^{\alpha_1+\cdots\alpha_K} H_x(s,\sigma_0)\sigma_1^{\alpha_1} \cdots \sigma_K^{\alpha_K} \right) ds,$$

et

$$Y_{K+1}, Q_{K+1}, \frac{\partial Y_{K+1}}{d\tau}, \frac{\partial Q_{K+1}}{d\tau} \quad \text{sont } C^1 \text{ par rapport à } t. \tag{76'}$$

4.3. Résultats de convergence. Maintenant on va se demander si on peut approcher le problème périodique par la solution du développement asymptotique. On utilisera la méthode de Bensoussan [1].

On note

$$\bar{x}(t)=\sum_{l=0}^{K} x_l\left(t,\frac{t}{\varepsilon}\right)\varepsilon^l, \qquad \bar{u}(t)=\sum_{l=0}^{K} u_l\left(t,\frac{t}{\varepsilon}\right)\varepsilon^l,$$

$$\bar{p}(t)=\sum_{l=0}^{K} p_l\left(t,\frac{t}{\varepsilon}\right)\varepsilon^l, \qquad \hat{x}(t)=x^\varepsilon(t)-\bar{x}(t),$$

$$\hat{u}(t)=v(t)-\bar{u}(t), \qquad \bar{\beta}(t)=(\bar{x}(t),\bar{u}(t)),$$

$$\hat{\beta}(t)=(\hat{x}(t),\hat{u}(t)), \qquad \bar{\sigma}(t)=(\bar{x}(t),\bar{u}(t),\bar{p}(t))$$

où $v(t)$ est un contrôle admissible et $x^\varepsilon(t)$ est l'état correspondant.

$$\frac{dx^\varepsilon}{dt}=g\left(\frac{t}{\varepsilon},x^\varepsilon(t),v(t)\right), \qquad x^\varepsilon(0)=x_0. \tag{77}$$

On a le lemme 9.

LEMME 9. *On fait les hypothèses du théorème* 2 *et* (66). *Alors on a*

$$\begin{aligned} J^\varepsilon(v(\cdot))=&\int_0^T\left[H\left(\frac{t}{\varepsilon},\bar{\sigma}(t)\right)-\bar{p}(t)\bar{x}(t)\right]dt+h(\bar{x}(T))\\ &+\int_0^T\int_0^1\int_0^1 \lambda H_{\beta\beta}\left(\frac{s}{\varepsilon},\bar{\beta}(t)+\lambda\mu\hat{\beta}(t),\bar{p}(t)\right)\hat{\beta}^2(t)\,d\lambda\,d\mu\,dt\\ &+\varepsilon^{K+1}O(|\hat{x}(T)|)+\varepsilon^{K+1}O(|\hat{\beta}|_{L^2(O,T)}). \end{aligned} \tag{78}$$

Démonstration. On a

$$\begin{aligned} J^\varepsilon(v(\cdot))&=\int_0^T l\left(\frac{t}{\varepsilon},x^\varepsilon(t),v(t)\right)dt+h^\varepsilon(x^\varepsilon(T))\\ &=\int_0^T H\left(\frac{t}{\varepsilon},x^\varepsilon(t),v(t),\bar{p}(t)\right)dt-\int_0^T p(t)\frac{dx^\varepsilon}{dt}\,dt+h(x^\varepsilon(T))\\ &=\int_0^T\left[H\left(\frac{t}{\varepsilon},\bar{\sigma}(t)\right)+H_\beta\left(\frac{t}{\varepsilon},\bar{\sigma}(t)\right)\hat{\beta}(t)\right.\\ &\quad\left.+\int_0^1\int_0^1\lambda H_{\beta\beta}\left(\frac{t}{\varepsilon},\bar{\beta}(t)+\lambda\mu\hat{\beta}(t)\bar{p}(t)\hat{\beta}^2(t)\right)d\lambda\,d\mu\right]dt\\ &\quad-\int_0^T\bar{p}(t)\frac{dx^\varepsilon}{dt}\,dt+h(x^\varepsilon(T)) \end{aligned} \tag{79}$$

$$\begin{aligned} &=\int_0^T\left(H\left(\frac{t}{\varepsilon},\bar{\sigma}(t)\right)-\bar{p}(t)\frac{d\bar{x}}{dt}\right)dt+h(\bar{x}(T))\\ &\quad+\int_0^T\int_0^1\int_0^1\lambda H_{\beta\beta}(\cdot)\hat{\beta}^2(t)\,d\lambda\,d\mu\,dt\\ &\quad+\int_0^T H_\beta\left(\frac{t}{\varepsilon},\bar{\sigma}(t)\right)\hat{\beta}(t)\,dt-\int_0^T\bar{p}(t)\frac{d\hat{x}}{dt}\,dt\\ &\quad+h_x(\bar{x}(T))\hat{x}(T)+\int_0^1\int_0^1\lambda h_{xx}(\bar{x}(T)+\lambda\mu\hat{x}(T))\hat{x}^2(T)\,d\mu\,d\lambda. \end{aligned}$$

Pour la 3ème intégrale à droite on a

$$
\begin{aligned}
&[H_v(\tau, \bar{\sigma}(t))]_{\langle l\rangle} = 0, \qquad l = 0, 1, \cdots, K,\\
&[H_x(\tau, \bar{\sigma}(t))]_{\langle l\rangle} = -\frac{\partial p_l}{\partial t} - \frac{\partial p_{l+1}}{\partial \tau}, \qquad l = 0, 1, \cdots, K-1,\\
&[H_x(\tau, \bar{\sigma}(t))]_{\langle k\rangle} = -\frac{\partial p_k}{\partial t} - \frac{\partial Q_{K+1}}{\partial \tau},
\end{aligned} \tag{80}
$$

où l'on note

$$
\left[\sum_{i=1}^{K} b_i \varepsilon^i + O(\varepsilon^{K+1})\right]_{\langle l\rangle} = b_l, \qquad l = 1, \cdots, k. \tag{81}
$$

Donc

$$
\begin{aligned}
\int_0^T H_\beta\left(\frac{t}{\varepsilon}, \bar{\sigma}(t)\right)\hat{\beta}(t)\, dt &\geqq \int_0^T \left(-\frac{\bar{\partial} p}{dt} - \varepsilon^K \frac{\partial Q_{K+1}}{d\tau}\left(t, \frac{t}{\varepsilon}\right)\right)\hat{x}(t)\, dt\\
&\quad - C\varepsilon^{K+1}\int_0^T |\hat{\beta}(t)|\, dt\\
&= \int_0^T \bar{p}(t)\frac{d\hat{x}}{dt}\, dt - \bar{p}(T)\hat{x}(T) - C\varepsilon^{K+1}\int_0^T |\hat{\beta}(t)|\, dt\\
&\quad - \varepsilon^K \int_0^T \frac{\partial Q_{K+1}}{d\tau}\left(t, \frac{t}{\varepsilon}\right)\hat{x}(t)\, dt.
\end{aligned} \tag{82}
$$

Pour le dernier terme on a

$$
\frac{\partial Q_{K+1}}{\partial \tau}\left(t, \frac{t}{\varepsilon}\right) = \varepsilon\left(\frac{dQ_{K+1}}{dt}\left(t, \frac{t}{\varepsilon}\right) - \frac{\partial Q_{K+1}}{\partial t}\left(t, \frac{t}{\varepsilon}\right)\right);
$$

donc

$$
\begin{aligned}
&-\varepsilon^K \int_0^T \frac{\partial Q_{K+1}}{d\tau}\left(t, \frac{t}{\varepsilon}\right)\hat{x}(t)\, dt = \varepsilon^{K+1}\int_0^T Q_{K+1}(t, \tau)\frac{d\hat{x}}{dt}\, dt,\\
&\varepsilon^{K+1}\int_0^T \frac{\partial Q_{K+1}}{d\tau}\left(t, \frac{t}{\varepsilon}\right)\hat{x}(t)\, dt = \varepsilon^{K+1} O\left(\int_0^T |\hat{\beta}(t)|\, dt\right) \quad \text{(d'après (3.76)')}.
\end{aligned} \tag{83}
$$

De (79), (82), (83), tenant compte de l'hypothèse (18), on a

$$
\begin{aligned}
J^\varepsilon(v(\cdot)) &= \int_0^T \left(H\left(\frac{t}{\varepsilon}, \bar{\sigma}(t)\right) - \bar{p}(t)\frac{d\bar{x}}{dt}\right) dt + h(\bar{x}(T))\\
&\quad + \int_0^T \int_0^1 \int_0^1 \lambda H_{\beta\beta}(\cdot)\hat{\beta}^2(t)\, d\lambda\, d\mu\, dt + O(\varepsilon^{K+1})\int_0^T |\hat{\beta}(t)|\, dt\\
&\quad + h_x(\bar{x}(T))\cdot\hat{x}(T) - \bar{p}(T)\hat{x}(T).
\end{aligned} \tag{84}
$$

Mais on sait que

$$
[h_x(\bar{x}(T))]_{\langle l\rangle} = p_l(T, \alpha_0) \tag{85}
$$

ce qui avec (84) implique (78). □

On a aussi le lemme 10.

LEMME 10. *On a*

$$
|\bar{x}^\varepsilon(t) - \bar{x}(t)|_{C(0,T)} \leqq C\varepsilon^{K+1} \tag{86}
$$

où $x^\varepsilon(t)$ est la solution de

$$\frac{d\bar{x}^\varepsilon}{dt} = g\left(\frac{t}{\varepsilon}, \bar{x}^\varepsilon(t), \bar{u}(t)\right), \qquad \bar{x}^\varepsilon(0) = x_0.$$

Démonstration. On a

$$\frac{d}{ds}(\bar{x}^\varepsilon(s) - \bar{x}(s)) = g\left(\frac{s}{\varepsilon}, \bar{x}^\varepsilon(s), \bar{u}(s)\right) - g\left(\frac{s}{\varepsilon}, \bar{x}(s), \bar{u}(s)\right) + G^\varepsilon(s)$$

où

$$|G^\varepsilon(s)|_{L^2(0,T)} \leqq C\varepsilon^{K+1}.$$

Avec la condition initiale

$$\bar{x}^\varepsilon(0) - \bar{x}(0) = 0$$

on peut déduire aisément (36). □

Maintenant on peut énoncer le théorème 11.

THEOREME 11. *On a*

$$\left|\inf_{v(\cdot)} J^\varepsilon(v(\cdot)) - J^\varepsilon(\bar{u}(\cdot))\right| \leqq C\varepsilon^{2K+2}. \tag{87}$$

De plus si $u^\varepsilon(\cdot)$ est un contrôle meilleur que $\bar{u}$, i.e., si

$$J^\varepsilon(u^\varepsilon(\cdot)) \leqq J^\varepsilon(\bar{u}(\cdot)). \tag{88}$$

Alors on a

$$|u^\varepsilon - \bar{u}|_{L^2(0,T)}, |x^\varepsilon - \bar{x}|_{C(0,T)} \leqq C\varepsilon^{K+1}. \tag{89}$$

Démonstration. On peut appliquer (78) avec $v(\cdot) = \bar{u}(\cdot)$. D'après (86), on a

$$\left|J^\varepsilon(\bar{u}(\cdot)) - \int_0^T \left(H\left(\frac{t}{\varepsilon}, \bar{\sigma}(t)\right) - \bar{p}(t)\bar{x}(t)\right) dt - h(\bar{x}(T))\right| \leqq C\varepsilon^{2K+1}. \tag{90}$$

Soit maintenant v un contrôle meilleur que $\bar{u}$, en tenant compte (78), (90) on a

$$\begin{aligned} C\varepsilon^{2k+2} \geqq & \int_0^T \int_0^1 \int_0^1 \lambda H_{\beta\beta}\left(\frac{s}{\varepsilon}\bar{\beta}(t) + \lambda\mu\hat{\beta}, \bar{p}(t)\right)\hat{\beta}^2(t)\, d\lambda\, d\mu\, dt \\ & - C\varepsilon^{K+1}|\hat{x}(t)| - C\varepsilon^{K+1}\int_0^T |\hat{\beta}(t)|\, dt. \end{aligned} \tag{91}$$

Mais d'après (3.17), (3.18) on a

$$H_{\beta\beta}\left(\frac{t}{\varepsilon}, \bar{\beta}(t) + \lambda\mu\hat{\beta}, \bar{p}(t)\right)\hat{\beta}^2(t) \geqq \beta|Z(\lambda, \mu, t)|^2 \tag{92}$$

où

$$Z(\lambda, \mu, t) = \hat{u}(t) + H_{vv}^{-1}H_{vx}\left(\frac{t}{\varepsilon}\bar{\beta} + \lambda\mu\hat{\beta}, \bar{p}\right)\hat{x}(t). \tag{93}$$

Donc

$$C\varepsilon^{2k+2} \geqq \beta\int_0^T \int_0^1 \int_0^1 \lambda|Z(\lambda, \mu, t)|^2\, d\lambda\, d\mu\, dt - C\varepsilon^{K+1}|\hat{x}(t)| - C\varepsilon^{K+1}\int_0^T |\hat{\beta}(t)|\, dt.$$

D'autre part, on peut vérifier que

$$\max_{0 \leqq t \leqq T} |\hat{x}(t)| \leqq C\varepsilon^{k+1} + C\int_0^T \int_0^1 \int_0^1 |Z(\lambda, \mu, t)|\, d\lambda\, d\mu\, ds. \tag{94}$$

En effet on a

$$\frac{d\hat{x}}{dt} = g\left(\frac{t}{\varepsilon}, x^{\varepsilon}(t), v(t)\right) - g\left(\frac{t}{\varepsilon}, \bar{x}(t), \bar{u}(t)\right) + G(t), \qquad \hat{x}(0) = 0$$

où d'après (86)

$$\int_0^T |G(t)|\, dt \leqq c\varepsilon^{K+1}; \tag{95}$$

donc

$$\begin{aligned}\frac{d\hat{x}}{dt} &= A\hat{x}(t) + B\hat{u}(s) + G(t)\\ &= \bar{A}\hat{x}(t) + BZ(\lambda, \mu, t) + G(t)\end{aligned}$$

où

$$\bar{A} = A - BH_{vv}^{-1}H_{vx}\left(\frac{t}{\varepsilon}, \bar{\beta}(t) + \lambda\mu\hat{\beta}\right) \text{ est borné,}$$

ce qui avec (95) implique (94). D'après la définition (93) on a

$$\int_0^T |\hat{u}(t)|\, dt \leqq C \int_0^T |Z(\lambda, \mu, t)|\, dt + C\varepsilon^{K+1} \tag{96}$$

ce qui avec (91), (92) implique

$$\int_0^T \int_0^1 \int_0^1 \lambda |Z(\lambda, \mu, t)|^2\, d\lambda\, d\mu\, dt \leqq C\varepsilon^{2k+2}. \tag{97}$$

Encore de (93), (95) on a

$$|\hat{x}(t)|_{C(0,T)} \leqq C\varepsilon^{K+1}, \tag{98}$$

$$\int_0^T |\hat{u}(t)|\, dt \leqq C\varepsilon^{K+1}. \tag{99}$$

On a donc (89), ce qui avec (78) implique (87). □

5. Résolution asymptotique de l'équation de Bellman. On va étudier dans ce paragraphe la méthode des perturbations pour l'équation de Bellman

$$\frac{\partial \Phi^{\varepsilon}}{dt} + \inf_{v}\left[D\Phi^{\varepsilon} g\left(\frac{T-t}{\varepsilon}, x, v\right) + l\left(\frac{T-t}{\varepsilon}, x, v\right)\right] = 0, \qquad \Phi^{\varepsilon}(x, T) = h(x). \tag{100}$$

De cette équation on peut déduire le feedback optimal $u^{\varepsilon}(x, t)$, solution de

$$\begin{aligned}&\frac{\partial \Phi^{\varepsilon}}{dt} + \left(D\Phi^{\varepsilon} g\left(\frac{T-t}{\varepsilon}, x, u^{\varepsilon}\right)\right) + l\left(\frac{T-t}{\varepsilon}, x, u^{\varepsilon}\right) = 0,\\ &D\Phi^{\varepsilon} \cdot g_v\left(\frac{T-t}{\varepsilon}, x, u^{\varepsilon}\right) + l_v\left(\frac{T-t}{\varepsilon}, x, u^{\varepsilon}\right) = 0, \qquad \Phi^{\varepsilon}(T, x) = h(x).\end{aligned} \tag{101}$$

On va montrer que ce contrôle feedback peut être approché par le contrôle feedback du problème homogénéisé. On s'intéresse aussi à l'approximation de contrôle feedback d'ordre plus élevé.

5.1. Développement asymptotique de l'équation de Bellman. On va essayer de trouver un développement de Φ^ε, u^ε de la forme

$$\begin{aligned}\Phi^\varepsilon(x,t)&=\Phi_0(x,t)+\varepsilon\Phi_1\left(x,t,\frac{T-t}{\varepsilon}\right)+\cdots,\\ u^\varepsilon(x,t)&=u_0\left(x,t,\frac{T-t}{\varepsilon}\right)+\varepsilon u_1\left(x,t,\frac{T-t}{\varepsilon}\right)+\cdots,\end{aligned}\tag{102}$$

où $\Phi_i(x,t,\tau)$, $u_i(x,t,\tau)$ sont 1-périodiques par rapport à τ. D'après (100), (101) on a

$$-\frac{\partial\Phi_1}{\partial\tau}+\frac{\partial\Phi_0}{\partial t}+D\Phi_0 g(\tau,x,u_0(x,t,\tau))+l(\tau,x,u_0(x,t,\tau))=0,\qquad \Phi_0(x,T)=h(x),\tag{103}$$

$$D\Phi_0 g_v(\tau,x,u_0(x,t,\tau))+l_v(\cdot)=0,\tag{104}$$

$$-\frac{\partial\Phi_2}{\partial\tau}+\frac{\partial\Phi_1}{\partial t}+D\Phi_1 g(\tau,x,u_0(x,t,\tau))=0,\qquad \Phi_1(x,T,0)=0.\tag{105}$$

Généralement si on note

$$\begin{aligned}H_0&=D\Phi_0 g(\tau,x,v)+l(\tau,x,v),\\ H_i&=D\Phi_i g(\tau,x,v),\qquad i=1,2,\cdots,\end{aligned}$$

de façon similaire à ce qui a été fait dans § 4, on peut développer (100) comme

$$\begin{aligned}&\frac{\partial\Phi_{2l}}{\partial t}-\frac{\partial\Phi_{2l+1}}{\partial\tau}+\sum_{\langle l,\alpha\rangle}^{2l}\frac{1}{\alpha_1!\alpha_2!\cdots\alpha_l!}D_v^{(\alpha_1+\cdots+\alpha_l)}H_\alpha(\cdot)u_1^{\alpha_1}\cdots u_l^{\alpha_l}=0,\\ &\frac{\partial\Phi_{2l+1}}{\partial t}-\frac{\partial\Phi_{2l+2}}{\partial\tau}+\sum_{\langle l,\alpha\rangle}^{2l+1}\frac{1}{\alpha_1!\cdots\alpha_l!}D_v^{(\alpha_1+\cdots+\alpha_l)}H_{\alpha_0}(\cdot)u_1^{\alpha_1}\cdots u_l^{\alpha_l}=0,\end{aligned}\tag{106}$$

$$\Phi_l(x,T,0)=0,\qquad l=1,2,\cdots,K,\tag{107}$$

$$\sum_{\langle l,\alpha\rangle}^{l}\frac{1}{\alpha_1!\cdots\alpha_l!}D_v^{(1+\alpha_1+\cdots+\alpha_l)}H_{\alpha 0}(\cdot)u_1^{\alpha_1}\cdots u_l^{\alpha_l}=0\tag{108}$$

où $\sum_{\langle l,\alpha\rangle}^{j}$ désigne

$$\sum_{\substack{\alpha_0+\alpha_1+\alpha_2+\cdots+l\alpha_l=j,\\ \alpha_1,\cdots,\alpha_n\geqq 0}}.\tag{109}$$

5.2. Résolution et estimation de Φ_i et u_i. On va montrer comment résoudre Φ_i, u_i, $i=0,1,\cdots$, de façon récursive. On va résoudre et estimer spécifiquement Φ_0, (x,t), $u_0(x,t,x)$, $\Phi_1(x,t,\tau)$, les autres peuvent se traiter de façon analogue.

On considère tout d'abord (103). D'après la remarque 6 pour que $\Phi_1(x,t,\tau)$ soit périodique par rapport à τ, on a nécessairement

$$\begin{aligned}&\frac{\partial\Phi_0}{\partial t}+D\Phi_0\int_0^1 g(\tau,x,u_0(t,\tau,x))\,d\tau+\int_0^1 l(\tau,x,u_0(t,\tau,x))\,d\tau=0,\\ &\Phi_0(T,x)=h(x);\end{aligned}\tag{110}$$

on peut relier (103) et (104) à un problème d'optimalité

$$\begin{aligned}&\frac{dx}{ds}=\int_0^1 g(\tau,x(s),u(s,\tau))\,d\tau,\quad v(s,\tau)\in L^2([t,\tau]\times[0,1];\mathbb{R}^K),\quad x(t)=x,\\ &\Phi_0(x,t)=\inf_{v(\cdot)}\left[\int_t^T\int_0^1 l(\tau,x(s),v(s,\tau))\,ds\,d\tau+h(x(T))\right].\end{aligned}\tag{111}$$

Mais on sait que sous les hypothèses du théorème 5, avec $p=2K$, on a

$$|D_x^{(j)}\Phi_0(x,t)| \leqq C(1+|x|)^{2-j}, \qquad 0 \leqq j \leqq 4K+1, \tag{112}$$

$$\left|D_x^{(j)}\frac{\partial^{(i)}}{\partial t^i}\Phi_0(x,t)\right| \leqq C(1+|x|)^{2-j}, \qquad 0 \leqq i+j \leqq 4K+1, \tag{113}$$

$$\left|D_x^{(j)}\frac{\partial^{(i)}}{\partial t^i}u_0(t,\tau,x)\right| \leqq C(1+|x|)^{1-j}, \qquad 0 \leqq i+j \leqq 4K. \tag{114}$$

On va montrer comment on peut trouver $\Phi_1(x,t,\tau)$, $\Phi_2(x,t,\tau)$, et $u_1(x,t,\tau)$, les autres peuvent se déduire de la même manière, de façon récursive.

Ayant résolu Φ_0, u_0, on peut résoudre Φ_1 de la façon suivante. On définit

$$\Phi_1(\bar{x},t,\tau) = \int_0^\tau \left[\frac{\partial\Phi_0}{\partial t} + D\Phi_0 g(s,x,u_0(x,t,s)) + l(s,x,u_0)\right] ds. \tag{115}$$

D'après la remarque 6, $\bar{\Phi}_1$ est 1-périodique, c'est également une solution de (103). Mais toujours, d'après la remarque 6, Φ_1 et $\bar{\Phi}_1$ peuvent différer d'une constante.

On peut donc écrire

$$\Phi_1(x,t,\tau) = \bar{\Phi}_1(x,t,\tau) + \psi_1(x,t) \tag{116}$$

où $\psi_1(x,t)$ peut se résoudre par (105). En effet, on a

$$\frac{\partial\psi_1}{\partial t} + D_x\psi_1 \int_0^1 g(\tau,x,u_0(x,t,\tau))\,d\tau + \int_0^1 \left(D_x\bar{\Phi}_1 g + \frac{\partial\bar{\Phi}_1}{\partial t}\right) d\tau = 0, \qquad \psi_1(T,x) = 0. \tag{117}$$

C'est un type de l'équation de Hamilton-Jacobi (linéaire).

Grâce au (112)-(114) on sait que

$$\left|D_x^{(j)}\frac{\partial^{(i)}}{\partial t^i}\Phi_1(x,t,\tau)\right| \leqq C(1+|x|)^{2-j}, \qquad 0 \leqq i+j \leqq 4K-1. \tag{118}$$

Maintenant on peut trouver $u_1(x,t,\tau)$. Si on considère (108) en cas où $l=1$, on a

$$D\Phi_1 g_v(\tau,x,u_0(x,t,\tau)) + (D_x\Phi_0 g_{vv} + l_{vv})u_1 = 0. \tag{119}$$

On a donc

$$\left|D_x^{(j)}\frac{\partial^{(i)}}{\partial t^i}u_1\right| \leqq C(1+|x|)^{1-j}, \qquad 0 \leqq i+j \leqq 4K-2. \tag{120}$$

De la même façon on peut noter

$$\Phi_2(x,t,\tau) = \bar{\Phi}_2(x,t,\tau) + \psi_2(x,t)$$

où $\bar{\Phi}_2(x,t,\tau)$ peut se résoudre par (105):

$$\bar{\Phi}_2(x,t,\tau) = \int_0^\tau \left(\frac{\partial\Phi_1}{\partial t} + D\Phi_1 g(\tau,x,u_0(t,\tau,x))\right) d\tau$$

et $\psi_2(x,t)$ peut se résoudre par (106) en cas où $l=1$.

Généralement on peut résoudre Φ_l, u_l par (106)-(108), de façon analogue.

De plus on a

$$\left|D_x^{(j)}\frac{\partial^{(i)}}{\partial t^1}\Phi_l(t,\tau,x)\right| \leqq C(1+|x|)^{2-j}, \qquad 0 \leqq i+j+2l \leqq 4K+1,$$

$$\left|D_x^{(j)}\frac{\partial^{(i)}}{\partial t^1}u_l(t,\tau,x)\right| \leqq C(1+|x|)^{1-j}, \qquad 0 \leqq i+j+2l \leqq 4K, \quad l \leqq K. \tag{121}$$

5.3. Résultat de convergence. On note que

$$\bar{\Phi}^\varepsilon(x, s) = \Phi_0(x, s) + \varepsilon\Phi_1\left(x, s, \frac{T-s}{\varepsilon}\right) + \cdots + \varepsilon^{2K+1}\Phi_{2K+1}\left(x, s, \frac{T-s}{\varepsilon}\right),$$

$$\bar{u}^\varepsilon(x, s) = u_0\left(x, s, \frac{T-s}{\varepsilon}\right) + \cdots + \varepsilon^K u_K\left(x, s, \frac{T-s}{\varepsilon}\right).$$

D'après (106)-(108) et les estimations (121), on a

$$\left[\frac{\partial\bar{\Phi}^\varepsilon}{\partial s} + D\bar{\Phi}^\varepsilon g\left(\frac{T-s}{\varepsilon}, x, \bar{u}^\varepsilon\right) + l\left(\frac{T-s}{\varepsilon}, x, \bar{u}^\varepsilon\right)\right]_{\langle l\rangle} = 0, \qquad l = 0, 1, \cdots, 2K+1.$$

Donc

$$\begin{aligned}
&\left[\frac{\partial\bar{\Phi}^\varepsilon}{\partial s} + D_x\bar{\Phi}^\varepsilon(x, s)\cdot g\left(\frac{T-s}{\varepsilon}, x, \bar{u}^\varepsilon\right) + l\left(\frac{T-s}{\varepsilon}, x, \bar{u}^\varepsilon\right)\right] \\
&\qquad \leqq C\varepsilon^{2K+2}\left(1 + \sum_{i=1}^{k}|u_i|^2 + \sum_{i=1}^{2K+1}(|D_x\Phi_i|^2 + |x|^2)\right) \qquad (122) \\
&\qquad \leqq c\varepsilon^{2K+2}(1+|x|^2).
\end{aligned}$$

On a le théorème 12.

THEOREME 12. *On fait les hypothèses du théorème 5 avec $p = 2K$. Alors on a*

$$|\Phi^\varepsilon(x, t) - \bar{\Phi}^\varepsilon(x, t)| \leqq c\varepsilon^{2K+2}(1+|x|^2). \qquad (123)$$

Démonstration. On note $x^\varepsilon(t)$, $v(t)$, solution de

$$\frac{dx^\varepsilon}{ds} = g\left(\frac{s}{\varepsilon}, x^\varepsilon(s), v(s)\right), \qquad x^\varepsilon(t) = x. \qquad (124)$$

On peut limiter les contrôles admissibles par

$$\int_t^T |U(s)|^2\, ds \leqq C(1+|x|^2). \qquad (125)$$

Par conséquent

$$|x^\varepsilon(s)|_{C(t,T)} \leqq C(1+|x|). \qquad (126)$$

On considère

$$\begin{aligned}
&\frac{\partial\bar{\Phi}^\varepsilon}{\partial s} + D_x\bar{\Phi}^\varepsilon g\left(\frac{s}{\varepsilon}, x^\varepsilon(s), v(s)\right) + l\left(\frac{s}{\varepsilon}, x^\varepsilon(s), v(s)\right) \\
&\quad = \frac{\partial\bar{\Phi}^\varepsilon}{\partial s} + D_x\bar{\Phi}^\varepsilon g\left(\frac{s}{\varepsilon}, x^\varepsilon(s), \bar{u}^\varepsilon(x^\varepsilon(s), s)\right) + l\left(\frac{s}{\varepsilon}, x^\varepsilon(s), \bar{u}^\varepsilon(\cdot)\right) \\
&\qquad + \left(D_x\bar{\Phi}^\varepsilon g_v\left(\frac{s}{\varepsilon}, x^\varepsilon(s), \bar{u}^\varepsilon\right) + l_v\left(\frac{s}{\varepsilon}, x^\varepsilon, \bar{u}^\varepsilon\right)\right)v(s) \\
&\qquad + \int_0^1\int_0^1 \lambda\left(D_x\bar{\Phi}^\varepsilon g_{vv}\left(\frac{s}{\varepsilon}, x^\varepsilon(s), \bar{u}^\varepsilon + \lambda\mu\hat{u}\right)\right. \\
&\qquad \left. + l_{vv}\left(\frac{s}{\varepsilon}, x^\varepsilon(s)^*, \bar{u}^\varepsilon + \lambda\mu\hat{u}\right)\right)(v(s))^2\, d\lambda\, d\mu.
\end{aligned}$$

D'après (126) et (121) on a

$$\frac{\partial \bar{\Phi}^\varepsilon}{\partial s} + D_x \bar{\Phi}^\varepsilon \cdot g\left(\frac{s}{\varepsilon}, x^\varepsilon(s), v(s)\right) \geqq -C\varepsilon^{2K+2}(1+|x^\varepsilon(s)|^2+|v(s)|^2)$$

(127)
$$- l\left(\frac{s}{\varepsilon}, x^\varepsilon(s), v(s)\right),$$

$$\bar{\Phi}^\varepsilon(x^\varepsilon(T), T) = h(x^\varepsilon(T)).$$

En intégrant des deux côtés de (127), on a

$$\bar{\Phi}^\varepsilon(x, t) \leqq \int_t^T l\left(\frac{s}{\varepsilon}, x^\varepsilon(s), v(s)\right) ds + h(x^\varepsilon(T)) - C\varepsilon^{2K+2} \int_t^T (1+|x^\varepsilon(s)|^2+|v(s)|^2)\, ds$$

d'après (125), (126)

$$\leqq \int_t^T l\left(\frac{s}{\varepsilon}, x^\varepsilon(s), v(s)\right) ds + h(x^\varepsilon(T)) - C\varepsilon^{2K+2}(1+|x|^2).$$

En particulier, on a

(128)
$$\Phi^\varepsilon(x, t) - \bar{\Phi}^\varepsilon(x, t) \geqq C\varepsilon^{2K+2}(1+|x|^2).$$

L'inégalité contraire peut être démontrée de la façon suivante. On introduit un système de contrôle feedback

(129)
$$\frac{dx^\varepsilon}{ds} = g\left(\frac{T-s}{\varepsilon}, x^\varepsilon(s), \bar{u}^\varepsilon\left(x^\varepsilon(s), s, \frac{T-s}{\varepsilon}\right)\right), \qquad x^\varepsilon(t) = x.$$

D'après (121), on a

(130)
$$|x^\varepsilon(s)|_{c(t,T)}, \left|\bar{u}^\varepsilon\left(x^\varepsilon(s), s, \frac{T-s}{\varepsilon}\right)\right|_{L^2(t,T)} \leqq C(1+|x|^2).$$

D'autre part, de (100) on a

$$\frac{\partial \Phi^\varepsilon}{\partial t} + D\Phi^\varepsilon \cdot g\left(\frac{T-s}{\varepsilon}, x^\varepsilon(s), \bar{u}^\varepsilon\right) + l\left(\frac{T-s}{\varepsilon}, x^\varepsilon(s), \bar{u}^\varepsilon\right) \geqq 0.$$

Ce qui avec (122) implique

(131)
$$\frac{\partial(\Phi^\varepsilon - \bar{\Phi}^\varepsilon)}{\partial s} + D(\Phi^\varepsilon - \Phi^{\bar{\varepsilon}}) \cdot g\left(\frac{s}{\varepsilon}, x^\varepsilon, \bar{u}^\varepsilon\right) \geqq -C\varepsilon^{2K+2}(1+|x|^2+|\bar{u}^\varepsilon|^2).$$

De (107)

(132)
$$\Phi^\varepsilon(x, T) - \bar{\Phi}^\varepsilon(x, T) = 0.$$

On intègre des deux côtés de (131), avec (130), (132).

On a finalement

(133)
$$\Phi^\varepsilon(t, x) - \bar{\Phi}^\varepsilon(t, x) \leqq C\varepsilon^{2K+2}(1+|x|^2).$$

Ce qui avec (128) complète la démonstration. □

6. Exemple. On suppose $0 < \theta < 1$, et

$$g(\tau, x, v) = \begin{cases} g_1(x, v), & 0 \leqq \tau < \theta, \\ g_2(x, v), & \theta \leqq \tau < 1, \end{cases}$$

$$l(\tau, x, v) = \begin{cases} l_1(x, v), & 0 \leqq \tau < \theta, \\ l_2(x, v), & \theta \leqq \tau < 1. \end{cases}$$

On cherche le problème limité du problème

$$\frac{\partial \Phi^\varepsilon}{\partial t}+\inf_v\left[D\Phi^\varepsilon g\left(\frac{t}{\varepsilon}, x, v\right)+l\left(\frac{t}{\varepsilon}, x, v\right)\right]=0, \qquad \Phi^\varepsilon(x, T)=h(x). \tag{134}$$

C'est donc l'équation de Bellman homogénéisée

$$\frac{\partial \Phi}{\partial t}+\inf_{v(\tau)}\left[\int_0^1 (D\Phi \cdot g(\tau, x, v(\tau))+l(\tau, x, v(\tau)))\, d\tau\right]=0, \qquad \Phi(x, T)=h(x). \tag{135}$$

Donc

$$\frac{\partial \Phi}{\partial t}+\inf_{v(\tau)}\left[\int_0^\theta (D\Phi \cdot g_1(x, v(\tau))+l_1(x, v(\tau)))\, d\tau + \int_\theta^1 (D\Phi \cdot g_2(x, v(\tau))+l_2(x, v(\tau)))\, d\tau\right]=0.$$

Cela est équivalent à

$$\frac{\partial \Phi}{\partial t}+\inf_{v_1, v_2}\left[D\Phi \cdot (\theta \cdot g_1(x, v_1)+(1-\theta)g_2(x, v_2))+\theta l_1(x, v_1)+(1-\theta)l_2(x, v_2)\right]=0.$$

Mais on sait que c'est l'équation de Bellman du problème d'optimisation

$$\begin{aligned}\frac{dx}{dt}&=(\theta g_1(x, t), v_1(t))+(1-\theta)g_2(x(t), v_2(t))\\ &\cdot \min_{v_1(t), v_2(t)}\left[\int_0^T (\theta l_1(x(t), v_1(t))+(1-\theta)l_2(x(t), v_2(t))\, dt+h(x(t))\right].\end{aligned} \tag{136}$$

OPTIMAL DESIGN FOR HEAT CONDUCTION PROBLEMS WITH HYSTERESIS*

MARTIN BROKATE† AND AVNER FRIEDMAN‡

Abstract. A model of controlling the temperature in heat conduction is considered; the control mechanism is accomplished by means of a hysteresis operator that depends on some parameters. A cost functional is introduced that depends on these parameters and then properties for the optimal parameters are derived.

Key words. heat equation, hysteresis, thermostat control, optimal design, Preisach operator

AMS(MOS) subject classifications. 93C20, 49A36, 49B22

0. Introduction. In this paper we consider optimal design of a thermostat-like feedback mechanism in order to regulate heat flux. Assume that the temperature $u = u(x, t)$ satisfies

$$
\begin{aligned}
&u_t(x, t) = u_{xx}(x, t) && \text{in } (0, a)\times(0, T),\\
&u(x, 0) = u_0(x) && \text{in } (0, a),\\
&-u_x(0, t) = k(t) && \text{in } (0, T),\\
&u_x(a, t) + u(a, t) = 1 - f(t) && \text{in } (0, T).
\end{aligned}
\tag{0.1}
$$

Here u_0 and k are known functions with values in $[0, 1]$, and f is determined by a feedback from the temperature $u(0, \cdot)$ at the left end. For this feedback, let us momentarily consider the standard thermostat described graphically in Fig. 1.

Figure 1 means that the "output" f switches from 0 to 1 if the "input" $\tilde{u}(t) = u(0, t)$ takes on the threshold value ρ_2, and from 1 to 0 at the threshold value ρ_1. Assume

for the moment that any choice $\rho = (\rho_1, \rho_2)$ of threshold values $\rho_1 < \rho_2$ defines an operator W_ρ such that the feedback

$$f(t) = [W_\rho(u(0, \cdot))](t) \tag{0.2}$$

together with (0.1) uniquely determine the temperature evolution $u = u(x, t)$. Feedback (0.2) means that there is a heat inflow at $x = a$ if temperature at $x = 0$ is low and a heat outflow at $x = a$ if temperature at $x = 0$ is high. We now can pose the question: How should we choose the threshold $\rho = (\rho_1, \rho_2)$ to achieve some prescribed goal? For example, we might want to minimize the expression

$$\int_0^T (u(0, t) - g(t))^2 \, dt, \tag{0.3}$$

given the function g. This is an optimal design problem. (Note that the choice of the initial condition u_0 should not matter very much if T is large.) As a second question we may ask whether thermostat control is optimal within a larger class of feedback mechanisms

$$f(t) = W(u(0, \cdot)), e, \tag{0.4}$$

where W now stands for a suitable family of input-output-operators parametrized by some design parameter e.

The present paper contributes to these questions from the viewpoint of first-order necessary optimality conditions. Its main line of reasoning is the following: For the thermostat feedback (0.2), the map $(\rho_1, \rho_2) \mapsto u = u(x, t)$ is discontinuous. We therefore replace the single thermostat by a family of thermostats, i.e., we use (0.4) with W being the Preisach operator, defined by

$$W(\tilde{u}, \mu)(t) = \int_\Delta (W_\rho \tilde{u})(t) \, d\mu(\rho) \tag{0.5}$$

where $\Delta = \{(\rho_1, \rho_2): 0 \leqq \rho_1 < \rho_2 \leqq 1\}$ and μ is a finite Borel measure on Δ. If μ is the Dirac measure concentrated in $\rho \in \Delta$, we get back to the thermostat, so looking for an optimal design μ can be viewed as a relaxation of the thermostat design problem. On the other hand, if the measure μ has a bounded density e, the map $\tilde{u} \mapsto W(\tilde{u}, \mu)$ is Lipschitz continuous on $C[0, T]$, but not differentiable. Such measures thus regularize the problem while retaining the hysteresis, which is the main feature of the thermostat, but still we cannot apply first-order optimality conditions directly. Therefore, we approximate W by smooth operators W_ε so as to get a smooth approximating optimal design problem for which first-order optimality conditions can be readily developed. We next restrict the set of admissible measures μ to a set parametrized by $v = (\eta, \rho_1, \rho_2) \in \mathbb{R}^3$ such that μ_v is a smooth approximation of the Dirac measure at (ρ_1, ρ_2) with support in the η-ball around (ρ_1, ρ_2). For this restricted optimal design problem, we are finally able to conclude some properties of the optimal parameters $(\eta^*, \rho_1^*, \rho_2^*)$ in the limit $\varepsilon \to 0$, i.e., with the feedback (0.4) and (0.5); unfortunately, we can only handle the case where the boundary condition in (0.1) at $x = a$ is replaced by

$$u_x(a, t) + u(a, t) = f(t) \quad \text{in } (0, T). \tag{0.6}$$

Having presented the main steps of this paper, some historical comments are in order. The Preisach operator W was introduced in Preisach [9] to model hysteresis phenomena in ferromagnetism. Mathematical treatment was given in Krasnosel'skii and Pokrovskii [8] (see also [7]) and by Visintin [10], and was recently extended in Brokate and Visintin [3]. So far, first-order conditions in optimization problems

involving the Preisach operator have not been discussed in the literature. For the standard optimal control problem for an ODE system, coupled with a hysteresis operator W being less general than the Preisach operator, a smooth approximation W_ε has been given in Brokate [1] (see also [2]), and the limit procedure $\varepsilon \to 0$ has been carried out successfully in the first-order necessary conditions. The approximation W_ε adopted in the present paper is, in fact, a generalization of the one in [1], based on the description of the Preisach operator in [3].

Since the optimal design problem treated here is smooth except for the Lipschitz continuous operator W, we are tempted to apply nonsmooth optimization theory directly, thereby avoiding the ε-problem and the limit procedure. However, the feedback equation (0.4) is a major obstacle for this approach, as it represents a nonsmooth equality constraint with infinite dimensional range.

The structure of the paper is as follows. In § 1 we introduce the control problem for heat conduction. The cost functional represents the objective of achieving "comfortable temperatures" at "low cost." We shall also derive necessary conditions for the optimal control v_* which, however, are merely formal (since W is not differentiable). In § 2 we develop some aspects of the theory of Preisach operators that are needed in the sequel; this is based on ideas and facts from Brokate and Visintin [3]. In § 3 we introduce the smooth approximations W_ε to the Preisach operator W. In § 4 the corresponding optimal control problem (P_ε) is introduced, and its solutions v_ε are shown to converge to v_* as $\varepsilon \to 0$. In § 5 we derive necessary optimality conditions for v_ε and in § 6 we establish some estimates (uniformly in ε); these are translated, in § 7, into specific properties of v_ε and, subsequently, also of v_*. Some generalizations are mentioned in § 8.

1. The optimal design problem. Consider the heat equation

$$u_t = u_{xx} \quad \text{in } Q_T = \{(x, t);\ 0 < x < a,\ 0 < t < T\} \tag{1.1}$$

with initial condition

$$u(x, 0) = u_0(x), \qquad 0 < x < a \tag{1.2}$$

and boundary conditions

$$-u_x(0, t) = k(t), \qquad 0 < t < T, \tag{1.3}$$

$$u_x(a, t) + u(a, t) = W(u(0, \cdot), Bv)(t), \qquad 0 < t < T. \tag{1.4}$$

Here $u_0 \in C[0, a]$ and $k \in C[0, T]$ are given functions, $W = W(u, e)$ is the Preisach hysteresis operator to be defined in detail in § 2, and e represents the density of the measure μ in (0.5). The variable v denotes the design parameter to be chosen,

$$v \in K \subset V$$

represents its admissible range, V being a Banach space (later on to be taken as $\mathbb{R}^3$);

$$B: V \to L^\infty(\Delta)$$

is a continuously (Fréchet-)differentiable map where

$$\Delta = \{(\rho_1, \rho_2):\ 0 \leqq \rho_1 < \rho_2 \leqq 1\}.$$

It is easy to prove that for any $v \in K$ there exists a unique solution $u = u(v)$ of (1.1)-(1.4) (see § 4). We introduce the cost functional

$$J(v) = \int_0^T \Phi(u(0, t), t)\, dt + h(v) \tag{1.5}$$

where $u = u(v)$; Φ and h are given continuously differentiable functions. For example, as in (0.3) we may set

$$\Phi(u, t) = (u - g(t))^2,$$

where g is a given continuous function.

Consider the problem:

Problem (P). Find $v_* \in K$ such that

$$J(v_*) = \min_{v \in K} J(v).$$

This problem represents a heat conduction model with a boundary feedback (1.4), chosen so as to be a relaxation of the standard thermostat feeedback for reasons explained in the Introduction. (If we set the right-hand side of (1.4) equal to $1 - W$ in order to conform to the thermostat (compare (0.1) and (0.3)), all the results of this paper except Lemma 6.2 and Theorem 7.1 remain true with obvious modifications.) The feedback can be adjusted with the control variable $v \in K$. The expense of heating (or cooling) at $x = a$ is measured by $h(v)$ and the goal of achieving desirable temperatures is measured by $\int_0^T \Phi(u(0, t), t)\, dt$. Various other functionals, expressing the goal of "desirable temperatures," can also be chosen; see § 8.

It is easy to prove (see § 4; cf. also [6]) that this problem has at least one solution v_*. Set $u_* = u(v_*)$ and introduce the sets

$$K^{\pm}(v) = \{w \in L^{\infty}(\Delta)\colon v \pm \lambda w \in K \text{ for all sufficiently small } \lambda,\ \lambda > 0\}.$$

Then

$$J(v_* + \lambda w) \geqq J(v_*) \quad \forall w \in K^{+}(v_*) \tag{1.6}$$

for any small λ, $\lambda > 0$. Assuming

$$u(v_* + \lambda w) = u_* + \lambda z + o(\lambda)$$

we get from (1.6), after letting $\lambda \to 0$,

$$\int_0^T \Phi_u(u_*(0, t), t) z(0, t)\, dt + Dh(v_*)w \geqq 0 \quad \forall w \in K^{+}(v_*). \tag{1.7}$$

Here and in the following, D denotes (Fréchet-) derivative and D_e, D_u, etc., denote partial derivatives $\Phi_u = D_u\Phi$. The function z in (1.7) satisfies (formally only, since W is not differentiable)

$$\begin{aligned}
&z_t = z_{xx} \quad \text{in } Q_T,\\
&z_x(0, t) = 0, \qquad 0 < t < T,\\
&z_x(a, t) + z(a, t) = [D_u W(u_*(0, \cdot), Bv_*) z(0, \cdot)](t)\\
&\qquad\qquad + D_e W(u_*(0, \cdot), Bv_*) DB(v_*) \cdot w](t), \qquad 0 < t < T,\\
&z(x, 0) = 0, \qquad 0 < x < a.
\end{aligned} \tag{1.8}$$

We shall use the abbreviation

$$D_u W = D_u W(u_*(0, \cdot), Bv_*), \qquad D_e W = D_e W(u_*(0, \cdot), Bv_*) DBv_*$$

and introduce the adjoint operator $D_u W^*$ by

$$\int_0^T p(t)(D_u W z)(t)\, dt = \int_0^T z(t)(D_u W^* p)(t)\, dt \quad \forall p, z \in C[0, T]. \tag{1.9}$$

Let p be the solution of the "adjoint problem":

$$
\begin{aligned}
&p_t + p_{xx} = 0 \quad \text{in } Q_T,\\
&p(x, T) = 0, \qquad 0 < x < a,\\
&-p_x(0, t) = [D_u W^* p(a, \cdot)](t) + \Phi_u(u_*(0, t), t), \qquad 0 < t < T,\\
&p_x(a, t) + p(a, t) = 0, \qquad 0 < t < T.
\end{aligned} \tag{1.10}
$$

We easily compute, using (1.8),

$$
\begin{aligned}
0 &= \int\int_{Q_T} p(z_t - z_{xx}) + \int\int_{Q_T} z(p_t + p_{xx})\\
&= \int_0^T (-pz_x + zp_x)\, dt \Big|_{x=0}^{x=a}\\
&= -\int_0^T p(z_x + z)\, dt \Big|^{x=a} + \int_0^T pz\, dt \Big|^{x=a} + \int_0^T p_x z\, dt \Big|_{x=0}^{x=a}\\
&= -\int_0^T z(0, t)[(D_u W^* p(a, \cdot))(t) + p_x(0, t)]\, dt\\
&\qquad + \int_0^T z(a, t)[p(a, t) + p_x(a, t)]\, dt - \int_0^T p(a, t)(D_e W \cdot w)(t)\, dt
\end{aligned}
$$

and therefore, by the last two conditions in (1.10),

$$
\int_0^T z(0, t)\Phi_u(u_*(0, t), t)\, dt = \int_0^T p(a, t)(D_e W \cdot w)(t)\, dt. \tag{1.11}
$$

Substituting this into (1.7), we obtain the optimality conditions:

$$
\int_0^T p(a, t)(D_e W \cdot w)(t) + Dh(v_*)w \geqq 0 \quad \forall w \in K^+(v_*). \tag{1.12}
$$

Similarly we get the reverse inequality for all $w \in K^-(v_*)$.

Since W is not differentiable, these conditions do not actually make any sense; what we will do later is approximate W by smooth operators W_ε and problem (P) by problems (P_ε) corresponding to W_ε, and then derive, by the above method, rigorous optimality conditions.

2. The Preisach operator. The standard thermostat as depicted in Fig. 1 can be formalized as an operator $W_\rho : C[0, T] \to L^\infty(0, T)$ mapping any continuous function $u = u(t)$ to a function $y_\rho = y_\rho(t)$ that takes on the values 0 and 1 only, according to the switching rule indicated by the arrows in the figure. Since we will not use this approach, we refer to [10] and [3] for definition and basic properties of W_ρ. We remark, however, that W_ρ is discontinuous, no matter how the norms are chosen.

The Preisach operator W is usually defined as

$$
W(u, e)(t) = \int_\Delta (W_\rho u)(t) e(\rho)\, d\rho \tag{2.1}
$$

with $e \in L^\infty(\Delta)$, Δ being some subset of $\{\rho_1 < \rho_2\}$ that we specify here as

$$
\Delta = \{\rho = (\rho_1, \rho_2) : 0 \leqq \rho_1 < \rho_2 \leqq 1\},
$$

so that W represents an average over a continuous family of thermostats with respect to the measure $d\mu = e\, d\rho$. Let us fix $e \in L^\infty(\Delta)$. To study the time evolution of $W(u, e)$ for any $u \in C[0, T]$ means to study the time evolution of the sets (whose disjoint union is Δ)

$$A^+(t) = \{\rho: \rho \in \Delta, (W_\rho u)(t) = 0\}, \qquad A^-(t) = \{\rho: \rho \in \Delta, (W_\rho u)(t) = 1\} \tag{2.2}$$

for some initial configurations $A^+(0)$, $A^-(0)$ of the values of the thermostats that we assume to be given (later we will always set $A^-(0) = \varnothing$). It turns out that the boundary

$$B(t) = \partial A^+(t) \cap \partial A(t), \qquad t > 0, \tag{2.3}$$

is either empty (in case one of the sets is empty) or defines a line in the (ρ_1, ρ_2)-plane that separates Δ and consists of horizontal and vertical segments, the number of corner points being either finite or infinite with a limit point on the main diagonal [8], [10], if $B(0)$ already has that property; see Fig. 2. (The fastest way to believe this is to draw pictures for simple piecewise linear functions u.)

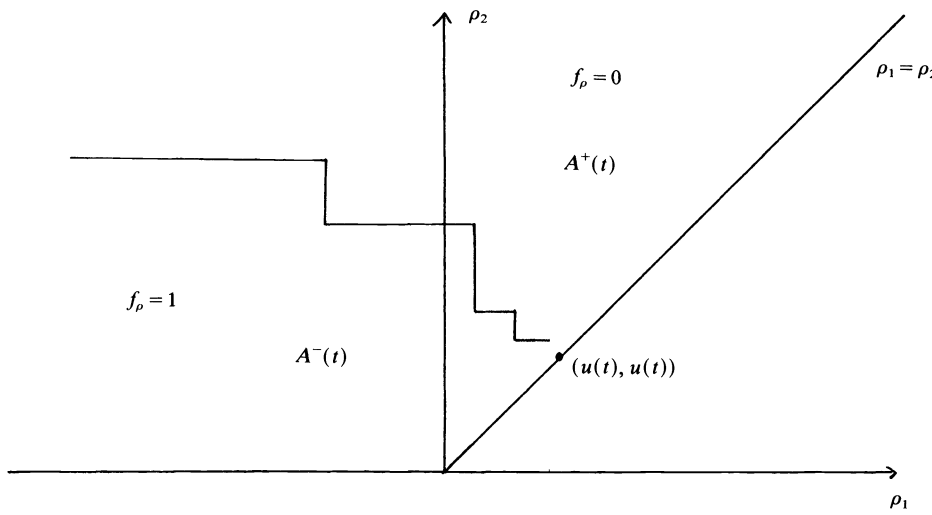

FIG. 2

Also, knowledge of $B(t)$ is all that is needed to determine $W(u, e)$ on $[t, T]$ from u on $[t, T]$, since it fixes the values of all thermostats except on the set $B(t)$ itself that has μ-measure zero. We may therefore interpret $B(t)$ as the internal state of a system whose input-output behavior is described by the Preisach operator (2.1) with fixed density e. Actually it is much more convenient for analysis to use such boundary curves as a basic description of the Preisach operator W, instead of the individual thermostats W_ρ. We only have to change coordinates to

$$r = \frac{\rho_2 + \rho_1}{2}, \qquad s = \frac{\rho_2 - \rho_1}{2}, \tag{2.4}$$

representing average and separation of the switching thresholds; then for any $t > 0$ the boundary curve $B(t)$ can be written as the graph of a Lipschitz function with slope ± 1, henceforth denoted by $\psi(t)$,

$$B(t) = \{(r, s) \in \tilde{\Delta}: s = \psi(t) r, r \geqq 0\},$$

where $\tilde{\Delta}$ is the image of Δ under the mapping (2.4), so that the internal state is now described by a function

$$\psi : [0, T] \to \mathrm{Lip}\,[0, \infty),$$

the values $\psi(t)r$ for $r \geqq 1$ being irrelevant for our specific choice of Δ. It is clear from (2.1)–(2.4) and Fig. 2 that, once the function ψ is known for a given $u \in C[0, T]$, we immediately obtain

$$W(u, e)(t) = \int_0^\infty \int_{-\infty}^{\psi(t)r} (\tilde{T}e)(r, s)\, ds\, dr,$$

where $\tilde{T}$ represents the transformation according to (2.4), extended by setting $\tilde{T}e(r, s) = 0$ for $(r, s) \notin \tilde{T}(\Delta)$.

This approach, investigated at length in [3], is of interest here mainly because we can readily obtain a smooth approximation W_ε of W from it. To make the present paper reasonably self-contained, we repeat some material from [3] as far as it is essential for the definition of W_ε.

From a rather informal discussion, we now switch to a formal one.

The spaces that will be used to define the internal states are the following:

$\tilde{\Psi}_0 = \{\phi : \phi \in C[0, \infty),\ \phi$ has compact support$\}$,

$\tilde{\Psi}_0$ is provided with sup-norm and its closure will be denoted by Ψ_0;

$\Psi_1 = \{\phi \in \Psi_0,\ \phi$ is Lipschitz continuous with Lipschitz constant $\leqq 1\}$.

We want to define a map

$$F : C[0, T] \times \Psi_1 \to C([0, T]; \Psi_1)$$

such that

$$\psi(t) = F(u, \psi_0)(t)$$

is the internal state at time t with respect to the (r, s)-coordinates, given an input u and an initial internal state ψ_0. The initial state ψ_0 fixes the values of the thermostats at time $t = 0$; here $\psi_0 \equiv 0$ corresponds to $A^-(0) = \varnothing$ so that all thermostats are off, whereas $\psi_0 \equiv 1$ corresponds to $A^-(0) = \Delta$.

LEMMA 2.1. *Define* $g : \mathbb{R}^3 \to \mathbb{R}$ *by*

$$g(x, p, r) = \min\{x + r, \max\{x - r, p\}\} \tag{2.5}$$

and $G : \mathbb{R} \times \Psi_0 \to \Psi_0$ *by*

$$G(x, \phi)(r) = g(x, \phi(r), r). \tag{2.6}$$

Then for all arguments we have

$$\|G(x_1, \phi_1) - G(x_2, \phi_2)\|_\infty \leqq \max\{|x_1 - x_2|, \|\phi_1 - \phi_2\|_\infty\}, \tag{2.7}$$

$$G : \mathbb{R} \times \Psi_1 \to \Psi_1, \tag{2.8}$$

$$G(x_1, \phi_1) \leqq G(x_2, \phi_2) \quad \text{if } x_1 \leqq x_2, \quad \phi_1 \leqq \phi_2. \tag{2.9}$$

Proof. Indeed (2.7) follows from

$$|g(x_1, p_1, r_1) - g(x_2, p_2, r_2)| \leqq \max\{|p_1 - p_2|, |x_1 - x_2| + |r_1 - r_2|\}, \tag{2.10}$$

(2.8) follows from (2.7), and (2.9) follows immediately from (2.6) and the appropriate monotonic behavior of g.

We may easily verify that, for monotone inputs $u \in C[0, T]$,

$$\psi(t) = G(u(t), \psi_0)$$

gives the correct boundary curve $B(t)$, if we choose ψ_0 corresponding to $B(0)$.

Denote by $C_{pm}[0, T]$ the set of functions $u \in C[0, T]$ that are piecewise monotone. We define

$$F: C_{pm}[0, T] \times \Psi_1 \to C([0, T]; \Psi_1)$$

by

$$\begin{aligned} &F(u, \psi_0)(0) = G(u(0), \psi_0), \\ &F(u, \psi_0)(t) = G(u(t), F(u, \psi_0)(t_i)) \quad \text{if } t \in [t_i, t_{i+1}], \end{aligned} \tag{2.11}$$

where $[t_j, t_{j+1}]$ are the intervals in which u is monotone.

LEMMA 2.2. *The function F satisfies*

$$\|F(u_1, \psi_{01}) - F(u_2, \psi_{02})\|_{C([0,T];\Psi_1)} \leqq \max \{\|u_1 - u_2\|_\infty, \|\psi_{01} - y_{02}\|_\infty\}. \tag{2.12}$$

Indeed this can be seen by induction on the monotonicity intervals of u_1, u_2.

From (2.12) with $\psi_{01} = \psi_{02}$ it follows that F can be extended into a Lipschitz continuous map with Lipschitz coefficient 1,

$$F: C[0, T] \times \Psi_1 \to C([0, T]; \Psi_1).$$

From (2.9), (2.11) we also deduce that

$$F(u_1, \psi_0) \leqq F(u_2, \psi_0) \quad \text{if } u_1 \leqq u_2. \tag{2.13}$$

Given any input $u \in C[0, T]$, we now define the internal state $\psi: [0, T] \to \Psi_1$ as

$$\psi(t) = F(u, \psi_0)(t). \tag{2.14}$$

For any $\phi \in \Psi_0$ we define the state-output map

$$E(\phi, e) = \int_0^\infty \int_{-\infty}^{\phi(r)} e(r, s)\, ds\, dr \tag{2.15}$$

where

$$e \in L^\infty(\mathbb{R}_+ \times \mathbb{R}), \qquad \operatorname{supp} e \subset \tilde{\Delta}$$

where $\tilde{\Delta}$ is the ρ-set Δ in the (r, s)-coordinates. Then

$$\begin{aligned} |E(\phi_1, e) - E(\phi_2, e)| &\leqq \int_0^1 \left| \int_{\phi_2(r)}^{\phi_1(r)} |e(r, s)|\, ds \right| dr \\ &\leqq \|\phi_1 - \phi_2\|_\infty \|e\|_\infty \end{aligned}$$

and

$$E(\phi, \cdot): L^\infty(\mathbb{R}_+ \times \mathbb{R}) \to \mathbb{R}$$

is linear continuous with

$$|E(\phi, e)| \leqq \|e\|_{L^1(\tilde{\Delta})} \leqq \|e\|_\infty \cdot \operatorname{meas}(\tilde{\Delta}).$$

We can verify that the Preisach operator as defined in (2.1) for the measure μ with $d\mu = e\, d\rho_1\, d\rho_2$ is precisely the operator

$$\begin{aligned} W(u, e)(t) &= E(\psi(t), \tilde{T}e) \\ &= E(F(u, \psi_0)(t), \tilde{T}e) \end{aligned} \tag{2.16}$$

where $\tilde{T}: L^\infty(\Delta) \to L^\infty(\tilde{\Delta})$ is defined by

$$(\tilde{T}e)(r, s) = e(s - r, s + r).$$

Combining properties of F and (2.16) we get Lemma 2.3.

LEMMA 2.3. *The operator W satisfies*

$$W: C[0, T]\times L^{\infty}(\Delta)\to C[0, T], \tag{2.17}$$

$$W(u, \cdot): L^{\infty}(\Delta)\to C[0, T] \text{ is a linear continuous operator,} \tag{2.18}$$

$$\|W(u, e)\|_{\infty}\leqq \text{meas}\,(\tilde{\Delta})\cdot\|e\|_{\infty}, \tag{2.19}$$

$$\|W(u_1, e)-W(u_2, e)\|\leqq\|u_1-u_2\|_{\infty}\|e\|_{\infty}. \tag{2.20}$$

If the input u is Lipschitz continuous then

$$\|F(u, \psi_0)(t)-F(u, \psi_0)(t')\|\leqq\|\dot{u}\|_{\infty}|t-t'| \quad \forall t, t'\in[0, T], \tag{2.21}$$

$\dot{u}$ denoting time derivative of u, as seen by considering first the case of piecewise monotone u's. Consequently,

$$|W(u, e)(t)-W(u, e)(t')|\leqq\|e\|_{\infty}\|\dot{u}\|_{\infty}|t-t'|. \tag{2.22}$$

Remark 2.1. In the sequel we shall continue to consider only the typical case of initial state $\psi_0\equiv 0$. However all the definitions and properties easily extend to the case of any initial state.

3. Regularization of the Preisach operator. In [1], a regularization of the so-called hysteresis operator of first kind has been developed. In this section, we extend this approach to the Preisach operator. Let $j\in C^{\infty}(\mathbb{R}^3)$, $j\geqq 0$ with support in the unit ball $\{|X|\leqq 1\}$, $\int j(X)\,dX=1$. For any small $\varepsilon>0$ set

$$j_{\varepsilon}(X)=\frac{1}{\varepsilon^3}j\left(\frac{X}{\varepsilon}\right)$$

and define the mollifier of the function g introduced in (2.5) by

$$g_{\varepsilon}(X)=(j_{\varepsilon}*g)(X)=\int_{\mathbb{R}^3}j_{\varepsilon}(X-Y)g(Y)\,dY, \qquad X\in\mathbb{R}^3.$$

Analogously to (2.6) we define $G_{\varepsilon}:\mathbb{R}\times\Psi_0\to\Psi_0$ by

$$G_{\varepsilon}(x, \phi)(r)=g_{\varepsilon}(x, \phi(r), r).$$

Then

$$g_{\varepsilon}\in C^{\infty}(\mathbb{R}^3; \mathbb{R}), \qquad G_{\varepsilon}\in C^{\infty}(\mathbb{R}\times\Psi_0; \Psi_0).$$

LEMMA 3.1. *The function G_{ε} satisfies, for every x_i, x in $\mathbb{R}$ and ϕ_i, ϕ in Ψ_0,*

$$\|G_{\varepsilon}(x_1, \phi_1)-G_{\varepsilon}(x_2, \phi_2)\|_{\infty}\leqq\max\{|x_1-x_2|, \|\phi_1-\phi_2\|_{\infty}\}, \tag{3.1}$$

$$G_{\varepsilon}(x_1, \phi_1)\leqq G_{\varepsilon}(x_2, \phi_2) \quad \text{if } x_1\leqq x_2,\ \phi_1\leqq\phi_2, \tag{3.2}$$

$$\|G_{\varepsilon}(x, \phi)-G(x, \phi)\|_{\infty}\leqq\varepsilon. \tag{3.3}$$

Proof. The inequalities (3.1), (3.2) follow easily from (2.7), (2.9), respectively. Next

$$\begin{aligned}
&|G_{\varepsilon}(x, \phi)(r)-G(x, \phi)(r)|\\
&\quad=\left|\int_{\mathbb{R}^3}j_{\varepsilon}(\xi, q, s)[g(x-\xi, \phi(r)-q, r-s)-g(x, \phi(r), s)]\,d\xi\,dq\,ds\right|\\
&\quad\leqq\left\{\int_{\mathbb{R}^3}j_{\varepsilon}(\xi, q, s)\,d\xi\,dq\,ds\right\}\varepsilon=\varepsilon \quad \text{by (2.10)}
\end{aligned}$$

and (3.3) follows.

To define F_ε we divide the interval $[0, T]$ by equidistant points $t_i = ih$ and then choose ε by $\sqrt{\varepsilon} = h$. We then define

$$F_\varepsilon : C[0, T] \times \Psi_0 \to \prod_i (C[t_i, t_{i+1}]: \Psi_0) \subseteq L^\infty([0, T]; \Psi_0)$$

by

$$\begin{aligned} &F_\varepsilon(u, \psi_0)(0) = G_\varepsilon(u(0), \psi_0), \qquad t \in [0, t_1], \\ &F_\varepsilon(u, \psi)(t) = G_\varepsilon(u(t), F_\varepsilon(u, \psi_0)(t_i - 0)), \qquad t \in [t_i, t_{i+1}]. \end{aligned} \tag{3.4}$$

LEMMA 3.2. *The function F_ε satisfies the following*:

$$\|F_\varepsilon(u_1, \psi_0) - F_\varepsilon(u_2, \psi_0)\|_{L^\infty(0,T;\Psi_0)} \leqq \|u_1 - u_2\|_\infty, \tag{3.5}$$

$$F_\varepsilon(u_1, \psi_0) \leqq F_\varepsilon(u_2, \psi_0) \quad \text{if } u_1 \leqq u_2. \tag{3.6}$$

Indeed, this follows easily from (3.1) (with $\psi_{01} = \psi_{02} = \psi_0$) and (3.2).

LEMMA 3.3. *There exists a positive constant C such that for any $u \in C^1[0, T]$, $\psi_0 \in \Psi_1$,*

$$\|F_\varepsilon(u, \psi_0) - F(u, \psi_0)\|_{L^\infty(0,T;\Psi_0)} \leqq C\sqrt{\varepsilon} + 2\|\dot{u}\|_\infty \varepsilon. \tag{3.7}$$

Proof. Denote by $\prod_\varepsilon u$ the piecewise linear function of t that coincides with $u(t_i)$ at each of the points t_i. Then

$$\begin{aligned} \|F_\varepsilon(u, \psi_0)(t) - F(u, \psi_0)(t)\| &\leqq \|F_\varepsilon(u, \psi_0)(t) - F_\varepsilon(\textstyle\prod_\varepsilon u, \psi_0)(t)\| \\ &\quad + \|F_\varepsilon(\textstyle\prod_\varepsilon u, \psi_0)(t) - F(\textstyle\prod_\varepsilon u, \psi_0)(t)\| \\ &\quad + \|F(\textstyle\prod_\varepsilon u, \psi_0)(t) - F(u, \psi_0)(t)\| \\ &\leqq 2\|u = \textstyle\prod_\varepsilon u\|_\infty + \|F_\varepsilon(\textstyle\prod_\varepsilon u, \psi_0)(t) - F(\textstyle\prod_\varepsilon u, \psi_0)(t)\| \end{aligned} \tag{3.8}$$

by (2.12) and (3.5). The last term on the right-hand side can be estimated in $[t_i, t_{i+1}]$, by

$$\begin{aligned} &\|G_\varepsilon(\textstyle\prod_\varepsilon u(t), \psi_\varepsilon(t_i)) - G(\textstyle\prod_\varepsilon u(t), \psi(t_i))\| \\ &\quad \leqq \|G_\varepsilon(\textstyle\prod_\varepsilon u(t), \psi_\varepsilon(t_i)) - G(\textstyle\prod_\varepsilon u(t), \psi_\varepsilon(t_i))\| \\ &\qquad + \|G(\textstyle\prod_\varepsilon u(t), \psi_\varepsilon(t_i)) - G(\textstyle\prod_\varepsilon u(t), \psi(t))\| \\ &\quad \leqq \varepsilon + \|\psi_\varepsilon(t_i) - \psi(t_i)\| \end{aligned}$$

by (3.2), (2.5), where

$$\psi_\varepsilon(t_i) = F_\varepsilon(\textstyle\prod_\varepsilon u, \psi_0)(t_i), \qquad \psi(t_i) = F(\textstyle\prod_\varepsilon u, \psi_0)(t_i).$$

Summing over i we conclude that the last term on the right-hand side of (3.8) is bounded by $(T/h)\varepsilon$, i.e., by $C\sqrt{\varepsilon}$. Finally, when we use the estimate

$$\|u - \textstyle\prod_\varepsilon u\|_\infty \leqq \|\dot{u}\|_\infty \varepsilon$$

in (3.8), the assertion (3.7) follows.

From the definition of F_ε in (3.4) it is clear that

$$F_\varepsilon : C[0, T] \times \Psi_0 \to \prod_i C([t_i, t_{i+1}], \Psi_0) \text{ is continuously differentiable.}$$

Now consider the state-output map E defined in (2.15). If e is not continuous, then we can regularize E by

$$E_\varepsilon(\phi, e) = E(\phi, j_\varepsilon * e). \tag{3.9}$$

The regularization W_ε of the Preisach operator W is then defined by

$$W_\varepsilon(u, e)(t) = E_\varepsilon(F_\varepsilon(u, \psi_0)(t), \tilde{T}e)$$

for the initial state $\psi_0 \equiv 0$. Since in the rest of this paper we deal exclusively with densities e that are continuous, we shall replace E_ε by E, i.e., we shall work with the simpler operators

$$W_\varepsilon(u, e)(t) = E(F_\varepsilon(u, \psi_0)(t), \tilde{T}e). \tag{3.10}$$

We introduce the mapping

$$\mathscr{E} : C([a, b]; \Psi_0) \times L^\infty(\mathbb{R}_+ \times R) \to C[a, b]$$

by

$$\mathscr{E}(\psi, e)(t) = E(\psi(t), e).$$

For $e \in C(\mathbb{R}_+ \times \mathbb{R})$ with compact support,

$$\mathscr{E}(\cdot, e) : C([a, b]; \Psi_0) \to C[a, b]$$

is continuously differentiable with derivative

$$(D_\psi \mathscr{E}(\psi, e)\chi)(t) = \int_0^\infty e(r, \psi(t)r)\chi(t)r\, dr \tag{3.11}$$

where $\psi(t)r$ is the value of the function $\psi(t)$ at the point r, and similarly for $\chi(t)r$. Indeed,

$$\left| \mathscr{E}(\psi + \chi, e)(t) - \mathscr{E}(\psi, e)(t) - \int_0^\infty e(r, \psi(t)r)\chi(t)r\, dr \right|$$

$$\leqq \int_0^\infty \left| \int_{\psi(t)r}^{\psi(t)r + \chi(t)r} |e(r, s) - e(r, \psi(t)r)|\, ds \right| dr$$

and if $\|\chi\| \to 0$ then the integrand converges to zero uniformly, and thus the integral is $o(\|\chi\|)$.

From (3.11) it follows that

$$\begin{aligned} &(D_\psi \mathscr{E}(\psi_n, e)\chi)(t) \to (D_\psi \mathscr{E}(\psi, e)\chi)(t) \text{ uniformly in } t, \\ &\qquad \text{if } \psi_n \to \psi \text{ in } C([a, b]; \Psi_0). \end{aligned} \tag{3.12}$$

Hence $W_\varepsilon(u, e)$ is continuously differentiable in u.

LEMMA 3.4. *The operator W_ε satisfies*

$$\|W_\varepsilon(u_1, e) - W_\varepsilon(u_2, e)\|_\infty \leqq \|e\|_\infty \|u_1 - u_2\|, \tag{3.13}$$

$$W_\varepsilon(u_1, e_1) \leqq W_\varepsilon(u_2, e_2) \quad \text{if } u_1 \leqq u_2,\ e_1 \leqq e_2; \tag{3.14}$$

furthermore, for any $e \in C(\mathbb{R}_+ \times \mathbb{R})$ with compact support and $N > 0$ there exists a positive constant C_0 such that

$$\|W_\varepsilon(u, e) - W(u, e)\|_\infty \leqq C_0\sqrt{\varepsilon} \quad \forall u \in W^{1,\infty}(0, T),\ \|\dot{u}\|_\infty \leqq N. \tag{3.15}$$

Proof. The estimates (3.13), (3.14) follow from (3.5), (3.6) respectively, and (3.15) follows by Lemma 3.3.

We emphasize that, in contrast to $W(u, e)$, $W_\varepsilon(u, e)$ is discontinuous as a function of time with discontinuities of order ε at the points $\{t_i\}$. (However, it is continuously differentiable in u.)

We conclude this section with some monotonicity properties with respect to translation of the measure e.

For $e \in C(\bar{\Delta})$, $\lambda \in \mathbb{R}$, set

$$(T_\lambda^1 e)(\rho_1, \rho_2) = e(\rho_1 - \lambda, \rho_2), \qquad (T_\lambda^2 e)(\rho_1, \rho_2) = e(\rho_1, \rho_2 - \lambda).$$

LEMMA 3.5. *If $e \geqq 0$, $\lambda \geqq 0$, $\phi \in \Psi_1$, then*

$$E(\phi, \tilde{T}T_\lambda^1 e) \leqq E(\phi, \tilde{T}e), \tag{3.16}$$

$$E(\phi, \tilde{T}T_\lambda^2 e) \leqq E(\phi, \tilde{T}e). \tag{3.17}$$

Proof. We have

$$\begin{aligned} E(\phi, \tilde{T}T_\lambda^1 e) &= \int_0^\infty \int_{-\infty}^\infty (\tilde{T}T_\lambda^1 e)(r, s)\, ds\, dr \\ &= \int_0^\infty \int_{-\infty}^{\phi(r)} e(s - r - \lambda, s + r)\, ds\, dr \\ &= \int_{\lambda/2}^\infty \int_{-\infty}^{\phi(r' - \lambda/2) - \lambda/2} e(s' - r', s' + r')\, ds'\, dr' \\ &\leqq \int_0^\infty \int_{-\infty}^{\phi(r')} (\tilde{T}e)(r', s')\, ds'\, dr' = E(\phi, \tilde{T}e) \end{aligned}$$

where the inequality follows from the fact that $\phi(r' - \lambda/2) \leqq \phi(r') + \lambda/2$. The proof of (3.17) is similar, provided we recall that supp $\tilde{T}e$ is contained in $\mathbb{R}_+ \times \mathbb{R}$.

4. The problems (P), (P_ε). Denote by $G(x, t; \xi, \tau)$ $(0 \leqq x, \xi \leqq a, 0 \leqq \tau < t \leqq T)$ the Green function for the heat equation in Q_T with the boundary conditions

$$G_x(0, t; \xi, \tau) = 0, \qquad G_x(a, t; \xi, \tau) + G(a, t; \xi, \tau) = 0. \tag{4.1}$$

G can be constructed by the parametrix method ([4] or [5, Chap. 1]) that involves the solution of a Volterra type integral equation; it can also be constructed by using existence and regularity theory of parabolic equations [5]. The function $G(x, t; \xi, \tau)$ satisfies in (ξ, τ) the backward heat equation and the boundary conditions (4.1), it has the same singularity as the fundamental solution

$$\frac{1}{\sqrt{4\pi(t - \tau)}} \exp\left\{-\frac{|x - \xi|^2}{4(t - \tau)}\right\},$$

and it is a positive value function. The solution of (1.1)-(1.4) can be represented in terms of G:

$$u(x,t)=\int_0^t G(x,t;a,\tau)\,W(u(0,\cdot),Bv)(\tau)\,d\tau + \int_0^t G(x,t;0,\tau)\,d\tau + \int_0^a G(x,t;\xi,0)u_0(\xi)\,d\xi. \tag{4.2}$$

THEOREM 4.1. *For any bounded measurable density function Bv there exists a unique solution of* (1.1)-(1.4).

Proof. Taking $x=0$ in (4.2) we obtain for $u(0,t)$ an integral equation of Volterra type:

$$u(0,t)=\int_0^t G(0,t;a,\tau)\,W(u(0,\cdot),Bv)(\tau)\,d\tau + \int_0^t G(0,t;0,\tau)k(\tau)\,d\tau + \int_0^a G(0,t;\xi,0)u_0(\xi)\,d\xi. \tag{4.3}$$

The integrand in the first integral is a nonanticipative Lipschitz continuous functional in $u(0,\cdot)$. By a standard method it follows that this integral equation has a unique solution $u(0,t)$, and then a solution $u(x,t)$ is obtained by solving (1.1)-(1.4) (since the right-hand side of (1.4) is now well defined). Uniqueness follows from the uniqueness of the solution $u(0,\cdot)$ of the integral equation (4.3).

We now specify the choice of admissible densities $e=Bv$ in problem (P). Let $\sigma(\rho)=\sigma(\rho_1,\rho_2)$ be a specific spherically symmetric continuously differentiable function such that

$$\sigma(\rho)=0 \quad \text{if } |\rho|\geqq 1, \qquad \sigma(\rho)>0 \quad \text{if } |\rho|<1,$$
$$\iint \sigma(\rho_1,\rho_2)\,d\rho_1\,d\rho_2=1, \tag{4.4}$$
$$\frac{\partial\sigma}{\partial\rho_i}>0\ (<0) \quad \text{if } \rho_i>0\ (<0), \quad |\rho|<1, \quad i=1,2,$$

and set

$$\sigma_\eta(\rho)=\frac{1}{\eta^2}\sigma\left(\frac{\rho_1}{\eta},\frac{\rho_2}{\eta}\right), \qquad \eta>0. \tag{4.5}$$

We define the control set $K\subset V$ for problem (P) setting

$$V=\mathbb{R}^3,$$
$$K=\{v=(\eta,\alpha,\beta):\ \eta_0\leqq\eta\leqq 1,\ \eta\leqq\alpha,\ \alpha+\eta\leqq\beta\leqq 1-\eta\} \tag{4.6}$$

where $\eta_0>0$ is a given number, $\eta_0\ll 1$. We define $B:\mathbb{R}_+\times\mathbb{R}^2\to L^\infty(\Delta)$ by

$$(Bv)(\rho_1,\rho_2)=\sigma_\eta(\rho_1-\alpha,\rho_2-\beta).$$

Then the admissible densities $e=Bv$ form a three parameter family, approximating Dirac measures that represent the thermostats.

THEOREM 4.2. *There exists an optimal control $v_*\in K$ of problem (P), that is,*

$$J(v_*)=\min_{v\in K} J(v).$$

Proof. Let v_n be a minimizing sequence and set $u_n = u(v_n)$. By parabolic estimates

$$\|u_n(0, \cdot)\|_{C^1[0,T]} \leqq C_0.$$

Using the representation (4.2) it is easy to see that a subsequence is convergent to a solution of problem (P).

Remark 4.1. Theorem 4.2 can be extended to the case where v varies in an infinite-dimensional space; the proof is similar to that of Theorem 3.1 in [5].

We now turn to the approximating problems (P_ε) whereby W in (1.4) is replaced by W_ε, and $J(v)$ is replaced by

$$J_\varepsilon(v) = \int_0^T \Phi(u_\varepsilon(0, t), t)\, dt + h(v) + |v - v_*|^2; \tag{4.7}$$

here $u_\varepsilon = u_\varepsilon(v)$ is the solution of (1.1)-(1.4) with W replaced by W_ε; the existence and uniqueness of $u_\varepsilon(v)$ is proved as in Theorem 4.1.

Problem (P_ε). Find v_ε in K such that

$$J_\varepsilon(v_\varepsilon) = \min_{v \in K} J_\varepsilon(v).$$

The proof of Theorem 4.1 applies also to problem (P_ε), showing that a solution v_ε exists.

THEOREM 4.3. *As* $\varepsilon \to 0$, $|v_\varepsilon - v_*| \to 0$ *and*

$$\|u_\varepsilon(v_\varepsilon) - u_*\|_{L^\infty(Q_T)} \to 0.$$

Proof. For convenience we write $J(v)$ also as $J(v, u(v))$ if $u(v)$ is the solution of (1.1)-(1.4) and as $J(v, u_\varepsilon(v))$ if $u_\varepsilon(v)$ is the solution of (1.1)-(1.4) with W replaced by W_ε, and set

$$J_\varepsilon(v, u) = J(v, u) + |v - v_*|^2.$$

Then, by the optimality of v_ε,

$$\begin{aligned} J_\varepsilon(v_\varepsilon, u_\varepsilon(v_\varepsilon)) &\leqq J_\varepsilon(v_*, u_\varepsilon(v_*)) \\ &= J(v_*, u_*) + R_\varepsilon \end{aligned} \tag{4.8}$$

where

$$R_\varepsilon = J(v_*, u_\varepsilon(v_*)) - J(v_*, u_*).$$

Analogously to (4.3),

$$\begin{aligned} u_\varepsilon(0, t) = &\int_0^t G(0, t; a, \tau)\, W_\varepsilon(u_\varepsilon(0, \cdot)Bv)(\tau)\, d\tau \\ &+ \int_0^t G(0, t; 0, \tau) k(\tau)\, d\tau + \int_0^a G(0, t; \xi, 0) u_0(\xi)\, d\xi. \end{aligned} \tag{4.9}$$

Subtracting this from (4.3) and using (3.15), we get

$$\|u_\varepsilon(v)(0, \cdot) - u(v)(0, \cdot)\|_\infty \leqq C\sqrt{\varepsilon} + \int_0^t |W(u_\varepsilon(0, \cdot), Bv) - W(u(0, \cdot), Bv)|\, d\tau.$$

Using (2.20) and Gronwall's inequality we deduce that

$$\|u_\varepsilon(v)(0, \cdot) - u(v)(0, \cdot)\|_\infty \to 0$$

as $\varepsilon \to 0$. It follows that $R_\varepsilon \to 0$, and (4.8) yields

$$\lim_{\varepsilon \to 0} J(v_\varepsilon, u_\varepsilon(v_\varepsilon)) + \overline{\lim_{\varepsilon \to 0}} |v_\varepsilon - v_*|^2 \leqq J(v_*, u_*). \tag{4.10}$$

On the other hand, for a subsequence,

$$v_\varepsilon \to \hat{v} \quad \text{and} \quad u_\varepsilon(v_\varepsilon) \to \hat{u} \quad \text{in } C(Q_T);$$

comparing (4.9) with (4.3) when $v = \hat{v}$, $u = u(\hat{v})$, and applying (3.15), we find that $u(\hat{v}) = \hat{u}$. It follows that

$$J(v_\varepsilon, u_\varepsilon(v_\varepsilon)) \to J(\hat{v}, u(\hat{v})) \geqq J(v_*, u_*)$$

by the optimality of v_*. Substituting this into (4.10) we find that $|v_\varepsilon - v_*| \to 0$, and the theorem follows.

5. Optimality conditions for (P_ε). Since W_ε is differentiable, the optimality conditions (1.12) can be rigorously derived for any solution $(v_\varepsilon, u(v_\varepsilon))$ of problem (P_ε), with a minor change due to the term $|v - v_*|^2$ in J_ε; it will suffice to write the conclusion.

We begin by setting

$$D_u W_\varepsilon = D_u W_\varepsilon(u_\varepsilon, Bv_\varepsilon), \qquad u_\varepsilon = u_\varepsilon(v_\varepsilon)(0, \cdot), \tag{5.1}$$

$$D_e W_\varepsilon = D_\varepsilon W_\varepsilon(u_\varepsilon, Bv_\varepsilon) DB(v_\varepsilon) \tag{5.2}$$

and introducing $D_u W_\varepsilon^*$ by

$$\int_0^T p(t)(D_u W_\varepsilon z)(t)\, dt = \int_0^T z(t)(D_u W_\varepsilon^* p)(t)\, dt \quad \forall p, z \in C[0, T]. \tag{5.3}$$

LEMMA 5.1. *For any $n \in \mathbb{N}$, set $h = 1/n$ and $\varepsilon = h^2$. Then there exist nonnegative functions $w_\varepsilon(t)$, $w_i^\varepsilon(t)$, continuous on every $[t_j, t_{j+1}]$ where $t_j = jh$, such that, for every $p \in L^2[0, T]$,*

$$D_u W_\varepsilon^* p(t) = w_\varepsilon(t) p(t) + \sum_i \left\{ \int_t^T p(s) w_i^\varepsilon(s)\, ds \right\} \delta_{t_i}(t) \tag{5.4}$$

where $\delta_{t_i}(t)$ is the Dirac measure at $t = t_i$.

Proof. From (3.4) we get, for $t_i \leqq t \leqq t_{i+1}$,

$$\begin{aligned}(D_u F_\varepsilon(u, \psi_0)z)(t) &= D_x G_\varepsilon(u(t), F_\varepsilon(u, \psi_0)(t_i - 0))z(t) \\ &\quad + [D_\psi G_\varepsilon(u(t), F_\varepsilon(u, \psi_0)(t_i - 0))](D_u F_\varepsilon(u, \psi_0)z)(t_i - 0).\end{aligned}$$

Defining the linear continuous operators $A(t)$, $A_j : \Psi_0 \to \Psi_0$ and $B(t)$, $B_j : \mathbb{R} \to \Psi_0$ by

$$\begin{aligned}A(t) &= D_\psi G_\varepsilon(u(t), F_\varepsilon(u, \psi_0)(t_i - 0)), \\ B(t) &= D_x G_\varepsilon(u(t), F_\varepsilon(u, \psi_0)(t_i - 0)), \\ A_{i+1} &= A(t_{i+1} - 0), \qquad B_{i+1} = B(t_{i+1} - 0),\end{aligned}$$

we get, taking $t = t_{i+1}$,

$$(D_u F_\varepsilon(u, \psi_0)z)(t_{i+1} - 0) = B(t_{i+1})z(t_{i+1}) + A_{i+1}(D_u F_\varepsilon(u, \psi_0)z)(t_i - 0).$$

It follows that for $t_i \leqq t \leqq t_{i+1}$

$$\begin{aligned}(D_u F_\varepsilon(u, \psi_0)z)(t) &= B(t)z(t) + A(t)B_i z(t_i) + A(t)A_{i-1}B_{i-1}z(t_{i-1}) \\ &\quad + \cdots + A(t)A_{i-1} \cdots A_1 B_1 z(t_1).\end{aligned} \tag{5.5}$$

Note that by (2.9)

$$A(t) \geqq 0, \qquad B(t) \geqq 0. \tag{5.6}$$

Now since

$$D_u W_\varepsilon : C[0, T] \to \prod_i C[t_i, t_{i+1}],$$

we have

$$D_u W_\varepsilon^* : \left(\prod_i C[t_i, t_{i+1}]\right)^* \to C[0, T]^*;$$

in particular, $D_u W_\varepsilon$ maps $C[0, T]$ into $L^2[0, T]$ and $D_u W_\varepsilon^*$ maps $L^2[0, T]$ into $C[0, T]^*$. Next, by (3.10), (5.5), with $\psi_\varepsilon = f_\varepsilon(u_\varepsilon, \psi_0)$,

$$\begin{aligned}(D_u W_\varepsilon z)(t) &= \int_0^\infty e(r, \psi_\varepsilon(t)r)((D_u F_\varepsilon \cdot z)(t))(r)\, dr \\ &= \int_0^\infty e(r, \psi_\varepsilon(t)r)[B(t)z(t) + A(t)B_i z(t_i) + \cdots](r)\, dr\end{aligned}$$

so that

$$(D_u W_\varepsilon(u_\varepsilon, \psi_\varepsilon)z)(t) = w_\varepsilon(t)z(t) + \sum_{0<t_i<t} w_i^\varepsilon(t) z(t_i)$$

where $w_\varepsilon(t) \geqq 0$, $w_i^\varepsilon(t) \geqq 0$ by (5.6) and w_ε, w_i^ε are continuous on $[t_j, t_{j+1}]$. Finally,

$$\begin{aligned}\int_0^T p(t)(D_u W_\varepsilon(u_\varepsilon, \psi_0)z)(t)\, dt &= \int_0^T \left[p(t)w_\varepsilon(t)z(t) + p(t) \sum_{0<t_i<t} w_i^\varepsilon(t) z(t_i) \right] dt \\ &= \int_0^T p(t)w_\varepsilon(t)z(t)\, dt + \sum_i \left[\int_{t_i}^T p(t) w_i^\varepsilon(t)\, dt \cdot z(t_i) \right],\end{aligned}$$

which is precisely the assertion (5.4).

Denote by $p = p_\varepsilon$ the solution of

$$\begin{aligned}&p_t + p_{xx} = 0 \quad \text{in } Q_T, \\ &p(x, T) = 0, \qquad 0 < x < a, \\ &-p_x(0, t) = (D_u W_\varepsilon^* p(a, \cdot))(t) + \Phi_u(u_\varepsilon(0, t), t), \qquad 0 < t < T, \\ &p_x(a, t) + p(a, t) = 0, \qquad 0 < t < T.\end{aligned} \tag{5.7}$$

Representing $p_\varepsilon(x, t)$ by means of Green's function G (cf. (4.2)) we obtain for $p(a, t)$ an integral equation of Volterra type (cf. (4.3)). Its solution yields a unique solution for (5.7).

The optimality conditions for $(v_\varepsilon, u_\varepsilon)$, whose derivation is the same as for (1.12), are:

$$\pm\left\{ \int_0^T p_\varepsilon(a, t)(D_e W_\varepsilon \cdot w)(t) + Dh(v_\varepsilon)w + 2(v_\varepsilon - v_*) \cdot w \right\} \geqq 0 \quad \forall w \in K^{\pm}(v_\varepsilon). \tag{5.8}$$

To derive properties for v_ε (and v_*) from (5.8), we need to establish some auxiliary properties for $D_e W_\varepsilon$, $D_u W_\varepsilon^*$ and p_ε; this is done in the next section.

6. Auxiliary properties of DW_ε.

LEMMA 6.1. *For any $p \in C[0, T]$,*

$$(D_u W_\varepsilon^*(u, e)p(\cdot))(t) \geqq 0 \quad \text{if } p \geqq 0. \tag{6.1}$$

Indeed, this follows from Lemma 5.1.

LEMMA 6.2. *If* $\Phi_u(u, s) > 0$, *then*

$$p_\varepsilon(x, t) > 0 \quad \text{for } 0 \leqq x \leqq a, \quad 0 \leqq t < T. \tag{6.2}$$

Proof. We can recast the proof of existence of the solution $p = p_\varepsilon$ in the following way. Given $p_0(t) \geqq 0$ solve (5.7) with $p(a, t) = p_0(t)$ and denote the solution by $\tilde{p}(x, t)$. Since $D_u W_\varepsilon^* p_0 \geqq 0$ (by Lemma 6.1), the maximum principle gives $\tilde{p}(x, t) \geqq 0$ if $0 \leqq x \leqq a$, $0 < t < T$ and, in particular, $p_1(t) \equiv \tilde{p}(a, t) \geqq 0$. Consider the mapping $S: p_1 = Sp_0$. Representing S (by means of Green's function G) as an integral operator of Volterra type, we deduce that S must have a fixed point $\tilde{p}(t)$, which then corresponds to a solution $p(x, t)$ of (5.7) with $p(a, t) = \tilde{p}(t) \geqq 0$. The conclusion (6.2) now readily follows.

LEMMA 6.3. *Write* $v_\varepsilon = (\eta_\varepsilon, \alpha_\varepsilon, \beta_\varepsilon)$, $w_1 = (0, 1, 0)$, $w_2 = (0, 0, 1)$. *Then*

$$D_e W_\varepsilon(u_\varepsilon, Bv_\varepsilon) DBv_\varepsilon \cdot w_i = W_\varepsilon(u_\varepsilon, e_i') \tag{6.3}$$

where $u_\varepsilon = u_\varepsilon(0, \cdot)$,

$$\begin{gathered} e_i' = -\frac{1}{\eta^3} D_i \sigma\left(\frac{\rho_1 - \alpha}{\eta}, \frac{\rho_2 - \beta}{\eta}\right), \\ D_1\sigma(s_1, s_2) = \frac{\partial}{\partial s_1}\sigma(s_1, s_2), \qquad D_2\sigma(s_1, s_2) = \frac{\partial}{\partial s_2}\sigma(s_1, s_2). \end{gathered} \tag{6.4}$$

The proof follows directly from the definition of $D_e W_\varepsilon$.

LEMMA 6.4. $W(u_\varepsilon, e_i') \leqq 0$, $W_\varepsilon(u_\varepsilon, e_i') \leqq 0$.

Indeed, this follows from Lemma 3.5.

LEMMA 6.5. *For any* $\delta > 0$, $N > 0$, *there exists a positive constant* $c_0 = c_0(\delta, N)$ *such that for any* $(\eta, \alpha, \beta) \in K$ (K *as in* (4.6)) *and* $u \in C^1[0, T]$ *with* $0 \leqq u(0) \leqq \beta - \eta$, $\|\dot{u}\|_\infty \leqq N$, *either*

$$W(u, e)(t) \leqq \delta \quad \forall 0 \leqq t \leqq T, \tag{6.5}$$

or

$$\int_0^{T-\delta} W(u, e_2')(t)\, dt \leqq -c_0, \tag{6.6}$$

where

$$e(\rho_1, \rho_2) = \frac{1}{\eta^2}\sigma\left(\frac{\rho_1 - \alpha}{\eta}, \frac{\rho_2 - \beta}{\eta}\right) \tag{6.7}$$

and e_2' *is defined by* (6.4).

Proof. We may assume that $\delta < \frac{1}{2}$. Suppose (6.5) is not true. Since the initial state is $\psi_0 \equiv 0$ so that $W(u, e)(0) = 0$, there must exist a first time $t = t_*$ such that $W(u, e)(t_*) \geqq \delta$. The internal state $\psi(t_*)$ (at $t = t_*$) in the Preisach plane (ρ_1, ρ_2) is a horizontal segment; see Fig. 3. Since

$$\begin{aligned} W(u, e)(t_*) &= \frac{1}{\eta^2}\int_{A^-(t_*)} \sigma\left(\frac{\rho_1 - \alpha}{\eta}, \frac{\rho_2 - \beta}{\eta}\right) d\rho_1\, d\rho_2 \\ &= \int_{A_0^-} \sigma(\rho_1 - \alpha, \rho_2 - \beta)\, d\rho_1\, d\rho_2 = \delta \qquad \left(A_0^\pm = \frac{1}{\eta} A^\pm(t_*)\right), \end{aligned}$$

it follows that

$$\text{meas } A_0^+ = \theta \text{ meas } A_0^- \quad \text{where } \theta = \theta(\delta) \in (0, 1); \tag{6.8}$$

θ is independent of η, α, β.

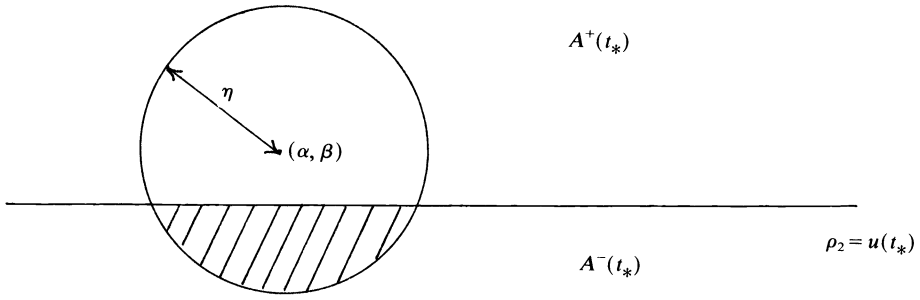

FIG. 3

Recalling that

$$\frac{\partial}{\partial \rho_2}\sigma(\rho_1, \rho_2) < 0 \quad (>0) \quad \text{if } \rho_1^2 + \rho_2^2 < 1 \quad \text{and } \rho_2 > 0 \quad (\rho_2 < 0), \tag{6.9}$$

and using (6.8), we can then estimate

$$\begin{aligned} W(u, e_2')(t_*) &= \int_{A^-(t_*)} e_2'(\rho_1, \rho_2)\, d\rho_1\, d\rho_2 \\ &= -\frac{1}{\eta}\int_{A_0^-} D_2\sigma(\rho_1 - \alpha, \rho_2 - \beta)\, d\rho_1\, d\rho_2 \leqq -\frac{c}{\eta} \qquad (c>0), \end{aligned} \tag{6.10}$$

where c is independent of η, α, β.

From (2.21) we see that the internal states $\psi(t)$ and $\psi(t_*)$ satisfy

$$\|\psi(t) - \psi(t_*)\| \leqq C|t - t_*|.$$

Therefore

$$|W(u, e_2')(t) - W(u, e_2')(t_*)| \leqq \int_{A_\eta} |\tilde{T} e_2'| \tag{6.11}$$

where A_η is the intersection of a disc with radius η with a polygonal strip of width $C|t - t_*|$ in the (r, s)-plane. Substituting $r \to r\eta$, $s \to s\eta$ we can estimate the right-hand side of (6.11) by $C|t - t_*|/\eta^2$, and then, by (6.10),

$$W(u, (\cdot), e_2')(t) < -\frac{c}{2\eta} \quad \text{if } |t - t_*| \leqq \frac{c}{2C}\,\eta. \tag{6.12}$$

The assertion (6.6) now follows from Lemma 6.4 and (6.12).

We finally state an extension of Lemma 6.5 to W_ε.

LEMMA 6.6. *For any $\delta > 0$, $N > 0$ there exist $c_0 = c_0(\delta, N) > 0$ and $\varepsilon_0 = \varepsilon(\delta, N, \eta) > 0$ such that for any $(\eta, \alpha, \beta) \in K$, $u \in C^1[0, T]$ with $0 \leqq u(0) \leqq \beta - \eta$, $\|\dot{u}\|_\infty \leqq N$, either*

$$W_\varepsilon(u(\cdot), e)(t) \leqq \delta \quad \forall 0 \leqq t \leqq T, \tag{6.13}$$

or

$$\int_0^{T-\delta} W_\varepsilon(u(\cdot), e_2')(t)\, dt \leqq -c_0, \tag{6.14}$$

provided $\varepsilon < \varepsilon_0$.

Proof. We apply Lemma 6.5 with δ replaced by $\delta/2$ and then use (3.15) to deduce that if $C_0\sqrt{\varepsilon} < \delta/2$ then either (6.13) holds or else (6.6) holds. Next, by (3.15) and (3.7),

$$\int_0^T |W_\varepsilon(u(\cdot), e_2') - W(u(\cdot), e_2')| \leqq \frac{C}{\eta^2} \|F_\varepsilon(u, \psi_0) - F(u, \psi_0)\|_\infty \leqq \frac{C_1\sqrt{\varepsilon}}{\eta^2}.$$

From this inequality and (6.6) we deduce the inequality (6.14).

7. Properties of the optimal control. The results of §§ 5 and 6 can be used to derive properties for the optimal control v_*. For simplicity we illustrate this in the case where η and α are fixed, whereas β is the only control variable, and $-\alpha + \eta \leqq \beta \leqq 1 - \eta$. We assume that

$$J(v) = \int_0^T \Phi(u(0, t), t)\, dt + \mu h_0(\beta) \tag{7.1}$$

where

$$\begin{aligned} &\Phi_u(u, g(t)) \geqq \gamma > 0 \quad \text{if } u \geqq 0, \quad 0 \leqq t \leqq T, \\ &h_0'(\beta) > 0 \quad \text{if } 0 \leqq \beta \leqq 1 \end{aligned} \tag{7.2}$$

and μ is a positive constant. As before we fix $\psi_0 \equiv 0$. We also assume that $u(0, 0) \leqq \alpha$.

Denote by β_*, u_* the solution to problem (P) with J given by (7.1), and by β_ε, u_ε the corresponding solution of problem (P_ε). The optimality conditions (5.8) become

$$\int_0^T p_\varepsilon(a, t)\, W_\varepsilon(u_\varepsilon(0, \cdot), e_1')(t)\, dt + \mu h_0'(\beta_\varepsilon) + 2(\beta_\varepsilon - \beta_*) \geqq 0 \quad \text{if } \beta_\varepsilon < 1 - \eta. \tag{7.3}$$

THEOREM 7.1. *For any small δ there exists a (small) $\mu_0 > 0$ depending only on δ, γ, a, T and $\|h_0'\|_\infty$ such that if $\mu < \mu_0$ then*

$$W(u_*(0, \cdot), e_*)(t) < \delta \quad \forall 0 \leqq t \leqq T, \tag{7.4}$$

provided $\beta_* < 1 - \eta$.

Taking $\Phi(u, g) = |u - g(t)|^2$, Theorem 7.1 can be interpreted as follows. If the desired temperature $g(t)$ is lower than any achievable temperature u and if the cost μh_0 of cooling is small ($\mu < \mu_0$) then, in the optimal situation, the thermostat is either set at $\beta = 1 - \eta$ so as to cool the rod at $x = a$ as much as possible, or it is set at such value of β so that essentially no heating will occur at $x = a$ (i.e., (7.4) holds).

Proof. Representing $p_\varepsilon(x, t)$ by Green's function and using the estimate $\Phi_u \geqq \gamma > 0$ and Lemmas 6.1, 6.2, we find that

$$p_\varepsilon(a, t) \geqq \int_0^t G(a, t; 0, \tau) \Phi_u(u_\varepsilon(0, \tau), \tau)\, d\tau \geqq c_1 t,$$

with $c_1 > 0$. If (6.14) holds, then upon using Lemma 6.4 we derive the inequality

$$\int_0^T W_\varepsilon(u_\varepsilon(0,), e_2')(t) p_\varepsilon(a, t)\, dt \leqq -c_2 < 0,$$

which is a contradiction to (7.3) if $\beta_\varepsilon < 1 - \eta$ and $\mu < \mu_0$, μ_0 small. Thus by Lemma 6.6 (here we use the assumptions that $u(0, 0) \leqq \alpha \leqq \beta - \eta$) it follows that (6.13) must be satisfied if $\beta_\varepsilon < 1 - \eta$ and, consequently, (7.4) must hold if $\beta_* < 1 - \eta$.

Remark 7.1. As η decreases (7.4) continues to hold provided $\beta_* = \beta_*(\eta) < 1 - \eta$. However, we cannot deal directly with the case $\eta = 0$ (i.e., with the case where the Preisach measure is a Dirac measure).

8. Generalizations. The results of §§ 4–7 extend to other functionals such as

$$J(v)=\int\int_{Q_T}\Phi(u(x,t),x,t)\,dx\,dt+h(v) \tag{8.1}$$

or

$$J(v)=\int_0^a \Phi(u(x,T),x)\,dx+h(v). \tag{8.2}$$

Thus in case (8.1) we formally replace (1.10) by

$$\begin{aligned} &p_t+p_{xx}=\Phi_u(u_*(x,t),x,t) \quad \text{in } Q_T,\\ &p(x,T)=0, \qquad 0<x<a,\\ &-p_x(x,0)=[D_uW^*p(a,\cdot)](t), \qquad 0<t<T,\\ &p_x(a,t)+p(a,t)=0, \qquad 0<t<T \end{aligned} \tag{8.3}$$

and $p(x,t)>0$ if $\Phi_u<0$; the optimality conditions (1.12) remain valid and the assertion of Theorem 7.1 continues to hold.

The results of §§ 4–7 extend to models whereby (1.4) is replaced by

$$u_x(a,t)+u(a,t)=m(t)+W(u(x_0,\cdot),Bv)(t) \tag{8.4}$$

with $m(t)$ a given function and $x_0=0$ or $x_0=a$. The case $x_0=a$ may be interpreted as a generalized cooling law with hysteresis.

In the above problems we may also take $Bv\equiv e$ fixed and consider the function $k(t)$ (in (1.3)) as the control variable, say in the class

$$K=\left\{0\leqq k(t)\leqq 1,\ \int_0^T k(t)\,dt=N\right\},$$

where $T>N$. Assuming $\Phi_u<0$ we find, for the solution p_ε of the corresponding adjoint problem of (P_ε), that

$$\int_0^T p_\varepsilon l\leqq 2\int_0^T (k_\varepsilon-k_*)l \quad \text{if } k_*+\lambda l\in K \quad \forall\lambda>0,\ \lambda \text{ small}.$$

Since $\int|k_\varepsilon-k_*|^2\to 0$ as $\varepsilon\to 0$, it follows that except for a subset of $[0,T]$ of measure $\leqq\eta_\varepsilon$

$$\begin{aligned} &k_\varepsilon=1 \quad \text{on } \{p_\varepsilon>\gamma_\varepsilon+\eta_\varepsilon\},\\ &k_\varepsilon=0 \quad \text{on } \{p_\varepsilon<\gamma_\varepsilon-\eta_\varepsilon\} \end{aligned} \tag{8.5}$$

for some number γ_ε, and $\eta_\varepsilon\to 0$ if $\varepsilon\to 0$. If we can show that the sets $\{a<p_\varepsilon<b\}$ have uniformly small measures as $b-a$ becomes small, then (8.5) would yield a bang-bang principle.

Consider finally a model where the last condition in (0.1) is replaced not by (1.4) but by

$$u_x(a,t)+u(a,t)=1-W(u(0,\cdot),Bv)(t) \tag{8.6}$$

(W appears here with negative coefficient). This represents the standard thermostat control. For this case we can still solve the adjoint problem for p_ε; however, the boundary condition

$$p_x(0,t)=W_u^*(u(0,\cdot),e)p(a,t)+\Phi_u(u(0,t),t) \tag{8.7}$$

is such that we cannot establish that p_ε has a fixed sign, no matter what Φ_u is. Therefore we are unable to derive specific properties of the optimal control for this model.

CONVERGENCE OF FINITE ELEMENT APPROXIMATIONS TO STATE CONSTRAINED CONVEX PARABOLIC BOUNDARY CONTROL PROBLEMS*

WALTER ALT† AND UWE MACKENROTH†

Abstract. This paper is concerned with the numerical solution of state constrained parabolic boundary control problems by finite element approximations. Error estimates for the optimal values, and in the coercive case for the optimal solutions, are derived. These estimates are used to prove convergence results under rather weak assumptions. In the noncoercive case a bang-bang principle is shown to obtain convergence results for the discrete controls also. A discussion of several numerical examples concludes the paper.

Key words. optimal control, state constraints, numerical solution, finite element method

AMS(MOS) subject classifications. 49D15, 65K10

1. Introduction. In this paper we are concerned with optimal control problems governed by a parabolic differential equation of the following kind:

$$\frac{\partial y}{\partial t} + Ay = 0, \tag{1.1}$$

$$\alpha y|_\Sigma + \beta \frac{\partial y}{\partial n_A} = u, \tag{1.2}$$

$$y(0) = 0. \tag{1.3}$$

Here, A denotes the second order elliptic operator

$$A := -\sum_{i,j=1}^{n} \frac{\partial}{\partial x_i}\left(a_{ij}\frac{\partial}{\partial x_j}\right) + a_0$$

with smooth coefficients a_{ij}, a_0, which are assumed to be defined on the closure of a bounded open domain $\Omega \subset \mathbb{R}^n$ with smooth boundary Γ. In addition we suppose that

$$a_{ij} = a_{ji}, \qquad i,j = 1, \cdots, n,$$

$$\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geqq c \sum_{i=1}^{n} \xi_i^2 \qquad \forall x \in \bar{\Omega}, \quad \forall \xi \in \mathbb{R}^n.$$

Let $\alpha \geqq 0$, $\beta \geqq 0$ be such that $\alpha + \beta \neq 0$ and define $\Sigma :=]0, T] \times \Gamma$ with fixed $T > 0$. It is well known that under these conditions, (1.1)-(1.3) have for each $u \in L^\infty(\Sigma)$ a unique solution $y = y(u)$ in $C([0, T]; L^2(\Omega))$ depending continuously on u.

Moreover, let $\nu \geqq 0$, $\rho_1 < \rho_2$, $y_T \in L^2(\Omega)$, and for all $t \in [0, T]$, let a closed convex set $C(t) \subset L^2(\Omega)$ be given. Independent of the considered space, we denote the L^2-norm on this space by $\|\cdot\|$. We are now in a position to introduce the following parabolic optimal control problem.

(P) Minimize $\|y(T) - y_T\|^2 + \nu\|u\|^2$

subject to

$u \in L^\infty(\Sigma)$, $y \in C([0, T]; L^2\Omega))$ such that (1.1)-(1.3) hold and

$\rho_1 \leqq u(t) \leqq \rho_2 \quad \forall' t \in [0, T]$,

$y(t) \in C(t) \qquad \forall t \in [0, T]$.

A typical example for $C(t)$ is given by

$$C(t) = \{v \in L^2(\Omega) \,|\, (v, g_\nu) \leqq \alpha_\nu(t),\ \nu = 1, \cdots, l\}$$

with $g_1, \cdots, g_l \in L^2(\Omega)$ and real-valued functions α_ν ($(\cdot, \cdot)$ denotes the scalar product of an L^2-space).

The main feature of problem (P) is the presence of a state constraint. There is already a rather long list of investigations on parabolic optimal control problems with a state constraint. We mention here only Barbu and Precupanu [2], Lasiecka [6], Mackenroth [9], [10], [12], and Tröltzsch [18]. These papers are mainly concerned with theoretical aspects such as characterization and qualitative behaviour of optimal controls. In contrast to this, we are concerned with numerical approximations of the optimal values and the optimal solutions.

Parabolic optimal control problems without state constraints are analyzed with respect to numerical solutions in great detail. In the coercive case ($\nu > 0$), the optimal control is in a certain sense regular, and therefore it is possible to derive rates of convergence for numerical approximations (cf. Lasiecka [7], Malanowski [14]). However, no general regularity conditions are known for the bang-bang case ($\nu = 0$), and as a consequence, only convergence in the L^p-norm without convergence rates can be shown (cf. Lasiecka [8], Knowles [5]). Thus, since for the state constrained problem (P) no regularity results are available, we cannot expect to get more than mere convergence. For different, but in some sense related, aspects of the theory, compare also Fattorini [4] and Tröltzsch [19].

The plan of the paper is as follows. In § 2 we put the problem into a more general framework and introduce discretizations in a rather abstract setting. Without requiring additional effort, this leads to a more transparent argumentation and, of course, to more generality; the general results could, for instance, also be applied to hyperbolic control problems. The main result of this section is Theorem 2, where error estimates for the optimal values and the optimal controls are given.

In § 3 we introduce a semidiscretization of (P). More precisely, only the space variable will be discretized while the time variable remains continuous. The finite element method is used to approximate both the controls and the states. An application of Theorem 2 then shows that under reasonable assumptions we obtain convergence for the optimal values and also in the coercive case for the optimal solutions. It is quite obvious that these results depend on the convergence properties of the finite element method for the partial differential equation (1.1)-(1.3). In this context we shall make use of convergence results given by Lasiecka [8] for Dirichlet boundary conditions and by Knowles [5] for Neumann and mixed boundary conditions.

In the noncoercive case, the general theory of § 2 only gives convergence of the optimal values. In § 4 we therefore use a more refined analysis to prove a bang-bang principle for the state constraint problem (P). Then it can be shown that, roughly speaking, the discrete optimal controls converge to the optimal control u_0 of (P) on the set $M \times \Gamma$, where M is the set of all $t \in [0, T]$ where the state constraint is not active.

The last section is entirely devoted to the discussion of numerical examples. The numerical results show that the described method leads within a reasonable computing time to a good approximation of the optimal value and the optimal control.

2. Error estimates for discretizations of an abstract control problem. Let U, Z be Banach spaces, E, W Hilbert spaces, $U_{ad} \subset U$, $K \subset Z$ closed convex sets, and let S be a linear continuous operator from U into $Z \times E$ (i.e., $S \in \mathscr{L}(U, Z \times E)$). Moreover, suppose that $U \subset W$ holds with continuous injection and assume that U is the dual

space of a separable Banach space $\tilde{U}$ such that $S^*(Z^* \times E^*) \subset \tilde{U}$. Then, with $\nu \geqq 0$, $y_T \in E$ we consider the following abstract optimal control problem.

($\hat{\mathrm{P}}$) Minimize $\| p_2 S_u - y_T \|_E^2 + \nu \| u \|_W^2$

subject to

$u \in U_{ad}, \qquad p_1 S_u \in K.$

By p_1 (respectively, p_2) we denote the canonical projection of $Z \times E$ onto Z (respectively, E). The proof of the following lemma is standard.

LEMMA 2.1. *Suppose U_{ad} is bounded or $\nu > 0$, $U = W$, and the feasible set is nonempty. Then* (P) *has an optimal solution u_0 which is unique for $\nu > 0$.*

The Slater condition will be needed for the optimality conditions as well as for the error estimates.

(SL) There is an $\bar{u} \in U_{ad}$ such that $p_1 S\bar{u} \in \operatorname{int} K$.

For $x \in X$, $\lambda \in X^*$ (X a Banach space) let $\langle x, \lambda \rangle := \lambda(x)$ and

$$f(u) := \| p_2 Su - y_T \|_E^2 + \nu \| u \|_W^2 \qquad \forall u \in U.$$

The next lemma is also well known.

LEMMA 2.2. *Suppose that* (SL) *is fulfilled. Then $u_0 \in U$ is optimal for* (P) *if and only if u_0 is feasible and there is a $\zeta \in Z^*$ such that*

$$\langle u - u_0, f'(u_0) + (p_1 S)^* \zeta \rangle \geqq 0 \qquad \forall u \in U_{ad}, \tag{2.1}$$

$$\langle p_1 Su_0 - z, \zeta \rangle \geqq 0 \qquad \forall z \in K. \tag{2.2}$$

This lemma will be needed for the error estimates. By calculating the derivative f', it is possible to characterize u_0 more explicitly. We have

$$\langle u, f'(u_0) \rangle = 2\langle u, (p_2 S)^*(p_2 Su_0 - y_T) \rangle + 2\nu \langle u, u_0 \rangle_W \quad \forall u \in U. \tag{2.3}$$

This implies

$$f''(u_0)(u, u) \geqq 2\nu \langle u, u \rangle_W \quad \forall u \in U. \tag{2.4}$$

Hence Lemma 2.2 can also be formulated in the following way.

LEMMA 2.3. *Suppose that* (SL) *is fulfilled. Then $u_0 \in U$ is optimal for* (P) *if and only if u_0 is feasible and there is a $\zeta \in Z^*$ such that for $w := S^*(\zeta, 2(p_2 Su_0 - y_T))$ the inequalities* (2.2) *and*

$$\langle u - u_0, w + 2\nu u_0 \rangle \geqq 0 \quad \forall u \in U_{ad} \tag{2.5}$$

are fulfilled.

We now introduce abstract discretizations for (P). To this end, let for every $i \in \mathbb{N}$ closed convex sets $U_{ad}^i \subset U$, $K_i \subset Z$ and an operator $S_i \in \mathcal{L}(U, Z \times E)$ with the property $S_i^*(Z^* \times E^*) \subset \tilde{U}$ be given. Then we define

($\hat{\mathrm{P}}_i$) Minimize $\| p_2 S_i u - y_T \|_E^2 + \nu \| u \|_W^2$

subject to

$u \in U_{ad}^i, \qquad p_1 S_i u_i \in K_i.$

For every $i \in \mathbb{N}$ let

$$D_i := \{ u \in U \mid p_1 S_i u \in K_i \},$$

and

$$D := \{u \in U \mid p_1 S_u \in K\}.$$

The proof of the following lemma is based on the proof of Theorem 2 in Robinson [15].

LEMMA 2.4. *Suppose that the following conditions are fulfilled.*

(i) *For the element* $\bar{u}$ *of* (SL) *there exists a sequence* $\{\bar{u}_i\}_{i\in\mathbb{N}}$ *such that* $\bar{u}_i \in U_{ad}^i$ *for all* $i \in \mathbb{N}$, $\lim_{i\to\infty} \|\bar{u}_i - \bar{u}\|_U = 0$ *and* $\lim_{i\to\infty} \|p_1 S_i \bar{u}_i - p_1 S\bar{u}\|_Z = 0$.

(ii) $K \subset K_i$ *for all* $i \in \mathbb{N}$.

Let now $u_0 \in U_{ad} \cap D$ *and a sequence* $\{u_i\}_{i\in\mathbb{N}}$ *with* $\lim_{i\to\infty} \|u_i - \bar{u}\|_U = 0$ *and* $u_i \in U_{ad}$ *for all* $i \in \mathbb{N}$ *be given. Then there are* $i_0 \in \mathbb{N}$, $c > 0$ *such that for all* $i \geqq i_0$ *there exists a* $v_i \in U_{ad}^i \cap D_i$ *with*

$$\|v_i - u_0\|_U \leqq \|u_i - u_0\|_U + c\|p_1 S_i u_i - p_1 S u_0\|_Z.$$

Proof. Let $\hat{S} := p_1 S$, $\hat{S}_i := p_1 \hat{S}_i$. By assumption (i) there are $\mu > 0$, $i_0 \in \mathbb{N}$ with $\hat{S}\bar{u} - \mu B \subset K$ and

$$\|\hat{S}_i \bar{u}_i - \hat{S}\bar{u}\|_Z \leqq \frac{\mu}{2} \quad \forall i \geqq i_0$$

(B denotes the unit ball of Z). This implies

$$\hat{S}_i \bar{u}_i - \frac{\mu}{2} B \subset S\bar{u} - \mu B \subset K \quad \forall i \geqq i_0.$$

Thus, from (ii) we get for $\eta := \dfrac{\mu}{2}$

$$\hat{S}_i \bar{u}_i - \eta B \subset K_i \quad \forall i \geqq i_0.$$

Now let $u_0 \in U_{ad} \cap D$ and a sequence $\{u_i\}_{i\in\mathbb{N}}$ such that $u_i \in U_{ad}^i$ for all $i \in \mathbb{N}$ and $\lim_{i\to\infty} \|u_i - u_0\|_U = 0$ be given. Let $i \geqq i_0$. If $\hat{S}_i u_i \in K_i$ define $v_i := u_i$. If $\hat{S}_i u_i \notin K_i$, define $d_i := d(\hat{S}_i u_i, K_i)$. Then for arbitrary $\delta > 0$ there is a $k_\delta \in K_i$ such that for $z_\delta := \hat{S}_i u_i - k_\delta$ the inequalities

$$0 < \|z_\delta\|_Z < d_i + \delta$$

hold. For $\varepsilon \in]0, \delta[\cap]0, \eta[$ we define $z_\varepsilon := -(\eta - \varepsilon)\|z_\delta\|_Z^{-1} z_d$. It follows $\|z_\varepsilon\|_Z = \eta - \varepsilon < \eta$, thus $z_\varepsilon \in \eta B$. Hence there is a $k_\varepsilon \in K_i$ such that $z_\varepsilon = \hat{S}_i \bar{u}_i - k_\varepsilon$. With $\lambda := [1 + (\eta - \varepsilon)\|z_\delta\|_Z^{-1}]^{-1}$ we obtain $0 < \lambda < 1$ and

$$\begin{aligned}\hat{S}_i((1-\lambda)u_i - \lambda\bar{u}_i) - ((1-\lambda)k_\delta - \lambda k_\varepsilon) &= (1-\lambda)(\hat{S}_i u_i - k_\delta) + \lambda(\hat{S}_i \bar{u}_i - k_\varepsilon) \\ &= (1-\lambda)z_\delta + \lambda z_\varepsilon = 0.\end{aligned}$$

For $v_i = (1-\lambda)u_i + \lambda\bar{u}_i$, $k_i = (1-\lambda)k_\delta + \lambda k_\varepsilon$, this implies $v_i \in U_{ad}^i$, $\hat{S}_i v_i = k_i \in K_i$ and therefore $v_i \in U_{ad}^i \cap D_i$. Further, we have

$$\|u_i - v_i\|_U = \|u_i - (1-\lambda)u_i - \lambda\bar{u}_i\|_U = \lambda\|u_i - \bar{u}_i\|_U.$$

Since the sequences $\{u_i\}_{i\in\mathbb{N}}$, $\{\bar{u}_i\}_{i\in\mathbb{N}}$, are bounded, there is a $c > 0$ with

$$\|u_i - \bar{u}_i\|_U \leqq c \quad \forall i \geqq i_0.$$

Because of $\lambda \leqq (\eta - \varepsilon)^{-1}\|z_\delta\|$, $\|z_\delta\| \leqq d_i + \delta$ we get

$$\|v_i - u_0\|_U \leqq \|u_i - u_0\|_U + \lambda\|u_i - \bar{u}_i\|_U \leqq \|u_i - u_0\|_U + \frac{c}{\eta - \varepsilon}(d(\hat{S}_i u_i, K_i) + \delta).$$

Since $\hat{S}u_0 \in K \subset K_i$ the proof is completed by letting δ and ε approach zero. □

LEMMA 2.5. *Suppose that* (SL) *holds. Then there exists* $c>0$ *such that for all* $u\in U_{ad}$ *there is a* $\tilde{u}\in U_{ad}\cap D$ *with*

$$\|u-\tilde{u}\|_U \leqq c\|u-\bar{u}\|_U\, d(p_1Su, K).$$

Proof. Define the multivalued function $F: U\to Z$ by

$$F(u) := \begin{cases} p_1 Su - K & \text{if } u\in U_{ad},\\ \varnothing & \text{if } u\notin U_{ad}.\end{cases}$$

Then F is a closed convex function, and by the assumptions of the lemma there exists $\eta>0$ with $\eta B\subset F(\bar{u})$. The assertion of the lemma is therefore a special case of Theorem 2 in Robinson [15]. □

The following Proposition is an immediate consequence of Lemma 2.1 and Lemma 2.4.

PROPOSITION 2.1. *Let the assumptions of Lemma* 2.1 *and Lemma* 2.4 *be fulfilled. Then there is an* $i_0\in\mathbb{N}$ *such that for all* $i\geqq i_0$ *the discrete problem* $(\hat{P}_i)$ *has an optimal solution.*

In the following we denote by c a generic constant. Let

$$f_i(u) := \|p_2S_iu - y_T\|_E^2 + \nu\|u\|_W^2 \quad \forall u\in U.$$

THEOREM 2.1. *In addition to the assumptions of Lemma* 2.1 *and Lemma* 2.4, *suppose that the following assertions hold.*

(i) $U_{ad}^i\subset U_{ad}\quad \forall i\in\mathbb{N}$.

(ii) *If* $M\subset U_{ad}$ *is bounded then* $\{S_iu \mid u\in M\}$ *is also bounded.*

Now let $\{w_i\}_{i\in\mathbb{N}}$ *be a sequence with* $w_i\in U_{ad}^i$ *for all* $i\in\mathbb{N}$ *and* $\lim_{i\to\infty}\|w_i-u_0\|_U=0$. *Then there are* $i_0\in\mathbb{N}$, $c>0$, *and a bounded sequence* $\{v_i\}_{i\geqq 0}$ *with* $v_i\in U_{ad}^i$, $p_1S_iv_i\in K_i$ *for all* $i\geqq i_0$ *such that the following error estimates hold for the optimal solutions* u_0 *of* $(\hat{P})$ *and* u_i *of* $(\hat{P}_i)$ $(i\geqq i_0)$:

(a) $f_i(u_i)-f(u_0)\leqq c\|p_2S_iv_i-p_2Sv_i\|_E + c\|p_1S_iw_i-p_1Sw_i\|_Z + c\|w_i-u_0\|_U$,

(b) $f(u_0)-f_i(u_i)\leqq c\|S_iu_i-Su_i\|_{Z\times E} + c\,d(p_1S_iu_i, K)$,

(c) $\nu\|u_i-u_0\|_W^2\leqq f_i(u_i)-f(u_0)+c\|S_iu_i-Su_i\|_{Z\times E}+c\,d(p_1S_iu_i, K)$.

Proof. Suppose $u_1, u_2\in U$ and define

$$\sigma := \max\{\|u_1\|_W, \|u_2\|_W, \|p_2S_iu_1\|_E, \|p_2S_iu_2\|_E\}.$$

Then it can be easily seen that

$$|f_i(u_1)-f(u_2)|\leqq c\sigma\|p_2S_iu_1-p_2Su_2\|_E + c\sigma\|u_1-u_2\|_W. \tag{2.6}$$

From Lemma 2.4 we deduce the existence of an $i_0\in\mathbb{N}$ such that for all $i\geqq i_0$ there is a $v_i\in U_{ad}^i$ with $p_1S_iv_i\in K_i$ and

$$\|v_i-u_0\|_U\leqq\|w_i-u_0\|_U + c\|p_1S_iw_i-p_1Su_0\|_Z.$$

This implies in particular that the sequence $\{v_i\}_{i\geqq i_0}$ is bounded. Thus, from (2.6) we get

$$|f_i(v_i)-f(u_0)|\leqq c\|p_2S_iv_i-p_2Su_0\|_E + c\|v_i-u_0\|_U.$$

Hence we obtain

$$\begin{aligned} f_i(u_i)-f(u_0) &\leqq f_i(v_i)-f(u_0)\\ &\leqq c\|p_2S_iv_i-p_2Sv_i\|_E + c\|v_i-u_0\|_U\\ &\leqq c\|p_2S_iv_i-p_2Sv_i\|_E + c\|p_1S_iw_i-p_1Su_0\|_Z + c\|w_i-u_0\|_U\\ &\leqq c\|p_2S_iv_i-p_2Sv_i\|_E + c\|p_1S_iw_i-p_1Sw_i\|_Z + c\|w_i-u_0\|_U. \end{aligned}$$

This shows inequality (a).

Lemma 2.5 shows that for every $i \in \mathbb{N}$ there is a $\tilde{u}_i \in U_{ad}$ with $p_1 S\tilde{u}_i \in K$ and

$$\|u_i - \tilde{u}_i\|_U \leqq c\|u_i - \bar{u}\|_U \, d(p_1 S u_i, K).$$

Thus, since U_{ad} is bounded, the sequence $\{u_i\}_{i \geqq i_0}$ is bounded, and we get

$$\|u_i - \tilde{u}_i\|_U \leqq c\, d(p_1 S u_i, K) \leqq c\|p_1 S_i u_i - p_1 S u_i\|_Z + c\, d(p_1 S_i u_i, K). \tag{2.7}$$

In particular $\{\tilde{u}_i\}_{i \geqq i_0}$ is bounded. Hence (2.6) shows

$$|f_i(u_i) - f(\tilde{u}_i)| \leqq c\|p_2 S_i u_i - p_2 S\tilde{u}_i\|_E + c\|u_i - \tilde{u}_i\|_U.$$

Thus we get the estimates

$$\begin{aligned} f(u_0) - f_i(u_i) &\leqq f(\tilde{u}_i) - f_i(u_i) \\ &\leqq c\|p_2 S_i u_i - p_2 S\tilde{u}_i\|_E + c\|u_i - \tilde{u}_i\|_U \\ &\leqq c\|p_2 S_i u_i - p_2 S u_i\|_E + c\|u_i - \tilde{u}_i\|_U \\ &\leqq c\|S_i u_i - S u_i\|_{Z \times E} + c\, d(p_1 S_i u_i, K). \end{aligned}$$

It remains to show (c). Let ζ be as in Lemma 2.2. Then we get from (2.1) and (2.4)

$$\begin{aligned} &f(u_i) + \zeta p_1 S(u_i) - (f(u_0) + \zeta p_1 S(u_0)) \\ &\quad = (f'(u_0) + (p_1 S)^* \zeta)(u_i - u_0) + \tfrac{1}{2} f''(u_0)(u_i - u_0, u_i - u_0) \geqq \nu \|u_i - u_0\|_W^2. \end{aligned}$$

Because of $p_1 S\tilde{u}_i \in K$, the inequalities (2.2), (2.6), (2.7) imply

$$\begin{aligned} &f(u_i) + \zeta p_1 S(u_i) - (f(u_0) + \zeta p_1 S(u_0)) \\ &\quad = f(u_i) - f(u_0) + \zeta p_1 S(u_i) - \zeta p_1 S(\tilde{u}_i) - \zeta(p_1 S u_0 - p_1 S\tilde{u}_i) \\ &\quad \leqq f(u_i) - f(u_0) + \zeta p_1 S(u_i - \tilde{u}_i) \\ &\quad \leqq f(u_i) - f_i(u_i) + f_i(u_i) - f(u_0) + c\|u_i - \tilde{u}_i\|_U \\ &\quad \leqq f_i(u_i) - f(u_0) + c\|p_2 S_i u_i - p_2 S u_i\|_E + c\|p_1 S_i u_i - p_1 S u_i\|_Z + c\, d(p_1 S_i u_i, K). \end{aligned}$$ □

We just mention the special case that ($\hat{\mathrm{P}}$) contains no state constraint.

COROLLARY 2.1. *Suppose that $K = Z$ and let the assumptions of Lemma* 2.1 *and assumptions* (i) *and* (ii) *of Theorem* 2.1 *be fulfilled. Let the sequence $\{w_i\}_{i \in \mathbb{N}}$ be as in Theorem* 2.1. *Then the following estimates hold*:

(a) $f_i(u_i) - f(u_0) \leqq c\|p_2 S_i w_i - p_2 S w_i\|_E + c\|w_i - u_0\|_U$,

(b) $f(u_0) - f_i(u_i) \leqq c\|p_2 S_i u_i - p_2 S u_i\|_E$,

(c) $\nu\|u_i - u_0\|_W^2 \leqq f_i(u_i) - f(u_0) + c\|p_2 S_i u_i - p_2 S u_i\|_E$.

Remark. If (P) has neither a state nor a control constraint, then estimate (a) of Corollary 2.1 can be sharpened. We get

$$f_i(u_i) - f(u_0) \leqq c\|p_2 S_i w_i - p_2 S w_i\|_E + c\|w_i - u_0\|_W^2. \tag{2.8}$$

The proof of (2.8) is an application of Lemma 2.2 and (2.6); we get

$$\begin{aligned} f_i(u_i) - f(u_0) &\leqq f_i(w_i) - f(w_i) + f(w_i) - f(u_0) \\ &\leqq f_i(w_i) - f(w_i) + f'(u_0)(w_i - u_0) + \tfrac{1}{2} f''(u_0)(w_i - u_0, w_i - u_0) \\ &\leqq c\|p_2 S_i w_i - p_2 S w_i\|_E + c\|w_i - u_0\|_W^2. \end{aligned}$$

Together with (c) of Corollary 2.1 this implies

$$\|u_i - u_0\|_W^2 \leqq c\|p_2 S_i u_i - p_2 S u_i\|_E + c\|p_2 S_i w_i - p_2 S w_i\|_E + c\|w_i - u_0\|_W^2. \tag{2.9}$$

The square in the last term of (2.9) can also be obtained if a control constraint is present (cf. Malanowski [14]), but obviously an estimate of this kind is limited to the coercive case without state constraints.

Remark. From Theorem 2.1 we easily obtain an abstract convergence theorem for the discrete optimal values and optimal solutions; but instead of applying such a result in a concrete situation, it is more convenient to use the estimates of Theorem 2.1 directly (compare, e.g., the proof of Theorem 3.1).

3. Error estimates for discretizations of the parabolic optimal control problem. In the first part of this section we define discretizations for the problem (P). We start with the partial differential equation for $\beta \neq 0$. In this case the variational form of (1.1)-(1.3) may be used in the usual way. To this end define

$$a(v, w) := \sum_{i,j=1}^{n} \left(a_{ij} \frac{\partial v}{\partial x_i}, \frac{\partial w}{\partial x_j} \right) + (a_0 v, w) + \alpha \beta^{-1} (v|_\Gamma, w|_\Gamma) \quad \forall u, w \in H^1(\Omega).$$

Equations (1.1), (1.2) are then equivalent to

$$\frac{d}{dt}(v, y(t)) + a(v, y(t)) = (v|_\Gamma, u(t)) \quad \forall v \in H^1(\Omega), \quad \forall' t \in [0, T]. \tag{3.1}$$

Let for all $h \in]0, h_0]$, $(h_0 > 0)$ a finite dimensional subspace V_h of $H^1(\Omega)$, be given. Then there is a unique function y_h such that $y_h(t) \in V_h$ for all $t \in [0, T]$, $y_h(0) = 0$, and

$$\frac{d}{dt}(v, y_h(t)) + a(v, y_h(t)) = (v|_\Gamma, u(t)) \quad \forall v \in V_h, \quad \forall' t \in [0, T]. \tag{3.2}$$

For the subspaces V_h we make the following assumptions ($\|\cdot\|_s$ denotes the norm of $H^s(\Omega)$, respectively, $H^s(\Gamma)$):

$$\inf_{w \in V_h} \{\|v - w\| + h\|v - w\|_1\} \leqq c_s h^s \|v\|_s \quad \forall v \in H^s(\Omega), \quad \forall s \in [1, 2]; \tag{3.3}$$

$$\|w\|_1 \leqq c h^{-1} \|w\| \quad \forall w \in V_h; \tag{3.4}$$

$$\text{the family } \{V_h\}_{h \in]0, h_0]} \text{ is dense in } L^2(\Omega). \tag{3.5}$$

An example for such spaces is given by the usual piecewise linear finite element spaces.

For problem (P) the operator S of § 2 is given by

$$Su := (y(u), y(u)(T)) \quad \forall u \in U,$$

where $y(u)$ solves (1.1)-(1.3). For the space U we may choose

$$U := L^p(0, T; L^2(\Gamma)) \tag{3.6}$$

with $p = 2$ if $\beta \neq 0$ and $p > 4$ if $\beta = 0$ (cf. Washburn [16], e.g.). As we have seen above, for $\beta \neq 0$ an approximation S_h^1 of S can be defined by

$$p_1 S_h^1(u) := y_h(u) \quad \text{for all } u \in U.$$

Now let $\beta = 0$. Then an application of the finite element method is much more complicated since the variational form cannot be used and since the controls are irregular. It is possible to overcome these difficulties by applying the input formula

$$y(u)(t) = \int_0^t AS(t - \tau) Du(\tau)\, d\tau \tag{3.7}$$

as it is shown in Lasiecka [8]. We can only give a short sketch of this method and refer the reader to Lasiecka [8] for all further details.

In (3.7) $S(t)$ denotes the semigroup generated by A and D denotes the Dirichlet map

$$Dv := w, \quad \text{where } Aw = 0,\ w|_\Gamma = v.$$

The operators A, $S(t)$, D are now approximated separately. To this end, let $\{V_h\}_{h\in]0,h_0]}$ be a family of subspaces of $H^1(\Omega)$ with the following properties:

(3.8) $\{V_h\}$ is an $S_h^{4,2}(\Omega)$-system;

(3.9) $$V_h|_\Gamma \subset H^1(\Gamma);$$

(3.10) $$\inf_{w\in V_h} \{\|v-w\| + h\|v-w\|_1 + h^{1/2}\|v|_\Gamma - w|_\Gamma\| + h^{3/2}\|v|_\Gamma - w|_\Gamma\|_1\} \leqq ch^s\|v_s\| \quad \forall v\in H^s(\Omega),\ \forall s\in[2,4];$$

(3.11) $$\left\|\frac{\partial v}{\partial n_A}\right\| \leqq ch^{-1/2}\|v\|_1 \quad \forall v\in V_h;$$

(3.12) $$\|v|_\Gamma\| \leqq ch^{1/2}\|v\|_1 \quad \forall v\in V_h;$$

(3.13) $$\|v\|_1 \leqq ch^{-1}\|v\| \quad \forall v\in V_h.$$

Define (with suitable $\gamma>0$) $A_h\colon V_h\to V_h$ by

$$(A_h v, w) := a(v,w) - \left(v|_\Gamma, \frac{\partial w}{\partial n_A}\right) - \left(\frac{\partial v}{\partial n_A}, w|_\Gamma\right) + \gamma h^{-1}(v|_\Gamma, w|_\Gamma) \quad \forall v, w\in V_h.$$

Let $\{\tilde U_h^\Gamma\}_{h\in]0,h_0]}$ be a family of spaces of piecewise constant functions on Γ and define $D_h\colon \tilde U_h^\Gamma \to V_h$ by

$$(-AD_h v, Aw) + h^{-3}(v|_\Gamma - (D_h v)|_\Gamma, w|_\Gamma) = 0 \quad \forall w\in V_h.$$

Then, for $u_h\in L^p(0,T;\tilde U_h^\Gamma)$ with

$$S_h(t) := e^{-A_h t} \quad \forall t>0$$

an approximation of $y(u_h)$ can be introduced by

$$y_h(u_h)(t) = \int_0^t A_h S_h(t-\tau) D_h u_h(\tau)\, d\tau.$$

Denote by $\tilde P_h$ the orthogonal projection of $L^2(\Gamma)$ onto $\tilde U_h^\Gamma$. Then, for $\beta = 0$ we define an approximation S_h^2 of S by

$$p_1 S_h^2 u = y_h(\tilde P_h u) \quad \forall u\in U.$$

In the case of $n=1$ and $\alpha\neq 0$, $\beta\neq 0$, the Fourier series of $y(u)$, can be used to derive a practically useful approximation of S. We have for all $u\in L^q(0,T)$ with $q>2$

(3.14) $$y(u)(t) = \sum_{k=1}^{\infty} v_k(1) \int_0^t e^{-\lambda_k(t-\tau)} u(\tau)\, d\tau\, v_k.$$

Here, λ_k (respectively, v_k) denote the eigenvalues (respectively, eigenfunctions) of the corresponding elliptic eigenvalue problem. We define $y_m(u)$ by replacing "∞" in (3.14) by "m" and

$$p_1 S_m^3 u = y_m(u) \quad \forall u\in L^q(0,T).$$

We remark that $y_m(u)$ may be viewed as a discretization in t and x since, at least for simple functions u, the integrals in (3.14) can be evaluated explicitly.

It is a well-known fact that in the above situation the functions v_k are uniformly bounded with respect to the maximum norm and that the eigenvalues λ_k behave asymptotically as k^2. Thus we have for $u \in L^\infty(0, T)$

$$\|y_m(u)(t) - y(u)(t)\|^2 \leqq \sum_{k=m+1}^{\infty} \left| \int_0^t e^{-\lambda_k(t-\tau)} u(\tau)\, d\tau \right|^2 \leqq \|u\|_\infty^2 \sum_{k=m+1}^{\infty} \left| \int_0^t e^{-\lambda_k(t-\tau)}\, d\tau \right|^2$$

$$\leqq c\|u\|_\infty^2 \sum_{k=m+1}^{\infty} \frac{1}{\lambda_k^2} \leqq c\|u\|_\infty^2 \int_{m+1}^{\infty} \frac{1}{x^4}\, dx \leqq c\|u\|_\infty^2 m^{-3},$$

and finally

$$\|y_m(u)(t) - y(u)(t)\| \leqq c m^{-3/2} \|u\|_\infty. \tag{3.15}$$

In the following Proposition, ε denotes an arbitrary small positive number.

PROPOSITION 3.1. (a) *If $\beta \neq 0$ and assumptions* (3.3)-(3.5) *are satisfied then for all $u \in L^\infty(0, T; L^2(\Gamma))$, the following estimate holds*:

$$\|p_1 Su(t) - p_1 S_h^1 u(t)\| \leqq c h^{3/2-\varepsilon} \|u\|_{L^\infty(0,T;L^2(\Gamma))} \quad \forall t \in [0, T].$$

(b) *If $\beta = 0$ and assumptions* (3.8)-(3.13) *are satisfied, then for all $u \in L^\infty(0, T; \tilde{U}_h^\Gamma)$ the following estimate holds*:

$$\|p_1 Su(t) - p_1 S_h^2 u(t)\| \leqq c h^{1/2-\varepsilon} \|u\|_{L^\infty(0,T;L^2(\Gamma))} \quad \forall t \in [0, T].$$

(c) *In the case of $\alpha \neq 0$, $\beta \neq 0$, $n = 1$ we have for every $u \in L^\infty(0, T)$*

$$\|p_1 Su(t) - p_1 S_m^3 u(t)\| \leqq c m^{-3/2} \|u\|_{L^\infty(0,T)} \quad \forall t \in [0, T].$$

Proof. Assumption (a) is only a slight modification of Proposition 1 in Knowles [5].
Assumption (b) follows from Theorem 2.2.1 of Lasiecka [8].
Assumption (c) was shown in (3.15). □

We can now apply Theorem 2.1. Let U be as given in (3.6). The choice of the sets Z, E, W, $\tilde{U}$, U_{ad} is obvious. Let K be defined by $K := \{z \in Z \mid z(t) \in C(t)\ \forall t \in [0, T]\}$. Let $\{U_h^\Gamma\}_{h \in]0, h_0]}$ be a family of subspaces of $L^2(\Gamma)$ with the following properties:

(3.16) For every $h \in]0, h_0]$ the set U_h^Γ is a space of piecewise constant functions on Γ. The family $\{U_h^\Gamma\}_h$ is dense in $L^2(\Gamma)$ and $h_1 > h_2$ implies $U_{h_1}^\Gamma \subset U_{h_2}^\Gamma$.

Let p be as in the definition of U and define $U_{ad}^h := U_h \cap U_{ad}$ with $U_h := L^p(0, T; U_h^\Gamma)$. In the case of $b = 0$, we choose $\tilde{U}_h^\Gamma = U_h^\Gamma$. Further, let an approximation $C_h(t)$ of $C(t)$ be given such that

$$C(t) \subset C_h(t) \quad \forall h \in]0, h_0], \quad \forall t \in [0, T]. \tag{3.17}$$

K_h is defined analogously to K. Denote by P_t the projection of $L^2(\Omega)$ onto $C(t)$, and suppose that for $j = 1, 2$ and $X := \{p_1 S_h^j u(t) \mid u \in U_{ad},\ t \in [0, T],\ h \in]0, h_0]\}$

$$\lim_{h \to 0} \sup_{t \in [0,T]} \sup_{v \in X \cap C_h(t)} \|v - P_t v\| = 0. \tag{3.18}$$

In this way we have obtained discretizations (P_h) of (P). Herein, S is approximated as in (a), respectively, (b) of Proposition 2.1. We still mention that (P) has an optimal solution u_0.

THEOREM 3.1. *Suppose that for* (P) *the Slater condition* (SL) *is fulfilled and that* (3.3)-(3.5), *respectively,* (3.8)-(3.13) *holds. In addition let* (3.16)-(3.18) *be satisfied. Then the following assertions are valid.*

(a) *There is* $h_1 \in]0, h_0]$ *such that problem* (P_h) *has an optimal solution* u_h *for every* $h \in]0, h_1]$.

(b) $\lim_{h\to 0} \min (P_h) = \min (P)$.

(c) $\lim_{h\to 0} \|u_h - u_0\| = 0$ *if* $\nu > 0$.

Proof. By (3.16) there is a sequence $\{\hat{w}_h\}_{h>0}$ in U with $\hat{w}_h \in U_h$ for every $h > 0$ and $\lim_{h\to 0} \|\hat{w}_h - u_0\| = 0$. Let Q be the projection of $L^2(\Gamma)$ onto U_{ad} and define $w_h := Q\hat{w}_h$. Since Q is Lipschitz continuous and $u_0 \in U_{ad}$, we have $w_h \in U_{ad}$ and $\lim_{h\to 0} \|w_h - u_0\| = 0$. In the same way, it follows that there is a sequence $\{\bar{u}_h\}_{h>0}$ with $\bar{u}_h \in U_{ad}^h$ for every $h > 0$ and $\lim_{h\to 0} \|\bar{u}_h - \bar{u}\| = 0$. Thus, by Proposition 3.1 and the fact that $\|\bar{u}_h\|_{L^\infty(\Sigma)} \leqq \max\{\rho_1, \rho_2\}$ for all $h > 0$, we see that assumption (i) of Lemma 2.4 is fulfilled. Hence (3.17) and Proposition 2.1 imply (a).

Assumption (i) of Theorem 2.1 is satisfied by the definition of U_{ad}^h, and assumption (ii) of Theorem 2.1 follows from Proposition 3.1. Thus we can apply the estimates (a)-(c) of Theorem 2.1. The terms containing S and S_h^j $(j = 1, 2)$ converge to zero again by Proposition 3.1 and the uniform boundedness of the sequences $\{v_h\}$, $\{w_h\}$, $\{u_h\}$ with respect to the norm of $L^\infty(\Sigma)$. Hence assertions (b) and (c) are shown if $\lim_{h\to 0} d(p_1 S_h^j u_h, K) = 0$, but this is an immediate consequence of (3.18). □

We briefly discuss assumption (3.18) for a typical example. Let

$$C := \{v \in L^2(\Omega) \,|\, (v, g_\nu) \leqq \alpha_\nu,\ \nu = 1, \cdots, l\} \tag{3.19}$$

with $g_\nu \in L^2(\Omega)$, $\alpha_\nu \in \mathbb{R}$, $\nu = 1, \cdots, l$. Under the assumptions of Proposition 3.1, the set X is bounded by $r > 0$. With $g_{\nu h} \in L^2(\Omega)$ and

$$\varepsilon_{\nu h} := r\|g_{\nu h} - g_\nu\| \tag{3.20}$$

we define

$$C_h := \{v \in L^2(\Omega) \,|\, (v, g_{\nu h}) \leqq \alpha_\nu + \varepsilon_{\nu h},\ \nu = 1, \cdots, l\}. \tag{3.21}$$

LEMMA 3.1. *Suppose that* $\|g_{\nu h} - g_\nu\| \leqq ch^\gamma$, $\nu = 1, \cdots, l$, *with* $\gamma > 0$. *Let the sets* C, C_h *be defined by* (3.19), (3.20), *and assume there exists* $w \in C$ *with* $(w, g_\nu) < \alpha_\nu$ *for all* $\nu \in \{1, \cdots, l\}$. *Then* $X \cap C \subset X \cap C_h$ *and*

$$\sup_{v \in X \cap C_h} \|v - Pv\| \leqq ch^\gamma,$$

where P *denotes the projection of* $L^2(\Omega)$ *onto* C.

Proof. The relation $X \cap C \subset X \cap C_h$ is an immediate consequence of the definition of $\varepsilon_{\nu h}$ and the fact that

$$(v, g_{\nu h}) \leqq \|v\|\,\|g_{\nu h} - g_\nu\| + (v, g_\nu).$$

Now let $v \in X \cap C_h$ be given with $v \notin C$. Then $I = \{\nu \,|\, (v, g_\nu) > \alpha_\nu\} \neq \varnothing$. For $\nu \in I$ define

$$\lambda_\nu = ((v, g_\nu) - \alpha_\nu)((v, g_\nu) - (w, g_\nu))^{-1},$$

and

$$\lambda = \max_{\nu \in I} \lambda_\nu, \quad \mu = \min_{\nu \in I} \{\alpha_\nu - (w, g_\nu)\}, \quad z = v + \lambda(w - v).$$

This implies $0 < \lambda < 1$, $\mu > 0$,

$$(z, g_\nu) = (v, g_\nu) + \lambda((w, g_\nu) - (v, g_\nu)) \leqq (v, g_\nu) + \lambda_\nu((w, g_\nu) - (v, g_\nu)) = \alpha_\nu$$

for all $\nu \in I$, and

$$(z, g_\nu) = (v, g_\nu) + \lambda((w, g_\nu) - (v, g_\nu)) \leqq (v, g_\nu) \leqq \alpha_\nu$$

for all $\nu \notin I$. Hence $z \in C$ and therefore

$$\|v - Pv\| \leqq \|v - z\| = \lambda \|w - v\| \leqq 2r\lambda.$$

Let $\nu \in I$ such that $\lambda = \lambda_\nu$. Then

$$\begin{aligned}\lambda &\leqq ((v, g_\nu) - \alpha_\nu)\mu^{-1} = ((v, g_{\nu h}) - \alpha_\nu + (v, g_\nu) - (v, g_{\nu h})\mu^{-1} \\ &\leqq (\varepsilon_{\nu h} + r\|g_\nu - g_{\nu h}\|)\mu^{-1} \leqq 2\mu^{-1} r h^\gamma,\end{aligned}$$

which completes the proof. □

Remark. In Lemma 3.1 we have only shown $X \cap C \subset X \cap C_h$. Since we can replace C by $X \cap C$, respectively, C_h by $X \cap C_h$ without changing (P) respectively, (P_h), we get $C \subset C_h$. Furthermore, it is obvious that this lemma can be easily extended to the more general situation where the functions g_ν and α_ν are time dependent.

We conclude this section by paying some attention to the case $n = 1$ where we obtain convergence rates due to the fact that only semidiscretizations are considered.

Let $\alpha \neq 0$, $\beta \neq 0$, let S be approximated by S_m^3, and let C, C_h be defined by (3.19)–(3.21) (where we write $g_{\nu m}$, $\varepsilon_{\nu m}$ instead of $g_{\nu h}$, $\varepsilon_{\nu h}$). This leads to a semidiscretized version (P_m) of (P), since the set of feasible controls requires no approximation here. The next theorem follows directly from Theorem 2.1 and Lemma 3.1.

THEOREM 3.2. *Let* (P), (P_m) *be as described above. Suppose that in addition to the Slater condition* (SL) *the following condition holds*:

$$\|g_{\nu m} - g_\nu\| \leqq cm^{-1}, \quad \nu = 1, \cdots, l.$$

Then for sufficiently large m the problem (P_m) *has an optimal solution* u_m. *Furthermore, the following estimate holds*:

(a) $\|\min(P_m) - \min(P)\| \leqq cm^{-1}$,

(b) $\|u_m - u_0\| \leqq cm^{-1/2}$ *if* $\nu > 0$.

Remark. 1. It is clear that Theorem 3.2 also holds for the situations described in Proposition 3.1(a), (b) (and $n = 1$).

2. As we have already mentioned, S_m^3 can be viewed as a discretization of S in t and x. This fact can be easily used to formulate a convergence theorem for a fully discretized problem in the case of one-space dimension.

4. The bang–bang case. The results of the preceding section contain no information about the convergence of the discrete optimal controls if $\nu = 0$. As we shall see, results in this direction require some knowledge about the qualitative behaviour of the optimal controls of the continuous problem (P). This is obtained by analyzing the optimality conditions. For simplicity we assume in this section that $\rho_2 = -\rho_1 = \rho > 0$.

Let $NBV(0, T; L^2(\Omega))$ be the space of all functions $v: [0, T] \to L^2(\Omega)$ vanishing at T which are of bounded variation and right continuous. It is well known that each functional $\zeta \in C([0, T]; L^2(\Omega))^*$ can be uniquely represented by a function $v_\zeta \in NBV(0, T; L^2(\Omega))$. Using this fact, the following lemma is a direct consequence of Lemma 2.3.

LEMMA 4.1. *Suppose* $\nu = 0$ *and let* (SL) *hold. Then* $u_0 \in U$ *is optimal for* (P) *if and only if* u_0 *is feasible and there is a functional* $\zeta \in C([0, T]; L^2(\Omega))^*$ *such that for* $w := S^*(\zeta, 2(p_2 Su_0 - y_T))$ *the following equations are fulfilled*:

$$u_0 w + \rho|w| = 0, \tag{4.1}$$

$$\sup_{z \in K} \int_0^T z(t)\, dv_\zeta = \int_0^T p_1 Su_0(t)\, dv_\zeta. \tag{4.2}$$

In order to get results on the structure of u_0, the equations of Lemma 4.1 must be analyzed in detail. This requires at first a precise description of S^*. To this end we quote some results of Mackenroth [9].

Each $z^* \in Z^*(Z = C([0, T]; L^2(\Omega)))$ can be written in the form

$$\langle z, z^* \rangle = (z(0), \zeta_0) + (z(T), \zeta_T) + \langle z, \hat{\zeta} \rangle \qquad \forall z \in Z \tag{4.3}$$

with $\zeta_0, \zeta_T \in L^2(\Omega)$ and a functional $\hat{\zeta} \in Z^*$ such that $v_{\hat{\zeta}}$ is continuous at zero and T (cf. Mackenroth [9, Satz 5.1]). Moreover, $\hat{\zeta}$ can be viewed as an element of $\mathcal{D}^*(]0, T[; V^*)$ (the space of distributions on $]0, T[$ with values in V^*) where

$$V := \left\{ v \in H^1(\Omega) \,|\, \alpha v|_\Gamma + \beta \frac{\partial v}{\partial n_A} = 0 \right\}.$$

Let the bilinear form a be defined as in § 3, but without the boundary term, and define the operator $\mathcal{A}$ by

$$\langle w, \mathcal{A}v \rangle = a(v, w) \quad \forall v, w \in V.$$

Then the following equation is well defined (in the sense of distributions on $\mathcal{D}^*(]0, T[; V^*)$):

$$-\frac{dp}{dt} + \mathcal{A}_p = \hat{\zeta}. \tag{4.4}$$

Moreover, it can be shown that (4.4) and

$$p(T) = 2(p_2 S u_0 - y_T) + \zeta_T \tag{4.5}$$

has a unique solution p with

$$p \in L^2(0, T; V) \cap NBV(0, T; V^*) \cap L^\infty(0, T; L^2(\Omega)) \tag{4.6}$$

(cf. Mackenroth [9, Satz 5.2, Satz 4.2], and Mackenroth [12, Thm. 5]).

LEMMA 4.2. *Let u_0, ζ, w, p be given as in Lemma* 4.1 (*respectively, as in* (4.3)-(4.5)). *Then we have*

$$w = p|_\Sigma, \qquad \text{if } \beta = 1$$

$$w = -\frac{\partial p}{\partial n_A}, \quad \text{if } \alpha = 1, \quad \beta = 0.$$

Proof. Set $S_1 := p_1 S$ and $U := L^\infty(0, T; L^2(\Gamma))$. We shall use the input formula

$$S_1 u(t) = \int_0^t AS(t - \tau) G u(\tau)\, d\tau \quad \forall t \in [0, T], \quad \forall u \in U,$$

where S denotes the semigroup associated with A. The map G is defined by $Gu := w$, where $u \in L^2(\Gamma)$ and $Aw = 0$, $\alpha w|_\Gamma + \beta(\partial w / \partial n_A) = u$. Let $v := v_{\hat{\zeta}}$. Then we get

$$\langle S_1 u, \zeta \rangle = \int_0^T \int_0^t AS(t - \tau) G u(\tau)\, d\tau\, dv = \int_0^T \int_\tau^T AS(t - \tau) G u(\tau)\, dv\, d\tau$$

$$= \int_0^T (u(\tau), \int_\tau^T (AS(t - \tau) G)^*\, dv)\, d\tau.$$

Here we have applied a vector-valued version of the Fubinis Theorem (cf. Dinculeanu [3]). This is possible since we have with $\theta = \frac{1}{4} - \varepsilon$ for $\beta \neq 0$ and $\theta = \frac{3}{4} - \varepsilon$ for $\beta = 0$ (and arbitrary small $\varepsilon > 0$)

$$\int_0^T \int_0^t \|AS(t-\tau)Gu(\tau)\| \, d\tau \, d\|v(t)\| \leqq \|u\|_U \int_0^T \int_0^t (t-\tau)^{-\theta} \, d\tau \, d\|v(t)\|$$

$$\leqq \|u\|_U \int_0^T t^{1-\theta} \, d\|v(t)\| < +\infty$$

(cf. Washburn [16]). Thus

$$S_1^* \hat{\zeta}(t) = \int_t^T (AS(\tau - t)G)^* \, dv. \tag{4.7}$$

Now let $\tilde{S}$ be defined by $\tilde{S}w := (y, y(T))$ where $w \in L^2(0, T; L^2(\Omega))$ with y satisfying (1.3) and

$$\frac{\partial y}{\partial t} + A_y = w, \qquad \alpha y|_\Sigma + \beta \frac{\partial y}{\partial n_A} = 0.$$

Then $\tilde{S}_1 := p_1 \tilde{S}$ can be written as

$$\tilde{S}_1 w(t) = \int_0^t S(t-\tau) w(\tau) \, d\tau.$$

From Mackenroth [9, Satz 5.3], we obtain $\tilde{S}^*(\hat{\zeta}) = q_1$, where q_1 is the solution of (4.4) and $q_1(T) = 0$. A computation quite similar to that made above shows

$$\tilde{S}_1^* \hat{\zeta}(t) = \int_t^T S^*(\tau - t) \, dv. \tag{4.8}$$

Let $Rw := w|_\Gamma$ for $\beta = 1$ and $Rw := -(\partial w / \partial n_A)$ for $\alpha = 1$, $\beta = 0$. Then we have (cf. Washburn [16, p. 664]) $(AS(\tau - t)G)^* = RS^*(\tau - t)$. Thus, using (4.7) and (4.8) we see

$$S_1^* \hat{\zeta} = R \int_t^T S^*(\tau - t) \, dv = Rq_1.$$

Let q_2 be the solution of

$$-\frac{dq_2}{dt} + \mathcal{A} q_2 = 0, \qquad q_2(T) = 2(p_2 S u_0 - y_T) + \zeta_T.$$

It is well known that $Rq_2 = (p_2 S)^*(2(p_2 S u_0 - y_T) + \zeta_T)$. Thus, since $p = q_1 + q_2$ the lemma is shown. □

To make the arguments in the following lemma somewhat simpler, we suppose from now on that $C(t)$ is time independent, i.e., $C(t) = C$, but this is in no way essential. For $u \in U_{ad}$ define

$$M_u := \{t \in [0, T] \mid y(u)(t) \in \operatorname{int} C\}.$$

LEMMA 4.3. *Let the situation be as in Lemma* 4.1. *Then* $v_\zeta|_{M_{u_0}} = 0$.

Proof. Set $y := y(u_0)$, $v := v_\zeta$, and let $]a, b[\subset M_{u_0}$ be given such that $[a, b] \subset M_{u_0}$. Since M_{u_0} is open, there is $\delta_0 > 0$ such that $I_{\delta_0} := [a - \delta_0, b + \delta_0] \subset M_{u_0}$. Let $z \in \dot{Z}$ be arbitrary and choose $w_\delta \in Z$ such that (with $\delta \in]0, \delta_0]$ and $I_\delta := [a - \delta, b + \delta]$)

$$w_\delta(t) := \begin{cases} w(t) & \forall t \in [a, b], \\ 0 & \forall t \in [0, T] \setminus I_\delta, \end{cases}$$

and $\|w_\delta\|_Z \leqq \|w\|_Z$. Denote by B the unit ball of $L^2(\Omega)$. There is a function $\varepsilon(t)$ on I_δ with the property

$$y(t)+\varepsilon(t)B \subset C \quad \forall t \in I_\delta$$

and ε can be chosen such that

$$\varepsilon_0 := \inf_{t\in I_\delta} \varepsilon(t) > 0.$$

For $z := y+\varepsilon_0\|w\|_Z^{-1}w_\delta$, we have $\|z(t)-y(t)\| \leqq \varepsilon_0$ if $t \in I_\delta$ and $z(t)=y(t)\in C$ if $t \in [0, T]\backslash I_\delta$, hence $z(t)\in C$ for all $t\in[0, T]$. Thus (4.2) implies

$$\int_a^b z\,dv \leqq \int_a^b y\,dv + \int_{J_\delta} (y-z)\,dv \leqq \int_a^b y\,dv + \varepsilon_0\mu_v(J_\delta)$$

with $J_\delta := I_\delta\backslash[a, b]$. μ_v denotes the regular Borel measure on $[0, T]$ associated with the function $\|v(t)\|$. Hence we have

$$\int_a^b w\,dv \leqq \|w\|_Z\mu_v(J_\delta) \quad \forall \delta \in]0, \delta_0].$$

Thus, since $\lim_{\delta\to 0}\mu_v(J_\delta)=0$, we get $\int_a^b w\,dv \leqq 0$. Since w is arbitrary, we conclude that $v|_{[a,b]}=0$. Using the fact that M_{u_0} can be written as the union of such intervals, the result follows. □

For each $u\in U_{ad}$, the set M_u can be written in the form

$$M_u := \bigcup_{i\in I}]a_i, b_i[, \tag{4.9}$$

$$]a_i, b_i[\cap]a_j, b_j[= \varnothing \quad \forall i, j \in I, \qquad i\neq j, \tag{4.10}$$

where I is a finite or countable index set. By $p(\hat{\zeta}, 2(p_2Su_0-y_T)+\zeta_T)$ we denote the solution of (4.4), (4.5). For an optimal control u_0, a functional $\zeta\in Z^*$ is called a multiplier if u_0 and ζ fulfill the equations of Lemma 4.1. With these notations the following assumption can be formulated.

(A) For each optimal control u_0 there exists a multiplier ζ such that

$$p(\hat{\zeta}, 2(p_2Su_0-y_T)+\zeta_T)(b_i-) \neq 0 \quad \forall i \in I.$$

Here, M_{u_0} is decomposed as in (4.9), (4.10). Finally we introduce the set

$$M = \{M_u \mid u \text{ is optimal}\}.$$

THEOREM 4.1. *Let $\nu=0$ and suppose that* (SL) *and* (A) *are fulfilled. Then each optimal control is bang-bang on $M\times\Gamma$, and*

$$|u_0(t,\xi)| = \rho \quad \forall'(t,\xi)\in M\times\Gamma.$$

Moreover, if u_1 is a further optimal control, then u_1 and u_0 coincide almost everywhere on $M\times\Gamma$.

Proof. Let ζ be a multiplier of u_0. Then Lemma 4.3 shows that $v|_{M_{u_0}}=0$ for $v=v_\zeta$, hence, in particular, $v|_{]a_i,b_i[}=0$ for all $i\in\mathbb{N}$. Thus (4.4) implies (with $p = p(\hat{\zeta}, 2(p_2Su_0-y_T)+\zeta_T)$

$$-\frac{\partial p}{\partial t} + Ap = 0 \qquad \text{on }]a_i, b_i[\times\Omega,$$

$$\alpha p|_\Sigma + \beta\frac{\partial p}{\partial n_A} = 0 \qquad \text{on }]a_i, b_i[\times\Gamma.$$

Suppose now that for an $i \in I$ the control u_0 is not bang-bang on $]a_i, b_i[\times \Gamma$. Then by (4.1) there is an open interval $]c, d[\subset]a_i, b_i[$ such that

$$Rp(t, \xi) = 0 \quad \forall (t, \xi) \in]c, d[\times \Gamma$$

(with R as in the proof of Lemma 4.2). Thus by Schmidt and Weck [17, Cor. 2.3] we conclude $p(t, x) = 0$ for all $(t, x) \in]a_i, b_i[\times \Omega$. This implies $p(b_i -) = 0$, which is a contradiction to assumption (A). Hence u_0 is bang-bang on $M_{u_0} \times \Gamma$.

Now let u_1 be a further optimal control. Then we have

$$\tfrac{1}{2} y(u_0)(t) + \tfrac{1}{2} y(u_1)(t) \in \operatorname{int} C \quad \forall t \in M_{u_0} \cup M_{u_1}.$$

This implies $M_{u_0} \cup M_{u_1} \subset M_{u_2}$ if we set $u_2 := \frac{1}{2} u_0 + \frac{1}{2} u_1$. Suppose that there is a set $\Sigma_0 \subset M_{u_1} \times \Gamma$ of positive measure such that $|u_0(t, \xi)| < \rho$ almost everywhere on Σ_0. Then

$$-\rho < u_2(t, \xi) = \tfrac{1}{2} u_0(t, \xi) + \tfrac{1}{2} u_1(t, \xi) < \rho \quad \text{a.e. on } \Sigma_0,$$

which is a contradiction. Hence u_0 is bang-bang on $M_{u_1} \times \Gamma$.

We assume that u_0 is not bang-bang on $M \times \Gamma$. Then there is an interval $]a, b[\subset M$ such that $|u_0(t, \xi)| < \rho$ almost everywhere on $]a, b[\times \Gamma$. Let $d := \frac{1}{2}(a + b)$. There must be an optimal control $\hat{u}$ and an interval $]a_i, b_i[$ with $d \in]a_i, b_i[\subset M_{\hat{u}}$. Hence, as we have seen above, u_0 is bang-bang on $M_{\hat{u}} \times \Gamma$ and in particular on $]d - \delta, d + \delta[\times \Gamma$ (with sufficiently small $\delta > 0$) which is a contradiction. Thus u_0 is bang-bang on $M \times \Gamma$.

If u_1 is a further optimal control, it must coincide with u_0 almost everywhere on $M \times \Gamma$, since both controls are bang-bang on this set. Otherwise, $u_2 := \frac{1}{2} u_0 + \frac{1}{2} u_1$ would be an optimal control not bang-bang on $M \times \Gamma$. □

Remark. If (P) has no state constraint, then (A) is fulfilled if y_T cannot be reached by a feasible control. This is the usual condition needed for the standard bang-bang case (cf. Schmidt and Weck [17]). In the general case, (A) has no such simple interpretation. In some special situations, it is possible to reduce (A) to a condition which is less complicated. Compare in this connection the generalized bang-bang principles in Tröltzsch [18] (see also Mackenroth [10]).

We now turn back to the question of whether a sequence $\{u_h\}$ of discrete optimal controls converges to an optimal control u_0 of (P). Let $N := [0, T] \setminus M$.

THEOREM 4.2. *Let $\nu = 0$ and suppose that the assumptions of Theorem* 2.1 *are fulfilled. Then the following assertions hold with $j = 1, 2$ as in* § 3.

(a) *We have*

$$\lim_{h \to 0} p_2 S_h^j u_h = p_2 S^j u_0.$$

If u_1 is a further optimal control, then $p_2 S u_1 = p_2 S u_0$.

(b) *There is a subsequence $\{w_h\}$ of $\{u_h\}$ which converges weakly in $L^2(\Sigma)$ to u_0. For each such subsequence we have*

$$\lim_{h \to 0} p_1 S_h^j w_h = p_1 S u_0, \quad \text{and} \quad \lim_{h \to 0} p_1 S w_h(t) \in \partial C \quad \forall t \in N.$$

(c) *If in addition* (A) *is true, then*

$$\lim_{h \to 0} \| u_h|_{M \times \Gamma} - u_0|_{M \times \Gamma} \|_{L^q(M \times \Gamma)} = 0 \quad \forall q \in [1, \infty].$$

Proof. Assertions (a) and (b) follow by standard arguments and the compactness of S from Theorem 2.1. Assertion (c) is an immediate consequence of Theorem 4.1 and Mackenroth [11, Lemma 2]. □

Remark. A similar result can be formulated for the one-dimensional case and S_m^3.

The question of the behaviour of $\{u_h\}$ on $N \times \Gamma$ is not answered by the preceding theorem. For $t \in N$ we have $p_1 S u_0(t) \in \partial C$ which often leads to an additional equation

for u_0. Then the second assertion of Theorem 4.2(b) can be interpreted as a result of the defects of the discrete optimal controls on N.

5. Numerical examples. In this section we consider some numerical examples for the case of space dimension $n=1$. A numerical example for $n=2$ can be found in Mackenroth [13].

We set $T=1$, $\Omega=]0, 1[$, $a_{11}=1$, $a_0=0$ and suppose that the boundary conditions are given by

$$\frac{\partial y}{\partial x}(t, 0)=0,$$

$$\alpha y(t, 1)+\frac{\partial y}{\partial x}(t, 1)=u(t),$$

with $\alpha=0.1$. Let $y_T(x)=0.7$, assume that the control constraint is given by

$$0 \leqq u(t) \leqq 1 \quad \forall' t \in [0, T],$$

and define

$$C(t)=\{z \in Z \,|\, (z(t), 1) \leqq \eta(t) \quad \forall t \in [0, T]\}$$

with $\eta \in C[0, T]$. We approximate $y(u)$ by $y_m(u)$ as described in (3.14). This can be easily implemented since for λ_k, v_k well-known explicit formulas are available. Experience has shown that for $m=20$, the Fourier series gives a very good approximation of $y(u)$ and the computational effort remains within reasonable limits.

For the numerical solution, it is of course necessary to discretize also the time t. We do this by using piecewise constant controls and by imposing the state constraint only at finitely many discrete points. Then it is an easy task to convert the discrete problems into a quadratic programming problem with inequality constraints. For the numerical solution of these problems we have used the program SOL/QPSOL by Gill et al. which worked very well. This program is available in the NAG-Library.

In our first example we consider the bang-bang case. If no state constraint is present, the optimal control is given by

$$u_0(t)=\begin{cases}1 & \text{if } t \in [0, t_s] \\ 0 & \text{if } t \in]t_s, 1]\end{cases}$$

with $t_s=0.767$. The integrated state, i.e., the function $(y(u)(\cdot), 1)$ is shown in Fig. 1. This picture shows that a state constraint with

$$\eta(t)=\begin{cases}-t+1 & \text{if } t \in [0, 0.6], \\ 2.5t-1.1 & \text{if } t \in [0.6, 1],\end{cases}$$

must affect the solution. The corresponding optimal control and integrated state (obtained by numerical computations) are depicted in Figs. 2 and 3.

We see that in this case, N consists only of a single point t_N. The optimal control u_0 is bang-bang on the whole interval $[0, 1]$ and has a jump at t_N. Thus u_0 behaves as predicted by the theory.

If we choose a differentiable function for η the situation becomes different. For

$$\eta(t)=0.1e^{3t-0.6}+0.15 \quad \forall t \in [0, 1]$$

the results are shown in Figs. 4 and 5. In this case, N consists of an interval with nonempty interior. On this set, u_0 seems to be smooth.

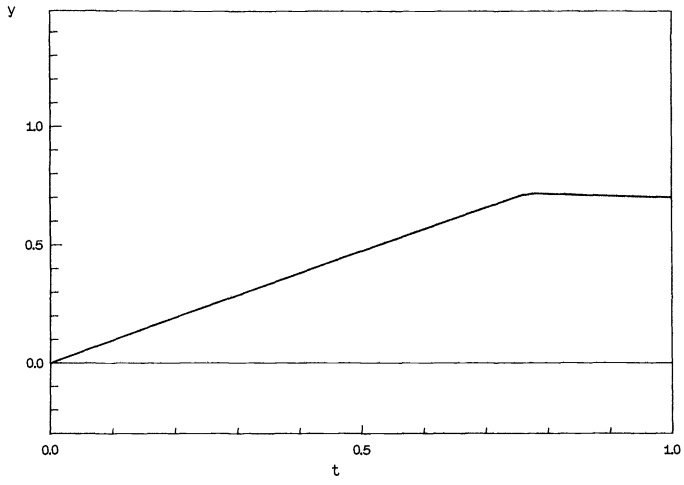

FIG. 1

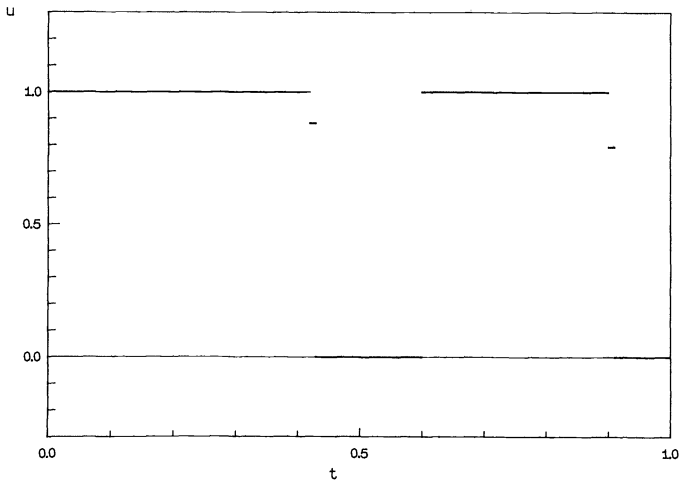

FIG. 2

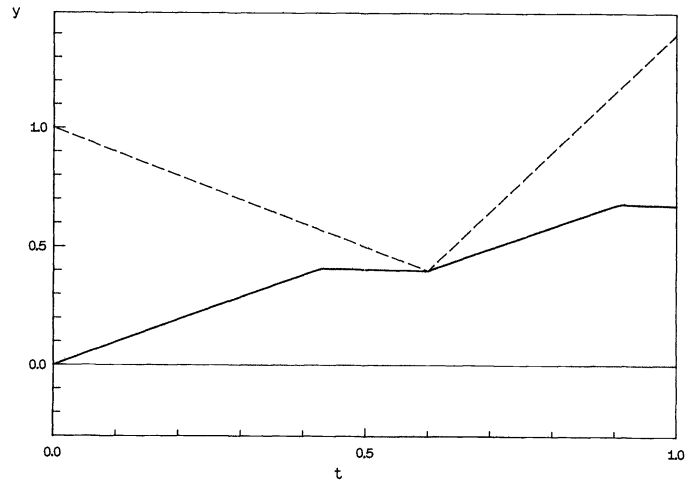

FIG. 3

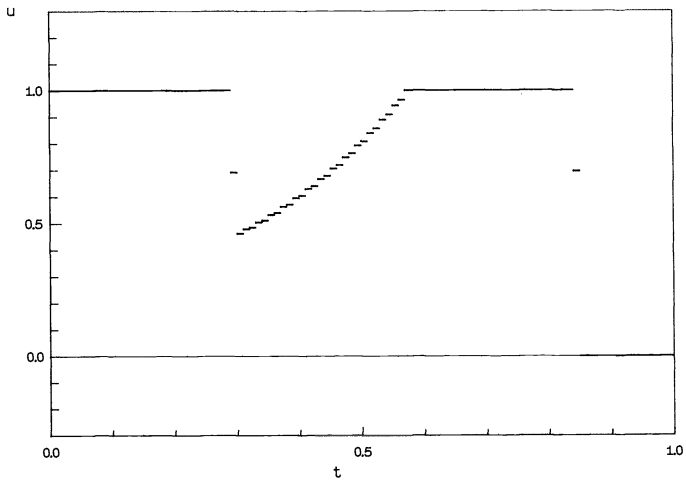

FIG. 4

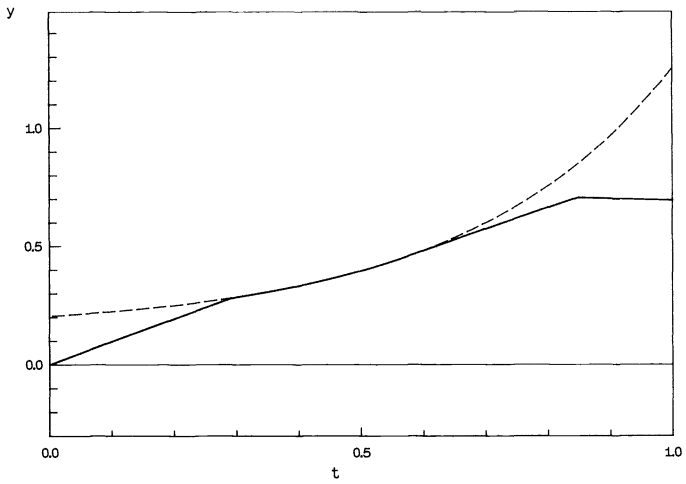

FIG. 5

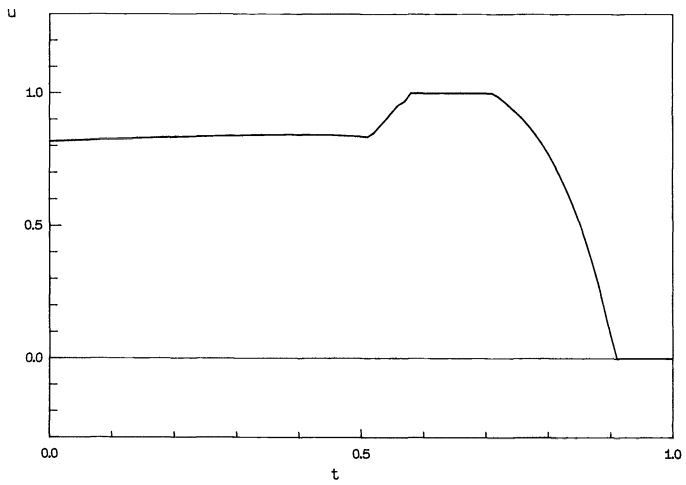

FIG. 6

Now let $\nu = 0.01$ and all other data as in the previous example. The corresponding optimal control is shown in Fig. 6. Here piecewise linear functions are chosen for the approximation of the controls. Further numerical examples with some additional theoretical results can be found in Alt and Mackenroth [1].

All computations have been performed on a VAX 11/780 in double precision. A typical computation time was about 15 seconds.

Acknowledgment. The authors thank one of the referees for a helpful hint concerning the proof of Proposition 3.1.

AN ELLIPSOID TRUST REGION BUNDLE METHOD FOR NONSMOOTH CONVEX MINIMIZATION*

KRZYSZTOF C. KIWIEL†

Abstract. This paper presents a bundle method of descent for minimizing a convex (possibly nonsmooth) function f of several variables. At each iteration the algorithm finds a trial point by minimizing a polyhedral model of f subject to an ellipsoid trust region constraint. The quadratic matrix of the constraint, which is updated as in the ellipsoid method, is intended to serve as a generalized "Hessian" to account for "second-order" effects, thus enabling faster convergence. The interpretation of generalized Hessians is largely heuristic, since so far this notion has been made precise by J. L. Goffin only in the solution of linear inequalities. Global convergence of the method is established and numerical results are given.

Key words. nonsmooth optimization, nondifferentiable programming, convex programming, descent methods, ellipsoid algorithm

1. Introduction. This paper presents a readily implementable algorithm for minimizing a convex (possibly nonsmooth) real-valued function f defined on R^N. We suppose that the set of minimum points of f:

$$X^* = \operatorname{Arg\,min} f = \{x^* \in R^N : f(x^*) \leqq f(x) \forall x \in R^N\}$$

is nonempty, and that we know center $x_c \in R^N$ and radius $r > 0$ of some ball $E = \{x \in R^N : |x - x_c| \leqq r\}$ that intersects X^*. The algorithm requires only the computation of $f(x)$ and one arbitrary subgradient $g_f(x) \in \partial f(x)$ of f at each $x \in R^N$.

The performance of the several existing methods for minimizing f depends on the shape of the level sets of f. The bundle methods of descent (see, e.g., [K2] for their survey), which can be derived by introducing a regularizing quadratic term in the cutting plane method [K1], seem to perform best when f is close to being piecewise linear (polyhedral) and the Haar condition [H1] holds at the minimum point. These methods are sensitive to objective scaling (multiplication of f by a positive number), since so far no scale-invariant rules are known for choosing the weights of their quadratic terms. On the other hand, the ellipsoid method (see [S1] and [Y1]), which can be described as a variable metric subgradient optimization method [G5], seems to work well when f has very elongated level sets, whereas its performance deteriorates for polyhedral functions with "fat" level sets (see [Y2, § 9.5] and [G5]). This method is insensitive to objective scaling.

The algorithm of this paper attempts to combine the best features of the ellipsoid and bundle methods. At each iteration it finds a trial point by minimizing a polyhedral model of f subject to an ellipsoid trust region constraint. The quadratic matrix of the constraint, which is updated as in the ellipsoid method, is intended to serve as a generalized "Hessian" to account for "second-order" effects, with the purpose of enabling faster convergence when the Haar condition does not hold. The subproblem of finding the trial point is solved approximately by estimating the Lagrange multiplier of its constraint and solving the resulting quadratic programming subproblem. In effect, the algorithm may also be viewed as a bundle method with an automatic choice of the quadratic term and its weight, which is, in principle, insensitive to objective scaling.

Our algorithm is intended for complex functions of relatively few variables, for which one function and subgradient evaluation dominates the effort per iteration involved in variable metric updates and quadratic programming subproblems. Hence it tries to minimize the number of function evaluations required to achieve a given accuracy. In particular, it evaluates f not at the center of the current ellipsoid, as do the existing ellipsoid methods (see [S2], [E1], [E2]), but at a point that should have a lower objective value according to the accumulated model of f.

Our interpretation of the generated ellipsoids as generalized "Hessians" is largely heuristic, since so far this notion has been made precise by Goffin [G4], [G7] only in the solution of linear inequalities. Alternative approaches to incorporating "second-order" models in the bundle methods are given in [L3], [L4], and [M1]. So far, they have not produced implementable algorithms.

We prove that the sequence of points generated by the method minimizes f. Rate-of-convergence results are still missing, but we report some encouraging numerical experience. Also, we will show that there is much freedom in implementing the algorithm, and we have only begun to explore some of the possibilities. In particular, we have been using simple ellipsoid cuts, whereas more refined ellipsoid updates would probably be more efficient.

We refer the reader to [A1] and [B1] for surveys and bibliographies of the ellipsoid method, and to [S3] for some of its modifications.

The paper is organized as follows. In § 2 we derive the algorithm, which is stated in detail in § 3. Its convergence is established in § 4. Various more efficient ellipsoid updating strategies are discussed in § 5. Section 6 describes an implementation of the method. Subgradient aggregation is introduced in § 7. Numerical results are reported in § 8. Section 9 concludes the paper.

We use the following notation. We denote by $\langle \cdot, \cdot \rangle$ and $|\cdot|$, respectively, the usual inner product and norm in finite-dimensional, real Euclidean space R^N. We use x_i to denote the ith component of the vector x. Superscripts are used to denote different vectors, e.g., x^1 and x^2. All vectors are column vectors. However, for convenience we sometimes write (x, y) for $(x^T, y^T)^T$, where T denotes transposition. For an $N \times N$ symmetric positive definite matrix A, we let A^{-1} denote the inverse of A, $A^{-T} = (A^{-1})^T$, $\langle x, y \rangle_A = \langle Ax, y \rangle = x^T Ay$, $|x|_A = \langle Ax, x \rangle^{1/2}$. The volume Vol (S) of a bounded measurable set S in R^N is its N-dimensional Lebesgue measure.

For any $x \in R^N$,

$$\partial f(x) = \{g \in R^N : f(y) \geqq f(x) + \langle g, y - x \rangle \forall y \in R^N\}$$

denotes the subdifferential of f at x. The mapping $\partial f(\cdot)$ is locally bounded and f is continuous (see, e.g., [D1, § 1.7.1 and Thm. 1.4.1]). $T(\alpha) = \{x \in R^N : f(x) \leqq \alpha\}$ is the α-level set of f.

2. Derivation of the method. The algorithm to be described will generate two sequences of points $\{x^k\}_{k=1}^{\infty}$ and $\{y^k\}_{k=1}^{\infty}$ in R^N, where $x^1 = y^1$ is a given starting point. The sequence $\{x^k\}$ will satisfy $f(x^{k+1}) < f(x^k)$ if $x^{k+1} \neq x^k$, and $f(x^k) \downarrow \min f$. The auxiliary trial points y^k will be used for computing $f(y^k)$ and $g^k = g_f(y^k)$ for all k (with $y^{k+1} = x^{k+1}$ if $x^{k+1} \neq x^k$; see below). Also a sequence of ellipsoids

$$E_k = \{x \in R^N : |x - x_c^k|_{A_k} \leqq 1\}$$

with centers $x_c^k \in R^n$ and symmetric positive definite matrices A_k will be generated such that $E_k \cap X^* \neq \varnothing$ for all k, where E_1 is a given starting ellipsoid.

At the kth iteration, the algorithm will try to find a point y^{k+1} such that $f(y^{k+1}) < f(x^k)$. Ideally, y^{k+1} should minimize f. Since $E_k \cap X^* \neq \varnothing$, we may restrict the minimiz-

ation to E_k, i.e., we may consider the subproblem

$$\text{minimize } f(y) \quad \text{over all } y \in E_k. \tag{2.1}$$

The trial point y^{k+1} will solve an approximate but manageable version of subproblem (2.1), which is derived as follows.

The algorithm will use the following polyhedral approximation to f:

$$\hat{f}^k(x) = \max\{f_j(x): j \in J^k\} \quad \text{for all } x,$$

where J^k is a subset of $\{1, \cdots, k\}$ and

$$f_j(x) = f(y^j) + \langle g_f(y^j), x - y^j \rangle \quad \text{for all } x$$

is the jth linearization of f satisfying $f(x) \geqq f_j(x)$ for all x. Replacing f by $\hat{f}^k$ in (2.1), we obtain the subproblem

$$\text{minimize } \hat{f}^k(y) \quad \text{over all } y \in E_k$$

and its equivalent form

$$\begin{aligned} &\text{minimize } u \text{ over all } (y, u) \in R^N \times R \\ &\text{satisfying } f_j(y) \leqq u \quad \text{for all } j \in J^k, \\ &\tfrac{1}{2}|y - x_c^k|_{A_k}^2 \leqq \tfrac{1}{2}. \end{aligned} \tag{2.2}$$

Let $\hat{\eta}^k$ denote the optimal Lagrange multiplier for the quadratic constraint of (2.2). It is not easy—and apparently not advisable—to solve (2.2) too accurately; the algorithm will find (y^{k+1}, u^k) to

$$\begin{aligned} &\text{minimize } \tfrac{1}{2}\eta^k |y - x_c^k|_{A_k}^2 + u \quad \text{over all } (y, u) \in R^{N+1} \\ &\text{satisfying } f_j(y) \leqq u \quad \text{for all } j \in J^k \end{aligned} \tag{2.3}$$

for some $\eta^k \geqq \hat{\eta}^k$, so that $y^{k+1} \in E_k$. The search for η^k, which will test increasing values of η^k, will be similar to that employed in the trust region methods (see [M2] for a survey). Section 6 will suggest another argument in favor of larger values of η^k.

Another motivation for subproblem (2.3) stems from the fact that, in a suitably transformed space, it reduces to the subproblems of the bundle methods of [K2, Chap. 2], thus inheriting their useful theoretical and computational properties. More specifically, the direction $\bar{d}^k = y^{k+1} - x_c^k$ and the predicted objective decrease

$$v^k = \hat{f}^k(y^{k+1}) - f(x^k) = u^k - f(x^k) \tag{2.4}$$

can be found by solving the subproblem

$$\begin{aligned} &\text{minimize } \tfrac{1}{2}\eta_k |\bar{d}|_{A_k}^2 + v \quad \text{over all } (\bar{d}, v) \in R^{N+1} \\ &\text{satisfying } -\bar{\alpha}_j^k + \langle g^j, \bar{d} \rangle \leqq v \quad \text{for } j \in J^k, \end{aligned} \tag{2.5}$$

where

$$\bar{\alpha}_j^k = f(x^k) - f_j(x_c^k) \quad \text{for } j \in J^k. \tag{2.6}$$

Let us represent the symmetric and positive definite matrices A_k and $B_k = A_k^{-1}$ as

$$A_k = \tilde{A}_k^T \tilde{A}_k \quad \text{and} \quad B_k = \tilde{B}_k \tilde{B}_k^T,$$

where $\tilde{B}_k = \tilde{A}_k^{-1}$ is a nonsingular $N \times N$ matrix (e.g., $\tilde{B}_k^T$ is the Cholesky factor B_k). Consider the space transformation

$$x \to \tilde{x} = \tilde{A}_k x,$$

which maps x^k, x_c^k, y^j, y^{k+1}, and $\bar{d}^k$ into $\tilde{x}^k$, $\tilde{x}_c^k$, $\tilde{y}^j$, $\tilde{y}^{k+1}$, and $\tilde{d}^k$, respectively. In the transformed space ($\tilde{x}$-space), $\tilde{g}^j = \tilde{B}_k^T g^j$ are the subgradients of the function $\tilde{f}(\tilde{x}) = f(\tilde{A}_k^{-1}\tilde{x})$ at $\tilde{y}^j$, for $j \in J^k$, whereas $(\tilde{d}^k, v^k)$ solves the transformed subproblem

$$\begin{aligned} &\text{minimize } \tfrac{1}{2}\eta^k|\tilde{d}|^2 + v \quad \text{over all } (\tilde{d}, v) \in R^{N+1} \\ &\text{satisfying } -\bar{\alpha}_j^k + \langle \tilde{g}^j, \tilde{d}\rangle \leqq v \quad \text{for } j \in J^k. \end{aligned} \tag{2.7}$$

The bundle methods of [K2, Chap. 2] use subproblem (2.7) for generating a descent direction for $\tilde{f}$ at $\tilde{x}_c^k$. (In fact, they use $\tilde{x}_c^k = \tilde{x}^k$ and $\eta^k = 1$ in (2.7), but η^k can be suppressed in (2.7) by replacing $\tilde{A}_k$ with $(\eta^k)^{1/2}\tilde{A}_k$ in the transformation.) Therefore, by transforming "back" the results of [K2, pp. 49, 64], we can establish the following properties of subproblem (2.5). Let $\lambda_j^k, j \in J^k$, denote the (possibly nonunique) Lagrange multipliers of (2.5), and let

$$(p^k, \bar{\alpha}_p^k) \equiv \sum_{j \in J^k} \lambda_j^k (g^j, \bar{\alpha}_j^k) \tag{2.8}$$

and $\tilde{p}^k = \tilde{B}_k^T p^k$. Then $\tilde{d}^k = -\tilde{p}^k/\eta^k$, $-v^k = |\tilde{p}^k|^2/\eta^k + \bar{\alpha}_p^k$,

$$\bar{d}^k = -\frac{1}{\eta^k} B_k p^k, \tag{2.9a}$$

$$v^k = -\left\{\frac{1}{\eta^k}|p^k|_{B_k}^2 + \bar{\alpha}_p^k\right\}. \tag{2.9b}$$

Moreover,

$$w^k = \frac{1}{2\eta^k}|p^k|_{B_k}^2 + \bar{\alpha}_p^k \tag{2.10}$$

is the optimal value of the dual subproblem

$$\begin{aligned} &\text{minimize } \frac{1}{2\eta^k}\left|\sum_{j \in J^k} \lambda_j \tilde{g}^j\right|^2 + \sum_{j \in J^k} \lambda_j \bar{\alpha}_j^k, \\ &\text{subject to } \sum_{j \in J} \lambda_j = 1, \quad \lambda_j \geqq 0 \quad \text{for } j \in J^k, \end{aligned} \tag{2.11}$$

whose solution set coincides with the set of Lagrange multipliers of (2.5). In particular,

$$\sum_{j \in J^k} \lambda_j^k = 1, \quad \lambda_j^k \geqq 0 \quad \text{for } j \in J^k. \tag{2.12}$$

In general, we would like the ellipsoid $E = E_k$ to be a tight approximation to (a portion of) X^*, since then the point $y^{k+1} \in E_k$ would be close to optimal. Whenever we identify a redundant portion E^- of E such that $E^- \cap X^* = \varnothing$, we may reduce E by replacing it with a smaller ellipsoid E_+ that contains the remaining portion $E \setminus E^-$ as in the ellipsoid methods (see, e.g., [S2]). The ellipsoid methods update E as follows. Using one or more cutting planes, they choose a portion of E that contains $E \cap X^*$ and no more than half of E, and let E_+ be the smallest-volume ellipsoid containing this portion. To ensure that at least half of E is cut off, so that $\text{Vol}(E_+) \leqq q\ \text{Vol}(E)$ with $q < e^{-1/(2N+2)} < 1$ (see [T1]), they use the hyperplane $\{x \in R^N : \langle g_f(x_c^k), x - x_c^k\rangle = 0\}$, or its translation (if $g_f(x_c^k) = 0$, they terminate with $x_c^k \in X^*$). Our algorithm will use the bounding hyperplane of

$$H_p^k = \{x \in R^N : \langle p^k, x - x_c^k\rangle \leqq \bar{\alpha}_p^k\} \tag{2.13}$$

defined via (2.8). This will save the computation of $g_f(x_c^k)$, but will provide a significant volume reduction only when $\bar{\alpha}_c^k \leqq 0$. More specifically, if we let E_+ be the least volume ellipsoid containing $E \cap H_p^k$, then $\mathrm{Vol}\,(E_+) \leqq q\,\mathrm{Vol}\,(E)$ if $\bar{\alpha}_p^k \leqq 0$ and $p^k \neq 0$, whereas $E_+ \cap X^* \neq \varnothing$ if $(E \cap H_p^k) \cap X^* \neq \varnothing$, which will hold if

$$T(f(x^k)) \subset H_p^k, \tag{2.14}$$

because $E_k \cap X^* \neq \varnothing$. Now, multiplying by λ_j^k the relations

$$\begin{aligned} f(x) &\geqq f(y^j) + \langle g_f(y^j),\, x - y^j\rangle = f_j(x) \\ &= f(x^k) + \langle g^j,\, x - x_c^k\rangle - \bar{\alpha}_j^k \quad \text{for all } x \end{aligned} \tag{2.15}$$

and summing over $j \in J^k$, we deduce from (2.8) and (2.12) that

$$f(x) \geqq f(x^k) + \langle p^k,\, x - x_c^k\rangle - \bar{\alpha}_p^k \quad \text{for all } x, \tag{2.16}$$

which establishes (2.14). Moreover, by (2.16), the algorithm may stop with $x^k \in X^*$ if $\bar{\alpha}_p^k \leqq 0$ and $p^k = 0$. Thus we may replace E with E_+ to obtain the desired volume reduction if $\bar{\alpha}_p^k \leqq 0$.

In geometric terms, the *aggregate cut* discussed above is provided by the *aggregate linearization*

$$\tilde{f}^k(x) = \sum_{j \in J^k} \lambda_j^k f_j(x) = \tilde{f}^k(x_c^k) + \langle p^k,\, x - x_c^k\rangle \quad \text{for all } x$$

with $\tilde{f}^k(x_c^k) = f(x^k) - \bar{\alpha}_p^k$; relation (2.16) means that $f(x) \geqq \tilde{f}^k(x)$ for all x, and we have $H_p^k = \{x \in R^N : \tilde{f}^k(x) \leqq f(x^k)\}$. A *deep* cut with $x_c^k \notin H_p^k$ is obtained if $\tilde{f}^k(x_c^k) > f(x^k)\,(\bar{\alpha}_p^k < 0)$. On the other hand, relation (2.15) shows that the "ordinary" linearizations f_j define cuts (called *supercuts* in [S2]) based on the relations

$$H_j^k = \{x \in R^n : \langle g^j,\, x - x_c^k\rangle \leqq \bar{\alpha}_j^k\} = \{x : f_j(x) \leqq f(x^k)\}, \qquad T(f(x^k)) \subset H_j^k. \tag{2.17}$$

Thus our aggregate cut is a convex combination of "ordinary" cuts (cf. (2.8) and (2.12)); it reduces to the *surrogate cut* of [G8] when f is polyhedral and $f(x^k) = \min f$. More will be said about cuts in § 5.

A useful stopping criterion can be derived from (2.16) as follows. Since $B_k = A_k^{-1}$ and the Cauchy-Schwarz inequality yields

$$\begin{aligned} |\langle p^k,\, x - x_c^k\rangle| &= |\langle B_k p^k,\, x - x_c^k\rangle_{A_k}| \leqq |B_k p^k|_{A_k} |x - x_c^k|_{A_k} \\ &= |p^k|_{B_k} |x - x_c^k|_{A_k}, \end{aligned}$$

we may set $x = x^* \in E_k \cap X^*$ in (2.16) to obtain

$$f(x^k) \leqq \min f + |p^k|_{B_k} + \bar{\alpha}_p^k. \tag{2.18}$$

Thus the algorithm may stop if $|p^k|_{B_k} + \bar{\alpha}_p^k\,(\geqq 0)$ is sufficiently small.

If neither an ellipsoid update nor termination occur, i.e., $\bar{\alpha}_p^k > 0$ and $p^k \neq 0$, then the predicted objective decrease v^k is negative (cf. (2.4) and (2.9b)). To ensure a significant objective reduction, the algorithm will take a *serious step* from x^k to $x^{k+1} = y^{k+1}$ only if

$$f(y^{k+1}) \leqq f(x^k) + m v^k, \tag{2.19}$$

where $m \in (0, 1)$ is a parameter. Otherwise, a *null step* with $x^{k+1} = x^k$ will occur, but the new linearization f_{k+1} of f at y^{k+1} will contribute to our finding a better next trial point y^{k+2}.

3. The method. We shall now state the simplest version of the method, postponing more efficient modifications until §§ 5 and 6.

ALGORITHM 3.1.

Step 0 (Initialization). Choose a point $x_c^1 \in R^N$ and a symmetric positive definite $N \times N$ matrix A_1 such that the ellipsoid $E_1 = \{x \in R^N : |x - x_c^1|_{A_1} \leqq 1\}$ satisfies $E_1 \cap X^* \neq \emptyset$. Select a starting point $x^1 \in R^N$, a final accuracy tolerance $\varepsilon_s \geqq 0$, a line search parameter $m \in (0, 1)$ and weight updating parameters $\eta_u > 0$ and $\chi \in (1, 100]$. Set $y^1 = x^1$ and $J^1 = \{1\}$. Compute $f(y^1)$, $g^1 = g_f(y^1)$ and $f_1(x_c^1) = f(y^1) + \langle g^1, x_c^1 - y^1 \rangle$. Choose $\eta^1 \in (0, \eta_u]$. Set the iteration counter $k = 1$ and the counter of serious steps $L = 0$. Set $k(0) = 1$ ($k(L)$ will denote the iteration number of the Lth (latest) serious step).

Step 1 (Direction finding). Find the solution $(\bar{d}^k, v^k)$ and Lagrange multipliers λ_j^k, $j \in J^k$, of subproblem (2.5), with $\bar{\alpha}_j^k$, $j \in J^k$, given by (2.6). Compute p^k and $\bar{\alpha}_p^k$ by (2.8).

Step 2 (Stopping criterion). If $|p^k|_{B_k} + \bar{\alpha}_p^k \leqq \varepsilon_s$, terminate. If $\bar{\alpha}_p^k > 0$, go to Step 4; otherwise, continue.

Step 3 (Ellipsoid updating). Find $x_c^+ \in R^N$ and a symmetric positive definite $N \times N$ matrix A_+ such that $E_+ = \{x \in R^N : |x - x_c^+|_{A_+} \leqq 1\}$ is the smallest-volume ellipsoid containing $E_k \cap H_p^k$, where H_p^k is given by (2.13). Replace x_c^k and A_k by x_c^+ and A_+, respectively, choose $\eta^+ \in (0, \eta_u]$, replace η^k by η^+, and go to Step 1.

Step 4 (Weight updating). If $|\bar{d}^k|_{A_k} \leqq 1$, go to Step 5. Otherwise, choose $\eta^+ \in [\chi\eta^k, 100\eta^k]$, set $\eta^k = \eta^+$, and go to Step 1.

Step 5 (Line search). Set $y^{k+1} = x_c^k + \bar{d}^k$ and compute $f(y^{k+1})$ and $g^{k+1} = g_f(y^{k+1})$. If $f(y^{k+1}) \leqq f(x^k) + mv^k$, set $x^{k+1} = y^{k+1}$, $k(L+1) = k+1$ and increase the counter of serious steps L by 1. Otherwise, set $x^{k+1} = x^k$.

Step 6 (Subgradient selection). Set $\hat{J}^k = \{j \in J^k : \lambda_j^k \neq 0\}$ and choose a set J^{k+1} satisfying $\hat{J}^k \cup \{k+1\} \subset J^{k+1} \subset J^k \cup \{k+1\}$.

Step 7. If $x^{k+1} = x^k$, set $\eta^{k+1} = \eta^k$; otherwise, choose $\eta^{k+1} \in (0, \eta_u]$. Set $x_c^{k+1} = x_c^k$ and $A_{k+1} = A_k$. Increase k by 1 and go to Step 1.

A few comments on the algorithm are in order.

Guidelines for choosing an initial ellipsoid can be found, for instance, in [G8] and [E2]. The obvious choice is to let $x_c^1 = x^1$ and $A_1 = (1/r)I$, where I is the identity matrix and $r > 0$ estimates the Euclidean distance from x^1 to X^*. It is reassuring to know that even if we had $E_1 \cap X^* = \emptyset$, the algorithm would still minimize f on E_1, as will be proved in § 4.

Step 1 can be implemented with the quadratic programming routine of [K3] (see § 6).

Termination at Step 2 implies that $f(x^k) \leqq \min f + \varepsilon_s$ (cf. (2.18)). (This estimate would be weakened to $f(x^k) \leqq \min \{f(x) : x \in E_1\} + \varepsilon_s$ if we had $E_1 \cap X^* = \emptyset$; see § 4.)

The ellipsoid update at Step 3 is well defined, since the algebraic distance (in the metric defined by $|\cdot|_{A_k}$) from x_c^k to H_p^k

$$\omega_p^k = -\bar{\alpha}_p^k / |p^k|_{B_k} = -\bar{\alpha}_p^k / |\tilde{p}^k| \tag{3.1}$$

satisfies $\omega_p^k \in [0, 1)$ when $\bar{\alpha}_p^k \leqq 0$ and $|\tilde{p}^k| + \bar{\alpha}_p^k > 0$ after Step 2; note that in the $\tilde{x}$-space $\tilde{E}_k = \tilde{A}_k E_k$ is the unit ball, whereas ω_p^k is the distance from $\tilde{x}_c^k$ to $\tilde{H}_p^k = \tilde{A}_k H_p^k = \{\tilde{x} : \langle \tilde{p}^k, \tilde{x} - \tilde{x}_c^k \rangle \leqq \bar{\alpha}_p^k\}$. Hence we can compute x_c^+ and $B_+ = A_+^{-1}$ as in [G8]; see § 6. At the kth iteration, an infinite number of returns to Step 1 from Steps 3 and 4 is possible only when $x^k \in X^*$ (see § 4), an unlikely situation when f is not polyhedral.

The restrictions on the choice of the weighting coefficient η^k attempt to limit its growth. Specific choices of η^k will be discussed in § 6. Here we may observe that if there is a cycle between Steps 1 and 4 without ellipsoid updates and we choose $\eta^+ = \chi\eta^k$ at Step 4, then the cycle will terminate (see § 4) with $\eta^k/\chi < \hat{\eta}^k \leqq \eta^k$.

Observe that $x^k \in E_k$ for all k if $x^1 \in E_1$, since x^k is never cut off at Step 3 due to (2.14), whereas $y^{k+1} \in E_k$ by construction, for all k.

The quadratic programming routine of [K3] will compute at most $N+1$ nonzero multipliers λ_j^k. Hence at Step 6 we can choose a set J^{k+1} with at most $N+2$ elements. This number of stored subgradients may be reduced by using subgradient aggregation (§ 7).

4. Convergence. In this section we show that the algorithm minimizes f. Naturally, we assume that the final accuracy tolerance ε_s is set to zero (and that $E_1 \cap X^* \neq \emptyset$ at Step 0).

We start with the ellipsoid updates.

LEMMA 4.1. *If Algorithm* 3.1 *did not stop before the kth iteration, then at Step* 1 *we have*

$$T(f(x^k)) \cap E_1 \subset E_k. \tag{4.1}$$

Proof. If $E_k = E_1$, the inclusion is obvious. Hence, suppose that for some $j < k$ we have $E_1 \cap T(f(x^j)) \subset E_j$ at Step 1 and a new ellipsoid E_+ is constructed at Step 3. Then $E_1 \cap T(f(x^j)) \subset E_j \cap T(f(x^j)) \subset E_j \cap H_p^j \subset E_+$ (cf. (2.14)). Since $f(x^{j+1}) \leqq f(x^j)$, the desired conclusion follows by induction.

Since $E_1 \cap X^* \neq \emptyset$ by assumption, relation (4.1) implies that $E_k \cap X^* \neq \emptyset$. Hence we may use (2.18) to obtain Lemma 4.2.

LEMMA 4.2. *If Algorithm* 3.1 *terminates at the kth iteration, then* $x^k \in X^*$.

From now on we suppose that the algorithm does not terminate.

Due to Lemma 4.1, the case of an infinite number of ellipsoid updates may be analyzed as in [G6].

LEMMA 4.3. *If Algorithm* 3.1 *executes Step* 3 *infinitely many times, then either* k *stays bounded and* $x^k \in X^*$, *or* $f(x^k) \downarrow \min f$ *as* $k \to \infty$.

Proof. By construction, when Step 3 is entered with $\omega_p^k \in [0, 1)$ (see (3.1)), E_+ satisfies $\operatorname{Vol}(E_+) < e^{-1/(2N+2)} \operatorname{Vol}(E_k)$ (see [T1]), and E_+ becomes E_k until the next update. Hence infinitely many updates lead to $\operatorname{Vol}(E_k) \downarrow 0$. Now, to derive a contradiction, suppose that there are infinitely many iterations with $f(x^k) \geqq \bar{f}$, where $\bar{f} > f(x^*)$ for some $x^* \in E_1 \cap X^*$. Then $\operatorname{Vol}(T(\bar{f}) \cap E_1) > 0$ from the continuity of f, whereas (4.1) yields $T(\bar{f}) \cap E_1 \subset E_k$. Thus, $0 < \operatorname{Vol}(T(\bar{f}) \cap E_1) \leqq \operatorname{Vol}(E_k)$ for all k, a contradiction to $\operatorname{Vol}(E_k) \downarrow 0$. Since $\{f(x^k)\}$ is nonincreasing, we deduce that $f(x^k) \downarrow f(x^*)$ if $k \to \infty$. If Step 3 is executed infinitely many times for some fixed k, the same arguments show that $x^k \in X^*$.

From now on we suppose that only a finite number of ellipsoid updates occur. Then there exist $k_E \geqq 1$ and an ellipsoid $\bar{E} = \{x : |x - \bar{x}_c|_{\bar{A}} \leqq 1\}$ with center $\bar{x}_c$ and a symmetric positive definite matrix $\bar{A}$ such that after the last return from Step 3 to Step 1 that occurred at iteration k_E, if any, Step 1 is entered with

$$E_k = \bar{E}, \quad x_c^k = \bar{x}_c, \quad A_k = \bar{A} \quad \text{if } k \geqq k_E. \tag{4.2}$$

Let $\gamma > 0$ denote the square root of the minimum eigenvalue of $\bar{A}$, so that

$$\gamma |x| \leqq |x|_{\bar{A}} \quad \text{for all } x. \tag{4.3}$$

We may now show that the algorithm cannot cycle infinitely between Steps 1 and 4 when its ellipsoid stays constant.

LEMMA 4.4. *Under the preceding assumptions, Algorithm* 3.1 *executes Step* 5 *at each iteration and there exists* $\hat{\eta} > 0$ *such that* $\eta^k \leqq \hat{\eta}$ *for all* k.

Proof. In view of the algorithm's rules, it suffices to show that there exists $\tilde{\eta} > 0$ such that if (4.2) holds, $k \geqq k_E$, and $\eta \geqq \tilde{\eta}$, then $|\bar{d}^k(\eta)|_{\bar{A}} \leqq 1$, where $(\bar{d}^k(\eta), u^k(\eta))$:

$$\text{minimize } \tfrac{1}{2}\eta|\bar{d}|_{\bar{A}}^2 + u \quad \text{over all } (d, u) \in R^{N+1}$$

$$\text{satisfying } f_j(\bar{x}_c) + \langle g^j, \bar{d}\rangle \leqq u \quad \text{for } j \in J^k.$$

Since $\bar{d} = 0$ and $u = f(\bar{x}_c) \geqq f_j(\bar{x}_c)$ for all $j \in J^k$ are feasible above,

$$\tfrac{1}{2}\eta|\bar{d}^k(\eta)|_{\bar{A}}^2 + u^k(\eta) \leqq f(\bar{x}_c). \tag{4.4}$$

The definition of f_j and the Cauchy-Schwarz inequality give

$$\begin{aligned} u^k(\eta) &= \max\{f_j(\bar{x}_c) + \langle g^j, \bar{d}^k(\eta)\rangle : j \in J^k\} \\ &\geqq \min\{f(y^j) + \langle g^j, \bar{x}_c - y^j\rangle : j \in J^k\} - |\bar{d}^k(\eta)| \max_{j \leqq k} |g^j|. \end{aligned}$$

Hence there exist constants $C_1 < f(\bar{x}_c)$ and $C_2 > 0$ such that

$$u^k(\eta) \geqq C_1 - |\bar{d}^k(\eta)|C_2 \quad \text{for all } \eta > 0 \text{ and } k \geqq k_E, \tag{4.5}$$

because $y^j \in E_j = \bar{E}$ if $j > k_E$, $\bar{E}$ is bounded, f is continuous, $g^j \in \partial f(y^j)$, and ∂f is locally bounded. Combining (4.3)-(4.5), we get

$$f(\bar{x}_c) - C_1 \geqq |\bar{d}^k(\eta)|_{\bar{A}}(\tfrac{1}{2}\eta|\bar{d}^k(\eta)|_{\bar{A}} - C_2/\gamma).$$

Therefore, if $|\bar{d}^k(\eta)|_{\bar{A}} > 1$ then $\eta/2 - C_2/\gamma \leqq f(\bar{x}_c) - C_1$, and the existence of $\tilde{\eta}$ is clear.

By the rules of Step 5,

$$x^k = x^{k(L)} \quad \text{if } k(L) \leqq k < k(L+1),$$

where for theoretical purposes we may let $k(L+1) = +\infty$ if the number L of serious steps stays bounded, i.e., if $x^k = x^{k(L)}$ for some fixed L and all $k \geqq k(L)$. First we consider the case of unbounded L.

LEMMA 4.5. *Suppose that Algorithm* 3.1 *executes infinitely many serious steps. Then* $x^k \to \bar{x}_c$ *and* $\bar{x}_c \in X^*$.

Proof. Let $K = \{k(L+1) - 1: L = 1, 2, \cdots\}$, so that at Step 5 $f(x^{k+1}) \leqq f(x^k) + mv^k$ for all $k \in K$. Since $-v^k = |p^k|_{B_k}^2/\eta^k + \bar{\alpha}_p^k > 0$ for $k \geqq k_E$ and $m \in (0, 1)$ is fixed, whereas $f(x^k) \geqq f(x^{k+1}) \geqq \min f$ for all k, passing to the limit with $k \in K$ in the inequality $f(x^k) - f(x^{k+1}) \geqq -mv^k$ yields $\bar{\alpha}_p^k \overset{K}{\to} 0$ and $|p^k|_{B_k}/\eta^k \overset{K}{\to} 0$. Letting $k \in K$ approach infinity in (2.18), we get $f(x^k) \downarrow \min f$. By (4.3), (4.2), and (2.9a), $\gamma|x^{k+1} - \bar{x}_c| \leqq |x^{k+1} - \bar{x}_c|_{\bar{A}} = |y^{k+1} - \bar{x}_c|_{A_k} = |\bar{d}^k|_{A_k} = |p^k|_{B_k}/\eta^k$ for large $k \in K$, so $|p^k|_{B_k}/\eta^k \overset{K}{\to} 0$ implies $x^k \to \bar{x}_c$. Hence $f(x^k) \downarrow f(\bar{x}_c)$ due to the continuity of f, and $f(\bar{x}_c) = \min f$, as desired.

It remains to consider the case of infinitely many successive null steps.

LEMMA 4.6. *Suppose that* $x^k = x^{k(L)} = \bar{x}$ *for some fixed* L *and all* $k \geqq k(L)$. *Then* $\bar{x} \in X^*$ *and* $\bar{x}_c \in X^*$.

Proof. In view of Lemma 4.4, the algorithm's rules imply the existence of $\bar{\eta} > 0$ and $\bar{k} > \max\{k(L), k_E\}$ such that $\eta^k = \bar{\eta}$ for all $k \geqq \bar{k}$; otherwise, successive increases of η^k with $\chi > 1$ at Step 4 would make it unbounded, a contradiction.

Let $k \geqq \bar{k}$ be fixed. Since $y^k = x_c^{k-1} + \bar{d}^{k-1}$, $x^k = x^{k-1} = \bar{x}$, $x_c^k = x_c^{k-1} = \bar{x}_c$ and $f(y^k) > f(x^{k-1}) + mv^{k-1}$, we obtain from (2.6)

$$\bar{\alpha}_k^k = f(\bar{x}) - f(y^k) - \langle g^k, \bar{x}_c - y^k\rangle, \qquad -\bar{\alpha}_k^k + \langle g^k, \bar{d}^{k-1}\rangle > mv^{k-1}. \tag{4.6}$$

Suppose the matrix $\bar{\eta}\bar{A}$ is factorized as $\bar{\eta}\bar{A} = \hat{A}^T\hat{A}$, where $\hat{A}$ is $N \times N$ and nonsingular, and consider the space transformation

$$x \to \hat{x} = \hat{A}x, \tag{4.7}$$

which maps x^k, $\bar{x}$, y^j, and $\bar{d}^k$ into $\hat{x}^k$, $\hat{x}$, $\hat{y}^j$, and $\hat{d}^k$, respectively. Also let $\hat{g}^j = \hat{A}^{-T} g^j$ and $\alpha_j^k = \bar{\alpha}_j^k + \langle g^j, x_c^k - x^k \rangle$ for all $j \in J^k$, $\hat{p}^k = \hat{A}^{-T} p^k$ and $\tilde{\alpha}_p^k = \bar{\alpha}_p^k + \langle p^k, x_c^k - x^k \rangle$.

Thus for $k \geqq \hat{k}$ we have $\eta^k A_k = \hat{A}^T \hat{A}$, $\bar{\alpha}_p^k > 0$ $(k > k_E)$, $\hat{d}^k = -\hat{p}^k$ and $-v^k = |\hat{p}^k|^2 + \bar{\alpha}_p^k$ by (2.9), $w^k = |\hat{p}^k|^2/2 + \bar{\alpha}_p^k$ by (2.10), $\hat{y}^{k+1} = \hat{x}_c^k + \hat{d}^k$ (with $\hat{x}_c^k = \hat{A}\bar{x}_c$), and, by (4.6), $-\bar{\alpha}_k^k + \langle \hat{g}^k, \hat{d}^{k-1} \rangle > m v^{k-1}$ with $0 < m < 1$. Hence we may use the various relations of § 2 to deduce that for all $k \geqq \bar{k}$, Algorithm 3.1 is essentially equivalent to the method of [K2, § 2.5] applied to the convex function $\hat{f}(\cdot) = f(\hat{A}^{-1} \cdot)$ in the space transformed via (4.7). Then the results in [K2, §§ 2.4, 2.5] imply that $w^k = |p^k|_B^2/2\eta^k + \bar{\alpha}_p^k \to 0$ (see (2.10)). Therefore, $|p^k|_{B_k} \to 0$ and $\bar{\alpha}_p^k \to 0$, since $\bar{\alpha}_p^k > 0$ and $\eta^k = \bar{\eta}$ for all $k > \bar{k}$, and (2.18) yields $\bar{x} \in X^*$.

It remains to show that $\bar{x}_c \in X^*$. Since $w^k \to 0$ and $\bar{\alpha}_p^k > 0$ for large k, (2.9b) and (2.10) imply that $v^k \to 0$. Hence $u^k = f(x^k) + v^k \to f(\bar{x})$. On the other hand, by (2.4),

$$u^k \geqq f_k(y^{k+1}) = f(y^k) + \langle g_f(y^k), y^{k+1} - y^k \rangle \tag{4.8}$$

because $k \in J^k$ for all k. Since $|y^{k+1} - \bar{x}_c|_{\bar{A}} = |p^k|_{B_k}/\bar{\eta}$ for large k, and $|p^k|_{B_k} \to 0$, (4.3) implies that $y^k \to \bar{x}_c$. Passing to the limit in (4.8), we get $f(\bar{x}) \geqq f(\bar{x}_c)$, since $u^k \to f(\bar{x})$, $y^k \to \bar{x}_c$, f is continuous and $g_f(\cdot)$ is locally bounded. Thus $\bar{x} \in X^*$ and $f(\bar{x}) \geqq f(\bar{x}_c)$, so $\bar{x}_c \in X^*$, as desired.

We conclude from Lemmas 4.5 and 4.6 that the case of a finite number of ellipsoid updates is rather unlikely, since then the center of the last ellipsoid must be optimal.

Combining Lemmas 4.2–4.6, we deduce our principal result.

THEOREM 4.7. *Either the sequence* $\{x^k\}$ *generated by Algorithm* 3.1 *is finite and its last element minimizes* f, *or* $\{x^k\}$ *is infinite and* $f(x^k) \downarrow \min f$ *as* $k \to \infty$.

The key condition needed to ensure convergence is $E_1 \cap X^* = \emptyset$. Even if it fails, we still have the following theorem.

THEOREM 4.8. *If Algorithm* 2 *is applied to a general convex function* f, *which does not necessarily attain its infimum on* R^N, *then either of the following holds*:

(i) *The sequence* $\{x^k\}$ *is finite and its last element* x^k *minimizes* f *on the set* $\bigcup_{j=1}^k E_j$;

(ii) $\{x^k\}$ *is infinite and* $\lim_{k\to\infty} f(x^k) \leqq \inf\{f(x): x \in \bigcup_{j=1}^\infty E_j\}$ (*e.g.*, $\lim_{k\to\infty} f(x^k) = -\infty$).

Proof. Extend Lemma 4.1 by showing that

$$T(f(x^k)) \cap \bigcup_{j=1}^k E_j \subset E_k \tag{4.9}$$

and use the proof of Lemma 4.3 with $\bar{f} > f(x)$ and an arbitrary $x \in \bigcup E_j$ to deduce that either (i) or (ii) holds if Step 3 is executed infinitely often. In the remaining case, suppose that $\{f(x^k)\}$ is bounded from below and obtain (ii) from the proofs of Lemmas 4.5 and 4.6.

Note that relations (2.16) and (4.9) imply that

$$f(x^k) \leqq \min\left\{f(x): x \in \bigcup_{j=1}^k E_j\right\} + |p^k|_{B_k} + \bar{\alpha}_p^k,$$

which justifies the stopping criterion of Step 2 in the general case.

5. Ellipsoid updating strategies. Proceeding as in [G6], we can establish an upper bound on the rate of convergence in objective values in terms of the rate of volume reduction of successive ellipsoids of the method. To obtain a faster volume reduction, the following modification will use more ellipsoid cuts.

Suppose that at Step 0 we choose a fixed $\bar{\omega} \in (-1/N, 0]$. Steps 2 and 3 are replaced by the following:

Step 2′ (Stopping criterion). If $|p^k|_{B_k} + \bar{\alpha}_p^k \leqq \varepsilon_s$ or $|g^j|_{B_k} + \bar{\alpha}_j^k \leqq \varepsilon_s$ for some $j \in J^k$, terminate; otherwise, continue.

Step 3′ (Ellipsoid updating). (i) Set the ellipsoid update indicator $i_E = 0$.

(ii) Compute the algebraic distances

$$\omega_p^k = -\bar{\alpha}_p^k / |p^k|_{B_k} \quad \text{if } i_E = 0 \quad \text{and} \quad \omega_j^k = o - \bar{\alpha}_j^k / |g^j|_{B_k} \quad \text{for } j \in J^k$$

from x_c^k to H_p^k and H_j^k, respectively (cf. (2.13), (2.17)). Let j^* maximize ω_j^k over $j \in J^k$. If $i_E = 0$ and $\omega_p^k \geqq \omega_{j^*}^k$, set $\omega = \omega_p^k$ and $H = H_p^k$; otherwise, set $\omega = \omega_{j^*}^k$ and $H = H_{j^*}^k$.

(iii) If $\omega < \bar{\omega}$, go to (v); otherwise, continue.

(iv) Let $E_+ = \{x \in R^N : |x - x_c^+|_{A_+} \leqq 1\}$ be the smallest-volume ellipsoid containing $E_k \cap H$. Set $i_E = 1$, replace x_c^k and B_k by x_c^+ and A_+^{-1}, and go to (ii).

(v) If $i_E = 0$, go to Step 4; otherwise, choose $\eta^+ \in (0, \eta_u]$, replace η^k by η^+, and go to Step 1.

The modification above uses "ordinary" cuts based on relations (2.17), which provide the following analogue of (2.18)

$$f(x^k) \leqq \min f + |g^j|_{B_k} + \bar{\alpha}_j^k \tag{5.1}$$

for the stopping criterion. Step 3′(ii) chooses the (possibly nonunique) *deepest* cut if $\omega > 0$, or the *least shallow* cut if $\omega \leqq 0$. The condition $\omega \geqq \bar{\omega} > -1/N$ ensures a significant volume reduction, since at Step 3′(iv) we have $\operatorname{Vol}(E_+) = q(\omega) \operatorname{Vol}(E_k)$ with

$$q(\omega) = \left(\frac{N^2}{N^2-1}\right)^{(N-1)/2} \frac{N}{N+1} (1-\omega^2)^{(N-1)/2}(1-\omega),$$

$$q(\omega) \leqq q(\bar{\omega}) \leqq \bar{q} := e^{-N(\bar{\omega}+1/N)^2/3} < 1$$

for $N > 1$ (see [T1], [G7]). On the other hand, $\omega < \bar{\omega}$ implies that

$$|\bar{\omega}| E_k \subset T^k \subset E_k, \tag{5.2}$$

where $T^k = E_k \cap \bigcap_{j \in J^k} H_j^k$ is an outer approximation to $E_k \cap T(f(x^k))$. If we had $\bar{\omega} = -1/N$ and $T^k = T(f(x^k))$, relation (5.2) would mean that the matrix A_k of E_k is a generalized "Hessian" of [G7]. (This terminology comes from the fact that for a smooth convex f with a minimizer x^* the classical Hessian at x^* is associated with the limit of the smallest ellipsoid containing (or the largest ellipsoid contained in) $[T(f(x^*) + \varepsilon^2/2) - x^*]/\varepsilon$ as $\varepsilon \downarrow 0$; see [G7] for details). Wanting E_k to be close to T^k, and hence to $T(f(x^k))$, we would like to have a large value of $|\bar{\omega}|$ in (5.2). Since such a value cannot, in general, be greater than $1/N$ (see [G7]), whereas $\bar{\omega}$ close to $-1/N$ may result in exceedingly many updates, in practice we use $\bar{\omega} = -1/2N$.

The *deepest aggregate* (or surrogate) cut is defined if x_c^k is cut off by at least one half-space H_j^k with $\bar{\alpha}_j^k > 0$. This cut is given by the half-space $\hat{H}^k$ containing $\bigcap_{j \in J^k} H_j^k$ that is furthest from x_c^k in the metric of $|\cdot|_{A_k}$. $\hat{H}^k$ can be found by projecting x_c^k on $\bigcap_j H_j^k$. Thus we may find for d_H^k:

$$\begin{aligned} &\text{minimize } \tfrac{1}{2}|d|_{A_k}^2, \\ &\text{subject to } -\bar{\alpha}_j^k + \langle g^j, d\rangle \leqq 0 \quad \text{for } j \in J^k, \end{aligned} \tag{5.3}$$

since $\hat{H}^k = \{x: \langle -A_k d_H^k, x - x_c^k \rangle \leqq -|d_H^k|_{A_k}^2\}$. Equivalently, we may find the Lagrange multipliers $\lambda_{H,j}^k$ of (5.3) that

$$\text{minimize } \frac{1}{2}\left|\sum_{j\in J^k} \lambda_j g^j\right|_{B_k}^2 + \sum_{j\in J^k} \bar{\alpha}_j^k,$$

$$\text{subject to } \lambda_j \geqq 0 \quad \text{for } j \in J^k,$$

and let

$$(p_H^k, \alpha_H^k) = \sum_{j\in J^k} \lambda_{H,j}^k (g^j, \bar{\alpha}_j^k),$$

since then $d_H^k = -B_k p_H^k$ and

$$\hat{H}^k = \{x \in R^N: \langle p_H^k, x - x_c^k \rangle \leqq \alpha_H^k\}. \tag{5.4}$$

Of course, finding the deepest aggregate cut involves additional work in quadratic programming. Therefore, it is worthwhile to observe that the usual aggregate cut may be close to the deepest one. For instance, $\hat{H}^k = H_p^k$ if $v^k = 0$. Indeed, in this case subproblems (2.5) and (5.3) produce $\bar{d}^k = d_H^k$, $p^k = p_H^k$, and $\bar{\alpha}_p^k = \alpha_H^k$, so that relations (2.13) and (5.4) imply that $H_p^k = \hat{H}^k$. This suggests that H_p^k approximates $\hat{H}^k$ whenever $|v^k|$ is small relative to $|g^j|_{B_k}$ for $j \in J^k$.

Note that at Step 3′ we could go from (iv) to (v) directly.

There exists an additional possibility for updating the ellipsoid after a serious step. When $x^{k+1} \neq x^k$ at Step 7, we may compute $\bar{\alpha}_j^{k+1}$, $j \in J^k$, $\bar{\alpha}_p^{k+1} = \bar{\alpha}_p^k + f(x^{k+1}) - f(x^k)$, increase k by 1, and, before going to Step 1, execute Steps 2′ and 3′.

So far we have restricted our discussion to single cuts. To obtain a greater reduction in volume, at Step 3′(iv) we may choose a subset J_H^k of J^k such that $\omega_j^k \geqq \bar{\omega}$ for some $j \in J_H^k$, and then let E_+ be the smallest-volume ellipsoid containing the set $S^k = E_k \cap \bigcap_{j\in J_H^k} H_j^k$. In practice the construction of E_+ may be too complicated if J_H^k has more than two elements (see [S3]); for two elements explicit formulae are given in [G1], [E1]. In fact, it is not absolutely necessary to use minimum volume ellipsoids, and we may let E_+ be any ellipsoid containing S^k such that $\text{Vol}(E_+) \leqq q(\bar{\omega})\,\text{Vol}(E_k)$. This extra freedom may facilitate the construction of E_+.

It is straightforward to verify that all the modifications discussed in this section are covered by the convergence analysis of § 4.

We conclude that the algorithm can use a variety of techniques for updating its ellipsoids. Naturally, the best strategy is open to question.

6. Implementation. In this section we discuss our implementation of the algorithm. As in [G8], at the kth iteration we use the factorization

$$B_k = LDL^T$$

with L a lower triangular $N \times N$ matrix with unit diagonal and $D = \text{diag}(d_1, \cdots, d_N)$ a diagonal matrix with positive diagonal. Let $\tilde{B}_k = LD^{1/2}$, so that $B_k = \tilde{B}_k \tilde{B}_k^T$. We do not store the subgradients g^j, but update the vectors

$$\tilde{g}^j = \tilde{B}_k^T g^j = D^{1/2} L^T g^j \quad \text{for } j \in J^k. \tag{6.1}$$

Step 1 is implemented with the quadratic programming routine of [K3]. This routine solves the following version of the dual subproblem (2.11):

$$\begin{aligned} &\text{minimize } \frac{1}{2}\left|\sum_{j\in J^k}\lambda_j\tilde{g}^j\right|^2+\sum_{j\in J^k}\lambda_j\eta^k\bar{\alpha}_j^k,\\ &\text{subject to } \sum_{j\in J^k}\lambda_j=1,\quad \lambda_j\geqq 0\quad \text{for } j\in J^k. \end{aligned} \tag{6.2}$$

It also computes, as byproducts, the quantities

$$(\tilde{p}^k,\bar{\alpha}_p^k)=\sum_{j\in J^k}\lambda_j^k(\tilde{g}^j,\bar{\alpha}_j^k), \tag{6.3}$$

$|p^k|_{B_k}^2=|\tilde{p}^k|^2$, and $\eta^k v^k=-\{|\tilde{p}^k|^2+\eta^k\bar{\alpha}_p^k\}$ (cf. (2.9b)). Hence we can calculate $|\bar{d}^k|_{A_k}^2=|\tilde{p}^k|^2/(\eta^k)^2$ and

$$\bar{d}^k=-(1/\eta^k)\tilde{B}_k\tilde{p}^k=-(1/\eta^k)LD^{1/2}\tilde{p}^k. \tag{6.4}$$

The algorithm terminates at Step 2′ if

$$\min\{|\tilde{p}^k|+\bar{\alpha}_p^k,|\tilde{g}^j|+\bar{\alpha}_j^k: j\in J^k\}\leqq\varepsilon_s(1+|f(x^k)|), \tag{6.5}$$

where $\varepsilon_s>0$ is the desired relative final accuracy in the objective value, i.e., $f(x^k)-\min f\leqq\varepsilon_s(1+|f(x^k)|)$ at termination; see (2.18), (5.1). (This stopping criterion is less sensitive to problem scaling than that of Algorithm 3.1.) Hence we compute the norms $|\tilde{g}^j|$, which are also needed by the quadratic programming routine.

For simplicity, we use the single cuts described at Step 3′ in § 5.

The ellipsoid updating at Step 3′(iv) is trivial if $N=1$. Hence, suppose that $N>1$ and H_p^k is used to cut E_k. As in [G8], we compute $\omega_p^k=-\bar{\alpha}_p^k/|\tilde{p}^k|$,

$$\begin{aligned} &\omega=\min\{\omega_p^k,1-\varepsilon_M\},\\ &t_c=(1+N\omega)/(N+1)|\tilde{p}^k|,\\ &x_c^+=x_c^k-t_cLD^{1/2}\tilde{p}^k,\\ &\delta=N^2(1-\omega^2)/(N^2-1),\\ &\sigma=2(1+N\omega)/(N+1)(1+\omega), \end{aligned} \tag{6.6}$$

where the use of the relative machine precision ε_M ensures that the updated matrix $B_+=A_+^{-1}$ given by

$$B_+=\delta[B_k-\sigma B_kp^k(B_kp^k)^T/|p^k|_{B_k}^2]$$

can be factorized as $B_+=L_+D_+L_+^T$ with L_+ lower triangular and D_+ diagonal with positive diagonal. More specifically, we compute

$$\gamma=D^{1/2}\tilde{p}^k/|\tilde{p}^k|,$$

so that $B_+=L[\delta(D-\sigma\gamma\gamma^T)]L^T$, and then find a diagonal matrix $\tilde{D}=\operatorname{diag}(\tilde{d}_1,\cdots,\tilde{d}_N)$ and a unit lower triangular matrix $\tilde{L}=(\tilde{l}_{ij})$ such that $D-\sigma\gamma\gamma^T=\tilde{L}\tilde{D}\tilde{L}^T$ by using the following recurrence relations:

(i) Set $t_{N+1}=(N-1)/(N+1)(1-\omega)/(1+\omega)$;

(ii) For $j=N-1,\cdots,1$ set

$$\begin{aligned} &t_j=t_{j+1}+\sigma\gamma_j^2/d_j,\\ &\tilde{d}_j=d_jt_{j+1}/t_j,\\ &\beta_j=-\sigma\gamma_j/(d_jt_{j+1}) \end{aligned}$$

and by setting $\tilde{l}_{ij} = \gamma_i \beta_j$ for $j < i$ (see [G3]). Then $D_+ = \delta \tilde{D}$ and the product $L_+ = (l_{ij}^+) V = L\tilde{L}$ can be computed from the recurrence relations (see [G2]):

(i) Set $q_N^N = \gamma_N$;

(ii) For $j = N-1, \cdots, 1$ set

$$\begin{aligned} q_j^j &= \gamma_j, \\ l_{ij}^+ &= l_{ij} + \beta_j q_i^{i+1} \\ q_i^j &= q_i^{j+1} + \gamma_j l_{ij} \end{aligned} \quad \text{for } i = j+1, \cdots, N.$$

To update the quantities $\bar{\alpha}_j^k = f(x^k) - f_j(x_c^k)$ we use the relations

$$f_j(x_c^+) - f_j(x_c^k) = \langle g^j, x_c^+ - x_c^k \rangle = \langle \tilde{g}^j, \tilde{B}_k^{-1}(x_c^+ - x_x^k) \rangle = -t_c \langle \tilde{g}^j, \tilde{p}^k \rangle,$$

which follow from (6.1) and (6.6). Next, to update the transformed subgradients (6.1), we note that

$$D_+^{1/2} L_+^T g^j = D_+^{1/2} \tilde{L}^T L^T g^j = D_+^{1/2} \tilde{L}^T D^{-1/2} \tilde{g}^j,$$

so that $\bar{g}^j = D_+^{1/2} L_+^T g^j$ can be computed from the backward recurrence (see [G2]):

(i) Set $s = 0$, $\bar{g}_N^j = \tilde{d}_N \tilde{g}_N^j$;

(ii) For $i = N, N-1, \cdots, 2$ set

$$\begin{aligned} s &= s + \tilde{\gamma}_i \tilde{g}_i^j, \\ \bar{g}_{i-1}^j &= \tilde{d}_{i-1} \tilde{g}_{i-1}^j + \tilde{\beta}_{i-1} s, \end{aligned}$$

where the quantities $\tilde{d}_i = (d_i^+ / d_i)^{1/2}$, $\tilde{\gamma}_i = \gamma_i / d_i^{1/2}$, $\tilde{\beta}_i = \beta_i (d_i^+)^{1/2}$ are computed beforehand, using the stored values of $d_i^{1/2}$ and $(d_i^+)^{1/2}$.

The convergence analysis of § 4 imposes only weak restrictions on the choice of $\{\eta^k\}$. Relation (5.2) with $|\bar{\omega}| = \frac{1}{2}N$ suggests that it may be useful to restrict the trial point finding to the smaller ellipsoid $|\bar{\omega}| E_k$ which, being an inner approximation to T^k, should be almost contained in $T(f(x^k))$. Hence our strategy for selecting η^k aims for y^{k+1} to

$$\begin{aligned} &\text{minimize } \hat{f}^k(y) \\ &\text{subject to } y \in r_e E_k \end{aligned}$$

or equivalently for $\bar{d}^k = y^{k+1} - x_c^k$ to

$$\begin{aligned} &\text{minimize } \hat{f}^k(x_c^k + \bar{d}) \\ &\text{subject to } |\bar{d}|_{A_k} \leqq r_e, \end{aligned} \tag{6.7}$$

where $r_e \in (0, 1]$ is a trust region radius. We use the fixed value $r_e = 1/2N$ (corresponding to $\bar{\omega} = -1/2N$), which seems to work better than $r_e = 1$, although an adaptive choice of r_e at each iteration could be more efficient.

We relate subproblems (6.2) and (6.7) through the following choice of η^k. At Steps 3'(v) and 7 we set η^+ and η^{k+1} (if $x^{k+1} \neq x^k$) to the value of $\eta_{\min} = 10^{-5}$, since smaller values may lead to inaccuracies at quadratic programming (cf. (6.4)). At Step 4, if $|\bar{d}^k|_{A_k} > 1.2 r_e$, η^k is increased to

$$\eta^+ = \max \{1.2 |\bar{d}^k|_{A_k} / r_e, \chi\} \eta^k, \tag{6.8}$$

where $\chi > 1$ is a parameter. When η^+ replaces η^k in (6.2), the corresponding $\tilde{p}^+$ and $\bar{d}^+$ given by (6.3) and (6.4) satisfy $|\tilde{p}^+| \geqq |\tilde{p}^k|$, $|\bar{d}^+|_{A_k} = |\tilde{p}^+| / \eta^+$ and

$$|\bar{d}^+|_{A_k} \geqq |\bar{d}^k|_{A_k} \eta^k / \eta^+ \geqq \min \{1/1.2, 1.2/\chi\} r_e.$$

Hence, eventually we get

$$\min\{1/1.2, 1.2/\chi\} r_e \leqq |\bar{d}^k|_{A_k} \leqq 1.2 r_e, \tag{6.9}$$

which implies satisfaction of the trust region constraint of (6.7) with the relative accuracy of 20 percent if $\chi = 1.5$. It might appear that, since η^k is not decreased after null steps with no ellipsoid updates, we could have $|\bar{d}^k|_{A_k}$ much smaller than r_e at Step 4. Yet in our calculations the bound (6.9) was (slightly) violated in negligibly few cases.

We could, of course, consider other ways of selecting η^k, e.g., safeguarded interpolation using parametric analysis of subproblem (6.2) with respect to η^k. We note that when the change of η^k is small enough, our quadratic programming routine [K3] can solve the new subproblem very quickly by exploiting the information gathered so far.

We use the following subgradient selection strategy. At Step 0 we choose the maximum number $M_g \geqq N+2$ of stored subgradients. At Step 6 we initially set $J^{k+1} = J^k \cup \{k+1\}$ and then, if necessary, drop from J^{k+1} an index $j \notin \hat{J}^k$ with the largest value of $f(x^{k+1}) - f_j(x_c^k)$, so that J^{k+1} has at most M_g elements.

It is worth adding that, in theory, the algorithm can be made invariant with respect to the objective scaling. To this end, consider the following version. At Step 0 we choose $r_e \in (0, 1]$ and set $\eta^1 = |\tilde{p}^1|/r_e$. At Step 2′ we delete the "1" from the stopping criterion (6.5). At Steps 3′(v) and 7 we set η^+ and η^{k+1} (if $x^{k+1} \neq x^k$) equal to $\eta_u \eta^k$. At Step 4 η^k is not changed if $|\bar{d}^k|_{A_k} \leqq 1.2 r_e$; otherwise, η^+ is calculated from (6.8). Moreover, suppose that the arbitrary decisions of Steps 3′(ii) and 6, concerning the selection of cuts and subgradients, are made according to some fixed rules that account for the possible ties. Note that the proof of Lemma 4.4 can be extended to cover this version.

The described version above is scale invariant in the following sense. Applying the algorithm to f, we get sequences $\{x^k\}$, $\{\bar{d}^k\}$, $\{A_k\}$, $\{\eta^k\}$, etc. Next, suppose we use the same parameters at Step 0 and apply the algorithm to sf, where $s > 0$ is fixed, with the subgradient mapping sg_f to get sequences $\{x_s^k\}$, $\{\bar{d}_s^k\}$, $\{A_k^s\}$, $\{\eta_s^k\}$. Then $x_s^k = x^k$, $d_s^k = \bar{d}^k$, $A_k^s = A_k$, and $\eta_s^k = s\eta^k$ for all k such that termination does not occur before iteration k. To save space, we omit an inductive proof of this fact. (Some hints for the proof: multiply the objective of (6.2) by s^2 and relations (6.3), (6.8), (2.4), and (2.19) by s, observe that the division in (6.4) cancels s, and use the uniqueness of $(\hat{p}^k, \bar{\alpha}_p^k)$ and relations (2.13) and (2.17) for ellipsoid updates.)

7. Subgradient aggregation. The algorithm described so far will typically use $N+2$ past subgradients at each iteration. We now show how the subgradient aggregation strategy of [K2] can be used to trade off storage and work per iteration for speed of convergence.

At Step 0 we choose the maximum number $M_g \geqq 1$ of stored "ordinary" subgradients. The aggregate subgradient is a convex combination of "ordinary" subgradients, which is generated recursively as follows. At Step 0 we define $p^0 = g^1$ and $\tilde{f}^0(x) = f(y^1) + \langle p^0, x - x^1 \rangle$ for all x. At Step 1 we append to subproblem (2.5) the aggregate constraint

$$-\bar{\alpha}_p^{k-1} + \langle p^{k-1}, \bar{d} \rangle \leqq v, \tag{7.1}$$

where $\bar{\alpha}_p^{k-1} = f(x^k) - \tilde{f}_p^{k-1}(x_c^k)$, and use the Lagrange multiplier λ_p^k of (7.1) to define

$$(p^k, \bar{\alpha}_p^k) = \sum_{j \in J^k} \lambda_j^k (g^j, \bar{\alpha}_j^k) + \lambda_p^k (p^{k-1}, \bar{\alpha}_p^{k-1}).$$

As before, we define $\tilde{f}^k(x) = f(x^k) - \bar{\alpha}_p^k + \langle p^k, x - x_c^k \rangle$ to close the recursion. Then at Step 6 we may let J^{k+1} contain $k+1$ as well as any other $M_g - 1$ past indices, e.g., indices j with the largest values of ω_j^k.

Reasoning as in [K2, § 2.4], we may verify that the convergence results of § 4 remain valid for the version with subgradient aggregation.

8. Numerical examples. We shall now report on computational testing of the algorithm using a double precision Fortran code on an IBM PC/XT clone microcomputer with relative accuracy $\varepsilon_m = 2.2 \times 10^{-16}$ ($= 2.2E-16$).

The parameters of the algorithm had the values $m = 0.1$, $\eta_u = 1E-5$, $\chi = 2$, $\bar{\omega} = -1/2N$ (cf. (5.2)), and $r_e = 1/2N$ (cf. (6.7)).

Table 8.1 summarizes results for several standard test problems taken from the literature, which are reviewed below. The following notation is used. N is the number of variables, M_g is the maximum number of stored past subgradients, x^* is the known solution of a problem, x^1 is the standard starting point, $V^1 = \mathrm{Vol}\,(E_1)$, k is the iteration number at termination, $V^k = \mathrm{Vol}\,(E_k)$ is the volume of the final ellipsoid, and m_e is the total number of ellipsoid updates. The stopping criterion (6.5) was used with a value of ε_s chosen for each problem so as to facilitate comparison with results reported in the literature. For each run of the algorithm, an initial ellipsoid was specified by choosing positive tolerances δ_i such that $|x_i^1 - x_i^*| \leqq \delta_i$ and setting $d_i = N\delta_i^2$ for $i = 1, \cdots, N$ in the initial matrix $B_1 = \mathrm{diag}\,(d_1, \cdots, d_N)$. Typically, three runs with increasing δ_i (denoted by δ^a, δ^b, and δ^c) are reported for each problem.

Example 8.1. The Shor problem has $N = 5$,

$$f(x) = \max\left\{ b_i \sum_{j=1}^{5} (a_{ij} - x_j)^2 : i = 1, \cdots, 10 \right\},$$

$$x^* = (1.12434, 0.97945, 1.47770, 0.92023, 1.12429),$$

$x^1 = 0, 0, 0, 0, 1)$, $\delta_i^{1,a} = |x_i^1 - x_i^*|$ for all i, $\delta_i^{1,b} = 2$ for all i, $\delta_i^{1,c} = 10$ for all i (see [S1, p. 137] for the data a_{ij} and b_i).

Example 8.2. The first Colville problem has $N = 5$,

$$f(x) = \sum_{j=1}^{5} d_j x_j^3 + \sum_{i=1}^{5} \sum_{j=1}^{5} c_{ij} x_i x_j + \sum_{j=1}^{5} e_j x_j + 50 \max\{F(x), 0\},$$

$$F(x) = \max\left\{ b_i - \sum_{j=1}^{5} a_{ij} x_j : i = 1, \cdots, 10 \right\},$$

$x^* = (0.3, 0.3335, 0.4, 0.4285, 0.224)$, $x^1 = (0, 0, 0, 0, 1)$, $\delta_i^{2,a} = |x_i^1 - x_i^*|$, $\delta_i^{2,b} = 1$ and $\delta_i^{2,c} = 10$ for all i (see, e.g., [K2, p. 350] for the problem data).

Example 8.3. The Rosen-Suzuki problem has $N = 4$,

$$f(x) = x_1^2 + x_2^2 + 2x_3^2 + x_4^2 - 5x_1 - 5x_2 - 21x_3 + 7x_4 + F(x),$$

$$F(x) = 5 \max\{F_1(x), F_2(x), F_3(x), 0\},$$

$$F_1(x) = x_1^2 + x_2^2 + x_3^2 + x_4^2 + x_1 - x_2 + x_5 - x_4 - 8,$$

$$F_2(x) = x_1^2 + 2x_2^2 + x_3^2 + 2x_4^2 - x_1 - x_4 - 10,$$

$$F_3(x) = x_1^2 + x_2^2 + x_3^2 + 2x_1 - x_2 - x_4 - 5,$$

$x^* = (0, 1, 2, -1)$, $x_1 = (0, 0, 0, 0)$, $\delta^{3,a} = (1E-4, 1, 2, 1)$, $\delta_i^{3,b} = 2$ and $\delta_i^{3,c} = 10$ for all i.

Example 8.4. Lemaréchal's MAXQUAD problem has $N = 10$,

$$f(x) = \max \{\langle A^L x, x\rangle - \langle b^L, x\rangle : L = 1, \cdots, 5\},$$
$$A_{ij}^L = A_{ji}^L = \exp(i/j)\cos(i \cdot j)\sin(L), \quad i \neq j,$$
$$A_{ii}^L = i|\sin(i)|/10 + \sum_{j \neq i} |A_{ij}^L|,$$
$$b_i^L = \exp(i/L)\sin(i \cdot L).$$

(This problem is difficult to quote: misprints abound in [K2, pp. 346-347], [L2, p. 151], [Z1, Ex. 7.2], etc.). In [L2, p. 152] the optimum value $f(\bar{x}) = -0.8414$ is quoted for a point $\bar{x}$ which in fact has $f(\bar{x}) = -0.8411$. The best point known to us is

$$x^* = (-0.126257, -3.43783E-2, -6.85716E-3, 2.63606E-2, 6.72949E-2,$$
$$-0.278400, 7.42187E-2, 0.138524, 8.4031E-2, 3.85804E-2)$$

with $f(x^*) = -0.841408$. We used $x^1 = 0$, $\delta_i^{4,a} = |x_i^*|$, $\delta_i^{4,b} = 0.3162$ (corresponding to $d_i = 1$) and $\delta_i^{4,c} = 2$ for all i.

Example 8.5. This academic problem MXHILB with

$$f(x) = \max\left\{\left|\sum_{j=1}^{N} x_i/(i+j-1)\right| : i = 1, \cdots, N\right\}, \qquad x^* = 0,$$

corresponds to solving the equation $Ax = b$, where $b = 0$ and A is an $N \times N$ section of the Hilbert matrix. We used $x^1 = (1, \cdots, 1)$ and $\delta_i^{5,a} = 5$ for all i with $N = 30$ and $N = 50$.

Example 8.6. Problem L1HILB with

$$f(x) = \sum_{j=1}^{N} \left|\sum_{i=1}^{N} x_i \Big/ (i+j-1)\right|, \qquad x^* = 0,$$

is a more difficult version of MXHILB, since it has 2^N linear pieces, whereas MXHILB has $2N$. We used $x_i^1 = 1$, $\delta_i^{6,a} = 5$ for $i = 1, \cdots, N = 30, 50$.

Example 8.7. Lemaréchal's SHELL DUAL problem [L2, p. 154] has a highly nonconvex objective function f of 15 variables, with $f(x^*) = 32.3488$ for

$$x^* = (0.3, 0.3335, 0.4, 0.4283, 0.224, 0, 0, 5.1741, 0, 3.0611, 11.8396, 0, 0, 0.1039, 0).$$

This problem seems to be very difficult for general-purpose descent methods (see [L1]). To tackle nonconvexity, we have incorporated in the algorithm the two-point line search of [K2, p. 103] (with parameters $\bar{t} = 0.01$, $\xi = 0.1$, $\gamma = 10$). To this end, we computed the search direction $d^k = \bar{d}^k + x_c^k - x^k$ from x^k, and the line search procedure found two stepsizes t_L^k and t_R^k, $0 \leqq t_L^k \leqq t_R^k \leqq 1$, the next iterate $x^{k+1} = x^k + t_L^k d^k$, and the next trial point $y^{k+1} = x^k + t_R^k d^k$ that provided the next linearization f_{k+1} of f. Of course, the algorithm is not guaranteed to minimize a nonconvex f. Nevertheless, for $x_i^1 = 1E-4$, $i \neq 12$, $x_{12}^1 = 60$ and

$$\delta = (0.3, 0.3335, 0.4, 0.4283, 0.224, 0.1, 0.1, 10, 0.1, 5, 15, 100, 0.1, 1, 0.1)$$

($f(x^1) = 2400$, $|x^1 - x^*|_{A_1} = 0.66$, $V^1 = 7.3E+5$), the algorithm did converge to an approximate solution, although the usual stopping criterion (6.5) did not work with $\varepsilon_s = 1E-4$ and termination occurred due to exceeding the function evaluation limit of 600. Table 8.2 illustrates the algorithm's progress, with NFEV denoting the total number of function and subgradient evaluations.

Our results for Examples 8.1-8.4 and 8.7 may be compared with those in [S1, p. 139], [L1], [Z1], and [K2, pp. 346-349]. Additionally, Table 8.3 gives results for f scaled by $s = 0.01$, 1, and 100. They were produced by the usual bundle method of [K2, Chap. 2], the present method and the shifted ellipsoid method suggested by a referee. This third method is obtained from Algorithm 3.1 by setting $x_c^1 = x^1$ at Step 0,

[1] Termination due to the iterations limit.

deleting Step 3 and setting $x_c^{k+1} = x^{k+1}$ and $A_{k+1} = A_k$ at Step 7; in effect, the initial ellipsoid trust region only shifts with its center x^k, but does not shrink. Using the same line search procedure for handling nonconvexity, the three methods were applied to scaled versions of the Shell Dual; see Tables 8.4-8.6. (For Examples 8.1-8.4 we quote results only for the smallest δ^a. With $\delta = \delta^b$ or δ^c both our method and the shifted ellipsoid method converge more slowly; cf. Table 8.1.)

A comment on the variation in η^k is in order. Usually the final η^k (at Step 5) decreases "smoothly" as k grows, e.g., from 1300 to $6E-4$, 1000 to 0.02, 660 to 0.013, 80 to 0.015, 1200 to $1.5E-5$, 4500 to $1.3E-5$, 8200 to $1E-5$, and from 3900 to $1E-5$

600	198	32.844	243	32.583	177	37.4

for the problems with $s=1$ reported in Table 8.3 for our method, respectively (and from $5.3E+5$ to 70 for the Shell Dual). A similar variation in η^k is observed for the shifted ellipsoid method. Naturally, η^k increases (decreases) for larger (smaller) s.

Of course, no firm conclusions should be drawn from such limited computational experience, but the test results indicate that our method is promising.

9. Conclusions. We have shown how to incorporate an ellipsoid variable metric in a bundle method for convex minimization. The method seems to be promising. We hope to increase its efficiency by using more refined ellipsoid updates.

Acknowledgment. I would like to thank Claude Lemaréchal and two anonymous referees for several helpful suggestions.

ASYMPTOTIC BEHAVIOR OF SOLUTIONS OF THE ONE-DIMENSIONAL WAVE EQUATION WITH A NONLINEAR BOUNDARY STABILIZER*

HAN-KUN WANG† AND GOONG CHEN‡

Abstract. The modeling of nonlinear passive damping devices or boundary frictions of an otherwise linear vibrating system often results in nonlinear elastic dissipative boundary conditions. Such systems occur increasingly often in engineering applications, whose control and stability analysis appear much more complex than the classical linear distributed parameter systems.

This paper uses the method of characteristics and nonlinear semigroup theory to study the effect of nonlinear boundary stabilization and analyze the asymptotic behavior of solutions of such systems. The authors are able to determine the ω-limit set of the dynamical system and the asymptotic rates of various solutions to the ω-limit set.

Key words. wave equation, nonlinear dissipative boundary condition, ω-limit set

AMS(MOS) subject classifications. 93D15, 93D20, 73D35

1. Introduction. The study of vibration control and suppression has always been an important research area in mechanical and aerospace engineering. Traditionally, as far as passive damping devices are concerned, the most commonly seen ones are probably the viscous dashpots, whose action is to cause a frictional force opposite to the direction of velocity. This frictional force versus velocity relationship is approximately linear, at least within a certain designed operating range. This makes the analysis, design, and control of such linear mechanical systems simple and easily understandable. Nevertheless, such classical linear dashpots are bulky, expensive, and inconvenient to replace and repair.

The advance of modern material science and technology has provided us with useful alternatives such as elastomeric and other viscoelastic damping materials which are generally light weight, durable, and convenient to service. Their utilization in high-performance helicopters, combat aircraft, and vessels in aerospace and naval engineering have sharply increased in the past decade. However, such visco-thermo-elastic materials have highly nonlinear characteristics that cause significant nonlinear response in the entire system. The questions of analysis, design, and control appear more difficult. To the best of our knowledge, research work on such nonlinear energy dissipating devices or materials in a distributed parameter system is rather incomplete.

In this paper, we wish to undertake some research in the above direction. As a modest model, we study a distributed parameter system whose governing equation is linear, viz., a simple one-dimensional wave equation, but the boundary condition is nonlinear dissipative as exemplified by the use of the aforementioned elastomeric material. We will study the effects of vibration and questions involving nonlinear friction. Let us describe our problem below.

Let a vibrating cable or string with mass density m and tension T satisfy the one-dimensional wave equation

$$m\frac{\partial^2 y(x,t)}{\partial t} - T\frac{\partial^2 y(x,t)}{\partial x^2} = 0, \qquad 0<x<1, \qquad t>0. \tag{1.1}$$

† Department of Mathematics, The Wichita State University, Wichita, Kansas 67208.

‡ Department of Mathematics, Texas A&M University, College Station, Texas 77843.

In the equation, $y(x, t)$ denotes the vertical displacement at x at time t, and the length has been normalized to 1. Assume that the string is fixed at the right end:

$$y(1, t) = 0 \quad \text{for all } t > 0. \tag{1.2}$$

At the left end, either some frictional force is present, or a damping device such as a dashpot is installed, as illustrated in Fig. 1. The function of the dashpot is to cause friction, thereby suppressing undesirable vibrations. For an idealized dashpot, the force is assumed to be negatively proportional to velocity at $x = 0$:

$$T\frac{\partial y(0, t)}{\partial x} = k\frac{\partial y(0, t)}{\partial t}, \qquad k > 0, \tag{1.3}$$

where it is known that the left-hand side represents the (negative of) vertical force component at point $x = 0$. If we choose the elastic constant k to be T/c, where $c \equiv (T/m)^{1/2}$ is the wave velocity, then (1.3) becomes

$$\frac{\partial y(0, t)}{\partial t} - c\frac{\partial y(0, t)}{\partial x} = 0, \tag{1.4}$$

which is the characteristic impedance boundary condition. It is known to cause maximum energy loss to the string; the vibration is completely suppressed at time $t = 2/c$.

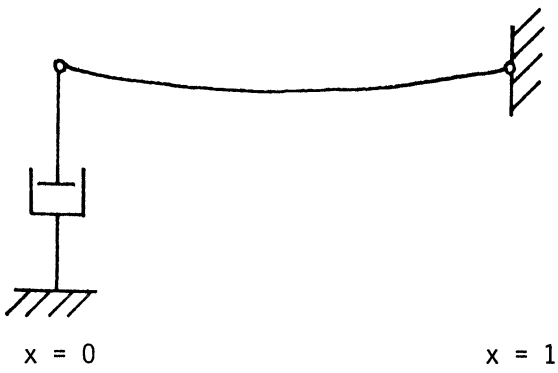

FIG. 1. *A vibrating string with a damping device at left end.*

Now, assume instead that a nonlinear damping device is used whose velocity-frictional force relationship as determined by material testing is as shown in Fig. 2, where a frictional force of magnitude F_0, called the Coulomb friction, is often found present in the nonlinear dashpot (e.g., due to the roughness of the dashpot wall, or due to the aforementioned elastomeric material). The left end point $x = 0$ can be set in motion only after this threshold of frictional force F_0 is overcome by the force exerted by the string at $x = 0$. The velocity range under testing is $[-v_0, v_0]$ for some $v_0 > 0$. Past v_0, plasticity sets in and the string does not behave elastically any more.

We must remark that the response curve as indicated in Fig. 2 has not incorporated the possible effects of *hysteresis*, i.e., the velocity may trace a different curve when it reverses its direction. We wish to address this in a future paper as we know that the hysteresis is an important, commonly observable phenomenon which needs to be carefully studied.

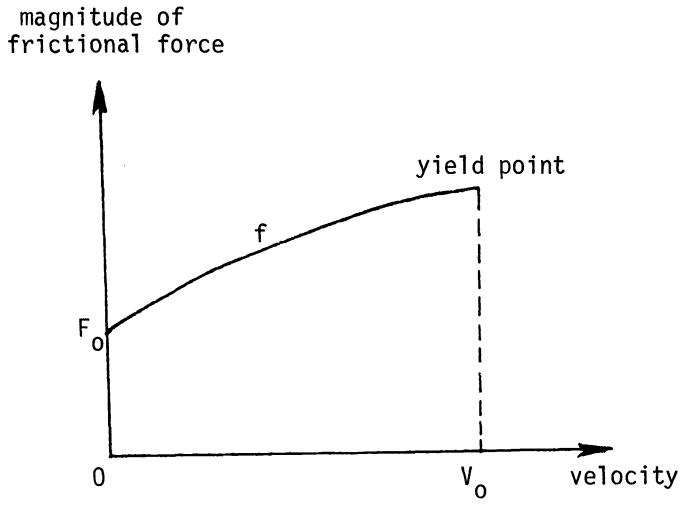

FIG. 2. *Velocity-force relation in a nonlinear dashpot.*

Therefore, we propose the following nonlinear elastic boundary condition as our model.

$$T\frac{\partial y(0,t)}{\partial x} = \bar{f}\left[\frac{\partial y(0,t)}{\partial t}\right], \tag{1.5}$$

where $\bar{f}(x)$ is a multivalued function defined by

$$\bar{f}(\eta) = \begin{cases} -F_0 + g(\eta), & -v_0 < \eta < 0, \\ [-F_0, F_0], & \eta = 0, \\ F_0 + g(\eta), & 0 < \eta < v_0, \end{cases} \tag{1.6}$$

where $[-F_0, F_0]$ denotes the closed interval from $-F_0$ to F_0, and $g(\eta) = f(\eta) - F_0$ for $\eta > 0$, $f(\eta)$ is the function as shown in Fig. 2, $g(\eta)$ satisfies

$$\begin{cases} g(\eta) \text{ is continuous and nondecreasing on } [-v_0, v_0], \\ g(\eta) > 0 \quad \text{if } \eta > 0, \\ g(0) = 0, \\ g(-\eta) = -g(\eta) \quad \text{for } \eta \geqq 0. \end{cases} \tag{1.7}$$

The restriction that the domain of definition of $\bar{f}$ is $[-v_0, v_0]$ is inconvenient. Let us enlarge it by extending g to be an arbitrary function outside $[-v_0, v_0]$ that still satisfies (1.7). Thus,

$$\bar{f}(\eta) = \begin{cases} -F_0 + g(\eta), & \eta < 0, \\ [-F_0, F_0], & \eta = 0, \\ F_0 + g(\eta), & \eta > 0. \end{cases} \tag{1.8}$$

Different extensions of g will not affect the solution provided that the initial data satisfies certain bounds (see the appendix). We also note that the function g may be *nondifferentiable.* Indeed, except for § 4, we do not need the differentiability of g in our treatment.

We wish to study the asymptotic behavior of the solution of (1.1), (1.2), and (1.5), with certain given initial conditions. Our main tools will be the method of characteristics and the nonlinear semigroup theory.

In § 2, we first transform the equation into a hyperbolic system. We show that there is a nonlinear semigroup corresponding to the evolution of the system.

In § 3, we determine the ω-limit set of the dynamical system. A solution may either enter the ω-limit set within finite time, or may circle around the ω-limit set indefinitely without entering it.

The asymptotic rates of convergence to the ω-limit set are determined for several cases in § 4.

2. A nonlinear semigroup of evolution. Define

$$\text{(2.1)}\qquad \begin{cases} \alpha(x,t)=\dfrac{1}{2}\left[\dfrac{\partial y(x,t)}{\partial t}-c\dfrac{\partial y(x,t)}{\partial x}\right] \\ \beta(x,t)=\dfrac{1}{2}\left[\dfrac{\partial y(x,t)}{\partial t}+c\dfrac{\partial y(x,t)}{\partial x}\right]. \end{cases}$$

Then the wave equation (1.1) implies

$$\text{(2.2)}\qquad \begin{cases} \dfrac{\partial}{\partial t}\begin{bmatrix}\alpha(\cdot,t)\\ \beta(\cdot,t)\end{bmatrix}+\begin{bmatrix} c\dfrac{\partial}{\partial x} & 0 \\ 0 & -c\dfrac{\partial}{\partial x}\end{bmatrix}\begin{bmatrix}\alpha(\cdot,t)\\ \beta(\cdot,t)\end{bmatrix}=0, \qquad t>0. \\ \text{with initial condition } (\alpha_0(\cdot),\beta_0(\cdot)) \text{ obtained by using} \\ \text{transformation (2.1).} \end{cases}$$

The right boundary condition (1.2) becomes

$$\text{(2.3)}\qquad \beta(1,t)=-\alpha(1,t), \qquad t>0.$$

Consider the left boundary condition (1.5). Since in (1.6), g satisfies $g(0)=0$, for the ease of treatment later on, we define $h(\eta)$ by

$$\text{(2.4)}\qquad h(\eta)=g(\eta)/\eta, \qquad \eta\in\mathbb{R}, \qquad \eta\neq 0.$$

Note that h may be discontinuous at $\eta=0$. From (1.6), using the newly defined h, we derive the following implicit boundary condition:

$$\text{(2.5)}\qquad \alpha(0,t)=\begin{cases} \dfrac{cF_0+[T-ch((\alpha+\beta)(0,t))]\beta(0,t)}{T+ch((\alpha+\beta)(0,t))}, & \beta(0,t)<-\dfrac{cF_0}{2T} \\ -\beta(0,t), & -\dfrac{cF_0}{2T}\leqq\beta(0,t)\leqq\dfrac{cF_0}{2T} \\ \dfrac{-cF_0+[T-ch((\alpha+\beta)(0,t))]\beta(0,t)}{T+ch((\alpha+\beta)(0,t))}, & \beta(0,t)>\dfrac{cF_0}{2T}. \end{cases}$$

For the evolution equation (2.2), the underlying Hilbert space is

$$\mathcal{H}=\left\{\begin{bmatrix}\alpha\\ \beta\end{bmatrix}\,\middle|\,\alpha,\beta\in\mathcal{L}^2(0,1)\right\}=\mathcal{L}^2(0,1)\times\mathcal{L}^2(0,1),$$

whose $\mathcal{L}^2\times\mathcal{L}^2$ product norm is equivalent to the energy of the wave equation. From now on, we will write $\begin{bmatrix}\alpha\\ \beta\end{bmatrix}$ and (α,β) interchangeably, depending on which is convenient.

Let A denote the operator

$$A=\begin{bmatrix} c\dfrac{\partial}{\partial x} & 0 \\ 0 & -c\dfrac{\partial}{\partial x} \end{bmatrix} \tag{2.6}$$

with domain

$$D(A)=\left\{\begin{bmatrix}\alpha\\ \beta\end{bmatrix}\in H^1(0,1)\times H^1(0,1)\,\middle|\,\begin{array}{l}\alpha,\beta \text{ satisfy (2.3) and (2.5)}\\ \text{(with } t \text{ dropped) at } x=0 \text{ and } x=1.\end{array}\right\} \tag{2.7}$$

In (2.7), $H^1(0,1)$ is the standard Sobolev space of order one.

To show that a solution of the problem under consideration exists, we prove that there exists a nonlinear contraction semigroup $S(t)$ corresponding to the dissipative set $-A$, whose minimal section $-A^0$ is the infinitesimal generator. It is known that if $(\alpha_0,\beta_0)\in D(-A^0)$, and if we regard

$$\begin{bmatrix}\alpha(\cdot,t)\\ \beta(\cdot,t)\end{bmatrix}\equiv S(t)\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix}$$

as our solution obtained from the semigroup, then $(\alpha(\cdot,t),\beta(\cdot,t))$ has the following smoothness properties:

(i) $(\alpha(\cdot,t),\beta(\cdot,t))\in D(A^0)$ for all $t\geqq 0$, and the function $t\to -A^0(\alpha(\cdot,t),\beta(\cdot,t))$ is continuous from the right on $[0,\infty)$.

(ii) $(\alpha,(\cdot,t),\beta(\cdot,t))$ has a right derivative with respect to t at every $t\geqq 0$ and

$$\frac{d^+}{dt}\begin{bmatrix}\alpha(\cdot,t)\\ \beta(\cdot,t)\end{bmatrix}=-A^0\begin{bmatrix}\alpha(\cdot,t)\\ \beta(\cdot,t)\end{bmatrix},\quad \text{for all } t\geqq 0.$$

(iii) $d/dt(\alpha(\cdot,t),\beta(\cdot,t))=-A^0(\alpha(\cdot,t),\beta(\cdot,t))$ exists and is continuous except at a countable number of points $t\geqq 0$.

We refer the reader to [1], [2] for the above and other relevant properties of nonlinear semigroups.

By [1], [2], $-A^0$ generates a nonlinear contraction semigroup if and only if A is maximal monotone. We want to verify this below. As much of the work is rather routine, we will be concise.

LEMMA 1. *A is monotone if and only if g is nondecreasing.*

Proof. For any given (α_1,β_1), $(\alpha_2,\beta_2)\in D(A)$, consider

$$I\equiv\left\langle A\begin{bmatrix}\alpha_1\\ \beta_1\end{bmatrix}-A\begin{bmatrix}\alpha_2\\ \beta_2\end{bmatrix},\begin{bmatrix}\alpha_1-\alpha_2\\ \beta_1-\beta_2\end{bmatrix}\right\rangle,$$

where $\langle\,,\rangle$ is the inner product in $\mathcal{H}$. Using (2.2) and integrating by parts, we get

$$I=\frac{c}{2}[(\beta_1(0)-\beta_2(0))^2-(\alpha_1(0)-\alpha_2(0))^2]. \tag{2.8}$$

We wish to show that $I\geqq 0$. We divide the real axis into three intervals. Because of the symmetry in (2.8) we need only consider the following cases:

(i) $\beta_1(0)>(cF_0/2T)$, $-(cF_0/2T)\leqq\beta_2(0)\leqq(cF_0/2T)$;

(ii) $\beta_1(0)<-(cF_0/2T)$, $-(cF_0/2T)\leqq\beta_2(0)\leqq(cF_0/2T)$;

(iii) $\beta_1(0)>(cF_0/2T)$, $\beta_2(0)<-(cF_0/2T)$;

(iv) $\beta_1(0)$, $\beta_2(0)$ belong to the same interval, $\beta_1(0)>\beta_2(0)$.

Case (i). $\beta_1(0)>(cF_0/2T)$, $-(cF_0/2T)\leqq\beta_2(0)\leqq(cF_0/2T)$.

Write β_1, β_2 for $\beta_1(0), \beta_2(0)$. From (2.8),

$$\frac{2}{c}\cdot I=(\beta_2-\beta_1)^2-\left[-\beta_2-\frac{(-cF_0)+(T-ch(\cdot))\beta_1}{T+ch(\cdot)}\right], \qquad (h(\cdot)\equiv h((\alpha_1+\beta_1)(0)))$$

$$=(\beta_1-\beta_2)^2-\left[\beta_1-\beta_2-\left(\frac{2T\beta_1-cF_0}{T+ch(\cdot)}\right)\right]^2$$

$$=\frac{2T\beta_1-cF_0}{T+ch(\cdot)}\left[2(\beta_1-\beta_2)-\left(\frac{2T\beta_1-cF_0}{T+ch(\cdot)}\right)\right]$$

$$=\frac{2T\beta_1-cF_0}{T+ch(\cdot)}\left[\frac{2ch(\cdot)(\beta_1-\beta_2)+(cF_0-2\beta_2T)}{T+ch(\cdot)}\right]\geqq 0.$$

Case (ii). $\beta_1<-(cF_0/2T)$, $-(cF_0/2T)\leqq\beta_2\leqq(cF_0/2T)$.
The verification is similar to Case (i).
Case (iii). $\beta_1>(cF_0/2T)$, $\beta_2<-(cF_0/2T)$.

$$|\alpha_1|=\left|\frac{-cF_0+(T-ch(\cdot))\beta_1}{T+ch(\cdot)}\right|=\left|\beta_1-\frac{2T\beta_1-cF_0}{T+ch(\cdot)}\right|<|\beta_1|,$$

$$|\alpha_2|=\left|\frac{cF_0+(T-ch(\cdot))\beta_2}{T+ch(\cdot)}\right|=\left|\beta_2-\frac{2T\beta_2+cF_0}{T+ch(\cdot)}\right|<|\beta_2|.$$

$$\frac{2}{c}I=(\beta_1-\beta_2)^2-(\alpha_1-\alpha_2)^2\geqq(|\beta_1|+|\beta_2|)^2-(|\alpha_1|+|\alpha_2|)^2\geqq 0.$$

So far we have not utilized the assumption that g is nondecreasing. It is crucial for the verification of Case (iv) below.

Case (iv). $\beta_1(0)>\beta_2(0)$ belong to the same interval.

It is easy to see that $I=0$ if β_1 and β_2 lie in the interval $[-(cF_0/2T), (cF_0/2T)]$. So let us consider $\beta_1\geqq\beta_2>(cF_0/2T)$. We have

$$\frac{2}{c}I=(\beta_1-\beta_2)^2-\{(\beta_1-\beta_2)-[(\beta_1+\alpha_1)-(\beta_2+\alpha_2)]\}^2.$$

Hence $I\geqq 0$ if and only if

$$0\leqq(\beta_1+\alpha_1)-(\beta_2+\alpha_2)\leqq 2(\beta_1-\beta_2) \quad \text{for all } \beta_1\geqq\beta_2>\frac{cF_0}{2T}. \tag{2.9}$$

We also have

$$\beta_i+\alpha_i=\frac{2T\beta_i-cF_0}{T+ch(\cdot)}=\frac{2(\beta_i-(cF_0/2T))}{1+(c/T)h(\cdot)}, \qquad i=1,2,$$

$$(\beta_i+\alpha_i)+\frac{c}{T}g(\beta_i+\alpha_i)=2\left(\beta_i-\frac{cF_0}{2T}\right), \qquad i=1,2, \tag{2.10}$$

$$(\beta_1+\alpha_1)-(\beta_2+\alpha_2)+\frac{c}{T}[g(\beta_1+\alpha_1)-g(\beta_2+\alpha_2)]=2(\beta_1-\beta_2). \tag{2.11}$$

Sufficiency. Assume that g is nondecreasing. For fixed $\beta, \beta+\alpha$ (hence α) is determined by (2.10). Note that now the function

$$G(\eta)\equiv\eta+\frac{c}{T}g(\eta)$$

is strictly increasing because g is nondecreasing. This gives

$$(\beta_1+\alpha_1)-(\beta_2+\alpha_2)\geqq 0 \quad \text{for all } \beta_1\geqq\beta_2>\frac{cF_0}{2T}.$$

From (2.11) we get

$$(\beta_1+\alpha_1)-(\beta_2+\alpha_2)\leqq 2(\beta_1-\beta_2),$$

so (2.9) is satisfied.

Necessity. Assume that A is monotone. Then (2.9) holds. Assume the contrary, i.e., that g is not nondecreasing. Then there exist $\eta_1>\eta_2>0$ such that $g(\eta_1)<g(\eta_2)$. Let $\beta_1+\alpha_1=\eta_1$, $\beta_2+\alpha_2=\eta_2$. The values of α_i, β_i, $i=1,2$ are determined by (2.5). By (2.9), we have

$$\beta_1>\beta_2>\frac{cF_0}{2T}.$$

From (2.10), we have

$$2(\beta_1-\beta_2)=(\beta_1+\alpha_1)-(\beta_2+\alpha_2)+\frac{c}{T}[g(\beta_1+\alpha_1)-g(\beta_2+\alpha_2)]$$

$$<(\beta_1+\alpha_1)-(\beta_2+\alpha_2), \quad \text{for some } \beta_1>\beta_2>\frac{cF_0}{2T},$$

as the term in the bracket is negative. This contradicts (2.9). Therefore, g must be nondecreasing.

The case when $\beta_1<\beta_2<-(cF_0/2T)$ can be treated similarly. □

LEMMA 2. *Let $\beta\in R$ be given. Then the implicit equation*

$$\alpha=\begin{cases}\dfrac{cF_0+[T-ch(\alpha+\beta)]\beta}{T+ch(\alpha+\beta)}, & \text{if } \beta<-\dfrac{cF_0}{2T},\\[2ex] -\beta, & \text{if } -\dfrac{cF_0}{2T}\leqq\beta\leqq\dfrac{cF_0}{2T},\\[2ex] \dfrac{-cF_0+[T-ch(\alpha+\beta)]\beta}{T+ch(\alpha+\beta)}, & \text{if } \beta>\dfrac{cF_0}{2T},\end{cases}$$

has a unique solution α for any $\beta\in R$ (cf. (2.5)).

Proof. If $\beta\in[-(cF_0/2T),(cF_0/2T)]$, then $\alpha=-\beta$, so α is unique. Consider the case $\beta>(cF_0/2T)$. α satisfies

$$\alpha=\frac{-cF_0+[T-ch(\alpha+\beta)]\beta}{T+ch(\alpha+\beta)}$$

$$=\frac{[-T-ch(\alpha+\beta)]\beta+2T\beta-cF_0}{T+ch(\alpha+\beta)}$$

$$=-\beta+\frac{-cF_0+2T\beta}{T+ch(\alpha+\beta)}.$$

So

$$(\alpha+\beta)\left[1+\frac{c}{T}h(\alpha+\beta)\right]=2\beta-\frac{cF_0}{T},$$

i.e.,

$$(\alpha+\beta)+\frac{c}{T}g(\alpha+\beta)=2\beta-\frac{cF_0}{T}.$$

As noted in the proof of Lemma 1 (cf. the arguments after (2.11)), the left-hand side above is equal to $G(\alpha+\beta)$, where G is strictly increasing (as g is nondecreasing) and the range of $G(\eta)$ for $\eta \geqq 0$ is $[0, +\infty)$. Therefore the equation

$$G(\eta)=\eta+\frac{c}{T}g(\eta)=2\left(\beta-\frac{cF_0}{2T}\right)$$

has a unique solution $\eta=\alpha+\beta$ because $\beta-(cF_0/2T)>0$. Hence the solution α is unique for given $\beta>(cF_0/2T)$.

If β satisfies $\beta<-cF_0/2T$, then we have instead that α satisfies

$$(\alpha+\beta)+\frac{c}{T}g(\alpha+\beta)=2\beta+\frac{cF_0}{T}<0.$$

Again, we note that G is strictly increasing and the range of $G(\eta)$ for $\eta \leqq 0$ is $(-\infty, 0]$. Therefore α is uniquely solvable for the similar reason as above. □

Remarks.

(i) From the physical point of view, it is completely natural that g be nondecreasing, because the magnitude of frictional force increases with respect to velocity.

(ii) From Lemma 2 we can see that α is uniquely determined once β is given in (2.5). Hence, the solution of the wave equation as constructed by the method of characteristics is *unique*. This solution coincides with the unique solution constructed from the nonlinear semigroup approach.

(iii) Let $(\alpha, \beta) \in D(A)$. Then β is continuous on $[0, 1]$ so $\beta(0)$ is defined. Then $\alpha(0)$ as determined from the multivalued equation

$$\frac{T}{c}(\beta(0)-\alpha(0)) \in \bar{f}(\alpha(0)+\beta(0)) \quad \text{(cf. (1.5) or (2.5))}$$

is unique (cf. (ii) above). This implies that the operator $-A$ is single valued and coincides with $-A^0$, its minimal section.

(iv) The above discussion also shows that the solution obtained by the method of characteristics is unique as long as the function

$$G(\eta) \equiv \eta+\frac{c}{T}g(\eta)$$

is strictly increasing, i.e., g need not be nondecreasing if we are only concerned with the uniqueness of solutions by the method of characteristics.

LEMMA 3. *A is maximal monotone.*

Proof. We want to show that for any $(\phi, \psi) \in H$, there exists an $(\alpha, \beta) \in D(A)$ such that

$$(I+A)\begin{bmatrix}\alpha\\ \beta\end{bmatrix}=\begin{bmatrix}1+c\dfrac{\partial}{\partial x} & 0\\ 0 & 1-c\dfrac{\partial}{\partial x}\end{bmatrix}\begin{bmatrix}\alpha\\ \beta\end{bmatrix}=\begin{bmatrix}\phi\\ \psi\end{bmatrix}. \tag{2.12}$$

We integrate (2.12) directly and obtain

$$\alpha(x) = \gamma_1 \exp((x-1)/c) + \frac{1}{c}\int_1^x \exp(-(x-\tau)/c)\phi(\tau)\,d\tau, \tag{2.13}$$

$$\beta(x) = \gamma_2 \exp((x-1)/c) - \frac{1}{c}\int_1^x \exp((x-\tau)/c)\psi(\tau)\,d\tau. \tag{2.14}$$

Condition (2.3) yields

$$\gamma_2 = -\gamma_1. \tag{2.15}$$

Thus

$$\alpha(0) = \gamma_1 e^{1/c} + \frac{1}{c}\int_1^0 e^{\tau/c}\phi(\tau)\,d\tau \equiv \gamma_1 e^{1/c} + \eta_1,$$

$$\beta(0) = -\gamma_1 e^{-1/c} - \frac{1}{c}\int_1^0 e^{-\tau/c}\psi(\tau)\,d\tau \equiv -\gamma_1 e^{-1/c} + \eta_2.$$

The constant γ_1 remains to be determined. We have three possibilities:

(i) $-(cF_0/2T) \leqq \beta(0) \leqq (cF_0/2T)$,

(ii) $\beta(0) > (cF_0/2T)$,

(iii) $\beta(0) < -(cF_0/2T)$.

Assume (i). Then $\alpha(0) = -\beta(0)$, so

$$\begin{aligned} \gamma_1 e^{1/c} + \eta_1 &= -(-\gamma_1 e^{-1/c} + \eta_2). \\ \gamma_1 &= -(\eta_1 + \eta_2)/(e^{1/c} - e^{-1/c}). \end{aligned} \tag{2.16}$$

For (i) to happen, we must have

$$-\frac{cF_0}{2T} \leqq \beta(0) = \frac{\eta_1 + \eta_2}{e^{1/c} - e^{-1/c}} \cdot e^{-1/c} + \eta_2 \leqq \frac{cF_0}{2T},$$

i.e.,

$$-\left(\frac{cF_0}{2T} + \eta_2\right)(e^{2/c} - 1) - \eta_2 \leqq \eta_1 \leqq \left(\frac{cF_0}{2T} - \eta_2\right)(e^{2/c} - 1) - \eta_2. \tag{2.17}$$

Next, assume (ii). Then by (2.5),

$$\alpha(0) = \gamma_1 e^{1/c} + \eta_1 = \frac{-cF_0 + [T - ch((\alpha+\beta)(0))](-\gamma_1 e^{-1/c} + \eta_2)}{T + ch((\alpha+\beta)(0))}. \tag{2.18}$$

By (2.4), $\eta h(\eta) = g(\eta)$. We substitute g and h and rewrite the above relation as

$$-\frac{T}{c}\{\gamma_1(e^{1/c} + e^{-1/c}) + \eta_1 - \eta_2\} = F_0 + g(\gamma_1(e^{1/c} - e^{-1/c}) + \eta_1 + \eta_2), \tag{2.19}$$

or

$$G_1(\gamma_1) = G_2(\gamma_1), \tag{2.20}$$

where G_1 and G_2 are defined, respectively, by the left- and right-hand sides of (2.19). If $g: \mathbb{R} \to \mathbb{R}$ is a bounded function, then (2.20) has a solution $\gamma_1 \in \mathbb{R}$. This is an immediate consequence of the Brouwer fixed point theorem. If g is not bounded, then by (1.7), g satisfies

$$g(\eta) \to \pm\infty \quad \text{as } \eta \to \pm\infty.$$

Thus G_1 and G_2 are continuous functions satisfying

$$G_1(\eta)\to\pm\infty \quad \text{as } \eta\to\mp\infty,$$

$$G_2(\eta)\to\pm\infty \quad \text{as } \eta\to\pm\infty,$$

so

$$G_1(\eta)-G_2(\eta)<0 \quad \text{as } \eta\to\infty,$$

$$G_1(\eta)-G_2(\eta)>0 \quad \text{as } \eta\to\infty.$$

Therefore (2.20), and hence (2.19), has a real solution γ_1.

In order for case (ii) to happen, η_1 and η_2 must satisfy

$$\beta(0)=\frac{cF_0-(T+ch((\beta+\alpha)(0))\eta_1+[T-ch((\alpha+\beta)(0))]\eta_2}{[T+ch((\alpha+\beta)(0))]e^{1/c}+[T-ch((\alpha+\beta)(0))]e^{-1/c}}+\eta_2>\frac{cF_0}{2T},$$

implying

$$\eta_1>\left(\frac{cF_0}{2T}-\eta_2\right)(e^{2/c}-1)-\eta_2. \tag{2.21}$$

Finally, we note that case (iii) can be treated in the same way as case (ii). Case (iii) happens when

$$\eta_1<-\left(\frac{cF_0}{2T}+\eta_2\right)(e^{2/c}-1)-\eta_2. \tag{2.22}$$

Therefore we see that depending on (2.17), (2.21), or (2.22), we have, respectively, (i), (ii), or (iii). In each case, γ_1 and γ_2 are solvable and (α,β) are given by (2.13), (2.14), which solves (2.9). □

3. The ω-limit set of the dynamical system. For a given solution y of a dynamical system

$$\begin{cases}\dfrac{d}{dt}y(\cdot,t)=f(y(\cdot,t)), & t>0,\\ y(\cdot,0)=y_0\end{cases} \tag{3.1}$$

in an infinite dimensional space, the ω-limit set of the solution is the intersection over $t\geqq 0$ of the closure of the orbit $\{y(x,t)\,|\,x\in[0,1]\}$. The ω-limit set of the dynamical system (3.1) is the union of the ω-limit sets of all the solutions of (3.1).

In this section, we will attempt to determine the ω-limit set of the system considered in §§ 1 and 2. Here by a "solution" we mean a solution $S(t)(\alpha_0,\beta_0)$ with $(\alpha_0,\beta_0)\in D(A^0)$.

Let

$$P\equiv\left\{(\alpha,\beta)\in D(A^0)\;\middle|\;-\frac{cF_0}{2T}\leqq f(x)\leqq\frac{cF_0}{2T},\quad \text{for } f=\alpha \text{ or } f=\beta\right\}.$$

It is easy to see that the conservation of energy

$$\left\|\begin{bmatrix}\alpha(\cdot,t)\\ \beta(\cdot,t)\end{bmatrix}\right\|_{\mathcal{H}}\equiv\left\|S(t)\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix}\right\|_{\mathcal{H}}=\left\|\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix}\right\|_{\mathcal{H}} \qquad t\geqq 0$$

is satisfied for any initial state $(\alpha_0, \beta_0) \in P$. Indeed, each solution $(\alpha(\cdot, t), \beta(\cdot, t))$ is periodic with period $\tau_0 = 2/c$, and $(\alpha(\cdot, t), \beta(\cdot, t)) \in P$ for any $t \geqq 0$. $S(t)$ is also *linear* on $\bar{P}$. $\bar{P}$ is a closed convex set with empty interior in $\mathcal{H}$ invariant under $S(t)$.

What happens if the initial state $(\alpha_0, \beta_0) \in D(A^0)$ is not in P? We have two cases.

Case (i).

(3.2) There exists $B > 0$ such that $h(x) \leqq T/c$ for all $x: |x| < B$.

We will show that there exists $T_0 > 0$ depending on (α_0, β_0) such that $S(t)(\alpha_0, \beta_0) \in P$ for all $t \geqq T_0$.

For any $x \in (0, 1)$, $t \geqq 0$, by the method of characteristics, we have

$$\beta(x, t+\tau_0) = \beta\left(1, t+\frac{1+x}{c}\right) = -\alpha\left(1, t+\frac{1+x}{c}\right) \qquad \left(\tau_0 = \frac{2}{c}\right)$$

$$= -\alpha\left(0, t+\frac{x}{c}\right)$$

$$= \begin{cases} [-cF_0 + T - ch(\cdot)]\beta(x, t)\}/[T + ch(\cdot)], & \text{if } \beta(x, t) < -\dfrac{cF_0}{2T}, \\ \beta(x, t), & \text{if } -\dfrac{cF_0}{2T} \leqq \beta(x, t) \leqq \dfrac{cF_0}{2T}, \\ [cF_0 - T - ch(\cdot)]\beta(x, t)\}/[T + ch(\cdot)], & \text{if } \beta(x, t) > \dfrac{cF_0}{2T}, \end{cases} \tag{3.3}$$

where $h(\cdot) \equiv h((\alpha+\beta)(0, t+x/c))$.

As we are primarily interested in the asymptotic behavior of solutions, we limit our discussion to those solutions $(\alpha(\cdot, t), \beta(\cdot, t))$ satisfying

$$|(\alpha+\beta)(0, t)| < B, \qquad t \geqq 0. \tag{3.4}$$

This is a very mild restriction as we expect that all solutions will lose the bulk of their energy and eventually satisfy (3.4), if B is not too small. See also the appendix.

We wish to prove that there exists $T_0 > 0$ such that

$$|\beta(x, T_0)| \leqq cF_0/2T, \quad \text{for all } x \in (0, 1).$$

Assume that there is some $x \in [0, 1]$ such that $\beta(x, 0) > cF_0/(2T)$. Then,

$$\beta(x, \tau_0) = \frac{cF_0}{T + ch((\alpha+\beta)(0, x/c))} - \frac{T - ch((\alpha+\beta)(0, x/c))}{T + ch((\alpha+\beta)(0, x/c))}\beta(x, 0)$$

$$< \frac{cF_0}{T + ch(\cdot)} - \frac{T - ch(\cdot)}{T + ch(\cdot)}\frac{cF_0}{2T} = \frac{cF_0}{2T},$$

where in the above, we use the shorthand $h(\cdot)$ in an obvious way from the previous expression. If $(-cF_0/(2T)) \leqq \beta(x, \tau_0) < (cF_0/(2T))$, then this x is all right. Otherwise this x satisfies

$$\beta(x, \tau_0) < -cF_0/(2T). \tag{3.5}$$

Therefore

$$
\begin{aligned}
&|\beta(x,0)|-|\beta(x,\tau_0)| \\
&\quad=\beta(x,0)-\left\{\frac{T-ch((\alpha+\beta)(0,x/c))}{T+ch((\alpha+\beta)(0,x/c))}\beta(x,0)-\frac{cF_0}{T+ch((\alpha+\beta)(0,x/c))}\right\} \\
&\quad=\frac{2h}{T+ch(\cdot)}\beta(x,0)+\frac{cF_0}{T+ch(\cdot)} \\
&\quad\geqq\frac{cF_0}{2T}, \quad \text{by (3.2), (3.4).}
\end{aligned}
\tag{3.6}
$$

Also, by (3.3)

$$
\begin{aligned}
\beta(x,2\tau_0)&=-\frac{cF_0}{T+ch((\alpha+\beta)(0,\tau_0+x/c))}-\frac{T-ch((\alpha+\beta)(0,\tau_0+x/c))}{T+ch((\alpha+\beta)(0,\tau_0+x/c))}\beta(x,\tau_0) \\
&>-\frac{cF_0}{T+ch(\cdot)}+\frac{T-ch(\cdot)}{T+ch(\cdot)}\frac{cF_0}{2T}=-\frac{cF_0}{2T}.
\end{aligned}
$$

If $(-cF_0/(2T))<\beta(x,2\tau_0)\leqq(cF_0/(2T))$ for this x, then we are done. Otherwise

$$
\beta(x,2\tau_0)>\frac{cF_0}{2T}, \quad \text{for this } x,
$$

$$
\begin{aligned}
|\beta(x,\tau_0)|-|\beta(x,2\tau_0)|&=|\beta(x,\tau_0)|-\left[\frac{T-ch((\alpha+\beta)(0,\tau_0+x/c))}{T+ch((\alpha+\beta)(0,\tau_0+x/c))}|\beta(x,\tau_0)|\right. \\
&\qquad\left.-\frac{cF_0}{T+ch((\alpha+\beta)(0,\tau_0+x/c))}\right] \\
&>\frac{cF_0}{2T}.
\end{aligned}
$$

If this process can be continued indefinitely, then

$$
|\beta(x,0)|-|\beta(x,2k\tau_0)|>2k\cdot\frac{cF_0}{2T}, \quad \text{for } k=1,2,3,\cdots,
$$

implying

$$
|\beta(x,0)|>|\beta(x,2k\tau_0)|+2k\cdot\frac{cF_0}{2T}\to\infty,
$$

which is impossible. Therefore for each $x\in[0,1]$, there is a positive integer $k(x)$ such that

$$
-cF_0/(2T)\leqq|\beta(x,k(x)\tau_0)|\leqq cF_0/(2T).
$$

As the interval $[0,1]$ is compact and $\beta(x,0)$ is continuous, we see that there exists an integer $n>0$ such that

$$
-CF_0/(2T)\leqq|\beta(x,n\tau_0)|\leqq cF_0/(2T), \quad \text{for all } x\in[0,1].
$$

Similarly,

$$
-cF/(2T)\leqq|\alpha(x,n\tau_0)|\leqq cF_0/(2T), \quad \text{for all } x\in[0,1],
$$

if n is chosen large enough.

Hence the dynamical system enters the set P at some time $t=t_0$. Once it enters P, energy no longer decays and the solution becomes periodic.

Case (ii).

(3.7) There exists $B>0$ such that $h(x)>T/c$ for all $x: |x|<B$.

Again, for the simplicity of presentation, we assume that (3.4) is in force.

For Case (ii), we will show that if the initial state (α_0, β_0) doesn't lie in P, then

$$S(t)\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix}\notin P \quad \text{for all } t\geqq 0, \tag{3.8}$$

and

$$\lim_{t\to\infty} d\left(S(t)\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix}, \bar{P}\right)=0, \tag{3.9}$$

where d denotes the distance metric.

Assume that $\beta(x, t)>(cF_0/(2T))$ for some $x\in[0, 1]$. Then by (3.3)

$$\begin{aligned}\beta(x, t+\tau_0)&=\frac{cF_0}{T+ch((\alpha+\beta)(0, t+x/c))}+\frac{ch((\alpha+\beta)(0, t+x/c))-T}{ch((\alpha+\beta)(0, t+x/c))+T}\beta(x, t)\\ &>\frac{cF_0}{T+ch(\cdot)}+\frac{ch(\cdot)-T}{ch(\cdot)+T}\frac{cF_0}{2T}=\frac{cF_0}{2T}.\end{aligned}$$

Therefore

$$\beta(x, t+\tau_0)>\frac{cF_0}{2T}$$

for this x, and

$$\begin{aligned}\beta(x, (k+1)\tau_0)&=\frac{cF_0}{T+ch((\alpha+\beta)(0, k\tau_0+t+x/c))}\\ &\quad+\frac{ch((\alpha+\beta)(0, k\tau_0+t+x/c))-T}{ch((\alpha+\beta)(0, k\tau_0+t+x/c))+T}\beta(x, k\tau_0)\\ &=\frac{cF_0}{T+ch(\cdot)}+\frac{ch(\cdot)-T}{ch(\cdot)+T}\left[\beta(x, k\tau_0)-\frac{cF_0}{2T}\right]+\frac{ch(\cdot)-T}{ch(\cdot)+T}\frac{F_0}{2c}\\ &=\frac{cF_0}{2T}+\frac{ch(\cdot)-T}{ch(\cdot)+T}\left[\beta(x, k\tau_0)-\frac{cF_0}{2T}\right], \qquad k=0, 1, 2, \cdots.\end{aligned}$$

That is,

$$0<\beta(x, (k+1)\tau_0)-\frac{cF_0}{2T}=\frac{ch(\cdot)-T}{ch(\cdot)+T}\left[\beta(x, k\tau_0)-\frac{cF_0}{2T}\right]. \tag{3.10}$$

If $x\in[0, 1]$ satisfies $\beta(x, t)<(-cF_0/2T)$, then we can do similarly and obtain

$$0>\beta(x, (k+1)\tau_0)+\frac{cF_0}{2T}=\frac{ch(\cdot)-T}{ch(\cdot)+T}\left[\beta(x, k\tau_0)+\frac{cF_0}{2T}\right]. \tag{3.11}$$

Identical relations (3.10) and (3.11) hold when β is replaced by α in (3.10) and (3.11). Hence the conclusion (3.8) and (3.9) follows.

From the above analysis, we can easily see that the ω-limit set of all solutions satisfying (3.4), (3.2), and (3.7) is $\bar{P}$.

4. Rate of convergence to the ω-limit set. For Case (ii) considered in the previous section, we can actually determine the rate of convergence of (3.9) if more information on the function $h(x)$ is available.

In engineering, the function g in (1.6), (1.7) is often approximated by a single polynomial function

$$g(x)=\begin{cases}\eta x^{\mu}, & x>0\\ -\eta|x|^{\mu}, & x<0\end{cases} \tag{4.1}$$

for some $\eta,\ \mu\in\mathbb{R},\ \eta,\ \mu>0$. Then

$$h(x)=\eta|x|^{\mu-1},\qquad x\in\mathbb{R},\qquad x\neq 0.$$

If $\mu>1$, then Case (i) in § 3 holds and

$$d\left(S(t)\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix},\bar{P}\right)=0\quad\text{for } t\geqq T_0\quad\text{for some } T_0\geqq 0.$$

If $\mu=1$, and $\eta\leqq T/c$, again Case (i) in § 3 is valid and (4.2) holds.

Therefore we need only consider

(a) $\mu=1$ and $\eta>T/c$; and

(b) $0<\mu<1$.

Our estimates are based on the relationships

$$\begin{aligned}&|\alpha(x,\,t+(k+1)\tau_0)|-\frac{cF_0}{2T}\\ &=\frac{ch((\alpha+\beta)(0,\,t+k\tau_0+x/c))-T}{ch((\alpha+\beta)(0,\,t+k\tau_0+x/c))+T}\left[|\alpha(x,\,t+k\tau_0)|-\frac{cF_0}{2T}\right]\end{aligned} \tag{4.2}$$

$$\begin{aligned}&|\beta(x,\,t+(k+1)\tau_0)|-\frac{cF_0}{2T}\\ &=\frac{ch((\alpha+\beta)(0,\,t+k\tau_0+x/c))-T}{ch((\alpha+\beta)(0,\,t+k\tau_0+x/c))-T}\left[|\beta(x,\,t+k\tau_0)|-\frac{cF_0}{2T}\right],\end{aligned} \tag{4.3}$$

which are consequences of (3.3).

Consider (a) first. From (4.2), (4.3) we have

$$|\alpha(x,\,t)|-\frac{cF_0}{2T}\leqq\gamma\,e^{-\delta t},$$

$$|\beta(x,\,t)|-\frac{cF_0}{2T}\leqq\gamma\,e^{-\delta t},$$

where $x\in[0,\,1]$ satisfies

$$|\alpha(x,\,0)|-\frac{cF_0}{2T}>0,$$

$$|\beta(x,\,0)|-\frac{cF_0}{2T}>0,$$

and

$$\delta\equiv\left(-\ln\left|\frac{c\eta-T}{c\eta+T}\right|\right)\Big/\tau_0$$

$$\gamma=\exp(\delta\tau_0)\cdot\sup_{\substack{0\leqq t\leqq\tau_0\\ 0\leqq y\leqq 1}}\left\{\left||\alpha(y,\,t)|-\frac{cF_0}{2T}\right|+\left||\beta(y,\,t)|-\frac{cF_0}{2T}\right|\right\}.$$

Now define a truncated generalized solution $(\bar{\alpha}, \bar{\beta})$ by

$$\bar{\phi}(x,t)=\begin{cases} -\dfrac{cF_0}{2T} & \phi(x,t)<-\dfrac{cF_0}{2T} \\ \phi(x,t) & \text{if } -\dfrac{cF_0}{2T}\leqq\phi(x,t)\leqq\dfrac{cF_0}{2T} \\ \dfrac{cF_0}{2T} & \phi(x,t)>\dfrac{cF_0}{2T}, \end{cases}$$

for $\phi=\alpha$ and $\phi=\beta$. This solution is actually some $S(t)(\bar{\alpha}_0, \bar{\beta}_0)$ with $(\bar{\alpha}_0, \bar{\beta}_0)\in\overline{D(A^0)}$, thus it is indeed a generalized solution $(\bar{\alpha}(\cdot,t), \bar{\beta}(\cdot,t))$ lying in $\bar{P}$ for all $t\geqq 0$.

$$\begin{aligned} d(t)&\equiv d\left(S(t)\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix}, \bar{P}\right)\leqq d\left(S(t)\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix}, \begin{bmatrix}\bar{\alpha}(\cdot,t)\\ \bar{\beta}(\cdot,t)\end{bmatrix}\right) \\ &=\left[\int_0^1 \{[\alpha(x,t)-\bar{\alpha}(x,t)]^2+[\beta(x,t)-\bar{\beta}(x,t)]^2\}\,dx\right]^{1/2}. \end{aligned} \tag{4.4}$$

For each $t\geqq 0$, let

$$\begin{aligned} E_1^t&=\{x\in[0,1]\,|\,\alpha(x,t)<-cF_0/(2T)\} \\ E_2^t&=\{x\in[0,1]\,|\,\alpha(x,t)>cF_0/(2T)\} \\ E_3^t&=\{x\in[0,1]\,|\,\beta(x,t)<-cF_0/(2T)\} \\ E_4^t&=\{x\in[0,1]\,|\,\beta(x,t)>cF_0/(2T)\}. \end{aligned}$$

Then

$$\begin{aligned} (4.4)&\leqq\left\{\int_{E_1^t}\left[\alpha(x,t)+\frac{cF_0}{2T}\right]^2 dx+\int_{E_2^t}\left[\alpha(x,t)-\frac{cF_0}{2T}\right]^2 dx\right. \\ &\quad\left.+\int_{E_3^t}\left[\beta(x,t)+\frac{cF_0}{2T}\right]^2 dx+\int_{E_4^t}\left[\beta(x,t)-\frac{cF_0}{2T}\right]^2 dx\right\}^{1/2} \\ &\leqq\sqrt{2}[\text{measure}\,(E_1^t\cup E_2^t\cup E_3^t\cup E_4^t)]^{1/2}\gamma\exp(-\delta t). \end{aligned}$$

Therefore *the rate of convergence is exponential.*

When $F_0=0$ in (1.6), $\bar{P}$ reduces to a single point $\{(0,0)\}$. The above exponential decay result for the linear equation is well-known. Thus the result is rather sharp.

Next, consider (b):

$$h(x)=\eta|x|^{\mu-1},\qquad \eta>0,\qquad 0<\mu<1.$$

Assume that $\beta(x,0)>(cF_0/(2T))$ for some $x\in[0,1]$. Then by (3.3)

$$\begin{aligned} \beta(x,(k+1)\tau_0)-\frac{cF_0}{2T}&=\frac{ch\left((\beta+\alpha)\left(0,k\tau_0+\dfrac{x}{c}\right)\right)-T}{ch\left((\beta+\alpha)\left(0,k\tau_0+\dfrac{x}{c}\right)\right)+T}\left[\beta(x,k\tau_0)-\frac{cF_0}{2T}\right] \\ &=\left[1-\frac{2T}{ch(\cdot)+T}\right]\left[\beta(x,k\tau_0)-\frac{cF_0}{2T}\right] \\ &\leqq\left[1-\frac{T}{ch(\cdot)}\right]\left[\beta(x,k\tau_0)-\frac{cF_0}{2T}\right] \\ &=\left[1-\frac{T}{c\eta}\left|(\beta+\alpha)\left(0,k\tau_0+\frac{x}{c}\right)\right|^{1-\mu}\right]\left[\beta(x,k\tau_0)-\frac{cF_0}{2T}\right]. \end{aligned} \tag{4.5}$$

Also from (3.3)

$$\alpha\left(0, k\tau_0+\frac{x}{c}\right)=\frac{-cF_0-\left[ch\left((\beta+\alpha)\left(0, k\tau_0+\frac{x}{c}\right)\right)-T\right]\beta\left(0, k\tau_0+\frac{x}{c}\right)}{ch\left((\beta+\alpha)\left(0, k\tau_0+\frac{x}{c}\right)\right)+T},$$

so

$$(\beta+\alpha)\left(0, k\tau_0+\frac{x}{c}\right)=\frac{-cF_0+2T\cdot\beta\left(0, k\tau_0+\frac{x}{c}\right)}{ch(\cdot)+T}$$

$$=2T\left[\beta\left(0, k\tau_0+\frac{x}{c}\right)-\frac{cF_0}{2T}\right]\cdot\frac{1}{ch(\cdot)}\left[1-\frac{T}{ch(\cdot)}+\frac{T^2}{c^2h^2(\cdot)}\pm\cdots\right],$$

provided that $ch((\beta+\alpha)(0, k\tau_0+x/c))\gg T$. Continuing from the above:

$$\geqq\frac{T}{ch(\cdot)}\left[\beta\left(0, k\tau_0+\frac{x}{c}\right)-\frac{cF_0}{2T}\right].$$

Hence

$$(\beta+\alpha)\left(0, k\tau_0+\frac{x}{c}\right)\geqq\frac{T}{c\eta}\left|(\beta+\alpha)\left(0, k\tau_0+\frac{x}{c}\right)\right|^{1-\mu}\left[\beta\left(0, k\tau_0+\frac{x}{c}\right)-\frac{cF_0}{2T}\right]$$

$$\left|(\beta+\alpha)\left(0, k\tau_0+\frac{x}{c}\right)\right|^{\mu}\geqq\frac{T}{c\eta}\left[(\beta+\alpha)\left(0, k\tau_0+\frac{x}{c}\right)-\frac{cF_0}{2T}\right]$$

$$=\frac{T}{c\eta}\left[\beta(x, k\tau_0)-\frac{cF_0}{2T}\right]. \tag{4.6}$$

$$\left|(\beta+\alpha)\left(0, k\tau_0+\frac{x}{c}\right)\right|^{1-\mu}\geqq\left(\frac{T}{c\eta}\right)^{((1-\mu)/\mu)}\left[\beta(x, k\tau_0)-\frac{cF_0}{2T}\right]^{((1-\mu)/\mu)}.$$

Using (4.6) in (4.5), we get

$$0<\beta(x, (k+1)\tau_0)-\frac{cF_0}{2T}\leqq\left[\beta(x, k\tau_0)-\frac{cF_0}{2T}\right]-\left(\frac{T}{c\eta}\right)^{1/\mu}\left[\beta(x, k\tau_0)-\frac{cF_0}{2T}\right]^{1/\mu}.$$

Similarly, if $\beta(x, 0)<-(cF_0/2T)$ for some $x\in[0, 1]$, then

$$0<-\beta(x, (k+1)\tau_0)-\frac{cF_0}{2T}\leqq\left[-\beta(x, k\tau_0)-\frac{cF_0}{2T}\right]$$

$$-\left(\frac{T}{c\eta}\right)^{1/\mu}\left[-\beta(x, k\tau_0)-\frac{cF_0}{2T}\right]^{1/\mu}.$$

By mathematical induction, we easily prove the convergence rate

$$\left||\beta(x, k\tau)|-\frac{cF_0}{2T}\right|\leqq\frac{d}{(1+k)^{\mu/(1-\mu)}},\quad\text{for some } D>0,\quad\text{for } k=1, 2, \cdots.$$

The same estimate also holds for $\|\alpha(x, k\tau)|-(cF_0/2T)|$. Thus we have the convergence rate $\mathcal{O}((1+t)^{-\mu/1-\mu})$ for (3.9).

Appendix. Different extensions of g.

Let g be a mapping from $[-v_0, v_0]$ into $\mathbb{R}$. Let g_1, g_2 be extensions of g:

$$\begin{cases} g_i : \mathbb{R} \to \mathbb{R}, & i = 1, 2, \\ g_i(\eta) = g(\eta) & \text{for } \eta \in [-v_0, v_0] \\ g_i \text{ satisfies (1.7)}, & i = 1, 2 \\ g_i \text{ is nondecreasing.} \end{cases}$$

As in (2.4), let

$$h_i(\eta) = g_i(\eta)/\eta, \qquad i = 1, 2, \qquad x \neq 0.$$

Let A_1, A_2 be (maximal) monotone operators in $\mathscr{H}$ defined similarly as A in § 2, except that the left end boundary condition (2.5) is now replaced by

$$\text{(A.1)} \quad \alpha_i(0) = \begin{cases} \dfrac{cF_0 + [T - ch_i((\alpha_i + \beta_i)(0))]\beta(0)}{T + ch_i((\alpha_i + \beta_i)(0))}, & \beta_i(0) < -cF_0/(2T), \\ -\beta_i(0), & -cF_0/(2T) \leqq \beta_i(0) \leqq cF_0/(2T), \\ \dfrac{-cF_0 + [T - ch_i((\alpha_i + \beta_i)(0))]\beta(0)}{T + ch_i((\alpha_i + \beta_i)(0))}, & \beta_i(0) > cF_0/(2T), \end{cases}$$

with $i = 1, 2$ for A_1 and A_2, respectively.

Assume that a given initial condition $(\alpha_0(\cdot), \beta_0(\cdot)) \in H^1(0, 1) \times H^1(0, 1)$ satisfies

$$\text{(A.2)} \quad \begin{cases} |\alpha_0(x)| \leqq \dfrac{v_0}{2} + \dfrac{cF_0}{2T} \\ |\beta_0(x)| \leqq \dfrac{v_0}{2} + \dfrac{cF_0}{2T} \end{cases}$$

on $[0, 1]$, and that $(\alpha_0, \beta_0) \in D(A_1^0)$. (The "0" superscript in $-A_1^0$ denotes the minimal section of $-A_1$.) Let $(\alpha_1(\cdot, t), \beta_1(\cdot, t)) = S_1(t)(\alpha_0, \beta_0)$ be the solution, where $S_1(t)$ is the nonlinear contraction semigroup generated by $-A_1^0$. We will show that $(\alpha_0, \beta_0) \in D(A_2^0)$ and that

$$\text{(A.3)} \qquad (\alpha_2(\cdot, t), \beta_2(\cdot, t)) = (\alpha_1(\cdot, t), \beta_1(\cdot, t)), \qquad t \geqq 0,$$

where $(\alpha_2(\cdot, t), \beta_2(\cdot, t)) = S_2(t)(\alpha_0, \beta_0)$ and $S_2(t)$ is the nonlinear contraction semigroup generated by $-A_2^0$.

First, due to (2.3), (A.1), (A.2), by the method of characteristics (cf. remarks after Lemma 2) it is easy to see that

$$|\alpha_1(x, t)| \leqq \frac{v_0}{2} + \frac{cF_0}{2T}$$

$$|\beta_1(x, t)| \leqq \frac{v_0}{2} + \frac{cF_0}{2T}$$

for all $t \geqq 0$. If $\beta_1(0, t)$ satisfies

$$|\beta_1(0, t)| \leqq cF_0/(2T),$$

then by (A.1),

$$\text{(A.4)} \qquad (\alpha_1 + \beta_1)(0, t) = 0.$$

If

$$\frac{cF_0}{2T} < \beta_1(0, t) \leqq \frac{v_0}{2} + \frac{cF_0}{2T},$$

then

$$\begin{aligned} 0 < (\alpha_1 + \beta_1)(0, t) &= \frac{-cF + 2T\beta_1(0, t)}{T + ch_1((\alpha_1 + \beta_1)(0, t))} \\ &\leqq \frac{-cF_0 + 2T\beta_1(0, t)}{T} \leqq v_0. \end{aligned} \tag{A.5}$$

Similarly, if

$$-\frac{v_0}{2} - \frac{cF_0}{2T} \leqq \beta_1(0, t) < -\frac{cF_0}{2t},$$

$$\begin{aligned} 0 > (\alpha_1 + \beta_1)(0, t) &= \frac{cF_0 + 2T\beta_1(0, t)}{T + ch_1((\alpha_1 + \beta_1)(0, t))} \\ &\geqq \frac{cF_0 + 2T\beta_1(0, t)}{T} \geqq -v_0. \end{aligned} \tag{A.6}$$

Combining (A.4), (A.5), and (A.6), we see that for all $t \geqq 0$,

$$|(\alpha_1 + \beta_1)(0, t)| \leqq v_0.$$

Since $h_1(x) = h_2(x)$ for $0 < |x| \leqq v_0$, we see that $(\alpha_0, \beta_0) \in D(A_2^0)$, and that (A.3) holds as a consequence of the method of characteristics.

Acknowledgments. The correct form of Lemma 1 was pointed out by the referees. We thank them for helpful comments.

A BOUNDARY VALUE PROBLEM FOR THE MINIMUM-TIME FUNCTION*

MARTINO BARDI†

Abstract. A natural boundary value problem for the dynamic programming partial differential equation associated with the minimum time problem is proposed. The minimum time function is shown to be the unique viscosity solution of this boundary value problem.

Key words. nonlinear systems, time-optimal control, dynamic programming, Hamilton-Jacobi equations, viscosity solutions

AMS(MOS) subject classifications. 35F30, 49C20

1. Introduction.

Given the control system

$$\dot{y}(s)+b(y(s), z(s))=0, \qquad s\geqq 0, \quad y\in\mathbb{R}^N, \quad z\in Z\subseteq\mathbb{R}^M, \tag{1.1}$$

the minimum time function $T(x)$ associates to a point $x\in\mathbb{R}^N$ the infimum of the times that the trajectories of (1.1) satisfying $y(0)=x$ take to reach the origin. The problem of determining T and the optimal controls realizing the minimum is one of the most extensively studied in the control-theoretic literature, especially in the linear case [1], [5], [6], [8], [15], [16], [20], [22]-[26].

It is well known that Bellman's Dynamic Programming Principle implies that at points of differentiability T satisfies the following first-order fully nonlinear partial differential equation (PDE) of Hamilton-Jacobi type:

$$\sup_{z\in Z} b(x, z)\cdot DT(x)=1. \tag{1.2}$$

It is also known that in general T is not differentiable everywhere, but it satisfies (1.2) in some generalized sense [8], [24]. In the last five years the new concept of viscosity solution for Hamilton-Jacobi equations has been introduced by Crandall and Lions [11] and the theory of such solutions has developed quickly (see, e.g., [9]-[12], [17], [21] and the references therein) and has been applied to many problems in control theory and differential games (see, e.g., [3], [4], [7], [13], [21], the survey paper of Fleming [14], and its long list of references). Following Lions [21] it is not hard to show that T satisfies (1.2) in the viscosity sense as soon as it is continuous. The goal of this paper is to complement (1.2) with a natural boundary condition and prove a uniqueness result for viscosity solutions of such a boundary value problem (BVP). Ishii [17] has proved the uniqueness of viscosity solutions of the Dirichlet problem in a bounded open set for a class of equations that includes (1.2). However the Dirichlet problem does not seem to be the most natural one for the minimum time function because in general we do not know a priori the value of T on the boundary of some given bounded set. Instead we consider (1.2) in the set $\mathcal{R}\backslash\{0\}$ where $\mathcal{R}$ is the set of points x such that there is a trajectory of (1.1) starting at x and reaching the origin in finite time, i.e., the largest set where T is defined (and finite); we propose the following boundary condition:

$$T(0)=0 \quad \text{and} \quad T(x)\to+\infty \quad \text{uniformly as } x\to\partial\mathcal{R}. \tag{1.3}$$

In § 2 we will prove that under quite general assumptions T satisfies (1.2) in $\mathcal{R}\backslash\{0\}$ in the viscosity sense and (1.3). In § 3 we will show that for any open set $\mathcal{R}$ having

† Dipartimento di Matematica Pura e Applicata, Università di Padova, I-35131 Padova, Italy.

zero in its interior there is at most one viscosity solution of (1.2) in $\mathcal{R}\backslash\{0\}$ satisfying (1.3) and bounded below.

The main result is the uniqueness theorem in § 3. It presents three difficulties with respect to standard uniqueness results in the Hamilton-Jacobi theory: (i) the Hamiltonian depends on the gradient of the unknown function but does not depend explicitly on the unknown function itself, while it is usually required that it be strictly monotone in such a variable; (ii) the infinite boundary condition (1.3) if $\mathcal{R} \neq \mathbb{R}^N$; and (iii) the lack of regularity of the solutions to be compared and of the Hamiltonian if b is not globally bounded and $\mathcal{R}$ is unbounded.

To overcome the first difficulty we introduce a change of the unknown variable first used for this goal by Kruzkov [18]. It turns out that this transforms the infinite boundary condition into a finite one, therefore automatically taking care of the second difficulty.

The third difficulty can be solved using the new approach to uniqueness presented in the paper of Crandall, Ishii, and Lions [10]. Indeed our uniqueness theorem has to be considered as a corollary of the methods developed in [10]. As one of the referees pointed out to us, this difficulty had already been overcome for different problems in an earlier paper by Ishii [28], whose methods could be applied effectively to our problem as well.

We remark that the proof of the uniqueness theorem does not make use of the convexity of the Hamiltonian. Therefore the methods of this paper can be employed to study the minimum time problem in games of pursuit and evasion (see Bardi and Soravia [27]).

After the completion of this work we have learned that Kruzkov's change of variables has been used recently by Lasry and Lions [19] to study the minimum time function of a differential game with state constraints in a bounded domain, and by Barles [2] for unbounded control problems. Moreover, one of the referees pointed out that a uniqueness theorem for discontinuous solutions of (1.2), (1.3) can be proved by combining the Kruzkov transform and the results by Barles and Perthame [3], provided the target to be reached is a smooth set instead of a single point.

In the last decade the use of the theory of subanalytic sets has led to very strong results on the regularity of the minimum time function and of feedback controls (see Brunovsky [6] and Sussmann [26] and the references therein). However it is also known that certain quite smooth systems exhibit very irregular behaviors that fail to fall within the theory of subanalyticity (see Lojasiewicz and Sussmann [22] or the classical Fuller's example in [23]). It is our hope that the PDE setting of the minimum time problem proposed in this paper could be of some help in the study of these problems.

2. The BVP of the minimum time function. We begin listing the assumptions to be used in the following.

(H1) $b:\mathbb{R}^N \times Z \to \mathbb{R}^N$, where $Z \subseteq \mathbb{R}^M$, is continuous and there exist L, $K \in \mathbb{R}$ such that $|b(x,z)-b(y,z)| \leqq L|x-y|$ and $|b(y,z)| \leqq K(1+|y|)$, for all x, $y \in \mathbb{R}^N$, and for all $z \in Z$.

Let $\mathcal{M}$ be the set of measurable functions $z:[0,\infty) \to Z$, and let $y(s)=y(s;x,z)$ be the solution of

$$y(s) = x - \int_0^s b(y(t), z(t))\, dt \tag{2.0}$$

for $s \geqq 0$, $x \in \mathbb{R}^N$, and $z \in \mathcal{M}$. Let $\mathcal{T} \subseteq \mathbb{R}^N$ be a given closed set, the *terminal set* (e.g.,

$\mathcal{T} = \{0\}$), and define

$$\mathcal{R} := \{x \in \mathbb{R}^N : \exists z \in \mathcal{M},\ t \geqq 0 \text{ such that } y(t; x, z) \in \mathcal{T}\}.$$

Clearly, $\mathcal{R} \supseteq \mathcal{T}$. Now define the minimum time function

$$T : \mathcal{R} \to [0, \infty), \qquad T(x) := \inf\{t : y(t; x, z) \in \mathcal{T} \text{ for some } z \in \mathcal{M}\}.$$

We will assume the following.

(H2) $\mathcal{R}$ is open.

(H3) T is continuous in $\mathcal{R}$.

(H4) For every $x_0 \in \partial\mathcal{R}$, $\lim_{x \to x_0} T(x) = +\infty$.

Conditions under which (H2)-(H4) are satisfied are well known in the literature, especially in the linear case. See, for instance, [1], [15], [20] for (H2), [25], [15], [1], [5], [8] for (H3), [8], [15] for (H4), and the references therein. Essentially (H2)-(H4) follow from some controllability around $\mathcal{T}$.

Next we define a suitable boundary condition for functions $u \in C(\mathcal{R} \setminus \mathcal{T})$:

(BC) u converges uniformly to 0 as $x \to \partial\mathcal{T}$ and to $+\infty$ as $x \to \partial\mathcal{R}$, i.e., for every ε, $M > 0$ there exists $\delta > 0$ such that $\operatorname{dist}(x, \partial\mathcal{T}) < \delta$ implies $|u(x)| < \varepsilon$ and $\operatorname{dist}(x, \partial\mathcal{R}) < \delta$ implies $u(x) > M$.

Before proving that T satisfies (BC) we need a technical lemma.

LEMMA 1. *Assume* (H1) *is true. If* $y(t; x, z) = x_1$, *then*

$$t \geqq \frac{1}{K} \log\left(1 + \frac{|x - x_1|}{1 + \min(|x|, |x_1|)}\right).$$

Proof. Hypothesis (H1) implies

$$|y(s) - x| \leqq Ks(1 + |x|) + \int_0^s K|y(\tau) - x|\, d\tau,$$

and then, using Gronwall's inequality, we get

$$|x_1 - x| \leqq (1 + |x|)(e^{Kt} - 1),$$

which gives

$$t \geqq \frac{1}{K} \log\left(1 + \frac{|x_1 - x|}{1 + |x|}\right).$$

The same calculation for $\tilde{y}(s) := y(t - s)$ leads to

$$t \geqq \frac{1}{K} \log\left(1 + \frac{|x_1 - x|}{1 + |x_1|}\right). \qquad \square$$

Remark 1. It follows easily from Lemma 1, choosing $x_1 \in \mathcal{T}$, that $T(x) > 0$ for all $x \in \mathcal{R} \setminus \mathcal{T}$ (since $\mathcal{T}$ is closed) and that $\mathcal{T}$ bounded implies $\lim_{|x| \to \infty} T(x) = +\infty$.

LEMMA 2. *Assume* (H1)-(H4) *and* $\mathcal{T}$ *bounded. Then* T *satisfies* (BC).

Proof. Since T is continuous, null on $\partial\mathcal{T}$, and $\mathcal{T}$ is bounded, the first part of (BC) is clearly satisfied.

To prove the second part we fix $M > 0$. From Lemma 1 and Remark 1 the existence of $R > 0$ such that $T(x) > M$ for $|x| > R$ follows. Now we use (H4) to get a covering of the compact set $\partial\mathcal{R} \cap \{x : |x| \leqq R\}$ made of a finite number of open balls B_i centered on $\partial\mathcal{R}$ and having small radius so that $T(x) > M$ for $x \in \mathcal{R} \cap B_i$. We conclude observing that there exists $\delta > 0$ such that $|x| \leqq R$ and $\operatorname{dist}(x, \partial\mathcal{R}) < \delta$ imply $x \in B_i$ for some i. $\square$

We recall that a continuous function u defined in an open set $\mathcal{O} \subseteq \mathbb{R}^N$ is defined to be a *viscosity solution* of

$$H(x, u, Du) = 0 \quad \text{in } \mathcal{O},$$

if for every $\phi \in C^1(\mathcal{O})$ and x_0 local maximum point of $u - \phi$ we have

$$H(x_0, u(x_0), D\phi(x_0)) \leqq 0,$$

while for x_0, local minimum point of $u - \phi$ we have

$$H(x_0, u(x_0), D\phi(x_0)) \geqq 0.$$

We will now prove that T is a viscosity solution of

$$\sup_{z \in Z} b(x, z) \cdot Du - 1 = 0 \quad \text{in } \mathcal{R} \setminus \mathcal{T}. \tag{HJ}$$

This fact is certainly known to experts, since it follows from arguments of Lions [21, Chap. 1]. We include a full proof for the sake of completeness.

Define for $z \in \mathcal{M}$, $x \in \mathbb{R}^N$, $t_x(z) := \inf\{t: y(t; x, z) \in \mathcal{T}\}$ and denote by $\chi_{\{t < t_x(z)\}}$ the function defined on $[0, \infty)$ which is one if $t < t_x(z)$ and zero if the opposite inequality holds.

LEMMA 3 (Dynamic Programming Principle). *Assume* (H1). *Then for all* $x \in \mathcal{R}$ *and* $t \geqq 0$

$$T(x) = \inf_{z \in \mathcal{M}} \{\min(t, t_x(z)) + \chi_{\{t < t_x(z)\}} T(y(t; x, z))\}.$$

Proof. Fix x and t and let A be the right-hand side of the above equality. To prove $T(x) \geqq A$ we fix an arbitrary $\varepsilon > 0$ and show that

$$T(x) \geqq A - \varepsilon. \tag{2.1}$$

Let $z_1 \in \mathcal{M}$ be such that

$$T(x) \geqq t_x(z_1) - \varepsilon. \tag{2.2}$$

If $t \geqq t_x(z_1)$, then (2.1) holds. Now suppose $t < t_x(z_1)$ and let $z_2(s) = z_1(t + s)$. Then

$$t_x(z_1) = t + t_{y(t;x,z_1)}(z_2) \geqq t + T(y(t; x, z_1)) \geqq A,$$

and so by (2.2) we have (2.1).

Now we want to prove

$$T(x) \leqq A + \varepsilon, \tag{2.3}$$

and for this we choose z_1 such that

$$A + \frac{\varepsilon}{2} \geqq \min(t, t_x(z_1)) + \chi_{\{t < t_x(z_1)\}} T(y(t; x, z_1)). \tag{2.4}$$

If $t \geqq t_x(z_1)$ then (2.3) holds. If $t < t_x(z_1)$ let $z_2 \in \mathcal{M}$ be such that

$$T(y(t; x, z_1)) \geqq t_{y(t;x,z_1)}(z_2) - \frac{\varepsilon}{2}. \tag{2.5}$$

Now define the control

$$z_3(s) := \begin{cases} z_1(s) & \text{if } s < t, \\ z_2(s - t) & \text{if } s \geqq t. \end{cases}$$

Clearly

$$t_x(z_3) = t + t_{y(t;x,z_1)}(z_2),$$

and therefore we get from (2.4) and (2.5)

$$A + \frac{\varepsilon}{2} \geqq t + T(y(t; x_1, z_1)) \geqq t_x(z_3) - \frac{\varepsilon}{2} \geqq T(x) - \frac{\varepsilon}{2},$$

which proves (2.3). By the arbitrariness of ε the proof is complete. □

THEOREM 1. *Assume* (H1)-(H3). *Then the minimum time function T is a positive viscosity solution of* (HJ). *If moreover* (H4) *holds and the terminal set $\mathcal{T}$ is bounded, then T satisfies the boundary condition* (BC) *as well.*

Proof. The second statement is just Lemma 2. To prove the first statement we begin by considering $x_0 \in \mathcal{R} \setminus \mathcal{T}$ and $\phi \in C^1(\mathcal{R} \setminus \mathcal{T})$ such that for all x sufficiently close to x_0,

$$T(x_0) - \phi(x_0) \geqq T(x) - \phi(x). \tag{2.6}$$

Let z_1 be any constant control, $z_1(s) \equiv \bar{z} \in Z$. By Lemma 3 we have for all $0 < s < T(x_0)$

$$T(x_0) - T(y(s; x_0, z_1)) \leqq s,$$

and so by (2.6) we have for sufficiently small positive s,

$$\frac{\phi(x_0) - \phi(y(s; x_0, z_1))}{s} \leqq \frac{T(x_0) - T(y(s; x_0, z_1))}{s} \leqq 1.$$

Now letting $s \searrow 0$ and using (2.0), we get

$$D\phi(x_0) \cdot b(x_0, \bar{z}) \leqq 1,$$

and by the arbitrariness of $\bar{z}$,

$$\sup_{z \in Z} b(x_0, z) \cdot D\phi(x_0) - 1 \leqq 0.$$

Let us now consider new x_0 and ϕ as above but such that

$$T(x_0) - \phi(x_0) \leqq T(x) - \phi(x)$$

for all x in a given neighborhood of x_0. By Lemma 1 there exists s_1 such that

$$\phi(x_0) - \phi(y(s; x_0, z_1)) \geqq T(x_0) - T(y(s; x_0, z)) \quad \forall s \leqq s_1, \quad \forall z \in \mathcal{M}.$$

Fix $\varepsilon > 0$. By Lemma 3 for every $s \leqq T(x_0)$ there is $z^* \in \mathcal{M}$ such that

$$T(x_0) \geqq s + T(y(s; x_0, z^*)) - \varepsilon s,$$

and thus for $0 < s \leqq s_2$

$$\frac{\phi(x_0) - \phi(y(s; x_0, z^*))}{s} \geqq 1 - \varepsilon. \tag{2.7}$$

Using (2.0) and the expansion

$$\phi(x) = \phi(x_0) + D\phi(x_0) \cdot (x - x_0) + m(x)|x - x_0| \quad \text{with } \lim_{x \to x_0} m(x) = 0,$$

we can write the left-hand side of (2.7) as follows:

$$\frac{1}{s} \int_0^s D\phi(x_0) \cdot b(y(t; x_0, z^*), z^*(t))\, dt - m(y(s; x_0, z^*)) \frac{1}{s} \left| \int_0^s b(y(t; x_0, z^*), z^*(t))\, dt \right|.$$

The second term in this expression can be made smaller than ε for small s by (H1) and Lemma 1; by using (H1) again, the first term can be written as $1/s \int_0^s D\phi(x_0) \cdot b(x_0, z^*(t))\, dt$ plus a correction term smaller than ε for small s. Then by (2.7),

$$\sup_{z \in Z} D\phi(x_0) \cdot b(x_0, z) \geqq \frac{1}{s} \int_0^s D\phi(x_0) \cdot b(x_0, z^*(t))\, dt \geqq 1 - 3\varepsilon,$$

which provides the desired inequality by the arbitrariness of ε. □

3. Uniqueness. In this section we will prove the following theorem.

THEOREM 2. *Assume* (H1), *let $\mathcal{R}$ be an open subset of $\mathbb{R}^N$, and let $\mathcal{T} \subseteq \mathcal{R}$ be a closed set. If $u_1, u_2 \in C(\mathcal{R} \setminus \mathcal{T})$ are viscosity solutions of* (HJ) *satisfying* (BC) *and bounded from below, then $u_1 = u_2$.*

The main tool of the proof is a lemma of Crandall, Ishii, and Lions [10, Lemma 1], which we report below in a version simplified for the present purpose. We say that $H : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ satisfies condition (H) if the following holds:

(H) H is continuous; there exist a Lipschitz continuous, everywhere differentiable function $\mu : \mathbb{R}^n \to [0, \infty)$ and a continuous, nondecreasing function $\sigma : [0, \infty) \to [0, \infty)$ satisfying $\sigma(0) = 0$, such that $H(x, p) - H(x, p + \lambda D\mu(x)) \leqq \sigma(\lambda)$, for all x, $p \in \mathbb{R}^n$, $\lambda \in [0, 1]$ and $\lim_{|x| \to \infty} \mu(x) = +\infty$.

LEMMA 4. *Let H satisfy condition* (H) *and let Ω be an open subset of $\mathbb{R}^n$. Let $z \in C(\bar{\Omega})$ be a viscosity solution of $z + H(x, Dz) = 0$ in Ω, and let $w \in C^1(\bar{\Omega})$ satisfy*

$$w(x) + H(x, Dw(x)) \geqq 0 \quad \text{and} \quad |Dw(x)| \leqq C \quad \forall x \in \Omega.$$

Assume that

$$\sup_{\partial\Omega} (z - w) < \sup_{\Omega} (z - w) < \infty.$$

Then $z \leqq w$ in Ω.

Proof. See [10] for the proof of this lemma. □

The other key tool in the proof of Theorem 2 is a change of the unknown variable in (HJ). For this we need a slight extension of Corollary I.8 in [11].

LEMMA 5. *Let u be a viscosity solution of $H(x, u, Du) = 0$ in $\mathcal{O}$, open subset of $\mathbb{R}^n$; let $\Phi \in C^1(\mathbb{R})$, $\Phi'(r) > 0$ for all r; and let $\Psi : \Phi(\mathbb{R}) \to \mathbb{R}$ be the inverse function of Φ. Then $v = \Phi \circ u$ is a viscosity solution of*

$$H(x, \Psi(v), \Psi'(v) Dv) = 0 \quad \text{in } \mathcal{O}.$$

Proof. Let $x_0 \in \mathcal{O}$ and $\zeta \in C^1(\mathcal{O})$ be such that $v - \zeta$ has a local maximum in x_0. Define $\xi(x) = \zeta(x) - \zeta(x_0) + v(x_0)$. We have

$$D\xi = D\zeta, \qquad \xi(x_0) = v(x_0) = \Phi(u(x_0)),$$

$$v(x) \leqq \xi(x) \quad \text{in a neighborhood of } x_0.$$

Since $\Phi(\mathbb{R})$ is open, $\Psi \circ \xi$ is defined in a neighborhood of x_0 and we extend it to $\eta \in C^1(\mathcal{O})$. By the monotonicity of Ψ we have

$$u(x_0) = \eta(x_0), \quad u(x) \leqq \eta(x) \quad \text{in a neighborhood of } x_0.$$

Then

$$H(x_0, u(x_0), D\eta(x_0)) \leqq 0,$$

and so

$$H(x_0, \Psi(v(x_0)), \Psi'(v(x_0))D\zeta(x_0)) \leqq 0.$$

If x_0 is a minimum point we get the desired inequality in the same way. □

Proof of Theorem 2. Define $\Phi(t) := 1 - e^{-t}$, $v_1 := \Phi \circ u_1$, $v_2 := \Phi \circ u_2$, $\mathcal{O} := \mathcal{R} \setminus \mathcal{T}$. By Lemma 5, v_1 and v_2 are viscosity solutions of

$$\sup_{z \in Z} \left\{ b(x, z) \cdot \left(\frac{1}{1-v} Dv \right) \right\} - 1 = 0 \quad \text{in } \mathcal{O},$$

and since $v_1, v_2 < 1$, they are also viscosity solutions of

$$v + \sup_{z \in Z} \{b(x, z) \cdot Dv\} - 1 = 0 \quad \text{in } \mathcal{O}, \tag{3.0}$$

as is easy to verify from the definition. They can be extended in a unique way to v_1, $v_2 \in C(\bar{\mathcal{O}})$ by setting

$$v_i = 0 \quad \text{on } \partial\mathcal{T}, \quad v_i = 1 \quad \text{on } \partial\mathcal{R}, \quad i = 1, 2.$$

Now define

$$H(x, p) := \sup_{z \in Z} \{b(x, z) \cdot p - 1\}.$$

We claim that H satisfies condition (H). Fix $\varepsilon > 0$ and choose $z_1 \in Z$ such that $H(x, p) \leqq b(x, z_1) \cdot p - 1 + \varepsilon$. Then by (H1)

$$\begin{aligned} H(x, p) - H(y, q) &\leqq b(x, z_1) \cdot p - b(y, z_1) \cdot q + \varepsilon \\ &\leqq L|x - y||p| + K(1 + |y|)|p - q| + \varepsilon, \end{aligned}$$

and thus

$$|H(x, p) - H(y, q)| \leqq L|x - y||p| + K(1 + |y|)|p - q|, \tag{3.1}$$

which implies the continuity of H. Now let $h \in C^1(\mathbb{R})$ be such that $h(0) = h'(0) = 0$, $h(e) = 1$, $h'(e) = 1/e$, and define

$$\mu(x) := \begin{cases} h(|x|) & \text{if } |x| < e, \\ \log(|x|) & \text{if } |x| \geqq e. \end{cases}$$

Clearly, $\mu \in C^1(\mathbb{R}^N)$ and it is Lipschitz continuous since $D\mu(x) = (1/|x|^2)x$ for $|x| \geqq e$. Moreover, by (3.1),

$$H(x, p) - H(x, p + \lambda D\mu(x)) \leqq K(1 + |x|)\lambda |D\mu(x)| \leqq \lambda C =: \sigma(\lambda)$$

for $\lambda > 0$, where $C := \max(2K, K(1 + e) \sup |h'|)$, which proves the claim.

Next we define, following Crandall, Ishii, and Lions [10],

$$\hat{H}(x, y, p, q) := H(x, p) - H(y, -q),$$

$$z(x, y) := v_1(x) - v_2(y),$$

and note that z is a viscosity solution of

$$z + \hat{H}(x, y, D_x z, D_y z) = 0 \quad \text{in } \mathcal{O} \times \mathcal{O}.$$

Our goal is to prove that $z(x, x) \leqq 0$, because by interchanging the roles of v_1 and v_2 we get $v_1 = v_2$ and then $u_1 = u_2$. To reach our goal we are going to apply Lemma 4 to z defined above, $\Omega := \Delta \cap (\mathcal{O} \times \mathcal{O})$ where

$$\Delta := \{(x, y) \in \mathbb{R}^{2N} : |x - y| < 1\},$$

and $w = w_\varepsilon$ for suitable ε where

$$w_\varepsilon(x, y) := (\varepsilon^{4L} + |x-y|^2)^{1/2L}/\varepsilon.$$

We have to show that there exists $\varepsilon_0 > 0$ such that for all $0 < \varepsilon \leqq \varepsilon_0$, w_ε satisfies the hypotheses of Lemma 4. Once this is done we have $z(x, x) \leqq w_\varepsilon(x, x) = \varepsilon$, and letting $\varepsilon \searrow 0$ we conclude.

Since

$$D_x w_\varepsilon(x, y) = \frac{1}{\varepsilon L}(\varepsilon^{4L} + |x-y|^2)^{(1/2L)-1}(x-y) = -D_y w_\varepsilon(x, y),$$

w_ε is Lipschitz continuous in $\bar{\Delta}$ and, moreover, by (3.1),

$$\begin{aligned} w_\varepsilon(x, y) + \hat{H}(x, y, D_x w_\varepsilon, D_y w_\varepsilon) &\geqq w_\varepsilon - L|x-y|^2(\varepsilon^{4L} + |x-y|^2)^{(1/2L)-1}/\varepsilon L \\ &\quad - K(1+|y|)|D_x w_\varepsilon + D_y w_\varepsilon| \\ &\geqq w_\varepsilon - w_\varepsilon = 0. \end{aligned}$$

Since u_1 and u_2 are bounded from below, v_1 and v_2 are bounded, and

$$\alpha_\varepsilon := \sup_\Omega (z - w_\varepsilon) \leqq A < \infty \quad \text{for all } \varepsilon > 0. \tag{3.2}$$

If

$$\liminf_{\varepsilon \searrow 0} \alpha_\varepsilon \leqq 0,$$

we immediately obtain $z(x, x) \leqq 0$. Thus it remains to prove that $\alpha_\varepsilon \geqq \alpha > 0$ and $0 < \varepsilon \leqq \varepsilon_0$ imply

$$\sup_{\partial\Omega} (z - w_\varepsilon) < \alpha_\varepsilon = \sup_\Omega (z - w_\varepsilon).$$

Suppose that $(\bar{x}, \bar{y}) \in \partial\Omega$ is such that

$$z(\bar{x}, \bar{y}) - w_\varepsilon(\bar{x}, \bar{y}) \geqq \frac{\alpha}{2} > 0. \tag{3.3}$$

Fix $0 < \delta < 1$ such that $x \in \partial\mathcal{O}$ and $|x-y| < \delta$ implies $|v_i(x) - v_i(y)| < \alpha/2$, $i = 1, 2$. This can be done because v_1 and v_2 take up their boundary values uniformly as a consequence of (BC). Suppose first that $|\bar{x} - \bar{y}| < \delta$ so that either $\bar{x}$ or $\bar{y}$, say $\bar{x}$, belongs to $\partial\mathcal{O}$. Then $z(\bar{x}, \bar{x}) = 0$ and $w_\varepsilon \geqq 0$ imply

$$z(\bar{x}, \bar{y}) - w_\varepsilon(\bar{x}, \bar{y}) \leqq v_1(\bar{x}) - v_2(\bar{y}) - v_1(\bar{x}) + v_2(\bar{x}) < \frac{\alpha}{2},$$

a contradiction to (3.3). On the other hand, if $|\bar{x} - \bar{y}| \geqq \delta$, (3.2) and (3.3) imply

$$z(\bar{x}, \bar{y}) - w_\varepsilon(\bar{x}, \bar{y}) \geqq \sup_\Omega (z - w_\varepsilon) - \alpha_\varepsilon \geqq z(\bar{x}, \bar{x}) - w_\varepsilon(\bar{x}, \bar{x}) - A,$$

from which we obtain

$$v_2(\bar{x}) - v_2(\bar{y}) \geqq w_\varepsilon(\bar{x}, \bar{y}) - \varepsilon - A.$$

The right-hand side of the last inequality can be made arbitrarily large choosing ε small because

$$\liminf_{\varepsilon \searrow 0} \{w_\varepsilon(x, y) : |x-y| \geqq \delta\} = +\infty,$$

and we get a contradiction because the left-hand side is bounded. □

Remark 2. Under the stronger assumption that $|b(y, z)| \leqq K$ for all $y \in \mathcal{R} \setminus \mathcal{T}$, $z \in Z$ (which excludes the linear case if $\mathcal{R}$ is unbounded), and strengthening the boundary conditions, we can give a weaker uniqueness theorem with a much shorter proof based on the earliest uniqueness result for viscosity solutions, that is, Theorem III.1 of Crandall and Lions [11]. In fact, under such an assumption on b, (3.1) implies that the Hamiltonian $H(x, p)$ is uniformly continuous in $\mathbb{R}^N \times \{p: |p| \leqq R\}$ for all $R > 0$. The additional boundary condition is

$$\text{(ABC)} \qquad \lim_{|x| \to \infty} u(x) = +\infty,$$

which is satisfied by the minimum time function T if $\mathcal{T}$ is bounded (see Remark 1). The proof of the weaker theorem begins with the same change of variables as the proof of Theorem 2. Next, we note that if u_1, u_2 satisfy (BC) and (ABC) then v_1, $v_2 \in BUC(\bar{\mathcal{O}})$ and that (3.0) satisfies the hypotheses of Theorem III.1(ii) in [11], which implies $v_1 = v_2$.

Remark 3. If $\mathcal{R}$ is bounded, u_1 and u_2 satisfy (ABC), they are zero on $\partial \mathcal{T}$, and they tend to $+\infty$ as $x \to x_0 \in \partial \mathcal{R}$, then the hypotheses of Theorem 2 are satisfied. In fact, u_1 and u_2 are clearly bounded from below, and they satisfy (BC) by the proof of Lemma 2.

Remark 4. If we drop the assumption that u_1 and u_2 are bounded below, then the conclusion of the theorem is false. In fact, if we take $b(x, z) = z$, Z the unit ball in $\mathbb{R}^N$, $\mathcal{T} = \{0\}$, then we get the BVP

$$|Du| - 1 = 0 \quad \text{in } \mathbb{R}^N \setminus \{0\},$$
$$u(0) = 0,$$

which has the classical solutions $u_1(x) = |x|$ and $u_2(x) = -|x|$.

Acknowledgment. The author thanks Alberto Bressan for some interesting conversations which stimulated this research.

OPTIMAL SENSOR SCHEDULING IN NONLINEAR FILTERING OF DIFFUSION PROCESSES*

JOHN S. BARAS† AND ALAIN BENSOUSSAN‡

Abstract. The nonlinear filtering problem of a vector diffusion process is considered when several noisy vector observations with possibly different dimension of their range space are available. At each time any number of these observations (or sensors) can be used in the signal processing performed by the nonlinear filter. The problem considered is the optimal selection of a schedule of these sensors from the available set, so as to optimally estimate a function of the state at the final time. Optimality is measured by a combined performance measure that allocates penalties for errors in estimation, for switching between sensor schedules, and for running a sensor. The solution is obtained in the form of a system of quasi-variational inequalities in the space of solutions of certain Zakai equations.

Key words. nonlinear filtering, sensor scheduling, quasi-variational inequalities

AMS(MOS) subject classifications. 35, 49, 60

1. Introduction.

1.1. Motivation and preliminaries. The problem of nonlinear filtering of diffusion processes has received considerable attention in recent years; see the anthologies [1]-[3] for a review of important developments. In current studies, as well as in related analyses of the partially observed stochastic control problem with such models [4], [5], a key role is played by the linear stochastic partial differential equation describing the evolution of the unnormalized conditional probability measure of the state process given the past of the observations, the so-called Zakai equation.

A significant byproduct of these advances is the feasibility of analyzing complex signal processing problems, including adaptive and sensitivity studies, in an integrated, systematic manner, without heuristic or ad hoc assumptions. A problem of interest in this area is the so-called *sensor scheduling problem.* Roughly speaking, this problem is concerned with the simultaneous selection (according to some performance measure) of a signal processing scheme *together* with the sensors that collect the data to be processed. Particular applications include multiple sensor platforms, distributed sensor networks, and large-scale systems. For example, in a multiple sensor platform, there is definite need for coordinating the data obtained from the various sensors, which may include radar, infrared, or sonar. The data obtained from different sensors are of varying quality and a systematic way is needed for allocating confidence or basing decisions on data collected from different types of sensors. For example, radar sensors are more accurate than infrared sensors for long-range tracking while the opposite is true for short-range tracking. In sensor networks we need to coordinate data collected from a large number of sensors distributed over a large geographical area. Conflicts should be resolved and a preferred set of sensors must be selected over finite (short) time intervals, and used in detection, estimation, or control decisions. Similarly, large-scale systems typically involve an attached information network with the objective of collecting data, processing it, and making the results available to the many control

agents for their decisions (actions). Again the need for coordinating this information in a systematic way is critical.

In such sensor scheduling problems, the systematic utilization of sensors should be the result of optimizing reasonably defined performance measures. Clearly these performance measures will include terms allocating penalties for errors in detection and/or estimation. But more importantly, they must include terms for costs associated with turning sensors on or off, and for switching from one sensor to another. Examples of such costs arising in practice abound. Turning on a radar sensor increases the detectability of the platform (since radars are active sensors) and this should be reflected as a switching cost. Deciding to use a more accurate, albeit more complex, sensor will require higher bandwidth communications and often more computational power allocated to that sensor. In distributed sensor networks it may mean the physical movement of a sensor carrying platform (such as a helicopter or airplane) to a particular geographical location. In large-scale systems the use of several sensors (often hundreds) for decision making may provide better average performance, but it certainly reduces the response speed of the system to changing conditions and increases computational and communication costs both in terms of hardware and software. The latter are obviously evident in large computer/communication networks. These running and switching costs will depend often on the part of the state space occupied by the state vector, i.e., they will be functions of the state as well. For example, sensors have different accuracy or noise characteristics when the state process takes values in different areas of the state space. There is additional cost associated with handling the transfer of information, or tracking record, when there are changes in the set of sensors used; these costs often depend on the state process.

It is not our intent to provide an extensive description of applications here. Detailed descriptions of some of these problems can be found elsewhere; see for example [6], [7]. The underlying thread in all these problem areas is the existence of a variety of sensors, which provide data (for processing), including information of widely varying quality about parameters or variables of interest, for control, detection, estimation, etc. Due to the complexity of these problems it is important to develop systematic conceptual, analytical, and numerical methods for their study and to reduce reliance on ad hoc, heuristic methods as much as possible. The present paper is offered as a contribution in this direction. It provides a general methodology to this problem by reducing it to the analysis of a system of quasi-variational inequalities (see § 3 for details). Numerical methods will be described elsewhere [13].

The sensor scheduling problem is considered here in the context of nonlinear filtering of diffusion processes, and is therefore applicable to detection problems with the same signal models. Modifications of the results apply to other situations including control. In the next section we present a somewhat heuristic definition of the problem, intended to describe the problem clearly, at an intuitive level. The intricacies of establishing this model in a rigorous mathematical fashion are given in § 2 and constitute one of the main contributions of the paper.

1.2. Preliminary description of the problem. The problem considered is as follows. A signal (or state) process $x(\cdot)$ is given, modeled by the diffusion

$$\begin{aligned} dx(t) &= f(x(t))\,dt + g(x(t))\,dw(t), \\ x(0) &= \xi \end{aligned} \tag{1.1}$$

in $\mathbb{R}^n$. We further consider M noisy observations of $x(\cdot)$, described by

$$\begin{aligned} dy^i(t) &= h^i(x(t))\,dt + R_i^{1/2}\,dv^i(t), \\ y^i(0) &= 0 \end{aligned} \tag{1.2}$$

with values in $\mathbb{R}^{d_i}$. Here $w(\cdot)$, $v^i(\cdot)$ are independent, standard, Wiener processes in $\mathbb{R}^n$, $\mathbb{R}^{d_i}$, respectively, and $R_i = R_i^T > 0$ are $d_i \times d_i$ matrices. Further mathematical details on the system (1.1), (1.2) will be given in § 2. Let us consider a finite time horizon $[O, T]$. To formulate the problem of determining an *optimal utilization schedule* for the available sensors, so as to *simultaneously minimize* the cost of errors in estimating a function of $x(\cdot)$ and the costs of using as well as of switching between various sensors, we need to specify these costs. To this end, let $c_i(x)$ denote the cost per unit time when using sensor i, and the state of the system is x; $k_{io}(x)$, $k_{oi}(x)$ denote the cost for turning off, respectively on, the ith sensor when the state of the system is x. The objective of the performed signal processing is to compute, at time T, an estimate $\hat{\phi}(T)$ of a given function $\phi(x(T))$ of the state. Penalties for errors in estimation are assessed according to the cost function

$$E\{c_e(\phi(x(T)) - \hat{\phi}(T))\} := E\{|\phi(x(T)) - \hat{\phi}(T)|^2\}. \tag{1.3}$$

We shall comment briefly on more general estimation problems in § 4 of this paper. In particular, the consideration of a quadratic $c_e(\cdot)$ is not a serious restriction.

Next we consider the set of all possible *sensor activation configurations*, denoted here by $\mathcal{N}$. An element $\nu \in \mathcal{N}$ is a *word* of length M from the alphabet $\{0, 1\}$. If the lth position is occupied by a 1, the lth sensor is activated (used); if by a zero, the lth sensor is off. There are $N = 2^M$ elements in $\mathcal{N}$. A *schedule of sensors is then a piecewise constant function* $u(\cdot) : [O, T] \to \mathcal{N}$. We let $\tau_j \in [O, T]$ denote the instants of changing schedule; i.e., the moments when at least one sensor is turned on or off. At such a switching moment, suppose the schedule before is characterized by $\nu \in \mathcal{N}$, and after by $\nu' \in \mathcal{N}$. Then the *switching cost associated with such a scheduling change* is

$$\mathbf{k}_{\nu\nu'}(x) := \sum_{\{i \in \nu\}\{i \notin \nu'\}} k_{io}(x) + \sum_{\{j \notin \nu\}\{j \in \nu'\}} k_{oj}(x). \tag{1.4}$$

The *total running cost, associated* with schedule $\nu \in \mathcal{N}$ is

$$\mathbf{c}_\nu(x) := \sum_{\{j \in \nu\}} c_j(x). \tag{1.5}$$

In (1.4), (1.5), *the symbol* $\{i \in \nu\}$ *denotes the set of all indices* (*from the set* $\{1, 2, \cdots, M\}$) *that are occupied by a* 1 *in* ν (i.e., the indices corresponding to the sensors that are on); similarly, the symbol $\{i \notin \nu\}$ denotes the set of indices corresponding to sensors that are off.

Using the above notation, the available observations, *under sensor schedule* $u(\cdot)$, are described by

$$dy(t, u(t)) := h(x(t), u(t))\, dt + r(u(t))\, dv(t), \tag{1.6}$$

where it is apparent that the available observations depend explicitly on the sensor schedule $u(\cdot)$. In (1.6), for $x \in \mathbb{R}^n$, $\nu \in \mathcal{N}$,

$$h(x, \nu) := \begin{bmatrix} h^1(x)\chi_{\{\nu\}}(1) \\ \vdots \\ h^i(x)\chi_{\{\nu\}}(i) \\ \vdots \\ h^M(x)\chi_{\{\nu\}}(M) \end{bmatrix}, \tag{1.7}$$

a block column vector, where in standard notation

$$\chi_{\{\nu\}}(i) := \begin{cases} 1 & \text{if the } i\text{th position in the word } \nu \text{ is occupied by a 1} \\ 0 & \text{otherwise.} \end{cases} \tag{1.8}$$

Similarly, for $\nu \in \mathcal{N}$,

$$r(\nu) := \text{block diagonal } \{R_i^{1/2} \chi_{\{\nu\}}(i)\}, \tag{1.9}$$

where R_i are the symmetric, positive matrices defined above. Finally

$$v(t) := \begin{bmatrix} v^1(t) \\ \vdots \\ v^M(t) \end{bmatrix} \tag{1.10}$$

is a higher-dimensional standard Wiener process. In view of (1.7), for all $\nu \in \mathcal{N}$

$$h(\cdot, \nu) : \mathbb{R}^n \to \mathbb{R}^D, \tag{1.11}$$

while

$$r(\nu) : \mathbb{R}^D \to \mathbb{R}^D \tag{1.12}$$

where

$$D = d_1 + d_2 + \cdots + d_M. \tag{1.13}$$

To make the notation clearer, consider the case $M = 2$, $N = 4$. Then $\mathcal{N} = \{00, 01, 10, 11\}$ and

$$\begin{aligned} h(x, 00) &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \qquad h(x, 01) = \begin{bmatrix} 0 \\ h^2(x) \end{bmatrix}, \\ h(x, 10) &= \begin{bmatrix} h^1(x) \\ 0 \end{bmatrix}, \qquad h(x, 11) = \begin{bmatrix} h^1(x) \\ h^2(x) \end{bmatrix}, \end{aligned} \tag{1.14}$$

while

$$\begin{aligned} r(00) &= \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \qquad r(10) = \begin{bmatrix} R_1^{1/2} & 0 \\ 0 & 0 \end{bmatrix}, \\ r(01) &= \begin{bmatrix} 0 & 0 \\ 0 & R_2^{1/2} \end{bmatrix}, \qquad r(11) = \begin{bmatrix} R_1^{1/2} & 0 \\ 0 & R_2^{1/2} \end{bmatrix}. \end{aligned} \tag{1.15}$$

Clearly the dimension of the range space of $y(\cdot, \nu)$ is

$$D_\nu := \sum_{i=1}^{M} d_i \chi_{\{\nu\}}(i). \tag{1.16}$$

Of course for all ν, $y(t, \nu) \in \mathbb{R}^D$.

Following established terminology (cf. [9]), we see that a sensor scheduling strategy is defined by an increasing sequence of switching times $\tau_j \in [O, T]$ and the corresponding sequence $\nu_j \in \mathcal{N}$ of sensor activation configurations. We shall denote such a strategy by $u(\cdot)$, where

$$u(t) = \nu_j, \quad t \in [\tau_j, \tau_{j+1}), \quad j = 1, 2, \cdots. \tag{1.17}$$

As stated earlier we are interested in the *simultaneous* minimization of costs due to estimation errors as well as sensor scheduling. We shall therefore consider *joint estimation and sensor scheduling strategies.* Such a strategy consists of two parts: the

sensor scheduling strategy u (see (1.17)) and the estimator $\hat{\phi}$. The set of admissible strategies U_{ad} is the customary set of strategies adapted to the sequence of σ-algebras

$$\mathcal{F}_t^{y(\cdot,u(\cdot))} := \sigma\{y(s, u(\cdot)), s \leqq t\}. \tag{1.18}$$

That is, we consider *strict sense* admissible controls in the sense of [4]. For the problem under investigation, this last statement must be interpreted very carefully. First, we have indicated in (1.18) that the available past observation data σ-algebra depends (as is evident from (1.6)-(1.9)) very strongly on the sensor schedule $u(\cdot)$. This dependence is nonstandard, as here the dimension of the observation vector and the noise covariance change drastically at each switching time τ_i. In standard stochastic control formulations [4], [5], the dependence of y on $u(\cdot)$ is much more implicit. This is a difficult part of the formulation here, since it prevents us from using Girsanov transformations in a straightforward manner. Second, (1.18) means that the switching times τ_i and the variables ν_i, which define $u(\cdot)$, must be adapted to the filtration $\mathcal{F}_t^{y(\cdot,u(\cdot))}$, *which depends essentially* on the values of τ_i and ν_i! Finally (1.18) also means that $\hat{\phi}(T)$ must be measurable with respect to $\mathcal{F}_t^{y(\cdot,u(\cdot))}$. We describe a rigorous mathematical construction of such a model in § 2.

Given such a strategy, the corresponding cost is

$$J(u(\cdot), \hat{\phi}) := E\Bigg\{ |\phi(x(T)) - \hat{\phi}(T)|^2 \tag{1.19}$$

$$+ \int_0^T c(x(t), u(t))\, dt \tag{1.20}$$

$$+ \sum_j k(x(t), u(\tau_{j-1}), u(\tau_j)) \Bigg\}. \tag{1.21}$$

Here for $x \in \mathbb{R}^n$, $\nu, \nu' \in \mathcal{N}$

$$c(x, \nu) := \mathbf{c}_\nu(x), \tag{1.22}$$

(cf. (1.5)), and

$$k(x, \nu, \nu') = \mathbf{k}_{\nu,\nu'}(x), \tag{1.23}$$

(cf. (1.4)).

The optimal sensor scheduling in nonlinear filtering is thus formulated as the determination of a strategy achieving

$$\inf_{u(\cdot),\hat{\phi}} J(u(\cdot), \hat{\phi}) \tag{1.24}$$

among all admissible strategies.

To somewhat simplify the notation, let us order the elements of $\mathcal{N}$ according to the numbers they represent in binary form. For example in the case $M = 2$, $N = 4$ we replace $\mathcal{N} = \{00, 01, 10, 11\}$ by the set of integers $\{1, 2, 3, 4\}$. That is, the one-to-one correspondence between $\mathcal{N}$ and $\{1, 2, \cdots, N\}$ is described by

$$\begin{aligned} &\nu \mapsto (\text{integer represented by } \nu) + 1, \\ &k \mapsto \text{binary representation of } (k-1). \end{aligned} \tag{1.25}$$

So in the sequel of the paper we replace all the ν, ν' in (1.4)-(1.23) by the corresponding integers from $\{1, 2, \cdots, N\}$.

The structure of the paper is as follows. In § 2 a precise mathematical formulation is given and the corresponding stochastic control problem is precisely defined. In § 3 the set of quasi-variational inequalities solving the problem is derived. In § 4 we offer

some comments and discussion for extensions, further developments, and computational methods.

2. The stochastic control formulation.

2.1. Setting of the model. Let $(\Omega, \mathcal{A}, P)$ be a complete probability space, on which a filtration $\mathcal{F}_t$ is given, $\mathcal{A} = \mathcal{F}_\infty$. Let $w(\cdot)$ and $z(\cdot)$ be two independent, standard $\mathcal{F}_t$-Wiener processes with values in $\mathbb{R}^n$ and $\mathbb{R}^D$, respectively, carried by this probability space. On the same space we consider also an $\mathbb{R}^n$-valued random variable ξ, independent of $w(\cdot)$, $z(\cdot)$, and with probability distribution function π_0.

We consider the Itô equation (1.1), where $f(\cdot)$ is $\mathbb{R}^n$-valued, bounded, and Lipschitz, while $g(\cdot)$ is $\mathbb{R}^{n\times n}$-valued, bounded, and Lipschitz. Letting $a = \frac{1}{2}gg^T$, we assume $a > \alpha I_n$, where $\alpha > 0$ and I_n is the $n \times n$ identity matrix. The Lipschitz property is unnecessary and can be easily removed using Girsanov's transformation (i.e., consider weak solutions of (1.1)) [8]. It is assumed here to simplify the technicalities not related with the main issues of the paper. Under these assumptions (1.1) has a strong solution with well-known properties [8]. Note that *under P, $z(\cdot)$ is independent of $x(\cdot)$.*

Next consider functions $h^i(\cdot)$, $i = 1, \cdots, M$, from $\mathbb{R}^n$ into $\mathbb{R}^{d_i}$ that are bounded and Hölder continuous. We shall denote by L the infinitesimal generator of the Markov process $x(\cdot)$

$$L := \sum_{i,j=1}^{n} a_{ij}(x)\frac{\partial^2}{\partial x_i\,\partial x_j} + \sum_{i=1}^{n} f_i(x)\frac{\partial}{\partial x_i} \tag{2.1}$$

or in divergence form

$$L := \sum_{i,j=1}^{n} \frac{\partial}{\partial x_i} a_{ij}(x)\frac{\partial}{\partial x_j} - \sum_{i=1}^{n} a_i(x)\frac{\partial}{\partial x_i}, \tag{2.1a}$$

where

$$a_i(x) := -f_i(x) + \sum_{j=1}^{n} \frac{\partial a_{ij}(x)}{\partial x_j}. \tag{2.1b}$$

Let us next consider an *impulsive control* defined as follows. There is a sequence $\tau_1 < \tau_2 \cdots < \tau_k < \cdots$ of increasing $\mathcal{F}_t$-stopping times. To each time τ_i we attach an $\mathcal{F}_{\tau_i}$-measurable random variable u_i with values in the set of integers $\{1, 2, \cdots, N\}$.[1] We define

$$u(t) = u_i, \quad \tau_i \leqq t < \tau_{i+1}, \quad i = 0, 1, 2, \cdots \tag{2.2}$$

and set $\tau_0 = 0$. We require that

$$\tau_i \uparrow T \quad \text{as } i \uparrow \infty, \tag{2.3}$$

while $\tau_k = T$ is possible for some finite k.

Let ν_i be the element of $\mathcal{N}$, corresponding to u_i via (1.25).

Then define

$$h(x, u(t)) := h(x, \nu_i), \qquad \tau_i \leqq t < \tau_{i+1} \tag{2.4}$$

where $h(x, \nu)$ is defined by (1.7), in terms of the given functions $h^i(\cdot)$. Clearly $h(\cdot, u(t))$

[1] Recall that $N = 2^M$ and the binary representation of each integer $1, 2, \cdots, N$ determines a sensor activation configuration by (1.25).

maps $\mathbb{R}^n$ into $\mathbb{R}^D$ for all sensor schedules $u(\cdot)$ and is obviously bounded and Hölder continuous in x. Define also

$$r(u(t)) := r(\nu_i), \qquad \tau_i \leqq t < \tau_{i+1}, \tag{2.5}$$

where $r(\cdot)$ is defined by (1.9), in terms of the given matrices R_i, $i = 1, 2, \cdots, M$. Clearly $r(u(t))$ maps $\mathbb{R}^D$ into $\mathbb{R}^D$ for all sensor schedules $u(\cdot)$ but is *singular*. Next we define $\tilde{h}(x, \nu)$ to be the vector-valued function

$$\tilde{h}(x, \nu) := \begin{bmatrix} R_1^{-1/2} h^1(x) \chi_{\{\nu\}}(1) \\ \vdots \\ R_i^{-1/2} h^i(x) \chi_{\{\nu\}}(i) \\ \vdots \\ R_M^{-1/2} h^M(x) \chi_{\{\nu\}}(M) \end{bmatrix} \tag{2.6}$$

with $\chi_{\{\nu\}}(i)$ defined as in (1.8). Let

$$\tilde{h}(x, u(t)) := \tilde{h}(x, \nu_i), \qquad \tau_i \leqq t < \tau_{i+1}. \tag{2.7}$$

Clearly $\tilde{h}(\cdot, u(t))$ maps $\mathbb{R}^n$ into $\mathbb{R}^D$ for all sensor schedules $u(\cdot)$ and is obviously bounded and Hölder continuous in x. We shall refer to $u(\cdot)$ as the *impulsive control*. As we shall see, it describes essentially the decision to select at a sequence of decision times one of the functions $h(\cdot, k)$, $k \in \{1, 2, \cdots, N\}$. This is the precise mathematical implementation of the sensor selection decision described in the Introduction.

To see that indeed this is the case, we can, with the above preparation, use Girsanov's measure transformation method. Let us then consider the process

$$\zeta(t) = \exp\left\{ \int_0^t \tilde{h}(x(s), u(s))^T \, dz(s) - \frac{1}{2} \int_0^t \|\tilde{h}(x(s), u(s))\|^2 \, ds \right\}, \tag{2.8}$$

where T denotes transpose and $\|\cdot\|$ is the $\mathbb{R}^D$ norm. Note that the process $u(t)$ is adapted to $\mathcal{F}_t$. Then since $x(\cdot)$ is adapted to $\mathcal{F}_t^w \subset \mathcal{F}_t$ and $u(\cdot)$ is cadlag [8], (2.8) is well defined. Moreover, since $\tilde{h}$ is bounded, by Girsanov's theorem [8], [14], $\zeta(\cdot)$ is an $\mathcal{F}_t$-martingale. We can thus define a change of probability measure

$$\left. \frac{dP^{u(\cdot)}}{dP} \right|_{\mathcal{F}_t} = \zeta(t) \tag{2.9}$$

and consider the process

$$v(t) = z(t) - \int_0^t \tilde{h}(x(s), u(s)) \, ds. \tag{2.10}$$

By Girsanov's theorem [8], [14], under the probability measure $P^{u(\cdot)}$ on $(\Omega, \mathcal{A})$, $v(\cdot)$ is a standard $\mathcal{F}_t$-Wiener process with values in $\mathbb{R}^D$. Furthermore, by the independence of $w(\cdot)$ and $z(\cdot)$, $w(\cdot)$ remains a standard $\mathbb{R}^n$-valued, $\mathcal{F}_t$-Wiener process that is independent of $v(\cdot)$. Finally, ξ remains independent of $w(\cdot)$, $v(\cdot)$ while keeping its probability law, denoted by π_0. Thus $x(\cdot)$ also retains its probability law under $P^{u(\cdot)}$.

To relate this construction, i.e., (2.2)–(2.10), to the M noisy observations (sensors) loosely described in the Introduction (cf. in particular (1.6)), observe that (2.10) can be written as

$$r(u(t)) \, dz(t) = h(x(t), u(t)) \, dt + r(u(t)) \, dv(t) \tag{2.11}$$

in view of (1.7), (1.9), (2.4), (2.5), (2.6), and (2.7). Indeed,

$$
\begin{aligned}
r(u(t))\tilde{h}(x,(u(t))) = &\begin{bmatrix} R_1^{1/2}\chi_{\{\nu_i\}}(1) & 0 & 0 \\ 0 & R_2^{1/2}\chi_{\{\nu_i\}}(2) & 0 \\ & & \ddots \\ 0 & 0 & R_M^{1/2}\chi_{\{\nu_i\}}(M) \end{bmatrix} \\
&\cdot \begin{bmatrix} R_1^{-1/2}h^1(x)\chi_{\{\nu_i\}}(1) \\ R_2^{-1/2}h^2(x)\chi_{\{\nu_i\}}(2) \\ \vdots \\ R_M^{-1/2}h^M(x)\chi_{\{\nu_i\}}(M) \end{bmatrix} \\
&= h(x,\nu_i), \qquad \tau_i \leqq t < \tau_{i+1}.
\end{aligned} \tag{2.12}
$$

To give a precise meaning to (1.2), or (1.6), let us introduce the continuous path process in $\mathbb{R}^D$:

$$y(t,u(t)) := y^{\nu_i}(t), \qquad \tau_i \leqq t < \tau_{i+1} \tag{2.13}$$

where

$$dy^{\nu_i}(t) := r(\nu_i)\,dz(t) = h(x(t),\nu_i)\,dt + r(\nu_i)\,dv(t). \tag{2.14}$$

In other words, in the integration from (2.14) to (2.13), we use the left limits of $y(\ ,u(\cdot))$ to initialize. As a consequence, when a sensor is not used, the corresponding components of $y(t,u(t))$ will remain constant, a convention without any consequences. It is clear that if we select $u(t)=\nu$ for all t, where ν has zero everywhere except for one 1 in the ith location, then (1.2) results. It is also rather evident that $dy^{\nu}(t)\in\mathbb{R}^{D_\nu}$ and that in this case the Wiener process $r(\nu)v(\cdot)$ is also D_ν-dimensional (see (1.16) for the definition of D_ν). The process $dy^{\nu_i}(t)$ represents exactly the observation available in $[\tau_i,\tau_{i+1})$.

The next issue we wish to clarify relates to the measurability question we discussed in § 1.2, after (1.18). For any $u(\cdot)$, given the construction of $y(\cdot,u(\cdot))$ above, we can now consider $\mathscr{F}_t^{y(\cdot,u(\cdot))}$ as defined by (1.18). We shall say that $u(\cdot)$ is *admissible*, denoted $u\in U_{\text{ad}}$, if $u(t)$ is $\mathscr{F}_t^{y(\cdot,u(\cdot))}$ measurable, $t>0$, where $\mathscr{F}_t^{y(\cdot,u(\cdot))}$ is constructed as above. More precisely, this means that the τ_i are $\mathscr{F}_t^{u(\cdot,u(\cdot))}$-stopping times or that

$$\{\tau_i < t\} \subset \mathscr{F}_t^{y(\cdot,u(\cdot))} \tag{2.15}$$

and that

$$\nu_i \in \mathscr{F}_{\tau_i}^{y(\cdot,u(\cdot))}. \tag{2.16}$$

Note that since $\mathscr{F}_t^{y(\cdot,u(\cdot))}\subset\mathscr{F}_t$ for any sensor schedule $u(\cdot)$ adapted to $\mathscr{F}_t^{y(\cdot,u(\cdot))}$, if τ_i are $\mathscr{F}_t^{y(\cdot,u(\cdot))}$-stopping times they are also $\mathscr{F}_t$-stopping times, and the above construction (2.8)–(2.14) is still valid. The implication of (2.15), (2.16) is that we should check *that an optimizing strategy, obtained by some procedure, must satisfy the admissibility conditions.* Clearly U_{ad} is nonempty as strategies $u(t)=\nu$, $t\in[O,T]$, obviously are admissible. Also strategies with fixed switchings are admissible. Note that for an admissible control $\mathscr{F}_t^{y(\cdot,u(\cdot))}\subset\mathscr{F}_t^z$. This can be shown in a straightforward manner by proving by induction that $\mathscr{F}_{\tau_i\vee(t\wedge\tau_{i+1})}^{y(\cdot,u(\cdot))}\subset\mathscr{F}_{\tau_i\vee(t\wedge\tau_{i+1})}^z$ using (2.14) and the convention employed in constructing (2.13) from (2.14).

We have thus established in this section the precise mathematical models of nonlinear filtering problems where selection of sensors is possible. In particular we have succeeded in circumventing the subtleties associated with the definition of admissible sensor schedules discussed in § 1.2.[2]

2.2. The optimization problem. For the dynamical system described in § 2.1, we consider now the cost functional (1.19) where the underlying probability measure is $P^{u(\cdot)}$. As indicated in the Introduction, the general problem where the function ϕ will be in a nice class, e.g., bounded C^2, or polynomial, or C^∞ can be treated along identical lines. To simplify the notation we have chosen to formulate the problem for $\phi(x) = x$. The technical difficulties for this case are identical to the ones in the more general cases discussed above, particularly since this $\phi(\cdot)$ is unbounded on $\mathbb{R}^n$. For this choice the selection of the optimal estimator $\hat{\phi}(T)$ is the conditional mean

$$\hat{\phi}(T) = E^{u(\cdot)}\{x(T) \mid \mathcal{F}_T^{y(\cdot, u(\cdot))}\} \tag{2.17}$$

where $E^{u(\cdot)}$ denotes expectation with respect to $P^{u(\cdot)}$. Let $\mu(u, t)$ denote the conditional probability measure of $x(t)$, given $\mathcal{F}_t^{y(\cdot, u(\cdot))}$, on $\mathbb{R}^n$. It is convenient to express (2.17) as a vector valued functional of $\mu(u, t)$:

$$\hat{\phi}(T) = \Phi(\mu(u, T)) = \int_{\mathbb{R}^n} x \, d\mu(u, T). \tag{2.18}$$

We shall further assume that the running and switching cost functions $\mathbf{c}_i(\cdot)$, $\mathbf{k}_{ij}(\cdot)$, $i, j \in \{1, \cdots, N\}$, introduced in (1.4) and (1.5) have the following regularity:

$$\mathbf{c}_i(\cdot), \mathbf{k}_{ij}(\cdot) \quad \text{are in } C_b(\mathbb{R}^n) \text{ (i.e., bounded and continuous).} \tag{2.19}$$

As a result of this simple transformation we can rewrite the cost as a function of the impulsive control $u(\cdot)$ only (i.e., the selection of $\hat{\phi}(\cdot)$ has been eliminated):

$$\begin{aligned} J(u(\cdot)) = E^{u(\cdot)}\Big\{ &\|x(T) - \Phi(\mu(u, T))\|^2 + \int_0^T c(x(t), u(t))\, dt \\ &+ \sum_{j=1}^{\infty} k(x(\tau_j), u(\tau_{j-1}), u(\tau_j)) \chi_{\tau_j < T} \Big\} \end{aligned} \tag{2.20}$$

where $\chi_{\tau_i < T}$ is the characteristic function of the Ω-set $\{\omega;\ \tau_i(\omega) < T\}$. We further assume that the switching costs are uniformly bounded below

$$k(x, i, j) \geqq k_o, \quad x \in \mathbb{R}^n, \quad i, j \in \{1, \cdots, N\} \tag{2.21}$$

with k_0 a positive constant. Note that as a consequence of (2.20) if for some admissible $u(\cdot)$ with positive probability, the number of times $\tau_i < T$ is infinite, then the cost $J(u(\cdot))$ will be infinite. Therefore for T finite the optimal policy will exhibit a finite number of sensor switchings.

The optimal sensor selection problem can now be stated precisely as the optimization problem:

$\mathcal{P}$: Find an admissible impulsive control $u^*(\cdot)$ such that

$$J(u^*(\cdot)) = \inf_{u(\cdot) \in U_{\text{ad}}} J(u(\cdot)) \tag{2.22}$$

[2] Since $r(u(t))$ is a singular matrix, this stage is more delicate than in standard stochastic control theory, where $\mathcal{F}_t^z$ would suffice.

where U_{ad} are all impulsive control strategies adapted to $\mathcal{F}^{y(\cdot),u(\cdot))}$, or equivalently, satisfying (2.15), (2.16). Problem $\mathcal{P}$ is a *nonstandard* stochastic control problem of a partially observed diffusion.

2.3. The equivalent fully-observed problem. In this section we transform the problem of § 2.2 into a fully-observed stochastic control problem by introducing appropriate Zakai equations. As is customary in the theory of nonlinear filtering [1]–[4], we introduce the operator

$$p(u(\cdot), t)(\psi) = E\{\zeta(t)\psi(x(t)) \mid \mathcal{F}_t^{y(\cdot),u(\cdot))}\} \tag{2.23}$$

for each impulsive control $u(\cdot)$. The notation is chosen so as to emphasize the dependence on $u(\cdot)$, which is due to the dependence of $\zeta(\cdot)$ on $u(\cdot)$ as introduced in (2.8).[3] The operator (2.23) maps the set of Borel bounded functions on $\mathbb{R}^n$, into the set of real-valued stochastic processes adapted to $\mathcal{F}_t^{y(\cdot),u(\cdot))}$. Note that $p(u(\cdot), t)$ can be viewed as a positive finite measure on $\mathbb{R}^n$. It is the *unnormalized conditional probability measure* of $x(t)$ given $\mathcal{F}_t^{y(\cdot),u(\cdot))}$ [1], [2].

With the help of these measures we can rewrite the various cost terms in (2.20) as follows:

$$\begin{aligned} E^{u(\cdot)}\{\|x(T) - \Phi(\mu(u, T))\|^2\} &= E\{\zeta(T)\|x(T) - \Phi(\mu(u, T))\|^2\} \\ &= E\{p(u(\cdot), T)(\theta)\} \end{aligned} \tag{2.24}$$

where

$$\theta(x) := \left\| x - \frac{p(u(\cdot), T)(\chi)}{p(u(\cdot), T)(\mathbb{1})} \right\|^2, \tag{2.25}$$

with χ representing the function $\chi(x) := x$ and $\mathbb{1}$ the function $\mathbb{1}(x) := 1$, $x \in \mathbb{R}^n$. A straightforward computation implies that

$$E^{u(\cdot)}\{\|x(T) - \Phi(\mu(u, T))\|^2\} = E\{\Psi(p(u(\cdot), T))\} \tag{2.26}$$

where Ψ is the functional on finite measures of $\mathbb{R}^n$ defined by

$$\Psi(\mu) = \mu(\chi^2) - \frac{\|\mu(\chi)\|^2}{\mu(\mathbb{1})} \tag{2.27}$$

where $\chi^2(x) = \|x\|^2$, $x \in \mathbb{R}^n$, and μ is any finite measure on $\mathbb{R}^n$ such that the quantities $\mu(\chi^2)$ and $\mu(\chi)$ make sense.

Next, we have

$$\begin{aligned} E^{u(\cdot)}\left\{\int_0^T c(x(t), u(t))\, dt\right\} &= E\left\{\zeta(T)\int_0^T c(x, (t), u(t))\, dt\right\} \\ &= E\left\{\int_0^T E\{\zeta(T)c(x(t), u(t)) \mid \mathcal{F}_t\}\, dt\right\} \\ &= E\left\{\int_0^T E\{\zeta(T) \mid \mathcal{F}_t\}c(x(t), u(t))\, dt\right\} \\ &= E\left\{\int_0^T \zeta(t)c(x(t), u(t))\, dt\right\} \end{aligned} \tag{2.28}$$

[3] But the expectation is with respect to P and not $P^{u(\cdot)}$.

because $x(t)$, $u(t)$ are measurable with respect to $\mathcal{F}_t$ and $\zeta(\cdot)$ is an $\mathcal{F}_t$-martingale. Now define a map C with values in $C_b(\mathbb{R}^n)$ via

$$C(u_i) := \mathbf{c}_{u_i}(\cdot), \qquad u_i \in \{1, 2, \cdots, N\}. \tag{2.29}$$

Then in view of (2.29), (2.23), we can rewrite (2.28) as

$$\begin{aligned} E^{u(\cdot)}\left\{\int_0^T c(x(t), u(t))\, dt\right\} &= E\left\{\int_0^T E\{\zeta(t)c(x(t), u(t)) \,|\, \mathcal{F}_t^{y(\cdot, u(\cdot))}\}\, dt\right\} \\ &= E\left\{\int_0^T p(u(\cdot), t)(C(u(t)))\, dt\right\}. \end{aligned} \tag{2.30}$$

Finally,

$$\begin{aligned} E^{u(\cdot)}\{k(x(\tau_i), u(\tau_{i-1}), u(\tau_i))\chi_{\tau_i<T}\} &= E\{\zeta(\tau_i)k(x(\tau_i), u(\tau_{i-1}), u(\tau_i))\chi_{\tau_i<T}\} \\ &= E\{E\{\zeta(\tau_i)k(x(\tau_i), u(\tau_{i-1}), u(\tau_i))\chi_{\tau_i<T} \,|\, \mathcal{F}_{\tau_i}^{y(\cdot, u(\cdot))}\}\} \\ &= E\{p(u(\cdot), \tau_i)(K(u(\tau_{i-1}), u(\tau_i)))\chi_{\tau_i<T}\}. \end{aligned} \tag{2.31}$$

Here we have introduced the function K with values in $C_b(\mathbb{R}^n)$ via

$$K(u_i, u_j) = \mathbf{k}_{u_i, u_j}(\cdot), \qquad u_u, u_j \in \{1, 2, \cdots, N\}, \tag{2.32}$$

and we have used the admissibility of $u(\cdot)$. Note that in the simpler case, where $\mathbf{c}_i(\cdot), \mathbf{k}_{ij}(\cdot)$, $i, j \in \{1, 2, \cdots, N\}$ are constant independent of x, (2.30) simplifies to

$$E^{u(\cdot)}\left\{\int_0^T c(x(t), u(t))\, dt\right\} = E\left\{\int_0^T p(u(\cdot), t)(\mathbb{1})\mathbf{c}_{u(t)}\, dt\right\} \tag{2.33}$$

and (2.31) simplifies to

$$E^{u(\cdot)}\{k(x(\tau_i), u(\tau_{i-1}), u(\tau_i))\chi_{\tau_i<T}\} = E\{\mathbf{k}_{u_{i-1}, u_i}\chi_{\tau_i<T}p(u(\cdot), \tau_i)(\mathbb{1})\}. \tag{2.34}$$

Utilizing (2.26), (2.30), (2.31), we can rewrite the cost corresponding to policy $u(\cdot)$, given in (2.20), as follows:

$$\begin{aligned} J(u(\cdot)) = E\Bigg\{\Psi(p(u(\cdot), T)) &+ \int_0^T p(u(\cdot), t)(C(u(t)))\, dt \\ &+ \sum_{i=1}^{\infty} p(u(\cdot), \tau_i)(K(u_{i-1}, u_i))\chi_{\tau_i<T}\Bigg\}. \end{aligned} \tag{2.35}$$

In (2.35) we have succeeded in displaying the cost as a functional of the unnormalized conditional measure $p(u(\cdot), \cdot)$, which is the "information" state of the equivalent fully-observed stochastic control problem. To complete this transformation we need to derive the evolution equation for $p(u(\cdot), \cdot)$, i.e., the Zakai equation. We turn this problem next and derive a weak form of the Zakai equation for $p(u(\cdot), \cdot)$ in the following lemma. Here $C_b^{2,1}$ denotes the space of all functions $\psi(x, t)$ on $\mathbb{R}^n \times \mathbb{R}$ that are bounded, continuous together with their first and second derivatives with respect to x, and first derivatives with respect to t.

LEMMA 2.1. *For any $\psi \in C_b^{2,1}$ we have the relation*

$$\begin{aligned} p(u(\cdot), t)(\tilde{\psi}(t)) = \pi_0(\tilde{\psi}(0)) &+ \int_0^t p(u(\cdot), s)\left(\frac{\partial \tilde{\psi}}{\partial s} + L\tilde{\psi}\right) ds \\ &+ \int_0^t \sum_{i=1}^{D} p(u(\cdot), s)(\tilde{H}_i(u(s))\tilde{\psi}(s))\, dz_i(s) \end{aligned} \tag{2.36}$$

where

$$
\begin{aligned}
&[\tilde{H}_i(u(s))\phi](x) := \tilde{h}_i(x, u(s))\phi(x), \qquad i = 1, 2, \cdots, D, \quad \phi \in C_b^2, \\
&\tilde{\psi}(s)(x) := \psi(x, s),
\end{aligned} \tag{2.37}
$$

and $\tilde{h}_i$ *is the ith component of* $\tilde{h}$ *(see* (2.6)).

Proof. Let $\beta(\cdot) \in L^\infty(0, T; \mathbb{R}^D)$ given and consider the $\mathcal{F}_t$-martingale $\rho(t)$, defined by

$$
d\rho(t) = \rho(t)\beta(t)^T dz(t), \qquad \rho(0) = 1. \tag{2.38}
$$

Recall that by definition of $\zeta(t)$ (cf. eq. (2.8))

$$
d\zeta(t) = \zeta(t)\tilde{h}(z(t), u(t))^T dz(t), \qquad \zeta(0) = 1. \tag{2.39}
$$

Therefore by Itô's rule [8]

$$
\begin{aligned}
&d(\zeta(t)\rho(t)) = \zeta(t)\rho(t)[(\tilde{h}(x(t), u(t)) + \beta(t))^T dz(t) + \tilde{h}^T(x(t), u(t))\beta(t)\, dt] \\
&\zeta(0)\rho(0) = 1.
\end{aligned} \tag{2.40}
$$

and since $\psi \in C_b^{2,1}$

$$
d\psi(x(t), t) = \left(\frac{\partial \psi(x(t), t)}{\partial t} + L\psi(x(t), t)\right) dt + [\nabla \psi(x(t), t)]^T g(x(t))\, dw(t) \tag{2.41}
$$

where L is given in (2.1). Therefore, with some arguments suppressed for ease of notation

(2.42)

$$
d[\psi(x(t), t)\zeta(t)\rho(t)] = \zeta(t)\rho(t)\left[\left(\frac{\partial \psi}{\partial t} + L\psi + \tilde{h}^T\beta\psi\right) dt + \nabla\psi^T g\, dw(t) + \psi(\tilde{h} + \beta)^T dz(t)\right].
$$

In (2.41), (2.42) we use the notation $\nabla\psi = (\partial\psi/\partial x_1, \cdots, \partial\psi/\partial x_n)^T$. Integrating (2.42), and taking expectations, we deduce

$$
E\{\psi(x(t), t)\zeta(t)\rho(t)\} = \pi_0(\tilde{\psi}(0)) + E\left\{\int_0^t \zeta(s)\rho(s)\left[\frac{\partial \psi}{\partial s} + L\psi + \tilde{h}^T\beta\psi\right] ds\right\}. \tag{2.43}
$$

We can then write

$$
\begin{aligned}
E\left\{\int_0^t \zeta(s)\rho(s)\left[\frac{\partial \psi}{\partial s} + L\psi\right] ds\right\} &= E\left\{\int_0^t E\left\{\rho(s)\zeta(s)\left(\frac{\partial \psi}{\partial s} + L\psi\right) \,\middle|\, \mathcal{F}_s^{y(\cdot, u(\cdot))}\right\} ds\right\} \\
&= E\left\{\int_0^t \rho(s)p(u(\cdot), s)\left(\frac{\partial \psi}{\partial s} + L\psi\right) ds\right\} \\
&= E\left\{\rho(t)\int_0^t p(u(\cdot), s)\left(\frac{\partial \psi}{\partial s} + L\psi\right) ds\right\}
\end{aligned} \tag{2.44}
$$

by virtue of the $\mathcal{F}_t$-martingale property of $\rho(\cdot)$. Similarly,

$$
\begin{aligned}
&E\left\{\int_0^t \zeta(s)\rho(s)\tilde{h}(x(s), u(s))^T\beta(s)\psi(x(s), s)\, ds\right\} \\
&\quad = E\left\{\rho(t)\int_0^t \zeta(s)\psi(x(s), s)\tilde{h}(x(s), u(s))^T dz(s)\right\} \\
&\quad = E\left\{\rho(t)\int_0^t \sum_{i=1}^D p(u(\cdot), s)(\tilde{h}_i(\cdot, u(s))\psi(\cdot, s))\, dz_i(s)\right\}
\end{aligned} \tag{2.45}
$$

where in the first equality we have used the representation $\rho(t) = 1 + \int_0^t \rho(s)\beta(s)^T dz(s)$, and the well-known isomorphism between Itô stochastic integrals and L^2 [8]. Finally,

$$E\{\psi(x(t), t)\zeta(t)\rho(t)\} = E\{\rho(t)p(u(\cdot), t)(\tilde{\psi}(t))\}. \tag{2.46}$$

Using (2.44), (2.45), (2.46) in (2.43), we obtain

$$E\left\{\rho(t)\left[p(u(\cdot), t)(\tilde{\psi}(t)) - \pi_0(\tilde{\psi}(0)) - \int_0^t p(u(\cdot), s)\left(\frac{\partial \psi}{\partial s} + L\psi\right) ds \right.\right. \\ \left.\left. - \int_0^t \sum_{i=1}^{D} p(u(\cdot), s)(\tilde{H}_i(u(s))\tilde{\psi}(s))\, dz_i(s)\right]\right\} = 0. \tag{2.47}$$

We can replace $\rho(t)$ in (2.47) by a linear combination of such variables, with different β. The set of corresponding variables is dense in $L^2(\Omega, \mathcal{F}_t^z, P)$. However, the random variable in the brackets in the right-hand side of (2.47) is clearly in $L^2(\Omega, \mathcal{F}_t^{y(\cdot, u(\cdot))}, P)$ and therefore in $L^2(\Omega, \mathcal{F}_t^z, P)$, since $\mathcal{F}_t^{y(\cdot, u(\cdot))} \subset \mathcal{F}_t^z$. Then (2.47) implies the result of the lemma (2.36).

Remark. Note that the assumed nondegeneracy of $x(\cdot)$ implies that the solution of (2.36) is unique. In general this can be proved under our working hypotheses for solutions that are measure-valued processes. Here we outline such a proof for the case when these conditional measures are absolutely continuous with respect to Lebesgue measure on $\mathbb{R}^n$, i.e., in the case unnormalized conditional densities exist. For this we need to assume in addition that

$$\pi_0 \text{ has a density } p_0 \text{ with respect to Lebesgue measure; } p_0 \in L^2(\mathbb{R}^n). \tag{2.48}$$

We denote by L^* the formal adjoint of L (see (2.1), (2.1a), (2.1b)):

$$L^* = \sum_{i,j=1}^{n} \frac{\partial}{\partial x_i} a_{ij}(x) \frac{\partial}{\partial x_j} + \sum_{i=1}^{n} \frac{\partial}{\partial x_i} a_i, \tag{2.49}$$

and consider the Hilbert space form of the Zakai equation [10]

$$\begin{aligned} dp &= L^* p\, dt + p\tilde{h}(\cdot, u(t))^T dz(t), \\ p(0) &= p_0. \end{aligned} \tag{2.50}$$

The function space in which the solution is sought is

$$L^2(\Omega, \mathcal{A}, P; C(0, T; L^2(\mathbb{R}^n))) \cap L^2_{\mathcal{F}^{y(\cdot, u(\cdot))}}(0, T; H^1(\mathbb{R}^n)). \tag{2.51}$$

Here H^1 is the usual Sobolev space on $\mathbb{R}^n$ [11], and the subindex $\mathcal{F}^{y(\cdot, u(\cdot))}$ in the second L^2 space denotes that the solution is adapted to the filtration $\mathcal{F}_t^{y(\cdot, u(\cdot))}$, $t \geqq 0$. It follows from the results of Pardoux [11] that a unique solution of (2.49) exists in the function space (2.50) under the assumptions made here. We can then establish the following.

LEMMA 2.2. *The following property holds*:

$$p(u(\cdot), t)(\psi) = (p(u(\cdot), t), \psi) \tag{2.52}$$

for all ψ in $L^2(\mathbb{R}^n)$ and bounded, where $(\cdot, \cdot)$ denotes inner product in $L^2(\mathbb{R}^n)$.

Proof. By slight abuse of notation we use the same symbol to denote the conditional unnormalized measure *and* density (whenever the latter exists). Let us prove inductively

that

$$p(u(\cdot), \tau_i \vee (t \wedge \tau_{i+1}))(\psi) = (p(u(\cdot), \tau_i \vee (t \wedge \tau_{i+1})), \psi), \tag{2.53}$$

where the left-hand notation refers to the measure appearing in (2.36) and the right-hand notation to the solution of (2.50), which is uniquely defined. The induction is necessary because the right-hand side of (2.55) is discontinuous and so we can only examine (2.55) on the intervals $(\tau_i, \tau_i \vee (t \wedge \tau_{i+1}))$. Suppose then that (2.53) holds for $i-1$, and therefore, in particular,

$$p(u(\cdot), \tau_i)(\psi) = (p(u(\cdot), \tau_i), \psi) \quad \forall \psi. \tag{2.54}$$

Now consider the solution η of

$$\begin{aligned} &\frac{\partial \eta}{\partial s} + L\eta = -\eta \tilde{h}(\cdot, u(s))^T \beta(s), \qquad s \in (\tau_i, \tau_i \vee (t \wedge \tau_{i+1})), \\ &\eta(x, \tau_i \vee (t \wedge \tau_{i+1})) = \psi(x) \end{aligned} \tag{2.55}$$

where $\psi \in C_0^\infty(\mathbb{R}^n)$ and β is a smooth deterministic function with values in $\mathbb{R}^D$. From the assumptions on f, g and h^i (it is here that we use the assumed Hölder continuity of h^i), we can assert that the solution of (2.55) belongs to $C_b^{2,1}(\mathbb{R}^n \times (\tau_i, \tau_i \vee (t \wedge \tau_{i+1})))$, for any sample ω [11]. Therefore (2.36) implies (using (2.55))

$$\begin{aligned} p(u(\cdot), \tau_i \vee (t \wedge \tau_{i+1}))(\psi) &= p(u(\cdot), \tau_i)(\tilde{\eta}(\tau_i)) \\ &\quad - \int_{\tau_i}^{\tau_i \vee (t \wedge \tau_{i+1})} \sum_{j=1}^{D} p(u(\cdot), s)(\tilde{H}_j(u(s))\tilde{\eta}(s))\beta_j(s)\, ds \\ &\quad + \int_{\tau_i}^{\tau_i \vee (t \wedge \tau_{i+1})} \sum_{j=1}^{D} p(u(\cdot), s)(\tilde{H}_j(u(s))\tilde{\eta}(s))\, dz_j(s) \end{aligned} \tag{2.56}$$

where $\tilde{H}_j$ is as defined in Lemma 2.1, and $\tilde{\eta}(s)(x) := \eta(x, s)$. Therefore, by Itô's rule and recalling that $\rho(t)$ is the martingale associated with $\beta(t)$, we have

$$\begin{aligned} &p(u(\cdot), \tau_i \vee (t \wedge \tau_{i+1}))(\psi)\rho(\tau_i \vee (t \wedge \tau_{i+1})) \\ &\quad = p(u(\cdot), \tau_i)(\tilde{\eta}(\tau_i))\rho(\tau_i) + \int_{\tau_i}^{\tau_i \vee (t \wedge \tau_{i+1})} \rho(s) \sum_{j=1}^{D} p(u(\cdot), s)(\tilde{H}_j(u(s))\tilde{\eta}(s))\, dz_j(s) \\ &\qquad + \int_{\tau_i}^{\tau_i \vee (t \wedge \tau_{i+1})} \rho(s) \sum_{j=1}^{D} p(u(\cdot), s)(\tilde{H}_j(u(s))\tilde{\eta}(s))\beta_j(s)\, dz_j(s). \end{aligned} \tag{2.57}$$

Hence

$$E\{p(u(\cdot), \tau_i \vee (t \wedge \tau_{i+1}))(\psi)\rho(\tau_i \vee (t \wedge \tau_{i+1}))\} = E\{p(u(\cdot), \tau_i)(\tilde{\eta}(\tau_i))\rho(\tau_i)\}. \tag{2.58}$$

On the other hand, from (2.50) and (2.55) we obtain

$$\begin{aligned} (p(u(\cdot), \tau_i \vee (t \wedge \tau_{i+1})), \psi) &= (p(u(\cdot), \tau_i), \tilde{\eta}(\tau_i)) \\ &\quad + \int_{\tau_i}^{\tau_i \vee (t \wedge \tau_{i+1})} \sum_{j=1}^{D} (p(u(\cdot), s)\tilde{h}_j(\cdot, u(s)), \tilde{\eta}(s))\, dz_j(s) \\ &\quad - \int_{\tau_i}^{\tau_i \vee (t \wedge \tau_{i+1})} \sum_{j=1}^{D} (p(u(\cdot), s), \tilde{H}_j(u(s))\tilde{\eta}(s))\beta_j(s)\, ds, \end{aligned} \tag{2.59}$$

and thus also

$$E\{(p(u(\cdot), \tau_i \vee (t \wedge \tau_{i+1})), \psi)\rho(\tau_i \vee (t \wedge \tau_{i+1}))\} = E\{(p(u(\cdot), \tau_i), \tilde{\eta}(\tau_i))\rho(\tau_i)\}. \tag{2.60}$$

But from the inductive hypothesis (2.54), the right-hand sides of (2.58) and (2.60) are equal. Hence the left-hand sides coincide. Varying β, we easily deduce that (2.53) holds, at least for $\psi \in C_0^\infty(\mathbb{R}^n)$, which is sufficient to conclude the proof of the lemma.

With this result we can rewrite the cost (2.35) as follows:

$$\begin{aligned} J(u(\cdot)) = E\Big\{ & \Psi(p(u(\cdot), T)) + \int_0^T (p(u(\cdot), t), C(u(t)))\, dt \\ & + \sum_{i=1}^{\infty} \chi_{\tau_i < T}(p(u(\cdot), \tau_i), K(u_{i-1}, u_i)) \Big\} \end{aligned} \tag{2.61}$$

where (see (2.27))

$$\Psi(p(u(\cdot), T)) = (p(u(\cdot), T), \chi^2) - \frac{\|(p(u(\cdot), T), \chi)\|^2}{(p(u(\cdot), T), \mathbb{1})}. \tag{2.62}$$

Since (2.62) involves unbounded functions we must show that it makes sense.

At this point it is useful to introduce a weighted Hilbert space to express $\Psi(p(u(\cdot), T))$ in a more convenient form. To this end let

$$\mu(x) = 1 + \|x\|^4 \tag{2.63}$$

and $L^2(\mathbb{R}^n; \mu)$ denote the space of functions φ such that $\varphi\mu \in L^2(\mathbb{R}^n)$. Define in a similar way the space $L^1(\mathbb{R}^n; \mu)$. From the discussion of existence and uniqueness of solutions of (2.50) in the functional space (2.51) and if

$$p_0 \in L^2(\mathbb{R}^n; \mu) \cap L^1(\mathbb{R}^n; \mu),$$

it is easy to check that (2.50), under the assumptions made in § 2.1, has a unique solution in the space

$$L^2(\Omega, \mathcal{A}, P; C(0, T; L^2(\mathbb{R}^n; \mu) \cap L^1(\mathbb{R}^n; \mu))) \cap L^2(0, T; H^1(\mathbb{R}^n; \mu)) \tag{2.64}$$

where $H^1(\mathbb{R}^n; \mu)$ is the obvious modification of $H^1(\mathbb{R}^n)$. This justifies that the quantities arising in (2.62) have a meaning.

We note that $J(u(\cdot))$ is indexed implicitly (we do not include this in our notation) by π_0 (or p_0) and $u(0) = j$, $j \in \{1, \cdots, N\}$, which is deterministic since it is $\mathcal{F}_0^z$-measurable, by construction.

We close this section by rewriting the dynamics (2.50), in terms of the originally given observation nonlinearities h^i, and with forcing inputs the processes $y^i(\cdot)$ introduced in (2.13), (2.14). In view of (2.5), (2.6), (2.7), (2.13), (2.14), we have

$$\tilde{h}(\cdot, u(t))^T\, dz(t) = \sum_{j=1}^{M} h^{j^T}(\cdot)\chi_{\{\nu_i\}}(j) R_j^{-1/2}\, dz_j(t), \qquad \tau_i \leqq t < \tau_{i+1}$$

(where we have written $z = [z_1, z_2, \cdots z_M]^T$)

$$\begin{aligned} &= \sum_{j=1}^{M} h^{j^T}(\cdot)\chi_{\{\nu_i\}}(j) R_j^{-1} R_j^{1/2} \chi_{\{\nu_i\}}(j)\, dz_j(t), \qquad \tau_i \leqq t < \tau_{i+1} \\ &= \delta(\cdot, \nu_i)^T\, dy(t, \nu_i), \qquad \tau_i \leqq t < \tau_{i+1} \\ &=: \delta(\cdot, u(t))^T\, dy(t, u(t)) \end{aligned}$$

where

$$\delta(x,\nu)=\begin{bmatrix} R_1^{-1}h^1(x)\chi_{\{\nu\}}(1) \\ \vdots \\ R_i^{-1}h^i(x)\chi_{\{\nu\}}(u) \\ \vdots \\ R_M^{-1}h^M(x)\chi_{\{\nu\}}(M) \end{bmatrix}. \tag{2.65}$$

Therefore the system dynamics (2.50) can be written equivalently:

$$\begin{aligned} &dp(u(\cdot),t)=L^*p(u(\cdot),t)\,dt+p(u(\cdot),t)\delta(\cdot,u(t))^T\,dy(t,u(\cdot)),\\ &p(u(\cdot),0)=p_0, \end{aligned} \tag{2.66}$$

where $y(t,u(t))$ is defined in (2.13), (2.14). This makes precise the construction of a Zakai equation driven by "controlled" observations alluded to in the Introduction. It also now becomes clear that the spaces described by (2.51), (2.64) are the appropriate ones as far as solutions of (2.50) or (2.66) are concerned.

3. The solution of the optimization problem.

3.1. Setting up a system of quasi-variational inequalities. Let us consider the Banach space $H=L^2(\mathbb{R}^n;\mu)\cap L^1(\mathbb{R}^n;\mu)$ and the metric space H^+ of positive elements of H. Let

$$\begin{aligned} &\mathcal{B}:=\text{space of Borel measurable, bounded functions on } H^+,\\ &\mathcal{C}:=\text{space of uniformly continuous, bounded functions on } H^+. \end{aligned} \tag{3.1}$$

Let us now define semigroups $\Phi_j(t)$ on $\mathcal{B}$ or $\mathcal{C}$ as follows. Consider (2.50) with fixed schedule $u(t)=j$, and let p_j denote the corresponding density $p(\cdot,j)$. Then for $j\in\{1,2,\cdots,N\}$

$$dp_j=L^*p_j\,dt+p_j\tilde{h}^{j^T}\,dz(t),\qquad p_j(0)=\pi \tag{3.2}$$

where

$$\tilde{h}^j:=\tilde{h}(\cdot,j). \tag{3.3}$$

We set

$$\Phi_j(t)(F)(\pi)=E\{F(p_{j,\pi}(t))\},\qquad F\in\mathcal{B}\text{ or }\mathcal{C}, \tag{3.4}$$

where $p_{j,\pi}$ indicates the solution of (3.2) with initial value π. It is easy to see that Φ_j is a semigroup since $p_j(t)$ is a Markov process with values in H^+. It is also useful to introduce the subspaces $\mathcal{B}_1$ and $\mathcal{C}_1$ of functions such that

$$\|F\|_1=\sup_{\pi\in H^+}\frac{|F(\pi)|}{1+\|\pi\|_\mu}<\infty \tag{3.5}$$

where $\|\pi\|_\mu=\|\pi\|_{L^1(\mathbb{R}^n;\mu)}$. The spaces $\mathcal{B}_1$ and $\mathcal{C}_1$ are also Banach spaces. They are needed because we shall encounter functionals with linear growth in the cost function (2.61). To simplify the statement and analysis of the quasi-variational inequalities that solve the optimization problem considered here, we give the details for the case $N=2$ only in the sequel. We shall insert remarks to indicate how the results should be modified for the general case. Let us introduce the notation

$$\begin{aligned} &C_i:=C(i,\cdot),\qquad i=1,2,\\ &K_1:=K(1,2),\qquad K_2:=K(2,1). \end{aligned} \tag{3.6}$$

Since C_1, C_2, K_1, K_2 are bounded functions, we can use them to define elements of $\mathscr{C}_1$ via (for example)

$$C_1(\pi) = (C_1, \pi) \tag{3.7}$$

where a slight abuse of notation, in denoting the functional and the function by the same symbol, has been allowed. Similarly the functional on H^+:

$$\Psi(\pi) = (\pi, \chi^2) - \frac{\|(\pi, \chi)\|^2}{(\pi, \mathbb{1})} \tag{3.8}$$

belongs to $\mathscr{C}_1$ since it is positive and

$$\Psi(\pi) \leqq (\pi, \chi^2) \leqq \|\pi\|_\mu. \tag{3.9}$$

Consider now the set of functionals $U_1(\pi, t)$, $U_2(\pi, t)$ such that

$$\begin{aligned}
&U_1, U_2 \in C(0, T; \mathscr{C}_1),\\
&U_1(\cdot, t) \geqq 0, \qquad U_2(\cdot, t) \geqq 0,\\
&U_1(\pi, T) = U_2(\pi, T) = \Psi(\pi),\\
&U_1(\pi, t) \leqq \Phi_1(s-t) U_1(\pi, s) + \int_t^s \Phi_1(\lambda - t) C_1(\pi)\, d\lambda,\\
&U_2(\pi, t) \leqq \Phi_2(s-t) U_2(\pi, s) + \int_t^s \Phi_2(\lambda - t) C_2(\pi)\, d\lambda \quad \forall s \geqq t,\\
&U_1(\pi, t) \leqq K_1(\pi) + U_2(\pi, t),\\
&U_2(\pi, t) \leqq K_2(\pi) + U_1(\pi, t).
\end{aligned} \tag{3.10}$$

In what follows we occasionally use the notation $U_i(s)(\pi) = U_i(\pi, s)$, $i = 1, 2$.

3.2. Existence of a maximum element. We shall refer to (3.10) as the system of quasi-variational inequalities (QVI). Our first objective is to prove the following.

THEOREM 3.1. *We assume that the conditions on the data f, g, h^i introduced in* § 2.1 *hold. Then the set of functionals U_1, U_2 satisfying* (3.10) *is nonempty and has a maximum element, in the sense that if $\tilde{U}_1, \tilde{U}_2$ denotes this maximum element and U_1, U_2 satisfies* (3.10), *then*

$$\tilde{U}_1 \geqq U_1, \qquad \tilde{U}_2 \geqq U_2.$$

The proof will be carried out in several steps. In fact there is some difficulty due to the functional $\Psi(\pi)$. We shall modify it to assume that

$$0 \leqq \Psi(\pi) \leqq \bar{\Psi}(\pi, \mathbb{1}) \tag{3.11}$$

where $\bar{\Psi}$ is a constant. We shall prove the theorem with the additional assumption (3.11) and prove the probabilistic interpretation, i.e., the connection with the infimum of (2.61). The probabilistic formula will be used next in an approximation procedure. We can approximate, for instance, the functional Ψ defined by (3.8) in the following way. Set

$$\Psi_n(\pi) = \int \frac{\pi \|x\|^2}{1 + (\|x\|^2/n)}\, dx - \frac{\left\| \int (\pi x / ((1 + \|x\|^2/n)^{1/2}))\, dx \right\|^2}{\int \pi\, dx}, \tag{3.12}$$

which clearly satisfies (3.11) with $\bar{\Psi} = n$.

Proof of Theorem 3.1 *under assumption* (3.11). The set of functionals satisfying (3.10) is a subset of $\mathscr{B}_1$ or $\mathscr{C}_1$ defined in (3.5). However for this subset the norm (3.5) is unnecessarily restrictive. For those functionals it is sufficient to set

$$\begin{aligned} &\tilde{H} = L^2(\mathbb{R}^n) \cap L^1(\mathbb{R}^n), \\ &\tilde{H}^+ = \text{set of positive elements of } \tilde{H} \end{aligned} \tag{3.13}$$

and to consider $\tilde{\mathscr{B}}_1$, $\tilde{\mathscr{C}}_1$ the space of Borel or continuous functionals on $\tilde{H}^+$ such that

$$\|F\|_1 = \sup_{\pi \in \tilde{H}^+} \frac{|F(\pi)|}{1 + (\pi, \mathbb{1})} < \infty. \tag{3.14}$$

We shall then study the system (3.10) with $\mathscr{C}_1$ replaced by $\tilde{\mathscr{C}}_1$. Let us note that

$$H^+ \subset \tilde{H}^+,$$

and if we consider a functional F in $\tilde{\mathscr{B}}_1$ or $\tilde{\mathscr{C}}_1$, its restriction to H^+ belongs to $\mathscr{B}_1$ or $\mathscr{C}_1$; the injection

$$F \to \text{restriction of } F \text{ to } H^+$$

is continuous from $\tilde{\mathscr{B}}_1$ or $\tilde{\mathscr{C}}_1$ to $\mathscr{B}_1$ or $\mathscr{C}_1$. Therefore replacing $\mathscr{C}_1$ by $\tilde{\mathscr{C}}_1$ in (3.10) gives a stronger result.

In the proof we shall omit the symbol $\tilde{}$ and write $\mathscr{B}_1$, $\mathscr{C}_1$ instead of $\tilde{\mathscr{B}}_1$, $\tilde{\mathscr{C}}_1$, H^+ instead of $\tilde{H}^+$; the norm $\| \ \|_1$ is then given by (3.14).

The proof is then an adaptation of the methods of Bensoussan and Lions [9] to the present case to take into account the fact that we use $\mathscr{C}_1$ instead of $\mathscr{C}$.

First note that

$$\|\Phi_1(t)\|_{\mathscr{L}(\mathscr{C}_1; \mathscr{C}_1)} \leqq 1 \tag{3.15}$$

where $\mathscr{L}(\mathscr{C}_1; \mathscr{C}_1)$ is the space of linear continuous operators from $\mathscr{C}_1$ into itself. Indeed we have

$$\begin{aligned} \frac{|\Phi_1(t)(F)(\pi)|}{1 + (\pi, \mathbb{1})} &= \frac{|E\{F(p_{1,\pi}(t))\}|}{1 + (\pi, \mathbb{1})} \\ &\leqq \|F\|_1 \frac{(1 + E(p_{1,\pi}(t), \mathbb{1}))}{1 + (\pi, \mathbb{1})} \\ &= \|F\|_1 \end{aligned}$$

since from (3.2)

$$E(p_{1,\pi}(t), \mathbb{1}) = (\pi, \mathbb{1}). \tag{3.16}$$

Therefore

$$\|\Phi_1(t)(F)\|_1 \leqq \|F\|_1, \tag{3.17}$$

which implies (3.15).

Note also that a solution of (3.10) will satisfy

$$U_1(\pi, t) \leqq \Phi_1(T - t) U_1(\pi, T) + \int_t^T \Phi_1(\lambda - t) C_1(\pi) \, d\lambda \tag{3.18}$$

and due to positivity, we also have

$$\|U_1(t)\|_1 \leqq \|U_1(T)\|_1 + \|C_1\|_1 (T - t) \leqq \bar{\Psi} + \|C_1\| (T - t) \tag{3.19}$$

where $\|C_1\| = \sup_x C_1(x)$.

As it is customary in the study of QVI, we begin with the corresponding obstacle problem:

$$
\begin{aligned}
&U_1, U_2 \in C(0, T; \mathscr{C}_1),\\
&U_1(\cdot, t) \geqq 0,\ U_2(\cdot, t) \geqq 0,\\
&U_1(\pi, T) = U_2(\pi, T) = \Psi(\pi),\\
&U_1(\pi, t) \leqq \Phi_1(s-t) U_1(\pi, s) + \int_t^s \Phi_1(\lambda - t) C_1(\pi)\, d\lambda \qquad (3.20)\\
&U_2(\pi, t) \leqq \Phi_2(s-t) U_2(\pi, s) + \int_t^s \Phi_2(\lambda - t) C_2(\pi)\, d\lambda \quad \forall s \geqq t,\\
&U_1(\pi, t) \leqq K_1(\pi) + \zeta_2(\pi, t)\\
&U_2(\pi, t) \leqq K_2(\pi) + \zeta_1(\pi, t)
\end{aligned}
$$

where we assume that

$$
\begin{aligned}
&\zeta_1, \zeta_2 \in C(0, T; \mathscr{C}_1),\\
&\zeta_1(\pi, t) \geqq 0, \qquad \zeta_2(\pi, t) \geqq 0, \qquad (3.21)\\
&\zeta_1(\pi, T), \zeta_2(\pi, T) \geqq \Psi(\pi).
\end{aligned}
$$

We then have the following.

PROPOSITION 3.1. *For ζ_1, ζ_2 as in* (3.21), *the set of U_1, U_2 satisfying* (3.20) *is not empty and has a maximum element.*

It is clear that for ζ_1, ζ_2 given, the system of inequalities (3.20) can be decoupled and U_1, U_2 can be considered separately. Let us then omit indices momentarily and consider

$$
\begin{aligned}
&U \in C(0, T; \mathscr{C}_1),\\
&U(\cdot, t) \geqq 0,\\
&U(\pi, T) = \Psi(\pi),\\
&U(\pi, t) \leqq \Phi(s-t) U(\pi, s) + \int_t^s \Phi(\lambda - t) C(\pi)\, d\lambda \quad \forall s \geqq t, \qquad (3.22)\\
&U(\pi, t) \leqq \zeta(t)
\end{aligned}
$$

where ζ stands, for instance, for $K_1(\pi) + \zeta_2(\pi, t)$. To prove Proposition 3.1, it suffices to show that (3.22) has a maximum element. This can be done by the penalty method. So we look for U_ε solving

(3.23)

$$
\begin{aligned}
&U_\varepsilon(t) = \Phi(s-t) U_\varepsilon(s) + \int_t^s \Phi(\lambda - t) \left[C(\pi) - \frac{1}{\varepsilon} (U_\varepsilon(\lambda) - \zeta(\lambda))^+ \right] d\lambda \quad \text{for } t \leqq s \leqq T,\\
&U_\varepsilon(T)(\pi) = \Psi(\pi),\\
&U_\varepsilon \in C(0, T; \mathscr{C}_1),\\
&U_\varepsilon(\cdot, t) \geqq 0.
\end{aligned}
$$

We can then assert the following lemma.

LEMMA 3.1. *There is a unique solution of* (3.23).

Proof. Note that (3.23) is equivalent to

$$U_\varepsilon(t)=\Phi(T-t)U_\varepsilon(T)+\int_t^T \Phi(\lambda-t)\left[C(\pi)-\frac{1}{\varepsilon}(U_\varepsilon(\lambda)-\zeta(\lambda))^+\right]d\lambda \tag{3.24}$$

and also to

$$\begin{aligned} U_\varepsilon(t) &= e^{-1/\varepsilon(T-t)}\Phi(T-t)\Psi(\pi)+\int_t^T e^{-1/\varepsilon(\lambda-t)}\Phi(\lambda-t) \\ &\quad\cdot\left[C(\pi)+\frac{1}{\varepsilon}U_\varepsilon(\lambda)-\frac{1}{\varepsilon}(U_\varepsilon(\lambda)-\zeta(\lambda))^+\right]d\lambda. \end{aligned} \tag{3.25}$$

Let us define the transformation T_ε of $C(0, T; \mathscr{C}_1)$ into itself using the right-hand side of (3.25). Then the latter can be written as a fixed-point equation:

$$U_\varepsilon = T_\varepsilon U_\varepsilon. \tag{3.26}$$

Using (3.11) and (3.15), we can show precisely, as in Bensoussan and Lions [9, p. 488], that some power of T_ε is a contraction. Hence the result of the lemma follows.

We then can also prove, as in [9, pp. 489–490], that if $\varepsilon \leqq \varepsilon'$, $\|U_\varepsilon\|_1 \leqq K$, then $0 \leqq U_\varepsilon \leqq U_{\varepsilon'}$. As in [9, pp. 494–495] we then show that as $\varepsilon \downarrow 0$, $U_\varepsilon \downarrow U$, which is the maximum element of (3.22). The convergence takes place in $C(0, T; \mathscr{C}_1)$. This establishes Proposition 3.1.

We can then proceed with the proof of Theorem 3.1.

Proof of Theorem 3.1 (*continuation*). Let us consider the map H mapping $C(0, T; \mathscr{C}_1) \times C(0, T; \mathscr{C}_1)$ into itself defined by

$$H(\zeta_1, \zeta_2) = (U_1, U_2) \tag{3.27}$$

where the right-hand side represents the maximum element of (3.20). Now let

$$\begin{aligned} U_1^0(\pi, t) &= \Phi_1(T-t)\Psi(\pi)+\int_t^T \Phi_1(\lambda-t)C_1(\pi)\,d\lambda, \\ U_2^0(\pi, t) &= \Phi_2(T-t)\Psi(\pi)+\int_t^T \Phi_2(\lambda-t)C_2(\pi)\,d\lambda. \end{aligned} \tag{3.28}$$

Consider $\zeta_i(t)$, $\xi_i(t)$, $i = 1, 2$ such that

$$0 \leqq \zeta_i(t) \leqq \xi_i(t) \leqq U_i^o(t), \qquad i = 1, 2, \tag{3.29}$$

$$\xi_i(t) - \zeta_i(t) \leqq \gamma\xi_i(t), \qquad \gamma \in [0, 1]. \tag{3.30}$$

Then we have

$$0 \leqq H(\xi_1, \xi_2) - H(\zeta_1, \zeta_2) \leqq \gamma(1-\gamma')H(\xi_1, \xi_2), \tag{3.31}$$

where

$$\gamma' \leqq \frac{k_0}{k_0 + \bar{\Psi} + \max(\|C_1\|, \|C_2\|)T}. \tag{3.32}$$

Indeed, setting

$$\kappa = 1 - \gamma(1-\gamma'), \tag{3.33}$$

we have to prove that

$$\kappa H(\xi_1, \xi_2) \leqq H(\zeta_1, \zeta_2). \tag{3.34}$$

Let us set

$$(U_1, U_2) = H(\zeta_1, \zeta_2), \qquad (\tilde{U}_1, \tilde{U}_2) = H(\xi_1, \xi_2). \tag{3.35}$$

We need then to show that

$$\kappa\tilde{U}_1 \leqq U_1, \qquad \kappa\tilde{U}_2 \leqq U_2. \tag{3.36}$$

If we can establish that

$$\begin{aligned} \kappa K_1(\pi) + \kappa\xi_2(\pi, t) &\leqq K_1(\pi) + \zeta_2(\pi, t), \\ \kappa K_2(\pi) + \kappa\xi_1(\pi, t) &\leqq K_2(\pi) + \zeta_1(\pi, t), \end{aligned} \tag{3.37}$$

then (3.36) is implied by the monotonicity properties of variational inequalities. But

$$\xi_2(\pi, t)(1-\gamma) \leqq \zeta_2(\pi, t); \tag{3.38}$$

hence, it is enough to establish that

$$\begin{aligned} \kappa K_1(\pi) + \kappa\xi_2(\pi, t) &\leqq K_1(\pi) + (1-\gamma)\xi_2(\pi, t), \\ \kappa K_2(\pi) + \kappa\xi_1(\pi, t) &\leqq K_2(\pi) + (1-\gamma)\xi_1(\pi, t). \end{aligned} \tag{3.39}$$

The first of (3.39) will be satisfied if

$$[\kappa - (1-\gamma)]\xi_2(\pi, t) \leqq (1-\kappa)K_1(\pi) \tag{3.40}$$

or if

$$\gamma'\xi_2(\pi, t) \leqq (1-\gamma')K_1(\pi). \tag{3.41}$$

But observe that

$$\xi_2(\pi, t) \leqq U_2^0(\pi, t) \leqq (\bar{\Psi} + \|C_2\| T)(\pi, \mathbb{1}).$$

So it is enough to choose γ' so that

$$\gamma'(\bar{\Psi} + \|C_2\| T)(\pi, \mathbb{1}) \leqq (1-\gamma')k_0(\pi, \mathbb{1}) \tag{3.42}$$

where k_0 is the uniform lower bound (2.21), since $K_1(\pi) \geqq k_0(\pi, \mathbb{1})$. This last inequality requires

$$\gamma' \leqq \frac{k_0}{k_0 + \bar{\Psi} + \|C_2\| T}. \tag{3.43}$$

In an identical fashion, the second part of (3.39) will be satisfied if

$$\gamma' \leqq \frac{k_0}{k_0 + \bar{\Psi} + \|C_1\| T}. \tag{3.44}$$

So both parts of (3.39) will be satisfied if we choose γ' according to (3.32). The proof of the theorem then proceeds via the standard iteration

$$(U_1^{n+1}, U_2^{n+1}) = H(U_1^n, U_2^n) \tag{3.45}$$

as in [9, pp. 512–514].

Remark. The extension of this result to the general case $N \neq 2$ is straightforward. The system (3.10) has N functionals $U_1, \cdots, U_N$. Everything in (3.10) is the same except for the last two inequalities, which are replaced by

$$U_i(\pi, t) \leqq \min_{\substack{j \neq i \\ j=1,\cdots,N}} (K_{ij}(\pi) + U_j(\pi, t)), \qquad i = 1, \cdots, N. \tag{3.46}$$

We again introduce the system (3.20), where the last two inequalities are replaced by

$$U_i(\pi, t) \leqq \min_{\substack{j \neq i \\ j=1,\cdots,N}} (K_{ij}(\pi) + \zeta_j(\pi, t)), \qquad i = 1, \cdots, N \tag{3.47}$$

where $\zeta_i \in C(0, T; \mathscr{C}_1)$, and satisfy the remainder of (3.21). We then establish the analogue of Proposition 3.1 by penalization. The analogue of Theorem 3.1 is established by introducing a map H mapping $C(0, T; \mathscr{C}_1)^N$ into itself defined by

$$H(\zeta_1, \zeta_2, \cdots, \zeta_N) = (U_1, U_2, \cdots, U_N)$$

where the right-hand side is the maximum element of the analogue of (3.20).

3.3. Existence of an admissible sensor schedule. Our objective in this section is to show that the maximum element U_1, U_2 of the QVI (3.10) provides the value function for the optimization problem (2.61), (2.66) when assumption (3.11) holds. Furthermore, we want to show how an admissible optimal sensor schedule is determined once the pair U_1, U_2 is known.

We shall prove that

$$U_i(\pi, 0) = \inf_{\substack{u(0)=i \\ p(0)=\pi}} J(u(\cdot)), \quad i = 1, 2 \tag{3.48}$$

where $\pi \in H^+$ satisfies $(\pi, \mathbb{1}) = 1$. An optimal schedule will be constructed as follows. To fix ideas, suppose that $i = 1$. Then define

$$\tau_1^* = \inf_{t \leqq T} \{U_1(p_1(t), t) = K_1(p_1(t)) + U_2(p_1(t), t)\} \tag{3.49}$$

where again $p_i(t)$ is the solution of (3.2). We write

$$p^*(t) = p_1(t), \qquad t \in [0, \tau_1^*]. \tag{3.50}$$

Next we define

$$\tau_2^* = \inf_{\tau_1^* \leqq t \leqq T} \{U_2(p_2(t), t) = K_2(p_2(t)) + U_1(p_2(t), t)\}. \tag{3.51}$$

In (3.51), it must be kept in mind that $p_2(t)$ represents the solution of (3.2) with $j = 2$, starting at τ_1^* with value $p_1(\tau_1^*)$. We then define

$$p^*(t) = p_2(t), \qquad t \in [\tau_1^*, \tau_2^*]. \tag{3.52}$$

Note that, unless $\tau_1^* = T$,

$$\tau_2^* > \tau_1^*; \tag{3.53}$$

otherwise

$$\begin{aligned} U_1(p_1(\tau_1^*), \tau_1^*) &= K_1(p_1(\tau_1^*)) + U_2(p_1(\tau_1^*), \tau_1^*), \\ U_2(p_1(\tau_1^*), \tau_1^*) &= K_2(p_1(\tau_1^*)) + U_1(p_1(\tau_1^*), \tau_1^*), \end{aligned} \tag{3.54}$$

which is impossible since

$$K_1(p_1(\tau_1^*)) > 0, \qquad K_2(p_1(\tau_1^*)) > 0 \quad \text{a.s.} \tag{3.55}$$

Similarly we proceed to construct a sequence of $\tau_1^* < \tau_2^* < \tau_3^* < \cdots$ and the process $p^*(\cdot)$. We can then prove the following.

THEOREM 3.2. *With the same assumptions as in Theorem* 3.1, *and in addition, assuming that* (3.11) *holds, the sequence of stopping times* $\tau_1^*, \tau_2^*, \cdots$ *defines an optimal admissible sensor schedule.*

Proof. Considering (3.10) as a VI with obstacle ζ_2, ζ_1, we can write from the definition of τ_1^*:

$$U_1(\pi, 0) = E\left\{ U_1(p_1(\tau_1^*), \tau_1^*) + \int_0^{\tau_1^*} C_1(p_1(\lambda))\, d\lambda \right\}. \tag{3.56}$$

This can be established by using the penalization (3.23), along lines similar to those of [9, pp. 578-587]. Then

$$\begin{aligned} E\{U_1(p_1(\tau_1^*), \tau_1^*)\} &= E\{U_1(p^*(\tau_1^*)), \tau_1^*\} \\ &= E\{\Psi(p^*(T))\chi_{\tau_1^*=T}\} + E\{U_1(p^*(\tau_1^*), \tau_1^*)\chi_{\tau_1^*<T}\}. \end{aligned}$$

Substituting back in (3.56) and using the definition of τ_1^* in (3.49), we obtain

$$\begin{aligned} U_1(\pi, 0) = E\Bigg\{ &\Psi(p^*(T))\chi_{\tau_1^*=T} + \int_0^{\tau_1^*} C_1(p^*(\lambda))\, d\lambda \\ &+ K_1(p^*(\tau_1^*))\chi_{\tau_1^*<T} + U_2(p^*(\tau_1^*), \tau_1^*)\chi_{\tau_1^*<T} \Bigg\}. \end{aligned} \tag{3.57}$$

Furthermore, again by employing penalization, we can show that

$$E\{U_2(p^*(\tau_1), \tau_1^*)\} = E\{U_2(p_2(\tau_1^*), \tau_1^*)\} = E\left\{ U_2(p_2(\tau_2^*), \tau_2^*) + \int_{\tau_1^*}^{\tau_2^*} C_2(p_2(\lambda))\, d\lambda \right\}. \tag{3.58}$$

This implies

$$E\{U_2(p_2(\tau_1^*), \tau_1^*)\chi_{\tau_1^*<T}\} = E\left\{ U_2(p_2(\tau_2^*), \tau_2^*)\chi_{\tau_1^*<T} + \chi_{\tau_1^*<T} \int_{\tau_1^*}^{\tau_2^*} C_2(p_2(\lambda))\, d\lambda \right\}. \tag{3.59}$$

Next

$$E\{U_2(p_2(\tau_2^*), \tau_2^*)\chi_{\tau_1^*<T}\} = E\{\Psi(p^*(T))\chi_{\tau_1^*<T, \tau_2^*=T}\} + E\{U_2(p^*(\tau_2^*), \tau_2^*)\chi_{\tau_2^*<T}\}.$$

Substituting back in (3.57) and using the definition of τ_2^* in (3.51), we obtain

$$\begin{aligned} U_1(\pi, 0) = E\Bigg\{ &\Psi(p^*(T))\chi_{\tau_2^*=T} + K_1(p^*(\tau_1^*))\chi_{\tau_1^*<T} + K_2(p^*(\tau_2^*))\chi_{\tau_2^*<T} \\ &+ \int_0^{\tau_1^*} C_1(p^*(\lambda))\, d\lambda + \int_{\tau_1^*}^{\tau_2^*} C_2(p^*(\lambda))\, d\lambda + U_1(p^*(\tau_2^*), \tau_2^*)\chi_{\tau_2^*<T} \Bigg\}. \end{aligned} \tag{3.60}$$

Proceeding in a similar fashion and collecting results we can write:

$$\begin{aligned} U_1(\pi, 0) = E\Bigg\{ &\Psi(p^*(T))\chi_{\tau_n^*=T} + \sum_{i=1}^{n} K_i(p^*(\tau_i^*))\chi_{\tau_i^*<T} \\ &+ \sum_{i=0}^{n-1} \chi_{\tau_{i+1}^*<T} \int_{\tau_i^*}^{\tau_{i+1}^*} C_{i+1}(p^*(\lambda))\, d\lambda \Bigg\} \\ &+ U_{n+1}(p^*(\tau_n^*), \tau_n^*)\chi_{\tau_n^*<T} \end{aligned} \tag{3.61}$$

where we use the notation

$$\begin{aligned} K_i &= \begin{cases} K_1 & \text{if } i \text{ is odd,} \\ K_2 & \text{if } i \text{ is even,} \end{cases} \\ C_i &= \begin{cases} C_1 & \text{if } i \text{ is odd,} \\ C_2 & \text{if } i \text{ is even,} \end{cases} \\ U_i &= \begin{cases} U_1 & \text{if } i \text{ is odd,} \\ U_2 & \text{if } i \text{ is even.} \end{cases} \end{aligned} \tag{3.62}$$

However, observe that necessarily $\tau_n^* = T$ for n large enough (random). Otherwise we have $\tau_n^* < T$ for all n, on a set $\Omega_0 \subset \Omega$ of positive probability. But $\tau_n^* \uparrow \tau^* \leqq T$ and

$$(p^*(\tau_i^*), \mathbb{1}) \to (p^*(\tau^*), \mathbb{1}) \tag{3.63}$$

where (since $(\pi, \mathbb{1}) = 1$)

$$(p^*(\tau^*), \mathbb{1}) = 1 + \int_0^{\tau^*} p^* \delta^T dy \tag{3.64}$$

(see (2.66)) and

$$(p^*(\tau^*), \mathbb{1}) = E\{\zeta(\tau^*) \mid \mathscr{F}_{\tau^*}^{y(\cdot, u^*)}\} > 0 \quad \text{a.s.} \tag{3.65}$$

where $\zeta(\cdot)$ is the process introduced by (2.8). Therefore on Ω_0, as $n \to \infty$

$$\sum_{i=1}^{n} K_i(p^*(\tau_i^*)) \chi_{\tau_i^* < T} \to +\infty \tag{3.66}$$

and since Ω_0 has positive probability, as $n \to \infty$

$$E\left\{\sum_{i=1}^{n} K_i(p^*(\tau_i^*)) \chi_{\tau_i^* < T}\right\} \to \infty, \tag{3.67}$$

which contradicts (3.19).

We can thus assert that

$$\chi_{\tau_n^* = T} \to 1 \quad \text{a.s.} \tag{3.68}$$

In particular, it follows that the sequence $\tau_1^*, \tau_2^*, \cdots$, defines an admissible schedule denoted by u^*. The corresponding state solution of (2.66) coincides with p^* and (3.61) implies

$$U_1(\pi, 0) \geqq J(u^*(\cdot)). \tag{3.69}$$

But by standard arguments, we check that

$$U_1(\pi, 0) \leqq J(u(\cdot)) \quad \forall u(\cdot) \in U_{\text{ad}} \tag{3.70}$$

and therefore $u^*(\cdot)$ is indeed optimal.

3.4. The main result. We want now to get rid of (3.11) and consider the original functional Ψ in (3.8). Let us consider the approximation (3.12) Ψ_n of Ψ. To Ψ_n corresponds a system of QVI:

$$\begin{aligned}
&U_1^n, U_2^n \in C(0, T; \tilde{\mathscr{C}}_1),\\
&U_1^n, U_2^n \geqq 0,\\
&U_1^n(\pi, T) = U_2^n(\pi, T) = \Psi_n(\pi),\\
&U_1^n(\pi, t) \leqq \Phi_1(s-t) U_1^n(\pi, s) + \int_t^s \Phi_1(\lambda - t) C_1(\pi)\, d\lambda,\\
&U_2^n(\pi, t) \leqq \Phi_2(s-t) U_2^n(\pi, s) + \int_t^s \Phi_2(\lambda - t) C_2(\pi)\, d\lambda \quad \forall s \geqq t\\
&U_1^n(\pi, t) \leqq K_1(\pi) + U_2^n(\pi, t),\\
&U_2^n(\pi, t) \leqq K_2(\pi) + U_1^n(\pi, t).
\end{aligned} \tag{3.71}$$

From Theorem 3.2, we can assert that

$$U_i^n(\pi, 0) = \inf_{\substack{u(0)=i \\ p(0)=\pi}} J^n(u(\cdot)), \qquad i = 1, 2 \tag{3.72}$$

where

$$J^n(u(\cdot)) = E\left\{\Psi^n(p(u(\cdot), T)) + \int_0^T (p(u(\cdot), t), C(u(t)))\, dt + \sum_{i=1}^{\infty} \chi_{\tau_i < T}(p(u(\cdot), \tau_i), K(u_{i-1}, u_i))\right\}. \tag{3.73}$$

Therefore we deduce that

$$J^n(u(\cdot)) - J(u(\cdot)) = E\{\Psi_n(p(u(\cdot), T)) - \Psi(p(u(\cdot), T))\} \tag{3.74}$$

and from (3.12) we deduce

$$\begin{aligned} |J^n(u(\cdot)) - J(u(\cdot))| \leqq{}& E\left\{\int \frac{p(u(\cdot), T)\|x\|^4}{n + \|x\|^2}\, dx\right\} \\ &+ E\left\{\left(\int p(u(\cdot), T)x\left(1 - \frac{1}{(1 + \|x\|^2/n)^{1/2}}\right) dx\right)^T \right. \\ &\cdot \left(\int p(u(\cdot), T)x\left(1 + \frac{1}{(1 + \|x\|^2/n)^{1/2}}\right) dx\right) \\ &\left. \cdot \frac{1}{\int p(u(\cdot), T)\, dx}\right\}. \end{aligned} \tag{3.75}$$

But using (2.50) yields (see (2.1a))

$$\begin{aligned} &E\left\{\int \frac{p(u(\cdot), t)\|x\|^4}{n + \|x\|^2}\, dx\right\} \\ &= E\left\{\int_0^t \int p(u(\cdot), s)(x)\left\{\frac{\partial a_{ij}}{\partial x_i} \frac{2\|x\|^2(2n + \|x\|^2)x_j}{(n + |x|^2)^2}\right.\right. \\ &\qquad + a_{ij}\left(\delta_{ij}\frac{2\|x\|^2(2n + \|x\|^2)}{(n + \|x\|^2)^2} + \frac{8x_i x_j n^2}{(n + \|x\|^2)^3}\right) \\ &\qquad \left.\left. - a_i \frac{2\|x\|^2(2n + \|x\|^2)x_i}{(n + \|x\|^2)^2}\right\} ds + \int \frac{\pi(x)\|x\|^4}{n + \|x\|^2}\, dx\right\} \end{aligned}$$

where we employ the summation convention over repeated indices. Hence after majorizing conveniently, we have

$$\begin{aligned} &E\left\{\int \frac{p(u(\cdot), t)(x)\|x\|^4}{n + \|x\|^2}\, dx\right\} \\ &\leqq \int \frac{\pi(x)\|x\|^4}{n + \|x\|^2}\, dx + \Gamma \int_0^t E\left\{\int \frac{p(u(\cdot), s)(x)\|x\|^4}{n + \|x\|^2}\, dx\right\} ds + \frac{\Gamma t}{n}. \end{aligned} \tag{3.76}$$

We shall use capital Greek letters, $\Gamma, \Delta, \cdots$, to indicate constants in the following estimates. Finally we deduce that

$$E\left\{\int \frac{p(u(\cdot),t)(x)\|x\|^4}{n+\|x\|^2}\,dx\right\} \leqq \Gamma_t\left[\int \frac{\pi(x)\|x\|^4}{n+\|x\|^2}\,dx+\frac{1}{n}\right] \leqq \Gamma_t\left[\frac{1}{n}\int \pi(x)\|x\|^4\,dx+\frac{1}{n}\right]. \tag{3.77}$$

Next consider

$$\frac{p(u(\cdot),t)}{(p(u(\cdot),t),\mathbb{1})} = \sigma(u(\cdot),t),$$

which is the normalized conditional probability measure and satisfies Kushner's equation

$$d(\sigma(t)(\varphi)) = \sigma(t)(L\varphi)\,dt + (\sigma(t)(\tilde{h}\varphi) - \sigma(t)(\varphi)\sigma(t)(\tilde{h}))\cdot(dz - \sigma(t)(\tilde{h})\,dt). \tag{3.78}$$

If we apply (3.78) with $\varphi = \|x\|^2 = \chi^2$, we obtain

$$\begin{aligned} dE\{\sigma(t)(\chi^2)\} &= E\{\sigma(t)(L\chi^2) - \sigma(t)(\tilde{h})[\sigma(t)(\tilde{h}\chi^2) - \sigma(t)(\chi^2)\sigma(t)(\tilde{h})]\}\,dt \\ &\leqq \Delta_0(1+E\{\sigma(t)(\chi^2)\})\,dt. \end{aligned} \tag{3.79}$$

Finally,

$$E\{\sigma(t)(\chi^2)\} \leqq \Delta_t \int \pi(x)\|x\|^2\,dx.$$

But the second term in (3.75) is

$$\begin{aligned} &E\left\{\sigma(T)\left(\chi\left(1+\frac{1}{(1+\chi^2/n)^{1/2}}\right)\right)^T (p(T))\left(\chi\left(1-\frac{1}{(1+\chi^2/n)^{1/2}}\right)\right)\right\} \\ &\quad\leqq \left[E\left\{\left\|\sigma(T)\left(\chi\left(1+\frac{1}{(1+\chi^2/n)^{1/2}}\right)\right)\right\|^2\right\}\right]^{1/2} \\ &\qquad\cdot\left[E\left\{\left\|p(T)\left(\chi\left(1-\frac{1}{(1+\chi^2/n)^{1/2}}\right)\right)\right\|^2\right\}\right]^{1/2} \\ &\quad\leqq \Delta^1(E\{\sigma(T)(\chi^2)\})^{1/2}\left(E\left\{\left\|p(T)\left(\chi\left(1-\frac{1}{(1+\chi^2/n)^{1/2}}\right)\right)\right\|^2\right\}\right)^{1/2} \\ &\quad\leqq \Delta^2\left[E\left\{\left\|p(T)\left(\chi\left(1-\frac{1}{(1+\chi^2/n)^{1/2}}\right)\right)\right\|^2\right\}\right]^{1/2} \\ &\quad= \Delta^3\left[E\left\{\sum_i\left(p(T)\left(\chi_i\left(1-\frac{1}{(1+\chi^2/n)^{1/2}}\right)\right)\right)^2\right\}\right]^{1/2} \\ &\quad\leqq \Delta^3\left[E\left\{p(T)(\chi^2)p(T)\left(\frac{\chi^2}{n+\chi^2}\right)\right\}\right]^{1/2}. \end{aligned} \tag{3.81}$$

We easily check that

$$E\{(p(T)(\chi^2))^2\} \leqq \Delta^4 + \left(\int \pi(x)\|x\|^2\,dx\right)^2 \leqq \Delta^5,$$

$$\begin{aligned} dE\left\{\left|p(t)\left(\frac{\chi^2}{n+\chi^2}\right)\right|^2\right\} &\leqq 2E\left\{p(t)\left(L\frac{\chi^2}{n+\chi^2}\right)p(t)\left(\frac{\chi^2}{n+\chi^2}\right)\right\}dt \\ &\quad+\Delta^5 E\left\{\left|p(t)\left(\frac{\chi^2}{n+\chi^2}\right)\right|^2\right\}dt. \end{aligned}$$

But

$$L\frac{\chi^2}{n+\chi^2}\leqq\frac{\Delta^6}{\sqrt{n}}; \tag{3.82}$$

hence

$$dE\left\{\left|p(t)\left(\frac{\chi^2}{n+\chi^2}\right)\right|^2\right\}\leqq\left[\Delta^5 E\left\{\left|p(t)\left(\frac{\chi^2}{n+\chi^2}\right)\right|^2\right\}+\frac{\Delta^7}{n}\right]dt, \tag{3.83}$$

which implies

$$\begin{aligned} E\left\{\left|p(t)\left(\frac{\chi^2}{n+\chi^2}\right)\right|\right\}&\leqq\Theta_t\left[\frac{1}{n}+\left(\int\frac{\pi(x)\|x\|^2\,dx}{n+\|x\|^2}\right)^2\right]\\ &\leqq\frac{\Theta_t}{n}\left(1+\int\pi(x)\|x\|^4\,dx\right). \end{aligned} \tag{3.84}$$

Therefore, continuing from (3.81), the second term in (3.75) is majorized by $\Gamma_0/n^{1/4}$. Collecting results (from (3.75), (3.77), (3.81), (3.84)), we can assert that

$$|J^n(u(\cdot))-J(u(\cdot))|\leqq\frac{\Delta}{n^{1/4}} \tag{3.85}$$

provided the initial distribution of $p(0)$, i.e., π satisfies

$$\int\pi(x)\|x\|^4\,dx<\infty. \tag{3.86}$$

The estimate in (3.85) is uniform with respect to n. Therefore

$$\left|U_i^n(\pi,0)-\inf_{u(0)=i,p(0)=\pi}J(u(\cdot))\right|\leqq\frac{\Delta}{n^{1/4}}. \tag{3.87}$$

In fact we can replace zero by any $t\in[0,T]$ and consider the function

$$U_i(\pi,t)=\inf_{u(t)=i,p(t)=\pi}J_t(u(\cdot)) \tag{3.88}$$

where $J_t(u(\cdot))$ corresponds to a problem analogous to (2.50), (2.61) starting in t instead of zero. Therefore we have

$$|U_i^n(\pi,t)-U_i(\pi,t)|\leqq\frac{\Delta}{n^{1/4}}. \tag{3.89}$$

However we must be careful of the fact that the constant in (3.89) depends on a bound on $\int\pi(x)\|x\|^4\,dx$. More precisely, we have proved that

$$U_i^n(\pi,t)-U_i(\pi,t)|\leqq\frac{\Delta'}{n^{1/4}}\left(1+\int\pi(x)\|x\|^4\,dx\right) \tag{3.90}$$

where Δ' here does not depend on π (assuming that π is a probability). It follows that

$$U_i^n(\pi,t)\to U_i(\pi,t)\quad\text{in } C(0,T;\mathscr{C}_1). \tag{3.91}$$

Taking the limit in (3.71), we obtain that U_1, U_2 is a solution of (3.10), and moreover

$$U_i(\pi,0)=\inf_{\substack{u(0)=i\\p(0)=\pi}}J(u(\cdot)). \tag{3.92}$$

However, by a probabilistic argument already used in § 3.3, any solution of (3.10) is smaller than the right-hand side of (3.92). This completes the proof of Theorem 3.1, and also provides the same statement as in Theorem 3.2, without assumption (3.11) and for our original Ψ given by (3.8).

FREQUENCY-SCALE DECOMPOSITION OF H^∞-DISK PROBLEMS*

D. WILLIAM LUSE† AND JOSEPH A. BALL‡

Abstract. Time- and frequency-scale decomposition methods have been used extensively for the simplification of automatic control problems. This paper considers the problem of parametrizing all functions in a specified H^∞-function disk over the unit ball in H^∞. This problem arises in the design of stabilizing feedback compensators to minimize a weighted sensitivity matrix in the H^∞-norm sense. It is shown that an H^∞-disk problem, whose data has two-frequency-scale behavior, can be broken down into slow and fast subproblems. If solutions can be found for both subproblems, then the solutions can be combined to give an approximate solution for the original problem.

Key words. singular perturbation, optimal control, factorization theory, Beurling–Lax Theorem

1. Introduction.

Frequency-domain plots have been used for many years to represent control system specifications and to aid in the design of feedback compensators. The use of such plots has proved very useful for scalar systems. For multivariable systems, frequency-domain plots still have a strong physical interpretation [1]; but compensator design based on them seems to require a great deal of experience on the part of the designer. Thus, there is a pressing need to automate frequency-domain system design. As pointed out in [2], the constraints diagrammed in frequency-domain plots can usually be translated mathematically into "function disk" inclusions, in which the "disks" are described in terms of H^∞ and L^∞ norms. The development of [2] further notes the existence of a well-developed mathematical theory for treating problems of this type. We now consider the problem (e.g., [3]) of choosing a stabilizing compensator that minimizes the weighted sensitivity of a feedback loop with respect to open-loop plant perturbations. The minimization is to be done in the H^∞ sense. The following notation will be used. $\mathbb{C}$ will denote the complex numbers and $\mathbb{C}^+$ will denote the open half-plane $\operatorname{Re}(s) > 0$. $\mathbb{R}$ will denote the real numbers. H^∞ and H^2 are as defined in [4] and [2]. The notations S and $M(\cdot)$ are borrowed from [3]. S is the ring of proper, stable (bounded on C^+), real rational functions of the complex variable s. We can give S a norm by imbedding it in H^∞. In other words, S is "real rational H^∞." $M(\cdot)$ is shorthand notation for the set of all matrices whose elements lie in some set. Thus, $M(S)$ stands for the set of all rational, proper, stable transfer matrices. When the $M(\cdot)$ notation is used, it is assumed that the sizes of the matrices can be determined by context. Borrowing standard notation from algebra, the field of real rational functions of s is $\mathbb{R}(s)$. The sensitivity minimization problem [3] can now be formulated. Referring to Fig. 1.1, we assume that $Q(s) \in M(\mathbb{R}(s))$ is given and that we wish to find $C(s) \in M(\mathbb{R}(s))$ such that the sensitivity $S(s)$ given by (1.1) is a minimum, and the (four-block) closed-loop transfer matrix of Fig. 1.1 is an element of $M(S)$. We assume in this paper that Q is square:

$$S(s) = (I + Q(s)C(s))^{-1}. \tag{1.1}$$

The sense of the minimum is the weighted H^∞ norm sense. Thus, the problem is to

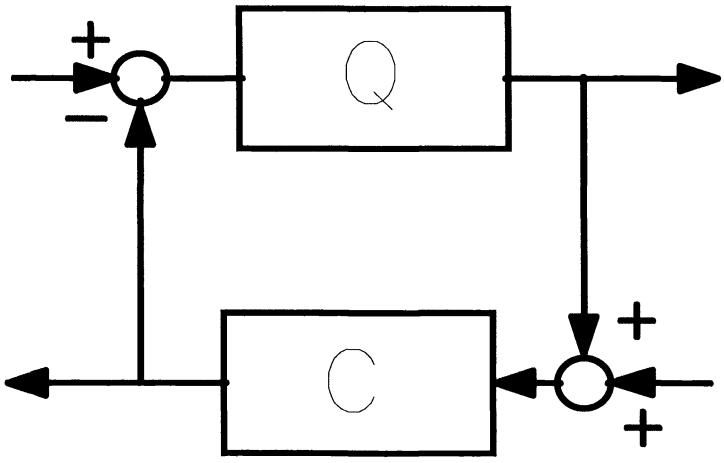

FIG. 1.1

find a compensator $C(s)$ that leaves the closed-loop system of Fig. 1.1 stable and makes the quantity $\rho(C)$ given in (1.2) a minimum:

$$\begin{aligned}\rho(C) &= \sup_{\mathrm{Re}\,(s)>0} \bar{\sigma}(W_1(s)S(s)W_2(s)) \\ &= \sup_{\omega \in R} \bar{\sigma}(W_1(j\omega)S(j\omega)W_2(j\omega)) \\ &= \|W_1 S W_2\|_\infty .\end{aligned} \tag{1.2}$$

We assume that W_1 and W_2 are rational matrix functions such that $W_j \in M(S)$ and $W_j^{-1} \in M(S)$ for $j = 1, 2$.

It is a matter of controversy whether this problem is actually one that control engineers want to solve. In general, the optimal compensator is not physically realizable. Sometimes a sequence of compensators can be found for which the quantity (1.2) converges to the optimal value. This is not true, however, in the case of a strictly proper, stable, scalar plant. In this case, the optimal value of (1.2) is zero, while the minimum realizable value of (1.2) is at least $\|W_1(\infty)W_2(\infty)\|$. This follows because $C(\infty) = 0$ for any realizable compensator. In general, the optimal value of (1.2) can be attained by using a physically realizable compensator only when $Q(s)$ has no poles or zeros on the extended imaginary axis. In [5] it is demonstrated that control engineers often want to make tradeoffs between several quantities similar to (1.2). There are often several function disks within which the control system designer wants various system transfer matrices to lie. Unfortunately, there is no known solution to such "multidisk" problems. Thus, the sensitivity minimization problem described here can be viewed either as an intermediate step toward further research or as a design tool that may aid in evaluating candidate system designs.

The sensitivity minimization problem as stated above has been solved in a number of different ways. In this paper, we use the approach of [6]. The first step toward solution is to rewrite the sensitivity minimization problem as a matrix interpolation problem. Let Q be expressed as left- and right-coprime matrix fractions over $M(S)$ as shown in (1.3) [3]:

$$Q = ND^{-1} = \tilde{D}^{-1}\tilde{N}, \tag{1.3}$$

$$XN + YD = I, \tag{1.4a}$$

$$\tilde{N}\tilde{X} + \tilde{D}\tilde{Y} = I. \tag{1.4b}$$

Let $X, Y, \tilde{X}, \tilde{Y} \in M(S)$ be such that the Bezout equations (1.4) hold. Then any stabilizing compensator can be expressed as

$$C = (Y - R\tilde{N})^{-1}(X + R\tilde{D}) \tag{1.5}$$

where $R \in M(S)$. Equation (1.5) is one of two equivalent parametrizations given on page 108 of [3]. It is customary to require that $\det(Y - R\tilde{N}) \neq 0$ in (1.5). It should be noted, however, that such "infinite" compensators are only some of the many unrealizable compensators that can be produced by inserting various values of R into the parametrization (1.5). A parametrization of all "possible sensitivities" that result from a stabilizing compensator can be produced by substituting (1.5) and (1.3) into (1.1) [3]. The result of this is that every "possible sensitivity" can be expressed as

$$S = \tilde{Y}\tilde{D} - NR\tilde{D}. \tag{1.6}$$

Every "possible weighted sensitivity" can now be expressed as

$$W_1 S W_2 = W_1 \tilde{Y}\tilde{D} W_2 - W_1 NR\tilde{D} W_2$$

where $R \in M(S)$. The sensitivity minimization problem has now been reduced to

$$\min_{R \in M(S)} \| W_1 \tilde{Y}\tilde{D} W_2 - W_1 NR\tilde{D} W_2 \|_\infty. \tag{1.7}$$

It is generally agreed that the minimization problem (1.7) should be considered solved if the suboptimal problem (1.8) is solved. Clearly, this could be done by repeating the solution of (1.8) for a sequence of values of ρ:

$$\text{Characterize } \{R \in M(S): \| W_1 \tilde{Y}\tilde{D} W_2 - W_1 NR\tilde{D} W_2 \|_\infty \leqq \rho\}. \tag{1.8}$$

It should also be noted that the solution to (1.8) is likely to be more useful than the solution to (1.7), since it may be used to allow "breathing room" on the sensitivity so that other constraints may be added.

Using (1.8) as a starting point, it can be shown that all "possible sensitivities" (1.6) that satisfy

$$\| W_1 S W_2 \|_\infty \leqq \rho$$

can be parametrized according to (1.9) using methods described in [20]:

$$S = [\theta_{11} G + \theta_{12}][\theta_{21} G + \theta_{22}]^{-1} \tag{1.9}$$

where $\|G\|_\infty \leqq 1$. This characterizes the set (1.8), in principle, because (1.6) can be backsolved for R. The corresponding compensator can then be computed from (1.5), or (1.1) can be backsolved for $C(s)$.

The idea of a two-frequency-scale rational matrix was introduced in [7]. Two-frequency-scale matrices are parameter-dependent rational matrices whose behavior becomes increasingly separated into high- and low-frequency categories as the parameter approaches a certain specified critical value. In this paper, the perturbation parameter is ε and the critical value is zero. A number of results concerning two- and multiple-frequency scale matrices are given in [7] and [8].

The objective of this paper is to show that if the data (Q, W_1, and W_2) of the sensitivity minimization problem all have two-frequency-scale behavior and satisfy certain regularity conditions, then approximate solutions can be generated by solving

two similar reduced-order subproblems. It is then shown, with considerably more difficulty, that the matrices θ_{ij} of (1.9) are two-frequency-scale if the data for the problem is two-frequency-scale.

The remainder of this paper is organized as follows. Section 2 gives background on two-frequency-scale systems and on the solution of (1.8). The background developed in § 2 is applied to give the main results of the paper in § 3.

2. Background.

2.1. Two-frequency-scale matrices. Consider a transfer matrix $H(s, \varepsilon)$ that is rational in s with coefficients that depend analytically on the parameter ε. In this paper, ε is assumed at all times to be a nonnegative real variable. The general behavior of such a transfer matrix is very complicated. The concept of a two-frequency-scale rational matrix narrows down the many possible types of behavior to a degree that allows many nontrivial results to be proved. The following three statements give an intuitive description of the two-frequency-scale property.

(1) All coefficients are real analytic in ε at $\varepsilon = 0$.

(2) The poles fall into two classes. Those in one class approach finite values as ε approaches zero. Those in the other class go to infinity as $K(\varepsilon)/\varepsilon$, where K approaches a nonzero constant as $\varepsilon \to 0$. K may have an algebraic singularity at $\varepsilon = 0$. Thus, the poles fall into two frequency scales—the low or "slow" frequency scale s and the high or "fast" frequency scale $p = \varepsilon s$. The slow poles approach finite limits in the s frequency scale as $\varepsilon \to 0$. The remaining fast poles approach finite, nonzero limits in the p frequency scale as $\varepsilon \to 0$. Thus, the polynomial $\varepsilon s^2 + 1$ is not allowable as a pole polynomial because the poles $\pm j/\sqrt{\varepsilon}$ neither go to finite values as $\varepsilon \to 0$, nor can they be expressed as $K(\varepsilon)/\varepsilon$, where $K(\varepsilon)$ has the required properties. An attempt gives $K(\varepsilon) = \pm j\sqrt{\varepsilon}$, which goes to zero as $\varepsilon \to 0$. An example of an allowable pole polynomial is $\varepsilon s + 1$. In this case, $K(\varepsilon) = -1$.

(3) Two-frequency-scale matrices must be rational and proper for all sufficiently small fixed values of ε. Furthermore, they must behave as rational, proper matrices in an asymptotic way in each frequency range. Thus, they behave as dynamical systems for all sufficiently small ε, and in the limit as $\varepsilon \to 0$ in each frequency range.

The preceding verbal descriptions of the two-frequency-scale matrices will now be made mathematically precise. We first let R_ε denote the ring of germs [9] of real-valued functions analytic in the real variable ε at $\varepsilon = 0$, and let F_ε be the field of quotients of R_ε. A rigorous definition of two-frequency-scale rational matrices can now be given.

DEFINITION 2.1. A matrix-valued function $H(s, \varepsilon)$ is two-frequency-scale if:

(1) $H(s, \varepsilon) \in F_\varepsilon(s)$; $H(s, \varepsilon)$ is proper in s.

(2) $H(s, 0) \in \mathbb{R}(s)$; $H(s, 0)$ is proper:

$$H\left(\frac{p}{\varepsilon}, \varepsilon\right)\Big|_{\varepsilon=0} \in \mathbb{R}(p), \qquad H\left(\frac{p}{\varepsilon}, \varepsilon\right)\Big|_{\varepsilon=0} \text{ is proper.}$$

(3) Each pole s_j of $H(s, \varepsilon)$ can be expanded in one of the following two ways:

$$\text{(2.1)} \quad \text{(A)} \qquad s_j(\varepsilon) = \sum_{i=0}^{\infty} a_{ji}\varepsilon^{i/q};$$

$$\text{(2.2)} \quad \text{(B)} \qquad s_j(\varepsilon) = \frac{1}{\varepsilon}\sum_{i=0}^{\infty} b_{ji}\varepsilon^{i/q}, \qquad b_{j0} \neq 0;$$

q is a positive integer that may depend on j.

It should be noted that part (B) of condition (3) above rules out denominators such as $\varepsilon^2 s+1$ and εs^2+1. Poles are forced to be "exactly" $O(1)$ or $O(1/\varepsilon)$ as $\varepsilon \to 0$. The positive integer q takes on nonunity values for denominators such as $s^2+\varepsilon=0$. The matrices computed in part (2) of Definition 2.1 are, for some purposes, approximations of the matrix $H(s, \varepsilon)$ for low and high frequency. These approximations are given a special notation for convenience in the following definition.

DEFINITION 2.2. Let $H(s, \varepsilon)$ be a two-frequency-scale rational matrix. Then the matrices H_S and H_F over $\mathbb{R}(s)$ and $\mathbb{R}(p)$, respectively, are given by

$$H_S(s) = H(s, 0), \tag{2.3}$$

$$H_F(p) = H\left(\frac{p}{\varepsilon}, \varepsilon\right)\Big|_{\varepsilon=0}. \tag{2.4}$$

Several senses in which H_S and H_F are approximations of H are made precise in [7] and [8].

The following theorem connects the frequency-domain concept of a two-frequency-scale rational matrix with the state-space idea of a singularly perturbed system, for which there is an extensive literature.

THEOREM 2.1. *A matrix $H(s, \varepsilon)$ is two-frequency-scale if and only if there exists a minimal realization of the form* (2.5) *for $H(s, \varepsilon)$ in which the matrices C_i, A_{ij}, B_j, and D are in $M(R_\varepsilon)$; and* $\det A_{22}(0) \neq 0$:

$$\dot{x}_1 = A_{11}x_1 + A_{12}x_2 + B_1 u, \tag{2.5a}$$

$$\dot{x}_2 = \frac{1}{\varepsilon} A_{21}x_1 + \frac{1}{\varepsilon} A_{22}x_2 + \frac{1}{\varepsilon} B_2 u, \tag{2.5b}$$

$$y = C_1 x_1 + C_2 x_2 + Du. \tag{2.5c}$$

Proof. For the proof see [10]. □

In words, Theorem 2.1 says that a matrix $H(s, \varepsilon)$ is two-frequency-scale if and only if it has a minimal analytic realization as a singularly perturbed system of differential equations. Showing that (2.5) has a two-frequency-scale transfer matrix is a straightforward computation involving system matrices [11]. Showing the converse requires a theorem for the realization of systems over rings [12]. It should be noted that "minimal" here means roughly "minimal for almost all sufficiently small ε."

It is clear that regularly perturbed systems, that is, systems of the form (2.5) with the dimension of x_2 equal to zero, form a subset of the singularly perturbed systems. Thus, any behavior that can occur in regularly perturbed systems is possible also for singularly perturbed systems. It is well known that a system depending on a single parameter that is completely controllable and observable for almost all values of the parameter may lose controllability and/or observability at discrete parameter values. In other words, the order of a minimal realization is a discontinuous function of the parameter in general. It turns out that a singularly perturbed system of form (2.5) can have poles that become asymptotically uncontrollable and/or unobservable as $\varepsilon \to 0$ in either or both of its frequency ranges. From the frequency-domain viewpoint, a two-frequency-scale rational matrix may have poles that do not appear in either $H_S(s)$ or $H_F(p)$. The concept of "lost poles," referring to poles that are "lost" in the limiting process as $\varepsilon \to 0$, is introduced to deal with this on a systematic basis. Lost poles are defined in [7] through the use of parameter-dependent system matrices. They are defined here, in an equivalent way, using state-space ideas. We first note that if the rational matrix $H(s, \varepsilon)$ has minimal realization (2.5), then the slow and fast descriptions

(2.3) and (2.4) can be expressed in terms of the blocks of (2.5) as follows:

$$H_S(s) = C_S(sI - A_S)^{-1}B_S + D_S, \tag{2.6}$$

$$H_F(p) = C_F(pI - A_F)^{-1}B_F + D_F \tag{2.7}$$

where

$$C_S = C_1 - C_2A_{22}^{-1}A_{21}|_{\varepsilon=0}, \tag{2.8a}$$

$$A_S = A_{11} - A_{12}A_{22}^{-1}A_{21}|_{\varepsilon=0}, \tag{2.8b}$$

$$B_S = B_1 - A_{12}A_{22}^{-1}B_2|_{\varepsilon=0}, \tag{2.8c}$$

$$D_S = D - C_2A_{22}^{-1}B_2|_{\varepsilon=0}, \tag{2.8d}$$

$$C_F = C_2(0), \tag{2.8e}$$

$$A_F = A_{22}(0), \tag{2.8f}$$

$$B_F = B_2(0), \tag{2.8g}$$

$$D_F = D(0). \tag{2.8h}$$

The subsystems (C_S, A_S, B_S, D_S) and (C_F, A_F, B_F, D_F) appear frequently in the time-domain singular perturbation literature (e.g., [13], [18]). Noting from the above discussion that the above-mentioned subsystems are not necessarily minimal, we can now define lost poles.

DEFINITION 2.3. Let $H(s, \varepsilon)$ be a two-frequency-scale rational matrix. Let (2.5) be a minimal-order realization whose existence is guaranteed by Theorem 2.1, and let C_S, A_S, B_S, and D_S be defined by (2.8). Then the lost slow poles of $H(s, \varepsilon)$ are those poles of the system (C_S, A_S, B_S, D_S) that are uncontrollable or unobservable. Similarly, the lost fast poles of $H(s, \varepsilon)$ are those poles of the system (C_F, A_F, B_F, D_F) that are uncontrollable or unobservable.

To apply coprime factorization theory to two-frequency-scale transfer matrices, an analogue of the set S is needed. The following definition of stable two-frequency-scale rational matrices is borrowed from [14].

DEFINITION 2.4. S_ε is the set of two-frequency-scale rational matrices whose poles satisfy the following condition. Slow poles (those that satisfy (2.1)) have Re $a_{j0} < 0$; fast poles (those that satisfy (2.2)) have Re $b_{j0} < 0$.

By Lemma 2.3 of [14], Definition 2.4 could also be stated as follows: a two-frequency-scale rational matrix $H(s, \varepsilon)$ is in S_ε if $H_S(s)$ and $H_F(p)$ are both stable and $H(s, \varepsilon)$ has no unstable lost poles. A portion of a theorem from [14] will now be extracted and paraphrased.

THEOREM 2.2. *Let $H(s, \varepsilon)$ be a two-frequency-scale rational matrix with no unstable lost poles. Then $H(s, \varepsilon)$ has right- and left-coprime factorizations over $M(S_\varepsilon)$ as follows*:

$$\begin{aligned} H(s, \varepsilon) &= N(s, \varepsilon)D(s, \varepsilon)^{-1} \\ &= \tilde{D}(s, \varepsilon)^{-1}\tilde{N}(s, \varepsilon). \end{aligned}$$

Furthermore, there exist X, Y, $\tilde{X}$, and $\tilde{Y}$ in $M(S_\varepsilon)$ such that

$$X(s, \varepsilon)N(s, \varepsilon) + Y(s, \varepsilon)D(s, \varepsilon) = I, \qquad \tilde{N}(s, \varepsilon)\tilde{X}(s, \varepsilon) + \tilde{D}(s, \varepsilon)\tilde{Y}(s, \varepsilon) = I.$$

Proof. For the proof see [14]. □

The proof of Theorem 2.2 is not obvious because the ring S_ε is not a Bezout domain. The proof in [14] is done through state-space methods. The results on

parametetrization of all stabilizing compensators described in § 1 now apply to two-frequency-scale rational matrices. It should be noted that "stable" means "in $M(S_\varepsilon)$" as pointed out in [14]. All allowable sensitivities can be generated by inserting any R in $M(S_\varepsilon)$ into (1.6). It should also be noted that the corresponding compensator need not be two-frequency-scale even if it is not infinite. This is not surprising in view of the remark following (1.5).

The theory of two-frequency-scale matrices described in this section is based on taking R_ε as the real germs at $\varepsilon = 0$. This leads to the matrices H_S and H_F having real coefficients. Although the results of [7], [8] were developed for complex germs, a nearly identical theory results if only real germs are considered.

The following result on block diagonalization of (2.5) is also needed [15].

THEOREM 2.3. *There exists a similarity transformation $T(\varepsilon) \in M(R_\varepsilon)$ that transforms system* (2.5) *into block-diagonal form as follows*:

$$T(\varepsilon)\begin{bmatrix} A_{11}(\varepsilon) & A_{21}(\varepsilon) \\ \frac{1}{\varepsilon}A_{21}(\varepsilon) & \frac{1}{\varepsilon}A_{22}(\varepsilon) \end{bmatrix} T(\varepsilon)^{-1} = A_D(\varepsilon)$$

$$= \begin{bmatrix} A_S + 0(\varepsilon) & 0 \\ 0 & \frac{1}{\varepsilon}A_F + 0(1) \end{bmatrix}$$

$$= \begin{bmatrix} A_1(\varepsilon) & 0 \\ 0 & \frac{1}{\varepsilon}A_2(\varepsilon) \end{bmatrix}.$$

Furthermore, $T(\varepsilon)$ and $T(\varepsilon)^{-1}$ have the following forms:

$$T(\varepsilon) = \begin{bmatrix} I + O(\varepsilon) & -\varepsilon A_{12}(0)A_F^{-1} + O(\varepsilon^2) \\ A_F^{-1}A_{21}(0) + O(\varepsilon) & I + O(\varepsilon) \end{bmatrix},$$

$$T(\varepsilon)^{-1} = \begin{bmatrix} I + O(\varepsilon) & \varepsilon A_{12}(0)A_F^{-1} + O(\varepsilon^2) \\ -A_F^{-1}A_{21}(0) + O(\varepsilon) & I + O(\varepsilon) \end{bmatrix}.$$

This theorem is the main tool of a number of papers on time-domain singular perturbation theory.

2.2. Solution of the function-disk problem. The state-space approach of [16] will be used to solve problem (1.8). A fairly algorithmic treatment will be discussed here since a theoretical discussion would be too lengthy to include. Let it suffice to mention that the approach, for the case $W_1 = W_2 = I$, involves looking at the graph space of the operator $S(s)$, treated as a mapping from $\tilde{D}^{-1}H_m^2$ to H_m^2, in a Krein space (indefinite inner product space) setting. The connection with (1.8) is that if ρ is normalized to 1, we require that the quantity within the norm symbol be a contraction mapping. A relationship between the graph spaces of contraction mappings and negative subspaces of the Krein space is then exploited.

A blanket assumption is that $Q(s)$ has no poles or zeros on the imaginary axis. This will guarantee that the process about to be described leads to a well-defined solution. If pure-imaginary poles or zeros of the plant are present, the algorithm will try to cancel them with pure-imaginary compensator zeros and poles.

We further assume that $Q(s)$ is square. Although the approach of [6] works in general, the state-space formulas of [16] are currently available only for the case when

$Q(s)$ is square and nonsingular at ∞. The first step is to form the matrices L, J', and J as follows:

$$L=\begin{bmatrix} W_1\tilde{Y} & W_1N \\ W_2^{-1}\tilde{D}^{-1} & 0 \end{bmatrix}, \quad J'=\begin{bmatrix} I & 0 \\ 0 & -\rho^2 I \end{bmatrix}, \quad J=\begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix} \tag{2.9}$$

where the matrices N, $\tilde{D}$, and $\tilde{Y}$ are as discussed in § 1. We now compute $\Theta(s)$ such that

$$L(s)=\Theta(s)F(s), \tag{2.10}$$ (1)

$$\Theta(-s)^*J'\Theta(s)=J, \tag{2.11}$$ (2)

F and F^{-1} are in $M(S)$. (2.12) (3)

Such a Θ, if it exists, is unique up to a J unitary constant right factor. If such a Θ can be found and the set (1.8) is nonvacuous, then all rational allowable sensitivities can be parametrized as

$$S(s)=[\theta_{11}(s)G(s)+\theta_{12}(s)][\theta_{21}(s)G(s)+\theta_{22}(s)]^{-1} \tag{2.13}$$

where $G(s)\in M(S)$ with $\|G\|_\infty \leqq 1$ and Θ is subdivided as

$$\Theta=\begin{bmatrix} \theta_{11} & \theta_{12} \\ \theta_{21} & \theta_{22} \end{bmatrix}. \tag{2.14}$$

Thus, problem (1.8) has been converted to a J-inner-outer factorization problem.

The J-inner-outer factorization problem described above is solved in [16], with the unit disk as the domain of H^2 functions. This work is restated here for the right half-plane. The initial data for the problem is, by assumption, a minimal state-space realization for the matrix $L(s)$ defined in (2.9):

$$L(s)=C(sI-A)^{-1}B+D. \tag{2.15}$$

Viewing all matrices as operators, we now define

$$A^x=A-BD^{-1}C, \tag{2.16a}$$

$P=$ Reisz projection of A for the right half-plane restricted to its image (2.16b)

$$=\frac{1}{2\pi j}\int_\Gamma (sI-A)^{-1}\,ds,$$

where Γ encircles all right-half-plane eigenvalues of A.

$P^x=$ Riesz projection of A^x for the right half-plane restricted to its image, (2.16c)

$$C_-=J'^{-1}D^{-*}B^*\,|\,\mathrm{Im}\ P^{x*}, \tag{2.16d}$$

$$C_+=C\,|\,\mathrm{Im}\ P, \tag{2.16e}$$

$$B_-=P^*C^*J', \tag{2.16f}$$

$$B_+=P^xBD^{-1}, \tag{2.16g}$$

$$A_{p-}=-A^{x*}\,|\,\mathrm{Im}\ P^{x*}, \tag{2.16h}$$

$$A_{p+}=A\,|\,\mathrm{Im}\ P, \tag{2.16i}$$

$$S_1=-\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} P^*(t+A^*)^{-1}C^*J'C(t-A)^{-1}P\,dt, \tag{2.16j}$$

$$S_2=\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} P^x(t-A^x)^{-1}BD^{-1}J'^{-1}D^{-*}B^*(t+A^{x*})^{-1}P^{x*}\,dt, \tag{2.16k}$$

$$\mathscr{L} = \begin{bmatrix} P^* & S_1 \\ S_2 & P^x \end{bmatrix} \quad \text{where } \mathscr{L}\colon \operatorname{Im} P^{x*} + \operatorname{Im} P \to \operatorname{Im} P^* + \operatorname{Im} P^x. \tag{2.16l}$$

With these definitions, an expression for Θ (when it exists) can now be written down. It turns out that Θ exists if and only if $\mathscr{L}$ is invertible, and then

$$\Theta(s) = \left\{ I + [C_- C_+] \begin{bmatrix} s - A_{p-} & 0 \\ 0 & s - A_{p+} \end{bmatrix}^{-1} \mathscr{L}^{-1} \begin{bmatrix} B_- \\ B_+ \end{bmatrix} \right\} \Theta(\infty). \tag{2.17}$$

We note that Θ satisfying (2.10)-(2.12) exists if and only if $\mathscr{L}$ is invertible. If $\mathscr{L}$ is not invertible, it can be made invertible by making ρ slightly larger. It is possible to test whether the set (1.8) is nonvacuous by computing a generalized Pick matrix [6]. Another way to see if (1.8) is nonempty is to compute Θ using (2.17) and look at a sample output of the linear fractional map (2.13).

It is not obvious that (2.17) always produces the same result because there are arbitrary choices of the factorization (1.3)-(1.4) and of the state-space realization (2.15). It turns out, however, that the result is unique given Q, W_1, W_2, and $\Theta(\infty)$. This is because Θ is determined (up to the (J, J')-unitary constant $\Theta(\infty)$) by the behavior of Q, W_1, and W_2 at the right-half-plane poles and zeros of Q. This section ends with some facts from the theory of system matrices [11]. The system matrix notion provides a method of describing systems that is somewhat more general than state-space representation. This allows for a wider range of transformations that preserve the transfer matrix. The notation is defined by the relationship

$$\begin{bmatrix} T & U \\ -V & W \end{bmatrix} \sim VT^{-1}U + W. \tag{2.18}$$

It can be shown easily that system matrices can be left-multiplied by nonsingular lower-block-triangular factors from the left without changing the transfer matrix. A similar statement holds for right-multiplication by nonsingular upper-block-triangular factors. The following theorem, which concerns the special case when $W = I$, follows easily from formula (6.4) of [11] and several system matrix operations.

THEOREM 2.4. *Let H_i, for $i = 1, 2$, have system matrix descriptions*

$$\begin{bmatrix} T_i & U_i \\ -V_i & I \end{bmatrix} \sim H_i.$$

Then the product H_2H_1 has the following system matrix description:

$$\begin{bmatrix} -U_2V_1 & T_2 & U_2 \\ T_1 & 0 & U_1 \\ -V_1 & -V_2 & I \end{bmatrix} \sim H_2H_1. \tag{2.19}$$

3. A two-frequency-scale disk problem. We now consider the case where the plant Q of Fig. 1.1 and the weights W_i of (1.8) are two-frequency-scale and satisfy a set of regularity conditions. The regularity conditions essentially require that the solution to the problem defined by (1.8) is well-defined in each frequency scale, and that there are no singularities induced by unstable lost poles as discussed in the previous section. We start with two lemmas. The first concerns inversion of rational matrices in terms of a state-space form.

LEMMA 3.1 [19]. *Let $H(s)$ be a square rational matrix over an arbitrary field F, and suppose that $H(s)$ has a state-space realization*

$$H(s) = C(sI - A)^{-1}B + D$$

with D invertible. Then $H(s)^{-1}$ can be written

$$H(s)^{-1} = D^{-1} - D^{-1}C(sI - A^x)^{-1}BD^{-1}$$

where $A^x = A - BD^{-1}C$.

Proof. Lemma 3.1 can be proved easily using the Schur complement formula [17]. □

The next lemma concerns two-frequency-scale weighting matrices.

LEMMA 3.2. Let $W(s, \varepsilon)$ be a square two-frequency-scale matrix with no unstable lost poles. Suppose that $W_S(s)$ and $W_F(p)$ are both stable, and both have stable inverses. Then there exists $\varepsilon^* > 0$ such that for $\varepsilon \in [0, \varepsilon^*)$, $W(s, \varepsilon)$ is stable and has a stable inverse. Furthermore, $W(s, \varepsilon)^{-1}$ is two-frequency-scale and $[W(s, \varepsilon)^{-1}]_S = W_S(s)^{-1}$, and $[W(s, \varepsilon)^{-1}]_F = W_F(p)^{-1}$.

Proof. We first note that Theorem 3.5 of [7] shows that $W(s, \varepsilon)$ is stable for $\varepsilon \in [0, \varepsilon^*)$ for some $\varepsilon^* > 0$.

The corresponding fact for $W(s, \varepsilon)^{-1}$ will now be shown. Since $W_S(s)$ and $W_F(p)$ have stable inverses, they must be nonsingular at ∞. Lemma 2.5 of [14] shows that $W(s, \varepsilon)^{-1}$ is two-frequency-scale. The expressions for $[W(s, \varepsilon)^{-1}]_S$ and $[W(s, \varepsilon)^{-1}]_F$ follow by direct substitution. At this point, the only thing remaining to prove is that $W(s, \varepsilon)^{-1} \in S_\varepsilon$. Since $[W(s, \varepsilon)^{-1}]_S$ and $[W(s, \varepsilon)^{-1}]_F$ are both stable, we need to verify only that all lost poles of $W(s, \varepsilon)^{-1}$ are stable, by virtue of Lemma 2.3 of [14] as mentioned after Definition 2.4. It can be seen from Lemma 3.1 that the lost poles of $W(s, \varepsilon)^{-1}$ are the same as the lost poles of $W(s, \varepsilon)$. One way to show this is to use the Popov–Belevitch–Hautus rank tests [17, p. 136]. □

The following assumption is motivated by the lemma above.

Assumption A1. This assumption holds for $W_i(s, \varepsilon)$ with $i = 1, 2$. $W_i(s, \varepsilon)$ is two-frequency-scale and has no unstable lost poles in either frequency scale. Furthermore, the matrices $W_{iS}(s)$, $[W_{iS}(s)]^{-1}$, $W_{iF}(p)$, and $[W_{iF}(p)]^{-1}$ are all in $M(S)$. That is, they are stable and have stable inverses.

The assumption in A1 on lost poles is needed, for otherwise the stability of S would not be equivalent to the stability of $W_1 S W_2$. The need for the next assumption is clear, for if the plant had unstable lost poles, then the existence of a stabilizing, two-frequency-scale compensator would not be guaranteed, and Theorem 2.2 could not be applied.

Assumption A2. The plant $Q(s, \varepsilon)$ is square, is two-frequency-scale, and has no unstable lost poles in either frequency scale. Furthermore, $Q_S(s)$ and $Q_F(p)$ have no poles or zeros on the extended imaginary axis.

The objective of this section is to show that a full-order problem can be decomposed into two reduced-order subproblems, and that the solutions to the two subproblems can be combined to yield an approximate solution to the full-order problem. For the purpose of this paper, we will consider that solving problem (1.8) is equivalent to finding Θ satisfying (2.10)–(2.12) because of the parametrization (2.13)–(2.14).

FULL-ORDER PROBLEM. Given $Q(s, \varepsilon)$, $W_1(s, \varepsilon)$, and $W_2(s, \varepsilon)$ satisfying Assumptions A1 and A2, form left and right coprime factorizations of $Q(s, \varepsilon)$ whose existence is guaranteed by Theorem 2.2. Using the notation of this theorem, compute the blocks of the following matrix to produce $L(s, \varepsilon)$:

$$L(s, \varepsilon) = \begin{bmatrix} W_1(s, \varepsilon)\tilde{Y}(s, \varepsilon) & W_1(s, \varepsilon)N(s, \varepsilon) \\ W_2(s, \varepsilon)^{-1}\tilde{D}(s, \varepsilon)^{-1} & 0 \end{bmatrix}. \tag{3.1}$$

Find $\Theta(s, \varepsilon)$ satisfying:

(1) $L(s, \varepsilon) = \Theta(s, \varepsilon)F(s, \varepsilon)$;

(2) $\Theta(-s, \varepsilon)^* J' \Theta(s, \varepsilon) = J$;

(3) $F(s, \varepsilon)$ and $[F(s, \varepsilon)]^{-1}$ are in $M(S_\varepsilon)$;

(4) $$\Theta(\infty) = \begin{bmatrix} I & 0 \\ 0 & \rho^{-1} I \end{bmatrix}.$$

We now define the slow and fast subproblems.

SLOW SUBPROBLEM. Given Q, W_1, and W_2 satisfying Assumptions A1 and A2, compute $Q_S(s)$, $W_{1S}(s)$, and $W_{2S}(s)$, as well as left- and right-coprime factorizations of $Q_S(s)$. From the matrix

(3.2) $$L^S(s) = \begin{bmatrix} W_{1S}\tilde{Y}^S & W_{1S}N^S \\ W_{2S}^{-1}(\tilde{D}^S)^{-1} & 0 \end{bmatrix}.$$

Find $\Theta^S(s)$ such that:

(3.3a) $$L^S(s) = \Theta^S(s)F^S(s);$$

(3.3b) $$\Theta^S(-\bar{s})^* J' \Theta^S(s) = J;$$

(3.3c) $$F^S \text{ and } (F^S)^{-1} \text{ are in } M(S);$$

(3.3d) $$\Theta^S(\infty) = \operatorname{diag}(I, \rho^{-1} I).$$

FAST SUBPROBLEM. Given Q, W_1, and W_2 satisfying Assumptions A1 and A2, compute $Q_F(p)$, $W_{1F}(p)$, and $W_{2F}(p)$, as well as left- and right-coprime factorizations of $Q_F(p)$. Form the matrix

(3.4) $$L^F(p) = \begin{bmatrix} W_{1F}\tilde{Y}^F & W_{1F}N^F \\ W_{2F}^{-1}(\tilde{D}^F)^{-1} & 0 \end{bmatrix}.$$

Find $\Theta^F(p)$ satisfying obvious analogues of (3.3a)-(3.3d). That is, replace every occurrence of the superscript "S" by the superscript "F."

It should be noted that the matrices N^S, D^S, X^S, Y^S, $\tilde{N}^S$, $\tilde{D}^S$, $\tilde{X}^S$, and $\tilde{Y}^S$ are computed only from knowledge of Q_S, W_{1S}, and W_{2S}. Thus $L^S \neq L_S$ in general. A similar comment holds for the fast subproblem.

A theorem on compensator design can now be stated. In words, it says that an approximate solution of the full-order problem can be obtained by solving the two reduced-order subproblems. The approach is to show that a stabilizing compensator for the full-order system that "almost" satisfies the constraint of (1.8) can be produced by finding a pair of compensators from the slow and fast subproblem solutions and combining the results. We note that $\Theta_1(s)$ given by

(3.5) $$\Theta_1(s) = \Theta^S(s) \operatorname{diag}(I, \rho I)\Theta^F(0)$$

is the value of Θ for the slow subproblem when $\Theta(\infty)$ is set to the (J, J')-unitary value $\Theta^F(0)$.

THEOREM 3.1. *Let $Q(s, \varepsilon)$, $W_1(s, \varepsilon)$, and $W_2(s, \varepsilon)$ satisfy Assumptions* A1 *and* A2. *Suppose that solutions $\Theta^S(s)$ and $\Theta^F(p)$ to the two subproblems exist and that the set* (1.8) *is nonvacuous for both subproblems. Let $G^S(s)$ and $G^F(p)$ be matrices in $M(S)$ such that $G^S(\infty) = G^F(0)$ and the following inequalities are satisfied*:

(3.6a) $$\|G^S\|_\infty \leqq 1,$$

(3.6b) $$\|G^F\|_\infty \leqq 1.$$

Suppose that the linear fractional map (2.13) *is applied to* G^S *using* Θ_1 *defined in* (3.5) *to produce* S^S; *and that* (2.13) *is applied to* G^F *using* Θ^F *to produce* S^F. *Let* C^S *be the compensator generated by backsolving* (1.1) *for* C *when* S *is set equal to* S^S *and* Q *is set to* Q_S. *Let* C^F *be the same when* S *is set to* S^F *and* Q *is set to* Q_F. *Suppose the* C^S *and* C^F *produced this way are proper. Then the compensator* $\hat{C}(s, \varepsilon)$ *defined by*

$$\hat{C}(s, \varepsilon) = C^S(s) + C^F(\varepsilon s) - C^F(0) \tag{3.7}$$

stabilizes $Q(s, \varepsilon)$ *for all sufficiently small* ε. *Furthermore,*

$$\| W_1(s, \varepsilon) S(s, \varepsilon) W_2(s, \varepsilon) \|_\infty \leqq \rho + O(\varepsilon) \tag{3.8}$$

where

$$S(s, \varepsilon) = (I + Q(s, \varepsilon)\hat{C}(s, \varepsilon))^{-1}. \tag{3.9}$$

Proof. We first point out that C^S and C^F generated as above satisfy

$$C^S(\infty) = C^F(0). \tag{3.10}$$

This is true because $\Theta_1(\infty) = \Theta^F(0)$ and $G^S(\infty) = G^F(0)$. Thus, the linear fractional map (2.13) produces S^S and S^F that satisfy

$$S^S(\infty) = S^F(0).$$

Thus, since backsolving (1.1) gives a well-defined unique result, (3.10) holds. Clearly, $\hat{C}$ defined by (3.7) is two-frequency-scale and

$$\hat{C}_S(s) = C^S(s), \qquad \hat{C}_F(p) = C^F(p).$$

Since $\hat{C}_S$ stabilizes Q_S, $\hat{C}_F$ stabilizes Q_F, and there are no unstable lost poles of Q or $\hat{C}$ ($\hat{C}$ has no lost poles by construction), $\hat{C}(s, \varepsilon)$ stabilizes $Q(s, \varepsilon)$ by Corollary (3.1) of [7].

We now show that $S(s, \varepsilon)$ defined by (3.9) satisfies (3.8). $S(s, \varepsilon)$ is two-frequency-scale and has no pure imaginary lost poles (the closed-loop lost poles are also open-loop lost poles—see [7]). Theorem 4.2 of [8] shows that

$$\| S(s, \varepsilon) - \hat{S}(s, \varepsilon) \|_\infty = 0(\varepsilon)$$

where $\hat{S}(s, \varepsilon) = S_S(s) + S_F(\varepsilon s) - S_S(\infty)$.

By limiting arguments shown in the Appendix, we have

$$\| \hat{S}(s, \varepsilon) \|_\infty = \rho + O(\varepsilon).$$

We can now write

$$\begin{aligned} \| S(s, \varepsilon) \|_\infty &= \| S(s, \varepsilon) - \hat{S}(s, \varepsilon) + \hat{S}(s, \varepsilon) \|_\infty \\ &\leqq \| S(s, \varepsilon) - \hat{S}(s, \varepsilon) \|_\infty + \| \hat{S}(s, \varepsilon) \|_\infty \\ &= \rho + O(\varepsilon). \end{aligned}$$

□

The next theorem, which concerns the representor $\Theta(s, \varepsilon)$, shows that more can be said about this problem decomposition, and that results stronger than the "one-way" result of Theorem 3.1 may be possible. Also, it might ultimately prove more useful to approximate $\Theta(s, \varepsilon)$ by singular perturbations rather than by individual sensitivities satisfying (1.2). This is because it is difficult, in general, to express all of the physical constraints of a control problem as a single "disk" of the form (1.2) [5]. Thus, a possible approach is to first compute Θ and then incorporate other constraints by restricting the choice of the parameter G.

THEOREM 3.2. *Let $Q(s, \varepsilon)$, $W_1(s, \varepsilon)$, and $W_2(s, \varepsilon)$ satisfy Assumptions* A1 *and* A2. *Suppose that solutions $\Theta^S(s)$ and $\Theta^F(p)$, to the slow and fast subproblems, respectively, exist. Then a solution $\Theta(s, \varepsilon)$ to the full-order problem exists for all sufficiently small ε. Furthermore, $\Theta(s, \varepsilon)$ is two-frequency-scale and*

$$\Theta_S(s) = \Theta^S(s)\ \mathrm{diag}\,(I, \rho I)\Theta^F(0), \qquad \Theta_F(p) = \Theta^F(p).$$

Proof. We first note that $L(s, \varepsilon)$ given by (3.1) is two-frequency-scale. This follows from Assumptions A1 and A2, and from Lemma 3.2. Since $L(s, \varepsilon)$ is two-frequency-scale, it has a state-space realization of the form (2.5). The matrix $D(0)$ in (2.8h) is nonsingular because all of the following matrices are nonsingular at ∞: $W_{1F}(p)$, $N_F(p)$, $W_{2F}(p)^{-1}$, and $\tilde{D}_F(p)^{-1}$. This shows that Lemma 3.1 applies to $L(s, \varepsilon)$. The next step is to insert the state-space realization for $L(s, \varepsilon)$ into (2.16a)-(l) and generate the corresponding $\Theta(s, \varepsilon)$ using (2.17). Formula (2.17) is not quite in state-space form: the multiplication of $\mathscr{L}^{-1}$, $[B_-^T B_+^T]^T$, and $\Theta(\infty)$ would have to be carried out. The term multiplying $\Theta(\infty)$, however, fits naturally into the system matrix format. Formula (2.17) gives a minimal state-space realization of Θ if the appropriate multiplications are carried out. Thus, the domain restrictions were made so the state-space is as small as possible. It turns out that it is easier to use some unrestricted operators here. The validity of the following system matrix representation is easily seen from (2.17):

$$\Theta(s, \varepsilon)\Theta(\infty, \varepsilon)^{-1} \sim \begin{bmatrix} P^*(s + A^{x*})P^{x*} & P^*S_1(s - A)P & P^*C^*J' \\ P^xS_2(s + A^{x*})P^{x*} & P^x(s - A)P & P^xBD^{-1} \\ -J'^{-1}D^{-*}B^*P^{x*} & -CP & I \end{bmatrix} \tag{3.11}$$

where (C, A, B, D) is a state-space realization of $L(s, \varepsilon)$ of the form (2.5). Thus,

$$A = \begin{bmatrix} A_{11} & A_{12} \\ \dfrac{1}{\varepsilon} A_{21} & \dfrac{1}{\varepsilon} A_{22} \end{bmatrix}, \quad B = \begin{bmatrix} B_1 \\ \dfrac{1}{\varepsilon} B_2 \end{bmatrix}, \quad C = [C_1 \quad C_2]$$

with $A_{22}(0)$ nonsingular. The remainder of the blocks of (3.11) are defined in (2.16). System matrix operations are now performed on (3.11) to show that $\Theta(s, \varepsilon)$ is two-frequency-scale and to compute $\Theta_S(s)$ and $\Theta_F(p)$.

As a first step toward this end, we note that the projection matrices $P(\varepsilon)$ and $P(\varepsilon)^x$ are analytic at $\varepsilon = 0$; furthermore, they have a special structure in the limit as ε approaches zero. Using the notation of Theorem 2.3, and letting $\Gamma(\varepsilon)$ be a curve that encircles all of the right-half-plane eigenvalues of A, we have

$$\begin{aligned} P(\varepsilon) &= \int_{\Gamma(\varepsilon)} (s - A)^{-1}\, ds \\ &= T(\varepsilon)^{-1} \int_{\Gamma(\varepsilon)} T(\varepsilon)(s - A)^{-1} T(\varepsilon)^{-1}\, ds\, T(\varepsilon) \\ &= T(\varepsilon)^{-1} \int_{\Gamma(\varepsilon)} (s - A_D)^{-1}\, ds\, T(\varepsilon) \\ &= T(\varepsilon)^{-1} P_D(\varepsilon) T(\varepsilon) \end{aligned} \tag{3.12}$$

where

$$\begin{aligned} &P_D(\varepsilon) = \mathrm{diag}\,(P_S(\varepsilon), P_F(\varepsilon)), \\ &P_S(\varepsilon) = \text{RHP Riesz projection for } A_1(\varepsilon), \\ &P_F(\varepsilon) = \text{RHP Riesz projection for } A_2(\varepsilon). \end{aligned}$$

P_S and P_F are analytic in ε by virtue of (2.16b). The block expressions for $T(\varepsilon)$ and $T(\varepsilon)^{-1}$ can be inserted into (3.12) to show that

$$P(\varepsilon)=\begin{bmatrix} P_S+O(\varepsilon) & \varepsilon[-P_SA_{12}A_{22}^{-1}+A_{12}A_{22}^{-1}P_F]+O(\varepsilon^2) \\ -A_{22}^{-1}A_{21}P_S+P_FA_{22}^{-1}A_{21}+O(\varepsilon) & P_F+O(\varepsilon) \end{bmatrix}. \tag{3.13}$$

All quantities A_{ij} on the right-hand side of (3.13) are evaluated at $\varepsilon=0$. Formulas similar to (3.12) and (3.13) for P^x can be written as follows. The analogue of (3.12) is

$$P^x(\varepsilon)=T^x(\varepsilon)^{-1}P_D^x(\varepsilon)T^x(\varepsilon) \tag{3.14}$$

where $T^x(\varepsilon)$ block diagonalizes A^x as in Theorem 2.3 and $P_D^x(\varepsilon)$ is the (block diagonal) right-half-plane Riesz projection for A_D^x.

We can now take advantage of the singular perturbation structure of (3.11) by replacing $P(\varepsilon)$ with (3.12) and replacing $P^x(\varepsilon)$ with (3.14). After doing this, the system matrix is simplified by the following steps:

(1) Left-multiplying the first block row by T^{-*};
(2) Left-multiplying the second block row by T^*;
(3) Right-multiplying the first block column by $(T^x)^{-*}$;
(4) Right-multiplying the second block column by T^{-1}.

These operations transform (3.11) to

$$\begin{bmatrix} P_D^*T^{-*}(s+A^{x*})P_D^{x*} & P_D^*T^{-*}S_1(s-A)T^{-1}P_D & P_D^*T^{-*}C^*J' \\ P_D^xT^xS_2(s+A^{x*})T^{x*}P_D^{x*} & P_D^xT^x(s-A)T^{-1}P_D & P_D^xT^xBD^{-1} \\ J'^{-1}D^{-*}B^*T^{x*}P_D^{x*} & CT^{-1}P_D & I \end{bmatrix}. \tag{3.15}$$

Matrix (3.15) can be further simplified by inserting the identity terms $T^{x*}(T^x)^{-*}$, $T^{-1}T$, $T^{x*}(T^x)^{-*}$, and $T^{-1}T$ into the (1, 1), (1, 2), (2, 1), and (2, 2) blocks of (3.15), respectively. This substitution reduces (3.15) to the following form:

$$\begin{bmatrix} P_D^*(T^{-*}T^{x*})(s+A_D^{x*})P_D^{x*} & P_D^*S_{1D}(s-A_D)P_D & P_D^*C_D^*J' \\ P_D^xS_{2D}(s+A_D^{x*})P_D^{x*} & P_D^x(T^xT^{-1})(s-A_D)P_D & P_D^xB_D \\ -J'^{-1}B_D^*P_D^{x*} & -C_DP_D & I \end{bmatrix}. \tag{3.16}$$

The following new notation has been introduced:

$$S_{1D}=T^{-*}S_1T^{-1}, \tag{3.17a}$$

$$S_{2D}=T^xS_2(T^x)^{-1}, \tag{3.17b}$$

$$B_D=T^xBD^{-1}, \tag{3.17c}$$

$$C_D=CT^{-1}. \tag{3.17d}$$

The objective here is to express all blocks appearing in (3.16) in terms of quantities associated with the slow and fast subsystems. We define

$$S_{1S}=-\frac{1}{2\pi j}\int_{-j\infty}^{j\infty}P_S^*(t+A_S^*)^{-1}C_S^*J'C_S(t-A_S)^{-1}P_S\,dt, \tag{3.18a}$$

$$S_{1F}=-\frac{1}{2\pi j}\int_{-j\infty}^{j\infty}P_F^*(t+A_F^*)^{-1}C_F^*J'C_F(t-A_F)^{-1}P_F\,dt, \tag{3.18b}$$

$$S_{2S}=\frac{1}{2\pi j}\int_{-j\infty}^{j\infty}P_S^x(t-A_S^x)^{-1}B_SD_S^{-1}J'^{-1}D_S^{-*}B_S^*(t+A_S^{x*})^{-1}P_S^{x*}\,dt, \tag{3.18c}$$

$$S_{2F}=\frac{1}{2\pi j}\int_{-j\infty}^{j\infty}P_F^x(t-A_F^x)^{-1}B_FD_F^{-1}J'^{-1}D_F^{-*}B_F(t+A_F^{x*})^{-1}P_F^{x*}\,dt. \tag{3.18d}$$

It should be noted here that the quantities S_{1S} and S_{2S} would be calculated in solving the slow subproblem if the *particular* factorization

$$N^S(s) = N_S(s), \quad \tilde{D}^S(s) = \tilde{D}_S(s), \quad \tilde{Y}^S(s) = \tilde{Y}_S(s)$$

had been used in forming $L^S(s)$, in (3.2), and if the *particular* realization (C_S, A_S, B_S, D_S) had been used to compute $\Theta^S(s)$. Thus, the expressions (3.18a, c) *could* arise in solving the slow subproblem. A similar statement concerning S_{1F} and S_{2F} holds. We wish to express (3.17a–d), and thus the entire system matrix (3.16), in terms of quantities of this type. It can be shown through rather extensive calculation that (3.17a–d) take the following forms:

$$S_{1D} = \begin{bmatrix} S_{1S} + O(\varepsilon) & \varepsilon G_1 + O(\varepsilon^2) \\ \varepsilon G_1^* + O(\varepsilon^2) & \varepsilon S_{1F} + O(\varepsilon^2) \end{bmatrix} \tag{3.19a}$$

where

$$G_1 = P_S^* C_S J' C_F^* A_F^{-*} P_F, \tag{3.19b}$$

$$S_{2D} = \begin{bmatrix} S_{2S} + O(\varepsilon) & H_1 + O(\varepsilon) \\ H_1^* + O(\varepsilon) & \dfrac{1}{\varepsilon} S_{2F} + O(1) \end{bmatrix} \tag{3.19c}$$

where

$$H_1 = -P_S^x B_S D_S^{-1} J'^{-1} D_F^{-*} B_F (A_F^x)^{-*} P_F^{x*}, \tag{3.19d}$$

$$B_D = \begin{bmatrix} B_S D_S^{-1} + O(\varepsilon) \\ \dfrac{1}{\varepsilon} B_F D_F^{-1} + O(1) \end{bmatrix}, \tag{3.19e}$$

$$C_D = [C_S + O(\varepsilon) \quad C_F + O(\varepsilon)]. \tag{3.19f}$$

Results on gramians (solutions of Lyapunov equations) already exist in the time-domain literature (e.g., [18]). The elegance of the complex variable proof, however, warrants the inclusion of a sample computation in this paper. A derivation of (3.19a) appears in the Appendix along with the computations for (3.19e).

We are now in a position to compute $\Theta_F(p)$. To do this, we must substitute $p = \varepsilon s$ in (3.16), make the resulting system matrix analytic in ε by multiplying appropriate block columns by ε, and set ε to zero. If the upper-left block of the resulting (ε-independent) system matrix is nonsingular, then it is a system matrix representation of $\Theta_F(p)$. We now have five block rows and five block columns. It turns out that if we make the substitution and multiply the first three block columns and the fourth block row by ε, the the resulting matrix is analytic. When this is done, the following system matrix results:

$$\begin{bmatrix} P_D^* \begin{bmatrix} P & -K_L(p + A_F^{x*}) \\ 0 & p + A_F^{x*} \end{bmatrix} P_D^{x*} & P_D^* \begin{bmatrix} S_{1S} p & G_1(p - A_F) \\ 0 & S_{1F}(p - A_F) \end{bmatrix} P_D & P_D^* \begin{bmatrix} C_S^* \\ C_F^* \end{bmatrix} J' \\ P_D^x \begin{bmatrix} S_{2S} p & H_1(p + A_F^{x*}) \\ 0 & S_{2F}(p + A_F^{x*}) \end{bmatrix} P_D^{x*} & P_D^x \begin{bmatrix} P & K_U(p - A_F) \\ 0 & p - A_F \end{bmatrix} P_D & P_D^x \begin{bmatrix} B_S D_S^{-1} \\ B_F D_F^{-1} \end{bmatrix} \\ -J'^{-1}[0 \quad D_F^{-*} B_F^*] P_D^{x*} & -[0 \quad C_F] P_D & I \end{bmatrix} \tag{3.20}$$

G_1 and H_1 are defined by (3.19b) and (3.19d), respectively. The product of transformations $T^x T^{-1}$ clearly has the form (3.21)

$$T^x T^{-1} = \begin{bmatrix} I + O(\varepsilon) & \varepsilon K_U + O(\varepsilon^2) \\ K_L + O(\varepsilon) & I + O(\varepsilon) \end{bmatrix} \tag{3.21a}$$

where

$$K_L = A_F^{-x} A_{21}^x(0) - A_F^{-1} A_{21}(0), \tag{3.21b}$$

$$K_U = A_{12}(0) A_F^{-1} - A_{12}^x(0)(A_F^x)^{-1}. \tag{3.21c}$$

When the remaining multiplications are written out in (3.20) it can be seen that rearrangement of the first four block rows and columns yields the following structure:

$$\begin{bmatrix} * & * & * & * & * \\ * & * & * & * & * \\ ? & ? & 0 & 0 & ? \\ ? & ? & 0 & 0 & ? \\ ? & ? & 0 & 0 & I \end{bmatrix}.$$

The *'s and ?'s represent possibly nonzero entries. A system matrix of this form may be reduced, by deleting rows and columns, leaving only the ?'s.

After this is sorted out, we get

$$\Theta(p/\varepsilon)\cdot\Theta(\infty)^{-1}\big|_{\varepsilon=0} \sim \begin{bmatrix} P_F^*(p + A_F^{x*})P_F^{x*} & P_F^* S_{1F}(p - A_F)P_F & P_F^* C_F^* J' \\ P_F^x S_{2F}(p + A_F^{x*})P_F^{x*} & P_F^x(p - A_F)P_F & P_F^x B_F D_F^{-1} \\ J'^{-1} D_F^{-*} B_F^* P_F^{x*} & C_F P_F & I \end{bmatrix}. \tag{3.22}$$

Clearly, the blocks of (3.22) could be the result of a computation of $\Theta^F(p)$ (i.e., the fast subproblem computation) if a particular factorization for the plant and a particular state-space realization for $L^F(p)$ were chosen. Thus,

$$\Theta_F(p) = \Theta\left(\frac{p}{\varepsilon}, \varepsilon\right)\Big|_{\varepsilon=0} = \Theta^F(p). \tag{3.23}$$

The computation of $\Theta_S(s)$ follows along a similar line. If system matrix (3.16) is viewed as having five block rows and five block columns (after the substitutions (3.19) are made), it can be made analytic in ε by multiplying the third block row and the second block column by ε. After setting ε to zero, (3.24) is obtained:

(3.24)

$$\begin{bmatrix} P_D^* \begin{bmatrix} s + A_S^{x*} & K_L^* A_F^{x*} \\ 0 & A_F^{x*} \end{bmatrix} P_D^{x*} & P_D^* \begin{bmatrix} S_{1S}(s - A_S) & -G_1 A_F \\ 0 & -S_{1F} A_F \end{bmatrix} P_D & P_D^* \begin{bmatrix} C_S^* \\ C_F^* \end{bmatrix} J' \\ P_D^x \begin{bmatrix} S_{2S}(s + A_F^{x*}) & H_1 A_F^{x*} \\ 0 & S_{2F} A_F^{x*} \end{bmatrix} P_D^{x*} & P_D^x \begin{bmatrix} s - A_S & -K_U A_F \\ 0 & -A_F \end{bmatrix} P_D & P_D^x \begin{bmatrix} B_S D_S^{-1} \\ B_F D^{-1} \end{bmatrix} \\ -J'^{-1}[D_S^{-*} B_S^* \quad D^{-*} B_F^*] P_D^{x*} & -[C_S \quad C_F] P_D & I \end{bmatrix}.$$

The rows and columns of (3.24) can be interchanged to place all of the zeros in the same block. This leaves (3.25), which is similar in form to (2.25):

$$\begin{bmatrix} X & T_2 & U_2 \\ T_1 & 0 & U_1 \\ -V_1 & -V_2 & I \end{bmatrix} \tag{3.25}$$

where

$$X = \begin{bmatrix} P_S^* K_L^* A_F^{x*} P_F^{x*} - P_S^* G_1 A_F P_F \\ P_S^x H_1 A_F^{x*} P_F^{x*} - P_S^x K_U A_F P_F \end{bmatrix},$$

$$T_2=\begin{bmatrix} P_S^*(s+A_S^{x*})P_S^{x*} & P_S^*S_{1S}(s-A_S)P_S \\ P_S^xS_{2S}(s+A_S^{x*})P_S^{x*} & P_S^x(s-A_S)P_S \end{bmatrix}, \qquad U_2=\begin{bmatrix} P_S^*C_S^* & J' \\ P_S^*B_S & D_S^{-1} \end{bmatrix},$$

$$T_1=\begin{bmatrix} P_F^*A_F^{x*}P_F^{x*}-P_F^*S_{1F}A_FP_F \\ P_F^xS_{2F}A_F^{x*}P_F^{x*}-P_F^xA_FP_F \end{bmatrix}, \qquad U_1=\begin{bmatrix} P_F^*C_F^*J' \\ P_F^*B_FD^{-1} \end{bmatrix},$$

$$V_1=[-J'^{-1}D^{-*}B_F^*P_F^{x*} \quad C_FP_F], \qquad V_2=[-J'^{-1}D_S^{-*}B_S^*P_S^{x*} \quad C_SP_S].$$

A calculation shows that indeed, X is equal to $-U_2V_1$, making the match to (2.25) complete. It is easily seen that

$$\begin{bmatrix} T_1 & U_1 \\ -V_1 & I \end{bmatrix} \sim \Theta^F(0)\ \mathrm{diag}\,(I, \rho I), \tag{3.26}$$

$$\begin{bmatrix} T_2 & U_2 \\ -V_2 & I \end{bmatrix} \sim \Theta^S(s)\ \mathrm{diag}\,(I, \rho). \tag{3.27}$$

Thus, from Theorem 2.4, we see that

$$\Theta(s, \varepsilon)|_{\varepsilon=0}\ \mathrm{diag}\,(I, \rho I)=\Theta^S(s)\cdot \mathrm{diag}\,(I, \rho I)\cdot \Theta^F(0)\cdot \mathrm{diag}\,(I, \rho I).$$

We have shown that $\Theta(s, \varepsilon)$ obeys parts (1) and (2) of Definition 2.1. Part (3) follows immediately from (2.17). The poles of $\Theta(s, \varepsilon)$ fall into two categories: they are eigenvalues of either $-A^{x*}$ or A. In either case, the poles obey (2.1) or (2.2) because both $-A^{x*}$ and A have the "singularly perturbed" form. □

Appendix.

Proof of (3.19*a*).

$$\begin{aligned} T^{-*}S_1T^{-1} &= -\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} T^{-*}P^*(t+A^*)^{-1}C^*J'C(t-A)^{-1}PT^{-1}\,dt \\ &= -\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} T^{-*}P^*T^*T^{-*}(t+A^*)^{-1}T^*T^{-*}C^*J'CT^{-1} \\ &\quad \times T(t-A)^{-1}T^{-1}TPT^{-1}\,dt \\ &= -\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} P_D^*(t+A_D^*)^{-1}T^{-*}C^*J'CT^{-1}(t-A_D)^{-1}P_D\,dt \\ &= \begin{bmatrix} X_{11} & X_{12} \\ X_{12}^* & X_{22} \end{bmatrix}+\begin{bmatrix} E_{11} & E_{12} \\ E_{12}^* & E_{22} \end{bmatrix} \end{aligned} \tag{A1}$$

where

$$X_{11}=-\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} P_S^*(t+A_1^*)^{-1}C_S^*J'C_S(t-A_1)^{-1}P_S\,dt, \tag{A2}$$

$$X_{12}=-\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} P_S^*(t+A_1^*)^{-1}C_S^*J'C_F\left(t-\frac{1}{\varepsilon}A_2\right)^{-1}P_F\,dt, \tag{A3}$$

$$X_{22}=-\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} P_F^*\left(t+\frac{1}{\varepsilon}A_2^*\right)^{-1}C_F^*J'C_F\left(t-\frac{1}{\varepsilon}A_2\right)^{-1}P_F\,dt, \tag{A4}$$

and $A_D=\mathrm{diag}\,(A_1, (1/\varepsilon)A_2)$. Since

$$T^{-*}C^*J'CT^{-1}=\begin{bmatrix} C_S^*J'C_S & C_S^*J'C_F \\ C_F^*J'C_S & C_F^*J'C_F \end{bmatrix}+O(\varepsilon),$$

each E_{ij} will be one order of ε smaller than the corresponding X_{ij}. In other words, the X_{ij}'s form a first-order approximation of the gramian (A1). We first note that $X_{11}(0) = S_{1S}$ because $A_1 = A_S + O(\varepsilon)$. X_{22} can be computed by changing variables. Let $p = \varepsilon t$

$$X_{22} = -\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} P_F^*(p + A_2^*)^{-1} C_F^* J' C_F (p - A_2)^{-1} P_F \cdot \varepsilon^2 \frac{dp}{\varepsilon}$$

$$= \varepsilon \cdot S_{1F} + O(\varepsilon^2),$$

since $A_2 = A_F + O(\varepsilon)$.

The cross-term X_{12} can be computed by contour integration:

$$X_{12}^* = -\frac{1}{2\pi j}\int_{-j\infty}^{j\infty} P_F^*\left(t + \frac{1}{\varepsilon} A_2^*\right)^{-1} C_F^* J' C_S (t - A_1)^{-1} P_S \, dt.$$

Since the integrand falls off as $O(1/t^2)$ for large t, this integral can be replaced by a large D-shaped contour integral. This is diagrammed in Fig. A1. Thus, if the radius of Γ is assumed of order larger than $1/\varepsilon$,

$$X_{12}^* = -\frac{1}{2\pi j}\int_{\Gamma} P_F^*\left(t + \frac{1}{\varepsilon} A_2^*\right)^{-1} C_F^* J' C_S (t - A_1)^{-1} P_S \, dt.$$

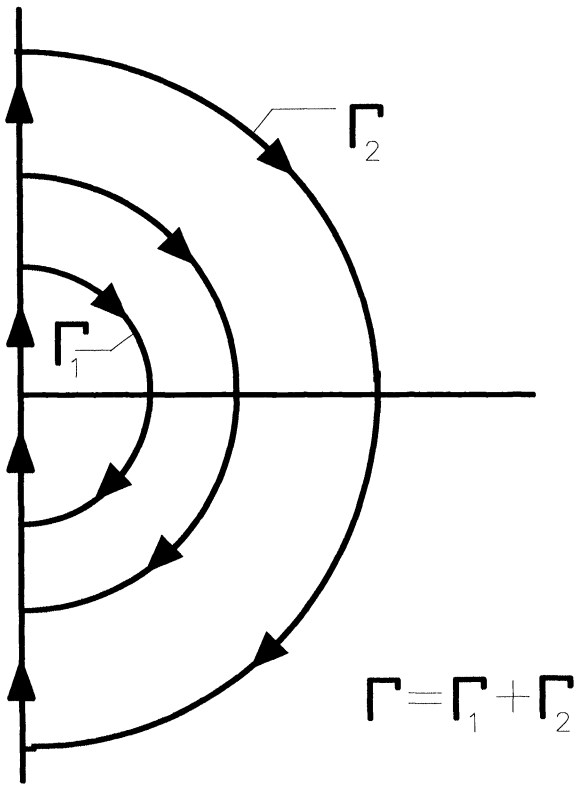

FIG. A1

We now note that

$$P_F^*\left(t+\frac{1}{\varepsilon}A_2^*\right)^{-1} = P_F^*\left(t+\frac{1}{\varepsilon}A_2^*\right)^{-1}P_F^*$$

is stable for all sufficiently small ε, and all the poles of $(t-A_1)^{-1}$ remain finite as $\varepsilon \to 0$. Choose ε^* so that Γ_1 encircles all the poles of $(t-A_1)^{-1}$ for all $\varepsilon < \varepsilon^*$. We can express the contour Γ as $\Gamma = \Gamma_1 + \Gamma_2$. The integral, however, is zero over Γ_2 because the integrand is analytic inside Γ_2 (at least for small ε). Thus,

$$\begin{aligned} X_{12}^* &= -\frac{1}{2\pi j}\int_{\Gamma_1} P_F^*\left(t+\frac{1}{\varepsilon}A_2^*\right)^{-1} C_F^* J' C_S (t-A_1)^{-1} P_S \, dt \\ &= -\frac{\varepsilon}{2\pi j}\int_{\Gamma_1} P_F^*(\varepsilon t + A_2^*)^{-1} C_F^* J' C_S (t-A_1)^{-1} P_S \, dt \\ &= -\frac{\varepsilon}{2\pi j}\int_{\Gamma_1} P_F^* A_2^{-*} C_F^* J' C_S (t-A_1)^{-1} P_S \, dt + \text{higher-order terms in } \varepsilon \\ &= \varepsilon P_F^* A_F^{-*} C_F^* J' C_S P_S \end{aligned}$$

because $-(1/2\pi j)\int_{\Gamma_1}(t-A_1)^{-1}\,dt = P_S$. Therefore, $X_{12} = \varepsilon P_S^* C_S^* J' C_F A_F^{-1} P_F + O(\varepsilon^2)$ and $G_1 = P_S^* C_S^* J' C_F A_F^{-1} P_F$. The proof of (3.19c) goes in a similar manner. □

Proof of (3.19e). We first note that a system of the form (2.5) has corresponding A^x given by

$$A^x = \begin{bmatrix} A_{11} - B_1 D^{-1} C_1 & A_{12} - B_1 D^{-1} C_2 \\ \dfrac{A_{21} - B_2 D^{-1} C_1}{\varepsilon} & \dfrac{A_{22} - B_2 D^{-1} C_2}{\varepsilon} \end{bmatrix}.$$

The transformation T^x of A^x to block diagonal form given by Theorem 2.3 can now be expressed as follows:

$$T^x = \begin{bmatrix} I & -\varepsilon(A_{12} - B_1 D^{-1} C_2) & (A_{22} - B_2 D^{-1} C_2)^{-1} \\ (A_{22} - B_2 D^{-1} C_2)^{-1} & (A_{21} - B_2 D^{-1} C_1) & I \end{bmatrix} + \begin{bmatrix} O(\varepsilon) & O(\varepsilon^2) \\ O(\varepsilon) & O(\varepsilon) \end{bmatrix}.$$

B has the form

$$B = \begin{bmatrix} B_1 \\ (1/\varepsilon) B_2 \end{bmatrix}.$$

Let

$$T^x B D^{-1} = \begin{bmatrix} X_1 \\ X_2 \end{bmatrix}.$$

Clearly,

$$\begin{aligned} X_2 &= \frac{B_2 D^{-1}}{\varepsilon} + O(1) \\ &= \frac{B_F D_F^{-1}}{\varepsilon} + O(1). \end{aligned}$$

The computation of the limiting behavior of X_1 is more complicated. Multiplying T^x, B, and D^{-1}, we see that

$$X_1 = [B_1 - (A_{12} - B_1 D^{-1} C_2)(A_{22} - B_2 D^{-1} C_2)^{-1} B_2] D^{-1} + O(\varepsilon).$$

We can now expand $B_S D_S^{-1}$ (the right-hand side of the following expression is evaluated at $\varepsilon = 0$):

$$B_S D_S^{-1} = (B_1 - A_{12}A_{22}^{-1}B_2)(D - C_2 A_{22}^{-1}B_2)^{-1}.$$

The Schur complement formula gives us

$$\begin{aligned} D_S^{-1} &= (D - C_2 A_{22}^{-1}B_2)^{-1} \\ &= D^{-1} + D^{-1}C_2(-B_2 D^{-1}C_2 + A_{22})^{-1}B_2 D^{-1}. \end{aligned}$$

Thus, $B_S D_S^{-1} = (B_1 - A_{12}A_{22}^{-1}B_2)[I + D^{-1}C_2(A_{22} - B_2 D^{-1}C_2)^{-1}B_2]D^{-1}$. After multiplying out and collecting the term $(A_{22} - B_2 D^{-1}C_2)^{-1}B_2$, we get

$$\begin{aligned} B_S D_S^{-1} &= \{B_1 + [-A_{12} + A_{12}A_{22}^{-1}B_2 D^{-1}C_2 + B_1 D^{-1}C_2 - A_{12}A_{22}^{-1}B_2 D^{-1}C_2] \\ &\quad \times (A_{22} - B_2 D^{-1}C_2)^{-1}B_2\} D^{-1} \\ &= [B_1 - (A_{12} - B_1 D^{-1}C_2)(A_{22} - B_2 D^{-1}C_2)^{-1}B_2]D^{-1} \\ &= X_1 + O(\varepsilon). \end{aligned}$$

This proves (3.19e). □

Completion of the proof of Theorem 3.1. We start with the following lemma.

LEMMA A1. *Let $A(z)$ and $B(z)$ be matrices real analytic at $z = 0$, and let r be real with $0 < r \leqq \frac{1}{2}$. Also, let $A(0) \neq 0$ and $B(0) = 0$, and let*

$$\|A(j\xi)\|_2 \leqq \rho \quad \textit{for all } \xi \in \mathbb{R}.$$

Then $\|A(j\varepsilon^r) + B(j\varepsilon^{1-r})\|_2 \leqq \rho + O(\varepsilon)$ $(\varepsilon \to 0)$. Furthermore, the implicit bounding constant is independent of r.

Proof. We assume, without loss of generality, that $\|A(0)\|_2 = \rho$, since if $\|A(0)\|_2 \leqq \rho$, then the lemma follows immediately. We note that $\|\cdot\|_2$ is a continuous function of its argument. Thus,

$$\|A(j\varepsilon^r) + B(j\varepsilon^{1-r})\|_2 = \|A(0)\|_2 + f(\varepsilon) = \rho + f(\varepsilon)$$

where $f(\varepsilon)$ is continuous at zero and $f(0) = 0$. By elementary properties of the matrix norm, there exists a vector function $x(\varepsilon)$ such that $\|x(\varepsilon)\|_2 = 1$ and

$$\|[A(j\varepsilon^r) + B(j\varepsilon^{1-r})]x(\varepsilon)\|_2 = \rho + f(\varepsilon). \tag{A5}$$

Note that $\|A(j\varepsilon^r)x(\varepsilon)\|_2$ is bounded away from zero for small ε, since (A5) implies

$$\begin{aligned} \|A(j\varepsilon^r)x(\varepsilon)\|_2 &\geqq \rho + f(\varepsilon) - \|B(j\varepsilon^{1-r})x(\varepsilon)\|_2 \\ &\to \rho \quad \text{as } \varepsilon \to 0. \end{aligned}$$

The left-hand side of (A5) can be rewritten as

$$\begin{aligned} \|[A(j\varepsilon^r) + B(j\varepsilon^{1-r})]x(\varepsilon)\|_2 &= \{x(\varepsilon)^*[A(j\varepsilon^r) + B(j\varepsilon^{1-r})]^*[A(j\varepsilon^r) \\ &\quad + B(j\varepsilon^{1-r})]x(\varepsilon)\}^{1/2} \\ &= \{x(\varepsilon)^*[A^T(-j\varepsilon^r)A(j\varepsilon^r) + B^T(-j\varepsilon^{1-r})A(j\varepsilon^r) \\ &\quad + A^T(-j\varepsilon^r)B(j\varepsilon^{1-r}) + B^T(-j\varepsilon^{1-r})B(j\varepsilon^{1-r})]x(\varepsilon)\}^{1/2}. \end{aligned}$$

We now consider individual terms. It is assumed that the functions $A(z)$ and $B(z)$ have power series expansions valid for all argument values under consideration. Thus,

$$A(z)=\sum_{n=0}^{\infty} A_n z^n, \qquad B(z)=\sum_{n=0}^{\infty} B_n z^n,$$

$$x(\varepsilon)^* A^T(-j\varepsilon^r)A(j\varepsilon^r)x(\varepsilon) \leqq \|A(j\varepsilon^r)\|_2^2 \leqq \rho^2,$$

$$\begin{aligned} x(\varepsilon)^*[B^T(-j\varepsilon^{1-r})A(j\varepsilon^r)+A(-j\varepsilon^r)B(j\varepsilon^{1-r})]x(\varepsilon) \\ &= x(\varepsilon)^*\{B_1^T\cdot(-j\varepsilon^{1-r})\cdot A_0 + A_0^T\cdot B_1\cdot(j\varepsilon^{1-r})+O(\varepsilon)\}x(\varepsilon) \\ &= x(\varepsilon)^*\{[A_0^T B_1 - B_1^T A_0]\cdot j\varepsilon^{1-r}+O(\varepsilon)\}x(\varepsilon) \\ &= O(\varepsilon) \qquad (\varepsilon\to 0). \end{aligned}$$

This follows because the matrix in brackets is skew-symmetric, giving a zero quadratic form value.

Clearly, the remaining term is also $O(\varepsilon)$ because of the restricted range of r. Thus,

$$x(\varepsilon)^* B^T(-j\varepsilon^{1-r})B(j\varepsilon^{1-r})x(\varepsilon)=O(\varepsilon) \qquad (\varepsilon\to 0).$$

We now have

$$\begin{aligned} \|A(j\varepsilon^r)+B(j\varepsilon^{1-r})\|_2 &= \{\|A(j\varepsilon^r)x(\varepsilon)\|_2^2+O(\varepsilon)\}^{1/2} \\ &= \|A(j\varepsilon^r)x(\varepsilon)\|_2\cdot\{1+O(\varepsilon)\}^{1/2} \\ &\leqq \rho+O(\varepsilon). \end{aligned}$$

The middle equality above follows because $\|A(j\varepsilon^r)x(\varepsilon)\|_2$ is bounded away from zero. The last statement in the lemma is easily verified. □

We are now ready to prove the unproved portion of Theorem 3.1:

$$\begin{aligned} \|\hat{S}(j\omega,\varepsilon)\|_\infty &= \sup_{\omega\in R}\|S_S(j\omega)+S_F(j\varepsilon\omega)-S_S(\infty)\|_2, \\ &= \max\left\{\sup_{\omega\in[0,1/\sqrt{\varepsilon}]}\|S_S(j\omega)+S_F(j\varepsilon\omega)-S_S(\infty)\|_2,\right. \\ &\qquad \left.\sup_{\omega\in[1/\sqrt{\varepsilon},\infty)}\|S_S(j\omega)+S_F(j\varepsilon\omega)-S_S(\infty)\|_2\right\}. \end{aligned} \tag{A6}$$

We will show that the first term in braces satisfies the required inequality. The proof for the second term is done by an analogous process. Observe that for any $\varepsilon>0$ and $R>1$, the following set equality is valid:

$$[0,1/\sqrt{\varepsilon}]=[0,R]\cup\{\varepsilon^{-r}: 0<r\leqq\tfrac{1}{2}\}.$$

The function $S_S(s)$ has a power series expansion at ∞ that is valid for all $|s|>R_1$, for some R_1:

$$\begin{aligned} S_S(s) &= S_S(\infty)+\frac{S_{S1}}{s}+\frac{S_{S2}}{s^2}+\cdots \quad |s|>R_1. \\ &\triangleq P\left(\frac{1}{s}\right). \end{aligned} \tag{A7}$$

Let $R=\max\{1, R_1\}$.

The first term in braces in (A6) can be rewritten as

$$\sup_{\omega\in[0,1/\sqrt{\varepsilon}]}\|\hat{S}(j\omega,\varepsilon)\|_2 = \max\left\{\sup_{\omega\in[0,R]}\|\hat{S}(j\omega,\varepsilon)\|_2,\ \sup_{r\in(0^+,1/2]}\|\hat{S}(j\varepsilon^{-r},\varepsilon)\|_2\right\} \tag{A8}$$

The symbol 0^+ means that we do not sup over any r for which $\varepsilon^{-r} < R$. The first term in braces in (A8) is easily seen to be bounded by $\rho + O(\varepsilon)$. The second term in braces in (A8) can be rewritten, using (A7), as

$$\sup_{r\in(0^+,1/2]} \|\hat{S}(j\varepsilon^{-r}, \varepsilon)\|_2 = \sup_{r\in(0^+,1/2]} \|S_S(j\varepsilon^{-r}) + S_F(j\varepsilon^{1-r}) - S_S(\infty)\|_2$$

$$= \sup_{r\in(0^+,1/2]} \|P(-j\varepsilon^{r}) + S_F(j\varepsilon^{1-r}) - S_S(\infty)\|_2.$$

The result follows after making the identifications

$$A(z) = P(-z), \qquad B(z) = S_F(z) - S_S(\infty),$$

and applying Lemma A1. One final remark is in order. The $O(\varepsilon)$ result seems to require a lengthy proof. The weaker result

$$\|\hat{S}(j\omega, \varepsilon)\|_\infty \leqq \rho + O(\sqrt{\varepsilon})$$

is an almost immediate consequence of (A6).

COMPLEMENTARITY PROBLEMS OVER LOCALLY COMPACT CONES*

M. SEETHARAMA GOWDA†

Abstract. This paper proves an existence result for a complementarity problem (on a locally convex space) where the mapping is copositive, positive homogeneous, and of monotone type on a locally compact cone. A perturbation theorem is proved that extends a result of Mangasarian and Doverspike proved for $n \times n$ matrices on the nonnegative orthant.

Key words. copositive, positive homogeneous, locally compact cone, complementarity problem, Mackey topology

AMS(MOS) subject classifications. 49A99, 90C33

1. Introduction. Let (X, τ) be a real locally convex space, let K be a closed convex cone in X, and let q be in X^*. For a mapping $T: K \to X^*$, the *Complementarity Problem* (denoted by CP(X, T, K, q) or by CP(T, K, q) when X is fixed) is to find

$$x \in K \quad \text{such that } Tx + q \in K^* \quad \text{and} \quad \langle Tx + q, x \rangle = 0.$$

Here $K^* := \{y \in X^* : \langle y, k \rangle \geqq 0 \text{ for all } k \in K\}$, where $\langle y, x \rangle = y(x)$ for $y \in X^*$, $x \in X$. In the finite-dimensional setting, (linear) complementarity problems are related to linear (and quadratic) programming, bimatrix games, etc. (see Cottle and Dantzig [3]). Certain problems in engineering and economics can be posed as (linear) complementarity problems. In the infinite-dimensional setting, complementarity problems are related to variational inequalities. They also appear in certain engineering problems (see Cryer and Dempster [4], Isac [11], and references therein).

In this article, we prove an existence result (Theorem 1) for a copositive T that is positive homogeneous and of monotone type on a locally compact cone. We also state a perturbation result (Theorem 2) that extends a result of Mangasarian and Doverspike [16], [5] stated for matrices on $\mathbb{R}^n$. Banach space applications of our results can be obtained by working with the weak topology. Our results are new even in the finite-dimensional setting and generalize our earlier results in [8].

2. Preliminaries. (X, τ) denotes a real locally convex space. K, X^*, q, and T, respectively, denote a closed convex cone in X, the dual of X, an element of X^*, and a mapping from K into X^*. $\sigma(X, X^*)$ stands for the weak topology on X and $\sigma(X^*, X)$ denotes the *weak** topology on X^*. $\mathcal{M}(X^*, X)$ denotes the Mackey topology on X^*, which is the topology of uniform convergence on balanced, convex, $\sigma(X, X^*)$-compact subsets of X. (When X is a reflexive Banach space, Mackey topology coincides with the norm topology.) We use the result $(X^*, \mathcal{M}(X^*, X))^* = X$ (see Horvath [9, p. 205]). For $f \in X^*$, $x \in X$, $\langle f, x \rangle$ denotes $f(x)$. For $E \subseteq X$, $F \subseteq X^*$, we define $E^* := \{f \in X^* : \langle f, x \rangle \geqq 0 \text{ for all } x \in E\}$, $F^* := \{x \in X : \langle f, x \rangle \geqq 0 \text{ for all } f \in F\}$. We denote the *solution set* of CP(T, K, q) by Sol(T, K, q). We note that (since K is a cone) $x \in \text{Sol}(T, K, q)$ if and only if $\langle Tx + q, y - z \rangle \geqq 0$ for all $y \in K$. We say that:

(a) T is *copositive* on K if $\langle Tx, x \rangle \geqq 0$ for all $x \in K$.

(b) T is *copositive plus* on K if T is copositive on K and $x \in K$, $\langle Tx, x \rangle = 0 \Rightarrow \langle Tx, k \rangle + \langle Tk, x \rangle = 0$ for all $k \in K$.

* Received by the editors April 25, 1988; accepted for publication (in revised form) October 5, 1988.

† Department of Mathematics and Statistics, University of Maryland, Baltimore County, Baltimore, Maryland 21228.

(c) T is *copositive star* on K if T is copositive on K and $x \in K$, $Tx \in K^*$, $\langle Tx, x\rangle = 0 \Rightarrow -x \in (T(K))^*$.

(d) T is *pseudomonotone* on K if for all $x, y \in K$, $\langle Ty, x-y\rangle \geqq 0 \Rightarrow \langle Tx, x-y\rangle \geqq 0$.

(e) T is *positive homogeneous on* K if there is a positive γ such that $T(\lambda x) = \lambda^{\gamma} Tx$ for all $\lambda \geqq 0$, for all $x \in K$.

(f) T is of *monotone type* on K if either

(i) $x \to \langle Tx, x-y\rangle$ is lower semicontinuous on (K, τ) for each fixed $y \in K$, or

(ii) T is monotone on K (i.e., $\langle Tx - Ty, x-y\rangle \geqq 0$, for all $x, y \in K$) and semicontinuous on K (i.e., continuous from lines in K to $\sigma(X^*, X)$).

It can be easily shown that copositive plus mappings as well as pseudomonotone, positive homogeneous mappings are copositive star. In this article we deal with locally compact cones. Examples of locally compact cones include finite-dimensional cones and cones in the dual X^* of a normed linear space defined, for any $\alpha \in (0, 1)$ and $e \in X$, by $K = \{f \in X^*: \alpha \|f\| \leqq f(e)\}$.

When K is locally compact, K can be written as the direct sum of a finite dimensional subspace $M (= K \cap -K)$ of X and a cone L with compact base B given by $B = \{x \in L: \langle e, x\rangle = 1\}$ for some $e \in K^*$. (This follows from Thm. 3.12.8 of [13].)

For $x \in K$ we can write $x = \lambda b + m$ ($\lambda \geqq 0$, $m \in M$, $b \in B$) and define $g(x) := \lambda + \|m\| (= \langle e, x\rangle + \|Pm\|$ where P is the projection of X onto M). We see that $g(x)$ is continuous on (K, τ) and that the set $\{x \in K: g(x) = 1\}$ is compact. We observe that $\{x \in K: g(x) \leqq 1\}$ is compact and convex.

3. Results. Throughout this section we assume the following:

(a) T is copositive, positive homogeneous, and of monotone type on K;

(b) K is locally compact in (X, τ).

Let $S := \{x \in K: Tx \in K^*, \langle Tx, x\rangle = 0\}$. Recall that Sol (T, K, q) is the set of all solutions of CP (T, K, q).

THEOREM 1. *Suppose that* $0 \neq x \in S$ *implies* $\langle q, x\rangle > 0$. *Then* Sol $(T, K, q) \neq \emptyset$. *If further* $T: (K, \tau) \to (X^*, \sigma(X^*, X))$ *is continuous, then* Sol (T, K, q) *is compact in* (X, τ).

Proof. For the function g defined in § 2, we see that the set $\{x \in K: g(x) \leqq 1, \langle q, x\rangle \leqq 0\}$ is compact and convex. The argument in Theorem 1 (ii) of Borwein [2] then shows that the variational inequality

$$\tilde{H}(g, g, q): \langle Tx + (1 - g(x))q, y - x\rangle \geqq 0 \quad \forall y \in K, \quad g(y) \leqq 1, \quad \langle q, y\rangle \leqq 0$$

is solvable for some $x \in K$ with $g(x) \leqq 1$ and $\langle q, x\rangle \leqq 0$. Fix this x and define $f(y) := \langle Tx + (1 - g(x))q, y - x\rangle$, $(y \in K)$. Since zero solves CP (T, K, q) when $q \in K^*$, we can assume that $q \notin K^*$. Then there is a $k \in K$ such that $g(k) < 1$ and $\langle q, k\rangle < 0$. Thus, the convex program

$$f(x) = \min \{f(y): g(y) \leqq 1, \langle q, y\rangle \leqq 0, y \in K\}$$

satisfies the Slater condition. Hence, there are $t \geqq 0$ and $s \geqq 0$ such that

$$f(x) \leqq f(y) + t(g(y) - 1) + s\langle q, y\rangle \quad (\forall y \in K) \tag{3.1}$$

and $t(g(x) - 1) = 0 = s\langle q, x\rangle$ (cf. [10, Thm. 2, p. 68]). If $g(x) < 1$, then $t = 0$, and (3.1) leads to

$$\langle Tx + (1 - g(x) + s)q, y - x\rangle \geqq 0$$

(since $f(x) = 0$ and $s\langle q, x\rangle = 0$). Also, $g(x) < 1$ gives $1 - g(x) + s > 0$; hence (by homogeneity of T), $(1 - g(x) + s)^{-1/\gamma} x$ solves CP (T, K, q).

Now suppose that $g(x)=1$. Writing (3.1) in the subdifferential form (see, e.g., [10, Thm. 2′, p. 69]), we get

$$0 \in \partial f(x) + t\partial g(x) + sq - (K-x)^*.$$

In this case,

$$\langle Tx + tp + sq, y - x\rangle \geqq 0 \quad (\forall y \in K) \tag{3.2}$$

for some $p \in \partial g(x)$. From this we get $\langle Tx + tp + sq, x\rangle = 0$, i.e., $\langle Tx, x\rangle + t\langle p, x\rangle = 0$. Since $p \in \partial g(x)$ we have $\langle p, x\rangle \geqq g(x) = 1$; hence, $\langle Tx, x\rangle = 0$ (by copositivity of T) and $t\langle p, x\rangle = 0$, which leads to $t=0$. If $s=0$, then (3.2) gives $Tx \in K^*$ and $\langle Tx, x\rangle = 0$, i.e., $x \in S$. Since $g(x)=1$ and $\langle q, x\rangle \leqq 0$, this leads to a contradiction. Hence $s>0$, and in this case (3.2) shows (since $t=0$ and T is positive homogeneous) that $s^{-(1/\gamma)}x$ solves CP(T, K, q).

Now suppose that $T: (K, \tau) \to (X^*, \sigma(X^*, X))$ is continuous. From this it follows that the solution set of CP(T, K, q) is closed. To get compactness of this set (from the local compactness of K) it is enough to show that the solution set is bounded. Suppose, if possible, that $\{x_\alpha\}$ is an unbounded net (consisting of nonzero elements) in the solution set. Using the decomposition $K = L \oplus M$, we can write (as in § 2), $x_\alpha = \lambda_\alpha b_\alpha + m_\alpha$ and observe from the nonnegativity of λ_α that $g(x_\alpha) = \lambda_\alpha + \|m_\alpha\|$ is an unbounded net in $\mathbb{R}_+$. The net $\{g(x_\alpha)^{-1}x_\alpha\}$ is contained in the compact set $\{x \in K: g(x) = 1\}$; hence, a subnet $\{g(x_\beta)^{-1}x_\beta\}$ converges to, say, $\bar{x}$ (in K) such that $g(\bar{x})=1$.

Then $\langle Tx_\beta + q, y\rangle \geqq 0$ (for all $y \in K$, for all β) leads to $\langle T(g(x_\beta)^{-1}x_\beta) + qg(x_\beta)^{-\gamma}, y\rangle \geqq 0$, which, upon taking limits (and using the continuity of T), gives

$$\langle T\bar{x}, y\rangle \geqq 0 \quad (\forall y \in K). \tag{3.3}$$

Also,

$$\langle Tx_\beta, x_\beta\rangle + \langle q, x_\beta\rangle = 0 \quad (\forall \beta) \tag{3.4}$$

leads to $\langle q, x_\beta\rangle \leqq 0$ (by copositivity) and hence to $\langle q, g(x_\beta)^{-1}x_\beta\rangle \leqq 0$. Upon taking limits we get

$$\langle q, \bar{x}\rangle \leqq 0. \tag{3.5}$$

Further, (3.4) gives

$$\langle Tg(x_\beta)^{-1}x_\beta, g(x_\beta)^{-1}x_\beta\rangle + g(x_\beta)^{-\gamma}\langle q, g(x_\beta)^{-1}x_\beta\rangle = 0 \quad (\forall \beta).$$

Now continuity of T gives

$$\langle T\bar{x}, \bar{x}\rangle = 0. \tag{3.6}$$

We see that $\bar{x} \in S$ and $\langle q, \bar{x}\rangle \leqq 0$. This contradicts our hypothesis, since $g(\bar{x}) = 1$ implies that $\bar{x} \neq 0$. Thus Sol(T, K, q) is bounded, and compactness of this set follows. □

Remark 1. When $X = \mathbb{R}^n$ and T is an $n \times n$ matrix copositive on $\mathbb{R}^n_+$, LCP$(T, \mathbb{R}^n_+, q)$ is solvable for all $q \in S^*$. This is a result of Lemke [15, p. 104]. It can be easily shown that this same result holds when $\mathbb{R}^n_+$ is replaced by a polyhedral cone (Gowda [6]). However, for general cones, the implication $0 \neq x \in S \Rightarrow \langle q, x\rangle \geqq 0$ need not give the solvability of CP(T, K, q). This can be easily seen by taking in $\mathbb{R}^3$, $K = \{(x, y, z): x, z \geqq 0, 2xz \geqq y^2\}$, $T(x, y, z) = (x, y, 0)$, and $q = (1, 1, 0)$. (We observe that in this example, T is positive semidefinite and that CP(T, K, q) is feasible. Thus, on a nonpolyhedral cone, feasibility need not give solvability even for a positive semidefinite matrix.)

THEOREM 2. *Consider the following*:

(a) q *belongs to the* $\mathcal{M}$*-interior of the closed convex cone generated by* $K^* - T(K)$.

(b) $0 \neq x \in S \Rightarrow \langle q, x\rangle > 0$.

(c) CP(T, K, q) *has a solution.*

(d) CP(T, K, q) has a nonempty compact solution set.

We have the following:

(i) *If* T *is copositive star on* K *then* (a)$\Rightarrow$(b)$\Rightarrow$(c).

(ii) *If* T *is copositive star and* T *is continuous from* (K, τ) *into* $(X^*, \sigma(X^*, X))$, *then* (a)$\Rightarrow$(b)$\Rightarrow$(d).

(iii) *If* T *is copositive plus, linear, and continuous from* (K, τ) *into* $(X^*, \sigma(X^*, X))$, *then* (a)$\Leftrightarrow$(b)$\Leftrightarrow$(d).

Proof. (i) Let T be copositive star on K. In view of Theorem 1, we need only show that (a)$\Rightarrow$(b) and to this end suppose that (b) is false. Then there exist $x \neq 0$, $x \in S$, and $\langle q, x\rangle \leqq 0$. We have $-x \in (TK)^*$; hence,

$$\langle q, x\rangle \leqq 0 \leqq \langle k^* - T(k), x\rangle \quad \forall k^* \in K^*, \quad k \in K.$$

This says that q can be separated from $K^* - T(K)$ by a hyperplane, i.e., (a) is false.

(ii) This part follows from Theorem 1 and (i).

(iii) (d)$\Rightarrow$(b): Suppose there is a $d(\neq 0)$ in S such that $\langle q, d\rangle \leqq 0$. Let x be any solution of CP(T, K, q). Since T is copositive plus, we have $\langle Tx, d\rangle + \langle Td, x\rangle = 0$. We see from the linearity of T that $T(x + \lambda d) + q \in K^*$ (for all $\lambda \geqq 0$) and

$$\begin{aligned}\langle T(x+\lambda d), x+\lambda d\rangle &= \langle Tx + q, x\rangle + \lambda\{\langle Tx, d\rangle + \langle Td, x\rangle\} + \lambda^2\langle Td, d\rangle + \langle q, d\rangle \\ &= \langle q, d\rangle \leqq 0.\end{aligned}$$

But this says that $x + \lambda d$ solves CP(T, K, q) for all $\lambda \geqq 0$, contradicting the compactness of the solution set. Thus (d)$\Rightarrow$(b).

(b)$\Rightarrow$(a): Suppose that (a) is false. Then there is a net $\{q_\alpha\}$ such that $q_\alpha \notin \mathcal{M}$-closed convex cone generated by $K^* - T(K)$ and $q_\alpha \to q$ in $(X^*, \mathcal{M})$. Using $(X^*, \mathcal{M})^* = X$ and a separation theorem, we get $x_\alpha (\neq 0) \in X$ such that

$$\langle q_\alpha, x_\alpha\rangle < 0 \leqq \langle k^* - T(k), x_\alpha\rangle \quad \forall k^* \in K^*, \quad k \in K, \quad \forall \alpha.$$

This shows that $x_\alpha \in K$, $\langle Tx_\alpha, x_\alpha\rangle = 0$, and $\langle -Tk, x_\alpha\rangle \geqq 0$ for all $k \in K$, for all α. From this we get

$$\begin{aligned}\langle Tx_\alpha, k\rangle &= \langle Tx_\alpha, k\rangle + \langle Tk, x_\alpha\rangle - \langle Tk, x_\alpha\rangle \\ &= 0 - \langle Tk, x_\alpha\rangle \quad \text{(since } T \text{ is copositive plus)} \\ &\geqq 0 \quad \forall k \in K, \quad \forall \alpha.\end{aligned}$$

Thus $0 \neq x_\alpha \in S$. As in the proof of Theorem 1, we can show that $g(x_\alpha)^{-1}x_\alpha$ has a subnet $g(x_\beta)^{-1}x_\beta$ converging to, say, $\bar{x}$. This $\bar{x} \neq 0$ and is in S. Now the set $E := \{x \in K : g(x) \leqq 1\}$ is compact convex in τ and hence in $\sigma(X, X^*)$. The balanced hull $[-1, 1]E$ of this set is also compact convex in $\sigma(X, X^*)$.

Since $q_\beta \to q$ in $\mathcal{M}$ and $g(x_\beta)^{-1}x_\beta \to \bar{x}$ in E, we have

$$\langle q, \bar{x}\rangle = \lim \langle q_\beta, g(x_\beta)^{-1}x_\beta\rangle \leqq 0.$$

Thus $0 \neq \bar{x} \in S$ and $\langle q, \bar{x}\rangle \leqq 0$, i.e., (b) fails.

Hence (b)$\Rightarrow$(a). □

Remark 2. The proof of (b)$\Rightarrow$(a) in (iii) is valid if T is copositive, linear, and continuous (because in this situation, $x \in K$, $\langle Tx, x\rangle = 0 \Rightarrow \langle Tx, k\rangle + \langle Tk, x\rangle \geqq 0$ for all $k \in K$).

Remark 3. Theorem 2(iii) generalizes our earlier Hilbert space results (Theorems 4.1 and 6.1 of [8]), where a condition equivalent to the local compactness condition has been used. When $X=\mathbb{R}^n$, $K=\mathbb{R}^n_+$, and T is an $n\times n$ copositive plus matrix, the equivalence of (a) and (d) is the well-known result of Mangasarian and Doverspike [16], [5] that CP$(T,\mathbb{R}^n_+,\bar{q})$ is feasible for all $\bar{q}$ near q and only if CP$(T,\mathbb{R}^n_+,q)$ has compact solution set.

Remark 4. In [1] Allen proves that if there is an $x_0\in K$ such that $F(x_0)\in \mathcal{M}$-int(K^*), where $F(x):=Tx+q$ is pseudomonotone and $\langle Tx, x\rangle$ is weak lower semicontinuous on K, then CP(T,K,q) has a solution. (As Isac [12] shows, we need the weak lower semicontinuity of $x\to\langle Tx, x-y\rangle$ for any $y\in K$ to get this result.) This is different from our results even for matrices. While Allen assumes the pseudomonotonicity of $x\to Tx+q$ and gets the solvability of CP(T,K,q), we assume the pseudomonotonicity (rather, the copositive star property) of T and get the solvability of CP(T,K,q) for *any* $q\in$ int$(K^*-T(K))$. We wish to note that pseudomonotonicity of T need not imply the pseudomonotonicity of the mapping $x\to Tx+q$. For example, let

$$T=\begin{bmatrix}0 & -1\\ 2 & 0\end{bmatrix},\quad q=\begin{bmatrix}1\\ -2\end{bmatrix},\quad u=\begin{bmatrix}1\\ 1\end{bmatrix},\quad v=\begin{bmatrix}2\\ 0\end{bmatrix}.$$

It is easily seen that T is pseudomonotone on $\mathbb{R}^2_+$ (see, e.g., [7]) while the mapping $x\to Tx+q$ is not (since $\langle Tu+q, v-u\rangle=0$ and $\langle Tv+q, v-u\rangle=-1$).

THEOREM 3. *Consider the following*:

(a) $S=\{0\}$;

(b) CP(T,K,q) *has a solution for all* $q\in X^*$;

(c) CP(T,K,q) *is feasible for all* $q\in X^*$.

We have the following:

(i) (a)$\Rightarrow$(b)$\Rightarrow$(c).

(ii) *If* T *is copositive star on* K *then* $(a)\Leftrightarrow(b)\Leftrightarrow(c)$.

Proof. (i) (a)$\Rightarrow$(b) follows from Theorem 1. (b)$\Rightarrow$(c) is obvious.

(ii) Let T be copositive star on K. If (a) is false then there is a $d\neq 0$ such that $d\in K$, $Td\in K^*$, and $\langle Td, d\rangle=0$. Since T is copositive star we have $\langle Tx, d\rangle\leqq 0$, for all $x\in K$. Hence $\langle Tx-d, d\rangle<0$, showing the infeasibility of CP$(T,K,-d)$. Thus (c) is false and (c)$\Rightarrow$(a). □

Remark 5. Theorem 3(i) also follows from Theorem 5 in Borwein [2]. Theorem 3(ii) extends Corollary 7 in Borwein [2], where it is proved for copositive plus (linear) mappings.

WEIGHTED OPTIMIZATION THEORY FOR NONLINEAR SYSTEMS*

CIPRIAN FOIAS† AND ALLEN TANNENBAUM‡

Abstract. In this paper, the solution of a nonlinear version of the weighted sensitivity H^∞-optimization problem is discussed. It is shown that the natural object to be considered in this context is a certain "sensitivity operator," which will be optimized locally in a given "energy ball" (see § 5 for the details). In the linear case, the authors are reduced again to the classical sensitivity minimization technique of Zames [21]. The methods were very strongly influenced by the complex analytic power series ideas of [3], [4], [5]. See also the recent results of Ball and Helton [6] for another approach to this subject.

Key words. sensitivity operator, nonlinear control, dilation theory, skew Toeplitz operator

AMS(MOS) subject classifications. 93B35, 93C05

1. Introduction. Recently, there has been a great deal of research devoted to the weighted H^∞-optimization of linear systems. See [13] for a rather extensive list of references. Much of the underlying theory for this work has been based on the ideas of Adamjan, Arov, and Krein [1], generalized interpolation theory in H^∞ due to Sarason [17], and, most generally, on the Sz.-Nagy–Foias commutant lifting theorem [19].

In the papers [3], [4] an extension of the commutant lifting theorem to a local nonlinear setting was given, together with a discussion of how this result could be used to develop a design procedure for nonlinear systems. In the present paper, we continue this line of research with a constructive extension of the linear H^∞ theory to nonlinear systems. We should note that our colleagues Ball and Helton [6] have developed a completely different, novel approach to this problem based on a nonlinear version of Ball–Helton theory.

In the theory presented below, we will consider majorizable input/output operators (see § 3 for the precise definition). In particular, these operators are analytic in a ball around the origin in a complex Hilbert space, and it turns out that it is possible to express each n-linear term of the Taylor expansion of such an operator as a linear operator on a certain tensor space. (Our class of operators also includes Volterra series of fading memory [8].) This allows us to iteratively apply the classical commutant lifting theorem in designing a compensator. (The general technique we call the *iterative commutant lifting procedure.* See § 6 for the details.) For single input/single output (SISO) systems, this leads to the construction of a compensator which is optimal relative to a certain sensitivity function that will be defined in § 5. Moreover, in complete generality (i.e., for multiple input/multiple output (MIMO) systems), our procedure will ameliorate (in the sense of our nonlinear weighted sensitivity criterion) any given design. We note that for linear systems, our method reduces to the standard H^∞ design technique as discussed, for example, in [13] and initiated in [21].

In developing the present theory, we have had to extend some of the skew Toeplitz techniques of [7] and [11] to linear operators defined on certain tensor spaces. This

has led to several novel results in computational operator theory, and, for example, provides a way of iteratively constructing the nonlinear intertwining dilation of the nonlinear commutant lifting theorem considered in [3] and [4]. Moreover, we provide a generalization of a formula due to Sarason [17] for the optimal interpolant in terms of a maximal vector. See § 8 for the details.

An important point is that many of our results are constructive and lead to physically implementable compensators. In fact, we reduce a nonlinear optimization problem to an iterative linear procedure, each step of which we know how to solve. This is illustrated by an example in § 9.

2. Analytic mappings on Hilbert space. We would like to discuss here a few standard results about analytic mappings on Hilbert spaces. We are essentially following the treatments of [3]–[5] and [8] to which the reader may refer for all of the details. In particular, input/output operators that admit Volterra expansions are special cases of the operators which we study here. See [8], [16], [20].

Let G and H denote complex Hilbert spaces. Set

$$B_{r_o}(G) := \{g \in G: \|g\| < r_o\}$$

(the open ball of radius r_o in G about the origin). Then we say that a mapping $\phi: B_{r_o}(G) \to H$ is *analytic* if the complex function $(z_1, \cdots, z_n) \to \langle \phi(z_1 g_1 + \cdots + z_n g_n), h\rangle$ is analytic in a neighborhood of $(1, 1, \cdots, 1) \in \mathbf{C}^n$ as a function of the complex variables $z_1, \cdots, z_n$ for all $g_1, \cdots, g_n \in G$ such that $\|g_1 + \cdots + g_n\| < r_o$, for all $h \in H$, and for all $n > 0$. (Note that we denote the Hilbert space norms in G and H by $\|\ \|$ and the inner products by $\langle\ ,\ \rangle$.)

We will now assume that $\phi(0) = 0$. It is easy to see that if $\phi: B_{r_o}(G) \to H$ is analytic, then ϕ admits a convergent Taylor series expansion, i.e.,

$$\phi(g) = \phi_1(g) + \phi_2(g, g) + \cdots + \phi_n(g, \cdots, g) + \cdots,$$

where $\phi_n: G \times \cdots \times G \to H$ is an n-linear map. Clearly, without loss of generality we may assume that the n-linear map $(g_1, \cdots, g_n) \to \phi_n(g_1, \cdots, g_n)$ is symmetric in the arguments $g_1, \cdots, g_n$. This assumption will be made throughout this paper for the various analytic maps that we consider. For ϕ a Volterra series, ϕ_n is basically the nth-Volterra kernel.

Now set

$$\hat{\phi}_n(g_1 \otimes \cdots \otimes g_n) := \phi_n(g_1, \cdots, g_n).$$

Then $\hat{\phi}_n$ extends in a unique manner to a dense subset of $G^{\otimes n} := G \otimes \cdots \otimes G$ (tensor product taken n times). Note by $G^{\otimes n}$ we mean the Hilbert space completion of the algebraic tensor product of the G's. Clearly if $\hat{\phi}_n$ has finite norm on this dense subset, then $\hat{\phi}_n$ extends by continuity to a bounded linear operator $\hat{\phi}_n: G^{\otimes n} \to H$. By abuse of notation, we will set $\phi_n := \hat{\phi}_n$, and $\phi_n(g) := \phi_n(g \otimes \cdots \otimes g)$ (the tensor product taken n times).

It is important to note that in principle we can determine ϕ_n quite easily from the input/output operator ϕ. Indeed, we have the following elementary lemma.

LEMMA 2.1. *Let $\phi: B_{r_o}(G) \to H$ be analytic, $\phi(0) = 0$. Suppose, moreover, that if*

$$\phi(g) = \phi_1(g) + \cdots \phi_n(g) + \cdots,$$

then each of the ϕ_n defines a bounded linear operator $G^{\otimes n} \to H$ as above (and is symmetric in its arguments). Then for $g_j \in G$ $(j = 1, \cdots, n)$ with $\|g_1\| = \cdots = \|g_n\| < r_o$, we have

$$n!\,\phi_n(g_1 \otimes \cdots \otimes g_n) = \frac{1}{(2\pi)^n} \int_0^{2\pi} \cdots \int_0^{2\pi} \phi(\exp(i\theta_1)g_1 + \cdots + \exp(i\theta_n)g_n) \times \exp(-i(\theta_1 + \cdots + \theta_n))\, d\theta_1 \cdots d\theta_n.$$

Proof. Expand $\phi(z_1g_1+\cdots+z_ng_n)$ in powers of $z_1, \cdots, z_n$. Then it is easy to see that the coefficient of $z_1 \cdots z_n$ is precisely $n!\phi_n(g_1\otimes\cdots\otimes g_n)$. The required result then follows immediately from the Cauchy formula. □

Remark 2.2. We should note that if ϕ is analytic, then each ϕ_n is continuous (as an n-multilinear map); hence, the associated linear map extends to the nth projective power of G. Lemma 2.1 is valid in this more general situation as well.

We now conclude this section with two key definitions.

DEFINITION 2.3. (i) Notation as above. By a *majorizing sequence* for the holomorphic map ϕ, we mean a sequence of positive numbers α_n $n = 1, 2, \cdots$ such that $\|\phi_n\| < \alpha_n$ for $n \geqq 1$. Suppose that $\rho := \limsup \alpha_n^{1/n} < \infty$. Then it is completely standard ([8]) that the Taylor series expansion of ϕ converges at least on the ball $B_r(G)$ of radius $r = 1/\rho$.

(ii) If ϕ admits a majorizing sequence as in (i), then we will say that ϕ is *majorizable.*

We will see in the next section that a very important class of input/output operators from systems and control theory are in point of fact majorizable.

3. Operators with fading memory. In this section, we will show that perhaps the most natural class of input/output operators from the systems standpoint are majorizable. Moreover, for this class of operators we will even derive an a priori majorizing sequence. We begin with the following key definition:

DEFINITION 3.1. An analytic map $\phi: B_{r_0}(G) \to H$, $\phi(0) = 0$ has *fading memory* if its nonlinear part $\phi - \phi'(0)$ admits a factorization

$$\phi - \phi'(0) = \hat{\phi} \circ W,$$

where $\hat{\phi}$ is an analytic map defined in some neighborhood of $0 \in G$, and W is a linear Hilbert-Schmidt operator. (In this case, we can assume that there exists an orthonormal basis of eigenvectors for W in G, $\{e_k\}$, $k = 1, 2, \cdots$ such that $We_k = \lambda_k e_k$ with

$$\|W\|_2^2 := \sum_{k=1}^{\infty} |\lambda_k|^2 < \infty.$$

$\|W\|_2$ is called the *Hilbert-Schmidt norm* of W.)

Remark 3.2. System-theoretically fading memory input/output operators have the property that any two input signals, which are close in the recent past but not necessarily close in the remote past, will yield present outputs which are close. For more details about this important class of operators, see [8].

For fading memory operators, we can construct an explicit majorizing sequence.

LEMMA 3.3. *Let $\phi: B_{r_0}(G) \to H$, $\phi(0) = 0$, have fading memory. Suppose, moreover, that if we write*

$$\phi - \phi'(0) = \hat{\phi} \circ W$$

as in (3.1), *then $\hat{\phi}: B_{r_1}(G) \to B_{r_2}(H)$. Then the sequence*

$$\alpha_1 := \|\phi'(0)\|$$

$$\alpha_n := \frac{r_2 e^n \|W\|_2^n}{r_1^n}$$

for $n \geqq 2$, is a majorizing sequence for ϕ.

Proof. For complete details see [4, Lemma (3.5)]. However, since we will need some estimates from the proof for Proposition (3.5) below, we will give an outline.

First, without loss of generality we may assume that W is positive. Since $\hat{\phi}: B_{r_1}(G) \to B_{r_2}(H)$, from (2.1) we obtain

$$\|\phi_n(g_1 \otimes \cdots \otimes g_n)\| \leqq \frac{1}{n!} r_2,$$

for $\|g_1\| = \cdots = \|g_n\| \leqq r_1/n$.

Now, since $\{e_{i_1} \otimes \cdots \otimes e_{i_n}: 1 \leqq i_1, \cdots, i_n\}$ is an orthonormal basis of $G^{\otimes n}$, we can write $g \in G^{\otimes n}$ as

$$\sum_{1 \leqq i_1, \cdots, i_n}^{\infty} \alpha_{i_1 \cdots i_n} e_{i_1} \otimes \cdots \otimes e_{i_n}$$

and

$$\|\hat{g}\|^2 = \sum_{1 \leqq i_1, \cdots, i_n}^{\infty} |\alpha_{i_1 \cdots i_n}|^2 < \infty.$$

Now, from the above we can easily compute (see [4] for the details) that

$$\begin{aligned}
&\left\| \phi_n \left(\sum_{1 \leqq i_1, \cdots, i_n}^{\infty} \alpha_{i_1 \cdots i_n} e_{i_1} \otimes \cdots \otimes e_{i_n} \right) \right\| \\
&\qquad \leqq \frac{n^n}{r_1^n} \sum |\lambda_{i_1} \cdots \lambda_{i_n} \alpha_{i_1 \cdots i_n}| \left\| \hat{\phi}_n \left(\frac{r_1}{n} e_{i_1} \otimes \cdots \otimes \frac{r_1}{n} e_{i_n} \right) \right\| \\
&\qquad \leqq \frac{n^n}{r_1^n} \frac{r_2}{n!} \sum |\lambda_{i_1} \cdots \lambda_{i_n} \alpha_{i_1 \cdots i_n}| \\
&\qquad \leqq \frac{n^n}{r_1^n} \frac{r_2}{n!} \|W\|_2^n \| \sum \alpha_{i_1 \cdots i_n} e_{i_1} \otimes \cdots \otimes e_{i_n} \|.
\end{aligned}$$

This implies that

$$\|\phi_n\| \leqq \frac{n^n}{r_1^n} \frac{r_2}{n!} \|W\|_2^n \leqq r_2 \frac{e^n}{r_1^n} \|W\|_2^n$$

for $n \geqq 2$ as required. □

Remark 3.4. (i) From the above proof it follows that $\hat{\alpha}_n$, where

$$\hat{\alpha}_1 := \|\phi'(0)\|$$

$$\hat{\alpha}_n := \frac{n^n r_2 \|W\|_2^n}{n! r_1^n} \quad \text{for } n \geqq 2$$

is a majorizing sequence for ϕ. In computations it turns out that it is easier to work with the majorizing sequence α_n given in the formulation of Lemma 3.3.

(ii) Note, moreover, we have that

$$\rho := \limsup (\alpha_n)^{1/n} = \frac{e\|W\|_2}{r_1}.$$

(iii) In what follows, we will assume that all of the input/output operators we consider are causal and are majorizable.

An interesting and useful property of fading memory operators is the following proposition.

PROPOSITION 3.5. *The notation and hypotheses are as in Lemma* 3.3. *Then each* ϕ_n (*regarded as a linear operator on* $G^{\otimes n}$) *is compact for* $n \geqq 2$.

Proof. Let the sequence in $G^{\otimes n}$

$$x^{(k)} := \sum_{i_1,\cdots,i_n=1}^{\infty} \alpha_{i_1\cdots i_n}^{(k)} e_{i_1} \otimes \cdots \otimes e_{i_n} \to 0$$

weakly. Define a projection in G for each natural number $N > 0$ by

$$P_N e_j = \begin{cases} 0 & j \leqq N \\ e_j & j \geqq N+1. \end{cases}$$

Then from the above proof of Lemma 3.3, for fixed n, we have that there exist constants C and $\hat{C}$ such that

$$\begin{aligned} \|\phi_n(x^{(k)})\| &\leqq C \sum_{i_1,i_2,\cdots,i_n \geqq 1} |\lambda_{i_1} \cdots \lambda_{i_n} \alpha_{i_1\cdots i_n}^{(k)}| \\ &\leqq C \sum_{i_1,i_2,\cdots,i_n \leqq N} |\lambda_{i_1} \cdots \lambda_{i_n} \alpha_{i_1\cdots i_n}^{(k)}| + \hat{C} \| WP_N \|_2 \| W \|_2^{n-1}. \end{aligned}$$

Thus,

$$\limsup \|\phi_n(x^{(k)})\| \leqq \hat{C} \| WP_N \|_2 \| W \|_2^{n-1}.$$

Hence as $N \to \infty$, we see that

$$\limsup \|\phi_n(x^{(k)})\| = 0,$$

which shows that ϕ_n is compact. □

4. Control theoretic preliminaries. We start here with the control problem definition. First, we will need to consider the precise kind of input/output operator we will be considering. See [3], [4] for closely related discussions. As mentioned above, we are assuming that all of the operators we consider are causal and are majorizable. For a discussion of causality in the nonlinear context, see [3]–[6]. Throughout this paper, $H^2(\mathbf{C}^k)$ will denote the standard Hardy space of $\mathbf{C}^k$-valued functions on the unit circle (k may be infinite, i.e., in this case $\mathbf{C}^k$ is replaced by h^2, the space of one-sided square-summable sequences). We now have the following definition.

DEFINITION 4.1. Let $S: H^2(\mathbf{C}^k) \to H^2(\mathbf{C}^k)$ denote the canonical unilateral right shift. Then we say an input/output operator ϕ is *locally stable* if it is causal and majorizable, $\phi(0) = 0$, and if there exists an $r > 0$ such that $\phi: B_r(H^2(\mathbf{C}^k)) \to H^2(\mathbf{C}^k)$ with $S\phi = \phi \circ S$ on $B_r(H^2(\mathbf{C}^k))$. We set

$$C_l := \{\text{space of locally stable operators}\}.$$

Since the theory we are considering is local, the notion of local stability is sufficient for all of the applications we have in mind. The interested reader can compare this notion with the more global notions of stability as, for example, discussed in [6].

The theory we are about to give holds for all plants which admit coprime locally stable factorizations. However, for simplicity we will assume that our plant is also locally stable. Accordingly, let P, W denote locally stable operators, with W invertible. Referring to Fig. 1, P represents the plant, and W the weight or filter. Now we say that the feedback compensator C *locally stabilizes* the closed loop if the operators

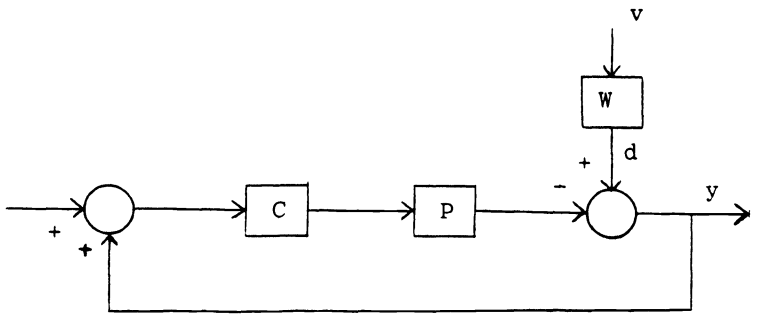

FIG. 1

$(I+P\circ C)^{-1}$ and $C\circ(I+P\circ C)^{-1}$ are well defined and locally stable. By a result of [2], C locally stabilizes the closed loop if and only if

$$C=\hat{q}\circ(I-P\circ\hat{q})^{-1} \tag{1}$$

for some $\hat{q}\in C_l$. Note then that the weighted sensitivity $(I+P\circ C)^{-1}\circ W$ can be written as $W-P\circ q$, where $q:=\hat{q}\circ W$. (Since W is invertible, the data q and $\hat{q}$ are equivalent.) In this context, we will call such a q a *compensating parameter.* From the compensating parameter q, we get a locally stabilizing compensator C via the formula (1).

The problem we would like to solve here is a version of the classical disturbance attenuation problem associated to the feedback loop in Fig. 1 (see [7], [21]). This, of course, corresponds to the "minimization" of the "sensitivity" $W-P\circ q$ taken over all locally stable q. In order to formulate a precise mathematical problem, we need to say in what sense we want to minimize $W-P\circ q$. This we will do in the next section where we will propose a notion of "sensitivity minimization" which seems quite natural to analytic input/output operators.

5. Sensitivity function. In this section we define a fundamental object, namely a nonlinear version of *sensitivity.* We will see that while the optimal H^∞ sensitivity is a real number in the linear case, the measure of performance which seems to be more natural in this nonlinear setting is a certain function defined in a real interval.

In order to define our notion of sensitivity, we will first have to partially order the space of analytic mappings defined in a ball about the origin. All of the input/output operators here will be locally stable. We also follow here our convention that for given $\phi\in C_l$, ϕ_n will denote the bounded linear map on the tensor space $(H^2(\mathbf{C}^k))^{\otimes n}$ associated with the n-linear part of ϕ, which we also denote by ϕ_n (and which we always assume without loss of generality is symmetric in its arguments). The context will always make the meaning of ϕ_n clear.

We can now state the following key definitions.

DEFINITION 5.1. (i) For $W, P, q\in C_l$ (W is the weight, P the plant, and q the compensating parameter), we define the *sensitivity functions* $S(q)$,

$$S(q)(\rho):=\sum_{n=1}\rho^n\|(W-P\circ q)_n\|$$

for all $\rho>0$ such that the sum converges. Note that for fixed P and W, for each $q\in C_l$, we get an associated sensitivity function.

(ii) We write $S(q)\lesssim S(\tilde{q})$, if there exists a $\rho_o>0$ such that $S(q)(\rho)\leqq S(\tilde{q})(\rho)$ for all $\rho\in[0,\rho_o]$. If $S(q)\lesssim S(\tilde{q})$ and $S(\tilde{q})\lesssim S(q)$, we write $S(q)\cong S(\tilde{q})$. This means that $S(q)(\rho)=S(\tilde{q})(\rho)$ for all $\rho>0$ sufficiently small, i.e., $S(q)$ and $S(\tilde{q})$ are equal as germs of functions.

(iii) If $S(q) \lesssim S(\tilde{q})$, but $S(\tilde{q}) \not\lesssim S(q)$, we will say that q *ameliorates* $\tilde{q}$. Note that this means $S(q)(\rho) < S(\tilde{q})(\rho)$ for all $\rho > 0$ sufficiently small.

Now with Definition 5.1, we can define a notion of "optimality" relative to the sensitivity function.

DEFINITION 5.2. (i) $q_o \in C_l$ is called *optimal* if $S(q_o) \lesssim S(q)$ for all $q \in C_l$.

(ii) We say $q \in C_l$ is *optimal with respect to its* nth *term* q_n, if for every n-linear $\hat{q}_n \in C_l$, we have

$$S(q_1 + \cdots + q_{n-1} + q_n + q_{n+1} \cdots) \lesssim S(q_1 + \cdots + q_{n-1} + \hat{q}_n + q_{n+1} + \cdots).$$

If $q \in C_l$ is optimal with respect to all of its terms, then we say that it is *partially optimal.*

Clearly, if q is optimal, then it is partially optimal; however, the converse may not hold. Note, moreover, that if ϕ is a Volterra series, then our definition of sensitivity measures in a precise sense the amplification of energy of each Volterra kernel on signals whose energy is bounded by a given ρ. For this reason, it appears that in this context, Definition 5.1 of the sensitivity function $S(q)$ seems physically natural. In the next section, we will discuss a procedure for constructing partially optimal compensating parameters, and then in § 7 we will show how this procedure leads to the construction of optimal compensating parameters for SISO systems. Of course, from formula (1) above, we can derive the corresponding partially optimal (respectively, optimal) compensator from the partially optimal (respectively, optimal) compensating parameter.

6. Iterative commutant lifting method. In this section, we discuss the main construction of this paper from which we will derive both partially optimal and optimal compensators relative to the sensitivity function given in Definition 5.1 above. As before, P will denote the plant and W the weighting operator, both of which we assume are locally stable. As in the linear case, we always suppose that P_1 is an isometry, i.e. P_1 is *inner.* In order to state our results, we will need to make a few preliminary remarks and set up some notation.

We begin by noting the following key relationship:

$$(W - P \circ q)_k = W_k - \sum_{1 \leqq j \leqq k} \sum_{i_1 + \cdots + i_j = k} P_j(q_{i_1} \otimes \cdots \otimes q_{i_j}).$$

Note that once again for ϕ majorizable, ϕ_n denotes the n-linear part of ϕ, as well as the associated linear operator on the appropriate tensor space.

We are now ready to formulate the *iterative commutant lifting procedure.* Let $\Pi : H^2(\mathbf{C}^k) \to H^2(\mathbf{C}^k) \ominus P_1 H^2(\mathbf{C}^k)$ denote orthogonal projection. Using the linear commutant lifting theorem (CLT) (see [19] for the details), we may choose q_1 such that

$$\| W_1 - P_1 q_1 \| = \| \Pi W_1 \|.$$

Now given this q_1, we choose (using the CLT) q_2 such that

$$\| W_2 - P_2(q_1 \otimes q_1) - P_1 q_2 \| = \| \Pi(W_2 - P_2(q_1 \otimes q_1)) \|.$$

Inductively, given $q_1, \cdots, q_{n-1}$, set

$$A_n := (W_n - \sum_{2 \leqq j \leqq n} \sum_{i_1 + \cdots + i_j = n} P_j(q_{i_1} \otimes \cdots \otimes q_{i_j})) \tag{2}$$

for $n \geqq 2$. Then from the CLT, we may choose q_n such that

$$\| A_n - P_1 q_n \| = \| \Pi A_n \|. \tag{2a}$$

We now come to the key point on the convergence of the iterative commutant lifting method.

PROPOSITION 6.1. *With the above notation, let* $q^{(1)} := q_1 + q_2 + \cdots$. *Then* $q^{(1)} \in C_l$.

Proof. It suffices to show that $\sum \|q_n\| \rho^n$ converges for all $0 \leqq \rho$ sufficiently small. Then from (2a)

$$\|A_n - P_1 q_n\| = \|\Pi A_n\| \leqq \|A_n\|$$

and so (using the fact that P_1 is an isometry)

$$\|q_n\| \leqq 2\|A_n\| \leqq 2\|W_n\| + 2 \sum_{2 \leqq j \leqq n} \sum_{i_1 + \cdots + i_j = n} \|P_j(q_{i_1} \otimes \cdots \otimes q_{i_j})\|. \tag{3}$$

Clearly from the majorizability hypothesis, we can find positive constants M_o, R_o, M, R such that

$$\|W_i\| \leqq \tfrac{1}{2} M_o R_o^i \tag{4}$$

$$\|P_j\| \leqq \tfrac{1}{2} M R^j \tag{5}$$

for $i \geqq 1$, and for $j \geqq 2$. Thus, $\|q_1\| \leqq M_o R_o$ and

$$\|q_n\| \leqq M_o R_o^n + \sum_{2 \leqq j \leqq n} M R^j \sum_{i_1 + \cdots + i_j = n} \|q_{i_1}\| \cdots \|q_{i_j}\| \tag{6}$$

for $n \geqq 2$. Let $f(z) = \sum_{n=0}^{\infty} f_n z^n$, and $g(z) = \sum_{n=0}^{\infty} g_n z^n$ be formal power series. Then we write $f \ll g$ if $|f_n| \leqq |g_n|$ for all $n \geqq 0$.

We introduce the notation

$$\tilde{q}(z) := \sum_{n=1}^{\infty} \|q_n\| z^n$$

$$a(z) := \sum_{n=1}^{\infty} M_o R_o^n z^n$$

$$b(z) := \sum_{n=2}^{\infty} M R^n z^n.$$

With this notation, (3) may be equivalently written as

$$\tilde{q}(z) \ll a(z) + b(\tilde{q}(z)). \tag{7}$$

Now (formally) define

$$\mu(z) \equiv a(z) + b(\mu(z)).$$

Then we claim the following:

(i) $\mu(z) \gg 0$;

(ii) $\tilde{q}(z) \ll \mu(z)$;

(iii) μ is analytic in some sufficiently small neighborhood of zero.

Clearly, the verification of this claim would complete the proof of the proposition.

In order to do this, let f be analytic in some ball of radius r_o centered at the origin. Then we set

$$\|f\|_{(r)} := \sup \{|f(z)| : |z| \leqq r\}$$

for $r < r_o$. Next, we define an operator on the set of analytic functions defined in some neighborhood of the origin by $F(f) := a + b(f)$ whenever $F(f)$ is well defined as an analytic function near zero. Then for given $\delta > 0$, and $r \leqq 1/2R_o < 1/R_o$ (this choice for r will be made clear below), we let

$$B := \{f \text{ analytic near } 0 : \|f - a\|_{(r)} \leqq \delta\}.$$

We want to choose δ, such that F is well defined in B, $F: B \to B$, and such that F is contractive in B.

Now it is easy to see that

$$\|f\|_{(r)} \leqq \delta + \|a\|_{(r)} \leqq \delta + \frac{M_o R_o r}{1 - R_o r} \leqq \delta + 2M_o R_o r.$$

Clearly, we can choose r, δ such that

$$0 < \delta + 2M_o R_o r \leqq \frac{1}{2R} < \frac{1}{R}. \tag{8a}$$

However,

$$\|F(f) - a\|_{(r)} \leqq \|b(f)\|_{(r)} \leqq \frac{MR^2(\delta + 2M_o R_o r)^2}{1 - (\delta + 2M_o R_o r)R} \leqq 2MR^2(\delta + 2M_o R_o r)^2. \tag{8b}$$

We require then that δ and r satisfy

$$2MR^2(\delta + 2M_o R_o r)^2 \leqq \delta. \tag{9}$$

With these choices we clearly have that $F: B \to B$. Now

$$\begin{aligned}
\|F(f) - F(g)\|_{(r)} \leqq \|b(f) - b(g)\|_{(r)} &\leqq \left\| \frac{M^2 f^2}{1 - Mf} - \frac{M^2 g^2}{1 - Mg} \right\|_{(r)} \\
&\leqq \left\| \frac{M^2(f^2 - g^2)}{1 - Mf} \right\|_{(r)} + M^2 \|g^2\|_{(r)} \left\| \frac{1}{1 - Mf} - \frac{1}{1 - Mg} \right\|_{(r)} \\
&\leqq 2M^2 \|f + g\|_{(r)} \|f - g\|_{(r)} + 4M^3 \|g\|_{(r)}^2 \|f - g\|_{(r)} \\
&\leqq (4M^2(\delta + 2M_o R_o r) + 4M^3(\delta + 2M_o R_o r)^2) \|f - g\|_{(r)}.
\end{aligned}$$

If we choose δ and r such that

$$\theta := (4M^2(\delta + 2M_o R_o r) + 4M^3(\delta + 2M_o R_o r)^2) < 1,$$

we see that

$$\|F(f) - F(g)\|_{(r)} \leqq \theta \|f - g\|_{(r)}.$$

Hence by the contraction mapping theorem, we get (iii). Moreover, (i) now follows immediately by definition of μ and the fact that $a(z) \gg 0$ and $b(z) \gg 0$. Finally, we can prove (ii) by induction. Indeed, let

$$\tilde{q}_k(z) := \sum_{n=1}^{k} \|q_n\| z^n$$

$$\mu_k(z) := \sum_{n=1}^{k} \mu_n z^n.$$

Clearly $\tilde{q}_1(z) \ll \mu_1(z)$, and suppose by induction that $\tilde{q}_n(z) \ll \mu_n(z)$ for $1 \leqq n \leqq N$. Then, note that there exists a polynomial p with positive coefficients depending on a and b such that $\tilde{q}_{N+1}(z) \ll p(\tilde{q}_1, \cdots, \tilde{q}_N)$ and $\mu_{N+1} = p(\mu_1, \cdots, \mu_N)$, from which (ii) follows immediately. This completes the proof of Proposition 6.1. □

Note that given any $q \in C_l$, we can apply the iterative commutant lifting procedure to $W - P \circ q$. Now set

$$S_\Pi(q)(\rho) := \sum_{n=1} \rho^n \|\Pi(W - P \circ q)_n\|.$$

Clearly, $S_\Pi(q) \subseteqq S(q)$ (as functions). We can now state the following result whose proof is immediate from the above discussion.

PROPOSITION 6.2. *Given $q \in C_l$, there exists $\tilde{q} \in C_l$, such that $S(\tilde{q}) \equiv S_\Pi(q)$. Moreover, $\tilde{q}$ may be constructed from the iterated commutant lifting procedure.*

Moreover, we easily have the following result.

PROPOSITION 6.3. *q is partially optimal if and only if $S(q) \cong S_\Pi(q)$ (i.e., $S(q)(\rho) = S_\Pi(q)(\rho)$ for all $\rho > 0$ sufficiently small; see § 5).*

Proof. Assume that q is partially optimal. Then, q must be optimal with respect to its first term q_1. However, we have seen that there exists $\hat{q}_1$ such that $\| W_1 - P_1 \hat{q}_1 \| = \| \Pi W_1 \|$. If $\| W_1 - P_1 q_1 \| > \| \Pi W_1 \|$, then since we are considering germs of functions, we would have $S(q) \not\cong S(\hat{q}_1 + q_2 + \cdots)$, contradicting the partial optimality of q.

By induction, assume that we have proven

$$\| (W - P \circ q)_j \| = \| \Pi (W - P \circ q)_j \|$$

for $1 \leqq j \leqq n$. Then again if

$$\| (W - P \circ q)_{n+1} \| > \| \Pi (W - P \circ q)_{n+1} \|,$$

by the above construction, using the commutant lifting theorem, we can find a $\hat{q}_{n+1}$ such that

$$\| \Pi (W - P \circ q)_{n+1} \| = \| (W - P \circ (q_1 + q_2 + \cdots + q_n + \hat{q}_{n+1} + \cdots))_{n+1} \|.$$

So once more, $S(q) \not\cong S(q_1 + \cdots + q_n + \hat{q}_{n+1} + q_{n+2} + \cdots)$, contradicting the partial optimality of q. Hence, we get that $S(q) \cong S_\Pi(q)$. The proof of the converse direction is similar. □

We can now summarize the above discussion with the following theorem.

THEOREM 6.4. *For given P and W as above, any $q \in C_l$ is either partially optimal or can be ameliorated by a partially optimal compensating parameter.*

Proof. The proof follows immediately from Propositions 6.1–6.3. □

It is important to emphasize that a partially optimal compensating parameter need not be optimal in the sense of Definition 5.1(i). Basically, what we have shown here is that using the iterated commutant lifting procedure, we can ameliorate any given design. The question of optimality will be considered in the next section.

7. Optimal compensators. In this section we will derive our main results about optimal compensators. Basically, we will show that in the single input/single output setting, the iterated commutant lifting procedure leads to an optimal design. We begin with the following theorem.

THEOREM 7.1. *There exist optimal compensators.*

Proof. We will only sketch the proof. Note that our proof is not constructive and makes use of the weak compactness property of weakly closed, bounded, convex sets of operators on Hilbert space.

First of all, set

$$O^{(1)} := \{q_1 : q_1 \text{ is optimal relative to } W_1 \text{ and } P_1\} = \{q_1 : \| \Pi W_1 \| = \| W_1 - P_1 q_1 \|\}.$$

It follows from the classical theory [1] that $O^{(1)}$ is a bounded, weakly closed, convex set of operators. Now set

$$\begin{aligned} O^{(2)}_{q_1} &:= \{q_2 : q_2 \text{ is optimal relative to } W_2 - P_2(q_1 \otimes q_1) \text{ and } P_1\} \\ &= \{q_2 : \| W_2 - P_2(q_1 \otimes q_1) - P_1 q_2 \| = \| \Pi (W_2 - P_2(q_1 \otimes q_1)) \|\}. \end{aligned}$$

Next let

$$\hat{W}_2(q) := W_2 - P_2(q \otimes q).$$

Further, we write

$$O^{(2)} := \bigcup_{q_1 \in O^{(1)}} O^{(2)}_{q_1}.$$

Then we can find a sequence $q_{2j} \in O^{(2)}_{q_{1j}}$ such that

$$\| \hat{W}_2(q_{1j}) - P_1 q_{2j} \| \to \inf \{ \| \hat{W}_2(q_1) - P_1 q_2 \| : q_1 \in O^{(1)}, q_2 \in O^{(2)} \} =: \sigma_2.$$

Without loss of generality, we can assume that $q_{1j} \to q_1$ weakly. Obviously $q_1 \in O^{(1)}$. Moreover, since $\{q_{2j}\}$ is a bounded sequence, we can also assume without loss of generality that $q_{2j} \to q_2$ weakly. Thus,

$$\| \hat{W}_2(q_1) - P_1 q_2 \| \leqq \liminf \| \hat{W}_2(q_{1j}) - P_1 q_{2j} \|,$$

and hence $\| \hat{W}_2(q_1) - P_1 q_2 \| = \sigma_2$.

Clearly the above procedure can be iterated step by step. Convergence follows by the same argument as that used in Proposition 6.1. □

For the construction of the optimal compensator in Theorem 7.3 below, we will need one more technical result. Accordingly, we will need to set up a bit more notation. First set $H^2 := H^2(\mathbf{C})$, and $H^\infty := H^\infty(\mathbf{C})$ (the space of bounded analytic complex-valued functions on the unit disc). Let $m \in H^\infty$ be a nonconstant inner function, let $\Pi_1 : H^2 \to H^2 \ominus mH^2 =: H(m)$ denote orthogonal projection, and set $T := \Pi_1 S | H(m)$, where S is the canonical unilateral shift on H^2. (T is the compressed shift.) For H a complex separable Hilbert space, let $S_\infty : H \to H$ denote a unilateral shift, i.e., an isometric operator with no unitary part. This means that $S_\infty^{*n} h \to 0$ for all $h \in H$ as $n \to \infty$. (See [15] and [19].) We can now state the following generalization of a nice result which appears in [18].

LEMMA 7.2. *Notation as above. Let $A : H \to H^2 \ominus mH^2$ be a bounded linear operator which attains its norm, i.e., such that there exists $h_0 \in H$ with $\|Ah_0\| = \|A\| \, \|h_0\| \neq 0$. Suppose moreover that*

$$AS_\infty = TA.$$

Then there exists a unique minimal intertwining dilation B of A, i.e., an operator $B : H \to H^2$ such that $BS_\infty = SB$, $\|A\| = \|B\|$, and $\Pi_1 B = A$.

Proof. First of all, without loss of generality, we can assume that $\|A\| = 1$. The existence of B follows from the commutant lifting theorem [19]. For the uniqueness, we use the results of [10]. Indeed, let

$$\mathbf{F} := \{ D_T Ah \oplus D_A h : h \in H \}^-$$

where for a contraction K, we set $D_K^2 := (I - K^*K)$, $D_K \geqq 0$. Then by [10], B is unique if $\mathbf{F} = \mathbf{D}_T \oplus \mathbf{D}_A$, where $\mathbf{D}_T = \overline{D_T H(m)}$, and $\mathbf{D}_A = \overline{D_A H}$. Now it is well known that $D_T f = \langle f, \mu \rangle \hat{\mu}$ where $\mu := \bar{z}(m(z) - m(0))$, and $\hat{\mu} := \mu / \|\mu\|$. Thus $D_T Ah = \langle Ah, \mu \rangle \hat{\mu}$, and so

$$\mathbf{F} = \{ \langle Ah, \mu \rangle \hat{\mu} \oplus D_A h : h \in H \}^-.$$

Since $h_0 \in H$ is such that $\|Ah_0\| = \|h_0\| \neq 0$, we have

$$D_T Ah_0 \oplus D_A h_0 = \langle Ah_0, \mu \rangle \hat{\mu} \oplus 0.$$

We consider the following two cases.

Case (i). Suppose $\langle Ah_0, \mu \rangle \neq 0$. Then $\mathbf{C}\hat{\mu} \oplus 0 \subset \mathbf{F}$, which implies that $\mathbf{F} \supset 0 \oplus \mathbf{D}_A$, from which we get that $\mathbf{F} = \mathbf{D}_T \oplus \mathbf{D}_A$.

Case (ii). Suppose $\langle Ah_0, \mu\rangle = 0$. We claim that there exists $j \geqq 1$ such that $\langle T^j Ah_0, \mu\rangle \neq 0$. Indeed, suppose not. Then $\langle T^j Ah_0, \mu\rangle = 0$ for all $j \geqq 1$; hence, $\|T^j Ah_0\| = \|Ah_0\| = \|h_0\|$. Let M be the Hilbert space generated by the elements $T^j Ah_0$ for $j \geqq 0$. Then M is T-invariant, and $T|M$ is an isometry. Since T is of class C_0 (see [19]), this is impossible. Thus, we can find a minimal j such that $\langle T^{j+1} Ah_0, \mu\rangle \neq 0$. However,

$$\|AS_\infty^j h_0\| = \|T^j Ah_0\| = \|Ah_0\| = \|h_0\|.$$

Hence replacing h_0 by $S_\infty^j h_0$, we are back to the first case, from which we can complete the proof. □

We now come to the main result of this section.

THEOREM 7.3. *Let W and P be* SISO *locally stable operators, with W the weight and P the plant. Suppose that ΠW_j is compact for $j \geqq 1$ and ΠP_k is compact for $k \geqq 2$. ($\Pi : H^2 \to H^2 \ominus P_1 H^2$ denotes orthogonal projection.) Let q_{opt} be a partially optimal compensating parameter as constructed by the iterated commutant lifting procedure. Then q_{opt} is optimal.*

Proof. First of all, since ΠW_1 attains its norm, from Lemma 7.2 we have that the optimal q_1 constructed relative to W_1 and P_1 is unique. (Actually, in this special case, since we are working in H^2, this follows from [18].) Now from our above hypotheses, each ΠA_k is compact for $k \geqq 2$; hence, each ΠA_k attains its norm. Therefore, by Lemma 7.2 each optimal q_k constructed by the iterated commutant lifting procedure is unique. Theorem 7.3 now follows immediately from Theorem 6.4. □

COROLLARY 7.4. *Let P be locally stable and* SISO, *with linear part P_1 rational. Then the partially optimal compensating parameter q_{opt} constructed by the iterated commutant lifting procedure is optimal.*

Proof. Indeed, since P_1 is SISO rational (recall that we also always assume that P_1 is inner), $H^2 \ominus P$, H^2 is finite-dimensional, and so we are done by Theorem 7.3. □

Remark 7.5. Corollary 7.4 gives a constructive procedure for finding the optimal compensator under the given hypotheses. Indeed, when P_1 is SISO rational, the iterative commutant lifting procedure can be reduced to *finite dimensional matrix calculations.* We will illustrate this important point via an example in § 9. In a subsequent paper, we will show that when the hypotheses of Theorem 7.3 are satisfied, the skew Toeplitz theory of [7] provides an algorithmic design procedure for distributed nonlinear systems as well.

8. Maximal vectors and optimal interpolants. In order to apply the iterative commutant lifting procedure to an actual example, we will need a generalization of a result due to Sarason [17] on the optimal interpolant. More precisely, for K a bounded linear operator on a Hilbert space, k_0 is a *maximal vector*, if $\|Kk_0\| = \|K\| \|k_0\| \neq 0$. Then for SISO systems, Sarason [17] derives a formula for the optimal interpolant in terms of a maximal vector of the associated Hankel operator (see [1] for a similar result).

In order to state our result, we will first need a few preliminary remarks. Let $H := H^2(\mathbf{C}^k)$. As above, we let $m \in H^\infty$ be nonconstant inner, and let $\Pi_1 : H^2 \to H^2 \ominus mH^2 =: H(m)$ denote orthogonal projection, with T the compression of the canonical shift on H^2 to $H(m)$. Moreover, S_∞ will denote the canonical shift on H, defined by multiplication by e^{it}. Now given $h \in H$, we can write h as a column vector (perhaps infinite)

$$h = \begin{bmatrix} h_1 \\ h_2 \\ \vdots \\ \vdots \end{bmatrix}.$$

We then set

$$h^* := [\bar{h}_1\ \bar{h}_2 \cdots].$$

Moreover, given any bounded linear operator $B: H \to H^2$ such that $BS_\infty = SB$, we have that for $z \in D$ (the unit disc),

$$(Bh)(z) = \sum_{j \geq 1} b_j(z) h_j(z).$$

That is, we can express B as the row matrix

$$[b_1\ b_2 \cdots]$$

with $b_j \in H^\infty$ for $j \geq 1$. We will identify B with this row matrix. With this notation, we can now state the following resulting proposition.

PROPOSITION 8.1. *Notation as above. Let $A: H \to H^2 \ominus mH^2$ be a bounded linear operator such that $AS_\infty = TA$. Suppose, moreover, that A has a maximal vector h_0. Let $B: H \to H^2$ be the minimal intertwining dilation of A, i.e., $\Pi_1 B = A$, $BS_\infty = SB$, and $\|A\| = \|B\|$. Then if we let $\lambda := \|A\|^2$, we have that*

$$B = \frac{\lambda h_0^*}{\overline{Ah_0}}.$$

Proof. First of all, given $h_0 \in H$, we represent h_0 as a column vector with components h_j, $j \geq 1$ as above. Then, as we have seen, we have that $(Bh)(z) = \sum_{j \geq 1} b_j(z) h_j(z)$ (for $z \in D$), and

$$\|B\| = \sup\left\{\left(\sum_{j=1}^{\infty} |b_j(z)|^2\right)^{1/2} : |z| < 1\right\} = \operatorname{ess\,sup}\left\{\left(\sum_{j=1}^{\infty} |b_j(\zeta)|^2\right)^{1/2} : |\zeta| = 1\right\}.$$

However,

$$\|A\|^2 \|h_0\|^2 = \|Ah_0\|^2 \leq \|Bh_0\|^2 \leq \|B\|^2 \|h_0\|^2 = \|A\|^2 \|h_0\|^2.$$

Thus $\|Ah_0\|^2 = \|Bh_0\|^2$, and since $\Pi Bh_0 = Ah_0$, we have that $Ah_0 = Bh_0$. Next note that $\sum_{j \geq 1} |b_j(e^{it})|^2 \leq \lambda$ almost everywhere, and

$$\frac{1}{2\pi} \int_0^{2\pi} \left(\lambda \sum_{j=1}^{\infty} |h_j(e^{it})|^2 - \left|\sum_{j=1}^{\infty} b_j(e^{it}) h_j(e^{it})\right|^2\right) dt = 0.$$

(This follows from the fact that $\lambda \|h_0\|^2 = \|Bh_0\|^2$.) But using the Cauchy-Schwarz inequality, the expression under the integral sign is nonnegative. Thus,

$$\lambda \sum_{j \geq 1} |h_j(e^{it})|^2 = \left|\sum_{j \geq 1} b_j(e^{it}) h_j(e^{it})\right|^2 \leq \left(\sum_{j \geq 1} |b_j(e^{it})|^2\right)\left(\sum_{j \geq 1} |h_j(e^{it})|^2\right) \leq \lambda \sum_{j \geq 1} |h_j(e^{it})|^2$$

almost everywhere, which implies that

$$\sum_{j \geq 1} |b_j(e^{it})|^2 = \lambda$$

almost everywhere, and

$$h_j = \phi(e^{it})\overline{b_j(e^{it})}$$

almost everywhere for all $j \geq 1$, and for some function $\phi \in H^2$ satisfying

$$Ah_0 = Bh_0 = \lambda\phi.$$

Thus, for

$$B(e^{it}) = [b_1(e^{it}) b_2(e^{it}) \cdots]$$

we have

$$B(e^{it})\overline{Ah_0(e^{it})} = \lambda h_0(e^{it})^*$$

almost everywhere, as required. □

We will apply Proposition 8.1 in our computation of an optimal compensator in the next section.

9. Example. In this section, we will give an example of our nonlinear design procedure. Since we have been working in the disc, we will here take discrete-time systems, even though our techniques obviously go through in a similar manner for continuous-time systems as well. In what follows below, H_{D^2} will denote the space of $\mathbf{C}$-valued analytic functions on the bidisc D^2 with square integrable boundary values.

We let

$$W(z) = \frac{1-z}{2}$$

and $P = P_1 + P_2$, where $P_1 = z^2$ (in the discrete Fourier domain), and

$$P_2(F) = \frac{1}{2\pi i}\int_{|\zeta|=1} F(z\zeta^{-1}, \zeta)\frac{d\zeta}{\zeta}$$

for $F \in H_{D^2} \cong H^2 \otimes H^2$. More precisely, as we explained above, we can regard a bilinear map P_2 on $H^2 \times H^2$ as a linear map on $H^2 \otimes H^2$, and then it is easy to see that $H^2 \otimes H^2$ can be naturally identified with H_{D^2}. (The identification is given by $z \otimes 1 \to z_1$ and $1 \otimes z \to z_2$.) Note that in the discrete-time domain, P_2 is just a discrete Fourier transform of the "squaring" map, i.e., given the square integrable sequence $\{a_n\}$, we have that P_2 is the Fourier transform of the mapping $\{a_n\} \to \{a_n^2\}$.

We now apply our procedure to the weight W and the plant P. Accordingly, if we let $M_W : H^2 \to H^2$ denote multiplication by W, and let $\Pi : H^2 \to H^2 \ominus P_1 H^2 =: H_1$ be orthogonal projection, we set $A_0 := \Pi M_W | H_1$. Notice that $H_1 \cong \mathbf{C}^2$, and that via this isomorphism, we have the identification

$$A_0 = \begin{bmatrix} \frac{1}{2} & 0 \\ -\frac{1}{2} & \frac{1}{2} \end{bmatrix}.$$

However,

$$A_0^* A_0 = \begin{bmatrix} \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{4} \end{bmatrix}$$

from which we get that $\|A_0\| = (\sqrt{5}+1)/2$, and that a maximal vector h_0 (i.e., a vector such that $\|A_0 h_0\| = \|A_0\| \, \|h_0\| \neq 0$) is given by

$$h_0 := \begin{bmatrix} 1 \\ -\beta \end{bmatrix}$$

where $\beta := (\sqrt{5}-1)/2$. Using then the Sarason formula [17] mentioned in the previous section, we can then compute that the optimal compensating parameter is

$$q_1 := \frac{\beta}{2(1-\beta z)}.$$

Of course, the above computation was based on standard linear H^∞-optimization theory. We now want to show how to get the optimal second-order compensating parameter. Accordingly, following the iterative commutant lifting procedure, we note that

$$P_2(q_1\otimes q_1)(F)=\frac{1}{2\pi i}\int_{|\zeta|=1} q_1(z\zeta^{-1})q_1(\zeta)F(z\zeta^{-1},\zeta)\frac{d\zeta}{\zeta}$$
$$=\frac{\beta^2}{8\pi i}\int_{|\zeta|=1}\frac{1}{1-\beta z\zeta^{-1}}\frac{1}{1-\beta\zeta}F(z\zeta^{-1},\zeta)\frac{d\zeta}{\zeta}$$

for $F\in H_{D^2}$. $P_2(q_1\otimes q_1)$ will be the "weight" for which we will apply the commutant lifting procedure relative to the "plant" P_1.

For $F\in H_{D^2}$, let

$$F(z_1,z_2)=\sum_{j,k=0}^{\infty}F_{jk}z_1^j z_2^k.$$

Then,

$$\frac{4}{\beta^2}P_2(q_1\otimes q_1)(F)=\sum_{j,k=0}^{\infty}\left(\frac{1}{2\pi i}\int_{|\zeta|=1}\frac{\zeta}{\zeta-\beta z}\frac{1}{1-\beta\zeta}z^j\zeta^{k-j}\frac{d\zeta}{\zeta}\right)F_{jk}$$
$$=\sum_{j,k=0}^{\infty}z^jF_{jk}\frac{(\beta z)^{k-j}}{1-\beta^2 z}+\sum_{j,k=0}^{\infty}z^jF_{jk}\frac{1}{2\pi i}\int_{0<|\zeta|=\varepsilon\ll 1}\frac{\zeta^{k-j}}{(\zeta-\beta z)(1-\beta\zeta)}d\zeta$$
$$=\sum_{j,k=0}^{\infty}F_{jk}\frac{\beta^{k-j}z^k}{1-\beta^2 z}+\sum_{j>k}\frac{z^jF_{jk}}{-\beta z}\frac{1}{2\pi i}$$
$$\times\int_{0<|\zeta|=\varepsilon\ll 1}\frac{(\sum_{l=0}^{\infty}\zeta^l/(\beta z)^l)(\sum_{l=0}^{\infty}\beta^l\zeta^l)}{\zeta^{j-k}}d\zeta$$
$$=\sum_{j,k=0}^{\infty}\frac{\beta^{k-j}z^k}{1-\beta^2 z}+\sum_{j>k}z^{j-1}F_{jk}\frac{-1}{\beta}\frac{1}{2\pi i}\int_{0<|\zeta|=\varepsilon\ll 1}\frac{\sum_{h,l}\beta^h(\zeta^{h+l}/(\beta z)^l)}{\zeta^{j-k}}d\zeta$$
$$=\sum_{j,k=0}^{\infty}F_{jk}\frac{\beta^{k-j}z^k}{1-\beta^2 z}+\sum_{j>k}\frac{-1}{\beta}F_{jk}\sum_{l+h=j-k-1}\beta^{h-l}z^{h+k}$$
$$=\sum_{j\leqq k}F_{jk}\frac{\beta^{k-j}z^k}{1-\beta^2 z}+\sum_{j>k}\beta^{k-j}F_{jk}z^k\frac{(z\beta^2)^{j-k}}{1-\beta^2 z}$$
$$=\sum_{j,k}F_{jk}\frac{\beta^{|k-j|}z^{\max\{j,k\}}}{1-\beta^2 z}.$$

Set $A:=-\Pi P_2(q_1\otimes q_1)$. Then from the above computations, we have that

$$-\frac{4}{\beta^2}AF=F_{00}+(\beta F_{10}+\beta F_{01})z+\beta^2F_{00}z+F_{11}z.$$

Moreover, if we let

$$A_1:=-\frac{4}{\beta^2}A|(\ker A)^\perp$$

we clearly have that

$$A_1\begin{bmatrix} F_{00} \\ F_{10} \\ F_{01} \\ F_{11} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ \beta^2 & \beta & \beta & 1 \end{bmatrix}\begin{bmatrix} F_{00} \\ F_{10} \\ F_{01} \\ F_{11} \end{bmatrix}$$

where we identify $(\ker A)^{\perp}$ with $\mathbf{C}^4$ in the natural way. Now

$$A_1A_1^* = \begin{bmatrix} 1 & \beta^2 \\ \beta^2 & (\beta^2+1)^2 \end{bmatrix},$$

and then it is easy to compute that $\|A_1\|^2 =: \lambda \cong 2.048924$, $\|A_1\| \cong 1.431406$, and that a maximal vector for A_1 is given by

$$h_1 := \begin{bmatrix} \lambda \\ (\lambda-1)/\beta \\ (\lambda-1)/\beta \\ (\lambda-1)/\beta^2 \end{bmatrix}.$$

Now we must write the Fourier representation of h_1 in order to apply Proposition 8.1, and so we must express H_{D^2} as some $H^2(\mathbf{C}^k)$. Accordingly, we apply the techniques of [19], to which we refer the reader for all the details about Fourier representations. More precisely, given $F = \sum_{j,k=0}^{\infty} F_{jk} z_1^j z_2^k$, we have that the Fourier representation of F, denoted by $F(\zeta)$, is given by

$$F(\zeta) := \sum_{n=0}^{\infty} \zeta^n \begin{bmatrix} F_{n,n} \\ F_{n+1,n} \\ F_{n,n+1} \\ F_{n+2,n} \\ F_{n,n+2} \\ \vdots \end{bmatrix} \tag{10}$$

for $\zeta \in \partial D$. Thus via the above identifications, the Fourier representation of h_1, denoted by $h_1(\zeta)$, is

$$h_1(\zeta) = \begin{bmatrix} \lambda \\ (\lambda-1)/\beta \\ (\lambda-1)/\beta \\ 0 \\ 0 \\ 0 \\ \vdots \end{bmatrix} + \zeta \begin{bmatrix} (\lambda-1)/\beta^2 \\ 0 \\ 0 \\ 0 \\ \vdots \end{bmatrix}.$$

Applying Proposition 8.1 (and using the same notation), we get that the minimal intertwining dilation of A_1, B_1, is given (in the Fourier space) by

$$B_1(\zeta) = \frac{\zeta\left[\lambda \dfrac{\lambda-1}{\beta} \dfrac{\lambda-1}{\beta} 0\,0\cdots\right] + \left[\dfrac{\lambda-1}{\beta^2} 0\,0\cdots\right]}{\zeta + (\lambda-1)/\beta^2}.$$

(Note that $(\lambda-1)/\beta^2$ is about $2.74>1$, and hence $1/(z+(\lambda-1)/\beta^2)$ is analytic and bounded in $\bar{D}$.) Using the Fourier representation (10) of F, we have that in the Fourier space

$$(B_1F)(\zeta)=B_1(\zeta)\sum_{n=0}^{\infty}\zeta^n\begin{bmatrix}F_{n,n}\\F_{n+1,n}\\F_{n,n+1}\\F_{n+2,n}\\F_{n,n+2}\\\vdots\end{bmatrix}$$

$$=\sum_{n=0}^{\infty}\zeta^n\frac{\zeta(\lambda F_{n,n}+(\lambda-1)\beta^{-1}F_{n+1,n}+(\lambda-1)\beta^{-1}F_{n,n+1})+(\lambda-1)\beta^{-2}F_{n,n}}{\zeta+(\lambda-1)\beta^{-2}}.$$

We are almost done! Indeed, still working with the Fourier representations, the optimal q_2 may be derived from the equality (for $z\in D$)

$$-(4/\beta^2)P_2(q_1\otimes q_1)F-z^2q_2F=-B_1F.$$

Thus, we see that

$$\begin{aligned}(q_2F)(z)&\\&=\frac{1}{z^2}\frac{(\sum_{n=0}^{\infty}z^n\{z(\lambda F_{n,n}+(\lambda-1)\beta^{-1}F_{n+1,n}+(\lambda-1)/\beta^{-1}F_{n,n+1})+(\lambda-1)\beta^{-2}F_{n,n}\})}{z+(\lambda-1)\beta^{-2}}\\&\quad-\frac{1}{z^2}\sum_{j,k}F_{jk}\frac{\beta^{|k-j|}z^{\max\{j,k\}}}{1-\beta^2z}.\end{aligned}\tag{11}$$

Despite its seemingly complicated form, we will now see that q_2 has an integral expression in the Fourier domain, which translates into a rather simple two-linear function in the time-domain. Explicitly, we may write (11) equivalently as

$$\begin{aligned}q_2=S_1-S_2+\frac{\lambda F_{1,1}+(\lambda-1)\beta^{-1}(F_{2,1}+F_{1,2})}{z+(\lambda-1)\beta^{-2}}-\frac{\lambda F_{1,1}}{(1-\beta^2z)(z+(\lambda-1)\beta^{-2})}\\-\frac{\beta^2\lambda F_{0,0}+\beta\lambda(F_{1,0}+F_{0,1})}{(1-\beta^2z)(z+(\lambda-1)\beta^{-2})},\end{aligned}\tag{12}$$

where

$$S_1:=\frac{(\sum_{n=2}^{\infty}z^{n-2}\{z(\lambda F_{n,n}+(\lambda-1)/\beta F_{n+1,n}+(\lambda-1)/\beta F_{n,n+1})+(\lambda-1)/\beta^2F_{n,n}\})}{z+(\lambda-1)/\beta^2}$$

and

$$S_2:=\sum_{n=2}^{\infty}\frac{z^{n-2}}{1-\beta^2z}\left(\sum_{0\leqq j\leqq n}(F_{jn}+F_{nj})\beta^{n-j}\right).$$

Clearly in order to find a computable expression for q_2, we must first find such an expression for the map $M_{m,n}:H_{D^2}\to\mathbf{C}$, defined by $M_{m,n}(F):=F_{m,n}$ where $m,n=0,1,\cdots$ are fixed. Let $a=\{a_j\}$ and $b=\{b_j\}$ $(j\geqq 0)$ be sequences in the "discrete time-domain" h^2. By slight abuse of notation, we also let $a=a(\zeta)=\sum_{j=0}^{\infty}a_j\zeta^j$, and $b=b(\zeta)=\sum_{j=0}^{\infty}b_j\zeta^j$ denote their discrete Fourier transforms. Then it is easy to see that

$$M_{m,n}(a\otimes b)=M_{m,n}(a,b)=\left(\frac{1}{2\pi i}\right)^2\int_{|\zeta_1|=1}\int_{|\zeta_2|=1}\zeta_1^{-m}\zeta_2^{-n}a(\zeta_1)b(\zeta_2)\frac{d\zeta_1}{\zeta_1}\frac{d\zeta_2}{\zeta_2}=a_mb_n.$$

In this way, we get that

$$S_1 = \frac{1}{z+(\lambda-1)/\beta^2}\, T_1(F)$$

where

$$T_1(F) := \sum_{n=2}^{\infty} z^{n-2}\{z(\lambda F_{n,n}+(\lambda-1)/\beta F_{n+1,n}+(\lambda-1)/\beta F_{n,n+1})+(\lambda-1)/\beta^2 F_{n,n}\}.$$

Hence, we see that

$$T_1(a\otimes a) = \lambda \sum_{n=2}^{\infty} z^{n-1}a_n^2 + 2(\lambda-1)\beta^{-1}\sum_{n=2}^{\infty} z^{n-1}a_n a_{n+1} + (\lambda-1)\beta^{-2}\sum_{n=2}^{\infty} z^{n-2}a_n^2$$

which, of course, is the transform of a very simple quadratic map in the time domain. In the exact same way, we can write down explicit expressions for all the terms of q_2 appearing in formula (12).

Note that our above computations essentially amount to finite-dimensional matrix manipulations. We have then that q_1+q_2 is the optimal compensating parameter up to order two. A similar computation allows us to find the optimal compensating parameter up to any order, and by Proposition 6.1, our procedure is guaranteed to converge.

10. Conclusions. In this paper we have introduced a novel notion of "sensitivity minimization," and have given a method for constructing optimal compensators for SISO systems, and partially optimal compensators for MIMO systems. This generalizes the standard H^∞ linear theory in a rather natural way. However, in contrast to the linear case, the measure of performance is now given by (the germ of) a certain sensitivity function instead of a real number. The key idea is the utilization of an iterative commutant lifting procedure which can also be employed to ameliorate any given design in the sense of § 5.

The techniques we have used here are local and very much inspired by the previous work in [3]–[5]. The interested reader can contrast this approach with the nonlinear Ball–Helton method as given in [6]. An intriguing problem would be to compare nonlinear designs derived from these two approaches (which, of course, coincide in the linear case). This we would like to consider in some future work as well as attempt to derive a more global theory. There are, of course, a number of open questions still remaining even in our local setting. A key problem is to design optimal controllers for nonlinear MIMO plants. Indeed, even though we can ameliorate any design, because of nonuniqueness in the choice of the various minimal intertwining dilations in the iterative commutant lifting procedure, for MIMO systems we cannot guarantee optimality but only partial optimality. In a subsequent paper, we plan to show how the skew Toeplitz techniques of [7] provide a design methodology for distributed nonlinear systems as well.

At the Systems Research Center of Honeywell in Minneapolis, an interesting partial dynamic inversion technique due to Elgersma and Morton [9] has recently been employed to obtain some nonlinear designs related to a sixth degree of freedom aircraft model. A project on which we are now embarked is the utilization of the iterative commutant lifting procedure in order to ameliorate this kind of design. Finally, in the SISO case (in which there is a rather complete theory), our procedure is algorithmic, and we are presently working on software for its digital implementation with our colleagues at Honeywell along the lines of the work already done in the linear framework based on [11] and [12].

NONLINEAR OPTIMAL CONTROL WITH INFINITE HORIZON FOR DISTRIBUTED PARAMETER SYSTEMS AND STATIONARY HAMILTON–JACOBI EQUATIONS*

P. CANNARSA† AND G. DA PRATO‡

Abstract. Optimal control problems, with no discount, are studied for systems governed by nonlinear "parabolic" state equations, using a dynamic programming approach.

If the dynamics are stabilizable with respect to cost, then the fact that the value function is a generalized viscosity solution of the associated Hamilton-Jacobi equation is proved. This yields the feedback formula. Moreover, uniqueness is obtained under suitable stability assumptions.

Key words. optimal control, Hamilton-Jacobi equations, viscosity solutions, evolution equations, unbounded operators

AMS(MOS) subject classifications. 49C20, 34G20

1. Introduction and setting of the problem. Let us consider two separable reflexive Banach spaces, X (the *state space*) and U (the *control space*). We denote by $|\ |$ the norm of X, which we assume to be continuously differentiable in $X\backslash\{0\}$, by X^* the dual space of X and by $\langle\ ,\ \rangle$ the pairing between X and X^*. We denote by $\partial|x|$ the subgradient of $|x|$, which is obviously single-valued on $X\backslash\{0\}$. The same symbols will also be used in the Banach space U. Moreover, we will use the following notation:

(i) For any Banach space K and any nonnegative integer k we denote by $C^k(X; K)$ the set of all the mappings $f: X \to K$ that are continuous and bounded on all bounded sets of X, together with their derivatives of order less than or equal to k.

(ii) We denote by $C^{k,1}(X; K)$ (respectively, $C^{k,1}(X; K)_{\text{loc}}$), the set of all the mappings f in $C^k(X; K)$ whose derivative of order k is Lipschitz continuous in X (in every bounded set of X).

We are interested in the following optimal control problem.

Minimize

$$J_\infty(u, x) = \int_0^\infty \{g(y(s)) + h(u(s))\}\, ds \tag{1.1}$$

over all $u \in L^1(0, \infty; U)_{\text{loc}}$, subject to state equation

$$y' = Ay + F(y) + Bu, \qquad y(0) = x. \tag{1.2}$$

Following the dynamic programming approach, we will study the Hamilton-Jacobi equation

$$H(B^*DV(x)) - \langle Ax + F(x), DV(x)\rangle - g(x) = 0 \tag{1.3}$$

where H denotes the Legendre transform of h, that is,

$$H(v) = \sup_{v \in U} \{-\langle u, v\rangle - h(u)\}. \tag{1.4}$$

The connections between (1.3) and problem (1.1)-(1.2) are well known.

† Dipartimento di Matematica, Università di Pisa, Via F. Buonarroti, 2, 56127 Pisa, Italy.

‡ Scuola Normale Superiore, 56126 Pisa, Italy.

We assume the following hypotheses.

(SL) (i) $A: D(A) \subset X \to X$ generates an analytic semigroup e^{tA} in X and there exists $\omega \in \mathbf{R}$ such that $\|e^{tA}\| \leqq e^{\omega t}$.

(ii) The embedding $D(A) \to X$ is compact.

(iii) $B \in \mathscr{L}(U; X)$.

(iv) $F \in C^{1,1}(X, X)_{\text{loc}}$ and there exists $a \in \mathbf{R}$ such that $\langle F(x), x^* \rangle \leqq a|x|$, for all $x^* \in \partial|x|$, for all $x \in X$.

(v) $g \in C^{1,1}(X, \mathbf{R})_{\text{loc}}$ and $g(x) \geqq 0$ for all $x \in X$.

(vi) $h \in C^{1,1}(U, \mathbf{R})_{\text{loc}}$ is strictly convex and there exists $p > 1$ such that $h(u) \geqq \gamma|u|^p$ for all $u \in U$ and some $\gamma > 0$.

We remark that, if (SL) are fulfilled, then, by classical arguments (see, for instance, [21]), problem (1.2) has a unique global mild solution $y \in C([0, \infty[; X)$.

In the analysis of (1.3), we meet with two immediate difficulties: the nonsmoothness of solutions and the unboundedness of A. In fact, first-order partial differential equations have, in general, no global classical solutions even in finite dimensions. Therefore, a suitable notion of weak solution is required. Moreover, such a generalized solution will have to take care of the fact that Ax is defined only on a dense subspace of X.

The first problem can be successfully treated by the notion of viscosity solution, introduced by Crandall and Lions [12]-[15]. In [16] they have also extended their definition of solutions to problems involving unbounded operators. Further results in these directions have been obtained in [4] and [10] by an approximation procedure.

Stationary Hamilton-Jacobi equations have been extensively studied (see [20] for general references and results; see also [13]-[16]) mainly in the case when the equation contains an additional term of the form λV with $\lambda > 0$. This corresponds to the introduction of a discount factor $e^{-\lambda t}$ in the cost.

However, in many applications we are required not to have such a discount, as in linear quadratic optimal control problems. A large amount of work has been devoted to the analysis of this case (see, for instance, the review paper [22]). For linear quadratic optimal control problems, the Hamilton-Jacobi equation is replaced by the algebraic Riccati equation, as it is well known. In general, uniqueness is false for this equation. Therefore, we do not expect to have uniqueness for (1.3).

Optimal control problems with a linear state equation and a convex cost functional are also studied in [3] and [6]. Some generalizations to the nonconvex case, by using variational methods, are contained in [4], [6], and [7].

The main idea of our approach is to obtain a viscosity solution V of (1.3) as

$$V(x) = \lim_{t \to \infty} \phi(t, x) \tag{1.5}$$

where ϕ solves the forward equation (in the generalized sense of [10]):

$$\phi_t(t, x) + H(B^* \nabla \phi(t, x)) - \langle Ax + F(x), \nabla \phi(t, x) \rangle - g(x) = 0, \qquad \phi(0, x) = 0. \tag{1.6}$$

For the value function of the control problem (1.1)-(1.2) to be finite, we introduce the notion of stabilizability that generalizes a well-known concept in linear quadratic control (see, e.g., [22]).

DEFINITION 1.1. We say that $(A + F, B, h)$ is *stabilizable with respect to the observation* g (or, for brevity, that problem (1.1)-(1.2) is stable) if for any $x \in X$ there exists $u_x \in L^1(0, \infty; U)_{\text{loc}}$ such that $J_\infty(u_x, x) < \infty$. Such a control u_x will be called an *admissible control* at x.

Finally, we define the *value function* of problem (1.1) (1.2) as

$$V_\infty(x) = \inf\{J_\infty(u, x);\ u \in L^1(0, \infty; U)_{\text{loc}}\}. \tag{1.7}$$

We say that $u^* \in L^1(0, \infty; U)_{\text{loc}}$ is an *optimal control* if $J(u^*) = V_\infty(x)$; in this case, we call the corresponding solution y^* of (1.2) an *optimal state* and (u^*, y^*) an *optimal pair* at x.

In this paper we show that, if $(A+F, B, h)$ is g-stabilizable, then V_∞ is a generalized viscosity solution of (1.3). Moreover, we obtain the existence of optimal pairs as well as the feedback formula (see Theorem 4.4).

In § 3 we study the "stability" of the closed-loop system. When this system is stable and B is invertible, we prove the uniqueness of the nonnegative generalized viscosity solution of (1.3) vanishing at zero (Theorem 5.4).

An application to a nonlinear control problem for a distributed parameter system is illustrated in § 6.

We now explain our definition of generalized solutions. We define solutions of (1.3) as stationary solutions of the following evolution equation:

$$-W_t(t, x) + H(B^*\nabla W(t, x)) - \langle Ax + F(x), \nabla W(t, x)\rangle = g(x). \tag{1.8}$$

More precisely, we have the following definition.

DEFINITION 1.2. Assume (SL). We say that $V \in C^{0,1}(X; \mathbf{R})_{\text{loc}}$ is a *generalized viscosity solution* of (1.3) if $W(t, x) := V(x)$ is the generalized viscosity solution of (1.8) in $[0, T] \times X$ with terminal data $W(T, x) = V(x)$, for all $T > 0$.

We recall below the definition of generalized viscosity solutions of the Cauchy problem (see [10])

$$\begin{aligned} &-W_t(t, x) + H(B^*\nabla W(t, x)) - \langle Ax + F(x), \nabla W(t, x)\rangle = g(x) \\ &W(T, x) = \phi_0(x), \qquad x \in X, \quad t \in [0, T] \end{aligned} \tag{1.9}$$

where

$$\phi_0 \in C^{0,1}(X; \mathbf{R})_{\text{loc}}. \tag{1.10}$$

DEFINITION 1.3. Assume (SL) and (1.10). We say that $W \in C([0, T] \times X; \mathbf{R})$ is a *generalized viscosity solution* of (1.9) if we have

$$\lim_{n\to\infty} W_n(t, x) = W(t, x), \quad \forall x \in D(A), \quad \forall t \in [t, T] \tag{1.11}$$

where W_n is the viscosity solution (in the sense of Crandall and Lions [13]) of the problem

$$\begin{aligned} &-W_{nt}(t, x) + H(B^*\nabla W_n(t, x)) - \langle A_n x + F(x), \nabla W_n(t, x)\rangle - g(x) = 0, \\ &W_n(T, x) = \phi_0(x) \end{aligned} \tag{1.12}$$

where

$$A_n = nA(n - A)^{-1}. \tag{1.13}$$

We note that problem (1.12) has a unique viscosity solution (see [13] and also [10]).

A property of generalized viscosity solutions that turns out to be essential to our approach is semiconcavity (see [9]).

In applications it is also useful to consider the following more general assumptions:

(SL') (i) Hypotheses (SL) (i), (ii), (iii), (v) and (vi) hold.

(ii) there exists a Banach space Z (with pairing denoted $\langle\ ,\ \rangle_Z$), continuously embedded in X, such that the part of A in Z, A_Z, generates an analytic semigroup in Z with domain $D(A_Z)$ (not necessarily dense in Z)

$$D(A_Z)=\{x\in D(A)\cap Z;\ Ax\in Z\}.$$

Moreover, $\|e^{tA_Z}\|\leqq e^{\mu t}$ for all $t\geqq 0$ and some $\mu\in\mathbf{R}$.

(iii) There exists $\alpha\in]0,1-1/p[$, $a\in\mathbf{R}$, and two continuous functions β, $\rho:[0,\infty[\to[0,\infty[$, such that $D_A(\alpha,p)$ is embedded in Z and

$$F\in C^{1,1}(D_A(\alpha,p);X)_{\mathrm{loc}}, \tag{1.14}$$

$$\langle F(z),z^*\rangle_Z\leqq a|z|_Z\quad\forall z\in Z,\quad\forall z^*\in\partial|z|_Z, \tag{1.15}$$

$$|F(x)|\leqq\beta(|x|_Z)+\rho(|x|_Z)|x|_{\alpha,p}\quad\forall x\in D_A(\alpha,p). \tag{1.16}$$

We recall that $D_A(\alpha,p)$ is the real interpolation space between $D(A)$ and X, introduced by Lions and Peetre [19], with norm

$$|x|_{\alpha,p}=\left[\int_0^\infty \tau^{p-p\alpha-1}|Ae^{\tau A}x|^p\,d\tau\right]^{1/p}.$$

Definition 1.2 remains unchanged under assumptions (SL'), except for the fact that we assume $V\in C^{0,1}(D_A(\alpha,p);\mathbf{R})_{\mathrm{loc}}$. Moreover, in Definition 1.3 we assume $W\in C([0,T]\times D_A(\alpha,p);\mathbf{R})$ and replace (1.12) by

$$-W_{nt}(t,x)+H(B^*\nabla W_n(t,x))-\langle A_nx+F(n(n-A)^{-1}x),\nabla W_n(t,x)\rangle-g(x)=0,$$

$$W_n(T,x)=\phi_0(x).$$

2. Preliminaries. In this section we recall the basic results on the time-dependent Hamilton–Jacobi equation (1.9).

PROPOSITION 2.1. *Assume* (1.10) *and either* (SL) *or* (SL'). *Then, there exists a unique generalized viscosity solution* W *of problem* (1.9) *given by*

$$W(t,x)=\inf\left\{\int_t^T[g(y(s))+h(u(s))]\,ds+\phi_0(y(T));\quad u\in L^1(t,T;U)_{\mathrm{loc}}\right\} \tag{2.1}$$

where y *is the solution of*

$$y'(s)=Ay(s)+F(y(s))+Bu(s),\qquad t\leqq s\leqq T,\quad y(t)=x. \tag{2.2}$$

Moreover, W *satisfies* (1.9) *in the sense that for every* $(t,x)\in[0,T]\times D(A)$ *we have*

$$\text{(i)}\quad\forall(p_t,p_x)\in D^+W(t,x),\qquad -p_t+H(B^*p_x)-\langle Ax+F(x),p_x\rangle\leqq g(x), \tag{2.3}$$

$$\text{(ii)}\quad\forall(p_t,p_x)\in D^-W(t,x),\qquad -p_t+H(B^*p_x)-\langle Ax+F(x),p_x\rangle\geqq g(x).$$

We recall the definition of the semidifferentials D^+ and D^-:

$$D^+W(t,x)=\left\{(p_t,p_x)\in\mathbf{R}\times X^*;\ \limsup_{(s,y)\to(t,x)}\frac{W(s,y)-W(t,x)-(s-t)p_t-\langle y-x,p_x\rangle}{|s-t|+|y-x|}\leqq 0\right\},$$

$$D^-W(t,x)=\left\{(p_t,p_x)\in\mathbf{R}\times X^*;\ \liminf_{(s,y)\to(t,x)}\frac{W(s,y)-W(t,x)-(s-t)p_t-\langle y-x,p_x\rangle}{|s-t|+|y-x|}\geqq 0\right\}. \tag{2.4}$$

Remark 2.2. The results of Proposition 2.1 are proved in Theorems 3.3 and 3.7 of [10] in a slightly different form that is equivalent to the one above in view of the coercivity assumption on h.

We now recall the Maximum Principle [8], the feedback formula [4], [9], and some regularity properties of optimal pairs [9].

PROPOSITION 2.3. *Assume* (SL) (*respectively*, (SL')) *and* (1.10). *Let W be given by* (2.1) *and* $(t, x) \in [0, T] \times X$ (*respectively*, $(t, x) \in [0, T] \times D_A(\alpha, p)$). *Let* (u^*, y^*) *be an optimal pair for W at* (t, x). *Then, there exists* $p^* \in C([t, T]; X^*)$ *such that*

$$p^{*\prime}(s) + A^* p^*(s) + (DF(y^*(s))^* p^*(s) + Dg(y^*(s)) = 0, \quad p^*(T) = D\phi(y^*(T)), \tag{2.5}$$

$$u^*(s) = -DH(B^* p^*(s)), \qquad t \leqq s \leqq T. \tag{2.6}$$

We call p^* *a* <u>*dual arc*</u>. *Moreover,*

$$u^*(s) \in -DH(B^* \nabla^+ W(s, y^*(s))), \qquad t \leqq s \leqq T \tag{2.7}$$

where

$$\nabla^+ W(s, x) = \left\{ q \in X^*; \limsup_{y \to x} \frac{W(s, y) - W(s, x) - \langle y - x, q \rangle}{|y - x|} \leqq 0 \right\}. \tag{2.8}$$

Furthermore, there exists $\delta \in]0, 1[$ *such that*

$$y^* \in C^{1,\delta}(]t, T[; X), \tag{2.9}$$

$$p^* \in C^{1,\delta}(]t, T[; X), \qquad u^* \in C^{0,\delta}(]t, T[; X). \tag{2.10}$$

Above we have denoted by $C^{1,\delta}(I; X)$, for any real interval I, the space of functions that are Hölder continuous with exponent δ, together with their first derivative, on each subinterval $[a, b]$ contained in I.

Finally, the following results are proved in [4] and [9].

PROPOSITION 2.4. *Assume* (SL) (*respectively*, (SL')) *and* (1.10) *and let W be given by* (2.1). *Then we have the following*:

(2.11) (i) $W(t, .)$ *is locally Lipschitz in X for all* $t \in [0, T]$;
(ii) $W(., x)$ *is Lipschitz continuous in* $[0, T]$ *for all* $x \in D(A)$.

Furthermore, if $B^{-1} \in \mathcal{L}(H; U)$, *then* $W(t, .)$ *is semiconcave in X for all* $t \in [0, T[$; *that is, for all* $r > 1/T$ *there exists* $C_r > 0$ *such that*

$$\lambda W(t, x + (1 - \lambda)x') + (1 - \lambda) W(t, x - \lambda x') - W(t, x) \leqq C_r \lambda (1 - \lambda)|x'|^2$$

for all $t \in [0, T - 1/r]$, $|x|, |x'| \leqq r$, $\lambda \in [0, 1]$.

Along with the backward Cauchy problem (1.9), we will consider the forward problem:

$$\begin{gathered} \phi_t(t, x) + H(B^* \nabla \phi(t, x)) - \langle Ax + F(x), \nabla \phi(t, x) \rangle - g(x) = 0; \\ \phi(0, x) = \phi_0(x). \end{gathered} \tag{2.12}$$

We say that $\phi \in C([0, T] \times X; \mathbf{R})$ (respectively, $\phi \in ([0, T] \times D_A(\alpha, p); \mathbf{R})$) is the *generalized viscosity solution* of (2.12) if $W(t, x) = \phi(T - t, x)$ is the generalized viscosity solution of (1.9).

We prove now the analogue of representation formula (2.1).

PROPOSITION 2.5. *Assume* (SL) (*respectively*, (SL')) *and* (1.10). *Let* ϕ *be the generalized viscosity solution of* (2.12). *Then we have*

$$\phi(t, x) = \inf \left\{ \int_0^t [g(y(s)) + h(u(s))]\, ds + \phi_0(y(t)); u \in L^1(0, \infty; U)_{\text{loc}} \right\} \tag{2.13}$$

where y is the solution of (1.2).

Proof. By definition we have

$$\phi(t,x)=\inf\Big\{\int_{T-t}^{T}\{g(y(s))+h(u(s))\}\,ds+\phi_0(y(T));$$

$$u\in L^1(T-t,T;U),\ y'(s)=Ay(s)+F(y(s))+Bu(s),\ y(T-t)=x\Big\}. \tag{2.14}$$

Set $\sigma=s-T+t$ to obtain

$$\phi(t,x)=\inf\Big\{\int_0^t g(y(\sigma+T-t))+h(u(\sigma+T-t))\,d\sigma+\phi_0(y(T));$$

$$u\in L^1(T-t,T:U),\ y'(s)=Ay(s)+F(y(s))+Bu(s),\ y(T-t)=x\Big\}.$$

Now, let $\underline{y}(s)=y(s+T-t)$, $\underline{u}(s)=u(s+T-t)$; then

$$\phi(t,x)=\inf\Big\{\int_0^t\{g(\underline{y}(s))+h(\underline{u}(s))\}\,ds+\phi_0(\underline{y}(t));$$

$$\underline{u}\in L^1(0,t;U),\ \underline{y}'(s)=A\underline{y}(s)+F(\underline{y}(s))+B\underline{u}(s),\ \underline{y}(0)=x\Big\}$$

and the assertion is proved. □

3. Sufficient conditions for stabilizability. To our knowledge there are no general conditions that yield global stabilizability in the sense of Definition 1.1 (for local results see [2] and [18]). In the following we give some sufficient conditions that may be applied to various situations. For instance, the problem we analyze in § 6 fits into the framework of Proposition 3.3 below.

The simplest case for which there is stabilizability is when the dynamical system $\eta(t,x)$ generated by $A+F$, that is the solution of

$$\eta'=A\eta+F(\eta),\qquad \eta(0)=x, \tag{3.1}$$

is "exponentially stable." Indeed, in this case it suffices to take $u=0$ in (1.2). More precisely, we can easily prove the following proposition.

PROPOSITION 3.1. *Assume* (SL) (*respectively*, (SL')). *Let* $h(0)=0$ *and suppose that there exist positive constants* C, R, σ, τ, *and* δ *such that*

$$|\eta(t,x)|\leqq Ce^{-\delta t}|x|^{\tau}\quad \textit{for all } x\in X, \tag{3.2}$$

$$|g(x)|\leqq C|x|^{\sigma}\qquad \textit{for } |x|\leqq R. \tag{3.3}$$

Then, (1.1)-(1.2) *is stable.*

Remark 3.2. A typical assumption that implies (3.2) is that $A+F+\varepsilon$ be dissipative for some $\varepsilon>0$, i.e.,

$$\langle Ax+F(x)+\varepsilon x,x^*\rangle\leqq 0\quad \text{for all } x\in D(A) \text{ and } x^*\in\partial|x|. \tag{3.4}$$

Next, when B is invertible, we can prove a quite general result.

PROPOSITION 3.3. *Assume* (SL) (*respectively*, (SL')) *and let* $B^{-1}\in\mathscr{L}(X;U)$. *Suppose further that there exist positive constants* C, R, *and* σ *such that*

$$|F(x)|\leqq C|x|^{\sigma}\quad \textit{for } |x|\leqq R \ (\textit{respectively}, |F(x)|\leqq C(|x|_{\alpha,p})^{\sigma} \textit{ for } |x|_{\alpha,p}\leqq R), \tag{3.5}$$

$$|g(x)|\leqq C|x|^{\sigma}\quad \textit{for } |x|\leqq R, \tag{3.6}$$

$$|h(u)|\leqq C|u|^{\sigma}\quad \textit{for } |u|\leqq R. \tag{3.7}$$

Then, (1.1)-(1.2) *is stable.*

Proof. We set

$$u(t) = -B^{-1}\{(\omega+1)\, e^{t(A-\omega-1)}x + F(e^{t(A-\omega-1)}x)\}. \tag{3.8}$$

Then

$$|u(t)| \leqq \|B^{-1}\|_{\mathscr{L}(X;U)}\{|\omega+1||x|\, e^{-t} + C|x|\, e^{-\gamma t}\} \quad \text{for } t > \log(|x|/R)/\gamma.$$

So, the corresponding solution of the state equation (1.2) is given by $y(t) = e^{t(A-\omega-1)}x$. In view of (3.5), (3.6), and (3.7), u is an admissible control at x and the proof is complete. □

Now we consider the case when F is "small."

PROPOSITION 3.4. *Assume* (SL) (*respectively* (SL')) *and that there exist positive constants* C, R, *and* σ *such that* (3.5), (3.6), *and* (3.7) *hold. Assume in addition that there exists* $K \in \mathscr{L}(X; U)$ *such that* $A - BK$ *is exponentially stable, i.e., that* (A, B) *is stabilizable by a feedback* K. *There exists* $\varepsilon_0 > 0$ *such that if*

$$\begin{aligned} &|F(x) - F(y)| \leqq \varepsilon_0 |x - y| \quad \textit{for all } x, y \in X \\ &(\textit{respectively}, |F(x) - F(y)| \leqq \varepsilon_0 |x - y|_{\alpha,p} \textit{ for all } x, y \in D_A(\alpha, p)); \end{aligned} \tag{3.9}$$

then (1.1)-(1.2) *is stable.*

Proof. Assume that (3.9) hold for some ε, and let $x \in X$. We will show that, if ε is sufficiently small, then the following control

$$u_x(t) = e^{t(A-BK)}x \tag{3.10}$$

is admissible. Let $N > 0$ and $c > 0$ be such that

$$\|e^{t(A-BK)}\| \leqq N e^{-2ct}, \qquad t \geqq 0 \tag{3.11}$$

and set

$$\begin{aligned} &\|v\|_c = \sup\{e^{ct}|v(t)|;\ t \geqq 0\}, \qquad v \in C([0, \infty[;\ X), \\ &(\text{respectively, } \|v\|_c = \sup\{e^{ct}|v(t)|_{\alpha,p};\ t \geqq 0\}, \qquad v \in C([0, \infty[;\ D_A(\alpha, p)), \end{aligned} \tag{3.12}$$

$$\begin{aligned} &\Sigma = \{v \in C([0, \infty[;\ X);\ \|v\|_c < \infty\} \\ &(\text{respectively, } \Sigma = \{v \in C([0, \infty[;\ D_A(\alpha, p));\ \|v\|_c < \infty\}). \end{aligned} \tag{3.13}$$

Σ, equipped with the norm $\|\ \|_c$, is a Banach space. Now consider the problem

$$z' = (A - BK)z + F(z), \qquad z(0) = x. \tag{3.14}$$

By a fixed point argument we can easily show that if ε is small, then (3.14) has a unique solution in Σ. Since z coincides with the solution of the state equation (1.2) when $u = u_x$, we have obtained the conclusion. □

4. Existence. In this section we prove that the existence of solutions to the Hamilton-Jacobi equation

$$H(B^*DV_\infty(x)) - \langle Ax + F(x), DV_\infty(x)\rangle - g(x) = 0 \tag{4.1}$$

is equivalent to the fact that $(A + F, B, h)$ is g-stabilizable. We will obtain V_∞ as the limit of the generalized viscosity solution to the problem

$$\phi_t(t, x) + H(B^*\nabla\phi(t, x)) - \langle Ax + F(x), \nabla\phi(t, x)\rangle - g(x) = 0, \qquad \phi(0, x) = 0 \tag{4.2}$$

when $t \to +\infty$.

PROPOSITION 4.1. *Assume* (SL) *and suppose that problem* (1.1)-(1.2) *is stable. Let* ϕ *be the generalized viscosity solution to* (4.2) *and let* V_∞ *be given by* (1.4). *Then, for all* $x \in X$ *we have*

$$V_\infty(x) = \lim_{t \uparrow \infty} \phi(t, x). \tag{4.3}$$

Proof. By Proposition 2.5 it follows that $\phi(t, x)$ is increasing in t for any $x \in X$ and $\phi(t, x) \leqq V_\infty(x)$. Thus

$$\phi_\infty(x) = \lim_{t \uparrow \infty} \phi(t, x) \leqq V_\infty(x). \tag{4.4}$$

Now let (u_t, y_t) be such that

$$\phi(t, x) = \int_0^t \{g(y_t(s)) + h(u_t(s))\}\, ds$$

where $u \in L^1(0, t; U)$ and $y_t'(s) = Ay_t(s) + f(y_t(s)) + Bu_t(s)$; $y_t(0) = x$. Then we have

$$V_\infty(x) \geqq \int_0^t h(u_t(s))\, ds \geqq \gamma \|u_t\|^p_{L^p(0,t;H)}. \tag{4.5}$$

Set $\underline{u}_t(s) = u_t(s)$ if $s \in [0, t]$ and $\underline{u}_t(s) = 0$ is $s > t$; since by (4.5) $\{\underline{u}_t\}$ is bounded in $L^p(0, \infty; U)$, there exists

$$t_n \uparrow +\infty \text{ such that } v_n := \underline{u}_{t_n} \to u^* \text{ weakly in } L^p(0, \infty; U); \text{ set } z_n = \underline{y}_{t_n}.$$

Now fix $T > 0$; since e^{tA} is compact for all $t > 0$ (by hypothesis (SL)(ii)) we have that $z_n \to y^*$ in $C([0, T]; X)$, where y^* is the solution of (1.2) with $u = u^*$. Since h is convex it follows that

$$\phi_\infty(x) \geqq \int_0^T \{g(y^*(s)) + h(u^*(s))\}\, ds.$$

But T is arbitrary, so $g(y^*)$ and $h(u^*)$ belong to $L^1(0, \infty; \mathbf{R})$ and

$$\phi_\infty(x) \geqq \int_0^\infty \{g(y^*(s)) + h(u^*(s))\}\, ds \geqq V_\infty(x). \qquad \square$$

Under assumptions (SL′) a similar result can be proved.

PROPOSITION 4.2. *Assume* (SL′) *and suppose that problem* (1.1)-(1.2) *is stable. Let* ϕ *be the generalized viscosity solution to* (4.1) *and* V_∞ *the value function given by* (1.4). *Then, for all* $x \in D_A(\alpha, p)$ *we have*

$$V_\infty(x) = \lim_{t \uparrow \infty} \phi(t, x). \tag{4.6}$$

Proof. The reasoning is similar to the one above. Since F is only defined in $D_A(\alpha, p)$, now we must prove that

$$z_n \to y^* \quad \text{in } C([0, t]; D_A(\alpha, p)). \tag{4.7}$$

From (SL′)(ii) and (1.15) it follows that

$$\frac{d^+}{dt} |z_n(t)|_Z \leqq (a + \omega)|z_n(t)|_Z + |Bv_n(t)| \tag{4.8}$$

where d^+/dt denotes the right derivative. Thus, there exists $C(T)>0$ such that $|z_n(t)|_Z \leqq C(T)$ for every $t\in[0, T]$. We set $\zeta_n = F(z_n)+Bv_n$. Then, from the representation formula

$$z_n(t) = e^{tA}x + \int_0^t e^{(t-s)A}\zeta_n(s)\,ds \tag{4.9}$$

and the fact that v_n is bounded in $L^p(0,\infty; U)$, we conclude that there exists $C_1(T)>0$ such that $|z_n(t)|_{\alpha,p}\leqq C_1(T)$ for every $t\in[0, T]$. Therefore, $\{\zeta_n\}$ is bounded in $L^p(0, T; X)$ and we can find a subsequence, still denoted by $\{\zeta_n\}$, such that $\zeta_n\to\zeta^*$ weakly in $L^p(0, T; X)$. Moreover, $z_n\to y^*$ in $C([0, t]; X)$.

To show (4.7) note that, for all $t, \varepsilon\in]0, T[$,

$$\begin{aligned}|y^*(t)-z_n(t)|_{\alpha,p} &\leqq \int_\varepsilon^T |e^{(t-s)A}\zeta_n(s)|_{\alpha,p}\,ds \\ &\quad + \left(\int_0^\varepsilon \|e^{(t-s)A}\|^{p/(p-1)}_{\mathscr{L}(X,D_A(\alpha,p))}\,ds\right)^{(p-1)/p}\left(\int_0^\varepsilon |\zeta_n(s)|^p\,ds\right)^{1/p}.\end{aligned} \tag{4.10}$$

Also,

$$\|e^{tA}\|_{\mathscr{L}(X,D_A(\alpha,p))}\leqq\frac{\text{const}}{t^\alpha}\quad\forall t>0. \tag{4.11}$$

So, using the fact that e^{tA}, $t>0$, is a compact operator from X into $D_A(\alpha, p)$ and recalling that $\alpha\in]0, 1-1/p[$, we can easily derive (4.7) from (4.10) and (4.11). □

To prove our existence result, we need a lemma.

LEMMA 4.4. *Assume* (SL) (*respectively*, (SL')). *For any* $T>0$ *and* $x\in X$ (*respectively*, $x\in D_A(\alpha, p)$) *we have*

$$\begin{aligned}V_\infty(x) = \inf\Big\{&\int_0^T [g(y(s))+h(u(s))]\,ds + V_\infty(y(T)); \\ &u\in L^1(0, T; U),\ y'(s)+Ay(s)+F(y(s))+Bu(s),\ y(0)=x\Big\}.\end{aligned} \tag{4.12}$$

Proof. Denote by V^* the right-hand side of (4.12). Let u be an admissible control and let y be the corresponding solution of (1.2). Then,

$$\begin{aligned}\int_0^\infty \{g(y(s))+h(u(s))\}\,ds &= \int_0^T \{g(y(s))+h(u(s))\}\,ds \\ &\quad + \int_0^\infty \{g(y(\sigma+T))+h(u(\sigma+T))\}\,d\sigma\end{aligned}$$

whence

$$\int_0^\infty \{g(y(s))+h(u(s))\}\,ds \geqq \int_0^T \{g(y(s))+h(u(s))\}\,ds + V_\infty(y(T)),$$

which implies that $V^*\geqq V_\infty(x)$. We now prove the reverse inequality. Fix $T>0$ and $u\in L^1(0, T; U)$; let $y\in C([0, T]; X)$ be the corresponding solution of (1.2) and (u_T, y_T) be an optimal pair for problem (1.1), (1.2) with $x=y(T)$. Set

$$\underline{u}(s)=u(s)\quad\text{if } 0\leqq s\leqq T,\qquad \underline{u}(s)=u_T(s-T)\quad\text{if } s\geqq T.$$

Since $y_T(0)=y(T)$, we have

$$\underline{y}(s)=y(s)\quad\text{if } 0\leqq s\leqq T,\qquad \underline{y}(s)=y_T(s-T)\quad\text{if } s\geqq T.$$

Then,

$$V_\infty(x) \leqq \int_0^T \{g(y(s))+h(u(s))\}\,ds + \int_T^\infty \{g(y_T(s-T))+h(y_T(s-T))\}\,ds$$
$$= \int_0^T \{g(y(s))+h(u(s))\}\,ds + V_\infty(y(T)),$$

which implies $V_\infty(x) \leqq V^*$. □

The main result of this section is the following theorem.

THEOREM 4.4. *Assume* (SL) (*respectively,* (SL′)) *and suppose that problem* (1.1)-(1.2) *is stable. Then* V_∞ *is a generalized viscosity solution of equation* (4.1). *Moreover, for any* $x \in X$ (*respectively,* $x \in D_A(\alpha, p)$) *there exists an optimal pair* (u^*, y^*) *and the following feedback formula holds*:

$$u^*(t) \in -DH(B^*\nabla^+ V_\infty(y^*(t))), \qquad t \geqq 0. \tag{4.13}$$

Proof. By Lemma 4.3 and by Proposition 2.1 it follows that $V_\infty(x) = W(t, x)$ where W is the generalized viscosity solution of the problem

$$\begin{aligned} -W_t(t,x) + H(B^*DW(t,x)) - \langle Ax+F(x), DW(t,x)\rangle - g(x) = 0, \\ W(T,x) = V_\infty(x). \end{aligned} \tag{4.14}$$

Then, V_∞ is a generalized viscosity solution of (4.1). The existence of an optimal pair (u^*, y^*) was implicitly obtained in the proof of Proposition 4.1 (respectively, Proposition 4.2). Finally, Proposition 2.3 yields the feedback formula (4.13). □

Remark 4.5. From (2.3) we also obtain that, for all $x \in D(A)$,

$$H(B^*p) - \langle Ax+F(x), p\rangle - g(x) \leqq 0 \quad \forall p \in D^+V_\infty(x), \tag{4.15}$$

$$H(B^*p) - \langle Ax+F(x), p\rangle - g(x) \geqq 0 \quad \forall p \in D^-V_\infty(x). \tag{4.16}$$

Remark 4.6—(Maximum principle). Assume (SL) (respectively, (SL′)). From Proposition 2.3 we conclude that, if $x \in X$ (respectively, $x \in D_A(\alpha, p)$) and (u^*, y^*) is an optimal pair at x, then there exists $p^* \in C([0, \infty[; X)$ such that

$$\begin{aligned} &p^{*\prime}(s) + A^*p^*(s) + (DF(y^*(s))^* + Dg(y(^*s))) = 0, \\ &p^*(s) \in D^+V_\infty(y^*(s)), \\ &u^*(s) \in -DH(B^*D^+V_\infty(y^*(s))) \end{aligned} \tag{4.17}$$

for any $s \in [0, T]$.

Remark 4.7—(Feedback dynamical system). Assume (SL) (respectively, (SL′)) and let (u^*, y^*) be an optimal pair at $x \in X$ (respectively, $x \in D_A(\alpha, p)$). Then, by Remark 4.6, y^* is a solution of the closed loop equation

$$y'(t) \in Ay(t) + F(y(t)) - BDH(B^*D^+V_\infty(y(t))), \quad y(0) = x, \quad t \geqq 0. \tag{4.18}$$

Moreover, by Proposition 2.3, there exists $\delta \in]0, 1[$ such that

$$y^* \in C^{1,\delta}(]0, \infty[; X). \tag{4.19}$$

Now, we denote by S_t the dynamical system generated by (4.18), that is,

$$S_t(x) = y(t), \qquad t \geqq 0, \quad x \in X. \tag{4.20}$$

Then, from the Dynamic Programming Principle (4.12) it follows that S_t is a semigroup of nonlinear operators in X.

We remark that no theory is available to directly solve the initial value problem (4.18) except for special situations such as

$$X = U \text{ Hilbert space}, \quad B = 1, \quad h(x) = \tfrac{1}{2}\|x\|^2, \quad V_\infty \text{ convex}.$$

In this case the operator in the right-hand side of (4.18) becomes m-dissipative (see [6]).

Finally we note that

$$g(S_t x) \in L^1(0, \infty; X) \quad \forall x \in X \quad \text{(respectively, } x \in D_A(\alpha, p)\text{)}. \tag{4.21}$$

5. Uniqueness. To make the context of this section clearer to the reader, we recall some known results from linear quadratic control that correspond to the following choice of data:

$$H(x) = \tfrac{1}{2}|x|^2, \quad f(x) = 0, \quad g(x) = \tfrac{1}{2}|Cx|^2, \quad C \in \mathcal{L}(X) \quad x \in X \tag{5.1}$$

where X is a Hilbert space. In this case, setting $V(x) = \frac{1}{2}\langle Px, x\rangle$, (1.3) reduces to the algebraic Riccati equation:

$$A^*P + PA - PBB^*P + C^*C = 0. \tag{5.2}$$

As it is well known, if (A, B) is stabilizable with respect to the observation C, then there exists a minimal positive solution P_∞ of (5.2). Moreover, if the feedback operator

$$L = A - BB^*P_\infty \tag{5.3}$$

is exponentially stable, then P_∞ is unique among the positive solutions of (5.2).

In general, no necessary and sufficient condition for uniqueness of positive solutions is known. A sufficient condition for L to be exponentially stable (which would yield uniqueness), is that C be invertible (more generally that (A, C) be *detectable*; see [25]).

The aim of this section is to generalize the previous results to the general Hamilton-Jacobi equation

$$H(B^*DV(x)) - \langle Ax + F(x), DV(x)\rangle - g(x) = 0. \tag{5.4}$$

Throughout this section we assume either (SL) or (SL′) and that

(5.5) (i) Problem (1.1)-(1.2) is stable;
(ii) $g(0) = 0$, $h(0) = 0$.

By Theorem 4.5 we know that (5.4) has a generalized viscosity solution given by V_∞.

First we remark that V_∞ is minimal.

LEMMA 5.1. *Assume* (SL) (*respectively*, (SL′)) *and* (5.5). *Let V be a nonnegative generalized viscosity solution of* (5.4) *such that* $V(0) = 0$. *Then* $V_\infty(x) \leqq V(x)$, *for all* $x \in X$ (*respectively*, $x \in D_A(\alpha, p)$).

Proof. By Proposition 2.5 it follows that $\phi(t, x) \leqq V(x)$ where ϕ is the solution of (4.2). Then, Propositions 4.1 and 4.2 yield the conclusion. □

Now, to prove uniqueness we must show that V_∞ is maximal. A sufficient condition for maximality is that $B^{-1} \in \mathcal{L}(H; U)$ and the semigroup of nonlinear operators $S_t(x)$, defined in (4.20), be "stable" for any x in X.

LEMMA 5.2. *Assume* (SL) (*respectively*, (SL′)) *and* (5.5). *Suppose that* $B^{-1} \in \mathcal{L}(H; U)$ *and*

$$\forall x \in X \text{ (respectively, } x \in D_A(\alpha, p)) \ \exists r \geqq 1 \text{ such that } t \to S_t(x) \text{ belongs to } L^r(0, \infty; X). \tag{5.6}$$

Then V_∞ is maximal, that is if V is a generalized viscosity solution of (5.4) *such that* $V(0)=0$, *then*

$$V_\infty(x) \geqq V(x) \quad \forall x \in X. \tag{5.7}$$

Proof. Let $x \in X$ (respectively, $x \in D_A(\alpha, p)$) be fixed. Set $y(t)=S_t(x)$. Recalling Proposition 2.4, we have that $D^+V=\partial V$ (see [9]), where ∂V denotes the generalized gradient in the sense of Clarke [11]. So, by (4.19) and Theorem 2.3.10 of [11], we can differentiate the function $t \to V(y(t))$ in the following sense. There exists $q(t) \in D^+V(y(t))$ such that

$$\frac{d}{dt}V(y(t)) = \langle Ay(t)+F(y(t))+Bu(t), q(t)\rangle \geqq -g(y(t))+\langle u(t), B^*q(t)\rangle + H(B^*q(t))$$

$$\geqq -g(y(t))-h(u(t)).$$

The first of the inequalities above follows from (4.15). Hence,

$$V(y(t))+\int_0^t \{g(y(s))+h(u(s))\} \geqq V(x).$$

Since $y \in L^r(0,\infty; X)$, there exists a sequence $\{t_n\} \uparrow \infty$, such that $y(t_n) \to 0$. Thus, by the above inequality, we conclude that $V_\infty(x) \geqq V(x)$ as required. □

Remark 5.3. A sufficient condition that yields (5.6) is the coercivity of g, that is,

$$g(x) \geqq C|x|^r \quad \forall x \in X \tag{5.8}$$

for some constant $C>0$.

From Lemmas 5.1 and 5.2 we deduce the following uniqueness result.

THEOREM 5.4. *Assume* (SL) (*respectively*, (SL′)), (5.5), *and* (5.6). *Then* (5.4) *has a unique generalized viscosity solution that is nonnegative and vanishes at* $x=0$.

6. Application to a semilinear parabolic state equation. Let Ω be a bounded open set of $\mathbf{R}^n$ with smooth boundary $\partial\Omega$. Consider the following optimal control problem:

Minimize

$$J(u,x)=\frac{1}{p}\int_0^\infty dt \int_\Omega \{|y(t,\xi)|^p+|u(t,\xi)|^p\}\, d\xi \tag{6.1}$$

over all controls $u \in L^p([0,\infty[\times\Omega)$, $p>1$, and states y satisfying

$$\frac{\partial y}{\partial t}(t,\xi)=\Delta_\xi y(t,\xi)+\Gamma(y(t,\xi), \nabla_\xi y(t,\xi))+u(t,\xi) \quad \text{in } [0,\infty[\times\Omega, \tag{6.2}$$

$$y(t,\xi)=0 \quad \text{on } [0,\infty[\times\partial\Omega, \tag{6.3}$$

$$y(0,\xi)=x(\xi) \quad \text{on } \Omega \tag{6.4}$$

where $\Gamma(r,s)$ is a real-valued function defined in $\mathbf{R}\times\mathbf{R}^n$ and $x \in L^p(\Omega)$.

To apply the results of §§ 3–5, we proceed to check the assumptions (SL′). Let $X=U=L^p(\Omega)$, A be defined by

$$D(A)=W^{2,p}(\Omega)\cap W_0^{1,p}(\Omega) \quad Az=\Delta_\xi z \quad \forall z \in D(A) \tag{6.5}$$

and let $B=1$. Then A generates an analytic semigroup in $L^p(\Omega)$ by [1] and the embedding of $D(A)$ in $L^p(\Omega)$ is compact in view of the Rellich Theorem. Also, we set

$$g(x)=\frac{1}{p}\int_\Omega |x(\xi)|^p\, d\xi, \qquad h(u)=\frac{1}{p}\int_\Omega |u(\xi)|^p\, d\xi. \tag{6.6}$$

Then, it is well known that $g, h \in C^2(L^p(\Omega))$, provided that

$$p \geqq 2. \tag{6.7}$$

So far, we have shown that assumptions (SL')(i) are satisfied.

Now we check (SL')(ii). For this purpose we define

$$Z = C(\bar{\Omega})$$

and note that by the results of [23] the part of A in Z, A_Z, generates an analytic semigroup. This semigroup is also contracting in view of the maximum principle and so (SL')(ii) holds with $\mu = 0$. Next, to verify (SL')(iii), recall the following well-known characterization of the interpolation spaces $D_A(\alpha, p)$ (see, for instance, [24]):

$$D_A(\alpha, p) = \begin{cases} \{f \in W^{2\alpha,p}(\Omega); f_{|\partial\Omega} = 0\} & \text{if } \alpha \in \left]\frac{1}{2p}, 1\right[, \\ W^{2\alpha,p}(\Omega) & \text{if } \alpha \in \left]0, \frac{1}{2p}\right[. \end{cases}$$

By the Sobolev Embedding Theorem,

$$D_A(\alpha, p) \subset C(\bar{\Omega}) = z \quad \text{if } \alpha > \frac{n}{2p}. \tag{6.8}$$

Note that the constraint in (6.8) is compatible with the requirement $\alpha \in]0, 1 - 1/p[$ if

$$p > \frac{n+2}{2}. \tag{6.9}$$

Let $F(x) = \Gamma(x, \nabla_\xi x)$ and assume

$$\Gamma \in C^2(\mathbf{R} \times \mathbf{R}^n). \tag{6.10}$$

From the Sobolev Embedding Theorem it follows that

$$\alpha > \frac{n+p}{2p} \Rightarrow W^{2\alpha,p}(\Omega) \subset C^1(\bar{\Omega}), \tag{6.11}$$

which in turn implies that F fulfills (1.14). Note again that the constraint in (6.11) is compatible with the requirement $\alpha \in]0, 1 - 1/p[$ if

$$p > n + 2. \tag{6.12}$$

We will now show that the condition

$$r\Gamma(r, 0) \leqq ar^2 \quad \text{for all } r \in \mathbf{R} \text{ and some } a \in \mathbf{R} \tag{6.13}$$

implies (1.15). The argument is known; nevertheless, we recall it for the reader's convenience. First, let

(6.14) $z \in C^1(\bar{\Omega})$ be such that $|z|$ has a unique maximum point, say $\xi_0 \in \Omega$.

Then, we can easily show that $\partial|z| = \{z^*\}$, where

$$z^* = \begin{cases} \delta_{\xi_0} & \text{if } z(\xi_0) = |z|_Z, \\ -\delta_{\xi_0} & \text{if } z(\xi_0) = -|z|_Z, \end{cases}$$

and δ denotes the Dirac measure. Thus,

$$\langle F(z), z^* \rangle = \begin{cases} \Gamma(|z|_Z, 0) & \text{if } z(\xi_0) = |z|_Z, \\ -\Gamma(-|z|_Z, 0) & \text{if } z(\xi_0) = -|z|_Z. \end{cases} \tag{6.15}$$

From (6.13) and (6.15) we get

$$\langle F(z), z^*\rangle \leqq a|z|_Z \tag{6.16}$$

for all z satisfying (6.14). On the other hand, it is well known (see, for instance, [17, Lemma II-7-1]) that $z \in Z$ satisfies (6.16) if and only if

$$|z| \leqq |z+\lambda(F(z)-az)| \quad \forall \lambda > 0. \tag{6.17}$$

Since the set of functions z satisfying (6.14) is dense in Z, the proof of (1.15) is complete. Finally, if we assume that

$$|\Gamma(r, s)| \leqq \beta(|r|)+\rho(|r|)|s| \tag{6.18}$$

where $\beta, \rho : [0, \infty[\to [0, \infty[$ are continuous functions, then (1.16) easily follows. Therefore, assumptions (SL′) are fulfilled if

(6.19) $(n+p)/2p < \alpha < 1-1/p$, $p > n+2$, and (6.10), (6.13), and (6.18) hold.

Our next goal is to show that $(A+F, B, h)$ is g-stabilizable. This will be given by Proposition 3.3 if we assume that the function β in (6.18) satisfies

$$\beta(r) \leqq Cr^\sigma \quad \forall r \in [0, R] \tag{6.20}$$

for some constants $C, R \geqq 0$.

Now, Theorem 5.4 yields the following theorem.

THEOREM 6.1. *Assume* (6.19) *and* (6.20). *Then the Hamilton-Jacobi equation*

$$(p-1)|DV(x)|_{X^*}^{p'} - p\langle \Delta_\xi x + \Gamma(x, \nabla_\xi x), DV(x)\rangle - |x|_X^p = 0, \qquad p' = \frac{p}{p-1} \tag{6.21}$$

has a unique generalized viscosity solution $V_\infty \geqq 0$ *such that* $V_\infty(0) = 0$. V_∞ *is the value function of the control problem* (6.1)-(6.4). *Moreover, for any* $x \in D_A(\alpha, p)$ *there exists an optimal pair* (u^*, y^*) *at* x *and the following feedback formula holds*:

$$u^*(t) \in |D^+V(y^*(t))|^{p'-2}D^+V(y^*(t)). \tag{6.22}$$

REGULARITY OF THE VALUE FUNCTION FOR A TWO-DIMENSIONAL SINGULAR STOCHASTIC CONTROL PROBLEM*

H. METE SONER† AND STEVEN E. SHREVE‡

Abstract. It is desired to control a two-dimensional Brownian motion by adding a (possibly singularly) continuous process to it so as to minimize an expected infinite-horizon discounted running cost. The Hamilton-Jacobi-Bellman characterization of the value function V is a variational inequality which has a unique *twice* continuously differentiable solution. The optimal control process is constructed by solving the Skorokhod problem of reflecting the two-dimensional Brownian motion along a free boundary in the $-\nabla V$ direction.

Key words. singular stochastic control, variational inequality, free boundary problem, Skorokhod problem

AMS(MOS) subject classifications. 93E20, 35R35

1. Introduction.

We study regularity of the solution of the variational inequality associated with a two-dimensional singular stochastic control problem with a convex running cost. The solution u of this variational inequality, which is the value function for the control problem, is shown to be of class C^2. We also study the regularity of the free boundary in $\mathbb{R}^2$ which divides the region where u satisfies a second-order elliptic equation from the region where it does not. The free boundary is shown to be smooth, and this fact is instrumental in our construction of the optimal process for the stochastic control problem.

Previous work on the regularity of the value function in singular stochastic control has focused on one-dimensional problems. Beneš, Shepp, and Witsenhausen (1980) suggested that the value function for these problems should be of class C^2 and used this so-called "principle of smooth fit" to determine some otherwise free parameters that arose in the solution of their problems. It has been used in the same way by Harrison (1985), Harrison and Taylor (1978), Harrison and Taksar (1983), Karatzas (1981), (1983), Lehoczky and Shreve (1986), Shreve, Lehoczky, and Gaver (1984), and Taksar (1985). (But see Menaldi and Robin (1983), Chow, Menaldi, and Robin (1985), and Sun (1987) for a variational inequality approach to singular control that does not use the principle of smooth fit.) An important question is whether the principle of smooth fit can be expected to apply to multidimensional singular control problems, or is it strictly a one-dimensional phenomenon. Karatzas and Shreve (1986) suggested that it might apply in higher dimensions. These authors studied the singular control of a one-dimensional Brownian motion under a constraint on the total variation of the control process (a "finite-fuel" constraint). The fuel remaining constitutes a second state variable, and the value function for this problem was found to be of class C^2 jointly in both state variables. One should observe, however, that the second state variable in this problem is not a diffusion; indeed, the fuel remaining is constant until control is exercised, at which time it decreases an amount equal to the displacement caused by the control.

This paper concerns the control of a two-dimensional Brownian motion, and control can cause displacement in any direction. Thus, the discovery of a C^2 value function provides strong support for belief in a widely applicable principle of smooth fit. Nevertheless, the argument of this paper depends heavily on the fact that only two dimensions are involved (see Remark 6.2), and we have not found a way to obtain a similar result in higher dimensions.

This paper is organized as follows. Section 2 defines the underlying stochastic control problem, and § 3 relates it to a free boundary problem, the so-called Hamilton-Jacobi-Bellman (HJB) equation. Section 4 constructs a $C^{1,1}$, nonnegative convex solution u to the HJB equation and proves its uniqueness. Sections 5–10 upgrade the regularity of u to C^2. The key idea here is to use the gradient flow of u to change to a more convenient pair of coordinates. This is a generalization of the device used by many authors in one-dimensional problems of differentiating the Bellman equation so as to obtain a more standard free boundary problem. In § 11 the free boundary is shown to be of class $C^{2,\alpha}$ for any $\alpha \in (0, 1)$. In § 12 we return to the stochastic control problem, which now reduces to the Skorokhod problem of finding a Brownian motion reflected along the free boundary in the $-\nabla u$ direction. The established regularity of u and the free boundary allow us to assert the existence and uniqueness of a solution to the Skorokhod problem and finally complete the proof, begun in § 3, that u is the value function for the stochastic control problem of § 2.

2. The singular stochastic control problem. Let $\{W_t, \mathcal{F}_t; 0 \leqq t < \infty\}$ be a standard, two-dimensional Brownian motion defined on a complete probability space $(\Omega, \mathcal{F}, P)$, and let $\{\mathcal{F}_t\}$ be the augmentation of the filtration generated by W (see Karatzas and Shreve (1987, p. 89)). The *state process* for our control problem is

$$X_t \triangleq x + \sqrt{2}\, W_t + \int_0^t N_s \, d\zeta_s, \qquad 0 \leqq t < \infty, \tag{2.1}$$

where $x \in \mathbb{R}^2$ is the initial condition and the *control process pair* $\{(N_t, \zeta_t); 0 \leqq t < \infty\}$ is $\{\mathcal{F}_t\}$-adapted and satisfies the conditions:

$$|N_t| = 1, \quad \forall 0 \leqq t < \infty \quad \text{a.s.}, \tag{2.2}$$

where $|\cdot|$ denotes the Euclidean norm, and

$$\zeta \text{ is nondecreasing, left-continuous, and } \zeta_0 = 0 \quad \text{a.s.}. \tag{2.3}$$

The process N gives the direction and ζ gives the intensity of the "push" applied by the controller to the state X.

Given control processes N and ζ, we define the corresponding cost

$$V_{N,\zeta}(x) \triangleq E^x \int_0^\infty e^{-t}[h(X_t)\, dt + d\zeta_t], \tag{2.4}$$

where $h: R^2 \to \mathbb{R}$ is a strictly convex function satisfying, for appropriate positive constants C_0, c_0, and q:

$$h \in C^{2,1}_{loc}(\mathbb{R}^2), \tag{2.5}$$

$$0 \leqq h(x) \leqq C_0(1 + |x|^q) \quad \forall x \in \mathbb{R}^2, \tag{2.6}$$

$$|\nabla h(x)| \leqq C_0(1 + h(x)) \quad \forall x \in \mathbb{R}^2, \tag{2.7}$$

$$c_0 |y|^2 \leqq D^2 h(x) y \cdot y \leqq C_0 |y|^2 (1 + h(x)) \quad \forall x \in \mathbb{R}^2, y \in \mathbb{R}^2. \tag{2.8}$$

Without loss of generality, we also assume that

$$0 = h(0) \leqq h(x) \quad \forall x \in \mathbb{R}^2. \tag{2.9}$$

For $x \in \mathbb{R}^2$, we define the *value function*

$$V(x) \triangleq \inf_{N,\zeta} V_{N,\zeta}(x). \tag{2.10}$$

3. The Hamilton–Jacobi–Bellman equation. We shall show that the value function V of (2.10) is characterized by the *Hamilton-Jacobi-Bellman* (HJB) equation

$$\max\{u - \Delta u - h, |\nabla u|^2 - 1\} = 0. \tag{3.1}$$

The following theorem gives a partial description of the relationship between V and the HJB equation. More definitive results are proved in § 12.

THEOREM 3.1. *Let $u: \mathbb{R}^2 \to \mathbb{R}$ be a convex, C^2 solution of* (3.1). *Then $u \leqq V$. For a given $x \in \mathbb{R}^2$, suppose there exists a control process pair (N, ζ) such that $V_{N,\zeta}(x) < \infty$ and the corresponding state process* (2.1) *satisfies*

$$u(X_t) - \Delta u(X_t) - h(X_t) = 0 \quad \forall t \in (0, \infty), \quad \text{a.s.}, \tag{3.2}$$

$$\int_0^t 1_{\{N_s = -\nabla u(X_s)\}}\, d\zeta_s = \zeta_t \quad \forall t \in [0, \infty), \quad \text{a.s.}, \tag{3.3}$$

$$u(X_t) - u(X_{t+}) = \zeta_{t+} - \zeta_t \quad \forall t \in [0, \infty), \quad \text{a.s.} \tag{3.4}$$

Then

$$u(x) = V(x) = V_{N,\zeta}(x),$$

i.e., (N, ζ) is optimal at x.

Proof. Let $x \in \mathbb{R}^2$ and any control process pair (N, ζ) be given. Applying Itô's rule for semimartingales (Meyer (1976, pp. 278, 301)) to $e^{-t}u(X_t)$, adjusting the result to account for the fact that ζ is left-continuous rather than right-continuous, and observing that $|\nabla u| \leqq 1$ so $E\int_0^t e^{-s}\nabla u(X_s)\, dW_s = 0$, we obtain for $t \geqq 0$:

$$\begin{aligned} u(x) = {} & E\, e^{-t}u(X_t) + E\int_0^t e^{-s}[u(X_s) - \Delta u(X_s) - h(X_s)]\, ds \\ & + E\int_0^t e^{-s}h(X_s)\, ds + E\int_0^t [-e^{-s}\nabla u(X_s)\cdot N_s]\, d\zeta_s \\ & + E\sum_{0 \leqq s < t} e^{-s}[u(X_s) - u(X_{s+}) + \nabla u(X_s)\cdot N_s(\zeta_{s+} - \zeta s)]. \end{aligned} \tag{3.5}$$

The second and fifth terms on the right-hand side of (3.5) are nonpositive because of (3.1) and the convexity of u, respectively. Because $|\nabla u| \leqq 1$, the fourth term is dominated by $E\int_0^t e^{-s}\, d\zeta_s$, and thus we have

$$u(x) \leqq E\, e^{-t}u(X_t) + E\int_0^t e^{-s}[h(X_s)\, ds + d\zeta_s]. \tag{3.6}$$

We wish to let $t \to \infty$ in (3.6) to obtain

$$u(x) \leqq E\int_0^\infty e^{-s}[h(X_s)\, ds + d\zeta_s] = V_{N,\zeta}(x). \tag{3.7}$$

Assume $E\int_0^\infty e^{-s}h(X_s)<\infty$, for otherwise (3.7) is obviously true. This implies that

$$\underline{\lim}_{t\to\infty} E\,e^{-t}h(X_t)=0.$$

Now (2.8), (2.9), and the inequality $|\nabla u|\leq 1$ (from (3.1)) imply that for all $y\in\mathbb{R}^2$,

$$u(y)\leqq u(0)+|y|\leqq u(0)+1+|y|^2\leqq u(0)+1+\frac{2}{c_0}h(y), \tag{3.8}$$

so

$$\underline{\lim}_{t\to\infty} E\,e^{-t}u(X_t)=0.$$

We may therefore pass to the limit in (3.6) along a sequence $\{t_n\}_{n=1}^\infty$ such that $E\,e^{-t_n}u(X_{t_n})\to 0$ as $t_n\to\infty$, and (3.7) follows. Since (N,ζ) is an arbitrary control process pair, we have $u(x)\leqq V(x)$.

If (3.2)–(3.4) are satisfied, then the second and fifth terms on the right-hand side of (3.5) are zero, and the fourth term is $E\int_0^t e^{-s}\,d\zeta_s$. It follows that equality holds in (3.6), and hence also in (3.7), i.e.,

$$u(x)\leqq V(x)\leqq V_{(N,\zeta)}(x)=u(x). \qquad \square$$

Remark 3.2. Equation (3.1) is similar but not equivalent to a problem arising in elastic-plastic torsion (Ting (1966), (1967), Duvant and Lanchon (1967), Brezis and Sibony (1971)). The elastic-plastic problem is posed on a bounded domain $\Omega\subset\mathbb{R}^n$, and is to minimize

$$J(v)\triangleq\int_\Omega \frac{1}{2}|\nabla v|^2-vh$$

over $K\triangleq\{v\in H_0^1(\Omega);\ \|\nabla v\|_\infty\leqq 1\}$. Equivalently, one seeks $u\in K$ satisfying

$$\int h(v-u)-\int \nabla u\cdot(\nabla v-\nabla u)\leqq 0 \quad \forall v\in K.$$

If u solves the elastic-plastic torsion problem, then

$$(\Delta u+h)(|\nabla u|-1)=0,$$

but $\Delta u+h$ may be negative. In the special case that h is a nonnegative constant function, a solution to the elastic-plastic problem also satisfies a variational inequality like (3.1) (see Evans (1979, § 6), but such an h is not interesting in the control problem.

4. Solution of the Hamilton–Jacobi–Bellman equation. The existence of a $W^{2,\infty}_{loc}$ solution to the HJB equation (3.1) follows from a modification of Evans (1979) (see also Ishii and Koike (1983)), who treated a bounded domain and general h and space dimension. We need to refer to this construction in the next section, so we provide it here.

Let $\beta:\mathbb{R}\to\mathbb{R}$ be a C^∞ function satisfying

$$\beta(r)=0 \quad \forall r\in(-\infty,0], \tag{4.1i}$$

$$\beta(r)>0 \quad \forall r\in(0,\infty), \tag{4.1ii}$$

$$\beta(r)=r-1 \quad \forall r\in[2,\infty), \tag{4.1iii}$$

$$\beta'(r)\geqq 0,\quad \beta''(r)\geqq 0 \quad \forall r\in\mathbb{R}. \tag{4.1iv}$$

For each $\varepsilon > 0$, we form the penalization function

$$\beta_\varepsilon(r) \triangleq \beta\left(\frac{r-1}{\varepsilon}\right) \quad \forall r \in \mathbb{R}, \tag{4.2}$$

and we consider the *penalized equation*

$$u^\varepsilon - \Delta u^\varepsilon + \beta_\varepsilon(|\nabla u^\varepsilon|^2) = h. \tag{4.3}$$

The following lemma is proved in the appendix.

LEMMA 4.1. *For every $\varepsilon \in (0,1)$, there exists a nonnegative, convex, C^2solution u^ε* to (4.3). *There exist positive constants C_1, C_2, and p, indepenent of ε, such that for all $\varepsilon \in (0,1)$, for all $x \in \mathbb{R}^2$:*

$$0 \leqq u^\varepsilon(x) \leqq C_1(1+|x|^p), \tag{4.4}$$

$$|\nabla u^\varepsilon(x)| \leqq C_1(1+|x|^p), \tag{4.5}$$

and for every $y \in \mathbb{R}^2$,

$$0 \leqq D^2 u^\varepsilon(x) y \cdot y \leqq C_2 |y|^2 (1+u^\varepsilon(x)). \tag{4.6}$$

DEFINITION 4.2. We define a norm on the vector space of 2×2 matrices by

$$\|A\| \triangleq \sqrt{\text{trace}\,(AA^T)}.$$

If A is symmetric with eigenvalues λ_1 and λ_2, then

$$\|A\| = \sqrt{\lambda_1^2 + \lambda_2^2}. \tag{4.7}$$

THEOREM 4.3. *The* HJB *equation* (3.1) *has a nonnegative, convex solution $u \in W^{2,\infty}_{loc}$ satisfying*

$$\|D^2 u(x)\| \leqq C_3(1+|x|^m), \quad \text{a.e. } x \in \mathbb{R}^2, \tag{4.8}$$

for some $C_3 > 0$ and $m \in \mathbb{N}$.

Proof. Because $D^2 u^\varepsilon$ is locally bounded uniformly in $\varepsilon \in (0,1)$, we may choose a decreasing sequence $\{\varepsilon_n\}_{n=1}^\infty$ with limit zero such that $\{u^{\varepsilon_n}\}_{n=1}^\infty$ and $\{\nabla u^{\varepsilon_n}\}_{n=1}^\infty$ converge uniformly on compact sets, and $\{D^2 u^{\varepsilon_n}\}_{n=1}^\infty$ converges in the L^∞_{loc}-weak* topology. Define $u = \lim_{n\to\infty} u^{\varepsilon_n}$, so that $\nabla u = \lim_{n\to\infty} \nabla u^{\varepsilon_n}$ and the weak* limit of $\{D^2 u^{\varepsilon_n}\}_{n=1}^\infty$ is $D^2 u$. Passage to the limit in (4.3) gives (3.1). □

LEMMA 4.4. *Let $u \in W^{2,\infty}_{loc}$ be a nonnegative, convex solution to the* HJB *equation* (3.1), *and define*

$$\mathscr{C} \triangleq \{x \in \mathbb{R}^2; |\nabla u(x)|^2 < 1\}. \tag{4.9}$$

Then for every unit vector ν,

$$u_{\nu\nu} \triangleq (D^2 u)\nu \cdot \nu > 0 \quad \text{on } \mathscr{C}. \tag{4.10}$$

$\mathscr{C}$ is bounded, and u attains its unique minimum over $\mathbb{R}^2$ inside $\mathscr{C}$.

Proof. We have

$$u - \Delta u = h \quad \text{on } \mathscr{C}, \tag{4.11}$$

and $h \in C^{2,1}_{loc}(\mathbb{R}^2)$, so $u \in C^{4,\alpha}(\mathscr{C})$ for all $\alpha \in (0,1)$. Differentiating (4.11), we obtain

$$u_{\nu\nu} - \Delta u_{\nu\nu} = h_{\nu\nu} \quad \text{on } \mathscr{C}.$$

and since $h_{\nu\nu} > 0$, relation (4.10) holds. Equation (4.11) also implies that $u \geqq h$ on $\mathscr{C}$, and since $|\nabla u| \leqq 1$ on $\mathbb{R}^2$ but h grows at least quadratically (see (2.8)), $\mathscr{C}$ must be bounded.

Let $\delta \in (0, \frac{1}{2})$ be given, and choose $x^\delta \in \mathbb{R}^2$ such that

$$u(x^\delta) \leqq u(x) + \delta \quad \forall x \in \mathbb{R}^2.$$

Define

$$\psi_\delta(x) \triangleq u(x) + \delta|x - x^\delta|^2 \quad \forall x \in \mathbb{R}^2,$$

and note that ψ_δ attains its minimum over $\mathbb{R}^2$ at some point y^δ. In particular,

$$0 = \nabla \psi_\delta(y^\delta) = \nabla u(y^\delta) + 2\delta(y^\delta - x^\delta). \tag{4.12}$$

But also

$$u(y^\delta) + \delta|y^\delta - x^\delta|^2 = \psi_\delta(y^\delta) \leqq \psi_\delta(x^\delta) = u(x^\delta) \leqq u(y^\delta) + \delta.$$

It follows that $|y^\delta - x^\delta| \leqq 1$, and returning to (4.12), we see that $|\nabla u(y^\delta)| \leqq 2\delta < 1$. Therefore, $y^\delta \in \mathscr{C}$ for all $\delta \in (0, \frac{1}{2})$, and the sequence $\{y^{1/n}\}_{n=3}^\infty$ accumulates at some $y^0 \in \bar{\mathscr{C}}$. From (4.12) we have $\nabla u(y^0) = 0$, so $y^0 \in \mathscr{C}$, and the convexity of u on $\mathbb{R}^2$ implies that u attains its minimum at y_0. This minimum is unique because of (4.10). □

THEOREM 4.5. *There is only one nonnegative, convex solution $u \in W^{2,\infty}_{loc}$ to the* HJB *equation* (3.1).

Proof. *Let* u_1 and u_2 be two nonnegative, convex solutions to (3.1), and let y^0 be the point where u_2 attains its minimum. Given $\delta > 0$, define

$$\varphi_\delta(x) \triangleq u_1(x) - u_2(x) - \delta|x - y^0|^2 \quad \forall x \in \mathbb{R}^2.$$

The function φ_δ attains its maximum at some $x^\delta \in \mathbb{R}^2$, and $0 = \nabla \varphi_\delta(x^\delta) = \nabla u_1(x^\delta) - \nabla u_2(x^\delta) - 2\delta(x^\delta - y^0)$. Consequently,

$$1 \geqq |\nabla u_1(x^\delta)|^2 = |\nabla u_2(x^\delta)|^2 + 4\delta^2|x^\delta - y^0|^2 + 4\delta \nabla u_2(x^\delta) \cdot (x^\delta - y^0).$$

Because u_2 is convex, $\nabla u_2(x^\delta) \cdot (x^\delta - y^0) \geqq 0$, so either $|\nabla u_2(x^\delta)|^2 < 1$ or $x^\delta = y^0$. This last equality would imply that $\nabla u_2(x^\delta) = 0$, so in any event, $|\nabla u_2(x^\delta)|^2 < 1$. From (3.1) we have

$$\Delta u_2(x^\delta) = u_2(x^\delta) - h(x^\delta).$$

Because φ attains its maximum at x^δ, we have from the Bony maximum principle (Bony (1967), Lions (1983))

$$\begin{aligned} 0 &\geqq \liminf_{x \to x^\delta} \operatorname{ess}\, \Delta\, \varphi_\delta(x) \\ &= \liminf_{x \to x^\delta} \operatorname{ess}\, [\Delta u_1(x) - \Delta u_2(x) - 4\delta] \\ &\geqq u_1(x^\delta) - u_2(x^\delta) - 4\delta. \end{aligned}$$

It follows that for all $x \in \mathbb{R}^2$,

$$\begin{aligned} u_1(x) - u_2(x) &= \varphi_\delta(x) + \delta|x - y^0|^2 \\ &\leqq \varphi_\delta(x^\delta) + \delta|x - y^0|^2 \\ &\leqq \delta(4 + |x - y^0|^2). \end{aligned}$$

Letting $\delta \downarrow 0$, we obtain $u_1 \leq u_2$. The reverse inequality is proved by interchanging u_1 and u_2. □

Remark 4.6. Throughout the remainder of the paper, u will denote the unique nonnegative, convex solution in $W^{2,\infty}_{loc}$ to (3.1). The set $\mathscr{C}$ will be given by (4.9), and $y^0 \in \mathscr{C}$ will denote the unique minimizer of u. We shall prove that $u \in C^{2,\alpha}_{loc}(\mathbb{R}^2)$ for all $\alpha \in (0,1)$ (Theorem 10.3), $\partial\mathscr{C}$ is of class $C^{2,\alpha}$ for all $\alpha \in (0,1)$ (Corollary 11.3), and $n(x) \cdot \nabla u(x) \geqq \sigma$ for all $x \in \partial\mathscr{C}$, where $n(x)$ is the outward normal to $\mathscr{C}$ at x and σ is a positive constant (Lemma 12.2).

5. An obstacle problem. Let us return to the construction of u in the proof of Theorem 4.3 as the limit of a sequence of functions $\{u^{\varepsilon_n}\}_{n=1}^{\infty}$, where each u^{ε_n} satisfies (4.3). Define $w^{\varepsilon_n} \triangleq |\nabla u^{\varepsilon_n}|^2$ and compute the product of ∇u^{ε_n} with the gradient of both sides of (4.3) to obtain

$$w^{\varepsilon_n} - \tfrac{1}{2}\Delta w^{\varepsilon_n} + 2\beta'_{\varepsilon_n}(w^{\varepsilon_n})(D^2 u^{\varepsilon_n})\nabla u^{\varepsilon_n} \cdot \nabla u^{\varepsilon_n} = H^{\varepsilon_n} \tag{5.1}$$

where

$$H^{\varepsilon_n} \triangleq \nabla h \cdot \nabla u^{\varepsilon_n} - \|D^2 u^{\varepsilon_n}\|^2.$$

Along a subsequence, which we also call $\{\varepsilon_n\}_{n=1}^{\infty}$, $\{H^{\varepsilon_n}\}_{n=1}^{\infty}$ converges to

$$\bar{H} \triangleq \nabla h \cdot \nabla u - \chi, \tag{5.2}$$

where χ is the limit of $\|D^2 u^{\varepsilon_n}\|^2$ in the weak* topology on L^{∞}_{loc}. We will show that

$$w = |\nabla u|^2 = \lim_{n \to \infty} |\nabla u^{\varepsilon_n}|^2$$

solves an obstacle problem involving $\bar{H}$, and we will then obtain $W^{2,p}_{loc}$ regularity for w by invoking the theory of variational inequalities.

For $r > 0$ chosen so that $B_r(0) \triangleq \{x \in \mathbb{R}^2; |x| < r\}$ contains $\mathscr{C}$, define

$$K_r \triangleq \{v \in W^{1,2}(B_r);\ 0 \leqq v \leqq 1 \text{ on } B_r \text{ and } v - 1 \in W^{1,2}_0(B_r)\}.$$

We pose the problem of finding $\varphi \in K_r$ such that

$$\frac{1}{2}\int_{B_r(0)} \nabla\varphi \cdot (\nabla v - \nabla\varphi) \geqq \int_{B_r(0)} (\bar{H} - w)(v - \varphi) \quad \forall v \in K_r. \tag{5.3}$$

LEMMA 5.1. *The function* $w = |\nabla u|^2$ *solves* (5.3).

Proof. Let $v \in K_r$ be given. From (5.1) we have

$$\begin{aligned} &\int_{B_r(0)} \left(w^{\varepsilon_n} - \frac{1}{2}\Delta w^{\varepsilon_n} - H^{\varepsilon_n} \right)(v - w^{\varepsilon_n}) \\ &\qquad = -\int_{B_r(0)} 2\beta'_{\varepsilon_n}(w^{\varepsilon_n})(D^2 u^{\varepsilon_n})\nabla u^{\varepsilon_n} \cdot \nabla u^{\varepsilon_n}(v - w^{\varepsilon_n}). \end{aligned} \tag{5.4}$$

The function u^{ε_n} is convex, $\beta'_{\varepsilon_n}(w^{\varepsilon_n}) = 0$ whenever $w^{\varepsilon_n} \leqq 1$, and $v - w^{\varepsilon_n} < 0$ whenever $w^{\varepsilon_n} > 1$. Therefore, the right-hand side of (5.4) is nonnegative, and integration by parts yields

$$\begin{aligned} &-\frac{1}{2}\int_{\partial B_r(0)} (v - w^{\varepsilon_n})\nabla w^{\varepsilon_n} \cdot n + \frac{1}{2}\int_{B_r(0)} \nabla w^{\varepsilon_n} \cdot (\nabla v - \nabla w^{\varepsilon_n}) \\ &\qquad \geqq \int_{B_r(0)} (H^{\varepsilon_n} - w^{\varepsilon_n})(v - w^{\varepsilon_n}), \end{aligned} \tag{5.5}$$

where n is the outward normal on $\partial B_r(0)$. Now $w^{\varepsilon_n} \to v$ uniformly on $\partial B_r(0)$, $w^{\varepsilon_n} \to w$ uniformly on $B_r(0)$, and $H^{\varepsilon_n} \to \bar{H}$, $\nabla w^{\varepsilon_n} \to \nabla w$, both the latter convergences being weak*

in $L^\infty(B_r(0))$. Because the weak* limit of $|\nabla w^{\varepsilon_n}|^2$ dominates $|\nabla w|^2$, we may pass to the limit in (5.5) to obtain

$$\frac{1}{2}\int_{B_r(0)} \nabla w\cdot(\nabla v-\nabla w)\geqq \int_{B_r(0)} (\bar H - w)(v-w) \quad \forall v\in K_r. \tag{5.6}$$ □

THEOREM 5.2. *For every* $p\in(1,\infty)$, $w\triangleq|\nabla u|^2\in W^{2,p}_{loc}$.

Proof. This is a classical result. See, for example, Lemma 5.1 and Theorem 3.11, p. 29 of Chipot (1984). □

COROLLARY 5.3. *We have* $w\in C^{1,\alpha}(\mathbb{R}^2)$ *for any* $\alpha\in(0,1)$.

Proof. This follows from Sobolev imbedding (Gilbarg and Trudinger (1983, Thm. 7.17, p. 163)). □

Remark 5.4. Integration by parts allows us to rewrite (5.6) as

$$\int_{B_r(0)} (w-\tfrac{1}{2}\Delta w-\bar H)(v-w)\geqq 0 \quad \forall v\in K_r,$$

for all sufficiently large r, and so

$$\max\{w-\tfrac{1}{2}\Delta w-\bar H,\ w-1\}=0. \tag{5.7}$$

Now χ appearing in (5.2) dominates $\|D^2u\|$, and so $\bar H$ is dominated by

$$H\triangleq \nabla h\cdot\nabla u-\|D^2u\|^2. \tag{5.8}$$

But let $x^0\in\mathscr{C}$ be given and choose $\varepsilon>0$ such that the closed disk $\overline{B_{2\varepsilon}(x_0)}$ is contained in $\mathscr{C}$. Choose a positive integer N such that

$$|\nabla u^{\varepsilon_n}(x)|<1 \quad \forall n\geqq N,\quad x\in\overline{B_{2\varepsilon}(x^0)}.$$

From (4.1i), (4.2), and (4.3), we see that

$$u^{\varepsilon_n}-\Delta u^{\varepsilon_n}=h \quad \text{on } \overline{B_{2\varepsilon}(x^0)}.$$

According to Gilbarg and Trudinger (1983, Thm. 4.6, p. 6), for every $\alpha\in(0,1)$, $|u^{\varepsilon_n}|_{C^{2,\alpha}(B_\varepsilon(x^0))}$ is bounded uniformly in $n\geqq N$. Thus, on $B_\varepsilon(x^0)$, $D^2u^{\varepsilon_n}$ is continuous and converges uniformly to D^2u, $\chi=\|D^2u\|^2$, and $\bar H=H$. We conclude that (5.7) remains valid if $\bar H$ is replaced by H, i.e.,

$$\max\{w-\tfrac{1}{2}\Delta w-H,\ w-1\}=0. \tag{5.9}$$

6. D^2u inside $\bar{\mathscr{C}}$. Inside the set $\mathscr{C}$ defined by (4.9), u satisfies the elliptic equation $u-\Delta u=h$, and is therefore smooth (at least $C^{4,\alpha}$ for all $\alpha\in(0,1)$ because h is $C^{2,1}$). In this section, we describe the behavior of D^2u as $\partial\mathscr{C}$ is approached from inside $\mathscr{C}$.

LEMMA 6.1. *Let* $z\in\partial\mathscr{C}$ *be given. As* $x\in\mathscr{C}$ *approaches* z, $D^2u(x)$ *approaches the matrix*

$$A(z)\triangleq(u(z)-h(z))\begin{bmatrix} u_2^2(z) & -u_1(z)u_2(z)\\ -u_1(z)u_2(z) & u_1^2(z)\end{bmatrix},$$

where u_i *denotes the ith partial derivative of* u.

Proof. Because $w=|\nabla u|^2=1$ on $\partial\mathscr{C}$, $A(z)$ can be characterized as the unique 2×2 positive semidefinite matrix with eigenvalues zero and $u(z)-h(z)$, and with $\nabla u(z)$ an eigenvector corresponding to the eigenvalue zero. Let v be a unit vector orthogonal to the unit vector $\nabla u(z)$. It suffices to show that

$$\lim_{\substack{x\to z\\ x\in\mathscr{C}}} D^2u(x)\nabla u(z)=0 \tag{6.1}$$

$$\lim_{\substack{x\to z\\ x\in\mathscr{C}}} D^2u(x)v=(u(z)-h(z))v. \tag{6.2}$$

Because $w = |\nabla u|^2$ attains its maximum value of 1 at z, and ∇w is continuous (Corollary 5.3), we have

$$0 = \nabla w(z) = \lim_{\substack{x \to z \\ x \in \mathscr{C}}} \nabla w(x) = \lim_{\substack{x \to z \\ x \in \mathscr{C}}} D^2 u(x) \nabla u(x).$$

Since ∇u is continuous and $D^2 u \in L^\infty_{loc}$, (6.1) follows.

Let $0 = \lambda_1(x) \leqq \lambda_2(x)$ denote the eigenvalues of $D^2 u(x)$. Then $u(x) - h(x) = \Delta u(x) = \lambda_1(x) + \lambda_2(x)$ for all $x \in \mathscr{C}$, and (6.1) shows that $\lim_{x \to z, x \in \mathscr{C}} \lambda_1(x) = 0$. Consequently,

$$\lim_{\substack{x \to z \\ x \in \mathscr{C}}} \lambda_2(x) = u(z) - h(z), \tag{6.3}$$

which is thus nonnegative. If $u(z) - h(z) = 0$, then $D^2 u(x)$ approaches the zero matrix and (6.2) holds. If $u(z) - h(z) > 0$, then (6.1) implies that any unit eigenvector corresponding to $\lambda_1(x)$ must, as $x \in \mathscr{C}$ approaches z, approach colinearity with $\nabla u(z)$. Hence, any unit eigenvector corresponding to $\lambda_2(x)$ approaches colinearity with ν, and (6.2) follows from (6.3). □

Remark 6.2. The characterization of $A(z)$ used in the proof of Lemma 6.1 makes critical use of the fact that our problem is posed in two dimensions. The two-dimensional nature of the problem also plays a fundamental role in Lemma 8.1, and together these lemmas provide the basis for § 10, where the existence of a continuous version of $D^2 u$ on $\mathbb{R}^2$ is established.

THEOREM 6.3. *For every $\alpha \in (0,1)$, $u \in C^{2,\alpha}(\bar{\mathscr{C}})$, i.e., $D^2 u$ restricted to $\mathscr{C}$ has an α-Hölder continuous extension to $\bar{\mathscr{C}}$.*

Proof. Because $|\nabla u| = 1$ on $\partial \mathscr{C}$, we can choose an open set $G \subset \mathscr{C}$ such that $|\nabla u|$ is bounded away from zero on $\mathscr{C} \setminus G$. Elliptic regularity implies the Hölder continuity of $D^2 u$ on $\bar{G}$, so it suffices to prove uniform Hölder continuity of $D^2 u$ on $\mathscr{C} \setminus G$.

Let a unit vector ν be given, and define on $\mathscr{C} \setminus G$, $\eta \triangleq \nabla u / |\nabla u|$, $z \triangleq \nu - (\nu \cdot \eta)\eta$,

$$\gamma \triangleq \begin{cases} \dfrac{z}{|z|} & \text{if } z \neq 0, \\ \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \eta & \text{if } z = 0. \end{cases}$$

Observe that $\eta \cdot \gamma = 0$ and $|\eta| = |\gamma| = 1$. Therefore,

$$\Delta u = (D^2 u)\eta \cdot \eta + (D^2 u)\gamma \cdot \gamma \quad \text{on } \mathscr{C} \setminus G.$$

Direct calculation shows that on $\mathscr{C} \setminus G$,

$$\begin{aligned} (D^2 u)\nu \cdot \nu &= (D^2 u) z \cdot z + 2(\nu \cdot \eta)(D^2 u)\eta \cdot z + (\nu \cdot \eta)^2 (D^2 u)\eta \cdot \eta \\ &= |z|^2 (\Delta u - (D^2 u)\eta \cdot \eta) + 2(\nu \cdot \eta)(D^2 u)\eta \cdot (\nu - (\nu \cdot \eta)\eta) \\ &\quad + (\nu \cdot \eta)^2 (D^2 u)\eta \cdot \eta. \end{aligned}$$

Since $\Delta u = u - h$ and $2(D^2 u)\eta = (\nabla w / |\nabla u|)$ on $\mathscr{C} \setminus G$, we have

$$\begin{aligned} (D^2 u)\nu \cdot \nu &= |\nu - \frac{(\nu \cdot \nabla u)}{|\nabla u|^2} \nabla u|^2 \left(u - h - \frac{1}{2} \frac{(\nabla w \cdot \nabla u)}{|\nabla u|^2} \right) \\ &\quad + \frac{(\nu \cdot \nabla u)}{|\nabla u|^2} \nabla w \cdot \nu - \frac{(\nu \cdot \nabla u)^2}{2|\nabla u|^4} \nabla w \cdot \nabla u \quad \text{on } \mathscr{C} \setminus G. \end{aligned} \tag{6.4}$$

All the terms appearing on the right-hand side of (6.4) are uniformly Hölder continuous in $\mathscr{C}\backslash G$ (recall Corollary 5.3). □

7. The gradient flow. Recalling Remark 4.6, we let $y^0 \in \mathscr{C}$ denote the unique minimizer of u. Using the strict convexity of u in $\mathscr{C}$ (Lemma 4.4), we choose $\delta > 0$, $\mu > 0$ such that

$$B_{2\delta}(y^0) \subset \mathscr{C}, \tag{7.1}$$

$$D^2u(x)y \cdot y \geqq \mu |y|^2 \quad \forall x \in B_{2\delta}(y^0), \tag{7.2}$$

$$\mu \leqq |\nabla u(x)|^2 \leqq \tfrac{1}{2} \quad \forall x \in \partial B_\delta(y^0), \tag{7.3}$$

$$\nabla u(y^0 + \delta\theta) \cdot \theta \geqq \mu \quad \forall \theta \in S_1, \tag{7.4}$$

where $S_1 \triangleq \partial B_1(0)$ is the set of unit vectors in $\mathbb{R}^2$. For $\theta \in S_1$, we define the *gradient flow* $\psi(t, \theta)$ to be the unique solution to the differential equation

$$\frac{d}{dt}\psi(t, \theta) = \nabla u(\psi(t, \theta)), \qquad t \geqq 0, \tag{7.5}$$

with the initial condition

$$\psi(0, \theta) = y^0 + \delta\theta. \tag{7.6}$$

We will find it convenient to use ψ to change coordinates in $\mathbb{R}^2$. The following theorem justifies this.

THEOREM 7.1. *The map ψ is a homeomorphism from $[0, \infty] \times S_1$ onto $\mathbb{R}^2 \backslash B_\delta(y^0)$.*

Proof. Let us for the moment fix $\theta \in S_1$ and define $n(t) \triangleq \psi(t, \theta) - y^0$ for all $t \geqq 0$. Because $|\nabla u| \leqq 1$, we have $|n(t)| \leqq t + \delta$, and $y^0 + (\delta \wedge t/t)n(t) \in B_{2\delta}(y^0)$ for all $t > 0$. We conclude from the convexity of u on $\mathbb{R}^2$ and from (7.2) that for $t > 0$:

$$\begin{aligned}
\frac{d}{dt}|n(t)|^2 &= 2\nabla u(y^0 + n(t)) \cdot n(t) \\
&= 2\left[\nabla u(y^0 + n(t)) - \nabla u\left(y^0 + \frac{\delta \wedge t}{t} n(t)\right)\right] \cdot n(t) \\
&\quad + 2\left[u\left(y^0 + \frac{\delta \wedge t}{t} n(t)\right) - \nabla u(y^0)\right] \cdot n(t) \qquad (7.7) \\
&\geqq 2\int_0^{\delta \wedge t/t} D^2u(y^0 + \tau n(t))n(t) \cdot n(t)\, d\tau \\
&\geqq 2\mu\left(1 \wedge \frac{\delta}{t}\right)|n(t)|^2.
\end{aligned}$$

Since $|n(0)|^2 = \delta^2$, we can integrate (7.7) to obtain the inequality

$$|\psi(t, \theta) - y^0|^2 \geqq \delta^2\left(1 \vee \frac{t}{\delta}\right)^{2\mu\delta} e^{2\mu(t \wedge \delta)} \quad \forall t \geqq 0, \quad \theta \in S_1. \tag{7.8}$$

One consequence of (7.8) is that

$$|\psi(s, \theta) - \psi(0, \varphi)| > 0 \quad \forall s > 0, \quad \theta \in S_1, \quad \varphi \in S_1. \tag{7.9}$$

Now let $s,\ t \in [0,\infty)$ and $\theta,\ \varphi \in S_1$ be given. Again using the convexity of u, we may write

$$
\begin{aligned}
|\psi(t+s,\theta)-\psi(t,\varphi)|^2 &= |\psi(s,\theta)-\psi(0,\varphi)|^2 \\
&\quad +2\int_0^t [\nabla u(\psi(\tau+s,\theta))-\nabla u(\psi(\tau,\varphi))]\cdot[\psi(\tau+s,\theta)-\psi(\tau,\varphi)]\,d\tau \\
&\geqq |\psi(s,\theta)-\psi(0,\varphi)|^2.
\end{aligned} \tag{7.10}
$$

If θ, φ are in S_1 and t_1, t_2 are in $[0,\infty)$ and $t_1 \neq t_2$, then (7.9), (7.10) imply that $\psi(t_1,\theta) \neq \psi(t_1,\varphi)$. If $t_1 = t_2$ but $\theta \neq \varphi$, then the uniqueness of solutions to (7.5) implies that $\psi(t_1,\theta) \neq \psi(t_2,\varphi)$. This concludes the proof that ψ is injective.

It is clear from its definition that ψ is continuous. Define

$$D \triangleq \psi([0,\infty)\times S_1) \subset \mathbb{R}^2 \backslash B_\delta(y^0)$$

to be the range of ψ. Let $x \in D$ and $\varepsilon > 0$ be given. It follows from (7.8) that there exists $T > 0$ such that

$$D \cap B_\varepsilon(x) \subset \psi([0,T]\times S_1).$$

But an injective, continuous map on a compact set has a continuous inverse, so ψ^{-1} is continuous at x.

It remains to show that $D = \mathbb{R}^2 \backslash B_\delta(y^0)$. There is a function $\hat{\psi}:[0,\infty)\times\mathbb{R}\to\mathbb{R}^2$ such that

$$\hat{\psi}(t,\beta) = \psi(t,(\cos\beta,\sin\beta)) \quad \forall (t,\beta)\in[0,\infty)\times\mathbb{R},$$

and $\hat{\psi}$ is continuous and locally injective. It follows from Deimling (1985, Thm. 4.3, p. 23) that

$$D \cap (\mathbb{R}^2 \backslash \overline{B_\delta(y^0)}) = \hat{\psi}((0,\infty)\times\mathbb{R})$$

is open. On the other hand, if $\{x^n\}_{n=1}^\infty \subset D$ is a sequence with limit $x^0 \in \mathbb{R}^2$, then (7.8) shows that $\{\psi^{-1}(x^n)\}_{n=1}^\infty$ is bounded and thus has an accumulation point $(t^0,\theta^0) \in [0,\infty)\times S_1$. The continuity of ψ implies that $x^0 = \psi(t^0,\theta^0)$, so D is closed. It follows that $D = \mathbb{R}^2 \backslash B_\delta(y^0)$. □

COROLLARY 7.2. *For $\theta \in S_1$ and $\gamma \in [\frac{1}{2},1]$, define*

$$T_\gamma(\theta) \triangleq \inf\{t \geqq 0;\ |\nabla u(\psi(t,\theta))|^2 \geqq \gamma\}. \tag{7.11}$$

Then

$$\sup_{\substack{1/2\leqq\gamma\leqq 1\\ \theta\in S_1}} T_\gamma(\theta) \leqq \sup_{\theta\in S_1} T_1(\theta) < \infty.$$

Proof. According to Lemma 4.4, $\mathscr{C}$ is bounded. We can use (7.8) to choose $t^* \in (0,\infty)$ such that

$$\mathscr{C} \subset \psi([0,t^*]\times S^1). \qquad \square$$

THEOREM 7.3. *The homeomorphism ψ is Lipschitz continuous on compact subsets of $[0,\infty)\times S_1$, and ψ^{-1} is Lipschitz continuous on all of $\mathbb{R}^2 \backslash B_\delta(y^0)$.*

Proof. It follows immediately from (7.5) that $|(d/dt)\psi(t,\theta)| \leqq 1$ for all $(t,\theta) \in [0,\infty)\times S_1$. Now let $T>0$ be given and use Theorem 4.3 to choose a Lipschitz constant C for ∇u on $\psi([0,T]\times S_1)$. For $\theta, \varphi \in S_1$ and $t \in [0,T]$, we have

$$\begin{aligned}|\psi(t,\theta)-\psi(t,\varphi)| &\leqq |\psi(0,\theta)-\psi(0,\psi)| \\ &\quad + \int_0^t |\nabla u(\psi(\tau,\theta))-\nabla u(\psi(\tau,\varphi))|\,d\tau \\ &\leqq \delta|\theta-\varphi| + C\int_0^t |\psi(\tau,\theta)-\psi(\tau,\varphi)|\,d\tau.\end{aligned}$$

Gronwall's inequality gives

$$|\psi(t,\theta)-\psi(t,\varphi)| \leqq \delta\, e^{CT}|\theta-\varphi|,$$

and the local Lipschitz continuity of ψ is proved.

To prove the global Lipschitz continuity of ψ^{-1}, we let $x^1, x^2 \in \mathbb{R}^2\backslash B_\delta(y^0)$ be given and define $(t_1,\theta_1)=\psi^{-1}(x^1)$, $(t_2,\theta_2)=\psi^{-1}(x^2)$. Assume without loss of generality that $|x^1-x^2| \leqq 1$ and that $t_1 \geqq t_2$. Set $s=t_1-t_2$. According to (7.10) and (7.8),

$$\begin{aligned}|x^1-x^2| &\geqq |\psi(s,\theta_1)-\psi(0,\theta_2)| \\ &\geqq |\psi(s,\theta_1)-y^0| - |y^0-\psi(0,\theta_2)| \\ &\geqq \delta\left(1\vee\frac{s}{\delta}\right)^{\mu\delta} e^{\mu(s\wedge\delta)} - \delta \\ &\geqq \delta\mu\left(1\vee\frac{s}{\delta}\right)^{\mu\delta}(s\wedge\delta).\end{aligned} \tag{7.12}$$

If $0 \leqq s \leqq \delta$, then (7.12) yields

$$|t_1-t_2| \leqq \frac{1}{\delta\mu}|x^1-x^2|. \tag{7.13}$$

If $s \geqq \delta$ and $\mu\delta \geqq 1$, (7.12) again yields (7.13). Finally, if $s \geqq \delta$ and $0<\mu\delta<1$, (7.12) yields $|x^1-x^2| \geqq \mu\delta^{1-\mu\delta}s^{\mu\delta}$, so

$$|t_1-t_1| \leqq (\mu\delta^{1-\mu\delta})^{1/\mu\delta}|x^1-x^2|^{1/\mu\delta} \leqq (\mu\delta^{1-\mu\delta})^{1/\mu\delta}|x^1-x^2|. \tag{7.14}$$

Relations (7.14) and (7.15) imply the global Lipschitz continuity of the first component of ψ^{-1}, i.e., there exists a constant $L>0$ such that

$$|t_1-t_2| \leqq L|\psi(t_1,\theta_1)-\psi(t_2,\theta_2)| \quad \forall (t_1,\theta_1),(t_2,\theta_2) \in [0,\infty)\times S_1. \tag{7.15}$$

Now let $x^1, x^2 \in \mathbb{R}^2\backslash B_\delta(y^0)$ be given, and define (t_1,θ_1), (t_2,θ_2), and $s=t_1-t_2 \geqq 0$ as before. From (7.10), (7.5), and (7.6), we have

$$\begin{aligned}|x^1-x^2| &\geqq |\psi(s,\theta_1)-\psi(0,\theta_2)| \\ &\geqq -|\psi(s,\theta_1)-\psi(0,\theta_1)| + |\psi(0,\theta_1)-\psi(0,\theta_2)| \\ &\geqq -s+\delta|\theta_1-\theta_2|.\end{aligned}$$

Relation (7.15) gives us

$$|\theta_1-\theta_2| \leqq \frac{1}{\delta}|t_1-t_2| + \frac{1}{\delta}|x^1-x^2| \leqq \frac{1}{\delta}(1+L)|x^1-x^2|. \qquad \square$$

Remark 7.4. In much of what follows, we will use the coordinates $(t, \theta) \in [0, \infty) \times S_1$ rather than the coordinates $x \in \mathbb{R}^2 \setminus B_\delta(y^0)$. We may identify S_1 with the unit circle, and let $[0, \infty) \times S_1$ have the product of Lebesgue measure and arc length measure. An important consequence of Theorem 7.3 is that ψ maps measure zero subsets of $[0, \infty) \times S_1$ onto Lebesgue measure zero subsets of $\mathbb{R}^2 \setminus B_\delta(y^0)$. Likewise, ψ^{-1} preserves measure zero sets.

8. $W^{2,\infty}$ regularity for the obstacle problem. The purpose of this section is to show that the function $w = |\nabla u|^2$ is in $W^{2,\infty}_{loc}$. This improves the regularity result of Theorem 5.2.

LEMMA 8.1. *We have*

$$(D^2u)\nabla u = 0, \quad \|D^2u\| = \Delta u \quad \text{a.e. on } \mathbb{R}^2 \setminus \mathscr{C}. \tag{8.1}$$

Proof. By the definition of $\mathscr{C}$, w attains its maximum value of 1 at every point in $\mathbb{R}^2 \setminus \mathscr{C}$, so $\nabla w = 0$ everywhere on $\mathbb{R}^2 \setminus \mathscr{C}$. But $\nabla w = 2(D^2u)\nabla u$ almost everywhere on $\mathbb{R}^2$, and the first part of (8.1) follows. Since D^2u is singular almost everywhere on $\mathbb{R}^2 \setminus \mathscr{C}$, the second part of (8.1) also holds. □

Remark 8.2. Because D^2u is positive definite on $\mathscr{C}$ and positive semidefinite almost everywhere on $\mathbb{R}^2$, and since (recalling Remark 7.4)

$$\frac{d}{dt} w(\psi(t, \theta)) = 2D^2u(\psi(t, \theta))\nabla u(\psi(t, \theta)) \cdot \nabla u(\psi(t, \theta)) \tag{8.2}$$

$$\text{a.e. } (t, \theta) \in [0, \infty) \times S^1,$$

the function $t \mapsto w(\psi(t, \theta))$ is nondecreasing for almost every $\theta \in S^1$. In particular, with $T_1(\theta)$ defined by (7.11), we have

$$w(\psi(t, \theta)) \equiv 1 \quad \forall t \geqq T_1(\theta), \quad \text{a.e. } \theta \in S^1. \tag{8.3}$$

THEOREM 8.3. *The function $w = |\nabla u|^2$ is in $W^{2,\infty}$.*

Proof. Recall that w satisfies (5.9), where for all $\alpha \in (0, 1)$, $H \triangleq \nabla h \cdot \nabla u - \|D^2u\|^2$ is of class $C^{0,\alpha}$ inside $\mathscr{C}$, and H is defined up to almost everywhere equivalence on $\mathbb{R}^2 \setminus \mathscr{C}$. We define

$$\hat{H}(x) \triangleq \begin{cases} \nabla h(x) \cdot \nabla u(x) - \|D^2u(x)\|^2 & \forall x \in \mathscr{C} \\ \nabla h(x) \cdot \nabla u(x) - [(u(x) - h(x))^+]^2 & \text{if } x \in \mathbb{R}^2 \setminus \mathscr{C}. \end{cases} \tag{8.4}$$

Now $u - h = \Delta u \geqq 0$ on $\mathscr{C}$, so $u - h \geqq 0$ on $\partial\mathscr{C}$. Theorem 6.3 and Lemma 6.1 then show that $\hat{H}$ is locally Hölder continuous with exponent α for any $\alpha \in (0, 1)$. Because of (3.1) and Lemma 8.1,

$$u - h \leqq \Delta u = \|D^2u\| \quad \text{a.e. on } \mathbb{R}^2 \setminus \mathscr{C}.$$

But $\Delta u \geqq 0$ almost everywhere $\mathbb{R}^2$, so

$$[(u - h)^+]^2 \leqq \|D^2u\|^2 \quad \text{a.e. on } \mathbb{R}^2 \setminus \mathscr{C}.$$

Therefore $\hat{H} \geqq H$ amost everywhere $\mathbb{R}^2 \setminus \mathscr{C}$, and $\hat{H} = H$ on $\mathscr{C}$, so (5.9) yields

$$\max\{w - \tfrac{1}{2}\Delta w - \hat{H}, w - 1\} = 0. \tag{8.5}$$

With the aid of (8.5) and the Hölder continuity of $\hat{H}$, we can obtain the $W^{2,\infty}$ regularity of w from the theory of variational inequalities. More precisely, choose r so that $\mathscr{C} \subset B_r(0)$ and observe that the Dirichlet problem

$$\varphi - \tfrac{1}{2}\Delta\varphi = \hat{H} \quad \text{on } B_r(0), \quad \varphi = 0 \quad \text{on } \partial B_r(0).$$

has a solution φ which is in $C^{2,\alpha}(\overline{B_r(0)})$ for any $\alpha \in (0,1)$ (Ladyzhenskaya and Ural'tseva (1968, Thm. 3.1.3, p. 115)). Set $\bar{w} \triangleq w - \varphi$, so that $\bar{w} \in W^{2,p}(\overline{B_r(0)})$ for any $p \in (1,\infty)$ and

$$\max\{\bar{w} - \tfrac{1}{2}\Delta\bar{w}, \bar{w} - 1 + \varphi\} = 0 \quad \text{in } B_r(0), \tag{8.6}$$

$$\bar{w} = 1 \quad \text{on } \partial B_r(0). \tag{8.7}$$

Define

$$L_r \triangleq \{v \in W^{1,2}(B_r(0)); -\varphi \leqq v \leqq 1 - \varphi \text{ on } B_r(0) \text{ and } v - 1 \in W_0^{1,2}(B_r)\},$$

and note from (8.6), (8.7) that $\bar{w} \in L_r$ and

$$\frac{1}{2}\int_{B_r(0)} \nabla\bar{w}\cdot(\nabla v - \nabla\bar{w}) \geqq -\int_{B_r(0)} \bar{w}(v - \bar{w}) \quad \forall v \in L_r.$$

It follows from Chipot (1984, Thm. 3.25, p. 49), that $\bar{w} \in W^{2,\infty}(B_r(0))$, so also $w \in W^{2,\infty}(B_r(0))$. On $\mathbb{R}^2 \setminus B_r(0)$, $w \equiv 1$. □

COROLLARY 8.4. *We have* $D^2u \in W^{1,\infty}(\bar{\mathscr{C}})$.

Proof. Use the $W^{1,\infty}$ regularity of ∇w in (6.4). □

9. Lipschitz continuity of T_γ. Recall the mappings $T_\gamma : S_1 \mapsto [0,\infty)$ defined by (7.11) for each $\gamma \in [\frac{1}{2}, 1]$. The continuity of $\nabla u \circ \psi$ implies the lower semicontinuity of each T_γ. In this section we prove that for each $\gamma \in [\frac{1}{2}, 1]$, T_γ is, in fact, Lipschitz continuous.

LEMMA 9.1. *We have*

$$K \triangleq \sup_{\nu \in S_1, x \in \mathscr{C}} \frac{|\nabla w(x)|}{D^2u(x)\nu\cdot\nu} < \infty. \tag{9.1}$$

Proof. Let ν, $\eta \in S_1$ be given and set $f \triangleq (D^2u)\nu\cdot\nu$ and $g \triangleq \nabla w \cdot \eta$. Then in $\mathscr{C}$,

$$f - \Delta f = (D^2h)\nu\cdot\nu \geqq c_0, \qquad g - \Delta g = 2\nabla H\cdot\eta - g,$$

where $c_0 > 0$ is the constant in (2.8), and H, defined by (5.8), is in $W^{1,\infty}(\bar{\mathscr{C}})$ because of Corollary 8.4. Furthermore, $g = 0 \leqq f$ on $\partial\mathscr{C}$. Therefore the maximum principle implies that $g - Kf \leqq 0$ in $\mathscr{C}$, where

$$K \triangleq \frac{1}{c_0}(2\|\nabla H\|_{L^\infty(\bar{\mathscr{C}})} + \|\nabla w\|_{L^\infty(\bar{\mathscr{C}})}).$$

In other words, $\nabla w\cdot\eta \leqq K(D^2u)\nu\cdot\nu$. □

THEOREM 9.2. *For each $\gamma \in [\frac{1}{2}, 1]$, the mapping $T_\gamma : S_1 \mapsto [0,\infty)$ is Lipschitz continuous with a Lipschitz constant which is independent of γ.*

Proof. For each $\gamma \in [\frac{1}{2}, 1]$, define

$$\mathscr{C}_\gamma \triangleq \{\psi(t,\theta); 0 \leqq t < T_\gamma(\theta)\} \cup B_\delta(y^0)$$

(with ψ, δ, and y^0 as in (7.1)–(7.6)). Each $\mathscr{C}_\gamma$ is open, $w < \gamma$ on $\mathscr{C}_\gamma$ and $w = \gamma$ on $\partial\mathscr{C}_\gamma$. For $\gamma \in [\frac{1}{2}, 1)$, we also have $\mathscr{C}_\gamma \subset \mathscr{C}$. Because of (4.10), ∇w does not vanish on $\mathscr{C}$, so for fixed $\gamma \in [\frac{1}{2}, 1)$ and $z \in \partial\mathscr{C}_\gamma$, the outward normal to $\mathscr{C}_\gamma$ exists and is

$$n(z) \triangleq \frac{\nabla w(z)}{|\nabla w(z)|} = \frac{2D^2u(z)\nabla u(z)}{|\nabla w(z)|}.$$

In fact D^2w is continuous in $\mathscr{C}$ and bounded in $\mathbb{R}^2$ (Theorem 8.3), so for every $\gamma \in [\frac{1}{2}, 1)$, $\partial\mathscr{C}_\gamma$ has bounded curvature, i.e., there are constants $\varepsilon > 0$, $K_\gamma > 0$ such that for every $z \in \partial\mathscr{C}_\gamma$, and for every $x \in B_\varepsilon(z)$:

$$(x - z)\cdot n(z) \geqq K_\gamma |x - z|^2 \Rightarrow x \in \mathbb{R}^2 \setminus \mathscr{C}_\gamma. \tag{9.2}$$

We may use the local boundedness of $(d^2/dt^2)\psi(t,\theta)=\frac{1}{2}\nabla w(\psi(t,\theta))$ and the Lipschitz continuity of ψ to choose a constant $K_2>0$ such that for every $\gamma\in[\frac{1}{2},1)$, every $\beta\in[0,1]$, and every $\theta,\varphi\in S_1$:

$$|\psi(T_\gamma(\theta)+\beta,\theta)-\psi(T_\gamma(\theta),\theta)-\beta\nabla u(\psi(T_\gamma(\theta),\theta))|\leqq K_2\beta^2, \tag{9.3}$$

$$|\psi(T_\gamma(\theta)+\beta,\theta)-\psi(T_\gamma(\theta)+\beta,\varphi)|\leqq K_2|\theta-\varphi|. \tag{9.4}$$

With K as in (9.1), choose $L>\max\{\frac{1}{2}KK_2,1\}$. Let $\theta,\varphi\in S_1$ be given with $|\theta-\varphi|\leqq 1/L$, and set

$$\beta=L|\theta-\varphi|,\quad z=\psi(T_\gamma(\theta),\theta),\quad x=\psi(T_\gamma(\theta)+\beta,\varphi).$$

Then (9.3), (9.4) imply the existence of vectors $\nu,\eta\in B_1(0)$ such that

$$x=z+\beta\nabla u(z)+K_2\beta^2\nu+K_2|\theta-\varphi|\eta.$$

We calculate

$$\begin{aligned}(x-z)\cdot n(z)&=\frac{2\beta D^2u(z)\nabla u(z)\cdot\nabla u(z)}{|\nabla w(z)|}+K_2\beta^2 n(z)\cdot\nu+K_2|\theta-\varphi|n(z)\cdot\eta\\&\geqq\frac{2\beta}{K}-K_2\beta^2-K_2|\theta-\varphi|\\&=\left(\frac{2L}{K}-K_2\right)|\theta-\varphi|-K_2L^2|\theta-\varphi|^2,\end{aligned}$$

and

$$\begin{aligned}K_\gamma|x-z|^2&=K_\gamma|\beta\nabla u(z)+K_2\beta^2\nu+K_2|\theta-\varphi|\eta|^2\\&\leqq 9K_\gamma(L^2+K_2^2L^4+K_2^2)|\theta-\varphi|^2.\end{aligned}$$

It is clear that for $|\theta-\varphi|$ sufficiently small, $x\in B_\varepsilon(z)$ and

$$(x-z)\cdot n(z)\geqq K_\gamma|x-z|^2,$$

from which we conclude (see (9.2)) that $x\in\mathbb{R}^2\setminus\mathscr{C}_\gamma$, i.e.,

$$T_\gamma(\varphi)\leqq T_\gamma(\theta)+\beta=T_\gamma(\theta)+L|\theta-\varphi|.$$

Interchanging the roles of θ and φ, we obtain

$$|T_\gamma(\theta)-T_\gamma(\varphi)|\leqq L|\theta-\varphi|$$

for all $\theta,\varphi\in S_1$ such that $|\theta-\varphi|$ is sufficiently small.

For each $\theta\in S_1$, the mapping $t\mapsto w(\psi(t,\theta))$ is strictly increasing on $[0,T_1(\theta)]$ (see (8.2) and (4.10)). Therefore, the mapping $\gamma\mapsto T_\gamma(\theta)$ is continuous on $[\frac{1}{2},1]$. The Lipschitz continuity of T_1 follows from the uniform Lipschitz continuity of T_γ for $\gamma\in[\frac{1}{2},1)$. □

COROLLARY 9.3. *With ψ, δ, and y^0 as in* (7.1)-(7.6), *we have*

$$\mathscr{C}=\{\psi(t,\theta);\ \theta\in S^1,\ t\in[0,T_1(\theta))\}\cup B_\delta(y^0). \tag{9.5}$$

Proof. Define $\tilde{\mathscr{C}}$ to be the set on the right-hand side of (9.5). It is clear that $\tilde{\mathscr{C}}\subset\mathscr{C}$, and because of (8.3) and Remark 7.4, the Lebesgue measure of $\mathscr{C}\setminus\tilde{\mathscr{C}}$ is zero. Let $x\in\mathscr{C}\setminus\tilde{\mathscr{C}}$ be given, and define $(t,\theta)\triangleq\psi^{-1}(x)$. Then $t\geqq T_1(\theta)$, but because $w(T_1(\theta),\theta)=1$, we must in fact have $t>T_1(\theta)$. The continuity of T_1 and w allows us to chose an open neighborhood of (t,θ) contained in $\mathscr{C}\setminus\tilde{\mathscr{C}}$, and this contradicts the Lebesgue negligibility of $\mathscr{C}\setminus\tilde{\mathscr{C}}$. □

10. D^2u outside $\mathscr{C}$. We saw in Lemma 8.1 that D^2u is singular almost everywhere in $\mathbb{R}^2\setminus\mathscr{C}$. Indeed

$$u_{11}u_1+u_{12}u_2=0, \quad u_{12}u_1+u_{22}u_2=0 \quad \text{a.e. on } \mathbb{R}^2\setminus\mathscr{C}, \tag{10.1}$$

and because $u_1^2+u_2^2=1$ on $\mathbb{R}^2\setminus\mathscr{C}$, we have

$$D^2u=\Delta u\begin{bmatrix} u_2^2 & -u_1u_2 \\ -u_1u_2 & u_1^2 \end{bmatrix} \quad \text{a.e. on } \mathbb{R}^2\setminus\mathscr{C}. \tag{10.2}$$

Because u has continuous first partial derivatives on $\mathbb{R}^2$, the proof of continuity of D^2u on $\mathbb{R}^2\setminus\mathscr{C}$ reduces to a search for a continuous version of Δu on this set. In order for D^2u to be continuous across $\partial\mathscr{C}$, we must also have $\Delta u=u-h$ on $\partial\mathscr{C}$ (see Lemma 6.1).

We shall construct the desired continuous version of Δu in the (t,θ) variables. Indeed, if we set

$$\lambda(t,\theta)=\Delta u(\psi(t,\theta)) \quad \forall\theta\in S^1, \quad t\geqq T_1(\theta),$$

then a formal calculation relying on (10.2) and the constancy of w on $\mathbb{R}^2\setminus\mathscr{C}$ leads to

$$\begin{aligned}\frac{d}{dt}\lambda(t,\theta)&=\frac{1}{2}\Delta w(\psi(t,\theta))-\|D^2u(\psi(t,\theta))\|^2\\ &=-\lambda^2(t,\theta) \quad \forall\theta\in S^1, \quad t\geqq T_1(\theta).\end{aligned} \tag{10.3}$$

Integrating this equation and invoking the condition $\Delta u=u-h$ on $\partial\mathscr{C}$, we obtain

$$\lambda(t,\theta)=\frac{u(\psi(T_1(\theta),\theta))-h(\psi(T_1(\theta),\theta))}{1+(t-T_1(\theta))[u(\psi(T_1(\theta),\theta))-h(\psi(T_1(\theta),\theta))]} \tag{10.4}$$

$$\forall\theta\in S_1, \quad t\geqq T_1(\theta).$$

The task before us is to show that with λ defined by (10.4), the function $\lambda\circ\psi^{-1}$ is a version of Δu on $\mathbb{R}^2\setminus\mathscr{C}$. This is essentially a justification of the formal differentiation in (10.3), which involved third-order derivatives of u.

Let $\rho:\mathbb{R}^2\to[0,\infty)$ be a C^∞ function with support in $B_1(0)$ and satisfying $\int_{\mathbb{R}^2}\rho=1$. For $n=1,2,\cdots$, we define mollifications of u by

$$u^{(n)}(x)\triangleq\int_{\mathbb{R}^2}u\left(x-\frac{1}{n}\xi\right)\rho(\xi)\,d\xi=n^2\int_{\mathbb{R}^2}u(\xi)\rho(n(x-\xi))\,d\xi. \tag{10.5}$$

Then $\nabla u^{(n)}$ and $D^2u^{(n)}$ are locally bounded, uniformly in n, and $u^{(n)}\to u$, $\nabla u^{(n)}\to\nabla u$, and $D^2u^{(n)}\to D^2u$ in L^1_{loc}. By passing to subsequences if necessary, we assume that these convergences occur almost everywhere. We define for $(t,\theta)\in[0,\infty)\times S^1$:

$$l^{(n)}(t,\theta)\triangleq\Delta u^{(n)}(\psi(t,\theta)), \qquad n=1,2,\cdots, \tag{10.6}$$

$$l(t,\theta)\triangleq\Delta u(\psi(t,\theta)), \tag{10.7}$$

and observe that $l^{(n)}(t,\theta)\to l(t,\theta)$ for almost every $(t,\theta)\in[0,\infty)\times S^1$ (Remark 7.4).

LEMMA 10.1. *The functions*

$$\dot{l}^{(n)}(t,\theta)=\nabla\Delta u^{(n)}(\psi(t,\theta))\cdot\nabla u(\psi(t,\theta)) \tag{10.8}$$

are locally bounded, uniformly in n.

Proof. Observe first of all that

$$\begin{aligned}\dot{l}^{(n)}&=\nabla\Delta u^{(n)}\cdot\nabla u^{(n)}+\nabla\Delta u^{(n)}\cdot(\nabla u-\nabla u^{(n)})\\ &=\tfrac{1}{2}\Delta(|\nabla u^{(n)}|^2)-\|D^2u^{(n)}\|^2+\nabla\Delta u^{(n)}\cdot(\nabla u-\nabla u^{(n)}),\end{aligned}$$

where $\dot{l}^{(n)}$ is evaluated at (t, θ), and the right-hand side is evaluated at $\psi(t, \theta)$. It suffices to obtain uniform local bounds on $\Delta(|\nabla u^{(n)}|^2)$ and $\nabla \Delta u^{(n)} \cdot (\nabla u - \nabla u^{(n)})$.

Define for $i \in \{1, 2\}$ the functions

$$\begin{aligned} F_{ii}^{(n)}(x) &\triangleq \int_{\mathbb{R}^2} \left(\left| \nabla u\left(x - \frac{1}{n}\xi\right)\right|^2 \right)_{i,i} \rho(\xi)\, d\xi \\ &= n \int_{\mathbb{R}^2} \left(\left| \nabla u\left(x - \frac{1}{n}\xi\right)\right|^2 \right)_{i} \rho_i(\xi)\, d\xi \\ &= 2n \int_{\mathbb{R}^2} \nabla u_i\left(x - \frac{1}{n}\xi\right) \cdot \nabla u\left(x - \frac{1}{n}\xi\right) \rho_i(\xi)\, d\xi, \end{aligned}$$

$$n = 1, 2, \cdots,$$

and note that these functions are uniformly bounded in n (Theorem 8.3). Then

$$\begin{aligned} (|\nabla u^{(n)}(x)|^2)_{ii} &= 2n^6 \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla u(\xi) \cdot \nabla u(\eta) [\rho_{ii}(n(x-\xi))\rho(n(x-\eta)) \\ &\qquad + \rho_i(n(x-\xi))\rho_i(n(x-\eta))]\, d\xi\, d\eta \\ &= 2n^2 \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla u\left(x - \frac{1}{n}\xi\right) \cdot \nabla u\left(x - \frac{1}{n}\eta\right) [\rho_{ii}(\xi)\rho(\eta) \\ &\qquad + \rho_i(\xi)\rho_i(\eta)]\, d\xi\, d\eta \\ &= 2n \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla u_i\left(x - \frac{1}{n}\xi\right) \cdot \nabla u\left(x - \frac{1}{n}\eta\right) \rho_i(\xi)\rho(\eta)\, d\xi\, d\eta \\ &\quad + 2 \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla u_i\left(x - \frac{1}{n}\xi\right) \nabla u_i\left(x - \frac{1}{n}\eta\right) \rho(\xi)\rho(\eta)\, d\xi\, d\eta. \end{aligned}$$

The last term is locally bounded in x, uniformly in n. The next-to-last term is

$$F_{ii}^{(n)}(x) + 2n \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \nabla u_i\left(x - \frac{1}{n}\xi\right) \cdot \left[\nabla u\left(x - \frac{1}{n}\eta\right) - \nabla u\left(x - \frac{1}{n}\xi\right)\right] \rho_i(\xi)\rho(\eta)\, d\xi\, d\eta,$$

which is also locally bounded in x, uniformly in n, because for all $\xi, \eta \in B_1(0)$,

$$\left| \nabla u\left(x - \frac{1}{n}\eta\right) - \nabla u\left(x - \frac{1}{n}\xi\right)\right| \leqq \frac{2}{n} \sup_{B_1(x)} \|D^2 u\|.$$

This provides a uniform local bound on $\Delta(|\nabla u^{(n)}|^2)$.

On the other hand,

$$\begin{aligned} &\nabla \Delta u^{(n)}(x) \cdot (\nabla u(x) - \nabla u^{(n)}(x)) \\ &\quad = n^5 \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \Delta u(\xi) \\ &\qquad \times [\nabla u(x) - \nabla u(\eta)] \cdot \nabla \rho(n(x-\xi))\rho(n(x-\eta))\, d\xi\, d\eta \\ &\quad = n \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} \Delta u\left(x - \frac{1}{n}\xi\right) \\ &\qquad \times \left[\nabla u(x) - \nabla u\left(x - \frac{1}{n}\eta\right)\right] \cdot \nabla \rho(\xi)\rho(\eta)\, d\xi\, d\eta, \end{aligned}$$

and the boundedness of this expression follows from the local Lipschitz continuity of ∇u. □

Because of Lemma 10.1, a subsequence of $\{\dot{l}^{(n)}\}_{n=1}^{\infty}$ converges in the L^{∞}_{loc}-weak* topology to a function $\zeta \in L^{\infty}_{loc}([0,\infty)\times S_1)$. We assume without loss of generality that the full sequence converges. For each nonnegative integer k, choose a number $t_k > k$ such that $\{l^{(n)}(t_k,\theta)\}_{n=1}^{\infty}$ converges for almost every $\theta \in S_1$, and define $\lambda_k(t_k,\theta)$ to be this limit. (Whereas $l(\cdot,\cdot)$ is defined up to almost everywhere equivalence on $[0,\infty)\times S_1$, the functions $\lambda_k(t_k,\cdot)$ are defined up to almost everywhere equivalence on S_1.) We insist furthermore that t_0 be chosen so that $\psi(t_0,\theta)\in\mathscr{C}$ for all $\theta\in S_1$. Then $\Delta u(\psi(t_0,\cdot))$ is defined pointwise on S_1 because Δu is continuous on $\mathscr{C}$, and so we may require that

$$\lambda_0(t_0,\theta) = \Delta u(\psi(t_0,\theta)) \quad \forall \theta \in S_1.$$

For each $k = 0, 1, \cdots$, define $\lambda_k : [0,\infty)\times S^1 \mapsto \mathbb{R}$ by

$$\lambda_k(t,\theta) \triangleq \lambda_k(t_k,\theta) + \int_{t_k}^{t} \zeta(s,\theta)\, ds,$$

so that any two versions $\hat{\lambda}_k$ and $\tilde{\lambda}_k$ of this function have the property that the set $\{\theta\in S_1 |$ there exists $t\in[0,\infty]$ with $\hat{\lambda}_k(t,\theta)\neq\tilde{\lambda}_k(t,\theta)\}$ has measure zero.

We now relate the functions λ_k, $k=0,1,\cdots$, to the function l of (10.7). Let φ be a continuous, real-valued function on $[0,\infty)\times S_1$, and define

$$\Phi(t,\theta) \triangleq \int_0^t \varphi(s,\theta)\, ds \quad \forall (t,\theta)\in[0,\infty)\times S_1.$$

For $k = 0, 1, \cdots$,

$$\begin{aligned}
&\int_{S_1}\int_0^{t_k} \lambda_k(s,\theta)\varphi(s,\theta)\, ds\, d\theta \\
&\quad = \int_{S_1}\left[\lambda_k(t_k,\theta)\Phi(t_k,\theta) - \int_0^{t_k}\zeta(s,\theta)\varphi(s,\theta)\, ds\right] d\theta \\
&\quad = \lim_{n\to\infty}\int_{S_1}\left[l^{(n)}(t_k,\theta)\Phi(t_k,\theta) - \int_0^{t_k}\dot{l}^{(n)}(s,\theta)\varphi(s,\theta)\, ds\right] d\theta \\
&\quad = \lim_{n\to\infty}\int_{S_1}\int_0^{t_k} l^{(n)}(s,\theta)\varphi(s,\theta)\, ds\, d\theta \\
&\quad = \int_{S_1}\int_0^{t_k} l(s,\theta)\varphi(s,\theta)\, ds\, d\theta.
\end{aligned}$$

It follows that $\lambda_k = l$ almost everywhere on $[0,t_k]\times S_1$. In particular, for any two nonnegative integers k and m, λ_k and λ_m agree almost everywhere on $[0, t_k\wedge t_m]\times S_1$, and hence almost everywhere on $[0,\infty)\times S_1$. In particular,

$$\lambda_0(t,\theta) = \Delta u(\psi(t,\theta)), \quad \text{a.e. } (t,\theta)\in[0,\infty)\times S^1, \tag{10.9}$$

and for almost every $\theta\in S_1$,

$$\lambda_0(t,\theta) = \Delta u(\psi(t_0,\theta)) + \int_{t_0}^{t}\zeta(s,\theta)\, ds \quad \forall t\in[0,\infty). \tag{10.10}$$

LEMMA 10.2. *Almost everywhere on the set*

$$\psi^{-1}(\mathbb{R}^2\setminus\mathscr{C}) = \{(t,\theta)\in[0,\infty)\times S_1;\ t \geqq T_1(\theta)\},$$

the function ζ appearing in (10.10) *is equal to* $-\lambda_0^2$.

Proof. From (10.8) we have

$$\begin{aligned}\dot{l}^{(n)}\circ\psi^{-1}+(l\circ\psi^{-1})(l^{(n)}\circ\psi^{-1})&=\nabla\Delta u^{(n)}\cdot\nabla u+\Delta u\,\Delta u^{(n)}\\&=(u_{12}^{(n)}u_2+u_{11}^{(n)}u_1)_1+(u_{12}^{(n)}u_1+u_{22}^{(n)}u_2)_2\\&\quad+u_{11}^{(n)}u_{22}+u_{11}u_{22}^{(n)}-2u_{12}^{(n)}u_{12}.\end{aligned}$$

Now $u_{11}^{(n)}u_{22}+u_{11}u_{22}^{(n)}-2u_{12}^{(n)}u_{12}$ is locally bounded, uniformly in n, and converges almost everywhere to $2\det D^2u$, which is zero on $\mathbb{R}^2\setminus\bar{\mathscr{C}}$. It follows from (10.1) that for any function $\varphi\in C_0^1(\mathbb{R}^2\setminus\bar{\mathscr{C}})$,

$$\begin{aligned}&\lim_{n\to\infty}\int_{\mathbb{R}^2\setminus\bar{\mathscr{C}}}[\dot{l}^{(n)}\circ\psi^{-1}+(l\circ\psi^{-1})(l^{(n)}\circ\psi^{-1})]\varphi\\&\quad=\lim_{n\to\infty}\int_{R^2\setminus\bar{\mathscr{C}}}[(u_{12}^{(n)}u_2+u_{11}^{(n)}u_1)_1+(u_{12}^{(n)}u_1+u_{22}^{(n)}u_2)_2]\varphi\\&\quad=-\lim_{n\to\infty}\int_{\mathbb{R}^2\setminus\bar{\mathscr{C}}}(u_{12}^{(n)}u_2+u_{11}^{(n)}u_1)\varphi_1+(u_{12}^{(n)}u_1+u_{22}^{(n)}u_2)\varphi_2\\&\quad=0.\end{aligned}$$

Because the functions $\dot{l}^{(n)}\circ\psi^{-1}+(l\circ\psi^{-1})(l^{(n)}\circ\psi^{-1})$ are locally bounded, uniformly in n, we can show that for every $\varphi\in L^1(\mathbb{R}^2\setminus\bar{\mathscr{C}})$,

$$\lim_{n\to\infty}\int_{\mathbb{R}^2\setminus\bar{\mathscr{C}}}[\dot{l}^{(n)}\circ\psi^{-1}+(l\circ\psi^{-1})(l^{(n)}\circ\psi^{-1})]\varphi=0. \tag{10.11}$$

Now let $\gamma\in L^1(\psi^{-1}(\mathbb{R}^2\setminus\bar{\mathscr{C}}))$ be given so that $(\gamma\circ\psi^{-1})|J\Psi^{-1}|\in L^1(\mathbb{R}^2\setminus\bar{\mathscr{C}})$, where $|J\psi^{-1}|$ is the bounded (Theorem 7.3) determinant of the Jacobian of ψ^{-1}. From (10.11) it follows that

$$\begin{aligned}&\lim_{n\to\infty}\int_{\psi^{-1}(\mathbb{R}^2\setminus\bar{\mathscr{C}})}(\dot{l}^{(n)}+ll^{(n)})\gamma\\&\quad=\lim_{n\to\infty}\int_{\mathbb{R}^2\setminus\bar{\mathscr{C}}}[\dot{l}^{(n)}\circ\psi^{-1}+(l\circ\psi^{-1})(l^{(n)}\circ\psi^{-1})](\gamma\circ\psi^{-1})|J\psi^{-1}|\\&\quad=0.\end{aligned}$$

On the other hand, $\dot{l}^{(n)}+ll^{(n)}$ converges in the L^∞_{loc}-weak* topology on $[0,\infty)\times S_1$ to $\zeta+l^2=\zeta+\lambda_0^2$ almost everywhere, and the lemma follows. □

THEOREM 10.3. *There is a Lipschitz continuous version of D^2u on $\mathbb{R}^2$.*

Proof. For $\theta\in S_1$ and $0\leqq t<T_1(\theta)$, define

$$\lambda(t,\theta)\triangleq\Delta u(\psi(t,\theta)), \tag{10.12}$$

where, of course, we mean the Lipschitz continuous version of Δu inside $\mathscr{C}$ (Corollary 8.4). For $\theta\in S_1$ and $t\geqq T_1(\theta)$, define $\lambda(t,\theta)$ by (10.4), which gives us a Lipschitz function. At $t=T_1(\theta)$, the Lipschitz continuity of λ follows from (10.4), Lemma 6.1, and the equality $|\nabla u|^2=1$ on $\partial\mathscr{C}$. The Lipschitz continuity of ψ^{-1} implies the Lipschitz continuity of $\lambda\circ\psi^{-1}$.

It remains to show that $\lambda\circ\psi^{-1}$ is a version of Δu, or equivalently,

$$\lambda(t,\theta)=\Delta u(\psi(t,\theta)),\quad\text{a.e. }(t,\theta)\in[0,\infty)\times S_1. \tag{10.13}$$

In light of (10.9) and (10.12), we need only show that for almost every $\theta\in S_1$,

$$\lambda(t,\theta)=\lambda_0(t,\theta)\quad\forall t\geqq T_1(\theta). \tag{10.14}$$

But (10.10) shows that for almost every $\theta \in S_1$, the function $t \mapsto \lambda_0(t, \theta)$ is absolutely continuous on $[0, \infty)$; in particular,

$$\begin{aligned} \lambda_0(T_1(\theta), \theta) &= \lim_{t \uparrow T_1(\theta)} \lambda_0(t, \theta) \\ &= \lim_{t \uparrow T_1(\theta)} \Delta u(\psi(t, \theta)) \\ &= \lim_{t \uparrow T_1(\theta)} [u(\psi(t, \theta)) - h(\psi(t, \theta))] \\ &= u(\psi(T_1(\theta), \theta)) - h(\psi(T_1(\theta), \theta)). \end{aligned} \tag{10.15}$$

Equation (10.10) and Lemma 10.2 imply that for almost every $\theta \in S_1$,

$$\dot{\lambda}_0(t, \theta) = -\lambda_0^2(t, \theta), \quad \text{a.e. } t \geqq T_1(\theta). \tag{10.16}$$

Equations (10.15) and (10.16) imply (10.14). □

11. Regularity of the free boundary. In this section we apply known regularity results for free boundaries to show that the boundary of $\mathscr{C}$ is of class $C^{2,\alpha}$ for all $\alpha \in (0, 1)$. In order to apply these results, we recall that $w = |\nabla u|^2$ is a $W^{2,\infty}$ function (Theorem 8.3) which satisfies (see (5.9)) $1 - w \geqq 0$ on $\mathbb{R}^2$ and

$$\tfrac{1}{2}\Delta(1 - w) = H - w \quad \text{on } \mathscr{C}, \tag{11.1}$$

where we recall that $H \triangleq \nabla h \cdot \nabla u - \|D^2 u\|^2$. We shall establish the strict positivity of the forcing term $H - w$ on $\partial\mathscr{C}$. Recall that

$$w - \tfrac{1}{2}\Delta w - H \leqq 0 \quad \text{on } \mathbb{R}^2,$$

and $w = 1$, $\Delta w = 0$ on $\mathbb{R}^2 \setminus \bar{\mathscr{C}}$, so

$$H - w = H - 1 \geqq 0 \quad \text{on } \mathbb{R}^2 \setminus \mathscr{C}. \tag{11.2}$$

LEMMA 11.1. *The function H is locally Lipschitz continuous, and $H > 1$ on $\partial\mathscr{C}$.*

Proof. The local Lipschitz continuity of H follows from Theorem 10.3. To prove that $H > 1$ on $\partial\mathscr{C}$, we assume that there exists a point on $\partial\mathscr{C}$ where $H = 1$. Without loss of generality, we take this point to be the origin $(0, 0)$, and we take $\nabla u(0, 0) = (-1, 0)$.

We first obtain an upper bound on H near $(0, 0)$. Inside $\mathscr{C}$, H is differentiable and

$$\nabla H \cdot \nabla u = (D^2 h)\nabla u \cdot \nabla u + (D^2 u)\nabla u \cdot \nabla h - \nabla(\|D^2 u\|^2) \cdot \nabla u. \tag{11.3}$$

Let ν^1 and ν^2 be unit eigenvectors for $D^2 u$, and let λ_1 and λ_2 denote their respective (nonnegative) eigenvalues. Then

$$\begin{aligned} \nabla(\|D^2 u\|^2) \cdot \nabla u &= \operatorname{tr}(D^2 w D^2 u) - 2 \operatorname{tr}[(D^2 u)^3] \\ &= \lambda_1 (D^2 w)\nu^1 \cdot \nu^1 + \lambda_2 (D^2 w)\nu^2 \cdot \nu^2 - 2(\lambda_1^3 + \lambda_2^3) \\ &\leqq 2\|D^2 u\|_{L^\infty(\mathscr{C})} \sup_{\nu \in S_1} (D^2 w)\nu \cdot \nu. \end{aligned} \tag{11.4}$$

Applying Theorem 1 and the remark following it from Caffarelli (1977) to the function $1 - w$, we have that for some positive constants C and ε,

$$\sup_{\nu \in S_1} D^2 w(x, y)\nu \cdot \nu \leqq C|\log(\operatorname{dist}((x, y), \partial\mathscr{C}))|^{-\varepsilon} \quad \forall (x, y) \in \mathscr{C}. \tag{11.5}$$

Combining (11.3)–(11.5), we conclude that

$$\begin{aligned} \nabla H(x, y) \cdot \nabla u(x, y) \geqq\ & D^2 h(x, y)\nabla u(x, y) \cdot \nabla u(x, y) + \tfrac{1}{2}\nabla w(x, y) \cdot \nabla h(x, y) \\ & - 2\|D^2 u\|_{L^\infty(\mathscr{C})} C|\log(\operatorname{dist}((x, y), \partial\mathscr{C}))|^{-\varepsilon} \quad \forall (x, y) \in \mathscr{C}. \end{aligned} \tag{11.6}$$

As (x, y) approaches $(0, 0) \in \partial \mathscr{C}$, $|\nabla u(x, y)|$ approaches 1 and $\nabla w(x, y)$ approaches zero. Using (2.8) and (11.6), we can choose $\tilde{\varepsilon} > 0$ such that

$$\nabla H(x, y) \cdot \nabla u(x, y) \geqq \frac{c_0}{2} \quad \forall (x, y) \in [-\tilde{\varepsilon}, \tilde{\varepsilon}]^2 \cap \mathscr{C}. \tag{11.7}$$

Let $\theta_0 \in S_1$ be such that $\psi(T_1(\theta_0), \theta_0) = (0, 0)$. For $t \in (0, T_1(\theta_0))$ chosen so that $\psi(t, \theta_0) \in [-\tilde{\varepsilon}, \varepsilon]^2$,

$$\frac{d}{dt} H(\psi(t, \theta_0)) = \nabla H(\psi(t, \theta_0)) \cdot \nabla u(\psi(t, \theta_0)) \geqq \frac{c_0}{2}.$$

It follows that for some $\tau > 0$,

$$\begin{aligned} H(\psi(T_1(\theta_0) - t, \theta_0)) &\leqq H(\psi(T_1(\theta_0), \theta_0)) - \tfrac{1}{2} c_0 t \\ &= 1 - \tfrac{1}{2} c_0 t \quad \forall t \in (0, \tau). \end{aligned} \tag{11.8}$$

But also

$$\begin{aligned} |\psi(T_1(\theta_0) - t, \theta_0) - (t, 0)| &= |\psi(T_1(\theta_0) - t, \theta_0) - \psi(T_1(\theta_0), \theta_0) \\ &\qquad + t \nabla u(\psi(T_1(\theta_0), \theta_0))| \\ &\leqq t^2 \| D^2 u \|_{L^\infty(\mathscr{C})} \quad \forall t \in (0, T_1(\theta_0)). \end{aligned} \tag{11.9}$$

Let $\beta > 0$ be a Lipschitz constant for H in a sufficiently large neighborhood of $(0, 0)$. From (11.8), (11.9), we have for all $t \in (0, \tau)$:

$$\begin{aligned} H(t, 0) &\leqq H(\psi(T_1(\theta) - t, \theta_0)) + |H(t, 0) - H(\psi(T_1(\theta_0) - t, \theta_0))| \\ &\leqq 1 - \tfrac{1}{2} c_0 t + \beta t^2 \| D^2 u \|_{L^\infty(\mathscr{C})}. \end{aligned}$$

Choosing τ smaller, if necesary, we have $H(t, 0) \leqq 1 - \frac{1}{3} c_0 t$ for all $t \in (0, \tau)$. Again using the Lipschitz continuity of H, we obtain the desired upper bound

$$H(x, y) \leqq 1 - \tfrac{1}{3} c_0 x + \beta |y| \quad \forall (x, y) \in [0, \tau] \times [-\tau, \tau]. \tag{11.10}$$

We next construct a function $\varphi : \mathbb{R}^2 \to \mathbb{R}$ such that for appropriate $\rho, \sigma \in (0, \tau)$,

$$\varphi - \tfrac{1}{2} \Delta \varphi \geqq H \quad \text{on } [0, \rho] \times [-\sigma, \sigma], \tag{11.11}$$

$$\varphi \geqq 1 \quad \text{on } \partial([0, \rho] \times [\sigma, \sigma]), \tag{11.12}$$

$$\varphi(0, 0) = 1. \tag{11.13}$$

For this purpose, choose $0 < \rho < \min\{\tau, (c_0 / 6\sqrt{2}\beta)\}$ such that

$$\left(1 - \frac{\rho^2}{4}\right) \sinh \sqrt{2}\rho \geqq \sqrt{2}\rho. \tag{11.14}$$

Then define

$$\sigma \triangleq \min\left\{\tau, \frac{\rho^2}{4\sqrt{2}}\right\} \tag{11.15}$$

$$A \triangleq \frac{c_0}{3}\left(1 - \frac{\sqrt{2}\rho}{\sinh \sqrt{2}\rho \cosh \sqrt{2}\sigma}\right)^{-1}, \tag{11.16}$$

$$\begin{aligned} \varphi(x, y) \triangleq 1 &+ \beta\sigma\left(2 - \frac{\cosh\sqrt{2}y}{\cosh\sqrt{2}\sigma}\right)\left(1 - \frac{\sinh\sqrt{2}x + \sinh\sqrt{2}(\rho - x)}{\sinh\sqrt{2}\rho}\right) \\ &+ A\rho\left(1 - \frac{\cosh\sqrt{2}y}{\cosh\sqrt{2}\sigma}\right)\left(-\frac{x}{\rho} + \frac{\sinh\sqrt{2}x}{\sinh\sqrt{2}\rho}\right) \quad \forall (x, y) \in \mathbb{R}^2. \end{aligned}$$

Then

$$\varphi(0, y) = \varphi(\rho, y) = 1 \quad \forall y \in [-\sigma, \sigma],$$

$$\varphi(x, \pm\sigma) = 1 + \beta\sigma\left[1 - \frac{\sinh\sqrt{2}x + \sinh\sqrt{2}(\rho - x)}{\sinh\sqrt{2}\rho}\right] \geqq 1 \quad \forall x \in [0, \rho]$$

because

$$\begin{aligned} \sinh a + \sinh b &\leqq \sinh a \cosh b + \sinh b \cosh a \\ &= \sinh(a + b) \quad \forall a, b \in \mathbb{R}. \end{aligned} \tag{11.17}$$

It remains to verify (11.11). Direct computation reveals

$$\begin{aligned} \varphi(x, y) - \frac{1}{2}\Delta\varphi(x, y) &= 1 + 2\beta\sigma - Ax + A\rho\frac{\sinh\sqrt{2}x \cosh\sqrt{2}y}{\sinh\sqrt{2}\rho \cosh\sqrt{2}\sigma} \\ &\quad - \beta\sigma\frac{\cosh\sqrt{2}y}{\cosh\sqrt{2}\sigma}\left(\frac{\sinh\sqrt{2}x + \sinh\sqrt{2}(\rho - x)}{\sinh\sqrt{2}\rho}\right) \\ &\geqq 1 + \beta\sigma - Ax + A\rho\frac{\sqrt{2}x}{\sinh\sqrt{2}\rho \cosh\sqrt{2}\sigma} \\ &\geqq 1 - \left(1 - \frac{\sqrt{2}\rho}{\sinh\sqrt{2}\rho \cosh\sqrt{2}\sigma}\right)Ax + \beta\sigma \\ &\geqq 1 - \tfrac{1}{3}c_0 x + \beta|y| \\ &\geqq H(x, y) \quad \forall (x, y) \in [0, \rho] \times [-\sigma, \sigma], \end{aligned}$$

where we have used (11.17), the inequality $a \leqq \sinh a$ for all $a \geqq 0$, (11.16), and (11.10).

On the other hand, (5.9) implies that

$$\begin{aligned} w - \tfrac{1}{2}\Delta w &\leqq H \quad \text{on } [0, \rho] \times [-\sigma, \sigma] \\ w &\leqq 1 \quad \text{on } \partial([0, \rho] \times [-\sigma, \sigma]). \end{aligned}$$

The maximum principle implies that $w \leqq \varphi$ on $[0, \rho] \times [-\sigma, \sigma]$. In particular, for all $x \in [0, \rho]$,

$$w(x, 0) - w(0, 0) = w(x, 0) - 1 \leqq \sigma(x, 0) - 1 = \varphi(x, 0) - \varphi(0, 0),$$

and thus

$$0 = \frac{\partial}{\partial x} w(0, 0) \leqq \frac{\partial}{\partial x} \varphi(0, 0). \tag{11.18}$$

The final step in the proof is to show that $(\partial/\partial x)\varphi(0, 0) < 0$, so (11.18) is contradicted, as well as the assumption that $H = 1$ at some point on $\partial\mathscr{C}$. We compute

$$\begin{aligned} \frac{\partial}{\partial x}\varphi(0, 0) &= \sqrt{2}\beta\sigma\left(2 - \frac{1}{\cosh\sqrt{2}\sigma}\right)\left(\frac{\cosh\sqrt{2}\rho - 1}{\sinh\sqrt{2}\rho}\right) \\ &\quad - A\left(1 - \frac{1}{\cosh\sqrt{2}\sigma}\right)\left(1 - \frac{\sqrt{2}\rho}{\sinh\sqrt{2}\rho}\right). \end{aligned} \tag{11.19}$$

The first term on the right-hand side of (11.19) is bounded above by

$$2\sqrt{2}\beta\sigma\left(\frac{\cosh\sqrt{2}\rho - 1}{\sinh\sqrt{2}\rho}\right) \leqq 2\beta\sigma\rho.$$

As for the second term, (11.14) and the inequality $\cosh\sqrt{2}\sigma - 1 \geqq \sqrt{2}\sigma$ imply that

$$\begin{aligned} & A\left(1-\frac{1}{\cosh\sqrt{2}\sigma}\right)\left(1-\frac{\sqrt{2}\rho}{\sinh\sqrt{2}\rho}\right) \\ &= \frac{c_0}{3}\left[\left(1-\frac{\sqrt{2}\rho}{\sinh\sqrt{2}\rho}\right)^{-1} + (\cosh\sqrt{2}\sigma - 1)^{-1}\right]^{-1} \\ &\geqq \frac{c_0}{3}\left[\frac{4}{\rho^2}+\frac{1}{\sqrt{2}\sigma}\right]^{-1} \\ &= \frac{c_0}{3}\left(\frac{\sqrt{2}\rho^2\sigma}{\rho^2+4\sqrt{2}\sigma}\right). \end{aligned}$$

Therefore,

$$\frac{\partial}{\partial x}\varphi(0,0) \geqq \sigma\left[2\beta\rho - \frac{c_0}{3}\left(\frac{\sqrt{2}\rho^2}{\rho^2+4\sqrt{2}\sigma}\right)\right],$$

and (11.15) and the choice of ρ show that

$$\frac{\partial}{\partial x}\varphi(0,0) \geqq \sigma\left[2\beta\rho - \frac{c_0}{3\sqrt{2}}\right] < 0. \qquad \square$$

THEOREM 11.2. *The free boundary $\partial\mathscr{C}$ is of class C^1, and w has continuous second partial derivatives inside $\mathscr{C}$ up to $\partial\mathscr{C}$.*

Proof. Because T_1 is Lipschitz (Theorem 9.2), for every $\bar{\theta} \in S_1$, the point $(T_1(\bar{\theta}), \theta)$ is a point of positive density with respect to the measure of Remark 7.4 for the set $\{(t,\theta) \mid \theta \in S^1,\ t \in (T_1(\theta), \infty)\} = \psi(\mathbb{R}^2 \setminus \bar{\mathscr{C}})$. But ψ and ψ^{-1} are locally Lipschitz, so every point of $\partial\mathscr{C}$ is a point of positive Lebesgue density for $\mathbb{R}^2 \setminus \mathscr{C}$. It follows from Theorem 2 of Caffarelli (1977) that $\partial\mathscr{C}$ is Lipschitz. Caffarelli's Theorem 3 can now be applied (with v in Caffarelli's Assumption (H1) equal to our $1-w$), and it yields the desired results. $\square$

COROLLARY 11.3. *The boundary $\partial\mathscr{C}$ is of class $C^{2,\alpha}$ for every $\alpha \in (0,1)$.*

Proof. In light of Theorems 6.3 and 11.2 and equation (6.4), D^2u has a C^1 extension from $\mathscr{C}$ to $\bar{\mathscr{C}}$. Therefore, $H-w$ appearing on the right-hand side of (11.1) has a C^1 extension from $\mathscr{C}$ to $\bar{\mathscr{C}}$, and because $\partial\mathscr{C}$ is of class C^1, $H-w$ has a C^1 extension to an open set containing $\bar{\mathscr{C}}$. (In Lemma 12.4, we explain in some detail how to construct a similar extension.) Lemma 11.1 and Theorem 11.2 permit us to apply a theorem of Kinderlehrer & Nirenberg (1977) (see also Friedman (1982, Thm. 1.1(i), p. 129)), to conclude that $\partial\mathscr{C}$ is of class $C^{1,\alpha}$ for every $\alpha \in (0,1)$.

Now observe that ∇w solves the problem

$$\nabla w - \tfrac{1}{2}\Delta\nabla w = \nabla H \quad \text{in } \mathscr{C},$$

$$\nabla w = 0 \quad \text{on } \partial\mathscr{C}.$$

Since ∇H is continuous up to $\partial\mathscr{C}$ and $\partial\mathscr{C}$ is $C^{1,\alpha}$, Theorem 8.34 of Gilbarg and Trudinger (1983, p. 211), implies that ∇w is of class $C^{1,\alpha}$ on $\mathscr{C}$ up to $\partial\mathscr{C}$. Inserting this regularity into (6.4), we conclude that D^2u, and hence $H-w$, are of class $C^{1,\alpha}$ on $\mathscr{C}$ up to $\partial\mathscr{C}$. We may again appeal to Friedman (1982, Thm. 1.1) to conclude that $\partial\mathscr{C}$ is of class $C^{2,\alpha}$ for every $\alpha \in (0,1)$. $\square$

Remark 11.4. The bootstrapping in Corollary 11.3 can be continued until the regularity of h is exhausted. If, in place of assumption (2.5), we assume that $h \in C^{k,\alpha}_{loc}$ for some $k \geqq 3$ and $\alpha \in (0,1)$, then the free boundary is of class $C^{k,\alpha}$, w is of class $C^{k,\alpha}$

inside $\mathscr{C}$ up to $\partial\mathscr{C}$, and u is of class $C^{k+1,\alpha}$ inside $\mathscr{C}$ up to $\partial\mathscr{C}$. This argument uses Ladyzhenskaya and Ural'tseva (1968, Thm. 1.1, p. 107), to wit, if ∇H is of class $C^{k-3,\alpha}$ up to $\partial\mathscr{C}$ and $\partial\mathscr{C}$ is $C^{k-1,\alpha}$, then ∇w is of class $C^{k-1,\alpha}$ up to $\partial\mathscr{C}$.

12. Construction of the optimal control process.

DEFINITION 12.1. Let $x \in \bar{\mathscr{C}}$ be given. A control process pair $\{(N_t, \zeta_t);\ 0 \leqq t < \infty\}$ as in § 2 is called a solution to the *Skorokhod problem for reflected Brownian motion in* $\bar{\mathscr{C}}$ *starting at x and with reflection direction* $-\nabla u$ *along* $\partial\mathscr{C}$ provided that:

(a) ζ is continuous,

(b) the process X defined by (2.1) satisfies $X_t \in \bar{\mathscr{C}}$, $0 \leqq t < \infty$, almost surely and

(c) for all $0 \leqq t < \infty$,

$$\zeta_t = \int_0^t 1_{\{X_s \in \partial\mathscr{C},\, N_s = -\nabla u(X_s)\}}\, d\zeta_s, \tag{12.1}$$

For every $x \in \bar{\mathscr{C}}$, the Skorokhod problem of Definition 12.1 has a solution starting at x. This follows from Lions and Sznitman (1984, Thm. 4.3), provided that the following three conditions are satisfied:

(C1) $\mathscr{C}$ has a C^1 boundary and satisfies a uniform exterior sphere condition,

(C2) There exists $\sigma > 0$ such that $\nabla u(x) \cdot n(x) \geqq \sigma$ for all $x \in \partial\mathscr{C}$, where $n(x)$ is the outward normal vector for $\mathscr{C}$ at x,

(C3) ∇u on $\mathscr{C}$ has an extension to a C^2 function on an open set containing $\bar{\mathscr{C}}$.

Condition (C1) is implied by Corollary 11.3. We establish (C2) and (C3).

LEMMA 12.2. *Condition* (C2) *is satisfied.*

Proof. Let $x \in \partial\mathscr{C}$ be given. We construct a sequence $\{x_k\}_{k=2}^{\infty}$ in $\mathscr{C}$ such that $x_k \to x$ and $(\nabla w(x_k)/|\nabla w(x_k)|) \to n(x)$. With K as in Lemma 9.1, we have

$$\frac{\nabla w(x_k) \cdot \nabla u(x_k)}{|\nabla w(x_k)|} \geqq \frac{2}{K},$$

and (C2) follows.

As for the construction of $\{x_k\}_{k=2}^{\infty}$, we choose $r > 0$ such that $B_r(x + rn(x)) \cap \mathscr{C} = \phi$. Define $\bar{x} = x + \frac{1}{2}rn(x)$, so $B_{r/2}(\bar{x}) \cap \mathscr{C} = \phi$ and $x \in \partial B_{r/2}(\bar{x})$. Given $k \geqq 2$, we define $\mathscr{C}_k \triangleq \{x \in \mathbb{R}^2;\ w(x) < 1 - (1/k)\}$. We then translate $B_{r/2}(\bar{x})$ in the $-n(x)$ direction until it touches $\partial\mathscr{C}_k$, i.e., we define

$$\rho_k = \sup\{\rho > 0;\ B_{r/2}(\bar{x} - \rho n(x)) \cap \mathscr{C}_k = \phi\},$$

and we choose $x_k \in \overline{B_{r/2}(\bar{x} - \rho_k n(x))} \cap \partial\mathscr{C}_k$. Then $B_{r/2}(\bar{x} - \rho_k n(x))$ is an exterior sphere for $\partial\mathscr{C}_k$ at x_k, so the outward normal to $\mathscr{C}_k$ at x_k is

$$\frac{\nabla w(x_k)}{|\nabla w(x_k)|} = \frac{\bar{x} - \rho_k n(x) - x_k}{|\bar{x} - \rho_k n(x) - x_k|}.$$

As $k \to \infty$, we have $x_k \to x$ and $\rho_k \to 0$, so $(\nabla w(x_k)/|\nabla w(x_k)|) \to n(x)$. □

LEMMA 12.3. *Condition* (C3) *is satisfied.*

Proof. Given $\varepsilon > 0$, we can find a finite set of open discs $\{B_k\}_{k=1}^n$, each with radius ε, such that $\bar{\mathscr{C}} \subset \cup_{k=1}^n B_k$, and we can find C^∞ functions $\gamma_k : \mathbb{R}^2 \to [0, 1]$ such that $\overline{\operatorname{supp} \gamma_k} \subset B_k$ for every k and $\sum_{k=1}^n \gamma_k = 1$ on $\mathscr{C}$. We can decompose ∇u on $\mathscr{C}$ as $\sum_{k=1}^n \gamma_k \nabla u$, so it suffices to show that each $v_k \triangleq \gamma_k \nabla u$ has a C^2 extension from $B_k \cap \mathscr{C}$ to B_k. For sufficiently small $\varepsilon > 0$, in each B_k there is a C^2 change of coordinates which results in $B_k \cap \bar{\mathscr{C}} \subset \{(x, y) \mid x \leqq 0\}$ and $B_k \setminus \bar{\mathscr{C}} \subset \{(x, y) \mid x > 0\}$. Now v_k has a C^2

extension from $B_k \cap \mathscr{C}$ to $B_k \cap \bar{\mathscr{C}}$ (proof of Corollary 11.3), and taking v_k to be zero on $\{(x, y) \mid x \leqq 0\} \setminus (B_k \cap \bar{\mathscr{C}})$, we have a C^2 function on the closed left half-plane. For $x > 0$, $y \in \mathbb{R}$, define

$$v_k(x, y) = 3v_k(0, y) - 3v_k(-x, y) + v_k(-2x, y).$$

It is easy to check that this extended v_k is C^2 on all of $\mathbb{R}^2$. □

THEOREM 12.4. *Let $x \in \mathbb{R}^2$ be given. If $x \in \bar{\mathscr{C}}$, then the solution to the Skorokhod problem of Definition* 12.1 *is an optimal control process pair for the singular stochastic control problem with initial condition x posed in* § 2. *If $x \notin \bar{\mathscr{C}}$, then there exists a unique pair $(t, \theta) \in [0, \infty) \times S_1$ such that $x = \psi(t, \theta)$. Define $\hat{x} \triangleq \psi(T_1(\theta), \theta)$ and let $(\hat{N}, \hat{\zeta})$ be a solution to the Skorokhod problem starting at $\hat{x}$. Then (N, ζ) is optimal for the control problem with initial condition x, where*

$$N_t \triangleq \begin{cases} -\nabla u(\bar{x}) & \text{if } t = 0, \\ \hat{N}_t & \text{if } t > 0, \end{cases} \tag{12.2}$$

$$\zeta_t \triangleq \begin{cases} 0 & \text{if } t = 0 \\ \hat{\zeta}_t + |x - \hat{x}| & \text{if } t > 0. \end{cases} \tag{12.3}$$

In either case, we have that $u(x) = V(x)$, where u is the solution to the HJB *equation* (3.1) (*see Theorem* 4.6), *and V is the value function for the control problem defined by* (2.10).

Proof. The theorem follows immediately from Theorem 3.1 once we observe that in the case $x \notin \bar{\mathscr{C}}$, Lemma 8.1 implies that for all $s \geqq T_1(\theta)$,

$$\begin{aligned} \nabla u(\psi(s, \theta)) &= \nabla u(\hat{x}) + \int_{T_1(\theta)}^{s} \frac{d}{d\tau} \nabla u(\psi(\tau, \theta))\, d\tau \\ &= \nabla u(\hat{x}) + \int_{T_1(\theta)}^{s} D^2 u(\psi(\tau, \theta)) \nabla u(\psi(\tau, \theta))\, d\tau \\ &= \nabla u(\hat{x}). \end{aligned}$$

Thus, when $x \notin \bar{\mathscr{C}}$, the control process pair (N, ζ) of (12.2), (12.3) causes the state to jump from $X_0 = x$ to $X_{0^+} = \hat{x}$ and $u(x) - u(\hat{x}) = |x - \hat{x}|$. After this initial jump, the state is kept inside $\bar{\mathscr{C}}$ by reflection in the $-\nabla u$ direction along $\partial \mathscr{C}$. □

13. Appendix. Proof of Lemma 4.1. For $\varepsilon \in (0, 1)$, $R > 0$, denote by $u^{\varepsilon, R}$ the solution to

$$u^{\varepsilon, R} - \Delta u^{\varepsilon, R} + \beta_\varepsilon(|\nabla u^{\varepsilon, R}|^2) = h \quad \text{on } B_R(0), \tag{13.1}$$

$$u^{\varepsilon, R} = 0 \quad \text{on } \partial B_R(0). \tag{13.2}$$

The existence of $u^{\varepsilon, R} \in C^2(\overline{B_R(0)})$ follows from Ladyzhenskaya and Ural'tseva (1968, Thm. 4.8.3, p. 301); uniqueness follows from the following lemma.

LEMMA 13.1. *Suppose that φ is a subsolution and ψ is a supersolution to* (13.1). *Then for all $x \in B_R(0)$:*

$$\varphi(x) - \psi(x) \leqq \sup_{y \in \partial B_R(0)} [\varphi(y) - \psi(y)]^+. \tag{13.3}$$

Proof. If $\varphi - \psi$ attains its maximum over $\overline{B_R(0)}$ at an interior point x^*, then $\nabla \varphi(x^*) = \nabla \psi(x^*)$ and $0 \geqq \Delta \varphi(x^*) - \Delta \psi(x^*) = \varphi(x^*) - \psi(x^*)$. □

LEMMA 13.2. *Let $q > 0$ be as in* (2.6). *There exists a constant $C_1 > 0$, independent of ε and R, such that*

$$0 \leqq u^{\varepsilon, R}(x) \leqq C_1(1 + |x|^q) \quad \forall x \in B_R(0). \tag{13.4}$$

Proof. To prove the nonnegativity of $u^{\varepsilon,R}$, take $\varphi \equiv 0$ and $\psi = u^{\varepsilon,R}$ in Lemma 13.1. To obtain the upper bound on $u^{\varepsilon,R}$, take $\varphi = u^{\varepsilon,R}$ and

$$\psi(x) = E\int_0^{\tau_x} e^{-t} h(x+\sqrt{2}W_t)\,dt,$$

where $\tau_x \triangleq \inf\{t \geqq 0; |x+\sqrt{2}W_t| \geqq R\}$. Then $\psi - \Delta\psi = h$ on $B_R(0)$, $\psi = 0$ on $\partial B_R(0)$, and Lemma 13.1 and (2.6) imply that

$$\begin{aligned} u^{\varepsilon,R}(x) &\leqq E\int_0^{\tau_x} e^{-t} h(x+\sqrt{2}W_t)\,dt \\ &\leqq E\int_0^{\infty} e^{-t} h(x+\sqrt{2}W_t)\,dt \\ &\leqq 2^q C_0 E\int_0^{\infty} e^{-t}(|x|^q + |\sqrt{2}W_t|^q)\,dt \\ &\leqq C_1(1+|x|^q) \end{aligned}$$

LEMMA 13.3. *There exist constants $C > 0$ and $p > 0$, independent of ε and R, such that*

$$\max_{x\in\partial B_R(0)} |\nabla u^{\varepsilon,R}(x)| \leqq C(1+R^p) \quad \forall \varepsilon \in (0,1), \quad R > 0. \tag{13.5}$$

Proof. Let N be a positive integer greater than $q/2$, and define $g, B : [0,\infty) \to \mathbb{R}$ by

$$g(r) = \sum_{k=0}^{N} \frac{r^{2k}}{4^k (k!)^2}, \quad B(r) = \sum_{k=0}^{\infty} \frac{r^{2k}}{4^k (k!)^2}.$$

Then

$$g(r) - \frac{1}{r} g'(r) - g''(r) = \frac{r^{2N}}{4^N (N!)^2},$$

and

$$B(r) - \frac{1}{r} B'(r) - B''(r) = 0. \tag{13.6}$$

For $R > 0$, define

$$\begin{aligned} \psi_R(x) &= 2C_0 + C_0 4^N (N!)^2 g(|x|) \\ &\quad - [2C_0 + C_0 4^N (N!)^2 g(R)] \frac{B(|x|)}{B(R)} \quad \forall x \in \mathbb{R}, \end{aligned}$$

so

$$\begin{aligned} \psi_R(x) - \Delta\psi_R(x) &= C_0(2+|x|^{2N}) \geqq h(x) \quad \forall x \in B_R(0), \\ \psi_R(x) &= 0 \quad \forall x \in \partial B_R(0). \end{aligned}$$

It follows from Lemma 13.1 that $u^{\varepsilon,R} \leqq \psi_R$ on $B_R(0)$, and because these functions agree on $B_R(0)$ and because $\nabla u^{\varepsilon,R}$ on $\partial B_R(0)$ must point inward, where $u^{\varepsilon,R}$ is nonnegative, we have

$$|\nabla u^{\varepsilon,R}(x)| \leqq |\nabla \psi_R(x)| \quad \forall x \in \partial B_R(0).$$

But on $\partial B_R(0)$,

$$|\nabla \psi_R(x)| = \left| C_0 4^N (N!)^2 g'(R) - [2C_0 + C_0 4^N (N!)^2 g(R)] \frac{B'(R)}{B(R)} \right|.$$

Equation (13.6) and the nonnegativity of B'' show that

$$0 \leqq B'(r) \leqq rB(r) \quad \forall r > 0,$$

so we may bound the growth of $\max_{x \in \partial B_R(0)} |\nabla \psi_R(x)|$ by a constant times $(1 + R^{2N+1})$. □

LEMMA 13.4. *There exist constants $C > 0$, $p > 0$, $\lambda > 0$, independent of ε and R, such that*

$$|\nabla u^{\varepsilon,R}(x)| \leqq \lambda u^{\varepsilon,R}(x) + C|x|^p + C \quad \forall x \in B_R(0), \quad \varepsilon \in (0,1), \quad R > 0. \tag{13.7}$$

Proof. With $C \geqq 1$ and $p \geqq 2$ satisfying (13.5), and C_0 as in (2.7), define $\lambda \triangleq \max\{2, C_0\}$, $B \triangleq Cp^p + C_0$, and consider the auxiliary function

$$\varphi(x) \triangleq \nabla u^{\varepsilon,R}(x) \cdot \nu - \lambda u^{\varepsilon,R}(x) - C|x|^p - B,$$

where $\varepsilon \in (0,1)$, $R > 0$ are fixed, and ν is a fixed unit vector. It suffices to show that $\varphi(x) \leqq 0$ for all $x \in B_R(0)$, so let x^* be a point at which φ attains its maximum over $\overline{B_R(0)}$. If $x^* \in \partial B_R(0)$, then (13.5) implies that $\varphi(x^*) \leqq 0$. Thus, we need only consider the case that $x^* \in B_R(0)$, for which we have

$$0 \geqq \Delta\varphi(x^*) = \Delta \nabla u^{\varepsilon,R}(x^*) \cdot \nu - \lambda \Delta u^{\varepsilon,R}(x^*) - Cp^2 |x^*|^{p-2}.$$

Using (13.1), we may rewrite this as

$$\begin{aligned} 0 \geqq{}& \nabla u^{\varepsilon,R}(x^*) \cdot \nu + 2\beta_\varepsilon'(r^*) \nabla[\nabla u^{\varepsilon,R}(x^*) \cdot \nu] \cdot \nabla u^{\varepsilon,R}(x^*) \\ & - \nabla h(x^*) \cdot \nu - \lambda u^{\varepsilon,R}(x^*) - \lambda \beta_\varepsilon(r^*) + \lambda h(x^*) - Cp^2 |x^*|^{p-2}, \end{aligned} \tag{13.8}$$

where r^* denotes $|\nabla u^{\varepsilon,R}(x^*)|^2$. Because of (2.7),

$$|\nabla h(x)| \leqq C_0 + \lambda h(x) \quad \forall x \in \mathbb{R}.$$

Furthermore,

$$\begin{aligned} Cp^2 |x|^{p-2} &\leqq Cp^p \left| \frac{x}{p} \right|^{p-2} \\ &\leqq C|x|^p + Cp^p \quad \forall x \in \mathbb{R}. \end{aligned}$$

Adding these two inequalities, we see that

$$|\nabla h(x^*)| + Cp^2 |x^*|^{p-2} \leqq \lambda h(x^*) + C|x^*|^p + B.$$

Substitution into (13.8) yields

$$0 \geqq \varphi(x^*) + 2\beta_\varepsilon'(r^*) \nabla[\nabla u^{\varepsilon,R}(x^*) \cdot \nu] \cdot \nabla u^{\varepsilon,R}(x^*) - \lambda \beta_\varepsilon(r^*). \tag{13.9}$$

Because $\nabla \varphi(x^*) = 0$, we also have

$$\begin{aligned} 0 &= \nabla \varphi(x^*) \cdot \nabla u^{\varepsilon,R}(x^*) \\ &= \nabla[\nabla u^{\varepsilon,R}(x^*) \cdot \nu] \cdot \nabla u^{\varepsilon,R}(x^*) - \lambda r^* \\ &\quad - Cp|x^*|^{p-2} x^* \cdot \nabla u^{\varepsilon,R}(x^*). \end{aligned} \tag{13.10}$$

Substitution of (13.10) into (13.9) results in the inequality

$$\varphi(x^*) \leqq \lambda[\beta_\varepsilon(r^*) - 2\beta_\varepsilon'(r^*) r^*] - 2Cp|x^*|^{p-2} \beta_\varepsilon'(r^*) x^* \cdot \nabla u^{\varepsilon,R}(x^*).$$

Let us assume that $\varphi(x^*) > 0$. Then

$$\sqrt{r^*} \geq \nabla u^{\varepsilon,R}(x^*) \cdot \nu \geqq B \geqq 2,$$

so $r^* \geqq 4$ and for all $\varepsilon \in (0,1)$,

$$\beta_\varepsilon(r^*) = \frac{r^*-1}{\varepsilon} - 1, \qquad \beta'_\varepsilon(r^*) = \frac{1}{\varepsilon}.$$

Consequently,

$$0 < \varphi(x^*) \leqq -\frac{\lambda}{\varepsilon}(|\nabla u^{\varepsilon,R}(x^*)|^2 + 1 + \varepsilon) - \frac{2Cp}{\varepsilon}|x^*|^{p-2}x^* \cdot \nabla u^{\varepsilon,R}(x^*)$$

$$\leqq -\frac{\lambda}{\varepsilon}(|\nabla u^{\varepsilon,R}(x^*)|^2 + 1 + \varepsilon) + \frac{2Cp}{\varepsilon}|x^*|^{p-1}|\nabla u^{\varepsilon,R}(x^*)|,$$

which implies that

$$|\nabla u^{\varepsilon,R}(x^*)| \leqq \frac{2Cp}{\lambda}|x^*|^{p-1} \leqq Cp^p \left|\frac{x^*}{p}\right|^{p-1} \leqq C|x^*|^p + B.$$

This inequality contradicts the assumption that $\varphi(x^*) > 0$. □

LEMMA 13.5. *For each $\varepsilon \in (0,1)$, there is an increasing sequence $\{R_n\}_{n=1}^\infty$ of positive numbers converging to infinity and a function $u^\varepsilon \in C^2(\mathbb{R}^2)$ such that $\{u^{\varepsilon,R_n}\}_{n=1}^\infty$ and $\{\nabla u^{\varepsilon,R_n}\}_{n=1}^\infty$ converge uniformly to u^ε and ∇u^ε, respectively, on compact sets. Furthermore, u^ε is a solution to* (4.3) *and satisfies* (4.4), (4.5), *with C_1 and p independent of ε.*

Proof. Let $\varepsilon \in (0,1)$ be fixed and let $r > 0$ be given. Then $u^{\varepsilon,R}$ and $\nabla u^{\varepsilon,R}$ are bounded on $B_{2r}(0)$, uniformly in R and ε (Lemmas 13.2, 13.4). Elliptic regularity implies Hölder continuity of $\nabla u^{\varepsilon,R}$ on $B_r(0)$, uniformly in $R \in [2r, \infty)$ (Gilbarg and Trudinger, Thm. 3.9, p. 41), and by the Arzela–Ascoli Theorem, we can find a sequence $\{R_n\}_{n=1}^\infty$ along which $\{u^{\varepsilon,R_n}\}_{n=1}^\infty$ and $\{\nabla u^{\varepsilon,R_n}\}_{n=1}^\infty$ converge uniformly on $B_r(0)$. Indeed, by diagonalization we can select $\{R_n\}_{n=1}^\infty$ so that $\{u^{\varepsilon,R_n}\}_{n=1}^\infty$ and $\{\nabla u^{\varepsilon,R_n}\}_{n=1}^\infty$ converge uniformly on compact sets to limits u^ε and ∇u^ε, respectively, where $u^\varepsilon \in C^{1,\alpha}$ for all $\alpha \in (0,1)$. Passing to the limit in (13.1), we see that Δu^ε exists in the distributional sense and is equal to $u^\varepsilon + \beta_\varepsilon(|\nabla u^\varepsilon|^2) - h$, which is a $C^{0,\alpha}$ function. Elliptic regularity implies that $D^2 u^\varepsilon$ in fact exists in the classical sense and u^ε is $C^{2,\alpha}$. (By bootstrapping, we could conclude that u^ε is $C^{4,\alpha}$ because h is $C^{2,1}$.) □

The convexity of u^ε will be established by representing u^ε as the value function of a stochastic control problem with convex cost functions. With β_ε defined by (4.2), we define a convex function $g_\varepsilon : \mathbb{R}^2 \to \mathbb{R}$ and its (convex) Legendre transform $l_\varepsilon : \mathbb{R}^2 \to \mathbb{R}$ by

$$g_\varepsilon(x) \triangleq \beta_\varepsilon(|x|^2), \qquad l_\varepsilon(y) \triangleq \sup_{x \in \mathbb{R}^2}\{x \cdot y - g_\varepsilon(x)\}. \tag{13.11}$$

For every $y \in \mathbb{R}^2$,

$$l_\varepsilon(y) \geqq \frac{\varepsilon}{2}|y|^2 - g_\varepsilon\left(\frac{\varepsilon}{2}y\right) \geqq \frac{\varepsilon}{4}|y|^2. \tag{13.12}$$

Furthermore, the supremum in the definition of l_ε is attained if x is related to y by $y = 2\beta'_\varepsilon(|x|^2)\, x$, i.e.,

$$l_\varepsilon(2\beta'_\varepsilon(|x|^2)x) = 2\beta'_\varepsilon(|x|^2)|x|^2 - \beta_\varepsilon(|x|^2) \quad \forall x \in \mathbb{R}^2. \tag{13.13}$$

A *control process* is any two-dimensional, absolutely continuous process η adapted to the Brownian motion $\{W_t, \mathcal{F}_t; 0 \leqq t < \infty\}$ and satisfying $\eta_0 = 0$ almost surely. Given an initial state $x \in \mathbb{R}^2$, the corresponding *state process* is

$$Y_t \triangleq x + \sqrt{2} W_t - \eta_t. \tag{13.14}$$

For each $R > 0$, we define the cost corresponding to η up to the exit from $B_R(0)$ as

$$v_\eta^{\varepsilon,R}(x) \triangleq E^x \int_0^{T_R} e^{-t} [h(Y_t) + l_\varepsilon(\dot{\eta}_t)]\, dt,$$

where $\tau_R \triangleq \inf\{t \geqq 0; |Y_t| \geqq R\}$, and $\dot{\eta}_t = (d/dt)\eta_t$. The value function up to the exit from $B_R(0)$ is

$$v^{\varepsilon,R}(x) \triangleq \inf_\eta v_\eta^{\varepsilon,R}(x).$$

It is clear that $v^{\varepsilon,R}(x)$ is nondecreasing in R, and

$$\lim_{R\to\infty} v^{\varepsilon,R}(x) \leqq v^\varepsilon(x) \triangleq \inf_\eta E^x \int_0^\infty e^{-t} [h(Y_t) + l_\varepsilon(\dot{\eta}_t)]\, dt, \tag{13.15}$$

where v^ε is the value function for a control problem on $\mathbb{R}^2$.

LEMMA 13.6. *For each $\varepsilon \in (0,1)$, $R > 0$, the solution $u^{\varepsilon,R}$ of* (13.1), (13.2) *agrees with $v^{\varepsilon,R}$ on $B_R(0)$.*

Proof. Itô's lemma implies that for a given control process η, $x \in B_R(0)$ and $t \geqq 0$:

$$\begin{aligned} E^x e^{-t\wedge\tau_R} u^{\varepsilon,R}(Y_{t\wedge\tau_R}) &= u^{\varepsilon,R}(x) + E^x \int_0^{t\wedge\tau_R} e^{-s} [\beta_\varepsilon(|\nabla u^{\varepsilon,R}(Y_s)|^2) \\ &\qquad - h(Y_s) - \nabla u^{\varepsilon,R}(Y_s)\cdot \eta_s)]\, ds \\ &\geqq u^{\varepsilon,R}(x) - E^x \int_0^{t\wedge\tau_R} e^{-s} [h(Y_s) + l_\varepsilon(\dot{\eta}_s)]\, ds. \end{aligned} \tag{13.16}$$

Letting $t \to \infty$, we see that $v_\eta^{\varepsilon,R}(x) \geqq u^{\varepsilon,r}(x)$ for all all η, so $v^{\varepsilon,R}(x) \geqq u^{\varepsilon,R}(x)$. However, if Y^R is the solution to

$$Y_t^R = x - \int_0^t 2\beta_\varepsilon'(|\nabla u^{\varepsilon,R}(Y_s^R)|^2) \nabla u^{\varepsilon,R}(Y_s^R)\, ds + \sqrt{2} W_t, \qquad 0 \leqq t \leqq \tau_R,$$

then the corresponding control process satisfies

$$\dot{\eta}_t^R = 2\beta_\varepsilon'(|\nabla u^{\varepsilon,R}(Y_t^R)|^2) \nabla u^{\varepsilon,R}(Y_t^R), \qquad 0 \leqq t \leqq \tau_R,$$

and equality holds in (13.16) because of (13.13), i.e.,

$$v_{\eta^R}^{\varepsilon,R}(x) = u^{\varepsilon,R}(x) \leqq v^{\varepsilon,R}(x),$$

and thus $u^{\varepsilon,R}(x) = v^{\varepsilon,R}(x)$. □

LEMMA 13.7. *For each $\varepsilon \in (0,1)$, the function u^ε constructed in Lemma* 13.5 *agrees with the value function v^ε defined in* (13.15).

Proof. We have immediately from (13.15) and Lemma 13.6 that $u^\varepsilon \leqq v^\varepsilon$. For the reverse inequality, let $x \in \mathbb{R}^2$ be given and define Y^∞ (up to the time of a possible explosion) by

$$Y_t^\infty = x - \int_0^t 2\beta_\varepsilon'(|\nabla u^\varepsilon(Y_t^\infty)|^2) \nabla u^\varepsilon(Y_t^\infty)\, dt + \sqrt{2} W_t.$$

Imitating (13.16), we have from Itô's lemma and (13.13) that for every $R > 0$,

$$u^\varepsilon(x) = E^x \int_0^{t\wedge\tau_R} e^{-s}[h(Y_s^\infty) + l_\varepsilon(\dot\eta_s^\infty)]\,ds + E^x\, e^{-t\wedge\tau_R} u^\varepsilon(Y_{t\wedge\tau_R}^\infty), \tag{13.17}$$

where

$$\dot\eta_t^\infty \triangleq 2\beta_\varepsilon'(|\nabla u^\varepsilon(Y_t^\infty)|^2)\nabla u^\varepsilon(Y_t^\infty), \qquad \tau_R \triangleq \inf\{t \geqq 0; |Y_t^\infty| \geqq R\}.$$

Deleting the (nonnegative) second term on the right-hand side of (13.17) and letting $R \to \infty$, $t \to \infty$, we obtain

$$u^\varepsilon(x) \geqq E^x \int_0^{\tau_\infty} e^{-s}[h(Y_s^\infty) + l_\varepsilon(\dot\eta_s^\infty)]\,ds, \tag{13.18}$$

where $\tau_\infty \triangleq \lim_{R\to\infty} \tau_R$ is finite if and only if Y^∞ explodes in finite time.

To see that $\tau_\infty = \infty$ almost surely, observe that for all $t \geqq 0$, $R > 0$,

$$|\eta_{t\wedge\tau_R}^\infty|^2 = 2\int_0^{t\wedge\tau_R} \eta_s^\infty \cdot \dot\eta_s^\infty\,ds \leqq \int_0^{t\wedge\tau_R} |\dot\eta_s^\infty|^2\,ds + \int_0^{t\wedge\tau_R} |\eta_{s\wedge\tau_R}^\infty|^2\,ds.$$

Gronwall's inequality implies

$$\max_{0\leqq s\leqq t\wedge\tau_R} |\eta_s^\infty|^2 \leqq e^t \int_0^{t\wedge\tau_R} |\dot\eta_s^\infty|^2\,ds \leqq \frac{4e^t}{\varepsilon}\int_0^{t\wedge\tau_R} l_\varepsilon(\dot\eta_s^\infty)\,ds,$$

where we have used (13.12). Letting $R \to \infty$ and taking expectations, we conclude that

$$E^x \sup_{0\leqq s<t\wedge\tau_\infty} |\eta_s^\infty|^2 \leqq E^x \frac{4e^t}{\varepsilon}\int_0^{t\wedge\tau_\infty} l_\varepsilon(\dot\eta_s^\infty)\,ds \leqq \frac{4e^{2t}}{\varepsilon} u^\varepsilon(x) < \infty, \quad \forall t \geqq 0.$$

But

$$\sup_{0\leqq s<t\wedge\tau_\infty} |Y_s^\infty| \leqq x + \sup_{0\leqq s<t\wedge\tau_\infty} |\eta_s^\infty| + \sqrt{2}\max_{0\leqq s\leqq t} |W_s|$$

and $\sup_{0\leqq s<t\wedge\tau_\infty} |Y_s^\infty| < \infty$ on $\{\tau_\infty \leqq t\}$. It follows that $P^*\{\tau_\infty \leqq t\} = 0$ for all $t \geqq 0$. Inequality (13.18) can now be restated as

$$u^\varepsilon(x) \geqq E^x \int_0^\infty e^{-s}[h(Y_s^\infty) + l_\varepsilon(\dot\eta_s^\infty)]\,ds \geqq v^\varepsilon(x). \qquad \square$$

COROLLARY 13.8. *For each* $\varepsilon \in (0, 1)$, *the function* u^ε *constructed in Lemma* 13.5 *is convex.*

COROLLARY 13.9. *For each* $\varepsilon \in (0, 1]$, $\lim_{|x|\to\infty} u^\varepsilon(x) = \infty$.

Proof. In light of (2.8), (2.9), (13.12), and (13.15), we have

$$u^\varepsilon(x) \geqq \inf_\eta E^x \int_0^\infty e^{-t}\left[\frac{c_0}{2}|Y_t|^2 + \frac{\varepsilon}{4}|\dot\eta_t|^2\right] dt.$$

But the right-hand side is the value associated with a linear-quadratic-Gaussian problem, which is easily computed to be $\frac{1}{2}\alpha|x|^2 + 2\alpha$, where α is the positive root of the quadratic equation $(2/\varepsilon)\alpha^2 + \alpha - c_0 = 0$. $\square$

LEMMA 13.10. *There is a constant* C_2, independent of ε, such that for every $\varepsilon \in (0, 1)$, *the function* u^ε *constructed in Lemma* 13.5 *satisfies* (4.6).

Proof. Let ν be a unit vector and define $u_{\nu\nu}^\varepsilon \triangleq (D^2u)\nu \cdot \nu$. It suffices to produce a constant C_2, independent of ε and ν, such that

$$u_{\nu\nu}^\varepsilon \leqq C_2(1 + u^\varepsilon).$$

We begin by differentiating (4.3) to obtain

$$\begin{aligned} h_{\nu\nu} &= u^\varepsilon_{\nu\nu} - \Delta u^\varepsilon_{\nu\nu} + 2\beta'_\varepsilon(|\nabla u^\varepsilon|^2)(\nabla u^\varepsilon_{\nu\nu}\cdot\nabla u^\varepsilon + |(D^2u^\varepsilon)\nu|^2) \\ &\quad + 4\beta''_\varepsilon(|\nabla u^\varepsilon|^2)(D^2u^\varepsilon\nabla u^\varepsilon\cdot\nu)^2 \\ &\geqq u^\varepsilon_{\nu\nu} - \Delta u^\varepsilon_{\nu\nu} + 2\beta'_\varepsilon(|\nabla u^\varepsilon|^2)\nabla u^\varepsilon_{\nu\nu}\cdot\nabla u^\varepsilon. \end{aligned} \tag{13.19}$$

Let x^ε be a minimizing point for u^ε, choose $p>0$ satisfying (4.4), (4.5), choose $C_0>0$ to satisfy (2.8), let $\delta>0$ be given, and define the auxiliary function

$$\varphi_\delta(x) = u^\varepsilon_{\nu\nu}(x) - C_0u^\varepsilon(x) - \delta|x-x^\varepsilon|^{p+2}.$$

This function attains its maximum at some point y^δ, where we have

$$0 = \nabla\varphi_\delta(y^\delta) = \nabla u^\varepsilon_{\nu\nu}(y^\delta) - C_0\nabla u^\varepsilon(y^\delta) - \delta(p+2)|y^\delta-x^\varepsilon|^p(y^\delta-x^\varepsilon), \tag{13.20}$$

$$0 \geqq \Delta\varphi_\delta(y^\delta) = \Delta u^\varepsilon_{\nu\nu}(y^\delta) - C_0\Delta u^\varepsilon(y^\delta) - \delta(p+2)^2|y^\delta-x^\varepsilon|^p. \tag{13.21}$$

Substituting (4.3) into (13.21) and using (13.19), we obtain

$$\begin{aligned} 0 &\geqq u^\varepsilon_{\nu\nu}(y^\delta) + 2\beta'_\varepsilon(|\nabla u^\varepsilon(y^\delta)|^2)\nabla u^\varepsilon_{\nu\nu}(y^\delta)\cdot\nabla u^\varepsilon(y^\delta) \\ &\quad - h_{\nu\nu}(y^\delta) - C_0u^\varepsilon(y^\delta) - C_0\beta_\varepsilon(|\nabla u^\varepsilon(y^\delta)|^2) \\ &\quad + C_0h(y^\delta) - \delta(p+2)^2|y^\delta-x^\varepsilon|^p \\ &= \varphi_\delta(y^\delta) + 2\beta'_\varepsilon(|\nabla u^\varepsilon(y^\delta)|^2)\nabla u^\varepsilon_{\nu\nu}(y^\delta)\cdot\nabla u^\varepsilon(y^\delta) \\ &\quad - h_{\nu\nu}(y^\delta) - C_0\beta_\varepsilon(|\nabla u^\varepsilon(y^\delta)|^2) + C_0h(y^\delta) \\ &\quad - \delta(p+2)^2|y^\delta-x^\varepsilon|^p + \delta|y^\delta-x^\varepsilon|^{p+2} \\ &\geqq \varphi_\delta(y^\delta) + 2\beta'_\varepsilon(|\nabla u^\varepsilon(y^\delta)|^2)\nabla u^\varepsilon_{\nu\nu}(y^\delta)\cdot\nabla u^\varepsilon(y^\delta) \\ &\quad - C_0(1+h(y^\delta)) - C_0\beta_\varepsilon(|\nabla u^\varepsilon(y^\delta)|^2) + C_0h(y^\delta) \\ &\quad - 2\delta p^{(p/2)}(p+2)^{(p+2)/2} \end{aligned} \tag{13.22}$$

because of (2.8) and the fact that

$$-\delta(p+2)^2r^p + \delta r^{p+2} \geqq -2\delta p^{(p/2)}(p+2)^{(p+2)/2} \quad \forall r\geqq 0.$$

But (13.20) implies that

$$\begin{aligned} \nabla u^\varepsilon_{\nu\nu}(y^\delta)\cdot\nabla u^\varepsilon(y^\delta) &= C_0|\nabla u^\varepsilon(y^\delta)|^2 + \delta(p+2)|y^\delta-x^\varepsilon|^p(y^\delta-x^\varepsilon)\cdot\nabla u^\varepsilon(y^\delta) \\ &\geqq C_0|\nabla u^\varepsilon(y^\delta)|^2 \end{aligned} \tag{13.23}$$

because u^ε is convex and attains its minimum at x^ε. Substitution of (13.23) into (13.22) yields

$$\begin{aligned} 0 &\geqq \varphi_\delta(y^\delta) + 2C_0\beta'_\varepsilon(|\nabla u^\varepsilon(y^\delta)|^2)|\nabla u^\varepsilon(y^\delta)|^2 - C_0\beta_\varepsilon(|\nabla u^\varepsilon(y^\delta)|^2) \\ &\quad - C_0 - 2\delta p^{(p/2)}(p+2)^{(p+2)/2}. \end{aligned} \tag{13.24}$$

The convexity of β_ε implies that

$$\beta'_\varepsilon(r)r \geqq \beta_\varepsilon(r) - \beta_\varepsilon(0) = \beta_\varepsilon(r) \quad \forall r\geqq 0,$$

so (13.24) reduces to

$$\varphi_\delta(x) \leqq \varphi_\delta(y^\delta) \leqq C_0 + 2\delta p^{(p/2)}(p+2)^{(p+2)/2} \quad \forall x\in\mathbb{R}^2.$$

Letting $\delta\downarrow 0$, we obtain

$$u^\varepsilon_{\nu\nu}(x) \leqq C_0(1+u^\varepsilon(x)) \quad \forall x\in\mathbb{R}^2. \qquad \square$$

SIAM J. CONTROL AND OPTIMIZATION
Vol. 27, No. 5, pp. 909–915, September 1989

A TRIBUTE TO E. J. McSHANE

This special issue of the *SIAM Journal on Control and Optimization* is dedicated to E. J. McShane on the occasion of his 85th birthday.[1] During his long career, he has had a leading role in the development of several mathematical areas that bear significantly on present-day control theory. In addition, he served in several capacities as a national leader in mathematical and science policy matters. Those of us who have had the privilege to know Jim McShane have the highest regard for him as a mathematician, a scientific statesman, and a person.

McShane was born in New Orleans on May 10, 1904, and grew up there. His father was a medical doctor and his mother a former school teacher. He graduated from Tulane University in 1925, receiving simultaneously Bachelor of Engineering and Bachelor of Science degrees. He turned down an offer from General Electric and instead continued as a student instructor of mathematics at Tulane, receiving a Master's degree in 1927.

In the summer of 1927, McShane entered graduate school at the University of Chicago, from which he received the Ph.D. in 1930 under the supervision of G. A. Bliss. He interrupted his studies during 1928–29 for financial reasons to teach at the University of Wichita. It was at Chicago that McShane's long-standing interest in the calculus of variations began. From 1930 to 1932 he held a National Research Council fellowship, spent at Princeton, Ohio State, Harvard, and Chicago. This was a very productive period. It resulted in thirteen research papers, containing a wealth of new ideas. Another fortunate event was his marriage to Virginia Haun in 1931.

Because of the Great Depression, openings in mathematics departments were virtually nonexistent in 1932. The McShanes spent 1932–33 at Gottingen, during which time he translated into English the two volumes of Courant's *Differential and Integral Calculus*. They also saw firsthand some frightening aspects of the onset of Nazi power in Germany.

After two years (1933–35) on the Princeton faculty, McShane joined the Department of Mathematics at the University of Virginia as a full professor in the fall of 1935. He has remained there ever since. In 1939 and 1940, McShane's important papers on general necessary conditions in the form of multiplier rules and on a strong existence theorem for the Bolza problem of calculus of variations appeared. With the onset of World War II, McShane agreed to head a mathematics group at the Ballistics Research Laboratory in Aberdeen, Maryland. During this time he wrote a book with J. L. Kelley and F. V. Reno entitled *Exterior Ballistics*, which is regarded as the definitive work on the subject.

After the war, McShane developed a serious interest in the mathematical foundations of quantum mechanics and quantum field theory. While this ambitious program did not reach fruition, the attempt profoundly influenced his subsequent work on integration processes and stochastic calculus. This is seen, for example, in his excellent *Bulletin of the American Mathematical Society* survey article "Integrals Designed for Special Purposes" (1963) and his book *Stochastic Calculus and Stochastic Models* (1974), which is the definitive treatment of his approach to that subject.

McShane served as President of the Mathematical Association of America during 1953–54. He took an active interest in efforts just then getting underway to revitalize undergraduate mathematics in the U.S. During McShane's term as President, the MAA

[1] After this issue was compiled, we were saddened to learn of the death of E. J. McShane on June 1, 1989, at the age of 85.

Committee on the Undergraduate Program in Mathematics was established. Since that time the Committee has been a leader in these endeavors. He was elected to the National Academy of Science in 1948 and served on the National Science Board from 1956 to 1968. During 1958 and 1959, he was also President of the American Mathematical Society.

McShane has had a lifelong interest in music. His early interest in opera led him to learn to read Italian libretti. This knowledge, in turn, led G. A. Bliss to suggest to McShane that he read the then new book *Fondamenti di Calcolo delle Variazione* by Leonida Tonelli, which started McShane on his study of multiple integral problems in the calculus of variations. Later, in the 1950s, McShane learned to play the cello, and he has been an amateur chamber music performer ever since.

The injustices suffered by some of his colleagues during the post World War II anticommunist hysteria deeply offended McShane. He himself, in response to the question on the Aberdeen Proving Grounds security form that asked whether he had ever been involved with organizations that at any time advocated the overthrow of the U.S. government by force and violence, replied that, yes, he was an employee of the state of Virginia. During the McCarthy era, the House Un-American Activities Committee (HUAC) "invited" him to express his views, but he was not subpoened. He did not cooperate with HUAC, but wrote a letter in which he stated his views and backed them up with quotations from various sources.

Victor Klee, recalling his experience as a graduate student at Virginia from 1945 to 1949, writes: "... He [McShane] was very popular with the graduate students because of his clear lectures, his amusing anecdotes, and unusual kindness." Klee goes on to tell how McShane turned his office over to the graduate students, who had no offices of their own, and says, "... His generosity contributed a lot to the quality of the graduate program by providing a place for the graduate students to meet with each other and talk about mathematics.... It is simply impossible, in a few words, to convey the extent of the graciousness, kindness, and hospitality that have been [and are] exhibited by Virginia and Jimmy McShane in their relations with those lucky enough to know them. These go far beyond professional matters."

The portion of McShane's work that is significant for present-day control theory falls into four broad categories: (a) Multiple integral problems in the calculus of variations; (b) Relaxed controls, necessary conditions and existence theorems for single integral problems and control problems; (c) Integration theory; (d) Stochastic calculus.

(a) The late 1920s and 1930s saw many changes in the calculus of variations. L. Tonelli's book had introduced the "direct method," which was advantageous for proving semicontinuity and the existence of absolute minima. The solution to Plateau's problem by J. Douglas and T. Rado stimulated the rapid development of the calculus of variations for multiple integral problems and the theory of Lebesgue area of surfaces. (The Plateau problem is to find a surface of minimum area with given boundary.) McShane was at the forefront of these developments. While still a graduate student, McShane obtained the necessary condition of Weierstrass for quasiconvex variational problems with an arbitrary number of functions of several variables. Soon afterward he turned to questions of semicontinuity and existence of a minimum for multiple integral geometric calculus of variations, of which the Plateau problem was a prototype. Hidden in these problems were notorious analytical and topological difficulties, which were later overcome by other mathematicians (including Cesari, Federer, and Rado) as part of Lebesgue surface area theory. McShane provided an elegant solution for geometric variational integrands which do not vary spatially. The key idea was that it suffices to find the minimum in the smaller class of "saddle surfaces,"

which are representable parametrically by a vector function monotone in Lebesgue's sense.

(b) In 1939 McShane published a paper in the *American Journal* entitled "On Multipliers for Lagrange Theory," which has had a profound, but not generally recognized, influence on optimal control theory and nonlinear programming. In this paper, McShane showed that the Weierstrass condition holds along a curve, without making any assumptions about the normality of the curve. Although this result was important in and of itself, the method of proof turned out to be a major contribution to the theory of necessary conditions in optimization problems. The key and novel elements of the proof were, first, the construction of a convex cone generated by first-order approximations to the end points of perturbations of the optimal trajectory and, second, showing that optimality implies that this cone and a certain half-ray can be separated by a hyperplane. Twenty years later, this idea was used by Pontryagin and his coworkers in their proof of the necessary condition now known as the Pontryagin maximum principle. In his 1959 Uspekhi paper, Pontryagin states that the proof will utilize certain constructions due to McShane. No such acknowledgment exists in the classic book by Pontryagin, Boltyanskii, Gamkrelidze, and Mischchenko entitled *The Mathematical Theory of Optimal Processes*, which collected their previous work. This book appears to have popularized the convex cone and separation constructions, which were subsequently used by most authors in deriving necessary conditions, not only for control problems, but also for nonlinear programming problems and abstract optimization problems.

Another body of work, which was definitive, in a sense, for problems in the calculus of variations in one independent variable, was the series of three papers that appeared in 1940 in volumes six and seven of the *Duke Journal.* In the first of these papers, McShane showed that if the problem of Bolza is phrased in terms of generalized curves (which were introduced in 1937 for simple problems in the plane by L. C. Young) then the problem of Bolza has a solution. In the second paper, he derived the generalizations of the standard necessary conditions that must hold along a minimizing generalized curve. In the last paper, he gave conditions under which the minimizing generalized curve is an ordinary curve. Definitive as this work was, it did not seem to attract attention outside the circle of cognoscenti in the calculus of variations until twenty years later, in the 1960s, when generalized curves were rediscovered by control theorists as relaxed controls, or sliding states. In 1967, McShane, in a *SIAM Journal on Control* paper, adapted his 1940 work to the control theory setting [*SIAM J. Control.*, 5 (1967), pp. 438–485]. This paper is more elementary and self-contained than most treatments of relaxed controls and reflects McShane's dedication to teaching as well as research.

McShane's proof, with R. B. Warfield, of a general version of Filippov's implicit function theorem (*Proceedings of the American Mathematical Society*, 1967; corrigenda and addenda, 1969) was an important contribution to control theory. This lemma gives conditions that guarantee the existence of a measurable solution to an equation whenever a pointwise solution exists and is one of the basic tools in optimal control theory.

Another example of McShane's interest in instruction is his 1973 paper in the *American Mathematical Monthly* entitled "The Lagrange Multiplier Rule." Here he gives a penalty function proof of the Fritz-John and Kuhn-Tucker necessary conditions for nonlinear programming problems that is short and accessible to anyone who knows the Bolzano-Weierstrass Theorem. Later, other authors applied the arguments used here to obtain necessary conditions for a variety of control and optimization problems.

(c) Over the years McShane has achieved an extraordinarily deep understanding of integration processes as they arise in various guises. He wrote three books on integration, in addition to a number of research articles and the 1963 *Bulletin of the American Mathematical Society* survey already mentioned. His 1944 volume *Integration* gave a readable introduction to the Lebesgue theory at a time when few such books existed in English. The 1953 monograph, *Order Preserving Maps and Integration Processes*, was an outgrowth of his search for a mathematically correct setting in which to treat divergent integrals in quantum physics. In 1957, J. Kurzweil defined a modification of the Riemann integral, which turned out to be more general than the Lebesgue integral. McShane's 1983 volume *Unified Integration* develops in a similar vein a complete theory of integrals, together with a wealth of applications to physics, differential equations, and probability. An appealing feature of this approach, from a pedagogical standpoint, is that point set topology and measurability issues can be deferred.

(d) During the 1960s and 1970s McShane's interests turned toward developing a stochastic differential and integral calculus. The K. Itô stochastic calculus was by then already in existence. It provided a convenient way to represent an important class of stochastic processes, called Markov diffusions, as the solutions to stochastic differential equations. The random inputs to an Itô-sense stochastic differential equation are Brownian motion processes, whose formal time derivatives are "white noises." At that time, however, there was considerable confusion in the engineering literature about the correct interpretation if an idealized white noise is replaced either by a physical "wide band" noise or by some discrete process introduced for numerical approximation to the solution of the stochastic differential equation. This issue was clarified by the work of McShane, Stratonovich, and Wong-Zakai.

McShane's solution was to introduce a stochastic calculus, in which stochastic differential equations take the form (for scalar-valued processes x_t, z_t)

$$dx_t = f(x_t)\,dt + g(x_t)\,dz_t + h(x_t)(dz_t)^2,$$

where z_t is a stochastic process representing the random inputs. If z_t has Lipschitz sample paths, then one should take $(dz_t)^2 = 0$; while $(dz_t)^2 = dt$ for a standard Brownian motion z_t. Let $h = \frac{1}{2}gg'$. Then McShane's stochastic integral has the following consistency property. Let $z_t^{(n)}$ be a sequence of processes with Lipschitz sample paths, such that $z_t^{(n)}$ tends (in a suitable sense) to a Brownian motion z_t on a time interval $0 \leqq t \leqq T$. Then the solution $x_t^{(n)}$ to the $z_t^{(n)}$-driven stochastic differential equation tends to the corresponding solution x_t of the solution to the z_t-driven stochastic differential equation. The function h is called the Wong-Zakai correction. McShane's *Stochastic Calculus and Stochastic Models* (1974) gives a definitive account of this work. Even today the consistency question is often not addressed in the applied literature in such areas as chemical physics, financial economics, and biology. Consistency becomes a more delicate matter when T is large (or infinite) as happens in questions of large deviations or ergodicity. It is perhaps ironic that it has been left to probabilists to sort out these practical consistency questions.

For these many contributions and services to mathematics in general and to control theory in particular, we thank and honor Jim McShane, a true scholar and gentleman.

THE CALCULUS OF VARIATIONS FROM THE BEGINNING THROUGH OPTIMAL CONTROL THEORY*

E. J. McSHANE†

Before I begin this talk, I would like to sketch briefly what I plan to do. I hope to speak of some of the important stages of the development of the calculus of variations, with a disproportionately large part of the hour allotted to recent developments. But I have no intention of listing important discoveries with their dates. Rather, I shall try to say something of the underlying patterns of thought at each stage and to comment on the change in that pattern produced by each of the new ideas. It may seem that I am deriding our predecessors for not having seen at once all that we have learned. I have no such intention. We must all do our thinking on the foundation of what we already know. It is hard to assimilate a genuinely new idea, and even harder to realize that ideas we have earlier acquired have become obsolete.

Preparing this talk has forced me to formulate with at least some pretension to clarity what is meant by the calculus of variations. There is no universal agreement on the definition of the subject, and I have gradually come to the conclusion that part of the reason is that there are at least two related but different sets of ideas that are often brought together under the same name. The first set might be called the theory of extrema. A functional is defined on some class of functions; the problem is to find a function in the given class that minimizes or maximizes the functional on that class. If this theory of extrema is included in the calculus of variations, Caratheodory may be justified in asserting that the first problem in the calculus of variations was that of finding a curve of given length that joins the ends of a line segment, and together with that segment encloses the greatest possible area. This was solved, according to Caratheodory, by Pappus, in about A.D. 290.

The second set of ideas is concerned with functionals on linear topological spaces, usually function spaces, and constitutes a part of a differential calculus on such spaces. The central problem in this part of the theory is that of finding stationary points of functionals; that is, points at which the directional derivatives in all directions exist and are all zero. Since such points are characterized by means of investigating the effect on the functional produced by small variations of the function which is the independent variable, this study of stationary points can reasonably be called the calculus of variations.

The two sets of ideas both have important applications, but to different problems. At one extreme we have those problems such as the isoperimetric problem of Pappus just mentioned and, more recently, problems in which a function is to be found that produces a best possible result in some sense, such as propelling an airplane between given points with least expenditure of fuel. At the other extreme we have situations in which the presence or absence of a maximum or minimum is irrelevant; only the consequences of stationarity matter. These consequences often include the satisfaction of a set of differential equations. According to what is misnamed "the principle of least action," the motion of a set of particles follows a time-development for which a certain integral, called the "action," is stationary. The function for which the action

* Reprinted with permission (with minor editorial changes) from *Optimal Control and Differential Equations*, A. B. Schwarzkopf, Walter G. Kellet, and Stanley B. Eliason, eds., Academic Press, New York, 1978, pp. 3-51.

† Professor E. J. McShane passed away on June 1, 1989. At the time of his death, he was affiliated with the Department of Mathematics, University of Virginia, Charlottesville, Virginia 22903.

is stationary is the one for which the classical equations of motion are satisfied, and the satisfaction of those equations is all that we want.

In between these two extremes we have the problems of relative extrema. Let us say that a function y is in the weak ε-neighborhood of another function y_0 if there is a homeomorphism between their graphs such that at corresponding points, the values of y and y_0 differ by less than ε, and so do the values of their derivatives. The function y is in the strong ε-neighborhood of y_0 if this holds with the reference to the derivatives deleted. A functional has a weak (strong) relative minimum at y_0 if for some positive ε, the functional has at y_0 its least value on the set of all those y in the domain of the functional that are in the weak (strong) ε-neighborhood of y_0. These concepts have some applications, related to stable and unstable equilibrium; but I have a strong suspicion that relative maxima and minima were usually studied, not because they were really wanted, but because available theory did not permit the study of absolute maxima and minima.

For lack of time I shall say little about the second set of ideas, based on stationarity. This means that I shall disregard some important pure mathematics and some important applications. I have mentioned that the principle of least action is of this type. So too is Hamilton's study of optics and its extension into calculus of variations by Jacobi. So is all the mathematics of quantum theory that is based on a Hamiltonian. So, too, is Marston Morse's theory of the calculus of variations in the large. I shall choose for my principal subject the development of the first set of ideas that I have called the theory of extrema.

In the eighteenth century the distinction between the two sets of ideas was hardly noticed. If it could be shown that any curve that minimized some functional had to satisfy a certain condition, and a curve could be found that did satisfy that condition, it was accepted without comment that that curve did furnish the minimum. Nor has such a feeling quite disappeared. On page 16 of the book by Gelfand and Fomin [1] (English translation) we read: "In fact, the existence of an extremum is often clear from the physical or geometric meaning of the problem, e.g., in the brachistochrone problem, the problem concerning the shortest distance between two points, etc. If in such a case there exists only one extremal satisfying the boundary conditions of the problem, this extremal must perforce be the curve for which the extremum is achieved." I disagree with this on three counts. First, if the calculus of variations is mathematics, our conclusions must be deducible logically from the hypotheses, with no use of anything that is "clear from the physical meaning"—even if anything is ever that clear in physics. Second, if the mathematical expression is meant to be a model of a physical situation, we are not entitled to unshakable confidence that the model we have chosen is perfect in all details; rather, we should keep in mind that a mathematical model of a physical system is necessarily a simplification and idealization. Third, the principle as stated is untrustworthy. For example, if A and B are two points in the upper half-plane, there always exists a curve joining them such that the surface of revolution obtained by rotating it about the x-axis has least area. If A and B are properly located, there is just one extremal that joins them, and it does not furnish the least area. (See G. A. Bliss [2, p. 116].)

In the early eighteenth century the necessary conditions for a minimum in various specific problems were found by ingenious devices, usually involving replacing a short arc of the curve by another short arc with the same ends. In 1760, Lagrange unified these special solutions by means of the idea of a variation. Suppose that a function $x \to y_0(x)$ $(x_0 \leqq x \leqq x_1)$ minimizes a functional $J(y(\cdot))$ in a certain class K of functions. Suppose further that we can find a family of functions $y_\alpha(-b < \alpha < b)$ such that for

each α in $(-b, b)$, the function $x \to y_\alpha(x)(x_{0,\alpha} < x < x_{1,\alpha})$ is in the given class K. Then the derivative at $\alpha = 0$ of the function $J(y_\alpha(\cdot))$, if it exists, must be zero. The function

$$x \to \eta(x) = \partial y_\alpha(x)/\partial\alpha \qquad (\alpha = 0)$$

is often called a variation of y_0; Lagrange used the term "variation" and the symbol δy for the product of this by $d\alpha$. The variation of the functional, which is the derivative of $J(y_\alpha(\cdot))$ at $\alpha = 0$, is the directional derivative of J in the direction η. In many interesting cases its vanishing is equivalent to the satisfaction of a certain differential equation; this is the Euler-Lagrange equation.

For the purposes of mechanics, the goal had now been reached. The Euler-Lagrange equation permitted the introduction of general coordinate systems, and the concept of stationary curve unified the whole theory of classical mechanics, as Lagrange showed in his masterful work. But it was a mental confusion, consistent with the somewhat uncritical ideas of the period, to think that any stationary curve would certainly furnish a maximum or a minimum, as wished. In his *Principia* (1687), Isaac Newton had discussed the problem of finding a surface of revolution with assigned base and altitude that minimized a functional that Newton thought represented the drag when the body is moved through a fluid. Legendre published his necessary condition for a minimum in 1786, a century later; but in 1788, he published another paper, entitled "Mémoire sur la manière de distinguer les maxima des minima dans le calcul de variations," in which he pointed out that a curve could satisfy the Euler-Lagrange equation for the integral expressing the Newtonian resistance and still not give the surface of least resistance. The most interesting feature of his proof is that he showed that the Weierstrass condition for a minimum was not satisfied—and Weierstrass was not born until twenty-seven years later. This work must not have had the immediate effect that it deserved. Mathematicians continued to act as though the only feature of importance was the satisfaction of the condition for stationarity. More than two decades later Robert Woodhouse, F.R.S., a Fellow of Caius College, Cambridge, published a book entitled *Treatise on Isoperimetrical Problems and the Calculus of Variations* (1810), in which Legendre is not mentioned. In this book, Woodhouse poses the problem of maximizing the integral

$$\int [d^2y/dx^2]^2\, dx,$$

the class of curves not being clearly specified. By use of variations, he came to the conclusion that the maximum is provided by the line segment joining the endpoints. Had he used Legendre's results, he would have recognized the falsity of his conclusion. But even without having read Legendre, he should have noticed that unless the endpoints coincide, no maximum can exist, and the line segment gives to the integral the value zero, an obvious minimum.

The guiding principle during the eighteenth century and more than half the nineteenth seemed to be that if a minimizing function is sought for some functional, then by inventing more and more necessary conditions for a minimum, we can feel steadily more confident that a function that passes all the tests is in fact the minimizing function sought. The first necessary condition was stationarity, established when the curve being tested can be varied in arbitrary directions. The next in order of time was the Legendre condition, still in the domain of Lagrange-type variations, and in fact needing only variations that leave the function unchanged outside a small interval. Next came the condition of Jacobi. Like that of Legendre, it expressed the fact that

for a minimum, all directional second derivatives (second variations) must be nonnegative; but unlike Legendre's, it required the variation of the function along long intervals. Next came the necessary condition of Weierstrass. Unlike the others, it cannot be established by means of Lagrange-type variations or directional derivatives. The function being tested is compared with other functions near it in position but widely different in derivative. That is to say, the Weierstrass condition is necessary for a strong relative minimum, not for a weak one.

But Weierstrass made a more significant contribution than the discovery of a new necessary condition. For unconditioned problems, in which the minimum of an integral

$$\int_{x_0}^{x_1} f(x, y(x), y'(x))\, dx$$

is sought in the class of all sufficiently well-behaved functions with assigned end-values, he was able to prove that when a function $y(\cdot)$ satisfies conditions that are slight strengthenings of the four known necessary conditions, it will provide a strong relative minimum for the integral. Now, at last, instead of feeling confident without conclusive proof that a curve gave a minimum to the integral, we could feel certain that it gave a kind of minimum—not indeed the absolute minimum that we were seeking, but at least a strong relative minimum.

This was truly a great step forward in the theory of the calculus of variations. (It might help to promote humility among us workers in that field if we notice that in his biography of Weierstrass in *Men of Mathematics*, E. T. Bell [3] does not even mention that Weierstrass wrote on the calculus of variations.) But it had a psychological drawback. Like the ideas introduced by Lagrange a century earlier, the means used by Weierstrass were so highly esteemed that they became ends in themselves. No matter what the calculus of variations was formally stated to be, in the hands of many of its workers it became a procedure of proving in each new type of problem some analogues of the necessary conditions of Euler and Lagrange, of Legendre, of Jacobi, and of Weierstrass, and then of proving a sufficiency theorem of some sort. This is not astonishing. When I studied calculus, a mere fifty-five years ago, the theory of maxima and minima consisted of finding points at which the derivative of a function is zero and then looking at the value of the second derivative. I learned a needed lesson years later, when for quite practical reasons I needed to find the absolute minimum of a function, and discovered that setting the derivative equal to zero located the maximum; the minimum that I needed was at an endpoint, where the derivative was not zero.

Beginners in calculus today are taught a better method of finding minima of functions f on a closed interval $[a, b]$. First it is shown (or at least asserted in an authoritative tone of voice) that a minimum exists. Next, conditions are found that must be satisfied at the point x_0 at which f is minimum; either x_0 is a or b, or the derivative exists at x_0 and is zero, or the derivative does not exist at x_0. In many problems, these necessary conditions rule out all but a few values of x. One of these gives f its least value; which one can be determined by calculating f at these points. A similar method could be used to find the absolute minimum of a functional provided that first an existence theorem is proved, and then necessary conditions are found that have to be satisfied at the minimizing function. If these necessary conditions rule out all but a few functions, calculating the corresponding values of the functional will permit us to find which one furnishes the absolute minimum.

Early in this century David Hilbert proved an existence theorem for certain unconditioned problems. Later, Leonida Tonelli showed that if an integrand $f(x, y, y')$ is convex as a function of y', its integral is lower semicontinuous; if a sequence of

functions $y_1, y_2, \cdots$ tends in the strong topology to a limit function y_0, the limit inferior of the integral along y_n is at least equal to the integral along y_0. This, with some other very reasonable hypotheses, gave excellent existence theorems for unconditioned problems. But when applied to conditioned problems, such as isoperimetric problems and Bolza problems, it produced no results of interest. These conditioned problems are neither new nor artificial. As to newness, Forsythe asserts that the word "isoperimetric" was first used in the early fifth century by Bishop Synesius. As to artificiality, the engineering problems that led the Russian mathematicians to devise the modern form of control theory are almost invariably conditioned problems. Conditioned problems were unmanageable until L. C. Young invented what he called generalized curves.

For those of us who have not encountered generalized curves, a bit of explanation might be helpful. Suppose that we wish to minimize the integral

$$\int_0^1 [y^2+(y'^2-1)^2]\,dx \tag{1}$$

in the class of absolutely continuous functions $y(\cdot)$ on $[0, 1]$. If we divide $[0, 1]$ into $2n$ intervals of equal length and define y_n to be the function with $y_n(0)=0$ and $y'=1$ and $y'=-1$ on alternate subintervals, the graph of y_n is a sawtooth polygon, and the integral has value $1/12n^2$. So the lower bound of the integral is zero. But y_n tends uniformly to the zero function, for which the integral (1) has value 1. We need a different approach. Let us plot each value of y_n' on a u-axis. If we select a subinterval of $[0, 1]$ and choose an x at random in it, there is a certain probability that $y_n'(x)=1$, and this probability tends to $\frac{1}{2}$ as n increases; and likewise, the probability that $y_n'(x)=-1$ tends to $\frac{1}{2}$ as n increases. So we construct a new kind of object. Instead of having a number $y'(x)$ associated with each x in $[0, 1]$, it has a probability distribution P_x that assigns probability $\frac{1}{2}$ to each of the numbers 1, -1 and the probability zero to the rest of the real number system. This is what we would have in the unrealizable situation that on every subinterval of $[0, 1]$, $y'(x)$ were $+1$ half the time and -1 half the time. This distribution takes the place of the single number $y'(x)$, which can be thought of as a distribution in which probability 1 is assigned to the number $y'(x)$ and zero to the rest of the real numbers. Thus instead of having $y_0(x_1)$ equal to the integral of $y_0'(x)$ from zero to $x_1 (0 \leqq x_1 \leqq 1)$, we have

$$y_0(x_1)=\int_0^{x_1}\left\{\int_R uP_x(du)\right\}dx=0;$$

and likewise, the replacement for the integral (1) is

$$\int_0^1\left\{\int_R [y_0^2+(u^2-1)^2]P_x(du)\right\}dx,$$

which has the value zero. Young's generalized curves are objects of this new kind. A generalized curve can be thought of as a pair $((y(x), P_x): a \leqq x \leqq b)$ in which the y is a function on $[a, b]$, and for each x in $[a, b]$, P_x is a probability distribution on R, and

$$y(x_1)=\int_a^{x_1}\left\{\int_R uP_x(du)\right\}dx, \qquad (a \leqq x_1 \leqq b).$$

(This is close to Young's original formulation; in his book *Calculus of Variations and Optimal Control Theory* [4], he prefers to regard a generalized curve as a functional on a class of integrands, somewhat like Schwartz distributions.) This can be generalized at once to higher dimensions.

The space of generalized curves can be topologized by defining the statement that a sequence of generalized curves $((y_n(x), P_{n,x})\colon a_n \leqq x \leqq b_n)$ tends to a generalized curve $((y_0(x), P_{0,x})\colon a_0 \leqq x \leqq b_0)$ if and only if

$$\lim_{n\to\infty} \int_{a_n}^{b_n} \left\{ \int_R \phi(x, y_n(x), u) P_{n,x}(du) \right\} dx = \int_{a_0}^{b_0} \left\{ \int_R \phi(x, y_0(x), u) P_{0,x}(du) \right\} dx$$

for every continuous function ϕ that vanishes outside a bounded set. The extension to higher dimensions is obvious. The remarkable fact is that with this topology, the space of generalized curves has sufficiently strong compactness properties so that for a large class of problems, not merely unconditioned problems, a minimizing generalized curve can be found for the integral under consideration. Young applied this in 1937 to unconditioned problems. In 1940, I published a sequence of three papers in which, for problems of Bolza in parametric form, it was shown first, that under weak hypotheses a minimizing generalized curve exists; second, that it satisfies necessary conditions that are generalizations of the Euler-Lagrange, Legendre and Weierstrass conditions; and third, that under some extra hypotheses, the minimizing generalized curve has each probability measure P_x concentrated at a single point, so that it is in fact an ordinary curve in another notation [5]-[7].

This set of papers burst on the mathematical world with all the éclat of a butterfly's hiccough. The reaction of mathematicians was like that of the little boy who wrote his grandmother: "Thank you for the book about penguins. It taught me more than I wanted to know about penguins." Because it provided a means of finding extrema analogous to today's method of treating minima in calculus, it extended to mathematicians the privilege of forgetting about semicontinuity and about sufficiency theorems. But it was superfluous. Without it, almost all of them had already forgotten about semicontinuity and about sufficiency theorems. And they were justified. The problem of Bolza was the most general of the single-integral problems of the calculus of variations. Its mastery gave us the power to answer many deep and complicated questions that no one was asking. The whole subject was introverted. We who were working in it were striving to advance the theory of the calculus of variations as an end in itself, without attention to its relation with other fields of activity.

In contrast, the theory of optimal control attracted great attention as soon as Pontryagin and his followers published it in the late 1950s; and I think that that is as it should be. In my mind, the greatest difference between the Russian approach and ours was in mental attitude. Pontryagin and his students encountered some problems in engineering and in economics that urgently asked for answers. They answered the questions, and in the process they incidentally introduced new and important ideas into the calculus of variations. I think it is excusable that none of us in this room found answers in the 1930s for questions that were not asked until the 1950s. But I for one regret that when the questions arose, I did not notice them. Like most mathematicians in the United States, I was not paying attention to the problems of engineers.

In order to discuss this new aspect of the calculus of variations, it is convenient to introduce a different method of formulating extremum problems that includes all the older formulations and also the new problems that arose in the 1950s. A curve $t \to y(t)$ can be regarded as the path of a moving point, and the motion can be controlled by choosing a value of $\dot{y}(t)$ for each t. But with conditioned problems, we may not be able to choose $\dot{y}$ arbitrarily. For example, the n components of the vector $\dot{y}(t)$ may have to satisfy some differential equations, fewer than n of them. Also, we may not wish to choose $\dot{y}(t)$ directly, but to fix it by choosing some parameters u that determine

$\dot{y}$. Therefore, we shall suppose that there exist $n+1$ functions $(t, y, u) \to f^i(t, y, u)$, defined for all (t, y) in $(n+1)$-space R^{n+1} and all u in a set $\Omega(t, y)$. We control the curve by choosing a function $t \to u(t)$. If there is an n-vector-valued function $t \to y(t)$ $(a \leqq t \leqq b)$ such that for all t in $[a, b]$, $u(t) \in \Omega(t, y(t))$ and

$$y^i(t) = y^i(a) + \int_a^t f^i(\tau, y(\tau), u(\tau))\, d\tau, \qquad (i = 1, \cdots, n), \tag{2}$$

the function u is an admissible control function and $y(\cdot)$ is the response, or trajectory, corresponding to it. The problem is to find an admissible control $u(\cdot)$ such that the integral

$$\int_a^b f^0(t, y(t), u(t))\, dt \tag{3}$$

attains its least value among all admissible controls for which the responses satisfy certain end-conditions.

This formulation not only includes all previous ones; it is easier to work with. Magnus Hestenes stated it in 1950; but his results were published in a RAND report with little circulation and at a time when the calculus of variations was at ebb-tide, and they did not attract the attention they deserved. Even earlier, in a paper published in the *Transactions of the American Mathematical Society* in 1933, L. M. Graves had transformed the problem of Lagrange into the control formulation and had established analogues of the Lagrange multiplier rule (the Euler-Lagrange equation) and the Weierstrass condition. These together are equivalent to the "Pontryagin maximum principle," but only when the set $\Omega(t, y)$ is all of a Euclidean space and the minimizing curve satisfies an annoying condition called "normality." Apparently Pontryagin and his associates did not notice that Graves and Hestenes had both made use of the notation, and they invented it independently. But they introduced one important new feature. They allowed the sets $\Omega(t, y)$ to be closed sets, not demanding that they be open as previous researchers had. To me, as a participant in the older research, it is of interest to distinguish what it was that they adapted from work of their predecessors and what they introduced that was quite new. But I lack the time, and I suspect that most of us lack the interest, for such historical research. However, I do wish to point out that in their book, published in English translation in 1962, Pontryagin and his co-authors made a great step forward in one respect, but a step backward in another. They stated a "maximum principle" that is a generalization of the necessary conditions of Euler and Lagrange, of Legendre and of Weierstrass; but like the mathematicians of the eighteenth century, they gave no sufficient conditions for a minimum, and they stated an existence theorem only for a quite special and simple case. Except for this last theorem, their theory is what L. C. Young calls the "naive" theory.

Other authors proved existence theorems, but usually under the restrictive condition that the image in R^{n+1} of $\Omega(t, y)$ under the mapping

$$u \to (f^0(t, y, u), \cdots, f^n(t, y, u))$$

is a convex set. Far better results can be obtained by generalizing the problem to allow "relaxed" controls, an obvious extension of the idea of generalized curves. For each t, instead of choosing a point $u(t)$ in $\Omega(t, y(t))$, we choose a probability measure P_t on $\Omega(t, y(t))$. Then equations (2) are replaced by

$$y^i(t) = y^i(a) + \int_a^t \left\{ \int_{\Omega(\tau, y(\tau))} f^i(\tau, y(\tau), u) P_\tau(du) \right\} d\tau \tag{4}$$

and the integral to be minimized is

$$\int_a^b \left\{ \int_{\Omega(\tau, y(\tau))} f^0(\tau, y(\tau), u) P_\tau(du) \right\} d\tau. \tag{5}$$

Since we shall mention these often, it is expedient to introduce some notation and terminology. We shall sometimes write $P_\cdot$ for the distribution-valued function $t \to P_t$. An *admissible pair* is a pair

$$C = (y(\cdot), P_\cdot) = ((y(t), P_t): a \leqq t \leqq b)$$

in which for each t in $[a, b]$, P_t is a probability distribution on $\Omega(t, y(t))$, and the functions $(f^i(t, y(t), u): u \in \Omega(t, y(t))$ are defined and are integrable with respect to P_t over $\Omega(t, y(t))$, and equations (4) are satisfied. The integral (5) will be denoted by $J(C)$:

$$J(C) = \int_a^b \left\{ \int_{\Omega(t, y(t))} f^0(t, y(t), u) P_t(du) \right\} dt.$$

For simplicity we shall restrict our attention to the important special case in which $\Omega(t, y)$ is independent of t and y; we denote it simply by Ω. We shall suppose that F^* denotes a closed set in R^{n+1} and E^* a bounded closed set in R^{2n+2}; the problem is to find an admissible pair C such that the points $(t, y(t))$ lie in F^* and the endpoints $(a, y(a), b, y(b))$ in E^*, and $J(C)$ is the least value of J for all such admissible pairs. If Ω is compact and the f^i are continuous, and some condition is satisfied that guarantees the existence of a minimizing sequence that lies in a bounded subset of F^*, the minimum can be shown to exist. The proof can be found in several research papers and several books in varying degrees of generality and simplicity.

However, in order to carry out our suggested program of solving the minimizing problem, the necessary conditions for an optimum relaxed control should apply to the kind of optimum that has been shown to exist. This is not taken care of in all books and papers on the subject. However, it was done in 1962 in three independent papers, by J. Warga [8], by T. Wazewski [9], and by R. V. Gamkrelidze [10]. It is easily accessible in the books on control theory by L. C. Young [4] and by J. Warga [11]. Young proves an existence theorem somewhat more general than that of the preceding paragraph. For brevity, we shall restrict its generality, but allow its extension to problems in parametric form. A control problem is in parametric form if the control set Ω is a cone, so that whenever u is in Ω so is pu for all nonnegative p; and the end-conditions are independent of t; and the functions f^i are independent of t and are positively homogeneous of degree 1 in u, so that

$$f^i(y, pu) = pf^i(y, u)$$

for u in Ω and $p \geqq 0$. It can then be shown that if F^*, E^*, and Ω are closed and E^* is bounded, and Ω is independent of y, and the f^i are continuous on $F^* \times \Omega$, and either Ω is bounded or the problem is in parametric form, and there exists a minimizing sequence of admissible pairs for which

$$\int_a^b \left\{ \int_\Omega |u| P_t(du) \right\} dt$$

is bounded, then there exists an admissible pair $C = (y(\cdot), P_\cdot)$ for which the integral $J(C)$ has its least value. Moreover, if the problem is in parametric form, the range of t can be taken to be $[0, 1]$, and the probability distribution P_t can be so chosen that for a certain positive number L the support of P_t is in $\{u \in \Omega: |u| = L\}$; that is,

$$P_t\{u \in \Omega: |u| \neq L\} = 0 \qquad (0 \leqq t \leqq 1).$$

For discussing necessary conditions for optimal controls, we consider only the case in which for the optimizing pair $(y(\cdot), P_\cdot)$ the points $(t, y(t))$ lie in the interior of the set F^*. Also, for simplicity we shall consider only the fixed-end-point problem. For these it is proven, in Young's book and elsewhere, that the following theorem holds.

THEOREM. *Let* $((y(t), P_t): a \leqq t \leqq b)$ *be an optimal pair for the problem described above. For each* t *in* $[a, b]$, *let* $(t, y(t))$ *be interior to* F^*, *and the support of* P_t *in a bounded subset of* Ω. *Then there exist a constant* ψ_0, *with value zero or* -1, *and* n *absolutely continuous functions* $\psi_1, \cdots, \psi_n$ *on* $[a, b]$, *with the following properties.*

(i) $\psi_0, \psi_1(t), \cdots, \psi_n(t)$ *are not all zero for any* t *in* $[a, b]$.

(ii) *If for each* t *in* $[a, b]$, *each* y *in* F^* *and each* u *in* Ω *we define*

$$H(t, y, u) = \psi_0 f^0(t, y, u) + \sum_{i=1}^{n} \psi_i(t) f^i(t, y, u),$$

then the maximum value of $H(t, y(t), u)$ *on* Ω *is a continuous function of* t *on* $[a, b]$; *and if the problem is in parametric form, the value of this maximum is zero.*

(iii) *For almost all* t *in* $[a, b]$, *the support of* P_t *is contained in the set on which* $H(t, y(t), u)$ *attains its maximum value*; *and by changing* P_t *on at most a set of measure zero, we can cause this to hold for all* t *in* $[a, b]$.

(iv) *The functions* ψ_i *satisfy*

$$d\psi_i(t)/dt = -\int_\Omega \frac{\partial H}{\partial y^i}(t, y(t), u) P_t(du)$$

for almost all t *in* $[a, b]$.

This theorem and its generalizations are well known to have interesting applications in problems of optimal control. Many of them are contained in the books by Pontryagin et al., by L. C. Young, and by L. D. Berkovitz [12]. But if the optimal control formulation is, as I believe, the modern replacement for the classical calculus of variations, it must be able to provide solutions for the problems of the classical calculus of variations, and it should do so with at most little additional effort. Doubts have been expressed that the ancient problems can be at all conveniently solved by optimal control methods, without transferring back to the old notation. I do not think that that is so, and to bear out my opinion I have worked out several very old problems by optimal control theory. Since the point of the task is to show that a treatment in full detail can be presented without especial difficulty, I lack time and space to present all these calculations in this talk. Instead, I have prepared some sheets [the Appendix] on which I have written out the details of the solutions of four classical problems. Although these problems have been discussed in many books, the treatment there is "naïve," with no existence theorems being established. More surprisingly, even from the naïve point of view many of the discussions are incomplete or incorrect. The fourth problem is to me the most interesting. It is the ancient problem of Newton: to find a surface of revolution for which a certain integral, believed by Newton to represent the resistance encountered by that surface when moved through a fluid, has least possible value. Newton did not clearly specify the curves he permitted. So in practically all discussions, all piecewise smooth functions $x \to y(x)$ are allowed, and it is then shown that the problem is unsolvable. Only Goursat, in the third volume of his *Cours d'Analyse*, points out that it is physically reasonable to assume y monotonic; this might well have been what Newton meant. In no book, not even in Goursat's, is Newton's statement about the solution quoted in full. But the solution of the problem with monotone y exists, and it can be found by the methods of optimal control theory, and it is just

what Newton said it is. In this problem it appears that the optimal control procedures are essential; the solution is not accessible by classical procedures.

From what I have just said, it is easy to deduce what I believe should be done about the teaching of the calculus of variations. Ordinary undergraduate students of mathematics should be taught a form of control theory simple enough to be understood and general enough to be applicable to many problems. This may call for some quite new chapters in advanced calculus texts, but I think it is not unattainable, and not even very difficult. But another quite different matter is the direction of research. During the twentieth century the interest in what might be called traditional calculus of variations has sunk to a low ebb. I think that that is a natural consequence of the introversion of the subject. Theorems were proved of increasing intricacy, of interest to a steadily shrinking collection of experts in the subject. The newer calculus of variations will go the same way unless its practitioners are sensitive to the questions that arise naturally and demand answers. My own guess is that some of these have to do with the consideration of problems in which random events play an important part. There has, in fact, been a considerable development of stochastic control theory. But both in it and in the deterministic theory I feel that the tendency toward introversion is showing up. The theorems are becoming more baroque. In particular, in quite complicated situations we can show that a solution exists; but only in simple situations can we find a usable approximation to that solution without vast computational effort. The situation is bad in the deterministic case and worse in the stochastic. I am no expert in computation, but I have been told that the direct application of the maximum principle to problems of even moderate complexity is unsatisfactory. This is easy to believe, because the direct application of the maximum principle would require us to find the value of u at which $H(t, y(t), u)$ takes its maximum value, and it is hard to find precisely where a maximum occurs. For stochastic problems, the situation is worse. In some cases solutions have been stated which in my opinion are not solutions at all, since they ask the controller to perform infinitely many adjustments of the controls guided by the instantaneous availability of infinitely many bits of information. Others, for example, Balakrishnan, have worked on the problem of finding approximate solutions that are humanly attainable. But a great deal remains to be done both in the deterministic and in the stochastic cases. A friend of mine, a logician, once gave a talk in which he proved that no matter how many problems in mathematics have been solved at any given time, there will always remain unanswered questions. We hardly need that theorem. Just within optimal control theory there are *good* problems enough to fill all the time and demand all the brain power that all the available mathematicians can give to them.

Appendix: Four classical problems of the calculus of variations

The four problems we shall solve are in parametric form. In each, F^* is a closed set in n-space, and y_0 and y_1 are points of n-space, and Ω is a closed cone in r-space. The functions

$$(y, u) \to f^i(y, u) \qquad (i = 1, \cdots, n)$$

are continuous on $F^* \times \Omega$ and are positively homogeneous of degree 1 in u for each fixed y. The minimum of

$$J(C) = \int_a^b \left\{ \int_\Omega f^0(y(t), u) P_t(du) \right\} dt$$

is sought in the class of all admissible pairs $((y(t), P_t)\colon a \leqq t \leqq b)$ for which every $y(t)$

is in F^*, and

$$y^i(t) = y_0^i + \int_a^t \left\{ \int_\Omega f^i(y(\tau), u) P_\tau(du) \right\} d\tau \qquad (a \leqq t \leqq b),$$

and

$$y^i(b) = y_1^i.$$

For such problems it is known that a minimizing pair $((y(t), P_t): 0 \leqq t \leqq 1)$ exists, the support of P_t being contained in a set $\{u \in \Omega: |u| = L\}$, provided that there exists a minimizing sequence of admissible pairs $((y_n(t), P_{n,t}): a_n \leqq t \leqq b_n)$ for which the integrals

$$\int_{a_n}^{b_n} \left\{ \int_\Omega |u| P_{n,t}(du) \right\} dt$$

are bounded.

It can also be shown, as a corollary of the "maximum principle," that if $((y(t), P_t): a \leqq t \leqq b)$ is a minimizing pair for this problem, and for each t in $[a, b]$ the support of P_t is bounded and $y(t)$ is interior to F^*, there exist a constant ψ_0 $(=0$ or $-1)$ and n absolutely continuous functions on $[a, b]$, called $\psi_1, \cdots, \psi_n$, such that $\psi_0, \psi_1(t), \cdots, \psi_n(t)$ never vanish simultaneously and

(i) for t in $[a, b]$ the maximum value of

$$H(t, y, u) = \psi_0 f^0(y, u) + \sum_{i=1}^n \psi_i(t) f^i(y, u) \qquad (u \in \Omega)$$

is zero;

(ii) for almost all t in $[a, b]$, this maximum is attained at each point of the support of P_t;

(iii) $$\psi_i(t) = \psi_i(a) - \int_a^t \left\{ \int_\Omega \frac{\partial H}{\partial y^i}(\tau, y, u) P_\tau(du) \right\} d\tau$$

$(a \leqq t \leqq b)$.

In all four problems $r = 2$, and to avoid superscripts, we shall write (u, v) instead of (u^1, u^2). Likewise, points in two-space shall be denoted by (x, y) instead of (y^1, y^2), and points in three-space by (x, y, z).

1. The classical isoperimetric problem. Given a line segment AB, we are to find a curve of length L_0 that goes from B to A and together with AB encloses the greatest possible area. (See Fig. 1.)

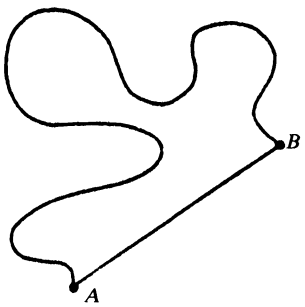

FIG. 1

If the curve is $x = x(t)$, $y = y(t)$, $a \leqq t \leqq b$, the area enclosed is constant $+ \int_a^b [x\dot{y} - y\dot{x}]\, dt$.

We restate the problem in relaxed-control form. We denote B, A by (x_0, y_0), (x_1, y_1), respectively; we define Ω to be the (u, v)-plane; and we define

$$f^0(x, y, z, u, v) = yu - xv,$$

$$f^1(x, y, z, u, v) = u,$$

$$f^2(x, y, z, u, v) = v,$$

$$f^3(x, y, z, u, v) = |(u, v)| = [u^2 + v^2]^{1/2}.$$

The problem is to find an admissible pair $C = ((x(t), y(t), z(t), P_t)\colon a \leqq t \leqq b)$ with

$$\begin{aligned} &x(a) = x_0, \quad y(a) = y_0, \quad z(a) = 0, \\ &x(b) = x_1, \quad y(b) = y_1, \quad z(b) = L_0, \end{aligned} \tag{6}$$

for which the integral

$$J(C) = \int_a^b \left\{ \int_\Omega f^0(x(t), y(t), z(t), u, v) P_t(du, dv) \right\} dt$$

is minimum. Since the endpoints are fixed and the lengths bounded, a solution exists, by the existence theorem on page 926. For it we can assume that for a certain L, the support of P_t is on the circle $|(u, v)| = L$. Since F^* is the whole (x, y, z)-space, the necessary conditions on page 926 hold; H has the form

$$H(t, x, y, z, u, v) = \psi_0[yu - xv] + \psi_1(t)u + \psi_2(t)v + \psi_3(t)|(u, v)|.$$

In particular, H is independent of z, so by (iii) ψ_3 is a constant. If this constant were zero, we would have

$$H(t, x, y, z, u, v) = [\psi_0 y + \psi_1(t)]u + [-\psi_0 x + \psi_2(t)]v.$$

In order for this linear function to have a maximum on Ω the coefficients of u and v must be zero, so that

$$\psi_1(t) = -\psi_0 y, \qquad \psi_2(t) = \psi_0 x.$$

If $\psi_0 = 0$, all four ψ_i are zero, which is false. If $\psi_0 = -1$, these last equations are incompatible with (iii). So $\psi_3 \neq 0$.

We consider two cases.

Case 1. $\psi_0 = 0$.

By (iii), ψ_2 and ψ_1 are both constants. Then H assumes its maximum on the circle $|(u, v)| = L$ at just one point, independent of t, so $\dot{x}$ and $\dot{y}$ are constants and $(x(t), y(t))$ traverses a line segment from B to A. This is possible, with the end-conditions (6), if and only if L_0 is equal to the distance from B to A. In this case, we have shown that the line segment BA gives the maximum area. But this is obvious without the discussion, since then there is only one curve that satisfies the conditions for admissibility.

Case 2. $\psi_0 = -1$.

In this case,

$$H(t, x, y, z, u, v) = [-y + \psi_1(t)]u + [x + \psi_2(t)]v + \psi_3(t)|(u, v)|. \tag{7}$$

For (u, v) on the circle $|(u, v)| = L$, this has maximum value at just one point. So for each t, the support of P_t consists of a single point, and the optimal pair is ordinary. By (iii) on page 926,

$$d\psi_1(t)/dt = -\int_\Omega [\partial H/\partial x] P_t(du, dv) = -\int_\Omega v P_t(du, dv) = -\dot{y}(t)$$

for almost all t. Likewise, for almost all t,

$$d\psi_2(t)/dt = \dot{x}(t).$$

Therefore there exist constants c_1, c_2 such that

$$\psi_1(t) = 2c_2 - y(t), \qquad \psi_2(t) = x(t) - 2c_1.$$

We substitute this in (7). By (iii), when P_t has only one point in its support, that point is $(\dot{x}(t), \dot{y}(t))$, so H has its maximum there, and its partial derivatives as to u and v are zero. This yields

$$2c_2 - 2y(t) + \psi_3 \dot{x}(t)/L = 0,$$
$$2x(t) - 2c_1 + \psi_3 \dot{y}(t)/L = 0.$$

Therefore

$$\frac{d}{dt}[(x(t) - c_1)^2 + (y(t) - c_2)^2] = 2(x(t) - c_1)\dot{x}(t) + 2(y(t) - c_2)\dot{y}(t) = 0,$$

and the optimal curve is a circular arc with endpoints B and A.

It should be observed that there may be several such arcs. For example, in Fig. 2, $BCADEBCA$ is one, and so is BCA. But an arc that passes more than once through A yields the same area as a curve obtained by rotating through 180° a loop beginning and ending at A, as in Fig. 2(b). This new curve $BCAD'E'A$ does not furnish the maximum area, because it is not a circular arc. Therefore, neither did the multiply-traversed circular arc from which we obtained it. The curve that encloses the greatest area is a circular arc without multiple points that goes from B to A.

2. The brachistochrone. We next consider the problem of the brachistochrone, first proposed by John Bernouilli in 1696.

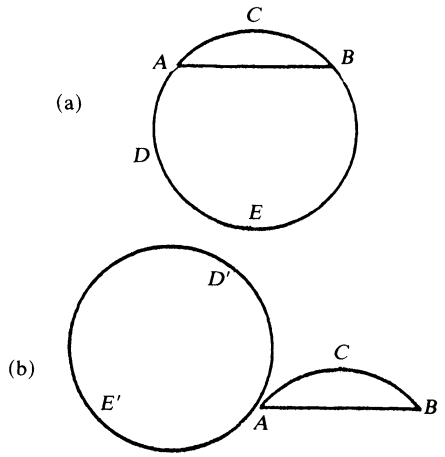

FIG. 2

Let us choose axes in the plane with the y-axis vertically downward. A bead descends by gravity, starting from rest, along a frictionless wire beginning at $(0, 0)$ and ending at a point (x_1, y_1) with $x_1 > 0$ and $y_1 \geqq 0$. It is required to find the shape of the wire along which the time of descent will be shortest.

In order for the wire to be traversible at all it must lie in the half-plane

$$F^* = \{(x, y): y \geqq 0\}.$$

Along a curve $x = x(t)$, $y = y(t)$ $(a \leqq t \leqq b)$ in F^* with absolutely continuous $x(\cdot)$ and $y(\cdot)$ the time of descent is proportional to

$$\int_a^b \left[\frac{\dot{x}(t)^2 + \dot{y}(t)^2}{y(t)}\right]^{1/2} dt;$$

we are to minimize this. We extend the problem to relaxed-control form. We define F^* as above, and define Ω to be the (u, v)-plane. Admissible pairs are those pairs $C = ((x(t), y(t), P_t): a \leqq t \leqq b)$ that satisfy

$$x(t) = \int_a^t \left\{\int_\Omega u P_\tau(du, dv)\right\} d\tau,$$

$$y(t) = \int_a^t \left\{\int_\Omega v P_\tau(du, dv)\right\} d\tau$$

and the end-conditions

$$x(b) = x_1, \qquad y(b) = y_1,$$

and have $(x(t), y(t))$ in F^* for all t. Among these we seek a pair C for which the integral

$$J(C) = \int_a^b \left\{\int_\Omega f^0(x(t), y(t), u, v) P_t(du, dv)\right\} dt$$

is a minimum, where

$$f^0(x, y, u, v) = [u^2 + v^2]^{1/2}/y^{1/2}.$$

Although the existence theorem on page 926 does not apply to this problem, the integrand being discontinuous at $y = 0$, a slight modification using a limit process can be used to show that a minimizing pair exists, with $a = 0$, $b = 1$, and the support of P_t contained in the set $\{|(u, v)| = L\}$. We omit the details of this proof.

Suppose that there is a t^* in the open interval $(0, 1)$ for which $y(t^*) = 0$. Since $J(C)$ is finite, y is not identically zero on $[0, t^*]$ or on $[t^*, 1]$. We can therefore find a positive number c and numbers t_1, t_2 such that $0 < t_1 < t^* < t_2 < 1$, and $y(t_1) = y(t_2) = c$, and $y(t) < c$ on (t_1, t_2). Then

$$\int_{t_1}^{t_2} \left\{\int_\Omega y^{-1/2}[u^2 + v^2]^{1/2} P_t(du, dv)\right\} dt > \int_{t_1}^{t_2} \left\{\int_\Omega c^{-1/2} u P_t(du, dv)\right\} dt$$

$$= \int_{t_1}^{t_2} c^{-1/2} \dot{x}(t)\, dt.$$

So if we replace C by a pair C^* in which on the interval $[t_1, t_2]$ the relaxed pair $(x(\cdot), y(\cdot), P_\cdot)$ is replaced by the ordinary curve $x = x(t)$, $y = c$, C^* is an admissible pair, and $J(C^*) < J(C)$, which is impossible. So $y(t) > 0$ for $0 < t < 1$.

For every subinterval $[a, b]$ of the open interval $(0, 1)$, the admissible pair $((x(t), y(t), P_t)\colon a \leqq t \leqq b)$ minimizes the integral

$$\int_a^b \left\{ \int_\Omega y(t)^{-1/2}[u^2+v^2]^{1/2} P_t(du, dv) \right\} dt$$

in the class of admissible pairs with the same endpoints, and the points of its trajectory lie in the interior of F^*. Therefore, the necessary conditions on page 926 are satisfied. H has the form

$$H(t, x, y, u, v) = \psi_0 y^{-1/2}[u^2+v^2]^{1/2} + \psi_1(t)u + \psi_2(t)v,$$

and it attains its maximum at each point in the support of P_t. If ψ_0 were zero, H could have no maximum, so $\psi_0 = -1$. This implies that H can have its maximum value at only one point of the circle $|(u, v)| = L$, so the curve is ordinary, and the one point in the support of P_t is (by (iii)) the point $(\dot{x}(t), \dot{y}(t))$ for almost all t.

By the first of equations (iii), $\psi_1(t)$ is a constant. If it were zero, the maximum value of H on $|(u, v)| = L$ would occur at $(0, L)$ or at $(0, -L)$, yielding $\dot{x}(t) = 0$ for almost all t. But then $x(b) = x(a)$, and by letting a tend to zero and b to 1 we find $x(1) = x(0)$, which is false. So $\psi_1 \neq 0$.

For almost all t, $(\dot{x}(t), \dot{y}(t))$ is the only point in the support of P_t, so $H(t, x(t), y(t), u, v)$ attains its maximum at that point. Therefore at $(\dot{x}(t), \dot{y}(t))$

$$0 = \partial H/\partial u = -y(t)^{-1/2}\dot{x}(t)[\dot{x}(t)^2+\dot{y}(t)^2]^{-1/2} + \psi_1.$$

Since $\psi_1 \neq 0$, this implies that $\dot{x}(t)$ is bounded away from zero and has the same sign as ψ_1 (necessarily positive). So the function $t \to x(t)$ $(0 \leqq t \leqq 1)$ has an inverse $x \to t(x)$ $(0 \leqq x \leqq x_1)$, and the optimizing curve has the representation

$$x \to Y(x) = y(t(x)) \qquad (0 \leqq x \leqq x_1).$$

By the preceding equation,

$$Y(x)[1+(dY/dx)^2] = \psi_1^{-2}.$$

This is a familiar equation. Its solution is a cycloid; see, for example, El'gol'ts [13, p. 38].

3. The surface of revolution of least area. Euler proposed the problem of finding the curve that joins two points in the (x, y)-plane and, among such curves, generates when revolved about the x-axis that surface that has least area. If these endpoints are (x_0, y_0) and (x_1, y_1), and the curve has a representation $x = x(t)$, $y = y(t)$, $(a \leqq t \leqq b)$ in which $x(\cdot)$ and $y(\cdot)$ are absolutely continuous, the area of the surface of revolution is

$$2\pi \int_a^b |y(t)|[\dot{x}(t)^2+\dot{y}(t)^2]^{1/2}\, dt; \tag{8}$$

and this is the integral to be minimized. It is rather obvious that this is the same problem as minimizing the integral

$$\int_a^b y(t)[\dot{x}(t)^2+\dot{y}(t)^2]^{1/2}\, dt \tag{9}$$

in the class of absolutely continuous functions x, y with the given endpoints and lying in the half-plane

$$F^* = \{(x, y)\colon y \geqq 0\}; \tag{10}$$

see, for example, Bliss' Carus monograph [2, p. 89]. This apparently minor point has led to false assertions in several books. For example, both in Gelfand and Fomin [1] and in El'gol'ts [13] we find the statement that the area is given by (8) with the absolute value sign omitted; this is incorrect, and without the qualification $y \geqq 0$ (which they do not mention) the integral (9) has no lower bound. Bliss correctly states the problem, but on p. 90 says that the necessary conditions previously deduced apply without change to this problem, which is incorrect because the minimizing curve can lie in part along the boundary of F^*.

We restate the problem as a relaxed-control problem. Let F^* be defined by (10), and let Ω be the (u, v)-plane. Define

$$f^0(x, y, u, v) = y[u^2+v^2]^{1/2} \qquad ((x, y) \text{ in } F^*, \text{ all } (u, v)).$$

Among all admissible pairs $((x(t), y(t), P_t)\colon a \leqq t \leqq b)$ that have $(x(t), y(t))$ in F^* for all t, and have endpoints $x(a) = x_0, y(a) = y_0, x(b) = x_1, y(b) = y_1$, and satisfy equations

$$\begin{aligned} x(t) &= x_0 + \int_a^t \left\{ \iint_\Omega uP_\tau(du, dv) \right\} d\tau, \\ y(t) &= y_0 + \int_a^t \left\{ \iint_\Omega vP_\tau(du, dv) \right\} d\tau, \end{aligned} \tag{11}$$

we wish to find one that minimizes the integral

$$J(C) = \int_a^b \left\{ \iint_\Omega f^0(x(t), y(t), u, v) P_t(du, dv) \right\} dt.$$

Let m be the infimum of $J(C)$ in the class of pairs admitted. A minimizing sequence is a sequence of admissible pairs

$$C_n = ((x_n(t), y_n(t), P_{n,t})\colon a_n \leqq t \leqq b_n) \qquad (n = 1, 2, 3, \cdots)$$

satisfying the requirements and such that the integrals $J(C_n)$ tend to m. We distinguish two cases.

Case 1. There exists a minimizing sequence for which the minimum value of $y_n(t)$ on $[a_n, b_n]$ is arbitrarily near zero.

In this case we can choose a subsequence (which without loss of generality we may take to be the original sequence) for which

$$\lim_{n\to\infty} \min \{y_n(t)\colon a_n \leqq t \leqq b_n\} = 0. \tag{12}$$

Let c_n be a point in $[a_n, b_n]$ at which y_n attains its least value. Then

$$\begin{aligned} \int_{a_n}^{c_n} \left\{ \iint_\Omega y_n(t)[u^2+v^2]^{1/2} P_{n,t}(du, dv) \right\} dt &\geqq \int_{a_n}^{c_n} \left\{ \iint_\Omega y_n(t)[-u] P_{n,t}(du, dv) \right\} dt \\ &= -\int_{a_n}^{c_n} y_n(t)\dot{y}_n(t)\, dt = [y_0^2 - y_n(c_n)^2]/2, \end{aligned}$$

and similarly,

$$\begin{aligned} \int_{c_n}^{b_n} \left\{ \iint_\Omega y_n(t)[u^2+v^2]^{1/2} P_{n,t}(du, dv) \right\} dt &\geqq \int_{c_n}^{b_n} \left\{ \iint_\Omega y_n(t) u P_{n,t}(du, dv) \right\} dt \\ &= \int_{c_n}^{b_n} y_n(t)\dot{y}_n(t)\, dt = [y_1^2 - y_n(c_n)^2]/2. \end{aligned}$$

By adding these we obtain

$$[y_0^2+y_1^2-2y_n(c_n)^2]/2 \leqq J(C_n).$$

Since $y_n(c_n)$ is the least value of y_n and $J(C_n)$ tends to m, by (12)

$$[y_0^2+y_1^2]/2 \leqq m.$$

The left member of this inequality is $J(C)$ for the ordinary curve C which is the polygon with successive vertices (x_0, y_0), $(x_0, 0)$, $(x_1, 0)$, (x_1, y_1), so that polygon minimizes $J(C)$ in the class of admissible pairs with the given endpoints.

Case 2. For each minimizing sequence, all y_n have a common positive lower bound.

Choose a minimizing sequence with the same notation as before. Let $c>0$ be a lower bound for all the y_n. Then

$$\int_{a_n}^{b_n}\left\{\int_\Omega [u^2+v^2]^{1/2}P_{n,t}(du, dv)\right\}dt \leqq c^{-1}\int_{a_n}^{b_n}\left\{\int_\Omega y_n(t)[u^2+v^2]^{1/2}P_{n,t}(du, dv)\right\}dt$$

$$= J(C_n)/c.$$

So the integrals are bounded, and by the existence theorem on page 926 a minimizing admissible pair exists, and it can be chosen to be a pair for which $a=0$ and $b=1$, and the support of P_t is contained in a circle $|(u, v)| = L$. For this pair, the minimum of y is positive; otherwise, a sequence of infinitely many repetitions of C would be a minimizing sequence in which the minima of the y_n are arbitrarily near zero, and in the case we are considering that cannot happen. Since $y(t)$ is always positive, the trajectory lies in the interior of F^*, and the necessary conditions on page 926 must be satisfied. Let ψ_0 (=0 or -1), $\psi_1(t)$, $\psi_2(t)$ be the multipliers, so that

$$H(t, x, y, u, v) = \psi_0 y(t)[u^2+v^2]^{1/2}+\psi_1(t)u+\psi_2(t)v.$$

If ψ_0 were 0 this would be a linear function and have no maximum on Ω. Therefore $\psi_0 = -1$.

On the circle $\{|(u, v)| = L\}$ the function $H(t, x(t), y(t), u, v)$ attains its maximum at only one point, and by (11) this is $(\dot{x}(t), \dot{y}(t))$ for almost all t. So the optimal control is ordinary. Since H is independent of x, by the first of equations (iii), ψ_1 is constant. If this constant were zero, the maximum of H would occur at either $(0, L)$ or at $(0, -L)$, and in either case $\dot{x}(t) = 0$. This is impossible, since it would imply $x(1) = x(0)$, which is false. So $\psi_1 \neq 0$. The maximum value of H occurs at $(\dot{x}(t), \dot{y}(t))$, so its partial derivative with respect to u vanishes at that point:

$$0 = -y(t)[\dot{x}^2(t)+\dot{y}^2(t)]^{-1/2}\dot{x}(t)+\psi_1.$$

The quantity in square brackets has value L^2, so $\dot{x}(t)$ is bounded away from zero, and y can be expressed as a function of x. The preceding equation then yields

$$y(t) = \psi_1[1+(dy/dx)^2]^{1/2}.$$

The solution of this is well known to be

$$y = \psi_1 \cosh\ [(x-h)/\psi_1],$$

where h is a constant. This is the equation of a catenary. It is shown in many places that there are at most two such catenaries through (x_0, y_0) and (x_1, y_1). So the absolute minimum of the surface of revolution is given by the polygon or by one of these at most two catenaries.

4. The solid of revolution of least resistance. In his *Principia*, Isaac Newton discussed the resistance encountered by bodies moving through a fluid. Although he never stated a law of resistance specifically, his reasoning in Book II, Proposition XXXIV, Theorem XXVIII (in the discussion of the resistance of a sphere) leads to the following law:

The resisting pressure at any point of the surface *not sheltered from the fluid by some part of the body* is proportional to the square of the component of the velocity along the normal to the surface.

This is Forsythe's formulation, except for the italicized words, which I have added. They are justified by Newton's reasoning and by his ignoring pressure on the sheltered hemisphere. If a solid of revolution is generated by revolving a curve $x = x(t)$, $y = y(t)$ about the y-axis and moves in the direction of the positive y-axis, and x is not monotonic increasing, there will be sheltered arcs such as ABC (see Fig. 3). By Newton's reasoning, there will be no resisting pressure on this part of the solid, and we can replace the arc ABC by the line segment AC without affecting the resistance. So we may, and henceforth shall, assume that $x(\cdot)$ is nondecreasing.

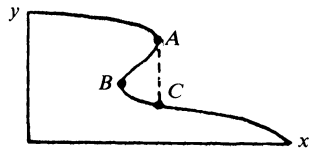

FIG. 3

Newton's assertion about the solid of least resistance is contained in the following two paragraphs of the Scholium following the theorem just cited.

"Incidentally, . . . , it follows from the above that, if the solid $ADBE$ be generated by the convolution of an elliptical or oval figure $ADBE$ about its axis AB, and the generating figure be touched by three right lines FG, GH, HI in the points F, B, and I, so that GH shall be perpendicular to the axis in the point of contact B, and FG, HI may be inclined to GH in the angles FGB, BHI of 135 degrees: the solid arising from the convolution of the figure $ADFGHIE$ about the same axis AB will be less resisted than the former solid, provided that both move forwards in the direction of their axis AB, and that the extremity B of each go forward. This Proposition I conceive may be of use in the building of ships.

"If the figure $DNFG$ be such a curve, that if, from any point thereof, as N, the perpendicular NM be let fall on the axis AB, and from the given point G there be drawn the right line GR parallel to a right line touching the figure in N, and cutting the axis produced in R, MN becomes to GR as GR^3 to $4BR \cdot GB^2$, the solid described by the revolution of this figure about its axis AB, moving in the before-mentioned rare medium from A toward B, will be less resisted than any other circular solid whatsoever, described of the same length and breadth."

Let us equip Newton's figure with an x-axis vertically upward through D and a y-axis along AR, positive in that direction (see Fig. 4). Then B is $(0, y_0)$ and D is $(x_1, 0)$. We denote the length of BG by the perhaps startling symbol $2\psi_2$. The statements in the quoted paragraphs transform into twentieth century notation thus. Let the optimal curve $BGFND$ joining B to D be the graph $x \to y(x)$ $(0 \leqq x \leqq x_1)$. Then $y(x)$ is constantly y_0 for $0 \leqq x \leqq 2\psi_2$; at $2\psi_2$, the right derivative of y is -1; and on $[2\psi_2, x_1]$ the function

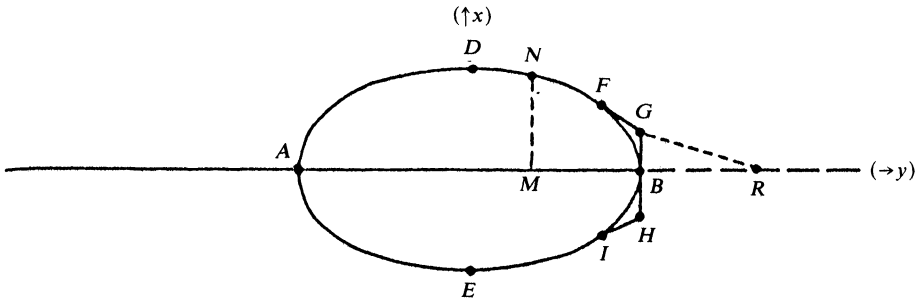

FIG. 4

$y(\cdot)$ satisfies the equation

$$x = -\psi_2[1+(dy/dx)^2]^2/2(dy/dx). \tag{13}$$

In none of the books on the calculus of variations that I have consulted have I found any such statement. They all deduce (13), but omit all reference to the line-segment BG and the corner at G.

Newton did not specify the class of comparison curves allowed. We shall allow only curves $x = x(t)$, $y = y(t)$ in which x is nondecreasing (which, as we have seen, is very nearly implied by Newton's discussion) and $y(\cdot)$ is nonincreasing. Newton might have been willing to accept this reasoning. If y is not monotonic nonincreasing, the solid of revolution will have a trough generated by the revolution of an arc such as DEF (see Fig. 5). When the body moves in the direction of the positive y-axis, this trough will fill with stagnant fluid, and the line-segment DF will be the effective surface, giving a nonincreasing y. Newton makes no such statement. But in the first paragraph quoted above, he specifically considers "oval" solids, and in the Principia and in a letter (presumably written to David Gregory in 1694) only convex figures appear. So we feel that we are not misrepresenting Newton when we attach his name to the following problem:

To find a curve $x = x(t)$, $y = y(t)$, $a \leqq t \leqq b$ in which $x(\cdot)$ is nondecreasing and $y(\cdot)$ is nonincreasing, and

$$x(a) = 0, \quad y(a) = y_0, \quad x(b) = x_1, \quad y(b) = y_1 \qquad (x_1 \text{ and } y_0 \text{ positive}) \tag{14}$$

and which in that class of curves generates the surface of revolution about the y-axis that offers least resistance to motion in the direction of the positive y-axis, the law of resistance being that stated above.

We shall show that this problem has a solution, and that the solution is exactly what Newton asserted it to be.

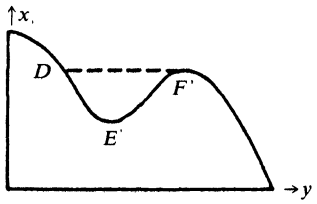

FIG. 5

According to Newton's law of resistance, the resistance at a given velocity is proportional to

$$J(C)=\int_a^b \frac{x(t)\dot{x}(t)^3}{\dot{x}(t)^2+\dot{y}(t)^2}\,dt, \tag{15}$$

and this is the integral to be minimized. We restate the problem in relaxed control form.

Let Ω be the control region

$$\Omega=\{(u, v): u\geqq 0,\ v\geqq 0\}.$$

Define

$$f^0(x, y, u, v)=xu^3/[u^2+v^2],$$
$$f^1(x, y, u, v)=u,$$
$$f^2(x, y, u, v)=-v.$$

A pair $((x(t), y(t), P_t): a\leqq t\leqq b)$ is admissible if P_t is a probability distribution on Ω, and

$$x(t)=\int_a^t\left\{\int_\Omega f^1(x(\tau), y(\tau), u, v)P_\tau(du, dv)\right\}d\tau,$$
$$y(t)=y_0+\int_a^t\left\{\int_\Omega f^2(x(\tau), y(\tau), u, v)P_\tau(du, dv)\right\}d\tau \qquad (a\leqq t\leqq b),$$

and the end-conditions (14) are satisfied. Among all admissible pairs, we seek one that minimizes

$$J(C)=\int_a^b\left\{\int_\Omega f^0(x(t), y(t), u, v)P_t(du, dv)\right\}dt.$$

The simpler existence theorems do not apply to this problem, nor to the analogous problem in ordinary controls, because f^0 is not a convex function. But by the existence theorem on page 926, an admissible (relaxed) pair does exist that minimizes $J(C)$ among all such pairs. It has also the property that $a=0$, and $b=1$, and for all t, the support of P_t is contained in the circular arc

$$\Omega_L=\{(u, v): 0\leqq u, 0\leqq v, u^2+v^2=L^2\}.$$

Since F^* in this problem is the whole plane, the necessary conditions on page 926 are satisfied. As before, we define

$$H(t, x, y, u, v)=\psi_0 f^0(x, y, u, v)+\sum_{i=1}^{2}\psi_i(t)f^i(x, y, u, v);$$

the ψ_0 and ψ_i have the properties on page 926. In particular, since H is independent of y, ψ_2 is a constant.

We shall first prove that $\psi_0\neq 0$. Suppose it were zero. Then

$$H=\psi_1(t)u-\psi_2 v.$$

If H were positive at some (u, v) in Ω, it would be unbounded on the set of points (pu, pv) with $p>0$, which is impossible because H has a maximum attained on Ω_L. So H is nonpositive, and its maximum value on Ω is 0, attained at $(0, 0)$. So H is nonpositive at $(1, 0)$ and at $(0, 1)$, and

$$\psi_1(t)\leqq 0\leqq\psi_2.$$

If $\psi_2 > 0$, the maximum value of H on Ω_L occurs at $(L, 0)$ only, so only $(L, 0)$ is in the support of P_t. Therefore, $\dot{y}(t) = 0$ for almost all t, and $y(t) = y_0$ for all t, which is false. If $\psi_2 = 0$, $\psi_1(t)$ must never be zero, since ψ_0, ψ_1, and ψ_2 never vanish simultaneously. So $\psi_1(t) < 0$ for all t. Then the only point of Ω_L at which H is maximum is $(0, L)$. This implies $x(t) = 0$ for all t, which is false. So the assumption $\psi_0 = 0$ leads to a contradiction, and ψ_0 is -1. Now

$$H(t, x, y, u, v) = -xu^3/[u^2 + v^2] + \psi_1(t)u - \psi_2 v. \tag{16}$$

We next prove $\psi_2 \neq 0$. If $\psi_2 = 0$, let t be any point at which $x(t) > 0$, and let (u^*, v^*) be in the support of P_t. Then H has its maximum value zero at (u^*, v^*), so

$$-x(t)u^{*3}/[u^{*2} + v^{*2}] + \psi_1(t)u^* = 0.$$

If $u^* > 0$, this would imply

$$H(t, x(t), y(t), u^*, v^* + 1) > 0,$$

which is impossible. So $u^* = 0$. Therefore the only point in the support of P_t is $(0, L)$, and $dx/dt = 0$ at almost all points at which $x(t) > 0$. This is incompatible with the end-conditions (14), so the assumption $\psi_2 = 0$ has led to a contradiction. Therefore $\psi_2 > 0$. This, in turn, implies $\psi_1(0) = 0$. For if not, then $\psi_1(0) < 0$, and the function

$$H(0, x(0), y(0), u, v) = \psi_1(0)u - \psi_2 v$$

would assume its maximum value zero only at $(0, 0)$, not at any point in Ω_L. It also implies that $(0, L)$ is not in the support of P_t for any t in $[0, 1]$; for

$$H(t, x(t), y(t), 0, L) = -\psi_2 L < 0.$$

Then

$$\dot{x}(t) = \int_\Omega u P_t(du, dv) > 0$$

for almost all t, so $x(t)$ is strictly increasing.

For $t > 0$, no point (u, v) of Ω with $0 < v < u$ is in the support of P_t. For suppose $0 < v < u$. Define $\theta = v/u$. Then

$$\begin{aligned} 0 = H(t, x(t), y(t), u, v) &= -x(t)u^3/[u^2 + v^2] + \psi_1(t)u - \psi_2 v \\ &= -x(t)u/[1 + \theta^2] + \psi_1(t)u - \psi_2 \theta u, \\ H(t, x(t), y(t), u, 0) &= -x(t)u + \psi_1(t)u, \\ H(t, x(t), y(t), u, u) &= -x(t)u/2 + \psi_1(t)u - \psi_2 u. \end{aligned}$$

From the last two equations,

$$(1 - \theta)H(t, x(t), y(t), u, 0) + \theta H(t, x(t), y(t), u, u) = -x(t)(1 - \theta/2)u + \psi_1(t)u - \psi_2 \theta u.$$

Since

$$(1 - \theta/2) - (1 + \theta^2)^{-1} = -\theta(1 - \theta)^2/2(1 + \theta)^2 < 0,$$

this implies that one of the numbers $H(t, x(t), y(t), u, u)$, $H(t, x(t), y(t), u, 0)$ is positive, in contradiction to the fact that the maximum value of H is zero. So no point (u, v) with $0 < v < u$ is in the support of P_t for any t in $[0, 1]$.

Let A be the set of t in $[0, 1]$ such that $(L, 0)$ is in the support of P_t. If t is in A,

$$0 = H(t, x(t), y(t), L, 0) \geqq H(t, x(t), y(t), L, L),$$

so

$$-x(t)L+\psi_1(t)L-0\geqq -x(t)(L/2)+\psi_1(t)L-\psi_2 L.$$

This implies

$$x(t)\leqq 2\psi_2.$$

If t is in $[0, 1]\backslash A$, the support of P_t contains some point (u, v) with $v\neq 0$, therefore with $0<u\leqq v$. For all t we have by equations (iii) on page 926

$$\psi_1(t)=\int_0^t\left\{\int_\Omega \frac{u^3}{u^2+v^2}P_\tau(du, dv)\right\}d\tau\leqq\int_0^t\left\{\int_\Omega uP_\tau(du, dv)\right\}d\tau=x(t).$$

So if the support of P_t contains (u, v) with $v>0$,

$$\begin{aligned}0=H(t, x(t), y(t), u, v)&=-x(t)u^3/[u^2+v^2]+\psi_1(t)u-\psi_2 v\\&\leqq x(t)\{-u^3/[u^2+v^2]+u\}-\psi_2 v=\{x(t)uv/[u^2+v^2]-\psi_2\}v.\end{aligned}$$

Hence

$$\psi_2\leqq x(t)\{uv/[u^2+v^2]\}\leqq x(t)\{\tfrac{1}{2}\},$$

and therefore

$$x(t)\geqq 2\psi_2.$$

So all points t with $x(t)$ in $[0, 2\psi_2]$ are in A, and all points t with $x(t)$ in $(2\psi_2, 1]$ are in $[0, 1]\backslash A$. For t with $x(t)$ in $[0, 2\psi_2)$, the support of P_t consists of $(L, 0)$ alone, so

$$x(t)=\int_0^t\left\{\int_\Omega uP_\tau(du, dv)\right\}d\tau=\int_0^t L\,d\tau=Lt,$$

$$y(t)=y_0-\int_0^t\left\{\int_\Omega vP_\tau(du, dv)\right\}d\tau=y_0.$$

So if we define $t^*=2\psi_2/L$,

$$x(t^*)=2\psi_2,$$

and $y(t)$ is constantly y_0 on $[0, t^*]$. For $t<t^*$, $(L, 0)$ is in the support of P_t, so

$$H(t, x(t), y(t), L, 0)=0.$$

By continuity,

$$H(t^*, x(t^*), y(t^*), L, 0)=0.$$

For $t>t^*$, the support of P_t is contained in $\{(u, v)$ in Ω: $v\geqq u>0\}$. But when $v\geqq u>0$,

$$\partial^2 H/\partial v^2=2x(t)u^3(u^2+v^2)^{-3}(u^2-3v^2)<0.$$

If the maximum value of H were attained at two different points of Ω_L, there would be two rays $v=m_1u$, $v=m_2u$ $(m_2>m_1\geqq 1)$ on which H and its first partial derivatives vanish. That is,

$$\frac{\partial}{\partial v}H(t, x(t), y(t), 1, m_1)=\frac{\partial}{\partial v}H(t, x(t), y(t), 1, m_2)=0.$$

But this is impossible, since

$$\frac{\partial^2 H}{\partial v^2}(t, x(t), y(t), 1, v)<0\qquad(m_1\leqq v\leqq m_2).$$

Therefore the support of P_t consists of a single point of the arc Ω_L. The optimal pair is an ordinary pair.

We have shown that

$$x(t^*) = \psi_1(t^*) = 2\psi_2,$$

so

$$H(t^*, x(t^*), y(t^*), u, v) = -2\psi_2 u^3/[u^2+v^2] + 2\psi_2 u - \psi_2 v.$$

Therefore

$$\begin{aligned} H(t^*, x(t^*), y(t^*), L, 0) &= 0, \\ H(t^*, x(t^*), y(t^*), L/\sqrt{2}, L/\sqrt{2}) &= 0. \end{aligned} \tag{17}$$

For each point t in $(t^*, 1]$, the support of P_t consists of a single point of Ω_L, which we denote by $(u(t), v(t))$. Let $(\alpha(t), \beta(t))$ be any point that is the limit of $(u(t_n), v(t_n))$ for some sequence of points $t_1, t_2, t_3, \cdots$ of $(t^*, 1]$ tending to t. Then $\beta(t) \geqq \alpha(t)$. By continuity

$$H(t, x(t), y(t), \alpha(t), \beta(t)) = \lim_{n\to\infty} H(t_n, x(t_n), y(t_n), u(t_n), v(t_n)) = 0.$$

But there is only one point $(\alpha(t), \beta(t))$ on Ω_L with $\beta(t) \geqq \alpha(t)$ that satisfies this. If $t > t^*$, $(\alpha(t), \beta(t))$ has to be $(u(t), v(t))$. If $t = t^*$, by (17)

$$\alpha(t) = L/\sqrt{2}, \qquad \beta(t) = L/\sqrt{2}.$$

So the limit of $(u(t), v(t))$ as t tends to t^* from above is $(L/\sqrt{2}, L/\sqrt{2})$.

For t in $(t^*, 1]$, the support of P_t contains a single point, which for almost all t has to be $(\dot{x}(t), \dot{y}(t))$. Since H has its maximum value at this point, its partial derivatives vanish there, so

$$2x(t)\dot{x}(t)^3\dot{y}(t)[\dot{x}(t)^2+\dot{y}(t)^2]^{-2} + \psi_2 = 0. \tag{18}$$

This implies that $\dot{x}$ cannot be zero, so y can be written as a function of x, and (18) amended accordingly. We now have accumulated the following information about the minimizing function, written as $x \to y(x)$:

For $0 \leqq x \leqq 2\psi_2$, $y(x) = y_0$. At $x = 2\psi_2$, there is a corner: the right derivative of y with respect to x is -1. For $x > 2\psi_2$,

$$x = -\psi_2[1+(dy/dx)^2]^2/2[dy/dx]. \tag{19}$$

This is exactly what Newton stated the solution to be.

Parametric equations for the part of the curve to the right of $x = 2\psi_2$ are easily obtained. If we define $\tau = v(t)/u(t)$, by (18) or (19) we find that for almost all t, the function $X(\tau) = x(t(\tau))$ satisfies

$$X(\tau) = (1+\tau^2)^2\psi_2/2\tau. \tag{20}$$

From this,

$$dX/d\tau = (\psi_2/2)[-\tau^{-2}+2+3\tau^2].$$

Let $Y(\tau) = y(t(\tau))$. Since $dY/d\tau = [v/u]\, dX/d\tau = \tau[dX/d\tau]$,

$$dY/d\tau = (\psi_2/2)[-\tau^{-1}+2\tau+3\tau^3],$$

whence

$$Y(\tau) = C + (\psi_2/2)[-\log\tau + \tau^2 + 3\tau^4/4]. \tag{21}$$

We let τ approach 1; then $X(\tau)$ and $Y(\tau)$ approach $x(t^*)=2\psi_2$ and $y(t^*)=y_0$, respectively, and from (21) we obtain

$$C = y_0-(\psi_2/2)(7/4).$$

Substituting this in (21) yields

$$Y(\tau)=y_0+(\psi_2/2)[-\log\tau+\tau^2+3\tau^4/4-7/4].$$

This and (20) are parametric equations for the part of the curve to the right of the straight section $y=y_0$ $(0\leqq x\leqq 2\psi_2)$.

Note added in proof. Professor John Burns has pointed out to me that Newton's least-resistance problem is discussed in *Applied Optimal Control* by A. E. Bryson and Y.-C. Ho [14, pp. 52–55]. Their treatment is of the type we have called "naïve," and also it is not rigorous. But they arrive at Newton's solution, as given above, and they exhibit graphs for three special cases. Also they assert that Newton's formula for the resistance, while inaccurate for subsonic speeds, is very good at speeds above the speed of sound.

RAPID OSCILLATIONS, CHATTERING SYSTEMS, AND RELAXED CONTROLS*

ZVI ARTSTEIN†

This paper is dedicated to the memory of E. J. McShane.

Abstract. Chattering systems serve as a limit model for control systems with rapidly oscillating control coefficients. This paper investigates the applicability of relaxed controls to chattering systems. In particular, the robustness of optimal relaxed controls and their ordinary approximations are examined. In the case of complete chattering, it is found that the relaxation of the optimal controls can be eliminated.

Key words. relaxed controls, chattering systems, rapid oscillations, robustness

AMS(MOS) subject classifications. 49A10, 49B50

1. Introduction.

An advantage of working with relaxed controls is that under mild conditions, existence of optimal solutions is guaranteed. A justification of coming up with a relaxed solution is that is can usually be approximated well by an ordinary control, namely, the performance is not changed drastically when the optimal relaxed solution is replaced by the approximation. These aspects are explained and demonstrated in the fundamental works of Warga (see [8]) on control systems and Young (see [10]) on the calculus of variations. McShane [7] has developed a general theory of relaxed unbounded controls and has shown when a seemingly optimal relaxed solution is actually an ordinary one.

Robustness is a desired property of optimal solutions and their approximations. Namely, the performance of the chosen control should not be harmed greatly if a small change in the system occurs. A situation where this property may not prevail is when an approximation to a relaxed control is applied to a system with rapidly oscillating coefficients. Indeed, the standard approximations of a relaxed control are rapidly oscillating controls. If the oscillations of the approximating controls are not synchronized with the oscillations of the parameters, a resonance phenomenon may occur, with cost far from optimal. This problem is even more acute when the oscillation rate of the parameters is subject to errors or uncertainties; then the synchronization of the two oscillation rates may become a difficult matter.

The sensitivity to a small change in the highly oscillatory parameters arises not only in connection with relaxed controls. In general, we would like to have a robust model for rapid oscillations, and then analyze the uncertain parameters as small deviations from that model. Such a model has been offered in [1] and [2]. It allows instantaneous oscillations of the parameters; a convergence mode is then defined with which the rapidly oscillating parameters can indeed be treated as deviations from the model. The systems with the infinitely rapid change of parameters are termed *chattering systems.*

In this paper we develop the relaxed controls aspect of the chattering systems. The first interesting phenomenon that we discover is that relaxation can actually be eliminated in case of complete chattering. The reason is that the oscillations of the parameters can be used to generate the oscillations that the good approximations of

* Received by the editors August 10, 1988; accepted for publication (in revised form) December 7, 1988.
† Department of Theoretical Mathematics, The Weizmann Institute of Science, Rehovot 76100, Israel.

the relaxed solutions need; in the limit, ordinary controls suffice. However, there are cases where relaxed controls are needed for optimality. We study them, with their approximations, and examine the robustness property.

We find it best to exhibit the ideas by working out in detail a simple example. This is done in the next section. The abstract theory is treated in § 3, where chattering systems are recalled and relaxed controls for chattering systems are introduced. The elimination of relaxation is examined in § 4. In the closing section we analyze the robustness of relaxed solutions and their ordinary approximations.

2. An example in detail. Consider the following optimal control problem:

$$\begin{aligned} &\text{minimize} && \int_0^1 (x^2(t)+(u^2(t)-1)^2)\,dt, \\ &\text{subject to} && \dot{x}(t)=a_j(t)u(t), \\ &&& x(0)=0. \end{aligned} \tag{2.1}$$

Here the state $x(t)$ and the control $u(t)$ are scalar functions, defined on $[0, 1]$. The index j in the coefficients appears since later on we consider a sequence of problems. For a given control $u(\cdot)$ the integral to be minimized in (2.1) is referred to as the *cost* of using $u(\cdot)$.

We assume that $a_j(t)$ is not identically zero on any subinterval of $[0, 1]$. The infimal cost is then zero, but it cannot be achieved with an ordinary control. To achieve zero cost it is necessary to have $|u(t)|=1$, but then $x(t)$ is not identically zero, and thus zero cost is impossible. To get close to the zero cost, the interval $[0, 1]$ can be divided into k intervals of equal length, and $u_k(t)$ chosen equal to $+1$ or to -1 on alternate intervals; then the cost tends to zero as $k\to\infty$. An optimal relaxed control exists. It is the control, say $v(t)$, which assigns to each t the values $+1$ and -1 with equal probabilities. The sequence $u_k(\cdot)$ constructed earlier converges, indeed, to the optimal relaxed control $v(\cdot)$ as $k\to\infty$ (see Berkovitz [4, § IV.4] or Warga [8, § III.3]).

Consider now a sequence of optimization problems of the type (2.1), each determined by its coefficients $a_j(t)$. We wish to examine systems with rapidly oscillating coefficients; for definiteness we take

$$a_j(t)=\cos 2\pi jt \tag{2.2}$$

and we are interested in the behavior for large j, say $j\to\infty$. An interpretation that we adopt is that j is subject to uncertainty; thus the solution to the optimization problem should be robust with respect to the uncertainty.

As mentioned, the relaxed control $v(t)$ is an optimal solution of (2.1) regardless of the coefficients $a_j(t)$. The performance of the approximations $u_k(t)$ depends strongly, however, on the coefficients. For instance, if $j=k$ the control $u_k(t)$ is a bad replacement of the optimal relaxed control. (If k is fixed, however, and $j\to\infty$, then the approximation is valid. This is not accidental, as we show in the closing section.)

The chattering systems were developed (see [1], [2]) as a robust model for systems with rapidly oscillating coefficients. The abstract framework is recalled in the next section; here we describe the chattering limit of (2.1) as $j\to\infty$. Since the oscillation rate grows indefinitely, in the limit we wish to allow instantaneous oscillations, say at time t_0. This is done by computing the distribution of the values $\cos 2\pi jt$ of the coefficients, in a small neighborhood of t_0, and taking the limit as $j\to\infty$. The limit distribution as the neighborhood shrinks to t_0 depicts the infinitely rapid oscillation at t_0. In the case of (2.1) it is easy to make the computation; the limit distribution

does not depend on t_0 (due to periodicity) and it is given by

$$d\beta = \frac{1}{\pi(1-\sigma^2)^{1/2}}\, d\sigma \tag{2.3}$$

where $\sigma \in [-1, 1]$ and $d\sigma$ is the Lebesgue measure. The interpretation is that in the limit the coefficient $a(t_0)$ "oscillates" at t_0 according to $d\beta$. The control function, in turn, may also oscillate and respond instantaneously to the change of the coefficient. Thus, the control function has the form $u(t, \sigma)$, and the interpretation is that the value $u(t, \sigma)$ is applied when the time is t and the value of the coefficient is σ. The chattering variational problem therefore has the form

$$\begin{aligned} &\text{minimize} && \int_0^1 \left(x^2(t) + \int_{-1}^{1} (u^2(t, \sigma) - 1)^2 \, d\beta \right) dt, \\ &\text{subject to} && \dot{x}(t) = \int_{-1}^{1} \sigma u(t, \sigma)\, d\beta, \\ & && x(0) = 0. \end{aligned} \tag{2.4}$$

By inspection we see that (2.4) has an ordinary optimal solution. Indeed, β is symmetric around 0, and hence the choice $u(t, \sigma) = 1$ for all (t, σ) yields a zero cost. If this optimal solution is applied to the sequence of problems (2.1), the resulting cost tends to zero as $j \to \infty$. (Note that $u(t, \sigma) = 1$ is quite far from the suggested approximations $u_k(t)$, which did not work uniformly anyway.) The phenomenon has a natural explanation as follows. Although the control $u(t, \sigma) = 1$ does not oscillate, the combination of the control with the oscillating parameters $a_j(t)$ provides the dither necessary to mimic the optimal relaxed behavior.

There is also an optimal relaxed control of (2.4); indeed the relaxed control $v(t)$ described earlier is one. It can be interpreted as an optimal relaxed control of the form $v(t, \sigma)$ by letting $v(t, \sigma) = v(t)$. It can be approximated in the topology of relaxed controls by ordinary controls $u_k(t, \sigma)$ in various ways (see Example 3.2, or Warga [8, § III.3]). One possibility is the sequence $u_k(t)$ defined earlier, and indeed, if $u_k(t)$ with large k is fixed, then the cost of applying it to the jth problem is small, as $j \to \infty$.

These observations reflect the properties in the general case analyzed in the rest of the paper.

3. Relaxed controls for chattering systems. First we recall what chattering systems are (following [1]). Then we examine how relaxed controls are applied to the chattering systems.

The ordinary control systems in this paper are of the following form:

$$\begin{aligned} &\text{minimize} && \int_b^a Q(x(t), u(t), t)\, dt, \\ &\text{subject to} && \dot{x} = f(x, t) + g(u, t), \\ & && x(a) = x_0. \end{aligned} \tag{3.1}$$

The chattering system is obtained when at each t the unique control function $g(\cdot, t)$ is replaced by a distribution ζ_t, which is a probability measure on the space G of functions $g(u)$: $R^m \to R^n$ (here $x \in R^n$, $u \in R^m$). The admissible controls, in turn, are functions $u(t, g)$ of both the time t and the coefficient $g(\cdot) \in G$. (We still call g the

coefficient of u, as in (2.1), although in the general case g is a function of u.) The optimization with a chattering system, therefore, has the form

$$\text{minimize} \quad \int_a^b \int_G Q(x(t), u(t, g), t)\zeta_t(dg)\, dt,$$

$$\text{subject to} \quad \dot{x} = f(x, t) + \int_G g(u(t, g))\zeta_t(dg), \tag{3.2}$$

$$x(a) = x_0.$$

Here dg indicates that the integration is done with respect to the variable g; the measure ζ_t depends on the time t. The system (2.4) is an example of type (3.2) with G consisting of $g_\sigma(u) = \sigma u$ and $\sigma \in [-1, 1]$, and $\zeta_t = \beta$ is time invariant. The ordinary system (3.1) is a particular case of (3.2), when ζ_t assigns a unit mass to $g(\cdot, t)$.

We now display the technical assumptions concerning the data.

The function $Q(x, u, t)$, which generates the cost in (3.1) and (3.2), is defined on $R^n \times R^m \times [a, b]$, and it is assumed continuous in the three variables.

Let λ_1 and κ_1 be two positive constants. Let $\mathcal{F}$ denote the collection of mappings $f: R^n \times [a, b] \to R^n$ that are measurable in t and satisfy $|f(x, t)| \leqq \lambda_1(|x|+1)$ and $|f(x, t) - f(y, t)| \leqq \kappa_1|x - y|$. We assume that the function f in (3.2) belongs to $\mathcal{F}$.

Let λ_2 and κ_2 be two positive constants. Let G denote the collection of continuous functions $g(u): R^m \to R^n$ satisfying $|g(u)| \leqq \lambda_2(|u|+1)$ and $|g(u_1) - g(u_2)| \leqq \kappa_2|u_1 - u_2|$. The space G with the topology of uniform convergence on compact sets is compact and metrizable (see, e.g., [1]). Denote by Prob (G) the space of probability measures on G endowed with the weak convergence of measures; the latter is metrizable and Prob (G) is then a compact metric space (see Billingsley [5]). We assume that $t \to \zeta_t$ as a function from $[a, b]$ into Prob (G) is measurable. We denote by $\mathcal{P}$ the space of all such measure-valued functions.

In this paper we work under the following assumption for the sake of simplicity.

Assumption. Let U be a compact set in R^m; all control functions are restricted to have values in U.

With little complication of notation, the set U can be made dependent on t and g. Unbounded controls can also be accounted for by using the techniques of McShane [7] or Warga [8, § VI.4]. We omit the details.

The admissible controls, therefore, are the functions

$$u(t, g): [a, b] \times G \to U, \tag{3.3}$$

which are measurable in both variables.

We now describe how to apply relaxed controls to the chattering systems. Following the ideas of Warga we allow the control function to assign to each (t, g) a probability distribution on U. Thus, if Prob (U) denotes the space of probability distributions on U, then a relaxed control is a mapping

$$v(t, g): [a, b] \times G \to \text{Prob}\,(U) \tag{3.4}$$

assumed measurable in both variables (compare with (3.3)) and where the compact metric structure on Prob (U) is induced by the weak convergence of measures. The ordinary control $u(t, g)$ is a particular case of a relaxed control with the identification of the value $u(t, g)$ with a measure concentrated on $u(t, g)$.

A relaxed control $v(\cdot, \cdot)$ affects (3.2) by averaging for each (t, g) the effects of the points $u \in U$ according to the distribution $v(t, g)$. To employ another integral notation in (3.2) would complicate the formulas. We therefore adopt the notation

introduced in Young [9] (thanks are due to a referee for this reference), and also used in McShane [7], as follows. If $R(u)$ is a function of the variable u, and if $v(t, g)$ is a measure on U, then $\mathfrak{M}(R(v(t, g)))$ denotes the average $\int_U R(u)v(t, g)(du)$. With this notation, the optimization problem (3.2) with the availability of relaxed controls has the following form:

$$\begin{aligned} &\text{minimize} && \int_a^b \int_G \mathfrak{M}(Q(x(t), v(t, g), t))\zeta_t(dg)\, dt, \\ &\text{subject to} && \dot{x} = f(x, t) + \int_G \mathfrak{M}(g(v(t, g)))\zeta_t(dg), \\ & && x(a) = x_0. \end{aligned} \tag{3.5}$$

Existence of optimal solutions to (3.5), and the possibility of approximating them with ordinary controls, follow from the general theory of Warga [8, Chap. 4]. We derive these results from the following similar observations that are used in the sequel.

A relaxed control function $v(\cdot, \cdot)$ induces a measure, say V, on $[a, b] \times G \times U$ as follows. If $[c, d] \subset [a, b]$, $G_0 \subset G$, and $U_0 \subset U$, then

$$V([c, d] \times G_0 \times U_0) = \int_c^d \int_{G_0} v(t, g)(U_0)\zeta_t(dg)\, dt. \tag{3.6}$$

This measure is a $(b-a)$-multiple of a probability measure, since $v(t, g)$ and ζ_t are probability measures. We say that the relaxed controls $v_k(t, g)$ converge to $v_0(t, g)$ if the induced measures V_k converge to V_0 in the weak convergence of measures. With this convergence we have the following.

LEMMA 3.1. *The space of relaxed controls is metric compact; the ordinary controls are dense in it.*

Proof. The space of bounded measures with the weak convergence of measures is metric compact (see Billingsley [5]). Therefore we have only to show that if V_0 is a limit of V_k and the latter are generated by relaxed controls, then so is V_0. But this is a simple disintegration fact, since $\zeta_t \otimes dt$ is fixed in the construction (3.6) and $v_k(t, g)$ are all probability measures. This verifies the compactness. The approximation by ordinary controls can be exhibited by a straightforward construction, since on $[a, b] \times G$ the measure $\zeta_t \otimes dt$ is atomless, as in Berkovitz [4, IV.4] or Warga [8, § III.3].

Example 3.2. An optimal relaxed control for (2.4) is the constant measure-valued control $v(t, \sigma)$ that assigns $+1$ and -1 with equal probabilities. A sequence that converges to it in the topology of relaxed control is the sequence $u_k(t)$ defined in § 2. Another sequence can be constructed by dividing $[-1, 1]$ into k intervals of equal length, and let $u_k(t, \sigma) = +1$ if σ belongs to the even intervals and $u_k(t, \sigma) = -1$ otherwise.

LEMMA 3.3. *If $v_k(\cdot, \cdot)$ converge to $v_0(\cdot, \cdot)$, then the cost of $v_k(\cdot, \cdot)$ converges to the cost of $v_0(\cdot, \cdot)$.*

Proof. To each $v_k(\cdot, \cdot)$ we associate the function

$$\gamma_k(t) = \int_G \mathfrak{M}(g(v_k(t, g)))\zeta_t(dg).$$

The convergence of v_k to v_0 implies (immediately from (3.6)) that $\gamma_k(\cdot)$ converges to $\gamma_0(\cdot)$ in the weak-L_1 convergence on $[a, b]$. A standard continuous dependence result implies that the solutions $x_k(\cdot)$ of the differential equations in (3.5) with v_k converge

uniformly to the solution $x_0(\cdot)$ of the differential equation when v_0 is applied. Define

$$q_k(t) = \int_G \mathfrak{M}(Q(x_k(t), v_k(t, g), t))\zeta_t(dg).$$

The continuity of Q together with the convergence of v_k to v_0 imply that $q_k(\cdot)$ converge weakly in $L_1([a, b])$ to $q_0(\cdot)$. Since the integral of $q_k(\cdot)$ is the cost of v_k, the proof is complete.

THEOREM 3.4. *The optimization problem* (3.5) *has an optimal relaxed control, say* $v_0(\cdot, \cdot)$. *There is a sequence of ordinary controls* $u_k(\cdot, \cdot)$ *which converge to* $v_0(\cdot, \cdot)$ *in the topology of relaxed controls; in particular the cost of* u_k *converges to the infimal cost.*

Proof. The result is a direct consequence of Lemmas 3.1 and 3.3.

4. Elimination of relaxation. If the chattering in the system (3.5) is complete, in a sense to be defined, the ordinary controls yield the same performance as relaxed controls. This is the subject of the present section. The phenomenon is similar to the bang-bang principle (see, e.g., Berkovitz [4]). Here it is the integration with respect to the measures ζ_t that enables the elimination of the relaxation. Indeed, ordinary controls suffice when for each t the measure ζ_t has no atoms (namely, no single point g has positive measure). We call this property complete chattering; the other extreme, no chattering, is the case where for each t the measure ζ_t is concentrated on one point, namely, the ordinary case (3.1).

Before stating the results, we introduce the following convenient tool. Define

$$F(t, g, x) = \{(g(u), Q(x, u, t)): u \in U\}; \tag{4.1}$$

thus $(t, g, x) \to F(t, g, x)$ is a set-valued map with values being subsets of R^{n+1}. The continuity of $g(\cdot)$ and $Q(\cdot, \cdot, \cdot)$, and the topology on G, imply that F has a closed graph. In particular, if $x(t)$ is continuous, then $(t, g) \to F(t, g, x(t))$ has closed values and a closed graph.

We need to integrate the set-valued function F with respect to ζ_t on a subset $G_N(t)$ of G as follows. Let $G_N(t)$ denote the collection of points $g \in G$ such that g is not an atom of ζ_t. The set $G_N(t)$ is then the t-section of the set $G_N = \{(t, g): g$ is not an atom of $\zeta_t\}$. The latter set is measurable with respect to the Lebesgue field on $[a, b]$ and the Borel field on G (see [3, Lemma 4.4]). Denote

$$\Gamma(t, x) = \int_{G_N(t)} F(t, g, x)\zeta_t(dg) \tag{4.2}$$

where the integral is defined to be the set in R^{n+1} of integrals (on $G_N(t)$ with respect to ζ_t) of integrable functions $\gamma(\cdot)$ where $\gamma(g)$ is a selection of F, namely, $\gamma(g) \in F(t, g, x)$ for ζ_t-almost every g. This is the standard integration of set-valued maps (see, e.g., Klein and Thompson [6]). Here t and x are parameters of the integration; parametrized integration of set-valued maps was examined in [3], and the main result of the latter is the tool we use in the sequel.

The result we state and prove is somewhat more general than the one promised in the beginning of the section; the latter follows as a simple consequence.

THEOREM 4.1. *Let* $v_0(t, g)$ *be a relaxed control for* (3.5). *Let* $x_0(t)$ *be the trajectory generated by* v_0 *and let* c_0 *be its cost. There exists a relaxed control* $v_1(t, g)$ *with the same cost, that generates the same trajectory, and that has the property that whenever* g *is not an atom of* ζ_t, $v_1(t, g)$ *is concentrated on one point.*

Proof. Denote

$$\theta_0(t, g) = \mathfrak{M}(g(v_0(t, g)), Q(x_0(t), v_0(t, g), t)), \tag{4.3}$$

namely, $\theta_0(t, g)$ is the integrand in the problem (3.5) when $v_0(t, g)$ is applied to it. Clearly, $\theta_0(t, g)$ is in co $F(t, g, x_0(t))$, the convex hull of $F(t, g, x_0(t))$. Denote

$$\gamma_0(t) = \int_{G_N(t)} \theta_0(t, g)\zeta_t(dg). \tag{4.4}$$

Then $\gamma_0(t) \in \text{co}\,\Gamma(t, x_0(t))$ (see, e.g., Klein and Thompson [6, Thm. 18.1.9]). Since ζ_t is atomless on $G_N(t)$, the set $\gamma(t, x(t))$ is actually convex [6, Cor. 18.1.10], and it follows that $\gamma_0(t) \in \Gamma(t, x_0(t))$. By the theorem in Artstein [3], it follows that there exists a measurable selection $\theta_1(t, g)$ of $F(t, g, x_0(t))$ such that

$$\int_{G_N(t)} \theta_1(t, g)\zeta_t(dg) = \gamma_0(t). \tag{4.5}$$

A standard implicit functions lemma (see, e.g., Berkovitz [4, Thm. 7.1]) implies the existence of an ordinary control $u_1(t, g)$ defined on G_N such that

$$\theta_1(t, g) = (g(u_1(t, g)), Q(x_0(t), u_1(t, g), t)).$$

Consider the relaxed control $v_1(t, g)$ that is equal to $v_0(t, g)$ if g is an atom of ζ_t, and equal to the ordinary control $u_1(t, g)$ if g is not an atom of ζ_t. By (4.3)-(4.5) it follows that $x_0(t)$ is also the trajectory generated by $u_1(t, g)$ and, given that, it follows that v_0 and v_1 have the same cost. This completes the proof.

COROLLARY 4.2. *Suppose that for every t the measure ζ_t is atomless. Let $v_0(t, g)$ be a relaxed control, let $x_0(t)$ be the trajectory generated by it, and let c_0 be its cost. Then there exists an ordinary control $u_0(t, g)$ that generates the same trajectory and has the same cost. In particular, the problem* (3.2) *then has an optimal ordinary solution.*

Proof. The first part is a particular case of Theorem 4.1; the conclusion then follows from Theorem 3.4.

5. Robustness. The control policy that we recommend when rapid oscillations with uncertainty are present is as follows. First solve the limit chattering problem. Then apply the solution to the case of rapid oscillations. Success of such a plan is the robustness in the title of the section. It holds, however, only under some restrictions on the control functions that are used. In this section we determine these restrictions and establish the existence of ordinary controls satisfying these restrictions. Results in this direction appear in [1, § 7] for ordinary controls; here we complement these results and examine in particular the relaxed controls case.

We recall the limit notion that we use to determine if a problem of type (3.2), or (3.1), is a small perturbation of another problem. Note that each problem is characterized by a pair $(f(x, t), \zeta_t) \in \mathcal{F} \times \mathcal{P}$ (see § 3).

Let $f_j, j = 0, 1, 2, \cdots$, belong to $\mathcal{F}$. We say that f_j converge to f_0 if for every $x \in R^n$ and $t \in [a, b]$ the sequence $\int_a^t f_j(x, s)\,ds$ converges to $\int_a^b f_0(x, s)\,ds$. This is the standard convergence that ensures continuous dependence of solutions. The topology induced by it on $\mathcal{F}$ is metric and compact (see [1]).

We now define a convergence on $\mathcal{P}$. First we identify the measure-valued map $t \to \zeta_t$ with the measure $\boldsymbol{\zeta} = \int_a^b \zeta_t \otimes dt$ on $[a, b] \times G$, namely,

$$\boldsymbol{\zeta}(D) = \int_a^b \zeta_t(D_t)\,dt$$

when $D \subset [a, b] = G$ and D_t is the t-section of D. Then $\boldsymbol{\zeta}$ is a $(b-a)$-multiple of a probability measure. With this identification, the convergence on $\mathcal{P}$ is then the weak convergence of measures (see, e.g., Billingsley [5]). With this convergence $\mathcal{P}$ becomes metric and compact (see [1]).

We need the following notation. By cost (v, f, ζ) we denote the cost of the control v when applied to the problem generated by $(f, \zeta) \in \mathcal{F} \times \mathcal{P}$. The first robustness result is under strong conditions on the controls, as follows.

PROPOSITION 5.1. *Let $v_0(t, g)$ be an admissible relaxed control that is continuous in the g variable. Let (f_j, ζ_j) converge to (f_0, ζ_0) in $\mathcal{F} \times \mathcal{P}$. Then* cost (v_0, f_j, ζ_j) *converge to* cost (v_0, f_0, ζ_0).

Proof. Proposition 7.1 of [1] is the analogous result for ordinary controls; the proof is similar. Here is the key step. Let $\gamma_j(t)$ be defined by (4.3)–(4.4) above, when v_0 is the control and (f_j, ζ_j) the data of the problem. The continuity of $v_0(t, \cdot)$ and the convergence on $\mathcal{F} \times \mathcal{P}$ imply that $\gamma_j(\cdot)$ converge to $\gamma_0(\cdot)$ in the weak-L_1 sense on $[a, b]$. This implies the convergence of the cost.

The continuity condition may be severe in some situations; for instance, if U is disconnected (say U contains a finite number of points) and when we look for ordinary controls. (Note, however, that both the optimal relaxed solution and the optimal ordinary solution in (2.4) are continuous, with $U = \{-1, 1\}$.) The following result establishes only a near robustness result, but under eased conditions, which, as we see later, can be fulfilled in general.

PROPOSITION 5.2. *Let $K \subset [a, b] \times G$ be a compact set such that $\zeta_0(([a, b] \times G) \setminus K) < \delta$. Let $v_0(t, g)$ be an admissible relaxed control such that $(t_0, g_0) \in K$ implies that $v_0(t_0, \cdot)$ is continuous at the point g_0. Suppose (f_j, ζ_j) converge to (f_0, ζ_0) in $\mathcal{F} \times \mathcal{P}$. Then* limsup $|\text{cost}\,(v_0, f_j, \zeta_j) - \text{cost}\,(v_0, f_0, \zeta_0)| \leqq \varepsilon(\delta)$, *with $\varepsilon(\delta) \to 0$ as $\delta \to 0$.*

Proof. Define $v_1(t, g)$ such that $v_1(t, g) = v_0(t, g)$ if $(t, g) \in K$ and $v_2(t, g)$ is continuous in the variable g. This can be done in a standard way, since the space of probability measures on U is convex. By the previous proposition cost (v_1, f_j, ζ_j) converges to cost (v_1, f_0, ζ_0). The result would then follow if we prove that $|\text{cost}\,(v_1, f_0, \zeta_0) - \text{cost}\,(v_0, f_0, \zeta_0)| \leqq \varepsilon(\delta)$ with $\varepsilon(\delta) \to 0$ as $\delta \to 0$. But this follows directly from (3.5). Indeed, the continuous dependence implies that the trajectory $x_1(t)$ generated by v_1 is close to the trajectory $x_0(t)$ generated by v_0; the continuity of $Q(\cdot, u, t)$ and the fact that the cost is an integral on $[a, b] \times G$ with respect to ζ_0, and $([a, b] \times G) \setminus K$ has ζ_0 measure δ, imply the result.

Optimal solutions of (3.2) may not satisfy the robustness or the near robustness conditions of the previous results. We wish, therefore, to establish the existence of approximate solutions that satisfy the conditions. The following result verifies the existence of a nearly robust approximate solution in the general case, and a robust approximate solution under an additional condition on U. In particular, since the optimal solutions may be relaxed, we wish to verify the existence of robust, or nearly robust, ordinary controls.

Denote by $\rho(v_1, v_2)$ the distance between the control functions $v_1(t, g)$ and $v_2(t, g)$; namely, the metric that generates the convergence of control functions (see Lemma 3.1). Recall that the cost is continuous with respect to this metric.

THEOREM 5.3. *Let $v(t, g)$ be an admissible control for the problem* (3.2) *generated by the data (f, ζ). Let $\varepsilon > 0$ and $\delta > 0$ be given. There exists an ordinary control function $u(t, g)$ such that $\rho(v, u) < \varepsilon$ and such that a compact set $K \subset [a, b] \times G$ exists, with $\zeta(([a, b] \times G) \setminus K) < \delta$ and $u(t_0, \cdot)$ is continuous at points g_0 with $(t_0, g_0) \in K$. If, in addition, U is a convex set, then K can be chosen equal to $[a, b] \times G$.*

Proof. The ordinary controls are dense in the space of relaxed controls (Lemma 3.1), therefore an admissible, namely measurable, ordinary control $u_1(t, g)$ exists such that $\rho(v, u_1) < \varepsilon/2$. Given $\delta_1 > 0$, by the Lusin Theorem (Warga [8, p. 70]) there exists a $K \subset [a, b] \times G$ such that $\zeta(([a, b] \times G) \setminus K) < \delta_1$ and u_1 restricted to K is continuous. The number δ_1 can be chosen such that $\delta_1 \leqq \delta$ and such that any extension u of the

restriction of u_1 to K, to the space $[a, b] \times G$, will satisfy $\rho(u_1, u) < \varepsilon/2$. What we should show now is the existence of such an extension, with the desired continuity properties. If U is convex, then, since K is compact, a standard extension technique provides a continuous extension u of the restriction of u_1 to K, which is the second claim of the theorem. If U is not convex, we proceed as follows. To each $(t, g) \notin K$ we associate the subset $K(t, g)$ of K, consisting of all points in K closest in the space $[a, b] \times G$ to (t, g). Then $K(t, g)$ is a multifunction with a closed graph and nonempty values. It has a measurable selection (e.g., Klein and Thompson [6, Chap. 14]), say $r(t, g)$. Define $u(t, g)$ by $u(t, g) = u_1(t, g)$ if $(t, g) \in K$ and $u(t, g) = u_1(r(t, g))$ otherwise. Then u is measurable, and continuous at points (t, g) in K. This completes the proof.

Clearly, without the convexity of U there may not exist an ordinary control $u(t, g)$ near the optimal control, and that is continuous in g. Take for instance the differential equation in (2.2) and (2.4), with $Q(x, u, t) = x$, and $U = \{-1, 1\}$. The optimal control is $u(t, \sigma) = -\operatorname{sgn} \sigma$, and it cannot be approximated by a control continuous in σ.

A conclusion of the previous discussion is that near (in the topology of relaxed controls) every optimal relaxed solution there exists an ordinary solution that is either robust or nearly robust. However, note that this robustness is not uniform, as we have seen in the example of § 2. When u_k is fixed near the optimal relaxed control v, then for $j \to \infty$ only a small error is guaranteed. But with a varying index k, there is no small bound on the errors as $j \to \infty$.

OBSERVABILITY OF SYSTEMS UNDER UNCERTAINTY*

JEAN-PIERRE AUBIN† AND HALINA FRANKOWSKA†

This paper is dedicated to the memory of E. J. McShane.

Abstract. The evolution of the state $x(\cdot)$ of a system under uncertainty governed by a differential inclusion

$$\text{for almost all } t \in [0, T], \quad x'(t) \in F(t, x(t))$$

is observed through an observation map H:

$$\forall t \in [0, T], \quad y(t) \in H(x(t)).$$

The set-valued character due to the uncertainty leads to the introduction of the following:

Sharp input-output map, which is the (usual) product

$$\forall x_0 \in X, \quad I_-(x_0) := (H \circ \mathcal{S})(x_0) := \bigcup_{x(\cdot) \in \mathcal{S}(x_0)} H(x(\cdot)).$$

Hazy input–output map, which is the **square product**

$$\forall x_0 \in X, \quad I_+(x_0) := (H \square \mathcal{S})(x_0) := \bigcap_{x(\cdot) \in \mathcal{S}(x_0)} H(x(\cdot)).$$

Where $\mathcal{S}$ denotes the solution map, recovering the input x_0 from the outputs $I_-(x_0)$ or $I_+(x_0)$ means that these input-output maps are "injective" in the sense that, locally,

$$x_1 \neq x_2 \Rightarrow I(x_1) \cap I(x_2) = \emptyset.$$

Criteria for both sharp and hazy local observability are provided in terms of (global) sharp and hazy observability of the variational inclusion

$$w'(t) \in DF(t, \bar{x}(t), \bar{x}'(t))(w(t)),$$

which is a "linearization" of the differential inclusion along a solution $\bar{x}(\cdot)$, where for almost all t, $DF(t, x, y)(u)$ denotes the contingent derivative of the set-valued map $F(t, \cdot, \cdot)$ at a point (x, y) of its graph. These conclusions are reached by implementing the following strategy:

1. Provide a general principle of local injectivity and observability of a set-valued map I, which derives these properties from the fact that the kernel of an adequate derivative of I is equal to zero.
2. Supply chain rule formulas that allow computation of the derivatives of the usual product I_- and the square product I_+ from the derivatives of the observation map H and the solution map $\mathcal{S}$.
3. Characterize the various derivatives of the solution map $\mathcal{S}$ in terms of the solution maps of the associated variational inclusions.
4. Piece together these results for deriving local sharp and hazy observability of the original system from sharp and hazy observability of the variational inclusions.
5. Study global sharp and hazy observability of the variational inclusions.

1. Introduction.

We describe the evolution $t \in [0, T] \mapsto x(t) \in X$ of the state $x(\cdot)$ of a system under uncertainty by a differential inclusion

$$\text{for almost all } t \in [0, T], \quad x'(t) \in F(t, x(t)) \tag{1}$$

where the set-valued map takes into account disturbances and/or perturbations of the

† CEREMADE, Université de Paris-Dauphine, Paris, France and International Institute for Applied Systems Analysis, Laxenburg, Austria.

system. Let us mention a familiar representation of uncertainty:

$$\text{for almost all } t \in [0, T], \quad x'(t) = f(t, x(t)) + g(t, d(t)), \quad d(t) \in D(t).$$

This system is observed through an observation map H that generally is a set-valued map from the state space X to some observation space Y, that associates with each solution to the differential inclusion (1) an observation $y(\cdot)$ satisfying

$$\forall t \in [0, T], \quad y(t) \in H(x(t)). \tag{2}$$

For instance, y may be given in a parametrized form:

$$\forall t \in [0, T], \quad y(t) = h(x(t)) + \varepsilon(t), \quad \varepsilon(t) \in Q(t).$$

We assume for simplicity that H does not depend on the time t, but we shall provide in the appropriate remarks the extensions to the time-dependent case.

Observability concepts deal with the possibility of recovering the initial state $x_0 = x(0)$ of the system knowing only the evolution of an observation $t \in [0, T] \mapsto y(t)$ during the interval $[0, T]$, and naturally, knowing the laws (1) and (2). Once we get the initial state x_0, we may, by studying the differential inclusion, gather information about the solutions starting from x_0, using many results provided by the theory of differential inclusions. For instance, under an adequate Lipschitz property, we know that for every $\bar{x}(\cdot) \in \mathcal{S}(x_0)$,

$$\mathcal{S}(x_0) \in \bar{x}(\cdot) + M \int_0^T \operatorname{diam}(F(t, \bar{x}(t)))\, dt\, B$$

where $\mathcal{S}(x_0)$ denotes the set of all trajectories of (1) starting at x_0, M is a constant independent of $\bar{x}(\cdot)$ and B denotes the closed unit ball in the Sobolev space $W^{1,1}(0, T)$.

Let $\mathcal{S} := \mathcal{S}_F$ from X to $\mathscr{C}(0, T; X)$ denote the solution map associating with every initial state $x_0 \in X$ the (possibly empty) set $\mathcal{S}(x_0)$ of solutions to the differential inclusion (1) starting at x_0 at the initial time $t = 0$.

In other words, we have introduced an input-output system where the

1. inputs are the **initial states** x_0, and the

2. outputs are the **observations** $y(\cdot) \in H(x(\cdot))$ of the evolution of the state of the system through H:

$$\begin{array}{ccccc}
\textbf{Inputs} & \overset{\mathcal{S}}{\rightsquigarrow} & \textbf{States} & \overset{H}{\mapsto} & \textbf{Outputs} \\
\downarrow & & \downarrow & & \downarrow \\
X \ni x_0 & \rightsquigarrow & x(\cdot) \in \mathcal{S}(x_0) & \mapsto & y(\cdot) \in H(x(\cdot)) \\
\uparrow & & \uparrow & & \uparrow \\
\text{Initial states} & & \begin{cases} x'(t) \in F(t, x(t)) \\ x(0) = x_0 \end{cases} & & \text{Observations.}
\end{array}$$

It remains to define an input-output map. But, because of the set-valued character (the presence of uncertainty), we can conceive two dual ways for defining composition products of the set-valued maps $\mathcal{S}$ from X to the space $\mathscr{C}(0, T; X)$ and H from $\mathscr{C}(0, T; X)$ to $\mathscr{C}(0, T; Y)$. So, for systems under uncertainty, we have to deal with **two input–output maps** from X to $\mathscr{C}(0, T; Y)$:

Sharp input–output map, which is the (usual) product

$$\forall x_0 \in X, \quad I_-(x_0) := (H \circ \mathcal{S})(x_0) := \bigcup_{x(\cdot) \in \mathcal{S}(x_0)} H(x(\cdot)).$$

Hazy input–output map, which is the **square product**

$$\forall x_0 \in X, \quad I_+(x_0) := (H \square \mathcal{S})(x_0) := \bigcap_{x(\cdot) \in \mathcal{S}(x_0)} H(x(\cdot)).$$

The **sharp** input-output map tracks the evolution of **at least one** state starting from some initial condition x_0 whereas the **hazy** input-output map tracks **all** such evolutions.

Opinions may differ about which would be the "right" input-output map, just because they depend on the context in which a given problem is stated. So, we shall study observability properties of **both** the sharp and hazy input-output maps.

Recovering the input x_0 from the outputs $I_-(x_0)$ or $I_+(x_0)$ means that the set-valued maps are "injective" in some sense.

When H and $\mathcal{S}$ are single-valued maps, the input-output map is called observable whenever the product $I := H \circ \mathcal{S}$ is injective, i.e.,

$$H\mathcal{S}(x_1) = H\mathcal{S}(x_2) \Rightarrow x_1 = x_2. \tag{3}$$

When we adapt this definition to the set-valued case, we come up with two possibilities: If I stands now for either I_- or I_+, we can require either the property

$$I(x_1) = I(x_2) \Rightarrow x_1 = x_2$$

or the stronger condition

$$I(x_1) \cap I(x_2) \neq \emptyset \Rightarrow x_1 = x_2.$$

The first way would not be, in general, useful in the framework of uncertain systems since we often observe just one output $y(\cdot) \in H\mathcal{S}(x_0)$ and not the whole set of possible outputs $H\mathcal{S}(x_0)$. That is why we will adopt the second point of view, by saying that the sharp or hazy input-output map I is "observable" if

$$x_1 \neq x_2 \Rightarrow I(x_1) \cap I(x_2) = \emptyset. \tag{4}$$

If this property holds only on a neighborhood of some x_0, we shall say that I is "locally observable" around x_0.

This is a very pleasant concept that we will study for hazy input-output maps.

However, it is a bit too strong for sharp observability, and we will be content with the weaker condition that the inverse image $I^{-1}(y_0)$ of some observation y_0 contains **at most** one input x_0:

$$x_1 \neq x_0 \Rightarrow y_0 \notin I(x_1). \tag{5}$$

If this is the case, we will say that the input-output map I is "observable" **at** (x_0, y_0) and "locally observable" **at** (x_0, y_0) if it holds only on a neighborhood of x_0.

In other words, sharp observability at $(x_0 y_0)$ means that whenever y_0 is an observation of some solution $x^*(\cdot)$, i.e., $y_0 \in H(x^*(\cdot))$, then $x^*(0) = x_0$. Local sharp observability means that the above holds true only for those $x^*(0)$ not too far from x_0.

Hazy observability at (x_0, y_0) means that y_0 can be a "common" observation only for one input x_0. In other words, if we (hopefully) observe an output y_0, which is a common observation of all solutions $x(\cdot) \in \mathcal{S}(\bar{x}_0)$, then $\bar{x}_0 = x_0$.

Actually, the purpose of this paper is to derive local observability of both the sharp and hazy input-output maps from the global sharp and hazy observability at zero of "variational inclusions" through a linearization of the input-output map. The linearization techniques based on the differential calculus and inverse function theorems for set-valued maps has been successfully used in the study of local controllability of differential inclusions and control systems with feedbacks. (See [12], [13], [10], [11], [20].)

Here, variational inclusions are "linearizations" of the differential inclusion (1) along a solution $\bar{x}(\cdot) \in \mathcal{S}(x_0)$ of the form

$$w'(t) \in DF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \tag{6}$$

where for almost all t, $DF(t, x, y)(u)$ denotes an adequate concept of derivative (the contingent derivative, defined below) of the set-valued map $F(t, \cdot, \cdot)$ at a point (x, y) of its graph. Let us just say for the time that they are set-valued analogues of continuous linear operators.

(These linearized differential inclusions are called **variational inclusions** because they extend (in various ways) the classical variational equations of ordinary differential equations: their solutions starting at some u provide the directional derivative of the solution to the initial system in the direction u.)

To say that the variational inclusion is **hazily** (respectively, **sharply**) observable at zero amounts to saying that whenever **all** (respectively, **at least one**) solutions $w(\cdot)$ to the variational inclusion (6) starting at u satisfy

$$\forall t \in [0, T], \quad H'(\bar{x}(t))w(t) = 0 \tag{7}$$

then $u = 0$.

To reach such conclusions, we shall choose the following strategy:

1. Provide a general principle of local injectivity and observability of a set-valued map I that derives these properties from the fact that the kernel of an adequate derivative of I is equal to zero.
2. Supply chain rule formulas that allow computing the derivatives of the usual product I_- and the square product I_+ from the derivatives of the observation map H and the solution map $\mathcal{S}$.
3. Characterize the various derivatives of the solution map $\mathcal{S}$ in terms of the solution maps of the associated variational inclusions.
4. Piece together these results for deriving local sharp and hazy observability of the original system from sharp and hazy observability of the variational inclusions.
5. Study global sharp and hazy observability of the variational inclusions. (This has already been done in [5], for time-independent closed convex processes, where it was shown that sharp observability is a dual concept of controllability and where various characterizations were provided. See the last section for the comments on the observability of a system around an equilibrium).

But, before implementing this program, we have to avoid the trivial case when the hazy input-output map I_+ takes (locally) empty values.

For doing that, we "project" the differential inclusion (1) onto a differential inclusion

$$\text{for almost all } t \in [0, T], \quad y'(t) \in G(t, y(t)) \tag{8}$$

in such a way that the following property holds true:

$$\begin{aligned} &\forall (x_0, y_0) \in \text{Graph}\,(H) \text{ all solutions } x(\cdot) \text{ to (1) and } y(\cdot) \text{ to (8) satisfy} \\ &\forall t \in [0, T], y(t) \in H(x(t)). \end{aligned} \tag{9}$$

If such is the case, then the hazy input-output map I_+ is well defined.

To proceed further, we need to introduce the concept of "contingent derivative" of a set-valued map H from a Banach space X to a Banach space Y at a point (x, y)

of its graph: It is the set-valued map $DH(x, y): X \rightsquigarrow Y$ that associates with any direction u the set $DH(x, y)(u)$ of directions v satisfying

$$\liminf_{h \to 0+,\, u' \to u} d\left(v, \frac{H(x+hu')-y}{h}\right) = 0. \tag{10}$$

The choice of this particular derivative is motivated by the fact that its graph is the **contingent cone** to the graph of H at (x, y), where the contingent cone $T_K(x)$ to $K \subset X$ at $x \in K$ is the set of directions $v \in X$ such that

$$\liminf_{h \to 0} d(x+hv, K)/h = 0.$$

For our purpose, the contingent cone plays a major role compared to other tangent cones. However, we shall need other tangent cones and associated derivatives.

The map H is said to be "derivable" if for every (x, y) in the graph of H, v belongs to $DH(x, y)(u)$ if and only if

$$\lim_{h \to 0+} d\left(v, \frac{H(x+hu)-y}{h}\right) = 0.$$

We extend the concept of $\mathscr{C}^1$-function by saying that H is "sleek" if and only if

$$\text{Graph}\,(H) \ni (x, y) \rightsquigarrow \text{Graph}\,(DH(x, y)) \text{ is lower semicontinuous}$$

where $\rightsquigarrow$ means "maps to." (It underlines the set-valued character of the map under consideration.) In this case, the graph of $DH(x, y)$ is a closed convex cone. Maps whose graphs are closed convex cones, called closed convex processes, are the set-valued analogues of continuous linear operators, and enjoy most of their properties.

Returning to the projection problem, we shall say that a set-valued map $G: [0, T] \times Y \rightsquigarrow Y$ is a "Lipschitzian square projection" of the set-valued map $F: [0, T] \times X \rightsquigarrow X$ by H if and only if

$$\begin{aligned} &\text{(i)} \quad F \times G \text{ is Lipschitzian around } [0, T] \times \text{Graph}\,(H), \\ &\text{(ii)} \quad \forall (x, y) \in \text{Graph}\,(H),\ G(t, y) \subset \bigcap_{v \in F(t,x)} DH(x, y)(v). \end{aligned} \tag{11}$$

In this paper "F is Lipschitzian on $K \subset [0, T] \times X$" means that for all (t, x), $(t, y) \in K$

$$F(t, x) \subset F(t, y) + k(t)\|x-y\|B,$$

where $k \in L^1(0, T)$. We shall prove that *if there exists a Lipschitzian square projection of F by H, then the hazy input-output map $I_+ := H \square \mathcal{S}$ has nonempty values for any initial value $y_0 = H(x_0)$.*

We state now the observability properties of the hazy input-output map around a solution $\bar{x}(\cdot)$ to the differential inclusion (1). We assume that F satisfies the following assumptions:

$$\begin{aligned} &\text{(i)} \quad \forall x \in X \text{ the set-valued map } F(\cdot, x) \text{ is measurable,} \\ &\text{(ii)} \quad \forall t \in [0, T],\ \forall x \in X,\ F(t, x) \text{ is a closed nonempty set,} \\ &\text{(iii)} \quad \exists k(\cdot) \in L^1(0, T) \text{ such that for almost all } t \in [0, T] \\ &\qquad \text{the map } F(t, \cdot) \text{ is } k(t)\text{-Lipschitzian.} \end{aligned} \tag{12}$$

THEOREM 1.1. *Let us assume that H is continuously differentiable, that F satisfies assumptions* (12), *that it has linear growth in the sense that*

$$\exists c > 0 \quad \textit{such that } \|F(t, x)\| := \sup_{y \in F(t,x)} \|y\| \leqq c(\|x\|+1)$$

and that is has a Lipschitzian square projection G by H.

1) *If F is derivable and if for some $\bar{x}(\cdot) \in \mathcal{S}(x_0)$ the contingent variational inclusion*

(13) *for almost all $t \in [0, T]$, $w'(t) \in DF(t, \bar{x}(t), \bar{x}'(t))(w(t))$*

is globally hazily observable through $H'(\bar{x}(\cdot))$ at zero, then the system (1) *is locally hazily observable through H* **at** *$(x_0, H(\bar{x}))$.*

2) *If F is sleek and if for every solution $x(\cdot)$ to the differential inclusion* (1) *starting at x_0, the contingent variational inclusion*

(14) *for almost all $t \in [0, T]$, $w'(t) \in DF(t, x(t), x'(t))(w(t))$*

is globally hazily observable through $H'(x(\cdot))$ at 0, then the system (1) *is locally hazily observable through H* **around** *x_0.*

Observability properties of sharp input-output maps require stronger assumptions. We state first the result for the simpler, convex case.

THEOREM 1.2. *Let us assume that H is linear and that the graphs of the set-valued maps $F(t, \cdot): X \rightsquigarrow X$ are closed and convex. If for some $\bar{x}(\cdot) \in \mathcal{S}(x_0)$ the contingent variational inclusion* (13) *is globally sharply observable through H at zero, then the system* (1) *is globally sharply observable through H at $(x_0, H(\bar{x}))$.*

A more general case requires some additional assumptions.

THEOREM 1.3. *Assume that F has closed convex images, is continuous, derivable, Lipschitz in the second variable with a constant independent of t and that the growth of F is linear with respect to the state. Let H be a twice continuously differentiable function from X to another finite-dimensional vector-space Y. Consider an observation $y^* \in I_-(x_0)$ and assume that for every solution $\bar{x}(\cdot)$ to the differential inclusion* (1) *satisfying $y^*(\cdot) = H(\bar{x}(\cdot))$ and for all $t \in [0, T]$ we have*

$$\operatorname{Ker} H'(\bar{x}(t)) \cap [F(t, \bar{x}(t)) - F(t, \bar{x}(t))]^{\perp} = \{0\}.$$

If for all $\bar{x}(\cdot)$ as above the contingent variational inclusion (13) *is globally sharply observable through $H'(\bar{x}(\cdot))$ at 0, then the system* (1) *is locally sharply observable through H at (x_0, y^*).*

2. Hazy and sharp input–output systems. Let us consider a set-valued input-output system of the following form built through a differential inclusion

(15) for almost all $t \in [0, T]$, $x'(t) \in F(t, x(t))$

whose dynamics are described by a set-valued map F from $[0, T] \times X$ to X, where X is a finite-dimensional vector-space (the **state space**) and $0 < T \leqq \infty$. It governs the (uncertain) evolution of the state $x(\cdot)$ of the system. The **inputs** are the **initial states** x_0 and the **outputs** are the **observations** $y(\cdot) \in H(x(\cdot))$ of the evolution of the state of the system through a single-valued (or set-valued) map H from X to an **observation space** Y.

Let $\mathcal{S} := \mathcal{S}_F$ from X to $\mathcal{C}(0, T; X)$ denote the solution map associating with every initial state $x_0 \in X$ the (possibly empty) set $\mathcal{S}(x_0)$ of solutions to differential inclusion (15) starting at x_0 at the initial time $t = 0$.

We can conceive two dual ways for defining composition products of set-valued maps G from a Banach space X to a Banach space Y and a set-valued map H from Y to a Banach space Z (which naturally coincide when H and G are single-valued).

DEFINITION 2.1. Let X, Y, Z be Banach spaces and $G: X \rightsquigarrow Y$, $H: Y \rightsquigarrow Z$ be set-valued maps.

1. The usual composition product (called simply the **product**) $H \circ G: X \rightsquigarrow Z$ of H and G at x is defined by

$$(H \circ G)(x) := \bigcup_{y \in G(x)} H(y).$$

2. The **square product** $H \square G: X \rightsquigarrow Z$ of H and G at x is defined by

$$(H \square G)(x) := \bigcap_{y \in G(x)} H(y).$$

Remarks. 1. The observability problems that we address involve the inversion of these input-output maps.

There are two ways to adapt to the set-valued case the formula that states that the inverse of a product is the product of the inverses (in reverse order), since we know that there are two ways of defining the inverse image by a set-valued map $\mathcal{S}$ of a subset M:

$$\text{(a)} \quad \mathcal{S}^-(M) := \{x \mid \mathcal{S}(x) \cap M \neq \varnothing\},$$

$$\text{(b)} \quad \mathcal{S}^+(M) := \{x \mid \mathcal{S}(x) \subset M\}.$$

We then observe the following formulas of the inverse of composition products:

$$\text{(i)} \quad (H \circ \mathcal{S})^{-1}(y) = \mathcal{S}^-(H^{-1}(y)),$$

$$\text{(ii)} \quad (H \square \mathcal{S})^{-1}(y) = \mathcal{S}^+(H^{-1}(y)).$$

This may provide a further justification of the introduction of these two "dual" composition products.

2. Recall also that a set-valued map $\mathcal{S}$ is upper semicontinuous if and only if the inverse images $\mathcal{S}^+$ of open subsets are open and that it is lower semicontinuous if and only if the inverse images $\mathcal{S}^-$ of open subsets are open.

3. Observe finally that square products are implicitly involved in the factorization of maps. Let X be a subset, $\mathcal{R}$ be an equivalence relation on X and ϕ denote the canonical surjection from X onto the factor space $X/\mathcal{R}$. If f is a single-valued map from X to Y, its factorization $\tilde{f}: X/\mathcal{R} \mapsto Y$ is defined by

$$\tilde{f}(\xi) := (f \square \phi^{-1})(\xi).$$

It is nontrivial if and only if f is consistent with the equivalence relation $\mathcal{R}$, i.e., if and only if $f(x) = f(y)$ whenever $\phi(x) = \phi(y)$.

When $F: X \rightsquigarrow Y$ is a set-valued map, we can define its factorization $\tilde{F}: X/\boldsymbol{R} \rightsquigarrow Y$ by

$$\tilde{F}(\xi) := (F \square \phi^{-1})(\xi).$$

We can associate with this system described through state-space representation two input-output maps.

DEFINITION 2.2. Let us consider a system (F, H) defined by the set-valued map F describing the dynamics of the differential inclusion and the observation map H.

Let $\mathcal{S} := \mathcal{S}_F$ denote the solution map of the differential inclusion. We shall say that

1) The product $I_- := H \circ \mathcal{S}$, from X to $\mathscr{C}(0, T; Y)$ defined by

$$\forall x_0 \in X, \quad I_-(x_0) := \bigcup_{x(\cdot) \in \mathcal{S}(x_0)} H(x(\cdot))$$

is the **sharp** input-output map.

2) The "square product" $I_+ := H \square S$, from X to $\mathscr{C}(0, T; Y)$ defined by

$$\forall x_0 \in X, \quad I_+(x_0) := \bigcap_{x(\cdot) \in \mathcal{S}(x_0)} H(x(\cdot))$$

is the **hazy** input-output map.

Remark. Observe that when the observation map is single-valued, the use of a nontrivial hazy input-output map requires that all solutions $x(\cdot) \in \mathcal{S}(x_0)$ yield the

same observation $y(\cdot) = H(x(\cdot))$. Hence we have to study when this possibility occurs, by projecting the differential inclusion (15) onto a differential equation that "tracks" all the solutions to the differential inclusion. This is the purpose of the next section. □

3. Projection of a system onto the observation space. Our first task is to provide conditions implying that the hazy input-output map $I_+ := H \square \mathcal{S}$ is not trivial, above all when the observation map is single-valued.

We shall tackle this issue by "projecting" the differential inclusion given in the state space X onto a differential inclusion in the observation space Y in such a way that solutions to the projected differential inclusion are observations of solutions to the original differential inclusion.

Let us consider a differential inclusion

$$x'(t) \in F(t, x(t)), \qquad x(0) = x_0 \tag{16}$$

where $F: [0, T] \times X \rightsquigarrow X$ is a nontrivial set-valued map and an observation map $H: X \rightsquigarrow Y$ from X to another finite-dimensional vector-space Y.

We project the differential inclusion (16) to a differential inclusion (or a differential equation) in the observation space Y described by a set-valued map G (or a single-valued map g)

$$y'(t) \in G(t, y(t)) \quad (\text{or } y'(t) = g(t, y(t))), \quad y(0) = y_0 \tag{17}$$

that allows us to track partially or completely solutions $x(\cdot)$ to the differential inclusion (16) in the following sense:

(18)
- (a) $\forall (x_0, y_0) \in \text{Graph}(H)$ there exist solutions $x(\cdot)$ and $y(\cdot)$ to (16) and (17) such that $\forall t \in [0, T]$, $y(t) \in H(x(t))$,
- (b) $\forall (x_0, y_0) \in \text{Graph}(H)$ all solutions $x(\cdot)$ and $y(\cdot)$ to (16) and (17) satisfy $\forall t \in [0, T]$, $y(t) \in H(x(t))$.

The second property means that the differential inclusion (17) is, so to speak, "blind" to the solutions to the differential inclusion (16). When it is satisfied, we see that for all $x_0 \in H^{-1}(y_0)$, all the solutions to the differential inclusion (16) do satisfy

$$\forall t \in [0, T], \quad y(t) \in H(x(t)).$$

We need the following definition.

DEFINITION 3.1. Let (x, y) belong to the graph of a set-valued map $F: X \rightsquigarrow Y$ from a normed space X to another Y. Then the **contingent derivative** $DF(x, y)$ of F at (x, y) is the set-valued map from X to Y defined by

$$v \in DF(x, y)(u) \Leftrightarrow \liminf_{h \to 0+, u' \to u} d\left(v, \frac{F(x + hu') - y}{h}\right) = 0$$

and the **paratingent derivative** $PF(x, y)$ of F at (x, y) is the set-valued map from X to Y defined by

$$v \in PF(x, y)(u) \Leftrightarrow \liminf_{h \to 0+, (x', y') \to_F (x, y), u' \to u} d\left(v, \frac{F(x' + hu') - y'}{h}\right) = 0$$

where $\to_F$ denotes the convergence in Graph (F).

(See [23] for the study of paratingent cones and the applications of Choquet's Theorem.)

When F is pseudo-Lipschitzian around $(x, y) \in \text{Graph}(F)$ in the sense that

$$\exists k > 0 \text{ such that } \forall (x', y') \in \text{Graph } F \text{ near } (x, y), \forall x'' \in X \text{ near } x,$$
$$F(x'') \subset F(x') + k\|x' - x''\| B$$

the above formulas become

$$\text{(i)}\quad v \in DF(x,y)(u) \Leftrightarrow \liminf_{h\to 0+} d\left(v, \frac{F(x+hu)-y}{h}\right) = 0,$$

$$\text{(ii)}\quad v \in PF(x,y)(u) \Leftrightarrow \liminf_{h\to 0+,(x',y')\to_F(x,y)} d\left(v, \frac{F(x'+hu)-y'}{h}\right) = 0.$$

Moreover, in this case the derivative $DF(x, y)$ has nonempty images and is k-Lipschitzian (see [12]).

PROPOSITION 3.1. *Let us consider a closed set-valued map H from X to Y.*

1. *Let us assume that F and G are nontrivial upper semicontinuous set-valued maps with nonempty compact convex images and with linear growth. We posit the assumption*

$$\forall (x,y) \in \text{Graph}\,(H),\quad G(t,y) \cap (DH(x,y) \circ F)(t,x) \neq \emptyset. \tag{19}$$

Then property (18)(a) *holds true.*

2. *Let us assume that $F \times G$ is nontrivial Lipschitzian on a neighborhood of* $[0, T] \times$ Graph (H) *and has a linear growth. We posit the assumption*

$$\forall (x,y) \in \text{Graph}\,(H),\quad G(t,y) \subset (DH(x,y) \square F)(t,x). \tag{20}$$

Then property (18)(b) *is satisfied.*

Proof. It follows obviously from the viability and invariance theorems of the graph of H for the set-valued map $F \times G$.

1. When $G(t, y)$ intersects $(DH(x, y) \circ F)(t, x) = \cup_{v \in F(t,x)} DH(x, y)(v)$, we deduce that Graph (H) is a viability domain of $F \times G$ $(t, \cdot)$. Hence we apply the Viability Theorem (see [14], [1, Thm. 4.2.1, p. 180]).

2. When $F \times G$ is Lipschitzian and satisfies (20), we deduce that Graph (H) is invariant by $F \times G(t, \cdot)$. Hence we apply the Invariance Theorem (see [8], [1, Thm. 4.6.2]). □

In particular, we have obtained a sufficient condition for the hazy input-output set-valued map I_+ to be nontrivial.

First, it will be convenient to introduce the following definition.

DEFINITION 3.2. Let us consider $F : [0, T] \times X \rightsquigarrow X$ and $H : [0, T] \times X \rightsquigarrow Y$. We shall say that a nontrivial set-valued map $G : [0, T] \times Y \rightsquigarrow Y$ is a **Lipschitzian square projection** of a set-valued map $F : [0, T] \times X \rightsquigarrow X$ by H if and only if

(i) $F \times G$ is Lipschitzian around $[0, T] \times$ Graph (H),

(ii) $\forall (x, y) \in \text{Graph}\,(H)$, $G(t, y) \subset (DH(x, y) \square F)(t, x)$.

Therefore, for being able to use nontrivial hazy input-output maps, we shall use the following consequence of Proposition 3.1.

PROPOSITION 3.2. *Let us assume that $F : [0, T] \times X \rightsquigarrow X$ and $H : X \rightsquigarrow Y$ are given. If there exists a Lipschitzian square projection of F by H, then the hazy input-output map $I_+ := H \square \mathcal{S}$ has nonempty values for any initial value $y_0 \in H(x_0)$.*

Remark. When the observation map H is single-valued and differentiable, then conditions (19) and (20) become, respectively,

(i) $\forall y \in H^{-1}(x)$, $G(t, y) \cap (\cup_{v \in F(t,x)} H'(x)(v)) \neq \emptyset$
or $G(t, y) \cap (H'(x) \circ F)(t, x) \neq \emptyset$,

(ii) $\forall y \in H^{-1}(x)$, $G(t, y) \subset \cap_{v \in F(t,x)} H'(x)(v)$
$=: (H'(x) \square F)(t, x)$.

When $G = g$ is a single-valued map, we obtain naturally the following consequence.

COROLLARY 3.1. *Let us consider a closed set-valued map H from X to Y.*

1) *Let us assume that F is an upper semicontinuous set-valued map with nonempty compact convex images and with linear growth and that there exists a continuous selection g with linear growth of the product*

$$\forall (x, y) \in \text{Graph}\,(H), \quad g(t, y) \in (DH(x, y) \circ F)(t, x).$$

Then property (18)(a) *holds true.*

2) *Let us assume that $F \times g$ is Lipschitzian on a neighborhood of* $[0, T] \times \text{Graph}\,(H)$ *with linear growth. If g satisfies*

$$\forall (x, y) \in \text{Graph}\,(H), \quad g(t, y) \in (DH(x, y) \square F)(t, x),$$

then property (18)(b) *is satisfied.*

Remark. Naturally, these formulas have their analogues when the observation maps are time-dependent.

Conditions (19) and (20) becomes, respectively,

(i) $\forall (t, x, y) \in \text{Graph}\,(H)$, $G(t, y) \cap (\cup_{v \in F(t,x)} DH(t, x, y)(1, v)) \neq \emptyset$,

(ii) $\forall (t, x, y) \in \text{Graph}\,(H)$, $G(t, y) \subset \cap_{v \in F(t,x)} DH(t, x, y)(1, v)$.

When the observation map H is single-valued and differentiable, then these conditions can be written in the form

(i) $\forall (t, x) \in \text{Dom}\,(H)$,
$G(t, H(x)) \cap (\partial / \partial t\, H(t, x) + \cup_{v \in F(t,x)} H'_x(t, x)v) \neq \emptyset$, or
$G(t, H(x)) \cap (\partial / \partial t\, H(t, x) + (H'_x(t, x) \circ F)(t, x)) \neq \emptyset$;

(ii) $\forall (t, x) \in \text{Dom}\,(H)$,
$G(t, H(x)) \subset \partial / \partial t\, H(t, x) + \cap_{v \in F(t,x)} H'_x(t, x)v$
$=: \partial / \partial t\, H(t, x) + (H'_x(t, x) \square F)(t, x)$.

Remark. We observe that when the set-valued maps F and G are time-independent, Proposition 3.1 can be reformulated in terms of commutativity of schemes for square products.

Let us denote by Φ the solution map associating to any y_0 a solution to the differential inclusion (equation) (17) starting at y_0 (when G is single-valued and Lipschitzian such solution is unique).

Then we can deduce that property (18)(b) is equivalent to

$$\forall y_0 \in \text{Im}\,(H), \quad \Phi(y_0) \subset ((H \square \mathcal{S}) \square H^{-1})(y_0).$$

Condition (20) becomes: for all $y \in \text{Im}\,(H)$,

$$G(y) \subset \bigcap_{x \in H^{-1}(y)} \bigcap_{v \in F(x)} DH(x, y)(v) := (DH(x, y) \square F) \square H^{-1}(y).$$

In other words, the second part of Proposition 3.1 implies that if the scheme

$$\begin{array}{ccc} & X & \overset{F}{\rightsquigarrow} & X & \\ H^{-1} & \uparrow & \overset{G}{\rightsquigarrow} & \downarrow & DH(x, y) \\ & Y & & Y & \end{array}$$

is "commutative for the square products," then the derived scheme

$$\begin{array}{ccccc} & X & & \overset{\mathscr{S}}{\rightsquigarrow} & \mathscr{C}(0, T; X) \\ H & \Updownarrow & H^{-1} & \downarrow & H \\ & Y & & \overset{\Phi}{\rightsquigarrow} & \mathscr{C}(0, T; Y) \end{array}$$

is also commutative for the square products.

4. Hazy and sharp observability. The observability concepts deal with the possibility of recovering the input—here, the initial state—from the observation of the evolution of the state. In other words, they are related to the injectivity of the sharp and hazy input-output set-valued maps, or, more generally, to the single-valuedness of the inverses of those input-output maps.

So, we start with precise definitions.

DEFINITION 4.1. Let $\mathscr{F}: X \rightsquigarrow Y$ be a set-valued map. We shall say that it enjoys **local inverse single-valuedness at** an element (x^*, y^*) of its graph if and only if there exists a neighborhood $N(x^*)$ such that

$$\{x \,|\, y^* \in \mathscr{F}(x)\} \cap N(x^*) = \{x^*\}.$$

If the neighborhood $N(x^*)$ coincides with the domain of $\mathscr{F}$, $\mathscr{F}$ is said to have **(global) inverse single-valuedness** at y^*.

We shall say that it is **locally injective** around x^* if and only if there exists a neighborhood $N(x^*)$ such that, for all $x_1 \neq x_2 \in N(x^*)$, we have $\mathscr{F}(x_1) \cap \mathscr{F}(x_2) = \varnothing$. It is said to be (**globally**) **injective** if we can take for neighborhood $N(x^*)$ the whole domain of $\mathscr{F}$.

With these definitions at hand, we are able to adapt some of the observability concepts to the set-valued case.

DEFINITION 4.2. Assume that the sharp and hazy input-output maps are defined on nonempty open subsets. Let $y^* \in H(\mathscr{S}(x_0))$ be an observation associated with an initial state x_0.

We shall say that the system is **sharply observable at** (respectively, **locally sharply observable at**) (x_0, y^*) if and only if the sharp input-output map I_- enjoys the global inverse single-valuedness (respectively, **local**) at (x_0, y^*).

Hazily observable and locally hazily observable systems are defined in the same way when the sharp input-output map is replaced by the hazy input-output map I_+.

The system is said to be **hazily (locally) observable around** x_0 if the hazy input-output map I_+ is (*locally*) injective around x_0.

Remarks. Several obvious remarks are in order. We observe that the system is sharply locally observable **at** (x_0, y^*) if and only if there exists a neighborhood $N(x_0)$ of x_0 such that

$$\text{If } x(\cdot) \in \mathscr{S}(N(x_0)) \text{ is such that } y^*(\cdot) \in H(x(\cdot)), \text{ then } x(0) = x_0,$$

i.e., sharp observability at (x_0, y^*) means that an observation $y^*(\cdot)$ characterizes the input x_0.

The system is hazily locally observable **at** (x_0, y^*) if and only if there exists a neighborhood $N(x_0)$ of x_0 such that, for all $x_1 \in N(x_0)$,

$$\text{If } \forall x(\cdot) \in \mathscr{S}(x_1),\ y^*(\cdot) \in H(x(\cdot)), \text{ then } x_1 = x_0.$$

It is also clear that sharp local (respectively, global) observability implies hazy local (respectively, global) observability.

We mention that if we consider two systems $\mathcal{F}_1$ and $\mathcal{F}_2$ such that

$$\forall x \in X, \quad \mathcal{F}_1(x) \subset \mathcal{F}_2(x),$$

then

1. If $\mathcal{F}_2$ is sharply locally (respectively globally) observable, so is $\mathcal{F}_1$;
2. If $\mathcal{F}_1$ is hazily locally (respectively globally) observable, so is $\mathcal{F}_2$.

We shall derive local observability and injectivity of a set-valued map $\mathcal{F}: X \rightsquigarrow Y$ from a general principle based on the differential calculus of set-valued maps.

For that purpose, we shall use its contingent and paratingent derivatives $D\mathcal{F}(x^*, y^*)$ and $P\mathcal{F}(x^*, y^*)$, which are closed processes from X to Y (see the previous section for precise definitions).

Since $0 \in D\mathcal{F}(x^*, y^*)(0)$, we observe that to say that the "linearized map" $D\mathcal{F}(x^*, y^*)$ enjoys the inverse single-valuedness at zero amounts to saying that the inverse image $D\mathcal{F}(x^*, y^*)^{-1}(0)$ contains only one element, i.e., that its kernel $\operatorname{Ker} D\mathcal{F}(x^*, y^*)$ is equal to zero, where the kernel is naturally defined by

$$\operatorname{Ker} D\mathcal{F}(x^*, y^*) := D\mathcal{F}(x^*, y^*)^{-1}(0).$$

THEOREM 4.1. *Let $\mathcal{F}$ be a set-valued map from a finite dimensional vector-space X to a Banach space Y and (x^*, y^*) belong to its graph.*

1. *If the kernel of the contingent derivative $D\mathcal{F}(x^*, y^*)$ of $\mathcal{F}$ at (x^*, y^*) is equal to $\{0\}$, then there exists a neighborhood $N(x^*)$ such that*

$$\{x \mid y^* \in \mathcal{F}(x)\} \cap N(x^*) = \{x^*\}. \tag{21}$$

2. *Let us assume that there exists $\gamma > 0$ such that $\mathcal{F}(x^* + \gamma B)$ is relatively compact and that $\mathcal{F}$ has a closed graph (then $\mathcal{F}(x^* + \gamma B)$ is compact). If for all $y \in \mathcal{F}(x^*)$ the kernels of the paratingent derivatives $P\mathcal{F}(x^*, y)$ of $\mathcal{F}$ at (x^*, y) are equal to $\{0\}$, then $\mathcal{F}$ is locally injective around x^*.*

Proof. 1. Assume that the conclusion (21) is false. Then there exists a sequence of elements $x_n \neq x^*$ converging to x^* satisfying

$$\forall n \geqq 0, \quad y^* \in \mathcal{F}(x_n).$$

Let us set $h_n := \|x_n - x^*\|$, which converges to zero, and

$$u_n := (x_n - x^*)/h_n.$$

The elements u_n do belong to the unit sphere, which is compact. Hence a subsequence (again denoted) u_n does converge to some u different from zero. Since the above equation can be written as

$$\forall n \geqq 0, \quad y^* + h_n 0 \in \mathcal{F}(x^* + h_n u_n)$$

we deduce that

$$0 \in D\mathcal{F}(x^*, y^*)(u).$$

Hence we have proved the existence of a nonzero element of the kernel of $D\mathcal{F}(x^*, y^*)$, which is a contradiction.

2. Assume that $\mathcal{F}$ is not locally injective. Then there exists a sequence of elements $x_n^1, x_n^2 \in N(x^*)$, $x_n^1 \neq x_n^2$, converging to x^* and y_n satisfying

$$\forall n \geqq 0, \quad y_n \in \mathcal{F}(x_n^1) \cap \mathcal{F}(x_n^2).$$

Let us set $h_n := \|x_n^1 - x_n^2\|$, which converges to zero, and

$$u^n := (x_n^1 - x_n^2)/h_n.$$

The elements u_n do belong to the unit sphere, which is compact. Hence a subsequence (again denoted) u_n does converge to some u different from zero.

Then for all large n

$$y_n \in \mathcal{F}(x_n^1) \cap \mathcal{F}(x_n^2) := \mathcal{F}(x_n^2 + h_n u_n) \cap \mathcal{F}(x_n^2) \subset \mathcal{F}(x^* + \gamma B).$$

We deduce that a subsequence (again denoted) y_n converges to some $y \in \mathcal{F}(x^*)$ (because Graph $(\mathcal{F})$ is closed).

Since the above equation implies that

$$\forall n \geqq 0, \quad y_n + h_n 0 \in \mathcal{F}(x_n^2 + h_n u_n)$$

we deduce that

$$0 \in P\mathcal{F}(x^*, y)(u).$$

Hence we have proved the existence of a nonzero element of the kernel of $P\mathcal{F}(x^*, y)$, which is a contradiction. □

When $\mathcal{F}$ is convex (i.e., its graph is convex), we have a simple criterion for global observability: Define the algebraic derivative $D_a\mathcal{F}(x, y)$ of $\mathcal{F}$ at (x, y) by

$$v \in D_a\mathcal{F}(x, y)(u) \Leftrightarrow \exists h > 0 \quad \text{such that } y + hv \in \mathcal{F}(x + hu).$$

Then $\overline{\text{Graph } D_a\mathcal{F}(x, y)} = \text{Graph } D\mathcal{F}(x, y)$.

PROPOSITION 4.1. *Let $\mathcal{F}$ be a convex set-valued map from a Banach space X to a Banach space Y and (x^*, y^*) belong to its graph. If the kernel of $D_aF(x^*, y^*)$ is equal to zero, then*

$$x \neq x^* \Rightarrow y^* \notin \mathcal{F}(x).$$

Proof. If not, there exists $x \neq x^*$ such that $y^* \in \mathcal{F}(x)$. We set $u := x - x^*$. Equality

$$y^* + 0 = y^* \in \mathcal{F}(x) = \mathcal{F}(x^* + u)$$

implies that u, which is different from zero, does belong to the kernel of $D_a\mathcal{F}(x^*, y^*)$. □

Therefore, using this result for proving sufficient conditions for sharp and/or hazy observability, we need:

1. To have chain rule formulas for composition and square products of set-valued maps;
2. To characterize the derivatives of the solution map in terms of solutions to the associated variational equations.

The next proposition provides chain rule formulas for square products that are needed for estimating the contingent and paratingent derivatives of the hazy input-output map I_+ in terms of the adjacent and circatangent derivatives of the map G at (x^*, y^*).

Despite the fact that both adjacent and circatangent derivatives can be defined for any set-valued map F, the formulas are simpler when we deal with pseudo-Lipschitzian set-valued maps. Since we use them only in this context in this paper, we provide their definitions in this limited case.

DEFINITION 4.3. Let (x, y) belong to the graph of a set-valued map $F: X \rightsquigarrow Y$ from a normed space X to another Y. Assume that F is pseudo-Lipschitzian around $(x, y) \in \text{Graph } (F)$, then the **adjacent derivative** $D^\flat F(x, y)$ and the **circatangent derivative** $CF(x, y)$ are the set-valued maps from X to Y, respectively, defined by

$$v \in D^\flat F(x, y)(u) \Leftrightarrow \lim_{h \to 0+} \left(v, \frac{F(x + hu) - y}{h} \right) = 0$$

and

$$v \in CF(x, y)(u) \Leftrightarrow \lim_{h \to 0+, (x', y') \to_F (x, y)} d\left(v, \frac{F(x'+hu) - y'}{h}\right) = 0.$$

Several remarks are in order. First, all these derivatives are positively homogeneous and their graphs are closed.

We observe the obvious inclusions

$$CF(x, y)(u) \subset D^\flat F(x, y)(u) \subset DF(x, y)(u) \subset PF(x, y)(u)$$

and that the definitions of contingent and adjacent derivatives on the one hand, the paratingent and circatangent derivatives, on the other, are symmetric. When $F := f$ is single-valued, we set

$$Df(x) := Df(x, f(x)), \quad D^\flat f(x) := D^\flat f(x, f(x)), \quad Cf(x) := Cf(x, f(x)).$$

We see easily that

$$Df(x)(u) \ni f'(x)u \qquad \text{if } f \text{ is Gâteaux differentiable,}$$

$$D^\flat f(x)(u) = f'(x)u \qquad \text{if } f \text{ is Fréchet differentiable,}$$

$$Cf(x)(u) = f'(x)u \qquad \text{if } f \text{ is continuously differentiable.}$$

The choice of these strange limits is dictated by the fact that the graph of each of these derivatives is the corresponding tangent cone to the graph of F at (x, y). (The graphs of the circatangent derivatives are the Clarke tangent cones to the graphs, which are always convex.)

The most familiar instance of set-valued maps is the inverse of a noninjective single-valued map. The **derivative of the inverse of a set-valued map F is the inverse of the derivative:**

$$P(F)^{-1}(y, x) = PF(x, y)^{-1},$$

$$D(F)^{-1}(y, x) = DF(x, y)^{-1},$$

$$D^\flat(F)^{-1}(y, x) = D^\flat F(x, y)^{-1},$$

$$C(F)^{-1}(y, x) = CF(x, y)^{-1},$$

and enjoy a now well investigated calculus.

The circatangent derivatives are closed convex processes, because their graph are closed convex cones, i.e., they are set-valued analogues of the continuous linear operators. We refer to [21] and [2, Chap. 7] for various properties of closed convex processes.

We say that a set-valued map F is **derivable** at $(x, y) \in \text{Graph}(F)$ if $DF(x, y) = D^\flat F(x, y)$ and that it is **derivable** if it is derivable at every point of its graph.

We say that a set-valued map F is **sleek** at $(x, y) \in \text{Graph}(F)$ if

$$\text{Graph}(F) \ni (x', y') \rightsquigarrow \text{Graph}(DF(x', y')) \text{ is lower semicontinuous at } (x, y)$$

and it is **sleek** if it is sleek at every point of its graph. In this case, we can prove that **the contingent, adjacent, and circatangent derivatives coincide.**

PROPOSITION 4.2. *Let us consider a set-valued map G from a Banach space X to a Banach space Y and a single-valued map H from Y to a Banach space Z. Assume that G is Lipschitzian around x^*. If H is differentiable at some $y^* \in G(x^*)$, then*

1. *The contingent derivative of $H \square G$ is contained in the square product of the derivative of H and the adjacent derivative of G:*

$$\forall u \in \mathrm{Dom}\,(D^{\flat}G(x^*, y^*)), \quad D(H \square G)(x^*, H(y^*))(u) \subset H'(y^*) \square D^{\flat}G(x^*, y^*)(u);$$

2. *If H is continuously differentiable around y^*, then the paratingent derivative of $H \square G$ is contained in the square product of the derivative of H and the circatangent derivative of G:*

$$\forall u \in \mathrm{Dom}\,(CG(x^*, y^*)), \quad P(H \square G)(x^*, H(y^*))(u) \subset H'(y^*) \square CG(x^*, y^*)(u).$$

Proof. 1. Let $u \in \mathrm{Dom}\, D^{\flat}G(x^*, y^*)$ and w belong to $D(H \square G)(x^*, H(y^*))(u)$. Hence there exist a sequence $h_n > 0$ converging to zero and sequences of elements u_n, w_n converging to u and w, respectively, such that

$$\forall n \geqq 0, \quad H(y^*) + h_n w_n \in \bigcap_{y \in G(x^* + h_n u_n)} H(y).$$

Take now any v in $D^{\flat}G(x^*, y^*)(u)$. Since G is Lipschitzian around x^*, there exists a sequence of elements v_n converging to v such that

$$\forall n \geqq 0, \quad y^* + h_n v_n \in G(x^* + h_n u_n).$$

Therefore,

$$\forall n \geqq 0, \quad H(y^*) + h_n w_n = H(y^* + h_n v_n).$$

Since H is differentiable at y^*, we infer that

$$H'(y^*)v = w.$$

Since this is true for every element v of $D^{\flat}G(x^*, y^*)(u)$, we deduce that

$$w \in \bigcap_{v \in D^{\flat}G(x^*, y^*)(u)} H'(y^*)v = H'(y^*) \square D^{\flat}G(x^*, y^*)(u).$$

2. Let $u \in \mathrm{Dom}\, CG(x^*, y^*)$ and w belong to $P(H \square G)(x^*, H(y^*))(u)$. Hence there exist a sequence $h_n > 0$ converging to zero and sequences of elements $(x_n, z_n) \in \mathrm{Graph}\,(H \square G)$, u_n and w_n converging to (x^*, z^*), u and w, respectively, such that

$$\forall n \geqq 0, \quad z_n + h_n w_n \in \bigcap_{y \in G(x_n + h_n u_n)} H(y).$$

The set-valued map G being Lipschitzian, there exists a sequence of elements $y_n \in G(x_n)$ converging to y^*. By definition of the square product, we know that $z_n = H(y_n)$.

Now take any v in $CG(x^*, y^*)(u)$. Since G is Lipschitzian around x^*, there exists a sequence of elements v_n converging to v such that

$$\forall n \geqq 0, \quad y_n + h_n v_n \in G(x_n + h_n u_n).$$

Therefore,

$$\forall n \geqq 0, \quad H(y_n) + h_n w_n = H(y_n + h_n v_n).$$

Since H is continuously differentiable around y^*, we infer that

$$H'(y^*)v = w.$$

Since this is true for every element v of $CG(x^*, y^*)(u)$, we deduce that

$$w \in \bigcap_{v \in CG(x^*, y^*)(u)} H'(y^*)v = H'(y^*) \square CG(x^*, y^*)(u). \qquad \square$$

For the usual product, it is easy to check that

$$H'(y) \circ DG(x, y)(u) \subset D(H \circ G)(x, H(y))(u).$$

Naturally, equality holds true for algebraic derivatives: If $H \in \mathscr{L}(Y, Z)$ is a linear operator, we check that

$$H \circ D_a G(x, y)(u) = D_a(H \circ G)(x, H(y))(u). \tag{22}$$

We do not know for the time other elegant criteria implying the chain rule for the usual composition product of set-valued maps in infinite-dimensional spaces. Let us mention, however, the following result involving the **co-subdifferential** $DG(x_0, y_0)^{0*}$, which is the closed convex process from Y^* to X^* defined by

$$p \in DG(x, y)^{0*}(q) \quad \text{if and only if } \forall (x', y') \in \text{Graph}\,(G), \quad \langle p, x' - x\rangle \leqq \langle q, y' - y\rangle.$$

Let us assume that H is a continuous linear operator $H \in \mathscr{L}(Y, Z)$ from Y to Z. Equality

$$D(H \circ G)(x_0, Hy_0)(u) = \overline{H \circ DG(x_0, y_0)(u)}$$

holds true if X and Y are reflexive Banach spaces and the co-subdifferential of G at (x_0, y_0) satisfies

$$\text{Im}\,(H^*) + \text{Dom}\,(DG(x_0, y_0)^{0*}) = Y^*.$$

Furthermore, this condition implies that the kernels of $D(H \circ G)(x_0, Hy_0)$ and $\overline{H \circ DG(x_0, y_0)}$ are equal to $\{0\}$ (see [6]).

5. Variational inclusions. We now provide estimates of the contingent, adjacent, and circatangent derivatives of the solution map $\mathscr{S}$ associated to the differential inclusion

$$x'(t) \in F(t, x(t)), \quad \text{a.e. in } [0, T]. \tag{23}$$

We shall express these estimates in terms of the solution maps of adequate linearizations of differential inclusion (23) of the form

$$w'(t) \in F'(t, x(t), x'(t))(w(t))$$

where for almost all t, $F'(t, x, y)(u)$ denotes one of the (contingent, adjacent, or circatangent) derivatives of the set-valued map $F(t, \cdot, \cdot)$ at a point (x, y) of its graph (in this section the set-valued map F is regarded as a family of set-valued maps $x \rightsquigarrow F(t, x)$ and *the derivatives are taken with respect to the state variable only*).

These linearized differential inclusions can be called the **variational inclusions**, since they extend (in various ways) the classical variational equations of ordinary differential equations.

Let $\bar{x}$ be a solution of the differential inclusion (23). We assume that F satisfies the following assumptions:

$$\begin{aligned} &\text{(i)} && \forall x \in X \text{ the set-valued map } F(\cdot, x) \text{ is measurable,} \\ &\text{(ii)} && \forall t \in [0, T],\ \forall x \in X,\ F(t, x) \text{ is a nonempty closed set,} \\ &\text{(iii)} && \exists \beta > 0,\ k(\cdot) \in L^1(0, T) \text{ such that for almost all } t \in [0, T] \\ & && \text{the map } F(t, \cdot) \text{ is } k(t) - \text{Lipschitz on } \bar{x}(t) + \beta B. \end{aligned} \tag{24}$$

Under the above assumptions the map $x_0 \rightsquigarrow \mathscr{S}(x_0)$ is pseudo-Lipschitzian around $(\bar{x}(0), \bar{x})$. Consider the **adjacent variational inclusion**, which is the "linearized" along the trajectory $\bar{x}$ inclusion

$$\begin{aligned} &w'(t) \in D^\flat F(t, \bar{x}(t), \bar{x}'(t))(w(t)) \quad \text{a.e. in } [0, T], \\ &w(0) = u \end{aligned} \tag{25}$$

where $u \in X$. In Theorems 5.1 and 5.2 below we consider the solution map $\mathscr{S}$ as the set-valued map from $\mathbf{R}^n$ to the Sobolev space $W^{1,1}(0, T; \mathbf{R}^n)$.

THEOREM 5.1 (adjacent variational inclusion [11]). *If the assumptions* (24) *hold true, then for all* $u \in X$, *every solution* $w \in W^{1,1}(0, T; X)$ *to the linearized inclusion* (25) *satisfies* $w \in D^\flat \mathcal{S}(\bar{x}(0), \bar{x})(u)$.

In other words,

$$\{w(\cdot) \mid w'(t) \in D^\flat F(t, \bar{x}(t), \bar{x}'(t))(w(t)),\ w(0) = u\} \subset D^\flat \mathcal{S}(\bar{x}(0), \bar{x})(u).$$

Proof. Filippov's theorem (see, for example, [1, Thm. 2.4.1, p. 120]) implies that the map $u \to \mathcal{S}(u)$ is pseudo-Lipschitzian on a neighborhood of $(\bar{x}(0), \bar{x})$. Let $h_n > 0$, $n = 1, 2, \ldots$ be a sequence converging to zero. Then, by the very definition of the adjacent derivative, for almost all $t \in [0, T]$,

$$\lim_{n\to\infty} d\left(w'(t), \frac{F(t, \bar{x}(t) + h_n w(t)) - \bar{x}'(t)}{h_n}\right) = 0. \tag{26}$$

Moreover, since $\bar{x}'(t) \in F(t, \bar{x}(t))$ almost everywhere in $[0, T]$, by (24), for all sufficiently large n and almost all $t \in [0, T]$

$$d(\bar{x}'(t) + h_n w'(t), F(t, \bar{x}(t) + h_n w(t))) \leqq h_n(\|w'(t)\| + k(t)\|w(t)\|).$$

This, (26), and the Lebesgue dominated convergence theorem yield

$$\int_0^T d(\bar{x}'(t) + h_n w'(t), F(t, \bar{x}(t) + h_n w(t)))\, dt = o(h_n) \tag{27}$$

where $\lim_{n\to\infty} o(h_n)/h_n = 0$. By the Filippov Theorem (see, for example, [1, Thm. 2.4.1, p. 120]) and by (27) there exist $M \geqq 0$ and solutions $y_n \in \mathcal{S}(\bar{x}(0) + h_n u)$ satisfying

$$\|y_n' - \bar{x}' - h_n w'\|_{L^1(0,T;X)} \leqq M o(h_n).$$

Since $(y_n(0) - \bar{x}(0))/h_n = u = w(0)$ this implies that

$$\lim_{n\to\infty} \frac{y_n - \bar{x}}{h_n} = w \quad \text{in } C(0, T; X), \qquad \lim_{n\to\infty} \frac{y_n' - \bar{x}'}{h_n} = w' \quad \text{in } L^1(0, T; X).$$

Hence

$$\lim_{n\to\infty} d\left(w, \frac{\mathcal{S}(\bar{x}(0) + h_n u) - \bar{x}}{h_n}\right) = 0.$$

Since u and w are arbitrary the proof is complete. □

Next consider the **circatangent variational inclusion,** which is the linearization involving circatangent derivatives:

$$\begin{aligned} &w'(t) \in CF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \quad \text{a.e. in } [0, T], \\ &w(0) = u \end{aligned} \tag{28}$$

where $u \in X$. The next theorem is similar to Lemma 4.11 of [11].

THEOREM 5.2 (circatangent variational inclusion). *Assume that conditions* (24) *hold true. Then for all* $u \in X$, *every solution* $w \in W^{1,1}(0, T; X)$ *to the linearized inclusion* (28) *satisfies* $w \in C\mathcal{S}(\bar{x}(0), \bar{x})(u)$.

In other words,

$$\{w(\cdot) \mid w'(t) \in CF(t, \bar{x}(t), \bar{x}'(t))(w(t)),\ w(0) = u\} \subset C\mathcal{S}(\bar{x}(0), \bar{x})(u).$$

Proof. By Filippov's theorem the map $u \to \mathcal{S}(u)$ is pseudo-Lipschitzian on a neighborhood of $(\bar{x}(0), \bar{x})$. Consider a sequence x_n of trajectories of (23) converging to $\bar{x}$ in $W^{1,1}(0, T; X)$ and let $h_n \to 0+$. Then there exists a subsequence $x_j := x_{n_j}$ such that

$$\lim_{j\to\infty} x_j'(t) = \bar{x}'(t) \quad \text{a.e. in } [0, T]. \tag{29}$$

Set $\lambda_j = h_{n_j}$. Then, by definition of circatangent derivative and by (29), for almost all $t \in [0, T]$

$$\lim_{j\to\infty} d\left(w'(t), \frac{F(t, x_j(t)+\lambda_j w(t)) - x_j'(t)}{\lambda_j}\right) = 0. \tag{30}$$

Moreover, using the fact that $x_j'(t) \in F(t, x_j(t))$ almost everywhere in $[0, T]$, we obtain that for almost all $t \in [0, T]$ and for all j large enough

$$d\left(x_j'(t)+\lambda_j w'(t), F(t, x_j(t)+\lambda_j w(t))\right) \leqq \lambda_j(\|w'(t)\| + k(t)\|w(t)\|).$$

This, (30), and the Lebesgue dominated convergence theorem yield

$$\int_0^T d\left(x_j'(t)+\lambda_j w'(t), F(t, x_j(t)+\lambda_j w(t))\right) dt = o(\lambda_j) \tag{31}$$

where $\lim_{j\to\infty} o(\lambda_j)/\lambda_j = 0$. By the Filippov Theorem and (31), there exist $M \geqq 0$ and solutions $y_j \in \mathcal{S}(x_j(0)+\lambda_j u)$ satisfying

$$\|y_j' - x_j' - \lambda_j w'\| L^1(0, T; X) \leqq M o(\lambda_j).$$

Since $(y_j(0) - x_j(0))/\lambda_j = u = w(0)$, this implies that

$$\lim_{j\to\infty} \frac{y_j - x_j}{h_{n_j}} = w \quad \text{in } C(0, T; X), \qquad \lim_{j\to\infty} \frac{y_j' - x_j'}{h_{n_j}} = w' \quad \text{in } L^1(0, T; X).$$

Hence

$$\lim_{j\to\infty} d\left(w, \frac{\mathcal{S}(x_j(0)+h_{n_j}u) - x_j}{h_{n_j}}\right) = 0. \tag{32}$$

Therefore we have proved that for every sequence of solutions x_n to (23) converging to $\bar{x}$ and every sequence $h_n \to 0+$, there exists a subsequence $x_j = x_{n_j}$ that satisfies (32). This yields that for every sequence of solutions x_n converging to $\bar{x}$ and $h_n \to 0+$

$$\lim_{n\to\infty} d\left(w, \frac{\mathcal{S}(x_n(0)+h_n u) - x_n}{h_n}\right) = 0.$$

Since u and w are arbitrary the proof is complete. □

We now consider the **contingent variational inclusion**

$$\begin{aligned} &w'(t) \in \overline{\text{co}}\, DF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \quad \text{a.e. in } [0, T], \\ &w(0) = u. \end{aligned} \tag{33}$$

THEOREM 5.3. (contingent variational inclusion). *Let us consider the solution map $\mathcal{S}$ as a set-valued map from $\mathbf{R}^n$ to $W^{1,\infty}(0, T; \mathbf{R}^n)$ supplied with the weak-$*$ topology and let $\bar{x}(\cdot)$ be a solution of the differential inclusion* (23) *starting at x_0. Then the contingent derivative $D\mathcal{S}(x_0, \bar{x}(\cdot))$ of the solution map is contained in the solution map of the contingent variational inclusion* (33), *in the sense that*

$$D\mathcal{S}(x_0, \bar{x}(\cdot))(u) \subset \{w(\cdot) \mid w'(t) \in \overline{\text{co}}\, DF(t, \bar{x}(t), \bar{x}'(t))(w(t)),\ w(0) = u\}. \tag{34}$$

To prove the above theorem we need to recall a property of Kuratowski's upper limit: Let K_n be a sequence of subsets of a Banach space X. We say that the set

$$\operatorname*{co\text{-}lim\,sup}_{n\to\infty} K_n := \bigcap_{N>0} \overline{\text{co}} \bigcup_{n>N} K_n$$

is the **convex upper limit** of the sequence K_n. Recall that the **Kuratowski upper limit** of the K_n's is defined by

$$\limsup_{n\to\infty} K_n := \bigcap_{\varepsilon>0} \bigcap_{N>0} \bigcup_{n\geqq N} (K_n + \varepsilon B).$$

It is clear that the convex upper limit is closed and convex. Moreover, since $\operatorname{co} \bigcup_{n\geqq N} (K_n + \varepsilon B) = \operatorname{co} \bigcup_{n\geqq N} K_n + \varepsilon B$, we obtain

$$\operatorname{co\text{-}lim\,sup}_{n\to\infty} K_n := \bigcap_{\varepsilon>0} \bigcap_{N>0} \overline{\operatorname{co}} \bigcup_{n>N} (K_n + \varepsilon B).$$

Hence the convex upper limit contains the closed convex hull of the Kuratowski upper limit. The convex hull of an upper limit and the convex upper limit are related by the following lemma.

LEMMA 5.1. *Let us consider a sequence of subsets K_n contained in a bounded subset of a finite-dimensional vector-space X. Then*

$$\operatorname{co\text{-}lim\,sup}_{n\to\infty} K_n = \overline{\operatorname{co}}(\limsup_{n\to\infty} K_n).$$

Proof. Since an element x of co-lim $\sup_{n\to\infty} K_n$ is the limit of a subsequence of convex combinations v_N of elements of $\bigcup_{n>N} K_n$ and since the dimension of X is an integer p, Carathéodory's Theorem allows us to write

$$v_N := \sum_{j=0}^{p} a_j^N x_{N_j} \quad \text{where } \sum_{j=0}^{p} a_j^N = 1, \quad a_j^N \geqq 0$$

where $N_j \geqq N$ and where x_{N_j} belongs to K_{N_j}. The vector a^N of $p+1$ components a_j^N contains a converging subsequence (again denoted) a^N that converges to some non-negative vector a of $p+1$ components a_j such that $\sum_{j=0}^{p} a_j = 1$.

The subsets K_n being contained in a compact subset, we can extract successively subsequences (again denoted) x_{N_j} converging to elements x_j that belong to the Kuratowski upper limit of the subsets K_n. Hence x is equal to the convex combination $\sum_{j=0}^{p} a_j x_j$ and the lemma is proved. □

Proof. Fix a direction $u \in \mathbf{R}^n$ and let $w(\cdot)$ belong to $D\mathscr{S}(x_0, \bar{x}(\cdot))(u)$. By definition of the contingent derivative, there exist sequences of elements $h_n \to 0+$, $u_n \to u$ and $w_n(\cdot) \to w(\cdot)$ in the weak-* topology of $W^{1,\infty}(0, T; \mathbf{R}^n)$ and $c > 0$ satisfying

$$\begin{aligned} &\text{(i)} \quad \|w_n'(t)\| \leqq c \quad \text{a.e. in } [0, T], \\ &\text{(ii)} \quad \bar{x}'(t) + h_n w_n'(t) \in F(t, \bar{x}(t) + h_n w_n(t)) \quad \text{a.e. in } [0, T], \\ &\text{(iii)} \quad w_n(0) = u_n. \end{aligned} \tag{35}$$

Hence

$$\begin{aligned} &\text{(i)} \quad w_n(\cdot) \text{ converges pointwise to } w(\cdot), \\ &\text{(ii)} \quad w_n'(\cdot) \text{ converges weakly in } L^1(0, T; \mathbf{R}^n) \text{ to } w'(\cdot). \end{aligned} \tag{36}$$

By Mazur's Theorem and (36)(ii), a sequence of convex combinations

$$v_m(t) := \sum_{p=m}^{\infty} a_m^p w_p'(t)$$

converges strongly to $w'(\cdot)$ in $L^1(0, T; X)$. Therefore a subsequence (again denoted) $v_m(\cdot)$ converges to $w'(\cdot)$ almost everywhere. By (35)(i),(ii) for all p and almost all $t \in [0, T]$

$$w_p'(t) \in \frac{F(t, \bar{x}(t) + h_p w_p(t)) - \bar{x}'(t)}{h_p} \cap cB.$$

Let $t \in [0, T]$ be a point where $v_m(t)$ converges to $w'(t)$ and $x'(t) \in F(t, x(t))$. Fix an integer $n \geqq 1$ and $\varepsilon > 0$. By (36)(i), there exists m such that $h_p \leqq 1/n$ and $\|w_p(t) - w(t)\| \leqq 1/n$ for all $p \geqq m$.

Then, by setting

$$\Phi(y, h) := \frac{F(t, \bar{x}(t) + hy) - \bar{x}'(t)}{h} \cap cB$$

we obtain that

$$v_m(t) \in K_n := \operatorname{co}\left(\bigcup_{h \in]0, 1/n],\ y \in w(t) + B/n} \Phi(y, h) \right)$$

and therefore, by letting m go to ∞, that

$$w'(t) \in \overline{\operatorname{co}}\left(\bigcup_{h \in]0, 1/n],\ y \in w(t) + B/n} \Phi(y, h) \right).$$

Since this is true for any n, we deduce that $w'(t)$ belongs to the convex upper limit:

$$w'(t) \in \bigcap_{n \geqq 1} \overline{\operatorname{co}}\left(\bigcup_{h \in]0, 1/n],\ y \in w(t) + B/n} \Phi(y, h) \right).$$

Since the subsets $\Phi(y, h)$ are contained in the ball of radius c, we infer from the last lemma that $w'(t)$ belongs to the closed convex hull of the Kuratowski upper limit

$$w'(t) \in \overline{\operatorname{co}} \bigcap_{\varepsilon > 0, n \geqq 1} \left(\bigcup_{h \in]0, 1/n],\ y \in w(t) + B/n} (\Phi(y, h) + \varepsilon B) \right).$$

We observe now that

$$\bigcap_{\varepsilon > 0, n \geqq 1} \left(\bigcup_{h \in]0, 1/n],\ y \in w(t) + B/n} (\Phi(y, h) + \varepsilon B) \right) \subset DF(t, \bar{x}(t), \bar{x}'(t))(w(t))$$

to conclude that $w(\cdot)$ is a solution to the differential inclusion

$$w'(t) \in \overline{\operatorname{co}}\, DF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \quad \text{a.e. in } [0, T],$$
$$w(0) = u.$$

Since $w \in D\mathcal{S}(x_0, \bar{x}(\cdot))(u)$ is arbitrary we proved (34).

6. Local observability theorems. In this section we piece together the general principle on local inverse univocity and local injectivity (Theorem 4.1), the chain rule formulas (Proposition 4.2) and the estimates of the derivatives of the solution map in terms of solution maps of the variational equations (Theorems 5.1, 5.2 and 5.3) to prove the statements we have announced on local hazy and sharp observability.

Throughout the whole section we assume that H is differentiable and F has a linear growth. We impose also some regularity assumptions on the derivatives of F. In the next theorem it is assumed that $F(t, \cdot)$ is derivable in the sense that its contingent and adjacent derivatives do coincide.

THEOREM 6.1. *Let us assume that for every $t \in [0, T]$, $F(t, \cdot)$ is derivable, satisfies assumptions* (12), *and that it has a Lipschitzian square projection G by H. Let $\bar{x}(\cdot) \in \mathcal{S}(x_0)$. If the contingent variational inclusion*

(37) *for almost all $t \in [0, T]$, $w'(t) \in DF(t, \bar{x}(t), \bar{x}'(t))(w(t))$*

is globally hazily observable through $H'(\bar{x}(\cdot))$ at zero, then the system (23) *is locally hazily observable through H* **at** *$(x_0, H(\bar{x}))$.*

Proof. We apply the general principle (Theorem 4.1) to the hazy input-output map $I_+ := H \square \mathcal{S}$, which is defined since we have assumed that there exists a square projection G (see Definition 3.2 and Proposition 3.2). We have to prove that the kernel of the contingent derivative $DI_+(x_0, y_0)$ of I_+ (where $y_0 := H(\bar{x}(\cdot))$) is equal to zero. By Filippov's Theorem, the solution map $\mathcal{S}$ is Lipschitzian around x_0. Then we can apply Proposition 4.2 which states that for all $u \in \mathrm{Dom}\,(D^\flat \mathcal{S}(x_0, \bar{x}(\cdot)))$

$$DI_+(x_0, y_0)(u) \subset (H'(\bar{x}(\cdot)) \square D^\flat \mathcal{S}(x_0, \bar{x}(\cdot)))(u).$$

By Theorem 5.1, we know that for any $u \in X$, the set $\Phi(u)$ of solutions to the adjacent variational inclusion (25) starting at u is contained in the adjacent derivative of $\mathcal{S}$:

$$\begin{aligned} \Phi(u) &:= \{w(\cdot) \mid w'(t) \dot{\in} D^\flat F(t, \bar{x}(t), \bar{x}'(t))(w(t)) \text{ and } w(0) = u\} \\ &= \{w(\cdot) \mid w'(t) \in DF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \text{ and } w(0) = u\} \qquad (38) \\ &\subset D^\flat \mathcal{S}(x_0, \bar{x})(u). \end{aligned}$$

We also know that for all $(x, y) \in \mathrm{Graph}\,(F(t, \cdot))$, the contingent derivative $DF(tx, y)$ is $k(t)$-Lipschitz (see [12]). Hence, by the Filippov Theorem [1, Thm. 2.4.1, p. 120] for every $u \in \mathbf{R}^n$, the contingent variational inclusion (37) has a solution starting at u. Therefore, by (38), $\mathrm{Dom}\,(D^\flat \mathcal{S}(x_0, \bar{x}(\cdot)))$ is equal to the whole space. This yields

$$\forall u \in \mathbf{R}^n, \quad DI_+(x_0, y_0)(u) \subset (H'(\bar{x}) \square \Phi)(u)$$

so that the kernel of $DI_+(x_0, y_0)$ is contained in the kernel of $H'(\bar{x}) \square \Phi$. But to say that the kernel of $H'(\bar{x}) \square \Phi$ is equal to zero amounts to saying that the linearized system (37) is hazily globally observable at zero through $H'(\bar{x}(\cdot))$. Hence the kernel of $DI_+(x_0, y_0)$ is equal to zero, and thus, the inverse image of hazy input-output map $I_+^{-1}(y_0)$ contains locally a unique element x_0. □

Remark. The above result remains true with DF in (37) replaced by $D^\flat F$ if instead of derivability of F we assume that

$$\mathrm{Dom}\,(D^\flat \mathcal{S}(x_0, \bar{x}(\cdot))) = \mathbf{R}^n.$$

In the next theorem we assume that F is sleek, so that its contingent and circatangent derivatives do coincide.

THEOREM 6.2. *Let us assume that F is sleek, has convex images, satisfies assumptions* (12), *and that it has a Lipschitzian square projection G by H. If for all $\bar{x}(\cdot) \in \mathcal{S}(x_0)$ the contingent variational inclusion* (37) *is globally hazily observable through $H'(\bar{x}(\cdot))$* **at** 0, *then the system* (23) *is hazily observable through H* **around** x_0.

Proof. We apply the second part of the general principle on local injectivity (Theorem 4.1) to the hazy input-output map $I_+ := H \square \mathcal{S}$, which is defined since we have assumed that there exists a square projection G. We have to prove that the kernels of the paratingent derivatives $PI_+(x_0, y)$ of I_+ are equal to zero (where $y(\cdot) := H(\bar{x}(\cdot))$ and $\bar{x}(\cdot) \in \mathcal{S}(x_0)$). In the way similar to Theorem 2.2.1 of [1, p. 104], we prove that for all $\gamma > 0$, the set $\mathcal{S}(x_0 + \gamma B)$ is compact in $C(0, T; \mathbf{R}^n)$. Hence $I_+(x_0 + \gamma B)$ is relatively compact in $C(0, T; \mathbf{R}^n)$. By Filippov's Theorem, the solution map $\mathcal{S}$ is Lipschitzian around x_0. This and compactness of $\mathcal{S}(x_0 + \gamma B)$ imply that Graph (I_+) is a closed set. Then we can apply the second part of Proposition 4.2 which states that for all $u \in \mathrm{Dom}\,(C\mathcal{S}(x_0, \bar{x}(\cdot)))$

$$PI_+(x_0, y)(u) \subset H'(\bar{x}(\cdot)) \square C\mathcal{S}(x_0, \bar{x}(\cdot))(u).$$

By Theorem 5.2, we know that for all u, the set $\Phi(u)$ of solutions to the circatangent variational inclusion (24) starting at u is contained in the circatangent derivative of $\mathcal{S}$:

$$\begin{aligned}\Phi(u) &:= \{w(\cdot) \mid w'(t) \in CF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \text{ and } w(0) = u\} \\ &= \{w(\cdot) \mid w'(t) \in DF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \text{ and } w(0) = u\} \\ &\subset C\mathcal{S}(x_0, \bar{x})(u).\end{aligned}$$

But from the proof of Theorem 6.1 we know that $\mathrm{Dom}\,(\Phi) = \mathbf{R}^n$. Therefore,

$$PI_+(x_0, y)(u) \subset (H'(\bar{x}) \square \Phi)(u)$$

so that the kernel of $PI_+(x_0, y)$ is contained in the kernel of $H'(\bar{x}) \square \Phi$. But to say that the kernel of $H'(\bar{x}) \square \Phi$ is equal to zero amounts to saying that the linearized system (37) is globally hazily observable through $H'(\bar{x})$ at zero. Hence the kernel of $PI_+(x_0, y)$ is equal to zero, and thus, the hazy input-output map is locally injective around x_0. □

We consider now the sharp input-output map.

THEOREM 6.3. *Let us assume that the graphs of the set-valued maps $F(t, \cdot): X \rightsquigarrow X$ are closed and convex. Let H be a linear operator from X to another finite-dimensional vector-space Y. Let $\bar{x}(\cdot)$ be a solution to differential inclusion* (23). *If the contingent variational inclusion* (37) *is globally sharply observable through H at zero, then the system* (23) *is globally sharply observable through H at $(x_0, H(\bar{x}))$.*

Proof. We apply Proposition 4.1 to the sharp input-output map $I_- := H \circ \mathcal{S}$. We have to prove that the kernel of the algebraic derivative $D_a I_-(x_0, y_0)$ of I_- (where $y_0 := H(\bar{x})$) is equal to zero. Consider $\mathcal{S}$ as a map from $\mathbf{R}^n$ to the Sobolev space $W^{1,1}(0, T; \mathbf{R}^n)$.

Since the graph of the solution map $\mathcal{S}$ is convex (for the graphs of the set-valued maps $F(t, \cdot)$ are assumed to be convex), and since the map H is linear, we know that the chain rule (22) holds true:

$$D_a I_-(x_0, y_0)(u) = (H \circ D_a \mathcal{S}(x_0, \bar{x}(\cdot)))(u). \tag{39}$$

It remains to check that the algebraic derivative $D_a\mathcal{S}(x_0, \bar{x})(u)$ of $\mathcal{S}$ is contained in the subset $\Psi_a(u)$ of solutions to the algebraic variational inclusion starting at u:

$$D_a\mathcal{S}(x_0, \bar{x}(\cdot))(u) \subset \Psi_a(u) := \{w(\cdot) \mid w'(t) \in D_a F(\bar{x}(t), \bar{x}'(t))(w(t)) \text{ and } w(0) = u\}.$$

Since the algebraic derivative of a convex set-valued map is contained in the contingent derivative, then the set $\Psi_a(u)$ is contained in the subset $\Psi(u)$ of solutions to the contingent variational inclusion (37) starting at u. Hence the kernel of $D_a I_-(x_0, y_0)$ is contained in the kernel of $H \circ \Psi$. But to say that the kernel of $H \circ \Psi$ is equal to zero amounts to saying that the contingent variational inclusion (37) is sharply globally observable through H at zero. Therefore the kernel of $D_a I_-(x_0, y_0)$ is equal to zero, and thus, the inverse image of sharp input-output map at y_0 contains a unique element. This concludes the proof. □

If we assume that the chain rule holds true, we can state the following proposition, a consequence of the general principle (Theorem 4.1) and of Theorem 5.3 on the estimate of the contingent derivative of the solution map.

PROPOSITION 6.1. *Let us assume that the solution map of the differential inclusion* (23) *and the differentiable observation map H do satisfy the chain rule*

$$DI_-(x_0, y_0)(u) = (H'(\bar{x}) \circ D\mathcal{S}(x_0, \bar{x}(\cdot)))(u)$$

(*where* $y_0 = H(\bar{x})$). *If the contingent variational inclusion*

$$w'(t) \in \overline{\text{co}}\, DF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \quad \text{a.e. } in\ [0, T]$$

is globally sharply observable through $H'(\bar{x}(\cdot))$ *at zero, then the system* (23) *is locally sharply observable through* H *at* $(x_0, H(\bar{x}))$.

However, we can bypass the chain rule formula and attempt to obtain directly other criteria of local sharp observability in the nonconvex case.

THEOREM 6.4. *Assume that* F *has closed convex images, is continuous, Lipschitz in the second variable with a constant independent of* t *and that the growth of* F *is linear with respect to the state. Let* H *be a twice continuously differentiable function from* X *to another finite-dimensional vector-space* Y. *Consider an observation* $y^* \in I_-(x_0)$ *and assume that for every solution* $\bar{x}(\cdot)$ *to the differential inclusion* (23) *satisfying* $y^*(\cdot) = H(\bar{x}(\cdot))$ *and for all* $t \in [0, T]$ *we have*

$$\text{Ker } H'(\bar{x}(t)) \subset (F(t, \bar{x}(t)) - F(t, \bar{x}(t)))^{\perp}. \tag{40}$$

If for all $\bar{x}$ *as above the contingent variational inclusion*

$$w'(t) \in \overline{\text{co}}\, DF(t, \bar{x}(t), \bar{x}'(t))(w(t)) \quad \text{a.e. in } [0, T] \tag{41}$$

is globally sharply observable through $H'(\bar{x}(t))$ *at zero, then the system* (23) *is locally sharply observable through* H *at* (x_0, y^*).

Proof. Assume for a moment that the inclusion (23) is not locally sharply observable through H at (x_0, y^*). Then there exists a sequence $x_0^n \neq x_0$, $x_0^n \to x_0$ such that $y^* \in I_-(x_0^n)$, i.e., for some $x_n \in \mathcal{S}(x_0^n)$

$$y^* = H(x_n(\cdot)). \tag{42}$$

Taking a subsequence if needed and keeping the same notation, we may assume that $x_n \to \bar{x}$ weakly in $W^{1,\infty}(0, T; \mathbf{R}^n)$. Then (42) yields that for every $t \in [0, T]$ where $\bar{x}'(t)$, $x_n'(t)$ do exist

$$H'(\bar{x}(t))\bar{x}'(t) = H'(x_n(t))x_n'(t). \tag{43}$$

We shall prove that the convergence is actually strong and even more, that there exists a constant $c > 0$ such that

$$\|x_n'(t) - \bar{x}'(t)\| \leqq c\|x_n(t) - \bar{x}(t)\| \quad \text{a.e. in } [0, T]. \tag{44}$$

Indeed otherwise there exist sequences t_k and n_k such that

$$x_{n_k}'(t_k) \in F(t_k, x_{n_k}(t_k)), \qquad \bar{x}'(t_k) \in F(t_k, \bar{x}(t_k)),$$

$$\|x_{n_k}'(t_k) - \bar{x}'(t_k)\| \geqq k\|x_{n_k}(t_k) - \bar{x}(t_k)\|.$$

Taking a subsequence and keeping the same notation, by continuity of F, we may assume that for some $t \in [0, T]$, $p \in F(t, \bar{x}(t))$

$$t_k \to t, \qquad \bar{x}'(t_k) \to p. \tag{45}$$

Let ρ denote the Lipschitz constant of F with respect to x and let $y(t_k) \in F(t_k, \bar{x}(t_k))$ be such that

$$\|y(t_k) - \bar{x}_{n_k}'(t_k)\| \leqq \rho\|x_{n_k}(t_k) - \bar{x}(t_k)\|. \tag{46}$$

Since H' is locally Lipschitz and x'_{n_k} are equibounded, from the last inequality and (43) we deduce that for some constants M, $M_1 > 0$

$$
\begin{aligned}
&\|H'(\bar{x}(t_k))(y(t_k) - \bar{x}'(t_k))\| \\
&\quad \leqq \|H'(\bar{x}(t_k))(x'_{n_k}(t_k) - \bar{x}'(t_k))\| + \rho\|H'(\bar{x}(t_k))\|\,\|x_{n_k}(t_k) - \bar{x}(t_k)\| \\
&\quad \leqq \|H'(x_{n_k}(t_k))x'_{n_k}(t_k) - H'(\bar{x}(t_k))\bar{x}'(t_k)\| + M\|x_{n_k}(t_k) - \bar{x}(t_k)\|\,\|x'_{n_k}(t_k)\| \\
&\qquad + \rho\|H'(\bar{x}(t_k))\|\,\|x_{n_k}(t_k) - \bar{x}(t_k)\| \leqq M_1\|x_{n_k}(t_k) - \bar{x}(t_k)\|.
\end{aligned} \tag{47}
$$

From (46) and the choice of t_k, we obtain

$$
\frac{\|y(t_k) - \bar{x}'(t_k)\|}{\|x_{n_k}(t_k) - \bar{x}(t_k)\|} \to \infty \quad \text{when } k \to \infty. \tag{48}
$$

It is also not restrictive to assume that for some u of $\|u\| = 1$

$$
u_k := \frac{y(t_k) - \bar{x}'(t_k)}{\|y(t_k) - \bar{x}'(t_k)\|} \to u. \tag{49}
$$

Then (47), (48) yield

$$
u \in \operatorname{Ker} H'(\bar{x}(t)).
$$

On the other hand, u_k is contained in the space spanned by $F(t_k, \bar{x}(t_k)) - F(t_k, \bar{x}(t_k))$ and, by continuity of F, u is contained in the space spanned by $F(t, \bar{x}(t)) - F(t, \bar{x}(t))$. Since $u \neq 0$ this contradicts (40) and therefore (44) follows.

From the Gronwall inequality and (44) we deduce that for some $M_2 > 0$

$$
\|x_n(t) - \bar{x}(t)\| \leqq M_2\|x_n(0) - \bar{x}(0)\|.
$$

Setting $h_n = \|x_0^n - x_0\|$, we obtain

$$
\|x_n - \bar{x}\|_{W^{1,\infty}(0,T)} \leqq M_2 h_n.
$$

Taking a subsequence and keeping the same notation, we may assume that

$$
\frac{x_n - \bar{x}}{h_n} \to w \quad \text{weakly in } W^{1,\infty}(0, T).
$$

By Theorem 5.3, w is a solution of the contingent variational inclusion of (41). Moreover, $w(0) \neq 0$. Since $H(x_n(\cdot)) = H(\bar{x}(\cdot))$ taking the derivatives we obtain that for every $t \in [0, T]$, $H'(\bar{x}(t))w(t) = 0$. This contradicts the assumptions of Theorem 6.4 and completes the proof. □

Example. Observability around an equilibrium. Let us consider the case of a time-independent system (F, H): this means that the set-valued map $F: X \rightsquigarrow X$ and the observation map $H: X \rightsquigarrow Y$ do not depend on the time.

We shall observe this system around an equilibrium $\bar{x}$ of F, i.e., a solution to the equation

$$
0 \in F(\bar{x}). \tag{50}
$$

For simplicity, we assume that the set-valued map F is **sleek** at the equilibrium. Hence all the derivatives of F at $(\bar{x}, 0)$ do coincide with the contingent derivative $DF(\bar{x}, 0)$, which is a closed convex process from X to itself.

The theorems on local observability reduce the local observability around the equilibrium $\bar{x}$ to the study of the observability properties of the variational inclusion

$$
w'(t) \in DF(\bar{x}, 0)(w(t)) \tag{51}
$$

through the observation map $H'(\bar{x})$ around the solution zero of this variational inclusion.

We mention below a characterization of sharp observability of the variational inclusion in terms of "viability domains" of the restriction of the derivative $DF(\bar{x}, 0)$ to the kernel of $H'(\bar{x})$.

Recall that a subset $P \subset \ker H'(\bar{x})$ is a "viability domain" if

$$\forall w \in P, \quad DF(\bar{x}, 0)(w) \cap T_P(w) \neq \varnothing$$

where $T_P(w)$ denotes the "contingent cone to P at $w \in P$."

PROPOSITION 6.2. *Let us assume that F is sleek at its equilibrium $\bar{x}$ and that H is differentiable at $\bar{x}$. Then the variational inclusion* (51) *is sharply observable through $H'(\bar{x})$ at zero if and only if the* **largest closed viability domain** *of the restriction to* $\ker H'(\bar{x})$ *of the contingent derivative $DF(\bar{x}, 0)$ is equal to zero.*

Proof. Let us denote by E the restriction of the contingent derivative $DF(\bar{x}, 0)$ to the kernel of $H'(\bar{x})$ defined by

$$E(u) := \begin{cases} DF(\bar{x}, 0)(u) & \text{if } u \in \ker H'(\bar{x}), \\ \varnothing & \text{if } u \notin \ker H'(\bar{x}). \end{cases} \tag{52}$$

We consider the associated differential inclusion

$$w'(t) \in E(w(t)). \tag{53}$$

We know that the **largest closed viability domain** of the closed convex process E is the domain of the solution map of the associated differential inclusion (53). (See [6] and [7].)

But if we denote by $\mathcal{R}$ the solution map of the variational inclusion (51) and by $\mathcal{B}$ the set of functions $x(\cdot)$ such that

$$\forall t \in [0, T], \quad x(t) \in \ker H'(\bar{x}),$$

then we observe that the solution map of the differential inclusion (53) is the set-valued map $u \rightsquigarrow \mathcal{R}(u) \cap \mathcal{B}$. Hence its domain is the set $\mathcal{R}^{-}(\mathcal{B})$. Since

$$\mathcal{R}^{-}(\mathcal{B}) = \ker (H'(\bar{x}) \circ \mathcal{R}),$$

we infer that **the largest viability domain of E is the kernel of the sharp input–output map** $H'(\bar{x}) \circ \mathcal{R}$.

Consequently, the variational inclusion (51) being sharply observable if and only if the kernel of $H'(\bar{x}) \circ \mathcal{R}$ is equal to zero, our proposition ensues. □

Remark. In the same way, the variational inclusion (51) is hazily observable if and only if the kernel of $H'(\bar{x}) \square \mathcal{R}$ is equal to zero.

There are also some relations between the kernel of the hazy input-output map $H'(\bar{x}) \square \mathcal{R}$ and the largest invariance domain of the restriction of the derivative to the kernel of $H'(\bar{x})$. First, we remark that

$$\mathcal{R}^{+}(\mathcal{B}) = \ker (H'(\bar{x}) \square \mathcal{R}),$$

i.e., that the kernel of $H'(\bar{x}) \square \mathcal{R}$ is the largest set enjoying the "invariance property": for any $u \in \ker H'(\bar{x}) \square \mathcal{R}$, all solutions to differential inclusion (53) remain in this kernel.

When F is Lipschitzian in a neighborhood of $\ker H'(\bar{x})$, any closed subset $P \subset \ker H'(\bar{x})$ that is "invariant" in the sense that

$$\forall w \in P, \quad DF(\bar{x}, 0)(w) \subset T_P(w)$$

enjoys the invariance property. The converse is true only if we assume that the domain of $DF(\bar{x}, 0)$ is the whole space.

Then, if such is the case, *the variational inclusion is hazily observable through* $H'(\bar{x})$ *at zero if and only if the largest closed invariance domain of the restriction to* $\ker H'(\bar{x})$ *of the derivative* $DF(\bar{x}, 0)$ is equal to zero.

Remark. We have proved in [5] that under some further conditions the sharp observability of the variational inclusion at zero is equivalent to the controllability of the adjoint system

$$-p'(t) \in DF(\bar{x}, 0)^*(p(t)) + H'(\bar{x})^* u(t), \qquad u(t) \in Y^*. \tag{54}$$

PROPOSITION 6.3. *We posit the assumptions of Proposition* 6.2, *we assume that* $DF(\bar{x}, 0)(0) = 0$ *and we suppose that*

$$\ker H'(\bar{x}) + \mathrm{Dom}\,(DF(\bar{x}, 0)) = X. \tag{55}$$

Then the sharp observability at zero of the variational inclusion (51) *is equivalent to the controllability of the adjoint system* (54).

(About eleven characterizations of this property are supplied in [5].)

Proof. Assumption (55) implies that the transpose E^* of the restriction E of the closed convex process $DF(\bar{x}, 0)$ to $\ker H'(\bar{x})$ is given by the formula

$$(DF(\bar{x}, 0)|_{\ker H'(\bar{x})})^* = DF(\bar{x}, 0)^* + \mathrm{Im}\,(H'(\bar{x})^*) \tag{56}$$

(see [2, Cor. 3.3.17, p. 142]).

We also know (see [5, Prop. 1.12, p. 1198]) that if the domain of the transpose E^* of E is the whole space, then a vector subspace P is an invariance domain of E if and only if its orthogonal $P^\perp$ is a viability domain of E^* (this is also true when the domain of E is the whole space. But this does not apply to our case, since the domain of E is the kernel of $H'(\bar{x})$). Since the domain of E^* is equal to the domain of $DF(\bar{x}, 0)^*$ (thanks to formula (56)), this condition is equivalent to $DF(\bar{x}, 0)(0) = 0$.

Hence the variational inclusion (51) being sharply observable at zero if and only if the largest closed viability domain of E is equal to zero (by Proposition 6.2), we deduce that this happens if and only if the smallest invariance domain of E^* is equal to X, i.e., if and only if the adjoint system (54) is controllable.

Therefore, our statement follows from Theorem 5.5 of [5, p. 1207]. □

GLOBAL DIRECTIONAL CONTROLLABILITY*

J. WARGA†

This paper is dedicated to the memory of E. J. McShane.

Abstract. This paper derives sufficient conditions for the image of a function $\varphi_1: Q \to \mathbb{R}^m$ to cover an open segment originating at $\varphi_1(\bar{q})$ and with direction w (or even a neighborhood of such an interval) subject to restrictions of the form $\varphi_2(q) \in C$ or $\varphi_2(q) + G \subset C$. Here $\varphi_2: Q \to \mathscr{Z}$, Q is an arbitrary set, C a convex subset of the topological vector space $\mathscr{Z}$, and G a neighborhood of 0 in $\mathscr{Z}$. Also derived are similar directional controllability conditions subject to the additional restriction $q \in \mathscr{U} \subset Q$ for an "abundant" subset $\mathscr{U}$ of Q. These conditions are applicable to unilateral problems of control theory and of (infinite-dimensional) mathematical programming. These results are global and apply to problems defined by functions whose restrictions to certain finite-dimensional sets are differentiable (but not necessarily C^1) or are locally uniform limits of differentiable functions.

Key words. directional controllability, conical controllability, sufficient conditions, inclusion restrictions, attainable sets, nonsmooth data

AMS(MOS) subject classifications. 45E15, 49E30

1. Introduction.

The concepts of controllability originally arose in the study of linear control systems and their attainable sets [1], [12] and were later applied to smooth nonlinear systems [3], [4]. In our own studies (e.g., in [6]-[9]) we had adapted this concept to nonlinear and nonsmooth systems subject to infinite-dimensional inclusion restrictions. A model of such control systems is provided by the objects

$$\bar{q} \in Q, \quad \mathscr{U} \subset Q, \quad C \subset \mathscr{Z}, \quad \varphi = (\varphi_1, \varphi_2): Q \to \mathbb{R}^m \times \mathscr{Z},$$

where Q is an arbitrary set (but usually assumed to be a convex subset of a real vector space), $\mathscr{U}$ an "abundant" subset of Q, C a convex subset of a topological vector space $\mathscr{Z}$, and $\varphi_2(\bar{q}) \in C$. In the context of control theory, $\mathscr{U}$ may represent the set of ordinary control functions (or a subset closed under measurable concatenations), Q the corresponding set of relaxed controls, φ_1 an m-dimensional function determined by the solution $x(\cdot)$ of the (differential or functional-integral) equation of motion controlled by $u \in \mathscr{U}$ or $q \in Q$, and the restriction $\varphi_2(q) \in C$ a unilateral state constraint such as $x(t) \in A$ for all t.

Crudely speaking, we say that φ_1 is controllable at $\bar{q}$ if $\varphi_1(\mathscr{A})$ covers a neighborhood of $\varphi_1(\bar{q})$, where $\mathscr{A}$ is the set $\mathscr{U} \cap \varphi_2^{-1}(C)$ or, in a stronger type of controllability,

$$\mathscr{A} = \{u \in \mathscr{U} \mid \varphi_2(u) + G \subset C\}$$

for some neighborhood G of 0 in $\mathscr{Z}$. Typically, controllability is studied at points $\bar{q}$ that are extremals (or stationary points) of the problem because controllability rules out $\bar{q}$ as a solution of a related optimization problem. However, even if φ_1 is not (or cannot be shown to be) controllable at $\bar{q}$, it is still of interest to determine whether $\varphi_1(\mathscr{A})$ extends in the direction w from $\varphi_1(\bar{q})$, i.e., whether $\varphi_1(\mathscr{A})$ covers an open segment originating at $\varphi_1(\bar{q})$ and with direction w or even a neighborhood of such a segment. We had initiated the study of such directional controllability in a previous paper [11] which deals with higher-order conditions for local conical controllability, the term "conical" referring to the shape of the neighborhood. In the present paper we study first-order conditions for global directional controllability without smoothness

assumptions ("smoothness" being the term used in nonsmooth analysis to mean "continuous differentiability" and not necessarily C^∞ behavior).

We present the basic results in § 2, some examples in § 3, and the proofs in § 4.

2. Covering theorems. We shall assume given the objects $\bar{q}$, Q, $\mathcal{U}$, C, $\mathcal{Z}$, φ as described in § 1. We endow each space $\mathbb{R}^s$ for $s = 1, 2, \cdots$ with the norm $|(x_1, \cdots, x_s)| = \sum_{i=1}^{s} |x_i|$, and denote by B_s and $\bar{B}_s$ the open and closed unit balls in $\mathbb{R}^s$, by $d[p, A]$ the distance of the point p to the set A, and by A°, $\bar{A}$, and co A the interior, the closure, and the convex hull of a set A. We refer to a set B as a neighborhood of a point x, respectively, of a set A if $x \in B^\circ$, respectively, $A \subset B^\circ$. For A, $B \subset \mathcal{Z}$, we write

$$A \ominus B := \{z \in \mathcal{Z} \mid z + B \subset A\}.$$

If W is a convex subset of $\dot{\mathbb{R}}^k$ with $W^\circ \neq \varnothing$, $p: W \to \mathbb{R}^m \times \mathcal{Z}$, and $x \in W$ (but x is not necessarily in W°) we say that p is differentiable at x and has the derivative $p'(x)$ [5, p. 167] if $p'(x)$ is a linear operator from $\mathbb{R}^k$ to $\mathbb{R}^m \times \mathcal{Z}$ such that

$$\lim |\xi - x|^{-1}[p(\xi) - p(x) - p'(x)(\xi - x)] = 0 \quad \text{as } \xi \to x, \quad \xi \in W \backslash \{x\}.$$

Condition 2.0. Let $X \subset \mathbb{R}^k$ and $\hat{q}: X \to Q$. We say that φ and $\hat{q}$ satisfy Condition 2.0 if for every $x \in X$ there exists a sequence $(u_n(x))$ in $\mathcal{U}$ such that

$$\lim_n \varphi(u_n(x)) = \varphi(\hat{q}(x)) \quad \text{uniformly for } x \in X$$

and

$$x \to \varphi(u_n(x)): X \to \mathbb{R}^m \times \mathcal{Z} \text{ is continuous for each } n = 1, 2, \cdots.$$

Remark. This definition is motivated by problems of optimal control in which $\mathcal{U}$ represents an "abundant" set of ordinary controls (e.g., a set closed under measurable concatenations) and Q the corresponding set of relaxed controls. If φ is continuous (with respect to the weak star topology of relaxed controls [5, Chap. IV]),

$$X = \left\{ \theta = (\theta_1, \cdots, \theta_k) \mid \theta_j \geqq 0, \sum_{i=1}^{k} \theta_i \leqq 1 \right\}, \quad \bar{q} \in Q, \quad y_j \in Q - \bar{q},$$

and

$$\hat{q}(\theta) = \bar{q} + \sum_{j=1}^{k} \theta_j y_j,$$

then φ and $\hat{q}$ satisfy Condition 2.0 [5, Thm. IV.3.9, p. 285].

THEOREM 2.1. *Let $w \in \mathbb{R}^m$, $\alpha_0 > 0$, X be a closed subset of $\mathbb{R}^k$, $0 \in X$, G an open neighborhood of 0 in $\mathcal{Z}$, $\mathcal{T} \subset \mathbb{R}^k$ compact and convex, and $\psi = (\psi_1, \psi_2): X \to \mathbb{R}^m \times \mathcal{Z}$.*

Assume that

(a) $\psi_2(0) \in C$,

(b) *ψ is differentiable at every $x \in X$,*

(c) *for each $x \in X \cap [0, \alpha_0]\mathcal{T}$ there exist $\eta(x) \in \mathcal{T}$ and $r(x)$, $r_1(x) > 0$ such that*

$$\psi'(x)\eta(x) \in \{w\} \times [C \ominus G - \psi_2(x)]$$

$$\eta(x) + r(x)\bar{B}_k \subset \mathcal{T}, \qquad x + [0, r_1(x)][\eta(x) + r(x)\bar{B}_k] \subset X.$$

Then

$$(*) \quad \psi_1(0) + \alpha w \in \{\psi_1(x) \mid x \in X \cap \alpha\mathcal{T}, \psi_2(x) + (1 - e^{-\alpha})G \subset C\} \qquad \forall \alpha \in [0, \alpha_0].$$

If, furthermore,

(d) $\varphi: Q \to \mathbb{R}^m \times \mathscr{Z}$ *and* $\hat{q}: X \to Q$ *satisfy Condition* 2.0, $\bar{q} = \hat{q}(0)$, *and* $\psi(x) = \varphi(\hat{q}(x))$ *for all* $x \in X$,
and

(e) $\psi_1'(x)$ *is of full rank for all* $x \in X \cap [0, \alpha_0]\mathscr{T}$
then for every $\alpha \in (0, \alpha_0)$ *and* $s \in (0, 1)$, *there exists a neighborhood* $V_{s,\alpha}$ *of* 0 *in* $\mathbb{R}^m$ *such that*

$$(**) \qquad \varphi_1(\bar{q}) + \alpha w + V_{s,\alpha} \subset \{\varphi_1(u) \,|\, u \in \mathscr{U},\ \varphi_2(u) + (1 - e^{-\alpha}) sG \subset C\}.$$

If condition (d) *holds and*
(f) *the functions*

$$\rho: [0, \alpha_0] \to (0, 1], \quad \beta: (0, \alpha_0] \to [0, \infty), \quad \delta: [0, \alpha_0] \to (0, 1)$$

are pointwise limits from below of positive continuous functions and such that, for all $\alpha \in [0, \alpha_0]$ *and* $x \in X \cap \alpha\mathscr{T}$,

$$\rho(\alpha) \leqq r(x), \quad \psi_1'(x)\bar{B}_k \supset \beta(\alpha)\bar{\beta}_m, \quad r(\alpha)\psi_2'(x)\bar{B}_k \subset [1 - \delta(\alpha)]G$$

then, setting

$$I(\alpha) = \int_0^\alpha \rho(t)\beta(t)\, dt, \qquad J(\alpha) = \int_0^\alpha e^{-(\alpha - t)}\delta(t)\, dt,$$

we have

$$(***) \qquad \varphi_1(\bar{q}) + \alpha w + I(\alpha)\bar{B}_m \subset \{\varphi_1(q) \,|\, q \in Q,\ \varphi_2(q) + J(\alpha)G \subset C\}$$

$$\forall \alpha \in [0, \alpha_0]$$

and

$$(****) \qquad \varphi_1(\bar{q}) + \alpha w + I(\alpha)\bar{B}_m \subset \{\varphi_1(u) \,|\, u \in \mathscr{U},\ \varphi_2(u) + sJ(\alpha)G \subset C\}$$

$$\forall \alpha \in (0, \alpha_0),\ s \in (0, 1).$$

Remarks.

1. A special case of Theorem 2.1 (and of Theorem 2.2 below) applies to problems without inclusion restrictions. If $\varphi = \varphi_1: Q \to \mathbb{R}^m$ and $\psi = \psi_1: X \to \mathbb{R}^m$ are given, then we can apply Theorem 2.1 by setting

$$\mathscr{Z} = C = \mathbb{R}, \quad \varphi_2(q) = \psi_2(x) = 0 \quad \forall q \in Q, x \in X.$$

Then all the assumptions referring to C, $\mathscr{Z}$, φ_2, ψ_2 are automatically satisfied.

2. We observe that the last two conditions in (c) are automatically satisfied for appropriate choices of $r(x)$, $r_1(x)$ if X is a cone, $\mathscr{T} \subset X$ and $\eta(x) \in \mathscr{T}^\circ$ for all $x \in \alpha_0\mathscr{T}$.

3. In Theorem 2.2 below we drop the assumption of Theorem 2.1 that the function ψ is differentiable. We assume, instead, that ψ can be locally uniformly approximated by differentiable functions that essentially satisfy the conditions of Theorem 2.1. This approach is related to the previously introduced concepts of derivate containers [6]-[8], [10] and of Frankowska's $\mathscr{P}_b$-set [2] but, in the present case, it requires somewhat weaker hypotheses.

THEOREM 2.2. *Let* $w \in \mathbb{R}^m$, G *be a neighborhood of* 0 *in* $\mathscr{Z}$, X *a closed subset of* $\mathbb{R}^k$, $0 \in X$, $\mathscr{T} \subset \mathbb{R}^k$ *compact and convex,* $\alpha_0 > 0$, *and* $\hat{q}: X \to Q$ *such that the function*

$$x \to \psi(x) := \varphi(\hat{q}(x)): X \to \mathbb{R}^m \times \mathscr{Z}$$

is continuous, and $\psi_2(0)=\varphi_2(\bar{q})\in C$, *where* $\bar{q}:=\hat{q}(0)$. *Assume that for each* $\bar{x}\in X\cap[0,\alpha_0]\mathcal{T}$ *there exist a closed neighborhood* $W(\bar{x})$ *of* $\bar{x}$ *and differentiable functions* $\psi^i=(\psi_1^i,\psi_2^i):X\cap W(\bar{x})\to\mathbb{R}^m\times\mathcal{Z}$ *for all* $i=1,2,\cdots$ *such that*

$$\lim_i \psi^i=\psi \text{ uniformly on } X\cap W(\bar{x})$$

and each ψ^i *satisfies condition* (c) *of Theorem* 2.1. *Then*

$$\varphi_1(\bar{q})+\alpha w\in\{\psi_1(x)\,|\,x\in X\cap\alpha\mathcal{T},\ \psi_2(x)+(1-e^{-\alpha})G\subset C\}$$
$$\subset\{\varphi_1(q)\,|\,q\in Q,\ \varphi_2(q)+(1-e^{-\alpha})G\subset C\}\quad\forall\alpha\in[0,a_0].$$

3. Examples. In the two examples below there are no inclusion restrictions.

Example I. Let

$$Q=\mathcal{U}=\mathbb{R}^2,\quad \varphi=(\varphi^1,\varphi^2),\quad x=(x_1,x_2),$$
$$\varphi^1(x)=x_1+|x_1+x_2|^{1/2},\qquad \varphi^2(x)=x_1-x_2.$$

We choose an arbitrary $\alpha_0\geqq 1$ and set

$$X=\{x\in\mathbb{R}^2\,|\,x_1+x_2\geqq 0\},\qquad \mathcal{T}=X\cap\bar{B}_2$$
$$\hat{q}(x)=x,\quad \psi=\varphi|_X,\quad \eta(x)=(\eta_1,\eta_2)(x).$$

In the neighborhood of any $x\in X$, we approximate ψ by functions $\chi_j(=\chi_j^1,\chi_j^2)$, defined by

$$\chi_j^1(y)=y_1+h_j(y_1+y_2),\qquad \chi_j^2(y)=y_1-y_2,$$

where $h_j(z)$ can be any increasing differentiable functions that uniformly approximate $z^{1/2}$ on $[0,1]$ as $j\to\infty$, e.g.,

$$h_j(z)=\tfrac{3}{4}j^{-1/2}+\tfrac{1}{4}j^{3/2}z^2\quad\text{for } 0\leqq z\leqq 1/j,\qquad h_j(z)=z^{1/2}\quad\text{for } z>1/j.$$

For $w\in\mathbb{R}^2$, the equation $x_j'(x)\eta(x)=w$ is of the form

$$(1+a)\eta_1(x)+a\eta_2(x)=w_1,\qquad \eta_1(x)-\eta_2(x)=w_2,$$

where $a=h_j'(x_1+x_2)$. This equation has the solution

(1) $$\eta_1(x)=(1+2a)^{-1}[w_1+aw_2],\qquad \eta_2(x)=(1+2a)^{-1}[w_1-(1+a)w_2].$$

Since $a\geqq 0$, it follows that

(2) $$|\eta(x)|=|\eta_1(x)|+|\eta_2(x)|\leqq|w_2|+2|w_1|.$$

Thus, by (1) and (2), $\eta(x)\in\mathcal{T}^\circ$ (i.e., $\eta_1(x)+\eta_2(x)>0$ and $|\eta(x)|<1$) if

$$w\in W:=\{v=(v_1,v_2)\in\mathbb{R}^2\,|\,2v_1-v_2>0,\ |v_2|+2|v_1|<1\}.$$

Since X is a convex cone and $\mathcal{T}\subset X$, it follows, by Theorem 2.2, that for all $a_0>1$ and $w\in W$, we have

(3) $$\psi(0)+\alpha w=\alpha w\in\psi(\alpha\mathcal{T})\quad\forall\alpha\in[0,\alpha_0].$$

Since $\alpha\mathcal{T}$ is compact, relation (3) remains valid for all $w\in\bar{W}$ and, since α_0 can be taken arbitrarily large, we have

(4) $$\psi(\{x\,|\,x_1+x_2\geqq 0\})\supset\{v=\{v_1,v_2)\,|\,2v_1-v_2\geqq 0\}.$$

We can verify that this result is the best possible by setting

$$\zeta_1=x_1+x_2,\qquad \zeta_2=x_1-x_2$$

which transforms the equation $\psi(x)=v=(v_1,v_2)$ into

(5) $$\zeta_1+2|\zeta_1|^{1/2}=2v_1-v_2,\qquad \zeta_2=v_2.$$

On the other hand, (5) can also be solved when $2v_1 - v_2 < 0$ but that requires that we restrict ourselves to values of $\zeta_1 = x_1 + x_2 < -4$. This suggests that we might proceed as above but with

$$X = \{x \in \mathbb{R}^2 \,|\, x_1 + x_2 \leqq 0\}.$$

However, as will be seen below, Theorem 2.2 is based on Theorem 2.1, which is derived by a procedure bearing some similarity to an approximate integration of the differential equation $dx/d\alpha = \eta(x)$ with the initial condition $x(0) = 0$ (a differential equation which is unconventional because its right-hand side may be discontinuous). Therefore, this theorem cannot yield results requiring an immediate jump from 0 to $x_1 + x_2 < -4$. However, if we set

$$y_1 = -2 - x_1, \qquad y_2 = -2 - x_2$$

and use (y_1, y_2) as the new variable, with X and $\mathcal{T}$ defined as before, then we can use Theorem 2.1 to show that

$$\varphi(\mathbb{R}^2) \supset \{v = (v_1, v_2) \,|\, 2v_1 - v_2 \leqq 0\}$$

and therefore, by combination with relation (4), that $\varphi(\mathbb{R}^2) = \mathbb{R}^2$.

Example II. Let $Q = \mathcal{U} = \mathbb{R}^3$, $x = (x_1, x_2, x_3)$,

$$\varphi^1(x) = |x_2 - x_1^2| + x_3, \qquad \varphi^2(x) = x_1 + x_2 + x_3.$$

We at first choose some $R \geqq 1$ and set

$$X = X_1 = \{x \in \mathbb{R}^3 \,|\, x_2 \leqq 0\},$$

$$\mathcal{T} = \mathcal{T}_1 = \{x \in \mathbb{R}^3 \,|\, x_2 \leqq 0, |x_1| + |x_2|/R + |x_3|/R \leqq 1\} \subset X_1,$$

$$\alpha_0 = \tfrac{1}{4}, \quad \hat{q}(x) = x, \quad \psi = \varphi|_{X_1}, \quad \eta(x) = (\eta_1, \eta_2)(x).$$

For each $x \in X$ and $w = (w_1, w_2) \in \mathbb{R}^2$, the equation $\psi'(x)\eta = w$ has the form

$$\eta_1(2x_1, 1) + \eta_2(-1, 1) + \eta_3(1, 1) = (w_1, w_2).$$

This equation will have a solution $\eta(x)$ in $\mathcal{T}^\circ$ for all $x \in X \cap [0, \frac{1}{4}]\mathcal{T}$—and $\eta(x)$ will thus satisfy the relations

$$\eta(x) + r(x)\bar{B}_k \subset \mathcal{T}, \qquad x + [0, r_1(x)][\eta(x) + r(x)\bar{B}_k] \subset X$$

for appropriate $r(x)$, $r_1(x) > 0$—if $w \in \psi'(x)\mathcal{T}^\circ$ for all $x \in X \cap [0, \frac{1}{4}]\mathcal{T}$. It is easily seen that this is the case if w is in the interior of

$$P_R = \operatorname{co}\{(\tfrac{1}{2}, 1), R(1, -1), R(1, 1), R(-1, -1)\} \subset X.$$

Thus, by relation (*) of Theorem 2.1, for every choice of $R \geqq 1$, $\alpha \in [0, \frac{1}{4}]$, and $w \in P_R$, we have

$$\alpha w = \psi(0) + \alpha w \in \psi(X \cap [0, \tfrac{1}{4}]\mathcal{T}).$$

Therefore,

$$\psi(X_1) \supset P := \tfrac{1}{4} \bigcup_{R \geqq 1} P_R = \{(v_1, v_2) \in \mathbb{R}^2 \,|\, v_2 < v_1 + \tfrac{1}{8}\}. \tag{2}$$

We next consider the complement of P. To do so, we redefine X, $\mathcal{T}$, and ψ as

$$X = X_2 := \{x \in \mathbb{R}^3 \,|\, x_2 \geqq x_1^2, x_1 \geqq 0\}, \qquad \mathcal{T} = \mathcal{T}_2 := 5\bar{B}_3, \qquad \psi = \psi|_{X_2}.$$

For each $x \in X$ and $w = (w_1, w_2) \in \mathbb{R}^2$, the equation $\psi'(x)\eta = w$ now has the form

$$\eta_1(-2x_1, 1) + (\eta_1 + \eta_2)(1, 1) = (w_1, w_2). \tag{3}$$

Assume that $|w| \leqq 1$ and $w_2 - w_1 > 0$, and set

$$\eta_1 = (2x_1+1)^{-1}(w_2 - w_1), \qquad \eta_2 = 3x_1(2x_1+1)^{-1}(w_2 - w_1),$$
$$\eta_3 = (2x_1+1)^{-1}(w_1 + 2x_1 w_2) - \eta_2 \qquad \text{if } x \in X,\ x_1 > 0,$$
$$\eta_1 = w_2 - w_1, \quad \eta_2 = 1, \quad \eta_3 = w_1 - 1 \quad \text{if } x \in X,\ x_1 = 0.$$

Then $\eta(x) = (\eta_1, \eta_2, \eta_3) \in \mathcal{T}$ and $\eta(x)$ is a solution of (3) satisfying the relations $\eta_1 > 0$, $\eta_2 > 2x_1\eta_1$. Thus $\psi(x)$ and $\eta(x)$ satisfy conditions (a)-(c) of Theorem 2.1 for every choice of $\alpha_0 > 0$. It follows that

$$\alpha w = \psi(0) + \alpha w \in \psi(X_2) \quad \text{if } \alpha \geqq 0,\ |w| \leqq 1 \text{ and } w_2 - w_1 > 0$$

so that $\psi(X_2) \supset \{(v_1, v_2) \mid v_2 - v_1 > 0\}$. Together with relation (2) this shows that $\varphi(X_1 \cup X_2) = \mathbb{R}^2$.

4. Proofs.

LEMMA 4.1. *Let A, B, B_1, B_2, $G \subset \mathcal{X}$, and G be an open neighborhood of* 0. Then

(a) $(A \ominus B_1) \ominus B_2 = A \ominus (B_1 + B_2) = (A \ominus B_2) \ominus B_1$

and

(b) $A \ominus G = A^\circ \ominus G = \overline{A \ominus G}$.

If A is convex then

(c) $A \ominus B = A \ominus \operatorname{co} B$ *and this set is convex,*

(d) $\bar{A} \ominus G = A^\circ \ominus G = A \ominus G$,

(e) $A \ominus \lambda_2 G \subset A \ominus \lambda_1 G$ *if* $0 \leqq \lambda_1 \leqq \lambda_2$,

and

(f) $(A + B) \ominus B = A$ *if A is closed and either $A^\circ \neq \varnothing$ or $\mathcal{X}$ is finite-dimensional.*

Proof. We have

$$(A \ominus B_1) \ominus B_2 + B_1 + B_2 = [(A \ominus B_1) \ominus B_2 + B_2] + B_1$$
$$\subset A \ominus B_1 + B_1 \subset A;$$

hence,

$$(A \ominus B_1) \ominus B_2 \subset A \ominus (B_1 + B_2).$$

Conversely, since

$$A \ominus (B_1 + B_2) + B_1 + B_2 \subset A$$

we have

$$A \ominus (B_1 + B_2) + B_2 \subset A \ominus B_1.$$

Therefore,

$$A \ominus (B_1 + B_2) \subset (A \ominus B_1) \ominus B_2,$$

which proves (a).

Let $\bar{x} \in \overline{A \ominus G}$ and $g \in G$. Then $g + V + V \subset G$ for some symmetric neighborhood V of 0. We can find $x \in A \ominus G$ such that $\bar{x} \in x + V$, whence it follows that

$$\bar{x} + g + V \subset x + g + V + V \subset x + G \subset A,$$

implying that $\bar{x} + g \in A^\circ$. Since this is valid for every $g \in G$, we have $\bar{x} + G \subset A^\circ$, hence $\bar{x} \in A^\circ \ominus G$. Thus

$$\overline{A \ominus G} \subset A^\circ \ominus G \subset A \ominus G,$$

which proves (b).

Now assume that A is convex. Then $z \in A \ominus B$ implies that $z + B \subset A$, hence $z + \operatorname{co} B \subset A$ and $z \in A \ominus \operatorname{co} B$ which proves (c). Furthermore, $A^\circ = (\bar{A})^\circ$ and therefore, by (b) (replacing A with $\bar{A}$),

$$\bar{A} \ominus G = (\bar{A})^\circ \ominus G = A^\circ \ominus G,$$

whence relation (d) follows because

$$A^\circ \ominus G \subset A \ominus G \subset \bar{A} \ominus G.$$

By (c), $A \ominus \lambda G = A \ominus \lambda \operatorname{co} G$ for all $\lambda \in \mathbb{R}$ and, since $\lambda_1 \operatorname{co} G \subset \lambda_2 \operatorname{co} G$ for $0 \leqq \lambda_1 \leqq \lambda_2$, we have

$$A \ominus \lambda_2 G = A \ominus \lambda_2 \operatorname{co} G \subset A \ominus \lambda_1 \operatorname{co} G = A \ominus \lambda_1 G,$$

which proves (e).

Finally, let the assumptions of (f) be satisfied, $z \in (A + B) \ominus B$, and l belong to $\mathscr{X}^*$, the set of continuous linear functionals on $\mathscr{X}$. Then $z + B \subset A + B$; hence

$$lz + \inf lB \geqq \inf l(A + B) = \inf lA + \inf lB,$$

implying $lz \geqq \inf lA$. Since $l \in \mathscr{X}^*$ is arbitrary, it follows from the convex separation theorem that $z \in A$. Thus $(A + B) \ominus B \subset A$. Conversely, if $a \in A$ then $a + B \subset A + B$ so that $A \subset (A + B) \ominus B$. This proves (f). □

LEMMA 4.2. *Let X be a closed subset of $\mathbb{R}^k$, $\mathscr{T} \subset \mathbb{R}^k$, $\mathscr{T}$ convex and compact, G an open neighborhood of 0 in $\mathscr{X}$, $\alpha_0 > 0$, $\psi = (\psi_1, \psi_2) : X \to \mathbb{R}^m \times \mathscr{X}$ continuous, $d \in \mathscr{X}$, and $C \subset \mathscr{X}$ convex. Assume that*

$$\lim_j a_j = \lim_j \beta_j = \lim_j \gamma_j = 0, \quad \lim_j s_j = 1, \quad \alpha \in [0, \alpha_0),$$

$$0 \leqq \alpha + \beta_j \leqq \alpha_0 \quad \forall j = 1, 2, \cdots,$$

and

(1) $p \in \alpha_j \bar{B}_m + \{\psi_1(x) \mid x \in X \cap (\alpha + \beta_j)\mathscr{T}, \psi_2(x) + s_j G \subset C + \gamma_j(C - d)\} \quad \forall j = 1, 2, \cdots.$

Then

$$p \in \{\psi_1(x) \mid x \in X \cap \alpha\mathscr{T}, \psi_2(x) \in C \ominus G\}.$$

Proof. By (1), for every $j \in \{1, 2, \cdots\}$ and $g \in G$, there exist

$$x_j \in X, \quad z_j \in \bar{B}_m, \quad c_{g,j} \in C$$

such that

(2) $$p = \alpha_j z_j + \psi_1(x_j), \quad x_j \in (\alpha + \beta_j)\mathscr{T}, \quad \psi_2(x_j) + s_j g = (1 + \gamma_j)c_{g,j} - \gamma_j d.$$

We may assume that

$$\lim_j x_j = x_0 \in X \cap [0, \alpha_0]\mathscr{T}, \qquad \lim_j z_j = z \in \bar{B}_m,$$

otherwise choosing appropriate subsequences. Then (2) implies that $p = \psi_1(x_0)$, $x_0 \in \alpha\mathscr{T}$, and

$$\lim_j c_{g,j} = \lim_j (1 + \gamma_j)^{-1}[\psi_2(x_j) + s_j g + \gamma_j d] = \psi_2(x_0) + g \quad \forall g \in G.$$

Thus $\psi_2(x_0) + g \in \bar{C}$ for all $g \in G$, hence $\psi_2(x_0) \in \bar{C} \ominus G$ and, by Lemma 4.1, $\psi_2(x_0) \in C \ominus G$. □

LEMMA 4.3. *Let X be a closed subset of $\mathbb{R}^k$, $0 \in X$, $\mathcal{T} \subset \mathbb{R}^k$, $\mathcal{T}$ convex and compact, G an open neighborhood of 0 in $\mathcal{Z}$,*

$$\beta > 0, \quad m \in \{1, 2, \cdots, k\}, \quad w \in \mathbb{R}^m, \quad r, r_1 > 0, \quad \eta \in \mathcal{T}, \quad \gamma \in (0, 1),$$

and $\psi = (\psi_1, \psi_2) : X \to \mathbb{R}^m \times \mathcal{Z}$ a continuous function such that

(a) *$\psi'(0)$ exists and $\psi'(0)\eta \in \{w\} \times [C \ominus G - \psi_2(0)]$;*

(b) *$\psi_1'(0)\bar{B}_k \supset \beta \bar{B}_m$;*

(c) *$\eta + r\bar{B}_k \subset \mathcal{T}$, $[0, r_1][\eta + r\bar{B}_k] \subset X$, $r\psi_2'(0)\bar{B}_k \subset \gamma G$, $\psi_2(0) \in C$.*

Then for every $\varepsilon \in (0, r)$ there exists $\hat{\alpha} > 0$ such that

$$(*) \qquad \psi_1(0) + \alpha[w + (r - \varepsilon)\beta \bar{B}_m] \subset \{\psi_1(x) \mid x \in X \cap \alpha\mathcal{T}, \psi_2(x) + \alpha(1 - \gamma)G \subset C\} \quad \forall \alpha \in [0, \hat{\alpha}].$$

If, furthermore,

(d) *$\varphi : Q \to \mathbb{R}^m \times \mathcal{Z}$, $\hat{q} : X \to Q$ and $u_n : X \to \mathcal{U}$ for $n = 1, 2, \cdots$ satisfy Condition* 2.0 *and $\psi(x) = \varphi(\hat{q}(x))$ then*

$$\begin{aligned} &\varphi_1(\hat{q}(0)) + \alpha[w + (r - \varepsilon)\beta \bar{B}_m] \\ (**) \qquad &\subset \{\varphi_1(u_n(x)) \mid x \in X \cap \alpha\mathcal{T}, \varphi_2(u_n(x)) + \alpha(1 - \gamma)G \subset C, n \in \{1, 2, \cdots\}\} \\ &\subset \{\varphi_1(u) \mid u \in \mathcal{U}, \varphi_2(u) + \alpha(1 - \gamma)G \subset C\} \quad \forall \alpha \in (0, \hat{\alpha}]. \end{aligned}$$

Proof. Let $e_1, \cdots, e_m$ be the columns of the unit $m \times m$ matrix and $b_1, \cdots, b_m \in \bar{B}_k$ such that

$$\psi_1'(0)b_\mu = \beta e_\mu \quad \forall \mu = 1, \cdots, m.$$

Let

$$a(\theta) = \eta + \sum_\mu \theta_\mu b_\mu \quad \forall \theta = (\theta_1, \cdots, \theta_m) \in r\bar{B}_m.$$

Since $r\psi_2'(0)\bar{B}_k$ is compact and γG open, it follows from (c) that there exists $\gamma_1 \in (0, \gamma)$ such that

$$(1) \qquad a(\theta) \in \mathcal{T}, \quad [0, r_1]a(\theta) \in X, \quad \sum_\mu \theta_\mu \psi_2'(0)b_\mu \in \gamma_1 G \quad \forall \theta \in r\bar{B}_m.$$

Furthermore, by (a),

$$(2) \qquad \psi_1'(0)a(\theta) = \psi_1'(0)\eta + \sum_\mu \theta_\mu \psi_1'(0)b_\mu = w + \beta\theta.$$

Now assume that condition (d) is satisfied. For $\theta \in r\bar{B}_m$ and $\alpha \subset (0, r_1]$, we set

$$(3) \qquad \begin{aligned} h^n(\theta, \alpha) &= \frac{1}{\alpha}[\varphi(u_n(\alpha a(\theta))) - \psi(\alpha a(\theta))] \\ d(\theta, \alpha) &= \frac{1}{\alpha}[\psi(\alpha a(\theta)) - \psi(0) - \alpha\psi'(0)a(\theta)]. \end{aligned}$$

Let $0 < \varepsilon < r$. We observe that we can determine $\alpha_1 \in (0, r_1]$ sufficiently small so that

$$(4) \qquad |d_1(\theta, \alpha)| \leqq \tfrac{1}{2}\varepsilon\beta, \quad d_2(\theta, \alpha) \in \tfrac{1}{2}(\gamma - \gamma_1)G \quad \forall \alpha \in (0, \alpha_1], \theta \in r\bar{B}_m.$$

Since $\lim_n \varphi(u_n(\alpha a(\theta))) = \psi(\alpha a(\theta))$ uniformly for all θ and α, for each $\alpha \in (0, \alpha_0]$ we can determine $N(\alpha)$ such that

$$(5) \qquad |h_1^{N(\alpha)}(\theta, \alpha)| \leqq \tfrac{1}{2}\varepsilon\beta, \qquad h_2^{N(\alpha)}(\theta, \alpha) \in \tfrac{1}{2}(\gamma - \gamma_1)G.$$

For arbitrary $z \in (r-\varepsilon)\beta \bar{B}_m$ and $\alpha \in (0, \alpha_1]$, we consider the equation

$$\varphi_1(u_{N(\alpha)}(\alpha a(\theta)) = \varphi_1(\hat{q}(0)) + \alpha(w+z) = \psi_1(0) + \alpha(w+z). \tag{6}$$

We have

$$\begin{aligned} \varphi(u_{N(\alpha)}(\alpha a(\theta)) &= \psi(\alpha a(\theta)) + \alpha h^{N(\alpha)}(\theta, \alpha) \\ &= \psi(0) + \alpha[\psi'(0)a(\theta) + d(\theta, \alpha) + h^{N(\alpha)}(\theta, \alpha)], \end{aligned} \tag{7}$$

and thus, by (2), (6) is equivalent to

$$\theta = \frac{1}{\beta}[z - d_1(\theta, \alpha) - h_1^{N(\alpha)}(\theta, \alpha)].$$

By (3)-(5), the right side of the above equation defines a continuous mapping of $r\bar{B}_m$ into itself. Therefore, this equation admits a solution $\bar{\theta}$ that also satisfies (6).

Now let $\hat{\alpha} := \min(\alpha_1, \varepsilon/\gamma)$. Then, by (a), (c), (1), (4), (5), (7), and Lemma 4.1,

$$\begin{aligned} \varphi_2(u_{N(\alpha)}(\theta, \alpha)) &= \psi_2(0) + \alpha\left[\psi_2'(0)\eta + \sum_{\mu} \theta_\mu \psi_2'(0) b_\mu + d_2(\theta, \alpha) + h_2^{N(\alpha)}(\theta, \alpha)\right] \\ &\in \psi_2(0) + \alpha[C \ominus G - \psi_2(0)] + \gamma_1 \alpha G + \tfrac{1}{2}\alpha(\gamma - \gamma_1)G + \tfrac{1}{2}\alpha(\gamma - \gamma_1)G \\ &\subset \psi_2(0) + \alpha[C \ominus (1-\gamma)G - \psi_2(0)] \subset C \ominus \alpha(1-\gamma)G \quad \forall \alpha \in (0, \bar{\alpha}]. \end{aligned} \tag{8}$$

Thus, the first two relations of (1), (6) (with its solution $\bar{\theta}$), and (8) yield relation (**).

The same argument, in a simpler form, will prove the validity of relation (*) without the use of assumption (d) if we redefine Q as X, φ as ψ, $\hat{q}(x)$ as x, and $u_n(x)$ as x. □

LEMMA 4.4. *Let X be a closed subset of $\mathbb{R}^k$, $\mathcal{T} \subset \mathbb{R}^k$, $\mathcal{T}$ convex and compact, G an open neighborhood of 0 in $\mathcal{X}$,*

$$m \in \{1, 2, \cdots, k\}, \quad w \in \mathbb{R}^m, \quad r, r_1 > 0, \quad \beta > 0, \quad \eta \in \mathcal{T},$$
$$\alpha_0 > 0, \quad \bar{\alpha} \in [0, \alpha_0), \quad \bar{x} \in X \cap \bar{\alpha}\mathcal{T}, \quad \gamma \in (0, 1),$$

and $\psi = (\psi_1, \psi_2) : X \to \mathbb{R}^m \times \mathcal{X}$ continuous. Let, furthermore, $\varepsilon_1 \geqq 0$, $\tau \in [0, 1)$, I be the unit $m \times m$ matrix, and M the $m \times k$ matrix of the form $[I, 0]$. Assume that

(a) *$\psi'(\bar{x})$ exists and $\psi'(\bar{x})\eta \in \{w\} \times [C \ominus G - \psi_2(\bar{x})]$;*

(b) *$[\psi_1'(\bar{x}) + \varepsilon_1 M]\bar{B}_k \supset \beta \bar{B}_m$;*

(c) *$\eta + r\bar{B}_k \subset \mathcal{T}$, $\bar{x} + [0, r_1][\eta + r\bar{B}_k] \subset X$,*

$$r\psi_2'(\bar{x})\bar{B}_k \subset (1-\tau)\gamma G, \qquad \psi_2(\bar{x}) \in C \ominus \tau G.$$

Then for every $\varepsilon \in (0, r)$ there exists $\hat{\alpha} \in (0, \alpha_0 - \bar{\alpha})$ such that

$$\begin{aligned} &\psi_1(\bar{x}) + (\alpha - \bar{\alpha})[w + (r-\varepsilon)\beta \bar{B}_m] \\ &\quad \subset \{\psi_1(x) + \varepsilon_1 M[x - \bar{x} - (\alpha - \bar{\alpha})\eta] \mid x \in X \cap \alpha\mathcal{T}, \\ &\qquad \psi_2(x) + (\alpha - \bar{\alpha})(1-\gamma)(1-\tau)G \subset C \ominus \tau G\} \qquad \forall \alpha \in [\bar{\alpha}, \bar{\alpha} + \hat{\alpha}]. \end{aligned}$$

In particular, if $z \in r\beta B_m$ then there exists a function $\alpha \to x_\alpha$ on $[\bar{\alpha}, \bar{\alpha} + \hat{\alpha}]$ such that

$$x_\alpha \in \alpha\mathcal{T}, \qquad x_\alpha - \bar{x} \in (\alpha - \bar{\alpha})\mathcal{T},$$
$$\psi_1(x_\alpha) = \psi_1(\bar{x}) + (\alpha - \bar{\alpha})(w + z) - \varepsilon_1 M[x_\alpha - \bar{x} - (\alpha - \bar{\alpha})\eta],$$
$$\psi_2(x_\alpha) + (\alpha - \bar{\alpha})(1-\gamma)(1-\tau)G \subset C \ominus \tau G.$$

Proof. Let $\alpha_0^\# = \alpha_0 - \bar{\alpha}$, $X^\# = X - \bar{x}$ and, for all $x \in X^\#$,

$$\psi_1^\#(x) = \psi_1(\bar{x} + x) + \varepsilon_1 Mx, \quad \psi_2^\#(x) = \psi_2(\bar{x} + x), \quad \psi^\#(x) = (\psi_1^\#, \psi_2^\#)(x)$$
$$G^\# = (1-\tau)G, \quad C^\# = C \ominus \tau G, \quad w^\# = w + \varepsilon_1 M\eta.$$

Then

$$\psi_1^{\#\prime}(0)\eta = \psi_1'(\bar{x})\eta + \varepsilon_1 M\eta = w + \varepsilon_1 M\eta = w^{\#}, \qquad \psi_1^{\#\prime}(0)\bar{B}_k \supset \beta\bar{B}_m$$

$$\psi_2^{\#}(0) = \psi_2(\bar{x}) \in C \ominus \tau G_2 = C^{\#}, \qquad r\psi_2^{\#\prime}(0)\bar{B}_k \subset \gamma G^{\#}$$

and, by Lemma 4.1,

$$\psi_2^{\#\prime}(0)\eta = \psi_2'(\bar{x})\eta \in C \ominus G - \psi_2(\bar{x})$$
$$\subset C^{\#} \ominus (1-\tau)G - \psi_2^{\#}(0) = C^{\#} \ominus G^{\#} - \psi_2^{\#}(0).$$

Thus the function $\psi^{\#}$ satisfies the assumptions of Lemma 4.3, with the symbols denoted by $^{\#}$ replacing similarly named symbols in Lemma 4.3. It follows then, by relation (*) of Lemma 4.3, that for every $\varepsilon \in (0, r)$ there exists $\hat{\alpha}$ such that

$$\psi_1(\bar{x}) + \alpha[w + (r-\varepsilon)\beta\bar{B}_m] + \alpha\varepsilon_1 M\eta = \psi_1^{\#}(0) + \alpha[w^{\#} + (r-\varepsilon)\bar{B}_m]$$
$$\subset \{\psi_1^{\#}(x) \,|\, x \in X^{\#} \cap \alpha\mathcal{T},\ \psi_2^{\#}(x) + \alpha(1-\gamma)G^{\#} \subset C^{\#}\}$$
$$= \{\psi_1(\bar{x}+x) + \varepsilon_1 Mx \,|\, x \in X^{\#} \cap \alpha\mathcal{T},\ \psi_2(\bar{x}+x) + \alpha(1-\gamma)(1-\tau)G \in C \ominus \tau G\}$$
$$\forall \alpha \in [0, \hat{\alpha}].$$

We observe that, since $\mathcal{T}$ is convex and $\bar{x} \in \bar{\alpha}\mathcal{T}$, the relation $x \in \alpha\mathcal{T}$ implies $\bar{x} + x \in (\bar{\alpha} + \alpha)\mathcal{T}$. If we replace $\bar{\alpha} + \alpha$ by α and, in the expression on the right-hand side, $\bar{x} + x$ by x, then the conclusions follow directly. □

Proof of Theorem 2.1. *Step* 1. We may, and shall, assume that $k \geqq m$. Indeed, let $r(x)$ be as described in condition (c). Then

$$\sigma := \sup\{|r(x)| \,|\, x \in X \cap [0, \alpha_0]\mathcal{T}\} < \infty$$

because $\mathcal{T}$ is compact. Therefore, if $k < m$, we may replace

$$k,\ X,\ \mathcal{T},\ \psi(x_1, \cdots, x_k), \qquad \eta(x_1, \cdots, x_k)$$

by

$$k^{\#} = m, \quad X^{\#} = X \times \mathbb{R}^{m-k}, \quad \mathcal{T}^{\#} = \mathcal{T} \times \sigma\bar{B}_{m-k},$$

$$\psi^{\#}(x_1, \cdots, x_m) = \psi(x_1, \cdots, x_k), \qquad \eta^{\#}(x_1, \cdots, x_m) = (\eta(x_1, \cdots, x_k), 0, \cdots, 0),$$

which yields an equivalent problem that also satisfies conditions (a)-(c). (It is clear that, for $k < m$, conditions (e) and (f) cannot be satisfied.)

Let $s \in (0, 1)$, $T = \max\{|x| \,|\, x \in \mathcal{T}\}$ and

$$P_{\alpha,s} = \{\psi_1(x) \,|\, x \in X \cap \alpha\mathcal{T},\ \psi_2(x) \in C \ominus (1 - e^{-\alpha})sG\} \quad \forall \alpha \in [0, \alpha_0].$$

We shall show that, for all $\varepsilon \in (0, 1]$ and $\alpha \in [0, \alpha_0]$,

$$d[\psi_1(0) + \alpha w, P_{\alpha,s}] \leqq 2\varepsilon\alpha T. \tag{1}$$

With s and ε fixed, let

$$A = \{a \in [0, \alpha_0] \,|\, (1) \text{ is valid for } \alpha \in [0, \alpha]\}.$$

Each of the sets $P_{\alpha,s}$ and A is closed because ψ is continuous, $\mathcal{T}$ compact and, by Lemma 4.1, the set $C \ominus (1 - e^{-\alpha})sG$ closed. We easily verify that $0 \in A$. Now assume, by way of contradiction, that $\bar{\alpha} := \max A < a_0$. Since $\bar{\alpha} \in A$, there exists $\bar{x} \in X \cap \bar{\alpha}\mathcal{T}$ such that

$$|\psi_1(\bar{x}) - [\psi_1(0) + \bar{\alpha}w]| \leqq 2\varepsilon\bar{\alpha}T, \qquad \psi_2(\bar{x}) \in C \ominus (1 - e^{-\bar{\alpha}})sG. \tag{2}$$

Let M be the $m \times k$ matrix of the form $[I, 0]$, where I is the $m \times m$ unit matrix. We observe that $\psi_1'(\bar{x}) + \varepsilon_1 M$ is of full rank except for at most m values of ε_1. We may, therefore, choose $\varepsilon_1 \in (0, \varepsilon]$ so as to preserve full rank, and then determine $\beta > 0$ such that $[\psi_1'(\bar{x}) + \varepsilon_1 M]\bar{B}_k \supset \beta \bar{B}_m$. Let

$$\tau = s(1 - e^{-\bar{\alpha}}), \quad \gamma = (1 - s + se^{-\bar{\alpha}})^{-1}(1 - s), \quad r_1 = r_1(\bar{x}).$$

Since $\psi'(\bar{x})\bar{B}_k$ is compact, it follows from (c) that there exists $r \in (0, r(\bar{x})]$ such that

$$\eta(\bar{x}) + r\bar{B}_m \in \mathcal{T}, \quad \bar{x} + [0, r_1](\eta(\bar{x}) + r\bar{B}_m) \subset X, \quad r\psi_2'(\bar{x})\bar{B}_k \subset \gamma(1 - \tau)G.$$

It follows then, by Lemma 4.4 (with $\eta = \eta(\bar{x})$ and $z = 0$), that there exist $\hat{\alpha} \in (0, \alpha_0 - \bar{\alpha})$ and a function $\alpha \to x_\alpha : [\bar{\alpha}, \bar{\alpha} + \hat{\alpha}] \to X$ such that, for all $\alpha \in [\bar{\alpha}, \bar{\alpha} + \hat{\alpha}]$,

$$x_\alpha \in \alpha\mathcal{T}, \qquad x_\alpha - \bar{x} \in (\alpha - \bar{\alpha})\mathcal{T},$$

$$\psi_1(x_\alpha) = \psi_1(\bar{x}) + (\alpha - \bar{\alpha})w - \varepsilon_1 M[x_\alpha - \bar{x} - [\alpha - \bar{\alpha}]\eta(\bar{x})], \tag{3}$$

$$\psi_2(x_\alpha) + (\alpha - \bar{\alpha})(1 - \gamma)(1 - \tau)G \subset C \ominus \tau G.$$

This last relation implies (using Lemma 4.1) that

$$\psi_2(x_\alpha) \in C \ominus \sigma G,$$

where

$$\sigma = \tau + (\alpha - \bar{\alpha})(1 - \gamma)(1 - \tau),$$

and we verify that $\sigma \geqq s(1 - e^{-\alpha})$ for $\alpha \geqq \bar{\alpha}$. Thus (again by Lemma 4.1),

$$\psi_2(x_\alpha) \in C \ominus s(1 - e^{-\alpha})G \quad \forall \alpha \in [\bar{\alpha}, \bar{\alpha} + \hat{\alpha}]. \tag{4}$$

Relations (2) and (3) imply that

$$\begin{aligned} |\psi_1(x_\alpha) - [\psi_1(0) + \alpha w]| &\leqq |\psi_1(x_\alpha) - \psi_1(\bar{x}) - (\alpha - \bar{\alpha})w| + |\psi_1(\bar{x}) - [\psi_1(0) + \bar{\alpha}w]| \\ &\leqq \varepsilon_1 |M[x_\alpha - \bar{x} - (\alpha - \bar{\alpha})\eta(\bar{x})]| + 2\varepsilon\bar{\alpha}T \leqq 2\varepsilon(\alpha - \bar{\alpha})T + 2\varepsilon\bar{\alpha}T \\ &= 2\varepsilon\bar{\alpha}T \qquad \forall \alpha \in [\bar{\alpha}, \bar{\alpha} + \hat{\alpha}]. \end{aligned}$$

This last inequality, together with (4), shows that relation (1) is valid for all $\alpha \in [0, \bar{\alpha} + \hat{\alpha}]$, contrary to the definition of $\bar{\alpha}$. Thus (1) holds for all $\alpha \in [0, \alpha_0]$.

Since $P_{\alpha,s}$ is closed for each α and s and since ε can be chosen arbitrarily small, it follows that $\psi_1(0) + \alpha w \in P_{\alpha,s}$ for all $\alpha \in [0, \alpha_0]$ and $s \in (0, 1)$. By Lemma 4.2, this implies that validity of relation (*).

Step 2. We next proceed to prove relation (***) under assumptions (d) and (f). However, we at first replace (f) by the stronger assumption

H_1: assumption (f) holds with continuous $\rho(\cdot)$, $\beta(\cdot)$, and $\delta(\cdot)$.

Under assumptions (d) and H_1 we first prove that, for every

$$p \in B_m, \quad s \in (0, 1) \quad \text{and} \quad \alpha \in [0, \alpha_0],$$

we have

$$\psi_1(0) + \alpha w + sI(\alpha)p \in \{\psi_1(x) \mid x \in X \cap \alpha\mathcal{T}, \psi_2(x) \in C \ominus sJ(\alpha)G_2\} \tag{5}$$

for all $\alpha \in [0, \alpha_0]$. Let p and s be fixed, and let

$$A = \{a \in [0, \alpha_0] \mid (5) \text{ is valid for } \alpha \in [0, a]\}.$$

The functions $\alpha \to I(\alpha)$ and $\alpha \to J(\alpha)$ are continuous and positive and $J(\alpha) < 1$ for all $\alpha \in [0, \alpha_0]$. It follows that A is closed, and clearly $0 \in A$. Assume, by way of contradiction, that $\bar{\alpha} := \max A < \alpha_0$. Since $\bar{\alpha} \in A$, there exists $\bar{x} \in X \cap \bar{\alpha}\mathcal{T}$ such that

$$\psi_1(\bar{x}) = \psi_1(0) + \bar{\alpha}w + sI(\bar{\alpha})p, \qquad \psi_2(\bar{x}) \in C \ominus sJ(\bar{\alpha})G_2. \tag{6}$$

It follows now from (6) and Lemma 4.4, with the redefined parameters

$$\tau = sJ(\bar{\alpha}), \quad \varepsilon_1 = 0, \quad r = \rho(\bar{\alpha}), \quad r_1 = r_1(\bar{x}), \quad \beta = \beta(\bar{\alpha}),$$
$$\gamma = (1-\tau)^{-1}(1-\delta(\bar{\alpha})), \quad \varepsilon = r(1-|p|), \quad \eta = \eta(\bar{x})$$

that there exists $\hat{\alpha} \in (0, \alpha_0 - \bar{\alpha}]$ such that

$$\psi_1(\bar{x}) + (\alpha - \bar{\alpha})(w + r\beta[0,1]p) = \psi_1(0) + \alpha w + (sI(\bar{\alpha}) + (\alpha - \bar{\alpha})r\beta[0,1][0,1])p$$
$$\subset \{\psi_1(x) \,|\, x \in X \cap \alpha\mathcal{T}, \psi_2(x) \in C \ominus [\tau + (\alpha - \bar{\alpha})(\delta(\bar{\alpha}) - \tau)]G\} \tag{7}$$
$$\forall \alpha \in [\bar{\alpha}, \bar{\alpha} + \hat{\alpha}].$$

Since $\rho(\cdot)$, $\beta(\cdot)$, and $\delta(\cdot)$ are assumed to be positive and continuous and $0 < s < 1$, there exists $a_1 \in (0, \hat{\alpha}]$ such that, for all $\alpha \in [\bar{\alpha}, \bar{\alpha} + a_1]$,

$$(\alpha - \bar{\alpha})\rho(\bar{\alpha})\beta(\bar{\alpha}) \geqq s \int_{\bar{\alpha}}^{\alpha} \rho(t)\beta(t)\, dt = s[I(\alpha) - I(\bar{\alpha})],$$

and, therefore, there exists $\theta(\alpha) \in [0, 1]$ such that

$$sI(\bar{\alpha}) + (\alpha - \bar{\alpha})\rho(\bar{\alpha})\beta(\bar{\alpha})\theta(\alpha) = sI(\alpha). \tag{8}$$

Furthermore, we observe that $\alpha \to J(\alpha)$ satisfies the equation

$$J'(\alpha) + J(\alpha) = \delta(\alpha),$$

and, therefore, we can reduce a_1, if necessary, so that

$$\Delta J(\alpha)/\Delta\alpha + J(\bar{\alpha}) \leqq \frac{1}{s}\delta(\bar{\alpha}) \quad \text{for} \quad \alpha \in (\bar{\alpha}, \bar{\alpha} + a_1],$$

where

$$\Delta J(\alpha)/\Delta\alpha := (\alpha - \bar{\alpha})^{-1}[J(\alpha) - J(\bar{\alpha})].$$

If we recall that, in this step, $\tau = sJ(\bar{\alpha})$, then the last inequality implies

$$sJ(\alpha) \leqq sJ(\bar{\alpha}) + (\alpha - \bar{\alpha})[\delta(\bar{\alpha}) - sJ(\bar{\alpha})] = \tau + (\alpha - \bar{\alpha})[\delta(\bar{\alpha}) - \tau].$$

This relation, (7), and (8) yield

$$\psi_1(0) + \alpha w + sI(\alpha)p \in \{\psi_1(x) \,|\, x \in X \cap \alpha\mathcal{T}, \psi_2(x) \in C \ominus sJ(\alpha)G\}$$
$$\forall \alpha \in (\bar{\alpha}, \bar{\alpha} + a_1].$$

This shows that the relation (5) holds for all $\alpha \in [0, \bar{\alpha} + a_1]$, contradicting the definition of $\bar{\alpha}$, and thus proves that relation (5) holds for all $\alpha \in [0, \alpha_0]$.

We now replace assumption H_1 with the weaker assumption (f). We observe that assumption (f) remains satisfied if we replace $\rho(\cdot)$, $\beta(\cdot)$, $\delta(\cdot)$ by the continuous functions

$$\rho_n(\alpha) \leqq \rho(\alpha), \quad \beta_n(\alpha) \leqq \beta(\alpha), \quad \delta_n(\alpha) \leqq \delta(\alpha) \quad \forall j = 1, 2, \cdots, \quad \alpha \in [0, \alpha_0]$$

whose existence is postulated in (f). Since these functions are positive and converge pointwise from below, we have

$$\lim_n I_n(\alpha) = I(\alpha), \quad \lim_n J_n(\alpha) = J(\alpha) \quad \forall \alpha \in [0, \alpha_0],$$

where

$$I_n(\alpha) := \int_0^\alpha \rho_n(t)\beta_n(t)\,dt, \qquad J_n(\alpha) := \int_0^\alpha e^{-(\alpha-t)}\delta_n(t)\,dt,$$

and we have just shown that relation (5) is valid with $I(\alpha)$, $J(\alpha)$ replaced by $I_n(\alpha)$, $J_n(\alpha)$. We now choose a point $\bar{p} \in \bar{B}_m$ and sequences (s_n) in $(0,1)$ and (p_n) in B_m converging to 1 and $\bar{p}$. Since relation (5) holds with s, p, $I(\alpha)$, $J(\alpha)$ replaced by s_n, p_n, $I_n(\alpha)$, $J_n(\alpha)$, and since ψ is continuous and $\mathcal{T}$ compact, it follows from (5) (as modified) and Lemma 4.2 that

$$\psi_1(0) + \alpha w + I(\alpha)\bar{B}_m \subset \{\psi_1(x) \mid x \in X \cap \alpha\mathcal{T},\ \psi_2(x) + J(\alpha)G \subset C\} \quad \forall \alpha \in [0, \alpha_0]. \tag{9}$$

Thus relation (9) holds under assumptions (d) and (f). This proves relation (***).

Step 3. Our next goal is to prove relation (**) under assumptions (d) and (e). Let $0 < \bar{\alpha} < \alpha_0$, and let u_n be defined as in Condition 2.0. By (*) and (d), there exists $\bar{x} \in X \cap \bar{\alpha}\mathcal{T}$ such that

$$\psi_1(\bar{x}) = \varphi_1(\bar{q}) + \bar{\alpha}w, \qquad \psi_2(\bar{x}) = \varphi_2(\hat{q}(\bar{x})) \in C \ominus (1 - e^{-\bar{\alpha}})G.$$

Now fix $s \in (0,1)$. Then, by Condition 2.0, we may determine a sufficiently small $\rho \in (0, \alpha_0 - \bar{\alpha}]$ and a sufficiently large N so that

$$\psi_2(u_n(\bar{x}+x)) - \varphi_2(\hat{q}(\bar{x})) \in (1-s)(1-e^{-\bar{\alpha}})G;$$

hence, by Lemma 4.1,

$$\varphi_2(u_n(\bar{x}+x)) \in C \ominus (1-e^{-\bar{\alpha}})sG \quad \forall n \geqq N, \quad x \in X \cap [\bar{\alpha}, \bar{\alpha}+\rho]\mathcal{T}. \tag{10}$$

We than set

$$\begin{aligned} &\alpha_0^* = \rho, \quad \eta^* = 0 \in \mathbb{R}^k, \quad w^* = 0 \in \mathbb{R}^m, \quad X^* = X - x, \quad r^* = r(\bar{x}), \quad r_1^* = r_1(\bar{x}), \\ &\hat{q}^*(x) = \hat{q}(\bar{x}+x), \quad u_n^*(x) = u_n(\bar{x}+x), \quad \psi_1^*(x) = \varphi_1(\hat{q}^*(x)) \quad \forall x \in X^*. \end{aligned} \tag{11}$$

Since $\psi_1^{*\prime}(0) = \psi_1'(\bar{x})$ is of full rank, there exists $\beta^* > 0$ such that $\psi_1^{*\prime}(0)\bar{B}_k \supset \beta^*\bar{B}_m$. Thus the assumptions of Lemma 4.3 are satisfied by the function φ_1 and the objects defined in (11) (neglecting the relations in $\mathcal{X}$). Therefore, there exists $\hat{\alpha}^* \in (0, \alpha_0^*]$ (corresponding to $\varepsilon = 1 - s$) such that

$$\begin{aligned} \psi_1^*(0) + \alpha[w^* + s\beta^*\bar{B}_m] &= \varphi_1(\bar{q}) + \bar{\alpha}w + \alpha s\beta^*\bar{B}_m \\ &\subset \{\varphi_1(u_n^*(x)) \mid x \in X^* \cap \alpha\mathcal{T}\} \quad \forall \alpha \in (0, \hat{\alpha}^*]. \end{aligned}$$

Since $\mathcal{T}$ is convex, we have $\bar{x} + x \in (\bar{\alpha} + \alpha)\mathcal{T}$ and, therefore, in view of (10), this yields, for $\alpha = \alpha_1 = \min(\hat{\alpha}^*, \rho)$ and $V_{s,\bar{\alpha}} = \alpha_1 s\beta^*\bar{B}_m$,

$$\varphi_1(\bar{q}) + \bar{\alpha}w + V_{s,\bar{\alpha}} \subset \{\varphi_1(u) \mid u \in \mathcal{U},\ \varphi_2(u) + (1-e^{-\bar{\alpha}})sG \subset C\}.$$

This proves relation (**).

Step 4. We use a similar argument to prove relation (****). Specifically, assume that conditions (d) and (f) hold, and let $0 < \bar{\alpha} < \alpha_0$ and $p \in \bar{B}_m$. Then, as was shown in Step 2, relation (9) is valid and implies that there exists $\bar{x} \in X \cap \bar{\alpha}\mathcal{T}$ such that

$$\psi_1(\bar{x}) = \psi_1(0) + \bar{\alpha}w + I(\bar{\alpha})p, \qquad \psi_2(\bar{x}) = \varphi_2(\hat{q}(\bar{x})) \in C \ominus J(\bar{\alpha})G. \tag{12}$$

Now let $s \in (0, 1)$. We may determine a sufficiently small $\rho \in (0, a_0 - \bar{\alpha}]$ and a sufficiently large N so that

$$\varphi_2(u_n(\bar{x}+x)) \in C \ominus sJ(\bar{\alpha})G \quad \forall n \geqq N, \quad x \in X \cap (\bar{\alpha}+\rho)\mathscr{T}. \tag{13}$$

We then set

$$\begin{gathered} \alpha_0^* = \rho, \quad \eta^* = 0 \in \mathbb{R}^k, \quad w^* = 0 \in \mathbb{R}^m, \quad X^* = X - \bar{x}, \\ \beta^* = \beta(\bar{\alpha}), \quad \gamma^* = 1 - \delta(\bar{\alpha}), \quad r^* = r(\bar{x}), \quad r_1 = r_1(\bar{x}), \\ q^*(x) = \hat{q}(\bar{x}+x), \quad u_n^*(x) = u_n(\bar{x}+x), \quad \psi_1^*(x) = \varphi_1(\hat{q}^*(x)) \quad \forall x \in X^*. \end{gathered} \tag{14}$$

Then the assumptions of Lemma 4.3 are satisfied by the function φ_1 and the objects defined in (14) if we neglect the relations in $\mathscr{Z}$. Therefore, in view of (12), for every $\varepsilon \in (0, 1)$ there exists $\hat{\alpha} > 0$ such that

$$\begin{aligned} &\varphi_1(\bar{q}) + \bar{\alpha}w + I(\bar{\alpha})p = \psi_1(\bar{x}) = \varphi_1(\hat{q}(\bar{x})) \\ &\quad \in \varphi_1(\hat{q}^*(0)) + \alpha[w^* + (r^* - \varepsilon)\beta^* \bar{B}_m] \subset \{\varphi_1(u_n^*(x)) \,|\, x \in X^* \cap \alpha\mathscr{T},\ n = 1, 2, \cdots\} \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \forall \alpha \in (0, \hat{\alpha}]; \end{aligned}$$

hence, in view of relation (13) and setting $\alpha = \hat{\alpha}$ above, we have

$$\varphi_1(\bar{q}) + \bar{\alpha}w + I(\bar{\alpha})p \in \{\varphi_1(u) \,|\, u \in \mathscr{U},\ \psi_2(u) \in C \ominus sJ(\bar{\alpha})G\}.$$

This proves relation (****). □

Proof of Theorem 2.2. *Step* 1. Let $W = W(0)$ and ψ^i correspond to $\bar{x} = 0$, and let $s \in (0, 1)$. We can determine $\alpha_s > 0$ sufficiently small and i_s sufficiently large so that

$$X \cap \alpha_s\mathscr{T} \subset W, \quad \psi_2^i(x) - \psi_2(0) \in (1-s)G \quad \forall i \geqq i_s, \quad x \in X \cap \alpha_s\mathscr{T}.$$

Now let $i \geqq i_s$. Then ψ^i restricted to $X \cap \alpha_s\mathscr{T}$ satisfies the assumptions (a)-(c) of Theorem 2.1, with α_0 and C replaced by α_s and C_s, where C_s is the closure of $C + (1-s)$ co G. Therefore, by relation (*) of Theorem 2.1, for every $\alpha \in [0, \alpha_s]$ we have

$$\psi_1^i(0) + \alpha w \in \{\psi_1^i(x) \,|\, x \in X \cap \alpha\mathscr{T},\ \varphi_2^i(x) + (1 - e^{-\alpha})G \subset C_s\}$$

so that for each $i \geqq i_s$ there exists $x^i \in X \cap \alpha\mathscr{T}$ such that

$$\psi_1^i(0) + \alpha w = \psi_1^i(x^i), \qquad \psi_2^i(x^i) + (1 - e^{-\alpha})G \subset C_s.$$

We may choose a subsequence of (x^i) converging to some $x^\alpha \in X \cap \alpha\mathscr{T}$ and conclude that

$$\psi_1(0) + \alpha w = \psi_1(x^\alpha), \qquad \psi_2(x^\alpha) + (1 - e^{-\alpha})G \subset C_s,$$

which implies that, for all $\alpha \in [0, \alpha_s]$,

$$\psi_1(0) + \alpha w \in \{\psi_1(x) \,|\, x \in X \cap \alpha\mathscr{T},\ \psi_2(x) + (1 - e^{-\alpha})G \subset C_s\}. \tag{1}$$

Let

$$A = \{a \in [0, \alpha] \,|\, \text{relation (1) holds for all } \alpha \in [0, a]\}.$$

The set A is closed because ψ is continuous and $\mathscr{T}$ compact, and clearly $0 \in A$. Thus $\bar{\alpha} := \sup A \in A$ and there exists $\bar{x} \in X \cap \bar{\alpha}\mathscr{T}$ such that

$$\psi_1(\bar{x}) = \psi_1(0) + \bar{\alpha}w, \qquad \psi_2(\bar{x}) \in C_s \ominus (1 - e^{-\bar{\alpha}})G.$$

Now assume that $\bar{\alpha} < \alpha_0$, and set, for $X^* = X - \bar{x}$ and $x \in X^* \cap (\alpha_0 - \bar{\alpha})\mathscr{T}$,

$$\psi^*(x) = \psi(\bar{x}+x), \quad C^* = C_s \ominus (1 - e^{-\bar{\alpha}})G, \quad G^* = e^{-\bar{\alpha}}G.$$

By Lemma 4.1, C^* is convex and $C^* \ominus G^* = C_s \ominus G$. Therefore, our argument leading to relation (1) is valid, with ψ, α_0, C, and G replaced by ψ^*, $\alpha_0 - \bar{\alpha}$, C^*, and G^*, and implies that there exists $\alpha_s \in (0, \alpha_0 - \bar{\alpha}]$ such that

$$\psi_1^*(0) + \alpha w \in \{\psi_1^*(x) \mid x \in X^* \cap \alpha \mathcal{T}, \psi_2^*(x) + (1 - e^{-\alpha}) G^* \subset C^*\} \tag{2}$$

$$\forall \alpha \in [0, \alpha_s].$$

We have

$$1 - e^{-\bar{\alpha}} + e^{-\bar{\alpha}}(1 - e^{-\alpha}) = 1 - e^{-(\bar{\alpha}+\alpha)}$$

and therefore, by Lemma 4.1,

$$C^* \ominus (1 - e^{-\alpha}) G^* = C_s \ominus (1 - e^{-(\bar{\alpha}+\alpha)}) G.$$

Thus, by (2), for all $\alpha \in [0, \alpha_s]$ we have

$$\psi_1(0) + (\bar{\alpha} + \alpha) w \in \{\psi_1(x) \mid x \in X \cap (\bar{\alpha} + \alpha) \mathcal{T}, \psi_2(x) + (1 - e^{-(\bar{\alpha}+\alpha)}) G \subset C_s\}.$$

This shows that $\max A \geqq \bar{\alpha} + \alpha_s > \bar{\alpha}$, contradicting the definition of $\bar{\alpha}$. Therefore, $A = [0, \alpha_0]$ and relation (1) is valid for all $s \in (0, 1)$ and $\alpha \in [0, \alpha_0]$. Our final conclusion now follows from (1) and Lemmas 4.1 and 4.2 by letting $s \to 1$. □

OPTIMAL FEEDBACK CONTROLS*

LEONARD D. BERKOVITZ†

This paper is dedicated to the memory of E. J. McShane.

Abstract. Optimal control problems governed by ordinary differential equations with control constraints that are not necessarily compact are considered. Conditions imposed on the data and on the structure of the terminal sets imply that the minimum is attained and that the value function is locally Lipschitz. A necessary condition in terms of lower directional Dini derivates of the value function is given. The condition reduces to the Bellman-Hamilton-Jacobi (BHJ) condition at points of differentiability of the value, and for a subclass of the problems considered implies that the value is a viscosity solution of the BHJ equation. A strengthened version of the necessary condition gives an optimal feedback control and a procedure for approximating optimal controls.

Key words. optimal feedback control, synthesis of optimal control, lower directional Dini derivates, Bellman-Hamilton-Jacobi equation, viscosity solution

AMS(MOS) subject classifications. 49B05, 49C05

1. Introduction. An important optimal control problem is the following. The state of a system at time t is described by an n-vector $x(t)=(x^1(t), \cdots, x^n(t))$ whose evolution is governed by a system of differential equations

$$x' = f(t, x, u(t)), \qquad x(\tau) = \xi \tag{1.1}$$

where u is a control function, or simply control, selected from some preassigned class of functions. A terminal set $\mathcal{T}$ is given in (t, x)-space, as is a real-valued function g defined on $\mathcal{T}$. Let $\phi(\cdot) = \phi(\ , \tau, \xi, u)$ be a solution of (1.1) such that at some time t_f, the trajectory $\phi(\cdot)$ hits the set $\mathcal{T}$ for the first time. The optimal control problem is to select a control u^* that minimizes $g(t_f, \phi(t_f))$.

Another problem, whose solution is even more useful in applications, is that of finding the optimal feedback, or optimal control synthesis. In this problem we seek a function U in some class defined on a region $\mathcal{R}$ of (t, x) space such that for all initial points (τ, ξ) in $\mathcal{R}$ the solution of

$$x' = f(t, x, U(t, x)), \qquad x(\tau) = \xi \tag{1.2}$$

lies in $\mathcal{R}$ and minimizes $g(t_f, \phi(t_f))$ for the initial point selected.

Suppose that the values $u(t)$ of the controls u are required to lie in some set $Z(t)$ in $\mathbb{R}^n$. Suppose that for each (τ, ξ) in some region $\mathcal{R}$, the optimal control problem has a solution and that u^* and ϕ^* are the control and corresponding trajectory that achieve the minimum. Let $W(\tau, \xi)$ denote the value of the minimum for the problem with initial point (τ, ξ). If W is continuously differentiable on $\mathcal{R}$, if the data of the problem are sufficiently differentiable, and if u is piecewise continuous, then the well-known dynamic programming argument shows that all points (t, x) of $\mathcal{R}$

$$W_t(t, x) + \min_{z \in Z(t)} \langle W_x(t, x), f(t, x, z) \rangle = 0 \tag{1.3}$$

where $\langle\ ,\ \rangle$ denotes inner product. Moreover, the minimum is attained at the values of the optimal controls at time t for the problem with initial point (t, x).

† Department of Mathematics, Purdue University, West Lafayette, Indiana 47907.

Relation (1.3) can also be used as a sufficient condition for optimality, an observation first made by Carathéodory [4, § 231] in connection with problems in the calculus of variations. Let W be a continuously differentiable function such that

$$W(t_f, x_f) = g(t_f, x_f) \tag{1.4}$$

at points (t_f, x_f) of the terminal set. Let u^* and ϕ^* be a control and corresponding trajectory for the problem with initial point (τ, ξ) such that if for all $\tau \leqq t \leqq t_f^*$, whenever we substitute $x = \phi^*(t)$ in (1.3), then the minimum is attained at $z = u^*(t)$. Then (ϕ^*, u^*) is optimal. To see this we note, assuming the requisite differentiability, that if u is a control and ϕ is the corresponding trajectory that

$$\begin{aligned} W(t_f, \phi(t_f)) - W(\tau, \xi) &= \int_\tau^{t_f} \left\{ \frac{d}{ds} W(s, \phi(s)) \right\} ds \\ &= \int_\tau^{t_f} \{ W_t(t, \phi(t)) + \langle W_x(t, \phi(t)), f(t, \phi(t), u(t)) \rangle \} \, ds. \end{aligned}$$

By (1.3) the integrand is nonnegative, so that $W(t_f, \phi(t_f)) \geqq W(\tau, \xi)$. On the other hand, if we take $(\phi, u) = (\phi^*, u^*)$, the integrand is zero and so $W(t_f^*, \phi^*(t_f^*)) = W(\tau, \xi)$. But by (1.4), $W(t_f, \phi(t_f)) = g(t_f, \phi(t_f))$ and $W(t_f^*, \phi^*(t_f^*)) = g(t_f^*, \phi(t_f^*))$. Thus (ϕ^*, u^*) minimizes.

Suppose further that a function U^* can be found such that the minimum in (1.3) is attained at $z = U^*(t, x)$ and such that (1.2) with $U(t, x)$ replaced by $U^*(t, x)$ has solutions for all (τ, ξ). If the function U^* has the requisite smoothness properties, the arguments of the preceding paragraph show that U^* is an optimal feedback control.

Unfortunately, in many specific problems the sufficiency theorem and the method of obtaining optimal feedback controls outlined above cannot be applied because the value function W does not have the requisite smoothness properties, nor does there exist any other solution W of (1.2) with the requisite smoothness.

Various authors have attempted to salvage the Carathéodory approach. One technique applicable to many examples is to assume that the field of extremals—that is, trajectories along which the Pontryagin maximum principle holds—has a certain structure. The ideas of Carathéodory can then be adapted to these situations. See Berkovitz [2], Boltyanskii [3], and Young [12], for example. Another approach, in which (1.3) is replaced by an equation involving the Clarke generalized gradient, was taken by Vinter and by Clarke and Vinter. See [6] and [7]. Reference [7] gives references to earlier work of Vinter.

In this paper we shall develop yet another modification of Carathéodory's ideas. We first recall a definition. Let L be a real-valued function defined on $\mathbb{R} \times \mathbb{R}^n$. The lower Dini derivate of L at the point (t, x) in the direction $(1, h)$, where $h \in \mathbb{R}^n$, is denoted by $D^- L(t, x; 1, h)$ and is defined by

$$D^- L(t, x; 1, h) = \liminf_{\delta \downarrow 0} \frac{L(t + \delta, x + \delta h) - L(t, x)}{\delta}. \tag{1.5}$$

Similarly, the upper Dini derivate of L at (t, x) in the direction $(1, h)$ is denoted by $D^+ L(t, x; 1, h)$ and is defined as in (1.5) with lim inf replaced by lim sup. The function L is said to have a directional derivative at (t, x) in the direction $(1, h)$ if $D^+ L(t, x; 1, h) = D^- L(t, x; 1, h)$. We denote the directional derivative by $DL(t, x; 1, h)$. If L is differentiable at (t, x), then $DL(t, x; 1, h)$ exists for every $h \in \mathbb{R}^n$ and

$$DL(t, x; 1, h) = L_t(t, x) + \langle L_x(t, x), h \rangle.$$

To describe our approach as simply as possible we shall assume that for each t the set $Z(t)$ is a fixed compact set Z. In the paper itself more general constraints will be allowed. Let $Q(t, x) = \{h: h = f(t, x, z), z \in Z\}$. In the problems that we consider the value function W will be locally Lipschitz continuous. We shall show that W satisfies

$$\min_{h \in Q(t,x)} D^- W(t, x; 1, h) = 0 \tag{1.6}$$

at each point (t, x) of $\mathcal{R}$. This is the generalization of (1.3). At points of differentiability of W, relation (1.6) implies (1.3). Relation (1.6) also implies that W is a viscosity solution of the Hamilton–Jacobi equation (1.3).

Now let W be any locally Lipschitz function that satisfies (1.6) at all points of $\mathcal{R}$ and that satisfies the boundary condition (1.4) at points of $\mathcal{T}$. For (t, x) in $\mathcal{R}$ let

$$\begin{aligned} F(t, x) &= \arg\min_{h \in Q(t,x)} D^- W(t, x; 1, h) \\ &\equiv \{h: h \in Q(t, x), D^- W(t, x; 1, h) = 0\}. \end{aligned} \tag{1.7}$$

Then $F(t, x)$ is nonempty, and the function F may be set-valued. It is an easy calculation, which we shall give in Lemma 5.1 below, that any absolutely continuous solution ψ of the differential inclusion

$$x' \in F(t, x), \qquad x(\tau) = \xi \tag{1.8}$$

is optimal. Thus, if (1.8) has a solution for each initial point (τ, ξ) in $\mathcal{R}$, then F will be an optimal feedback control in the sense described. In this paper we shall impose conditions on F that guarantee the existence of a solution of (1.8). The proof will describe a constructive method for approximating such solutions.

In conclusion we point out that with minor modifications in wording and hypotheses to suit the new context, our results and arguments apply to control problems in which the state of the system is governed by a differential inclusion

$$x' \in Q(t, x), \qquad x(\tau) = \xi.$$

The interested reader will have no trouble in interpreting our results in this context.

Results related to some of ours have been obtained in the differential inclusion context by Frankowska [8].

2. Assumptions and problem formulation. As indicated in the Introduction, t denotes time and x denotes a vector in $\mathbb{R}^n$, the state space. The letter z denotes a vector in $\mathbb{R}^m$, the range space of the controls. Components of vectors are denoted by superscripts. Thus $x = (x^1, \cdots, x^n)$, $z = (z^1, \cdots, z^m)$, etc. The Euclidean norm of a vector is denoted by $|\cdot|$. Let $T > 0$ be fixed.

A mapping from $[0, T] \times \mathbb{R}^n \times \mathbb{R}^m$ to $\mathbb{R}^n$ is denoted by f, and g denotes a mapping from $[0, T] \times \mathbb{R}^n$ to $\mathbb{R}$. The letter Z denotes a mapping from $[0, T]$ to the subsets of $\mathbb{R}^m$. If $\mathcal{Y}$ is a subset of some Euclidean space, by an ε-neighborhood of $\mathcal{Y}$, we mean the set $\mathcal{N}_\varepsilon(\mathcal{Y})$ defined by $\mathcal{N}_\varepsilon(\mathcal{Y}) = \{y': |y' - y| < \varepsilon \text{ for some } y \in \mathcal{Y}\}$.

A mapping Q from a subset $\mathcal{Y}$ of a Euclidean space $\mathbb{R}^p$ to subsets of a Euclidean space $\mathbb{R}^q$ is said to satisfy property (Q) at a point y in $\mathcal{Y}$ if

$$Q(y) = \bigcap_{\delta > 0} \operatorname{clco} \{Q(\mathcal{N}_\delta(y) \cap \mathcal{Y})\}. \tag{2.1}$$

Note that if the mapping Q satisfies property (Q) then $Q(y)$ must be closed and convex.

We now state our assumptions on the data of the problem.

ASSUMPTION I. (1) The mapping f is continuous on $[0, T]\times\mathbb{R}^n\times\mathbb{R}^m$.

(2) For every $R>0$, there exists a constant $K_R>0$ such that for all $t\in[0, T]$, $z\in\mathbb{R}^m$ and x, $\bar{x}$ in $\mathbb{R}^n$ with $|x|\leqq R$, $|\bar{x}|\leqq R$,

$$|f(t, x, z)-f(t, \bar{x}, z)|\leqq K_R|x-\bar{x}|.$$

(3) There exists a real-valued function β in $L_\infty[0, T]$ such that for almost all $t\in[0, T]$ and all $x\in\mathbb{R}^n$, $z\in\mathbb{R}^m$

$$|f(t, x, z)|\leqq\beta(t)(1+|x|).$$

(4) For each (t, x) in $[0, T]\times\mathbb{R}^n$ let

$$Q(t, x)=\{h: h=f(t, x, z),\ z\in Z(t)\}.$$

The mapping Q satisfies property (Q) at every point of $[0, T]\times\mathbb{R}^n$.

(5) For every $R>0$ there exists a constant $K'_R>0$ such that for all t, $\bar{t}$ in $[0, T]$ and all x, $\bar{x}$ such that $|x|\leqq R$, $|\bar{x}|\leqq R$,

$$|g(\bar{t}, \bar{x})-g(t, x)|\leqq K'_R(|\bar{t}-t|+|\bar{x}-x|).$$

Remark 2.1. The requirement that Q satisfies property (Q) is imposed to ensure the existence of optimal solutions, since we do not assume that the sets $Z(t)$ are compact. The mapping $Z=Z(\cdot)$ is said to be upper semicontinuous with respect to inclusion (u.s.c.i) at t_0 if for every $\varepsilon>0$ there exists a $\delta>0$ such that $Z(t)\subseteq\mathcal{N}_\varepsilon(Z(t_0))$ whenever $|t-t_0|<\delta$. In problems with compact constraint sets $Z(t)$, in order to guarantee the existence of optimal solutions it is assumed that at each t in $[0, T]$ the set $Z(t)$ is compact and the mapping Z is u.s.c.i. It is also assumed that at each (t, x) in $[0, T]\times\mathbb{R}^n$ the set $Q(t, x)$ is convex. It is known that for f continuous, these conditions imply that Q satisfies property (Q) in $[0, T]\times\mathbb{R}^n$. Thus, our treatment includes the compact case. See [1] and [5].

Remark 2.2. If the sets $Q(t, x)$ are not convex, we consider the relaxed problem in which the right-hand side of (1.1) is replaced by

$$\tilde{f}(t, x, \tilde{z}, \pi)\equiv\sum_{i=1}^{n+1}\pi^i f(t, x, z_i)$$

where $\tilde{z}=(z_1, \cdots, z_{n+1})\in\mathbb{R}^{(n+1)m}$ and $\pi=(\pi^1, \cdots, \pi^{n+1})\in\mathbb{R}^{n+1}$. The state variable for this problem is x and the control variables are $\tilde{z}$ and π. If $z\in Z(t)$ is the control constraint for the original problem, then the control constraint for the relaxed problem is $\tilde{z}\in\tilde{Z}(t)$, where $\tilde{Z}(t)$ denotes the Cartesian product of $Z(t)$ with itself $(n+1)$ times, and $\pi\in\Gamma\equiv\{\pi: \pi^i\geqq 0, \sum_{i=1}^{n+1}\pi^i=1\}$. In the relaxed problem the sets

$$\tilde{Q}(t, x)=\{h: h\in\tilde{f}(t, x, \tilde{z}, \pi),\ (\tilde{z}, \pi)\in\tilde{Z}(t)\times\Gamma\}$$

are convex. We henceforth suppose that if the sets $Q(t, x)$ are not convex, then we are considering the relaxed problem. We shall, however, retain the notation of the original problem. Note, however, that in the noncompact case we must still postulate that $\tilde{Q}(t, x)$ is closed and that (2.1) holds at each point $y=(t, x)$ in $[0, T]\times\mathbb{R}^n$.

A *control* u on $[\tau, T]$, $0\leqq\tau<T$, will be defined to be a measurable function defined on $[\tau, T]$ with $u(t)\in Z(t)$ almost everywhere on $[\tau, T]$.

Standard theorems concerning the existence and uniqueness of solutions of ordinary differential equations, elementary arguments and Gronwall's Lemma give the following result.

LEMMA 2.1. *Let f satisfy* (1)-(3) *of Assumption* I. *Then for each* (τ, ξ) *in* $[0, T)\times\mathbb{R}^n$ *and each control* u *on* $[\tau, T]$ *the differential equation* (1.1) *has a unique solution* $\phi(\ , \tau, \xi)$ *defined on* $[\tau, T]$. *Let* $\mathscr{K}$ *be a compact set contained in* $[0, T)\times\mathbb{R}^n$. *Then these exists a constant* $R>0$ *that depends only on* $\mathscr{K}$, *such that for any* (τ, ξ) *in* $\mathscr{K}$ *and any control* u *on* $[\tau, T]$ *the unique solution* $\phi(\ , \tau, \xi)$ *of* (1.1) *satisfies*

$$|\phi(t, \tau, \xi)| \leqq R \quad \text{for } \tau \leqq t \leqq T \tag{2.2}$$

and

$$|\phi(t, \tau, \xi) - \phi(t', \tau, \xi)| \leqq (1+R)|t - t'| \tag{2.3}$$

for all t, t' *in* $[\tau, T]$. *Moreover, there exists a constant* $K_1>0$ *that depends only on* $\mathscr{K}$ *such that for any pair of points* (τ, ξ) *and* (τ', ξ') *in* $\mathscr{K}$ *and any control* u *defined on* $[\max(t, \tau'), T]$

$$|\phi(t, \tau, \xi) - \phi(t, \tau', \xi')| \leqq K_1(|\tau - \tau'| + |\xi - \xi'|) \tag{2.4}$$

for $\max(\tau, \tau') \leqq t \leqq T$.

Given an initial point (τ, ξ) and a control u on $[\tau, T]$, we shall refer to $\phi(\ , \tau, \xi)$ as the trajectory corresponding to u.

We now discuss the nature of the terminal set $\mathscr{T}$. Let $\mathscr{F}$ be a closed domain in $[0, \infty)\times\mathbb{R}^n$ whose boundary is a $C^{(2)}$ manifold. We suppose that the intersection of $\mathscr{F}$ with the hyperplane $t = T$ has nonvoid interior relative to the hyperplane.

If $[T, \infty)\times\mathbb{R}^n \not\subseteq \mathscr{F}$, then we define

$$\mathscr{T} = \mathscr{F} \cup ([T, \infty)\times\mathbb{R}^n) \tag{2.5}$$

and say that the terminal set $\mathscr{T}$ is of Type I.

Example. To illustrate terminal sets of Type I consider the problem of reaching an ε-neighborhood of the origin in minimum time, where we restrict the time so as not to exceed some fixed time T. The set $\mathscr{F}$ for this problem is the half-cylinder $\{(t, x): t \geqq 0, |x| \leqq \varepsilon\}$ and the set $\mathscr{T}$ is the union of this half cylinder and the halfspace $[T, \infty)\times\mathbb{R}^n$. The function g is defined by $g(t, x) = t$.

If $[T, \infty)\times\mathbb{R}^n \subseteq \mathscr{F}$, then we define

$$\mathscr{T} = \mathscr{F} \tag{2.6}$$

and say that the terminal set $\mathscr{T}$ is of Type II.

Let

$$\mathscr{R} = \{(\tau, \xi): (\tau, \xi) \in [0, T)\times\mathbb{R}^n, (\tau, \xi) \notin \mathscr{T}\}. \tag{2.7}$$

It follows from Lemma 2.1 and the definition of $\mathscr{T}$, that for any (τ, ξ) in $\mathscr{R}$ and any control u on $[\tau, T]$, the corresponding trajectory $\phi(\ , \tau, \xi)$ will intersect $\mathscr{T}$ at a first time $t_1 = t_1(\tau, \xi, u) = \min\{t: (t, \phi(t, \tau, \xi)) \in \mathscr{T}\}$. We call t_1 the terminal time of the trajectory ϕ.

The stopping rule for our problem will be, "Stop at time t_1."

For each (τ, ξ) in $\mathscr{R}$ such that controls exist on $[\tau, T]$ we formulate the following problem.

PROBLEM I. Minimize $J(\tau, \xi, u) \equiv g(t_1, \phi(t_1, \tau, \xi))$ subject to (1.1) over all controls u on $[\tau, T]$.

It is known that under Assumption I and our assumptions on $\mathscr{T}$ that if the set of controls is nonempty, then there exists a control u^* on $[\tau, T]$ that furnishes a minimum. See [1] and [5].

To carry out our analysis we will need to impose a further condition relating the dynamics to the boundary. If $\mathcal{T}$ is of Type I, let $\hat{\partial}\mathcal{F}$ denote those boundary points of $\mathcal{F}$ that do not belong to $(T, \infty)\times\mathbb{R}^n$, i.e.,

$$\hat{\partial}\mathcal{F} = \partial\mathcal{F} \cap [0, T]\times\mathbb{R}^n. \tag{2.8}$$

If $\mathcal{T}$ is of Type II, let $\hat{\partial}\mathcal{F} = \partial\mathcal{T} = \partial\mathcal{F}$.

Note that $\hat{\partial}\mathcal{F}$ is smooth, since it is a subset of the boundary of $\mathcal{F}$. In our example $\hat{\partial}\mathcal{F} = \{(t, x)\colon 0 \leqq t \leqq T,\ |x| = \varepsilon\}$.

For $p^0 \in \mathbb{R}$, $p \in \mathbb{R}^n$, define

$$B(t, x, p_0, p) = \sup\{p_0 + \langle p, f(t, x, z)\rangle\colon z \in Z(t)\}. \tag{2.9}$$

At $(t, x) \in \hat{\partial}\mathcal{F}$ let $(\nu_0, \nu) = (\nu_0(t, x), \nu(t, x))$ denote the unit normal to $\partial\mathcal{F}$ that points to the exterior of $\mathcal{T}$.

ASSUMPTION II. For every compact subset $\mathcal{B}$ of $\hat{\partial}\mathcal{F}$ there exists an $\varepsilon > 0$ and a constant $c > 0$, where ε and c depend only on $\mathcal{B}$ such that the following holds. If $(t', x') \in \mathcal{B}$, if $(t, x) \in \mathcal{N}_\varepsilon(t', x')$ and if $(p^0, p) \in \mathcal{N}_\varepsilon(\nu_0(t', x'), \nu(t', x'))$ then $B(t, x, p_0, p) \leqq -c$.

Remark 2.3. If for each t, the set $Z(t)$ is compact and the mapping Z is u.s.c.i. on $[0, T]$, then the assumption

$$\nu^0 + \langle \nu, f(t, x, z)\rangle < 0$$

for all $(t, x) \in \hat{\partial}\mathcal{F}$ implies Assumption II.

3. Lipschitz continuity of the value. We henceforth assume that for each $0 \leqq \tau < T$ there exists at least one control on $[\tau, T]$. We have already noted that under this assumption Problem I has a solution for each initial point (τ, ξ) in $\mathcal{R}$. Let $W(\tau, \xi)$ denote the value of the minimum for the problem with initial point (τ, ξ). The function W is thus defined on all of $\mathcal{R}$.

We extend the definition of W to $\mathcal{R} \cup \partial\mathcal{T} = \bar{\mathcal{R}}$ by the formula

$$W(t_1, x_1) = g(t_1, x_1) \quad \text{if } (t_1, x_1) \in \partial\mathcal{T}. \tag{3.1}$$

We now state the principal result of § 3.

THEOREM 3.1. *Let Assumptions* I *and* II *hold and let* W *be defined as above. Then for every compact set* $\mathcal{K}$ *contained in* $\mathcal{R} \cup \partial\mathcal{T}$, *there exists a constant* $K > 0$ *such that for* (τ, ξ) *and* $(\bar{\tau}, \bar{\xi})$ *in* $\mathcal{K}$,

$$|W(\tau, \xi) - W(\bar{\tau}, \bar{\xi})| \leqq K(|\tau - \bar{\tau}| + |\xi - \bar{\xi}|). \tag{3.2}$$

COROLLARY 3.1. $W(\tau, \xi) \to g(t_1, x_1)$ *as* $(\tau, \xi) \to (t_1, x_1)$, *for all* $(t_1, x_1) \in \partial\mathcal{T}$, *and the convergence is uniform on compact subsets of* $\partial\mathcal{T}$.

The corollary is an immediate consequence of the theorem and (3.1).

Our proof will utilize the function ρ defined on $[0, \infty)\times\mathbb{R}^n$ as follows: $\rho(t, x) =$ signed distance of (t, x) to $\partial\mathcal{F}$, where we take $\rho(t, x) > 0$ if $(t, x) \notin \mathcal{F}$ and $\rho(t, x) < 0$ if $(t, x) \in (\mathcal{F} - \partial\mathcal{F})$. Since $\partial\mathcal{F}$ is $C^{(2)}$ it follows that if $\mathcal{B}$ is a compact subset of $\partial\mathcal{F}$, then there exists an $\varepsilon_0 > 0$ such that ρ is C' on $\mathcal{N}_{\varepsilon_0}(\mathcal{B})$. Also, at points (t_1, x_1) of $\partial\mathcal{F}$

$$(\rho_t(t, x), \rho_x(t, x)) \to (\nu^0, \nu)$$

as $(t, x) \notin \mathcal{F}$ tends to (t_1, x_1). Moreover, on compact subsets of $\partial\mathcal{F}$, the convergence is uniform. It therefore follows from Assumption II that for any compact subset $\mathcal{B}$ of $\partial\mathcal{F}$, and hence for any compact subset $\mathcal{B}$ of $\hat{\partial}\mathcal{F}$, there exist an $\varepsilon_1 > 0$ and a $c > 0$ such that for all $(t, x) \in \mathcal{N}_{\varepsilon_1}(\mathcal{B})$

$$\sup_{z \in Z(t)} [\rho_t(t, x) + \langle \rho_t(t, x), f(t, x, z)\rangle] \leqq -c. \tag{3.3}$$

Since $\mathscr{K}$ is compact it suffices to show that there exist a $K>0$ and a $\delta>0$, both of which depend only on $\mathscr{K}$, such that (3.2) holds whenever $|(\tau,\xi)-(\tau',\xi')|<\delta$.

We first consider the case in which both (τ,ξ) and $(\bar\tau,\bar\xi)$ are in $\mathscr{K}\cap\mathscr{R}$; neither point is on the boundary. To every control u on $[\tau,T]$ we associate a control $\bar u$ on $[\bar\tau,T]$ as follows. If $\bar\tau>\tau$, let $\bar u(t)=u(t)$ for $\bar\tau\leqq t\leqq T$. If $\bar\tau<\tau$, let $\hat u$ be any control on $[\bar\tau,T]$. Define $\bar u(t)=\hat u(t)$ for $\bar\tau\leqq t<\tau$ and $\bar u(t)=u(t)$ for $\tau\leqq t\leqq T$. Let $\phi(\ )=\phi(\ ,\tau,\xi)$ and $\bar\phi(\cdot)=\bar\phi(\ ,\bar\tau,\bar\xi)$ denote the trajectories corresponding to u and $\bar u$, respectively. Let $t_1=t_1(\tau,\xi)$ and $\bar t_1=\bar t_1(\bar\tau,\bar\xi)$ denote the corresponding terminal times.

LEMMA 3.1. *There exist a constant $K_2>0$ and a $\delta_1>0$, both of which depend only on $\mathscr{K}$, such that if (τ,ξ) and $(\bar\tau,\bar\xi)$ are in $\mathscr{K}\cap\mathscr{R}$ and $|(\tau,\xi)-(\bar\tau,\bar\xi)|<\delta_1$, then*

$$|t_1-\bar t_1|\leqq K_2(|\tau-\bar\tau|+|\xi-\bar\xi|). \tag{3.4}$$

We first note that if both t_1 and $\bar t_1$ equal T, then (3.4) is trivially true. We therefore suppose henceforth that at least one of the inequalities $t_1<T$ or $\bar t_1<T$ holds.

By (2.2) of Lemma 2.1 there exists an $R>0$ that depends on $\mathscr{K}$ such that the terminal point $(t_1,\phi(t_1))$ of any trajectory with initial point (τ,ξ) in $\mathscr{K}$ will lie in $([0,T]\times B_R)\cap\partial\mathscr{T}$, where B_R denotes the closed ball of radius R in $\mathbb{R}^n$. Let $\mathscr{B}_R=([0,T]\times B_R)\cap\hat\partial\mathscr{F}$. Then $\mathscr{B}_R$ is a compact subset of $\hat\partial\mathscr{F}$. Also, any trajectory ϕ with initial point in $\mathscr{K}$ whose terminal time t_1 is less than T satisfies $(t_1,\phi(t_1))\in\mathscr{B}_R$.

Let $\varepsilon_1=\varepsilon_1(\mathscr{B}_R)$ and $c=c(\mathscr{B}_R)$ be the constants in Assumption II associated with this $\mathscr{B}_R$.

By (2.4) of Lemma 2.1 there exists a $\delta_1>0$ such that if $|(\tau,\xi)-(\bar\tau,\bar\xi)|<\delta_1$, then for all $\max(\tau,\bar\tau)\leqq t\leqq T$,

$$|\phi(t,\tau,\xi)-\bar\phi(t,\bar\tau,\bar\xi)|<\varepsilon_1/2.$$

We now suppose that $|(\tau,\xi)-(\bar\tau,\bar\xi)|<\delta_1$ and that $t_1<\bar t_1$. Then $t_1<T$ and $(t_1,\phi(t_1))\in\mathscr{B}_R$. Since $|(t_1,\phi(t_1))-(t_1,\bar\phi(t_1))|=|\phi(t_1)-\bar\phi(t_1)|<\varepsilon_1/2$, it follows that $(t_1,\bar\phi(t_1))\in\mathscr{N}_{\varepsilon_1/2}(\mathscr{B}_R)$.

Let $\bar\theta(t)=\rho(t,\bar\phi(t))$. Then $\bar\theta$ is absolutely continuous and

$$\frac{d\bar\theta}{dt}=\rho_t(t,\bar\phi(t))+\langle\rho_x(t,\bar\phi(t)),f(t,\bar\phi(t),\bar u(t))\rangle \quad \text{a.e.} \tag{3.5}$$

From (3.3) we see that as long as $(t,\bar\phi(t))$ stays in $\mathscr{N}_{\varepsilon_1}(\mathscr{B}_R)$, the right-hand side of (3.5) does not exceed $-c$. Since $(t_1,\bar\phi(t_1))\in\mathscr{N}_{\varepsilon_1/2}(\mathscr{B}_R)$, it follows from the continuity of $\bar\phi$ that there exists a maximal interval $[t_1,t_1+\alpha)$ with $t_1+\alpha\leqq\bar t_1$ such that if t is in $[t_1,t_1+\alpha)$, then $(t,\bar\phi(t))\in\mathscr{N}_{\varepsilon_1}(\mathscr{B}_R)$ and $(t,\bar\phi(t))\notin\mathscr{T}$. For all t in this interval we have

$$\bar\theta(t)-\bar\theta(t_1)\leqq -c(t-t_1). \tag{3.6}$$

From (3.6) we first see that $t_1+\alpha<\bar t_1$ is not possible. For then, since $\bar\theta(t_1)<\varepsilon_1/2$, and $\bar\theta(t_1+\alpha)=\varepsilon_1$, we would have $c\alpha\leqq-\varepsilon_1/2$, which is impossible. Hence (3.6) holds for $t_1\leqq t\leqq\bar t_1$. If $\bar t_1<T$, then $\bar\theta(\bar t)=0$ and we get from (3.6) that

$$(\bar t_1-t_1)\leqq c^{-1}\bar\theta(t_1)\leqq c^{-1}|(t_1,\phi(t_1))-(t_1,\bar\phi(t_1))|=c^{-1}|\phi(t_1)-\bar\phi(t_1)|.$$

It now follows from (2.4) that

$$(\bar t_1-t_1)\leqq K_2(|\tau-\bar\tau|+|\xi-\bar\xi|) \tag{3.7}$$

where $K_2=K_1/c$. If $\bar t_1=T$, then $\bar\theta(T)\geqq 0$, in which case (3.7) still holds.

If $\bar{t}_1 < t_1$, we reverse the roles of t_1 and $\bar{t}$, and obtain that (3.7) holds with left-hand side equal to $t_1 - \bar{t}_1$. From these two inequalities the lemma follows.

LEMMA 3.2. *With the notation as above, there exists a constant $K_3 > 0$ that depends only on $\mathscr{X}$, such that for (τ, ξ) and $(\bar{\tau}, \bar{\xi})$ in $\mathscr{X} \cap \mathscr{R}$,*

$$|\bar{\phi}(\bar{t}_1) - \phi(t_1)| \leqq K_3(|\tau - \bar{\tau}| + |\xi - \bar{\xi}|)$$

whenever $|(\tau, \xi) - (\bar{\tau}, \bar{\xi})| \leqq \delta_1$.

Proof. $|\bar{\phi}(\bar{t}_1) - \phi(t_1)| \leqq |\bar{\phi}(\bar{t}_1) - \phi(\bar{t}_1)| + |\phi(\bar{t}_1) - \phi(t_1)|$. By (2.3) and (2.4) of Lemma 2.1, the right-hand side of the preceding inequality does not exceed $K_1(|\tau - \bar{\tau}| + |\xi - \bar{\xi}|) + (1 + R)|\bar{t}_1 - t_1|$. Lemma 3.2 now follows from this and from Lemma 3.1.

From (5) of Assumption I and the two preceding lemmas we obtain the following:

$$\begin{aligned} g(\bar{t}_1, \bar{\phi}(\bar{t}_1)) - g(t_1, \phi(t_1)) &\leqq K_R(|t_1 - \bar{t}_1| + |\phi(t_1) - \bar{\phi}(\bar{t}_1)|) \\ &\leqq K_3(|\tau - \bar{\tau}| + |\xi + \bar{\xi}|). \end{aligned}$$

Recall that $\bar{u}$ depends on u. Hence

$$W(\bar{\tau}, \bar{\xi}) \leqq W(\tau, \xi) + K_3(|\tau - \bar{\tau}| + |\xi - \bar{\xi}|).$$

Reversing the roles of (τ, ξ) and $(\bar{\tau}, \bar{\xi})$ gives (3.2) with $K = K_3$ when both (τ, ξ) and $(\bar{\tau}, \bar{\xi})$ are in $\mathscr{X} \cap \mathscr{R}$.

We now suppose that $(\tau, \xi) \in \mathscr{X} \cap \mathscr{R}$ and that $(\bar{\tau}, \bar{\xi}) \in \mathscr{X} \cap \partial\mathscr{T}$. To emphasize that $(\bar{\tau}, \bar{\xi}) \in \partial\mathscr{T}$ we shall write this point as $(\bar{t}_1, \bar{x}_1)$.

We first consider the case in which $\bar{t}_1 = T$.

As above, let (t_1, x_1) be the terminal point of $\phi(\cdot) = \phi(\ , \tau, \xi, u)$, where u is a control in $[\tau, T]$. Then

$$0 \leqq \bar{t}_1 - t_1 = T - t_1 < T - \tau = \bar{t}_1 - \tau = \bar{\tau} - \tau. \tag{3.8}$$

Also,

$$\begin{aligned} |x_1 - \bar{x}_1| &= |\xi + \int_\tau^{t_1} f(s, \phi(s), u(s))\, ds - \bar{x}_1| \\ &\leqq |\xi - \bar{x}_1| + c'|\bar{t}_1 - \tau| \end{aligned} \tag{3.9}$$

for some constant $c' > 0$.

We now consider the case $\bar{t}_1 \neq T$. Then $(\bar{t}_1, \bar{x}_1) \in \hat{\partial}\mathscr{F}$. Since $(\bar{t}_1, \bar{x}_1) = (\bar{\tau}, \bar{\xi})$ belongs to $\mathscr{X}$ we also have that $(\bar{t}_1, \bar{x}_1) \in \mathscr{B}_R$. Let ε_1 and c be as before. We take (τ, ξ) to be such that $(\tau, \xi) \in \mathscr{N}_{\varepsilon_1/2}(\mathscr{B}_R)$ and $|(\tau, \xi) - (\bar{\tau}, \bar{\xi})| < \delta_1$.

Let $\theta(t) = \rho(t, \phi(t))$ for $\tau \leqq t \leqq t_1$ and note that $t_1 \leqq T$. Then arguing as before, we get that $\theta(t) - \theta(\tau) \leqq -c(t - \tau)$ for all $\tau \leqq t \leqq t_1$. If $t_1 < T$, then $\theta(t_1) = 0$ and we get

$$0 < t_1 - \tau \leqq c^{-1}\theta(\tau) \leqq c^{-1}(|\tau - \bar{t}_1| + |\xi - \bar{x}_1|). \tag{3.10}$$

If $t_1 = T$, we get

$$0 < t_1 - \tau \leqq c^{-1}(\theta(\tau) - \theta(T)) \leqq c^{-1}\theta(\tau),$$

so that (3.10) still holds. Hence we always have

$$|t_1 - \bar{t}_1| \leqq |t_1 - \tau| + |\tau - \bar{t}_1| \leqq A(|\tau - \bar{t}_1| + |\xi - \bar{x}_1|) \tag{3.11}$$

for some constant $A > 0$. Comparing (3.11) with (3.8), we see that (3.11) holds whether or not $\bar{t}_1 = T$.

Also, by (3) of Assumption I and (3.10),

$$\begin{aligned} |x_1 - \bar{x}_1| &\leqq |x_1 - \xi| + |\xi - \bar{x}_1| \\ &\leqq \int_\tau^{t_1} |f(s, \phi(s), u(s))\, ds\,| + |\xi - \bar{x}_1| \\ &\leqq B|t_1 - \tau| + |\xi - \bar{x}_1| \\ &\leqq C(|\tau - \bar{t}_1| + |\xi - \bar{x}_1|). \end{aligned} \tag{3.12}$$

Comparing (3.12) with (3.9) we see that (3.12) also holds whether or not $\bar{t}_1 = T$.

It now follows from (3.11) and (3.12) and (5) of Assumption I, that if $|(\tau, \xi) - (\bar{t}_1, \bar{x})| < \delta$, where $\delta \equiv \min(\varepsilon_1/2, \delta_1)$, then there exists a $K_4 > 0$ such that

$$\begin{aligned} g(t_1, x_1) - W(\bar{t}_1, \bar{x}_1) &= g(t_1, x_1) - g(\bar{t}_1, \bar{x}_1) \\ &\leqq K'_R(|t_1 - \bar{t}_1| + |\bar{x}_1 - x_1|) \\ &\leqq K_4(|\tau - \bar{t}_1| + |\xi - \bar{x}|). \end{aligned}$$

From this inequality (3.2) follows with $K = K_4$.

If both (τ, ξ) and $(\bar{\tau}, \bar{\xi})$ belong to $\partial\mathcal{T}$ then (3.2) follows with $K = K'_R$ from (3.1) and (5) of Assumption I.

Hence the theorem holds with $\delta = \min(\varepsilon_1/2, \delta_1)$ and $K = \max(K_3, K_4, K'_R)$.

4. A necessary condition. The principal result of this section is the following theorem.

THEOREM 4.1. *Let Assumptions* I *and* II *hold and for each* $0 \leqq \tau < T$ *let there exist a control* u *on* $[\tau, T]$. *For each* τ *in* $[0, T]$ *and each* z *in* $Z(t)$ *let there exist a* $\delta_0 > 0$ *and a control* u *in* $[\tau, \tau + \delta_0)$ *such that* $\lim_{t \to \tau+0} u(t) = z$. *Then for each* (τ, ξ) *in* $\mathcal{R}$,

$$\min_{h \in Q(\tau, \xi)} D^- W(\tau, \xi; 1, h) = 0. \tag{4.1}$$

Before we prove Theorem 4.1 we discuss some of its implications.

We have already pointed out that Assumptions I and II imply that if for each τ the set of controls on $[\tau, T]$ is not empty, then Problem I with initial point (τ, ξ) in $\mathcal{R}$ has a solution. Thus W is well defined on $\mathcal{R}$. In Theorem 3.1 we have shown that W is locally Lipschitz in $\mathcal{R} \cup \mathcal{T}$. Thus W is differentiable almost everywhere on $\mathcal{R}$. At points of differentiability (4.1) becomes

$$W_t(\tau, \xi) + \min_{z \in Z(t)} \langle W_t(\tau, \xi), f(t, x, z) \rangle = 0 \tag{4.2}$$

where $W_x = (\partial W/\partial x^1, \cdots, \partial W/\partial x^n)$.

Let (τ, ξ) be a point in $\mathcal{R}$ and let $\psi(\ ) = \psi(\ , \tau, \xi)$ denote an optimal trajectory for the problem with initial point (τ, ξ). Since W is Lipschitz continuous and ψ is absolutely continuous, the function ω defined on $[\tau, t_1]$ by the formula $\omega(t) = W(t, \psi(t))$ is absolutely continuous. Thus almost all points of $[\tau, t_1]$ are simultaneously

Lebesgue points of ψ and points of differentiability of ω. At such a point we have

$$\begin{aligned}\frac{d\omega}{dt} &= \lim_{\delta\to 0}[\,W(t+\delta,\psi(t+\delta))-W(t,\psi(t))]\delta^{-1}\\ &= \lim_{\delta\to 0}\left[\,W\left(t+\delta,\psi(t)+\int_t^{t+\delta}\psi'(s)\,ds\right)-W(t,\psi(t))\right]\delta^{-1}\\ &= \lim_{\delta\to 0}[\,W(t+\delta,\psi(t)+\delta\psi'(t)+o(\delta))-W(t,\psi(t))]\delta^{-1}\\ &= DW(t,\psi(t);1,\psi'(t))\end{aligned}$$

where in passing to the last line we have used the Lipschitz continuity of W.

On the other hand, the Principle of Optimality, discussed below, gives the relation

$$W(t+\delta,\psi(t+\delta))-W(t,\psi(t))=0.$$

Hence $DW(t,\psi(t);1,\psi'(t))=0$. Combining this relation with (4.1) gives the following result that can be considered as a form of the Pontryagin maximum principle.

COROLLARY 4.1. *At almost all points of* $[\tau,t_1]$,

$$0=DW(t,\psi(t);1,\psi'(t))\leqq DW^-(t,\psi(t);1,h)$$

for all $h\in Q(t,\psi(t))$.

If for each t in $[0,T]$ the set $Z(t)$ is compact, or if we strengthen (3) of Assumption I to require that β be finite-valued for all t and that (3) holds for all t, then

$$H(t,x,p)=\min_{h\in Q(t,x)}\langle p,h\rangle=\min_{z\in Z(t)}\langle p,f(t,x,z)\rangle$$

is defined and finite on $[0,T]\times\mathbb{R}^n\times\mathbb{R}^n$. In this case, an elementary argument due to Lions and Souganidis [10] and based on one of the equivalent definitions of viscosity solution shows that (4.1) implies that W is a viscosity solution of

$$\begin{aligned}&u_t+H(t,x,u_x)=0, && (t,x)\in\mathcal{R},\\ &u(t,x)=g(t,x), && (t,x)\in\partial\mathcal{T}.\end{aligned}\tag{4.3}$$

The next theorem is the Principle of Optimality for Problem I. Note that we do not require Assumption II to hold for the terminal set.

THEOREM 4.2. *Let* $\mathcal{R}$ *be a connected set in* $[0,T)\times\mathbb{R}^n$ *and let* $\mathcal{T}'$ *be a set in* $[0,T]\times\mathbb{R}^n$ *such that* $\partial\mathcal{T}'\subseteq\partial\mathcal{R}$. *For each* (τ,ξ) *in* $\mathcal{R}$ *let Problem* I *with terminal set* $\mathcal{T}'$ *have a solution* $(u^*(\cdot),\phi^*(\cdot))$ *where* $u^*(\cdot)=u^*(\ ,\tau,\xi)$ *and* $\phi^*(\cdot)=\phi^*(\ ,\tau,\xi)$. *Then if* t_f^* *is the terminal point of* ϕ^*,

$$W(t,\phi^*(t))=W(\tau,\xi),\qquad \tau\leqq t\leqq t_f^*.\tag{4.4}$$

If (u,ϕ) *is any other control trajectory pair with initial point* (τ,ξ) *and terminal point* t_f, *then*

$$W(t,\phi(t))\geqq W(\tau,\xi),\qquad \tau\leqq t\leqq t_f.\tag{4.5}$$

The proof is well known and will be omitted.

We shall also need the following result, whose proof we omit.

LEMMA 4.1. *Let* K *be a set in* $\mathbb{R}^n$ *of positive finite Lebesgue measure and let* $\lambda: K\to\mathbb{R}^n$ *be Lebesgue integrable on* K. *Let* $\mathcal{H}$ *denote the set of regular probability measures* μ *such that* $\int_K f\,d\mu$ *exists. Then the sets* $\mathcal{P}=\operatorname{clco}\{f(x): x\in K\}$ *and* $\mathcal{P}_\mu=\operatorname{cl}\{\int_K f\,d\mu: \mu\in\mathcal{H}\}$ *are equal.*

We now take up the proof of Theorem 4.1. We first show that

$$\inf_{h\in Q(\tau,\xi)} D^-W(\tau,\xi;1,h)\geqq 0.\tag{4.6}$$

Let $h \in Q(\tau, \xi)$. Then there exists a z in $Z(\tau)$ such that $h = f(\tau, \xi, z)$. Also, there exists a control u defined on $[\tau, \tau+\delta_0)$ with $u(\tau) = z$ that is continuous from the right at $t = \tau$. This control can be extended to $[\tau, T]$, and we denote the extended control also by u. Let ϕ be the trajectory corresponding to u and having initial point (τ, ξ). Then for $\delta > 0$

$$\begin{aligned} \phi(\tau+\delta) &= \xi + \int_{\tau}^{\tau+\delta} f(s, \phi(s), u(s))\, ds \\ &= \xi + \int_{\tau}^{\tau+\delta} [f(\tau, \xi, z) + o(1)]\, ds \\ &= \xi + \delta f(\tau, \xi, z) + o(\delta), \end{aligned} \tag{4.7}$$

where o is as $\delta \to 0$.

By the Principle of Optimality,

$$[W(\tau+\delta, \phi(\tau+\delta)) - W(\tau, \xi)]\delta^{-1} \geqq 0.$$

If we substitute the rightmost expression of (4.7) into this inequality and use the Lipschitz continuity of W, we get that

$$[W(\tau+\delta, \xi+\delta h) - W(\tau, \xi)]\delta^{-1} + o(1) \geqq 0.$$

From this, (4.6) follows.

We next show that there exists an $h^* \in Q(\tau, \xi)$ such that $D^- W(\tau, \xi; 1, h^*) \leqq 0$. This in conjunction with (4.6) will establish the theorem.

Let ψ denote the optimal trajectory for the problem with initial point (τ, ξ). Then

$$\psi(\tau+\delta) = \xi + \int_{\tau}^{\tau+\delta} \psi'(s)\, ds \tag{4.8}$$

where $\psi'(s) \in Q(s, \psi(s))$ for almost all $\tau \leqq s \leqq T$. Hence, since ψ is continuous, given an $\varepsilon > 0$, there exists a $\delta = \delta(\varepsilon) > 0$ such that if $\tau \leqq s \leqq \tau+\delta$ then

$$\psi'(s) \in Q(\mathcal{N}_\varepsilon(\tau, \xi)) \quad \text{a.e.} \tag{4.9}$$

Let K_ε denote the set of points in $[\tau, \tau+\delta]$ at which the inclusion (4.9) holds. Then the measure of K_ε equals δ. Thus

$$\int_{\tau}^{\tau+\delta} \psi'(s)\, ds = \delta \int_{\tau}^{\tau+\delta} \psi'(s)\left(\frac{ds}{\delta}\right) = \delta \int_{K_\varepsilon} \psi'(s)\left(\frac{ds}{\delta}\right).$$

From (4.9) we get that

$$\operatorname{clco}\{\psi'(s): s \in K_\varepsilon\} \subseteq \operatorname{clco}\{Q(\mathcal{N}_\varepsilon(\tau, \xi))\}.$$

From this relationship and from Lemma 4.1 we get that

$$\int_{K_\varepsilon} \psi'(s)\left(\frac{ds}{\delta}\right) \in \operatorname{clco}\{Q(\mathcal{N}_\varepsilon(\tau, \xi))\}.$$

Let

$$h_\delta \equiv \int_{\tau}^{\tau+\delta} \psi'(s)\left(\frac{ds}{\delta}\right).$$

We have shown that for every $\varepsilon > 0$, there exists a $\delta > 0$ and a point h_δ such that

$$\psi(\tau+\delta) = \xi + \delta h_\delta, \qquad h_\delta \in \operatorname{clco}(\mathcal{N}_\varepsilon(\tau, \xi)). \tag{4.10}$$

Since

$$|h_\delta| \leqq \delta^{-1} \int_{\tau}^{\tau+\delta} |\psi'(s)|\, ds \leqq \delta^{-1} \int_{\tau}^{\tau+\delta} |1 + \psi(s)|\, \|\beta\|_\infty\, ds$$

where $\|\beta\|_\infty$ is the $L_\infty[0, T]$ norm of β, it follows from (2.2) of Lemma 2.1 that there exists a constant A such that $|h_\delta| \leqq A$ for all $\delta < \delta(\varepsilon)$. Hence there exist sequences $\varepsilon_k \to 0$ and $\delta_k = \delta_k(\varepsilon_k) \to 0$ such that $h_k \in \operatorname{clco}\{Q(\mathcal{N}_{\varepsilon_k}(\tau, \xi))\}$ and such that h_k converges to some element h^* in $\mathbb{R}^n$.

Let $\varepsilon > 0$ be fixed, but arbitrary. Then there exists an integer k' such that if $k > k'$, then $Q(\mathcal{N}_{\varepsilon_k}(\tau, \xi)) \subseteq Q(\mathcal{N}_\varepsilon(\tau, \xi))$. Hence $\operatorname{clco}\{Q(\mathcal{N}_{\varepsilon_k}(\tau, \xi))\} \subseteq \operatorname{clco}\{Q(\mathcal{N}_\varepsilon(\tau, \xi))\}$, and so $h_k \in \operatorname{clco}\{Q(\mathcal{N}_\varepsilon(\tau, \xi))\}$. Hence, $h^* \in \operatorname{clco}\{Q(\mathcal{N}_\varepsilon(\tau, \xi))\}$ for arbitrary $\varepsilon > 0$. It now follows from property (Q) that $h^* \in Q(\tau, \xi)$.

We return to our sequences $\{\delta_k\}$ and $\{h_k\}$. From the definition of h^* and from (4.10) we get that

$$\psi(\tau + \delta_k) = \xi + \delta_k h^* + o(\delta_k). \tag{4.11}$$

From the Principle of Optimality we have that

$$[W(\tau + \delta_k, \psi(\tau + \delta_k)) - W(\tau, \xi)]\delta_k^{-1} = 0.$$

Substituting (4.11) into this relation and using the Lipschitz continuity of W, we get that

$$\lim_{k \to \infty} [W(\tau + \delta, \xi + \delta_k h^*) - W(\tau, \xi)]\delta_k^{-1} = 0.$$

Recall that $\delta_k \to 0$ as $k \to \infty$. Hence

$$\liminf_{\delta \to 0+} [W(\tau + \delta, \xi + \delta h^*) - W(\tau, \xi)]\delta^{-1} \leqq 0,$$

so that $D^- W(\tau, \xi; 1, h^*) \leqq 0$. This proves the theorem. Note that our argument shows that $D^- W(\tau, \xi; 1, h^*) = 0$, so that we are justified in writing min in (4.1).

5. Optimal synthesis. Let V be a real-valued function that is continuous on $\mathcal{R} \cup \partial\mathcal{T}$, that is locally Lipschitz on $\mathcal{R}$, and that satisfies

$$\begin{aligned} &\min_{h \in Q(t, x)} D^- V(t, x; 1, h) = 0, && (t, x) \in \mathcal{R}, \\ &V(t_1, x_1) = g(t_1, x_1), && (t_1, x_1) \in \partial\mathcal{T}. \end{aligned} \tag{5.1}$$

We have shown in Theorems 3.1 and 4.1 that if the assumptions of Theorem 4.1 hold, then the value function W is one such function. In the case of compact constraints, or in the case that (3) of Assumption I is strengthened to require that β be finite-valued for all t and that (3) holds for all t, any viscosity solution of (4.3) that is continuous on $\mathcal{R} \cup \mathcal{T}$ and locally Lipschitz continuous on $\mathcal{R}$ can be shown to satisfy (5.1). The proof of this assertion makes use of the definition of viscosity solution and arguments similar to, but simpler than, those of Theorem 4.1. No uniqueness theorems for viscosity solutions are used.

For each (t, x) in $\mathcal{R}$ let

$$F(t, x) = \{h: h \in Q(t, x), D^- V(t, x; 1, h) = 0\}. \tag{5.2}$$

The set-valued function F furnishes a generalized optimal synthesis or feedback in $\mathcal{R}$ in the following sense.

LEMMA 5.1. *For each (τ, ξ) in $\mathcal{R}$, any solution of the differential inclusion*

$$x' = F(t, x), \qquad x(\tau) = \xi \tag{5.3}$$

that is defined on an interval $[\tau, \tau + \alpha)$ such that ψ hits $\mathcal{T}$ at a time $t_1 < \alpha$ is an optimal trajectory for Problem I *with initial point (τ, ξ).*

Let ψ be a solution of (5.3) with the hypothesized properties. Since $F(t, x) \subseteq Q(t, x)$, the solution ψ also satisfies $\psi'(t) \in Q(t, \psi(t))$ almost everywhere. By Filippov's Lemma there exists a control v such that $\psi'(t) = f(t, \psi(t), v(t))$ almost everywhere. Thus v and ψ are a control and trajectory pair.

To see that (ψ, v) is optimal, let (ϕ, u) be any control trajectory pair for the problem with initial point (τ, ξ). Then the function Φ on $[\tau, t_1]$, defined by $\Phi(t) = V(t, \phi(t))$, is absolutely continuous on $[\tau, t_1]$. Hence

$$
\begin{aligned}
V(t_1, \phi(t_1)) - V(\tau, \xi) &= \int_\tau^{t_1} \left[\frac{d}{ds} W(s, \phi(s)) \right] ds \\
&= \int_\tau^{t_1} DV(s, \phi(s); 1, \phi'(s))\, ds \geqq 0.
\end{aligned} \tag{5.4}
$$

The second equality follows by the same argument that was used to calculate dw/dt in the proof of Corollary 4.1 and the last inequality follows from the first condition in (5.1). From (5.4) and the second condition in (5.1) we get that

$$
g(t_1, \phi(t_1)) \geqq V(\tau, \xi). \tag{5.5}
$$

If we take $(\phi, u) = (\psi, v)$ in the preceding argument, then the last inequality in (5.4) will be replaced by an equality. Hence we get $g(\bar{t}_1, \psi(\bar{t}_1)) = V(\tau, \xi)$, where $\bar{t}_1$ is the terminal time of ψ. If we combine this relation with (5.5) we get that for all control trajectory pairs (ϕ, u) for the problem with initial point (τ, ξ), $g(t_1, \phi(t_1)) \geqq g(\bar{t}_1, \psi(\bar{t}_1))$.

COROLLARY 5.1. *If for each (τ, ξ) in $\mathcal{R}$ equation (5.3) has a solution $\psi(\ , \tau, \xi)$ on an interval sufficiently large for ψ to intersect $\mathcal{T}$, then $V = W$.*

Remark 5.1. We have already noted that in the case of compact constraints or a suitably strengthened (3) of Assumption I, a viscosity solution of (4.3) that is locally Lipschitz continuous on $\mathcal{R}$ satisfies (5.1). Thus, such a solution of (4.3) will give a synthesis of optimal control in the sense indicated.

We now define a sequence of functions that will converge to a solution of (5.3) when F satisfies certain conditions. This will give a constructive procedure for finding solutions that, in principle, can be implemented to obtain approximations to solutions.

For each $n = 1, 2, 3, \cdots$ we define a Euler polygon approximation E_n of order n for (5.3). To emphasize the dependence of E_n on the initial point (τ, ξ) we write $E_n(\ , \tau, \xi)$. Let π_n be a partition of $[\tau, T]$ with partition points $\tau = \tau_0 < \tau_1 < \cdots < \tau_{2n} = T$ with the following properties. (i) For $i > 0$, $|\beta(\tau_i)| \leqq \|\beta\|_\infty$, where β is the function in (3) of Assumption I. (ii) For $i > 0$, (3) of Assumption I holds with $t = \tau_i$. (iii) If $\delta_n \equiv \max\{0 \leqq i \leqq 2n-1\colon \tau_{i+1} - \tau_i\}$, then $\delta_n \leqq (T - \tau)/n$.

Let h_0 be an element of $F(\tau_0, \xi_0)$, which is fixed for a particular sequence of Euler polygons. For $\tau_0 \leqq t \leqq \tau_1$ define

$$
E_n(t) = \xi_0 + h_0(t - \tau_0). \tag{5.6}
$$

Now suppose that $E_n(t)$ has been defined for $\tau_0 \leqq t \leqq \tau_i$, where $1 \leqq i < 2n-1$. Let $\xi_i = E_n(\tau_i)$, and let h_i be any element of $F(\tau_i, \xi_i)$. Then for $\tau_i \leqq t \leqq \tau_{i+1}$ define

$$
E_n(t) = \xi_i + h_i(t - \tau_i). \tag{5.7}
$$

Thus, E_n is defined for all $\tau_0 \leqq t \leqq T$. Note that the triple (τ_0, ξ_0, h_0) is independent of n, but that for $i > 0$, the triple (τ_i, ξ_i, h_i) depends on n.

LEMMA 5.2. *Given $(\tau, \xi) \in \mathcal{R}$ and a choice $h_0 \in F(\tau, \xi)$, then there exist constants $R > 0$ and $M > 0$ such that for all all n and all $\tau \leqq t \leqq T$, we have $|E_n(t)| \leqq R$ and $|E_n'(t)| \leqq M$. At the partition points τ_i, $E_n'(\tau_i)$ is interpreted as either of the one-sided derivatives.*

To establish $|E_n(t)| \leqq R$ it suffices to show that $|\xi_i| \leqq R$ for all n and all $0 \leqq i \leqq 2n$, where we take $\xi_{2n} = E_n(T)$. Let $R_1 = \max(|h_0|, \|\beta\|_\infty)$. It then follows from (5.6) and (3) of Assumption I that $1+|\xi_1| \leqq (1+|\xi_0|)(1+R_1\delta_n)$. By a simple induction argument, (5.7) and (3) of Assumption I, we get that for all n and all $0 \leqq i \leqq 2n-1$,

$$1+|\xi_{i+1}| \leqq (1+|\xi_0|)(1+TR_1n^{-1})^{2n}.$$

From this it follows that there exists an $R>0$ such that $|\xi_i| \leqq R$ for all n and all $0 \leqq i \leqq 2n-1$.

For $\tau \leqq t \leqq T$, $E_n'(t) = h_i$ for appropriate $0 \leqq i \leqq 2n$. By construction and (3) of Assumption I, for $i>0$ we have $|h_i| \leqq \|\beta\|_\infty(1+|\xi_i|)$. Since h_0 is independent of n and $|\xi_i| \leqq R$ for all n and $0 \leqq i \leqq 2n$, the relation $|E_n'(t)| \leqq M$ follows.

The functions $\{E_n\}$ are uniformly bounded and equicontinuous, so there exists a subsequence that we again label as $\{E_n\}$, that converges uniformly on $[\tau, T]$ to a continuous function ψ. Since the integrals $\int_\tau^t E_n'(s)\,ds$, $\tau \leqq t \leqq T$ are uniformly bounded and uniformly absolutely continuous, the function ψ is absolutely continuous and the derivatives E_n' converge weakly in $L_1[\tau, T]$ to ψ'. If we could show that $\psi'(t) \in F(t, \psi(t))$ almost everywhere on $[\tau, t_1]$, where t_1 is the terminal time, then by Lemma 5.1, ψ would be optimal. Moreover, the convergent subsequence $\{E_n\}$ would approximate ψ uniformly.

We now take up conditions that are sufficient for ψ to be a solution of (5.3).

DEFINITION 5.1. A subset $\mathscr{E}$ of $\mathscr{R}$ is said to be an exceptional set for the synthesis if for each (τ, ξ) in $\mathscr{R}$ there exists a limit point $\psi(\ , \tau, \xi)$ in $C^n[\tau, T]$ of some sequence $\{E_n(\ , \tau, \xi)\}$ of Euler polygons such that the set

$$\mathscr{J}(\psi) = \{\tau \leqq t \leqq t_1 : (t, \psi(t)) \in \mathscr{E}\} \tag{5.8}$$

has Lebesgue measure zero. Here t_1 is the terminal point of ψ.

Remark 5.2. Any set $\mathscr{E}_0$ whose projection on $[0, T]$ has measure zero can be an exceptional set. Exceptional sets also arise as "dispersal surfaces," in the terminology of Isaacs [9] for control problems. Example 5.1 below illustrates a simple case of this.

THEOREM 5.1. *Let the mapping F satisfy property (Q) at each point (t, x) of $\mathscr{R}$, with the possible exception of points in an exceptional set $\mathscr{E}$. Then for each (τ, ξ) in $\mathscr{R}$ any uniform limit $\psi(\ , \tau, \xi)$ of a sequence $E_n(\tau, \xi)$ of Euler polygons that satisfies* meas $\mathscr{J}(\psi) = 0$ *satisfies* (5.3) *almost everywhere on $[\tau, T]$ and is optimal.*

Proof. In view of the discussion preceding Definition 5.1, we need only prove that ψ satisfies (5.3).

We have already shown that $E_n' \to \psi'$ weakly in $L_1[\tau, T]$. Hence by Mazur's Theorem there exists a sequence of functions ψ_{n_j} defined by the formulas

$$\psi_{n_j} = \sum_{i=1}^{k(n_j)} \alpha_{n_j,i} E_{n_j+i}, \quad \alpha_{n_j,i} \geqq 0, \qquad \sum_{i=1}^{k(n_j)} \alpha_{n_j,i} = 1$$

where $n_{j+1} > n_j + k(n_j)$, and such that $\psi_{n_j}' \to \psi'$ in $L_1[\tau, T]$. An elementary argument shows that the uniform convergence of E_n to ψ implies that $\psi_{n_j} \to \psi$ uniformly on $[\tau, T]$. Since $\psi_{n_j}' \to \psi'$ in $L_1[\tau, T]$, there exists a subsequence that we again label as ψ_{n_j} such that $\psi_{n_j}' \to \psi'$ almost everywhere.

Let $t_0 > \tau$ be a point of $[\tau, T]$ such that $\psi_{n_j}'(t_0) \to \psi'(t_0)$ and $t_0 \notin \mathscr{J}(\psi)$. The set of such points has full measure. We conclude the proof by showing at such a point $\psi'(t_0) \in F(t_0, \psi(t_0))$.

Let $\delta > 0$ be given. Since $|E_n'(t)| \leqq M$ for all t in $[\tau, T]$ and all n, there exists a positive η such that $\eta < \delta/3$ and if $|t'-t''| < \eta$, then $|E_n(t') - E_n(t'')| < \delta/3$ for all n. Also, there exists a positive integer N_1 such that for $n > N_1$, $|E_n(t) - \psi(t)| < \delta/3$ for all t in $[\tau, T]$.

There exists a positive integer N_2 such that for all $n > N_2$, the partition π_n has partition points in $(t_0 - \eta, t_0]$. Let $\nu = \nu(n)$ be the index such that τ_ν is a partition point of π_n in $(t_0 - \eta, t_0]$ and satisfies $\tau_\nu \leqq t_0 < \tau_{\nu+1}$.

Let $N = \max(N_1, N_2)$. Then for $n > N$, (recall that $\nu = \nu(n)$)

$$|(\tau_\nu, E_n(\tau_\nu)) - (t_0, \psi(t_0))| \leqq |\tau_\nu - t_0| + |E_n(\tau_\nu) - \psi(t_0)|$$

$$\leqq |\tau_\nu - t_0| + |E_n(\tau_\nu) - E_n(t_0)| + |E_n(t_0) - \psi(t_0)| < \delta.$$

In other words, we have $(\tau_\nu, E_n(\tau_\nu)) \in \mathcal{N}_\delta(t_0, \psi(t_0))$. By our definition of E_n, we have that $E_n'(\tau_\nu + 0) \in F(\tau_\nu, E_n(\tau_\nu))$. Hence, $E_n'(\tau_\nu + 0) \in F(\mathcal{N}_\delta(t_0, \psi(t_0)))$. But by our choice of ν and the definition of E_n, we have that $E_n'(\tau_\nu + 0) = E_n'(t_0)$. Hence $E_n'(t_0) \in F(\mathcal{N}_\delta(t_0, \psi(t_0)))$, for $n > N$. This in turn implies that there exists a positive integer $J = J(\delta)$ such that for $j > J$,

$$\psi_{n_j}'(t_0) \in \operatorname{co}\{F(\mathcal{N}_\delta(t_0, \psi(t_0)))\}.$$

Since $\psi_{n_j}'(t_0) \to \psi'(t_0)$, the preceding statement implies that $\psi'(t_0) \in \operatorname{clco}\{F(\mathcal{N}_\delta(t_0, \psi(t_0)))\}$. Since $\delta > 0$ was arbitrary

$$\psi'(t_0) \in \bigcap_{\delta > 0} \operatorname{clco}\{F(\mathcal{N}_\delta(t_0, \psi(t_0)))\}.$$

Finally since property (Q) holds at $(t_0, \psi(t_0))$, we get that $\psi'(t_0) \in F(t_0, \psi(t_0))$, and the theorem is proved.

We illustrate Theorem 5.1 with a simple example.

Example 5.1. Let $n = 1$, let $T = 1$, let the terminal set be $[1, \infty) \times \mathbb{R}$, and let $g(t, x) = -x^2$. We wish to minimize $g(1, \phi(1)) = -(\phi(1))^2$, over all ϕ that satisfy $x' = u$, $x(\tau) = \xi$, and $-1 \leqq u \leqq 1$.

It is clear that for (τ, ξ) with $\xi > 0$, the optimal control is $u(t) = 1$ for $\tau \leqq t \leqq 1$ and the optimal trajectory is the straight line of slope one through (τ, ξ). Similarly for (τ, ξ) with $\xi < 0$, the optimal control is $u(t) = -1$ and the optimal trajectory is the straight line of slope negative one. For (τ, ξ) with $\xi = 0$, both $u(t) = +1$ and $u(t) = -1$ are optimal controls and both the lines with slope plus one and minus one are optimal. The value function W is given by $W(\tau, \xi) = -[\xi + (1 - \tau)]^2$ if $\xi \geqq 0$ and by $W(\tau, \xi) = -[\xi - (1 - \tau)]^2$ if $\xi \leqq 0$.

The partial derivative W_t is continuous on $[0, 1] \times \mathbb{R}^n$, but the partial derivative W_ξ is discontinuous at all points $(\tau, 0)$ with $0 \leqq \tau \leqq 1$. Thus, the classical dynamic programming approach to this problem fails. We show how our theory applies. For (τ, ξ) with $\xi > 0$ we have that $DW(\tau, \xi; 1, h)$ exists for all $h \in Q(t, x) = [-1, 1]$ and $DW(\tau, \xi; 1, h) = 2(1 - h)[\xi + (1 - \tau)]$. Hence $\min\{DW(\tau, \xi; 1, h): h \in [-1, 1]\} = 0$ and occurs at $h = 1$. Thus $F(\tau, \xi) = 1$ if $\xi > 0$. For (τ, ξ) with $\xi < 0$ we calculate that $DW(\tau, \xi; 1, h) = -2(1 + h)[\xi - (1 - \tau)]$, so that $F(\tau, \xi) = -1$. For points (τ, ξ) with $\xi = 0$ we have that if $h \geqq 0$, then $DW(\tau, 0; 1, h) = 2(1 - \tau)(1 - h)$, while if $h \leqq 0$, then $DW(\tau, 0; 1, h) = 2(1 - \tau)(1 + h)$. Hence $F(\tau, 0) = \{+1\} \cup \{-1\}$.

The mapping F clearly satisfies property (Q) at all points of $[0, 1) \times \mathbb{R}$, except for those points on the line $\xi = 0$. We take the exceptional set $\mathscr{E}$ to be the line segment $\{(\tau, \xi): 0 \leqq \tau < 1, \xi = 0\}$. It is clear for any (τ, ξ) with $\xi \neq 0$, that the Euler polygons will all be the unique optimal trajectories from the point and will never intersect $\mathscr{E}$. For initial points on $\mathscr{E}$, the Euler polygons will either be lines of slope plus one or minus one, depending on whether $h_0 = +1$ or $h_0 = -1$. In either case the resulting trajectory only has the initial point in common with $\mathscr{E}$. Thus the function $\mathscr{F}$ clearly gives the optimal feedback.

6. Other terminal sets. The terminal sets that we have considered in this paper are $(n+1)$-dimensional with n-dimensional boundaries. In many applications the terminal sets $\mathscr{T}$ are of lower dimension. For example, in the "time optimal to the origin" problem the terminal set is the t-axis.

One treatment of such problems is to replace the problem by an approximation to the problem in which the terminal set has the structure that we have considered here. We illustrate with the time optimal to the origin problem. We take T to be very large and $\varepsilon > 0$ to be very small. We take the terminal set $\mathscr{T}$ to be the union of $[T, \infty) \times \mathbb{R}^n$ and $\mathscr{F}$, where $\mathscr{F}$ is the half-cylinder $\{(t, x): t \geqq 0, \|x\| \leqq \varepsilon\}$. The new terminal set $\mathscr{T}$ falls within the purview of our theory. If we succeed in obtaining an optimal synthesis for this problem, then we can determine those points from which we can reach $\mathscr{F}$ in minimum time t_1, where $t_1 \leqq T$. For many practical situations this model is adequate.

Another treatment of problems with lower-dimensional terminal sets that are closed is the following. The problem is first transformed into a problem with fixed terminal time, say $T = 1$. This can always be done (see, e.g., [1, p. 27]). In the transformed problem the terminal set will be some closed set $\mathscr{C}$ in the hyperplane $t = T$. The transformed problem is then replaced by a sequence of problems P_n in which the terminal set $\mathscr{T}$ is always $[T, \infty) \times \mathbb{R}^n$ and the payoffs are functions $\{g_n\}$ defined by

$$g_n(t, x) = \hat{g}(x) + n \operatorname{dist}(x, \mathscr{C})$$

where $\hat{g}$ is the payoff of the transformed problem and $\operatorname{dist}(x, \mathscr{C}) = \min\{|x - y|: y \in \mathscr{C}\}$.

Each problem P_n falls within the purview of our theory and has a value function W_n. Vinter and Mendoza [11] have shown that the values W_n converge to a function $\hat{W}$ that is the value of the transformed problem. Thus the optimal feedback syntheses of the problems P_n are approximations to the optimal synthesis for the transformed problem.

HAMILTONIAN TRAJECTORIES AND DUALITY IN THE OPTIMAL CONTROL OF LINEAR SYSTEMS WITH CONVEX COSTS*

R. T. ROCKAFELLAR†

This paper is dedicated to the memory of E. J. McShane.

Abstract. A duality theorem is proved for problems of optimal control of linear dynamical systems in continuous time subject to linear constraints and convex costs, such as penalties. Optimality conditions are stated in terms of a "minimaximum principle" in which the primal and dual control vectors satisfy a saddle point condition at almost every instant of time. This principle is shown to be equivalent to a generalized Hamiltonian differential equation in the primal and dual state variables, along with a transversality condition that likewise is in Hamiltonian form.

Key words. convex optimal control, duality, Hamiltonian trajectories, generalized problems of Bolza, calculus of variations, continuous convex programming, intertemporal convex programming

AMS(MOS) subject classifications. 49B10, 90C20, 90C05

1. Introduction. This paper focuses on optimal control problems of convex type and the special properties they enjoy, in particular, properties of duality. A fundamental problem form, intended for approximations of more complicated control situations as well as direct use in mathematical modeling, is introduced in terms of linear dynamics and linear constraints that may be represented by penalties, either finite or infinite. A duality theorem is proved and is made the basis for deriving necessary and sufficient conditions for the optimality of control functions and state trajectories. The work extends the author's recent results on continuous time problems with piecewise linear-quadratic costs [1], [2]. It ties in more generally with the theory of dual problems of Bolza in the calculus of variations, as developed earlier by methods of convex analysis in Rockafeller [3], [4]. A bridge is thereby provided to a conceptual framework dominated by a Hamiltonian function and its gradients or subgradients in the expression of optimality condition.

The chief aim, besides setting up the duality, is to demonstrate that solutions to problems in the chosen class can be characterized in two quite different, yet equivalent, ways. First, there is a "minimaximum principle," which expresses the primal and dual optimal control vectors at any time as giving a saddle point of a certain convex-concave function. Second, there is a generalized Hamiltonian differential equation in terms of primal and dual states but no direct mention of controls.

The minimaximum principle is suggestive of computational approaches that depend on generating sequences of control functions as in various algorithms of convex programming. The Hamiltonian system, on the other hand, is of interest in that it can be solved like an ordinary differential equation from any choice of initial primal and dual states. While this may or may not be a practical tool in calculating optimal trajectories, it reveals important information about such trajectories, for example, that under our assumptions they can be realized by optimal control functions that are

essentially bounded. Knowledge of the Hamiltonian function is crucial also to the prospects of applying Hamilton-Jacobi theory in its latest forms to convex problems of optimal control.

The model problem we start from is not the broadest possible problem that would fit under the heading of convex optimal control. It is selected, rather, to yield strong results while still encompassing a wide spectrum of applications. The details of structure are designed to facilitate dualization.

To help keep formulas compact and readable, we write x_t and u_t as the state and control vectors at time t instead of $x(t)$ and $u(t)$. These vectors belong to $\mathbb{R}^n$ and $\mathbb{R}^k$, respectively. We also make use of an auxiliary control vector $u_e \in \mathbb{R}^{k_e}$, which affects endpoint costs and constraints; the subscript e is utilized also to designate data elements connected with endpoints. (See [1] for a discussion of the modeling possibilities with endpoint controls.) Inner products of vectors in $\mathbb{R}^n$ and $\mathbb{R}^k$ will be expressed in the notation $\langle \cdot, \cdot \rangle$ and the Euclidean norm by $|\cdot|$.

We denote by $\mathcal{U}$ the space of all control elements u consisting of a choice of vector u_e and an *essentially bounded*, measurable function $t \mapsto u_t$ defined over the interval $[t_0, t_1]$, which is fixed throughout the paper. We handle $\mathcal{U}$ as a Banach space in the norm $\|u\| = \max\{|u_e|, \operatorname{ess\,sup}_t |u_t|\}$. Each $u \in \mathcal{U}$ determines a state trajectory $x: t \mapsto x_t \in \mathbb{R}^n$, which is Lipschitz continuous over $[t_0, t_1]$. The time derivative of x_t, which exists for almost every t, is denoted by $\dot{x}_t$. The space of all such Lipschitz continuous arcs x in $\mathbb{R}^n$ is denoted by $\mathcal{A}^\infty = \mathcal{A}_n^\infty[t_0, t_1]$. This is a Banach space in the norm $\|x\|_\infty = \max\{|x_{t_0}|, \operatorname{ess\,sup}_t \dot{x}_t\}$. (The superscript ∞ is a reminder that the derivative function $t \mapsto \dot{x}_t$ belongs to $\mathcal{L}_n^\infty[t_0, t_1]$.)

The control problem we address takes the following form:

Minimize the functional

$$(\mathcal{P}) \qquad \begin{aligned} F(u) = &\int_{t_0}^{t_1} [\langle p_t, u_t \rangle + \varphi_t(u_t) + \psi_t(q_t - C_t x_t - D_t u_t) - \langle c_t, x_t \rangle]\, dt \\ &+ [\langle p_e, u_e \rangle + \varphi_e(u_e) + \psi_e(q_e - C_e x_{t_1} - D_e u_e) - \langle c_e, x_{t_1} \rangle] \end{aligned}$$

over $u \in \mathcal{U}$, where x is determined from u by

$$\dot{x}_t = A_t x_t + B_t u_t + b_t \text{ a.e.}, \quad x_{t_0} = B_e u_e + b_e.$$

Here φ_t and φ_e are functions on $\mathbb{R}^k$ and $\mathbb{R}^{k_e}$, while ψ_t and ψ_e are functions on certain spaces $\mathbb{R}^l$ and $\mathbb{R}^{l_e}$. The dimensions of the various vectors and matrices in $(\mathcal{P})$ are of course completely determined by the dimensions of these spaces. In general we assume the following:

(A1) φ_t, φ_e, ψ_t, ψ_e, are lower semicontinuous, proper, convex functions.

(A2) φ_t and ψ_t depend epi-continuously on $t \in [t_0, t_1]$.

(A3) A_t, B_t, b_t, C_t, c_t, D_t, p_t, q_t, depend continuously on $t \in [t_0, t_1]$.

By (A3) we are assured, in particular, that each choice of $u \in \mathcal{U}$ gives rise to a unique trajectory x, which belongs to the space $\mathcal{A}^\infty$ because the function $t \mapsto A_t x_t + B_t u_t + b_t$ is essentially bounded. The mapping $u \mapsto x$ is continuous. The properness in (A1) asserts that the functions φ_t, φ_e, ψ_t, ψ_e, do not take on the value $-\infty$, although they might in some cases take on ∞ as long as they do not have this value everywhere. The role of ∞ is to provide an infinite penalty for certain constraint violations; more about this will follow.

Assumption (A2) means that the epigraphs sets epi φ_t and epi ψ_t, which are closed convex subsets of $\mathbb{R}^{k+1}$ and $\mathbb{R}^{l+1}$, depend continuously on t in the sense of set

convergence. This form of continuity has been studied by many authors in recent years (see Salinetti and Wets [5], Wets [6], for properties and references). As a special case, of course, epi-continuity is present when φ_t and ψ_t do not actually vary with t.

PROPOSITION 1.1. *Under* (A1)-(A3), *the functional F in problem* $(\mathcal{P})$ *is well defined on the Banach space* $\mathcal{U}$ *with values in* $(-\infty, \infty]$. *Furthermore, F is convex and lower semicontinuous.*

Proof. The epi-continuity of $t \mapsto \operatorname{epi} \varphi_t$ in (A2) entails that the function $(t, w) \mapsto \varphi_t(w)$ is lower semicontinuous on $[t_0, t_1] \times \mathbb{R}^k$. Therefore, this function is definitely a normal integrand in the sense of [7] and is bounded below on $[t_0, t_1] \times W$ for every bounded set $W \subset \mathbb{R}^k$. It follows that $\varphi_t(u_t)$ is measurable in t when u_t is measurable in t, and it is essentially bounded from below when u_t is essentially bounded in t. For any $u \in \mathcal{U}$, then, the integral of $\varphi_t(u_t)$ has a well-defined value in $(-\infty, \infty]$. Similar properties hold for ψ_t. Since (A3) implies $q_t - C_t x_t - D_t u_t$ is a bounded measurable function of t when u_t is such a function of t (here we note that x_t, as determined by the dynamics, is continuous in t), we conclude that the integral of $\psi_t(q_t - c_t x_t - D_t u_t)$ likewise has a well-defined value in $(-\infty, \infty]$ for any $u \in \mathcal{U}$. Thus $F(u)$ is well defined on $\mathcal{U}$ with values in $(-\infty, \infty]$. The convexity of F follows, obviously, from the convexity in (A1) and the fact that the dynamical mapping $u \mapsto x$ is affine. Lower semicontinuity in the norm topology of $\mathcal{U}$ follows from the lower semicontinuity in (A1) and continuity in (A3), as well as the continuity of $u \mapsto x$, by Fatou's Lemma (cf. [7]). □

Problem $(\mathcal{P})$ may involve *implicit constraints* beyond the ones already mentioned, due to the possibility of ∞ values. Recall that the effective domain dom F consists of the elements $u \in \mathcal{U}$ such that $F(u) < \infty$; similarly for dom φ_t and dom φ_e. Minimizing F over $\mathcal{U}$ is the same as minimizing F over dom F. Obviously the condition $u \in \operatorname{dom} F$ requires u to belong to the set

$$U := \left\{ u \in \mathcal{U} \;\middle|\; \int_{t_0}^{t_1} \varphi_t(u_t)\, dt < \infty \text{ and } \varphi_e(u_e) < \infty \right\} \tag{1.1}$$

and satisfy

$$u_t \in U_t \text{ a.e. and } u_e \in U_e, \text{ where } U_t := \operatorname{dom} \varphi_t \text{ and } U_e := \operatorname{dom} \varphi_e, \tag{1.2}$$

$$q_t - C_t x_t - D_t u_t \in R_t \text{ a.e. and } q_e - C_e x_{t_1} - D_e u_e \in R_e, \quad \text{where } R_t := \operatorname{dom} \psi_t \text{ and } R_e := \operatorname{dom} \psi_e. \tag{1.3}$$

The control problem *dual* to $(\mathcal{P})$ involves dual states $y_t \in \mathbb{R}^n$ and dual controls $v_t \in \mathbb{R}^l$ and $v_e \in \mathbb{R}^{l_e}$. Let us denote by $\mathcal{V}$ the set of control elements v consisting of a choice of v_e and an essentially bounded, measurable function $t \mapsto v_t$. This is a Banach space in the same way as described above for $\mathcal{U}$. The dual problem takes the following form:

Maximize the function

$$\begin{aligned} G(v) = \int_{t_0}^{t_1} & [\langle q_t, v_t \rangle - \psi_t^*(v_t) - \varphi_t^*(B_t^* y_t + D_t^* v_t - p_t) - \langle b_t, y_t \rangle]\, dt \\ & + [\langle q_e, v_e \rangle - \psi_e^*(v_e) - \varphi_e^*(B_e^* y_{t_0} + D_e^* v_e - p_e) - \langle b_e, y_{t_0} \rangle] \end{aligned} \tag{2}$$

over $v \in \mathcal{V}$, where y is determined from v by

$$-\dot{y}_t = A_t^* y_t + C_t^* v_t + c_t \text{ a.e.}, \quad y_{t_1} = C_e^* v_e + c_e.$$

The asterisk on a matrix denotes transpose, but on a convex function it indicates the conjugate function (Legendre-Fenchel transform) in the sense of convex analysis [8].

Note that the dual dynamical system goes backward in time and uniquely determines a Lipschitz continuous trajectory $y \in \mathscr{A}^\infty$ for each $v \in \mathscr{V}$.

Just as (A3) is preserved in passing to transposes, assumptions (A1) and (A2) imply the corresponding properties for the conjugate functions:

(A1*) $\varphi_t^*, \varphi_e^*, \psi_t^*, \psi_e^*$, are lower semicontinuous, proper, convex functions.

(A2*) φ_t^* and ψ_t^* depend epi-continuously on $t \in [t_0, t_1]$.

The equivalence between (A2) and (A2*) follows from Wijsman's Theorem [9] on the continuity of the Legendre-Fenchel transform with respect to epi-convergence. Therefore, we immediately get the version of Proposition 1.1 that applies to the dual problem.

PROPOSITION 1.2. *Under* (A1)-(A3), *the functional G in problem* ($\mathscr{Q}$) *is well defined on the Banach space* $\mathscr{V}$ *with values in* $[-\infty, \infty)$. *Furthermore, G is concave and upper semicontinuous.*

Implicit in ($\mathscr{Q}$) are the constraints that v should belong to the set

$$V := \left\{ v \in \mathscr{V} \;\middle|\; \int_{t_0}^{t_1} \psi_t^*(v_t)\, dt < \infty \text{ and } \psi_e^*(v_e) < \infty \right\} \tag{1.4}$$

and satisfy

$$v_t \in V_t \text{ a.e. and } v_e \in V_e, \text{ where } V_t := \operatorname{dom} \psi_t^* \text{ and } V_e := \operatorname{dom} \psi_e^*, \tag{1.5}$$

$$B_t^* y_t + D_t^* v_t - p_t \in S_t \text{ a.e. and } B_e^* y_{t_0} + D_e^* v_e - p_e \in S_e, \quad \text{where } S_t := \operatorname{dom} \varphi_t^* \text{ and } S_e := \operatorname{dom} \varphi_e^*. \tag{1.6}$$

The special case of these primal and dual problems that was treated in [1] and [2] as *extended linear-quadratic* optimal control is obtained by taking

$$\begin{aligned} &\varphi_t(u_t) = \tfrac{1}{2}\langle u_t, P_t u_t\rangle \quad \text{for } u_t \in U_t, \quad \varphi_t(u_t) = \infty \quad \text{for } u_t \notin U_t, \\ &\varphi_e(u_e) = \tfrac{1}{2}\langle u_e, P_e u_e\rangle \quad \text{for } u_e \in U_e, \quad \varphi_e(u_e) = \infty \quad \text{for } u_e \notin U_e, \\ &\psi_t^*(v_t) = \tfrac{1}{2}\langle v_t, Q_t v_t\rangle \quad \text{for } v_t \in V_t, \quad \psi_t^*(v_t) = \infty \quad \text{for } v_t \notin V_t, \\ &\psi_e^*(v_e) = \tfrac{1}{2}\langle v_e, Q_e v_e\rangle \quad \text{for } v_e \in V_e, \quad \psi_e^*(v_e) = \infty \quad \text{for } v_e \notin V_e, \end{aligned} \tag{1.7}$$

for *polyhedral* sets U_t, U_e, V_t, V_e, and *positive semidefinite* symmetric matrices P_t, P_e, Q_t, Q_e. The philosophy behind this is fully explained in [1] and will not be repeated here, except to say that the functions ψ_t, ψ_e, φ_t^*, φ_e^*, are then piecewise linear-quadratic and yield a version of linear-quadratic optimal control in which piecewise linear-quadratic penalty terms may be present and are readily dualized.

In general, the terms involving ψ_t and ψ_e in ($\mathscr{P}$) may be viewed as *monitoring* the vectors $s_t = q_t - C_t x_t - D_t u_t$ and $s_e = q_e - C_e x_{t_1} - D_e u_e$. A simple example would be the one where ψ_t vanishes on a certain set K but has the value ∞ outside of K. Then the ψ_t term expresses through infinite penalties the condition that $s_t \in K$ almost everywhere. This condition might represent a system of equations or inequalities. Instead ψ_t could have finite, positive values outside of K, and then we would have a finite penalty representation of such a constraint system. Similarly, ψ_e could play this role for constraints on the endpoint x_{t_1}, while φ_t^* and φ_e^* could have such interpretations in the dual problem. Many examples are worked out in [1].

Our strongest results will eventually call for a further assumption:

(A4) φ_t and φ_e are coercive, while ψ_t and ψ_e are everywhere finite.

Coercivity of φ_t means that $\lim_{|w|\to\infty} \varphi_t(w)/|w| = \infty$, which is true in particular when the control set U_t in (1.2) is bounded; similarly for φ_e and U_e. It is known from convex

analysis [8, § 13] that φ_t and φ_e are coercive if and only if the conjugate functions φ_t^* and φ_e^* are finite everywhere. Likewise, ψ_t and ψ_e are finite everywhere if and only if ψ_t^* and ψ_e^* are coercive. Thus (A4), like the earlier assumptions, has an equivalent dual form:

(A4*) ψ_t^* and ψ_e^* are coercive, while φ_t^* and φ_e^* are everywhere finite.

The interpretation of (A4), then, is that *there are effectively no exact implicit constraints of type* (1.3) *and* (1.6) *in the primal and dual problems.* In other words, this additional assumption corresponds to the situation where all the monitoring of $q_t - C_t x_t - D_t u_t$ and $q_e - C_e x_{t_1} - D_e u_e$ in the primal problem and of $B_t^* y_t + D_t^* v_t - p_t$ and $B_e^* y_{t_0} + D_e^* v_e - p_e$ in the dual problem proceeds with *finite* values: no infinite penalties. Such a property may naturally be present in a given application, or it may be achieved as a mode of approximation for a problem one is really interested in. Anyway, we may argue that it is vital for the development of computational methods for problems like $(\mathcal{P})$ and $(\mathcal{Q})$. Conditions on x or on x and u jointly that are modeled as exact constraints can lead to serious numerical complications, whereas such conditions on u alone, as in (1.2), present relatively little difficulty. See [1] for more on this issue.

PROPOSITION 1.3. *Under* (A4), *the epi-continuity assumption* (A2) *is equivalent to having* $\varphi_t^*(r)$ *and* $\psi_t(s)$ *be continuous in* $t \in [t_0, t_1]$ *for each* $r \in \mathbb{R}^k$ *and* $s \in \mathbb{R}^l$. *Then in fact* $\varphi_t^*(r)$ *is continuous with respect to* (t, r), *and* $\psi_t(s)$ *is continuous with respect to* (t, s).

Proof. For finite convex functions, epi-continuity with respect to t is equivalent to pointwise continuity with respect to t; (see Salinetti and Wets [5, Cors. 4, 5]). Furthermore, finite convex functions whose values depend continuously on t are jointly continuous in t and their other variables [8, Thm. 10.7].

PROPOSITION 1.4. *Under assumptions* (A1)-(A3), *the sets* U *and* V *in* (1.1) *and* (1.4) *are convex and nonempty. When* (A4) *holds too,* U *is identical to the set of feasible controls for* $(\mathcal{P})$, *i.e., the elements* $u \in \mathcal{U}$ *for which* $F(u)$ *is finite, and likewise* V *is the set of feasible controls for* $(\mathcal{Q})$. *In particular, feasible controls do exist, then, for both problems.*

Proof. The convexity of U and V is obvious from their definitions by the convexity in (A1). Clearly $F(u) = \infty$ when $u \notin U$, and $G(v) = -\infty$ for $v \notin V$. According to (A2), the multifunction $t \mapsto \operatorname{epi} \varphi_t$, whose values are nonempty closed convex sets by (A1), is continuous. For such a multifunction the continuous selection theorem of Michael [10] applies: it is possible to choose $(u_t, \alpha_t) \in \operatorname{epi} \varphi_t$ continuously with respect to $t \in [t_0, t_1]$. Then $\varphi_t(u_t) \leqq \alpha_t$, so the integral of $\varphi_t(u_t)$ cannot be ∞ and therefore must be finite. Taking any u_e in U_e, a set which is nonempty by the properness of φ_e in (A1), we obtain a control element $u \in U$. Thus $U \neq \emptyset$. Any $u \in U$, on the other hand, makes all the terms in the formula for $F(u)$ in $(\mathcal{P})$ be finite except perhaps for the integral of $\psi_t(s_t)$, where $s_t = q_t - C_t x_t + D_t u_t$. The function $t \mapsto s_t$ is essentially bounded in t by (A3). The continuity of $(t, s) \mapsto \psi_t(s)$ asserted by Proposition 1.3 implies that the latter function is bounded on $[t_0, t_1] \times W$ for any bounded set $W \subset \mathbb{R}^l$. We thereby obtain the essential boundedness of $\psi_t(s_t)$ in t and hence the finiteness of its integral. This yields the desired conclusion in the case of $(\mathcal{P})$. The corresponding result for $(\mathcal{Q})$ follows by duality. □

2. Minimax representation. The close relationship between problems $(\mathcal{P})$ and $(\mathcal{Q})$ that leads to their being called dual to each other stems from a joint representation in terms of a minimax problem in $\mathcal{U} \times \mathcal{V}$. To give this, we introduce the functional

$$J(u, v) := \int_{t_0}^{t_1} J_t(u_t, v_t)\, dt + J_e(u_e, v_e) - j(u, v) \tag{2.1}$$

in the notation

$$
\begin{aligned}
J_t(u_t, v_t) &:= \langle p_t, u_t\rangle + \langle q_t, v_t\rangle - \langle v_t, D_t u_t\rangle + \varphi_t(u_t) - \psi_t^*(v_t),\\
J_e(u_e, v_e) &:= \langle p_e, u_e\rangle + \langle q_e, v_e\rangle - \langle v_e, D_t u_t\rangle + \varphi_e(u_e) - \psi_e^*(v_e),
\end{aligned} \tag{2.2}
$$

and with j taken to be the bi-affine functional on $\mathcal{U} \times \mathcal{V}$ that corresponds to the dynamics and is expressed in terms of the trajectories x and y associated with u and v by

$$
\begin{aligned}
j(u, v) &:= \int_{t_0}^{t_1} \langle y_t, B_t u_t + b_t\rangle\, dt + \langle y_{t_0}, B_e u_e + b_e\rangle\\
&= \int_{t_0}^{t_1} \langle x_t, C_t^* v_t + c_t\rangle\, dt + \langle x_{t_1}, C_e^* v_e + c_e\rangle.
\end{aligned} \tag{2.3}
$$

(The validity of the equation in (2.3) is proved in [1, § 6].) Because some of the terms in (2.2) can take on the value ∞ while others are $-\infty$, a convention is necessary to ensure that $J(u, v)$ is well defined. The one we follow is standard in convex analysis: $\infty - \infty = \infty$. This clarifies the meaning of $J_t(u_t, v_t)$ and $J_e(u_e, v_e)$ in all cases in (2.2):

$$
J_t(u_t, v_t) = \begin{cases} \text{finite value} & \text{when } u_t \in U_t \text{ and } v_t \in V_t,\\ -\infty & \text{when } u_t \in U_t \text{ and } v_t \notin V_t,\\ \infty & \text{when } u_t \notin U_t, \end{cases}
$$

$$
J_e(u_e, v_e) = \begin{cases} \text{finite value} & \text{when } u_e \in U_e \text{ and } v_e \in V_e,\\ -\infty & \text{when } u_e \in U_e \text{ and } v_e \notin V_e,\\ \infty & \text{when } u_e \notin U_e, \end{cases} \tag{2.4}
$$

where the sets U_t, U_e, V_t, V_e, are the effective domains in (1.2) and (1.5). The convention enters into the formula for $J(u, v)$ in resolving the integral as ∞ whenever the positive part of the integrand (which is always measurable by the argument given in the proof of Proposition 1.1) has integral ∞ while the negative part has integral $-\infty$. (This amounts to writing $J(u, v)$ with the terms $\int_{t_0}^{t_1} \varphi_t(u_t)\, dt$ and $-\int_{t_0}^{t_1} \psi_t^*(v_t)\, dt$ separated out and then invoking the convention $\infty - \infty = \infty$ in forming the overall sum. The first of these terms is unambiguously finite or ∞, as seen in Proposition 1.1, while the second is finite or $-\infty$.)

PROPOSITION 2.1. *The functional J is convex-concave on $\mathcal{U} \times \mathcal{V}$ with finite values on $U \times V$ but infinite values everywhere else. For each $v \in V$, $J(u, v)$ is lower semicontinuous in $u \in \mathcal{U}$, while for each $u \in U$, $J(u, v)$ is upper semicontinuous in $v \in \mathcal{V}$. The objective functionals F and G in $(\mathcal{P})$ and $(\mathcal{Q})$ are given by*

$$
F(u) = \inf_{u \in \mathcal{U}} J(u, v) = \inf_{u \in U} J(u, v) \quad \text{and} \quad G(v) = \sup_{v \in \mathcal{V}} J(u, v) = \sup_{v \in V} J(u, v).
$$

Proof. In view of the definitions of U and V in (1.1) and (1.4), the convention adopted in the formula for $J(u, v)$ entails, having

$$
J(u, v) = \begin{cases} \text{finite value} & \text{when } u \in U \text{ and } v \in V,\\ -\infty & \text{when } u \in U \text{ and } v \notin V,\\ \infty & \text{when } u \notin U. \end{cases} \tag{2.5}
$$

The fact that $J(u, v)$ is convex in u and concave in v relative to the product set $U \times V$ is obvious from the convexity of the functions φ_t, φ_e, ψ_t^*, ψ_e^*. The semicontinuity follows from (A1) and (A3) by Fatou's Lemma (cf. [7]).

To establish the formula asserted for $G(v)$, it suffices because of the infinities in (2.5) to prove the first equality in the case of $v \in V$. This is done by taking the first of the forms for $j(u, v)$ in (2.3) and calculating

$$\inf_{u \in \mathcal{U}} J(u, v) = \int_{t_0}^{t_1} [\langle q_t, v_t \rangle - \psi_t(v_t) - \langle y_t, v_t \rangle]\, dt + [\langle q_e, v_e \rangle - \psi_e(v_e) - \langle y_{t_0}, v_e \rangle]$$
$$+ \inf_{u \in \mathcal{U}} \left\{ \int_{t_0}^{t_1} [\langle p_t - B_t^* y_t, u_t \rangle + \varphi_t(u_t)]\, dt + [\langle p_e - B_e^* y_{t_0}, u_e \rangle + \varphi_e(u_e)] \right\}.$$

The infimum on the right equals $-\int_{t_0}^{t_1} \varphi_t^*(B_t^* y_t - p_t)\, dt - \varphi_e^*(B_e^* y_{t_0} - p_e)$ through the conjugacy formulas

$$\varphi_t^*(r) = \sup_{u \in \mathbb{R}^k} \{\langle r, u \rangle - \varphi_t(u)\} \quad \text{and} \quad \varphi_e^*(r) = \sup_{u_e \in \mathbb{R}^{k_e}} \{\langle r, u_e \rangle - \varphi_e(u_e)\}$$

and the fundamental theorem on conjugates of integral functionals, (cf. [7, Thm. 3C]). The proof of the formula for $F(u)$ follows the same pattern. (The apparent lack of symmetry in (2.5) is restored though the observation already made that only the values of J on $U \times V$ really matter.) □

THEOREM 2.2. *Under* (A1)-(A3), *the optimal values in problems* $(\mathcal{P})$ *and* $(\mathcal{Q})$ *always satisfy* $\inf(\mathcal{P}) \geqq \sup(\mathcal{Q})$. *A pair* $(\bar{u}, \bar{v})$ *furnishes a saddle point of* J *on* $\mathcal{U} \times \mathcal{V}$ *if and only if* $\bar{u}$ *is optimal for* $(\mathcal{P})$, $\bar{v}$ *is optimal for* $(\mathcal{Q})$, *and one actually has* $\inf(\mathcal{P}) = \sup(\mathcal{Q})$. *This saddle point condition is equivalent to the following, where* $\bar{x}$ *and* $\bar{y}$ *denote the primal and dual trajectories generated by* $\bar{u}$ *and* $\bar{v}$:

$$\begin{aligned} &(\bar{u}_t, \bar{v}_t) \text{ is a saddle point of } J_t(u_t, v_t) - \langle B_t^* \bar{y}_t, u_t \rangle - \langle C_t \bar{x}_t, v_t \rangle \text{ on } U_t \times V_t \quad \text{for a.e. } t, \\ &(\bar{u}_e, \bar{v}_e) \text{ is a saddle point of } J_e(u_e, v_e) - \langle B_e^* \bar{y}_{t_0}, u_e \rangle - \langle C_e \bar{x}_e, v_e \rangle \text{ on } U_e \times V_e. \end{aligned} \tag{2.6}$$

Proof. Up to the equivalence of the saddle point condition with (2.6), the assertions are well-known consequences of the relationship displayed in Proposition 2.1, where primal and dual objectives are derived as "halves" of a minimax problem. The saddle point condition has the means by definition that

$$\bar{u} \in \operatorname*{argmin}_{u \in U} J(u, \bar{v}) \quad \text{and} \quad \bar{v} \in \operatorname*{argmax}_{v \in V} J(\bar{u}, v).$$

Due to (2.5), it requires that $\bar{u} \in U$ and $\bar{v} \in V$. Then in terms of the notation

$$\begin{aligned} \bar{J}_t(u_t, v_t) &:= J_t(u_t, v_t) - \langle B_t^* \bar{y}_t, u_t \rangle - \langle C_t \bar{x}_t, v_t \rangle, \\ \bar{J}_e(u_e, v_t) &:= J_e(u_e, v_e) - \langle B_e^* \bar{y}_{t_0}, u_e \rangle - \langle C_e \bar{x}_{t_1}, v_e \rangle, \end{aligned} \tag{2.7}$$

it reduces, by the calculation in the proof of Proposition 2.1, to

$$\bar{u}_t \in \operatorname*{argmin}_{u_t \in \mathbb{R}^k} \bar{J}_t(u_t, \bar{v}_t) \quad \text{and} \quad \bar{v}_t \in \operatorname*{argmax}_{v_t \in \mathbb{R}^l} \bar{J}_t(\bar{u}_t, v_t) \quad \text{a.e.},$$

$$\bar{u}_e \in \operatorname*{argmin}_{u_e \in \mathbb{R}^{k_e}} \bar{J}_e(u_e, \bar{v}_e) \quad \text{and} \quad \bar{v}_e \in \operatorname*{argmax}_{v_e \in \mathbb{R}^{l_e}} \bar{J}_e(\bar{u}_e, v_e).$$

These relations assert that $(\bar{u}_t, \bar{v}_t)$ is a saddle point of $\bar{J}_t$ on $\mathbb{R}^k \times \mathbb{R}^l$ for almost every t and $(\bar{u}_e, \bar{v}_e)$ is a saddle point of $\bar{J}_e$ on $\mathbb{R}^{k_e} \times \mathbb{R}^{l_e}$. But $\bar{J}_t$ and $\bar{J}_e$ have the structure (2.4) relative to $U_t \times V_t$ and $U_e \times V_e$. The saddle points in question are therefore expressed equivalently with respect to $U_t \times V_t$ and $U_e \times V_e$. This is all that has to be proved. □

The saddle point conditions in (2.6) will be referred to as the *minimaximum principle* for $(\mathcal{P})$ and $(\mathcal{Q})$. This principle is *always sufficient* for optimality according to the Theorem 2.2, and it is necessary for optimality in any circumstances where we

happen to know that $\inf(\mathcal{P}) = \sup(\mathcal{Q})$ and that both problems have solutions. We shall prove in due course that assumption (A4) provides such a circumstance. Our method requires us to examine an auxiliary pair of problems in which trajectories are optimized without direct mention of controls. This will be done in the next section.

The minimaximum principle can be stated in terms of a duality between finite-dimensional optimization problems at every instant of time. With x and y as parameter vectors in $\mathbb{R}^n$, consider the problems

$$(\mathcal{P}_t(x, y)) \qquad \min_{u \in U_t} \{\langle p_t - B_t^* y, u\rangle + \varphi_t(u) + \psi_t(q_t - C_t x - D_t u)\},$$

$$(\mathcal{Q}_t(x, y)) \qquad \max_{v \in V_t} \{\langle q_t - C_t x, v\rangle - \psi_t^*(v) - \varphi_t(B_t^* y + D_t^* v - p_t)\},$$

for each $t \in [t_0, t_1]$ and also the problems

$$(\mathcal{P}_e(x, y)) \qquad \min_{u_e \in U_e} \{\langle p_e - B_e^* y, u_e\rangle + \varphi_e(u_e) + \psi_e(q_e - C_e x - D_e u_e)\},$$

$$(\mathcal{Q}_e(x, y)) \qquad \max_{v_e \in V_e} \{\langle q_e - C_e x, v_e\rangle - \psi_e^*(v_e) - \varphi_e(B_e^* y + D_e^* v_e - p_e)\}.$$

PROPOSITION 2.3. *The minimaximum principle* (2.6) *is equivalent to the following set of conditions on $\bar{u}$ and $\bar{v}$, as expressed through the corresponding trajectories $\bar{x}$ and $\bar{y}$:*

$$\bar{u}_t \text{ solves } (\mathcal{P}_t(\bar{x}_t, \bar{y}_t)),\ \bar{v}_t \text{ solves } (\mathcal{Q}_t(\bar{x}_t, \bar{y}_t)),\ \inf(\mathcal{P}_t(\bar{x}_t, \bar{y}_t)) = \sup(\mathcal{Q}_t(\bar{x}_t, \bar{y}_t)),$$

$$\bar{u}_e \text{ solves } (\mathcal{P}_e(\bar{x}_{t_1}, \bar{y}_{t_0})),\ \bar{v}_e \text{ solves } (\mathcal{Q}_e(\bar{x}_{t_1}, \bar{y}_{t_0})),\ \inf(\mathcal{P}_e(\bar{x}_{t_1}, \bar{y}_{t_0})) = \sup(\mathcal{Q}_e(\bar{x}_{t_1}, \bar{y}_{t_0})).$$

Proof. Elementary minimax theory informs us that $(\bar{u}_t, \bar{v}_t)$ has the saddle point property in (2.6) for a given t if and only if $\bar{u}_t$ minimizes over $u \in U_t$ the function

$$f_t(u) := \sup_{v \in V_t} \{J_t(u, v) - \langle B_t^* \bar{y}_t, u\rangle - \langle C_t \bar{x}_t, v\rangle\},$$

$\bar{v}_t$ maximizes over $v \in V_t$ the function

$$g_t(v) := \inf_{u \in U_t} \{J_t(u, v) - \langle B_t^* \bar{y}_t, u\rangle - \langle C_t \bar{x}_t, v\rangle\},$$

and $\inf_{U_t} f_t = \sup_{V_t} g_t$. These functions are calculated from the reciprocal conjugacy formulas:

$$\psi_t(s) = \sup_{v \in V_t} \{\langle s, v\rangle - \psi_t^*(v)\} \quad \text{and} \quad \psi_e(s_e) = \sup_{v_e \in V_e} \{\langle s_e, v_e\rangle - \psi_e^*(v_e)\}$$

to be the objectives in $(\mathcal{P}_t(\bar{x}_t, \bar{y}_t))$ and $(\mathcal{Q}_t(\bar{x}_t, \bar{y}_t))$, respectively. The assertion concerning this pair of problems is therefore valid. The one for $(\mathcal{P}_e(\bar{x}_{t_1}, \bar{y}_{t_0}))$ and $(\mathcal{Q}_e(\bar{x}_{t_1}, \bar{y}_{t_0}))$ is similarly proved. □

3. Bolza formulations. Generalized problems of Bolza in the calculus of variations concern trajectories as elements of the space $\mathcal{A}^1 = \mathcal{A}_n^1[t_0, t_1]$ consisting of all the absolutely continuous arcs x in $\mathbb{R}^n$ over $[t_0, t_1]$. (The superscript 1 refers to the fact that the function $t \mapsto \dot{x}_t$ is an element of $\mathcal{L}_n^1[t_0, t_1]$.) Such problems have the form

$$(\mathcal{P}_B) \qquad \text{Minimize } \Phi(x) := \int_{t_0}^{t_1} L_t(x_t, \dot{x}_t)\, dt + L_e(x_{t_0}, x_{t_1}) \text{ over all } x \in \mathcal{A}^1,$$

where the functions L_t and L_e on $\mathbb{R}^n \times \mathbb{R}^n$ may be extended-real-valued. In the *convex* case, where L_t and L_e are convex functions on $\mathbb{R}^n \times \mathbb{R}^n$, there is a dual problem

$$(\mathcal{Q}_B) \qquad \text{Maximize } \Psi(y) := -\int_{t_0}^{t_1} M_t(y_t, \dot{y}_t)\, dt - M_e(y_{t_0}, y_{t_1}) \text{ over all } y \in \mathcal{A}^1,$$

in which M_t and M_e are derived from L_t and L_e by

$$M_t(y_t, \dot{y}_t) = L_t^*(\dot{y}_t, y_t) \quad \text{and} \quad M_e(y_{t_0}, y_{t_1}) = L_e^*(y_{t_0}, -y_{t_1}). \tag{3.1}$$

An extensive duality theory for convex problems of Bolza was developed in [3] and [4]. We intend to apply this theory to gain insights into the relationship between the control problems $(\mathcal{P})$ and $(\mathcal{Q})$. For this purpose we choose to define

$$\begin{aligned} L_t(x, w) &= \inf_{\substack{u \in U_t \\ A_t x + B_t u + b_t = w}} \{\langle p_t, u\rangle + \varphi_t(u) + \psi_t(q_t - C_t x - D_t u) - \langle c_t, x\rangle\}, \\ L_e(x_0, x_1) &= \inf_{\substack{u_e \in U_e \\ B_e u_e + b_e = x_0}} \{\langle p_e, u_e\rangle + \varphi_e(u_e) + \psi_e(q_e - C_e x_1 - D_e u_e) - \langle c_e, x_1\rangle\}. \end{aligned} \tag{3.2}$$

(Here x and u are temporarily just dummy vectors in $\mathbb{R}^n$ and $\mathbb{R}^k$, and similarly x_0 and x_1 in $\mathbb{R}^n$.) Our work with these expressions will make use of the concept of the *recession function* associated with a lower semicontinuous, proper, convex function f on $\mathbb{R}^n$, denoted by $\operatorname{rc} f$. Many facts about such recession functions are assembled in [8, §§ 8, 13]. We mention in particular that

$$(\operatorname{rc} f)(z) = \lim_{\lambda \to \infty} [f(\bar{z} + \lambda z) - f(\bar{z})]/\lambda \quad \text{for any } \bar{z} \in \operatorname{dom} f, \tag{3.3}$$

and that coercivity of f is equivalent to $\operatorname{rc} f$ being the indicator function δ_0 of the origin, where

$$\delta_0(z) = \infty \quad \text{for } z \neq 0, \qquad \delta_0(0) = 0.$$

PROPOSITION 3.1. *Under assumptions* (A1)-(A4), *the Bolza functional* Φ *in* $(\mathcal{P}_B)$ *is well defined on* $\mathcal{A}^1$ *and is convex. The functions* L_t *and* L_e *are themselves lower semicontinuous, proper, and convex on* $\mathbb{R}^n \times \mathbb{R}^n$, *and* L_t *depends epi-continuously on* t. *The infima defining* L_t *and* L_e *are attained whenever finite, i.e., whenever the given constraints in* (3.2) *can be satisfied. The recession functions are expressed by*

$$\begin{aligned} (\operatorname{rc} L_t)(x, w) &= (\operatorname{rc} \psi_t)(-C_t x) - \langle c_t, x\rangle + \delta_0(w - A_t x), \\ (\operatorname{rc} L_e)(x_0, x_1) &= (\operatorname{rc} \psi_e)(-C_t x_1) - \langle c_e, x_1\rangle + \delta_0(x_0). \end{aligned} \tag{3.4}$$

Proof. Consider the functions

$$\begin{aligned} K_t(x, w, u) &= \langle p_t, u\rangle + \varphi_t(u) \\ &\quad + \psi_t(q_t - C_t x - D_t u) - \langle c_t, x\rangle + \delta_0(w - A_t x - B_t u - b_t), \\ K_e(x_0, x_1, u_e) &= \langle p_e, u_e\rangle + \varphi_e(u_e) \\ &\quad + \psi_e(q_e - C_e x_1 - D_e u_e) - \langle c_e, x_1\rangle + \delta_0(x_0 - B_e u_e + b_e). \end{aligned} \tag{3.5}$$

By virtue of (A1) these are lower semicontinuous, proper, convex functions on $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^k$ and $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^{k_e}$. The definitions given for L_t and L_e in (3.2) are equivalent to

$$L_t(x, w) = \inf_{u \in \mathbb{R}^k} K_t(x, w, u) \quad \text{and} \quad L_e(x_0, x_1) = \inf_{u_e \in \mathbb{R}^{k_e}} K_e(x_0, x_1, u_e). \tag{3.6}$$

In the language of convex analysis, therefore, L_t is the image of K_t under the projection $(x, w, u) \mapsto (x, w)$, while L_e is the image of K_e under $(x_0, x_1, u_e) \mapsto (x_0, x_1)$. We wish to apply a general theorem about such images, namely Theorem 9.2 of [8]. This involves

a condition on the recession functions of K_t and K_e, which are calculated via (3.3) and the coercivity of φ_t and φ_e in (A4) to be

$$
\begin{aligned}
(\operatorname{rc} K_t)(x, w, u) &= \langle p_t, u\rangle + \delta_0(u) + (\operatorname{rc}\psi_t)(-C_t x - D_t u) \\
&\quad -\langle c_t, x\rangle + \delta_0(w - A_t x - B_t u) \\
&= \delta_0(u) + (\operatorname{rc}\psi_t)(-C_t x) - \langle c_t, x\rangle + \delta_0(w - A_t x), \\
(\operatorname{rc} K_e)(x_0, x_1, u_e) &= \langle p_e, u_e\rangle + \delta_0(u_e) + (\operatorname{rc}\psi_e)(-C_e x_1 - D_e u_e) \\
&\quad -\langle c_e, x_1\rangle + \delta_0(x_0 - B_e u_e) \\
&= \delta_0(u_e) + (\operatorname{rc}\psi_e)(-C_e x_1) - \langle c_e, x_1\rangle + \delta_0(x_0).
\end{aligned} \tag{3.7}
$$

(We make use of the coercivity of φ_t and φ_e in replacing rc φ_t and rc φ_e by δ_0.) The fact that $(\operatorname{rc} K_t)(0, 0, u) = 0$ only for $u = 0$, and $(\operatorname{rc} K_e)(0, 0, u_e) = 0$ only for $u_e = 0$ guarantees by the theorem just cited from [8] that L_t and L_e are lower semicontinuous, proper, convex functions for which the infima in (3.6) are always attained (i.e., the ones in (3.2) are attained when the constraints can be satisfied), and that

$$(\operatorname{rc} L_t)(x, w) = \inf_{u\in\mathbb{R}^k} (\operatorname{rc} K_t)(x, w, u) \quad \text{and} \quad (\operatorname{rc} L_e)(x_0, x_1) = \inf_{u_e\in\mathbb{R}^{k_e}} (\operatorname{rc} K_e)(x_0, x_1, u_e).$$

The latter formulas are the same as those claimed in (3.4) because of the special nature of rc K_t and re K_e in (3.7).

We must verify that L_t depends epi-continuously on t. We shall do this by way of theorems of McLinden and Bergstrom [11], showing first that K_t depends epi-continuously on t. Let us write $K_t = K_t^1 + K_t^2 + K_t^3$ with

$$K_t^1(x, w, u) = \langle p_t, u\rangle + \psi_t(q_t - C_t x - D_t u) - \langle c_t, x\rangle,$$
$$K_t^2(x, w, u) = \varphi_t(u), \qquad K_t^3(x, w, u) = \delta_0(w - A_t x - B_t u).$$

The functions in this decomposition are lower semicontinuous, proper, and convex on $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^k$. We argue first that each depends epi-continuously on t. This is obvious for K_t^2 because of (A2). It holds for K_t^1 because this is a finite convex function by (A4) whose values depend continuously on t (cf. Proposition 1.3). (A finite convex function depends epi-continuously on t if and only if its value at each point depends continuously on t [5, Cors. 4, 5].) In the case of K_t^3 the epi-continuity follows from Theorem 8 of [11] because the linear transformation $(x, w, u) \mapsto w - A_t x - B_t u$ depends continuously on t (by (A3)) and has all of $\mathbb{R}^n$ as its range. We deduce next from Theorem 5 of [11] that $K_t^2 + K_t^3$ depends epi-continuously on t, because the set dom $K_t^2 -$ dom K_t^3 is all of $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^k$ and therefore certainly contains the origin in its interior. The same theorem of [11] applied to $K_t^1 + (K_t^2 + K_t^3)$ then yields the desired epi-continuity of K_t with respect to t, since dom $K_t^1 -$ dom $(K_t^2 + K_t^3)$ too is all of $\mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^k$. Recalling now that L_t is the image of K_t under the projection $(x, w, u) \mapsto (x, w)$, and $(\operatorname{rc} K_t)(0, 0, u) = 0$ only for $u = 0$, we obtain from Theorem 7 of [11] that L_t depends continuously on t. This property of L_t implies in particular that $L_t(x, w)$ is lower semicontinuous with respect to (t, x, w). The integrand in the formula for the Bolza functional Φ is certainly measurable then. The functional is well defined in this case under the $\infty - \infty = \infty$ convention explained earlier. Its convexity follows from that of L_t and L_e. □

COROLLARY 3.2. *Under assumptions* (A1)-(A4), *the dual Bolza functional* Ψ *in* $(\mathcal{Q}_B)$ *is well defined on* $\mathcal{A}_n^1[t_0, t_1]$ *and is concave. The functions* M_t *and* M_e *are lower semicontinuous, proper, and convex on* $\mathbb{R}^n \times \mathbb{R}^n$, *and* M_t *depends epi-continuously on* t. *These functions satisfy the reciprocal conjugacy formulas*

$$L_t(x_t, \dot{x}_t) = M_t^*(\dot{x}_t, x_t) \quad \text{and} \quad L_e(x_{t_0}, x_{t_1}) = M_e^*(x_{t_0}, -x_{t_1}). \tag{3.8}$$

Proof. This merely invokes the basic properties of the Legendre-Fenchel transform [8, § 12], including the fact that it preserves epi-convergence of convex functions [9].

Now it will be demonstrated that the dual Bolza functional Ψ bears the same relationship to the elements of the dual control problem $(\mathcal{Q})$ as the primal Bolza functional Φ does through (3.2) to the elements of $(\mathcal{P})$. □

PROPOSITION 3.3. *Under* (A1)-(A4), *the dual functions M_t and M_e are expressed by*

$$
\begin{aligned}
-M_t(y, z) &= \sup_{\substack{v \in V_t \\ A_t^* y + C_t^* v + c_t = -z}} \{\langle q_t, v\rangle - \psi_t^*(v) - \varphi_t^*(B_t^* y + D_t^* v - p_t) - \langle b_t, y\rangle\}, \\
-M_e(y_0, y_1) &= \sup_{\substack{v_e \in V_e \\ C_e^* v_e + c_e = y_1}} \{\langle q_e, v_e\rangle - \psi_e^*(v_e) - \varphi_e^*(B_e^* y_0 + D_e^* u_e - p_e) - \langle b_e, y_0\rangle\}
\end{aligned} \tag{3.9}
$$

where the suprema are attained whenever the indicated constraints can be satisfied. The recession functions of M_t and M_e are given by

$$
\begin{aligned}
(\mathrm{rc}\, M_t)(y, z) &= (\mathrm{rc}\, \varphi_t^*)(-B_t^* y) - \langle b_t, y\rangle + \delta_0(z + A_t^* y), \\
(\mathrm{rc}\, M_e)(y_0, y_1) &= (\mathrm{rc}\, \varphi_e^*)(-B_e^* y_0) - \langle b_e, y_0\rangle + \delta_0(y_1).
\end{aligned} \tag{3.10}
$$

Proof. Starting toward the proof of the formula for M_t in (3.9), we observe that the definition of M_t in (3.1), which means

$$
M_t(y, z) = \sup_{x,w} \{\langle z, x\rangle + \langle y, w\rangle\} = L_t(x, w),
$$

can be combined with the specification of L_t in (3.2) to yield

$$
\begin{aligned}
M_t(y, z) &= \sup_{x,u} \{\langle z, x\rangle + \langle y, A_t x + B_t u + b_t\rangle - \langle p_t, u\rangle \\
&\qquad - \varphi_t(u) - \psi_t(q_t - C_t x - D_t u) + \langle c_t, x\rangle\} \\
&= \langle b_t, y\rangle - \inf_{x,u} \{f(x, u) - g(E(x, u))\},
\end{aligned} \tag{3.11}
$$

where E is the linear transformation given by $E(x, u) = C_t x + D_t u$ and f and g are the convex and concave functions given by

$$
\begin{aligned}
f(x, u) &= \varphi_t(u) - \langle z + A_t^* y + c_t, x\rangle - \langle B_t^* y + p_t, u\rangle, \\
g(s) &= -\psi_t(q_t - s).
\end{aligned}
$$

Inasmuch as g is finite everywhere by (A4), we can apply Fenchel's Duality Theorem as stated in Corollary 31.2.1 of [8] to write

$$
\inf_{x,u} \{f(x, u) - g(E(x, u))\} = \max_{v} \{g^*(v) - f^*(E^*(v))\}
$$

where the "max" indicates attainment. The adjoint linear transformation E^* takes v into the pair $(C_t^* v, D_t^* v)$. Direct calculation of the conjugate functions f^* and g^* yields

$$
\begin{aligned}
f^*(s, r) &= \delta_0(s + z + A_t^* y + c_t) + \varphi_t^*(r + B_t^* y - p_t), \\
g^*(v) &= \langle q_t, v\rangle - \psi_t^*(v).
\end{aligned}
$$

Therefore

$$
\begin{aligned}
-M_t(y, z) = &-\langle b_t, y\rangle \\
&+ \max_{v} \{\langle q_t, v\rangle - \psi_t^*(v) - \delta_0(C_t^* v + z + A_t^* y + c_t) - \varphi_t^*(D_t^* v + B_t^* y - p_t)\}.
\end{aligned}
$$

This is equivalent to the formula asserted in (3.9). The argument for M_e runs parallel. We have from (3.1) that

$$M_e(y_0, y_1) - \sup_{x_0, x_1} \{\langle y_0, x_0\rangle + \langle y_1, x_1\rangle - L_e(x_0, x_1)\},$$

and combining this with (3.2) we get

$$\begin{aligned} M_e(y_0, y_1) = \sup_{x_0, x_1} \{&\langle y_0, B_e u_e + b_e\rangle - \langle y_1, x_1\rangle - \langle p_e, u_e\rangle - \varphi_e(u_e) \\ &- \psi_e(q_e - C_e x_1 - D_e u_e) - \langle c_e, x_1\rangle\} \\ = \langle b_e, y_0\rangle - \inf_{x_1, u_e} &\{f_e(x_1, u_e) - g_e(E_e(x_1, u_e))\} \end{aligned}$$

where $E_e(x_1, u_e) = C_e x_1 + D_e u_e$ and

$$f_e(x_1, u_e) = \varphi_e(u_e) + \langle y_1, x_1\rangle - \langle B_e^* y_0 - p_e, u_e\rangle,$$

$$g_e(s_e) = -\psi_e(q_e - s_e).$$

Fenchel's Duality Theorem brings us to

$$-M_e(y_0, y_1) = -\langle b_e, y_0\rangle + \max_{v_e} \{g_e^*(v_e) - f^*(E_e^*(v_3))\},$$

where $E_e^*(v_e) = (C_e^* v_e, D_e^* v_e)$ and

$$f_e^*(s, r_e) = \delta_0(y_1) + \varphi_e^*(r_e + B_e^* y_0 - p_e),$$

$$g_e^*(v_e) = \langle q_e, v_e\rangle - \psi_e^*(v_e),$$

and this representation is equivalent to the one claimed for M_e in (3.9). Because of the symmetry between the formulas in (3.9) and (3.2), we can obtain the recession function expressions in (3.10) by appealing to Proposition 3.1 in dual form. □

These results prepare us for demonstrating that the Bolza problems $(\mathcal{P}_B)$ and $(\mathcal{Q}_B)$ are reduced representations of control problems quite close to, but somewhat broader than, $(\mathcal{P})$ and $(\mathcal{Q})$. The extended control problems, which we denote by $(\mathcal{P}')$ and $(\mathcal{Q}')$, are obtained simply by replacing $\mathcal{U}$ and $\mathcal{V}$ by the slightly larger control spaces:

$$\mathcal{U}' := \{u \mid u_e \in \mathbb{R}^{k_e},\ u_t \in \mathbb{R}^k \text{ measurable in } t \text{ with } t \mapsto B_t u_t \text{ summable}\},$$

$$\mathcal{V}' := \{v \mid v_e \in \mathbb{R}^{l_e},\ v_t \in \mathbb{R}^l \text{ measurable in } t \text{ with } t \mapsto C_t^* v_t \text{ summable}\}.$$

Thus the extended primal problem is

$(\mathcal{P}')$ minimize the functional

$$\begin{aligned} F(u) = &\int_{t_0}^{t_1} [\langle p_t, u_t\rangle + \varphi_t(u_t) + \psi_t(q_t - C_t x_t - D_t u_t) - \langle c_t, x_t\rangle]\, dt \\ &+ [\langle p_e, u_e\rangle + \varphi_e(u_e) + \psi_e(q_e - C_e x_{t_1} - D_e u_e) - \langle c_e, x_{t_1}\rangle] \end{aligned}$$

over $u \in \mathcal{U}'$, where x is determined from u by

$$\dot{x}_t = A_t x_t + B_t u_t + b_t \text{ a.e.}, \quad x_{t_0} = B_e u_e + b_e$$

while the extended dual problem is

Maximize the functional

$$(\mathcal{Q}') \qquad G(v) = \int_{t_0}^{t_1} [\langle q_t, v_t\rangle - \psi_t^*(v_t) - \varphi_t^*(B_t^* y_t + D_t^* v_t - p_t) - \langle b_t, y_t\rangle]\, dt$$
$$+ [\langle q_e, v_e\rangle - \psi_e^*(v_e) - \varphi_e^*(B_e^* y_{t_0} + D_e^* v_e - p_e) - \langle b_e, y_{t_0}\rangle]$$

over $v \in \mathcal{V}'$, where y is determined from v by

$$-\dot{y}_t = A_t^* y_t + C_t^* v_t + c_t \text{ a.e.}, \quad y_{t_1} = C_e^* v_e + c_e.$$

Note that each $u \in \mathcal{U}'$ does determine a unique trajectory $x \in \mathcal{A}^1$ in $(\mathcal{P}')$, and similarly each $v \in \mathcal{V}'$ determines a unique $y \in \mathcal{A}^1$ in $(\mathcal{Q}')$. We shall say in this situation that x and y are *realized* by the controls u and v. For the moment we think of the functionals F and G in the extended sense of $(\mathcal{P}')$ and $(\mathcal{Q}')$ as being defined with the appropriate conventions regarding infinite values, but it will emerge from further analysis that actually $F(u) > -\infty$ and $G(v) < \infty$.

PROPOSITION 3.4. *Assume* (A1)-(A4). *Then the primal problems* $(\mathcal{P}_B)$ *and* $(\mathcal{P}')$ *are equivalent to each other in the sense that*

$$\Phi(x) = \inf\{F(u) \mid u \in \mathcal{U}', x \text{ realized by } u\}, \text{ with attainment when } \Phi(x) < \infty.$$

Likewise, the dual problems $(\mathcal{Q}_B)$ *and* $(\mathcal{Q}')$ *are equivalent to each other in the sense that*

$$\Psi(y) = \sup\{G(v) \mid v \in \mathcal{V}', y \text{ realized by } v\}, \text{ with attainment when } \Psi(y) > -\infty.$$

Proof. In terms of the functions K_t and K_e in (3.5) define

$$\Upsilon(x, u) = \int_{t_0}^{t_1} K_t(x_t, \dot{x}_t, u_t)\, dt + K_e(x_{t_0}, x_{t_1}).$$

The representations (3.6) lead to

$$(3.12) \qquad \Phi(x) = \min\{\Upsilon(x, u) \mid u_e \in \mathbb{R}^{k_e},\ u_t \in \mathbb{R}^k \text{ measurable in } t\}.$$

This is justified by the fundamental result in [12, p. 316] on control formulations versus Bolza formulations. (The inf-boundedness condition in the hypothesis of that result is fulfilled because of the recession function property of K_t established in (3.7).) Formula (3.12) is equivalent to the assertion made in the present theorem about the primal problems. Symmetry yields the corresponding fact about the dual problems. □

4. Hamiltonian functions and duality. Further progress in applying the theory of Bolza problems to the original control problems $(\mathcal{P})$ and $(\mathcal{Q})$ will depend on a study of the *Hamiltonian* function for problems $(\mathcal{P}_B)$ and $(\mathcal{Q}_B)$, which in general is defined on $\mathbb{R}^n \times \mathbb{R}^n$ by

$$(4.1) \qquad H_t(x, y) = \sup_{w \in \mathbb{R}^n} \{\langle y, w\rangle - L_t(x, w)\}.$$

PROPOSITION 4.1. *Under assumptions* (A1)-(A4), *the Hamiltonian* $H_t(x, y)$ *is finite everywhere, concave in* $x \in \mathbb{R}^n$, *convex in* $y \in \mathbb{R}^n$, *and continuous in* (t, x, y).

Proof. The fact that $H_t(x, y)$ is concave in x and convex in y follows simply from the convexity of $L_t(x, w)$ in (x, w), as in the theory of convex problems of Bolza more generally. The defining equation (4.1) says that $H_t(x, \cdot)$ is the function conjugate to $L_t(x, \cdot)$. For each choice of t and x, $L_t(x, \cdot)$ is not only lower semicontinuous and convex but proper on $\mathbb{R}^n$. This is evident from (3.2) and the finiteness of ψ_t assumed in (A4). Moreover, the recession function of $L_t(x, \cdot)$ is (rc L_t)$(0, \cdot)$ on the general basis of (3.3), and the formula in Proposition 3.1 shows (rc L_t)$(0, \cdot)$ to be δ_0. Thus $L_t(x, \cdot)$ is coercive, so that its conjugate must be finite everywhere. In other words, $H_t(x, y)$ must be finite for all (t, x, y).

We claim next that for fixed x, $L_t(x,\cdot)$ depends epi-continuously on t. This is equivalent to the assertion that the function $(z,w)\mapsto(L_t+f)(z,w)$ depends epi-continuously on t when for fixed x we define $f(z,w)=\delta_0(z-x)$. Such epi-continuity is justified by Theorem 5 of [11], because $\operatorname{dom}L_t-\operatorname{dom}f$ is all of $\mathbb{R}^n\times\mathbb{R}^n$. The Legendre-Fenchel transform preserves epi-convergence [9], so in passing to the conjugate function $H_t(x,\cdot)$ of $L_t(x,\cdot)$ we have $H_t(x,\cdot)$ depending epi-continuously on t. Because $H_t(x,\cdot)$ is finite everywhere, its epi-continuity with respect to t is the same as the continuity of $H_t(x,y)$ in t for fixed (x,y) [5, Cors. 4, 5]. This implies the continuity of $H_t(x,y)$ in (t,x,y) by [8, Thm. 35.4], due to the concavity-convexity. □

THEOREM 4.2. *Assumptions* (A1)-(A4) *guarantee that the Bolza problems* $(\mathcal{P}_B)$ *and* $(\mathcal{Q}_B)$ *both have solutions, and the same for the extended control problems* $(\mathcal{P}')$ *and* $(\mathcal{Q}')$. *Moreover,*

$$-\infty<\inf(\mathcal{P}')=\inf(\mathcal{P}_B)=\sup(\mathcal{Q}_B)=\sup(\mathcal{Q}')<\infty.$$

Proof. Only the part concerning the Bolza problems needs to be dealt with, because the rest will then follow immediately from Proposition 3.4. We shall apply the main results of the duality theory for Bolza problems in [4, Thm. 1, Thm. 3 and its Cor. 1]. The background for this application is the finiteness of the Hamiltonian as proved in Proposition 4.1, which guarantees by the corollary on p. 17 of [4] that certain basic integrability conditions, called (C_0) and (D_0) in that paper, are fulfilled. The duality results say then that we have $\infty>\inf(\mathcal{P}_B)=\sup(\mathcal{Q}_B)>\infty$ with solutions existing for both problems, provided that the following two criteria are met in terms of arcs x and y in $\mathcal{A}^1$ (this is a slightly specialized case of the results in question):

$$\int_{t_0}^{t_1}(\operatorname{rc}L_t)(x_t,\dot{x}_t)\,dt+(\operatorname{rc}L_e)(x_{t_0},x_{t_1})\leqq 0\quad\text{only for } x=0,$$

$$\int_{t_0}^{t_1}(\operatorname{rc}M_t)(y_t,\dot{y}_t)\,dt+(\operatorname{rc}M_e)(y_{t_0},y_{t_1})\leqq 0\quad\text{only for } y=0.$$

The recession function formulas provided in Propositions 3.1 and 3.3 indicate that this is indeed true in the present circumstances, because a linear ordinary differential equation has no solution starting from the origin except the 0-solution. □

The conversion of this duality and existence theorem into one for the original control problems $(\mathcal{P})$ and $(\mathcal{Q})$ will rely on the theory of optimality conditions for convex problems of Bolza as developed in [3], [4], and [13]. In addition to a generalized Hamiltonian differential equation involving subgradients of H_t, there is a transversality condition on endpoints that usually is expressed through subgradients of L_e or M_e but will now be posed in a new form. This form involves subgradients of what we shall call the *endpoint Hamiltonian*:

$$H_e(x_1,y_0):=\sup_{x_0\in\mathbb{R}^n}\{\langle x_0,y_0\rangle-L_e(x_0,x_1)\}. \tag{4.2}$$

PROPOSITION 4.3. *Under* (A1)-(A4), *the endpoint Hamiltonian* H_e *is a finite concave-convex function on* $\mathbb{R}^n\times\mathbb{R}^n$.

Proof. Definition (4.2) expresses $H_e(x_1,\cdot)$ as the function conjugate to $L_e(\cdot,x_1)$. The latter function, as seen from its definition in (3.2), is not identically ∞ for any choice of x_1 and is therefore by Proposition 3.1 a lower semicontinuous, proper, convex function on $\mathbb{R}^n$. Moreover, its recession function is $(\operatorname{rc}L_e)(\cdot,0)$, and this is δ_0 by formula (3.4) in Proposition 3.1. Hence $L_e(\cdot,x_1)$ is coercive. Consequently, its conjugate $H_e(x_1,\cdot)$ is finite everywhere [8, § 13]. This means that $H_e(x_1,y_0)$ is finite for every

choice of (x_1, y_0) in $\mathbb{R}^n \times \mathbb{R}^n$. The concavity of $H_e(x_1, y_0)$ in y_0 is a general consequence of the joint convexity of $L_e(x_0, x_1)$ in (x_0, x_1) in (4.2), cf. [8, Thm. 33.1].

Optimality conditions for the Bolza problems will be presented now in terms of subgradients of the concave-convex functions H_t and H_e. The theory of such subgradients may be found in §§ 35-37 of [8]. □

THEOREM 4.4. *For arcs $\bar{x}$ and $\bar{y}$ to be optimal for $(\mathcal{P}_B)$ and $(\mathcal{Q}_B)$ under* (A1)-(A3), *the following pair of conditions is always sufficient, and when* (A4) *holds they are also necessary*:

$$\begin{aligned} &(-\dot{\bar{y}}_t, \dot{\bar{x}}_t) \in \partial H_t(\bar{x}_t, \bar{y}_t) \quad \text{for a.e. } t \in [t_0, t_1], \\ &(\bar{y}_{t_1}, \bar{x}_{t_0}) \in \partial H_e(\bar{x}_{t_1}, \bar{y}_{t_0}). \end{aligned} \tag{4.3}$$

Proof. If the second condition in (4.3) were replaced by the usual transversality condition $(\bar{y}_{t_0}, -\bar{y}_{t_1}) \in \partial L(\bar{x}_{t_0}, x_{t_1})$, the general result would become a special case of Theorems 5 and 6 of [3], because of the equality of optimal values in Theorem 4.2. It remains only to observe that the stated conditions in terms of H_e and L_e are equivalent to each other by a general fact of subgradient theory in the case of the relationship between H_e and L_e in (4.2), namely, Theorem 37.5 of [8]. □

COROLLARY 4.5. *Suppose* (A1)-(A4) *hold. Then for an arc $\bar{x}$ to be optimal in the Bolza problem $(\mathcal{P}_B)$ it is necessary and sufficient that there exist an arc $\bar{y}$ such that the Hamiltonian conditions in* (4.3) *are satisfied. Any such arc $\bar{y}$ then solves $(\mathcal{Q}_B)$.*

Proof. This combines Theorem 4.4 with the existence assertions in Theorem 4.2. □

Generalized Hamiltonian differential equations formulated for convex problems of Bolza as in (4.3) have been studied for their own sake in [13] and also, incidentally, play a central role for Bolza problems in the nonconvex case (cf. Clarke [14]). Next we need to determine the specific form they take relative to the given data structure.

PROPOSITION 4.6. *Under* (A1)-(A4) *one has*

$$\begin{aligned} H_t(x, y) &= \langle y, A_t x\rangle + \langle b_t, y\rangle + \langle c_t, x\rangle + J_t^*(B_t^* y, C_t x), \\ H_e(x_1, y_0) &= \langle b_e, y_0\rangle + \langle c_e, x_1\rangle + J_e^*(B_e^* y_0, C_e x_1) \end{aligned} \tag{4.4}$$

where J_t^* and J_e^* are the concave-convex functions on $\mathbb{R}^n \times \mathbb{R}^n$ conjugate to J_t and J_e in (2.2) *and given by*

$$\begin{aligned} J_t^*(r, s) &= \sup_{u \in U_t} \inf_{v \in V_t} \{\langle r, u\rangle + \langle s, v\rangle - J_t(u, v)\} \\ &= \inf_{v \in V_t} \sup_{u \in U_t} \{\langle r, u\rangle + \langle s, v\rangle - J_t(u, v)\}, \\ J_e^*(r_e, s_e) &= \sup_{u_e \in U_e} \inf_{v_e \in V_e} \{\langle r_e, u_e\rangle + \langle s_e, v_e\rangle - J_e(u_e, v_e)\} \\ &= \inf_{v_e \in V_e} \sup_{u_e \in U_e} \{\langle r_e, u_e\rangle + \langle s_e, v_e\rangle - J_e(u_e, v_e)\}. \end{aligned} \tag{4.5}$$

These functions are finite everywhere, and $J_t^*(r, s)$ depends continuously on (r, s).

Proof. The conjugacy formulas

$$\begin{aligned} \psi_t(q_t - C_t x - D_t u) &= \sup_{v \in \mathbb{R}^{l_t}} \{\langle q_t - C_t x - D_t u, v\rangle - \psi_t^*(v)\} \\ &= \sup_{v \in V_t} \{\langle q_t - C_t x - D_t u, v\rangle - \psi_t^*(v)\}, \\ \psi_e(q_e - C_e x_1 - D_e u_e) &= \sup_{v_e \in \mathbb{R}^{l_e}} \{\langle q_e - C_e x_1 - D_e u_e, v_e\rangle - \psi_e^*(v_e)\} \\ &= \sup_{v_e \in V_e} \{\langle q_e - C_e x_1 - D_e u_e, v_e\rangle - \psi_e^*(v_e)\}, \end{aligned}$$

allow us to rewrite the defining formulas (3.2) for L_t and L_e in the notation (2.2) as

$$L_t(x, w) = \inf_{\substack{u \in U_t \\ A_t x + B_t u + b_t = w}} \sup_{v \in V_t} \{J_t(u, v) - \langle c_t, x\rangle - \langle C_t x, v\rangle\},$$

$$L_e(x_0, x_1) = \inf_{\substack{u \in U_e \\ B_e u + b_e = x_0}} \sup_{v_e \in V_e} \{J_e(u_e, v_e) - \langle c_e, x_1\rangle - \langle C_e x_1, v_e\rangle\}.$$

These expressions can be substituted into the definitions (4.1) of H_t and (4.2) of H_e to obtain

$$\begin{aligned} H_t(x, y) &= \sup_{u \in U_t} \{\langle y, A_t x + B_t u + b_t\rangle - \sup_{v \in V_t} \{J_t(u, v) - \langle c_t, x\rangle - \langle C_t x, v\rangle\}\} \\ &= \langle y, A_t x\rangle + \langle b_t, y\rangle + \langle c_t, x\rangle + \sup_{u \in U_t} \inf_{v \in V_t} \{\langle C_t x, v\rangle + \langle B_t^* y_t, u\rangle - J_t(u, v)\}, \\ H_e(x_1, y_0) &= \sup_{u_e \in U_e} \{\langle y_0, B_e u_e + b_e\rangle - \sup_{v_e \in V_e} \{J_e(u_e, v_e) - \langle c_e, x_1\rangle - \langle C_e x_1, v_e\rangle\}\} \\ &= \langle b_e, y_0\rangle + \langle c_t, x_1\rangle + \sup_{u \in U_e} \inf_{v \in V_e} \{\langle C_t x_1, v_e\rangle + \langle B_e^* y_0, u_e\rangle - J_e(u_e, v_e)\}. \end{aligned}$$

In the final versions of these formulas, inf and sup can be interchanged because of the coercivity of the functions φ_t, φ_e, ψ_t^*, ψ_t^*, in the definitions (2.2) of J_t and J_e and the structure (2.4). This is justified as a minimax theorem by Theorem 37.3 of [8], a result that establishes at the same time the finiteness of the expressions (4.5).

Our last task in the proof is to demonstrate that $J_t^*(r, s)$ depends continuously on (t, r, s). This could be carried out in detail with arguments like those that established the continuity of $H_t(x, y)$ in (t, x, y) in Proposition 4.1. There is a shortcut, however. The argument for H_t made no use of any particular properties of the vectors and matrices in (A3) other than their continuous dependence on t. The continuity property would therefore be present in particular if B_t and C_t were identity matrices, in which case the continuity property of H_t reduces to that of J_t. Thus $J_t(r, s)$ must be continuous with respect to (t, r, s) as claimed.

The next theorem establishes the equivalence between the Hamiltonian and minimax approaches to optimality.

THEOREM 4.7. *Under assumptions* (A1)-(A4), *the Hamiltonian optimality conditions in* (4.3) *are satisfied by a pair of arcs* $\bar{x}$ *and* $\bar{y}$ *in* $\mathscr{A}^1$ *if and only if* $\bar{x}$ *and* $\bar{y}$ *are trajectories in* $\mathscr{A}^\infty$ *realized by controls* $\bar{u} \in \mathscr{U}$ *and* $\bar{v} \in \mathscr{V}$ *that satisfy the minimaximum principle* (2.5).

Proof. This result will be developed from the following formulas for the subgradients of H_t and H_e, which are based on the representations of these functions in Proposition 4.6. Here ∂_1 and ∂_2 designate subgradients with respect to the first and second arguments of a bivariate function. We have

$$\begin{aligned} \partial_1 H_t(x, y) &= A_t^* y + c_t + C_t^* \partial_2 J_t^*(B_t^* y, C_t x), \\ \partial_2 H_t(x, y) &= A_t x + b_t + B_t \partial_1 J_t^*(B_t^* y, C_t x), \\ \partial_1 H_e(x_1, y_0) &= c_e + C_e^* \partial_2 J_e^*(B_e^* y_0, C_e x_1), \\ \partial_2 H_e(x_1, y_0) &= b_e + B_e \partial_1 J_e^*(B_e^* y_0, C_e x_1). \end{aligned}$$

These formulas are obtained by the calculus in Theorems 23.8 and 23.9 of [8] and are justified by the finiteness of the concave-convex functions J_t and J_e that was proved in Proposition 4.6. We combine these formulas with the fact that

$$\partial H_t(x, y) = \partial_1 H_t(x, y) \times \partial_2 H_t(x, y) \quad \text{and} \quad \partial H_e(x_1, y_0) = \partial_1 H_e(x_1, y_0) \times \partial_2 H_e(x_0, y_0)$$

(cf. [8, § 35]) and similarly for J_t^* and J_e^* to see that

$$\begin{aligned}\partial H_t(x, y) &= \{(A_t^* y + C_t^* v + c_t, A_t x + B_t u + b_t) | (u, v) \in \partial J_t^*(B_t^* y, C_t x)\},\\ \partial H_e(x_1, y_0) &= \{(C_e^* v_e + c_t, B_e u_e + b_e) | (u_e, v_e) \in \partial J_e^*(B_e^* y_0, C_e x_1)\}.\end{aligned} \tag{4.6}$$

A further observation is that the subdifferentials of J_t^* and J_e^* give sets of saddle points:

$$\begin{aligned}\partial J_t^*(B_t^* y, C_t x) &= \operatorname*{argminimax}_{u \in U_t, v \in V_t} \{J_t(u, v) - \langle B_t^* y, u\rangle - \langle C_t x, v\rangle\},\\ \partial J_e^*(B_e^* y_0, C_e x_1) &= \operatorname*{argminimax}_{u_e \in U_e, v_e \in V_e} \{J_e(u_e, v_e) - \langle B_e^* y_0, u_e\rangle - \langle C_e x_1, v_e\rangle\},\end{aligned} \tag{4.7}$$

which is true by conjugacy [8, Thms. 36.6, 37.5]. As far as endpoints are concerned, we have from (4.6) and (4.7) that

$$\begin{aligned}&(\bar y_{t_1}, \bar x_{t_0}) \in \partial H_e(\bar x_{t_1}, \bar y_{t_0}) \Leftrightarrow\\ &\quad \exists (\bar u_e, \bar v_e) \in \operatorname*{argminimax}_{u_e \in U_e, v_e \in V_e} \{J_e(u_e, v_e) - \langle B_e^* y_0, u_e\rangle - \langle C_e x_1, v_e\rangle\}\\ &\qquad\qquad \text{with } \bar x_{t_0} = B_e \bar u_e + b_e, \quad \bar y_{t_1} = C_e^* \bar v_e + c_e.\end{aligned} \tag{4.8}$$

Similarly, for any t it is true that

$$\begin{aligned}&(-\dot{\bar y}_t, \dot{\bar x}_t) \in \partial H_t(\bar x_t, \bar y_t) \Leftrightarrow \exists (\bar u_t, \bar v_t) \in \operatorname*{argminimax}_{u \in U_t, v \in V_t} \{J_t(u, v) - \langle B_t^* y, u\rangle - \langle C_t x, v\rangle\}\\ &\qquad\qquad \text{with } \dot{\bar x}_t = A_t \bar x_t + B_t \bar u_t + b_t, \; -\dot{\bar y}_t = A_t^* \bar y_t + C_t^* \bar v_t + c_t.\end{aligned} \tag{4.9}$$

If the minimaximum principle (2.6) holds for some choice of $\bar u \in \mathcal{U}$ and $\bar v \in \mathcal{V}$, and $\bar x$ and $\bar y$ are the corresponding state trajectories in the control problems $(\mathcal{P})$ and $(\mathcal{Q})$, we do have (4.7) and (4.8), the latter for almost every t. Then, according to the formulas we have arrived at, $\bar x$ and $\bar y$ satisfy the Hamiltonian conditions (4.3) and belong to $\mathcal{A}^\infty$ instead of just $\mathcal{A}^1$.

Conversely, suppose $\bar x$ and $\bar y$ are elements of $\mathcal{A}^1$ for which the Hamiltonian conditions (2.6) hold. Certainly then there is a choice of $\bar u_e$ and $\bar v_e$ for which (4.8) holds. We know further that for almost every t we can find $\bar u_t$ and $\bar v_t$ satisfying (4.9). It must be shown that these vectors can be chosen in such a way that the functions $t \mapsto u_t$ and $t \mapsto v_t$ are *measurable and essentially bounded.* Inasmuch as J_t^* is finite everywhere, the subgradient set $\partial J_t^*(r, s)$ is always nonempty and compact (by [8, Thm. 23.4] as applied to the separate arguments). The continuity of $J_t^*(r, s)$ in t implies further that the multifunction $(t, r, s) \mapsto \partial J_t^*(r, s)$ is locally bounded and of closed graph [8, Thm. 24.5]. Therefore the multifunction $t \mapsto \partial J_t^*(\bar x_t, \bar y_t)$ is locally bounded and of closed graph, as well as nonempty-valued. A measurable selection then exists (cf. [7, Cor. 1C]) and must be essentially bounded. This selection is in the form of a function $t \mapsto (\bar u_t, \bar v_t)$ with exactly the properties we need.

We have arrived at the main duality theorem in this paper.

THEOREM 4.8. *Assumptions* (A1)-(A4) *guarantee that the primal and dual control problems* $(\mathcal{P})$ *and* $(\mathcal{Q})$ *are both solvable and satisfy*

$$-\infty < \inf(\mathcal{P}) = \inf(\mathcal{P}_B) = \sup(\mathcal{Q}_B) = \sup(\mathcal{Q}) < \infty.$$

An arc $\bar x$ *solves* $(\mathcal{P}_B)$ *if and only if it is realized by a control* $\bar u$ *that is optimal in* $(\mathcal{P})$, *and an arc* $\bar y$ *solves* $(\mathcal{Q}_B)$ *if and only if it is realized by a control* $\bar v$ *that is optimal in* $(\mathcal{P})$.

Proof. Mostly this is a corollary of Theorems 4.2, 4.4, and 4.7, combined. In general we would of course have $\inf(\mathcal{P}) \geqq \inf(\mathcal{P}')$ and $\sup(\mathcal{Q}) \leqq \inf(\mathcal{Q}')$. To obtain the full result, we need only show that when $\bar u \in \mathcal{U}$ and $\bar v \in \mathcal{V}$ satisfy the minimaximum

principle, then $F(\bar{u}) = G(\bar{v})$. The minimaximum principle implies by Proposition 2.3 that

$$\langle p_t - B_t^* \bar{y}_t, \bar{u}_t \rangle + \varphi_t(\bar{u}_t) + \psi_t(q_t - C_t \bar{x}_t - D_t \bar{u}_t)$$
$$= \langle q_t - C_t \bar{x}_t, \bar{v}_t \rangle - \psi_t^*(\bar{u}_t) - \varphi_t^*(B_t^* \bar{y}_t + D_t^* \bar{v}_t - p_t)$$

for almost every t and

$$\langle p_e - B_e^* \bar{y}_{t_0}, \bar{u}_e \rangle + \varphi_e(\bar{u}_e) + \psi_e(q_e - C_e \bar{x}_{t_1} - D_e \bar{u}_e)$$
$$= \langle q_e - C_e \bar{x}_{t_1}, \bar{v}_e \rangle - \psi_e^*(\bar{u}_e) - \varphi_e^*(B_e^* \bar{y}_{t_0} + D_e^* \bar{v}_e - p_e).$$

Integrating the first equation with respect to $t \in [t_0, t_1]$ and adding it to the second equation, we obtain

$$F(\bar{u}) - \int_{t_0}^{t_1} \langle B_t^* \bar{y}_t, \bar{u}_t \rangle \, dt + \int_{t_0}^{t_1} \langle c_t, \bar{x}_t \rangle \, dt - \langle B_e^* \bar{y}_{t_0}, \bar{u}_e \rangle + \langle c_e, \bar{x}_{t_1} \rangle$$
$$= G(\bar{v}) - \int_{t_0}^{t_1} \langle C_t \bar{x}_t, \bar{v}_t \rangle \, dt + \int_{t_0}^{t_1} \langle b_t, \bar{y}_t \rangle \, dt - \langle C_e \bar{x}_{t_1}, \bar{v}_e \rangle + \langle b_e, \bar{y}_{t_0} \rangle.$$

This reduces to $F(\bar{u}) = G(\bar{v})$ because of the identity in (2.3).

The methods used to obtain this result have relied heavily on assumption (A4), which as we have seen corresponds to the absence of any exactly modeled constraints on the primal or dual states. A more general theory in which state constraints are present might well be possible, but results for convex problems of Bolza in that case in [15]-[17], indicate it would require consideration of impulse controls and trajectories with jumps.

OPTIMIZATION OF GLOBALLY CONVEX FUNCTIONS*

T. C. HU†, VICTOR KLEE‡, AND DAVID LARMAN§

This paper is dedicated to the memory of E. J. McShane.

Abstract. Convex functions have nice properties with respect to both minimization and maximization. Similar properties are established here for functions that are permitted to have bad local behavior but are globally convex in the sense that they behave "convexly" on triples of collinear points that are widely dispersed. The results illustrate a development that seems desirable in the interest of more realistic mathematical modeling: the "globalization" of important function properties. In connection with the maximization of globally convex functions over convex bodies in a given finite-dimensional normed space E, there is interest in estimating the maximum, for points c of bodies $C \subset E$, of the ratio between two measures of how close c comes to being an extreme point of C. Good estimates are obtained for the cases in which E is Euclidean or has the "max" norm.

Key words. convex, quasiconvex, maximum, minimum, optimization, extreme points, norm

Introduction. In the mathematical modeling of practical optimization problems, the following assumptions are often made:

(a) The feasible region C is a convex subset of a Minkowski space E (a normed finite-dimensional real vector space);

(b) The objective function φ is convex, that is, φ is a real-valued function on C such that

$$\varphi(y) \leqq \lambda\varphi(x) + (1-\lambda)\varphi(z) \tag{1}$$

for all

$$x, z \in C \quad \text{with } x \neq z, \quad 0 < \lambda < 1, \quad y = \lambda x + (1-\lambda)z. \tag{2}$$

Because of the following well-known facts, convexity is useful in connection with both minimization and maximization:

(P1) Each local minimum of a convex function is a global minimum.

(P2) If a convex function attains a maximum, then (under mild restrictions on the domain) it does so at an extreme point of its domain.

Each of the properties (P1) and (P2) serves to narrow the search for the extreme values of a convex function, and each is the basis of algorithms for finding or approximating these values and the points of the domain C where they are attained. (There are many references for convex minimization. See [13] for a survey of approaches to convex maximization.) However, in a number of situations it seems that (a) is fully justified while (b) is dictated as much by mathematical convenience as by realism. Even when the real objective function appears to be convex when viewed globally, it is likely to exhibit small "blips" in local behavior that cause it to deviate from the

mathematical ideal expressed in (b). Similar statements apply to other important function properties, such as linearity and monotoneity. The main purpose of the present paper is to suggest the desirability of "globalizing" various function properties that are important in optimization—that is, of formulating definitions that permit bad local behavior while preserving the function property in some global sense—and of studying the consequences of these definitions. The resulting mathematical framework may turn out to be especially appropriate for some of the many practical optimization problems in which rapid solution is more important than precise solution, so that the practical needs can be met by any algorithm that is sufficiently fast and comes sufficiently close to finding the optimum. (This is the consideration, for example, that has led to the popularity of simulated annealing as an algorithmic tool for solving problems in VLSI design and other areas [9], [16].)

It is not clear which generalizations of the notion of convex function will prove to be most useful in modeling. That can be determined only by extensive computational practice in conjunction with development of the underlying theory. However, in the previous generalizations with which we are familiar [14], [4], [3], [1], [15], local behavior is restricted in ways that exclude the sort of blips that we want to permit. To illustrate the sort of mathematical developments that we have in mind, we here formulate some notions of global convexity or global quasiconvexity that depend on a nonnegative parameter δ. They reduce to the usual notions when $\delta = 0$, but for $\delta > 0$ they do permit wild local behavior and they lead to "δ-versions" of (P1) and (P2).

Our main δ-versions of (P1) are Theorems 2.1 and 2.2, which are straightforward and easy to prove. However, the search for quantitative precision in the case of (P2) leads to some difficult problems concerning the relationship between two measures of how close a nonextreme point c of a body C comes to being extreme. (The term *body* is used to mean a finite-dimensional line-free closed convex set, so the existence of extreme points is guaranteed.) The obvious measure is $\xi(C, c)$, the minimum distance of c from C's set of extreme points, and we want to find a φ-maximizing point c for which this distance is not too large. The search for such a point turns out to involve $\mu(C, c)$, half the length of a longest segment in C that has c as its midpoint. Our main δ-version of (P2) is Theorem 4.3, which implies that if the objective function φ is δ-convex or δ-quasiconvex in an appropriate sense, and if φ attains a maximum on C, then φ attains a maximum at a point $q \in C$ such that $\xi(C, q) \leqq \delta\rho(C)$, where

$$\rho(C) = \sup\{\xi(C, c)/\mu(C, c)\text{: nonextreme } c \in C\}.$$

By way of illustration, suppose that X is a Euclidean disk of unit radius centered at a point p. When an interior point x of X is at distance r from p, it is true that $\xi(X, x) = 1 - r$, $\mu(X, x) = (1 - r^2)^{1/2}$, and $\rho(X, x) = ((1 - r)/(1 + r))^{1/2}$; hence $\rho(X) = \rho(X, p) = 1$. If Y is an equilateral triangle inscribed in X, then $\rho(Y) = \rho(Y, p) = \sqrt{3}$. However, the supremum $\rho(C)$ appears to be difficult to compute for most choices of C and of the underlying Minkowski space E, and because of ρ's role in the extension of (P2) this leads to interest in estimating the quantity

$$\rho(E) = \sup\{\rho(C)\text{: body } C \subset E\}$$

for various choices of E. It is proved here that $\rho(E) \leqq d$ for all d-dimensional E (this bound is attained), while $d - 1 \leqq \rho(E) \leqq d$ when E has the "max" norm and

$$\sqrt{d} \leqq \rho(E) \leqq \frac{d}{d-1}\sqrt{5d}$$

when E is Euclidean. Also,

$$\rho(\text{Euclidean plane}) = \sqrt{3}.$$

Our section headings are as follows: §1. Some global versions of convexity; §2. Minima; §3. Qualitative properties of $\rho(C, c)$; §4. Maxima; §5. Estimation of $\rho(E)$.

1. Some global versions of convexity. With respect to optimization, some important properties of convex functions extend to quasiconvex functions. A function φ is *quasiconvex* if its domain is a convex set and

$$\varphi(y) \leqq \max\{\varphi(x), \varphi(z)\} \tag{3}$$

whenever (2) holds. We "globalize" the notions of convexity and quasiconvexity by saying (for $\delta \geqq 0$) that a function φ is *δ-convex* (respectively, *δ-quasiconvex*) if it is real-valued, its domain is a convex set C in a normed (real) vector space, and the inequality (1) (respectively, (3)) holds for all x, y, z, and λ that satisfy both (2) and

$$\|x-y\| \geqq \delta/2 \quad \text{and} \quad \|z-y\| \geqq \delta/2. \tag{4}$$

In other words, the function φ behaves "convexly" or "quasiconvexly" on collinear triples that are sufficiently dispersed. Note that the 0-convex functions are precisely those that are convex in the usual sense; similarly for the 0-quasiconvex functions. However, as is suggested by Fig. 1, small blips are permitted in the function's local behavior when $\delta > 0$.

A function φ is *strictly δ-convex* (respectively, *strictly δ-quasiconvex*) if it is real-valued, its domain is convex, and strict inequality holds in (1) (respectively, (3)) for all x, y, z, and λ that satisfy both (2) and (4). Actually, it suffices for present

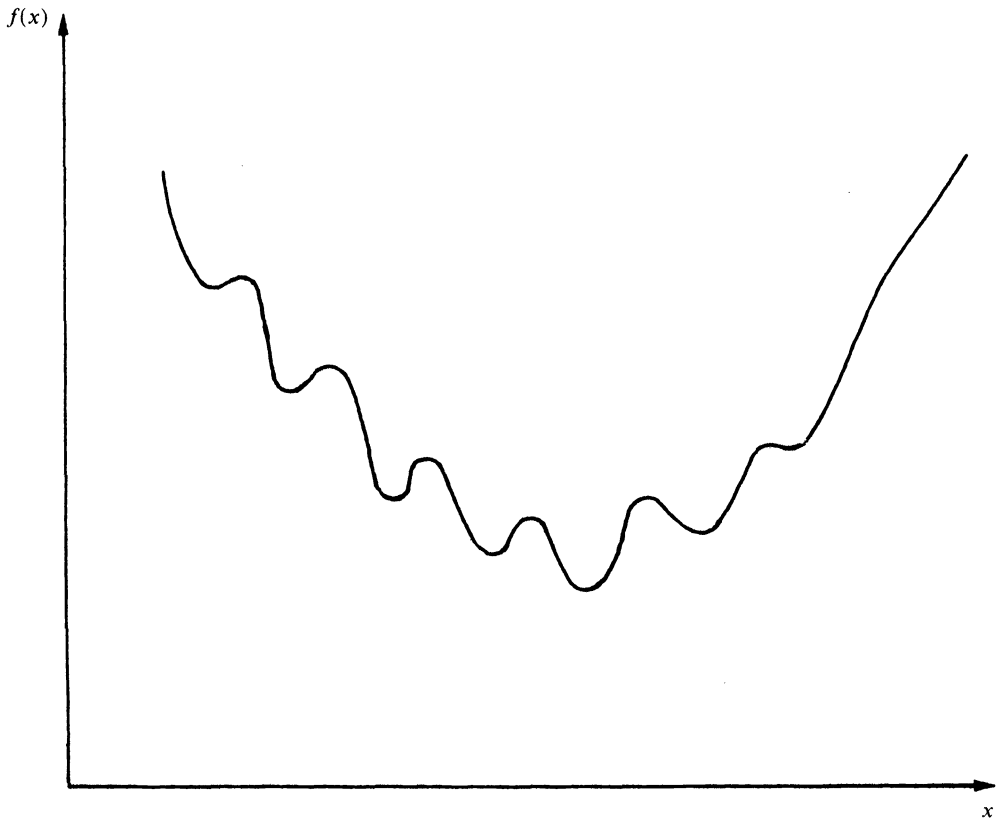

FIG. 1

purposes to require that (1) or (3) holds for all x, y, and z that satisfy (2) and (4) with $\lambda = \frac{1}{2}$. This amounts to requiring that

$$\varphi(\tfrac{1}{2}x + \tfrac{1}{2}z) \leqq \tfrac{1}{2}\varphi(x) + \tfrac{1}{2}\varphi(z) \tag{5}$$

or

$$\varphi(\tfrac{1}{2}x + \tfrac{1}{2}z) \leqq \max\{\varphi(x), \varphi(z)\} \tag{6}$$

whenever $\|x - z\| \leqq \delta$. These weak notions are called *midpoint δ-convexity and midpoint δ-quasiconvexity*, respectively, and the related strict notions are defined in the obvious way.

The following remark provides some insight into the notions just defined.

THEOREM 1.1. *For a convex subset C of a normed linear space, and for $\delta > 0$, let C^δ (respectively, C_δ) denote the set of all points $c \in C$ such that c is not the midpoint (respectively, not an endpoint) of any line segment of length δ in C. Suppose that ψ and ω are real-valued functions on C such that*

$$\psi(c) \geqq 0 \quad \text{for all } c \in C^\delta, \qquad \psi(c) = 0 \quad \text{for all } c \notin C^\delta,$$

$$\omega(c) \geqq 0 \quad \text{for all } c \in C_\delta, \qquad \omega(c) = 0 \quad \text{for all } c \notin C_\delta.$$

Then whenever a function φ on C has any of the δ-convexity properties defined above, the function $\varphi + \psi - \omega$ has the same property.

Proof. If $c \in C^\delta$, then (because of (4)) c cannot appear as the y in any of the defining inequalities (1) or (3). When c appears as the x or z in any of these inequalities, increasing the value of $\varphi(c)$ (by adding $\psi(c)$ when $\psi(c) > 0$) merely serves to strengthen the inequality. Similarly, if $c \in C_\delta$ then c cannot appear as x or z, and when c appears as y, reducing the value of $\varphi(c)$ (by subtracting $\omega(c)$ when $\omega(c) > 0$) strengthens the inequality. □

When the domain C is of diameter less than δ, every real-valued function on C is strictly δ-convex because no triple (x, y, z) of points of C satisfies condition (4). Thus it is clear that for the δ-convexity of an objective function to be useful in practice, the value of δ must be appropriately related to the geometry of the domain C. Even when the domain is in all senses large with respect to δ, the above δ-notions permit much wilder behavior (at least near extreme points of the domain) than will be encountered in practice. Nevertheless, we are able to establish sharp δ-versions of (P1) and (P2) for functions that are midpoint δ-convex or midpoint δ-quasiconvex. It does not seem that sharper conclusions could be obtained by adding local smoothing conditions such as continuity, and in any case we would not want to assume continuity because it is lacking in some important applications such as the fixed-charge problem of Hirsch and Dantzig [7].

If we wanted to augment the δ-requirement by a weak global smoothing condition to limit the wildest behavior of the function φ to the extreme points of its domain, the following assumption might be appropriate, where $]x, z[$ (respectively, $[x, z]$) denotes the open (respectively, closed) line segment whose ends are x and z.

(7) For each triple of distinct points x, y, and z of C such that $y \in]x, z[$, the segment $[x, z]$ is contained in a segment $[x', z']$ in C for which $\varphi(y) \leqq \max\{\varphi(x'), \varphi(z')\}$.

We shall see that the property (P2) follows from (7) alone, without the intervention of any δ-requirement. However, (7) has no effect on (P1).

Note that if φ (with convex domain C) satisfies condition (7), then without destroying this property the function φ may be redefined at all extreme points of C by assigning arbitrary new values that are not less than the original values. However, we do not want to rule out this aspect, because the same is true of the usual notion of convexity.

If a function φ has any of the convexity or quasiconvexity properties defined above, the same is true of each positive multiple of φ. The convexity properties are also preserved under addition of functions, but that is not true of the quasiconvexity properties or of (7). For example, let φ and ζ both have $[0, 1]$ as domain, with

$$\varphi(x) = \zeta(x) = 0 \quad \text{for } 0 < x < 1,$$
$$\varphi(0) = \zeta(1) = 1, \qquad \varphi(1) = \varphi(0) = -2.$$

Then φ and ζ are both quasiconvex and hence also satisfy condition (7). However, the function $\varphi + \zeta$ does not satisfy (7) and it is δ-quasiconvex only for $\delta < \frac{1}{2}$. This example is easily modified to produce one in which the functions are continuous.

The next two theorems deal with an example that was chosen to illustrate the extent to which midpoint δ-convexity and midpoint δ-quasiconvexity are weaker than the usual notions or convexity and quasiconvexity.

THEOREM 1.2. *Suppose that η is a positive constant, and let*

$$\varphi(t) = \eta t^2 + \cos t \quad \textit{for all } t \in \mathbb{R}.$$

Then the following three conditions are equivalent: φ is convex; φ is quasiconvex; $\eta \geqq \frac{1}{2}$.

Proof. For equivalence of the first and third condition, observe that $\varphi''(t) = 2\eta - \cos t$, whence the second derivative φ'' is everywhere nonnegative if and only if $\eta \geqq \frac{1}{2}$. To complete the proof, note that the following is a corollary of the next result: if φ is midpoint quasiconvex, then $\eta \geqq \frac{1}{2}$. □

To simplify the notation in the next statement and proof, we define

$$\psi(\delta) = \frac{1}{2}\frac{\sin^2 \delta}{\delta^2} \quad \text{for } 0 < \delta < 2\pi,$$

whence of course $\psi(\delta) \to \frac{1}{2}$ as $\delta \to 0$. It follows from l'Hôpital's rule that as $\delta \to 0$,

$$\frac{\psi(\delta)}{\frac{1}{2} - \frac{1}{6}\delta^2} \to 1$$

and hence

$$\psi(\tfrac{1}{2}\delta) \sim \tfrac{1}{2} - \tfrac{1}{24}\delta^2 \quad \text{and} \quad \psi(\tfrac{1}{4}\delta) \sim \tfrac{1}{2} - \tfrac{1}{96}\delta^2.$$

THEOREM 1.3. *Suppose that η is a positive constant, and let*

$$\varphi(t) = \eta t^2 + \cos t \quad \textit{for all } t \in \mathbb{R}.$$

Suppose that $0 < \delta < 2\pi$. Then

(i) *φ is midpoint δ-convex if and only if $\eta \geqq \psi(\frac{1}{4}\delta)$;*

(ii) *φ is midpoint δ-quasiconvex if and only if $\eta \geqq \psi(\frac{1}{2}\delta)$.*

Proof. Let us first consider (i). The function φ is midpoint δ-convex if and only if (5) holds whenever $x + \delta \leqq z$. Writing $h = z - x \geqq 0$ and setting

$$g(x, h) = 2\cos(x + \tfrac{1}{2}h) - \cos x - \cos(x + h),$$

we see that the desired condition is

$$g(x, h) \leqq \frac{\eta}{2} h^2 \quad \text{for } h \geqq \delta. \tag{8}$$

To obtain a more useful expression for $g(x, h)$, apply the trigonometric addition formulas to see that

$$g(x, h) = \cos x[2(\cos \tfrac{1}{2}h - 1) + 1 - \cos h] + \sin x(\sin h - 2 \sin \tfrac{1}{2}h),$$

then apply the half-angle formulas and regroup to obtain

$$g(x, h) = 4(\sin \tfrac{1}{4}h)^2 \cos (x + \tfrac{1}{2}h).$$

Thus in terms of the function ψ defined earlier, the desired condition (8) becomes

$$\psi(\tfrac{1}{4}\delta) \cos (x + \tfrac{1}{2}h) \leqq \eta \quad \text{for } h \geqq \delta. \tag{9}$$

Now recall that in the range $0 < \theta \leqq \pi/2$, $\sin \theta / \theta$ is a decreasing function of θ and hence

$$\frac{2}{\pi} \leqq \frac{\sin \theta}{\theta} \leqq 1.$$

Since

$$\frac{\sin \frac{1}{4}h}{\frac{1}{4}h} \leqq \frac{2}{\pi} \quad \text{when } h \geqq 2\pi,$$

it follows that the maximum value of $\psi(\frac{1}{4}h)$ for $|h| \geqq \delta$ is attained when $h = \delta$. Hence the condition

$$\eta \geqq \psi(\tfrac{1}{4}\delta) \tag{10}$$

is sufficient for (9). On the other hand, for each given h there exists an x for which $\cos (x + \frac{1}{2}h) = 1$, and hence the condition (10) is necessary as well as sufficient for the desired midpoint δ-convexity.

We turn now to (ii). The function φ is midpoint δ-quasiconvex if and only if

$$\varphi(x) \leqq \max \{\varphi(x - h), \varphi(x + h)\} \quad \text{for all } h \geqq \delta$$

(and we are concerned here only with $0 \leqq \delta \leqq \pi$). Thus the desired condition is that, with + or −, it should be true that

$$\eta x^2 + \cos x \leqq \eta(x \pm h)^2 + \cos (x \pm h),$$

or, equivalently,

$$\pm 2 \sin \frac{h}{2} \sin \left(x \pm \frac{h}{2}\right) \leqq \pm \eta h(2x \pm h). \tag{11±}$$

Now let us suppose (without loss of generality) that $x \geqq 0$ and $h \geqq 0$, and consider the inequalities

$$\frac{1}{2} \frac{\sin (h/2)}{h/2} \frac{\sin ((h/2) \pm x)}{(h/2) \pm x} \leqq \eta. \tag{12±}$$

Elementary manipulation shows that (11+) is equivalent to (12+), while (11−) is equivalent to (12−) when $2x - h < 0$ and to

$$\frac{1}{2} \frac{\sin (h/2)}{h/2} \frac{\sin ((h/2) \pm x)}{(h/2) \pm x} \geqq \eta \tag{13}$$

when $2x - h > 0$.

To deal with the case in which $x < h/2$, note that $(\sin\theta)/\theta$ is a concave function on $[-\pi, \pi]$, whence

$$\frac{\sin((h/2)-x)}{(h/2)-x}+\frac{\sin((h/2)+x)}{(h/2)+x}\leqq 2\sin\frac{h}{2},$$

and thus at least one of the summands is at most

$$\frac{\sin(h/2)}{h/2}.$$

Hence requiring that

$$\eta\geqq\frac{1}{2}\frac{\sin(\delta/2)}{\delta/2}$$

will guarantee that

$$\eta\geqq\frac{1}{2}\max_{h\geqq\delta}\left(\frac{\sin(h/2)}{h/2}\right)^2$$

and thus assure that (12±) holds. Furthermore, by taking $x=0$ and $h=\delta$ we see that this is the best possible lower bound for η when $x<h/2$.

Only the case in which $x>h/2$ remains. For this case, (12−) or (13) must be established, and we show in fact that (12−) holds. Indeed, if the number y is defined by the condition that

$$x+\frac{h}{2}=y+\frac{\delta}{2},$$

then (12−) becomes

$$\frac{\sin(y+\delta/2)}{y+\delta/2}\leqq\frac{\sin(\delta/2)}{\delta/2},$$

and this holds for all $y\geqq 0$. □

2. Minima. When $\delta>0$ and φ is a function with domain C, we say that φ attains a *δ-local minimum* (respectively, *strict δ-local minimum*) at a point $q\in C$ if $\varphi(q)\leqq\varphi(c)$ (respectively, $\varphi(q)<\varphi(c)$) for all points $c\in C\backslash\{q\}$ at distance less than δ from the point q.

THEOREM 2.1. *If $\delta>0$ and φ is a midpoint δ-convex or strictly midpoint δ-quasiconvex function that attains a δ-local minimum at a point q of its domain, then the global minimum of φ is attained at q.*

THEOREM 2.2. *If $\delta>0$ and φ is a midpoint δ-quasiconvex function that attains a δ-local strict minimum at a point q of its domain, then the strict global minimum of φ is attained at q.*

Proofs. As stated, the above theorems fail when $\delta=0$ and thus they do not cover the classical cases of convex and quasiconvex functions. To cover these cases as well, simply replace the δ-local minima by ε-local minima for some positive $\varepsilon\geqq\delta$. The proofs below are phrased in terms of this ε.

If the conclusion of Theorem 2.1 (respectively, 2.2) fails, there is a point $z_1\in C\backslash\{q\}$ such that $\varphi(z_1)<\varphi(q)$ (respectively, $\leqq\varphi(q)$). Of course, $\|z_1-q\|\geqq\varepsilon$, and hence with $z_2=\frac{1}{2}(z_1+q)$ it is true that $\|z_1-z_2\|\geqq\varepsilon/2$ and $\|q-z_2\|\geqq\varepsilon/2$. For Theorem 2.1, it follows from the midpoint δ-convexity of φ that

$$\varphi(z_2)\leqq\frac{\delta}{2}\varphi(z_1)+\frac{\delta}{2}\varphi(q)<\varphi(q),$$

or from the strict midpoint δ-quasiconvexity of φ that

$$\varphi(z_2) < \max\{\varphi(z_1), \varphi(q)\} \leqq \varphi(q).$$

For Theorem 2.2 it follows from the midpoint δ-quasiconvexity of φ that

$$\varphi(z_2) \leqq \max\{\varphi(z_1), \varphi(q)\} \leqq \varphi(q).$$

But then $\|z_2 - q\| \geqq \varepsilon$, so with $z_3 = \frac{1}{2}(z_2 + q)$ we have $\varphi(z_3) < \varphi(q)$ in Theorem 2.1 and $\varphi(z_3) \leqq \varphi(q)$ in Theorem 2.2. Continuing in this manner, we form a sequence $z_1, z_2, \cdots$ in $C\backslash\{q\}$ such that always $\varphi(z_i) < \varphi(q)$ (respectively, $\leqq \varphi(q)$). Since the sequence converges to q, we have reached a contradiction that completes the proof. □

Theorems 2.1 and 2.2 are sharp in the following two senses:

(a) In Theorem 2.1, the conditions on φ cannot be replaced by δ-quasiconvexity.

(b) In Theorems 2.1 and 2.2, the conclusions may fail if φ is δ-convex but the δ-local conditions are replaced by δ'-local conditions with $\delta' < \delta$.

To obtain examples in support of (a) and (b), suppose that $\alpha < \beta < \gamma$. For (a), let φ be constant with value σ on the closed interval $[\alpha, \beta]$ and constant with value $\eta > \sigma$ on the half-open interval $]\beta, \gamma]$. Then φ is quasiconvex and each point of its domain $[\alpha, \gamma]$ provides a local minimum for φ. However, the points of $]\beta, \gamma]$ actually provide global maxima rather than global minima. For (b), note that if $\gamma - \alpha < \delta$ then every real-valued function on $[\alpha, \gamma]$ is (trivially) δ-convex. If, in addition, $\gamma - \beta = \delta' < \delta$, there are many functions on $[\alpha, \gamma]$ for which γ provides a δ'-local strict minimum but either there is no global minimum or the global minimum is attained only in $[\alpha, \beta]$.

For another example in support of (b), let $C = [-1, 2[$ and let the function φ on C be such that

$$\varphi(-1) = 1, \quad \varphi(t) = 0 \quad \text{for } -1 < t < 1, \quad \varphi(t) \geqq t \quad \text{for } 1 \leqq t < 2.$$

Then φ is strictly 2-convex, and for $0 < \delta' < 2$ it has a δ'-local minimum at the point $\delta' - 1$ but does not have a global minimum there. If φ is modified to give it the value $-\frac{1}{2}$ at the point $\delta' - 1$, then φ is still strictly 2-convex and now has a δ'-local strict minimum at $\delta' - 1$.

3. Qualitative properties of $\rho(C, c)$. For the results of § 2, the convex domain C need not be closed and it may lie in an arbitrary normed linear space. However, from now on its convenient to work with the following.

STANDING HYPOTHESES. *E is a finite-dimensional normed vector space and C is a body in E, meaning that C is closed, convex, has nonempty interior, and does not contain any line. The sets of extreme and nonextreme points of C are denoted, respectively, by C_e and C_m.*

It is known that C_e is nonempty, and in fact C is the convex hull of the union of its extreme points and extreme rays [10]. For each $c \in C$, let

$$\xi(C, c) = \inf\{\|c - p\| : p \in C_e\},$$

the distance from the point c to the set C_e. This is a measure of how close the point c comes to being an extreme point of C. Another such measure is given by $\mu(C, c)$, defined as zero when $c \in C_e$ and defined for $c \in C_m$ as half the length of a longest segment in C that has c as its midpoint. (The existence of such a segment follows from an easy argument using the compactness of E's unit sphere, the closedness of C, and the fact that C contains no line.) Note that $\mu(C, c)$ is the smallest number σ such that each line L in E through c includes an endpoint of $L \cap C$ at distance at most σ from c.

When C is fixed, the function $\xi(C, c)|_{c\in C}$ will be denoted by $\xi(C, \cdot)$; similarly for the functions $\mu(C, c)|_{c\in C}$ and $\rho(C, c)|_{c\in C_m}$, where

$$\rho(C, c) = \frac{\xi(C, c)}{\mu(C, c)}.$$

Of course, $\rho(C, \cdot) \equiv 1$ when C is one-dimensional, but in general the two measures of near-extremeness are different and the behavior of the function $\rho(C, \cdot)$ is of interest. As was explained in the Introduction, the extreme value

$$\rho(C) = \sup\{\rho(C, c): c \in C_m\}$$

plays an essential role in Theorem 4.3's extension of property (P2) to δ-convex functions. Hence the extreme value

$$\rho(E) = \sup\{\rho(C): \text{body } C \subset E\}$$

is also of interest, and it is estimated in § 5.

It would be of interest, under various assumptions concerning the body C, to know the complexity of computing $\xi(C, c)$, $\mu(C, c)$, $\rho(C, c)$, and $\rho(C)$ and also, when C is bounded, the complexity of computing

$$\xi(C) = \sup\{\xi(C, c): c \in C\} \quad \text{and} \quad \mu(C) = \sup\{\mu(C, c): c \in C\}.$$

Of course, $\xi(C) \leqq \frac{1}{2}\delta(C)$ and $\mu(C) \leqq \frac{1}{2}\delta(C)$, where $\delta(C)$ is C's diameter. When C is a polytope presented in terms of its vertices, $\delta(C)$ and $\xi(C, c)$ are easy to compute but computation of the other numbers appears to be difficult. For a polytope presented in terms of its bounding hyperplanes, the computation of $\delta(C)$ is NP-hard in l^p-spaces with $1 \leqq p < \infty$ [6], and the same may well be true of the other numbers.

The remainder of the present section is devoted to some qualitative properties of the functions $\xi(C, \cdot)$, $\mu(C, \cdot)$, and $\rho(C, \cdot)$. For these properties, it suffices to deal with the usual Euclidean norm for $\mathbb{R}^d$, since each norm for $\mathbb{R}^d$ is caught between two positive multiples of the Euclidean norm. However, the quantitative details in §§ 4 and 5 depend on the choice of norm.

THEOREM 3.1. *For each body C, the function $\xi(C, \cdot)$ is everywhere continuous and the function $\mu(C, \cdot)$ is everywhere upper semicontinuous.*

Proof. Routine use of the triangle inequality shows that $|\xi(C, x) - \xi(C, y)| \leqq \|x - y\|$, whence of course $\xi(C, \cdot)$ is continuous. The upper semicontinuity of $\mu(C, \cdot)$ follows from a simple argument based on the closedness of C and the compactness of the unit sphere in the containing space. □

For each $d \geqq 3$, there exists a compact body $C \subset \mathbb{R}^d$ whose set C_e of extreme points is not closed. (For example, let C be the convex hull of the union of a $(d-1)$-dimensional spherical ball B and a segment S that is orthogonal to B's hyperplane and is centered at a point p in the boundary A of B. Then $p \in C_m$ but $A \setminus \{p\} \subset C_e$.) Clearly the function $\mu(C, \cdot)$ is discontinuous at each point p of C_m that belongs to the closure of C_e, and in fact the restriction of $\mu(C, \cdot)$ to $C_m \cup \{p\}$ is also discontinuous at p.

Although the function $\mu(C, \cdot)$ need not be everywhere continuous, continuity at certain points can be established. The following lemma is useful for that purpose. (As the terms are used here, a *polyhedron* is a set that is the intersection of a finite number of closed halfspaces: a *polytope* is a bounded polyhedron.)

LEMMA 3.2. *Suppose that C is a body in $\mathbb{R}^d$, the origin 0 is the midpoint of an open segment $]-q, q[$ in C, and H is the hyperplane through 0 orthogonal to the segment. If*

C is a polyhedron or the origin is interior to C, then for each $\lambda \in]0, 1[$ there is a neighborhood U of 0 in $C \cap H$ such that the vector sum

$$U + \lambda\,]-q, q[= \{u + \lambda q : u \in U, |\tau| < \lambda\}$$

is a neighborhood of 0 in C.

Proof. The case in which $0 \in \operatorname{int} C$ is left to the reader. In the remaining case, there is a representation of C in the form $C = \bigcap_{i=1}^{n} K_i$, where each K_i is a closed halfspace with bounding hyperplane J_i and where, for some $m \geqq 1$, $0 \in \bigcap_{i=1}^{m} J_i$ and $0 \in \operatorname{int} \bigcap_{i=m+1}^{n} K_i$. By a well-known theorem [5], [11], the polyhedron $K = \bigcap_{i=1}^{n} K_i$ is the direct sum of the subspace $J = \bigcap_{i=1}^{m} J_i$ and the polyhedral cone $K \cap J^{\perp}$, where $J^{\perp}$ is the orthogonal complement of J. Of course, $[-q, q] \subset J$, whence $J^{\perp} \subset H$. Since the segment $[-\lambda q, \lambda q]$ is interior to the intersection $\bigcap_{i=m+1}^{n} K_i$, there is a positive η such that this intersection contains the vector sum of the segment $[-\lambda q, \lambda q]$ and the η-neighborhood V of the origin in $\mathbb{R}^d$. Then the set $U = V \cap C \cap H$ is the desired neighborhood of 0 in $C \cap H$. □

THEOREM 3.3. *The function $\mu(C, \cdot)$ is continuous at each interior point of C, and if C is polyhdral then $\mu(C, \cdot)$ is continuous everywhere.*

Proof. By Theorem 3.1, the function $\mu(C, \cdot)$ is everywhere upper semicontinuous. To complete the proof, we show that if p is interior to C, or $p \in C$ and C is polyhedral, then $\mu(C, \cdot)$ is lower semicontinuous at p. This is obvious when $\mu(C, p) = 0$ for the function μ is nonnegative. Suppose then that $\mu(C, p) > 0$, assume without loss of generality that $p = 0$, and let $[-q, q]$ be a longest segment in C that has 0 as midpoint. Now consider an arbitrary $\lambda \in]0, 1[$, and let U be as in Lemma 3.2. Then for each $\varepsilon \in]0, \lambda[$, the set $W = U + \varepsilon\,]-q, q[$ is a neighborhood of 0 in C, and for each $w \in W$ it is true that

$$w + (\lambda - \varepsilon)\,]-q, q[\subset U + \lambda\,]-q, q[\subset C$$

and hence $\mu(C, w) \geqq (\lambda - \varepsilon)\|q\|$. This shows that the function $\mu(c, \cdot)$ is lower semicontinuous at p. □

LEMMA 3.4. *If the body C is a pointed cone, then the function $\rho(C, \cdot)$ attains a positive minimum on C. If C is a pointed polyhedral cone, then $\rho(C, \cdot)$ also attains a maximum on C.*

Proof. We assume without loss of generality that the origin is the apex of C, whence there is a hyperplane H that misses the origin and there is a compact body B in H such that $C = [0, \infty[\,B$. Since C is a cone, $C_m = C \setminus \{0\}$, and for each $c \in C_m$ and $\lambda > 0$ it is true that $\xi(C, \lambda c) = \lambda \xi(C, c)$ and $\mu(C, \lambda c) = \lambda \mu(C, c)$. Hence the range of the function $\rho(C, \cdot)$ on C_m is equal to its range on B.

On the set B, the functions $\xi(C, \cdot)$ and $\mu(C, \cdot)$ are both positive. By Theorem 3.1, $\xi(C, \cdot)$ is continuous and $\mu(C, \cdot)$ is upper semicontinuous. Hence their quotient $\rho(C, \cdot)$, being lower semicontinuous and positive on the compact set B, attains a positive minimum on B.

If C is polyhedral then, by Theorem 3.3, the function $\mu(C, \cdot)$ is actually continuous on C, whence $\rho(C, \cdot)$ is continuous and hence attains a maximum on the compact set B. □

LEMMA 3.5. *If the body C is unbounded and its set C_e of extreme points is bounded, then*

$$\limsup_{n \to \infty} \{\rho(C, c) : c \in C_m, \|c\| \geqq n\} = 1.$$

Proof. We may assume without loss of generality that the origin 0 belongs to the bounded set C_e. Let K denote the union of all rays that issue from the origin 0 and are

contained in C, and let B denote the closed convex hull of C_e. Then K is a pointed closed convex cone, B is a compact convex set, and $C = B + K$. Let $\beta = \sup\{\|b\|: b \in B\}$. Since $0 \in C_e$, it is true for each point $c \in C$ that $\xi(C, c) \leqq \|c\|$. Each point $c \in C \setminus B$ has at least one representation in the form $c = b + k$ with $b \in B$ and $k \in K \setminus \{0\}$. For each such representation, it is true that $b + 2k \in C$, whence $c \in C_m$ with $\mu(C, c) \geqq \|k\|$ and hence

$$\rho(C, c) \leqq (\|k\| + \beta)/\|k\|.$$

From this it follows that

$$\limsup_{n\to\infty} \{\rho(C, c): c \in C_m, \|c\| \geqq n\} \leqq 1.$$

When the point $c \in K \setminus B$ belongs to R, $[0, 2c]$ is the unique longest segment in C that has c as its midpoint, and hence

$$\rho(C, c) \geqq (\|k\| - \beta)/\|c\| = 1.$$

This implies that

$$\limsup_{n\to\infty} \{\rho(C, c): c \in C_m, \|c\| \geqq n\} \geqq 1. \qquad \square$$

THEOREM 3.6. *If the body C is a polyhedron, then the function $\rho(C, \cdot)$ attains a maximum $\rho(C) \geqq 1$.*

Proof. Consider an arbitrary edge or extreme ray R of C, and an endpoint p of R. Then $p \in C_e$ and the set C_e is finite, so for each point $c \in R \setminus \{p\}$ sufficiently close to p it is true that $c \in C_m$ and

$$\xi(C, c) = \|c - p\| = \mu(C, c).$$

This implies that the function $\rho(C, \cdot)$ attains the value 1.

Now suppose that the function $\rho(C, \cdot)$ does not attain a maximum on c_m, and let $c_1, c_2, \cdots$ be a sequence in C_m such that

$$\rho(C, c_n) \to \rho(C) \quad \text{as } n \to \infty.$$

If $\|c_n\| \to \infty$, then $\rho(C) \leqq 1$ by Lemma 3.5, and the desired conclusion follows from the preceding paragraph.

In the remaining case, we may assume that the sequence $c_1, c_2, \cdots$, converges to a point $p \in C$. If $p \in C_m$ then $\rho(C, c) = \rho(C)$ by Theorem 3.3. If $p \in C_m$, then $p \in C_e$. It is not hard to verify that the values of $\rho(C, c)$ attained when the point $c \in C_m$ belongs to a sufficiently small neighborhood of the extreme point p are precisely the values attained by the function $\rho(K, \cdot)$ where K is the cone consisting of all rays that issue from p and pass through the various points of C. When C is a polyhedron, this cone K is also polyhedral and the function $\rho(K, \cdot)$ attains a maximum by Lemma 3.4. $\square$

To end this section, we note that for each two-dimensional body C, the following four conditions are equivalent: (a) C is a polyhedron; (b) the set C_e is finite; (c) the function $\rho(C, \cdot)$ attains a minimum; (d) the infimum of $\rho(C, \cdot)$ is positive. Of course, (a) implies (b)-(d) in any dimension. However, for bodies in $\mathbb{R}^3$, (b) & (c) & (d) does not imply (a), (c) does not imply (b) or (d), and some other questions about implications among these conditions are unsettled. In particular, we do not know whether (d) implies (c) nor whether (d) implies (b).

4. Maxima. The following remark illustrates the manner in which the quantity $\rho(C)$ enters into the δ-version of (P2).

LEMMA 4.1. *If φ is a midpoint strictly δ-quasiconvex function on a body C, and q is a point of C at which φ attains its maximum, then there is an extreme point x of C such that $\|q-x\| \leqq \delta\rho(C)$.*

Proof. It suffices to show that $\mu(C, q) \leqq \delta$, for then

$$\xi(C, q) = \mu(C, q)\rho(C, q) < \delta\rho(C, q).$$

In the contrary case, q is the midpoint of a segment $[p, r]$ in C of length exceeding δ. But then, by the definition of midpoint strict δ-quasiconvexity, $\varphi(p) < \varphi(q)$ or $\varphi(r) > \varphi(q)$. This contradicts the assumed maximizing property of q. □

Our main tool for dealing with maxima is the following lemma from [12].

LEMMA 4.2. *Suppose that K is a convex set and the partial ordering $\prec$ on K is defined as follows: $v \prec w$ if and only if, for the line L through v and w, it is true that v is an inner point and w is an endpoint of the intersection $L \cap K$. (Intuitively, w can see beyond v in K, but v cannot see beyond w.) With respect to this ordering, each linearly ordered subset of K is affinely independent.*

This lemma yields a quick proof of the theorem of Hirsch and Hoffman [8] (essentially (P2) of the Introduction) asserting that if a convex function attains its maximum on a finite-dimensional line-free closed convex set, then it does so at an extreme point. As we now show, it also yields extensions of this result to functions that are globally convex or quasiconvex.

THEOREM 4.3. *Suppose that φ is a real-valued function defined on the body C. Suppose also that φ is midpoint δ-quasiconvex and C is compact, or that φ is midpoint δ-convex and is bounded above on each ray in C. Then for each value α of φ there are points q and x of C such that $\varphi(q) \geqq \alpha$, x is an extreme point of C, and $\|q-x\| < \delta\rho(C)$.*

Proof. In terms of the ordering $\prec$ described in Lemma 4.2, we define a second ordering $\ll$ by saying that $v \ll w$ provided that $v \prec w$ and $\varphi(v) \leqq \varphi(w)$. Every set that is linearly ordered by $\ll$ is also linearly ordered by $\prec$, and hence by Lemma 4.2 is of cardinality at most $d+1$ where d is the dimension of C. Now consider an arbitrary point $c \in C$ such that $\varphi(c) = \alpha$, and let

$$c = c_0 \ll c_1 \ll \cdots \ll c_k \tag{14}$$

be a $\ll$-ordered sequence that starts with the point c and cannot be extended. Set $q = c_k$, whence of course $\varphi(q) \geqq \alpha$. To complete the proof it suffices to show that $\mu(C, q) < \delta$, for then $q \in C_e$ or we have

$$\xi(C, q) = \frac{\xi(C, q)}{\mu(C, q)}\mu(C, q) = \rho(C, q)\mu(C, q) < \rho(C)\delta.$$

Suppose that $\mu(C, q) \geqq \delta$, let p and r be the endpoints of a longest segment in C that has q as a midpoint, and let L denote the line through p and r. At least one of p and r must be an endpoint of the intersection $L \cap C$, and we may assume that p is such an endpoint. If the intersection $L \cap C$ is a segment $[p, s]$ (where of course $r \in [p, s]$), it follows from the midpoint δ-quasiconvexity of φ that $\varphi(p) \geqq \varphi(q)$ or $\varphi(s) \geqq \varphi(q)$. Then the sequence (14) can be extended by adding p or s at the end, and the assumed maximality of the sequence is contradicted.

In the remaining case, the intersection $L \cap C$ is a ray R that issues from p and passes through r. This ray includes the point $r_k = q + k(q-p)$ for each integer $k \geqq -1$. From the midpoint δ-convexity of φ it follows that for each $k \geqq 1$,

$$\varphi(r_k) \geqq \varphi(r_{k-1}) + (\varphi(r_{k-1}) - \varphi(r_{k-2})),$$

and k successive applications of this inequality lead to the conclusion that

$$\varphi(r_k) \geqq (k+1)\varphi(r_0) - k\varphi(r_{-1}) = \varphi(q) + k(\varphi(q) - \varphi(p)).$$

Since, by hypothesis, φ is bounded above on the ray R, it follows that $\varphi(p) \geqq \varphi(q)$. But then the sequence (14) can be extended by adding p, and the contradiction completes the proof. □

Now suppose that the function $\rho(C, \cdot)$ attains a maximum on C at a point $c \in C_m$. (By Theorem 3.6, this occurs whenever C is a polytope.) Let $\delta = \mu(C, c)$, whence of course $\xi(C, c) = \delta\rho(C)$. Then Theorem 4.3 is sharp for C in the following sense.

For each $\eta > \delta$ there exists a continuous η-convex function φ on C such that the maximum of φ is attained only at c. Hence δ is the largest "modulus of global convexity" ε such that the ε-convexity of a continuous φ ensures the existence of an extreme point of C within $\delta\rho(C)$ of c.

To construct the desired function φ, start from an arbitrary continuous convex function ψ that is bounded above on C. Then let $\varphi = \psi + \zeta$, where

$$\zeta(x) = 1 - \frac{\|x - c\|}{\eta - \delta} \quad \text{for } \|x - c\| < \eta - \delta,$$

and $\zeta = 0$ elsewhere.

In the Introduction, we have mentioned a possible smoothing condition (7). A weakened form of this condition appears as a hypothesis in the following theorem.

THEOREM 4.4. *Suppose that the body C is compact and the function φ on C satisfies the following condition: each point $y \in C_m$ is an inner point of a segment $[x, z]$ in C such that $\varphi(y) \leqq \max\{\varphi(x), \varphi(z)\}$. Then for each value α of φ there is an extreme point x of C such that $\varphi(x) \geqq \alpha$. In particular, if φ attains a maximum on C then it does so at an extreme point.*

Proof. The proof follows the first two paragraphs of the proof of Theorem 4.3. □

5. Estimation of $\rho(E)$.

LEMMA 5.1. *For each $c \in C_m$ there exists a ball B centered at c such that $\rho(C, c) = \rho(C \cap B, c)$.*

Proof. Let x be an extreme point of C, and let $[p, r]$ have maximum length among the segments that are centered at c and contained in C. Let B be any ball that is centered at c and contains x, p, and r. Then of course $\mu(C \cap B, c) = \mu(C, c)$. Also, $\xi(C \cap B, c) = \xi(C, c)$, because each point of $(C \cap B)_e \setminus C_e$ belongs to the boundary of B and hence is at distance at least $\|x - c\|$ from c. □

LEMMA 5.2. *If C is bounded and $c \in C_m$, there exists a d-simplex S such that $c \in S$ and the vertices of S are extreme points of C. For each such S, it is true that $c \in S_m$ and $\rho(C, c) \leqq \rho(S, c)$.*

Proof. Since $C = \operatorname{con} C_e$, the existence of S follows from Carathéodory's Theorem [2]. It is obvious that $c \in S_m$, $\xi(C, c) \leqq \xi(S, c)$, and $\mu(C, c) \geqq \mu(S, c)$. □

THEOREM 5.3. *For each d-dimensional E, $\rho(E) \leqq d$.*

Proof. In view of Lemmas 5.1 and 5.2, it suffices to show that if the origin 0 belongs to a d-simplex S with vertices $v_0, \cdots, v_d$, and if $\|v_i\| \geqq 1$ for all i, then S contains a segment of length at least $2/d$ centered at the origin.

Since $0 \in S$, there are numbers $\lambda_i \geqq 0$ such that

$$\sum_{i=0}^{d} \lambda_i = 1 \quad \text{and} \quad \sum_{i=0}^{d} \lambda_i v_i = 0.$$

Then $\lambda_i \geqq 1/(d+1)$ for at least one value of i, and we may assume without loss of generality that this is λ_0. From the fact that $-\lambda_0 v_0 = \sum_{i=1}^{d} \lambda_i v_i$, it follows that the point

$$p = -\frac{\lambda_0}{1 - \lambda_0} v_0$$

is a convex combination of $\{v_1, \cdots, v_d\}$ and hence $p \in S$. But then S contains the segment $[p, v_0]$, and hence contains the segment $[-p, p]$ centered at 0. Since $\lambda_0 \geqq 1/(d+1)$, it is true that

$$\|p\| \geqq \frac{\lambda_0}{1-\lambda_0}\|v_0\| \geqq \frac{1/(d+1)}{1-1/(d+1)} = \frac{1}{d}. \qquad \square$$

For each positive integer d, and for $1 \leqq p < \infty$, let $\mathbb{R}_p^d$ denote the space $\mathbb{R}^d$ with the norm of

$$x = (x_1, \cdots, x_d) \in \mathbb{R}^d$$

given by

$$\|x\| = \left(\sum_{i=1}^{d} |x_i|^p \right)^{1/p} \qquad (1 \leqq p < \infty).$$

Let $\mathbb{R}_\infty^d$ denote the space $\mathbb{R}^d$ with the norm

$$\|x\| = \max \{|x_1|, \cdots, |x_d|\}.$$

THEOREM 5.4. *If E is the d-dimensional subspace of $\mathbb{R}_\infty^{d+1}$ consisting of all points for which the sum of the coordinates is zero, then $\rho(E) = d$.*

Proof. Let S denote the d-simplex in R_∞^{d+1} consisting of all points $x = (x_1, \cdots, x_{d+1})$ such that $\sum_{i=1}^{d+1} x_i = 1$ and $x_i \geqq 0$ for all i. Then $\rho(S) \leqq d$ by Theorem 5.3. To complete the proof of Theorem 5.4, we show that $\rho(S, c) \geqq d$ for the centroid c of S. Since the distance from c to each extreme point of S is $d/(d+1)$, we want to show that whenever p is a point of the space such that $c+p \in S$ and $c-p \in S$, then $\|p\| \leqq 1/(d+1)$. But that is obvious, for if some coordinate of p exceeds $1/(d+1)$ in absolute value, then $c+p$ or $c-p$ has a negative coordinate and hence does not belong to S. $\square$

In the d-dimensional space E of Theorem 5.4, the unit ball is a hyperplane section of a $(d+1)$-cube. When $d=2$, it is a regular hexagon. In the general case, it is of the form $T \cap -T$, where T is a d-simplex whose centroid is the origin. Theorem 5.4 establishes the sharpness of Theorem 5.3 in the sense that for each d there exists a d-dimensional E for which $\rho(E) = d$. However, it is also of interest to determine (or at least find sharp estimates for) $\rho(E)$ for the "standard" spaces $\mathbb{R}_p^d (1 \leqq p \leqq \infty)$. The following lemma is useful in dealing with the case $p = \infty$.

LEMMA 5.5. *If E is a subspace of F, then $\rho(E) \leqq \rho(F)$.*

Proof. It suffices to consider the case in which E is a hyperplane through the origin in F. Let $p \in F \setminus E$. For each $\eta < \rho(E)$, there exists a compact convex body C in E and a point $c \in C_m$ such that $\rho(C, c) > \eta$. For each $\lambda > 0$, let $C_\lambda = C + [-\lambda, \lambda]p$, a compact convex body in F. Since it is clear that

$$\lim_{\lambda \to 0} \rho(C_\lambda, c) = \rho(C, c),$$

the desired conclusion follows. $\square$

COROLLARY 5.6. *For each d,*

$$d - 1 \leqq \rho(\mathbb{R}_\infty^d) \leqq d.$$

Proof. To prove the corollary we use Theorems 5.3 and 5.4 and Lemma 5.5. $\square$

Before turning to the case of Euclidean d-space $\mathbb{R}_2^d$, we establish one more geometric lemma that applies to all spaces and is of some interest in itself.

LEMMA 5.7. *For each $\eta < \rho(E)$, there exists in E a d-simplex S such that the origin is interior to S, each vertex of S is at distance 1 from the origin, and $\eta < \rho(S, 0)$.*

Proof. By the definition of $\rho(E)$ in conjunction with Lemmas 5.1 and 5.2, there exists a d-simplex $T \subset E$ and a point $t \in T_m$ such that $\rho(T, p) > \eta$. By an easy continuity argument, $\rho(T, s) > \eta$ for each interior point s of T sufficiently close to t. Now with s fixed, let x be an extreme point of T closest to s. We may assume without loss of generality that $s = 0$ and $\|x\| = 1$. Then for each vertex v of T, let

$$\bar{v} = \frac{v}{\|v\|} \in T,$$

and let S be the simplex whose vertices are the $\bar{v}$'s. It is clear that the pair $(S, 0)$ has the stated properties. □

LEMMA 5.8. *If S is a regular Euclidean d-simplex and s is the centroid of S, then*

$$\rho(S, s) = \begin{cases} \sqrt{d} & \text{when } d \text{ is odd,} \\ \sqrt{d+1} & \text{when } d \text{ is even.} \end{cases}$$

Proof. With $u_0, \cdots, u_d$ denoting the standard unit basis vectors for $\mathbb{R}_2^{d+1}$, let

$$c = \frac{1}{d+1} \sum_{i=0}^{d} u_1 \quad \text{and} \quad S = \operatorname{con}\{u_0 - c, \cdots, u_d - c\}.$$

Then S is a regular Euclidean d-simplex with centroid $s = 0$, and

$$\xi(S, s) = \left(\frac{d}{d+1}\right)^{1/2}.$$

We want to compute $\mu(S, s)$, which is half of the maximum of the norm on the set $S \cap -S$.

The points x of $S \cap -S$ are characterized by the existence of nonnegative numbers $\lambda_0, \cdots, \lambda_d$ with sum 1 and nonnegative numbers $\eta_0, \cdots, \eta_d$ with sum 1 such that

$$\sum_{i=0}^{d} \lambda_i (u_i - c) = x = \sum_{i=0}^{d} \eta_i (c - u_i).$$

From this it follows that

$$\sum_{i=0}^{d} (\lambda_i + \eta_i) u_i = 2c$$

and by linear independence of the u_i's that

$$\lambda_0 + \eta_0 = \lambda_1 + \eta_1 = \cdots \lambda_d + \eta_d = \frac{2}{d+1}.$$

Note also that since the origin is the orthogonal projection of the point c onto the hyperplane aff S, maximizing $\|x\|$ over $x \in S \cap -S$ is equivalent to maximizing $\|x - c\|^2$ over $x \in S \cap -S$. And for $x = \sum_{i=0}^{d} \eta_i u_i$ as described,

$$\|x - c\|^2 = \sum_{i=0}^{d} \eta_i^2.$$

We claim that for any x that maximizes $\|x\|^2$ over $S \cap -S$, there is at most one index i for which the numbers λ_i and η_i are both positive. For suppose there are two such indices, say 1 and 2 with $\eta_1 \geqq \eta_2$. Then for a sufficiently small positive ε we may increase η_1 and λ_2 by ε and decrease η_2 and λ_1 by ε without violating the above conditions, and since

$$(\eta_1 + \varepsilon)^2 - (\eta_2 - \varepsilon)^2 - \sum_{i=0}^{d} \eta_i^2 = \sum_{i=0}^{d} \eta_i^2 + 2\delta(\eta_1 - \eta_2 + \varepsilon) > \sum_{i=0}^{d} \eta_i^2 = x - \|c\|^2,$$

the maximizing property of x is contradicted. It follows, therefore, that for each index i with at most one exception, either $\lambda_i = 0$ and $\eta_i = 2/(d+1)$ or $\lambda_i = 2/(d+1)$ and $\eta_i = 0$. And since $\sum_{i=0}^{d} \eta_i = 1$, no more than half of the $d+1$ η_i's can be equal to $2/(d+1)$.

From the above observations we see that when d is odd—say $d = 2n+1$—the maximum of $\|v\|$ for $v \in S \cap -S$ is attained by setting

$$v = \frac{1}{d+1}\left(\sum_{i=0}^{n} u_i\right) - c.$$

Then $\|v\| = 1/\sqrt{2n-2} = \sqrt{d+1}$ and $\rho(S, s) = \xi(S, s)/\|v\| = \sqrt{d}$.

When d is even—say $d = 2n$—there is a maximizing x such that for some $r \leqq n$,

$$\eta_i = \frac{2}{d+1} \quad \text{for } 0 \leqq i < r \quad \text{and} \quad \eta_i = 0 \quad \text{for } r < i \leqq d.$$

From the fact that

$$\frac{2r}{d+1} + \eta_r = 1 \quad \text{and} \quad 0 \leqq \eta_r \leqq \frac{2}{d+1},$$

it follows that $2r \geqq d-1$, whence $r = n$ and $\eta_r = 1/d$. Hence the point

$$w = \left(\frac{2}{d+1}\sum_{i=0}^{n-1} u_i + \frac{1}{d+1} u_n\right) - c$$

is a point of $S \cap -S$ farthest from the origin, and we have

$$\|w\| = \frac{\sqrt{2n}}{2n+1} = \frac{\sqrt{d}}{d+1} \quad \text{and} \quad \rho(S, s) = \frac{\xi(S, s)}{\|w\|} = \sqrt{d+1}. \qquad \square$$

For each dimension d, Lemma 5.8 provides a lower bound for $\rho(\mathbb{R}_2^d)$ and it may be that this bound is sharp. We are able to show that it is sharp for $d \leqq 2$ (i.e., $\rho(\mathbb{R}_2^2) = \sqrt{3}$), and for $d \geqq 3$ to establish an upper bound that is no more than $\sqrt{5}$ times the lower bound. It follows from Lemma 5.7 that in seeking an upper bound for $\rho(\mathbb{R}_2^d)$, we may confine our attention to the ratio $\rho(Z, 0)$, where Z satisfies the conditions of the following lemma. Under these conditions, $\xi(Z, 0) = 1$ and we seek a lower bound on $\mu(Z, 0)$.

LEMMA 5.9. *With $d \geqq 2$, suppose that the origin in $\mathbb{R}_2^d$ is interior to a d-simplex Z whose vertices $z_0, \cdots, z_d$ are all of unit norm, and that the positive numbers λ_i are such that*

$$\sum_{i=0}^{d} \lambda_i = 1 \quad \textit{and} \quad \sum_{i=0}^{d} \lambda_i z_i = 0.$$

Let

$$S = \operatorname{con}\{z_1, \cdots, z_d\} \quad \textit{and} \quad s = -\frac{\lambda_0}{1-\lambda_0} z_0 \in S.$$

Then the following statements are true:

(i) *S is the facet of Z opposite z_0;*

(ii) *s belongs to the interior of S relative to the hyperplane* aff S;

(iii) *for each i, $\lambda_i < \frac{1}{2}$;*

(iv) $S \cap -Z \supset (1-2\lambda_0)((S-s) \cap (s-S)) + s.$

(Thus the intersection $S \cap -Z$ contains a contraction in the ratio $1-2\lambda_0$ of the reflection of the set S in the point s.)

Proof. The assertion (i) is obvious, and (ii) follows from the fact that

$$s = -\frac{1}{1-\lambda_0}(\lambda_0 z_0) = -\frac{1}{1-\lambda_0}\left(-\sum_{i=1}^{d} \lambda_i z_i\right) = \sum_{i=1}^{d} \frac{\lambda_1}{1-\lambda_0} z_i.$$

For (iii), note that if $\langle \cdot \rangle$ denotes the usual inner product, then

$$\lambda_0 = \lambda_0 \langle z_0, z_0 \rangle = \langle z_0, \lambda_0 z_0 \rangle = \left\langle z_0, -\sum_{i=1}^{d} \lambda_i z_i \right\rangle = \sum_{i=1}^{d} \lambda_i (-\langle z_0, z_i \rangle)$$

$$\leqq \sum_{i=1}^{d} \lambda_1 |\langle z_0, z_i \rangle| \leqq \sum_{i=1}^{d} \lambda_i = 1 - \lambda_0.$$

From this it follows that $\lambda_0 \leqq \frac{1}{2}$, with $\lambda_0 = \frac{1}{2}$ only if each of the points $z_1, \cdots, z_d$ is equal to $-z_0$. Equality is excluded by the assumption that the origin is interior to Z.

Now let $T = S - s$. To establish (iv), we observe that

$$\begin{aligned} S \cap -Z &\supseteq (T+s) \cap ((1-2\lambda_0)(-T-s+z_0) - z_0) \\ &= (T+s) \cap ((1-2\lambda_0)(-T)+s) \\ &\supseteq T \cap ((1-2\lambda_0)(-T)) + s \\ &\supseteq ((1-2\lambda_0)T) \cap ((1-2\lambda_0)(-T)) + s \\ &\supseteq (1-2\lambda_0)(T \cap -T) + s \\ &= (1-2\lambda_0)(S-s) \cap (s-S) + s. \end{aligned}$$

The first $\supseteq$ or $=$ follows from the fact that $S = T + s$ and

$$\begin{aligned} (1-2\lambda_0)(-T-s+z_0) - z_0 &= (1-2\lambda_0)(-S) + (2\lambda_0)(-z_0) \\ &\subset \operatorname{con}((-S) \cup \{-z_0\}) = -Z. \end{aligned}$$

For the second, use the fact that $s = (-\lambda_0/(1-\lambda_0))z_0$. The third, fifth, and sixth are obvious. For the fourth, note that since $0 < 1-2\lambda_0 < 1$ by (iii), and since the set T is convex and includes the origin, it is true that $T \supset (1-2\lambda_0)T$.

(Actually,

$$S \cap -Z = (T+s) \cap ((1-2\lambda_0)(-T)+s),$$

but we do not use this fact.) □

THEOREM 5.10. $\rho(\mathbb{R}_2^2) = \sqrt{3}$.

Proof. Let the notation be as in Lemma 5.9. With p denoting the foot of the perpendicular from the origin to the line aff S through z_1 and z_2, let the z_i's and λ_i's be relabeled to obtain $\|p\| \geqq \frac{1}{2}$. (It is easy to see that this is possible.) With

$$\delta = (1 - \|p\|^2)^{1/2} - \|s-p\|,$$

the situation is as shown in Fig. 2, and it follows from (iv) of Lemma 5.9 that there exists $q \in S \cap -Z$ such that

$$\|q-p\| \geqq \|s-p\| + (1-2\lambda_0)\delta.$$

Let us define $y = \|s-p\|$ and $r = \|p\|$, whence $\|s\| = (y^2+r^2)^{1/2}$ and it follows that

$$\lambda_0 = \frac{(y^2+r^2)^{1/2}}{1+(y^2+r^2)^{1/2}}.$$

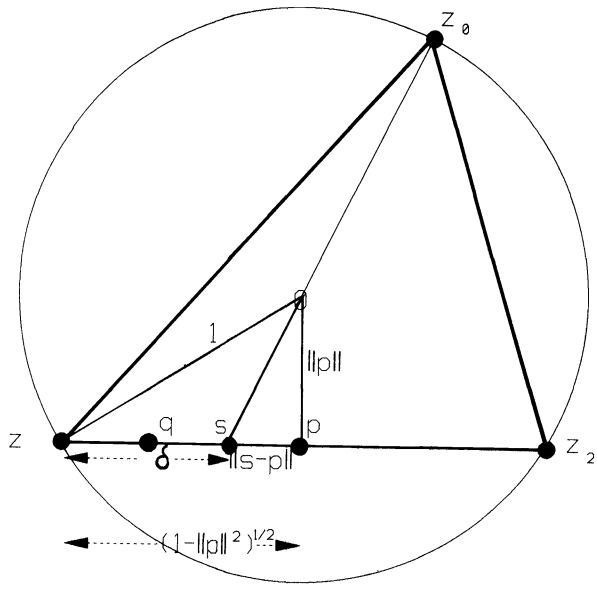

FIG. 2

Hence the lower bound on $\|q-p\|$ may be written as

$$g(y)=y+\left(1-\frac{2(y^2+r^2)^{1/2}}{1+(y^2+r^2)^{1/2}}\right)((1-r^2)^{1/2}-y)$$
$$=\frac{2(y^2+r^2)^{1/2}y}{1+(y^2+r^2)^{1/2}}+\left(1-\frac{2(y^2+r^2)^{1/2}y}{1+(y^2+r^2)^{1/2}}\right)(1-r^2)^{1/2}.$$

We claim that for each fixed $r\geqq\frac{1}{2}$, the value of $g(y)$ is minimized by setting $y=0$. Since

$$\frac{1}{2}(g(y)-g(0))=\frac{y(y^2+r^2)^{1/2}(1+r)+(r-(y^2+r^2)^{1/2})(1-r^2)^{1/2}}{(1+r)(1+(y^2+r^2)^{1/2})},$$

it will suffice to show that $f(y)\geqq f(0)$ for all $y\geqq 0$, where

$$f(y)=(y(1+r)-(1-r^2)^{1/2})(y^2+r^2)^{1/2}.$$

Now

$$f'(y)=(1+r)(y^2+r^2)^{1/2}+y(y^2+r^2)^{-1/2}(y(1+r)-(1-r^2)^{1/2})$$
$$=(2(1+r)y^2-y(1-r^2)^{1/2}+(1+r)r^2)(y^2+r^2)^{-1/2}$$

and since the discriminant $(1-r^2)-8(1+r)^2r^2$ is positive when $r\geqq\frac{1}{2}$ it follows that $f'(y)\geqq 0$ for all $y\geqq 0$. But then $f(y)\geqq 0$, and from this it follows that

$$g(y)\geqq g(0)=\frac{(1-r)^{3/2}}{(1+r)^{1/2}}.$$

Recalling the relevant definitions, we see that there is a point q of $S\cap -Z$ such that $\|q-p\|\geqq g(0)$, whence by the Pythagorean Theorem the squared norm of q is at least

$$h(r)=\frac{(1-r)^3}{1+r}+r^2.$$

Now

$$h'(r)=\frac{4}{(1+r)^2}(r^2+2r-1),$$

and this is positive when $r\geqq\frac{1}{2}$. Hence for $r\geqq\frac{1}{2}$,

$$h(r)\geqq\frac{(1/2)^3}{3/2}+\frac{1}{4}=\frac{1}{3},$$

whence the half-length of the segment $[-q, q]\subset Z\cap -Z$ is at least $1/\sqrt{3}$. This implies that $\rho(Z,0)\leqq\sqrt{3}$, whence $\rho(\mathbb{R}_2^2)\leqq\sqrt{3}$. The reverse inequality appears in Lemma 5.8. □

In preparation for the next result, we require a computational lemma.

LEMMA 5.11. *If the sequence* $\gamma_1, \gamma_2, \cdots$ *is defined by the condition that* $\gamma_1=1$ *and*

$$\gamma_d=\frac{1}{d^2}-\frac{(d-1)^4}{d^2(d+1)^2}\gamma_{d-1},$$

for $d\geqq 2$, *then*

$$\gamma_d=\frac{1}{15d^3(d+1)^2}(3d^4+15d^3-2d^2+15d+2)\geqq\frac{1}{5d}\left(1-\frac{1}{d}\right)^2.$$

Proof. Let $\alpha_d=d^2\gamma_d$, so that $\alpha_1=1$ and

$$\begin{aligned}\alpha_d&=1+\left(\frac{d-1}{d+1}\right)^2\alpha_{d-1}=1+\left(\frac{d-1}{d+1}\right)^2\left(1+\left(\frac{d-2}{d}\right)^2\alpha_{d-2}\right)\\&=1+\left(\frac{d-1}{d+1}\right)^2+\left(\frac{d-1}{d+1}\right)^2\left(\frac{d-2}{d}\right)^2\left(1+\left(\frac{d-3}{d-1}\right)^2\alpha_{d-3}\right)\\&=\frac{1}{d^2(d+1)}(2d^2(d^2+1)+(d-1)^2(d-2)^2+(d-2)^2(d-3)^2\alpha_{d-3})\\&=\frac{1}{d^2(d+1)^2}\left(2d^2(d^2+1)+\sum_{i=2}^{d-2}i^2(i+1)^2\right).\end{aligned}$$

A straightforward induction shows that

$$\sum_{i=1}^{n}i^2(i+1)^2=\frac{1}{15}n(n+1)(n+2)(3n^2+6n+1).$$

With $d=n-2$ this yields

$$\alpha_d=\frac{1}{15d(d+1)^2}(3d^4+15d^3+2d^2+15d+2)$$

and hence

$$\begin{aligned}\alpha_d=\frac{1}{d^2}\alpha&>\frac{1}{15d^3(d+1)^2}(3d^4-6d^2+3)=\frac{3}{15d^3(d+1)^2}(d+1)^2(d-1)^2\\&=\frac{1}{5d^3}(d-1)^2=\frac{1}{5d}\left(1-\frac{1}{d}\right)^2.\end{aligned}$$

□

THEOREM 5.12. *If* $d\geqq 2$, *then*

$$\frac{d}{d-1}\sqrt{5d}\geqq\rho(\mathbb{R}_2^d)\geqq\begin{cases}\sqrt{d} & \text{for odd } d,\\ \sqrt{d+1} & \text{for even } d.\end{cases}$$

Proof. The lower bounds $\sqrt{d}$ and $\sqrt{d+1}$ come from Lemma 5.8. To justify the upper bound, it is more convenient to work with $\beta_d = 1/\rho(\mathbb{R}_2^d)$. We already know that $\beta_1 = 1$ and $\beta_2 = 1/\sqrt{3}$. To prove

$$\beta_d \geqq \frac{d-1}{d\sqrt{5d}}$$

for a given $d \geqq 2$, it will suffice, in view of Lemma 5.11, to show that

$$\beta_k^2 \geqq \frac{1}{k^2} + \frac{(k-1)^4}{k^2(k+1)^2}\beta_{k-1}$$

for all $k \leqq d$. This will be accomplished by induction on d.

With the notation as in Lemma 5.9, let the z_i's and λ_i's be relabeled to obtain $\lambda_0 \geqq 1/(d+1)$, let p denote the orthogonal projection of the origin on the hyperplane aff S, and let

$$\delta = (1 - \|p\|^2)^{1/2} - \|s - p\|.$$

Of course,

$$\frac{\mu(S, s)}{\xi(S, s)} \geqq \beta_{d-1}$$

and with the aid of (iv) of Lemma 5.9 we see that

$$\mu(S \cap -Z, s) \geqq (1 - 2\lambda_0)\mu(S, s).$$

For $1 \leqq j \leqq d$ it follows from the Pythagorean Theorem that

$$\|p - v_j\|^2 + \|p\|^2 = \|v_j\|^2 = 1$$

and from the triangle inequality that

$$\|p - v_j\| \leqq \|p - s\| + \|s - v_j\|.$$

Hence $\xi(S, s) \geqq \delta$ and we have

$$\mu(S \cap -Z, s) \geqq (1 - 2\lambda_0)\mu(S, s) \geqq (1 - 2\lambda_0)\beta_{d-1}\delta.$$

That is, the set $S \cap -Z$ contains a segment that is centered at s and has half-length at least $(1 - 2\lambda_0)\beta_{d-1}\delta$. For at least one end of this segment, the squared distance from p is at least

$$\|p - s\|^2 + (1 - 2\lambda_0)^2\beta_{d-1}^2\delta^2$$

and from the origin it is at least

$$Q = \|p - 2\|^2 + (1 - 2\lambda_0)^2\beta_{d-1}^2\delta^2 + \|p\|^2.$$

To prove Theorem 5.12 it will suffice, in view of Lemmas 5.7 and 5.11 and the fact that $\xi(Z, 0) = 1$, to show that

$$Q \geqq \frac{1}{d^2} + \frac{(d-1)^4}{d^2(d+1)^2}\beta_{d-1}.$$

For notational convenience, we write

$$y = \|s\| = \frac{\lambda_0}{1 - \lambda_0} \geqq \frac{1}{d} \quad \text{and} \quad r = \|p\| \leqq y \leqq 1.$$

Then $\lambda_0 = y/(1+y)$, and Q becomes

$$h(y) = y^2 + \left(1 - \frac{2y}{1+y}\right)^2 \beta_{d-1}^2((1-r^2)^{1/2} - (y^2-r^2)^{1/2})^2$$
$$= y^2 + (1-y)^4 \beta_{d-1}^2((1-r^2)^{1/2} + (y^2-r^2)^{1/2})^{-2}.$$

For each fixed y, the value of $h(y)$ decreases with decreasing $|r|$. Hence $h(y) \geqq f(y)$, where

$$f(y) = y^2 + \frac{(1-y)^4}{(1+y)^2}\beta_{d-1}^2$$

and

$$f'(y) = (1+y)^{-3}(2y(1+y)^3 - 4(1-y)^3(1+y)\beta_{d-1}^2 - 2(1-y)^4\beta_{d-1}^2)$$
$$\geqq (1+y)^{-3}(2y(1+y)^3 - 6\beta_{d-1}^2) \quad \text{when } \frac{1}{d} \leqq y \leqq 1.$$

With $\beta_{d-1} \leqq 1/\sqrt{d-1}$ and $y \geqq 1/d$, we have $f'(y) \geqq 0$ and hence

$$f(y) \geqq \left(f\left(\frac{1}{d}\right)\right)^2 = \frac{1}{d^2} + \frac{(1-1/d)^4}{(1+1/d)^2}\beta_{d-1}. \qquad \square$$

For bodies C lying in certain Minkowski spaces E, Theorems 5.3, 5.4, 5.10, and 5.12 bound the number $\rho(C)$ from above. Because of the relevance of $\rho(C)$ to the maximization of δ-convex functions, it is also of interest to know how *small* $\rho(C)$ can be for bodies $C \subset E$. It is easy to see that whenever $\dim E \geqq 2$, there are pointed polyhedral cones $K \subset E$ that have arbitrarily small values for $\rho(K)$. (Simply let K have a "large opening.") However, the situation for bounded bodies is much less obvious, and hence the following observation seems worth including.

THEOREM 5.13. *For each $d \geqq 2$, the set $\{\rho(C)$: bounded body $C \subset \mathbb{R}_2^d\}$ is equal to the interval $]0, \rho(\mathbb{R}_2^d)]$. In particular, when $d = 2$ it is the interval $]0, \sqrt{3}]$.*

Proof. We first show that if $\varepsilon > 0$, and if C_ε is the lens in the xy-plane formed by intersecting the disks of radius $R = (1+\varepsilon^2)/(2\varepsilon)$ centered at the points $(-R+\varepsilon, 0)$ and $(R-\varepsilon, 0)$, then $\rho(C_\varepsilon) \leqq \varepsilon$. Consider an arbitrary point $p = (x, y) \in C_\varepsilon$ with $x, y \geqq 0$. The point q of ∂C_ε nearest to p is the radial extension to ∂C_ε of p from the point $(-R+\varepsilon, 0)$. At q, ∂C has a tangent line L, and we consider the cap D that contains the point q and is cut from C_ε by the line M parallel to L and passing through the point $z = (0, 1)$. Let r denote the point at which M intersects the segment joining the point $(-R+\varepsilon, 0)$ to q. We consider separately the two possibilities: $p \in [r, q]$; $r \in [p, q]$.

Suppose first that $p \in [r, q]$, and let $\eta = \|p - q\|$. Then there is a chord of C_ε that passes through p, is centered at p, and is of length $2\sqrt{2\eta R - \eta^2}$. Hence

$$\rho(C_\varepsilon, p) \leqq \frac{\eta}{\sqrt{2\eta R - \eta^2}} \leqq \varepsilon.$$

Now suppose that $r \in [p, q]$, and note that if the lens subtends an angle θ at z, then $\tan\theta = 1/(-\varepsilon)$. Consequently, if η is as before, then $\eta = \psi + \phi$ where $\psi = \|p - r\|$, $\phi = \|r - q\|$, and

$$\|p - r\| = \psi \leqq \|z - r\|(\tan\theta) = (R\phi - \phi^2)^{1/2}/(R - \phi).$$

Now C_ε contains the chord $[z, p - z]$ centered at p, and the square of half the length of this chord is given by

$$\|p - r\|^2 + \|z - r\|^2 \geqq \|z - r\|^2 = 2R\phi - \phi^2.$$

As $\eta = \psi + \phi$, we have

$$\eta \leqq \phi + (R\phi - \phi^2)^{1/2}/(R - \phi).$$

For small ε,

$$\phi \geqq (R\phi - \phi^2)^{1/2}/(R - \phi)$$

and consequently $\phi \geqq \eta/2$. Thus C_δ contains a chord centered at p of half-length at least $R\eta - \frac{1}{4}\eta^2$, and it follows that

$$\rho(C_\varepsilon) \leqq \eta(R\eta - \tfrac{1}{4}\eta^2)^{1/2} \leqq \varepsilon.$$

That completes the discussion of the case $d = 2$.

Now for $d \geqq 3$, write $\mathbb{R}_2^d = \mathbb{R}_2^2 \times \mathbb{R}_2^{d-2}$ in the usual way, so that each point $p \in \mathbb{R}_2^d$ can be written as $\mathrm{p} = (\mathrm{p}', \mathrm{p}'')$ with $p' \in \mathbb{R}_2^2$ and $p'' \in \mathbb{R}_2^{d-2}$. Let μ be the gauge-function of the body $C_\varepsilon \subset \mathbb{R}^2$, let $\| \cdot \|$ denote the Euclidean norm for $\mathbb{R}^{d-2}$, and define

$$K_\varepsilon = \{p: (\mu(p'))^2 + \|p''\|^2 \leqq 1\}.$$

Then K_ε is a body in $\mathbb{R}^d$, and it is not hard to verify that $\rho(K_\varepsilon) \leqq \varepsilon$. (When $d = 3$, K_ε is obtained by rotating the set C_ε about its axis of symmetry.)

To complete the proof, note that by a simple continuity argument, it is true for each space E that the set

$$\{\rho(C): \text{bounded body } C \subset E\}$$

is a connected subset of $\mathbb{R}$. □

APPLICATIONS OF OPTIMAL MULTIPROCESSES*

FRANK H. CLARKE† AND RICHARD B. VINTER‡

This paper is dedicated to the memory of E. J. McShane.

Abstract. In a previous paper a theory of necessary conditions for optimal multiprocess problems was supplied, that is, problems in dynamic optimization involving a collection of control systems coupled through constraints on the endpoints of the trajectories and the cost functions. Here the scope of the new theory is illustrated by application to optimization problems in investment planning, impulse control, optics, robotics, and renewable resources.

Key words. optimal control, necessary conditions, differential inclusions

AMS(MOS) subject classifications. 49B10, 49B99

1. Introduction. Optimal multiprocess problems are dynamic optimization problems involving a collection of control systems, coupled through constraints in the endpoints of the constituent state trajectories and through the cost function. Such problems arise, for example, in flight mechanics (optimal control of multistage rockets [11]), optimal investment [21], routing problems over variable domains [13], [16], and plasma control [22]. To date, necessary conditions of optimality and minimization algorithms for these problems have been studied, for the most part, by ad hoc techniques on a case-by-case basis.

Our earlier paper provided a unified theory of necessary conditions for optimal multiprocess problems. The present paper is a companion piece in which we explore applications of the theory. On the one hand, we deduce from the general theory necessary conditions of optimality for certain special classes of problems of interest. On the other hand, we use the theory to study specific problems in detail and to determine the optimal multiprocesses involved.

In selecting problems for inclusion in this paper, our object has not been exclusively to give instances where established methods fail and we must have recourse to the theory of optimal multiprocesses. Indeed both the free time investment problem of § 4 and the robot arm problem of § 7 can be solved by traditional "two stage" techniques in which we freeze certain choice parameters, thereby reducing the problems to ones that can be solved by application of the classical Pontryagin maximum principle; we then minimize a value function (the minimum cost as a function of the frozen parameter values) to determine the optimum parameter values. The emphasis is rather on *interpretation* of conditions in the optimal multiprocess maximum principle. A recurring theme is that the "extra" conditions in our maximum principle correspond to stationarity of the value function.

Necessary conditions in optimization, in addition to providing the basis for solution of certain problems by analytical means, serve as inspiration for optimization algorithms and give information concerning asymptotic properties of sequences generated by these algorithms. These aspects of necessary conditions are illustrated, in the context of optimal control theory, in, for example, [15] and [25]. We expect that the optimal multiprocess maximum principle will also be the source of optimization algorithms,

in the case of optimal multiprocess problems. Now outside the simplest cases we cannot reasonably expect convenient formulae for the appropriate value functions to be available to us. It is significant therefore that the optimal multiprocess maximum principle makes no explicit reference to value functions, and implementation of optimization procedures associated with it will not depend on availability of such formulae in any way.

An important feature of our theory is that it treats dynamic optimization problems where the data is merely measurable in the time variable. Our purpose in treating the investment problem of § 4 is in part to illustrate a free time problem where we can expect the optimal free time to coincide with a point of discontinuity of the data, and that the optimal multiprocess maximum principle can provide useful information in such instances. When the data is discontinuous in the time variable, the standard boundary condition on the maximized Hamiltonian function is replaced by an inclusion involving the "essential values" of this function. On the face of it the essential value condition is rather weak, and it is somewhat surprising that it can supply quite precise information about solutions to dynamic optimization problems. It does so in the problem in § 4, for example. Drawing an analogy with convex optimization is helpful here. The condition "$0 \in \partial f(x)$," where ∂ denotes the subdifferential, appears a meager condition for x to be a minimizer of the convex function $f: \mathbb{R}^n \to \mathbb{R}$. But on the contrary it is necessary and sufficient. The point is that if the convex function f has a discontinuous derivative at a point x, then x is a rather likely location for a minimizer, and this is reflected in $\partial f(x)$ being set-valued and the optimality condition being somewhat unrestrictive. Likewise for free time dynamic optimization problems, a time at which the cost integral and/or dynamics are discontinuous is a likely location for the optimal free time, and an optimality condition in the form of an inclusion is not inappropriate.

The form this paper takes is such as to make it a convenient reference in further applications of the theory of optimal multiprocesses. It includes a number of useful results for computing the normal cones typically encountered. The optimal multiprocess maximum principle of [6] has been recast to include the kind of integral cost terms that often arise, and a slightly weaker version of the transversality condition than that in [6] is given, but one which is more convenient for many applications.

2. Preliminaries. Frequent reference is made to generalized gradients and normal cones. These are understood in the sense of Clarke [4].

DEFINITION 2.1. Let N be an open subset of $\mathbb{R}^k$, let x be a point in N, and let $f: N \to \mathbb{R}$ be a locally Lipschitz continuous function. Then the generalized gradient $\partial f(x)$ of f at x is the set

$$\partial f(x) = \overline{\text{co}} \left\{ \lim_i \nabla f(x_i) \,|\, x_i \to x, \quad \nabla f(x_i) \text{ exists for } i = 1, 2, \cdots \right\}.$$

Given a closed set $S \subset \mathbb{R}^k$, $d_C: \mathbb{R}^k \to \mathbb{R}$ denotes the Euclidean distance function

$$d_C(x) = \min_{y \in C} |y - x|.$$

DEFINITION 2.2. Let $C \subset \mathbb{R}^k$ be a closed subset of $\mathbb{R}^k$ and x a point in C. Then the normal cone to C at x, written $N_C(x)$, is

$$N_C(x) = \text{cl} \left\{ \bigcup_{\lambda \geqq 0} \lambda \, \partial d_C(x) \right\}. \tag{2.1}$$

Application of the theory of optimal multiprocesses usually involves analysis of

generalized gradients and normal cones. The following identities and estimates will be useful in this regard.

PROPOSITION 2.1. (i) *For any closed subset* $C \subset \mathbb{R}^k \times \mathbb{R}^l$ *and point* $(a, b) \in C$, *we have*

$$N_{\{(x,x,y)|(x,y)\in C\}}((a, a, b)) \subset \{(p, q, r) | (p+q, r) \in N_C((a, b))\}.$$

(ii) *For any closed subset* $C \subset \mathbb{R}^k \times \mathbb{R}^l$ *and point* (a, b, c) *such that* $(a-b, c) \in C$, *we have*

$$N_{\{(x,y,z)|(x-y,z)\in C\}}((a, b, c)) \subset \{(p, -p, r) | (p, r) \in N_C((a, b))\}.$$

(iii) *For closed sets* $C_1 \subset \mathbb{R}^k$ *and* $C_2 \subset \mathbb{R}^l$, *and points* $x \in C_1$ *and* $y \in C_2$ *we have*

$$N_{C_1 \times C_2}(x, y) = N_{C_1}(x) \times N_{C_2}(y).$$

(iv) *Let* $\tilde{f}: \mathbb{R}^k \times \mathbb{R}^l$ *be a given locally Lipschitz continuous function and take a point* $(a, b, c) \in \mathbb{R}^k \times \mathbb{R}^k \times \mathbb{R}^l$. *Define* $f: \mathbb{R}^k \times \mathbb{R}^k \times \mathbb{R}^l \to \mathbb{R}$ *to be*

$$f(x, y, z) = \tilde{f}(x-y, z).$$

Then

$$\partial f((a, b, c)) = \{(p, -p, q) | (p, q) \in \partial \tilde{f}((a-b, c))\}.$$

Properties (i) and (ii) follow from Theorem 2.5.6 of [4]. For (iii) see page 54 of [4]; Property (iv) is a consequence of the chain rule [4, Thm. 2.3.10].

We also call upon the concept of "essential values," introduced in [6].

DEFINITION 2.3. Let $I \subset \mathbb{R}$ be an open interval and let $g: I \to \mathbb{R}^k$ be a measurable function. Take a point $t \in I$. Then the set of essential values of g at t, written $\operatorname{ess}_{s\to t} g(s)$, comprises the points $x \in \mathbb{R}^k$ such that, for any $\varepsilon > 0$, the set

$$\{s | |x(s) - x| \leqq \varepsilon, |s - t| \leqq \varepsilon\}$$

has positive measure.

We remark that if the function g has finite left and right limits at t (written $g(t^-)$ and $g(t^+)$), then

$$\operatorname*{ess}_{s\to t} g(s) = \{g(t^-), g(t^+)\}$$

and so, in particular, if g is continuous, then

$$\operatorname*{ess}_{s\to t} g(s) = \{g(t)\}.$$

3. A maximum principle for optimal multiprocesses. The following data is given:

positive integers k and $n_i, m_i, \quad i = 1, \cdots, k,$

functions $\phi_i: \mathbb{R} \times \mathbb{R}^{n_i} \times \mathbb{R}^{m_i} \to \mathbb{R}^{n_i},$

subsets U^i of $\mathbb{R} \times \mathbb{R}^{m_i}, \quad i = 1, \cdots, k,$

and subsets X^i of $\mathbb{R} \times \mathbb{R}^{n_i}, \quad i = 1, \cdots, k.$

We recall a notational device from [6]. A point $((a_1, b_1, \cdots), (a_2, b_2, \cdots), \cdots, (a_k, b_k, \cdots))$ is written $\{a_i, b_i, \cdots\}$.

A multiprocess is a k-tuple $\{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\}$ each element in which comprises left and right endpoints τ_0^i, τ_1^i of a closed interval, an absolutely continuous function $y_i(\cdot):[\tau_0^i, \tau_1^i] \to \mathbb{R}^{n_i}$, and a measurable function $w_i(\cdot):[\tau_0^i, \tau_1^i] \to \mathbb{R}^{n_i}$ such that

$$\dot{y}_i(t) = \phi_i(t, y_i(t), w_i(t)), \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i],$$

$$w_i(t) \in U_t^i \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i],$$

$$y_i(t) \in X_t^i \quad \text{for all } t \in [\tau_0^i, \tau_1^i].$$

(Here X_t^i denotes $\{x: (t, x) \in X^i\}$, etc.)

The individual elements are called component processes, the $y_i(\cdot)$'s component trajectories, the $w_i(\cdot)$'s component control functions, and the intervals $[\tau_0^i, \tau_1^i]$ component time intervals.

Now let

$$L_i: \mathbb{R} \times \mathbb{R}^{n_i} \times \mathbb{R}^{m_i} \to \mathbb{R}, \qquad i = 1, \cdots, k,$$

$$f: E \to \mathbb{R}$$

be given functions, in which $E = \prod_i (\mathbb{R} \times \mathbb{R} \times \mathbb{R}^{n_i} \times \mathbb{R}^{n_i})$, and let

$$\Lambda \subset \{\{\tau_0^i, \tau_1^i, y_0^i, y_1^i\} \in E \mid \tau_1^i \geqq \tau_0^i, i = 1, \cdots, k\}$$

be a given closed set. The optimal multiprocess problem is:

(P)
$$\text{minimize} \quad f(\{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\}) + \sum_i \int_{\tau_0^i}^{\tau_1^i} L_i(t, y_i(t), w_i(t))\, dt$$

over multiprocesses $\{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\}$ satisfying $\{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\} \in \Lambda$.

Define $\tilde{\phi}_i = [\phi_i, L_i]$, $i = 1, \cdots, k$. We invoke the following hypotheses.

(H1) For each $x \in \mathbb{R}^{n_i}$, $\tilde{\phi}_i(\cdot, x, \cdot)$ is $(\mathscr{L} \times \mathscr{B})$-measurable for $i = 1, \cdots, k$. Here $\mathscr{L}$ denotes the Lebesgue subsets in $\mathbb{R}$ and $\mathscr{B}$, the Borel subsets in $\mathbb{R}^{m_i}$.

(H2) U^i is a Borel measurable set for $i = 1, \cdots, k$.

(H3) There exists a constant K such that, for $i = 1, \cdots, k$, $|\tilde{\phi}_i(t, y, w)| \leqq K$ whenever $(t, y, w) \in \mathbb{R} \times X_t^i \times U_t^i$ and

(H4) $$|\tilde{\phi}_i(t, y, w) - \tilde{\phi}_i(t, y', w)| \leqq K|y - y'|$$
whenever $(t, y, w), (t, y', w) \in \mathbb{R} \times X_t^i \times U_t^i$.

(H5) f is locally Lipschitz continuous.

We now state a version of the optimal multiprocess maximum principle particularly suited to the applications to follow. Here, the functions H_i, $i = 1, \cdots, k$ are the Hamiltonian functions

$$H_i(t, x, u, p, \lambda) := p \cdot \phi_i(t, x, u) - \lambda L_i(t, x, u).$$

THEOREM 3.1. *Let $\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}$ be an optimal multiprocess. Suppose that*

$$\text{graph}\,\{x_i(\cdot)\} \subset \text{interior}\,\{X^i\},$$

for $i = 1, \cdots, k$, and that hypotheses (H1)-(H5) *are satisfied. Then there exist a real number λ equal to zero or one, real numbers h_0^i, h_1^i, $i = 1, \cdots, k$, and absolutely continuous*

functions $p_i(\cdot):[T_0^i, T_1^i]\to\mathbb{R}^{n_i}$, $i=1,\cdots,k$, *such that* $\lambda+\sum_i|p_i(T_1^i)|>0$,

$$-\dot{p}_i(t)\in\partial_x H_i(t, x_i(t), u_i(t), p_i(t), \lambda), \qquad \text{a.e. } t\in[T_0^i, T_1^i],$$

$$H_i(t, x_i(t), u_i(t), p_i(t), \lambda)=\max_{w\in U_t^i} H_i(t, x_i(t), w, p_i(t), \lambda), \quad \text{a.e. } t\in[T_0^i, T_1^i],$$

$$h_0^i\in \operatorname{co}\operatorname*{ess}_{t\to T_0^i}\left[\sup_{w\in U_t^i} H_i(t, x_i(T_0^i), w, p_i(T_0^i), \lambda)\right],$$

$$h_1^i\in \operatorname{co}\operatorname*{ess}_{t\to T_1^i}\left[\sup_{w\in U_t^i} H_i(t, x_i(T_1^i), w, p_i(T_1^i), \lambda)\right],$$

for $i=1,\cdots$ *and*

$$\{-h_0^i, h_1^i, p(T_0^i), -p(T_1^i)\}\in N_\Lambda+\lambda\,\partial f.$$

The normal cone N_Λ *and the generalized gradient* ∂f *are evaluated at the point* $\{T_0^i, T_1^i, x(T_0^i), x(T_1^i)\}$.

Theorem 3.2 of [6] addresses optimal multiprocess problems with no integral cost terms and it incorporates a transversality condition expressed in terms of the generalized gradient of the distance function from Λ, ∂d_Λ. The Maximum Principle, Theorem 3.1, is derived from Theorem 3.2 of [6] by a componentwise application of the standard state augmentation techniques of optimal control theory, and by noting the inclusion

$$\bigcup_{\alpha\geqq 0}\alpha\,\partial d_\Lambda\subset N_\Lambda,$$

which follows from (2.1).

We conclude this section with a result that extends to multiprocesses the fact (familiar in the single process case) that for autonomous problems the Hamiltonian is constant. The problem (P) is autonomous when the functions ϕ_i and L_i have no dependence on t, and when the control set U_t^i is the same set U_0^i for all t.

COROLLARY 3.1. *Under the hypotheses of Theorem* 3.1, *when in addition* (P) *is autonomous, then the conclusions of the theorem can be supplemented by the following. For each* i, *there is a constant* h^i *such that* $h_0^i=h_1^i=h^i$ *and*

$$h^i=\sup_{w\in U_0^i} H_i(x_i(t), w, p_i(t), \lambda) \quad \textit{for all } t \textit{ in } [T_0^i, T_1^i].$$

We shall merely sketch the proof, which parallels closely that of Theorem 3.6.1 of [4]. We introduce new (additional) control variables v_i (joining w_i) and state variables z_i (joining y_i) ($i=1, 2,\cdots, k$), together with the following modified dynamics:

$$\dot{y}_i=(1+v_i)\phi_i(y_i, w_i), \qquad \dot{z}_i=(1+v_i).$$

The control components v_i are constrained to $[-\varepsilon, \varepsilon]$, where ε is a small positive number. With the help of these additional variables we define a new multiprocess problem ($\tilde{\text{P}}$) in terms of states (z_i, y_i) and controls (v_i, w_i) for which each of the k components evolves on the fixed time interval $[T_0^i, T_1^i]$, and in which the quantity

$$f(\{z_i(T_0^i), z_i(T_1^i), y_i(T_0^i), y_i(T_1^i)\})$$

is to be minimized. The corresponding endpoint constraint set $\tilde{\Lambda}$ is given by

$$\tilde{\Lambda}=\{\{\tau_0^i, \tau_1^i, z_0^i, y_0^i, z_1^i, y_1^i\}: \tau_0^i=T_0^i, \tau_1^i=T_1^i, \{z_0^i, z_1^i, y_0^i, y_1^i\}\in\Lambda\}.$$

We note that the state-control components

$$\{\{z_i\equiv t), x_i, (v_i\equiv 0), u_i\}$$

are admissible for the new problem ($\tilde{\text{P}}$). In fact, a standard use of the "Erdmann transformation" (see [4, § 3.6]) shows that (for ε small) this new multiprocess is optimal

for $(\tilde{P})$. On applying Theorem 3.1, we deduce the existence of certain adjoint variables (q_i, p_i), where the q_i are (scalar) constants and where the p_i satisfy the required adjoint equation. The maximization condition is seen to assert that, almost everywhere, the function

$$(v, w) \to (1+v)\{H_i(x_i(t), w, p_i(t), \lambda) + q_i\}$$

is maximized over $[-\varepsilon, \varepsilon] \times U_0^i$ at $(v, w) = (0, u_i(t))$. It follows that for all $t \in [T_0^i, T_1^i]$ we have

$$-q_i = \max_{w \in U_0^i} H_i(x_i(t), w, p_i(t), \lambda),$$

and that the constant h^i in the statement of the corollary may be taken to be $-q_i$. The transversality conditions for $(\tilde{P})$ translate directly to the requisite ones for (P). Finally, we need to confirm that if λ is zero, then $\sum_i \| p_i(T_1^i) \|$ is not. Suppose to the contrary that both vanish. It follows then from the equation above that q_i is zero for each i, contradicting the known fact that (when $\lambda = 0$) $\sum_i \| (p_i(T_1^i), q_i) \|$ is positive.

4. The free time optimal control problem. In the case that the integer $k = 1$, the optimal multiprocess problem can be expressed as follows:

$$\text{minimize} \quad \int_a^b L(t, x(t), u(t))\, dt + f(a, b, x(a), x(b))$$

subject to

(E1)
$$\begin{aligned} &\dot{x}(t) = \phi(t, x(t), u(t)) && \text{a.e. } t \in [a, b], \\ &u(t) \in U_t && \text{a.e. } t \in [a, b], \\ &x(t) \in X_t && \text{for all } t \in [a, b], \\ &(a, b, x(a), x(b)) \in C. \end{aligned}$$

(We have written L in place of L_1, etc.)

Here we recognize a version of the free time optimal control problem. Necessary conditions for solutions to free time optimal control problems date back to the work of Pontryagin and his associates in the 1950s [18], their applicability has been extended by a number of authors [9], [24], [17], [4] and they feature in many expository accounts of optimal control theory. In these optimality conditions, the maximum principle for the fixed time problem is supplemented by a boundary condition on the Hamiltonian function $H := p \cdot \phi - \lambda L$ evaluated along the optimal process $(x^*(\cdot), u^*(\cdot))$ and costate function:

$$t \to \max_{w \in U_t} H(t, x^*(t), w, p(t), \lambda).$$

The hypotheses under which this extra condition has been proved require, at the very least, the Hamiltonian function to be continuous in some sense at the optimal endtimes. (See, e.g., [2] or [7].) Now optimal control problems arise where, possibly as a result of an instantaneous change in an exogeneous input, the data is discontinuous in the time variable. This accounts for developments in fixed time optimal control theory in which the smoothness hypotheses in [18], regarding time dependence, are relaxed to measurability (see, e.g., [2], [9], [4]). The reasons for treating free time problems with data merely measurable in the time variable are as cogent, yet a maximum principle for a general class of problems having this feature has until now been lacking. This omission is remedied by the following theorem. As usual H denotes the Hamiltonian function

$$H(t, x, u, p, \lambda) = p \cdot \phi(t, x, u) - \lambda L(t, x, u).$$

THEOREM 4.1. *Let* $(a^*, b^*, x^*(\cdot), u^*(\cdot))$ *solve problem* (E_1). *Assume the following*:

- *For each* $y \in \mathbb{R}^n$, $\phi(\cdot, y, \cdot)$ *is* $\mathcal{L} \times \mathcal{B}$ *measurable.*
- $U \subset \mathbb{R} \times \mathbb{R}^m$ *is Borel measurable.*

There exists a constant K *such that*

- $|\phi(t, y, w)| \leqq K$ *whenever* $(t, y, w) \in \mathbb{R} \times X_t \times U_t$, *and*
- $|\phi(t, y, w) - \phi(t, y', w)| \leqq K|y - y'|$ *whenever* $(t, y, w), (t, y', w) \in \mathbb{R} \times X_t \times U_t$,

and

$$\text{graph}\,\{x^*(\cdot)\} \subset \text{interior}\,\{X\}.$$

Then there exist real numbers h_0, h_1, *and* λ $(\lambda = 0$ *or* $1)$ *and an absolutely continuous function* $p(\cdot) : [a^*, b^*] \to \mathbb{R}^n$ *such that* $\lambda + |p(b^*)| > 0$,

$$-\dot{p}(t) \in \partial_x H(t, x^*(t), u^*(t), p(t), \lambda) \quad \text{a.e. } t \in [a^*, b^*],$$

$$H(t, x^*(t), u^*(t), p(t), \lambda) = \max_{w \in U_t} H(t, x^*(t), w, p(t), \lambda) \quad \text{a.e. } t \in [a^*, b^*],$$

$$h_0 \in \text{co ess}_{t \to a^*} \left[\sup_{w \in U_t} H(t, x(a^*), w, p(a^*), \lambda) \right],$$

$$h_1 \in \text{co ess}_{t \to b^*} \left[\sup_{w \in U_t} H(t, x(b^*), w, p(b^*), \lambda) \right],$$

$$(-h_0, h_1, p(a^*), -p(b^*)) \in N_C + \lambda\, \partial f,$$

where the normal cone N_C *and the generalized gradient* ∂f *are evaluated at* $(a^*, b^*, x(a^*), x(b^*))$.

Example. A problem in production planning illustrates application of the new maximum principle for free time problems:

$$\text{minimize} \quad -g(T, x(T)) + \int_0^T \alpha(t) u(t)\, dt$$

subject to

$$(E_1)' \qquad \dot{x}(t) = -x(t) + u(t) \quad \text{a.e. } t \in [0, T],$$

$$x(0) = 0,$$

$$u(t) \in [0, 1] \quad \text{a.e. } t \in [0, T].$$

Here $g : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is a given continuously differentiable function and the function α is taken to be

$$\alpha(t) = \begin{cases} 0.5 & \text{if } 0 \leqq t \leqq 2, \\ \bar{\alpha} & \text{if } 2 < t. \end{cases}$$

The termination time T is a choice variable, constrained to satisfy $0 \leqq T \leqq \bar{T}$. ($\bar{T} > 2$ is a given constant.)

An interpretation of this problem is as follows. Money is borrowed and invested in production. The sum borrowed at time t, $u(t)$, is constrained: $0 \leqq u(t) \leqq 1$. The interest rate is $\alpha(t) = 0.5$ up to time $t = 2$, when it jumps to the punitive level $\bar{\alpha}$. $x(t)$ represents the amount of product available for sale at time t. Production is terminated at time $t = T$, and a gross profit $g(T, x(T))$ is realised. We aim to maximize net profit over the class of borrowing policies $\{u(t): 0 \leqq t \leqq T\}$. Net profit is clearly expressible as the negative of the cost function. The purpose of the high interest rate $\bar{\alpha}$ is to discourage borrowing after time $t = 2$. We might ask then how high must $\bar{\alpha}$ be set to make production unprofitable after time $t = 2$? Theorem 4.1 supplies a condition on the value of $\bar{\alpha}$ for $T = 2$ to be an optimal termination time. To state this we define a

process $\{(x(t), u(t)), 0 \leqq t \leqq T\}$ to be an extremal on $[0, T]$ when there exists an absolutely continuous function $p(\cdot)$ on $[0, T]$ such that

$$\begin{aligned}
&\dot{x}(t) = -x(t) + u(t) \quad \text{a.e. } t \in [0, T],\\
&x(0) = 0,\\
&\dot{p}(t) = p(t) \qquad\qquad \text{a.e. } t \in [0, T],\\
&p(T) = g_x(T, x(T)),\\
&u(t) = \begin{cases} 1 & \text{if } p(t) - \alpha(t) > 0 \quad \text{a.e. } t \in [0, T],\\ 0 & \text{otherwise.} \end{cases}
\end{aligned}$$

In applying Theorem 4.1 we have in the present case

$$f(\tau_0, \tau_1, x_0, x_1) = -g(\tau_1, x_1), \qquad C = \{0\} \times [0, \bar{T}] \times \{0\} \times \mathbb{R}.$$

It is a simple matter to deduce the following proposition.

PROPOSITION 4.2. *Suppose there exists a minimizing process for problem* $(E_1)'$ *with termination time* $T = 2$. *Then there exists an extremal* $\{(x(t), u(t)), 0 \leqq t \leqq 2\}$ *on* $[0, 2]$ *such that*

$$g_x x(2) - g_T \in [0, \infty) \cap [g_x - \bar{\alpha}, g_x - 0.5]. \tag{4.1}$$

In this last inclusion the partial derivatives g_T and g_x are evaluated at $(T, x) = (2, x(2))$. Condition (4.1) is the new information provided by Theorem 4.1 beyond the content of the classical maximum principle; it corresponds to the part of the transversality condition involving the essential value h_1.

It is of interest to examine how closely the inclusion (4.1) captures the range of $\bar{\alpha}$ values for which $T = 2$ is an optimal termination point. To do this we specialize somewhat and consider a particular function $g(T, x)$:

$$g(T, x) = Tx \quad \text{for all } T \geqq 0, \quad x \in \mathbb{R}. \tag{4.2}$$

For each $T \geqq 0$, let us denote by $E_1'(T)$ a variant of $(E_1)'$ in which T is treated as a fixed parameter. For each $T \geqq 0$ we can determine the process that satisfies the necessary conditions for optimality of the fixed time maximum principle (there is just one such process). But $E_1'(T)$ can be shown to have a solution and consequently the process so derived actually solves it. Substituting back into the cost function we obtain a formula for the value function $\eta(T)$, relative to T, namely

$$\eta(T) = \min E_1'(T), \qquad T \geqq 0.$$

We find the following:

(a) If $\bar{\alpha} > 2$ and $|T - 2|$ is small enough

$$\eta(T) = \begin{cases} -Te^{-(T-2)} + 0.5[1 - \ln(0.5/T)] - 0.5(T-2) & \text{for } T > 2,\\ -T + 0.5[1 - \ln(0.5/T)] & \text{for } T \leqq 2. \end{cases}$$

(b) If $\bar{\alpha} \leqq 2$ and $|T - 2|$ is small enough

$$\eta(T) = \begin{cases} -T + 0.5[\ln(0.5/T)] + (\bar{\alpha} - 0.5)(T-2) & \text{for } T > 2,\\ -T + 0.5[1 - \ln(0.5/T)] & \text{for } T \leqq 2. \end{cases}$$

The value function η has left and right derivatives of all orders at $T = 2$. These are easily calculated. Of interest are the following:

$$\begin{aligned}
&D^-\eta(T=2) = -0.75\\
&D^+\eta(T=2) = \begin{cases} -0.75 & \text{if } \bar{\alpha} > 2,\\ -1.25 + \bar{\alpha} & \text{if } \bar{\alpha} \leqq 2, \end{cases}\\
&(D^+)^2\eta(T=2) = -0.25 \quad \text{if } \bar{\alpha} = 1.25.
\end{aligned}$$

It is clear from these values that $T=2$ *is a local minimum of* η *if and only if* $\bar{\alpha}>1.25$.

We return now to the condition on $\bar{\alpha}$ provided by the free time maximum principle. If $\{x(t), u(t); 0\leqq t\leqq 2\}$ is the extremal on $[0, 2]$ of Proposition 4.2, then it is easy to show that $x(2)=0.75$.

The inclusion now becomes $1.5-0.75\in[0,\infty)\cap[2-\bar{\alpha}, 2-0.5]$, i.e., $2-\bar{\alpha}\leqq 0.75\leqq 1.5$ or $\bar{\alpha}\geqq 1.25$.

Comparing this inequality with our findings from calculating the value function, we see that the free time maximum principle provides a rather precise estimate, namely $[1.25,\infty)$, of the set $(1.25,\infty)$ of $\bar{\alpha}$ values for which borrowing a short time after time $t=2$ is unprofitable. It fails to catch the point $\bar{\alpha}=1.25$ since if $\bar{\alpha}=1.25$ profits can be increased by overrunning the time $t=2$ can be ascertained only from second-order properties of the value function, and the maximum principle is a first-order optimality condition.

This example draws attention to the fact that even if data associated with a class of free time problems is discontinuous in the time variable at just one point, instances when this point is the optimal termination time are hardly anomalous. Indeed this is the case for a whole range of values of $\bar{\alpha}$. We see also that the information supplied by the new free time maximum principle can be rather precise in such circumstances.

Suppose there is an optimal process for problem $(E_1)'$, with termination time $T=2$. Limiting attention to the particularly simple terminal cost term (4.2), we find that information present in the free time maximum principle regarding the optimal free time amounts to

$$0\in\partial\eta(T=2), \tag{4.3}$$

i.e., $T=2$ is a stationary point of the value function. We emphasize however that condition (4.1) from the free time maximum principle supplies information about optimal processes even when we cannot derive a convenient formula for the value function and use inclusion (4.3) directly.

5. Impulse control. In this section we derive from Theorem 3.1 a maximum principle for optimal impulse control problems of the following form:

$$\text{minimize}\quad g(a, x(a), \tau, x(\tau^-), x(\tau^+), b, x(b))+\int_a^b L(t, x(t), u(t))\,dt$$

subject to

$$(E_2)\qquad \begin{aligned} &\dot{x}(t)=\phi(t, x(t), u(t)) && \text{a.e. } t\in[a, b],\\ &u(t)\in U_t && \text{a.e. } t\in[a, b],\\ &x(t)\in X_t && \text{for all } t\in[a, b],\\ &(a, x(a), \tau, x(\tau^-), x(\tau^+), b, x(b))\in C. \end{aligned}$$

Here, $L:\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^m\to\mathbb{R}$, $\phi:\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^m\to\mathbb{R}^n$ and $g:(\mathbb{R}\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{R}^n)\to\mathbb{R}$ are given functions and $U\subset\mathbb{R}\times\mathbb{R}^m$, $X\subset\mathbb{R}\times\mathbb{R}^m$ and $C\subset\{((t_1, x_1), (t_2, x_2^-, x_2^+), (t_3, x_3))\,|\,t_1\leqq t_2\leqq t_3\}$ are given sets.

Minimization is conducted over elements

$$\{a, \tau, b, x(\cdot):[a, b]\to\mathbb{R}^n, u(\cdot):[a, b]\to\mathbb{R}^m\}$$

in which a, τ and b are numbers that satisfy $a\leqq\tau\leqq b$, $x(\cdot)$ is a function whose restrictions to $[a, \tau)$ and $(\tau, b]$ are absolutely continuous, and $u(\cdot)$ is a measurable

function. The state $x(t)$ is permitted to jump at time $t=\tau$. The departure and arrival states are denoted by $x(\tau^-), x(\tau^+)$:

$$x(\tau^-) := \begin{cases} \lim_{s\uparrow\tau} x(s) & \text{if } \tau > a, \\ x(a) & \text{if } \tau = a, \end{cases}$$

and

$$x(\tau^+) := \begin{cases} \lim_{s\downarrow\tau} x(s) & \text{if } \tau < b, \\ x(b) & \text{if } \tau = b. \end{cases}$$

We write $H = p\cdot\phi - \lambda L$.

THEOREM 5.1. *Let* $\{a^*, \sigma, b^*, x^*(\cdot), u^*(\cdot)\}$ *solve problem* (E_2). *Assume that hypotheses* (H1)-(H4) *of* § 3 *are satisfied when we substitute* ϕ, L, U *and* X *in place of* ϕ^i, L^i U^i *and* X^i. *Suppose also that* g *is locally Lipschitz continuous,* C *is closed, and there exists* $\varepsilon > 0$ *such that*

$$\text{graph}\,\{x^*(\cdot)\} + \varepsilon B \subset X.$$

Then there exist numbers $\alpha, \beta^-, \beta^+, \gamma,$ *and* λ $(\lambda \geqq 0)$ *and a function* $p(\cdot):[a^*, b^*]\to\mathbb{R}^n$ *such that the restrictions of* $p(\cdot)$ *to* $[a^*, \sigma)$ *and* $(\sigma, b^*]$ *are absolutely continuous,* $\lambda + |p(\cdot)|_{L_1} \neq 0$,

$$-\dot{p}(t) \in \partial_x H(t, x^*(t), u^*(t), p(t), \lambda) \quad \text{a.e. } t\in[a^*, b^*],$$

$$H(t, x^*(t), u^*(t), p(t), \lambda) = \max_{w\in U_t} H(t, x^*(t), u^*(t), w, p(t), \lambda) \quad \text{a.e. } t\in[a^*, b^*],$$

$$\alpha \in \text{co}\,\operatorname*{ess}_{t\to a^*} \mathcal{H}(t, x^*(a^*), p(a^*)), \qquad \beta^- \in \text{co}\,\operatorname*{ess}_{t\to\sigma} \mathcal{H}(t, x^*(\sigma^-), p(\sigma^-)),$$

$$\beta^+ \in \text{co}\,\operatorname*{ess}_{t\to\sigma} \mathcal{H}(t, x^*(\sigma^+), p(\sigma^+)), \qquad \gamma \in \text{co}\,\operatorname*{ess}_{t\to b^*} \mathcal{H}(t, x^*(b^*), p(b^*)),$$

$$(-\alpha, p(a^*), -(\beta^+ - \beta^-), -p(\sigma^-), p(\sigma^+), \gamma, -p(b^*)) \in N_C + \lambda\,\partial g.$$

Here $\mathcal{H}(t, x, p) := \sup_{w\in U_t} H(t, x, w, p, \lambda)$. *The normal cone* N_C *and generalized gradient* ∂g *are evaluated at*

$$(a^*, x^*(a^*), \sigma, x^*(\sigma^-), x^*(\sigma^+), b^*, x^*(b^*)).$$

Observe that problem (E_2) can be reformulated as an optimal multiprocess problem as in § 3. Two component processes are involved, associated with the restrictions of the control function and state trajectory to either side of the jump time τ. The dynamics and state and control constraints are the same as those in problem (E_2) for both component processes. The fact that the component processes are concatenated is taken account of by choosing the set Λ in problem (P) of § 3 to be

$$\Lambda = \{\{\tau_0^i, \tau_1^i, x_0^i, x_1^i\} \mid \tau_1^1 = \tau_0^2 \text{ and } (\tau_0^1, x_0^1, \tau_1^1, x_1^1, x_0^2, \tau_1^2, x_1^2) \in C\}. \tag{5.1}$$

The assertions of Theorem 5.1 follow now from application of Theorem 3.1, in which the optimal multiprocess considered is that associated with $\{a^*, \sigma, b^*, x^*(\cdot), u^*(\cdot)\}$. Bearing in mind the special structure of Λ (see (5.1)), we obtain the transversality condition by an application of Proposition 2.1(i), and by observing that the function g in the cost function can be assumed to have values that do not depend on the τ_1^1 variable.

Let us consider a special case, where the conditions in Theorem 5.1 simplify considerably. The problem in question is one where the underlying time interval $[a, b]$, is fixed and where it is the jump vector, $x(\tau^+) - x(\tau^-)$, rather than the departure and

arrival states of the jump, $x(\tau^+)$ and $x(\tau^-)$, which feature explicitly in the cost and constraints:

$$\text{minimize} \qquad g_1(x(a), x(b)) + \mathscr{K}(\tau, x(\tau^+) - x(\tau^-)) + \int_a^b L(t, x(t), u(t))\, dt$$

$$(E_3) \quad \text{subject to } \dot{x} = \phi, \quad u(t) \in U_t, x(t) \in X_t,$$

$$(x(a), x(b)) \in C_1, (\tau, x(\tau^+) - x(\tau^-)) \in C_2, \qquad a \leqq \tau \leqq b.$$

Let $\{\tau = \sigma, x^*(\cdot), u^*(\cdot)\}$ solve problem (E_3). It is assumed that the data of problem (E_3) satisfies the hypotheses of Theorem 5.1, when viewed as a special case of problem (E_2).

Applying Theorem 5.1, and taking note of Proposition 2.1(ii), we can show the following corollary.

COROLLARY 5.2. *Take* $\{\tau = \sigma, x^*(\cdot), u^*(\cdot)\}$ *as above. Then, under the stated hypotheses, there exists an absolutely continuous function* $p(\cdot): [a, b] \to \mathbb{R}^n$ *and* $\lambda \geqq 0$ $(\lambda + \| p(1) \| \neq 0)$ *such that*

$$(5.2) \qquad -\dot{p}(t) \in \partial_x H(t, x^*(t), u^*(t), p(t), \lambda) \quad \text{a.e.},$$

$$(5.3) \qquad H(t, x^*(t), u^*(t), p(t), \lambda) = \max_{v \in U_t} H(t, x^*(t), v, p(t), \lambda) \quad \text{a.e.},$$

$$(5.4) \qquad (p(a), -p(b)) \in N_{C_1}(x^*(a), x^*(b)) + \lambda\, \partial_{g_1}(x^*(a), x^*(b)),$$

$$(5.5) \qquad (\beta^+ - \beta^-, p(\sigma)) \in N_{C_2}(\sigma, x^*(\sigma^+) - x^*(\sigma^-)) + \lambda\, \partial \mathscr{K}(\sigma, x^*(\sigma^+) - x^*(\sigma^-))$$

where

$$\beta^- \in \operatorname{co} \operatorname*{ess}_{t \to \sigma} \mathscr{h}(t, x^*(\sigma^-), p(\sigma)) \quad \text{and} \quad \beta^+ \in \operatorname{co} \operatorname*{ess}_{t \to \sigma} \mathscr{h}(t, x^*(\sigma^+), p(\sigma)).$$

(H and $\mathscr{h}$ were defined in, and preceding, the statement of Theorem 5.1).

We recognize in these optimality conditions the assertions of the standard maximum principle for fixed time problems involving an absolutely continuous costate function $p(\cdot): [a, b] \to \mathbb{R}^n$, namely (5.2)-(5.4), supplemented by certain information concerning the jump, namely (5.5). In the case that the function $\mathscr{h}$ is continuous, $C_2 = \mathbb{R} \times \mathbb{R}^n$ and $\mathscr{K} \equiv 0$, for instance, this takes the form

$$p(\sigma) = 0$$

and

$$\sup_w H(\sigma, p(\sigma), x^*(\sigma^+), w, \lambda) = \sup_w H(\sigma, p(\sigma), x^*(\sigma^-), w, \lambda).$$

For simplicity of exposition so far we have considered impulse control problems involving at most one jump. As a simple corollary of Theorem 5.1 we also obtain optimality conditions for a problem similar to (E_2), but where we permit jumps at (at most) k times τ_i, $i = 1, \cdots, k$. These jump times are choice variables that, along with the endpoints of the state trajectories and their values near the jump times, are constrained according to

$$(a, x(a), \{\tau_i, x(\tau_i^-), x(\tau_i^+)\}, b, x(b)) \in \tilde{C}$$

and enter into the cost through a term:

$$\tilde{g}(a, x(a), \{\tau_i, x(\tau_i^-), x(\tau_i^+)\}, b, x(b)).$$

(Note that cases where there are less than k jumps are accommodated since we permit $\tau_i^- = \tau_i^+$ for some i.) We will call such problems general impulse control problems. Let $(a = a^*, b = b^*, \{\tau_i = \sigma_i\}, x(\cdot), u(\cdot))$ solve the general impulse control problem. Then conditions are satisfied similar to those in Theorem 5.1, except that now the costate function $p(\cdot)$ may jump at times τ_i, $i = 1, \cdots, k$ and the transversality condition takes the form

$$(-\alpha, p(a^*), \{-(\beta_i^+ - \beta_i^-), -p(\sigma_i^-), p(\sigma_i^+)\}, \gamma, -p(b^*)) \in N_{\tilde{C}} + \lambda\, \partial \tilde{g}$$

in which

$$\beta_i^- \in \operatorname{co} \operatorname*{ess}_{t \to \sigma_i} \mathcal{H}(t, x^*(\sigma_i^-), p(\sigma_i^-)) \quad \text{and} \quad \beta_i^+ \in \operatorname{co} \operatorname*{ess}_{t \to \sigma_i} \mathcal{H}(t, x^*(\sigma_i^+), p(\sigma_i^+)), \qquad i = 1, \cdots, k.$$

Impulse control problems of the type studied here arise in, for example, operations research and production planning (see [10]) and have been the subject of earlier research. Previous work has been directed for the most part at characterization of optimal processes in terms of solutions to a Hamilton-Jacobi equation [1] and [10]. By contrast, we provide *necessary conditions* of optimality in the form of a maximum principle.

It is true that there is an existing necessary conditions literature for optimal control problems where the state trajectories are permitted to be functions of bounded variation. This is an outgrowth of certain problems in flight mechanics and investment planning. The state trajectories in question are associated with generalized control functions that are measures (see, e.g., [19], [20], [23] and [24]). The formulation employed in such work is suited to problems where the number of jumps is unbounded and the cost and constraints are expressed in terms of such quantities as the total variation of the jumps. If specialized to apply to the kinds of problems addressed by Theorem 5.1 (and its multiple jump analogues), stringent additional hypotheses need to be made. We require the a priori information that the constraint on the number of jumps is nonbinding and the measures involved has no continuous singular component, and we also require that the cost on the jumps is expressible in terms of a positively homogeneous function of the jump vector.

Derivations of certain special cases of Theorem 5.1 and of its multiple jump counterpart, together with some heuristic calculations, are to be found in [21] and [22] and the references therein. Recently Frankowska [8] has given necessary conditions for a class of multiple jump impulse control problems, in which the data is assumed continuous in the time variable.

6. Laws of reflection and refraction. Fermat's principle in optics identifies the path of a ray of light with an arc, joining the endpoints in question, along which light travels in minimum time. In the case of reflection, the minimum is with respect to arcs which visit the reflecting surface.

It is well known (see, e.g., [12]) that Fermat's principle predicts Snell's laws of reflection and refraction; namely, for reflection,

$$\theta_1 = \theta_2,$$

where θ_1 is the angle of incidence and θ_2 is the angle of reflection, and for refraction,

$$g_1 \sin \theta_1 = g_2 \sin \theta_2$$

where g_1 is the refractive index of the medium of the incident ray, θ_1 is the angle of incidence, g_2 is the refractive index of the medium of the refracted ray and θ_2 is the angle of refraction.

The traditional approach is to obtain a formula for the path that satisfies Fermat's principle and then to check Snell's laws directly. The minimization is carried out in two phases. Initially the point of incidence is fixed at an arbitrary value. The transit time is subsequently minimized over points of incidence. This approach, dependent as it is on obtaining a formula for the minimizing path, is very restrictive as far as permitted geometry of the boundary and variation of refractive index in the media is concerned.

The problem of predicting Snell's laws fits neatly into optimal multiprocess theory. We have here a dynamic optimization problem that breaks into two regimes connected at the point of incidence.

We shall find that optimal multiprocess theory predicts a version of Snell's law for a very large class of inhomogeneous media, and for interfaces Σ which are required to be merely closed sets.

The following data is given:

$$\text{functions } g_1 : \mathbb{R}^n \to \mathbb{R}, \qquad g_2 : \mathbb{R}^n \to \mathbb{R},$$

a closed set Σ and points x_0, x_1 in $\mathbb{R}^n$. It is assumed that g_1 and g_2 are locally Lipschitz continuous, and have values everywhere greater than zero.

Consider the following optimization problem:

$$\text{minimize } \int_0^\tau g_1(y(\sigma))\, d\sigma + \int_\tau^T g_2(y(\sigma))\, d\sigma$$

$$\text{subject to } 0 \leqq \tau \leqq T, \tag{E_4}$$

$$\dot{y}(\sigma) \in S \quad \text{a.e. } \sigma \in [0, T],$$

$$y(0) = x_0, \quad y(T) = x_1, \quad y(\tau) \in \Sigma.$$

Here the numbers τ and T, and the Lipschitz continuous function $y : [0, T] \to \mathbb{R}^n$ are the choice variables. S is the surface of the unit ball in $\mathbb{R}^n$.

In this problem we interpret the independent variable σ as arclength. Keeping in mind that the refractive index is the reciprocal of the speed of light, we recognize the cost function as the transit time through two adjoining media. The constraint "$\dot{y}(\sigma) \in S$" simply corresponds to the well-known relationship between increments of the coordinate values and arclength along a curve, namely

$$\sum_i \left(\frac{dy_i}{d\sigma} \right)^2 = 1.$$

A version of Fermat's principle then is that the path of a ray of light is a minimizer for this problem. There is the implicit assumption in our formulation that if we fix the point of incidence at a minimizing value, then the segments of the path on the first and second sides are governed entirely by g_1 and g_2, respectively.

THEOREM 6.1. *Let* $((y : [0, T] \to \mathbb{R}^n), \tau, T)$ *be a solution to* (E_4) *and suppose that* $0 \leqq \tau < T$. *Then* $y(\cdot)$ *is continuously differentiable on* $[0, \tau)$ *and* (τ, T), *and* $\dot{y}(\cdot)$ *has left and right limits* $\dot{y}(\tau^-)$ *and* $\dot{y}(\tau^+)$ *at* τ. *We have, either*

$$g_1(y(\tau)) = g_2(y(\tau)) \quad \textit{and} \quad \dot{y}(\tau^-) = \dot{y}(\tau^+),$$

or there exists some nonzero vector $d \in N_\Sigma(y(\tau))$ *such that both conditions* (i) *and* (ii) *below are satisfied*:

(i) $$\dot{y}(\tau^+) \in \text{span}\,\{\dot{y}(\tau^-), d\},$$

(ii) $$g_1(y(\tau)) \sin \theta_1 = g_2(y(\tau)) \sin \theta_2,$$

where

$$\theta_1 = \cos^{-1}\left(\frac{d \cdot \dot{y}(\tau^-)}{\|d\|\,\|\dot{y}(\tau^-)\|}\right) \quad \textit{and} \quad \theta_2 = \cos^{-1}\left(\frac{d \cdot \dot{y}(\tau^+)}{\|d\|\,\|\dot{y}(\tau^+)\|}\right).$$

In this theorem, θ_1 (respectively, θ_2) will be recognized as the angle between the tangent vector to the incoming (respectively, outgoing) ray at the point of incidence and the normal vector d.

When we treat refraction, we view $g_1(g_2)$ as the refractive index in the interior of the medium through which the incident (refracted) ray travels. The theorem also covers the phenomenon of reflection. Here we set $g_1 = g_2 (=: g)$. Since g is positive-valued, condition (ii) simply becomes

$$\theta_1 = \theta_2.$$

Proof. We may identify (E_4) with a multiprocess problem in which the two components are the state arc $y(\cdot)$ of (E_4) restricted to $[0, \tau]$ and to $[\tau, T]$, and in which Λ is the set

$$\{[0, \tau, x_0, y, \tau, T, y, x_1]: 0 \leqq \tau \leqq T, y \in \Sigma\}.$$

Now apply the corollary to Theorem 3.1. Since the component processes are concatenated, the necessary conditions can be considered as expressed in terms of a cost multiplier $\lambda \geqq 0$ and a *single* function $p(\cdot):[0, T] \to \mathbb{R}^n$, both of which do not vanish. We see that the following conditions are satisfied:

$$\begin{aligned} &\|p(t)\| - \lambda g_1(y(t)) = 0, \qquad t \leqq t < \tau, \\ &\|p(t)\| - \lambda g_2(y(t)) = 0, \qquad \tau < t \leqq T, \end{aligned} \tag{6.1}$$

$$p(t) \cdot u(t) = \max\{p(t) \cdot v \mid \|v\| = 1\} \quad \text{a.e. } t \in [0, T] \tag{6.2}$$

(both (6.1) and (6.2) follow from the "maximization of the Hamiltonian" condition and the fact that h_1^2 is zero)

$$((-p(\tau^-), p(\tau^+)) \in N_{\tilde{\Sigma}}(y(\tau), y(\tau)) \tag{6.3}$$

(the transversality condition). Here $p(\tau^-)$ and $p(\tau^+)$ are the limits of the function $p(\cdot)$ from the left and the right, respectively. The set $\tilde{\Sigma}$ is

$$\tilde{\Sigma} := \{(a, a): a \in \Sigma\}.$$

We must have $\lambda \neq 0$ since otherwise $p(\cdot) \equiv 0$ by (6.1) in violation of the nontriviality of the multipliers. Then we are permitted to set $\lambda = 1$. By hypothesis, $g_1, g_2 \geqq \varepsilon$ for some $\varepsilon > 0$. In view of (6.1), $\|p(t)\| \geqq \varepsilon$ a.e. By continuity then, $p(\tau^-), p(\tau^+)$ and $p(t), t \in [0, T] \backslash \{\tau\}$ are all nonzero.

From (6.2)

$$u(t) = p(t)/\|p(t)\| \quad \text{a.e. } t \in [0, T].$$

Since the function on the right-hand side is continuous at all points in $[0, T] \backslash \tau$ and has left and right limits at τ, and since $y(\cdot)$ is Lipschitz continuous and satisfies $\dot{y}(t) = u(t)$ almost everywhere, it follows that $y(\cdot)$ is continuously differentiable on $[0, \tau)$ and $(\tau, T]$, and that $\dot{y}(\cdot)$ has left and right limits, $\dot{y}(\tau^-)$ and $\dot{y}(\tau^+)$, at τ given by

$$\dot{y}(\tau^-) = \frac{p(\tau^-)}{\|p(\tau^-)\|} \quad \text{and} \quad \dot{y}(\tau^+) = \frac{p(\tau^+)}{\|p(\tau^+)\|}. \tag{6.4}$$

By (6.3) and Proposition 2.1(i) however

$$-p(\tau^-)+p(\tau^+)=d \tag{6.5}$$

for some $d \in N_\Sigma(y(\tau))$.

We deduce from (6.1) and the continuity properties of y, p, g_1 and g_2 that

$$\|p(\tau^-)\| = g_1(y(\tau)) \quad \text{and} \quad \|p(\tau^+)\| = g_2(y(\tau)).$$

It now follows from (6.4) and (6.5) that

$$g_2(y(\tau))\dot{y}(\tau^+) - g_1(y(\tau))\dot{y}(\tau^-) = d. \tag{6.6}$$

Since $g_2 > 0$ by hypothesis, we deduce that

$$\dot{y}(\tau^+) \in \text{span}\,\{\dot{y}(\tau^-), d\}.$$

It is now convenient to consider two cases.

First suppose $d = 0$. Taking norms across (6.6) we deduce $g_2(y(\tau)) = g_1(y(\tau))$. A further appeal to (6.6) yields the information $\dot{y}(\tau^+) = \dot{y}(\tau^-)$, in accordance with the theorem.

The remaining case is $d \neq 0$. We deduce from (6.6) that

$$g_1(y(\tau))\left[\dot{y}(\tau^-) - \frac{(\dot{y}(\tau)\cdot d)}{\|d\|^2}d\right] = g_2(y(\tau))\left[\dot{y}(\tau^+) - \frac{(\dot{y}(\tau^+)\cdot d)}{\|d\|^2}d\right],$$

i.e.,

$$g_1(y(\tau))\pi^- = g_2(y(\tau))\pi^+ \tag{6.7}$$

where π^- and π^+ are the projections of the vectors $\dot{y}(\tau^-)$ and $\dot{y}(\tau^+)$, respectively, onto the subspace in $\mathbb{R}^n$ orthogonal to the vector d. Since $\dot{y}(\tau^-)$ and $\dot{y}(\tau^+)$ have unit length

$$\|\pi^-\| = \sin\theta_1 \quad \text{and} \quad \|\pi^+\| = \sin\theta_2$$

where

$$\theta_1 = \cos^{-1}\frac{\dot{y}(\tau^-)\cdot d}{\|d\|\,\|\dot{y}(\tau^-)\|} \quad \text{and} \quad \theta_2 = \cos^{-1}\frac{\dot{y}(\tau^+)\cdot d}{\|d\|\,\|\dot{y}(\tau^+)\|}.$$

These identities and (6.7) combine to complete the proof of the theorem.

7. Minimum time control for a robot arm. We pursue our investigations with a detailed analysis of a dynamic optimization problem in which the dynamical equations change at some time τ, where τ is a choice variable. The example is representative of a number of optimization problems having this feature that arise, for example, in the area of multistage rocket control [11], optimal investment [21], and plasma control [22]. We have chosen a relatively simple problem, and one for which an explicit solution may be found by other means, simply to illustrate the nature of the information that the theory of optimal multiprocesses supplies. The example of the next section (taken from renewable resource theory) is one in which explicit two-stage optimization is not available.

The problem is to control a robot arm so that it transfers an object from one location to another as quickly as possible. The mass of the object is comparable with that of the arm, with the result that different dynamical equations apply depending on whether or not the object is being carried.

We adopt a simple mathematical model, involving one spatial variable. The unit (the arm or the arm carrying the load) is initially at rest at the origin. It must be guided to location $x = L$, where it changes mass, and then back to rest at the origin again. A precise formulation is as follows (as usual τ^- and τ^+ will denote limits from the left and right at the point τ):

$$\text{minimize} \quad T$$

$$\text{subject to}$$

$$\ddot{x}(t) = \begin{cases} m_1^{-1}u(t), & 0 \leqq t < \tau \\ m_2^{-1}u(t), & \tau < t \leqq T \end{cases} \quad \text{a.e. } t \in [0, T],$$

$$u(t) \in [-1; +1] \quad \text{a.e. } t \in [0, T], \tag{E$_5$}$$

$$0 \leqq \tau \leqq T,$$

$$\dot{x}(\tau^+) = K\dot{x}(\tau^-),$$

$$x(\tau) = L,$$

$$x(0) = \dot{x}(0) = x(T) = \dot{x}(T) = 0.$$

Minimization is conducted over control policies that, in this instance, are taken to mean triples $(u(\cdot), \tau, T)$ in which τ, T are nonnegative numbers such that $0 \leqq \tau \leqq T$ and $u(\cdot)$ is a measurable function on $[0, T]$ taking values almost everywhere in $[-1, +1]$. The solution of the differential equation that satisfies the left-hand boundary condition is called the corresponding state trajectory. In this program, K, m_1, m_2 and L are positive constants. We shall treat the general problem but special cases of interest are the following:

Dropoff. $m_1 > m_2$, $K = 1$. A load is carried to location $x = L$ and dropped.

Hard pickup. $m_1 < m_2$, $K = m_1/m_2$. A load is picked up at location $x = L$. The load is at rest prior to pick up and the instantaneous change in velocity v of the unit is governed by the principle of conservation of momentum,

$$m_1 v(\tau^-) = m_2 v(\tau^+).$$

Soft pickup. $m_1 < m_2$, $K = 1$. This is the same as the hard pickup case, except that the load may be moving prior to pickup and we are free to choose its velocity at pickup, provided it is the same as that of the robot arm at that instant.

Concerning the solution of this problem, we have Proposition 7.1.

PROPOSITION 7.1. *There is a unique minimizing control policy* $(u^*(\cdot), \tau, T)$ *for problem* (E$_5$). *Let* $v = \dot{x}^*(\tau^-)$, *where* $x^*(\cdot)$ *is the state trajectory corresponding to this control policy. Then* v *is the unique solution of the equation*

$$\frac{m_1^2 v}{(m_1 L + \frac{1}{2}m_1^2 v^2)^{1/2}} + \frac{(Km_2)^2 v}{(m_1 L + \frac{1}{2}m_2^2 K^2 v^2)^{1/2}} = m_1 - Km_2, \tag{7.1}$$

and $(u^*(\cdot), \tau, T)$ *is expressed in terms of* v *according to*

$$T = (Km_2 - m_1)v + 2(m_1 L + \tfrac{1}{2}m_1^2 v^2)^{1/2} + 2(m_2 L + \tfrac{1}{2}m_2^2 K^2 v^2)^{1/2}, \tag{7.2}$$

$$\tau = -m_1 v + 2(m_1 L + \tfrac{1}{2}m_1^2 v^2)^{1/2}, \tag{7.3}$$

$$u^*(t) = \begin{cases} +1, & 0 \leqq t \leqq t_1. \\ -1, & t_1 < t < t_2, \\ +1, & t_2 \leqq t \leqq T. \end{cases} \tag{7.4}$$

In the formula for $u^*(\cdot)$, the switching times, t_1 and t_2, are

$$t_1 = (m_1 L + \tfrac{1}{2} m_1^2 v^2)^{1/2}, \tag{7.5}$$

$$t_2 = (Km_2 - m_1)v + 2(m_1 L + \tfrac{1}{2} m_1^2 v^2)^{1/2} + (m_2 L + \tfrac{1}{2} m_2^2 K^2 v^2)^{1/2}. \tag{7.6}$$

We note that, in the dropoff case, the object is dropped on the outward journey, when the velocity of the arm is positive. In the hard pickup case, the arm has zero velocity at pick up (thus, while impact with the object is permitted, it does not occur). Finally, for soft pickup, the arm picks up the object on the return journey to its starting position, when the velocity is negative.

Proof of Proposition 7.1. Following introduction of the state vector y with components (x, v), where x and v are the position and velocity of the arm, the problem takes the following form:

$$\text{minimize} \quad T$$

$$\text{subject to}$$

$$\dot{y} = \begin{cases} Ay(t) + b_1 u(t), & \text{a.e. } t \in [0, \tau), \\ Ay(t) + b_2 u(t), & \text{a.e. } t \in [\tau, T], \end{cases}$$

$$u(t) \in [-1, +1] \quad \text{a.e. } t \in [0, T], \tag{E_5)$'$}$$

$$0 \leqq \tau \leqq T,$$

$$x(0) = v(0) = x(T) = v(T) = 0,$$

$$x(\tau^+) = x(\tau^-),$$

$$v(\tau^+) = Kv(\tau^-).$$

Here,

$$A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad b_1 = \begin{bmatrix} 0 \\ m_1^{-1} \end{bmatrix}, \quad b_2 = \begin{bmatrix} 0 \\ m_2^{-1} \end{bmatrix}.$$

The problem is readily expressible as an optimal multiprocess problem, in which the component control functions are obtained by restricting the function $u(\cdot)$ in problem $(E_5)'$ to the intervals $[0, \tau]$ and $[\tau, T]$, and so on. Let $\{u^*(\cdot), \tau, T\}$ be an optimal control policy, and let $y^*(\cdot) = (x^*(\cdot), v^*(\cdot))$ be the corresponding trajectory. Enlisting the help of Proposition 2.1(i), in computing the normal cone, we make the following deductions from Theorem 3.1. There exist scalar valued functions $p(\cdot)$ and $q(\cdot)$ and a number $\lambda \geqq 0$, not all zero, such that the restrictions of $p(\cdot)$ and $q(\cdot)$ to the intervals $[0, \tau)$ and $(\tau, T]$ are Lipschitz continuous,

$$q(t)u^*(t) = \max_{u \in [-1, +1]} q(t)u, \quad \text{a.e. } t \in [0, T], \tag{7.7}$$

$$\dot{p}(t) = 0, \ \dot{q}(t) = -p(t) \qquad \text{a.e. } t \in [0, T],$$

$$p(\tau^-)v(\tau^-) + m_1^{-1}|q(\tau^-)| = p(\tau^+)v(\tau^+) + m_2^{-1}|q(\tau^+)|,$$

$$q(\tau^+) = K^{-1} q(\tau^-), \tag{7.8}$$

$$m_1^{-1}|q(T)| = \lambda.$$

Before we move on to examine the implications of these conditions, it is convenient to draw attention to certain features of feasible controls, i.e., ones which together with their corresponding trajectories satisfy the constraints of the problem.

We say a control policy $(u(\cdot), \tau, T)$ is a bang-bang policy (with k switches) if there is a finite partition $0\ (=\sigma_0) < \sigma_1 < \cdots < \sigma_k < T(=\sigma_{k+1})$ of the interval $[0, T]$ such that $u(\cdot)$ restricted to $[\sigma_i, \sigma_{i+1}]$ either takes value $+1$ almost everywhere, or takes value -1 almost everywhere, for $i = 0, \cdots, k$. The σ_i's are the switching times. A little study of the phase plane portraits for $(x, \dot{x})$ corresponding to $u(\cdot) \equiv 1$ and to $u(\cdot) \equiv -1$ reveals the following lemma.

LEMMA. (i) *For any feasible bang-bang control policy there must be at least two switching times.*

(ii) *For any feasible bang-bang control policy with two switching times, the control function must assume values in the sequence* $+1, -1, +1$.

Returning now to the necessary conditions, we see that $p(\cdot)$ must be a piecewise constant function and $q(\cdot)$ a piecewise affine function. For both functions the discontinuity (in value or derivative) occurs at time τ.

CLAIM. $q(\tau^-) \neq 0$. Suppose to the contrary that $q(\tau^-) = 0$. We can exclude the possibility that $q(\cdot) \equiv 0$, for then $p(\cdot) \equiv 0$ and $\lambda = 0$, in contradiction to the nontriviality of the multipliers. It follows either $q(\cdot)$ is nonzero on $[0, \tau)$ or on $(\tau, T]$. Suppose first that $q(\cdot)$ is nonzero on $(\tau, T]$. Then $p(\tau^+) \neq 0$. Also, by (7.7), $u^*(\cdot)$ is constant on $(\tau, T]$. It follows that $v(\tau^+) \neq 0$, for clearly the point $(x, v) = (L, 0)$ in phase space cannot be driven to $(x, v) = (0, 0)$ by a constant control. But by (7.8), and since $q(\tau^-) = q(\tau^+) = 0$, we have $p(\tau^-) \neq 0$. This means that $q(\cdot)$ is also nonzero on $[0, \tau)$. But then by (7.7) $u^*(\cdot)$ is constant on $[0, \tau)$. We conclude that $(u^*(\cdot), \tau, T)$ is a feasible bang-bang control policy with at most one switch. This is impossible by the lemma. Similar reasoning excludes the possibility that $q(\cdot)$ is nonzero on $[0, \tau)$. The claim is substantiated.

In view of (7.7) and part (i) of the lemma, $q(\cdot)$ must take value zero at two interior points. There are then two possible configurations for $q(\cdot)$. One corresponds to a bang-bang control sequence $-1, +1, -1$, and is ruled out by the second part of the lemma. The remaining configuration is illustrated in Fig. 1.

We conclude from Fig. 1 that $u^*(\cdot)$ takes the form

$$u^*(t) = \begin{cases} +1 & \text{a.e. } t \in [0, t_1], \\ -1 & \text{a.e. } t \in (t_1, t_2), \\ +1 & \text{a.e. } t \in [t_2, T], \end{cases} \tag{7.9}$$

for some numbers t_1, t_2 satisfying

$$0 < t_1 < \tau < t_2 < T.$$

These are the zero crossing points in Fig. 1.

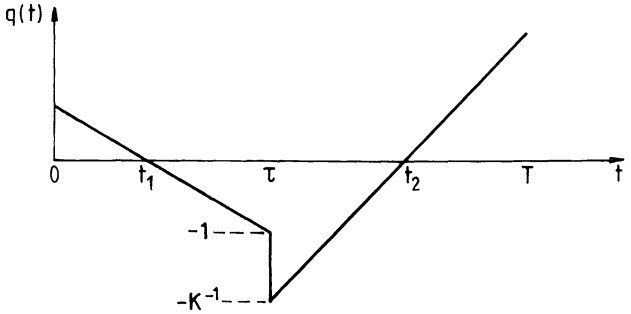

FIG. 1. *Robot arm problem: graph of the costate function* $q(\cdot)$.

Now write v for $v(\tau^-)$. On the interval $[0, \tau]$ the control function $u^*(\cdot)$ drives the unit, which has mass m_1, from the origin to the point $(x = L, \dot{x} = v)$ in the phase plane. Then on the interval $(\tau, T]$ it drives the unit, now with mass m_2, from $(x = L, \dot{x} = Kv)$ back to the origin. A straightforward analysis of phase plane portraits for responses to $m_1\ddot{x} = \pm 1$ and $m_2\ddot{x} = \pm 1$ reveals that

$$-(2L/m_2^2)^{1/2} < v < +(2L/m_1^2)^{1/2}$$

and t_1, t_2, τ and T are determined by the formulae (7.2)-(7.6), once v is found.

What do the optimality conditions say about v? We deduce from the graph of $q(\cdot)$ that

$$q(\tau^-) = -1,\ q(\tau^+) = -K^{-1},$$

$$p(\tau^-)(= -\dot{q}(\tau^-)) = (\tau - t_1)^{-1} = [(m_1 L + \tfrac{1}{2}m_1^2 v^2)^{1/2} - m_1 v]^{-1},$$

$$p(\tau^+)(= -\dot{q}(\tau^+)) = -K^{-1}(t_2 - \tau)^{-1} = K^{-1}[(m_2 L + \tfrac{1}{2}m_2^2 K^2 v^2)^{1/2} + m_2 K v]^{-1}.$$

It follows now from (7.8) that

$$\frac{v}{(m_1 L + \frac{1}{2}m_1^2 v^2)^{1/2} - m_1 v} + \frac{v}{(m_2 L + \frac{1}{2}m_2^2 K^2 v^2)^{1/2} + m_2 K v} = (Km_2)^{-1} - m_1^{-1}.$$

Multiplying across the equation by $Km_1 m_2(\mathscr{L}_1 - m_1 v)(\mathscr{L}_2 + m_2 K v)$ where

$$\mathscr{L}_1 = (m_1 L + \tfrac{1}{2}m_1^2 v^2)^{1/2} \quad \text{and} \quad \mathscr{L}_2 = (m_2 L + \tfrac{1}{2}m_2^2 K^2 v^2)^{1/2}$$

and cancelling terms, we obtain the equation

$$((Km_2)^2 \mathscr{L}_1 + m_1^2 \mathscr{L}_2)v = (m_1 - Km_2)\mathscr{L}_1 \mathscr{L}_2,$$

which implies

$$\frac{m_1^2 v}{(m_1 L + \frac{1}{2}m_1^2 v^2)^{1/2}} + \frac{(Km_2)^2 v}{(m_2 L + \frac{1}{2}m_2^2 K^2 v^2)^{1/2}} = m_1 - m_2 K.$$

This is (7.1).

But the left-hand side of (7.1) defines a function of v which is strictly monotone increasing and assumes all values in the interval

$$(-\sqrt{2}(m_1 + Km_2), \sqrt{2}(m_1 + Km_2)).$$

There is therefore a unique number v satisfying the equation.

We have shown that there is at most one control policy satisfying the necessary conditions, and such a control policy is determined by the formulae in the proposition. We deduce from the existence of feasible control policies (as defined by (7.2)-(7.6) when $v = 0$, for instance) and standard compactness arguments that an optimal control policy exists. There must then be a unique optimal control policy, and it is the one satisfying the necessary conditions. The proposition is proved. For purposes of comparison, we sketch a solution to problem (E_5) by traditional techniques. With every $w \in \mathbb{R}$ we associate an optimization problem $E_5(w)$, a modification of problem (E_5) in which we add a constraint

$$\text{“}x(\tau^-) = w.\text{”}$$

Let $J(\cdot)$ denote corresponding value function,

$$J(w) := \inf E_5(w) \quad \text{for all } w \in \mathbb{R}.$$

For each $w \in \mathbb{R}$, problem $E_5(w)$ decouples into two standard optimal control problems ("time optimal transfer of a double integrator plant with amplitude bounded controls between two fixed points in the phase plane"). A traditional approach is to find v (the minimizing velocity) such that

$$J(v) \leqq J(w) \quad \text{for all } w \in \mathbb{R}$$

and then to determine the optimal control policy as a solution to $E_5(v)$.

Define $\tilde{J}: \mathbb{R} \to \mathbb{R}$ to be

$$\tilde{J}(w) := (m_2K - m_1)w + 2(m_1L + \tfrac{1}{2}m_1^2w^2)^{1/2} + 2(m_2L + \tfrac{1}{2}m_2^2K^2w^2)^{1/2}.$$

Some lengthy but routine calculations along the lines of those in [14] yield the following explicit formula for $J(\cdot)$:

$$J(w) = \begin{cases} (m_2K + m_1)w + 2(-m_1L + \tfrac{1}{2}m_1^2w^2)^{1/2} + 2(m_2L + \tfrac{1}{2}m_2^2K^2w^2)^{1/2} & \text{if } w \geqq \bar{V}, \\ \tilde{J}(w) \quad \text{if } \underline{V} < w < +\bar{V}, \\ -(m_2K - m_1)w + 2(m_1L + \tfrac{1}{2}m_1^2w^2)^{1/2} + 2(-m_2L + \tfrac{1}{2}m_2^2K^2w^2)^{1/2} & \text{if } w \leqq \underline{V}. \end{cases}$$

Here,

$$\bar{V} := (2L/m_1)^{1/2} \quad \text{and} \quad \underline{V} := -(2L/K^2m_2)^{1/2}.$$

We mention that for each $w \in \mathbb{R}$, $E_5(w)$ has a unique optimal control policy, which is a bang-bang policy. For $w \in (\underline{V}, \bar{V})$ the values of the control functions involved switch twice, and for $w \notin [\underline{V}, \bar{V}]$ they switch three times. Relevant phase trajectories are shown in Fig. 2. Note that in solving the problem through multiprocess theory, it was unnecessary to consider controls involving more than two switches.

It can be shown that

$$J(w) \geqq \tilde{J}(w) \quad \text{for all } w \in \mathbb{R}. \tag{7.10}$$

Of course we have

$$J(w) = \tilde{J}(w) \quad \text{for } w \in (\underline{V}, \bar{V}). \tag{7.11}$$

Now it is easy to show that $\tilde{J}(\cdot)$ is a strictly convex, continuously differentiable function that achieves its minimum value over $\mathbb{R}$ at some point in $(\underline{V}, \bar{V})$. It follows from properties (7.10) and (7.11) that $J(\cdot)$ has a unique minimizer v over $\mathbb{R}$ and it coincides with that for $\tilde{J}(\cdot)$. This minimizer v is the unique solution of the equation

$$\nabla \tilde{J}(v) = 0. \tag{7.12}$$

We calculate

$$\nabla \tilde{J}(w) = m_2K - m_1 + \frac{m_1^2w}{(m_1L + \frac{1}{2}m_1^2w^2)^{1/2}} + \frac{(Km_2)^2w}{(m_2L + \frac{1}{2}m_2^2K^2w^2)^{1/2}}.$$

Thus the optimal control policy for the original problem is that for problem $E_5(v)$, where v satisfies (7.12).

It is interesting to note that condition (7.1) in Proposition 7.1 determining the optimum velocity v at dropoff or pickup, which was previously derived from the optimal multiprocess maximum principle, can be interpreted as a statement that the gradient of the function $\tilde{J}$ (related to the value function) vanishes at v.

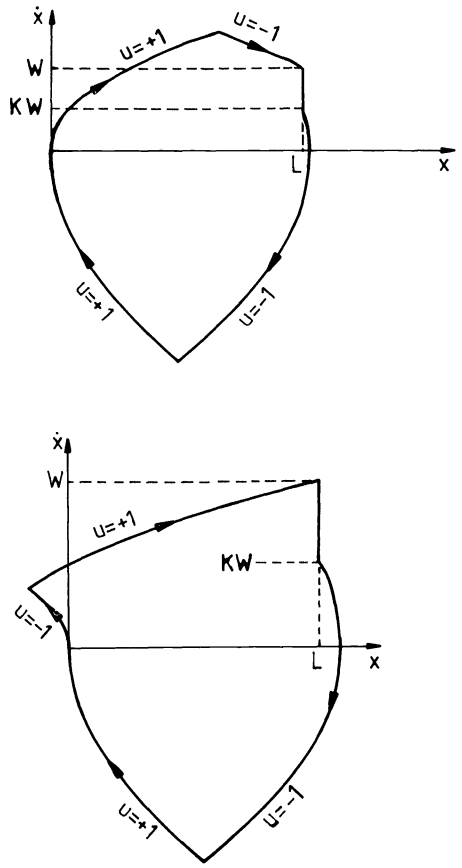

FIG. 2. *Robot arm problem: optimal phase plane trajectory when w is fixed (two switches).* $((2L/K^2m_1)^{1/2} \geqq w \geqq -(2L/K^2m_2)^{1/2}$, $m_2 = \frac{1}{2}m_1$, $K = \frac{1}{2})$. (b) *Robot arm problem: optimal phase plane trajectory when w is fixed (three switches).* $(w > (2L/K^2m_1)^{1/2}$, $m_2 = \frac{1}{2}m_1$, $K = \frac{1}{2})$.

Of course our success in solving problem (E_5) by traditional "two stage" optimization techniques very much depended on availability of a simple explicit formula for the value function. (It would be difficult to use these techniques when we refined the model, say to include damping and higher-order dynamics.) By contrast the theory of optimal multiprocesses would provide conditions on the solutions, even in the absence of such a formula.

Another point in favour of the theory of optimal multiprocesses as it bears on problem (E_5), is that it gives us certain information, prior to detailed analysis, about the number of switches in the optimal control policy (there are at most two of them). The two stage approach required us to consider the possibility of three switches, if only later to reject it, with consequent extra burden of analysis.

8. A problem in renewable resources. The most widely used tool in the theory of renewable resources is the Gordon-Schaefer model and its many variations (see, e.g., [3], [5]). Before giving the variation which constitutes our present example, we recapitulate the basic model. A population whose size x varies over time evolves

according to the law

$$\dot{x}(t) = F(x(t)) - \sigma x(t)u(t),$$

where F is a given (natural growth) function, u represents harvesting effort by the exploiter of the resource, and σ is a positive constant. Effort u is constrained to a given interval $[0, E]$. The initial value $x(0) = x_0$ is known. The exploiter's net return over a given interval of time $[0, T]$ is given in present value terms by

$$\int_0^T e^{-\delta t}\{\pi x(t) - c\}u(t)\, dt,$$

where δ is the discount rate, π the unit resource price, and c the unit effort cost. The problem is to choose the effort profile $u(\cdot)$ to maximize this quantity.

Under standard hypotheses that we omit, the solution to the problem is known to be of "turnpike" type. Specifically, there is a certain population level x^* (the formula for which we omit) in terms of which the solution may be described as follows (for definiteness, let us suppose that x_0 exceeds x^*). Initially maximum effort is applied ($u = E$) until $x(t)$ is driven down to x^*, at time $t = s_1$ (say). Then $x(t)$ is kept at the value x^* (by the appropriate effort) until $t = s_2$. And between s_2 and T there is another period of maximum effort ($u = E$). If the horizon T is too short, the intermediate (turnpike) portion of the solution may be absent.

The switching times s_1, s_2 are determined implicitly by certain boundary-value problems associated to the data of the model (in fact, s_2 is characterized in terms of the adjoint equation of the maximum principle together with the standard transversality condition).

Suppose now that a further possibility is open to the exploiter, that of shifting the operation from the initial population (which we shall now designate x_1, with data x_0^1, F_1, σ_1, π_1, c_1) to a different population x_2 (with data x_0^2, F_2, σ_2, π_2, c_2). The shift, which can occur at any chosen time τ, and that will be assumed instantaneous for simplicity, entails a lump cost ϕ_0 (at time τ). The problem then becomes that of minimizing

$$\phi_0\, e^{-\delta\tau} - \int_0^\tau e^{-\delta t}\{\pi_1 x_1 - c_1\}u\, dt - \int_\tau^T e^{-\delta t}\{\pi_2 x_2 - c_2\}u\, dt$$

over the admissible controls $u(\cdot)$ on $[0, T]$ and shift times τ in $[0, T]$. The dynamics are the initial ones on $[0, \tau)$, and those corresponding to the second population on $[\tau, T]$. Note that the initial condition appropriate to the dynamics on $[\tau, T]$ is given by $x_2(\tau) = z(\tau)$, where $z(\cdot)$ is the solution to

$$\dot{z}(t) = F_2(z(t)), \qquad z(0) = x_0^2. \tag{8.1}$$

We shall proceed to analyse the problem, assuming for simplicity that x_0^1 and x_0^2 are relatively large (i.e., exceed x_1^* and x_2^*, respectively).

It is clear that the problem is one of multiprocesses, with $k = 2$, $n_1 = n_2 = m_1 = m_2 = 1$. The set Λ and function f are given by

$$\{[0, \tau, x_0^1, x, \tau, T, z(\tau), y]\colon \tau \in [0, T],\ x \in \mathbb{R},\ y \in \mathbb{R}\},$$

$$f(\tau_0^1, \tau_1^1, x_0^1, x_1^1, \tau_0^2, \tau_1^2, x_0^2, x_1^2) = \phi_0\, e^{-\delta\tau_1^1}.$$

We suppose that the solution to the problem incorporates a shift at τ in $(0, T)$. At any point (τ, τ, z) in the set $\{[\tau, \tau, z(\tau)]\colon 0 \leqq \tau \leqq T\}$ having $0 < \tau < T$, the normal cone (space)

is spanned by the vector $[1, -1, 0]$ and $[1, 0, -\dot{z}(\tau)]$. With this in mind, it can be seen that the transversality condition of Theorem 3.1 yields in the present case:

$$h_0^2 = h_1^1 + p_2(\tau)\dot{z}(\tau) + \delta\phi_0\, e^{-\delta t}, \tag{8.2}$$

$$p_1(\tau) = p_2(T) = 0. \tag{8.3}$$

The latter conclusion (8.3) is familiar and expected from the original single-process problem, and expresses the fact that the imputed shadow price p is zero at the end of the planning period. This remains so for p_1 and p_2 because of the fact that (x_1, u) is optimal for the original problem restricted to $[0, \tau]$, while (x_2, u) is optimal for the second population studied on $[\tau, T]$.

Let us now examine (8.2), which constitutes the essential new information. From the single-process case it is known that (regardless of the lengths of the intervals $[0, \tau]$ and $[\tau, T]$) $u(t) = E$ on some interval to the left of τ and also on some interval to the right of τ. Thus we have

$$h_0^2 = p_2(\tau)[F_2(z(\tau)) - \sigma_2 z(\tau)E] + e^{-\delta\tau}[\pi_2 z(\tau) - c_2]E, \qquad h_1^1 = e^{-\delta\tau}[\pi_1 x_1(\tau) - c_1]E$$

(where we have used $p_1(\tau) = 0$). Substituting these expressions into (8.2) along with $\dot{z}(\tau) = F_2(z(\tau))$, we arrive at

$$[\pi_2 x_2(\tau) - c_2]E = [\pi_1 x_1(\tau) - c_1]E + \delta\phi_0 + e^{\delta\tau} p_2(\tau)\sigma_2 x_2(\tau)E. \tag{8.4}$$

This condition, which determines the shift time τ, can be given an economic interpretation. The (rate of) marginal revenue at τ from harvesting x_1 is given by $[\pi_1 x_1 - c_1]E$. The condition above states that when the shift occurs, the corresponding value for x_2, i.e., $[\pi_2 x_2 - c_2]E$, must equal that for x_1 plus a term corresponding to the (marginal) cost of making the shift (i.e., $\delta\phi_0$), plus a term $(e^{\delta\tau} p_2(\tau)\sigma_2 x_2(\tau)E)$ which is the (current) shadow value of the increased potential revenue from x_2 if x_2 were continued to be left to grow instead of being harvested.

Just as in the original single-process problem, the solution is completely but implicitly defined by the necessary conditions. In fact, much the same ingredients are involved in (8.4). For example, $x_1(\tau)$ is the final value of the optimal state for the single-process problem on $[0, \tau]$. This is known to coincide with $\max[y(\tau), x_f]$, where $y(\cdot)$ satisfies

$$\dot{y}(t) = F_1(y(t)) - \sigma_1 E y(t), \qquad y(0) = x_0^1$$

and where x_f is a certain constant determined by the data. Thus $x_1(\tau)$ is accessible, as is the adjoint value $p_2(\tau)$, although in this case it is a certain two-dimensional state-adjoint system that determines it. Finally, the value $x_2(\tau)$ in (8.4) is simply given by (8.1). In summary then, (8.4) permits us to determine the shift time τ. We remark that in this example it does not appear to be practical to solve the problem in a two-stage fashion, in view of the absence of explicit formulae for the appropriate value functions. On the other hand, the multiprocess necessary conditions have led directly to a characterization of the solution.

OPTIMAL MULTIPROCESSES*

FRANK H. CLARKE† AND RICHARD B. VINTER‡

This paper is dedicated to the memory of E. J. McShane.

Abstract. A theory of necessary conditions for optimal multiprocesses is presented. Optimal multiprocesses are solutions to dynamic optimization problems described by families of control systems coupled through the boundary conditions and cost functions. The theory treats in a unified fashion a wide range of nonstandard dynamic optimization problems, and in many cases provides new optimality conditions. These include problems arising in impulse control, robotics, and optimal investment. Even when specialized to the (single process) free time optimal control problem, the theory improves on known necessary conditions. Detailed analysis of a number of applications and special cases appears in a companion paper.

Key words. optimal control, necessary conditions, differential inclusions

AMS(MOS) subject classifications. 49B10, 49B99

1. Introduction.

The theory presented in this paper originates in the authors' efforts in recent years to solve a variety of nonstandard problems in dynamic optimization. It became increasingly apparent in this earlier work that, although the problems considered were at first sight distinct, the task of finding good first-order conditions of optimality in each case called for development of similar analytical techniques. It was natural then to study these problems in a single comprehensive framework. We refer to this framework as multiprocesses.

Our companion paper [5], in which we analyse in detail a number of specific optimal multiprocess problems and special cases, testifies to the scope of the theory. The common feature of these problems is a family of dynamical equations with control term, coupled by a constraint on the boundary values of the constituent state trajectories and also by a function of these boundary values in the cost. We briefly describe some examples.

Consider the problem of determining an optimal control strategy for a multistage rocket, when the stage ejection times are included in the choice variables. (See, e.g., [8].) Standard optimality conditions of control theory, which accommodate changes in the dynamics only at fixed times, cannot be applied directly to such problems. It is true that we can sometimes overcome these difficulties by means of ad hoc techniques where, to begin with, we solve a family of problems involving fixed ejection times and then minimize over the ejection times ("two stage" optimization) or, alternatively, where we reduce the free ejection times to fixed ones by transformation of the time variable. To carry out two-stage optimization however we require tractable formulae describing the value function relative to the ejection times; unfortunately we cannot expect to derive such formulae for complicated problems. As for time transformation techniques, these are typically applicable only when certain regularity conditions are imposed on the data and this rules out certain significant applications. But if we view trajectory segments between ejection times as component trajectories, we arrive at an optimal multiprocess problem, for which our new theory supplies optimality conditions under very mild hypotheses.

Next we consider a modification of the standard optimal control problem in which state trajectories are permitted to be discontinuous at a finite number of times, and the jump times are choice variables. The jump times, as well as the end states of the jumps, appear in the cost and are constrained to lie in some closed set. There is also a constraint on the number of jumps. Problems such as this arise in optimal investment and inventory control, and have been called "impulse control" problems. Necessary conditions of optimality are available (see, e.g., [11]-[15]) but these are limited to only a narrow class of cost functions and constraints, as far as the jumps are concerned, and apply only when the constraint on the number of jumps is inactive. We can view these impulse control problems as another instance of an optimal multiprocess problem, however. Here we interpret restrictions of trajectories (in the original problem) to intervals between jumps as component trajectories (in the optimal multiprocess problem). We thereby obtain necessary conditions of optimality when restrictions in the earlier theory, on the manner in which the jumps are included in the cost and constraints, are lifted.

An example of a variational problem to which our theory is applicable is the derivation of Snell's law of refraction from Fermat's principle of least time. If the two media involved are homogeneous we derive a simple formula for the minimum time as a function of the point of incidence, and deduce Snell's law by setting the gradient to zero. For inhomogeneous media this "two stage" approach is no longer available to us outside the simplest cases. However we can proceed alternatively by regarding the light ray as solving an optimal multiprocess problem: the component trajectories are the path segments in each medium and the constraint on the boundary values is that the path segments match at the interface. We can thereby validate Snell's Law in a very general setting.

It is remarkable that, even when we specialize the theory to treatment of the standard optimal control problem, significant advances on known results ensue. For free time optimal control problems the Pontryagin maximum principle provides a boundary condition on the maximized Hamiltonian, evaluated along the optimal trajectory. The boundary condition has previously been proved only under the assumption that the data is continuous in the time variable. Multiprocess theory, by contrast, yields a version of the boundary condition when the data is merely measurable in the time variable.

There is a long tradition of research whose aim is unification of optimality conditions for as wide a range of optimization problems as possible (in mathematical programming, control, and the calculus of variations), within a single general theory. Notable contributions here are Neustadt's abstract variational theory [10] and the general multiplier rules of Warga [14] and Ioffe [9]. The price paid for the comprehensiveness of these theories is the labour involved in checking hypotheses (most notably in applications to optimal control) and, in the case of Neustadt's theory, the ingenuity required in devising certain approximating sets. The theory of optimal multiprocesses is a general theory and so must be considered as partly in this tradition. But it is a departure too, since it is targeted specifically at problems in dynamic optimization. Consequently, for such problems, checking hypotheses is usually a trivial task. Our applications in [5] illustrate that generating optimality conditions for specific classes of problems is usually a routine matter of calculating normal cones.

We make some comments concerning the analytical techniques employed in this paper. These follow the lead of a number of recent publications in which optimality conditions are proved by considering limits of normal vectors to the epigraph of a suitable value function. This approach ("proximal normal analysis"), which was first

adopted in [2], besides being useful for proving necessary conditions, provides new interpretations of the Lagrange multipliers involved in terms of sensitivity of the minimum cost to data perturbations. Interpretations of this kind have been obtained by other methods in mathematical programming (see, e.g., [7], [12]) and via proximal normal analysis by Clarke and Loewen [3] for optimal control problems. The proofs of this paper illustrate the power of proximal normal analysis to also generate new optimality conditions.

Our results admit extensions in various directions. These will be the subject of future work. In particular, a similar but more intricate analysis leads to a maximum principle when unilateral state constraints are introduced in the optimal multiprocess problem. Under more stringent assumptions we can also provide an accompanying sensitivity analysis.

Finally we mention that a simple proof can be given of a restricted form of the optimal multiprocess maximum principle when the data is smooth in time. This is based on a reduction of the optimal multiprocess problem to a standard optimal control problem by transformation of the time variable. The restricted form of the principle is inadequate, however, for certain applications (see [5]).

2. Essential values. For free time dynamic optimization problems, such as those studied here, we can expect optimality conditions to incorporate conditions on boundary values of functions constructed from the costate variables. When the data is merely measurable in the time variable, the elementary definition of boundary value, namely evaluation at a point, cannot be adopted, basically because it is not robust under the limiting arguments employed in derivation of optimality conditions. Instead we must interpret boundary values as "essential values."

Let $S \subset \mathbb{R}$ be an open set, T a point in S, and $\psi : S \to \mathbb{R}^k$ a measurable function. The set of essential values of ψ at T, denoted $\operatorname{ess}_{t \to T} \psi(t)$, is defined as follows. ζ belongs to this set if and only if, for any positive number $\varepsilon > 0$, the following set has positive Lebesgue measure:

$$\{t: T - \varepsilon < t < T + \varepsilon, |\zeta - \psi(t)| < \varepsilon\}.$$

If a point lies in $\operatorname{co} \operatorname{ess}_{t \to T} \psi(t)$ we say it is a convex essential value of ψ at T.

It is clearly the case that if ψ is continuous at T then

$$\operatorname*{ess}_{t \to T} \psi(t) = \{\psi(T)\},$$

i.e., the essential value is merely the value of the function.

Given a set $D \subset \mathbb{R}^l$ and a multifunction $A : D \rightrightarrows \mathbb{R}^k$, we say that A is *closed* if, for any convergent subsequences $\{y_i\} \subset D$ and $\{a_i\} \subset \mathbb{R}^k$ (we write the limits y and a, respectively) such that $a_i \in Ay_i$ for $i = 1, 2, \cdots$ and $y \in D$, we have $a \in Ay$. The following closedness property of the multifunction obtained by applying the operation of taking essential values of a function accounts for its significance in optimization theory.

LEMMA 2.1. *Let P, Q be open subsets of $\mathbb{R}$, $\mathbb{R}^n$, respectively, and let $h : P \times Q \to \mathbb{R}^k$ be a given function. Suppose*

$$x \to h(t, x) \text{ is continuous, uniformly in } t, \text{ and}$$

$$t \to h(t, x) \text{ is measurable for every } x \in Q.$$

Then the multifunction $G : P \times Q \rightrightarrows \mathbb{R}^k$ defined by $G(t, x) = \operatorname{ess}_{s \to t} h(s, x)$ is closed. If in addition we have

$$\sup_{x \in P} \operatorname*{ess}_{s \to t} |h(s, x)| < \infty,$$

then $(t, x) \to \operatorname{co} G(t, x)$ is also a closed multifunction. Here "co" denotes convex hull.

Proof. Consider the first assertion. Let $t_i \to t$, $x_i \to x$ and $r_i \to r$ where $t \in P$, $x \in Q$, and $r_i \in \operatorname{ess}_{s \to t_i} h(s, x_i)$ for each i, $t \in P$, and $x \in Q$. We must show that $r \in \operatorname{ess}_{s \to t} h(s, x)$. Choose $\varepsilon > 0$ and define

$$S_i^\varepsilon = \{s \in (t_i - \varepsilon/2,\ t_i + \varepsilon/2) \cap P \,|\, |h(s, x_i) - r_i| < \varepsilon/2\}.$$

By definition of essential values, the set S_i^ε has positive measure. But for i sufficiently large $|t_i - t| < \varepsilon/2$ and $|h(s, x_i) - h(s, x)| + |r - r_i| < \varepsilon/2$ for all $s \in P$ by uniform continuity. It follows that

$$S_i^\varepsilon \subset S^\varepsilon$$

where

$$S^\varepsilon = \{s \in (t - \varepsilon,\ t + \varepsilon) \cap P \,|\, |h(s, x) - r| < \varepsilon\}.$$

The set S^ε then has positive measure. Since ε is arbitrary, $r \in \operatorname{ess}_{s \to t} h(s, t)$. A simple compactness argument, and application of Caratheodory's Theorem, now give the second assertion.

3. A maximum principle for optimal multiprocesses. Frequent reference is made to points in product spaces, and to products of product spaces. In this connection, a point $((a_1, b_1, \cdots), (a_2, b_2, \cdots), \cdots, (a_k, b_k, \cdots))$ is denoted by $\{a_i, b_i, \cdots\}_{i=1}^k$ or, briefly, $\{a_i, b_i, \cdots\}$.

The following data are given:

positive integers k, and n_i, m_i,	$i = 1, \cdots, k$,
functions $\phi_i : \mathbb{R} \times \mathbb{R}^{n_i} \times \mathbb{R}^{m_i} \to \mathbb{R}^{n_i}$,	$i = 1, \cdots, k$,
subsets U^i of $\mathbb{R} \times \mathbb{R}^{m_i}$,	$i = 1, \cdots, k$,
subsets X^i of $\mathbb{R} \times \mathbb{R}^{n_i}$,	$i = 1, \cdots, k$.

We term multiprocess a point $\{\tau_0^i, \tau_1^i, x_i(\cdot), w_i(\cdot)\}$ comprising left and right endpoints τ_0^i, τ_1^i of a closed subinterval of $\mathbb{R}$, absolutely continuous functions $x_i(\cdot) : [\tau_0^i, \tau_1^i] \to \mathbb{R}^{n_i}$ and measurable functions $w_i(\cdot) : [\tau_0^i, \tau_1^i] \to \mathbb{R}^{m_i}$ such that

$$\begin{aligned}
&\dot{x}_i(t) = \phi_i(t, x_i(t), w_i(t)) && \text{a.e. } t \in [\tau_0^i, \tau_1^i], \\
&w_i(t) \in U_t^i, && \text{a.e. } t \in [\tau_0^i, \tau_1^i], \\
&x_i(t) \in X_t^i, && \text{for all } t \in [\tau_0^i, \tau_1^i],
\end{aligned}$$

for $i = 1, \cdots, k$. Here U_t^i is the set $\{u \,|\, (t, u) \in U^i\}$, and X_t^i is likewise defined.

It is assumed that the data satisfies the following hypotheses.

(H1) For each $x \in \mathbb{R}^{n_i}$, $\phi_i(\cdot, x, \cdot)$ is $\mathscr{L} \times \mathscr{B}$ measurable (where $\mathscr{L}$ is the class of Lebesgue subsets of $\mathbb{R}$ and $\mathscr{B}$, the class of Borel subsets of $\mathbb{R}^{m_i}$) for $i = 1, \cdots, k$.

(H2) U^i is a Borel measurable set for $i = 1, \cdots, k$.

There exists a constant K with the following properties.

(H3) $|\phi_i(t, y, w)| \leqq K$ whenever $(t, y, w) \in \mathbb{R} \times X_t^i \times U_t^i$.

(H4) $|\phi_i(t, y, w) - \phi_i(t, y', w)| \leqq K |y - y'|$ whenever (t, y, w), $(t, y', w) \in \mathbb{R} \times X_t^i \times U_t^i$.

We aim to give optimality conditions for an optimization problem posed over multiprocesses. However, as is common, we approach the optimization problem via analysis of boundary points of a reachable set.

Let C be a given closed set in

$$\prod_i \{(\tau_0^i, \tau_1^i, a_0^i) \mid a_0^i \in \mathbb{R}^{n_i},\ \tau_0^i, \tau_1^i \in \mathbb{R},\ \tau_0^i \leqq \tau_1^i\}$$

and let $\psi : \mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_k} \to \mathbb{R}^d$ be a given Lipschitz continuous function. We define the reachable set (with respect to C and ψ), written $\mathcal{R}_{\psi,C}$, to be

$$\mathcal{R}_{\psi,C} := \{\psi(\{y_i(\tau_1^i)\}) \mid \{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\} \text{ is a multiprocess such that } \{\tau_0^i, \tau_1^i, y_i(\tau_0^i)\} \in C\}.$$

We say that a multiprocess $\{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\}$ is a boundary multiprocess relative to ψ and C if

$$\{\tau_0^i, \tau_1^i, y_i(\tau_0^i)\} \in C \quad \text{and} \quad \psi(\{y_i(\tau_1^i)\}) \in \partial \mathcal{R}_{\psi,C}$$

(∂ denotes boundary). Define the unmaximized Hamiltonian function H_i to be

$$H_i(t, x, u, p) := p \cdot \phi_i(t, x, u), \qquad i = 1, \cdots, k.$$

The following theorem is a necessary condition that a multiprocess be associated with a boundary point of the reachable set.

THEOREM 3.1. *Let $\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}$ be a boundary multiprocess (with respect to C and ψ). Assume that*

$$\text{graph}\,\{x_i(\cdot)\} \subset \text{interior}\,\{X^i\}$$

for $i = 1, \cdots, k$ and that hypotheses (H1)-(H4) *are satisfied. Then there exists a vector v of unit length, numbers h_0^i, h_1^i and absolutely continuous functions $p_i(\cdot) : [T_0^i, T_1^i] \to \mathbb{R}^{n_i}$ for $i = 1, \cdots, k$, and a number c (whose magnitude is governed by the constant K in hypotheses* (H3) *and* (H4) *together with the Lipschitz rank of ψ restricted to some neighbourhood of $\{x_i(T_1^i)\}$), with the following properties*:

$$-\dot{p}_i(t) \in \partial_x H_i(t, x_i(t), u_i(t), p_i(t)) \quad \text{a.e. } t \in [T_0^i, T_1^i],$$

$$H_i(t, x_i(t), u_i(t), p_i(t)) = \max_{w \in U_t^i} H_i(t, x_i(t), w, p_i(t)) \quad \text{a.e. } t \in [T_0^i, T_1^i],$$

$$h_0^i \in \text{co ess}_{t \to T_0^i} \left[\sup_{w \in U_t^i} H_i(t, x_i(T_0^i), w, p_i(T_0^i)) \right],$$

$$h_1^i \in \text{co ess}_{t \to T_1^i} \left[\sup_{w \in U_t^i} H_i(t, x_i(T_1^i), w, p_i(T_1^i)) \right]$$

for $i = 1, \cdots, k$,

$$\{p_i(T_1^i)\} \in \partial \psi^*(\{x_i(T_1^i)\}) v$$

and

$$\{-h_0^i, h_1^i, p_i(T_0^i)\} \in c \partial d_C(\{T_0^i, T_1^i, x_i(T_0^i)\}).$$

Here $\partial_x H_i$ denotes the partial generalized gradient in the second variable and $\partial \psi^*$ is the transpose of the generalized Jacobian of ψ. (Generalized gradients and Jacobians are understood in the sense of Clarke [2]). *The operation of taking essential values* "ess" *has been defined in* § 2. *d_C is the Euclidean distance function from the set C.*

The theorem is proved in § 6.

Let

$$f: \quad \prod_i (\mathbb{R} \times \mathbb{R} \times \mathbb{R}^{n_i} \times \mathbb{R}^{n_i}) \to \mathbb{R}$$

be a given locally Lipschitz continuous function and let

$$\Lambda \subset \prod_i \{(\tau_0^i, \tau_1^i, a_0^i, a_1^i) | \tau_0^i, \tau_1^i \in \mathbb{R}, a_0^i, a_1^i \in \mathbb{R}^{n_i}, \tau_0^i \leqq \tau_1^i\}$$

be a given closed set.

We now pose the optimal multiprocess problem:

$$(P) \quad \begin{array}{l} \text{minimize } f(\{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\}) \text{ over multiprocesses } \{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\} \\ \text{that satisfy } \{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\} \subset \Lambda. \end{array}$$

In § 7 we shall derive from Theorem 3.1 the following maximum principle for solutions to the optimal multiprocess problem.

THEOREM 3.2. *Let* $\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}$ *be a solution to* (P). *Assume that*

$$\text{graph } \{x_i(\cdot)\} \subset \text{interior } \{X^i\}$$

for $i = 1, \cdots, k$ *and that hypotheses* (H1)-(H4) *are satisfied. Then there exists a real number* $\lambda \geqq 0$, *real numbers* h_0^i, h_1^i, *and absolutely continuous functions* $p_i(\cdot) : [T_0^i, T_1^i] \to \mathbb{R}^{n_i}$ *for* $i = 1, \cdots, k$, *and a constant* c (*whose magnitude is determined by the constant* K *of hypotheses* (H3) *and* (H4) *together with the Lipschitz rank of* f *in a neighbourhood of* $\{T_0^i, T_1^i, x_i(T_0^i), x_i(T_1^i)\}$) *such that* $\lambda + \sum_i |p_i(T_1^i)| = 1$ *and we have*

$$(3.1) \quad -\dot{p}_i(t) \in \partial_x H_i(t, x_i(t), u_i(t), p_i(t)) \quad \text{a.e. } t \in [T_0^i, T_1^i],$$

$$H_i(t, x_i(t), u_i(t), p_i(t)) = \max_{w \in U_t^i} H_i(t, x_i(t), w, p_i(t)) \quad \text{a.e. } t \in [T_0^i, T_1^i],$$

$$(3.2) \quad h_0^i \in \text{co ess}_{t \to T_0^i} \left[\sup_{w \in U_t^i} H_i(t, x_i(T_0^i), w, p_i(T_0^i)) \right],$$

$$h_1^i \in \text{co ess}_{t \to T_1^i} \left[\sup_{w \in U_t^i} H_i(t, x_i(T_1^i), w, p_i(T_1^i)) \right]$$

for $i = 1, \cdots, k$, *and*

$$(3.3) \quad \{-h_0^i, h_1^i, p_i(T_0^i), -p_i(T_1^i)\} \in c\, \partial d_\Lambda + \lambda \partial f$$

where the generalized gradients ∂d_Λ *and* ∂f *are evaluated at* $\{T_0^i, T_1^i, x_i(T_0^i), x_i(T_1^i)\}$.

Note that all the ingredients of the traditional maximum principle, namely costate functions $p(\cdot)$, costate differential inclusions (3.1), and maximization of the Hamiltonian (3.2), are present in the multiprocess maximum principle. The costate differential inclusions and the Hamiltonian maximizing properties separate out into statements about the individual component processes. The fact that the component processes in the optimal multiprocess problem are coupled through an endpoint constraint and the cost function gives rise to a corresponding coupling of the component costate functions, the $p_i(\cdot)$'s, through their endpoints via the multiprocess transversality condition (3.3).

Our formulation of the optimization problem (P) incorporates the constraints "$y_i(t) \in X_t^i$" mainly for the purpose of hypothesis refinement. A consequence of our theorem is that the assertions remain valid if $\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}$ is merely a local solution to (P), in the sense that it is minimizing with respect to all multiprocesses $\{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\}$ that satisfy

$$\text{graph } \{y_i(\cdot)\} \subset \text{graph } \{x_i(\cdot)\} + \varepsilon B$$

for some $\varepsilon > 0$ (B denotes the open unit ball). It follows also that the boundedness and uniform Lipschitz continuity hypotheses ((H3) and (H4)) need to be checked only on neighbourhoods of the graphs of the minimizing $x_i(\cdot)$'s. (For confirmation we have

only to replace each X_i by its intersection with the relevant neighbourhood of graph $\{x_i\}$ and apply the original theorem.) In the event that $x_i(\cdot)$ strikes the boundary of the set X_i for some i, the hypotheses of Theorem 3.2 are violated; in such circumstances necessary conditions of optimality, which involve possible discontinuous component costate functions $\{p_i(\cdot)\}$, may be derived. We do not pursue such extensions here.

4. Coupled dynamic optimization problems: a differential inclusion formulation. It is well known that we may choose a variety of starting points for derivation of conditions on solutions to dynamic optimization problems over a single time interval. Two notable instances are, first, that where the dynamics are modeled by a differential equation with control and, second, that involving a differential inclusion. The first-order optimality conditions derivable for each of these formulations are distinct; examples of problems are known where the differential equations conditions give more information about solutions than the differential inclusions conditions, and vice versa.

Equally, distinct sets of necessary conditions for solutions to coupled dynamic optimization problems over a family of time intervals result, according to whether the dynamics are described by differential equations or differential inclusions. We have already given necessary conditions in the differential equations case. In this section we do the same for differential inclusions.

Our necessary conditions on solutions to coupled dynamic optimization problems in a differential inclusions context, in addition to providing independent information about solutions in certain cases, will be important here as constituting the first step in our proof of the maximum principle governing optimal multiprocesses.

The following data are given:

positive integers k, and n_i, $\quad i = 1, \cdots, k$,

a function $g: \prod_{i=1}^{k} (\mathbb{R} \times \mathbb{R} \times \mathbb{R}^{n_i} \times \mathbb{R}^{n_i}) \to \mathbb{R}$,

multifunctions $F_i : \mathbb{R} \times \mathbb{R}^{n_i} \rightrightarrows \mathbb{R}^{n_i}$, $\quad i = 1, \cdots, k$,

sets $\Gamma^i \subset \mathbb{R} \times \mathbb{R}^{n_i}$, $\quad i = 1, \cdots, k$,

and a subset M of

$$\prod_{i=1}^{k} \{(\tau_0^i, \tau_1^i, a_0^i, a_1^i) | \tau_0^i, \tau_1^i \in \mathbb{R}, a_0^i, a_1^i \in \mathbb{R}^{n_i} \text{ and } \tau_0^i \leqq \tau_1^i\}.$$

Now consider the following problem:

$$\begin{aligned} &\text{minimize} \quad g(\{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\}) \\ &\text{subject to} \\ (\mathrm{Q}) \qquad &\dot{y}_i(t) \in F_i(t, y_i(t)) \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i], \\ &\dot{y}_i(t) \in \Gamma_t^i \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i], \\ &\{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\} \in M. \end{aligned}$$

The underlying elements in the minimization problem here are k-tuples $\{\tau_0^i, \tau_1^i, y_i(\cdot)\}_{i=1}^k$ in which τ_0^i and τ_1^i are, respectively, left and right endpoints of a closed subinterval of $\mathbb{R}$, and $y_i(\cdot)$ is an absolutely continuous n_i vector valued function on $[\tau_0^i, \tau_1^i]$, $i = 1, \cdots, k$.

The hypotheses invoked will be as follows:

(I1) g is locally Lipschitz continuous.

(I2) M is closed.

(I3) For each i, F_i takes values closed, convex sets, and given any point $x \in \mathbb{R}^{n_i}$ and closed set $D \subset \mathbb{R}^{n_i}$, the set $\{t \mid D \cap F_i(t, x) \neq \emptyset\}$ is Lebesgue measurable.

There exists a constant K such that we have the following:

(I4) $|v| \leqq K$ whenever $v \in F_i(t, x)$, $(t, x) \in \Gamma^i$, $i = 1, \cdots, k$.

(I5) $\operatorname{dist}\{F_i(t, x), F_i(t, y)\} \leqq K|x - y|$, whenever (t, x), $(t, y) \in \Gamma^i$, $i = 1, \cdots, k$ ("dist" is the Hausdorff distance function).

We define the Hamiltonian functions $\mathscr{H}_i : \Gamma^i \times \mathbb{R}^{n_i} \to \mathbb{R}$ to be

$$\mathscr{H}_i(t, x, p) := \sup_{e \in F_i(t,x)} p \cdot e, \qquad i = 1, \cdots, k.$$

THEOREM 4.1. *Let* $\{T_0^i, T_1^i, x_i(\cdot)\}$ *solve problem* (Q). *Assume that*

$$\operatorname{graph}\{x_i(\cdot)\} \subset \operatorname{interior}\{\Gamma^i\}$$

for $i = 1, \cdots, k$, *and that hypotheses* (I1)-(I5) *are satisfied. Then there exists a real number* $\lambda \geqq 0$, *real numbers* h_0^i, h_1^i, *absolutely continuous functions* $p_i(\cdot) : [T_0^i, T_1^i] \to \mathbb{R}^{n_i}$, $i = 1, \cdots, k$, *and a constant* c (*whose magnitude is determined by the constant* K *of hypotheses* (I4) *and* (I5) *together with the Lipschitz rank of* g *in a neighbourhood of* $\{T_0^i, T_1^i, x_i(T_0^i), x_i(T_1^i)\}$), *such that* $\lambda + \sum_i |p_i(T_1^i)| = 1$ *and we have*

$$(-\dot{p}_i(t), \dot{x}_i(t)) \in \partial_{x,p} \mathscr{H}_i(t, x_i(t), p_i(t)) \quad \text{a.e. } t \in [T_0^i, T_1^i],$$

$$h_0^i \in \operatorname{co} \operatorname*{ess}_{t \to T_0^i} \mathscr{H}_i(t, x_i(T_0^i), p_i(T_0^i)), \; h_1^i \in \operatorname{co} \operatorname*{ess}_{t \to T_1^i} \mathscr{H}_i(t, x_i(T_1^i), p_i(T_1^i))$$

for $i = 1, \cdots, k$, *and* $\{-h_0^i, h_1^i, p_i(T_0^i), -p_i(T_1^i)\} \in c\, \partial d_M + \lambda\, \partial g$. *Here* $\partial_{x,p} \mathscr{H}_i$ *denotes the partial generalized gradient of* $\mathscr{H}_i$ *in the second and third variables. The generalized gradients* ∂d_C *and* ∂g *are evaluated at* $\{T_0^i, T_1^i, x_i(T_0^i), x_i(T_1^i)\}$.

Theorem 4.1 is proved in § 5.

5. Proof of Theorem 4.1.

A special case. Our strategy is first to prove the theorem in the presence of two supplementary hypotheses. These will be disposed of at a later stage. For the time being then we impose the following hypotheses.

(IU) $\{(T_0^i, T_1^i, x_i(\cdot)\}$ is the unique solution to (Q).

(IL) g is a linear function of the form $g(\{\tau_0^i, \tau_1^i, y_0^i, y_1^i\}) = \sum_{i=1}^k g_i \cdot y_1^i$ in which g_i is a given vector in $\mathbb{R}^{n_i}$, $i = 1, \cdots, k$.

The proof hinges on an introduction of a family of problems $Q(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$ generated by perturbations to the constraint set M. Choose $\varepsilon > 0$ (this will remain fixed) with the property

$$\operatorname{graph}\{x_i(\cdot)\} + 2\varepsilon B \subset \Gamma^i, \qquad i = 1, \cdots, k,$$

and define the closed sets $\tilde{\Gamma}^i$, $i = 1, \cdots, k$ to be

$$\tilde{\Gamma}^i := \operatorname{graph}\{x_i(\cdot)\} + \varepsilon \bar{B}.$$

For each vector $\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\} \in \prod_i (\mathbb{R} \times \mathbb{R} \times \mathbb{R}^{n_i} \times \mathbb{R}^{n_i})$ problem $Q(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$ is taken to be the following:

$$\begin{aligned}
&\text{minimize} \quad g(\{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\}) \\
&\text{subject to} \\
&\qquad \dot{y}_i(t) \in F_i(t, y_i(t)) \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i], \\
&\qquad \dot{y}_i(t) = 0 \qquad\qquad\; \text{a.e. } t \in I_i \backslash [\tau_0^i, \tau_1^i], \\
&\qquad \operatorname{graph}\{y_i(\cdot)\} \subset \tilde{\Gamma}^i
\end{aligned}$$

for $i=1,\cdots,k$ and

$$\{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\} \in M + \{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}. \tag{5.1}$$

In the above, set I_i is the fixed time interval

$$I_i = [T_0^i - \varepsilon,\ T_1^i + \varepsilon],$$

$i=1,\cdots,k$. Minimization is conducted over k-tuples of elements $\{\tau_0^i, \tau_1^i, y_i(\cdot)\}_{i=1}^k$ comprising Lipschitz continuous functions $y_i(\cdot): I_i \to \mathbb{R}^{n_i}$ and endpoints τ_0^i, τ_1^i of closed intervals satisfying $[\tau_0^i, \tau_1^i] \subset I_i$. A k-tuple of such elements satisfying the constraints of the problem, with the possible exception of (5.1), is called a *trajectory*. In the event (5.1) is satisfied as well, the trajectory is said to be *admissible* (for $Q(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$. Problem $Q(\{0,0,0,0\})$ will be recognized as a refinement of problem (Q) in which the constraint set Γ^i is replaced by the closed subset $\tilde{\Gamma}^i$. Clearly the point $\{T_0^i, T_1^i, x_i(\cdot)\}$ remains a solution to $Q(\{0,0,0,0\})$.

We denote by V the value function associated with these perturbations of problem (Q): given $\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\} \in \prod_i (\mathbb{R}\times\mathbb{R}\times\mathbb{R}^{n_i}\times\mathbb{R}^{n_i})$ then $V(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$ is taken to be the infimum cost of problem $Q(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$. (The infimum cost is interpreted as "$+\infty$" if no admissible trajectory exists.)

Standard sequential compactness arguments of existence theory (see, e.g., [2, Thm. 3.1.7]) together with (IU) yield the fact that $Q(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$ has a solution if there is an admissible trajectory, along with the following information.

LEMMA 5.1. (i) *Let* $\{\bar{\rho}_0^i, \bar{\rho}_1^i, \bar{\sigma}_0^i, \bar{\sigma}_1^i\}$ *represent terms in a sequence converging to* $\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}$ *and let* $\{\bar{\tau}_0^i, \bar{\tau}_1^i, \bar{y}_i(\cdot)\}$ *be a solution to* $Q(\{\bar{\rho}_0^i, \bar{\rho}_1^i, \bar{\sigma}_0^i, \bar{\sigma}_1^i\})$. *Then, following replacement of the original sequence by a subsequence if necessary, we have that* $\bar{\tau}_0^i \to \tau_0^i$, $\bar{\tau}_1^i \to \tau_1^i$ *for each* i, *and* $\bar{y}_i(\cdot) \to y_i(\cdot)$ *uniformly for each* i *where* $\{\tau_0^i, \tau_1^i, y_i(\cdot)\}$ *is an admissible trajectory for* $Q(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$.

(ii) *If in part* (i) $\{\rho_0^i, \rho_i^i, \sigma_0^i, \sigma_i^i\} = \{0,0,0,0\}$ *and also* $V(\{\bar{\rho}_0^i, \bar{\rho}_1^i, \bar{\sigma}_0^i, \bar{\sigma}_1^i\}) \to V\{0,0,0,0\}$ *then* $\{\tau_0^i, \tau_1^i, y_i(\cdot)\} = \{T_0^i, T_1^i, x_i(\cdot)\}$.

(iii) *The epigraph of* V, epi V, *is closed.*

We now proceed to an analysis of proximal normals to epi V at a point

$$[\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\},\ V(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}) + \delta]$$

(with $\delta \geqq 0$). Recall that a nonzero vector ζ is a proximal normal to a closed set $S \subset \mathbb{R}^q$ at one of its points s provided that, for some $m \geqq 0$, we have

$$-\zeta \cdot s' + m|s'-s|^2 \geqq -\zeta \cdot s \quad \text{for all } s' \in S. \tag{5.2}$$

In the present analysis the role of S is played by epi V and the only fact required about proximal normals is that a dense subset of points s in the boundary of S admit a proximal normal (or perpendicular [2, p. 66]).

LEMMA 5.2. *Let* $[\{h_0^i, -h_1^i, -s_0^i, s_1^i\}, -\lambda]$ *be a proximal normal to* epi V *at the point* $[\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\},\ V(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}) + \delta]$. *Let* $\{\tau_0^i, \tau_1^i, z_i(\cdot)\}$ *solve* $Q(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$ *and suppose that graph* $\{z_i(\cdot): [\tau_0^i, \tau_1^i] \to \mathbb{R}^{n_i}\}$ *is interior to* $\tilde{\Gamma}^i$ *for* $i=1,\cdots,k$. *Let* $\{\alpha_0^i, \alpha_1^i, \gamma_0^i, \gamma_1^i\}$ *be the point in* M *such that* $\{\tau_0^i, \tau_1^i, z_i(\tau_0^i), z_i(\tau_1^i)\} = \{\alpha_0^i, \alpha_1^i, \gamma_0^i, \gamma_1^i\} + \{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}$. *Then for* $i=1,\cdots,k$ *there exists an absolutely continuous function* $p_i(\cdot): I_i \to \mathbb{R}^{n_i}$ *such that*

$$(-\dot{p}_i(t), \dot{z}_i(t)) \in \begin{cases} \partial \mathscr{H}_i(t, z_i(t), p_i(t)) & \text{a.e. on } [(\tau_0^i, \tau_1^i]), \\ \{0, 0\} & \text{a.e. } I_i \backslash [(\tau_0^i, \tau_1^i]), \end{cases} \tag{5.3}$$

$$p_i(\tau_0^i) = s_0^i, \tag{5.4}$$

$$p_i(\tau_1^i) = s_1^i - \lambda g_i, \tag{5.5}$$

$$h_0^i \in \operatorname{co} \operatorname*{ess}_{t \to \tau_0^i} \mathscr{H}_i(t, z_i(\tau_0^i), p_i(\tau_0^i)), \tag{5.6}$$

$$h_1^i \in \operatorname{co} \operatorname*{ess}_{t \to \tau_1^i} \mathscr{H}_i(t, z_i(\tau_1^i), p_i(\tau_1^i)). \tag{5.7}$$

Furthermore,

$$\{h_0^i, -h_1^i, -s_0^i, s_1^i\} \in |\{h_0^i, -h_1^i, -s_0^i, s_1^i\}| \partial d_M(\{\alpha_0^i, \alpha_1^i, \gamma_0^i, \gamma_1^i\}). \tag{5.8}$$

Proof. Let $\{t_0^i, t_1^i, y_i(\cdot)\}$ be an arbitrary trajectory. Let $\{\bar{\alpha}_0^i, \bar{\alpha}_1^i, \bar{\gamma}_0^i, \bar{\gamma}_1^i\}$ be any point in M and $\bar{\delta}$ any nonnegative number. Observe that, by definition of the epigraph, the point

$$\left[\{t_0^i - \bar{\alpha}_0^i, t_1^i - \bar{\alpha}_1^i, y_i(t_0^i) - \bar{\gamma}_0^i, y_i(t_1^i) - \bar{\gamma}_1^i\}, \sum_i g_i \cdot y_i(t_1^i) + \bar{\delta}\right]$$

lies in epi V; we use this in the proximal normal inequality (5.2). The role of s is played by

$$\left[\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}, \sum_i g_i \cdot z_i(\tau_1^i) + \delta\right],$$

which equals

$$\left[\{\tau_0^i - \alpha_0^i, \tau_1^i - \alpha_1^i, z_i(\tau_0^i) - \gamma_0^i, z_i(\tau_1^i) - \gamma_1^i\}, \sum_i g_i z_i(\tau_1^i) + \delta\right]$$

and ζ is of course $[\{h_0^i, -h_1^i, -s_0^i, s_1^i\}, -\lambda]$.

Substitution into (5.2) leads to the following conclusions:

$$\begin{aligned} \sum_i \Big[& -h_0^i(t_0^i - \bar{\alpha}_0^i - \tau_0^i + \alpha_0^i) + h_1^i(t_1^i - \bar{\alpha}_1^i - \tau_1^i + \alpha_1^i) \\ & + s_0^i \cdot (y_i(t_0^i) - \bar{\gamma}_0^i - z_i(\tau_0^i) + \gamma_0^i) - s_1^i \cdot (y_i(t_1^i) - \bar{\gamma}_1^i - z_i(\tau_1^i) + \gamma_1^i) \\ & + \lambda \left(\sum_i g_i \cdot y_i(t_1^i) + \bar{\delta} - \sum_i g_i \cdot z_i(\tau_1^i) - \delta \right) \Big] + m\Delta \geqq 0. \end{aligned} \tag{5.9}$$

Here m is some nonnegative number and

$$\begin{aligned} \Delta = & \left| \sum_i g_i \cdot y_i(t_1^i) + \bar{\delta} - \sum_i g_i \cdot z_i(\tau_1^i) - \delta \right|^2 \\ & + \sum_i (|t_0^i - \bar{\alpha}_0^i - \tau_0^i + \alpha_0^i|^2 + |t_1^i - \bar{\alpha}_1^i - \bar{\tau}_1^i + \alpha_1^i|^2) \\ & + \sum_i (|y_i(t_0^i) - \bar{\gamma}_0^i - z_i(\tau_0^i) + \gamma_0^i|^2 + |y_i(t_1^i) - \bar{\gamma}_1^i - z_i(\tau_1^i) + \gamma_1^i|^2). \end{aligned}$$

In (5.9) we set

$$\{t_0^i, t_1^i, y_i(\cdot)\} = \{\tau_0^i, \tau_1^i, z_i(\cdot)\}$$

to derive

$$\sum_i (-h_0^i(\alpha_0^i - \bar{\alpha}_0^i) + h_1^i(\alpha_1^i - \bar{\alpha}_1^i) + s_0^i(\gamma_0^i - \bar{\gamma}_0^i) - s_1^i(\gamma_1^i - \bar{\gamma}_1^i)) + \lambda(\bar{\delta} - \delta)$$

$$+ m\left(\sum_i (|\alpha_0^i - \bar{\alpha}_0^i|^2 + |\alpha_1^i - \bar{\alpha}_1^i|^2 + |\gamma_0^i - \bar{\gamma}_0^i|^2 + |\gamma_1^i - \bar{\gamma}_1^i|^2 + |\delta - \bar{\delta}|^2\right) \geqq 0,$$

for all $\bar{\delta} \geqq 0$ and points $\{\bar{\alpha}_0^i, \bar{\alpha}_1^i, \bar{\gamma}_0^i, \bar{\gamma}_1^i\}$ in M. We conclude from this inequality, along with [2, Props. 2.3.2, 2.4.2], that $\lambda \geqq 0$ and the inclusion (5.8) holds.

We now return to (5.9). Set $(\bar{\alpha}_0^j, \bar{\alpha}_1^j, \bar{\gamma}_0^j, \bar{\gamma}_1^j) = (\alpha_0^j, \alpha_1^j, \gamma_0^j, \gamma_1^j)$, $t_0^j = \tau_0^j$ and $t_1^j = \tau_1^j$ for all j, $1 \leqq j \leqq k$, and set $\bar{\delta} = \delta$. Select an integer i, $1 \leqq i \leqq k$, and set $y_j(\cdot) = z_j(\cdot)$ for all $j \neq i$. We deduce that $z_i(\cdot)$ solves the free-endpoint, fixed time problem of minimizing

$$\lambda g_i \cdot y(\tau_1^i) + s_0^i \cdot y(\tau_0^i) - s_1^i \cdot y(\tau_1^i)$$

$$+ m[|g_i \cdot y(\tau_1^i) - g_i \cdot z_i(\tau_1^i)|^2 + |y(\tau_0^i) - z_i(\tau_0^i)|^2 + |y(\tau_1^i) - z_i(\tau_1^i)|^2]$$

over component trajectories $y(\cdot): [\tau_0^i, \tau_1^i] \to \mathbb{R}^{n_i}$.

Suppose first that $\tau_0^i \neq \tau_1^i$. Since graph $\{z_i(\cdot)\}$ is assumed to be interior to $\bar{\Gamma}_i$ we can apply known necessary conditions [2, Thm. 3.2.6] to this problem, and conclude existence of an absolutely continuous function $p_i(\cdot)$ satisfying (5.3), (5.4), and (5.5). If $\tau_0^i = \tau_1^i$ (=: τ^i), the minimizing property of $z_i(\cdot)$ implies that $\lambda g_i + s_0^i - s_1^i = 0$. Otherwise expressed, there exists a vector that we write as $p_i(\tau^i)$, such that $p_i(\tau^i) = s_0^i$ and $p_i(\tau^i) = s_1^i - \lambda g_1$. Thus (5.4) and (5.5) are verified. In this case (5.3) is trivially satisfied.

There remains (5.6) and (5.7). Select an integer i, $1 \leqq i \leqq k$. It is convenient to separate the cases in which the time interval $[\tau_0^i, \tau_1^i]$ is degenerate and nondegenerate. Suppose first that $\tau_1^i > \tau_0^i$. Since z_i is assumed to have graph interior to $\tilde{\Gamma}^i$, we may choose $t_1^i \in I_i$ such that $t_1^i > \tau_1^i$. We proceed to extend $z_i(\cdot)|_{[\tau_0^i, \tau_1^i]}$ to $[\tau_0^i, t_1^i]$ thereby defining a component trajectory $y_i(\cdot)$. The hypotheses are satisfied under which Aumann's Selection Theorem (see [1]) applies to yield an absolutely continuous function $\xi: [\tau_1^i, t_1^i] \to \mathbb{R}^{n_i}$ such that $\xi(\tau_1^i) = z_i(\tau_1^i)$ and whose derivative has the following selection property:

$$\dot{\xi}(t) \in F_i(t, z_i(\tau_1^i)) \cap E_i(t) \quad \text{a.e.}$$

Here

$$E_i(t) = \{e \,|\, p_i(\tau_1^i) \cdot e = \max [p_i(\tau_1^i) \cdot e' \,|\, e' \in F_i(t, z_i(\tau_1^i))]\}.$$

Then

$$p_i(\tau_1^i) \cdot \dot{\xi}(t) = \mathcal{H}_i(t, z(\tau_1^i), p_i(\tau_1^i)) \quad \text{a.e. } t \in [\tau_1^i, t_1^i]. \tag{5.10}$$

It now follows from Theorem [2] of 3.1.6 and the hypotheses on $F_i(\cdot, \cdot)$ that there exists an absolutely continuous function $\xi(\cdot): [\tau_1^i, t_1^i] \to \mathbb{R}^{n_i}$ for which the following is true:

$$\begin{aligned} &\dot{\xi}(t) \in F_i(t, \xi(t)) \quad \text{a.e. } t \in [\tau_1^i, t_1^i], \\ &\xi(t_1^i) = z_i(\tau_1^i), \\ &[t_1^i - \tau_1^i]^{-1} \int_{\tau_1^i}^{t_1^i} |\dot{\xi}(s) - \dot{\bar{\xi}}(s)| \, ds \leqq K^2 \exp\{K(t_1^i - \tau_1^i)\}(t_1^i - \tau_1^i). \end{aligned} \tag{5.11}$$

Note that this bound has limit zero as $t_1^i \downarrow \tau_1^i$.

Now examine inequality (5.9) in the following situation. We take $\bar{\delta} = \delta$ and $\{\bar{\alpha}_0^j, \bar{\alpha}_1^j, \bar{\gamma}_0^j, \bar{\gamma}_1^j\} = \{\alpha_0^j, \alpha_1^j, \gamma_0^j, \gamma_1^j\}$ for all j, $1 < j \leqq k$. For $j \neq i$ take $(t_0^j, t_1^j, y_j(\cdot)) = (\tau_0^j, \tau_1^j, z_j(\cdot))$. Take also $t_0^i = \tau_0^i$ and define $y_i(\cdot) : [\tau_0^i, t_1^i] \to \mathbb{R}^{n_i}$ to be

$$y_i(t) = \begin{cases} z_i(t) & \text{for } t \in [\tau_0^i, \tau_1^i], \\ \xi(t) & \text{for } t \in [\tau_1^i, t_1^i]. \end{cases}$$

Write $\varepsilon' = t_1^i - \tau_1^i$ and divide across by ε'. There results

$$h_1^i - (s_1^i - \lambda g_i)\left((\varepsilon')^{-1} \int_{\tau_1^i}^{\tau_1^i + \varepsilon'} \dot{\xi}(s)\, ds\right) + (\varepsilon')^{-1} m\Delta \geqq 0.$$

Since $p_i(\tau_1^i) = s_1^i - \lambda g_i$, and by (5.10),

$$-h_1^i + (\varepsilon')^{-1} \int_{\tau_1^i}^{\tau_1^i + \varepsilon'} \mathscr{H}_i(t, z_i(\tau_1^i), p_i(\tau_1^i))\, dt$$

$$\leqq (\varepsilon')^{-1} m\Delta + (\varepsilon')^{-1} p_i(\tau_1^i) \cdot \int_{\tau_1^i}^{\tau_1^i + \varepsilon'} |\dot{\xi}(s) - \dot{\bar{\xi}}(s)|\, ds.$$

Because of the bound on F_i we have $|y_i(t_1^i) - z_i(\tau_1^i)| \leqq K|t_1^i - \tau_0^i|$, from which it follows that $\Delta/\varepsilon' \to 0$ as $\varepsilon' \downarrow 0$. The second term on the right-hand side is zero in the limit, by (5.11). It follows that

$$\limsup_{\varepsilon' \downarrow 0} (\varepsilon')^{-1} \int_{\tau_1^i}^{\tau_1^i + \varepsilon'} [\mathscr{H}_i(t, z_i(\tau_1^i), p_i(\tau_1^i)) - h_1^i]\, dt \leqq 0.$$

This means that

$$h_1^i \in \operatorname*{ess}_{t \to \tau_1^i} \mathscr{H}_i(t, z_i(\tau_1^i), p_i(\tau_1^i)) + [0, \infty), \tag{5.12}$$

since otherwise $\mathscr{H}_i - h_1^i > 0$ almost everywhere on some neighbourhood of τ_1^i, in contradiction of the inequality. Similar reasoning, but where we now choose $t_1^i < \tau_1^i$, produces

$$\liminf_{\varepsilon' \downarrow 0} (\varepsilon')^{-1} \int_{\tau_1^i - \varepsilon'}^{\tau_1^i} [\mathscr{H}_i(t, z_i(\tau_1^i), p_i(\tau_1^i)) - h_1^i]\, dt \geqq 0$$

from which it follows that

$$h_1^i \in \operatorname*{ess}_{t \to \tau_1^i} \mathscr{H}_i(t, z_i(\tau_1^i), p_i(\tau_1^i)) + (-\infty, 0]. \tag{5.13}$$

The two inclusions (5.12) and (5.13) imply

$$h_1^i \in \operatorname{co} \operatorname*{ess}_{t \to \tau_1^i} \mathscr{H}_i(t, z_i(\tau_1^i), p_i(\tau_1^i)).$$

The same arguments applied to the left endtime τ_0^i of the ith component trajectory $x_i(\cdot)$ yield

$$h_0^i \in \operatorname{co} \operatorname*{ess}_{t \to \tau_0^i} \mathscr{H}_i(t, z_i(\tau_0^i), p_i(\tau_0^i)).$$

We have proved (5.6) and (5.7) in the case $\tau_1^i > \tau_0^i$. To deal with the remaining case we suppose that $\tau_1^i = \tau_0^i$ $(=: \tau^i)$. Those aspects of earlier reasoning concerned with extending component trajectories to left or right remain valid in the degenerate case and yield the inequalities

$$\limsup_{\varepsilon' \downarrow 0} (\varepsilon')^{-1} \int_{\tau^i}^{\tau^i + \varepsilon'} [\mathscr{H}_i(t, z_i(\tau^i), p_i(\tau^i)) - h_1^i]\, dt \leqq 0,$$

$$\liminf_{\varepsilon' \downarrow 0} (\varepsilon')^{-1} \int_{\tau^i - \varepsilon}^{\tau^i} [\mathscr{H}_i(t, z_i(\tau^i), p_i(\tau^i)) - h_0^i]\, dt \geqq 0.$$

We will be able to conclude the desired inclusions (5.6) and (5.7) from these inequalities provided we can show that $h_1^i = h_0^i$. To this end we return to inequality (5.9). We set $\bar{\delta} = \delta$, and, for $j \neq i$, $\{\bar{\alpha}_0^j, \bar{\alpha}_1^j, \bar{\gamma}_0^j, \bar{\gamma}_1^j\} = \{\alpha_0^j, \alpha_1^j, \gamma_0^j, \gamma_1^j\}$ and $y_j(\cdot) = z_j(\cdot)$. We also set $t_1^i = \tau^i + \varepsilon'$ for some small nonzero ε' and $y_i(\cdot) \equiv z_i(\tau^i)$. Dividing across by ε' and passing to the limit as $\varepsilon' \to 0$, both from above and below, we obtain $0 \leqq -h_0^i + h_1^i \leqq 0$, i.e., $h_1^i = h_0^i$, as required. Proof of the lemma is complete.

The next step of the proof is to regard the proximal normal $[\{h_0^i, -h_1^i, -s_0^i, s_1^i\}, -\lambda]$ of Lemma 5.2, and its base point $[\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}, V(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}) + \delta]$ in epi V, as general terms in sequences such that

$$\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\} \to \{0, 0, 0, 0\} \quad \text{and} \quad V(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\}) + \delta \to V(\{0, 0, 0, 0\}).$$

Let $\{\tau_0^i, \tau_1^i, z_i(\cdot)\}$ be a solution to $Q(\{\rho_0^i, \rho_1^i, \sigma_0^i, \sigma_1^i\})$. We can arrange by subsequence extraction that $\tau_0^i \to T_0^i$, $\tau_1^i \to T_1^i$ and $z_i(\cdot) \to x_i(\cdot)$ uniformly, and also that the graph of $z_i(\cdot)$ is interior to $\tilde{\Gamma}^i$ along the sequence. Now apply Lemma 5.1. It follows from (5.4), (5.6), and (5.8) and hypotheses (I4) and (I5) that

$$\{-h_0^i, h_1^i, p_i(\tau_0^i), -p_i(\tau_1^i)\} \in \lambda \partial g + c\left[\sum_i |p_i(T_1^i)| + \lambda\right] \partial d_M. \tag{5.14}$$

Here ∂g and ∂d_Λ are evaluated at the point

$$\{\tau_0^i - \rho_0^i, \tau_1^i - \rho_1^i, z_i(\tau_0^i) - \sigma_0^i, z_i(\tau_1^i) - \sigma_1^i\}.$$

The magnitude of the number c is determined solely by the constant K of hypotheses (I4) and (I5) and by $\sum_i |g_i|$. We readily deduce from the fact that the proximal normal vector $[\{h_0^i, -h_1^i, -s_0^i, s_1^i\}, -\lambda]$ is nonzero that $[\sum_i |p_i(\tau_1^i)| + \lambda]$ is nonzero. Replace $\{p_i(\cdot)\}$ and λ by scaled versions, and so arrange that $[\sum_i |p_i(\tau_1^i)| + \lambda] = 1$. We thereby render the $p_i(\cdot)$'s elements in uniformly bounded and equicontinuous families of functions. By subsequence extraction we can then arrange that each $p_i(\cdot)$ has uniform limit a Lipschitz continuous function on I_i. We can also arrange that each $x_i(\cdot)$ has uniform limit $x_i(\cdot)$ (we appeal to Lemma 5.1 at this point) and the bounded sequences with general terms h_0^i, h_1^i and λ have limits also.

The differential inclusion (5.3) is preserved in the limit (see [2, Thm. 3.1.7]) along with the transversality condition (5.14) (by the upper semicontinuity properties of generalized gradients), in which component processes $z_i(\cdot)$ are replaced by $x_i(\cdot)$ and the generalized gradients ∂g and ∂d_M are evaluated at $\{T_0^i, T_1^i, x(T_0^i), x(T_1^i)\}$. Clearly we have $[\sum_i |p_i(T_1^i)| + \lambda] = 1$ in the limit. Finally we note that, since $z_i(\tau_1^i) \to x_i(T_1^i)$ and $p_i(\tau_1^i)$ converges to the value of the limiting costate function at T_1^i and in view of Lemma 2.1, the interpretation (5.6) and (5.7) of the h_0^i's and h_1^i's as convex essential values continue to hold good in the limit. This concludes proof of Theorem 4.1 in the presence of the supplementary hypotheses (IU) and (IL).

Removal of (IL). We next prove the special case of Theorem 4.1 in which the data is assumed to satisfy hypotheses (I1)–(I5) and (IU), but possibly not (IL).

We add an additional scalar-valued component trajectory $z(\cdot)$ and supplement the former dynamical equations as follows:

$$\dot{y}_i \in F_i(t, y_i) \quad \text{a.e. on } [\tau_0^i, \tau_1^i]$$

for $i = 1, \ldots, k$, and

$$\dot{z} \in \{0\}, \quad \text{a.e. on } [\sigma_0, \sigma_1].$$

The endpoints of the trajectories are constrained to satisfy

$$(\{\tau_0^i, \tau_1^i, y_i(\tau_0^i), y_i(\tau_1^i)\}, (\sigma_0, \sigma_1, z(\sigma_0), z(\sigma_1)) \in \tilde{M}.$$

The set $\tilde{M}$ is taken to be

$$\tilde{M} := \{(a, 0, 1, z_0, z_1) | a \in M, z_0 \geqq g_e(a, 0, 1, z_1)\}$$

in which g_e is the extension of $\hat{g}$ to $\prod_{i=1}^{k} (\mathbb{R}\times\mathbb{R}\times\mathbb{R}^{n_i}\times\mathbb{R}^{n_i})\times(\mathbb{R}\times\mathbb{R}\times\mathbb{R})$ defined by

$$g_e(a, (\sigma_0, \sigma_1, z_1)) = g(a).$$

(Note in particular that the endtimes of the new component trajectory are fixed at $t=0$ and 1 and its value at the right endtime is unconstrained.) The new objective function is

$$\tilde{g}(a, (\sigma_0, \sigma_1, z_0, z_1)) = z_1.$$

It is a simple matter to see that this modified problem continues to satisfy the hypotheses (I1)-(I5) as well as (IU) and that it has a solution

$$(\{T_0^i, T_1^i, x_i(\cdot)\}, (0, 1, y(\cdot)) \equiv g(\{T_0^i, T_1^i, x_i(T_0^i), x_i(T_1^i)\})).$$

Since, in addition, the problem clearly satisfies (IL), the conclusions of the theorem for this problem are available to us. These are seen to imply existence of a number $\lambda \geqq 0$, numbers α, β, and q, and functions $p_i(\cdot)$ and numbers h_0^i, h_1^i for $i=1, \ldots, k$, such that $[\sum_i |p_i(T_1^i)| + q + \lambda] = 1$, the Hamiltonian inclusions are satisfied, the h_0^i, h_1^i's are convex essential values of the Hamiltonian functions, and

$$(5.15) \quad \{-h_0^i, h_1^i, p_i(T_0^i), -p_i(T_1^i)\}, (\alpha, \beta, -q, q) \in c\,\partial d_{\tilde{M}} + \lambda[0, (0, \cdots, 0, 1)].$$

Here c is a number whose magnitude is governed by the constant K of hypotheses (I4) and (I5). $\partial d_{\tilde{M}}$ is evaluated at $(\bar{a}, (0, 1, g(\bar{a}), g(\bar{a})))$ in which $\bar{a}$ denotes $\{T_0^i, T_1^i, x_i(T_0^i), x_i(T_1^i)\}$.

We pause to take note of the following estimate on points in the generalized gradient of a distance function (see [4, Lemma 4.1]).

LEMMA 5.3. *Let $S \subset \mathbb{R}^k$ be a closed set and take a point $\bar{s} \in S$. Suppose there is a constant $\delta > 0$ and a function $l: \bar{s} + \delta B \to \mathbb{R}$ such that l is Lipschitz continuous of rank at most K_l on $\bar{s} + \delta B$. Then for all $R \geqq (1 + K_l^2)^{1/2}$ we have*

$$\partial d_{\mathrm{epi}(l+\psi_S)}(\bar{s}, l(\bar{s})) \subset \{(\zeta, -\varepsilon) | \zeta \in \varepsilon\partial l(\bar{s}) + R\,\partial d_S(\bar{s}), \varepsilon \geqq 0\}.$$

Here $\psi_S(s)$ equals zero if $s \in S$, $+\infty$ otherwise.

Appealing to this lemma, and also to the fact that

$$(5.16) \qquad \partial d_{M\times\{0\}\times\{1\}\times\mathbb{R}} \subset \partial d_M \times B \times B \times \{0\}$$

(see [2, Thm. 2.5.6]), we deduce from (5.15) that $q = \lambda$ and

$$\{-h_0^i, h_1^i, p_i(T_0^i), -p_i(T_1^i)\} \in \lambda\,\partial g + c(1 + \bar{K}^2)^{1/2}\,\partial d_M.$$

Here $\bar{K}$ is an upper bound on the Lipschitz rank of g on a neighbourhood of $\{T_0^i, T_1^i, x_i(T_0^i), x_i(T_1^i)\}$. It remains to replace the $p_i(\cdot)$'s and λ by scaled versions which have the property that $\sum_i |p_i(T_1^i)| + \lambda = 1$, as is possible since $\lambda = q$. The Hamiltonian inclusions are unaffected. As for the transversality condition, this is clearly valid provided $c(1 + \bar{K}^2)^{1/2}$ is replaced by $2c(1 + \bar{K}^2)^{1/2}$, a number whose magnitude is governed by the constant K of hypotheses (I4) and (I5) and by $\bar{K}$.

Removal of (IU). Suppose finally that the data of the problem satisfy hypotheses (I1)-(I5), but possibly not (IU). As usual $\{T_0^i, T_1^i, x_i(\cdot)\}$ is the solution to (P) under consideration.

Consider a modified version of the problem in which each component trajectory has its state dimension increased by one and is now governed by the dynamics

$$\dot{z}_i = (y_i - x_i(t))^2 \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i],$$
$$\dot{y}_i \in F_i(t, y_i) \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i].$$

The objective functional is now taken to be $\tilde{g}$:

$$\tilde{g}(\{\tau_0^i, \tau_1^i, (z_0^i, y_0^i), (z_1^i, y_1^i)\}) = g(\{\tau_0^i, \tau_1^i, y_0^i, y_1^i\}) + \sum_i (|z_i(\tau_1^i)|^2 + |\tau_0^i - T_0^i|^2 + |\tau_1^i - T_1^i|^2)$$

and the original constraint set M is replaced by $\tilde{M}$:

$$\tilde{M} = \{\{\tau_0^i, \tau_1^i, (z_0^i, y_0^i), (z_1^i, y_1^i)\} | \{\tau_0^i, \tau_1^i, y_0^i, y_1^i\} \in M \text{ and } z_0^i = 0 \text{ for } i = 1, \cdots, k\}.$$

Note that $\{T_0^i, T_1^i, (z_i(\cdot) \equiv 0, x_i(\cdot))\}$ is a solution to this problem, and furthermore this solution is unique because we have arranged that deviations from it are penalized. It is clear that the modified problem satisfies (IU) in addition to hypotheses (I1)-(I5). We are permitted then to apply the special case of the theorem already proved. The conclusions of the theorem for the original problem are seen to follow. (Presence of squared terms in the modified problem ensures that the additional dynamics and perturbations to the objective functional do not impinge on the necessary conditions.)

6. Proof of Theorem 3.1. Our proof of Theorem 3.1, by application of Theorem 4.1 to an auxiliary problem, has much in common with the proof of the maximum principle of Clarke for boundary points of the attainable set [2, pp. 201-209]. We enter into the details of the argument only when there is a significant departure, most notably in the setting up of the auxiliary problem.

Choose $\varepsilon > 0$ such that

$$\text{graph } \{x_i(\cdot)\} + 2\varepsilon B \subset X^i, \qquad i = 1, \cdots, k,$$

and define the sets $\tilde{X}^i$, $i = 1, \cdots, k$, to be

$$\tilde{X}^i = \text{graph } \{x_i(\cdot)\} + \varepsilon \bar{B}, \qquad i = 1, \cdots, k.$$

Now let I_i denote the interval $[T_0^i - \varepsilon, T_1^i + \varepsilon]$, $i = 1, \cdots, k$.

A point of terminology: An "extended multiprocess" is just a multiprocess $\{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\}$ with $[\tau_0^i, \tau_1^i] \subset I_i$ and graph $\{y_i(\cdot)\} \subset \tilde{X}_i$, $i = 1, \cdots, k$, in all respects except $y_i(\cdot)$ is viewed as a function with domain I_i, obtained from the original multiprocess by constant extrapolation to left and right, and $w_i(\cdot)$ is now taken to represent an equivalence class of functions equal almost everywhere, $i = 1, \cdots, k$. Denote by W the set of extended processes that satisfy $\{\tau_0^i, \tau_1^i, y_i(\tau_0^i)\} \in C$. Let $\Delta: W \times W \to \mathbb{R}$ be the function

$$\Delta(\{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\}, \{\bar{\tau}_0^i, \bar{\tau}_1^i, \bar{y}_i(\cdot), \bar{w}_i(\cdot)\})$$
$$:= \sum_i [|\tau_0^i - \bar{\tau}_0^i| + [|\tau_1^i - \bar{\tau}_1^i| + |y_i(\tau_0^i) - \bar{y}_i(\bar{\tau}_0^i)|$$
$$+ \mathscr{L}\text{-meas } \{t \in [\tau_0^i \vee \bar{\tau}_0^i, \tau_1^i \wedge \bar{\tau}_1^i] | w_i(t) \neq \bar{w}_i(t)\}].$$

Here $a \vee b$, $a \wedge b$ denote the maximum and minimum of a and b, respectively. Simple modifications of the proof of Lemma 1 of [2, p. 202] establish the following lemma.

LEMMA 6.1. *The function Δ is a metric on W, and (W, Δ) is a complete metric space. Let $\{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\}$ represent the general term in a sequence of points in (W, Δ) converging to a point $\{\bar{\tau}_0^i, \bar{\tau}_1^i, \bar{y}_i(\cdot), \bar{w}_i(\cdot)\}$. Then* $\limsup_{t \in I_i} |y_i(t) - \bar{y}_i(t)| = 0$, *for* $i = 1, \cdots, k$.

Let n be a positive integer and let ζ be a point in $\psi(\{x_i(T_1^i)\})+n^{-2}B$ such that $\zeta \notin \mathscr{R}_{\psi,C}$, and define the function $F:(W,\Delta)\to\mathbb{R}$ to be

$$F(\{\tau_0^i, \tau_1^i, y_i(\cdot), u_i(\cdot)\}) := |\zeta - \psi(\{y_i(\tau_1^i)\})|.$$

By Lemma 6.1, F is a continuous function. We have

$$F(\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}) < \inf_{e\in W} F(e) + n^{-2}.$$

(There is a minor abuse of notation here that we shall repeat. The same symbols are used for the solution $\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}$ and the corresponding *extended* multiprocess.) The hypotheses are met under which Ekeland's Theorem [6] is applicable. This tells us that there exists a point $\bar{e}=\{\bar{T}_0^i, \bar{T}_1^i, \bar{x}_i(\cdot), \bar{u}_i(\cdot)\}$ in W such that, writing $e=\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}$, we have

$$\Delta(e,\bar{e}) \leqq n^{-1} \tag{6.1}$$

$$F(\bar{e}) \leqq F(e') + n^{-1}\Delta(e',\bar{e}) \quad \text{for all } e'\in W. \tag{6.2}$$

In view of (6.1), we may arrange that

$$\operatorname{graph}\{\bar{x}_i(\cdot)\} + (\varepsilon/2)B \subset \tilde{X}^i, \qquad i=1,\cdots,k$$

by choosing n sufficiently large. The following lemma is then a consequence of the minimizing property (6.2) of $\bar{e}$.

LEMMA 6.2. *Let* $\{\tau_0^i, \tau_1^i, y_i(\cdot), w_i(\cdot)\}$ *be any multiprocess such that* $\{\tau_0^i, \tau_1^i, y_i(\tau_0^i)\}\in C$ *and*

$$\sup_{t\in I_i} |y_i(t)-\bar{x}_i(t)| \leqq \frac{\varepsilon}{2}$$

for $i=1,\cdots,k$. *Then*

$$|\zeta-\psi(\{y_i(\tau_1^i)\})| + n^{-1}\sum_i \left([(\tau_0^i-\bar{T}_0^i)\vee 0] + [(\bar{T}_1^i-\tau_1^i)\vee 0] + |y(\tau_0^i)-\bar{x}(\tau_0^i)| + \int_{\tau_0^i}^{\tau_1^i} \mathscr{X}_i(t, w_i(t))\,dt \right) \geqq |\zeta-\psi(\{\bar{x}(T_1^i)\})|.$$

Here

$$\mathscr{X}_i(t,w) := \begin{cases} 1 & \text{if } t\notin [T_0^i, T_1^i] \text{ or } w\neq \bar{u}_i(t), \\ 0 & \text{otherwise.} \end{cases}$$

We proceed to interpret Lemma 6.2 in such a way that Theorem 4.1 becomes applicable. This requires us to consider new component state vectors $Y_i=(z_i, y_i)$ and associated differential inclusions with right-hand sides

$$F_i(t, Y_i) := \{[\mathscr{X}_i(t,w), \phi(t,y,w)] \mid w\in U_i^i\}.$$

We take the endpoint constraint set Λ to be

$$\Lambda := \{\{\tau_0^i, \tau_1^i, (z_0^i, y_0^i), (z_1^i, y_1^i)\} \mid \{\tau_0^i, \tau_1^i, y_0^i\}\in C,\ z_0^i=0,\ i=1,\cdots,k\}$$

and the function g to be

$$g(\{\tau_0^i, \tau_1^i, Y_0^i, Y_1^i\}) := |\zeta-\psi(\{y_1^i\})| + n^{-1}\sum_i (z_1^i + (\tau_0^i-\bar{T}_0^i)\vee 0 + (\bar{T}_1^i-\tau_1^i)\vee 0 + |y_0^i-\bar{x}(\bar{T}_0^i)|)$$

in which $Y_0^i=(z_0^i, y_0^i)$ and $Y_1^i=(z_1^i, y_1^i)$.

It is a simple matter to deduce from Lemma 6.2 that $(\bar{T}_0^i, \bar{T}_1^i, (\bar{z}(t) \equiv \int_0^t \mathscr{X}(s, \bar{u}(s))\, ds, \bar{x}(\cdot)))$ is a solution to the following optimization problem, which we label (P(n)):

(P(n))
$$\text{minimize} \quad g(\{\tau_0^i, \tau_1^i, Y_i(\tau_0^i), Y_i(\tau_1^i)\})$$
$$\text{subject to}$$

(6.3)
$$\dot{Y}_i(t) \in F_i(t, Y_i(t)) \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i],$$
$$\text{graph}\,\{Y_i(\cdot)\} \subset \mathbb{R} \times (\text{graph}\,\{\bar{x}(\cdot)\} + (\varepsilon/2)B), \qquad i = 1, \cdots, k,$$

(6.4)
$$\{\tau_0^i, \tau_1^i, Y_i(\tau_0^i), Y_i(\tau_1^i)\} \in \Lambda.$$

From this point the proof follows closely from [2, pp. 205–209] and we merely outline what is involved. We impose for the time being the following supplementary hypothesis.

(HF)
$$U_t^i \text{ is a finite set, for } t \in \mathbb{R},\ i = 1, \cdots, k.$$

Observe that condition (6.4) leaves $\{Y_i(\tau_1^i)\}$ unconstrained. We deduce by means of standard arguments (see, e.g., [2, p. 117]) that elements $\{Y_i(\cdot)]$ in problem (P(n)) that satisfy (6.3) and (6.4) can be approximated uniformly by elements associated with the differential inclusions

(6.5)
$$\dot{Y}_i(t) \in \text{co}\, F_i(t, Y_i(t)) \quad \text{a.e. } t \in [\tau_0^i, \tau_1^i],$$

which satisfy (6.4). (Hypothesis (HF) is significant at this point, since it ensures that F_i has closed values.) Because g is a continuous function, we can conclude that $\{\bar{T}_0^i, \bar{T}_1^i, \bar{z}_i(\cdot), \bar{x}_i(\cdot)\}$ is also a solution to a new problem, denoted by co (P(n)), in which condition (6.3) in (P(n)) is replaced by its convexification (6.5).

Problem co (P(n)) meets the requirements for application of Theorem 4.1. Arguing as in [2], we show that for each n sufficiently large there exist functions $\{p_i(\cdot): I_i \to \mathbb{R}^{n_i}\}$ (which are uniformly bounded and equicontinuous with respect to the index n), a vector v of unit length and measurable sets $A_i(n) \subset [T_0^i, T_1^i]$ such that

(6.6)
$$\mathscr{L} - \text{meas}\,\{A_i(n)\} \to T_1^i - T_0^i \quad \text{as } n \to \infty,$$
$$p_i(\bar{T}_1^i) \in \partial\psi^*(\{\bar{x}_i(\bar{T}_1^i)\})v$$

and for all $t \in A_i(n)$

(6.7)
$$-\dot{p}_i(t) \in \partial_x H(t, \bar{x}_i(t), u_i(t), p_i(t))$$

(6.8)
$$H_i(t, \bar{x}_i(t), u_i(t), p_i(t)) \geqq \max_{w \in U_t^i} \{H_i(t, \bar{x}_i(t), w, p_i(t))\} - n^{-1}.$$

(The hypothesis (HF) is once again involved.)

We can also show that

(6.9)
$$\{-h_0^i, h_1^i, p_i(\bar{T}_0^i)\} \in \bar{K}\partial_C(\{\bar{T}_0^i, \bar{T}_1^i, \bar{x}_i(\bar{T}_0^i)\}) + n^{-1}\bar{K}B$$

for some elements $\{h_0^i, h_1^i\}$ that satisfy

(6.10)
$$h_0^i \in \text{co} \operatorname*{ess}_{t \to T_1^i} \mathscr{h}_i(t, \bar{x}_i(\bar{T}_0^i), p_i(\bar{T}_1^i)) + n^{-1}\bar{K}B,$$

(6.11)
$$h_1^i \in \text{co} \operatorname*{ess}_{t \to T_1^i} \mathscr{h}_i(t, \bar{x}_i(\bar{T}_1^i), p_i(\bar{T}_1^i)) + n^{-1}\bar{K}B.$$

Here $\bar{K}$ is a number whose magnitude is governed by the constant K of hypotheses (H3) and (H4) and by the Lipschitz rank of ψ in a neighbourhood of $\{x_i(T_1^i)\}$. The function $\mathscr{h}_i$ is

$$\mathscr{h}_i(t, x, p) := \max_{w \in U_t^i} H_i(t, x, w, p).$$

We now extract subsequences to ensure that the h_0^i's, h_1^i's and v have limits and the $p_i(\cdot)$'s have uniform limits as $n \to \infty$ (we retain the symbols h_0^i, h_i^i, v, $p_i(\cdot)$ for the limits), and that

$$A := \bigcup_n \bigcap_{n \leqq m} A_i(m)$$

has measure $T_1^i - T_0^i$. The $\bar{x}_i(\cdot)$'s converge uniformly to $x_i(\cdot)$ by (6.1), as $n \to \infty$. Appealing to Theorem 3.1.7 of [2] and the upper semicontinuity properties of generalized gradients, we can take the limit, $n \to \infty$, in (6.7) and (6.8) for all $t \in A$, and in (6.6) and (6.7). Passing to the limit in (6.10) and (6.11) is justified by Lemma 2.1. There result the assertions of Theorem 3.1.

We recall that the theorem has been proved under the supplementary hypothesis (HF); this is disposed of by a componentwise application of techniques on p. 207 of [2].

Proof of Theorem 3.2. Let $\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}$ solve (P). Consider multiprocesses with state vectors $((y_1, \cdots, y_k), (\bar{y}_1, \cdots, \bar{y}_k), z) \in (\mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_k}) \times (\mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_k}) \times \mathbb{R}$. The dynamical equations and associated constraints are now taken to be

$$\begin{aligned}
&\dot{y}_i = f_i(t, y_i, u_i) && \text{a.e. } [\tau_0^i, \tau_1^i],\\
&u_i(t) \in U_t^i && \text{a.e. } [\tau_0^i, \tau_1^i],\\
&y_i(t) \in X_t^i && \text{for all } [\tau_0^i, \tau_1^i],\\
&\dot{\bar{y}}_i = \bar{u}_i && \text{a.e. } [\sigma_0^i, \sigma_1^i],\\
&\bar{u}_i(t) \in \{0\} && \text{a.e. } [\sigma_0^i, \sigma_1^i],
\end{aligned}$$

for $i = 1, \cdots, k$, and

$$\begin{aligned}
&\dot{z} = w && \text{a.e. } [\sigma_0^i, \sigma_1^i],\\
&w(t) \in \{0\} && \text{a.e. } [\sigma_0^i, \sigma_1^i].
\end{aligned}$$

The endpoints constraint of interest is

$$(\{\tau_0^i, \tau_1^i, y_i(\tau_0^i)\}, \{\sigma_0^i, \sigma_1^i, \bar{y}_i(\sigma_0^i)\}, \{\sigma_0, \sigma_1, z(\sigma_0)\}) \in C^+$$

where C^+ is the set

$$C^+ := S_1 \cap S_2$$

in which

$$\begin{aligned}
S_1 &:= \{(\{\tau_0^i, \tau_1^i, x_0^i\}, \{0, 1, \bar{x}_0^i\}, (0, 1, z_0)) | \{\tau_0^i, \tau_1^i, x_0^i, \bar{x}_0^i\} \in \Lambda\},\\
S_2 &:= \{(\{\tau_0^i, \tau_1^i, x_0^i\}, \{\sigma_0^i, \sigma_1^i, \bar{x}_0^i\}, (\sigma_0, \sigma_1, z_0)) | (\{\tau_0^i, \tau_1^i, x_0^i, \bar{x}_0^i\}, z_0) \in \operatorname{epi} f\}.
\end{aligned}$$

Now consider the mapping

$$\psi^+ : (\mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_k}) \times (\mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_k}) \times \mathbb{R} \to (\mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_k}) \times \mathbb{R}$$

defined by

$$\psi^+(\{x_i\}, \{\bar{x}_i\}, z) = (\{x_i - \bar{x}_i\}, z).$$

It can be shown by means of a simple contradiction argument that

$$\begin{aligned}
&(\{T_0^i, T_1^i, x_i(\cdot), u_i(\cdot)\}, \{0, 1, \bar{x}_i(\cdot) \equiv x_i(T_1^i), \bar{u}_i(\cdot) \equiv 0\},\\
&(0, 1, z(\cdot) \equiv f(\{T_0^i, T_1^i, x_i(T_0^i, x_i(T_1^i)\}), w(\cdot) \equiv 0))
\end{aligned}$$

is a boundary multiprocess with respect to C^+ and ψ^+.

All hypotheses are satisfied under which Theorem 3.1 is applicable. Accordingly there exist real numbers q, d_0, d_1 and h_0^i, h_1^i, $\bar{h}_0^i$, $\bar{h}_1^i$ for $i=1,\cdots,k$, vectors $\bar{p}_i \in \mathbb{R}^{n_i}$, $i=1,\cdots,k$, absolutely continuous functions $p_i(\cdot):[T_0^i, T_1^i]\to\mathbb{R}^{n_i}$, $i=1,\cdots,k$, vectors $\{s_i\}$, a number λ, and a positive number $\bar{K}$ whose magnitude is governed solely by the constant K of hypothesis (H3) and (H4) such that

$$-\dot{p}_i(t)\in\partial_x H_i, \qquad H_i(t, x_i(t), u_i(t), p_i(t)) = \max_{w\in U_i^i} H_i(t, x_i(t), w, p_i(t)).$$

$-h_0^i$ and h_1^i are convex essential values of the Hamiltonian functions, for almost everywhere $t\in[T_0^i, T_1^i]$, $i=1,\cdots,k$,

$$\{-h_0^i, h_1^i, p_i(T_0^i)\}, \{-\bar{h}_0^i, \bar{h}_1^i, \bar{p}_i\}, (-d_0, d_1, q)\in \bar{K}\,\partial d_{C^+}(\{T_0^i, T_1^i, x_i(T_0^i)\}, \{0, 1, x_i(T_1^i)\}, (0, 1, f)) \tag{7.1}$$

where f is evaluated at $e := \{T_0^i, T_1^i, x_i(T_0^i), x_i(T_1^i)\}$,

$$(\{-p_i(T_1^i), -\bar{p}_i\}, -q) = (\{s_i, -s_i\}, \lambda), \tag{7.2}$$

and

$$|(\{s_i, -s_i\}, \lambda)| = 1. \tag{7.3}$$

Keeping in mind Lemma 5.3 and inclusion (5.16), we deduce from (7.1) that $q\leqq 0$ and

$$\{-h_0^i, h_1^i, p_i(T_0^i), \bar{p}_i\}\in -q\partial f + \bar{K}(1+K_f^2)^{1/2}\partial d_\Lambda.$$

Here K_f is the Lipschitz rank of f in a neighbourhood of e. We conclude from this inclusion, from (7.2), and from (7.3) that $\lambda\geqq 0$, and the p_i's and λ can be scaled so that

$$\{-h_0^i, h_1^i, p_i(T_0^i), -p_i(T_1^i)\}\in \lambda\partial f + c\partial d_\Lambda \qquad \sum_i |p_i(T_1^i)| + \lambda = 1.$$

Here $c = 2^{3/2}\bar{K}(1+\bar{K}^2)^{1/2}$, a number whose magnitude is governed by the constant K of hypotheses (H3) and (H4) and by the Lipschitz rank of f in a neighbourhood of e. Surveying these relationships, we see that the elements $\{p_i(\cdot)\}$ and λ have all the properties of the component costate functions and the cost multiplier listed in Theorem 3.2. This concludes the proof.

ON THE MINIMUM PRINCIPLE FOR CONTROLLED DIFFUSIONS ON MANIFOLDS*

M. H. A. DAVIS† AND M. P. SPATHOPOULOS‡

This paper is dedicated to the memory of E. J. McShane.

Abstract. This paper concerns optimal control of a family of nondegenerate diffusions evolving on a compact manifold. Feedback controls based on complete observations are used. The controlled process is constructed by the horizontal lifting technique of Eells and Elworthy, and a minimum principle is derived from a dynamic programming argument. It is shown that the adjoint variable appearing in the minimum principle, which here is a one-form valued stochastic process, can be evaluated by solving a "heat equation" on the manifold.

Key words. stochastic control, dynamic programming, minimum principle, stochastic differential equation, diffusion on manifolds

AMS(MOS) subject classifications. 93E20, 60H10

1. Introduction. Stochastic versions of the Pontryagin minimum principle of optimal control theory have been a topic of interest since the pioneering work of Kushner [13] in the mid-1960s. In the case of controlled nondegenerate diffusions, the subject is best approached via dynamic programming; the Bellman equation is a quasilinear second-order parabolic partial differential equation that has much smoother solutions than the first-order equation arising in deterministic control theory.[1] A complete treatment is given by Fleming and Rishel [8]. The adjoint variable in the stochastic minimum principle is seen to be $p_t := \partial V(t, x_t)/\partial x$, where $V(t, x)$ is the value function and x_t the state of the controlled process. p_t can be characterized further by using a result from stochastic flow theory, namely, that the solution $x_{t,s}(x)$ of a stochastic differential equation (SDE) with initial point $x_{s,s}(x) = x$ depends (almost surely) smoothly on x. If the cost function is the terminal cost $\mathbb{E}[\theta(x_{1,s}(x))]$ and $\mathbb{E}^*$ denotes expectation with respect to the measure of the optimally controlled process, then $V(s, x) = \mathbb{E}^*[\theta(x_{1,s}(x))]$ and hence

$$\frac{\partial}{\partial x} V(s, x) = \mathbb{E}^*\left[\sum_{i,j} \frac{\partial \theta}{\partial x^i} \frac{\partial}{\partial x^j} x^i_{1,s}(x)\right].$$

Since $\partial x^i_{1,s}(x)/\partial x^j$ is computed from the "linearized equations" corresponding to the controlled SDE, this shows that the stochastic adjoint variable p_t is just the conditional expectation, given the information available at time t, of its deterministic counterpart. There is a slight modification in the formulation of the linearized equations due to the fact that feedback rather than "open loop" controls are being used. All of this is explained by Haussmann [9], [10].

In [3] a pathwise solution for the nonlinear filtering problem of a diffusion process x_t specified by its generator on a manifold has been derived using the horizontal lifting technique of Eells and Elworthy [6]. Motivated by this technique we formulate the completely observable stochastic control problem in the setting of controlled diffusions on manifolds specified by their generators. There are two reasons for doing so. First,

[1] Vinter [17] gives an up-to-date discussion of the deterministic case.

there are important problems, such as controlling the orientation of a rigid body, that are naturally formulated in this way, and indeed it seems surprising that use of geometric methods in control theory has so far largely been restricted to qualitative questions such as controllability. Second, we obtain a new interpretation of the adjoint variable $\partial V/\partial x$: it satisfies a form of the so-called "heat equation for tensor fields" involving an intrinsic operator on tensor fields known as the *de Rham-Kodaira Laplacian.*

There is some related work by Duncan [5]. Duncan defines the solutions of stochastic systems in Riemannian manifolds in virtually the same way as we do here—and independently of Eells and Elworthy [6]—and treats stochastic control by martingale methods in the manner of Davis and Varaiya [4]. This however leaves the adjoint variable only as an implicitly-defined object.

The paper is organized as follows. Section 2 is a preliminary section giving some geometric notions and outlining the construction of Brownian motion on a manifold by "horizontal lifting." The control problem is formulated in § 3 and the dynamic programming results that in $\mathbb{R}^d$ are the same as those of Fleming and Rishel [8] are given in § 4. The last two sections, §§ 5 and 6, are devoted to obtaining the characterization of the adjoint variable mentioned above. This is the main result of the paper, and is stated as Theorem 6.6. Appendix A gives the proof of a technical result concerning the Bellman equation on manifolds.

2. Preliminaries. All of the following information can be found in Boothby [1] and Ikeda and Watanabe [11, Chap. 5]. Throughout the paper the summation convention over repeated indices is used. The Stratonovich and Itô stochastic integrals are denoted $\beta \circ dw$ and $\beta\, dw$, respectively.

Let M be a compact[2] C^∞ manifold of dimension d. Denote by $T_x(M)$ and $T_x^*(M)$, respectively, the tangent and cotangent spaces at $x \in M$. The *tangent bundle* is $TM = \{(x, v)\colon x \in M,\ v \in T_x(M)\}$ and the *bundle of linear frames* is

$$\mathrm{GL}(M) = \{r = (x, e)\colon x \in M,\ e = [e_1, \cdots, e_d],$$
$$e_i \in T_x(M) \text{ and } [e_1, \cdots, e_d] \text{ is a basis for } T_x(M)\}.$$

A *Riemannian metric* is a C^∞ field $\Phi = \{\Phi_x, x \in M\}$ of positive-definite symmetric bilinear forms on TM. Then Φ_x defines an inner product on $T_x(M)$. The *orthonormal frame bundle* $\mathrm{O}(M)$ is defined as

$$\mathrm{O}(M) = \{r = (x, e) \in \mathrm{GL}(M)\colon \Phi_x(e_i, e_j) = \delta_{ij},\ i, j = 1 \cdots d\}.$$

Both $\mathrm{GL}(M)$ and $\mathrm{O}(M)$ are themselves C^∞ manifolds. Let $\mathfrak{X}(M)$ denote the set of vector fields on M, i.e., the set of functions $X : x \mapsto X(x) \in T_x(M)$ such that $Xf(x)$ is a C^∞ function for each $f \in C^\infty(M)$. A *Riemannian* or *Levi-Civita connection* is a mapping $\nabla : \mathfrak{X}(M) \times \mathfrak{X}(M) \to \mathfrak{X}(M)$, written $(X, Y) \mapsto \nabla_X Y$ such that (i) $\nabla_X Y$ is bilinear in X, Y; (ii) $\nabla_{fX+gY} = f\nabla_X + g\nabla_Y$; (iii) $\nabla_X(fY) = f\nabla_X Y + (Xf)\,Y$ (here $f, g \in C^\infty(M)$); (iv) $\nabla_X Y - \nabla_Y X = XY - YX$; and (v) $X\Phi(Y, Z) = \Phi(\nabla_X Y, Z) + \Phi(Y, \nabla_X Z)$. There is a uniquely determined Riemannian connection corresponding to each Riemannian metric. In local coordinates, with $X(x) = \alpha^i \partial/\partial x^i$, $Y(x) = \beta^i \partial/\partial x^i$ we have $\Phi_x(X, Y) = a_{ij}(x)\alpha^i\beta^j$ for some positive definite symmetric matrix $[a_{ij}(x)]$ and

$$\nabla_{\partial_i}\partial_j = \Gamma_{ij}^k \frac{\partial}{\partial x^k} \qquad \left(\partial_i = \frac{\partial}{\partial x^i}\right)$$

[2] Undoubtedly, all results in this paper will extend to noncompact manifolds if some uniform non-explosion condition is imposed.

where the coefficients Γ_{ij}^k (the *Christoffel symbols*) are given by

$$\Gamma_{ij}^k = \frac{1}{2}\left(\frac{\partial}{\partial x^i} a_{mj} + \frac{\partial}{\partial x^j} a_{im} - \frac{\partial}{\partial x^m} a_{ij}\right) a^{km}$$

($[a^{km}] = [a_{km}]^{-1}$). An element $v \in T_r(\mathrm{O}(M))$ takes the form

$$v = \alpha^i \frac{\partial}{\partial x^i} + \beta_j^k \frac{\partial}{\partial e_j^k}$$

where $r = (x, e) \in \mathrm{O}(M)$ and $e_i = e_i^j \partial/\partial x^j$.

The connection defines a d-dimensional *horizontal subspace* H_r of $T_r(\mathrm{O}(M))$ as follows:

$$H_r = \left\{ v = \alpha^i \frac{\partial}{\partial x^i} - \Gamma_{kl}^i(x) e_j^l \alpha^k \frac{\partial}{\partial e_j^i} : (\alpha^i) \in R^d \right\}.$$

We denote by $\pi : \mathrm{O}(M) \to M$ the projection map $\pi r = x$. If $Y \in T_x(M)$, then $\tilde{Y} \in T_r(\mathrm{O}(M))$ is the *horizontal lift* of Y if $x = \pi r$, $\tilde{Y} \in H_r$, and $T_\pi \tilde{Y} = Y$, where $T_\pi \tilde{Y} f(r) = \tilde{Y}(f \circ \pi)(r)$. Any $X \in \mathfrak{X}(M)$, $X = X^i(x)(\partial/\partial x^i)$, has a unique horizontal lift to a vector field $\tilde{X} \in \mathfrak{X}(\mathrm{O}(M))$ defined by

$$\tilde{X}(x, e) = X^i(x) \frac{\partial}{\partial x^i} - \Gamma_{kl}^i X^k(x) e_j^l \frac{\partial}{\partial e_j^i}. \tag{2.1}$$

For each $m = 1, \cdots, d$ there is a vector field $L_m \in \mathfrak{X}(\mathrm{O}(M))$ such that $L_m(r)$ is the horizontal lift of e_m, where $r = (x, e_1, \cdots, e_d)$. L_m is given by (2.1) with $X^i := e_m^i$. $(L_1, \cdots, L_d)$ is the system of *canonical horizontal vector fields*. The horizontal lift $\tilde{X}$ given in (2.1) of an arbitrary vector field X can be expressed as (see [3, Lemma 2.2])

$$\tilde{X} = \alpha_X^j(r) L_j \tag{2.2}$$

where

$$\alpha_X^i(r) = [e^{-1}]_j^i X^i(x) \tag{2.3}$$

and (e^{-1}) denotes the inverse of the matrix (e_j^i). It is easily shown that $\alpha_X^1, \cdots, a_X^d$ are intrinsic functions on $\mathrm{O}(M)$, i.e., independent of choice of local coordinates.

Let $(\Omega, \mathfrak{F}, (\mathfrak{F}_t), \mathbb{P}, w)$ be the canonical d-dimensional Wiener space and consider the Stratonovich stochastic differential equation (SDE) on $\mathrm{O}(M)$

$$\begin{aligned} &df(r_t) = L_j f(r_t) \circ dw_t^j, \qquad f \in C^\infty(M), \\ &r_0 = r \in \mathrm{O}(M). \end{aligned} \tag{2.4}$$

This equation has a unique solution that defines a diffusion process $r(t)$ evolving in $\mathrm{O}(M)$. By writing (2.4) in terms of the Itô integral, we find that the generator of $r(t)$ is *Bochner's horizontal Laplacian* $\frac{1}{2}\sum_j L_j^2$. Define $x(t, r, w) = \pi r(t)$ (r is the starting point). It is not hard to show that $x(t, r, w)$ has the following property:

$$x(t, T_A r, w) = x(t, r, Aw) \tag{2.5}$$

where A is any orthogonal $d \times d$ matrix, $r = (x, e)$, and $T_A r = (x, \bar{e}_1, \cdots, \bar{e}_d)$ with $\bar{e}_k = A_k^j e_j$. However, d-dimensional Brownian motion is rotation invariant, so Aw is another Brownian motion and (2.5) shows that the law of $x(t, r, w)$ for $r = (x, e)$ depends only on x, not on e. Hence $x(t, r, w)$ is a diffusion process on M. Its generator is the Laplace–Beltrami operator on M:

$$\Delta_M = a^{ij} \frac{\partial^2 f}{\partial x^i \partial x^j} - a^{ij} \Gamma_{ij}^k \frac{\partial f}{\partial x^k}. \tag{2.6}$$

For this reason $x(t, r, w)$ is known as *Brownian motion on M.* This construction is due to Eells and Elworthy [6].

3. Problem formulation. Let M be as above and U be a compact metric space. Consider a family of second-order differential operators given in local coordinates by

$$A^y = \frac{1}{2} a^{ij}(x) \frac{\partial}{\partial x^i} \frac{\partial}{\partial x^j} + b^i(x, y) \frac{\partial}{\partial x^i} \qquad x \in M, \quad y \in U.$$

We assume that a^{ij} is positive definite: $a^{ij}(x)\xi_i\xi_j > 0$ for $\xi \in \mathbb{R}^d$, $\xi \neq 0$, and that $a^{ij} \in C^2(M)$, $b^i \in C^{1,0}(M \times U)$, $i, j = 1, \cdots, d$. We denote by $\mathfrak{U}$ the set of *feedback controls*

$$\mathfrak{U} = \{u: [0, 1] \times M \to U, u \text{ Borel measurable}\}.$$

For each $u \in \mathfrak{U}$ we have a time varying family of differential operators, denoted by slight abuse of notation A^u, defined by

$$A^u = \frac{1}{2} a^{ij}(x) \frac{\partial}{\partial x^i} \frac{\partial}{\partial x^j} + b^i(x, u(t, x)) \frac{\partial}{\partial x^i}. \tag{3.1}$$

We want to regard A^u as the differential generator of a diffusion process (x_t^u) on M over the time interval $[0, 1]$ and then to pose the optimal control problem of finding $u^* \in \mathfrak{U}$ such that

$$\mathbb{E}[\theta(x_1^{u^*})] = \min_{u \in \mathfrak{U}} \mathbb{E}[\theta(x_1^u)] \tag{3.2}$$

where $\theta \in C^2(M)$ is a given function and $\mathbb{E}$ denotes expected value. We could have more general forms of cost function, but we stick to the terminal cost (3.2) for simplicity.

By considering how the coefficients a^{ij} behave under coordinate transformations we can show that the inverse matrix $a_{ij} = [a^{ij}]^{-1}$, which is also symmetric and positive definite, defines a Riemannian metric on M. We can now construct Brownian motion on M as outlined in § 2, i.e., by solving the SDE

$$df(r_t) = L_j f(r_t) \circ dw_t^j, \qquad f \in C^\infty(\mathrm{O}(M)) \tag{3.3}$$

where L_j are the canonical horizontal vector fields and w_t is Brownian motion in $\mathbb{R}^d$. Then $r_t = (x_t, e_t)$ is an $\mathrm{O}(M)$-valued process whose "downstairs" component $x_t = \pi r_t$ is an M-valued diffusion with generator (2.6). To obtain the required generator (3.1) we use the Girsanov transformation. Let

$$\bar{b}^k(x, y) = b^k(x, y) + \tfrac{1}{2} a^{ij}(x) \Gamma_{ij}^k(x), \qquad x \in M, \quad y \in U. \tag{3.4}$$

For each $y \in U$, $\bar{b}^k(\cdot, y)$ defines a vector field X_0^y on M (i.e., the $\bar{b}^k$ transform correctly under coordinate changes). The horizontal lift L_0^y of X_0^y is then given as in (2.3) by

$$L_0^y = \alpha^j(r, y) L_j \tag{3.5}$$

where

$$\alpha^j(r, y) = [e^{-1}]_i^j \bar{b}^i(x, y).$$

Now take $u \in \mathfrak{U}$ and define a probability measure $\mathbb{P}^u$ on $\mathfrak{F}$ by

$$\frac{d\mathbb{P}^u}{d\mathbb{P}} = \exp\left(\sum_{i=1}^d \left(\int_0^1 \alpha^i(r_t, u(t, x_t))\, dw_t^i - \frac{1}{2} \int_0^1 (\alpha^i(r_t, u(t, x_t)))^2\, dt \right) \right\}$$

where (r_t) is the solution of (3.3). Under measure $\mathbb{P}^u$, the process w_t^u given by

$$dw_t^{u,i} = dw_t^i - \alpha^i(r_t, u(t, x_t))\, dt$$

is Brownian motion, and we can rewrite (3.3) as

$$df(r_t) = L_0^u f(r_t)\, dt + L_i f(r_t) \circ dw_t^{u,i}, \qquad f \in C^\infty(\mathrm{O}(M)) \tag{3.6}$$

where

$$L_0^u := \alpha^j(r, u(t,x))L_j.$$

The generator of $r(t)$ is $\tilde{A}^u = L_0^u + \frac{1}{2}\sum_1^d L_i^2$. By taking $f \in C^\infty(M)$ and defining $\tilde{f} = f \circ \pi$ we find that $\tilde{A}^u \tilde{f} = A^u f$, i.e.,

$$M_t^f := f(x_t) - \int_0^t A^u f(s, x_s)\, ds$$

is a martingale on $(\Omega, (\mathfrak{F}_t), \mathbb{P}^u)$, where A^u is given by (3.1), and hence (x_t) is, under $\mathbb{P}^u$, a diffusion process with extended generator A^u, in accordance with the "martingale problem" formulation of diffusion theory [14], [16]. The *cost* associated with $u \in \mathfrak{U}$ is now defined as $J(0, x, u)$ where

$$J(s, x, u) = \mathbb{E}_{s,x}^u[\theta(x_1)] \tag{3.7}$$

and $\mathbb{E}_{s,x}^u$ denotes expectation with respect to the measure $\mathbb{P}_{s,x}^u$ on path space $C([s, 1], O(M))$ generated by the solution of (3.6) with initial condition $r_s = (x, e)$ (e arbitrary). We now have the precisely defined optimal control problem of choosing $u \in \mathfrak{U}$ so as to minimize $J(0, x, u)$.

For technical reasons it is necessary to introduce another class of controls, the so-called *nonanticipative controls.* An *admissible system* is a collection

$$\nu = \{\Xi, \mathfrak{G}, (\mathfrak{G}_t)_{t\in[0,1]}, \mu, (\beta_t, u_t)_{t\in[0,1]}\} \tag{3.8}$$

where $(\Xi, \mathfrak{G}, (\mathfrak{G}_t), \mu)$ is a filtered probability space and $\beta_t(\xi) u_t(\xi)$, $\xi \in \Xi$ are $\mathfrak{G}_t$-predictable processes taking values in $\mathbb{R}^d$, U, respectively, such that (β_t) is a $\mathfrak{G}_t$-Brownian motion. Denote by $\mathfrak{N}$ the set of admissible systems; we call (u_t) a *nonanticipative control* if it is the control process of some $\nu \in \mathfrak{N}$. For any admissible system $\nu \in \mathfrak{N}$ the SDE

$$df(r_t) = \check{L}_0^u f(r_t)\, dt + L_i f(r_t) \circ d\beta_t^i \tag{3.9}$$

has a unique strong (Itô) solution starting at $r_s = (x, e)$, where

$$\check{L}_0^u := \alpha^j(r, u_t(\xi))L_j. \tag{3.10}$$

(We will consistently use the "hacek" notation $\check{L}$ to denote a vector field depending on a control which enters as a "random parameter.") Now define

$$K(s, x, \nu) = \int_\Xi \theta(x_1(\xi))\mu(d\xi)$$

and note that again this does not depend on the initial frame e, since property (2.5) still holds. Of course, (r_t) and (x_t) are not generally Markov processes. We have the inclusion $\mathfrak{U} \subset \mathfrak{N}$ in that each $u \in \mathfrak{U}$ defines the admissible system $\hat{\nu}_u = \{\Omega, \mathfrak{F}, (\mathfrak{F}_t), \mathbb{P}^u, (w_t^u, u_t = u(t, x_t))\}$, and $K(s, x, \hat{\nu}_u) = J(s, x, u)$. Thus

$$\inf_{\nu\in\mathfrak{N}} K(s, x, \nu) \leqq \inf_{u\in\mathfrak{U}} J(s, x, u).$$

4. Dynamic programming. The control problem as formulated in the previous section is to minimize $J(0, x, u)$ given by (3.7) over the class $\mathfrak{U}$ of feedback controls subject to the dynamic constraint (3.6). The Bellman equation for this problem, to be solved for a function $V: [0, 1] \times M \to \mathbb{R}$, is

$$\begin{aligned} &\frac{\partial V}{\partial t}(t, x) + \min_{y\in U}[A^y V(t, x)] = 0, \qquad (t, x) \in [0, 1) \times M, \\ &V(1, x) = \theta(x), \qquad x \in M. \end{aligned} \tag{4.1}$$

THEOREM 4.1. *Suppose that* $a^{ij}(x) \in C^1(M)$, $b^i(x, u) \in C^{1,1}(M \times U)$ *and* $\theta \in C^2(M)$. *Then equation* (4.1) *has a unique solution in* $C^{1,2}([0, 1] \times M)$. *There is Borel function* $u^* : [0, 1] \times M \to U$ *such that*

$$\min_{y \in U} [A^y V(t, x)] = A^{u^*} V(t, x).$$

The proof of this result is given in Appendix A. It is proved by a patching technique: we use the corresponding result for diffusions in bounded regions of $\mathbb{R}^d$ (Theorem VI.6.1 of Fleming and Rishel [8]) in regions covered by a single coordinate chart, and obtain compatability of boundary conditions by a fixed-point argument.

THEOREM 4.2. *Let* u^*, V *be as in Theorem* 4.1. *Then* $u^* \in \mathfrak{U}$ *is optimal in the class* $\mathfrak{N}$ *of nonanticipative controls, and*

$$V(s, x) = \min_{u \in \mathfrak{U}} J(s, x, u) = \min_{\nu \in \mathfrak{N}} K(s, x, \nu).$$

Thus V *is the value function for the control problem.*

Proof. This is the conventional "verification theorem" (cf. Theorem VI.4.1 of [8]). Take any $\nu \in \mathfrak{N}$ as in (3.8) and let $r_t = (x_t, e_t)$ be the corresponding solution of (3.9). Define $\tilde{V} : [s, 1] \times \mathrm{O}(M) \to \mathbb{R}$ by $\tilde{V}(t, r) = V(t, \pi r)$. Then from (3.9) applying the Itô rule and using the fact that $V \in C^{1,2}(M)$ we find that for $t \in [s, 1]$,

$$V(t, x_t) - V(s, x) = \int_s^t \left(\frac{\partial V}{\partial t}(\tau, x_\tau) + A^u V(\tau, x_\tau) \right) d\tau + \int_s^t L_i \tilde{V}(\tau, r_\tau)\, d\beta_\tau^i.$$

From (4.1) the integrand in the first term on the right is nonnegative, and the second term is a martingale (M is compact and the integrand is bounded). Thus the process $t \mapsto V(t, x_t)$ is a μ-submartingale, and hence

$$V(s, x) \leqq \mathbb{E}^{\mu}_{s,x}[V(1, x_1)] = \mathbb{E}^{\mu}_{s,x}[\theta(x_1)] = K(s, x, \nu) \tag{4.2}$$

(we have used the boundary condition from (4.1)). When $\nu = \hat{\nu}_{u^*}$, inequality is replaced by equality in (4.2). The result follows. □

The Bellman equation (4.1) implies that the optimal control u^* satisfies the minimum principle

$$L_0^{u^*} V(t, x) = \min_{y \in U} L_0^y V(t, x) \tag{4.3}$$

where L_0^y is given by (3.5), or, in local coordinates, from (3.4),

$$b^i(x, u^*(t, x)) \frac{\partial V}{\partial x^i}(t, x) = \min_{y \in U} b^i(x, y) \frac{\partial V}{\partial x^i}(t, x).$$

Denote by $\langle \alpha \,|\, X \rangle_x$ the pairing between a 1-form $\alpha \in T_x^*(M)$ and a tangent vector $X \in T_x(M)$, and recall that for $f \in C^1(M)$, df is the 1-form defined by $\langle df \,|\, X \rangle_x = Xf(x)$. We can then write (4.3) as

$$\langle dV(t) \,|\, L_0^{u^*} \rangle_x = \min_{y \in U} \langle dV(t) \,|\, L_0^y \rangle_x.$$

This shows that the "adjoint variable" is the 1-form valued process p_t defined by

$$p_t = dV(t, x_t), \tag{4.4}$$

in that the optimal control u^* minimizes the Hamiltonian functional $\langle p_t \,|\, L_0^y \rangle_{x_t}$ at each t almost surely when p_t is given by (4.4). To characterize p_t further, we need to introduce the derivative or linearized system equations. These are discussed in the next section, and we then return to a characterization of p_t in § 6.

5. Derivative systems of SDEs. We will first discuss derivative systems in the context of SDEs evolving on M. For $X_0, \cdots, X_d \in \mathfrak{X}(M)$ the SDE

$$df(x_t) = X_0 f(x_t)\, dt + X_i f(x_t) \circ dw_t^i, \qquad f \in C^\infty(M) \tag{5.1}$$

has an almost surely unique solution $x_t(x)$ and, furthermore, almost surely the map $x \mapsto x_t(x)$ is a diffeomorphism for each $t \geqq 0$ (see [11], [14]). The Itô version of (5.1) is

$$df(x_t) = \left[X_0 f(x_t) + \frac{1}{2} \sum_{i=1}^{d} X_i^2 f(x_t) \right] dt + X_i f(x_t)\, dw_t^i,$$

which shows that x_t is a diffusion process with generator $X_0 + \frac{1}{2}\sum_i X_i^2$. This is a second-order operator that in local coordinates is similar to (3.1). Let $X \in \mathfrak{X}(M)$ and denote by $\phi_t(x)$ the integral curve of X, i.e., the solution of the ordinary differential equation

$$\frac{d}{dt} f(\phi_t(x)) = Xf(\phi_t(x)), \qquad f \in C^\infty(M),$$

$$\phi_0(x) = x.$$

The *derivative vector field* δX is a vector field on $\mathrm{GL}(M)$ defined by

$$(\delta X) f(r) = \frac{d}{dt} f(\phi_t(x), \phi_{t*} e)|_{t=0}, \qquad r = (x, e) \in \mathrm{GL}(M), \quad f \in C^\infty(\mathrm{GL}(M)).$$

Here $\phi_{t*} e = [\phi_{t*} e_1, \cdots, \phi_{t*} e_d]$ and ϕ_{t*} denotes the derivative map

$$(\phi_{t*} v) g(x) = v(g \circ \phi_t)(\phi_t^{-1}(x)), \qquad g \in C^\infty(M).$$

Now consider the following SDE on $\mathrm{GL}(M)$:

$$\begin{aligned} &df(r_t) = \delta X_0 f(r_t)\, dt + \delta X_i f(r_t) \circ dw_t^i, \qquad f \in C^\infty(\mathrm{GL}(M)), \\ &r_0 = r = (x, e) \in \mathrm{GL}(M). \end{aligned} \tag{5.2}$$

Again, this has an almost surely unique solution, and we can show that

$$r_t(r) = (x_t(x), x_{t*}(e)). \tag{5.3}$$

Taking $(x, v) \in TM$, i.e., $v \in T_x(M)$, we can also think of (5.2) as defining the flow $(x, v) \mapsto (x_t(x), x_{t*}(v))$ on the tangent bundle. When $M = \mathbb{R}^d$, (5.2) is equivalent to the usual system of "linearized equations" written in matrix form. In § 6 below we need to consider the evolution of functionals of the form $\langle W(t, x_t) \,|\, v_t \rangle$ where $W(t, x)$ is a time-varying 1-form field and (x_t, v_t) denotes the solution of (5.2) thought of as a flow on the tangent bundle TM. The following lemma will be useful.

LEMMA 5.1. *Let $\bar{\omega}(x)$ be a 1-form field defined in a neighborhood of $x \in M$, and take $v \in T_x(M)$ and $X \in \mathfrak{X}(M)$. Then*

$$\delta X \langle \bar{\omega}(x) | v \rangle = \langle \nabla_X \bar{\omega} \,|\, v \rangle + \langle \bar{\omega} \,|\, \nabla_v X \rangle$$

and

$$\langle \bar{\omega}(x) \,|\, \nabla_v X \rangle = \langle (\nabla X) \bar{\omega} \,|\, v \rangle.$$

Here ∇_v denotes the covariant derivative, and $(\nabla X)\bar{\omega} := \nabla X(\bar{\omega}, \cdot)$, where ∇X denotes the $(1, 1)$ tensor field given in local coordinates by $(\bar{\omega}, v) \mapsto u_j^i \omega_i v^j$ for $\bar{\omega} = \omega_i\, dx^i$, $v = v^j (\partial/\partial x^j)$ with

$$u_j^i = \frac{\partial}{\partial x^j} X^i(x) + \Gamma_{kj}^i X^k(x).$$

These formulas can be checked directly from the definitions (see Elworthy [7, Lemma VII.9C]). By repeated application of Lemma 5.1 we obtain the following.

COROLLARY 5.2. $(\delta X_0+\frac{1}{2}\sum_{i=1}^{d}(\delta X_i)^2)\langle\bar\omega(x)\,|\,v\rangle=\langle B\bar\omega(x)\,|\,v\rangle$, *where the operator* B *on* 1*-forms is defined by*

$$B\bar\omega(x)=\nabla_{X_0}\bar\omega+(\nabla X_0)\bar\omega+\frac{1}{2}\sum_{i=1}^{d}\{\nabla_{X_i}(\nabla_{X_i}\bar\omega)+2(\nabla X_i)(\nabla_{X_i}\bar\omega)+\nabla(\nabla_{X_i}X_i)\bar\omega\}.$$

We now introduce the notion of the "heat equation for 1-forms." Theorem 5.3 below gives the probabilistic representation for the solution of the heat equation (5.4). While this result is not subsequently used in exactly the form stated here, it needs to be understood since the idea behind it underpins all the developments in § 6. We consider the following equation for a time-varying 1-form field $\bar\omega(t,x)$, where $\theta\in C^2(M)$ is a given function:

$$\begin{aligned}&\frac{\partial}{\partial t}\bar\omega(t,x)+B\bar\omega(t,x)=0, \qquad (t,x)\in[0,1[\times M,\\ &\bar\omega(1,x)=d\theta(x), \qquad x\in M.\end{aligned}\tag{5.4}$$

THEOREM 5.3. *Suppose* $\bar\omega(t,x)$ *satisfies* (5.4). *Then*

$$\langle\bar\omega(s,x)\,|\,v\rangle=\mathbb{E}_{s,(x,v)}\langle d\theta(x_1)\,|\,v_1\rangle\tag{5.5}$$

where $r_t=(x_t,v_t)$ *is the solution of* (5.2) *on* TM *for* $t\in[s,1]$ *with* $r_s=(x,v)$.

Proof. Let $\bar\omega(t,x)$ satisfy (5.4) and define a function f on $[0,1]\times TM$ by

$$f(t,r)=\langle\bar\omega(t,x)\,|\,v\rangle, \qquad r=(x,v).$$

Writing (5.2) in Itô form we have

$$\begin{aligned}df(t,r_t)&=\left[\frac{\partial f}{\partial t}+\delta X_0 f+\frac{1}{2}\sum_i(\delta X_i)^2 f\right]dt+\delta X_i f\,dw^i,\\ &=\left\langle\left(\frac{\partial}{\partial t}+B\right)\bar\omega(t,x)\,|\,v_t\right\rangle dt+\delta X_i f\,dw^i.\end{aligned}\tag{5.6}$$

In view of (5.4) the first term vanishes, and the second term is a martingale. Thus

$$\langle\bar\omega(s,x)\,|\,v\rangle=\mathbb{E}_{s,(x,v)}\langle\bar\omega(1,x_1)\,|\,v_1\rangle.$$

Invoking the boundary condition in (5.4), we obtain (5.5).

6. A characterization of the adjoint process. Let us now return to the control problem of §§ 3 and 4. We cannot directly define the derivative system of the SDE (3.6) under the optimal control u^* since u^* is only known to be a Borel function and the "drift" $b^i{}^*(t,x):=b^i(x,u^*(t,x))$ may fail to be differentiable in x. This is where the nonanticipative controls $\mathfrak{N}$ come in. First, we have the following simple lemma.

LEMMA 6.1. (cf. [10, Lemma VI.7.3]). *Suppose* $f,\ g\in C^1(M)$ *are such that* $f(x)\geqq g(x)$ *for all* $x\in M$ *and* $f(\xi)=g(\xi)$ *at some* $\xi\in M$. *Then* $df(\xi)=dg(\xi)$ (*equality in* $T^*_\xi(M)$).

Fix $(s,\xi)\in[0,1[\times M$ and consider the control problem on the time interval $[s,1]$ with initial condition $x_s=\xi$. Let $u^*(s,x)$ be the optimal control and $\hat u_t:=u^*(t,x_t)$ the control process in the corresponding admissible system $\hat\nu$. Then from Theorem 4.2,

$$V(s,\xi)=J(s,\xi,u^*)=K(s,\xi,\hat\nu).$$

The same control process $\hat{u}_t$ used from another initial state x will be possibly suboptimal, so we have

$$V(s, x) \leqq K(s, x, \hat{\nu}), \qquad x \in M.$$

Applying Lemma 6.1 with $f = K(s, \cdot, \hat{\nu})$ and $g = V(s, \cdot)$ we see that

$$dV(s, \xi) = dK(s, \xi, \hat{\nu}). \tag{6.0}$$

We thus need to calculate dK. We will henceforth write $\hat{\mathbb{P}}$, $\hat{\mathbb{E}}$ for $\mathbb{P}^{u^*}$, $\mathbb{E}^{u^*}$ and β^i for w^{i,u^*}. As a general point of notation, we define $\tilde{\theta}(r) = \theta \circ \pi(r)$ and similarly for other functions on M. We then have for $r = (x, e) \in \mathrm{O}(M)$,

$$K(s, x, \nu) = \tilde{K}(s, r, \nu) = \hat{\mathbb{E}}[\tilde{\theta}(r_{1,s}(r))]$$

where $r_{1,s}(r)$ denotes the solution of (3.9) at time 1 with $r_s = r$. Take $v \in T_x(M)$ and let v' be any element of $T_r\mathrm{O}(M)$ such that $T_\pi v' = v$. Then, with $K(s) := K(s, \cdot, \nu)$,

$$\langle dK(s) \,|\, v\rangle_x = \langle d\tilde{K}(s) \,|\, v'\rangle_r = \hat{\mathbb{E}}[(r_{1,s*}v')\tilde{\theta}(r)] = \hat{\mathbb{E}}\langle d\tilde{\theta} \,|\, r_{1,s*}v'\rangle_{r_1}. \tag{6.1}$$

The derivative system of (3.9) is the SDE

$$\begin{aligned} &df(\varphi_t) = \delta \check{L}_0^{\hat{u}} f(\varphi_t)\, dt + \delta L_i f(\varphi_t) \circ d\beta_t^i, \qquad f \in C^\infty(\mathrm{GL}(\mathrm{O}(M))), \\ &\varphi_s = (r, e') \end{aligned} \tag{6.2}$$

evolving in the frame bundle $\mathrm{GL}(\mathrm{O}(M))$ where (r, e') is a frame in $T_r\mathrm{O}(M)$, with solution

$$\varphi_t = (r_{t,s}(r), r_{t,s*}(e')).$$

(Recall that in (6.2) $\hat{u}_t$ appears as a "random parameter," as in (3.10), and our notational convention of using "$\check{}$" to denote a vector field containing a control as random parameter.) System (6.2) also defines a flow $(r, v') \to (r_{t,s}(r), r_{t,s*}(v'))$ in the tangent bundle $T\mathrm{O}(M)$.

Comparing (5.5) with (6.1) we see that the expressions are the same, except that (6.1) involves the $\mathrm{O}(M)$-valued process r_t, with derivative system (6.2) in $\mathrm{GL}(\mathrm{O}(M))$ in place of the M-valued process x_t with derivative system (5.2) in $\mathrm{GL}(M)$. Thus we can get a representation for dK by reformulating Theorem 5.3 on $\mathrm{O}(M)$. The remainder of this paragraph is devoted to showing that there is a characterization for the value function as a solution of a "heat equation" for 1-form fields.

To consider the heat equation for 1-forms the Laplacian of de Rham-Kodaira is introduced (for more detail see [11]). Define by $\Lambda_p(M)$ the totality of all p-forms on M. An inner product is defined on $\Lambda_p(M)$ denoted as $(\omega, \beta)_p$. The operator $\delta : \Lambda_p(M) \to \Lambda_{p-1}(M)$ is defined by

$$(d\omega, \beta)_p = (\omega, \delta\beta)_{p-1}, \qquad \omega \in \Lambda_{p-1}(M), \quad \beta \in \Lambda_p(M)$$

where $d\omega$ is the exterior derivative[3] of the form ω. The de Rham-Kodaira Laplacian $\square : \Lambda_p(M) \to \Lambda_p(M)$ is defined by

$$\square = -(d\delta + \delta d).$$

The action of this operator on a 1-form $\bar{\omega} = \omega_i(x)\, dx^i$ is given in local coordinates by

$$(\square\bar{\omega})_i = (\Delta\bar{\omega})_i + R_i^j\omega_j \tag{6.3}$$

[3] The exterior derivative $d\omega$ of a p-form ω is a $(p+1)$-form defined by $(d\omega)(x) = (\partial/\partial x^i)\omega_{i_1 i_2 \cdots i_p}(x)\, dx^i \wedge dx^{i_1} \wedge dx^{i_2} \cdots \wedge dx^{i_p}$.

where Δ is the Laplace-Beltrami operator [11, p. 270], and

$$R_i^j = a^{kl} R_{kli}^j .$$

Here

$$R_{jkl}^i = \frac{\partial}{\partial x_k}\Gamma_{lj}^i - \frac{\partial}{\partial x_l}\Gamma_{kj}^i + (\Gamma_{lj}^m \Gamma_{km}^i - \Gamma_{kj}^m \Gamma_{lm}^i)$$

are the components of the curvature tensor. Relation (6.3) is a special case of *Weitzenböck's formula* for differential forms [11, p. 286].

For a 1-form field $\bar{\omega}$ on M we define a function $f: TO(M) \to \mathbb{R}$ by

$$f(r, v) = \langle \bar{\omega} \circ \pi(r) \,|\, T_\pi v \rangle, \qquad r \in O(M), \quad v \in T_r O(M), \tag{6.4}$$

and consider the Itô formula (5.6) with $\check{L}_0^{\hat{u}}$ and L_i replacing X_0, X_i, respectively. Now $\check{L}_0^{\hat{u}}$ is the horizontal lift of $\check{X}_0^{\hat{u}}$, so from Lemma 5.1 we have

$$\delta \check{L}_0^{\hat{u}} f(r, v) = \langle (\nabla_{\check{X}_0^{\hat{u}}} + (\nabla \check{X}_0^{\hat{u}}))\bar{\omega} \circ \pi(r) | T_\pi v \rangle \tag{6.5}$$

where due to the form of the function $f(r, v)$ only the "downstairs" parts of the vector fields remain (see [15]). On the other hand L_i is a canonical horizontal vector field, and from Theorem VII.12.D of [4] we have the following result.

LEMMA 6.2. *Suppose $\bar{\omega}(x)$ is a closed 1-form, i.e., $d\bar{\omega} = 0$, and f is given by* (6.4). *Then*

$$\sum_{i=1}^{d} (\delta L_i)^2 f(r, v) = \langle \Box \bar{\omega} \circ \pi(r) \,|\, T_\pi v \rangle. \tag{6.6}$$

From relations (6.5) and (6.6) we get the following corollary.

COROLLARY 6.3. *Suppose $\bar{\omega}(x)$ is a closed 1-form. Then*

$$\left(\delta \check{L}_0^{\hat{u}} + \frac{1}{2} \sum_{i=1}^{d} (\delta L_i)^2 \right) \langle \bar{\omega} \circ \pi(r) \,|\, T_\pi v \rangle = \langle E\bar{\omega}(x) \,|\, v \rangle$$

where the operator E on 1-forms is defined by

$$E\bar{\omega}(x) = \tfrac{1}{2} \Box \bar{\omega}(x) + (\nabla_{\check{X}_0^{\hat{u}}} + (\nabla \check{X}_0^{\hat{u}}))\bar{\omega}(x).$$

Next consider the following lemma that will be used below.

LEMMA 6.4. *For $X \in \mathfrak{X}(M)$, suppose that $\phi(t, x)$ satisfies the following* PDE *for 1-forms*

$$\begin{aligned} &\frac{\partial \phi}{\partial t}(t, x) = \Box \phi(t, x) + \nabla_X \phi(t, x) + (\nabla X)\phi(t, x), \qquad (t, x) \in]0, 1[\times M, \\ &\phi(0, x) = \tilde{\phi} \end{aligned} \tag{6.7}$$

where $\tilde{\phi}$ is a given 1-form. Then $\phi(t, \cdot)$ is a closed form for each $t \leqq 1$ if $\tilde{\phi}$ is closed.

Proof. First we remark that the Laplacian of de Rham-Kodaira $\Box$ satisfies

$$d \Box \phi = \Box d\phi.$$

Indeed, since $d(d(\cdot)) = 0$,

$$d(d\delta + \delta d) = dd\delta + d\delta d + \delta dd = (d\delta + \delta d)d.$$

Next we remark that

$$\nabla_X \phi + \nabla X \phi = d\langle X \,|\, \phi \rangle.$$

Thus,

$$\frac{\partial\, d\phi}{\partial t} = d\frac{\partial \phi}{\partial t} = d\Box\phi + dd\langle V \,|\, \phi\rangle = \Box\, d\phi, \qquad d\phi(0) = 0.$$

Since zero is the unique solution of this equation in 1-forms [11, § V.5], this shows that $d\phi \equiv 0$, i.e., $\phi(t)$ is a closed form.

Now consider the following heat equation for a time varying 1-form field $W(t, x)$. We write $\hat{X}_0$ in place of $X_0^{u^*}$ (i.e., $\hat{X}_0$ is given in local coordinates by (3.4) with $y = u^*(t, x)$):

$$\frac{\partial}{\partial t} W(t,x) + \frac{1}{2}\Box W(t,x) + \nabla_{\hat{X}_0} W(t,x) + (\nabla \hat{X}_0)\, W(t,x) = 0, \qquad (t,x) \in [0,1[\times M, \tag{6.8}$$

$$W(1,x) = d\theta(x). \tag{6.9}$$

THEOREM 6.5. *Equation* (6.8), (6.9) *has a unique solution* $W(t, x)$ *such that* $W \in W^{1,2}([0,1] \times \mathcal{U})$ *for any open set* $\mathcal{U} \subset M$ *covered by a single coordinate chart, and*

$$W(t,x) = dV(t,x).$$

Proof. Equation (6.8) does not have a $C^{1,2}$ solution since $\hat{X}_0$ is not a smooth function of x. But an argument identical to that of Haussmann [9, Thm. 5.5] shows (see [15]) that it has a unique solution that is (on any coordinate chart) in the Sobolev space $W^{1,2}$ (first derivatives in t, and first and second derivatives in x^i, square integrable). The proof of Lemma 6.4 goes through when (6.7) is solved in $W^{1,2}$. Hence we conclude that the solution $W(t, \cdot)$ of (6.8), (6.9) is a closed 1-form for each $t \in [0, 1]$. (Note that $d\theta$ is closed.) In the following argument, Krylov's extended Itô formula for $W^{1,2}$ functions [12, Thm. 2.10.1] replaces the usual Itô formula.

Take arbitrary $\hat{x} \in M$ and $\hat{v} \in T_x(M)$, denote $\hat{r} = (\hat{x}, \hat{v})$, and let $\tilde{\chi} = (\tilde{r}, \tilde{v})$ be any element of $TO(M)$ such that $x = \pi\tilde{r}$ and $\hat{v} = T_\pi \tilde{v}$. For $(t, \chi) \in [0,1] \times TO(M)$, $\chi = (r, v)$, define

$$f(t,\chi) = \langle W(t, \pi r) \,|\, T_\pi v\rangle.$$

Writing (6.2) in Itô form as the equation for a flow $\chi_t = (r_t, v_t)$ on $TO(M)$ starting at $\chi_s = \tilde{\chi}$, and using Corollary 6.3, we have

$$\begin{aligned} df(t,\chi_t) &= \left[\frac{\partial f}{\partial t} + \delta\check{L}_0^u f + \frac{1}{2}\sum_i^d (\delta L_i)^2 f\right] dt + \delta L_i f\, d\beta_t^i \\ &= \left\langle \left(\frac{\partial}{\partial t} + E\right) W(t, \pi r_t) \,\middle|\, T_\pi v_t \right\rangle dt + \delta L_i f d\beta_t^i. \end{aligned}$$

In view of (6.8) the first term vanishes, and the second term is a martingale. Thus, using the boundary condition (6.9) and the properties of the derivative system (6.2) we see that

$$\begin{aligned} \langle W(s,\hat{x}) \,|\, \hat{v}\rangle_{\hat{x}} &= \langle W(s, \pi\tilde{r}) \,|\, T_\pi \tilde{v}\rangle_{\hat{r}} \\ &= \hat{\mathbb{E}}_{s,\tilde{\chi}} \langle W(1, \pi r_1) \,|\, T_\pi v_1\rangle_{r_1} \\ &= \hat{\mathbb{E}}_{s,\tilde{\chi}} \langle d\tilde{\theta}(r_1) \,|\, T_\pi v_1\rangle \\ &= \hat{\mathbb{E}} \langle d\tilde{\theta} \,|\, r_{1,s*}\tilde{v}\rangle_{r_1}. \end{aligned} \tag{6.10}$$

We thus see from (6.1) and (6.10) that

$$\langle dK(s) \,|\, \hat{v}\rangle = \langle W(s,\hat{x}) \,|\, \hat{v}\rangle_{\hat{x}}.$$

Since this holds for arbitrary $(\hat{x}, \hat{v})$, $dK(s) = W(s, \hat{x})$, and from (6.0),

$$dV(s, \hat{x}) = W(s, \hat{x}).$$

This completes the proof. □

We can now summarize our results, and state the stochastic minimum principle as follows.

THEOREM 6.6. *Let $u^* \in \mathcal{U}$ be an optimal control for the problem* (3.6), (3.7). *Then there exists a unique solution $W(t, x)$ to the heat equation* (6.8), (6.9) *as described in Theorem* 6.5. *Let $X_0(x, y) := X_0^y(x)$ denote the vector field defined by* (3.4). *Then for almost all $(t, x) \in [0, 1] \times M$,*

$$\langle W(t, x) \,|\, X_0(x, u^*(t, x)) \rangle = \min_{y \in U} \langle W(t, x) \,|\, X_0(x, y) \rangle. \tag{6.11}$$

If W is expressed in local coordinates as $W(t, x) = \omega_i(t, x)\, dx^i$ then (6.11) *becomes*

$$\omega_i(t, x) b^i(x, u^*(t, x)) = \min_{y \in U} \omega_i(t, x) b^i(x, y)$$

where b^i are the coefficients appearing in (3.1). *The "adjoint process" as defined in* (4.4) *is thus*

$$p_t := W(t, x_t).$$

Appendix A. This Appendix is devoted to the proof of Theorem 4.1, i.e., showing that the Bellman equation (4.1) has a $C^{1,2}$ solution. Throughout, we shall use a specific system of charts on M constructed as follows. (A similar system was used by Clark [2].) We take an atlas $\{(U_i, g_i), i = 1, \cdots, k\}$ of coordinate charts covering M such that for each i, $g_i(U_i) = B_1$ (the ball of radius one in $\mathbb{R}^d$) and such that $\{E_i, i = 1, \cdots, k\}$ also covers M, where $E_i := g_i^{-1}(B_{3/4})$. Set $D_1 := E_1$ and $D_i := E_i \backslash \cup_{j<i} E_j$ for $i > 1$. Then the D_i are disjoint and cover M.

First we need the following lemmas concerning PDEs in $\mathbb{R}^d$.

LEMMA A1. *Fix $i \in \{1, \cdots, k\}$. Then with the atlas described above $g_i(U_i) = B_1 = \cup_j \tilde{D}_j$ where $\tilde{D}_j = g_i(D_j \cap U_i)$. Denote $Q := [0, 1] \times B_1$ and $Q_j := [0, 1] \times \tilde{D}_j$. Consider the following* PDE *to hold in Q*:

$$\psi_s + A(s)\psi + \Lambda(s, y) = 0 \tag{A1}$$

with boundary data

$$\psi(s, y) = \Psi(s, y), \qquad (s, y) \in \partial^* Q = [0, 1) \times \partial B_1,$$

$$\psi(1, y) = \theta(y), \qquad y \in B_1.$$

Here

$$A(s)\psi = \tfrac{1}{2} a^{ij}(y) \psi_{y_i y_j} + b^i(s, y) \psi_{y_i} + c(s, y)\psi.$$

The coefficients of the PDE (A1) *are supposed to satisfy the following conditions*:

(a) *a^{ij}, b^i, c, Λ satisfy a Hölder condition on Q; $a^{ij} = a^{ji}$ and there exists $\gamma > 0$ such that $a^{ij}(s, y) q_i q_j \geqq \gamma |q|^2$ for all $q \in R^d$.*

(b) *$\theta(y)$ is C^2 on B_1 and $\Psi(s, y) = \tilde{\Psi}(s, y)$ for $t \leqq s < 1$, $y \in \partial B_1$, for some function $\tilde{\Psi}(s, y) : Q \to R$ such that $\tilde{\Psi} | Q_j$ is C^2, $j = 1, \cdots, k$.*

Then (A1) *has a unique solution ψ such that $\psi \in C^{1,2}(\bar{Q}')$ for any open set Q' with $\bar{Q}' \subset Q$.*

Remark. This is the result of Fleming and Rishel [8, Appendix E, first paragraph, p. 208] except that here the boundary data Ψ is "piecewise C^2" as opposed to

everywhere C^2 in [8]. The strategy of the proof is to smooth out the boundary data by convolution of $\tilde{\Psi}$ with a mollifying function, apply the result of [8, Appendix E] and then use a limiting argument. The details, which are lengthy but standard, are omitted here. A complete proof is given in [15].

COROLLARY A2. *Let Q, Ψ be as in Lemma* A1 *and consider data satisfying the following conditions*:

(a) *U is compact*;

(b) *$a^{ij}(x)$ is of class $C^1(\bar{Q})$, and $b^i(x)$ is of class $C^{1,1}(\bar{Q}\times U)$ and the generator A^u is nondegenerate.*

Then the following PDE (*dynamic programming equation*) *in* $\mathbb{R}^d$

$$\frac{\partial V(t,x)}{\partial t}+\min_{y\in U} A^y V=0$$

with boundary data

$$V(s,y)=\Psi(s,y), \qquad (s,y)\in \partial^* Q,$$
$$V(1,y)=\theta(y), \qquad y\in B_1$$

has a unique solution in Q' such that V is in $C^{1,2}(\bar{Q}')$, $\bar{Q}'\subset Q$, where Q' is any open subset of Q.

Proof. This result is the same as Theorem VI.6.1 of Fleming and Rishel [8] except for the conditions on the boundary data Ψ, which is now only piecewise C^2. The proof given in [8, pp. 208–209] goes through unchanged, since Lemma A1 above shows that the statements of [8, first Paragraph, p. 208] are still valid under our wider conditions.

Proof of Theorem 4.1. Let the sets U_i, D_i, $i=1,\cdots,k$ be as defined at the beginning of this Appendix. As is customary we will not distinguish notationally between $U_i\subset M$ and $g_i(U_i)\subset\mathbb{R}^d$. Fix i and in U_i consider the following PDE:

$$\frac{\partial V^i(t,x)}{\partial t}+\min_{y\in U} A^y V^i(t,x)=0, \qquad (t,x)\in[0,1[\times U_i,$$

(A2)
$$V^i(t,x)=\phi(t,x), \qquad 0\leqq t\leqq 1, \quad x\in\partial U_i,$$
$$V^i(1,x)=\theta(x), \qquad x\in U_i$$

where $\phi(t,x)=[0,1]\times M\to\mathbb{R}$ is a given C^2 function. For each (t,x) define

$$L\phi(t,x):=V^i(t,x), \qquad x\in D_i.$$

From results for PDEs in $\mathbb{R}^d$ [5] we know that

$$L\phi(t,x)\in C^{1,2}([0,1]\times D_i)$$

but $L\phi(t,x)$ is "piecewise-continuous" on $([0,1]\times M)$ since in each D_i a "different" PDE is considered. Clearly for every choice of initial point $(t,x)\in[0,1)\times D_i$

$$L\phi(t,x)=\min_{u\in\mathrm{II}} \mathbb{E}^u_{t,x}[\theta(x_1)I_{1=\sigma_i}+\phi(\sigma_i x_{\sigma_i})I_{1>\sigma_i}]$$

where I_A is the characteristic function of A and σ_i denotes the first hitting time of $([0,1]\times\partial U_i)\cup(\{1\}\times U_i)$ by the controlled system of § 3 starting at $x_t=x$. We will define $T_1=\sigma_i$ when $x\in D_i$. We now define $L^2\phi=L(L\phi)$ by replacing ϕ by $L\phi$ in (A2) i.e., solving the PDE (A2) with the following boundary conditions:

$$V^i(t,x)=L\phi(t,x), \qquad 0\leqq t\leqq 1, \quad x\in\partial U_i,$$
$$V^i(t,x)=\theta(x), \qquad x\in U_i.$$

These are the boundary conditions considered in Lemma A1. Then for such $(t, x) \in [0, 1) \times D_i$

$$L^2\phi(t, x) := L(L\phi)(t, x) = V^i(t, x)$$

$$= \min_{u \in \mathrm{ll}} \mathbb{E}^u_{t,x} \left\{ \theta(x_1) I_{1=\sigma_i} + \sum_{j \neq i} L\phi(\sigma_i, x_{\sigma_i}) I_{1>\sigma_i} I_{x_{\sigma_i} \in D_j} \right\}$$

from which is follows that for $x \in D_i$

$$L^2\phi(t, x) = \min_{u \in \mathrm{u}} \mathbb{E}^u_{t,x}[\theta(x_1) I_{1=T_2} + \phi(T_2, x_{T_2}) I_{1>T_2}]$$

where T_2 is defined by

$$T_2 := 1 \wedge \inf\{t > \sigma_i : x_t \in \partial U_{i(x_{\sigma_i})}\}$$

and $i(\cdot)$ is the indicator function $i(\xi) = j$ if $\xi \in D_j$. From Corollary A2 it follows that $L^2\phi(t, x)$ is in $C^{1,2}([0, 1) \times D_i)$, but again "piecewise-continuous" on $[0, 1] \times M$. Similarly, for each (t, x)

$$L^n\phi(t, x) = \min_{u \in \mathrm{ll}} \mathbb{E}^u_{t,x}[\theta(x_1) I_{1=T_n} + \phi(T_n, x_{T_n}) I_{1>T_n}]$$

where T_n is an exit time defined by

$$T_n := 1 \wedge \inf[t > T_{n-1} : x_t \in \partial U_{i(x_{T_{n-1}})}].$$

Now $V^n(t, x) \equiv L^n\phi(t, x)$ is the value of a control problem stopped at T_n. The sequence of exit times T_n is strictly increasing by the construction of the disjoint sets D_j and the nondegeneracy of our problem. It has been proved by Clark [2] that $\sup_n T_n = \infty$ so by the above construction $L^n\phi(t, x)$ is defined for all n. We will show below that as $n \to \infty$, $V^n(t, x)$ converges to the value function of the unstopped problem (4.1). The space $C([0, 1] \times M)$ is a Banach space with the norm

$$\|\phi\| = \sup_{(x,t) \in M \times [0,1]} |\phi(t, x)|.$$

Next we shall show that the map L is a contraction, and hence that $\|L^n\phi - V\| \to 0$, where V is a fixed point of L. Indeed, in D_i

$$L\phi(t, x) - L\psi(t, x) = \min_{u \in \mathrm{ll}} \mathbb{E}^u_{t,x}[\theta(x_1) I_{1=\sigma_i} + \phi(\sigma_i, x_{\sigma_i}) I_{I>\sigma_i}]$$

$$- \min_{u \in \mathrm{ll}} \mathbb{E}^u_{t,x}[\theta(x_1) I_{1=\sigma_i} + \psi(\sigma_i, x_{\sigma_i}) I_{1>\sigma_i}]$$

$$\leqq \mathbb{E}^{u^*}[\theta(x_1) I_{1=\sigma_i}) + \phi(\sigma_i, x_{\sigma_i}) I_{1>\sigma_i}]$$

$$- \mathbb{E}^{u^*}[\theta(x_1) I_{1=\sigma_i} + \psi(\sigma_i, x_{\sigma_i}) I_{1>\sigma_i}]$$

where u^* is the control that minimizes

$$\mathbb{E}^u_{t,x}[\theta(x_1) I_{1=\sigma_i} + \psi(\sigma_i, x_{\sigma_i}) I_{1>\sigma_i}].$$

This can be constructed by a selection theorem as in Fleming and Rishel (see [8, Lemma VI.6.1]). It follows that

$$L\phi - L\psi \leqq \|\phi - \psi\| \mathbb{P}^{u^*}_{t,x}[\sigma_i < 1].$$

Interchanging the roles of ϕ and ψ we conclude that

$$|L\sigma(t, x) - L\psi(t, x)| \leqq \|\phi - \psi\| \mathbb{P}^{u^*}_{t,x}[\sigma_i < 1], \qquad x \in D_i,$$

and hence that $\|L\phi - L_\psi\| \leqq \rho \|\phi - \psi\|$, where $\rho = \max_i \rho_i$ and

$$\rho_i = \sup_{x \in D_i} \mathbb{P}^{u^*}_{t,x}[\sigma_i < 1].$$

Since (D_i) is a finite partition, the contraction property is established once we show that $\rho_i < 1$ for each i. First, since $D_i \subset \text{int}\{U_i\}$, it is a standard result for nondegenerate diffusions that

$$\mathbb{P}^{u^*}_{t,x}[\sigma_i = 1] > 0 \quad \text{for each } x \in D_i,\ t \in [0, 1].$$

Next we remark that $\psi(t, x) = \mathbb{P}^{u^*}_{t,x}[\sigma_i = 1]$ is the solution of the following PDE on U_i:

$$\frac{\partial \psi}{\partial t} + A^{u^*}\psi = 0,$$

$$\psi(1, x) = 1, \qquad x \in U_i,$$

$$\psi(t, x) = 0, \qquad (t, x) \in [0, 1[\times \partial U_i.$$

Hence $\psi(t, x)$ is continuous and by the above argument $\psi(t, x) > 0$ for each x. Thus on the compact set $\bar{D}_i \subset U_i$

$$\pi_i := \min_{x \in D_i} \mathbb{P}^{u^*}_{t,x}[\sigma_i = 1] > 0$$

and thus

$$\rho_i = \sup_{x \in D_i} \mathbb{P}^{u^*}_{t,x}[\sigma_i < 1] < 1.$$

This shows that L is a contraction mapping and hence has a unique fixed point V. We now show that the function V is independent of the construction of the disjoint sets D_i and the defined sequence of stopping times T_i. Indeed, the probabilistic formula for $L^n\phi$ gives

$$L^n\phi = \min_{u \in \mathcal{U}} \mathbb{E}^u_{t,x}[\theta(x_1) I_{1 = T_n} + \phi(T_n, x_{T_n}) I_{T_n < 1}].$$

We observe that as $n \to \infty$ we have $T_n \to \infty$ almost surely and

$$L^n\phi \to \min_{u \in \mathcal{U}} \mathbb{E}^u_{t,x}[\theta(x_1)] \equiv V$$

since

$$\sup_{u \in \mathcal{U}} |\mathbb{E}^u_{t,x}[(\theta(x_1) + \phi(T_n, x_{T_n})) I_{T_n < 1}]| \leqq \|\theta + \phi\| \sup_{u \in \mathcal{U}} \mathbb{P}^u_{t,x}[T_n < 1] \to 0 \quad \text{as } n \to \infty.$$

The above argument essentially means that the probability to pay a penalty $\phi(T_n, x_{T_n})$ at T_n as $n \to \infty$ is negligible. Therefore the fixed point of the map L is equal to the value function V of the unstopped problem and does not depend on the construction of the disjoint set D_i.

For any $x \in D_1$ we know by a standard dynamic programming argument that V satisfies

$$V(t, x) = \min_{u \in \mathcal{U}} \mathbb{E}^u_{t,x}[\theta(x_1) I_{\tau = 1} + V(t, x_\tau) I_{\tau < 1}]$$

where $\tau := 1 \wedge \inf\{s \geqq t: x_s \in \partial D_1\}$. This is a control problem on a single coordinate chart, and we know from results of [8] that $V(t, x) = \tilde{V}(t, x)$ where $\tilde{V}(t, x)$ is the unique $C^{1,2}([0, 1[\times D_1)$ solution of the Bellman equation

$$\frac{\partial \tilde{V}}{\partial t}(t, x) + \min_{y \in U}[A^y \tilde{V}(t, x)] = 0, \qquad (t, x) \in [0, 1[\times D_1,$$

$$\tilde{V}(t, x) = V(t, x), \qquad (t, x) \in [0, 1[\times \partial D_1,$$

$$\tilde{V}(t, x) = \theta(x), \qquad x \in D_1.$$

Thus V is $C^{1,2}$ at any $[t, x] \in [0, 1[\times \text{int}\{D_1\}$. Since D_1 was arbitrary, this shows that in fact $V \in C^{1,2}([0, 1] \times M)$.

STOCHASTIC APPROXIMATION AND LARGE DEVIATIONS: UPPER BOUNDS AND w.p.1 CONVERGENCE*

PAUL DUPUIS† AND HAROLD J. KUSHNER‡

This paper is dedicated to the memory of E. J. McShane.

Abstract. With probability one convergence results are obtained for stochastic recursive approximation algorithms under very general conditions. The gain sequence $\{a_n\}$ can go to zero very slowly and state-dependent noise, discontinuous dynamical equations, and the projected or constrained algorithm are all treated. The basic technique is the theory of large deviations. Prior results obtained via this theory are extended in many directions. Let $\dot{x} = \bar{b}(x)$ denote the "mean" equation for the algorithm, let $\delta > 0$ be given, and let $G(\theta)$ be a neighborhood of a stable point θ of that ordinary differential equation. Then, asymptotic upper bounds to $a_N \log P\{X_n \notin G(\theta),\ n \geqq N \,|\, |X_N - \theta| \leqq \delta\}$ are obtained. These are often more informative than the usual classical rate of convergence results (that use a "local linearization") and, furthermore, are obtained for the constrained and nonsmooth cases, for which there are no "rate of convergence" results. The methods are also used to extend currently available upper bounds for algorithms with constant gains, with simpler proofs.

Key words. stochastic approximation, large deviations, recursive algorithms, errors for tracking systems

AMS(MOS) subject classifications. 60F10, 62L20, 93E10, 93E12

1. Introduction. We obtain with probability one (w.p.1) convergence results as well as useful (nonclassical) estimates of "rate of convergence" for fairly general stochastic approximation (SA) processes such as (1.1), via the theory of large deviations (R^r = Euclidean r-space)

$$X_{n+1} = X_n + a_n b_n(X_n, \xi_n), \quad X_n \in R^r, \quad 0 < a_n \to 0, \quad \Sigma a_n = \infty, \quad n \geqq 0. \tag{1.1}$$

We also treat the projection algorithm (1.2), where π_G denotes the nearest point of a compact and not necessarily convex set G:

$$X_{n+1} = \pi_G(X_n + a_n b_n(X_n, \xi_n)). \tag{1.2}$$

Such algorithms have been the subject of considerable attention [1]-[4], [8], [28], [29], [31], under a great variety of conditions. They appear in various guises in many places in control and communication theory.

In (1.1), the $\{\xi_n\}$ is a random process that might be state dependent itself in the sense that $P\{\xi_{n+1} \in A \,|\, \xi_i, X_i, i \leqq n\} \neq P\{\xi_{n+1} \in A \,|\, \xi_i, i \leqq n\}$. The b_n might simply be a function of X_n, ξ_n. The formulation allows $\{b_n\}$ to be a sequence of vector-valued (R^r) mutually independent, but not necessarily stationary, *random fields* parametrized by X_n, ξ_n. In this case b_n is characterized by the distribution function (which will depend on n in the nonstationary case)

$$P\{b_n \in B \,|\, X_i, \xi_i, b_{i-1}, i \leqq n\} = P\{b_n \in B \,|\, X_n, \xi_n\}. \tag{1.3}$$

The actual model used includes these as special cases and is defined at the beginning of § 2. There are many applications where the random field notation is useful since it

is awkward or difficult to express explicitly all the random variables that might be involved (e.g., the X_n, ξ_n might determine other random variables that are used, in turn, to calculate X_{n+1} from X_n). For example, consider an adaptive routing problem, where X_n denotes the routing parameter and ξ_n the (vector) buffer occupancies at time n. Then b_n might be a random variable that depends on, e.g., arrivals, completed services, and on acceptances of arrivals, at time n, and each of these might be related to X_n, ξ_n only statistically—but the exact relation is either too complicated to write (perhaps involving a sum of indicator functions of various possible events) or not necessary to write.

If b_n is simply a function of X_n, ξ_n, $(b_n = b(X_n, \xi_n))$, then we call it a *deterministic random field.* Even in this case, the ξ_n might be state dependent, correlated, or $b(\cdot)$ might be discontinuous. If $\{b_n\}$ is a deterministic random field, we write it simply as $b(X_n, \xi_n)$. Of course, since $\{\xi_n\}$ is a random sequence, $\{b(X_n, \xi_n)\}$ is not deterministic, in the usual sense.

Perhaps the weak convergence-based methods [3], [5], [6] are the most powerful general methods for dealing with the asymptotic properties of (1.1) or (1.2). The conditions for the validity of such methods are often readily verifiable. One common approach is to derive an ordinary differential equation (ODE) for the "mean" dynamics $\dot{x} = \bar{b}(x) = Eb(x, \xi)$ (where this is well defined) and to show that the asymptotic path of $\{X_n\}$ is arbitrarily close to that of the asymptotic solutions to $\dot{x} = \bar{b}(x)$ in the sense of the weak convergence theory. Typically, under some stability property of the ODE, this method locates the points (or point) near which $\{X_n\}$ spends "nearly all of its time." Nevertheless, there is still considerable interest in actual w.p.1 convergence. A powerful method would use a weak convergence approach to find the "asymptotic" points or sets, and then use a "local" method to show w.p.1 convergence of $\{X_n\}$ to an appropriate stable point of the ODE, under the usual condition that some compact set in its domain of attraction is entered infinitely often (that would itself often be shown by a weak convergence-based method).

Among methods that can be used to prove w.p.1 convergence, those based on the theory of large deviations have a number of advantages. The methods developed here yield a fairly unified approach for problems with state-dependent noise and discontinuous dynamics as well as for constrained problems. These facts imply the availability of a rather powerful technique for getting w.p.1 convergence. The state-dependent noise model used here is more general than allowed in [3] and [7], and is essentially the same as that in [28], [29], and [31]. The mathematical development here seems to be no more complicated than the powerful "martingale" based methods of [4], [8], [28], and [29]. Particularly in view of the fact that once certain basic general results are proved, we do not need to treat the various special cases independently. We can handle more slowly (and erratically) converging gains, the constrained case, the random field model, and get a very informative estimate of the rate of convergence even when the classical "local" smoothness conditions are violated. This latter point is particularly important. Although we do not do so here, the basic theorems can also be used to obtain results for models with random gains. The underlying idea is relatively simple. The proof of w.p.1 convergence reduces to showing the differentiability of a certain function defined in terms of conditional expectations taken with respect to the process itself. We show this readily for the usual cases covering the bulk of work in the literature, as well as for some new cases. New cases appearing in future applications can be dealt with in the same way. Our methods can have difficulty with problems where the qth moments of the ξ_n or $b_n(x, \xi_n)$ grow too fast as $q \to \infty$ (say, faster than those for b_n = Gaussian), but this rarely seems to be a serious problem in applications.

Typically, the large deviations estimates involve both an upper and a lower bound for a (suitably normalized) probability of a "rare" event (say the event that the stochastic approximation (asymptotically) escapes from a small neighborhood of a stable point of $\dot{x} = \bar{b}(x)$). To get the w.p.1 convergence here, only an *upper bound* is needed, and this allows a result under weaker conditions than would be required if both bounds were desired. The upper bound serves as a useful indicator of the rate of convergence, perhaps even more useful than that obtained by the classical methods. It is obtainable for constrained problems and is often obtainable even for nonstationary problems, in contrast to the classical "rate" results.

The "rate" calculated by the classical methods is just the asymptotic variance of $(X_n - \theta)/a_n^{1/2}$, where θ is the limit point. Its derivation requires a certain "regularity" in the way $a_n \to 0$, and a local expansion of the dynamics about θ. Assuming appropriate smoothness (usually twice differentiability of $b(x, \xi)$ at $x = \theta$, which is not needed by the large deviations method) of b for x near θ, the classical rate depends only on the gradient of $Eb(x, \xi)$ for $x = \theta$ and on the statistics of $\{b(\theta, \xi_n)\}$. In many applications, we are more interested in an (suitably normalized) estimate of the probability that the path $\{X_n, \infty > n \geqq N\}$ will escape from some given neighborhood of θ for large N. This would involve the full stabilizing effect of the dynamics and "destabilizing" effect of the noise in that interval, and such a useful estimate is obtainable from our results.

Our rate estimate takes the following form. Let D denote a compact set in the domain of attraction of a stable point θ of the ODE $\dot{x} = \bar{b}(x)$ and with $\theta \in D^0$, the interior of D. Let $\delta > 0$ be given. Let $A_D(T)$ denote the set of continuous functions $\phi(\cdot)$ with $|\phi(0) - \theta| \leqq \delta$ and $\phi(t) \notin D$ for some $t < T$. We will exhibit a function $\bar{L}(\phi, \dot{\phi}, t) \geqq 0$ that is zero if and only if $\dot{\phi} \equiv \bar{b}(\phi)$ and a function $\bar{S}(x, T, \phi)$:

$$\bar{S}(x, T, \phi) = \begin{cases} \displaystyle\int_0^T \bar{L}(\phi(s), \dot{\phi}(s), s)\, ds & \text{(for } \phi \text{ absolutely continuous, with } \phi(0) = x\text{)}, \\ \infty & \text{(otherwise)}, \end{cases}$$

such that

$$\overline{\lim_{n\to\infty}}\, a_n \log P\{X_m \notin D, \text{ some } m \geqq n \,|\, |X_n - \theta| \leqq \delta\} \leqq - \inf_{\substack{\phi \in A_D(T) \\ T > 0}} \bar{S}(\phi(0), T, \phi) < 0. \tag{1.4}$$

The right-hand side of (1.4) can yield estimates that are very useful for a "rate" of convergence, and for the dependence of this rate on the behavior of the algorithm in the set of interest D, as well as for the comparison of algorithms.

In [9]-[11], sharp upper and lower bounds have been obtained for SA algorithms by the methods of large deviations theory, and a great deal of useful information has been presented concerning the bounds and the structure of the H and L-functionals. These references require that $a_n \to 0$ in special ways, the noise is "exogenous," and the dynamical term b is a smooth function of x. The methods are unable to handle the constrained problems. Strictly speaking, the results in these references are not w.p.1 convergence results. They deal with sequences of sequences $\{X_m^n, m \geqq 0\}$, $n = 1, 2, \cdots$, defined by $X_{m+1}^n = X_m^n + a_{n+m} b(X_m^n, \xi_{n+m})$, $X_0^n = x$. Although the analysis of such processes is basic to the convergence result, in this paper we deal with the actual process itself. Also, since we are concerned with upper (large deviations) bounds only, we use $\overline{\lim}$ to define the various functionals, rather than lim, as illustrated in the sequel. This allows a result under weaker conditions on the $\{a_n, \xi_n, b_n\}$, as will be seen below.

To obtain the general results, we proceed as follows. First, a general and somewhat abstract assumption (Assumption 2.1 in § 2) is made. Under this (and some more

readily verifiable and reasonable) assumptions, the w.p.1 convergence theorem and the rate of convergence estimates are obtained (§ 3). In § 4, we show that all parts of Assumption 2.1 (except for part (i)) hold for the case of bounded dynamical terms. The extension to the unbounded case is disposed of in § 7. Then, to get the large deviation upper bound (and hence the w.p.1 result) for specific examples, we need only verify that a certain $\bar{H}(x, \alpha, t)$-functional, defined in § 4, has an α-derivative at $\alpha = 0$. This is done in § 5 for models covering the bulk of cases dealt with in the literature, and a general method for verification is discussed. (It is worth noting that the α-differentiability requirement is in a certain sense necessary and sufficient for a stochastic process to possess a nontrivial large deviation upper bound. The sufficiency is the point of Theorems 4.1 and 7.1, while the necessity can be shown to follow (under weak assumptions on the process) from the application of a theorem of Varadhan's [21] to the problem of evaluating (4.1).) Section 6 treats the constrained case, basically by showing how a "continuity" theorem for large deviations estimates can be used to carry the "unconstrained" result over to the constrained case. There are numerous advantages to our method, in comparison with existing methods. A more detailed comparison is given in § 8.

The key to the entire development is the result of § 4, obtaining an upper bound in a very quick and efficient way, without using the usually complicated sequence of estimates for special cases often associated with large deviations bounds. This method applies equally well to the case where the gains $\{a_n\}$ are constant. For this case, we obtain large deviations upper bounds for stochastic difference equations of the type in [27], but with weaker conditions and an easier proof, and the same "action functional." See, in particular, § 5.1.a and Example 7.1.

2. Background and assumptions. In this section, we introduce some rather detailed assumptions that will be used to prove the main convergence theorem and the rate estimate in § 3. The basic large deviation upper bound given in Assumption 2.1(iv) is of course not simple to verify, but is used simply to facilitate the proofs in § 3. We give some examples of processes that satisfy these assumptions at the end of this section as well as in §§ 5 and 7, where we give readily verifiable sufficient conditions that cover a wide variety of applications.

Assume that our algorithm is given by

$$X_{n+1} = X_n + a_n F_n. \tag{2.1}$$

Define

$$t_n = \sum_{0}^{n-1} a_i, \qquad t_0 = 0. \tag{2.2}$$

We define a continuous parameter interpolated version of $\{X_n\}$ by

$$X(t) = [(t - t_n)X_{n+1} + (t_{n+1} - t)X_n]/a_n, \qquad t \in [t_n, t_{n+1}], \tag{2.3}$$

and the interpolated version *starting at time* t_N by

$$X^N(t) = X(t + t_N). \tag{2.4}$$

When we say that $\overline{\lim}_n f_n \leqq f$ uniformly in a parameter α for some sequence $\{f_n\}$ and some f, we mean that for each $\varepsilon > 0$, there is $n_\varepsilon < \infty$ such that $\sup_{n \geqq n_\varepsilon} f_n \leqq f + \varepsilon$ for all α. For a set or point A, we use $N_h(A)$ for the h-neighborhood of A. Let $C[0, T]$ denote the set of R^r-valued functions on $[0, T]$ with the sup-norm topology.

ASSUMPTION 2.1. There exists a family of σ-algebras $\mathcal{F}_n \supset \sigma(X_i, i \leqq n)$, and a functional $\bar{S}(x, T, \phi)$ defined for $x \in R^r$, $T > 0$, and $\phi(\cdot) \in C[0, T]$ with the following properties:

(i) There exists $\bar{b}(x)$ such that $\bar{S}(x, T, \phi) = 0$ if and only if $\dot{\phi} = \bar{b}(\phi)$ almost surely, $\phi(0) = x$;

(ii) $\bar{S}(x, T, \phi) \geqq 0$;

(iii) Given compact $F \subset R^r$, $T > 0$, and $s \in [0, \infty)$, the set $\{\phi: \phi(0) \in F, \bar{S}(\phi(0), T, \phi) \leqq s\}$ is compact;

(iv) Given compact $F \subset R^r$, $T > 0$, $h > 0$ and $s \in [0, \infty)$, $\overline{\lim}_N a_N \log P\{X^N(\cdot) \notin N_h(\Phi(X^N(0), T, s)) \mid \mathcal{F}_N\} \leqq -s$, uniformly in $X^N(0) \in F$, and ω (w.p.1), where $\Phi(x, T, s) = \{\phi: \bar{S}(x, T, \phi) \leqq s\}$.

Remarks. (1) By part (iii) above, the functional $\bar{S}(\cdot, T, \cdot)$ is lower semicontinuous (l.s.c.).

(2) We consider $X^N(\cdot)$ in part (iv) as restricted to $[0, T]$.

(3) A weaker form of (iv) is actually sufficient for our needs below. If we assume that given $M_1 < \infty$ we can prove the lim sup is uniform save on a set of ω's with probability less than $\exp -M_1/a_N$, then the conclusions of § 3 may still be obtained, since the sets where the uniformity fails are negligible from the point of view of the large deviations estimates. We refer to this extended assumption as Assumption 2.1^e. Let us mention an example where these considerations are useful. If F_n takes the form $b(X_n) + \sigma(X_n)\xi_n$, where the ξ_n are obtained as the solution of a stable linear system driven by independently and identically distributed (i.i.d.) and zero mean Gaussian noise, then for $b(\cdot)$ and $\sigma(\cdot)$ Lipschitz we obtain Assumption 2.1(iv) only with the weaker uniformity described above, but this is enough to obtain the w.p.1 convergence. We will return to this example at the end of this section.

(4) In §§ 4, 5, and 7 we prove Assumption 2.1 for many interesting cases, and indicate the connection between the statistics of the process $\{X_n\}$ and the functions $\bar{b}(x)$ and $\bar{S}(x, T, \phi)$. We note at this time that Assumption 2.1 implies that the conditional distribution of $X^N(\cdot)$ given $X^N(0) = x$ converges weakly to the measure concentrated at the point $\phi(\cdot)$, where $\dot{\phi} = \bar{b}(\phi)$, $\phi(0) = x$ (if this solution is unique), and that the probability that $X^N(\cdot)$ deviates from $\phi(\cdot)$ by more than $\gamma > 0$ on any interval $[0, T]$ (in the sup-norm sense) decays as does $\exp -\delta/a_N$, for some $\delta > 0$.

(5) From Assumption 2.1(iv) we may obtain the following [15, Thm. 3.3]. Let compact $F \subset R^r$, $T > 0$, $\delta > 0$ and $s \geqq 0$ be given. Then there is $N_0 < \infty$ such that for any $x \in F$, any closed set $A \subset C[0, T]$ satisfying $\inf_{\phi \in A} \bar{S}(x, T, \phi) \geqq s$, and any $N \geqq N_0$, we have

$$a_N \log P\{X^N(\cdot) \in A \mid \mathcal{F}_N, X^N(0) = x\} \leqq -s + \delta \quad \text{a.s.} \tag{2.5}$$

(6) The uniformity of the estimates in Assumption 2.1(iv) with respect to ω imply that (2.5) continues to hold if we replace N by any stopping time $M \geqq N_0$ almost surely.

(7) The t-dependence of $\bar{S}$ occurs owing to the fact that a_n are not constant. See, e.g., Example 2.1, and the results in § 5.

The Limit ODE. To get any sort of useful convergence for $\{X_n\}$, the ODE

$$\dot{x} = \bar{b}(x) \tag{2.6}$$

must have at least one stable point. We assume the following.

ASSUMPTION 2.2. The ODE (2.6) has a unique solution for each initial condition and there is a point θ that is asymptotically (not necessarily globally) stable in the sense of Lyapunov, with domain of attraction Λ.

Assumption 2.2 implies that for any compact $G \subset \Lambda$ and $\delta > 0$ there is $T < \infty$ such that all solutions originating in G are in $N_\delta(\theta)$, a δ-neighborhood of θ, for $t \geqq T$.

Finally, we state the slowest rate at which we can allow $a_n \to 0$.

ASSUMPTION 2.3. For every $\delta > 0$, $\sum_n \exp -\delta/a_n < \infty$, and $\sum a_n = \infty$.

For example, let $a_n = c_n/\log n$, with $c_n \to 0$ and $\sum a_n = \infty$. Then Assumption 2.3 holds. If c_n does not go to zero, then there will not be convergence w.p.1. This is the case in the "annealing" process [30].

Example 2.1. We take $F_n = b(X_n) + \sigma(X_n)\xi_n$ in (2.1), where $b(\cdot)$ and $\sigma(\cdot)$ are Lipschitz and $a_n = 1/n^\gamma$, $0 < \gamma \leqq 1$. We assume that $\xi_{n+1} = A\xi_n + B\theta_n$, with $\{\theta_n\}$ an i.i.d. mean-zero Gaussian sequence, and that the roots of A are contained in the interior of the unit circle. Then [11] Assumption 2.1^e holds, with

$$\bar{S}(x, T, \phi) = \begin{cases} \int_0^T \bar{L}(\phi, \dot{\phi}, s)\, ds & \text{if } \phi \text{ is absolutely continuous and } \phi(0) = x, \\ \infty & \text{otherwise,} \end{cases}$$

$$\bar{L}(x, \beta, s) = (\beta - b(x))'[(\sigma(x)(A-I)^{-1}B)(\sigma(x)(A-I)^{-1}B)']^{-1}(\beta - b(x))h(s)/2,$$

(if the indicated inverse exists) and $\bar{b}(x) = b(x)$. The function $h(s)$ is $\exp s$ if $\gamma = 1$, and 1 if $\gamma < 1$. If the indicated inverse does not exist, $\bar{L}$ takes a different form [11], although Assumption 2.1^e continues to hold with $\bar{b}(x) = b(x)$. For additional examples see [11].

The sequences $\{a_n\}$ and the functions $b(\cdot)$ and $\sigma(\cdot)$ considered above are more "regular" than is actually needed to obtain Assumption 2.1^e. This is because the indicated reference was concerned with *both upper and lower large deviation bounds.* For the upper bound alone, which is the only part of the theory we use, much less "regularity" is required. We shall see more of this in §§ 5 and 7. In particular, Example 7.2 contains Example 2.1 as a special case.

3. The basic convergence theorem.

THEOREM 3.1. *Suppose that Assumptions* 2.1, 2.2, *and* 2.3 *hold, and that there is a compact neighborhood* $G(\theta)$ *of* θ, *with* $G(\theta) \subset \Lambda^0$, *and such that there is* (*almost surely*) *a* (*random*) *sequence* $\{n_i\}$ *satisfying* $X_{n_i} \in G(\theta)$. *Then* $X_n \to \theta$ w.p.1.

Remarks. If not all paths visit some neighborhood of θ infinitely often (i.o.) then we will have $X_n \to \theta$ w.p.1 with respect to those paths that do. It is expected that the recurrence condition would be verified by a weak convergence argument.

Proof. For $\delta > 0$, let $N_\delta(\theta)$ denote $\{x: |\theta - x| \leqq \delta\}$. We will first prove that if $\{X_n\}$ visits $G(\theta)$ infinitely often w.p.1, then $\{X_n\}$ visits $N_\delta(\theta)$ infinitely often w.p.1. We can suppose that $N_\delta(\theta) \subset G(\theta)$.

Owing to the stability assumption (Assumption 2.2), there is $T_1 < \infty$ such that if $\phi(\cdot)$ satisfies $\dot{\phi} = \bar{b}(\phi)$ and $\phi(0) = x \in G(\theta)$, then $\phi(t) \in N_{\delta/2}(\theta)$ for $t \geqq T_1$. Let $\Delta > 0$, and set $T_1' = T_1 + \Delta$. Define the set of paths

$$A_1 = \{\phi(\cdot) \in C[0, T_1']: \phi(0) \in G(\theta), \phi(t) \notin N_\delta(\theta) \quad \text{for some } t \in [T_1, T_1']\}.$$

We claim that there is a $c_1 > 0$ such that ($\bar{A}$ and A^0 denote the closure and interior, respectively, of the set A)

$$\inf_{\phi \in \bar{A}_1} \bar{S}(\phi(0), T_1', \phi) = c_1 > 0. \tag{3.1}$$

If (3.1) does not hold, then there is a sequence $\{\phi_i(\cdot)\} \subset A_1$ such that $\bar{S}(\phi_i(0), T_1', \phi_i) \to 0$. By Assumption 2.1(iii), the set $\{\phi_i(0)\}$ is precompact. We extract a subsequence (again indexed by i) such that $\{\phi_i(\cdot)\}$ converges, and denote the limit by $\phi^*(\cdot)$. The lower semicontinuity of $\bar{S}(\phi(0), T_1', \phi)$ implies that $\bar{S}(\phi^*(0), T_1', \phi^*) = 0$, which

implies that

$$\dot{\phi}^* = \bar{b}(\phi^*), \qquad \phi^*(0) \in G(\theta).$$

Since by its definition $\bar{A}_1$ does not contain a solution of $\dot{\phi} = \bar{b}(\phi)$, we obtain a contradiction.

Define the events

$$E_n^1 = \{X_n \in G(\theta), X(t+t_n) \notin N_\delta(\theta) \text{ for some } t \in [T_1, T_1']\}.$$

We have $E_n^1 = \{X^n(\cdot) \in A_1\}$. Assumptions 2.1 and 2.3, and (3.1) then imply that

$$\sum_n P\{E_n^1\} \leqq \sum_n P\{E_n^1 \mid X_n \in G(\theta)\} < \infty$$

and the Borel-Cantelli Lemma gives

$$P\{E_n^1 \text{ occurs infinitely often}\} = 0.$$

Define $m(t) = \min\{n: t_n \leqq t\}$. Since $a_n \to 0$, we conclude that the event $\{X_n \in G(\theta), X_{m(T_1'+t_n)} \notin N_\delta(\theta)\}$ occurs only finitely often, w.p.1. Thus, if $\{X_n\}$ visits $G(\theta)$ infinitely often, w.p.1, it must visit $N_\delta(\theta)$ infinitely often w.p.1 for each $\delta > 0$.

Next let $\delta_1 > 0$ be such that $N_{\delta_1}(\theta) \subset \Lambda^0$. By the stability assumption there is $\delta_1 > \delta_2 > 0$ such that for any $x \in N_{\delta_2}(\theta)$, if $\phi(\cdot)$ satisfies $\dot{\phi} = \bar{b}(\phi)$ and $\phi(0) = x$, then $\phi(t) \in N_{\delta_1/2}(\theta)$ for $t \geqq 0$. By the preceding argument, we can assume that

$$P\{X_n \in N_{\delta_2}(\theta) \text{ infinitely often}\} = 1.$$

Let $T_2 < \infty$ be such that if $\phi(\cdot)$ satisfies $\dot{\phi} = \bar{b}(\phi)$ and $\phi(0) = x \in N_{\delta_2}(\theta)$, then $\phi(t) \in N_{\delta_2/2}(\theta)$ for all $t \geqq T_2$. Define

$$A_2 = \{\phi(\cdot) \in C[0, T_2]: \phi(0) \in N_{\delta_2}(\theta) \text{ and there is } t \leqq T_2 \text{ such that } \phi(t) \notin N_{\delta_1}(\theta) \text{ and/or } \phi(T_2) \notin N_{\delta_2}(\theta)\}.$$

By an argument analogous to that used to get (3.1), there is a $c_2 > 0$ such that

$$\inf_{\phi \in \bar{A}_2} \bar{S}(\phi(0), T_2, \phi) = c_2 > 0.$$

Define $E_n^2 = \{X_n \in N_{\delta_2}(\theta)$ and there is $t \leqq T_2$ such that $X(t+t_n) \notin N_{\delta_1}(\theta)$ and/or $X(T_2+t_n) \notin N_{\delta_2}(\theta)\}$. Then $E_n^2 = \{X^n(\cdot) \in A_2\}$.

Let $\{m_k\}$ denote the return times of $\{X_n\}$ to $N_{\delta_2}(\theta)$ and note that the $\delta_i > 0$ can be made arbitrarily small. Since $m_k < \infty$ for all k w.p.1, to prove the theorem it is sufficient to show that $\lim P\{X_{m_k+i} \notin N_{\delta_1}(\theta), \text{ for some } i < \infty\} = 0$. But this holds if we show that (w.p.1)

$$\lim_n P\{X_{n+i} \notin N_{\delta_1}(\theta), \text{ for some } i < \infty \mid X_n \in N_{\delta_2}(\theta)\} = 0. \tag{3.2}$$

We have the obvious inclusion (letting A^c denote the complement of the set A)

$$\begin{aligned}
&\{X_{n+i} \notin N_{\delta_1}(\theta), \text{ for some } i < \infty \text{ and } X_n \in N_{\delta_2}(\theta)\} \\
&\quad \subset \{X_i \notin N_{\delta_1}(\theta) \text{ for some } m(jT_2+t_n) < i \leqq m(jT_2+T_2+t_n) \\
&\qquad \text{and/or } X_{m(jT_2+T_2+t_n)} \notin N_{\delta_2}(\theta), \text{ for some } 0 \leqq j < \infty, \text{ and } X_n \in N_{\delta_2}(\theta)\} \\
&\quad = \bigcup_{0 \leqq j < \infty} E^2_{m(jT_2+t_n)} \bigcap_{i<j} (E^2_{m(iT_2+t_n)})^c \cap \{X_n \in N_{\delta_2}(\theta)\}.
\end{aligned}$$

It follows that

$$\begin{aligned}
&P\{X_{n+i} \notin N_{\delta_1}(\theta), \text{ for some } i < \infty \mid X_n \in N_{\delta_2}(\theta)\} \\
&\qquad \leqq \sum_{j=0}^{\infty} P\left\{ E^2_{m(jT_2+t_n)} \,\middle|\, \bigcap_{i<j} (E^2_{m(iT_2+t_n)})^c \cap \{X_n \in N_{\delta_2}(\theta)\} \right\}.
\end{aligned} \tag{3.3}$$

Note that for any fixed j, inclusion in the conditioning set in the jth term in the sum implies that $X_{m(jT_2+t_n)} \in N_{\delta_2}(\theta)$. Thus (3.2) follows from (3.3), and Assumptions 2.1 and 2.3. □

To obtain our "rate" estimate, we make a weak assumption on the form of $\bar{S}(x, T, \phi)$.

ASSUMPTION 3.1. There exists a measurable function $\bar{L}(x, \beta, s) \geqq 0$ such that

$$\bar{S}(x, T, \phi) = \begin{cases} \int_0^T \bar{L}(\phi, \dot{\phi}, s)\, ds & \text{if } \phi \text{ is absolutely continuous and } \phi(0) = x, \\ \infty & \text{otherwise} \end{cases}$$

and that as a function of t, $\bar{L}(x, \beta, t)$ is nondecreasing for each pair (x, β).

This representation of $\bar{S}(x, T, \phi)$ holds for every example of a "decreasing gain" stochastic approximation process having a large deviation upper bound known to the authors. For the processes studied in this paper, we will define L by (4.1) and (4.2) below.

THEOREM 3.2. *Assume Assumptions* 2.1, 2.2, 2.3, *and* 3.1 *hold, and, in addition, that given* $\varepsilon > 0$ *there is* $\bar{N} < \infty$ *such that* $a_i / a_N \leqq 1 + \varepsilon$ *for all* $i \geqq N \geqq \bar{N}$. *Then, for* $G(\theta)$ *a neighborhood of* θ

$$\begin{aligned} &\overline{\lim_N}\, a_N \log P\{X_n \notin G(\theta), \text{ for some } n \geqq N \,|\, |X_N - \theta| \leqq \delta\} \\ &\leqq - \inf_{\substack{\phi : |\phi(0) - \theta| \leqq \delta \\ \phi(t) \notin G(\theta), \text{some } t < \infty}} \bar{S}(\phi(0), t, \phi) \equiv -\bar{S}^* \end{aligned} \tag{3.4}$$

uniformly in ω, w.p.1.

Remark. The stability assumption and the lower semicontinuity of $\bar{S}(\cdot, T, \cdot)$ imply that the right side of (3.4) is strictly negative for small enough $\delta > 0$.

Proof. Let $\bar{T} > 0$ be fixed and $T \geqq \bar{T}$, and let $N_\delta(\theta) \subset G(\theta)$. Define that set of paths

$$\begin{aligned} A(T) = \{\phi : |\phi(0) - \theta| \leqq \delta, \text{ and either } \phi(t) \notin G(\theta) \text{ for some } t \leqq T, \\ \text{or } |\phi(t) - \theta| \geqq \delta/2 \text{ for } \bar{T} \leqq t \leqq T\}. \end{aligned}$$

We claim that for large enough T,

$$\inf_{\phi \in \overline{A(T)}} \bar{S}(\phi(0), T, \phi) \geqq \bar{S}^*. \tag{3.5}$$

First note that the same proof as that of (3.1) implies there are $c_3 > 0$ and $T_3 < \infty$ such that if we define $A_3 = \{\phi : \phi(0) \in G(\theta), \phi(T_3) \notin N_{\delta/2}(\theta)\}$, then

$$\inf_{\phi \in \bar{A}_3} \bar{S}(\phi(0), T_3, \phi) \geqq c_3.$$

Let i equal the integer part of $(T - \bar{T})/T_3$. Then for the paths in $A(T)$ that do not escape from $G(\theta)$ and for which $|\phi(t) - \theta| \geqq \delta/2$ for $\bar{T} \leqq t \leqq T$, we have

$$\bar{S}(\phi(0), T, \phi) \geqq i c_3,$$

which implies (3.5) (when T is large).

Now define the stopping times τ_i^N by $\tau_0^N = N$, $\tau_{i+1}^N = \inf\{n \geqq m(t_{\tau_i^N} + \bar{T}) : X_n \notin N_\delta(\theta)\} \wedge \inf\{n \geqq \tau_i^N : X_n \notin G(\theta)\}$ and the events

$$E_i^N = \{X_{\tau_{i+1}^N} \notin G(\theta) \text{ or } t_{\tau_{i+1}^N} - t_{\tau_i^N} \geqq T\} \subset \{X^{\tau_i^N}(\cdot) \in A(T)\}.$$

We use the following estimate that is derived in the same way as (3.3).

$$P\{X_n \notin G(\theta), \text{ for some } n \geqq N \mid X_N \in N_\delta(\theta)\}$$

$$\leqq \sum_{j=0}^{\infty} P\left\{ E_j^N \,\middle|\, \bigcap_{i<j} (E_i^N)^c \cap \{X_N \in N_\delta(\theta)\} \right\} \quad \text{(w.p.1)}. \tag{3.6}$$

Fix $h_1 > 0$. By Assumption 2.1 and (3.5), an upper bound (w.p.1) to the right-hand side of (3.6) is given by (for any $h_2 \geqq 0$)

$$\sum_{i=N}^{\infty} \exp -(\bar{S}^* - h_1)/a_i = (\exp -(\bar{S}^* - h_2)/a_N) \sum_{i=N}^{\infty} \exp [-(\bar{S}^* - h_1)/a_i + (\bar{S}^* - h_2)/a_N]$$

when N is large. Thus (3.4) follows if we prove that given $h_2 > 0$ there is $h_1 > 0$, $\bar{N} < \infty$, and $M < \infty$ so that for $N \geqq \bar{N}$,

$$\sum_{i=N}^{\infty} \exp [-(\bar{S}^* - h_1)/a_i + (\bar{S}^* - h_2)/a_N] \leqq M. \tag{3.7}$$

To prove (3.7), take $\varepsilon = (h_2/8\bar{S}^*) \wedge \frac{1}{2}$, and $h_1 = \varepsilon \bar{S}^*/2$. Pick $\bar{N}$ large enough so that $a_i/a_N \leqq 1+\varepsilon$ for $i \geqq N \geqq \bar{N}$. Then for each i such that $a_i/a_N \geqq 1-\varepsilon$ we have

$$[-\bar{S}^* + h_1 + (\bar{S}^* - h_2)a_i/a_N]/a_i \leqq [h_1 + \varepsilon\bar{S}^* - h_2(1-\varepsilon)]/a_i \leqq [-h_2/4]/a_i.$$

On the other hand, if $a_i/a_N < 1-\varepsilon$, we obtain the following bound for the exponent:

$$[h_1 - \varepsilon\bar{S}^*]/a_i = [-\varepsilon\bar{S}^*/2]/a_i.$$

Hence (3.7) follows from Assumption 2.3. □

4. A proof showing that Assumption 2.1(ii)–(iv) holds for bounded noise. In this section we make the following simplifying assumption.

ASSUMPTION 4.1. The sequence $\{|F_n|\}$ is (almost surely) bounded by $K < \infty$.

The main result of this section is that under this condition, the proof that Assumption 2.1 holds reduces to verifying the existence of the derivative at $\alpha = 0$ of the function $\bar{H}(x, \alpha, t)$ defined below. In § 5 we will show the existence of this derivative for a wide variety of processes.

For $\phi \in C[0, T]$ let $D^\Delta\phi(t) = \phi(t+\Delta) - \phi(t)$. We define the function $\bar{H}(x, \alpha, t)$ by

$$\bar{H}(x, \alpha, t) = \overline{\lim_{\Delta \to 0}} \overline{\lim_{N \to \infty}} \overline{\lim_{\substack{y \to x \\ s \to t}}} \operatorname*{ess\,sup}_{\omega} a_N \log E[\exp \langle \alpha, D^\Delta X^N(s) \rangle / a_N \mid \mathscr{F}_N, X^N(s) = y]/\Delta. \tag{4.1}$$

Although the expression defining $\bar{H}$ appears formidable, we shall see in § 5 that it simplifies greatly for "typical" classes of models. The advantage of dealing with the definition as stated is that it yields Theorem 4.1 below under minimal assumptions.

Remark on the use of $\overline{\lim}$ *rather than* lim *in* (4.1). The use of $\overline{\lim}$ is somewhat equivalent to taking a worst case. For example, let $b_n(x, \xi) = b(x) + \xi$, where $\{\xi_n\}$ is a sequence of zero-mean mutually independent Gaussian random variables with covariances $\{\Sigma_n\}$, and let $a_n = 1/n^\gamma$, where $\gamma \in (0, 1)$. Since

$$\frac{1}{n} \log E \exp \left\langle \alpha, \sum_{N+1}^{N+n} (b(x) + \xi_j) \right\rangle = \langle \alpha, b(x) \rangle + \frac{1}{2n} \sum_{N+1}^{N+n} \langle \alpha, \Sigma_j \alpha \rangle,$$

we can prove that the $\overline{\lim}$ in (4.1) is just $\langle \alpha, b(x) \rangle + \alpha' \Sigma \alpha / 2$, where Σ is the $\overline{\lim}$ of $(1/n) \sum_{N+1}^{N+n} \Sigma_i$ in the sense of nonnegative definite matrices. In many problems, the

dynamics are stable enough so that if the noise terms are multiplied by some factor (to take, say, Σ_n to Σ) we still have the required "stability" to get the desired w.p.1 convergence. Additional examples appear in § 5.

Owing to its definition, the function $\bar{H}(x, \alpha, t)$ enjoys the following properties:

(i) The convergence in (4.1) is uniform in ω (almost surely);

(ii) $\bar{H}(x, \alpha, t)$ is convex in α and is upper semicontinuous in (x, t);

(iii) $\bar{H}(x, 0, t) = 0$ for all pairs (x, t);

(iv) $\bar{H}(x, \alpha, t) \leqq K|\alpha|$ for all pairs (x, t), where K is an upper bound to $|F_n|$.

Define $\bar{L}(x, \beta, t)$ as the Legendre transform (in α) of $\bar{H}(x, \alpha, t)$:

$$\bar{L}(x, \beta, t) = \sup_{\alpha} [\langle \alpha, \beta \rangle - \bar{H}(x, \alpha, t)]. \tag{4.2}$$

The properties of $\bar{H}$ mentioned above imply the following properties of $\bar{L}$:

(v) $\bar{L}(x, \beta, t)$ is convex in β and is lower semicontinuous in (x, β, t);

(vi) $\bar{L}(x, \beta, t) \geqq 0$ for all (x, β, t);

(vii) $\bar{L}(x, \beta, t) = +\infty$ if $|\beta| > K$, for all pairs (x, t).

Here (ii)$\Rightarrow$(v), (iii)$\Rightarrow$(vi), (iv)$\Rightarrow$(vii).

Finally, we define an "action functional" in terms of $\bar{L}$ by

$$\bar{S}(x, T, \phi) = \int_0^T \bar{L}(\phi, \dot{\phi}, s)\, ds \tag{4.3}$$

if $\phi(0) = x$ and ϕ is absolutely continuous, and $\bar{S}(x, T, \phi) = \infty$ otherwise.

Remark. We refer to $\bar{S}$ as an action functional, even though it yields only upper bounds. In the sequel we will define an action functional simply by writing an equation like (4.3), the "absolute continuity" and $\phi(0) = x$ qualifications being understood.

THEOREM 4.1. *Assume Assumption* 4.1, *and define* $\bar{H}$, $\bar{L}$, *and* $\bar{S}$ *by* (4.1), (4.2), *and* (4.3), *respectively. Then parts* (ii)-(iv) *of Assumption* 2.1 *hold.*

Remarks. With this theorem, it is clear that as far as bounded noise is concerned, the main task associated with any specific model is verifying Assumption 2.1(i) for a vector field $\bar{b}(\cdot)$ with the correct stability properties. We discuss this problem at length in § 5. The proof below will yield Assumption 2.1(iv) with the same σ-algebra as that used to define $\bar{H}$ in (4.1), which is in fact open to choice. However, we want to choose $\mathcal{F}_N$ to obtain the "best" upper bound (i.e., largest $\bar{L}$, or smallest $\bar{H}$). Usually the "best" choice is quite obvious. We also have flexibility with regard to the gain sequence $\{a_i\}$. If the sequence $\{a_i|F_i|/\bar{a}_i\}$ is bounded (almost surely), then we obviously obtain an upper bound with normalizing sequence $\{\bar{a}_i\}$, although with a possibly different functional $\bar{S}$.

Proof of (ii) *and* (iii). The nonnegativity of $\bar{L}$ implies that of $\bar{S}$. The lower semicontinuity of $\bar{L}$ and the lower bound $\bar{L}(x, \beta, t) = \infty$ for $|\beta| > K$ are sufficient to prove [14] that $\bar{S}(\phi(0), T, \phi)$ is lower semicontinuous in $\phi(\cdot)$. Since $\bar{S}(\phi(0), T, \phi) < \infty$ implies $|\dot{\phi}(t)| \leqq K$ almost surely, Ascoli's Theorem yields the compactness.

(iv) Fix compact $F \subset R^r$, $T > 0$, $s < \infty$, and $h > 0$. Let θ: $[0, T] \to R^r$ be continuous, and for the remainder of the proof let $y(\cdot)$ be a Lipschitz continuous function (with constant K) with $y(0)$ in F.

For $\gamma > 0$, define

$$\bar{H}^{\gamma}(x, \alpha, t) = \sup_{|x-y| \leqq \gamma} \sup_{|t-s| \leqq \gamma} \bar{H}(y, \alpha, s).$$

Then $\bar{H}^{\gamma}$ is convex in α and upper semicontinuous in (x, t), and $\bar{H}^{\gamma}(x, \alpha, t) \downarrow \bar{H}(x, \alpha, t)$ as $\gamma \to 0$. Let $\bar{L}^{\gamma}$ denote the Legendre transform of $\bar{H}^{\gamma}$.

For each N, set

$$G_N^\gamma(\theta, y) = \sum_N^{m(t_N+T)} \langle \theta(t_i - t_N), y(t_{i+1} - t_N) - y(t_i - t_N) \rangle - \sum_N^{m(t_N+T)} \bar{H}^\gamma(y(t_i - t_N), \theta(t_i - t_N), t_i - t_N) a_i. \tag{4.4}$$

Due to the definition of $\bar{H}^\gamma$,

$$\lim_{N\to\infty} G_N^\gamma(\theta, y) \geqq \int_0^T \langle \theta(t), \dot{y}(t) \rangle \, dt - \int_0^T \bar{H}^{2\gamma}(y(t), \theta(t), t) \, dt \equiv G^{2\gamma}(\theta, y)$$

uniformly in $y(\cdot)$. For functions $y(\cdot)$ which are not Lipschitz with constant K, we set $G^{2\gamma}(\theta, y) = +\infty$. Note that $G^{2\gamma}(\theta, y)$ is l.s.c. in $y(\cdot)$ for each $\theta(\cdot)$.

Let $x \in F$, and let $\varepsilon > 0$ be given. By the definition (4.1), for any compact set F' there is $\tau > 0$ such that $\Delta \leqq \tau$, $N \geqq 1/\tau$, $|y - x| \leqq \tau$, and $|t - s| \leqq \tau$ imply that

$$E[\exp \langle \alpha, D^\Delta X^N(s) \rangle / a_N \mid \mathcal{F}_N, X^N(s) = y] \leqq \exp (\bar{H}^\gamma(x, \alpha, t) + \varepsilon)\Delta / a_N$$

(almost surely in ω), whenever $x \in F'$. If we choose F' to contain the range of $X^N(\cdot)$ on the interval $[0, T]$, then

$$a_N \log E\left[\exp \sum_{i=0}^{T/\Delta - 1} (\langle \alpha, X^N(i\Delta + \Delta) - X^N(i\Delta) \rangle - \bar{H}^\gamma(X^N(i\Delta), \alpha, i\Delta)\Delta)/a_N \,\middle|\, \mathcal{F}_N, X_N = x \right] \leqq T\varepsilon.$$

By using the continuity of $\theta(\cdot)$ and the fact that ε can be made arbitrarily small, we get

$$\overline{\lim_{N\to\infty}} a_N \log E[\exp G_N^\gamma(\theta, X^N)/a_N \mid \mathcal{F}_N, X_N = x] \leqq 0 \tag{4.5}$$

uniformly in ω (almost surely) and $x \in F$. Let closed A be given. Then, by Chebyshev's inequality, for each $\theta(\cdot) \in C([0, t]; R^r)$

$$P\{X^N(\cdot) \in A \mid \mathcal{F}_N, X_N = x\} \leqq E\left[\exp (G_N^\gamma(\theta, X^N) - \inf_{\phi \in A} G_N^\gamma(\theta, \phi))/a_N \mid \mathcal{F}_N, X_N = x \right].$$

We also have

$$\overline{\lim_N} \left[-\inf_{\phi \in A} G_N^\gamma(\theta, \phi) \right] \leqq -\inf_{\phi \in A} G^{2\gamma}(\theta, \phi).$$

Combining these facts, we obtain

$$\overline{\lim_N} a_N \log P\{X^N(\cdot) \in A \mid \mathcal{F}_N, X_N = x\} \leqq -\inf_{\phi \in A} G^{2\gamma}(\theta, \phi), \tag{4.6}$$

uniformly in ω almost surely and $x \in F$, for each $\gamma > 0$.

Define (the set $\Phi(x, T, s)$ is defined in Assumption 2.1(iv))

$$s^*(\gamma) = \inf_{\phi \notin N_h(\Phi(x,T,s))} \sup_{\theta \in C([0,T];R^r)} G^\gamma(\theta, \phi).$$

We shall assume that for each $\gamma > 0$ that $s^*(\gamma) < \infty$. The case $s^*(\gamma) = \infty$ requires only obvious modifications. Let $\delta > 0$ be given. For any $\phi(\cdot) \notin N_h(\Phi(x, T, s))$ there is

$\theta(\phi)(\cdot)$ such that $G^\gamma(\theta(\phi), \phi) \geqq s^*(\gamma) - \delta$. The l.s.c. of $G^\gamma(\theta, \cdot)$ implies that there is a neighborhood $N(\phi)$ of $\phi(\cdot)$ (with radius less than $h/2$) such that for all $\psi(\cdot) \in N(\phi)$, $G^\gamma(\theta(\phi), \psi) \geqq s^*(\gamma) - 2\delta$. Choose $\phi_i(\cdot)$, $i = 1, \cdots, I$, such that the $N(\phi_i)$ cover the compact set given by $\{\phi(\cdot): \phi(0) = x, |\dot{\phi}(t)| \leqq K, \ t \leqq T, \ x \in F\}$. Let $I(x, s) = \{i: \phi_i(\cdot) \notin N_h(\Phi(x, T, s))\}$. By (4.6) and the comments above in this paragraph,

$$\begin{aligned}
&\overline{\lim_N} a_N \log P\{X^N(\cdot) \notin N_h(\Phi(x, T, s)) \mid \mathcal{F}_N, X_N = x\} \\
&\quad \leqq \overline{\lim_N} a_N \log \sum_{i \in I(x,s)} P\{X^N(\cdot) \in N(\phi_i) \mid \mathcal{F}_N, X_N = x\} \\
&\quad \leqq -s^*(\gamma) + 2\delta
\end{aligned}$$

(uniformly in $x \in F$ and in ω almost surely). Since the inequality between the second and third lines holds if only one term appeared in the sum, it holds as stated. If we show that $\liminf_{\gamma \to 0} s^*(\gamma) \geqq s$, then (since $\delta > 0$ is arbitrary) we have proved Assumption 2.1(iv).

Now fix $\phi(\cdot)$, and consider $\sup_\theta G^\gamma(\theta, \phi)$. Assume $\int_0^T \bar{L}^\gamma(\phi, \dot{\phi}, t)\, dt < 0$. (The case $\int_0^T \bar{L}^\gamma(\phi, \dot{\phi}, t)\, dt = \infty$ is handled similarly.) Given $n < \infty$, we can find a measurable function $\theta^n(\cdot)$ such that

$$\begin{aligned}
\int_0^T [\langle \theta^n(t), \dot{\phi}(t) \rangle - \bar{H}^\gamma(\phi(t), \theta^n(t), t)]\, dt &\geqq \int_0^T \sup_\alpha [\langle \alpha, \dot{\phi}(t) \rangle - \bar{H}^\gamma(\phi(t), \alpha, t)]\, dt - 1/n \\
&= \int_0^T \bar{L}^\gamma(\phi(t), \dot{\phi}(t), t)\, dt - 1/n.
\end{aligned}$$

Next choose a sequence of continuous functions $\theta_i^n(\cdot)$ such that $\theta_i^n \to \theta^n$ almost everywhere. By dominated convergence

$$\lim_i G^\gamma(\theta_i^n, \phi) \geqq \int_0^T \bar{L}^\gamma(\phi(t), \dot{\phi}(t), t)\, dt - 1/n.$$

Therefore,

$$s^*(\gamma) = \inf_{\phi \notin N_h(\Phi(x,T,s))} \int_0^T \bar{L}^\gamma(\phi(t), \dot{\phi}(t), t)\, dt.$$

By extracting from a minimizing sequence $\phi^\gamma(\cdot)$ a subsequence such that $\dot{\phi}^\gamma(\cdot)$ converges weakly and applying Fatou's lemma, we obtain

$$\liminf_{\gamma \to 0} s^*(\gamma) \geqq \inf_{\phi \notin N_h(\Phi(x,T,s))} \bar{S}(x, T, \phi) \geqq s. \qquad \square$$

Remark. Suppose that in the definition of $\bar{H}$ (given by (4.1)) we restrict the ess sup to $\omega \in \Omega_N$, where $\overline{\lim}_N a_N \log P(\Omega \backslash \Omega_N) = -\infty$. In this case the proof of Theorem 4.1 will yield parts (ii), (iii), and (iv) of Assumption 2.1^e, and not Assumption 2.1. However, as remarked below Assumption 2.1, this is sufficient for the convergence proof.

With this theorem we have proved (for the case of bounded $\{F_n\}$) that for $\bar{H}$, $\bar{L}$, and $\bar{S}$ defined through (4.1), (4.2), and (4.3), respectively, we obtain Assumption 2.1 parts (ii), (iii), and (iv), respectively. The only part of Assumption 2.1 not shown is the existence of $\bar{b}(x)$ such that $\bar{L}(x, \beta, t) = 0$ if and only if $\beta = \bar{b}(x)$. We take this matter up in the next section, where we consider this problem in the context of several specific system models. We show this to be true if and only if $\bar{H}_\alpha(x, 0, t)$ exists, in which case we identify $\bar{b}(x)$ as the "asymptotic mean drift" at the point x.

5. On verifying Assumption 2.1(i) for bounded noise. In this section we consider the problem of verifying the only part of Assumption 2.1 not covered by Theorem 4.1. While the proof of Theorem 4.1 made no use of the properties of the noise term $\{F_n\}$ (aside from boundedness), its conclusions may well be vacuous if we do not prove something similar to Assumption 2.1(i) as well. Suppose, for example, that we have $\bar{H}(x, \alpha, t) = K|\alpha|$ for all (x, t). In this case we obtain

$$\bar{L}(x, \beta, t) = \begin{cases} 0, & |\beta| \leqq K, \\ \infty, & |\beta| > K, \end{cases} \tag{5.1}$$

which implies $\bar{S}(\phi(0), T, \phi) < \infty$ if and only if ϕ is Lipschitz with constant K, in which case it is also true that $\bar{S}(\phi(0), T, \phi) = 0$. But, then Assumption 2.1(iv) is nothing more than the trivial statement that $X^N(\cdot)$ is Lipschitz with constant K w.p.1. For Assumption 2.1(iv) to be truly meaningful, we must at least have $\bar{L}(x, \beta, t) > 0$ for some points (x, β, t) with $|\beta| < K$. The proof of such a fact will clearly depend on the model chosen for $\{F_n\}$. In this section we consider a number of interesting models, and in fact prove that Assumption 2.1(i) holds. As a preliminary to the results on specific models, we present two general theorems that are useful in many cases. The first theorem spells out the relationships between the existence of a derivative (in α) of $\bar{H}(x, \alpha, t)$ at $\alpha = 0$, the existence of a unique β such that $\bar{L}(x, \beta, t) = 0$, and the "mean asymptotic" dynamics of $X^N(\cdot)$, given $X_N = x$.

THEOREM 5.1. *Define $\bar{H}(x, \alpha, t)$ and $\bar{L}(x, \beta, t)$ by* (4.1) *and* (4.2), *and assume that $\bar{H}(x, \alpha, t)$ is differentiable in α at $\alpha = 0$ for all (x, t). Then $\bar{H}_\alpha(x, 0, t)$ is independent of t, and $\bar{L}(x, \beta, t) = 0$ if and only if $\beta = \bar{H}_\alpha(x, 0, t)$. Furthermore,*

$$\bar{H}_\alpha(x, 0, t) = \lim_{\Delta \to 0} \lim_{N \to \infty} \lim_{\substack{y \to x \\ s \to t}} E[D^\Delta X^N(s) \mid \mathcal{F}_N, X^N(s) = y]/\Delta \quad \text{(a.s.)}. \tag{5.2}$$

Remarks. Recall that $D^\Delta x(s) = x(s + \Delta) - x(s)$. We use $\bar{b}(x)$ to denote $\bar{H}_\alpha(x, 0, t)$, when it exists. The theorem provides a simple means of verifying Assumption 2.1(i). This is clearly consistent with our previous reference to $\bar{b}(x)$ as the "mean dynamics."

Proof. We make use of the following facts regarding convex functions. The proof of (i) is straightforward, while (ii) is Theorem 24.5 of [32].

(i) Let $\{f_i(\cdot)\}$ be convex on R^r and satisfy $f_i(0) = 0$. Let $\partial f(\alpha)$ denote the set of subdifferentials of a given convex function $f(\cdot)$ at α. Then for $f(\cdot)$ defined by $f(\alpha) = \sup_i f_i(\alpha)$, $\partial f(0)$ is the closed convex hull of $\cup_i \partial f_i(0)$.

(ii) Let $\{f_i(\cdot)\}$ be a sequence of convex functions and suppose that $f_i(\alpha) \to f(\alpha)$ in a neighborhood of $\alpha = 0$. Let $N_\varepsilon(y)$ denote the open ball of radius ε around y. Then given $\varepsilon > 0$ there is i_ε such that for $i \geqq i_\varepsilon$, $\partial f_i(0) \subset N_\varepsilon(\partial f(0))$.

We assume existence of the derivative of $\bar{H}(x, \alpha, t)$ in α at $\alpha = 0$.

Fix $\varepsilon > 0$. By using the two facts above and the definition of $\overline{\lim}$, we can obtain $\Delta_0 > 0$, $N_0 < \infty$, and $\delta > 0$ such that for all $0 < \Delta < \Delta_0$, $N \geqq N_0$, $y \in N_\delta(x)$, and $s \in N_\delta(t)$,

$$\frac{\partial}{\partial \alpha}(a_N \log E[\exp \langle \alpha, D^\Delta X^N(s) \rangle / a_N \mid \mathcal{F}_N, X^N(s) = y]/\Delta)|_{\alpha = 0} \subset N_\varepsilon(H_\alpha(x, 0, t)) \quad \text{(a.s.)}.$$

Using properties of conditional expectation to compute the derivative we obtain (for all such Δ, etc.)

$$E[D^\Delta X^N(s) \mid \mathcal{F}_N, X^N(s) = y]/\Delta \in N_\varepsilon(\bar{H}_\alpha(x, 0, t)) \quad \text{(a.s.)}.$$

By letting $\Delta \to 0$, $N \to \infty$, and $\delta \to 0$ through a subsequence we obtain (5.2). Owing to the way we define $X^N(\cdot)$ as a shifted version of $X(\cdot)$, the right-hand side of (5.2) must be independent of t (almost surely). Hence so is $\bar{H}_\alpha(x, 0, t)$. Finally, we note

that since $\bar{b}(x)$ is the unique subdifferential of $\bar{H}(x, \cdot, t)$ at $\alpha = 0$, $\bar{H}(x, \alpha, t) - \langle \alpha, \beta \rangle \geqq 0$ for all α if and only if $\beta = \bar{b}(x)$. Consequently, $\bar{L}(x, \beta, t) = 0$ if and only if $\beta = \bar{b}(x)$. □

We consider the following assumption on the sequence $\{a_n\}$.

ASSUMPTION 5.1.

$$\lim_{\substack{|t_n - t_m| \to 0 \\ n,m \to \infty}} \frac{a_n}{a_m} = 1.$$

Define $K_N(t) = a_{m(t_N+t)}/a_N$, and $K(t) = \overline{\lim}_{N\to\infty} K_N(t)$. For given $\delta > 0$ there are $c(\delta) > 0$ and $N(\delta) < \infty$ such that $N \geqq N(\delta)$ and $|t - s| \leqq c(\delta)$ imply $|K_N(t) - K_N(s)| \leqq \delta$. Thus $K(\cdot)$ is continuous, with $0 < K(t) < \infty$ for $0 \leqq t < \infty$.

Examples. Let $a_n = 1/n$. Then $m(t_n + s)/n(\exp s) \to 1$ as $n \to \infty$, and $K_N(s) \to \exp -s$. Let $a_n = 1/n^\gamma$, $\gamma \in (0, 1)$. Then $m(t_n + s)/(n + sn^\gamma) \to 1$ as $n \to \infty$ and $K_N(s) \to 1$. If $a_n = c/\log n$, then $m(t_n + s)/(n + s) \to 1$ and $K_N(s) \to 1$. In general, if a_n is nonincreasing, then $K(t) \leqq 1$.

Even if not explicitly stated, Assumptions 4.1 and 5.1 are assumed for the rest of § 5.

The next theorem shows how to simplify the calculation of $\bar{H}(x, \alpha, t)$ under Assumption 5.1 by justifying the replacement of $\{a_i\}$ by an appropriate constant sequence (for the purposes of calculating $\bar{H}$).

THEOREM 5.2. *Suppose that Assumptions* 4.1 *and* 5.1 *hold. Then*

$$\bar{H}(x, \alpha, t) \leqq K^{-1}(t) \overline{\lim_{\Delta\to 0}} \overline{\lim_{N\to\infty}} \overline{\lim_{\substack{y\to x \\ s\to t}}} \operatorname*{ess\,sup}_{\omega}$$

$$\cdot \log E\left[\exp\left\langle \alpha K(t), \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} F_i \right\rangle \middle| \mathcal{F}_N, X_{m(t_N+s)} = y\right] \Big/ \tag{5.3}$$

$$(m(t_N + s + \Delta) - m(t_N + s)).$$

Proof. Let $\delta > 0$ be given. If Δ is small and N is large, then Assumptions 4.1 and 5.1 imply

$$E\left[\exp\left\langle \alpha, \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} a_i F_i \right\rangle \Big/ a_N \middle| \mathcal{F}_N, X_{m(t_N+s)} = y\right]$$

$$\leqq E\left[\exp\left\langle \alpha a_{m(t_N+s)}, \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} F_i \right\rangle \Big/ a_N \middle| \mathcal{F}_N, X_{m(t_N+s)} = y\right]$$

$$\cdot \exp \delta(m(t_N + s + \Delta) - m(t_N + s)).$$

Hence

$$\bar{H}(x, \alpha, t) \leqq \overline{\lim_{\Delta\to 0}} \overline{\lim_{N\to\infty}} \overline{\lim_{\substack{y\to x \\ s\to t}}} \operatorname*{ess\,sup}_{\omega} a_N \log E$$

$$\cdot \left[\exp\left\langle \alpha a_{m(t_N+s)}, \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} F_i \right\rangle \Big/ a_N \middle| \mathcal{F}_N, X_{m(t_N+s)} = y\right] \Big/ \Delta.$$

By differentiating

$$\log E\left[\exp\left\langle \alpha a_{m(t_N+s)}, \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} F_i \right\rangle \Big/ a_N \middle| \mathcal{F}_N, X_{m(t_N+s)} = y\right] \Big/ \Delta \tag{5.4}$$

with respect to $a_{m(t_N+s)}$, we see that it is convex and zero if $a_{m(t_N+s)}=0$. Given a convex function $H(\alpha)$ such that $H(0)=0$, the inequality $H(s\alpha')\leqq sH(\alpha')$ is valid for all $0\leqq s\leqq 1$, and all α'. The definition of $K(\cdot)$ implies the existence of $c_N(\Delta)$ such that $c_N(\Delta)\to 0$ if $N\to\infty$ and then $\Delta\to 0$, and such that $a_{m(t_N+s)}/a_N\leqq K(s)+c_N(\Delta)$. Combining these facts we obtain the upper bound

$$\frac{a_{m(t_N+s)}}{a_N(K(s)+c_N(\Delta))} \cdot \log E\left[\exp\left\langle \alpha, \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} [K(s)+c_N(\Delta)]F_i\right\rangle \middle| \mathcal{F}_N, X_{m(t_N+s)}=y\right]\Big/\Delta \tag{5.4a}$$

for (5.4). Since

$$a_{m(t_N+s)}(m(t_N+s+\Delta)-m(t_N+s))/\Delta\to 1$$

and

$$K(s)+c_N(\Delta)\to K(t)$$

as $s\to t$, $N\to\infty$, and $\Delta\to 0$, we are done. □

Remarks. We have used the fact that Assumption 5.1 implies $K_N^{-1}(t)$ is bounded from above uniformly in N for N large. Suppose all that is known about $\{a_i\}$ is that for large i the sequence is nonincreasing. If we define

$$\bar{a}_i = a_i \vee (c_i/\log i), \qquad \bar{F}_i = a_iF_i/\bar{a}_i$$

where c_i tends monotonically to zero in a "regular" way (e.g., $c_i=1/\log i$), then $\{\bar{a}_i\}$ satisfies Assumption 5.1, with $K(t)\leqq 1$. If Assumption 2.3 holds for $\{a_i\}$, then it holds for $\{\bar{a}_i\}$ as well. Hence we can apply Theorems 3.1 and 3.2 to analyze the process $X_{i+1}=X_i+\bar{a}_i\bar{F}_i$. Note that the only difference is that we are now using interpolation intervals that might be larger than the original $\{a_i\}$. Application of Theorem 5.2 yields (5.3) with F_i replaced by $\bar{F}_i=a_iF_i/\bar{a}_i$. If we can choose $\{\bar{a}_i\}$ so that $\{a_i/\bar{a}_i\}$ is nonincreasing, we can exploit convexity to obtain (5.3) as written (note, however, that $\bar{H}(x,\alpha,t)$ is now a large deviation functional for the process defined in terms of $\{\bar{a}_i\}$ and $\{\bar{F}_i\}$, and *not* $\{a_i\}$ and $\{F_i\}$).

We now consider a number of concrete examples to show that Theorems 5.1 and 5.2 can be quite convenient to use.

5.1. Random vector fields.

5.1.a. The i.i.d. case. We consider a family of probability measures parametrized by $x\in\mathbb{R}^r$, denoted by μ_x. We assume the μ_x are weakly continuous in x. The boundedness assumption implies that for every x the support of μ_x is contained in $N_K(x)$. We then consider a sequence of i.i.d. random vector fields $\{b_n(x)\}$ such that $P\{b_n(x)\in A\}=\mu_x(A)$, and set $F_n=b_n(X_n)$. Define $H(x,\alpha)=\log E\exp\langle\alpha, b_n(x)\rangle$ and $\mathcal{F}_n=\sigma(X_i, i\leqq n)$. Note that the weak continuity of μ_x implies that $H(\cdot,\cdot)$ is continuous. For the constant $a_n\equiv a$ case, and under stronger conditions on the μ_x, [27] contains a development of both the upper and lower large deviations bounds. It follows from our method that the same upper bound can be obtained more easily and under weaker conditions. (See also Example 7.1.)

THEOREM 5.3. *Under Assumptions* 4.1 *and* 5.1, $\bar{H}(x,\alpha,t)$ (*defined through* (4.1)) *is bounded above by* $K^{-1}(t)H(x,K(t)\alpha)$, *and Assumption* 2.1(i) *holds with* $\bar{b}(x)=Eb_n(x)=\int\beta\mu_x(d\beta)$.

Proof. By Theorem 5.2

$$\bar{H}(x, \alpha, t) \leqq K^{-1}(t) \overline{\lim_{\Delta \to 0}} \overline{\lim_{N \to \infty}} \overline{\lim_{\substack{y \to x \\ s \to t}}} \cdot \log E\left[\exp\left\langle \alpha K(t), \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} b_n(X_n)\right\rangle \middle| X_{m(t_N+s)} = y\right] \Big/ (m(t_N+s+\Delta) - m(t_N+s)).$$

Using the fact that $|X_n - y| \leqq K\Delta$ (almost surely) if $m(t_N+s) \leqq n \leqq m(t_N+s+\Delta)$ and $X_{m(t_N+s)} = y$, and the continuity of $H(x, \alpha)$, we can use the properties of conditional expectation to compute

$$\bar{H}(x, \alpha, t) \leqq K^{-1}(t) \overline{\lim_{\Delta \to 0}} \overline{\lim_{N \to \infty}} \sum_{m(t_N+t)}^{m(t_N+t+\Delta)} \cdot [H(x, K(t)\alpha) + O_n(\Delta)]/(m(t_N+t+\Delta) - m(t_N+t)) \tag{5.5}$$

where $O_n(\Delta) \to 0$ as $\Delta \to 0$, uniformly in n. The conclusion of the theorem obviously follows from this. □

5.1.b. The non-i.i.d. case. We consider the generalization of Section 5.1.a to the case where the $\{b_i(\cdot)\}$ are independent, but not identically distributed. We assume that the limit of

$$E \sum_{N+1}^{N+n} \frac{b_i(x)}{n}$$

exists as N and n tend to infinity (for each x). Denote the limit by $\bar{b}(x)$. We also assume that the measures induced by the $b_i(x)$ are weakly continuous in x, uniformly in i. This implies that $\bar{b}(x)$ is continuous.

Define

$$H(x, \alpha) = \overline{\lim_{N,n}} \sum_{N+1}^{N+n} \log E \exp\langle \alpha, b_i(x)\rangle / n.$$

Then the assumptions above imply that $H(\cdot, \cdot)$ is continuous and that $H_\alpha(x, 0)$ exists, which by Theorem 5.1 must equal $\bar{b}(x)$. The proof of Theorem 5.3 yields the following.

THEOREM 5.4. *Under Assumptions* 4.1 *and* 5.1, $\bar{H}(x, \alpha, t)$ *is bounded above by* $K^{-1}(t)H(x, K(t)\alpha)$, *and Assumption* 2.1(i) *holds with* $\bar{b}(x)$ *as above.*

5.2. Exogenous noise. In this section we take as our model $F_n = b(X_n, \xi_n)$, where the process $\{\xi_n\}$ is *exogenous* and takes values in a set M, i.e., for any n and Borel set $A \subset M$,

$$P\{\xi_n \in A \mid (X_i, \xi_{i-1}), i \leqq n\} = P\{\xi_n \in A \mid \xi_{i-1}, i \leqq n\} \quad \text{(a.s.)}.$$

In this section, we always assume that $b(\cdot, \xi)$ is continuous, uniformly in $\xi \in M$.

5.2.a. Markov noise. Suppose that $\{\xi_n\}$ is a Markov chain, with state space M, and with one-step transition function $P(\xi, \cdot)$. Under a uniform (in the initial condition) recurrence condition on the process $\{\xi_n\}$, the following facts are proved in [24]. Let $C(M)$ denote the continuous real-valued functions on M and define an operator mapping $C(M) \to C(M)$ by

$$\hat{P}(x, \alpha)(f)(\xi) = \int_M \exp\langle \alpha, b(x, \psi)\rangle f(\psi) P(\xi, d\psi). \tag{5.6}$$

The eigenvalue $\lambda(x, \alpha)$ of $\hat{P}(x, \alpha)$ with the maximum modulus is real, simple, and larger than unity for $\alpha \neq 0$. If we define $H(x, \alpha) = \log \lambda(x, \alpha)$, then $H(x, \alpha)$ is analytic in α, and

$$H(x, \alpha) = \lim_n \frac{1}{n} \log E_\xi \exp \left\langle \alpha, \sum_1^n b(x, \xi_i) \right\rangle, \tag{5.7}$$

uniformly in $\xi = \xi_0$. In this case, $\bar{b}(x) = \int b(x, \xi)\mu(d\xi)$, where $\mu(\cdot)$ is the unique invariant measure of $\{\xi_n\}$.

The conclusion of Theorem 5.4 holds in this case as well, with a similar proof that we now outline. Using the continuity properties of $b(\cdot, \xi)$ and the bound on $|X_n - y|$ for $m(t_N + s) \leqq n \leqq m(t_N + s + \Delta)$, and the fact that the convergence in (5.7) is uniform in ξ_0, we obtain (5.5). The conclusion follows from this.

5.2.b. Stationary *m*-dependent noise. We consider exogenous noise where $\{\xi_i\}$ is stationary and m-dependent, i.e., for any n, $\{\xi_i, i \leqq n\}$ and $\{\xi_i, i > n + m\}$ are mutually independent. We set (for $\mathcal{F}_n = \sigma(\xi_i, i \leqq n)$)

$$H(x, \alpha) = \overline{\lim_n} \operatorname*{ess\,sup}_\omega \frac{1}{n} \log E_{\mathcal{F}_0} \exp \left\langle \alpha, \sum_1^n b(x, \xi_i) \right\rangle.$$

We first prove that $H(x, \alpha)$ is "smooth" in α at $\alpha = 0$. Define $D_q(x, \alpha) = E \exp \sum_0^{q-1} \langle \alpha, b(x, \xi_i) \rangle$ and $H_q(x, \alpha) = (\log D_q(x, \alpha))/(q + m)$. By the m-dependent property and the stationarity,

$$\begin{aligned} &\frac{1}{kq + km} \log E_{\mathcal{F}_{-m}} \exp \sum_1^{kq+km} \langle \alpha, b(x, \xi_i) \rangle \\ &\quad \leqq \frac{1}{kq + km} \log \left([\exp |\alpha| Kkm] \sum_{l=1}^{k} E_{\mathcal{F}_{lq-m}} \exp \sum_{lq}^{lq+q-1} \langle \alpha, b(x, \xi_i) \rangle \right) \\ &\quad \equiv \delta_q |\alpha| + H_q(x, \alpha) \end{aligned}$$

where $\delta_q = Km/(q + m) \to 0$ as $q \to \infty$. Thus, $H(x, \alpha) \leqq H_q(x, \alpha) + \delta_q |\alpha|$. At $\alpha = 0$, the gradient of $H_q(x, \alpha)$ equals $E \sum_1^q b_i(x, \xi_i)/(q + m)$, which converges to a limit $\bar{b}(x)$ as $q \to \infty$. Since the convex (in α) function $H(x, \alpha)$ is bounded above by the convex functions $H_q(x, \alpha) + \delta_q |\alpha|$, and since $H(x, 0) = H_q(x, 0) = 0$, the set of subdifferentials of $H(x, \cdot)$ at $\alpha = 0$ is contained in the set of subdifferentials of $H_q(x, \cdot) + \delta_q |\cdot|$ for every q. This latter set converges to the point $\bar{b}(x)$ as $q \to \infty$. Hence $H(x, \cdot)$ has $\bar{b}(x)$ as its unique subdifferential at $\alpha = 0$, which implies that $H_\alpha(x, 0)$ exists and equals $\bar{b}(x)$.

Using these facts and the same argument as that in § 5.2.a, we again obtain the conclusion of Theorem 5.4.

5.3. State-dependent noise. To model state-dependency effects, we consider a model of the form $F_n = b_n(X_n, \xi_n)$, such that the pair (X_n, ξ_{n-1}) is Markovian. We assume the following:

(1) $\{b_i(\cdot, \cdot)\}$ is a sequence of i.i.d. random vector fields;

(2) There is a transition kernel $P^x(\xi, \cdot)$ such that

$$P\{\xi_n \in \cdot \mid \xi_{n-1} = \xi, X_n = x, \xi_{i-1}, X_i, i < n\} = P^x(\xi, \cdot).$$

This approach to modeling state-dependent effects includes some of the models of [28], [29], and [31] that restrict $\{b_i\}$ to the case of a deterministic vector field. An extensive study of lower and upper large deviations bounds for a more restricted version of such models is in [20].

In addition to the "true" noise process, we will make use of a fixed-x Markov process $\{\xi_i^x\}$ that is simply the process generated by the kernel $P^x(\cdot,\cdot)$.

Let $P^{x,n}(\xi, d\psi)$ denote the n-step transition kernel of $\{\xi_i^x\}$. Then we have the following basic assumptions on the model.

(i) There exist $n_0 < \infty$ and $\delta > 0$ (which may depend on x) such that for all Borel $A \subset M$,

$$\inf_{\xi \in M} P^{x,n_0}(\xi, A) \geqq \delta \sup_{\xi \in M} P^{x,n_0}(\xi, A).$$

(ii) $E \int_M \exp\langle \alpha, b_n(x, \psi)\rangle P^x(\xi, d\psi)$ is continuous in x, uniformly in ξ.

Remarks. Assumption (i) implies that there is a uniform (in ξ) rate at which the measures induced by ξ_i^x converge to the invariant measure, given $\xi_0^x = \xi$. There are obviously many sets of sufficient conditions that yield (ii). It is also possible (though notationally cumbersome) to consider a weaker form of (ii) that requires the existence of $n < \infty$ such that

$$E \int\int \cdots \int \exp\langle \alpha, b_n(x, \psi)\rangle P^{x_0}(\xi, d\xi_1) P^{x_1}(\xi_1, d\xi_2) \cdots P^{x_n}(\xi_n, d\psi)$$

is continuous in $(x_0, \cdots, x_n)$, uniformly in $\xi \in M$.

The basic method for proving that an analogue of Theorem 5.4 holds for this model is to first show that something like (5.7) holds for the fixed-x process, and to then use the continuity properties assumed in (ii) above. The analogue of (5.6) for this case will be

$$\hat{P}(x, \alpha)(f)(\xi) = E \int_M \exp\langle \alpha, b_i(x, \psi)\rangle f(\psi) P^x(\xi, d\psi).$$

Under the above assumptions, the results in [24] apply here as well, and we find that the limit

$$H(x, \alpha) = \lim_n \frac{1}{n} \log E_\xi \exp\langle \alpha, b_i(x, \xi_i^x)\rangle \tag{5.8}$$

exists uniformly in $\xi = \xi_0^x$, where $H(x, \alpha)$ is continuous in x and analytic in α. The assumptions also imply that for each x, the process $\{\xi_i^x\}$ has a unique invariant measure $\mu^x(\cdot)$, and that

$$\bar{b}(x) = H_\alpha(x, 0) = E \int b_i(x, \xi) \mu^x(d\xi).$$

Proof of Theorem 5.4 (*for the present case*). By (i) and (ii) above, (5.8) holds [24], where once again (see § 5.2) $H(x, \alpha)$ is defined as the log of an eigenvalue of the operator $\hat{P}(x, \alpha)$. To simplify the notation, we set $n_0 = 1$. The general proof is very similar. Let F be a fixed compact set. Using Theorem 5.2 (as was done in Theorem 5.3), it is sufficient to restrict our attention to estimates on terms of the form (5.9) below, where $|X_i - y| \leqq \delta$ for all $1 \leqq i \leqq n$. The transition kernel used to get the ξ_n in $b_n(X_n, \xi_n)$ will be $P^{X_n}(\xi_{n-1}, \cdot)$. Then for $\xi = \xi_0$,

$$\begin{aligned} & E_\xi \exp\left\langle \alpha, \sum_1^n b_i(X_i, \xi_i)\right\rangle \\ & = E_\xi\left[\exp\left\langle \alpha, \sum_{i=1}^{n-1} b_i(X_i, \xi_i)\right\rangle E_\xi[\exp\langle \alpha, b_n(X_n, \xi_n)\rangle \mid \xi_{n-1}, X_n]\right] \\ & = E_\xi\left[\left[\exp\left\langle \alpha, \sum_{i=1}^{n-1} b_i(X_i, \xi_i)\right\rangle\right]\right. \\ & \quad \left. \cdot E_\xi\left[\int_M \exp\langle \alpha, b_n(X_n, \psi)\rangle P^{X_n}(\xi_{n-1}, d\psi) \mid \xi_{n-1}, X_n\right]\right]. \end{aligned} \tag{5.9}$$

Under (ii) above, there is $\gamma(\delta) > 0$ such that $\gamma(\delta) \to 0$ as $\delta \to 0$, and such that the last bracketed terms are bounded above by

$$E_\xi \int_M \exp \langle \alpha, b_n(y, \psi) \rangle P^y(\xi_{n-1}, d\psi) \exp \gamma(\delta). \tag{5.10}$$

Using (5.10) in (5.9) and continuing to iterate backward to approximate all the X_i by y plus an "error," we obtain the upper bound to (5.9) of

$$E_\xi \exp \left[\left\langle \alpha, \sum_1^n b_i(y, \xi_i^y) \right\rangle + n\gamma(\delta) \right].$$

The proof is now essentially the same as that of Theorem 5.3 save that we use (5.8). The σ-algebra here should be $\mathcal{F}_n = \sigma(X_i, \xi_{i-1}, i \leqq n)$.

5.4. A level-2 and level-3 large deviation approach. We have seen that when the state process $\{X_n\}$ is Markov, or when it is one component of a Markov process (such as our "state-dependent noise" process $\{X_n, \xi_{n-1}\}$) satisfying certain "uniformly recurrent" conditions, it is possible to prove the differentiability of $\bar{H}(x, \alpha, t)$ for a wide class of such processes by using analytical techniques and the characterization of the time-independent (constant gain) version $H(x, \alpha)$ as the log of the eigenvalue of largest modulus of an operator associated to the process (as in (5.6)). We again refer the reader to [24] for details on how this approach may be used in a general setting. However, for many of the processes arising in the study of stochastic systems, the assumptions required by this approach do not hold. As a very common example, we may consider the ARMA model to be discussed below.

In this section, we outline a method for proving the differentiability of $H(x, \alpha)$ at $\alpha = 0$ (which, as we have seen, will imply that of $\bar{H}(x, \alpha, t)$) that is based on well-known "level 2" and "level 3" large deviations results and that is general enough to cover many of the non-Markov processes encountered in recursive algorithms.

In applications, we would not want to be concerned with the abstract level of results in this section. But, they make it clear that the α-differentiability assumption is not restrictive and can be treated in many different ways. We work only with the exogenous noise case and $F_n = b(X_n, \xi_n)$ and with $b(\cdot, \cdot)$ bounded for simplicity of exposition. Define the sample occupation measure (over the Borel sets Γ) by

$$L_N(\Gamma, \omega) = \frac{1}{N} \sum_1^N I_{\{b(x, \xi_i) \in \Gamma\}},$$

and the space $\mathcal{M}$ as the set of probability measures on R^r, endowed with the topology of weak convergence. The $L_N(\cdot, \omega)$ are in $\mathcal{M}$. Assume the following large deviations estimate (x is fixed throughout):

ASSUMPTION 5.2. There is a lower-semicontinuous nonnegative functional I_x on $\mathcal{M}$ such that the sets $\{\gamma \in \mathcal{M}: I_x(\gamma) \leqq s\}$ are compact for $s < \infty$, and for Borel $A \subset \mathcal{M}$ and each ω (w.p.1)

$$\overline{\lim_N} \frac{1}{N} \log P_{\mathcal{F}_0}\{L_N \in A\} \leqq -\inf_{v \in \bar{A}} I_x(v). \tag{5.11}$$

Sufficient conditions for this assumption and Assumption 5.3 below are contained in many places (e.g., [22], [23]).

ASSUMPTION 5.3. There is a unique measure $\bar{v}_x \in \mathcal{M}$ such that $I_x(\bar{v}_x) = 0$.

It follows that $L_N(\cdot, \omega)$ converges (w.p.1) to $\bar{v}_x(\cdot)$.

Remark. Instead of Assumption 5.2 we can consider a weaker version (that we call Assumption 5.2^e). Under this assumption we require that there exist $\Omega_N \subset \Omega$ such that $\overline{\lim}_N a_N \log P(\Omega \backslash \Omega_N) = -\infty$ and such that (5.11) holds uniformly for $\omega \in \Omega_N$. Under Assumptions 5.2^e and 5.3, the arguments below and Theorem 4.1 yield Assumption 2.1^e (see the remark following the proof of Theorem 4.1).

We now show that Assumptions 5.2 and 5.3 imply the desired α-differentiability. Then an example will be given, and the approach discussed.

By Varadhan's Theorem on the asymptotic evaluation of integrals [21] and the boundedness and continuity of $b(x, \cdot)$, the following inequality holds (w.p.1):

$$\begin{aligned} \overline{\lim_N} \frac{1}{N} \log E_{\mathcal{F}_0} \exp \left\langle \alpha, \sum_1^N b(x, \xi_i) \right\rangle &\leqq \sup_v \left[\int \langle \alpha, y \rangle v(dy) - I_x(v) \right] \\ &\equiv H^*(x, \alpha). \end{aligned} \tag{5.12}$$

Define $H(x, \alpha)$ as the left-hand side of (5.12). Obviously, $H(x, \alpha) \leqq H^*(x, \alpha)$. Since both functions are convex and $H(x, 0) = H^*(x, 0) = 0$, $H(x, \alpha)$ is α-differentiable at $\alpha = 0$ if $H^*(x, \alpha)$ is.

Next note that

$$\begin{aligned} H^*(x, \alpha) &= \sup_\beta \sup_{\{v \in M : \int y v(dy) = \beta\}} \left[\int \langle \alpha, y \rangle v(dy) - I_x(v) \right] \\ &= \sup_\beta \left[\langle \alpha, \beta \rangle - L^*(x, \beta) \right] \end{aligned} \tag{5.13}$$

where

$$L^*(x, \beta) = \inf_{\{v \in \mathcal{M} : \int y v(dy) = \beta\}} I_x(v).$$

Since $H^*(x, 0) = 0$, β^* is a subdifferential of $H^*(x, \alpha)$ at $\alpha = 0$ if and only if

$$H^*(x, \alpha) - \langle \alpha, \beta^* \rangle \geqq 0 \quad \text{for all } \alpha. \tag{5.14}$$

But (5.14) holds if and only if $L^*(x, \beta^*) = 0$ since H^* is the Legendre transform of L^*. Since $H^*(x, \cdot)$ is convex, it is differentiable at $\alpha = 0$ if and only if the set of subdifferentials at $\alpha = 0$ contains only one element. By Assumption 5.3, $\beta^* = \int y \bar{v}_x(dy)$ is the unique value of β for which $L^*(x, \beta) = 0$. Thus $\beta^* = \int y \bar{v}_x(dy)$ is the unique subdifferential, and the α-differentiability is proved. Note that $\beta^* = \bar{b}(x)$, as defined in Theorem 5.1.

Discussion. We have phrased our requirement in terms of the differentiability of $H(x, \alpha)$ at $\alpha = 0$, but as shown above this is obviously *equivalent to the uniqueness of the β^* satisfying $L(x, \beta^*) = 0$*. The reason for our choice is that in most of the work on large deviations for dynamical systems [12], as well as the work generalizing Cramer's original paper [16], [24], [25], the differentiability of $H(x, \alpha)$ in α is taken as a fundamental assumption. As a consequence, this was the condition that was typically verified for a given noise process.

We illustrate the method with an example.

Example. Suppose that $b(x, \cdot)$ is continuous, and that $\{\xi_n\}$ is a stationary ARMA process with representation

$$A_0 \xi_n + A_1 \xi_{n-1} + \cdots + A_{d_1} \xi_{n-d_1} = B_0 \psi_n + B_1 \psi_{n-1} + \cdots + B_{d_2} \psi_{n-d_2}$$

where $\{\psi_i\}$ is a sequence of zero mean, bounded, i.i.d. random variables. For simplicity, we assume both ξ_i and ψ_i take values in R^r. It is also assumed that the roots of $\det(A_0 + A_1 s + \cdots + A_{d_1} s^{d_1})$ lie outside of the closed unit disc.

Define $S = (R^r)^z$ (the space of bounded infinite sequences $\{q_i, -\infty < i < \infty\}$ with values in R^r), and consider the mapping $F: S \to S$ defined by $(F(\ )_j$ denotes the jth component)

$$F(\{s_i\})_j = b(x, p_j)$$

where $\{s_i\}$ and $\{p_i\}$ are related by

$$A_0 p_n + \cdots + A_{d_1} p_{n-d_1} = B_0 s_n + \cdots + B_{d_2} s_{n-d_2}, \qquad -\infty < n < \infty.$$

This relation defines $\{p_n\}$ uniquely in terms of $\{s_n\}$. We can metrize S in such a way that F is continuous (and in fact uniformly continuous on a subset $A \subset S$ such that $\{\psi_i\} \subset A$ (w.p.1)). (For example, for $0 < \lambda < 1$, use the metric $d(\{s_j\}, \{s'_j\}) = \sum_{-\infty}^{\infty} \lambda^{|j|} \min\{1, |s_j - s'_j|\}$.) It is then relatively straightforward to show that Assumptions 5.2 and 5.3 follow from the (so-called "level 3") large deviations results for the process $\{\psi_i\}$ that are given in [23], under a suitable application of the "contraction principle" (a "continuous mapping" technique) [21, § 2]. We omit all details here, since they would take us too far afield, and the techniques are known in large deviations theory.

In general, if a given process $\{\xi_i\}$ can be represented as a continuous transformation of a simpler process $\{\psi_i\}$ for which the appropriate "level 3" results exist, then we may obtain Assumptions 5.2 and 5.3 via the "contraction principle."

Although this approach may seem abstract, it, in fact, easily yields the α-differentiability for a wide variety of the noise processes of interest in stochastic systems theory, which often *do* have such a representation.

6. The constrained algorithm. In this section we show that Assumption 2.1 holds for the "constrained" (or "projected") version of any of the models considered in § 5.

Let G be a bounded open set contained in $\mathbb{R}^r$. We define the set of exterior normals at $x \in \partial G$ by

$$n(x) = \{n' \in \mathbb{R}^r: |n'| = 1, \exists c > 0 \text{ such that } \langle x - y, n' \rangle + (1/2c)|x - y|^2 \geqq 0 \text{ for } y \in G\}.$$

It follows that $n' \in n(x)$ if and only if there is $c > 0$ such that $N_c(x + cn') \cap G = \varnothing$. We make the following assumptions on the set G.

ASSUMPTION 6.1. (1) The boundary of G is the union of a countable number of smooth (C^2) surfaces.

(2) G satisfies a "uniform exterior sphere condition": there is $c_0 > 0$ such that for all $x \in \partial G$ and all $n' \in n(x)$, $N_{c_0}(x + c_0 n') \cap G = \varnothing$.

(3) There are $\delta > 0$ and $\tau \in (0, 1]$ such that given any $x \in \partial G$ there is a unit vector $l(x)$ such that $\langle l(x), n'' \rangle \geqq \tau$ for all $n'' \in \{n' \in n(y): y \in N_\delta(x) \cap \partial G\}$.

Remarks. Part (2) is satisfied if G is convex, or if G has a piecewise smooth boundary with "convex corners." Part (3) is *Condition* (B) of [17], and is implied by a "*uniform interior cone condition*" (see [17]). In particular, (3) is satisfied if G is convex and bounded, with nonempty interior.

It is well known, under these conditions on G, that to each point x in the c_0-neighborhood of G we may associate a unique closest point $\pi_G(x)$ in $\bar{G}$. Furthermore, if $x \notin G$, then there is $\gamma \geqq 0$ and $n' \in n(\pi_G(x))$ such that $x - \pi_G(x) = \gamma n'$.

All the models of § 5 fall into either of two classes. For those processes in the first class we have $F_n = b_n(X_n, \xi_n)$, where $\{b_n(\cdot, \cdot)\}$ is a sequence of independent vector

fields, and the process $\{\xi_n\}$ is *exogenous.* Recall that by "exogenous," we mean that for all Borel A and integer n,

$$P\{\xi_n \in A \mid X_i, \xi_{i-1}, i \leqq n\} = P\{\xi_n \in A \mid \xi_{i-1}, i \leqq n\}.$$

In this case the "projected" version of (2.1) is defined by

$$X_{n+1} = \pi_G(X_n + a_n b_n(X_n, \xi_n)). \tag{6.1}$$

Alternatively, we have considered models such that the $\{b_n(\cdot, \cdot)\}$ is as above but where the pair (X_n, ξ_{n-1}) is Markov, with the distribution of ξ_n given $X_n = x$ and $\xi_{n-1} = \xi$ specified by the kernel $P^x(\xi, \cdot)$. We define the constrained version of this type of model by defining X_{n+1} via (6.1), and then generating ξ_{n+1} according to the kernal $P^{X_{n+1}}(\xi_n, \cdot)$.

With the "projected" version defined in this way, we use $X(\cdot)$ and $X^N(\cdot)$ to denote the usual piecewise linearly interpolated and shifted versions. For each N we also define an "unprojected" version:

$$\tilde{X}_n^N = \sum_N^{n-1} a_i b_i(X_i, \xi_i) + X_N, \qquad n \geqq N. \tag{6.2}$$

Note that $\{X_i, i \geqq N\}$ can be constructed from $\{\tilde{X}_i^N, i \geqq N\}$. We let $\tilde{X}^N(\cdot)$ denote the piecewise linear interpolated version of this process that starts at X_N at time $t = 0$, and uses interpolation intervals $\{a_i, i \geqq N\}$.

The method of proving that the appropriate analogue of Assumption 2.1 holds for $X^N(\cdot)$ involves first proving a large deviation upper bound for $\tilde{X}^N(\cdot)$, and then "transferring" it to $X^N(\cdot)$. Large deviations upper bounds are obtainable from §§ 4 and 5, since $|X_{i+1} - X_i| = O(a_i) = |\tilde{X}_{i+1}^N - \tilde{X}_i^N|$. To "transfer" such a bound to the constrained algorithm, an appropriate "continuous mapping" between $\tilde{X}^N(\cdot)$ and $X^N(\cdot)$ is needed. This requires some additional definitions, but they are only intermediaries in the proof.

We next define a collection of mappings $\{C_i^N\}$ on sequences $\{x_j\}$, $x_j \in \mathbb{R}^r$. For each N, and $i \geqq N$, we define the function $C_i^N(\cdot)$ and the vectors $\bar{x}_i$ recursively by $\bar{x}_N = x_N = C_N^N(\{x_j\})$, and for $i \geqq N$, $\bar{x}_{i+1} = C_{i+1}^N(\{x_j\}) = \pi_G(\bar{x}_i + (x_{i+1} - x_i))$. With this definition, the sequence $\{\tilde{X}_i\}$ defined by (6.2) can also be written as

$$\tilde{X}_{i+1}^N = \tilde{X}_i^N + a_i b_i(C_i^N(\{\tilde{X}_j^N, j = N, \cdots, i\}), \xi_i).$$

The maps C_i^N are obviously continuous in the following sense. Given any sequence $\{x_i, i \geqq N\}$ such that $|x_{i+1} - x_i| \leqq c_0/2$ for all $i \geqq N$, we have (for $i_2 \geqq i_1$)

$$|C_{i_1}^N(\{x_j\}) - C_{i_2}^N(\{x_j\})| \leqq B \sum_{i_1}^{i_2 - 1} |x_{j+1} - x_j| \tag{6.3}$$

where B is the Lipschitz constant of $\pi_G(\cdot)$ on the $c_0/2$-neighborhood of G.

The appropriate definition of $\bar{H}(x, \alpha, t)$ for this case is

$$\bar{H}(x, \alpha, t) = \overline{\lim_{\Delta \to 0}} \overline{\lim_{N \to \infty}} \overline{\lim_{\substack{y \to x \\ s \to t}}} \operatorname*{ess\,sup}_{\omega} a_N \cdot \log E[\exp \langle \alpha, D^\Delta \tilde{X}^N(s) \rangle / a_N \mid \mathcal{F}_N, X_{m(t_N + s)} = y]/\Delta.$$

Note that y in this expression is the value the "true" projected version takes at time $m(t_N + s)$.

Important Remark. For any of the models of § 5 the function $\bar{H}$ so defined is the same as that of the corresponding "unprojected" version.

This fact follows from the proofs for the "unprojected" versions, simply by making use of (6.3). In particular, since $\bar{H}_\alpha(x, 0, t)$ exists for the "unprojected" version of each of the models of § 5, it exists here as well. We define $\bar{L}(x, \beta, t)$ as usual.

Before stating the theorem we must define the appropriate $\bar{L}$ and $\bar{S}$ functionals for the constrained problem. For $x \in \bar{G}$, and $v \in \mathbb{R}^r$, we set

$$\pi_G(x, v) = \lim_{\Delta \downarrow 0} [\pi_G(x + \Delta v) - x]/\Delta. \tag{6.4}$$

Then [26, Lemma 4.6] $\pi_G(x, v)$ equals v if $x \in G^0$ (the interior of G) or if $x \in \partial G$ and $\sup_{\gamma \in n(x)} \langle \gamma, v \rangle < 0$ (i.e., where v points inward). In general, it equals $v - \langle v, \gamma^* \rangle \gamma^*$ if $x \in \partial G$, $\sup_{\gamma \in n(x)} \langle \gamma, v \rangle \geqq 0$ and γ^* is a maximizer.

We now define the "constrained" L-functional by

$$\bar{L}_G(x, \beta, t) = \inf_{v : \pi_G(x,v) = \beta} \bar{L}(x, v, t). \tag{6.5}$$

For $x \notin \bar{G}$ or if the infimizing set is empty, set $\bar{L}_G(x, \beta, t) = +\infty$. Then $\bar{L}_G(x, \beta, t) = \bar{L}(x, \beta, t)$ if $x \in G^0$ or if $x \in \partial G$ and $\langle \gamma, \beta \rangle < 0$ for all $\gamma \in n(x)$ (i.e., β points to the interior of G). If $x \in \partial G$ and there is $\gamma \in n(x)$ such that $\langle \gamma, \beta \rangle > 0$ (β points "out" of G), then $\bar{L}_G(x, \beta, t) = \infty$. The interesting case is when $\sup_{\gamma \in n(x)} \langle \gamma, \beta \rangle = 0$; i.e., β points "along the boundary." In this case, there is a true (nontrivial) minimization. Since $\bar{L}(x, \beta, t)$ is l.s.c. in β and $\bar{L}(x, \beta, t) \to \infty$ as $|\beta| \to \infty$, the infima is attained. Define

$$\bar{S}_G(x, T, \phi) = \int_0^T \bar{L}_G(\phi(s), \dot{\phi}(s), s)\, ds, \tag{6.6}$$

and the ODE for the projected mean dynamics

$$\dot{x} = \pi_G(x, \bar{b}(x)) \tag{6.7}$$

where $\bar{b}(\cdot)$ is defined by $\bar{H}_\alpha(x, 0, t)$.

One of the main difficulties as well as points of interest for the constrained algorithm is that in many applications the escape of $\{X_n\}$ from a neighborhood of a stable point of (6.7) will be essentially along the boundary, and when such neighborhoods are entered from the outside it is often essentially along the boundary as well.

THEOREM 6.1. *Consider the "projected" form* (6.1) *of any of the models of* § 5. *Then under Assumption* 6.1 *on the set G, Assumption* 2.1 *holds, but with* $\bar{b}(x)$ *replaced by* $\pi_G(x, \bar{b}(x))$, *and* $\bar{S}(x, T, \phi)$ *replaced by* $\bar{S}_G(x, T, \phi)$.

It follows that the essential large deviation assumption required by Theorems 3.1 and 3.2 is as easy to obtain for the "projected" algorithm as for the "unprojected" algorithm, under Assumption 6.1.

Proof. Let J be the set of Lipschitz continuous (constant K) paths starting in G. For $y(\cdot) \in J$, define $y_i^N = y(t_i - t_N)$ for $i \geqq N$, and $z_i^N = C_i^N(\{y_j^N, j \geqq N\})$. Let $z^N(\cdot)$ denote the usual piecewise linear interpolation of $\{z_i^N\}$, $i \geqq N$, with interpolation intervals $\{a_i, i \geqq N\}$. We make the following claim. Considered as functions on $[0, T]$, $z^N(\cdot) \to z(\cdot)$ uniformly, where

$$\dot{z} = \pi_G(z, \dot{y}), \qquad z(0) = y(0). \tag{6.8}$$

We denote this relationship by $z(\cdot) = C(y(\cdot))$. Furthermore, this convergence is uniform in $y(\cdot) \in J$, and $C(y(\cdot))$ is continuous in $y(\cdot) \in J$.

Before proving this claim, we give the proof of the theorem. When we assume the claim, the same proof as that of Theorem 4.1 (part (iv)) yields that $\tilde{X}^N(\cdot)$ satisfies a large deviation upper bound (in the sense of Assumption 2.1(iv)), with functional

$$\bar{S}^*(x, T, \phi) = \int_0^T \bar{L}(C(\phi)(s), \dot{\phi}(s), s)\, ds.$$

Using the claim again, we obtain

$$\sup_{t\in[0,T]} |X^N(t) - C(\tilde{X}^N(\cdot))(t)| \to 0$$

uniformly, w.p.1. Since $C(\cdot)$ is continuous (see the comment concerning this in the proof of the claim below), $X^N(\cdot)$ satisfies an upper bound (in the sense of Assumption 2.1(iv)) by the Proof of Theorem 3.3.1 [15], with functional

$$\bar{S}_G(x, t, \phi) = \inf_{\psi:\, \phi = C(\psi)} \bar{S}^*(x, T, \psi).$$

Due to our Assumption 6.1 on G, this $\bar{S}_G$ is exactly the same as defined by (6.5) and (6.6) [26, Lemma 4.7].

The remaining properties given by Assumption 2.1 follow easily from the definition of $\bar{S}_G$. Part (i) is obvious, as is (ii) due to the definition of $\bar{L}_G(x, \beta, s)$, while (iii) is immediate from the continuity of $C(\cdot)$ and the compactness of the level sets of $\bar{S}^*$.

Finally, we consider the proof of the claim. Let $\bar{y}^N(t) = y_i^N$ and $\bar{z}^N(t) = z_i^N$ for $t \in [t_i - t_N, t_{i+1} - t_N)$. Then the pair $(\bar{z}^N(\cdot), \bar{z}^N(\cdot) - \bar{y}^N(\cdot))$ comprise a solution of the *Skorokhod Problem* (for the path $\bar{y}^N(\cdot)$ and domain G) in the sense of [17, § 1]. It follows from Theorem 4.1 of [17] that $\bar{z}^N(\cdot) \to z(\cdot)$ (where $z(\cdot)$ is defined by (6.8)) uniformly on $[0, T]$, and that $z(\cdot)$ depends continuously on $y(\cdot)$. A review of the method of proof employed in [17] also shows that the convergence is uniform for all $y(\cdot)$ satisfying a common Lipschitz condition and starting in G. This completes the proof. □

7. Unbounded noise. An analogue of Theorem 4.1 holds for unbounded noise as well, under an assumption on the "tails" of the noise.

ASSUMPTION 7.1. There exist a σ-algebra $\mathcal{F}_n \supset \sigma(X_i, i \leqq n)$, $\gamma > 1$, and $B < \infty$ such that for all n and $s \geqq 0$,

$$P\{|F_n| \geqq s \,|\, \mathcal{F}_n\} \leqq B \exp -s^\gamma \quad \text{a.s.} \tag{7.1}$$

THEOREM 7.1. *Under Assumptions* 2.3, 5.1, *and* 7.1, *the conclusion of Theorem* 4.1 *holds.*

Proof. Assumption 2.1(ii) again follows from $\bar{H}(x, 0, t) = 0$. Under Assumption 7.1, there is a fixed convex function in $H(\alpha)$ that takes a finite value for each $\alpha \in \mathbb{R}^r$, and such that $\bar{H}(x, \alpha, t) \leqq H(\alpha)$ for all (x, t). By convex duality, $\bar{L}(x, \beta, t) \geqq L(\beta)$, where L is the Legendre transform of H. Since $H(\alpha)$ is finite for each α, $L(\cdot)$ grows faster than linearly: $L(sv)/s \to +\infty$ as $s \to +\infty$, for all $v \in \mathbb{R}^r$ with $|v| \neq 0$. The lower-semicontinuity of $\bar{L}$ and this fact are sufficient for Assumption 2.1(iii) [14].

Finally we consider part (iv). If it is demonstrated that, for each $M_1 < \infty$, $T < \infty$ and compact F, there is a compact set of paths J in $C[0, T]$ such that for all $x \in F$

$$P\{X^N(\cdot) \notin J \,|\, X_N = x, \mathcal{F}_N\} \leqq \exp -M_1/a_N \quad \text{(a.s.)} \tag{7.2}$$

when N is sufficiently large, then the same proof as that of Theorem 4.1 applies, since we can effectively ignore sample paths outside of J.

To prove (7.2), we let a compact set $F \subset \mathbb{R}^r$ be given and define $J(\delta)$, $\delta > 0$, as the compact set of paths $\{\phi(\cdot)\}$ that start in F at time zero and satisfy

$$\sup_{\substack{|s-t| \leqq \varepsilon \\ s,t \in [0,T]}} |\phi(s) - \phi(t)| \leqq \varepsilon^\delta. \tag{7.3}$$

It follows that for $x \in F$ and w.p.1,

$$
\begin{aligned}
&P\{X^N(\cdot) \notin J(\delta) \mid X_N = x, \mathcal{F}_N\} \\
&\quad \leqq P\{|F_i| \geqq a_i^{\delta-1}, \text{ some } i \in [N, m(t_N + T)] \mid X_N = x, \mathcal{F}_N\} \\
&\quad \leqq \sum_{N}^{m(T+t_N)} B \exp -a_i^{\gamma(\delta-1)} \\
&\quad \leqq B \exp -M_1/a_N \left[\sum_{N}^{m(T+t_N)} \exp\left(-a_i^{\gamma(\delta-1)} + M_1 a_N^{-1}\right) \right].
\end{aligned} \tag{7.4}
$$

We are finished if we prove that the bracketed term at the end of (7.4) is bounded for large N. Choose $\delta > 0$ such that $\gamma(\delta - 1) < -1$ (this is possible since $\gamma > 1$). By Assumption 5.1, $a_i^{\gamma(\delta-1)} \geqq 2M_1 a_N^{-1}$ for large N and for all $i \geqq N$. Hence the bracketed term is obviously bounded (for large N) by Assumption 2.3. □

Remarks. It is not actually necessary to use Assumption 2.3 to bound the bracketed term, since we sum over a finite number of indices. This is important in (for example) the constant gain analogues of the processes considered here (such as in [12]) where a_i is replaced by a fixed value $\varepsilon > 0$ and we consider the behavior of the linearly interpolated process (with interpolation interval ε) as $\varepsilon \to 0$. Here $m(T + t_N) - N = T/\varepsilon$, and we are then interested in bounding

$$(T/\varepsilon) \exp\left(-\varepsilon^{\gamma(\delta-1)} + M_1 \varepsilon^{-1}\right).$$

This quantity is obviously bounded as $\varepsilon \to 0$ if we choose δ so that $\gamma(\delta - 1) < -1$. If instead of requiring (7.1) to hold almost surely we only require that it hold for all $\omega \in \Omega_N$ and $N \leqq n \leqq m(t_N + T)$, where Ω_N is such that $\overline{\lim}\, a_N \log P(\Omega \backslash \Omega_N) = -\infty$, then we obtain the conclusion of Theorem 4.1 with Assumption 2.1^e replacing Assumption 2.1.

Theorem 5.1 does not require boundedness of $\{F_i\}$, and so holds here as well. The proof of Theorem 5.2 must be modified slightly.

THEOREM 7.2. *Suppose Assumptions* 5.1 *and* 7.1 *hold. Then the conclusion of Theorem* 5.2 *follows.*

Proof. For $\delta > 0$ define

$$F_i^\delta = \begin{cases} F_i, & |F_i| \leqq 1/\delta, \\ F_i/|F_i|\delta, & |F_i| > 1/\delta. \end{cases}$$

Fix $\alpha \in \mathbb{R}^r$. Using Assumption 7.1 and the bound (under Assumption 5.1) on a_i/a_N for $N \leqq i \leqq m(t_N + T)$, there is $c(\delta) \to 0$ as $\delta \to 0$ such that for all such i

$$E[\exp\langle \alpha, a_i F_i\rangle / a_N \mid \mathcal{F}_i] \leqq E[\exp\langle \alpha, a_i F_i^\delta\rangle / a_N \mid \mathcal{F}_i] \exp c(\delta) \tag{7.5}$$

and

$$E[\exp\langle \alpha K(t), F_i^\delta\rangle \mid \mathcal{F}_i] \leqq E[\exp\langle \alpha K(t), F_i\rangle \mid \mathcal{F}_i] \exp c(\delta) \tag{7.6}$$

almost surely.

Using properties of conditional expectation, we have

$$
\begin{aligned}
\bar{H}(x, \alpha, t) \leqq \overline{\lim_{\Delta \to 0}}\, \overline{\lim_{N \to \infty}}\, \overline{\lim_{\substack{y \to x \\ s \to t}}}\, \operatorname*{ess\,sup}_{\omega} a_N \\
\cdot \log E\left[\exp\left\langle \alpha, \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} a_i F_i^\delta \right\rangle \Big/ a_N \mid \mathcal{F}_N, X^N(s) = y \right] \Big/ \Delta + c'(\delta)
\end{aligned}
$$

where

$$c'(\delta) = \overline{\lim_{\Delta\to 0}}\ \overline{\lim_{N\to\infty}}\ \overline{\lim_{s\to t}}\ a_N(m(t_N+s+\Delta)-m(t_N+s))c(\delta)/\Delta$$

tends to zero as $\delta \to 0$. Applying Theorem 5.2, we obtain

$$\begin{aligned}\bar{H}(x,\alpha,t) \leqq K^{-1}(t)\ &\overline{\lim_{\Delta\to 0}}\ \overline{\lim_{N\to\infty}}\ \overline{\lim_{\substack{y\to x\\ s\to t}}}\ \operatorname*{ess\,sup}_{\omega} \log E \\ &\cdot\left[\exp\left\langle \alpha K(t), \sum_{m(t_N+s)}^{m(t_N+s+\Delta)} F_i^{\delta}\right\rangle \,\middle|\, \mathcal{F}_N, X_{m(t_N+s)} = y\right] \\ &\div (m(t_N+s+\Delta)-m(t_N+s)) + c'(\delta).\end{aligned} \tag{7.7}$$

Using (7.6), we obtain (7.7) with F_i^{δ} replaced by F_i, and $c'(\delta)$ replaced by $c'(\delta)+c''(\delta)$, $c''(\delta) = K^{-1}(t)c(\delta)$. Since $\delta > 0$ is arbitrary, we obtain (5.3). □

Example 7.1. We consider the extension of the model of § 5.1.a to the case where the support of μ_x is possibly unbounded. We assume that μ_x is weakly continuous in x, and that there are $\gamma > 0$ and $B < \infty$ such that

$$\int I_{\{y:|y|\geqq s\}}\,\mu_x(dy) \leqq B\exp -s^{\gamma} \tag{7.8}$$

for all x.

From Theorem 7.1 we obtain (under Assumption 5.1) parts (ii)-(iv) of Assumption 2.1. As usual, the only part left is identifying an upper bound for $\bar{H}(x,\alpha,t)$. It is simple to prove under (7.8) that there is $M(\delta,\Delta)$ such that for each fixed $\delta > 0$, $M(\delta,\Delta)\to\infty$ as $\Delta\to 0$, and such that (for any N and $s\in[0,T]$)

$$P\{|X^N(s+\tau)-X^N(s)| \geqq \delta \text{ for some } \tau\in[0,\Delta]\} \leqq \exp -M(\delta,\Delta)/a_N. \tag{7.9}$$

Define $H(x,\alpha) = \log E\exp\langle\alpha, b_i(x)\rangle$. Using (7.9) and Theorem 7.2 (as Theorem 5.2 was used in the proof of Theorem 5.3), we obtain (with $c(N,t,\Delta) = m(t_N+t+\Delta)-m(t_N+t)$)

$$\begin{aligned}\bar{H}(x,\alpha,t) \leqq K^{-1}(t)\ &\overline{\lim_{\Delta\to 0}}\ \overline{\lim_{N\to\infty}} \log\Big(\exp\left[(H(x,K(t)\alpha)+O(\delta))c(N,t,\Delta)\right] \\ &+\exp\left[-M(\delta,\Delta)a_N^{-1}+\sup_y H(y,K(t)\alpha)c(N,t,\Delta)\right]\Big)\Big/ c(N,t,\Delta)\end{aligned}$$

where $O(\delta)\to 0$ as $\delta\to 0$. By Assumption 5.1, $a_N^{-1} \geqq \Delta c(N,t,\Delta)\theta$, for some $\theta > 0$. Taking limits in the order $\Delta\to 0$, then $\delta\to 0$, we obtain

$$\bar{H}(x,\alpha,t) \leqq K^{-1}(t)H(x,K(t)\alpha).$$

Example 7.2. Assume $\{\xi_n\}$ is generated as in Example 2.1, and define $F_n = b(X_n,\xi_n)$. Assume also that $b(\cdot,\cdot)$ is continuous and that it satisfies a linear growth condition in ξ, uniformly in x. Then Assumption 2.1^e holds. The sets Ω_N needed in defining $\bar{H}$ and in (7.1) are easily characterized in terms of the values of $|\xi_N|$ (see the remarks after the proofs of Theorems 4.1 and 7.1).

The simplest method of proving the α-differentiability of $\bar{H}(x,\alpha,t)$ at $\alpha = 0$ is to combine the method used in Example 7.1 with that of § 5.4, where in place of Assumption 5.2 we use the weaker assumption (Assumption 5.2^e) that requires uniformity only for $\omega\in\Omega_N$.

8. Concluding remarks and comparison with other results. There is a great deal of overlap in the models covered by our approach and those in [3], [8], [28], and [29]. All the methods are quite powerful. The method in [8] is similar (and seemingly simpler) than that in [28] and [29]. It allows for nonstationary state-dependent noise

and nonstationary correlated non-Markov noise, but it is restricted to $\sum a_i^2 < \infty$ and uses faster decrease conditions on the "tails" of the noise distributions. The method in [3] is simple, but the results for state-dependent noise or discontinuous dynamics are not very strong. The works [28] and [29] allow for slower decrease in the "tails" of the noise distributions than we do here, and for a slower rate of decrease in the correlation of the (Markov) noise, but are more restrictive in the requirements on $\{a_n\}$. They essentially require $\Sigma a_n^{1+\gamma} < \infty$ for some $\gamma > 0$ and that the sequence $\{a_n\}$ is ultimately decreasing. The latter condition is rather restrictive. They do not treat the constrained case. In fact, the method used in [28] and [29], as set up now, essentially requires stationarity in the noise process—or time homogeneity in the transition function for the state-dependent noise case (due to the method of construction and use of the solution to the Poisson equation defined in [29, p. 220]). Our upper-bounding technique allows for considerable nonstationarity. For example, we may consider processes driven by the noise model $\xi_{n+1} = A\xi_n + B\psi_n$, where the roots of A are inside the unit circle, the (bounded or Gaussian) ψ_n are mutually independent, zero mean, and where the covariances Σ_n are simply bounded. The differences will probably narrow as more work is done on both approaches.

Although we have not put the details in this paper, all the noise models can allow a more flexible x-dependence. For example,

$$P\{\xi_{n+1} \in A \mid X_i, i \leqq n+1, \xi_i, i \leqq n\} = P_0(X_{n+1}, X_n, X_{n-1}, \cdots, X_{n-k}, \xi_n, A)$$

where P_0 is continuous in $(X_{n+1}, \cdots, X_{n-k})$, uniformly in ξ_n, A. Similarly for models

$$\xi_n = \sum_{-\infty}^{n} c_{n-i}(X_n, \cdots, X_{n-k})\psi_{n-i}$$

with appropriate rate of decrease and continuity properties of the $\{c_n(\cdot)\}$. A further extension, not currently covered under the scheme in [28] and [29] (although that method can probably be extended to cover this case) occurs when all the components of F_n are not available simultaneously (e.g., as in adaptive data networks where time delays in the transmission of messages must be taken into account). For example, let the updating of the scalar components of X_n alternate.

Another feature of our approach is that we do not require continuity of the "mean" dynamics. (Note that the mean dynamics for the constrained case might be discontinuous just because of the boundary.)

Finally, we obtain a very useful upper bound to the "tails" of the escape probabilities, and have provided a setup where more general noise models can be treated—simply by appealing to new developments in the theory of large deviations. The use of the "continuity" method to handle the constrained problem (in § 6) illustrates how estimates for one (relatively simple) process can be converted into estimates for a much more complex process—simply by finding the appropriate "continuity map."

CONVEX DUALITY APPROACH TO THE OPTIMAL CONTROL OF DIFFUSIONS*

WENDELL H. FLEMING† AND DOMOKOS VERMES‡

This paper is dedicated to the memory of E. J. McShane.

Abstract. An alternative to the usual dynamic programming approach to the optimal control of Markov processes is considered. It is based on duality of convex analysis. The control problem is embedded in a convex mathematical programming problem on a space of measures. The dual problem is to find the supremum of smooth subsolutions to the Hamilton-Jacobi-Bellman equation.

Key words. stochastic control, diffusion processes, convex duality, weak and strong solutions

AMS(MOS) subject classification. 93E20

1. Introduction. We consider $\mathbf{R}^n$-valued diffusion processes governed by the stochastic differential equation

$$dx_s = b(s, x_s, u_s)\,ds + \sigma(s, x_s, u_s)\,dw_s, \qquad x_t = x \tag{1.1}$$

with w_s an $\mathbf{R}^n$-valued Brownian motion and u_s a nonanticipative $Y \subset\subset \mathbf{R}^n$-valued control process. The objective is to minimize the expected (possibly discounted) cost

$$J^u(t, x) := \mathsf{E}^u_{t,x} \int_t^T e^{-c(s,x_s,u_s)} l(s, x_s, u_s)\,ds \tag{1.2}$$

over all control processes u. Here T is a finite or infinite planning horizon. Additional terminal costs could also be included.

An important feature of the present paper is that we do not make any ellipticity assumption; the matrix σ can be degenerate or even identically zero. This means the approach covers both deterministic and stochastic control theory.

Another specialty is that the running cost (and terminal cost if present) is not required to be bounded or continuous, but merely lower semicontinuous and of polynomial growth. This makes it possible, among other things, to also include problems where the objective is, e.g., to minimize the probability of the event that the state ever leaves a closed subset of the state space or to maximize the hitting probability of a target set; and in particular to cover the fixed endpoint problem of deterministic control theory.

In distinction from most papers in the field, the present approach does not use dynamic programming but is based on duality of convex analysis. We embed our control problem into a convex mathematical programming problem on a space of measures and consider its dual that turns out to involve the Hamilton-Jacobi-Bellman (HJB) equation. More precisely, we find that the dual of the original minimization

problem is to seek the supremum of all smooth subsolutions of the Hamilton-Jacobi-Bellman equation. From the existence of an equilibrium value for the primal-dual game it then follows, in particular, that the optimal value function of the control problem is the upper envelope of the smooth subsolutions of the Hamilton-Jacobi-Bellman equation.

The proof consists of two major steps. First we construct the minimization problem on the space of measures that contains the original control problem embedded (§ 3) and apply the Fenchel-Rockafellar duality theorem [4] to arrive at the HJB equation (§ 4). In the second step we prove that the embedding is actually tight; the infimum is the same both in the original and in the extended problem (§§ 5-6). This second part of the proof is based on the separation theorem and uses some analytic tools like mollification and Sobolev estimates, that in turn are derived by control-theoretic arguments. Roughly we could say that the separation is carried out by a sufficiently smooth control problem.

The possibility of approaching control problems via duality theory in abstract spaces was first demonstrated by Vinter and Lewis [6], [7] who proved similar results for deterministic control problems. Their approach was made available for stochastic control problems in [5] by basing it on the theory of occupation (potential and harmonic) measures and infinitesimal operators. The present paper extends the method to the optimal control of diffusions. Since the diffusion matrix is allowed to degenerate, the presented results apply uniformly to both deterministic and stochastic control problems. The novel proof of the tightness of the embedding is not only more general but even in the classical deterministic case it is more direct than the arguments of [6].

The first application of duality theory in optimal control was the representation of the adjoint co-state processes in terms of conjugate convex functions by Rockafellar [9]. A similar approach to stochastic control problems is due to Bismut [8]. In both cases the duality relationship is established in the finite-dimensional state/co-state spaces rather than between the spaces of measures and of continuous functions. Consequently both their methods and the nature of their results are very different from ours.

In [3] Lions characterizes the optimal value function of stochastic control as the largest generalized subsolution of the Hamilton-Jacobi-Bellman equation. The approach and method of proof differs from the one followed here.

2. Formulation of the problem. Let T be the planning horizon, either a nonnegative number or $+\infty$. We take $0 \leqq t \leqq T$. If $T < \infty$, then the state space will be $E^0 := [0, T] \times \mathbf{R}^n$, and if $T = +\infty$, then $E^0 := [0, T) \times \mathbf{R}^n$. We denote by E the one-point compactification of E^0 and introduce the notation $S^0 := E^0 \times Y$ and $S := E \times Y$. Note that E and S are compact.

The coefficients $\sigma(t, x, y)$ and $b(t, x, y)$ as well as the discount rate $c(t, x, y) \geqq 0$ are assumed to be bounded continuous functions on S^0 such that their first partial derivatives with respect to t and second partial derivatives with respect to x exist and, together with the functions themselves can continuously be extended to S. The running cost l is assumed to be lower semicontinuous on S and of at most polynomial growth. The case of additional terminal costs will be considered in § 8.

For simplicity we assume that either the planning horizon T is finite or that there is a strict discounting, i.e., $c_0 = \inf_{\sigma \in S^0} c(\sigma) > 0$. The effect of the discounting will be included into the process as an exponential killing or a jump to the fictitious isolated cemetery state Δ at the killing time Θ. In what follows all expectation signs E will refer to the killed process. The only exception is the sans serif E in formula (1.2) that

denotes the expectation of the nonkilled process, i.e.,

$$E\Phi(x_r) = \mathsf{E}\Phi(x_r) \cdot 1_{\{\Theta \geqq r\}} = \mathsf{E}\Phi(x_r)\, e^{-\int_t^r c(s,x_s,u_s)\, ds}.$$

We will also use the notation $\tau := \min(\Theta, T)$ and refer to it as the lifetime of the processes. The cost J^u can then be expressed in the three equivalent forms:

$$\begin{aligned} J^u(t,x) &= \mathsf{E}^u_{t,x} \int_t^T e^{-c(s,x_s,u_s)} l(s, x_s, u_s)\, ds \\ &= \mathsf{E}^u_{t,x} \int_t^\tau l(s, x_s, u_s)\, ds = E^u_{t,x} \int_t^T l(s, x_s, u_s)\, ds. \end{aligned} \tag{1.2'}$$

The assumptions about the boundedness of the coefficients, growth of the costs, and boundedness of the expected lifetime can be substantially relaxed. In fact, the proofs use a much less stringent but also less explicit assumption (cf. the remark following Lemma 2.1).

The spaces of functions on S^0 and E^0 that are continuously extendable to S and E will be denoted by $C(S)$ and $C(E)$, respectively, and they are considered to be Banach spaces normed by the supremum norm. In Lemma 2.1 we will introduce a continuous positive weight function $\gamma : [0, T) \times \mathbf{R}^n \to (0, \infty)$ associated with the control problem under investigation. We will consider the weighted spaces

$$C_\gamma(S) := \{f \in C(S^0) : f/\gamma \in C(S),\ \|f\|_\gamma := \sup_{\xi \in E, y \in Y} |f(\xi, y)|/\gamma(\xi) < \infty$$

$$\text{and } \lim_{|\xi| \to \infty} |f(\xi, y)|/\gamma(\xi) = 0\}.$$

$C_\gamma(E)$ is defined analogously.

$$C^2_\gamma(E) := \{\Phi \in C_\gamma(E) : \Phi(T,x)/\gamma(T,x) = 0,\ \Phi_t, \Phi_{x_i}, \Phi_{x_i x_j} \in C_\gamma(E) \quad \forall i, j = 1, \cdots, n\}.$$

In the subsequent expositions C^2_γ can always be substituted by the set of all infinitely often differentiable functions satisfying the boundary condition $\Phi(T,x)/\gamma(T,x) = 0$ and with all derivatives in $C_\gamma(E)$. We will refer to the elements of C^2_γ as smooth functions.

$\mathcal{M}^\gamma_\pm(S)$ will denote the space of all signed Borel measures M on S^0 for which the norm $\|M\|_\gamma = \int \gamma\, dM^+ + \int \gamma\, dM^-$ is finite. Here M^+ and M^- are the positive and negative parts of the Jordan decomposition of M. With obvious identification elements of $\mathcal{M}^\gamma_\pm(S)$ can be considered as signed measures on S not assigning mass to $\{\infty\} \times Y$.

If Γ is a positive constant then $\mathcal{M}^{\gamma,\Gamma}(S)$ will denote those nonnegative measures from $\mathcal{M}^\gamma_\pm(S)$ for which $\|M\|_\gamma \leqq \Gamma < +\infty$.

The set $\mathcal{U}$ of all admissible controls consists of all Y-valued control processes u_s which are progressively measurable with respect to the filtration of the Brownian motion w_s. If $u \in \mathcal{U}$ then x^u_s denotes the solution of the stochastic differential equation (1.1) corresponding to u, satisfying the initial condition $x^u_t = x$ and killed at rate $c(\cdot)$. The corresponding expectation operator will be denoted by $E^u_{t,x}$ and if no confusion can arise, the superscript u will be omitted from x^u_t inside the expectation.

With each control $u \in \mathcal{U}$ we associate the measure M^u defined on the compact space $S = E \times Y$ which is the extension of

$$\begin{aligned} M^u(B_t \times B_x \times B_y) &:= E^u_{t,x} \int_{[t,T] \cap B_t} 1_{B_x}(x^u_s) \cdot 1_{B_y}(u_s)\, ds \\ M(\infty \times Y) &:= 0. \end{aligned} \tag{2.1}$$

Here $B_t \subset [0, \infty]$, $B_x \subset \mathbf{R}^n$, $B_y \subset Y$ are arbitrary Borel sets and 1_B denotes the indicator function of the set B. Note that though the notation does not indicate it, the measures M^u depend on the initial condition $x_t = x$ in (1.1) which is considered to be fixed. We will denote the set of all such M^u corresponding to some $u \in \mathcal{U}$ by $\mathfrak{M}^S(t, x)$.

Intuitively, $M([t, t'] \times B_x \times B_y)$ measures the expected time before t' spent by the *killed* process x_s^u in the set B_x while control values from $B_y \subset Y$ were applied. In particular, $M^u(\cdot, \cdot, Y)$ is the potential (or occupation) measure of the killed time-space process (s, x_s^u).

The infinitesimal operator of the killed Markov process x_t^y corresponding to the constant control $u_t \equiv y \in Y$ is defined for each $\Phi \in C^2(E^0)$ and is given by the expression

$$A^y\Phi(t, x) = \frac{\partial \Phi(t, x)}{\partial t} + \sum_{i,j=1}^{n} a_{i,j}(t, x, y) \frac{\partial^2 \Phi(t, x)}{\partial x_i \, \partial x_j} + \sum_{i=1}^{m} b_i(t, x, y) \frac{\partial \Phi(t, x)}{\partial x_i}$$

$$- c(t, x, y)\Phi(t, x)$$

with $(a_{ij}) = \frac{1}{2}\sigma^T \cdot \sigma$. We will use this notation also for nonsmooth functions Φ i.e., to denote the value of the expression on the right-hand side at every point (t, x) where the corresponding partial derivatives exist.

To interconnect the assumptions on discounting, termination and growth as well as to express them in a technically convenient analytic form, we prove the following lemma.

LEMMA 2.1. *There exist constants $0 < \alpha < \bar{\alpha}$ and a twice continuously differentiable function $\gamma\colon [0, T) \times \mathbf{R}^n \to (0, \infty)$ satisfying*

$$0 < \alpha\gamma \leqq -A^y\gamma \leqq \bar{\alpha}\gamma \tag{2.2}$$

everywhere in $(0, T) \times \mathbf{R}^n$ for all $y \in Y$.

Proof. We will construct γ separately for the discounted and for the finite horizon case.

1. *Discounted case.* The infinitesimal operator of the exponentially killed process is of the form $A\Phi = D\Phi - c\Phi$ with D a (possibly degenerate) second order differential operator. We define

$$\gamma(t, x) := (\cosh pt) \prod_{i=1}^{n} \cosh px_i \tag{2.3}$$

with a p yet to be determined.

A straightforward calculation shows that

$$-K(p)\gamma(t, x) \leqq D\gamma(t, x) \leqq K(p)\gamma(t, x) \tag{2.4}$$

with $K(p) = \sum_{i=1}^{n} \|a_{ij}\| p^2 + \sum_{i=1}^{n} \|b_i\| p = \bar{a}p^2 + \bar{b}p$. Consequently,

$$K(p) + \|c\| \cdot \gamma \leqq A\gamma = D\gamma - c \cdot \gamma \leqq (K(p) - c) \cdot \gamma. \tag{2.5}$$

If $c_0 = \inf c > 0$, then the quadratic equation $\bar{a}p^2 + \bar{b}p - c_0 = 0$ has exactly one positive root p_0. Choosing p from the interval $(0, p_0)$, we get that $c_0 - K(p) > 0$, and hence (2.2) is satisfied with $\alpha := c_0 - K(p)$ and $\bar{\alpha} := \|c\| + K(p)$.

2. *Finite horizon case.* We define

$$\gamma(t, x) := [1 + (T - t)] \cdot \prod_{i=1}^{n} \cosh px_i = [1 + (T - t)]\gamma_0(x).$$

When we use the notation $A\Phi = \partial\Phi/\partial t + D_x\Phi$ a calculation analogous to that of the discounted case yields

$$
\begin{aligned}
-A\gamma(t,x) &= \gamma_0(x) - (1+T-t)D_x\gamma_0(x) \\
&\geqq [(1+T-1)^{-1} - K(p)] \cdot (1+T-t) \cdot \gamma_0(x).
\end{aligned} \tag{2.6}
$$

With $(1+T)^{-1}$ in place of c_0, the above argument shows that if p is chosen from $(0, p_0)$, then γ satisfies (2.2) with $\alpha := (1+T)^{-1} - K(p) > 0$ and $\bar{\alpha} := 1 + K(p)$. The proof of the lemma is complete.

We formulate some consequences of Lemma 2.1 that will be used at various places during the subsequent expositions.

COROLLARY. (1) $\int \gamma\, dM^u \leqq \gamma(t,x)/\alpha < +\infty$ *for every* $M^u \in \mathfrak{M}^S(t,x)$. *In other words, the constant* $\Gamma := \gamma(t,x)/\alpha < +\infty$ *is a uniform upper bound for the expressions* $E^u_{t,x}\int_t^T \gamma(s, x^u_s)\, ds$ *for every process* x^u_t *generated by a control* $u \in \mathcal{U}$ *and starting from initial state* $x_t = x$.

(2) $\gamma(t,x)$ *grows asymptotically not faster than an exponential function as* $|x| \to \infty$, $t \to \infty$.

(3) *For every* $(t,x) \in E^0$, $0 \leqq s < +\infty$ *and* $u \in \mathcal{U}$ *we have*

$$
1 - e^{-\alpha s} \leqq 1 - \gamma^{-1}(t,x)E^u_{t,x}\gamma(t+s, x_{t+s}) \leqq 1. \tag{2.7}
$$

Proof. The proof of (1) follows from Dynkin's formula. In fact, if $T < \infty$ we have

$$
\begin{aligned}
\int \gamma\, dM^u &\leqq \frac{1}{\alpha}\int (-A^u\gamma)\, dM^u = \frac{1}{\alpha} E^u_{t,x}\int_t^T (-A^u\gamma)(s, x^u_s)\, ds \\
&= \frac{1}{\alpha}[\gamma(t,x) - E^u_{t,x}\gamma(T, x_T)] \leqq \gamma(t,x)/\alpha.
\end{aligned}
$$

Since the bound is independent of T, the inequality remains true as $T \to +\infty$.

The proof of (2) is immediate from the construction of γ in the proof of Lemma 2.1.

(3) The left-hand side of (2.2) can be written as $A^u\gamma + \alpha\gamma \leqq 0$. By the Feynman–Kac formula it follows that $E^u_{t,x}e^{\alpha s}\gamma(t+s, x^u_{t+s}) \leqq \gamma(t,x)$ with an $\alpha > 0$. Subtracting both sides of inequality $E^u_{t,x}\gamma(t+s, x^u_{t+s}) \leqq e^{-\alpha s}\gamma(t,x)$ from $\gamma(t,x)$, we obtain $\gamma - E\gamma \geqq \gamma(1 - e^{-\gamma s})$, which proves the left-hand side of (2.7). The right-hand side is trivial since $\gamma^{-1}E\gamma \geqq 0$.

Remark. The growth, discounting, and termination conditions required earlier in this section will be used in the subsequent expositions only indirectly through the statement of Lemma 2.1. Consequently all results of this paper remain valid under other sets of assumptions that assure the existence of a γ with property (2.2). Examples of other possible sets of such assumptions are:

(i) Coefficients a_{ij}, b_i satisfy linear growth conditions, the discounting is strict, the running cost is bounded. In this case γ can be chosen asymptotically as $|x|^p$ with $p < c_0$ and $\alpha = c_0 - p$.

(ii) Coefficients a_{ij}, b_i satisfy linear growth conditions, the time horizon is finite, the running cost is of polynomial growth. Then we can choose $\gamma(t,x) \sim [1 + K(T-t)]|x|^p$ with an appropriate K and p.

Now we return to our original control problem. Although we assumed l to be only lower semicontinuous, in §§ 3–6 of the paper we will consider continuous running costs. The extension of all obtained results to the general semicontinuous case will be an additional step in § 7. With the notation introduced, the control problem we will consider in §§ 3–6 can be formulated as the Strong Problem.

STRONG PROBLEM. For a given running cost $l \in C_\gamma(E)$ and initial state $(t, x) \in E^0$:

$$\text{Minimize} \int l\, dM^u \quad \text{over all } M^u \in \mathfrak{M}^S(t, x).$$

We can define the optimal value ψ of the Strong Problem as a function of the initial state

$$\psi(t, x) := \inf\left\{ \int l\, dM^u : M^u \in \mathfrak{M}^S(t, x) \right\}.$$

3. The weak formulation of the control problem. It follows from Itô's formula, that for arbitrary nonanticipative control process $u \in \mathcal{U}$ the generalization of the fundamental theorem of calculus (Dynkin's formula) holds true. For every twice continuously differentiable Φ we have

$$E^u_{t,x}\Phi(\sigma, x_\sigma) - \Phi(t, x) = E^u_{t,x} \int_t^\sigma A^{u_s}\Phi(s, x_s)\, ds \tag{3.1}$$

provided $\sigma \leqq \tau$ is a stopping time such that the expectations exist.

If we apply this formula to the terminal time τ and to smooth functions $\Phi \in C^2_\gamma$ that vanish at the terminal state Δ, then by $\Phi(\tau, x_\tau) = \Phi(\Delta) = 0$ we find that

$$-\Phi(t, x) = \int A^\gamma \Phi(t', x') M^u(dt', dx', dy) \tag{3.2}$$

holds true for every $u \in \mathcal{U}$ whenever $A\Phi \in C_\gamma$.

We introduce the notation

$$\mathcal{M}_A(t, x) := \left\{ M \in \mathcal{M}^\gamma_\pm(S) : -\Phi(t, x) = \int A\Phi\, dM \quad \text{for all } \Phi \in C^2_\gamma(E) \right\},$$

$$\mathfrak{M}^W(t, x) := \mathcal{M}^{\gamma,\Gamma}(S) \cap \mathcal{M}_A(t, x) \quad \text{with } \Gamma = \gamma(t, x)/\alpha.$$

Since for every $u \in \mathcal{U}$ the measure $M^u \in \mathfrak{M}^S(t, x)$ is in both $\mathcal{M}^{\gamma,\Gamma}(S)$ and $\mathcal{M}_A(t, x)$ our original control problem, the Strong Problem is embedded in the following problem.

WEAK PROBLEM.

$$\text{Minimize} \int l\, dM \quad \text{over } M \in \mathfrak{M}^W(t, x). \tag{3.3}$$

This is a minimization problem on the space of measures with linear objective and convex constraints. In fact, if $l \in C_\gamma(S)$, then by the Riesz Theorem $\int l\, dM$ is a continuous linear functional on the space of signed measures $\mathcal{M}^\gamma_\pm$. For each $\Phi \in C^2_\gamma$ relation (3.2) imposes a continuous linear restriction on M, consequently their intersection $\mathcal{M}_A(t, x)$ is a closed linear set in $\mathcal{M}^\gamma_\pm$. Finally, $\mathcal{M}^{\gamma,\Gamma}$ is a w^*-compact convex subset of $\mathcal{M}^\gamma_\pm$.

The feasible set of the Strong Problem consists of all $M^u \in \mathfrak{M}^S$ generated by a control $u \in \mathcal{U}$ via the stochastic differential equation (1.1). This set is contained in the feasible set $\mathfrak{M}^W$ of the weak problem, thus the optimal value $\psi(t, x) := \inf\{\int l\, dM^u : u \in \mathcal{U}\}$ is not less than the minimum $\Psi(t, x) = \inf\{\int l\, dM;\ M \in \mathfrak{M}^W(t, x)\}$ in the Weak Problem. Note that the initial state (t, x) is involved in the Strong Problem through the initial condition (1.2) and in the Weak Problem through the definition of $\mathcal{M}_A(t, x)$.

In what follows, we will first characterize the value function $\Psi(t, x)$ of the Weak Problem by solving its dual, a maximization problem in the function space $C_\gamma(E) \subset C_\gamma(S)$. More precisely, it will turn out that the dual of the minimization problem (3.3) is to find the supremum of all smooth subsolutions to the Hamilton-Jacobi equation.

To make duality methods applicable it is convenient to bring the Weak Problem to the Fenchel normal form. Using extended valued functions we reformulate the convexly constrained linear problem as an unconstrained convex problem. In fact, we introduce the functionals h_1 and $h_2: \mathcal{M}_+^\gamma(S) \to \bar{\mathbf{R}}^1$ by

$$h_1(M) := \begin{cases} \int l\, dM & \text{if } M \in \mathcal{M}^{\gamma,\Gamma}(S), \\ +\infty & \text{otherwise,} \end{cases}$$

$$h_2(M) := \begin{cases} 0 & \text{if } M \in \mathcal{M}_A(t, x), \\ -\infty & \text{otherwise.} \end{cases}$$

Both h_1 and $-h_2$ are convex and lower semicontinuous. It is immediate that the weak problem is equivalent to the following problem.

FENCHEL PROBLEM. Minimize $h_1(M) - h_2(M)$ over all $M \in \mathcal{M}_+^\gamma(S)$.

4. Duality and the Hamilton–Jacobi problem. Recall that the space S is compact, thus by the Riesz Theorem $C_\gamma^*(S) = \mathcal{M}_+^\gamma(S)$. In other words, $C_\gamma(S)$ and $\mathcal{M}_+^\gamma(S)$ are spaces in duality connected by the bilinear form:

$$\langle \phi, \mu \rangle = \int \phi\, d\mu \qquad \phi \in C_\gamma, \quad \mu \in \mathcal{M}_+^\gamma. \tag{4.1}$$

The norm topology of C_γ and the weak*-topology of $\mathcal{M}_+^\gamma$ are compatible with the pairing, the continuous linear functionals on both spaces are exactly those representable by the bilinear form. If H and h are convex real-valued functions defined on $C_\gamma(S)$ and $\mathcal{M}_+^\gamma(S)$, respectively, then their Legendre-Fenchel transforms (convex conjugates) are defined by

$$H^*(\mu) := \sup \left\{ \int \phi\, d\mu - H(\phi) \colon \phi \in C_\gamma(S) \right\}, \tag{4.2}$$

$$h^*(\phi) := \sup \left\{ \int \phi\, d\mu - h(\mu) \colon \mu \in \mathcal{M}_+^\gamma(S) \right\}. \tag{4.3}$$

If the original function h or H is convex and lower semicontinuous, then it coincides with its double conjugate, i.e., $H^{**} = H$, $h^{**} = h$. Conjugates of concave functions are defined analogously but with inf in place of sup, and have the corresponding properties.

Now we compute the Legendre-Fenchel transforms of the functionals h_1 and h_2. We use the quantities γ and α as they were introduced in Lemma 2.1.

LEMMA 4.1. $h_1^*(\phi) = \alpha^{-1} \cdot \gamma(t, x) \cdot \|(\phi - l)^+\|_\gamma = \alpha^{-1} \cdot \gamma(t, x) \cdot \sup\{[\phi(\sigma) - l(\sigma)]/\gamma(\theta, \xi)$: *over all* $\sigma = (\theta, \xi, \eta) \in S$ *such that* $\phi(\sigma) - l(\sigma) \geqq 0\}$.[1]

Proof.

$$\begin{aligned} h_1^*(\phi) &= \sup \left\{ \int \phi\, d\mu - h_1(\mu) \colon \mu \in \mathcal{M}_+^\gamma \right\} = \sup \left\{ \int (\phi - l)\, dM \colon M \in \mathcal{M}^{\gamma,\Gamma} \right\} \\ &= \sup \left\{ \int [(\phi - l)/\gamma] \gamma\, dM \colon M \geqq 0, \int_\gamma dM \leqq \Gamma = \gamma(t, x)/\alpha \right\}. \end{aligned} \tag{4.4}$$

[1] $(f)^+$ denotes the positive part of the function f, i.e., $f^+(x) = \max\{0, f(x)\}$.

Since ϕ and l are in C_γ, the continuous function $(\phi - l)/\gamma$ attains its maximum at some point $\sigma_0 = (t_0, x_0, y_0)$ of the compact set S. If $(\phi - l)(t_0, x_0, y_0)/\gamma(t_0, x_0) > 0$, then $t_0 < \infty$, $x_0 \neq \infty$ and the sup in (3.4) can be attained by concentrating all available mass of the measure $\gamma\, dM$ to the point $\sigma_0 \in S$. We have to choose $M(ds) := \gamma(t, x)/(\alpha \cdot \gamma(t_0, x_0))\delta_{\sigma_0}(ds)$ with δ_{σ_0} denoting the Dirac measure assigning unit mass to the singleton $\{\sigma_0\}$. Then we have

$$h_1^*(\phi) = \gamma(t, x)(\phi - l)(\sigma_0)/(\alpha \cdot \gamma(t_0, x_0)) = \alpha^{-1} \cdot \gamma(t, x)\|(\phi - l)\|_\gamma \tag{4.5}$$

provided $\sup(\phi - l) > 0$.

If $\sup(\phi - l) \leqq 0$, i.e., if $\phi(\sigma) < l(\sigma)$ for all $\sigma \in S$, then the maximum of the expression (4.4) is zero and is attained for $M \equiv 0$. This together with (4.5) proves the lemma.

LEMMA 4.2.

$$h_2^*(\phi) = \begin{cases} -\lim \Phi_i(t, x) & \text{if } \phi = \lim_{i\to\infty} A\Phi_i \text{ with } \Phi_i \in C_\gamma^2(E), \\ -\infty & \text{otherwise.} \end{cases} \tag{4.6}$$

Proof. Since h_2 is concave, $h_2^*(\phi) := \inf\{\int \phi\, dM - h_2(M)\colon M \in \mathcal{M}_A(t, x)\}$.

Let us first assume that $\phi = A\Phi \in C_\gamma$ with some $\Phi \in C_\gamma^2$. Then, by the definition of $\mathcal{M}_A(t, x)$ for every $M \in \mathcal{M}_A(t, x)$ we have $\int \phi\, dM = \int A\Phi\, dM = -\Phi(t, x)$. Since $\mathcal{M}_A$ is nonempty, $A\Phi_1 \equiv A\Phi_2$ implies $\Phi_1(t, x) = \Phi_2(t, x)$, and hence we have $\int \phi\, dM = \int A\Phi\, dM = -\Phi(t, x)$ whenever $\phi = A\Phi \in C_\gamma$ with some $\Phi \in C_\gamma^2$.

Let us assume now that there exists a sequence $\Phi^k \in C_\gamma^2$ such that $\|\phi - A\Phi^k\|_\gamma \to 0$. This means that $A\Phi^k/\gamma \to \phi/\gamma$ uniformly on S as $k \to \infty$. By this uniform convergence and the finiteness of the measure $\gamma\, dM$ for every $M \in \mathcal{M}_A(t, x) \subset \mathcal{M}_\pm^\gamma$ we have

$$\int \phi\, dM = \int \frac{\phi}{\gamma} \cdot \gamma\, dM = \int \lim_{k\to\infty} \frac{A\Phi^k}{\gamma} \cdot \gamma\, dM = \int \lim_{k\to\infty} A\Phi^k\, dM = \lim \Phi^k(t, x)$$

independently of the particular choice of the sequence $A\Phi^k$. Since $-\lim \Phi^k(t, x)$ does not depend on $M \in \mathcal{M}_A(t, x)$, we have proved the first line of (4.6).

It remains to show that $h_2^*(\phi) = -\infty$ if ϕ is not in the $\|\ \|_\gamma$ closure of the functions $A\Phi$ with $\Phi \in C_\gamma^2$. Assume $\phi_0 \in C_\gamma$ is not in the closed subspace $W := \{\phi \in C_\gamma(S)\colon \lim_{k\to\infty} \|\phi - A\Phi^k\|_\gamma = 0 \text{ with } \Phi^k \in C_\gamma^2\}$. Then ϕ_0 and W can be separated by a closed hyperplane. That is, there exists an $M' \in \mathcal{M}_\pm^\gamma(S)$ such that $\int \phi_0\, dM' < 0$ while $\int \phi\, dM' = 0$ for all $\phi \in W$. In particular, we have $\int A\Phi\, dM' = 0$ for all $\Phi \in C_\gamma^2$ and consequently, $M + \Theta M' \in \mathcal{M}_A(t, x)$ for every $M \in \mathcal{M}_A(t, x)$ and $\Theta \in \mathbf{R}^1$. If $\bar{M}$ denotes an arbitrary fixed element of $\mathcal{M}_A(t, x)$, then we have

$$h_2^*(\phi_0) = \inf_{M\in\mathcal{M}_A} \int \phi_0\, dM \leqq \inf_{\Theta\in\mathbf{R}^1} \int \phi_0\, d(\bar{M} + \Theta M')$$

$$= \int \phi_0\, d\bar{M} + \inf_{\Theta\in\mathbf{R}^1} \Theta \cdot \int \phi_0\, dM' = -\infty.$$

Here we used that by assumption $\int \phi_0\, dM' \neq 0$ and that Φ can be arbitrary. This completes the proof of the lemma.

The next theorem is the main result of this section. Roughly, it states that seeking the maximal solution of the Hamilton-Jacobi-Bellman equation is the dual to the weak problem formulated in the previous section. As under the current weak assumptions no smooth solutions to the Hamilton-Jacobi-Bellman equation need exist, the precise formulation of the duality relationship is the following. The value function

(i.e., the minimum) of the Weak Problem is the upper envelope (i.e., supremum) of the smooth subsolutions of the Hamilton-Jacobi equation.

THEOREM 1.

$$\Psi(t,x) := \min\left\{\int l\,dM\colon M \in \mathcal{M}_A(t,x) \cap \mathcal{M}^{\gamma,\Gamma}\right\}$$

$$= \sup\{\Phi(t,x)\colon \Phi \in C_\gamma^2,\ A\Phi + l \geqq 0\}.$$

Proof. If applied to $C_\gamma^* = \mathcal{M}_\pm^\gamma$, Rockafellar's duality theorem [4] states that

$$\min\{h_1(M) - h_2(M)\colon M \in \mathcal{M}_\pm^\gamma(S)\} = \sup\{h_2^*(\phi) - h_1^*(\phi)\colon \phi \in C_\gamma(S)\} \tag{4.7}$$

whenever the set $\{\phi\colon h_2^*(\phi) > -\infty\}$ contains a finite continuity point of h_1^*. But this condition is satisfied since h_1^* is continuous and finite on whole C_γ and $h_2^*(\phi)$ is not identically $-\infty$, and hence (4.7) holds true.

Substituting the explicit expressions for h_1^* and h_2^* from Lemmas 4.1 and 4.2 into (4.7) and using the fact that $\{A\Phi\colon \Phi \in C_\gamma^2\}$ is dense in $\{\phi\colon h_2^*(\phi) > -\infty\}$, we obtain

$$\Psi(t,x) = \min\{h_1(M) - h_2(M)\colon M \in \mathcal{M}_\pm^\gamma(S)\}$$

$$= \sup\{\Phi(t,x) - \alpha^{-1}\cdot\gamma(t,x)\cdot\|(A\Phi + l)^-\|_\gamma\colon \Phi \in C_\gamma^2\}.$$

To conclude the proof it is sufficient to show that for every $\Phi \in C_\gamma^2$ there exists a $\Phi^\sim \in C_\gamma^2$ such that $A\Phi^\sim + l \geqq 0$ and $\Phi^\sim(t,x) \geqq \Phi(t,x) - \alpha^{-1}\cdot\gamma(t,x)\cdot\|(A\Phi + l)^-\|_\gamma$. Choose $\Phi^\sim := \Phi - \alpha^{-1}\cdot\gamma\|(A\Phi + l)^-\|_\gamma$. Then by Lemma 2.1 $-A\gamma \geqq \alpha\gamma$ holds and consequently, we have

$$A\Phi^\sim + l = A\Phi + l - \alpha^{-1}\cdot\|(A\Phi + l)^-\|_\gamma\cdot A\gamma \geqq A\Phi + l + \gamma\cdot\|(A\Phi + l)^-\|_\gamma$$

$$= A\Phi + l + \gamma\cdot\sup_{(t',x',y')\in S}|(A\Phi + l)^-(t',x',y')/\gamma(t',x')| \geqq 0.$$

The proof of the theorem is complete.

In a less compressed form Theorem 1 states that the weak value function Ψ is the upper envelope of all $\Phi \in C_\gamma^2(E)$ satisfying the Hamilton-Jacobi inequality:

$$\Phi_t(t,x) + \min_{y\in Y}\left\{\sum_{i,j=1}^n a(t,x,y)\Phi_{x_ix_j}(t,x) + \sum_{i=1}^n b_i(t,x,y)\Phi_{x_i}(t,x)\right.$$

$$\left. - c(t,x,y)\Phi(t,x) + l(t,x,y)\right\} \geqq 0. \tag{4.8}$$

Recall that the definition of C_γ^2 includes $\Phi(T,x) = 0$ whenever $T < +\infty$.

The fact that $A\Phi_1 \geqq A\Phi_2$ implies $\Phi_1 \leqq \Phi_2$ justifies calling the functions $\Phi \in C_\gamma^2$ satisying (4.8) *subsolutions* of the Hamilton-Jacobi equation.

The results of the present paragraph remain valid under much more general assumptions than those made in § 2. In fact, we did *not* use either the finite dimensionality of the state-space or the specific properties of diffusion processes. Besides Rockafellar's duality theorem, our approach was based on the validity of Dynkin's formula, but not even the denseness of C_γ^2 was exploited. Since Dynkin's formula is a special case of the "general fundamental theorem of calculus" in semigroup theory, all results of the present paragraph can be generalized to the case, when the state and control spaces are locally compact separable metric spaces and C_γ^2 is substituted by a linear subset $\mathcal{L}$ of $C_\gamma(E)$. Of course, this latter change affects the definition of $\mathcal{M}_A$ and consequently the Weak Problem itself. But still, the dual of this new "$\mathcal{L}$-Weak" Problem will be the problem of finding the upper envelope of all subsolutions in $\mathcal{L}$

of the Hamilton-Jacobi-Bellman equation involving the operator A. The coincidence of the primal and dual values remain preserved too.

5. Equivalence of the strong and weak formulations. We prove the equivalence under the assumption of a special approximation property of the value function corresponding to smooth costs. In § 6 we will show that under the assumptions of the present paper this approximability is always true.

THEOREM 2. *Let $f \in C_\gamma^2(S)$ denote an arbitrary smooth "running cost" and denote F the corresponding (strong) value function.*

Suppose that every such value function F can be approximated in the $\| \ \|_\gamma$-norm by a sequence of functions $F^{(\varepsilon)}$, each of which has first and second derivatives essentially bounded in γ-norm and satisfies $AF^{(\varepsilon)} + f \geqq 0$ almost everywhere as well as $F^{(\varepsilon)}(T, x) = 0$ whenever $T < \infty$. Then, for each $(t, x) \in E^0$ and l as in § 2 the weak and strong formulations are equivalent; their optimal value functions coincide.

Note that Theorem 2 assumes the approximability of value functions generated by smooth costs and makes a statement about the more general control problem that involves general continuous or (later) even only lower semicontinuous running cost l.

Proof. Assume that the statement of the theorem is false; then there exists an initial state (t_0, x_0) such that $\Psi(t_0, x_0) < \psi(t_0, x_0)$. This means that there exists a measure $M_0 \in \mathfrak{M}^W(t_0, x_0) \setminus \mathfrak{M}^S(t_0, x_0)$ that gives rise to a cost $\int l \, dM_0$ lower than $\psi(t_0, x_0)$, the infimum over all costs generated by controls $u \in \mathcal{U}$, i.e.,

$$\int l \, dM_0 < \inf \left\{ \int l \, dM^u : u \in \mathcal{U} \right\}. \tag{5.1}$$

This means that the w^*-continuous linear functional $\int l \, dM$ on $\mathcal{M}_+^\gamma(S)$ separates an element $M_0 \in \mathfrak{M}^W$ from the w^* convex-closure of the set $\mathfrak{M}^S = \{M^u : u \in \mathcal{U}\}$. In other words, $\mathfrak{M}^W$ is strictly larger than the closure of $\mathfrak{M}^S$. If this is so, then M_0 and the compact set $\bar{\mathfrak{M}}^S$ can also be separated by a functional $\int f \, dM$ generated by a smooth $f \in C_\gamma^2(S)$. More precisely, since smooth functions form a dense subset in C_γ there must exist an $f \in C_\gamma^2$ such that

$$\int f \, dM_0 < \inf \left\{ \int f \, dM^u : M^u \in \mathfrak{M}^S \right\}. \tag{5.2}$$

Let us introduce the strong value function F corresponding to the running cost f

$$F(t, x) := \inf \left\{ \int f \, dM : M \in \mathfrak{M}^S(t, x) \right\} = \inf_{u \in \mathcal{U}} E_{t,x} \int_t^T f(t, x_t^u, u_t) \, dt. \tag{5.3}$$

Then, according to the assumptions of the theorem, for every $\varepsilon > 0$ there exists an $F^{(\varepsilon)}$ such that all the partial derivatives $F_t^{(\varepsilon)}$, $F_{x_i}^{(\varepsilon)}$, $F_{x_i x_j}^{(\varepsilon)}$ are defined almost everywhere, are essentially bounded, and for every $y \in Y$ the inequality

$$A^y F^{(\varepsilon)}(t, x) + f(t, x, y) \geqq 0 \tag{5.4}$$

is satisfied for almost every $(t, x) \in E$ and $\| F^{(\varepsilon)} - F \|_\gamma < \varepsilon$.

The generalized Dynkin formula (3.2) cannot be applied directly to (5.4) because $F^{(\varepsilon)}$ is not smooth; it should first be approximated by C_γ^2 functions. The details of this approximation are presented in the next two lemmas. When we use them, the conclusion of the proof of Theorem 2 will be straightforward.

LEMMA 5.1. *For every $\delta > 0$ there exists an $F^{(\varepsilon,\delta)} \in C_\gamma^2(E)$ such that*

$$\begin{aligned} &\| F^{(\varepsilon)} - F^{(\varepsilon,\delta)} \|_\gamma < \delta, \qquad \| AF^{(\varepsilon,\delta)} \|_\gamma \leqq \| AF^{(\varepsilon)} \|_\gamma + \delta, \\ &AF^{(\varepsilon,\delta)} + f \geqq -\delta \cdot \gamma \quad \text{on } [\delta, T - \delta] \times \mathbf{R}^n \times Y. \end{aligned} \tag{5.5}$$

Proof. First we extend the definition of $F^{(\varepsilon)}$ from $[0, T]\times\mathbf{R}^n$ to $[-T, 2T]\times\mathbf{R}^n$ by

$$\begin{aligned} &F^{(\varepsilon)}(-s, x) := F^{(\varepsilon)}(0, x), \qquad s\in[0, T], \quad x\in\mathbf{R}^n, \\ &F^{(\varepsilon)}(T+s, x) := F^{(\varepsilon)}(T-s, x), \end{aligned} \tag{5.6}$$

and the functions a, b, c, and f from $[0, T]\times\mathbf{R}^n\times Y$ to $[-T, 2T]\times\mathbf{R}^n\times Y$ by reflection over 0 and T; i.e., $a(-s, x, y)=a(s, x, y)$ and $a(T+s, x, y)=a(T-s, x, y)$ if $s\in[0, T]$, $x\in\mathbf{R}^n$, $y\in Y$, and similarly for b, c, and f.

Note that

$$\begin{aligned} &A^y F^{(\varepsilon)}(-s, x) = -F_t^{(\varepsilon)}(s, x) + A^y F^{(\varepsilon)}(s, x), \qquad s\in[0, T], \quad x\in\mathbf{R}^n, \quad y\in Y, \\ &A^y F^{(\varepsilon)}(T+s, x) = 2F_t^{(\varepsilon)}(s, x) - A^y F^{(\varepsilon)}(T-s, x). \end{aligned} \tag{5.7}$$

Moreover, because of the Lipschitz continuity of $F^{(\varepsilon)}$ we have

$$\sup_{[-T,2T]\times\mathbf{R}^n\times Y} |AF^{(\varepsilon)}/\gamma| = K$$

with some finite number K. (We reserve the notation $\|\cdot\|_\gamma$ for sup over $[0, T]\times\mathbf{R}^n\times Y$.)

Let $\rho_r(t, x)$ be a nonnegative symmetric C^∞-mollifier (partition of unity) with $\iint \rho_r(\sigma, \xi)\, d\sigma\, d\xi = 1$ and $\rho_r(\sigma, \xi)=0$ if $|\sigma|+|\xi|>r$. If $\phi\in C([-T, 2T]\times\mathbf{R}^n)$, then we define $\phi * \rho_r$ on $[0, T]\times\mathbf{R}^n$ by

$$(\phi * \rho_r)(t, x) = \iint \phi(t+\sigma, x+\xi)\rho_r(\sigma, \xi)\, d\sigma\, d\xi \quad \text{if } 0<r<T.$$

From the second relation of (5.6) it follows that $(F^{(\varepsilon)} * \rho_r)(T, x)=0$; moreover, $F^{(\varepsilon)} * \rho_r$ is infinitely often differentiable on $[0, T]\times\mathbf{R}^n$ and $\|F^{(\varepsilon)} * \rho_r\|_\gamma \leqq K$. Consequently, $F^{(\varepsilon)} * \rho_r \in C_\gamma^2(E)$ for every $0<r<T$.

Since by (5.4) $AF^{(\varepsilon)}+f\geqq 0$ holds almost everywhere on $[0, T]\times\mathbf{R}^r\times Y$, it follows that

$$(AF^{(\varepsilon)}) * \rho_r + f * \rho_r \geqq 0 \quad \text{on } [r, T-r]\times\mathbf{R}^n\times Y.$$

We want to show that for every $\delta>0$ there exists an $r>0$ such that $F^{(\varepsilon,\delta)} := F^{(\varepsilon)} * \rho_r$ satisfies (5.5). Clearly, we can assume $r<\delta$, i.e., $[\delta, T-\delta]\subset[r, T-r]$ and thus it is sufficient to show that

$$\|(AF^{(\varepsilon)}) * \rho_r - A(F^{(\varepsilon)} * \rho_r)\|_\gamma \to 0 \quad \text{and} \quad \|f * \rho_r - f\|_\gamma \to 0.$$

We have

$$\begin{aligned} &\frac{1}{\gamma(t, x)}[(AF^{(\varepsilon)} * \rho_r - A(F^{(\varepsilon)} * \rho_r)](t, x, y) \\ &= \frac{1}{\gamma(t, x)} \iint \Big\{ \sum_{i,j=1}^n [a_{ij}(t+\sigma, x+\xi, y) - a_{ij}(t, x, y)] F^{(\varepsilon)}_{x_i x_j}(t+\sigma, x+\xi) \\ &\qquad + \sum_{i=1}^n [b_i(t+\sigma, x+\xi, y) - b_i(t, x, y)] F^{(\varepsilon)}_{x_i}(t+\sigma, x+\xi) \\ &\qquad - [c(t+\sigma, x+\xi, y) - c(t, x, y)] F^{(\varepsilon)}(t+\sigma, x+\xi) \Big\} \rho_r(\sigma, \xi)\, d\sigma\, d\xi \\ &\leqq \sum \tilde{a}_{ij}(r) \|F^{(\varepsilon)}_{x_i x_j}\|_\gamma + \sum \tilde{b}_{ij}(r) \|F^{(\varepsilon)}_{x_i}\|_\gamma + \tilde{c}(r) \|F^{(\varepsilon)}\|_\gamma \end{aligned} \tag{5.8}$$

where $\tilde{a}_{ij}$, $\tilde{b}_i$, $\tilde{c}$ denote the moduli of continuity of the corresponding coefficients. Since the coefficients were assumed to be uniformly continuous and the $\|\cdot\|_\gamma$-norms of $F^{(\varepsilon)}_{x_i x_j}$,

$F_{x_i}^{(\varepsilon)}$, and $F^{(\varepsilon)}$ are finite by the assumption of the theorem, the right-hand side of the inequality tends to zero as $r \to 0$, thus proving the lemma.

LEMMA 5.2.

$$\int_{[t_1,t_2]\times \mathbf{R}^n \times Y} \gamma \, dM \leqq (t_2 - t_1) \cdot \gamma(t, x) \tag{5.9}$$

holds true for every $M \in \mathfrak{M}^W(t, x)$ *and* $0 \leqq t_1 \leqq t_2 \leqq T$.

Proof. Denote $\chi(s) := (t_2 - t_1) - \int_0^s 1_{[t_1,t_2]}(\sigma)\, d\sigma$ and let $\chi_k : [0, T] \to \mathbf{R}^1$ be a monotonely decreasing sequence of functions that is continuously differentiable in $(0, T)$, for which $\chi_k(T) = 0$ and such that $\chi_k \searrow \chi$ and $\chi_k' \nearrow -1_{[t_1, t_2]} = \chi'$ as $k \to \infty$.

For $M \in \mathfrak{M}^W(t, x) \subset \mathcal{M}_A(t, x)$, the generalized Dynkin formula (3.2) can be applied to the functions $\Phi_k(\sigma, \xi) := \chi_k(\sigma) \cdot \gamma(\sigma, \xi)$. Using relation

$$A\Phi_k = \gamma \cdot A\chi_k + \chi_k \cdot A\gamma = \gamma \cdot \chi_k' - \gamma \cdot c \cdot \chi_k + \chi_k \cdot A\gamma$$

and the fact that $c \cdot \gamma$, $-A\gamma$, and M are nonnegative, we obtain

$$\begin{aligned}(t_2 - t_1) \cdot \gamma(t, x) &\geqq \gamma(t, x) \cdot \chi(t) = \lim_{k\to\infty} \gamma(t, x) \cdot \chi_k(t) \\ &= \lim_{k\to\infty} \Phi_k(t, x) = \lim_{k\to\infty} \int -A\Phi_k \, dM \\ &= \lim_{k\to\infty} \int -\chi_k' \cdot \gamma \, dM + \int \chi_k c \cdot \gamma \, dM + \int \chi_k(-A\gamma)\, dM \\ &\geqq \lim_{k\to\infty} \int -\chi_k' \cdot \gamma \, dM = \int 1_{[t_1,t_2]} \cdot \gamma \, dM,\end{aligned}$$

thus proving the lemma.

Conclusion of the Proof of Theorem 2. Since $F^{(\varepsilon,\delta)} \in C_\gamma^2(E)$ and $M_0 \in \mathfrak{M}^W \subset \mathcal{M}_A(t, x)$, we can apply the generalized Dynkin formula and by (5.5) and (5.9) obtain

$$\begin{aligned}F^{(\varepsilon,\delta)}(t, x) &= -\int_{[0,T]\times \mathcal{R}^n \times Y} AF^{(\varepsilon,\delta)} \, dM_0 \\ &\leqq \int_{[\delta, T-\delta]\times \mathbf{R}^n \times Y} f \, dM_0 + \delta \cdot \int_{[\delta, T-\delta]\times \mathbf{R}^n \times Y} \gamma \, dM_0 \\ &\quad + \|AF^{(\varepsilon,\delta)}\|_\gamma \cdot \int_{([0,\delta]\cup[T-\delta,T])\times \mathbf{R}^n \times Y} \gamma \, dM_0.\end{aligned}$$

Since $M_0 \in \mathfrak{M}^W \subset \mathcal{M}^{\gamma,\Gamma}$, we have $0 \leqq \int_S \gamma \, dM_0 \leqq \Gamma$. From Lemma 5.2 it follows that the integral in the last term is not greater than $2\delta \cdot \gamma(t, x) = 2\delta \cdot \alpha \cdot \Gamma$ and since by Lemma 5.1 $\|AF^{(\varepsilon,\delta)}\|_\gamma \leqq \|AF^{(\varepsilon)}\|_\gamma + \delta$, we have

$$F^{(\varepsilon,\delta)}(t, x) \leqq \int_S f \, dM_0 + \delta \cdot 2(1 + \alpha \|AF^{(\varepsilon)}\|_\gamma) \cdot \Gamma. \tag{5.10}$$

Choosing first ε then δ sufficiently small, from $\|F - F^{\varepsilon,\delta}\| \leqq \varepsilon + \delta$ and relation (5.10) it follows that

$$F(t, x) = \inf\left\{\int f \, dM^u : M^u \in \mathfrak{M}^S\right\} \leqq \int f \, dM_0$$

in contradiction to the choice (5.2) of f as a separating functional. This proves the equivalence of the strong and weak formulations.

Remark. Assumptions on the derivatives of $F^{(\varepsilon)}$ were only needed to obtain estimate (5.8). Note that since $F^{(\varepsilon)}$ is locally Lipschitzian, its first derivatives exist

almost everywhere and are locally bounded. This fact alone is sufficient to prove the equivalence of the Strong and Weak Problems provided the diffusion coefficients a_{ij} do not depend on t and x. In fact, in this case the terms $[a_{ij}(t+\sigma, x+\xi, y)-a_{ij}(t, x, y)]$ are zero and no assumptions on the second derivatives $F_{x_i x_j}$ are needed, shortcutting the approximation by $F^{(\varepsilon)}$ and the entire § 6.

COROLLARY 1. *Suppose that l is of at most linear growth, i.e., $|l(t, x, y)| \leqq r_0+r_1|x|+r_2 t$. If the processes are deterministic ($a_{ij} \equiv 0$) or the diffusion coefficients are independent of time and space, then the strong and weak problems are equivalent.*

Proof. If l is of linear growth, then γ can be chosen to be $\bar{r} \cdot (1+|x|+t)$ with $\bar{r} > \max(r_0, r_1, r_2)$. Consequently, f will be uniformly Lipschitzian and so will F. Moreover, F can be represented as the sum of a concave and of a smooth function, and hence the first and second partial derivatives of F exist almost everywhere and the first partials are uniformly bounded. The corollary then follows from the previous remark.

The measure M_0 introduced in the proof of Theorem 2 could not be in the w^* convex closure of $\mathfrak{M}^S(t_0, x_0)$. The argument there in fact proves the following corollary.

COROLLARY 2. *$\mathfrak{M}^W(t, x)$ is the w^* convex closure of $\mathfrak{M}^S(t, x)$.*

6. A Sobolev approximation of the value function. To complete the proof of the equivalence of the Strong and Weak Problems, it remains to show that the value function generated by a smooth running cost can be approximated by a $W_\infty^{1,2}$ function in the way required by the assumptions of Theorem 2. This kind of approximability of the value function that does not use any nondegeneracy assumptions is also of independent interest in other branches of control theory unrelated to the strong and weak formulations. This section is devoted to the proof of the result.

THEOREM 3. *Let $f \in C_\gamma^2(S)$ and let F be the corresponding value function defined by* (5.3). *Then for every $\varepsilon > 0$ there exists a function $F^{(\varepsilon)} \in C_\gamma(E)$ with the following properties*:

(a) $\|F-F^{(\varepsilon)}\|_\gamma \leqq \varepsilon$;

(b) *The partial derivatives $F_t^{(\varepsilon)}$, $F_{x_i}^{(\varepsilon)}$, $F_{x_i, x_j}^{(\varepsilon)}$ exist almost everywhere for every $1 \leqq i, j \leqq n$ and satisfying $|||F^{(\varepsilon)}|||_\gamma \leqq K(\varepsilon)$ with some constant $K(\varepsilon)$ where*

$$|||F^{(\varepsilon)}|||_\gamma := \|F^{(\varepsilon)}\|_\gamma + \|F_t^{(\varepsilon)}\|_\gamma + \sum_{i=1}^n \|F_{x_i}^{(\varepsilon)}\|_\gamma + \sum_{i=1}^n \|F_{x_i x_j}^{(\varepsilon)}\|_\gamma;$$

(c) $A^y F^{(\varepsilon)}(t, x)+f(t, x) \geqq 0$ *for almost every* $(t, x) \in E$, *for every* y, *and* $F^{(\varepsilon)}(T, x) = 0$ *whenever* $T < \infty$.

We denote the weighted Sobolev space of all functions satisfying (b) by $W_{\gamma,\infty}^{1,2}$.

The idea of the proof is to extend the control set of the original problem by one additional "smoothing control" giving rise to an n-dimensional Brownian motion. The value function of the extended problem will then have the required smoothness properties and, by charging a sufficiently high penalty for the "smoothing," its domain of application can be kept small and this way the smoothed value function can be forced to remain close to the original one.

To be more precise, let us introduce one more additional control η so that the extended control set will be $Y \cup \{\eta\}$. The process associated with η will be the standard n-dimensional Brownian motion discounted at the lowest possible rate $c_0 = \inf_{t,x,y} c(t, x, y)$ so that we have

$$E_{t,x}^\eta \Phi(x_{t+s}^\eta) = \frac{e^{-c_0 s}}{(2\pi s)^{n/2}} \int \Phi(t+s, \xi) \exp\left[-\frac{|\xi-x|^2}{2s}\right] d\xi =: (\beta_s * \Phi)(t, x).$$

The infinitesimal operator corresponding to the exponentially killed Brownian motion is

$$A^{\eta}\Phi = \tfrac{1}{2}\Delta\Phi - c_0\Phi$$

where Δ denotes the Laplacian. Recall that in Lemma 2.1 inequality (2.2) holds not only for the family of operators $\{A^{\gamma}\}_{\gamma\in Y}$ but with possibly different numbers α and $\bar{\alpha}$ also for the extended family $\{A^{\gamma}\}_{\gamma\in Y\cup\{\eta\}}$. In particular, we have $0<\alpha\gamma\leqq -A^{\eta}\gamma$.

During the period of time when the new control η is applied we charge the running cost

$$f(s,x,\eta) := L\cdot(-A^{\eta}\gamma)(s,x) = L\cdot(c_0\gamma(s,x)-\tfrac{1}{2}\Delta\gamma(s,x))$$

with some constant L to be determined later. For simplicity we only allow η to be applied during at most one nonrandom interval of time. In other words, the extended set $\mathcal{U}_{\eta}$ of admissible controls will be the set of all functions of the form

$$v(\omega,s)=\begin{cases}\eta & \text{if } t_1\leqq s<t_2,\\ u(\omega,s) & \text{otherwise,}\end{cases}$$

with all possible choices of $0\leqq t_1\leqq t_2\leqq T$ and $u\in\mathcal{U}$. Note that because of the possibility of killing, the processes may die before t_1 or t_2.

The value function of the extended problem can then be written as

$$\begin{aligned}F^{L}(t,x) &:= \inf_{v\in\mathcal{U}_{\eta}} E^{v}_{t,x}\int_t^T [f(s,x^{v}_s,v_s)1_{Y}(v_s)+L\cdot(-A^{\eta}\gamma)(s,x_s)1_{\{\eta\}}(v_s)]\,ds\\ &= \inf_{\substack{t\leqq t_1\leqq t_2\leqq T\\ u\in\mathcal{U}}} E^{u}_{t,x}\Bigg\{\int_t^{t_1} f(s,x^{u}_s,u_s)\,ds\\ &\qquad + E^{\eta}_{t_1,x^{u}_{t_1}}\Bigg[\int_{t_1}^{t_2} L\cdot(-A^{\eta}\gamma)(s,x^{\eta}_s)\,ds+F(t_2,x^{\eta}_{t_2})\Bigg]\Bigg\} \qquad (6.1)\\ &\leqq \inf_{\substack{t\leqq t_1\leqq t_2\leqq T\\ u\in\mathcal{U}}} E^{u}_{t,x}\Bigg\{\int_t^{t_1} f(s,x^{u}_s,u_s)\,ds+(\beta_{t_2-t_1}*F)(t_1,x^{u}_{t_1})\\ &\qquad + L\cdot(\gamma-\beta_{t_2-t_1}*\gamma)(t_1,x^{u}_{t_1})\Bigg\}.\end{aligned}$$

Now we show that setting the penalty L high will keep the optimal cost F^{L} close to F.

PROPOSITION 6.1. *For every $\varepsilon>0$ there exists a $0\leqq L_{\varepsilon}<\infty$ such that $\|F-F^{L_{\varepsilon}}\|_{\gamma}\leqq\varepsilon$.*

Proof. $F^{L}\leqq F$ is trivial since Φ^{L} is the value functional of the extended control problem that contains the original problem embedded, as $t_2=t_1$ is permitted.

To show that $F-F^{L_{\varepsilon}}\leqq\varepsilon\cdot\gamma$, observe that since F/γ is bounded and uniformly continuous there exists a t_{ε} such that $\|F/\gamma-\beta_h*(F/\gamma)\|\leqq\varepsilon/2$ for all $0\leqq h<t_{\varepsilon}$. With this t_{ε} let us choose $L_{\varepsilon}:=3\|f\|_{\gamma}/(\alpha\cdot t_{\varepsilon})$. Now let us consider an arbitrary $(t,x)\in E$. Since $F^{L_{\varepsilon}}$ is the pointwise infimum in (6.1), we can find an $\varepsilon/2$-optimal triple $\bar{u}$, $0\leqq\bar{t}_1\leqq\bar{t}_2$, i.e., such that

$$\begin{aligned}\bar{F}(t,x) &:= E^{\bar{u}}_{t,x}\Bigg\{\int_t^{\tau_1} f(\bar{x}_s,\bar{u}_s)+(\beta_h*F)(\bar{t}_1,\bar{x}_{\bar{t}_1})+L_{\varepsilon}\cdot E^{\beta}_{\bar{t}_1,\bar{x}_{\bar{t}_1}}\int_{\bar{t}_1}^{\bar{t}_2}(-A^{\eta}\gamma)(w_s)\,ds\Bigg\}\\ &\leqq F^{L_{\varepsilon}}(t,x)+\frac{\varepsilon}{2}\cdot\gamma(t,x).\end{aligned}$$

We use the notation $\bar{x}_s = x_s^{\bar{u}}$ and $h = \bar{t}_2 - \bar{t}_1$. Keep in mind that although $\bar{u}$, $\bar{t}_1$, $\bar{t}_2$ do depend on (t, x), the numbers t_ε and L_ε were chosen before (t, x) was picked, hence estimates involving only t_ε and L_ε will hold for every $(t, x) \in E$.

With the quantities just defined we can write

$$\begin{aligned} F(t,x) - F^{L_\varepsilon}(t,x) &= [F(t,x) - \bar{F}(t,x)] + [\bar{F}(t,x) - F^{L_\varepsilon}(t,x)] \\ &\leqq [F(t,x) - \bar{F}(t,x)] + \gamma(t,x) \cdot \varepsilon/2 \end{aligned} \tag{6.2}$$

and it remains to show that $F(t, x) - \bar{F}(t, x) \leqq \gamma(t, x) \cdot \varepsilon/2$.

We increase the value if we fix $\bar{u}$ for the initial interval $[t, \bar{t}_1)$ and allow minimization only after $\bar{t}_1$:

$$\begin{aligned} F(t,x) - \bar{F}(t,x) &\leqq E_{t,x}^{\bar{u}} \left\{ \int_t^{\bar{t}_1} f(s, \bar{x}_s, \bar{u}_s)\, ds + F(\bar{t}_1, \bar{x}_{\bar{t}_1}) \right\} - \bar{F}(t,x) \\ &= E_{t,x}^{\bar{u}} \{ ([F - \beta_h * F] - L_\varepsilon \cdot [\gamma - \beta_h * \gamma])(\bar{t}_1, \bar{x}_{\bar{t}_1}) \}. \end{aligned} \tag{6.3}$$

The expression in the first bracket under the expectation sign normalized by γ can be estimated at an arbitrary $(t^1, x^1) \in E$ as

$$\begin{aligned} \frac{1}{\gamma(t', x')} [F(t', x') - (\beta_h * F)(t', x')] &= \left(\frac{F}{\gamma} - \beta * \frac{F}{\gamma} \right)(t', x') + \left(\beta * \frac{F}{\gamma} - \frac{\beta * F}{\gamma} \right)(t', x') \\ &\leqq \left\| \frac{F}{\gamma} - \beta * \left(\frac{F}{\gamma} \right) \right\| + \|F\|_\gamma \cdot \left(1 - \frac{\beta_h * \gamma(t', x')}{\gamma(t', x')} \right). \end{aligned}$$

Consequently, if we divide the whole expression under the expectation in (6.3) by γ we obtain for it

$$\begin{aligned} \chi(t', x') &:= \frac{1}{\gamma(t', x')} \cdot ([F - \beta_h * F] - L_\varepsilon \cdot [\gamma - \beta_h * \gamma])(t', x') \\ &\leqq \left\| \frac{F}{\gamma} - \beta_h * \frac{F}{\gamma} \right\| - (L_\varepsilon - \|F\|_\gamma) \cdot \left(1 - \frac{\beta_h * \gamma(t', x')}{\gamma(t', x')} \right). \end{aligned} \tag{6.4}$$

Now there are two possibilities: either $h \leqq t_\varepsilon$ or $h > t_\varepsilon$. If $h \leqq t_\varepsilon$ then by the definition of t_ε we have $\|F/\gamma - \beta_h * (F/\gamma)\| \leqq \varepsilon/2$. Since $L_\varepsilon \geqq \|f\|_\gamma/\alpha \geqq \|F\|_\gamma$ and $\gamma \geqq \beta_h * \gamma$, the last term is nonnegative; we may subtract it and we get $\chi(t', x') \leqq \varepsilon/2$ for arbitrary $(t', x') \in E$.

On the other hand, if $h > t_\varepsilon$, then $1 - e^{-\alpha h} \geqq 1 - e^{\alpha t_\varepsilon}$; thus by Corollary 3 to Lemma 2.1 and the choice of L_ε, we have

$$(L_\varepsilon - \|F\|_\gamma) \cdot \left(1 - \frac{\beta_h * \gamma(t', x')}{\gamma(t', x')} \right) \geqq \frac{2\|f\|_\gamma}{\alpha(1 - e^{-\alpha t_\varepsilon})} \cdot (1 - e^{-\alpha h}) \geqq \frac{2\|f\|_\gamma}{\alpha} \geqq 2\|F\|_\gamma.$$

Since both F/γ and $\beta_h * (F/\gamma)$ are bounded by $\|F\|_\gamma$, from (6.4) we find that $\chi(t', x') \leqq 0 \leqq \varepsilon/2$ for every $(t', x') \in E$.

Substituting this result back in (6.3) we find by Corollary 3 to Lemma 2.1 that

$$F(t,x) - \bar{F}(t,x) \leqq E_{t,x}^{\bar{u}} \gamma(t_1, \bar{x}_{t_1}) \cdot \chi(t_1, \bar{x}_{t_1}) \leqq \frac{\varepsilon}{2} E_{t,x}^{\bar{u}} \gamma(t_1, \bar{x}_{t_1}) \leqq \frac{\varepsilon}{2} \cdot \gamma(t,x).$$

This, together with (6.2) gives $F - F^{L_\varepsilon} \leqq \varepsilon \cdot \gamma$, which completes the proof of the proposition.

It is well known (cf., e.g., [2, Thm. 4.2]) that under the conditions of Theorem 3 the value function F^L permits the decomposition $F^L = \tilde{F}^L + \hat{F}^L$ where $\tilde{F}^L \in C_\gamma$ is smooth, its partial derivatives $\tilde{F}^L_t$, $\tilde{F}^L_{x_i}$, $\tilde{F}^L_{x_i x_j}$ belong to C_γ while $\hat{F}^L \in C_\gamma$ is concave in x and monotone in t. In fact, for every control $J^u \in C^2_\gamma$, the infimum of continuously parametrized family of C^2_γ functions has the above decomposition property. For such functions the generalization of Alexandrov's Theorem [1] holds true; for almost every (t, x) the derivatives F^L_t, $F^L_{x_i}$, $F^L_{x_i x_j}$ exist and satisfy

$$\begin{aligned} F^L(t+\sigma, x+\xi) = F^L(t, x) + F^L_t(t, x)\cdot\sigma + \sum F^L_{x_i}(t, x)\xi_i \\ + \sum\sum F^L_{x_i x_j}(t, x)\xi_i\xi_j + o(|t|+|\xi|^2). \end{aligned} \tag{6.5}$$

It is easy to see that F^L satisfies the Hamilton-Jacobi-Bellman inequality of the extended problem almost everywhere. In fact, the next proposition is only a slight modification of known results (cf. [2], [3]) that we prove here only because the easy proof makes our exposition self-contained.

PROPOSITION 6.2. *For every* $y \in Y \cup \{\eta\}$,

$$A^y F^L(t, x) + f(t, x, y)\cdot 1_Y(y) + L\cdot(-A^y\gamma)(t, x)1_{\{\eta\}}(y) \geqq 0 \tag{6.6}$$

for almost every $(t, x) \in E$.

Proof. Suppose there exists a $y \in Y_0$ and a $(t_0, x_0) \in E$ from the nonexceptional set such that

$$A^{Y_0} F^L(t_0, x_0) + f(t_0, x_0, y_0) \leqq -\delta < 0.$$

Then, by the continuity of the underlying processes, there exists an $s_0 > 0$ such that for all $s \leqq s_0$

$$s^{-1}[E^{y_0}_{t_0, x_0} F^L(t_0 + s, x_s) - F^L(t_0, x_0)] + f(t_0, x_0, y_0) \leqq -\delta/2 < 0.$$

Let $u^\delta_\xi \in \mathcal{U}_\eta$ be a $\delta_{s_0}/3$-optimal control for the initial state $(t_0 + s_0, \xi)$ and define

$$u^0(\omega, r) := \begin{cases} y_0 & \text{if } t_0 \leqq r < t_0 + s_0, \\ u^\delta_\xi & \text{if } r \geqq t_0 + s_0 \text{ and } x_{t_0+s_0}(\omega) = \xi. \end{cases}$$

Then this control is again in $\mathcal{U}_\eta$ and will yield the cost

$$\begin{aligned} E^{u_0}_{t_0, x_0} \int_{t_0}^{\tau} f(s, x_s, u_0(s))\, ds &\leqq f(t_0, x_0, y_0)\cdot s_0 + E^{y_0}_{t_0, x_0}\{F^L(t_0 + s, x_{t_0+s_0}) + \delta_{s_0}/3\} \\ &\leqq F^L(t_0, x_0) - \delta_{s_0}/6 < 0 \end{aligned}$$

in contradiction to the definition of F^L as the infimum over all $u \in \mathcal{U}_\eta$. The proof for $y_0 = \eta$ is the same.

Conclusion of the Proof of Theorem 3. Let us choose $F^{(\varepsilon)} := F^{L_\varepsilon}$ according to Proposition 6.1. Then we have $\|F - F^{(\varepsilon)}\|_\gamma \leqq \varepsilon$. The derivatives $F^{(\varepsilon)}_t$, $F^{(\varepsilon)}_{x_i}$, $F^{(\varepsilon)}_{x_i, x_j}$ exist almost everywhere by Alexandrov's Theorem, and Proposition 6.2 shows that the Hamilton-Jacobi inequality holds true for every $y \in Y$ and for almost every $(t, x) \in E$. The smooth component $\tilde{F}^{(\varepsilon)}$ and its derivatives are in C_γ by Krylov's cited result [2, Thm. 4.2].

It remains to show that the derivatives of the concave component $\hat{F}^{(\varepsilon)}$ are essentially bounded by $K(\varepsilon)\cdot\gamma$.

Consider the first derivative in an arbitrary direction of the (t, x)-space. By the concavity of $\hat{F}^{(\varepsilon)}$ this directional derivative is monotone along each line parallel to the chosen direction. Suppose that this (one-dimensional) derivative function exceeds $K\cdot\gamma$ for every K. Then by its monotonicity it follows that neither can its integral

function be bounded by $K_1 \cdot \gamma$. But this contradicts $\hat{F}^{(\varepsilon)} \in C_\gamma$, which follows from Proposition 6.1. Hence there must be a $K_2(\varepsilon)$ such that $|\hat{F}_t^{(\varepsilon)}(t,x)| + \sum_{i=1}^n |\hat{F}_{x_i}^{(\varepsilon)}(t,x)| \leqq K_2(\varepsilon)\gamma(t,x)$ almost everywhere.

As for the second derivatives, $\hat{F}_{x_i,x_j}^{(\varepsilon)}(t,x) \leqq K_3(\varepsilon)$ follows from the concavity of $\hat{F}^{(\varepsilon)}$. To show that $|F_{x_i x_j}^{(\varepsilon)}| \leqq K(\varepsilon) \cdot \gamma$, consider inequality (6.6) of Proposition 6.2 for $y = \eta$. This claims that

$$F_t^{(\varepsilon)} + \tfrac{1}{2}\Delta F^{(\varepsilon)} - c_0 F^{(\varepsilon)} \geqq L_\varepsilon \cdot A^\eta \gamma \geqq L_\varepsilon \cdot \bar{\alpha} \cdot \gamma$$

where the last inequality follows from the right-hand side of (2.2). Using the estimates already obtained for $F^{(\varepsilon)}$, $F_t^{(\varepsilon)}$, $\tilde{F}_{x_i,x_j}^{(\varepsilon)}$ we get

$$\begin{aligned}\Delta \hat{F}^{(\varepsilon)}(t,x) &\geqq -2\left(c_0 \|F^{(\varepsilon)}\|_\gamma + \|F_t^{(\varepsilon)}\|_\gamma + \frac{1}{2}\sum_{ij=1}^n \|\tilde{F}_{x_i x_j}\|_\gamma + L_\varepsilon \bar{\alpha} \right) \cdot \gamma(t,x) \\ &= -K_4(\varepsilon)\gamma(t,x).\end{aligned}$$

This lower bound for the sum $\sum \hat{F}_{x_i x_j}^{(\varepsilon)}/\gamma$ together with the upper bound for the individual summands $\hat{F}_{x_i,x_j}^{(\varepsilon)}$ obtained from the concavity of $\hat{F}^{(\varepsilon)}$ implies that $\|F_{x_i,x_j}^{(\varepsilon)}\|_\gamma \leqq K(\varepsilon)$ for every $1 \leqq i, j \leqq n$. This completes the proof of Theorem 3.

7. Semicontinuous costs. In the previous paragraphs, in particular in §§ 3 and 4, we assumed the running cost to be continuous $l \in C_\gamma$. Now we are going to remove this assumption and allow l to be lower semicontinuous and of growth less than γ. More precisely we denote by LC_γ the set of all functions l satisfying the following:

(i) l is lower semicontinuous;

(ii) $\sup_{(\theta,y)\in\mathcal{S}} |l(\xi,y)|/\gamma(\xi) < \infty$;

(iii) $\limsup_{|\xi|\to\infty} l(\xi,y)/\gamma(\xi) = 0$.

Such functions can be represented as upper envelopes of continuous functions $l = \sup\{f : f \in C_\gamma, f \leqq l\}$ or even as limits of nondecreasing sequences of C_γ functions.

The aim of the present paragraph is to show that all results proved for continuous l in the preceding paragraphs remain true for control problems with lower semicontinuous cost functions $l \in LC_\gamma$. The key tool in approximating lower semicontinuous costs by continuous ones will be the following min-max type argument.

PROPOSITION 7.1. *Suppose $l \in LC_\gamma$ and let $\mathcal{K}$ denote an arbitrary w^*-compact subset of $\mathcal{M}_+^\gamma(\mathcal{S})$. Then*

$$\inf_{\mu\in\mathcal{K}} \int l\,d\mu = \inf_{\mu\in\mathcal{K}} \sup_{f\leqq l, f\in C_\gamma} \int f\,d\mu = \sup_{f\leqq l, f\in C_\gamma} \inf_{\mu\in\mathcal{K}} \int f\,d\mu. \tag{7.1}$$

Proof. Note first, that every $l \in LC_\gamma$ defines a convex, lower w^*-semicontinuous functional on $\mathcal{M}_+^\gamma$, and hence all infima in (7.1) are attained for some elements of the w^*-compact set $\mathcal{K}$.

The Monotone Convergence Theorem and the obvious inequality $\inf\sup \geqq \sup\inf$ yield

$$I_0 := \inf_{\mu\in\mathcal{K}} \int l\,d\mu = \inf_{\mu\in\mathcal{K}} \sup_{f\leqq l, f\in C_\gamma} \int f\,d\mu \geqq \sup_{f\leqq l, f\in C_\gamma} \inf_{\mu\in\mathcal{K}} \int f\,d\mu.$$

Let μ^f denote the measure, for which $\int f\,d\mu^f = \inf_{\mu\in\mathcal{K}} \int f\,d\mu$. To prove the proposition it is sufficient to show the existence of a $\mu^* \in \mathcal{K}$ for which

$$\sup_{f\leqq l, f\in C_\gamma} \int f\,d\mu^f \geqq \int l\,d\mu^* \tag{7.2}$$

holds true.

Let f_k denote a monotone nondecreasing sequence of continuous functions with $f_k \in C_\gamma(S)$ and $f_k \nearrow l$ as $k \to \infty$. Since $\mathcal{K}$ is sequentially compact, we can select a subsequence k_i such that $\mu_i := \mu^{f_{k_i}}$ converge weakly* to a limit $\mu^* \in \mathcal{K}$ as $i \to \infty$.

Let us consider the following array of reals:

$$I(i, j) := \int f_{k_i}\, d\mu_j, \qquad i, j = 1, 2, \cdots.$$

If $i' < i$ then $I(i', j) \leqq I(i, j)$ because the sequence f_{k_i} is monotone nondecreasing. The measure μ_i is by definition minimizing $\int f_{k_i}\, d\mu$ and as $f_{k_i} \leqq l$, we have

$$I(i, i) = \int f_{k_i}\, d\mu_i = \inf_{\mu \in \mathcal{K}} \int f_{k_i}\, d\mu \leqq \inf_{\mu \in \mathcal{K}} \int l\, d\mu = I_0.$$

Consequently all elements $I(i, j)$ with $i \leqq j$ (i.e., above the diagonal) are uniformly bounded by I_0. From the monotonicity of the sequence f_{k_i} it follows that the diagonal sequence $I(i, i)$ is monotone nondecreasing and so $I_\infty := \lim_{i \to \infty} I(i, i) \leqq I_0$ exists.

Since f_{k_i} is continuous and $\mu^* = w^* - \lim \mu_j$, it follows that the sequence $I(i, j)$ converges for any fixed i to a limit $I(i, \infty) = \int f_{k_i}\, d\mu^*$ as $j \to \infty$. From $I(i, j) \leqq I(j, j)$ for $i \leqq j$ it follows that

$$I(i, \infty) = \lim_{j \to \infty} I(i, j) \leqq \lim_{j \to \infty} I(j, j) = I_\infty.$$

Recall that the sequence f_k was chosen such that $f_k \nearrow l$. Consequently the monotone convergence theorem yields

$$I(i, \infty) = \int f_{k_i}\, d\mu^* \nearrow \int l\, d\mu^* \leqq I_\infty = \sup_{f \leqq l, f \in C_\gamma} \int f\, d\mu^f.$$

In other words μ^* satisfies (7.2) and the proof is complete.

THEOREM 4. *Suppose $l \in LC_\gamma$. Then the (strong) value function of the stochastic control problem formulated in §§ 1-2 is the upper envelope of the smooth subsolutions of the Hamilton-Jacobi-Bellman equation, i.e.,*

$$\Psi(t, x) = \sup \{\Phi(t, x) \colon \Phi \in C_\gamma^2,\ A\Phi + l \geqq 0\}. \tag{7.3}$$

Proof. It was shown in §§ 5-6 that $\mathfrak{M}^W$ is the closed convex hull of $\mathfrak{M}^S$. Since $\int l\, dM$ is a convex, lower w^*-semicontinuous functional on $\mathcal{M}_\pm^\gamma$ whenever $l \in LC_\gamma$, it follows that its infimum over $\mathfrak{M}^S$ is the same as its minimum attained in $\mathfrak{M}^W$. Consequently the strong and weak value functions coincide even if l is only lower semicontinuous $l \in LC_\gamma$.

We know from Theorem 1 that the value function permits representation (7.3) if l is continuous ($l \in C_\gamma$). Proposition 7.1 can be applied to $l \in LC_\gamma$ and $\mathcal{K} = \mathfrak{M}^W$ as $\mathfrak{M}^W$ is a w^*-compact set and we obtain

$$\begin{aligned}\Psi(t, x) &= \inf_{M \in \mathfrak{M}^W(t,x)} \int l\, dM = \sup_{f \leqq l, f \in C_\gamma} \inf_{M \in \mathfrak{M}^W} \int f\, dM \\ &= \sup_{f \leqq l, f \in C_\gamma} \sup \{\Phi(t, x) \colon \Phi \in C_\gamma^2(E),\ A\Phi + f \geqq 0\} \\ &\leqq \sup \{\Phi(t, x) \colon \Phi \in C_\gamma^2,\ A\Phi + l \geqq 0\}.\end{aligned}$$

The opposite inequality is immediate, since for every $\Phi \in C_\gamma^2$ with $A\Phi + l \geqq 0$ and for every $M \in \mathfrak{M}^W = \mathcal{M}_\gamma^\Gamma \cap \mathcal{M}_A$ Dynkin's formula yields

$$\Phi(t, x) = \int (-A\Phi)\, dM \leqq \int l\, dM.$$

Taking infimum over $M \in \mathfrak{M}^W$, we obtain $\Phi(t, x) \leqq \inf_{M \in \mathfrak{M}^W} \int l\, dM = \psi(t, x)$ for every $\Phi \in C_\gamma^2$ with $A\Phi + l \geqq 0$, which completes the proof of the theorem.

8. Inclusion of terminal penalties. In this final paragraph we explain how to extend the main results of the paper to problems where the cost function also includes an additional terminal penalty, i.e., where the objective is to minimize the functional

$$J^u(t, x) = E_{t,x}^u \left\{ \int_t^T l(t, x_t, m_t)\, dt + L(x_T) \right\} \qquad (T < \infty) \tag{8.1}$$

over all controls $u \in \mathcal{U}$. Here both l and L are lower semicontinuous functions of growth less than γ at infinity. This will extend the scope of the results to include problems like the maximization of the hitting probability of a closed target set or the fixed endpoint problem of deterministic control theory that were beyond the reaches of the other approaches to the Hamilton–Jacobi theory.

The key to the extension is to consider a more elaborate state space $\tilde{S}$ that is composed of S_0, the compactification of the "interior" of the state-space, and of S_∂, the compactified "terminal boundary," as two separate components. More precisely, let $\tilde{S}$ denote the compact metric space that consists of the two isolated subsets $S_0 := E \times Y$ and $S_\partial := \bar{\mathbf{R}}^n$. Note that S_0 is the same space that was denoted by S in § 2.

Every continuous function $\Phi \in C_\gamma(\tilde{S})$ will then correspond to the pair $\Phi|_{S_0} \in C_\gamma(S_0)$ and $\Phi|_{S_\partial} \in C_\gamma(S_\partial)$ where $C_\gamma(S_0)$ is $C_\gamma(S)$ of § 2 and

$$C_\gamma(S_\partial) := \left\{ \phi \in C(\mathbf{R}^n) \colon \sup_{x \in \mathbf{R}^n} |\phi(x)|/\gamma(T, x) < \infty \quad \text{and} \quad \lim_{|x| \to \infty} |\phi(x)|/\gamma(T, x) = 0 \right\}.$$

$LC_\gamma(\tilde{S})$ will denote the set of all lower semicontinuous functions on $\tilde{S}$, i.e., those that can be represented as upper envelopes of families of $C_\gamma(\tilde{S})$ functions. The dual space to $C_\gamma(\tilde{S})$ will be the set $\mathcal{M}_\pm^\gamma(\tilde{S})$ of all pairs of measures $M = (M_0, M_\partial)$ with $M_0 \in \mathcal{M}_\pm^\gamma(S_0)$, $M_\partial \in \mathcal{M}_\pm^\gamma(S_\partial)$ provided with the norm $\|M\|_\gamma = \int \gamma(t', x') |M_0(dt', dx', dy)| + \int \gamma(T, x) |M_\partial(dx)|$. The set of all nonnegative measures $M \in \mathcal{M}_\pm^\gamma(\tilde{S})$ with $\|M\|_\gamma \leqq \Gamma < +\infty$ will be denoted by $\mathcal{M}_\pm^{\gamma,\Gamma}(\tilde{S})$.

Observe that the function

$$\tilde{l}(\sigma) := \begin{cases} l(\tau, \xi, y) & \text{if } \sigma = (\tau, \xi, y) \in S_0, \\ L(x) & \text{if } \sigma = x \in S_\partial \end{cases}$$

is in $LC_\gamma(\tilde{S})$. The measure $\tilde{M}^u$ defined on the Borel sets B of $\tilde{S}$ by

$$\tilde{M}^u(B) := \begin{cases} M^u(B) & \text{of (2.1) if } B \subset S_0, \\ P_{t,x}^u(x_T^u \in B) & \text{if } B \subset S_\partial \end{cases}$$

is in $\mathcal{M}^{\gamma, 1+T}(\tilde{S}) \subset \mathcal{M}_\pm^\gamma(\tilde{S})$. With this notation the (strong) optimal control problem with both running and terminal costs can be formulated as follows:

$$\text{Minimize} \int \tilde{l}\, d\tilde{M}^u \quad \text{over all } u \in \mathcal{U}. \tag{8.2}$$

Let $C_\gamma^2(\tilde{E})$ denote the set of all twice continuously differentiable functions Φ defined on $[0, T) \times \mathbf{R}^n$ for which Φ, Φ_t, Φ_{x_i}, $\Phi_{x_i x_j}$ are all in $C_\gamma(E)$ $(i, j = 1, 2, \cdots, n)$. The difference to the definition of $C_\gamma^2(E)$ in § 2 is that now we do not require functions to vanish on the exit boundary $[T] \times \mathbf{R}^n$ for $T < \infty$. Recall that for every $\Phi \in C_\gamma^2(\tilde{E})$ Dynkin's formula

$$E_{t,x}^u \Phi(T, x_T) - \Phi(t, x) = E_{t,x}^u \int_0^T A^{u_s} \Phi(s, x_s)\, ds \tag{8.3}$$

holds true. If we introduce the operator $\tilde{A}$: $C_\gamma^2(\tilde{E}) \to C_\gamma(\tilde{S})$ by

$$\tilde{A}\Phi(\sigma) = \begin{cases} A^y\Phi(t, x) & \text{if } \sigma = (t, x, y) \in S_0, \\ -\Phi(T, x) & \text{if } \sigma = x \in S_\sigma, \end{cases}$$

then with the above notation Dynkin's formula can be written in the more compact form

$$-\Phi(t, x) = \int_{\tilde{S}} \tilde{A}\Phi \, d\tilde{M}^u. \tag{8.4}$$

The Weak Problem corresponding to (8.2) can be formulated as follows:

$$\text{Minimize} \int \tilde{l} \, d\tilde{M} \quad \text{over all } \tilde{M} \in \mathcal{M}^{\gamma, 1+T}(\tilde{S}) \cap \mathcal{M}_{\tilde{A}}(t, x)$$

with $\mathcal{M}_{\tilde{A}}(t, x) := \{\tilde{M} \in \mathcal{M}_+^\gamma(\tilde{S})$: for which (8.4) holds for all $\Phi \in C_\gamma^2(\tilde{E})\}$.

All the expositions of §§ 3–7 can be repeated word by word for this extended notation and we obtain the following theorem.

THEOREM 5. *The dual to the problem* (8.2) *is to find the supremum of all smooth subsolutions of the Hamilton–Jacobi–Bellman equation, and we have*

$$\psi(t, x) = \inf_{u \in \mathcal{U}} E_{t,x}^u \left\{ \int_t^T l(s, x_s, u_s) \, ds + L(x_T) \right\}$$

$$= \sup \Big\{ \Phi(t, x) \text{ over all } \Phi \in C_\gamma^2(\tilde{E}) \text{ satisfying}$$

$$\inf_{y \in Y} A^y\Phi(\tau, \xi) + l(\tau, \xi, y) \geqq 0 \text{ if } 0 < \tau < T, \xi \in \mathbf{R}^n$$

$$\text{and } \Phi(T, \xi) \leqq L(\xi) \quad \xi \in \mathbf{R}^n \Big\}.$$

PIECEWISE MONOTONE FILTERING WITH SMALL OBSERVATION NOISE*

W. H. FLEMING† AND E. PARDOUX‡

This paper is dedicated to the memory of E. J. McShane.

Abstract. Nonlinear filtering of Markov diffusion processes is considered, in the case in which a piecewise monotone function of the state is observed with additive small observation noise. Under a certain detectability hypothesis, statistical tests are given to discriminate among the intervals of monotonicity during time intervals in which the state does not cross critical points of the observation function. During such time intervals, accurate approximate finite dimensional filters can be used.

Key words. nonlinear filtering, small noise, approximate finite-dimensional filters

AMS(MOS) subject classification. 93E11

1. Introduction.

There is substantial literature on the nonlinear filter model

$$\begin{aligned} dx_t &= f(x_t)\,dt + g(x_t)\,dw_t, \\ dy_t^\varepsilon &= h(x_t)\,dt + \varepsilon\,dv_t, \qquad t \geqq 0 \end{aligned} \tag{1.1}$$

where $x_t \in \mathfrak{R}^n$, $y_t \in \mathfrak{R}^l$ and w_t, v_t are independent standard Brownian motions. The random variable x_0 has distribution μ_0 and $y_0 = 0$. Finding the mean square optimal estimate $\hat{x}_t$ for x_t given $\sigma\{y_s^\varepsilon, 0 \leqq s \leqq t\}$ requires solving the nonlinear filter problem to find the conditional distribution μ_t. The dynamics of μ_t are described by the nonlinear filter equation, or by some partial differential equation equivalent to it (e.g., Zakai or pathwise filter equations [2], [7]). Thus, the nonlinear filtering problem is inherently infinite-dimensional. There are exact finite-dimensional filters only for the well-known linear case (Kalman–Bucy) and for a few special nonlinear problems (see [5] and [11]). Suppose that $\varepsilon > 0$ is small. An attractive alternative to trying to solve the nonlinear filter problem is to seek a good approximation m_t to $\hat{x}_t$, such that m_t is computable from the solution to a finite-dimensional system of stochastic differential equations driven by the observation process y_t. Moreover, we would like the number of stochastic differential equations describing the approximate filter to be small if n and l are small. There are a number of results concerning the case $n = l$ and $h(x)$ one-to-one. In this case x_t is observed exactly if $\varepsilon = 0$. For small $\varepsilon > 0$ we expect the conditional distribution μ_t to be mostly concentrated near x_t. Under some additional technical assumptions this has been shown to be correct, and good approximate filters of dimension n or $n + n^2$ have been found (see [6], [8a], [8b], and [12]–[14]). For $n = l = 1$, the simplest one-dimensional approximation m_t to $\hat{x}_t$ satisfies

$$dm_t = f(m_t)\,dt + \varepsilon^{-1}[\operatorname{sgn} h'(m_t)]g(m_t)[dy_t^\varepsilon - h(m_t)\,dt], \tag{1.2}$$

with $m_0 = Ex_0$. For $t \geqq t_0 > 0$ this gives $m_t = \hat{x}_t + O(\varepsilon)$. Certain two-dimensional approximations (m_t, R_t), where R_t is some approximation to the conditional variance, give

$m_t = \hat{x}_t + O(\varepsilon^{3/2})$. The accuracy is better in case $g(x)$ is constant and $h(x)$ is linear (see Picard [12, p. 1100]).

If h is not one-to-one there are substantial additional difficulties. For small $\varepsilon > 0$, $h(x_t)$ can be estimated accurately but not in general x_t itself. Moreover, when $l < n$ there are typically multiple timescales in the filtering equations (see [9] and [16]). However, when $l = n$, it often happens that enough information is contained in measurements of $h(x_t)$ plus low-intensity white noise to accurately estimate x_t, even though h is not one-to-one. It is this question with which this paper is concerned. For simplicity we consider scalar state x_t and observation $y_t (n = l = 1)$. Extensions to $n = l > 1$ are indicated in § 8. We suppose that $h(x)$ has a finite number of critical points, located at $x_1^*, \cdots, x_k^*$, with

$$h'(x_i^*) = 0, \quad h''(x_i^*) \neq 0, \quad i = 1, \cdots, k.$$

The conditional distribution μ_t may then have several peaks, located in $(-\infty, x_1^*)$, (x_k^*, ∞) and in intervals (x_i^*, x_{i+1}^*) between successive critical points. This possibility cannot always be avoided. For example, if $x_t = w_t$ and $h(-x) = h(x)$, then μ_t is symmetric about zero. However, in many instances a hypothesis test can be performed that determines, with probability very nearly one, that x_t lies in an interval of monotonicity of h. Once this is known, either an approximate filter of type (1.2) or a more accurate two-dimensional version of it can be used to estimate $\hat{x}_t$. A similar technique is used in [3] when $h(x)$ is piecewise linear and $g(x)$ is constant.

To simplify the exposition, in most of the paper the case when $h(x)$ has a single critical point ($k = 1$) is considered. Extensions of the results to $k > 1$ are discussed in § 8. Our work appears to be related to a modification of the extended Kalman filter technique to allow for Gaussian sum approximations to conditional densities that may have multiple peaks [1, § 8.4]. We shall show that under a certain "detectability" hypothesis (see (2.1), (5.10) or (8.1)) below, multiple peaks of the conditional density are improbable during time intervals in which x_t remains away from the set of critical points x_i^* of h. During such time intervals, an approximate filter of the type valid for monotone h can be used (for example, a filter of type (1.2)). Precise versions of these rough statements appear in the following sections.

The paper is organized as follows. We take the single critical point of h to be a global minimum at $x = 0$ with $h(0) = 0$. After some introductory material in §§ 2 and 3, two possible approximations m_t^+ and m_t^- to the conditional mean $\hat{x}_t$ are introduced in § 4. These satisfy equations such as (1.2) in which h is replaced by certain functions h_+ and h_-, respectively. These functions have the property that $h(x) = h_+(x)$ on a "large" interval of $\{x > 0\}$ and $h(x) = h_-(x)$ on a "large" interval of $\{x < 0\}$. Lemma 4.1 provides a test to guarantee that x_t does not cross zero during a finite time interval $a \leqq t \leqq b$, with exponentially small probability of error. Next, a test based on quadratic variations is given in § 5, to decide whether $x_t > 0$ on $[a, b]$ or $x_t < 0$ on $[a, b]$. A second test to decide between these two alternatives, based on likelihood ratios, is given in § 6. If the positive alternative is chosen then m_t^+ is used as an approximation to $\hat{x}_t$; and m_t^- is used if the negative alternative is chosen. Estimates for the error $\hat{x}_t - m_t^{\pm}$ are given in § 7. Finally, in § 8 extensions to multiple critical points of h and to dimension $n = l > 1$ are considered.

2. Assumptions: problem formulation. The following assumptions are made about the functions f, g, h in (1.1).

(A1) f, g, h are smooth with $g(x) > 0$. Moreover, f', g, g', g^{-1}, h', h'' are bounded on $-\infty < x < \infty$.

(A2) h has a single critical point, located at $x=0$, with $0=h(0)=h'(0)$ and $h(x)>0$ for $x\neq 0$. Moreover, $|h(x)|\to\infty$ as $|x|\to\infty$.

(A3) There exist y_1, y_2 with $0<y_1<y_2$ and $c>0$ such that

(2.1) $h(x^-)=h(x^+)=y$, $y_1\leqq y\leqq y_2$, and $x^-<0<x^+$ imply

$$|[g(x^-)h'(x^-)]^2-[g(x^+)h^-(x^+)]^2|>c.$$

Assumptions (A1) and (A2) imply that $\operatorname{sgn} h'(x)=\operatorname{sgn} x$, and that $\inf\{|h'(x)|: x\in K\}>0$ for any compact set $K\subset\Re^1-\{0\}$. Roughly speaking, the "detectability" condition (2.1) will be needed to distinguish whether $x_t>0$ or $x_t<0$ after observing y_s over a time interval during which no zero crossing of x_s has been detected. A sufficient condition for (2.1) is that $\psi'(x)\neq 0$ in some open interval containing $x=0$, where

$$\psi(x)=\frac{[g(x)h'(x)]^2}{h(x)}.$$

If $g(x)=$ constant, this sufficient condition holds provided $h''(x)>0$ and $h'''(0)\neq 0$. In [3] the case in which $h(x)$ is piecewise linear and $g(x)=$ constant is considered. In that case (2.1) is equivalent to the property that $h(-x)\neq h(x)$ for $x\neq 0$. The need for some condition like (2.1) is illustrated by the simple example $x_t=w_t$. If $h(-x)=h(x)$ for all x, the conditional distribution is always symmetric about $x=0$.

We formulate the nonlinear filter problem on the canonical sample space $\Omega=C(\Re_+)\times C(\Re_+)$, whose sample elements are denoted by (ω_1,ω_2) with $x_t(\omega)=\omega_1(t)$, $y_t(\omega)=\omega_2(t)$. Let $\mathcal{F}$ be the Borel field of Ω and P^ε a probability measure on $(\Omega,\mathcal{F})$ such that

$$x_t=x_0+\int_0^t f(x_s)\,ds+\int_0^t g(x_s)\,dw_s, \tag{2.2}$$

$$y_t=\frac{1}{\varepsilon}\int_0^t h(x_s)\,ds+v_t^\varepsilon \tag{2.3}$$

where w_t and v_t^ε are two mutually independent Brownian motions. The random variable x_0 is independent of $\{w_t, v_t^\varepsilon;\ t\geqq 0\}$ and for some $k>0$

$$E^\varepsilon[\exp(kx_0^2)]<\infty. \tag{2.4}$$

Note that y_t has the role of $\varepsilon^{-1}y_t^\varepsilon$ in (1.1). It is well known that P^ε exists and is unique (see, e.g., Stroock and Varadhan [17]). We define $\mathcal{Y}_t=\sigma\{y_s;\ 0\leqq s\leqq t\}$. The nonlinear filter problem is to find the conditional distribution μ_t of x_t given $\mathcal{Y}_t$. Our aim is to obtain an asymptotic result, as $\varepsilon\to 0$, concerning a finite-dimensional approximation to the nonlinear filter.

3. Approximations to $h(x_t)$. Let H be smooth for $-\infty<x<\infty$, with

$$0<c_1\leqq H'(x)\leqq c_2 \text{ and } H''(x) \text{ bounded}. \tag{3.1}$$

(In § 4 we shall take $H=h_+$, where h_+ is defined there.) Let m_t be the solution of

$$dm_t=f(m_t)\,dt+g(m_t)(dy_t-\varepsilon^{-1}H(m_t)\,dt) \tag{3.2}$$

with $m_0=E(x_0)$. Note that (3.2) has the same form as (1.2), except that h is replaced by H (recall that $H'(x)>0$ by (3.1)).

LEMMA 3.1. *Let* $0<a<b$. *Then for every* $\alpha>0$ *there exist positive* $\varepsilon_0=\varepsilon_0(\alpha)$, $K=K(\alpha)$, *such that*

$$P^\varepsilon\left(\sup_{[a,b]}|h(x_t)-H(m_t)|>\alpha\right)\leqq\exp\left(-\frac{K}{\varepsilon}\right),\qquad 0<\varepsilon<\varepsilon_0.$$

Proof. Let

$$L\phi=f(x)\phi'+\tfrac{1}{2}g^2(x)\phi'',$$

the generator of the Markov diffusion x_t. The Itô differential rule and (1.1), (3.2) imply

$$h(x_t)=h(x_0)+\int_0^t Lh(x_s)\,ds+\int_0^t (gh')(x_s)\,dw_s, \tag{3.3}$$

$$H(m_t)=H(m_0)+\int_0^t LH(m_s)\,ds+\int_0^t (gH')(m_s)(dy_s-\varepsilon^{-1}H(m_s))\,ds.$$

Let

$$z_t=h(x_t)-H(m_t),\qquad \rho_t=(gH')(m_t),$$
$$\zeta_t=Lh(x_t)-Lh(m_t),\qquad B_t=(w_t,v_t^\varepsilon),$$
$$\psi_t=((gh')(x_t),-(gH')(m_t)).$$

From (A1) and (3.1), $\rho_t\geqq\beta>0$. From (3.3) and (1.1)

$$z_t=z_0-\frac{1}{\varepsilon}\int_0^t\rho_s z_s\,ds+\int_0^t\zeta_s\,ds+\int_0^t\psi_s\cdot dB_s.$$

We write $z_t=z_t^{(1)}+z_t^{(2)}+z_t^{(3)}$, where

$$z_t^{(1)}=z_0\exp\left[-\frac{1}{\varepsilon}\int_0^t\rho_s\,ds\right],$$

$$z_t^{(2)}=\int_0^t\exp\left[-\frac{1}{\varepsilon}\int_s^t\rho_u\,du\right]\zeta_s\,ds,$$

$$z_t^{(3)}=\int_0^t\exp\left[-\frac{1}{\varepsilon}\int_s^t\rho_u\,du\right]\psi_s\cdot dB_s.$$

Then

$$|z_1^{(1)}|\leqq|z_0|\exp\left(-\frac{\beta t}{\varepsilon}\right),$$

$$P^\varepsilon\left(\sup_{[a,b]}|z_t^{(1)}|>\frac{\alpha}{3}\right)\leqq P^\varepsilon\left(|z_0|\geqq\frac{\alpha}{3}\exp\left(\frac{\beta a}{\varepsilon}\right)\right)\leqq\exp\left(-\frac{K_1}{\varepsilon}\right) \tag{3.4}$$

for $0<\varepsilon<\varepsilon_1(\alpha)$, using (2.4) and the Bienaymé-Chebyshev inequality. By the assumptions (A1) on f and g in § 2, there exists $k>0$ such that

$$E\exp(k\|\zeta\|_b)<\infty$$

where $\|\zeta\|_t=\sup_{[0,t]}|\zeta_s|$. Then

$$|z_t^{(2)}|\leqq\|\zeta\|_t\int_0^t\exp\left[-\frac{\beta(t-s)}{t}\right]ds.\qquad \|z^{(2)}\|_b\leqq\frac{\varepsilon}{\beta}\|\zeta\|_b,$$

$$P^\varepsilon\left(\|z^{(2)}\|_b>\frac{\alpha}{3}\right)\leqq P^\varepsilon\left(k\|\zeta\|_b>\frac{k\beta\alpha}{3\varepsilon}\right)\leqq\exp\left(-\frac{K_2}{\varepsilon}\right), \tag{3.5}$$

for $0<\varepsilon<\varepsilon_2(\alpha)$.

It remains to estimate $\|z^{(3)}\|_b$. Now $z_t^{(3)}$ satisfies the linear stochastic differential equation

$$dz_t^{(3)} = -\frac{1}{\varepsilon}\rho_t z_t^{(3)}\,dt + \psi_t \cdot dB_t, \qquad \rho_t \geqq \beta > 0$$

with $z_0^{(3)} = 0$. Moreover, by assumptions (A1) $|\psi_t|^2 \leqq k < \infty$. Define the linear operators L_t by

$$L_t F(z) = -\frac{1}{\varepsilon}\rho_t z F'(z) + \frac{1}{2}|\psi_t|^2 F''(z).$$

Let

$$F(z) = \exp\left(\frac{1}{2}\lambda z^2\right), \qquad \lambda = \frac{\beta}{k\varepsilon}.$$

Then

$$L_t F(z) = \left[\frac{1}{2}|\psi_t|^2(\lambda^2 z^2 + \lambda) - \frac{1}{\varepsilon}\lambda\rho_t z^2\right]F(z),$$

$$L_t F + \lambda F = \frac{1}{2}\lambda\left[2 + |\psi_t|^2 + \left(\lambda|\psi_t|^2 - \frac{2\rho_t}{\varepsilon}\right)z^2\right]F,$$

$$2 + |\psi_t|^2 + \left(\lambda|\psi_t|^2 - \frac{2\rho_t}{\varepsilon}\right)z^2 \leqq 2 + k - \frac{\beta}{\varepsilon}z^2,$$

since $\rho_t \geqq \beta$ and $\lambda k = \beta\varepsilon^{-1}$. Thus

$$L_t F + \lambda F \leqq 0 \quad \text{if } z^2 \geqq \frac{\varepsilon(2+k)}{\beta},$$

which implies

$$L_t F + \lambda F \leqq \frac{\lambda}{2}\max\left\{(2 + k + \lambda k z^2)F(z) : |z|^2 \leqq \frac{\varepsilon(2+k)}{\beta}\right\},$$

$$L_t F \leqq -\lambda F + N\lambda, \qquad N = \left(1 + \frac{k}{2}\right)\left(1 + \exp\left(\frac{2+k}{2k}\right)\right).$$

Following Kushner [10, pp. 79-80], for $0 \leqq t \leqq b$ let

$$W(z, t) = e^{\rho t}F(z) + \theta(e^{\rho b} - e^{\rho t})$$

where ρ and θ are to be chosen. Then

$$\frac{\partial W}{\partial t} + L_t W = e^{\rho t}[\rho F + L_t F - \theta\rho]$$

$$\leqq e^{\rho t}[(\rho - \lambda)F + N\lambda - \theta\rho].$$

We choose $\rho = \lambda^{1/2}$, $\theta = N\lambda^{1/2}$. Then for $\lambda \geqq 1$, $W(z_t^{(3)}, t)$ is a nonnegative supermartingale. Hence, for any $d > 0$

$$P^{\varepsilon}\left(\sup_{[0,b]} W(z_t^{(3)}, t) \geqq d\right) \leqq \frac{F(z_0) + \theta(e^{\rho b} - 1)}{\alpha}.$$

Since

$$\exp\left(\frac{1}{2}\lambda z^2\right) \leqq W(z, t) \quad \text{for } 0 \leqq t \leqq b \text{ and } F(z_0) = 1,$$

$$|z^{(3)}\|_b > \frac{\alpha}{3} \Rightarrow \sup_{[0,b]} W(z_t^{(3)}, t) \geqq \exp\left(\frac{\lambda\alpha^2}{18}\right),$$

$$P^\varepsilon\left(\|z^{(3)}\|_b > \frac{\alpha}{3}\right) \leqq \exp\left(-\frac{\lambda\alpha^2}{18}\right)[(1 + N\lambda^{1/2}b)\exp(\lambda^{1/2}b)].$$

Since $\lambda = \beta(k\varepsilon)^{-1}$ there exist K_3 and ε_3 such that

$$P^\varepsilon\left(\|z^{(3)}\|_b > \frac{\alpha}{3}\right) \leqq \exp\left(-\frac{K_3}{\varepsilon}\right), \qquad 0 < \varepsilon < \varepsilon_3. \tag{3.6}$$

From (3.4)-(3.6) we get Lemma 3.1.

4. Two possible approximate filters. We now define m_t^+ and m_t^- that satisfy equations like (1.2). A test will be given to determine whether x_t is positive and bounded away from zero on some time interval, with probability nearly one. When this test is positive, then m_t^+ will be used as an approximation to $\hat{x}_t$. Similarly, m_t^- will be used as an approximation to $\hat{x}_t$ when a corresponding test for negativity of x_t applies.

We first choose $\delta > 0$ such that

$$h(x) \geqq y_1 \quad \text{implies } |x| \geqq 2\delta \tag{4.1}$$

with $y_1 > 0$ as in (A3).

We also choose $y_3 > y_2$ and $r > 0$ (y_1 and y_2 are as in (A3)). Let

$$\bar{y}_1 = \sup_{|x| \leqq \delta} h(x), \qquad \bar{y}_3 = \inf_{|x| \geqq r} h(x).$$

By (A2), $\bar{y}_1 < y_1$ and $\bar{y}_3 > y_3$, provided we choose r large enough. The numbers y_3 and r may be regarded as large cutoffs for $h(x)$ and $|x|$, respectively. They will play a role only in § 7. In earlier sections, we can take $r = y_3 = \infty$.

We choose $h_+(x)$ and $h_-(x)$ such that

$$\begin{aligned} &h_+(x) = h(x) \quad \text{if } \delta \leqq x \leqq r, \\ &h_-(x) = h(x) \quad \text{if } -r \leqq x \leqq -\delta, \\ &c_1 \leqq h'_-(x) \leqq c_2, \qquad c_1 \leqq -h'_-(x) \leqq c_2 \end{aligned} \tag{4.2}$$

for all x, where $0 < c_1 < c_2$ and $h''_\pm(x)$ is bounded and continuous. Consider the following processes m_t^+, m_t^- for $t \geqq 0$:

$$dm_t^+ = f(m_t^+)\,dt + g(m_t^+)\left(dy_t - \frac{1}{\varepsilon}h_+(m_t^+)\,dt\right), \tag{4.3}$$

$$dm_t^- = f(m_t^-)\,dt - g(m_t^-)\left(dy_t - \frac{1}{\varepsilon}h(m_t^-)\,dt\right) \tag{4.4}$$

with initial data $m_0^\pm = E^\varepsilon(x_0)$. Note that $m_t^\pm$ depend on ε. Equations (4.3) and (4.4) are like (1.2) with h replaced by h_+ and h_-, respectively.

Lemma 3.1 provides a convenient test to determine whether x_t remains in one of the two intervals $[-r, -\delta]$ or $[\delta, r]$ during a time interval $[a, b]$. Define $B^{\pm} = B^{\pm}(a, b)$ and $C_\varepsilon^0 = C_\varepsilon^0(a, b)$ by

$$\begin{aligned} B^+ &= \{\delta \leqq x_t \leqq r \text{ for } a \leqq t \leqq b\}, \\ B^- &= \{-r \leqq x_t \leqq -\delta \text{ for } a \leqq t \leqq b\}, \\ C_\varepsilon^0 &= \{y_1 \leqq h_+(m_t^+) \leqq y_3 \text{ for } a \leqq t \leqq b\}. \end{aligned} \tag{4.5}$$

In Lemma 3.1 we now take $H = h_+$, $m_t = m_t^+$ and $\alpha < \min(y_1 - \bar{y}, \bar{y}_3 - y_3)$.

LEMMA 4.1. *Let $0 < a < b$. Then there exist positive ε_0 and K such that*

$$P^\varepsilon[(B^+ \cup B^-)^c \cap C_\varepsilon^0] \leqq \exp\left(-\frac{K}{\varepsilon}\right), \qquad 0 < \varepsilon < \varepsilon_0. \tag{4.6}$$

On B^+, $h_+(x_t) = h(x_t)$ for $a \leqq t \leqq b$. Since $h_+' \geqq c_1 > 0$ we also have from Lemma 3.1 the following. Given $\gamma > 0$ there exist ε_0 and K such that

$$P^\varepsilon\left(B^+ \cap \left\{\sup_{[a,b]} |x_t - m_t^+| > \delta\right\}\right) \leq \exp\left(-\frac{K}{\varepsilon}\right), \qquad 0 < \varepsilon < \varepsilon_0. \tag{4.7}$$

If we take α small enough in Lemma 3.1, then

$$P^\varepsilon(C_\varepsilon^0) \geqq P^\varepsilon(y_1 + \alpha \leqq h(x_t) \leqq y_3 - \alpha,\ a \leqq t \leqq b) - \exp\left(-\frac{K}{\varepsilon}\right).$$

Hence,

$$\liminf_{\varepsilon \to 0} P^\varepsilon(C_\varepsilon^0) > 0, \tag{4.8}$$

which implies an estimate like (4.6) for the conditional probability

$$P^\varepsilon[(B^+ \cup B^-)^c \,|\, C_\varepsilon^0].$$

5. Quadratic variation test. Next we let

$$C_\varepsilon = \{y_1 \leqq h_+(m_t^+) \leqq y_2 \text{ for } a \leqq t \leqq b\} \tag{5.1}$$

where y_1 and y_2 are as in (A3). Since $C_\varepsilon \subset C_\varepsilon^0$ we know from Lemma 4.1 that $P^\varepsilon[(B^+ \cup B^-)^c \cap C_\varepsilon]$ is exponentially small. Essentially the same proof as for (4.8) shows that $P^\varepsilon(C_\varepsilon) \geqq k > 0$ for small ε. Thus $P^\varepsilon[(B^+ \cup B^-)^c \,|\, C_\varepsilon]$ is also exponentially small. We shall introduce a test to decide between B^+ and B^-. This test is based on quadratic variations associated with the observation process y_t. It will be used in the course of justifying in § 6 another test of likelihood ratio type. Let $M = [\varepsilon^{-1}(b-a)]$ and for $j = 0, 1, \cdots, M-1$ define $t_j = a + j\varepsilon$

$$\begin{aligned} Y_j &= (y_{t_{j+1}} - y_{t_j}), \qquad S_j = \frac{1}{\varepsilon}\int_{t_j}^{t_{j+1}} h(x_s)\, ds, \\ V_j &= v_{t_{j+1}}^\varepsilon - v_{t_j}^\varepsilon. \end{aligned} \tag{5.2}$$

By (2.3), $Y_j = S_j + V_j$. If we consider only j even, then the random variables $V_{j+1} - V_j$ are independent. For the quadratic variation test, we need to estimate $\sum_j (Y_{j+1} - Y_j)^2$ for j even. For this purpose we first estimate $\sum_j (S_{j+1} - S_j)^2$ where the sum is taken over j even. We have

$$\begin{aligned} S_{j+1} - S_j &= \frac{1}{\varepsilon}\int_{t_j}^{t_{j+1}} [h(x_{s+\varepsilon}) - h(x_s)]\, ds \\ &= \frac{1}{\varepsilon}\int_{t_j}^{t_{j+1}} \int_s^{s+\varepsilon} p_\lambda\, dw_\lambda\, ds + \psi_j \end{aligned}$$

where $p_s = g(x_s)h'(x_s)$ and

$$\psi_j = \frac{1}{\varepsilon}\int_{t_j}^{t_{j+1}} \int_s^{s+\varepsilon} Lh(x_\lambda)\, d\lambda\, ds$$

with $Lh = f(x)h' + \frac{1}{2}g^2(x)h''$.

By assumption (A1)

$$|\psi_j| \leqq K\varepsilon \|x\|_b. \tag{5.3}$$

Let us introduce the "sawtooth" function ϕ such that, for j even,

$$\phi_s = \begin{cases} \dfrac{s - t_j}{\varepsilon} p_s, & s \in [t_j, t_{j+1}], \\ \dfrac{t_{j+2} - s}{\varepsilon} p_s, & s \in [t_{j+1}, t_{j+2}]. \end{cases}$$

By exchanging order of integration, we get

$$S_{j+1} - S_j = \int_{I_j} \phi_s\, dw_s + \psi_j \tag{5.4}$$

where $I_j = [t_j, t_{j+2}]$. Let

$$e = \sum_{j \text{ even}} \left[\left(\int_{I_j} \phi_s\, dw_s \right)^2 - \int_{I_j} \phi_s^2\, ds \right] \tag{5.5}$$

and define θ_s by

$$\theta_s = \int_{t_j}^{s} \phi_u\, dw_u, \qquad s \in I_j.$$

The Itô differential rule implies that

$$e = 2 \sum_{j \text{ even}} \int_{I_j} \theta_s \phi_s\, dw_s = 2 \int_a^b \theta_s \phi_s\, dw_s.$$

LEMMA 5.1. *Given $d > 0$ there exist positive ε_0 and K such that*

$$P^\varepsilon(|e| \geqq d) \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right), \qquad 0 < \varepsilon < \varepsilon_0.$$

Proof. We have

$$P^\varepsilon(|e| \geqq d) \leqq P^\varepsilon(\|\theta\| \geqq \varepsilon^{1/4}) + P^\varepsilon(|e| \geqq d, \|\theta\| < \varepsilon^{1/4})$$

where $\| \ \|$ is the sup-norm on $[a, b]$. Now

$$P^\varepsilon(\|\theta\| \geqq \varepsilon^{1/4}) = P^\varepsilon\left(\sup_{j \text{ even}} \sup_{I_j} |\theta_s| \geqq \varepsilon^{1/4} \right)$$

$$\leqq \sum_{j \text{ even}} P^\varepsilon\left(\sup_{I_j} |\theta_s| \geqq \varepsilon^{1/4} \right).$$

Since $|\phi_u^2| \leqq k$, a standard estimate (Theorem 18 of [15, p. 54]) gives

$$P^\varepsilon\left(\sup_{I_j} |\theta_s| \geqq c \right) \leqq 2 \exp\left(-\frac{c^2}{2k\varepsilon}\right).$$

We take $c = \varepsilon^{1/4}$ to get

$$P^\varepsilon(\|\theta\| \geqq \varepsilon^{1/4}) \leqq \frac{b-a}{\varepsilon} \exp\left(-\frac{1}{2k\varepsilon^{1/2}}\right).$$

By a slight modification of the argument in [15] just cited,

$$P^\varepsilon(|e| \geqq d, \|\theta\| < \varepsilon^{1/4}) \leqq 2 \exp\left(-\frac{d^2}{2k(b-a)\sqrt{\varepsilon}}\right).$$

We take $K < \min(1/2k, d^2/2k(b-a))$.

We now introduce Z_ε, on which the quadratic variation test will be based:

$$Z_\varepsilon = \frac{1}{b-a} \sum_{j \text{ even}} (Y_{j+1} - Y_j)^2. \tag{5.6}$$

LEMMA 5.2. *Given $d > 0$ there exist positive ε_0 and K such that*

$$P^\varepsilon\left(\left|Z_\varepsilon - \frac{1}{3(b-a)} \int_a^b (gh')^2(x_s)\, ds - 1\right| > d\right) \leqq \exp\left(-\frac{k}{\sqrt{\varepsilon}}\right)$$

for $0 < \varepsilon < \varepsilon_0$.

Remark. A similar result holds for *j odd*. Thus, for $\varepsilon < \varepsilon_0$,

$$P^\varepsilon\left(\left|\frac{1}{b-a}\left[\sum_{j=0}^{M-1} (Y_{j+1} - Y_j)^2 - \frac{2}{3}\int_a^b (gh')^2(x_s)\, ds\right] - 2\right| > 2d\right) \leqq 2 \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right).$$

This remark is useful when quadratic variations tests are implemented numerically [4].

Proof of Lemma 5.2. We write $Z_\varepsilon = \Gamma_1 + \Gamma_2 + \Gamma_3$, where

$$\Gamma_1 = \frac{1}{b-a} \sum_{j \text{ even}} (S_{j+1} - S_j)^2,$$

$$\Gamma_2 = \frac{2}{b-a} \sum_{j \text{ even}} (S_{j+1} - S_j)(V_{j+1} - V_j),$$

$$\Gamma_3 = \frac{1}{b-a} \sum_{j \text{ even}} (V_{j+1} - V_j)^2.$$

The lemma will be proved if we show that, for small ε

$$P^\varepsilon\left(\left|\Gamma_1 - \frac{1}{3(b-a)} \int_a^b (gh')^2(x_s)\, ds\right| > \frac{d}{3}\right) \leqq \exp\left(-\frac{K_1}{\sqrt{\varepsilon}}\right), \tag{5.7}$$

$$P^\varepsilon\left(|\Gamma_2| > \frac{d}{3}\right) \leqq \exp\left(-\frac{K_2}{\sqrt{\varepsilon}}\right), \tag{5.8}$$

$$P^\varepsilon\left(|\Gamma_3 - 1| > \frac{d}{3}\right) \leqq \exp\left(-\frac{K_3}{\sqrt{\varepsilon}}\right). \tag{5.9}$$

The random variables $V_{j+1} - V_j$, j even, $j = 0, 1, \cdots, M-1$, are independent and Gaussian, with the mean 0 and variance 2ε. Hence (5.9) follows from a standard large deviations theorem. We next recall (5.4) and write $\Gamma_1 = G_1 + G_2 + G_3$, where

$$G_1 = \frac{1}{b-a} \sum_{j \text{ even}} \left(\int_{I_j} \phi_s\, dw_s\right)^2,$$

$$G_2 = \frac{2}{b-a} \sum_{j \text{ even}} \psi_j \int_{I_j} \phi_s\, dw_s,$$

$$G_3 = \frac{1}{b-a} \sum_{j \text{ even}} \psi_j^2.$$

By standard estimates for stochastic differential equations, for fixed $\alpha > 0$ and small ε

$$P^\varepsilon\left(\sup_{|s-u|\leqq\varepsilon}|x_s - x_u| \geqq \alpha\right) \leqq \exp\left(-\frac{k}{\sqrt{\varepsilon}}\right).$$

Using Lemma 5.1, we then obtain

$$P^\varepsilon\left(\left|G_1 - \frac{1}{3(b-a)}\int_a^b (gh')^2(x_s)\,ds\right| > d_1\right) \leqq \exp\left(-\frac{K_1}{\sqrt{\varepsilon}}\right).$$

By (5.3), $|G_3| \leqq K\varepsilon\|x\|_b^2$, from which

$$P^\varepsilon(|G_3| > d_2) \leqq P\left(\|x\|_b > \left(\frac{d_2}{K\varepsilon}\right)^{1/2}\right) \leqq \exp\left(-\frac{k_2}{\sqrt{\varepsilon}}\right),$$

using the fact that $E\exp c\|x\|_b^2 < \infty$ for some $c < 0$. Finally, for any $\lambda > 0$,

$$|G_2| \leqq \lambda|G_1| + \frac{1}{\lambda}|G_3|,$$

$$P^\varepsilon(|G_2| > d_2) \leqq P^\varepsilon\left(\lambda|G_1| > \frac{d_2}{2}\right) + P^\varepsilon\left(\frac{1}{\lambda}|G_3| > \frac{d_2}{2}\right).$$

We then obtain (5.7) by choosing suitable $d_i < d/9$, $r = 1, 2, 3$ and λ sufficiently small.

To obtain (5.8) we first recall (5.3) and (5.4). Then

$$\begin{aligned} P^\varepsilon\left(\left|\sum_{j\text{ even}}\psi_j(V_{j+1} - V_j)\right| > \alpha\right) &\leqq P^\varepsilon\left(\frac{K\varepsilon M}{2}\|x\|_b \sup_{j\text{ even}}|V_{j+1} - V_j| > \alpha\right) \\ &\leqq P^\varepsilon\left(\frac{K(b-a)}{2\alpha}\|x\|_b > \varepsilon^{-1/4}\right) \\ &\quad + \left(\frac{M}{2}\right)P^\varepsilon(|V_{j+1} - V_j| > \varepsilon^{1/4}). \end{aligned}$$

At the last step we used mutual independence of the processes x_t, v_t^ε. By (2.4) and Theorem 5.7.2 of [7], $E^\varepsilon\exp[\sigma\|x\|_b^2] < \infty$ for some $\sigma > 0$. Thus,

$$P^\varepsilon\left(\left|\sum_{j\text{ even}}\psi_j(V_{j+1} - V_j)\right| > \alpha\right) \leqq \exp\left(-\frac{\gamma}{\sqrt{\varepsilon}}\right) + \frac{b-a}{2\varepsilon}\exp\left(-\frac{1}{8\sqrt{\varepsilon}}\right) \leqq \exp\left(-\frac{k_3}{\sqrt{\varepsilon}}\right),$$

for $k_3 < \min(\gamma, 1/8)$ and for small ε.

Next let us write

$$\sigma_s = \begin{cases} 1, & s \in [t_{j+1}, t_{j+2}), \\ -1, & s \in [t_j, t_{j+1}), \end{cases}$$

and consider the piecewise constant process ζ_s (independent of $\{V_j\}$) such that

$$\zeta_s = \int_{I_j}\phi_u\,dw_u \quad \text{for } s \in I_j.$$

Let $N_t = \int_a^t \zeta_s\sigma_s\,dv_s^\varepsilon$. Then N_t is a $\mathcal{F}_r$-martingale, and

$$N_b = \sum_{j\text{ even}}\left(\int_{I_j}\phi_u\,dw_u\right)(V_{j+1} - V_j),$$

$$\begin{aligned} \langle N\rangle_t &= \int_a^t \zeta_s^2\,ds = 2\varepsilon\sum_{k\text{ even}}\left(\int_{I_k}\phi_u\,dw_u\right)^2 \\ &= 2\varepsilon\int_a^b \phi_s^2\,ds + 2e\varepsilon. \end{aligned}$$

Since ϕ_s is bounded, by Lemma 5.1 we have for some Γ, $\Delta > 0$

$$P^\varepsilon(\langle N\rangle_t \geqq 2\Gamma\varepsilon) \leqq \exp\left(-\frac{\Delta}{\sqrt{\varepsilon}}\right).$$

We introduce the stopping time

$$\tau = b \wedge \inf\{t \in [a, b]: \langle N\rangle_t \geqq 2\Gamma\varepsilon\},$$

and let $N'_t = N_{t\wedge\tau}$. For any $\lambda > 0$

$$M_t = \exp\left(\lambda N'_t - \frac{\lambda^2}{2}\langle N'\rangle_t\right)$$

is a $\mathscr{F}_t$-martingale. Moreover, $\langle N\rangle_b \leqq 2\Gamma\varepsilon$ implies $N_t = N'_t$ for all $t \in [a, b]$. For $\alpha > 0$, $N_b > \alpha$, $\langle N\rangle_b \leqq 2\Gamma\varepsilon$ imply

$$M_b = \exp\left[\lambda N_b - \frac{\lambda^2}{2}\langle N\rangle_b\right] \geqq \exp(\lambda\alpha - \lambda^2\Gamma\varepsilon),$$

$$P^\varepsilon(N_b > \alpha, \langle N\rangle_b \leqq 2\Gamma\varepsilon) \leqq \exp(-\lambda\alpha + \lambda^2\Gamma\varepsilon).$$

We take $\lambda = \varepsilon^{-1}\theta$ with $\theta\Gamma < \alpha$, and conclude that for small ε

$$P^\varepsilon(N_b > \alpha) \leqq \exp\left(-\frac{k_4}{\sqrt{\varepsilon}}\right).$$

A similar argument, with λ replaced by $-\lambda$ gives, for small ε,

$$P^\varepsilon(N_b < -\alpha) \leqq \exp\left(-\frac{k_4}{\sqrt{\varepsilon}}\right).$$

We take $\alpha < d/6$ to obtain (5.8). This proves Lemma 5.2.

We shall now use assumption (A3) and Lemma 5.2 to describe a test for positivity or negativity of x_t on an interval $[a, b]$. As a function of y, $x^+(y)$ and $x^-(y)$ in (A3) are continuous. Under (A3), $(gh')^2(x^+) - (gh')^2(x^-)$ is continuous and not zero on the interval $[y_1, y_2]$. There are two possibilities: either

$$(gh')^2(x^-) < (gh')^2(x^+) - c \tag{5.10a}$$

for all $x^+ > 0$, $x^- < 0$ satisfying $h(x^+) = h(x^-) = y$, $y_1 \leqq y \leqq y_2$; or

$$(gh')^2(x^+) < (gh')^2(x^-) - c \tag{5.10b}$$

for all such x^+, x^-, y. We shall suppose that (5.10a) holds, the case of (5.10b) being entirely similar with a reversal of inequality signs in (5.11). Since x_s cannot itself be observed, we must approximate $(gh')^2(x_s)$ in Lemma 5.2 by quantities computable from an observation sample path. Let

$$\rho_s^+ = (gh'_+)(m_s^+), \qquad \rho_s^- = (gh'_-)(m_s^-),$$

and define $C_\varepsilon^\pm = C_\varepsilon^\pm(a, b)$ by

$$\begin{aligned} C_\varepsilon^+ &= C_\varepsilon \cap \left\{Z_\varepsilon > 1 + \frac{1}{6(b-a)}\int_a^b [(\rho_s^+)^2 + (\rho_s^-)^2]\, ds\right\}, \\ C_\varepsilon^- &= C_\varepsilon \cap \left\{Z_\varepsilon \leqq 1 + \frac{1}{6(b-a)}\int_a^b [(\rho_s^+)^2 + (\rho_s^-)^2]\, ds\right\}. \end{aligned} \tag{5.11}$$

Clearly $C_\varepsilon = C_\varepsilon^+ \cup C_\varepsilon^-$ and $C_\varepsilon^+ \cap C_\varepsilon^- = \varnothing$.

LEMMA 5.3. *There exist positive ε_0 and K such that, for $0<\varepsilon<\varepsilon_0$*

$$P^\varepsilon[(B^+)^c \cap C_\varepsilon^+] \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right), \qquad P^\varepsilon[(B^-)^c \cap C_\varepsilon^-] \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right).$$

Proof. We prove the first inequality, the second being similar. First of all,

$$P^\varepsilon[(B^+)^c \cap C_\varepsilon^+] \leqq P^\varepsilon[(B^+ \cup B^-)^c \cap C_\varepsilon^0] + P^\varepsilon(B^- \cap C_\varepsilon^+).$$

The first term on the right side is estimated using Lemma 4.1. It remains to bound the last term. By (A1) and (5.10a) there exists $\alpha_0>0$ such that $\xi^+ \geqq 0$, $\xi^- <0$,

$$|h(x)-h(\xi^\pm)|<\alpha_0, \qquad y_1-\alpha_0 \leqq h(x) \leqq y_2+\alpha_0,$$

imply $\xi^+ \geqq \delta$, $\xi^- \leqq -\delta$ and

$$(gh')^2(\xi^-) < (gh')^2(\xi^+) - \frac{c}{2}.$$

Here δ is as in (4.1). Moreover, since gh' is bounded and Lipschitz

$$|(gh')^2(x)-(gh')^2(\xi^-)| \leqq K_1|x-\xi^-|.$$

Since $|h'(x)|$ is bounded away from zero for $|x| \geqq \delta$

$$|(gh')^2(x)-(gh')^2(\xi^-)| \leqq K_2|h(x)-h(\xi^-)|$$

for $x \leqq -\delta$, $\xi^- \leqq -\delta$.

We now take $x=x_s$, $\xi^\pm = m_s^\pm$. For $\alpha<\alpha_0$ consider the events

$$A_1 = \left\{(gh')^2(m_s^-) < (gh')^2(m_s^+) - \frac{c}{2}\right\},$$

$$A_2^+ = \{|(gh')^2(x_s)-(gh')^2(m_s^+)| < K_2\alpha\},$$

$$A_2^- = \{|(gh')^2(x_s)-(gh')^2(m_s^-)| < K_2\alpha\}.$$

We use Lemma 3.1 with $H=h_\pm$. For small ε

$$P^\varepsilon\left(\sup_{[a,b]}|h(x_t)-h_+(m_t^+)|>\alpha\right) \leqq \exp\left(-\frac{K}{\varepsilon}\right),$$

$$P^\varepsilon\left(\sup_{[a,b]}|h(x_t)-h_-(m_t^-)|>\alpha\right) \leqq \exp\left(-\frac{K}{\varepsilon}\right).$$

If $|h(x_t)-h_t(m_t^+)| \leqq \alpha$ and $|h(x_t)-h_-(m_t^-)| \leqq \alpha$, then

$$m_t^+ \geqq \delta, \qquad h_+(m_t^+) = h(m_t^+),$$

$$m_t^- \leqq -\delta, \qquad h_-(m_t^-) = h(m_t^-).$$

We have

$$B^- \cap C_\varepsilon \cap \left\{\sup_{[a,b]}|h(x_t)-h_\pm(m_t^\pm)| \leqq \alpha\right\} \subset A_1 \cap A_2^-,$$

$$P^\varepsilon[B^- \cap C_\varepsilon \cap (A_1 \cap A_2^-)^c] \leqq \exp\left(-\frac{K}{\varepsilon}\right)$$

for small ε.

We have on $B^- \cap C_\varepsilon \cap A_1 \cap A_2^-$,

$$\left| \int_a^b (gh')^2(x_s)\, ds - \int_a^b (\rho_s^-)^2\, ds \right| \leqq K_2(b-a)\alpha,$$

$$\int_a^b (\rho_s^-)^2\, ds < \int_a^b (\rho_s^+)^2\, ds - \frac{c}{2}(b-a),$$

$$1 + \frac{1}{3(b-a)} \int_a^b (gh')^2(x_s)\, ds < 1 + \frac{K_2\alpha}{3} + \frac{1}{3(b-a)} \int_a^b (\rho_s^-)^2\, ds$$

$$< 1 + \frac{K_2\alpha}{3} - \frac{c}{12} + \frac{1}{6(b-a)} \int_a^b [(\rho_s^+)^2 + (\rho_s^-)^2]\, ds.$$

We now take, in Lemma 5.2,

$$d = \frac{c}{12} - \frac{K_2\alpha}{3} > 0 \quad \text{if } \alpha < \frac{c}{4K_2},$$

to get for small ε

$$P^\varepsilon(B^- \cap C_\varepsilon^+ \cap A_1 \cap A_2^-) \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right).$$

From these estimates we get Lemma 5.3.

The quadratic variation test now proceeds, roughly speaking, as follows. According to Lemma 4.1 the probability that x_t crosses zero during $[a, b]$ is exponentially small, if $C_\varepsilon^0(a, b)$. We will decide between $B^+(a, b)$ and $B^-(a, b)$ based on observing one of the two possible events $C_\varepsilon^+(a, b_1)$ or $C_\varepsilon^-(a, b_1)$, where $a < b_1 < b$. Thus, we let

$$Q_\varepsilon^+(a, b) = C_\varepsilon^0(a, b) \cap C_\varepsilon^+(a, b_1), \qquad Q_\varepsilon^-(a, b) = C_\varepsilon^0(a, b) \cap C_\varepsilon^-(a, b_1). \tag{5.12}$$

THEOREM 5.4. *There exist positive ε_0 and K such that, for $0 < \varepsilon < \varepsilon_0$:*

$$P^\varepsilon(B^+(a, b)^c \,|\, Q_\varepsilon^+(a, b)) \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right), \qquad P^\varepsilon(B^-(a, b)^c \,|\, Q_\varepsilon^-(a, b)) \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right),$$

$$P^\varepsilon([B^+(a, b) \cup B^-(a, b)]^c \cap [Q_\varepsilon^+(a, b) \cup Q_\varepsilon^-(a, b)]) \leqq \exp\left(-\frac{K}{\varepsilon}\right).$$

Proof. We have

$$B^+(a, b)^c \cap Q_\varepsilon^+(a, b) \subset [B^+(a, b_1)^c \cap C_\varepsilon^+(a, b_1)] \cup [B^+(a, b_1) \setminus B^+(a, b) \cap C_\varepsilon^0(a, b)].$$

By Lemmas 4.1 and 5.3, for small ε and suitable K_1,

$$P^\varepsilon(B^+(a, b)^c \cap Q_\varepsilon^+(a, b)) \leqq \exp\left(-\frac{K_1}{\sqrt{\varepsilon}}\right). \tag{5.13}$$

By modifying arguments used in the proof of Lemma 5.3 we can easily show that

$$\liminf_{\varepsilon \to 0} P^\varepsilon(Q_\varepsilon^+(a, b)) > 0. \tag{5.14}$$

This implies the first inequality in Theorem 5.4, and the second inequality is similar. The third inequality is immediate from Lemma 4.1.

Remark. It can be seen that the constants K and ε_0 are uniform with respect to a, b_1, b, provided

$$0 < a^* \leqq a, \quad b \leqq b^* < \infty, \quad b - a \geqq t^* > 0,$$

where a^*, b^*, t^* are given. The result $C_\varepsilon^{\pm}(a, b_1)$ of testing on the interval $[a, b_1]$ is then used to decide whether to use the approximate filter m_t^+ or m_t^- up to time b. The accuracy of the approximate filter is discussed in § 7.

In this paper we consider the length $b_1 - a$ of the testing interval as fixed. In fact, an appropriate sequential decision test for positivity or negativity of x_t turns out to give a smaller mean decision time, for the same probabilities of incorrect decisions. This is discussed in [4], which considers a discrete time analogue of the model and in which some numerical results are reported.

6. Likelihood ratio test. Now we want to show how a decision between $B^+(a, b)$ and $B^-(a, b)$ can be made from the output m_t^+, m^- of the two approximate filters (4.4). For $a < d < b$ let us define the following test statistics, based on likelihood ratio considerations:

$$L_\varepsilon = \int_d^b (\hat{h}_s^+ - \hat{h}_s^-)\, dy_s - \frac{1}{2\varepsilon}\int_d^b [(\hat{h}_s^+)^2 - (\hat{h}_s^-)^2]\, ds \tag{6.1}$$

where $\hat{h}_s^+ = h_+(m_s^+)$, $\hat{h}_s^- = h_-(m_s^-)$. Using the representation

$$dy_s = \frac{1}{\varepsilon}\hat{h}_s\, ds + dv_s^\varepsilon \tag{6.2}$$

where $\hat{h}_s = E^\varepsilon[h(x_s)\,|\,\mathcal{Y}_s]$ and v_t^ε (the innovation) is a standard Brownian motion, L_ε can be rewritten in two ways. Let

$$z_s = \hat{h}_s^+ - \hat{h}_s^-.$$

Then

$$L_\varepsilon = \frac{1}{2\varepsilon}\int_d^b z_s^2\, ds + \int_d^b z_s\, dv_s^\varepsilon + \frac{1}{\varepsilon}\int_d^b z_s(\hat{h}_s - \hat{h}_s^+)\, ds, \tag{6.3$^+$}$$

$$L_\varepsilon = -\frac{1}{2\varepsilon}\int_d^b z_s^2\, ds + \int_d^b z_s\, dv_s^\varepsilon + \frac{1}{\varepsilon}\int_d^b z_s(\hat{h}_s - \hat{h}_s^-)\, ds. \tag{6.3$^-$}$$

We will show that the first term on the right side of (6.3$^\pm$) dominates the other two terms, except for events of small probability. In fact, this term is of order $O(1)$ (see Lemma 6.3). The sign of L_ε will then provide a test for positivity or negativity of x_t on $[a, b]$ (see Theorem 6.5).

Let us choose e with $a < e < d < b$. We need estimates for $\int_e^b |\hat{h}_s - \hat{h}_s^+|^2\, ds$. These are obtained in two steps, in Lemma 6.1 and 6.2. First, we replace $\hat{h}_s^+$ by a related quantity $\tilde{h}_s^+$ obtained after a change of probability measure. Second, we estimate $\hat{h}_s^+ - \tilde{h}_s^+$. Consider the following filtering problem:

$$dx_t = f(x_t)\, dt + g(x_t)\, dw_t,$$

$$dy_t = \frac{1}{\varepsilon}[h(x_t)1_{\{t \leqq e\}} + h_+(x_t)1_{\{t > e\}}]\, dt + dv_t^+.$$

The change of probability argument we now describe is due essentially to Ji. Define

$$\gamma_t = h_+(x_t) - h(x_t),$$

$$Z_t = \exp\left[\frac{1}{\varepsilon}\int_e^t \gamma_s\, dv_s^\varepsilon - \frac{1}{2\varepsilon^2}\int_e^t \gamma_s^2\, ds\right], \qquad e \leqq t \leqq b,$$

with $Z_t = 1$ for $0 \leqq t \leqq e$. Then v_t^+ is a P^+ standard Brownian motion, where

$$Z_b = \frac{dP^+}{dP^\varepsilon}.$$

Note that $P^+ = P^{+\varepsilon}$ depends on ε. Let us calculate $\hat{Z}_t = E(Z_t \mid \mathcal{Y}_t)$. We have

$$dZ_t = \frac{1}{\varepsilon}\gamma_t Z_t\, dv_t^\varepsilon, \qquad dy_t = \frac{1}{\varepsilon}h(x_t)\, dt + dv_t^\varepsilon.$$

The nonlinear filtering formula implies

$$d\hat{Z}_t = \frac{1}{\varepsilon}[\widehat{Z_t h_t} - \hat{Z}_t\hat{h}_t + \widehat{\gamma_t Z_t}]\, dv_t^\varepsilon$$

with $h_t = h(x_t)$ and with v_t^ε the innovation. Also

$$\widehat{Z_t\zeta_t} = \hat{Z}_t\tilde{\zeta}_t, \quad \text{where } \tilde{\zeta}_t = E^+(\zeta_t \mid \mathcal{Y}_t).$$

We take $\zeta_t = h_t$ and $\zeta_t = \gamma_t$ to get

$$d\hat{Z}_t = \frac{\hat{Z}_t}{\varepsilon}[\tilde{h}_t - \hat{h}_t + \tilde{\gamma}_t]\, dv_t^\varepsilon.$$

Moreover, $\tilde{\gamma}_t = \tilde{h}_t^+ - \tilde{h}_t$, where

$$\tilde{h}_t^+ = E^+(h_+(x_t) \mid \mathcal{Y}_t). \tag{6.4}$$

Hence,

$$d\hat{Z}_t = \frac{\hat{Z}_t}{\varepsilon}(\tilde{h}_t^+ - \hat{h}_t)\, dv_t^\varepsilon,$$

$$\log \hat{Z}_t = \int_e^t \left[\frac{1}{\varepsilon}(\tilde{h}_s^+ + \hat{h}_s)\, dv_s^\varepsilon - \frac{1}{2\varepsilon^2}(\tilde{h}_s^+ - \hat{h}_s)^2\, ds\right]. \tag{6.5}$$

By Jensen's inequality

$$-\log \hat{Z}_t \leqq -\widehat{\log Z_t}.$$

Since $\widehat{\log Z_t}$ and $\log \hat{Z}_t$ are continuous functions of t, and $C_\varepsilon^+(a, e)$ is $\mathcal{Y}_e$-measurable, we have that for any $\{\mathcal{Y}_t\}$-stopping time τ with $e \leqq \tau \leqq b$

$$E^\varepsilon[1_{C_\varepsilon^+(a,e)}\widehat{\log Z_\tau}] = E^\varepsilon[1_{C_\varepsilon^+(a,e)}\log Z_\tau],$$

$$E^\varepsilon\left[\frac{1}{2\varepsilon^2}\int_e^\tau (\tilde{h}_s^+ - \hat{h}_s)^2\, ds;\, C_\varepsilon^+(a, e)\right] = -E^\varepsilon[1_{C_\varepsilon^+(a,e)}\log \hat{Z}_\tau]$$

$$\leqq \frac{1}{2e^2}E^\varepsilon\left[\int_e^\tau (h_s^+ - h_s)^2\, ds;\, C_\varepsilon^+(a, e)\right].$$

We now take

$$\tau = b \wedge \inf\{t \geqq e\colon h_+(m_t^+) \notin [y_1, y_2]\}. \tag{6.6}$$

Then $h_s^+ = h_+(x_s) = h(x_s) = h_s$ on $B^+(e, \tau)$. By Cauchy-Schwartz

$$E^\varepsilon\left[\int_e^\tau (\tilde{h}_s^+ - \hat{h}_s)^2\, ds;\, C_\varepsilon^+(a, e)\right]$$

$$\leqq \left[E^\varepsilon\left(\int_a^b (h_s^+ - h_s)^2\, ds\right)^2\right]^{1/2}[P^\varepsilon(C_\varepsilon^+(a, e) \cap (B^+)^c(e, \tau))]^{1/2}$$

$$\leqq K[P^\varepsilon(C_\varepsilon^+(a, e) \cap (B^+)^c(e, \tau))]^{1/2}.$$

Also, on $B^+(a, e) \cap B^+(e, \tau)^c$,

$$\sup_{[e,b]} |h(x_t) - h_+(m_t^+)| > \alpha$$

for some $\alpha > 0$. We now apply Lemma 5.3 on the interval $[a, e]$ and Lemma 4.1 (or Lemma 3.1) on the interval $[e, b]$ to obtain Lemma 6.1.

LEMMA 6.1. *There exist positive $\varepsilon_0 > 0$ and K such that, for $0 < \varepsilon < \varepsilon_0$*

$$E^\varepsilon\left[\int_e^\tau (\tilde{h}_s^+ - \hat{h}_s)^2 \, ds;\ C_\varepsilon^+(a, e)\right] \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right).$$

We next estimate $\tilde{h}_s^+ - \hat{h}_s^+$ on $[e_1, b]$ where $e < e_1 < d < b$. We recall that m_t^+ as defined by (4.4) is an approximate filter of the form (1.2), when h is replaced by h_+ and v_t^ε by v_t^+. By (6.4) and Picard [12, formula (5.17)] there exist $\varepsilon_0 > 0$ and Γ_q (any $q \geqq 1$) such that for $\varepsilon < \varepsilon_0$

$$E^+[|\tilde{h}_s^+ - \hat{h}_s^+|^q] \leqq \Gamma_q \varepsilon^q, \qquad e_1 \leqq s \leqq b. \tag{6.7}$$

LEMMA 6.2. *For every $\alpha > 0$, $\mu > 0$, $q \geqq 1$,*

$$P^\varepsilon\left(\left\{\int_{e_1}^b |\tilde{h}_s^+ - \hat{h}_s^+|^q \, ds \geqq \alpha\varepsilon^\mu\right\} \cap B^+(a, b)\right) \leqq \frac{(b-a)\Gamma_q}{\alpha} \varepsilon^{q-\mu}.$$

Proof. We recall that $P^\varepsilon(D) = P^+(D)$ if $D \subset B^+(a, b)$. Lemma 6.2 then follows from (6.7).

Let us return to $z_s = \hat{h}_s^+ - \hat{h}_s^-$ in (6.3$^\pm$). From (4.2)-(4.4) and the Itô differential rule,

$$d\hat{h}_s^+ = (Lh_+)_s \, ds + \rho_s^+\left(\frac{\hat{h}_s - \hat{h}_s^+}{\varepsilon}\right) ds + \rho_s^+ \, d\nu_s^\varepsilon,$$

$$d\hat{h}_s^- = (Lh_-)_s \, ds - \rho_s^-\left(\frac{\hat{h}_s - \hat{h}_s^-}{\varepsilon}\right) ds - \rho_s^- \, d\nu_s^\varepsilon$$

where $(Lh_\pm)_s = Lh_\pm(m_s^\pm)$ and $\rho_s^\pm = (gh'_\pm)(m_s^\pm)$. Then

$$dz_s = [(Lh_+)_s - (Lh_-)_s] \, ds + \frac{\rho_s^-}{\varepsilon} z_s \, ds + \sigma_s \, d\nu_s^\varepsilon + \sigma_s\left(\frac{\hat{h}_s - \hat{h}_s^+}{\varepsilon}\right) ds, \tag{6.8}$$

$$\sigma_s = \rho_s^+ + \rho_s^-.$$

From assumptions (A1) and (4.2), $-\rho_s^- \geqq \beta > 0$. Moreover, by (5.10a), $x^+ > 0$, $x^- < 0$, $h(x^+) = h(x^-) \in [y_1, y_2]$ imply

$$(gh')(x^+) + (gh')(x^-) \geqq 2c_1 > 0,$$

for some $c_1 > 0$.

Using the notation of the proof of Lemma 5.3, we have

$$B^- \cap C_\varepsilon \cap \left\{\sup_{[a,b]} |h(x_t) - h_-(m_t^-)| \leqq \alpha\right\} \subset A_2^-,$$

$$B^+ \cap C_\varepsilon \cap \left\{\sup_{[a,b]} |h(x_t) - h_+(m_t^+)| \leqq \alpha\right\} \subset A_2^+.$$

By using Lemma 3.1 in the same way as in the proof of Lemma 5.3, together with Lemma 4.1, we have

$$P^\varepsilon\left(\left\{\min_{[a,b]}\sigma_s < c_1\right\}\cap C_\varepsilon(a,b)\right)\leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right) \tag{6.9}$$

for small ε.

We now define

$$A_\varepsilon^+ = C_\varepsilon^+(a,e)\cap C_\varepsilon(a,b),\quad A_\varepsilon^- = C_\varepsilon^-(a,e)\cap C_\varepsilon(a,b). \tag{6.10}$$

LEMMA 6.3. *There exist positive* γ, ε_m, K_m, $m=1,2,\cdots$, *such that for* $0<\varepsilon<\varepsilon_m$

$$P^\varepsilon\left(\left\{\frac{1}{\varepsilon}\int_d^b z_s^2\,ds<\gamma\right\}\cap A_\varepsilon^+\right)\leqq K_m\varepsilon^m.$$

Proof. We write $z_s = z_s^{(1)}+z_s^{(2)}$, where $z_{e_1}^{(1)}=0$ and (see (6.8))

$$dz_s^{(1)} = \frac{\rho_s^- z_s^{(1)}}{\varepsilon}\,ds+\sigma_s\,d\nu_s^\varepsilon,$$

$$dz_s^{(2)} = \frac{\rho_s^- z_s^{(2)}}{\varepsilon}\,ds+[(Lh_+)_s-(Lh_-)_s]\,ds+\sigma_s\left(\frac{\hat h_s-\hat h_s^+}{\varepsilon}\right)ds.$$

We first show that the contribution of $z_s^{(2)}$ is small. We have

$$z_t^{(2)} = z_{e_1}\exp\int_{e_1}^t\frac{\rho_s\,ds}{\varepsilon}+\int_{e_1}^t\exp\left[\int_s^t\frac{\rho_u^-\,du}{\varepsilon}\right][(Lh_+)_s-(Lh_-)_s]\,ds+\xi_t+\eta_t,$$

$$\xi_t = \int_{e_1}^t\exp\left[\int_s^t\frac{\rho_u^-\,du}{\varepsilon}\right]\sigma_s\frac{(\hat h_s-\tilde h_s^+)}{\varepsilon}\,ds,$$

$$\eta_t = \int_{e_1}^t\exp\left[\int_s^t\frac{\rho_u^-\,du}{\varepsilon}\right]\sigma_s\frac{(\tilde h_s^+-\hat h_s^+)}{\varepsilon}\,ds.$$

Since $\rho_s^-\leqq-\beta<0$, the first term is exponentially small on $[d,b]$. Since $(Lh_\pm)_s$ is bounded, the second term is of order ε. An argument similar to one in the proof of Lemma 3.1 shows that it suffices to estimate ξ_t and η_t. Using $\rho_u^-\leqq-\beta<0$, σ_s bounded and Cauchy-Schwartz

$$\xi_t^2\leqq N\int_s^t\frac{(\hat h_s-\tilde h_s^+)^2\,ds}{\varepsilon}.$$

Now $A_\varepsilon^+\subset C_\varepsilon^+(a,e)$ and $\tau=b$ on A_ε^+. By Lemma 6.1, given $\theta>0$

$$P^\varepsilon\left(\left\{\frac{1}{\varepsilon}\sup_{[e_1,b]}\xi_t^2\geqq 0\right\}\cap A_\varepsilon^+\right)\leqq P^\varepsilon\left(\left\{\int_{e_1}^\tau(\hat h_s-\tilde h_s^+)^2\,ds\geqq\frac{\theta\varepsilon^2}{N}\right\}\cap C_\varepsilon^+(a,e)\right)$$

$$\leqq\frac{N}{\theta\varepsilon^2}\exp\left(-\frac{K}{\sqrt{\varepsilon}}\right)<\varepsilon^m$$

for small ε (depending on m).

To estimate η_t^2 we use Hölder's inequality with $1<p<2$, $p^{-1}+q^{-1}=1$:

$$\eta_t^2\leqq\frac{k_1}{\varepsilon^2}\left(\int_{e_1}^t\exp\left[\frac{p}{\varepsilon}\int_s^t\rho_u^-\,du\right]ds\right)^{2/p}\left(\int_{e_1}^t|\tilde h_s^+-\hat h_s^+|^q\,ds\right)^{2/q}.$$

Since $\rho_s^-\leqq-\beta<0$,

$$\frac{1}{\varepsilon}\eta_t^2 \leqq k_2 \varepsilon^{2/p-3}\left(\int_{e_1}^{t} |\tilde{h}_s^+ - \hat{h}_s^+|^q \, ds\right)^{2/q},$$

$$P^\varepsilon\left(\left\{\frac{1}{\varepsilon}\sup_{[e,b]} \eta_t^2 \geqq \theta\right\} \cap A_\varepsilon^+\right) \leqq P^\varepsilon(B^+(a,b)^c \cap A_\varepsilon^+)$$

$$+ P^\varepsilon\left(\left\{\int_{e_1}^{b} |\tilde{h}_s^+ - \hat{h}_s^+|^q \, ds \geqq \alpha\varepsilon^\mu\right\} \cap B^+(a,b)\right),$$

with $\alpha = k_2^{-q/2}$ and

$$\mu = \left(3 - \frac{2}{p}\right)\left(\frac{q}{2}\right) = \frac{1}{2} + 1.$$

The same proof as for Lemma 5.3 shows that

$$P^\varepsilon(B^+(a,b)^c \cap A_\varepsilon^+) \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right), \qquad 0 < \varepsilon < \varepsilon_0,$$

with a similar inequality for B^- and A_ε^-.

By Lemma 6.2 we then have

$$P^\varepsilon\left(\left\{\frac{1}{\varepsilon}\sup_{[e,b]} \eta_t^2 \geqq \theta\right\} \cap A_\varepsilon^+\right) \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right) + \frac{(b-a)\Gamma_q}{\alpha}\varepsilon^{q/2-1} < \varepsilon^m$$

for small ε, if we choose $q > 2m+2$.

It remains to consider $z_s^{(1)}$. Let

$$\begin{aligned} &u = \varepsilon^{-1}(s - e_1), \qquad \zeta_u = \varepsilon^{-1/2} z_s^{(1)}, \\ &\phi_u = -\rho_s^-, \quad \Sigma_u = \sigma_s, \quad V_u = \varepsilon^{-1/2}\nu_s^\varepsilon. \end{aligned} \tag{6.11}$$

Then V_u is a standard Brownian motion and

$$d\zeta_u = -\phi_u \zeta_u \, du + \Sigma_u \, dV_u, \qquad u \geqq 0, \quad \zeta_0 = 0. \tag{6.12}$$

Moreover,

$$\frac{1}{\varepsilon}\int_d^b [z_s^{(1)}]^2 \, ds = \frac{b-e_1}{U}\int_{U_1}^{U} \zeta_u^2 \, du \quad \text{where } U_1 = \frac{d-e_1}{\varepsilon}, \quad U = \frac{b-e_1}{\varepsilon}.$$

Since $\phi_u \geqq \beta > 0$, to complete the proof of Lemma 6.3 it will suffice to show that, for some $\bar{c} > 0$, there exist $\bar{\varepsilon}_m$, $\bar{K}_m$ such that

$$P^\varepsilon\left(\left\{\frac{1}{U}\int_{U_1}^{U} \phi_u \zeta_u^2 \, du < \bar{c}\right\} \cap A_\varepsilon^+\right) \leqq \bar{K}_m \varepsilon^m, \qquad 0 < \varepsilon < \bar{\varepsilon}_m. \tag{6.13}$$

We write $\zeta_u^2 = \psi_u + \bar{\psi}_u$, where from (6.12) and the Itô differential rule

$$\begin{aligned} d\psi_u &= \left(-2\phi_u\psi_u + \Sigma_u^2\right) du, \qquad \psi_0 = 0, \\ d\bar{\psi}_u &= -2\phi_u\bar{\psi}_u + 2\,\Sigma_u\,\zeta_u \, dV_u, \qquad \bar{\psi}_0 = 0. \end{aligned}$$

Let $\bar{A}_\varepsilon^+ = A_\varepsilon^+ \cap \{\sum_u \geqq c_1\}$, with c_1 as in (6.9).

For small ε

$$P^\varepsilon(A_\varepsilon^+ \setminus \bar{A}_\varepsilon^+) \leqq \exp\left(-\frac{K}{\sqrt{\varepsilon}}\right). \tag{6.14}$$

Since $0 \leqq \beta \leqq \phi_u \leqq M < \infty$ and $\sum_u$ is bounded, elementary estimates imply that on $\bar{A}_\varepsilon^+$

$$\psi_u \geqq \frac{c_1^2}{2M}(1 - e^{-2Mu}) \geqq \frac{c_1^2}{3M}$$

for $u \geqq U_1$ and small enough ε. Thus, on $\bar{A}_\varepsilon^+$

$$\frac{1}{U}\int_{U_1}^{U} \phi_u \psi_u \, du \geqq \frac{c_1^2 \beta}{3M}\left(1 - \frac{U}{U_1}\right) \geqq c_2 > 0 \quad \text{since } \frac{U_1}{U} = \frac{d - e_1}{b - e_1}. \tag{6.15}$$

In (6.13) we take $\bar{c} = \frac{1}{2}c_2$.

On the other hand,

$$\bar{\psi}_u = -2\int_0^u \phi_v \bar{\psi}_v \, dv + M_u \quad \text{where } M_u = 2\int_0^u \Sigma_v \, \zeta_v \, dV_v.$$

Since ζ_u satisfies (6.12) with $\sum_u$ bounded and $\phi_u \geqq \beta > 0$, standard arguments imply that $E|\zeta_u|^l$ is bounded on $0 \leqq u < \infty$, for each $l \geqq 1$. Since $\sum_u$ is bounded and M_u is a martingale, this implies

$$E\|M\|_U^{2m} \leqq \Lambda_m U^m, \qquad m = 1, 2, \cdots,$$

for suitable Λ_m. Since $\tilde{\psi}_u = \zeta_u^2 - \psi_u$, and ψ_u is bounded, by taking $l = 4m$ we see that $E|\tilde{\psi}_u|^{2m}$ is bounded for each m. Then, for small ε,

$$P^\varepsilon\left(\frac{1}{U}\left|\int_{U_1}^{U} \phi_v \tilde{\psi}_v \, dv\right| > \frac{\bar{c}}{2}\right) \leqq P^\varepsilon\left(\frac{1}{U}(|\tilde{\psi}_U| + |\tilde{\psi}_{U_1}|) > \frac{\bar{c}}{8}\right) + P^\varepsilon\left(\frac{1}{U}|M_{U_1}| > \frac{\bar{c}}{8}\right) \leqq \bar{\Lambda}_m \varepsilon^m,$$

using Chebyshev's inequality. From this, together with (6.14) and (6.15), we obtain (6.13) and hence Lemma 6.3.

LEMMA 6.4. *There exist positive* ε_m, K_m, $m = 1, 2, \cdots$, *such that for* $0 < \varepsilon < \varepsilon_m$:

$$P^\varepsilon(\{L_\varepsilon < 0\} \cap A_\varepsilon^+) \leqq K_m \varepsilon^m, \qquad P^\varepsilon(\{L_\varepsilon \geqq 0\} \cap A_\varepsilon^-) \leqq K_m \varepsilon^m.$$

Proof. Let us prove the first estimate only. Using (6.3^+) we rewrite L_ε as

$$L_\varepsilon = \left[\frac{1}{4\varepsilon}\int_d^b z_s^2 \, ds + \int_d^b z_s \, d\nu_s\right] + \left[\frac{1}{4\varepsilon}\int_d^b z_s^2 \, ds + \frac{1}{\varepsilon}\int_d^b z_s(\hat{h}_s - \hat{h}_s^+) \, ds\right].$$

Let us first show that the sum of the last two terms is nonnegative on A_ε^+ with probability nearly one. Indeed, it is bounded below by

$$X = \frac{1}{8\varepsilon}\int_d^b z_s^2 \, ds - \frac{2}{\varepsilon}\int_d^b (\hat{h}_s - \hat{h}_s^+)^2 \, ds.$$

The same arguments used in the proof of Lemma 6.3 to estimate ξ_t and η_t show that

$$P^\varepsilon\left(\left\{\frac{16}{\varepsilon}\int_d^b (\hat{h}_s - \tilde{h}_s^+)^2 \, ds > \frac{\gamma}{2}\right\} \cap A_\varepsilon^+\right) \leqq \bar{K}_m \varepsilon^m$$

and hence from Lemma 6.3,

$$P^\varepsilon(\{X < 0\} \cap A_\varepsilon^+) \leqq K^{(2)} \varepsilon^m$$

for small ε. Let

$$M_t = \varepsilon^{-1/2}\int_d^t z_s \, d\nu_s^\varepsilon.$$

The sum of the first two terms is negative provided that

$$M_b + \frac{1}{4\sqrt{\varepsilon}}\langle M\rangle_b < 0.$$

Let $\alpha < \gamma$ with γ as in Lemma 6.3, and let

$$D = \left\{ M_b < -\frac{1}{4\sqrt{\varepsilon}}\langle M\rangle_b \right\} \cap \{M_b \geqq \alpha\}.$$

For $\lambda < 0$ we have on D

$$\lambda M_b - \frac{\lambda^2}{2}\langle M\rangle_b \geqq \left(-\frac{\lambda}{4\sqrt{\varepsilon}} - \frac{\lambda^2}{2}\right)\langle M\rangle_b \geqq \alpha\left(-\frac{\lambda}{4\sqrt{\varepsilon}} - \frac{\lambda^2}{2}\right).$$

Since $E^\varepsilon[\exp(\lambda M_b - \frac{1}{2}\lambda^2\langle M\rangle_b)] = 1$, we have by choosing λ suitable that for any $k > 0$ and small ε,

$$P^\varepsilon(D) \leqq \exp\left(-\frac{k}{\sqrt{\varepsilon}}\right).$$

This completes the proof of Lemma 6.4.

From (5.11) and (6.10), $C_\varepsilon = A_\varepsilon^+ \cup A_\varepsilon^-$ and $A_\varepsilon^+ \cap A_\varepsilon^- = \varnothing$. We then conclude from Lemmas 4.1 and 6.4, together with (6.11), the following corollary.

COROLLARY 6.5. *There exist positive* ε_m, K_m, $m = 1, 2, \cdots$, *such that for* $0 < \varepsilon < \varepsilon_m$,

$$P^\varepsilon(\{L_\varepsilon < 0\} \cap C_\varepsilon(a, b) \cap B^+(a, b)) < K_m\varepsilon^m,$$
$$P^\varepsilon(\{L_\varepsilon \geqq 0\} \cap C_\varepsilon(a, b) \cap B^-(a, b)) < K_m\varepsilon^m.$$

In much the same way as for the test $Q_\pm^\varepsilon$ at the end of § 5, we now introduce a test $R_\pm^\varepsilon$ based on L_ε. In (6.1) let us now write $L_\varepsilon = L_\varepsilon(d, b)$. We consider $a < d < b_1 < b$, and let

$$\begin{aligned} R_\varepsilon^+(a, b) &= C_\varepsilon^0(a, b) \cap \{L_\varepsilon(d, b_1) \geqq 0\} \cap C_\varepsilon(a, b_1), \\ R_\varepsilon^-(a, b) &= C_\varepsilon^0(a, b) \cap \{L_\varepsilon(d, b_1) < 0\} \cap C_\varepsilon(a, b_1). \end{aligned} \tag{6.16}$$

From Lemma 4.1 and Corollary 6.5, we obtain, by the same proof as for Theorem 5.4, the following theorem.

THEOREM 6.6. *There exist positive* K, ε_m, K_m *for* $m = 1, 2, \cdots$, *such that for* $0 < \varepsilon < \varepsilon_m$,

$$P^\varepsilon(B^+(a, b)^c \,|\, R_\varepsilon^+(a, b)) \leqq K_m\varepsilon^m, \qquad P^\varepsilon(B^-(a, b)^c \,|\, R_\varepsilon^-(a, b)) \leqq K_m\varepsilon^m,$$
$$P^\varepsilon([B^+(a, b) \cup B^-(a, b)]^c \cap [R_\varepsilon^+(a, b) \cup R_\varepsilon^-(a, b)]) \leqq \exp\left(-\frac{K}{\varepsilon}\right).$$

7. Approximations to the conditional mean. In §§ 5 and 6 we described two tests to decide between the events $B^+(a, b)$ and $B^-(a, b)$, with small probability of error when ε is small. It remains to estimate how well the conditional mean $\hat{x}_t$ is approximated by m_t^+ in the positive case or by m_t^- in the negative case. Let us consider the events $Q_\varepsilon^\pm(a, b)$ defined by (5.12), using the quadratic variations test. The discussion with $R_\varepsilon^\pm(a, b)$ defined by (6.16) is similar, except that estimates exponential in ε are replaced by estimates polynomial in ε.

For brevity we write $B^\pm = B^\pm(a, b)$, $Q_\varepsilon^\pm = Q_\varepsilon^\pm(a, b)$, etc.

LEMMA 7.1. *For each* $q > 0$ *there exist positive* ε_q, K_q *such that, for* $0 < \varepsilon < \varepsilon_q$

$$E^\varepsilon[|\hat{x}_b - m_b^+|^q;\ Q_\varepsilon^+ \cap (B^+)^c] \leqq \exp\left(-\frac{K_q}{\sqrt{\varepsilon}}\right).$$

Proof. By Cauchy-Schwartz,

$$\text{leftside} \leqq (E^\varepsilon|\hat{x}_b - m_b^+|^{2q})^{1/2}(P^\varepsilon(Q_\varepsilon^+ \cap (B^+)^c))^{1/2}.$$

The last term is estimated by (5.13). Since $E^\varepsilon|\hat{x}_b|^{2q}$ is bounded, it remains only to bound $E^\varepsilon|m_b^+|^{2q}$. Let $z_t = h(x_t) - h_+(m_t^+)$. Then as in the proof of Lemma 3.1,

$$dz_t = -\frac{1}{\varepsilon}\rho_t z_t\,dt + \zeta_t\,dt + \psi_t \cdot dB_t$$

with $\rho_t \geqq \beta > 0$, ζ_t and ψ_t bounded, and $B_t = (w_t, v_t^\varepsilon)$ a two-dimensional Brownian motion. This implies a bound on $E^\varepsilon|z_b|^{2q}$; in fact it is of order ε^q. Since $E^\varepsilon|h(x_b)|^{2q}$ is bounded and $|m_b^+| \leqq k_1|h_+(m_b^+)| + k_2$, we obtain the required bound for $E^\varepsilon|m_b^+|^{2q}$. This proves Lemma 7.1.

We next make a change of probability measure, from P^ε to P^+ with

$$\frac{dP^+}{dP^\varepsilon} = Z_b, \qquad Z_t = \exp\left[\frac{1}{\varepsilon}\int_a^t \gamma_s\,dv_s^\varepsilon - \frac{1}{2\varepsilon^2}\int_a^t \gamma_s^2\,ds\right],$$

$$\gamma_s = h_+(x_s) - h(x_s).$$

This is the same as in § 6, except that the lower limit e is replaced by a.

LEMMA 7.2. *There exist positive ε_0, K such that*

$$P^+((B^+)^c \cap C_\varepsilon^0) \leqq \exp\left(-\frac{K}{\varepsilon}\right), \qquad 0 < \varepsilon < \varepsilon_0.$$

This is proved in the same way as Lemma 4.1 with h replaced by h_+, recalling (4.1) and (4.2).

We use the notation $\phi_t = \phi(x_t)$, and

$$\hat{\phi}_t = E^\varepsilon[\phi_t \mid \mathcal{Y}_t], \qquad \tilde{\phi}_t = E^+[\phi_t \mid \mathcal{Y}_t]. \tag{7.1}$$

As already used in the proof of Lemma 6.1,

$$\widehat{Z_t\phi_t} = \hat{Z}_t\tilde{\phi}_t.$$

LEMMA 7.3. *Let ϕ be bounded and continuous and $\alpha > 0$. Then, for every $q > 0$, there exist positive ε_q, K_q such that*

$$P^\varepsilon(\{|\widehat{\phi_b Z_b} - \hat{\phi}_b| > \alpha\varepsilon^q\} \cap Q_\varepsilon^+) \leqq \exp\left(-\frac{K_q}{\sqrt{\varepsilon}}\right)$$

for $0 < \varepsilon < \varepsilon_0$.

Proof. We recall that $P^\varepsilon(E) = P^+(E)$ for $E \subset B^+$ and that $Z_b = 1$ on B^+. If D is $\mathcal{Y}_b$-measurable, then

$$\int_D (\widehat{\phi_b Z_b} - \hat{\phi}_b)\,dP^\varepsilon = \int_D \phi_b Z_b\,dP^\varepsilon - \int_D \phi_b\,dP^\varepsilon$$

$$= \int_{D\cap(B^+)^c} \phi_b\,dP^+ - \int_{D\cap(B^+)^c} \phi_b\,dP^\varepsilon.$$

Let

$$D = \{\widehat{\phi_b Z_b} - \hat{\phi}_b > \alpha\varepsilon^q\} \cap Q_\varepsilon^+.$$

Using (5.13), Lemma 7.2 and $Q_\varepsilon^+ \subset C_\varepsilon^0$, we have for small ε and suitable K_q

$$P^\varepsilon(\{\widehat{\phi_b Z}_b - \hat{\phi}_b > \alpha\varepsilon^q\} \cap Q_\varepsilon^+) \leqq \frac{\|\phi\|}{\alpha\varepsilon^q}[P^+((B^+)^c \cap Q_\varepsilon^+) + P^\varepsilon((B^+)^c \cap Q_\varepsilon^+)]$$

$$\leqq \frac{1}{2}\exp\left(-\frac{K_q}{\sqrt{\varepsilon}}\right).$$

Similarly, for small ε,

$$P^\varepsilon(\{\widehat{\phi_b Z}_b - \hat{\phi}_b < -\alpha\varepsilon^q\} \cap Q_\varepsilon^+) \leqq \frac{1}{2}\exp\left(-\frac{K_q}{\sqrt{\varepsilon}}\right).$$

This proves Lemma 7.3.

Lemma 7.3 holds in particular for $\phi_t = 1$. Thus, for small ε,

$$P^\varepsilon(\{|\hat{Z}_b - 1| > \alpha\varepsilon^q\} \cap Q_\varepsilon^+) \leqq \exp\left(-\frac{K_q}{\sqrt{\varepsilon}}\right).$$

We then conclude from Lemma 7.3 that given $\theta > 0$ we have for suitable $\bar{\varepsilon}_q$, $\bar{K}_q$

$$P^\varepsilon(\{|\tilde{\phi}_b - \hat{\phi}_b| > \theta\varepsilon^q\} \cap Q_\varepsilon^+) \leqq \exp\left(-\frac{\bar{K}_q}{\sqrt{\varepsilon}}\right) \tag{7.2}$$

for $0 < \varepsilon < \bar{\varepsilon}_q$.

With r as in § 4, we choose ϕ bounded and continuous such that $\phi(x) = x$ if $|x| \leqq r$ and $|\phi(x)| \leqq |x|$ for all x.

LEMMA 7.4. *There exist positive ε_0 and K such that, for $0 < \varepsilon < \varepsilon_0$, and any $D \subset Q_\varepsilon^+$ which is $\mathcal{Y}_b$-measurable*

$$\left|\int_D (\hat{\phi}_b - \hat{x}_b)\, dP^\varepsilon\right| \leqq \exp\left(-\frac{K}{\varepsilon}\right), \qquad \left|\int_D (\tilde{\phi}_b - \tilde{x}_b)\, dP^+\right| \leqq \exp\left(-\frac{K}{\varepsilon}\right).$$

Proof. Let $B_r = \{|x_t| \leqq r \text{ for } a \leqq t \leqq b\}$. Then

$$\left|\int_D (\hat{\phi}_b - \hat{x}_b)\, dP^\varepsilon\right| = \left|\int_D (\phi_b - X_b)\, dP^\varepsilon\right|$$

$$\leqq (E\phi_b^2 + Ex_b^2)^{1/2}[P^\varepsilon(Q_\varepsilon^+ \cap B_r^c)]^{1/2}.$$

The first inequality then follows from Lemma 4.1, since $Q_\varepsilon^+ \subset C_\varepsilon^0$ and $B_r^c \subset (B^+ \cup B^-)^c$. The second inequality is proved in the same way, using Lemma 7.2 and $B_r^c \subset (B^+)^c$. Next, we recall from Picard [12] that for any $q > 0$ there exists N_q, such that for small ε

$$E^+[|\tilde{x}_b - m_b^+|^q] \leqq N_q\varepsilon^q. \tag{7.3}$$

THEOREM 7.5. *Let $0 < p < 1$. Then, for $l = 1, 2, \cdots$ there exist ε_l, K_l such that*

$$P^\varepsilon(|\hat{x}_b - m_b^+| > \varepsilon^p \,|\, Q_\varepsilon^+) \leqq K_l\varepsilon^l,$$

$$P^\varepsilon(|\hat{x}_b - m_b^-| > \varepsilon^p \,|\, Q_\varepsilon^-) \leqq K_l\varepsilon^l, \qquad 0 < \varepsilon < \varepsilon_l.$$

Proof. It suffices to prove the first inequality. We have

$$P^\varepsilon(|\hat{x}_b - m_b^+| > \varepsilon^p;\, Q_\varepsilon^+) \leqq P^\varepsilon((B^+)^c \cap Q_\varepsilon^+) + P^\varepsilon(|\hat{x}_b - m_b^+| > \varepsilon^p;\, B^+ \cap Q_\varepsilon^+).$$

The first term on the right side is estimated from (5.13). To estimate the second term, we write

$$\bar{x}_b - m_b^+ = \hat{x}_b - \tilde{x}_b + \tilde{x}_b - m_b^+.$$

Let us choose ϕ as in Lemma 7.4. Then

$$P^\varepsilon(\hat{x}_b - \tilde{x}_b > \tfrac{1}{2}\varepsilon^p; Q_\varepsilon^+) \leqq P^\varepsilon(|\hat{\phi}_b - \tilde{\phi}_b| > \tfrac{1}{6}\varepsilon^p; Q_\varepsilon^+) + P^\varepsilon(\hat{\phi}_b - \hat{x}_b > \tfrac{1}{6}\varepsilon^p; Q_\varepsilon^+)$$
$$+ P^\varepsilon(\tilde{\phi}_b - \tilde{x}_b > \tfrac{1}{6}\varepsilon^p; Q_\varepsilon^+).$$

The first term on the right side is estimated from (7.2) with $q = p$. The last two terms are estimated from Lemma 7.4 with $D = \{\hat{\phi}_b - \hat{x}_b > \varepsilon^p/6\} \cap Q_\varepsilon^+$ and $D = \{\tilde{\phi}_b - \tilde{x}_b > \varepsilon^p/6\} \cap Q_\varepsilon^+$. Thus, for small ε and suitable $k_1 > 0$

$$P^\varepsilon\left(\hat{x}_b - \tilde{x}_b > \frac{1}{2}\varepsilon^p; Q_\varepsilon^+\right) \leqq \exp\left(-\frac{k_1}{\sqrt{\varepsilon}}\right).$$

Similarly,

$$P^\varepsilon\left(\hat{x}_b - \tilde{x}_b < -\frac{1}{2}\varepsilon^p; Q_\varepsilon^+\right) \leqq \exp\left(-\frac{k_1}{\sqrt{\varepsilon}}\right).$$

Finally, using (7.3),

$$P^\varepsilon\left(|\tilde{x}_t - m_t^+| > \frac{1}{2}\varepsilon^p; B^+ \cap Q_\varepsilon^+\right) = P^+\left(|\tilde{x}_t - m_t^+|^q > \frac{1}{2}\varepsilon^{pq}; B^+ \cap Q_\varepsilon^+\right)$$
$$\leqq \frac{2N_q}{\varepsilon^{pq}} \cdot \varepsilon^q = 2N_q\varepsilon^{(1-p)q} < \frac{\varepsilon^l}{2}$$

for small ε, provided q is chosen large enough that $(1-p)q > l$. By combining these inequalities and recalling (5.14) we obtain Theorem 7.5.

8. Extensions of results. Let us outline how the quadratic variations and likelihood ratio tests can be modified to deal with more complicated situations. To begin with, let us again consider state x_t and observation y_t of dimension one. Afterward we outline an extension to state x_t and observation y_t of the same dimension $n > 1$.

Let us again assume (A1) of § 2. Instead of (A2) and (A3) we assume:

(A2′) h has a finite number of critical points x_i^*, $i = 1, \cdots, m$ with $x_1^* < \cdots < x_m^*$. Moreover, $|h(x)| \to \infty$ as $|x| \to \infty$.

To state the next assumption (A3′) let us make the convention that $x_0^* = \infty$, $x_{m+1}^* = +\infty$. Let

$$O_i = (x_{i-1}^*, x_i^*), \qquad i = 1, \cdots, m+1$$
$$N = \{x_1^*, \cdots, x_m^*\}.$$

(A3′) There exist $\gamma > 0$, $c > 0$ and for every $i < j$ such that $h(O_i) \cap h(O_j) \neq \varnothing$ a compact interval Δ_{ij} with the following properties:

(i) $\Delta_{ij} \subset h(O_i) \cap h(O_j)$;

(ii) $\gamma \leqq \operatorname{dist}(h(N), \Delta_{ij})$;

(iii) $x_i \in O_i$, $x_j \in O_j$, $h(x_i) = h(x_j) = y \in \Delta_{ij}$

imply

$$|[g(x_i)h'(x_i)]^2-[g(x_j)h'(x_j)]^2|>c. \tag{8.1}$$

In previous sections we considered $m=1$, $x_1^*=0$, $h(0)=0$, $\gamma=y_1$, $\Delta_{12}=[y_1, y_2]$.

Let us first describe a test like Lemma 4.1, which will imply that, on a time interval $a\leqq t\leqq b$, x_t remains outside a neighborhood of the set of critical points with the probability very nearly one. We choose $\delta>0$ such that

$$\text{dist}\,[h(x), h(N)]\geqq\gamma \quad \text{implies dist}\,(x, N)>2\delta. \tag{8.2}$$

As in § 4 we introduce "cutoffs" r and y_3, such that $\Delta_{ij}\subset[-y_3, y_3]$ for all $i<j$ and $y_3<|h(x)|$ whenever $|x|\geqq r$. Without loss of generality we may assume that $h'(x)<0$ on O_1.

Let

$$\begin{aligned}\Gamma_1&=(-r, x_1^*-\delta),\\ \Gamma_i&=[x_{i-1}^*+\delta, x_i^*-\delta], \qquad i=2,\cdots, m,\\ \Gamma_{m+1}&=[x_m^*+\delta, r].\end{aligned}$$

We choose h_i, $i=1,\cdots, m+1$, such that h_i'' is bounded and continuous, and

$$h_i(x)=h(x), \quad x\in\Gamma_i, \qquad 0<c_1\leqq|h_i'(x)|\leqq c_2. \tag{8.3}$$

We also define m_t^i for $t\geqq 0$, $i=1,\cdots, m+1$, by

$$dm_t^i=f(m_t^i)\,dt+(-1)^i g(m_t^i)\left(dy_t-\frac{1}{\varepsilon}h_i(m_t^i)\,dt\right) \tag{8.4}$$

with initial data $m_0^i=E^\varepsilon(x_0)$. As in (4.5) we define

$$\begin{aligned}&B_i=\{x_t\in\Gamma_i \text{ for } a\leqq t\leqq b\},\\ &C_\varepsilon^0=\{|h_I(m_t^I)|\leqq y_3, \text{dist}\,(h_I(m_t^I), h(N))\geqq\delta \text{ for } a\leqq t\leqq b\}\end{aligned} \tag{8.5}$$

for some particular I (e.g., $I=m+1$). The analogue of (4.6) is now

$$P^\varepsilon\left[\left(\bigcup_{i=1}^{m+1}B_i\right)^c\cap C_\varepsilon^0\right]\leqq\exp\left(-\frac{K}{\varepsilon}\right), \qquad 0<\varepsilon<\varepsilon_0. \tag{8.6}$$

If $h_I(m_t^I)\in\Delta_{ij}$ for $a\leqq t\leqq b$, then we need a test to discriminate between B_i and B_j. An analogue of Lemma 5.3 is as follows. Suppose that in (8.1) we have, as in (5.10a),

$$(gh')^2(x_i)<(gh')^2(x_j)-c. \tag{8.7}$$

If the opposite inequality holds, the discussion is similar. Let us set

$$\rho_s^-=(gh_i')(m_s^i), \qquad \rho_s^+=(gh_j')(m_s^j)$$

and define $C_\varepsilon=C_\varepsilon^{ij}=\{h_I(m_t^I)\in\Delta_{ij} \text{ for } a\leqq t\leqq b\}$. We again define $C_\varepsilon^+=C_\varepsilon^{+ij}$, $C_\varepsilon^-=C_\varepsilon^{-ij}$ by (5.11). Then, for small ε,

$$P^\varepsilon(B_i\cap C_\varepsilon^+)\leqq\exp\left(-\frac{K}{\sqrt{\varepsilon}}\right), \qquad P^\varepsilon(B_j\cap C_\varepsilon^-)\leqq\exp\left(-\frac{K}{\sqrt{\varepsilon}}\right). \tag{8.8}$$

We then define $Q_\pm^\varepsilon=Q_\pm^{\varepsilon ij}$ as in (5.12) and obtain, as in (5.12), for small ε

$$P^\varepsilon(B_i|Q_\varepsilon^+)\leqq\exp\left(-\frac{K}{\sqrt{\varepsilon}}\right), \qquad P^\varepsilon(B_j|Q_\varepsilon^-)\leqq\exp\left(-\frac{K}{\sqrt{\varepsilon}}\right). \tag{8.9}$$

Similarly, given $i<j$ we define $L_\varepsilon = L_\varepsilon^{ij}$ as in (6.1) by

$$L_\varepsilon^{ij} = \int_d^b (\hat{h}_s^j - \hat{h}_s^i)\, dy_s - \frac{1}{2\varepsilon}\int_d^b [(\hat{h}_s^j)^2 - (\hat{h}_s^i)^2]\, ds$$

where $\hat{h}_s^i = h_i(m_s^i)$. If we again assume (8.7) then the analogue of Theorem 6.6 states that, for small ε and suitable K_m, $m = 1, 2, \cdots$,

$$P^\varepsilon(B_i \mid R_\varepsilon^+) \leqq K_m \varepsilon^m, \qquad P^\varepsilon(B_j \mid R_\varepsilon^-) \leqq K_m \varepsilon^m. \tag{8.10}$$

Remark. There is also a "local" version of these tests in which only $j = i+1$ is considered. This version can be used to detect a crossing of the critical point x_i^* by x_t, from O_i to O_{i+1} or vice versa.

Extensions to dimension $n>1$. Now let $h : \Re^n \to \Re^n$. We merely indicate how the results for $n=1$ can be modified, without spelling out in precise detail the results. Let $Dh(x)$ denote the matrix of partial derivatives and $Jh(x) = \det Dh(x)$ its Jacobian determinant. In the analogue of the (A1), the matrix $g(x)$ is assumed to have a bounded inverse $g^{-1}(x)$. Instead of (A2′) we suppose that there are disjoint open sets $O_i, \cdots, O_{m+1}$ such that

$$\Re^n = O_1 \cup \cdots \cup O_{m+1} \cup N,$$

$$N = \bigcup_{i=1}^{m+1} \partial O_i,$$

and the boundary of O_i consists of pieces of finitely many smooth $(n-1)$-dimensional manifolds. It is assumed that the restriction of h to each O_i is one-to-one with $Jh(x) \neq 0$ on O_i. Moreover, $|h(x)| \to \infty$ as $|x| \to \infty$.

Given $\gamma > 0$ we again choose $\delta > 0$ as in (8.2) and let

$$\Gamma_i = O_i \cap \{\text{dist}\,(x, N) \geqq \delta\} \cap \{|x| \leqq r\}$$

where r is a suitable "cutoff." We also choose h_i such that $h_i(x) = h(x)$ for $x \in \Gamma_i$ and that h_i satisfies the assumptions of Picard [13]. Principal among these is an analogue of (8.3), which asserts that h_i has an inverse h_i^{-1} with Dh_i^{-1} bounded. Let

$$T_i^2(x) = \text{trace}\,[(Dh_i)(gg^*)(Dh_i)^*](x). \tag{8.11}$$

Then $T_i^2(x) \geqq k_i > 0$. In (A3′), condition (8.1) is replaced by

$$|T_i^2(x_i) - T_j^2(x_j)| > c, \tag{8.12}$$

and Δ_{ij} is the closure of some bounded, open connected set (rather than an interval). As in Picard [13] the approximate filters m_t^i are defined by

$$dm_t^i = f(m_t^i)\, dt + [Dh_i(m_t^i)]^{-1} T_i(m_t^i)(dy_t - \varepsilon^{-1} h(m_t^i)\, dt) \tag{8.13}$$

with $m_0^i = E^\varepsilon(x_0)$. We then proceed as for $n=1$, with evident notational changes. For example, in the definition (5.6) we now have

$$Z_\varepsilon = \frac{1}{b-a} \sum_{j \text{ even}} |Y_{j+1} - Y_j|^2.$$

Acknowledgment. We thank J. Walsh for a helpful suggestion regarding the calculation above Lemma 5.1.

OPTIMAL FEEDBACK CONTROL OF INFINITE-DIMENSIONAL PARABOLIC EVOLUTION SYSTEMS: APPROXIMATION TECHNIQUES *

H.T. BANKS† AND C. WANG‡

This paper is dedicated to the memory of E.J. McShane.

Abstract. This paper presents a general approximation framework for the computation of optimal feedback controls in linear quadratic regulator problems for nonautonomous parabolic distributed parameter systems. This is done in the context of a theoretical framework using general evolution systems in infinite-dimensional Hilbert spaces. The authors discuss conditions for preservation under approximation of stabilizability and detectability hypotheses on the infinite-dimensional system. The special case of periodic systems is also treated.

Key words. evolution equations, LQR problem, feedback control, approximation techniques

1. Introduction.

In this paper we present a theoretical approximation framework for the computation of optimal feedback controls in linear quadratic regulator (LQR) problems governed by parabolic partial differential equations with time dependent coefficients. Our efforts were originally motivated by the desire to develop control strategies (distributed in nature) for insect dispersal models (see Chapter 1 of [BK2] and the references therein) which have been shown to involve time dependent coefficients.

The presentation below is somewhat in the spirit of that for autonomous parabolic systems in [BK1] and [LT] in that we attempt to develop a convergence theory in which uniform stabilizability of the original system is preserved under approximation. It differs substantially from [BK1] and [LT] since we do not directly use sectorial properties of the operators and resolvent and spectral set arguments to establish preservation of stabilizability and detectability. (Indeed, the time dependent nature of our system prevents this.) Nor do we use the Trotter–Kato theorem (which is not well suited for use with nonautonomous control systems) in our convergence arguments.

In §2 we summarize previous results for abstract LQR problems on infinite time intervals and formulate these in a form readily used in our subsequent discussions. This formulation is based on the abstract frameworks found in [CP], [G], [BK1], and [Da], [DI1], [DI2]; we rely heavily on the ideas of Da Prato and Ichikawa that guarantee uniqueness of solutions of the associated Riccati integral equations under certain stabilizability and detectability assumptions.

An approximation framework for abstract evolution systems in the spirit of [G] and [BK1] is given in §3; convergence of the approximate Riccati operators (and, of course, the corresponding controls and trajectories) is established under uniform

stabilizability and detectability hypotheses on the approximate evolution control systems.

Our major contributions are given in §4, along with the presentations in §§5 and 6, where we show how the hypotheses of §4 can be verified for rather wide classes of problems of interest. In §4 we focus attention on parabolic systems described by time dependent sesquilinear forms (in the spirit of the autonomous system frameworks in [BK1], [BI1], [BI2]) and associated evolution equations. We make substantial use of the results of Tanabe [T] to formulate our problems in a weak (V^*) sense. Our fundamental convergence results (Theorem 4.4) for the uncontrolled systems rely on a sesquilinear or variational formulation of the systems, strong V-ellipticity of the parabolic evolution systems, approximation properties for the spaces approximating the state space, and the Gronwall inequality. (Certain aspects of this approach can be relaxed to allow us to treat weakly damped hyperbolic systems—see [BKS], [BKW].) We are then able to reduce convergence questions for the controlled systems (e.g., convergence of Riccati variables, optimal controls, and feedback evolution systems) to conditions of uniform stabilizability and uniform detectability of the approximate systems (Theorem 4.5).

We show in §5 that we can obtain these uniform stabilizability/detectability conditions by preservation under approximation of dissipative inequalities for certain classes of evolution control systems. Sufficient conditions that are readily checked in many examples are given and several special cases are noted.

An alternative approach is presented in §6 where we restrict our considerations to parabolic systems for which the domain V of the generator of the evolution system embeds compactly in the state space H. In this case, it is shown that stabilizability/detectability of the original system is preserved under approximation.

Finally, in §7 we give an example of a class of parabolic partial differential equation control problems for which all the hypotheses of our theoretical framework can be easily verified.

We have used the ideas presented in this paper to develop and test computational packages for solving nonautonomous parabolic control problems of the type discussed in §7. However, since our presentation here is already quite long and since a presentation of our detailed numerical findings would entail lengthy discussions, we will not discuss the numerical examples. A separate manuscript is under preparation; the interested reader can also consult [W].

We believe that the present paper offers new results for time dependent infinite-dimensional control systems. Moreover, our arguments are such that we offer an attractive alternative approach to those found in [G], [BK1], and [LT] even in the case of autonomous parabolic systems.

2. The abstract linear quadratic regulator problem on an infinite time interval. In this section we formulate a linear quadratic regulator problem for evolution system dynamics in a Hilbert space and present a collection of functional analytic and control theoretic results related to such problems. The results we give in this section are known even though in some cases we have modified the statements to present the results in a form most suited to our purposes. The reader can easily refer to the cited literature for proofs. In particular, we use freely results found in [CP] and [G] and rely heavily on recent results of Da Prato and Ichikawa [Da], [DI1], and [DI2].

We first recall results for evolutionary systems. Let H be a Hilbert space with inner product $< \cdot, \cdot >$. Let $\triangle(t_0, t_f) = \{(t,s) \mid t_0 \leq s \leq t \leq t_f\}$, $\triangle_\infty(t_0) = \{(t,s) \mid t_0 \leq s \leq t < \infty\}$ and $L(H)$ be the Banach algebra of bounded linear operators

on H. We use $B_\infty([t_0,t_f];L(H))$ to denote the set of strongly measurable operator valued functions that are bounded on $[t_0,t_f]$. We recall that $T(\cdot,\cdot):\triangle(t_0,t_f)\mapsto L(H)$ is called an *evolution operator* if T satisfies the following conditions: (i) $T(t,s)=T(t,r)T(r,s)$, for $t_0\le s\le r\le t\le t_f$; (ii) $T(t,t)=I$, for $t\in[t_0,t_f]$; and (iii) $T(t,s)$ is strongly continuous in s on $[t_0,t]$ and strongly continuous in t on $[s,t_f]$. We say that an evolution operator has *exponential growth* if there exists $M_1\ge 1,\omega>0$ such that $\|T(t,s)x\|\le M_1e^{\omega(t-s)}\|x\|$, for $(t,s)\in\triangle_\infty(t_0),x\in H$. An evolution operator is said to be *uniformly exponentially stable* if there exists $M\ge 1$ and $\alpha>0$ such that $\|T(t,s)x\|\le Me^{-\alpha(t-s)}\|x\|$, for $(t,s)\in\triangle_\infty(t_0),x\in H$. We have the following fundamental results of Datko which will be crucial to our presentation.

LEMMA 2.1. [Dt]. *Consider an evolution operator $T(\cdot,\cdot)$ with exponential growth. Then $T(\cdot,\cdot)$ is uniformly exponentially stable if and only if there exists an M_2 such that*

$$\int_s^\infty \|T(t,s)x\|^2dt\le M_2\|x\|^2,\quad \textit{for } s\ge t_0, x\in H.$$

Furthermore, we can find constants $M_3\ge 1,\alpha>0$ depending only on M_1,M_2, and ω for which the following estimate holds:

$$\|T(t,s)\|\le M_3e^{-\alpha(t-s)},\quad \textit{for } (t,s)\in\triangle_\infty(t_0).$$

The original statement and proof of this theorem are due to Datko. We have modified slightly (see Appendix A of [W]) the original proof in [Dt] to point out the relationship between the constants M_3,α and M_1,M_2, and ω. This will be essential for our subsequent use with approximation systems. In [W] it is shown that the constants M_3 and α can be chosen as:

$$M_3=2M_1e^{4M_2{M_1}^2\omega(2\omega M_2+1)},\quad \alpha=\frac{\log 2}{4M_2{M_1}^2(2\omega M_2+1)}.$$

In our discussions of control systems, perturbations of evolution operators (see [CP]) will play an important role. Let $t_f<\infty$. Consider a uniformly bounded evolution operator $T(\cdot,\cdot)$ and $C(\cdot)\in B_\infty([t_0,t_f];L(H))$. Then the integral equation for $S(t,s)\in L(H)$ given by

$$S(t,s)x=T(t,s)x+\int_s^t T(t,\eta)C(\eta)S(\eta,s)xd\eta,\quad \text{for } x\in H,$$

has a unique solution $S(\cdot,\cdot)$ in the class of strongly continuous operator valued functions. Moreover, $S(\cdot,\cdot)$ is an evolution operator and is called the *perturbed evolution operator* corresponding to the perturbation of $T(\cdot,\cdot)$ by $C(\cdot)$. In addition, $S(\cdot,\cdot)$ is also the unique solution of

$$S(t,s)x=T(t,s)x+\int_s^t S(t,\eta)C(\eta)T(\eta,s)xd\eta,\quad \text{for } x\in H.$$

We turn next to our formulation of the regulator problem for an evolution system. We let H,U be real Hilbert spaces with inner products $<\cdot,\cdot>_H$, $<\cdot,\cdot>_U$; H,U are the state space and the control space, respectively. Consider an evolution operator

$T(\cdot,\cdot)$ defined on $\triangle_\infty(t_0)$. For any $u \in L^2([t_0,\infty);U)$, the control system trajectories are defined by:

$$x(t) = T(t,s)x(s) + \int_s^t T(t,\tau)B(\tau)u(\tau)d\tau, \quad \text{for } (t,s) \in \triangle_\infty(t_0). \tag{2.1}$$

The cost functional is given by

$$J_\infty(u;t_0,x_0) = \int_{t_0}^\infty \{< W(t)x(t),x(t) >_H + < R(t)u(t),u(t) >_U\}\, dt, \tag{2.2}$$

where $x(\cdot)$ is the trajectory corresponding to u with $x(t_0) = x_0$. For each given t_0, x_0, the optimal control problem is to find a control u^* which minimizes (2.2) over all $u \in L^2([t_0,\infty);U)$.

We can consider (2.2) as the limit as $t_k \to \infty$ of

$$\begin{aligned} J(u;t_0,t_k,x_0) =& < Gx(t_k),x(t_k) >_H \\ &+ \int_{t_0}^{t_k} \{< W(t)x(t),x(t) >_H + < R(t)u(t),u(t) >_U\}\, dt, \end{aligned} \tag{2.3}$$

with $G = 0$. Here we shall summarize existence results for optimal controls in the infinite time interval, existence and uniqueness of the solutions of the Riccati integral equation on an infinite time interval, and stability of the feedback system.

We make the following *standing assumptions* for all subsequent discussions of (2.1), (2.2): (i) The evolution operator $T(\cdot,\cdot)$ has exponential growth. (Thus, in particular, $T(t,s)$ is uniformly bounded for s,t in any bounded sub-interval of $[t_0,\infty)$); (ii) The strongly measurable operator valued function $B(\cdot) : [t_0,\infty) \mapsto L(U,H)$ is uniformly bounded in $[t_0,\infty)$, i.e., there exists M_B such that $\|B(t)\|_{L(U,H)} \le M_B$ for all $t \in [t_0,\infty)$; (iii) The strongly measurable operator valued function $W(\cdot) : [t_0,\infty) \mapsto L(H)$ is uniformly bounded in the interval $[t_0,\infty)$, and $W(t)$ is nonnegative definite self-adjoint for all $t \in [t_0,\infty)$; (iv) The strongly measurable operator valued function $R(\cdot) : [t_0,\infty) \mapsto L(U)$ is uniformly bounded in the interval $[t_0,\infty)$, and $R(t)$ is positive definite self-adjoint for all $t \in [t_0,\infty)$. Furthermore, there exists a constant $r > 0$ such that $< R(t)u,u >_U \ge r\|u\|_U^2$, for all $u \in U$ and $t \ge t_0$.

Under these assumptions, we consider the linear quadratic control problem in the interval $[t_0,t_k]$ for $t_k < \infty$. That is, we consider the cost functional (2.3) with our system (2.1). Then for any bounded self-adjoint nonnegative definite linear operator G, it is well known that for each given $x_0 \in H$, there exists a unique control u such that

$$J(u;t_0,t_k,x_0) \le \min_{v \in L^2([t_0,t_k];U)} J(v;t_0,t_k,x_0).$$

This control u can be written in a feedback form $u(t) = -R^{-1}(t)B^*(t)Q(t)x(t)$, for $t \in [t_0,t_k]$, where $x(\cdot)$ is the corresponding trajectory and $Q(\cdot) : [t_0,t_f] \mapsto L(H)$, is the unique self-adjoint solution of the Riccati integral equation (RIE)

$$\begin{aligned} Q(t)x =& T^*(t_k,t)GT(t_k,t)x + \int_t^{t_k} T^*(\eta,t)W(\eta)T(\eta,t)x\,d\eta \\ &- \int_t^{t_k} T^*(\eta,t)Q(\eta)B(\eta)R^{-1}(\eta)B^*(\eta)Q(\eta)T(\eta,t)x\,d\eta \end{aligned} \tag{2.4}$$

for all $t \in [t_0, t_k]$ and $x \in H$.

We note that in the case $G = 0$, the above equation reduces to

$$Q(t)x = \int_t^{t_k} T^*(\eta, t)[W(\eta) - Q(\eta)B(\eta)R^{-1}(\eta)B^*(\eta)Q(\eta)]T(\eta, t)x d\eta, \tag{2.5}$$

for all $t \in [t_0, t_k]$ and $x \in H$. We also note that (2.4) is equivalent to

$$\begin{aligned} Q(s)x &= T^*(t,s)Q(t)T(t,s)x + \int_s^t T^*(\eta,s)W(\eta)T(\eta,s)x d\eta \\ &\quad - \int_s^t T^*(\eta,s)Q(\eta)B(\eta)R^{-1}(\eta)B^*(\eta)Q(\eta)T(\eta,s)x d\eta \\ Q(t_k)x &= Gx \end{aligned} \tag{2.6}$$

for all $t_0 \le s \le t \le t_k$ and $x \in H$. Solutions of this latter equation have a representation that is often used in control theoretic arguments. Consider any $u(\cdot) \in L^2([t_0, t_k]; U)$, and for $x \in H$, define a H-valued function $y(\cdot)$ by

$$y(t) = T(t,s)x + \int_s^t T(t,\tau)B(\tau)u(\tau)d\tau, \quad \text{for } t \in [s, t_k].$$

If $Q(\cdot)$ is a self-adjoint solution of (2.6), then

$$\begin{aligned} < Q(s)x, x >_H &= < Gy(t_k), y(t_k) >_H \\ &\quad + \int_s^{t_k} \{< W(t)y(t), y(t) >_H + < R(t)u(t), u(t) >_U\} dt \\ &\quad - \int_s^{t_k} < R(t)z(t), z(t) >_U dt, \end{aligned} \tag{2.7}$$

where $z(t) = u(t) + R^{-1}(t)B^*(t)Q(t)y(t)$. This can be used to show that (2.6) has a unique self-adjoint solution.

Before continuing our discussion, let us introduce additional notation. Let

$$\Sigma^+ = \left\{ E \mid E \in L(H), E \text{ self-adjoint, nonnegative definite.} \right\}$$
$$\mathcal{C}_s([t_0, t_k]; \Sigma^+) = \left\{ K : [t_0, t_k] \mapsto \Sigma^+ \mid K \text{ strongly continuous.} \right\}$$

By the uniqueness of the solution of (2.6), we can define a mapping $\Lambda : \Sigma^+ \mapsto \mathcal{C}_s([t_0, t_k]; \Sigma^+)$ as follows: for each $G \in \Sigma^+$, ΛG is the unique nonnegative definite self-adjoint solution of (2.6). Under our general assumptions, it is easily seen that for fixed G the map Λ depends only on t_k; if we consider the linear quadratic regulator problem on two bounded intervals $[t_0, t_1]$ and $[t_0, t_2]$, we will use Λ_1, Λ_2 to denote the maps associated with each interval, respectively.

Now consider a increasing sequence $\{t_k\}_{k=1}^{\infty}$, with $t_k < \infty$. The map Λ_k associates with each finite interval problem the Riccati equation on $[t_0, t_k]$. Let $G = 0$ and $Q_k(\cdot) = \Lambda_k G$. For simplicity, consider a bounded interval $[a, b] \subset [t_0, t_1]$, and for each $t \in [a, b], x \in H$, we assume that there exists a constant $M(t, x)$ such that for all k

$$< Q_k(t)x, x >_H \quad \le \quad M(t, x). \tag{2.8}$$

The following theorem (see [Da], [G] establishes the connection between control problems on a finite time interval and problems on an infinite time interval.

THEOREM 2.1. *Under the standing assumptions and* (2.8), *we can conclude the following:*

(i) *For each* $t \in [a,b]$, *there exists a unique operator* $Q(t) \in \Sigma^+$ *such that* $Q_k(t) \to Q(t)$ *strongly and the convergence is uniform in* $[a,b]$. *Therefore,* $Q(\cdot)$ *is strongly continuous, so uniformly bounded in* $[a,b]$.

(ii) *As a consequence of (i), we can define the perturbed evolution systems* $S_k(\cdot,\cdot)$, $S(\cdot,\cdot)$ *corresponding to the perturbation of* $T(\cdot,\cdot)$ *by* $-BR^{-1}B^*Q_k$ *and* $-BR^{-1}B^*Q$, *respectively. We have* $S_k(t,s)x \to S(t,s)x$, *for all* $x \in H$, *and* $a \le s \le t \le b$. *Furthermore, the convergence is uniform in* t *for* $t \in [s,b]$. *If* $T(\cdot,\cdot)$ *is jointly strongly continuous, then the convergence is uniform for all* $a \le s \le t \le b$.

The only assumption on the sequence $\{t_k\}$ is that t_k increase as a function of k. In particular, the above theorem is valid when $t_k \to \infty$, as $k \to \infty$. Paralleling the usual approach to finite-dimensional regulator problems, we can use these results to establish results for the control problem on an infinite time interval. To that end, consider a sequence $\{t_k\}_{k=1}^{\infty}$ with $t_k \to \infty$ as $k \to \infty$. Let $Q_k(\cdot), S_k(\cdot,\cdot)$ be defined as above. If for each $t \ge t_0$ we can find a constant $M(t)$ such that $< Q_k(t)x, x >_H \le M(t)\|x\|^2$, then by Theorem 2.1, we have $Q(\cdot), S(\cdot,\cdot)$ defined on $[t_0,\infty)$. Furthermore, for any $(t,s) \in \Delta_\infty(t_0)$, Q satisfies

$$
\begin{aligned}
(2.9) \qquad Q(s)x &= T^*(t,s)Q(t)T(t,s)x + \int_s^t T^*(\eta,s)W(\eta)T(\eta,s)x\,d\eta \\
&\quad - \int_s^t T^*(\eta,s)Q(\eta)B(\eta)R^{-1}(\eta)B^*(\eta)Q(\eta)T(\eta,s)x\,d\eta.
\end{aligned}
$$

Equation (2.9) is called the Riccati integral equation (RIE) for the infinite time interval. We know from Theorem 2.1 that Q is strongly continuous and uniformly bounded in any bounded interval, but Q is not necessarily uniformly bounded in the entire interval $[t_0,\infty)$. If Q is not uniformly bounded, that implies the minimal cost for some initial state x will tend to infinity as t_k tends to infinity; that is, there is no control yielding finite cost for the infinite time interval problem. Let us state a condition which prohibits this situation.

DEFINITION 2.1. (W-stabilizability). We say that (2.1), (2.2) is *W-stabilizable* if there exists a constant M such that for any $s \ge t_0$ and $x \in H$, we can find a control $u \in L^2([t_0,\infty);U)$ satisfying

$$
(2.10) \qquad J_\infty(u;s,x) \le M\|x\|^2.
$$

One can then prove (see [DI1, Thm. 3.1]) that $Q = \lim Q_k$ is a uniformly bounded solution of the Riccati integral equation (2.9) in $[t_0,\infty)$ if and only if (2.1), (2.2) is W-stabilizable. In this case we have $Q(t) \le M \cdot I$ for $t \in [t_0,\infty)$. Furthermore, if $\hat{Q}$ is any other bounded self-adjoint solution of (2.9), we have that $Q(t) \le \hat{Q}(t)$ for $t \in [t_0,\infty)$. It follows that using any sequence $\{t_k\}$, with $t_k \to \infty$, in the above limiting procedure yields the same solution Q to (2.9), which we shall refer to as the

minimal bounded nonnegative self-adjoint solution of the Riccati integral equation on $[t_0, \infty)$ and denote by $Q_{\min}$.

We note that if the system (2.1), (2.2) is W-stabilizable, then for any $s \geq t_0$ and $x \in H$, the unique optimal control for the infinite time interval problem is given by $u(t) = -R^{-1}(t)B^*(t)Q(t)S(t,s)x$.

Next we consider a uniformly bounded solution $\hat{Q}$ of (2.9) and let $\hat{S}$ be the evolution operator corresponding to the perturbation of T by $-BR^{-1}B^*\hat{Q}$. We say that $\hat{Q}$ is a *stability solution* of (2.9) if $\hat{S}(t,s)x \to 0$ as $t \to \infty$ for all $s \geq t_0$, $x \in H$.

It is shown in [DI1] that there is at most one stability solution of (2.9). Moreover, if $\hat{Q}$ is a stability solution satisfying $\hat{Q}(t) \leq M \cdot I$ and Q_k is the solution on $[t_0, t_k]$ with $Q_k(t_k) = M \cdot I$, then $\hat{Q}(t) \leq Q_k(t)$ for $t \in [t_0, t_k]$ and $Q_k(t)x \to \hat{Q}(t)x$ as $k \to \infty$ for each $x \in H$. In addition, if Q is any uniformly bounded solution, then $Q(t) \leq \hat{Q}(t)$, $t \in [t_0, \infty)$; that is, any stability solution is the *maximal* (uniformly bounded) solution. Finally, if the system (2.1), (2.2) is W-stabilizable and if the minimal solution $Q_{\min}$ of (2.9) is a stability solution, then it is the unique uniformly bounded solution of the RIE (2.9).

From the above remarks, it is clear that it is desirable to have conditions that guarantee a solution of the RIE be a stability solution. One such condition is a detectability condition which plays a role in infinite dimensional systems that is analogous to its role in finite dimensional systems (see [R], [DI1]).

DEFINITION 2.2. (W-detectability). Let $V(t) = \sqrt{W(t)}$. We say that the system (2.1), (2.2) is *W-detectable* if there exists a uniformly bounded function $K(\cdot)$ with $K(t) \in L(H)$ such that the evolution operator T_{KV} corresponding to the perturbation of T by KV is uniformly exponentially stable.

We then have the following result.

THEOREM 2.2. *Suppose that the system* (2.1), (2.2) *is W-stabilizable and W-detectable. Then the minimal solution $Q_{\min}$ of the* RIE *is the unique uniformly bounded solution of* (2.9) *and the evolution operator S defined by perturbation of T by $-BR^{-1}B^*Q_{\min}$ is uniformly exponentially stable. In fact,*

$$\|S(t,s)\| \leq Me^{-\alpha(t-s)}, \quad (t,s) \in \triangle_\infty(t_0),$$

where the constants M and α depend only on the bounds for $B, K, R^{-1}, Q_{\min}$, and M_{KV}, β in the bound $\|T_{KV}(t,s)\| \leq M_{KV} \exp\{-\beta(t-s)\}$.

The first part of this theorem follows from [DI1, Prop. 3.3]. That the constants M and α depend only on the bounds indicated follows from use of the modified Datko lemma, Lemma 2.1 above. As we shall see in the next section on approximation, this dependence (or lack thereof) will allow us to infer a uniform exponential stability of the approximate feedback control systems whenever we have a uniform W-detectability condition satisfied by the approximate systems.

To conclude this section, we recall that an evolution operator is said to be θ-periodic if for any $(t,s) \in \triangle_\infty(t_0)$, we have $T(t+\theta, s+\theta)x = T(t,s)x$, for all $x \in H$. We note that any θ-periodic evolution operator satisfies the exponential growth assumption that is part of our standing assumptions in this paper. It is also easily argued (e.g., see [W]) that if the linear quadratic regulator problem is θ-periodic (i.e., B, W, R, and T of (2.1), (2.2) are θ-periodic), then the minimal solution and the stability solution of the RIE are θ-periodic. Of course, we cannot argue that every

uniformly bounded solution of the RIE is periodic under a periodicity assumption on the problem.

We turn next to approximation results for the abstract linear regulator problem on an infinite time interval.

3. Approximation of linear quadratic regulator problems on an infinite time interval. Let H^N and U^N be families of finite-dimensional subspaces of the original state space and control space H, U, respectively. For each N an approximate control system is described by

$$x^N(t) = T^N(t,s)x^N(s) + \int_s^t T^N(t,\eta)B^N(\eta)u^N(\eta)d\eta, \quad \text{for } (t,s) \in \triangle_\infty(t_0), \tag{3.1}$$

where $T^N(\cdot,\cdot) : \triangle_\infty(t_0) \mapsto L(H^N)$ is an evolution operator, and $B^N(\cdot) : U^N \mapsto H^N$. The cost functional is given by

$$\begin{aligned} J_\infty^N(u^N; t_0, x_0^N) = &\int_{t_0}^\infty < W^N(t)x^N(t), x^N(t) >_H \, dt \\ &+ \int_{t_0}^\infty < R^N(t)u^N(t), u^N(t) >_U \, dt \end{aligned} \tag{3.2}$$

where $x^N(\cdot)$ satisfies (3.1) and $x^N(t_0) = x_0^N$. Suppose that each of the approximate systems and cost functionals satisfies the standing assumptions for (2.1), (2.2) given above and that each is W-stabilizable. Then we can guarantee existence of $Q^N(\cdot)$, the minimal uniformly bounded solution of the associated Riccati integral equation on the infinite time interval $[t_0, \infty)$. Let $S^N(\cdot,\cdot)$ be the perturbed evolution operator corresponding to the perturbation of T^N by $-B^N(R^N)^{-1}B^{*N}Q^N$. In this section, we present results on the strong convergence of Q^N, S^N.

We need to make some basic assumptions on the approximate systems. Let $\{H^N\}_{N=1}^\infty$, $\{U^N\}_{N=1}^\infty$ be subspaces of H, U, respectively, and P_H^N, P_U^N be projection operators which are assumed to satisfy $\|P_H^N x - x\|_H \to 0$, $\|P_U^N u - u\|_U \to 0$, as $N \to \infty$, for all $x \in H, u \in U$.

We note that the usual orthogonal projections of H and U onto H^N, U^N respectively, satisfy these assumptions if H^N, U^N approximate H and U in an appropriate sense. (We shall specify approximation systems that satisfy these conditions in subsequent sections.) We make the further assumptions on our approximate systems.

Hypothesis 3.1. (*Uniform boundedness*).

(i) There exist constants $M \geq 1$ and $\omega > 0$ such that

$$\|T(t,s)\|_{L(H)} \leq Me^{\omega(t-s)}, \quad \|T^N(t,s)\|_{L(H^N)} \leq Me^{\omega(t-s)}$$

hold for all N and $(t,s) \in \triangle_\infty(t_0)$;

(ii) There exists a constant K_B such that

$$\|B(t)\|_{L(U,H)} \leq K_B, \quad \|B^N(t)\|_{L(U^N,H^N)} \leq K_B$$

for all N and $t \in [t_0, \infty)$;

(iii) There exists a constant K_W such that

$$\|W(t)\|_{L(H)} \leq K_W, \quad \|W^N(t)\|_{L(H^N)} \leq K_W$$

for all N and $t \in [t_0, \infty)$. Furthermore, $W(t), W^N(t)$ are nonnegative definite self-adjoint for all $t \in [t_0, \infty)$.

(iv) There exists a constant K_R such that

$$\|R(t)\|_{L(U)} \leq K_R, \quad \|R^N(t)\|_{L(U^N)} \leq K_R$$

for all N and $t \in [t_0, \infty)$. In addition, $R(t), R^N(t)$ are positive definite self-adjoint for all $t \in [t_0, \infty)$. There exists a constant $r > 0$ such that $R(t) \geq r \cdot I$, $R^N(t) \geq r \cdot I$, for all $t \in [t_0, \infty)$.

Hypothesis 3.2. (*Pointwise convergence*). The operators $T^N(t,s)$, $T^{*N}(t,s)$, $B^N(t)$, $B^{*N}(t)$, G^N, $W^N(t)$, $R^N(t)$ converge strongly to $T(t,s)$, $T^*(t,s)$, $B(t)$, $B^*(t)$, G, $W(t)$, $R(t)$ for any $t_0 \leq s \leq t < \infty$, where G, G^N are nonnegative self-adjoint operators in $L(H), L(H^N)$, respectively.

From arguments in [DI1] and [W], it is readily seen that W-stabilizability (i.e., condition (2.10)) is equivalent to the following: there exists a constant $M > 0$, and a uniformly bounded feedback operator $K(\cdot) : [t_0, \infty) \mapsto L(H, U)$ such that if $T_K(\cdot, \cdot)$ is the perturbed evolution operator corresponding to the perturbation of T by BK, then for any $s \geq t_0$, $x \in H$, the cost of the feedback control $u(t) = B(t)K(t)T_K(t,s)x$ satisfies $J_\infty(u; s, x) \leq M\|x\|^2$.

To guarantee the existence of uniformly bounded solutions of the Riccati integral equation on the infinite time interval for each of the approximate systems, we make a uniform W-stabilizability assumption.

Hypothesis 3.3. (*Uniform W-stabilizability*). There exists a constant $M > 0$ such that for all N, there exist uniformly bounded feedback operators $K^N(\cdot) : [t_0, \infty) \mapsto L(H^N, U^N)$ satisfying the following: for all $s \geq t_0$ and $x^N \in H^N$, the feedback control $u^N(t) = B^N(t)K^N(t)T^N_{K^N}(t,s)x^N$ has a cost satisfying

$$J^N_\infty(u^N; s, x^N) \leq M\|x^N\|^2_H.$$

Now consider $\{t_k\}_{k=1}^\infty$ with $t_k \to \infty$ as $k \to \infty$. For each N, let Σ^{+N} be the set of nonnegative self-adjoint linear operators in H^N; we define the map $\Lambda^N_k : \Sigma^{+N} \mapsto \mathcal{C}_s([t_0, t_k]; \Sigma^{+N})$ via the finite dimensional Riccati integral equation on $[t_0, t_k]$ as before. Let $G \in \Sigma^+$, and $G^N \in \Sigma^{+N}$. Define $Q^N_k(\cdot) = \Lambda^N_k G^N$, and $Q_k(\cdot) = \Lambda_k G$. Let the evolution operators S^N_k and S_k correspond to the perturbation of T^N, T by $-B^N(R^N)^{-1}B^{*N}Q^N_k$ and $-BR^{-1}B^*Q_k$, respectively. The theories of the approximation of linear quadratic control problems on a finite time interval (e.g., see [G], [BK1]) guarantee that under Hypotheses 3.1 and 3.2, for each k, $Q^N_k(t)$ and $S^N_k(t,s)$ converge strongly to $Q_k(t)$ and $S_k(t,s)$, respectively, as $N \to \infty$ for every $t_0 \leq s \leq t \leq t_k$. Furthermore the convergence is uniform in the interval $[t_0, t_k]$, if we replace Hypothesis 3.2 by the following assumptions.

Hypothesis 3.4. (*Continuity and uniform convergence*). The operator valued functions $B(t)$, $B^*(t)$, $W(t)$, $R(t)$ are strongly piecewise continuous in t (with only a finite number of discontinuity points in any bounded interval); the evolution operators T, T^* are jointly strongly continuous. The convergences in Hypothesis 3.2 are uniform in t and (t,s) on any bounded interval.

From the theory of the linear quadratic control problem for the infinite time intervals, there are two cases where Q^N_k converges strongly as $k \to \infty$. In the first

case, let $Q^N_{\min}(t)$ be the minimal uniformly bounded solution of the Riccati integral equation in H^N on the infinite time interval $[t_0, \infty)$. If $G = G^N = 0$, then for any N we have $Q^N_k(t)x^N \to Q^N_{\min}(t)x^N$, as $k \to \infty$. Furthermore the convergence is uniform in t for t in any bounded interval $[t_0, t_f]$. In the second case, we assume the following conditions hold.

Hypothesis 3.5. Assume that there exists a stability solution $Q_s(\cdot)$ of the Riccati integral equation for the infinite time interval infinite-dimensional system and there exists a stability solution $Q^N_s(\cdot)$ of the Riccati integral equation on the infinite time interval for each approximate system. (Then the evolution operator S^N corresponding to the perturbation of T^N by $-B^N(R^N)^{-1}B^{*N}Q^N_s$ satisfies $S^N(t,s)x \to 0$, as $t \to \infty$, for $s \geq t_0, x \in H^N$.) Furthermore, assume that there exists a constant M such that for each N, $Q^N_s(t) \leq M \cdot I$ for all $t \geq t_0$. Also assume $Q_s(t) \leq M \cdot I$ for all $t \geq t_0$.

Assuming that Hypothesis 3.5 holds, we let $G = G^N = M \cdot I$ and Q^N_k, Q_k be the solutions of the RIE on $[t_0, t_k]$ satisfying $Q^N_k(t_k) = G^N$, $Q_k(t_k) = G$. Then from our results for stability solutions given in §2, we have $Q^N_k(t)x^N \to Q^N_s(t)x^N$, $Q_k(t)x \to Q_s(t)x$ as $k \to \infty$ for all $x^N \in H^N$ and $x \in H$.

We note that if $S^N(t,s)x \to 0$ uniformly in N, then we have $Q_k(s)$ and $Q^N_k(s)$ uniformly bounded for all k and N. To see this, we consider Q_k, Q_s as given above. Then we have, using the relationship in (2.7) where $y(t) = S(t,s)x$ and S is the evolution operator corresponding to the perturbation of T by $-BR^{-1}B^*Q_s$,

$$\begin{aligned} < (Q_k(s) - Q_s(s))x, x >_H &\leq < (Q_k(t_k) - Q_s(t_k))y(t_k), y(t_k) >_H \\ &\leq 2M\|y(t_k)\|^2. \end{aligned}$$

Since $y(t_k) \to 0$, it follows from the uniform boundedness principle that $Q_k(s)$ is uniformly bounded for all k. Repeating this argument with $Q^N_k(s), Q^N_s(s)$ and $y^N(t) = S^N(t,s)x$, we see that the uniform (in N) decay of S^N yields the claimed uniform boundedness for $Q^N_k(s)$.

In each of the two cases above, we have the following situation:

$$\begin{array}{ccc} Q^N_k(t)P^N_H x & \overset{k\to\infty}{\to} & Q^N_s(t)P^N_H x \\ N \to \infty \downarrow & & \downarrow ?N \to \infty \\ Q_k(t)x & \overset{k\to\infty}{\to} & Q_s(t)x. \end{array}$$

It is desirable in computations to work directly with Q^N_s and hence we seek results which will guarantee the convergence $Q^N_s \to Q_s$ of this diagram. To obtain such a result, we shall make use of a uniform decay rate for the S^N defined via Q^N_s.

THEOREM 3.1. *Assume that Hypotheses* 3.1–3.3, 3.5 *hold. Further, assume that for all* $s \geq t_0$, $x \in H$, *and* $\epsilon > 0$, *we can find* $\hat{t}$ *such that for all* $t \geq \hat{t}$, *we have* $\|S(t,s)x\| \leq \epsilon$ *and* $\|S^N(t,s)P^N_H x\| \leq \epsilon$ *for all* N. *Then* $Q^N_s(t)P^N_H x \to Q_s(t)x$ *for all* $t_0 \leq t < \infty$.

Proof. Let M be the bound for Q_s and Q^N_s that are the stability solutions of Hypothesis 3.5. Let Q^N_k and Q_k be the related RIE solutions on $[t_0, t_k]$ satisfying $Q^N_k(t_k) = M \cdot I$, $Q_k(t_k) = M \cdot I$. Then for $t \leq t_k$ we have

$$\begin{aligned} \|Q^N_s(t)P^N_H x - Q_s(t)x\|^2 &\leq \|(Q^N_s(t) - Q^N_k(t))P^N_H x\|^2 + \|Q^N_k(t)P^N_H x - Q_k(t)x\|^2 \\ &\quad + \|(Q_s(t) - Q_k(t))x\|^2. \end{aligned}$$

Recalling that $Q_k^N(t) \geq Q_s^N(t)$, $Q_k(t) \geq Q_s(t)$ by construction, and using the uniform boundedness of Q_k^N and Q_s^N following from the uniform decay rate and the arguments above, we obtain for some $\hat{M}$

$$\begin{aligned} \|(Q_s^N(t) - Q_k^N(t))P_H^N x\|^2 &\leq 2\hat{M} < (Q_k^N(t) - Q_s^N(t))P_H^N x, P_H^N x >_H \\ \|(Q_s(t) - Q_k(t))x\|^2 &\leq 2\hat{M} < (Q_k(t) - Q_s(t))x, x >_H . \end{aligned}$$

Again using (2.7), we have

$$\begin{aligned} &< (Q_k^N(t) - Q_s^N(t))P_H^N x, P_H^N x >_H \\ &\quad \leq < (Q_k^N(t_k) - Q_s^N(t_k))S^N(t_k,t)P_H^N x, S^N(t_k,t)P_H^N x >_H, \end{aligned}$$

and

$$< (Q_k(t) - Q_s(t))x, x >_H \leq < (Q_k(t_k) - Q_s(t_k))S(t_k,t)x, S(t_k,t)x >_H .$$

Combining the above inequalities, we obtain

$$\begin{aligned} \|Q_s^N(t)P_H^N x - Q_s(t)x\|^2 \leq \|Q_k^N(t)P_H^N x - Q_k(t)x\|^2 \\ +4M\hat{M}(\|S^N(t_k,t)x\|^2 + \|S(t_k,t)x\|^2). \end{aligned}$$

Let k be large enough so that

$$\|S(t_k,t)x\| \leq \epsilon/(12M\hat{M}), \quad \|S^N(t_k,t)P_H^N x\| \leq \epsilon/(12M\hat{M}),$$

for all N. Then let N be large enough to obtain $\|Q_k^N(t)P_H^N x - Q_k(t)x\|^2 \leq \epsilon/3$. From the previous estimates we thus find $\|Q_s^N(t)P_H^N x - Q_s(t)x\|^2 \leq \epsilon$ which yields the desired results.

We note that if Hypothesis 3.4 holds and the uniform decay assumption in Theorem 3.1 is replaced by the following: there exists $\hat{t}$ such that for any $t \geq \hat{t}$ and for any $s \in [t_0, t_f]$, $\|S(t+s,s)x\| \leq \epsilon$, $\|S^N(t+s,s)P_H^N x\| \leq \epsilon$, for all N, then the convergence of Theorem 3.1 is uniform in the bounded interval $[t_0, t_f]$.

Theorem 3.1 is not very useful in practice, since the uniform decay assumption is difficult to verify directly. However, it does provide some insight and suggests more realistic conditions that might be verifiable. Recalling the definition of W-detectability and our discussions following it, we are prompted to formulate the following assumptions.

Hypothesis 3.6. (*Uniform W-detectability*). The original system is detectable and there exist constants M_K, M_{KV}, and $\beta > 0$ such that for each N, there exists a uniformly bounded operator valued function $K^N(\cdot) : H^N \mapsto H^N$, with $\|K^N(t)\|_{L(H^N)} \leq M_K$, for $t \in [t_0, \infty)$. If $T_{K^N}^N$ is the evolution operator corresponding to the perturbation of T^N by $K^N\sqrt{W^N}$, then $\|T_{K^N}^N(t,s)\|_{L(H^N)} \leq M_{KV}e^{-\beta(t-s)}$, for $(t,s) \in \triangle_\infty(t_0)$.

If Hypothesis 3.6 holds, then $Q_{\min}^N$ is the unique uniformly bounded solution of the Riccati integral equation on the infinite time interval for H^N. Under the uniform W-stabilizability Hypothesis 3.3, we have $Q_{\min}^N(t) \leq M \cdot I$, for all $t \in [t_0, \infty)$. Furthermore, by an application of Theorem 2.2, there exist constants $M_s, \alpha > 0$ independent of N such that the evolution operator S^N defined via $Q_{\min}^N$ satisfies

$$\|S^N(t,s)\| \leq M_s e^{-\alpha(t-s)}, \quad \text{for } (t,s) \in \triangle_\infty(t_0).$$

Thus, by Theorem 3.1, $Q^N_{\min}(t)$ converges to $Q_{\min}(t)$ as $N \to \infty$. We summarize the results in a major convergence theorem.

THEOREM 3.2. *Assume that system* (2.1), (2.2) *and its approximate systems* (3.1), (3.2) *satisfy Hypotheses* 3.1 *and* 3.2 *and the uniform* W*-stabilizability and uniform* W*-detectability conditions of Hypotheses* 3.3, 3.6. *Then the unique uniformly bounded solutions* Q^N *of the approximating Riccati integral equations* ((2.9) *with* T, B, W, R *replaced by* T^N, B^N, W^N, R^N) *on* $[t_0, \infty)$ *in* H^N *converge strongly to the unique uniformly bounded solution* Q *of the Riccati integral equation* (2.9) *on the infinite time interval in* H. *Furthermore, if Hypothesis* 3.2 *is replaced by Hypothesis* 3.4, *then this convergence is uniform in* t *for* t *in any bounded interval.*

We note that in the case of a periodic system, the uniform convergence in one period implies that Q^N converges to Q uniformly in the entire interval $[t_0, \infty)$. We further remark that the convergence of the Riccati operator guaranteed by Theorem 3.2 is sufficient (using standard arguments, see [G], [BK1]) to guarantee convergence of the optimal approximate feedback system trajectories $S^N(t,s)P^N_H x$ and optimal approximate controls u^N to the optimal system trajectories $S(t,s)x$ and optimal controls u (see Theorem 3.1 of [BK1]). Moreover, one also obtains convergence of the system generated by using the approximate feedback gains with the original infinite-dimensional control system (a feature that is of great practical importance), e.g., see the related remarks in §4 of [BK1].

The hypotheses of Theorem 3.2 are much more readily verified than others guaranteeing convergence that can be found in the literature (e.g., see [G, Thm. 5.3], where one is required to show that the approximate systems are uniformly stabilized by the feedback with a uniformly bounded sequence of approximate Riccati operators). As we shall see in the later sections, there are two distinct approaches that lead to rather easy use of our Theorem 3.2 in the event one is dealing with parabolic evolution systems.

4. Parabolic evolution equations: control and approximation. In this section, we formulate the linear quadratic regulator problem for an abstract parabolic control system. We focus our attention on systems associated with a time dependent sesquilinear form. First we review the theory of parabolic evolution equations (relying heavily on [T]) and extend some related results in a form applicable to control problems. Then a control system is defined for which general assumptions of stabilizability and detectability are made. A framework for approximation schemes is presented and conditions for convergence of the operators involved are discussed under assumptions of uniform stabilizability and uniform detectability for the approximate systems. Our discussions here are in the spirit of the approaches taken in [BK1], [BI1], [BI2].

Let H, V be two complex separable Hilbert spaces with $< \cdot, \cdot >_H$, $< \cdot, \cdot >_V$ as inner products and $\| \cdot \|_H$, $\| \cdot \|_V$ as norms, respectively. Let V^* be the dual space of V with $< \cdot, \cdot >_{V^*,V}$ denoting the duality pairing. The space V is assumed to be densely and continuously embedded in H, and thus there exists a constant c such that for all $\psi \in V$, $\|\psi\|_H \le c\|\psi\|_V$. Since for each element φ of H, we can define a bounded linear functional on V by $< \varphi, \psi >_H$, for $\psi \in V$, we have the usual embedding relationship $V \subset H \subset V^*$.

For each t in the interval $[t_0, \infty)$, consider a sesquilinear form $\sigma(t; \cdot, \cdot)$ defined on $V \times V$. We assume throughout that σ has the following properties:

Hypothesis 4.1. (V*-Continuity*). For each bounded interval $[t_0, t_1]$, there exists a

constant c_1 such that

$$|\sigma(t;\varphi,\psi)| \le c_1\|\varphi\|_V\|\psi\|_V, \quad \text{for } t \in [t_0,t_1], \varphi,\psi \in V. \tag{4.1}$$

Hypothesis 4.2. (*V-Ellipticity*). For each bounded interval $[t_0,t_1]$, there exist constants $c_2 > 0$, m such that

$$\text{Re } \sigma(t;\varphi,\varphi) \ge c_2\|\varphi\|_V^2 - m\|\varphi\|_H^2, \quad \text{for } t \in [t_0,t_1], \varphi \in V. \tag{4.2}$$

Under the above assumptions, we have a well-known ([FM], [K], [T], [S]) result: For each $t \in [t_0,t_1]$, there exists a unique closed operator $A(t) : V \mapsto V^*$ such that

$$\sigma(t;\varphi,\psi) = - < A(t)\varphi,\psi >_{V^*,V}, \quad \text{for } \psi \in V. \tag{4.3}$$

Furthermore, if $\hat{A}(t)$ is defined using the same method with a sesquilinear form σ^* defined by $\sigma^*(t;\varphi,\psi) = \overline{\sigma(t;\psi,\varphi)}$, then $\hat{A}(t)$ is identical to the adjoint operator $A^*(t)$ of $A(t)$. Both operators $A(t)$, $A(t)^*$ are infinitesimal generators of analytic semigroups in V^*, and an abstract parabolic evolution equation can be defined by

$$\frac{d}{dt}x(t) = A(t)x(t), \quad x(t_0) = x_0 \in V^*.$$

In order to insure the existence of an evolution operator for this equation, we must make additional assumptions on the continuity of σ with respect to t.

Hypothesis 4.3. (*Smoothness in t*). For each bounded interval $[t_0,t_1]$, there exist constants K and α, $0 < \alpha \le 1$, such that for all $t,s \in [t_0,t_1]$, and for all $\varphi,\psi \in V$, we have

$$|\sigma(t;\varphi,\psi) - \sigma(s;\varphi,\psi)| \le K|t-s|^\alpha\|\varphi\|_V\|\psi\|_V.$$

Under the above assumptions, there exists an evolution operator associated with the above evolution equation. The following theorem summarizes the properties of this evolution operator.

THEOREM 4.1. ([T, pp.127, pp.145-155]). *Let Hypotheses* 4.1–4.3 *hold. Then there exists a unique evolution operator* $\tilde{T}(\cdot,\cdot)$ *in* V^* *satisfying the following conditions:*

(i) *For any* $t_0 \le s < t \le t_1$, *the range* $\mathcal{R}(\tilde{T}(t,s))$ *of operator* $\tilde{T}(t,s)$ *is a subset of* V.

(ii) *The operator* $\tilde{T}(t,s)A(s)$ *has a unique bounded extension in* $L(V^*)$, *for all* $t_0 \le s < t \le t_1$; *therefore, we can and will use the same expression for the extension.*

(iii) *For each* $\varphi \in V^*$, *the* V^**-valued function* $\tilde{T}(t,s)\varphi$ *is continuously differentiable in* t *for* $t \in (s,t_1]$, *and continuously differentiable in* s *for* $s \in [t_0,t)$. *Furthermore, for* $\varphi \in V^*$

$$\begin{aligned} \frac{d}{dt}\tilde{T}(t,s)\varphi &= A(t)\tilde{T}(t,s)\varphi, \\ \frac{d}{ds}\tilde{T}(t,s)\varphi &= -\tilde{T}(t,s)A(s)\varphi. \end{aligned}$$

(iv) *The restriction of* $\tilde{T}(t,s)$ *on* H *is strongly continuous in the* H *norm. For all* $x_0 \in H$, *the function* $x(t) = \tilde{T}(t,s)x_0$ *is in* $L^2([s,t_1];V)$ *and the derivative* $\dot{x}(t) = A(t)\tilde{T}(t,s)x_0$ *is in* $L^2([s,t_1];V^*)$. *Furthermore, there exist constants* C_1, C_2, *depending only on* c_1, c_2, m, K, *and* α *such that*

$$\|\tilde{T}(t,s)x_0\|_V \leq C_1(t-s)^{-1/2}\|x_0\|_H. \tag{4.4}$$

$$\|\tilde{T}(\cdot,s)x_0\|_{L^2([s,t_1];V)} \leq C_2\|x_0\|_H. \tag{4.5}$$

All the statements in the above theorem can be found in [T]. However, they are organized into several sections with somewhat different notation; we therefore give a brief argument which collects the results from the book.

Proof. Existence. Taking $X = V^*$, we let $A(t)$ be defined as in (4.3). As indicated in [T, p. 144], using Theorem 5.2.1 of [T], we find there exists an evolution operator $\tilde{T}$ on V^*. The range $\mathcal{R}(\tilde{T}(t,s))$ is a subset of $\mathcal{D}(A(t)) = V$ for all $t_0 \leq s < t \leq t_1$. For any $\varphi \in V^*$, $\tilde{T}(t,s)\varphi$ is continuously differentiable in t for $t \in (s,t_1]$. Now let the sesquilinear form σ^* be defined by

$$\sigma^*(t;\varphi,\psi) = \overline{\sigma(t;\psi,\varphi)}, \quad \varphi,\psi \in V.$$

Let $A^*(t)$ be the linear operator defined via σ^*; then $A^*(t)$ is the adjoint operator of $A(t)$. As indicated by the remarks following Lemma 5.4.6 of [T], we can use the results of §5.2 (with $\tilde{S}$ and A^* replacing U and A of [T]) to construct an operator-valued function $\tilde{S}(t,s)$, such that for all $t_0 \leq s < t \leq t_1$, $A^*(s)\tilde{S}(t,s)$ is a bounded operator in V^*, and for any $\varphi \in V^*$, $\tilde{S}(t,s)\varphi$ is continuously differentiable in s for $s \in [t_0,t)$. Furthermore, for $\varphi \in V^*$

$$\frac{d}{ds}\tilde{S}(t,s)\varphi = -A^*(s)\tilde{S}(t,s)\varphi.$$

In fact, $\tilde{S}(t,s)$ can be constructed as follows. Let $\exp\{tA^*(s)\}$ be the semigroup generated by $A^*(s)$ and we define

$$\begin{aligned} \tilde{S}(t,s) &= \exp\{(t-s)A^*(t)\} + W(t,s), \\ W(t,s) &= \int_s^t \exp\{(\tau-s)A^*(\tau)\}R(t,\tau)d\tau, \end{aligned}$$

where the function R can be computed by iterative methods using

$$R(t,s) - \int_s^t R_1(\eta,s)R(t,\eta)d\eta = R_1(t,s),$$

with $R_1(t,s) = (A^*(t) - A^*(s))\exp\{(t-s)A^*(t)\}$. Then following the same type of arguments as in [T, p. 149], we can conclude that $\tilde{S}(t,s) = \tilde{T}^*(t,s)$. Therefore, $\tilde{T}(t,s)A(s)$ has a unique bounded extension in V^*. For all $\varphi \in V^*$, $\tilde{T}(t,s)\varphi$ is strongly differentiable in s for $s \in [t_0,t)$.

Finally, statement (iv) of the above theorem can be found in the §§5.4 and 5.5 of [T]. We note that in these sections of [T], the space X plays the role of our space H. Let $T(t,s)$ be the restriction of $\tilde{T}(t,s)$ to H; by Theorem 5.4.1 of [T], $T(t,s)$ is strongly continuous in the H norm. Furthermore the estimate (4.4) holds. For

any $x_0 \in H$, let $x(t) = T(t,s)x_0$. By Lemma 5.5.2 and Proposition 5.5.1 of [T, pp. 152–153] with $f \equiv 0$, the function $x(\cdot)$ is in $L^2([s,t_1];V)$ and $\dot{x}(\cdot)$ is in $L^2([s,t_1];V^*)$. In addition, the estimate (4.5) holds. We note that the constants C_1, C_2 depend only on the constants c_1, c_2, m, K, and α.

Uniqueness. By Theorem 5.2.3 of [T, p.128], we can conclude that the evolution operator satisfying the conditions (i)–(iv) must be unique.

We remark that the same theorem holds if we use the sesquilinear form σ^*; therefore, properties (i)–(iv) hold for the adjoint evolution operator $\tilde{T}^*(\cdot,\cdot)$. As a consequence of (iv), the restriction T of $\tilde{T}$ to H is an evolution operator in H as defined in § 2. We wish to take H as our state space since it is in this Hilbert space that our control problems are defined and our subsequent computational considerations are readily pursued; therefore, we use primarily the evolution operator T in this paper. The operator $\tilde{T}$ is used in the remainder of the current section in several proofs of uniqueness theorems. The only precaution one must take is that $T(t,s)\varphi$ is continuously differentiable with respect to t in the V^* sense and the derivative of $T(t,s)\varphi$ is an element of V^*. In particular, for each $\psi \in V$, $< T(t,s)\varphi, \psi >_H$ is differentiable with respect to t, and

$$\frac{d}{dt} < T(t,s)\varphi, \psi >_H = < A(t)T(t,s)\varphi, \psi >_{V^*,V} = -\sigma(t; T(t,s)\varphi, \psi).$$

The conclusions of this theorem are very useful in defining our control system. However, the conditions of Hypothesis 4.3 are too restrictive for our use, since we may need to perturb the equation with nonsmooth but bounded (feedback) terms. We can show that if σ is perturbed with a sesquilinear form that is uniformly bounded in H, then there exists an associated evolution operator T_K which preserves most of the desirable properties of the evolution operator T. In fact, let $K(\cdot) : [t_0, \infty) \mapsto L(H)$ be a uniformly bounded operator valued measurable function. We can then define a sesquilinear form σ_K in $V \times V$ as

$$\sigma_K(t; \varphi, \psi) = \sigma(t; \varphi, \psi) - < K(t)\varphi, \psi >_H, \quad \varphi, \psi \in V.$$

It is easy to see that for each bounded interval $[t_0, t_1]$, Hypotheses 4.1 and 4.2 hold. Therefore, we can find an operator $A_K(t)$ defined on V such that (4.3) holds for σ_K and $A_K(t)$. Furthermore, we have by the definitions of $A(t)$ and $A_K(t)$ that $A_K(t)\varphi = A(t)\varphi + K(t)\varphi$ for $\varphi \in V$ and we may establish the following result.

THEOREM 4.2. *Consider a sesquilinear form σ satisfying Hypotheses* 4.1–4.3 *and let $K(\cdot)$, σ_K be defined as above. Then there exists a unique evolution operator $T_K(\cdot,\cdot)$ in H for which the following properties hold:*

(i) *The range $\mathcal{R}(T_K(t,s))$ of the operator $T_K(t,s)$ is a subset of V, for all $t_0 \leq s < t \leq t_1$.*

(ii) *For $\varphi \in H$, the function $T_K(t,s)\varphi$ is differentiable with respect to t in the V^* sense, and*

$$\frac{d}{dt} T_K(t,s)\varphi = A_K(t)T_K(t,s)\varphi.$$

(iii) *For all $x_0 \in H$, the function $x(t) = T_K(t,s)x_0$ is in $L^2([s,t_1];V)$ and its derivative $\dot{x}(t)$ is in $L^2([s,t_1];V^*)$. Furthermore, there exists constants C_1, C_2 depending only on c_1, c_2, m, K, and α such that*

$$\|T_K(t,s)x_0\|_V \leq C_1(t-s)^{-1/2}\|x_0\|_H,$$
$$\|T_K(\cdot,s)x_0\|_{L^2([s,t_1];V)} \leq C_2\|x_0\|_H.$$

Proof. Existence. Let T_K be the unique evolution operator in H corresponding to the perturbation of T by K. From the results on perturbations given in § 2, we have that T_K satisfies for all $\varphi \in H$

$$T_K(t,s)\varphi = T(t,s)\varphi + \int_s^t T(t,\eta)K(\eta)T_K(\eta,s)\varphi d\eta, \tag{4.6}$$

$$T_K(t,s)\varphi = T(t,s)\varphi + \int_s^t T_K(t,\eta)K(\eta)T(\eta,s)\varphi d\eta.$$

Since the function $K(\eta)T_K(\eta,s)\varphi$ is uniformly bounded in H norm by some constant C, using the estimate (4.4), we can find a constant $\tilde{C}$ such that for $\eta \in [s,t]$

$$\|T(t,\eta)K(\eta)T_K(\eta,s)\varphi\|_V \leq \tilde{C}(t-\eta)^{-1/2}\|\varphi\|_H.$$

Therefore, the integral term in (4.6) converges in the V sense and hence, $T_K(t,s)\varphi \in V$ for $\varphi \in H$.

Letting $x_0 \in H$, we define $x(t) = T_K(t,t_0)x_0$, and $f(t) = K(t)x(t)$. From (4.6), the function $x(t)$ can be written as

$$x(t) = T(t,t_0)x_0 + \int_{t_0}^t T(t,\eta)f(\eta)d\eta.$$

By the strong continuity of T_K and uniform boundedness of K, it is obvious that $f(\cdot) \in L^2([t_0,t_1];H)$ and hence $f(\cdot) \in L^2([t_0,t_1];V^*)$. By Theorem 5.5.1 of [T], $x(\cdot)$ is in $L^2([t_0,t_1];V)$, is differentiable with $\dot{x}(\cdot)$ in $L^2([t_0,t_1];V^*)$ and satisfies $\dot{x}(t) = A_K(t)x(t)$. Using the equality (4.6) and the boundedness of the perturbation, by modifying the constants C_1, C_2 in (4.4), (4.5), we can easily obtain

$$\|T_K(t,s)\varphi\|_V \leq C_1(t-s)^{-1/2}\|\varphi\|_H,$$
$$\|T_K(\cdot,t_0)\varphi\|_{L^2([t_0,t_1];V)} \leq C_2\|\varphi\|_H,$$

for all $\varphi \in H$.

Uniqueness. Let $\hat{T}_K$ satisfy the conclusions (i)–(ii) of Theorem 4.2. For all $\varphi \in H$, consider $\hat{T}_K(t,s)\varphi$ as a V^* valued function. Then we have

$$\begin{aligned}\frac{d}{d\eta}\tilde{T}(t,\eta)\hat{T}_K(\eta,s)\varphi &= -\tilde{T}(t,\eta)A(\eta)\hat{T}_K(\eta,s)\varphi \\ &\quad +\tilde{T}(t,\eta)(A(\eta)+K(\eta))\hat{T}_K(\eta,s)\varphi \\ &= \tilde{T}(t,\eta)K(\eta)\hat{T}_K(\eta,s)\varphi.\end{aligned}$$

Integrating both sides of the above equation from s to t, we obtain

$$\hat{T}_K(t,s)\varphi = \tilde{T}(t,s)\varphi + \int_s^t \tilde{T}(t,\eta)K(\eta)\hat{T}_K(\eta,s)\varphi d\eta.$$

Since T is the restriction of $\tilde{T}$ to H, $\hat{T}_K$ is a solution of (4.6). By the uniqueness results of § 2 for perturbed evolution operators, we have $\hat{T}_K = T_K$. Hence, the unique solution of (4.6) is the unique evolution operator T_K generated in the theorem.

Now consider a function $f(\cdot) \in L^2([t_0, t_1]; H)$. We can then define

$$z(t) = T(t, t_0)z_0 + \int_{t_0}^{t} T(t, \eta)f(\eta)d\eta.$$

The function $z(\cdot)$ is the unique solution of the following initial value problem:

$$\begin{aligned} z(t) &= T(t, s)z(s) + \int_s^t T(t, \eta)f(\eta)d\eta, \quad t_0 \le s \le t \le t_1. \\ z(t_0) &= z_0. \end{aligned} \tag{4.7}$$

Henceforth, we consider (4.7) as the definition of our basic evolution system. The function z corresponds to the solution of a weaker formulation of the evolution equation.

LEMMA 4.1. ([T, Thm. 5.5.1]). *The function $z(\cdot)$ given by* (4.7) *is the unique function in $L^2([t_0, t_1]; V)$ with derivative $\dot{z}(\cdot)$ in $L^2([t_0, t_1]; V^*)$ for which the following equation holds for $\psi \in V$*

$$\begin{aligned} < z(t) - z(t_0), \psi >_H &= \int_{t_0}^{t} \{-\sigma(\eta; z(\eta), \psi) + < f(\eta), \psi >_H\} d\eta, \\ z(t_0) &= z_0. \end{aligned} \tag{4.8}$$

LEMMA 4.2. ([T, Lemma 5.5.1]). *For any two functions $z(\cdot), w(\cdot)$ in $L^2([t_0, t_1]; V)$ with derivatives $\dot{z}, \dot{w}$ in $L^2([t_0, t_1]; V^*)$, the following equality holds:*

$$\begin{aligned} < z(t), w(t) >_H &= < z(s), w(s) >_H \\ &\quad + \int_s^t \left\{ < \dot{z}(\eta), w(\eta) >_{V^*, V} + \overline{< \dot{w}(\eta), z(\eta) >_{V^*, V}} \right\} d\eta, \end{aligned}$$

for all $t_0 \le s \le t \le t_1$.

As a consequence of these lemmas, if for any $x_0 \in H$, we let $x(t) = T(t, t_0)x_0$, then

$$\|x(t)\|_H^2 = \|x_0\|_H^2 - 2\int_{t_0}^{t} \operatorname{Re}\, \sigma(\eta; x(\eta), x(\eta))d\eta. \tag{4.9}$$

We note that if Hypotheses 4.1–4.3 hold, then for each bounded interval $[t_0, t_1]$, we can define $T(t, s)$ uniquely. Therefore, $T(t, s)$ is also uniquely defined for all $t_0 \le s \le t < \infty$. The equality (4.9) suggests a sufficient condition for the stability of T.

Hypothesis 4.4. There exists a constant $k > 0$ such that

$$\operatorname{Re}\, \sigma(t; \varphi, \varphi) \ge k\|\varphi\|_H^2, \quad \text{for } t_0 \le t < \infty, \quad \varphi \in V.$$

THEOREM 4.3. *In addition to Hypotheses* 4.1–4.3, *under Hypothesis* 4.4, *T is uniformly exponentially stable.*

Proof. For any $x_0 \in H$, let $x(t) = T(t, s)x_0$. Then by (4.9), we have

$$\|x(t)\|_H^2 \le \|x_0\|_H^2 - 2\int_s^t k\|x(\eta)\|^2 d\eta,$$

for all $t_0 \leq s \leq t < \infty$. This implies

$$\|T(t,s)\|_{L(H)} \leq 1, \quad \int_s^t \|T(\eta,s)x_0\|_H^2 \leq \frac{1}{2k}\|x_0\|_H^2.$$

Therefore, by Lemma 2.1, T is uniformly exponentially stable. Note, moreover, that by Lemma 2.1, under Hypothesis 4.4, we can find $M, \alpha > 0$ depending only on k such that

$$\|T(t,s)\|_{L(H)} \leq Me^{-\alpha(t-s)}.$$

We can now use these considerations to define an evolution equation control system of the form (4.7) via a sesquilinear form. The space H will serve as our state space, with subspace V and the sesquilinear form σ defined as above and Hypotheses 4.1–4.3 holding. Let the control space U be a Hilbert space, and let $B(\cdot) : [t_0, \infty) \mapsto L(U,H)$ be a strongly measurable operator-valued function. We assume that there exists a constant M_B such that

$$\|B(t)\|_{L(U,H)} \leq M_B, \quad \text{for } t \in [t_0, \infty).$$

For any control $u(\cdot) : [t_0, \infty) \mapsto U$, belonging to $L^2([t_0,\infty);U)$, the corresponding trajectories satisfy for $\psi \in V$

$$(4.10) \qquad < z(t) - z(s), \psi >_H = -\int_s^t \{\sigma(\eta; z(\eta), \psi) - < B(\eta)u(\eta), \psi >_H\}\, d\eta,$$

for all $(t,s) \in \triangle_\infty(t_0)$. Let $T(\cdot,\cdot)$ be the evolution operator defined via σ. By Lemma 4.1, an equivalent form of (4.10) is given by

$$(4.11) \qquad z(t) = T(t,s)z(s) + \int_s^t T(t,\eta)B(\eta)u(\eta)d\eta, \quad \text{for } (t,s) \in \triangle_\infty(t_0).$$

Let $z_0 \in H$ be the initial state of the system at t_0 and let the cost for control $u(\cdot)$ be given by

$$(4.12) \qquad J_\infty(u; z_0, t_0) = \int_{t_0}^\infty < W(t)z(t), z(t) >_H + < R(t)u(t), u(t) >_U \, dt,$$

where $W(\cdot) : [t_0,\infty) \mapsto L(H)$, $R(\cdot) : [t_0,\infty) \mapsto L(U)$ are strongly measurable. The operators $W(t), R(t)$ are assumed to be self-adjoint nonnegative definite operators, uniformly bounded in the entire interval $[t_0,\infty)$. Furthermore, there exists a constant $r > 0$ such that

$$< R(t)v, v >_U \quad \geq \quad r\|v\|_U^2, \quad \text{for } t \geq t_0, \quad v \in U.$$

Recalling the discussions of § 2, we note that the standing assumptions of that section hold. Therefore, for a given nonnegative definite self-adjoint operator G on H, the Riccati integral equation in each finite time interval $[t_0, t_k]$,

$$\begin{aligned} Q_k(s)x \quad &= \quad T^*(t_k,s)GT(t_k,s)x \\ &\quad + \int_s^{t_k} T^*(\eta,s)\left[W(\eta) - Q_k(\eta)B(\eta)R^{-1}(\eta)B^*(\eta)Q_k(\eta)\right]T(\eta,s)x d\eta \end{aligned}$$

has a unique self-adjoint solution Q_k.

For the control problem in the infinite time interval $[t_0, \infty)$, we need stabilizability and detectability conditions to assure existence and uniqueness of a uniformly bounded solution of the Riccati integral equation.

Hypothesis 4.5. (*Detectability*). There exists a strongly measurable uniformly bounded operator valued function $\Psi(\cdot) : [t_0, \infty) \mapsto L(H)$, such that if we denote by S_Ψ the evolution operator corresponding to the perturbation of T by $\Psi(\cdot)W^{1/2}(\cdot)$, the following estimate holds for $x \in H$:

$$\|S_\Psi(t,s)x\|_H \leq Me^{-\omega(t-s)}\|x\|_H,$$

for some constants $M, \omega > 0$.

Hypothesis 4.6. (*Stabilizability*). There exists a strongly measurable uniformly bounded operator valued function $K(\cdot) : [t_0, \infty) \mapsto L(H, U)$, such that if we denote by S_K the evolution operator corresponding to the perturbation of T by $B(\cdot)K(\cdot)$, the following estimate holds for $x \in H$:

$$\|S_K(t,s)x\|_H \leq Me^{-\omega(t-s)}\|x\|_H,$$

for some constants $M, \omega > 0$.

We remark that Hypothesis 4.6 is stronger than "W-stabilizability"; however, under Hypothesis 4.5, by Theorem 2.2, these two types of stabilizability assumption are equivalent.

To this point we have defined a control system using an abstract parabolic evolution equation that fits into the general framework of § 3. Under Hypotheses 4.5 and 4.6, we may apply the theory of the previous sections to establish the following results for our control problem:

(i) The Riccati integral equation in the infinite time interval $[t_0, \infty)$ has a unique uniformly bounded solution $Q(\cdot)$.

(ii) Let S_Q be the evolution operator corresponding to the perturbation of $T(\cdot,\cdot)$ by $-BR^{-1}B^*Q(\cdot)$. For each initial state z_0, the unique optimal trajectory is given by $S_Q(t, t_0)z_0$.

We turn next to giving results for finite-dimensional approximations of our control system. As in § 3, let $\{H^N\}_{N=1}^\infty$ be a sequence of finite-dimensional subspaces of $V \subset H$. Let P_H^N be the orthogonal projection operator from H onto H^N. Since H^N is an approximation of H, we assume that for every $\varphi \in H$, $\|P_H^N\varphi - \varphi\|_H \to 0$, as $N \to \infty$. In addition, we require that H^N is an approximation of V as well, so that for all $\varphi \in V$, $\|P_H^N\varphi - \varphi\|_V \to 0$, as $N \to \infty$. We note that in fact this latter convergence implies the convergence in H for $\varphi \in H$ since V is continuously and densely embedded in H.

Let $\{U^N\}_{N=1}^\infty$ be a sequence of finite-dimensional subspaces of U. Let P_U^N be the orthogonal projection operator from U onto U^N. We assume U^N approximates U in the following sense: for $v \in U$, $\|P_U^N v - v\|_U \to 0$, as $N \to \infty$.

For each N, we define a sesquilinear form σ^N as the restriction of σ to $H^N \times H^N$ and define a linear operator $A^N(t) : H^N \mapsto H^N$ by

$$- < A^N(t)\varphi^N, \psi^N >_H = \sigma^N(t; \varphi^N, \psi^N), \quad \text{for } \varphi^N, \psi^N \in H^N.$$

By continuity of σ with respect to t, the operator valued function $A^N(t)$ is continuous in time. As a consequence, there exists a unique differentiable evolution operator $T^N(\cdot,\cdot)$ in H^N generated by $A^N(t)$; that is, for $\varphi^N \in H^N$ we have

$$\frac{d}{dt}T^N(t,s)\varphi^N = A^N(t)T^N(t,s)\varphi^N.$$

Note immediately that the σ^N's satisfy Hypotheses 4.1–4.3 with the same constants c_1, c_2, m, α, and K; therefore, for each fixed interval $[t_0,t_1]$, there exist constants C_1, C_2 independent of N such that for all $\varphi^N \in H^N$,

$$\|T^N(t,s)\varphi^N\|_V \le C_1(t-s)^{-\frac{1}{2}}\|\varphi^N\|_H; \tag{4.13}$$

$$\|T^N(\cdot,t_0)\varphi^N\|_{L^2([t_0,t_1];V)} \le C_2\|\varphi^N\|_H. \tag{4.14}$$

The approximation properties of the evolution operator T^N are summarized by the the following convergence theorem.

THEOREM 4.4. *Let Hypotheses* 4.1–4.3 *hold and let* $T(\cdot,\cdot)$ *and* $T^N(\cdot,\cdot)$ *be defined as above where* $\|P_H^N\varphi - \varphi\|_V \to 0$ *as* $N \to \infty$ *for* $\varphi \in V$*; then the following properties hold:*

(i) *There exist constants* M_T *and* ω *such that for all* N,

$$\|T^N(t,s)\|_{L(H^N)} \le M_T e^{\omega(t-s)}, \|T(t,s)\|_{L(H)} \le M_T e^{\omega(t-s)}, \quad t_0 \le s \le t < \infty.$$

(ii) *For any finite interval* $[a,b] \subset [t_0,\infty)$ *and any* $\varphi \in H$, *we have*

$$\|T^N(t,s)P_H^N\varphi - T(t,s)\varphi\|_H \to 0, \quad \text{as } N \to \infty, \quad a \le s \le t \le b.$$

Furthermore, the convergence is uniform for all $a \le s \le t \le b$.

Proof. (i) By Lemma 4.2 and (4.9), for every $\varphi \in H^N$ we have

$$\|T^N(t,s)\varphi\|_H^2 = \|\varphi\|_H^2 - 2\int_s^t \operatorname{Re}\, \sigma^N(\eta; T^N(\eta,s)\varphi, T^N(\eta,s)\varphi)d\eta.$$

Under Hypothesis 4.2,

$$\|T^N(t,s)\varphi\|_H^2 \le \|\varphi\|_H^2 + 2\int_s^t m\|T^N(\eta,s)\varphi\|_H^2 d\eta.$$

Using Gronwall's inequality, we obtain

$$\|T^N(t,s)\varphi\|_H^2 \le \|\varphi\|_H^2 e^{2|m|(t-s)}.$$

Noting that the same estimates hold for $T(t,s)\varphi$, we obtain (i).

(ii) Let $\varphi \in H$, define $w(t) = T(t,s)\varphi$ and $w^N(t) = T^N(t,s)P_H^N\varphi$, and let $z^N(t) = w(t) - w^N(t)$. We note that $z^N(t)$ is not an element of H^N; in fact

$$z^N(t) - P_H^N z^N(t) = w(t) - P_H^N w(t). \tag{4.15}$$

Since $w(t)$ is differentiable in the V^* sense, $w^N(t)$ is differentiable, and both functions are in $L^2([a,b];V)$ with derivatives in $L^2([a,b];V^*)$. By (4.9), Lemma 4.2, and

definitions of the operators $A(t), A^N(t)$, we obtain

$$\begin{aligned}
&\|z^N(t)\|_H^2 \\
&\quad = \|z^N(0)\|_H^2 + 2\int_s^t \text{Re } < A(\eta)w(\eta) - A^N(\eta)w^N(\eta), z^N(\eta) >_{V^*,V} d\eta \\
&\quad = \|z^N(0)\|_H^2 - 2\int_s^t \text{Re } \{\sigma(\eta; w(\eta), z^N(\eta)) - \sigma^N(\eta; w^N(\eta), P_H^N z^N(\eta))\} d\eta \\
&\quad -2\int_s^t < A^N(\eta)w^N(\eta), z^N(\eta) - P_H^N z^N(\eta) >_{V^*,V} d\eta.
\end{aligned}$$

Since the duality pairing reduces to the H-inner product on $H \times H$, we have

$$\begin{aligned}
&< A^N(\eta)w^N(\eta), z^N(\eta) - P_H^N z^N(\eta) >_{V^*,V} \\
&\quad =< A^N(\eta)w^N(\eta), z^N(\eta) - P_H^N z^N(\eta) >_H .
\end{aligned}$$

Moreover, P_H^N is the orthogonal projection operator and hence the last term in the above equation equals to zero. Using the definition of σ^N, the sesquilinearity of σ and (4.15), we find

$$\begin{aligned}
\|z^N(t)\|_H^2 &= \|\varphi - P_H^N\varphi\|_H^2 - 2\int_s^t \text{Re } \sigma(\eta; w(\eta), z^N(\eta) - P_H^N z^N(\eta))d\eta \\
&\quad -2\int_s^t \text{Re } \sigma(\eta; w(\eta), P_H^N z^N(\eta))d\eta \\
&\quad +2\int_s^t \text{Re } \sigma^N(\eta; w^N(\eta), P_H^N z^N(\eta))d\eta \\
&= \|\varphi - P_H^N\varphi\|_H^2 - 2\int_s^t \text{Re } \sigma(\eta; w(\eta), w(\eta) - P_H^N w(\eta))d\eta \\
&\quad -2\int_s^t \text{Re } \sigma(\eta; w(\eta) - P_H^N w(\eta), P_H^N z^N(\eta))d\eta \\
&\quad -2\int_s^t \text{Re } \sigma^N(\eta; P_H^N z^N(\eta), P_H^N z^N(\eta))d\eta.
\end{aligned}$$

Since P_H^N is the orthogonal projection, we find $< P_H^N z^N, w - P_H^N w >_H = 0$, so that from (4.15)

$$\|P_H^N z^N(t)\|_H^2 = \|z^N(t)\|_H^2 - \|w(t) - P_H^N w(t)\|_H^2.$$

Combining this with the previous equation, we have

$$\|P_H^N z^N(t)\|_H^2 = \Theta^N(t,s) - 2\int_s^t \text{Re } \sigma^N(\eta; P_H^N z^N(\eta), P_H^N z^N(\eta))d\eta,$$

where $\Theta^N(t,s)$ is given by

$$\begin{aligned}
\Theta^N(t,s) &= \|\varphi - P_H^N\varphi\|_H^2 - \|w(t) - P_H^N w(t)\|_H^2 \\
&\quad -2\int_s^t \text{Re } \sigma(\eta; w(\eta), w(\eta) - P_H^N w(\eta))d\eta \\
&\quad -2\int_s^t \text{Re } \sigma(\eta; w(\eta) - P_H^N w(\eta), P_H^N z^N(\eta))d\eta.
\end{aligned}$$

Using the V-ellipticity of σ^N, we find

$$\|P_H^N z^N(t)\|_H^2 \leq |\Theta^N(t,s)| + 2|m| \int_s^t \|P_H^N z^N(\eta)\|_H^2 d\eta. \tag{4.16}$$

To use Gronwall's inequality to conclude convergence of $P_H^N z^N$, it suffices to show that $|\Theta^N(t,s)|$ goes to zero uniformly for all $a \leq s \leq t \leq b$. By the continuity and uniform boundedness of T, the term $\|T(t,s)\varphi - P_H^N T(t,s)\varphi\|_H^2$ goes to zero uniformly for all $a \leq s \leq t \leq b$. Using the V-continuity of σ, the two integrals in Θ can be bounded by

$$2c_1 \int_s^t \left\{ \|P_H^N w(\eta) - w(\eta)\|_V \|P_H^N \dot{z}^N(\eta)\|_V + \|w(\eta)\|_V \|P_H^N w(\eta) - w(\eta)\|_V \right\} d\eta$$

$$\leq 2c_1 \left[\|w(\cdot)\|_{L^2([a,b];V)} + \|P_H^N z^N(\cdot)\|_{L^2([a,b];V)} \right] \left[\int_s^t \|w(\eta) - P_H^N w(\eta)\|_V^2 d\eta \right]^{\frac{1}{2}}.$$

Using the inequalities (4.5) and (4.14), we observe that the functions w, w^N are in a bounded subset of $L^2([a,b];V)$. By dominated convergence arguments, the above integral converges to zero. Furthermore, by taking $t = b$, $s = a$, we obtain that this convergence is uniform for all $a \leq s \leq t \leq b$. Therefore, $|\Theta^N(t,s)|$ converges to zero uniformly for all $a \leq s \leq t \leq b$. Finally, from (4.15), we have

$$\|T(t,s)\varphi - T^N(t,s)P_H^N\varphi\|_H^2 = \|P_H^N z^N(t)\|_H^2 + \|w(t) - P_H^N w(t)\|_H^2,$$

and the uniform convergence of $P_H^N z^N(t)$ in t implies $T^N(t,s)P^N\varphi$ converges to $T(t,s)\varphi$ uniformly for all $a \leq s \leq t \leq b$.

Since we can define operators $A^*(t), A^{*N}, T^*(t,s)$ and $T^*(t,s)$ by using the sesquilinear form σ^* as we indicated after (4.3), the convergence of $T^{*N}(t,s)$ to $T^*(t,s)$ can be shown using the same arguments as in the proof of the above theorem.

Having defined our approximate (uncontrolled) system and established the convergence of Theorem 4.4, we return to the control problem for (4.10)–(4.12). Approximations of functions B, W, R are defined as follows:

$$\begin{array}{lll} B^N(\cdot) : [t_0,\infty) \mapsto L(U^N, H^N), & B^N(t)v^N = P_H^N B(t)v^N, & v^N \in U^N; \\ W^N(\cdot) : [t_0,\infty) \mapsto L(H^N), & W^N(t)\varphi^N = P_H^N W(t)\varphi^N, & \varphi^N \in H^N; \\ R^N(\cdot) : [t_0,\infty) \mapsto L(U^N), & R^N(t)v^N = P_U^N R(t)v^N, & v^N \in U^N. \end{array}$$

Let G be the nonnegative self-adjoint operator in the finite interval cost functional associated in the usual manner with (4.12) for our control system in H. Let $G^N = P_H^N G$ and $z_0^N = P_H^N z_0$.

In each subspace H^N, a finite-dimensional control system is thus defined by

$$z^N(t) = T^N(t,s)z^N(s) + \int_s^t T^N(t,\eta)B^N(\eta)u^N(\eta)d\eta, \tag{4.17}$$

with $u^N(\cdot) \in L^2([t_0,\infty);U^N)$ and $z^N(t_0) = z_0^N$. The cost functionals for the associated finite time interval problems are given by

$$J^N(u^N; z_0^N, t_0, t_k) = < G^N z^N(t_k), z^N(t_k) >_H + \int_{t_0}^{t_k} \left\{ < W^N(t)z^N(t), z^N(t) >_H + < R^N(t)u^N(t), u^N(t) >_U \right\} dt, \tag{4.18}$$

while the cost functional for the infinite time interval problem is given by

$$J_\infty^N(u^N; z_0^N; t_0) = \int_{t_0}^{\infty} \{< W^N(t)z^N(t), z^N(t) >_H + < R^N(t)u^N(t), u^N(t) >_U\} dt. \tag{4.19}$$

To obtain the uniform convergence of the operator valued functions, we make additional assumptions on the continuity of B, W, R.

Hypothesis 4.7. (*Parameter smoothness*). The operator valued functions B, W, R are piecewise strongly continuous functions on $[t_0, \infty)$.

LEMMA 4.3. *Under Hypothesis* 4.7, *the following convergence is uniform in* t *for* t *in any bounded interval:*

$$\begin{aligned}
&\|B^N(t)P_U^N v - B(t)v\|_H \to 0, && v \in U;\\
&\|B^{*N}(t)P_H^N \varphi - B^*(t)\varphi\|_U \to 0, && \varphi \in H;\\
&\|W^N(t)P_H^N \varphi - W(t)\varphi\|_H \to 0, && \varphi \in H;\\
&\|R^N(t)P_U^N v - R(t)v\|_U \to 0, && v \in U,
\end{aligned}$$

as $N \to \infty$. *The operator* $G^N P_H^N$ *also converges strongly to* G *as* $N \to \infty$.

Proof. We only prove the uniform convergence of B^N; the remainder of the arguments are similar. For simplicity, we without loss of generality assume that the function $t \mapsto B(t)$ is strongly continuous. For a given $v \in U$, the pointwise convergence of the functions $B^N(t)P_U^N v$ to $B(t)v$ is given by our assumptions on the approximation properties of the spaces H^N, U^N. To conclude uniform convergence in t, it is enough to show that the functions $B^N(t)P_U^N v$ are equicontinuous. That is, for any $\epsilon > 0$, there exists $\delta > 0$ such that for all N, if $|t - s| \leq \delta$, we have $\|B^N(t)P_U^N v - B^N(s)P_U^N v\|_H \leq \epsilon$. By definition of B^N, we have

$$\begin{aligned}
\|B^N(t)P_U^N v - B^N(s)P_U^N v\|_H &\leq \|B(t)P_U^N v - B(s)P_U^N v\|_H\\
&\leq \|B(t)(P_U^N v - v)\|_H + \|B(t)v - B(s)v\|_H\\
&\quad + \|B(s)(P_U^N v - v)\|_H\\
&\leq 2M_B\|P_U^N v - v\|_U + \|B(t)v - B(s)v\|_H.
\end{aligned}$$

By continuity of B, we conclude that $B^N(t)P_U^N v$ are equicontinuous functions of t in a bounded interval. Hence the convergence is uniform in any bounded interval.

It is easy to verify that B^N, W^N, R^N are uniformly bounded and W^N, R^N are nonnegative self-adjoint operators. In addition, there exists a constant $r > 0$ such that for all N,

$$< R^N(t)v^N, v^N >_U \geq r\|v^N\|_U^2, \quad \text{for } t \in [t_0, \infty), v^N \in U^N.$$

Consider any finite time interval $[t_0, t_k]$, and let Q_k, Q_k^N be the unique self-adjoint solutions of the Riccati integral equations in H and H^N associated with the control systems (4.11), (4.17), respectively. Then it follows from Theorem 4.4 and the discussions of §3 (in particular, see Hypotheses 3.1, 3.2, and the remarks just prior to Hypothesis 3.4) that for each k, $Q_k^N(t)$ converges to $Q_k(t)$ strongly and the convergence is uniform in t for $t \in [t_0, t_k]$.

We assumed above (Hypotheses 4.5, 4.6) that the control system (4.10)–(4.12) in H is detectable and stabilizable. Therefore, there exists a unique uniformly bounded solution Q of the Riccati integral equation on the infinite time interval $[t_0, \infty)$. In order to approximate Q by a uniformly bounded solution of the Riccati integral equation in H^N, we show that the approximate control systems defined here are also detectable and stabilizable. More importantly, recalling the results (e.g., see Theorem 3.2) of §3, to apply our results, we need uniform detectability and uniform stabilizability for the approximate systems (4.17), (4.19).

Based on the stabilizability and detectability properties of the original system, for a given approximation scheme, we would like to show that the following conditions hold.

Condition US (*Uniform stabilizability*). There exist constants $M_K, M, \omega > 0$ independent of N such that for each of the approximate systems, we can find a uniformly bounded operator valued function $K^N(\cdot) : [t_0, \infty) \mapsto L(H^N, U^N)$ such that

$$\|K^N(t)\|_{L(H^N,U^N)} \leq M_K,$$

and if T_K^N is the evolution operator corresponding to the perturbation of T^N by $B^N K^N(\cdot)$, then

$$\|T_K^N(t,s)\|_{L(H^N)} \leq Me^{-\omega(t-s)}, \quad \text{for } (t,s) \in \triangle_\infty(t_0).$$

Condition UD (*Uniform detectability*). There exist constants $M_\Psi, M, \omega > 0$ independent of N such that for each of the approximation systems, we can find a uniformly bounded operator valued function $\Psi^N(\cdot) : [t_0, \infty) \mapsto L(H^N)$ such that

$$\|\Psi^N(t)\|_{L(H^N)} \leq M_\Psi,$$

and if T_Ψ^N is the evolution operator corresponding to the perturbation of T^N by $\Psi^N(W^N)^{1/2}(\cdot)$, then

$$\|T_\Psi^N(t,s)\|_{L(H^N)} \leq Me^{-\omega(t-s)}, \quad \text{for } (t,s) \in \triangle_\infty(t_0).$$

We may summarize our findings as follows.

THEOREM 4.5. *Under Hypotheses* 4.1–4.3, 4.5–4.7, *the conditions* $\|P_H^N\varphi - \varphi\|_V \to 0$ *for* $\varphi \in V$, $\|P_U^N v - v\|_U \to 0$ *for* $v \in U$, *and the Conditions US and UD, there exists a unique uniformly bounded solution* Q^N *of the Riccati integral equation on the infinite time interval* $[t_0, \infty)$ *for each approximate system in* H^N. *Furthermore, the sequence* $Q^N(t)P_H^N$ *converges strongly to* $Q(t)$ *and the convergence is uniform in* t *for* t *in any bounded interval.*

These results follow from Theorem 3.2 and our discussions above. We have thus reduced our problem of ensuring convergence of the Riccati variables to one of guaranteeing uniform stabilizability and detectability of the approximate systems. In the following two sections, two different approaches to obtaining uniform detectability (Condition UD) and stabilizability (Condition US) are presented.

5. Dissipativity and uniform stabilizability / detectability. The original control system (4.10) defined in §4 was assumed to be stabilizable and detectable (i.e., we assumed Hypotheses 4.5, 4.6 held). For a given evolution system, often an easy way to ascertain stability is using the dissipativity of the system. In particular, if a system satisfies Hypothesis 4.4, by Theorem 4.3 the associated evolution operator is uniformly exponentially stable. This naturally suggests a sufficient condition for stabilizability of a control system.

Hypothesis 5.1. There exists a uniformly bounded function $K(\cdot) : [t_0, \infty) \mapsto L(H, U)$ and a constant $k > 0$ such that for all $\varphi \in V$,

$$\sigma(t; \varphi, \varphi) + < B(t)K(t)\varphi, \varphi >_H \geq k\|\varphi\|_H^2, \quad \text{for } t \in [t_0, \infty).$$

LEMMA 5.1. *Under Hypothesis* 5.1, *the control system defined by* (4.10)–(4.12) *is stabilizable. In fact if* T_K *is the evolution operator corresponding to the perturbation of the evolution operator* T *by* $-BK$, *we can find constants* $M, \alpha > 0$ *such that*

$$\|T_K(t, s)\|_{L(H)} \leq Me^{-\alpha(t-s)}, \quad \textit{for } (t, s) \in \triangle_\infty(t_0).$$

As a consequence, there exists a constant C *such that for all* $x_0 \in H$, *we can find a control* $u(\cdot) \in L^2([s, \infty); U)$ *with a cost*

$$J_\infty(u; x_0, s) \leq C\|x_0\|^2, \quad \textit{for } s \in [t_0, \infty).$$

Proof. Let $K(\cdot)$ be the operator valued function in Hypothesis 5.1. Define the perturbed sesquilinear form $\sigma_K(t; \varphi, \psi) = \sigma(t; \varphi, \psi) + < B(t)K(t)\varphi, \psi >_H$. Then T_K is associated with σ_K as in Theorem 4.2 with $-B(t)K(t)$ as the perturbation term. Under our assumptions, by Theorem 4.3, there exist $M, \alpha > 0$ such that

$$\|T_K(t, s)\|_{L(H)} \leq Me^{-\alpha(t-s)}, \quad \text{for } (t, s) \in \triangle_\infty(t_0).$$

For any $x_0 \in H$, let $v(t) = -K(t)T_K(t, s)x_0$; it is easy to see that the corresponding trajectory is $x(t) = T_K(t, s)x_0$.

By our standing assumptions, the operator valued functions $W(\cdot), R(\cdot), B(\cdot)$ are uniformly bounded in the entire interval $[t_0, \infty)$. We choose C such that

$$C \geq (\|W(t)\|_{L(H)} + \|K^*(t)R(t)K(t)\|_{L(H)})M^2/2\alpha, \quad \text{for } t \geq t_0.$$

Then

$$\begin{aligned} J_\infty(v; x_0, s) &= \int_s^\infty \{< W(t)x(t), x(t) >_H + < R(t)K(t)x(t), K(t)x(t) >_U\} dt \\ &\leq \int_s^\infty \left\{\|W(t)\|_{L(H)} + \|K^*(t)R(t)K(t)\|_{L(H)}\right\} M^2 e^{-2\alpha(t-s)}\|x_0\|_H^2 dt \\ &\leq C\|x_0\|_H^2. \end{aligned}$$

Similarly, a sufficient condition for detectability can be stated as follows.

Hypothesis 5.2. There exists a uniformly bounded operator valued function $\Psi(\cdot) : [t_0, \infty) \mapsto L(H)$, and constant $\lambda > 0$ such that

$$\sigma(t; \varphi, \varphi) + < \Psi(t)W^{\frac{1}{2}}(t)\varphi, \varphi >_H \geq \lambda\|\varphi\|_H^2, \quad \varphi \in V.$$

LEMMA 5.2. *Under Hypothesis* 5.2, *the control system defined by* (4.10)– (4.12) *is detectable.*

In the remainder of the current section, we assume that Hypotheses 5.1, 5.2 hold for our control system in H. The strict H-dissipativity Hypotheses 5.1, 5.2 on the evolution systems are stronger than the usual stabilizability and detectability hypotheses; however, they are in general easy to verify for a wide class of problems. Moreover, the constants M and the decay rates α depend only on the values of k and λ (which, of course, are dependent on K and Ψ). Thus, this type of approach suggests that approximate systems which preserve the H-dissipativity might be uniformly stabilizable and uniformly detectable. Pursuing this type of argument, we shall try to show that the following conditions are implied by Hypothesis 5.1, 5.2. (As in the discussions of §4 surrounding (4.17)– (4.19), we assume that $B^N(t) = P_H^N B(t)$ and $W^N(t) = P_H^N W(t)$.)

Condition 5.1. There exists a constant $\tilde{k} > 0$ such that for every N, there exists a uniformly bounded operator valued function $K^N(\cdot) : [t_0, \infty) \mapsto L(H^N, U^N)$ so that

$$\sigma^N(t; \varphi^N, \varphi^N) + < B^N(t)K^N(t)\varphi^N, \varphi^N >_H \geq \tilde{k}\|\varphi^N\|_H^2 \tag{5.1}$$

holds for all $\varphi^N \in H^N$.

Condition 5.2. There exists a constant $\tilde{\lambda} > 0$ such that for every N, there exists a uniformly bounded operator valued function $\Psi^N(\cdot) : [t_0, \infty) \mapsto L(H^N)$ so that

$$\sigma^N(t; \varphi^N, \varphi^N) + < \Psi^N(t)(W^N(t))^{\frac{1}{2}}\varphi^N, \varphi^N >_H \geq \tilde{\lambda}\|\varphi^N\|_H^2 \tag{5.2}$$

holds for all $\varphi^N \in H^N$.

Note that if the original system satisfies Hypotheses 5.1 and 5.2, by the definition of σ^N we have

$$\sigma^N(t; \varphi^N, \varphi^N) + < P_H^N B(t)K(t)\varphi^N, \varphi^N >_H \geq k\|\varphi^N\|_H^2 \tag{5.3}$$

$$\sigma^N(t; \varphi^N, \varphi^N) + < P_H^N \Psi(t)W^{\frac{1}{2}}(t)\varphi^N, \varphi^N >_H \geq \lambda\|\varphi^N\|_H^2. \tag{5.4}$$

Let us compare inequality (5.3) to (5.1); if we could take $K^N(t) = K(t)$ in (5.1), then Condition 5.1 holds trivially. However, a careful examination of inequalities (5.3) and (5.4) reveals that they do not provide stabilizability and detectability of the approximate system. In the case of (5.3) vs. (5.1) we observe that the range of the operator $K(\cdot)$ hypothesized in Hypothesis 5.1 is not necessarily in U^N, and $K(\cdot)$ cannot be used as a stability operator for the control system in H^N, U^N as required in Condition 5.1. Comparing (5.4) and (5.2) and recalling that $W^N(t) = P_H^N W(t)$, we see that the the choice $\Psi^N = P_H^N \Psi P_H^N$ would suffice only in the case where $P_H^N (P_H^N W(t))^{1/2} = W^{1/2}(t)$.

Before we state additional conditions for the approximate systems, let us consider several interesting cases for which stabilizability and detectability are preserved.

Case I. *Dissipative systems.* Suppose that Hypotheses 5.1, 5.2 hold for $K(t) \equiv 0$ and $\Psi(t) \equiv 0$; then by definition of the sesquilinear form σ^N, Conditions 5.1, 5.2 hold

with $K^N(t) \equiv 0$ and $\Psi^N(t) \equiv 0$. This is the case when the homogeneous system is itself dissipative.

Case II. *Finite-dimensional control.* Suppose the control space U is finite-dimensional. Taking $U^N = U$, we can use $K^N(t) = K(t)$ and the approximate systems are uniformly stabilizable.

Case III. *Special stability operators.* Consider the inequalities in Hypotheses 5.1, 5.2 again. We can assume that these inequalities hold where $B(t)K(t)$ and $\Psi(t)W^{1/2}(t)$ are nonnegative definite self-adjoint operators. Suppose that there exist scalar functions $\kappa(t) \geq 0$ and $\mu(t) \geq 0$ such that

$$B(t)K(t) \leq \kappa(t)B(t)B^*(t), \quad \Psi(t)W^{1/2}(t) \leq \mu(t)W(t).$$

Then taking $K(t) = \kappa(t)B^*(t)$ and $\Psi(t) = \mu(t)W^{1/2}(t)$, we find Hypotheses 5.1 and 5.2 also hold. If we modify slightly the definition of the sesquilinear form σ^N by

$$\begin{aligned}\hat{\sigma}^N(t;\varphi^N,\psi^N) &= \sigma^N(t;\varphi^N,\psi^N) + < B(t)[I - P_U^N]K(t)\varphi^N, \psi^N > \\ &\quad + < \Psi(t)[I - P_H^N]W^{\frac{1}{2}}(t)\varphi^N, \psi^N >,\end{aligned}$$

the sesquilinear form $\hat{\sigma}^N$ satisfies Conditions 5.1 and 5.2. Indeed, we note that the perturbation terms satisfy

$$\begin{aligned}&< B(t)[I - P_U^N]K(t)\varphi^N, \varphi^N > \\ &\quad = \kappa(t) < [I - P_U^N]B^*(t)\varphi^N, [I - P_U^N]B^*(t)\varphi^N >_U \geq 0, \\ &< \Psi(t)[I - P_H^N]W^{1/2}\varphi^N, \varphi^N > \\ &\quad = \mu(t) < [I - P_H^N]W^{1/2}(t)\varphi^N, [I - P_H^N]W^{1/2}(t)\varphi^N >_H \geq 0.\end{aligned}$$

Thus by taking $K^N(t) = P_U^N K(t)$, $\Psi^N(t) = P_H^N \Psi(t)$, Conditions 5.1, 5.2 hold for $\hat{\sigma}^N$. On the other hand, the perturbation terms go to zero as N goes to ∞. Therefore if we use $\hat{\sigma}^N$ as the sesquilinear form for the approximate control system in H^N, the corresponding evolution operator $\hat{T}^N$ should also converge to T.

The three cases above motivate us to consider the following modifications of the sesquilinear form in H^N. Let the operator valued functions $K(\cdot), \Psi(\cdot)$ be as in Hypotheses 5.1 and 5.2; define $\hat{\sigma}^N$ as:

$$\begin{aligned}\hat{\sigma}^N(t;\varphi^N,\psi^N) &= \sigma^N(t;\varphi^N,\psi^N) + < B(t)[I - P_U^N]K(t)\varphi^N, \psi^N > \\ &\quad + < \Psi(t)[I - P_H^N]W^{\frac{1}{2}}(t)\varphi^N, \psi^N >,\end{aligned}$$

for all $\varphi^N, \psi^N \in H^N$. Let $\hat{A}^N(t) : H^N \mapsto H^N$ be defined by

$$- < \hat{A}^N(t)\varphi^N, \psi^N >_H = \hat{\sigma}^N(t;\varphi^N,\psi^N), \quad \varphi^N, \psi^N \in H^N.$$

Let $\hat{T}^N(\cdot,\cdot)$ be the evolution operator generated by $\hat{A}^N(t)$.

We can repeat the arguments in the proof of Theorem 4.4 using $\hat{T}^N$ in place of T^N. In the arguments, there is an extra term

$$2\int_s^t \mathrm{Re}\ < \Lambda^N(\eta)w^N(\eta), z^N(\eta) >_H \, d\eta$$

on the right side of the inequalities, where $\Lambda^N(\eta) \in L(H^N)$ is given by

$$\Lambda^N(t) = P_H^N B(t)[I - P_U^N]K(t) + P_H^N \Psi(t)[I - P_H^N]W^{1/2}(t).$$

There exists a constant C independent of N (the projections P_H^N and P_U^N are convergent) such that

$$\|\Lambda^N(\eta)\|_{L(H^N)} \leq C, \quad \eta \in [a,b],$$

and, furthermore,

$$\|\Lambda^N(\eta)P_H^N\varphi\|_H \to 0, \quad \text{for } \varphi \in H.$$

Recalling $z^N = w - w^N$ and using (4.15), we have $w^N = w - z^N = P_H^N w - P_H^N z^N$. We thus find (suppressing the argument η throughout)

$$\begin{aligned} \text{Re } < \Lambda^N w^N, z^N >_H &= \left| < \Lambda^N (P_H^N w - P_H^N z^N), P_H^N z^N >_H \right| \\ &\leq \|\Lambda^N P_H^N w\|_H \|P_H^N z^N\|_H + C\|P_H^N z^N\|_H^2 \\ &\leq \frac{1}{2}\|\Lambda^N P_H^N w\|_H^2 + (C + \frac{1}{2})\|P_H^N z^N\|_H^2. \end{aligned}$$

The integral (with respect to η) of the first term in this last expression $\to 0$ uniformly in t, s and can be added to the term $\Theta^N(t,s)$ in (4.16), while the integral of the second term can be included with the integral term in the right side of (4.16). We thus have the following argument.

THEOREM 5.1. *Under Hypotheses* 5.1, 5.2, *the conclusions* (i), (ii) *of Theorem* 4.4 *hold for* $\hat{T}^N$.

Now consider $\hat{T}^N$ as the evolution operator for our approximate control systems in H^N; the convergence of the solutions of the Riccati integral equation in any finite time interval still holds. To generalize the arguments in the three special cases I–III above, we make the following additional assumptions.

Hypothesis 5.3. Consider $K(\cdot), \Psi(\cdot)$ as in Hypotheses 5.1, 5.2 and assume there exist constants $\hat{k} < k$, $\hat{\lambda} < \lambda$ and $\hat{N}$ such that for all $N \geq \hat{N}$

$$\begin{aligned} < (I - P_U^N)K(t)\varphi^N, (I - P_U^N)B^*(t)\varphi^N > &\geq -\hat{k}\|\varphi^N\|_H^2, \\ < (I - P_H^N)W^{\frac{1}{2}}(t)\varphi^N, (I - P_H^N)\Psi^*(t)\varphi^N > &\geq -\hat{\lambda}\|\varphi^N\|_H^2, \end{aligned}$$

for all $\varphi^N \in H^N$.

LEMMA 5.3. *Under Hypotheses* 5.1–5.3, *the approximate control systems are uniformly stabilizable and detectable.*

Proof. We assume without loss of generality that $\hat{N} = 1$. Let $\tilde{k} = k - \hat{k}$ and $\tilde{\lambda} = \lambda - \hat{\lambda}$. By Hypothesis 5.3, $\tilde{k} > 0$ and $\tilde{\lambda} > 0$. Take $K^N(t) = P_U^N K(t)$ and $\Psi^N(t) = P_H^N \Psi(t)$; then with this choice of K^N, Ψ^N, Conditions 5.1, 5.2 hold for $\hat{\sigma}^N$. Let $\hat{T}_K^N$, $\hat{T}_\Psi^N$ be evolution operators corresponding to the perturbations of $\hat{T}^N$ by $B^N K^N$ and $\Psi^N (W^N)^{1/2}$, respectively. By Theorem 4.3, there exist constants $M, \alpha > 0$ depending on $\tilde{k}$, $\tilde{\lambda}$ only such that

$$\|\hat{T}_K^N(t,s)\|_{L(H^N)} \leq Me^{-\alpha(t-s)}, \quad \|\hat{T}_\Psi^N(t,s)\|_{L(H^N)} \leq Me^{-\alpha(t-s)}.$$

By the general framework of §3, there exists a unique solution $\hat{Q}^N$ of the Riccati equation on the infinite time interval for each control system in H^N. The operator

$\hat{Q}^N(t)P_H^N$ converges strongly to the unique solution $Q(t)$ of the Riccati integral equation for the original system in H as $N \to \infty$. The convergence is uniform in t for t in any bounded interval.

We summarize the results for our dissipativity approach to uniform stabilizability and detectability in the following theorem.

THEOREM 5.2. *Consider the parabolic control system defined by* (4.10)– (4.12) *under Hypotheses* 4.1–4.3, 4.5–4.7, *and the corresponding approximate systems as defined via* $\hat{\sigma}^N$, $\hat{T}^N$ *as above where* $P_H^N \to I$ *strongly in* V *and* $P_U^N \to I$ *strongly in* U. *Under the "H-dissipativity" Hypotheses* 5.1, 5.2 *and the consistency Hypothesis* 5.3, *the following conclusions hold:*

(i) *There exist unique uniformly bounded solutions* $\hat{Q}^N, Q$ *of the Riccati integral equations in the infinite time interval* $[t_0, \infty)$ *for each of the approximate control systems and the original system, respectively. There exists a constant* M *such that for all* $t \in [t_0, \infty)$ *and all* N

$$\|\hat{Q}^N(t)\|_{L(H^N)} \leq M, \quad \|Q(t)\|_{L(H)} \leq M.$$

(ii) *Let* $\hat{S}^N$, S *be the perturbed evolution operator corresponding to the perturbations of* $\hat{T}^N, T$ *by* $-B^N(R^N)^{-1}B^{*N}\hat{Q}^N$ *and* $-BR^{-1}BQ$, *respectively; then there exist constants* M *and* $\alpha > 0$ *independent of* N *such that*

$$\|\hat{S}^N(t,s)\|_{L(H^N)} \leq Me^{-\alpha(t-s)}, \quad \|S(t,s)\|_{L(H)} \leq Me^{-\alpha(t-s)},$$

for all $(t,s) \in \triangle_\infty(t_0)$.

(iii) *As* $N \to \infty$, $\hat{Q}^N, \hat{S}^N$ *converge to* Q, S *in the following sense: for all* $\varphi \in H$

$$\|\hat{Q}^N(t)P_H^N\varphi - Q(t)\varphi\|_H \to 0,$$
$$\|\hat{S}^N(t,s)P_H^N\varphi - S(t,s)\varphi\|_H \to 0.$$

The convergence is uniform in (t,s) *in any bounded interval.*

The advantage of using the dissipativity approach outlined above is that the hypotheses are readily checked. The H-dissipativity can sometimes be replaced by even weaker dissipativity conditions for which one can obtain an exponential decay rate (e.g., see [Ch], [La]). For parabolic systems with strict V-ellipticity, we can avoid use of this type of argument as we shall see in the next section. However these results might be useful for systems without strict V-ellipticity or possibly even some hyperbolic systems (e.g., see [BKS], [BKW]).

6. Periodic systems: compactness and uniform stabilizability/detectability. One of the special features of parabolic evolution systems as defined in §4 is that the evolution operator $T(t,s)$ is also a bounded linear operator from H to V. Since often the space V is compactly embedded in H, $T(t,s)$ is thus a compact operator. Using this fact, we can show that the convergence of the sequence of operators $T^N(t,s)$ to $T(t,s)$ is in a stronger sense. In this section, by combining periodicity and compactness of the evolution operators T^N and T, we can show that the approximation schemes discussed in §4 preserve detectability and stabilizability.

The fundamental ideas on the stability of periodic evolution operators used in our arguments here can be found in [H1], [H2]. The use of compact embedding ideas for the proof of operator norm convergence can be found in [BI2] (The authors gratefully acknowledge K. Ito for fruitful discussions regarding this approach).

In this section we make a periodicity assumption for our control system:

Hypothesis 6.1. There exists a constant $\theta > 0$ such that
(i) The sesquilinear form σ is θ-periodic in time;
(ii) The operator valued functions B, R, W are periodic in time with period θ.

LEMMA 6.1. *Under the above assumption, the evolution operator $T(\cdot,\cdot)$ of the corresponding homogeneous evolution equation is θ-periodic.*

Proof. For any $s \leq t$, and all $\varphi, \psi \in V$, we have

$$\begin{aligned} < T(t+\theta, s+\theta)\varphi, \psi >_H &= < \varphi, \psi >_H - \int_{s+\theta}^{t+\theta} \sigma(\tau; T(\tau, s+\theta)\varphi, \psi) d\tau \\ &= < \varphi, \psi >_H - \int_s^t \sigma(\tau; T(\tau+\theta, s+\theta)\varphi, \psi) d\tau. \end{aligned}$$

By the uniqueness of the solution of the weak form of our evolution equation, we have $T(t+\theta, s+\theta)\varphi = T(t,s)\varphi$, for $\varphi \in H$.

Under the periodicity Hypothesis 6.1, the continuity assumptions and the uniform boundedness assumptions of the control system need only to be verified in the bounded interval $[0, \theta]$. The above lemma shows that the periodicity of the evolution operator is given by the periodicity of the corresponding sesquilinear form σ. The following theorem plays a very important role in the study of periodic systems. We give its proof in order to remind the reader of the dependency of certain bounds involved.

THEOREM 6.1. ([H1], [H2]) *Let $T(\cdot,\cdot)$ be a θ-periodic evolution operator. Then $T(\cdot,\cdot)$ is uniformly exponentially stable if and only if there exist an integer n and a constant $\beta < 1$ such that*

$$\|T(n\theta, 0)\|_{L(H)} \leq \beta. \tag{6.1}$$

Proof. a) Let $T(\cdot,\cdot)$ be uniformly exponentially stable; that is, there exist constants $M, \omega > 0$ such that

$$\|T(t,s)\|_{L(H)} \leq M e^{-\omega(t-s)}, \quad (t,s) \in \triangle_\infty(0).$$

Therefore, if we take n large enough such that $M \exp\{-\omega n\theta\} < 1$, and let $\beta = M \exp\{-\omega n\theta\}$, we have that (6.1) holds.

b) Suppose (6.1) holds. Let C be a constant such that for all $0 \leq s \leq t \leq n\theta$, $\|T(t,s)\| \leq C$. Now for any $0 \leq s \leq t < \infty$ and $t - s > \theta$, we can find integers k and m such that

$$k \leq \frac{t-s}{n\theta} \leq k+1, \quad (m-1)\theta \leq s \leq m\theta.$$

Therefore, by the semigroup property of $T(\cdot,\cdot)$, we get

$$T(t,s) = T(t, (nk+m)\theta) T((nk+m)\theta, m\theta) T(m\theta, s).$$

By definition of k and m, we have $m\theta - s \leq n\theta$ and $t - (nk+m)\theta \leq n\theta$; then by (6.1), we have

$$\|T(t,s)\|_{L(H)} \leq C^2 \beta^k \leq C^2 e^{k \log \beta}.$$

Since $\beta < 1$, we have $\log \beta < 0$; therefore we find

$$\|T(t,s)\|_{L(H)} \leq C^2 e^{-\log \beta} \cdot e^{(k+1)\log \beta} \leq M e^{-\omega(t-s)}.$$

with $M = C^2/\beta$ and $\omega = -\log \beta / n\theta$.

Since the evolution operator T is also $n\theta$-periodic, we can therefore assume without loss of generality that $\|T(\theta,0)\|_{L(H)} \leq \beta < 1$. The following lemma is an interesting consequence of the above theorem.

LEMMA 6.2. *For a periodic system, if the stabilizability and the detectability assumptions are satisfied, then there exist θ-periodic operator valued functions $\hat{K}(\cdot)$ and $\hat{\Psi}(\cdot)$ such that the evolution operator $\hat{T}_K$ and $\hat{T}_\Psi$ corresponding to the perturbation of the evolution operator T by $B\hat{K}$, $\hat{\Psi}W^{1/2}$ are also uniformly exponentially stable.*

Proof. Suppose K, Ψ are operator valued functions in the stabilizability and detectability assumptions. Let T_K, T_Ψ be the evolution operators corresponding to perturbation of T by BK and $\Psi W^{1/2}$ respectively. Without lost of generality, we can assume that there exists a constant $\beta < 1$ such that

$$\|T_K(\theta,0)\| \leq \beta; \tag{6.2}$$

$$\|T_\Psi(\theta,0)\| \leq \beta. \tag{6.3}$$

Now define θ-periodic operator valued functions $\hat{K}, \hat{\Psi}$ as $\hat{K}(t) = K(t)$, $\hat{\Psi}(t) = \Psi(t)$, for $t \in [0,\theta)$, and extend periodically for $t \geq \theta$. Then we have $\hat{T}_K(\theta,0) = T_K(\theta,0)$, $\hat{T}_\Psi(\theta,0) = T_\Psi(\theta,0)$; therefore (6.2), (6.3) still hold for the new evolution systems. By Theorem 6.1, we conclude that $\hat{T}_K$, $\hat{T}_\Psi$ are also uniformly exponentially stable.

As a consequence of this lemma, we can assume without loss of generality that the operator valued functions K, Ψ in Hypotheses 4.5 and 4.6 are θ-periodic. In fact we can make the following equivalent assumptions.

Hypothesis 6.2. There exist a constant $\beta < 1$ and θ-periodic operator valued functions K, Ψ, such that if T_K, T_Ψ are the evolution operators corresponding to the perturbation of the evolution operator T by $BK, \Psi W^{1/2}$, respectively, then

$$\|T_K(\theta,0)\| \leq \beta, \quad \|T_\Psi(\theta,0)\| \leq \beta.$$

For the remainder of this section, we shall assume Hypotheses 6.1 and 6.2 hold and we focus on the uniform stabilizability and the uniform detectability of the approximate control systems. Let $K^N(t) = P_U^N K(t)$, $\Psi^N(t) = P_H^N \Psi$ and T_K^N, T_Ψ^N be the evolution operators corresponding to the perturbations of T^N by $B^N K^N$ and $\Psi^N (W^N)^{1/2}$, respectively. As we have seen in the proof of the Theorem 6.1, the constant M and decay rate ω depend only on the uniform bound of T and constant β. We already know (use the arguments of Theorem 4.4 and uniform boundedness of the perturbations) that $\|T_K^N(t,s)\|_{L(H^N)}$ and $\|T_\Psi^N(t,s)\|_{L(H^N)}$ can be uniformly bounded by a constant C independent of N for all $0 \leq s \leq t \leq \theta$; therefore, to obtain uniform stabilizability and uniform detectability, we only have to show (see b) of the proof of Theorem 6.1) that we can find $\hat{\beta} < 1$ and N_0 such that for all $N \geq N_0$, we have

$$\|T_K^N(\theta,0)\|_{L(H^N)} \leq \hat{\beta}; \tag{6.4}$$

$$\|T_\Psi^N(\theta,0)\|_{L(H^N)} \leq \hat{\beta}. \tag{6.5}$$

If, on the other hand, the convergence of $T_K^N(t,s)P_H^N$ to $T_K(t,s)$ ($T_\Psi^N(t,s)P_H^N$ to $T_\Psi(t,s)$) is in the operator norm, then we can readily establish that (6.4), (6.5) hold for N large enough. The following theorem is very useful in the proof of this desired convergence.

THEOREM 6.2. *Let H, V be Hilbert spaces as defined in §4 with V compactly embedded in H. Consider a sequence of bounded linear operators $\mathcal{T}^N$ defined on H and bounded linear operator $\mathcal{T}$ defined on H. Suppose the range of $\mathcal{T}^N$ and $\mathcal{T}$ are in V, and the following conditions hold:*

(i) *There exists a constant C such that*

$$\|\mathcal{T}^N\|_{L(H,V)} \le C, \quad \|\mathcal{T}\|_{L(H,V)} \le C;$$

(ii) *For any $\varphi \in H$, we have*

$$\|\mathcal{T}^N\varphi - \mathcal{T}\varphi\|_H \to 0, \quad \|\mathcal{T}^{*N}\varphi - \mathcal{T}^*\varphi\|_H \to 0,$$

as $N \to \infty$.

Then the convergence of the sequence of operators $\mathcal{T}^N$ to $\mathcal{T}$ is in the operator norm, that is, $\|\mathcal{T}^N - \mathcal{T}\|_{L(H)} \to 0$, as $N \to \infty$.

Before we give the proof of this theorem, let us state a useful lemma.

LEMMA 6.3. *Consider a nonincreasing sequence of compact sets $E_k \subset H$, $E_k \supseteq E_{k+1}$, $k = 1, 2, 3, \ldots$. If we have $\bigcap_{k=1}^\infty E_k = \{0\}$, then for each $\epsilon > 0$, we can find k_0 large enough such that for all $k \ge k_0$, E_k is a subset of a ball $B(0,\epsilon)$ in H defined by $B(0,\epsilon) = \{\varphi \in H \mid \|\varphi\|_H \le \epsilon\}$.*

Proof. Suppose there exists $\epsilon > 0$ such that for every k, we can find $\varphi_k \in E_k$, such that $\|\varphi_k\|_H > \epsilon$. Since the sequence $\{\varphi_k\}$ is in E_1 which is compact, we can assume that φ_k converges to an element φ in E_1. Obviously $\|\varphi\|_H > \epsilon/2$. On the other hand, φ must be in E_k for all k, therefore φ is also in the set $E = \bigcap_{k=1}^\infty E_k$. But since $E = \{0\}$, this is a contradiction.

Proof of Theorem 6.2. i) By definition of the operator norm, we have

$$\|\mathcal{T}^N - \mathcal{T}\|_{L(H)} = \sup\left\{\|\mathcal{T}^N\varphi - \mathcal{T}\varphi\|_H \mid \varphi \in H, \|\varphi\|_H \le 1\right\}.$$

Now let us define the set F_k as

$$F_k = \bigcup_{N=k}^\infty \{\mathcal{T}^N\varphi - \mathcal{T}\varphi \mid \varphi \in H, \|\varphi\|_H \le 1\}.$$

Let E_k be the H closure of F_k. The sequence of operators $\mathcal{T}^N$ converges to $\mathcal{T}$ in operator norm if and only if for all $\epsilon > 0$, we can find k_0 such that for all $k \ge k_0$, we have $E_k \subseteq B(0,\epsilon)$.

ii) We observe that E_k is a closed set in H and hence in V, and by our assumption $E_k \subset V$ is bounded in V norm, in fact

$$E_k \subset \{\varphi \mid \varphi \in V, \|\varphi\|_V \le 2C\}.$$

Therefore, E_k is a compact set. By definition of E_k, we know that $\{E_k\}$ is a nonincreasing sequence of compact sets.

iii) Let us define $E = \bigcap_{k=1}^{\infty} E_k$. Suppose $\varphi \in E$; since φ is in the closure of F_k for all k, we can find a sequence γ^N with $\|\gamma^N\|_H \leq 1$, such that $\varphi^N = (\mathcal{T}^N - \mathcal{T})\gamma^N$ converges to φ. Therefore, for any $\psi \in H$, we have

$$\begin{aligned} < \varphi, \psi >_H &= \lim_{N\to\infty} < \varphi^N, \psi >_H \\ &= \lim_{N\to\infty} < \gamma^N, (\mathcal{T}^{*N} - \mathcal{T}^*)\psi >_H . \end{aligned}$$

Since γ^N is uniformly bounded in N and $(\mathcal{T}^{*N} - \mathcal{T}^*)\psi$ goes to zero as $N \to \infty$, we have $< \varphi, \psi >_H = 0$ for all $\psi \in H$, and therefore $\varphi = 0$.

Using the previous lemma and i), we obtain $\|\mathcal{T}^N - \mathcal{T}\|_{L(H)} \to 0$, as $N \to \infty$.

Now recall the definition of the approximate control systems defined in §4, and consider $\mathcal{T}^N = T_K^N(\theta, 0)P_H^N$, $\mathcal{T} = T_K(\theta, 0)$. By the results in §4, we can easily verify that the assumptions of Theorem 6.2 are satisfied. Therefore, we have

$$\|T_K^N(\theta, 0)P_H^N - T(\theta, 0)\|_{L(H)} \to 0,$$

as $N \to \infty$. Now let β be the constant in Hypothesis 6.2; letting $\epsilon = 1 - \beta$, we can find N_0 large enough such that for all $N \geq N_0$ we have

$$\|T_K^N(\theta, 0)P_H^N - T(\theta, 0)\|_{L(H)} \leq \frac{\epsilon}{2}.$$

Therefore, for all $N \geq N_0$, we have

$$\begin{aligned} \|T_K^N(\theta, 0)\|_{L(H^N)} &\leq \|T_K(\theta, 0)\|_{L(H)} + \|T_K^N(\theta, 0)P_H^N - T_K(\theta, 0)\|_{L(H)} \\ &\leq 1 - \frac{\epsilon}{2}. \end{aligned}$$

We summarize our discussion in the following theorem.

THEOREM 6.3. *Let H, V be the Hilbert spaces used in the §4 and assume that V is compactly embedded in H. Suppose that Hypotheses 4.1–4.3, 4.7, and 6.1, 6.2 hold. Let $H^N \subset V$ be the finite dimensional approximation spaces and let the approximate control system be defined as in §4. Then there exists N_0 large enough such that for all $N \geq N_0$, the approximate control systems are uniformly stabilizable and uniformly detectable. As a consequence, if Q^N, Q are the unique solutions of the Riccati integral equations on the infinite time interval in H^N, H, respectively, and S^N, S are the evolution operators corresponding to the perturbations of T^N, T by $-B^N(R^N)^{-1}B^{*N}Q^N$, $-BR^{-1}B^*Q$, respectively, then we have:*

$$\|Q^N(t)P_H^N\varphi - Q(t)\varphi\|_H \to 0, \quad \|S^N(t, s)P_H^N - S(t, s)\|_{L(H)} \to 0,$$

as $N \to \infty$. The convergences are uniform in $[0, \theta]$ and for $(t, s) \in \triangle(0, \theta)$, respectively.

We remark that an autonomous system is a particular case of a periodic system; therefore, the approach used here can also be applied to time invariant systems as considered in [BK1]. In the case of parabolic systems with strict V-ellipticity where V is compactly embedded in H, the arguments in this section offer an alternative (and more succinct) approach to uniform stabilizability/detectability from the dissipativity approach of §5.

7. Parabolic partial differential equation control systems: An example. In this section we consider control systems governed by second-order parabolic partial differential equations with distributed scalar control. We indicate briefly how one formulates the associated control and approximate problems in the framework of §4. For this class of systems we show that one can, under standard assumptions, readily verify the conditions for continuity, ellipticity, stabilizability and detectability required in §4. For Galerkin-type approximation schemes based on spline subspaces, Conditions US and UD are readily established.

Let Ω be a bounded open subset of $\Re^n$ with an infinitely differentiable boundary Γ given by a variety of dimension $n-1$ and consider the following homogeneous second-order parabolic partial differential equation ([L1], [L2, p. 100]):

$$\frac{\partial}{\partial t}z(t,\xi) = \sum_{i,j=1}^{n}\frac{\partial}{\partial \xi_i}\left(a_{i,j}(t,\xi)\frac{\partial}{\partial \xi_j}z(t,\xi)\right)+\sum_{i=1}^{n}b_i(t,\xi)\frac{\partial}{\partial \xi_i}z(t,\xi) + c(t,\xi)z(t,\xi), \quad t>0, \xi\in\Omega, \tag{7.1}$$

where $\xi=(\xi_1,\cdots,\xi_n)\in\Re^n$. Generic boundary conditions are given by

$$\gamma(\xi)\sum_{i,j=1}^{n}a_{i,j}(t,\xi)\frac{\partial}{\partial \xi_j}z(t,\xi)\eta_i(\xi)+\beta(t,\xi)z(t,\xi)=0, \quad t>0,\xi\in\Gamma, \tag{7.2}$$

where $\eta(\xi)=(\eta_1(\xi),\cdots,\eta_n(\xi))$ is the outward unit normal vector at a point ξ on the boundary Γ of Ω. Note that for all $\xi\in\Gamma$, if $\gamma(\xi)\neq 0$, we can divide (7.2) by $\gamma(\xi)$; therefore, we can assume without loss of generality that γ takes only values 0 or 1. We choose as our state space $H=L^2(\Omega)$; the appropriate choice for V depends on the boundary conditions and we consider several special cases.

(i) Consider the case $\gamma(\xi)\equiv 0$, $\beta(t,\xi)\equiv 1$, and thus equation (7.2) specifies the usual Dirichlet boundary condition. We then define $V=H_0^1(\Omega)$, and a sesquilinear form σ_1 by

$$\sigma_1(t;\varphi,\psi) = \int_\Omega \sum_{i,j=1}^{n}a_{i,j}(t,\xi)\frac{\partial}{\partial\xi_j}\varphi(\xi)\frac{\partial}{\partial\xi_i}\bar{\psi}(\xi)d\xi - \int_\Omega\sum_{i=1}^{n}\left\{b_i(t,\xi)\frac{\partial}{\partial\xi_i}\varphi(\xi)\bar{\psi}(\xi)+c(t,\xi)\varphi(\xi)\bar{\psi}(\xi)\right\}d\xi.$$

(ii) If we consider the case for $\gamma(\xi)\equiv 1$, $\beta(t,\xi)\equiv 0$, we obtain a Neumann boundary condition. We then choose $V=H^1(\Omega)$ and note that the integrals in the definition of σ_1 above are also defined for any functions φ,ψ in $H^1(\Omega)$. Therefore, the sesquilinear form σ_2 for Neumann boundary conditions can be taken as the same as for Dirichlet conditions,$\sigma_2=\sigma_1$, and thus only the spaces V are changed.

(iii) Consider the case $\gamma(\xi)\equiv 1$ and $\beta(t,\xi)\not\equiv 0$ which results in Robin or mixed boundary conditions. We again choose $V=H^1(\Omega)$, and define a sesquilinear form σ_3 by

$$\sigma_3(t;\varphi,\psi)=\sigma_2(t;\varphi,\psi)+\int_\Gamma\beta(t,\xi)\varphi(\xi)\bar{\psi}(\xi)d\xi.$$

By taking $\gamma(\xi)=0$ on a part Γ_1 of the boundary and $\gamma(\xi)=1$ on $\Gamma-\Gamma_1$, we can obtain other mixed boundary conditions. The choice of space V should also be

modified accordingly. In all the cases above, let V be the appropriate choice of Sobolev space (either H_0^1 or H^1), and let σ denote the corresponding sesquilinear form defined on $V \times V$. Then a solution $z(t)$ of (7.1) and (7.2) satisfies

$$\frac{d}{dt} < z(t), \psi >_H = -\sigma(t; z(t), \psi), \quad \text{for all } \psi \in V. \tag{7.3}$$

As usual, (7.3) is called the weak form of (7.1) and (7.2); see (4.7), (4.8), and (4.10), (4.11) of §4.

The continuity and the ellipticity conditions for the sesquilinear forms σ_i can be characterized by properties of the coefficients $a_{i,j}, b_i, c$, and β. The standard assumptions ([L2, p.100]) for V-continuity and Hölder continuity of the sesquilinear forms σ_i are as follows: For each fixed t, the functions $a_{i,j}(t,\cdot)$, $b_i(t,\cdot)$, $c(t,\cdot)$ are elements of $L^\infty(\Omega)$, while the function $\beta(t,\cdot)$ is an element of $L^\infty(\Gamma)$. Furthermore, for each bounded interval $[a,b]$, there exist constants $C > 0$ and $0 < \gamma \leq 1$, such that each of the coefficients $a_{i,j}, b_i, c, \beta$ satisfy the bounds $\|f(t,\cdot)\|_{L^\infty} \leq C$ and $\|f(t,\cdot) - f(s,\cdot)\|_{L^\infty} \leq C|t-s|^\alpha$ for t, s in $[a,b]$, where L^∞ is $L^\infty(\Omega)$ or $L^\infty(\Gamma)$ as appropriate.

It is easily seen that under these assumptions, the V-continuity and V-Hölder continuity Hypotheses 4.1 and 4.3 hold for σ_1 and σ_2 defined above. In the case of σ_3, a boundary integral is involved; but under our assumptions on the smoothness of the boundary, the following estimates hold (see [L2, p.17, Thm. 3.2, p.23]): For any $\varphi, \psi \in H^1(\Omega)$, the restrictions of φ, ψ to the boundary Γ belong to $L^2(\Gamma)$. Furthermore, there exists a constant C such that

$$\left| \int_\Gamma \varphi \bar{\psi} d\xi \right| \leq \|\varphi\|_{L^2(\Gamma)} \|\psi\|_{L^2(\Gamma)} \leq C \|\varphi\|_{H^1(\Omega)} \|\psi\|_{H^1(\Omega)}.$$

Furthermore, for all $\epsilon > 0$, there exists constant $C(\epsilon)$ such that

$$\|\varphi\|^2_{L^2(\Gamma)} \leq \epsilon \|\varphi\|^2_{H^1(\Omega)} + C(\epsilon) \|\varphi\|^2_{L^2(\Omega)}.$$

With these estimates, it is readily argued that σ_3 also satisfies the Hypotheses 4.1 and 4.3 of §4.

To assure V-ellipticity we again make standard assumptions: for any bounded interval $[a,b]$, there exists a constant $\nu > 0$ such that for all $t \in [a,b]$ and $\xi \in \Omega$,

$$\nu \sum_{i=1}^n \zeta_i^2 \leq \sum_{i,j=1}^n a_{i,j}(t,\xi) \zeta_i \zeta_j,$$

for all $\zeta = (\zeta_1, \cdots, \zeta_n) \in \Re^n$. Under this assumption, it is readily seen that for each bounded time interval $[a,b]$, there exist constants $c_2 > 0$ and m, such that

$$\text{Re } \sigma_i(t; \varphi, \varphi) \geq c_2 \|\varphi\|^2_V - m \|\varphi\|^2_H,$$

for all $\varphi \in V$ and $t \in [a,b]$. That is, each of the sesquilinear forms σ_i, $i = 1,2,3$, defined above satisfies Hypothesis 4.2.

In the remaining part of the this section, let H, V be the spaces of functions appropriate for a specific problem, and let σ be the sesquilinear form defined for that problem as above. For the control space U, we choose $U = L^2(\Omega)$, with the control system being defined by (see (4.10)–(4.12))

$$\frac{d}{dt} < z(t), \psi >_H = -\sigma(t; z(t), \psi) + < B(t)u(t), \psi >_H, \tag{7.4}$$

for all ψ in V. We choose the cost functional given by (4.12). Here we define the operators $B(t), W(t), R(t)$ by the following

$$\begin{aligned}
[B(t)v](\xi) &= b(t,\xi)v(\xi), \quad \text{for } v \in L^2(\Omega),\\
[W(t)\varphi](\xi) &= w(t,\xi)\varphi(\xi), \quad \text{for } \varphi \in L^2(\Omega),\\
[R(t)v](\xi) &= r(t,\xi)v(\xi), \quad \text{for } v \in L^2(\Omega),
\end{aligned}$$

where b, w, r are scalar valued functions on $[t_0, \infty) \times \Omega$. In this case, the uniform boundedness and the positivity of the corresponding operators can be readily characterized by conditions on the functions b, w, and r. We assume that for each fixed t, $b(t,\cdot), w(t,\cdot)$, and $r(t,\cdot)$ are elements of $L^\infty(\Omega)$. As $L^\infty(\Omega)$ valued functions of t, these functions are assumed continuous. Furthermore, assume there exists a constant C such that for all $t \in [t_0, \infty)$, the functions $b(t,\cdot), w(t,\cdot), r(t,\cdot)$ satisfy the bound $\|f(t,\cdot)\|_{L^\infty(\Omega)} \leq C$. The functions w, r are assumed to be nonnegative and, indeed, we assume there exists a constant $r_0 > 0$ such that $r(t,\xi) \geq r_0$, almost everywhere in Ω, for $t \geq t_0$.

Under these assumptions, the operator valued functions B, W, R satisfy the standing assumptions of §§2 and 4. It remains to consider Hypotheses 4.5 and 4.6 (stabilizability and detectability of the original system) as well as Conditions US and UD once we have introduced approximations. For the problems considered here, we can use the definition of the sesquilinear forms to give sufficient conditions for Hypotheses 5.1 and 5.2 (and hence Hypotheses 4.5 and 4.6) to hold. To this end, we assume that there exist constants $\mu > 0$ and $\rho > 0$ such that for $t \in [t_0, \infty)$, $|b(t,\xi)| \geq \mu$, $|w(t,\xi)| \geq \rho$, almost everywhere in Ω.

Under this assumption, it is readily seen that there exists constants $l \geq 0$ and $k > 0$, such that each of the sesquilinear forms σ_i satisfies for $\varphi \in V$

$$\sigma(t;\varphi,\varphi) + l < B(t)B^*(t)\varphi, \varphi >_H \geq k\|\varphi\|_H^2,$$

and

$$\sigma(t;\varphi,\varphi) + l < W(t)\varphi, \varphi >_H \geq k\|\varphi\|_H^2.$$

Thus, Hypotheses 5.1 and 5.2 hold with $K(t) = lB^*(t)$ and $\Psi(t) = lW^{1/2}(t)$.

For our approximate systems, we choose approximation spaces H^N and U^N as in §§3 and 4 generated by finite element or spline basis elements chosen so that $H^N \subset V$ and $U^N \subset U$ yield the desired convergence properties for P_H^N and P_U^N respectively (see [C, Chaps. 2, 3], [B], [Sc]). The approximating systems are then defined as in §5. It follows immediately that Hypothesis 5.3 holds and hence the conclusions of Theorem 5.2 are valid for the class of examples considered in this section.

We note that under periodicity assumptions we could have applied the alternative approach of §6 to these examples since (see [A]) both $V = H^1(\Omega)$ and $V = H_0^1(\Omega)$ embed compactly in $H = L^2(\Omega)$.

In some of our related efforts, we have numerically tested the ideas presented in this paper on one-dimensional versions of the example of this section. In these examples $\Omega = (0,1)$ and we have to date used either linear or cubic B-splines to generate the approximation spaces H^N and U^N. (In fact, when Ω is a parallelepiped, the above theory still is applicable and tensor products of one dimensional elements are a good choice for approximation elements.) We have considered several examples with time dependent periodic coefficients; for these examples we could use eigendirection

analysis (see [W]) to give an analytic analysis for the feedback control problems. The resulting analytical solutions were used for comparison with the numerical solutions obtained using software implementations based on the theory developed in this paper. Quite satisfactory results were obtained and, as noted in the Introduction, these are being detailed in a separate manuscript under preparation.

In conclusion we note that the theory in this paper is also applicable to higher order parabolic systems (as well as to some boundary damped hyperbolic systems [BKS], [BKW]). In particular, one-dimensional Euler–Bernoulli beam models with Kelvin–Voigt damping satisfy (see [BI1]) the strong ellipticity assumptions needed in the theory developed above. While boundary control (as treated in [BI2]) for such models constitute an obvious class of problems, distributed control as treated in this paper is essential in cases where nonuniform piezoelectric layers along the beam are used to implement the feedback controls.

Invited Expository Article

This paper is another in the continuing series of expository papers that were invited by the editors. These papers undergo the same refereeing procedure as do research papers submitted directly by the authors, although the refereeing guidelines are modified to suit the largely expository nature of the paper. Due to the rapid recent technical development of a number of areas in control and optimization, many of the seminal papers are quite specialized and are readily accessible to a limited group of experts only. Moreover, the original motivations and practical importance of the ideas are sometimes difficult to find in the mathematical development. The purpose of these papers is to bring the ideas, techniques, and applications of a few selected areas to the attention of a wider audience, so that their basic importance can be more easily and widely appreciated.

OPTIMIZATION PROBLEMS IN THE THEORY OF CONTINUOUS TRADING*

IOANNIS KARATZAS†

This paper is dedicated to Dr. Václav E. Beneš on the occasion of his 60th birthday.

Abstract. A unified approach, based on stochastic analysis, to the problems of *option pricing*, *consumption/investment*, and *equilibrium* in a financial market with asset prices modelled by continuous semimartingales is presented.

For the first of these problems, the valuation of both "European" and "American" contingent claims is discussed; the former can be exercised only at a specified time T (the maturity date), whereas the latter can be exercised at any time in $[0, T]$. Notions and results from the theory of *optimal stopping* are employed in the treatment of American options.

A general *consumption/investment* problem is also considered, for an agent whose actions cannot affect the market prices and whose intention is to maximize total expected utility of both consumption and terminal wealth. Under very general conditions on the utility functions of the agent, it is shown how to approach the above problem by considering separately the two, more elementary ones of maximizing utility from consumption only and of maximizing utility from terminal wealth only, and then appropriately composing them. The optimal consumption and wealth processes are obtained quite explicitly. In the case of a market model with constant coefficients, the optimal portfolio and consumption rules are derived very explicitly in feedback form (on the current level of wealth). The Hamilton-Jacobi-Bellman equation of dynamic programming associated with this problem is reduced to the study of two *linear* parabolic equations that are then solved in closed form.

The results of this analysis lead to an explicit computation of the portfolio that maximizes capital growth rate from investment, and to a precise expression for the maximal growth rate.

Finally, the results on the consumption/investment problem for a single agent are applied to study the question of *equilibrium* in an economy with several financial agents whose joint optimal actions determine the price of a traded commodity by "clearing" the markets.

Some familiarity with stochastic analysis, including the fundamental martingale representation and Girsanov theorems, is assumed. Previous exposure to financial economics and/or stochastic control theory is desirable, but not necessary.

Key words. option pricing, consumption/investment optimization, equilibrium, stochastic analysis and control

1. Introduction and summary.

Our aim in this article is to report, hopefully to a wider audience than the already well-informed, on certain recent advances in the theory

* Received by the editors July 12, 1988; accepted for publication (in revised form) January 22, 1989. This research was supported in part by National Science Foundation grant DMS-87-23078.

of continuous trading which have been made possible thanks to the methodologies of stochastic analysis. All the questions treated here are formulated in the context of a financial market which includes a risk-free asset called the *bond*, and several risky assets called *stocks*; the prices of these latter are driven by an equal number of independent Brownian motions, which model the exogenous forces of uncertainty that influence the market. The interest rate of the bond, the appreciation rates of the stocks as well as their volatilities, constitute the *coefficients* of the market model; we allow them to be arbitrary bounded measurable processes, adapted to the Brownian filtration, but require that a certain nondegeneracy (or "completeness") condition (2.3) be satisfied.

The questions that we address include the following:

(i) A general treatment of the *pricing of contingent claims* such as options, both European (to be exercised only at maturity) and American (which can be exercised any time before or at maturity);

(ii) The resolution of *consumption/investment problems* for a "small investor" (i.e., an economic agent whose actions cannot influence the market prices) with quite general utility functions; and

(iii) The associated study of *equilibrium models*. These are formulated in the context of an economy with several small investors and one commodity, whose price is determined by the joint optimal actions of all these agents in a way that "clears" the markets (i.e., equates supply and demand for the commodity at all times).

Instrumental in the approach that we adopt are two fundamental results of stochastic analysis: the *Girsanov change of probability measure* and the *representation of Brownian martingales as stochastic integrals*. The former constructs processes that are independent Brownian motions under a new, equivalent probability measure which, roughly speaking, "equates the appreciation rates of all the stocks to the interest rate of the bond." The latter of these results provides the "right portfolios" (investment strategies) for the investors in the above-mentioned problems. We assume that the reader is familiar with both these results; they are discussed in several monographs and texts dealing with stochastic analysis, such as Ikeda and Watanabe (1981) and Karatzas and Shreve (1987).

Here is an outline of the paper. Sections 2 and 3 set up the model for the financial market and for the small investor, respectively; the latter has at his disposal the choice of a *portfolio* (investment strategy) and a *consumption strategy*, which determine the evolution of his wealth. The notion of admissible portfolio/consumption strategies, which avoid negative terminal wealth with probability one, is introduced and expounded on in § 4, which can be regarded as the cornerstone of the paper.

Based on the results of § 4, we treat the pricing of European contingent claims in § 5; we provide the fair price and the subsequent values for such instruments, and derive the celebrated Black and Scholes (1973) formula for European call options as a special case of these results. The analogous problems for American contingent claims are taken up in § 6; predictably, their treatment requires notions and results from the theory of optimal stopping.

Sections 7–11 are concerned with *optimization problems* for a small investor. We introduce the concept of utility function in § 7, and treat first a problem in which utility is derived only from consumption (§ 8); based on the methodology of § 4, we provide quite explicit expressions for the optimal consumption and wealth processes, as well as for the associated value $V_1(x)$ of this problem, as a function of the initial wealth $x>0$. The "dual" situation, with utility derived only from terminal wealth, is discussed in § 9; again, explicit expressions are obtained for the above-mentioned quantities,

including the new value function $V_2(x)$. As a byproduct of this analysis, we obtain an explicit computation of the portfolio that maximizes the growth rate from investment, and an equally explicit expression for the maximal capital growth rate (§ 9.6).

We combine the two problems in § 10, where we take up the more realistic case of utility coming from *both* consumption and terminal wealth; it is shown then that a reasonable "compromise" between the two competing objectives can be achieved in the following fashion. At time $t=0$, we let the investor divide his initial capital $x>0$ into two parts $x_1>0$, $x_2>0$, $x_1+x_2=x$; for the initial capital x_1 (respectively, x_2) *he* faces, from then on, a problem in which utility comes only from consumption (respectively, only from terminal wealth). It is shown that this simple procedure, in the form of the superposition of his actions for the two individual problems, yields optimal strategies for the composite problem, provided that x_1 and x_2 are chosen so that $V_1'(x_1)=V_2'(x_2)$. Again, explicit expressions are provided for the optimal consumption and wealth processes, and for the resulting value function $V(x)=V_1(x_1)+V_2(x_2)$.

This type of analysis provides in general no information about the optimal portfolio strategy for the problem of § 10, except for guaranteeing its existence. To amend this drawback, in § 11, we specialize the problem to the case of *constant coefficients*, and reduce the associated Hamilton-Jacobi-Bellman equation to a system of two *linear* parabolic partial differential equations. With the help of the Feynman-Kac theorem and the Black and Scholes formula, we obtain the solutions of these equations in closed form, and from them the value function $V(x)$ by composition; we also derive very explicit expressions for the optimal portfolio and investment strategies, in feedback form on the current level of wealth.

In § 12 we apply the theory of § 8 to the study of an *equilibrium model.* We consider an economy with several agents, who can invest in the financial market and receive continuously endowment streams in units of a certain commodity (consumption good); this latter is traded in the market at a spot price $\psi(\cdot)$. It is shown that the optimal actions of these small investors determine, in principle, the price ψ according to the law of "supply and demand," which mandates that the commodity be consumed entirely as it enters the economy and that the net demand for each financial asset be zero.

2. The financial market model. We shall deal exclusively in this paper with a financial market in which $d+1$ assets (or "securities") can be traded continuously. One of them is a non-risky asset, called the *bond*, with price $P_0(t)$ given by

$$dP_0(t)=P_0(t)r(t)\,dt, \qquad P_0(0)=1. \tag{2.1}$$

The remaining d assets are risky; we shall refer to them as *stocks*, and assume that the price $P_i(t)$ per share of the ith stock is governed by the linear stochastic differential equation

$$dP_i(t)=P_i(t)\left[b_i(t)\,dt+\sum_{j=1}^{d}\sigma_{ij}(t)\,dW_j(t)\right], \qquad P_i(0)=p_i, \quad i=1,2,\cdots,d. \tag{2.2}$$

In this model, $W(t)=(W_1(t),\cdots,W_d(t))^*$ is a Brownian motion in $\mathcal{R}^d$, whose components represent the external, independent sources of uncertainty in the market; with this interpretation, the volatility coefficient $\sigma_{ij}(\cdot)$ in (2.2) models the instantaneous intensity with which the jth source of uncertainty influences the price of the ith stock. Notice that in this model there are as many stocks as there are sources of uncertainty.

The probabilistic setting will be as follows: the Brownian motion W will be defined on the complete probability space $(\Omega, \mathcal{F}, \mathbf{P})$, and we shall denote by $\{\mathcal{F}_t\}$ the $\mathbf{P}$-augmentation of the natural filtration

$$\mathcal{F}_t^W=\sigma(W(s);\,0\leqq s\leqq t), \qquad 0\leqq t<\infty.$$

The *interest rate* process $r(t), 0 \leq t < \infty$ of the bond, the *appreciation rate* vector process $b(t) = (b_1(t), \cdots, b_d(t))^*$, $0 \leq t < \infty$ of the stocks, and the *volatility* matrix-valued process $\sigma(t) = \{\sigma_{ij}(t)\}_{1 \leq i,j \leq d}, 0 \leq t < \infty$, will all be progressively measurable with respect to $\{\mathcal{F}_t\}$, and bounded uniformly in $(t, \omega) \in [0, \infty) \times \Omega$. We shall also assume that the *covariance matrix* process $a(t) = \sigma(t)\sigma^*(t)$ is strongly nondegenerate: i.e., there exists a number $\varepsilon > 0$ such that

$$\xi^* \sigma(t, \omega)\sigma^*(t, \omega)\xi \geq \varepsilon \|\xi\|^2 \quad \forall\, \xi \in \mathcal{R}^d, \quad (t, \omega) \in [0, \infty) \times \Omega. \tag{2.3}$$

We shall refer to $r(\cdot), b(\cdot), \sigma(\cdot)$ collectively as the *coefficients of the market model.*

It follows easily from (2.3) that the inverses of both matrices $\sigma(t, \omega)$ and $\sigma^*(t, \omega)$ exist and are bounded, i.e.,

$$\|(\sigma(t, \omega))^{-1}\xi\| \leq \frac{1}{\sqrt{\varepsilon}} \|\xi\| \quad \forall\, \xi \in \mathcal{R}^d, \tag{2.4}$$

$$\|(\sigma^*(t, \omega))^{-1}\xi\| \leq \frac{1}{\sqrt{\varepsilon}} \|\xi\| \quad \forall\, \xi \in \mathcal{R}^d \tag{2.5}$$

for every $(t, \omega) \in [0, \infty) \times \Omega$.

The nondegeneracy condition (2.3) will allow us to introduce an auxiliary probability measure $\tilde{\mathbf{P}}$, equivalent to $\mathbf{P}$, which is going to be the "catalyst" for all future developments in this paper. To this end, let us introduce the $\mathcal{R}^d$-valued process

$$\theta(t) = (\sigma(t))^{-1}[b(t) - r(t)\mathbf{1}] \tag{2.6}$$

which is bounded, measurable, and adapted to $\{\mathcal{F}_t\}$ thanks to our assumptions, as well as the exponential martingale

$$Z(t) = \exp\left\{ -\int_0^t \theta^*(s)\, dW(s) - \frac{1}{2}\int_0^t \|\theta(s)\|^2\, ds \right\}. \tag{2.7}$$

We fix, from now on, a finite time-horizon $[0, T]$, on which we are going to treat almost all our problems.[1] The auxiliary probability measure $\tilde{\mathbf{P}}$ is defined then on $(\Omega, \mathcal{F}_T)$ by

$$\tilde{\mathbf{P}}(A) = \mathbf{E}[Z(T).1_A], \tag{2.8}$$

and according to the Girsanov theorem the process

$$\tilde{W}(t) = W(t) + \int_0^t \theta(s)\, ds, \qquad 0 \leq t \leq T \tag{2.9}$$

is an $\mathcal{R}^d$-valued Brownian motion under $\tilde{\mathbf{P}}$ (cf. Girsanov (1960) or Karatzas and Shreve (1987, § 3.5)).

In order to understand the significance of the auxiliary probability measure $\tilde{\mathbf{P}}$, let us rewrite (2.2) with the help of (2.6), (2.9) as

$$dP_i(t) = P_i(t)\left[r(t)\, dt + \sum_{j=1}^{d} \sigma_{ij}(t)\, d\tilde{W}_j(t) \right], \qquad i = 1, \cdots, d. \tag{2.10}$$

Comparing (2.10) with (2.2), and recalling that $\tilde{W}$ is a $\tilde{\mathbf{P}}$-Brownian motion, we can say that $\tilde{\mathbf{P}}$ is the "risk-neutral" probability measure of the market model: *it equates the appreciation rates of all the stocks to the interest rate of the bond.* Equivalently, we

[1] The only exceptions are the problems that we discuss in § 6.7 and in § 9.6.

can solve the equations (2.10), and observe that the discounted stock prices $\beta(t)P_i(t)$ with

$$\beta(t) \triangleq \frac{1}{P_0(t)} = \exp\left\{-\int_0^t r(s)\,ds\right\}, \tag{2.11}$$

are given as

$$\beta(t)P_i(t) = p_i \cdot \exp\left\{\int_0^t \sigma_i^*(s)\,d\tilde{W}(s) - \frac{1}{2}\int_0^t \|\sigma_i(s)\|^2\,ds\right\} \tag{2.12}$$

where $\sigma_i(t) = (\sigma_{i1}(t), \cdots, \sigma_{id}(t))^*$. In particular, it follows from (2.12) that *the discounted stock prices βP_i are martingales under $\tilde{\mathbf{P}}$.*

Remark 2.1. The existence of a probability measure $\tilde{\mathbf{P}}$ with the above properties will guarantee that the model is free of "arbitrage," i.e., of opportunities to make some money out of nothing (cf. Remark 4.8); on the other hand, the uniqueness of such a $\tilde{\mathbf{P}}$ will guarantee that all the risk in the market, generated by the sources of uncertainty $(W_1, \cdots, W_d)$, can be "hedged against" by skillful trading in the financial assets (Theorem 4.6 and Proposition 4.7).

These are precisely the features that will allow us to solve the option pricing (§§ 5, 6) and consumption/investment problems (§§ 8–11) in the generality of the present model.

3. A "small investor." Let us consider now an economic agent, who invests in the various securities and whose decisions cannot affect the prices in the market (a "small investor"). We shall denote by $X(t)$ the *wealth* of this agent at time t, by $\pi_i(t)$ the amount that he invests in the ith stock at that time $(1 \leqq i \leqq d)$, and by $c(t)$ the rate at which he withdraws funds for consumption.

Notice that we allow here any $\pi_i(t)$, $1 \leqq i \leqq d$ to become negative, which amounts to selling the ith stock short. Similarly, the amount of money

$$X(t) - \sum_{i=1}^{d} \pi_i(t)$$

invested in the bond at any particular time, may also become negative; this is to be interpreted as borrowing at the interest rate $r(t)$.

DEFINITION 3.1. A *portfolio process* $\pi(t) = (\pi_1(t), \cdots, \pi_d(t))^*$, $0 \leqq t \leqq T$ is an $\mathcal{R}^d$-valued process, which is progressively measurable with respect to $\{\mathcal{F}_t\}$ and satisfies

$$\int_0^T \|\pi(t)\|^2\,dt < \infty \quad \text{a.s.} \tag{3.1}$$

DEFINITION 3.2. A *consumption rate process* $c(t)$, $0 \leqq t \leqq T$ is nonnegative, progressively measurable with respect to $\{\mathcal{F}_t\}$, and satisfies

$$\int_0^T c(t)\,dt < \infty \quad \text{a.s.} \tag{3.2}$$

The adaptivity condition in Definitions 3.1 and 3.2 means of course that the investor cannot anticipate the future values of the prices; that is, "insider trading" is excluded.

With the above interpretations and notation, we obtain the following equation for the wealth $X(t)$ of the agent:

$$\begin{aligned} dX(t) &= \sum_{i=1}^{d} \pi_i(t)\left[b_i(t)\,dt + \sum_{j=1}^{d} \sigma_{ij}(t)\,dW_j(t) \right] - c(t)\,dt \\ &\quad + \left[X(t) - \sum_{i=1}^{d} \pi_i(t) \right] r(t)\,dt. \end{aligned} \tag{3.3}$$

The three terms on the right-hand side of (3.3) account, respectively, for: (a) capital gains or losses from investments in stocks, (b) the decrease in wealth due to consumption, and (c) capital gains or losses from money invested in bonds.

With the help of (2.6), (2.9) we can re-cast the wealth equation (3.3) in its vector form

$$\begin{aligned} dX(t) &= [r(t)X(t) - c(t)]\,dt + \pi^*(t)[b(t) - r(t)\mathbf{1}]\,dt + \pi^*(t)\sigma(t)\,dW(t) \\ &= [r(t)X(t) - c(t)]\,dt + \pi^*(t)\sigma(t)\,d\tilde{W}(t). \end{aligned} \tag{3.4}$$

The solution of (3.4) with initial wealth $X(0) = x \geqq 0$ is easily seen to be given, in the notation of (2.11), by

$$\beta(t)X(t) = x - \int_0^t \beta(s)c(s)\,ds + \int_0^t \beta(s)\pi^*(s)\sigma(s)\,d\tilde{W}(s), \qquad 0 \leqq t \leqq T. \tag{3.5}$$

Remark 3.3. It is easily seen from (3.5) that the process

$$M(t) = \beta(t)X(t) + \int_0^t \beta(s)c(s)\,ds, \qquad 0 \leqq t \leqq T, \tag{3.6}$$

consisting of current discounted wealth plus total discounted consumption to-date, is a continuous local martingale under $\tilde{\mathbf{P}}$. Let us introduce now the process

$$\zeta(t) = \beta(t)Z(t), \tag{3.7}$$

which modifies the discount factor of (2.11) in order to take into account the presence of the financial market. From Remark 3.3, and with the help of the "Bayes rule"

$$\tilde{\mathbf{E}}[\,Y|\mathcal{F}_s] = \frac{\mathbf{E}[\,YZ(t)|\mathcal{F}_s]}{Z(s)}, \tag{3.8}$$

which is valid for $0 \leqq s < t \leqq T$ for every $\mathcal{F}_t$-measurable, $\tilde{\mathbf{P}}$-integrable random variable Y (cf. Karatzas and Shreve (1987, p. 193)), we can deduce that the process

$$N(t) = \zeta(t)X(t) + \int_0^t \zeta(s)c(s)\,ds, \qquad 0 \leqq t \leqq T \tag{3.9}$$

is a continuous local martingale under $\mathbf{P}$, and that *N is a $\mathbf{P}$-supermartingale, if and only if M is a $\tilde{\mathbf{P}}$-supermartingale.*

Remark 3.4. The process ζ of (3.7) will play a fundamental role in the sequel. We shall see that it acts as a "deflator," in the sense that multiplication by $\zeta(t)$ converts wealth held at time t to the equivalent amount of wealth held at time zero.

It is interesting to note that (3.7), (2.11), and (2.7) lead to the linear stochastic differential equation

$$d\zeta(t) = -\zeta(t)[r(t)\,dt + \theta^*(t)\,dW(t)] \tag{3.10}$$

for the process ζ.

4. Admissible strategies. We shall single out those pairs (π, c) for which the investor avoids negative wealth at the terminal time, with probability one.

DEFINITION 4.1. A pair (π, c) of portfolio and consumption rate processes is called *admissible* for the initial capital $x \geq 0$, if the corresponding wealth process X of (3.5) satisfies

$$X(T) \geq 0 \quad \text{and} \quad \zeta(t)X(t) \geq -K, \quad \forall\, 0 \leq t \leq T \tag{4.1}$$

almost surely, for some nonnegative and $\mathbf{P}$-integrable random variable $K = K(\pi, c)$.

The class of such pairs is denoted by $\mathcal{A}(x)$.

For every $(\pi, c) \in \mathcal{A}(x)$, the continuous, $\mathbf{P}$-local martingale N of (3.9) is bounded from below; an application of Fatou's lemma shows then that N is a supermartingale under $\mathbf{P}$, and therefore that the process M of (3.6) is a supermartingale under $\tilde{\mathbf{P}}$. Consequently, with $\mathcal{S}_{u,v}$ denoting the class of $\{\mathcal{F}_t\}$-stopping times with values in the interval $[u, v]$, we have by the optional sampling theorem the equivalent inequalities

$$\mathbf{E}\left[\zeta(\tau)X(\tau) + \int_0^\tau \zeta(s)c(s)\,ds\right] \leq x, \tag{4.2}$$

$$\tilde{\mathbf{E}}\left[\beta(\tau)X(\tau) + \int_0^\tau \beta(s)c(s)\,ds\right] \leq x \tag{4.3}$$

for every $\tau \in \mathcal{S}_{0,T}$.

Remark 4.2. With the interpretation of the process ζ as a "deflator," the inequality (4.2) acquires the significance of a *budget constraint*; it mandates that "the expected total value of current wealth and consumption-to-date, both deflated down to $t = 0$, does not exceed the initial capital."

DEFINITION 4.3. For every given number $x \geq 0$, denote by

(i) $\mathcal{C}(x)$ the class of consumption rate processes c which satisfy

$$\tilde{\mathbf{E}} \int_0^T \beta(s)c(s)\,ds \leq x, \tag{4.4}$$

and by

(ii) $\mathcal{L}(x)$ the class of nonnegative, $\mathcal{F}_T$-measurable random variables B which satisfy

$$\tilde{\mathbf{E}}[\beta(T)B] \leq x. \tag{4.5}$$

From the inequality (4.3) we deduce

$$(\pi, c) \in \mathcal{A}(x) \Rightarrow c \in \mathcal{C}(x), \qquad X(T) \in \mathcal{L}(x). \tag{4.6}$$

In the next two theorems, we discuss the extent to which the opposite implications are true.

THEOREM 4.4. *For every $c \in C(x)$, there exists a portfolio process π such that $(\pi, c) \in \mathcal{A}(x)$.*

Proof. Given $c \in \mathcal{C}(x)$, introduce the random variable $D = \int_0^T \beta(s)c(s)\,ds$ and the $(\{\mathcal{F}_t\}, \tilde{\mathbf{P}})$-martingale

$$u(t) = \tilde{\mathbf{E}}(D|\mathcal{F}_t) - \tilde{\mathbf{E}}D, \qquad 0 \leq t \leq T. \tag{4.7}$$

The fundamental martingale representation theorem (e.g., Ikeda and Watanabe (1981, p. 80) or Karatzas and Shreve (1987, pp. 184, 375)) shows that u can be written as a stochastic integral with respect to $\tilde{W}$, i.e.,

$$u(t) = \int_0^t \phi^*(s)\,d\tilde{W}(s), \qquad 0 \leq t \leq T \tag{4.8}$$

for some $\{\mathcal{F}_t\}$-progressively measurable, $\mathcal{R}^d$-valued process ϕ with $\int_0^T \|\phi(s)\|^2\, ds < \infty$, almost surely. Finally, defining $\pi(t) = P_0(t)(\sigma^*(t))^{-1}\phi(t)$, we see that (4.8) is equivalently rewritten as

$$u(t) = \int_0^t \beta(s)\pi^*(s)\sigma(s)\, d\tilde{W}(s) \tag{4.9}$$

and that π is a portfolio process (i.e., (3.1) is satisfied).

The wealth process X corresponding to the pair (π, c) is given by

$$\begin{aligned} \beta(t)X(t) &= x - \int_0^t \beta(s)c(s)\, ds + u(t) \\ &= \tilde{\mathbf{E}}\left[\int_t^T \beta(s)c(s)\, ds \,\middle|\, \mathcal{F}_t\right] + x - \tilde{\mathbf{E}}D, \qquad 0 \leqq t \leqq T \end{aligned} \tag{4.10}$$

thanks to (3.5), (4.9), and (4.7). It is easily seen that this process has continuous, nonnegative paths with $X(T) = (x - \tilde{\mathbf{E}}D)P_0(T) \geqq 0$, almost surely. In other words, the pair (π, c) is admissible. □

We shall say that two measurable stochastic processes A, B on $[0, T]$ are *equivalent*, if $A(t, \omega) = B(t, \omega)$ holds for $\lambda \times \mathbf{P}$-almost everywhere $(t, \omega) \in [0, T] \times \Omega$.

Here, λ stands for Lebesgue measure.

PROPOSITION 4.5. *For every consumption rate process c in the class*

$$\mathcal{D}(x) = \left\{ c \in \mathcal{C}(x);\ \tilde{\mathbf{E}} \int_0^T \beta(s)c(s)\, ds = x \right\} \tag{4.11}$$

we have the following:

(i) *The portfolio π of Theorem* 4.4 *is unique up to equivalence.*

(ii) *The corresponding wealth process X satisfies $X(T) = 0$, almost surely.*

(iii) *The process M of* (3.6) *is a $\tilde{\mathbf{P}}$-martingale. In particular,*

$$\beta(t)X(t) = \tilde{\mathbf{E}}\left[\int_t^T \beta(s)c(s)\, ds \,\middle|\, \mathcal{F}_t\right], \qquad 0 \leqq t \leqq T.$$

Proof. For a given $c \in \mathcal{D}(x)$, and any portfolio π such that $(\pi, c) \in \mathcal{A}(x)$, we have from (4.3) the inequality

$$\tilde{\mathbf{E}}[\beta(T)X(T)] \leqq x - \tilde{\mathbf{E}} \int_0^T \beta(s)c(s)\, ds = 0,$$

which justifies (ii), as well as

$$\tilde{\mathbf{E}}M(T) = \tilde{\mathbf{E}} \int_0^T \beta(s)c(s)\, ds = x = \tilde{\mathbf{E}}M(0),$$

which establishes (iii) by showing that the supermartingale M of (3.6) has constant expectation.

Now for any two portfolios π_1, π_2 such that $(\pi_1, c) \in \mathcal{A}(x)$ and $(\pi_2, c) \in \mathcal{A}(x)$, let X_1, X_2 represent the corresponding wealth processes and M_1, M_2 the corresponding $\tilde{\mathbf{P}}$-martingales of (3.6). The martingale

$$(M_1 - M_2)(t) = \int_0^t \beta(s)(\pi_1(s) - \pi_2(s))^*\sigma(s)\, d\tilde{W}(s), \qquad 0 \leqq t \leqq T$$

is identically zero, because $M_1(T) = M_2(T) = \int_0^T \beta(s)c(s)\,ds$. Therefore,

$$\langle M_1 - M_2\rangle(t) = \int_0^t \beta^2(s)\|(\pi_1(s) - \pi_2(s))^*\sigma(s)\|^2\,ds = 0, \qquad 0 \leqq t \leqq T,$$

which shows that π_1, π_2 are equivalent. □

The following "controllability" result is analogous to Theorem 4.4, and characterizes the *levels of wealth attainable by an initial capital* $X(0) = x$.

THEOREM 4.6. *For every* $B \in \mathcal{L}(x)$, *there exists a pair* $(\pi, c) \in \mathcal{A}(x)$ *such that the corresponding wealth process* X *satisfies* $X(T) = B$, *almost surely.*

Proof. By analogy with the proof of Theorem 4.4, introduce the $\tilde{\mathbf{P}}$-martingale

$$v(t) = \tilde{\mathbf{E}}[B\beta(T)|\mathcal{F}_t] - \tilde{\mathbf{E}}[B\beta(T)], \qquad 0 \leqq t \leqq T \tag{4.12}$$

and conclude that it can be represented in the form (4.9), i.e.,

$$v(t) = \int_0^t \beta(s)\pi^*(s)\sigma(s)\,d\tilde{W}(s),$$

for a suitable portfolio π. Now the continuous process X defined by

$$\beta(t)X(t) = x - \rho t + v(t), \qquad 0 \leqq t \leqq T \tag{4.13}$$

and $\rho = (x - \tilde{\mathbf{E}}[B\beta(T)])/T$, represents the wealth corresponding to the pair (π, c) with $c(t) = \rho P_0(t)$. But then it follows from (4.12), (4.13) that

$$\beta(t)X(t) = \tilde{\mathbf{E}}[B\beta(T)|\mathcal{F}_t] + (x - \tilde{\mathbf{E}}[B\beta(T)]) \cdot \left(1 - \frac{t}{T}\right). \tag{4.14}$$

We deduce from (4.5) and (4.14) that X is nonnegative, so that in particular the pair (π, c) is admissible, and $X(T) = B$ almost surely. □

We can also establish an analogue of Proposition 4.5; we omit the easy proof.

PROPOSITION 4.7. *For any random variable* B *in the class*

$$\mathcal{M}(x) = \{B \in \mathcal{L}(x);\ \tilde{\mathbf{E}}[B\beta(T)] = x\} \tag{4.15}$$

we have the following:

(i) *The pair* (π, c) *of Theorem* 4.6 *is unique and* $c \equiv 0$, *up to equivalence.*

(ii) *The corresponding wealth process* X *is given by*

$$\beta(t)X(t) = \tilde{\mathbf{E}}[B\beta(T)|\mathcal{F}_t], \qquad 0 \leqq t \leqq T. \tag{4.16}$$

Remark 4.8. Let us define an *arbitrage opportunity* as a portfolio π such that

(i) $(\pi, 0) \in \mathcal{A}(0)$, and

(ii) The wealth process X, which corresponds to $(\pi, 0)$ and the initial capital $x = 0$, satisfies $\mathbf{P}[X(T) > 0] > 0$.

In other words, an arbitrage opportunity is an investment strategy that achieves, with zero initial capital, an amount of terminal wealth which is almost surely nonnegative and positive with positive probability. It is also sometimes called a "free lunch," for obvious reasons.

Our model excludes arbitrage opportunities; indeed, the necessary condition for admissibility (4.3) yields with $x = 0$ and $c \equiv 0$: $\tilde{\mathbf{E}}[\beta(T)X(T)] \leqq 0$, leading to $X(T) = 0$, almost surely.

Remark 4.9. Theorem 4.6 and Proposition 4.7 still hold, if T is replaced by a positive stopping time $\tau \in \mathcal{S}_{0,T}$ and B by a nonnegative, $\mathcal{F}_\tau$-measurable random variable (recall (4.3)). We would have to replace (4.14) by

$$\beta(t)X(t) = \tilde{\mathbf{E}}[B\beta(\tau)|\mathcal{F}_t] + (x - \tilde{\mathbf{E}}[B\beta(\tau)])\left(1 - \frac{t \wedge \tau}{\tau}\right)$$

and take $c(t) \equiv 0$, $\pi(t) \equiv 0$ for $\tau \leq t \leq T$. The rest of the argument goes through without change.

5. The pricing of European options. Suppose that at time $t = 0$ we sign a contract which gives us the option to buy, at the specified time T (maturity, expiration date), one share of the stock $i = 1$ at a specified price q (the contractual "exercise price"). At maturity, if the price $P_1(T)$ of the share is below the exercise price, the contract is worthless to us; on the other hand, if $P_1(T) > q$, we can exercise our option at $t = T$, buy one share of the stock at the pre-assigned price q, and then sell the share immediately in the market for $P_1(T)$.

Thus, this contract is equivalent to a payment of $(P_1(T) - q)^+$ at maturity; it is called a *European option*, in contradistinction with "American options" which can be exercised at any stopping time in $[0, T]$ (cf. § 6).

The following definition generalizes the concept of European option.

DEFINITION 5.1. A *European Contingent Claim* (ECC) is a financial instrument consisting of a payment B at maturity; here, B is a nonnegative, $\mathcal{F}_T$-measurable random variable with

$$\mathbf{E}(B^\mu) < \infty \quad \text{for some } \mu > 1. \tag{5.1}$$

Remark 5.2. Using the boundedness of the processes r and θ, as well as the Hölder inequality, it is not hard to see that (5.1) implies

$$\tilde{\mathbf{E}}[B\beta(T)] < \infty. \tag{5.2}$$

DEFINITION 5.3. A *hedging strategy* against the ECC of Definition 5.1 is a pair $(\pi, c) \in \mathcal{A}(x)$ for some $x > 0$, such that $X(T) = B$ almost surely.

We denote by $\mathcal{H}(x)$ the class of hedging strategies with initial wealth $X(0) = x$.

In words, a hedging strategy $(\pi, c) \in \mathcal{H}(x)$ starts out with initial wealth x and "reproduces the payoff from the ECC" at $t = T$.

What is a fair price to pay at $t = 0$ for the ECC? If there exists a hedging strategy for some $x > 0$, then an agent who contemplates buying the ECC at time $t = 0$ can instead invest in the market according to the portfolio π and consume at the rate c, and still achieve the same wealth at $t = T$ as the payment from the ECC. Therefore, the price he should be prepared to pay at $t = 0$ for the ECC cannot possibly be greater than this amount x.

It is natural then to define the fair price as the *smallest* value of the initial wealth, which allows the construction of a hedging strategy.

DEFINITION 5.4. The number

$$v \triangleq \inf\{x > 0;\ \exists (\pi, c) \in \mathcal{H}(x)\} \tag{5.3}$$

is called the *fair price* at $t = 0$ for the ECC of Definition 5.1.

THEOREM 5.5. *The fair price v of Definition* 5.4 *is given as*

$$v = \tilde{\mathbf{E}}\left[B \exp\left(-\int_0^T r(u)\, du \right) \right]. \tag{5.4}$$

There exists a portfolio process π with $(\pi, 0) \in \mathcal{H}(v)$; this portfolio is unique up to equivalence, and the corresponding wealth process is given by

$$X(t) = \tilde{\mathbf{E}}\left[B \exp\left(\int_t^T r(u)du \right) \middle| \mathcal{F}_t \right], \qquad 0 \leq t \leq T. \tag{5.5}$$

Proof. All the claims follow directly from Theorem 4.6 and Proposition 4.7. □

The random variable $X(t)$ of (5.5) is called the *value at time t* of the ECC.

Example 5.6. Consider a financial market model with constant interest rate $r(t) \equiv r \geqq 0$ and volatility matrix $\sigma(t) \equiv \sigma$, as well as and a contingent claim with $B = \varphi(P(T))$. Here, $\varphi : \mathcal{R}_+^d \to [0, \infty)$ is a continuous function and

$$P(t) = (P_1(t), \cdots, P_d(t))^* \tag{5.6}$$

is the vector of stock price processes which satisfy, in this case, the equations (2.10) in the form

$$dP_i(t) = P_i(t)\left[r\,dt + \sum_{j=1}^{d} \sigma_{ij}\, d\tilde{W}_j(t) \right], \qquad 1 \leqq i \leqq d. \tag{5.7}$$

The solution of these equations is given by (2.12), namely

$$P_i(t) = p_i \exp\left[\left(r - \frac{1}{2} a_{ii} \right) t + \sum_{j=1}^{d} \sigma_{ij} \tilde{W}_j(t) \right]. \tag{5.8}$$

We introduce now the function $h(t, p, y)$: $[0, \infty) \times \mathcal{R}_+^d \times \mathcal{R}^d \to \mathcal{R}_+^d$ via

$$h_i(t, p, y) \triangleq p_i \exp\left[\left(r - \frac{1}{2} a_{ii} \right) t + y_i \right], \qquad 1 \leqq i \leqq d, \tag{5.9}$$

and observe that (5.8) can be written in the vector form

$$P(t) = h(t, p, \sigma \tilde{W}(t)). \tag{5.10}$$

Coming now to the ECC with $B = \varphi(P(T))$, we see from (5.5), (5.9) that its value is given by

$$\begin{aligned} X(t) &= \tilde{\mathbf{E}}[e^{-r(T-t)} \varphi(P(T)) | \mathcal{F}_t] \\ &= \tilde{\mathbf{E}}[e^{-r(T-t)} \varphi(h(T-t, P(t), \sigma(\tilde{W}(T) - \tilde{W}(t)))) | \mathcal{F}_t] \\ &= e^{-r(T-t)} \int_{\mathcal{R}^d} \varphi(h(T-t, P(t), \sigma z)) \Gamma_{T-t}(z)\, dz \end{aligned}$$

almost surely $\tilde{\mathbf{P}}$, for every $t \in [0, T)$, where

$$\Gamma_t(z) \triangleq (2\pi t)^{-d/2} \exp\left\{ -\frac{\|z\|^2}{2t} \right\}, \qquad z \in \mathcal{R}^d, \quad t > 0$$

is the fundamental Gaussian kernel in $\mathcal{R}^d$. It follows that, with

$$v(t, p) \triangleq \begin{cases} e^{-r(T-t)} \displaystyle\int_{\mathcal{R}^d} \varphi(h(T-t, p, \sigma z)) \Gamma_{T-t}(z)\, dz, & 0 \leqq t < T, \quad p \in \mathcal{R}_+^d, \\ \varphi(p), & t = T, \quad p \in \mathcal{R}_+^d, \end{cases} \tag{5.11}$$

the value at time t of the ECC is given by

$$X(t) = v(t, P(t)). \tag{5.12}$$

In this case it is even possible to "compute" the portfolio $\pi(t)$ that achieves the value process of (5.12). Indeed, under appropriate growth conditions on φ, the function $v(t, p)$ of (5.11) is the unique solution of the Cauchy problem

$$\begin{gathered} \frac{\partial v}{\partial t} + \frac{1}{2} \sum_{i=1}^{d} \sum_{j=1}^{d} a_{ij} p_i p_j \frac{\partial^2 v}{\partial p_i \partial p_j} + \sum_{i=1}^{d} r p_i \frac{\partial v}{\partial p_i} - rv = 0 \quad \text{on } [0, T) \times \mathcal{R}_+^d, \\ v(T, p) = \varphi(p), \qquad p \in \mathcal{R}_+^d \end{gathered}$$

by the Feynman-Kac theorem (e.g., Karatzas and Shreve (1987, p. 366)). Applying Itô's rule to the process X of (5.12) and using the above equation and (5.7), we arrive at

$$dX(t) = rX(t)\,dt + \sum_{i=1}^{d}\sum_{j=1}^{d} \sigma_{ij}P_i(t)\frac{\partial}{\partial p_i}v(t, P(t))\,d\tilde{W}_j(t).$$

A comparison with (3.4) gives then

$$\pi_i(t) = P_i(t)\cdot\frac{\partial}{\partial p_i}v(t, P(t)), \qquad 0 \leqq t \leqq T, \quad 1 \leqq i \leqq d$$

for the portfolio process of Theorem 5.5. In other words, we should hold $N_i(t) = (\partial/\partial p_i)v(t, P(t))$ shares of the ith stock at time t.

Remark 5.7. In the particular case of a European option as in Example 5.6, with $d = 1$, $\varphi(p) = (p-q)^+$ and exercise price $q > 0$, the integration in (5.11) can be carried out in a somewhat more explicit form. Indeed, with $\Phi(z) \triangleq (1/\sqrt{2\pi})\int_{-\infty}^{z}\exp(-x^2/2)\,dx$ and

$$\nu_{\pm}(t, p; q) \triangleq \frac{1}{\sigma_{11}\sqrt{t}}\left[\log\left(\frac{p}{q}\right) + \left(r \pm \frac{1}{2}\sigma_{11}^2\right)t\right],$$

we have

(5.13)
$$v(t, p; q) = \begin{cases} p\Phi(\nu_+(T-t, p; q)) - qe^{-r(T-t)}\Phi(\nu_-(T-t, p; q)), & 0 \leqq t < T, \quad 0 < p < \infty, \\ (p-q)^+, & t = T, \quad 0 < p < \infty. \end{cases}$$

Together with

$$X(t; q) \triangleq \tilde{\mathbf{E}}[e^{-r(T-t)}(P_1(T)-q)^+ | \mathcal{F}_t] = v(t, P_1(t); q), \qquad 0 \leqq t \leqq T, \tag{5.14}$$

the expression (5.13) constitutes the celebrated *Black and Scholes* (1973) *formula.*

Note that in this formula, as well as in (5.11), the appreciation rates of the stocks do not appear; this fact makes the formulas particularly attractive and useful, because appreciation rates are usually very difficult to estimate in practice. By contrast, the interest rate $r(\cdot)$ is directly observable, and the volatilities $\sigma(\cdot)$ can in principle be estimated—albeit with some difficulty—on the basis of observations on the price processes $(P_1(t), \cdots, P_d(t))$.

More generally, any convex and piecewise C^2 function $h:[0, \infty) \to [0, \infty)$ with $h(0) = h'(0) = 0$ can be represented as

$$h(p) = \int_0^\infty (p-q)^+ h''(q)\,dq.$$

For an ECC with $B = h(P_1(T))$, the value at time t is given then by (5.5) as

$$X(t) = \tilde{\mathbf{E}}[e^{-r(T-t)}h(P_1(T))|\mathcal{F}_t] = \int_0^\infty h''(q)v(t, P_1(t); q)\,dq \qquad \text{a.s.}$$

for every $0 \leqq t \leqq T$, thanks to the Fubini theorem and (5.14).

Remark 5.8. If the expiration date T is replaced by a stopping time $\tau \in \mathcal{S}_{0,T}$ and the payment B is an $\mathcal{F}_\tau$-measurable random variable, the theory of this section still

goes through with minor changes. A hedging strategy (Definition 5.3) now has to satisfy $X(\tau) = B$ almost surely, and (5.4), (5.5) become, respectively, thanks to Remark 4.9:

$$v^{(\tau)} = \tilde{\mathbf{E}}\left[B \exp\left(-\int_0^\tau r(u)du \right) \right], \tag{5.4)'}$$

$$X^{(\tau)}(t) = \tilde{\mathbf{E}}\left[B \exp\left(-\int_t^\tau r(u)\, du \right) \middle| \mathcal{F}_t \right]. \tag{5.5)'}$$

6. The pricing of American options.[2] For the purposes of this section only, we shall need to modify slightly the model of § 3 for the small investor. First, we will have to deal with cumulative consumptions C_t up to time t, rather than with consumption rate processes.

DEFINITION 6.1. A *consumption process* $C = \{C_t;\ 0 \leqq t \leqq T\}$ is continuous, increasing, adapted to $\{\mathcal{F}_t\}$, and satisfies $C_0 = 0$, $C_T < \infty$, almost surely.

Second, we have to allow the possibility for the stocks to pay *dividends* to the stockholders, at the rate $\mu_i(t);\ 0 \leqq t \leqq T$ for every dollar invested in the ith stock, $i = 1, \cdots, d$. These are nonnegative, bounded, and $\{\mathcal{F}_t\}$-progressively measurable processes, and we denote by $\mu(t) = (\mu_1(t), \cdots, \mu_d(t))^*$ the resulting vector process.

Then the wealth process X associated to a portfolio process π (Definition 3.1) and a consumption process C (Definition 6.1) satisfies the following analogue of equations (3.3) and (3.4):

$$\begin{aligned} dX(t) &= r(t)X(t)\, dt - dC_t + \pi^*(t)[b(t) + \mu(t) - r(t)\mathbf{1}]\, dt + \pi^*(t)\sigma(t)\, dW(t) \\ &= r(t)X(t)\, dt - dC_t + \pi^*(t)\sigma(t)\, d\tilde{W}(t) \end{aligned} \tag{6.1}$$

in the notation of (2.7)-(2.9), with (2.6) replaced by

$$\theta(t) \triangleq (\sigma(t))^{-1}[b(t) + \mu(t) - r(t)\mathbf{1}]. \tag{2.6)'}$$

The notion of admissibility for a pair (π, C) remains the same as in Definition 4.1, and (4.3) becomes

$$\tilde{\mathbf{E}}\left[X(\tau)\beta(\tau) + \int_0^\tau \beta(s)\, dC_s \right] \leqq x, \qquad \forall \tau \in \mathcal{S}_{0,T} \tag{6.2}$$

for every $(\pi, C) \in \mathcal{A}(x)$.

After this setting of the stage, let us introduce the primary object of this section.

DEFINITION 6.2. An *American Contingent Claim* (ACC) is a financial instrument consisting of the following:

(i) An expiration date $T \in (0, \infty)$;

(ii) The selection of a stopping time $\tau \in \mathcal{S}_{0,T}$; and

(iii) A payoff $f(\tau)$ on exercise.

Here, $\{f(t);\ 0 \leqq t \leqq T\}$ is a continuous, nonnegative process, adapted to $\{\mathcal{F}_t\}$, which satisfies

$$\mathbf{E}\left(\sup_{0 \leqq t \leqq T} f(t) \right)^\mu < \infty \quad \text{for some } \mu > 1. \tag{6.3}$$

For instance, if $f(t) = (P_1(t) - q)^+$, we have an *American option* on the first stock that can be exercised at the price $q \geqq 0$, at any stopping time τ on $[0, T]$. We restrict attention to stopping times, in order to exclude clairvoyance.

[2] This section may be omitted on first reading, without loss of continuity; its results will not be used in the sequel.

As in § 5, we are interested in the following *pricing problem* for the ACC: What is a fair price to pay at $t=0$ for this instrument? How much is it worth at any later time $t \in (0, T]$?

Let us suppose for a moment that the selection of $\tau \in \mathcal{S}_{0,T}$ ((ii) in Definition 6.2) has been made; then we have, from Remark 5.8, the expressions

$$X^{(\tau)}(t) = \tilde{\mathbf{E}}\left[f(\tau) \exp\left(-\int_t^\tau r(s)\, ds \right) \middle| \mathcal{F}_t \right],$$

$$v^{(\tau)} = X^{(\tau)}(0) = \tilde{\mathbf{E}}\left[f(\tau) \exp\left(-\int_0^\tau r(s)\, ds \right) \right]$$

for the value of the claim and for its fair price at $t=0$. It is conceivable then that, in order to find the corresponding quantities for the ACC, we would merely have to maximize over stopping times. In particular, we should expect the fair price at $t=0$ to be given by

$$\sup_{\tau \in S_{0,T}} \tilde{\mathbf{E}}\left[f(\tau) \exp\left(-\int_0^\tau r(s)\, ds \right) \right],$$

and the value of the ACC at any time $t \in [0, T]$ by

$$\operatorname*{ess\,sup}_{\tau \in \mathcal{S}_{t,T}} \tilde{\mathbf{E}}\left[f(\tau) \exp\left(-\int_t^\tau r(s)\, ds \right) \middle| \mathcal{F}_t \right] \quad \text{a.s.}$$

The question is whether this process is the wealth corresponding to an admissible portfolio/consumption process pair, that somehow again *duplicates* the payoff from the contingent claim and does so with minimal initial capital.

DEFINITION 6.3. Fix $x > 0$; a pair $(\pi, C) \in \mathcal{A}(x)$ is called a *hedging strategy* against the ACC with initial wealth x, if the corresponding wealth process X satisfies

(i) $X(t) \geqq f(t)$, for all $0 \leqq t \leqq T$,

(ii) $X(T) = f(T)$,

almost surely. We denote by $\hat{\mathcal{H}}(x)$ the collection of all such pairs.

DEFINITION 6.4. The number

$$\hat{v} \triangleq \inf\{x > 0;\ \exists (\pi, C) \in \hat{\mathcal{H}}(x)\} \tag{6.4}$$

is called the *fair price* for the ACC of Definition 6.2.

For every $(\pi, C) \in \hat{\mathcal{H}}(x)$, we have from (6.2): $\tilde{\mathbf{E}}[f(\tau)\beta(\tau)] \leqq x$, for all $\tau \in \mathcal{S}_{0,T}$. Therefore, with

$$u(t) \triangleq \sup_{\tau \in \mathcal{S}_{t,T}} \tilde{\mathbf{E}} Q(\tau), \quad Q(t) = f(t)\beta(t), \quad 0 \leqq t \leqq T, \tag{6.5}$$

we obtain $u(0) \leqq x$, whence

$$u(0) \leqq \hat{v}. \tag{6.6}$$

We shall show that equality actually holds in (6.6).

THEOREM 6.5. *The fair price $\hat{v}$ of Definition 6.4 is given by*

$$\hat{v} = u(0) = \sup_{\tau \in \mathcal{S}_{0,T}} \tilde{\mathbf{E}}\left[f(\tau) \exp\left(-\int_0^\tau r(s)\, ds \right) \right]. \tag{6.7}$$

There exists a pair $(\hat{\pi}, \hat{C}) \in \hat{\mathcal{H}}(u(0))$, such that the corresponding wealth process $\hat{X}$ is given as

$$\hat{X}(t) = \operatorname*{ess\,sup}_{\tau \in \mathcal{S}_{t,T}} \tilde{\mathbf{E}}\left[f(\tau) \exp\left(-\int_t^\tau r(s)\, ds \right) \middle| \mathcal{F}_t \right] \quad \text{a.s.} \tag{6.8}$$

for every $t \in [0, T]$, *and*

$$\int_0^T 1_{\{\hat{X}(t) > f(t)\}}\, d\hat{C}_t = 0 \quad \text{a.s.} \tag{6.9}$$

holds.

In view of (6.6), only the second claim needs to be discussed. For this purpose, we have to recall some basic facts from the *theory of optimal stopping* for a continuous process such as Q (cf. Fakeev (1970), Bismut and Skalli (1977), El Karoui (1981)). We know from these sources that there exists a nonnegative, RCLL (Right-Continuous with Left-hand Limits) $\tilde{\mathbf{P}}$-supermartingale $\{Y(t), \mathcal{F}_t;\ 0 \leqq t \leqq T\}$, such that the function $u(\cdot)$ of (6.5) is given as

$$u(t) = \tilde{\mathbf{E}}\, Y(t), \qquad 0 \leqq t \leqq T, \tag{6.10}$$

and

$$Y(t) = \operatorname*{ess\,sup}_{\tau \in \mathcal{S}_{t,T}} \tilde{\mathbf{E}}[Q(\tau) | \mathcal{F}_t] \quad \text{a.s.} \tag{6.11}$$

holds for every $t \in [0, T]$. Y is the *Snell envelope* of Q, i.e., the smallest RCLL supermartingale that dominates Q, and provides the optimal stopping time τ_t for the problem of (6.5): $u(t) = \tilde{\mathbf{E}} Q(\tau_t)$, in the form

$$\tau_t \triangleq \inf\{s \in [t, T];\ Y(s) = Q(s)\}. \tag{6.12}$$

Using (6.3) and the Doob and Jensen inequalities, it can be shown that Y *is of class* $D[0, T]$ *under* $\tilde{\mathbf{P}}$, i.e., that

$$\{Y(\tau)\}_{\tau \in \mathcal{S}_{0,T}} \quad \text{is a } \tilde{\mathbf{P}}-\text{uniformly integrable family.} \tag{6.13}$$

Bismut and Skalli (1977) also show that Y *is regular*:

$$\begin{aligned} &\text{For every monotone sequence } \{\sigma_n\}_{n=1}^{\infty} \subseteq \mathcal{S}_{0,T} \text{ with} \\ &\lim_{n\to\infty} \sigma_n = \sigma \in \mathcal{S}_{0,T}, \text{ we have } \lim_{n\to\infty} \tilde{\mathbf{E}}\, Y(\sigma_n) = \tilde{\mathbf{E}}\, Y(\sigma). \end{aligned} \tag{6.14}$$

Proof of Theorem 6.5. From (6.13), (6.14) we conclude that Y admits the Doob-Meyer decomposition (e.g., Karatzas and Shreve (1987, § 1.4)):

$$Y(t) = u(0) + M(t) - A(t), \qquad 0 \leqq t \leqq T,$$

where $\{M(t), \mathcal{F}_t\}$ is a $\tilde{\mathbf{P}}$-martingale and A is a *continuous*, nondecreasing process, with $M(0) = A(0) = 0$. As in the proof of Theorem 4.4, we have the representation

$$M(t) = \int_0^t \beta(s) \hat{\pi}^*(s) \sigma(s)\, d\tilde{W}(s), \qquad 0 \leqq t \leqq T$$

of the martingale M as a stochastic integral with respect to $\tilde{W}$, for a suitable portfolio process $\hat{\pi}$. Now define

$$\hat{X}(t) = Y(t) P_0(t), \qquad 0 \leqq t \leqq T, \tag{6.15}$$

and apply Itô's rule to obtain

$$d\hat{X}(t) = r(t) \hat{X}(t)\, dt - d\hat{C}_t + \hat{\pi}^*(t) \sigma(t)\, d\tilde{W}(t)$$

for the choice

$$\hat{C}_t = \int_0^t P_0(s)\, dA(s). \tag{6.16}$$

In other words, $\hat{X}$ is the wealth process corresponding to the portfolio/consumption process pair $(\hat{\pi}, \hat{C})$, which is easily seen to belong to $\hat{\mathcal{H}}(u(0))$. The representation (6.8) follows from (6.11), and (6.9) from

$$\int_0^T 1_{\{Y(t)>Q(t)\}}\, dA(t) = 0 \quad \text{a.s.}$$

(cf. Bismut and Skalli (1977), El Karoui (1981)). □

The stopping time τ_t of (6.12) can be written equivalently as

$$\tau_t = \inf\{s \in [t, T]; \quad \hat{X}(s) = f(s)\} \quad \text{a.s.}; \tag{6.17}$$

obviously, τ_0 *provides the optimal exercise time for the* ACC. The random variable $\hat{X}(t)$ of (6.8) gives the value of the ACC at time t.

Remark 6.6. Suppose that the process Q of (6.5) is a submartingale under $\tilde{P}$; then $u(t) = \tilde{\mathbf{E}}Q(T)$, $\tau_t = T$ for every $0 \leqq t \leqq T$, and *the* ACC *should not be exercised before the expiration date* (i.e., is equivalent to an ECC).

For instance, in the setting of Example 5.6, suppose that the function $\varphi : \mathcal{R}_+^d \to [0, \infty)$ is of class C^2 and satisfies

$$\frac{1}{2}\sum_{i=1}^d \sum_{j=1}^d a_{ij} p_i p_j \frac{\partial^2 \varphi(p)}{\partial p_i \partial p_j} + \sum_{i=1}^d (r - \mu_i) p_i \frac{\partial \varphi(p)}{\partial p_i} \geqq r\varphi(p)$$

as well as a polynomial growth condition. Then $Q(t) = e^{-rt}\varphi(P(t))$ is a $\tilde{\mathbf{P}}$-submartingale, and the value process for the ACC with $f(t) = \varphi(P(t))$ is given by (5.12), with the understanding that r has to be replaced by $r - \mu_i$ in the expressions (5.7)-(5.9).

As another example, take the American option with $d = 1$, $f(t) = (P_1(t) - q)^+$, $q > 0$ written on a stock which pays no dividends: $\mu_1(t) \equiv 0$, $r(t) \geqq 0$. Then

$$Q(t) = (P_1(t)\beta(t) - q\beta(t))^+$$

is a $\tilde{\mathbf{P}}$-submartingale, and we recover a result of Merton (1973): *an American option with positive exercise price, written on a stock that pays no dividends, should not be exercised before the expiration date.*

Remark 6.7. *The infinite horizon case.* In the setting of Example 5.6 and with $\mu_i(t) \equiv \mu$, $f(t) = \varphi(P(t))$, the value process $\hat{X}$ of (6.8) for $T = \infty$ is given, formally at least, as

$$\hat{X}(t) = v(P(t)), \qquad 0 \leqq t < \infty, \tag{6.18}$$

where $v : \mathcal{R}_+^d \to [0, \infty)$ is the least r-excessive majorant of the function φ (Fakeev (1971)).

More specifically, if $d = 1$ and $\varphi(p) = (p-1)^+$, the function v of (6.18) was computed by McKean (1965) as

$$v(p) = \begin{cases} (\kappa - 1)(p/\kappa)^\gamma; & 0 < p < \kappa \\ p - 1; & \kappa \leqq p < \infty \end{cases}$$

with $\gamma = (1/\sigma^2)(\sqrt{\delta^2 + 2r\sigma^2} - \delta)$, $\alpha = r - \mu > 0$, $\delta = \alpha - \sigma^2/2$, $\kappa = \gamma/(\gamma - 1) > 1$, and the optimal exercise time of (6.17) is given by

$$\tau_t = \inf\{s \geqq t;\ P_1(s) \geqq \kappa\}.$$

The finite-horizon version of this problem is studied in Van Moerbeke (1976); we then face a genuine *free-boundary problem*, for a moving boundary $\kappa(t)$, $0 \leqq t \leqq T$ rather than a point κ as above. Van Moerbeke studies this question by reducing it to a free-boundary problem of the Stefan type.

7. Utility functions. To formulate meaningful optimization problems for the small investor of § 3, we shall need the concept of utility function.

Let $U:[0, T]\times(0, \infty)\to\mathcal{R}$ be a $C^{0,1}$ function with the following properties for each $t\in[0, T]$:

(i) $U(t, \cdot)$ is strictly increasing and strictly concave;

(ii) The derivative $U'(t, c)\triangleq(\partial/\partial c)U(t, c)$ satisfies $\lim_{c\to\infty}U'(t, c)=0$ and $U'(t, 0+)\triangleq\lim_{c\downarrow 0}U'(t, c)=\infty$.

A function with these properties will be called a *utility function.*

Remark 7.1. The assumption (i) says that the investor prefers higher levels of consumption and/or terminal wealth to lower levels (strict increase of $U(t, \cdot)$), but that he is also *risk-averse*, i.e., that his marginal utility $U'(t, c)$ is decreasing in the argument c (strict concavity of $U(t, \cdot)$) and tends to zero as $c\to\infty$ (a "saturation effect").

The assumption $U'(t, 0+)=\infty$ of (ii) is not necessary, and is imposed here only for simplicity of exposition; in the optimization problems of §§ 8, 9 it will guarantee that the constraint $c(t)\geqq 0$ on consumption (respectively, $X(T)\geqq 0$ on terminal wealth) will never be active.

We shall denote by $I(t, \cdot)$ the inverse of the strictly decreasing mapping $U'(t, \cdot)$ from $(0, \infty)$ onto itself. The inequality

$$U(t, I(t, y))\geqq U(t, c)+y[I(t, y)-c], \quad \forall c\geqq 0, \tag{7.1}$$

valid for every $(t, y)\in[0, T]\times(0, \infty)$, is then an elementary consequence of the concavity of $U(t, \cdot)$.

For certain of our results we shall need to impose the additional conditions

$$U(t, \cdot)\in C^2((0, \infty)), \quad \forall t\in[0, T], \tag{7.2}$$

$$U''(t, c)\triangleq\frac{\partial^2}{\partial c^2}U(t, c) \quad \text{is nondecreasing in } c\in(0, \infty) \text{ for all } t\in[0, T]. \tag{7.3}$$

Under (7.2) and (7.3), $I(t, \cdot)$ is convex and of class C^1 on $(0, \infty)$, and we have

$$\frac{\partial}{\partial y}U(t, I(t, y))=y\frac{\partial}{\partial y}I(t, y), \quad \forall y\in(0, \infty). \tag{7.4}$$

8. Maximization of utility from consumption. In this section we shall try to address the following question. How should a small investor, endowed with initial wealth $x>0$, choose at every time his stock portfolio $\pi(t)$ and his consumption rate $c(t)$, from among admissible pairs $(\pi, c)\in\mathcal{A}(x)$, in order to obtain a maximum expected utility from consumption?

In order to give a precise meaning to this question, let us consider a utility function U_1, and try to maximize the *expected utility from consumption*

$$J_1(x; \pi, c)=\mathbf{E}\int_0^T U_1(t, c(t))\,dt \tag{8.1}$$

over the class $\mathcal{A}_1(x)$ of pairs $(\pi, c)\in\mathcal{A}(x)$ which satisfy

$$\mathbf{E}\int_0^T U_1^-(t, c(t))\,dt<\infty. \tag{8.2}$$

We shall denote by

$$V_1(x)=\sup_{(\pi, c)\in\mathcal{A}_1(x)}J_1(x; \pi, c) \tag{8.3}$$

the *value function* of this problem.

Now according to Theorem 4.4, *the problem* (8.3) *amounts to maximizing the expression* $\mathbf{E}\int_0^T U_1(t, c(t))\,dt$ *subject to* (8.2) *and the requirement* $c \in \mathscr{C}(x)$:

$$\tilde{\mathbf{E}}\int_0^T \beta(t)c(t)\,dt = \mathbf{E}\int_0^T \zeta(t)c(t)\,dt \leqq x, \tag{8.4}$$

where ζ is the process of (3.7).

But this question is straightforward, and concerns only the consumption process; elementary Lagrange multiplier considerations suggest that the optimal c should satisfy $U_1'(t, c(t)) = y\zeta(t)$, or equivalently

$$c(t) = I_1(t, y\zeta(t)), \qquad 0 \leqq t \leqq T \tag{8.5}$$

for an appropriate constant $y > 0$. This latter should be determined so that the requirement (8.4) is satisfied as an *equality*, i.e.,

$$\mathbf{E}\int_0^T \zeta(t)I_1(t, y\zeta(t))\,dt = x, \tag{8.6}$$

because we are trying to maximize total expected utility from consumption, and this utility increases as the consumption increases.

Let us now substantiate the heuristics of the preceding paragraph. We start by introducing the function

$$\mathscr{X}_1(y) = \mathbf{E}\int_0^T \zeta(t)I_1(t, y\zeta(t))\,dt, \qquad 0 < y < \infty, \tag{8.7}$$

and assuming that

$$\mathscr{X}_1(y) < \infty, \quad \forall y \in (0, \infty). \tag{8.8}$$

It is not hard to show that $\mathscr{X}_1 : (0, \infty) \to (0, \infty)$ *is continuous and strictly decreasing, with* $\mathscr{X}_1(0+) = \infty$ *and* $\mathscr{X}_1(\infty) = 0$. Therefore, $\mathscr{X}_1$ has the inverse $\mathscr{Y}_1 = \mathscr{X}_1^{-1}$, and there is exactly one number $y = \mathscr{Y}_1(x_1)$ that satisfies (8.6) for any given $x = x_1 > 0$. We consider then the corresponding consumption process in (8.5), namely

$$c_1(t) = I_1(t, \mathscr{Y}_1(x_1) \cdot \zeta(t)), \qquad 0 \leqq t \leqq T. \tag{8.9}$$

By construction, c_1 belongs to the class $\mathscr{D}(x_1)$ of (4.11), and according to Proposition 4.5 there exists a unique (up to equivalence) portfolio process π_1 such that $(\pi_1, c_1) \in \mathscr{A}(x_1)$; the wealth process X_1 corresponding to this pair is given by

$$\begin{aligned} \beta(t)X_1(t) &= \tilde{\mathbf{E}}\left[\int_t^T \beta(s)c_1(s)\,ds \,\middle|\, \mathscr{F}_t\right] \\ &= x_1 - \int_0^t \beta(s)c_1(s)\,ds + \int_0^t \beta(s)\pi_1^*(s)\sigma(s)\,d\tilde{W}(s). \end{aligned} \tag{8.10}$$

In particular, X_1 is positive on $[0, T)$ and vanishes at $t = T$, almost surely.

THEOREM 8.1. *Assume that* (8.8) *holds. Then for any* $x_1 > 0$ *and with* c_1 *given by* (8.9), *the above pair* (π_1, c_1) *belongs to* $\mathscr{A}_1(x_1)$ *and is optimal for the problem of* (8.3):

$$V_1(x_1) = \mathbf{E}\int_0^T U_1(t, c_1(t))\,dt. \tag{8.11}$$

Proof. We need to show that c_1 satisfies (8.2), and that for any other $c \in \mathscr{C}(x_1)$ which satisfies this condition we have the comparison

$$\mathbf{E}\int_0^T U_1(t, c_1(t))\,dt \geqq \mathbf{E}\int_0^T U_1(t, c(t))\,dt. \tag{8.12}$$

Now for any such c, the inequality (7.1) gives

$$U_1(t, c_1(t)) \geqq U_1(t, c(t)) + \mathscr{Y}_1(x_1)[\zeta(t) I_1(t, \mathscr{Y}_1(x_1)\zeta(t)) - \zeta(t)c(t)], \qquad 0 \leqq t \leqq T. \tag{8.13}$$

The constant consumption $c(t) \equiv \hat{c} \triangleq x_1/\mathbf{E}\int_0^T \zeta(s)\,ds$ belongs to $\mathscr{D}(x_1)$, and for this choice the right-hand side of (8.13) is $\lambda \times \mathbf{P}$-integrable (the value of its integral is actually $\int_0^T U_1(t, \hat{c})\,dt$). It follows that c_1 satisfies (8.2).

Now for any $c \in \mathscr{C}(x_1)$ satisfying (8.2), integrate both members of (8.13) with respect to $\lambda \times \mathbf{P}$, to obtain

$$\mathbf{E}\int_0^T U_1(t, c_1(t))\,dt \geqq \mathbf{E}\int_0^T U_1(t, c(t))\,dt + \mathscr{Y}_1(x_1)\cdot\left[x_1 - \mathbf{E}\int_0^T \zeta(t)c(t)\,dt\right].$$

The expression in the brackets is nonnegative, and (8.12) follows. □

In order to characterize the value function V_1 of (8.3) a little more precisely, we study the expected utility associated with a consumption rate process of the form (8.5), namely

$$G_1(y) \triangleq \mathbf{E}\int_0^T U_1(t, I_1(t, y\zeta(t)))\,dt, \qquad y \in (0, \infty) \tag{8.14}$$

under the assumption

$$\mathbf{E}\int_0^T |U_1(t, I_1(t, y\zeta(t)))|\,dt < \infty, \quad \forall y \in (0, \infty). \tag{8.15}$$

Then G_1 is a continuous, strictly decreasing function, and from Theorem 8.1 the value function of (8.3) is obviously given as

$$V_1 = G_1 \circ \mathscr{Y}_1. \tag{8.16}$$

Furthermore, formal differentiations in (8.7), (8.14) yield

$$\mathscr{X}_1'(y) = \mathbf{E}\int_0^T \zeta^2(t)\frac{\partial}{\partial y} I_1(t, y\zeta(t))\,dt$$

and

$$G_1'(y) = E\int_0^T \zeta(t) U_1'(I_1(t, y\zeta(t)))\frac{\partial}{\partial y} I_1(t, y\zeta(t))\,dt = y\mathscr{X}_1'(y).$$

These formalities can be made rigorous under the conditions (7.2), (7.3) and their consequence (7.4). We then arrive at the following characterization.

PROPOSITION 8.2. *Under the conditions* (8.8), (8.15) *on the utility function* U_1, *the value* $V_1(\cdot)$ *of the problem* (8.3) *is given by* (8.16).

Furthermore, if (7.2) *and* (7.3) *are also satisfied by* U_1, *then the strictly decreasing functions* $\mathscr{X}_1$ *and* G_1 *of* (8.7), (8.14) *are also continuously differentiable, and we have* $G_1'(y) = y\mathscr{X}_1'(y)$, *for all* $0 < y < \infty$ *as well as its consequence*

$$V_1' = \mathscr{Y}_1 \tag{8.17}$$

from (8.16); *in particular,* V_1 *is strictly increasing and strictly concave.*

Example 8.3. In the important special case $U_1(t, c) = \exp\{-\int_0^t \mu(s)\, ds\} \cdot \log c$ with bounded, measurable $\mu : [0, T] \to \mathcal{R}$, we obtain

$$\mathscr{X}_1(y) = \frac{\alpha_1}{y}, \qquad G_1(y) = -\alpha_1 \cdot \log y + \delta_1 \tag{8.18}$$

and hence

$$V_1(x) = \alpha_1 \cdot \log\left(\frac{x}{\alpha_1}\right) + \delta_1,$$

where

$$\begin{aligned} \alpha_1 &= \int_0^T \exp\left(-\int_0^t \mu(s)\, ds\right) dt, \\ \delta_1 &= \mathbf{E}\int_0^T \exp\left(-\int_0^t \mu(s)\, ds\right)\left\{\int_0^t \left(r(s) + \frac{1}{2}\|\theta(s)\|^2 - \mu(s)\right) ds\right\} dt. \end{aligned} \tag{8.19}$$

In particular, (8.8) and (8.15) are satisfied trivially in this case.

Example 8.4. In the special case $U_1(t, c) = -\exp\{-\int_0^t \mu(s)\, ds\}/c$, with μ as in Example 8.3, we obtain

$$\mathscr{X}_1(y) = \alpha_1 y^{-1/2}, \qquad G_1(y) = -\alpha_1 y^{1/2}, \tag{8.20}$$

and thus $V_1(x) = -\alpha_1^2/x$, where now

$$\alpha_1 = \mathbf{E}\int_0^T \exp\left(-\frac{1}{2}\int_0^t (\mu(s) + r(s))\, ds\right) Z^{1/2}(t)\, dt. \tag{8.21}$$

Again, (8.8) and (8.15) are obviously satisfied in this case.

Remark 8.5. If $U_1(0) > -\infty$, we have $\mathscr{A}_1(x) = \mathscr{A}(x)$, and it can be shown easily that (8.15) implies (8.8).

9. Maximization of utility from investment. Let us take up now the complementary problem to that of § 8, namely the maximization of the *expected utility from terminal wealth*

$$J_2(x; \pi, c) = \mathbf{E}\, U_2(T, X(T)), \tag{9.1}$$

over the class $\mathscr{A}_2(x)$ of pairs $(\pi, c) \in \mathscr{A}(x)$ that satisfy

$$\mathbf{E}\, U_2^-(T, X(T)) < \infty. \tag{9.2}$$

Here, U_2 is a utility function as in § 7, and

$$V_2(x) \triangleq \sup_{(\pi, c) \in \mathscr{A}_2(x)} J_2(x; \pi, c) \tag{9.3}$$

is the *value function* of this problem.

In this setting the agent obviously tries to maximize the utility from his terminal wealth, within the constraints imposed by the level of his initial capital and quantified by the *budget constraint* (4.5), i.e.,

$$\tilde{\mathbf{E}}[\beta(T) X(T)] = \mathbf{E}[\zeta(T) X(T)] \leqq x, \tag{9.4}$$

which mandates that "the expected terminal wealth, deflated down to $t = 0$, should not exceed the initial capital."

According to Theorem 4.6, *the problem* (9.3) *amounts to maximizing the expression* $\mathbf{E}\, U_2(T, X(T))$ *over the class of nonnegative,* $\mathscr{F}_T$*-measurable random variables* $X(T)$ *that satisfy* (9.2) *and* (9.4).

The situation is completely analogous to that of the previous section, so we just outline the results. We introduce the decreasing function

$$\mathscr{X}_2(y) = \mathbf{E}[\zeta(T) I_2(T, y\zeta(T))], \qquad 0 < y < \infty, \tag{9.5}$$

assume that

$$\mathscr{X}_2(y) < \infty, \qquad \forall y \in (0, \infty), \tag{9.6}$$

and show that $\mathscr{X}_2 : (0, \infty) \to (0, \infty)$ is continuous and strictly decreasing with $\mathscr{X}_2(0+) = \infty$, $\mathscr{X}(\infty) = 0$. Denoting by $\mathscr{Y}_2 = \mathscr{X}_2^{-1}$ the inverse of this function, and fixing an initial capital $x = x_2 > 0$, we introduce the $\mathscr{F}_T$-measurable random variable

$$X_2(T) = I_2(T, \mathscr{Y}_2(x_2)\zeta(T)) \tag{9.7}$$

and observe that it belongs to the class $\mathscr{M}(x_2)$ of (4.15). From Proposition 4.7, there exists a unique (up to equivalence) pair $(\pi_2, c_2) \in \mathscr{A}(x_2)$ that almost surely achieves the terminal wealth of (9.7); for this pair we have $c_2 \equiv 0$, and the corresponding wealth process X_2 is given by

$$\begin{aligned} \beta(t) X_2(t) &= \tilde{\mathbf{E}}[\beta(T) X_2(T) | \mathscr{F}_t] \\ &= x_2 + \int_0^t \beta(s) \pi_2^*(s) \sigma(s)\, d\tilde{W}(s), \qquad 0 \leqq t \leqq T. \end{aligned} \tag{9.8}$$

THEOREM 9.1. *Under the assumption* (9.6), *fix* $x_2 > 0$ *and consider the random variable* $X_2(T)$ *of* (9.7). *Then the above pair* $(\pi_2, 0)$ *belongs to* $\mathscr{A}_2(x_2)$ *and achieves the supremum in* (9.3):

$$V_2(x_2) = \mathbf{E} U_2(T, X_2(T)). \tag{9.9}$$

Sketch of Proof. Using the inequality (7.1) we show that the random variable $X_2(T)$ of (9.7) satisfies (9.2), and that

$$\mathbf{E} U_2(T, X_2(T)) \geqq \mathbf{E} U_2(T, X(T)) \tag{9.10}$$

holds for any other random variable $X(T) \in \mathscr{L}(x_2)$ satisfying (9.2). The details are completely analogous to those in the Proof of Theorem 8.1, and are left to the reader. □

We also have the following characterization of the value function.

PROPOSITION 9.2. *Under the conditions* (9.6) *and*

$$\mathbf{E}|U_2(T, I_2(T, y\zeta(T))| < \infty, \quad \forall y \in (0, \infty) \tag{9.11}$$

on the utility function U_2, *the value* V_2 *of the problem* (9.3) *is given as*

$$V_2 = G_2 \circ \mathscr{Y}_2, \tag{9.12}$$

where G_2 *is the continuous, strictly decreasing function*

$$G_2(y) \triangleq \mathbf{E} U_2(T, I_2(T, y\zeta(T))), \qquad 0 < y < \infty. \tag{9.13}$$

Furthermore, if (7.2) *and* (7.3) *are also satisfied by* U_2, *then the functions* $\mathscr{X}_2$, G_2 *of* (9.5), (9.13) *are also continuously differentiable, and satisfy* $G_2'(y) = y\mathscr{X}_2'(y)$ *for all* $0 < y < \infty$. *In that case we have*

$$V_2' = \mathscr{Y}_2, \tag{9.14}$$

which implies that V_2 *is strictly increasing and strictly concave.*

Example 9.3. In the special case $U_2(T, c) = \exp\{-\int_0^T \mu(s)\, ds\} \log c$, with μ as in Example 8.3, we deduce easily

$$\mathscr{X}_2(y) = \frac{\alpha_2}{y}, \quad G_2(y) = -\alpha_2 \cdot \log y + \delta_2, \quad \text{and}$$
$$V_2(x) = \alpha_2 \cdot \log\left(\frac{x}{\alpha_2}\right) + \delta_2, \tag{9.15}$$

where

$$\alpha_2 = \exp\left(\int_0^T \mu(s)\, ds\right),$$
$$\delta_2 = \mathbf{E}\left[\exp\left(-\int_0^T \mu(s)\, ds\right)\left\{\int_0^T \left(r(s) + \frac{1}{2}\|\theta(s)\|^2 - \mu(s)\right) ds\right\}\right]. \tag{9.16}$$

In particular, take $\mu \equiv 0$; then $I_2(T, y) = \mathscr{X}_2(y) = 1/y$, and from (9.7) we obtain

$$\beta(T) X_2(T) = x_2 \cdot \exp\left\{\int_0^T \theta^*(s)\, dW(s) + \frac{1}{2}\int_0^T \|\theta(s)\|^2\, ds\right\}.$$

On the other hand, (9.8) gives the optimal wealth process X_2 as

$$\beta(t) X_2(t) = x_2 \cdot \exp\left\{\int_0^t \theta^*(s)\, dW(s) + \frac{1}{2}\int_0^t \|\theta(s)\|^2\, ds\right\}, \tag{9.17}$$

and it follows from an easy application of Itô's rule that the process βX_2 satisfies the linear wealth equation

$$\beta(t) X_2(t) = x_2 + \int_0^t \beta(s) X_2(s) \theta^*(s)[dW(s) + \theta(s)\, ds]. \tag{9.18}$$

A comparison with (9.8) shows that *the optimal portfolio for maximizing* $E[\log X(T)]$ *is given explicitly as*

$$\pi_2(t) = X_2(t)(\sigma^*(t))^{-1}\theta(t). \tag{9.19}$$

Note that the processes X_2, π_2 can be defined by (9.17), (9.19) on the entirety of $[0, \infty)$, and that the above maximization holds then for every finite $T > 0$.

Remark 9.4. A similar analysis can be carried out in the context of Example 8.3 with $\mu \equiv 0$; it leads to the explicit computations $X_1(t) = x_1(T-t)/T\zeta(t)$, $c_1(t) = X_1(t)/(T-t)$, and $\pi_1(t) = X_1(t)(\sigma^*(t))^{-1}\theta(t)$ for the optimal wealth, consumption, and portfolio processes. We leave the details to the care of the diligent reader.

Example 9.5. In the special case $U_2(T, c) = -\exp\{-\int_0^T \mu(s)\, ds\}/c$, with μ as in Example 8.3, we have

$$\mathscr{X}_2(y) = \alpha_2 y^{-1/2}, \quad G_2(y) = -\alpha_2 y^{1/2}, \quad V_2(x) = -\frac{\alpha_2^2}{x}, \tag{9.20}$$

where

$$\alpha_2 = \mathbf{E}\left[\exp\left\{-\frac{1}{2}\int_0^T (\mu(s) + r(s))\, ds\right\} \cdot Z^{1/2}(T)\right]. \tag{9.21}$$

9.6. Maximizing the growth rate from investment. For the purposes of this paragraph only, let us call an $\{\mathcal{F}_t\}$-progressively measurable process $\pi(t,\omega):[0,\infty)\times\Omega\to\mathcal{R}^d$ an *admissible portfolio*, if it satisfies (3.1) for every finite $T>0$, and if the wealth process X corresponding to π and zero consumption, i.e.,

$$\beta(t)X(t)=x_2+\int_0^t \beta(s)\pi^*(s)\sigma(s)[dW(s)+\theta(s)\,ds], \qquad 0\leqq t<\infty, \tag{9.22}$$

is nonnegative, almost surely. Certainly the portfolio π_2 of (9.19) is admissible, since the corresponding wealth process X_2 in (9.18) is actually positive.

Quite obviously, π_2 *maximizes the expected growth rate* $\underline{\lim}_{T\to\infty}(1/T)\,E[\log X(T)]$ *from investment*; indeed, we noticed in Example 9.3 that $E[\log X(T)]\leqq E[\log X_2(T)]$ holds for every finite $T>0$, where X is the wealth process corresponding to an arbitrary admissible portfolio π. It then follows that

$$\begin{aligned}\varliminf_{T\to\infty}\frac{1}{T}E[\log X(T)]&\leqq\varliminf_{t\to\infty}\frac{1}{T}E[\log X_2(T)]\\&=\varliminf_{T\to\infty}\frac{1}{T}\int_0^T E\left\{r(s)+\frac{1}{2}\|\theta(s)\|^2\right\}ds.\end{aligned} \tag{9.23}$$

Consider now the problem of *maximizing the actual growth rate* $\underline{\lim}_{T\to\infty}(1/T)\log X(T)$, *over admissible portfolios* π. The comparison (9.23) suggests π_2 as a very strong candidate for this problem as well. In fact, we shall show that the comparison

$$\varlimsup_{T\to\infty}\frac{1}{T}\log X(T)\leqq\varliminf_{T\to\infty}\frac{1}{T}\log X_2(T)=\varliminf_{T\to\infty}\frac{1}{T}\int_0^T\left\{r(s)+\frac{1}{2}\|\theta(s)\|^2\right\}ds \tag{9.24}$$

holds almost surely, for every admissible portfolio π and its associated wealth process X.

The equality in (9.24) follows easily from (9.17) and the fact that $\lim_{T\to\infty}(1/T)\int_0^T\theta^*(s)\,dW(s)=0$, almost surely. To obtain the inequality, we apply Itô's rule to the ratio $\Lambda(t)=X(t)/X_2(t)$; in conjunction with (9.22) and (9.18), this leads to

$$d\Lambda(t)=X_2^{-1}(t)[\pi^*(t)\sigma(t)-X(t)\theta^*(t)]\,dW(t)$$

and shows that Λ is a nonnegative local martingale, hence a supermartingale. As a nonnegative supermartingale, Λ has a last element $\Lambda(\infty)\triangleq\lim_{t\to\infty}\Lambda(t)$, and satisfies the inequality

$$e^{\delta n}P[\sup_{n\leqq t<\infty}\Lambda(t)>e^{\delta n}]\leqq E\Lambda(n)\leqq 1$$

for every integer $n\geqq 1$ and $\delta>0$ (cf. Karatzas and Shreve (1987, Problem 1.3.16, Theorem 1.3.8)). It follows that

$$\sum_{n=1}^{\infty}P[\sup_{n\leqq t<\infty}\log\Lambda(t)>\delta n]\leqq\sum_{n=1}^{\infty}e^{-\delta n}<\infty,$$

and by the Borel-Cantelli Lemma there exists an integer-valued random variable N_δ such that, for almost every $\omega\in\Omega$ we have

$$\log\Lambda(t,\omega)\leqq\delta n\leqq\delta t,\quad\forall\, n\geqq N_\delta(\omega),\quad t\geqq n.$$

It follows that $\sup_{t\geq n}(1/t)\log\Lambda(t,\omega)\leq\delta$ holds for every $n\geq N_\delta(\omega)$, and thus also

$$\overline{\lim_{t\to\infty}}\frac{1}{t}\log\Lambda(t,\omega)\leq\delta \quad \text{for a.e.} \quad \omega\in\Omega.$$

The inequality of (9.24) is now a consequence of the arbitrariness of $\delta>0$.

10. Maximization of utility from both consumption and terminal wealth. Let us consider now an investor who derives utility both from "living well" (i.e., from consumption) and from "becoming rich" (i.e., from terminal wealth). His *expected total utility* is then

$$\begin{aligned} J(x;\pi,c) &\triangleq J_1(x;\pi,c)+J_2(x;\pi,c) \\ &= \mathbf{E}\int_0^T U_1(t,c(t))\,dt+\mathbf{E}U_2(T,X(T)), \end{aligned} \tag{10.1}$$

and he tries to maximize $J(x;\pi,c)$ over $\mathcal{A}_{1,2}(x)\triangleq\mathcal{A}_1(x)\cap\mathcal{A}_2(x)$:

$$V(x)\triangleq\sup_{(\pi,c)\in\mathcal{A}_{1,2}(x)}J(x;\pi,c). \tag{10.2}$$

Here again, U_1 and U_2 are utility functions in the sense of § 7.

In contrast to the problems of §§ 8 and 9, this one calls for balancing *competing objectives.* We shall show that the right compromise can be drawn in a very simple manner: at time $t=0$, the investor just divides his endowment x into two nonnegative parts x_1 and x_2, with $x_1+x_2=x$. For x_1, he solves the problem of § 8 (with utility U_1 from consumption); for x_2, he solves the problem of § 9 (with utility U_2 from terminal wealth). The superposition of his actions for these two problems will lead to the optimal policy for the problem of (10.2), provided x_1 and x_2 are chosen judiciously. We shall show exactly how this can be done (cf. (10.10) below).

For concreteness, we assume throughout this section that the value functions U_1, U_2 satisfy (7.2) and (7.3), as well as the requirements (8.8), (8.15) and (9.6), (9.11).

Let us start with an arbitrary pair $(\pi,x)\in\mathcal{A}_{1,2}(x)$ and define

$$x_1\triangleq\tilde{\mathbf{E}}\int_0^T\beta(t)c(t)\,dt, \qquad x_2\triangleq x-x_1. \tag{10.3}$$

Denoting by X the wealth process corresponding to this pair, we conclude from (4.3), (10.3) that

$$c\in\mathcal{D}(x_1), \qquad X(T)\in\mathcal{L}(x_2). \tag{10.4}$$

Theorem 8.1 gives us a pair $(\pi_1,c_1)\in\mathcal{A}_1(x_1)$ which is optimal for $V_1(x_1)$, with corresponding wealth process X_1 satisfying $X_1(T)=0$, almost surely. On the other hand, Theorem 9.1 provides a pair $(\pi_2,0)\in\mathcal{A}_2(x_2)$ which is optimal for $V_2(x_2)$, with corresponding wealth process X_2. If we define now

$$\tilde{\pi}\triangleq\pi_1+\pi_2, \quad \tilde{c}\triangleq c_1, \quad \text{and} \quad \tilde{X}\triangleq X_1+X_2 \tag{10.5}$$

and add (8.10), (9.8) memberwise, we obtain

$$\begin{aligned} \beta(t)\tilde{X}(t) &= \tilde{\mathbf{E}}\left[\int_t^T\beta(s)\tilde{c}(s)\,ds+\beta(T)\tilde{X}(T)\,\middle|\,\mathcal{F}_t\right] \\ &= x-\int_0^t\beta(s)\tilde{c}(s)\,ds+\int_0^t\beta(s)(\tilde{\pi}(s))^*\sigma(s)\,d\tilde{W}(s). \end{aligned} \tag{10.6}$$

In other words, $\tilde{X}$ *is the wealth process corresponding to the pair* $(\tilde{\pi},\tilde{c})\in\mathcal{A}_{1,2}(x)$.

But now recall (10.4), and add up (8.12), (9.10) memberwise to obtain

$$J(x;\pi,c)\leqq V_1(x_1)+V_2(x_2),$$

whence

$$V(x)\leqq V_*(x)\triangleq \max_{\substack{x_1\geqq 0,x_2\geqq 0\\ x_1+x_2=x}}[V_1(x_1)+V_2(x_2)]. \tag{10.7}$$

Therefore, the question is to find x_1, x_2 for which this maximum is achieved, because then the total expected utility corresponding to the pair $(\hat{\pi},\hat{c})$ of (10.5) will be *exactly* equal to $V_*(x)$; this will in turn imply

$$V(x)\equiv V_*(x) \tag{10.8}$$

from (10.7), and thus the above-mentioned pair will be shown to be *optimal* for the problem of (10.2).

But the maximization in (10.7) is easy: it amounts to selecting x_1, x_2 so that $V_1'(x_1)=V_2'(x_2)$ or, thanks to (8.17), (9.14): $\mathcal{Y}_1(x_1)=\mathcal{Y}_2(x_2)=\lambda\Leftrightarrow x_1=\mathcal{X}_1(\lambda), x_2=\mathcal{X}_2(\lambda)$. In other words, we find those values of x_1, x_2 for which the "marginal expected utilities" $V_1'(x_1)$, $V_2'(x_2)$ from the two individual optimization problems are identical.

The constant λ is determined uniquely as follows: we introduce the function

$$\mathcal{X}(y)\triangleq \mathcal{X}_1(y)+\mathcal{X}_2(y)=\mathbf{E}\left[\int_0^T \zeta(t)I_1(t,y\zeta(t))\,dt+\zeta(T)I_2(T,y\zeta(T))\right] \tag{10.9}$$

on $(0,\infty)$, which is continuous and strictly decreasing with $\mathcal{X}(0+)=\infty$, $\mathcal{X}(\infty)=0$. Let $\mathcal{Y}=\mathcal{X}^{-1}$ be the inverse of $\mathcal{X}$; then $\lambda=\mathcal{Y}(x)$, and the "optimal partition" of the initial wealth is given by

$$x_1=\mathcal{X}_1(\mathcal{Y}(x)),\qquad x_2=\mathcal{X}_2(\mathcal{Y}(x)). \tag{10.10}$$

If we also introduce the function

$$\begin{aligned} G(y)&\triangleq G_1(y)+G_2(y)\\ &=\mathbf{E}\left[\int_0^T U_1(t,I_1(t,y\zeta(t)))\,dt+U_2(T,I_2(T,y\zeta(T)))\right], \end{aligned} \tag{10.11}$$

which is continuous and decreasing on $(0,\infty)$, it is easy to see from (8.16), (9.12) that

$$V_*(x)=G(\mathcal{Y}(x)). \tag{10.12}$$

We have established the following result.

THEOREM 10.1. *Under the conditions of this section, the value function V of* (10.2) *is given as*

$$V=G\circ\mathcal{Y}. \tag{10.13}$$

For a fixed initial capital $x>0$, the optimal consumption rate process and the optimal level of terminal wealth are given by

$$\hat{c}(t)=I_1(t,\mathcal{Y}(x)\zeta(t)),\quad 0\leqq t\leqq T,\quad \text{and}\quad \hat{X}(T)\triangleq I_2(T,\mathcal{Y}(x)\zeta(T)), \tag{10.14}$$

respectively; there exists a portfolio process $\hat{\pi}$ such that $(\hat{\pi},\hat{c})$ is optimal in $\mathcal{A}_{1,2}(x)$ for (10.2), *and the corresponding wealth process $\hat{X}$ is given by*

$$\hat{X}(t)=\frac{1}{\beta(t)}\tilde{\mathbf{E}}\left[\int_t^T \beta(s)I_1(s,\mathcal{Y}(x)\zeta(s))\,ds+\beta(T)I_2(T,\mathcal{Y}(x)\zeta(T))\,\middle|\,\mathcal{F}_t\right] \tag{10.15}$$

almost surely, for every $0\leqq t\leqq T$.

Notice that the process M of (3.6), corresponding to the pair $(\hat{\pi}, \hat{c})$ of Theorem 10.1, takes the form

$$\hat{M}(t) = \tilde{\mathbf{E}}\left[\int_0^T \beta(s) I_1(s, \mathcal{Y}(x)\zeta(s))\, ds + \beta(T) I_2(T, \mathcal{Y}(x)\zeta(T)) \,\middle|\, \mathcal{F}_t\right];$$

in particular, it is a $\tilde{\mathbf{P}}$-martingale.

Example 10.2. In the case $U_1(t, c) = U_2(t, c) = \exp\{-\int_0^t \mu(s)\, ds\} \log c$, the functions of (10.9), (10.11), and (10.13) are given by

$$\mathcal{X}(y) = \frac{\alpha}{y}, \quad G(y) = -\alpha \cdot \log y + \delta, \quad 0 < y < \infty, \quad \text{and}$$

$$V(x) = \alpha \cdot \log\left(\frac{x}{\alpha}\right) + \delta, \qquad 0 < x < \infty$$

where $\alpha = \alpha_1 + \alpha_2$, $\delta = \delta + \delta_2$ in the notation of (8.19) and (9.16).

Example 10.3. In the case $U_1(t, c) = U_2(t, c) = -\exp\{-\int_0^t \mu(s)\, ds\}/c$, we obtain

$$\mathcal{X}(y) = \alpha y^{-1/2}, \quad G(y) = -\alpha y^{1/2}, \quad 0 < y < \infty, \quad \text{and}$$

$$V(x) = -\frac{\alpha^2}{x}, \qquad 0 < x < \infty$$

where $\alpha = \alpha_1 + \alpha_2$ in the notation of (8.21) and (9.21).

11. The case of constant coefficients. The theory developed in the last three sections, culminating with Theorem 10.1, provides a very precise characterization of the value function for the optimization problem (10.2) (cf. expression (10.13)), as well as explicit formulas for the optimal processes of consumption rate $\hat{c}$ and wealth $\hat{X}$ (in (10.14), (10.15), respectively). But for the optimal portfolio process $\hat{\pi}$, the "martingale methodology" that we have employed so far is able to ascertain only its existence (except in special cases, such as that of Example 9.3); in general, there is no constructive algorithm, or a useful characterization, that could lead to its computation.

Our intent in the present section is to improve this situation; we shall impose Draconian assumptions on the model, which will enable us in particular to obtain the optimal $\hat{\pi}$, $\hat{c}$ in a very explicit *feedback form on the current level of wealth* (cf. (11.23), (11.24)).

Specifically, we shall assume throughout this section that

$$r(t) \equiv r, \quad b(t) \equiv b, \quad \sigma(t) \equiv \sigma \quad \forall t \in [0, T] \tag{11.1}$$

for given $r \in \mathcal{R}$, $b \in \mathcal{R}^d$, and σ a nonsingular $(d \times d)$ matrix. We shall also assume separable utility functions, of the form $U_i(t, c) = e^{-\mu t} U_i(c)$, for $i = 1, 2$ and some real number $\mu \neq 0$. These assumptions will allow us to use "Markovian" methods, such as the Feynman-Kac representation of solutions to partial differential equations and the Hamilton-Jacobi-Bellman (HJB) equation of dynamic programming.

In order to make these methodologies available to us, we shall need a temporal as well as spatial parametrization; to wit, we write the analogues of the wealth equation (3.3) and of the value function (10.2) on the horizon $[t, T]$, for arbitrary $0 \leqq t \leqq T$, as

$$\begin{aligned} X(s) = x &+ \int_t^s (rX(u) - c(u))\, du + \int_t^s \pi^*(u)(b - r\mathbf{1})\, du \\ &+ \int_t^s \pi^*(u)\sigma\, dW(u), \qquad t \leqq s \leqq T \end{aligned} \tag{11.2}$$

and

$$V(t,x)=\sup_{(\pi,c)\in\mathcal{A}(t,x)}\mathbf{E}\left[\int_t^T e^{-\mu s}U_1(c(s))\,ds+e^{-\mu T}U_2(X(T))\right], \tag{11.3}$$

respectively. We shall also impose the purely technical assumptions

$$U_i(0)>-\infty,\quad \lim_{c\downarrow 0}\frac{(U_i'(c))^2}{U_i''(c)}\text{ exists},\quad \lim_{c\to\infty}\frac{(U_i'(c))^\alpha}{U_i''(c)}=0,\quad i=1,2 \tag{11.4}$$

for some $\alpha>2$. They will permit the analysis to go through conveniently, and include as special cases the so-called HARA (for Hyperbolic Absolute Risk Aversion) utility functions of the type $U(c)=(c+\eta)^\delta$; $0<\delta<1$, $\eta\geqq 0$. However, they are far from being the weakest possible conditions under which the fundamental results will hold.

By analogy with our previous analysis and notation, let us introduce the vector $\theta=\sigma^{-1}(b-r\mathbf{1})\in\mathcal{R}^d$, the processes

$$Z_s^{(t)}\triangleq\exp\{-\theta^*(W_s-W_t)-\tfrac{1}{2}\|\theta\|^2(s-t)\},\quad \phi_s^{(t)}\triangleq e^{(\mu-r)(s-t)}Z_s^{(t)},\quad\text{and}$$
$$Y_s^{(t,y)}\triangleq y\phi_s^{(t)},\qquad t\leqq s\leqq T,\quad 0<y<\infty,$$

as well as the functions $I_i=(U_i')^{-1}$, $i=1,2$ and

$$G(t,y)\triangleq\mathbf{E}\left[\int_t^T e^{-\mu(s-t)}U_1(I_1(Y_s^{(t,y)}))\,ds+e^{-\mu(T-t)}U_2(I_2(Y_T^{(t,y)}))\right], \tag{11.5}$$

$$\mathcal{X}(t,y)\triangleq\mathbf{E}\left[\int_t^T e^{-\mu(s-t)}\phi_s^{(t)}I_1(y\phi_s^{(t)})\,ds+e^{-\mu(T-t)}\phi_T^{(t)}I_2(y\phi_T^{(t)})\right], \tag{11.6}$$

$$S(t,y)\triangleq y\mathcal{X}(t,y)=\mathbf{E}\left[\int_t^T e^{-\mu(s-t)}Y_s^{(t,y)}I_1(Y_s^{(t,y)})\,ds+e^{-\mu(T-t)}Y_T^{(t,y)}I_2(Y_T^{(t,y)})\right] \tag{11.7}$$

for $(t,y)\in[0,T]\times(0,\infty)$. To avoid trivialities, we suppose $\theta\neq\mathbf{0}$; then for every $t\in[0,T)$ the function $\mathcal{X}(t,\cdot)$ is continuous and strictly decreasing on $(0,\infty)$, with $\mathcal{X}(t,0+)=\infty$ and $\mathcal{X}(t,\infty)=0$. We denote its inverse by $\mathcal{Y}(t,\cdot)$, i.e.,

$$\mathcal{Y}(t,\mathcal{X}(t,y))=y,\qquad 0\leqq t<T,\quad 0\leqq y\leqq\infty$$

and by analogy with the characterization (10.13) of Theorem 10.1 we have

$$V(t,x)=e^{-\mu t}G(t,\mathcal{Y}(t,x)),\qquad (t,x)\in[0,T]\times(0,\infty). \tag{11.8}$$

The point here is that we have reduced the study of the control problem (11.3) (or equivalently, of the nonlinear HJB equation (11.19) below, which is associated with it) to the study of the functions G, S of (11.5), (11.7); because, once these two are known, then $\mathcal{X}(t,y)$ is obtained straightaway as $y^{-1}S(t,y)$ and the value function V becomes available from (11.8). Now from the Feynman–Kac theorem, the functions G and S are characterized uniquely in terms of the Cauchy problems

$$\left(\frac{\partial}{\partial t}+L\right)G(t,y)+U_1(I_1(y))=0,\qquad (t,y)\in[0,T)\times(0,\infty) \tag{11.9}$$

$$G(T,y)=U_2(I_2(y)),\qquad y\in(0,\infty) \tag{11.10}$$

and

$$\left(\frac{\partial}{\partial t}+L\right)S(t,y)+yI_1(y)=0,\qquad (t,y)\in[0,T)\times(0,\infty) \tag{11.11}$$

$$S(T,y)=yI_2(y),\qquad y\in(0,\infty), \tag{11.12}$$

respectively, for the *linear* differential operator

$$L\varphi(t,y) \triangleq \frac{1}{2}\|\theta\|^2 y^2 \frac{\partial^2 \varphi(t,y)}{\partial y^2} + (\mu - r) y \frac{\partial \varphi(t,y)}{\partial y} - \mu \varphi(t,y).$$

Indeed, using the conditions (11.4) it can be shown that G, S satisfy growth conditions of the type

$$\max_{0 \leqq t \leqq T} |u(t,y)| \leqq K(1 + y^{\alpha} + y^{-\alpha}), \qquad 0 < y < \infty \tag{11.13}$$

for some positive constants α, K, and that among such functions they are the unique solutions of their respective Cauchy problems. *We shall show how to compute these solutions in closed form* (Proposition 11.1).

To this end, let us recall Remark 5.7 and observe that the unique solution to the auxiliary Cauchy problem

$$\left(\frac{\partial}{\partial t} + L\right) v(t,y;\xi) = 0, \qquad (t,y) \in [0,T) \times (0,\infty)$$

$$v(T,y;\xi) = (\xi - y)^+, \qquad y \in (0,\infty)$$

is given by the Black and Scholes-type formula for a "put" option (the right to *sell* one share of the stock at the pre-assigned price $\xi > 0$):

(11.14)

$$v(t,y;\xi) = \mathbf{E}[e^{-\mu(T-t)}(\xi - Y_T^{(t,y)})^+]$$

$$= \begin{cases} \xi e^{-\mu(T-t)} \Phi(-\nu_-(T-t,y;\xi)) - y e^{-r(T-t)} \Phi(-\nu_+(T-t,y;\xi)); & 0 \leqq t < T \\ (\xi - y)^+; & t = T \end{cases}$$

for every $(y,\xi) \in (0,\infty)^2$, where $\nu_{\pm}(t,y;\xi) \triangleq (1/\sqrt{2\gamma t})[\log(y/\xi) + t(\mu - r \pm \gamma)]$ and $\gamma \triangleq \|\theta\|^2/2$. Let us also introduce the functions

$$g(y) \triangleq \frac{U_1(I_1(y))}{\mu} - \frac{1}{\gamma(\lambda_+ - \lambda_-)} \left\{ \frac{y^{1+\lambda_+}}{1+\lambda_+} J_+(y) - \frac{y^{1+\lambda_-}}{1+\lambda_-} J_-(y) \right\}, \tag{11.15}$$

$$s(y) \triangleq \frac{y I_1(y)}{r} - \frac{1}{\gamma(\lambda_+ - \lambda_-)} \left\{ \frac{y^{1+\lambda_+}}{\lambda_+} J_+(y) - \frac{y^{1+\lambda_-}}{\lambda_-} J_-(y) \right\} \tag{11.16}$$

where $\lambda_+ > 0$ and $\lambda_- < 0$ are the roots of the quadratic equation $\gamma\lambda^2 - (r - \mu - \gamma)\lambda - r = 0$ and

$$J_+(y) = \int_0^{I_1(y)} (U_1'(c))^{-\lambda_+} \, dc, \qquad J_-(y) = \int_1^{I_1(y)} (U_1'(c))^{-\lambda_-} \, dc.$$

It is easy to verify that g, s solve the ordinary differential equations

$$Lg(y) + U_1(I_1(y)) = 0 \quad \text{and} \quad Ls(y) + y I_1(y) = 0,$$

respectively.

We can now put the various results together to arrive at the promised closed-form solutions.

PROPOSITION 11.1. *The functions G, S of* (11.5), (11.7) *have the stochastic representations*

$$G(t,y) = g(y) + \mathbf{E}[e^{-\mu(T-t)}\{U_2(I_2(Y_T^{(t,y)})) - g(Y_T^{(t,y)})\}],$$
$$S(t,y) = s(y) + \mathbf{E}[e^{-\mu(T-t)}\{Y_T^{(t,y)} I_2(Y_T^{(t,y)}) - s(Y_T^{(t,y)})\}],$$

which lead to the closed-form expressions

$$G(t,y) = g(y) + \left(U_2(0) - \frac{U_1(0)}{\mu}\right) e^{-\mu(T-t)} + \int_0^\infty (U_2(I_2(\xi)) - g(\xi))'' v(t,y;\xi)\, d\xi, \tag{11.17}$$

$$S(t,y) = s(y) + \int_0^\infty (\xi I_2(\xi) - s(\xi))'' v(t,y;\xi)\, d\xi. \tag{11.18}$$

Moreover, the function $V:[0,T]\times[0,\infty)\to\mathcal{R}$ *of* (11.8) *satisfies the* HJB *Equation of Dynamic Programming*

$$\max_{\substack{c\geqq 0\\ \pi\in\mathcal{R}^d}} [\tfrac{1}{2}\|\pi^*\sigma\|^2 V_{xx}(t,x) + \{(rx-c) + \pi^*(b-r\mathbf{1})\} V_x(t,x) + e^{-\mu t} U_1(c)] = -V_t(t,x) \quad \text{in } [0,T)\times(0,\infty) \tag{11.19}$$

and the terminal-boundary conditions

$$V(T,x) = e^{-\mu T} U_2(x), \qquad 0 \leqq x < \infty, \tag{11.20}$$

$$V(t,0) = \left(U_2(0) - \frac{U_1(0)}{\mu}\right) e^{-\mu T} + \frac{U_1(0)}{\mu} e^{-\mu t}, \qquad 0 \leqq t \leqq T, \tag{11.21}$$

respectively.

It is noteworthy that we have obtained a closed-form solution for the *nonlinear* HJB equation (11.19), by solving instead the two *linear* equations (11.9), (11.11) subject to the appropriate terminal and growth conditions, and then performing the composition (11.8).

The maximizations over $c\geqq 0$, $\pi\in\mathcal{R}^d$ in (11.19) are achieved by

$$\hat{c} = I_1(\mathcal{Y}(t,x)), \qquad \hat{\pi} = -(\sigma\sigma^*)^{-1}(b-r\mathbf{1})\frac{\mathcal{Y}(t,x)}{\mathcal{Y}_x(t,x)}.$$

This suggests that we should be able to justify similar *feedback form expressions* (on the current level of wealth) *for the optimal consumption rate and portfolio processes.* We choose to do this by studying directly the optimal wealth process.

PROPOSITION 11.2. *The optimal wealth process* $X^{(t,x)}$ *for the problem* (11.3) *is given by*

$$X^{(t,x)}(s) = \mathcal{X}(s, \eta_s^{(t,x)}), \qquad t \leqq s \leqq T, \tag{11.22}$$

where $\eta_s^{(t,x)} \triangleq \mathcal{Y}(t,x)\phi_s^{(t)} = Y_s^{(t,\mathcal{Y}(t,x))}$. *In terms of* $X^{(t,x)}$, *the optimal pair* $(\pi^{(t,x)}, c^{(t,x)})$ *can be expressed as*

$$c^{(t,x)}(s) = I_1(\mathcal{Y}(s, X^{(t,x)}(s))), \tag{11.23}$$

$$\pi^{(t,x)}(s) = -(\sigma\sigma^*)^{-1}(b-r\mathbf{1})\frac{\mathcal{Y}(s, X^{(t,x)}(s))}{\mathcal{Y}_x(s, X^{(t,x)}(s))} \tag{11.24}$$

for $t \leqq s \leqq T$.

Proof. By analogy with (10.15), the optimal wealth process is almost surely given by

$$X^{(t,x)}(s) = \mathbf{E}\left[\int_s^T e^{-r(\theta-s)} Z_\theta^{(s)} I_1(\eta_\theta^{(t,x)})\, d\theta + e^{-r(T-s)} Z_T^{(s)} I_2(\eta_T^{(t,x)}) \,\middle|\, \mathcal{F}_s\right]$$

$$= \frac{1}{Y_s^{(t,y)}} \mathbf{E}\left[\int_s^T e^{-\mu(\theta-s)} Y_\theta^{(t,y)} I_1(Y_\theta^{(t,y)})\, d\theta + e^{-\mu(T-t)} Y_T^{(t,y)} I_2(Y_T^{(t,y)}) \,\middle|\, \mathcal{F}_s\right]$$

$$= \frac{S(s, Y_s^{(t,y)})}{Y_s^{(t,y)}}$$

with $y = \mathcal{Y}(t, x)$, for every $s \in [t, T]$; but this is (11.22). Now it is easily seen from (3.10) that $\eta^{(t,x)}$ satisfies the linear stochastic equation

$$d\eta_s^{(t,x)} = \eta_s^{(t,x)}[(\mu - r)\, ds - \theta^*\, dW(s)], \qquad \eta_t^{(t,x)} = x. \tag{11.25}$$

On the other hand, by substituting $S(t, y) = y\mathcal{X}(t, y)$ into (11.11), we arrive at the linear parabolic equation

$$\mathcal{X}_t + \gamma y^2 \mathcal{X}_{yy} + (\mu - r + 2\gamma) y \mathcal{X}_y - r\mathcal{X} + I_1(y) = 0, \qquad 0 \leqq t < T, \quad 0 < y < \infty \tag{11.26}$$

for $\mathcal{X}(t, y)$. An application of Itô's rule to (11.22), in conjunction with (11.25) and (11.26), leads to

$$dX^{(t,x)}(s) = (rX^{(t,x)}(s) - c^{(t,x)}(s))\, ds + (\pi^{(t,x)}(s))^*[(b - r\mathbf{1})\, ds + \sigma\, dW(s)]$$

in the notation of (11.23), (11.24). But a comparison of this equation with (3.3) shows that $X^{(t,x)}$ is the wealth associated with the pair $(\pi^{(t,x)}, c^{(t,x)})$. □

Example 11.3. In the special case $U_1(c) = U_2(c) = c^\delta$ for some $0 < \delta < 1$, we have

$$G(t, y) = p(t)\left(\frac{y}{\delta}\right)^{\delta/(\delta-1)}, \quad S(t, y) = \delta G(t, y), \quad \mathcal{X}(t, y) = p(t)\left(\frac{y}{\delta}\right)^{1/(\delta-1)}$$

and

$$V(t, x) = e^{-\mu t}(p(t))^{1-\delta} x^\delta,$$

as well as

$$c^{(t,x)}(s) = \frac{X^{(t,x)}(s)}{p(s)}, \quad \pi^{(t,x)}(s) = (\sigma\sigma^*)^{-1}(b - r\mathbf{1})\frac{X^{(t,x)}(s)}{1-\delta}, \quad t \leqq s \leqq T,$$

where

$$p(t) = \begin{cases} (1/k)[1 - e^{-k(T-t)}] + e^{-k(T-t)}; & k \neq 0 \\ 1 + T - t & k = 0 \end{cases},$$

$$k = \frac{1}{1-\delta}\left(\mu - r\delta - \frac{\gamma\delta}{1-\delta}\right).$$

12. An equilibrium model. Let us consider in this final section an *economy* that consists of the following:

(i) The same financial market as in § 2;

(ii) A single consumption good or "commodity," traded at the spot price $\psi = \{\psi(t);\ 0 \leqq t \leqq T\}$; and

(iii) A finite number n of economic agents (small investors). Each one receives an exogenous *endowment* at the rate $\varepsilon_k = \{\varepsilon_k(t);\ 0 \leqq t \leqq T\}$, denominated in units of the commodity; he can either consume this endowment or turn it into cash, and invest the proceeds in the financial market. Each agent also has a *utility function* U_k, and attempts to maximize his expected total utility from consumption (as in § 8).

The *equilibrium problem* for such an economy is to determine a spot price ψ, so that the markets clear when each agent behaves optimally and the commodity is traded at the price ψ. We shall show that the methodology of § 8 is ideally suited to handle this question.

We shall assume throughout this section that the processes ψ and $\varepsilon_1, \cdots, \varepsilon_n$ are positive and progressively measurable with respect to $\{\mathcal{F}_t\}$. On the other hand, both the "deflated spot price" $\zeta(t)\psi(t)$ and the "aggregate endowment rate"

$$\varepsilon(t) = \sum_{k=1}^{n} \varepsilon_k(t), \qquad 0 \leqq t \leqq T \tag{12.1}$$

processes, will be assumed to take values in intervals of the form $[\delta, \Delta]$, for finite constants $\Delta > \delta > 0$.

For a given spot price process ψ, the kth agent has at his disposal the choice of a portfolio process $\pi_k(t) = (\pi_{k1}(t), \cdots, \pi_{kd}(t))^*$ and a consumption rate process $c_k(t)$, $0 \leqq t \leqq T$, as in Definitions 3.1 and 3.2 (except that (3.2) is now replaced by $\int_0^T \psi(t)c_k(t)\,dt < \infty$, almost surely). For every such pair (π_k, c_k), the corresponding *wealth process* X_k satisfies, by analogy with (3.3), the equation

$$\begin{aligned} dX_k(t) = r(t)X_k(t)\,dt + \psi(t)[\varepsilon_k(t) - c_k(t)]\,dt + \pi_k^*(t)[b(t) - r(t)\mathbf{1}]\,dt \\ + \pi_k^*(t)\sigma(t)\,dW(t). \end{aligned}$$

In terms of the $\tilde{\mathbf{P}}$-Brownian motion $\tilde{W}$ of (2.9), the solution is given by

$$\beta(t)X_k(t) = \int_0^t \beta(s)\psi(s)[\varepsilon_k(s) - c_k(s)]\,ds + \int_0^t \beta(s)\pi_k^*(s)\sigma(s)\,d\tilde{W}(s). \tag{12.2}$$

The kth agent's *optimization problem* is to maximize the expected total utility

$$\mathbf{E}\int_0^T U_k(t, c_k(t))\,dt \tag{12.3}$$

from consumption, over all admissible pairs (π_k, c_k)—as in Definition 4.1—that satisfy

$$\mathbf{E}\int_0^T U_k^-(t, c_k(t))\,dt < \infty. \tag{12.4}$$

Let us denote by $(\hat{\pi}_k, \hat{c}_k)$ the optimal pair for this problem, and by $\hat{X}_k$ the associated wealth process.

We are now in a position to define the notion of equilibrium for the economy.

DEFINITION 12.1. A spot price process ψ is called an *equilibrium spot price process*, if we have the following:

(a) Clearing of the commodity market, i.e.,

$$\sum_{k=1}^{n} \hat{c}_k(t) = \varepsilon(t), \qquad \forall\, 0 \leqq t \leqq T, \qquad \text{and} \tag{12.5}$$

(b) Clearing of the financial markets, i.e.,

$$\sum_{k=1}^{n} \hat{\pi}_{ki}(t) = 0, \quad \lambda \times \mathbf{P}\text{-a.e. on } [0, T] \times \Omega, \qquad \forall\, i = 1, \cdots, d \tag{12.6}$$

$$\sum_{k=1}^{n} \hat{X}_k(t) = 0, \qquad \forall\, 0 \leqq t \leqq T \tag{12.7}$$

almost surely.

For a given ψ, let us try to solve the kth agent's optimization problem. First, here is an analogue of Theorem 4.4 and Proposition 4.5.

THEOREM 12.2. *Every admissible pair (π_k, c_k) for the kth agent satisfies*

$$\mathbf{E}\int_0^T \zeta(t)\psi(t)c_k(t)\,dt \leqq \mathbf{E}\int_0^T \zeta(t)\psi(t)\varepsilon_k(t)\,dt. \tag{12.8}$$

Conversely, if a consumption rate process c_k satisfies (12.8), *there exists a portfolio π_k such that the pair (π_k, c_k) is admissible for the kth agent. In particular, if* (12.8) *is satisfied as an equality, then the portfolio π_k is unique up to equivalence and the corresponding wealth process X_k is given by*

$$\beta(t)X_k(t) = \tilde{\mathbf{E}}\left[\int_t^T \beta(s)(c_k(s)-\varepsilon_k(s))\,ds \,\middle|\, \mathcal{F}_t\right], \qquad 0 \leqq t \leqq T. \tag{12.9}$$

Proof. For every portfolio/consumption process pair (π_k, c_k), the analogues

$$M_k(t) = \beta(t)X_k(t) + \int_0^t \beta(s)\psi(s)[c_k(s)-\varepsilon_k(s)]\,ds, \tag{12.10}$$

$$N_k(t) = \zeta(t)X_k(t) + \int_0^t \zeta(s)\psi(s)[c_k(s)-\varepsilon_k(s)]\,ds \tag{12.11}$$

of the processes in (3.6), (3.9) are continuous, local martingales under $\tilde{\mathbf{P}}$ and $\mathbf{P}$, respectively. Now if the pair (π_k, c_k) is admissible, N_k is bounded from below by a $\mathbf{P}$-integrable random variable, and is thus a $\mathbf{P}$-supermartingale (which implies that M_k is a $\tilde{\mathbf{P}}$-supermartingale); (12.8) follows from this property, in conjunction with $X_k(T) \geqq 0$, almost surely.

Conversely, for every consumption rate process c_k that satisfies (12.8), we introduce the random variable

$$D_k = \int_0^T \beta(s)\psi(s)[\varepsilon_k(s)-c_k(s)]\,ds; \tag{12.12}$$

the condition (12.8) amounts to $\tilde{\mathbf{E}}D_k \geqq 0$, and the martingale

$$u_k(t) \triangleq \tilde{\mathbf{E}}D_k - \tilde{\mathbf{E}}(D_k|\mathcal{F}_t), \qquad 0 \leqq t \leqq T \tag{12.13}$$

is representable as in (4.9):

$$u_k(t) = \int_0^t \beta(s)\pi_k^*(s)\sigma(s)\,d\tilde{W}(s), \tag{12.14}$$

for a suitable portfolio process π_k. From (12.2) and (3.8), the wealth process X_k corresponding to (π_k, c_k) is given as

$$\begin{aligned} X_k(t) &= \frac{1}{\beta(t)}\left[\int_0^t \beta(s)\psi(s)\{\varepsilon_k(s)-c_k(s)\}\,ds + u_k(t)\right] \\ &= \frac{1}{\zeta(t)}\left[Z(t)\tilde{\mathbf{E}}D_k - \mathbf{E}\left(\int_t^T \zeta(s)\psi(s)\{\varepsilon_k(s)-c_k(s)\}\,ds \,\middle|\, \mathcal{F}_t\right)\right], \end{aligned} \tag{12.15}$$

almost surely. Both requirements of (4.1) for admissibility follow easily from this last representation.

The remaining claims follow as in the proof of Proposition 4.5. □

According to Theorem 12.2, the kth agent's optimization problem is reformulated as follows: *to maximize* $\mathbf{E}\int_0^T U_k(t, c_k(t))\,dt$, *over consumption rate processes c_k that*

satisfy (12.8) *and* (12.4). But the solution to this problem is known from § 8: the optimal consumption rate process is of the form

$$\hat{c}_k(t) = I_k(t, y_k\zeta(t)\psi(t)), \qquad 0 \leqq t \leqq T, \quad k \in \{1, \cdots, n\} \tag{12.16}$$

where y_k is the unique number in $(0, \infty)$ that satisfies

$$\mathbf{E}\int_0^T \zeta(t)\psi(t)I_k(t, y_k\zeta(t)\psi(t))\,dt = \mathbf{E}\int_0^T \zeta(t)\psi(t)\varepsilon_k(t)\,dt, \qquad k = 1, \cdots, n. \tag{12.17}$$

In particular, $\hat{c}_k$ satisfies (12.8) as an equality.

The outstanding question now is whether we can find a spot price process ψ for which (12.5)–(12.7) are satisfied.

PROPOSITION 12.3. *Let ψ be an equilibrium spot price process, and let the vector $Y = (y_1, \cdots, y_n) \in (0, \infty)^n$ be defined in terms of ψ by* (12.17). *Then ψ and Y must satisfy*

$$\sum_{k=1}^{n} I_k(t, y_k\zeta(t)\psi(t)) = \varepsilon(t), \qquad 0 \leqq t \leqq T. \tag{12.18}$$

Conversely, suppose that $Y \in (0, \infty)^n$ and the spot price process ψ are such that (12.17), (12.18) *are satisfied; then ψ is an equilibrium spot price process.*

Proof. The first claim follows directly, by substituting the expressions (12.16) into (12.5). For the second claim notice that, under the spot price ψ in question, the optimal consumption processes $\{\hat{c}_k\}_{k=1}^n$ are still given by (12.16) and satisfy (12.5); letting $\hat{D}_k$, $\hat{u}_k$ and $\hat{\pi}_k$, $\hat{X}_k$ be the corresponding quantities in (12.12), (12.13), and (12.14), (12.9), respectively, we obtain with the help of (12.5), (12.1): $\sum_{k=1}^n \hat{X}_k(t) \equiv 0, \sum_{k=1}^n \hat{D}_k = 0$, and $\sum_{k=1}^n \hat{u}_k(t) \equiv 0$, almost surely. From this last identity and (12.14), we conclude that (12.6) holds. □

A further reduction in the characterization of equilibrium is obtained by introducing the function

$$I(t, h; \Lambda) \triangleq \sum_{k=1}^{n} I_k(t, h\lambda_k^{-1}), \qquad (t, h) \in [0, T] \times (0, \infty) \tag{12.19}$$

for every $\Lambda = (\lambda_1, \cdots, \lambda_n) \in (0, \infty)^n$, and denoting by $H(t, \cdot\,; \Lambda)$ the inverse of the strictly decreasing mapping $I(t, \cdot\,; \Lambda)\colon [0, \infty] \xrightarrow{\text{onto}} [0, \infty]$, with fixed $t \in [0, T]$ and $\Lambda \in (0, \infty)^n$. The function H enjoys the *positive homogeneity property*

$$H(t, c; \rho\Lambda) = \rho H(t, c; \Lambda), \quad \forall \rho > 0 \tag{12.20}$$

and in terms of H the equations (12.18), (12.17) are rewritten as

$$\psi(t) \equiv \psi(t; \Lambda) = \frac{1}{\zeta(t)} H(t, \varepsilon(t); \Lambda), \qquad 0 \leqq t \leqq T, \tag{12.21}$$

$$\begin{aligned} &\mathbf{E}\int_0^T H(t, \varepsilon(t); \Lambda) I_k\left(t, \frac{1}{\lambda_k} H(t, \varepsilon(t); \Lambda)\right) dt \\ &\qquad = \mathbf{E}\int_0^T H(t, \varepsilon(t); \Lambda)\varepsilon_k(t)\,dt, \qquad k = 1, \cdots, n, \end{aligned} \tag{12.22}$$

respectively, with the identification $\Lambda = (\lambda_1, \cdots, \lambda_n) = (1/y_1, \cdots, 1/y_n) \in (0, \infty)^n$.

We conclude from this analysis that *the search for equilibrium has been reduced to the search for a vector $\Lambda \in (0, \infty)^n$ which satisfies* (12.22); the corresponding equilibrium

spot price and optimal consumption rate processes would then be given by (12.21) and

$$\hat{c}_k(t) \equiv \hat{c}_k(t;\Lambda) = I_k\left(t, \frac{1}{\lambda_k} H(t, \varepsilon(t);\Lambda)\right), \qquad 0 \leqq t \leqq T, \quad k = 1, \cdots, n, \tag{12.23}$$

respectively (cf. (12.16)).

Now it is seen from (12.20), (12.22) that if $\Lambda \in (0,\infty)^n$ is a solution of (12.22), then the entire ray $\{\rho\Lambda;\ \rho \in (0,\infty)\}$ is a family of solutions. The following result provides a sufficient condition, under which there is only one such ray.

THEOREM 12.4. *Suppose that, for every* $(t,k) \in [0,T] \times \{1, \cdots, n\}$,

$$c \mapsto cU_k'(t,c) \quad \textit{is a nondecreasing function.} \tag{12.24}$$

Then there exists a vector $\Lambda \in (0,\infty)^n$ *satisfying* (12.22); *if* Λ_1, Λ_2 *are two such vectors, then there exists a* $\gamma > 0$ *such that*

$$\Lambda_1 = \gamma\Lambda_2, \qquad \psi(\cdot;\Lambda_1) = \gamma\psi(\cdot;\Lambda_2) \tag{12.25}$$

$$\hat{c}_k(\cdot;\Lambda_1) = \hat{c}_k(\cdot;\Lambda_2), \qquad k = 1, \cdots, n. \tag{12.26}$$

In other words, equilibrium spot prices can be determined only up to a multiplicative constant, since there can always be a re-valuation of currency; this is not going to affect, however, the way in which *real* wealth, measured in units of optimal consumption for the commodity, will be distributed in equilibrium among the agents.

Example 12.5. Suppose that all the agents have the same utility function $U_k(t,c) = c^\delta \exp\{-\int_0^t \mu(s)\,ds\}$, with $0 < \delta < 1$ and μ as in Example 8.3. Then

$$\lambda_k = \left(\frac{\mathbf{E}\int_0^T \exp\left(-\int_0^t \mu(s)\,ds\right)\varepsilon_k(t)(\varepsilon(t))^{\delta-1}\,dt}{\mathbf{E}\int_0^T \exp\left(-\int_0^t \mu(s)\,ds\right)(\varepsilon(t))^{\delta}\,dt}\right)^{1-\delta}, \qquad k = 1, \cdots, n \tag{12.27}$$

gives the unique solution of (12.22) subject to $\sum_{k=1}^n \lambda_k^{1/(1-\delta)} = 1$; the corresponding processes of (12.21), (12.23) are

$$\psi(t) = \frac{\text{const.} \exp\left(-\int_0^t \mu(s)\,ds\right)}{\zeta(t)(\varepsilon(t))^{1-\delta}}, \qquad \hat{c}_k(t) = \lambda_k^{1/(1-\delta)}\varepsilon(t). \tag{12.28}$$

Example 12.6. If $U_k(t,c) = \exp\{-\int_0^t \mu(s)\,ds\}\log c$, for every $k \in \{1, \cdots, n\}$, we obtain the same results as in (12.27), (12.28) but with $\delta = 0$.

Example 12.7. Suppose that $U_k(t,c) = -\exp\{-\int_0^t \mu(s)\,ds\}/c$ holds for every $k \in \{1, \cdots, n\}$. Then the unique solution of (12.22) subject to $\sum_{k=1}^n \lambda_k^{1/2} = 1$ is given by

$$\lambda_k = \left(\frac{\mathbf{E}\int_0^T \exp\left(-\int_0^t \mu(s)\,ds\right)(\varepsilon(t))^{-2}\varepsilon_k(t)\,dt}{\mathbf{E}\int_0^T \exp\left(-\int_0^t \mu(s)\,ds\right)(\varepsilon(t))^{-1}\,dt}\right)^2, \qquad k = 1, \cdots, n.$$

The equilibrium spot price and optimal consumption rate processes are then given as

$$\psi(t) = \frac{\text{const.} \exp\left(-\int_0^t \mu(s)\,ds\right)}{\zeta(t)(\varepsilon(t))^2}, \qquad \hat{c}_k(t) = \lambda_k^{1/2}\varepsilon(t).$$

It should be noted that the condition (12.24) is satisfied by the utility functions of Examples 12.5 and 12.6, but not by that of Example 12.7 (in fact, in this latter example, the function $c \mapsto cU_k'(t,c)$ is strictly decreasing). Thus, the condition (12.24) is far from being necessary for the validity of the results of Theorem 12.4.

We send the interested reader to Karatzas, Lakner, Lehoczky, and Shreve (1988) for the proof of Theorem 12.4 and suggest the relaxation (or removal) of condition (12.24) as an interesting open problem.

13. Notes.

Section 1. The theory of continuous trading is a specialized but important topic in financial economics; see the recent books by Ingersoll (1987) and Duffie (1988) for a broad and exhaustive overview of the theory of financial decision making. The book by Malliaris and Brock (1982) is a good survey of stochastic models in economics and finance; for the early work on this subject, see the articles in the volume edited by Cootner (1964), in particular the papers "Brownian Motion in the Stock Market" and "Periodic Structure in the Brownian Motion of Stock Prices," by M. Osborne.

Sections 2, 3. The idea of introducing a probability measure, under which the discounted stock prices of (2.12) are martingales, is due to Harrison and Kreps (1979) and Harrison and Pliska (1981), (1983). The model that we have adopted, with the particular nondegeneracy condition (2.3), is due to Bensoussan (1984).

Condition (2.3) is essential in our development; by contrast, the boundedness of the process $r(\cdot)$, $b(\cdot)$ has been imposed only for simplicity. If we assume that these processes are just square-integrable almost surely on $[0, T]$, then the entire analysis on a finite horizon $[0, T]$ goes through with minor changes, provided that the process Z of (2.7)—always a supermartingale under the very weak almost sure condition $\int_0^T \|\theta(t)\|^2\, dt < \infty$—is actually a *martingale.* A sufficient condition for this, due to Novikov, is $E[\exp\{\frac{1}{2}\int_0^T \|\theta(t)\|^2\, dt\}] < \infty$ (cf. Karatzas and Shreve (1987, Prop. 3.5.12). We only have to replace the condition (5.1) by (5.2), and (6.3) by the requirement $\tilde{E}[\sup_{0\leq t\leq T} f(t)\beta(t)] < \infty$.

For results with "incomplete market models" (i.e., with more sources of uncertainty than stocks in the market model), see Föllmer and Sondermann (1986), Schweizer (1988), Pagès (1987), He and Pearson (1988), and Pagès (1989); consult also Karatzas, Lehoczky, Shreve, and Xu (1989).

Section 4. The material here is drawn from Karatzas and Shreve (1987, § 5.8) and Karatzas, Lehoczky, and Shreve (1987). The terminology "attainable levels of terminal wealth" is due to Pliska (1986), who has a result similar to Proposition 4.7.

The existence of an equivalent probability measure under which the discounted prices are martingales (an "equivalent martingale measure" as it is sometimes called), implies the absence of arbitrage opportunities (Remark 4.8). This property holds for very general price processes. The converse, i.e., the existence of an equivalent martingale measure in the absence of arbitrage opportunities, is known to hold in discrete time (cf. Taqqu and Willinger (1987) for finite probability spaces, and the very recent work by Dalang, Morton, and Willinger (1988) for arbitrary probability spaces). As far as we know, the question is open for general, continuous-time price processes.

Section 5. We follow Karatzas and Shreve (1987). Example 5.6 is adapted from Harrison and Pliska (1981). For comprehensive accounts of option pricing, see Samuelson (1973), Merton (1973), Smith (1976), and Ingersoll (1987). For a model of option pricing, in which the borrowing rate is higher than the interest rate of the bond, see Barron and Jensen (1988).

Section 6. Section 6 is adapted from Karatzas (1988); see also Bensoussan (1984), for a different approach to the stopping problem. For more recent work, in general semimartingale models, see the doctoral dissertation of Schweizer (1988).

Section 7. The assumption $U'(t, 0+) = \infty$ is made only for simplicity; for full treatments of the *consumption/investment* and *equilibrium* problems that do not rely on this assumption, see Karatzas, Lehoczky, and Shreve (1987) and (1988), respectively.

Sections 8–11. Sections 8–11 come essentially from Karatzas, Lehoczky, and Shreve (1987) (with the exception of §§ 9.3, 9.4, 9.6); that article should be consulted for some details which are only sketched here. The model with constant coefficients and utility from consumption was introduced by Samuelson (1969) and Merton (1969), (1971) for utility functions of the HARA class; it was studied in great detail by Karatzas et al. (1986) for general utility functions, using the HJB equation of dynamic programming and allowing for general patterns of behaviour upon *bankruptcy.*

Related results have been obtained independently by Cox and Huang (1986), (1987). For models with *constraints* (on borrowing, short-selling, etc.) see the recent works by Xu (1989), Zariphopoulou (1989), Grossman and Vila (1988), He and Pearson (1988).

Recent work by Davis and Norman (1988) treats a model with constant coefficients, one stock, and utility $U(t, c) = e^{-\mu t} c^{\delta}$, $0 < \delta < 1$ from consumption, but with *costs of transaction* between the two assets (see also Taksar et al. (1988), Eastham and Hastings (1988), Leland (1985)). On the other hand, Pontier and Picqué (1988) discuss the consumption/investment problem in a market model with $d = 2$, and stock prices driven by independent Brownian and Poisson processes. For a model with consumption in several goods with quite arbitrary prices, see Lakner (1989).

For maximization of the growth rate from investment, in discrete-time settings, see the articles by Cover (1984), (1988), and Algoet and Cover (1988), as well as Breiman (1961), Hakansson and Lin (1970), Hakansson (1971), Latané (1959), and Thorp (1971).

Much of the analysis in § 11 goes through if $r(\cdot), b(\cdot), \sigma(\cdot)$ are deterministic functions of time. We can also handle models in which the interest rate $r(\cdot)$ and the stock prices $\underset{\sim}{P}(t) = (P_1(t), \cdots, P_d(t))$ are quite general Markov diffusion processes driven by the Brownian motion W; the optimal portfolio/consumption policies can then be obtained in feedback form on the current level of the "extended state" $(X(t), r(t), \underset{\sim}{P}(t))$.

As the referee points out, the objective functions of (8.1), (10.1) mandate that utility at time t is derived from the level of consumption at that time only, for every $t \in (0, T)$; this excludes, for instance, situations like the "ratchet effect" (according to which the utility derived from consumption at one time is influenced by consumption levels at earlier times in such a way that a rise of consumption levels produces high utility but a decline produces low utility). A recent reference on such intertemporal dependence on preferences is Sundaresan (1985).

Section 12. Section 12 is taken from Karatzas et al. (1988). See also Duffie (1986), Duffie and Huang (1985), (1987), Duffie and Zame (1988) and Huang (1987) for related equilibrium models, as well as Cox, Ingersoll, and Ross (1985).

Acknowledgments. This paper is an expanded version of my notes entitled "Applications of Stochastic Calculus in Financial Economics," for lectures delivered at the Systems Research Center, University of Maryland, July 20–31, 1987. These notes are scheduled to appear in the series Lecture Notes in Control and Information Sciences, Springer-Verlag, Berlin, New York.

I wish to thank Professor Harold Kushner for the invitation to transform those lecture notes into a full-fledged survey paper, and to express my appreciation to the referees for their careful reading of the manuscript and for their helpful comments and suggestions. Thanks are also due to Professor Herbert Robbins, for bringing to my attention the articles of Algoet and Cover (1988) and Cover (1984), (1988), which prompted the investigation that led to the results of § 9.6.

I am indebted to Mr. X. X. Xue for ideas and arguments that led to the proof of uniqueness in Propositions 4.5 and 4.7, and to Dr. Walter Willinger for helpful discussions and for bringing the results of his work (Dalang, Morton, and Willinger (1988)) to my attention.

Dedication. This article is dedicated to Vic Beneš with affection and respect.

A SEQUENTIAL LINEAR PROGRAMMING ALGORITHM FOR SOLVING MONOTONE VARIATIONAL INEQUALITIES*

PATRICE MARCOTTE† AND JEAN-PIERRE DUSSAULT‡

Abstract. Applied to strongly monotone variational inequalities, Newton's algorithm achieves local quadratic convergence. In this paper it is shown how the basic Newton method can be modified to yield an algorithm whose global convergence can be guaranteed by monitoring the monotone decrease of the "gap function" associated with the variational inequality. Each iteration consists in the solution of a linear program in the space of primal-dual variables and of a linesearch. Convergence does not depend on strong monotonicity. However, under strong monotonicity and geometric stability assumptions, the set of active constraints at the solution is implicitly identified, and quadratic convergence is achieved.

Key words. mathematical programming, variational inequalities, nonlinear complementarity, Newton's method

AMS(MOS) subject classifications. 49D05, 49D10, 49D15, 49D35

0. Introduction. In this paper we consider the variational inequality problem defined on a convex compact polyhedron in R^n. Since this problem can be formulated as a fixed-point problem involving an upper semicontinuous mapping, it can be solved by simplicial or homotopy methods for which there already exists a vast literature (see Zangwill [16], Todd [14], Saigal [13]). For large-scale problems, however, these algorithms tend to become inefficient, both in terms of computer memory and running time requirements. This explains the renewed interest in algorithms closely related to procedures originally devised for iteratively solving systems of nonlinear equations (Ortega and Rheinboldt [10]) such as the Jacobi, Gauss–Seidel, and Newton schemes (see Pang and Chan [11], Josephy [5], Robinson [12]) or projection algorithms (Bertsekas and Gafni [2], Dafermos [4]) where the cost function is approximated, at each iteration, by a simpler, e.g., linear, separable, or symmetric function. Local or global convergence of the latter methods usually hinges on the a priori knowledge of lower bounds for the Lipschitz constant of the cost function, either in a neighborhood of a solution (for local convergence) or uniformly on the feasible domain (for global convergence). These conditions are difficult, while not impossible, to verify in practice.

Our approach is basically different. We choose as a merit function the complementary term (or *gap function*) associated with the primal-dual formulation of the variational inequality and find its global minimum by application of a first-order minimization algorithm. For monotone cost functions, we show that the algorithm converges globally to an equilibrium solution and possesses the finite termination property if the function is affine. Furthermore, under geometric stability and strong monotonicity assumptions, the algorithm implicitly identifies the set of constraints that are binding at the equilibrium solution, and convergence toward the equilibrium solution is quadratic. Numerical results comparing this method to Newton's method with and without linesearch (Marcotte and Dussault [9]) are provided.

1. Problem formulation. Notation and basic definitions. Let $\Phi = \{Bx \leqq b\}$, where B is an $m \times n$ matrix $(m > n)$, represent a nonempty convex compact polyhedron in R^n and let F be a continuously differentiable function from Φ into R^n with Jacobian F'. The *variational inequality problem* (VIP) associated with F and Φ consists in finding some vector x^* in Φ, called an *equilibrium solution*, satisfying the variational inequality (VI):

$$(x^* - x)^t F(x^*) \leqq 0 \tag{1}$$

for all x in Φ. Since an equilibrium solution is a fixed point of the upper semicontinuous mapping defined by $x \to T(x) = \{\arg\max_{y \in \Phi} (x-y)^t F(x)\}$ it follows from Kakutani's Theorem [6] and the compactness of Φ that the set S of equilibria is nonempty.

If the Jacobian $F'(x)$ is symmetric for all x in Φ then the function $F(x)$ is the gradient of some function $f: \Phi \to R^n$, and (1) is the mathematical expression of the first-order necessary conditions corresponding to the optimization problem:

$$\min_{x \in \Phi} f(x) = \int_0^x F(t)\, dt \tag{2}$$

where the line integral is independent of the path of integration and therefore unambiguously defined.

In order that a feasible point x be an equilibrium, it is necessary and sufficient that x be optimal for the linear program

$$\min_{y \in \Phi} y^t F(x). \tag{3}$$

The optimality conditions for (3) are met by x if and only if we have

$$\begin{aligned} &\lambda \geqq 0, \quad F(x) + B^t \lambda = 0 \quad \text{dual feasibility,} \\ &\lambda^t (Bx - b) = 0 \quad \text{complementary slackness,} \\ &Bx \leqq b \quad \text{primal feasibility.} \end{aligned} \tag{4}$$

In the following, (4) will be referred to as the *complementary formulation* of VIP. If F' is symmetric, (4) corresponds to the Kuhn–Tucker necessary optimality conditions for the optimization problem (2). If the constraint set Φ is not polyhedral, a formulation similar to (4) can be obtained by imposing a suitable constraint qualification condition on the problem. The constraints $Bx \leqq b$ will be referred to as the *structural constraints* associated with the variational inequality problem, and the constraints $F(x) + B^t \lambda = 0$, $\lambda \geqq 0$ as the *nonstructural constraints.*

DEFINITION 1. The function F is

(i) *Monotone* on Φ if $(x-y)^t (F(x) - F(y)) \geqq 0$ for all x, y in Φ;

(ii) *Strictly monotone* on Φ if $(x-y)^t (F(x) - F(y)) > 0$ for all x, y in Φ $(x \neq y)$;

(iii) *Strongly monotone* on Φ if there exists a positive number κ such that

$$(x-y)^t (F(x) - F(y)) \geqq \kappa \|x - y\|^2 \quad \text{for all } x, y \text{ in } \Phi.$$

When F is the gradient of some differentiable function f, then the various concepts of monotonicity previously defined correspond, respectively, to convexity, strict convexity, and strong convexity of f on Φ. For differentiable functions, we also have the following characterization (see Auslender [1]):

(i) Monotonicity on Φ: $(x-y)^t F'(x-y) \geqq 0$ for all x, y in Φ;

(ii) Strong monotonicity on Φ: $(x-y)^t F'(x)(x-y) \geqq \kappa \|x-y\|^2$ for all x, y in Φ, for some positive number κ.

The solution set S of (1) is nonempty, as noted earlier, convex if F is monotone, and a singleton if F is strictly monotone.

DEFINITION 2. The *gap function* associated with a VIP is defined, for x in Φ, as

$$g(x) = \max_{y \in \Phi} (x-y)^t F(x).$$

It is clear that a feasible point x is a solution of VIP if and only if it is a global minimizer for the gap function, i.e., $g(x) = 0$. Using this concept, VIP can be formulated as the linearly constrained optimization problem

$$\min_{x \in \Phi} g(x). \tag{5}$$

Although, in general, neither quasiconvex nor differentiable, it will be shown in Lemma 3 that any stationary point of (5) is an equilibrium solution. In particular, a globally convergent algorithm using the gap function as a merit function has been proposed by Marcotte [7].

DEFINITION 3. The *dual gap function* associated with VIP is defined as

$$\bar{g}(x) = \max_{y \in \Phi} (x-y)^t F(y).$$

The dual gap function is convex, but its evaluation requires the solution of a nonconvex (in contrast with linear for the gap function) mathematical program. Under a monotonicity assumption, any global minimizer of the problem $\min_{x \in \Phi} \bar{g}(x)$ is a solution to VIP. A solution algorithm based on direct minimization of the dual gap function can be found in Nguyen and Dupuis [17].

DEFINITION 4. We say that VIP is *geometrically stable* if $(y-x^*)^t F(x^*) \leqq 0$ for any equilibrium solution x^* implies that y lies in the optimal face T^*, i.e., the minimal face of Φ containing the set S of all solutions to VIP.

The above stability condition, especially useful when S is a singleton, ensures that T^* is stable under slight perturbations to the cost function F. It is implied by the generalization to VIP of the usual strict complementarity condition:

$$\{Bx^* = b \Leftrightarrow \lambda^* > 0\} \tag{6}$$

where λ^* is an optimal dual vector corresponding to x^* in the complementarity formulation (4). If F is strongly monotone, then geometric stability implies the strong regularity condition of Robinson [12]. Also, under geometric stability, there must exist at least one solution of VIP satisfying the strict complementarity condition (6); however it need not be unique, and there might exist optimal primal-dual couples that are not strictly complementary. Figure 1 provides examples where geometric stability holds while strict complementarity is not satisfied. In the first case, the problem is caused by a redundant constraint, while in the second case it is due to the linear dependence of the constraints' gradients at x^*.

2. Newton's algorithm. Since Newton's method is central to our local convergence analysis we recall its definition and main properties. Applied to VIP, Newton's method generates a sequence of iterates $\{x^k\}$ where x^0 is any vector in Φ and $x^{k+1} (k \geqq 0)$ is a solution to the VIP obtained by replacing F by its first-order Taylor expansion around x^k, i.e.,

$$(x^{k+1}-y)^t (F(x^k) + F'(x^k)(x-x^k)) \leqq 0 \quad \forall y \in \Phi. \tag{7}$$

The linearized problem will be denoted LVIP (x^k) and its (nonempty) set of solutions

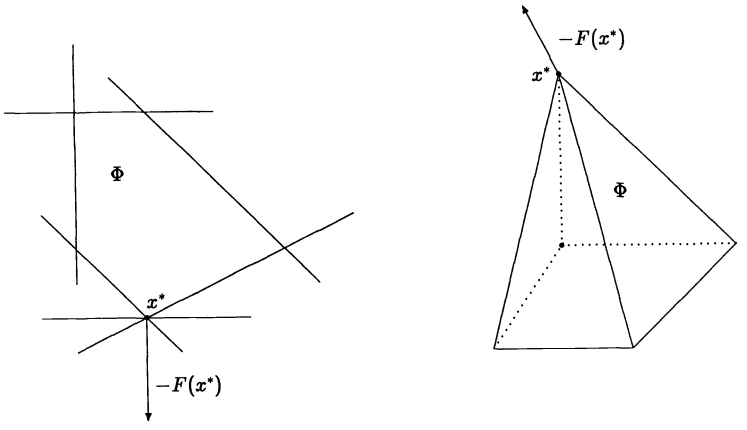

FIG. 1. *Geometric stability does not imply strict complementarity.* (a) *Redundant constraint.* (b) *Dependent constraints' gradients.*

NEW (x^k). The gap function associated with LVIP (x^k) (the *linearized gap function*) will be denoted $\mathrm{Lg}(x^k, x)$ and its mathematical expression is

$$\mathrm{Lg}(x^k, x) = \max_y (x-y)^t(F(x^k)+F'(x^k)(x-x^k)). \tag{8}$$

In a similar fashion we define the *linearized dual gap function* $\mathrm{L\bar{g}}(x^k, x)$:

$$\mathrm{L\bar{g}}(x^k, x) = \max_y (x-y)^t(F(x^k)+F'(x^k)(y-x^k)). \tag{9}$$

When F is strongly monotone and its F' is Lipschitzian, it can be shown that Newton's method is locally quadratically convergent. We quote Pang and Chan's [11] version of this result, also obtained by Josephy [5].

THEOREM 1. *If the matrix $F'(x^*)$ is positive definite and the function F' is Lipschitz continuous at x^* then there exists a neighborhood N of x^* such that if $x^k \in N$ then the sequence $\{x^k\}$ is well-defined and converges quadratically to x^*, i.e., there exists a constant ζ such that*

$$\|x^{k+1}-x^*\| \leqq \zeta \|x^k-x^*\|^2 \quad \forall k \text{ such that } x^k \in N \tag{10}$$

where $\|\cdot\|$ denotes the Euclidian norm in R^n.

The next result shows that Newton's algorithm has the capability of identifying T^*. Actually we will prove this result for a broad class of approximation algorithms where, at each iteration, x^{k+1} is defined as a solution to a VI where $F(x)$ is replaced by the function $G(x, x^k)$ parameterized in x^k and such that

(11) (i) $G(x, y)$ is strictly monotone in x;

(12) (ii) $G(x, y)$ is continuous as a function of (x, y);

(13) (iii) $G(x, x) = F(x)$.

Property (i) above ensures that x^{k+1} is unambiguously defined. Property (iii) ensures that if $x^{k+1} = x^k$ then x^k is the solution to the original VIP. In many practical situations, G is chosen as a strongly monotone function with symmetric Jacobian. Popular choices

for G are:

$G_i(x, y) = F_i(y_1, \cdots, y_{i-1}, x_i, y_{i+1}, \cdots, y_n), \quad i = 1, \cdots, n$ Jacobi iteration,

$G_i(x, y) = F_i(x_1, \cdots, x_i, y_{i+1}, \cdots, y_n), \quad i = 1, \cdots, n$ Gauss-Seidel iteration,

$G(x, y) = F(y) + F'(y)(x - y)$ Newton's method,

$G(x, y) = Ax + \rho[F(y) - Ay]$ Projection method,

where $\rho > 0$ and A is a symmetric positive definite matrix.

Other choices for G may be found in Pang and Chan [11] and Marcotte [8].

PROPOSITION 1. *Assume that F is monotone and that geometric stability holds for* VIP. *Let x^{k+1} be a solution to the* VI:

$$(x^{k+1} - y)^t G(x^{k+1}, x^k) \leqq 0 \quad \textit{for all } y \in \Phi$$

where G satisfies (11), (12), (13). *Then, for each optimal solution x^* of* VIP *there exists a neighborhood V of x^* such that if $x^k \in V$ then $x^{k+1} \in T^*$.*

Proof. Assume that the result does not hold. Then there exists an extreme point u of $\Phi - T^*$ and a subsequence $\{x^k\}_{k \in I}$ converging to some x^* such that

$$(x^{k+1} - u)^t G(x^{k+1}, x^k) = 0 \quad \text{for all } k \in I.$$

Taking the limit as $k \to \infty$ $(k \in I)$ we obtain

$$(x^* - u)^t F(x^*) = (x^* - u)^t G(x^*, x^*) \leqq 0$$

implying, by geometric stability, that $u \in T^*$, a contradiction. □

3. A linear approximation algorithm. In this section we present a model algorithm for solving VIP based on its complementarity formulation (4) that proceeds by successive linear approximations of both the objective and the nonstructural, usually nonlinear, constraints. Throughout this section the function F will be assumed monotone with Lipschitz continuous Jacobian F'.

Any solution to (4) is clearly a global minimizer for the following (usually) nonconvex, nonlinearly constrained mathematical program:

$$\begin{aligned} &\min_{x,\lambda} h(x, \lambda) \overset{\text{def}}{=} \lambda^t(b - Bx) = x^t F(x) + b^t \lambda \\ &\text{subject to} \quad F(x) + B^t \lambda = 0, \quad Bx \leqq b, \quad \lambda \geqq 0. \end{aligned} \tag{14}$$

The following lemma relates the objective in (14) to the gap function.

LEMMA 1. *We have*

$$\begin{aligned} &g(x) = \min_{\lambda} h(x, \lambda) \\ &\textit{subject to} \quad F(x) + B^t \lambda = 0, \quad \lambda \geqq 0. \end{aligned} \tag{15}$$

Proof.

$$\begin{aligned} g(x) &= \max_{y \in \Phi} (x - y)^t F(x) \\ &= x^t F(x) - \min_{By \leqq b} y^t F(x) \\ &= x^t F(x) - \max_{\substack{B^t \mu = F(x) \\ \mu \leqq 0}} b^t \mu \end{aligned}$$

by linear programming duality theory. Hence

$$g(x) = x^t F(x) + \min_{\substack{F(x)+B^t\lambda=0 \\ \lambda \geqq 0}} b^t\lambda$$

after setting $\lambda = -\mu$, and the result follows if we replace $F(x)$ by the equivalent term $-B^t\lambda$. □

The next lemma, basic to our global convergence analysis, states that any stationary point of the mathematical program (14) is actually an equilibrium solution to VIP and justifies the use of an algorithm based on identifying points satisfying first-order conditions of (14). The proof does not rely on any sort of constraint qualification for the nonlinearly constrained problem (14).

LEMMA 2. *Let* $(\bar{x}, \bar{\lambda})$ *be a vector satisfying the first-order necessary optimality conditions for* (14). *Then* $\bar{x}$ *is a solution to* VIP.

Proof. It suffices to show that $h(\bar{x}, \bar{\lambda}) = 0$. Assume that $h(\bar{x}, \bar{\lambda}) > 0$. Without loss of generality we also assume that $h(\bar{x}, \bar{\lambda}) = g(\bar{x})$; otherwise, $\bar{\lambda}$ would not be optimal for the linear program

$$\begin{aligned} &\min_{\lambda} \bar{h}(x, \lambda) \\ &\text{subject to} \quad F(\bar{x}) + B^t\lambda = 0, \quad \lambda \geqq 0 \end{aligned} \tag{16}$$

and an optimal λ-solution to (16) would constitute, together with $\bar{x}$, an obvious descent direction for h at $(\bar{x}, \bar{\lambda})$.

Consider the linearized problem LVIP $(\bar{x})$ with its gap function Lg $(\bar{x})$ and complementarity formulation:

$$\begin{aligned} &\min_{x,\lambda} \bar{h}(x, \lambda) \overset{\text{def}}{=} x^t[F(\bar{x}) + F'(\bar{x})(x - \bar{x})] + b^t\lambda \\ &\text{subject to} \quad F(\bar{x}) + F'(\bar{x})(x - \bar{x}) + B^t\lambda = 0, \quad \lambda \geqq 0. \end{aligned} \tag{17}$$

Problem (17) constitutes a positive semidefinite quadratic program whose optimal solution's primal vector corresponds to a (not necessarily unique) Newton direction. Consider a Frank-Wolfe direction $d = (\tilde{x} - \bar{x}, \tilde{\lambda} - \bar{\lambda})$ for (17) at the point $(\bar{x}, \bar{\lambda})$. Direction d is a feasible descent direction for the linearized gap function Lg at $\bar{x}$. Since $\nabla h(\bar{x}, \bar{\lambda})$ is identical with $\nabla \bar{h}(\bar{x}, \bar{\lambda})$, and so are the directional derivatives of Lg and g, it follows that $\tilde{x} - \bar{x}$ is also a feasible descent direction for g at $\bar{x}$. □

We are now in a position to give a precise statement of our algorithm.

ALGORITHM N^*.
Initialization.
Let x^0 be any vector in Φ and

$$\lambda^0 \in \arg\min_{\lambda \geqq 0} b^t\lambda$$

$$\text{subject to} \quad F(x) + B^t\lambda = 0$$

and set $k \leftarrow 1$.
while convergence criterion not met
do 1) Find descent direction *d*.

Let $(d_x(x^k), d_\lambda(x^k))$ be an *extremal* solution to the linear problem

$$\min_{\substack{x\in\Phi\\ \lambda\geqq 0}} x^t(F(x^k)+F'^t(x^k)x^k)+b^t\lambda$$

$$\text{subject to} \quad F(x^k)+F'(x^k)(x-x^k)+B^t\lambda=0. \tag{18}$$

Set $d\leftarrow(d_x(x^k)-x^k, d_\lambda(x^k)-\lambda_k)$.

2) Perform arc search on the gap function.

$$\text{if } g(d_x(x^k))\leqq\tfrac{1}{2}g(x^k) \text{ then } \bar\theta\leftarrow 1$$
$$\text{else } \bar\theta\in\arg\min_{\theta\in[0,1]} g[x^k+\theta(d_x(x^k)-x^k)]. \tag{19}$$

3) Update.

$$x^{k+1}\leftarrow x^k+\bar\theta(d_x(x^k)-x^k)$$

$$\lambda^{k+1}\in\arg\min_{\substack{\lambda\geqq 0\\ F(x^{k+1})+B^t\lambda=0}} b^t\lambda$$

$$k\leftarrow k+1$$

endwhile.

Some comments are in order:

(1) At step 2) of Algorithm N^*, the minimization, with respect to the primal vector x, of the nondifferentiable objective g could be seen as a search along an arc in the space of primal-dual variables (x, λ). Since dual vectors λ have to be computed repeatedly, this operation can be carried out efficiently using reoptimization techniques of linear programming.

(2) It is not required, or even advisable, that the arc search be carried out exactly. For instance, the Armijo–Goldstein stepsize rule, or any rule guaranteeing a "sufficient" decrease of the objective along the search direction could be implemented.

(3) For affine functions $F=Ax+a$, Algorithm N^* reduces to the standard Frank–Wolfe procedure for solving quadratic programming problems, as then the nonstructural constraints become linear.

4. Convergence analysis. We first state and prove a global convergence result for Algorithm N^*.

PROPOSITION 2. *Any point of accumulation of a sequence generated by Algorithm N^* is an equilibrium solution.*

Proof. If $g(d_x(x^k))\leqq .5g(x^k)$ infinitely often at (19), then $\lim_{k\to\infty} g(x^k)=0$. Otherwise the linesearch in (19) is asymptotically always performed and, to prove global convergence, we will strive to check the conditions behind Zangwill's global convergence theorem, namely:

(i) All points generated by the algorithm lie in a compact set.

(ii) The algorithmic map is closed outside the set of solution points S.

(iii) At each iteration, strict decrease of the objective function occurs.

(i) Since Φ is compact by assumption, it is sufficient to show that the sequence $\{d_\lambda(x^k)\}$ is bounded. By definition of the sequence $\{d_\lambda(x^k)\}$ we have

$$d_\lambda(x^k)\in\arg\min_{\lambda\geqq 0} b^t\lambda$$

$$\text{subject to} \quad B^t\lambda=H(x^k) \tag{20}$$

where $H(x^k)\overset{\text{def}}{=}F(x^k)+F'(x^k)(d_x(x^k)-x^k)\in R^n$.

First observe that the linear program:

$$\min_{\lambda \geqq 0} b^t\lambda \qquad \text{subject to} \quad B^t\lambda = -H(x^k) \tag{21}$$

is the dual of the linear program

$$\max_{x \in \Phi} -x^t F(x^k) \tag{22}$$

that is feasible and bounded; hence, by linear programming duality, we have that (17) is also feasible and bounded, i.e., that (17) possesses at least one optimal basic solution. Let $\{N_e\}_{e=1,\cdots,p}$ denote the set of full rank square submatrices (basis) of B^t. Since $d_\lambda(x^k)$ is extremal, we have

$$d_\lambda(x^k) = -N_e^{-1}H(x^k)$$

for some $e \in \{1, \cdots, p\}$. From the continuity of F and F' we deduce that $H(x^k)$ must lie in some compact set K independent of x^k. Therefore $d_\lambda(x^k) \in C \stackrel{\text{def}}{=} \cup_{e=1}^p -N_e^{-1}K$, which is bounded. The same continuity argument is then used to show boundedness of the sequence $\{\lambda^{k+1}\}$.

(ii) The closedness of the algorithmic map follows directly from the continuity of F' and the closedness of the linesearch strategy used.

(iii) We must prove that $h(x^{k+1}, \lambda^{k+1}) < h(x^k, \lambda^k)$ if the latter term is positive (not zero). This is a direct consequence of Lemma 2. □

PROPOSITION 3. *If F is monotone on Φ and affine, then Algorithm $N^\#$ converges in a finite number of iterations.*

Proof. Replacing F by $Ax + a$ in (16) yields a quadratic programming problem. Its solution set is a face $\bar{T}$ of the polyhedron $\{Ax + B^t\lambda = 0,\ Bx \leqq b,\ \lambda \geqq 0\}$. For some iterate k we must have that $(d_x(x^k), d_\lambda(x^k))$ lies in $\bar{T}$ (otherwise the iterates would always be bounded away from $\bar{T}$, contradicting global convergence of the method). When $(d_x(x^k), d_\lambda(x^k)) \in \bar{T}$ we have $\bar{\theta} = 1$ and $(x^{k+1}, \lambda^{k+1}) \in \bar{T}$. □

Remark. The preceding result is also valid under the assumption that T^* is a singleton (F monotone but not necessarily affine). The proof is similar.

To obtain a rate-of-convergence result for Algorithm $N^\#$ we assume, until explicitly stated otherwise, that the function F is strongly monotone in a neighborhood of the solution x^* with strong monotonicity coefficient κ and that the geometric stability condition is satisfied at x^*. This implies that the entire sequence $\{x^k\}$ converges to the unique solution x^*. Under these assumptions we will show that Algorithm $N^\#$ is locally equivalent to Newton's method, thus implying quadratic convergence and implicit identification of the set of active constraints at x^*. We first show that the descent direction d obtained from Algorithm $N^\#$ satisfies $d_x(x^k) = \text{NEW}(x^k)$ if x^k is sufficiently close to x^*. The following lemmas will be used in the proof.

LEMMA 3. *The optimal dual vector $y(x^k)$ associated with the nonstructural constraint $F(x) + B^t\lambda = 0$ of (18) satisfies $\lim_{k\to\infty} y(x^k) = x^*$.*

Proof. Write the Lagrangian dual of the linear program (18):

$$\max_{y} \min_{\substack{x \in \Phi \\ \lambda \geqq 0}} x^t[F(x^k) + F'^t(x^k)x^k] + b^t\lambda - y^t[F(x^k) + F'(x^k)(x - x^k) + B^t\lambda].$$

Then observe that the inner minimum has value $-\infty$ unless $By \leqq b$, in which case the minimum over nonnegative λ is achieved when λ is zero, yielding

$$\max_{y \in \Phi} \min_{x \in \Phi} x^t[F(x^k) + F'^t(x^k)x^k] - y^t[F(x^k) + F'(x^k)(x - x^k)].$$

This expression is equivalent, modulo a constant term, to

$$\max_{y\in\Phi}\min_{x\in\Phi}(x-y)^t[F(x^k)+F'(x^k)(x-x^k)]-(x-x^k)F'(x^k)(x-x^k) \tag{23}$$

and constitutes a quadratic perturbation of the dual gap function $L\bar{g}$ at x^k. Since $y(x^k)$ is dual-optimal for (18) it must correspond to the y-part of a solution to (23). If $y(x^k)$ does not converge to x^* then there exists a subsequence $\{x^k\}_{k\in I}$ such that $\lim_{k\to\infty,k\in I} y(x^k)=\tilde{y}\neq x^*$. Passing to the limit in (23) we obtain, after setting x to $\tilde{x}$:

$$\begin{aligned}
&\lim_{\substack{k\to\infty\\ k\in I}}\max_{y\in\Phi}\min_{x\in\Phi}(x-y)^t[F(x^k)+F'(x^k)(x-x^k)]-(x-x^k)^tF'(x^k)(x-x^k)\\
&\quad\leqq(\tilde{y}-\tilde{y})^t[F(x^*)+F'(x^*)(\tilde{y}-x^*)]-(\tilde{y}-x^*)^tF'(x^*)(\tilde{y}-x^*)\\
&\quad\leqq-\kappa\|\tilde{y}-x^*\|^2 \quad\text{by strong monotonicity}\\
&\quad<0.
\end{aligned}$$

But this contradicts the optimality of the sequence $\{y(x^k)\}_{k\in I}$ since we obtain, by taking $y=x^*$:

$$\begin{aligned}
&\lim_{k\to\infty}\min_{x\in\Phi}(x-x^*)^t[F(x^k)+F'(x^k)(x-x^k)]-(x-x^k)^tF'(x^k)(x-x^k)\\
&\quad=\min_{x\in\Phi}(x-x^*)^tF(x^*)\\
&\quad=0 \quad\text{by definition of } x^*.
\end{aligned}$$

□

LEMMA 4. *There exists an index K such that $k\geqq K$ implies $d_x(x^k)\in T^*$.*

Proof. From (23) we get

$$\begin{aligned}
d_x(x^k)\in D(x^k)\overset{\text{def}}{=}\arg\min_{x\in\Phi}\,&(x-y(x^k))^t[F(x^k)+F'(x^k)(x-x^k)]\\
&-(x-x^k)^tF'(x^k)(x-x^k).
\end{aligned} \tag{24}$$

Since $y(x^k)\to x^*$ as $k\to\infty$ (Lemma 3), (24) represents, for x^k close to x^*, a small quadratic perturbation of the linear program: $\min_{x\in\Phi}x^tF(x^*)$. It follows from the geometric stability assumption that $d_x(x^k)\in T^*$. □

COROLLARY. $d_x(x^*)\in T^*$.

Proof. Since F' is continuous, the point-to-set mapping $\bar{x}\to\{d_x(\bar{x})\}$ is upper semicontinuous. Hence $d_x(x^*)\in\{d_x(\lim_{k\to\infty}x^k)\}=\lim_{k\to\infty}\{d_x(x^k)\}\in T^*$. □

LEMMA 5. $\lim_{k\to\infty}d_x(x^k)=x^*$.

Proof. From the proof of Lemma 2, we have

$$g'(x^k;\,d_x(x^k)-x^k)<0.$$

Passing to the limit and using upper semicontinuity there comes

$$g'(x^*;\,d_x(x^*)-x^*)\leqq 0.$$

But, by Danskin's rule of differentiation of max-functions (see [18]), we have

$$g'(x^*;\,d_x(x^*)-x^*)=\max_{y\in T^*}[d_x(x^*)-x^*]^t[F(x^*)-F'^t(x^*)(y-x^*)].$$

Assume that T^* is not the singleton x^* (otherwise the result follows trivially from Lemma 5) and let ε be a positive number such that $\hat{y}\overset{\text{def}}{=}x^*-\varepsilon(d_x(x^*)-x^*)\in T^*$ (see

Fig. 2). Then we have

$$\begin{aligned} 0 &\geqq g'(x^*;\, d_x(x^*) - x^*) \\ &\geqq \varepsilon[d_x(x^*) - x^*]'[F(x^*) + F''(x^*)(d_x(x^*) - x^*)] \\ &\geqq \varepsilon\kappa \|d_x(x^*) - x^*\|^2, \end{aligned}$$

implying that $d_x(x^*) = x^*$. □

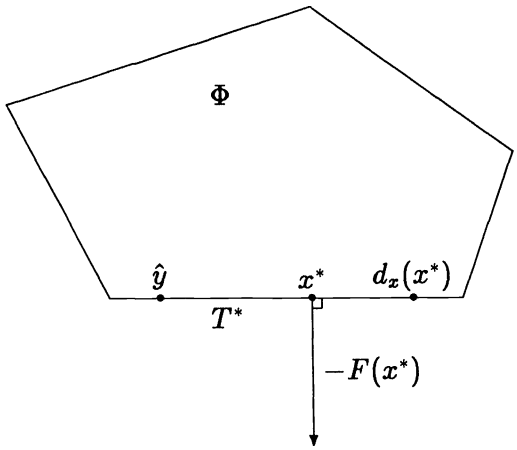

FIG. 2

LEMMA 6. *There exists an index K such that for* $k \geqq K$, $d_x(x^k) = \text{NEW}(x^k)$.

Proof. From (18), $d_\lambda(x^k)$ is an optimal dual vector for the linear program

$$\min_{z \in \Phi} z'[F(x^k) + F'(x^k)(d_x(x^k) - x^k)]. \tag{25}$$

For k large, $d_x(x^k)$ is close to x^* (Lemma 5) and problem (25) is an arbitrary small perturbation of the linear program

$$\min_{z \in \Phi} z'F(x^*)$$

whose set of optimal solutions is T^*, by definition. Therefore the optimal solutions to (25) lie in T^* by geometric stability. From the complementary slackness theorem of linear programming we can write

$$d_\lambda(x^k)'(Bd_x(x^k) - b) = 0.$$

We conclude that the couple $(d_x(x^k), d_\lambda(x^k))$ is optimal for the quadratic program (17). Since its solution is unique in x and equal by definition to NEW (x^k) we conclude that $d_x(x^k) = \text{NEW}(x^k)$. □

PROPOSITION 4. *There exist positive constants* α *and* β *such that*

$$\alpha \|x - x^*\| \leqq g(x) \leqq \beta \|x - x^*\|.$$

Proof. It suffices to prove the result in a neighborhood of x^*.

(26) (i) Proof that $g(x) \leqq \beta \|x - x^*\|$.

$$\begin{aligned} g(x) &= \max_{y \in \Phi} (x-y)^t F(x) \\ &= (x-x^*)^t F(x) + \max_{y \in \Phi} (x^*-y)^t F(x) \\ &\leqq \|x-x^*\| \cdot \|F(x)\| + \max_{y \in \Phi} (x^*-y)^t F(x^*) \\ &\quad + \max_{y \in \Phi} (x^*-y)^t (F(x)-F(x^*)) \\ &\leqq \|x-x^*\| \cdot \|F(x)\| + D\|x-x^*\| \sup_{\xi \in \Phi} \|F'(\xi)\| \\ &\leqq (M + M' \operatorname{diam}(\Phi)) \|x-x^*\| \end{aligned}$$

where $M \overset{\text{def}}{=} \sup_{x \in \Phi} \|F(x)\|$, $M' \overset{\text{def}}{=} \sup_{\xi, \eta \in \Phi, \xi \neq \eta} \|F(\xi) - F(\eta)\| / \|\xi - \eta\|$, and D is the diameter of Φ. Then set $\beta = M + M'D$.

(27) (ii) Proof that $g(x) \geqq \alpha \|x - x^*\|$.

We consider three mutually exclusive cases.

Case 1. $T^* = x^*$. (Fig. 3.) For x sufficiently close to x^* we have

$$\begin{aligned} g(x) &= (x-x^*)^t F(x) \\ &= (x-x^*)^t F(x^*) + (x-x^*)^t (F(x) - F(x^*)) \\ &\geqq \|x-x^*\| \cdot \|F(x^*)\| \cos(x-x^*, F(x^*)) + \kappa \|x-x^*\|^2. \end{aligned}$$

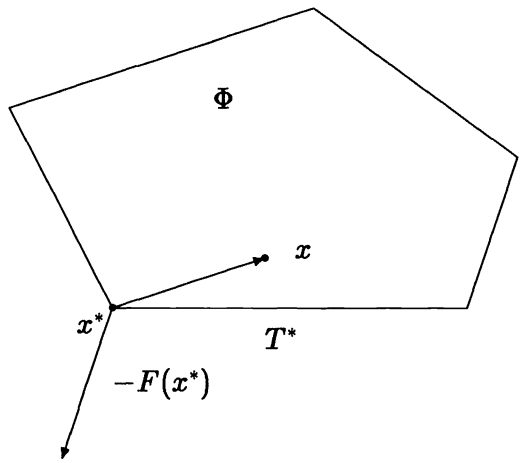

FIG. 3. *Case* 1.

Since $F(x^*)$ is orthogonal to no feasible direction from x^* into Φ (by geometric stability) we must have that $\cos(x-x^*, F(x^*))$ is positive and bounded away from zero. Hence (27) holds with

$$\alpha = \bar{\alpha} \overset{\text{def}}{=} \inf_{\substack{\xi \in \Phi \\ \xi \neq x^*}} \{\cos(\xi - x^*, F(x^*))\} \|F(x^*)\| > 0.$$

Case 2. $T^* \neq \{x^*\}$ and $x \in T^*$. (Fig. 4.) Let ρ be a positive number such that the mapping $\text{Proj}_\Phi(x-(1/\rho)F(x))$, defined for $x \in \Phi$, is contracting, where Proj_Φ denotes the projection operator on Φ, in the usual Euclidean norm. The existence of such a number ρ is a consequence of, say, Example 3.1 of Dafermos [4]. For x sufficiently

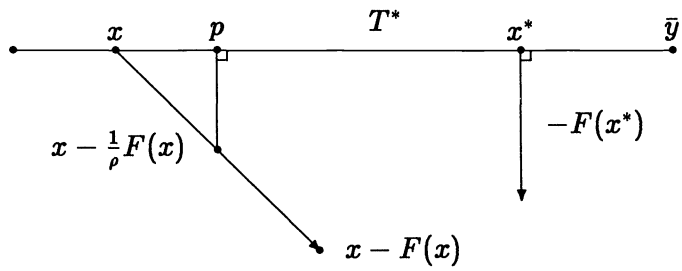

FIG. 4. *Case* 2.

close to x^*, $p \overset{\text{def}}{=} \text{Proj}_\Phi(x-(1/\rho)F(x))$ lies in T^* (see Proposition 1). Let $\theta \in [0,1]$ be the contraction constant, dependent on ρ; we have $\|p-x^*\| \leqq \theta\|x-x^*\|$. We have

$$\begin{aligned}\|p-x\| &\geqq \|x-x^*\| - \|x^*-p\| \quad \text{by the triangle inequality} \\ &\geqq (1-\theta)\|x-x^*\|.\end{aligned} \tag{28}$$

Also by construction of p

$$(x-p)^t F(x) = \rho\|x-p\|^2. \tag{29}$$

Define

$$\psi = \max\{\phi \mid x+\phi(p-x) \in T^*\} \tag{30}$$

(ψ must be positive since x lies in the relative interior ri (T^*)) and $\bar{y} = x+\psi(p-x)$. We have

$$\begin{aligned}(x-\bar{y})^t F(x) &= \psi(x-p)^t F(x) \\ &= \rho\psi\|x-p\|^2 \quad \text{by (29)} \\ &\geqq \rho\psi\|x-p\|(1-\theta)\|x-x^*\| \quad \text{by (28)}.\end{aligned}$$

Now $\psi\|x-p\| = \|x-\bar{y}\|$ must be bounded from below by some positive number s since x lies in ri (T^*) and $\bar{y}$ is on the boundary of T^*. It follows that

$$\begin{aligned}g(x) &\geqq (x-\bar{y})^t F(x) \\ &\geqq \rho(1-\theta)s\|x-x^*\|\end{aligned}$$

and the result holds with $\alpha = \rho s(1-\theta)$.

Case 3. $x \notin T^*$ (consequently $T^* \neq \Phi$). (Fig. 5.) Define $p = \text{Proj}_{T^*}(x)$. First we will show that $\cos(x-p, F(x^*))$ is bounded below by some positive number γ.

Define, for $x \notin T^*$, the function $x \to \eta(x)$ where $\eta(x)$ is the intersection of the line going through the segment $[p, x]$ with the boundary of Φ, in the direction $x-p$. Let $B_\varepsilon(x^*)$ be a ball of radius ε about x^*, $H = B_\varepsilon(x^*) \cap \Phi - T^*$, and E the closure of $\eta(H)$ (see Fig. 6). We have $E \cap T^* = \varnothing$ and

$$\begin{aligned}\cos(x-p, F(x^*)) &= \cos(\eta(x)-p, F(x^*)) \\ &\geqq \min_{v \in E} \cos(v-p, F(x^*)).\end{aligned} \tag{31}$$

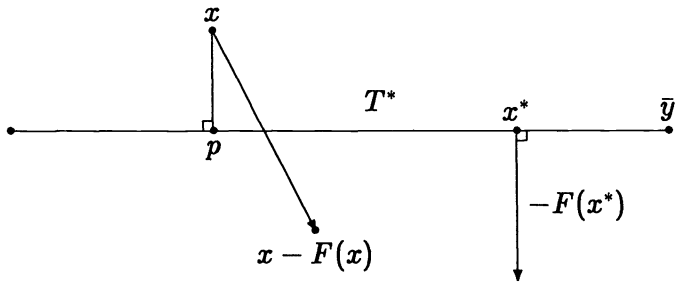

FIG. 5. *Case* 3.

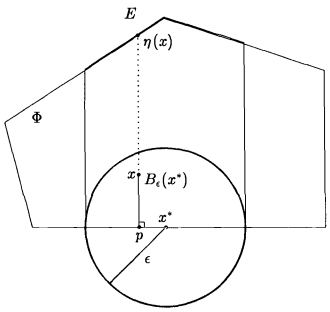

FIG. 6

But $\cos(v-p, F(x^*))>0$ $(p\in T^*)$ for each $v\notin T^*$ by geometric stability. Hence, $\cos(x-p, F(x^*))\geqq\gamma>0$.

We then write $(x-p)^tF(x^*)\geqq\gamma\|x-p\|\cdot\|F(x^*)\|$. Thus

$$(x-p)^tF(x)\geqq\frac{\gamma}{2}\|x-p\|\cdot\|F(x^*)\| \tag{32}$$

for x sufficiently close to x^*. Now consider the following two subcases.

Case 3.1. $\|x-p\|\leqq\zeta\|p-x^*\|$ with $\zeta=\rho s(1-\theta)/2\theta DM'$. Define $\bar{y}$ as in Case 2 (see Fig. 4). Then

$$\begin{aligned}
g(x)&\geqq(x-\bar{y})^tF(x)\\
&=(x-p)^tF(x)+(p-\bar{y})^tF(x)\\
&=0+(p-\bar{y})^tF(p)+(p-\bar{y})^t(F(x)-F(p))\\
&\geqq\rho s(1-\theta)\|x-x^*\|-\zeta\|p-x^*\|DM' \quad \text{since } p\in T^* \quad \text{(see Case 2)}\\
&\geqq(\rho s(1-\theta)-\zeta\theta DM')\|x-x^*\|\\
&\geqq\frac{\rho s(1-\theta)}{2}\|x-x^*\|.
\end{aligned}$$

Set $\alpha=\rho s(1-\theta)/2$.

Case 3.2. $\|x-p\|\geqq\zeta\|p-x^*\|$. We have

$$\|x-x^*\|\leqq\|x-p\|+\|p-x^*\|\leqq(1+\zeta)\|x-p\|. \tag{33}$$

We obtain

$$g(x) \geqq (x-p)^t F(x)$$

$$\geqq \frac{\gamma}{2}\|x-p\| \cdot F(x^*) \quad \text{by (32)}$$

$$\geqq \frac{\gamma}{2}\frac{1}{1+\zeta}\|x-x^*\| \cdot \|F(x^*)\|$$

by (28) and (29), with $F(x^*) \neq 0$, and the result holds with $\alpha = \gamma\|F(x^*)\|/2(1+\zeta)$. □

Remark 1. The above general proof does not require differentiability of the cost mapping F. If F is differentiable, the proof of Proposition 4 can be somewhat streamlined (see Dussault and Marcotte [21]).

Remark 2. Proposition 4 strengthens a result of Pang [19] who derives an estimate of the form

$$\|x-x^*\| \leqq \omega\sqrt{g(x)}$$

for some positive constant ω.

PROPOSITION 5. *Let $\{x^k\}$ be a sequence generated by Algorithm N^*. Then there exists an index K such that for $k \geqq K$, $x^{k+1} = \text{NEW}(x^k)$, the Newton iterate.*

Proof. We must prove that $g(\text{NEW}(x^k)) \leqq \frac{1}{2}g(x^k)$ for $k \geqq K$, in which case Algorithm N^* will set x^{k+1} to $d_x(x^k)$, which is equal to $\text{NEW}(x^k)$ by Lemma 6:

$$g(\text{NEW}(x^k)) \leqq \beta\|\text{NEW}(x^k)-x^*\| \quad \text{by Proposition 4}$$

$$\leqq \beta c\|x^k-x^*\|^2 \quad \text{from (10)}$$

$$\leqq \frac{\beta c}{\alpha}\|x^k-x^*\|g(x^k) \quad \text{by Proposition 4}$$

$$\leqq \frac{1}{2}g(x^k)$$

as soon as $\|x^k-x^*\| \leqq \alpha/2\beta c$. □

The preceding results can be summarized in a theorem.

THEOREM 2. *Consider a* VIP *with monotone cost function F and let $\{x^k\}$ be a sequence generated by Algorithm N^*. If* VIP *is geometrically stable, then*

(i) $g(x^{k+1}) < g(x^k)$ *if* $g(x^k) \neq 0$.

(ii) $\lim_{k\to\infty} g(x^k) = 0$.

(iii) *If F is affine or T^* is a singleton then there exists an index K such that $g(x^k) = 0$ for $k \geqq K$ (finite convergence).*

(iv) *If F is strongly monotone then the sequence $\{x^k\}$ converges quadratically to the point x^* and there exists an index K such that $x^k \in T^*$ whenever $k \geqq K$.*

5. Numerical results. A working version of Algorithm N^* has been developed, using a standard linear programming code, and contrasted against Newton's method, with or without linesearch. The asymmetric linear complementarity subproblems in Newton's method have been solved by Lemke's Complementary Pivoting Algorithm.

In the test problems, Φ has been taken as the unit simplex $\sum_{i=1}^{n} x_i = 1$, $x \geqq 0$ and the mapping F assumed the general form

$$F(x) = (A - A^t)x + B^t Bx + \gamma C(x) + b$$

where the entries of matrices A and B are randomly generated uniform variates, $C(x)$ is a nonlinear diagonal mapping with components $C_i(x) = \arctan(x_i)$, and the constant vector b is chosen such that the exact optimum be known a priori. The parameter γ is used to vary the asymmetry and nonlinearity of the cost function.

Sixteen five-dimensional and sixteen 15-dimensional problems have been generated, with γ-values ranging from 10-40. Newton's search direction differs from Algorithm $N^{\#}$'s direction in 18 of the 32 problems. In some instances (Figs. 7-10) Algorithm $N^{\#}$ yields a direction as good or better than Newton's direction. For some other problems (Figs. 11-14) Newton's direction is slightly superior. In all cases, the difference in the number of iterations required to achieve a very low gap value is small.

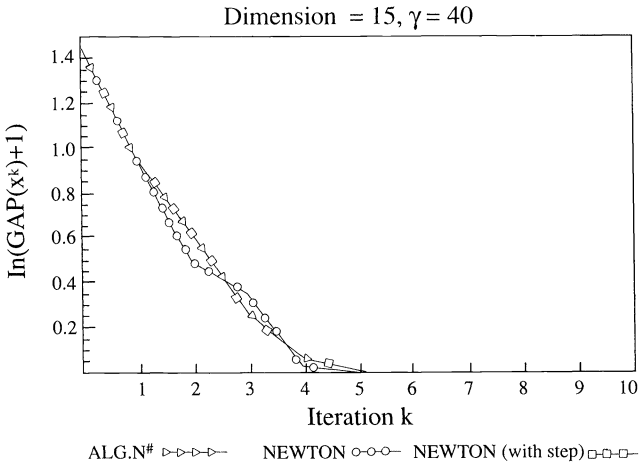

FIG. 7

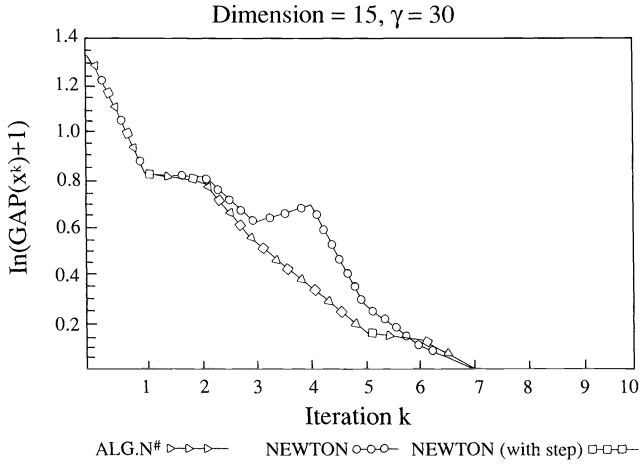

FIG. 8

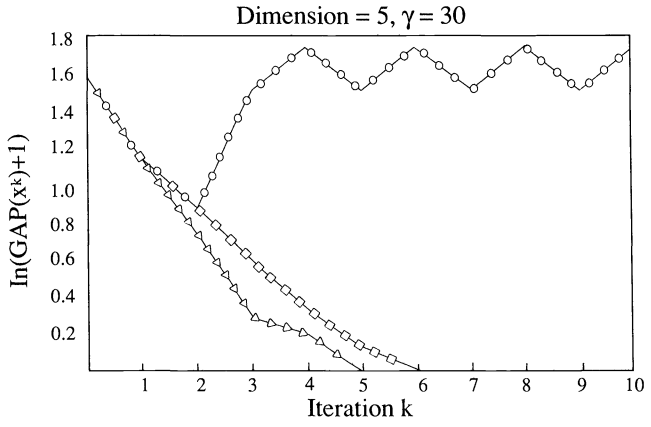

FIG. 9

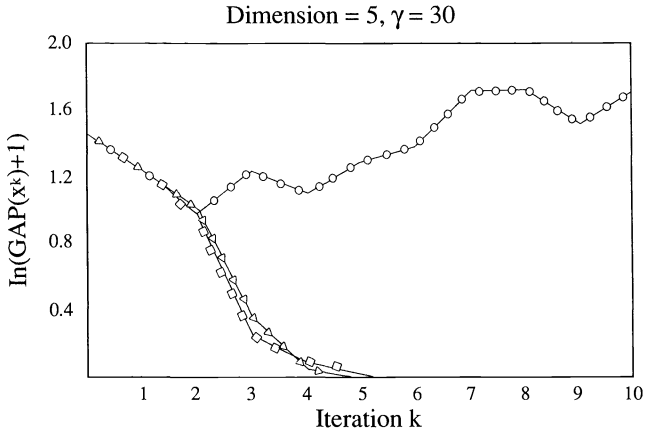

FIG. 10

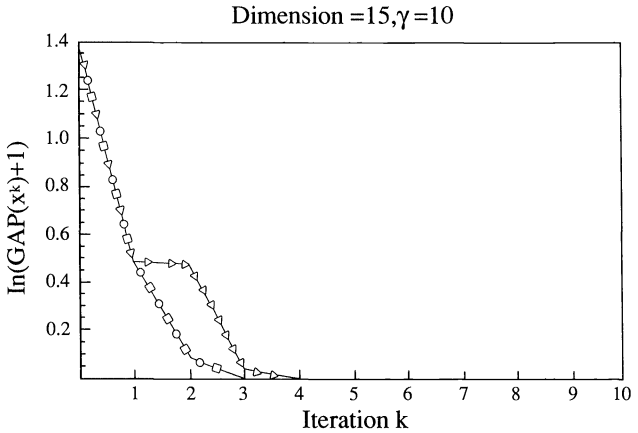

FIG. 11

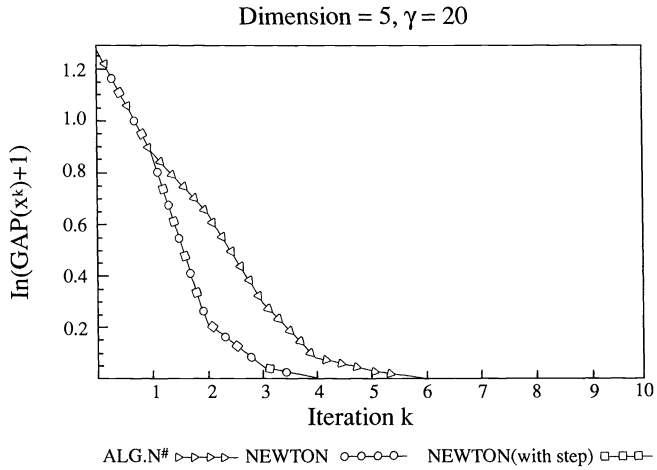

FIG. 12

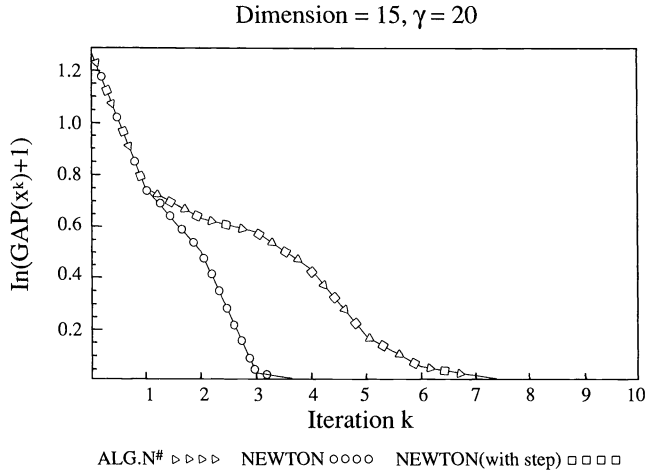

FIG. 13

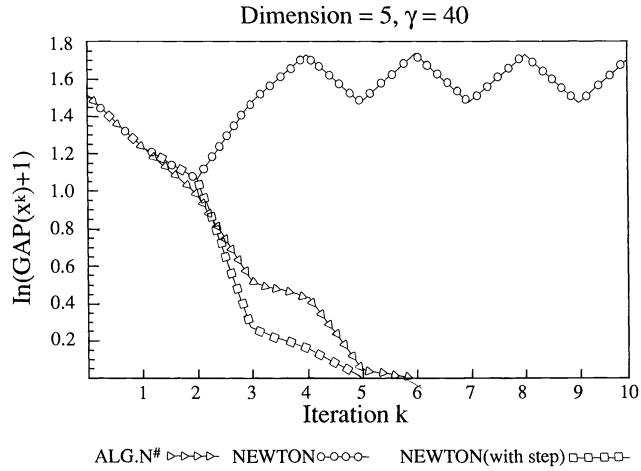

FIG. 14

This preliminary testing shows some promise for the linearization algorithm. Its direction finding subproblem involves a linear program, versus an asymmetric linear complementarity problem for Newton's method. The linear subproblem bears close resemblance to the linear program that must be solved to evaluate the gap function, and as such could benefit from some fine tuning of the computer code. Moreover, it may well prove unnecessary to solve the subproblem exactly, yielding another area for further improvement. In contrast, solving linear complementarity problems yields a feasible solution only at termination, therefore making the implementation of an inexact strategy more difficult.

Finally let us mention that Marcotte and Guélat [20] have successfully implemented Algorithm N^* to solve large-scale network equilibrium problems when the mapping F, i.e., its Jacobian matrix, is highly asymmetric.

6. Conclusion. The main result of this paper has been to prove global and quadratic convergence of an algorithm for solving monotone variational inequalities. The algorithm operates by solving linear programs in the space of primal-dual variables. Computational experiments show that the algorithm is efficient for solving both small-scale and large-scale problems.

Acknowledgments. The authors are indebted to anonymous referees for relevant comments on an earlier version of this paper that led to numerous improvements.

THE PARTIALLY OBSERVED STOCHASTIC MINIMUM PRINCIPLE*

JOHN S. BARAS†, ROBERT J. ELLIOTT‡, AND MICHAEL KOHLMANN§

Abstract. Using stochastic flows and the generalized differentiation formula of Bismut and Kunita, the change in cost due to a strong variation of an optimal control is explicitly calculated. Differentiating this expression gives a minimum principle in both the partially observed and stochastic open loop situations. In the latter case the equation satisfied by the adjoint process is obtained by applying a martingale representation result.

Key words. stochastic control, minimum principle, adjoint process, stochastic flow

AMS(MOS) subject classification. 93E20

1. Introduction. Various proofs have been given of the minimum principle satisfied by an optimal control in a partially observed stochastic control problem. See, for example, the papers by Bensoussan [1], Elliott [8], Haussmann [11], and the recent paper [14] by Haussmann in which the adjoint process is identified. The simple case of a partially observed Markov chain is discussed in the University of Maryland lecture notes [9] of Elliott.

In this article we show that the minimum principle for a partially observed diffusion can be obtained by differentiating the statement that a control u^* is optimal. The results of Bismut [5], [6] and Kunita [16] on stochastic flows enable us to compute in an easy and explicit way the change in the cost due to a "strong variation" of an optimal control. The only technical difficulty is the justification of the differentiation. As we wished to exhibit the simplification obtained by using the ideas of stochastic flows, the result is not proved under the weakest possible hypotheses. In § 6, stochastic open loop controls are considered and a similar minimum principle with an explicit adjoint process is derived in § 7. If the optimal control is Markov, the equation satisfied by the adjoint process is obtained in § 8 using the martingale representation result of [10]. This simplifies the proof of Haussmann [12]. Finally in § 9 it is pointed out how Bensoussan's minimum principle [2] follows from our result if the drift coefficient is differentiable in the control variable.

2. Dynamics. Suppose the state of the system is described by a stochastic differential equation

$$\begin{aligned} &d\xi_t = f(t, \xi_t, u)\,dt + g(t, \xi_t)\,dw_t, \\ &\xi_t \in R^d, \quad \xi_0 = x_0, \quad 0 \leqq t \leqq T. \end{aligned} \tag{2.1}$$

The control parameter u will take values in a compact subset U of some Euclidean space R^k. We shall make the following assumptions:

(A_1) x_0 is given; if x_0 is a random variable and P_0 its distribution, the situation when $\int |x|^q P_0(dx) < \infty$ for some $q > n+1$ can be treated, as in [14], by including an extra integration with respect to P_0.

(A_2) $f:[0, T]\times R^d \times U \to R^d$ is Borel measurable, continuous in u for each (t, x), continuously differentiable in x and for some constant K_1, $(1+|x|)^{-1}|f(t, x, u)|+|f_x(t, x, u)| \leqq K_1$.

(A_3) $g:[0, T]\times R^d \to R^d \otimes R^n$ is a matrix-valued function, Borel measurable, continuously differentiable in x, and for some constant K_2, $|g(t, x)|+|g_x(t, x)| \leqq K_2$.

The observation process is given by

$$dy_t = h(\xi_t)\,dt + dv_t, \qquad y_t \in R^m, \quad y_0 = 0, \quad 0 \leqq t \leqq T. \tag{2.2}$$

In the above equations $w=(w^1, \cdots, w^n)$ and $v=(v^1, \cdots, v^d)$ are independent Brownian motions. We also assume the following:

(A_4) $h: R^d \to R^m$ is Borel measurable, continuously differentiable in x, and for some constant K_3, $|h(t, x)|+|h_x(t, x)| \leqq K_3$.

Remark 2.1. These hypotheses can be weakened. For example, in (A_4), h can be allowed linear growth in x. Because g is bounded, a delicate argument then implies the exponential Z of (2.3) is in some L^p space, $1 < p < \infty$. (See, for example, Theorem 2.2 of [13].) However, when h is bounded, Z is in all the L^p spaces (see Lemma 2.3). Also, if we require f to have linear growth in u, then the set of control values U can be unbounded as in [14]. Our objective, however, is not the greatest generality but is to demonstrate the simplicity of the techniques of stochastic flows.

Let $\hat{P}$ denote Wiener measure on $C([0, T], R^n)$ and μ denote Wiener measure on $C([0, T], R^m)$. Consider the space $\Omega = C([0, T], R^n)\times C([0, T], R^m)$ with coordinate functions (w_t, y_t) and define Wiener measure P on Ω by

$$P(dw, dy) = \hat{P}(dw)\mu(dy).$$

DEFINITION 2.2. Write $Y=\{Y_t\}$ for the right continuous complete filtration on $C([0, T], R^m)$ generated by $Y_t^0 = \sigma\{y_s: s \leqq t\}$. The set of admissible control functions $\underline{U}$ will be the Y-predictable functions on $[0, T]\times C([0, T], R^m)$ with values in U.

For $u \in \underline{U}$ and $x \in R^d$ write $\xi^u_{s,t}(x)$ for the strong solution of (2.1) corresponding to control u, and with $\xi^u_{s,s}(x) = x$. Write

$$Z^u_{s,t}(x) = \exp\left(\int_s^t h(\xi^u_{s,r}(x))'\,dy_r - \frac{1}{2}\int_s^t h(\xi^u_{s,r}(x))^2\,dr\right) \tag{2.3}$$

and define a new probability measure P^u on Ω by $dP^u/dP = Z^u_{0,T}(x_0)$. Then under P^u, $(\xi^u_{0,t}(x_0), y_t)$ is a solution of (2.1) and (2.2), that is, $\xi^u_{0,t}(x_0)$ remains a strong solution of (2.1) and there is an independent Brownian motion v such that y_t satisfies (2.2). A version of Z defined for every trajectory y of the observation process is obtained by integrating by parts the stochastic integral in (2.3).

LEMMA 2.3. *Under hypothesis* (A_4) *for* $t \leqq T$,

$$E[(Z^u_{0,t}(x_0))^p] < \infty \quad \textit{for all } u \in \underline{U} \textit{ and all } p, \quad 1 \leqq p < \infty.$$

Proof.

$$Z^u_{0,t}(x_0) = 1 + \int_0^t Z^u_{0,r}(x_0) h(\xi^u_{0,r}(x_0))'\,dy_r.$$

Therefore, for any p there is a constant C_p such that

$$E[(Z^u_{0,t}(x_0))^p] \leqq C_p\left[1+E\left(\int_0^t (Z^u_{0,r}(x_0))^2 h(\xi^u_{0,r}(x_0))^2\,dr\right)^{p/2}\right].$$

The result follows by Gronwall's inequality.

Cost 2.4. We shall suppose the cost is purely terminal and given by some bounded, continuously differentiable function

$$c(\xi^u_{0,T}(x_0)),$$

which has bounded derivatives. Then the expected cost, if control $u \in \underline{U}$ is used, is

$$J(u) = E_u[c(\xi^u_{0,T}(x_0))].$$

In terms of P, under which y_t is always a Brownian motion, this is

$$J(u) = E[Z^u_{0,T}(x_0)c(\xi^u_{0,T}(x_0))]. \tag{2.4}$$

3. Stochastic flows. For $u \in \underline{U}$ write

$$\xi^u_{s,t}(x) = x + \int_s^t f(r, \xi^u_{s,r}(x), u_r)\,dr + \int_s^t g(r, \xi^u_{s,r}(x))\,dw_r \tag{3.1}$$

for the solution of (2.1) over the time interval $[s, t]$ with initial condition $\xi^u_{s,s}(x) = x$. In the sequel we wish to discuss the behavior of (3.1) for each trajectory y of the observation process. We have already noted that there is a version of Z defined for every y. The results of Bismut [5] and Kunita [16] extend easily and show the map

$$\xi^u_{s,t}: R^d \to R^d$$

is, almost surely, for each $y \in C([0, T], R^m)$ a diffeomorphism. Bismut [5] initially gives proofs when the coefficients f and g are bounded, but points out that a stopping time argument extends the results to when, for example, the coefficients have linear growth.

Write $\|\xi^u(x_0)\|_t = \sup_{0\leqq x\leqq t} |\xi^u_{0,s}(x_0)|$. Then, as in Lemma 2.1 of [13], for any p, $1 \leqq p < \infty$, using Gronwall's and Jensen's inequalities,

$$\|\xi^u(x_0)\|^p_T \leqq C\left(1+|x_0|^p + \left|\int_0^t g(r, \xi^u_{0,r}(x_0))\,dw_r\right|^p\right)$$

almost surely, for some constant C.

Therefore, using Burkholder's inequality and hypothesis (A_3), $\|\xi^u(x_0)\|_T$ is in L^p for all p, $1 \leqq p < \infty$.

Suppose $u^* \in \underline{U}$ is an optimal control; then $J(u^*) \leqq J(u)$ for any other $u \in \underline{U}$. Write $\xi^*_{s,t}(\cdot)$ for $\xi^{u^*}_{s,t}(\cdot)$. The derivative $\partial\xi^*_{s,t}(x)/\partial x$ is the matrix solution C_t of the equation for $s \leqq t$,

$$dC_t = f_x(t, \xi^*_{s,t}(x), u^*)C_t\,dt + \sum_{i=1}^n g^{(i)}_x(t, \xi^*_{s,t}(x))C_t\,dw^i_t \quad \text{with } C_s = I. \tag{3.2}$$

Here I is the $n \times n$ identity matrix and $g^{(i)}$ is the ith column of g. From hypotheses (A_2) and (A_3), f_x and g_x are bounded. When we write $\|C\|_t = \sup_{0\leqq s\leqq t} |C_s|$, an application of Gronwall's, Jensen's, and Burkholder's inequalities again implies $\|C\|_T$ is in

L^p for all p, $1 \leqq p < \infty$. Consider the related matrix-valued stochastic differential equation

$$
\begin{aligned}
D_t = I - \int_s^t D_r f_x(r, \xi^*_{s,r}(x), u^*_r)' \, dr - \sum_{i=1}^n \int_s^t D_r g_x^{(i)}(r, \xi^*_{s,r}(x))' \, dw_r^i \\
+ \sum_{i=1}^n \int_s^t D_r (g_x^{(i)}(r, \xi^*_{s,r}(x))')^2 \, dr.
\end{aligned} \tag{3.3}
$$

Then it can be checked that $D_t C_t = I$ for $t \geqq s$, so that D_t is the inverse of the Jacobian, that is, $D_t = (\partial \xi^*_{s,t}(x)/\partial x)^{-1}$. Again, because f_x and g_x are bounded we have that $\|D\|_t$ is in every L^p, $1 \leqq p < \infty$.

For a d-dimensional semimartingale z_t Bismut [5] shows that $\xi^*_{s,t}(z_t)$ is well-defined and gives the semimartingale representation of this process. In fact if $z_t = z_s + A_t + \sum_{i=1}^n \int_s^t H_i \, dw_r^i$ is a d-dimensional semimartingale, Bismut's formula states that

$$
\begin{aligned}
\xi^*_{s,t}(z_t) = z_s + \int_s^t \left(f(r, \xi^*_{s,r}(z_r), u^*_r) + \sum_{i=1}^n g_x^{(i)}(r, \xi^*_{s,r}(z_r), u^*_r) \frac{\partial \xi^*_{s,r}}{\partial x}(z_r) H_i \right. \\
\left. + \frac{1}{2} \sum_{i=1}^n \frac{\partial^2 \xi^*_{s,r}(z_r)}{\partial x^2}(H_i, H_i) \right) dr \\
+ \int_s^t \frac{\partial \xi^*_{s,r}(z_r)}{\partial x} \, dA_r + \sum_{i=1}^n \int_s^t \left(g^{(i)}(r, \xi^*_{s,r}(z_r)) + \frac{\partial \xi^*_{s,r}}{\partial x}(z_r) H_i \right) dw_r^i.
\end{aligned} \tag{3.4}
$$

DEFINITION 3.1. We shall consider perturbations of the optimal control u^* of the following kind. For $s \in [0, T)$, $h > 0$ such that $0 \leqq s < s + h \leqq T$, for any other admissible control $\tilde{u} \in \mathcal{U}$ and $A \in Y_s$ define a strong variation of u^* by

$$
u(t, w) = \begin{cases} u^*(t, w) & \text{if } (t, w) \notin [s, s+h] \times A, \\ \tilde{u}(t, w) & \text{if } (t, w) \in [s, s+h] \times A. \end{cases}
$$

Applying (3.4) as in Theorem 5.1 of [7], we have the following result.

THEOREM 3.2. *For the perturbation u of the optimal control u^* consider the process*

$$
z_t = x + \int_s^t \left(\frac{\partial \xi^*_{s,r}(z_r)}{\partial x} \right)^{-1} (f(r, \xi^*_{s,r}(z_r), u_r) - f(r, \xi^*_{s,r}(z_r), u^*_r)) \, dr. \tag{3.5}
$$

Then the process $\xi^*_{s,t}(z_t)$ is indistinguishable from $\xi^u_{s,t}(x)$.

Proof. Note that the equation defining z_t involves only an integral in time; there is no martingale term, so to apply (3.4) we have $H_i = 0$ for all i. Therefore, from (3.4)

$$
\begin{aligned}
\xi^*_{s,t}(z_t) = x + \int_s^t f(r, \xi^*_{s,r}(z_r), u^*_r) \, dr \\
+ \int_s^t \left(\frac{\partial \xi^*_{s,r}(z_r)}{\partial x} \right) \left(\frac{\partial \xi^*_{s,r}(z_r)}{\partial x} \right)^{-1} (f(r, \xi^*_{s,r}(z_r), u_r) - f(r, \xi^*_{s,r}(z_r), u^*_r)) \, dr \\
+ \int_s^t g(r, \xi^*_{s,r}(z_r)) \, dw_r.
\end{aligned}
$$

However, the solution of (3.1) is unique so

$$
\xi^*_{s,t}(z_t) = \xi^u_{s,t}(x).
$$

Remark 3.3. Note that the perturbation $u(t)$ equals $u^*(t)$ if $t > s + h$ so $z_t = z_{s+h}$ if $t > s + h$ and

$$
\xi^*_{s,t}(z_t) = \xi^*_{s,t}(z_{s+h}) = \xi^*_{s+h,t}(\xi^u_{s,s+h}(x)).
$$

4. Augmented flows. Consider the augmented flow that includes as an extra coordinate the stochastic exponential $Z^*_{s,t}$ with a "variable" initial condition $z \in R$ for $Z^*_{s,s}(\cdot)$. That is, consider the $(d+1)$-dimensional system given by

$$\xi^*_{s,t}(x) = x + \int_s^t f(r, \xi^*_{s,r}(x), u^*_r)\, dr + \int_s^t g(r, \xi^*_{s,r}(x))\, dw_r,$$

$$Z^*_{s,t}(x, z) = z + \int_s^t Z^*_{s,r}(x, z) h(\xi^*_{s,r}(x))'\, dy_r.$$

Therefore, from the first equation in the proof of Lemma 2.3 we have

$$\begin{aligned} Z^*_{s,t}(x, z) &= z Z^*_{s,t}(x) \\ &= z \exp\left(\int_s^t h(\xi^*_{s,r}(x))'\, dy_r - \frac{1}{2} \int_s^t h(\xi^*_{s,r}(x))^2\, dr \right) \end{aligned}$$

and we see there is a version of the enlarged system defined for each trajectory y by integrating by parts the stochastic integral. The augmented map $(x, z) \to (\xi^*_{s,t}(x), Z^*_{s,t}(x, z))$ is then almost surely a diffeomorphism of R^{d+1}. Note that $\partial \xi^*_{s,t}(x)/\partial z = 0$, $\partial f/\partial z = 0$ and $\partial g/\partial z = 0$. The Jacobian of this augmented map is, therefore, represented by the matrix

$$\tilde{C}_t = \begin{pmatrix} \partial \xi^*_{s,t}(x)/\partial x & 0 \\ \partial Z^*_{s,t}(x, z)/\partial x & \partial Z^*_{s,t}(x, z)/\partial z \end{pmatrix},$$

and for $1 \leqq i \leqq d$ as in (3.2)

$$\begin{aligned} \frac{\partial Z^*_{s,t}(x, z)}{\partial x_i} = \sum_{j=1}^m \int_s^t \Bigg(& Z^*_{s,r}(x, z) \frac{\partial h^j(\xi^*_{s,r}(x))}{\partial \xi_k} \cdot \frac{\partial \xi^*_{k,s,r}(x)}{\partial x_i} \\ & + h^j(\xi^*_{s,r}(x)) \frac{dZ^*_{s,r}(x, z)}{\partial x_i} \Bigg)\, dy^j_r. \end{aligned} \tag{4.1}$$

(Here the double index k is summed from 1 to n.)

We shall be interested in the solution of this differential system (4.1) only in the situation when $z = 1$, so we shall write $Z^*_{s,t}(x)$ for $Z^*_{s,t}(x, 1)$. The following result is motivated by formally differentiating the exponential formula for $Z^*_{s,t}(x)$.

LEMMA 4.1.

$$\frac{\partial Z^*_{s,t}(x)}{\partial x} = Z^*_{s,t}(x) \left(\int_s^t h_x(\xi^*_{s,r}(x)) \cdot \frac{\partial \xi^*_{s,r}(x)}{\partial x} \cdot dv_r \right)$$

where $v = (v^1, \cdots, v^n)$ is the Brownian motion in the observation process.

Proof. From (4.1) we see $\partial Z^*_{s,t}(x)/\partial x$ is the solution of the stochastic differential equation

$$\frac{\partial Z^*_{s,t}(x)}{\partial x} = \int_s^t \left(\frac{\partial Z^*_{s,r}(x)}{\partial x} h'(\xi^*_{s,r}(x)) + Z^*_{s,r}(x) h_x(\xi^*_{s,r}(x)) \frac{\partial \xi^*_{s,r}(x)}{\partial x} \right) dy_r. \tag{4.2}$$

Write

$$L_{s,t}(x) = Z^*_{s,t}(x) \left(\int_s^t h_x \cdot \frac{\partial \xi^*_{s,r}}{\partial x} \cdot dv_r \right)$$

where

$$dy_r = h(\xi^*_{s,t}(x))\, dt + dv_t.$$

Because

$$Z^*_{s,t}(x) = 1 + \int_s^t Z^*_{s,r}(x) h'(\xi^*_{s,r}(x))\, dy_r$$

the product rule gives

$$\begin{aligned} L_{s,t}(x) &= \int_s^t Z^*_{s,r}(x) h_x \cdot \frac{\partial \xi^*_{s,r}}{\partial x}\, dv_r + \int_s^t \left(\int_s^r h_x \cdot \frac{\partial \xi^*_{s,\sigma}}{\partial x} \cdot dv_\sigma \right) Z^*_{s,r}(x) h'(\xi^*_{s,r}(x))\, dy_r \\ &\quad + \int_s^t Z^*_{s,r}(x) h'(\xi^*_{s,r}(x)) \cdot h_x \cdot \frac{\partial \xi^*_{s,r}}{\partial x}\, dr \\ &= \int_s^t L_{s,r}(x) h'(\xi^*_{s,r}(x))\, dy_r + \int_s^t Z^*_{s,r}(x) h_x \cdot \frac{\partial \xi^*_{s,r}}{\partial x} \cdot dy_r. \end{aligned}$$

Therefore, $L_{s,t}(x)$ is also a solution of (4.2), so by uniqueness

$$L_{s,t}(x) = \frac{\partial Z^*_{s,t}(x)}{\partial x}.$$

Remark 4.2. As noted at the beginning of this section we can consider the augmented flow

$$(x, z) \to (\xi^*_{s,t}(x), Z^*_{s,t}(x, z)) \quad \text{for } x \in R^d,\ z \in R,$$

and we are only interested in the situation when $z = 1$, so we write $Z^*_{s,t}(x)$.

LEMMA 4.3. *$Z^*_{s,t}(z_t) = Z^u_{s,t}(x)$ where z_t is the semimartingale defined in* (3.6).

Proof. $Z^u_{s,t}(x)$ is the process uniquely defined by

$$Z^u_{s,t}(x) = 1 + \int_s^t Z^u_{s,r}(x) h'(\xi^u_{s,r}(x))\, dy_r. \tag{4.3}$$

Consider an augmented $(d+1)$-dimensional version of (3.5) defining a semimartingale $\bar{z}_t = (z_t, 1)$, so the additional component is always identically one. Then applying (3.4) to the new component of the augmented process, we have

$$\begin{aligned} Z^*_{s,r}(z_r) &= 1 + \int_s^t Z^*_{s,r}(z_r) h'(\xi^*_{s,r}(z_r))\, dy_r \\ &= 1 + \int_s^t Z^*_{s,r}(z_r) h'(\xi^u_{s,r}(x))\, dy_r \end{aligned}$$

by Theorem 3.2. However, (4.3) has a unique solution so $Z^*_{s,t}(z_t) = Z^u_{s,t}(x)$.

Remark 4.4. Note that for $t > s + h$

$$Z^*_{s,t}(z_t) = Z^*_{s,t}(z_{s+h}).$$

5. The minimum principle. Control u will be the perturbation of the optimal control u^* as in Definition 3.1. We shall write $x = \xi^*_{0,s}(x_0)$. Then the minimum cost is

$$\begin{aligned} J(u^*) &= E[Z^*_{0,T}(x_0) c(\xi^*_{0,T}(x_0))] \\ &= E[Z^*_{0,s}(x_0) Z^*_{s,T}(x) c(\xi^*_{s,T}(x))]. \end{aligned}$$

The cost corresponding to the perturbed control u is

$$\begin{aligned} J(u) &= E[Z^*_{0,s}(x_0) Z^u_{s,T}(x) c(\xi^u_{s,T}(x))] \\ &= E[Z^*_{0,s}(x_0) Z^*_{s,T}(z_{s+h}) c(\xi^*_{s,T}(z_{s+h}))] \end{aligned}$$

by Theorem 3.2 and Lemma 4.3. Now $Z^*_{s,T}(\cdot)$ and $c(\xi^*_{s,T}(\cdot))$ are almost surely differentiable with continuous derivatives and z_t, given by (3.5), is absolutely continuous. Therefore,

$$J(u)-J(u^*)=E[Z^*_{0,s}(x_0)(Z^*_{s,T}(z_{s+h})c(\xi^*_{s,T}(z_{s+h}))-Z^*_{s,T}(x)c(\xi^*_{s,T}(x)))]$$
$$=E\left[\int_s^{s+h}\Gamma(s,z_r)(f(r,\xi^*_{s,r}(z_r),u^*_r)-f(r,\xi^*_{s,r}(x),u^*_r))\,dr\right]$$

where by Lemma 4.1

$$\Gamma(s,z_r)=Z^*_{0,s}(x_0)Z^*_{s,T}(z_r)\left\{c_\xi(\xi^*_{s,T}(z_r))\frac{\partial\xi^*_{s,T}(z_r)}{\partial x}\right.$$
$$\left.+c(\xi^*_{s,T}(z_r))\left(\int_s^T h_\xi(\xi^*_{s,\sigma}(z_r))\frac{\partial\xi^*_{s,\sigma}}{\partial x}(z_r)\,dv_\sigma\right)\right\}\left(\frac{\partial\xi^*_{s,r}}{\partial x}(z_r)\right)^{-1}.$$

Note that this expression gives an explicit formula for the change in the cost resulting from a variation in the optimal control. The only remaining problem is to justify differentiating the right-hand side.

From Lemma 2.3, Z is in every L^p space, $1\leqq p<\infty$, and from the remarks at the beginning of § 3, $C_T=\partial\xi^*_{s,T}/\partial x$ and $D_T=(\partial\xi^*_{s,T}/\partial x)^{-1}$ are in every L^p space, $1\leqq p<\infty$. Consequently, Γ is in every L^p space, $1\leqq p<\infty$.

Therefore,

$$J(u)-J(u^*)=\int_s^{s+h}E[(\Gamma(s,z_r)-\Gamma(s,x))(f(r,\xi^*_{s,r}(z_r),u_r)-f(r,\xi^*_{s,r}(z_r),u^*_r))]\,dr$$
$$+\int_s^{s+h}E[(\Gamma(s,x)-\Gamma(r,x))(f(r,\xi^*_{s,r}(z_r),u_r)-f(r,\xi^*_{s,r}(z_r),u^*_r))]\,dr$$
$$+\int_s^{s+h}E[\Gamma(r,x)(f(r,\xi^*_{s,r}(z_r),u_r)-f(r,\xi^*_{s,r}(z_r),u^*_r)$$
$$-f(r,\xi^*_{s,r}(x),u_r)+f(r,\xi^*_{s,r}(x),u^*_r))]\,dr$$
$$+\int_s^{s+h}E[\Gamma(r,x)(f(r,\xi^*_{0,r}(x_0),u_r)-f(r,\xi^*_{0,r}(x_0),u^*_r))]\,dr$$
$$=I_1(h)+I_2(h)+I_3(h)+I_4(h),\quad\text{say.}$$

Now,

$$|I_1(h)|\leqq K_1\int_s^{s+h}E[|\Gamma(s,z_r)-\Gamma(s,x)|(1+\|\xi^u(x_0)\|_{s+h})]\,dr$$
$$\leqq K_1h\sup_{s\leqq r\leqq s+h}E[|\Gamma(s,z_r)-\Gamma(s,x)|(1+\|\xi^u(x_0)\|_{s+h})],$$
$$|I_2(h)|\leqq K_2\int_s^{s+h}E[|\Gamma(s,x)-\Gamma(r,s)|(1+\|\xi^u(x_0)\|_{s+h})]\,dr$$
$$\leqq K_2h\sup_{s\leqq r\leqq s+h}E[|\Gamma(s,x)-\Gamma(r,x)|(1+\|\xi^u(x_0)\|_{s+h})],$$
$$|I_3(h)|\leqq K_3\int_s^{s+h}E[|\Gamma(r,x)|\,\|\xi^*_{s,r}(z_r)-\xi^*_{s,r}(x)\|]\,dr$$
$$\leqq K_3h\sup_{s\leqq r\leqq s+h}E[|\Gamma(r,x)|\,\|\xi^u_{s,\cdot}(x)-\xi^*_{s,\cdot}(x)\|_{s+h}].$$

The differences $|\Gamma(s, z_r)-\Gamma(s, x)|$, $|\Gamma(s, x)-\Gamma(r, x)|$ and $\|\xi^u_{s,\cdot}(x)-\xi^*_{s,\cdot}(x)\|_{s+h}$ are all uniformly bounded in some L^p, $p \geqq 1$, and

$$\lim_{r\to s} |\Gamma(s, z_r)-\Gamma(s, x)| = 0 \quad \text{a.s.},$$

$$\lim_{r\to s} |\Gamma(s, x)-\Gamma(r, x)| = 0 \quad \text{a.s.},$$

$$\lim_{h\to 0} \|\xi^u_{s,\cdot}(x)-\xi^*_{s,\cdot}(x)\|_{s+h} = 0.$$

Therefore,

$$\lim_{r\to s} \|\Gamma(s, z_r)-\Gamma(s, x)\|_p = 0,$$

$$\lim_{r\to s} \|\Gamma(s, x)-\Gamma(r, x)\|_p = 0, \quad \text{and}$$

$$\lim_{h\to 0} \|(\|\xi^u_{s,\cdot}(x)-\xi^*_{s,\cdot}(x)\|_{s+h})\|_p = 0 \quad \text{for some } p.$$

Consequently, $\lim_{h\to 0} h^{-1} I_k(h) = 0$, for $k = 1, 2, 3$.

The only remaining problem concerns the differentiability of

$$I_4(h) = \int_s^{s+h} E[\Gamma(r, x)(f(r, \xi^*_{0,r}(x_0), u_r)-f(r, \xi^*_{0,r}(x_0), u^*_r))]\, dr.$$

The integrand is almost surely in $L^1([0, T])$ so $\lim_{h\to 0} h^{-1} I_4(h)$ exists for almost every $s \in [0, T]$. However, the set of times $\{s\}$ where the limit may not exist might depend on the control u. Consequently we must restrict the perturbations u of the optimal control u^* to perturbations from a countable dense set of controls. In fact:

(1) Because the trajectories are, almost surely, continuous, Y_ρ is countably generated by sets $\{A_{i\rho}\}$, $i = 1, 2, \cdots$ for any rational number $\rho \in [0, T]$. Consequently, Y_t is countably generated by the sets $\{A_{i\rho}\}$, $\rho \leqq t$.

(2) Let G_t denote the set of measurable functions from (Ω, Y_t) to $U \subset R^k$. (If $u \in \underline{U}$ then $u(t, w) \in G_t$.) Using the L^1-norm, as in [8], there is a countable dense subset $H_\rho = \{u_{j\rho}\}$ of G_ρ, for rational $\rho \in [0, T]$. If $H_t = \bigcup_{\rho \leqq t} H_\rho$ then H_t is a countable dense subset of G_t. If $u_{j\rho} \in H_\rho$ then, as a function constant in time, $u_{j\rho}$ can be considered as an admissible control over the time interval $[t, T]$ for $t \geqq \rho$.

(3) The countable family of perturbations is obtained by considering sets $A_{i\rho} \in Y_t$, functions $u_{j\rho} \in H_t$, where $\rho \leqq t$, and defining as in (3.1) the following:

$$u^*_{j\rho}(s, w) = \begin{cases} u^*(s, w) & \text{if } (s, w) \notin [t, T] \times A_{i\rho}, \\ u_{j\rho}(s, w) & \text{if } (s, w) \in [t, T] \times A_{i\rho}. \end{cases}$$

Then for each i, j, ρ

$$\lim_{h\to 0} h^{-1} \int_s^{s+h} E[\Gamma(r, x)(f(r, \xi^*_{0,r}(x_0), u^*_{j\rho})-f(r, \xi^*_{0,r}(x_0), u^*))]\, dr \tag{5.1}$$

exists and equals

$$E[\Gamma(s, x)(f(s, \xi^*_{0,s}(x_0), u_{j\rho})-f(s, \xi^*_{0,s}(x_0), u^*)) I_{A_{i\rho}}]$$

for almost all $s \in [0, T]$. Therefore, considering this perturbation we have

$$\lim_{h\to 0} h^{-1}(J(u^*_{j\rho})-J(u^*)) = E[\Gamma(s, x)(f(s, \xi^*_{0,s}(x_0), u_{j\rho})-f(s, \xi^*_{0,s}(x_0), u^*)) I_{A_{i\rho}}]$$

$$\geqq 0 \quad \text{for almost all } s \in [0, T].$$

Consequently there is a set $S \subset [0, T]$ of zero Lebesgue measure such that, if $s \notin S$, the limit in (5.1) exists for all i, j, ρ, and gives

$$E[\Gamma(s, x)(f(s, \xi^*_{0,s}(x_0), u_{j\rho}) - f(s, \xi^*_{0,s}(x_0), u^*))I_{A_{i\rho}}] \geqq 0.$$

Using the monotone class theorem, and approximating an arbitrary admissible control $u \in \underline{U}$, we can deduce that if $s \notin S$, then

$$E[\Gamma(s, x)(f(s, \xi^*_{0,s}(x_0), u) - f(s, \xi^*_{0,s}(x_0), u^*))I_A] \geqq 0 \quad \text{for any } A \in Y_s. \tag{5.2}$$

Write

$$p_s(x) = E^*\left[c_\xi(\xi^*_{0,T}(x_0)) \frac{\partial \xi^*_{s,T}(x)}{\partial x} + c(\xi^*_{0,T}(x_0))\left(\int_s^T h_\xi(\xi^*_{0,\sigma}(x_0)) \frac{\partial \xi^*_{s,\sigma}(x)}{\partial x}\, dv_\sigma \right) \middle| \, Y_s \vee \{x\} \right]$$

where, as before, $x = \xi^*_{0,s}(x_0)$ and E^* denotes expectation under $P^* = P^{u^*}$. Then $p_s(x)$ is the co-state variable and we have in (5.2) proved the following "conditional" minimum principle.

THEOREM 5.1. *If $u^* \in \underline{U}$ is an optimal control there is a set $S \subset [0, T]$ of zero Lebesgue measure such that if $s \notin S$*

$$E^*[p_s(x)f(s, x, u^*) \mid Y_s] \geqq E^*[p_s(x)f(s, x, u) \mid Y_s] \quad a.s.$$

That is, the optimal control u^* almost surely minimizes the conditional Hamiltonian and the adjoint variable is $p_s(x)$.

6. Stochastic open loop controls. We shall again suppose the state of the system is described by a stochastic differential equation

$$d\xi_t = f(t, \xi_t, u)\, dt + g(t, \xi_t)\, dw_t, \qquad \xi_t \in R^d, \quad \xi_0 = x_0, \quad 0 \leqq t \leqq T \tag{6.1}$$

where x_0, f, and g satisfy the same assumptions A_1, A_2, and A_3 as in § 2.

Suppose $w = (w^1, \cdots, w^n)$ is an n-dimensional Brownian motion on a probability space (Ω, F, P), with a right continuous complete filtration $\{F_t\}$, $0 \leqq t \leqq T$. Rather than controls depending on some observation process y we now consider controls that depend on the "noise process" w. These are sometimes called "stochastic open loop" controls [4].

DEFINITION 6.1. The set of admissible controls $\underline{V}$ will be the F_t-predictable functions on $[0, T] \times \Omega$ with values in a compact subset V of some Euclidean space R^k.

Remark 6.2. For each $u \in \underline{V}$ there is, therefore, a strong solution of (6.1) and we shall write $\xi^u_{s,t}(x)$ for the solution trajectory given by

$$\xi^u_{s,t}(x) = x + \int_s^t f(r, \xi^u_{s,r}(x), u_r)\, dr + \int_s^t g(r, \xi^u_{s,r}(x))\, dw_r. \tag{6.2}$$

Again, because u is a (predictable) parameter the results of [2], [5], or [16] extend to this situation, so the derivative $\partial \xi^u_{s,t}/\partial x(x) = C^u_{s,t}$ exists and is the solution of

$$C^u_{s,t} = I + \int_s^t f_\xi(r, \xi^u_{s,r}(x), u_r) C^u_{s,r}\, dr + \sum_{k=1}^n \int_s^t g^{(k)}_\xi(r, \xi^u_{s,r}(x)) C^u_{s,r}\, dw^k_r. \tag{6.3}$$

Suppose $D^u_{s,t}$ is the matrix-valued process defined by

$$\begin{aligned} D^u_{s,r} = I &- \int_s^t D^u_{s,t}\left(f_\xi(r, \xi^u_{s,r}(x), u_r) - \sum_{k=1}^n g^{(k)}_\xi(r, \xi^u_{s,r}(x))^2 \right) dr \\ &- \sum_{k=1}^n \int_s^t D^u_{s,r} g^{(k)}_\xi(r, \xi^u_{s,r}(x))\, dw^k_r. \end{aligned} \tag{6.4}$$

Using the Itô rule as in § 3 we see that $d(D^u_{s,t}C^u_{s,t})=0$ and $D^u_{s,s}C^u_{s,s}=I$, so

$$D^u_{s,t}=(C^u_{s,t})^{-1}.$$

As before, if

$$\|\xi^u(x_0)\|_t=\sup_{0\leqq s\leqq t}|\xi^u_{0,s}(x_0)|,$$

$$\|C^u\|_T=\sup_{0\leqq s\leqq T}|C^u_{0,s}|,\qquad \|D^u\|_T=\sup_{0\leqq s\leqq T}|D^u_{0,s}|,$$

then applications of Gronwall's, Jensen's, and Burkholder's inequalities imply that

$$\|\xi^u(x_0)\|_k,\quad \|C^u\|_T,\quad \text{and}\quad \|D^u\|_T$$

are in L^p for all p, $1\leqq p<\infty$.

Cost 6.3. As in § 2, we shall suppose the cost is purely terminal and given by a bounded C^2 function

$$c(\xi^u_{0,T}(x_0)).$$

Furthermore, we shall assume

$$|c(x)|+|c_x(x)|+|c_{xx}(x)|\leqq K_3(1+|x|^q)$$

for some $q<\infty$.

The expected cost if a control $u\in\underline{V}$ is used, therefore, is

$$J(u)=E[c(\xi^u_{0,T}(x_0))].$$

Suppose there is an optimal control $u^*\in\underline{V}$ so that

$$J(u^*)\leqq J(u)\quad \text{for all } u\in\underline{V}.$$

Notation 6.4. If u^* is an optimal control, write ξ^* for ξ^{u^*}, C^* for C^{u^*}, etc.

DEFINITION 6.5. Consider perturbations of u^* of the following kind. For $s\in[0,T]$, $h>0$ such that $0\leqq s<s+h\leqq T$ and $A\in F_s$ define, for any other $\tilde{u}\in\underline{V}$, a strong variation of u^* by

$$u(t,w)=\begin{cases}u^*(t,w) & \text{if } (t,w)\notin[s,s+h]\times A,\\ \tilde{u}(t,w) & \text{if } (t,w)\in[s,s+h]\times A.\end{cases}$$

The following result is established exactly as Theorem 3.2.

THEOREM 6.6. *For any perturbation u of u^* consider the process*

$$z_r=x+\int_s^t\left(\frac{\partial\xi^*_{s,r}}{\partial x}(z_r)\right)^{-1}(f(r,\xi^*_{s,r}(z_r),u_r)-f(r,\xi^*_{s,r}(z_r),u^*_r))\,dr. \tag{6.5}$$

Then the process $\xi^*_{s,t}(z_t)$ is indistinguishable from $\xi^u_{s,t}(x)$.

Note if $t>s+h$, $\xi^*_{s,t}(z_t)=\xi^*_{s,t}(z_{s+h})=\xi^*_{s+h,t}(\xi^u_{s,s+h}(x))$.

7. An open loop minimum principle. Now

$$\begin{aligned}J(u^*)&=E[c(\xi^*_{0,T}(x_0))]\\&=E[c(\xi^*_{s,T}(x))]\end{aligned}$$

where $x=\xi^*_{0,s}(x_0)$.

Similarly,

$$\begin{aligned}J(u)&=E[c(\xi^u_{0,T}(x_0))]\\&=E[c(\xi^u_{s,T}(x))]\\&=E[c(\xi^*_{s,T}(z_{s+h}))].\end{aligned}$$

Therefore,

$$J(u)-J(u^*)=E[c(\xi^*_{s,T}(z_{s+h}))-c(\xi^*_{s,T}(x))].$$

Because $\xi^*_{s,T}(\cdot)$ is differentiable this is

$$= E\left[\int_s^{s+h} c_\xi(\xi^*_{s,T}(z_r))\frac{\partial \xi^*_{s,T}}{\partial x}(z_r)\cdot\left(\frac{\partial \xi^*_{s,r}}{\partial x}(z_r)\right)^{-1}(f(r,\xi^*_{s,r}(z_r),u_r) - f(r,\xi^*_{s,r}(z_r),u^*_r))\,dr\right]. \tag{7.1}$$

As in § 5, this gives an explicit formula for the change in the cost resulting from a "strong variation" in the optimal stochastic open loop control. It involves a time integration over $[s, s+h]$ and, again, the only remaining problem is to justify the differentiation of the right-hand side of (7.1).

Write

$$\Gamma(s,r,z_r)=c_\xi(\xi^*_{s,T}(z_r))\frac{\partial \xi^*_{s,T}}{\partial x}(z_r)\left(\frac{\partial \xi^*_{s,r}}{\partial x}(z_r)\right)^{-1}$$

and

$$\begin{aligned} p_s(x) &= E\left[c_\xi(\xi^*_{0,T}(x_0))\frac{\partial \xi^*_{s,T}}{\partial x}(x)\,|\,F_s\right] \\ &= E[\Gamma(s,s,x)\,|\,F_s], \end{aligned} \tag{7.2}$$

where, as above, $x=\xi^*_{0,s}(x_0)$.

Then arguments similar to those of § 5—but in fact simpler because Z is not involved—enable us to show that there is a set $S\subset[0,T]$ of zero Lebesque measure such that if $s\notin S$,

$$E[\Gamma(s,s,x)(f(s,\xi^*_{0,s}(x_0),u)-f(s,\xi^*_{0,s}(x_0),u^*))I_A]\geqq 0$$

for any $u\in V$ and $A\in F_s$.

That is, in terms of the adjoint variable $p_s(x)$ we have the following minimum principle for stochastic open loop controls.

THEOREM 7.1. *If $u^*\in V$ is an optimal stochastic open loop control there is a set $S\subset[0,T]$ of zero Lebesgue measure such that if $s\notin S$*

$$p_s(x)f(s,x,u^*)\leqq p_s(x)f(s,x,u)\quad a.s.$$

for all $u\in V$. That is, the optimal control u^* almost surely minimizes the Hamiltonian with adjoint variable $p_s(x)$.

Remark 7.2. Under certain conditions the minimum cost attainable under the stochastic open loop controls is equal to the minimum cost attainable under the Markov feedback controls of the form $u(s,\xi^u_{0,s}(x_0))$. See for example [3], [12]. If u_M is a Markov control, with a corresponding, possibly weak, solution trajectory ξ^{u_M}, then u_M can be considered as a stochastic open loop control $u_M(w)$ by putting

$$u_M(w)=u_M(s,\xi^{u_M}_{0,s}(x_0,w)).$$

This means the control in effect "follows" its original trajectory ξ^{u_M} rather than any new trajectory. That is, the control is similar to the adjoint strategies considered by Krylov [15]. The significance of this is that when we consider variations in the state trajectory ξ, and derivatives of the map $x\to\xi_{s,t}(x)$, the control does not react, and so we do not introduce derivatives in the u variable.

If the optimal control u^* is the Markov, then the process ξ^* is Markov and

$$\begin{aligned} p_s(x) &= E[\Gamma(s, s, x) \mid F_s] \\ &= E[\Gamma(s, s, x) \mid x]. \end{aligned} \tag{7.3}$$

8. The adjoint process. Suppose the optimal stochastic open loop control u^* is Markov. The Jacobian $\partial \xi^*_{s,T}/\partial x$ exists, as does $(\partial \xi^*_{s,T}/\partial x)^{-1}$ and higher derivatives.

THEOREM 8.1. *Suppose the optimal control u^* is Markov. Then*

$$\begin{aligned} p_s(x) = E[c_\xi(\xi^*_{0,T}(x_0))C_{0,t}] &- \int_0^s p_r(\xi^*_{0,r}(x_0)) f_\xi(r, \xi^*_{0,r}(x_0), u^*_r)\, dr \\ &+ \int_0^s p_x(r, \xi^*_{0,r}(x_0)) g(r, \xi^*_{0,r}(x_0))\, dw_r \\ &- \int_0^s p_x(r, \xi^*_{0,r}(x_0)) g(r, \xi^*_{0,r}(x_0)) g_\xi(r, \xi^*_{0,r}(x_0))\, dr. \end{aligned}$$

Proof. Write $f_\xi(r)$ for $f_\xi(r, \xi^*_{0,r}(x_0), u^*_r)$ and $g(r)$ for $g(r, \xi^*_{0,r}(x_0))$, etc. By uniqueness of the solutions to (6.1)

$$\xi^*_{0,T}(x_0) = \xi^*_{s,T}(\xi^*_{0,s}(x_0)) \tag{8.1}$$

so, differentiating,

$$C_{0,T} = C_{s,T} C_{0,s} \tag{8.2}$$

where $C_{0,T} = C^*_{0,T}$, etc. (without the *).

From (7.2) and (7.3)

$$p_s(x) = E[c_\xi(\xi^*_{0,T}(x_0))C_{s,T} \mid F_s],$$

so from (8.2)

$$p_s(x)C_{0,s} = E[c_\xi(\xi^*_{0,T}(x_0))C_{0,T} \mid F_s], \tag{8.3}$$

and this is a $(P, \{F_t\})$ martingale. Write $x = \xi^*_{0,s}(x_0)$, $C = C_{0,s}$. From the martingale representation result [10], the integrand in the representation of $p_s(x)C$ as a stochastic integral is obtained by the Itô rule, noting that only the stochastic integral terms will appear. These involve the derivatives in x and C. In fact, by considering the system $\bar{\xi}_{0,t}$ with components $\xi^*_{0,t}$ and $C_{0,t}$ and any real C^2 function Φ, the martingale

$$\begin{aligned} M_s &= E[\Phi(\bar{\xi}_{0,T} \mid F_s] = E[\Phi(\bar{\xi}_{0,T}) \mid x, C] = V(s, x, C) \\ &= V(0, x_0, I) + \int_0^s V_x(r, \xi^*_{0,r}(x_0), C_{0,r}) g(r)\, dw_r \\ &\quad + \sum_{k=1}^n \int_0^s V_C(r, \xi^*_{0,r}(x_0), C_{0,r}) g^{(k)}_\xi(r) C_{0,r}\, dw^k_r. \end{aligned}$$

Therefore, for the vector martingale (8.3)

$$\begin{aligned} p_s(x)C = E[c_\xi(\xi_{0,T}(x_0))C_{0,T}] &+ \int_0^s p_x(r, \xi^*_{0,r}(x_0)) g(r)\, dw_r C_{0,r} \\ &+ \sum_{k=1}^n \int_0^s p_r(\xi^*_{0,r}(x_0)) g^{(k)}_\xi(r) C_{0,r}\, dw^k_r. \end{aligned} \tag{8.4}$$

Recall that $D_{0,s} = C^{-1}$, so forming the product of (6.4) and (8.4) by using the Itô rule, we have

$$
\begin{aligned}
p_s(x) &= (p_x(x)C)D_{0,s} \\
&= E[c_\xi(\xi^*_{0,T}(x_0))C_{0,T}] - \int_0^s p_r(\xi^*_{0,r}(x_0))f_\xi(r)\,dr \\
&\quad - \sum_{k=1}^n \int_0^s p_r(\xi^*_{0,r}(x_0))g^{(k)}_\xi(r)\,dw^k_r + \sum_{k=1}^n \int_0^s p_r(\xi^*_{0,r}(x_0))(g^{(k)}_\xi(r))^2\,dr \\
&\quad + \int_0^s p_x(r, \xi^*_{0,r}(x_0))g(r)\,dw_r + \sum_{k=1}^n \int_0^s p_r(\xi^*_{0,r}(x_0))g^{(k)}_\xi(r)\,dw^k_r \\
&\quad - \sum_{k=1}^n \int_0^s p_x(r, \xi^*_{0,r}(x_0))g(r)g^{(k)}_\xi(r)\,dr - \sum_{k=1}^n \int_0^s p_r(\xi^*_{0,r}(x_0))(g^{(k)}_\xi(r))^2\,dr \\
&= E[c_\xi(\xi^*_{0,T}(x_0))C_{0,T}] - \int_0^s p_r(\xi^*_{0,T}(x_0))f_\xi(r)\,dr \\
&\quad + \int_0^s p_x(r, \xi^*_{0,r}(x_0))g(r)\,dw_r - \sum_{k=1}^n \int_0^s p_x(r, \xi^*_{0,r}(x_0))g(r)g^{(k)}_\xi(r)\,dr,
\end{aligned}
$$

thus establishing the result.

This verifies by a simple, direct method the formula of Haussmann [12] without any requirement that the diffusion coefficient matrix gg^* is nonsingular. However we do not identify $p_s(x)$ with the gradient of the minimum cost process; this follows from arguments as in [12].

9. Conclusion. Using the theory of stochastic flows the effect of a perturbation of an optimal control is explicitly calculated in both the partially observed and stochastic open loop cases. The only difficulty is to justify the differentiation. The adjoint variable $p_s(x)$ is explicitly identified.

THEOREM 9.1. *If f is differentiable in the control variable u, and if the random variable $x = \xi^*_{0,s}(x_0)$ has a conditional density $q_s(x)$ under the measure P^*, then the inequality of Theorem* 5.1 *implies*

$$
\sum_{j=1}^k (u_j(x) - u^*_j(s)) \int_{R^d} \Gamma(s, x) \frac{\partial f}{\partial u_j}(s, x, u^*) q_s(x)\,dx \geqq 0.
$$

This is the result of Bensoussan's paper [1].

OPTIMAL AND APPROXIMATELY OPTIMAL CONTROL POLICIES FOR QUEUES IN HEAVY TRAFFIC*

HAROLD J. KUSHNER†‡ AND K. M. RAMACHANDRAN†§

Abstract. The "approximately" optimal control problem for tandem queueing or production networks (with local feedback allowed) under heavy traffic is treated. The buffers (scaled with traffic) are finite. The controls allow various inputs, connecting links, and the processors to be shut down or opened to manage the system. The service and arrival rates, as well as the routing probabilities, can also be controlled, and the system statistics can depend on the system state (scaled buffer occupancies). The associated costs involve holding costs, costs for shutting off/turning on the links or processors and the opportunity cost for lost production. It is shown that the (scaled) controlled system converges weakly (in an appropriate sense) to a controlled limit "reflected" diffusion. In the rescaled time, the actions of the controllers lead to multiple "simultaneous" impulses in the limit problem. Thus a nonstandard limit control problem is obtained, and the usual methods of weak convergence for systems under heavy traffic must be modified. Since it is usually not possible to obtain the optimal or nearly optimal controls for the physical process, it is of considerable interest to know whether an optimal or nearly optimal control for the limit process is also nearly optimal for the physical system with heavy traffic. This is shown to be true under reasonable conditions. Although the limit control problem is nonstandard and there is little available theory concerning it, acceptable numerical procedures are available.

Key words. weak convergence, queueing networks, production networks, heavy traffic approximations, controlled reflected diffusions, controlled queueing networks, approximately optimal stochastic controls, numerical methods for stochastic control

AMS(MOS) subject classifications. 93E20, 93E25, 90B22, 60F17, 60K25

1. Introduction.

We consider optimal and "nearly optimal" control problems for the open queueing networks in heavy traffic of the type dealt with in the fundamental papers of Reimann [1] and Harrison [2], [3]. Owing to the state and control dependence of the processes here, much of their methodology cannot be carried over. One of the main motivations behind the heavy traffic approximations [1]-[4] of queueing networks is the idea that the limit process is usually much easier to analyze than the actual physical process, and that it is much easier to find good control policies for the limit.

In [1], there are several interconnected service or processing stations, and at each there is an infinite buffer (ours is finite, but suitably scaled). At each there are possible arrivals from outside the network as well as arrivals routed from other service stations. Eventually with probability one (w.p.1) all customers leave the network. Under reasonable conditions on the interarrival and service times and with appropriate spatial and temporal normalizations, in the heavy traffic case the vector of the normalized queue lengths converges weakly to a reflected Brownian motion with constant drift and covariance parameters [1]. This will be generalized here in several directions, although we work with a somewhat simpler network structure.

Although it underlies much of the motivation for the limit theorems, there has been little work on the usefulness of the limit process for purposes of getting a good

or nearly optimum control for the physical process. Let ε index the traffic intensity. As $\varepsilon \to 0$, the "intensity" goes to one. For whatever cost criterion is used (this will be defined in later sections), let $V^\varepsilon(\pi)$ denote its value for the physical system when a policy π is used. Suppose that $\bar{\pi}^\varepsilon$ is an "adaptation" of the optimal or δ-optimal policy for the limit, applied to the physical process. (We will say more about such adaptations later.) For $\bar{\pi}^\varepsilon$ to be a "good" policy for the physical process we need at least that $V^\varepsilon(\bar{\pi}^\varepsilon) - \inf_\pi V^\varepsilon(\pi)$ be small for small ε, where the inf is over an appropriate set of policies for the physical process. This is the problem addressed here. In the course of the development, a number of interesting and nonclassical problems arise; for example, the appropriate "limit" control problem might involve multiple "simultaneous" impulses, and we must treat state-dependent service, arrival, and routing processes.

We choose a problem formulation that illustrates the main problems and allows the development of a method that applies to many other formulations. Our work differs from earlier work in several important respects. If the service or arrival rates can be controlled, then the limit process is no longer a reflected Brownian motion with constant coefficients. Owing to the control, there might be "travel" along the boundaries of the state space. Some control actions (e.g., on/off controls with associated impulsive costs) might yield a sequence of paths that do not converge in the Skorokhod topology, but there still is a meaningful sense in which the limit is a well-defined impulsively controlled process, perhaps with "multiple simultaneous impulses." The lumping together of all idle times as done in equation (3) of [1] in the $B_k(t)$ argument is a very slick idea, but it is inappropriate in our context owing to the state and control dependencies. We must show that the "limit" controls and other quantities are "admissible," or nonanticipative with respect to the limit Brownian motions. In fact, we combine the ideas of [1] with those of the martingale method and the weak convergence techniques of [5] and [6].

The present work is a continuation of the lines of development in [6]–[8] where approximations to other optimal control problems are dealt with.

In § 2, the basic system is described, the control problem is defined and the assumptions are stated. To avoid some quite complicated bookkeeping, we eventually specialize to the case where there are only two processors and feedback is only allowed from a processor to itself. The general results can be readily extended to problems where (except for the possibility of rerouting an output back to the input of the same processor), the flow is all "forward." In § 3, we discuss representations for the processes that facilitate the weak convergence analysis, and in § 4 we describe the proper "limit" control problem; i.e., the appropriate controlled reflected diffusion whose optimal (or δ-optimal) controls are to be used for the physical process.

Section 5 contains the basic weak convergence results, and we state and prove the results concerning the "almost optimality" of the δ-optimal (for small δ) controls for the limit process, when applied to the physical process. Some computational questions are discussed in § 6. Although the "limit" control problem is not always simple, effective and convenient numerical methods are available. Reference [10] contains an analysis of the dynamic programming equation for a one-dimensional version of the limit problem.

2. Problem description and assumptions. We start by describing a network with K service stations (processors), the ith referred to as P_i. Each processor services only one customer at a time, although batch or multiserver cases can all be handled. Shortly, we specialize to the case $K = 2$, but it is simpler to first use a unified terminology. We

retain the basic structure of [1], but use a discrete time parameter for notational simplicity. Each processor can be connected to an external input as well as receive (and deliver) outputs from (to) other processors.

Let $\{\alpha_n^{i,\varepsilon}\}$ denote the sequence of interarrival times of the customers coming to P_i from the exterior of the network, and let $\xi_n^{i,\varepsilon}$ denote the indicator of the event that there was an arrival from the exterior to P_i at time n. We use the convenient representation (as in [11]) where the processor keeps processing even if the queue is empty, with the "errors" generated by this convention accounted for by an added reflection term. With this convention in mind, let $\{\Delta_n^{i,\varepsilon}\}$ denote the sequence of service times for P_i, and $\psi_n^{i,\varepsilon}$ the indicator of the event that a service at P_i is completed at time n (whether or not there are actual "physical" customers in P_i at that time). As in [11], we suppose that if there is an arrival to P_i in the midst of a service interval when the queue at P_i is empty, then the actual service time for that customer is just the residual service time for the current service interval. Under the heavy traffic assumption, this does not affect the limit formulas. An outline of the proof is in the Appendix. Let $I_n^{ij,\varepsilon}$, $i=1,\cdots,K$, $j=0,\cdots,K$, denote the indicator function of the event that a completed service at P_i at time n is scheduled to be sent to P_j (or to the exterior, if $j=0$). We use $\{p_{ij}, i, j=1,\cdots,K\}$ to denote the probability that a completed service from P_i is to be routed to P_j, and write $p_{i0}=1-\sum_{j=1}^{K} p_{ij}$. The buffer size at P_i is $B_i/\sqrt{\varepsilon}$, for $B_i>0$.

We will impose the following assumptions: We work with impulsive controls only, although the results can be extended to the case where the service and interarrival "rates" are controlled continuously. The processor P_i can be shut off for a time, at a cost $k_i>0$, to be paid *at the moment of shut off*. The external inputs to P_i can be shut off for a time, at a cost $k_{0i}>0$, *to be paid at the moment of shut off*. If P_i communicates with P_j, in lieu of shutting off P_i, we can open or break the link connecting P_i to P_j. In that case the output of P_i destined for P_j will be shunted to the exterior and lost, or sold as a "partially completed" product. The cost for shutting off the link is $k_{ij}>0$, *to be paid at the moment of shut off*, and there will be an additional cost for the lost customers. This cost is $q_{ij}\sqrt{\varepsilon}$ per lost customer, $q_{ij}>0$. By convention, we allow all customers in P_i who have completed service there and are destined to return to P_i immediately to do so. If the buffer of P_i is full, then one or more inputs must be turned off, i.e., either the input links to P_i are shunted to the exterior, or the P_j connecting to P_i are shut off.

Let $P_n^{i,\varepsilon}$, $P_n^{0i,\varepsilon}$ and $P_n^{ji,\varepsilon}$, respectively, denote the indicators of the events that P_i is working at time n (i.e., processing or not shut off), the external input to P_i is not shut off at time n, and the link connecting P_j to P_i is open at time n, respectively. Let $N_n^{i,\varepsilon}$ (respectively, $\tilde{N}_n^{i,\varepsilon}$) denote the nth time that P_i is turned off (respectively, turned back on), and set $\tilde{N}_0^{i,\varepsilon}=0$. Let $N_n^{ij,\varepsilon}$ $(i=0,1,\cdots,K,\ j=1,\cdots,K)$ (respectively, $\tilde{N}_n^{ij,\varepsilon}$) denote the nth time that the link connecting P_i to P_j is shut off (turned back on, respectively). (If $i=0$, then it is for the link connecting the exterior to P_j.) Define $v_n^{i,\varepsilon}=\varepsilon N_n^{i,\varepsilon}$, $v_n^{ij,\varepsilon}=\varepsilon N_n^{ij,\varepsilon}$, and similarly define $\tilde{v}_n^{i,\varepsilon}$ and $\tilde{v}_n^{ij,\varepsilon}$.

Let $X_n^{i,\varepsilon}=\sqrt{\varepsilon}$ (number of customers in or waiting for service at P_i at time n) and set $X^{i,\varepsilon}(t)=X_{t/\varepsilon}^{i,\varepsilon}$. This is the quantity of interest in the desired interpolated time and amplitude scale. Then, in this interpolated scale, $[v_n^{i,\varepsilon}, \tilde{v}_n^{i,\varepsilon})$, $n\geq 1$, etc., are the intervals of closure of P_i, etc. When ratios t/ε are used as indices, we use the integral part. Until §§ 5 and 6, and for notational convenience, we always assume that all processors and links are working at $t=0$. Thus $\tilde{v}_0^{\alpha}\equiv 0$ and $\tilde{v}_n^{\alpha,\varepsilon}>v_n^{\alpha,\varepsilon}$ for $n>0$.

To keep track of the flows in the system in a way that allows a convenient development of the limit theorems, we need to separate the corrections to the flows due to empty queues and to the flow components due to the control actions. This is

why (2.1)-(2.4) are introduced. *Throughout the paper, ε-superscripts will be omitted in the terms in sums or integrals.* Define

$$Y^{ij,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{n=1}^{t/\varepsilon} \psi_n^i I_n^{ij} P_n^i I_{\{X_n^i = 0\}}, \tag{2.1a}$$

$$U^{ij,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{n=1}^{t/\varepsilon} \psi_n^i I_n^{ij} (1 - P_n^i), \qquad i \neq 0, \quad j \neq i, \tag{2.1b}$$

$$U^{0i,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{n=1}^{t/\varepsilon} \xi_n^i (1 - P_n^{0i}), \qquad i \neq 0, \tag{2.2a}$$

$$U_c^{ji,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{n=1}^{t/\varepsilon} \psi_n^j I_n^{ji} (1 - P_n^{ji} P_n^j), \qquad j \neq i, \quad j \neq 0, \tag{2.2b}$$

$$Y_c^{ji,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{n=1}^{t/\varepsilon} \psi_n^j I_n^{ji} P_n^j P_n^{ji} I_{\{X_n^j = 0\}}, \qquad j \neq i, \quad j \neq 0, \tag{2.2c}$$

$$A^{i,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{n=1}^{t/\varepsilon} \xi_n^i, \quad D^{ij,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{n=1}^{t/\varepsilon} \psi_n^i I_n^{ij}, \quad i \neq 0, \tag{2.3}$$

$$Z^{ij,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{n=1}^{t/\varepsilon} \psi_n^i I_n^{ij} (1 - P_n^{ij}) P_n^i I_{\{X_n^i \neq 0\}}, \qquad i \neq j, \quad i, j \neq 0. \tag{2.4}$$

With the definitions (2.1)-(2.3), we can write

$$\begin{aligned} X^{i,\varepsilon}(t) = {} & A^{i,\varepsilon}(t) + \sum_{j \neq i} D^{ji,\varepsilon}(t) - \sum_{j \neq i} D^{ij,\varepsilon}(t) + \sum_{j \neq i} Y^{ij,\varepsilon}(t) \\ & - \sum_{j \neq i} Y_c^{ji,\varepsilon}(t) - U^{0i,\varepsilon}(t) + \sum_{j \neq i} U^{ij,\varepsilon}(t) - \sum_{j \neq i} U_c^{ji,\varepsilon}(t). \end{aligned} \tag{2.5}$$

The first term in (2.5) respresents the potential external arrivals to P_i, the second represents potential arrivals from other P_j, $j \neq i$, all neglecting the effects of controls or empty queues. The third term represents potential departures from P_i, again neglecting the effects of controls or empty queues. The other terms correct for these omissions. The $Y^{ij,\varepsilon}(\cdot)$ corrects for departures from P_i when P_i is working and its queue is empty, and the $Y_c^{ji,\varepsilon}(\cdot)$ corrects for arrivals to P_i from P_j when the buffer of P_j is empty and neither P_j nor the link from P_j to P_i is shut off. The $U^{0i,\varepsilon}(\cdot)$ corrects for the stopped external arrivals, when the input to P_i from the exterior is shut off. The $U^{ij,\varepsilon}(\cdot)$ corrects for the stopped departures from P_i when P_i is closed, and the $U_c^{ji,\varepsilon}(\cdot)$ corrects for the stopped arrivals from P_j to P_i when either P_j is not working or the link from P_j to P_i is shut off (i.e., shunted to the exterior).

The $Z^{ij,\varepsilon}(\cdot)$ represents the lost output when the link from P_i to P_j is shunted to the exterior. There can only be lost output at time n if $X_n^{i,\varepsilon} > 0$ and $P_n^{i,\varepsilon} = 1$ and $P_n^{ij,\varepsilon} = 0$. Write $X^\varepsilon = (X^{1,\varepsilon}, \cdots, X^{K,\varepsilon})$ and let π^ε or π denote control policies (i.e., rules for determining the $v^{i,\varepsilon}$, $\tilde{v}^{i,\varepsilon}$, $v^{ij,\varepsilon}$, $\tilde{v}^{ij,\varepsilon}$), and let E_x^π denote the expectation, given policy π and initial condition $X_0^\varepsilon = x$. Let P_t denote the *vector* of *indicator functions* $\{P_t^\alpha\}$ of the processors and links at time t. (We set $P_0^\alpha = 1$ until § 5). Then, for a bounded and continuous $k(\cdot)$ and $\beta > 0$, our cost will be of the discounted form:

$$\begin{aligned} V^\varepsilon(\pi, x, P) = {} & E_x^\pi \int_0^\infty e^{-\beta t} k(X^\varepsilon(t))\, dt + E_x^\pi \sum_{i=1}^K k_i \sum_n e^{-\beta v_n^{i,\varepsilon}} + E_x^\pi \sum_{i=0}^K \sum_{j=1}^K k_{ij} \sum_n e^{-\beta v_n^{ij,\varepsilon}} \\ & + E_x^\pi \int_0^\infty e^{-\beta t} \left[\sum_i q_{0i}\, dU^{0i,\varepsilon}(t) + \sum_{i,j=1}^K q_{ij}\, dZ^{ij,\varepsilon}(t) \right]. \end{aligned} \tag{2.6}$$

We now specialize to the case of Fig. 2.1, since it is very awkward to keep track of the effects of the controls in a network with general feedback allowed. With mainly notational changes, the case dealt with here can be extended to the general feedforward case.

Refer to Fig. 2.1, and assume (A2.1). The first part of this assumption says that if a queue is empty, then we will not continue to "starve" it—but will turn on all the inputs. The assumption seems to be quite unrestrictive, and it does simplify the bookkeeping quite a bit.

(A2.1) If $X_n^{2,\varepsilon}=0$, then all inputs to P_2 are open; i.e., $P_n^{1,\varepsilon}=P_n^{12,\varepsilon}=P_n^{02,\varepsilon}=1$. If $X_n^{1,\varepsilon}=0$, then the input to P_1 is open (i.e., $P_n^{01,\varepsilon}=1$). If some $X_n^{i,\varepsilon}=B_i$, then all inputs to P_i are closed.

For the system of Fig. 2.1, and under (A2.1), we have that (2.1)-(2.5) take the forms (2.7)-(2.9). Here, $P_n^{2,\varepsilon}\equiv 1$, since there is never a need to shut off P_2:

$$
\begin{aligned}
Y_c^{12,\varepsilon}(t) &= \sqrt{\varepsilon}\sum_1^{t/\varepsilon}\psi_n^1 I_n^{12} P_n^1 P_n^{12} I_{\{X_n^1=0\}},\\
Y^{20,\varepsilon}(t) &= \sqrt{\varepsilon}\sum_1^{t/\varepsilon}\psi_n^2 I_n^{20} I_{\{X_n^2=0\}},\\
Z^{12,\varepsilon}(t) &= \sqrt{\varepsilon}\sum_1^{t/\varepsilon}\psi_n^1 I_n^{12}(1-P_n^{12})P_n^1 I_{\{X_n^1\neq 0\}}\\
&= U_c^{12,\varepsilon}(t)-U^{12,\varepsilon}(t)-\sum_1^{\infty}\int_{v_n^{12}\cap t}^{\tilde v_n^{12}\cap t} dY^{12,\varepsilon}(s).
\end{aligned}
\tag{2.7}
$$

The $Y^{12,\varepsilon}(\cdot)$ will converge to a continuous function and $\tilde v_n^{12,\varepsilon}-v_n^{12,\varepsilon}\overset{\varepsilon}{\to}0$. Thus the last term on the right of the last equation will disappear in the limit. Define $U^{1,\varepsilon}(\cdot)=U^{10,\varepsilon}(\cdot)+U^{12,\varepsilon}(\cdot)$. Then

$$X^{1,\varepsilon}(t)=A^{1,\varepsilon}(t)-D^{10,\varepsilon}(t)-D^{12,\varepsilon}(t)+Y^{10,\varepsilon}(t)+Y^{12,\varepsilon}(t)-U^{01,\varepsilon}(t)+U^{1,\varepsilon}(t), \tag{2.8a}$$

$$X^{2,\varepsilon}(t)=A^{2,\varepsilon}(t)-D^{20,\varepsilon}(t)+D^{12,\varepsilon}(t)+Y^{20,\varepsilon}(t)-Y_c^{12,\varepsilon}(t)-U^{02,\varepsilon}(t)-U_c^{12,\varepsilon}(t), \tag{2.8b}$$

$$
\begin{aligned}
V^{\varepsilon}(\pi,x,P) &= E_x^{\pi}\int_0^{\infty} e^{-\beta t}k(X^{\varepsilon}(t))\,dt + k_1 E_x^{\pi}\sum_n e^{-\beta v_n^{1,\varepsilon}} + \sum_{i=1}^{2} k_{0i}E_x^{\pi}\sum_n e^{-\beta v_n^{0i,\varepsilon}}\\
&\quad + k_{12}E_x^{\pi}\sum_n e^{-\beta v_n^{12,\varepsilon}} + E_x^{\pi}\int_0^{\infty} e^{-\beta t}\left[\sum_{i=1}^{2} q_{0i}\,dU^{0i,\varepsilon}(t) + q_{12}\,dZ^{12,\varepsilon}(t)\right].
\end{aligned}
\tag{2.9}
$$

We now give some more definitions and state the heavy traffic assumptions. It will sometimes be convenient to write the multiple sequence $v^{\varepsilon}\equiv\{v_n^{i,\varepsilon}, \tilde v_n^{i,\varepsilon}, v_n^{ij,\varepsilon}, \tilde v_n^{ij,\varepsilon}\}$

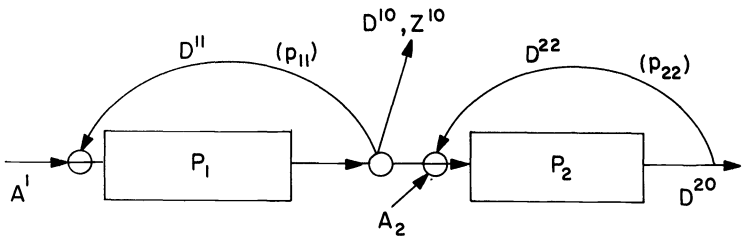

FIG. 2.1. *The system configuration.*

as a single sequence. Let $\{\tau_n^\varepsilon\}$ denote the sequence of event *times* indicated by all the elements of v^ε in nonincreasing order, but without respect to which events they indicate, or whether they indicate multiple events. Define $R_n^\varepsilon = (R_n^{1,\varepsilon}, R_n^{01,\varepsilon}, R_n^{02,\varepsilon}, R_n^{12,\varepsilon})$, where $R_n^{\alpha,\varepsilon} = 1, -1$, or 0 depending on whether or not the "control" with the same superscript was opened (turned on), closed (turned off) or left unchanged at τ_n^ε. *From* $\{R_n^\varepsilon, \tau_n^\varepsilon, \delta U_n^\varepsilon\}$, *we can recover all the control actions and their times and values.*

Define

$$\delta U_n^\varepsilon = (U^{1,\varepsilon}(\tau_{n+1}^\varepsilon) - U^{1\varepsilon}(\tau_n^\varepsilon),\ U^{01,\varepsilon}(\tau_{n+1}^\varepsilon) - U^{01,\varepsilon}(\tau_n^\varepsilon),$$
$$U^{02,\varepsilon}(\tau_{n+1}^\varepsilon) - U^{02,\varepsilon}(\tau_n^\varepsilon),\ U_c^{12,\varepsilon}(\tau_{n+1}^\varepsilon) - U_c^{12,\varepsilon}(\tau_n^\varepsilon)).$$

If τ_n^ε is not defined for some n, ω, then let it equal to infinity there, and define the associated R_n^ε and δU_n^ε arbitrarily.

Let $S_{a,n}^{i,\varepsilon} = \sum_{j=1}^n \alpha_j^{i,\varepsilon}$, $S_{d,n}^{i,\varepsilon} = \sum_{j=1}^n \Delta_j^{i,\varepsilon}$. Let $E_{a,n}^{i,\varepsilon}$ denote the expectation given the arrival, departure, and control intervals and actions that ended by real time $S_{a,n}^{i,\varepsilon}$, as well as the lengths of all other arrival and service intervals (other than $\alpha_{n+1}^{i,\varepsilon}$) that started by, but might not have been completed by, time $S_{a,n}^{i,\varepsilon}$. Analogously, $E_{d,n}^{i,\varepsilon}$ denotes the expectation given the arrival, departure, and control intervals and actions that ended by real time $S_{d,n}^{i,\varepsilon}$, as well as the lengths of all other arrival and service intervals (other than $\Delta_{n+1}^{i,\varepsilon}$) that started by $S_{d,n}^{i,\varepsilon}$. Define the conditional variances $\mathrm{var}_{a,n}^{i,\varepsilon}$, $\mathrm{var}_{d,n}^{i,\varepsilon}$ analogously.

Define

$$E_{a,n}^{i,\varepsilon}\alpha_{n+1}^{i,\varepsilon} = \bar{\alpha}_{n+1}^{i,\varepsilon}, \qquad \mathrm{var}_{a,n}^{i,\varepsilon}\ \alpha_{n+1}^{i,\varepsilon} = (\sigma_{a,n+1}^{i,\varepsilon})^2,$$
$$E_{d,n}^{i,\varepsilon}\Delta_{n+1}^{i,\varepsilon} = \bar{\Delta}_{n+1}^{i,\varepsilon}, \qquad \mathrm{var}_{d,n}^{i,\varepsilon}\ \Delta_{n+1}^{i,\varepsilon} = (\sigma_{d,n+1}^{i,\varepsilon})^2.$$

Henceforth when we say that P_i, P_{0i}, *or* P_{12}, *respectively, is open* (*closed*) *at time n, we mean that processor i is working, the link from the exterior to* P_i *is open or* (*respectively*), *the link from* P_1 *to* P_2 *is open for traffic.*

We will use the following assumption.

(A2.2) There are positive numbers g_{ai} and g_{di} and bounded continuous functions $a^i(\cdot)$ and $d^i(\cdot)$ such that

$$[\bar{\alpha}_{n+1}^{i,\varepsilon}]^{-1} = g_{ai} + \sqrt{\varepsilon}\ a_{in} + o(\sqrt{\varepsilon}), \qquad [\bar{\Delta}_{n+1}^{i,\varepsilon}]^{-1} = g_{di} + \sqrt{\varepsilon}\ d_{in} + o(\sqrt{\varepsilon}),$$

where $a_{in} = a^i(X_{S_{a,n}^{i,\varepsilon}}^\varepsilon)$ and $d_{in} = d^i(X_{S_{d,n}^{i,\varepsilon}}^\varepsilon)$.

Comment on (A2.2). We allow the (marginal) external interarrival intervals and the service intervals to depend on the system state. The argument $X_{S_{a,n}^{i,\varepsilon}}^\varepsilon$ (for example) is the proper one, since $S_{a,n}^{i,\varepsilon}$ is the moment of arrival to P_i of the $(n+1)$st customer from the outside, and $X_{S_{a,n}^{i,\varepsilon}}^\varepsilon$ is the system state at that time. At some expense in details, we could let the marginal mean rates $a^i(\cdot)$ and $d^i(\cdot)$ be controlled. We would then use the forms $a^i(X_{S_{a,n}^{i,\varepsilon}}^i, r_{S_{a,n}^{i,\varepsilon}}^{i,\varepsilon})$ etc., where the r_β^α represents controls. The condition (A2.2) together with (A2.4) imply that the total load put on processor P_i is very close to its processing capacity. In other words, the idle time is negligible in the sense that it converges to zero as $\varepsilon \downarrow 0$.

(A2.3) The set $\{|\alpha_n^{i,\varepsilon}|^2, |\Delta_n^{i,\varepsilon}|^2, i, n < \infty$, small ε, all control actions$\}$ is uniformly integrable.

(A2.4) (Heavy traffic assumption)

$$g_{a1} = (1 - p_{11})g_{d1}, \qquad [p_{12}g_{d1} + g_{a2}]/(1 - p_{22}) = g_{d2}.$$

Assumption (A2.4) is also what we would get from Reimann's [1] formulas for the case of Fig. 2.1.

(A2.5) The routing variables $\{I_k^{ij,\varepsilon}, i, j, k\}$ are mutually independent and independent of the $\{\alpha_k^{i,\varepsilon}, \Delta_k^{i,\varepsilon}\}$ and $P\{I_k^{ij,\varepsilon}=1\}=p_{ij}$.

(A2.6) There are continuous functions $\sigma_{ai}(\cdot)$, $\sigma_{di}(\cdot)$ such that

$$\sigma_{a,n+1}^{i,\varepsilon}=\sigma_{a,i}(X^{\varepsilon}_{S_{a,n}^{i,\varepsilon}})+\delta'_{\varepsilon}, \qquad \sigma_{d,n+1}^{i,\varepsilon}=\sigma_{d,i}(X^{\varepsilon}_{S_{d,n}^{i,\varepsilon}})+\delta''_{\varepsilon}$$

where $\delta_{\varepsilon}^{\alpha} \overset{\varepsilon}{\to} 0$, uniformly in all other variables.

Comment on (A2.5) *and* (A2.6). We allow the conditional variance to depend on the state here, just to show the possibilities. The sequence of interarrival times or service intervals can be correlated (in ways other than via the "state" dependence used here). This would involve a more complex method for obtaining the weak convergence. The perturbed test function methods of [5] can be used, but the additional notational burden hardly seems worth it now.

3. A convenient representation for $X^{\varepsilon}(\cdot)$. In this section, we center and rewrite the terms of (2.8) to facilitate the weak convergence analysis in § 5. We will do three things. First, the A and D processes will be centered, the centering terms simplified, and the centered processes written as a rescaling of simpler processes. This is similar to the procedure of [1]. Then we will represent the $Y^{ij,\varepsilon}$ and $U^{ij,\varepsilon}$ in terms of simpler processes $Y^{i,\varepsilon}$ and $U^{i,\varepsilon}$ plus a term that will go to zero as $\varepsilon\to 0$. Finally, we will represent $Y^{i,\varepsilon}$ and $X^{i,\varepsilon}$ as continuous functions of the "other" data.

Centering of the arrival and departure processes. Define $\bar{S}_a^{i,\varepsilon}(t)$ (and analogously $\bar{S}_d^{i,\varepsilon}(t)$) to be the *inverse* of the interpolated arrival time function $\varepsilon S_{a,t/\varepsilon}^{i,\varepsilon}$. More precisely, define

$$\bar{S}_a^{i,\varepsilon}(t)=\max\{\varepsilon k\colon \varepsilon S_{a,k}^{i,\varepsilon}\leqq t\}.$$

Define the centered processes

$$\begin{aligned}\tilde{A}_0^{i,\varepsilon}(t)&=\sqrt{\varepsilon}\sum_{k=1}^{t/\varepsilon}\sum_{l=S_{a,k}^{i,\varepsilon}}^{S_{a,k+1}^{i,\varepsilon}-1}\left[\xi_l^i-\frac{1}{\bar{\alpha}_k^i}\right]\\&=\sqrt{\varepsilon}\sum_{1}^{t/\varepsilon}\left(1-\frac{\alpha_k^i}{\bar{\alpha}_k^i}\right),\\ \tilde{D}_0^{ij,\varepsilon}(t)&=\sqrt{\varepsilon}\sum_{k=1}^{t/\varepsilon}\sum_{l=S_{d,k}^{i,\varepsilon}}^{S_{d,k+1}^{i,\varepsilon}-1}\left[\psi_l^i I_l^{ij}-\frac{p_{ij}}{\bar{\Delta}_k^i}\right]\\&=\sqrt{\varepsilon}\sum_{k=1}^{t/\varepsilon}\left[I^{ij}_{S_{d,k}^i}-p_{ij}\frac{\Delta_k^i}{\bar{\Delta}_k^i}\right].\end{aligned} \tag{3.1}$$

The second equality in the first definition follows from the fact that $\xi_l^{i,\varepsilon}=1$ only at the left endpoint in the interval $[S_{a,k}^{i,\varepsilon}, S_{a,k+1}^{i,\varepsilon})$ and the length of the interval is $\alpha_k^{i,\varepsilon}$.

Owing to the independence assumptions in (A2.5), we can replace the $I^{ij}_{S_{d,k}^i}$ by I_k^{ij}. We can write the $A^{i,\varepsilon}(\cdot)$ of (2.3) in the form

$$\begin{aligned}A^{i,\varepsilon}(t)&=\sqrt{\varepsilon}\sum_{k=1}^{\varepsilon^{-1}\bar{S}_a^{i,\varepsilon}(t)}\sum_{l=S_{a,k}^{i,\varepsilon}}^{S_{a,k+1}^{i,\varepsilon}-1}\left[\xi_l^i-\frac{1}{\bar{\alpha}_k^i}\right]+\sqrt{\varepsilon}\sum_{k=1}^{\varepsilon^{-1}\bar{S}_a^{i,\varepsilon}(t)}\frac{\alpha_k^i}{\bar{\alpha}_k^i}\\&\equiv\tilde{A}_0^{i,\varepsilon}(\bar{S}_a^{i,\varepsilon}(t))+\tilde{B}_a^{i,\varepsilon}(t)\equiv\tilde{A}^{i,\varepsilon}(t)+\tilde{B}_a^{i,\varepsilon}(t).\end{aligned} \tag{3.2}$$

Doing the same thing for the $D^{ij,\varepsilon}(\cdot)$, we have

$$D^{ij,\varepsilon}(t) = \tilde{D}_0^{ij,\varepsilon}(\bar{S}_d^{i,\varepsilon}(t)) + \tilde{B}_d^{ij,\varepsilon}(t) \equiv \tilde{D}^{ij,\varepsilon}(t) + \tilde{B}_d^{ij,\varepsilon}(t) \tag{3.3}$$

where

$$\tilde{B}_d^{ij,\varepsilon}(t) = \sqrt{\varepsilon} \sum_{k=1}^{\varepsilon^{-1}\bar{S}_d^{i,\varepsilon}(t)} \frac{\Delta_k^i}{\bar{\Delta}_k^i} p_{ij}. \tag{3.4}$$

For purposes of calculation below, write

$$\tilde{D}_0^{10,\varepsilon}(t) + \tilde{D}_0^{12,\varepsilon}(t) = \sqrt{\varepsilon} \sum_1^{t/\varepsilon} \left[(1 - I_k^{11}) - (1 - p_{11}) \frac{\Delta_k^i}{\bar{\Delta}_k^i} \right].$$

We now cancel the "principal parts" of the $\tilde{B}_\alpha^{i,\varepsilon}$ terms. By taking the terms in the order in which they would appear in the centering of the first three terms of (2.8a) and using the expansion in (A2.2), we write

$$\begin{aligned} \tilde{B}_a^{1,\varepsilon}(t) - (\tilde{B}_d^{10,\varepsilon}(t) + \tilde{B}_d^{12,\varepsilon}(t)) &= \sqrt{\varepsilon} \sum_{k=1}^{\varepsilon^{-1}\bar{S}_a^{1,\varepsilon}(t)} \alpha_k^1 [g_{a1} + \sqrt{\varepsilon}\, a_{1k} + o(\sqrt{\varepsilon})] \\ &\quad - \sqrt{\varepsilon} \sum_{k=1}^{\varepsilon^{-1}\bar{S}_d^{1,\varepsilon}(t)} \Delta_k^1 [g_{d1} + \sqrt{\varepsilon}\, d_{1k} + o(\sqrt{\varepsilon})](1 - p_{11}). \end{aligned} \tag{3.5}$$

Since $\sum_{\varepsilon k=1}^{\bar{S}_a^{1,\varepsilon}(t)} \alpha_k^1 = 1/\varepsilon \pmod{O(1)}$, the principal term of the first sum is $g_{a1}t/\sqrt{\varepsilon}$ $(\text{mod } O(\sqrt{\varepsilon}))$, and of the second is $(1-p_{11})g_{d1}t/\sqrt{\varepsilon}$ $(\text{mod } O(\sqrt{\varepsilon}))$. These cancel by (A2.4). By using the definitions of α_k^1 and a_{1k}, we can write the sum of the middle terms in the first sum of (3.5) as

$$\varepsilon \sum_1^{t/\varepsilon} a^1(X_k) + \delta_\varepsilon^0(t)$$

(where all $\delta_\varepsilon^i(\cdot)$ here and below go to zero uniformly on bounded time intervals as $\varepsilon \to 0$), and similarly for the analogous terms in the second sum.

With the above cancellations and the last representation, we can rewrite (3.5) as

$$\begin{aligned} \varepsilon \sum_1^{t/\varepsilon} [a^1(X_k) - (1-p_{11})d^1(X_k)] + \delta_\varepsilon^1(t) &\equiv \int_0^t b^1(X^\varepsilon(s))\, ds + \delta_\varepsilon^1(t) \\ &\equiv B^{1,\varepsilon}(t) + \delta_\varepsilon^1(t). \end{aligned} \tag{3.6}$$

Repeating the procedure for the "biases" arising from (2.8b), we get

$$\begin{aligned} \tilde{B}_a^{2,\varepsilon}(t) - \tilde{B}_d^{20,\varepsilon}(t) + \tilde{B}_d^{12,\varepsilon}(t) &\equiv B_2^{2,\varepsilon}(t) + \delta_\varepsilon^2(t) = \int_0^t b^2(X^\varepsilon(s))\, ds + \delta_\varepsilon^2(t) \\ &= \varepsilon \sum_1^{t/\varepsilon} [a^2(X_k) - (1-p_{22})d^2(X_k) + p_{12}d^1(X_k)] + \delta_\varepsilon^2(t) \\ &= \int_0^t b^2(X^\varepsilon(s))\, ds + \delta_\varepsilon^2(t) = B^{2,\varepsilon}(t) + \delta_\varepsilon^2(t). \end{aligned} \tag{3.7}$$

A representation for $U^{ij,\varepsilon}$, $Y^{ij,\varepsilon}$. Define the processes (with $P_n^{2,\varepsilon} \equiv 1$)

$$Y^{1,\varepsilon}(\cdot) = Y^{10,\varepsilon}(\cdot) + Y^{12,\varepsilon}(\cdot), \qquad Y^{2,\varepsilon}(\cdot) = Y^{20,\varepsilon}(\cdot). \tag{3.8}$$

We can also write

$$U^{12,\varepsilon}(t) = \sum_{n=1}^{\infty} \int_{v_n^{1,\varepsilon} \cap t}^{\tilde{v}_n^{1,\varepsilon} \cap t} dU_c^{12,\varepsilon}(s). \tag{3.9a}$$

It will turn out (see § 5) that the limits in (3.9b) hold:

$$
\begin{aligned}
&U^{1j,\varepsilon}(\cdot) - U^{1,\varepsilon}(\cdot)p_{1j}/(1-p_{11}) \Rightarrow 0, \qquad j = 0, 2,\\
&U_c^{12,\varepsilon}(t) - \sqrt{\varepsilon}\, p_{12} \sum_0^{t/\varepsilon} \psi_n^1 (1 - P_n^1 P_n^{12}) \Rightarrow 0,\\
&Z^{12,\varepsilon}(\cdot) - [U_c^{12,\varepsilon}(\cdot) - U^{12,\varepsilon}(\cdot)] \Rightarrow 0,\\
&\tilde{v}_n^{\alpha,\varepsilon} - v_n^{\alpha,\varepsilon} \to 0 \quad \text{for all } \alpha, n,\\
&Y^{12,\varepsilon}(\cdot) - \frac{p_{12}}{p_{10}+p_{12}}\, Y^{1,\varepsilon}(\cdot) \Rightarrow 0,\\
&Y_c^{12,\varepsilon}(\cdot) - Y^{12,\varepsilon}(\cdot) \Rightarrow 0.
\end{aligned}
\tag{3.9b}
$$

To prepare for the utilization of these convergences and simplifications, rewrite (2.8) as (3.10), where the $\rho^{i,\varepsilon}(\cdot)$ are linear combinations of the $\delta_\varepsilon(\cdot)$ in (3.6) and (3.7) and $\hat{\rho}^{2,\varepsilon}(\cdot) = \rho^{2,\varepsilon}(\cdot) + (Y_c^{12,\varepsilon}(\cdot) - p_{12}Y^{1,\varepsilon}(\cdot)/(p_{10}+p_{12}))$, and the $W^{i,\varepsilon}(\cdot)$, $i = 1, 2$, are defined to be the sum of the first three terms in the middle part of (3.10a) and (3.10b), respectively:

$$
\begin{aligned}
X^{1,\varepsilon}(t) &= \tilde{A}^{1,\varepsilon}(t) - (\tilde{D}^{10,\varepsilon}(t) + \tilde{D}^{12,\varepsilon}(t)) + B^{1,\varepsilon}(t)\\
&\quad + (Y^{10,\varepsilon}(t) + Y^{12,\varepsilon}(t)) - U^{01,\varepsilon}(t) + U^{1,\varepsilon}(t) + \rho^{1,\varepsilon}(t)\\
&= W^{1,\varepsilon}(t) + B^{1,\varepsilon}(t) + Y^{1,\varepsilon}(t) - U^{0,1\varepsilon}(t) + U^{1,\varepsilon}(t) + \rho^{1,\varepsilon}(t),
\end{aligned}
\tag{3.10a}
$$

$$
\begin{aligned}
X^{2,\varepsilon}(t) &= \tilde{A}^{2,\varepsilon}(t) - \tilde{D}^{20,\varepsilon}(t) + \tilde{D}^{12,\varepsilon}(t) + B^{2,\varepsilon}(t)\\
&\quad + Y^{20,\varepsilon}(t) - Y_c^{12,\varepsilon}(t) - U^{02,\varepsilon}(t) - U_c^{12,\varepsilon}(t) + \rho^{2,\varepsilon}(t)\\
&= W^{2,\varepsilon}(t) + B^{2,\varepsilon}(t) + Y^{2,\varepsilon}(t) - p_{12}Y^{1,\varepsilon}(t)/(p_{12}+p_{10})\\
&\quad - U^{02,\varepsilon}(t) - U_c^{12,\varepsilon}(t) + \hat{\rho}^{2,\varepsilon}(t).
\end{aligned}
\tag{3.10b}
$$

We also write

$$
V^\varepsilon(\pi, x) = [(2.9) \text{ with } Z^{12,\varepsilon}(\cdot) = U_c^{12,\varepsilon}(\cdot) - U^{12,\varepsilon}(\cdot) + \hat{\rho}^{3,\varepsilon}(\cdot)]
\tag{3.11}
$$

where $\hat{\rho}^{3,\varepsilon}(\cdot)$ is an "error" term. We have $\sup_{t \leqq T} |\rho^{i,\varepsilon}(t)| \to 0$ in distribution as $\varepsilon \to 0$, for each $T < \infty$. Also, it will be shown in § 5 that, for any sequence of controls π^ε with $\sup V^\varepsilon(\pi^\varepsilon, x) < \infty$, $\sup_{t \leqq T} |\hat{\rho}^{i,\varepsilon}(t)| \to 0$ in distribution for any $T < \infty$.

Owing to the impulsive nature of the "control" part of the cost (2.9), on any bounded time interval there are only a finite number (w.p.1) of subintervals on which the controls are active. By the definitions, the reflection terms $Y^{ij,\varepsilon}(\cdot)$ cannot increase on these "control intervals." In particular, $Y^{1,\varepsilon}(\cdot)$ can only increase when both P_{01} and P_1 are on (recall that P_{01} must be on when $X^1 = 0$). Also, $Y^{2,\varepsilon}(\cdot)$ can increase only when all of P_1, P_{12}, and P_{02} are on (by (A2.1), if $X_n^{2,\varepsilon} = 0$, then all inputs must be turned on). Because of this and the feedforward nature of the problem, the simplest form of the reflection principle can be used to obtain the "reflection" terms as continuous functions of the other "noncontrol" data, simply by working with the appropriate "noncontrol" time segments, and we now formalize this.

The following result is well known and is a special case of the cited results in [1] and [12].

LEMMA 3.1. *Let $z(\cdot)$ be in $D[0, \infty)$, the space of real-valued functions with left-hand limits and that are right continuous, and with the* sup *norm topology. There is a unique $y(\cdot)$ in $D[0, \infty)$ such that $x(\cdot) = z(\cdot) + y(\cdot)$ and $x(t) \geqq 0$, $y(0) = 0$, and $y(\cdot)$ is nondecreasing and increases only when $x(\cdot) = 0$. In particular, $y(t) = -\min\{0, \inf_{s \leqq t} z(s)\}$. The map $z \to y$ is continuous in the* sup *norm on each finite interval* $[0, T]$.

Remark. In all cases below, the functions that replace z, x, and y will be the obvious terms from (3.10). We will want a representation of $y^\varepsilon(\cdot)$ as a continuous function of the other terms on the right-hand side of (3.10) to simplify the weak convergence proof.

Let $J_n^{1,\varepsilon} = [\mu_n^{1,\varepsilon}, \tilde{\mu}_n^{1,\varepsilon})$ denote the sequence of successive intervals (of interpolated time) such that $P_k^{1,\varepsilon} = P_k^{01,\varepsilon} = 1$ for $\varepsilon k \in J_n^{1,\varepsilon}$, and let $J_n^{2,\varepsilon} = [\mu_n^{2,\varepsilon}, \tilde{\mu}_n^{2,\varepsilon})$ denote the successive intervals such that $P_k^{1,\varepsilon} = P_k^{12,\varepsilon} = P_k^{02,\varepsilon} = 1$ for $\varepsilon k \in J_n^{2,\varepsilon}$. The $Y^{i,\varepsilon}(\cdot)$ can increase only on the $J_n^{i,\varepsilon}$.

We apply the representation in Lemma 3.1 to get an alternative representation of the increments of $Y^{i,\varepsilon}(\cdot)$ on the time segments between the control actions. For any function $f(\cdot)$ in $D[0,\infty)$, define the function $\delta_{in}^\varepsilon f(\cdot)$ in $D[0,\infty)$ by $\delta_{in}^\varepsilon f(\cdot) = f((\mu_n^{i,\varepsilon}+\cdot) \cap \tilde{\mu}_n^{i,\varepsilon}) - f(\mu_n^{i,\varepsilon})$. The function $\delta_{in}^\varepsilon f(\cdot)$ is just the segment of the function $f(\cdot)$, stopped at $\tilde{\mu}_n^{i,\varepsilon}$, shifted left by $\mu_n^{i,\varepsilon}$ and centered by subtracting the new "initial value" $f(\mu_n^{i,\varepsilon})$. We now apply Lemma 3.1 on the intervals $J_n^{1,\varepsilon}$ and $J_n^{2,\varepsilon}$ in turn.

By Lemma 3.1, for $t \geqq 0$ we have

$$\delta_{1n}^\varepsilon Y^{1,\varepsilon}(t) = -\min\left[\inf_{s \leqq t}(X^{1,\varepsilon}(\mu_n^{1,\varepsilon}) + \delta_{1n}^\varepsilon W^{1,\varepsilon}(s) + \delta_{1n}^\varepsilon B^{1,\varepsilon}(s) + \delta_{1n}^\varepsilon \rho^{1,\varepsilon}(s)), 0\right],$$

$$\delta_{2n}^\varepsilon Y^{2,\varepsilon}(t) = -\min\left[\inf_{s \leqq t}\left(X^{2,\varepsilon}(\mu_n^{2,\varepsilon}) + \delta_{2n}^\varepsilon W^{2,\varepsilon}(s) + \delta_{2\varepsilon}^\varepsilon B^{2,\varepsilon}(s) + \frac{p_{12}}{p_{12}+p_{10}}\delta_{2\varepsilon}^\varepsilon Y^{1,\varepsilon}(s) + \delta_{2n}^\varepsilon \hat{\rho}^{2,\varepsilon}(s)\right), 0\right]. \tag{3.12}$$

Also, we have

$$Y^{i,\varepsilon}(t) = \sum_{n:\, \mu_n^{i,\varepsilon} \leqq t} \delta_{in}^\varepsilon Y^{i,\varepsilon}(t - \mu_n^{i,\varepsilon}).$$

We use the following notation for functions of infinitely many variables. Let S_n be a metric space with metric $d_n(\cdot)$ and canonical point s_n or s_n'. On $S = \prod_n S_n$, with canonical point $s = (s_1, \cdots)$ or $s' = (s_1', \cdots)$, we use the metric $d(s, s') = \sum_n 2^{-n} d_n(s_n, s_n')/[1 + d_n(s_n, s_n')]$. Suppose that the number of control actions on each bounded time interval is finite. Then, from (3.12), we can construct a unique function $F(\cdot)$ with values in $D^2[0,\infty)$ and such that

$$(Y^{1,\varepsilon}(\cdot), Y^{2,\varepsilon}(\cdot)) = F(X_0^\varepsilon, W^\varepsilon(\cdot), B^\varepsilon(\cdot), X^{i,\varepsilon}(\mu_n^{i,\varepsilon}), \mu_n^{i,\varepsilon}, \tilde{\mu}_n^{i,\varepsilon}, \quad i = 1, 2,\ n = 1, 2, \cdots) \tag{3.13}$$

where $F(\cdot)$ is continuous (recall that we use the sup norm topology on bounded intervals on $D[0,\infty)$ here), and $Y^{i,\varepsilon}(\cdot)$ can increase only when $X^{i,\varepsilon}(t)$ equals zero. Also $X^{i,\varepsilon}(\cdot) \geqq 0$, always.

A tentative form for the limit control problem. To motivate the form of the limit process, suppose that the arguments of $F(\cdot)$ converge to $W(\cdot), B(\cdot), \cdots, \rho(\cdot)$, where $\rho(\cdot) = 0$, and let $Y^i(\cdot)$ be the limit of $Y^{i,\varepsilon}(\cdot)$. Then, on each bounded time interval, the complement of the intervals $\{[\mu_n^i, \tilde{\mu}_n^i), n < \infty]$ will just be a finite set of points, and the controls will be impulses acting at these points. Using this assumed convergence and the approximations in (3.9b), we can characterize the limit process as

$$\begin{aligned} X^1(t) &= X^1(0) + W^1(t) + B^1(t) + Y^1(t) - U^{01}(t) + U^1(t), \\ X^2(t) &= X^2(0) + W^2(t) + B^2(t) + Y^2(t) \\ &\quad - p_{12} Y^1(t)/(p_{12}+p_{10}) - U^{02}(t) - U_c^{12}(t). \end{aligned} \tag{3.14}$$

The sense will be made precise in Theorem 5.1.

The $Y_c^{12}(\cdot)$ can be obtained from the limit $Y^1(\cdot)$ via (3.9). The limits $Y^1(\cdot) = \lim_\varepsilon (Y^{10,\varepsilon}(\cdot) + Y^{12,\varepsilon}(\cdot))$ and $Y^2(\cdot) = \lim_\varepsilon Y^{20,\varepsilon}(\cdot)$ are obtained from the limit of (3.13). Furthermore (as in [1]), the $Y^i(\cdot)$ obtained from the limits in (3.13) are the unique continuous functions that can increase only when $X^i(t)$ is zero and that guarantee $X^i(t) \geqq 0$.

The $U_c^{12}(\cdot)$ can be used to define $U^{12}(\cdot)$ via the limits in (3.9). It will turn out that $U^{12}(\cdot) = p_{12}U^1(\cdot)/(1-p_{11})$.

4. Description of the limit control problem. In this section, we define the proper limit control problem for the system of Fig. 2.1. First, it will be convenient to describe the effects of various control actions on the $X^\varepsilon(\cdot)$ for small ε. We do this in some detail, since the limit problem is somewhat nonstandard, owing to the possibility of "multiple simultaneous impulses."

For the "limit" problem to make sense as an approximation to the physical problem, for any admissible policy π for $X(\cdot)$, there must be a sequence π^ε of policies that can be applied to the $X^\varepsilon(\cdot)$ (e.g., P_{ij}, P_i on/off) and such that, under π^ε, $X^\varepsilon(\cdot)$ converges to $X(\cdot)$ under policy π, and the associated costs also converge. Because of this, the limit control problem must be defined in terms of limits of what is possible for the $X^\varepsilon(\cdot)$.

Controls for the limit problem. Refer to Fig. 4.1, where some typical paths are constructed, under the heavy traffic conditions. Start at point (a) with all P_i, P_{ij} on except that P_{01} is off. The path moves to the left and as $\varepsilon \to 0$, it converges to the horizontal line (a, b). The mean (interpolated) movement to the left in time Δ is $g_{ai}\Delta/\sqrt{\varepsilon} + O(\Delta)$. Hence in the limit, as $\varepsilon \to 0$, there is an impulsive change.

Now, restart at (d) with only P_{12} off. The path drops, and as $\varepsilon \to 0$ it tends to the vertical line (d, e). In time Δ, the mean drop is $p_{12}g_{d1}\Delta/\sqrt{\varepsilon} + O(\Delta)$. The same path is followed if only P_{02} is off or if P_1 and P_{01} are both off, although the "drop" speed will be different. Now, restart at (e) with only P_1 off. The path moves toward (f) (for

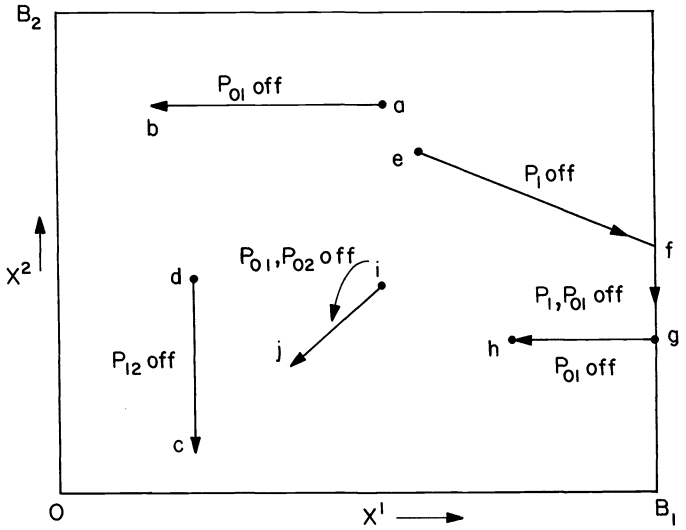

FIG. 4.1. *Impulsive changes in $X^\varepsilon(\cdot)$ or $X(\cdot)$ due to the control actions.*

small ε), and the limit slope can be calculated from

$$\frac{\text{net mean flow into } P_2}{\text{net mean flow into } P_1} = \frac{g_{a2}-(1-p_{22})g_{d2}}{g_{a1}} = -\frac{p_{12}g_{d1}}{g_{a1}}. \tag{4.1}$$

If the path reaches (f), then P_{01} must be turned off. If, at (g), we turn P_1 back on (but leave P_{01} off), then the path moves toward (h). The effects of both P_1 and P_{12} being off simultaneously are the same as for P_1 being off alone. Over small intervals of length Δ, the $\tilde{A}$, $\tilde{D}$, and Y terms in (3.10) contribute very little to the paths (compared to the effects of the control actions), since they converge weakly to continuous functions.

Now refer to (i), and let only P_{01} and P_{02} be off. Then the path moves to (j) with a limit slope $[(1-p_{22})g_{d2}-p_{12}g_{d1}]/(1-p_{11})g_{d1}$.

All finite sequences of arbitrary lengths of the impulses described in connection with Fig. 4.1 are possible. Suppose $(e)\to(f)\to(g)\to(h)$. Then as $\varepsilon\to 0$, it would appear that the limit $X(\cdot)$ jumps from (e) to (h) directly. But this $(e)\to(h)$ impulse must be realized as a concatenation of the basic impulses described above. In general the limit control is specified by a sequence of off/on actions for the P_i, P_{ij}, in a *specified order*, and with the impulsive distance traveled between successive ("simultaneous") control actions specified. The cost paid for the impulses is precisely the impulsive costs defined by (2.9). The described limitation on the ways in which the impulses for $X(\cdot)$ can be created is important, if the control problem for the limit $X(\cdot)$ is to be properly related to that for $X^\varepsilon(\cdot)$. In § 6, we show that the problem can be quite tractable from a numerical point of view.

The instantaneous changes in the $U^\alpha(\cdot)$ can be readily read off from the limit sequences of simultaneous impulses. For illustration, we do it for the (e, f, g, h) sequence of Fig. 4.1. Let e_i, etc. denote the ith coordinate of the point (e), and let δU^α denote the increment in U^α. On (e, f), $\delta U^{10}+\delta U^{12}=f_1-e_1$, $\delta U_c^{12}=e_2-f_2$. On (f, g), $\delta U^{01}=\delta U^{10}+\delta U^{12}$, and the value is unimportant, since their effects cancel in (2.8a). Also, $\delta U_c^{12}=f_2-g_2$. On (g, h), $\delta U^{01}=g_1-h_1$. All nonspecified δU^α are zero. The δU^{1i} always occur together as the sum $(\delta U^{10}+\delta U^{12})$.

The limit dynamical system. The Wiener process. The limit system will be (3.14), where the $W^i(\cdot)$ can be written in terms of the limits of the terms in (3.10) that are used to define them:

$$W^1(\cdot)=\tilde{A}^1(\cdot)+W_d^1(\cdot),\ W_d^1(\cdot)=-\tilde{D}^{10}(\cdot)-\tilde{D}^{12}(\cdot), \tag{4.2}$$

$$W^2(\cdot)=\tilde{A}^2(\cdot)+W_d^2(\cdot),\ W_d^2(\cdot)=-\tilde{D}^{20}(\cdot)+\tilde{D}^{12}(\cdot). \tag{4.3}$$

Here, all the terms are continuous martingales, with $\tilde{A}^1(\cdot)$, $\tilde{A}^2(\cdot)$, $\tilde{D}^{20}(\cdot)$ and $(\tilde{D}^{10}(\cdot), \tilde{D}^{12}(\cdot))$ being mutually orthogonal. The quadratic variation of $\tilde{A}^i(\cdot)$ is $\int_0^t g_{ai}^3\sigma_{ai}^2(X(s))\,ds$ and that of $W_d(\cdot)=(W_d^1(\cdot), W_d^2(\cdot))$ is $\Sigma(t)=\{\Sigma_{ij}(t)\}$, where

$$\begin{aligned}
\Sigma_{11}(t) &= g_{d1}\left[p_{11}(1-p_{11})t+g_{d1}^2(1-p_{11})^2\int_0^t \sigma_{d1}^2(X(s))\,ds\right],\\
\Sigma_{12}(t) &= -g_{d1}^3p_{12}(1-p_{11})\int_0^t \sigma_{d1}^2(X(s))\,ds-p_{12}p_{11}g_{d1}t,\\
\Sigma_{22}(t) &= g_{d2}\left[p_{20}(1-p_{20})t+p_{20}^2g_{d2}^2\int_0^t \sigma_{d2}^2(X(s))\,ds\right]\\
&\quad+g_{d1}\left[p_{12}(1-p_{12})t+p_{12}^2g_{d1}^2\int_0^t \sigma_{d1}^2(X(s))\,ds\right].
\end{aligned} \tag{4.4}$$

If the σ_{di}^2 and σ_{ai}^2 are constants, then the covariance is precisely that obtained by Reimann [1] (with a different notation used there).

It is evident from (4.4) and the cited orthogonality properties that there are mutually independent Wiener processes $w_a^i(\cdot)$, $w_d^i(\cdot)$, $w_d^{20}(\cdot)$, $\{w_d^{11}(\cdot), w_d^{12}(\cdot)\}$, where each scalar valued process is standard, and with respect to which $X(\cdot)$ is nonanticipative and $Ew_d^{11}(t)w_d^{12}(t) = -[p_{11}p_{12}/(1-p_{11})(1-p_{12})]^{1/2}t$ and

$$\tilde{A}^i(t) = g_{ai}^{3/2}\int_0^t \sigma_{ai}(X(s))\,dw_a^i(s),$$

$$W_d^1(t) = [g_{d1}p_{11}(1-p_{11})]^{1/2}w_d^{11}(t) + (1-p_{11})g_{d1}^{3/2}\int_0^t \sigma_{d1}(X(s))\,dw_d^1(s), \tag{4.5}$$

$$W_d^2(t) = [g_{d2}p_{20}(1-p_{20})]^{1/2}w_d^{20}(t) + [g_{d1}p_{12}(1-p_{12})]^{1/2}w_d^{12}(t)$$
$$+ p_{20}g_{d2}^{3/2}\int_0^t \sigma_{d2}(X(s))\,dw_d^2(s) - p_{12}g_{d1}^{3/2}\int_0^t \sigma_{d1}(X(s))\,dw_d^1(s).$$

The drift terms $B^i(\cdot)$ in (3.14) came from (3.6) and (3.7) and are

$$B^1(t) = \int_0^t [a^1(X(s)) - (1-p_{11})d^1(X(s))]\,ds,$$
$$B^2(t) = \int_0^t [a^2(X(s)) - (1-p_{22})d^2(X(s)) + p_{12}d^1(X(s))]\,ds. \tag{4.6}$$

Admissible control actions. The U_c^α and U^α in (3.14) are nondecreasing piecewise constant functions having only a finite number of jumps on each finite interval, and they can be taken to be right continuous. They thus correspond to "impulsive" controls. The allowed impulsive effects of U^1 in (3.14) are those described for $U^{1,\varepsilon}$ in (2.8), as $\varepsilon \to 0$. Also the impulsive effects of U_c^{12} are the limits of those of $U_c^{12,\varepsilon}$, and the effects of the U^{0i} are those of the $U^{0i,\varepsilon}$ as $\varepsilon \to 0$. This completely characterizes the possibilities for the impulse control of (3.14). Generally, several components of the controls might jump simultaneously, or a single jump in one component might be a consequence of a multiple simultaneous off/on sequence. We must allow these possibilities and distinguish an order for the "simultaneity," as discussed above, not only because they are possible control actions, but because they are possible limits of control actions for the physical processes. Thus, we count the parts of the multiple simultaneous impulses as distinct impulses. We now develop the notation for keeping track of the necessary information. Recall the definitions of τ_n^ε and R_n^ε given below (2.9).

Let τ_n denote the sequence of event times. The τ_n are not necessarily distinct, but $\tau_{n+1} \geqq \tau_n$ and the subscript n denotes the correct ordering, "simultaneous" or not. At each event time one or more of P_i or P_{ij} might shut off or turn on. What happens is indicated by the vector $R_n = (R_n^{01}, R_n^1, R_n^{02}, R_n^{12})$, where $R_n^{ij} = 1, -1$ or 0 (respectively, R_n^1) according to whether or not P_{ij} (respectively, P_1) is turned on, off, or not changed at τ_n. *Associated with* (τ_n, R_n) *is* $\delta U_n = (\delta U_n^{01}, \delta U_n^{02}, \delta U_n^1, \delta U_{c,n}^{12})$, *the instantaneous* (*at* τ_n) *change in the controls* $U(\cdot)$. To illustrate the procedure refer to the path (e, f, g, h) in Fig. 4.1. There are four event times: τ_1 associated with (e), τ_2 with (f), etc. Also $\tau_1 = \tau_2 = \tau_3 = \tau_4$. At τ_1, $R^1 = 1$. At τ_2, $R^{01} = 1$. At τ_3, $R^1 = -1$ and at τ_4, $R^{01} = -1$. All nonlisted R^α are zero. The associated impulses δU_n are given in the discussion below (4.3).

The $\{\delta U_n, \tau_n, R_n\}$ is said to be a control policy. The policy is said to be *admissible* if the function

$$\hat{\mathcal{R}}(t) = \{X_0, \delta U_n I_{\{\tau_n \leqq t\}}, \tau_n I_{\{\tau_n \leqq t\}}, R_n I_{\{\tau_n \leqq t\}}, I_{\{\tau_n \leqq t\}}, n < \infty, X(t), Y(t)\} \tag{4.7}$$

is nonanticipative with respect to the Wiener processes $w_\beta^\alpha(\cdot)$. An equivalent definition of admissibility is if the $\tilde{A}^i$, $\tilde{D}^{ij}(\cdot)$ are martingales with respect to the filtration generated by $\{\hat{\mathcal{R}}(t), \tilde{A}^i(\cdot), \tilde{D}^{ij}(\cdot)\}$, with the quadratic variation defined in and above (4.4).

The $Y(\cdot)$ in (3.14) is obtained from (5.1) below that is in turn obtained by taking limits in (3.13).

For an admissible policy, the cost function (the limit of (2.9)) is

$$
\begin{aligned}
V(\pi, x, P) = E_x^\pi \int_0^\infty e^{-\beta t} k(X(t))\, dt + k_1 E_x^\pi \sum_n e^{-\beta v_n^i} \\
+ \sum_1^2 k_{0i} E_x^\pi \sum_n e^{-\beta v_n^{0i}} + k_{12} E_x^\pi \sum_n e^{-\beta v_n^{12}} \\
+ E_x^\pi \int_0^\infty e^{-\beta t} \left[\sum_{i=1}^2 q_{0i}\, dU^{0i}(t) + q_{12}\, d[U_c^{12}(t) - U^{12}(t)] \right].
\end{aligned} \tag{4.8}
$$

In (4.8), the v_n^{ij}, v_n^i are defined as the moments of shutting off/turning on the indicated links or processors, as in § 2.

5. Weak convergence. Throughout the section, we use the Skorokhod topology on the products of $D[0, \infty)$, and the Euclidean topology on the Euclidean spaces.

We will use the following assumption:

(A5.1) The uncontrolled $X(\cdot)$ has a unique solution (in the weak sense) for each initial condition.

Note that (A5.1) implies weak uniqueness of the solution $X(\cdot)$ for any admissible control policy. Lemmas 5.1 and 5.2 are preparatory for the main convergence Theorem 5.1.

In the ensuing analysis, we ignore the possible increase of $Y_n^{1,\varepsilon}$ when $P_n^{12,\varepsilon} = 0$ (and $P_n^{1,\varepsilon} = 1$) for simplicity. This does not affect the result for the following reason. Shutting off the link from P_1 to P_2 does not affect the input or output process from P_1. Also, the mean number of times that the link can be shut off on any bounded time interval is bounded uniformly in ε, for otherwise the cost will go to infinity, as $\varepsilon \to 0$. Furthermore, the total mean interpolated time that the link is shut off on any bounded time interval goes to zero as $\varepsilon \to 0$, for otherwise the "$Z^{12,\varepsilon}(\cdot)$ component" of the cost will go to infinity as $\varepsilon \to 0$. A heavy traffic analysis of P_1 by itself yields a continuous limit $Y^1(\cdot)$ (see Lemma 5.3). The above facts imply that the mean increase of $Y^{1,\varepsilon}(\cdot)$ during all the intervals (on any $[0, T]$) when $P_n^{12,\varepsilon} = 0$ (and $P_n^{1,\varepsilon} = 1$) must go to zero as $\varepsilon \to 0$.

LEMMA 5.1. *Assume* (A2.1)-(A2.6) *and* (A5.1) *and let* $\sup_\varepsilon V^\varepsilon(\pi^\varepsilon, X_0^\varepsilon) < \infty$ *for* $\pi^\varepsilon = \{R_n^\varepsilon, \tau_n^\varepsilon, \delta u_n^\varepsilon, n < \infty\}$ *admissible. Then the first four convergences in* (3.9b) *all hold. On each interval* $[0, t]$ *the mean number of control actions is bounded uniformly in* ε *and each control interval collapses to a point as* $\varepsilon \to 0$.

Proof. We prove (3.9b) only for the process $\tilde{U}^{10,\varepsilon}(\cdot) = U^{10,\varepsilon}(\cdot) - p_{10} U^{1,\varepsilon}(\cdot)/(p_{10} + p_{12})$, since the rest are treated in the same way. Due to the mutual independence of the $\{I_n^{ij,\varepsilon}, n < \infty\}$ and its independence of $\{\psi_n^{1,\varepsilon}, P_n^1\}$,

$$
\tilde{U}^{10,\varepsilon}(t) = \sqrt{\varepsilon} \sum_1^{t/\varepsilon} \frac{[I_n^{10} p_{12} - I_n^{12} p_{10}]}{(p_{10} + p_{12})} \psi_n^1 (1 - P_n^1)
$$

is a martingale and its variance is bounded by $O(\varepsilon) E \sum_1^{t/\varepsilon} (1 - P_n^1) = C^\varepsilon(t)$. It is easily seen that $\overline{\lim}_\varepsilon \sqrt{\varepsilon}\, E \sum_1^{t/\varepsilon} (1 - P_n^1) < \infty$, for otherwise the buffer of P_1 will fill up (one or more times), forcing P_{01} to shut off (one or more times) such that $\overline{\lim}_\varepsilon E\, U^{01,\varepsilon}(t)$

and the associated costs will go to infinity. Thus $C^\varepsilon(t) \to 0$ as $\varepsilon \to 0$, yielding the desired result that $\tilde{U}^{10,\varepsilon}(\cdot)$ converges weakly to the zero process. The last assertion is obvious. □

Define $X_n^{i,\varepsilon}(\cdot) = X^{i,\varepsilon}((\mu_n^{i,\varepsilon} + \cdot) \cap \tilde{\mu}_n^{i,\varepsilon})$. Then (the $\delta_{in}^\varepsilon W$, etc., are defined above (3.12)) we can write

$$
\begin{aligned}
X_n^{1,\varepsilon}(t) &= X^{1,\varepsilon}(\mu_n^{1,\varepsilon}) + \delta_{1n}^\varepsilon W^{1,\varepsilon}(t) + \delta_{1n}^\varepsilon B^{1,\varepsilon}(t) + \delta_{1n}^\varepsilon \rho^{1,\varepsilon}(t) + \delta_{1n}^\varepsilon Y^{1,\varepsilon}(t), \\
X_n^{2,\varepsilon} &= X^{2,\varepsilon}(\mu_n^{2,\varepsilon}) + \delta_{2n}^\varepsilon W^{2,n}(t) + \delta_{2n}^\varepsilon B^{2,n}(t) + \delta_{2n}^\varepsilon \hat{\rho}^{2,\varepsilon}(t) \\
&\quad - p_{12}/(p_{12} + p_{10}) \delta_{2n}^\varepsilon Y^{1,\varepsilon}(t) + \delta_{2n}^\varepsilon Y^{2,\varepsilon}(t).
\end{aligned} \tag{5.1}
$$

In (5.1), $\{\mu_n^{1,\varepsilon}\}$ is the subset of $\{\tau_n^\varepsilon\}$ at which both P_1 and P_{01} are on, with at least one turned off at τ_{n-1}^ε, and $\{\mu_n^{2,\varepsilon}\}$ is the subset of times at which all of P_1, P_{12}, and P_{02} are on, with at least one being off at τ_{n-1}^ε.

LEMMA 5.2. *Assume the conditions of Lemma* 5.1. *For $\alpha = a$ and d, the processes $\varepsilon S_{\alpha, t/\varepsilon}^{i,\varepsilon}$ and $\bar{S}_\alpha^{i,\varepsilon}(\cdot)$ converge weakly to $S_\alpha^1(\cdot)$ and $\bar{S}_\alpha^i(\cdot)$, respectively, where $S_\alpha^i(t) = t/g_{\alpha i}$ and $\bar{S}_\alpha^i(t) = t g_{\alpha i}$. The $\{\tilde{A}^{1,\varepsilon}(\cdot), \tilde{A}^{2,\varepsilon}(\cdot), (\tilde{D}^{1,\varepsilon}(\cdot), \tilde{D}^{2,\varepsilon}(\cdot)), \tilde{D}^{20}(\cdot)\}$ is tight in $D^5[0,\infty)$ and the limits of any weakly convergent subsequence of the four sets (we pair $\tilde{D}^{10}$ and $\tilde{D}^{12}$) are strongly orthogonal continuous martingales. The $\{\delta_{in}^\varepsilon Y^{i,\varepsilon}(\cdot), \varepsilon > 0\}$ are tight and the weak limits are continuous, and similarly for the $\{Y^{i,\varepsilon}(\cdot), \varepsilon > 0\}$. The $\{X_n^{i,\varepsilon}(\cdot), \varepsilon > 0\}$ are tight and have continuous limits. The last two parts of* (3.9b) *hold, and the $\rho^{i,\varepsilon}(\cdot)$ and $\hat{\rho}^{i,\varepsilon}(\cdot)$ in* (3.10), (3.11), *all converge to the zero process.*

Proof. We now prove the first assertion and do only one case. We have

$$
\varepsilon S_{a,t/\varepsilon}^{i,\varepsilon} - S_a^i(t) = \varepsilon \sum_1^{t/\varepsilon} [\alpha_n^{i,\varepsilon} - \bar{\alpha}_n^{i,\varepsilon}] + O(\sqrt{\varepsilon}).
$$

The summands are martingale differences, since they are centered about their conditional expectations, given the "past." Thus, the variance of the sum is $O(\varepsilon)$. The weak convergence follows from this.

Owing to the above results, for the second assertion of the lemma we need only prove that the set $\{\tilde{A}_0^{1,\varepsilon}(\cdot), \tilde{A}_0^{2,\varepsilon}(\cdot), (\tilde{D}_0^{10,\varepsilon}(\cdot), \tilde{D}_0^{12,\varepsilon}(\cdot)), \tilde{D}_0^{20,\varepsilon}(\cdot)\}$ is tight and that the limits are continuous martingales, whose quadratic covariation = 0.

By the fact that the terms in the summands in each sum in the above set are centered about their conditional expectations (given the "past"), and the square integrability (A2.3), each term is a sum of martingale differences and is tight in the Skorokhod topology. This follows from the Aldous criterion [5, Thm. 3.3, Part 2].

By the uniform integrability in (A2.3), for each $T < \infty$, $\delta > 0$,

$$
P\left\{ \sup_{k \leq T/\varepsilon} |\sqrt{\varepsilon}(1 - \alpha_k^i / \bar{\alpha}_k^i)| > \delta \right\} \to 0.
$$

Then the jumps in $\tilde{A}_0^{i,\varepsilon}(\cdot)$ are "uniformly small." This implies that any weak limit of $\{\tilde{A}_0^{i,\varepsilon}(\cdot), \varepsilon > 0\}$ must have continuous paths w.p.1. This is similar for the other terms.

We next prove that all weak limits are orthogonal martingales. We first show the orthogonality of $\tilde{D}_0^{ij,\varepsilon}(\cdot)$ and $\tilde{A}_0^{i,\varepsilon}(\cdot)$. Take a "typical" term from each sum and use the definition of $E_{\alpha,n}^{i,\varepsilon}$ above (A2.2) and the centering in (3.1) to get (drop the ε for simplicity)

$$
\begin{aligned}
E\left[I_k^{ij} - p_{ij} \frac{\Delta_k^i}{\bar{\Delta}_k^i} \right] \left[1 - \frac{\alpha_n^i}{\bar{\alpha}_n^i} \right] &= E\left[I_k^{ij} - p_{ij} \frac{\Delta_k^i}{\bar{\Delta}_k^i} \right] I_{\{S_{d,k-1}^{i,\varepsilon} \leq S_{a,n-1}^{i,\varepsilon}\}} E_{a,n-1}^{i,\varepsilon} \left(1 - \frac{\alpha_n^i}{\bar{\alpha}_n^i} \right) \\
&\quad + E\left[1 - \frac{\alpha_n^i}{\bar{\alpha}_n^i} \right] I_{\{S_{a,n-1}^{i,\varepsilon} < S_{d,k-1}^{i,\varepsilon}\}} E_{d,k-1}^{i,\varepsilon} \left(I_k^{ij} - p_{ij} \frac{\Delta_k^i}{\bar{\Delta}_k^i} \right) = 0.
\end{aligned}
$$

By a similar calculation we can show the following. Let $h(\cdot)$ be a bounded and continuous function of its argument and let t_i, $i=1,\cdots,k$, t and s be such that $t_i \leqq t < t+s$. Then

$$Eh(\tilde{A}_0^{i,\varepsilon}(t_j), \tilde{D}_0^{ij,\varepsilon}(t_j), j \leqq k)[\tilde{A}_0^{i,\varepsilon}(t+s)\tilde{D}_0^{ij,\varepsilon}(t+s) - \tilde{A}_0^{i,\varepsilon}(t)\tilde{B}_0^{i,\varepsilon}(t)] = 0.$$

If $\tilde{A}_0^i(\cdot)$, $\tilde{D}_0^{ij}(\cdot)$ are weak limits, then

$$Eh(\tilde{A}_0^i(t_j), \tilde{D}_0^{ij}(t_j), j \leqq k)[\tilde{A}_0^i(t+s)\tilde{D}_0^{ij}(t+s) - \tilde{A}_0^i(t)\tilde{D}_0^{ij}(t)] = 0.$$

Due to the arbitrariness of $h(\cdot)$, k, t_j, t, $t+s$, this expression implies that $\tilde{A}_0^i(\cdot)$ and $\tilde{D}_0^{ij}(\cdot)$ are strongly orthogonal martingales. (The fact that they are martingales can be seen by repeating the argument and dropping one of the processes.) This argument yields the third sentence of the theorem, when applied to all the processes there.

The $\rho^{i,\varepsilon}(\cdot)$ satisfy $E\sup_{1\leqq T}|\rho^{i,\varepsilon}(t)| \overset{\varepsilon}{\to} 0$ for each T. The fact that $\{\delta_{1n}^{\varepsilon} Y^{i,\varepsilon}(\cdot), n=1,2,\cdots, \varepsilon>0\}$ is tight and has continuous limits follows from the above assertions concerning tightness and continuous limits of the processes in the arguments of the first part of (3.12). The assertion concerning $\{Y^{1,\varepsilon}(\cdot), \varepsilon>0\}$ follows from this argument and the fact that there are only finitely many control actions w.p.1 on each bounded time interval.

We now show that $(p_{10}+p_{12})Y^{12,\varepsilon}(\cdot) - p_{12}Y^{1,\varepsilon}(\cdot)$ converges to the zero process as $\varepsilon \to 0$. This expression equals $\sqrt{\varepsilon}\sum_1^{t/\varepsilon}[p_{10}I_n^{12} - p_{12}I_n^{10}]P_n^1 I_{\{X_n^1=0\}}$, which is a sum of martingale differences and has variance $O(\varepsilon)E\sum_1^{t/\varepsilon} I_{\{X_n^1=0\}}$. The fact that $Y^{1,\varepsilon}(\cdot)$ converges weakly to a continuous process implies that

$$P\left\{O(\varepsilon)\sum_1^{T/\varepsilon} I_{\{X_n^1=0\}} \geqq \delta\right\} \overset{\varepsilon}{\to} 0$$

for any $T>0$, $\delta>0$. The tightness and continuity of the weak limits of $\{\delta_{2n}^{\varepsilon} Y^{2,\varepsilon}(\cdot), n=1,2,\cdots, \varepsilon>0\}$ and of $\{Y^{2,\varepsilon}(\cdot), \varepsilon>0\}$ follows from the above assertions and the representation in the second line of (3.12). □

The following lemma is a corollary of Lemma 5.2.

LEMMA 5.3. *Assume the conditions of Lemma* 5.1. *Let ε index a weakly convergent subsequence of $\{X_n^{i,\varepsilon}(\cdot), \mu_n^{i,\varepsilon}, \tilde{\mu}_n^{i,\varepsilon}, W^{i,\varepsilon}(\cdot), \varepsilon>0, i=1,2, n=1,2,\cdots\}$ with limit denoted by $\{X_n^i(\cdot), \mu_n^i, \tilde{\mu}_n^i, W^i(\cdot), i=1,2, n=1,2,\cdots\}$. Then $\mu_{n+1}^i = \tilde{\mu}_n^i$ and $X_n^i(0) = \lim_{\varepsilon} X^{i,\varepsilon}(\mu_n^{i,\varepsilon})$. For a real-valued function $G(\cdot)$ on $[0,\infty)$, define the function $\delta_{in}G(\cdot) = G((\mu_n^i+\cdot)\cap\mu_{n+1}^i) - G(\mu_n^i)$. Then $\{Y^{i,\varepsilon}(\cdot), i=1,2, \varepsilon>0\}$ converges weakly to $(Y^1(\cdot), Y^2(\cdot))$, where $Y^i(\cdot) = \sum_{n:\mu_n^i\leqq t}\delta_{in}Y^i(t-\mu_n^i)$ and $\delta_{in}Y^i(\cdot)$ is just the weak limit of $\{\delta_{in}^{\varepsilon}Y^{i,\varepsilon}(\cdot), \varepsilon>0\}$. We have*

$$X_n^1(t) = X_n^1(0) + \delta_{1n}W^1(t) + \delta_{1n}B^1(t) + \delta_{1n}Y^1(t),$$

$$X_n^2(t) = X_n^2(0) + \delta_{2n}W^2(t) + \delta_{2n}B^2(t) + \delta_{2n}Y^2(t) - p_{12}\delta_{2n}Y^1(t)/(p_{12}+p_{10}).$$

The $\delta_{in}Y^i(\cdot)$ are continuous and can increase only at those times when $X_n^i(\cdot)$ equals zero. Also $X_n^i(t) \geqq 0$, for all t, n, i.

The proof follows from Lemma 5.2, the representation (3.12), and the weak convergence.

Notation for Theorem 5.1. Let $\mathscr{R}^{\varepsilon}$ denote the set $\{X_0^{\varepsilon}, \tilde{A}^{i,\varepsilon}(\cdot), \tilde{D}^{ij,\varepsilon}(\cdot), B^{\varepsilon}(\cdot), R_n^{\varepsilon}(\cdot), \tau_n^{\varepsilon}, \delta U_n^{\varepsilon}, i,j,n\}$, where the $\mathscr{R}$, τ and δU are defined below (2.9). If ε indexes a weakly convergent subsequence of $\{\mathscr{R}^{\varepsilon}\}$ with limit $\mathscr{R}$, we use the following notation.

Define the process

$$\mathscr{R}(\cdot) = \{X_0, \tilde{A}^i(\cdot), \tilde{D}^{ij}(\cdot), B(\cdot), i, j, (R_n, \tau_n, \delta U_n)I_{\{\tau_n\leqq\cdot\}}, n<\infty\},$$

and let $\mathcal{B}(t)$ denote the σ-algebra induced by $\{\mathcal{R}(s), s \leqq t\}$. Analogously to the definition of R_n^ε and δU_n^ε, we write $R_n = (R_n^1, R_n^{01}, R_n^{02}, R_n^{12})$ and $\delta U_n = (\delta U_n^1, \cdots, \delta U_{cn}^{12})$. Define $U^\alpha(t) = \sum_{n:\tau_n \leqq t} \delta U_n^\alpha$. The $\{\mu_n^i\}$ is a subset of $\{\tau_n\}$.

THEOREM 5.1. *Assume the conditions of Lemma* 5.1. *Then* $\{\mathcal{R}^\varepsilon\}$ *is tight. Let* ε *index a weakly convergent subsequence with limit* $\mathcal{R}$. *Let* $X(\cdot)$ *denote the process with paths in* $D[0, \infty)$ *that equals* $X_n^i(t - \mu_n^i)$ *for* $t \in [\mu_n^i, \mu_{n+1}^i)$. *Then* $(X^1(\cdot), X^2(\cdot))$ *satisfy* (3.14), *where* $W^1(\cdot) = \tilde{A}^1(\cdot) - (\tilde{D}^{10}(\cdot) + \tilde{D}^{12}(\cdot))$ *and* $W^2(\cdot) = \tilde{A}^2(\cdot) - \tilde{D}^{20}(\cdot) + \tilde{D}^{12}(\cdot)$. *The* $Y^i(\cdot)$ *can increase only when* $X^i(\cdot)$ *takes the value zero, and* $X^i(t) \in [0, B_i]$. *Then* $\tilde{A}^i(\cdot)$ *and* $\tilde{D}^{ij}(\cdot)$ *are continuous* $\mathcal{B}(t)$*-martingales with quadratic variations given in and above* (4.4). *The limit policy* $\pi = \{R_n, \tau_n, \delta U_n\}$ *is admissible for* $X(\cdot)$.

Remark. We might not have $X^\varepsilon(\cdot) \Rightarrow X(\cdot)$ in the Skorokhod topology. The problem concerns the behavior during the "control intervals." For example, let $t_0 = \varepsilon k_\varepsilon > 0$ and consider the sequence of right continuous and piecewise constant functions defined by $M^\varepsilon(t) = 0$ for $t \leqq t_0$, and that then increases at each $t = \varepsilon k$ $(k \geqq k_0)$ by $\sqrt{\varepsilon}$ until the value of one is reached. In an obvious sense, the limit is a step function—with an increase of unity at t_0, but the convergence is not in the Skorokhod topology. We still get what is desired for our control problem.

Proof. By Lemmas 5.1 and 5.2, the processes and random variables in R^ε are tight, so that we can extract and work with a weakly convergent subsequence. Also, the limits of the "~" processes are continuous martingales. The assertion concerning $Y^i(\cdot)$ and the representation (3.14) follows from Lemma 5.3.

Owing to the strong orthogonality of the four processes $\tilde{A}^{i,\varepsilon}(\cdot)$, etc., it is sufficient to prove the "quadratic variation" property separately for each component. We do it only for $(\tilde{D}^{10}(\cdot), \tilde{D}^{12}(\cdot))$. Let ε index a weakly convergent subsequence of $\{\mathcal{R}^\varepsilon\}$. Let $f(\cdot)$ be a smooth function with compact support and $h(\cdot)$ a bounded and continuous function, both being real valued. Let the t, $t+s$ and $t_k \leqq t$ below be points such that the probability $P\{\tau_n$ equals t or $t+s$ or $t_k\} = 0$ for each n, k. Define $\delta\psi_n^{ij,\varepsilon} = I_n^{ij,\varepsilon} - p_{ij}\Delta_n^{i,\varepsilon}/\bar{\Delta}_n^{i,\varepsilon}$.

By the uniform integrability (A2.3), the representation of $\tilde{D}^{ij,\varepsilon}(\cdot)$ as a sum of the $\delta\psi_n^{ij,\varepsilon}$, and a truncated Taylor series expansion, for each $N < \infty$ we can write

$$
\begin{aligned}
&Eh(X^\varepsilon(t_k), \tilde{A}^{i,\varepsilon}(t_k), \tilde{D}^{ij,\varepsilon}(t_k), B^{i,\varepsilon}(t_k), (R_n^\varepsilon, \tau_n^\varepsilon, \delta\bar{U}_n^\varepsilon) I_{\{\tau_n^\varepsilon \leqq t_k\}}, k, n \leqq N) \\
&\quad \cdot \Bigg[f(\tilde{D}^{10,\varepsilon}(t+s), \tilde{D}^{12,\varepsilon}(t+s)) - f(\tilde{D}^{10,\varepsilon}(t), \tilde{D}^{12,\varepsilon}(t)) \\
&\qquad - \sqrt{\varepsilon} \sum_{\alpha=0,2} \sum_{\varepsilon n = \bar{S}_d^{1,\varepsilon}(t)}^{\bar{S}_d^{1,\varepsilon}(t+s)} f_{x_\alpha}\left(\sqrt{\varepsilon} \sum_1^{n-1} \delta\psi_k^{10}, \sqrt{\varepsilon} \sum_1^{n-1} \delta\psi_k^{12}\right) \cdot \delta\psi_n^{1\alpha} \\
&\qquad - \frac{1}{2}\varepsilon \sum_{\alpha,\beta=0,2} \sum_{\varepsilon n = \bar{S}_d^{1,\varepsilon}}^{\bar{S}_d^{1,\varepsilon}(t+s)} f_{x_\alpha x_\beta}\left(\sqrt{\varepsilon} \sum_1^{n-1} \delta\psi_k^{10}, \sqrt{\varepsilon} \sum_1^{n-1} \delta\psi_k^{12}\right) \cdot \delta\psi_n^{1\alpha} \delta\psi_n^{1\beta} \Bigg] \\
&\quad \overset{\varepsilon}{\to} 0.
\end{aligned} \tag{5.2}
$$

Equation (5.2) holds since the conditional expectation of the bracketed quantity, given the data in the argument of $h(\cdot)$, goes to zero in the mean as $\varepsilon \to 0$.

By the properties of conditional expectations, (5.2) remains true if we replace each term of the sums in the bracket by its conditional expectation given any data that includes the data in the argument of $h(\cdot)$. Now, to exploit this, use the definition of $E_{d,n}^{1,\varepsilon}$ given above (A2.2), the centering of $\delta\psi_k^{ij,\varepsilon}$ and the assumption (A2.6) on the conditional variances, to replace $\delta\psi_k^{1\alpha}$ in the first sum in (5.2) by zero $(E_{d,k-1}^{1,\varepsilon}\delta\psi_k^{1\alpha} = 0)$,

and the $\delta\psi_k^{1\alpha}\delta\psi_k^{1\beta}$ in the second by $E_{d,k-1}^{1,\varepsilon}\delta\psi_k^{1\alpha}\delta\psi_k^{1\beta}$. For k any random time $\geqq \bar{S}_d^{1,\varepsilon}(t)$, this latter quantity is

$$E_{d,k-1}^{1,\varepsilon}\left[I_k^{1\alpha}-p_{1\alpha}\frac{\Delta_k^1}{\bar{\Delta}_k^1}\right]\left[I_k^{1\beta}-p_{1\beta}\frac{\Delta_k^1}{\bar{\Delta}_k^1}\right]=p_{1\alpha}\delta_{\alpha\beta}-p_{1\alpha}p_{1\beta}+p_{1\alpha}p_{1\beta}\,\mathrm{var}_{d,k-1}^{1,\varepsilon}\,\Delta_k^1/(\bar{\Delta}_k^1)^2$$

$$=p_{1\alpha}\delta_{\alpha\beta}-p_{1\alpha}p_{1\beta}+p_{1\alpha}p_{1\beta}g_{d1}^2\sigma_{d1}^2(X^{\varepsilon}_{S_{d,k-1}^{1,\varepsilon}})+(\text{negligible terms}). \tag{5.3}$$

With these replacements, the limit (as $\varepsilon\to 0$) of the double sum in (5.2) is

$$\frac{1}{2}\sum_{\alpha,\beta=0,2}\int_{\bar{S}_d^1(t)}^{\bar{S}_d^1(t+s)} f_{x_\alpha x_\beta}(\tilde{D}_0^{10}(\tau),\tilde{D}_0^{12}(\tau))\cdot\hat{\Sigma}_{\alpha\beta}(\tau)\,d\tau$$

where

$$\hat{\Sigma}_{00}(t)=p_{10}-p_{10}^2+p_{10}^2g_{d1}^2\sigma_{d1}^2(X(t/g_{d1})),$$
$$\hat{\Sigma}_{02}(t)=-p_{10}p_{12}+p_{10}p_{12}g_{d1}^2\sigma_{d1}^2(X(t/g_{d1})),$$
$$\hat{\Sigma}_{22}(t)=p_{20}-p_{20}^2+p_{20}^2g_{d1}^2\sigma_{d1}^2(X(t/g_{d1}))$$

where we used (5.3) and the fact that $\varepsilon S_{d,t/\varepsilon}^{1,\varepsilon}\to t/g_{d1}$ to get the proper limit of the argument of $\sigma_{d1}^2(\cdot)$. The right-hand sides are defined for all t that are not points of control action (i.e., for all but a finite number of t, w.p.1).

Now, recalling that $\bar{S}_d^i(t)=g_{di}t$, and taking limits in (5.2), we obtain

$$Eh(X(t_k),\tilde{A}^i(t_k),\tilde{D}^{ij}(t_k),B^i(t_k),(R_n,\tau_n,\delta U_n)I_{\{\tau_n\leqq t_k\}},n\leqq N,k\})$$
$$\cdot\Big[f(\tilde{D}^{10}(t+s),\tilde{D}^{12}(t+s))-f(\tilde{D}^{10}(\tau),\tilde{D}^{12}(t))$$
$$-\frac{1}{2}\sum_{\alpha,\beta=0,2}\int_{tg_{di}}^{(t+s)g_{di}} f_{x_\alpha x_\beta}(\tilde{D}^{10}(\tau),\tilde{D}^{12}(\tau))\hat{\Sigma}_{\alpha\beta}(\tau)\,d\tau\Big]=0. \tag{5.4}$$

The arbitrariness of $h(\cdot)$, $f(\cdot)$, N, t, $t+s$, and $\{t_i\}$ implies that the expectation of the bracketed term, conditional on $\mathcal{B}(t)$, is zero. Thus, (5.4) implies the asserted martingale property of $\tilde{D}^{1i}(\cdot)$.

The quadratic variation can be obtained from (5.4) by observing that $\tilde{D}_0^{1i}(t)=\tilde{D}^{1i}(g_{di}t)$ and using the change of variables $\tau/g_{d1}\to\tau$ and setting $f(x,y)$ to either x^2, xy, or y^2.

With analogous calculations for $\tilde{D}^{20,\varepsilon}(\cdot)$ and for the $\tilde{A}^{i,\varepsilon}(\cdot)$, we get the quadratic variation for the $W_\alpha^i(\cdot)$, $\tilde{A}^i(\cdot)$, $\tilde{D}^{ij}(\cdot)$, as given in § 4.

By the above argument, the limit policy $\{\tau_n,R_n,\delta U_n\}$ is "nonanticipative" with respect to the martingales. Owing to the way it was obtained as a limit of the $\{\tau_n^\varepsilon,R_n^\varepsilon,\delta U_n^\varepsilon\}$, the limit policy $\{\tau_n,R_n,\delta U_n\}$ is admissible in the sense that it corresponds to admissible sequences of impulses corresponding to the sequence of off/on controls as discussed in § 4. □

Extension. Consider the graph of $X^\varepsilon(\cdot)$ ($X^{1,\varepsilon}(\cdot)$ plotted versus $X^{2,\varepsilon}(\cdot)$) in the state space during a fixed control action. It can be shown that the graph converges uniformly (in probability) to the limit straight lines given by, for example, Fig. 4.1. The convergence is in the sense that the maximum value of the distance between any point on (this part of) the graph of $X^\varepsilon(\cdot)$ and the closest point on the limit straight line goes to zero in probability.

Alternatively, during the "control sections," use a rescaling with ε used for both the amplitude and timescale. Then the processes during this control interval converge in the Skorokhod topology, to straight lines whose graphs are precisely the graph referred to above.

THEOREM 5.2. *Assume* (A2.1)-(A2.6) *and* (A5.1), *and let* ε *index a weakly convergent subsequence with limit* $\mathcal{R}(\cdot)$. *Then* (*with* π *defined as in Theorem* 5.1) *for any* P

$$\underline{\lim_{\varepsilon}}\, V^{\varepsilon}(\pi^{\varepsilon}, x, P) \geqq V(\pi, x, P). \tag{5.5}$$

Define $N^{\alpha,\varepsilon}(t)$ *to be the number of actions of the control* P_α *on the interval* $[0, t]$. *If*

$$\{N^{\alpha,\varepsilon}(n+1) - N^{\alpha,\varepsilon}(n), \alpha, n < \infty\} \tag{5.6}$$

is uniformly integrable, then

$$V^{\varepsilon}(\pi^{\varepsilon}, x, P) \to V(\pi, x, P). \tag{5.7}$$

Proof. The relation (5.5) is just a consequence of Fatou's Lemma and the weak convergence. Now, let the uniform integrability hold. Then the holding costs and the impulsive control costs in (2.9) converge to their limits, as given by the terms in (4.8). We need only work with the last integral in (2.9). The arguments for each component are essentially the same, and we work with the $U^{01,\varepsilon}(\cdot)$ term only and assume that P_1 is on. If P_1 might also be off part of the time, the argument is a little more involved (involving the $X^{2,\varepsilon}$ as well as the $X^{1,\varepsilon}$), but is essentially the same.

When P_{01} is off, the increments in the $Y^{1,\varepsilon}(\cdot)$ are zero. (If $X^{1,\varepsilon}(t) = 0$, we must have P_{01} on, by (A2.1).) We can write

$$\begin{aligned} U^{01,\varepsilon}(t) &= \sum_n [U^{01,\varepsilon}(\tilde{v}_n^{01,\varepsilon} \cap t) - U^{01,\varepsilon}(v_n^{01,\varepsilon} \cap t)] \\ &= \sum_n [W^{1,\varepsilon}(\tilde{v}_n^{01,\varepsilon} \cap t) - W^{1,\varepsilon}(v_n^{01,\varepsilon} \cap t)] \\ &\quad - \sum_n [X^{1,\varepsilon}(\tilde{v}_n^{01,\varepsilon} \cap t) - X^{1,\varepsilon}(v_n^{01,\varepsilon} \cap t)] \\ &\quad + \sum_n [B^{1,\varepsilon}(\tilde{v}_n^{01,\varepsilon} \cap t) - B^{1,\varepsilon}(v_n^{01,\varepsilon} \cap t)] \\ &\quad + (\text{terms that go to zero as } \varepsilon \to 0). \end{aligned}$$

For some $K_1 < \infty$, the last two sums on the right are bounded by $K_1 N^{01,\varepsilon}(t)$, which is uniformly integrable by hypothesis. By the orthogonality properties of the summands in the expression for the $W^{1,\varepsilon}(\cdot)$, the mean square value of the middle term is $O(t+1)$. This yields the uniform integrability of $\{U^{01,\varepsilon}(t)\}$ for each t and of $\{U^{01,\varepsilon}(n+1) - U^{01,\varepsilon}(n), \varepsilon > 0, n < \infty\}$. By the weak convergence and the uniform integrability of these and the other terms in the last integral of (2.9), the assertion (5.7) follows. □

It is not a priori obvious that there is a control policy for which (5.6) is uniformly integrable, since we must shut off the inputs to P_i whenever its buffer is full. We will define a standard "comparison" control policy called the Δ_0-*boundary policy*, for which (5.6) is uniformly integrable. Since we can switch to this policy at any time, for any $\delta > 0$ there is a δ-optimal policy for which (5.6) is uniformly integrable. Let $\Delta_0 \in (0, \min(B_1, B_2)/4)$ and refer to Fig. 5.1. If $X^{2,\varepsilon} = B_2$ then shut off all inputs to P_2 until $X^{2,\varepsilon}$ reaches $B_2 - \Delta_0$. Then turn them back on. If at the end of that time $B_1 - \Delta_0 < X^{1,\varepsilon} \leqq B_1$, shut off P_{01} until $X^{1,\varepsilon} = B_1 - \Delta_0$. If $X^{1,\varepsilon} = B_1$, then shut off P_{01} until $X^{1,\varepsilon}$ reaches $B_1 - \Delta_0$. Then turn P_{01} back on. We use the analogous definition for the Δ_0-boundary policy for $X(\cdot)$. Then, if ever $X^{\varepsilon}(\cdot)$ or $X(\cdot)$ hits the outer boundary, we control it to a distance at least Δ_0 (in each coordinate) from the outer boundary.

THEOREM 5.3. *Assume* (A2.2)-(A2.6). *Then for the* Δ_0-*boundary control and each* $k < \infty$

$$\sup_{\substack{\varepsilon \text{ small} \\ \alpha, x, n}} E_x |N^{\alpha,\varepsilon}(n+1) - N^{\alpha,\varepsilon}(n)|^k < \infty \quad \textit{for all } \alpha, \tag{5.8}$$

and similarly for the "jump numbers" of the limit process $X(\cdot)$.

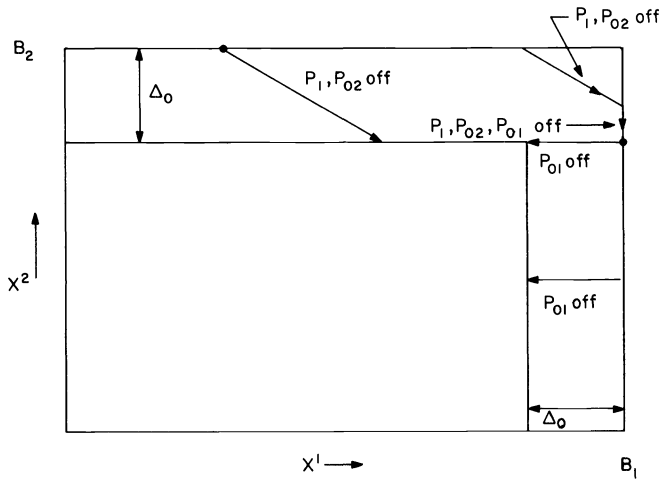

FIG. 5.1. *The comparison Δ_0-boundary control.*

Remark on the proof. Refer to Fig. 5.1. Let t_i^ε denote the ith time of return of $X^\varepsilon(\cdot)$ to the outer boundary after the ith time that the control takes the process to the set $[0, (B_1-\Delta_0)]\times[0, (B_2-\Delta_0)]$. We can readily show that for any $\delta_0 \in (0, 1)$, there is $T_0 > 0$ such that

$$\sup_{\substack{\omega,i,\\ \text{small } \varepsilon}} P\{t_{i+1}^\varepsilon - t_i^\varepsilon < T_0 \,|\, \text{data up to } t_i^\varepsilon\} \leqq 1-\delta_0. \tag{5.9}$$

This is just a consequence of the properties of $W^\varepsilon(\cdot)$ and $B^\varepsilon(\cdot)$ and of the fact that $dU^{\alpha,\varepsilon}(\cdot) = 0$ on the intervals of interest. With (5.9), it is not hard to show that all the moments of $N^{\alpha,\varepsilon}(iT_0+T_0) - N^{\alpha,\varepsilon}(iT_0)$ are bounded, uniformly in i and ε and in the initial condition (similarly, for the $X(\cdot)$ process). This yields the desired result. See the proof of Theorem 5.3 of [7] of a related result for a problem with a more complicated statistical structure.

The optimality and "almost" optimality theorem. At the present time almost nothing is known about optimal or δ-optimal ($\delta > 0$) policies for the $X^\varepsilon(\cdot)$. This is one of the basic reasons for considering suitably adapted policies that are "good" for $X(\cdot)$. Unfortunately, we know little about the optimal or δ-optimal policies for $X(\cdot)$. Thus, we must postulate (in (A5.2)) the existence of a δ-optimal policy with certain smoothness properties. The assumption appears to be eminently reasonable, since there is usually enormous flexibility in the smoothing that can be put on δ-optimal controls. The numerical results obtained via the methods described in § 6 satisfy (A5.2) for all the cases tried, in the sense that the "control decision" surfaces (discretized for the numerical calculation) seem to have the required properties. In fact, the situation in Fig. 5.1 seems to be typical, in the sense that some continuous deformation of these decision surfaces is what is seen in the numerical calculations.

For our current purposes, it is best to view the path $X(\cdot)$ as its graph in the state space. The uncontrolled sections are the graphs of the paths of the uncontrolled reflected diffusion, and the controlled sections are straight lines or "broken" straight lines, each segment corresponding to a different value of the set of indicators $P = (P^{01}, P^{02}, P^1, P^{12})$. In a sense, (A5.2) is a long-winded and formal way of saying that (for some δ-optimal policy) the lengths of the line segments are piecewise continuous in their starting point. It also deals with the possibility that the initial P might be

inappropriate for the initial state x, and that we might have to change the control settings instantaneously at $t=0$. We tried to give a general description of what reasonably seems to be expected. The situation might be simpler in special cases—but it seems likely that the useful δ-optimal control policies would be described by (A5.2), due to the nature of the impulse sequences. Note that

$$1+\sup_{x,P}[V(x,P)+1]/\min_{\alpha} k_\alpha \equiv \bar{K}$$

is an upper bound for the number of "simultaneous impulses" for the δ-optimal controls, with $\delta \leqq 1$.

We require some "smoothness" in the δ-optimal "feedback" controls, since we need to adapt them for use with the $X^\varepsilon(\cdot)$ process and will require that the corresponding sequence $\{X^\varepsilon(\cdot)\}$ (and the associated costs) converge appropriately to $X(\cdot)$ (and its associated cost).

The boundaries of the sets $G(1)$ and $G_i(P)$ below are smooth in that they are composed of a finite number of differentiable curves that are not tangent at the points of intersection. We use P to denote the control value just before a decision to change the control is made, and P_1 to denote the new control value just after the decision is made. Recall that $P=1$ is used for $P=(1,1,1,1)$.

We could replace (A5.2) by the simpler assumption that for each $\delta>0$ there is a δ-optimal admissible policy π_δ for $X(\cdot)$ and admissible policies π_δ^ε for $X^\varepsilon(\cdot)$ such that $X^\varepsilon(\cdot)$ (under π_δ^ε) converges weakly to $X(\cdot)$ (under π_δ), and the associated costs converge. Assumption (A5.2) simply defines a reasonable π_δ for which this can be done. The interiors of all sets in (A5.2) are relative to $G=[0,B_1]\times[0,B_2]$.

(A5.2) For each $\delta>0$, there is a policy π_δ for $X(\cdot)$ that is δ-optimal in the sense that it satisfies (A2.1) and

$$V(x,P)=\inf_{\pi \text{ adm.}} V(\pi,x,P) \geqq V(\pi_\delta,x,P)-\delta \tag{5.10}$$

for all x, P and that has the following properties:

(a) Let $P=1$. Then there is a decision set $G(1)$, whose boundary is divided into a finite number of segments. Each segment is associated with a switch to some $P_1 \neq 1$ when $X(\cdot)$ hits it from the exterior of $G(1)$. The segment associated with each P_1 is strictly interior to one of the sets $G_i(P_1)$ below.

(b) For each $P \neq 1$, there are a finite number (perhaps zero—see remark in (c) below) of sets $G_i(P)$ whose interiors are disjoint. If $x \in G_i(P)$ and P is used, then it is used until the boundary of $G_i(P)$ is reached. The distance (taken by the graph of $X(\cdot)$, a straight line) from $x \in G_i(P)$ to the exit point on the boundary of $G_i(P)$ is a continuous function of x. The (straight line) graph is (uniformly) not tangent to the boundary at any point of contact. The boundary is divided into a finite number of segments, each associated with a new control setting, perhaps with $P=1$. These segments are strictly interior to some set $G_j(P_1)$ for the new value P_1.

At the corners of the segments of $\partial G_i(P)$ or $\partial G(1)$, any policy associated with the intersecting segments can be used. There is $\Delta_1>0$ such that after a finite number of switches, we have $P=1$ and $X(\cdot)$ is a distance $\geqq \Delta_1$ from $G(1)$.

(c) It is possible that there will be immediate (or several) changes $P \to$ some $P_1 \neq P$ at $t=0$, until (a), (b) above are active.

Remark. The assumption concerning "points in common" to several $\partial G_i(P)$ does not seem to be restrictive. Generally, in dynamic programming, when the state is on the boundary of sets corresponding to different policies, any one of the policies is optimal.

Adapting π_δ to $X^\varepsilon(\cdot)$. By adapting the policy π_δ for use with $X^\varepsilon(\cdot)$ we simply take as the moments of decision the moments when $X^\varepsilon(\cdot)$ hits the decision boundary segments.

We now prove the "almost δ-optimality" of π_δ-applied to $X^\varepsilon(\cdot)$. This justifies the use of the limit approximations for purposes of getting nearly optimal controls.

THEOREM 5.4. *Assume* (A2.2)-(A2.6), (A5.1), *and* (A5.2). *Let π_δ^ε denote the policy of* (A5.2) *adapted to $X^\varepsilon(\cdot)$. Then*

$$V^\varepsilon(\pi_\delta^\varepsilon, x, P) \to V(\pi_\delta, x, P). \tag{5.11}$$

For admissible π^ε and small ε,

$$\sup_{\{\pi^\varepsilon\}} [V^\varepsilon(\pi_\delta^\varepsilon, x, P) - V^\varepsilon(\pi^\varepsilon, x, P)] \leqq 2\delta. \tag{5.12}$$

Proof. The proof is a consequence of the weak convergence in Theorems 5.1 and 5.3, the piecewise continuity properties of (A5.2) and an estimate of the type obtained in Theorem 5.2, and we only outline some of the argument.

(a) Let $\mathscr{R}^\varepsilon$ denote a sequence (as used in Theorem 5.1) associated with admissible π^ε. Let $\mathscr{R}_\delta^\varepsilon$ (respectively, $\mathscr{R}_\delta$) denote a convergent subsequence associated with π_δ^ε (its limit, respectively). Let $\bar{\mathscr{R}}_\delta$ and $\bar{X}_\delta(\cdot)$ denote the quantities associated with policy π_δ—with the understanding of the "multiple choices" at the corners in (A5.2)(b). Suppose that $N^\varepsilon(t)$ denotes the number of distinct control actions on $[0, t]$, and suppose that $\{N^{\alpha,\varepsilon}(n+1) - N^{\alpha,\varepsilon}(n),\ n < \infty,\ (\text{small})\ \varepsilon > 0\}$ is uniformly integrable for π_δ^ε. Now, suppose that if $\mathscr{R}_\delta$ is the limit of a subsequence of $\{\mathscr{R}_\delta^\varepsilon\}$, then $\bar{\mathscr{R}}_\delta = \mathscr{R}_\delta$. Then (5.11) holds.

The expression (5.12) is a consequence of the δ-optimality of π_δ and Theorem 5.2. Thus, we need only prove the uniform integrability and the fact that $\bar{\mathscr{R}}_\delta = \mathscr{R}_\delta$.

(b) The uniform integrability property is proved by a method similar to that used for the Δ_0-boundary policy.

(c) We examine only the case where $X(0) = X^\varepsilon(0) = x \notin G(1)$ and where there is no switch at $t = 0$, for the other cases are dealt with in a similar way. To get the desired weak convergence, we need to show that the hitting times and locations on the decision sets converge (as $\varepsilon \to 0$) to those that would hold under π_δ. Until the last remark below, we assume for simplicity that the hitting locations of the limits $X_\delta(\cdot)$ are not on the "corners." We first make the following observation.

Let H denote a compact set which is the closure of its interior and with differentiable boundary. Then for any $T < \infty$, the functions $\tau(x(\cdot)) = \min\{T, \text{hitting time of } x(\cdot) \text{ on } H\}$, $x(\tau(x(\cdot)))$ on $C[0, T]$ (sup norm) are continuous w.p.1 with respect to Wiener measure (similarly, if H satisfies the conditions that we put on $G(1)$). Let ε index a weakly convergent subsequence of $\{X^\varepsilon(\cdot)\}$ with limit denoted by $X_\delta(\cdot)$. We assume for simplicity that the hitting locations on the switching curves of $X_\delta(\cdot)$ are not on the corners (w.p.1). This is unrestrictive since by (A5.2) any of the actions that can be chosen at the corners yield the same cost. Then by the above "continuity" comment and the nondegeneracy of $(W^1(\cdot), W^2(\cdot))$, the first hitting times τ_1^ε of $X^\varepsilon(\cdot)$ on $G(1)$ converge weakly to τ_1, the first hitting time of $X_\delta(\cdot)$ on $G(1)$ and $X^\varepsilon(\tau_1^\varepsilon) \Rightarrow X_\delta(\tau_1)$.

Suppose that the first hitting point of $X_\delta^\varepsilon(\cdot)$ on $G(1)$ involves a switch to $P_1 \neq 1$, and is in the set $G_1(P_1)$. Let τ_2^ε denote the hitting time of the next decision set. Then (see comments after the proof of Theorem 5.1) the graph of $X^\varepsilon(\cdot)$ on $[\tau_1^\varepsilon, \tau_2^\varepsilon]$ converges to a straight line. By (A5.2), this straight line hits the boundary of the next decision set at precisely the same point where the $\bar{X}_\delta(\cdot)$ would hit it, if both started at $X_\delta(\tau_1)$ on $\partial G(1)$. A continuation of this argument yields that both the "diffusion" and "control" sections of $X_\delta(\cdot)$ are those of $\bar{X}_\delta(\cdot)$, which is what was to be proved. □

6. A numerical method for approximating the optimal value function and control. The control problem defined by the cost (4.8), system (3.14) and the control actions described by the possibilities associated with the off/on impulses associated with the discussion about Fig. 4.1 can be approximated by the numerical methods studied in [9]. The method in [9] involves a Markov chain (indexed by a "finite difference" parameter) approximation to the optimal continuous-time problem. We then show that the sequence of value functions for the chains converges to the optimal value function for the continuous parameter problem, and that suitable continuous parameter interpolations of the chain converge weakly to the optimal controlled continuous parameter process. The methods of [9] can be readily adapted to our problem, and only an outline will be given. The weak convergence methods used in [9] will have to be replaced by the methods here—owing to the reflection term, but the general idea is the same.

Let h be a finite-difference parameter, and let B_i be integral multiples of h. Let G_h denote the h-grid on $G = [0, B_1] \times [0, B_2]$. Define a_{ij} by $\Sigma_{ij}(t) = \int_0^t a_{ij}(X(s))\, ds$, and omit the x-argument in the $a_{ij}(\cdot)$ and $b^i(\cdot)$ below. For the Markov chain approximation, the status of the controls at any time is defined by the vector $P = (P^{01}, P^{02}, P^1, P^{12})$, where $P^\alpha = 1$ (respectively, 0) denotes that the control is on (the link is operating normally) (respectively, closed). Recall that, when $P = (1, 1, 1, 1)$, we write $P = 1$.

Let $\{X_n^h\}$ denote the approximating Markov chain, and let x denote the canonical current state, y the canonical successor state, and P_1 the canonical control that will be used at state x to bring the chain to the next state. Define $X^h(\cdot)$, the interpolated process, to be the right continuous piecewise constant process with interpolation intervals $\Delta t^h(x, P_1)$. Both these intervals and the transition probabilities $p^h(x, y \mid P_1)$ depend on the new chosen control as well as on the current state. If $P_1 \neq 1$, we use $\Delta t^h(x, P_1) = 0$; i.e., the interpolation interval has zero length. In this case, several steps of $\{X_n^h\}$ all occur simultaneously in the interpolation $X^h(\cdot)$. Define $Q_h(x) = 2[a_{11} + a_{22} - |a_{12}|] + h(|b^1| + |b^2|)$, and let $a_{ii} - |a_{12}| \geqq 0$, $i = 1, 2$. For $P_1 = 1$, we use $\Delta t^h(x, P_1) = h^2 / Q_h(x)$.

We now define the transition probabilities $p^h(x, y \mid P_1)$ for the chain when $P_1 = 1$, for $x, y \in G_h$. Let e_i denote the unit vector in the ith coordinate direction. We use

$$
\begin{aligned}
&p^h(x, x \pm e_i h \mid P_1 = 1) = [a_{ii} - |a_{12}| + h(b^i)^\pm] / Q_h(x), \\
&p^h(x, x + e_1 h - e_2 h \mid P_1 = 1) = p^h(x, x - e_1 h + e_2 h \mid P_1 = 1) \\
&\qquad = |a_{12}| / Q_h(x).
\end{aligned} \tag{6.1}
$$

If some x^i (the ith component of x) equals zero—then the transition probability (6.1) is modified as follows, as a concatenation of two transitions, the first being (6.1). For the second (the "reflection") step, we distinguish two cases.

Case 1. Either ($y^1 \geqq 0$, $y^2 < 0$) or ($y^1 < 0$, $y^2 \leqq 0$). Then simply project (reflect) the process back to the nearest point in G_h.

Case 2. $y^1<0$, $y^2>0$. Project to $(0, y^2)$ with probability $1-p_{12}/(p_{12}+p_{10})$ and to $(0, y^2-h)$ with probability $p_{12}/(p_{12}+p_{10})$. This step is to account for the $p_{12}y^1/(p_{12}+p_{10})$ term in (3.14).

Let P denote the control used to get the current state x. The actual state for the problem is the pair (x, P), since the cost associated with the next transition depends on whether or not some element of the current control vector is changed. Let $K^h(x, P, P_1)$ denote the costs associated with the transition, when current state is x, and control P changes to P_1. For $P_1=1$, $K^h(x, P, 1)=\Delta t^h(x, 1)k(x)$, the holding cost only.

We now define some of the transition probabilities and costs when $P_1\neq 1$. There are 15 possibilities, and only some typical ones will be described. These are constructed so that the limit (as $h\to 0$) of $X^h(\cdot)$ will be the reflected controlled $X(\cdot)$, and so that the associated costs for $X^h(\cdot)$ will also converge to that for $X(\cdot)$. We write $P=(P^{01}, P^{02}, P^{12}, P^1)$, $P_1=(P_1^{01}, P_1^{02}, P_1^{12}, P_1^1)$.

Let $P_1^{01}=0$, with other $P_1^\alpha=1$. Then use $p^h(x, x-e_1h\,|\,P_1)=1$ (by (A2.1), $x^1>0$ here) and $K^h(x, P, P_1)=q_{01}h+k_{01}I_{\{p^{01}=1, p_1^{01}=0\}}$. Now, let $P_1^{02}=0$ with other $P_1^\alpha=1$. Then $p^h(x, x-e_2h\,|\,P_1)=1$ and $K^h(x, P, P_1)=q_{02}h+k_{02}I_{\{p^{02}=1, p_1^{02}=0\}}$. For $P_1^{12}=0$ and other $P_1^\alpha=1$, we have $p^h(x, x-e_2h\,|\,P_1)=1$ and $K^h(x, P, P_1)=q_{12}h+k_{12}I_{\{p^{12}=1, p_1^{12}=0\}}$.

Now, let $P_1^1=0$ with other $P_1^\alpha=1$. Let $p_{12}g_{d1}\leqq g_{a1}$ (the reverse case is treated analogously) and refer to Fig. 6.1. The line from x to (a) is the mean direction of the appropriate impulse, and its slope (see § 4) is $[g_{a2}-(1-p_{22})g_{d2}]/g_{a1}=-p_{12}g_{d1}/g_{a1}$.

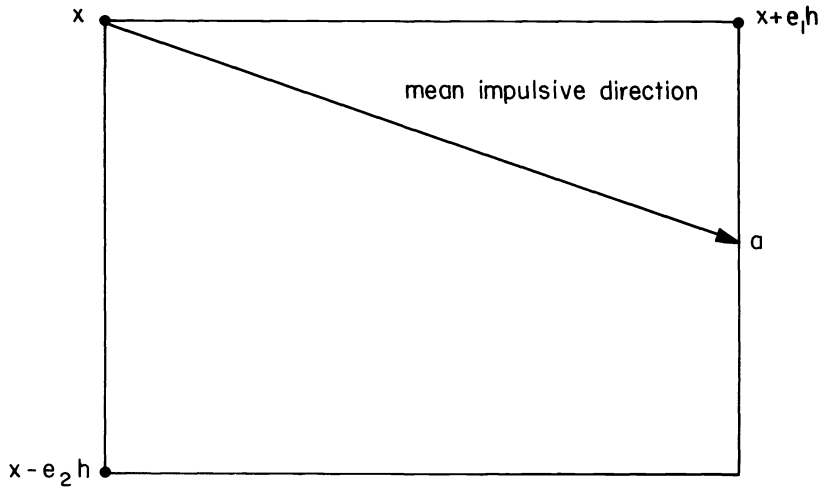

FIG. 6.1. $P^h(x, x+e_1h-e_2h/P_1)=1-P^h(x, x+e_1h/P_1)=p_{12}g_{d1}/g_{a1}$, $p_{12}g_{d1}\leqq g_{a1}$. *Transition probabilities for* $P_1^1=0$, *other* $P_1^\alpha=1$.

To "simulate" this mean line, we use

$$p^h(x, x+e_1h-e_2h\,|\,P_1)=p_{12}g_{d1}/g_{a1}=1-p^h(x, x+e_1h\,|\,P_1).$$

The instantaneous cost is $K^h(x, P, P_1)=k_1I_{\{p^1=1, p_1^1=0\}}$.

Now, let $P_1^{12}=P_1^{02}=0$ with all other $P_1^\alpha=1$. Then $p^h(x, x-e_2h\,|\,P_1)=1$. The "impulsive" part of $K^h(x, P, P_1)$ is obvious, namely, $k_{12}I_{\{p^{12}=1, p_1^{12}=0\}}+k_{02}I_{\{p^{02}=1, p_1^{02}=0\}}$. But the "opportunity" cost—that due to Z^{12} and U^{02} is less obvious. This is obtained from the relative rates at which $X^2(\cdot)$ decreases due to the effects of P_{12} and P_{02}

(respectively) being off. This is (respectively) $p_{12}g_{d1}$ and g_{a2}. Thus we use the "opportunity" cost

$$h[q_{12}p_{12}g_{d1}+q_{02}g_{a2}]/(p_{12}g_{d1}+g_{a2}).$$

The $p^h(x, y \mid P_1)$ and $K^h(x, P, P_1)$ are calculated in a similar way for all the other possibilities.

The dynamic programming equation for our "approximation" problem is

$$V^h(x, P)=\min_{P_1}\left[(\exp -\beta\Delta t^h(x, P_1))\sum_y p^h(x, y \mid P_1)V^h(y, P_1)+K^h(x, P, P_1)\right]. \tag{6.2}$$

The weak convergence methods of this paper can be used to show that $V^h(x, P)\to V(x, P)=\inf_{\pi\,\text{adm.}} V(\pi, x, P)$. For reasonable grid sizes, say 50×50, the numerical problem is quite tractable.

For the numerical problem, we do not need to duplicate the dynamics of the original system $X^\varepsilon(\cdot)$, but we can use any controlled process having the same controlled limit equation. See [9] for a fuller development of this computational point of view for a large class of more classical problems.

Appendix. We have used the assumption that if the first queue is empty at the start of a new "service interval" of length Δ, and an arrival occurs at some $\Delta'<\Delta$ later, then the service interval for that arrival is the residual time $\Delta-\Delta'$, and similarly for the second queue. In Theorem 1 of [11, p. 159], Iglehart and Whitt have shown that such an assumption does not affect the limit equations. A proof very similar to theirs works here, and we only outline the ideas and differences—with heavy reference to the cited theorem. We work only with the first queue because the second is treated in essentially the same way.

Let $\tilde{Q}^{1,\varepsilon}(\cdot)$ and $\tilde{X}^{1,\varepsilon}(\cdot)$ (set $\tilde{Q}^{1,\varepsilon}(\cdot)=\tilde{X}^{1,\varepsilon}(\cdot)/\sqrt{\varepsilon}$, $Q^{1,\varepsilon}(\cdot)=X^{1,\varepsilon}(\cdot)/\sqrt{\varepsilon}$) denote the quantities that would be obtained for the true queue; i.e., where an arrival to an empty queue has the correct—not the residual—service time. In [11], a sequence of potential "service times" has been constructed that (or some subsequence of which) has been used for *both* $Q^{1,\varepsilon}(\cdot)$ and $\tilde{Q}^{1,\varepsilon}(\cdot)$, and this has enabled a comparison of the two processes. We do the same thing here, following the method of [11] for their case $s=1$. The only difference is due to the state-dependence of the intervals here. Except for the t_0 of [11, p. 160], we use our own terminology (our $(Q, \tilde{Q}, \varepsilon, \Delta_k^{1,\varepsilon})$ is their $(Q', Q, 1/n, v_k^1)$). (First note an addendum to the proof in [11], for a case omitted there. If, given t, $\tilde{Q}^{1,\varepsilon}(\tau)\geqq 1$ for all $\tau\leqq t$, then set their $t_0=0$ and use $\tilde{Q}^{1,\varepsilon}(0)=Q^{1,\varepsilon}(0)$, and proceed as in their construction.) Let $Q^\varepsilon(0)\geqq 1$; otherwise, the result can be deduced from the argument below. The actual sequence of service intervals will be the same for both $\tilde{Q}^1$ and Q^1 until the first time that they equal zero.

Suppose that $\tilde{Q}^{1,\varepsilon}(\cdot)$ reaches zero at time τ, at the end of the kth service interval. Then generate a service interval $\Delta_{k+1}^{1,\varepsilon}$ as in the text, but with distribution determined by $\tilde{X}^\varepsilon(\tau)$ (the first component of which equals zero). Suppose that no arrival occurs between τ and $\tau+\Delta_{k+1}^{1,\varepsilon}$. Then generate the next interval $\Delta_{k+2}^{1,\varepsilon}$ as in the text, but with the distribution being determined by $\tilde{X}^\varepsilon(\tau+\Delta_{k+1}^{1,\varepsilon})$. On the other hand, suppose that an actual arrival occurs at $\tau<\tau'<\tau+\Delta_{k+1}^{1,\varepsilon}$. Then for $\tilde{Q}^{1,\varepsilon}(\cdot)$ generate another potential service interval $\Delta_{k+2}^{1,\varepsilon}$, with the distribution determined by $\tilde{X}^\varepsilon(\tau')$. We continue in this way to generate the (used and unused) service intervals for $\tilde{Q}^{1,\varepsilon}(\cdot)$. This sequence has the correct distribution for the true queue. Use the sequence $\{\Delta_k^{1,\varepsilon}\}$ for the queue $Q^{1,\varepsilon}(\cdot)$, with "residual" times used as in the text.

This procedure is precisely the one used in Theorem 1 of [11] except there the intervals are all independently and identically distributed. But, the association of particular intervals with particular service periods for both queues is exactly the same. We need only show that (A2.2), (A2.3), (A2.6) hold. In Theorem 1 of [11] it has been shown that for any T (our notation) $\sup_{t\leq T}|\tilde{X}^{1,\varepsilon}(t)-X^{1,\varepsilon}(t)|\to 0$ if (our notation) $\sqrt{\varepsilon}$ (maximum length of generated service intervals unused by $\tilde{Q}^{1,\varepsilon}(\cdot)$ on $[0, T]$) $\overset{\varepsilon}{\to} 0$. But this holds under our construction and the conditions on the intervals. This result, and the continuity and boundedness of $d_1(\cdot)$ yield

$$\begin{aligned} E^{1,\varepsilon}_{d,n}\Delta^{1,\varepsilon}_{n+1} &= g_{d1}+\sqrt{\varepsilon}\, d_1(\tilde{X}^{\varepsilon}_{S^{1,\varepsilon}_{d,n}})+o(\sqrt{\varepsilon}) \\ &= g_{d1}+\sqrt{\varepsilon}\, d_1(X^{\varepsilon}_{S^{1,\varepsilon}_{d,n}})+o(\sqrt{\varepsilon}), \end{aligned}$$

and similarly for the expression for the conditional variance. Thus, the generated service time sequence satisfies (A2.2), (A2.3), and (A2.6).

ON DISTURBANCE DECOUPLING IN DESCRIPTOR SYSTEMS*

L. R. FLETCHER† AND A. AASARAAI†

Abstract. The disturbance decoupling problem for a linear multivariable control system is to determine when and how a state feedback may be chosen so that some class of disturbances has no effect on the system output. The development of necessary and sufficient conditions for the solvability of this problem for state space systems by Wonham and his co-workers has profoundly influenced geometric control theory, particularly by means of the concept of an (A, B)-invariant subspace. This paper develops necessary and sufficient conditions for solvability of this problem for linear systems described by a mixture of algebraic and differential equations. Although the argument presented has the same structure as in the state space case, and incorporates a generalisation of (A, B)-invariant subspaces to descriptor systems, there are some additional issues. Demanding particularly careful attention is the ensuring of existence and uniqueness of classical solutions of the underlying differential equations, which cannot be taken for granted. The geometric structure of the solution space is investigated and a general notion of invariance of subspaces for descriptor systems is proposed.

Key words. descriptor systems, smooth solutions, disturbance decoupling, invariant subspaces

1. Introduction.

We study a linear multivariable control system in descriptor form:

$$E\dot{x}(t) = Ax(t) + Bu(t) + Sd(t), \qquad x(0) = x_0, \tag{1}$$

$$y(t) = Cx(t). \tag{2}$$

Here x, y, u, d are functions of time with values in $\mathscr{X} = \mathbb{R}^n$, $\mathbb{R}^p$, $\mathbb{R}^m$, $\mathbb{R}^q$, respectively, and E, A, B, C, S are real, constant, matrices of suitable sizes. Although we have in mind that E is singular, this is nowhere essential to our argument. Furthermore, many papers on such systems assume that E and A are square; following Wong [8], we will not make this assumption. A selection of examples of systems where descriptor models are useful is given by Luenberger [4] and a recent survey of results has been provided by Lewis [3]; however, implicit in this latter paper is the assumption that E and A are square. There are also intriguing, but unexplored, similarities to the work of Manitius [5] on retarded differential systems.

In (1) the function d represents unknown or unmodeled disturbances affecting the system. We investigate the questions of when and how the real $m \times n$ matrix F in the state feedback control law

$$u(t) = -Fx(t) \tag{3}$$

may be chosen so that the output $y(t)$ of the closed loop system (1)-(3) is independent of $d(t)$. In the state space case, that is when E is a nonsingular square matrix, this problem is discussed in detail in Chapter 4 of [9] and a complete solution is presented, using constructive arguments to obtain conditions on the system necessary and sufficient for the existence of F. Specifically, the following is a simple extension of Theorem 4.2 of [9]; here and throughout this paper we use $\mathscr{B}$ to denote the subspace spanned by the columns of the matrix B.

THEOREM 1.1. *Suppose E is a nonsingular square matrix. Then a necessary and sufficient condition for the existence of a feedback F such that for any continuous function d there exists an initial condition x_0 for which $y(t) \equiv 0$ is the existence of a subspace $\mathscr{V}$*

* Received by the editors October 19, 1987; accepted for publication (in revised form) December 23, 1988.

of ker C *such that*

$$A\mathcal{V} \subseteq E\mathcal{V} + \mathcal{B}, \qquad \text{Im } S \subseteq E\mathcal{V}. \tag{4}$$

It is a straightforward deduction from the proof of this result given by Wonham [9] that, for some suitably chosen F, a given initial condition x_0 leads to $y(t) \equiv 0$ whatever the disturbance function $d(t)$ if and only if $x_0 \in \mathcal{V}^*$, the unique maximal element of the set of subspaces $\mathcal{V}$ satisfying the conditions in the theorem.

Our aim in this paper is the generalisation of Theorem 1.1 to the case when E is singular and perhaps not square. Some work on disturbance decoupling in descriptor systems appears in [10] but there the class of feedbacks considered is different from ours as defined in (3). Our arguments follow closely those in [9] but there is a major new issue to be attended to in the descriptor case. It is essential that the feedback F be chosen so that the closed loop system

$$E\dot{x} = (A - BF)x + Sd, \qquad x(0) = x_0 \tag{5}$$

has appropriate regularity properties. To be precise about our objectives in this respect we need to refer to a time-invariant, first-order, linear system of differential and algebraic equations

$$E\dot{x}(t) = Mx(t) + f(t), \qquad x(0) = x_0 \tag{6}$$

in which E and x are as before, M is a matrix of the same size as E, and $f(t)$ is a vector function of time with the appropriate number of components. The theory of systems such as (5) or (6) depends on what is meant by a solution; throughout this paper we adopt the following definition.

DEFINITION 1.1. A function $x : [0, \infty) \to \mathbb{R}^n$ is a *solution* of the initial value problem (6) if

(i) $\dot{x}(t)$ exists and satisfies the differential equation for all $t > 0$;

(ii) $x(0) = x_0$;

(iii) $\dot{x}(0+)$ exists and $E\dot{x}(0+) = Mx_0 + f(0)$.

This stipulation about the admissible solutions to (5) or (6) implies some regularity properties of the function $f(t)$ and an appropriate relation between the behaviour of f at zero and x_0. It is recognised that this is suitable for some applications and not for others [6]; however, it is essential in all approaches that F be chosen so that uniqueness of solutions to (5) prevails. Thus we have the following definition.

DEFINITION 1.2. We shall say that the system (6) is *semiregular* if it has at most one solution for any initial condition.

It is shown in [1] that (6) is semiregular if and only if the matrix $M - \lambda E$ has linearly independent columns for some value of λ. Moreover, this is equivalent to requiring that the pencil $M - \lambda E$ is nonsingular in the sense of [8] so this definition is a generalisation for possibly nonsquare E and A of the classical notion of regularity [3, § 2]. Ultimately, a feedback F that achieves disturbance decoupling must also ensure that the system (5) is semiregular in this sense, so we need to avoid at the outset the pathological situation that for no F does closed loop regularity hold. It is shown in [1] that this is equivalent to the following assumption.

REGULARISABILITY ASSUMPTION. We will assume that for at least one complex number λ the matrix

$$[A - \lambda E, B]$$

has (at least) n linearly independent columns.

Note that we do not need to assume that the open loop system enjoys uniqueness of solutions. On the other hand our regularisability assumption can only be satisfied if in (1) there are at least n equations.

In discussing (6) it is important to bear in mind that, eventually, in constructing a feedback matrix to solve the disturbance decoupling problem, the matrix M is replaced by the closed loop system matrix $A-BF$, which is unknown at the outset, and $f(t)$ represents the disturbance function $Sd(t)$ where $d(t)$ is unknown throughout. For these reasons the well-known analysis of (6) by means of the Kronecker canonical form (see, for example, [7]) does not meet our needs. Although it might be possible to describe by such means the features of the pencil $A-\lambda E$ that are desirable for disturbance decoupling, it is not known at present to what extent the Kronecker canonical form of $A-BF-\lambda E$ can be assigned by a suitable choice of the matrix F. We must therefore adopt a different approach to (4) as exemplified by the following key concept.

DEFINITION 1.3. A pair of subspaces $\mathcal{U}$, $\mathcal{V}$ will be said to be $(\{A, E\}, B)$-*invariant* if

(i) $A\mathcal{V} \subseteq E\mathcal{V} + \mathcal{B}$;

(ii) $\mathcal{V} \cap \ker E = \{0\}$;

(iii) $E\mathcal{U} \subseteq A\mathcal{U} + \mathcal{B}$;

(iv) $\dim (E\mathcal{U} \cap \mathcal{B}) \leqq \dim \{u \in \mathcal{U}: Au \in \mathcal{B}\}$.

The final ingredient in our main result is a statement of what we mean by "disturbance decoupling."

DEFINITION 1.4. We shall say that a feedback matrix F *achieves disturbance decoupling* for the system (1), (2) if the closed loop system (5), (2) has the following properties.

(i) For no initial condition x_0 and disturbance function $d(t)$ does (5) have more than one solution;

(ii) For every disturbance function $d(t)$ that is sufficiently differentiable there is a solution of (5) for any initial value x_0 in a certain affine subspace of $\mathcal{X}$;

(iii) $y(t)$ is independent of $d(t)$ in that for any sufficiently differentiable d there are initial conditions, admissible in the sense of (ii), such that $y(t) \equiv 0$.

Now we can state our main result.

MAIN THEOREM. *So that there exists a matrix F achieving disturbance decoupling for the system* (1), (2) *it is necessary and sufficient that there exists an* $(\{A, E\}, B)$-*invariant pair of subspaces $\mathcal{U}$, $\mathcal{V}$ contained in* $\ker C$ *such that*

$$\operatorname{Im} S \subseteq E\mathcal{V} + \mathcal{L}$$

for some $\mathcal{L}$ satisfying the following:

(a) $E\mathcal{U} \subseteq \mathcal{L} \subseteq A\mathcal{U} + \mathcal{B}$;

(b) $\dim \mathcal{L} \cap \mathcal{B} \leqq \dim \{u \in \mathcal{U}: Au \in \mathcal{B}\}$.

We have not been able to determine simple conditions on x_0 necessary and sufficient for the existence of a solution (in the sense of Definition 1.1) of (5) for a suitably chosen F in which $y(t) \equiv 0$ whatever the disturbance function $d(t)$. The main obstacle is that the admissibility of x_0 depends on the values of d and its derivatives at $t=0$ so that a given initial condition, $x_0 = 0$ say, might be admissible for one disturbance function and not for another; this issue is addressed in (iii) of Definition 1.4. In the proof of the Main Theorem the value of $v(0)$ in (19) below is the crucial point. It is not difficult to deduce some sufficient conditions on x_0 from the argument at the end of § 3. For example, if the disturbance function $d(t)$ is such that $Sd(t) \in E\mathcal{V}$ in some interval $[0, t_0)$ and $x_0 \in \mathcal{V}$ then, for some suitably chosen F, $y(t) \equiv 0$. However, these conditions are not necessary.

The linear algebraic arguments in § 2 below form the heart of the paper. They provide a feedback characterisation of those subspaces that are invariant in the sense

of satisfying Definition 1.3. In § 3 we prove the sufficiency claim in our Main Theorem. Finally, in § 4, we examine the Kronecker canonical form of a closed loop system in which disturbance decoupling is assumed to have been achieved, in order to prove the necessity part of the Main Theorem.

2. Invariant subspaces for descriptor systems. Our main objective in this section is a proof of the following key result:

THEOREM 2.1. *If the pair of subspaces $\mathcal{U}$, $\mathcal{V}$ is $(\{A, E\}, B)$-invariant, then there exists a matrix F and a subspace $\mathcal{W}$ with $\mathcal{V} \subseteq \mathcal{W} \subseteq \mathcal{U} + \mathcal{V}$ such that*

$$(A - BF)\mathcal{W} \subseteq E\mathcal{W}, \qquad E\mathcal{U} \subseteq (A - BF)\mathcal{U}$$

and the matrix $A - BF - \lambda E$ has linearly independent columns for some complex number λ.

Our proof of this result is couched entirely in terms of linear algebra and is somewhat intricate so we proceed by means of a sequence of lemmas. The first of these is of some interest in its own right.

LEMMA 2.2. *For a given subspace $\mathcal{U}$ there exists a matrix F such that*

$$E\mathcal{U} \subseteq (A - BF)\mathcal{U} \tag{7}$$

if and only if $\mathcal{U}$ satisfies (iii) *and* (iv) *of Definition* 1.3. *Moreover, in these circumstances we can arrange that $\mathcal{L} \subseteq (A - BF)\mathcal{U}$ for any subspace $\mathcal{L}$ satisfying conditions* (a) *and* (b) *in the Main Theorem.*

Proof. Let $u_1, \cdots, u_s$ be elements of $\mathcal{U}$ such that $Eu_1, \cdots, Eu_r$ is a basis of $E\mathcal{U} \cap \mathcal{B}$ and $u_{r+1}, \cdots, u_s$ is a basis of $\mathcal{U} \cap \ker E$ and let $u_{s+1}, \cdots, u_t$ be the remainder of a basis of $\mathcal{U}$.

Suppose (7) holds for some matrix F then, clearly, (iii) of Definition 1.3 holds. Furthermore, there exist $w_1, \cdots, w_r \in \mathcal{U}$ such that

$$Eu_i = (A - BF)w_i \quad \text{for } i = 1, \cdots, r$$

and so for $i = 1, \cdots, r$ we have

$$Aw_i = Eu_i + BFw_i \in \mathcal{B}.$$

Thus $w_1, \cdots, w_r$ are linearly independent elements of the subspace $\{u \in \mathcal{U}: Au \in \mathcal{B}\}$ so (iv) of Definition 1.3 holds.

Conversely, suppose (iii) and (iv) of Definition 1.3 hold. Then

$$Eu_i = Aw_i + Bv_i \quad \text{for } i = 1, \cdots, t \tag{8}$$

for some $w_1, \cdots, w_t \in \mathcal{U}$. Clearly, $w_{s+1}, \cdots, w_t$ are linearly independent and we can take $w_1 = \cdots = w_r = 0$. We are assuming that there exist linearly independent vectors $\tilde{w}_1, \cdots, \tilde{w}_r \in \mathcal{U}$ such that

$$A\tilde{w}_i = B\tilde{v}_i \quad \text{for } i = 1, \cdots, r.$$

We show first that the vectors $\tilde{w}_1, \cdots, \tilde{w}_r$; $w_{s+1}, \cdots, w_t$ are linearly independent. Indeed were there scalars $\alpha_{s+1}, \cdots, \alpha_t$, not all zero, such that

$$\sum_{i=s+1}^{t} \alpha_i Aw_i \in \mathcal{B},$$

then, according to (8), the vector

$$\sum_{i=s+1}^{t} \alpha_i Eu_i = \sum_{i=s+1}^{t} \alpha_i Aw_i + B \sum_{i=s+1}^{t} \alpha_i v_i$$

would also lie in $\mathcal{B}$, contrary to the definition of the integer s. Now define F by

$$F\tilde{w}_i = \tilde{v}_i - v_i, \qquad i = 1, \cdots, r,$$

$$Fw_i = -v_i, \qquad i = s+1, \cdots, t$$

and extend F to the whole of $\mathcal{X}$ arbitrarily. Then for $i = 1, \cdots, r$ we have

$$\begin{aligned}(A - BF)\tilde{w}_i &= B\tilde{v}_i - B(\tilde{v}_i - v_i) \\ &= Bv_i = Eu_i\end{aligned}$$

for $i = r+1, \cdots, s$ we have

$$Eu_i = (A - BF)0$$

and for $i = s+1, \cdots, t$ we have

$$(A - BF)w_i = Aw_i + Bv_i = Eu_i.$$

Thus $E\mathcal{U} \subseteq (A - BF)\mathcal{U}$ as required.

Now suppose $\mathcal{Z}$ is a subspace satisfying conditions (a) and (b) of the Main Theorem. Let $z_1, \cdots, z_p$ be a basis of $\mathcal{Z} \cap \mathcal{B}$. Then, by condition (b), there exist linearly independent elements $v_1, \cdots, v_p$ of $\mathcal{U}$ such that $Av_i \in \mathcal{B}$. There exists a matrix F such that (7) holds, so there are vectors $v_1, \cdots, v_p \in \mathcal{U}$ and $g_1, \cdots, g_p$ satisfying

$$z_i = (A - BF)v_i + Bg_i \quad \text{for } i = 1, \cdots, p. \tag{9}$$

Now let $z_{p+1}, \cdots, z_q$ be linearly independent elements of $E\mathcal{U}$ such that $z_1, \cdots, z_q$ is a basis of $(\mathcal{Z} \cap \mathcal{B}) + E\mathcal{U}$. Then for $i = p+1, \cdots, q$ there exist $u_i, v_i \in \mathcal{U}$ such that

$$Eu_i = z_i = (A - BF)v_i. \tag{10}$$

Our next step is to show that the subspaces of $\mathcal{U}$ spanned by $v_1, \cdots, v_p$ and by $v_{p+1}, \cdots, v_q$ intersect trivially. First note that, since $E\mathcal{U} \cap \mathcal{B} \subseteq \mathcal{Z} \cap \mathcal{B}$, the space spanned by $z_{p+1}, \cdots, z_q$ does not intersect $\mathcal{B}$. Now suppose

$$\sum_{i=1}^{p} \alpha_i v_i = \sum_{i=p+1}^{q} \beta_i v_i.$$

Then, by (9) and (10)

$$\sum_{i=1}^{p} \alpha_i z_i - B \sum_{i=1}^{p} \alpha_i g_i = \sum_{i=p+1}^{q} \beta_i z_i.$$

But the left-hand side here lies in $\mathcal{B}$, and, as we have just remarked, the right-hand side does not, unless it is zero. Thus the subspaces of $\mathcal{U}$ we are considering do intersect trivially so there exists a matrix F_0 such that

$$F_0 v_i = -g_i, \qquad i = 1, \cdots, p,$$

$$F_0 v_i = 0, \qquad i = p+1, \cdots, q.$$

Putting $F_1 = F + F_0$ we see that

$$z_i = (A - BF_1)v_i \quad \text{for } i = 1, \cdots, q$$

and

$$E\mathcal{U} \subseteq (A - BF_1)\mathcal{U}.$$

To complete the proof of Lemma 2.2, let $z_{q+1}, \cdots, z_r$ be the remainder of a basis of $\mathscr{Z}$ and choose a matrix F_1 so that for the largest possible integer k there exist $v_1, \cdots, v_k \in \mathscr{U}$ such that

$$z_i = (A - BF_1)v_i \quad \text{for } i = 1, \cdots, k. \tag{11}$$

To complete the proof of this lemma we show that $k = r$; we have shown in the previous paragraph that $k \geqq q$. Suppose $k < r$; then, by condition (a) of the Main Theorem, there is some nonzero g_{k+1} such that

$$z_{k+1} = (A - BF_1)v_{k+1} + Bg_{k+1}.$$

Were v_{k+1} dependent on $v_1, \cdots, v_k$ in (11), say

$$v_{k+1} = \sum_{i=1}^{k} \alpha_i v_i$$

then we would have

$$\sum_{i=1}^{k} \alpha_i z_i = z_{k+1} - Bg_{k+1}$$

so that

$$Bg_{k+1} = z_{k+1} - \sum_{i=1}^{k} \alpha_i z_i \in \mathscr{Z} \cap \mathscr{B}.$$

But $z_1, \cdots, z_p$ is a basis of $\mathscr{Z} \cap \mathscr{B}$ and $k+1 > p$ so we would have a contradiction. Since, then, v_{k+1} is not dependent on $v_1, \cdots, v_k$ there exists a matrix F_2 such that

$$F_2 v_i = 0 \quad \text{for } i = 1, \cdots, k,$$

$$F_2 v_{k+1} = -g_{k+1}.$$

Replacing F_1 by $F_1 + F_2$ would increase the value of k, which would be a contradiction. Thus $k = r$.

This completes the proof of Lemma 2.2.

It is worth noting that conditions (i) and (ii) of Definition 1.3 are necessary and sufficient for the existence of a matrix F such that

$$(A - BF)\mathscr{V} \subseteq E\mathscr{V} \tag{12}$$

and the matrix $A - BF - \lambda E$ has linearly independent columns for some complex number λ. As far as necessity is concerned, we need only point out that if (12) holds then

$$(A - BF - \lambda E)\mathscr{V} \subseteq E\mathscr{V}$$

so $A - BF - \lambda E$ having linearly independent columns implies that $\dim E\mathscr{V} = \dim \mathscr{V}$. Sufficiency will follow from Theorem 2.1 with $\mathscr{U} = \{0\}$.

Continuing with the proof of Theorem 2.1, from the set of F satisfying the requirements of Lemma 2.2, we aim to select one that also satisfies the other requirements of Theorem 2.1 for a suitable subspace $\mathscr{W}$.

LEMMA 2.3. *If $\mathscr{U}$ satisfies* (iii) *of Definition* 1.3 *then there exist subspaces $\mathscr{Q}$, $\mathscr{T}$ of $\mathscr{U}$ such that*

$$\mathscr{U} = \mathscr{Q} \oplus \mathscr{T}, \qquad E\mathscr{Q} \subseteq (A - BF)\mathscr{Q},$$

$$E\mathscr{T} = (A - BF)\mathscr{T}, \qquad \mathscr{T} \cap \ker E = \{0\}.$$

Proof. Let $G: \mathcal{U} \to \mathcal{U}$ be a linear mapping obtained by writing for $u \in \mathcal{U}$

$$Gu = w$$

where $w \in \mathcal{U}$ is a solution of the equation

$$Eu = (A - BF)w.$$

Now let

$$\mathcal{Q} = \bigcup_i \ker G^i, \qquad \mathcal{T} = \bigcap_i \operatorname{Im} G^i.$$

It is a well-known general property of linear transformations (see, for example, p. 48–49 of [2]) that, with these definitions

$$\mathcal{Q} \oplus \mathcal{T} = \mathcal{U}, \quad G\mathcal{Q} \subseteq \mathcal{Q}, \quad G\mathcal{T} = \mathcal{T}, \quad \mathcal{T} \cap \ker G = \{0\}.$$

It is easy to see that this completes the proof of Lemma 2.3.

DEFINITION 2.1. For an $(\{A, E\}, B)$-invariant pair $\mathcal{U}, \mathcal{V}$ let $\mathcal{W}$ be a subspace that is maximal subject to the following:

(i) $\mathcal{V} \subseteq \mathcal{W} \subseteq \mathcal{V} + \mathcal{T}$;

(ii) $A\mathcal{W} \subseteq E\mathcal{W} + \mathcal{B}$;

(iii) $\mathcal{W} \cap \ker E = \{0\}$ where $\mathcal{T}$ is the subspace of $\mathcal{U}$ whose existence is established in Lemma 2.3.

Since $\mathcal{V}$ itself satisfies these conditions such subspaces $\mathcal{W}$ exist although, in general, $\mathcal{W}$ is not uniquely determined. However, we have the following useful result.

LEMMA 2.4. *If $\mathcal{W}_1$, $\mathcal{W}_2$ are both maximal subject to satisfying* (ii) *and* (iii) *of Definition* 2.1, *then* $E\mathcal{W}_1 = E\mathcal{W}_2$.

Proof. We show that $\mathcal{W}_1 \subseteq \mathcal{W}_2 + \ker E$. Let $H: \mathcal{W}_1 \to \mathcal{W}_1$ be the linear transformation given by $Hw = z$ where $z \in \mathcal{W}_1$ is chosen to satisfy

$$Aw = Ez + b$$

for some $b \in \mathcal{B}$. If w_1 is an eigenvector of H, say $Hw_1 = \lambda w_1$, then, for some $b_1 \in \mathcal{B}$,

$$Aw_1 = \lambda Ew_1 + b_1.$$

Now the space spanned by w_1 and W_2 satisfies Definition 2.1(iii) and so, by the maximality of $\mathcal{W}_2$

$$w_1 \in \mathcal{W}_2 + \ker E.$$

Thus

$$Aw_1 = Ew_2 + b_1$$

for some $w_2 \in \mathcal{W}_2$.

Now suppose $v_1 \in \mathcal{W}_1$ such that $Hv_1 = \lambda v_1 + w_1$; that is, v_1 is a principal vector of H with respect to the eigenvalue λ. Then

$$\begin{aligned} Av_1 &= E(\lambda v_1 + w_1) + b_2 \\ &= \lambda Ev_1 + Ew_2 + b_2 \end{aligned}$$

for some $b_2 \in \mathcal{B}$. Now the subspace spanned by $\mathcal{W}_2$ and v_1 satisfies Definition 2.1(iii) so, by the maximality of $\mathcal{W}_2$

$$v_1 \in \mathcal{W}_2 + \ker E.$$

Continuing in this way shows that the entire root space [2] of H in $\mathcal{W}_1$ relating to λ is contained in $\mathcal{W}_2+\ker E$. Repeating this for each eigenvalue of H shows that $\mathcal{W}_1 \subseteq \mathcal{W}_2+\ker E$.

This completes the proof of Lemma 2.4.

COROLLARY 2.5. *In the notation of Definition* 2.1

$$E\mathcal{T} \subseteq E\mathcal{W}.$$

Proof. The subspace $\mathcal{T}$ satisfies (ii) and (iii) of Definition 2.1.

LEMMA 2.6. *For an* $(\{A, E\}, B)$*-invariant pair* $\mathcal{U}$, $\mathcal{V}$ *the matrix* F *can be chosen to satisfy*

$$(A-BF)\mathcal{W} \subseteq E\mathcal{W}$$

(*in addition to the requirements of Lemma* 2.2).

Proof. Let $w_1, \cdots, w_k$ be a basis of $\mathcal{W} \cap \mathcal{T}$ and $w_{k+1}, \cdots, w_l$ be the remainder of a basis of $\mathcal{W}$. Then, for $i=1, \cdots, k$ there exist $t_1, \cdots, t_k \in \mathcal{T}$ such that

$$(A-BF)w_i = Et_i$$

and so, by Corollary 2.5,

$$(A-BF)w_i \in E\mathcal{W} \quad \text{for } i=1, \cdots, k.$$

Now $w_{k+1}, \cdots, w_l \in \mathcal{W} \setminus \mathcal{U}$ by the construction of $\mathcal{W}$ and also there exist $v_i \in \mathcal{W}$ and g_i such that

$$Aw_i = Ev_i + Bg_i \quad \text{for } i=k+1, \cdots, l.$$

If we arrange that

$$Fw_i = g_i \quad \text{for } i=k+1, \cdots, l,$$

then $F|\mathcal{U}$ can remain unaltered and

$$(A-BF)w_i \in E\mathcal{W} \quad \text{for } i=k+1, \cdots, l.$$

This completes the proof of Lemma 2.6.

Finally in this section we show that a matrix F can be chosen from amongst those satisfying the requirements of Lemmas 2.2 and 2.6 and such that, for some complex number λ, the matrix $A-BF-\lambda E$ has linearly independent columns. To do this, let $w_1, \cdots, w_k$ continue to denote a basis of $\mathcal{W}$, let $u_{k+1}, \cdots, u_l$ be linearly independent vectors in $\mathcal{Q}$ such that $Eu_{k+1}, \cdots, Eu_l$ complement $E\mathcal{W}$ in $E(\mathcal{U}+\mathcal{V})$ and let $w_{k+1}, \cdots, w_l$ be vectors in $\mathcal{Q}$ such that $Eu_i = (A-BF)w_i$ for $i=k+1, \cdots, l$.

LEMMA 2.7. *Suppose* F *satisfies the requirements of Lemmas* 2.2 *and* 2.6. *For all but a finite number of values of* λ, *if* w *is a nonzero linear combination of* $w_1, \cdots, w_l$ *then* $(A-BF-\lambda E)w \neq 0$.

Proof. The choice of $w_{k+1}, \cdots, w_l$ ensures that the vectors $(A-BF)w_i = Eu_i$ for $i=1, \cdots, l$ are linearly independent. Indeed if

$$(A-BF)\sum_{i=1}^{k} \alpha_i w_i = (A-BF)\sum_{i=k+1}^{l} \alpha_i w_i,$$

then, since $(A-BF)\mathcal{W} \subseteq E\mathcal{W}$, there exists $v \in \mathcal{W}$ such that

$$Ev = \sum_{i=k+1}^{l} \alpha_i Eu_i$$

contrary to the choice of $u_{k+1}, \cdots, u_l$ unless $\alpha_{k+1} = \cdots = \alpha_l = 0$. Now, if P is a matrix whose columns are a basis of $(E\mathcal{W})^{\perp}$ and $Q_0 = [w_{k+1}, \cdots, w_l]$ is a matrix with the

columns shown, then we have just proved that the matrix $P^T(A-BF-\lambda E)Q_0$ has linearly independent columns when $\lambda=0$. Hence it has linearly independent columns for all but a finite number of values of λ or, in other words, for only a finite number of values of λ is there a vector w such that $Ew \in E(\mathcal{U}+\mathcal{V})\backslash E\mathcal{W}$ and $(A-BF-\lambda E)w \in E\mathcal{W}$.

Now let $H: \mathcal{W} \to \mathcal{W}$ denote the linear transformation given by $Hw=v$ for $v, w \in \mathcal{W}$ satisfying

$$(A-BF)w = Ev.$$

Then

$$\begin{aligned}(A-BF-\lambda E)w &= Ev-\lambda Ew\\ &= E(H-\lambda I)w.\end{aligned}$$

If λ is not an eigenvalue of H then, recalling that $\mathcal{W}\cap\ker E=\{0\}$, it is clear that $(A-BF-\lambda E)w=0$ for $w\in\mathcal{W}$ only if $w=0$.

If λ does not belong to either of these exceptional sets then the conclusion of Lemma 2.7 holds.

Proof of Theorem 2.1. Let $w_{l+1}, \cdots, w_n$ be the remainder of a basis of $\mathcal{X}$. Choose F from amongst those that satisfy the requirements of Lemma 2.6 and λ so that, for the largest possible value of the integer r, the vectors

$$(A-BF-\lambda E)w_i \quad \text{for } i=1,\cdots,r \tag{13}$$

are linearly independent. We must show that $r=n$; Lemma 2.7 shows that $r\geqq l$. Suppose $r<n$. By our regularisability assumption, the matrix $[A-\mu E, B]$ has at least n linearly independent columns for some μ and, hence, for almost all μ. We can assume, therefore, that the λ just chosen is not one of these exceptional values of μ and hence that the vectors

$$(A-BF-\lambda E)w_i \quad \text{for } i=r+1,\cdots,n$$

are linearly dependent on those in (13) and that there are vectors $g_{r+1}, \cdots, g_n$ such that

$$Bg_{r+1}, \cdots, Bg_n \tag{14}$$

are linearly independent of those in (13). Define $F_1: \mathcal{X} \to \text{span}\{g_{r+1}, \cdots, g_n\}$ by

$$F_1 w_i = 0 \quad \text{for } i=1,\cdots,r,$$

$$F_1 w_i = g_i \quad \text{for } i=r+1,\cdots,n.$$

Since $r\geqq l$, $F_1 w=0$ for all $w\in\mathcal{W}$ and

$$Eu_i = (A-B(F+F_1))w_i \quad \text{for } i=k+1,\cdots,l,$$

$F+F_1$ satisfies the requirements of Lemmas 2.2 and 2.6. On the other hand, the vectors

$$(A-B(F+F_1)-\lambda E)w_i \quad \text{for } i=1,\cdots,n$$

span the same space as the vectors in (13) and (14). This contradicts the choice of F and λ so $r=n$.

This completes the proof of Theorem 2.1.

3. The proof of the Main Theorem: sufficiency. In this section we show that the conditions in the Main Theorem are sufficient to ensure the existence of a feedback matrix F achieving disturbance decoupling in the sense we have defined it. More precisely, we prove that any matrix F satisfying the conclusions of Theorem 2.1 and

Lemma 2.2 with respect to the given $\mathcal{U}$, $\mathcal{V}$, $\mathcal{Z}$ will suffice. Note that the uniqueness of solutions to the closed loop equation

$$E\dot{x} = (A - BF)x + Sd(t), \qquad x(0) = x_0 \tag{15}$$

follows, by Theorem 1 of [1], from the matrix $A - BF - \lambda E$ having linearly independent columns for some complex number λ. Thus it is sufficient to consider existence of solutions; the argument we provide illuminates some more general issues so we postpone any consideration of $y(t)$ until the end of this section.

For most of this section we discuss the existence of solutions of the system (6), assuming that the pencil $M - \lambda E$ is nonsingular in the sense of Wong [8]. We have already noted that the Kronecker canonical form is not an appropriate technique and we will also require information about the subspaces in which a solution evolves in more detail than is provided by existing approaches. On the other hand, most of the linear algebra we require is available in [8], though it will be necessary for us to reformulate some of Wong's results. We begin with a simple result about the case $f(t) \equiv 0$.

LEMMA 3.1. *Let $\mathcal{X}_0$ be a subspace of $\mathcal{X}$ and let $\mathcal{V}^*$ denote the unique maximal element of the collection*

$$\{\mathcal{V} \subseteq \mathcal{X}_0 \colon M\mathcal{V} \subseteq E\mathcal{V}\} \tag{16}$$

of subspaces of $\mathcal{X}_0$. Then the equation

$$E\dot{x}(t) = Mx(t), \qquad x(0) = x_0 \tag{17}$$

has a solution such that $x(t) \in \mathcal{X}_0$ for all $t \geqq 0$ if and only if $x_0 \in \mathcal{V}^*$.

Proof. Suppose $x_0 \in \mathcal{V}^*$. Since $M\mathcal{V}^* \subseteq E\mathcal{V}^*$, there exists a linear transformation $\mathcal{X} \to \mathcal{X}$ with matrix L such that $L\mathcal{V}^* \subseteq \mathcal{V}^*$ and $Mv = ELv$ for all $v \in \mathcal{V}^*$. If $x_0 \in \mathcal{V}^*$ then $x(t) = e^{Lt}x_0$ satisfies (17) and has $x(t) \in \mathcal{X}_0$ for all $t \geqq 0$.

Conversely, suppose $x(t)$ satisfies (17) with $x(t) \in \mathcal{X}_0$ for all $t \geqq 0$. Let $\mathcal{V}$ be the smallest subspace of $\mathcal{X}_0$ such that $x(t) \in \mathcal{V}$ for all $t \geqq 0$; we show that $\mathcal{V}$ is one of the subspaces (16). If $v \in \mathcal{V}$ then $v = x(t_1) + x(t_2) + \cdots + x(t_k)$ for some $t_1, t_2, \cdots, t_k$ and so

$$Mv = E\dot{x}(t_1) + E\dot{x}(t_2) + \cdots + E\dot{x}(t_k).$$

Thus, to show that $M\mathcal{V} \subseteq E\mathcal{V}$, it is sufficient to prove that $\dot{x}(t) \in \mathcal{V}$ for all $t \geqq 0$. But

$$\dot{x}(t) = \lim_{\delta t \to 0} \frac{x(t + \delta t) - x(t)}{\delta t} \tag{18}$$

(with $\delta t > 0$ if $t = 0$) where, by definition, $x(t + \delta t)$, $x(t) \in \mathcal{V}$. Moreover, $\mathcal{V}$ is closed since $\mathcal{X}$ is finite-dimensional, so proceeding to the limit in (18) does not leave $\mathcal{V}$. Thus $x(t) \in \mathcal{V}^*$ for all $t \geqq 0$ so $x(0) \in \mathcal{V}^*$, as required.

This completes the proof of Lemma 3.1.

The main result of this section is Theorem 3.2.

THEOREM 3.2. *Suppose $\mathcal{U}$ and $\mathcal{W}$ are subspaces of $\mathcal{X}$ satisfying*

$$E\mathcal{U} \subseteq M\mathcal{U}, \qquad M\mathcal{W} \subseteq E\mathcal{W}.$$

Then (6) has a solution $x(t)$ if f is differentiable dim $\mathcal{U}$ *times and such that*

$$f(t) \in E\mathcal{W} + M\mathcal{U} \quad \text{for all } t \geqq 0$$

and x_0 belongs to an appropriate affine subspace of $\mathcal{U} + \mathcal{W}$. Furthermore, $x(t) \in \mathcal{U} + \mathcal{W}$ for all $t \geqq 0$.

The key step in the proof of this theorem is a result in linear algebra. Define subspaces $\mathcal{U}^*$, $\mathcal{W}^*$ of $\mathcal{U}+\mathcal{W}$ as follows:

$$\mathcal{U}^* = \sup\{\mathcal{U}_1 \subseteq \mathcal{U}+\mathcal{W}\colon E\mathcal{U}_1 \subseteq M\mathcal{U}_1\},$$

$$\mathcal{W}^* = \sup\{\mathcal{W}_1 \subseteq \mathcal{U}+\mathcal{W}\colon M\mathcal{W}_1 \subseteq E\mathcal{W}_1\}.$$

Then we have Lemma 3.3.

LEMMA 3.3. *There exists a subspace $\mathcal{Q}$ of $\mathcal{X}$ such that*

$$E\mathcal{Q} \subseteq M\mathcal{Q}, \qquad \mathcal{U}+\mathcal{W} = \mathcal{W}^* \oplus \mathcal{Q}.$$

Proof. It follows from Lemma 3.1 that $\mathcal{W}^*$ is the set of admissible initial conditions for (10) which lie in $\mathcal{U}+\mathcal{W}$, analogous to the subspace H_I in [8]. Note that whatever the value of λ, $(M-\lambda E)\mathcal{W}^* \subseteq E\mathcal{W}^*$, so by the semiregularity of the pencil $M-\lambda E$, $\ker E \cap \mathcal{W}^* = \{0\}$ and, similarly, $\ker M \cap \mathcal{U}^* = \{0\}$. Furthermore, if $Mu = Ev$ for $u \in \mathcal{U}^*$, $v \in \mathcal{W}^*$ then, by maximality, $u \in \mathcal{W}^*$ so that $E\mathcal{W}^* \cap M\mathcal{U}^* = M(\mathcal{U}^* \cap \mathcal{W}^*)$. Hence,

$$\begin{aligned}
\dim(E(\mathcal{U}+\mathcal{W}) + M(\mathcal{U}+\mathcal{W})) &= \dim(E(\mathcal{U}^*+\mathcal{W}^*) + M(\mathcal{U}^*+\mathcal{W}^*)) \\
&\geqq \dim(E\mathcal{W}^* + M\mathcal{U}^*) \\
&= \dim E\mathcal{W}^* + \dim M\mathcal{U}^* - \dim(E\mathcal{W}^* \cap M\mathcal{U}^*) \\
&= \dim \mathcal{W}^* + \dim \mathcal{U}^* - \dim \mathcal{U}^* \cap \mathcal{W}^* \\
&= \dim(\mathcal{U}^*+\mathcal{W}^*) \\
&= \dim(\mathcal{U}+\mathcal{W}).
\end{aligned}$$

It now follows from Lemma 3.1(i) and Theorem 3.2 of [8] that the subspace denoted by H_N in [8] will serve as $\mathcal{Q}$.

This completes the proof of Lemma 3.3.

Proof of Theorem 3.2. It is easy to see that

$$E\mathcal{W} + M\mathcal{U} = E(\mathcal{W}+\mathcal{U}) + M(\mathcal{W}+\mathcal{U}) = E\mathcal{W}^* + M\mathcal{Q}$$

and so

$$f(t) = Eg(t) + Mh(t) \quad \text{for all } t \geqq 0$$

where $g(t) \in \mathcal{W}^*$ and $h(t) \in \mathcal{Q}$ for all $t \geqq 0$. Now we split (6) into two parts:

$$E\dot{v}(t) = Mv(t) + Eg(t), \qquad v(0) = x_0 - q(0), \tag{19}$$

$$E\dot{q}(t) = Mq(t) + Mh(t) \tag{20}$$

where $v(t) \in \mathcal{W}^*$ and $q(t) \in \mathcal{Q}$ for all $t \geqq 0$. Clearly, if we can solve (19) and (20), then the sum of the solutions satisfies (6). To solve (20) let $K : \mathcal{X} \to \mathcal{X}$ be (the matrix of) a linear transformation such that

$$K\mathcal{Q} \subseteq \mathcal{Q}, \quad MKu = Eu \quad \text{for all } u \in \mathcal{Q}.$$

It is shown in Lemma 3.1(iii) of [8] that K is nilpotent on $\mathcal{Q}$, say $K^s = 0$. Now it is easy to see, by direct substitution, that a solution of (20) is

$$q(t) = -\sum_{i=0}^{s-1} \frac{d^i}{dt^i} K^i h(t).$$

Note that the solution determines $q(0)$, so the omission of initial conditions from (20) was deliberate.

Equation (19) has a solution if and only if $v(0) \in \mathcal{W}^*$, so this determines the affine subspace of $\mathcal{X}$ referred to in the statement of the theorem. Then it is easy to see, again by direct substitution, that

$$v(t) = e^{Lt}v_0 + \int_0^t e^{L(t-\tau)}g(\tau)\,d\tau,$$

where L is the matrix introduced in the proof of Lemma 3.1, satisfies (19).

This completes the proof of Theorem 3.2.

Now we can easily establish that the existence of subspaces $\mathcal{U}$, $\mathcal{V}$, $\mathcal{Z}$ as specified in the Main Theorem is sufficient for the existence of F achieving disturbance decoupling. Indeed, if F satisfies the requirements of Theorem 2.1 and Lemma 2.2 with respect to these subspaces, then the hypotheses of Theorem 3.2 are satisfied with $M = A - BF$ and $f(t) = Sd(t)$. Thus, (15) has a solution contained in $\mathcal{U} + \mathcal{W} = \mathcal{U} + \mathcal{V} \subseteq \ker C$ whatever the function $d(t)$ provided that it is sufficiently differentiable and that x_0 is appropriately related to the value of d and its derivatives at time $t = 0$.

This completes the proof of sufficiency in the Main Theorem.

4. Proof of the Main Theorem: necessity. In this section we complete the proof of the Main Theorem by outlining a proof that the conditions for disturbance decoupling are necessary, as well as sufficient. Suppose F is a feedback achieving disturbance decoupling in the closed loop system

$$\begin{aligned} &E\dot{x} = (A - BF)x + Sd(t), \qquad x(0) = x_0, \\ &y = Cx. \end{aligned} \tag{21}$$

Let $\mathcal{X}_0 \subseteq \ker C$ be the subspace of $\mathcal{X}$ minimal subject to containing every solution of (21) for which $y(t) \equiv 0$. It is clear that if $x(t) \in \mathcal{X}_0$ for all $t \geqq 0$, then $\dot{x}(t) \in \mathcal{X}_0$ for all $t \geqq 0$. Since F achieves disturbance decoupling

$$\operatorname{Im} S \subseteq E\mathcal{X}_0 + (A - BF)\mathcal{X}_0$$

and we have Lemma 4.1.

LEMMA 4.1. *To prove the necessity of the conditions in the Main Theorem it is enough to show that*

$$\mathcal{X}_0 = \mathcal{U} \oplus \mathcal{V}$$

for some subspaces $\mathcal{U}$, $\mathcal{V}$ satisfying

$$E\mathcal{U} \subseteq (A - BF)\mathcal{U}, \qquad (A - BF)\mathcal{V} \subseteq E\mathcal{V}.$$

Proof. If the conditions of this lemma hold, then

$$\begin{aligned} \operatorname{Im} S &\subseteq E(\mathcal{U} + \mathcal{V}) + (A - BF)(\mathcal{U} + \mathcal{V}) \\ &\subseteq E\mathcal{V} + (A - BF)\mathcal{U}. \end{aligned}$$

It is easy to see that $\mathcal{Z} = (A - BF)\mathcal{U}$ satisfies (a) and (b) of the Main Theorem.

This completes the proof of Lemma 4.1.

We sketch a construction of the subspaces $\mathcal{U}$, $\mathcal{V}$ referred to here using the Kronecker canonical form $A_1 - \lambda E_1$ of the pencil $A_0 - \lambda E_0$, where A_0 and E_0 are the matrices of the linear mappings obtained by restricting $A - BF$ and E, respectively, to $\mathcal{X}_0$. It will be convenient to refer to [7] for details of the Kronecker canonical form as Wilkinson is directly concerned with the differential equations

$$E_1\dot{x}(t) = A_1x(t) + f(t).$$

We recall that we may be dealing with a singular pencil since A_0 and E_0 might not be square matrices. We begin therefore by referring to [7, p. 249], where

> ... the essential features introduced by singularity (are) summarised as follows:
> Corresponding to each (of the minimal column indices) the general solution contains one arbitrary function ...
> Corresponding to each (of the minimal row indices) $\eta \cdots$ a compatibility relation is required between
>
> $$f_i, Df_{i+1}, D^2 f_{i+2}, \cdots, D^\eta f_{i+\eta} \left(D = \frac{d}{dt} \right)$$
>
> ...

Since we are insisting on uniqueness of solutions, $A_1 - \lambda E_1$ contains no minimal column indices and, as we are allowing any sufficiently differentiable $d(t)$ without any compatibility requirement, all the minimal row indices are zero. Thus there exist nonsingular matrices P and Q such that

$$P(A_0 - \lambda E_0)Q = A_1 - \lambda E_1 = \begin{pmatrix} 0 \\ A_2 - \lambda E_2 \end{pmatrix}$$

where $A_2 - \lambda E_2$ is a regular pencil. Furthermore, $A_2 - \lambda E_2$ can be taken to be block diagonal with diagonal blocks given either by

$$I - \lambda J(0) \tag{22}$$

or by

$$J(\lambda_i) - \lambda I \tag{23}$$

where "$J(\cdots)$" denotes "a Jordan matrix with eigenvalue ..." and λ_i ranges over the finite eigenvalues of the pencil $A_0 - \lambda E_0$. We will assume that the diagonal blocks are arranged so that all those of the first kind appear above and to the left of any of the second kind. Thus

$$P(A_0 - \lambda E_0)Q = \begin{pmatrix} 0 & 0 \\ A_3 - \lambda E_3 & 0 \\ 0 & A_4 - \lambda E_4 \end{pmatrix} \tag{24}$$

where all the infinite eigenvalues of $A_0 - \lambda E_0$ are accounted for in $A_3 - \lambda E_3$ and the finite eigenvalues in $A_4 - \lambda E_4$.

The matrices A_1 and E_1 may be taken to act on the space of column vectors given by $\mathscr{X}_1 = Q^{-1}\mathscr{X}_0$. Let $\mathscr{U}_1$, $\mathscr{V}_1$ denote subspaces of $\mathscr{X}_1$ corresponding to a partition of these column vectors conformable to that in (24). Then it is clear that

$$\mathscr{X}_1 = \mathscr{U}_1 \oplus \mathscr{V}_1, \quad E_1\mathscr{U}_1 \subseteq A_1\mathscr{U}_1, \quad A_1\mathscr{V}_1 \subseteq E_1\mathscr{V}_1$$

and so $\mathscr{U} = Q\mathscr{U}_1$ and $\mathscr{V} = Q\mathscr{V}_1$ satisfy the requirements of Lemma 4.1.

This completes the proof of the necessity of the conditions in the Main Theorem, so we have now proved the Main Theorem in its entirety.

5. Conclusion. We have provided necessary and sufficient conditions for the existence of a state feedback that achieves disturbance decoupling in a linear time-invariant descriptor system. We have taken care to ensure that the resulting closed loop system has smooth solutions for a wide class of disturbance functions and initial conditions and that, when a solution exists, it is unique. Although different application will require different stipulations about the existence of solutions, "control" in the context of descriptor systems seems almost certain to require uniqueness of solutions.

Our mode of argument has been in the spirit of Wonham [9] and the structure of our proof clearly resembles that of the corresponding result in the state space case. However, we have found the usual presentation, in terms of the properties of uniquely determined maximal elements of certain collections of subspaces, neither possible nor essential in the descriptor case. This has meant that our proofs are less constructive than we would like; some work is needed to integrate our notions with other, more algorithmic, approaches. It would be particularly interesting to identify, in a constructive way, the maximal subspace that is the image under E of a subspace $\mathcal{V}$ of $\ker C$ satisfying (i) and (ii) of Definition 1.3. Lemma 2.4 shows that this subspace is uniquely determined.

Throughout this paper we have had in mind a linear system described by a mixture of algebraic and *differential* equations; the extension of our results to the discrete-time case should not present any major difficulty.

Acknowledgment. It is a pleasure to acknowledge that detailed comments from referees of an earlier version of this paper led to clearer thinking and sharper results.

EXACT PENALTY FUNCTIONS IN CONSTRAINED OPTIMIZATION*

G. DI PILLO† AND L. GRIPPO‡

Abstract. In this paper formal definitions of exactness for penalty functions are introduced and sufficient conditions for a penalty function to be exact according to these definitions are stated, thus providing a unified framework for the study of both nondifferentiable and continuously differentiable penalty functions. In this framework the best-known classes of exact penalty functions are analyzed, and new results are established concerning the correspondence between the solutions of the constrained problem and the unconstrained minimizers of the penalty functions.

Key words. exact penalty functions, nonlinear programming, constrained optimization

AMS(MOS) subject classifications. 49D30, 49D37, 90C30

1. Introduction.

A considerable amount of investigation, both from the theoretical and the computational point of view, has been devoted to methods that attempt to solve nonlinear programming problems by means of a single minimization of an unconstrained function. Methods of this kind are usually termed *exact penalty methods*, as opposed to the *sequential penalty methods*, which include the quadratic penalty method and the method of multipliers (see, e.g., [4], [23], and [26]).

We can subdivide exact penalty methods into two classes: methods based on *exact penalty functions* and methods based on *exact augmented Lagrangian functions.* In our terminology, the term "exact penalty function" is used when the variables of the unconstrained problem are in the same space as the variables of the original constrained problem, whereas the term "exact augmented Lagrangian function" is used when the unconstrained problem has to be minimized on the product space of the problem variables and of the multipliers.

Exact penalty functions can be subdivided, in turn, into two main classes: *nondifferentiable* exact penalty functions and *continuously differentiable* exact penalty functions.

Nondifferentiable exact penalty functions were introduced for the first time in [39] and have been widely investigated in recent years (see, e.g., [1], [2], [5]-[10], [22], [25], [29], and [35]). Continuously differentiable exact penalty functions were introduced in [24] for equality constrained problems and in [28] for problems with inequality constraints; further contributions have been given in [14], [15], and [34].

Exact augmented Lagrangian functions were introduced in [11] and [12] and have been further investigated in [3], [4], [19]-[21], [31], and [38].

In this paper we restrict our attention to exact penalty functions, with the aim of providing a unified framework which applies both to the nondifferentiable and to the continuously differentiable case.

We start from the introduction of formal definitions of various kinds of exactness that attempt to capture the most relevant aspects of the notion of exactness in the context of constrained optimization. This is motivated by the fact that in the current

literature the term *exact penalty function* seems to be used without a definite agreement on its meaning. In particular, as noted in [29], most of the literature on this subject is mainly concerned with conditions that ensure that the penalty function has a local (global) minimum at a local (global) minimum point of the constrained problem. On the other hand, since the penalty approach is an attempt to solve a constrained problem by the minimization of an unconstrained function, this characterization is fully satisfactory only when both the constrained problem and the penalty function are convex. In the nonconvex case, the study of converse properties appears to be of greater interest, as they ensure that local (global) minimizers of the penalty function are local (global) solutions of the constrained problem.

Moreover, again in the nonconvex case, a distinction has to be made between properties of exactness pertaining to global solutions and properties pertaining to local solutions. It will be shown that, for the same penalty function, different kinds of exactness can be established under different regularity requirements on the problem constraints.

Finally, the correspondence between the constrained and the unconstrained minimization problem can only be established with reference to a compact set containing the problem solutions, and this must be carefully taken into account in the analysis of the properties of exactness.

The formal definitions mentioned so far constitute the basis for the development of sufficient conditions for a penalty function to be exact according to some specified notion of exactness. In particular, we establish sufficient conditions which apply both to the nondifferentiable and to the continuously differentiable case, thus providing a unified framework for the analysis and the construction of exact penalty functions. In this framework, we consider the best-known classes of exact penalty functions, and we provide a complete analysis of their properties, recovering known results and establishing new ones.

The paper is organized as follows. Section 2 contains the problem statement, basic notation, and preliminary results. In § 3 we formalize the definitions of various kinds of exactness of penalty functions, which are classified as *weak exactness*, *exactness*, *strong exactness*, and *global* (*weak*, *strong*) *exactness*. Section 4 deals with nondifferentiable penalty functions: we analyze the properties of l_q exact penalty functions as well as those of the globally exact nondifferentiable penalty function considered in [16]. In § 5 we study continuously differentiable exact penalty functions, and we introduce a globally exact differentiable penalty function for mixed equality and inequality constrained problems by extending the results given in [15].

Computational aspects are beyond the scope of this paper. We refer, e.g., to [3], [4], [9], [18], [21], [27], [28], [33], [34], [36], and [37] for some algorithmic applications of exact penalty functions.

2. Problem statement, basic notation and preliminary results. The problem considered here is the general nonlinear programming problem:

$$\text{(P)} \qquad \begin{aligned} &\text{minimize } f(x) \\ &\text{subject to } g(x) \leqq 0, \qquad h(x) = 0, \end{aligned}$$

where $f: \mathbb{R}^n \to \mathbb{R}$, $g: \mathbb{R}^n \to \mathbb{R}^m$, $h: \mathbb{R}^n \to \mathbb{R}^p$, $p \leqq n$ are continuously differentiable functions and the feasible set

$$\mathcal{F} := \{x \in \mathbb{R}^n : g(x) \leqq 0, h(x) = 0\}$$

is assumed to be nonempty.

We denote by $\mathcal{G}_{\mathcal{P}}$ and $\mathcal{L}_{\mathcal{P}}$, respectively, the set of global solutions and the set of local solutions of problem (P) and we assume that $\mathcal{G}_{\mathcal{P}}$ is nonempty.

The Lagrangian function associated with problem (P) is the function $L: \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^p \to \mathbb{R}$ defined by

$$L(x, \lambda, \mu) := f(x) + \lambda' g(x) + \mu' h(x).$$

A *Kuhn-Tucker triple* for problem (P) is a triple $(\bar{x}, \bar{\lambda}, \bar{\mu}) \in \mathbb{R}^m \times \mathbb{R}^m \times \mathbb{R}^p$ such that

$$\nabla_x L(\bar{x}, \bar{\lambda}, \bar{\mu}) = 0,$$
$$\bar{\lambda}' g(\bar{x}) = 0,$$
$$\bar{\lambda} \geqq 0,$$
$$g(\bar{x}) \leqq 0,$$
$$h(\bar{x}) = 0.$$

We denote by $\mathcal{T}$ the set

$$\mathcal{T} := \{\bar{x} \in \mathbb{R}^n : \text{there exist } (\bar{\lambda}, \bar{\mu}) \text{ such that}$$
$$(\bar{x}, \bar{\lambda}, \bar{\mu}) \text{ is a K-T triple for problem (P)}\}.$$

For any $x \in \mathbb{R}^n$ we define the index sets:

$$I_0(x) := \{i : g_i(x) = 0\}$$
$$I_+(x) := (i : g_i(x) \geqq 0\}.$$

We adopt the following terminology.

The *linear independence constraint qualification* (LICQ) holds at $x \in \mathbb{R}^n$ if the gradients $\nabla g_i(x)$, $i \in I_0(x)$, $\nabla h_j(x)$, $j = 1, \cdots, p$ are linearly independent.

The *Mangasarian-Fromovitz constraint qualification* (MFCQ) holds at $x \in \mathbb{R}^n$ if $\nabla h_j(x)$, $j = 1, \cdots, p$ are linearly independent and there exists a $z \in \mathbb{R}^n$ such that

$$\nabla g_i(x)' z < 0, \qquad i \in I_0(x)$$
$$\nabla h_j(x)' z = 0, \qquad j = 1, \cdots, p.$$

It can be shown, by using the theorems of the alternative [32] that the MFCQ can be restated as follows.

The MFCQ holds at $x \in \mathbb{R}^n$ if there exist no u_i, $i \in I_0(x)$, and v_j, $j = 1, \cdots, p$ such that

$$\sum_{i \in I_0(x)} u_i \nabla g_i(x) + \sum_{j=1}^{p} v_j \nabla h_j(x) = 0,$$
$$u_i \geqq 0, \qquad i \in I_0(x),$$
$$(u_i, i \in I_0(x), v_j, \qquad j = 1, \cdots, p) \neq 0.$$

In some cases we shall make use of a stronger constraint qualification, which is stated in the following equivalent formulations.

The *extended Mangasarian-Fromovitz constraint qualification* (EMFCQ) holds at $x \in \mathbb{R}^n$ if $\nabla h_j(x)$, $j = 1, \cdots, p$ are linearly independent and there exists a $z \in \mathbb{R}^n$ such that

$$\nabla g_i(x)' z < 0, \qquad i \in I_+(x)$$
$$\nabla h_j(x)' z = 0, \qquad j = 1, \cdots, p.$$

The EMFCQ holds at $x \in \mathbb{R}^n$ if there exist no u_i, $i \in I_+(x)$, and v_j, $j = 1, \cdots, p$ such that

$$\sum_{i \in I_+(x)} u_i \nabla g_i(x) + \sum_{j=1}^{p} v_j \nabla h_j(x) = 0,$$

$$u_i \geqq 0, \qquad i \in I_+(x),$$

$$(u_i, i \in I_+(x), v_j, \qquad j = 1, \cdots, p) \neq 0.$$

It can be noted that the LICQ implies the MFCQ and that the EMFCQ implies the MFCQ.

It is known that if $\bar{x}$ is a local solution of problem (P) and if the MFCQ holds at $\bar{x}$, then $\bar{x} \in \mathcal{T}$, that is, there exist K-T multipliers $(\bar{\lambda}, \bar{\mu})$ associated with $\bar{x}$.

We recall that a nonempty set $\mathcal{C}^* \subseteq \mathcal{C}$ is called an *isolated set* of $\mathcal{C}$ if there exists a closed set $\mathcal{H}$ such that $\mathcal{C}^*$ is contained in the interior $\mathring{\mathcal{H}}$ of $\mathcal{H}$ and such that if $x \in \mathcal{H} - \mathcal{C}^*$, then $x \notin \mathcal{C}$. Isolated sets of local minimum points possess the property stated in the following lemma, which is proved in [23].

LEMMA 1. *Let $\mathcal{C}^*$ be an isolated compact set of local minimum points of problem* (P), *corresponding to the local minimum value f^*; then there exists a compact set $\mathcal{H} \subset \mathbb{R}^n$, such that $\mathcal{C}^* \subset \mathring{\mathcal{H}}$, and for any point $x \in \mathcal{H} \cap \mathcal{F}$, if $x \notin \mathcal{C}^*$, then $f(x) > f^*$.*

We also state the following lemma, which for $q \geqq 2$ is an obvious consequence of the equivalence of the norms $\| \cdot \|_q$ and $\| \cdot \|_{q-1}$ on $\mathbb{R}^n$.

LEMMA 2. *Let $q \in \mathbb{R}$, $1 < q < \infty$. Then, there exists a number $\mu > 0$ such that for all $z \in \mathbb{R}^n$, we have*:

$$\sum_{i=1}^{n} |z_i|^{q-1} \geqq \mu \|z\|_q^{q-1}.$$

Proof. The assertion follows from a more general result on positive homogeneous continuous functions ([30, Thm. 5.4.4]). □

In the sequel we shall be concerned with compact perturbations of the feasible set. In particular, we shall consider the case in which $\mathcal{F}$ is compact and there exists a vector $\beta = (\alpha_0, \alpha')'$ with $\alpha_0 \in \mathbb{R}$, $\alpha \in \mathbb{R}^m$, $\beta > 0$, such that the set

$$\mathcal{S}_\beta := \{x \in \mathbb{R}^n : g(x) \leqq \alpha, \|h(x)\|_2^2 \leqq \alpha_0\}$$

obtained by relaxing the problem constraints is compact. It can be shown, by extending a similar result given in [15] for the inequality constrained case, that under the following assumptions:

(i) there exists a $\bar{\beta} \in \mathbb{R}^{m+1}$, $\bar{\beta} > 0$, such that $\mathcal{S}_{\bar{\beta}}$ is compact,

(ii) the MFCQ holds on $\mathcal{F}$,

there exists a compact set S_β, with $\beta > 0$, where the EMFCQ is satisfied.

We make use of the following notation. Given the set $\mathcal{A}$, we denote by $\mathring{\mathcal{A}}$, $\partial\mathcal{A}$, and $\bar{\mathcal{A}}$, respectively, the interior, the boundary, and the closure of $\mathcal{A}$. Given a vector u with components u_i, $i = 1, \cdots, m$ we denote by u^+ the vector with components:

$$u_i^+ := \max [0, u_i], \qquad i = 1, \cdots, m$$

and by U the diagonal matrix defined by:

$$U := \operatorname{diag}(u_i), \qquad i = 1, \cdots, m.$$

Given a function $F : \mathbb{R}^n \to \mathbb{R}$, we denote by $DF(x, d)$ the directional derivative of F at x along the direction d. We say that $\bar{x}$ is a *critical point* of F if $DF(x, d) \geqq 0$ for all $d \in \mathbb{R}^n$. If $\bar{x}$ is a critical point of F and F is differentiable at $\bar{x}$, we have $\nabla F(\bar{x}) = 0$; in this case we say that $\bar{x}$ is a *stationary point* of F.

Finally, we denote by $\mathcal{B}(\bar{x}; \rho)$ the open ball around $\bar{x}$ with radius $\rho > 0$.

3. Definitions of exactness for penalty functions. Roughly speaking, an *exact penalty function* for problem (P) is a function $F(x;\varepsilon)$, where $\varepsilon>0$ is a *penalty parameter*, with the property that there is an appropriate parameter choice such that a single unconstrained minimization of $F(x;\varepsilon)$ yields a solution to problem (P). In particular, we require that there is an *easy* way for finding correct parameter values by imposing that exactness is retained for all ε ranging on some set of nonzero measure. More specifically, we take $\varepsilon\in(0,\varepsilon^*]$ where $\varepsilon^*>0$ is a suitable *threshold value.*

In practice, the existence of a threshold value for the parameter ε, and hence the possibility of constructing the exact penalty function $F(x;\varepsilon)$, can only be established with reference to some compact set $\mathcal{D}$. Therefore, instead of problem (P) we shall consider the following problem.

$$(\tilde{\mathrm{P}}) \qquad \text{minimize } f(x), \qquad x\in\mathcal{F}\cap\mathcal{D},$$

where $\mathcal{D}$ is a compact subset of $\mathbb{R}^n$ such that $\mathcal{F}\cap\mathring{\mathcal{D}}\neq\varnothing$. It can be observed that if $\mathcal{F}\subset\mathcal{D}$, then problem ($\tilde{\mathrm{P}}$) and problem (P) are equivalent.

We denote by $\mathcal{G}_{\tilde{\mathcal{P}}}$ and $\mathcal{L}_{\tilde{\mathcal{P}}}$, respectively, the set of global solutions and the set of local solutions of problem ($\tilde{\mathrm{P}}$), that is:

$$\mathcal{G}_{\tilde{\mathcal{P}}}:=\{x\in\mathcal{F}\cap\mathcal{D}: f(x)\leqq f(y), \text{ for all } y\in\mathcal{F}\cap\mathcal{D}\}$$

$$\mathcal{L}_{\tilde{\mathcal{P}}}:=\{x\in\mathcal{F}\cap\mathcal{D}: \text{ for some } \rho>0\ f(x)\leqq f(y), \text{ for all } y\in\mathcal{F}\cap\mathcal{D}\cap\mathcal{B}(x;\rho)\}.$$

We have, obviously, that $\mathcal{L}_{\tilde{\mathcal{P}}}\cap\mathring{\mathcal{D}}=\mathcal{L}_{\mathcal{P}}\cap\mathring{\mathcal{D}}$; moreover, if $\mathcal{G}_{\mathcal{P}}\cap\mathring{\mathcal{D}}\neq\varnothing$, we have also $\mathcal{G}_{\mathcal{P}}\cap\mathring{\mathcal{D}}=\mathcal{G}_{\tilde{\mathcal{P}}}\cap\mathring{\mathcal{D}}$.

For any given $\varepsilon>0$, let $F(x;\varepsilon)$ be a continuous real function defined on a set $\mathcal{E}$, such that $\mathring{\mathcal{D}}\subseteq\mathcal{E}\subseteq\mathcal{D}$ and consider the following problem.

$$(\mathrm{Q}) \qquad \text{minimize } F(x;\varepsilon), \qquad x\in\mathring{\mathcal{D}}.$$

Since $\mathring{\mathcal{D}}$ is an open set, any local solution of problem (Q), provided it exists, is unconstrained; thus problem (Q) can be considered as an essentially unconstrained problem. The sets of global and local solutions of problem (Q) are denoted, respectively, by $\mathcal{G}_{\mathcal{Q}}(\varepsilon)$ and $\mathcal{L}_{\mathcal{Q}}(\varepsilon)$:

$$\mathcal{G}_{\mathcal{Q}}(\varepsilon):=\{x\in\mathring{\mathcal{D}}: F(x;\varepsilon)\leqq F(y;\varepsilon), \text{for all } y\in\mathring{\mathcal{D}}\}$$

$$\mathcal{L}_{\mathcal{Q}}(\varepsilon):=\{x\in\mathring{\mathcal{D}}: \text{ for some } \rho>0\ F(x;\varepsilon)\leqq F(y;\varepsilon), \text{for all } y\in\mathring{\mathcal{D}}\cap\mathcal{B}(x;\rho)\}.$$

There are different kinds of relationships between problem ($\tilde{\mathrm{P}}$) and problem (Q), which can be associated with different notions of exactness.

A first possibility is that of considering a correspondence between global minimizers of problem ($\tilde{\mathrm{P}}$) and global minimizers of problem (Q). This correspondence is established formally in the following definition.

DEFINITION 1. We say that the function $F(x;\varepsilon)$ is a *weakly exact penalty function* for problem (P) with respect to the set $\mathcal{D}$ if there exists an $\varepsilon^*>0$ such that, for all $\varepsilon\in(0,\varepsilon^*]$, any global solution of problem ($\tilde{\mathrm{P}}$) is a global minimum point of problem (Q) and conversely; that is if for some $\varepsilon^*>0$:

$$\mathcal{G}_{\tilde{\mathcal{P}}}=\mathcal{G}_{\mathcal{Q}}(\varepsilon), \quad \text{for all } \varepsilon\in(0,\varepsilon^*].$$

The property stated above guarantees that the constrained problem can actually be solved over $\mathcal{D}$ by means of the *global unconstrained minimization* of $F(x;\varepsilon)$ for sufficiently small values of the parameter ε.

We remark that if all global solutions of problem (P) are contained in $\mathring{\mathcal{D}}$, then problem (P) and problem ($\tilde{\mathrm{P}}$) possess the same global solutions. In this case, weak exactness implies that global solutions of problem (P) and global minimizers of problem (Q) are the same.

The notion of exactness expressed by Definition 1 appears to be of limited value for general nonlinear programming problems, since it does not give a meaning to local minimizers of the penalty function, while unconstrained minimization algorithms determine only local minimizers. Therefore, we introduce a further requirement concerning local minimizers which gives rise to a stronger notion of exactness.

DEFINITION 2. We say that the function $F(x; \varepsilon)$ is an *exact penalty function* for problem (P) with respect to the set $\mathcal{D}$ if there exists an $\varepsilon^* > 0$ such that, for all $\varepsilon \in (0, \varepsilon^*]$, $\mathcal{G}_{\mathcal{P}} = \mathcal{G}_{\mathcal{Q}}(\varepsilon)$ and, moreover, any local unconstrained minimizer of problem (Q) is a local solution of problem (P), that is:

$$\mathcal{L}_{\mathcal{Q}}(\varepsilon) \subseteq \mathcal{L}_{\mathcal{P}}, \quad \text{for all } \varepsilon \in (0, \varepsilon^*].$$

It must be remarked that the notion of exactness given in Definition 2 does not require that all local solutions of problem (P) in $\mathring{\mathcal{D}}$ correspond to local minimizers of the exact penalty functions. A one-to-one correspondence of local minimizers does not seem to be required, in practice, to give a meaning to the notion of exactness, since the condition $\mathcal{G}_{\mathcal{P}} = \mathcal{G}_{\mathcal{Q}}(\varepsilon)$ ensures that global solutions of problem ($\tilde{\mathrm{P}}$) are preserved. However, for the classes of exact penalty functions considered in the sequel, it will be shown that this correspondence can be established, also, at least with reference to isolated compact sets of local minimizers of problem (P) contained in $\mathring{\mathcal{D}}$. Thus, we can also consider the following definition.

DEFINITION 3. We say that the function $F(x; \varepsilon)$ is a *strongly exact penalty function* for problem (P) with respect to the set $\mathcal{D}$ if there exists an $\varepsilon^* > 0$ such that, for all $\varepsilon \in (0, \varepsilon^*]$, $\mathcal{G}_{\mathcal{P}} = \mathcal{G}_{\mathcal{Q}}(\varepsilon)$, $\mathcal{L}_{\mathcal{Q}}(\varepsilon) \subseteq \mathcal{L}_{\mathcal{P}}$, and, moreover, any local solution of problem (P) belonging to $\mathring{\mathcal{D}}$ is a local unconstrained minimizer of $F(x; \varepsilon)$, that is:

$$\mathcal{L}_{\mathcal{P}} \cap \mathring{\mathcal{D}} \subseteq \mathcal{L}_{\mathcal{Q}}(\varepsilon) \quad \text{for all } \varepsilon \in (0, \varepsilon^*].$$

The properties considered in the preceding definitions do not characterize the behavior of $F(x; \varepsilon)$ on the boundary of $\mathring{\mathcal{D}}$. Although this may be irrelevant from the conceptual point of view in connection with the notion of exactness, it may assume a considerable interest from the computational point of view, when unconstrained descent methods are employed for the minimization of $F(x; \varepsilon)$. In fact, it may happen that there exist points of $\mathring{\mathcal{D}}$ such that a descent path for $F(x; \varepsilon)$ that originates at some of these points crosses the boundary of $\mathring{\mathcal{D}}$. This implies that the sequence of points produced by an unconstrained algorithm may be attracted toward a stationary point of $F(x; \varepsilon)$ out of $\mathring{\mathcal{D}}$ or may not admit a limit point. Therefore, it could be difficult to construct minimizing sequences for $F(x; \varepsilon)$ which are globally convergent on $\mathring{\mathcal{D}}$ toward the solutions of the constrained problem. In order to avoid this difficulty, it is necessary to impose further conditions on $F(x; \varepsilon)$, and we are led to introduce the notion of *global exactness* of a penalty function.

DEFINITION 4. The function $F(x; \varepsilon)$ is said to be a *globally* (*weakly, strongly*) *exact penalty function* for problem (P) with respect to the set $\mathcal{D}$ if it is (weakly, strongly) exact and, moreover, for any $\varepsilon > 0$ and for any $\hat{x} \in \partial\mathcal{D}$ there exists a neighborhood $\mathcal{B}(\hat{x}, \rho)$ such that if $\{x_k\} \subset \mathring{\mathcal{D}}$ and $\lim_{k\to\infty} x_k = \hat{x}$, we have:

$$\liminf_{k\to\infty} F(x_k; \varepsilon) > F(x; \varepsilon),$$

for all $x \in \mathcal{B}(\hat{x}; \rho) \cap \mathring{\mathcal{D}}$.

The condition given above excludes the existence of minimizing sequences for $F(x; \varepsilon)$ originating in $\mathring{\mathcal{D}}$ that have limit points on the boundary. In fact, we can state the following proposition.

PROPOSITION 1. *Let $F(x;\varepsilon)$ be a (weakly, strongly) globally exact penalty function with respect to the set $\mathscr{D}$ and let $\{x_k\}\subset \mathring{\mathscr{D}}$ be a sequence such that $F(x_{k+1};\varepsilon)\leqq F(x_k;\varepsilon)$. Then, any limit point of $\{x_k\}$ belongs to $\mathring{\mathscr{D}}$.*

Proof. By the compactness of $\mathscr{D}$ there exists a subsequence, which we relabel $\{x_k\}$, such that $x_k\to\hat{x}\in\mathscr{D}$. Reasoning by contradiction, assume that $\hat{x}\in\partial\mathscr{D}$. Then, recalling Definition 4, we have, for sufficiently large values of j, $\liminf_{k\to\infty} F(x_k;\varepsilon)>F(x_j;\varepsilon)$, which contradicts the assumption $F(x_k;\varepsilon)\leqq F(x_j;\varepsilon)$ for all $k\geqq j$. □

4. Sufficient conditions for exactness. In this section we state sufficient conditions which imply that a penalty function $F(x;\varepsilon)$ possesses some of the properties of exactness considered in the preceding section. Everywhere below we suppose that the following assumption holds.

Assumption (A1). Any global solution of problem $(\tilde{\mathrm{P}})$ belongs to the set $\mathring{\mathscr{D}}$, that is: $\mathscr{G}_{\tilde{\mathscr{P}}}\subset\mathring{\mathscr{D}}$.

We note that Assumption (A1) concerns the selection of the set $\mathscr{D}$ and implies that $\mathscr{G}_{\tilde{\mathscr{P}}}\subset\mathscr{L}_{\mathscr{P}}$; it can be satisfied, in particular, by a proper choice of $\mathscr{D}$, whenever the global solutions of problem (P) belong to a bounded subset of $\mathscr{F}$.

Let $\mathscr{K}$ be the subset of $\mathscr{F}\cap\mathring{\mathscr{D}}$ where the function $F(x;\varepsilon)$ takes the same values of $f(x)$, that is:

$$\mathscr{K}:=\{x\in\mathscr{F}\cap\mathring{\mathscr{D}}\colon F(x;\varepsilon)=f(x)\text{ for all }\varepsilon>0\}. \tag{1}$$

The next theorem establishes a sufficient condition for $F(x;\varepsilon)$ to be a weakly exact penalty function in the sense of Definition 1.

THEOREM 1. *Let $F(x;\varepsilon)$ be such that the following conditions are satisfied.*

(a_1) *For any $\varepsilon>0$, the function $F(x;\varepsilon)$ admits a global minimum point on a set $\mathscr{E}$, such that $\mathring{\mathscr{D}}\subseteq\mathscr{E}\subseteq\mathscr{D}$.*

(a_2) *If $\{\varepsilon_k\}$ and $\{x_k\}\subseteq\mathscr{E}$ are sequences such that $\lim_{k\to\infty}\varepsilon_k=0$, $\lim_{k\to\infty}x_k=\hat{x}\in\mathscr{D}$ and $\limsup_{k\to\infty}F(x_k,\varepsilon_k)<\infty$, we have $\hat{x}\in\mathscr{F}\cap\mathscr{D}$ and $f(\hat{x})\leqq\limsup_{k\to\infty}F(x_k,\varepsilon_k)$.*

(a_3) $\mathscr{G}_{\tilde{\mathscr{P}}}\subseteq\mathscr{K}$.

(a_4) *For any $\hat{x}\in\mathscr{G}_{\tilde{\mathscr{P}}}$ there exist numbers $\varepsilon(\hat{x})>0$ and $\sigma(\hat{x})>0$ such that, for all $\varepsilon\in(0,\varepsilon(\hat{x})]$, if $\mathscr{G}_{\mathscr{Q}}(\varepsilon)\neq\varnothing$ and $x_\varepsilon\in\mathscr{G}_{\mathscr{Q}}(\varepsilon)$ is a global minimum point of problem* (Q) *satisfying $\|x_\varepsilon-\hat{x}\|\leqq\sigma(\hat{x})$, we have $x_\varepsilon\in\mathscr{K}$.*

Then, $F(x;\varepsilon)$ is a weakly exact penalty function for problem (P) *with respect to the set $\mathscr{D}$.*

Proof. We show first that there exists an $\varepsilon^*>0$ such that, for all $\varepsilon\in(0,\varepsilon^*]$ we have $\mathscr{G}_{\mathscr{Q}}(\varepsilon)\neq\varnothing$ and $\mathscr{G}_{\mathscr{Q}}(\varepsilon)\subseteq\mathscr{G}_{\tilde{\mathscr{P}}}$. Recalling condition ($a_1$), we have that, for any given $\varepsilon>0$, there exists a point $x_\varepsilon^*\in\mathscr{E}$ such that:

$$F(x_\varepsilon^*;\varepsilon)=\min_{x\in\mathscr{E}}F(x;\varepsilon).$$

We prove, by contradiction, that there exists an $\varepsilon^*>0$ such that, for all $\varepsilon\in(0,\varepsilon^*]$ the point x_ε^* is a global solution to problem $(\tilde{\mathrm{P}})$. Suppose that this assertion is false. Then, for any integer k there must exist an $\varepsilon_k\leqq 1/k$ and a global minimizer x_k of $F(x;\varepsilon_k)$ on $\mathscr{E}$ such that x_k is not a global solution of problem $(\tilde{\mathrm{P}})$. Let $\tilde{x}$ be a global minimizer of problem $(\tilde{\mathrm{P}})$; then, by (a_3) we have $\tilde{x}\in\mathscr{K}$, so that, by definition of the set $\mathscr{K}$, we have:

$$F(\tilde{x};\varepsilon_k)=f(\tilde{x}).$$

Then, as $\mathscr{K}\subseteq\mathscr{F}\cap\mathring{\mathscr{D}}\subseteq\mathscr{E}$, we can write:

$$F(x_k,\varepsilon_k)=\min_{x\in\mathscr{E}}F(x;\varepsilon_k)\leqq F(\tilde{x};\varepsilon_k)=f(\tilde{x}). \tag{2}$$

Since $\mathcal{D}$ is compact and $\mathcal{E} \subseteq \mathcal{D}$, there exists a convergent subsequence, which we relabel $\{x_k\}$, such that $\lim_{k\to\infty} x_k = \hat{x} \in \mathcal{D}$. By (2) we have:

$$\limsup_{k\to\infty} F(x_k, \varepsilon_k) \leqq f(\tilde{x}),$$

so that (a_2) implies:

$$\hat{x} \in \mathcal{F} \cap \mathcal{D} \quad \text{and} \quad f(\hat{x}) \leqq f(\tilde{x}),$$

whence it follows that $\hat{x}$ is a global minimum point of problem $(\tilde{P})$. Recalling Assumption (A1), we have $\hat{x} \in \mathring{\mathcal{D}}$ and therefore, since $\lim_{k\to\infty} x_k = \hat{x}$, it follows that for sufficiently large values of k, say $k \geqq k_0$, the point x_k belongs to $\mathring{\mathcal{D}}$. As $\mathring{\mathcal{D}} \subseteq \mathcal{E}$, this implies that

$$F(x_k, \varepsilon_k) = \min_{x\in\mathcal{E}} F(x; \varepsilon_k) \leqq \min_{x\in\mathring{\mathcal{D}}} F(x; \varepsilon_k),$$

that is: $\mathcal{G}_{\mathcal{D}}(\varepsilon_k) \neq \emptyset$ and $x_k \in \mathcal{G}_{\mathcal{D}}(\varepsilon_k)$ for $k \geqq k_0$. Moreover, since $\hat{x} \in \mathcal{G}_{\tilde{\mathcal{P}}}$, $\lim_{k\to\infty} \varepsilon_k = 0$ and $\lim_{k\to\infty} x_k = \hat{x}$, we have that there exists an integer $k_1 \geqq k_0$ such that, for all $k \geqq k_1$, $x_k \in \mathcal{G}_{\mathcal{D}}(\varepsilon_k)$, $\varepsilon_k \leqq \varepsilon(\hat{x})$ and $\|x_k - \hat{x}\| \leqq \sigma(\hat{x})$, where $\varepsilon(\hat{x})$ and $\sigma(\hat{x})$ are the numbers considered in condition (a_4). Therefore (a_4) implies that $x_k \in \mathcal{K}$ for all $k \geqq k_1$, so that, by (2), we obtain:

$$f(x_k) = F(x_k; \varepsilon_k) \leqq f(\tilde{x}), \qquad k \geqq k_1.$$

Hence, $x_k \in \mathcal{F} \cap \mathring{\mathcal{D}}$ is both a global minimum point of $F(x; \varepsilon_k)$ on $\mathcal{E}$ and a global minimum point of problem $(\tilde{P})$ and this contradicts our original assumption. It can be concluded that there exists an $\varepsilon^* > 0$ such that for all $\varepsilon \in (0, \varepsilon^*]$ any global minimizer x_ε^* of $F(x; \varepsilon)$ on $\mathcal{E}$ is a global solution to problem $(\tilde{P})$. On the other hand, by Assumption (A1), the global solutions of problem $(\tilde{P})$ are in $\mathring{\mathcal{D}}$ and hence, for all $\varepsilon \in (0, \varepsilon^*]$, we have that $x_\varepsilon^* \in \mathring{\mathcal{D}}$ is a global minimizer for problem (Q).

Thus we have proved that for $\varepsilon \in (0, \varepsilon^*]$, $\mathcal{G}_{\mathcal{D}}(\varepsilon) \neq \emptyset$ and $\mathcal{G}_{\mathcal{D}}(\varepsilon) \subseteq \mathcal{G}_{\tilde{\mathcal{P}}}$. Now let $\varepsilon \in (0, \varepsilon^*]$ and let x_ε be any point in $\mathcal{G}_{\mathcal{D}}(\varepsilon) \subseteq \mathcal{G}_{\tilde{\mathcal{P}}}$. By condition (a_3) we have $\mathcal{G}_{\mathcal{D}}(\varepsilon) \subseteq \mathcal{K}$ so that:

$$f(x_\varepsilon) = F(x_\varepsilon; \varepsilon). \tag{3}$$

If $\bar{x}$ is another global minimizer of Problem $(\tilde{P})$, again by (a_3), we have

$$f(\bar{x}) = F(\bar{x}; \varepsilon). \tag{4}$$

Therefore, as $f(x_\varepsilon) = f(\bar{x})$, (3) and (4) imply that $F(\bar{x}; \varepsilon) = F(x_\varepsilon; \varepsilon)$ and this proves that $\bar{x}$ is a global solution to problem (Q). Thus, $\mathcal{G}_{\tilde{\mathcal{P}}} \subseteq \mathcal{G}_{\mathcal{D}}(\varepsilon)$ for all $\varepsilon \in (0, \varepsilon^*]$ and this completes the proof. □

A short discussion of conditions (a_1)-(a_4) is in order.

Condition (a_1) requires the existence of a global minimizer of $F(x; \varepsilon)$ on the set $\mathcal{E}$. Two cases are of interest: the case $\mathcal{E} = \mathcal{D}$ and the case $\mathcal{E} = \mathring{\mathcal{D}}$. When $\mathcal{E} = \mathcal{D}$, recalling that $\mathcal{D}$ is compact, the existence of a global minimizer is ensured by the continuity of $F(x; \varepsilon)$; if $\mathcal{E} = \mathring{\mathcal{D}}$, we must specify some further condition on the behavior of $F(x; \varepsilon)$ on $\partial\mathcal{D}$. We shall address this problem later in connection with sufficient conditions for global exactness.

Condition (a_2) indicates the role played by the penalty parameter ε; it requires, in particular, that, as ε goes to zero, if the penalty function remains bounded from above, the constraints are satisfied in the limit.

With regard to (a_3), we may note that this condition is satisfied whenever, for all $\varepsilon > 0$:

$$F(x; \varepsilon) = f(x), \quad \text{for } x \in \mathcal{F} \cap \mathring{\mathcal{D}}.$$

In fact, in this case we have, by (1), that $\mathscr{K} = \mathscr{F} \cap \mathring{\mathscr{D}}$. The different classes of exact penalty functions considered in the sequel are associated with different characterizations of $\mathscr{K}$. In particular, in the case of nondifferentiable penalty functions, we have $\mathscr{K} = \mathscr{F} \cap \mathring{\mathscr{D}}$. However, this requirement would be too strong to allow the construction of continuously differentiable exact penalty functions, as will be apparent from the content of § 5. Thus, in the case of continuously differentiable exact penalty functions, the set $\mathscr{K}$ turns out to be a subset of $\mathscr{F} \cap \mathring{\mathscr{D}}$ containing a region where suitable necessary optimality conditions for problem $(\tilde{\mathrm{P}})$ are satisfied.

Finally, we may note from the proof of Theorem 1 that condition (a_4) is of major relevance in order to establish the properties of exactness considered, since the first three conditions are usually satisfied in the case of sequential penalty functions also.

We give now a sufficient condition for $F(x; \varepsilon)$ to be an exact penalty function in the sense of Definition 2, which is obtained by replacing (a_4) of Theorem 1 with a stronger condition and by imposing that $F(x; \varepsilon)$ is bounded above by $f(x)$ on the set $\mathscr{F} \cap \mathring{\mathscr{D}}$.

More specifically, we state the following theorem.

THEOREM 2. *Let $F(x; \varepsilon)$ be such that conditions (a_1)-(a_3) of Theorem 1 are satisfied and assume further that the following conditions hold.*

(a_5) *There exists an $\bar{\varepsilon} > 0$ such that, for all $\varepsilon \in (0, \bar{\varepsilon}]$, if $\mathscr{L}_{\mathscr{D}}(\varepsilon) \neq \emptyset$ and $x_\varepsilon \in \mathscr{L}_{\mathscr{D}}(\varepsilon)$, we have $x_\varepsilon \in \mathscr{K}$;*

(a_6) *$F(x; \varepsilon) \leqq f(x)$ for all $\varepsilon > 0$ and $x \in \mathscr{F} \cap \mathring{\mathscr{D}}$.*

Then, $F(x; \varepsilon)$ is an exact penalty function for problem (P) *with respect to the set $\mathscr{D}$, in the sense of Definition* 2.

Proof. We observe first that condition (a_5) is stronger than condition (a_4) of Theorem 1 so that the function $F(x; \varepsilon)$ is a weakly exact penalty function in the sense of Definition 1. Hence, there exists an $\tilde{\varepsilon} > 0$ such that for all $\varepsilon \in (0, \tilde{\varepsilon}]$ we have $\mathscr{G}_{\mathscr{D}}(\varepsilon) = \mathscr{G}_{\mathscr{F}}$ and this implies $\mathscr{L}_{\mathscr{D}}(\varepsilon) \neq \emptyset$. Now let $\varepsilon^* = \min[\tilde{\varepsilon}, \bar{\varepsilon}]$, where $\bar{\varepsilon}$ is the number considered in condition (a_5), let $\varepsilon \in (0, \varepsilon^*]$, and assume that $x_\varepsilon \in \mathscr{L}_{\mathscr{D}}(\varepsilon)$. Then, by (a_5), we have $x_\varepsilon \in \mathscr{K}$ so that we get $F(x_\varepsilon; \varepsilon) = f(x_\varepsilon)$. This implies that for $\varepsilon \in (0, \varepsilon^*]$ and for some $\rho > 0$ it can be written:

$$f(x_\varepsilon) \leqq F(x; \varepsilon) \quad \text{for all } x \in \mathscr{F} \cap \mathscr{B}(x_\varepsilon; \rho). \tag{5}$$

Hence, by (5) and (a_6) we have:

$$f(x_\varepsilon) \leqq f(x) \quad \text{for all } x \in \mathscr{F} \cap \mathscr{B}(x_\varepsilon; \rho),$$

so that x_ε is a local minimizer of problem (P). □

As already observed in the proof of the preceding theorem, condition (a_5) is considerably stronger than (a_4) of Theorem 1; it requires, in particular, that for sufficiently small values of ε *any local minimum point of problem* (Q) *is a feasible point for problem* (P). It will be shown in the sequel that satisfaction of condition (a_5) requires the introduction of a suitable constraint qualification in problem (P).

In order to give sufficient conditions for strong exactness, we now establish a condition which ensures that isolated compact sets of local minimizers of problem (P) correspond to local unconstrained minimizers of $F(x; \varepsilon)$ for sufficiently small values of ε.

PROPOSITION 2. *Let $\mathscr{C}^*$ be a nonempty isolated compact set of local minimum points of problem* (P) *corresponding to the local minimum value f^*, such that $\mathscr{C}^* \subset \mathscr{F} \cap \mathring{\mathscr{D}}$. Let $F(x; \varepsilon)$ be such that the following conditions are satisfied.*

(b_1) *If $\{\varepsilon_k\}$ and $\{x_k\} \subset \mathring{\mathscr{D}}$ are sequences such that $\lim_{k\to\infty} \varepsilon_k = 0$, $\lim_{k\to\infty} x_k = \hat{x} \in \mathscr{D}$, and $\limsup_{k\to\infty} F(x_k, \varepsilon_k) < \infty$, we have $\hat{x} \in \mathscr{F} \cap \mathscr{D}$ and $f(\hat{x}) \leqq \limsup_{k\to\infty} F(x_k, \varepsilon_k)$.*

(b_2) $\mathscr{C}^* \subseteq \mathscr{K}$.

(b_3) *For any* $\tilde{x} \in \mathscr{C}^*$ *there exist numbers* $\varepsilon(\tilde{x}) > 0$ *and* $\sigma(\tilde{x}) > 0$ *such that, for all* $\varepsilon \in (0, \varepsilon(\tilde{x})]$, *if* $\mathscr{L}_{\mathscr{D}}(\varepsilon) \neq \emptyset$ *and* $x_\varepsilon \in \mathscr{L}_{\mathscr{D}}(\varepsilon)$ *is a local minimum point of problem* (Q) *satisfying* $\|x_\varepsilon - \tilde{x}\| \leqq \sigma(\tilde{x})$, *we have* $x_\varepsilon \in \mathscr{K}$.

Then, there exists an $\varepsilon^* > 0$ *such that for all* $\varepsilon \in (0, \varepsilon^*]$, $\bar{x} \in \mathscr{C}^*$ *implies that* $\bar{x}$ *is a local minimum point of problem* (Q).

Proof. Let $\mathscr{K}$ be the compact set considered in Lemma 1. Since $\mathscr{C}^* \subset \mathring{\mathscr{D}} \cap \mathring{\mathscr{K}}$, we can find a compact set $\mathscr{R} \subset \mathbb{R}^n$ satisfying

$$\mathscr{C}^* \subset \mathring{\mathscr{R}} \quad \text{and} \quad \mathscr{R} \subset \mathring{\mathscr{D}} \cap \mathring{\mathscr{K}},$$

such that

$$f(x) > f^* \quad \text{for all } x \in \mathscr{F} \cap \mathscr{R}, \qquad x \notin \mathscr{C}^*. \tag{6}$$

Now consider the following problem.

$$\text{minimize } f(x), \qquad x \in \mathscr{F} \cap \mathscr{R}. \tag{7}$$

Then, by (6), we have that $\mathscr{C}^* \subset \mathring{\mathscr{R}}$ is the set of global solutions of problem (7). Recalling Theorem 1, it can be easily verified that the function $F(x; \varepsilon)$ is weakly exact with respect to the set $\mathscr{R}$, and hence there exists an $\varepsilon^* > 0$ such that for all $\varepsilon \in (0, \varepsilon^*]$, $\bar{x} \in \mathscr{C}^*$ implies that $\bar{x}$ is a global minimum point of the following problem.

$$\text{minimize } F(x; \varepsilon), \qquad x \in \mathring{\mathscr{R}}. \tag{8}$$

On the other hand, since $\mathring{\mathscr{R}} \subset \mathring{\mathscr{D}}$, any global solution of problem (8) is a local minimizer of problem (Q) and this completes the proof. □

Using the preceding result, we can establish a sufficient condition for strong exactness under the following assumption on problem (P).

Assumption (A2). There exists a finite number of isolated compact sets $\mathscr{C}^*(f_i^*)$, $i = 1, \cdots, r$ of local minimum points of problem (P) corresponding to the local minimum values f_i^*, such that $\mathscr{C}^*(f_i^*) \subset \mathring{\mathscr{D}}$ and

$$\mathscr{L}_{\mathscr{P}} \cap \mathring{\mathscr{D}} = \bigcup_{i=1}^{r} \mathscr{C}^*(f_i^*).$$

Assumption (A2) requires that any local minimizer of problem (P) in $\mathring{\mathscr{D}}$ belongs to an isolated compact set of local minimizers and that the number of these sets contained in $\mathring{\mathscr{D}}$ is finite.

Then, we have the following theorem.

THEOREM 3. *Suppose that Assumption* (A2) *holds. Let* $F(x; \varepsilon)$ *be such that the following conditions are satisfied.*

(c_1) *For any* $\varepsilon > 0$, *the function* $F(x; \varepsilon)$ *admits a global minimum point on a set* $\mathscr{E}$, *such that* $\mathring{\mathscr{D}} \subseteq \mathscr{E} \subseteq \mathscr{D}$.

(c_2) *If* $\{\varepsilon_k\}$ *and* $\{x_k\} \subset \mathscr{E}$ *are sequences such that* $\lim_{k\to\infty} \varepsilon_k = 0$, $\lim_{k\to\infty} x_k = \hat{x} \in \mathscr{D}$, *and* $\limsup_{k\to\infty} F(x_k, \varepsilon_k) < \infty$, *we have* $\hat{x} \in \mathscr{F} \cap \mathscr{D}$ *and* $f(\hat{x}) \leqq \limsup_{k\to\infty} F(x_k, \varepsilon_k)$.

(c_3) $\mathscr{L}_{\mathscr{P}} \cap \mathring{\mathscr{D}} \subseteq \mathscr{K}$.

(c_4) *There exists an* $\bar{\varepsilon} > 0$ *such that, for all* $\varepsilon \in (0, \bar{\varepsilon}]$, *if* $\mathscr{L}_{\mathscr{D}}(\varepsilon) \neq \emptyset$ *and* $x_\varepsilon \in \mathscr{L}_{\mathscr{D}}(\varepsilon)$, *we have* $x_\varepsilon \in \mathscr{K}$;

(c_5) $F(x; \varepsilon) \leqq f(x)$ *for all* $\varepsilon > 0$ *and* $x \in \mathscr{F} \cap \mathring{\mathscr{D}}$.

Then, $F(x; \varepsilon)$ *is a strongly exact penalty function for problem* (P) *with respect to the set* $\mathscr{D}$.

Proof. By Assumption (A1) we have $\mathscr{G}_{\mathscr{P}} \subseteq \mathscr{L}_{\mathscr{P}} \cap \mathring{\mathscr{D}}$; then, noting that the set of conditions (c_1)-(c_5) implies the conditions stated in Theorem 2, we have that the

function $F(x;\varepsilon)$ is exact in the sense of Definition 2 for some threshold value $\varepsilon_0>0$ of the penalty parameter. On the other hand, for $i=1,\cdots,r$ we have $\mathscr{C}^*(f_i^*)\subseteq\mathscr{K}$, so that, since conditions (c_1)-(c_5) also imply conditions (b_1)-(b_3) of Proposition 2, there exist values $\varepsilon_i>0$, $i=1,\cdots,r$ such that for all $\varepsilon\in(0,\varepsilon_i]$ we can assert that $\mathscr{C}^*(f_i^*)\subseteq\mathscr{L}_{\mathscr{D}}(\varepsilon)$. Thus, by letting $\varepsilon^*=\min_{0\leqq i\leqq r}\varepsilon_i$ we have that $F(x;\varepsilon)$ is exact, and, moreover, by Assumption (A2) we have

$$\mathscr{L}_{\mathscr{D}}\cap\mathring{\mathscr{D}}=\bigcup_{i=1}^{r}\mathscr{C}^*(f_i^*)\subseteq\mathscr{L}_{\mathscr{D}}(\varepsilon)$$

for all $\varepsilon\in(0,\varepsilon^*]$, so that the function $F(x;\varepsilon)$ is strongly exact in the sense of Definition 3. □

5. Nondifferentiable exact penalty functions. In this section we shall make use of the sufficient conditions given before in order to establish the exactness of the best-known class of nondifferentiable penalty functions.

We suppose that Assumption (A1) stated in § 4 is satisfied, that is, $\mathscr{G}_{\mathscr{D}}\subset\mathring{\mathscr{D}}$.

We consider the class of nondifferentiable penalty functions defined by

$$J_q(x;\varepsilon):=f(x)+\frac{1}{\varepsilon}\|[g^+(x)'h(x)']'\|_q,$$

where $1\leqq q\leqq\infty$. In particular, we have

$$J_q(x;\varepsilon)=f(x)+\frac{1}{\varepsilon}\left[\sum_{i=1}^{m}(g_i^+(x))^q+\sum_{j=1}^{p}|h_j(x)|^q\right]^{1/q},$$

for $1\leqq q<\infty$, and

$$J_\infty(x;\varepsilon)=f(x)+\frac{1}{\varepsilon}\max[g_1^+(x),\cdots,g_m^+(x),|h_1(x)|,\cdots,|h_p(x)|].$$

For this class of functions the set $\mathscr{K}$ defined in (1) is obviously obtained as

$$\mathscr{K}=\mathscr{F}\cap\mathring{\mathscr{D}}.$$

The expression of the directional derivative $DJ_q(x,d;\varepsilon)$ of $J_q(x;\varepsilon)$ is given in the following proposition, which is proved in full detail in [16].

PROPOSITION 3. *For all $\varepsilon>0$ and $d\in\mathbb{R}^n$, the function $J_q(x;\varepsilon)$ admits a directional derivative $DJ_q(x,d;\varepsilon)$.*

Let

$$\xi_i(x,d):=\begin{cases}\nabla g_i(x)'d, & \text{if } g_i(x)>0;\\ (\nabla g_i(x)'d)^+, & \text{if } g_i(x)=0;\\ 0, & \text{if } g_i(x)<0\end{cases}\tag{9}$$

and

$$\zeta_j(x,d):=\begin{cases}\nabla h_j(x)'d, & \text{if } h_j(x)>0;\\ |\nabla h_j(x)'d|, & \text{if } h_j(x)=0;\\ -\nabla h_j(x)'d, & \text{if } h_j(x)<0.\end{cases}\tag{10}$$

Then, we have:

(a) *for $q=1$*:

$$DJ_1(x,d;\varepsilon)=\nabla f(x)'d+\frac{1}{\varepsilon}\left(\sum_{i=1}^{m}\xi_i(x,d)+\sum_{j=1}^{p}\zeta_j(x,d)\right);$$

(b) *for* $1<q<\infty$, $x\notin\mathscr{F}$:

$$DJ_q(x,d;\varepsilon)=\nabla f(x)'d+\frac{1}{\varepsilon\|[g^+(x)'h(x)']'\|_q^{q-1}}\left[\sum_{i=1}^{m}(g_i^+(x))^{q-1}\xi_i(x,d)+\sum_{j=1}^{p}|h_j(x)|^{q-1}\zeta_j(x,d)\right];$$

(c) *for* $1<q<\infty$, $x\in\mathscr{F}$:

$$DJ_q(x,d;\varepsilon)=\nabla f(x)'d+\frac{1}{\varepsilon}\left[\sum_{i=1}^{m}(\xi_i(x,d))^q+\sum_{j=1}^{p}(\zeta_j(x,d))^q\right]^{1/q};$$

(d) *for* $q=\infty$:

$$DJ_\infty(x,d;\varepsilon)=\nabla f(x)'d+\frac{1}{\varepsilon}\max\left[\{\xi_i(x,d),i\in I_1(x)\},\{\zeta_j(x,d),j\in I_2(x)\}\right],$$

where

$$I_1(x):=\{i:\ g_i^+(x)=\|[g^+(x)'h(x)']'\|_\infty\}$$
$$I_2(x):=\{j:\ |h_j(x)|=\|[g^+(x)'h(x)']'\|_\infty\}.$$

The next two propositions, which have been proved in [17], play a significant role in establishing the exactness properties of $J_q(x;\varepsilon)$.

PROPOSITION 4. *Let* $\hat{x}\in\mathscr{F}$ *and assume that the* MFCQ *holds at* $\hat{x}$. *Then, there exist numbers* $\varepsilon(\hat{x})>0$ *and* $\sigma(\hat{x})>0$ *such that, for all* $\varepsilon\in(0,\varepsilon(\hat{x})]$, *if* x_ε *is a critical point of* $J_q(x;\varepsilon)$ *satisfying* $\|x_\varepsilon-\hat{x}\|\leqq\sigma(\hat{x})$, *we have* $x_\varepsilon\in\mathscr{F}$.

PROPOSITION 5. *Assume that the* EMFCQ *holds on* $\mathscr{D}$. *Then, there exists an* $\bar{\varepsilon}>0$ *such that, for all* $\varepsilon\in(0,\bar{\varepsilon}]$, *if* $x_\varepsilon\in\mathscr{D}$ *is a critical point of* $J_q(x;\varepsilon)$, *we have* $x_\varepsilon\in\mathscr{F}$.

We can now prove that, under suitable assumptions on problem (P), the function $J_q(x;\varepsilon)$ satisfies the sufficient conditions of exactness stated in the preceding section.

THEOREM 4. (a) *Assume that the* MFCQ *is satisfied at every global minimum point of problem* $(\tilde{\mathrm{P}})$. *Then, the function* $J_q(x;\varepsilon)$ *is a weakly exact penalty function for problem* (P) *with respect to the set* $\mathscr{D}$.

(b) *Assume that the* EMFCQ *is satisfied on* $\mathscr{D}$. *Then, the function* $J_q(x;\varepsilon)$ *is an exact penalty function for problem* (P) *with respect to the set* $\mathscr{D}$; *moreover, if Assumption* (A2) *holds, the function* $J_q(x;\varepsilon)$ *is a strongly exact penalty function for problem* (P) *with respect to the set* $\mathscr{D}$.

Proof. We show first that conditions (a_1)-(a_4) of Theorem 1 are satisfied.

Let $\mathscr{E}=\mathscr{D}$; then, (a_1) follows from the continuity of $J_q(x;\varepsilon)$ and the compactness of $\mathscr{D}$.

With regard to condition (a_2), let $\{\varepsilon_k\}$ and $\{x_k\}\subset\mathscr{D}$ be sequences such that $\varepsilon_k>0$, $\lim_{k\to\infty}\varepsilon_k=0$, $\lim_{k\to\infty}x_k=\hat{x}\in\mathscr{D}$, and assume that

$$\limsup_{k\to\infty}J_q(x_k;\varepsilon_k)=\eta<\infty.$$

This implies

$$f(\hat{x})+\limsup_{k\to\infty}\frac{1}{\varepsilon_k}\|[g^+(x_k)'h(x_k)']'\|_q=\eta,$$

whence it follows that

$$\|[g^+(\hat{x})'h(\hat{x})']'\|_q=0\quad\text{and}\quad f(\hat{x})\leqq\eta$$

so that (a_2) is satisfied.

Condition (a_3) follows from the definition of $J_q(x;\varepsilon)$, since

$$J_q(x;\varepsilon)=f(x) \quad \text{for all } x\in\mathcal{F}.$$

Finally, condition (a_4) follows from Proposition 4, since any global minimum point of problem (Q) is a critical point of $J_q(x;\varepsilon)$. This concludes the proof of (a).

Consider now the conditions stated in Theorem 2; we have already proved that (a_1)-(a_3) hold. Condition (a_5) is implied by the result given in Proposition 5 and condition (a_6) follows from the definition of $J_q(x;\varepsilon)$. It can be easily verified also that conditions (c_1), (c_2), (c_4), and (c_5) of Theorem 3 reduce to conditions (a_1), (a_2), (a_5), and (a_6), and that condition (c_3) follows from the definition of $J_q(x;\varepsilon)$. Thus (b) follows from Theorems 2 and 3. □

In the next two propositions we report additional results concerning the correspondence between critical points of $J_q(x;\varepsilon)$ and K-T triples of problem (P).

PROPOSITION 6. *Let $\bar{x}\in\mathcal{F}$; then, if $\bar{x}$ is a critical point of $J_q(x;\varepsilon)$ we have $\bar{x}\in\mathcal{T}$. Moreover, if the* EMFCQ *holds on $\mathcal{D}$, there exists an $\varepsilon^*>0$ such that for all $\varepsilon\in(0,\varepsilon^*]$, if $x_\varepsilon\in\mathring{\mathcal{D}}$ is a critical point of $J_q(x;\varepsilon)$, we have $x_\varepsilon\in\mathcal{T}$.*

Proof. Let us define the following set.

$$\mathcal{Z}:=\{z\in\mathbb{R}^n:\nabla g_i(\bar{x})'z\leqq 0,\ i\in I_0(\bar{x}),$$

$$\nabla h_j(\bar{x})'z=0, j=1,\cdots,p,\nabla f(\bar{x})'z<0\}.$$

It is known that, by Farkas' lemma, $\mathcal{Z}=\varnothing$ implies that there exist $\bar{\lambda}\in\mathbb{R}^m$ and $\bar{\mu}\in\mathbb{R}^p$ such that $(\bar{x},\bar{\lambda},\bar{\mu})$ is a K-T triple for problem (P). (See, e.g., [23, p. 18].)

We prove first that if $\bar{x}\in\mathcal{F}$ is a critical point of $J_q(x;\varepsilon)$, we have $\mathcal{Z}=\varnothing$. In fact, since $\bar{x}\in\mathcal{F}$, we have, by Proposition 3

$$DJ_q(\bar{x},z;\varepsilon)=\nabla f(\bar{x})'z+\frac{1}{\varepsilon}\left[\sum_{i\in I_0(\bar{x})}[(\nabla g_i(\bar{x})'z)^+]^q+\sum_{j=1}^{p}|\nabla h_j(\bar{x})'z|^q\right]^{1/q},$$

for $1\leqq q<\infty$, and

$$DJ_\infty(\bar{x},z;\varepsilon)=\nabla f(\bar{x})'z+\frac{1}{\varepsilon}\max[(\nabla g_i(\bar{x})'z)^+, i\in I_0(\bar{x}),|\nabla h_j(\bar{x})'z|, j=1,\cdots,p].$$

It follows that, whenever $\nabla g_i(\bar{x})'z\leqq 0$, for $i\in I_0(\bar{x})$ and $\nabla h_j(\bar{x})'z=0$, for $j=1,\cdots,p$ we have:

$$DJ_q(\bar{x},z;\varepsilon)=\nabla f(\bar{x})'z.$$

Therefore, as $\bar{x}$ is a critical point of $J_q(x;\varepsilon)$, we have $\nabla f(\bar{x})'z\geqq 0$ for all z satisfying

$$\nabla g_i(\bar{x})'z\leqq 0, \qquad i\in I_0(\bar{x})$$

$$\nabla h_j(\bar{x})'z=0, \qquad j=1,\cdots,p$$

and this implies $\mathcal{Z}=\varnothing$, so that $\bar{x}\in\mathcal{T}$. Now, recalling Proposition 5, we have that if the EMFCQ holds on $\mathcal{D}$ there exists an $\varepsilon^*>0$ such that for all $\varepsilon\in(0,\varepsilon^*]$ if $x_\varepsilon\in\mathring{\mathcal{D}}$ is a critical point of $J_q(x;\varepsilon)$ we have $x_\varepsilon\in\mathcal{F}$ and hence $x_\varepsilon\in\mathcal{T}$. □

PROPOSITION 7. *Let $(\bar{x},\bar{\lambda},\bar{\mu})$ be a* K-T *triple for Problem* (P). *Then*: (a) *$\bar{x}$ is a critical point of $J_q(x;\varepsilon)$, $1\leqq q<\infty$ for all $\varepsilon>0$ such that*

$$\bar{\lambda}_i\varepsilon\leqq(m+p)^{(1-q)/q}, \qquad i\in I_0(\bar{x})$$

$$|\bar{\mu}_j|\varepsilon\leqq(m+p)^{(1-q)/q}, \qquad j=1,\cdots,p.$$

(b) *$\bar{x}$ is a critical point of $J_\infty(x;\varepsilon)$, for all $\varepsilon>0$ such that*

$$\varepsilon\left[\sum_{i\in I_0(\bar{x})}\bar{\lambda}_i+\sum_{j=1}^{p}|\bar{\mu}_j|\right]\leqq 1.$$

Proof. Since $(\bar{x},\bar{\lambda},\bar{\mu})$ is a K-T triple for problem (P), we can write

$$\nabla f(x)=-\left(\sum_{i\in I_0(\bar{x})}\bar{\lambda}_i\nabla g_i(\bar{x})+\sum_{j=1}^{p}\bar{\mu}_j\nabla h_j(\bar{x})\right). \tag{11}$$

Consider first the case $1\leqq q<\infty$. As $\bar{x}\in\mathcal{F}$, by Proposition 3 we have, for any given $d\in\mathbb{R}^n$:

$$DJ_q(\bar{x},d;\varepsilon)=\nabla f(\bar{x})'d+\frac{1}{\varepsilon}\left[\sum_{i\in I_0(\bar{x})}[(\nabla g_i(\bar{x})'d)^+]^q+\sum_{j=1}^{p}|\nabla h_j(\bar{x})'d|^q\right]^{1/q},$$

so that, by (11):

$$DJ_q(\bar{x},d;\varepsilon)\geqq\frac{1}{\varepsilon}\left[\sum_{i\in I_0(\bar{x})}[(\nabla g_i(\bar{x})'d)^+]^q+\sum_{j=1}^{p}|\nabla h_j(\bar{x})'d|^q\right]^{1/q}$$
$$-\left[\sum_{i\in I_0(\bar{x})}\bar{\lambda}_i(\nabla g_i(\bar{x})'d)^+\sum_{j=1}^{p}|\bar{\mu}_j\|\nabla h_j(\bar{x})'d|\right].$$

Using Hölder's inequality, we can write

$$DJ_q(\bar{x},d;\varepsilon)\geqq\sum_{i\in I_0(\bar{x})}\left[\frac{1}{\varepsilon(m+p)^{(q-1)/q}}-\bar{\lambda}_i\right](\nabla g_i(\bar{x})'d)^+$$
$$+\sum_{j=1}^{p}\left[\frac{1}{\varepsilon(m+p)^{(q-1)/q}}-|\bar{\mu}_j|\right]|\nabla h_j(\bar{x})'d|$$

and this implies (a).

Consider now the case $q=\infty$. Since $\bar{x}\in\mathcal{F}$, we have, by Proposition 3:

$$DJ_\infty(\bar{x},d;\varepsilon)=\nabla f(\bar{x})'d+\frac{1}{\varepsilon}\max\left[(\nabla g_i(\bar{x})'d)^+, i\in I_0(\bar{x}), |\nabla h_j(\bar{x})'d|, j=1,\cdots,p\right].$$

By (11), we can write:

$$DJ_\infty(\bar{x},d;\varepsilon)\geqq\frac{1}{\varepsilon}\max\left[(\nabla g_i(\bar{x})'d)^+, i\in I_0(\bar{x}), |\nabla h_j(\bar{x})'d|, j=1,\cdots,p\right]$$
$$-\left[\sum_{i\in I_0(\bar{x})}\bar{\lambda}_i(\nabla g_i(\bar{x})'d)^+\sum_{j=1}^{p}|\bar{\mu}_j|\,|\nabla h_j(\bar{x})'d|\right]$$

whence, noting that

$$\sum_{i\in I_0(\bar{x})}\bar{\lambda}_i(\nabla g_i(\bar{x})'d)^+\sum_{j=1}^{p}|\bar{\mu}_j|\,|\nabla h_j(\bar{x})'d|$$
$$\leqq\left[\sum_{i\in I_0(\bar{x})}\bar{\lambda}_i+\sum_{j=1}^{p}|\bar{\mu}_j|\right]\max\left[(\nabla g_i(\bar{x})'d)^+, i\in I_0(\bar{x}), |\nabla h_j(\bar{x})'d|, j=1,\cdots,p\right]$$

we obtain (b). □

We consider now, under suitable compactness assumptions on the feasible set, the nondifferentiable penalty function with global exactness properties proposed in [16]. This function incorporates a barrier term which goes to infinity on the boundary

of a compact perturbation of the feasible set and can be viewed as a generalization of the "M_2" penalty function introduced in [22].

Let

$$\mathcal{S}_\beta := \{x \in \mathbb{R}^n,\ g(x) \leqq \alpha,\ \|h(x)\|_2^2 \leqq \alpha_0\}$$

be the set introduced in § 2 and suppose that the following assumption is satisfied.

Assumption (A3). The set $\mathcal{S}_\beta$ is compact.

Obviously, this assumption implies that the feasible set is compact. We can take $\mathcal{D} = \mathcal{S}_\beta$, so that $\mathcal{F} \subset \mathring{\mathcal{D}}$, problem ($\tilde{\mathrm{P}}$) reduces to the original problem (P), and Assumption (A1) of § 4 is satisfied.

Let us introduce the functions:

$$a_0(x) := \alpha_0 - \|h(x)\|_2^2$$

$$a_i(x) := \alpha_i - g_i(x), \qquad i = 1, \cdots, m$$

and denote by $A(x)$ the diagonal matrix:

$$A(x) := \operatorname{diag}(a_i(x)), \qquad i = 1, \cdots, m.$$

We have, obviously, that $a_i(x) > 0$, $i = 0, 1, \cdots, m$, for all $x \in \mathring{\mathcal{D}}$.

Then, we consider the following function

$$Z_q(x; \varepsilon) := f(x) + \frac{1}{\varepsilon} \left\| \left[(A^{-1}(x) g^+(z))' \frac{h(x)'}{a_0(x)} \right]' \right\|_q,$$

where $\varepsilon > 0$ and $1 \leqq q \leqq \infty$. In particular, we have:

$$Z_q(x; \varepsilon) = f(x) + \frac{1}{\varepsilon} \left[\sum_{i=1}^{m} \left(\frac{g_i^+(x)}{a_i(x)} \right)^q + \frac{1}{a_0(x)^q} \sum_{j=1}^{p} |h_j(x)|^q \right]^{1/q},$$

for $1 \leqq q < \infty$, and

$$Z_\infty(x; \varepsilon) = f(x) + \frac{1}{\varepsilon} \max \left[\frac{g_1^+(x)}{a_1(x)}, \cdots, \frac{g_m^+(x)}{a_m(x)}, \frac{|h_1(x)|}{a_0(x)}, \cdots, \frac{|h_p(x)|}{a_0(x)} \right].$$

An equivalent expression of $Z_q(x; \varepsilon)$ can be derived by defining the functions

$$\hat{g}_i(x) = \frac{g_i(x)}{a_i(x)}, \qquad i = 1, \cdots, m \tag{12}$$

$$\hat{h}_j(x) = \frac{h_j(x)}{a_0(x)}, \qquad j = 1, \cdots, p. \tag{13}$$

Using (12) and (13) we can write

$$Z_q(x; \varepsilon) = f(x) + \frac{1}{\varepsilon} \|[\hat{g}^+(x)' \hat{h}(x)']'\|_q.$$

Taking this into account, the expression of the directional derivative $DZ_q(x, d; \varepsilon)$ can be obtained from (a)-(d) of Proposition 4 by replacing $g(x)$ with $\hat{g}(x)$ and $h(x)$ with $\hat{h}(x)$. By this substitution we have for the gradients

$$\nabla \hat{g}_i(x) = \frac{a_i}{a_i^2(x)} \nabla g_i(x), \qquad i = 1, \cdots, m \tag{14}$$

$$\nabla \hat{h}_j(x) = \frac{1}{a_0(x)} \nabla h_j(x) + 2 \frac{h_j(x)}{a_0^2(x)} \frac{\partial h(x)'}{\partial x} h(x), \qquad j = 1, \cdots, p. \tag{15}$$

We can now perform the analysis of the exactness properties of the function $Z_q(x; \varepsilon)$ making use of the sufficient conditions given in the preceding section. The

analysis is based on the fact that, by construction, the function $Z_q(x;\varepsilon)$ is defined for all $x \in \mathring{\mathcal{D}}$ and goes to infinity for x converging to a point of $\partial\mathcal{D}$; then, by Definition 4 we have that $Z_q(x;\varepsilon)$ is a globally (weakly, strongly) exact penalty function for problem (P) with respect to the set $\mathcal{D}$ if it is (weakly, strongly) exact in the sense of Definitions 1, 2, and 3.

The following propositions, which have been established in [16], can be viewed as the analogues of Propositions 5 and 6.

PROPOSITION 8. *Let $\hat{x} \in \mathcal{F}$ and assume that the* MFCQ *holds at $\hat{x}$. Then, there exist numbers $\varepsilon(\hat{x}) > 0$ and $\sigma(\hat{x}) > 0$ such that, for all $\varepsilon \in (0, \varepsilon(\hat{x})]$, if $x_\varepsilon \in \mathring{\mathcal{D}}$ is a critical point of $Z_q(x;\varepsilon)$ satisfying $\|x_\varepsilon - \hat{x}\| \leqq \sigma(\hat{x})$, we have $x_\varepsilon \in \mathcal{F}$.*

PROPOSITION 9. *Assume that the* EMFCQ *holds on $\mathcal{D}$. Then, there exists an $\bar{\varepsilon} > 0$ such that, for all $\varepsilon \in (0, \bar{\varepsilon}]$, if $x_\varepsilon \in \mathring{\mathcal{D}}$ is a critical point of $Z_q(x;\varepsilon)$, we have $x_\varepsilon \in \mathcal{F}$.*

Using the preceding results, it is possible to establish the properties of exactness of $Z_q(x;\varepsilon)$, which are collected in the following theorem.

THEOREM 5. (a) *Assume that the* MFCQ *is satisfied at every global minimum point of problem* (P). *Then, the function $Z_q(x;\varepsilon)$ is a globally weakly exact penalty function for problem* (P) *with respect to the set $\mathcal{D}$.*

(b) *Assume that the* EMFCQ *is satisfied on $\mathcal{D}$. Then, the function $Z_q(x;\varepsilon)$ is a globally exact penalty function for problem* (P) *with respect to the set $\mathcal{D}$; moreover, if Assumption* (A2) *holds, the function $Z_q(x;\varepsilon)$ is a globally strongly exact penalty function for problem* (P) *with respect to the set $\mathcal{D}$.*

Proof. By construction, we have $\lim_{k\to\infty} Z_q(x_k;\varepsilon) = \infty$ for any sequence $\{x_k\} \subset \mathring{\mathcal{D}}$ such that $x_k \to y \in \partial\mathcal{D}$. Hence, by Definition 4 we have that $Z_q(x;\varepsilon)$ is globally (weakly, strongly) exact if it is (weakly, strongly) exact.

With regard to 5(a), letting $\mathcal{C} = \mathring{\mathcal{D}}$, we can proceed as in the proof of Theorem 4 making use of Proposition 8 in place of Proposition 4; the proof of 5(b) is similar to that of Theorem 4(b) provided that we employ Proposition 9 in place of Proposition 5. □

Finally, we state without proof the relationships between critical points of $Z_q(x;\varepsilon)$ and K-T triples of problem (P).

Noting that, for $x \in \mathcal{F}$ we have $\nabla \hat{g}_i(x)'z \leqq 0$ and $\nabla \hat{h}_j(x)'z = 0$ if and only if $\nabla g_i(x)'z \leqq 0$ and $\nabla h_j(x)'z = 0$, and recalling Proposition 9, the proof of Proposition 6 can be easily modified to yield the following result.

PROPOSITION 10. *Let $\bar{x} \in \mathcal{F}$; then, if $\bar{x}$ is a critical point of $Z_q(x;\varepsilon)$, we have $\bar{x} \in \mathcal{T}$. Moreover, if the* EMFCQ *holds on $\mathcal{D}$, there exists an $\varepsilon^* > 0$ such that for all $\varepsilon \in (0, \varepsilon^*]$, if $x_\varepsilon \in \mathring{\mathcal{D}}$ is a critical point of $Z_q(x;\varepsilon)$, we have $x_\varepsilon \in \mathcal{T}$.*

The next proposition is an analogue of Proposition 7 which can be established by taking into account formulas (14) and (15) when considering the expression $DZ_q(x, d;\varepsilon)$.

PROPOSITION 11. *Let $(\bar{x}, \bar{\lambda}, \bar{\mu})$ be a K-T triple for problem* (P). *Then*: (a) *$\bar{x}$ is a critical point of $Z_q(x;\varepsilon)$, $1 \leqq q < \infty$ for all $\varepsilon > 0$ such that*:

$$\bar{\lambda}_i \varepsilon \leqq \frac{1}{\alpha_i}(m+p)^{(1-q)/q}, \qquad i \in I_0(\bar{x})$$

$$|\bar{\mu}_j|\varepsilon \leqq \frac{1}{\alpha_0}(m+p)^{(1-q)/q}, \qquad j = 1, \cdots, p.$$

(b) *$\bar{x}$ is a critical point of $Z_\infty(x;\varepsilon)$, for all $\varepsilon > 0$ such that*:

$$\varepsilon\left[\sum_{i\in I_0(\bar{x})} \bar{\lambda}_i \alpha_i + \sum_{j=1}^{p} |\bar{\mu}_j|\alpha_0\right] \leqq 1.$$

6. Continuously differentiable exact penalty functions. In this section we study a class of continuously differentiable exact penalty functions, making use of the sufficient conditions established in § 4.

The key idea for the construction of continuously differentiable exact penalty functions is that of replacing the multiplier vectors (λ, μ) which appear in the augmented Lagrangian function of Hestenes, Powell, and Rockafellar [4] with continuously differentiable *multiplier functions* $(\lambda(x), \mu(x))$, depending on the problem variables.

Let

$$\mathscr{X} := \{x \in \mathbb{R}^n : \nabla g_i(x),\ i \in I_0(x),\ \nabla h_j(x),\ j = 1, \cdots, p \text{ are linearly independent}\};$$

then, for any $x \in \mathscr{X}$ we can consider the multiplier functions $(\lambda(x), \mu(x))$ introduced in [28], which are obtained by minimizing over $\mathbb{R}^m \times \mathbb{R}^p$ the quadratic function in (λ, μ) defined by:

$$\Psi(\lambda, \mu; x) := \|\nabla_x L(x, \lambda, \mu)\|^2 + \gamma^2 \|G(x)\lambda\|^2,$$

where $\gamma \neq 0$ and

$$G(x) := \operatorname{diag}(g_i(x)).$$

The function $\Psi(\lambda, \mu; x)$ can be viewed as a measure of the violation of the set of K-T necessary conditions:

$$\nabla_x L(x, \lambda, \mu) = 0, \qquad G(x)\lambda = 0.$$

Let $N(x)$ be the $(m+p)\times(m+p)$ matrix defined by:

$$N(x) := \begin{bmatrix} \dfrac{\partial g(x)}{\partial x}\dfrac{\partial g(x)'}{\partial x} + \gamma^2 G^2(x) & \dfrac{\partial g(x)}{\partial x}\dfrac{\partial h(x)'}{\partial x} \\ \dfrac{\partial h(x)}{\partial x}\dfrac{\partial g(x)'}{\partial x} & \dfrac{\partial h(x)}{\partial x}\dfrac{\partial h(x)'}{\partial x} \end{bmatrix}.$$

In the next proposition we recall some known results established in [28].

PROPOSITION 12. *Let $\bar{x} \in \mathscr{X}$ and $\gamma \neq 0$. Then*: (a) *the matrix $N(x)$ is positive definite*;

(b) *there exists a unique minimizer $(\lambda(x), \mu(x))$ of the quadratic function in (λ, μ), $\Psi(\lambda, \mu; x)$, given by*

$$\begin{bmatrix} \lambda(x) \\ \mu(x) \end{bmatrix} = -N^{-1}(x) \begin{bmatrix} \dfrac{\partial g(x)}{\partial x} \\ \dfrac{\partial h(x)}{\partial x} \end{bmatrix} \nabla f(x);$$

(c) *if $(\bar{x}, \bar{\lambda}, \bar{\mu}) \in \mathscr{X} \times \mathbb{R}^m \times \mathbb{R}^p$ is a triple such that $\nabla_x L(\bar{x}, \bar{\lambda}, \bar{\mu}) = 0$ and $G(\bar{x})\bar{\lambda} = 0$, we have $\lambda(\bar{x}) = \bar{\lambda}$ and $\mu(\bar{x}) = \bar{\mu}$*;

(d) *the Jacobian matrices of $\lambda(x)$ and $\mu(x)$ are given by*

$$\begin{bmatrix} \dfrac{\partial \lambda(x)}{\partial x} \\ \dfrac{\partial \mu(x)}{\partial x} \end{bmatrix} = -N^{-1}(x) \begin{bmatrix} R(x) \\ S(x) \end{bmatrix}, \tag{16}$$

where

$$R(x) := \frac{\partial g(x)}{\partial x} \nabla_x^2 L(x, \lambda(x), \mu(x)) + \sum_{i=1}^{m} e_i^m \nabla_x L(x, \lambda(x), \mu(x))' \nabla^2 g_i(x)$$

$$+ 2\gamma^2 \Lambda(x) G(x) \frac{\partial g(x)}{\partial x}$$

$$S(x) := \frac{\partial h(x)}{\partial x} \nabla_x^2 L(x, \lambda(x), \mu(x)) + \sum_{j=1}^{p} e_j^p \nabla_x L(x, \lambda(x), \mu(x))' \nabla^2 h_j(x)$$

$$\nabla_x L(x, \lambda(x), \mu(x)) := [\nabla_x L(x, \lambda, \mu)]_{\substack{\lambda=\lambda(x) \\ \mu=\mu(x)}}$$

$$\nabla_x^2 L(x, \lambda(x), \mu(x)) := [\nabla_x^2 L(x, \lambda, \mu)]_{\substack{\lambda=\lambda(x) \\ \mu=\mu(x)}}$$

$$\Lambda(x) := \operatorname{diag}(\lambda_i(x))$$

and $e_i^m (e_j^p)$ *denote the* ith$(j$th$)$ *column of the* $m \times m (p \times p)$ *identity matrix.*

Thus we can consider the penalty function introduced in [28], defined by

$$W(x; \varepsilon) := f(x) + \lambda(x)'(g(x) + Y(x; \varepsilon) y(x; \varepsilon)) + \frac{1}{\varepsilon} \|g(x) + Y(x; \varepsilon) y(x; \varepsilon)\|^2 + \mu(x)' h(x) + \frac{1}{\varepsilon} \|h(x)\|^2, \tag{17}$$

where

$$y_i(x; \varepsilon) := \left\{ -\min \left[0, g_i(x) + \frac{\varepsilon}{2} \lambda_i(x) \right] \right\}^{1/2}, \qquad i = 1, \cdots, m$$
$$Y(x; \varepsilon) := \operatorname{diag}(y_i(x; \varepsilon)). \tag{18}$$

It can be verified that the function $W(x; \varepsilon)$ can also be written in the form

$$W(x; \varepsilon) = f(x) + \lambda(x)' g(x) + \frac{1}{\varepsilon} \|g(x)\|^2 + \mu(x)' h(x) + \frac{1}{\varepsilon} \|h(x)\|^2 - \frac{1}{4\varepsilon} \sum_{i=1}^{m} \{\min [0, \varepsilon \lambda_i(x) + 2 g_i(x)]\}^2.$$

From the above expression and the differentiability assumptions on the problem functions, it follows that $W(x; \varepsilon)$ is continuously differentiable on $\mathscr{X}$. The expression of $W(x; \varepsilon)$ can be derived by means of the following reasoning.

Consider the transformed problem:

$$\text{minimize } f(x)$$
$$\text{subject to } g(x) + Yy = 0, \qquad h(x) = 0,$$

where y_i, $i = 1, \cdots, m$ are slack variables and $Y := \operatorname{diag}(y_i)$.

Define the augmented Lagrangian function for this problem:

$$L_a(x, y, \lambda, \mu; \varepsilon) := f(x) + \lambda'(g(x) + Yy) + \frac{1}{\varepsilon} \|g(x) + Yy\|^2 + \mu' h(x) + \frac{1}{\varepsilon} \|h(x)\|^2.$$

Then, by substituting $(\lambda(x), \mu(x))$ for (λ, μ) and minimizing with respect to y, we get the function $W(x; \varepsilon)$, that is,

$$W(x; \varepsilon) = L_a(x, y(x; \varepsilon), \lambda(x), \mu(x); \varepsilon) = \min_y L_a(x, y, \lambda(x), \mu(x); \varepsilon).$$

Since, by construction,

$$[\nabla_y L_a(x, y, \lambda, \mu; \varepsilon)]_{\substack{\lambda=\lambda(x) \\ \mu=\mu(x) \\ y=y(x; \varepsilon)}} = 0,$$

the gradient expression of $W(x;\varepsilon)$ can be obtained by treating formally $y(x;\varepsilon)$ as a constant vector. Thus, we have:

$$\nabla W(x;\varepsilon)=\nabla f(x)+\frac{\partial g(x)'}{\partial x}\lambda(x)+\frac{\partial h(x)'}{\partial x}\mu(x)$$
$$+\frac{2}{\varepsilon}\frac{\partial g(x)'}{\partial x}(g(x)+Y(x;\varepsilon)y(x;\varepsilon))+\frac{2}{\varepsilon}\frac{\partial h(x)'}{\partial x}h(x)$$
$$+\frac{\partial \lambda(x)'}{\partial x}(g(x)+Y(x;\varepsilon)y(x;\varepsilon))+\frac{\partial \mu(x)'}{\partial x}h(x),$$

where $\partial\lambda(x)/\partial x$ and $\partial\mu(x)/\partial x$ are the Jacobian matrices defined in (16).

Some properties of exactness of the function $W(x;\varepsilon)$ have been established in [15] for inequality constrained problems. Here we perform a more complete analysis for problems with both equality and inequality constraints, making use of the sufficient conditions given in § 4.

We suppose that Assumption (A1) of § 4 is satisfied, that is, $\mathscr{G}_{\mathscr{D}}\subset\mathring{\mathscr{D}}$, and that everywhere in this section the following assumption holds.

Assumption (A4). The LICQ is satisfied on $\mathscr{D}$, that is, $\mathscr{D}\subset\mathscr{K}$.

Some immediate consequences of the definition of $W(x;\varepsilon)$ are pointed out in the following proposition.

PROPOSITION 13. *Let* $(\bar{x},\bar{\lambda},\bar{\mu})$ *be a* K-T *triple for problem* (P), *such that* $\bar{x}\in\mathscr{D}$. *Then, for any* $\varepsilon>0$, *we have*: (a) $g(\bar{x})+Y(\bar{x};\varepsilon)y(\bar{x};\varepsilon)=0$;

(b) $W(\bar{x};\varepsilon)=f(\bar{x})$;

(c) $\nabla W(\bar{x};\varepsilon)=0$.

Proof. By Proposition 12 we have $\lambda(\bar{x})=\bar{\lambda}$ and $\mu(\bar{x})=\bar{\mu}$, so that, since $(\bar{x},\bar{\lambda},\bar{\mu})$ is a K-T triple for problem (P), we obtain $\nabla_x L(\bar{x},\lambda(\bar{x}),\mu(\bar{x}))=0$, $\lambda(\bar{x})\geqq 0$ and $\lambda_i(\bar{x})=0$ when $g_i(\bar{x})<0$. Then, (a) is satisfied by definition of $y(\bar{x};\varepsilon)$ and (b) follows directly from (17). Finally, (c) follows from (19), taking (a) into account and noting that, by assumption, $h(\bar{x})=0$ and $\nabla_x L(\bar{x},\lambda(\bar{x}),\mu(\bar{x}))=\nabla_x L(\bar{x},\bar{\lambda},\bar{\mu})$. □

Then, we have the following proposition.

PROPOSITION 14. *Let* $\hat{x}\in\mathscr{F}\cap\mathscr{D}$. *Then, there exist numbers* $\varepsilon(\hat{x})>0$ *and* $\sigma(\hat{x})>0$ *such that, for all* $\varepsilon\in(0,\varepsilon(\hat{x})]$, *if* $x_\varepsilon\in\mathring{\mathscr{D}}$ *is a stationary point of* $W(x;\varepsilon)$ *satisfying* $\|x_\varepsilon-\hat{x}\|\leqq\sigma(\hat{x})$, *we have that* $(x_\varepsilon,\lambda(x_\varepsilon),\mu(x_\varepsilon))$ *is a* K-T *triple for problem* (P).

Proof. Let $x\in\mathscr{K}$; then, by definition of $y(x;\varepsilon)$, we have

$$Y^2(x;\varepsilon)\lambda(x)=-\frac{2}{\varepsilon}Y^2(x;\varepsilon)(g(x)+Y(x;\varepsilon)y(x;\varepsilon)); \tag{20}$$

moreover, by definition of $\lambda(x)$ we can write:

$$\frac{\partial g(x)}{\partial x}\nabla_x L(x,\lambda(x),\mu(x))=-\gamma^2G^2(x)\lambda(x)$$
$$=-\gamma^2G(x)(G(x)+Y^2(x;\varepsilon))\lambda(x)+\gamma^2G(x)Y^2(x;\varepsilon)\lambda(x) \tag{21}$$
$$=-\gamma^2G(x)\Lambda(x)(g(x)+Y(x;\varepsilon)y(x;\varepsilon))+\gamma^2G(x)Y^2(x;\varepsilon)\lambda(x).$$

Therefore, by (20) and (21) we get

$$\varepsilon\frac{\partial g(x)}{\partial x}\nabla_x L(x,\lambda(x),\mu(x))=-\gamma^2G(x)(\varepsilon\Lambda(x)+2Y^2(x;\varepsilon))(g(x)+Y(x;\varepsilon)y(x;\varepsilon)),$$

so that, by (19), we can write

$$
\begin{aligned}
\varepsilon \frac{\partial g(x)}{\partial x} \nabla W(x;\varepsilon) &= \varepsilon \frac{\partial g(x)}{\partial x} \nabla_x L(x, \lambda(x), \mu(x)) \\
&\quad + \frac{\partial g(x)}{\partial x}\left(2\frac{\partial g(x)'}{\partial x} + \varepsilon \frac{\partial \lambda(x)'}{\partial x}\right)(g(x) + Y(x;\varepsilon)y(x;\varepsilon)) \\
&\quad + \frac{\partial g(x)}{\partial x}\left(2\frac{\partial h(x)'}{\partial x} + \varepsilon \frac{\partial \mu(x)'}{\partial x}\right)h(x) \\
&= K_{11}(x;\varepsilon)(g(x) + Y(x;\varepsilon)y(x;\varepsilon)) + K_{12}(x;\varepsilon)h(x),
\end{aligned} \tag{22}
$$

where

$$
\begin{aligned}
K_{11}(x;\varepsilon) &:= 2\left(\frac{\partial g(x)}{\partial x}\frac{\partial g(x)'}{\partial x} - \gamma^2 G(x) Y^2(x;\varepsilon)\right) \\
&\quad + \varepsilon\left(\frac{\partial g(x)}{\partial x}\frac{\partial \lambda(x)'}{\partial x} - \gamma^2 G(x)\Lambda(x)\right), \\
K_{12}(x;\varepsilon) &:= 2\frac{\partial g(x)}{\partial x}\frac{\partial h(x)'}{\partial x} + \varepsilon \frac{\partial g(x)}{\partial x}\frac{\partial \mu(x)'}{\partial x}.
\end{aligned}
$$

Now, by definition of $\mu(x)$, we have

$$
\frac{\partial h(x)}{\partial x} \nabla_x L(x, \lambda(x), \mu(x)) = 0
$$

and hence, by (19) we can write

$$
\varepsilon \frac{\partial h(x)}{\partial x} \nabla W(x;\varepsilon) = K_{21}(x;\varepsilon)(g(x) + Y(x;\varepsilon)y(x;\varepsilon)) + K_{22}(x;\varepsilon)h(x), \tag{23}
$$

where

$$
\begin{aligned}
K_{21}(x;\varepsilon) &:= 2\frac{\partial h(x)}{\partial x}\frac{\partial g(x)'}{\partial x} + \varepsilon \frac{\partial h(x)}{\partial x}\frac{\partial \lambda(x)'}{\partial x} \\
K_{22}(x;\varepsilon) &:= 2\frac{\partial h(x)}{\partial x}\frac{\partial h(x)'}{\partial x} + \varepsilon \frac{\partial h(x)}{\partial x}\frac{\partial \mu(x)'}{\partial x}.
\end{aligned}
$$

Thus, from (22) and (23) we get, for all $x \in \mathscr{X}$:

$$
\varepsilon \begin{bmatrix} \dfrac{\partial g(x)}{\partial x} \\ \dfrac{\partial h(x)}{\partial x} \end{bmatrix} \nabla W(x;\varepsilon) = K(x;\varepsilon) \begin{bmatrix} g(x) + Y(x;\varepsilon)y(x;\varepsilon) \\ h(x) \end{bmatrix}, \tag{24}
$$

where $K(x;\varepsilon)$ is the matrix defined by

$$
K(x;\varepsilon) := \begin{bmatrix} K_{11}(x;\varepsilon) & K_{12}(x;\varepsilon) \\ K_{21}(x;\varepsilon) & K_{22}(x;\varepsilon) \end{bmatrix}.
$$

Let now $\hat{x} \in \mathscr{F} \cap \mathscr{D}$; then, by definition of $y(x;\varepsilon)$ we have

$$
Y^2(\hat{x};0) = -G(\hat{x}),
$$

so that, by definition of $K(x;\varepsilon)$, we get

$$
K(\hat{x};0) = 2N(\hat{x}).
$$

Therefore, since Assumption (A4) implies that $N(x)$ is nonsingular, by continuity there exist numbers $\varepsilon(\hat{x})>0$ and $\sigma(\hat{x})>0$ such that the matrix $K(x;\varepsilon)$ is nonsingular for all $\varepsilon\in[0,\varepsilon(\hat{x})]$ and all x such that $\|x-\hat{x}\|\leqq\sigma(\hat{x})$. Let $\varepsilon\in[0,\varepsilon(\hat{x})]$ and let $x_\varepsilon\in\mathring{\mathscr{D}}$ be a stationary point of $W(x;\varepsilon)$ satisfying $\|x_\varepsilon-\hat{x}\|\leqq\sigma(\hat{x})$. By (24) we have

$$K(x_\varepsilon;\varepsilon)\begin{bmatrix} g(x_\varepsilon)+Y(x_\varepsilon;\varepsilon)y(x_\varepsilon;\varepsilon) \\ h(x_\varepsilon)\end{bmatrix}=0,$$

which implies, as $K(x_\varepsilon;\varepsilon)$ is nonsingular, $h(x_\varepsilon)=0$, and

$$g(x_\varepsilon)+Y(x_\varepsilon;\varepsilon)y(x_\varepsilon;\varepsilon)=0. \tag{25}$$

Therefore, since $\nabla W(x_\varepsilon;\varepsilon)=0$, we have from (19)

$$\nabla_x L(x_\varepsilon,\lambda(x_\varepsilon),\mu(x_\varepsilon))=0; \tag{26}$$

on the other hand, by definition of $\lambda(x)$ and $\mu(x)$, we have

$$\frac{\partial g(x)}{\partial x}\nabla_x L(x_\varepsilon,\lambda(x_\varepsilon),\mu(x_\varepsilon))+\gamma^2 G^2(x_\varepsilon)\lambda(x_\varepsilon)=0, \tag{27}$$

and hence, by (26) and (27) we obtain

$$G(x_\varepsilon)\lambda(x_\varepsilon)=0.$$

Finally, if $g_i(x_\varepsilon)=0$ for some i, we have, by (25), $y_i^2(x_\varepsilon;\varepsilon)=0$, which implies, by definition of $y(x;\varepsilon)$, that $\lambda_i(x_\varepsilon)\geqq 0$. Hence, the triple $(x_\varepsilon,\lambda(x_\varepsilon),\mu(x_\varepsilon))$ is a K-T triple for problem (P). □

The next proposition establishes the correspondence between stationary points of $W(x;\varepsilon)$ and K-T triples for problem (P) on the whole set $\mathscr{D}$.

PROPOSITION 15. *Assume that the* EMFCQ *holds on* $\mathscr{D}$. *Then, there exists an* $\varepsilon^*>0$ *such that, for all* $\varepsilon\in(0,\varepsilon^*]$, *if* $x_\varepsilon\in\mathring{\mathscr{D}}$ *is a stationary point of* $W(x;\varepsilon)$, *we have that* $(x_\varepsilon,\lambda(x_\varepsilon),\mu(x_\varepsilon))$ *is a* K-T *triple for problem* (P).

Proof. The proof is by contradiction. Assume that the assertion is false. Then, for any integer k, there exists an $\varepsilon_k\leqq 1/k$ and a point $x_k\in\mathring{\mathscr{D}}$ such that $\nabla W(x_k;\varepsilon_k)=0$, but $(x_k,\lambda(x_k),\mu(x_k))$ is not a K-T triple for problem (P).

Since $\mathscr{D}$ is compact, there exists a convergent subsequence (relabel it again $\{x_k\}$) such that $\lim_{k\to\infty}x_k=\hat{x}\in\mathscr{D}$. Moreover, since $\nabla W(x_k;\varepsilon_k)=0$ for all k and since $\varepsilon_k\to 0$, we have in the limit, by (19):

$$\frac{\partial g(\hat{x})'}{\partial x}(g(\hat{x})+Y(\hat{x};0)y(\hat{x};0))+\frac{\partial h(\hat{x})'}{\partial x}h(\hat{x})=0, \tag{28}$$

where, by definition of $y_i^2(x;\varepsilon)$ we have

$$y_i^2(\hat{x};0)=-\min[0,g_i(\hat{x})],\qquad i=1,\cdots,m.$$

It follows that (28) can be rewritten into the form:

$$\sum_{i\in I_+(\hat{x})}g_i(\hat{x})\nabla g_i(\hat{x})+\sum_{j=1}^{p}h_j(\hat{x})\nabla h_j(\hat{x})=0,$$

where $I_+(\hat{x})=\{i\colon g_i(\hat{x})\geqq 0\}$. Therefore, by the EMFCQ we have $g_i(\hat{x})=0$, $i\in I_+(\hat{x})$, and $h_j(\hat{x})=0, j=1,\cdots,p$ so that $\hat{x}\in\mathscr{F}\cap\mathring{\mathscr{D}}$. On the other hand, by Proposition 14 there exists an integer $\bar{k}$ such that for all $k\geqq\bar{k}$ we have that $(x_k,\lambda(x_k),\mu(x_k))$ is a K-T triple for problem (P) and we get a contradiction. □

The properties of exactness of $W(x;\varepsilon)$ are summarized in the following theorem.

THEOREM 6. (a) *The function* $W(x;\varepsilon)$ *is a weakly exact penalty function for problem* (P) *with respect to the set* $\mathscr{D}$.

(b) *Assume that the* EMFCQ *is satisfied on* $\mathscr{D}$. *Then, the function* $W(x;\varepsilon)$ *is an exact penalty function for problem* (P) *with respect to the set* $\mathscr{D}$; *moreover, if Assumption* (A2) *holds, the function* $W(x;\varepsilon)$ *is a strongly exact penalty function for problem* (P) *with respect to the set* $\mathscr{D}$.

Proof. Let $\mathscr{E}=\mathscr{D}$; we show first that conditions (a_1)-(a_4) of Theorem 1 are satisfied.

It is easily seen that (a_1) follows from the continuity of $W(x;\varepsilon)$ and the compactness of $\mathscr{D}$.

With regard to condition (a_2), let $\{\varepsilon_k\}$ and $\{x_k\}\subset\mathscr{D}$ be sequences such that $\varepsilon_k>0$, $\lim_{k\to\infty}\varepsilon_k=0$, $\lim_{k\to\infty}x_k=\hat{x}\in\mathscr{D}$ and assume that

$$\limsup_{k\to\infty} W(x_k;\varepsilon_k)<\infty.$$

By the continuity assumptions we get from (17)

$$g(\hat{x})+Y(\hat{x};0)y(\hat{x};0)=0, \qquad h(\hat{x})=0,$$

which imply $\hat{x}\in\mathscr{F}$ and

$$f(\hat{x})\leqq\limsup_{k\to\infty} W(x_k;\varepsilon_k),$$

so that (a_2) is satisfied.

We observe now that Assumptions (A1) and (A4) imply that $\mathscr{G}_{\mathscr{F}}\subseteq\mathscr{T}$. On the other hand, by (b) of Proposition 13 we obtain $\mathscr{T}\subseteq\mathscr{K}$. Therefore, we have $\mathscr{G}_{\mathscr{F}}\subseteq\mathscr{K}$ and hence condition (a_3) is satisfied.

Finally, condition (a_4) follows from Proposition 14, noting that $\mathscr{T}\subseteq\mathscr{K}$ and that, by the differentiability of $W(x;\varepsilon)$, any point $x_\varepsilon\in\mathscr{G}_{\mathscr{D}}(\varepsilon)$ is a stationary point of $W(x;\varepsilon)$. Thus (a) is proved.

With regard to (b), we have already shown that conditions (a_1)-(a_3) of Theorem 2 are satisfied. Condition (a_5) is implied by Proposition 15. Therefore we must show that (a_6) holds, that is,

$$W(x;\varepsilon)\leqq f(x) \quad \text{for all } \varepsilon>0 \quad \text{and} \quad x\in\mathscr{F}\cap\mathring{\mathscr{D}}.$$

Let $x\in\mathring{\mathscr{D}}$ be such that $g(x)\leqq 0$ and $h(x)=0$. Suppose first that $y_i^2(x;\varepsilon)=0$; this implies, by definition of $y_i^2(x;\varepsilon)$, that

$$2g_i(x)+\varepsilon\lambda_i(x)\geqq 0,$$

so that, since $g_i(x)\leqq 0$, we have

$$\frac{1}{\varepsilon}g_i^2(x)+\lambda_i(x)g_i(x)\leqq\frac{2}{\varepsilon}g_i^2(x)+\lambda_i(x)g_i(x)\leqq 0. \tag{29}$$

Now assume that $y_i^2(x;\varepsilon)>0$; in this case we obtain

$$g_i(x)+y_i^2(x;\varepsilon)=-\frac{\varepsilon}{2}\lambda_i(x),$$

whence:

$$\frac{1}{\varepsilon}(g_i(x)+y_i^2(x;\varepsilon))^2+\lambda_i(x)(g_i(x)+y_i^2(x;\varepsilon))=-\frac{\varepsilon}{4}\lambda_i^2(x)\leqq 0. \tag{30}$$

Therefore, by (29) and (30) we have, for any $i=1,\cdots,m$:

$$\frac{1}{\varepsilon}(g_i(x)+y_i^2(x;\varepsilon))^2+\lambda_i(x)(g_i(x)+y_i^2(x;\varepsilon))\leqq 0,$$

so that, by (17), we obtain $W(x;\varepsilon)\leqq f(x)$ and hence condition (a_6) is satisfied. It can be verified also that conditions (c_1), (c_2), (c_4), and (c_5) of Theorem 3 are satisfied and that condition (c_3) follows from (b) of Proposition 13. Thus (b) follows from Theorems 2 and 3. □

We now consider the construction of a continuously differentiable exact penalty function with global exactness properties, along the same lines followed in the non-differentiable case. As in § 5, we take $\mathcal{D}=\mathcal{S}_\beta$, and we suppose that Assumption (A3) holds. Then, we can define on the set $\mathcal{E}=\mathring{\mathcal{D}}$ the continuously differentiable exact penalty function:

$$Z(x;\varepsilon):=f(x)+\lambda(x)'(g(x)+\tilde{Y}(x;\varepsilon)\tilde{y}(x;\varepsilon))$$
$$+\frac{1}{\varepsilon}(g(x)+\tilde{Y}(x;\varepsilon)\tilde{y}(x;\varepsilon))'A^{-1}(x)(g(x)+\tilde{Y}(x;\varepsilon)\tilde{y}(x;\varepsilon))$$
$$+\mu(x)'h(x)+\frac{1}{\varepsilon a_0(x)}\|h(x)\|^2,$$

where $(\lambda(x),\mu(x))$ are the multiplier functions defined in Proposition 12, and

$$a_0(x):=\alpha_0-\|h(x)\|_2^2$$
$$a_i(x):=\alpha_i-g_i(x),\qquad i=1,\cdots,m$$
$$A(x):=\operatorname{diag}(a_i(x)),\qquad i=1,\cdots,m$$

with:

$$\tilde{Y}(x;\varepsilon):=\operatorname{diag}(\tilde{y}_i(x;\varepsilon)),\qquad i=1,\cdots,m$$
$$\tilde{y}_i(x;\varepsilon):=\left\{-\min\left[0,\, g_i(x)+\frac{\varepsilon}{2}a_i(x)\lambda_i(x)\right]\right\}^{1/2}.$$

In order to justify the expression of $Z(x;\varepsilon)$ we first consider the equality constrained problem obtained from problem (P) by introducing the vector Yy of squared slack variables into the inequality constraints $g(x)\leqq 0$.

Then, we define the augmented Lagrangian function:

$$\tilde{L}_a(x,y,\lambda,\mu;\varepsilon):=f(x)+\lambda'(g(x)+Yy)+\frac{1}{\varepsilon}(g(x)+Yy)'A^{-1}(x)(g(x)+Yy)$$
$$+\mu'h(x)+\frac{1}{\varepsilon a_0(x)}\|h(x)\|^2,$$

where the penalty terms are weighted by the barrier functions $A^{-1}(x)$ and $1/a_0(x)$.

Finally, by substituting $(\lambda(x),\mu(x))$ for (λ,μ) and minimizing with respect to y we get the function $Z(x;\varepsilon)$, that is,

$$Z(x;\varepsilon)=\tilde{L}_a(x,\tilde{y}(x;\varepsilon),\lambda(x),\mu(x);\varepsilon)$$
$$=\min_y \tilde{L}_a(x,y,\lambda(x),\mu(x);\varepsilon).$$

By construction, we have

$$[\nabla_y\tilde{L}_a(x,y,\lambda,\mu)]_{\substack{\lambda=\lambda(x)\\ \mu=\mu(x)\\ y=\tilde{y}(x;\varepsilon)}}=0$$

and hence the gradient expression of $Z(x;\varepsilon)$ can be obtained by taking $\tilde{y}(x;\varepsilon)$ as a constant vector.

Thus, we can write:

$$\begin{aligned}\nabla Z(x;\varepsilon) = {} & \nabla f(x) + \frac{\partial g(x)'}{\partial x}\lambda(x) + \frac{\partial h(x)'}{\partial x}\mu(x) \\ & + \frac{2}{\varepsilon}\frac{\partial g(x)'}{\partial x}A^{-1}(x)(g(x)+\tilde{Y}(x;\varepsilon)\tilde{y}(x;\varepsilon)) \\ & + \frac{1}{\varepsilon}\frac{\partial g(x)'}{\partial x}[G(x)+\tilde{Y}^2(x;\varepsilon)]A^{-2}(x)(g(x)+\tilde{Y}(x;\varepsilon)\tilde{y}(x;\varepsilon)) \\ & + \frac{2}{\varepsilon a_0(x)}\frac{\partial h(x)'}{\partial x}h(x) + \frac{2\|h(x)\|_2^2}{a_0^2(x)}\frac{\partial h(x)'}{\partial x}h(x) \\ & + \frac{\partial \lambda(x)'}{\partial x}(g(x)+\tilde{Y}(x;\varepsilon)\tilde{y}(x;\varepsilon)) + \frac{\partial \mu(x)'}{\partial x}h(x).\end{aligned} \tag{31}$$

The study of the properties of exactness of the function $Z(x;\varepsilon)$ can be performed along the same lines followed in the case of the function $W(x;\varepsilon)$, taking into account the expressions of $\tilde{y}(x;\varepsilon)$ and $\nabla Z(x;\varepsilon)$ and noting that $a_i(x) > 0$, $i = 0, 1, \cdots, m$ for $x \in \mathring{\mathcal{D}}$.

In particular, the next two propositions are the analogue of Propositions 13 and 14 and can be proved in a similar way.

PROPOSITION 16. *Let* $(\bar{x}, \bar{\lambda}, \bar{\mu})$ *be a* K-T *triple for problem* (P), *such that* $\bar{x} \in \mathcal{D}$. *Then, for any* $\varepsilon > 0$, *we have*:

(a) $g(\bar{x}) + \tilde{Y}(\bar{x};\varepsilon)\tilde{y}(\bar{x};\varepsilon) = 0$;

(b) $Z(\bar{x};\varepsilon) = f(\bar{x})$;

(c) $\nabla Z(\bar{x};\varepsilon) = 0$.

PROPOSITION 17. *Let* $\hat{x} \in \mathcal{F} \cap \mathcal{D}$. *Then, there exist numbers* $\varepsilon(\hat{x}) > 0$ *and* $\sigma(\hat{x}) > 0$ *such that, for all* $\varepsilon \in (0, \varepsilon(\hat{x})]$, *if* $x_\varepsilon \in \mathring{\mathcal{D}}$ *is a stationary point of* $Z(x;\varepsilon)$ *satisfying* $\|x_\varepsilon - \hat{x}\| \leqq \sigma(\hat{x})$, *we have that* $(x_\varepsilon, \lambda(x_\varepsilon), \mu(x_\varepsilon))$ *is a* K-T *triple for problem* (P).

We now need the following lemma which is proved in [15].

LEMMA 3. *Let* $\{\delta_k^{(i)}\}$, $i = 1, \cdots, r$ *be* r *sequences of positive numbers. Then, there exist an index* i^* *and subsequences* $\{\delta_k^{(i)}\}_K$, $i = 1, \cdots, r$ *corresponding to the same index set* K, *such that*:

$$\lim_{\substack{k\to\infty \\ k\in K}} \frac{\delta_k^{(i^*)}}{\delta_k^{(i)}} = l_i < +\infty, \quad i = 1, \cdots, r.$$

The following proposition establishes the correspondence between stationary points of $Z(x;\varepsilon)$ and K-T triples for problem (P).

PROPOSITION 18. *Assume that the* EMFCQ *holds on* $\mathcal{D}$. *Then, there exists an* $\varepsilon^* > 0$ *such that, for all* $\varepsilon \in (0, \varepsilon^*]$, *if* $x_\varepsilon \in \mathring{\mathcal{D}}$ *is a stationary point of* $Z(x;\varepsilon)$, *we have that* $(x_\varepsilon, \lambda(x_\varepsilon), \mu(x_\varepsilon))$ *is a* K-T *triple for problem* (P).

Proof. Reasoning by contradiction, we assume that for any integer k, there exists an $\varepsilon_k \leqq 1/k$ and a point $x_k \in \mathring{\mathcal{D}}$ such that $\nabla Z(x_k;\varepsilon_k) = 0$, but $(x_k, \lambda(x_k), \mu(x_k))$ is not a K-T triple for problem (P). Since $\mathcal{D}$ is compact, there exists a convergent subsequence (relabel it again $\{x_k\}$) such that $\lim_{k\to\infty} x_k = \hat{x} \in \mathcal{D}$.

We show first that $\hat{x} \in \mathring{\mathscr{D}}$. In fact, assume that $\hat{x} \in \partial\mathscr{D}$; this implies, by definition of $\mathscr{D}$, that there exists a subset J of $\{0, 1, \cdots, m\}$ such that:

$$\lim_{k\to\infty} a_i(x_k) = 0, \qquad i \in J. \tag{32}$$

By Lemma 3 we can define an index $i^* \in J$ and a subsequence (relabel it again $\{x_k\}$) such that

$$\lim_{k\to\infty} \frac{a_{i^*}(x_k)}{a_i(x_k)} = l_i < +\infty, \qquad i \in J, \tag{33}$$

where, in particular, $l_{i^*} = 1$. Recalling (31), we can write

$$\begin{aligned} 0 &= \varepsilon_k a_{i^*}^2(x_k) \nabla Z(x_k; \varepsilon_k) \\ &= \varepsilon_k a_{i^*}^2 \Big[\nabla_x L(x_k, \lambda(x_k), \mu(x_k)) \\ &\qquad + \frac{\partial \lambda(x_k)'}{\partial x} (g(x_k) + \tilde{Y}(x_k; \varepsilon_k) y(x_k; \varepsilon_k)) + \frac{\partial \mu(x_k)'}{\partial x} h(x_k) \Big] \\ &\quad + \sum_{i=1}^{m} \frac{a_{i^*}^2(x_k)}{a_i(x_k)} \left(2 + \frac{g_i(x_k) + \tilde{y}_i^2(x_k; \varepsilon_k)}{a_i(x_k)} \right) (g_i(x_k) + \tilde{y}_i^2(x_k; \varepsilon_k)) \nabla g_i(x_k) \\ &\quad + 2 \sum_{j=1}^{p} \frac{a_{i^*}^2(x_k)}{a_0(x_k)} \left(1 + \frac{\|h(x_k)\|_2^2}{a_0(x_k)} \right) h_j(x_k) \nabla h_j(x_k). \end{aligned} \tag{34}$$

Taking limits of (34) and recalling (32) we can write

$$\sum_{i=1}^{m} v_i \nabla g_i(\hat{x}) + \sum_{j=1}^{p} u_j \nabla h_j(\hat{x}) = 0, \tag{35}$$

where, by (33)

$$v_i = \begin{cases} l_i^2 (g_i(\hat{x}) + \tilde{y}_i^2(\hat{x}; 0))^2, & \text{if } i \in J; \\ 0, & \text{otherwise,} \end{cases}$$

and

$$u_j = \begin{cases} l_0^2 \|h(\hat{x})\|_2^2 h_j(\hat{x}) & \text{if } 0 \in J \\ 0, & \text{otherwise.} \end{cases}$$

Since $i \in J$ and $i \geqq 1$ imply $i \in I_+(\hat{x})$, we can rewrite (35) into the following form:

$$\sum_{i \in I_+(\hat{x})} v_i \nabla g_i(\hat{x}) + \sum_{j=1}^{p} u_j \nabla h_j(\hat{x}) = 0.$$

This implies, by the EMFCQ, that $v_i = 0$ for $i \in I_+(\hat{x})$ and $u_j = 0$, for $j = 1, \cdots, p$. On the other hand, as $l_{i^*} = 1$, we have either $h(\hat{x}) = 0$ (if $i^* = 0$) or $g_{i^*}(\hat{x}) + \tilde{y}_{i^*}^2(\hat{x}; 0) = 0$ (if $i^* \in \{1, \cdots, m\}$). In both cases we get a contradiction to (32). Then we can conclude that $\hat{x} \in \mathring{\mathscr{D}}$. Therefore, from (31) and (34), taking the limit of $\varepsilon_k \nabla Z(x_k; \varepsilon_k)$ over the subsequence converging to $\hat{x}$, we have

$$\begin{aligned} &\sum_{i=1}^{m} \left[2 \frac{g_i(\hat{x}) + \tilde{y}_i^2(\hat{x}; 0)}{a_i(\hat{x})} + \frac{(g_i(\hat{x}) + \tilde{y}_i^2(\hat{x}; 0))^2}{a_i^2(\hat{x})} \right] \nabla g_i(\hat{x}) \\ &\quad + \sum_{j=1}^{p} \left[2 \frac{h_j(\hat{x})}{a_0(\hat{x})} + \frac{\|h(\hat{x})\|_2^2}{a_0^2(\hat{x})} h_j(\hat{x}) \right] \nabla h_j(\hat{x}) = 0. \end{aligned}$$

Noting that, by definition of $\tilde{y}_i(x_k; \varepsilon_k)$, the inequality $g_i(\hat{x}) < 0$ implies $g_i(\hat{x}) + \tilde{y}_i^2(\hat{x}; 0) = 0$, we can write

$$\sum_{i \in I_+(\hat{x})} v_i \nabla g_i(\hat{x}) + \sum_{j=1}^{p} u_j \nabla h_j(\hat{x}) = 0,$$

where now

$$v_i := 2 \frac{g_i(\hat{x}) + \tilde{y}_i^2(\hat{x}; 0)}{a_i(\hat{x})} + \frac{(g_i(\hat{x}) + \tilde{y}_i^2(\hat{x}; 0))^2}{a_i^2(\hat{x})} \geqq 0$$

and

$$u_j := 2\left[1 + \frac{\|h(\hat{x})\|_2^2}{a_0(\hat{x})}\right] \frac{h_j(\hat{x})}{a_0(\hat{x})}.$$

Therefore, again by the EMFCQ, we have $v_i = 0, i \in I_+(\hat{x})$, and $\mu_j = 0, j = 1, \cdots, p$ which imply

$$g_i(\hat{x}) + \tilde{y}_i^2(\hat{x}; 0) = 0, \qquad i = 1, \cdots, m$$

$$h_j(\hat{x}) = 0, \qquad j = 1, \cdots, p,$$

so that $\hat{x} \in \mathscr{F}$. As $\varepsilon_k \to 0$, Proposition 17 implies that for sufficiently large values of k, the triple $(x_k, \lambda(x_k), \mu(x_k))$ is a K-T triple for problem (P) and this yields a contradiction. □

We can now summarize the properties of exactness of $Z(x; \varepsilon)$ in the following theorem.

THEOREM 7. (a) *The function $Z(x; \varepsilon)$ is a globally weakly exact penalty function for problem* (P) *with respect to the set $\mathscr{D}$.*

(b) *Assume that the* EMFCQ *is satisfied on $\mathscr{D}$. Then, the function $Z(x; \varepsilon)$ is a globally exact penalty function for problem* (P) *with respect to the set $\mathscr{D}$; moreover, if Assumption* (A2) *holds, the function $Z(x; \varepsilon)$ is a globally strongly exact penalty function for problem* (P) *with respect to the set $\mathscr{D}$.*

Proof. By construction, we have $\lim_{k \to \infty} Z(x_k; \varepsilon) = \infty$ for any sequence $\{x_k\} \subset \mathring{\mathscr{D}}$ such that $x_k \to y \in \partial \mathscr{D}$. Hence, by Definition 4 we have that $Z(x; \varepsilon)$ is globally (weakly, strongly) exact if it is (weakly, strongly) exact.

Letting $\mathscr{E} = \mathring{\mathscr{D}}$, assertion (a) can be proved along the same lines followed in the proof of Theorem 6, making use of Propositions 16 and 17 in place of Propositions 13 and 14.

With regard to (b), again letting $\mathscr{E} = \mathring{\mathscr{D}}$, we can proceed, as in the proof of Theorem 6, by employing Proposition 18 in place of Proposition 15 and making use of the inequality:

$$Z(x; \varepsilon) \leqq f(x) \quad \text{for all } x \in \mathscr{F},$$

which can be established in a way similar to that followed in the proof of Theorem 6 for the case of the function $W(x; \varepsilon)$. □

A GEOMETRIC ISOMORPHISM WITH APPLICATIONS TO CLOSED LOOP CONTROLS*

ROBERT B. GARDNER†, WILLIAM F. SHADWICK‡, AND GEORGE R. WILKENS§

Abstract. Feedback equivalence of n state, $n-1$ control systems satisfying certain regularity conditions divides such systems into two invariant classes. We show that class one corresponds, via a geometric isomorphism, to classical Lagrangian variational problems. We prove the existence of time critical closed loop controls for systems that satisfy the nondegeneracy condition that the analogue of the Hessian for the Lagrangian problem have full rank. We show that the vanishing of this Hessian characterizes the control linear systems in class one and identify the rank condition for local controllability for such systems as the nonvanishing of a differential invariant. The control linear systems in class two are also characterized by the vanishing of an invariant and the rank condition is identified.

Key words. feedback equivalence of control systems, classical Lagrangian variational problems, time critical closed loop controls

AMS(MOS) subject classifications. 49, 53

1. Introduction. In this paper we consider the problem of feedback equivalence of control systems, with n states and $n-1$ controls, as the equivalence problem for systems

$$\frac{dx}{dt} = F(x, u), \qquad x \in \mathbf{R}^n, \quad u \in \mathbf{R}^{n-1}, \tag{1.1}$$

under diffeomorphisms of the form

$$\Phi(t, x, u) = (t, \phi(x), \psi(x, u)). \tag{1.2}$$

By making use of Cartan's method of equivalence [3], [5], [6] we obtain an invariant splitting of regular systems into two classes. The first of these, on which we focus our attention, is identified, via a geometric isomorphism, with classical single integral variational problems. The existence of this isomorphism means that all of the rich geometry of classical Lagrangian mechanics is encoded in the control system (1.1) and may be applied to its study. The most basic elements of the Lagrangian problem are the notions of regularity and of the Euler-Lagrange equations for critical curves. We show that, as one would hope, these concepts translate into basic features of the control problem. The *vanishing* of the Hessian for the associated Lagrangian is necessary and sufficient for the control system to be equivalent to one in control-linear form

$$\frac{dx}{dt} = f(x) + \sum_{i=1}^{n-1} g_i(x) u^i. \tag{1.3}$$

At the other extreme, when the Hessian has full rank, we show that the Euler-Lagrange equations may be solved to provide closed loop controls. As the Lagrangian functional, applied to solution curves of (1.1), measures the *time* from initial to final endpoints,

§ Department of Mathematics, University of Hawaii at Manoa, Honolulu, Hawaii 96822.

these controls are time critical. Moreover, for a certain subclass of control systems, they are the geodesics of a pseudo-Riemannian metric intrinsic to the system as Wilkens found in the case $n=3$ [13].

The second class of systems corresponds to a nonclassical variational problem of the sort studied by Griffiths [8] and Bryant [2]. We will pursue the study of this aspect of the problem elsewhere. We show that every system in this class can be put in the form

$$\frac{dx^i}{dt}=u^i, \quad 1\leqq i\leqq n-1, \qquad \frac{dx^n}{dt}=g(x,u)$$

where g is homogeneous of degree one in the controls. We give necessary and sufficient conditions for the system to be control linear, in which case $g(x,u)=\sum g_i(x)u^i$. For such systems the controllability condition [1], [11] is that an invariant should not vanish. As there is no drift term, the condition will fail for any *linearizable* system in this class, however, there is an invariant skew symmetric matrix j that determines at least rank j equivalence classes of controllable control linear systems.[1]

The regularity mentioned after (1.2) is a set of conditions that is developed during the analysis of the problem. In particular, we will require that the rank of the $n\times(n-1)$ matrix $\partial F/\partial u$ be $n-1$ and that certain functions either vanish on an open set or never vanish on an open set. Finally we note that, while the restriction to consideration of systems with n states and $n-1$ controls is essential to the identification of a *classical first order* variational problem, the same techniques apply to the case of n states and p controls. This case requires the analysis of more general variational problems and is currently being studied.

2. The equivalence problem. Given the system (1.1) on $U_0\subset\mathbf{R}^{2n}$ with coordinates $t, x^1,\cdots,x^n, u^1,\cdots,u^{n-1}$ and a second system

$$\frac{d\bar{x}}{d\bar{t}}=\bar{F}(\bar{x},\bar{u})$$

on $\bar{U}_0\subset\mathbf{R}^{2n}$, the problem of local equivalence under feedback is the equivalence problem for maps

$$\Phi: U_0\to\bar{U}_0$$

of the form

$$\bar{t}\circ\Phi=t, \quad \bar{x}\circ\Phi=\phi(x), \quad \bar{u}\circ\Phi=\psi(x,u) \tag{2.1}$$

that satisfy

$$\Phi^*(d\bar{x}-\bar{F}\,d\bar{t})=T(dx-F\,dt) \tag{2.2}$$

for some $T: U_0\to \mathrm{GL}(n,\mathbf{R})$. This is an overdetermined equivalence problem and leads, as discussed in [7], to the following problem in standard form.

Let U and $\bar{U}$ be open sets on which F and $\bar{F}$ are nonzero and let A_0 and $\bar{A}_0$ be maps from U and $\bar{U}$ to $\mathrm{GL}(n,\mathbf{R})$ such that

$$A_0F=\bar{A}_0\bar{F}={}^t(1,0,\cdots,0).$$

A diffeomorphism Φ from U to $\bar{U}$ satisfies (2.1) and (2.2) if and only if

$$\bar{t}\circ\Phi=t$$

and

$$\Phi^*\left(\frac{\bar{A}_0\,d\bar{x}}{d\bar{u}}\right)=\left(\begin{array}{cc|c} 1 & A & 0\\ 0 & B & 0\\ \hline C & D & E\end{array}\right)\left(\frac{A_0\,dx}{du}\right) \tag{2.3}$$

[1] There is a normal form for the case where j has full rank; see *Feedback Equivalence for General Control Systems*, by Gardner and Shadwick (to appear).

with $B, E \in \mathrm{GL}(n-1, \mathbf{R})$. This now has the form considered in [5] and [6] where G is the subgroup of $\mathrm{GL}(2n-1, \mathbf{R})$ of matrices of the form

$$\begin{pmatrix} 1 & A & 0 \\ 0 & B & 0 \\ C & D & E \end{pmatrix} \tag{2.3'}$$

with B and E in $\mathrm{GL}(n-1, \mathbf{R})$. Thus we construct the vector of one-forms ${}^t(\eta^1, \cdots, \eta^n, \mu^1, \cdots, \mu^{n-1})$ on $U \times G$ given by

$$\begin{pmatrix} \eta \\ \hline \mu \end{pmatrix} = \left(\begin{array}{ccc|c} 1 & A & & 0 \\ 0 & B & & 0 \\ \hline C & D & & E \end{array}\right) \begin{pmatrix} \eta_U \\ \hline \mu_U \end{pmatrix} \tag{2.4}$$

where

$$\begin{pmatrix} \eta_U \\ \mu_U \end{pmatrix} = \begin{pmatrix} A_0\, dx \\ du \end{pmatrix}.$$

We now turn to the equivalence of classical first-order Lagrangian problems and show that it leads to the same structure. Here we consider functionals

$$\mathscr{L}(c) = \int_c L(\tau, q, \dot{q})\, d\tau$$

over curves c in $\mathbf{R}^{2p+1}$ that satisfy

$$\dot{q}^i \circ c = \frac{d}{d\tau}(q^i \circ c), \qquad 1 \leqq i \leqq p.$$

These curves are integrals of the contact system

$$\theta^i := dq^i - \dot{q}^i\, d\tau, \qquad 1 \leqq i \leqq p$$

with independence condition $d\tau \neq 0$. Given a second functional $\bar{\mathscr{L}}$, we will say that $\mathscr{L}$ and $\bar{\mathscr{L}}$ are simply equivalent [2] if there is a contact transformation Φ such that

$$\Phi^* \bar{L}\, d\bar{\tau} \equiv L\, d\tau \pmod{\theta^i}. \tag{2.5}$$

This is clearly an equivalence relation and preserves the value of the functionals on integrals of the contact system.

If we complete $\{L\, d\tau, \theta\}$ and $\{\bar{L}\, d\bar{\tau}, \bar{\theta}\}$ to coframes by adding one-forms ζ and $\bar{\zeta}$ and use the fact that Φ must preserve the contact system $\{\theta^i\}$, we may summarize the conditions on the Jacobian of an equivalence Φ by

$$\Phi^* \begin{pmatrix} \bar{L}\, d\bar{\tau} \\ \bar{\theta} \\ \bar{\zeta} \end{pmatrix} = \begin{pmatrix} 1 & A & 0 \\ 0 & B & 0 \\ C & D & E \end{pmatrix} \begin{pmatrix} L\, d\tau \\ \theta \\ \zeta \end{pmatrix}. \tag{2.6}$$

Thus, if $p = n-1$, (2.6) and (2.4) suggest the identification on η^1_U with $L\, d\tau$ and $\{\eta^2_U, \cdots, \eta^n_U\}$ with the contact system. It is easy to verify that if c is a solution of (1.1) we have

$$c^* A_0\, dx = {}^t(dt, 0, \cdots, 0)$$

so $c^* \eta^1 = dt$, $c^* \eta^i = 0$, $2 \leqq i \leqq n$, and

$$\int_c \eta^1 = \int_{t_0}^{t_1} dt.$$

Thus the variational problem we have identified is the *time optimization problem* for solutions of (1.1).

There is an integrability condition that obstructs the identification of $\{\eta^2, \cdots, \eta^n\}$ with a contact system: the derived structure of $\eta^2, \cdots, \eta^n$ must coincide with that of $\theta^1, \cdots, \theta^{n-1}$. We now show how this invariant arises by pursuing the equivalence problem calculation.

For the system (2.4) with $\bar{\eta} = {}^t(\eta^2, \cdots, \eta^n)$, the structure equations take the form

$$\begin{aligned} d\eta^1 &= {}^t\alpha \wedge \bar{\eta} + \eta^1\, {}^t m \wedge \mu, \\ d\bar{\eta} &= \beta \wedge \bar{\eta} + \eta^1 M \wedge \mu, \\ d\mu &= \gamma \wedge \eta^1 + \delta \wedge \bar{\eta} + \varepsilon \wedge \mu, \end{aligned} \tag{2.7}$$

after all torsion has been absorbed.

The matrix $\mathcal{M} := \binom{{}^t m}{M}$ is, up to left and right multiplication, just

$$A_0\left(\frac{\partial F}{\partial u}\right)$$

and hence the full rank case is the only one in which all $n-1$ controls are actually present. From the infinitesimal action on ${}^t m$ and M,

$$\begin{aligned} &d\,{}^t m - {}^t\alpha M + {}^t m\varepsilon \equiv 0 \\ &dM - \beta M + M\varepsilon \equiv 0 \end{aligned} \qquad (\mathrm{mod}\ \eta^1, \bar{\eta}, \mu), \tag{2.8}$$

we see that the rank of M is also an invariant and thus there are two cases to consider: rank $M = n-2$, and rank $M = n-1$. In either case, as we may assume that rank $\mathcal{M} = n-1$, we may put the original control system in a form similar to those observed by Hermann [9]

$$\frac{dx^i}{dt} = u^i, \quad 1 \leqq i \leqq n-1, \qquad \frac{dx^n}{dt} = g(x, u), \tag{2.9}$$

and we may choose A_0 to be given by

$$A_0 = \begin{pmatrix} 1/u^1 & 0 & 0 & \cdots & 0 \\ -u^2 & u^1 & 0 & \cdots & 0 \\ \vdots & & \ddots & & \vdots \\ -u^{n-1} & 0 & \cdots & u^1 & 0 \\ -g & 0 & \cdots & 0 & u^1 \end{pmatrix}. \tag{2.10}$$

A short calculation now shows that rank $M = n-2$ if and only if $\hat{g} := g - \sum u^i\, \partial g/\partial u^i = 0$, i.e., if and only if g is homogeneous of degree one, clearly a nongeneric condition.

Case 1. Rank $M = n-1$. We have $\hat{g} := g - \sum u^i\, \partial g/\partial u^i \neq 0$ and from (2.8) we may normalize M to the identity and ${}^t m$ to zero to obtain new congruences

$$\begin{aligned} &{}^t\alpha \equiv 0 \\ &\beta \equiv \varepsilon \end{aligned} \qquad (\mathrm{mod}\ \eta^1, \bar{\eta}, \mu). \tag{2.8'}$$

In this case, the identification suggested above is actually an isomorphism, as the structure equations are now identical with those of the classical Lagrangian problem [6], and we have the following theorem.

THEOREM 2.1. *If* rank $M = n-1$ *the system is isomorphic to the classical first-order Lagrangian system in* $n-1$ *dependent variables.*

The remainder of the equivalence problem is now precisely the calculations for the Lagrangian case carried out by Bryant and Gardner [6] and the parametric form of the invariants has recently been investigated by Sutton [12]. For our purposes, it suffices to consider the invariants introduced by the congruences (2.8′).

After absorption of torsion terms the structure equations become

$$\begin{aligned} d\eta^1 &= {}^t\mu H \wedge \bar{\eta} + {}^t\bar{\eta} j \wedge \bar{\eta} + \eta^1 {}^t k \wedge \bar{\eta}, \\ d\bar{\eta} &= \beta \wedge \bar{\eta} + \eta^1 \wedge \mu, \\ d\mu &= \gamma \wedge \eta^1 + \delta \wedge \bar{\eta} + \beta \wedge \mu. \end{aligned} \tag{2.11}$$

The integrability condition $d^2 = 0$ shows that H is a symmetric matrix, and in the Lagrangian variables, H is, up to conjugation, just the Hessian matrix $(\partial^2 L/\partial \dot{q}^i\, \partial \dot{q}^j)$.

THEOREM 2.2. *If $\hat{g} \neq 0$, H vanishes if and only if the system* (1.1) *is equivalent to*

$$\begin{aligned} \frac{dx^i}{dt} &= u^i, \qquad 1 \leqq i \leqq n-1, \\ \frac{dx^n}{dt} &= f(x) + \sum g_i(x) u^i. \end{aligned} \tag{2.12}$$

If $H = 0$ the rank condition for local controllability is satisfied if and only if $d\eta^1 \neq 0$. The condition $d\eta^1 = 0$ gives a conservation law generalizing Hermes [10].

Proof. To establish this result we look at the explicit parametric calculation for the normalization of ${}^t m$ to zero. If we adopt the parametrization given by (2.9) and (2.10), then

$$\begin{aligned} \eta^1 = \frac{dx^1}{u^1} &+ A_1(u^1\, dx^2 - u^2\, dx^1) + \cdots + A_{n-2}(u^1\, dx^{n-1} - u^{n-1}\, dx^1) \\ &+ A_{n-1}(u^1\, dx^n - g\, dx^1). \end{aligned}$$

It is easy to check that $d\eta^1 \equiv 0 \pmod{\bar{\eta}}$ requires

$$\begin{aligned} A_1 &= -A_{n-1} \frac{\partial g}{\partial u^2} \\ A_2 &= -A_{n-1} \frac{\partial g}{\partial u^3} \\ &\vdots \\ A_{n-2} &= -A_{n-1} \frac{\partial g}{\partial u^{n-1}} \end{aligned} \tag{2.13}$$

and $1/u^1 = A_{n-1}\hat{g}$. As $\hat{g} \neq 0$, we may solve for A_{n-1} to obtain

$$\eta^1 = \frac{1}{\hat{g}} \left(dx^n - \frac{\partial g}{\partial u^1}\, dx^1 - \frac{\partial g}{\partial u^2}\, dx^2 - \cdots - \frac{\partial g}{\partial u^{n-1}}\, dx^{n-1} \right). \tag{2.14}$$

Now $H = 0$ means

$$d\eta^1 \wedge \eta^1 = {}^t\bar{\eta} S \wedge \bar{\eta} \wedge \eta^1 \tag{2.15}$$

so the right-hand side has no component in μ and hence no component in du. But

$$\begin{aligned} d\eta^1 \wedge \eta^1 = -\frac{1}{\hat{g}^2} &\left\{ d\left(\frac{\partial g}{\partial u^1}\right) \wedge dx^1 + \cdots + d\left(\frac{\partial g}{\partial u^{n-1}}\right) \wedge dx^{n-1} \right\} \\ &\wedge \left\{ dx^n - \frac{\partial g}{\partial u^1}\, dx^1 - \frac{\partial g}{\partial u^2}\, dx^2 - \cdots - \frac{\partial g}{\partial u^{n-1}}\, dx^{n-1} \right\} \end{aligned}$$

and the vanishing of the terms in $du^i \wedge dx^n$ required by (2.15) forces $\partial^2 g/\partial u^i\, \partial u^j = 0$, $1 \leqq i, j \leqq n-1$, so $g = f(x) + \sum g_i(x) u^i$, where $f \neq 0$. It is clear that this condition is also

sufficient for $H=0$. When $H=0$ it follows from (2.14) that

$$\eta^1=\frac{1}{f(x)}\left(dx^n-g_1(x)\,dx^1-\cdots-g_{n-1}(x)\,dx^{n-1}\right). \tag{2.14'}$$

If we define $X_n:=f(x)\,\partial/\partial x^n$ and $X_i:=\partial/\partial x^i+g_i(x)\,\partial/\partial x^n$ the rank condition [1], [11] is satisfied unless $[X_n, X_i]=[X_i, X_j]=0$ for $1\leqq i, j\leqq n-1$ and it follows directly from (2.14') that this happens if and only if $d\eta^1=0$. □

Next we proceed to the case in which H has full rank. The infinitesimal action on H is given by $dH-{}^t\beta H-H\beta\equiv 0\ (\mathrm{mod}\ \eta^1, \bar{\eta}, \mu)$, showing that H is being conjugated. On an open set on which the rank and signature of H are constant, we may normalize H to a constant matrix Q with the same rank and signature. The remaining torsion terms j and k may both be normalized to zero, putting $d\eta^1$ in normal form:

$$d\eta^1={}^t\mu Q\wedge\bar{\eta}. \tag{2.16}$$

As described in [4] and more recently in [5], the *Euler-Lagrange equations* for the functional $\int\eta^1$ are the exterior equations

$$\mu=0,\qquad \bar{\eta}=0. \tag{2.17}$$

THEOREM 2.3. *If rank* $M=n-1$ *and rank* $H=n-1$ *the system* (2.17) *yields closed loop time critical controls for* (1.1).

Proof. The system $\{\eta^2,\cdots,\eta^n,\mu^1,\cdots,\mu^{n-1}\}$ is completely integrable and hence

$$\mu\equiv T\,dw\qquad(\mathrm{mod}\ \eta^2,\cdots,\eta^n)$$

for some nonsingular matrix T and vector function $w(x, u)$. Because

$$0\neq\mu^1\wedge\cdots\wedge\mu^{n-1}\wedge\eta^1\wedge\cdots\wedge\eta^n=\det T\det\frac{\partial w}{\partial u}\,du^1\wedge\cdots\wedge du^{n-1}\wedge\eta^1\wedge\cdots\wedge\eta^n$$

the system $w=z$, z constant, can be solved for $u^i(x)$, $1\leqq i\leqq n-1$. But, as we have already observed, the solutions of $dx/dt=F(x, u(x))$ solve $\bar{\eta}=0$ and, by construction, also satisfy $\mu=0$. Thus they are solutions of the Euler-Lagrange system (2.17) and as such are time critical. □

We also note that the same arguments given by Wilkens [13] show that there is a class of control systems for which the quadratic form $(\eta^1)^2+{}^t\bar{\eta}Q\bar{\eta}$ defines a pseudo-Riemannian metric on the state space and the solutions of (2.17) are geodesics of the metric.

Case 2. Rank $M=n-2$. We conclude by considering the second class of problems. After the reduction of $\mathcal{M}$ the only unabsorbable torsion is in $d\eta^n$ and

$$d\eta^n=\beta_n\wedge\eta^n+{}^t\bar{\mu}S\wedge\bar{\eta}+(\eta^1, {}^t\bar{\eta})T\wedge\begin{pmatrix}\eta^1\\ \bar{\eta}\end{pmatrix} \tag{2.18}$$

where ${}^tS=S$ and ${}^tT=-T$.

THEOREM 2.4. *If* $\hat{g}=0$ *then* $d\eta^n$ *can be put in the form* (2.18) *and* $S=0$ *if and only if the system is control linear. If* $S=0$ *the system satisfies the rank condition for local controllability if and only if* $T\neq 0$.

Proof. We can make the following choices for the one-forms η_U, μ_U:

$$\eta_U^1 = \frac{dx^1}{u^1}, \qquad \bar{\eta}_U^\alpha = dx^\alpha - u^\alpha \frac{dx^1}{u^1}, \quad 2 \leqq \alpha \leqq n-1,$$

$$\eta_U^n = dx^n - \sum \frac{\partial g}{\partial u^i}\, dx^i, \qquad \mu_U^1 = \frac{du^1}{u^1},$$

$$\bar{\mu}_U^\alpha = du^\alpha - u^\alpha \frac{du^1}{u^1}, \qquad 2 \leqq \alpha \leqq n-1,$$

and the reduction of $\mathcal{M}$ imposes the following relations on the group of matrices defined by (2.3′):

$$B = \begin{pmatrix} B_1 & B_2 \\ 0 & B_3 \end{pmatrix}, \qquad B_3 \in \mathbf{R},$$

$$E = \begin{pmatrix} 1 & A \\ 0 & B_1 \end{pmatrix}.$$

Since

$$\eta^n = B_3\left(dx^n - \sum \frac{\partial g}{\partial u^i}\, dx^i\right),$$

it is clear from (2.18) that $S = 0$ if and only if

$$\frac{\partial^2 g}{\partial u^\alpha\, \partial u^\beta} = 0, \qquad 2 \leqq \alpha, \quad \beta \leqq n-1.$$

This condition, together with the fact that

$$\sum_{i=1}^{n-1} u^i \frac{\partial g}{\partial u^i} = g,$$

implies that $S = 0$ if and only if

$$\frac{\partial^2 g}{\partial u^i\, \partial u^j} = 0, \qquad 1 \leqq i, \quad j \leqq n-1.$$

If $S = 0$ then

$$\eta^n = B_3(dx^n - g_1(x)\, dx^1 - \cdots - g_{n-1}(x)\, dx^{n-1})$$

and the condition $d\eta^n \equiv 0 \pmod{\eta^n}$ is precisely the condition that the vector fields $X_i := \partial/\partial x^i + g_i(x)\, \partial/\partial x^n$ all commute. □

PARAMETRIZED INTEGRATION OF MULTIFUNCTIONS WITH APPLICATIONS TO CONTROL AND OPTIMIZATION*

ZVI ARTSTEIN†

Abstract. Integration of a set-valued map depending on a parameter is examined. If a point in the range depends measurably on the parameter, then it is the integral of a selection that depends measurably on the parameter. This is proved in the paper and applied in two cases: a control setting, where a Filippov-type lemma for chattering systems is verified; and an optimization problem, where existence of unvarying solutions to asymptotic stochastic maximization is established.

Key words. set-valued maps, integration of multifunctions, selections, chattering controls, Filippov Lemma, optimization

AMS(MOS) subject classifications. 28B20, 93C15, 49A36

1. Introduction. Integration of set-valued functions is a powerful tool in many branches of applied mathematics, including control theory, optimization, statistics, and mathematical economics. Recent investigations in these applications have generated the need for what we term here parametrized integration, namely, the simultaneous integration of multifunctions that depend on a parameter. In this paper we verify a property of the parametrized integration, and present two applications of it.

The property we are interested in is an integral version of the implicit functions lemma used in control theory. It says, roughly, that a point in the range that depends measurably on the parameter can be realized as an integral that depends measurably on the parameter. We state the full result in the next section after recalling the basic definitions and setting the technical framework. The proof of the main result is given in § 5. It uses some known facts about multifunctions, that we recall in § 3, and some lemmas that are proved in § 4.

The two applications are given in §§ 6 and 7. The first application is in control theory; it is the analogue of the Filippov Lemma, here in the context of chattering equations. The second application deals with event depending cost in asymptotic stochastic optimization. We give enough details of these problems to make the arguments of the applications self-contained; however, for the complete background and motivation, the reader is sent elsewhere.

2. The main result. First we recall the notion of integrating set-valued functions, and set the framework in which the main result is stated.

Let S be a measure space, with β a probability measure on it. Let F be a mapping that assigns to each $s \in S$ a subset $F(s)$ of the Euclidean n-dimensional space. An integrable selection (with respect to β) of F is a function f that is β-integrable, and such that $f(s) \in F(s)$ for β-almost every s. The integral of F with respect to β is defined by

$$\int_S F(s)\beta(ds) = \left\{ \int_S f(s)\beta(ds) : f \text{ an integrable selection of } F \right\}. \tag{2.1}$$

This definition was introduced by Aumann [7]. See Castaing and Valadier [11], Hildenbrand [13], Klein and Thompson [14] and references therein for only part of the applicability of this concept.

* Received by the editors May 18, 1988; accepted for publication (in revised form) December 6, 1988.

Note that we use $\beta(ds)$ to denote integration with respect to the measure β and the variable s. This is convenient when more parameters are present in the formulas. If no confusion arises, we suppress the dependence on s or on β, and thus write $\int F\,d\beta$ or $\int F$ for the integral.

The framework we are interested in is such that the set-valued function depends on a parameter, say t, in a measure space T with a measure λ on it. Thus, for each $t \in T$ a set-valued map F_t and a probability measure β_t on S are given. For each t the integration of F_t with respect to β_t can be performed, resulting in

$$\Gamma(t) = \int_S F_t(s)\beta_t(ds), \tag{2.2}$$

which is a set in R^n, depending on the parameter t.

The problem we address is the following. Suppose γ is a selection of Γ, namely, $\gamma(t) \in \Gamma(t)$ for λ-almost every t. Then $\gamma(t)$ can be written as $\int f_t(s)\beta_t(ds)$, with $f_t(\cdot)$ a β_t-selection of $F_t(\cdot)$. Then can $f_t(s) = f(t, s)$ be chosen measurable in the two variables? Our answer is stated in the theorem below, after some notations are recalled and the underlying assumptions listed.

Notations. We switch at will between the notation $F_t(s)$ and $F(t, s)$. Multifunction = set-valued function. We write $|x|$ for the Euclidean norm of $x \in R^n$, and $\|K\| = \sup\{|x|: x \in K\}$ for $K \subset R^n$. General definitions for, and general properties of, set-valued functions are stated for a set-valued function G defined on a measure space U with a measure η on it.

The multifunction G is *measurable* if for every closed set C the set $\{u: G(u) \cap C \neq \emptyset\}$ is measurable. This is a standard definition, and it is equivalent to other common definitions in the case that G has closed values, a case that we adopt anyway. See Castaing and Valadier [11, Chap. III]. The set-valued map G is *η-integrably bounded* if there exists an η-integrable scalar function $b: U \to [0, \infty]$ such that $\|G(u)\| \leqq b(u)$ for all $u \in U$.

The space S, on which the probability measures β_t are defined, is assumed to be metric, separable, and complete. We consider the ensemble of probability measures on S as a metric space itself, with the metric being generated by the weak convergence of measures (see, e.g., Billingsley [9], or Hildenbrand [13, p. 48]). Thus, continuity or measurability properties of $t \to \beta_t$ are understood with respect to this metric structure.

The following conditions are assumed throughout.

Underlying Assumptions. (i) S is a complete separable metric space with its Borel structure.

(ii) T is a complete separable metric space, with its Borel structure, and λ is a σ-additive finite measure on T (in particular, λ is tight; see [9, p. 10]).

(iii) The mapping $t \to \beta_t$, which associates with each t a probability measure β_t on S, is measurable.

(iv) The values $F(t, s)$ are nonempty compact subsets of R^n.

(v) $F(\cdot, \cdot)$ is measurable on $T \times S$.

(vi) For each $t \in T$ the mapping $F_t(\cdot)$ is β_t-integrably bounded.

THEOREM. *Let $\gamma: T \to R^n$ be measurable and such that $\gamma(t) \in \Gamma(t)$ for λ-almost every t. Then there exists an $f(t, s)$, measurable on $T \times S$, such that for λ-almost every t, the inclusion $f(t, s) \in F(t, s)$ holds for β_t-almost every s, and $\int f(t, s)\beta_t(ds) = \gamma(t)$.*

3. Preliminary results. For the convenience of the reader here we collect some results about multifunctions and their integrals. We either provide references for a proof or hint how it goes.

Notation. When $x \in R^n$ and $K \subset R^n$ we write $\operatorname{dist}(x, K)$ for $\inf\{|x-y|: y \in K\}$. We denote by $p \cdot x$ the scalar product of p and x. We write $\sup p \cdot K$ for $\sup\{p \cdot x: x \in K\}$, and likewise $\inf p \cdot K = \inf\{p \cdot x: x \in K\}$; we may replace sup by max when the supremum is attained, e.g., when K is compact. The boundary of K in the direction p, namely $\{x \in K: p \cdot x = \sup p \cdot K\}$, is denoted K_p.

In what follows, U is a complete separable metric space with its Borel structure and η is a σ-additive finite measure on U. The multifunctions we treat have subsets of R^n as values.

PROPOSITION 3.1. *Let G be a measurable multifunction with closed nonempty values; then a measurable selection of G exists.*

Proof. See, e.g., Castaing and Valadier [11, p. 65], Hildenbrand [13, p. 54], or Rockafellar [15] for the proof.

PROPOSITION 3.2. *Let G be a measurable multifunction with compact nonempty values. Then $\|G(u)\|$ is measurable. If $h: U \to R^n$ is measurable, then $u \to \operatorname{dist}(h(u), G(u))$ is measurable, and there exists a selection g of G such that $\operatorname{dist}(h(u), G(u)) = |h(u) - g(u)|$.*

Proof. The measurability of $\|G(u)\|$ and $\operatorname{dist}(h(u), G(u))$ follows easily from the Castaing Representation Theorem (see Castaing and Valadier [11, Thm. III.7] or Rockafellar [15, Thm. 1B]). To prove the existence of $g(u)$, consider the multifunction H defined by $H(u) = G(u) \cap \{x: |x - h(u)| = \operatorname{dist}(h(u), G(u))\}$. It is measurable as the intersection of two measurable multifunctions (see Rockafellar [15, Thm. 1M]); any selection of H, existing by the previous result, is the desired g.

PROPOSITION 3.3. *Let G be an integrably bounded measurable multifunction with closed nonempty values. Then $\int G\, d\eta$ is nonempty and compact. If η is atomless then $\int G\, d\eta$ is a convex set.*

Proof. See Aumann [7], or see Klein and Thompson [14, Chap. 18] for the proof.

PROPOSITION 3.4. *Let G_k be a decreasing sequence of multifunctions, namely, $G_k(u) \supset G_{k+1}(u)$ for η-almost every u. Suppose that all G_k are measurable and have closed nonempty values and that G_1 is integrably bounded. Let $G(u) = \bigcap_{k=1}^{\infty} G_k(u)$. Then $\int G\, d\eta = \bigcap_{i=1}^{\infty} \int G_k\, d\eta$.*

Proof. G is measurable, by Rockafellar [15, Thm. 1M], and $\int G$ is trivially included in the intersection of the integrals. To prove the converse let x be a point in the intersection, therefore $x = \int g_k$ with g_k a selection of G_k. By Proposition 3.2 there exist selections h_k of G such that $|g_k(u) - h_k(u)| = \operatorname{dist}(g_k(u), G(u))$. The pointwise limit of the latter is zero, and therefore the Lebesgue Dominated Convergence Theorem implies that $\int (g_k - h_k)$ converge to zero as $k \to \infty$. Namely, $y_k = \int h_k$ converge to x. Since $y_k \in \int G$ and $\int G$ is compact (by Proposition 3.3), it follows that $x \in \int G$.

The following implicit functions property is used several times in the sequel. The above definition of measurability of multifunctions applies also to multifunctions with values being subsets of an abstract metric space.

PROPOSITION 3.5. *Let V be a locally compact separable metric space, and let Q be a multifunction that assigns to each $u \in U$ a closed subset $Q(u)$ of V. Let $\alpha: V \to R^n$ be continuous. Let $G(u) = \{\alpha(v): v \in Q(u)\}$. Suppose Q is measurable and let g be a measurable selection of G. Then there exists a measurable selection q of Q such that $g(u) = \alpha(q(u))$.*

Proof. The result is established under much weaker conditions in Castaing and Valadier [11, Thm. III.38]. Here is a proof in our case. The continuity of α implies easily that the multifunction $H(x) = \{v \in V: \alpha(v) = x\}$ is measurable. Then it is easy to see, e.g., by the Castaing Representation Theorem, that the composition of H and g, namely $Q_1(u) = \{v: \alpha(v) = g(u)\}$, is also a measurable multifunction. Therefore the

intersection $Q(u) \cap Q_1(u)$ generates a measurable multifunction; any selection of it, existing by Proposition 3.1, is a candidate for the desired g. This completes the proof.

In parallel with the definition of the integral of a set-valued function, we write

$$\sum_{i=1}^{\infty} K_i = \left\{ \sum_{i=1}^{\infty} x_i : x_i \in K_i \text{ and the series is summable} \right\}.$$

Note that if K_i is not empty for all i, then $\sum_{i=1}^{\infty} K_i$ is a bounded nonempty set exactly when $\sum_{i=1}^{\infty} \|K_i\| < \infty$. The following corollary is used in the proof of the main result.

COROLLARY 3.6. *For each i let $K_i(u)$ be a measurable multifunction with nonempty compact values in R^n. Suppose that for each u the set*

$$\Gamma_A(u) = \sum_{i=1}^{\infty} K_i(u)$$

is nonempty and bounded. Then Γ_A is a measurable multifunction with compact values. Let $\gamma_A(\cdot)$ be a measurable selection of Γ_A. Then there exist measurable selections $x_i(u)$ of $K_i(u)$ such that $\gamma_A(u) = \sum_{i=1}^{\infty} x_i(u)$.

Proof. Compactness of $\Gamma_A(u)$ is a simple exercise (and a particular case of Proposition 3.3). The measurability of Γ_A follows, e.g., from the Castaing Representation Theorem (see [11, Thm. III.7] or [15, Thm. 1B]). To prove the existence of $x_i(u)$ consider $V = R^n \times R^n$ and define $Q(u) = K_1(u) \times \sum_{i=2}^{\infty} K_i(u)$ and $\alpha(x, y) = x + y$. By Proposition 3.5 there are measurable selections $x_1(u)$ of $K_1(u)$ and $y_2(u)$ of $\sum_{i=2}^{\infty} K_i(u)$ such that $x_1(u) + y_2(u) = \gamma_A(u)$. Inductively, $x_1(u), \cdots, x_{j-1}(u)$ and $y_j(u)$ are defined, and y_j is a measurable selection of $\sum_{i=j}^{\infty} K_j$. Consider $Q(u) = K_j(u) \times \sum_{i=j+1}^{\infty} K_i(u)$. By Proposition 3.5 there are $x_j(u)$ and $y_{j+1}(u)$, selections of $K_j(u)$ and $\sum_{i=j+1}^{\infty} K_i(u)$ such that $x_j(u) + y_{j+1}(u) = y_j(u)$. In this way the sequence of measurable selections $x_1(u)$, $x_2(u) \cdots$ is defined. The boundedness of $K_1(u) + K_2(u) + \cdots$ implies the pointwise convergence of $y_j(u)$ to zero as $j \to \infty$, and hence $\gamma_A(u) = \sum x_i(u)$. This completes the proof.

The following two results are concerned with the boundary of the integral in the direction of a vector $p \in R^n$; see the definitions above.

PROPOSITION 3.7. *Let G be a measurable multifunction with closed values, and let $p \in R^n$. Then*

$$\int (G(u))_p \, d\eta = \left(\int G(u) \, d\eta \right)_p .$$

Furthermore, if g is a selection of G and $p \cdot g(u) < \sup p \cdot G(u)$ on a set of positive η-measure, then $\int g \, d\eta$ does not belong to $(\int G \, d\eta)_p$.

Proof. The proof follows, e.g., from Klein and Thompson [14, Prop. 18.1.8] or Hildenbrand [13, Prop. 6, p. 63].

Recall that the relative boundary of a convex set K is formed by first taking the linear hyperspace (flat) spanned by K, then the boundary of K in this hyperspace.

PROPOSITION 3.8. *Let K be a measurable multifunction with convex compact values. Let γ_N be a measurable selection of K such that $\gamma_N(u)$ is in the relative boundary of $K(u)$ for all u (in particular, $K(u)$ is never a singleton). Then a measurable $p(u) : U \to R^n$ exists such that $p(u) \cdot \gamma_N(u) = \max p(u) \cdot K(u) > \min p(u) \cdot K(u)$, for almost all u.*

Proof. We say that a vector p is parallel to the convex set C in R^n, if p is spanned by vectors of the form $x - y$ with x and y in C. With each convex compact set C and a vector y in the relative boundary of C we associate the set $P(C, y)$ of vectors p such that $|p| = 1$, p is parallel to C, and $p \cdot y = \max p \cdot C$ (namely, the vectors of norm 1, supporting C at y within the span of C). For $i = 1, \cdots, n$ let $\mathcal{C}_i$ be the collection of

compact convex sets of dimensionality i. On $\mathscr{C}_i$ the mapping $(C, y) \to P(C, y)$ has a closed graph, when the family of convex compact sets is endowed with the Hausdorff distance (for the latter see, e.g., [15]). Hence $P(C, y)$ is a measurable multifunction on $C \in \mathscr{C}_i$ and y in the relative boundary of C. But $\mathscr{C}_0, \mathscr{C}_1, \cdots, \mathscr{C}_n$ forms a measurable partition of the space of compact convex sets, e.g., since the dimension of C is a lower semicontinuous function. Hence $P(C, y)$ is a measurable multifunction on its domain. The mapping $u \to K(u)$ was assumed measurable as a set-valued mapping, but this is equivalent to its measurability as a point-valued mapping into the space of compact sets with the Hausdorff distance (see Rockafellar [15, Prop. 1G]). Therefore, the composition $u \to P(K(u), \gamma_N(u))$ is a measurable multifunction. The selection of it guaranteed by Proposition 3.1 is the desired function $p(u)$.

4. Lemmas. Some of the steps toward proving the theorem are collected in this section; some are of interest for their own sake.

LEMMA 4.1. *Let U be a measure space, and let η be a σ-additive measure on it. Let Θ be an ordered set, not necessarily countable. Let G_θ, $\theta \in \Theta$ be a decreasing family of multifunctions, namely, $\theta < \tau$ in Θ implies $G_\theta(u) \subset G_\tau(u)$ for η-almost every u. Suppose that each G_θ is measurable and takes compact subsets of R^n as values. Then there exists a denumerable cofinal sequence G_{θ_i}, namely, for each θ there is an element θ_i in the sequence such that $G_\theta(u) \supset G_{\theta_i}(u)$ for η-almost every u.*

Proof. We can assume that $\|G_\theta\|$ are bounded, say by 1; indeed, it suffices to prove the result for the multifunctions $d(u)G_\theta(u)$ where $d(u) = \min(1, \|G_{\theta_1}(u)\|^{-1})$, with θ_1 fixed. By Proposition 3.2, the function $d(u)$ is measurable.

Let $\{x_i\}$ be a dense sequence in the unit ball of R^n. With each θ in Θ we associate a real number $R(\theta)$ as follows. First, define

$$r_i(\theta, u) = \operatorname{dist}(x_i, G_\theta(u))$$

for $i = 1, 2, \cdots$. These functions are measurable in u (Proposition 3.2), and bounded by 2. Second, define

$$L(\theta, u) = \sum_{i=1}^{\infty} 2^{-i} r_i(\theta, u).$$

Then $L(\theta, u)$ is measurable and bounded by 2. Finally, let

$$R(\theta) = \int_U L(\theta, u)\eta(du).$$

We claim that $R(\theta) > R(\tau)$ implies that $\theta < \tau$ in Θ, and in particular $G_\theta(u) \subset G_\tau(u)$ for η-almost every u. Indeed, the inclusion property implies that the functions $r_i(\theta, u)$ are η-almost everywhere nondecreasing in θ, and hence so are $L(\theta, u)$ and $R(\theta)$. Once the claim is verified, it is clear that the desired cofinal sequence can be determined by a sequence $R(\theta_i)$, which is cofinal with respect to the usual order among the numbers $R(\theta)$, $\theta \in \Theta$; existence of such a sequence is trivial.

We now return to the framework of the main result and the underlying assumptions.

A convenient tool in our derivations is to consider the measure

$$\mu = \int_T \beta_t \, d\lambda, \tag{4.1}$$

which is a measure on $T \times S$ obtained by integrating the probability measures β_t with respect to λ. Namely, if $D \subset T \times S$ is measurable and $D_t = \{s: (t, s) \in D\}$, then

$$\mu(D) = \int_T \beta_t(D_t) \, d\lambda. \tag{4.2}$$

See, e.g., Bourbaki [10], where the integration is developed for locally compact based measures. It is justified in our case since, given $\varepsilon > 0$, by Lusin's Theorem there is a compact $T_\varepsilon \subset T$ with $\lambda(T \setminus T_\varepsilon) < \varepsilon$ and such that $t \to \beta_t$ is continuous on T_ε. By tightness then (see Billingsley [9]) there is a compact $S_\varepsilon \subset S$ such that $\beta_t(S \setminus S_\varepsilon) < \varepsilon$ for all $t \in T_\varepsilon$. Thus on $T_\varepsilon \times S_\varepsilon$ the integration is justified, and as $\varepsilon \to 0$ we get the integration over all T. This reliance on tightness with reference to Bourbaki [10] should be repeated in some of the lemmas below; we leave out the details. (A different approach used to obtain (4.2), as noted by a referee, is to define μ first for simple functions, and rectangulars, and then employ standard completion arguments in measure theory.)

LEMMA 4.2. *A measurable $f: T \times S \to R^n$ satisfies $f(t, s) \in F(t, s)$ for μ-almost every (t, s) if and only if for λ-almost every t, the inclusion $f(t, s) \in F(t, s)$ holds for β_t-almost every s.*

Proof. Applying Bourbaki [10, p. 11] to the function $\rho(t, s) = \text{dist}\,(f(t, s), F(t, s))$, which is measurable by Proposition 3.2, we obtain

$$\int_{T \times S} \rho(t, s)\, d\mu = \int_T d\lambda \int_S \rho(t, s) \beta_t(ds),$$

an equality that is equivalent to the desired conclusion.

Notation. We denote by $\mathcal{B}(S)$ the Borel σ-field on S, and by $\mathcal{B}_\lambda(T)$ the completion of the Borel σ-field on T with respect to the measure λ.

LEMMA 4.3. *For a measurable $E \subset S$ the function $t \to \beta_t(E)$ is $\mathcal{B}_\lambda(T)$-measurable.*

Proof. The indicator function 1_E is measurable; thus $\beta_t(E) = \int_S 1_E \beta_t(ds)$ is $\mathcal{B}_\lambda(T)$ measurable according to Bourbaki [10, p. 11].

LEMMA 4.4. *Define $w: T \times S \to [0, 1]$ by $w(t, s) = \beta_t\{s\}$, namely, assign to an atom s of β_t its weight, and assign the value zero otherwise. Then w is $\mathcal{B}_\lambda(T) \times \mathcal{B}(S)$ measurable. In particular, the set*

$$A = \{(t, s): \text{the point } s \text{ is an atom of } \beta_t\} \tag{4.3}$$

is $\mathcal{B}_\lambda(T) \times \mathcal{B}(S)$ measurable.

Proof. For each i let $\sigma_i = (E_{i,1}, E_{i,2}, \cdots)$ be a partition of S into measurable subsets, with the diameters of $E_{i,j}$ converging to zero as $i \to \infty$, and nested, namely, a set $E_{i,j}$ is included in one of the elements of σ_k if $k < i$. Define $w_i(t, s) = \beta_t(E_{i,j})$ if $(t, s) \in E_{i,j}$. Then the functions $w_i(\cdot, \cdot)$ are $\mathcal{B}_\lambda(T) \times \mathcal{B}(S)$ measurable by the preceding lemma. Since $w(t, s)$ is the pointwise limit of $w_i(t, s)$ as $i \to \infty$, the result is proved.

For each t the measure β_t has only a countable number of atoms. The following results show that these atoms, and the corresponding values of the multifunction F, can be enumerated in a measurable way.

LEMMA 4.5. *There exists a sequence of $\mathcal{B}_\lambda(T)$-measurable functions $q_i(t): T \to S$, each defined possibly on a subset of T, such that there is one-to-one correspondence between the atoms of β_t and the sequence $q_1(t), q_2(t), \cdots$, when defined.*

Proof. Consider the sets

$$A_j = \{(t, s): (j+1)^{-1} < w(t, s) \leqq j^{-1}\}$$

for $j = 0, 1, \cdots$, and where $w(t, s) = \beta_t\{s\}$ is the function introduced in the previous lemma. The sets A_j are $\mathcal{B}_\lambda(T) \times \mathcal{B}(S)$ measurable by Lemma 4.4. Each A_i is the graph of a multifunction, say $L_i(t)$, from T into subsets of S, with values consisting of a finite number of points (indeed, $L_i(t)$ cannot have more than $i+1$ elements). Therefore, each L_i is $\mathcal{B}_\lambda(T)$ measurable (see Castaing and Valadier[11, Thm. III.30]). Using the selection theorem, possibly $i+1$ times for L_i, it is easy to obtain $q_{i,1}(t), \cdots, q_{i,i+1}(t)$, functions of the type we want, that exhaust the elements in $L_i(t)$. The ensemble of all these $q_{i,j}$ forms the desired sequence.

COROLLARY 4.6. *There exists a sequence $K_i(t)$ of $\mathcal{B}_\lambda(T)$-measurable multifunctions on T, with values being compact, possibly empty, subsets of R^n, such that for a given t there is a one-to-one correspondence between the nonempty elements $K_1(t)$, $K_2(t), \cdots$, and the values $\beta_t(\{s_i\})F(t, s_i)$ when s_i go over all atoms of β_t. In particular, if we replace the empty values $K_i(t)$ by $\{0\}$ we get*

$$\sum_{i=1}^{\infty} K_i(t) = \int_{A_t} F(t, s)\beta_t(ds) \tag{4.4}$$

with $A_t = \{s$: the point s is an atom of $\beta_t\}$.

Proof. Define $K_i(t) = \beta_t(\{q_i(t)\})F(t, q_i(t))$, with $q_1(t)$, $q_2(t), \cdots$ given in the preceding lemma.

COROLLARY 4.7. *Let $G(t, s)$ be a measurable multifunction on $T \times S$, with compact values in R^n and suppose $G_t(\cdot)$ is β_t-integrably bounded. Then $t \to \int G(t, s)\beta_t(ds)$ is a $\mathcal{B}_\lambda(T)$-measurable multifunction.*

Proof. The integration is the sum $\Gamma_A(t) + \Gamma_N(t)$, with $\Gamma_A(t)$ the result of the integration on the atomic part of β_t, and $\Gamma_N(t)$ the result of the integration on the atomless part of β_t, both justified by Lemma 4.4. The sum would be measurable if each of the components is measurable (see, e.g., Rockafellar [15, Prop. 1J]). The same result, together with Corollary 4.6, imply that $\Gamma_A(t)$ is $\mathcal{B}_\lambda(T)$-measurable. The measurability of $\Gamma_N(t)$ is implied by Bourbaki [10, p. 11], once we recall that $\Gamma_N(t)$ is also the integral of the convex hull of $G(t, s)$, and integration of multifunctions with compact convex values coincides with the Bochner integration into a Banach space (see Klein and Thompson [14, p. 190]).

5. Proof of the theorem. Let $\mu = \int \beta_t \, d\lambda$ be the measure on $T \times S$ as defined in (4.1) and (4.2). Let $\mathcal{F}$ be a family of multifunctions defined on $T \times S$ with the following properties.

(a) Each $G \in \mathcal{F}$ is measurable, with compact values.

(b) $G(t, s) \subset F(t, s)$ for μ-almost every (t, s).

(c) $\int_S G(t, s)\beta_t(ds)$ contains $\gamma(t)$ for λ-almost every t.

The family $\mathcal{F}$ is not empty since $F \in \mathcal{F}$. On $\mathcal{F}$ consider the partial order of inclusion μ-almost everywhere.

CLAIM 1. *There exists a minimal element in $\mathcal{F}$, namely, a $G_0 \in \mathcal{F}$ such that if G_1 is in $\mathcal{F}$ and $G_1(t, s) \subset G_0(t, s)$ for μ-almost every (t, s), then the equality $G_1(t, s) = G_0(t, s)$ holds μ-almost everywhere.*

To verify the claim we use Zorn's Lemma. Let G_θ, $\theta \in \Theta$ be a decreasing family, not necessarily countable, of multifunctions in $\mathcal{F}$. By Lemma 4.1 there exists a denumerable cofinal subsequence G_{θ_i}. Define G by

$$G(t, s) = \bigcap_{i=1}^{\infty} G_{\theta_i}(t, s).$$

By Proposition 3.4, property (c) holds for G; it is clear that properties (a) and (b) hold as well, and thus G is a lower bound for G_θ, $\theta \in \Theta$. By Zorn's Lemma there exists a minimal element. This completes the proof of the claim.

Recall that A (of (4.3)) is the set of atoms of all β_t. Let N be the complement of A in $T \times S$. Both A and N are $\mathcal{B}_\lambda(T) \times \mathcal{B}(S)$ measurable by Lemma 4.4.

CLAIM 2. *Let G_0 be a minimal element in $\mathcal{F}$. For μ-almost every (t, s) in N the value $G_0(t, s)$ contains exactly one point, say, $G_0(t, s) = \{g_0(t, s)\}$.*

To prove the claim define

$$\Gamma_A(t) = \int_{A_t} G_0(t, s)\beta_t(ds), \qquad \Gamma_N(t) = \int_{N_t} G_0(t, s)\beta_t(ds) \tag{5.1}$$

and $\Gamma_A(t)=\{0\}$ or $\Gamma_N(t)=\{0\}$ in case the displayed formula is empty (and where A_t and N_t denote the t-sections of A and N). Both integrals are well defined by Lemma 4.4, and both multifunctions are $\mathcal{B}_\lambda(T)$-measurable by Corollary 4.7. Since $G_0 \in \mathcal{F}$ it follows that $\gamma(t) \in \Gamma_A(t)+\Gamma_N(t)$. By Corollary 3.6, for $i=1, 2$, there are selections $\gamma_A(t)$ of $\Gamma_A(t)$ and $\gamma_N(t)$ of $\Gamma_N(t)$ such that

$$\gamma_A(t)+\gamma_N(t)=\gamma(t). \tag{5.2}$$

By Proposition 3.3 the values $\Gamma_N(t)$ are compact and convex. We now examine two cases.

The first case is that for t in a subset, say T_1, of positive measure, the value $\Gamma_N(t)$ is not a singleton, and $\gamma_N(t)$ is in the relative interior of $\Gamma_N(t)$. Suppose, without loss of generality, that the Euclidean distance between $\gamma_N(t)$ and the relative boundary of $\Gamma_N(t)$ is at least $\varepsilon>0$ for $t \in T_1$ (if there is no lower bound for this distance we can consider a subset of T_1 on which there is a lower bound). Let $M \subset (T_1 \times S) \cap N$ be a measurable set with the property that for $(t, s) \in M$ the value $G_0(t, s)$ is not a singleton, and

$$\int_{M_t} \|G_0(t, s)\| \beta_t(ds) < \varepsilon. \tag{5.3}$$

Such a set exists by the β_t-integrability of $\|G_0(t, s)\|$. Define $H(t, s)=G_0(t, s)$ for $(t, s) \notin M$, and $H(t, s)=\{g(t, s)\}$ otherwise, when g is a selection of G_0. Then, in view of (5.3) and the location of $\gamma_N(t)$ in $\Gamma_N(t)$, the integral of H over N_t contains $\gamma_N(t)$, and hence $H \in \mathcal{F}$. But H is strictly smaller than G_0 in the inclusion μ-almost everywhere, a contradiction to the minimality of G_0.

The second case is that for t in a subset of positive measure, say T_2, the value $\Gamma_N(t)$ is not a singleton, and $\gamma_N(t)$ is in the relative boundary of $\Gamma_N(t)$. Let $p(t)$ be given by Proposition 3.8 with $K=\Gamma_N$. For $t \in T_2$ let us define $H(t, s)=G_0(t, s)_{p(t)}$, namely the boundary of $G_0(t, s)$ in the direction $p(t)$, and define $H(t, s)=G_0(t, s)$ if $t \notin t_2$. Then, by Proposition 3.7 we have that $\gamma_N(t)$ belongs to the integral of $H(t, s)$ over N_t with respect to β_t; therefore $H \in \mathcal{F}$. But the integral of G_0 contains more than that of H; hence H is strictly smaller than G_0 on the order of $\mathcal{F}$, which is a contradiction to the minimality of G_0.

Once the two cases are excluded, we conclude that $\Gamma_N(t)$ is a singleton for all t; hence the second claim is verified.

We now proceed with the definition of the desired $f(t, s)$. We define

$$f(t, s)=g_0(t, s) \quad \text{if } (t, s) \in N \tag{5.4}$$

where g_0 is given by Claim 2. We use Lemma 4.5 to determine a sequence $q_1(t)$, $q_2(t), \cdots$ that exhausts the atoms of β_t, and use Corollary 3.6 to determine $x_i(t)$, selections of the values $K_i(t)=\beta_t(q_i(t))G_0(t, q_i(t))$ such that $\Sigma x_i(t)=\gamma_A(t)$, and define

$$f(t, q_i(t))=x_i(t), \qquad i=1, 2, \cdots. \tag{5.5}$$

This defines $f(t, s)$ on $T \times S$ in a measurable way with respect to $\mathcal{B}_\lambda(T) \times \mathcal{B}(S)$. A change of μ-measure zero would make it Borel measurable, and a selection of F, according to Lemma 4.2. The desired equality, namely,

$$\int_S f(t, s)\beta_t(ds)=\gamma(t),$$

follows from (5.4) and (5.5), taking (5.2) into account. This completes the proof.

6. An application in control.

Background. Consider the control system

$$\dot{x} = f(x, t) + g(u, t), \qquad u \in U(t) \tag{6.1}$$

defined on $[t_0, t_1]$. The admissible controls are measurable functions $u(t): [t_0, t_1] \to R^m$ satisfying $u(t) \in U(t)$, the latter being a prescribed multifunction. A reduction can be performed as follows. Consider the system

$$\dot{x} = f(x, t) + v, \qquad v \in V(t) \tag{6.2}$$

where $V(t)$ encompasses the actual effect of the control on the dynamics, namely,

$$V(t) = \{g(u, t): u \in U(t)\}.$$

It is clear that an admissible control of (6.1) generates an admissible control of (6.2), namely, $v(t) = g(u(t), t)$, which yields the same trajectory. The question is whether or not the reduction (6.2) is actually equivalent to (6.1) in the sense that all admissible controls $v(t): [t_0, t_1] \to V(t)$, are generated by measurable functions $u(t): [t_0, t_1] \to U(t)$. The answer is positive, under mild conditions, and this equivalence was observed by Filippov and was the basis for introducing the differential inclusions $\dot{x} \in F(x, t)$ as a convenient model of control systems. See Filippov [12] and Berkovitz [8] for more on the Filippov Lemma and its applications in control theory. The implicit functions property that we quoted in Proposition 3.5 can be used in proving such an equivalence.

A similar equivalence question arises in [3] and [4] in a more complicated situation as follows.

The application. Let S be a separable complete metric space. For each $t \in [t_0, t_1]$ let β_t be a probability measure on S. Let $g(u, t, s): R^m \times [t_0, t_1] \times S \to R^n$ be given. The control system takes the form

$$\dot{x} = f(x, t) + \int_S g(u, t, s)\beta_t(ds), \qquad u \in U(t, s). \tag{6.3}$$

The admissible controls are measurable functions $u(t, s): [t_0, t_1] \times S \to R^m$ satisfying the constraints $u(t, s) \in U(t, s)$, the latter being a prescribed multifunction.

Such strange looking systems arise as variational limits of control systems with highly oscillatory control coefficients. The probability distribution β_t models the occurrence, in the limit, of instantaneous oscillations in the control parameters. This motivates the terminology chattering for such systems. See [3] and [4], for more details.

The system (6.3) can also be reduced to the form

$$\dot{x} = f(x, t) + v, \qquad v \in V(t), \tag{6.4}$$

this time with

$$V(t) = \left\{ \int_S g(u(s), t, s)\beta_t(ds): u \text{ measurable from } S \text{ into } U(t, s) \right\}.$$

And the question is again whether or not each admissible $v(t): [t_0, t_1] \to V(t)$ is generated by a measurable $u(t, s): [t_0, t_1] \times S \to U(t, s)$. We give an answer, employing the theorem of this paper.

Assumptions. Suppose $U(t, s)$ is a measurable multifunction with compact values. Suppose $g(u, t, s)$ is continuous in u and measurable in (t, s). Suppose that for each t the multifunction

$$F(t, s) = \{g(u, t, s): u \in U(t, s)\}$$

is β_t-integrably bounded in the s variable. Suppose $t \to \beta_t$ is measurable, and let λ be the Lebesgue measure on $[t_0, t_1]$.

Application 6.1. Under the assumptions, given an admissible control $v(t)$ of (6.4), there exists an admissible control $u(t, s)$ of (6.3) such that

$$v(t) = \int_S g(u(t, s), t, s)\beta_t(ds)$$

for λ-almost every t in $[t_0, t_1]$.

Proof. It follows from the definition of measurability and the continuity of $g(u, t, s)$ in the u variable that the multifunction $F(t, s)$ is measurable and has compact values. We claim that given a measurable selection $\gamma(t, s)$ of $F(t, s)$, there exists an admissible control $u(t, s)$ such that $\gamma(t, s) = g(u(t, s), t, s)$. The existence of such u follows from the implicit functions property given in Proposition 3.5.

In particular it follows that

$$V(t) = \int_S F(t, s)\beta_t(ds). \tag{6.5}$$

Let $v(t)$ be an admissible control of (6.4), namely, a measurable selection of $V(t)$. By the theorem in this paper (and the assumptions) there exists a selection $\gamma(t, s)$ of $F(t, s)$ such that

$$v(t) = \int_S \gamma(t, s)\beta_t(ds).$$

The previous argument, namely that $\gamma(t, s)$ can be realized as $g(u(t, s), t, s)$ with an admissible control u, completes the proof.

7. An application in optimization. Let T be a probability space, with probability measure λ. For each $t \in T$ and each interger k an optimization problem is given as follows:

$$\begin{aligned} (\mathcal{P}_k) \qquad & \text{maximize} && J(x, t), \\ & \text{subject to} && x \in H(t), \\ & && x = \frac{1}{k}(x_1(t) + \cdots + x_k(t)), \\ & && x_j(t) \in F_j(t) \end{aligned}$$

with constraints $H(t)$ and $F_j(t)$ prescribed, and independent of k. The optimal values and the optimal solutions of $(\mathcal{P}_k)$ may of course depend on the integer k. We are interested in the asymptotic behaviour as $k \to \infty$; in particular we are interested in obtaining an unvarying asymptotic solution, namely, a sequence of decisions

$$x_1(t), x_2(t), \cdots, \qquad x_j(t) \in F_j(t) \tag{7.1}$$

such that for large k the finite sequence $x_1(t), \cdots, x_k(t)$ (whose elements do not depend on k) is a good approximation for a solution. A formal way of expressing what properties an asymptotic solution has follows.

DEFINITION. Denote by $y_k(t)$ the average $(x_1(t) + \cdots + x_k(t))/k$. The sequence in (7.1) is an unvarying asymptotic solution of $(\mathcal{P}_k)$, as $k \to \infty$, if λ-almost everywhere dist $(y_k(t), H(t))$ converge to 0 and if $J(y_k(t), t) - v_k(t)$ converge to zero as $k \to \infty$, where $v_k(t)$ is the optimal value of $(\mathcal{P}_k)$.

Maximization problems like the one we treat, and the need for asymptotic unvarying solutions, arise in stochastic planning and in optimization under uncertainty. In mathematical economics, Arrow and Radner [1] offer a model of this type for decisions in large terms. A survey of relations between probabilistic limit laws for multifunctions and asymptotic values and asymptotic solutions of the problems $(\mathscr{P}_k)$ is presented in [2]. Indeed, existence of unvarying asymptotic solutions depends on asymptotic properties of the constraints $F_j(t)$; these asymptotic properties can be derived from stochastic characteristics of the $F_j(t)$ when interpreted as random variables. This is the connection with stochastic optimization in general, and optimization with stochastic constraints in particular.

In this section we employ the main theorem and derive unvarying asymptotic solutions under conditions weaker than those given in [2]. The framework is as follows.

Let S be a complete separable metric space. Let $F(t, s)$ be a multifunction, with values being compact subsets of R^n. The constraints $F_j(t)$ are obtained as

$$F_j(t) = F(t, s_j(t)) \tag{7.2}$$

with $s_j(t)$ a sequence of measurable functions from T into S; they represent t-dependent samplings of the parameter space S. For each t let β_t be a probability distribution on S. It is assumed in the statement of the application below that the realization $\{s_1(t), \cdots, s_k(t)\}$ is a good sample of β_t in some sense. This is done along the lines of [5] and [6]. In [1] and in [2] it is assumed that $F_j(t) = F(s_j(t))$, with $F(s)$ independent of t, and $s_1(t), s_2(t), \cdots$ are identically distributed and independent. This is a particular case of ours, and implies all the approximation properties that we demand for the sample.

Assumptions. The functional $J(x, t)$ is continuous in x and measurable in t. The multifunction $F(t, s)$ has compact values, is measurable in t and is continuous in s (with respect to the Hausdorff metric), and $F(t, \cdot)$ is bounded. The mapping $t \to \beta_t$ is measurable. For each t the set $\int F(t, s)\beta_t(ds)$ is convex, and has a nonempty intersection with $H(t)$. The multifunction $H(t)$ is measurable, with closed values.

Application 7.1. Denote $\Gamma(t) = H(t) \cap \int F(t, s)\beta_t(ds)$. Then $\Gamma(t)$ has compact values, and by Corollary 4.7, it is $\mathscr{B}_\lambda(T)$-measurable. Let $\Gamma_0(t)$ be the set of $x \in \Gamma(t)$ on which $J(x, t)$ achieves its maximum. The continuity of J in x implies that $\Gamma_0(t)$ is nonempty, and it is easy to verify that Γ_0 is $\mathscr{B}_\lambda(T)$-measurable. Let γ_0 be a selection of Γ_0.

By the theorem, there exists a measurable selection $f(t, s)$ of $F(t, s)$ such that

$$\int f(t, s)\beta_t(ds) = \gamma_0(t) \tag{7.3}$$

for λ-almost every t. Let $\beta_{t,k}$ be the empirical measure on S determined by the sample $\{s_1(t), \cdots, s_k(t)\}$. Suppose that for almost every t the measures $\beta_{t,k}$ converge, in the space of probability measures, to β_t and that $f(t, \cdot)$, when defined on the measure space $(S, \beta_{t,k})$, converge in distribution to $f(t, \cdot)$ when regarded as a function on (S, β_t). Then the sequence

$$x_j(t) = f(t, s_j(t)), \qquad j = 1, 2, \cdots \tag{7.4}$$

forms an unvarying asymptotic solution.

Proof. The weak convergence of $\beta_{t,k}$ to β_t and the continuity of $F(t, s)$ in the s variable imply that $\int \operatorname{co} F(t, s)\beta_{t,k}(ds)$ converge in the Hausdorff metric to $\int \operatorname{co} F(t, s)\beta_t(ds)$, where co K is the convex hull of the set K (see, e.g., Artstein and

Wets [5, Thm. 3.1]). Since $\int F(t, s)\beta_t(ds) = \Gamma(t)$ was assumed convex, and since $\beta_{t,k}$ is determined by the sample $s_1(t), \cdots, s_k(t)$, it follows that

$$\limsup_{k\to\infty} \frac{1}{k} \sum_{i=1}^{k} F_j(t) \text{ is included in } \Gamma(t).$$

In other words, $J(\gamma_0(t), t)$ is the maximal value of limits of optimal values $v_k(t)$ of the problems $(\mathcal{P}_k)$. We now show that $J(\gamma_0(t), t)$ is the limit of $J(y_k(t), t)$, where $y_k(t)$ is determined by the decisions $x_j(t)$ of (7.4) (see the definition). From the definition it would then follow that (7.4) forms an unvarying asymptotic solution. In fact, the continuity of $J(\cdot, t)$ implies that it suffices to show that $y_k(t) \to \gamma_0(t)$ for λ-almost every t. But this convergence follows from the assumption of convergence in distribution of $f(t, \cdot)$. Indeed, $y_k(t) = \int f(t, s)\beta_{t,k}(ds)$ while $\gamma_0(t) = \int f(t, s)\beta_t(ds)$. This completes the proof.

Remarks. There is an ad hoc assumption in the preceding application, namely, the assumption of convergence in distribution of the functions $f(t, \cdot)$. It would be desirable to deduce the existence of a selection f with this property from conditions on the data. We can come up with some conditions, e.g., if co $F(t, s)$ is strictly convex and $J(\cdot, t)$ is a convex function; but we do not dwell into these considerations here. Other conditions can be relaxed. The condition that $\Gamma(t)$ is convex can be dropped. Indeed, the sampling process averages out the contributions from the atoms of β_t; a modification of (7.4) along the lines of [2, Scheme 2, p. 74] would produce then an unvarying asymptotic solution. We leave out the details. As mentioned, stochasticity of the samples $s_j(t)$, for instance, if they are independent and identically distributed, would enable us to ease more conditions; for instance, the continuity of $F(t, \cdot)$ is not needed then, and the λ-almost everywhere convergence in distribution of $f(t, \cdot)$, demanded in the application, is then satisfied automatically.

A MATROID-THEORETIC APPROACH TO STRUCTURALLY FIXED MODES OF CONTROL SYSTEMS*

KAZUO MUROTA†

Abstract. The structurally fixed modes for a decentralized control system described in the descriptor form $F\dot{\mathbf{x}} = A\mathbf{x} + B\mathbf{u}$, $H\mathbf{y} = C\mathbf{x}$ are investigated under a physically reasonable assumption that the coefficients in the equations are classified into independent physical parameters and dimensionless fixed constants. A necessary and sufficient condition for the existence of structurally fixed modes is given in matroid-theoretic terms; the condition can be tested by an efficient algorithm for the independent-flow problem. The combinatorial canonical form of a layered mixed matrix plays a central role in deriving the condition.

Key words. structurally fixed mode, decentralized control system, layered mixed matrix, combinatorial canonical form, matroid-theoretic algorithm

AMS(MOS) subject classifications. 93, 93A15, 93B55, 15, 05C50

1. Introduction. The concept of fixed modes introduced by Wang and Davison [40] is now recognized as one of the fundamental concepts for the decentralized control, especially with respect to stabilization and pole assignment (see also Anderson and Clements [2], Corfmat and Morse [8], and Davison, Gesing, and Wang [10]). In line with the structural or generic approach to controllability initiated by Lin [22] and developed by Glover and Silverman [14], Kobayashi and Yoshikawa [19], Maeda [25], Shields and Pearson [37], and others, the concept of structurally fixed modes is proposed by Sezer and Šiljak [36] and its combinatorial or graph-theoretic characterizations are given by Sezer and Šiljak [36] and Pichai, Sezer, and Šiljak [33]. See also Reinschke [34].

In this paper, the structurally fixed modes for a decentralized control system described in a descriptor form are investigated in a physically reasonable framework (described in § 3) that has been proposed by Murota [26]-[28], [30] in formulating the structural controllability. That is, the structurally fixed modes are discussed under the assumption that the coefficients in the equations are classified into independent physical parameters and dimensionless fixed constants. A necessary and sufficient condition, of a combinatorial nature, for the existence of structurally fixed modes is derived in § 4 with the aid of the combinatorial canonical form (abbreviated as CCF) of a layered mixed matrix (abbreviated as LM-matrix), which is a mathematical tool useful for systems analysis in general [28], [30] and is described briefly in § 2. Furthermore, it is shown that the derived condition can be tested efficiently by a variant of the matroid-theoretic algorithm for the matroid union/partition problem [12], [21] or for the independent-flow problem [13]; the proposed algorithm, being expressed in terms of an auxiliary graph, is suitable for practical applications in that it is free from the numerical difficulty of rounding errors and is guaranteed to run in polynomial time in the size of the control system in question. The established criterion naturally reduces to the graph-theoretic criterion obtained by Pichai, Sezer, and Šiljak [33] in the case where all the nonzero coefficients can be regarded as independent parameters. It is also mentioned in § 7 that a hierarchical decomposition of a dynamical system with respect to an arbitrarily specified feedback structure is provided by the CCF of an LM-matrix associated with the decentralized system. No explicit reference to matroid

theory [41] is made in this paper, although extensive use is made of the results in linear algebra that have been obtained with the aid of matroid theory. In this connection the readers are also referred to [16]–[18], [28] for the use of matroid-theoretic concepts and algorithms in circuit theory.

To be specific, consider a linear time-invariant dynamical system with ν local control stations described as follows:

$$\dot{\mathbf{x}}(t) = A\mathbf{x}(t) + B\mathbf{u}(t), \tag{1.1a}$$

$$\mathbf{y}(t) = C\mathbf{x}(t) \tag{1.1b}$$

where $\mathbf{x}$ is the state-vector,

$$\mathbf{u} = \begin{pmatrix} \mathbf{u}_1 \\ \vdots \\ \mathbf{u}_\nu \end{pmatrix} \quad \text{and} \quad \mathbf{y} = \begin{pmatrix} \mathbf{y}_1 \\ \vdots \\ \mathbf{y}_\nu \end{pmatrix}$$

are the input-vector and the output-vector, respectively, consisting of the input-vectors $\mathbf{u}_i$ $(i = 1, \cdots, \nu)$ and the output-vectors $\mathbf{y}_i$ $(i = 1, \cdots, \nu)$ of the local control stations. The matrices A, B, and C are real and constant; corresponding to the local stations, B and C are partitioned into ν blocks as

$$B = (B_1 | \cdots | B_\nu), \qquad C = \begin{pmatrix} C_1 \\ \vdots \\ C_\nu \end{pmatrix}.$$

The local output feedback is specified by a block-diagonal real matrix

$$K = \text{block diag}\,[K_1, \cdots, K_\nu], \tag{1.2}$$

where the size of K_i is such that matrix product $B_iK_iC_i$ is defined $(i = 1, \cdots, \nu)$. That is, K represents the nondynamic decentralized output feedback

$$\mathbf{u}(t) = K\mathbf{y}(t), \tag{1.3}$$

i.e., $\mathbf{u}_i = K_i\mathbf{y}_i$ $(i = 1, \cdots, \nu)$. The local output feedback control with dynamic compensation is described by

$$\dot{\mathbf{z}}(t) = L\mathbf{z}(t) + M\mathbf{y}(t), \tag{1.4a}$$

$$\mathbf{u}(t) = N\mathbf{z}(t) + K\mathbf{y}(t) + P\mathbf{v}(t) \tag{1.4b}$$

where

$$\mathbf{z} = \begin{pmatrix} \mathbf{z}_1 \\ \vdots \\ \mathbf{z}_\nu \end{pmatrix} \quad \text{and} \quad \mathbf{v} = \begin{pmatrix} \mathbf{v}_1 \\ \vdots \\ \mathbf{v}_\nu \end{pmatrix},$$

and $\mathbf{z}_i$ and $\mathbf{v}_i$ are, respectively, the state-vector and the external input-vector of the ith feedback controller $(i = 1, \cdots, \nu)$; the matrices L, M, N, and P are block-diagonal real matrices of appropriate sizes.

Let $\mathcal{K}$ be the family of all real matrices K of the form (1.2). The greatest common divisor of the set of characteristic polynomials of $A + BKC$, for all $K \in \mathcal{K}$, is called the *fixed polynomial* of (A, B, C) with respect to $\mathcal{K}$, and denoted by $\psi(s) = \psi(s; A, B, C, \mathcal{K})$, i.e.,

$$\psi(s; A, B, C, \mathcal{K}) = \gcd\{\det(A + BKC - sI) \mid K \in \mathcal{K}\}. \tag{1.5}$$

A complex number $\lambda \in \mathbf{C}$ is called a *fixed mode* of (A, B, C) with respect to $\mathcal{K}$ if λ is an eigenvalue of $A+BKC$ for all $K \in \mathcal{K}$, i.e., if $\psi(\lambda; A, B, C, \mathcal{K}) = 0$. The importance of the concept of fixed modes is demonstrated by the following results due to Wang and Davison [40] and to Corfmat and Morse [8]: (i) the system (1.1) is stabilizable by the decentralized dynamic output feedback (1.4) if and only if all the fixed modes of (A, B, C) have negative real parts; and (ii) the spectrum of the closed-loop system (1.1) and (1.4) is freely assignable by means of $K \in \mathcal{K}$ if and only if there exist no fixed modes for (A, B, C).

As already noted in [40], the notions of fixed polynomial and fixed modes can be defined for (A, B, C) with respect to an arbitrarily specified family $\mathcal{K}$ of the matrices K, not necessarily of the form (1.2). In the special case where $\mathcal{K}$ is composed of all matrices of the compatible size (i.e., of size such that matrix product BKC is defined), the fixed mode with respect to $\mathcal{K}$ is called the *centralized fixed mode* in [10]. It is pointed out in [33] that the above-mentioned result (i) on the stabilizability can be extended to the situation where $\mathcal{K}$ consists of those matrices K that are subject to an arbitrarily specified zero/nonzero structure and where M in (1.4) is constrained to a structure consistent with that of K.

A fixed mode of (A, B, C) is called a *structurally fixed mode* if it stems not from accidental matching of the numerical values of system parameters but from the structure of the system [36]. In [33] and [36], however, the structurally fixed modes are defined with respect to the zero/nonzero structure of A, B, and C. Namely, the fixed modes are considered for the family $\mathcal{S}$ of systems that are "structurally equivalent" to (A, B, C), where a system $(\hat{A}, \hat{B}, \hat{C})$ is called structurally equivalent to (A, B, C) if $\hat{A}$, $\hat{B}$, and $\hat{C}$ have, respectively, the same zero/nonzero structure as that of A, B, and C. Obviously, the concept of structurally fixed modes can be defined with respect to a pair $(\mathcal{S}, \mathcal{K})$ of a more general family $\mathcal{S}$ of systems and a more general family $\mathcal{K}$ of output feedbacks.

It has been gradually recognized that in the design and analysis of large-scale systems in general, "structural" or qualitative considerations are no less important than "numerical" or quantitative ones. It should be emphasized that the "structure" should be defined on a physically sound basis, and that it is crucial in this respect to work with elementary mathematical representations of physical structures expressed in terms of elementary variables, and not with sophisticated and compact representations.

In the present case of dynamical systems, therefore, the "standard state-space form" (1.1) is not suitable for expressing the elementary physical structure in that the entries of the matrices A, B, and C usually have mutual algebraic relations among themselves. The so-called "descriptor form" (cf. Armentano [4], Cobb [6], [7], Luenberger [23], [24], Verghese, Lévy, and Kailath [38]) is more suitable. That is, (1.1) and (1.3) are to be replaced, respectively, by

$$F\dot{\mathbf{x}}(t) = A\mathbf{x}(t) + B\mathbf{u}(t), \tag{1.6a}$$

$$H\mathbf{y}(t) = C\mathbf{x}(t), \tag{1.6b}$$

$$G\mathbf{u}(t) = K\mathbf{y}(t). \tag{1.7}$$

Then, as advocated by Murota [28] and Murota and Iri [31], it is often justified to assume that the coefficients in these equations are classified into two groups, one of independent physical parameters and the other of fixed constants, typically simple integers such as ± 1.

In this paper we recognize the structure of a system in the above sense. That is, we set $\mathscr{S}$ to be the family of systems (A, B, C, F, H) of (1.6), in which the independent parameters of those coefficient matrices can take arbitrary real values while the fixed coefficients remain constants. As for the feedback structure constraint we assume that $\mathscr{K}$ consists of pairs (G, K) of the matrices G and K having structures specified similarly in terms of independent parameters and fixed constants. We will discuss the structurally fixed modes with respect to such $(\mathscr{S}, \mathscr{K})$ (see § 3 for the precise formulation of the problem). Combinatorial and algorithmic characterizations of the existence of structurally fixed modes will be established in Theorem 4.2 and Theorem 5.1.

The present formulation of the fixed modes for a general descriptor system (1.6) includes those treated in [8], [10], [33], [36], and [40] as special cases. When a decentralized control system is described by (1.6) with F and H being nonsingular, and $\mathscr{K}$ consists of all block-diagonal matrices (G, K) compatible with the locality of admissible feedbacks, the fundamental results of Wang and Davison [40] and Corfmat and Morse [8] mentioned above remain valid and clarify the control-theoretic significance of the fixed modes in the present formulation. In this case, nothing new is introduced to the concept of fixed modes of a particular system. Nevertheless, the descriptor form is more suitable for considering structurally fixed modes since it represents the physical structure more faithfully. A general descriptor system, however, may have the so-called impulsive modes that bring about complications [4], [7], [38]. Although substantial results seem to have been obtained so far on the pole assignment by state-feedback [3], [5], [6], the present author is not informed of results on pole assignment by dynamic compensation for a general descriptor system.

2. Preliminaries on mixed matrices. Let $\mathbf{K} \subseteq \mathbf{F}$ be fields. A matrix A is called a *mixed matrix* with respect to $\mathbf{K}$ if

$$A = Q + T \tag{2.1}$$

where (i) $Q = (Q_{ij})$ is a matrix over $\mathbf{K}$, and (ii) $T = (T_{ij})$ is a matrix over $\mathbf{F}$ such that the set $\mathscr{N}(T)$ is (collectively) algebraically independent [39] over $\mathbf{K}$, where $\mathscr{N}(\cdot)$ denotes in general the set of nonzero entries of a matrix. The following identity is fundamental where, for a matrix M in general, we denote the row-set and the column-set of M by Row (M) and Col (M), respectively, and the submatrix with row-set I and column-set J by $M[I, J]$; note also term-rank of M coincides with its generic rank if $\mathscr{N}(M)$ is algebraically independent. See Murota [28], [29], Murota and Iri [31], and Murota, Iri, and Nakamura [32] for the details of this section.

LEMMA 2.1. *For a mixed matrix* $A = Q + T$,

$$\text{rank } A = \max \{\text{rank } Q[R - I, C - J] + \text{term-rank } T[I, J] \mid I \subseteq R, J \subseteq C\},$$

where $R = \text{Row } (A)$, $C = \text{Col } (A)$.

A matrix A is called a *layered mixed matrix* (or an LM-matrix) with respect to $\mathbf{K}$ if it takes the following form (possibly after a permutation of rows):

$$A = \begin{pmatrix} Q \\ T \end{pmatrix} \tag{2.2}$$

and Q and T of (2.2) meet the requirements (i) and (ii) above.

By the *admissible transformation* for an LM-matrix A of (2.2) we mean the transformation of the form:

$$P_r \begin{pmatrix} S & O \\ O & I \end{pmatrix} \begin{pmatrix} Q \\ T \end{pmatrix} P_c \tag{2.3}$$

where S is a nonsingular matrix over the subfield $\mathbf{K}$, and P_r and P_c are permutation matrices. The admissible transformation brings an LM-matrix into another LM-matrix and two LM-matrices are said to be LM-*equivalent* if and only if they are connected by an admissible transformation.

There exists a finest block-triangular matrix, called the *combinatorial canonical form* (or CCF for short), among the matrices that are LM-equivalent to each other. Note that the CCF is a generalization of the canonical decomposition due to Dulmage and Mendelsohn [11] of a bipartite graph, or of a formal incidence matrix [35]. The CCF for a nonsingular LM-matrix is described as follows.

Let $\bar{A}$ be the CCF of a nonsingular A; Row $(\bar{A})$ and Col $(\bar{A})$ are, respectively, partitioned into nonempty blocks as

$$\{R_1, \cdots, R_r\}, \qquad \{C_1, \cdots, C_r\} \tag{2.4}$$

where

$$\emptyset \neq R_k \subseteq \text{Row}\,(\bar{A}), \quad \emptyset \neq C_k \subseteq \text{Col}\,(\bar{A}) \quad \text{for } k = 1, \cdots, r,$$
$$R_k \cap R_l = \emptyset, \quad C_k \cap C_l = \emptyset \quad \text{for } k \neq l.$$

LEMMA 2.2. *The* CCF $\bar{A}$ *of a nonsingular* LM-*matrix* A *has the following properties*:
(1) $\bar{A}$ *is block-triangularized with respect to the partitions* (2.4). *That is,*

$$\bar{A}[R_k, C_l] = O \quad \text{if } 1 \leqq l < k \leqq r.$$

(2) $$\text{rank}\,\bar{A}[R_k, C_k] = |R_k| = |C_k| > 0 \quad \text{for } k = 1, \cdots, r.$$

(3) $\bar{A}$ *is the finest block-triangular matrix with property* (2) *that is* LM-*equivalent to* A.

A nonsingular LM-matrix A will be called (LM)-*irreducible* if its CCF does not split into more than one block, that is, if $r = 1$ above. Each diagonal block $\bar{A}[R_k, C_k]$ of the CCF above is irreducible $(k = 1, \cdots, r)$. The following result of Murota [29] plays the central role in § 4. It is a generalization of the result of Ryser [35] for formal incidence matrices.

LEMMA 2.3. *Let* $A = \begin{pmatrix} Q \\ T \end{pmatrix}$ *be a nonsingular irreducible* LM-*matrix with respect to* $\mathbf{K}$, *and* $\mathcal{T} = \mathcal{N}(T)$ *denote the set of nonzero entries of* T.
(1) det A *is an irreducible polynomial in the ring* $\mathbf{K}[\mathcal{T}]$.
(2) *Each element of* $\mathcal{T}$ *appears in* det A.

3. Problem formulation. For the descriptor system (1.6) and (1.7) we define the fixed polynomial $\psi(s)$ with respect to a family $\mathcal{K}$ of allowable feedbacks (G, K) by

$$\psi(s) = \psi(s; A, B, C, F, H, \mathcal{K}) = \gcd\{\det D(s) \,|\, (G, K) \in \mathcal{K}\} \tag{3.1}$$

where

$$D = D(s) = \begin{pmatrix} A - sF & B & O \\ O & -G & K \\ C & O & -H \end{pmatrix} \tag{3.2}$$

and gcd is considered in $\mathbf{C}[s]$. Note that this is an extension of (1.5) since

$$\det(A + BKC - sI) = \det \begin{pmatrix} A - sI & B & O \\ O & -I & K \\ C & O & -I \end{pmatrix}. \tag{3.3}$$

We call a complex number $\lambda \in \mathbf{C}$ a fixed mode of (A, B, C, F, H) with respect to $\mathcal{K}$ if $\psi(\lambda) = 0$.

We now introduce the first physical observation that explains how we recognize the structure of a system. This will constitute the basis of our choice of the family $\mathcal{S}$ of systems. When a dynamical system is written in the form (1.6) and (1.7) in terms of elementary physical variables, it is often justified to assume that the nonzero entries of the coefficient matrices A, B, C, F, and H are classified into two groups, one of generic parameters and the other of fixed constants. In other words, as observed by Murota and Iri [31], we can distinguish two kinds of numbers that characterize physical systems as follows: (i) those numbers representing independent physical parameters such as resistances in electrical networks that, being contaminated by various noises and errors, take inaccurate values independent of one another, so that they can be modeled as algebraically independent generic numbers, and (ii) those numbers accounting for various sorts of conservation laws such as Kirchhoff's, that, stemming from topological incidence relations, are accurate (often ± 1) in value so that no serious numerical difficulty arises in arithmetic operations on them. See [31] or Chapter 4 of [28] for further discussions.

Based on this physical observation we assume that coefficient matrices A, B, C, F, and H are expressed as follows:

$$\begin{aligned} A = Q_A + T_A, \quad B = Q_B + T_B, \quad C = Q_C + T_C, \\ F = Q_F + T_F, \qquad H = Q_H + T_H, \end{aligned} \tag{3.4}$$

where Q_A, Q_B, etc., are matrices over $\mathbf{Q}$ (the field of rational numbers), and the sets $\mathcal{N}(T_A)$, $\mathcal{N}(T_B)$, etc., of nonzero entries are disjoint and

$$\mathcal{S} = \mathcal{N}(T_A) \cup \mathcal{N}(T_B) \cup \mathcal{N}(T_C) \cup \mathcal{N}(T_F) \cup \mathcal{N}(T_H) (\subseteq \mathbf{R}) \tag{3.5}$$

is algebraically independent over $\mathbf{Q}$. It should be clear that assuming algebraic independence of $\mathcal{S}$ is equivalent to regarding the members of $\mathcal{S}$ as independent parameters, and therefore to considering the family, to be denoted also by $\mathcal{S}$, of systems parametrized by those parameters in $\mathcal{S}$. Such a particular system has a fixed mode with respect to $\mathcal{K}$ if and only if each member of $\mathcal{S}$ has a fixed mode with respect to $\mathcal{K}$.

The feedback structure constraint $\mathcal{K}$ is assumed to be specified by means of a pair of mixed matrices

$$G = Q_G + T_G, \qquad K = Q_K + T_K. \tag{3.6}$$

That is, $\mathcal{K}$ is composed of (G, K) of (3.6), where the nonzero entries of T_G and T_K take any real values.

In this paper we are primarily concerned with combinatorial and algorithmic characterizations of the condition

$$\psi(s; A, B, C, F, H, \mathcal{K}) \in \mathbf{C} \tag{3.7}$$

for a system (A, B, C, F, H) such that

(A1) $\mathcal{S}$ of (3.5) is algebraically independent over $\mathbf{Q}$.

Remark 3.1. The rationality of the entries of Q_A, Q_B, etc., is not essential to the subsequent arguments. In case nonrational constants are involved, we may choose as $\mathbf{K}$ an appropriate extension field of $\mathbf{Q}$. The subfield $\mathbf{K}$ affects the computational complexity of the algorithm to be described in § 5.

Since the members of $\mathcal{N}(T_G) \cup \mathcal{N}(T_K)$ are independent parameters, (A1) implies that D of (3.2) is a mixed matrix (cf. § 2) with respect to $\mathbf{K} = \mathbf{Q}(s)$, i.e.,

$$D = Q_D + T_D \tag{3.8}$$

with

$$Q_D = Q_D(s) = \begin{pmatrix} Q_A - sQ_F & Q_B & O \\ O & -Q_G & Q_K \\ Q_C & O & -Q_H \end{pmatrix}, \tag{3.9}$$

$$T_D = T_D(s) = \begin{pmatrix} T_A - sT_F & T_B & O \\ O & -T_G & T_K \\ T_C & O & -T_H \end{pmatrix}. \tag{3.10}$$

The second physical observation made by Murota [26] (see also [27], [28, Chap. 4]) is that the fixed constants, or the accurate numbers, usually represent topological and/or geometrical incidence coefficients that have no physical dimensions. Therefore, it is natural to expect that the entries of Q_A, Q_B, etc., are dimensionless constants. On the other hand, the indeterminate s should have the physical dimension of the inverse of time, since it corresponds to the differentiation with respect to time. When combined with the principle of dimensional homogeneity [15], [20], this implies that

$$Q_D(s) = \mathrm{diag}\,[s^{r_1}, \cdots, s^{r_d}] \cdot Q_D(1) \cdot \mathrm{diag}\,[s^{-c_1}, \cdots, s^{-c_d}] \tag{3.11}$$

for some integers r_i and c_i $(i = 1, \cdots, d)$, where d is the size of the matrix D (see [26] and [28] for details). Note that $-r_i$ and $-c_i$ admit the natural physical interpretation of the exponents to the dimension of time associated, respectively, with the ith row (equation) and the ith column (variable) of D. It is known that (3.11) holds for some integers r_i and c_i $(i = 1, \cdots, d)$ if and only if

(A2) Every nonvanishing subdeterminant of $Q_D(s)$ is a monomial in s over $\mathbf{Q}$ (i.e., of the form αs^p with a rational number α and an integer p).

Our problem is to derive necessary and sufficient conditions for (3.7) under the assumptions (A1) and (A2).

4. Algebraic/combinatorial characterization of a fixed polynomial. We will solve our problem formulated in § 3 in a still more general form as follows. (Examples in § 6 will provide a concrete idea to the argument below.) Let s be an indeterminate over $\mathbf{C}$ and let

$$D = D(s) = Q_D + T_D \tag{4.1}$$

be a $d \times d$ nonsingular matrix such that

$$Q_D = Q_D(s) = Q^0 + sQ^1, \tag{4.2}$$

$$T_D = T_D(s) = (T^0 + sT^1) + \hat{K} \tag{4.3}$$

where

(A1) $\mathcal{S} \equiv \mathcal{N}(T^0) \cup \mathcal{N}(T^1)$ (disjoint union) $(\subseteq \mathbf{C})$ is algebraically independent over $\mathbf{Q}$.

(A2) Every nonvanishing subdeterminant of $Q_D(s)$ is a monomial in s over $\mathbf{Q}$.

(A3) The elements of $\mathcal{K} \equiv \mathcal{N}(\hat{K})$ are indeterminates over $\mathbf{C}(s)$.

Recall that (A2) implies

$$Q_D(s) = \mathrm{diag}\,[s^{r_1}, \cdots, s^{r_d}] \cdot Q_D(1) \cdot \mathrm{diag}\,[s^{-c_1}, \cdots, s^{-c_d}] \tag{4.4}$$

for some integers r_i and c_i $(i = 1, \cdots, d)$.

Remark 4.1. It should be clear that for the problem formulated in § 3 we have

$$Q^0=\begin{pmatrix} Q_A & Q_B & O \\ O & -Q_G & Q_K \\ Q_C & O & -Q_H \end{pmatrix}, \qquad Q^1=\begin{pmatrix} -Q_F & O & O \\ O & O & O \\ O & O & O \end{pmatrix},$$

$$T^0=\begin{pmatrix} T_A & T_B & O \\ O & O & O \\ T_C & O & -T_H \end{pmatrix}, \qquad T^1=\begin{pmatrix} -T_F & O & O \\ O & O & O \\ O & O & O \end{pmatrix},$$

$$\hat{K}=\begin{pmatrix} O & O & O \\ O & -T_G & T_K \\ O & O & O \end{pmatrix}$$

for the matrices introduced here.

In accordance with (3.1) we define the fixed polynomial $\psi(s)$ as the greatest common divisor in $\mathbf{C}[s]$ of all $\det D(s)$, where arbitrary real values are substituted into $\mathcal{K}$. Also we call a complex number $\lambda \in \mathbf{C}$ a fixed mode with respect to $\mathcal{K}$ if $\psi(\lambda)=0$.

Regarding $\det D(s)$ as a polynomial in $(s, \mathcal{S}, \mathcal{K})$ over $\mathbf{Q}$, let

$$\det D(s)=\prod_{k\in\Psi_0}\psi_k(s)\cdot\prod_{k\in\Psi_1}\psi_k(s,\mathcal{S})\cdot\prod_{k\in\Psi_2}\psi_k(s,\mathcal{S},\mathcal{K}) \tag{4.5}$$

be the decomposition into irreducible polynomials in $\mathbf{Q}[s, \mathcal{S}, \mathcal{K}]$, where $\psi_k(s)\in\mathbf{Q}[s]$ for $k\in\Psi_0$, $\psi_k(s,\mathcal{S})\in\mathbf{Q}[s,\mathcal{S}]-\mathbf{Q}[s]$ for $k\in\Psi_1$, and $\psi_k(s,\mathcal{S},\mathcal{K})\in\mathbf{Q}[s,\mathcal{S},\mathcal{K}]-\mathbf{Q}[s,\mathcal{S}]$ for $k\in\Psi_2$. The following would be obvious.

LEMMA 4.1. *The fixed polynomial* $\psi(s)\in\mathbf{C}[s]$ *is given as*

$$\psi(s)=\prod_{k\in\Psi_0}\psi_k(s)\cdot\prod_{k\in\Psi_1}\psi_k(s,\mathcal{S}). \tag{4.6}$$

Proof. It suffices to show that $\psi_k(\lambda,\mathcal{S},\mathcal{K})$ is not equal to zero as a polynomial in $\mathcal{K}$ over $\mathbf{C}$ for all $\lambda\in\mathbf{C}$ and for all $k\in\Psi_2$. Suppose, to the contrary, there exist $\lambda\in\mathbf{C}$ and $k\in\Psi_2$ such that $\psi_k(\lambda,\mathcal{S},\mathcal{K})=0$ in $\mathbf{C}[\mathcal{K}]$. As a polynomial in $(s,\mathcal{K})$ over $\mathbf{F}\equiv\mathbf{Q}(\mathcal{S})$, ψ_k is expressed as

$$\psi_k(s,\mathcal{S},\mathcal{K})=\sum_{\alpha}\rho_\alpha(s)\mathcal{K}^\alpha$$

where α denotes a multi-index, $\mathcal{K}^\alpha$ is a product of some elements in $\mathcal{K}$, and $\rho_\alpha(s)\in\mathbf{F}[s]$. Note that there exist more than one term in this expression since $\psi_k(s,\mathcal{S},\mathcal{K})\in\mathbf{Q}[s,\mathcal{S},\mathcal{K}]-\mathbf{Q}[s,\mathcal{S}]$ is irreducible. Then $\rho_\alpha(\lambda)=0$ for all α. This means [39] that $\rho_\alpha(s)$, for each α, is divisible in $\mathbf{F}[s]$ by the minimal polynomial of λ over $\mathbf{F}$. However, this contradicts the assumption since the irreducibility of $\psi_k(s,\mathcal{S},\mathcal{K})$ in $\mathbf{Q}[s,\mathcal{S},\mathcal{K}]$ implies [39] its irreducibility as a polynomial in $(s,\mathcal{K})$ over $\mathbf{F}=\mathbf{Q}(\mathcal{S})$.

Consider the first factor on the right-hand side of (4.5). It follows from (A2), or (4.4), that

$$\prod_{k\in\Psi_0}\psi_k(s)=\alpha s^p \qquad (\alpha\in\mathbf{Q}, p\in\mathbf{Z}). \tag{4.7}$$

LEMMA 4.2. $D(s)$ *is nonsingular* (s: *indeterminate*) *with* $p=0$ *in* (4.7) *if and only if* $D(0)$ *is nonsingular.*

The nonsingularity of $D(0)$ can be characterized combinatorially by Lemma 2.1 since $D(0)=Q^0+(T^0+\hat{K})$ is a mixed matrix with respect to $\mathbf{Q}$. (More generally it is

possible to compute the value of p by a matroid-theoretic algorithm. See Theorem 4.2 below.)

The remaining factors in (4.5) are determined as follows. Put

$$\tilde{D} = \tilde{D}(s; t_1, \cdots, t_d) = \begin{pmatrix} I_d & Q_D \\ -\mathrm{diag}\,[t_1, \cdots, t_d] & T_D \end{pmatrix} = \begin{pmatrix} \tilde{Q} \\ \tilde{T} \end{pmatrix} \tag{4.8}$$

where I_d is the unit matrix of order d, and t_i $(i = 1, \cdots, d)$ are indeterminates (distinct from s and $\mathcal{K}$). Obviously,

$$\det D(s) = \det \tilde{D}(s; 1, \cdots, 1). \tag{4.9}$$

The matrix $\tilde{D}$ is an LM-matrix with respect to $\mathbf{K} = \mathbf{Q}(s)$. Let

$$\bar{D} = \bar{D}(s; t_1, \cdots, t_d) = \begin{pmatrix} \bar{D}_1 & \bar{D}_{12} & \cdots & \bar{D}_{1,r-1} & \bar{D}_{1r} \\ O & \bar{D}_2 & \cdots & \bar{D}_{2,r-1} & \bar{D}_{2r} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ O & O & \cdots & \bar{D}_{r-1} & \bar{D}_{r-1,r} \\ O & O & \cdots & O & \bar{D}_r \end{pmatrix} \tag{4.10}$$

be the CCF of $\tilde{D}$ (cf. § 2). Since $\bar{D}$ is obtained from $\tilde{D}$ by the transformation (2.3) with nonsingular S over $\mathbf{Q}(s)$, we have $\det \bar{D} = \rho_0(s) \cdot \det \tilde{D}$ with $\rho_0(s) \in \mathbf{Q}(s) - \{0\}$. Furthermore, we may assume, by virtue of (A2), that $\rho_0(s)$ is a (possibly negative) power of s, i.e.,

$$\begin{aligned} \det \bar{D}(s; t_1, \cdots, t_d) &= \prod_{k=1}^{r} \det \bar{D}_k(s; t_1, \cdots, t_d) \\ &= \alpha_0 s^{p_0} \cdot \det \tilde{D}(s; t_1, \cdots, t_d) \quad (\alpha_0 \in \mathbf{Q}(s) - \{0\}, p_0 \in \mathbf{Z}) \end{aligned} \tag{4.11}$$

and that each entry of $\bar{D}$ belongs to $\mathbf{Q}[s, \mathcal{S}, \mathcal{K}, t_1, \cdots, t_d]$.

LEMMA 4.3. *For* $k = 1, \cdots, r$,

$$\det \bar{D}_k(s; 1, \cdots, 1) = \rho_k(s) \cdot \bar{\psi}_k(s) \tag{4.12}$$

where $\bar{\psi}_k(s) \in \mathbf{Q}[s, \mathcal{S}, \mathcal{K}] - \mathbf{Q}[s]$ *is irreducible and* $\rho_k(s) \in \mathbf{Q}[s]$.

Proof. Denote by $\mathcal{T}_i$ the set of elements of $\mathcal{T} \equiv \mathcal{S} \cup \mathcal{K}$ contained in the row of $\tilde{D}$ corresponding to t_i $(i = 1, \cdots, d)$ (cf. (4.8)). Put $f(\mathcal{T}_1, \cdots, \mathcal{T}_d; t_1, \cdots, t_d) = \det \bar{D}_k$ that is irreducible in $\mathbf{Q}(s)[\mathcal{T}_1, \cdots, \mathcal{T}_d, t_1, \cdots, t_d]$ by Lemma 2.3(1). From the expression

$$f(\mathcal{T}_1, \cdots, \mathcal{T}_d; t_1, \cdots, t_d) = \left(\prod_{t_i \in \mathcal{N}(\bar{D}_k)} t_i \right) \cdot f\left(\frac{\mathcal{T}_1}{t_1}, \cdots, \frac{\mathcal{T}_d}{t_d}; 1, \cdots, 1 \right)$$

(where the notation $\mathcal{T}_i / t_i$ $(i = 1, \cdots, d)$ on the right-hand side means substituting a / t_i for each indeterminate $a \in \mathcal{T}_i$), it follows that $\det \bar{D}_k(s; 1, \cdots, 1)$ is irreducible in $\mathbf{Q}(s)[\mathcal{S}, \mathcal{K}]$, completing the proof. □

When index sets $\bar{\Psi}_1$ and $\bar{\Psi}_2$ are defined by

$$\bar{\Psi}_1 = \{k \mid \bar{D}_k \text{ contains a variable of } \mathcal{S} \text{ and no variable of } \mathcal{K}\}, \tag{4.13a}$$

$$\bar{\Psi}_2 = \{k \mid \bar{D}_k \text{ contains a variable of } \mathcal{K}\}, \tag{4.13b}$$

Lemma 2.3 implies that

$$\bar{\psi}_k(s) = \bar{\psi}_k(s, \mathcal{S}) \in \mathbf{Q}[s, \mathcal{S}] - \mathbf{Q}[s], \qquad k \in \bar{\Psi}_1, \tag{4.14a}$$

$$\bar{\psi}_k(s) = \bar{\psi}_k(s, \mathcal{S}, \mathcal{K}) \in \mathbf{Q}[s, \mathcal{S}, \mathcal{K}] - \mathbf{Q}[s, \mathcal{S}], \qquad k \in \bar{\Psi}_2 \tag{4.14b}$$

where $\bar{\psi}_k(s)$ is defined by (4.12). Combining (4.5), (4.9), (4.11), (4.12), and (4.14), we see that

$$\{\psi_k(s, \mathcal{S}) \mid k \in \Psi_1\} = \{\bar{\psi}_k(s, \mathcal{S}) \mid k \in \bar{\Psi}_1\}, \tag{4.15a}$$

$$\{\psi_k(s, \mathcal{S}, \mathcal{K}) \mid k \in \Psi_2\} = \{\bar{\psi}_k(s, \mathcal{S}, \mathcal{K}) \mid k \in \bar{\Psi}_2\} \tag{4.15b}$$

where in these expressions two polynomials are considered equal if they are equal up to a nonzero multiplicative factor in $\mathbf{Q}$. To sum up, the decomposition (4.5) of $\det D(s)$ into irreducible factors is determined, up to a factor of monomial of s, by the CCF of $\tilde{D}$ of (4.8).

THEOREM 4.1. *Assume* (A1), (A2), *and* (A3) *as well as the nonsingularity of* $D(s)$ *of* (4.1). *The fixed polynomial* $\psi(s)$ *is given by*

$$\psi(s) = \alpha_1 s^{p_1} \prod_{k \in \bar{\Psi}_1} \bar{\psi}_k(s, \mathcal{S}) = \alpha_2 s^{p_2} \prod_{k \in \bar{\Psi}_1} \det \bar{D}_k(s),$$

where $\alpha_i \in \mathbf{Q} - \{0\}$ *and* $p_i \in \mathbf{Z}$ *for* $i = 1, 2$.

Proof. This follows from Lemma 4.1 and (4.15). □

This theorem shows that there exist no nonzero fixed modes if and only if $\bar{\psi}_k(s, \mathcal{S}) \in \mathbf{Q}[\mathcal{S}]$ for all $k \in \bar{\Psi}_1$. This condition can be stated in combinatorial terms as follows.

Recalling that $\bar{D}_k$ is an LM-matrix with respect to $\mathbf{Q}(s)$, express it in the form of (2.2) as

$$\bar{D}_k = \begin{pmatrix} \bar{Q}_k \\ \bar{T}_k \end{pmatrix}. \tag{4.16}$$

Put $\bar{C} = \mathrm{Row}\,(D) \cup \mathrm{Col}\,(D)$ and define $\zeta : \bar{C} \to \mathbf{Z}$ with reference to (4.4) by

$$\zeta(j) = \begin{cases} -r_j & \text{if } j \in \mathrm{Row}\,(D), \\ -c_j & \text{if } j \in \mathrm{Col}\,(D), \end{cases} \tag{4.17}$$

and

$$\zeta(J) = \sum_{j \in J} \zeta(j), \qquad J \subseteq \bar{C}.$$

Then

$$\deg_s \det \bar{Q}_k[\mathrm{Row}\,(\bar{Q}_k), J] = p_0 + \zeta(J) \tag{4.18}$$

for all $J \subseteq \bar{C}_k \equiv \mathrm{Col}\,(\bar{D}_k) \subseteq \bar{C}$ such that $\bar{Q}_k[\mathrm{Row}\,(\bar{Q}_k), J]$ is nonsingular, where p_0 is independent of J.

For $J \subseteq \bar{C}_k$ such that $\bar{T}_k[\mathrm{Row}\,(\bar{T}_k), J]$ is nonsingular, we denote by $\xi_k(J)$ and $\eta_k(J)$ the highest and lowest degrees in s of a nonzero term in $\det \bar{T}_k[\mathrm{Row}\,(\bar{T}_k), J]$.

(Note $\xi_k(J)$ and $\eta_k(J)$ can be computed by solving a bipartite weighted-matching problem. See also § 5.)

Then, we have

$$\deg_s \bar{\psi}_k(s) = \max\{\zeta(\bar{C}_k - J) + \xi_k(J) \mid J \in \mathcal{B}_k\} - \min\{\zeta(\bar{C}_k - J) + \eta_k(J) \mid J \in \mathcal{B}_k\} \tag{4.19}$$

where

$$\mathcal{B}_k = \{J \subseteq \bar{C}_k \mid \bar{Q}_k[\mathrm{Row}(\bar{Q}_k), \bar{C}_k - J] \text{ and } \bar{T}_k[\mathrm{Row}(\bar{T}_k), J] \text{ are nonsingular}\}, \tag{4.20}$$

since no cancellation occurs among terms with distinct J in the generalized Laplace expansion

$$\det \bar{D}_k = \sum_{J \in \mathcal{B}_k} \det \bar{Q}_k[\mathrm{Row}(\bar{Q}_k), \bar{C}_k - J] \cdot \det \bar{T}_k[\mathrm{Row}(\bar{T}_k), J].$$

Hence we obtain the following lemma concerning the nonzero fixed modes.

LEMMA 4.4. *Assume* (A1), (A2), *and* (A3) *as well as the nonsingularity of* $D(s)$ *of* (4.1). *The number of nonzero fixed modes is given by*

$$\sum_{k \in \bar{\Psi}_1} [\max\{\zeta(\bar{C}_k - J) + \xi_k(J) \mid J \in \mathcal{B}_k\} - \min\{\zeta(\bar{C}_k - J) + \eta_k(J) \mid J \in \mathcal{B}_k\}].$$

The combinatorial characterization of the nonexistence of fixed modes is now obtained, on the basis of which an efficient algorithm is designed in the next section.

THEOREM 4.2. *Assume* (A1), (A2), *and* (A3) *as well as the nonsingularity of* $D(s)$ *of* (4.1).

(1) $\lambda = 0$ *is not a fixed mode if and only if*

(C1) $D(0)$ *is nonsingular, i.e., there exist* $I \subseteq \mathrm{Row}(D)$ *and* $J \subseteq \mathrm{Col}(D)$ *such that* $Q^0[\mathrm{Row}(D) - I, \mathrm{Col}(D) - J]$ *and* $(T^0 + \hat{K})[I, J]$ *are nonsingular*;

(2) *The multiplicity of the zero fixed mode is given by*

$$\min\{\zeta(\bar{C} - J) + \eta(J) \mid J \in \mathcal{B}\} - \zeta(R)$$

where

$$\mathcal{B} = \{J \subseteq \bar{C} \mid \tilde{Q}[\mathrm{Row}(\tilde{Q}), \bar{C} - J] \text{ and } \tilde{T}[\mathrm{Row}(\tilde{T}), J] \text{ are nonsingular}\},$$

and $\eta(J)$ *is the lowest degree in* s *of a nonzero term in* $\det \tilde{T}[\mathrm{Row}(\tilde{T}), J]$ (*cf.* (4.8)).

(3) *There exist no nonzero fixed modes if and only if*

(C2) *For each* $k \in \bar{\Psi}_1$,

$$\max\{\zeta(\bar{C}_k - J) + \xi_k(J) \mid J \in \mathcal{B}_k\} = \min\{\zeta(\bar{C}_k - J) + \eta_k(J) \mid J \in \mathcal{B}_k\}.$$

Proof. (1) By Lemmas 4.2 and 2.1 applied to $D(0) = Q^0 + (T^0 + \hat{K})$ that is a mixed matrix with respect to $\mathbf{Q}$.

(2) See [26], or § 27 of [28].

(3) By Theorem 4.1, there exist no nonzero fixed modes if and only if $\deg_s \bar{\psi}_k(s) = 0$ for all $k \in \bar{\Psi}_1$ that is, in turn, equivalent to (C2) by (4.19). □

5. Algorithm of testing for the existence of fixed modes. In this section we describe an efficient algorithm for checking for the existence of fixed modes by means of Theorem 4.2. It is based on the algorithmic characterization of the irreducible components of the CCF of an LM-matrix (see § 22 of [28]) as well as on the fundamental facts concerning the independent-flow problem [13]. It would be interesting to compare this algorithm with those for testing the structural controllability (cf. [27] and § 29 of [28]) and for computing the dynamical degree (cf. [26] and § 27 of [28]).

First, note that (C1) in Theorem 4.2 can be checked readily by the efficient algorithm for computing the rank of a mixed matrix that uses arithmetic operations on rational numbers only [28], [31].

Before describing the concrete procedure for (C2), we will outline the basic idea in general terms. As shown in [28] and [32], the rank of an LM-matrix can be computed on the basis of Lemma 2.1 by finding a maximum independent flow [13] in a certain network and, moreover, the CCF can be obtained from the strong components [21] (or strongly connected components [1]) of the auxiliary network $\bar{N}$ associated with the maximum independent flow. By introducing appropriate costs associated with arcs, the quantities $\max\{\zeta(\bar{C}_k - J) + \xi_k(J)\}$ and $\min\{\zeta(\bar{C}_k - J) + \eta_k(J)\}$ appearing in (C2) are expressed as the maximum and the minimum of the cost of an independent flow in the strong component that corresponds to the block $\bar{D}_k$ of the CCF. If each arc in $\bar{N}$ is given the "length" $\bar{\gamma}$ that represents the imputed cost, then (C2) is equivalent to the graph-theoretic condition that there exists no directed cycle of nonzero length in the strong component. This condition is amenable to an efficient algorithm since, as noted in [27], this is equivalent to the existence of potentials associated with vertices such that the length of an arc is the difference of the potentials of the endvertices.

The concrete description of the algorithm for (C2) is as follows. It works with an auxiliary network $\bar{N} = (\bar{V}, \bar{A}; \bar{\gamma})$ with underlying graph $(\bar{V}, \bar{A})$ and length function $\bar{\gamma}$. Put $R = \mathrm{Row}\,(D)$, $C = \mathrm{Col}\,(D)$, and $V_Q = R_Q \cup C_Q$, $V_T = R_T \cup C_T$, where R_Q and R_T [respectively, C_Q and C_T] are disjoint copies of R [respectively, C]. Denote by $\varphi_Q : R \cup C \to R_Q \cup C_Q$ and $\varphi_T : R \cup C \to R_T \cup C_T$ the one-to-one correspondences. The vertex set $\bar{V}$ is defined as

$$\bar{V} = V_Q \cup V_T = (R_Q \cup C_Q) \cup (R_T \cup C_T). \tag{5.1}$$

The arc set $\bar{A}$ consists of five disjoint parts as follows:

$$\bar{A} = B_* \cup B^* \cup A_Q \cup A_T \cup A_M, \tag{5.2}$$

to be defined by (5.3), (5.4), (5.6), (5.7), and (5.8) below. The initial and terminal vertices of an arc $a \in \bar{A}$ are denoted, respectively, as $\partial^+ a$ and $\partial^- a$.

Denoting by $\hat{I} \subseteq R$ and $\hat{J} \subseteq C$ those subsets I and J that attain the maximum in Lemma 2.1 applied to $D(s)$ of (4.1), we put

$$B_* = \{(\varphi_T(i), \varphi_Q(i)) \mid i \in \hat{I}\} \cup \{(\varphi_T(j), \varphi_Q(j)) \mid j \in C - \hat{J}\}, \tag{5.3}$$

$$B^* = \{(\varphi_Q(i), \varphi_T(i)) \mid i \in R - \hat{I}\} \cup \{(\varphi_Q(j), \varphi_T(j)) \mid j \in \hat{J}\}. \tag{5.4}$$

Remark 5.1. Provided that $D(s)$ is nonsingular, both $Q_D(s)[R - \hat{I}, C - \hat{J}]$ and $T_D(s)[\hat{I}, \hat{J}]$ are nonsingular. Such a pair $(\hat{I}, \hat{J})$ can be found by an efficient algorithm using arithmetic operations in $\mathbf{Q}$ without involving s, since

$$\mathrm{rank}\, Q_D(s)[R - I, C - J] = \mathrm{rank}\, Q_D(1)[R - I, C - J], \qquad I \subseteq R, \quad J \subseteq C,$$

by (A2) and

$$\mathrm{rank}\, T_D(s)[I, J] = \text{term-rank}\, T_D(1)[I, J], \qquad I \subseteq R, \quad J \subseteq C,$$

by (A1) and (A3). See [28] and [31].

Let P be the pivotal transform of $Q \equiv Q_D(1) = Q^0 + Q^1$ with pivot $\hat{Q} \equiv Q[R-\hat{I}, C-\hat{J}]$, i.e., Row $(P) = (C-\hat{J}) \cup \hat{I}$, Col $(P) = (R-\hat{I}) \cup \hat{J}$, and

$$P = \begin{array}{c} \\ C-\hat{J} \\ \hat{I} \end{array} \begin{pmatrix} R-\hat{I} & \hat{J} \\ \hat{Q}^{-1} & \hat{Q}^{-1}Q[R-\hat{I}, \hat{J}] \\ -Q[\hat{I}, C-\hat{J}]\hat{Q}^{-1} & Q[\hat{I}, \hat{J}] - Q[\hat{I}, C-\hat{J}]\hat{Q}^{-1}Q[R-\hat{I}, \hat{J}] \end{pmatrix}. \tag{5.5}$$

With reference to P, we define

$$A_Q = \{(\varphi_Q(i), \varphi_Q(j)) \mid P_{ij} \neq 0,\ i \in (C-\hat{J}) \cup \hat{I},\ j \in (R-\hat{I}) \cup \hat{J}\}, \tag{5.6}$$

representing the linear dependence among the columns of the matrix $(I_d \mid Q_D)$ in (4.8).

The structure of T_D is represented by A_T and A_M. A_T has a one-to-one correspondence with the transcendental elements, i.e.,

$$A_T = \mathcal{S} \cup \mathcal{K} = \mathcal{N}(T^0) \cup \mathcal{N}(T^1) \cup \mathcal{N}(\hat{K}) \tag{5.7}$$

where we set $\partial^+ a = \varphi_T(i) \in R_T$ and $\partial^- a = \varphi_T(j) \in C_T$ if $a \in A_T$ is in the (i, j) entry of T_D. Note that parallel arcs can exist (e.g., if $T^0_{ij} T^1_{ij} \neq 0$). Since $T_D[\hat{I}, \hat{J}]$ is nonsingular, the bipartite graph $G_T = (R_T \cup C_T, A_T)$ with vertex set $R_T \cup C_T$ and arc set A_T has a matching $M (\subseteq A_T)$ such that $|M| = |\hat{I}| (= |\hat{J}|)$ and M covers $\hat{I}$ and $\hat{J}$ (i.e., $\hat{I} = \{\partial^+ a \mid a \in M\}$, $\hat{J} = \{\partial^- a \mid a \in M\}$). We define A_M as the set of reoriented arcs of M:

$$A_M = \{\bar{a} \mid a \in M\} \tag{5.8}$$

where $\bar{a}$ denotes the reorientation of a, i.e., $\partial^+ \bar{a} = \partial^- a$ and $\partial^- \bar{a} = \partial^+ a$.

The length $\bar{\gamma}: \bar{A} \to \mathbf{Z}$ is defined with reference to r_i and c_i $(i = 1, \cdots, d)$ of (4.4) as follows:

$$\begin{aligned}
&\bar{\gamma}(a) = r_i \quad \text{if } a = (\varphi_T(i), \varphi_Q(i)) \in B_*, \quad i \in \hat{I}, \\
&\bar{\gamma}(a) = c_j \quad \text{if } a = (\varphi_T(j), \varphi_Q(j)) \in B_*, \quad j \in C-\hat{J}, \\
&\bar{\gamma}(a) = -r_i \quad \text{if } a = (\varphi_Q(i), \varphi_T(i)) \in B^*, \quad i \in R-\hat{I}, \\
&\bar{\gamma}(a) = -c_j \quad \text{if } a = (\varphi_Q(j), \varphi_T(j)) \in B^*, \quad j \in \hat{J}, \\
&\bar{\gamma}(a) = 0 \quad \text{if } a \in A_Q, \\
&\bar{\gamma}(a) = 0 \quad \text{if } a \in \mathcal{N}(T^0) \cup \mathcal{N}(\hat{K}) \subseteq A_T, \\
&\bar{\gamma}(a) = 1 \quad \text{if } a \in \mathcal{N}(T^1) \subseteq A_T, \\
&\bar{\gamma}(a) = -\bar{\gamma}(a') \quad \text{if } a \in A_M \text{ is the reorientation of } a' \in M \subseteq A_T.
\end{aligned} \tag{5.9}$$

It may be noted here that $\bar{N}$ is defined with reference to a particular choice of $(\hat{I}, \hat{J})$ for the matrix $D(s)$, and without direct reference to $\bar{D}(s)$; however, the strong components of $\bar{N}$ are known to be determined independently of the choice of $(\hat{I}, \hat{J})$, and $\bar{D}(s)$ can be constructed easily from the strong components of $\bar{N}$.

Now we are ready to rephrase (C2) of Theorem 4.2 in terms of the network $\bar{N}$. For each strong component $\hat{G} = (\hat{V}, \hat{A})$ of $\bar{N}$ (where $\hat{V} \subseteq \bar{V}$, $\hat{A} \subseteq \bar{A}$), we consider the

condition that the sum of the lengths $\bar{\gamma}(a)$ along any directed cycle $\hat{C}$ in $\hat{G}$ is equal to zero, i.e.,

$$\sum_{a\in\hat{C}} \bar{\gamma}(a)=0 \quad (\forall \hat{C}\text{: directed cycle in } \hat{G}). \tag{5.10}$$

As observed in [27] and [28] (see also Remark 5.2 below), this condition is equivalent to the existence of a "potential" function $\pi: \hat{V}\to \mathbf{Z}$ such that

$$\bar{\gamma}(a)=\pi(\partial^- a)-\pi(\partial^+ a) \quad (\forall a\in \hat{A}). \tag{5.11}$$

THEOREM 5.1. *Assume* (A1), (A2), *and* (A3) *as well as the nonsingularity of* $D(s)$ *of* (4.1). *Condition* (C2) *in Theorem* 4.2 *holds if and only if*

(C3) *Each strong component of* $\bar{N}$ *either contains an arc of* $\mathcal{K}$ *or admits a potential function* π *such that* (5.11) *holds.*

Proof. First recall that the strong components on $\bar{N}$ correspond essentially to the irreducible diagonal blocks $\bar{D}_k$ of $\bar{D}$ of (4.10). As shown in § 4 (cf. (4.12)), we have

$$\det \bar{D}_k(s; 1, \cdots, 1)=\alpha_k s^{p_k}\cdot \bar{\psi}_k(s, \mathcal{S}, \mathcal{K})$$

with $\alpha_k\in\mathbf{Q}$, $p_k\in\mathbf{Z}$, and $\bar{\psi}_k(s, \mathcal{S}, \mathcal{K})\in \mathbf{Q}[s, \mathcal{S}, \mathcal{K}]-\mathbf{Q}[s]$ being irreducible. This polynomial $\bar{\psi}_k$ does not contain s, i.e., $\bar{\psi}_k\in\mathbf{Q}[\mathcal{S}, \mathcal{K}]$ if and only if the strong component corresponding to $\bar{D}_k$ satisfies (5.10). □

The overall computational complexity of testing (C1) and (C2), as well as testing for nonsingularity of $D(s)$, is dominated by that for the construction of the network $\bar{N}$ and is bounded by $O(d^3 \log d)$ in the worst case [9] and is usually much smaller than this worstcase bound (cf. [27] for the detail). Note also that the decomposition of $\bar{N}$ into strong components can be found [1] in time of $O(|\bar{A}|)$ and the potential function of (5.11) for a strong component $(\hat{V}, \hat{A})$, if any, can be found by constructing a spanning tree (cf. Remark 5.2) in time of $O(|\hat{A}|)$. It should be emphasized here that the whole algorithm involves only pivoting operations on the rational matrix Q_D whose entries are simple numbers such as ± 1 in practical applications.

Remark 5.2. The potential function π of (5.11) can be constructed as follows. First observe that, since $\hat{G}$ is strongly connected, (5.10) is equivalent to the condition that the length of a path depends only on the initial and terminal vertices of the path, i.e.,

$$\sum_{a\in P_1} \bar{\gamma}(a)=\sum_{a\in P_2} \bar{\gamma}(a)$$

if P_1 and P_2 are directed paths such that $\partial^+ P_1=\partial^+ P_2$ $(=u)$ and $\partial^- P_1=\partial^- P_2$ $(=v)$. In fact, taking a directed path P' with $\partial^+ P'=v$ and $\partial^- P'=u$ (such P' exists since $\hat{G}$ is strongly connected), we see

$$\sum_{a\in P_1} \bar{\gamma}(a)+\sum_{a\in P'} \bar{\gamma}(a)=0=\sum_{a\in P_2} \bar{\gamma}(a)+\sum_{a\in P'} \bar{\gamma}(a)$$

by (5.10). Hence the following procedure is valid: First fix a spanning tree $\hat{T}\subseteq \hat{A}$ and a vertex $u\in\hat{V}$; and for each $v\in\hat{V}$, set $\pi(v)$ equal to the length of the path in $\hat{T}$ connecting u to v; and finally check for the condition (5.11) for each $a\in\hat{A}-\hat{T}$.

Remark 5.3. The number of nonzero fixed modes can be computed efficiently based on Lemma 4.4 by solving the so-called independent-flow problem [13], [17] for each strong component of $\bar{N}$. The number of zero fixed modes can also be computed efficiently based on the formula of Theorem 4.2(2) using the matroid union/intersection algorithm.

Remark 5.4. In the particular case as treated in Pichai, Sezer, and Šiljak [33], the present characterization (i.e., Theorem 4.2 and Theorem 5.1) reduces to the graph-theoretic conditions given in Theorem 4 of [33], as follows.

When a system is described by (1.1) with "structured" matrices A, B, and C, having independent nonzero entries, and the feedback structure is specified by another "structured" matrix K, we have

$$Q_D = \begin{pmatrix} -sI & O & O \\ O & -I & O \\ O & O & -I \end{pmatrix}, \qquad T_D = \begin{pmatrix} A & B & O \\ O & O & K \\ C & O & O \end{pmatrix}$$

in (4.1) (see Remark 4.1). Note that the row-set R and the column-set C both correspond to the union of the sets X, U, and Y of variables $\mathbf{x}$, $\mathbf{u}$, and $\mathbf{y}$; let $\nu_R : R \to X \cup U \cup Y$ and $\nu_C : C \to X \cup U \cup Y$ denote the correspondence.

Then it is easy to see (by Linkage Lemma; cf., e.g., Proposition 7.1 of [28]) that (C1) in Theorem 4.2 is equivalent to (ii) in Theorem 4 of [33]. To define the network $\bar{N}$, we can choose $\hat{I} = \varnothing$, $\hat{J} = \varnothing$, since Q_D is nonsingular. The arc set of $\bar{N}$ consists of the following:

$$B_* = \{(\varphi_T(j), \varphi_Q(j)) \mid j \in C\},$$

$$B^* = \{(\varphi_Q(i), \varphi_T(i)) \mid i \in R\},$$

$$A_Q = \{(\varphi_Q(j), \varphi_Q(i)) \mid \nu_R(i) = \nu_C(j),\ i \in R, j \in C\},$$

$$A_T = \mathcal{N}(A) \cup \mathcal{N}(B) \cup \mathcal{N}(C) \cup \mathcal{N}(K),$$

$$A_M = \varnothing.$$

Note that B_*, B^*, and A_Q are in one-to-one correspondence to $X \cup U \cup Y$, and that cycles in $\bar{N}$ are in one-to-one correspondence to the cycles in the graph used in [33].

The matrix Q_D above satisfies (A2) with r_i and c_j in (4.4) defined as follows: $r_i = 1$ if $\nu_R(i) \in X$ and $=0$ otherwise; $c_j = 0$ for $j \in C$. Then the length $\bar{\gamma}(a)$ equals -1 if $a = (\varphi_Q(i), \varphi_T(i)) \in B^*$ and $\nu_R(i) \in X$, and vanishes otherwise. As easily seen, a strong component of $\bar{N}$ cannot admit a potential function π unless it consists of a single vertex. Therefore (i) in Theorem 4 of [33] implies (C3) in Theorem 5.1. Conversely, suppose (C3) holds together with (C1). Condition (C1) implies that the four vertices of $\bar{N}$ corresponding to one x-vertex are contained in a strong component of $\bar{N}$, which cannot admit a potential function, and therefore must contain an arc of $\mathcal{K}$. Thus, (C1) and (C3) together (in this special case) are equivalent to the two conditions given in Theorem 4 of [33]. See also Example 6.2.

6. Example.

Example 6.1. The algorithm described in § 5 as well as the derivation in § 4 is illustrated here by means of an example. Consider a matrix D of (4.1) (with $d = 9$)

given by

$$Q^0+sQ^1 = \begin{array}{c} \\ w_1 \\ w_2 \\ w_3 \\ w_4 \\ w_5 \\ w_6 \\ w_7 \\ w_8 \\ w_9 \end{array} \begin{array}{c} \begin{array}{ccccccccc} x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & x_7 & x_8 & x_9 \end{array} \\ \begin{pmatrix} 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & s & 0 & s & 0 \\ 1 & 0 & 1 & 0 & -1 & -s & s & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -s & 0 & -s & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \end{array},$$

$$T^0+sT^1 = \begin{array}{c} \\ w_1 \\ w_2 \\ w_3 \\ w_4 \\ w_5 \\ w_6 \\ w_7 \\ w_8 \\ w_9 \end{array} \begin{array}{c} \begin{array}{ccccccccc} x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & x_7 & x_8 & x_9 \end{array} \\ \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & sf_1 & 0 & 0 & 0 & 0 & a_1 & 0 & 0 \\ 0 & a_2 & sf_2 & a_3 & a_4 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_5 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_6 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_7 & a_8 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & a_9 & sf_3 & 0 & 0 & 0 \end{pmatrix} \end{array},$$

$$\hat{K} = \begin{array}{c} \\ w_1 \\ w_2 \\ w_3 \\ w_4 \\ w_5 \\ w_6 \\ w_7 \\ w_8 \\ w_9 \end{array} \begin{array}{c} \begin{array}{ccccccccc} x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & x_7 & x_8 & x_9 \end{array} \\ \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & k_1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & k_2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & k_3 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & k_4 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \end{array}.$$

Assumption (A2) is satisfied, where (4.4) holds true with

$$(r_1, \cdots, r_9) = (0, 0, 0, 0, 0, 0, 0, 1, 0),$$
$$(c_1, \cdots, c_9) = (0, 0, 0, 0, 0, -1, -1, -1, 1).$$

Note $\mathcal{S} = \{a_1, \cdots, a_9\} \cup \{f_1, \cdots, f_3\}$ and $\mathcal{K} = \{k_1, \cdots, k_4\}$.

By direct calculation we obtain

$$\det D = [s] \cdot [(a_9 - f_3)(f_1 f_2 s^2 - a_2)] \cdot [k_2(k_1 s + 1)(a_7 s - k_4 s + a_7 k_3 - a_6 k_4)]$$

where the brackets [ ] correspond to the three parts in (4.5). From this expression it follows by Lemma 4.1 that

$$\psi(s) = s \cdot (a_9 - f_3) \cdot (f_1 f_2 s^2 - a_2),$$

or

$$\psi(s) = s \cdot (f_1 f_2 s^2 - a_2),$$

since $(a_9 - f_3) \in \mathbf{C}$; note also that (4.7) holds with $\alpha = 1$ and $p = 1$.

The associated LM-matrix $\tilde{D}$ of (4.8) is given by

$$\tilde{D} = \left(\begin{array}{ccccccccc|ccccccccc}
w_1 & w_2 & w_3 & w_4 & w_5 & w_6 & w_7 & w_8 & w_9 & x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & x_7 & x_8 & x_9 \\
1 & & & & & & & & & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
 & 1 & & & & & & & & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
 & & 1 & & & & & & & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 & & & 1 & & & & & & -1 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
 & & & & 1 & & & & & 0 & 0 & 0 & 0 & 1 & s & 0 & s & 0 \\
 & & & & & 1 & & & & 1 & 0 & 1 & 0 & -1 & -s & s & 0 & 0 \\
 & & & & & & 1 & & & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 & & & & & & & 1 & & -s & 0 & -s & 0 & 0 & 0 & 0 & 0 & 1 \\
 & & & & & & & & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
-t_1 & & & & & & & & & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & k_1 \\
 & -t_2 & & & & & & & & 0 & sf_1 & 0 & 0 & 0 & 0 & a_1 & 0 & 0 \\
 & & -t_3 & & & & & & & 0 & a_2 & sf_2 & a_3 & a_4 & 0 & 0 & 0 & 0 \\
 & & & -t_4 & & & & & & 0 & 0 & 0 & k_2 & 0 & 0 & 0 & 0 & 0 \\
 & & & & -t_5 & & & & & 0 & 0 & 0 & 0 & 0 & 0 & k_3 & 0 & a_5 \\
 & & & & & -t_6 & & & & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_6 & 0 \\
 & & & & & & -t_7 & & & 0 & 0 & 0 & 0 & 0 & 0 & k_4 & a_7 & a_8 \\
 & & & & & & & -t_8 & & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 & & & & & & & & -t_9 & 0 & 0 & 0 & 0 & a_9 & sf_3 & 0 & 0 & 0
\end{array}\right).$$

By choosing, e.g.,

$$S = \begin{pmatrix}
1 & & & & & & & & \\
 & 1 & & & & & & & \\
 & & 1 & & & & & & \\
1 & & & 1 & & & & & \\
-1 & & & & 1 & 1 & & & \\
-1 & & & & & 1 & & & \\
 & & & & & & 1 & & \\
s & & & & & & & 1 & \\
 & & & & & & & & 1
\end{pmatrix}$$

in (2.3), we obtain the CCF $\bar{D}$ of (4.10):

$$\bar{D} = \left(\begin{array}{ccccccccccccccccc}
x_1 & w_2 & x_2 & x_3 & w_3 & x_4 & w_4 & x_5 & x_6 & w_9 & w_5 & w_6 & x_7 & x_8 & w_7 & w_1 & x_9 & w_8 \\
1 & & & 1 & & & & & & & & & & & & 1 & & \\
 & 1 & 0 & 1 & & & & & & & & & & & & & & \\
 & -t_2 & sf_1 & 0 & & & & & & & & & a_1 & & & & & \\
 & 0 & a_2 & sf_2 & -t_3 & a_3 & & a_4 & & & & & & & & & & \\
 & & & & 1 & & & & & & & & & & & & & \\
 & & & & & k_2 & -t_4 & & & & & & & & & & & \\
 & & & & & & 1 & & & & & & & & & 1 & & \\
 & & & & & & & -1 & -s & & & 1 & s & & & -1 & & \\
 & & & & & & & a_9 & sf_3 & -t_9 & & & & & & & & \\
 & & & & & & & & & 1 & & & & & & & & \\
 & & & & & & & & & & 1 & 1 & s & s & & -1 & & \\
 & & & & & & & & & & 0 & -t_6 & 0 & a_6 & & & & \\
 & & & & & & & & & & -t_5 & 0 & k_3 & 0 & & & a_5 & \\
 & & & & & & & & & & 0 & 0 & k_4 & a_7 & -t_7 & & a_8 & \\
 & & & & & & & & & & & & & & 1 & & & \\
 & & & & & & & & & & & & & & & s & 1 & 1 \\
 & & & & & & & & & & & & & & & -t_1 & k_1 & \\
 & & & & & & & & & & & & & & & & & -t_8
\end{array}\right).$$

The CCF $\bar{D}$ has 11 blocks with the following column sets: $\bar{C}_1 = \{x_1\}$, $\bar{C}_2 = \{w_2, x_2, x_3\}$, $\bar{C}_3 = \{w_3\}$, $\bar{C}_4 = \{x_4\}$, $\bar{C}_5 = \{w_4\}$, $\bar{C}_6 = \{x_5, x_6\}$, $\bar{C}_7 = \{w_9\}$, $\bar{C}_8 = \{w_5, w_6, x_7, x_8\}$, $\bar{C}_9 = \{w_7\}$, $\bar{C}_{10} = \{w_1, x_9\}$, $\bar{C}_{11} = \{w_8\}$.

The index sets of (4.13) are given by

$$\bar{\Psi}_1 = \{2, 6\}, \qquad \bar{\Psi}_2 = \{4, 8, 10\}$$

and $\bar{\psi}_k(s)$ of (4.12) for $k \in \bar{\Psi}_1 \cup \bar{\Psi}_2$ are as follows:

$$\bar{\psi}_2(s) = (f_1 f_2 s^2 - a_2), \qquad \bar{\psi}_6(s) = (a_9 - f_3),$$

$$\bar{\psi}_4(s) = k_2, \quad \bar{\psi}_8(s) = (a_7 s - k_4 s + a_7 k_3 - a_6 k_4), \quad \bar{\psi}_{10}(s) = (k_1 s + 1)$$

where note also that $\det \bar{D}_6 = s \cdot \bar{\psi}_6$.

We now apply the algorithm of § 5. Suppose we have found (cf. § 20 of [28])

$$\hat{I} = \{w_2, w_3, w_4, w_5, w_7, w_9\}, \qquad \hat{J} = \{x_2, x_3, x_4, x_6, x_7, x_8\},$$

and a matching

$$M = \{a_7, f_1, f_2, f_3, k_2, k_3\}.$$

Then we have the matrix P of (5.5) as follows:

$$P = \begin{array}{c} \\ x_1 \\ x_5 \\ x_9 \\ w_2 \\ w_3 \\ w_4 \\ w_5 \\ w_7 \\ w_9 \end{array} \begin{array}{c} \begin{array}{cccccccccc} w_1 & w_6 & w_8 & x_2 & x_3 & x_4 & x_6 & x_7 & x_8 \end{array} \\ \left(\begin{array}{cccccccccc} 1 & & & & 1 & & & & \\ 1 & -1 & & & & & 1 & -1 & \\ 1 & & 1 & & & & & & \\ & & & & 1 & & & & \\ & & & & & & & & \\ 1 & & & & & & & & \\ -1 & 1 & & & & & & 1 & 1 \\ & & & & & & & & \\ & & & & & & & & \end{array} \right) \end{array}$$

and the auxiliary network $\bar{N}$ as depicted in Fig. 6.1; we write $x_i^T = \varphi_T(x_i)$, $x_i^Q = \varphi_Q(x_i)$, etc. In Fig. 6.1, the five subsets in (5.2) can be identified as follows: an arc belongs to B_* if it is of the form (w_i^T, w_i^Q) or (x_j^T, x_j^Q); to B^* if (w_i^Q, w_i^T) or (x_j^Q, x_j^T); to A_T if (w_i^T, x_j^T); to A_M if (x_j^T, w_i^T); and to A_Q otherwise. The associated length $\bar{\gamma}(a)$ of (5.9) is as follows: $\bar{\gamma}(a) = 1$ if

$$a \in \{(x_6^Q, x_6^T), (x_7^Q, x_7^T), (x_8^Q, x_8^T), (x_9^Q, x_9^T), (w_2^T, x_2^T), (w_3^T, x_3^T), (w_9^T, x_6^T)\};$$

$\bar{\gamma}(a) = -1$ if

$$a \in \{(w_8^Q, w_8^T), (x_2^T, w_2^T), (x_3^T, w_3^T), (x_6^T, w_9^T)\};$$

and $\bar{\gamma}(a) = 0$ otherwise.

The blocks in the CCF are determined from the strong components of $\bar{N}$. In particular, the strong component $\hat{G}_2$ consisting of $\{w_2^T, w_2^Q, w_3^T, x_2^T, x_3^T, x_3^Q\}$ and $\hat{G}_6$ of $\{w_9^T, x_5^T, x_5^Q, x_6^T, x_6^Q\}$ correspond to the diagonal blocks of $\{2, 6\} = \bar{\Psi}_1$. These two strong components are extracted in Fig. 6.2, where the length $\bar{\gamma}(a)$ is attached in parentheses to each arc a.

Theorem 5.1 reveals that $\hat{G}_2$ brings about nonzero fixed modes since it contains a directed cycle of nonzero length. On the other hand $\hat{G}_6$, having no directed cycle of nonzero length, introduces no nonzero fixed modes; $\hat{G}_6$ admits a potential function π: $\pi(x_6^T) = 1$, $\pi(w_9^T) = \pi(x_5^T) = \pi(x_5^Q) = \pi(x_6^Q) = 0$. We also see by Theorem 4.2(1) that $\lambda = 0$ is a fixed mode since $D(0)$ is singular; furthermore, by Theorem 4.2(2), $\lambda = 0$ is simple (i.e., with multiplicity one).

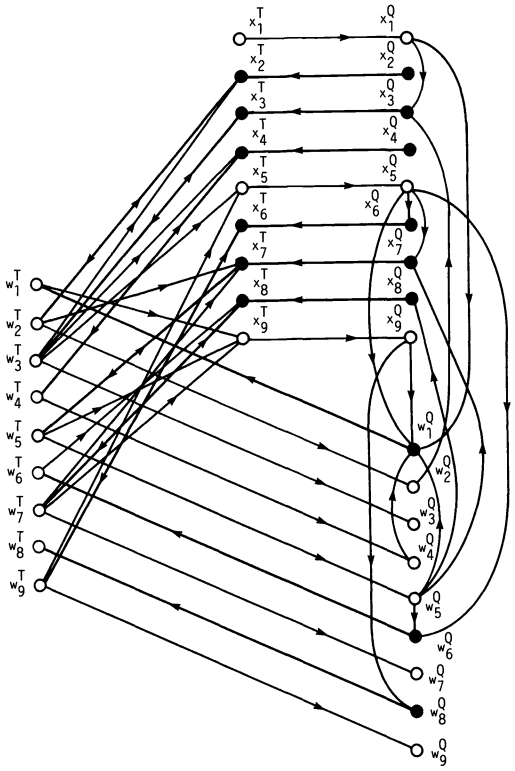

FIG. 6.1. *Auxiliary network* $\bar{N}$.

Example 6.2. Consider a scalar system in the state-space form (1.1) with $A=(0)$, $B=(b)$, $C=(c)$, and $K=(0)$. Obviously, this system has a simple fixed mode at $\lambda=0$, and no nonzero fixed modes. This fact is also revealed by Theorem 4.2(2) and (3). In particular, we see that $\lambda=0$ is a fixed mode since (C1) fails to hold, and that no nonzero fixed modes exist since (C2) (or equivalently (C3) in Theorem 5.1) holds true. In contrast, neither of the two conditions in Theorem 4 of Pichai, Sezer, and Šiljak [33] is satisfied. This shows that the conditions in [33] do not separate the existence of zero and nonzero fixed modes.

Example 6.3. Consider a decentralized system with three local stations described in the state space form (1.1) with

$$A=\begin{pmatrix} 0 & a_1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ a_2 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \qquad B=\begin{pmatrix} 0 & 0 & 0 \\ b_1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & b_2 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & b_3 \end{pmatrix},$$

and $C=I_6$, where a_1, a_2, b_1, b_2, b_3 are independent transcendentals; the feedback structure is specified by

$$K=\begin{pmatrix} k_1 & k_2 & 0 & 0 & 0 & 0 \\ 0 & 0 & k_3 & k_4 & 0 & 0 \\ 0 & 0 & 0 & 0 & k_5 & k_6 \end{pmatrix}.$$

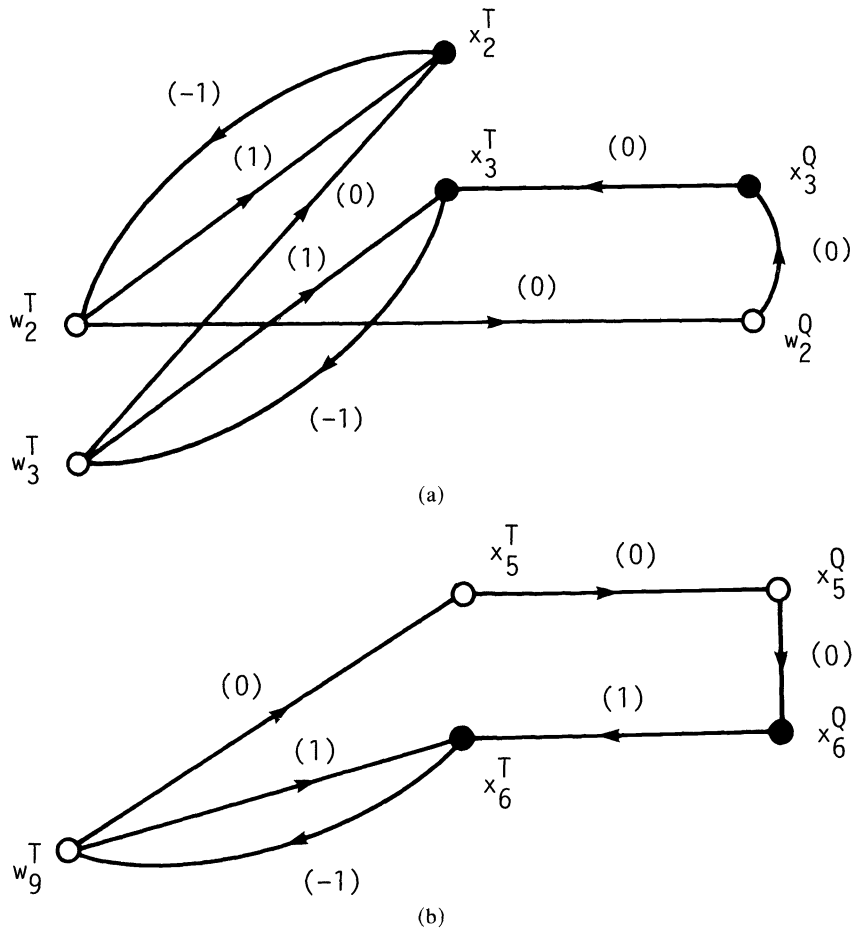

FIG. 6.2. *Strong components of* $\bar{\Psi}_1$. (a) *Strong component* $\hat{G}_2$. (b) *Strong component* $\hat{G}_6$.

(See Example 4 of Reinschke [33] and the references cited therein.)

The matrix Q_D in (4.1) is given by

$$Q_D = \begin{pmatrix} Q_A - sI_6 & O & O \\ O & -I_3 & O \\ I_6 & O & -I_6 \end{pmatrix}$$

where

$$Q_A = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

and satisfies (A2) with

$$(r_1, \cdots, r_{15}) = (1, 1, 1, 2, 1, 2; 0, 0, 0; 0, 0, 0, 1, 0, 1),$$
$$(c_1, \cdots, c_{15}) = (0, 0, 0, 1, 0, 1; 0, 0, 0; 0, 0, 0, 1, 0, 1)$$

Theorem 4.2 (as well as Theorem 5.1) reveals the fact that this system possesses the only fixed mode at $\lambda = 0$. The graph-theoretic criterion of Pichai, Sezer, and Šiljak [33] cannot detect this kind of fixed mode since $\lambda = 0$ would no longer be a fixed mode if the four unities in Q_A were replaced with independent variables.

7. Conclusion. The CCF of the matrix D of (3.2) provides a uniquely defined hierarchical decomposition of the set of variables $(\mathbf{x}, \mathbf{y}, \mathbf{u})$, where it is remembered that those variables correspond to the columns of the matrix D. The decomposition thus obtained is a generalization of the decomposition of the whole system into strongly connected subsystems that has played fundamental roles in various situations and is used, in particular, by Corfmat and Morse [8] in connection with the problem of pole assignment. In fact, when the system is in the usual state-space form (i.e., $F = I$, $G = I$, $H = I$ in (3.2)) and all the nonzero entries of A, B, C, and K are regarded as independent parameters (i.e., $Q_A = O$, $Q_B = O$, $Q_C = O$, and $Q_K = O$ in (3.4)), the decomposition of $(\mathbf{x}, \mathbf{y}, \mathbf{u})$ by means of the CCF agrees with the decomposition with respect to strong connectedness.

The hierarchical decomposition of $(\mathbf{x}, \mathbf{y}, \mathbf{u})$ induced by the CCF of D reveals which part of $\mathbf{x}$ depends on which part of the feedback loops. In particular, elimination of the feedback loops represented by those elements of $\mathcal{K}$ not contained in the diagonal blocks $\bar{D}_k$ in (4.10) never gives rise to fixed modes.

It is left for future investigation to clarify the practical significance of the decomposition by the CCF in relation to the pole assignment by dynamic compensation.

Acknowledgments. The author thanks Professor S. Shin of the University of Tsukuba for discussion. The comments of the anonymous referees were also helpful in revision.

A REMARK ON SIMULATED ANNEALING OF DIFFUSION PROCESSES*

G. ROYER†

Abstract. It is proved that simulated annealing for Kolmogorov processes takes place, as expected, for a cooling schedule corresponding to a fundamental constant of Wentzell and Freidlin.

Key words. diffusion, simulated annealing, large deviations

AMS(MOS) subject classifications. GOH10, GOJ70

1. Statement of the result. In their recent works Chiang, Hwang, and Sheu have proved convergence in law for diffusion processes Z_t on $\mathbb{R}^d$ ruled by

$$dZ_t = \varepsilon(t)\, dW_t - \nabla U(Z_t)\, dt, \tag{1}$$

$$\varepsilon(t) = \left(\frac{c}{\log(t)}\right)^{1/2} \qquad \text{(say for } t > 2\text{)} \tag{2}$$

toward a precise distribution supported by the set where the function U attains its global minimum. They get this result for $c > \frac{3}{2}\Lambda$, Λ being a fundamental nonnegative constant defined below, and conjectured that the condition $c > \Lambda$ is sufficient. In this note we prove this conjecture. Our method is just a patchwork combining estimates by Chiang, Hwang, and Sheu and by Gidas, Davies, and Simon.

We make the following assumptions:

(3_a) U is a C^2 function such that $U(\infty) = \infty$, $|\nabla U|(\infty) = \infty$, and $|\nabla U|^2 - \Delta U$ is bounded from below.

(3_b) The set of stationary points of U has a finite number of connected components.

Let us describe how Λ appears. When $\varepsilon > 0$ is fixed, the Kolmogorov process X_t^ε ruled by

$$dX_t^\varepsilon = \varepsilon\, dW_t - \nabla U(X_t^\varepsilon)\, dt \tag{4}$$

admit

$$\mu_\varepsilon = Z_\varepsilon^{-1} \exp(-2U/\varepsilon^2) \tag{5}$$

as invariant and reversible probability measure (the normalization constant Z is finite from hypothesis (3_a)). So we may view its transition semigroup P_t^ε as a semigroup of autoadjoint contractions in $L^2(\mu_\varepsilon)$. The corresponding infinitesimal generator is characterized by its action on test functions with compact support φ

$$L_\varepsilon(\varphi) = \frac{\varepsilon^2}{2}\Delta\varphi - \nabla U \cdot \nabla\varphi,$$

and the hypotheses on U ensures that its spectrum is discrete [7, Vol. IV, p. 120]. Let $\lambda(\varepsilon)$ be the first positive eigenvalue of L_ε and $\Lambda = \lim_{\varepsilon\to 0} -\varepsilon^2 \log(\lambda(\varepsilon))$.

Under the preceding hypothesis, Hwang and Sheu have established in [6], by purely probabilistic methods, the existence of $\Lambda = \lim_{\varepsilon\to 0} -\varepsilon^2 \log(\lambda(\varepsilon))$; they proved that $\Lambda \geqq 0$ and also give a formula for Λ. These results have their prototype in the book by Freidlin and Wentzell [3, p. 208].

Now we can state our slight improvement of the result of Chiang, Hwang, and Sheu. Let $\|\cdot\|$ be the total variation of a measure and let $P_{Z_t^x}$ be the law of a process satisfying (1), (2).

THEOREM 1.1. *If $c > \Lambda$, for any x, then $\|P_{Z_t^x} - \mu_{\varepsilon(t)}\|$ converges to zero when $t \to \infty$.*

We note that in most cases it is easy to prove the convergence of μ_ε when $\varepsilon \to 0$.

2. Proof. Let us sketch the strategy that we will follow. For annealing processes with finite or compact state space and discrete time, the annealing speed rate c (for a kind of convergence such as those in the preceding theorem) is directly linked with large deviations results for eigenvalues (see [4], [8]). On the other hand, the behavior of U at infinity is, to some extent, irrelevant for the calculus of Λ as well as c. In particular, in [1, p. 748], Theorem 1.1 is reduced to the "supernormal case," i.e., the case where $U(x) = |x|^4$ for $|x|$ greater than some fixed R_0 and (accessory) $\inf(U) = 0$. Fortunately, in this case some hypercontractive estimates of Nelson are available, under a suitable control when ε varies. We will therefore restrict ourselves to the supernormal case in the sequel. To begin, we adapt a lemma of Gidas [4] to a hypercontractive situation; we denote by Y_n a nonhomogenous Markov chain with arbitrary state space E and transition kernel N_n from n to $n+1$ (i.e., $E(f(Y_{n+1}) \mid Y_n) = (N_n f)(Y_n)$).

LEMMA 2.1. *Let (Y_n, N_n) defined for $n \geqq n_0$, obey the following hypotheses:*

(1°) *N_n admit reversible probabilities π_n and these π_n are mutually absolutely continuous.*

(2°) *For some constant K_n, for all measurable functions f on E,*

$$\|N_n f\|_{L^4(\pi_n)} \leqq K_n \|f\|_{L^2(\pi_n)}.$$

(3°) *Let $1 - r_n = \sup\{\|N_n f\|_2 / \|f\|_2;\ f \in L^2(\pi_n)$ and $\int f\, d\pi_n = 0\}$; then $\sum_{n \geqq n_0} r_n = +\infty$.*

(4°) *There exist constants $\gamma_n < 1$ and functions φ_n such that*

(a) $|\pi_{n+1} - \pi_n| \leqq \gamma_n \pi_n + \varphi_n \pi_{n+1}$, *as an inequality between measures,*

(b) $\gamma_n / r_n \to 0$,

(c) $K_n^2 \|\varphi_n\|_{L^2(\pi_n)} / r_n \to 0$.

(5°) *Y_n admit a density g_n with respect to π_n, and g_{n_0} is square-integrable.*

Then $\|P_{Y_n} - \pi_n\|$ converges to zero.

Proof. Suppose that $g_n \in L^2(\pi_n)$; then $N_n g_n$ is defined in $L^2(\pi_n)$ and from the reversibility of π_n, we easily get

$$g_{n+1}\pi_{n+1} = (N_n g_n)\pi_n. \tag{6}$$

Moreover, as $\gamma_n < 1$, $\pi_n \leqq ((1+\varphi_n)/(1-\gamma_n))\pi_{n+1}$. Let us denote in what follows by $\|\cdot\|_p$ the norm in $L^p(\pi_n)$. We have

$$\int g_{n+1}^2\, d\pi_{n+1} = \int (N_n g_n) g_{n+1}\, d\pi_n \leqq (1-\gamma_n)^{-1} \int (1+\varphi_n)(N_n g_n)^2\, d\pi_n$$

$$\leqq (1-\gamma_n)^{-1} \|1+\varphi_n\|_2 \|N_n g_n\|_4^2 \leqq (1-\gamma_n)^{-1} K_n^2 \|1+\varphi_n\|_2 \|g_n\|_2^2 < \infty.$$

Let $y_n = \int (1-g_n)^2\, d\pi_n = -1 + \int g_n^2\, d\pi_n$; from (6) we get

$$y_{n+1} = \int (1 - N_n g_n)^2\, d\pi_n + \int g_{n+1} N_n g_n (d\pi_n - d\pi_{n+1})$$

$$\leqq \int (N_n(1-g_n))^2\, d\pi_n + \gamma_n \int g_{n+1}^2\, d\pi_{n+1} + \int \varphi_n (N_n g_n)^2\, d\pi_n$$

$$\leqq (1-r_n)^2 y_n + \gamma_n (1 + y_{n+1}) + K_n^2 \|\varphi_n\|_2 (1 + y_n)$$

and finally

$$y_{n+1} \leqq a_n y_n + b_n, \tag{7}$$

where

$$a_n(1-\gamma_n) = (1-r_n)^2 + K_n^2 \|\varphi_n\|_2, \quad \text{and} \quad b_n(1-\gamma_n) = \gamma_n + K_n^2 \|\varphi_n\|_2.$$

Hypothesis (3°) yields $\prod_{n \geqq n_0} a_n = 0$ and $b_n/(1-a_n) \to 0$, and from (7) we easily deduce $y_n \to 0$ and a fortiori the lemma. □

To use this lemma, we will consider a process obtained by replacing in (1) the function $\varepsilon(t)$ by a stepwise function that is constant on each interval of some sequence $[t_n, t_{n+1}[$ and that takes there the value $e(n) = \varepsilon(t_n)$ (sometimes denoted also e_n below). It happens that the simple choice $t_n = n$ leads to processes that diverge too much from Z_t; instead we use $t_n = \sum_{k=1}^{n-1} k^{-\alpha}$, where $0 < \alpha < 1$. Later the exponent α will be chosen small enough. We have

$$e_n^{-2} \sim \left(\frac{1-\alpha}{c}\right) \log(n). \tag{8}$$

Precisely, we define inductively a process Y_n, as follows, for n no less than an n_0 to be fixed later; for Y_{n+1} we take the value at a certain time τ_n of the Kolmogorov process $X_t^{e(n)}$ with initial value Y_n (and naturally we impose that the Wiener process of (4) be independent of the Y_k, $k \leqq n$). The value of τ_n is chosen to easily compare Z_{t_n} to Y_n: as in [1], by the time change $t \to \beta(n, t)$ determined by

$$\int_{t_n}^{\beta(n,t)} \varepsilon^2(u)/e^2(n)\, du = t,$$

any annealing process (1) is transformed after t_n into $Z_{\beta(n,t)}$ owning the same martingale component (in law) $e(n) W_t$ as $X_t^{e(n)}$. So to compare the transition from Z_{t_n} to $Z_{t_{n+1}}$ to the transition from Y_n to Y_{n+1} we set $\beta(n, \tau_n) = t_{n+1}$, i.e., $\tau_n = \int_{t_n}^{t_{n+1}} \log(t_n)/\log(u)\, du$; it is easily seen that $\tau_n \sim n^{-\alpha}$. Now, we study why Lemma 2.1 applies to our Y_n. Hypothesis (1°) is satisfied with $\pi_n = \mu_{e(n)}$ given by (5), and $N_n = P_{\tau_n}^{e(n)}$. Using $P_t^\varepsilon = \exp(tL_\varepsilon)$, we see that $r_n = 1 - \exp(-\tau_n \exp((-\Lambda + \rho(n))/e_n^2))$, where $\lim \rho(n) = 0$; thus,

$$r_n \sim n^{-1+(1-\alpha)(1-\Lambda/c)} \tag{9}$$

and condition (3°) reduces to $c > \Lambda$.

Explicit constants for hypercontractivity are established in [2]. We now deduce K_n from this article; let ψ_ε be the groundstate of the Schrödinger operator $-\Delta + V_\varepsilon$ in $L^2(dx)$ that is unitarily equivalent to $-\underline{L}_\varepsilon = -2\varepsilon^{-2} L_\varepsilon = -\Delta + 2\varepsilon^{-2} \nabla U \cdot \nabla$. We know (see [2] that ψ_ε^2 is the density of μ_ε and that $V_\varepsilon = \varepsilon^{-4} |\nabla U|^2 - \varepsilon^{-2} \Delta U$.

LEMMA 2.2. *For some constant k_0 and small enough positive ε and δ, in the operator sense* $-2 \log(\psi_\varepsilon) \leqq \delta(-\Delta + V_\varepsilon) + k_0 \varepsilon^{-2} + (\varepsilon^2/4\delta^2)$.

Proof. We have $-2 \log(\psi_\varepsilon) = 2U\varepsilon^{-2} + \log(Z_\varepsilon)$; as $\varepsilon^2 \log(Z_\varepsilon) \to 0$ when $\varepsilon \to 0$ (recall that $\inf(U) = 0$), the corresponding term can be absorbed by $k\varepsilon^{-2}$.

$$2U \leqq \delta(\varepsilon^{-2} |\nabla U|^2 - \Delta U) + k_1 + \varepsilon^4/4\delta^2. \tag{10}$$

For $|x| \geqq R_0$, we have

$$U(x) = |x|^4, \quad \nabla U(x) = 4x|x|^2, \quad \Delta U(x) = 12|x|^2,$$

and for small δ we may use $2U(x) + \delta \Delta U(x) \leqq 4|x|^4$.

If $|x| \geqq \sup(R_0, \varepsilon(4\delta)^{-1/2})$, $4|x|^4 \leqq \delta\varepsilon^{-2} |\nabla U|^2(x)$ and (10) is valid.

If $R_0 \leqq |x| \leqq \varepsilon(4\delta)^{-1/2}$, $4|x|^4 \leqq \varepsilon^4/4\delta^2$ and (10) is also verified.

Finally, we can choose k_1 large enough to majorize $2U - \delta \Delta U$ for $|x|$ smaller than R_0. □

Lemma 2.2 provides us with the necessary estimate to apply Theorem 4.2 via Theorems 4.6 and 5.1 of [2]. We get that if

$$t = \int_2^4 \left(\frac{\delta}{p}\right) dp = \delta \log(2), \tag{11}$$

then

$$\|e^{-tL_\varepsilon} f\|_4 \leqq e^M \|f\|_2 \tag{12}$$

with

$$M = \int_2^4 2bp^{-2}\, dp = \frac{b}{2} \quad \text{and} \quad b = A - \frac{d \log(\delta)}{4} + k_0 \varepsilon^{-2} + \frac{\varepsilon^2}{4\delta^2}. \tag{13}$$

This last formula corresponds to (5.2) in [2], where the constant c can be taken to be zero, because $-L_\varepsilon$ is positive in $L^2(\mu_\varepsilon)$. (A is a constant depending only on the dimension d.) To get a hypercontractive estimate for N_n, we must use (12) for $t = \tau_n e_n^2/2$, so we choose $\delta = \tau_n e_n^2/2 \log(2)$, so (12), (13) gives a constant K_n such that

$$\log(K_n) \sim k \log(n) n^{2\alpha} \quad \text{with } k = (1-\alpha)\frac{\log^2(2)}{2c}. \tag{14}$$

To verify hypothesis (4°), we recall the formula

$$\frac{\partial}{\partial \beta} \nu_\beta(x) = -(U(x) - \bar{U}_\beta)\nu_\beta(x) \tag{15}$$

for the density of probability $\nu_\beta(x) = Z_\beta^{-1} \exp(-\beta U(x))$, where $\bar{U}_\beta$ is the mean of U with respect to ν_β, and β is a positive number (identified with $2\varepsilon^{-2}$ below). We denote by H_n the compact set $\{U \leqq n^{3\alpha}\}$. As $\bar{U}_\beta$ vanishes when β goes to infinity, using (15) we see that, when restricted to the exterior of H_n, π_{n+1} is smaller than π_n for n large; so (4°)(a) holds on $H_n^c = \mathbb{R}^d - H_n$ if we let φ_n be the restriction of the density π_n/π_{n+1} to H_n^c; then elementary Laplace theory yields $\log \|\varphi_n\|_{L^2(\pi_n)} \sim -((1-\alpha)/c) \log(n) n^{3\alpha}$. This estimate, joined to (9) and (14) gives (4°)(c). Let us study (4°)(a) on H_n; let x belong to H_n and $\beta_n = 2e_n^{-2}$; from (15) we get, if n is large enough to ensure $\bar{U}_\beta \leqq n^{3\alpha}$ for any $\beta \geqq \beta_n$:

$$|\nu_{\beta_{n+1}}(x) - \nu_{\beta_n}(x)| \leqq n^{3\alpha}(\beta_{n+1} - \beta_n) \sup\{\nu_\beta(x);\ \beta_n < \beta < \beta_{n+1}\}.$$

On the other hand, for any x and $\beta_n \leqq \beta \leqq \beta_{n+1}$ $\nu_\beta(x)/\nu_{\beta_n}(x) \leqq \exp((\beta_{n+1} - \beta_n) n^{3\alpha})/\nu_{\beta_n}(H_n)$; since $\beta_{n+1} - \beta_n \sim 2(1-\alpha)/cn$ this last quantity converges to one if $\alpha < \frac{1}{3}$. We select such an α and we see that (4°)(a) holds with $\gamma_n = n^{3\alpha}(\beta_{n+1} - \beta_n)$. And the hypothesis (4°)(b) is verified if we choose a small α, due to the estimate (9).

Finally, n_0 will be chosen according to all the conditions "n large enough" that appear above and in the sequel. For Y_{n_0} we take any variable whose law is the normalized restriction of the law of $Z(t_{n_0})$ to a ball; all hypothesis of Lemma 2.1 are fulfilled and therefore $\|P^n_{Y_{n_0}} - \pi_n\|$ converges to zero. To prove the theorem, we must estimate $\Delta_n = \|P_{Z(t_n)} - P_{Y_n}\|$. To begin with, $\varepsilon > 0$ being given, we may realize $\Delta_{n_0} \leqq \varepsilon$ when we build Y_{n_0}. For a given n, let us consider a process $\hat{Z}_t$, $t \geqq t_n$, with the same equation as Z_t but the same law at time t_n as Y_n. Clearly the law at time t_{n+1} of $\hat{Z}$ and Z will differ of a quantity less than Δ_n; thus

$$\Delta_{n+1} \leqq \Delta_n + d_{n+1} \quad \text{where } d_{n+1} = \|P_{Y_{n+1}} - P_{\hat{Z}(t_{n+1})}\|. \tag{16}$$

To bound d_{n+1}, we must compare at time τ_n two processes with the same initial law P_{Y_n}: $X_t^{e(n)}$ that obey (4), and $\bar{Z}_t := \hat{Z}_{\beta(n,t)}$; the time change β has been defined so that

$$d\bar{Z}_t = e(n)\, d\bar{W}_t - \nabla U(\bar{Z}_t) e^2(n) \varepsilon^{-2}(\beta(n,t))\, dt. \tag{17}$$

Let us first study how the law of X_t concentrates. From the proof of Lemma 2.1, we know that the density g_n has a norm bounded in L^2 by a constant a: so we have $P(Y_n \in K_p^c) \leqslant a(\pi_n(K_p^c))^{1/2}$ for any compact $K_p = \{U \leqslant p\}$, and the last quantity is for $c' > c(1-\alpha)^{-1}$ and n large majorized by $n^{-2p/c'}$; as the exponent $1+(\alpha/2)$ reappears below we call it s and we fix p so that

$$P(Y_n \in K_p^c) \leqq n^{-s}. \tag{18}$$

Let T_r be the exit time of the open ball B_r centered at zero. For a Kolmogorov process with parameter $e(n)$, starting from a point $x \in K_p$, we have for r suitably chosen and n large

$$P_x^{e(n)}(T_r \leqq 1) \leqq n^{-s} \quad \text{for } x \in K_p \tag{19}$$

it suffices to apply a result of Freidlin and Wentzell [3, p. 105], since the action

$$S = \inf\left\{\frac{1}{2}\int_0^1 |\dot{\varphi}(s) + \nabla U(\varphi(s))|^2\, ds\right\},$$

$$\varphi,\ \varphi(0) \in K_p, \quad \exists s \in [0,1] |\varphi(s)| \geqq r$$

can be made as large as we want (it is no less than $\inf_{x \in K_p, y \in B_r^c}\{2(U(y) - U(x))\}$).

Let χ be the indicator function of the event $\{|X_s| < r \text{ for } 0 \leqq s \leqq \tau_n\}$, ($X_s^{e(n)}$ is shortened to X_s), and let $\bar{\chi}$ be the analogous function relative to $\bar{Z}$. We have the Girsanov formula

$$E(\bar{\chi} f(\bar{Z}_{\tau_n}) - \chi f(X_{\tau_n})) = E((\varphi - 1)\chi f(X_{\tau_n})). \tag{20}$$

Because χ is present, we can modify U into $\bar{U}$ outside B_r to get a function with gradient bounded by M, and use as φ the martingale $\varphi = \exp(A - B/2)$ with

$$A = -\int_0^{\tau_n} e^{-1}(n) \nabla \bar{U}(X_u) q(u)\, dW_u, \qquad B = \int_0^{\tau_n} e^{-2}(n) |\nabla \bar{U}|^2(X_u) q^2(u)\, du,$$

$$q(u) = e^2(n)\varepsilon^{-2}((\beta(n,u))) - 1 = (\log(\beta(n,u))/\log(t_n)) - 1.$$

By a martingale argument we get (see [1] for details) $E(|\varphi - 1|) \leqq E^{1/2}((\varphi-1)^2) \leqq \|\exp(B) - 1\|_\infty^{1/2}$, and we have

$$c\|B\|_\infty \leqq M^2 \log(n) \int_0^{\tau_n} q^2(u)\, du \quad \text{(taking } \beta(n,u) = \beta \text{ as variable)}$$

$$= M^2 \int_{t_n}^{t_{n+1}} (\log(\beta) - \log(t_n))^2/\log(\beta)\, d\beta$$

$$\leqq M^2 (t_{n+1} - t_n)^3/3t_n^2 \log(t_n) \sim M^2(1-\alpha) n^{-2-\alpha}/3\log(n)$$

so

$$E(|\varphi - 1|) \leqq n^{-s} \quad \text{for large } n. \tag{21}$$

Now we apply (20), when $f = 1$, to the process conditioned to start at $x \in K_p$; due to estimate (19) we have $E(\chi) \geqq 1 - n^{-s}$ and thus $E(\bar{\chi}) \geqq 1 - 2n^{-s}$; and (20), (21) give $\|P_{\bar{Z}_{\tau(n)^x}} - P_{X_{\tau(n)^x}}\| \leqq 4n^{-s}$. Actually, since the starting distribution verifies only (18) we

have $d_n \leqq 6n^{-s}$, and (16) gives $\Delta_n \leqq \varepsilon + \sum_{n_0}^{n} 6k^{-s}$. Also, if n_0 is suitably chosen, $\Delta_n \leqq 2\varepsilon$ for $n \geqq n_0$; this proves the theorem since ε is arbitrary (we have only proved the convergence of the subsequence t_n, but a last step from t_n to t, $t \in [t_n, t_{n+1}[$ can be treated similarly).

Acknowledgment. I thank the referee for his effective help in rectifying the first version of this article.

ERGODIC THEOREMS FOR DISCRETE TIME STOCHASTIC SYSTEMS USING A STOCHASTIC LYAPUNOV FUNCTION*

SEAN P. MEYN†

Abstract. Sufficient conditions are established under which the law of large numbers and related ergodic theorems hold for nonlinear stochastic systems operating under feedback. It is shown that these conditions hold whenever a moment condition is satisfied; this may be interpreted as a generalizaton of the martingale property.

If, in addition, a stochastic controllability condition holds, then it is shown that the underlying distributions governing the system converge to an invariant probability at a geometric rate.

The key assumption used is that a Markov chain with stationary transition probabilities exists that serves as a state process for the closed loop system.

Key words. nonlinear systems, stochastic systems, Lyapunov functions, Markov chains

1. Introduction.

In this paper we study the asymptotic behavior of discrete time nonlinear stochastic systems under feedback. Our principal assumption is that a Markov chain with stationary transition probabilities $\mathbf{\Phi}$ exists that may serve as a state process for the closed loop system.

In a large number of applications $\mathbf{\Phi}$ evolves on a subset $\mathbf{X} \subset \mathbb{R}^n$, and is generated by a nonlinear difference equation

$$\Phi_{k+1} = F(\Phi_k, w_{k+1}), \qquad k \in \mathbb{Z}_+ \tag{1}$$

where the disturbance $\mathbf{w}$ is an independent and indentically distributed (i.i.d.) process on $\mathbb{R}^p$. Under the appropriate smoothness conditions on the function F and the distribution of $\mathbf{w}$, it has been shown in Meyn and Caines (1988) that the asymptotic behavior of $\mathbf{\Phi}$ is determined by invariant probabilities on $\mathbf{X}$ whenever a crude stability condition is satisfied, and the *weak stochastic controllability* condition holds. In this case there exist probabilities $\{\pi_x, \tilde{\pi}_x : x \in \mathbf{X}\}$ such that for every initial condition $\Phi_0 = x \in \mathbf{X}$,

$$\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) = \int f \, d\tilde{\pi}_x \quad \text{a.s. } [P_x], \tag{2}$$

$$\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} E_x[g(\Phi_k)] = \int g \, d\pi_x \tag{3}$$

for a large class of functions f and g on $\mathbf{X}$. When (1) is viewed as a deterministic input/output (i.o.) system with input $\mathbf{w}$ and output $\mathbf{\Phi}$, weak stochastic controllability is equivalent to the forward accessibility criterion used in nonlinear system theory (see Jakubczyk and Sontag (1988)).

It is worth noting that the left-hand side of (2) will be in general a random variable, and hence $\tilde{\pi}_x$ is a *random probability* (i.e., a countably additive function from $\mathcal{B}(\mathbf{X})$ to $L^1(\mathbf{X}^{Z_+}, \mathcal{B}(\mathbf{X}^{Z_+}), P_x)$ with the properties $\tilde{\pi}\{A\} \geqq 0$ almost surely (a.s.) $[P_x]$ for $A \in \mathcal{B}(\mathbf{X})$, and $\tilde{\pi}\{\mathbf{X}\} = 1$ a.s. $[P_x]$). With one or two exceptions (that will be brought to the attention of the reader where they occur), in the present paper only ordinary (deterministic) probabilities will be considered.

In the continuous time case, Φ is typically a diffusion process and the theory of stochastic Lyapunov functions has been a successful tool for assessing its stability properties (see Kushner (1967), Kushner (1972), and Has'minskiĭ (1980)). The idea is that if a positive function $V: \mathbf{X} \to \mathbb{R}_+$ exists such that $V(\Phi_k)$ is a super martingale and hence decreases in an average sense, then under general conditions Φ will converge to a level set of the function V with probability one.

It is reasonable to expect that stochastic Lyapunov functions should be a useful tool in the discrete time case as well, and this is indeed the case (see, for example, Kushner (1967), Solo (1978), and Goodwin, Ramadge, and Caines (1981)). However when Φ is weakly stochastically controllable, the existence of a stochastic Lyapunov function is all but ruled out. In many cases (for example, when V is a quadratic) the level sets of V are sets of Lebesgue measure zero, yet weak stochastic controllability implies that the set of limit points of the sequence

$$\{\Phi_k : k \in \mathbb{Z}_+\} \tag{4}$$

has nonempty interior with probability one for all initial conditions. In fact, for almost every sample path, the set of limit points of (4) is equal to the support of the probability $\tilde{\pi}_x$, that always has nonempty interior under the weak stochastic controllability hypothesis.

In this paper we examine an alternative stochastic Lyapunov function that is perfectly compatible with weak stochastic controllability, and that always exists for stable, linear systems even when conventional stochastic Lyapunov functions do not exist. If Φ is weakly stochastically controllable, then the existence of this Lyapunov function may be used to prove that (3) holds at an exponential rate for a large class of functions g, and will allow us to establish generalizations of (2) and (3) even when the weak stochastic controllability condition is not satisfied.

The existence of the limit (2) for general functions on $\mathbf{X}$ is closely connected to a condition called Harris recurrence (see § 2). The following result is taken from Meyn and Caines (1988) (for the "if" part) and Athreya and Ney (1980) (for the converse) and is valid for general Markov chains on a general state space.

PROPOSITION 1.1. *The Markov chain Φ is positive Harris recurrent if and only if a unique invariant probability π exists, and* (2) *holds with $\tilde{\pi}_x = \pi$ for every positive Borel function $f: \mathbf{X} \to \mathbb{R}_+$ and every initial condition $x \in \mathbf{X}$.*

Hence if Φ is not positive Harris recurrent then there will exist functions on $\mathbf{X}$ for which (2) fails to hold, and it is natural to search for a restricted class of functions for which the law of large numbers does hold.

Take, for example, a Markov chain defined by the linear model

$$\Phi_{k+1} = A\Phi_k + Bw_{k+1} \tag{5}$$

where A and B are, respectively, $n \times n$ and $n \times p$ matrices, $\mathbf{w} = \{w_k : k \geqq 1\}$ is an i.i.d. Gaussian stochastic process on $\mathbb{R}^p$ with $w_k \sim N(0, I)$ for all k, and the deterministic initial condition $\Phi_0 \in \mathbb{R}^n$ is given.

Suppose that the eigenvalues of A fall strictly within the unit disk in $\mathbb{C}$. In this case a unique invariant probability π exists that is supported on the controllability subspace $L \subset \mathbb{R}^n$. Hence if the pair (A, B) is not controllable, then π is supported on a subspace of $\mathbb{R}^n$ whose dimension is strictly less than n. In the case where the matrix A is full rank and the initial condition lies in the complement of the set L, the process Φ will approach the set L at a geometric rate, but never reach it. From these observations it is obvious that the law of large numbers cannot hold for general measurable functions on $\mathbb{R}^n$ when the initial condition lies outside of the set L. Take, for example, $f = \mathbf{1}_L$,

the indicator function of L. In this case the average on the left side of the equality in (2) is equal to zero for each $N \in \mathbb{Z}_+$, and the right-hand side of this equality is equal to one. However it may be verified that (2) will hold for continuous functions (whenever the right-hand side is meaningful) regardless of the controllability of (A, B).

In the theory of recurrent Markov chains, the set L^c would be regarded simply as a set of measure zero on which the process $\mathbf{\Phi}$ is transient. In cases where $\mathbf{\Phi}$ does not satisfy a recurrence condition, some other assumption must be used to connect points in the state space together, and in this paper we accomplish this by supposing that $\mathbf{\Phi}$ evolves on a metric space and that the Feller property holds. When a certain Lyapunov function exists, a complete generalization of the linear example will be established.

2. Preliminaries. Let $\mathbf{X}$ be a locally compact separable metric space. We let $\mathbf{C}$ denote the set of bounded and continuous functions $f: \mathbf{X} \to \mathbb{R}$, and $\mathcal{M}$ the set of probabilities on $\mathcal{B}(\mathbf{X})$, the Borel field on $\mathbf{X}$. A sequence $\{\mu_k : k \in \mathbb{Z}_+\} \subset \mathcal{M}$ of probabilities converges *weakly* to $\mu_\infty \in \mathcal{M}$ if

$$\lim_{k\to\infty} \int f\, d\mu_k = \int f\, d\mu_\infty \tag{6}$$

for all $f \in \mathbf{C}$, and this will be denoted $\mu_k \xrightarrow{\text{weakly}} \mu_\infty$ as $k \to \infty$. It is well known (see Billingsley (1968)) that $\mathcal{M}$ is a metrizable topological space and that a subset $\mathcal{A} \subset \mathcal{M}$ is precompact if and only if it is tight, i.e., for all $\varepsilon > 0$ there exists a compact set $K \subset \mathbf{X}$ such that

$$\mu\{K\} \geqq 1 - \varepsilon, \qquad \mu \in \mathcal{A}.$$

A function $V: \mathbf{X} \to \mathbb{R}_+$ is called a *moment* if there exists a sequence of compact sets $K_n \uparrow \mathbf{X}$ such that

$$\lim_{n\to\infty} \inf_{x \in K_n^c} V(x) = \infty$$

where we adopt the convention that the infimum of a function over the empty set is infinity. It is easily verified that $\mathcal{A} \subset \mathcal{M}$ is tight if and only if a moment V exists such that

$$\sup_{\mu \in \mathcal{A}} \int V\, d\mu < \infty.$$

In Theorem 6.6 of Parthasarathy (1967) it is shown that there exists a sequence of uniformly continuous functions $\{g_n : n \in \mathbb{Z}_+\} \subset \mathbf{C}$ with the property that

$$\mu_k \xrightarrow{\text{weakly}} \mu_\infty \quad \Leftrightarrow \quad \forall n \in \mathbb{Z}_+, \qquad \lim_{k\to\infty} \int g_n\, d\mu_k = \int g_n\, d\mu_\infty. \tag{7}$$

We let P denote a Feller Markov transition function on $(\mathbf{X}, \mathcal{B}(\mathbf{X}))$. That is, for all $x \in \mathbf{X}$, $A \in \mathcal{B}(\mathbf{X})$, and $f \in \mathbf{C}$,

$$P(x, \cdot) \text{ is a probability on } \mathcal{B}(\mathbf{X}),$$

$$P(\cdot, A) \text{ is } \mathcal{B}(\mathbf{X})\text{-measurable},$$

$$\int f(y) P(\cdot, dy) \text{ is continuous.}$$

The k-fold iterates of P are defined inductively by $P^1 \triangleq P$, and

$$P^{k+1}(x, A) \triangleq \int P(x, dy) P^k(y, A),$$

and for $f \in \mathbf{C}$ and $\mu \in \mathcal{M}$ we use the standard notation

$$P^k f(\cdot) \triangleq \int P^k(\cdot, dy) f(y), \qquad \mu P^k(\cdot) \triangleq \int \mu(dx) P^k(x, \cdot).$$

The majority of results in the theory of Markov chains on general state spaces, as well as the results to be presented here, require the following hypothesis (see, for example, Orey (1971) and Nummelin (1984)). We say Φ is *irreducible* if the following condition is satisfied. The event $\{\Phi \text{ enters } A\} \triangleq \cup_{k=0}^{\infty} \{\Phi_k \in A\}$, and the event $\{\Phi \in A \text{ i.o.}\} \triangleq \cap_{N=0}^{\infty} \cup_{k=N}^{\infty} \{\Phi_k \in A\}$.

Irreducibility Hypothesis. There exists a set $A \in \mathcal{B}(\mathbf{X})$, an integer n_0, a number $\lambda_0 > 0$, and a probability φ, such that

(i) $P_x\{\Phi \text{ enters } A\} > 0$ for all $x \in \mathbf{X}$;

(ii) $\sum_{k=1}^{n_0} P_x\{\Phi_k \in E\} \geqq \lambda_0 \varphi\{E\}$ for all $x \in A$, and $E \in \mathcal{B}(\mathbf{X})$.

Φ is called *Harris recurrent* if the following condition from Athreya and Ney (1980) is satisfied.

Recurrence Hypothesis. Φ satisfies the irreducibility hypothesis, and for every $x \in \mathbf{X}$,

$$P_x\{\Phi \text{ enters } A\} = 1.$$

A subset $B \subset \mathbf{X}$ is called *absorbing* if $P(x, B) = 1$ for every $x \in B$. If B is absorbing, then the Markov chain Φ may be restricted to the set B, and B is called a *Harris set* if the restricted process is Harris recurrent.

When Φ is irreducible, the set A used in the irreducibility hypothesis will be called *petite.* It may be verified that if Φ is Harris recurrent and the set A is petite, then it satisfies the smallness condition introduced in Nummelin and Tuominen (1982).

Many of the important limit theorems for Markov chains require the existence of an invariant measure. That is, a σ-finite measure π on $\mathcal{B}(\mathbf{X})$ with the property

$$\pi\{A\} = \int \pi(dx) P(x, A) \quad \text{for all } A \in \mathcal{B}(\mathbf{X}).$$

It is shown in Nummelin (1984), and Orey (1971) that if the recurrence hypothesis holds, then an essentially unique invariant measure π exists. If the invariant measure is finite, then it may be normalized to a probability measure and in this case Φ is called *positive Harris recurrent.*

If Φ is irreducible, then there exists an integer $m \in \mathbb{Z}_+$ called the *period* of Φ, and a collection of sets $\{E_1, \cdots, E_m\}$ with the property that

$$P\mathbf{1}_{E_{i+1}} = \mathbf{1}_{E_i} \quad \text{and} \quad P^m \mathbf{1}_{E_i} = \mathbf{1}_{E_i}$$

for each $1 \leqq i \leqq m$. If Φ is Harris recurrent with invariant measure π, then $\pi\{(\cup E_i)^c\} = 0$.

The following proposition shows that if Φ is positive Harris recurrent and aperiodic ($m = 1$), then its underlying distributions converge to the invariant probability for all initial conditions. If in addition, the distribution of the hitting time $\tau_A \triangleq \min\{k \geqq 1 : \Phi_k \in A\}$ to a petite set A possesses geometrically decaying tails, uniformly for initial conditions lying in A, then the underlying distributions of Φ converge to π at a geometric rate.

Define the total variation norm $\|\mu - \nu\|$ for $\nu, \mu \in \mathcal{M}$ by

$$\|\mu - \nu\| \triangleq \sup \left| \int f d\mu - \int f d\nu \right|$$

where the supremum is taken over all Borel functions $f : \mathbf{X} \to [-1, 1]$.

PROPOSITION 2.1. *Suppose that Φ is positive Harris recurrent and aperiodic with invariant probability π. Then,*

(i) *For each initial condition distribution $\mu \in \mathcal{M}$,*

$$\lim_{k\to\infty} \|\mu P^k - \pi\| = 0.$$

(ii) *If in addition the set $A \in \mathcal{B}(\mathbf{X})$ defined in the recurrence hypothesis satisfies*

$$\sup_{x\in A} E_x[r^{\tau_A}] < \infty, \tag{8}$$

for some $r > 1$, then there exists $\rho < 1$, and an extended real-valued function $M \in L^1(\mathbf{X}, \mathcal{B}(\mathbf{X}), \pi)$ such that for each $x \in \mathbf{X}$,

$$\|\delta_x P^k - \pi\| = \|P^k(x, \cdot) - \pi(\cdot)\| \leqq M(x)\rho^k, \qquad k \in \mathbb{Z}_+.$$

(iii) *If the conditions of* (ii) *hold, and an initial condition distribution $\mu_0 \in \mathcal{M}$ satisfies*

$$E_{\mu_0}[r^{\tau_A}] < \infty,$$

then there exists $\rho < 1$ and $M < \infty$ such that

$$\|\mu_0 P^k - \pi\| \leqq M\rho^k, \qquad k \in \mathbb{Z}_+.$$

(iv) *Suppose that the conditions of* (iii) *hold, and $f: \mathbf{X} \to \mathbb{R}$ satisfies*

$$\sup_{k\in\mathbb{Z}_+} E_{\mu_0}[|f(\Phi_k)|^{1+\delta}] < \infty$$

for some $\delta > 0$. Then there exists $\rho < 1$ and $M < \infty$ such that

$$\left| E_{\mu_0}[f(\Phi_k)] - \int f\, d\pi \right| \leqq M\rho^k, \qquad k \in \mathbb{Z}_+.$$

For a proof of Proposition 2.1(i) see Nummelin (1984). Results (ii) and (iii) may be found in Nummelin and Tuominen (1982) and result (iv) follows from (iii) and Hölder's inequality.

An aperiodic positive Harris recurrent Markov chain is sometimes called *ergodic.* If for all $x \in \mathbf{X}$ there exists $\rho(x) < 1$ and $M(x) < \infty$ such that

$$\|P^k(x, \cdot) - \pi(\cdot)\| \leqq M\rho^k, \qquad k \in \mathbb{Z}_+,$$

then Φ will be called *geometrically ergodic.* This is weaker then the notion of geometric ergodicity introduced in Tweedie (1983), and stronger than that of Nummelin (1984). In § 3 we present sufficient conditions for geometric ergodicity using a stochastic Lyapunov function.

The following stability conditions will be shown to be closely connected to Harris (respectively, positive Harris) recurrence:

(S1) For each initial condition $x \in \mathbf{X}$ and each $\varepsilon > 0$, there exists a compact subset $K \subset \mathbf{X}$ such that

$$P_x\{\Phi \in K \text{ i.o.}\} = \lim_{k\to\infty} P_x\left\{ \bigcup_{i=k}^{\infty} \{\Phi_i \in K\} \right\} \geqq 1 - \varepsilon.$$

(S2) For each initial condition $x \in \mathbf{X}$ and each $\varepsilon > 0$ there exists a compact subset $K \subset \mathbf{X}$ such that

$$\liminf_{k\to\infty} P_x\{\Phi_k \in K\} \geqq 1 - \varepsilon.$$

It may be shown that if a moment V exists such that

$$\liminf_{k\to\infty} V(\Phi_k) < \infty \quad \text{a.s. } [P_x]$$

for each $x \in \mathbf{X}$ then condition (S1) holds, and if

$$\limsup_{k\to\infty} E_x[V(\Phi_k)] < \infty$$

for each $x \in \mathbf{X}$ then condition (S2) is satisfied.

It is evident that condition (S2) implies condition (S1). In Rosenblatt (1971) a strengthening of condition (S1) is used to establish the existence of a σ-finite invariant measure for Feller Markov chains. Condition (S2) is called *boundedness in probability* in Meyn and Caines (1988), and is simply the tightness hypothesis of Billingsley (1968). In Beneš (1968) a similar condition (among other assumptions) is used to establish the existence of an invariant probability for a continuous time Feller Markov process, and under the assumptions already made on $\mathbf{\Phi}$, condition (S2) implies the existence of an invariant probability (see Foguel (1969)).

The following is a simple result, but it appears to be new.

PROPOSITION 2.2. *Suppose that $\mathbf{\Phi}$ satisfies the irreducibility condition with an open petite set A. Then $\mathbf{\Phi}$ is Harris recurrent if and only if condition* (S1) *is satisfied, and $\mathbf{\Phi}$ is positive Harris recurrent if and only if condition* (S2) *holds.*

Similar results may be found in Tuominen and Tweedie (1979). See, in particular, Proposition 3.5 or Theorem 7.1 of that paper. Theorem 7.1 gives sufficient conditions for a generalization of Harris and positive Harris recurrence. In this result it is assumed that the state space is compact, which is much stronger than condition (S2). On the other hand, the conditions that $\mathbf{\Phi}$ is Feller and an open petite set exist are stronger than the remaining hypotheses of Theorem 7.1(i) and (ii).

The proof of Proposition 2.2 will be given below. It would be very useful if Proposition 2.2 held without the assumption that the set A is open. However, this is not the case as can be seen from the following simple example. Let $\mathbf{X} = \mathbb{R}$, and consider the Markov transition function P defined by $P(0, \{0\}) = 1$, and

$$P(x, \{1/2x\}) = 2^{-|x|} \quad \text{for } x \in \mathbb{R},$$
$$P(x, \{0\}) = 1 - 2^{-|x|}, \qquad x \neq 0.$$

The corresponding Markov chain $\mathbf{\Phi}$ has the Feller property, satisfies condition (S2), and satisfies the irreducibility condition with $A = \{0\}$ and $\varphi = \delta_0$. However, $\mathbf{\Phi}$ is *not* Harris recurrent since for any $x \in \mathbf{X}$, $x \neq 0$,

$$P_x\{\Phi_k \neq 0 \text{ for all } k\} = 2^{-|x|}2^{-|x/2|}2^{-|x/4|} \cdots$$
$$= 2^{-2|x|} > 0.$$

Let $\Lambda : \mathbf{X} \times \mathcal{B}(\mathbf{X}) \to [0, 1]$ denote the function

$$\Lambda(x, A) \triangleq P_x\{\mathbf{\Phi} \text{ enters } A\} = P_x\left\{ \bigcup_{k=0}^{\infty} \{\Phi_k \in A\} \right\}. \tag{9}$$

The following result is taken from Orey (1971) and Lemma 4.1 of Cogburn (1975).

LEMMA 2.1. *Let $\mathbf{\Phi}$ be a Feller Markov chain on $\mathbf{X}$, and $B \in \mathcal{B}(\mathbf{X})$.*

(i) *For each $x \in \mathbf{X}$, $\lim_{k\to\infty} \Lambda(\Phi_k, B) = \mathbf{1}_{\{\mathbf{\Phi} \in B \text{ i.o.}\}}$ a.s. $[P_x]$.*

(ii) *If B is open then for each $k \in \mathbb{Z}_+$ the functions*

$$\Lambda(\cdot, B) \quad \text{and} \quad P^k(\cdot, B)$$

are lower semicontinuous.

One important consequence of Lemma 2.1(i) is that if the recurrence hypothesis holds, then $P_x\{\mathbf{\Phi} \in B \text{ i.o.}\} = 1$ for every set $B \in \mathcal{B}(\mathbf{X})$ of positive φ-measure, and every initial condition $x \in \mathbf{X}$. This is called φ-recurrence in Orey (1971) and is, in fact, the usual definition of Harris recurrence (see Nummelin (1984) for further details).

LEMMA 2.2. *Suppose that the irreducibility hypothesis is satisfied with an open petite set A. Then we have the following*:

(i) *If* $K \in \mathcal{B}(\mathbf{X})$ *has positive* φ*-measure, then*

$$\Lambda(x, K) > 0 \quad \text{for all } x \in \mathbf{X}.$$

(ii) *If K is compact, then there exists* $T_0 \in \mathbb{Z}_+$ *such that for all* $x \in K$,

$$\sum_{k=1}^{T_0} P^k(x, A) \geqq \frac{1}{T_0} \quad \text{and} \quad \sum_{k=1}^{2T_0} P^k(x, \cdot) \geqq \frac{\lambda_0}{T_0^2} \varphi\{\cdot\}.$$

Lemma 2.2 shows that when an open petite set exists, all compact sets of positive φ-measure are also petite. Conversely, in the common case where $P: \mathbf{C}_0 \to \mathbf{C}_0$, where $\mathbf{C}_0 \subset \mathbf{C}$ denotes the set of continuous functions on $\mathbf{X}$ that vanish at infinity, it may be shown that every petite set is precompact.

Proof of Lemma 2.2. Result (i) follows immediately from the irreducibility hypothesis.

By Lemma 2.1 and the irreducibility hypothesis, the sets

$$O_n \triangleq \left\{ x \in \mathbf{X}: \sum_{k=1}^{n} P^k(x, A) > \frac{1}{n} \right\}$$

form an open cover of K, and by compactness there exists $T_0 \in \mathbb{Z}_+$ such that $\sum_{k=1}^{T_0} P^k(x, A) > 1/T_0$ for all $x \in K$. This establishes the first inequality in (ii).

The second inequality follows from the first by integrating over the set A and using the irreducibility hypothesis. Assume that T_0 is so large that

$$\sum_{j=1}^{T_0} P^j(y, \cdot) \geqq \lambda_0 \mathbf{1}_{y \in A} \phi(\cdot), \qquad y \in \mathbf{X}.$$

Then for every $B \in \mathcal{B}(\mathbf{X})$ and $x \in K$,

$$\begin{aligned} \sum_{k=1}^{2T_0} P^k(x, B) &\geqq \frac{1}{T_0} \left(\sum_{i=0}^{T_0} P^i \right) \left(\sum_{j=1}^{T_0} P^j \right)(x, B) \\ &\geqq \frac{\lambda_0}{T_0} \left(\sum_{i=0}^{T_0} P^i \right)(x, A) \varphi\{B\} \\ &\geqq \left(\frac{\lambda_0}{T_0^2} \right) \varphi\{B\}. \end{aligned}$$

□

Proof of Proposition 2.2. If $\mathbf{\Phi}$ is Harris recurrent, then for all compact sets K that have positive φ-measure

$$P_x\{\mathbf{\Phi} \in K \text{ i.o.}\} = 1$$

for all $x \in \mathbf{X}$. This follows from the remark below Lemma 2.1. Hence Harris recurrence implies condition (S1).

If $\mathbf{\Phi}$ is positive Harris recurrent, then for each initial condition $x \in \mathbf{X}$ the invariant probability π may be decomposed

$$\pi = \frac{1}{\lambda} \sum_{k=1}^{\lambda} \nu_k^x$$

where $\lambda \in \mathbb{Z}_+$, $\{\nu_k^x: 1 \leqq k \leqq \lambda\}$ are probabilities on $\mathcal{B}(\mathbf{X})$, and for every set $B \in \mathcal{B}(\mathbf{X})$,

$$\lim_{k \to \infty} P_x\{\Phi_{k\lambda + i} \in B\} = \nu_i^x\{B\}.$$

It follows that for all compact sets K,

$$\liminf_{k \to \infty} P_x\{\Phi_k \in K\} \geqq \min_{1 \leqq i \leqq \lambda} \nu_i^x\{K\}$$

and this shows that positive Harris recurrence implies (S2).

We now show that (S1) implies Harris recurrence under the conditions of Proposition 2.2. Let $x \in \mathbf{X}$, $\varepsilon > 0$, and choose a compact set $K \subset \mathbf{X}$ such that

$$P_x\{\Phi \in K \text{ i.o.}\} \geqq 1 - \varepsilon. \tag{10}$$

By the irreducibility condition $\Lambda(x, A) > 0$ for all $x \in \mathbf{X}$, and by lower semicontinuity, the sets

$$\mathcal{O}_\delta \triangleq \{x \in \mathbf{X}: \Lambda(x, A) > \delta\}$$

form an open cover of K. By compactness there exists $\delta > 0$ such that

$$\Lambda(x, A) \geqq \delta \quad \text{for all } x \in K. \tag{11}$$

From this, Lemma 2.1, and (10) it follows that

$$\begin{aligned} P_x\{\lim_{k\to\infty} \Lambda(\Phi_k, A) = 1\} &= P_x\{\limsup_{k\to\infty} \Lambda(\Phi_k, A) \geqq \delta\} \\ &\geqq P_x\{\Phi \in K \text{ i.o.}\} \geqq 1 - \varepsilon. \end{aligned}$$

Since ε is arbitrary it follows that

$$\mathbf{1}_{\{\Phi \in A \text{ i.o.}\}} = \lim_{k\to\infty} \Lambda(\Phi_k, A) = 1 \quad \text{a.s. } [P_x],$$

and hence Φ is Harris recurrent.

If condition (S2) holds then since this implies condition (S1), Φ is Harris recurrent. Since an invariant probability exists when (S2) holds it follows that Φ is positive Harris recurrent. □

We now describe how the irreducibility condition may be established using ideas from nonlinear control theory. For precise definitions and results see § 5, and Meyn and Caines (1988).

For a Markov chain of the form (1), suppose that $\mathbf{X}$ is a smooth n-dimensional manifold, and that the disturbance process $\mathbf{w}$ evolves on an open set $\mathcal{O}_w \subset \mathbb{R}^p$. We call a point $y \in \mathbf{X}$ *attainable* from $x \in \mathbf{X}$ if for some $T \in \mathbb{Z}_+$, and some sequence $(w_1^*, \cdots, w_T^*) \in \mathcal{O}_w^T$,

$$\Phi_T = y \quad \text{when } \Phi_0 = x \text{ and } (w_1, \cdots, w_T) = (w_1^*, \cdots, w_T^*).$$

If for each $x \in \mathbf{X}$, the set of all attainable points from x has nonempty interior, then Φ is called *forward accessible* (see Jakubczyk and Sontag (1990)).

Suppose that the function $F: \mathbf{X} \times \mathbb{R}^p \to \mathbf{X}$ defined in (1) is C^∞, and that the distribution of the disturbance process $\mathbf{w}$ possesses a lower semicontinuous density p_w with $\mathcal{O}_w = \{x \in \mathbb{R}^p : p_w(x) > 0\}$. Under these conditions, the Markov chain Φ is called *weakly stochastically controllable* if it is forward accessible.

It is shown in Meyn and Caines (1988) that if Φ is weakly stochastically controllable, for every $x \in \mathbf{X}$ there exists an open set A_x containing x, and a probability φ_x such that condition (ii) of the irreducibility hypothesis holds.

Suppose now that there exists a distinguished point $x_0 \in \mathbf{X}$ such that for every initial condition $x \in \mathbf{X}$ and every $\varepsilon > 0$, there exists $T_0 \in \mathbb{Z}_+$ and some sequence $(w_1^*, \cdots, w_\infty^*) \in \mathcal{O}_w^\infty$ such that

$$|\Phi_T - x_0| < \varepsilon \quad \text{when } \Phi_0 = x \text{ and } (w_1, \cdots, w_T) = (w_1^*, \cdots, w_T^*), \qquad T \geqq T_0.$$

In this case Φ is called *asymptotically controllable* to x_0. This is actually much weaker than the standard definition but is sufficient for our purposes.

If Φ is weakly stochastically controllable and there exists a point $x_0 \in \mathbf{X}$ such that Φ is asymptotically controllable to x_0, then the irreducibility condition is satisfied with $A = A_{x_0}$ and $\varphi = \varphi_{x_0}$, and Φ is aperiodic.

3. Stochastic Lyapunov functions. In this section we show how stochastic Lyapunov functions may be used to verify the geometric ergodicity conditions of Proposition 2.1, and to hence establish the exponential asymptotic stability of the flow of distributions governing the process $\mathbf{\Phi}$.

Let $V:\mathbf{X}\to\mathbb{R}_+$ be a positive measurable function. The following drift condition was introduced in Kushner (1967) to compute estimates of the probability that a Markov chain will leave a compact set before a given finite time (see Theorem 3, p. 86).

For some $0<\lambda<1$, $K>0$, and all $x\in\mathbf{X}$,

$$PV(x)\leqq\lambda V(x)+K. \tag{12}$$

In terms of the stochastic process $\mathbf{\Phi}$ this condition may be expressed as

$$E[V(\Phi_{k+1})\,|\,\mathcal{F}_k]\leqq\lambda V(\Phi_k)+K$$

where $\mathcal{F}_k$ is the sigma algebra generated by past and present values of $\mathbf{\Phi}$:

$$\mathcal{F}_k\triangleq\sigma\{\Phi_0,\cdots,\Phi_k\}. \tag{13}$$

There is a great deal of motivation for introducing this condition. First, it is a natural generalization of the martingale property: in the degenerate case where $\lambda=1$ and $K=0$ (12) becomes

$$E[V(\Phi_{k+1})\,|\,\mathcal{F}_k]\leqq V(\Phi_k). \tag{14}$$

Hence in this case $(V(\Phi_k),\mathcal{F}_k)$ is a positive supermartingale, and by the martingale convergence theorem (see Doob (1953)) for each initial condition $x\in\mathbf{X}$ there exists a random variable $V_\infty=V_\infty(x)$ such that

$$\lim_{k\to\infty}V(\Phi_k)=V_\infty\quad\text{a.s.}\,[P_x],$$

and furthermore $E_x[V_\infty]\leqq V(x)<\infty$.

A positive function $V:\mathbf{X}\to\mathbb{R}_+$ satisfying (14) is called a *super harmonic* function in Nummelin (1984) and Revuz (1975), and a *stochastic Lyapunov function* in the stochastic systems theory literature.

As mentioned in the Introduction, if a Lyapunov function V satisfying (14) exists whose level sets have zero Lebesgue measure, then $\mathbf{\Phi}$ cannot be weakly stochastically controllable. Furthermore, if the irreducibility condition holds, then (14) implies that the irreducibility measure φ must be singular with respect to the Lebesgue measure, and this is ruled out in a large number of examples. On the other hand, (12) is extremely useful when the irreducibility condition is satisfied.

PROPOSITION 3.1. *Suppose that V is a continuous moment satisfying* (12), *and $\mathbf{\Phi}$ is a Feller Markov chain. If the irreducibility hypothesis holds for an open set $A\subset\mathbf{X}$, and if $\mathbf{\Phi}$ is aperiodic, then $\mathbf{\Phi}$ is geometrically ergodic.*

Similar results may be found in Nummelin (1984) and Nummelin and Tuominen (1982), and the proof will closely follow Theorem 3.1 of that paper. The principal difference between our result and these lies in our consideration of the topology of the state space. Our result also differs in the form of the "test function" V.

A connected result may also be found in the dissertation of Chan (1986) for a Markov chain of the form (1). However, this result relies on an exponential stability hypothesis on the deterministic dynamical system obtained when the disturbance $\mathbf{w}$ is set equal to zero, and a global Lipschitz condition on the function F.

The original inspiration for such test function methods for establishing positive recurrence lies in the paper by Foster (1953).

The hypothesis that V is a continuous moment is not crucial. This property is assumed because it implies that the set $K_t \triangleq \{x \in \mathbf{X}: V(x) \leqq t\}$ is compact, and hence by Lemma 2.2 petite for all t sufficiently large. If this property can be established by some other means for an arbitrary positive measurable function V, then the conclusions of Proposition 3.1 still hold. In fact, in this case the Feller property is no longer needed.

We have recently discovered that, under the conditions of Proposition 3.1, the Central Limit Theorem holds for measurable functions whose square is dominated by V. This result will appear in a sequel to this paper.

The following result exhibits the close relationship between the existence of a function satisfying (12), and the tail of the distribution of the first entrance time to a compact set.

LEMMA 3.1. (i) *Suppose that* $V: \mathbf{X} \to \mathbb{R}_+$ *is a positive measurable function satisfying* (12), *and let* $r \in \mathbb{R}_+$ *satisfy* $1 > r^{-1} > \lambda$. *Then for each* $t > K/(r^{-1} - \lambda)$, *there exists a constant* $B_1 > 0$ *such that for every* $x \in \mathbf{X}$,

$$E_x[r^{\tau_{K_t}}] \leqq B_1 V(x) + B_1.$$

(ii) *Let* $r \geqq 1$ *and* $A \in \mathcal{B}(\mathbf{X})$. *Then with*

$$V(\cdot) \triangleq \mathbf{1}_{A^c}(\cdot) E_{(\cdot)}[r^{\tau_A}]$$

we have

$$PV \leqq r^{-1} V \quad \text{on } A^c$$

and hence (12) *holds if* PV *is uniformly bounded on* A.

Proof. The proof of (ii) follows along the same lines as the proof of Proposition 6.1 of Tweedie (1975).

To prove (i) observe that by (12) we have for every $x \in \mathbf{X}$,

$$rPV(x) \leqq V(x) - ((1 - \lambda r) V(x) - rK). \tag{15}$$

Let $U(x) \triangleq (1 - \lambda r) V(x) - rK$ for $x \in \mathbf{X}$, $\varepsilon \triangleq (1 - \lambda r) t - rK > 0$, and observe that by the conditions of the lemma,

$$\mathbf{1}_{K_t^c}(x) U(x) \geqq \varepsilon \mathbf{1}_{K_t^c}(x) \quad \text{for all } x \in \mathbf{X}. \tag{16}$$

Equation (15) implies that for all $x \in \mathbf{X}$,

$$rP\mathbf{1}_{K_t^c} V(x) \leqq V(x) - U(x) \tag{17}$$

where the operator "$rP\mathbf{1}_{K_t^c}$" is defined for a positive function $f: \mathbf{X} \to \mathbb{R}_+$ by

$$rP\mathbf{1}_{K_t^c} f(x) \triangleq r \int_{K_t^c} P(x, dy) f(y).$$

Applying this operator to both sides of (17) gives

$$\begin{aligned} (rP\mathbf{1}_{K_t^c})^2 V &\leqq V - U - rP\mathbf{1}_{K_t^c} U \\ &\leqq V - U - \varepsilon rP\mathbf{1}_{K_t^c} 1, \end{aligned}$$

and by induction we have for all $x \in \mathbf{X}$,

$$\varepsilon \sum_{k=1}^{\infty} (rP\mathbf{1}_{K_t^c})^k 1(x) \leqq V(x) - U(x). \tag{18}$$

The left-hand side of this equation may be transformed as follows:

$$\begin{aligned}\sum_{k=1}^{\infty}(rP\mathbf{1}_{K_t^c})^k 1(x) &= \sum_{k=1}^{\infty} r^k P_x\{\tau_{K_t} > k\} \\ &= \sum_{k=1}^{\infty} r^k \sum_{i=k+1}^{\infty} P_x\{\tau_{K_t} = i\} \\ &= \sum_{i=2}^{\infty} P_x\{\tau_{K_t} = i\}\left(\sum_{k=1}^{i-1} r^k\right) \\ &= \frac{1}{r-1}\sum_{i=2}^{\infty} P_x\{\tau_{K_t} = i\}r^i - \frac{r}{r-1}P_x\{\tau_{K_t} > 1\} \\ &\geqq \frac{1}{r-1}(E_x[r^{\tau_{K_t}}] - rP_x\{\tau_{K_t} \leqq 1\}) - \frac{r}{r-1}P_x\{\tau_{K_t} > 1\} \\ &\geqq \frac{1}{r-1}E_x[r^{\tau_{K_t}}] - \frac{r}{r-1}.\end{aligned}$$

This together with (18) and the definitions of U and ε proves the lemma. □

Proof of Proposition 3.1. The existence of a moment satisfying (12) implies that

$$\limsup_{k\to\infty} E_x[V(\Phi_k)] \leqq \frac{K}{1-\lambda}$$

for all initial conditions, and hence also the stability condition (S2). By Proposition 2.2, $\mathbf{\Phi}$ is positive Harris recurrent.

Since V is a moment and is continuous, for each $t \in \mathbb{R}_+$, the set K_t defined above Lemma 3.1 is compact. By Lemma 2.2 we may choose t so large that K_t is petite, and so the proof follows from Proposition 2.1. □

In the following result we show that condition (12) is an extremely useful property even when the irreducibility condition is not satisfied. Proposition 3.2 will be used in §§ 4 and 5 to establish ergodic theorems for Markov chains that do not satisfy any recurrence condition.

PROPOSITION 3.2. *Suppose that V is a positive measurable function satisfying condition* (12). *Then the following inequalities are satisfied for every initial condition $x \in \mathbf{X}$:*

(i) $$P^k V(x) \leqq \lambda^k V(x) + \frac{K}{1-\lambda}, \qquad k \in \mathbb{Z}_+.$$

(ii) $$\limsup_{N\to\infty} \frac{1}{N}\sum_{k=1}^{N} \sqrt{V(\Phi_k)} \leqq \frac{\sqrt{K}}{1-\sqrt{\lambda}} \quad a.s.\,[P_x].$$

Proof. The result (i) follows immediately from (12) and induction.

To show that (ii) holds, fix $x \in \mathbf{X}$, and let $U = \sqrt{V}$, $\alpha = \sqrt{\lambda}$, and $L = \sqrt{K}$. The function U is a moment and by Jensen's inequality,

$$\begin{aligned} PU(\Phi_k) &= E[U(\Phi_{k+1}) \mid \Phi_k] \quad \text{a.s.}\,[P_x] \\ &\leqq \sqrt{E[V(\Phi_{k+1}) \mid \Phi_k]} \\ &\leqq \sqrt{\lambda V(\Phi_k) + K} \\ &\leqq \alpha U(\Phi_k) + L. \end{aligned} \tag{19}$$

It follows that for every $N \in \mathbb{Z}_+$,

$$\frac{1}{N}\sum_{k=1}^{N} U(\Phi_k) \leqq \frac{1}{N}\sum_{k=1}^{N} (U(\Phi_k) - PU(\Phi_{k-1})) + \frac{1}{N}\sum_{k=1}^{N} (PU(\Phi_{k-1}) - PU(\Phi_k)) + \frac{1}{N}\sum_{k=1}^{N} \alpha U(\Phi_k) + L.$$

Let $\eta_k = U(\Phi_k) - PU(\Phi_{k-1})$, and observe that the second summand in the equation above is a telescoping series. Hence,

$$(1-\alpha)\frac{1}{N}\sum_{k=1}^{N} U(\Phi_k) \leqq \left|\frac{1}{N}\sum_{k=1}^{N} \eta_k\right| + \frac{1}{N}|PU(\Phi_0) - PU(\Phi_N)| + L. \tag{20}$$

It follows by result (i) of the theorem and a straight forward calculation that

$$\sum_{N=1}^{\infty} E_x\left[\frac{1}{N^2}|PU(\Phi_0) - PU(\Phi_N)|^2\right] \leqq 2\left(V(x) + \frac{K}{1-\lambda}\right)^2 \sum_{N=1}^{\infty} \frac{1}{N^2} < \infty,$$

and hence by Chebyshev's inequality and the Borel-Cantelli Lemma the second summand in the right-hand side of (20) converges to zero as $N \to \infty$ a.s. $[P_x]$.

Another straightforward calculation yields

$$\sup_{k \in \mathbb{Z}_+} E_x[\eta_k^2] \leqq 2 \sup_{k \in \mathbb{Z}_+} E_x[V(\Phi_k)] \leqq 2V(x) + \frac{2K}{1-\lambda}$$

by inequality (i) of the proposition. Hence with $\mathcal{F}_k$ defined in (13), the sequence $\{(\eta_k, \mathcal{F}_k): k \in \mathbb{Z}_+\}$ is an L^2 bounded martingale difference process. Applying Theorem 5.2 of Chapter 4 of Doob (1953), it follows that the first summand in the right-hand side of (20) converges to zero as $N \to \infty$. Taking "lim sup's" on either side of (20) yields (ii) of the theorem. □

We now show how a moment satisfying (12) may be constructed. In the stable linear case (5) with $\mathbf{w} = 0$ such a construction was first carried out in Kalman and Bertram (1960). Corollary 3.2* of that paper implies that there exists a positive definite matrix M with $I \leqq M \leqq mI$ for some $m \geqq 1$, and

$$|Ax|_M^2 \leqq \lambda |x|_M^2 \tag{21}$$

where $|y|_M^2 \triangleq y^T M y$ for $y \in \mathbb{R}^n$, and $\lambda < 1$. In fact, we can take

$$M \triangleq I + \sum_{i=1}^{\infty} A^{Ti} A^i.$$

In the case where $\mathbf{w} \neq 0$, suppose that the i.i.d. process $\mathbf{w}$ defined in (5) satisfies $E[w_0^2] < \infty$, but is otherwise arbitrary, and let V be the moment on $\mathbb{R}^n$ defined by

$$V(x) \triangleq x^T M x, \qquad x \in \mathbf{X}.$$

Then for each $x \in \mathbf{X}$ we have

$$PV(x) = x^T A^T M A x + E[w_0^T B^T M B w_0] \leqq \lambda V(x) + m|B|^2 E[w_0^2],$$

showing that the function V satisfies (12). We remark that in general, no stochastic Lyapunov function satisfying (14) exists in the linear case.

In the nonlinear case

$$\Phi_{k+1} = F(\Phi_k, w_{k+1})$$

with $\mathbf{X}=\mathbb{R}^n$ and $F:\mathbf{X}\times\mathbb{R}^p\to\mathbf{X}$ sufficiently smooth, it is possible to generalize this construction (see Chan (1986) for the details). However this requires extremely restrictive stability conditions. The idea is to look at the *freely evolving system*

$$d_{k+1}=F^{k+1}(x)\triangleq F(d_k,0),\qquad k\in\mathbb{Z}_+$$

with $d_0=x\in\mathbf{X}$ given. If there exists a fixed $0<\lambda<1$ and $K>0$ such that

$$|d_k|\leqq K\lambda^k|x|$$

for all $k\in\mathbb{Z}_+$ and $x\in\mathbf{X}$, then for fixed $\alpha\in(\lambda,1)$ we may define the moment V by

$$V(x)\triangleq\sup_{k\geqq 0}\alpha^{-k}|F^k(x)|$$

where $F^0(x)\triangleq x$. Under the appropriate conditions, V will satisfy condition (12).

Among the difficulties with this approach is that to apply the Lyapunov function for the freely evolving system to the original system, a global Lipschitz condition on V is needed. Presently, the only way to obtain such a condition is by imposing a global Lipschitz condition on F, and this is ruled out in many examples.

However, in all of the examples previously studied (see Guo and Meyn (1988) and the examples in § 5) a function satisfying (12) may be shown to exist by a reasonably simple calculation even though no global Lipschitz condition is satisfied.

In the next section we drop the recurrence condition, and show that suitably strong stability conditions (implied by the existence of a continuous moment V satisfying (12)) allow us to establish useful ergodic theorems for the class of continuous and bounded functions on $\mathbf{X}$.

4. Law of large numbers. Our main objective in this section is to find conditions under which the law of large numbers (2) holds for all initial conditions.

To illustrate the difficulties in finding such conditions when $\mathbf{\Phi}$ is not positive Harris recurrent, suppose that an invariant probability π exists. By a theorem of Doob (1953), for each $f\in L^1(\mathbf{X},\mathcal{B}(\mathbf{X}),\pi)$ there exists a function $f_\infty\in L^1(\mathbf{X},\mathcal{B}(\mathbf{X}),\pi)$ and a Borel set $\mathbf{X}_f\subset\mathbf{X}$ of full π measure such that

$$\lim_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N}f(\Phi_k)=f_\infty(x)\quad\text{a.s.}\,[P_x] \tag{22}$$

whenever $x\in\mathbf{X}_f$. The function f_∞ is a version of the conditional expectation $E[f|\Sigma_I]$ where Σ_I is the σ-algebra of π-invariant events in $\mathcal{B}(\mathbf{X})$. Define the *occupation probabilities*

$$\tilde{\mu}_N\{A\}\triangleq\frac{1}{N}\sum_{k=1}^{N}\mathbf{1}_{\Phi_k\in A},\quad N\in\mathbb{Z}_+,\quad A\in\mathcal{B}(\mathbf{X}), \tag{23}$$

and let $\{g_n:n\in\mathbb{Z}_+\}$ denote the bounded continuous functions defined in (7). It follows from (22) that there exists a Borel set $\mathbf{X}_1\subset\mathbf{X}$, and bounded Borel functions $\{g_{n,\infty}:n\in\mathbb{Z}_+\}$ such that whenever $x\in\mathbf{X}_1$,

$$\lim_{k\to\infty}\int g_n\,d\tilde{\mu}_k=g_{n,\infty}(x)\quad\text{a.s.}\,[P_x]$$

for each $n\in\mathbb{Z}_+$.

It also follows from (22) that for a.e. $[\pi]$ $x\in\mathbf{X}$ the sequence of probabilities $\{1/N\sum_{k=1}^{N}P^k(x,\cdot):N\in\mathbb{Z}_+\}$ is tight, and hence we may assume that these probabilities are tight for each $x\in\mathbf{X}_1$. By the Dominated Convergence Theorem we have

for each $x \in \mathbf{X}_1$ and $n \in \mathbb{Z}_+$,

$$\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} \int P^k(x, dy) g_n(y) = g_{n,\infty}(x),$$

and taking any weak limit point of the probabilities

$$\left\{ \frac{1}{N} \sum_{k=1}^{N} P^k(x, \cdot) : N \in \mathbb{Z}_+ \right\}, \tag{24}$$

it follows from this and (7) that for every $x \in \mathbf{X}_1$ there exists a probability π_x such that $g_{n,\infty}(x) = \int g_n \, d\pi_x$. Furthermore, for each $x \in \mathbf{X}_1$, every weak limit point of (24) is necessarily invariant (see, for example, the proof of Lemma 4.1) and hence π_x is an invariant probability for such x.

The following result follows from these observations.

PROPOSITION 4.1. *If the Feller Markov chain Φ possesses an invariant probability π, then there exists a Borel set $\mathbf{X}_1 \subset \mathbf{X}$ and invariant probabilities $\{\pi_x : x \in \mathbf{X}_1\}$ such that $\pi\{\mathbf{X}_1\} = 1$. The invariant probabilities $\{\pi_x\}$ have the property that for every initial condition $\Phi_0 = x \in \mathbf{X}_1$, the occupation probabilities converge*:

$$\tilde{\mu}_k \xrightarrow{\text{weakly}} \pi_x \quad \text{as } k \to \infty \quad \text{a.s. } [P_x].$$

Observe that the limit on the right-hand side of (22) is nonrandom, and hence so are the probabilities $\{\pi_x : x \in \mathbf{X}_1\}$. This result cannot be expected to hold for all initial conditions in general. For example, when Doeblin's condition (Condition D of Doob (1953)) or a stochastic controllability condition is satisfied [Meyn and Caines (1988)], it may be shown that there exists, at most, a countable collection of disjoint absorbing sets $\{H_i : i \in \mathbb{Z}_+\}$ on which the process Φ is positive Harris recurrent. For every initial condition $x \in \mathbf{X}$,

$$\tilde{\mu}_k \xrightarrow{\text{weakly}} \tilde{\pi}_x \quad \text{as } k \to \infty, \tag{25}$$

where the invariant probability $\tilde{\pi}_x$ is defined for $f \in \mathbf{C}$ by

$$\int f \, d\tilde{\pi}_x \triangleq \sum_{k=0}^{\infty} \left(\mathbf{1}_{\{\Phi \text{ enters } H_k\}} \int f \, d\pi_k \right), \tag{26}$$

and for each $i \in \mathbb{Z}_+$ the invariant probability π_i is supported on H_i. When $x \in H_i$ it may be shown that $\tilde{\pi}_x = \pi_i$, but, in general, $\tilde{\pi}_x$ will be a random probability.

In general, one of the main difficulties in establishing (25) is finding a candidate limit probability $\tilde{\pi}_x$. To this end suppose that an invariant Markov transition function Π exists (Π is a Markov transition function and $P\Pi = P\Pi = \Pi$) satisfying

$$\frac{1}{N} \sum_{k=1}^{N} P^k(x, \cdot) \xrightarrow{\text{weakly}} \Pi(x, \cdot) \quad \text{as } N \to \infty, \quad x \in \mathbf{X}. \tag{27}$$

Then with $\mathcal{F}_k$ defined in (13), the pair $(\Pi(\Phi_k, A), \mathcal{F}_k)$ is a convergent martingale, and we then make the definition

$$\tilde{\pi}_x\{A\} \triangleq \lim_{k\to\infty} \Pi(\Phi_k, A) \tag{28}$$

when $\Phi_0 = x \in \mathbf{X}$. For example, in the special case where Doeblin's condition holds we have $\Pi(\Phi_k, A) \to \pi_i\{A\}$ on the event $\{\Phi \text{ enters } H_i\}$, showing that this definition agrees with (26).

An interesting problem remains open. Suppose that Φ is a Feller Markov chain satisfying condition (S2). (i) Does an invariant Markov transition function satisfying (27) exist? And if so, (ii) does the law of large numbers (25) hold with $\tilde{\pi}_x$ defined in (28) for every initial condition?

We do not see any way of answering this question, and so for the time being we will have to settle for less general results.

At present, there are at least two possible routes to establishing the law of large numbers for continuous bounded functions. One is to assume that the Markov chain is *regular* in the sense of Feller (1971). This together with condition (S2) implies that an invariant Markov transition function satisfying (27) exists, and under general conditions (ii) follows using the same argument to be presented below. Alternatively, we may assume that a unique invariant probability π exists since if this is the case, then the problem of finding a candidate limit probability in (25) is solved.

Below we present a result based on the second approach since the first requires the introduction of additional definitions and preliminary results. The proof of the law of large numbers for regular Markov chains will appear in a planned monograph concerning Markov chains on topological spaces.

Below we state some assumptions that will be needed.

(A1) A unique invariant probability π exists.

(A2) The collection of probabilities on $\mathcal{B}(\mathbf{X})$,

$$\left\{\frac{1}{N}\sum_{k=1}^{N} P^k(x,\cdot): x\in K, N\in\mathbb{Z}_+\right\}$$

is tight for every compact set $K\subset\mathbf{X}$.

(A3) For all initial conditions $x\in\mathbf{X}$ there exists a sequence of compact sets $K_n\uparrow\mathbf{X}$ such that

$$\lim_{n\to\infty}\liminf_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N}\mathbf{1}_{\Phi_k\in K_n}=1 \quad \text{a.s.}\,[P_x].$$

Assumption (A3) is the condition that the occupation probabilities are almost surely tight for each initial condition. This condition will hold if a moment V exists for which

$$\limsup_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N}V(\Phi_k)<\infty \quad \text{a.s.}\,[P_x]$$

for each initial condition $x\in\mathbf{X}$. Assumption (A2) will be satisfied if a moment V exists with the property

$$\sup_{\substack{k\geqq 0\\ x\in K}} E_x[V(\Phi_k)]<\infty$$

for every compact set $K\subset\mathbf{X}$.

Hence applying Proposition 3.2, (A2) and (A3) will hold if a continuous moment V satisfying (12) exists.

We may now state the main result of this section that is a generalization of the result [Breiman (1960)] to noncompact state spaces.

PROPOSITION 4.2. *Suppose that conditions* (A1)-(A3) *hold. Then for each initial condition* $x\in\mathbf{X}$,

$$\tilde{\mu}_k \xrightarrow{\text{weakly}} \pi \quad \text{as } k\to\infty \quad \text{a.s.}\,[P_x].$$

We remark that in the case where f is continuous but unbounded it is often still possible to establish (2) under the conditions of Proposition 4.2. A sufficient condition is for some $\delta > 0$,

$$\limsup_{N\to\infty} \int |f|^{1+\delta}\, d\tilde{\mu}_N \triangleq \limsup_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} |f(\Phi_k)|^{1+\delta} < \infty,$$

since this implies that the function f is uniformly integrable with respect to the occupation probabilities $\{\tilde{\mu}_k : k \in \mathbb{Z}_+\}$ with probability one (see Theorem 5.4 of Billingsley (1968)).

Under the conditions of Proposition 3.2,

$$\int \sqrt{V}\, d\pi \leqq \frac{\sqrt{L}}{1-\sqrt{\lambda}},$$

when π is an invariant probability. This implies that if V is a moment, the set of all invariant probabilities is tight. If, in addition, a uniquely invariant probability π exists, then by Proposition 4.2, $\tilde{\mu}_k \xrightarrow{\text{weakly}} \pi$ with probability one. A slight modification of the proof of Proposition 3.2 shows that

$$\limsup_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} V^p(\Phi_k) \leqq \frac{K^p}{1-\lambda^p} < \infty$$

for every $p \in (0, 1)$, which by uniform integrability implies that

$$\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} V^p(\Phi_k) = \int V^p\, d\pi \quad \text{a.s. } [P_x].$$

To prove Proposition 4.2 we will apply the following lemma.

LEMMA 4.1. *If conditions* (A1) *and* (A2) *hold then for every* $f \in \mathbf{C}$,

$$\frac{1}{N} \sum_{k=1}^{N} P^k f(\cdot) \to \int f\, d\pi$$

as $N \to \infty$, *uniformly on compact sets.*

Proof of Lemma 4.1. Suppose that (A1) and (A2) hold, and for $f \in \mathbf{C}$, $\delta > 0$, and $N \in \mathbb{Z}_+$ define

$$A_N^{\delta}(f) \triangleq \left\{ x \in \mathbf{X} : \left| \frac{1}{N} \sum_{k=1}^{N} P^k f(x) - \int f\, d\pi \right| \geqq \delta \right\}.$$

The proof is by contradiction. If the conclusion of the lemma is false, then there exists f, δ, a compact set $K \subset \mathbf{X}$, and a subsequence $\{N_i\}$ of $\mathbb{Z}_+$ such that

$$A_{N_i}^{\delta}(f) \cap K \neq \phi$$

for all $i \in \mathbb{Z}_+$.

For each $i \in \mathbb{Z}_+$ let $x_i \in A_{N_i}^{\delta}(f) \cap K$, and consider the sequence of probabilities

$$\left\{ \frac{1}{N_i} \sum_{k=1}^{N_i} P^k(x_i, \cdot) : i \in \mathbb{Z}_+ \right\}.$$

This collection is tight by assumption, and hence by choosing a further subsequence if necessary we may assume that a probability λ exists for which

$$\frac{1}{N_i} \sum_{k=1}^{N_i} P^k(x_i, \cdot) \xrightarrow{\text{weakly}} \lambda \quad \text{as } i \to \infty.$$

We will now show that λ is an invariant probability. For each $g \in \mathbf{C}$ we have by weak convergence,

$$\int\int P(x, dy)g(y)\lambda(dx) = \lim_{i\to\infty} \frac{1}{N_i} \sum_{k=1}^{N_i} \int P^{k+1}(x_i, dy)g(y)$$

$$= \int g\, d\lambda.$$

Applying Urysohn's Lemma and using the fact that probabilities on $\mathcal{B}(\mathbf{X})$ are regular, it may be shown that characteristic functions of Borel sets may be approximated in $L^1(\lambda)$ and $L^1(\lambda P)$ by elements of $\mathbf{C}$. It follows that λ is invariant, and applying (A1) we conclude that $\lambda = \pi$. However by construction of λ, δ, and the function f,

$$\left| \int f\, d\pi - \int f\, d\lambda \right| = \lim_{i\to\infty} \left| \frac{1}{N_i} \sum_{k=1}^{N_i} \int P^k f\,(x_i) - \int f\, d\pi \right| \geqq \delta > 0.$$

This contradiction proves the lemma. □

Proof of Proposition 4.2. Fix $f \in \mathbf{C}$ and $\Phi_0 = x \in \mathbf{X}$. For each N, $n \in \mathbb{Z}_+$ we have

$$\frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) - \int f\, d\pi = \sum_{i=0}^{n-1} \frac{1}{N} \sum_{k=1}^{N} (P^i f(\Phi_{k-i}) - P^{i+1} f(\Phi_{k-i-1}))$$

$$+ \frac{1}{N} \sum_{k=1}^{N} P^n f(\Phi_k) - \int f\, d\pi$$

$$+ \frac{1}{N} \sum_{k=1}^{N} (P^n f(\Phi_{k-n}) - P^n f(\Phi_k))$$

where we adopt the convention that $\Phi_k = \Phi_0$ for $k \leqq 0$. For each $M \in \mathbb{Z}_+$ we may average the right-hand side of this equality from $n = 1$ to M to obtain

$$\frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) - \int f\, d\pi = \frac{1}{M} \sum_{n=1}^{M} \left(\sum_{i=0}^{n-1} \frac{1}{N} \sum_{k=1}^{N} (P^i f(\Phi_{k-i}) - P^{i+1} f(\Phi_{k-i-1})) \right)$$

$$+ \frac{1}{N} \sum_{k=1}^{N} \left(\frac{1}{M} \sum_{n=1}^{M} P^n f(\Phi_k) \right) - \int f\, d\pi$$

$$+ \frac{1}{M} \sum_{n=1}^{M} \left(\frac{1}{N} \sum_{k=1}^{N} P^n f(\Phi_{k-n}) - P^n f(\Phi_k) \right).$$

The third term is a telescoping series, and hence letting $\|f\|_\infty \triangleq \sup_{x\in\mathbf{X}} |f(x)|$ we have

$$\left| \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) - \int f\, d\pi \right| \leqq \sum_{i=0}^{M-1} \left| \frac{1}{N} \sum_{k=1}^{N} (P^i f(\Phi_{k-i}) - P^{i+1} f(\Phi_{k-i-1})) \right|$$

$$+ \left| \frac{1}{N} \sum_{k=1}^{N} \left(\frac{1}{M} \sum_{n=1}^{M} P^n f(\Phi_k) \right) - \int f\, d\pi \right| + \frac{2M\|f\|_\infty}{N}. \tag{29}$$

For each fixed $0 \leqq i \leqq M-1$ the sequence

$$(P^i f(\Phi_{k-i}) - P^{i+1} f(\Phi_{k-i-1}), \mathcal{F}_{k-i}), \qquad k > i,$$

is a bounded martingale difference process, where $\mathcal{F}_k$ is defined in (13). Hence by Theorem 5.2 of Doob (1953, Chap. 4), the first summand converges to zero almost surely for every $M \in \mathbb{Z}_+$. Let $\varepsilon > 0$, and $\{\Phi_k\}$ be a sample for which the first summand

converges to zero for each M. By (A3), for almost every sample path there exists a compact set $K \subset \mathbf{X}$ such that

$$\liminf_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} \mathbf{1}_{\{\Phi_k \in K\}} \geqq 1 - \varepsilon.$$

Fix such a set K, and choose M so large that $|1/M \sum_{n=1}^{M} P^n f(x) - \int f\, d\pi| < \varepsilon$ on K. This is possible by (A1) and (A2), and Lemma 4.1. Hence by (29),

$$\begin{aligned}
&\limsup_{N\to\infty} \left| \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) - \int f\, d\pi \right| \\
&\quad \leqq \limsup_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} \left| \left(\frac{1}{M} \sum_{n=1}^{M} P^n f(\Phi_k) \right) - \int f\, d\pi \right| \\
&\quad \leqq \limsup_{N\to\infty} \|f\|_\infty \frac{1}{N} \sum_{k=1}^{N} \mathbf{1}_{\{\Phi_k \in K^c\}} \\
&\qquad + \limsup_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} \mathbf{1}_{\{\Phi_k \in K\}} \left| \left(\frac{1}{M} \sum_{n=1}^{M} P^n f(\Phi_k) \right) - \int f\, d\pi \right| \\
&\quad \leqq \varepsilon \|f\|_\infty + \varepsilon,
\end{aligned}$$

and this shows that (2) holds for all $f \in \mathbf{C}$ and all $x \in \mathbf{X}$.

Let $\{g_n\}$ be the continuous functions defined in (7). Then since (2) holds for each bounded and continuous function,

$$P_x \left\{ \lim_{k\to\infty} \int g_n\, d\tilde{\mu}_k = \int g_n\, d\pi \quad \text{for each } n \in \mathbb{Z}_+ \right\} = 1.$$

This together with (7) proves the theorem. □

We now give alternative sufficient conditions to establish (2) for continuous and bounded functions. Let $d(\cdot, \cdot)$ denote the metric on $\mathbf{X}$, and define

$$d(x, E) \triangleq \inf_{y \in E} d(x, y) \quad \text{and} \quad B_\delta(E) \triangleq \{y \in \mathbf{X} : d(y, E) < \delta\},$$

for $x \in \mathbf{X}$, $E \in \mathcal{B}(\mathbf{X})$, and $\delta > 0$.

In cases where a unique invariant probability π exists, the following conditions are often satisfied.

(A4) There exists a closed set $H \subset \mathbf{X}$ that supports π, and H is a Harris set. Furthermore, the support of π has nonempty interior in H.

(A5) For all initial conditions $\Phi_0 = x \in \mathbf{X}$,

$$\lim_{k\to\infty} d(\Phi_k, H) = 0 \quad \text{a.s. } [P_x].$$

PROPOSITION 4.3. *Suppose that conditions* (A1), (S2) *and* (A3)-(A5) *hold, and that the Markov chain* Φ *restricted to* H *has period* $r \geqq 1$. *Then for each initial condition* $x \in \mathbf{X}$,

$$\tilde{\mu}_k \xrightarrow{\text{weakly}} \pi \quad a.s.\ [P_x],$$

$$\frac{1}{r} \sum_{i=1}^{r} P^{k+i}(x, \cdot) \xrightarrow{\text{weakly}} \pi \quad as\ k \to \infty.$$

The idea of the proof is basically the same as that of Proposition 4.2. We show that for any compact set $K \subset \mathbf{X}$ the probability $1/r \sum_{i=1}^{r} P^{k+i}(x, \cdot)$ is close to π in the weak topology for all x in a neighborhood of $K \cap H$, and all $k \in \mathbb{Z}_+$ sufficiently large. The proof then follows using the same martingale difference argument as in Proposition 4.2.

The following result follows from Corollary 4.1 and Theorem 2.1 of Cogburn (1975).

LEMMA 4.2. *If condition* (A4) *holds, then for every* $\varepsilon > 0$ *and every compact set* $K \subset \mathbf{X}$, *there exists* $k = k(K) \in \mathbb{Z}_+$ *such that*

$$\left\| \frac{1}{r} \sum_{i=1}^{r} P^{k+i}(x, \cdot) - \pi(\cdot) \right| < \varepsilon$$

for every $x \in K \cap H$.

Proof of Proposition 4.3. Let $\varepsilon > 0$, let $K \subset \mathbf{X}$ be a compact set, and fix $f \in \mathbf{C}$. Under (A4) we may apply Lemma 4.2 to find $k_0 \in \mathbb{Z}_+$ such that

$$\left| \frac{1}{r} \sum_{i=1}^{r} P^{k_0+i} f(x) - \int f \, d\pi \right| < \varepsilon \tag{30}$$

for all $x \in H \cap K$, and by the Feller property it follows that for some $\delta > 0$, (30) holds for all $x \in B_\delta(H) \cap K$.

For all $n \in \mathbb{Z}_+$,

$$\frac{1}{r} \sum_{i=1}^{r} P^{k_0+i+n} f(x) = P^n \left(\frac{1}{r} \sum_{i=1}^{r} P^{k_0+i} f \right)(x).$$

Hence by (30) for every $x \in \mathbf{X}$,

$$\begin{aligned} &\limsup_{n \to \infty} \left| \frac{1}{r} \sum_{i=1}^{r} P^{k_0+i+n} f(x) - \int f \, d\pi \right| \\ &\quad \leqq \limsup_{n \to \infty} \varepsilon P^n(x, K \cap B_\delta(H)) + \|f\|_\infty (P^n(x, B_\delta^c(H)) + P^n(x, K^c)). \end{aligned}$$

By (S2) and (A5), and since $\varepsilon > 0$ and K compact are arbitrary, this proves the first assertion of the proposition.

By (29), (30), and applying the martingale difference argument used in the proof of Proposition 4.2, we have

$$\begin{aligned} &\limsup_{N \to \infty} \left| \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) - \int f \, d\pi \right| \\ &\quad \leqq \varepsilon + \|f\|_\infty \limsup_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} \mathbf{1}_{\Phi_k \notin K \cap B_\delta(H)} \\ &\quad \leqq \varepsilon + \|f\|_\infty \left(\limsup_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} \mathbf{1}_{\Phi_k \notin K} + \limsup_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} \mathbf{1}_{\Phi_k \notin B_\delta(H)} \right). \end{aligned}$$

Since we have assumed that $\mathbf{\Phi}$ converges to the set H with probability one, it follows that

$$\limsup_{N \to \infty} \left| \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) - \int f \, d\pi \right| \leqq \|f\|_\infty \limsup_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} \mathbf{1}_{\Phi_k \notin K} + \varepsilon.$$

By (A3), and since $\varepsilon > 0$ is arbitrary, it follows that

$$\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) = \int f d\pi \quad \text{a.s. } [P_x]$$

for each $f \in \mathbf{C}$ and, as was shown in the proof of Proposition 4.2, this implies that

$$\bar{\mu}_k \xrightarrow{\text{weakly}} \pi \quad \text{a.s. } [P_x]. \qquad \square$$

5. Examples. In this section we consider a number of examples to illustrate how the results above may be applied to specific control problems. With the exception of the example presented in § 5.2 where slightly different techniques are used, we assume that the Markov chain $\mathbf{\Phi}$ has the form

$$\Phi_{k+1} = F(\Phi_k, w_{k+1}), \qquad k \in \mathbb{Z}_+. \tag{1}$$

For all k, $\Phi_k \in \mathbf{X}$, a d-dimensional manifold, $w_k \in \mathbb{R}^p$, and $F : \mathbf{X} \times \mathbb{R}^p \to \mathbf{X}$ is continuously differentiable (C^1).

We further assume that $(\Phi_0, \mathbf{w})$ are random variables on the probability space $(\Omega, \mathcal{F}, P_{\Phi_0})$, Φ_0 is independent of $\mathbf{w}$, and that $\mathbf{w}$ is an independent and identically distributed process.

We will also require the following conditions on the distribution μ_w of the random variables w_k, $k \in \mathbb{Z}_+$, whenever the weak stochastic controllability condition is required:

(W1) The distribution μ_w of w_k, $k \in \mathbb{Z}_+$, possesses a density that is lower semicontinuous;

(W2) $0 \in \text{supp } \mu_w$;

Condition (W1) implies that μ_w possesses a density that is strictly positive on an open set $\mathcal{O}_w \subset \mathbb{R}^p$ and zero elsewhere, and hence supp $\mu_w = \bar{\mathcal{O}}_w$.

Before presenting the examples, we give some useful definitions from Meyn and Caines (1988), and present a result from that paper that will be needed in the examples that follow.

Here we give a precise definition of weak stochastic controllability. General conditions for weak stochastic controllability involving a controllability matrix may be found in Meyn and Caines (1988). Given two measures ν and μ on $\mathcal{B}(\mathbf{X})$ we say that ν is *absolutely continuous* with respect to μ (denoted $\nu \prec \mu$) if $\nu\{A\} = 0$ whenever $\mu\{A\} = 0$. We let $\mathbf{1}_A \mu$ denote the measure defined for $B \in \mathcal{B}(\mathbf{X})$ by $(\mathbf{1}_A \mu)\{B\} \triangleq \mu\{A \cap B\}$.

DEFINITION. The system (1) is called *weakly stochastically controllable* if for each initial condition $x \in \mathbf{X}$ there exists $T = T(x) \in \mathbb{Z}_+$, and an open set $\mathcal{O}_x \subset \mathbf{X}$ such that $P^T(x, \cdot) > \mathbf{1}_{\mathcal{O}_x} \mu^{Leb}$.

Hence if $\mathbf{\Phi}$ is weakly stochastically controllable, then the Radon-Nikodym derivative of the probability $P^T(x, \cdot)$ (with respect to Lebesgue measure) is strictly positive on an open set $\mathcal{O}_x \subset \mathbf{X}$.

We call the deterministic system

$$d_{k+1} = F(d_k, 0), \qquad k \in \mathbb{Z}_+ \tag{31}$$

with initial condition $d_0 \in \mathbf{X}$ the *freely evolving system.* The system (1) *satisfies condition* (GA) if there exists $d^* \in \mathbf{X}$ that is globally attracting for the freely evolving system. That is,

(GA) For each initial condition $x \in \mathbf{X}$, $\lim_{k\to\infty} d_k = d^*$.

Hence, if the disturbance sequence $\mathbf{w}$ is replaced by $(0, \cdots, 0, \cdots)$ in (1) then $\Phi_k \to d^*$ as $k \to \infty$ for all initial conditions.

The following result will be used together with Proposition 3.1 in the examples below.

PROPOSITION 5.1. *Suppose that $\mathbf{\Phi}$ is a Markov chain of the form* (1), *and that conditions* (W1) *and* (W2) *hold. If $\mathbf{\Phi}$ is weakly stochastically controllable and satisfies condition* (GA), *then the irreducibility condition is satisfied for an open set A containing d^*, and $\mathbf{\Phi}$ is aperiodic.*

We may now proceed with the first example.

5.1. Nonlinear control. Here we consider a linear single-input single-output stochastic state space system with nonlinear feedback control law

$$u_k \triangleq -\varphi(y_k) \quad \text{for all } k \in \mathbb{Z}_+ \tag{32}$$

where the function $\varphi \in C^1$. We assume that $\varphi(0) = 0$, and to simplify the analysis we also take $d\varphi/dt(0) \neq 0$.

The closed loop system equations are

$$\begin{aligned} x_{k+1} &= Ax_k - b\varphi(c^{\mathrm{T}}x_k + \zeta_{k+1}) + G\xi_{k+1}, \\ y_k &= c^{\mathrm{T}}x_k + \zeta_{k+1}, \qquad k \in \mathbb{Z}_+, \end{aligned} \tag{33}$$

and it is easily seen that if $\mathbf{w} \triangleq \binom{\xi}{\zeta}$ satisfies the conditions given at the beginning of this section, then $\mathbf{x}$ is a Feller Markov chain of the form (1) with state space $\mathbb{R}^n$.

In fact, $\mathbf{\Phi} \triangleq \binom{\mathbf{x}}{\mathbf{y}}$ will also be a Markov chain under the appropriate conditions whose state space $\mathbf{X} \triangleq \mathbb{R}^{n+1}$. However, we may show that almost any result of interest obtainable for the process $\mathbf{x}$ will carry over to the joint process $\mathbf{\Phi}$, and so we restrict our analysis to the simpler Markov chain.

This is a popular example in nonlinear systems theory (see, e.g., Zames (1966), Popov (1973), and Safonov (1980)) and is ideal for illustrating the general results presented in the previous sections.

The following stability and controllability conditions will be needed below. We say that the control φ defined in (32) lies in the sector (α, r) (see Safonov (1980)) if for all $x \in \mathbb{R}$,

$$|\varphi(x) - \alpha x| \leqq r|x|.$$

For a positive definite $n \times n$ matrix Q, a vector $z \in \mathbb{R}^n$, and an $n \times n$ matrix F we let

$$|z|_Q^2 = z^{\mathrm{T}}Qz \quad \text{and} \quad |F|_Q^2 = \sup_{z \neq 0} \frac{|Fz|_Q^2}{|z|_Q^2}.$$

(NC1) $E[|w_0|^{2+\delta}] < \infty$ for some $\delta > 0$:

(NC2) The control law φ lies in the sector (α, r), and for some positive definite $n \times n$ matrix Q,

$$\lambda \triangleq |(A - \alpha bc^{\mathrm{T}})|_Q + r|b|_Q|c|_{Q^{-1}} < 1.$$

(NC3) The pair $(A, [G|b])$ is controllable;

(NC4) The distribution μ_w of w_0 satisfies conditions (W1) and (W2).

Let P denote the Markov transition function on $\mathbf{X} = \mathbb{R}^{n+1}$ for the joint process $\mathbf{\Phi}$, and let $\tilde{\mu}_k$, $k \in \mathbb{Z}_+$, denote the occupation probabilities defined in § 4. The functions x, u, and y on $\mathbf{X}$ are defined so that

$$x_k = x(\Phi_k), \quad u_k = u(\Phi_k), \quad y_k = y(\Phi_k), \quad k \in \mathbb{Z}_+.$$

Our objective in this section is to prove Proposition 5.2.

PROPOSITION 5.2. *Suppose that conditions* (NC1), (NC2), *and* (NC4) *hold for* (33). *Then a unique invariant probability* π *exists, and the following limits hold for each initial condition* $x \in \mathbb{R}^{n+1}$

$$P^k(x, \cdot) \xrightarrow{\text{weakly}} \pi, \tag{34}$$

$$\tilde{\mu}_k \xrightarrow{\text{weakly}} \pi \quad a.s.\,[P_x], \tag{35}$$

$$\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} (x_k^2 + y_k^2 + u_k^2) = \int (x^2 + y^2 + u^2)\, d\pi \quad a.s.\,[P_x], \tag{36}$$

$$\lim_{k\to\infty} E_x[x_k^2 + y_k^2 + u_k^2] = \int (x^2 + y^2 + u^2)\, d\pi. \tag{37}$$

If in addition (NC3) *holds, then* $\mathbf{\Phi}$ *is geometrically ergodic, and* (37) *holds at a geometric rate.*

Proposition 5.2 will be proved in several steps. We first present sufficient conditions for the Markov chain $\mathbf{x}$ to be weakly stochastically controllable.

5.1.1. Controllability. The generalized controllability matrix associated with $\mathbf{x}$ (see Meyn and Caines (1988) and Meyn (1987)) is defined for an initial condition $x \in \mathbb{R}^n$ by

$$C_x^T = [A_{T-1} \cdots A_1 B_0 | A_{T-1} \cdots A_2 B_1 | \cdots | A_{T-1} B_{T-2} | B_{T-1}] \tag{38}$$

where, letting $\alpha_k \triangleq d\varphi/dt\,(y_k)$,

$$\begin{aligned} A_k &\triangleq \left[\frac{\partial F}{\partial x}\right]_{(x_k, w_{k+1})} = A - \alpha_k b c^{\mathsf{T}} \\ B_k &\triangleq \left[\frac{\partial F}{\partial z}\right]_{(x_k, w_{k+1})} = [G | -\alpha_k b] \end{aligned} \qquad \text{for all } k \in \mathbb{Z}_+. \tag{39}$$

Observe that the generalized controllability matrix C_x^T is a function of the random variables $\{y_k : 0 \leqq k \leqq T-1\}$, and hence is also random. By Theorem 2.1 of Meyn and Caines (1988), $\mathbf{x}$ is weakly stochastically controllable if for each $x \in \mathbb{R}^n$ there exists $T \in \mathbb{Z}_+$ such that the matrix C_x^T has rank n with positive probability.

The following lemma greatly simplifies the computation of the rank of the matrix C_x^T. For an $n \times m$ matrix H let co-ker (H) denote the n-dimensional vector space

$$\text{co-ker}\,(H) \triangleq \{x \in \mathbb{R}^n : x^{\mathsf{T}} H = 0\}.$$

LEMMA 5.1. *The generalized controllability matrix* C_x^T *satisfies*

$$\text{co-ker}\,(C_x^T) = \text{co-ker}\,([A^{T-1}[G|\alpha_0 b]| \cdots |[A[G|\alpha_{T-2} b]|[G|\alpha_{T-1} b]]) \tag{40}$$

and hence $\mathbf{x}$ *is weakly stochastically controllable under conditions* (NC3) *and* (NC4) *if* $d\varphi/dt(0) \neq 0$.

Proof of Lemma 5.1. We will proceed by showing inductively that for $k = 0, \cdots, T-1$ and $x \in \mathbb{R}^n$,

$$\begin{aligned} &x^{\mathsf{T}}[A_{T-1}^x \cdots A_{T-k}^x B_{T-k-1}^x | \cdots | A_{T-1}^x B_{T-2}^x | B_{T-1}^x] = 0 \\ &\text{if and only if} \\ &x^{\mathsf{T}}[A^k[G|\alpha_{T-k-1} b]| \cdots |A[G|\alpha_{T-2} b]|[G|\alpha_{T-1} b]] = 0. \end{aligned} \tag{41}$$

For $k=0$, (41) becomes

$$x^{\mathrm{T}}[G\,|\,\alpha_{T-1}b]=0 \Leftrightarrow x^{\mathrm{T}}[G\,|\,-\alpha_{T-1}b]=0,$$

and this is obvious. Suppose now that (41) has been established for $k=n-1\geqq 0$. To establish the implication ($\Rightarrow$) for $k=n$ observe that if $x\in\mathbb{R}^n$ satisfies

$$x^{\mathrm{T}}[A^x_{T-1}\cdots A^x_{T-n}B^x_{T-n-1}|\cdots|A^x_{T-1}B^x_{T-2}\,|\,B^x_{T-1}]=0 \tag{42}$$

then by the induction hypothesis,

$$x^{\mathrm{T}}[A^{n-1}[G\,|\,\alpha_{T-n}b]|\cdots|A[G\,|\,\alpha_{T-2}b]|[G\,|\,\alpha_{T-1}b]]=0. \tag{43}$$

Furthermore, by (42) and (43) it follows that

$$\begin{aligned}0&=x^{\mathrm{T}}[A^x_{T-1}\cdots A^x_{T-n}B^x_{T-n-1}]\\&=x^{\mathrm{T}}(A-\alpha_{T-1}bc^{\mathrm{T}})(A-\alpha_{T-2}bc^{\mathrm{T}})\cdots(A-\alpha_{T-n}bc^{\mathrm{T}})[G\,|\,-\alpha_{T-1-n}b]\\&=x^{\mathrm{T}}A^n[G\,|\,-\alpha_{T-1-n}b].\end{aligned}$$

This and (43) establishes the implication ($\Rightarrow$) in (41) when $k=n$.

To establish the reverse implication suppose that $x\in\mathbb{R}^n$ satisfies

$$x^{\mathrm{T}}A^i[G\,|\,\alpha_{T-1-i}b]=0 \quad \text{for all } 0\leqq i\leqq n, \tag{44}$$

so that by the induction hypothesis

$$x^{\mathrm{T}}[A^x_{T-1}\cdots A^x_{T-n+1}B^x_{T-n}|\cdots|B^x_{T-1}]=0. \tag{45}$$

To complete the proof of the lemma we are left to show that

$$x^{\mathrm{T}}A^x_{T-1}\cdots A^x_{T-n}B^x_{T-n-1}=0,$$

and this follows from (39) and (44):

$$\begin{aligned}&x^{\mathrm{T}}A^x_{T-1}\cdots A^x_{T-n+1}B^x_{T-n}\\&\quad=x^{\mathrm{T}}(A-\alpha_{T-1}bc^{\mathrm{T}})(A-\alpha_{T-2}bc^{\mathrm{T}})\cdots(A-\alpha_{T-n}bc^{\mathrm{T}})[G\,|\,-\alpha_{T-1-n}b]\\&\quad=x^{\mathrm{T}}A^n[G\,|\,-\alpha_{T-1-n}b]=0.\end{aligned}$$

This establishes the first part of the lemma. If (NC3) and (NC4) hold, and if $d\varphi/dt(0)\neq 0$, then by (40) it follows that the matrix $C^n_0(0)$ has rank n. Here $C^n_0(0)$ denotes the generalized controllability matrix at time n evaluated along the output sequence $\mathbf{y}\equiv 0$. Hence by Corollary 4.4 of Meyn and Caines (1988), the Markov chain $\mathbf{x}$ is weakly stochastically controllable. □

5.1.2. Stability. We now show that a moment on $\mathbb{R}^n$ exists that satisfies (12). Let Q be the matrix defined in (NC2), and let $V(\cdot)\triangleq|\cdot|_Q$.

LEMMA 5.2. *Suppose that conditions* (NC1) *and* (NC2) *are satisfied. Then*

(i) *Condition* (GA) *holds with* $d^*=0$.

(ii) *The moment* V *satisfies* (12).

(iii) *For all initial conditions*

$$\mathbf{\Phi}_0=\begin{pmatrix}x_0\\y_0\end{pmatrix}\in\mathbf{X}:$$

$$\sup_{k\in\mathbb{Z}_+}E_{\mathbf{\Phi}0}[|x_k|^{2+\delta}+|u_k|^{2+\delta}+|y_k|^{2+\delta}]<\infty,$$

$$\limsup_{N\to\infty}\int|x|^{2+\delta}+|u|^{2+\delta}+|y|^{2+\delta}\,d\tilde{\mu}_N$$

$$\triangleq\limsup_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N}(|x_k|^{2+\delta}+|u_k|^{2+\delta}+|y_k|^{2+\delta})<\infty \quad a.s.\,[P_{\Phi_0}]$$

where $\delta>0$ *is the constant used in condition* (NC1).

Proof. Equation (33) and (NC2) imply that

$$
\begin{aligned}
|x_{k+1}|_Q &\leqq |A-\alpha bc^{\mathsf{T}}|_Q|x_k|_Q + r|b|_Q|c^{\mathsf{T}}x_k+\zeta_{k+1}| + |\alpha||b|_Q|\zeta_{k+1}| + |G|_Q|\xi_{k+1}|_Q \\
&\leqq |A-\alpha bc^{\mathsf{T}}|_Q|x|_Q + r|b|_Q(|c|_{Q^{-1}}|x_k|_Q + |\zeta_{k+1}|) \\
&\qquad + |\alpha||b|_Q|\zeta_{k+1}| + |G|_Q|\xi_{k+1}|_Q \\
&\leqq \lambda|x_k|_Q + (|\alpha|+r)|b|_Q|\zeta_{k+1}| + |G|_Q|\xi_{k+1}|_Q.
\end{aligned} \tag{46}
$$

It immediately follows that (GA) holds, and that

$$
PV(x) \leqq \lambda V(x) + E[(\alpha+r)|b|_Q|\zeta_1| + |G|_Q|\xi_1|_Q]
$$

so that V satisfies (12).

Finally, if $\delta > 0$ is the constant used in (NC1), then (46) implies that for a constant B_1, and a random constant B_2,

$$
(E_x[|x_{k+1}|_Q^{2+\delta}])^{1/(2+\delta)} \leqq \lambda(E_x[|x_k|_Q^{2+\delta}])^{1/(2+\delta)} + B_1, \qquad k \in \mathbb{Z}_+,
$$

and

$$
\left(\frac{1}{N+1}\sum_{k=1}^{N+1}|x_k|_Q^{2+\delta}\right)^{1/(2+\delta)} \leqq \lambda\left(\frac{1}{N}\sum_{k=1}^{N}|x_k|_Q^{2+\delta}\right)^{1/(2+\delta)} + B_2, \qquad N \in \mathbb{Z}_+.
$$

By a geometric series argument, this shows that the third assertion of the lemma holds. □

We may now prove Proposition 5.2.

Proof of Proposition 5.2. We first suppose that (NC1)-(NC4) are satisfied. If this is the case then by Lemmas 5.1 and 5.2 and Proposition 5.1, the conditions of Proposition 3.1 are satisfied and hence $\mathbf{x}$ is geometrically ergodic. This implies that the joint process $\mathbf{\Phi} = \binom{\mathbf{x}}{\mathbf{y}}$ is also geometrically ergodic since $\mathbf{y}$ is virtually a function of $\mathbf{x}$.

Result (36) follows from this fact together with Proposition 1.1. To show that the convergence result (37) holds at a geometric rate, apply Proposition 2.1(iv).

We now relax condition (NC3). If the pair $(A, [G|b])$ is not controllable, then $\mathbf{x}$ may be decomposed into controllable and uncontrollable parts using a similarity transformation M where

$$
MAM^{-1} = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix},
$$

$$
M[G|b] = \begin{bmatrix} G_1 & b_1 \\ 0 & 0 \end{bmatrix},
$$

and $(A_{11}, [G_1|b_1])$ is controllable.

Letting

$$
\begin{pmatrix} x_k^c \\ x_k^0 \end{pmatrix} \triangleq Mx_k \quad \text{and} \quad c_1^{\mathsf{T}} = c^{\mathsf{T}}M^{-1}
$$

it follows that

$$
x_{k+1}^c = A_{11}x_k^c + A_{12}x_k^0 + b_1\varphi\left(c_1^{\mathsf{T}}\begin{pmatrix} x_k^c \\ x_k^0 \end{pmatrix} + \zeta_{k+1}\right) + G_1 w_{k+1},
$$

$$
x_{k+1}^0 = A_{22}x_k^0.
$$

If $x_0^0 = 0$ then $x_k^0 = 0$ for all $k \in \mathbb{Z}_+$, and in this case $\binom{\mathbf{x}^c}{\mathbf{y}}$ becomes a Markov chain for which the analysis above is valid.

By condition (GA), for all initial conditions $x \in \mathbf{X}$, $x_k^0 \to 0$ as $k \to 0$, and it follows that there exists a unique invariant probability π for $\mathbf{\Phi}$ under which $P_\pi\{\mathbf{x}^0 \equiv 0\} = 1$.

This shows that a hyperplane $H \subset \mathbb{R}^n$ exists that is a Harris set for the Markov chain $\mathbf{x}$. This set is necessarily a closed subset of $\mathbb{R}^n$, and by weak stochastic controllability (of $\mathbf{x}$ restricted to H) it follows that the support of π has nonempty interior in H. Hence (A4) and (A5) hold, and applying Proposition 4.3 completes the proof. □

5.2. Random linear system. Here we consider a randomly disturbed linear system

$$x_{k+1} = F(\xi_k)x_k + w_{k+1} \tag{47}$$

where $\mathbf{x}$ evolves on $\mathbb{R}^n$, ξ is a Feller Markov chain evolving on a compact m-dimensional manifold M, the disturbance process $\mathbf{w}$ is i.i.d., and $F: M \to gl(n, \mathbb{R})$ is continuous.

We also require these further assumptions:

(RLS1) $E[|w_1|^{2+\delta}] < \infty$ for some $\delta > 0$;
(RLS2) The processes $\mathbf{w}$ and ξ are independent;
(RLS3) ξ is aperiodic and positive Harris recurrent;
(RLS4) There exists $T_0 \in \mathbb{Z}_+$ and $\lambda_0 < 1$ such that
$E_{\xi_0}[F(\xi_0)^\tau \cdots F(\xi_{T_0})^\tau F(\xi_{T_0}) \cdots F[(\xi_0)] < \lambda_0 I$
for each $\xi_0 \in M$.

A similar example is treated in Feigin and Tweedie (1985), where geometric ergodicity is established under the condition that $\boldsymbol{\xi}$ is i.i.d., together with a nonsingularity assumption on the distribution of w_0.

It is easy to see that under the present conditions, $\mathbf{\Phi}$ is a Feller Markov chain with state space $\mathbf{X} \triangleq \mathbb{R}^n \times M$. Its Markov transition function P may be defined in terms of the Markov transition function Q for $\boldsymbol{\xi}$, and the system description (47).

Our main objective is to establish Proposition 5.3 below.

Let $x: \mathbf{X} \to \mathbb{R}^n$ denote the coordinate variable defined so that $x(\Phi_k) = x_k$, and let $\tilde{\mu}_k$, $k \in \mathbb{Z}_+$, denote the occupation probabilities defined in § 4.

PROPOSITION 5.3. *Suppose that the Markov chain* $\mathbf{\Phi} = \binom{x}{\xi}$ *defined in* (47) *satisfies conditions* (RLS1)-(RLS4). *Then there exists a unique invariant probability* π *on* $\mathbb{R}^n \times M$, *and for each initial condition* $x \in \mathbf{X}$,

$$P^k(x, \cdot) \xrightarrow{\text{weakly}} \pi \quad \text{as } k \to \infty, \tag{48}$$

$$\tilde{\mu}_k \xrightarrow{\text{weakly}} \pi \quad \text{as } k \to \infty \quad \text{a.s. } [P_x], \tag{49}$$

$$\lim_{k\to\infty} E_x[x_k^2] = \lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} x_k^2 = \int x^2 \, d\pi < \infty \quad \text{a.s. } [P_x]. \tag{50}$$

Observe that the statistical assumptions (RLS2) and (RLS3) and the stability assumptions (RLS1) and (RLS4) are all that is needed to establish the existence of a unique invariant probability π for $\mathbf{\Phi}$. The distributional assumptions (W1) and (W2) and the stochastic controllability hypothesis are not needed, and hence $\mathbf{\Phi}$ does not necessarily satisfy the irreducibility hypothesis.

We remark that under slightly stronger assumptions (conditions (W1) and (W2), and the condition that the support of the invariant probability for ξ has nonempty interior in M) the Markov chain $\mathbf{\Phi}$ will be geometrically ergodic. This follows from Lemma 5.3 below, and Proposition 3.1 applied to the sampled process $\{\Phi_{kT_0}: k \in \mathbb{Z}_+\}$.

To prove Proposition 5.3 we will require the following preliminary result.

LEMMA 5.3. *Under conditions* (RLS1)-(RLS4) *there exists a fixed constant* $B = B(E[|w_1|^2]) < \infty$ *such that*

$$E_{\Phi_0}[|x_{T_0+1}|^2] \leqq \lambda_0 |x_0|^2 + B$$

for every initial condition $\Phi_0 = \binom{x_0}{\xi_0} \in \mathbf{X}$.

Proof. We have for all $k \in \mathbb{Z}_+$ by (RLS2),

$$E_{\Phi_0}[|x_{k+1}|^2] = x_0^{\mathsf{T}} E_{\xi_0}[F(\xi_0)^{\mathsf{T}} \cdots F(\xi_k)^{\mathsf{T}} F(\xi_k) \cdots F(\xi_0)] x_0 + E_{\Phi_0}\left[w_{k+1}^{\mathsf{T}} w_{k+1} + \sum_{i=1}^{k} w_i^{\mathsf{T}} [F(\xi_i)^{\mathsf{T}} \cdots F(\xi_k)^{\mathsf{T}} F(\xi_k) \cdots F(\xi_i)] w_i \right].$$

Hence the conclusions of the lemma are satisfied with

$$B \triangleq E[|w_1|^2](T_0 \| F \|^{T_0}),$$

where $\|F\|$ denotes the supremum of the operator norm of F over the compact manifold M. □

We may now prove Proposition 5.3. We assume that an i.i.d. $N(0, I)$ stochastic process $\mathbf{d}$ on $\mathbb{R}^n$ exists such that $\mathbf{d}$, $\mathbf{w}$, and ξ are mutually independent. We then define the perturbed process $\mathbf{x}^\varepsilon$ for $\varepsilon \in [0, 1]$ by $x_0^\varepsilon = x_0$, and

$$x_{k+1}^\varepsilon = F(\xi_k) x_k^\varepsilon + w_{k+1} + \varepsilon d_{k+1}, \qquad k \in \mathbb{Z}_+. \tag{51}$$

To prove Proposition 5.3 we will show that for all $\varepsilon > 0$, the perturbed process is aperiodic and positive Harris recurrent, and that for ε sufficiently small, the process $\mathbf{x}^\varepsilon$ approximates the process $\mathbf{x}$, uniformly in $k \in \mathbb{Z}_+$.

Proof of Proposition 5.3. When $\varepsilon > 0$, the conditional probability on $\mathcal{B}(\mathbf{X})$ defined by

$$P_{(x_0, \xi_0)}\{x_{k+1}^\varepsilon \in A \,|\, \xi_1, \cdots, \xi_k\}$$

possesses a density that is continuous and everywhere positive on $\mathbb{R}^{2n} \times M^{k+1}$. If A is a petite set for ξ, then it follows that $A \times K$ is petite for any compact set K of positive Lebesgue measure. This together with an argument similar to the proof of Proposition 2.2 shows that $\mathbf{\Phi}^\varepsilon$ is Harris recurrent. Since Lemma 5.3 implies that condition (S2) holds, an invariant probability exists for all $\varepsilon > 0$ and we conclude that $\mathbf{\Phi}^\varepsilon$ is positive Harris recurrent for all $\varepsilon > 0$. The Markov chain $\mathbf{\Phi}^\varepsilon$ is aperiodic for $\varepsilon > 0$ by (RLS3), and since the distribution of x_k^ε possesses the same null sets as Lebesgue measure on $\mathbb{R}^n$ for all $k \geqq 1$.

From (51) and Lemma 5.3 there exists a constant $B < \infty$ such that

$$E_{\Phi_0}[|x_{T_0+1}^\varepsilon - x_{T_0+1}|^2] \leqq \frac{\varepsilon^2 B}{1 - \lambda_0}$$

for every initial condition $\Phi_0 \in \mathbf{X}$, and it follows that

$$\limsup_{\varepsilon \to 0} \sup_{k \geqq 0} E_{\Phi_0}[|x_k^\varepsilon - x_k|^2] = 0 \tag{52}$$

for all initial conditions.

Fix $f \in \mathbf{C}$ uniformly continuous. By (52) and Chebyshev's inequality

$$\limsup_{\varepsilon \to 0} \sup_{k \geqq 0} E_{\Phi_0}[|f(x_k^\varepsilon) - f(x_k)|] = 0, \tag{53}$$

and since $\mathbf{\Phi}^\varepsilon$ is aperiodic and positive Harris recurrent for each $\varepsilon > 0$, there exists an invariant probability π_ε on $\mathcal{B}(\mathbf{X})$ such that

$$\lim_{k \to \infty} E_{\Phi_0}[f(\Phi_k^\varepsilon)] = \int f \, d\pi_\varepsilon. \tag{54}$$

Using Lemma 5.3 it may be shown that the invariant probabilities $\{\pi_\varepsilon : 0 < \varepsilon \leqq 1\}$ possess uniformly bounded second moments, and hence are tight. We may therefore find a subsequence $\varepsilon_i \to 0$ as $i \to \infty$, and a probability π on $\mathcal{B}(\mathbf{X})$ such that

$$\pi_{\varepsilon_i} \xrightarrow{\text{weakly}} \pi \quad \text{as } i \to \infty. \tag{55}$$

Combining (53)-(55) we have for all $i \in \mathbb{Z}_+$,

$$\begin{aligned}
&\limsup_{k\to\infty} \left| E_{\Phi_0}[f(\Phi_k)] - \int f\,d\pi \right| \\
&\quad \leqq \limsup_{k\to\infty} |E_{\Phi_0}[f(\Phi_k)] - E_{\Phi_0}[f(\Phi_k^{\varepsilon_i})]| \\
&\qquad + \limsup_{k\to\infty} \left| E_{\Phi_0}[f(\Phi_k^{\varepsilon_i})] - \int f\,d\pi_{\varepsilon_i} \right| + \left| \int f\,d\pi_{\varepsilon_i} - \int f\,d\pi \right| \\
&\quad \leqq \sup_{j\in\mathbb{Z}_+} |E_{\Phi_0}[f(\Phi_j)] - E_{\Phi_0}[f(\Phi_j^{\varepsilon_i})]| + \left| \int f\,d\pi_{\varepsilon_i} - \int f\,d\pi \right|.
\end{aligned}$$

Letting $i \to \infty$ shows that

$$\lim_{k\to\infty} E_{\Phi_0}[f(\Phi_k)] = \int f\,d\pi.$$

This implies that π is an invariant probability for the unperturbed process, and also that π is the unique weak limit point of the probabilities $\{\pi_\varepsilon : \varepsilon > 0\}$. Hence $\pi_\varepsilon \xrightarrow{\text{weakly}} \pi$ as $\varepsilon \to 0$.

It follows that π is the unique invariant probability for $\mathbf{\Phi}$, and that for all $x \in \mathbf{X}$ the limit (48) holds. By a simple calculation

$$\sup_{k\geqq 0} E_{\Phi_0}[|x_k|^{2+\delta}] < \infty$$

for each deterministic initial condition, and this together with (48) implies that

$$\lim_{k\to\infty} E_x[x_k^2] = \int x^2\,d\pi < \infty.$$

To complete the proof of Proposition 5.3 we show that conditions (A2) and (A3) of § 4 are satisfied. Since we have shown that (A1) holds, result (49) will follow from Proposition 4.2. Since the proof is fairly routine, we will be brief.

By Lemma 5.3 there exists a constant $B < \infty$ such that

$$P^{T_0}|x|^2(x) \leqq \lambda_0 |x|^2 + B.$$

It is easily shown that the equation above implies condition (A2), and by a martingale difference sequence argument it may be shown that

$$\limsup_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} |x_k|^{2+\delta/2} < \infty \quad \text{a.s. } [P_{\Phi_0}]$$

for all initial conditions, and in particular, condition (A3) holds.

This shows that the result (49) holds, and result (50) follows from (48), (49), and the previous inequality that implies that the function x^2 is uniformly integrable with respect to the occupation probabilities with probability one. □

5.3. Stochastic adaptive control. Consider the single-input single-output random parameter system model

$$y_{k+1} = \theta_k y_k + u_k + v_{k+1}, \qquad k \in \mathbb{Z}_+ \tag{56}$$

where the parameter process $\boldsymbol{\theta}$ is the output of the (AR1) model

$$\theta_{k+1} = \alpha\theta_k + e_{k+1}, \qquad k \in \mathbb{Z}_+ \tag{57}$$

and $\alpha \in (-1, 1)$.

The parameter process $\boldsymbol{\theta}$ is assumed to be unknown, but is estimated by the gradient algorithm

$$\hat{\theta}_{k+1} = \alpha\hat{\theta}_k + \alpha \frac{y_k(y_{k+1} - \hat{\theta}_k y_k - u_k)}{1 + y_k^2}. \tag{58}$$

This is a simplified version of the example analyzed in Meyn and Caines (1987) where $\hat{\boldsymbol{\theta}}$ is a version of the conditional expectation $\hat{\theta}_k = E[\theta_k \mid \mathcal{Y}_k]$, with $\mathcal{Y}_k \triangleq \sigma\{y_0, \cdots, y_k\}$. The estimator (58) was obtained by setting the estimation error covariance P_k in the algorithm of Meyn and Caines (1987) to a constant. Hence in the present example the parameter estimates $\{\hat{\theta}_k\}$ have no simple interpretation.

Assume now that our goal is to choose a control $u_k \in \mathcal{Y}_k$ that makes the mean square output error $E[y_k^2]$ as small as possible. When we apply the certainty equivalence control law

$$u_k = -\hat{\theta}_k y_k, \qquad k \in \mathbb{Z}_+ \tag{59}$$

and defining $\tilde{\theta}_k \triangleq \theta_k - \hat{\theta}_k$, the closed loop system equations become

$$\Phi_{k+1} \triangleq \begin{pmatrix} y_{k+1} \\ \tilde{\theta}_{k+1} \end{pmatrix} = \begin{pmatrix} \tilde{\theta}_k y_k + v_{k+1} \\ \alpha \dfrac{\tilde{\theta}_k - y_k v_{k+1}}{1 + y_k^2} + e_{k+1} \end{pmatrix}, \qquad k \in \mathbb{Z}_+. \tag{60}$$

It is evident that, under the appropriate conditions on the process $\mathbf{w} \triangleq \binom{\mathbf{v}}{\mathbf{e}}$, the state process $\boldsymbol{\Phi}$ is a Feller Markov chain of the form (1) with state space $\mathbf{X} \triangleq \mathbb{R}^2$.

We henceforth assume that $\mathbf{w}$ satisfies (W1) and (W2) that $\mathbf{v}$ and $\mathbf{e}$ are independent, and that the following additional assumptions hold for some $\delta > 0$:

$$E[w_1] = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad E[|w_1|^{4+\delta}] < \infty, \quad E[|e_1|^{2+\delta}] < 1. \tag{61}$$

These conditions imply that $\sigma_e^2 \triangleq E[|e_1|^2] < 1$, $\sigma_v^2 \triangleq E[|v_1|^2] < \infty$, and $\gamma_v^4 \triangleq E[|v_1|^2] < \infty$.

The state process $\boldsymbol{\Phi}$ is weakly stochastically controllable, and satisfies condition (GA) with $d^* = 0$. By Proposition 5.1 we conclude that the irreducibility hypothesis holds for an open petite set $A \subset \mathbf{X}$ and that $\boldsymbol{\Phi}$ is aperiodic. Our next task is to find a moment satisfying (12) so that we may apply Proposition 3.1.

Let $y : \mathbf{X} \to \mathbb{R}$ and $\tilde{\theta} : \mathbf{X} \to \mathbb{R}$ denote the coordinate variables on $\mathbf{X}$ so that

$$y_k = y(\Phi_k), \quad \tilde{\theta}_k = \tilde{\theta}(\Phi_k) \quad \text{for all } k \in \mathbb{Z}_+,$$

and define the test function V on $\mathbf{X}$ by

$$V(y, \tilde{\theta}) = \tilde{\theta}^4 + \varepsilon_0 \tilde{\theta}^2 y^2 + \varepsilon_0^2 y^2 \tag{62}$$

where $\varepsilon_0 > 0$ is a small constant which will be specified below.

Letting P denote the Markov transition function for Φ we have by (60),

$$Py^2 = \tilde{\theta}^2 y^2 + \sigma_v^2. \tag{63}$$

This is far from (12), but applying the operator P to the function $\tilde{\theta}^2 y^2$ gives

$$\begin{aligned} P\tilde{\theta}^2 y^2 &= E\left[\left(\frac{\alpha\tilde{\theta} - \alpha y v_1}{1+y^2} + e_1\right)^2 (\tilde{\theta} y + v_1)^2\right] \\ &= \sigma_e^2 \tilde{\theta}^2 y^2 + \sigma_e^2 \sigma_v^2 + \left(\frac{\alpha}{1+y^2}\right)^2 E[(\tilde{\theta} - y v_1)^2 (\tilde{\theta} y + v_1)^2] \\ &= \sigma_e^2 \tilde{\theta}^2 y^2 + \sigma_e^2 \sigma_v^2 + \left(\frac{\alpha}{1+y^2}\right)^2 [\tilde{\theta}^4 y^2 + \tilde{\theta}^2 \sigma_v^2 - 4\tilde{\theta}^2 y^2 \sigma_v^2 + \tilde{\theta}^2 y^4 \sigma_v^2 + y^2 \gamma_v^4], \end{aligned}$$

and hence we may find a constant $B_1 < \infty$ such that

$$P\tilde{\theta}^2 y^2 \leqq \sigma_e^2 \tilde{\theta}^2 y^2 + B_1(\tilde{\theta}^4 + \tilde{\theta}^2 + 1). \tag{64}$$

From (60) it is easy to show that for some constant $B_2 > 0$

$$P\tilde{\theta}^4 \leqq \alpha^4 \tilde{\theta}^4 + B_2(\tilde{\theta}^2 + 1). \tag{65}$$

Combining equations (63)-(65) we may find a constant $K_3 < \infty$, such that for all $0 < \varepsilon < 1$,

$$\begin{aligned} P(\tilde{\theta}^4 + \varepsilon\tilde{\theta}^2 y^2 + \varepsilon^2 y^2) &\leqq (\alpha^4 + \varepsilon K_3)\tilde{\theta}^4 + (\sigma_e^2 + \varepsilon)\varepsilon\tilde{\theta}^2 y^2 + K_3(\tilde{\theta}^2 + 1) \\ &\leqq (\alpha^4 + 2\varepsilon K_3)\tilde{\theta}^4 + (\sigma_e^2 + \varepsilon)\varepsilon\tilde{\theta}^2 y^2 + 2K_3/\varepsilon \end{aligned} \tag{66}$$

where the second inequality follows from the estimate $\tilde{\theta}^2 \leqq \varepsilon\tilde{\theta}^4 + 1/\varepsilon$. Fix $1 > \lambda > \max(\sigma_e^2, \alpha^4)$. Then by (66) we may find $\varepsilon_0 > 0$ sufficiently small, and a constant $K > 0$ sufficiently large such that (12) holds with V defined in (62).

A modification of (63) and (64) may be used together with (61) to show that

$$\sup_{k \geqq 0} E_x[|y_k|^{2+\delta}] < \infty,$$

and applying Proposition 3.1 and Proposition 2.1 we obtain Proposition 5.4.

PROPOSITION 5.4. *The Markov chain Φ defined in* (60) *is geometrically ergodic, and for all initial conditions $x \in \mathbf{X}$,*

$$\lim_{k\to\infty} E_x[y_k^2] = \int y^2 \, d\pi$$

at a geometric rate, and

$$\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} y_k^2 = \int y^2 \, d\pi < \infty \quad a.s.\,[P_x].$$

6. Conclusions. The principal tool used in both stochastic and deterministic stability theory is some form of Lyapunov function. In this paper we have taken a specific Lyapunov function that at first sight appears to provide at most a very crude form of stability, but in fact has broad implications to ergodic theory and implies stronger stability results that might be expected.

We have shown that under general conditions its existence implies that the law of large numbers holds for a large class of functions of the Markov chain Φ and all initial conditions. Furthermore, if a stochastic controllability condition is satisfied, then the underlying distributions governing the system converge to an invariant

probability at a geometric rate. This is known as geometric ergodicity in the Markov chain literature, but may also be seen as a form of exponential asymptotic stability of the Markov transition operator P acting on $\mathcal{M}$ = the set of all probabilities on $\mathcal{B}(\mathbf{X})$.

There are at least two implications of these results that require further study. First of all, it appears that the results presented here will find application to the ODE (ordinary differential equation) method (see, for example, Kushner (1983)). One of the key hypotheses of Kushner (1983) is the existence of limits of the form

$$\lim_{N\to\infty} \sum_{k=n}^{N} a_k (P^{k-n} G(\Phi_n) - \bar{G})$$

where a_k is a square summable scalar sequence. We feel that geometric ergodicity is an obvious route to proving that this limit exists and computing bounds on the limit. If this is the case, then test functions satisfying (12) should be a powerful tool when combined with the ODE method. This idea has already been pursued in Arapostathis and Marcus (1988).

Another possible application is to the structural robustness of stochastic systems. It is well known that the solutions of the ordinary differential equation

$$\dot{x} = f(x) + \varepsilon(x, t)$$

will be uniformly bounded if the error term ε is sufficiently small in some sense, and the "ideal system" $\dot{x} = f(x)$ is sufficiently stable.

By considering the dynamical system on $\mathcal{M}$ generated by a Markov transition operator P, and using the fact that geometric ergodicity is simply a form of exponential asymptotic stability for P, it may be possible to extend this result to the stochastic case.

Acknowledgments. I thank Professor Peter Caines of McGill University for a number of stimulating discussions on stability theory at the time that I was writing § 3, and for suggesting the example on nonlinear control.

SIMULATED ANNEALING TYPE MARKOV CHAINS AND THEIR ORDER BALANCE EQUATIONS*

DANIEL P. CONNORS† AND P. R. KUMAR‡

Abstract. Generalized simulated-annealing type Markov chains where the transition probabilities are proportional to powers of a vanishing small parameter are considered. An "order of recurrence," which quantifies the asymptotic behavior of the state occupation probability, is associated with each state. These orders of recurrence satisfy a fundamental balance equation across every edge-cut in the graph of the Markov chain. Moreover, the Markov chain converges in a Cesaro-sense to the set of states having the largest recurrence orders. These results convert the analytic problem of determining the asymptotic properties of the time-inhomogeneous stochastic process into a purely algebraic problem of solving the balance equations to determine the recurrence orders.

Graph theoretic algorithms are provided to determine the solutions of the balance equations. By applying these results to the problem of optimization by simulated annealing, it is shown that the sum of the recurrence order and the cost is a constant for all states in a certain connected set, whenever a "weak-reversibility" condition is satisfied. This allows the necessary and sufficient condition for the optimization algorithm to hit the global minimum with probability one to be obtained.

Key words. simulated annealing, optimization, Markov chains

AMS(MOS) subject classifications. 60J10, 90C27

1. Introduction. We consider finite state Markov chains $\{x(t)\}$ with transition probabilities of the type

$$p_{ij}(t) = c_{ij}\varepsilon(t)^{V_{ij}},$$

where $\varepsilon(t)$ is a small parameter converging to zero. In a previous paper [7] we have shown that if we define "orders of recurrence" by (more precise definitions are given in § 2)

$$\beta_i := \sup\left\{c \geqq 0: \sum_{t=0}^{\infty} \varepsilon(t)^c \pi_i(t) = +\infty\right\},$$

then

(i) These recurrence orders satisfy a balance equation, $\max_{i\in A, j\in A^c}(\beta_i - V_{ij}) = \max_{i\in A, j\in A^c}(\beta_j - V_{ji})$, for every subset A; and

(ii) The Markov process converges to the set of states with the largest orders of recurrence.

This provides a novel approach to analyzing the asymptotic behavior of such time-inhomogeneous Markov processes. Specifically, we use (i) to solve the balance equations, and then (ii) provides the limiting behavior. Moreover, the orders of recurrence also provide information about the rates of convergence of the state occupation probabilities. This approach via recurrence orders therefore converts the analytic problem of determining the asymptotic behavior of the time-inhomogeneous process into a purely algebraic problem of solving the balance equations.

A significant motivation for studying such Markov chains lies in the fact that in the method of optimization by simulated annealing, if $\{W_i\}$ is the cost function whose minimum is sought, then we obtain a Markov chain with

$$p_{ij}(t) = c_{ij}\varepsilon(t)^{\max(0, W_j - W_i)}.$$

Thus simulated annealing is a special case where the powers V_{ij} satisfy

$$V_{ij} := \max(0,\ W_j - W_i),$$

for some $\{W_i\}$.

To pursue the above approach to analyzing such time-inhomogeneous Markov chains, it is necessary to be able to solve the balance equations. However, there can be nonunique solutions to the balance equations. We present graph-theoretic circulation based algorithms to obtain *a* solution, as well as *all* solutions, to the balance equations. We show by an example the interesting phenomenon that such nonuniqueness can arise when the asymptotic properties of the Markov process, and the recurrence orders, depend not just on the *exponents* V_{ij}, but also on the *proportionality constants* c_{ij}.

By applying these results to the Markov chain arising from the method of optimization by simulated annealing when the "weak reversibility" condition of Hajek [1] holds, we show that the sum of the recurrence order and the cost is a constant on sets connected by recurrent arcs. This allows us to obtain the necessary and sufficient condition for the optimization algorithm to hit the global minimum with probability one. Our necessity result is a stronger sample path result than is found in [1] or [2].

Background. Tsitsiklis [2] has also investigated Markov chains with transition probabilities proportional to powers of a small time-varying parameter. His analysis was based on observing that due to the slow variation of $\{\varepsilon(t)\}$, we can employ bounds on the state occupation probabilities for *stationary* Markov chains, where $\varepsilon(t)$ is held constant, to obtain bounds for the time-inhomogeneous case. His approach is quite different from ours.

Based on an analogy to the physical process of annealing, the sequence $\varepsilon(t)$ is called the "cooling schedule," and just as in the physical analogy it plays a key role in determining asymptotic behavior. It has been shown by Geman and Geman [3], Mitra, Romeo, and Sangiovanni-Vincentelli [4], and Gidas [5], that simulated annealing converges in probability to a minimum of the optimization problem provided $\sum_{t=0}^{\infty} \varepsilon(t)^p = +\infty$ for large enough p. Hajek [1] has determined the necessary and sufficient conditions on the value of p for the algorithm to converge *in probability* to the minimum when a "weak reversibility" assumption is satisfied.

2. Orders of recurrence and balance equations. Consider a Markov chain over a finite state space X whose transition probabilities are proportional to *powers* of a vanishing time varying parameter $\varepsilon(t)$; that is, the transition probabilities $p_{ij}(t) := \Pr(x(t+1) = j \mid x(t) = i)$ are given by

$$(1) \qquad p_{ij}(t) = c_{ij}\varepsilon(t)^{V_{ij}} \quad \text{for all } i, j \in X,\ i \neq j, \text{ and } t \in \mathscr{Z}^+, \text{ and } p_{ii}(t) = 1 - \sum_{j \neq i} p_{ij}(t)$$

where

$$(2) \qquad 0 \leqq V_{ij} \leqq +\infty \quad \text{for all } i, j \in X,\ i \neq j,$$

$$(3) \qquad c_{ij} \geqq 0 \quad \text{for all } i, j \in X,\ i \neq j, \text{ and } \sum_j c_{ij} = 1 \text{ for all } i.$$

Regarding the small parameter $\{\varepsilon(t)\}$, we will assume that,

$$0<\varepsilon(t)<1 \quad \text{for all } t\in\mathscr{Z}^+, \tag{4}$$

$$\exists M<\infty \text{ such that } \varepsilon(t)\leqq M\varepsilon(s) \text{ whenever } t\geqq s, \text{ and} \tag{5}$$

$$\sum_{t=1}^{\infty}\varepsilon(t)^p<\infty \quad \text{for some } p\in[1,+\infty). \tag{6}$$

In what follows we will assume that in (1)-(3) we have

$$c_{ij}=0\Leftrightarrow V_{ij}=+\infty,$$

which is clearly without any loss of generality. We shall denote by N_i the set of all states j with $c_{ij}>0$. Finally, we will assume that the Markov chain is "connected;" i.e., for every $i,j\in X$, there exists a path $i=i_0,\cdots,i_p=j$, with $i_l\in N_{i_{l-1}}$ for $1\leqq l\leqq p$.

Let $\pi_i(t):=\Pr(x(t)=i)$ be the probability distribution of $x(t)$, and let $\pi_{ij}(t):=\Pr(x(t)=i, x(t+1)=j)$ be the probability of a *transition* from state i to j at time t.

The following example motivates the notion of "orders of recurrence" introduced in [7].

Example 1. Suppose, for a certain Markov chain (with more than two states!), we have

$$\pi_1(t)=1/t^{1/3},\quad \pi_2(t)=1/t^{2/3},\quad \varepsilon(t)=1/t^{1/3}.$$

Then note that $\sum_{t=0}^{\infty}\varepsilon(t)^c\pi_1(t)$ is *finite* if $c>\beta_1:=2$ and $+\infty$ if $c\leqq\beta_1$. Similarly, $\sum_{t=0}^{\infty}\varepsilon(t)^c\pi_2(t)$ is *finite* if $c>\beta_2:=1$ and $+\infty$ if $c\leqq\beta_2$. Now $\pi_1(t)$ converges to zero more slowly than $\pi_2(t)$ and it is easy to see that this information is also captured by the demarcation points β_1 and β_2, which thus provide a measure by which to rank the rates at which $\pi_1(t)$ and $\pi_2(t)$ converge to zero.

Motivated by this we define the *recurrence orders* for the states and transitions of the Markov process, as follows.

DEFINITION 1. The order of recurrence of a state $i\in X$, denoted β_i, is

$$\beta_i:=\begin{cases}-\infty & \text{if } \sum_{t=0}^{\infty}\pi_i(t)<+\infty,\\ p^- & \text{if } p=\sup\left\{c\geqq 0:\sum_{t=0}^{\infty}\varepsilon(t)^c\pi_i(t)=+\infty\right\} \text{ and } \sum_{t=0}^{\infty}\varepsilon(t)^p\pi_i(t)<+\infty,\\ p & \text{if } p=\max\left\{c\geqq 0:\sum_{t=0}^{\infty}\varepsilon(t)^c\pi_i(t)=+\infty\right\}.\end{cases}$$

We say a state i is *transient* if $\beta_i=-\infty$; otherwise we say the state is *recurrent.*

In a similar manner we define the *order of recurrence of the transition from i to j.*

DEFINITION 2. The order of recurrence of the transition from state i to j, denoted β_{ij}, is

$$\beta_{ij}:=\begin{cases}-\infty & \text{if } \sum_{t=0}^{\infty}\pi_{ij}(t)<+\infty,\\ p^- & \text{if } p=\sup\left\{c\geqq 0:\sum_{t=0}^{\infty}\varepsilon(t)^c\pi_{ij}(t)=+\infty\right\} \text{ and } \sum_{t=0}^{\infty}\varepsilon(t)^p\pi_{ij}(t)<+\infty,\\ p & \text{if } p=\max\left\{c\geqq 0:\sum_{t=0}^{\infty}\varepsilon(t)^c\pi_{ij}(t)=+\infty\right\}.\end{cases}$$

Again, we say the transition from i to j is *transient* if $\beta_{ij}=-\infty$; otherwise we say the transition is *recurrent.*

It is also convenient to define ρ, the *order of cooling* of $\{\varepsilon(t)\}$, as follows.

DEFINITION 3. The order of the cooling schedule $\{\varepsilon(t)\}$, denoted ρ, is defined as

$$\rho := \begin{cases} -\infty & \text{if } \sum_{t=0}^{\infty} \varepsilon(t) < +\infty, \\ p^- & \text{if } p = \sup\left\{c \geqq 0: \sum_{t=0}^{\infty} \varepsilon(t)^c = +\infty\right\} \text{ and } \sum_{t=0}^{\infty} \varepsilon(t)^p < +\infty, \\ p & \text{if } p = \max\left\{c \geqq 0: \sum_{t=0}^{\infty} \varepsilon(t)^c = +\infty\right\}. \end{cases}$$

The relationship between β_i, β_{ij}, and ρ is given in the following lemma. It will be convenient in the sequel to define the operation "$\ominus$" as follows:

$$a \ominus b := \begin{cases} -\infty & \text{if } a < b, \\ a - b, & \text{if } a \geqq b. \end{cases}$$

LEMMA 1. *β_{ij} and β_i are related by*

$$\beta_{ij} = \beta_i \ominus V_{ij} \quad \textit{for all } i, j \in X, \tag{7}$$

while ρ and β_i are related by

$$\max_{i \in X} \beta_i = \rho. \tag{8}$$

Proof. If $j \notin N_i$, then it immediately follows that $\beta_{ij} = -\infty$. If $j \in N_i$, then application of the Chapman-Kolmogorov equation

$$\begin{aligned} \pi_{ij}(t) &= \pi_i(t) p_{ij}(t) \\ &= c_{ij} \varepsilon(t)^{V_{ij}} \pi_i(t), \end{aligned}$$

gives the first assertion. Similarly, since

$$\sum_{t=0}^{\infty} \varepsilon(t)^p = \sum_{i \in X} \sum_{t=0}^{\infty} \varepsilon(t)^p \pi_i(t),$$

the second assertion also follows. □

Knowledge of the β_i's provides useful information about the asymptotic properties of $\{x(t)\}$. The following theorem shows that the time-inhomogeneous Markov chain converges in a *Cesaro sense* to the set of states having the largest orders of recurrence.

THEOREM 1. *Let $\mathcal{M}$ be the set of states with the largest orders of recurrence*:

$$\mathcal{M} := \{i \in X: \beta_i = \rho\}.$$

Then

$$\limsup_{N \to \infty} \frac{1}{N} \sum_{t=1}^{N} \Pr(x(t) \in \mathcal{M}) = 1. \tag{9}$$

Proof. Let us first consider the set $\bar{\mathcal{M}}$ defined by

$$\bar{\mathcal{M}} := \begin{cases} \mathcal{M} & \text{if } \rho = 0, -\infty \text{ or } p^- \text{ for some } p \in \mathcal{R},\ p > 0, \\ \mathcal{M} \cup \{i \in X: \beta_i = p^-\} & \text{if } \rho = p \text{ for some } p \in \mathcal{R},\ p > 0. \end{cases}$$

Note that if $\rho = p$, then $\bar{\mathcal{M}}$ may be slightly larger than $\mathcal{M}$ since it includes states, if any, whose recurrence orders are p^-; otherwise it is the same as $\mathcal{M}$. We will first show that

$$\limsup_{N \to \infty} \frac{1}{N} \sum_{t=1}^{N} \Pr(x(t) \in \bar{\mathcal{M}}) = 1. \tag{10}$$

Consider first the case $\rho > 0$. Clearly, $\rho = p$ or p^- for some $p \in \mathcal{R}$, where $p > 0$. Let

$$Q = \{q \in \mathcal{R}: \text{ for some } i \in \bar{\mathcal{M}}^c,\ \beta_i = q \text{ or } q^-\}.$$

Let $\theta = \inf_{q \in Q} (p - q)$, where $\inf \varnothing = +\infty$. Let

$$\gamma = \begin{cases} \theta & \text{if } \theta < +\infty, \\ p & \text{if } \theta = +\infty. \end{cases}$$

Consider the states in $\bar{\mathcal{M}}^c$ and observe that for sufficiently small $\delta > 0$,

$$\sum_{t=0}^{\infty} \Pr(x(t) \in \bar{\mathcal{M}}^c) \varepsilon(t)^{p-\gamma+\delta} < +\infty,$$

since the state space is finite. An application of Kronecker's Lemma (see Chung [6]) gives

$$\lim_{N \to \infty} \varepsilon(N)^{p-\gamma+\delta} \sum_{t=1}^{N} \Pr(x(t) \in \bar{\mathcal{M}}^c) = 0;$$

that is,

$$\lim_{N \to \infty} (N\varepsilon(N)^{p-\gamma+\delta}) \frac{1}{N} \sum_{t=1}^{N} \Pr(x(t) \in \bar{\mathcal{M}}^c) = 0. \tag{11}$$

Now we claim that

$$\limsup_{N \to \infty} N\varepsilon(N)^{p-\gamma+\delta} > 0. \tag{12}$$

Suppose not. Then,

$$\lim_{N \to \infty} N\varepsilon(N)^{p-\gamma+\delta} = 0,$$

and so

$$\lim_{N \to \infty} \frac{1/N}{\varepsilon(N)^{p-\gamma+\delta}} = +\infty.$$

In particular, we have

$$\lim_{N \to \infty} \left(\frac{1/N}{\varepsilon(N)^{p-\gamma+\delta}} \right)^{(p-\delta)/(p-\gamma+\delta)} = +\infty,$$

implying that

$$\lim_{N \to \infty} \frac{(1/N)^{(p-\delta)/(p-\gamma+\delta)}}{\varepsilon(N)^{p-\delta}} = +\infty.$$

However, since $\sum_{t=0}^{\infty} \varepsilon(t)^{p-\delta} = +\infty$, this would imply that

$$\sum_{N=1}^{\infty} \left(\frac{1}{N} \right)^{(p-\delta)/(p-\gamma+\delta)} = +\infty \quad \text{for all small } \delta > 0,$$

which is false. Hence, (12) holds and from (11) we deduce that

$$\liminf_{N \to \infty} \frac{1}{N} \sum_{t=1}^{N} \Pr(x(t) \in \bar{\mathcal{M}}^c) = 0. \tag{13}$$

But since

$$\frac{1}{N}\sum_{t=1}^{N}\Pr\left(x(t)\in\bar{\mathcal{M}}\right)+\frac{1}{N}\sum_{t=1}^{N}\Pr\left(x(t)\in\bar{\mathcal{M}}^c\right)=1,$$

the result (10) follows.

Now turn to the case $\rho=0$. Then clearly, $\sum_{t=0}^{\infty}\Pr\left(x(t)\in\bar{\mathcal{M}}^c\right)<+\infty$, and so (13) is again true and the result (10) follows.

If $\rho=-\infty$, the result (10) is trivial.

To proceed from (10) to (9), it is clearly sufficient to show that in the case $\rho=p$ for some $p\in\mathcal{R}$, $p>0$,

$$\lim_{t\to\infty}\Pr\left(x(t)\in\{i\colon \beta_i=p^-\}\right)=0.$$

This involves some results on the structure of the recurrence orders and is demonstrated in Lemma 5. □

Thus, knowledge of the recurrence orders $\{\beta_i\}$ provides knowledge about the asymptotic properties of the time-inhomogeneous Markov chain. In fact, as the reader may see from Example 1, the recurrence orders also provide information about the rates of convergence.

Our goal therefore is to determine the recurrence orders, and critical to that will be the following result established in [7], which shows that there is a fundamental balance of recurrence orders across every edge-cut in the graph of the Markov chain.

THEOREM 2 (Order Balance).

$$\max_{i\in A,j\in A^c}\beta_{ij}=\max_{i\in A,j\in A^c}\beta_{ji}\quad \textit{for every } A\subseteq X. \tag{14}$$

Equivalently, using the "⊖" notation and (7),

$$\max_{i\in A,j\in A^c}\beta_i\ominus V_{ij}=\max_{i\in A,j\in A^c}\beta_j\ominus V_{ji}\quad \textit{for every } A\subseteq X. \tag{15}$$

Proof. We sketch the proof; see [7] for the precise proof. Choose $A\subseteq X$ and note that if $\{\tau(n)\}_{n\geqq 1}$ is the sequence of random times at which the process moves from A to A^c, while $\{\sigma(n)\}_{n\geqq 1}$ is the sequence of random times at which the process moves from A^c back to A, then we have

$$\tau(n)<\sigma(n)<\tau(n+1),$$

where we have assumed, without loss of generality, that $x(0)\in A$ to give $\tau(1)<\sigma(1)$. Using this it follows from (5) that

$$\begin{aligned}
\sum_{t=0}^{+\infty}\varepsilon(t)^c I(x(t)\in A^c, x(t+1)\in A) &= \sum_{n=1}^{+\infty}\varepsilon(\sigma(n))^c\\
&\leqq M^c\sum_{n=1}^{+\infty}\varepsilon(\tau(n))^c\\
&= M^c\sum_{t=0}^{+\infty}\varepsilon(t)^c I(x(t)\in A, x(t+1)\in A^c)\\
&= M^c\sum_{n=1}^{+\infty}\varepsilon(\tau(n+1))^c + M^c\varepsilon(\tau(1))^c\\
&\leqq M^{2c}\sum_{n=1}^{+\infty}\varepsilon(\sigma(n))^c + M^{2c}\varepsilon(0)^c\\
&= M^{2c}\sum_{t=0}^{+\infty}\varepsilon(t)^c I(x(t)\in A^c, x(t+1)\in A) + M^{2c}\varepsilon(0)^c.
\end{aligned}$$

By taking expected values and using the Monotone Convergence Theorem, it follows that

$$\sum_{t=0}^{\infty} \varepsilon(t)^c \sum_{i\in A, j\in A^c} \pi_{ij}(t) < +\infty \Leftrightarrow \sum_{t=0}^{\infty} \varepsilon(t)^c \sum_{i\in A^c, j\in A} \pi_{ij}(t) < +\infty.$$

Hence both sides above converge or diverge together. Now if c is so large that every term on the left-hand side with $i \in A$, $j \in A^c$ converges, then clearly c is also so large that every term on the right-hand side converges. Thus,

$$c > \max_{i\in A, j\in A^c} \beta_{ij} \Leftrightarrow c > \max_{i\in A, j\in A^c} \beta_{ji}.$$

Likewise if c is small enough so that some term on the left-hand side diverges, then c is also small enough so that some term on the right-hand side diverges, and so

$$c \leqq \max_{i\in A, j\in A^c} \beta_{ij} \Leftrightarrow c \leqq \max_{i\in A, j\in A^c} \beta_{ji}. \qquad \square$$

Note that through Theorems 1 and 2 we have converted the problem of determining the asymptotic properties of the time-inhomogeneous Markov chain into an *algebraic* problem of solving the balance equations (14). Note that (14) provides a maximum of $2^{|X|}$ equations, one for each edgecut.

3. The modified balance equations. Note that if $(\beta_1, \beta_2, \cdots, \beta_{|X|})$ satisfy (15), then $(\beta_1 - a, \beta_2 - a, \cdots, \beta_{|X|} - a)$ also satisfy (15) for every a, i.e., the solution set is *translation invariant.* Thus (8), which fixes the *maximum* of the β_i's, also needs to be taken into account.

However, (15), (8) together can *still* possess nonunique solutions for sufficiently small values of ρ. In this section, we will show how we can obtain *one* solution to (15), (8); in the next section we show how to obtain *all* solutions.

In cases where there is a unique solution to the order balance equations, the algorithm of this section gives an $O(|X|^3)$ algorithm for determining it, compared to the algorithm of § 4 for obtaining all solutions (in the nonunique case), which is exponential in $|X|$. Also, the results of this section are used in the analysis of the simulated annealing algorithm in § 5.

It is convenient to consider the following "modified" balance equations that, as we show in the sequel, always possess a unique solution. Given $\rho \geqq 0$ and $V_{ij} \geqq 0$ for $i, j = 1, \cdots, |X|$ with $i \neq j$, consider the problem of determining $\lambda := (\lambda_1, \cdots, \lambda_{|X|})$ such that

$$\max_{i\in A, j\in A^c} \lambda_i - V_{ij} = \max_{i\in A, j\in A^c} \lambda_j - V_{ji} \quad \text{for every } A \subseteq \{1, \cdots, |X|\}, \tag{16}$$

and

$$\max_i \lambda_i = \rho. \tag{17}$$

We call (16), (17) the "modified" balance equations. Observe that (16) differs from (15) in that the operation "$-$" is used in place of "$\ominus$." Also, the λ's can be negative in (16).

We have introduced the modified balance equations to avoid the difficulties in handling $-\infty$ that occur under the "$\ominus$" operation.

THEOREM 3 (Properties of Order Balance and Modified Balance Equations). (1) *If λ satisfies the modified balance equations for a given ρ and V, then β defined by*

$$\beta_i := \lambda_i \ominus 0 \tag{18}$$

satisfies the order balance equations (15), (8) *for the given ρ and V.*

(2) *For every given ρ and V, there exists a unique solution λ to the modified balance equations. Moreover, the solutions for different values of ρ are translates of each other.*

(3) *Whenever ρ is large enough, there exists a unique solution to the order balance equations* (15), (8). *These unique solutions are all translates of the solutions for the modified balance equations.*

Proof. Suppose that for a fixed ρ and V, there exist *two distinct* solutions β and $\hat{\beta}$ to the order balance equations. Define

$$A := \{k \in X: \hat{\beta}_k \leqq \beta_k\}.$$

Then we claim that

$$\max_{i \in A, j \in A^c} \beta_i \ominus V_{ij} = \max_{i \in A, j \in A^c} \beta_j \ominus V_{ji} = -\infty$$

and

$$\max_{i \in A, j \in A^c} \hat{\beta}_i \ominus V_{ij} = \max_{i \in A, j \in A^c} \hat{\beta}_j \ominus V_{ji} = -\infty.$$

We need only consider the case where $A \neq \varnothing$ and $A \neq X$ (otherwise the claim is trivially true), and let us suppose to the contrary that both expressions are nonnegative. Then

$$\max_{i \in A, j \in A^c} \hat{\beta}_i \ominus V_{ij} = \max_{i \in A, j \in A^c} \hat{\beta}_j \ominus V_{ji} > \max_{i \in A, j \in A^c} \beta_j \ominus V_{ji} = \max_{i \in A, j \in A^c} \beta_i \ominus V_{ij} \geqq \max_{i \in A, j \in A^c} \hat{\beta}_i \ominus V_{ij},$$

which is a contradiction. The other two cases follow similarly, and so the claim is true. This shows that solutions to the order balance equations do not differ arbitrarily; specifically, all the arcs that separate A from A^c are transient.

Hence in particular, whenever we can show that

$$\beta_i \ominus V_{ij} \geqq 0 \quad \text{for all } i, j, \text{ with } i \neq j, \text{ and } V_{ij} < +\infty, \tag{19}$$

there can only exist *one* solution to the order balance equations for the given (ρ, V).

Now we show that this is indeed the case when ρ is large, which will prove the first part of the assertion (3) above. Specifically, suppose now that $\rho \geqq 2 \sum_{i,j:\, V_{ij} < +\infty} V_{ij}$.

Let $i_0 \in X$ be a state with $\beta_{i_0} = \rho$. For arbitrary $s \in X$, let $(i^* = i_0, i_1, \cdots, i_p = s)$ be a path from i^* to s such that $V_{i_{k-1}, i_k} < +\infty$ for $k = 1, \cdots, p$ and $i_k \neq i_m$ for $k \neq m$. Let $l(i) = \arg\min_j V_{ij}$. With $A = \{i_k\}$ and applying the Order Balance Theorem 2, it is easy to see that

$$\beta_{i_{k-1}} \ominus V_{i_{k-1}, i_k} \leqq \beta_{i_k} \ominus V_{i_k, l(i_k)} = \max_{j \neq i_k} (\beta_{i_k} \ominus V_{i_k, j}). \tag{20}$$

To prove that $\beta_s \geqq \max_{i,j:\, V_{ij}} V_{ij} < +\infty$, it is sufficient to show that for $k = 1, \cdots, p$, along the path from i^* to s,

$$\beta_{i_k} \geqq \beta_{i_0} - V_{i_0, i_1} + V_{i_1, l(i_1)} - V_{i_1, i_2} + V_{i_2, l(i_2)} - \cdots - V_{i_{k-1}, i_k} + V_{i_k, l(i_k)}, \tag{21}$$

since $\beta_{i_0} = \rho \geqq 2 \sum_{i,j:\, V_{ij} < +\infty} V_{ij}$.

We prove (21) by induction. For $k = 1$, from (20) we see that

$$\beta_{i_0} \ominus V_{i_0, i_1} \leqq \beta_{i_1} \ominus V_{i_1, l(i_1)}. \tag{22}$$

Clearly, the left-hand side of (22) is nonnegative, implying that the right-hand side is also nonnegative. Thus, we can replace "$\ominus$" with "$-$" giving

$$\beta_{i_1} \geqq \beta_{i_0} - V_{i_0, i_1} + V_{i_1, l(i_1)}. \tag{23}$$

Now assume (21) holds for $k-1$. From (20) we have

$$\beta_{i_{k-1}} \ominus V_{i_{k-1}, i_k} \leqq \beta_{i_k} \ominus V_{i_k, l(i_k)}. \tag{24}$$

The left-hand side of (24) is nonnegative and so

$$\begin{aligned}\beta_{i_k} &\geqq \beta_{i_{k-1}} - V_{i_{k-1},i_k} + V_{i_k,l(i_k)} \\ &\geqq \beta_{i_0} - V_{i_0,i_1} + V_{i_1,l(i_1)} - V_{i_1,i_2} + V_{i_2,l(i_2)} - \cdots - V_{i_{k-1},i_k} + V_{i_k,l(i_k)},\end{aligned}$$

which completes the induction proof. This proves (19), and therefore there exists a unique solution whenever ρ is large enough, which is the first half of assertion (3) above.

Moreover, for the large enough ρ specified earlier, due to (19), we have $\beta_i \ominus V_{ij} = \beta_i - V_{ij}$. Hence $\{\beta_i\}$ itself satisfies the modified balance equations. In fact, this solution is unique to the modified balance equations since, if λ is any other solution, then we can prove in a fashion similar to the above, that $\lambda_i \geqq V_{ij}$ for all $j \in N_i$, thus yielding that $\lambda_i \ominus V_{ij} = \lambda_i - V_{ij}$, which in turn proves that λ is yet another solution to the order balance equations, which is a contradiction.

Hence, at least for large enough values of ρ we have proved the existence of a unique solution to the modified balance equations. However, it is easy to see that if λ satisfies the modified equations for a given (ρ, V), then $\lambda - \delta$ satisfies the modified balance equations for $(\rho - \delta, V)$, thus proving the existence of a unique solution to the modified balance equations for *all* (ρ, V). This proves the assertion (2) as well as the second half of the assertion (3) above.

Now we turn to the proof of assertion (1) above. Let A be arbitrary, and let $\{\lambda_i\}$ be the solution of the modified balance equations, and define $\beta_i := \lambda_i \ominus 0$. Suppose

$$\max_{i \in A, j \in A^c} \lambda_i - V_{ij} < 0.$$

Then by (16) we also have

$$\max_{i \in A, j \in A^c} \lambda_j - V_{ji} < 0.$$

However, then for each $i \in A$ and $j \in A^c$,

$$\beta_i \leqq \lambda_i < V_{ij} \quad \text{and} \quad \beta_j \leqq \lambda_j < V_{ji}.$$

Hence,

$$\beta_i \ominus V_{ij} = -\infty \quad \text{and} \quad \beta_j \ominus V_{ji} = -\infty,$$

and so

$$\max_{i \in A, j \in A^c} \beta_i \ominus V_{ij} = \max_{i \in A, j \in A^c} \beta_j \ominus V_{ji},$$

thus satisfying the original order balance equations. If, however,

$$\max_{i \in A, j \in A^c} \lambda_i - V_{ij} = \delta \geqq 0,$$

then by (16)

$$\max_{i \in A, j \in A^c} \lambda_j - V_{ji} = \delta \geqq 0.$$

Suppose that $(i_1, j_1) \in A \times A^c$ and $(i_2, j_2) \in A^c \times A$ are such that

$$\lambda_{i_1} - V_{i_1,j_1} = \lambda_{j_2} - V_{j_2,i_2} = \delta.$$

Then since

$$\lambda_{i_1} = V_{i_1,j_1} + \delta \geqq 0 \quad \text{and} \quad \lambda_{j_2} = V_{j_2,i_2} + \delta \geqq 0$$

we have

$$\beta_{i_1} = \lambda_{i_1} \quad \text{and} \quad \beta_{j_2} = \lambda_{j_2},$$

and so

$$\beta_{i_1} - V_{i_1,j_1} = \beta_{j_2} - V_{j_2,i_2}.$$

Also, since $\lambda_k \geqq \beta_k$, we have

$$\begin{aligned}\max_{i\in A, j\in A^c} \beta_i \ominus V_{i,j} &\leqq \max_{i\in A, j\in A^c} \lambda_i \ominus V_{ij} \\ &\leqq \max_{i\in A, j\in A^c} \lambda_i - V_{ij} \\ &= \lambda_{i_1} - V_{i_1,j_1} \\ &= \beta_{i_1} - V_{i_1,j_1} \\ &= \beta_{i_1} \ominus V_{i_1,j_1}.\end{aligned}$$

Similarly, $\max_{i\in A, j\in A^c} \beta_j \ominus V_{ji} = \beta_{j_2} \ominus V_{j_2,i_2}$, and so

$$\max_{i\in A, j\in A^c} \beta_i \ominus V_{ij} = \max_{i\in A, j\in A^c} \beta_j \ominus V_{ji}.$$

This proves the assertion (1) and the theorem. □

Remark 1. It is interesting to note that the existence of a solution to the modified balance equations has been proved by relying on the existence of a solution to the order balance equations, which in turn is guaranteed by the probabilistic arguments of Theorem 2. A separate independent constructive proof of existence, which does not use probabilistic arguments, can be found in [8].

We now give an algorithm for determining the *unique* solution to the modified balance equations. An illustrative example is convenient.

Example 2. Let $\rho = 5$ and

$$V = [V_{ij}] = \begin{Bmatrix} \bigstar & 4 & 3 & 1 \\ 6 & \bigstar & 3 & 7 \\ 6 & 2 & \bigstar & 4 \\ 2 & 6 & 5 & \bigstar \end{Bmatrix}.$$

Our goal is to determine $\lambda = (\lambda_1, \cdots, \lambda_4)$, which satisfies (16), (17). We shall refer to $\lambda_i - V_{ij}$ as the λ-*flow* along the arc (i, j). Consider first the modified balance equation for the edge cut $A = \{i\}$,

$$\max_{j\neq i} \lambda_i - V_{ij} = \max_{j\neq i} \lambda_j - V_{ji}. \tag{25}$$

Observe that the left-hand side of (25) can be written as

$$\lambda_i - \min_{j\neq i} V_{ij},$$

and so the arc of *maximum* λ-*flow* out of $A = \{i\}$ is the arc $(i, l(i))$ where

$$l(i) = \arg\min_{j\neq i} V_{ij}.$$

(Note that $l(i)$ may not be unique.)

We now construct the directed graph $G_1 = (V_1, E_1)$, with $V_1 = \{\{1\}, \cdots, \{4\}\}$ and $(i, j) \in E_1$ if $j = l(i)$. See Fig. 1.

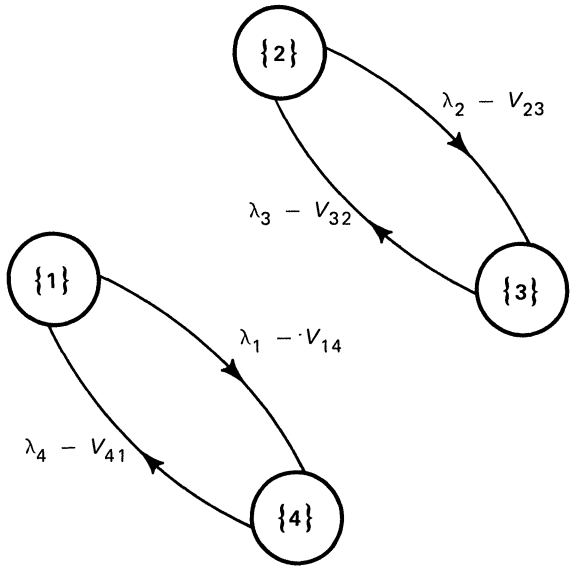

FIG. 1. *The graph G_1 of Example 2.*

Note that G_1 has two directed cycles $\{1\}\to\{4\}\to\{1\}$ and $\{2\}\to\{3\}\to\{2\}$. Let us examine the λ-flows on the directed cycle $\{1\}\to\{4\}\to\{1\}$. Since $\lambda_1 - V_{14}$ is the maximum λ-flow out of $\{1\}$, it is not smaller than any λ-flow into $\{1\}$, and so in particular

$$\lambda_1 - V_{14} \geqq \lambda_4 - V_{41}.$$

Also, $\lambda_4 - V_{41}$ is the maximum λ-flow out of $\{4\}$ and so

$$\lambda_4 - V_{41} \geqq \lambda_1 - V_{14}.$$

We thus observe that the λ-flows along the directed cycle $\{1\}\to\{4\}\to\{1\}$ are *equal*; that is,

$$\lambda_1 - V_{14} = \lambda_4 - V_{41},$$

and so

$$\lambda_1 - 1 = \lambda_4 - 2. \tag{26}$$

Thus, we have determined the *difference* between λ_1 and λ_4.

In exactly the same way, from the directed cycle $\{2\}\to\{3\}\to\{2\}$ we see that

$$\lambda_2 - 3 = \lambda_3 - 2, \tag{27}$$

thus determining the difference between λ_2 and λ_3.

At the next step of the algorithm, consider the modified balance equations for the edge cut (A, A^c) where $A = \{1, 4\}$ and $A^c = \{2, 3\}$. Observe that for $A = \{1, 4\}$, the left-hand side of the modified balance equation

$$\max_{i\in A, j\in A^c} \lambda_i - V_{ij} = \max_{i\in A, j\in A^c} \lambda_j - V_{ji} \tag{28}$$

can be written as

$$\max(\lambda_1 - V_{12}, \lambda_1 - V_{13}, \lambda_4 - V_{42}, \lambda_4 - V_{43});$$

that is,

$$\max(\lambda_1 - 4, \lambda_1 - 3, \lambda_4 - 6, \lambda_4 - 5).$$

We have previously determined that $\lambda_4 - \lambda_1 = 1$, and so the maximum is achieved by $\lambda_1 - V_{13} = \lambda_1 - 3$, and the arc of maximum λ-flow out of $\{1, 4\}$ is the arc $(1, 3)$.

In a similar fashion, examining the right-hand side of the modified balance equation (28), we determine that the maximum λ-flow out of $\{2, 3\}$ is achieved by $\lambda_3 - V_{34} = \lambda_3 - 4$, and so the arc of maximum λ-flow out of $\{2, 3\}$ is $(3, 4)$.

We now consider the directed graph $G_2 = (V_2, E_2)$, with $V_2 = \{\{1, 4\}, \{2, 3\}\}$ and $E_2 = \{(1, 3), (3, 4)\}$ shown in Fig. 2. Note that E_2 is the set of the arcs of maximum λ-flow out of the edge cuts in V_2.

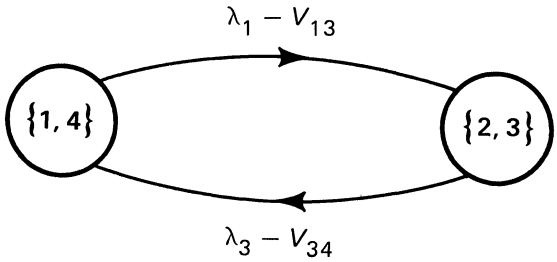

FIG. 2. *The graph G_2 of Example 2.*

Observe that G_2 has a directed cycle $\{1, 4\} \to \{2, 3\} \to \{1, 4\}$. Now note that $\lambda_1 - V_{13}$ is the maximum λ-flow out of $\{1, 4\}$ and $\lambda_3 - V_{34}$ is the maximum λ-flow out of $\{2, 3\}$ and so

$$\lambda_1 - V_{13} = \lambda_3 - V_{34};$$

that is,

$$\lambda_1 - 3 = \lambda_3 - 4. \tag{29}$$

Combining (26), (27), and (29), we obtain

$$\lambda_1 - 3 = \lambda_2 - 5 = \lambda_3 - 4 = \lambda_4 - 4. \tag{30}$$

We now know the *pairwise differences* between *all* of the λ_i's, and so we do not need to consider any additional edge cuts. To fix the values of $\{\lambda_i\}$, we use the value of ρ to give

$$\max_{i \in X} \lambda_i = \rho = 5.$$

Since, from (30), λ_2 is the largest, we set $\lambda_2 = 5$. We thus obtain the solution to the modified balance equations:

$$\lambda_1 = 3, \quad \lambda_2 = 5, \quad \lambda_3 = \lambda_4 = 4.$$

The principal idea used to solve the modified balance equations in Example 2 is summarized in the following lemma.

LEMMA 2. (1) *Given $A \subseteq X$ for which we know the pairwise differences between all the λ_i's for states in A, we can determine the arc of maximum λ-flow out of A (without knowing the λ_i's themselves).*

(2) *Let $A_1, A_2, \cdots, A_p$ be a partition of X and suppose for each A_k we know all the pairwise differences between the λ_i's for all states in A_k. Let (i_k, j_k) denote the arc of maximum λ-flow out of A_k. Construct the directed graph $G = (V, E)$, with $V = \{A_1, \cdots, A_p\}$ and $E = \{(i_1, j_1), \cdots, (i_p, j_p)\}$. There exists a directed cycle on G. If*

$\{A_{n_1}, \cdots, A_{n_m}\}$ is the list of vertices, in order, along the directed cycle, then the λ-flow on the directed cycle is constant; that is,

$$\lambda_{i_{n_1}} - V_{i_{n_1}, j_{n_1}} = \cdots = \lambda_{i_{n_m}} - V_{i_{n_m}, j_{n_m}},$$

and we can determine the pairwise differences between the values of the λ_i's for all the states in $\bigcup_{k=1}^{m} A_{n_k}$.

Proof. (1) Without loss of generality, suppose A is the set of states $\{1, 2, \cdots, r\}$. Let $\alpha_i := \lambda_1 - \lambda_i$. (We know the α_i's.) Then

$$\max_{i \in A, j \in A^c} \lambda_i - V_{ij} = \max_{i \in A, j \in A^c} \lambda_1 - \alpha_i - V_{ij} = \lambda_1 - \min_{i \in A, j \in A^c} (\alpha_i + V_{ij}).$$

Thus, the arc

$$(i^*, j^*) := \arg \min_{i \in A, j \in A^c} (\alpha_i + V_{ij})$$

is an arc of maximum λ-flow out of A.

(2) The out-degree of each vertex of G is at least one, and so from elementary graph theory it follows that G has a directed cycle. Suppose

$$A_{n_1} \to A_{n_2} \to \cdots \to A_{n_m} \to A_{n_1}$$

is such a directed cycle. Then we have the situation shown in Fig. 3. Now (i_{n_k}, j_{n_k}) is the arc of maximum λ-flow *out* of A_{n_k}, and so the λ-flow on this arc is not less than the λ-flow of any arc *into* A_{n_k}. In particular,

$$\lambda_{i_{n_k}} - V_{i_{n_k}, j_{n_k}} \geqq \lambda_{i_{n_{k-1}}, j_{n_{k-1}}} - V_{i_{n_{k-1}}, j_{n_{k-1}}} \quad \text{for } k = 1, \cdots, m,$$

where, for convenience, we implicitly identify i_{n_0} with i_{n_m} and j_{n_0} with j_{n_m}. Thus,

$$\begin{aligned} \lambda_{i_{n_m}} - V_{i_{n_m}, j_{n_m}} &\geqq \lambda_{i_{n_{m-1}}} - V_{i_{n_{m-1}}, j_{n_{m-1}}} \\ &\geqq \lambda_{i_{n_{m-2}}} - V_{i_{n_{m-2}}, j_{n_{m-2}}} \\ &\vdots \\ &\geqq \lambda_{i_{n_1}} - V_{i_{n_1}, j_{n_1}} \\ &\geqq \lambda_{i_{n_m}} - V_{i_{n_m}, j_{n_m}}. \end{aligned}$$

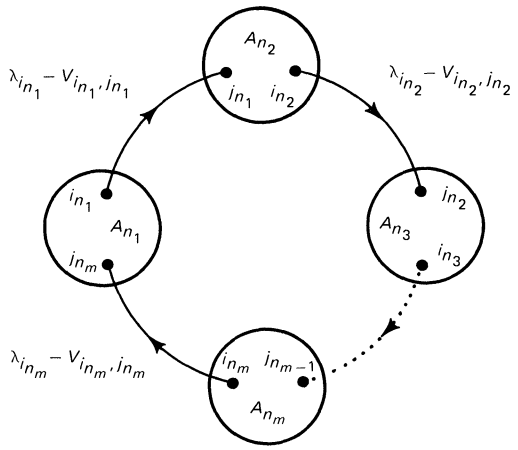

FIG. 3. *A directed cycle of maximum λ-flows in Lemma* 3.

Therefore, the λ-flow on the directed cycle is a constant:

$$\lambda_{i_{n_1}} - V_{i_{n_1},j_{n_1}} = \lambda_{i_{n_2}} - V_{i_{n_2},j_{n_2}} = \cdots = \lambda_{i_{n_m}} - V_{i_{n_m},j_{n_m}}. \tag{31}$$

For each A_{n_k} in the directed cycle, we know the pairwise differences between the λ_i's for states in A_{n_k}. Using (31) we can now easily determine the pairwise differences between all the λ_i's for states in $\cup_{k=1}^{m} A_{n_k}$. □

The algorithm for solving the modified balance equations is outlined below.

ALGORITHM TO SOLVE MODIFIED BALANCE EQUATIONS.

Step 1. Set $A_i^1 = \{i\}$ for $i = 1, \cdots, |X|$. We call the A_i^k's *coalitions at step k.* Note that for every i, the pairwise differences between the λ-values for all states in A_i^1 are (trivially) known. Set $A^1 := \{A_1^1, A_2^1, \cdots, A_{|X|}^1\}$. Let $N(1) = |A^1| =:$ the number of elements in the set $A^1 =$ number of coalitions at Step 1.

Step k. Given $A^k := \{A_1^k, A_2^k, \cdots, A_{N(k)}^k\}$, where for each $A_j^k \in A^k$ the pairwise differences between all of the λ_i's for i's in A_j^k are known, construct A^{k+1} as follows. Using Lemma 2, identify the directed cycles in the graph. (There exists at least one directed cycle.) The elements of A^{k+1} consist of the directed cycles identified in the graph, and those $A_j^k \in A^k$ that are not in any directed cycle. (More precisely, if $\{A_{n_1}^k, A_{n_2}^k, \cdots, A_{n_m}^k\}$ is a directed cycle, then $\cup_{i=1}^{m} A_{n_i}$ is an element of A^{k+1}.) Note that for every $A_j^{k+1} \in A^{k+1}$, the pairwise differences between all of the λ_i's for i's in A_j^{k+1} are known. Furthermore, if $N(k) := |A^k|$, then $N(k+1) < N(k)$.

Last Step. Stop when $N(k) = 1$. Note that the pairwise differences between *all* λ_i's are known, and the λ satisfying the modified balance equations can be obtained by a translation by using the given value of ρ. □

4. An algorithm to obtain all solutions of the order balance equations. We now characterize *all* solutions to the order balance equations, and describe an algorithm for generating *all* these solutions. To do so we will use the coalitions $\{A_i^k\}$ generated by the algorithm of the preceding section. Let us call $\lambda_i - V_{ij}$ and $\beta_{ij} = \beta_i \ominus V_{ij}$ as the *λ-flow* and *β-flow*, respectively, along the arc (i, j).

LEMMA 3. (1) *If (i, j) is an arc of maximum λ-flow out of A_l^k, then it is also an arc of maximum β-flow out of A_l^k.*

(2) *If $\{A_1^k, \cdots, A_p^k\}$ is a directed cycle obtained at step k, then the β-flow along the directed cycle is a constant.*

(3) *If the β-flow along the directed cycle $\{A_1^k, \cdots, A_p^k\}$ obtained at step k is $-\infty$, then the β-flow along any directed cycle obtained at step $n > k$ containing $A_l^n = \cup_{i=1}^{p} A_i^k$ as a node, is also $-\infty$.*

(4) *If the β-flow along the directed cycle $\{A_1^k, \cdots, A_p^k\}$ obtained at step k is $\geqq 0$, then for every $i, j \in A_l^{k+1} := \cup_{m=1}^{p} A_m^k$ there exists a path $(i = i_0, i_1, \cdots, i_q = j)$ such that $i_m \in A_l^{k+1}$ and $\beta_{i_m, i_{m+1}} \geqq 0$ for $0 \leqq m \leqq q-1$.*

Proof. We will first prove (1)–(3) by induction. Consider $k = 1$. Since A_l^k is then just a singleton, say $A_l^k = \{l\}$, an arc (l, m) of maximum λ-flow out of $\{l\}$ is just one for which $V_{lm} = \min_n V_{ln}$. Clearly this is also an arc for which $\beta_l \ominus V_{lm} = \min_n \beta_l \ominus V_{ln}$. Now suppose that $\{A_1^k, \cdots, A_p^k\}$ is a directed cycle of such maximum flows. Then an application of the Order Balance Theorem to each A_l^k shows that $\beta_{12} = \beta_{23} = \cdots = \beta_{p1}$. Suppose now that $\beta_{12} = \beta_{23} = \cdots = \beta_{p1} = -\infty$. Then if (l, m) is an arc of maximum β-flow out of $\cup_{i=1}^{p} A_i^k$, clearly $\beta_{lm} \leqq \beta_{l,l+1} = -\infty$. Thus the assertion is true for $k = 1$.

Now suppose that the assertion is true for $1, 2, \cdots, k-1$. Consider a coalition A_l^k. If the β-flow along some directed cycle $\{A_1^n, \cdots, A_q^n\}$ at some step $n < k$ with $A_l^k = \cup_{i=1}^{q} A_i^n$ was $-\infty$, then clearly the maximum β-flow out of A_l^k is $-\infty$, and so *any*

arc out of A_l^k is an arc of maximum β-flow. On the other hand if the β-flow along the directed cycle $\{A_1^n, \cdots, A_q^n\}$ is $\geqq 0$, then the differences between the β_i's for states $i \in A_l^k$ are the *same* as the differences between the λ_i's, i.e.,

$$\beta_i - \beta_j = \lambda_i - \lambda_j \quad \text{for all } i, j \in A_l^k, \tag{32}$$

and so the arc of maximum λ-flow out from A_l^k is also an arc of maximum β-flow out from A_l^k. Moreover, if $\{A_1^k, \cdots, A_p^k\}$ is a directed cycle at step k, then an application of the Order Balance Theorem to each A_l^k shows that the β-flow along the directed cycle is a constant. Finally, if this β-flow is $-\infty$, suppose that (r, m) is a maximum flow arc out of $\cup_{l=1}^p A_l^k$. Suppose that $r \in A_l^k$. Then clearly $\max_{i \in A_l^k, j \in A_l^{k^c}} \beta_{ij} \geqq \beta_{rm}$ and so $\beta_{rm} = -\infty$. This completes the induction and the proof.

Finally, to see (4), note first that from (1), (2), and (3), the β-flow along any directed cycles contained within A_l^{k+1} is $\geqq 0$. Since A_l^{k+1} is formed as the union of such directed cycles, the result follows. □

Motivated by (3) and (4) above, we introduce the following definition.

DEFINITION 4. We shall say that i is *recurrently connected* to j if there exists a path $(i = i_0, i_1, \cdots, i_q = j)$ with $\beta_{i_m, i_{m+1}} \geqq 0$ for $0 \leqq m \leqq q-1$.

We shall say that a set $A \subseteq X$ is a *recurrently connected set* if for every $i, j \in A$ and $k \in A^c$, i is recurrently connected to j but not to k.

From Lemma 3 it follows that recurrently connected sets are precisely those A_l^k's for which the β-flow out of A_l^k is $-\infty$, while the β-flows along the directed cycles contained within A_l^k are $\geqq 0$. Note also that the recurrently connected sets form a *partition* of X.

We now proceed to determine which sets are possible candidates for being recurrently connected sets. Consider a typical candidate A_l^{k+1}. Let $\mathscr{F}$ denote the β-flow on the cycle $\{A_1^k, \cdots, A_p^k\}$, where $A_l^{k+1} = \cup_{i=1}^p A_i^k$. Then if (i_m, j_m) is the arc of maximum flow out of A_m^k (and, by construction, into $A_{(m+1) \bmod p}^k$), we must have

$$\mathscr{F} = \beta_{i_1} - V_{i_1, j_1} = \beta_{i_2} - V_{i_2, j_2} = \cdots = \beta_{i_p} - V_{i_p, j_p} \geqq 0,$$

$$\max_{i \in A_l^{k+1}, j \notin A_l^{k+1}} \beta_i - V_{ij} < 0, \quad \max_{i \in A_l^{k+1}} \beta_i \leqq \rho.$$

We will now attempt to determine whether there exist $\{\beta_i : i \in A_l^{k+1}\}$ that satisfy these conditions. Note that if this is not feasible, then A_l^{k+1} cannot be a recurrently connected set.

Let (x, y) denote the arc of maximum β-flow out of A_l^{k+1}. Then $\beta_x < V_{xy}$. Fix m to be an arbitrarily chosen state from A_l^{k+1}. Then for every state $h \in A_l^{k+1}$ we know the value of $(\beta_h - \beta_m)$ from Lemma 3 above. Let us define

$$\zeta_h := \beta_h - \beta_m.$$

Then

$$\begin{aligned} \mathscr{F} &= \beta_{i_1} - V_{i_1, j_1} \\ &= \beta_m + \zeta_{i_1} - V_{i_1, j_1} \\ &= \beta_x - \zeta_x + \zeta_{i_1} - V_{i_1, j_1} \\ &< V_{xy} - \zeta_x + \zeta_{i_1} - V_{i_1, j_1} =: M_1, \end{aligned}$$

giving an upper bound on $\mathscr{F}$.

We must also satisfy the constraint $\max_{i \in A_l^{k+1}} \beta_i \leqq \rho$, and so let

$$\theta := \arg \max_{i \in A_l^{k+1}} \zeta_i.$$

Then it is clear that $\beta_\theta \geqq \max_{i \in A_l^{k+1}} \beta_i$. Thus,

$$\begin{aligned}\rho &\geqq \beta_\theta \\ &= \beta_m + \zeta_\theta \\ &= \beta_{i_1} - \zeta_{i_1} + \zeta_\theta \\ &= \beta_{i_1} - V_{i_1,j_1} + V_{i_1,j_1} - \zeta_{i_1} + \zeta_\theta \\ &= \mathscr{F} + V_{i_1,j_1} - \zeta_{i_1} + \zeta_\theta,\end{aligned}$$

and so

$$\mathscr{F} \leqq \rho - V_{i_1,j_1} + \zeta_{i_1} - \zeta_\theta =: M_2,$$

giving yet another upper bound on $\mathscr{F}$. (Note. If $A_l^{k+1} = \{i\}$, then $M_1 = \min_j V_{ij}$ and $M_2 = \rho$.)

Any choice of $\mathscr{F}$ from the interval

$$\Omega(A_l^{k+1}) := [0, M_1) \cap [0, M_2]$$

will allow assignments for the recurrence orders of states in A_l^{k+1} consistent with the assumption that the coalition A_l^{k+1} is a recurrently connected set. If $\Omega(A_l^{k+1}) = \varnothing$ then then there is no assignment, and so A_l^{k+1} is not a recurrently connected set.

We still need to determine the set of all recurrently connected sets. To do this we construct a *rooted tree* having the coalitions produced by the general procedure as nodes, and having a directed edge from coalition A_p^{k+1} to A_r^k if $A_p^{k+1} \supseteq A_r^{(k)}$. Hence, the root of the tree is X, and its leaves are the singleton sets $\{1\}, \{2\}, \cdots, \{n\}$. Let D_i be the set of the leaves of the tree that are *descendants* of the node i in the rooted tree.

We say that a set Ξ of nodes is a *proper cover* if

$$\bigcup_{A \in \Xi} D_A = X$$

and

$$D_A \cap D_{A'} = \varnothing \quad \text{for } A \neq A'.$$

Now the algorithm to determine all the solutions of (15), (8) proceeds as follows. Let a set $\Xi := \{A_1, A_2, \cdots, A_k\}$ be a proper cover. Now we will determine whether Ξ can be a set of *all* recurrently connected sets, as follows. First we determine $\Omega(A_j)$ for every $A_j \in \Xi$. (Note that if we guess X to be a recurrently connected set, then $\Omega(X) = [0, M_2]$, since the M_1 upper bound is $+\infty$ because there is no maximal flow out of X. Also, if we guess the singleton $\{i\}$ to be a recurrently connected set, then $\Omega(\{i\}) = -\infty \cup ([0, M_1) \cap [0, M_2])$. If *any* of the $\Omega(A_j)$'s is empty, then the guess Ξ is *not* a feasible set of recurrently connected sets. If *every* $\Omega(A_j)$ is nonempty, then let $\bar{\mathscr{F}}_j := \sup \Omega(A_j)$. If this "sup" is not attained, then we cannot assign ρ to any state in A_j. If this "sup" is attained, then we determine for each such A_j whether, with the choice of $\bar{\mathscr{F}}_j$, there is a state $i_j \in A_j$ with $\beta_{i_j} = \rho$. If no such state exists for *any* A_j, then again Ξ is *not* a feasible set of recurrently connected sets. Finally, if there exist such A_j's then let $\mathscr{A}(\Xi)$ be the set of all such A_j's. Now, the set of all solutions corresponding to Ξ is obtained by picking, in turn, an A_j from $\mathscr{A}(\Xi)$, fixing its flow as $\bar{\mathscr{F}}_j$ and choosing all other $\mathscr{F}_j$'s arbitrarily from the $\Omega(A_j)$'s. By checking *every* proper cover Ξ, we thus determine all solutions to the order balance equations, as the following theorem shows.

THEOREM 4. *All solutions to the order balance equations can be generated by using the method described above.*

Proof. Suppose β satisfies the order balance equations. Then for this solution determine the set Ξ of recurrently connected sets. This set must be a proper cover. For this set Ξ, there must be some A_j with corresponding β-flow equal $\bar{\mathcal{F}}_j$. Now determine the β-flows on the recurrently connected sets. We generate this solution β when we choose Ξ as the set of recurrently connected sets, and A_j as the coalition with maximum flow equal to $\bar{\mathcal{F}}_j$, and assign the correct β-flows on the other recurrently connected sets. □

This algorithm takes an exponential in $|X|$ number of steps, due to the necessity of checking all proper covers. However, the complexity issue is not the primary concern here, since the problem of asymptotic analysis of the stochastic process is not a priori known to be a problem resolvable by a finite algorithm.

We illustrate the procedure for determining all solutions to the order balance equations.

Example 3. We construct all solutions to the order balance equations for Example 2 when $\rho = 4$. See Fig. 4 for the rooted tree. We check the proper covers:

(1) $\Xi = \{X\}$: $\Omega(X)$ is empty, so X cannot be a recurrently connected set.

(2) $\Xi = \{\{1, 4\}, \{2, 3\}\}$: Using the method described above we obtain

$$\beta_1 = \alpha, \quad \beta_2 = 4, \quad \beta_3 = 3, \quad \beta_4 = 1 + \alpha$$

where $1 \leqq \alpha < 3$.

(3) $\Xi = \{\{1, 4\}, \{2\}, \{3\}\}$: $\max_{i \in X} \beta_i < 4$, a contradiction.

(4) $\Xi = \{\{1\}, \{4\}, \{2, 3\}\}$:

$$\beta_1 = \gamma, \quad \beta_2 = 4, \quad \beta_3 = 3, \quad \beta_4 = \theta$$

where $\gamma = -\infty$ or $0 \leqq \gamma < 1$, and $\theta = -\infty$ or $0 \leqq \theta < 2$.

(5) $\Xi = \{\{1\}, \{2\}, \{3\}, \{4\}\}$: $\max_{i \in X} \beta_i < 4$, and so $\{\{1\}, \{2\}, \{3\}, \{4\}\}$ is not a set of recurrently connected sets.

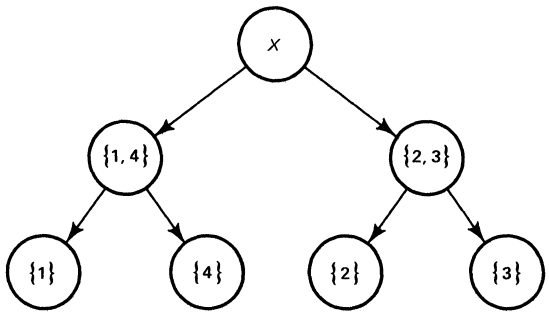

FIG 4. *The rooted tree of Example* 3.

We have checked all proper covers. Hence the set of all solutions is $\{(\alpha, 4, 3, 1+\alpha)$: $1 \leqq \alpha < 3\} \cup \{(\gamma, 4, 3, \theta)$: $\gamma = -\infty$ or $0 \leqq \gamma < 1$ and $\theta = -\infty$ or $0 \leqq \theta < 2\}$.

How can nonunique solutions to the order balance equations arise, and what is the implication of such nonuniqueness? First let us consider the case where a unique solution exists. Since such a solution is uniquely determined by the algorithm, it is clear that the recurrence orders of the states, and thus the rates of convergence of the transition probabilities, depend only on the V_{ij}'s in the transition probabilities $p_{ij}(t) = c_{ij}\varepsilon(t)^{V_{ij}}$, and *not* on the proportionality constants $\{c_{ij}\}$. However, in the case of *nonunique* solutions, the following example shows that the recurrence orders may even depend on the *proportionality constants* $\{c_{ij}\}$.

Example 4. Let $X = \{1, 2, 3\}$ and $V_{ij} = \max\{0, j - i\}$. Let $c_{13} = c_{23} = 1$, $c_{31} = 1 - \alpha$, and $c_{32} = \alpha$, where $\alpha \in (0, 1)$. Set $c_{ij} = 0$ for all other i, j. See Fig. 5. Let the cooling schedule be $\varepsilon(t) = 1/t$. Then the *complete* set of order balance equations obtained by using *all* edge cuts is:

$$\beta_2 \ominus V_{23} = \beta_3 \ominus V_{32}, \qquad \beta_3 \ominus V_{31} = \beta_1 \ominus V_{13},$$

$$\max(\beta_2 \ominus V_{23}, \beta_1 \ominus V_{13}) = \max(\beta_3 \ominus V_{32}, \beta_3 \ominus V_{31}),$$

with the maximum given by,

$$\max_{i \in X} \beta_i = 1.$$

The assignments

$$\beta_1 = 1, \quad \beta_2 = \gamma, \quad \beta_3 = -\infty$$

satisfy the order balance equations for *every* $\gamma \in \{-\infty\} \cup [0, 1)$. Thus any value of $\beta_2 < 1$ gives a solution of the order balance equations.

However, a calculation that can be found in [8] shows that the correct order of recurrence of state 2 is

$$\beta_2 = \alpha.$$

Thus, the order of recurrence, and the rate of convergence of the probability $\Pr(x(t) = 2)$ to zero, depends on the proportionality constant $c_{32} = \alpha$ involved.

Based on the above results, we obtain the following property of the orders of recurrence of the states in a recurrently connected set.

LEMMA 4. *Consider a recurrently connected set A.*

(1) *If* $\beta_i \in \mathcal{R}$ *for some* $i \in A$, *then* $\beta_j \in \mathcal{R}$ *for all* $j \in A$.

(2) *If for some* $i \in A$, $\beta_i = p_i^-$ *for some* $p_i \in \mathcal{R}$, *then for every* $j \in A$, $\beta_j = p_j^-$ *for some* $p_j \in \mathcal{R}$.

Proof. The proof follows immediately from (32). □

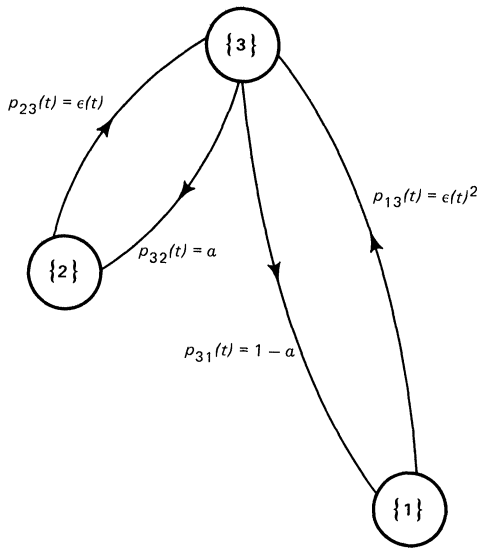

FIG. 5. *The Markov process of Example* 4.

Thus all recurrence orders in a recurrently connected set are of the same type, i.e., either they are all real numbers p_i, or they are all of the type p_i^-, or they are all $-\infty$ (see Definition 1).

This gives us the following lemma, which completes the proof of Theorem 1.

LEMMA 5. *Suppose the rate of cooling is* $\rho = p \in \mathcal{R}$, *with* $p > 0$, *i.e., the maximum is achieved in Definition* 3. *If there is a state* $i \in X$ *for which* $\beta_i = p^-$, *then* $\lim_{t\to\infty} \Pr(x(t) = i) = 0$.

Proof. Suppose A is the recurrently connected class to which i belongs. Since all arcs *between* recurrently connected sets are transient, it follows from the Borel-Cantelli Lemma that along almost every sample path ω there can only be a *finite* number of transitions between different recurrently connected sets. Hence for almost every ω, $\{x(t, \omega)\}$ converges to some recurrently connected set. Hence the limit $\lim_{t\to\infty} \Pr(x(t) \in A)$ exists. Now we show that this limit is zero. Suppose not, i.e., suppose $\lim_{t\to\infty} \sum_{j\in A} \pi_j(t) = \delta > 0$. Then it follows that $\sum_{t=0}^{\infty} \varepsilon(t)^p \sum_{j\in A} \pi_j(t) = +\infty$. Hence for some $j \in A$, $\beta_j = p$. But then by Lemma 4, $\beta_i \in \mathcal{R}$, which gives a contradiction. □

5. Weak reversibility and simulated annealing. We now turn our attention to the special class of Markov chains arising from the method of *optimization by simulated annealing*. Recall that the Markov chains in this class satisfy (1)-(6) with the special choice of

$$V_{ij} := \max\{0, W_j - W_i\}.$$

In [7] it was shown that under the "symmetric neighborhood" assumption, $c_{ij} > 0$ if and only if $c_{ji} > 0$, the orders of recurrence satisfy the following *detailed order balance*:

$$\beta_{ij} = \beta_{ji} \quad \text{for every } i, j \in X.$$

It is easy to see that the detailed order balance above is equivalent to the sum of the order of recurrence of a state and its cost being constant on recurrently connected sets.

In this section we will show that this constancy property of the sum of the recurrence order and cost on recurrently connected sets continues to hold under the much weaker assumption of "weak reversibility" introduced by Hajek in [1].

DEFINITION 5. A state i is said to be reachable from state j if there is a sequence of states $j = i_0, i_1, \cdots, i_p = i$ such that $c_{i_k, i_{k+1}} > 0$ for $0 \leqq k \leqq p-1$.

DEFINITION 6. A state i is reachable at height H from j if there is a path from j to i as in Definition 5 for which $W_{i_k} \leqq H$ for $0 \leqq k \leqq p$.

ASSUMPTION 1(Weak Reversibility). For any real number H and any two states i and j, i is reachable at height H from j if and only if j is reachable at height H from i.

In what follows we assume weak reversibility.

THEOREM 5 (The Potential Theorem). *Under Assumption* 1, *for every recurrently connected set* A *there exists a constant* $\alpha(A)$ *such that* $\beta_i + W_i = \alpha(A)$ *for every* $i \in A$.

Proof. We fix our attention on a particular recurrently connected set A. Assume to the contrary that A can be partitioned into *equipotential* sets $C_1, C_2, \cdots, C_r$ such that $\beta_i + W_i = \alpha(C_k)$ for every $i \in C_k$, where the $\alpha(C_k)$'s are distinct constants. We will show that there is only one equipotential set, namely, A.

For each equipotential set C_i, determine an arc of maximum β-flow out of the set. From Lemma 2, there exists a directed cycle of these equipotential sets, and the β-flow along the directed cycle is constant. Moreover, from Lemma 3, since A is a recurrently connected set, these β-flows are all nonnegative. Without loss of generality, label the sets along the directed cycle $C_1, C_2, \cdots, C_p$ such that the constant $\alpha(C_1)$ associated with the set C_1 is smallest. Let (i_s, j_s) be the arc of maximum β-flow out

of the set C_s. By construction, $i_s \in C_s$ and $j_s \in C_{(1+s) \bmod p}$ and

$$\beta_{i_1,j_1} = \beta_{i_2,j_2} = \cdots = \beta_{i_p,j_p} \geqq 0.$$

Knowing that $\beta_{i_1,j_1} \geqq 0$ we consider the two cases: (1) $W_{j_1} \geqq W_{i_1}$; or (2) $W_{j_1} < W_{i_1}$.

If case (1) is true then since j_1 is reachable at height W_{j_1} from i_1, by the weak reversibility assumption there exists a path from j_1 back to i_1 that does not go through any states with costs larger than W_{j_1}. Let (k, l) be the particular arc of that path that exits C_2. Note that

$$\begin{aligned}\beta_{i_1,j_1} &= \beta_{i_2,j_2} \\ &\geqq \beta_{kl},\end{aligned}$$

because β_{i_2,j_2} is the arc of maximum β-flow out of C_2. If $\beta_{kl} \geqq 0$ then $\beta_{kl} = \beta_k + W_k - W_l$. If $\beta_{kl} < 0$ then $\beta_k + W_k - W_l < 0$. In either case, since $\beta_{i_1,j_1} \geqq 0$, we have that

$$\beta_{i_1,j_1} = \beta_{i_1} + W_{i_1} - W_{j_1} \geqq \beta_k + W_k - W_l.$$

Now by the weak reversibility assumption, $W_{j_1} \geqq W_l$, and so

$$\beta_{i_1} + W_{i_1} \geqq \beta_k + W_k;$$

that is,

$$\alpha(C_1) \geqq \alpha(C_2),$$

which is a contradiction.

If case (2) is true, then there is a path from j_1 to i_1 that does not pass through any states with costs larger than i_1. Again, identify the particular arc of that path that exits C_2 as (k, l). Note that

$$\begin{aligned}\beta_{i_1} &= \beta_{i_1,j_1} \\ &= \beta_{i_2,j_2} \\ &\geqq \beta_{kl}.\end{aligned}$$

Using similar arguments as in case (1), since $\beta_{i_1} \geqq 0$ we have $\beta_{i_1} \geqq \beta_k + W_k - W_l$. Now by the weak reversibility assumption $W_{i_1} \geqq W_l$, and so $\alpha(C_1) \geqq \alpha(C_2)$, which is again a contradiction.

Hence there is only one equipotential set, A. □

Since $W_i + \beta_i = \alpha(A)$ for all $i \in A$, where A is a recurrently connected set, we obtain the following necessary and sufficient condition for simulated annealing to hit a *global minimum* with probability one from all states $i \in X$.

Let $M := \{i \in X: W_i \leqq W_j \text{ for all } j \in X\}$ be the set of global minima. We now have the following definition due to [1].

DEFINITION 7. Let d^* be the *smallest* number with the property that for every $i \in X$ there exists a path $(i = i_0, \cdots, i_p)$ with $c_{i_k,i_{k+1}} > 0$ for $0 \leqq k \leqq p-1$ and ending in a minimizer $i_p \in M$ such that

$$W_{i_k} - W_i \leqq d^* \quad \text{for } k = 1, \cdots, p.$$

We shall call d^* the *depth* of the minimization problem.

THEOREM 6 (Necessary and Sufficient Condition to Hit Global Minimum With Probability One). *Suppose that weak reversibility holds.*

(1) *If* $\sum_{t=1}^{\infty} \varepsilon(t)^{d^*} = +\infty$, *then for every initial condition* $x(0) \in X$,

$$\limsup_{N \to \infty} \frac{1}{N} \sum_{t=1}^{N} \Pr(x(t) \in M) = 1,$$

and the global minimum is hit with probability one.

(2) *If* $\sum_{t=1}^{\infty} \varepsilon(t)^{d^*} < +\infty$, *then there exists an initial condition* $x(0) \in X$ *for which*

$$\Pr(x(t) \in M^c \text{ for all } t \geqq 1) > 0.$$

Proof. The proof is the same as in Theorem (4.6) in [7] except that if $(i = i_0, \cdots, i_p = j)$ is a path from i to j with $c_{i_k, i_{k+1}} > 0$ and $W_{i_k} - W_i \leqq \gamma$ for $1 \leqq k \leqq p$, then instead of using the reversed path $(j = i_p, \cdots, i_0 = i)$ given by the assumption of symmetric neighborhoods, we use the path $(j = l_0, \cdots, l_q = i)$ with $c_{l_k, l_{k+1}} > 0$ and $W_{l_k} - W_i \leqq \gamma$ for $1 \leqq k \leqq q$, guaranteed by the weak reversibility assumption. □

The same condition $\sum_{t=1}^{\infty} \varepsilon(t)^{d^*} = \infty$ has been shown earlier by Hajek [1] to be necessary and sufficient for $\lim_{t \to \infty} \Pr(x(t) \in M) = 1$, i.e., for convergence *in probability.* Thus while result (1) above is weaker than his, since it involves Cesaro as opposed to regular convergence, the result (2) is a stronger sample path result.

The above result has been proved earlier in [7] under the stronger assumption of *symmetric neighborhoods*, $c_{ij} > 0 \Leftrightarrow c_{ji} > 0$. Moreover, under this assumption Connors and Kumar [7] have proved a *detailed balance* result that we can obtain as a corollary of Theorem 5, as we show below.

COROLLARY 1 (Detailed Balance). *Under the symmetric neighborhood assumption,*

$$\beta_{ij} = \beta_{ji} \quad \text{for every } i, j \in X.$$

Proof. If i and j are not neighbors, then $\beta_{ij} = \beta_{ji} = -\infty$.

If i and j are neighbors and $i \in R$ and $j \in T$, where R is the set of recurrent states and T is the set of transient states, then

$$\beta_{jk} = -\infty \quad \text{for all } k$$

and so

$$-\infty = \max_{k \neq j} \beta_{jk} = \max_{k \neq j} \beta_{kj} \geqq \beta_{ij},$$

showing that $\beta_{ij} = \beta_{ji} = -\infty$. A similar argument holds if $i \in T$ and $j \in R$.

Finally, if i and j are neighbors and $i, j \in R$, without loss of generality let us assume that $W_i \geqq W_j$. Then $\beta_{ij} = \beta_i \geqq 0$, and so i and j belong to a common recurrently connected set. Hence by Theorem 5, $\beta_i + W_i = \beta_j + W_j$. Since $\beta_{ij} = \beta_i$ and $\beta_{ji} = \beta_j + W_j - W_i$, it follows that $\beta_{ij} = \beta_{ji}$. □

Note that by the above results, if the order of recurrence of even *one* state in a connected component is known, then the orders of recurrence for *all* the states belonging to the connected component are determined. However, as Example 4 shows, it is not always possible to determine the order of recurrence of even one state in a connected component from the order balance equations alone. In that example, the connected components of recurrent states are the sets $\{1\}$ and $\{2\}$, and the detailed balance equations do not determine the order of recurrence β_2 of the *single* state in the connected component $\{2\}$. The reason for this inadequacy, as mentioned earlier in Example 4, is that the orders of recurrence do depend on the proportionality constants c_{ij} involved in the transition probabilities. In any case, the β-flows do satisfy Corollary 1.

6. Conclusions. The notion of order of recurrence provides a novel approach for analyzing the class of Markov chains whose transition probabilities are proportional to powers of a time-varying parameter $\varepsilon(t)$. These recurrence orders satisfy a set of balance equations, and the Markov chain converges in a Cesaro sense to the set of states with the largest recurrence orders. We have given an algorithm for generating a solution to the order balance equations and have also provided a method for characterizing all solutions to these equations. The algebraic methods presented in this

paper for solving the order balance equations are not always sufficient for determining the recurrence orders. In some situations where nonunique solutions exist, the orders of recurrence can depend on the proportionality constants involved in the transition probabilities, and not just on their orders of magnitude. This problem remains an open issue. The method of optimization by simulated annealing falls within the framework of this class of Markov chains. We have shown that if the Markov process is weakly reversible, then the sum of the recurrence order and the cost are constants on each sets of states connected by recurrent arcs. This allows us to determine the necessary and sufficient conditions on the cooling rate for the optimization algorithm to hit a global minimum with probability one from all initial states.

STABILIZATION OF UNCERTAIN SYSTEMS WITH NORM BOUNDED UNCERTAINTY—A CONTROL LYAPUNOV FUNCTION APPROACH*

MARIO A. ROTEA† AND PRAMOD P. KHARGONEKAR‡

Abstract. A robust stabilization problem in a state-space setting is treated. It is assumed that the states are available for feedback. Using a fixed Lyapunov function approach (*quadratic stability*) it is shown that an open loop stabilizability condition is equivalent to the existence of a stabilizing memoryless linear state-feedback controller. As a consequence, it is shown that the existence of a quadratically stabilizing nonlinear time-varying dynamic state-feedback controller implies the existence of a quadratically stabilizing memoryless linear time-invariant state-feedback compensator.

Key words. robust stabilization, quadratic stability and stabilizability, control Lyapunov functions, H^∞ control theory

1. Introduction.

Consider the uncertain linear system

(Σ_u):

$$\frac{dx}{dt}(t) = A(\delta(t))x(t) + B(\delta(t))u(t) \quad \text{a.e. } t \in \mathbb{R} \tag{1.1}$$

where $\delta(t)$ is a vector of unknown parameters belonging to a compact set. In this paper we will be particularly interested in the special case of "norm-bounded time-varying uncertainty" given by

(Σ_{nu}):

$$\frac{dx}{dt}(t) = Ax(t) + Bu(t) + Dw(t), \tag{1.2a}$$

$$e(t) = E_1 x(t) + E_2 u(t), \tag{1.2b}$$

$$w(t) = \Delta(t)e(t), \tag{1.2c}$$

$$\Delta(t) \in \mathbb{U} := \{U \in \mathbb{R}^{k \times p} : \|U\| \leqq 1\} \quad \text{a.e. } t \in \mathbb{R}. \tag{1.2d}$$

(For more precise and detailed descriptions, see §§ 2 and 3.) Uncertain linear systems of the form (1.2) have been investigated in [11], [15], [16], [18], and [23]. In this paper we will explore the problem of robust stabilization of the uncertain system (Σ_{nu}) using state feedback. There are two somewhat different but related approaches for studying this problem: (a) using the small gain theorem in combination with H^∞ control theory based synthesis procedures, and (b) using synthesis methods based on quadratic Lyapunov functions also known as quadratic stabilization theory. In both approaches, it is assumed that a linear time-invariant controller is to be designed. Under the assumption that a linear time-invariant controller is to be designed, it has been shown in [11] that these two apparently unrelated techniques are actually equivalent. It also has been shown how a stabilizing compensator can be obtained by solving an algebraic Riccati equation. Thus, under the assumption of linear time-invariant (dynamic) state feedback, the problem of quadratic stabilization has been completely resolved.

There is, however, no compelling reason to restrict our attention to linear time-invariant controllers. In fact, Petersen [14] gives an example of an uncertain system of the form (1.1) that can be quadratically stabilized by nonlinear state-feedback but for which there does not exist a stabilizing linear time-invariant state-feedback. On the other hand, Hollot and Barmish [5] show that if the input matrix B in the system (1.1) is fixed and known, then the system is quadratically stabilizable if and only if there exists a stabilizing linear time-invariant controller. Also, Petersen and Barmish [18] (for single input systems), and Petersen [16], show that if in (1.2) there is no uncertainty in the state matrix A (i.e., $E_1 = 0$), the system is quadratically stabilizable if and only if there exists a quadratically stabilizing linear time-invariant controller. In view of Petersen's example it is an interesting question whether for the uncertain system (Σ_{nu}) quadratic stabilizability implies the existence of a stabilizing linear time-invariant controller. This open question was also mentioned in [23].

In this paper we take an "open loop" approach to the problem of quadratic stabilization of the uncertain system (Σ_u) and, in particular, (Σ_{nu}). The concept of "control Lyapunov function" is introduced as an open loop definition of quadratic stabilizability. It is also a natural generalization, to the setting of uncertain systems, of an elementary Lyapunov function characterization of the well-known concept of stabilizability for finite-dimensional linear systems. Roughly speaking, for a positive definite matrix P, the function $v(x) = x'Px$ is called a control Lyapunov function if for each x in $\mathbb{R}^n$, there exists a control input u (that may be a function of δ) such that the derivative of $v(x)$ along solutions to (1.1) is strictly negative. In § 2 it is shown that if the system (Σ_u) is quadratically stabilizable using nonlinear time-varying controllers, then it admits a control Lyapunov function. Of course, this last fact also applies to the uncertain system (Σ_{nu}).

The main result of this paper shows that the uncertain system (1.2) *admits a control Lyapunov function if and only if there exists a quadratically stabilizing linear time-invariant controller of the form* $u = Kx$. A consequence of this approach using control Lyapunov functions is that if there exists a nonlinear time-varying quadratically stabilizing controller, then there exists a quadratically stabilizing controller of the form $u = Kx$.

These results fit nicely into a collection of recent results on the possible advantages of nonlinear time-varying controllers over linear time-invariant controllers for robust and H^∞ optimal control. See, for example, [4], [7], [9], [10], [12], [13], and [20]. In particular, our main results are consistent with the (qualitative) **Plant Uncertainty Principle** of Khargonekar and Poolla that in the present context states the following. *In robust control problems for linear time-invariant plants, nonlinear time-varying controllers yield no advantage over linear time-invariant controllers if the plant uncertainty is unstructured.* It will be intuitively obvious that the uncertainty considered in this paper is unstructured.

As mentioned above, if we restrict our attention to linear time-invariant controllers, then it is shown in [11] that the quadratic stabilization problem is mathematically equivalent to the standard problem in H^∞ control theory. It should be noted that this equivalence between quadratic stabilization and H^∞ optimization is not known to be true if we consider nonlinear time-varying controllers. Thus, our result on the equivalence between nonlinear time-varying controllers and linear time-invariant controllers cannot be obtained as a special case of earlier results of Khargonekar and Poolla [9] on such an equivalence for H^∞ optimal control.

The organization of this paper is as follows. In § 2 we discuss the concept of control Lyapunov functions. In § 3 we give the main results of the paper. It turns out that we need to prove a matrix-theoretic result (Theorem 3.15) to establish the main

results of this paper. Roughly speaking, if the "discriminant" of a quadratic form involving a self-adjoint (second-order) polynomial matrix is always negative, then for some choice of the independent variable the resulting matrix is sign definite. This result appears to be unknown in the matrix theory literature and generalizes a previous result of Petersen and Hollot (see, for example, [19]).

The notation used through this paper is fairly standard. $\mathbb{R}(X)$ and $\mathbb{N}(X)$ are used to denote the range and null spaces of a linear operator (matrix) X. The empty set is denoted by $\varnothing$, and if k is a positive integer, we use $\underline{k}$ to represent the set $\{1, 2, \cdots, k\}$. The identity matrix is denoted by I. For a constant real matrix X, X' denotes its transpose and $\|X\|$ the maximum singular value of X. Moreover, if X is symmetric, $\lambda_m(X)$ and $\lambda_M(X)$ denote its minimum and maximum eigenvalues, respectively.

2. Lyapunov functions and uncertain systems. Let Σ denote a continuous-time linear time-invariant system

(Σ):

$$\frac{dx}{dt}(t) = Ax(t) + Bu(t), \qquad t \in \mathbb{R} \tag{2.1}$$

where $x(t) \in \mathbb{R}^n$ is the state vector, $u(t) \in \mathbb{R}^m$ denotes the input vector, and A and B are real matrices of compatible dimensions. Let $P \in \mathbb{R}^{n \times n}$ be a symmetric positive definite matrix. We will say that the function $v(x) := x'Px$ is a *control Lyapunov function* for the linear system (Σ) if there exists $\alpha > 0$ such that for each $x \in \mathbb{R}^n$ there exists u (that may depend on x) $\in \mathbb{R}^m$ such that

$$L(x) := x'(A'P + PA)x + 2x'PBu \leqq -\alpha \|x\|^2.$$

Note that $L(x)$ is the derivative of $v(x)$ subject to (2.1).

LEMMA 2.2. *The system* (Σ) *admits a control Lyapunov function if and only if it is stabilizable.*

The proof of this result is left as an easy exercise for the reader. Thus, we may regard a control Lyapunov function as a Lyapunov stability type characterization of stabilizability. It can also be thought of as an open loop characterization of stabilizability, although such a characterization is not the most elementary. We would like to remark that this characterization of stabilizability is not new. In fact, Sontag in [22] has already used the notion of a control Lyapunov function as a characterization of asymptotic controllability for nonlinear systems. *The central aim of this paper is to generalize Lemma* 2.2 *to uncertain systems.*

The uncertain systems under consideration are described by state equations of the form

(Σ_u):

$$\frac{dx}{dt}(t) = A(\delta(t))x(t) + B(\delta(t))u(t) \quad \text{a.e. } t \in \mathbb{R} \tag{2.3}$$

where $x(t) \in \mathbb{R}^n$ is the state vector, $u(t) \in \mathbb{R}^m$ denotes the input vector, and the functions $A(.)$, $B(.)$ are assumed to be continuous real-valued matrix functions. The vector-valued function $\delta(.)$ represents the parameter uncertainty (possibly time-varying) and it is assumed to be a Lebesgue measurable function that satisfies $\delta(t) \in \mathbb{U}$ (compact set in $\mathbb{R}^k$), where $t \in \mathbb{R}$ almost everywhere. In the sequel such a function $\delta(.)$ will be called an admissible uncertainty.

As before, let $P \in \mathbb{R}^{n\times n}$ denote a positive definite matrix. We will say that the function $v(x) := x'Px$ is a *control Lyapunov function* for the uncertain system (Σ_u) if there exists $\alpha > 0$ such that for each pair $(x, \delta) \in \mathbb{R}^n \times \mathbb{U}$ there exists u (that may depend on x and $\delta) \in \mathbb{R}^m$ such that

$$L(x, \delta) := x'(PA(\delta) + A'(\delta)P)x + 2x'PB(\delta)u \leqq -\alpha \|x\|^2. \tag{2.4}$$

We regard the existence of a control Lyapunov function as an open loop notion of stabilizability for the uncertain system (Σ_u). In the remainder of this section we shall show that the existence of a control Lyapunov function is a necessary condition for the quadratic stabilizability (see, for example, [1] and [17]) of (Σ_u) by a nonlinear time-varying dynamic state feedback.

For the stabilization of the uncertain system (Σ_u), we will consider a nonlinear dynamic state-feedback controller (Σ_c) described by

(Σ_c):

$$\frac{dx_c}{dt}(t) = f(x(t), x_c(t), t), \tag{2.5a}$$

$$u(t) = h(x(t), x_c(t), t) \tag{2.5b}$$

where $t \in \mathbb{R}$, $x_c(t) \in \mathbb{R}^q$ denotes the state of the compensator, $h(x, x_c, t) \in \mathbb{R}^m$, $f(x, x_c, t) \in \mathbb{R}^q$, and the functions $f(.)$ and $h(.)$ are such that (2.5) is a well-defined dynamical system. Note that the closed loop system (Σ_{cl}) obtained from the feedback interconnection of the uncertain system (Σ_u) and the compensator (Σ_c) can be described by the following equations:

(Σ_{cl}):

$$\frac{dz}{dt}(t) = F(t)z(t) + G(t)p(z(t), t) \quad \text{a.e. } t \in \mathbb{R} \tag{2.6a}$$

where $z(t) \in \mathbb{R}^{n+q}$ denotes the composite state $[x'(t)\ x_c'(t)]'$, and

$$F(t) := \begin{bmatrix} A(\delta(t)) & 0 \\ 0 & 0 \end{bmatrix}, \tag{2.6b}$$

$$G(t) := \begin{bmatrix} B(\delta(t)) & 0 \\ 0 & I \end{bmatrix}, \tag{2.6c}$$

$$p(z, t) := \begin{bmatrix} h(x(t), x_c(t), t) \\ f(x(t), x_c(t), t) \end{bmatrix}. \tag{2.6d}$$

The stability of the closed loop system (Σ_{cl}) will be studied using Lyapunov stability theory. We will consider the case where the Lyapunov function is quadratic. More precisely, we have the following definition (see also [1] and [17]).

The uncertain system (Σ_u) is said to be *quadratically stabilizable* if:

(i) There exists an integer $q \geqq 0$, a feedback control law $p(.): \mathbb{R}^{n+q} \times \mathbb{R} \to \mathbb{R}^{m+q}$, with $p(0, t) = 0$ for all $t \in \mathbb{R}$, such that $p(., t)$ is continuous and $p(x, x_c, .)$ is an (essentially) bounded measurable function over $\mathbb{R}$; and

(ii) A symmetric positive definite matrix $P \in \mathbb{R}^{(n+q)\times(n+q)}$, and a constant $\alpha > 0$, such that the following condition is satisfied. Given any admissible uncertainty $\delta(.)$, the Lyapunov derivative, corresponding to the closed loop system (Σ_{cl}) and the Lyapunov function $z'Pz$, satisfies the inequality

$$L(z, t) := z'(PF(t) + F'(t)P)z + 2z'PG(t)p(z, t) \leqq -\alpha \|z\|^2 \quad \text{a.e. } t \in \mathbb{R}, \tag{2.7}$$

and for all $z \in \mathbb{R}^{n+q}$.

Finally, suppose that the system (Σ_u) is quadratically stabilizable and, in addition, the stabilizing control law can be chosen to be $u(t) = Kx(t)$, for some real matrix K; then, (Σ_u) is said to be *quadratically stabilizable via (memoryless) time-invariant linear control.*

Note that if the uncertain system (Σ_u) is quadratically stabilizable, then $z'Pz$ is a Lyapunov function for the closed loop system (2.6). As is well known, given any $t_0 \in \mathbb{R}$, any initial condition $z(t_0) = z_0$, and an admissible uncertainty $\delta(.)$, there exists $t_1 > t_0$ such that (2.6a) admits a unique solution on $[t_0, t_1]$, and such a solution is continuable over $[t_0, \infty)$. Moreover, in the view of (2.7), the equilibrium point $z_\infty = 0$ will be uniformly asymptotically stable in the large (see, for example, [1] and [17]).

Now we are ready to show the connection between the control Lyapunov function concept and the notion of quadratic stabilizability.

PROPOSITION 2.8. *Consider the uncertain system* (Σ_u) *defined by* (2.3). *If* (Σ_u) *is quadratically stabilizable, then* (Σ_u) *admits a control Lyapunov function.*

Proof. Suppose that the system (Σ_u) is quadratically stabilizable. Then, there exists an integer $q \geqq 0$, a control law $p(.): \mathbb{R}^{n+q} \times \mathbb{R} \to \mathbb{R}^{m+q}$, a symmetric positive definite matrix $P \in \mathbb{R}^{(n+q)\times(n+q)}$, and a constant $\alpha > 0$, such that (2.7) holds for any admissible uncertainty $\delta(.)$. If $q = 0$, the conclusion is obvious. Indeed, $v(x) = x'Px$ is a control Lyapunov function for the system (Σ_u). If q is nonzero, we proceed as follows.

Define the symmetric positive definite matrix $S := P^{-1}$ and let the change of coordinates $z = Sw$ be applied to (2.7). Then, it follows that

$$w'(F(t)S + SF'(t))w + 2w'G(t)\tilde{p}(w, t) \leqq -\tilde{\alpha}\|w\|^2 \quad \text{a.e. } t \in \mathbb{R}, \tag{2.9}$$

for all $w \in \mathbb{R}^{n+q}$, and some $\tilde{\alpha} > 0$, where $\tilde{p}(w, t) = p(z, t)$. In particular, for $w = [r' \ 0]'$, $r \in \mathbb{R}^n$, from (2.6), (2.9), and partitioning S as follows:

$$S = \begin{bmatrix} S_1 & S_2 \\ S_1' & S_3 \end{bmatrix}$$

where the dimension of S_1 is $n \times n$, the dimension of S_2 is $n \times q$, and the dimension of S_3 is $q \times q$, we obtain

$$r'(A(\delta(t))S_1 + S_1A'(\delta(t)))r + 2r'B(\delta(t))\tilde{h}(r, t) \leqq -\tilde{\alpha}\|r\|^2 \quad \text{a.e. } t \in \mathbb{R}, \tag{2.10}$$

for all $r \in \mathbb{R}^n$, and any admissible uncertainty $\delta(.)$, where $\tilde{h}(r, t) = h(S_1r, S_2'r, t)$.

Finally, considering (2.10) for a time-invariant uncertainty $\delta \in \mathbb{U}$, setting $t = t^*$ (any fixed time such that $\tilde{h}(., t^*)$ is well defined), and with the coordinate transformation $x = S_1r$, we conclude that there exists $\beta > 0$ such that

$$L(x, \delta) := x'(P_1A(\delta) + A'(\delta)P_1)x + 2x'P_1B(\delta)h^*(x) \leqq -\beta\|x\|^2,$$

for all $x \in \mathbb{R}^n$ and $\delta \in \mathbb{U}$, where P_1 is a symmetric positive definite matrix given by $P_1 := S_1^{-1}$ and $h^*(x) = \tilde{h}(P_1x, t^*)$. The proof is concluded observing that this last inequality implies that the function $v(x) := x'P_1x$ is a control Lyapunov function for the uncertain system (Σ_u). □

In [17], Petersen has obtained a result similar to Proposition 2.8, which states that if an uncertain system (Σ_u) (as defined in (2.3)) is quadratically stabilizable, then it is quadratically stabilizable via memoryless *nonlinear* state feedback. Note that, in general, the notion of control Lyapunov function is not equivalent to the notion of quadratic stabilization via memoryless compensators. In fact, the former is much weaker since the control input "u" is allowed to be a function of the uncertainty "δ" (see, for example, (2.4)).

3. Control Lyapunov functions and stabilizability by linear feedback. In this section the case of norm-bounded time-varying uncertainty is considered. Such an uncertainty representation has already been used by Petersen [15] and [16], Zhou and Khargonekar [23], and Khargonekar, Petersen, and Zhou [11], to develop necessary and sufficient conditions for the existence of linear (quadratically) stabilizing compensators not only for the state feedback case but also for output feedback. Here, we will show that those conditions are actually necessary for the existence of a control Lyapunov function. As a consequence, from Proposition 2.8 we conclude that, for the case of norm-bounded time-varying uncertainty, nonlinear time-varying dynamic compensators are not better than linear (memoryless) ones when the states are available for feedback and a single quadratic Lyapunov function is sought to establish the stability of the closed loop system.

A system (Σ_{nu}) with norm-bounded uncertainty is better described by the model given below rather than the general representation given in (2.3):

(Σ_{nu}):

$$\frac{dx}{dt}(t) = Ax(t) + Bu(t) + Dw(t), \tag{3.1a}$$

$$e(t) = E_1 x(t) + E_2 u(t), \tag{3.1b}$$

$$w(t) = \Delta(t) e(t), \tag{3.1c}$$

where $t \in \mathbb{R}$ almost everywhere, $x(t) \in \mathbb{R}^n$ is the state vector, $u(t) \in \mathbb{R}^m$ denotes the input vector, $w(t) \in \mathbb{R}^k$, and $e(t) \in \mathbb{R}^p$. The real matrices A, B, D, E_1, and E_2 are known and of appropriate dimensions. As before, the matrix-valued function $\Delta(.)$ is assumed to be Lebesgue measurable and satisfies

$$\Delta(t) \in \mathbb{U} := \{U \in \mathbb{R}^{k \times p} : \|U\| \leqq 1\} \quad \text{a.e. } t \in \mathbb{R}. \tag{3.1d}$$

Furthermore, to avoid trivial situations, it will be assumed that the dimension of the input is strictly less than the dimension of the state (i.e., $m < n$).

The main result of this paper is the following theorem.

THEOREM 3.2. *Consider the uncertain system* (Σ_{nu}) *defined in* (3.1). *Then, the following statements are equivalent*:

(i) *The uncertain system* (Σ_{nu}) *admits a control Lyapunov function.*

(ii) *The uncertain system* (Σ_{nu}) *is quadratically stabilizable.*

(iii) *The uncertain system* (Σ_{nu}) *is quadratically stabilizable via linear time-invariant* (*memoryless*) *control.*

It is obvious that (iii) implies (ii). In Proposition 2.8 it has been proved (in a more general situation) that (ii) implies (i). We will prove that (i) $\Rightarrow$ (iii). The proof is rather long and difficult. For ease of exposition, some intermediate results will be developed, leading to a proof of Theorem 3.2.

First note that if the uncertain system (Σ_{nu}) admits a control Lyapunov function, it readily follows from (2.4) and (3.1) that there exists a symmetric positive definite matrix $P \in \mathbb{R}^{n \times n}$ such that the following condition holds. Given any nonzero $x \in \mathbb{R}^n$, if

$$(B + D\Delta E_2)' Px = 0 \quad \text{for some } \Delta \in \mathbb{U}, \tag{3.3a}$$

then

$$x'(A'P + PA)x + 2x'(PD\Delta E_1)x < 0. \tag{3.3b}$$

Let $z \in \mathbb{R}^n$ be given and define the set

$$\Gamma(z) := \{\Gamma \in \mathbb{R}^{p \times k} : (B + D\Gamma' E_2)' z = 0, \|\Gamma\| \leqq 1\}, \tag{3.4}$$

and note that, when $\Gamma(z) \neq \emptyset$, it is a compact set. Then, from the discussion above we conclude that given any nonzero $z \in \mathbb{R}^n$, if $\Gamma(z) \neq \emptyset$, the following inequality holds:

$$\max \{z'(AS+SA')z + 2z'(D\Gamma' E_1 S)z : \Gamma \in \Gamma(z)\} < 0 \tag{3.5}$$

where $S := P^{-1}$ is a symmetric positive definite matrix. Indeed, making the change of coordinates $z = Px$ in (3.3) it follows that Δ satisfies (3.3a) if and only if $\Gamma = \Delta' \in \Gamma(z)$. Moreover, the left-hand side of (3.3b) is continuous in $\Gamma = \Delta'$.

It should be noted that the situation $\Gamma(z) = \emptyset$ for all nonzero $z \in \mathbb{R}^n$ is rather uninteresting. Indeed, the latter will never occur when the dimension of the input space (m) is less than the dimension of the state space (n). In the next lemma the set $\Gamma(z)$ is studied and the maximization problem introduced in (3.5) is solved.

For a matrix $W \in \mathbb{R}^{m \times p}$ the matrix $W^+ \in \mathbb{R}^{p \times m}$ will denote the Moore–Penrose inverse of W (see, for example [21, § 3.3]). Note that W^+ is the unique matrix that satisfies

$$WW^+W = W, \qquad (W^+W)' = W^+W, \tag{3.6a}$$

$$W^+WW^+ = W^+, \qquad (WW^+)' = WW^+. \tag{3.6b}$$

Conditions (3.6) amount to the requirement that

$$\Pi_1 := W^+W \quad \text{and} \quad \Pi_2 := WW^+, \tag{3.6c}$$

be the orthogonal projections onto $\mathbb{R}(W')$ and $\mathbb{R}(W)$, respectively.

LEMMA 3.7. *Let $W \in \mathbb{R}^{m \times p}$, $W \neq 0$; $d \in \mathbb{R}^k$; $b \in \mathbb{R}^m$; and $e \in \mathbb{R}^p$ be given matrices. Define the following set:*

$$\Gamma := \{\Gamma \in \mathbb{R}^{p \times k} : W\Gamma d = b, \|\Gamma\| \leqq 1\}. \tag{3.8}$$

Then, $\Gamma \neq \emptyset$ if and only if $b \in \mathbb{R}(W)$ and $\|W^+b\| \leqq \|d\|$, where $W^+ \in \mathbb{R}^{p \times m}$ is the Moore–Penrose inverse of W. Moreover, if $\Gamma \neq \emptyset$ and Π_1 is the matrix defined in (3.6c), *then*

$$\max \{e'\Gamma d : \Gamma \in \Gamma\} = e'W^+b + \|(I - \Pi_1)e\| \{\|d\|^2 - \|W^+b\|^2\}^{1/2}. \tag{3.9}$$

Proof. The proof is in two steps. First, we establish the necessary and sufficient conditions for the nonemptiness of the set Γ.

(Necessity.) Suppose that there exists Γ such that $W\Gamma d = b$ and $\|\Gamma\| \leqq 1$. Obviously, $b \in \mathbb{R}(W)$, and, from (3.6), $W^+b = \Pi_1 \Gamma d$. Since Π_1 is an orthogonal projection and $\|\Gamma\| \leqq 1$, the latter implies $\|W^+b\| \leqq \|\Pi_1\| \|\Gamma\| \|d\| \leqq \|d\|$.

(Sufficiency.) Suppose that $b \in \mathbb{R}(W)$ and $\|W^+b\| \leqq \|d\|$. We now consider two cases.

Case 1. $d = 0$. Obviously $\Gamma \neq \emptyset$ if and only if $b = 0$. Now, from the assumptions it follows that $b \in \mathbb{R}(W)$ and $b \in \mathbb{N}(W^+)$. When (3.6) is used, it follows that $\mathbb{N}(W^+) = \{\mathbb{R}(W)\}^\perp$. Hence, we conclude that $b = 0$.

Case 2. $d \neq 0$. Consider the following matrices:

$$\Gamma_0 := W^+bd^+, \qquad d^+ := (d'd)^{-1}d'. \tag{3.10}$$

It will be shown that $\Gamma_0 \in \Gamma$. From (3.6) and since $b \in \mathbb{R}(W)$ we obtain

$$\begin{aligned} W\Gamma_0 d &= WW^+b = WW^+Wc, \qquad c \in \mathbb{R}^p \\ &= Wc = b. \end{aligned}$$

Moreover, $\|\Gamma_0\| \leqq \|W^+b\| \|d^+\| \leqq \|W^+b\| / \|d\| \leqq 1$. This concludes the first part of the proof. We are now ready to establish (3.9).

Note first that, when $\mathbb{\Gamma} \neq \varnothing$, the right-hand side of (3.9) is well defined. We now consider two cases.

Case 1. $d = 0$. In this case $\mathbb{\Gamma} \neq \varnothing$ implies $b = 0$. The result follows by inspection.

Case 2. $d \neq 0$. In this case $\mathbb{\Gamma} \neq \varnothing$ implies $b \in \mathbb{R}(W)$ and $\|W^+ b\| \leqq \|d\|$. Let $e \in \mathbb{R}^p$ denote an arbitrary vector. First we show that the inequality

$$e'\Gamma d \leqq e' W^+ b + \|(I - \Pi_1)e\| \{\|d\|^2 - \|W^+ b\|^2\}^{1/2}, \tag{3.11}$$

holds for any $\Gamma \in \mathbb{\Gamma}$.

Let $\Gamma \in \mathbb{\Gamma}$ be given. Then Γ satisfies the equation $W\Gamma d = b$. Therefore, there exists $Z \in \mathbb{R}^{p \times k}$ such that (see, for example, [21, § 2.3])

$$\Gamma = \Gamma_0 + Z - \Pi_1 Z d d^+$$

where Γ_0 and d^+ were defined in (3.10). Thus, we obtain

$$\Gamma d = W^+ b + (I - \Pi_1) Z d. \tag{3.12}$$

Moreover, for any $Z \in \mathbb{R}^{p \times k}$, it follows from (3.6) that

$$(W^+ b)'(I - \Pi_1) Z d = 0. \tag{3.13}$$

Hence, (3.12), (3.13), and the fact that $\|\Gamma\| \leqq 1$, imply the following chain of inequalities:

$$\begin{aligned} e'\Gamma d &= e' W^+ b + e'(I - \Pi_1) Z d \\ &= e' W^+ b + ((I - \Pi_1)e)'(I - \Pi_1) Z d \\ &\leqq e' W^+ b + \|(I - \Pi_1)e\| \, \|(I - \Pi_1) Z d\| \\ &\leqq e' W^+ b + \|(I - \Pi_1)e\| \{\|\Gamma d\|^2 - \|W^+ b\|^2\}^{1/2} \\ &\leqq e' W^+ b + \|(I - \Pi_1)e\| \{\|d\|^2 - \|W^+ b\|^2\}^{1/2}. \end{aligned}$$

Since $\Gamma \in \mathbb{\Gamma}$ is arbitrary, this last row implies inequality (3.11).

To complete the proof we must show that the upper bound given in (3.11) is actually achieved. To that purpose we define

$$\Gamma^* := \begin{cases} \Gamma_0 + \gamma (I - \Pi_1) e d^+ & \text{if } (I - \Pi_1)e \neq 0, \\ \Gamma_0 & \text{otherwise} \end{cases} \tag{3.14a}$$

where Γ_0 and d^+ are as in (3.10), and

$$\gamma := \frac{\{\|d\|^2 - \|W^+ b\|^2\}^{1/2}}{\|(I - \Pi_1)e\|}. \tag{3.14b}$$

Note first that $\Gamma^* \in \mathbb{\Gamma}$. The case $\Gamma^* = \Gamma_0$ already has been done in the first part of the proof. When $(I - \Pi_1)e \neq 0$, a trivial computation using (3.6) and (3.14a) will show that $W\Gamma^* d = b$. To show that Γ^* is a contraction, we proceed as follows. Let $x \in \mathbb{R}^k$ be given. From (3.14a) we obtain

$$\begin{aligned} \Gamma^* x &= W^+ b d^+ x + \gamma (I - \Pi_1) e d^+ x \\ &= [W^+ b + \gamma (I - \Pi_1) e] d^+ x. \end{aligned}$$

When we use (3.13) and (3.14b), it follows that

$$\|\Gamma^* x\|^2 = \|d\|^2 (d^+ x)^2 \leqq \|d\|^2 \|d^+\|^2 \|x\|^2 = \|x\|^2.$$

Since x is arbitrary we conclude that $\|\Gamma^*\| \leqq 1$.

Finally, an easy calculation shows that $e'\Gamma^* d$ achieves the upper bound (3.11). □

The next result generalizes a previous result of Petersen and Hollot [19], and it will be used in the proof of Theorem 3.2. For the sake of clarity, its proof is given in a separate Appendix.

THEOREM 3.15. *Let* $A_1 = A_1'$, $A_2 = A_2' \geqq 0$, *and* $A_3 = A_3'$ *denote* $s \times s$ *real matrices. Suppose that for all* $x \neq 0$ *such that* $x'A_3x \geqq 0$, *we have*

(i) $x'A_1x < 0$; *and*

(ii) $\delta(x) := (x'A_1x)^2 - 4(x'A_2x)(x'A_3x) > 0$.

Then, there exists $\beta > 0$ *such that* $\beta^2 A_2 + \beta A_1 + A_3 < 0$.

We are now ready to prove Theorem 3.2.

Proof of Theorem 3.2. Consider the uncertain system (Σ_{nu}) defined in (3.1) and suppose that it admits a control Lyapunov function. It will be shown that (Σ_{nu}) is quadratically stabilizable via (memoryless) linear time-invariant control. Let us assume first that $E_2 \neq 0$. From the discussion below Theorem 3.2, it follows that there exists a symmetric positive definite matrix $S \in \mathbb{R}^{n\times n}$ such that given any nonzero $z \in \mathbb{R}^n$, if $\mathbb{\Gamma}(z) \neq \varnothing$ (see (3.4)), then inequality (3.5) holds.

With reference to the notation of Lemma 3.7, we now make the following association:

$$E_2' \leftrightarrow W,$$

$$D'z \leftrightarrow d,$$

$$-B'z \leftrightarrow b,$$

$$E_1Sz \leftrightarrow e,$$

$$\mathbb{\Gamma}(z) \leftrightarrow \Gamma,$$

and (as before) let $W^+ \in \mathbb{R}^{p\times m}$ denote the Moore–Penrose inverse of W and Π_1, Π_2 be defined by (3.6c). It now follows from (3.5) and Lemma 3.7 that for each $z \neq 0$, such that

$$B'z \in \mathbb{R}(W) \quad \text{and} \quad \|W^+B'z\| \leqq \|D'z\|, \tag{3.16a}$$

the following inequality holds:

$$\begin{aligned} z'(AS + SA')z - 2(E_1Sz)'W^+B'z \\ + 2\|(I - \Pi_1)E_1Sz\|\{\|D'z\|^2 - \|W^+B'z\|^2\}^{1/2} < 0. \end{aligned} \tag{3.16b}$$

Let $A_0 \in \mathbb{R}^{n\times n}$ be defined by

$$A_0 := A - BW^{+\prime}E_1, \tag{3.17}$$

and observe that from (3.6c) we obtain that $\mathbb{N}(I - \Pi_2) = \mathbb{R}(W)$. Hence, we may conclude that (3.16b) holds for any $z \neq 0$ such that $\|W^+B'z\| \leqq \|D'z\|$ and $z \in \mathbb{N}((I - \Pi_2)B')$.

Let X denote a (full column rank) real matrix whose columns span $\mathbb{N}((I - \Pi_2)B')$, and define the following symmetric matrices:

$$A_1 := X'(A_0S + SA_0')X, \quad A_0 \text{ defined in (3.17)},$$

$$A_2 := X'SE_1'(I - \Pi_1)E_1SX,$$

$$A_3 := X'(DD' - BW^{+\prime}W^+B')X.$$

Note that $A_2 \geqq 0$ (for $I - \Pi_1$ is an orthogonal projection). It follows from (3.16) that

$$y'A_1y + 2\{(y'A_2y)(y'A_3y)\}^{1/2} < 0,$$

for all $y \neq 0$ such that $y'A_3y \geqq 0$. Or equivalently, $y'A_1y < 0$ and $(y'A_1y)^2 - 4(y'A_2y) \times (y'A_3y) > 0$, for all $y \neq 0$ such that $y'A_3y \geqq 0$. Using Theorem 3.15 we may conclude that there exists $\beta > 0$ such that $\beta^2 A_2 + \beta A_1 + A_3 < 0$. Hence, letting $S_0 := \beta S > 0$ and $E_0 := (I - \Pi_1)E_1$, it follows that

$$z'(S_0E_0'E_0S_0 + A_0S_0 + S_0A_0' + DD' - BW^{+\prime}W^+B')z < 0, \tag{3.18}$$

for any $z \neq 0$ such that $z \in \mathbb{N}((I - \Pi_2)B')$.

Now, from (3.18), a standard argument using the Finsler Lemma (see, for example, [6, § 3.2.6]) shows that there exists $\varepsilon > 0$ such that the matrix

$$Q_0 := -\left(S_0E_0'E_0S_0 + A_0S_0 + S_0A_0' + DD' - BW^{+\prime}W^+B' - \frac{1}{\varepsilon} B(I - \Pi_2)B' \right),$$

is positive definite. Letting $P_0 := S_0^{-1} > 0$ and $Q := P_0Q_0P_0 > 0$, we conclude that the following Riccati equation holds:

$$A_0'P_0 + P_0A_0 + E_0'E_0 + P_0\left(DD' - BW^{+\prime}W^+B' - \frac{1}{\varepsilon} B(I - \Pi_2)B' \right)P_0 + Q = 0. \tag{3.19}$$

Consider the linear time-invariant memoryless feedback law given by

$$Y := \frac{1}{2\varepsilon}(I - \Pi_2) + W^{+\prime}W^+, \tag{3.20a}$$

$$u = p(x) := -YB'P_0x - W^{+\prime}E_1x. \tag{3.20b}$$

We will next show that $v(x) := x'P_0x$ is a Lyapunov function for the closed loop system resulting from the feedback interconnection of the uncertain system (Σ_{nu}) and the controller (3.20). In fact, given any admissible uncertainty $\Delta(.)$, the derivative of $v(x)$ along the system (Σ_{nu}) defined in (3.1) subject to the control law (3.20) is given by

$$L(x, t) := x'(P_0A + A'P_0)x + 2x'P_0Bp(x) + 2x'P_0D\Delta(t)(E_1x + E_2p(x)) \tag{3.21}$$

where $\Delta(t) \in \mathbb{U}$. Hence, from (3.21) we obtain

$$\begin{aligned} L(x, t) &\leqq x'(P_0A + A'P_0)x + 2x'P_0Bp(x) + 2\|D'P_0x\| \, \|E_1x + E_2p(x)\|, \\ &\leqq x'(P_0A + A'P_0)x + 2x'P_0Bp(x) + \|D'P_0x\|^2 \\ &\quad + \|E_1x + E_2p(x)\|^2 \quad \text{a.e. } t \in \mathbb{R}. \end{aligned} \tag{3.22}$$

Substituting (3.17) and (3.20) in (3.22), and using (3.6), it follows that

$$\begin{aligned} L(x, t) \leqq x'\Big(& P_0A_0 + A_0'P_0 + E_0'E_0 + P_0DD'P_0 - P_0BW^{+\prime}W^+B'P_0 - \frac{1}{\varepsilon} P_0B(I - \Pi_2)B'P_0 \Big)x \\ & - \|W^+B'P_0x\|^2 + \|W'YB'P_0x\|^2. \end{aligned}$$

From (3.19) and this last inequality we may conclude that

$$L(x, t) \leqq -x'Qx - \|W^+B'P_0x\|^2 + \|W'YB'P_0x\|^2. \tag{3.23}$$

Finally, substituting (3.20a) in (3.23) and since $W'Y = \Pi_1W^+$, we obtain that

$$\begin{aligned} L(x, t) &\leqq -x'Qx - \|W^+B'P_0x\|^2 + \|\Pi_1W^+B'P_0x\|^2 \\ &\leqq -x'Qx + (\|\Pi_1\|^2 - 1)\|W^+B'P_0x\|^2 \leqq -\lambda_m(Q)\|x\|^2, \end{aligned}$$

where $t \in \mathbb{R}$ almost everywhere, and for all $x \in \mathbb{R}^n$. Since $\lambda_m(Q) > 0$, the proof for the case $E_2 \neq 0$ has been completed.

Finally, suppose that $E_2 = 0$. From (3.3) it follows that there exists a positive definite matrix $P \in \mathbb{R}^{n\times n}$ such that

$$x'(A'P + PA)x + 2x'(PD\Delta E_1)x < 0 \tag{3.24}$$

for all nonzero $x \in \mathbb{N}(B'P)$ and for all $\Delta \in \mathbb{U}$. Maximizing (3.24) over all possible $\Delta \in \mathbb{U}$ as in [15] (see also [2]), we may conclude that there exist $P_0 > 0$ and $\varepsilon > 0$ such that the Riccati equation (3.19) holds, provided that we adopt $W^+ = 0$. The rest of the proof remains the same as the case $E_2 \neq 0$. □

The next result gives a necessary and sufficient open loop condition to test whether the uncertain system (3.1) is quadratically stabilizable. A restricted version of this result was first given by Khargonekar, Petersen, and Zhou in [11], within the context of linear time-invariant compensators. Consider the uncertain system (Σ_{nu}) defined in (3.1) and set $W := E_2'$. Let W^+, Π_1, and Π_2 be defined by (3.6) and define $A_0 := A - BW^{+\prime}E_1$. If $E_2 = 0$, we set $W^+ = 0$.

COROLLARY 3.25. *The uncertain system* (Σ_{nu}) *is quadratically stabilizable if there exists* $\varepsilon > 0$ *such that the Riccati equation*

$$A_0'P + PA_0 + P\left(DD' - BW^{+\prime}W^+B' - \frac{1}{\varepsilon}B(I-\Pi_2)B'\right)P + E_1'(I-\Pi_1)E_1 + \varepsilon I = 0 \tag{3.26}$$

has a symmetric positive definite solution $P \in \mathbb{R}^{n\times n}$. *Furthermore, if such a solution exists,*

$$u := -\left[\frac{1}{2\varepsilon}(I-\Pi_2) + W^{+\prime}W^+\right]B'Px - W^{+\prime}E_1x, \tag{3.27}$$

is a quadratically stabilizing linear time-invariant control law. Conversely, if the uncertain system (Σ_{nu}) *is quadratically stabilizable, then there exists* $\varepsilon_1 > 0$ *such that for all* ε *in* $(0, \varepsilon_1]$, *the Riccati equation* (3.26) *has a unique positive definite solution* P_0 *such that* $[A_0 + (DD' - BW^{+\prime}W^+B' - (1/\varepsilon)B(I-\Pi_2)B')P_0]$ *is asymptotically stable.*

(A solution P_0 such that $[A_0 + (DD' - BW^{+\prime}W^+B' - (1/\varepsilon)B(I-\Pi_2)B')P_0]$ is asymptotically stable is called the *stabilizing solution.*)

Corollary 3.25 follows immediately from Theorem 3.2 and earlier results of Khargonekar, Petersen, and Zhou in [11]. This corollary also leads to the following conceptual algorithm for checking quadratic stabilizability.

(i) Set ε to some starting value; i.e., $\varepsilon = 1$.

(ii) Find the unique stabilizing solution to the Riccati equation (3.26) using any standard algorithm. If this solution exists and it is positive definite, stop; the system is quadratically stabilizable (and a stabilizing compensator is given by (3.27)). Else go to step (iii) below.

(iii) Replace ε by $\varepsilon/2$. If ε is less than the computational accuracy, stop; the system is not quadratically stabilizable. Else repeat step (ii) above.

Finally, it should be noted that to test whether the uncertain system (Σ_{nu}) is quadratically stabilizable, a one-parameter search must be performed. This is not the case if $E_2'E_2$ is nonsingular. In fact, in this case $W^+ = E_2(E_2'E_2)^{-1}$ and $\Pi_2 = I$. Furthermore, from the connection established in [11] between quadratic stability and the Small Gain Theorem, and using the recent results of Doyle et al. [3], it follows that, when $E_2'E_2$ is nonsingular, Corollary 3.25 can be strengthened to the following result.

COROLLARY 3.28. *Consider the uncertain system* (Σ_{nu}) *defined in* (3.1). *Suppose* $\Theta := E_2'E_2$ *is nonsingular,* $\{(I - E_2\Theta^{-1}E_2')E_1, A - B\Theta^{-1}E_2'E_1\}$ *is observable, and* $\{A, B\}$

is stabilizable. Then, the uncertain system is quadratically stabilizable if and only if the Riccati equation

$$(A-B\Theta^{-1}E_2'E_1)'P+P(A-B\Theta^{-1}E_2'E_1)+P(DD'-B\Theta^{-1}B')P + E_1'(I-E_2\Theta^{-1}E_2')E_1=0 \tag{3.29}$$

admits a (unique) symmetric positive definite solution $P_0\in\mathbb{R}^{n\times n}$ *such that* $[A-B\Theta^{-1}E_2'E_1+(DD'-B\Theta^{-1}B')P_0]$ *is asymptotically stable. Furthermore, if such a solution exists,*

$$u:=-\Theta^{-1}[B'P_0+E_2'E_1]x, \tag{3.30}$$

is a quadratically stabilizing linear time-invariant control law.

Finally, the existence of the unique stabilizing solution P_0 in the above results can be checked and, if it exists, P_0 can be computed using the associated Hamiltonian matrix.

Appendix. First we establish the following weaker version of Theorem 3.15.

LEMMA A1. *Let* $A_1=A_1'$, $A_2=A_2'>0$, *and* $A_3=A_3'$ *denote* $s\times s$ *real matrices. Suppose the following*:

(i) *For all* $x\neq 0$, $\delta(x):=(x'A_1x)^2-4(x'A_2x)(x'A_3x)>0$; *and*

(ii) *For all* $x\neq 0$, *such that* $x'A_3x\geqq 0$, $x'A_1x<0$.

Then, there exists $\beta>0$ *such that*

$$M(\beta):=\beta^2A_2+\beta A_1+A_3\leqq 0. \tag{A2}$$

Proof. Without loss of generality we can assume $A_2=I$. For, if this is not the case, we can make the change of coordinates $z=A_2^{1/2}x$ to reduce the problem to one with $A_2=I$. (Note that the symmetry of A_1 and A_3 as well as assumptions (i) and (ii) above remain invariant under this coordinate transformation.)

Suppose that (A2) does not hold. Then, for each $\beta>0$ there exists $x(\beta)\neq 0$ such that

$$\phi(\beta):=\beta^2(x'(\beta)x(\beta))+\beta(x'(\beta)A_1x(\beta))+(x'(\beta)A_3x(\beta))>0. \tag{A3}$$

It will be shown later that $x(\beta)$ can be chosen to be a continuous function of β on the interval (β_0,∞), for some $\beta_0<0$ such that $\|x(\beta)\|=1$ and (A3) holds for all $\beta>0$.

Since for each $x\neq 0$, $\delta(x)>0$ it follows that

$$\rho_1(\beta):=\tfrac{1}{2}(-x'(\beta)A_1x(\beta)-\sqrt{\delta(x(\beta))}), \tag{A4a}$$

$$\rho_2(\beta):=\tfrac{1}{2}(-x'(\beta)A_1x(\beta)+\sqrt{\delta(x(\beta))}), \tag{A4b}$$

are real-valued functions and $\rho_2(\beta)>\rho_1(\beta)$ for every $\beta>0$. Moreover, the continuity of the mapping $\beta\to x(\beta)$ implies the continuity of the mappings $\beta\to\rho_1(\beta)$ and $\beta\to\rho_2(\beta)$ on the interval (β_0,∞). From (A3) and (A4) we must have

$$(\beta-\rho_1(\beta))(\beta-\rho_2(\beta))>0 \quad \text{for all } \beta>0. \tag{A5}$$

From (A5), it follows that given any $\beta^*>0$, either $\beta^*<\rho_1(\beta^*)<\rho_2(\beta^*)$ or $\beta^*>\rho_2(\beta^*)>\rho_1(\beta^*)$. Suppose first that for some $\beta^*>0$ we have $\beta^*<\rho_1(\beta^*)<\rho_2(\beta^*)$. Since $\beta-\rho_1(\beta)$ is continuous on the interval (β_0,∞), we observe that this function cannot change its sign over $(0,\infty)$. For if this is not the case, (A5) would be contradicted. Hence, it is concluded that $\beta-\rho_1(\beta)<0$, for all $\beta>0\Rightarrow 2\beta+x'(\beta)A_1x(\beta)<0$, for all $\beta>0\Rightarrow 2\beta+\lambda_m(A_1)<0$, for all $\beta>0$, which leads to the obvious contradiction $2\leqq 0$.

Now suppose that for some $\beta^* > 0$ we have $\beta^* > \rho_2(\beta^*) > \rho_1(\beta^*)$. Arguing as before, we conclude that

$$\beta - \rho_2(\beta) > 0, \text{ for all } \beta > 0 \Rightarrow 2\beta + x'(\beta)A_1 x(\beta) > \sqrt{\delta(x(\beta))}, \text{ for all } \beta > 0$$
$$\Rightarrow x_0' A_1 x_0 \geqq \sqrt{\delta(x_0)}$$

where $x_0 = \lim_{\beta \to 0} x(\beta) \neq 0$. (Note that this limit exists for $\beta \to x(\beta)$ continuous on (β_0, ∞), for some β_0 negative.) From the last inequality it follows that for such a nonzero x_0, $x_0' A_1 x_0 > 0$ and $x_0' A_3 x_0 \geqq 0$, which contradicts assumption (ii).

To complete the proof we must show that $x(\beta)$ can be chosen to be a continuous function of β. For each $\beta \in \mathbb{R}$, the matrix $M(\beta)$ defined in (A2) is symmetric, and therefore has real eigenvalues and s real orthonormal eigenvectors. That is, for each $\beta \in \mathbb{R}$ we can write

(A6a) $$M(\beta) = U(\beta)\Lambda(\beta)U'(\beta),$$

(A6b) $$\Lambda(\beta) = \operatorname{diag}(\lambda_j(\beta); j \in \underline{s}),$$

(A6c) $$U(\beta) = [u_1(\beta) u_2(\beta) \cdots u_s(\beta)], \qquad U'(\beta)U(\beta) = I.$$

Moreover, by suitable ordering, the mappings $\beta \to \lambda_j(\beta)$ and $\beta \to u_j(\beta)$ can be chosen to be continuous (in fact, analytic) for $\beta \in \mathbb{R}$ and $j \in \underline{s}$ (see, for example, [8, § 2.6]).

From inequality (A3) it follows that for each $\beta > 0$

(A7) $$\begin{aligned} \psi(\beta) &:= \max\{x'M(\beta)x : \|x\| = 1\} \\ &= \max\{\lambda_j(\beta) : j \in \underline{s}\} > 0. \end{aligned}$$

Clearly, ψ is a continuous function of β for all β in $\mathbb{R}$.

Let $0 < \beta_1 < \beta_2 < \cdots < \beta_k < \cdots$ denote the collection of exceptional points to the right of $\beta = 0$ (i.e., points where the graphs of the functions $\lambda_j(.)$ may cross to each other). For a more precise definition see § 2.1.8 of [8]. Note also that the ordering of the exceptional points given above makes sense, since there is always a finite number of them in every compact set of $\mathbb{R}$. It now follows that the function ψ defined in (A7) can be written as

(A8) $$\psi(\beta) = \begin{cases} \lambda_{j_0}(\beta) & \text{if } 0 < \beta \leqq \beta_1, \\ \lambda_{j_k}(\beta) & \text{if } \beta_k < \beta \leqq \beta_{k+1}, k \geqq 1 \end{cases}$$

where $j_k \in \underline{s}$ for all $k \geqq 0$ and $\lambda_{j_0}(\beta)$, $\lambda_{j_k}(\beta)$; $k \geqq 1$, denote the maximum eigenvalues of $M(\beta)$ on the intervals $(0, \beta_1]$ and $(\beta_k, \beta_{k+1}]$, respectively.

From (A7) and (A8) we observe that for each $k \geqq 1$, there exists $\varepsilon_k > 0$ such that both $\lambda_{j_{k-1}}(\beta)$ and $\lambda_{j_k}(\beta)$ are strictly positive on $|\beta - \beta_k| < \varepsilon_k$. Let $\beta_0 < 0$ be given, let $\varepsilon_0 = 0$, and define the following vector-valued function:

(A9) $$x(\beta) := \begin{cases} u_{j_k}(\beta) & \text{if } \beta_k + \varepsilon_k < \beta \leqq \beta_{k+1} - \varepsilon_{k+1}, \\ \dfrac{z_k(\beta)}{\|z_k(\beta)\|} & \text{if } \beta_{k+1} - \varepsilon_{k+1} < \beta \leqq \beta_{k+1} + \varepsilon_{k+1} \end{cases}$$

where $k \geqq 0$ and the functions $z_k(.)$ are defined by

(A10a) $$z_k(\beta) := (1 - g_k(\beta))u_{j_k}(\beta) + g_k(\beta)u_{j_{k+1}}(\beta),$$

(A10b) $$g_k(\beta) := \frac{1}{2\varepsilon_{k+1}}(\beta - (\beta_{k+1} - \varepsilon_{k+1}))$$

where the normal vector $u_{j_k}(\beta)$ is an eigenvector corresponding to $\lambda_{j_k}(\beta)$ (see equation (A6)).

Observing the following, the proof is complete:

(i) The analyticity of $\beta \to u_{j_k}(\beta)$, the continuity of $\beta \to g_k(\beta)$, and the fact that $z_k(\beta) \neq 0$ for all $k \geqq 0$, implies that $\beta \to x(\beta)$, as defined in (A9), is continuous on (β_0, ∞); and

(ii) A trivial computation using (A6)-(A10) shows that $x(\beta)'M(\beta)x(\beta) > 0$, for all $\beta > 0$. Moreover, from (A9) it is clear that $\|x(\beta)\| = 1$ for all $\beta > \beta_0$. □

We are now ready to prove Theorem 3.15.

Proof of Theorem 3.15. Suppose first that $A_3 < 0$, i.e., $\lambda_M(A_3) < 0$. In this case it is straightforward to verify that there always exists $\beta > 0$ (sufficiently small) such that $\beta^2 A_2 + \beta A_1 + A_3 < 0$.

Now, we need to consider the case $\lambda_M(A_3) \geqq 0$. The proof is in two steps. First, we show that there exists $\varepsilon > 0$ such that the symmetric matrices A_1, $\tilde{A}_2 := A_2 + \varepsilon I$, and A_3 satisfy all the assumptions of Lemma A1. Indeed, from assumption (ii) of Theorem 3.15, it follows that

$$\mu := \min \{\delta(x) : \|x\| = 1,\ x'A_3x \geqq 0\} > 0. \tag{A11}$$

(Note that δ is continuous in x and that the intersection of the unit sphere with $x'A_3x \geqq 0$ is a compact set.) Set $\varepsilon > 0$ such that

$$4\lambda_M(A_3)\varepsilon < \mu. \tag{A12}$$

Since μ is strictly positive, such an ε can always be found. Now, consider the function:

$$\tilde{\delta}(x) := (x'A_1x)^2 - 4(x'\tilde{A}_2x)(x'A_3x), \tag{A13}$$

and observe that since $A_2 \geqq 0$ and $\varepsilon > 0$, it follows that $\tilde{A}_2 := A_2 + \varepsilon I$ is positive definite. Hence, from (A13) we conclude that $\tilde{\delta}(x) > 0$ for all $x \neq 0$ such that $x'A_3x < 0$. On the other hand, from (A11) through (A13) we obtain,

$$\begin{aligned}
\tilde{\delta}(x) &= \delta(x) - 4\varepsilon(x'x)(x'A_3x), \\
&\geqq \delta(x) - 4\varepsilon\lambda_M(A_3)(x'x)^2, \\
&\geqq (\mu - 4\varepsilon\lambda_M(A_3))(x'x)^2,
\end{aligned}$$

for all $x \neq 0$ such that $x'A_3x \geqq 0$.

It follows that the matrices A_1, $\tilde{A}_2$, and A_3 satisfy all the assumptions of Lemma A1. Therefore, there exists $\beta > 0$ such that $\beta^2(A_2 + \varepsilon I) + \beta A_1 + A_3 \leqq 0$, which certainly implies $\beta^2 A_2 + \beta A_1 + A_3 \leqq -\varepsilon\beta^2 I < 0$. □

THE HAMILTON–JACOBI–BELLMAN EQUATION FOR TIME-OPTIMAL CONTROL*

L. C. EVANS† AND M. R. JAMES‡

Abstract. In this paper several assertions concerning viscosity solutions of the Hamilton-Jacobi-Bellman equation for the optimal control problem of steering a system to zero in minimal time are proved. First two rather general uniqueness theorems are established, asserting that any positive viscosity solution of the HJB equation must, in fact, agree with the minimal time function near zero; if also a boundary condition introduced by Bardi [*SIAM J. Control Optim.*, 27 (1988), pp. 776–785] is satisfied, then the agreement is global. Additionally, the Hölder continuity of any subsolution of the HJB equation is proved in the case where the related dynamics satisfy a Hörmander-type hypothesis. This last assertion amounts to a "half-derivative" analogue of a theorem of Crandall and Lions [*Trans. Amer. Math. Soc.*, 277 (1983), pp. 1–42] concerning Lipschitz viscosity solutions.

Key words. Hamilton-Jacobi-Bellman equation, viscosity solution, minimal time function

AMS(MOS) subject classifications. 35F30, 49C20, 49E30

1. Introduction. In this paper we study the *minimum time optimal control problem* for the system

$$\begin{aligned} &\dot{x}(t) = f(x(t), u(t)) \qquad \text{(a.e. } t > 0), \\ &x(0) = x \end{aligned} \tag{1.1}$$

where $x \in \mathbb{R}^n$ and

$$f : \mathbb{R}^n \times U \to \mathbb{R}^n$$

are given, and U denotes a compact subset of, say, $\mathbb{R}^m$. The measurable function

$$u(\cdot) : [0, \infty) \to U$$

is a *control*, and

$$x(\cdot) : [0, \infty) \to \mathbb{R}^n$$

is the corresponding *state*, sometimes written $x(\cdot) = x^u(\cdot)$. We are interested in studying the *minimum time function*

$$T : \mathbb{R}^n \to [0, \infty],$$

defined so that $T(x)$ is the infimum over all controls $u(\cdot)$ of the time taken for the solution of (1.1) to reach the origin.

It is known that under various controllability assumptions T is continuous and thus is a solution of the appropriate *Hamilton-Jacobi-Bellman* (HJB) *equation* in the viscosity sense (see, for example, [6], [9], [11], [15]). In addition, Hermes [6], Sussmann [15], and others have introduced methods for constructing optimal controls via feedback synthesis from appropriate solutions of this HJB equation.

Herein we prove two uniqueness results. The first asserts that if Ω is a neighborhood of zero and S is a positive viscosity solution of the HJB equation in $\Omega - \{0\}$ satisfying $S(0) = 0$, then there exists another neighborhood Ω' of zero in which S equals the minimal time function T. Quite recently we have seen a new paper of Bardi [2], who has introduced a boundary condition and obtained a uniqueness theorem for the resulting boundary value problem. Our second uniqueness result employs Bardi's boundary condition: If Ω is an open set containing 0 and S is a positive viscosity solution of the HJB equation in $\Omega - \{0\}$ satisfying $S(0) = 0$ and

$$S(x) \to \infty \quad \text{uniformly as } x \to \partial\Omega,$$

then S equals the minimum time function T in Ω. Our proof differs from Bardi's in that we use a representation technique and thereby identify S with T.

These assertions that we prove without any controllability hypotheses, answer a question posed by Hermes in [6]. The point is that if we can find, by any means whatsoever, a positive viscosity solution S of the HJB equation in a region $\Omega - \{0\}$ that vanishes at zero, then S must necessarily be the minimum time function, at least near zero, and consequently the system must in fact be small time locally controllable. Furthermore, if the above boundary condition is satisfied, then Ω coincides with the set C of points controllable to the origin. We see therefore that the explicit solutions constructed for various examples by Hermes in [6] are indeed the minimum time functions.

The proof of these uniqueness assertions appears in § 3, after some preliminaries in § 2.

In § 4 we discuss the regularity of a viscosity subsolution S of the HJB equation in Ω, for the special case that f has the form

$$f(x, u) \equiv \sum_{k=1}^{m} u_k f_k(x) \tag{1.2}$$

where now

$$U = [-1, 1]^m. \tag{1.3}$$

Imposing a simple Hörmander-type requirement concerning the Lie brackets of the vector fields $\{f_j\}_{j=1}^m$, we show that S is locally Hölder continuous with exponent $\frac{1}{2}$. This assertion is certainly clear near zero for viscosity solutions S, in view of § 3 and known regularity theorems for the minimum time function (e.g., Stefani [12], Liverovskii [10]). What we show, in fact, is that the HJB equation itself forces the Hölder continuity.

2. Preliminaries. We now restate our minimum time control problem more precisely as follows.

Let us assume that

$$f: \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$$

is a given smooth function satisfying the Lipschitz condition

$$|f(x, u) - f(y, u)| \leqq K|x - y|$$

for all $x, y \in \mathbb{R}^n$ and all $u \in U$, where $U \subset \mathbb{R}^m$ is compact. Then for any measurable mapping

$$u(\cdot): [0, \infty) \to U,$$

and any point $x \in \mathbb{R}^n$, problem (1.1) has a unique absolutely continuous solution $x(\cdot) = x^u(\cdot)$. We call $u(\cdot)$ an *admissible control* and denote by $\mathcal{U}$ the collection of all admissible controls.

Now let $\Omega \subset \mathbb{R}^n$ be open, with $0 \in \Omega$. We say that the system (1.1) is *controllable to the origin* from $x \in \Omega$ if there exists a control $u(\cdot) \in \mathcal{U}$ and a time

$$0 < \tau_x^u < \infty$$

so that

$$x(\tau_x^u) = 0.$$

Define the following:

$$C(t) \equiv \{x \in \Omega \,|\, \text{there exists a control } u(\cdot) \in \mathcal{U} \text{ with } \tau_x^u \leqq t\};$$

this is the set of states *controllable to the origin within time t.* The set of points controllable to the origin is defined by

$$C \equiv \bigcup_{t>0} C(t).$$

We say that the system (1.1) is *small time locally controllable* (STLC) at the origin if

$$0 \in \operatorname{int} C(t) \quad \text{for each } t > 0.$$

Finally, define the *minimum time function*

$$T(x) \equiv \inf\{\tau_x^u \,|\, u \in \mathcal{U}\}.$$

Then

$$T(0) = 0,$$

and

$$0 < T(x) \leqq +\infty \quad \text{for } x \in \Omega - \{0\}.$$

Furthermore, Sussmann [15] has shown that $T(\cdot)$ is continuous at 0 if and only if (1.1) is STLC at the origin.

The associated dynamic programming *Hamilton-Jacobi-Bellman* equation is the partial differential equation

$$H(x, DS) = 0 \quad \text{in } \Omega - \{0\}$$

where the Hamiltonian

$$H : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$$

is

$$H(x, p) \equiv \max_{u \in U} \{-f(x, u) \cdot p\} - 1 \qquad (x, p \in \mathbb{R}^n). \tag{2.1}$$

3. Uniqueness. Our first uniqueness assertion is Theorem 3.1.

THEOREM 3.1. *Assume* $S \in C(\Omega)$ *satisfies*

$$\begin{aligned} &\text{(a)} \quad S(0) = 0, \\ &\text{(b)} \quad S(x) > 0, \qquad x \in \Omega - \{0\}, \\ &\text{(c)} \quad H(x, DS) = 0 \quad \textit{in } \Omega - \{0\} \textit{ in the viscosity sense.} \end{aligned} \tag{3.1}$$

Then there exists $r > 0$ *such that*

$$S(x) = T(x) \quad \textit{for } x \in B(0, r) \subset \Omega;$$

and, in particular, the system (1.1) *is* STLC *at the origin.*

Note carefully that our sole hypothesis is the existence of a function $S \in C(\Omega)$ verifying (3.1)(a)-(c).

Proof. (1) We start by fixing some bounded smooth open set $\Omega' \subset\subset \Omega$ with $0 \in \Omega'$. Defining then

$$g(x) \equiv S(x) \qquad (x \in \partial\Omega'),$$

we see that $S \in C(\bar{\Omega}')$ is a viscosity solution of

$$H(x, DS) = 0 \quad \text{in } \Omega' - \{0\}, \qquad S = g \quad \text{on } \partial\Omega'. \tag{3.2}$$

Now set

$$\Phi(r) \equiv -\log(1-r) \qquad (r < 1), \tag{3.3}$$

$$\Psi(s) \equiv \Phi^{-1}(s) = 1 - e^{-s} \qquad (-\infty < s < \infty). \tag{3.4}$$

Write

$$R(x) \equiv \Psi(S(x)) \qquad (x \in \Omega'), \tag{3.5}$$

$$h(x) \equiv \Psi(g(x)) \qquad (x \in \partial\Omega'). \tag{3.6}$$

We note that clearly $R \in C(\bar{\Omega}')$ satisfies

$$R(0) = 0, \tag{3.7}$$

$$R(x) = h(x) \qquad (x \in \partial\Omega'). \tag{3.8}$$

In addition, we claim that

$$R + H(x, DR) = 0 \quad \text{in } \Omega' - \{0\} \quad \text{in the viscosity sense.} \tag{3.9}$$

To see this we note that Crandall, Evans, and Lions [4, Prop. 1.2] imply that $R = \Psi(S)$ solves

$$\tilde{H}(x, R, DR) = 0 \quad \text{in } \Omega' - \{0\} \tag{3.10}$$

in the viscosity sense, for

$$\tilde{H}(x, t, p) \equiv H\left(x, \frac{p}{1-r}\right).$$

But since $0 \leqq R < 1$, we have further that

$$(1-R)\tilde{H}(x, R, DR) = R + H(x, DR) = 0 \quad \text{in } \Omega' - \{0\}$$

in the viscosity sense, as required.

Note also now that R is the unique solution of (3.7)-(3.9), in view of Theorem III.1 in Crandall and Lions [3].

(2) We now obtain a control theoretic representation formula for R (and thus for S) in Ω'. For each point $x \in \Omega' - \{0\}$ and control $u(\cdot) \in \mathcal{U}$ define

$$\sigma_x^u \equiv \inf\{t > 0 \,|\, x(t) \in \{0\} \cup \partial\Omega'\}$$

where as usual $x(\cdot) = x^u(\cdot)$ is the solution of system (1.1) corresponding to the control $u(\cdot)$.

Now write the value function

$$V(x) \equiv \inf_{u \in \mathcal{U}} \left\{ \int_0^{\sigma_x^u} e^{-t}\, dt + e^{-\sigma_x^u} \chi_{\{x(\sigma_x^u) \in \partial\Omega'\}} h(x(\sigma_x^u)) \right\}. \tag{3.11}$$

We assert that then

$$R(x) = V(x) \quad \text{in } \bar{\Omega}'. \tag{3.12}$$

This equality follows from almost exactly the same proofs as in Lions [9] or Evans and Ishii [5, Thm. 4.1].

(3) We now claim that there exists $r>0$ such that

$$R(x)=\inf_{u\in\mathcal{U}}\{\Psi(\tau_x^u)\} \qquad (x\in B(0,r)\subset\Omega'). \tag{3.13}$$

To verify this we set

$$s\equiv\inf\{|y|\,|\,y\in\partial\Omega'\},$$
$$\|f\|\equiv\sup\{|f(x,u)|\,|\,x\in\Omega',\ u\in U\},$$
$$\|R\|_r\equiv\sup\{|R(x)|\,|\,|x|\leqq r\},$$
$$\tau_{x,y}^u\equiv\inf\{t>0\,|\,x^u(0)=x,\ x^u(t)=y\}\leqq\infty.$$

We denote by $\mathcal{U}_{x,y}$ the set of admissible controls with $\tau_{x,y}^u<\infty$.

Finally, let us write

$$U(x,y)\equiv\inf\{\tau_{x,y}^u\,|\,u(\cdot)\in\mathcal{U}_{x,y}\}.$$

Choose $0<r<s$ so small that

$$B(0,r)\subset\Omega'$$

and

$$\|R\|_r\leqq\frac{1}{2}\Psi\left(\frac{s-r}{2\|f\|}\right). \tag{3.14}$$

We must verify (3.13). Let us choose $x\in B(0,r)$, $y\in\mathbb{R}^n-B(0,s)$, and suppose $U(x,y)<\infty$. Then we select a control $u(\cdot)\in\mathcal{U}_{x,y}$ satisfying

$$U(x,y)\leqq\tau_{x,y}^u\leqq U(x,y)+\frac{s-r}{2\|f\|}. \tag{3.15}$$

In view of (1.1) we have

$$y-x=\int_0^{\tau_{x,y}^u}f(x(s),u(s))\,ds;$$

whence

$$s-r\leqq|y-x|\leqq\tau_{x,y}^u\|f\|. \tag{3.16}$$

Consequently, (3.15) implies

$$U(x,y)\geqq\frac{s-r}{2\|f\|} \quad \text{if } |x|\leqq r, \quad |y|\geqq s. \tag{3.17}$$

Now fix

$$0<\delta<\frac{1}{2}\Psi\left(\frac{s-r}{2\|f\|}\right). \tag{3.18}$$

Then if $x\in B(0,r)$, there exists a control $u(\cdot)\in\mathcal{U}$ with

$$\begin{aligned}\int_0^{\sigma_x^u}e^{-t}\,dt+e^{-\sigma_x^u}\chi_{\{x(\sigma_x^u)\in\partial\Omega'\}}h(x(\sigma_x^u))&\leqq V(x)+\delta\\ &=R(x)+\delta \quad \text{by (3.12).}\end{aligned} \tag{3.19}$$

First assume that

$$y \equiv x(\sigma_x^u) \in \partial\Omega'. \tag{3.20}$$

Then since

$$\Psi(s) = 1 - e^{-s} = \int_0^s e^{-t}\, dt,$$

it follows that

$$\Psi(\sigma_x^u) + e^{-\sigma_x^u} h(x(\sigma_x^u)) \leqq R(x) + \delta < \Psi\left(\frac{s-r}{2\|f\|}\right),$$

according to (3.14), (3.18). Since $h > 0$ and Ψ is strictly increasing, it follows that

$$\begin{aligned} \sigma_x^u &< \frac{s-r}{2\|f\|} \\ &\leqq U(x, y) \quad \text{by (3.17)}, \end{aligned}$$

a contradiction. Consequently, we must have

$$y \equiv x(\sigma_x^u) = 0$$

in (3.19). Hence (3.11), (3.12), and (3.19) imply that if $x \in B(0, r)$, then

$$\begin{aligned} R(x) = V(x) &= \inf_{u \in \mathcal{U}} \left\{ \int_0^{\sigma_x^u} e^{-t}\, dt \,|\, x^u(\sigma_x^u) = 0 \right\} \\ &= \inf_{u \in \mathcal{U}} \{\Psi(\tau_x^u)\}. \end{aligned}$$

This is formula (3.13).

(4) Finally, due to (3.5) and (3.13), we see

$$\begin{aligned} S(x) &= \Phi(R(x)) \\ &= \inf_{u \in \mathcal{U}} \{\tau_x^u\} \\ &= T(x) \end{aligned}$$

if $x \in B(0, r)$. □

Now we turn to our second uniqueness result that incorporates the boundary condition introduced by Bardi [2]. For $S \in C(\Omega)$ we say that

$$S(x) \to \infty \quad \text{uniformly as } x \to \partial\Omega$$

provided that for all $M > 0$ there exists $\delta > 0$ such that

$$S(x) \geqq M$$

provided $|x| \geqq 1/\delta$ or dist. $(x, \partial\Omega) \leqq \delta$.

THEOREM 3.2. *Assume $S \in C(\Omega)$ satisfies*

$$\begin{aligned} &\text{(a)} \quad S(0) = 0, \\ &\text{(b)} \quad S(x) > 0 \qquad (x \in \Omega - \{0\}), \\ &\text{(c)} \quad S(x) \to \infty \quad \textit{uniformly as } x \to \partial\Omega, \\ &\text{(d)} \quad H(x, DS) = 0 \quad \textit{in } \Omega - \{0\} \textit{ in the viscosity sense.} \end{aligned} \tag{3.21}$$

Then

$$S(x) = T(x) \quad \textit{for all } x \in \Omega,$$

and hence $\Omega = C$.

The proof is similar to that of Theorem 3.1, and so we indicate only the essential changes.

Proof. Defining

$$R(x) = \Psi(S(x)) \qquad (x \in \Omega)$$

we see that $R \in C(\Omega)$ satisfies

$$R + H(x, DR) = 0 \quad \text{in } \Omega - \{0\} \text{ in the viscosity sense,}$$

and also

$$R(0) = 0, \qquad 0 < R(x) < 1 \quad (x \in \partial\Omega - \{0\}). \tag{3.22}$$

In view of the boundary condition (3.21)(c), R can be uniquely extended to a function $R \in BUC(\bar{\Omega})$ by setting (cf. Bardi [2])

$$R(x) = 1 \qquad (x \in \partial\Omega).$$

Employing the methods of Lions [9] or Evans and Ishii [5], we obtain the following control theoretic representation. Define

$$\sigma_x^u \equiv \inf\{t > 0 \,|\, x(t) \in \{0\} \cup \partial\Omega\};$$

then

$$R(x) = \inf_{u \in \mathcal{U}} \left\{ \int_0^{\sigma_x^u} e^{-t}\, dt + e^{-\sigma_x^u} \chi_{\{x(\sigma_x^u) \in \partial\Omega\}} \right\}$$

for all $x \in \bar{\Omega}$.

In fact, we claim that

$$R(x) = \inf_{u \in \mathcal{U}} \{\Psi(\tau_x^u)\} \quad \text{for all } x \in \Omega. \tag{3.23}$$

To see this, note that if $x \in \Omega$, then (3.22) implies

$$\alpha \equiv 1 - R(x) > 0.$$

Choose $u \in \mathcal{U}$ such that

$$\int_0^{\sigma_x^u} e^{-t}\, dt + e^{-\sigma_x^u} \chi_{\{x(\sigma_x^u) \in \partial\Omega\}} \leqq R(x) + \frac{\alpha}{2}. \tag{3.24}$$

Suppose now that $x(\sigma_x^u) \in \partial\Omega$. Then (3.24) implies

$$1 = \int_0^{\sigma_x^u} e^{-t}\, dt + e^{-\sigma_x^u} \leqq R(x) + \frac{\alpha}{2},$$

a contradiction. Consequently, $x(\sigma_x^u) = 0$, and (3.23) follows. We conclude by noting that

$$S(x) = \Phi(R(x)) = T(x) \qquad (x \in \Omega). \qquad \square$$

4. Regularity.

Motivation. Let us now address the problem of the smoothness of solutions to the HJB equation in the case that f has the explicit form

$$f(x, u) = \sum_{k=1}^{m} u_k f_k(x), \tag{4.1}$$

where

$$f_k : \mathbb{R}^n \to \mathbb{R}^n \qquad (k = 1, \cdots, m)$$

are given smooth functions, and

$$u = (u_1, \cdots, u_m) \in U \equiv [-1, 1]^m.$$

In this case the corresponding HJB equation reads

$$\sum_{k=1}^{m} |f_k(x) \cdot DS| = 1 \quad \text{in } \Omega - \{0\}. \tag{4.2}$$

For heuristic purposes, let us for the moment suppose that S is a smooth solution of (4.2). Then (4.2) implies

$$|f_k \cdot DS| \leqq 1 \qquad (k = 1, \cdots, m) \tag{4.3}$$

in $\Omega - \{0\}$, so that the rate of change of S in the direction f_k is bounded ($k = 1, \cdots, m$). Thus, if

$$\text{span}\{f_k(x) \mid k = 1, \cdots, m\} = \mathbb{R}^n \tag{4.4}$$

for some point $x \in \Omega - \{0\}$, then we can derive from (4.2) an estimate on $|DS(x)|$. On the other hand, suppose (4.4) fails. Then we cannot generally hope to estimate $|DS(x)|$: we can deduce from (4.2) estimates only on the components of $DS(x)$ in the direction $f_1(x), \cdots, f_m(x)$.

Let us now however assume the *Hörmander condition* instead of (4.4):

$$\text{span}\{f_i(x), [f_j, f_k](x) \mid i, j, k = 1, \cdots, m\} = \mathbb{R}^n \tag{4.5}$$

for each $x \in \Omega - \{0\}$, where the pairing "[,]" denotes the usual Lie bracket. It is then well known from control theory that the minimum time function $T(x)$ is Hölder continuous with exponent $\frac{1}{2}$. In view of § 3 above it therefore seems reasonable to expect that our solution S of (4.2) will have this same regularity.

Below we show, more generally, that if (4.5) holds and S satisfies, say, (4.3) in the viscosity sense, then S is locally Hölder continuous with exponent $\frac{1}{2}$. This is a kind of "half-derivative" analogue of a theorem of Crandall and Lions [3] to the effect that if S is a viscosity solution of the partial differential equation

$$H(x, DS) = 0 \quad \text{in } \Omega \tag{4.6}$$

where

$$\lim_{|p| \to \infty} H(x, p) = +\infty,$$

then S is Lipschitz.

THEOREM 4.1. *Let C be a positive constant. Assume $S \in C(\Omega)$ satisfies*

$$|f_k \cdot DS| \leqq C \quad \text{in } \Omega \tag{4.7}$$

in the viscosity sense $(k=1,\cdots,m)$, *where the smooth vector fields* $\{f_k\}_{k=1}^m$ *satisfy condition* (4.5) *for each point* $x\in\Omega$. *Then*

$$S\in C^{0,1/2}_{\text{loc}}(\Omega).$$

Remark. More precisely, our hypothesis is that for each smooth function ϕ,

(4.8) If $S-\phi$ has a maximum at a point $x_0\in\Omega$, then $|f_k(x_0)\cdot D\phi(x_0)|\leqq C$ for $k=1,\cdots,m$.

Proof. (1) We first regularize our function S by setting for each $\varepsilon>0$

$$S^\varepsilon(x)=\sup_{y\in\Omega}\left[S(y)-\frac{1}{\varepsilon}|x-y|^2\right]\qquad(x\in\Omega). \tag{4.9}$$

This is the Yosida–Moreau sup-convolution, the importance of which for viscosity solution is discussed by Jensen, Lions, and Souganidis [7] (cf. also Lasry and Lions [8]). We easily check that

$$S^\varepsilon\in W^{1,\infty}_{\text{loc}}(\Omega).$$

Additionally, for each open set $\Omega'\subset\subset\Omega$, we have the estimate

$$|DS^\varepsilon|\leqq\frac{C(\Omega')}{\varepsilon^{1/2}}\quad\text{a.e. in }\Omega', \tag{4.10}$$

the constant $C(\Omega')$ depending only on S and dist $(\Omega',\partial\Omega)$.

(2) We claim now that for each sufficiently small $\varepsilon>0$ we have the estimate

$$|f_k(x)\cdot DS^\varepsilon(x)|\leqq C(\Omega')\quad\text{a.e. in }\Omega', \tag{4.11}$$

for some constant $C(\Omega')$ depending only on S and dist. $(\Omega',\partial\Omega)$. To see this, choose $\Omega'\subset\subset\Omega''\subset\subset\Omega$, and suppose that ϕ is a smooth function and that

$$S^\varepsilon-\phi\text{ has a local maximum at some point }x_0\in\Omega'. \tag{4.12}$$

We then deduce as in [7] that

$$S-\tilde\phi\text{ has a local maximum at }y_0,$$

for

$$\tilde\phi(y)\equiv\phi(y-y_0+x_0),$$

with y_0 selected so that

$$S^\varepsilon(x_0)=S(y_0)-\frac{1}{\varepsilon}|x_0-y_0|^2. \tag{4.13}$$

In view of (4.8) then

$$|f_k(y_0)\cdot D\tilde\phi(y_0)|=|f_k(y_0)\cdot D\phi(x_0)|\leqq C.$$

But now (4.12) implies

$$|x_0-y_0|\leqq C\varepsilon^{1/2},$$

C depending only on S and Ω''. Hence for each $k=1,\cdots,m$

$$\begin{aligned}|f_k(x_0)\cdot D\phi(x_0)|&\leqq C+|f_k(y_0)-f_k(x_0)||D\phi(x_0)|\\&\leqq C+C\varepsilon^{1/2}|D\phi(x_0)|\\&\leqq C,\end{aligned} \tag{4.14}$$

since (4.10) and (4.12) imply

$$|D\phi(x_0)| \leqq \frac{C}{\varepsilon^{1/2}}.$$

The constant C in (4.14) depends only on S and dist. $(\Omega', \partial\Omega)$, and so (4.11) is proved.

(3) Now fix any index $k \in \{1, \cdots, m\}$ and any point $x \in \Omega$, and consider the ordinary differential equation

$$\dot{x}(s) = f_k(x(s)), \quad x(0) = x \quad (s \in \mathbb{R}, x \in \Omega). \tag{4.15}$$

For later notational convenience, let us write

$$x(s) \equiv X^k(s)x \qquad (s \in \mathbb{R}, x \in \Omega) \tag{4.16}$$

to display the dependence on the vector field f_k and the initial point x.

(4) We now claim that if $z \in \Omega'$, then

$$|S^\varepsilon(z) - S^\varepsilon(X^k(t)z)| \leqq C|t| \qquad (k = 1, \cdots, m) \tag{4.17}$$

for some constant C and all sufficiently small $|t|$, $\varepsilon > 0$. To see this, note that we may as well assume $f_k(z) \neq 0$, since otherwise (4.17) is obvious. Now since S^ε is Lipschitz, Rademacher's Theorem implies that $DS^\varepsilon(y)$ exists for almost every $y \in \Omega$. Consequently by the Coarea Formula, we can find a sequence of points

$$z_l \to z,$$

and a sufficiently small time $|t| > 0$ such that

$$DS^\varepsilon \text{ exists and (4.11) holds at } x = X^k(s)z_l \text{ for a.e. } -|t| < s < |t|, \tag{4.18}$$

the a.e. (almost every) taken with respect to one-dimensional Lebesgue measure. Now for each l the mapping

$$s \mapsto S^\varepsilon(X^k(s)z_l)$$

is Lipschitz, with

$$\frac{d}{ds} S^\varepsilon(X^k(s)z_l) = DS^\varepsilon(X^k(s)z_l) \cdot f_k(X^k(s)z_l)$$

for a.e. $-|t| < s < |t|$, according to (4.15) and (4.18). Thus (4.18) and (4.11) imply

$$|S^\varepsilon(z_l) - S^\varepsilon(X^k(t)z_l)| \leqq C|t|.$$

Let l approach infinity to obtain (4.17).

(5) Now fix any point $x_0 \in \Omega'$. Because of the Hörmander condition (4.5) we can select $0 \leqq d \leqq 2m$ and indices $k_j \in \{1, \cdots, m\}$ $(j = 1, \cdots, d)$ such that the vectors

$$f_{k_1}(x_0), \cdots, f_{k_l}(x_0), \qquad [f_{k_{l+1}}, f_{k_{l+2}}](x_0), \cdots, [f_{k_{d-1}}, f_{k_d}](x_0)$$

are a basis of $\mathbb{R}^n$. On relabeling, if necessary, we may as well assume that

$$f_1(x_0), \cdots, f_l(x_0), \qquad [f_{a(l+1)}, f_{b(l+1)}](x_0), \cdots, [f_{a(n)}, f_{b(n)}](x_0)$$

form a basis, where $1 \leqq l \leqq n$ and

$$a, b : \{l+1, \cdots, n\} \to \{1, \cdots, m\} \tag{4.19}$$

are appropriate functions.

(4.20) By continuity the vectors

$$f_1(y), \cdots, f_l(y), \qquad [f_{a(l+1)}, f_{b(l+1)}](y), \cdots, [f_{a(n)}, f_{b(n)}](y)$$

also form a basis of $\mathbb{R}^n$, for each point y sufficiently close to x_0.

(6) Following Strichartz [13], let us now extend the notation introduced in (4.15), (4.16) by writing

$$X^{k,l}(s)x \equiv \begin{cases} X^l(-s^{1/2})X^k(-s^{1/2})X^l(s^{1/2})X^k(s^{1/2})x & \text{if } s>0, \\ x \quad \text{if } s=0, \\ X^k(-|s|^{1/2})X^l(-|s|^{1/2})X^k(|s|^{1/2})X^l(|s|^{1/2})x & \text{if } s<0. \end{cases} \tag{4.21}$$

A lengthy but well-known calculation reveals that

$$\frac{d}{ds} X^{k,l}(s)x\big|_{s=0} = [f_k, f_l](x). \tag{4.22}$$

Given now $t=(t_1, \cdots, t_n) \in \mathbb{R}^n$, set

$$y = \Phi(t) = X^{(a)n,b(n)}(t_n) \cdots X^{a(l+1),b(l+1)}(t_{l+1})X^l(t_l) \cdots X^2(t_2)X^1(t_1)x_0, \tag{4.23}$$

the mappings $a(\cdot)$, $b(\cdot)$ as in (4.19). Then

$$\Phi : \mathbb{R}^n \to \mathbb{R}^n$$

is C^1, and

$$\Phi(0) = x_0.$$

Additionally, using (4.20) and (4.22), we compute

$$\det D\Phi(0) \neq 0.$$

Invoking the Inverse Function Theorem, we deduce that Φ is a C^1 diffeomorphism of some neighborhood U of $t=0$ onto the open ball $U(x_0, r_0)$ for some $r_0>0$. Furthermore, there exists a constant C such that

$$|t| \leqq C|\Phi(t) - x_0| \qquad (t \in U).$$

(7) Now choose any $y \in U(x_0, r_0)$ and set

$$r = |y - x_0|. \tag{4.24}$$

By the above there exists a unique point $t \in U$ with

$$y = \Phi(t)$$

and

$$|t| \leqq Cr. \tag{4.25}$$

We inductively set

$$\begin{aligned} y_0 &= x_0 \\ y_1 &= X^1(t_1)y_0 \\ &\vdots \\ y_l &= X^l(t_l)y_{l-1}, \end{aligned} \tag{4.26}$$

$$
\begin{aligned}
y_{l+1} &= X^{a(l+1),b(l+1)}(t_{l+1})y_l \\
&\vdots \\
y_n &= X^{a(n),b(n)}(t_n)y_{n-1} = y.
\end{aligned} \tag{4.27}
$$

Then for $j = 1, \cdots, l$,

$$
\begin{aligned}
|S^\varepsilon(y_j) - S^\varepsilon(y_{j-1})| &\leqq C|t_j| \quad \text{by (4.17)} \\
&\leqq C|t|.
\end{aligned} \tag{4.28}
$$

Now assume $l+1 \leqq j \leqq n$. Then assuming for simplicity that $t_j > 0$, let us write

$$
\begin{aligned}
y_j^0 &= X^{a(t_j)}(-t_j^{1/2})X^{b(t_j)}(-t_j^{1/2})X^{a(t_j)}(t_j^{1/2})X^{b(t_j)}(t_j^{1/2})y_{j-1} = y_j, \\
y_j^1 &\equiv X^{b(t_j)}(-t_j^{1/2})X^{a(t_j)}(t_j^{1/2})X^{b(t_j)}(t_j^{1/2})y_{j-1}, \\
y_j^2 &\equiv X^{a(t_j)}(t_j^{1/2})X^{b(t_j)}(t_j^{1/2})y_{j-1}, \\
y_j^3 &\equiv X^{b(t_j)}(t_j^{1/2})y_{j-1}, \qquad y_j^4 \equiv y_{j-1}.
\end{aligned}
$$

In view of (4.17) again

$$
\begin{aligned}
|S^\varepsilon(y_j^s) - S^\varepsilon(y_{j-1}^{s+1})| &\leqq C|t_j|^{1/2} \\
&\leqq C|t|^{1/2} \quad (s = 0, 1, 2, 3).
\end{aligned}
$$

Thus

$$
|S^\varepsilon(y_j) - S^\varepsilon(y_{j-1})| \leqq C|t|^{1/2} \tag{4.29}
$$

for $j = l+1, \cdots, n$. Combining at last (4.28) and (4.29) we find

$$
\begin{aligned}
|S^\varepsilon(y) - S^\varepsilon(x_0)| &\leqq C(|t| + |t|^{1/2}) \\
&\leqq C|y - x_0|^{1/2} \quad \text{by (4.24), (4.25).}
\end{aligned} \tag{4.30}
$$

(8) Consequently S^ε is Hölder continuous with exponent $\frac{1}{2}$ at the point x_0. Furthermore, an analysis of the proof shows that we can select the constant C in (4.30) to hold also if x_0 is replaced by any nearby point x. Consequently, S^ε is Hölder continuous with exponent $\frac{1}{2}$ in some neighborhood of x_0, and so by compactness $S^\varepsilon \in C^{0,1/2}_{\text{loc}}(\Omega)$. Since the behavior of S^ε enters the proof only via inequality (4.17), where the constant C is independent of ε, we have

$$
\sup_{\varepsilon > 0} \|S^\varepsilon\|_{C^{0,1/2}(\Omega')} < \infty
$$

for each $\Omega' \subset\subset \Omega$. Since

$$
S^\varepsilon \to S
$$

as $\varepsilon \searrow 0$, we deduce that

$$
S \in C^{0,1/2}_{\text{loc}}(\Omega),
$$

as required. □

Remark. Our proof presumably extends to show that S is locally Hölder continuous with exponent k^{-1}, provided we suppose instead of (4.5) that the k-fold interated Lie brackets of the vector fields $\{f_j(x)\}_{j=1}^m$ span $\mathbb{R}^n$ at each point $x \in \Omega$ $(k = 3, 4, \cdots)$. We have not, however, attempted to work out the relevant details. □
