SIAM J. CONTROL AND OPTIMIZATION
Vol. 28, No. 1, pp. 1-33, January 1990

INVITED EXPOSITORY ARTICLE

This paper is another in the continuing series of expository papers that were invited by the editors. These papers undergo the same refereeing procedure as do research papers submitted directly by the authors, although the refereeing guidelines are modified to suit the largely expository nature of the paper. Due to the rapid recent technical development of a number of areas in control and optimization, many of the seminal papers are quite specialized and are readily accessible to a limited group of experts only. Moreover, the original motivations and practical importance of the ideas are sometimes difficult to find in the mathematical development. The purpose of these papers is to bring the ideas, techniques, and applications of a few selected areas to the attention of a wider audience, so that their basic importance can be more easily and widely appreciated.

CONTROLLABILITY OF NONLINEAR DISCRETE-TIME SYSTEMS: A LIE-ALGEBRAIC APPROACH*

BRONISLAW JAKUBCZYK† AND EDUARDO D. SONTAG‡

Abstract. This paper presents a geometric study of controllability for discrete-time nonlinear systems. Various accessibility properties are characterized in terms of Lie algebras of vector fields. Some of the results obtained are parallel to analogous ones in continuous-time, but in many respects the theory is substantially different and many new phenomena appear.

Key words. controllability, Lie algebras of vector fields, nonlinear systems, discrete time

AMS(MOS) subject classifications. 93C10, 93C55, 93B05

1. Introduction. This paper deals with questions of controllability for discrete-time nonlinear systems

$$x(t+1)=f(x(t), u(t)) \tag{1}$$

for which the control variables u and state variables x take continuous values. Systems of the type (1) but with discrete-valued states and controls have long been studied in automata and sequential machine theory, but the continuous case has only recently become the subject of serious investigation as far as controllability properties are concerned. Our objective here is to survey a number of known results and to present new characterizations involving geometric ideas.

The study of controllability questions for the better known continuous-time analogue of (1), the differential equation

$$\dot{x}(t)=\phi(x(t), u(t)), \tag{2}$$

has been the subject of a concentrated research effort, as documented, for instance, in the survey papers [2] and [7], the text [8], and the exposition [35]. It is known, for instance, that the set *accessible* from any given state x^0, that is to say, the set of points reachable from x^0, contains a smooth submanifold of the state space and is in turn contained in a submanifold of the same dimension. Thus, for instance, the cusp in Fig. 1 cannot be an accessible set for any system of the type (2). More interestingly perhaps, this dimension can be computed from the rank of certain matrices formed

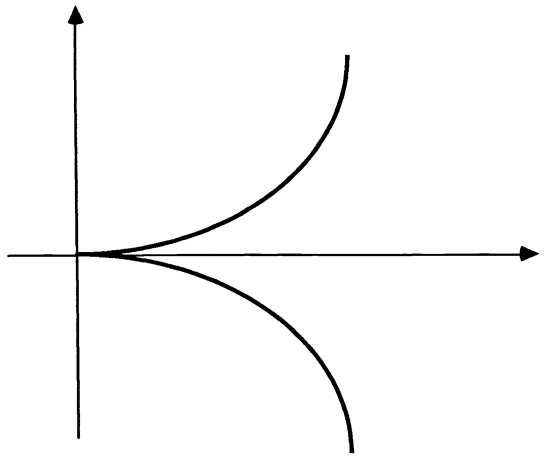

FIG. 1. *Impossible reachable set.*

by taking iterated Jacobians of the various vector fields $\phi(\cdot, u)$ evaluated at the state x^0. These Lie-theoretic characterizations are "direct" in that they do not involve integration of the differential equation, and they are closely related to more classical geometric material related to Frobenious' theorem.

(Certain technical hypotheses are of course required for the validity of the above and other assertions that we will make here; for purposes of providing an informal introduction we shall not make them precise yet; however, as a general rule, real-analyticity of f and ϕ and the assumption that states and controls take values in Euclidean space $\mathbb{R}^n$ and $\mathbb{R}^m$, respectively, are more than sufficient.)

Discrete control systems (1) are of interest for various reasons. Of course in many areas difference equation models are more natural than differential equations, but our interest has been motivated more by the problem of modeling physical systems under digital control via *sampling*. Recall that sampling is the process under which the state of a continuous time system is measured at discrete instants, and control actions are taken also at discrete instants. Figure 2 illustrates a typical approach to computer control. A discrete-time algorithm observes the state (or more generally, the outputs)

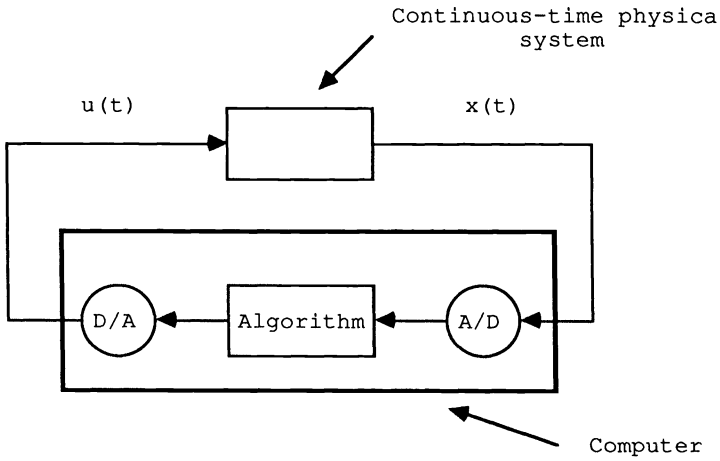

FIG. 2. *Digital control configuration.*

of a physical system, through an analogue-to-digital converter. Typically this observation is made at periodic time instants $\delta, 2\delta, \cdots$. On the basis of this observation the controller decides upon a control value u to be applied during the next period of length δ. This value is converted to analogue form and is held constant during that next period. So the controls applied to the physical system are restricted to be δ-sampled controls, constant on intervals $[k\delta, (k+1)\delta]$ (Fig. 3). The main point here is that, as far as the control algorithm is concerned, the physical system is a discrete-time system described by an equation of type (1), where $f(x, u)$ is the solution of the differential equation (2) at the end of an interval of length δ assuming that the initial state was x and control was held constantly equal to u.

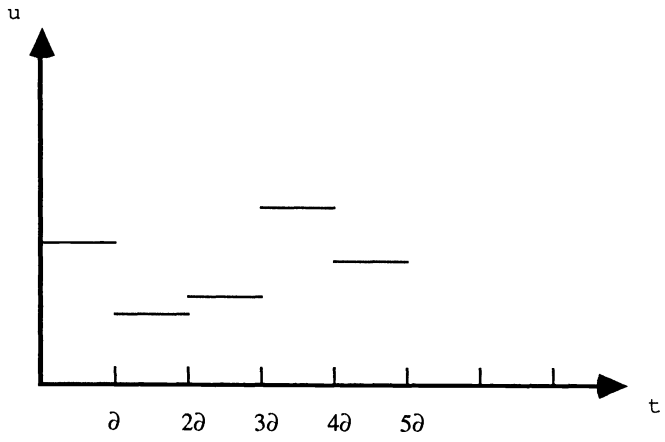

FIG. 3. *∂-sampled control.*

This description of sampling is oversimplified in many respects. For instance, analogue/digital conversion involves a quantization of the values of x into a discrete number of steps. Constant controls values may be smoothed out by a filter before being applied to the system. Multirate strategies, in which the sampling period is varied in a fixed set, may also be used. And the time involved in the algorithm actually computing the value of the control is sometimes nontrivial and must be included in the model as well. But even without these complications, the study of discrete-time control systems appears naturally.

Another area in which results from discrete-time nonlinear control theory are of importance is in the study of Markovian systems (1). There, the variables $u(t)$ are random, and together with the transitions f they characterize the probabilistic behavior of the process $x(\cdot)$. Accessibility conditions play a central role in establishing the existence and smoothness properties of equilibrium distributions; see for instance [15] and [16].

Yet another source of discrete-time control systems, related to but different from sampling, arises when numerically approximating the solution of a system (2). For instance, a Euler approximation with stepsize h gives the recursion

$$x(t+1) = x(t) + h\phi(x(t), u(t)).$$

These motivations notwithstanding, discrete-time systems have been studied much less than their continuous counterparts, and it has long been felt that their properties

may diverge considerably from those of the latter. Regarding control and observation problems, the paper [26] and the monograph [27] considered various aspects of discrete-time systems defined by polynomial evolution equations. However, the general theory remained, until recently, much weaker than that possible in the more classical continuous time case, for which a large body of knowledge, as described above, is now available.

One of the main difficulties in the general discrete-time case is due to the possible noninvertibility of the one-step transition maps

$$x \mapsto f(x, u),$$

which means that semigroups tend to appear where groups would appear in the continuous case, so less algebraic structure is available. Accessible sets with singularities such as the curve in Fig. 1 can then easily appear.

An important observation, however, is that—due to the time-reversibility of finite-dimensional differential equations—for those discrete-time systems that arise through sampling these transition maps, obtained by integrating (2) over an interval of length δ with control $\equiv u$, *are* invertible. More precisely, each of these maps is a diffeomorphism (possibly not everywhere defined) of the state space. This is analogous to the situation in classical dynamical system theory, where one studies time-one diffeomorphisms and Poincaré maps associated to differential equations. Invertible discrete-time systems are often also obtained in numerical schemes for discretizing continuous-time models, if mesh sizes are chosen small enough.

In this paper we shall restrict our attention to *invertible* systems, for which the maps $f(\cdot, u)$ are assumed to be diffeomorphisms. For such systems we derive several characterizations of accessibility and we study the geometric structure of accessible sets. As an example, we provide a theorem that shows that, at least from equilibrium states, a picture such as that in Fig. 1 can never hold for these sets. (Precise statements of results are given later.) As with continuous-time systems, we also give Lie-theoretic characterizations of accessibility. These characterizations have the advantage that they do not require the computation of arbitrary iterates of the transition map, save for those iterates corresponding to just one value of the control value set.

The basic fact that underlies our approach is that one has an analogue for difference equations of the infinitesimal information obtained in the continuous-time case by taking derivatives with respect to time. One uses here derivations *with respect to control values.* This idea can be traced back to the paper [9], the first to deal in detail with general invertible discrete nonlinear control systems, although in the context of realization theory rather than controllability problems. For the latter, and for the source of the closest related material to that presented here, the credit goes to Fliess and Normand-Cyrot ([3], [25]), who originally proposed the definition in this manner of Lie algebras associated to discrete-time systems. This is analogous to associating a Lie algebra action to any given Lie group action. Other work along those lines was carried out in [11], [32], [17], [29], and related papers. A particularly important line of work is that pursued in [18], [20], [22], as well as by other authors (see, e.g., [5]), who have shown how to frame a large number of problems of control design (decoupling, noninteracting control, immersion, and so forth) in this geometric formalism; we shall not deal with such questions in this paper, however. For other recent references on geometric discrete-time control, see, for instance, the following papers as well as references given there: [1], [6], [10], [12], [14], [19], [24], [28].

We close this introduction with the precise statement of a simplified version of one of our main results to illustrate the nature of our contribution. Assume that the

system (1) is analytic, in the sense that f is analytic, and invertible, meaning that each of the maps

$$f_u = f(\cdot, u): \mathbb{R}^n \to \mathbb{R}^n$$

is a global diffeomorphism of $\mathbb{R}^n$ for each control value u; for simplicity assume further that the control values are arbitrary real numbers, $u \in \mathbb{U} := \mathbb{R}$.

Denote by f_0^k the kth power of f_0 with respect to composition, and define the following vector fields depending on u:

$$X_u^+(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_u^{-1} \circ f_{u+v}(x),$$

$$X_u^-(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_u \circ f_{u+v}^{-1}(x),$$

and more generally for each integer k and for $\sigma = \pm$, $f_u^+ = f_u$, $f_u^- = f_u^{-1}$,

$$(\mathrm{Ad}_0^k X_u^\sigma)(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_0^{-k} \circ f_u^{-\sigma} \circ f_{u+v}^{\sigma} \circ f_0^k(x),$$

where $-\sigma = -$, $+$ if $\sigma = +$, $-$, respectively. These vector fields were introduced in [11], [17], [20], and [21].

In analogy with standard continuous time notions of accessibility, we call the system (1) *forward accessible* from the state $x^0 \in \mathbb{R}^n$ if its attainable set from x^0 has a nonempty interior. Similarly, we say that (1) is *backward accessible* from x^0 it its backward attainable set from x^0, the set of points controllable to x^0, has a nonempty interior. Finally, we say that the system is *forward-backward accessible* or *transitive* from x^0 if its orbit through this state (the smallest positive and negative-invariant set containing x^0) has a nonempty interior. The orbit turns out to be a submanifold, so forward-backward accessibility is equivalent to this orbit being an open subset of the state space.

By an equilibrium state x^0 we mean one that satisfies $f(x^0, 0) = 0$. Part (c) of the following theorem had already been stated in [11] (see also Theorem 7 in [20]) but parts (a) and (b) are totally new. The theorem is a specialization to analytic systems and equilibrium states of much more general results to be discussed later.

THEOREM 1. *The following statements hold for any analytic system* (1) *and equilibrium state* x^0:

(a) *System* (1) *is forward accessible from* x^0 *if and only if*

$$\dim \mathrm{Lie}\,\{\mathrm{Ad}_0^k X_u^+ | k \geqq 0,\ u \in \mathbb{U}\}(x^0) = n.$$

(b) *System* (1) *is backward accessible from* x^0 *if and only if*

$$\dim \mathrm{Lie}\,\{\mathrm{Ad}_0^k X_u^- | k \leqq 0,\ u \in \mathbb{U}\}(x^0) = n.$$

(c) *System* (1) *is forward-backward accessible from* x^0 *if and only if*

$$\dim \mathrm{Lie}\,\{\mathrm{Ad}_0^k X_u^\sigma | k \in \mathbb{Z},\ u \in \mathbb{U},\ \sigma = \pm\}(x^0) = n.$$

It is an easy corollary of this theorem that all three conditions (forward, backward, and forward-backward accessibility) coincide for analytic systems and equilibrium initial states. This gives a generalization of the well-known Chow Theorem in the continuous-time theory. More generally, the dimension of the corresponding (forward, etc.) accessible sets are given by the dimensions of the above subspaces, from which it follows that the (forward) accessible set is an open subset of a manifold (the orbit);

therefore, the cusp in Fig. 1 cannot be a forward accessible set. Later we give an example for which this cusp appears as the union of three orbits, corresponding to the origin and each of the two smooth branches.

Note that the conditions in Theorem 1 involve iterated compositions of transitions corresponding to only *one* control—arbitrarily taken as the zero control. The "naive" conditions that one can give based on the implicit function theorem for the above accessibility properties, reviewed below, would involve compositions of all transition mappings, as well as, for backward and forward-backward accessibility of their (possibly hard to compute) inverses. Moreover, in the particular case when the system has, for instance, the form

$$x(t+1) = x(t) + g(x(t), u(t))$$

with $g(x, 0) \equiv 0$, the "Ad's" become all the identity and no compositions at all need be computed.

In this paper, we present an exposition, including complete proofs, of the known transitivity (positive and negative-time accessibility) facts, as well as of new results for the substantially different (positive-time) forward accessibility problem. We also clarify the relationship between a large number of forward and/or backward controllability notions. Another topic studied is the role played by various continuous time systems derived mathematically from the original discrete time model, and we show how to view the more classical results for continuous-time systems as a particular case (essentially when "time" is thought of as a control) of our theory. Finally, we provide an application of our accessibility characterizations to the sampled control of continuous systems; the resulting explicit eigenvalue condition, which generalizes the classical (linear system) sampling theorem, illustrates the power of the techniques developed. An illustrative example is included towards the end of the paper, which ends with a brief description of the alternative approach due to Normand-Cyrot.

2. Basic definitions. We start by introducing basic notation and definitions. As stated previously, time takes integer values, $t \in \mathbb{Z}$. We introduce the following notations for the effect of shift operators:

$$x^+(t) = x(t+1) \quad \text{and} \quad x^-(t) = x(t-1).$$

In this way we can write equation (1) in the more compact form, with $f^+ = f$

$$x^+ = f^+(x, u), \qquad x(t) \in \mathbb{X},\ u(t) \in \mathbb{U}.$$

The state set $\mathbb{X}$ is a connected differentiable manifold of dimension n. To simplify the notation we first assume that the control is scalar, meaning that $\mathbb{U}$ is a subset of $\mathbb{R}$ contained in the closure of its interior,

$$\mathbb{U} \subset \operatorname{clos} \operatorname{int} \mathbb{U},$$

such that $0 \in \mathbb{U}$. Later we show how to generalize everything to the case where $\mathbb{U}$ is a subset of a more general manifold.

The system is *of class* C^k if the manifold $\mathbb{X}$ is of class C^k, Hausdorff, second countable, and the function $f: \mathbb{X} \times \mathbb{U} \to \mathbb{X}$ is of class C^k, meaning, to be precise, that there exists a C^k extension of f to an open neighborhood of $\mathbb{X} \times \mathbb{U}$ in $\mathbb{X} \times \mathbb{R}$. When $k = \infty$ we say simply *smooth*; for $k = \omega$, *analytic*.

Associated to each such system there is a family of maps

$$f_u = f(\cdot, u): \mathbb{X} \to \mathbb{X}, \qquad u \in \mathbb{U}.$$

DEFINITION 2.1. The system (1) is *invertible* if for each u in an open neighborhood of $\mathbb{U}$ the map f_u is a global diffeomorphism of $\mathbb{X}$.

Invertibility can be weakened in various ways. For instance, many results can be obtained under the assumption of *local invertibility at x*, meaning that for each $u \in \mathbb{U}$ f_u is a local diffeomorphism at x, i.e., rank $(\partial f_u/\partial x)(x) = n$, or the assumption that this holds for every state, *local invertibility* of the system. The paper [10] shows how a condition called *submersibility* is in fact enough to define many of the concepts that we use in this paper.

To any invertible system one can associate an *inverse* or *reversed-time* system with equations

$$x^- = f^-(x, u), \tag{3}$$

where $f^-(x, u) = f_u^{-1}(x)$. By the implicit mapping theorem, this is again of class C^k, and its inverse is the original system.

Unless otherwise stated, every system appearing in this paper will be assumed to be invertible. Furthermore, until § 6, *controls are scalar.*

The maps f_u and their inverses f_u^{-1} can be considered as "one step forward maps" (respectively, "one step backward maps"). If we apply a sequence of controls $u_1, \cdots, u_k$ then we obtain the composition of these maps denoted by

$$f_{u_k \cdots u_1} = f_{u_k} \circ \cdots \circ f_{u_1}. \tag{4}$$

Allowing backward as well as forward steps we obtain a larger family of maps

$$f_{u_k \cdots u_1}^{\varepsilon_k \cdots \varepsilon_1} = f_{u_k}^{\varepsilon_k} \circ \cdots \circ f_{u_1}^{\varepsilon_1}, \tag{5}$$

where each of $\varepsilon_1, \cdots, \varepsilon_k$ takes a value ± 1.

We shall denote by $A_k^+(x)$ the set of points attainable from x in k forward steps, and by $A^+(x)$ the set of points attainable from x in any nonnegative number of forward steps. Replacing forward steps by backward steps we obtain other sets, $A_k^-(x)$ and $A^-(x)$, which consist of points controllable to x in k steps, and controllable to x in any nonnegative number of steps, respectively. Finally, the set of points attainable from x in any number of positive and negative steps is called the *orbit* of x and is denoted by $A(x)$.

DEFINITION 2.2. The system (1) is *forward* (*backward*) *accessible from x* if its attainable set $A^+(x)$ (respectively, $A^-(x)$) has a nonempty interior. It is called *transitive from x* (*or forward-backward accessible from x*) if its orbit $A(x)$ has a nonempty interior (and so it is necessarily open).

Finally, the system is *forward* (*backward*) *accessible* if it is forward (backward) accessible from any $x \in \mathbb{X}$, and it is called *transitive* if it is transitive from any $x \in \mathbb{X}$.

Observe that there is a straightforward criterion for accessibility of the discrete time system, based on the rank of the following map. For each fixed state x and integer k define

$$\psi_{k,x}(\mathbf{u}) := f_{u_k \cdots u_1}(x),$$

where $\mathbf{u} = (u_1, \cdots, u_k)$ takes values in the kth Cartesian product $\mathbb{U}^k$. Notice that the attainable set $A_k^+(x)$ is by definition equal to the image of this map. The following proposition says that this set is of nonempty interior if and only if the linearization along some trajectory starting from x is controllable.

PROPOSITION 2.3. *Let* (1) *be smooth. For any fixed* x *and* k, *the interior of the attainable set* $A_k^+(x)$ *is nonempty if and only if*

$$\sup\left\{\operatorname{rank}\frac{\partial}{\partial \mathbf{u}}\psi_{k,x}(u), \mathbf{u}\in \mathbb{U}^k\right\} = n$$

and thus

$$\sup\left\{\operatorname{rank}\frac{\partial}{\partial \mathbf{u}}\psi_{k,x}(u), \mathbf{u}\in \mathbb{U}^k, k\geqq 1\right\} = n$$

is necessary and sufficient for forward accessibility of system (1) *from* x.

Proof. If there is a point $\mathbf{u}$ at which the rank of the map $\psi_{k,x}$ is equal to n, we may assume without loss of generality that $\mathbf{u}$ is in the interior of $\mathbb{U}$, because of the hypothesis that $\mathbb{U}\subset \operatorname{clos}\operatorname{int}\mathbb{U}$. It then follows from the implicit function theorem that the image of this map has a nonempty interior. Thus, the attainable set $A_k^+(x)$ has a nonempty interior. (Only that the system is of class C^1 is used for this implication.)

Conversely, if the rank of the map $\psi_{k,x}$ is less than n at each $u\in\mathbb{U}$, then every element of $A_k^+(x)$ is a critical value of $\psi_{k,x}$ as a map defined on an open subset of $\mathbb{R}^k$. It follows by Sard's theorem that the image of $\mathbb{U}$ under this map is of empty interior and is of measure zero under the measure induced by any Riemann metric on $\mathbb{X}$ (the Euclidean metric in $\mathbb{R}^n$). Therefore, the attainable set $A_k^+(x)$ must have an empty interior and it is even of measure zero.

The second statement follows from the first because a countable union of sets of measure zero again has measure zero. □

REMARK 2.4. Since the orbit $A(x)$ is the (countable) union of the images of the maps (5) we can use an analogous argument to give a criterion for transitivity from x, using the maps (5) rather than (4) to define a family of maps playing the role of the $\psi_{k,x}$'s.

The above proposition and remark might appear to give satisfactory criteria for forward accessibility and transitivity. Unfortunately, this is not the case. Although for simple systems they may be used to decide whether a given system is forward accessible or not, for more complicated sytems explicitly computing the functions $\psi_{k,x}$ may be highly nontrivial, since composition is hard to deal with computationally. As an example, consider for instance the problem of obtaining a general formula for the nth composition of the quadratic function $g(x)=ax^2+bx+c$ with itself or that of computing the function $\psi_{k,x}$ if $f(x,u)=g(x)+xu$. The problem becomes even more serious in the case of deciding the transitivity of the system, as this requires also finding the inverse maps f_u^{-1} needed for computing the composed maps (5). One approach here is to develop a calculus for these compositions, as in the work of Monaco and Normand-Cyrot; see the last section. But in any case, even for classes such as that of bilinear systems, Proposition 2.3 doesn't seem to provide much useful information regarding accessibility properties.

Also, from a purely theoretical point of view, Proposition 2.3 is of little interest. This is because it gives too limited an insight into the geometry of our systems and it provides an even more limited tool for their study. The maps appearing in the criteria do not have much algebraic and geometric structure.

The main aim of the next section is to introduce a sort of "infinitesimal description" of the discrete-time system. This is done by introducing certain vector fields associated to it. By doing so we immediately get a powerful tool and a rich algebraic and geometric structure based on the Lie product of vector fields. In particular, the accessibility properties of the system can be studied using natural Lie algebras of vector fields

associated to the system. The idea of introducing vector fields corresponding to infinitesimal perturbations of control values is a natural generalization of the concept of actions of Lie groups, and it was originally proposed in the context of nonlinear control in [3]. These vector fields also find natural applications in the study of controllability properties and the feedback linearizability of sampled systems ([29], [12]).

3. Vector fields associated to the system. We associate the following four families of vector fields to our discrete time system (1), one vector field for each $u \in \mathbb{U}$:

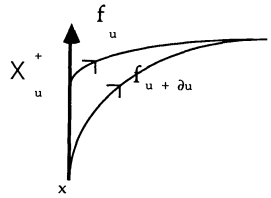
$$X_u^+(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_u^{-1} \circ f_{u+v}(x),$$

$$X_u^-(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_u \circ f_{u+v}^{-1}(x),$$

$$Y_u^+(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_{u+v}^{-1} \circ f_u(x),$$

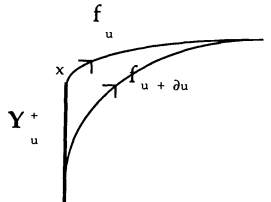
$$Y_u^-(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_{u+v} \circ f_u^{-1}(x).$$

The partial derivatives here are well defined in the interior of $\mathbb{U}$; therefore, they are also uniquely defined on the boundary of $\mathbb{U}$ because of continuity. The geometric



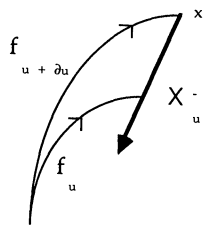
X_u^+

FIG. 4 (a)



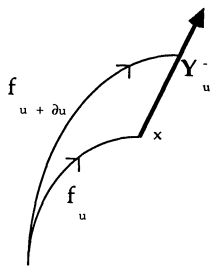
Y_u^+

FIG. 4 (c)



X_u^-

FIG. 4 (b)



Y_u^-

FIG. 4 (d)

meaning of these vector fields is illustrated by Fig. 4, and the interrelations between them are explained in the next proposition. These vector fields were also introduced in [17], [20], and [21], using somewhat different terminology. The last section will explain the relation between the different notations.

The special case in which the function f happens to correspond to the flow of a vector field Z, that is, $f(x, u) = \exp(uZ)$, will be important later when discussing continuous time systems within our framework. In that case all of the above vector fields are in fact independent of u, and they provide the same information about the system. This is because by the semigroup property of flows it holds that $f_{u+v} = f_u \circ f_v = f_v \circ f_u$, so that $X_u^+ = -X_u^- = Z = -Y_u^+ = Y_u^-$. These equalities help us to understand why the continuous time theory is considerably simpler than the discrete one.

Note that applying these definitions to the inverse system (3) instead of system (1) gives the same vector fields except that the pluses are changed for minuses and vice versa.

Given a vector field Y and a control value u, we can define another vector field from Y by applying a change of coordinates given by the diffeomorphism f_u,

$$(\mathrm{Ad}_u\, Y)(x) = (\mathrm{d}f_u(x))^{-1} Y(f_u(x)).$$

Here $\mathrm{d}f_u$ stands for the differential of f_u with respect to x. Using the diffeomorphisms (4), we may also define

$$(\mathrm{Ad}_{u_k \cdots u_1}\, Y)(x) = (\mathrm{d}f_{u_k \cdots u_1}(x))^{-1} Y(f_{u_k \cdots u_1}(x)),$$

and, applying the even more general family of diffeomorphisms (5),

$$(\mathrm{Ad}_{u_k \cdots u_1}^{\varepsilon_k \cdots \varepsilon_1}\, Y)(x) = (\mathrm{d}f_{u_k \cdots u_1}^{\varepsilon_k \cdots \varepsilon_1}(x))^{-1} Y(f_{u_k \cdots u_1}^{\varepsilon_k \cdots \varepsilon_1}(x)). \tag{6}$$

Clearly, the operators "Ad" so defined are linear operators acting on vector fields Y, and we have that

$$\mathrm{Ad}_{u_k \cdots u_1}^{\varepsilon_k \cdots \varepsilon_1}\, Y = \mathrm{Ad}_{u_1}^{\varepsilon_1} \cdots \mathrm{Ad}_{u_k}^{\varepsilon_k}\, Y. \tag{7}$$

(Note the reversal of indices.) We will use the abbreviated notation $\mathrm{Ad}_0^k\, Y$ for $\mathrm{Ad}_{0 \cdots 0}\, Y$ with $u = 0$ repeated k-times, if $k > 0$, and for $\mathrm{Ad}_{0 \cdots 0}^{-1 \cdots -1}\, Y$, if $k < 0$. Additionally, $\mathrm{Ad}_0^0\, Y = Y$. With this notation we have that

$$(\mathrm{Ad}_0^k\, X_u^+)(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_0^{-k} \circ f_u^{-1} \circ f_{u+v} \circ f_0^k(x)$$

(see Fig. 5) and, more generally,

$$(\mathrm{Ad}_{u_k \cdots u_1} X_{u_0}^+)(x) = \frac{\partial}{\partial v}\bigg|_{v=0} f_{u_k \cdots u_1}^{-1} \circ f_{u_0}^{-1} \circ f_{u_0+v} \circ f_{u_k \cdots u_1}(x).$$

Since our system is assumed to be invertible, we could apply all definitions to the inverse system (3) instead of (1). Then all the pluses in the superscripts change for minuses and Ad_u changes for Ad_u^{-1}, and vice versa. Therefore, we will have the following fact, which we shall use repeatedly.

REVERSION PRINCIPLE. *Any general property of systems of the type* (1) *that can be expressed in terms of the above defined vector fields is preserved if we change the pluses in the superscripts for the minuses and each* Ad_u *for* Ad_u^{-1}, *and vice versa.*

Remark 3.1. Some of the above defined vector fields can be equivalently defined as follows:

$$X_u^+(x) = (\mathrm{d}f_u(x))^{-1} \frac{\partial}{\partial u} f_u(x),$$

$$(\mathrm{Ad}_{u_k \cdots u_1} X_{u_0}^+)(x) = (\mathrm{d}f_{u_k \cdots u_1}(x))^{-1} X_{u_0}^+(f_{u_k \cdots u_1}(x)).$$

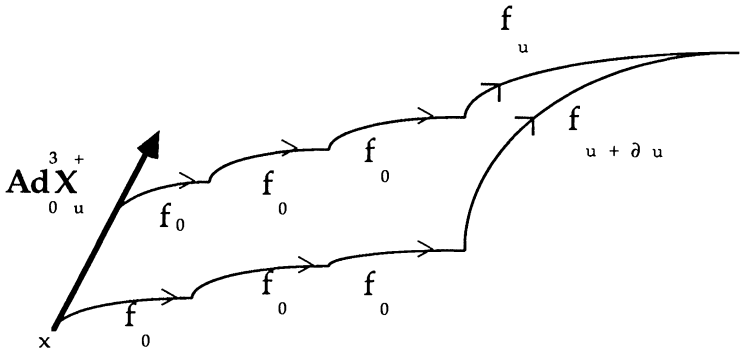


FIG. 5. $\mathrm{Ad}_0^3 X_u^+$.

Since the inverses f_u^{-1} do not appear, the right-hand sides now make sense for *locally* invertible systems. Those of our results that can be stated exclusively in terms of the above vector fields will also hold for locally invertible systems. Furthermore, criteria stated in their terms can be checked without computing the inverse of any diffeomorphism; only matrix inversions are required. For instance, take the system with $\mathbb{X} = \mathbb{R}$, $\mathbb{U} = [-1, 1]$, and equations

$$x^+ = x^3 + 2x + u \sin x.$$

Since for each fixed value of u the right-hand side is strictly increasing, this is an invertible system. We obtain here that

$$X_u^+(x) = \frac{\sin x}{3x^2 + 2 + u \cos x}$$

in the natural coordinates.

The basic interrelations between the vector fields X_u^+, X_u^-, Y_u^+, Y_u^- are given by the following proposition.

PROPOSITION 3.2. *The following equalities hold for each* $u \in \mathbb{U}$.

(*a*) $X_u^+ = -Y_u^+, \quad X_u^- = -Y_u^-$.

(b) $X_u^+ = -\mathrm{Ad}_u X_u^-, \quad Y_u^+ = -\mathrm{Ad}_u Y_u^-$.

Proof. To prove (a), we differentiate with respect to u the equality

$$f_u^{-1} \circ f_u(x) = x$$

and we get

$$Y_u^+(x) + X_u^+(x) = 0.$$

The second equality in (a) follows from the first by the reversion principle.

On the other hand, differentiating with respect to v the equality

$$f_u^{-1} \circ f_{u+v}(x) = f_u^{-1} \circ f_{u+v} \circ f_u^{-1} \circ f_u(x)$$

we get $X_u^+ = \mathrm{Ad}_u Y_u^-$, which together with (a) gives (b). The proof of the last equality now follows by the reversion principle. □

Later in the paper it will be very useful to have a formula for the derivative with respect to u of a vector field Y transformed by the diffeomorphism f_u. It was noted in [25], [11], [17], [18] that this derivative can be easily expressed via the above introduced vector fields and the Lie bracket; in fact, the next two propositions appear as the first steps in the proof of Theorem 3 on page 26 of [17] and of Lemma 3 in [18].

Here and further we shall use the standard notation $[Y, Z]$ for the Lie bracket of the vector fields Y and Z which, in $\mathbb{R}^n$, is given by $[Y, Z] = \partial Z/\partial x\ Y - \partial Y/\partial x Z$. We also denote $\operatorname{ad} Z(Y) = [Z, Y]$ and the kth iteration of the operator $\operatorname{ad} Z$, $\operatorname{ad}^k Z(Y) = \operatorname{ad} Z \cdots \operatorname{ad} Z(Y)$. The flow of the vector field Y is denoted by $\exp(tY)$.

PROPOSITION 3.3. *The following equalities hold for any vector field Z and any $u \in \mathbb{U}$:*

$$\frac{\partial}{\partial u} \operatorname{Ad}_u Z = \operatorname{ad} X_u^+(\operatorname{Ad}_u Z)$$

and

$$\frac{\partial}{\partial u} \operatorname{Ad}_u^{-1} Z = \operatorname{ad} X_u^-(\operatorname{Ad}_u^{-1} Z).$$

Proof. It is enough to prove each of the equalities locally, so we shall assume that we are in $\mathbb{R}^n$. We have that

$$\begin{aligned}
\frac{\partial}{\partial u} \operatorname{Ad}_u Z &= \frac{\partial}{\partial t}\bigg|_{t=0} \frac{\partial}{\partial u} f_u^{-1} \circ \exp(tZ) \circ f_u(x) \\
&= \frac{\partial}{\partial t}\bigg|_{t=0} \left(\frac{\partial}{\partial u} f_u^{-1}\right) \circ f_u \circ f_u^{-1} \circ \exp(tZ) \circ f_u(x) \\
&\quad + \frac{\partial}{\partial t}\bigg|_{t=0} \mathrm{d}(f_u^{-1} \circ \exp(tZ) \circ f_u)(x)(\mathrm{d}f_u(x))^{-1} \frac{\partial}{\partial u} f_u(x) \\
&= (\partial Y_u^+/\partial x)(x)\ \operatorname{Ad}_u Z(x) + (\partial \operatorname{Ad}_u Z/\partial x)(x) X_u^+(x) \\
&= [X_u^+, \operatorname{Ad}_u Z](x),
\end{aligned}$$

where we use the equality $X^+ = -Y^+$.

The second equality follows from the first by the reversion principle, replacing f_u by f_u^{-1}. □

In the next proposition and in the rest of the paper we shall use the following notational convention. Given a family of vector fields $\{Y_\alpha | \alpha \in A\}$, we denote by $\operatorname{Lie}\{Y_\alpha | \alpha \in A\}$ the Lie algebra generated by this family of vector fields and by $\operatorname{Lie}\{Y_\alpha | \alpha \in A\}(x)$ the subspace of the tangent space at x generated by the vector fields in this Lie algebra.

PROPOSITION 3.4. *For analytic systems and connected $\mathbb{U}$,*

$$\operatorname{Ad}_0^k X_u^+(x) \in \operatorname{Lie}\{\operatorname{Ad}_0^{k+1} X_u^- | u \in \mathbb{U}\}(x)$$

and

$$\operatorname{Ad}_0^{-k} X_u^-(x) \in \operatorname{Lie}\{\operatorname{Ad}_0^{-k-1} X_u^+ | u \in \mathbb{U}\}(x)$$

for each $x \in \mathbb{X}$, each $u \in \mathbb{U}$, and each integer k.

In the proof of this proposition we shall use the following lemma. This lemma is in fact about identities on free Lie algebras; we give a somewhat informal statement to avoid having to introduce considerably more machinery.

LEMMA 3.5. *For any $r \geqq 0$ there are coefficients $a_1, \cdots, a_p \in \mathbb{R}$ and $b_1, \cdots, b_q \in \mathbb{R}$ independent of x and u such that*

$$\mathrm{Ad}_u \left(\frac{\partial^r}{\partial u^r} X_u^- \right) = \sum a_i Y_i \text{ where } Y_i \in \mathrm{Lie} \left\{ X_u^+, \frac{\partial}{\partial u} X_u^+, \cdots, \frac{\partial^r}{\partial u^r} X_u^+ \right\} = M_u^{r,+},$$

$$\mathrm{Ad}_u^{-1} \left(\frac{\partial^r}{\partial u^r} X_u^+ \right) = \sum b_i Z_i \text{ where } Z_i \in \mathrm{Lie} \left\{ X_u^-, \frac{\partial}{\partial u} X_u^- \cdots, \frac{\partial^r}{\partial u^r} X_u^- \right\} = M_u^{r,-}.$$

Moreover, these coefficients, as well as the expressions of each Z_i and Y_i in terms of the generators of the corresponding Lie algebra of vector fields, are independent of the particular system.

Proof. From Proposition 3.2 it follows that the assertions are true for $r = 0$. Assume that the first of them is true for $r = k$. From Proposition 3.3 it follows that

$$\frac{\partial}{\partial u} \mathrm{Ad}_u \frac{\partial^k}{\partial u^k} X_u^- = \mathrm{ad}\, X_u^+ \, \mathrm{Ad}_u \frac{\partial^k}{\partial u^k} X_u^- + \mathrm{Ad}_u \frac{\partial^{k+1}}{\partial u^{k+1}} X_u^-. \tag{8}$$

In general for parametrized vector fields A_u, B_u we have that

$$\frac{\partial}{\partial u} [A_u, B_u] = \left[\frac{\partial}{\partial u} A_u, B_u \right] + \left[A_u, \frac{\partial}{\partial u} B_u \right].$$

Thus it follows from the induction assumption that the left side term in (8) is a linear combination of elements in $M^{k+1,+}$ and so is the first term on the right. Therefore, the second element on the right is a linear combination of elements in $M_u^{k+1,+}$ and the assertion is true for $r = k+1$.

The second part of the proposition follows from the first and the reversion principle. □

Proof of Proposition 3.4. In the proof we shall use the following corollary to the Taylor formula for an analytic, vector valued function g defined on a connected set $\mathbb{U}$ containing the origin: $\mathrm{span}\{g(u) | u \in \mathbb{U}\} = \mathrm{span}\{g^{(i)}(0) | i \geqq 0\}$. We have

$$\begin{aligned} \mathrm{span}\{\mathrm{Ad}_0^k X_u^+, u \in \mathbb{U}\}(x) &= \mathrm{Ad}_0^k \,\mathrm{span} \left\{ \left. \frac{\partial^r}{\partial u^r} \right|_{u=0} X_u^+, r \geqq 0 \right\}(x) \\ &\subset \mathrm{Ad}_0^k \left(\mathrm{Ad}_0 \,\mathrm{Lie} \left\{ \left. \frac{\partial^r}{\partial u^r} X_u^- \right|_{u=0}, r \geqq 0 \right\} \right)(x) \\ &= \mathrm{Lie}\{\mathrm{Ad}_0^{k+1} X_u^- | u \in \mathbb{U}\}(x). \end{aligned}$$

Here the inclusion follows from Lemma 3.5 (apply Ad_u to both sides of the second equation and then evaluate at $u = 0$); the first and the third equality follow from Taylor's formula.

The second assertion of the proposition is a consequence of the first and the reversion principle. □

Note that it is not claimed in Proposition 3.4 that, for instance, X_u^+ is in the Lie algebra generated by the vector fields $\mathrm{Ad}_0 X_u^-$. The statement pertains only to the equality of the associated distributions, that is, of the tangent spaces at each point.

4. Acessibility criteria. To state our criteria we shall need the following families of vector fields:

$$\Gamma^+ = \{\mathrm{Ad}_{u_k \cdots u_1} X_{u_0}^+ | k \geqq 0, u_0, \cdots, u_k \in \mathbb{U}\},$$

$$\Gamma^- = \{\mathrm{Ad}_{u_k \cdots u_1}^{-1 \cdots -1} X_{u_0}^- | k \geqq 0, u_0, \cdots, u_k \in \mathbb{U}\},$$

$$\Gamma = \{\mathrm{Ad}_{u_k \cdots u_1}^{\varepsilon_k \cdots \varepsilon_1} X_{u_0}^{\sigma} | k \geqq 0, u_0, \cdots, u_k \in \mathbb{U}, \varepsilon_1, \cdots, \varepsilon_k = \pm 1, \sigma = \pm\}.$$

As previously, for a family of vector fields Δ, we denote by Lie $\{\Delta\}$ the Lie algebra of vector fields generated by Δ, by $\Delta(x)$ the linear space spanned by the vectors at x given by the vector fields in Δ, and by Lie $\{\Delta\}(x)$ the linear space of tangent vectors at x given by the vector fields in the Lie algebra.

The following theorem gives criteria for accessibility of smooth systems. It will be one of the main results of this paper.

THEOREM 2. *The following properties hold for any smooth system* (1).

(a) *The system is forward accessible if and only if any of the following two equivalent conditions hold*:

$$\dim \Gamma^+(x) = n \quad \forall x \in \mathbb{X}, \quad \textit{or} \quad \dim \operatorname{Lie}\{\Gamma^+\}(x) = n \quad \forall x \in \mathbb{X}.$$

(b) *The system is backward accessible if and only if any of the following two equivalent conditions hold*:

$$\dim \Gamma^-(x) = n \quad \forall x \in \mathbb{X}, \quad \textit{or} \quad \dim \operatorname{Lie}\{\Gamma^-\}(x) = n \quad \forall x \in \mathbb{X}.$$

(c) *The system is transitive if and only if any of the following two equivalent conditions hold*:

$$\dim \Gamma(x) = n \quad \forall x \in \mathbb{X}, \quad \textit{or} \quad \dim \operatorname{Lie}\{\Gamma\}(x) = n \quad \forall x \in \mathbb{X}.$$

To state a stronger version of our result, valid for analytic systems, we need the following Lie algebras of vector fields:

$$L^+ = \operatorname{Lie}\{\operatorname{Ad}_0^k X_u^+ | k \geqq 0,\ u \in \mathbb{U}\},$$

$$L^- = \operatorname{Lie}\{\operatorname{Ad}_0^k X_u^- | k \leqq 0,\ u \in \mathbb{U}\},$$

$$L = \operatorname{Lie}\{\operatorname{Ad}_0^k X_u^\sigma | k \in \mathbb{Z},\ u \in \mathbb{U},\ \sigma \in \{+, -\}\}.$$

The following inclusions are evident:

$$L^+ \subset \operatorname{Lie} \Gamma^+, \quad L^- \subset \operatorname{Lie} \Gamma^-, \quad L \subset \operatorname{Lie} \Gamma.$$

In terms of this data, we now state another one of our main results. As remarked earlier, the transitivity case had been stated before ([11], [20]). Even for that case, however, we believe that this paper contains the first complete proof.

THEOREM 3. *The following properties hold for any analytic system* (1) *with connected* $\mathbb{U}$:

(a) *The system is forward accessible if and only if*

$$\dim L^+(x) = n \quad \textit{for any } x \in \mathbb{X}.$$

(b) *The system is backward accessible if and only if*

$$\dim L^-(x) = n \quad \textit{for any } x \in \mathbb{X}.$$

(c) *The system is transitive if and only if*

$$\dim L(x) = n \quad \textit{for any } x \in \mathbb{X}.$$

Remark 4.1. As a consequence of Proposition 3.4, if we were to take in the definition of the Lie algebra L only $\sigma = +$, or alternatively, only $\sigma = -$, a smaller set of vector fields may result, but the conclusions in the theorem would hold equally well.

There is a pointwise version of the above results. An *equilibrium point* $x_0 \in \mathbb{X}$ is one such that $f(x_0, 0) = 0$.

THEOREM 4. *The following properties hold, if* $\mathbb{U}$ *is connected*:

(a) *A smooth system* (1) *is transitive from* x *if and only if* $\dim \Gamma(x) = n$ (*equivalently*, $\dim \operatorname{Lie}\{\Gamma\}(x) = n$). *An analytic system* (1) *is transitive from* x *if and only if* $\dim L(x) = n$.

(b) *An analytic system* (1) *is forward* (*respectively, backward*) *accessible from an equilibrium point* x_0 *if and only if* $\dim L^+(x_0) = n$ (*respectively,* $\dim L^-(x_0) = n$).

The proofs of all these results are given later after we develop some further theory.

The second part of Theorem 4 will be strengthened as a consequence of the following proposition.

PROPOSITION 4.2. *If the system is analytic,* $\mathbb{U}$ *is connected, and* x_0 *is an equilibrium point, then*

$$L^+(x_0) = L^-(x_0) = L(x_0).$$

Proof. Since $L^+(x_0) \subset L(x_0)$, it is enough to show that $L^+(x_0)$ has the same dimension as $L(x_0)$ to conclude that they are equal. Pick a basis of the latter and assume that the elements in the basis involve vector fields of the form $\mathrm{Ad}_0^k X_u^+$, with the possible k bounded below by the integer k^*. (Recall Remark 4.1 to the effect that we may always assume that $\sigma = +$ in the definition of L.) Applying the operator

$$\mathrm{Ad}_0^{-k^*}$$

to these vector fields, we obtain vector fields in L^+. As x_0 is an equilibrium point, the operator $\mathrm{Ad}_0^{-k^*}$ preserves the tangent space at x_0 and we obtain a set of linearly independent vectors in $L^+(x_0)$, as desired. The argument for L^- follows by the reversion principle. □

The above theorem and proposition immediately imply the following corollary.

COROLLARY 4.3. *Assume that the system is analytic,* $\mathbb{U}$ *is connected, and* x_0 *is an equilibrium point. Then forward accessibility from* x_0, *backward accessibility from* x_0, *and transitivity from* x_0 *are all equivalent properties.*

We will prove the above theorems by splitting them into (somewhat stronger) sufficiency and necessity results.

Define the following families of vector fields:

$$X_u^{+,i} = \frac{\partial^i}{\partial u^i} X_u^+, \qquad X_u^{-,i} = \frac{\partial^i}{\partial u^i} X_u^-.$$

THEOREM 5. *The following statements hold for any smooth system* (1).

(a) *If*

$$\dim \mathrm{Lie}\,\{\Gamma^+\}(x) = n \quad \textit{for all } x \in \mathbb{X}, \tag{9}$$

then the system is forward accessible.

(b) *If* x_0 *is an equilibrium point and if*

$$\dim \mathrm{Lie}\,\{\mathrm{Ad}_0^k X_0^{+,i} | k \geqq 0,\ i \geqq 0\}(x_0) = n, \tag{10}$$

then the system is forward accessible from x_0.

(c) *The same statements hold for backward accessibility if we replace* Γ^+ *for* Γ^- *and* $X_u^{+,i}$ *for* $X_u^{-,i}$.

Proof. (a) Let us fix an $x \in \mathbb{X}$. Let p and $v_1^*, \cdots, v_p^*$ be such that the rank of the Jacobian of the map

$$(v_1, \cdots, v_p) \mapsto f_{v_p \cdots v_1}(x) \tag{11}$$

is maximal (over all $p \geqq 0$ and $v_1, \cdots, v_p \in \mathbb{U}$) at $v_1^*, \cdots, v_p^*$. Because $\mathbb{U} \subset \mathrm{clos\,int}\,\mathbb{U}$, we may assume that these are in the interior of $\mathbb{U}$. Let W be a neighborhood of $(v_1^*, \cdots, v_p^*)$ on which this rank is maximal and such that the image S of W under the above map is a submanifold. Since $S \subseteq A^+(x)$, it is enough to show that the dimension of S is equal to n, from which it will follow that S is an open subset of $\mathbb{X}$.

We now prove that each vector field of the type $\mathrm{Ad}_{u_k \cdots u_1} X^+_{u_0}$ is tangent to S. It will follow then that all the Lie brackets of these vector fields are tangent to the submanifold S. This, together with assumption (9), will imply that S is of dimension n.

Assume that the vector

$$\mu := (\mathrm{Ad}_{u_k \cdots u_1} X^+_{u_{k+1}})(y)$$

is not tangent to S at $y = f_{v_p \cdots v_1}(x)$, for some $u_1, \cdots, u_{k+1}$ (for convenience we denote u_0 by u_{k+1} now) and some $(v_1, \cdots, v_p) \in W$. Again, we may assume that these are all in the interior of $\mathbb{U}$. Thus

$$\mu = \frac{\partial}{\partial v}\bigg|_{v=0} (f_{u_k \cdots u_1})^{-1} \circ f^{-1}_{u_{k+1}} \circ f_{u_{k+1}+v} \circ f_{u_k \cdots u_1}(y)$$

is not tangent to S and therefore also

$$\frac{\partial}{\partial v}\bigg|_{v=0} f_{u_{k+1}+v} \circ f_{u_k \cdots u_1} \circ f_{v_p \cdots v_1} = (\mathrm{d} f_{u_{k+1} \cdots u_1})(y)\mu$$

is not tangent to the submanifold $f_{u_{k+1} \cdots u_1}(S)$. But this means that the rank of the Jacobian map of the mapping

$$(v_1, \cdots, v_p, u_1, \cdots, u_{k+1}) \to f_{u_{k+1} \cdots u_1 v_p \cdots v_1}(x)$$

is at least dim $S+1$ for this sequence $v_1, \cdots, v_p, u_1, \cdots, u_{k+1}$, contradicting maximality of the rank. It follows that the vector field $\mathrm{Ad}_{u_k \cdots u_1} X^+_{u_{k+1}}$ must indeed be tangent to S.

(b) The idea of this part of the proof is the same as in part (a) except that now the rank assumption is made at one point only. Thus, we have to construct the manifold S in a neighborhood of x_0 so that n linearly independent vector fields in the Lie algebra (10) are linearly independent in this neighborhood and tangent to this manifold.

Let V be a coordinate neighborhood of x_0 such that there are n vector fields in the Lie algebra (10) which are linearly independent on V. Suppose that these vector fields involve only $k \leqq k^*$. Let $V_\varepsilon \subset V$ denote the open ball of radius ε centered at x_0. Fix δ so that $V_\delta \subset V$ and denote by r_ε the supremum of the possible ranks of those maps (11) with $p \geqq 1$ and $x = x_0$ for which all the points of the trajectory

$$x_i = f_{v_i \cdots v_1}(x_0), \qquad i = 1, \cdots, p,$$

lie in V_ε. Note that r_ε is nondecreasing with ε. Let $r = \inf\{r_\varepsilon | 0 < \varepsilon < \delta\}$ and let $\varepsilon^* := \sup\{\varepsilon | r = r_\varepsilon\}$. Note that $\varepsilon^* > 0$. Take $0 < \sigma < \varepsilon^*$ such that all trajectories starting from V_σ stay in V_{ε^*} for the next k^*+1 steps, under the constant control $u = 0$. Let the corresponding supremum of ranks defining $r_\sigma = r$ be achieved at p and $(v_1^*, \cdots, v_p^*)$.

We define our manifold S as previously, where W is a neighborhood of $(v_1^*, \cdots, v_p^*)$ such that all trajectories corresponding to controls in W lie in V_σ. By an analogous argument as for (a) we see that the vector fields $\mathrm{Ad}_{u_k \cdots u_1} X^+_{u_0}$ are tangent to S, provided that $k \leqq k^*$ and $u_0, \cdots, u_k$ are close enough to zero so that our trajectory does not leave V_{ε^*}, and so the rank cannot increase over r (cf. the definition of σ). Taking $u_1 = \cdots = u_k = 0$ and the derivative $(\partial/\partial u_0)^i$ at u^* we conclude that the vector fields $\mathrm{Ad}^k_0 X^{+,i}_0$ are tangent to S. Therefore, their Lie brackets must be tangent to S, also. Because of our choice of the neighborhoods, there are n linearly independent vector fields among those Lie brackets and so S is an open subset of $\mathbb{X}$.

Statement (c) follows from (a) and (b) and the reversion principle. □

The above proof, part (a), gives a somewhat stronger result, actually, which we state below for further use.

COROLLARY 4.4. *If $y \in \mathbb{X}$ is a point forward reachable from x with maximal rank (in the sense of the ranks of maps* (11)*), then the condition* $\dim \operatorname{Lie}\{\Gamma^+\}(y) = n$ *implies that the system* (1) *is forward accessible from x.*

We are now ready to establish a converse to Theorem 5.

THEOREM 6. (a) *If system* (1) *is of class C^1 and forward accessible from x, then*

$$\dim \Gamma^+(x) = n.$$

(b) *If system* (1) *is analytic, forward accessible from x, and $\mathbb{U}$ is connected, then*

$$\dim L^+(x) = n.$$

(c) *Analogous results hold for backward accessibility with Γ^+, L^+ replaced by Γ^-, L^-.*

Remark 4.5. The case when $\mathbb{U}$ is a nonconnected subset of $\mathbb{R}$ can also be treated. Assume that $\mathbb{U}$ is a disjoint union of connected subsets of $\mathbb{R}$, each of which is in the closure of its interior. Then (b) also holds but we have to choose a subset $\mathbb{U}_0 \subset \mathbb{U}$ which has at least one point in each of these sets. Then

$$L^+ = \operatorname{Lie}\{\operatorname{Ad}_{u_k \cdots u_1} X_u^+ | k \geqq 0,\ u \in \mathbb{U},\ u_1, \cdots, u_k \in \mathbb{U}_0\}$$

must be used in this case as the definition of L^+.

Proof of Theorem 6. (a) If the system is accessible, then it follows from Proposition 2.3 that, for some $k \geqq 1$ the rank of the map $\psi_{k,x}$ is equal to n at some point. This means that the following vectors span an n-dimensional space, for some sequence $u_1, \cdots, u_k$:

$$\frac{\partial}{\partial u_i} f_{u_k \cdots u_1}(x), \qquad i = 1, \cdots, k.$$

Hence, also the vectors

$$(\mathrm{d} f_{u_k \cdots u_1}(x))^{-1} \frac{\partial}{\partial u_i} f_{u_k \cdots u_1}(x)$$

which can be equivalently written as

$$\frac{\partial}{\partial v}\bigg|_{v=0} f^{-1}_{u_{i-1} \cdots u_1} \circ f^{-1}_{u_i} \circ f_{u_i + v} \circ f_{u_{i-1} \cdots u_1}(x) = \operatorname{Ad}_{u_{i-1} \cdots u_1} X^+_{u_i},$$

$i = 1, \cdots, k$, span an n-dimensional space and statement (a) follows.

(b) The proof will be based on a reduction to continuous time systems, as done in [29] for the transitivity problem. A different proof, not involving such a reduction, is provided in a later section. If our system is accessible from x, then it follows from Proposition 2.3 that there exists a k such that the rank of the map

$$(u_1, \cdots, u_k) \mapsto f_{u_k \cdots u_1}(x)$$

is equal to n at some point $(u_1^*, \cdots, u_k^*)$, and so its image contains an open set V. Then $W = f_0^{-k}(V)$ is also open and $x \in W$. We will show that W is contained in the orbit through x of the Lie algebra L^+ (cf. [34]), which we denote by $\operatorname{Orb}_{L^+}(x)$. This will imply that the orbit is of dimension n and from a theorem of Nagano ([23], [34]) it will follow that $\dim L^+(x) = n$.

Let $y \in W$. We will show that $y \in \operatorname{Orb}_{L^+}(x)$ by showing the equivalent fact: $x \in \operatorname{Orb}_{L^+}(y)$. We have that

$$x = f^{-1}_{u_1} \circ \cdots \circ f^{-1}_{u_k} \circ f_0^k(y) = g_{1,u_1} \circ \cdots \circ g_{k,u_k}(y),$$

where

$$g_{i,u_i} = f_0^{-i+1} \circ f_{u_i}^{-1} \circ f_0^i.$$

Denote $y_k = y$, and

$$y_{i-1} = g_{i,u_i}(y_i), \qquad i = k, \cdots, 1.$$

We have that $y_0 = x$. It is enough to show that $y_{i-1} \in \mathrm{Orb}_{L^+}(y_i)$, for $i = 1, \cdots, k$.

Denote

$$\gamma(u) = f_0^{-i+1} \circ f_u^{-1} \circ f_0^i(y_i).$$

Then, for $u \in [0, u_i]$, γ is a curve in $\mathbb{X}$ joining y_i with y_{i-1}; its tangent vector at u is

$$\frac{\partial}{\partial u}\gamma(u) = \frac{\partial}{\partial v}\bigg|_{v=0} f_0^{-i+1} \circ f_{u+v}^{-1} \circ f_u \circ f_0^{i-1}(\gamma(u)) = \mathrm{Ad}_0^{i-1} Y_u^+(\gamma(u)).$$

As $\gamma(0) = y_i$ and $\mathbb{U}$ is connected, it follows that $y_{i-1} = \gamma(u_i)$ belongs to the orbit through y_i of the family of vector fields $\mathrm{Ad}_0^{i-1} Y_u^+$, $u \in \mathbb{U}$. Since $Y_u^+ = -X_u^+$, it then follows that y_{i-1} belongs to the orbit through y_i of the family $\mathrm{Ad}_0^{i-1} X_u^+$, $u \in \mathbb{U}$. □

Remark 4.6. If $\mathbb{U}$ is not connected, then the result still holds with the modified definition of the Lie algebra L^+ as given in the remark following Theorem 6. The necessary modifications in the above proof are as follows. We choose elements $v_1, \cdots, v_k \in \mathbb{U}_0$ so that v_i belongs to the same connected component of $\mathbb{U}$ as u_i^*. Then we define

$$W = f_{v_k}^{-1} \circ \cdots \circ f_{v_1}^{-1}(V).$$

Then we have that

$$x = g_{1,u_1} \circ \cdots \circ g_{k,u_k}(y), \quad g_{i,u_i} = f_{v_{i-1}\cdots v_1}^{-1} \circ f_{u_i}^{-1} \circ f_{v_i} \circ f_{v_{i-1}\cdots v_1}.$$

Finally, we take the curve

$$\gamma(u) = f_{v_{i-1}\cdots v_1}^{-1} \circ f_u^{-1} \circ f_{v_i \cdots v_1}(y_i),$$

with u in the interval joining u_i and v_i. Differentiation with respect to u now gives the vector fields in the modified Lie algebra L^+ as defined in the remark following Theorem 6.

To obtain criteria for transitivity using Theorems 5 and 6, we may apply the following trick which reduces the transitivity problem to the forward accessibility problem.

Define $\mathbb{U}^\pm$ as the disjoint union of two copies of $\mathbb{U}$ denoted by $\mathbb{U}^+$ and $\mathbb{U}^-$. Consider a system

$$x^+ = f^\pm(x, u), \quad x(t) \in \mathbb{X}, \quad u(t) \in \mathbb{U}^\pm = \mathbb{U}^+ \cup \mathbb{U}^- \tag{12}$$

where $f^\pm(x, u) = f(x, u)$ if $u \in \mathbb{U}^+$ and $f^\pm(x, u) = f^-(x, u) = f_u^{-1}(x)$ if $u \in \mathbb{U}^-$. As the control set $\mathbb{U}^\pm$ has two components, we define its Lie algebra of our new system L^+ using the definition in Remark 4.6 with $\mathbb{U}_0 = \{0^+, 0^-\}$, where $0^+ \in \mathbb{U}^+$ and $0^- \in \mathbb{U}^-$ are two copies of $0 \in \mathbb{U}$. Of course, there is no difficulty in embedding the new control set again in the reals. The following proposition is then clear.

PROPOSITION 4.7. (a) *The Lie algebra L^+ of the system* (12) *is equal to the Lie algebra L of the original system* (1).

(b) *The family of vector fields* Γ^+ *for system* (12) *is equal to the family* Γ *defined by system* (1).

(c) *The forward accessible set of system* (12) *is equal to the orbit of system* (1).

We may now complete the proofs of all the theorems in this section.

Proof of Theorem 2. Statement (a) follows immediately from Theorems 5 and 6, part (a). Statement (b) follows analogously from part (c) of these theorems. Finally, statement (c) is the consequence of statement (a) via the above reduction of the transitivity problem to the forward accessibility problem and Proposition 4.7. □

Proof of Theorem 3. Statement (a) follows from Theorem 5 (a) and the inclusion $L^+ \subset \text{Lie}\{\Gamma\}$ (sufficiency), and from Theorem 6(b). Statement (b) follows analogously from statements (c) of these theorems. Finally, statement (c) is the consequence of statement (a) via the above reduction trick and Proposition 4.7. □

Proof of Theorem 4. (a) In the smooth case the "if" part follows from Corollary 4.4 by the above reduction procedure and Proposition 4.7 as, for system (12) the point x is attainable from itself with full rank. The analytic case follows from the smooth case by the inclusion $L(x) \subset \text{Lie}\{\Gamma\}(x)$.

The "only if" part follows from Theorem 6 and Proposition 4.7 via the above reduction.

(b) The "only if" part is the consequence of Theorem 6. To prove the "if" part suppose that there are n linearly independent vectors in $L^+(x_0)$. Each of them can be taken in the form

$$\text{ad}\,(\text{Ad}_0^{k_1} X_{u_1}^+) \cdots \text{ad}\,(\text{Ad}_0^{k_{p-1}} X_{u_{p-1}}^+)(\text{Ad}_0^{k_p} X_{u_p}^+)(x_0). \tag{13}$$

If we take the partial derivatives of these vectors with respect to $u_1, \cdots, u_p$ at zero, we obtain vectors which appear in the Lie algebra in (10). From the Taylor formula it follows then that the rank condition in (10) is also satisfied and Theorem 5 implies the result. □

5. Nonaccessible systems. In this section we will briefly discuss nonaccessible and, more generally, nontransitive systems. The following "orbit theorem" is crucial in understanding such systems. The theorem has a long history starting with results of Chow, Nagano [23], Sussmann [34], and Stefan [33] in the continuous time case. In the discrete time case, analogous results to those in continuous time were provided in [9], [32], [11], and [29], the latter containing also a proof of a more abstract result dealing with a general notion of action on manifolds. These papers should be consulted for details of the proof, which we omit.

THEOREM 7. *Any orbit* $A(x)$ *of the smooth system* (1) *is an immersed submanifold of* $\mathbb{X}$ *with at most countably many connected components, whose tangent space is given by*

$$T_y A(y) = \Gamma(y)$$

at each $y \in A(x)$. *In the analytic case we have that*

$$T_y A(y) = L(y)$$

holds also.

As the attainable set from x lies in the orbit from x, there is no chance for forward or backward accessibility from x if there is no transitivity from x (that is, the orbit is not of full dimension). In this case it is reasonable to ask whether the attainable set has a nonempty interior in the orbit. In the case of analytic continuous time systems the answer is always positive, as proved by Sussmann and Jurdjevic [36]. The following theorem generalizes this result to discrete time systems.

THEOREM 8. *If x_0 is an equilibrium point of an analytic system* (1), *then each of the attainable sets $A^+(x_0)$ and $A^-(x_0)$ has a nonempty interior in the orbit $A(x_0)$.*

Proof. If we restrict our system to the orbit then the problem reduces to proving that the system is forward (backward) accessible from x_0, if it is transitive from x_0. But this follows immediately from Theorem 4 and Proposition 4.2. □

Remark 5.1. The above theorem provides an analogue of what is sometimes called the *positive form of Chow's lemma* for continuous time systems. In fact, the proof is related to that of the continuous time case. However, there is an interesting subtlety that appears here. Contrary to the continuous situation, it is *not* true now that the assumption that x_0 is an equilibrium state can be relaxed. In the paper [29, Remark 9.15], an example is given of an analytic system on $\mathbb{X}=\mathbb{R}$, with $\mathbb{U}=\mathbb{R}$, and a state $x\in\mathbb{X}$ such that $A(x)=\mathbb{X}$, but the system is not forward accessible from this x. In fact, the system in question arises from the sampling of a continuous time system.

We now give the basic outline of how such an example arises. A real-analytic function of one variable

$$g(x)$$

is first constructed, with the property that

$$|g'(x)|\leqq 1 \text{ for all } x\in\mathbb{R}$$

and whose zeros are exactly at the nonnegative integers $0, 1, 2, \cdots$. Now the system is given by equations

$$x^+ = 1 + x + ug(x)$$

with

$$\mathbb{U}=(-1, 1)$$

as control value set. Observe that this system is indeed invertible, since for each fixed u the right-hand side is a strictly increasing function of x. Furthermore, for each x the set

$$\{x, 1+x, 2+x, \cdots\}$$

is included in $A^+(x)$. When x is a nonnegative integer, this is *precisely* $A^+(x)$, while for any other x one can reach an open set in one step, and hence $A^+(x)$ is of dimension 1. Since each nonnegative integer x can be reached from, say, -1, it follows that $A(x)=A(-1)$ has dimension 1, so by connectedness, *the orbit through each point is all of* $\mathbb{X}=\mathbb{R}$, even though $A^+(0)$, $A^+(1), \cdots$ are discrete.

These remarks probably mean that the notion of transitivity is in the discrete time case too weak to be of interest.

The following families of vector fields will help us to better understand the geometry of the attainable sets $A^+(x)$ and $A^-(x)$ and, in particular, to estimate their dimensions. Define

$$\Delta_k^+ = \{\mathrm{Ad}_0^i X_u^+ | 0\leqq i\leqq k-1, u\in\mathbb{U}\}, \qquad L_k^+ = \mathrm{Lie}\,\Delta_k^+,$$

and

$$\Delta_k^- = \{\mathrm{Ad}_0^{-i} X_u^- | 0\leqq i\leqq k-1, u\in\mathbb{U}\}, \qquad L_k^- = \mathrm{Lie}\,\Delta_k^-.$$

For any family of vector fields Δ, let $\mathrm{Orb}_\Delta(x)$ denote the orbit of this family passing through x. This orbit has a natural structure of immersed second countable submanifold ([34], [33]). Further, the orbit of Lie Δ coincides with the orbit of Δ.

PROPOSITION 5.2. *For any smooth system with connected control set* $\mathbb{U}$ *we have that*

$$A_k^+(x) \subset \mathrm{Orb}_{\Delta_k^-}(y), \quad \textit{for any} \quad y \in A_k^+(x),$$

and

$$A_k^-(x) \subset \mathrm{Orb}_{\Delta_k^+}(y), \quad \textit{for any } y \in A_k^-(x).$$

Proof. It is enough to prove the first inclusion as the second will follow from the reversion principle. It is also enough to show this inclusion for any particular y in $A_k^+(x)$, since for any other y this will be implied by the general equality $\mathrm{Orb}_\Delta(y) = \mathrm{Orb}_\Delta(z)$ for any $z \in \mathrm{Orb}_\Delta(y)$. Our argument will be similar to that used in the proof of Theorem 6(b). Take

$$y = f_0^k(x)$$

and

$$z = f_{u_k \cdots u_1}(x) = f_{u_k} \circ \cdots \circ f_{u_1} \circ f_0^{-k}(y).$$

We have to show that $z \in \mathrm{Orb}_{\Delta_k^-}(y)$. The point z can be written in a different way as

$$z = g_{k,u_k} \circ \cdots \circ g_{1,u_1}(y),$$

where

$$g_{i,u} = f_0^{k-i} \circ f_u \circ f_0^{-k+i-1}, \qquad i = 1, \cdots, k.$$

Taking $z_0 = y$, $z_i = g_{i,u_i}(z_{i-1})$, $i = 1, \cdots, k$, it is enough to show that $z_i \in \mathrm{Orb}_{\Delta_k^-}(z_{i-1})$. Consider the curve $\gamma_i(u) = g_{i,u}(z_{i-1})$, which joins z_{i-1} with z_i when $u \in [0, u_i]$. The tangent vectors to this curve are given by

$$\begin{aligned}\frac{\partial}{\partial u}\gamma_i(u) &= \frac{\partial}{\partial v}\bigg|_{v=0} f_0^{k-i} \circ f_{u+v} \circ f_u^{-1} \circ f_0^{i-k}(\gamma_i(u)) \\ &= \mathrm{Ad}_0^{i-k}\, Y_u^-(\gamma_i(u)) = -\mathrm{Ad}_0^{i-k}\, X_u^-(\gamma_i(u)).\end{aligned}$$

As $-k+1 \leqq i-k \leqq 0$, it follows that the above curve lies in the orbit of the family Δ_k^- and the proof is complete. □

From the above proposition we immediately conclude the following necessary conditions for accessibility.

COROLLARY 5.3. *If an analytic system with connected* $\mathbb{U}$ *is forward accessible from* x, *then*

$$\dim L^-(y) = n \quad \textit{for any } y \in A^+(x).$$

Similarly, if it is backward accessible from x, *then*

$$\dim L^+(y) = n \quad \textit{for any } y \in A^-(x).$$

Proof. The first statement follows directly from the first inclusion in Proposition 5.2 and the inclusions

$$\bigcup_{k>0} A_k^+(x) = A^+(x), \quad \mathrm{Orb}_{\Delta_k^-}(x) \subset \mathrm{Orb}_{L^-}(x).$$

The second statement follows analogously. □

We now turn to yet another reason why our Lie algebras of vector fields emerge in studying controllability properties of discrete time systems. We will consider our system in another (time-dependent) system of coordinates. This is basically the same as the "local" dynamics defined in the references [18] and [20] in the context of invariant distributions for nonlinear discrete-time systems.

Consider the usual system $x(t+1)=f(x(t), u(t))$ and introduce the time-dependent change of variables

$$x(t)=f_0^t(z(t)),$$

where f_0^t is the tth power of f_0 (in the sense of composition). In the new coordinates our system becomes time-dependent and takes the form

$$z(t+1)=g(t, z(t), u(t)), \tag{14}$$

where

$$g(t, z, u)=f_0^{-t-1}\circ f_u\circ f_0^t(z).$$

What is simpler about the new system is that it has the "doing nothing" option, as $g(t, \cdot, 0)=\mathrm{id}$. As a consequence, if the control set $\mathbb{U}$ is connected then so are the attainable sets of system (14): $A^+(x)$, $A^-(x)$, and $A(x)$. In that case the next point on the trajectory, $z(t+1)$, can be connected with the previous one, $z(t)$, by the smooth curve $\gamma(u)=g(t, z(t), u)$, where $u\in[0, u(t)]$ if $u(t)>0$ and $u\in[u(t), 0]$ if $u(t)<0$. As

$$\begin{aligned}\partial\gamma/\partial u(u)&=\partial g/\partial u(t, z(t), u)\\&=\frac{\partial}{\partial v}\bigg|_{v=0}(f_0^{-t-1}\circ f_{u+v}\circ f_u^{-1}\circ f_0^{t+1}(\gamma(u)))\\&=\mathrm{Ad}_0^{t+1}\, Y_u^-(\gamma(u)),\end{aligned}$$

we see that the point $z(t)$ lies in the orbit through $z(t+1)$ of the family of vector fields $\mathrm{Ad}_0^{t+1}\, Y_u^-$, $u\in\mathbb{U}$. Since $Y_u^-=-X_u^-$, it follows by induction that for $t\leqq -1$ any point $z(t)$ on a trajectory of system (14) starting from $z(0)$ lies in the orbit through $z(0)$ of the family of vector fields Δ_k^-, where $k=-t$ and so also in the orbit through $z(0)$ of the Lie algebra L_k^-. By the reversion principle, or by the above argument applied for $t>0$, it also follows that any point $z(t)$ of any trajectory of system (14) starting from $z(0)$ lies in the orbit through $z(0)$ of the family of vector fields Δ_k^+, with $k=t$, and so also in the orbit through $z(0)$ of the Lie algebra L_k^+.

Because of our change of coordinates $x(t)=f_0^t(z(t))$ it follows that a point $x(t)$ on any trajectory of the original system (1) starting from x_0, lies in the image under the map f_0^k of the orbit $\mathrm{Orb}_{\Delta_k^+}(x_0)$ if $t=k>0$ (respectively, the image of $\mathrm{Orb}_{\Delta_k^-}(x_0)$, if $t<0$, $k=-t$). Thus, we have the following proposition.

PROPOSITION 5.4. *If the control set $\mathbb{U}$ is connected then, for any $k>0$, we have the inclusions*

$$A_k^+(x)\subset f_0^k(\mathrm{Orb}_{\Delta_k^+}(x))=f_0^k(\mathrm{Orb}_{L_k^+}(x))$$

and

$$A_k^-(x)\subset f_0^{-k}(\mathrm{Orb}_{\Delta_k^-}(x))=f_0^{-k}(\mathrm{Orb}_{L_k^-}(x)).$$

The orbits of discrete time systems can be expressed via the orbits of the Lie algebra L according to the formula

$$A(x)=\bigcup_{k\in\mathbb{Z}} f_0^k(\mathrm{Orb}_L(x)).$$

Proof. The first two inclusions follow from the argument above. It also follows from the above consideration that the vector fields in L are tangent to the orbit $A(x)$ (cf. Theorem 7). Thus, $\mathrm{Orb}_L(x)\subset A(x)$. As the maps f_0^k preserve the orbit $A(x)$ and the family of vector fields L, it follows that the inclusion "$\supset$" holds. On the other

hand, the computation preceding the proposition also shows that any two points which can be joined by a (forward or backward) step of the discrete time system can also be joined by a trajectory of a continuous time system

$$\dot{x} = h(x, u), \quad \text{where } h(x, u) = \mathrm{Ad}_0^k X_u^+(x)$$

and a (forward or backward) jump by f_0. It is well known that each trajectory of a continuous time system lies in a single orbit of this system. It follows then that any trajectory of the above system lies in an orbit of the family of vector fields L, and so the inclusion "$\subset$" follows. □

The relation between the inclusions in Propositions 5.2 and 5.4 can be further clarified by the following relation between the Lie algebras L_k^+ and L_k^-.

PROPOSITION 5.5. *For an analytic system the distributions spanned by the Lie algebras L_k^+ and L_k^- are related by the change of coordinates given by the diffeomorphism f_0^k, i.e.,*

$$(\mathrm{Ad}_0^k L_k^-)(x) = L_k^+(x), \quad \textit{and} \quad (\mathrm{Ad}_0^{-k} L_k^+)(x) = L_k^-(x) \quad \forall x \in \mathbb{X}.$$

Proof. Since the operator Ad_0 is a homomorphism of the Lie algebra of vector fields, it follows that

$$\mathrm{Ad}_0^k L_k^- = \mathrm{Lie}\,\{\mathrm{Ad}_0^i X_u^- | 1 \leqq i \leqq k\}.$$

From Proposition 3.4 it follows that

$$(\mathrm{Ad}_0^i X_u^-)(x) \in \mathrm{Lie}\,\{\mathrm{Ad}_0^{i-1} X_u^+ | u \in \mathbb{U}\}(x) \quad \forall x.$$

Thus, all the vector fields $\mathrm{Ad}_0^i X_u^-$, $i = 1, \cdots, k$ are tangent to the orbit of the Lie algebra L_k^+ and so

$$(\mathrm{Ad}_0^k L_k^-)(x) \subset L_k^+(x) \quad \forall x \in \mathbb{X}. \tag{15}$$

The reversion principle and the above inclusion yield

$$(\mathrm{Ad}_0^{-k} L_k^+)(x) \subset L_k^-(x) \quad \forall x \in \mathbb{X}.$$

Applying the operator Ad_0^k to both sides of the above inclusion gives the converse inclusion to (15) and proves the first equality in the proposition.

The second equality follows from the first and the reversion principle. □

6. Nonscalar controls. All our previous results can be extended, without difficulties, to the case of multidimensional controls. The basic modification needed is that, whenever derivatives with respect to u are used in the scalar control case, partial derivatives with respect to the components of u should be used in the multicontrol case.

We assume that the control set $\mathbb{U}$ is a subset of $\mathbb{R}^m$ and satisfies the assumption $\mathbb{U} \subset \mathrm{clos\,int}\,\mathbb{U}$. Additionally, we assume that any two points in the same connected component of $\mathbb{U}$ can be joined by a smooth curve lying entirely in $\mathrm{int}\,\mathbb{U}$ (except of endpoints, possibly). We denote $u = (u^1, \cdots, u^m)$ and $v = (v^1, \cdots, v^m)$.

The vector fields X_u^+ defined at the beginning of § 3 should now be redefined as follows:

$$X_{u,i}^+(x) = \frac{\partial}{\partial v^i}\bigg|_{v=0} f_u^{-1} \circ f_{u+v}(x),$$

one for each $i = 1, \cdots, m$. Analogously, we define $X_{u,i}^-$, $Y_{u,i}^+$ and $Y_{u,i}^-$.

The Lie algebras Γ^+, Γ^- and Γ are now defined as

$$\Gamma^+ = \{\mathrm{Ad}_{u_k \cdots u_1} X_{u_0,i}^+ | k \geqq 0, 1 \leqq i \leqq m, u_0, \cdots, u_k \in \mathbb{U}\},$$

$$\Gamma^- = \{\mathrm{Ad}_{u_k \cdots u_1}^{-1 \cdots -1} X_{u_0,i}^- | k \geqq 0, 1 \leqq i \leqq m, u_0, \cdots, u_k \in \mathbb{U}\},$$

$$\Gamma = \{\mathrm{Ad}_{u_k \cdots u_1}^{\varepsilon_k \cdots \varepsilon_1} X_{u_0,i}^{\sigma} | k \geqq 0, 1 \leqq i \leqq m, u_0, \cdots, u_k \in \mathbb{U}, \varepsilon_1, \cdots, \varepsilon_k = \pm 1, \sigma = \pm\}.$$

We also redefine the Lie algebras L^+, L^-, and L as follows. We choose a subset $\mathbb{U}_0 \subset \mathbb{U}$ which has at least one point in each connected component of $\mathbb{U}$. In particular, if the set $\mathbb{U}$ is connected and $0 \in \mathbb{U}$ we can take $\mathbb{U}_0 = \{0\}$. We define

$$L^+ = \text{Lie}\,\{\text{Ad}_{u_k \cdots u_1} X^+_{u,i} | k \geqq 0,\ 1 \leqq i \leqq m,\ u \in \mathbb{U},\ u_1, \cdots, u_k \in \mathbb{U}_0\},$$

$$L^- = \text{Lie}\,\{\text{Ad}^{-1 \cdots -1}_{u_k \cdots u_1} X^-_{u,i} | k \geqq 0,\ 1 \leqq i \leqq m,\ u \in \mathbb{U},\ u_1, \cdots, u_k \in \mathbb{U}_0\},$$

$$L = \text{Lie}\,\{\text{Ad}^{\varepsilon_k \cdots \varepsilon_1}_{u_k \cdots u_1} X^\sigma_{u,i} | k \geqq 0,\ 1 \leqq i \leqq m,\ u \in \mathbb{U},\ u_1, \cdots, u_k \in \mathbb{U}_0,\ \varepsilon_1, \cdots, \varepsilon_k = \pm 1,\ \sigma = \pm\}.$$

THEOREM 9. *With the above definitions of the Lie algebras Γ^+, Γ^-, Γ, L^+, L^-, and L, all the theorems stated in the preceding two sections remain true.*

The proof of the multicontrol versions are completely analogous to the scalar case. The main modifications needed are the replacement of derivatives with respect to u by partial derivatives with respect to the components of u, and the replacement of parameterizations of curves by u with parameterizations by components of u. We leave the details to the reader.

7. From discrete time to continuous time systems. In this section we have two goals. The first is the description of one manner in which the study of continuous time systems can be reduced to that of discrete time systems. The second is the development of a technique, based on expansions of the previously defined families of vector fields, which gives added power to the use of these vector fields and their associated Lie algebras. As an illustration of the use of this technique, we provide a short proof of part (b) of Theorem 6 which is independent of Nagano's theorem and of the orbit theorem. In this manner, not only does the discrete time theory become independent of continuous time techniques, but in fact it becomes itself a basis for the accessibility theory for the latter, via the reduction also described here.

To show how continuous-time systems can be viewed as a special case of discrete time systems, we consider a continuous-time system of the form

$$\dot{x} = h(x, v), \tag{16}$$

where $x(t) \in \mathbb{X}$ and $v(t) \in V$ is the control. We assume that the controls are piecewise constant (this assumption does not affect the controllability properties of the system we are studying). For the convenience of having all the maps defined everywhere we assume that our system is complete. We introduce the discrete-time system

$$x^+ = f(x, u), \quad x(t) \in \mathbb{X},\ u(t) \in \mathbb{U} = \mathbb{R}_+ \times V, \quad \mathbb{R}_+ = [0, \infty), \tag{17}$$

where $u = (t, v)$ and $f(x, u) = \exp(th(\cdot, v))(x)$. In this way, going forward by time t with a constant control v for the continuous-time system corresponds to a forward step using the control $u = (t, v)$ for the discrete time system. Analogously, going backward by time $-t$ with the control v corresponds to a backward step with $u = (t, v)$. This implies that the forward (respectively, backward) attainable sets as well as the orbits of both systems (16) and (17) coincide. Thus both systems have identical controllability properties.

It is convenient to endow V with the discrete topology. The set $\mathbb{U} = \mathbb{R}_+ \times V$ can be viewed then as the disjoint union of copies of $\mathbb{R}_+$. We compute the Lie algebras L^+, L^-, and L corresponding to system (17) according to the remark following Theorem 6. We choose the subset $\mathbb{U}_0 = \{(0, v) | v \in V\} \subset \mathbb{U}$. Then $f_0 = \text{id}$ and we can easily compute that

$$X^+_u = h(\cdot, v) = -X^-_u, \quad \text{for } u = (t, v).$$

Strictly speaking, the present set $\mathbb{U}$ is not an allowable control set, since it is not a subset of $\mathbb{R}^m$. However, the arguments in previous sections can be repeated as long

as we use in the definition of X_u^+ and X_u^- only differentiation with respect to t but not differentiation with respect to v. Finally, we obtain

$$L^+ = L^- = L = \text{Lie}\{h(\cdot, v) | v \in V\}.$$

Our aim now is to prove a discrete time version of the well-known Baker-Campbell-Hausdorff expansion formula for a vector field Y transformed by the flow of a vector field Z:

$$\text{Ad}_u Y = \sum_{k=0}^{\infty} \frac{1}{k!} \text{ad}^k Z(Y).$$

This is classical when Ad_u corresponds to $f_u = \exp(uZ)$, for which $X_u^+ = Z = -X_u^-$. Assume now that f is of the general form $f = f(x, u)$; we wish to generalize the above formula.

LEMMA 7.1. *For analytic f and Y we have the following expansions, for u sufficiently close to zero,*

$$\text{Ad}_u Y = \sum_{k=0}^{\infty} \int_0^u \int_0^{v_1} \cdots \int_0^{v_{k-1}} \text{ad } X_{v_1}^+ \cdots \text{ad } X_{v_k}^+ \text{Ad}_0 Y \, dv_k \cdots dv_1,$$

$$\text{Ad}_u^{-1} Y = \sum_{k=0}^{\infty} \int_0^u \int_0^{v_1} \cdots \int_0^{v_{k-1}} \text{ad } X_{v_1}^- \cdots \text{ad } X_{v_k}^- \text{Ad}_0^{-1} Y \, dv_k \cdots dv_1,$$

where the series converge pointwise at each $x \in \mathbb{X}$.

If f and Y are of class C^∞ only, then we have the formula

$$\text{Ad}_u^{\pm 1} Y = \sum_{i=0}^{k} \int_0^u \int_0^{v_1} \cdots \int_0^{v_{i-1}} \text{ad } X_{v_1}^{\pm} \cdots \text{ad } X_{v_i}^{\pm} \text{Ad}_0^{\pm 1} Y \, dv_i \cdots dv_1 + R_k, \tag{18}$$

where

$$R_k = \int_0^u \int_0^{v_1} \cdots \int_0^{v_k} \text{ad } X_{v_1}^{\pm} \cdots \text{ad } X_{v_{k+1}}^{\pm} \text{Ad}_{v_{k+1}}^{\pm 1} Y \, dv_{k+1} \cdots dv_1.$$

(Note the subscript "0" in $\text{Ad}_0^{\pm 1} Y$ in each of the above formulas except for the one for the reminder term R_k.)

In order to prove the above lemma we shall first prove the following estimate. Below we shall denote by $|\psi|$ the absolute value of ψ, if ψ is a scalar, and the "max" norm $|\psi| = \max\{|\psi_1|, \cdots, |\psi_n|\}$, if ψ is a vector $\psi = (\psi_1, \cdots, \psi_n)$.

LEMMA 7.2. *Let x be a point in $\mathbb{R}^n$. If $Y_0, \cdots, Y_k$ are real analytic vector fields on a subset of $\mathbb{R}^n$ containing x that have complex analytic continuations (denoted by the same letters) to the closed polydisc $D = D_{x,r} = \{z \in \mathbb{C}^n | |z_1 - x_1| \leqq r, \cdots, |z_n - x_n| \leqq r\}$, then*

$$|\text{ad } Y_k \cdots \text{ad } Y_2(Y_1)(x)| \leqq \sup_{z \in D} |Y_k(z)| \cdots \sup_{z \in D} |Y_1(z)| (2/r)^{k-1} k^k. \tag{19}$$

Proof. Before we prove the estimate in the lemma, we shall derive the following estimate. Let ϕ be a real analytic function which has a complex analytic extension to the polydisc D. Then the iterated derivative of ϕ along the vector fields $Y_1, \cdots, Y_k$ can be estimated by

$$|Y_k \cdots Y_1 \phi(x)| \leqq \sup_{z \in D} |\phi(z)| \sup_{z \in D} |Y_1(z)| \cdots \sup_{z \in D} |Y_k(z)| (k/r)^r. \tag{20}$$

To prove this estimate we use a method of Sussmann [34] (proof of Lemma 4.2) which reduces the problem to Cauchy inequalities. Consider the complex analytic vector

fields $z_1 Y_1, \cdots, z_k Y_k$ defined on D, where $z_1, \cdots, z_k$ are complex parameters in the unit disc $\{z \| z| \leqq 1\}$. Let $\exp(t z_i Y_i)$ denote the flow of $z_i Y_i$ in $\mathbb{C}^n$. Then

$$\phi \circ \exp(t_1 z_1 Y_1) \circ \cdots \circ \exp(t_k z_k Y_k)(x)$$

is a well-defined analytic function on the unit polydisc $|z_1| \leqq 1, \cdots, |z_k| \leqq 1$, if

$$|t_i| \leqq r(k \sup |Y(z)|_{z \in D})^{-1}, \qquad i = 1, \cdots, k \tag{21}$$

(as the concatenation of the trajectories of $z_1 Y_1, \cdots, z_k Y_k$ starting from x does not leave D if $t_1, \cdots, t_k$ satisfy the above inequalities). From the Cauchy inequality we obtain then that the iterated derivative at the origin of this function with respect to $z_1, \cdots, z_k$ is estimated by the supremum of this function on the unit polydisc. This gives the inequality

$$|(t_k Y_k) \cdots (t_1 Y_1)\phi(x)| \leqq \sup_{z \in D} |\phi(z)|.$$

If we take the maximal values of $t_1, \cdots, t_k$ in the inequalities (21), the above gives (20).

The estimate in (20) gives the inequalities

$$|Y_{i_k} \cdots Y_{i_1} \phi_i(x)| \leqq \sup_{z \in D} |Y_1(z)| \cdots \sup_{z \in D} |Y_k(z)| k^k r^{-k+1}, \tag{22}$$

for $\phi_i = x_i$ and $i_1, \cdots, i_k$ any permutation of $1, \cdots, k$. These inequalities imply the estimate in (19) as the left-hand side of this estimate can be replaced by the components of the vector field given by ad $Y_k \cdots$ ad $Y_1 \phi_i$ and each such component consists of 2^{k-1} terms of the form as in (22) (this follows from the definition of the Lie bracket as a commutator). □

Proof of Lemma 7.1. Integration of the first equation in Proposition 3.3 between 0 and u gives

$$\mathrm{Ad}_u Y = \mathrm{Ad}_0 Y + \int_0^u \mathrm{ad}\, X_v^+ (\mathrm{Ad}_v Y)\, \mathrm{d}v.$$

Replacing $\mathrm{Ad}_v Y$ on the right by this expression yields

$$\mathrm{Ad}_u Y = \mathrm{Ad}_0 Y + \int_0^u \mathrm{ad}\, X_v^+ (\mathrm{Ad}_0 Y)\, \mathrm{d}v + \int_0^u \int_0^{v_1} \mathrm{ad}\, X_{v_1}^+ \mathrm{ad}_{v_2}^+ (\mathrm{Ad}_{v_2} Y)\, \mathrm{d}v_2\, \mathrm{d}v_1.$$

Repeating such a replacing k times gives the "+" case of formula (18). The "−" case follows by the reversion principle.

To prove the first formula of the lemma we shall now use the estimate in Lemma 7.2. Our families of vector fields, X_u^+ and $\mathrm{Ad}_u Y$, are analytic with respect to x and u. Let us fix an $x \in \mathbb{X}$. Then, there exist an $r > 0$ and a u_0 such that both families have complex analytic extensions to the complex polydisc D in $\mathbb{C}^n$, with the (real) center at x and radius r, for all $u \in [0, u_0]$. Denote

$$C = \sup_{z \in D, u \in [0, u_0]} |X_u^+(z)|, \qquad D = \sup_{z \in D, u \in [0, u_0]} |\mathrm{Ad}_u Y(z)|.$$

Lemma 7.2 gives the following estimate for $R_k(x)$ with, if $u \in [0, u_0]$,

$$|R_k(x)| \leqq (2/r)^k (k+1)^{k+1} C^{k+1} D \int_0^u \int_0^{v_1} \cdots \int_0^{v_k} \mathrm{d}v_{k+1} \cdots \mathrm{d}v_1$$

$$= C D u_0 (2 C u_0 / r)^k \frac{(k+1)^{k+1}}{(k+1)!}.$$

From Stirling's formula,

$$\lim_{k\to\infty} (2\pi k)^{1/2} e^k k^k (k!)^{-1} = 1,$$

it follows then that $R_k(x)$ tends to zero as k tends to infinity. This implies that the first series in the lemma converges.

The second formula follows from the first by the reversion principle. □

Both expansions in Lemma 7.1 can be combined to obtain a more general expansion. In order to have a compact expression for this expansion we introduce the following notation. Define the following linear operators acting on vector fields Y or, more generally, on smooth families of vector fields $Y_{(\cdot)}$ depending on $u \in \mathbb{U}$:

$$\operatorname{ad} I_u^{\sigma,i} Y_{(\cdot)} := \int_0^u \int_0^{v_1} \cdots \int_0^{v_{i-1}} \operatorname{ad} X_{v_1}^{\sigma} \cdots \operatorname{ad} X_{v_i}^{\sigma} Y_{v_i} \, dv_i \cdots dv_1,$$

and $\operatorname{ad} I_u^{\sigma,0} Y_{(\cdot)} = Y_u$, where σ is either $+$ or $-$. With this notation, formula (18) in Lemma 7.1 takes the form

$$\operatorname{Ad}_u^{\pm 1} Y = \sum_{i=0}^{k} \operatorname{ad} I_u^{\pm,i} \operatorname{Ad}_0^{\pm 1} Y + \operatorname{ad} I_u^{\pm,k+1} \operatorname{Ad}_{(\cdot)}^{\pm 1} Y.$$

Finally, using analogous techniques as above, one can also establish the forward/backward version of the above.

LEMMA 7.3. *If f and the vector field Y are analytic, then the following expansion holds*:

$$\operatorname{Ad}_{u_k \cdots u_1}^{\varepsilon_k \cdots \varepsilon_1} Y = \sum_{i_1 \geqq 0, \cdots, i_k \geqq 0}^{\infty} \operatorname{ad} I_{u_k}^{\sigma_k, i_k} \operatorname{Ad}_0^{\varepsilon_k} \cdots \operatorname{ad} I_{u_1}^{\sigma_1, i_1} \operatorname{Ad}_0^{\varepsilon_1} Y,$$

where σ_j is the sign of ε_j, $j = 1, \cdots, k$, and the series converges pointwise for small enough u's.

From this we can draw the following conclusions.

COROLLARY 7.4. *If the system is analytic and $\mathbb{U}$ is connected, then*

$$L^+(x) = \Gamma^+(x), \quad L^-(x) = \Gamma^-(x), \quad L(x) = \Gamma(x),$$

for any $x \in \mathbb{X}$.

Again, the result is valid also in the nonconnected case provided that one modifies the definitions of the Lie algebras as explained in Remark 4.5.

Because of Corollary 7.4, part (b) is equivalent to part (a) in Theorem 6. This provides the promised direct proof of part (b) of Theorem 6.

8. Sampling. In this section, we explain briefly how some of our results can be applied to the sampling problem. More details are given in the conference paper [31]. For other related facts about sampling, the reader should consult [19] and [21].

When a continuous-time system is digitally controlled, decisions are often restricted to be taken at fixed times $0, \delta, 2\delta, \cdots$; $\delta > 0$ is the *sampling time.* Under what is often called zeroth-order hold sampled control, the resulting situation can be modeled through the constraint that the inputs applied be constant on intervals of length δ. It is thus of interest to characterize the preservation of basic system properties when the controls are so restricted. For controllability, this problem motivated the results in the classical paper of Kalman, Ho, and Narendra [13]. This studied the case of linear systems and established that controllability when sampling at intervals of length δ is preserved if $\delta(\lambda - \mu)$ is not of the form $2k\pi i$ for any pair of distinct eigenvalues of the A matrix. The dual version of this result, for observability, is basically the classical

Nyquist–Shannon sampling theorem from digital signal processing, and is often summarized by the statement that controllability (or observability) is preserved provided that one samples at more than twice the natural frequencies of the system. We sketch here how a similar result can be obtained for certain nonlinear systems, using the accessibility conditions given above. This is an improvement over the result in [30], where only the case of bilinear systems was treated, and more importantly, where only transitivity conditions were obtained.

Let $\tilde{\Sigma}_d$ denote the class of all continuous time systems Σ of the type

$$\dot{x} = Fx + \sum_{i=1}^{m} u_i g_i(x), \tag{23}$$

where F is an n by n matrix and the coordinates of all the g_i are polynomials of degree at most d. For instance, $\tilde{\Sigma}_0$ is the class of all linear systems (the g_i's are constant vectors), while $\tilde{\Sigma}_1$ is the class of bilinear systems. Here $x(t) \in \mathbb{R}^n$ and $u_i(t) \in \mathbb{R}$ for each t; n is the dimension of the system, m the number of independent controls. We shall study controllability properties of (23) from the initial state $x_0 = 0$. Nonequilibrium initial states can also be studied, but we restrict ourselves to the equilibrium case, always reducible to $x_0 = 0$, for simplicity. We let $f(x) = Fx$ be the linear vector field corresponding to the matrix F.

We shall say that the *natural frequencies* of the system (23) are the imaginary parts of the eigenvalues of F, and let $\Omega(\Sigma, 0)$, or just Ω, be the set of these numbers (counted with multiplicities). Note that since F is real, $-\omega \in \Omega$ whenever $\omega \in \Omega$. For each nonnegative integer j we denote by $\mathscr{B}_j$ the set of all linear combinations

$$\frac{1}{k} \sum_{i=1}^{n} \rho_i \omega_i \tag{24}$$

with k any nonzero integer, $\omega_1, \cdots, \omega_n$ the natural frequencies, and the ρ_i's nonnegative integers satisfying

$$\sum_{i=1}^{n} \rho_i = 2j + 2.$$

Note that if λ is the largest of the ω_i (equivalently, the largest absolute value of these), each element of $\mathscr{B}_j$ is in magnitude bounded by $(2j+2)\lambda$.

Denote the set of states of the continuous time system Σ that can be reached from 0 in time $T > 0$, using arbitrary (measurable locally integrable) controls $u(\cdot)$ by A^T. We shall say that the system (23) is (*forward*) *accessible from* 0 if A^T has nonempty interior for some $T > 0$. Let $\omega > 0$ be any real number. We shall say that Σ is *ω-accessible from* 0, or *accessible under sampling at frequency ω from* 0, if the set of states A_ω^T reachable from 0 in time T using controls sampled at that frequency has a nonempty interior. A control $u(\cdot)$ defined on an interval $[0, T]$ is said to be sampled at frequency ω (in radians/sec) if and only if T is an integer multiple of $\delta := 2\pi/\omega$, say $T = r\delta$, and there are vectors

$$v_1, \cdots, v_r$$

such that $u(t) \equiv v_i$ on the interval $[(i-1)\delta, i\delta)$. Thus accessibility under sampling corresponds to forward accessibility for a discrete time system derived from the corresponding Σ and ω. With this definition it is clear that ω-accessibility for even a single ω implies accessibility. The following theorem from [31] provides a converse to this fact. The corollary is immediate from the theorem and the discussion given above about the largest frequency λ.

THEOREM 10. *Assume that $\Sigma \in \tilde{\Sigma}_d$ is accessible from 0. If $\omega > 0$ is not in $\mathscr{B}_j$ for any $j \leqq d$, then Σ is also ω-accessible.*

COROLLARY 8.1. *Accessibility is preserved under sampling for systems in $\tilde{\Sigma}_d$ provided that the sampling frequency be larger than $2d+2$ times the largest natural frequency of the system.*

The reader is referred to [31] for the details of the reduction of the above theorem to the results given earlier in this paper. However, we wish to at least sketch this reduction here. For each fixed δ, the vector fields X^+ can be explicitly described using a Lie expansion formula ([4], see also [25], and especially [19], [21]):

$$X^+_{0,i} = \frac{\partial}{\partial \varepsilon}\bigg|_{\varepsilon=0} e^{-\delta f} e^{\delta(f+\varepsilon g_i)}(x).$$

(We will be interested here only on the case $u = 0$.) Under suitable assumptions, which are satisfied for the class of systems considered here, this can also be written as

$$\theta_\delta(\mathrm{ad}\, f)(g_i),$$

where as earlier $\mathrm{ad}\, f$ is the operator $\mathrm{ad}\, f(h) = [f, h]$ and for each fixed real number δ, θ_δ is the entire function

$$\theta_\delta(z) := \frac{e^{\delta z} - 1}{z}.$$

Finally, one also has a formal expression, for each fixed δ,

$$\mathrm{Ad}_0 = e^{\delta\, \mathrm{ad}\, f}.$$

This expression can be made rigorous when acting on polynomial vector fields such as those that appear in the classes $\tilde{\Sigma}_d$. Thus the Lie algebra L^+, for each fixed δ, contains the Lie algebra $\tilde{L}^+$ generated by the vector fields

$$\{\theta_\delta(\mathrm{ad}\, f)(g_1), \cdots, \theta_\delta(\mathrm{ad}\, f)(g_m), e^{\delta\, \mathrm{ad}\, f}\theta_\delta(\mathrm{ad}\, f)(g_1), \cdots, e^{\delta\, \mathrm{ad}\, f}\theta_\delta(\mathrm{ad}\, f)(g_m), \cdots,$$
$$e^{\delta k\, \mathrm{ad}\, f}\theta_\delta(\mathrm{ad}\, f)(g_1), \cdots e^{\delta k\, \mathrm{ad}\, f}\theta_\delta(\mathrm{ad}\, f)(g_m), \cdots\},$$

which equals the span of the vector fields

$$\{g_1, \cdots, g_m, [f, g_1], \cdots, [f, g_m], \cdots, \mathrm{ad}^k f(g_1), \cdots, \mathrm{ad}^k f(g_m), \cdots\}$$

when δ is as in Theorem 10 (see [31] for details). It follows that $\tilde{L}^+$ coincides with the strong accessibility Lie algebra associated to the original continuous time system, which has full rank at the origin due to the accessibility assumption. Then Theorem 4 gives the desired result.

9. An example. Consider the following invertible polynomial system with $\mathbb{X} = \mathbb{R}^3$.

$$\begin{aligned} x^+ &= x(z^2+1)^2 \\ y^+ &= y(z^2+1)^3 \\ z^+ &= z + u, \end{aligned} \tag{25}$$

where we are using the superscript + to denote time shift, and we denote coordinates as (x, y, z). Calculating, we obtain that $X^+_u = -2z(z^2+1)^{-1}Z - X^-_u$ and $X^-_u = (0, 0, -1)'$, where Z is the vector field

$$\begin{pmatrix} 2x \\ 3y \\ 0 \end{pmatrix},$$

for each $u \in \mathbb{R}$. Since the basic vector fields X_u^+ and X_u^- turn out to be independent of u in this example, we drop the subscripts u from now on. Further,

$$\text{Ad}_0 X^+ = \begin{pmatrix} -8xz(z^2+1)^{-1} \\ -12yz(z^2+1)^{-1} \\ 1 \end{pmatrix} = 2X^+ + X^-, \tag{26}$$

from which it follows that

$$\text{span}\{X^+, \text{Ad}_0 X^+\} = \text{span}\{X^+, X^-\}.$$

The identity $\text{Ad}_0 X^- = -X^+$ (cf. Proposition 3.2(b)) implies that

$$\text{Ad}_0^2 X^+ = 2\,\text{Ad}_0 X^+ - X^- \in \text{span}\{X^+, X^-\},$$

so the linear span of the set of all generators of L^+, $\{\text{Ad}_0^k X^+, k \geqq 0\}$, coincides with the span of X^+ and X^-. Similarly, applying Ad_0^{-1} to both sides of (26),

$$\text{Ad}_0^{-1} X^- = X^+ - 2\,\text{Ad}_0^{-1} X^+ = X^+ + 2X^-,$$

so the span of the $\{\text{Ad}_0^k X^-, k \leqq 0\}$, the generators of L^-, is again the same. Finally,

$$[X^+, X^-] = 2(1-z^2)(z^2+1)^{-2} Z,$$

from which it follows that $\{X^-, X^+, [X^+, X^-]\}$ and $\{X^-, Z\}$ span the same C^∞ submodule of vector fields. The latter set is involutive, and we conclude that, for this example,

$$L^+ = L^- = L.$$

Thus the orbits have dimension 2 through each point except at those points with $x = y = 0$, where Z vanishes, and there the dimension is 1. The tangent spaces are given by the vectors $\partial/\partial z$ and $2x\partial/\partial x + 3y\partial/\partial y$. The forward and backward accessible sets contain open subsets of each orbit, by the equality of these Lie algebras.

Of course, in this very simple example one can analyze the system directly. The initial states (x_0, y_0, z_0) with $x_0 = y_0 = 0$ are such that the only possible directions of movement are those in which z changes, as is clear from the equations (25), consistently with the above conclusion about tangent spaces. The points where exactly one of x_0 or y_0 is nonzero are also easy to analyze. Take now a point with both x_0 and y_0 nonzero. Consider the set C consisting of all points (x, y, z) with

$$y_0^2 x^3 = x_0^3 y^2.$$

This is the cross product of a cusp with a line. The forward accessible set consists of all (x, y, z) in C with sign $y = \text{sign } y_0$ for which $|x| \geqq |x_0|$ and $|y| \geqq |y_0|$. The backward accessible has both these inequalities reversed, and the orbit consists of the branch of C with just sign $y = \text{sign } y_0$. Note how each such set C, an algebraic variety, can be stratified into three submanifolds, which turn out to be its singular set (the orbit of $(0, 0, 0)$), the orbit of (x_0, y_0, z_0), and the orbit of the "conjugate" point $(x_0, -y_0, z_0)$. See Fig. 6 for a picture of a typical cross-section with constant z.

Thus in this example both the forward-accessible set and the orbit from each point are open subsets of an irreducible algebraic variety. More generally, similar behavior may be expected when dealing with invertible polynomial systems and equilibrium initial states. We conjecture that the orbit is an open subset of the *quasi-reachable* set in the sense of [26] and [27]. This is an algebraic variety, and it can be computed explicitly, via Jacobians of the n-step transition map. Note that polynomial invertible systems may exhibit highly nonlinear behavior, such as in the case $x^+ = x^3 + x + u$,

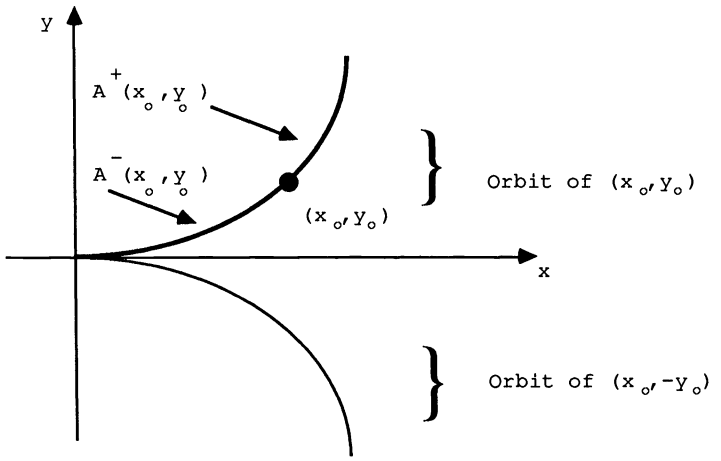

FIG. 6. *Forward and backward accessible sets in example* $(x_0, y_0 > 0)$.

where the inverse of the transition mapping is not even rational. We plan to study such systems in greater depth in the future.

10. An alternative formalism. We now briefly describe the formalism due to Monaco and Normand-Cyrot; the thesis [25] and the papers [17]–[22], as well as the references given there, should be consulted for details.

Their approach is based on the introduction of certain operators and the formal relations that these satisfy. As a first step, one writes the system equations as

$$x^+ = x + f(x, u)$$

so that the new "f" is our $f(x, u) - x$. Thus now f indicates what the increment is, rather than the new state, making things more analogous to differential equations. (This is similar to the introduction of the forward difference operator in numerical analysis.)

For simplicity we shall assume again that inputs are scalar, and also that $\mathbb{X} = \mathbb{R}^n$. Thus we may identify functions $F: \mathbb{R}^n \to \mathbb{R}^n$ (in particular, the functions $F = f(\cdot, u)$) with vector fields, in the usual coordinate system for $\mathbb{R}^n$,

$$F = \sum_{i=1}^{n} F_i(\cdot) \frac{\partial}{\partial x_i}.$$

We will work purely formally, since the intent is merely to point out the relations with the alternative notations in the papers mentioned above. Formally then, one introduces the operators on smooth functions

$$L_F^{\otimes k} := \sum_{i_1, \cdots i_k = 1}^{n} F_{i_1}(\cdot) \cdots F_{i_k}(\cdot) \frac{\partial^k}{\partial x_{i_1} \cdots \partial x_{i_k}}$$

and the complete series

$$\Delta_F := I + \sum_{k \geqq 1} \frac{1}{k!} L_F^{\otimes k}.$$

Now one can obtain similar series for compositions and inverses of the dynamics map.

Further, the vector fields that we use can be expressed then as

$$X_u^+(x) = \frac{\partial}{\partial v}\Big|_{v=0} \Delta_{f(\cdot,u+v)} \circ \Delta^{-1}_{f(\cdot,u)}(\mathrm{Id})|_x,$$

$$X_u^-(x) = \frac{\partial}{\partial v}\Big|_{v=0} \Delta^{-1}_{f(\cdot,u+v)} \circ \Delta_{f(\cdot,u)}(\mathrm{Id})|_x,$$

$$Y_u^+(x) = \frac{\partial}{\partial v}\Big|_{v=0} \Delta_{f(\cdot,u)} \circ \Delta^{-1}_{f(\cdot,u+v)}(\mathrm{Id})|_x,$$

$$Y_u^-(x) = \frac{\partial}{\partial v}\Big|_{v=0} \Delta^{-1}_{f(\cdot,u)} \circ \Delta_{f(\cdot,u+v)}(\mathrm{Id})|_x,$$

$$\mathrm{Ad}_0^k X_u^\sigma(x) = \frac{\partial}{\partial v}\Big|_{v=0} \Delta^k_{f(\cdot,0)}\Delta^\sigma_{f(\cdot,u+v)} \circ \Delta^{-\sigma}_{f(\cdot,u)}\Delta^{-k}_{f(\cdot,0)}(\mathrm{Id})|_x,$$

and many properties of these vector fields can be obtained from the corresponding expansions.

The reader is directed to the above references for details on how these expansions can be very useful in studying, among others, problems of disturbance decoupling, sampling, Volterra expansions, linearization, and realization.

A CONSTRAINED LEAST SQUARES REGULARIZATION METHOD FOR NONLINEAR ILL-POSED PROBLEMS*

CURTIS R. VOGEL†

Abstract. This paper deals with a method for solving ill-posed, nonlinear Hilbert space operator equations $F(x) = y$. Regularization is obtained by solving a constrained least squares regularization problem

$$\min \|F(x) - y\|^2 \quad \text{subject to } J(x) \leqq \beta^2.$$

β serves as a regularization parameter, and $J(x)$ is a quadratic penalty functional. To robustly and efficiently solve this regularization problem, we apply a trust region method. At each iteration, the quadratic penalty constraint is retained, a Gauss–Newton approximation to the objective functional is taken, and we add a quadratic trust region constraint. The resulting quadratic subproblem is then reformulated as a nonlinear complementarity problem and solved using Newton's method.

This paper applies methods to find approximate solutions to a severely ill-posed nonlinear first kind integral equation arising in geophysics. The method of Generalized Cross Validation (GCV) is used to pick the regularization parameter when random error is present in the discrete data.

Key words. inverse problems, ill-posed problems, regularization, constrained optimization

AMS(MOS) subject classifications. 45G, 49, 65

1. Introduction. In this paper we introduce a constrained least squares regularization method for solving nonlinear ill-posed problems in a Hilbert space setting. Unless otherwise indicated, "$\|\cdot\|$" refers to the appropriate Hilbert space norm. Consider the operator equation

$$F(x) = y, \tag{1.1}$$

where the operator F is nonlinear and maps a separable Hilbert space X into a separable Hilbert space Y. Problem (1.1) is *well-posed* provided: (i) for any $y \in Y$, there exists a solution $x \in X$ for which $F(x) = y$; (ii) the solution x is unique; (iii) the solution x depends continuously on the data y. Otherwise, the problem is *ill-posed.* Examples of ill-posed nonlinear problems include inverse (i.e., parameter estimation) problems for differential equations [1], [6], inverse scattering [7], and nonlinear Fredholm first kind integral equations [10], in which case F is an integral operator of the form

$$F(x)(t) = \int_a^b k(t, \tau, x(\tau))\, d\tau, \qquad a \leqq t \leqq b, \quad x \in X, \tag{1.2}$$

and k is nonlinear in x.

To obtain reasonable approximate solutions, we apply regularization. Regularization methods replace the ill-posed problem with a stabilized problem whose solution depends on a parameter, referred to as the regularization parameter. These methods should have the following features:

1. The regularized problem is well-posed in the sense that a solution exists. (For nonlinear problems, uniqueness and continuous dependence usually cannot be guaranteed.)

* Received by the editors October 20, 1986; accepted for publication March 24, 1989.

† Department of Mathematical Sciences, Montana State University, Bozeman, Montana 59717. This research was partially supported by the National Science Foundation grant DMS-86-02000.

2. One has a "reasonable" means of choosing the regularization parameter, especially when error is present in the data.

3. As the error in the data tends to zero, regularized solutions should converge to the solution of the unperturbed problem, provided the regularization parameter is picked correctly.

Perhaps the most widely used regularization method is the method of Tikhonov Regularization [13] (also known as Regularized Output Least Squares [3], and in statistical circles as the Penalized Likelihood Method [10], [7]) in which one solves the unconstrained minimization problem

$$\min_{x\in X}\{\|F(x)-y\|^2+\alpha J(x)\}. \tag{1.3}$$

Here $\alpha>0$ is the regularization parameter, and $J(x)$ is a penalty functional whose purpose is to stabilize the minimization and provide a priori information about the solution.

In this paper we consider an alternative approach in which regularization is obtained by solving the constrained least squares regularization problem

$$\min_{x\in X}\|F(x)-y\|^2 \quad \text{subject to } J(x)\leqq\beta^2. \tag{1.4}$$

For this method, β is the regularization parameter.

In § 2 we examine the well-posedness of the regularized problem (1.4). We also examine convergence of solutions of (1.4) to a solution of (1.1) as error in the data tends to zero when β is chosen appropriately. In addition, we discuss stability of regularized solutions.

In § 3 we present a nonlinear ill-posed model problem of the form (1.1), (1.2) arising in geophysics. We also discuss the choice of the spaces X and Y for this particular problem, and we show that the assumptions required in § 2 hold for our model problem.

In § 4 we consider the numerical solution of the regularized problem (1.4) when $J(x)$ is a quadratic functional using a trust region method. At each iteration we apply a Gauss-Newton approximation to the object functional $f(x)=\|F(x)-y\|^2$, thus obtaining a quadratic approximation to f. We retain the quadratic regularization constraint and impose an additional quadratic trust region constraint, where the trust region parameter is chosen to decrease the objective function. The resulting quadratic minimization subproblem is diagonalized using the singular value decomposition and then reformulated as a (quadratic) nonlinear complementarity problem. This dual problem in two variables (the Lagrange multipliers for the primal problem) is then solved using Newton's method. The resulting algorithm is robust and quite efficient.

Finally in § 5, we present some numerical results for our algorithm applied to the model problem of § 3. In this section, we also discuss the practical choice of the regularization parameter β when error is present in the discrete data. We apply the method of Generalized Cross Validation to an example where random error is added to the data.

2. Existence and characterization of regularized solutions. The results of the first two theorems below have been obtained by Seidman and Vogel [11] under somewhat more general conditions. We will verify that the assumptions used below are actually satisfied for our model problem in § 3. We first consider existence of regularized solutions.

To simplify notation, we define the objective functional in (1.4),

$$f(x):=\|F(x)-y\|^2,$$

and the constraint set

$$S_\beta := \{x \in X: J(x) \leqq \beta^2\}.$$

THEOREM 2.1. *Let $F: X \to Y$ be weakly continuous, and let the penalty functional $J: X \to R^+ \cup \{0\}$ be weakly lower semicontinuous. Suppose that for each $\gamma \geqq 0$, $\{x \in X: \|x\| \leqq \gamma\} \cap S_\beta$ is weakly compact. Also, suppose $f(x)$ and the penalty functional $J(x)$ are jointly coercive, i.e.,*

$$\lim_{\|x\| \to \infty} [f(x) + J(x)] = \infty.$$

Then problem (1.4) *has a solution.*

Proof. Let $\{x_k\}$ be a minimizing sequence for (1.4). Then by joint coercivity, there exists $\gamma \geqq 0$ such that $\|x_k\| \leqq \gamma$. By the weak compactness assumption, we can extract a subsequence $\{x_{k(j)}\}$ that converges weakly to some x_*. By weak lower semicontinuity of J, $J(x_*) \leqq \liminf J(x_{k(j)}) \leqq \beta^2$. By weak continuity of F and the lower semicontinuity of the Y-norm,

$$\begin{aligned} \|F(x_*) - y\|^2 &\leqq \liminf \|F(x_{k(j)}) - y\|^2 \\ &= \inf \{\|F(x) - y\|^2: x \in S_\beta\}. \end{aligned}$$

□

To obtain a convergence result for perturbed data, we need to assume local uniqueness of the solution to the unperturbed problem (1.1). We also make assumptions concerning solutions to (1.4) with perturbations to the data y and the operator F:

(A1) Let $\bar{y} \in Y$ and let $\bar{x}$ be the unique solution to $F(x) = \bar{y}$ in the region $S_{\bar{\beta}}$, where $\bar{\beta}^2 := J(\bar{x})$.

(A2) Let $y_k \to \bar{y}$ (strong convergence in Y) and $F_k \to F$ in the sense that if x_k converges weakly to x_*, then $F_k(x_k) \to F(x_*)$.

(A3) Let $\beta_k > 0$ and x_k be chosen so that

$$\|F_k(x_k) - y_k\|^2 = \inf \{\|F_k(x) - y_k\|^2: J(x) \leqq \beta_k^2\}, \qquad J(x_k) \leqq \beta_k^2,$$

and suppose $\lim \beta_k = \bar{\beta}$. (Note that such an x_k exists by Theorem 2.1.)

(A4) Suppose J and $f_k(x) := \|F_k(x) - y_k\|^2$ satisfy the coercivity condition

$$\lim_{\|x\| \to \infty} \inf_k [f_k(x) + J(x)] = \infty.$$

(A5) If $\beta_j^2 \to J(x)$, there exists a sequence $\{x_j\}$ for which $J(x_j) \leqq \beta_j^2$ and x_j converges weakly to x.

(A6) If x_k converges weakly to x_* and $J(x_k) \to J(x_*)$, then x_k converges strongly to x_*.

THEOREM 2.2. Under assumptions (A1)–(A6), x_k converges strongly to $\bar{x}$.

Proof. By the coercivity assumption (A4), $\{x_k\}$ is bounded, so we can extract a subsequence $\{x_{k(j)}\}$ converging weakly to some x_*. Since $\beta_{k(j)}^2 \to \bar{\beta}^2 = J(\bar{x})$, by assumption (A5) we can choose a sequence $\{\bar{x}_j\}$ such that $J(\bar{x}_j) \leqq \beta_{k(j)}^2$ and $\bar{x}_j$ converges weakly to $\bar{x}$. Then by the lower semicontinuity of the Y-norm,

$$\begin{aligned} \|F(x_*) - \bar{y}\| &\leqq \liminf \|F_k(x_{k(j)}) - y_{k(j)}\| \\ &= \liminf \{\|F_{k(j)}(x) - y_{k(j)}\|: J(x) \leqq \beta_{k(j)}^2\} \quad \text{by (A3)} \\ &\leqq \lim \|F_{k(j)}(\bar{x}_j) - y_{k(j)}\| \quad \text{by (A5)} \\ &\leqq \lim [\|F_{k(j)}(\bar{x}_j) - F(\bar{x})\| + \|y_{k(j)} - \bar{y}\|]. \end{aligned}$$

By assumption (A2), the last right-hand side goes to 0, so x_* solves $F(x) = \bar{y}$.

By the weak lower semicontinuity of J, $J(x_*) \leqq \liminf J(x_{k(j)}) \leqq \lim \beta_{k(j)}^2 = \bar{\beta}^2$. By the uniqueness assumption (A1), $x_* = \bar{x}$. Moreover, since the above argument can be repeated for any subsequence, x_k itself converges weakly to $\bar{x}$. We next show that $J(x_k) \to \bar{\beta}^2$. The theorem will then follow from assumption (A6).

By assumption (A3), $\limsup J(x_k) \leqq \bar{\beta}^2$. Now suppose $\liminf J(x_k) < \bar{\beta}^2$. Then there exists $\alpha < \beta$ and a subsequence $x_{k(j)}$ with $J(x_{k(j)}) \leqq \alpha^2$. As was done above, we can extract a further subsequence converging to some $\hat{x}$ for which $F(\hat{x}) = \bar{y}$ and $J(\hat{x}) \leqq \alpha^2 < \bar{\beta}^2$. But this contradicts the uniqueness assumption (A1). Hence, $\liminf J(x_k) = \limsup J(x_k) = \bar{\beta}^2 = J(\bar{x})$. □

Remark 2.3. Assumptions (A5) and (A6) hold for many commonly used penalty functionals. For instance, if $J(x) = \|x\|^2$, (A6) is the Afimov-Stekin condition. Assumption (A5) holds if the constraint sets S_{β_j} are closed and convex, in which case we may take x_j for which $\|x_j - x\| = \inf\{\|u - x\|: u \in S_{\beta_j}\}$.

Remark 2.4. Assuming existence but *not* local uniqueness of solutions to $F(x) = \bar{y}$, the above proof shows only the existence of a subsequence which converges weakly to a solution of $F(x) = \bar{y}$.

We next look at a characterization of regularized solutions. We assume that F is twice continuously differentiable with derivatives denoted by $F'(x)$ and $F''(x)$, respectively. Let the superscript "T" denote Hilbert space adjoint. We will also assume a quadratic form for the penalty functional,

$$J(x) = \langle Bx, x \rangle, \tag{2.1}$$

where B is a bounded, self-adjoint positive definite linear operator on X. Recall that $f(x) := \|F(x) - y\|^2$. In addition, we define the constraint functional

$$c(x) := J(x) - \beta^2.$$

THEOREM 2.5. *If x is a solution to* (1.4) *and $\beta > 0$, then there exists $\lambda \in \mathbf{R}$ such that*

$$f'(x) + \lambda c'(x) = 0, \tag{2.2}$$

$$c(x) \leqq 0, \lambda \geqq 0, \tag{2.3}$$

$$\lambda c(x) = 0. \tag{2.4}$$

Proof. See Luenberger [8, p. 249]. The left-hand side of (2.2) is half the gradient of the Lagrangian

$$L_\lambda(x) := f(x) + \lambda c(x).$$

To see that a solution x to (1.4) is a regular point for $c(x)$, take $h = -\frac{1}{2}x$. At such a solution, $c(x) \leqq 0$, and

$$c(x) + \langle c'(x), h \rangle = J(x) - \beta^2 - J(x) = -\beta^2 < 0. \qquad \square$$

In general, solutions to (1.4) need not be locally unique. The following theorem provides conditions for local uniqueness and continuous dependence of local solutions with respect to perturbations in the data y.

THEOREM 2.6. *Let $f_0(x) := \|F(x) - y_0\|^2$ and suppose x_0 is a solution to*

$$\min_{x \in X} f_0(x) \quad \textit{subject to } c(x) \leqq 0.$$

Suppose also that for some $\alpha > 0$, the Hessian of the Lagrangian,

$$L''_\lambda(x_0) := f_0''(x_0) + \lambda c''(x_0) = 2[F''(x_0)^T(F(x_0) - y_0) + F'(x_0)^T F'(x_0) + \lambda B],$$

satisfies

$$\langle L''_\lambda(x_0)s, s \rangle \geqq 2\alpha \|s\|^2 \textit{ whenever } \lambda \langle c'(x_0), s \rangle = 0. \tag{2.5}$$

Then there exists $\tilde{\alpha} > 0$, $\delta > 0$, $r > 0$ *such that* (1.4) *has a solution* x *which is locally unique in some neighborhood* $\|x - x_0\| < \delta$ *whenever* $\|y - y_0\| < r$, *and*

$$\|x - x_0\| \leqq \tilde{\alpha}\sqrt{\|y - y_0\|}. \tag{2.6}$$

Proof. Since F is twice continuously differentiable, so is f, and

$$f_0(x_0 + s) - f_0(x_0) = \langle f'(x_0), s\rangle + \tfrac{1}{2}\langle f''(x_0)s, s\rangle + o(\|s\|^2). \tag{2.7}$$

If $c(x_0) = 0$ and $c(x_0 + s) \leqq 0$, then since $c(x)$ is quadratic,

$$0 \geqq c(x_0 + s) - c(x_0) = \langle c'(x_0), s\rangle + \tfrac{1}{2}\langle c''(x_0)s, s\rangle.$$

Thus

$$f_0(x_0 + s) - f_0(x_0) \geqq \langle L'_\lambda(x_0), s\rangle + \tfrac{1}{2}\langle L''_\lambda(x_0)s, s\rangle + o(\|s\|^2).$$

By Theorem 2.5, $L'_\lambda(x_0) = f'_0(x_0) + \lambda c'(x_0) = 0$, and by (2.5),

$$f_0(x_0 + s) - f_0(x_0) \geqq \alpha\|s\|^2 + o(\|s\|^2).$$

Thus there exists $\delta > 0$ and $\bar{\alpha}$, $0 < \bar{\alpha} \leqq \alpha$, such that

$$f_0(x_0 + s) - f_0(x_0) \geqq \bar{\alpha}\|s\|^2 \tag{2.8}$$

whenever $\|s\| < \delta$. If $c(x_0) < 0$, then $f'(x_0) = 0$, $\lambda = 0$, and (2.8) follows directly from (2.7) and (2.5). Equation (2.6) now follows from Theorems 4 and 6 in the paper by Alt [2] with $\beta = 2$ and y playing the role of w. □

Remark 2.7. We will observe in § 5 that as β becomes large, λ becomes small, and problem (1.4) becomes unstable. To explain this behavior, suppose $\|F''(x_0)\| \leqq M$, $F'(x_0)$ is compact, and X is infinite-dimensional. We can then choose a sequence $\{s_k\}$ such that $\|s_k\| \leqq 1$, $\langle c'(x_0), s_k\rangle = 0$, and s_k converges weakly to 0. Then

$$\langle L''_\lambda(x_0)s_k, s_k\rangle \leqq 2[M\|F(x_0) - y_0\| + \|F'(x_0)s_k\|^2 + \lambda\|B\|],$$

and since $F'(x_0)$ is compact,

$$\limsup \langle L''_\lambda(x_0)s_k, s_k\rangle \leqq 2[M\|F(x_0) - y_0\| + \lambda\|B\|].$$

Consequently, any constant α for which (2.5) holds must satisfy

$$\alpha \leqq M\|F(x_0) - y_0\| + \lambda\|B\|.$$

Then if $\|F(x_0) - y_0\|$ and λ are very small, α is also very small. In Alt's proof [2], the Lipschitz constant $\tilde{\alpha}$ in (2.6) is inversely proportional to $\bar{\alpha} \leqq \alpha$. In this case, the Lipschitz constant $\tilde{\alpha}$ is very large. This is an indication that problem (1.4) is highly unstable.

3. A model problem. In this section we illustrate the results of § 2 with an example. Consider the nonlinear Fredholm first kind integral equation

$$y(t) = F(x)(t) := \int_a^b \log\left[\frac{(t-\tau)^2 + H^2}{(t-\tau)^2 + (H - x(\tau))^2}\right] d\tau, \tag{3.1}$$

where H is a positive parameter. This equation occurs in inverse gravimetry (see [13, p. 15]). The solution $x(\tau)$, $a \leqq \tau \leqq b$, represents the vertical deviation from constant depth H in the location of the boundary of an object buried beneath the surface of the earth. The geometry is shown in Fig. 1. The data $y(t)$, $a \leqq t \leqq b$, represents gravity measurements at the surface of the earth. In practice, observations of $y(t)$ are available at discrete points, but derivatives of y are not available. Thus we take $Y = L^2(a, b)$. We assume the solution vanishes outside the interval $[a, b]$ and is "smooth" in the

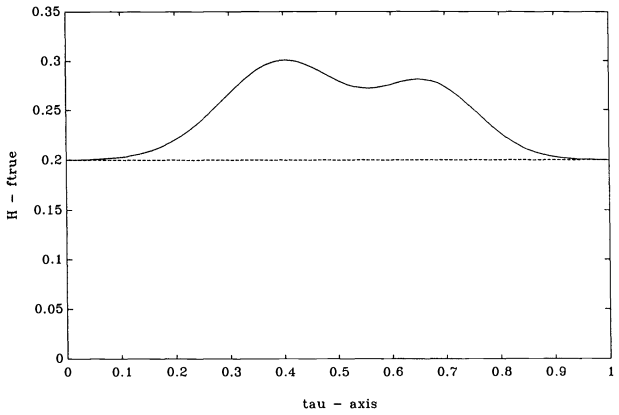

FIG. 1. *Geometry of the gravitational inverse problem.* $z = H - x_{\text{true}}$ *is plotted against* τ.

sense that $\int_a^b x'(\tau)^2\,d\tau$ is bounded. We take $X = H_0^1(a, b) = \{x(\tau), a \leqq \tau \leqq b: x$ is absolutely continuous; $x' \in L^2(a, b)$; $x(a) = x(b) = 0\}$ with inner product

$$\langle x, u\rangle := \int_a^b x'(\tau)u'(\tau)\,d\tau, \qquad x, u \in X, \tag{3.2}$$

and induced norm

$$\|x\| = \sqrt{\int_a^b x'(\tau)^2\,d\tau}, \quad x \in X. \tag{3.3}$$

Remark 3.1. Prilepko [9] has shown that if (3.1) has a solution, the solution is unique provided we make the restriction $H - x(\tau) > 0$. On the other hand, the fact that the right-hand side of (3.1) is analytic as a function of t implies that the range of F is a subset of the analytic functions which is in turn a (dense) proper subset of $Y = L^2(a, b)$. Thus a solution x will not exist for arbitrary $y \in Y$.

The following lemma shows that F is weakly continuous. Since closed balls $\{x \in X: \|x\| \leqq B\}$ are weakly compact, this implies that F is a compact operator. This also shows that the range of F is a proper subset of Y. In addition, the inverse image under F of (noncompact) neighborhoods $N_r(y) = \{z \in Y: \|z - y\| \leqq r\}$, $r > 0$, is unbounded. Hence, we do *not* have continuous dependence of solutions x on the data y.

LEMMA 3.2. *If* $X = H_0^1(a, b)$, $Y = L^2(a, b)$, $F: X \to Y$ *is given in* (1.2), *and* $\partial k/\partial x(t, \tau, x)$ *is continuous in all its arguments, then* F *is weakly continuous.*

Proof. Suppose $\{x_n\}$ converges weakly to x in $H^1(a, b)$. Then there exists $\gamma > 0$ such that $\gamma \geqq \|x_n\|_\infty := \sup\{|x_n(\tau)|: a \leqq \tau \leqq b\}$, and by the mean value theorem,

$$\begin{aligned} |F(x_n)(t) - F(x)(t)| &\leqq \int_a^b \left|\frac{\partial k}{\partial \eta}(t, \tau, \eta(\tau))\right| \cdot |x_n(\tau) - x(\tau)|\,d\tau \\ &\leqq (b-a)C\|x_n - x\|_\infty, \end{aligned}$$

where $\eta(\tau)$ lies between $x_n(\tau)$ and $x(\tau)$ and

$$C = \max\{|\partial k/\partial \eta(t, \tau, \eta)|: a \leqq t, \tau < b, |\eta| \leqq \gamma\}.$$

Consequently,

$$\|F(x_n) - F(x)\| \leqq (b-a)^{3/2}C\|x_n - x\|_\infty.$$

The lemma follows from the fact that weak convergence in $H^1(a, b)$ implies strong convergence in $C[a, b]$. □

COROLLARY 3.3. *Let* $X = H_0^1(a, b)$, $Y = L^2(a, b)$. *For* $F: X \to Y$ *given in* (3.1) *and* β *sufficiently small, problem* (1.4) *has a solution.*

Proof. Let

$$k(t, \tau, x) = \log\left[\frac{(t-\tau)^2 + H^2}{(t-\tau)^2 + (H-x)^2}\right]. \tag{3.4}$$

Then

$$\frac{\partial k}{\partial x}(t, \tau, x) = \frac{2(H-x)}{(t-\tau)^2 + (H-x)^2}. \tag{3.5}$$

If β is sufficiently small, then $H - x(\tau) > 0$ for each $\tau \in [a, b]$, and $\partial k/\partial x$ is continuous. Thus by Lemma 3.2, F is weakly continuous, and by Theorem 2.1, (1.4) has a solution. □

Remark 3.4. In practice, problem (1.4) must be solved numerically. Let P_n denote a projection of X onto an n-dimensional subspace X_n, and suppose $P_n^T \to I_X$ (pointwise convergence to the identity in X). Similarly, let Q_m denote a projection of Y onto an m-dimensional subspace Y_m with $Q_m \to I_Y$ and suppose the Q_m's are uniformly bounded. Define

$$F_{mn}(x) := Q_m F(P_n x). \tag{3.6}$$

Since F is weakly continuous, each F_{mn} is weakly continuous and by Theorem 2.1 we can find a solution x_{mn} to each problem

$$\min_{x \in X} \|F_{mn}(x) - y_m\|^2 \quad \text{subject to } J(x) \leqq \beta_{mn}.$$

Suppose x_{mn} converges weakly to some x_*. For each $u \in X$,

$$\begin{aligned} |\langle P_n x_{mn} - x_*, u\rangle| &\leqq |\langle x_{mn}, P_n^T u - u\rangle| + |\langle x_{mn} - x_*, u\rangle| \\ &\leqq \|x_{mn}\| \, \|(P_n^T - I_X)u\| + |\langle x_{mn} - x, u\rangle|, \end{aligned}$$

so $P_n x_{mn}$ converges weakly to x_*. Then by weak continuity of F,

$$\|F_{mn}(x_{mn}) - F(x_*)\| \leqq \|Q_m\| \, \|F(P_n x_{mn}) - F(x_*)\| + \|(Q_m - I)F(x_*)\| \to 0.$$

This shows F_{mn} converges to F in the sense of assumption (A2) in § 2.

Remark 3.5. The operator F in (3.1) is twice (Frechet) differentiable. The first derivative $F'(x)$: $X \to Y$ is given by

$$[F'(x)u](t) = \int_a^b \frac{\partial k}{\partial x}(t, \tau, x(\tau))u(\tau)\, d\tau, \qquad a \leqq t \leqq b,\ x, u \in X, \tag{3.7}$$

where the kernel $\partial k/\partial x(t, \tau, x)$ is defined in (3.5). $F'(x)$ is compact, since its kernel is square integrable. The second derivative $F''(x): X \times X \to Y$ is given by

$$[F''(x)(u, v)](t) = \int_a^b \frac{\partial^2 k}{\partial x^2}(t, \tau, x(\tau))u(\tau)v(\tau)\, d\tau, \qquad a \leqq t \leqq b,\ x, u, v \in X. \tag{3.8}$$

4. Numerical solution of the regularized problem. To numerically solve (1.4), we obtain a finite-dimensional problem by choosing linearly independent basis functions $\{\phi_j\}_{j=1}^n \subset X = H_0^1(a, b)$ and taking approximations

$$\tilde{x}(\tau) = \sum_{j=1}^n x_j \phi_j(\tau), \qquad x = [x_1, \cdots, x_n]^T \in R^n. \tag{4.1}$$

We also approximate the norm in $Y = L^2(a, b)$ by a discrete sum

$$\|y\| \approx \sqrt{\frac{1}{m} \sum_{i=1}^{m} y(t_i)^2}, \qquad \{t_i\}_{i=1}^{m} \subset [a, b]. \tag{4.2}$$

To put this approximation in the context of the projection operator Q_m of Remark 3.4, we might define

$$Q_m y = \sum_{i=1}^{m} \langle \psi_i, y \rangle \psi_i = \sum_{i=1}^{m} \int_a^b \psi_i(t) y(t)\, dt\, \psi_i,$$

where each ψ_i is a nonnegative "averaging function" whose support consists of disjoint subintervals of $[a, b]$. By the smoothness of $y = F(x)$ (see Remark 3.1), we can apply the mean value theorem for integrals to obtain

$$\langle \psi_i, y \rangle = y(t_i) \int_a^b \psi_i(t)\, dt$$

for some point t_i in the ith subinterval. By scaling the ψ_i's appropriately and by their orthogonality, we obtain the right-hand side of (4.2) by taking $\|Q_m y\|$.

Thus the integral operator F in (3.1) gives rise to an operator $F_{mn}: R^n \to R^m$:

$$[F_{mn}(x)]_i := \int_a^b k(t_i, \tau, \tilde{x}(\tau)), \qquad 1 \leqq i \leqq m. \tag{4.3}$$

Similarly the derivative operator $F'(x)$ in (3.5), (3.7) yields an $m \times n$ matrix:

$$[F'_{mn}(x)]_{ij} = \int_a^b \frac{\partial k}{\partial x}(t_i, \tau, \tilde{x}(\tau)) \phi_j(\tau)\, d\tau, \qquad 1 \leqq i \leqq m, 1 \leqq j \leqq n. \tag{4.4}$$

From (2.1) and (4.1), the constraint $J(\tilde{x}) \leqq \beta^2$ yields $x^T B x \leqq \beta^2$, where B is the symmetric, positive definite matrix with entries

$$[B]_{jk} = \langle B\phi_j, \phi_k \rangle = \int_a^b \frac{d}{d\tau}[(B\phi_j)(\tau)]\, d\tau, \qquad 1 \leqq j, k \leqq n. \tag{4.5}$$

Without loss of generality we may assume $B = I$. Otherwise, we can compute a Choleski factorization $B = R^T R$, R nonsingular, and consider the change of variables $\hat{x} = Rx$. Hence we take as our (finite-dimensional) penalty functional

$$J(x) := \|x\|^2 = x^T x.$$

Remark 4.1. If B is not strictly positive definite, one may apply a similar change of variables and consider the penalty functional $J(x) = \|Px\|^2$, where P is the orthogonal projection onto the orthogonal complement of the null space of B. Computational details appear in the paper by Elden [5].

The resulting finite-dimensional analogue of problem (1.4) is then

$$\min_{x \in \mathbf{R}^n} \|F_{mn}(x) - y\|^2 \quad \text{subject to } J(x) := \|x\|^2 \leqq \beta^2. \tag{4.6}$$

We implemented several constrained optimization codes from the widely available Numerical Algorithms Group (NAG) software library to solve (4.6). We found both the Augmented Lagrangian code and the Sequential Quadratic Programming code in the NAG library to be unreliable for our model problem (3.1) for moderately large values of the parameter H (e.g., $H \approx 0.1$). We suspect that this lack of robustness is due to deficiencies in the line search phase of these algorithms. The line searches rely

on merit functions which try to balance the often conflicting requirements of reducing the objective function and maintaining the constraint. Solutions to highly ill-conditioned problems appear to be very sensitive to parameters which determine this balance.

Trust region methods have long been popular for *unconstrained* optimization problems

$$\min_x f(x) \tag{4.7}$$

where $f: R^n \to R$ is "smooth." See Dennis and Schnabel [4] for a discussion of convergence theory and numerical implementation. In their simplest form, trust region methods generate a new approximation $x_{k+1} = x_k + s$ from the current approximation x_k as follows: One takes a quadratic approximation $Q(s)$ to $f(x_k + s)$ and then solves the subproblem

$$\min Q(s) \quad \text{subject to } \|s\|^2 \leqq \delta_k^2, \tag{4.8}$$

where $\delta_k > 0$. If the solution s decreases the objective functional, i.e., if $f(x_k + s) < f(x_k)$, one sets $x_{k+1} = x_k + s$ and proceeds. Otherwise, one decreases the trust region parameter δ_k and resolves (4.8) until either $f(x_k + s) < f(x_k)$ or $\delta_k \approx 0$, in which case the iteration is terminated.

To robustly solve the *constrained* problem (4.6), we consider the trust region iteration

$$x_{k+1} = x_k + s_k, \qquad k = 0, 1, \cdots,$$

where s_k solves the quadratic subproblem

$$\min_s Q(s) := \|As - b\|^2, \quad \text{where } A := F'_{mn}(x_k), \quad b := y - F_{mn}(x_k), \tag{4.9}$$

subject to

$$\begin{bmatrix} J(x_k + s) - \beta^2 \\ J(s) - \delta_k^2 \end{bmatrix} = \begin{bmatrix} (x_k + s)^T (x_k + s) - \beta^2 \\ s^T s - \delta_k^2 \end{bmatrix} \leqq 0. \tag{4.10}$$

At each iteration, the trust region parameter $\delta_k > 0$ is chosen so the objective function

$$f(x) := \|F_{mn}(x) - y\|^2 \tag{4.11}$$

is reduced. Note that Q in (4.9) is the usual Gauss-Newton approximation to f, which is obtained from the Taylor expansion $F_{mn}(x_k + s) = F_{mn}(x_k) + F'_{mn}(x_k)s + O(\|s\|^2)$.

The constraint region in (4.10) is convex and is nonempty provided $J(x_k) \leqq \beta^2$. If $A := F'_{mn}(x_k)$ has full column rank, then $Q(s)$ is strictly convex, and subproblem (4.9), (4.10) has a unique solution. The following theorem shows that when δ_k is small, our trust region method behaves like a projected gradient method. We will use "∇" to indicate derivative with respect to x.

THEOREM 4.2. *Suppose* $\beta^2 > 0$, $x_k \neq 0$, $J(x_k) \leqq \beta^2$, *and* $\nabla f(x_k) \neq 0$, *but* x_k *does not satisfy the first-order necessary conditions* (2.2)-(2.4). *Let* s *solve the quadratic subproblem* (4.9), (4.10). *Then*

$$\frac{s}{\|s\|} \to \frac{d}{\|d\|} \quad as \quad \delta_k \to 0,$$

where

$$d = -\nabla f(x_k), \quad if \quad \nabla f(x_k)^T \nabla J(x_k) > 0 \quad or \; if \quad J(x_k) < \beta^2. \tag{4.12}$$

Otherwise, $\nabla f(x_k)^T \nabla J(x_k) \leqq 0$, $J(x_k) = \beta^2$, *and*

$$d = -\nabla f(x_k) + \frac{\nabla f(x_k)^T \nabla J(x_k)}{\|\nabla J(x_k)\|^2} \nabla J(x_k). \tag{4.13}$$

Note that (4.12) *gives the negative gradient, or "steepest descent" direction for the objective function f. Equation* (4.13) *gives the projected gradient direction, which is the orthogonal projection of* $-\nabla f(x_k)$ *onto the tangent subspace* $\{s \in X: \nabla J(x_k)^T s = 0\}$.

Proof. To simplify notation, define $\nabla f := \nabla f(x_k) = -2A^T b$ and $\nabla J := \nabla J(x_k) = 2x_k$. First-order necessary conditions for a solution to (4.9), (4.10) give

$$\begin{aligned} s &= [A^T A + (\lambda + \mu) I]^{-1} (A^T b - \lambda x_k) \\ &= \tfrac{1}{2} [A^T A + (\lambda + \mu) I]^{-1} (-\nabla f - \lambda \nabla J), \end{aligned}$$

where $\lambda \geqq 0$, $\mu \geqq 0$, $J(x_k + s) \leqq \beta^2$, $J(s) \leqq \delta_k^2$, and $\lambda[J(x_k + s) - \beta^2] + \mu[J(s) - \delta_k^2] = 0$. Note that $\delta_k \to 0 \Leftrightarrow J(s) = \|s\|^2 \to 0 \Leftrightarrow \mu \to \infty$. Similarly, a straightforward calculation shows that

$$x_k + s = [A^T A + (\lambda + \mu) I]^{-1} [A^T (A x_k + b) + \mu x_k],$$

so that $\lambda \to \infty \Leftrightarrow J(x_k + s) = \|x_k + s\|^2 \to 0$. But then the constraint $J(x_k + s) \leqq \beta^2$ would become inactive, and $\lambda = 0$. This contradiction shows that λ must remain bounded. Thus for small δ^k,

$$s = \frac{-\nabla f - \lambda \nabla J}{2\mu} + O\left(\frac{1}{\mu^2}\right). \tag{4.14}$$

Since $\nabla f = -2A^T b$, the objective functional for the quadratic subproblem (4.9), (4.10) can then be expressed as

$$Q(s) = \frac{-\|\nabla f\|^2 - \lambda \nabla f^T \nabla J}{\mu} + O\left(\frac{1}{\mu^2}\right) + \|b\|^2. \tag{4.15}$$

Similarly, $\nabla J = 2x_k$ and $J(x_k + s) = J(x_k) + 2x_k^T s + J(s)$ yields

$$J(x_k + s) - \beta^2 = \frac{-\nabla f^T \nabla J - \lambda \|\nabla J\|^2}{\mu} + O\left(\frac{1}{\mu^2}\right) + J(x_k) - \beta^2 \leqq 0. \tag{4.16}$$

If $\nabla f^T \nabla J > 0$ or $J(x_k) < \beta^2$, we see from (4.16) that the constraint becomes inactive for μ sufficiently large, in which case the complementarity condition forces $\lambda = 0$. We then obtain (4.12) from (4.14) as $\delta_k \to 0$. On the other hand, if $\nabla f^T \nabla J \leqq 0$ and $J(x_k) = \beta^2$, (4.16) gives

$$\lambda \geqq \frac{-\nabla f^T \nabla J}{\|\nabla J\|^2} + O\left(\frac{1}{\mu}\right). \tag{4.17}$$

To minimize (4.15), we take equality in (4.17). Then as $\delta_k \to 0$, $\lambda \to -(\nabla f^T \nabla J / \|\nabla J\|^2)$, and we obtain (4.13) from (4.14). □

The following corollary shows that for δ_k sufficiently small, the objective function f is decreased.

COROLLARY 4.3. *Suppose the conditions of Theorem* 4.2 *hold. Then for s the solution to* (4.9), (4.10) *and* δ_k *sufficiently small,* $f(x_k + s) < f(x_k)$.

Proof. Since f is twice continuously differentiable,

$$f(x_k + s) = f(x_k) + \nabla f(x_k) s + O(\|s\|^2).$$

Hence, it suffices to show that there exists $\gamma > 0$ for which

$$\nabla f(x_k) s \leqq -\gamma \|s\| \tag{4.18}$$

whenever δ_k is sufficiently small. By Theorem 4.2 we have that as $\delta_k \to 0$, either

$$\nabla f(x_k)^T \frac{s}{\|s\|} \to -\|\nabla f(x_k)\|^2,$$

or else

$$\nabla f(x_k)^T \frac{s}{\|s\|} \to -\|\nabla f(x_k)\|^2 + \frac{|\nabla f(x_k)^T \nabla J(x_k)|^2}{\|\nabla J(x_k)\|^2}.$$

In this second case, by Schwartz's inequality,

$$|\nabla f(x_k)^T \nabla J(x_k)| \leqq \|\nabla f(x_k)\| \, \|\nabla J(x_k)\|,$$

with equality if and only if $\nabla f(x_k) = \lambda \nabla J(x_k)$. Since we have assumed the first-order necessary conditions (2.2)-(2.4) do not hold, Schwartz's inequality is strict. In either case,

$$\lim_{\delta_k \to 0} \nabla f(x_k)^T \frac{s}{\|s\|} < 0.$$

Equation (4.18) follows from the continuity of the solution s with respect to δ_k. □

This trust region approach gives decrease in the objective function outside the region of convergence of the Gauss-Newton method. Once we are inside this region of convergence, we take the Gauss-Newton step, the trust region constraint $J(s) \leqq \delta_k^2$ becomes inactive, and we obtain the following result. Note that

$$\nabla^2 f(x) = 2[F'(x)^T F'(x) + N(x)],$$

where

$$N(x) := F''(x)^T (F(x) - y).$$

THEOREM 4.4. *Define* $c(x) := J(x) - \beta^2 = \|x\|^2 - \beta^2$, *let* x_* *be a solution to* (4.6) *with corresponding Lagrange multiplier* λ_*, *and suppose the second-order sufficient condition*

$$s^T [\nabla^2 f(x_*) + \lambda_* \nabla^2 c(x_*)] s \geqq \alpha \|s\|^2 \quad \text{whenever } \lambda_* \nabla c(x_*)^T s = 0 \tag{4.19}$$

holds for some $\alpha > 0$. *Assume each* δ_k *has been chosen so the trust region constraint* $J(s) \leqq \delta_k$ *is inactive. If* $N(x_*)$ *is sufficiently small and* x_0 *is sufficiently close to* x_*, *then iteration* (4.9), (4.10) *converges to* x_*. *If* $N(x_*) = 0$, *the rate of convergence is locally q-quadratic. Otherwise, the rate is linear.*

Proof. If $\lambda_* = 0$, the standard analysis for the unconstrained Gauss-Newton method applies. See for example, Theorem 10.2.1 and Corollary 10.2.2 of Dennis and Schnabel [4]. Otherwise, x_* and $\lambda_* > 0$ are locally unique solutions to

$$\begin{aligned} \nabla f(x) + \lambda \nabla c(x) &= 0, \\ c(x) &= 0. \end{aligned} \tag{4.20}$$

For x_k and $x_{k+1} = x_k + s$ sufficiently close to x_* and s the solution to (4.9), (4.10), $c(x_k) = c(x_k + s) = 0$, and first-order necessary conditions give

$$\begin{aligned} \nabla Q(s) + \lambda_{k+1} \nabla c(x_k + s) &= 0, \\ c(x_k + s) &= 0. \end{aligned}$$

Since $\nabla Q(s) = \nabla f(x_k) + 2A^T As$ and $0 = c(x_k) = c(x_k + s) = c(x_k) + \nabla c(x_k)^T s + \frac{1}{2} s^T \nabla^2 c s$, where $\nabla^2 c = 2I$, setting $\lambda_{k+1} = \lambda_k + \Delta\lambda$ above gives

$$\begin{bmatrix} 2A^TA + \lambda_k \nabla^2 c & \nabla c(x_k) \\ \nabla c(x_k)^T & 0 \end{bmatrix} \begin{bmatrix} s \\ \Delta\lambda \end{bmatrix} = \begin{bmatrix} \nabla f(x_k) + \lambda_k \nabla c(x_k) \\ c(x_k) \end{bmatrix} + O(\Delta\lambda \|s\| + \|s\|^2).$$

The theorem follows from standard analysis of quasi-Newton methods for solving (4.20). As in the unconstrained case, if $N(x_*) = 0$, we obtain local quadratic convergence. If $0 < (\|N(x_*)\|/\alpha) < 1$, where α is the coercivity constant in (4.19), we obtain linear convergence. □

Remark 4.5. The quantity $(\|N(x_*)\|/\alpha)$ in the above proof governs the rate of local (linear) convergence when $N(x_*) \neq 0$. By an argument similar to that in Remark 2.7, we see that for large values of λ (which correspond to small values of the regularization parameter β) α is large. As λ decreases, one would expect α to also decrease. In this case, one observes much slower convergence of iteration (4.9), (4.10).

Solution to the quadratic subproblem. To solve subproblem (4.9), (4.10) in a numerically stable manner and to reduce the computational cost, we first diagonalize it using an approach similar to that of Elden [5]. We will also use the diagonal entries to determine a reasonable choice for the regularization parameter in § 5. We assume $A = F'(x_k)$ has full column rank. Let A have the singular value decomposition

$$A = UDV^T,$$

where U and V are orthogonal matrices and $D = \operatorname{diag}\{d_i\}$ has the (positive) singular values d_i of A as its diagonal entries. Subproblem (4.9), (4.10) is then equivalent to

$$\min_{\hat{s}} \|D\hat{s} - \hat{b}\|^2 \tag{4.21}$$

subject to

$$\begin{bmatrix} \|\hat{x} + \hat{s}\|^2 - \beta^2 \\ \|\hat{s}\|^2 - \delta_k^2 \end{bmatrix} \leqq 0, \tag{4.22}$$

where

$$\hat{s} := V^T s, \quad \hat{x} := V^T x, \quad \hat{b} := U^T b.$$

Our approach to solving (4.21), (4.22) follows ideas outlined in Pang's paper [12, p. 65]. First-order necessary conditions for the solution $\hat{s}$ are

$$\begin{gathered} D^T[D\hat{s} - \hat{b}] + \lambda(\hat{x} + \hat{s}) + \mu\hat{s} = 0, \\ \|\hat{x} + \hat{s}\|^2 \leqq \beta^2, \qquad \|\hat{s}\|^2 \leqq \delta_k^2, \\ \lambda \geqq 0, \qquad \mu \geqq 0, \\ \lambda[\|\hat{x} + \hat{s}\|^2 - \beta^2] + \mu[\|\hat{s}\|^2 - \delta_k^2] = 0. \end{gathered} \tag{4.23}$$

From this we obtain

$$\hat{s}(\bar{\lambda}) = [D^TD + (\lambda + \mu)I]^{-1}(D^T\hat{b} - \lambda\hat{x}), \tag{4.24}$$

$$\bar{\lambda} := \begin{bmatrix} \lambda \\ \mu \end{bmatrix} \geqq 0, \quad \bar{c}(\bar{\lambda}) := \begin{bmatrix} \|\hat{x} + \hat{s}(\bar{\lambda})\|^2 - \beta^2 \\ \|\hat{s}(\bar{\lambda})\|^2 - \delta_k^2 \end{bmatrix} \leqq 0, \qquad \bar{\lambda}^T \bar{c}(\bar{\lambda}) = 0. \tag{4.25}$$

Thus the Lagrange multipliers λ, μ are solutions to the nonlinear (quadratic) complementarity problem (4.25). Once these have been obtained, $\hat{s}$ is computed from (4.24), and $s = V\hat{s}$ is the solution to subproblem (4.9), (4.10).

We solve the quadratic complementarity problem (4.25) using the following Newton iteration: For $k=0, 1, \cdots$, let $\bar{\lambda}=\bar{\lambda}_{k+1}$ solve the linear complementarity problem

$$\bar{\lambda} \geqq 0, \tag{4.26}$$

$$\bar{c}(\bar{\lambda}_k)+\nabla \bar{c}(\bar{\lambda}_k)(\bar{\lambda}-\bar{\lambda}_k) \leqq 0, \tag{4.27}$$

$$\bar{\lambda}^T[\bar{c}(\bar{\lambda}_k)+\nabla \bar{c}(\bar{\lambda}_k)(\bar{\lambda}-\bar{\lambda}_k)]=0. \tag{4.28}$$

For a summary of convergence results of iteration (4.26)-(4.28) as well as a review of relevant literature, we refer the reader to Pang [12]. Note that this iteration is locally quadratically convergent. To obtain global convergence to a solution of (4.25), we added a line search. Define

$$h(\bar{\lambda}) := \min(\bar{\lambda}, \bar{c}(\bar{\lambda})),$$

(componentwise minimum) and observe that $\bar{\lambda}$ solves (4.25) if and only if $h(\bar{\lambda})=0$. Given a solution $\bar{\lambda}$ to (4.26)-(4.28) for which $\|h(\bar{\lambda})\|_1 \geqq \|h(\bar{\lambda}_k)\|_1$, we define the Newton step

$$\Delta=\bar{\lambda}-\bar{\lambda}_k,$$

and obtain a solution γ_* to the one-dimensional minimization problem

$$\min_{0 \leqq \gamma < 1} \|h(\bar{\lambda}_k+\gamma\Delta)\|_1.$$

We then take

$$\bar{\lambda}_{k+1}=\bar{\lambda}_k+\gamma_*\Delta$$

as the new estimate for the solution to (4.25).

5. Numerical results. We applied our constrained least squares regularization method to the model problem of § 3. All computations were performed on a Zenith (IBM-compatible) AT Personal Computer. F is the nonlinear integral operator in (3.1) with $a=0$, $b=1$, and $H=0.2$. We took approximate solutions x from the n-dimensional subspace of $H_0^1(0,1)$ spanned by piecewise linear functions

$$\phi_j(t) := \begin{cases} \dfrac{\tau-\tau_j}{h}, & \text{if } \tau_{j-1} \leqq \tau \leqq \tau_j, \\ \dfrac{\tau_{j+1}-\tau}{h} & \text{if } \tau_j \leqq \tau \leqq \tau_{j+1}, \\ 0, & \text{otherwise,} \end{cases} \tag{5.1}$$

where $\tau_j=jh$, $h=1/(n+1)$, $j=1, \cdots, n=25$. The integrals (4.3), (4.4) were computed numerically. We took as our true solution a linear combination of two Gaussians,

$$x_{\text{true}}(\tau)=c_1 \exp(d_1(\tau+p_1)^2)+c_2 \exp(d_2(\tau-p_2)^2)+c_3\tau+c_4,$$

where $c_1=-0.1$, $c_2=-0.075$, $d_1=-40$, $d_2=-60$, $p_1=0.4$, $p_2=0.67$, and c_3, c_4 are chosen so that $x(0)=x(1)=0$. $H-x_{\text{true}}(\tau)$ is plotted in Fig. 1. We took data points $y_i=y(t_i)+\varepsilon_i$, $t_i=i/(m+1)$, $i=1, \cdots, m=30$. The ε_i simulate measurement errors and are pseudorandom and normally distributed with mean 0 and variance σ^2 chosen so that the noise to signal ration was 0.2 percent, i.e.,

$$\frac{\sigma}{\|F_{mn}(x)\|}=.002.$$

We took as our (infinite-dimensional) penalty functional

$$J(x) = \|x\|^2 = \int_0^1 x'(\tau)^2 \, d\tau.$$

Figure 2 is a semilog plot of the singular values of the derivative $A = F'_{mn}(x)$ at the initial guess $x_0(\tau) \equiv 0$. The exponential decay rate of the singular values gives a quantitative indication of the server ill-posedness of the problem.

We solved a sequence of finite-dimensional problems (4.6) with increasing $\beta \in \{.2, .25, .275, .3, .35, .4, .5,\}$ using the trust region algorithm of the previous section. Resulting approximate solutions x_β are shown in Fig. 3 for $\beta = .2$ (dashed line), $\beta = .275$ (solid line), and $\beta = .5$ (dotted line). The true solution satisfies $J(x_{\text{true}}) = (.277)^2$ and is represented by +'s. The constraint $J(x) \leqq \beta^2$ was active in each case.

Figure 4 is a semilog plot of the corresponding Lagrange multipliers $\lambda = \lambda(\beta)$. From Remark 2.7, we would expect the regularization problem (4.6) to become highly ill-conditioned for larger values of β. Also, by Remark 4.5, we would expect the rate of convergence of iteration (4.9), (4.10) to slow considerably in the presence of noisy data. We have observed both these phenomena in our numerical experiments.

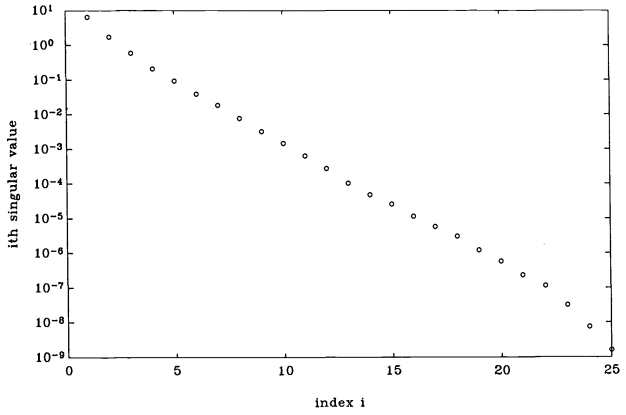

FIG. 2. *Semilog plot of singular values of discrete derivative operator in decreasing order of magnitude.*

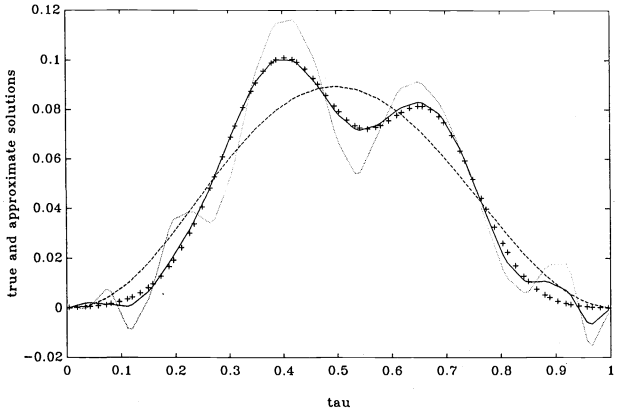

FIG. 3. *Approximate solutions* $-x_\beta$, *for* $\beta = .2$ (*dashed line*), $\beta = .275$ (*solid line*), *and* $\beta = .5$ (*dotted line*). *The* +*'s represent the negative true solution,* $-x_{\text{true}}$.

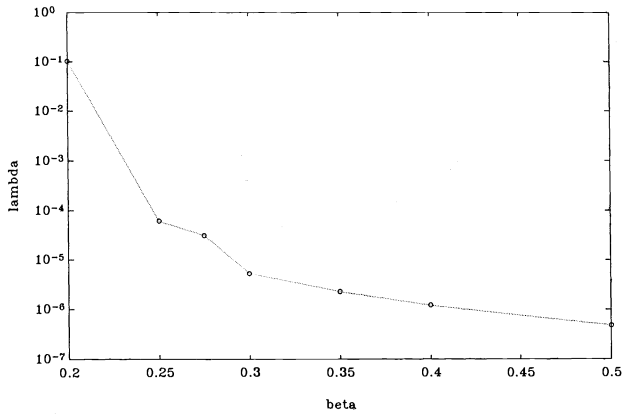

FIG. 4. *Semilog plot of the Lagrange multipliers λ versus the regularization parameter β.*

Figure 5 gives the error indicators as a function of the regularization parameter β. The curves represent, from top to bottom, (i) the "solution error"

$$e(\beta) := J(x_\beta - x_{\text{true}}) = \|x_\beta - x\|^2; \tag{5.2}$$

(ii) the generalized cross validation functional $V(\beta)$, defined in (5.5) below; and (iii) the weighted objective functional obtained from (4.11) and (4.3),

$$\frac{1}{m} f(x_\beta) := \frac{1}{m} \sum_{i=1}^{m} [F_{mn}(x_\beta)(t_i) - y_i]^2. \tag{5.3}$$

The fact that the solution error $e(\beta)$ increases for large β while the objective functional $f(x_\beta)$ continues to decrease is another consequence of the ill-posedness of this problem.

Remark 5.1. The practical choice of a regularization parameter for a given error-contaminated data set is a difficult matter. Many methods require prior knowledge of the magnitude of the error and/or the norm of the true solution. A statistical technique known as the method of Generalized Cross Validation (GCV) requires only that the error be random in the sense that

$$E(\varepsilon_i) = 0; \qquad E(\varepsilon_i \varepsilon_j) = \sigma^2 \delta_{ij}. \tag{5.4}$$

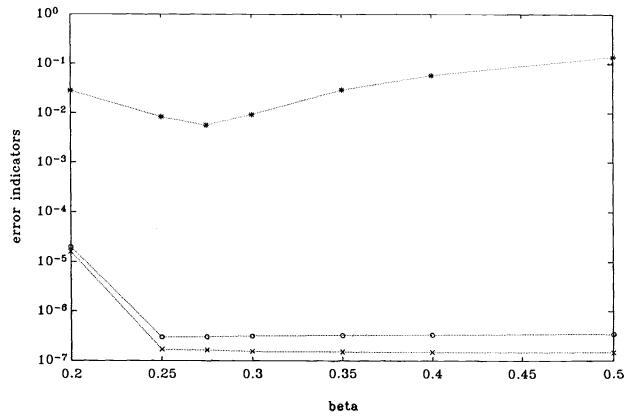

FIG. 5. *Semilog plot of error indicators: Solution error $e(\beta)$ (represented by *'s); GCV function $V(\beta)$ (represented by o's); and scaled objective functional $f(x_\beta)/m$ (represented by x's).*

GCV has been successfully applied to a variety of regularization methods including Tikhonov Regularization (see [15], [10]) and Truncated Singular Value Decomposition (See [14]). For the regularization problem (4.6), the GCV functional is given by

$$V(\beta) = \frac{\frac{1}{m} f(x_\beta)}{\left\{\frac{1}{m}\,\text{Trace}\,[I_m - A(A^TA+\lambda I)^{-1}A^T]\right\}^2}, \tag{5.5}$$

$$= \frac{\frac{1}{m} f(x_\beta)}{\left\{\frac{1}{m}\left[(m-n)+\lambda \sum_{i=1}^{n} \frac{1}{d_i^2+\lambda}\right]\right\}^2}$$

where $\lambda = \lambda(\beta)$ is the Lagrange multiplier for problem (4.6) and the d_i's are the singular values of the derivative $A = F'_{mn}(x_\beta)$. In Fig. 5 we see that although V is very flat, the minimum of $V(\beta)$ coincides with the minimum of the solution error $e(\beta)$. At least for this particular example, the minimizer of $V(\beta)$ provides a very reasonable choice for the regularization parameter.

THE SENSITIVITY OF THE ALGEBRAIC AND DIFFERENTIAL RICCATI EQUATIONS*

CHARLES KENNEY† AND GARY HEWER‡

Abstract. In this paper it is shown that the ideas developed by Byers in [*Proc. Summer Research Conference*, AMS Vol. 47, Contemporary Math., American Mathematical Society, Providence, RI, 1984, pp. 35-49] on the sensitivity of the algebraic Riccati equation can be sharpened and extended to norms other than the Frobenius norm. This extension is crucial from an interpretive point of view because use of the spectral norm allows an identification between the condition number of the algebraic Riccati equation and the damping properties of the closed-loop dynamical system. Moreover, this approach has the pleasant feature that it carries over to a completely parallel theory for the sensitivity of the differential Riccati equation, an area that has not been considered previously.

Key words. Riccati equation, condition number, closed-loop damping

AMS(MOS) subject classifications. 65F35, 65F30, 15A12

1. Introduction.

Algebraic and differential Riccati equations arise in the problem of optimal control of linear time-invariant systems of the form

$$\begin{aligned} &\dot{x}(t) = Ax(t) + Bu(t), \qquad x(0) = x_0, \\ &y(t) = Cx(t). \end{aligned} \tag{1.1}$$

Here $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{n\times m}$, $C \in \mathbb{R}^{k\times n}$; x, u, and y are the state, input, and output vectors, respectively. For a given symmetric positive semidefinite matrix P_1 and a terminal time t_1, the goal of optimal control is to find the input $u = u(t)$ that minimizes the cost functional

$$J(u, P_1, t_1) \equiv \int_0^{t_1} x^T(t)C^TCx(t) + u^T(t)u(t)\,dt + x^T(t_1)P_1x(t_1). \tag{1.2}$$

In this case, the input function, u_{t_1}, which minimizes the cost functional, is [16]

$$u_{t_1}(t) = -B^TP(t)x(t) \quad \text{for } 0 \leqq t \leqq t_1. \tag{1.3}$$

In (1.3), P is the solution to the differential Riccati equation

$$\dot{P}(t) = -G - A^TP(t) - P(t)A + P(t)FP(t), \qquad P(t_1) = P_1 \tag{1.4}$$

where $F = BB^T$ and $G = C^TC$. If u_{t_1} in (1.3) is used in (1.1), we obtain the closed-loop system

$$\dot{x}(t) = (A - FP(t))x(t), \quad x(0) = x_0, \quad 0 \leqq t \leqq t_1. \tag{1.5}$$

A related procedure involves letting t_1 go to infinity in (1.2). If (G, A) is detectable and (A, F) is stabilizable, then the algebraic Riccati equation

$$0 = G + A^TX + XA - XFX \tag{1.6}$$

has a unique symmetric positive semidefinite solution, X [4]. Moreover, as $t_1 \to \infty$ in (1.2), the initial matrix $P(0)$ in (1.4) converges to X, independently of the terminal matrix P_1, so long as $P_1 = P_1^T \geqq 0$. The resulting closed-loop system,

$$\dot{x}(t) = (A - FX)x(t), \qquad x(0) = x_0, \tag{1.7}$$

is stable in the sense that the eigenvalues of $A - FX$ have negative real part.

This paper has two objectives. The first is to study the sensitivity of the solutions to (1.4) and (1.6) to perturbations in the coefficient matrices A, F, and G. Good upper and lower sensitivity bounds for the algebraic Riccati equation were obtained by Byers in [2]. We will show that these results can be sharpened and extended to the differential Riccati equation.

Our second objective is to point out a very strong relationship between the sensitivity of the Riccati equations (1.4), (1.6) and the damping of the closed-loop systems (1.5), (1.7). We define the damping D of the closed-loop system (1.7) as

$$D \equiv \max_{\|x_0\|=1} \|x\|_{L_2} = \max_{\|x_0\|=1} \left[\int_0^\infty \|x(t)\|^2 \, dt \right]^{1/2} \tag{1.8}$$

where $\|\cdot\|$ denotes the 2-norm, $\|v\|^2 = \Sigma v_i^2$. The maximum in (1.8) is taken over solutions to (1.7). A similar definition of damping applies to (1.5).

For the algebraic Riccati equation, the connection between sensitivity and damping relies on the identity

$$\begin{aligned} \int_0^\infty \|x(t)\|^2 \, dt &= \int_0^\infty x^T(t)x(t) \, dt \\ &= \int_0^\infty x_0^T \, e^{A_C^T t} \, e^{A_C t} x_0 \, dt \\ &= x_0^T \int_0^\infty e^{A_C^T t} \, e^{A_C t} \, dt \, x_0 \\ &\equiv x_0^T H x_0. \end{aligned} \tag{1.9}$$

In (1.9), A_C denotes the closed-loop matrix $A - FX$ and the matrix H satisfies $\Omega(H) = -I$ with

$$\Omega(Z) \equiv A_C^T Z + Z A_C. \tag{1.10}$$

This identity shows that damping is related to the closed-loop Lyapunov operator Ω. Moreover, we show that $D^2 = \|H\| = \|\Omega^{-1}\|$, for the induced operator 2-norm

$$\|\Omega^{-1}\| = \max_{M \neq 0} \frac{\|\Omega^{-1}(M)\|}{\|M\|}. \tag{1.11}$$

When coupled with a slightly more general definition of damping, these results clearly show the connection between the dynamical behavior of the closed-loop system and the sensitivity of the associated Riccati equation. This complements the results of [9], in which the sensitivity of the solution to the Lyapunov equation $A^T X + XA = -W$, for A stable, was shown to be related to the damping behavior of the dynamical system $\dot{x} = Ax$.

The outline of the paper is as follows. In § 2, we develop sensitivity and damping results for the algebraic Riccati equation. Section 3 extends these results to the differential Riccati equation. Section 4 is devoted to numerical tests of the bounds in §§ 2 and 3.

2. Sensitivity of the algebraic Riccati equation. We will assume throughout this paper that F and G are positive semidefinite matrices with (A, F) stabilizable and (G, A) detectable. Let $X = X(A, F, G)$ denote the unique positive semidefinite symmetric solution to (1.6). Our goal is to investigate the variation in X with respect to changes in A, F, and G. More precisely, let $\tilde{A}$, $\tilde{F}$, and $\tilde{G}$ be matrices that are near A, F, and G with respect to the matrix 2-norm. (Except for Theorem 2.1, all the results in this paper are for the two-norm.) Define $\Delta A = \tilde{A} - A$, $\Delta F = \tilde{F} - F$, and $\Delta G = \tilde{G} - G$. We assume that $\tilde{F}$ and $\tilde{G}$ are of the form $\tilde{B}\tilde{B}^T$ and $\tilde{C}^T\tilde{C}$ for some $\tilde{B}$ and $\tilde{C}$, so we will require $\tilde{F}$ and $\tilde{G}$ to be symmetric and positive semidefinite. For $\|\Delta A\|$, $\|\Delta F\|$, and $\|\Delta G\|$ sufficiently small, $(\tilde{A}, \tilde{F})$ is stabilizable and $(\tilde{G}, \tilde{A})$ is detectable; hence the perturbed solution $\tilde{X} = X(\tilde{A}, \tilde{F}, \tilde{G})$ is well defined. Let $\Delta X = \tilde{X} - X$.

To relate $\|\Delta X\|$ to $\|\Delta A\|$, $\|\Delta F\|$, and $\|\Delta G\|$, we adopt the condition theory of Rice [19]. For sufficiently small $\delta > 0$, define $K_\delta = K_\delta(A, F, G)$ by

$$K_\delta \equiv \sup \left\{ \frac{\|\Delta X\|}{\delta \|X\|} \;\middle|\; \|\Delta A\| \leq \delta \|A\|, \|\Delta F\| \leq \delta \|F\|, \|\Delta G\| \leq \delta \|G\|, \tilde{F} \text{ and } \tilde{G} \right. \text{ symmetric positive semidefinite} \left. \right\}. \tag{2.1}$$

Taking the limit as δ goes to zero, we obtain the asymptotic condition number

$$K \equiv \lim_{\delta \to 0^+} K_\delta. \tag{2.2}$$

It is worth mentioning that this limit exists in an extended sense because K_δ is nonincreasing as δ goes to zero. Moreover, this limit is finite as we will see below.

We can obtain bounds on K by substituting $\tilde{A}$, $\tilde{F}$, $\tilde{G}$, and $\tilde{X}$ into (1.6). After some rearrangement, we find

$$\begin{aligned} A_C^T \Delta X + \Delta X A_C = &-\Delta G - \Delta A^T X - X \Delta A + X \Delta F X \\ &- (\Delta A - \Delta F X)^T \Delta X - \Delta X (\Delta A - \Delta F X) + \Delta X (F + \Delta F) \Delta X \end{aligned} \tag{2.3}$$

where $A_C = A - FX$ is the closed-loop matrix. The left-hand side of (2.3) has the form $\Omega(\Delta X)$, where Ω is defined by (1.10). Since A_C is stable, Ω is invertible [17] and

$$\Omega^{-1}(Z) = -\int_0^\infty e^{A_C^T t} Z e^{A_C t} \, dt. \tag{2.4}$$

We may rewrite (2.3) as

$$\begin{aligned} \Delta X = &-\Omega^{-1}(\Delta G + \Delta A^T X + X \Delta A - X \Delta F X) \\ &- \Omega^{-1}((\Delta A - \Delta F X)^T \Delta X + \Delta X (\Delta A - \Delta F X) - \Delta X (F + \Delta F) \Delta X). \end{aligned} \tag{2.5}$$

The first term on the right-hand side of (2.5) determines the norm of ΔX for ΔA, ΔG, and ΔF small, and is in fact the Fréchet derivative of the mapping $(A, F, G) \to X$. For the purposes of estimation and interpretation, it is convenient to break up this term into the sum of three linear operators (using the notation of Byers in [2]):

$$-\Omega^{-1}(\Delta G + \Delta A^T X + X \Delta A - X \Delta F X) = -\Omega^{-1}(\Delta G) - \Theta(\Delta A) + \Pi(\Delta F) \tag{2.6}$$

where

$$\Theta(Z) \equiv \Omega^{-1}(Z^T X + X Z), \qquad \Pi(Z) \equiv \Omega^{-1}(XZX). \tag{2.7}$$

In general, the operator Θ determines the sensitivity of X with respect to uncertainty in the state matrix A (e.g., modeling errors in the open-loop dynamics). Similarly,

Π and Ω^{-1} determine the sensitivity of X with respect to uncertainty in F (actuator errors) and G (sensors errors), respectively.

It is worth emphasizing that throughout this paper we are concerned only with the effects of "small" perturbations, i.e., we are dealing with a first-order sensitivity analysis.

Associated with (2.6) is the Byers approximate condition number

$$K_B \equiv \frac{\|\Omega^{-1}\|\,\|G\| + \|\Theta\|\,\|A\| + \|\Pi\|\,\|F\|}{\|X\|}. \tag{2.8}$$

The motivation for using this condition number is that if δ is small and $\|\Delta A\| \leqq \delta\|A\|$, $\|\Delta G\| \leqq \delta\|G\|$, $\|\Delta F\| \leqq \delta\|F\|$, then

$$\frac{\|\Delta X\|}{\delta\|X\|} \cong \frac{\|-\Omega^{-1}(\Delta G) - \Theta(\Delta A) + \Pi(\Delta F)\|}{\delta\|X\|}$$

$$\leqq \frac{\|\Omega^{-1}\|\,\|\Delta G\| + \|\Theta\|\,\|\Delta A\| + \|\Pi\|\,\|\Delta F\|}{\delta X} \leqq K_B.$$

Using a result from Stewart [20], Byers [2] was able to show that, for the Frobenius norm, K_B is a very good approximation to K.

THEOREM 2.1 (Byers [2]). *Define K and K_B by* (2.2) *and* (2.8) *for the Frobenius norm. Then* $(1/9)K_B \leqq K \leqq 4K_B$.

Proof. See [2] for the proof. □

Remark. From (2.7), $\|\Theta\| \leqq 2\|\Omega^{-1}\|\,\|X\|$ and $\|\Pi\| \leqq \|\Omega^{-1}\|\,\|X\|^2$. This leads to the "conservative" Byers condition number K_{CB}:

$$K_B \leqq K_{CB} \equiv \frac{\|\Omega^{-1}\|}{\|X\|}(\|G\| + 2\|A\|\,\|X\| + \|F\|\,\|X\|^2). \tag{2.9}$$

However, this simpler condition number is generally too conservative and is often several orders of magnitude larger than K_B (see [2]).

The next theorem shows that, for the matrix 2-norm, K_B is within a factor of 3 of K.

THEOREM 2.2. *Define K and K_B by* (2.2) *and* (2.8) *for the matrix 2-norm. Then* $\frac{1}{3}K_B \leqq K \leqq K_B$.

Proof. See Appendix 1 for the proof. □

These theorems show that K_B is entirely satisfactory as an estimator of K, especially in view of the fact that for most numerical purposes we only need to estimate K to within a factor of 10. However, the question arises as to what K_B means in terms of the original problem. While a geometric interpretation of ill-conditioning is difficult for the Frobenius norm, as noted in [2], it is rather easy for the spectral norm: X is sensitive to perturbations if the closed-loop system (1.7) is poorly damped with respect to the weighting matrices I, X, or X^2.

We define the damping of (1.7) with respect to X^k, for $k = 0, 1, 2$ by

$$D_k \equiv \max_{\|x_0\|=1} \|x\|_{L_2, X^k} \equiv \max_{\|x_0\|=1} \left[\int_0^\infty x^T(t) X^k x(t)\, dt\right]^{1/2}. \tag{2.10}$$

We will show that $D_0^2 = \|\Omega^{-1}\|$, $D_2^2 = \|\Pi\|$, and $2D_1^2 \leqq \|\Theta\| \leqq D_0 D_2$; thus establishing the intimate relationship between sensitivity and damping.

As a step in this direction, let H_k be the solution to the closed-loop Lyapunov equations,

$$A_C^T H_k + H_k A_C = -X^k \tag{2.11}$$

for $k = 0, 1, 2$. Since A_C is stable [17], $H_k = \int_0^\infty e^{A_C^T t} X^k e^{A_C t}\, dt$.

LEMMA 2.3. *Let x satisfy the closed-loop differential equation* (1.7). *Then* $x_0^T H_k x_0 = \|x\|^2_{L_2, X^k}$ *and* $\|H_k\| = \max_{\|x_0\|=1} \|x\|^2_{L_2, X^k} = D_k^2$.

Proof. Since $x(t) = e^{A_C t} x_0$, $\|x\|^2_{L_2, X^k} = \int_0^\infty x_0^T e^{A_C^T t} X^k e^{A_C t} x_0\, dt = x_0^T H_k x_0$. If $\|x_0\| = 1$ then $x_0^T H_k x_0 \leqq \|H_k\|$, because H_k is symmetric and positive definite. Thus $D_k^2 \leqq \|H_k\|$. Moreover, if we let x_0 be a unit eigenvector of H_k corresponding to $\lambda_{\max}(H_k) = \|H_k\|$, then we obtain equality: $D_k^2 = \|H_k\|$. □

The connection between damping and sensitivity relies on the observation that

$$H_0 = -\Omega^{-1}(I), \quad 2H_1 = -\Theta(I), \quad H_2 = -\Pi(I). \tag{2.12}$$

THEOREM 2.4. *Define* Ω, Θ, Π, *and* H_k *by* (1.10), (2.7), *and* (2.11). *Then*

$$\|\Omega^{-1}\| = \|H_0\|, \tag{2.13}$$

$$\|\Pi\| = \|H_2\|, \tag{2.14}$$

and

$$2\|H_1\| \leqq \|\Theta\| \leqq 2\|H_0\|^{1/2} \|H_2\|^{1/2}. \tag{2.15}$$

Proof. See Appendix 1 for the proof. □

COROLLARY 2.5.

$$D_0^2 = \|\Omega^{-1}\|, \quad D_2^2 = \|\Pi\|, \quad 2D_1^2 \leqq \|\Theta\| \leqq D_0 D_2. \tag{2.16}$$

Proof. The proof is immediate from Lemma 2.3 and Theorem 2.4. □

Remark. These results are novel in that they provide an exact expression (in two different forms!) for $\operatorname{sep}(M, -M^T) \equiv \min((\|M^T Z + ZM\|)/\|Z\|)$, where M is any stable matrix in $\mathbb{R}^{n\times n}$ [20]. This is because $\operatorname{sep}(M, -M^T) = \min(\|\Omega(Z)\|/\|Z\|) = \min(\|Y\|/\|\Omega^{-1}(Y)\|) = 1/\|\Omega^{-1}\|$, where $\Omega(Z) \equiv M^T Z + ZM$. From the preceding arguments, $\operatorname{sep}(M, -M^T) = 1/\|H\|$, where $M^T H + HM = -I$; and $\operatorname{sep}(M, -M^T) = 1/D^2$, where $D = \max_{\|x_0\|=1} \|x\|_{L_2}$ for solutions to $\dot{x} = Mx$, $x(0) = x_0$. This is important in another respect because it means that the damping measure, $D = D(M)$ is nicely stable: Stewart has shown [20, Thm. 4.6] that

$$\operatorname{sep}(M, -M^T) - 2\|E\| \leqq \operatorname{sep}(M + E, -(M+E)^T) \leqq \operatorname{sep}(M, -M) + 2\|E\|.$$

Thus, $D(M)/\sqrt{1 + 2\|E\| D^2(M)} \leqq D(M+E) \leqq D(M)/\sqrt{1 - 2\|E\| D^2(M)}$, where we assume that E is small enough that $M + E$ is stable and $2\|E\| D^2(M) < 1$.

From Theorem 2.4 we see that large norms for H_0, H_1, and H_2, which are indicative of poor damping in the closed-loop dynamical system, mean that K_B is large. Consequently, X will be sensitive to small perturbations in A, F, and G. Conversely, if the norms of H_0, H_1, and H_2 are not large then the problem is well-conditioned. A mixture of large and small norms among the H_k indicates selective sensitivity. For example, if the closed-loop dynamic system (1.7) is poorly damped with respect to the identity as a weighting matrix but not with respect to X or X^2, so that $\|H_0\|$ is large relative to $\|H_1\|$ and $\|H_2\|$, then we can expect that X is more sensitive to variations in the sensor matrix G than in the open loop matrix A or the controller matrix F. Examples showing selective sensitivity are given in § 4.

Although Theorem 2.4 gives exact values for $\|\Omega^{-1}\|$ and $\|\Pi\|$ in terms of $\|H_0\|$ and $\|H_2\|$, the upper and lower bounds on $\|\Theta\|$ in (2.15) are not very useful unless

$$\|H_1\| \cong \|H_0\|^{1/2}\|H_2\|^{1/2}. \tag{2.17}$$

The next lemma shows that this approximate equality must hold whenever X is moderately well-conditioned with respect to inversion.

LEMMA 2.6. *Assume that* $X>0$ *and let* $K(X)=\|X\|\,\|X^{-1}\|$. *Then*

$$\left[\frac{\|H_0\|\,\|H_2\|}{K(X)}\right]^{1/2} \leqq \|H_1\| \leqq [\|H_0\|\,\|H_2\|]^{1/2}.$$

Proof. By (2.15) we need only show $\|H_0\|\,\|H_2\| \leqq K(X)\|H_1\|^2$. Let v be any unit vector in $\mathbb{R}^n$. Then,

$$v^T H_1 v = \int_0^\infty v^T e^{A_C^T t} X e^{A_C t} v\, dt \geqq \lambda_{\min}(X) \int_0^\infty v^T e^{A_C^T t} e^{A_C t} v\, dt = \lambda_{\min}(X) v^T H_0 v.$$

This gives $\|H_1\| \geqq \lambda_{\min}(X)\|H_0\| = \|H_0\|/\|X^{-1}\|$. Similarly,

$$v^T H_1 v = \int_0^\infty v^T e^{A_C^T t} X X^{-1} X e^{A_C t} v\, dt \geqq \lambda_{\min}(X^{-1}) v^T H_2 v.$$

This gives $\|H_1\| \geqq \lambda_{\min}(X^{-1})\|H_2\| = \|H_2\|/\|X\|$. Thus $\|H_1\|^2 \geqq \|H_0\|\,\|H_2\|/K(X)$. □

For all but one of the problems that we tested the approximate equality (2.17) was true to within about 15 percent—even for some problems with $K(X)$ large. However, the following example shows that $\|H_0\|^{1/2}\|H_2\|^{1/2}$ can be very much larger than $\|H_1\|$.

Example 1. Let

$$A=\begin{bmatrix}0 & \lambda\\ 0 & 0\end{bmatrix}, \quad B=\begin{bmatrix}0\\ 1\end{bmatrix}, \quad C=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}. \tag{2.18}$$

Then

$$X=\begin{bmatrix}\sqrt{1+2\lambda}/\lambda & 1\\ 1 & \sqrt{1+2\lambda}\end{bmatrix},$$

$$\|H_0\| \cong \sqrt{\lambda/8}, \quad \|H_1\| \cong 1, \quad \|H_2\| \cong \sqrt{(9/8)\lambda}.$$

For example, if $\lambda = 10^8$ then $1 \cong \|H_1\| \leqq \|H_0\|^{1/2}\|H_2\|^{1/2} \cong 6124$.

Fortunately, there is a simple procedure that can be used to estimate $\|\Theta\|$ accurately even when $\|H_1\| \ll \|H_0\|^{1/2}\|H_2\|^{1/2}$. To motivate this method, we briefly consider the related problem of finding the Frobenius norms of Ω^{-1}, Θ, and Π.

Let Vec M denote the vector formed by stacking the columns of a matrix M and define the Kronecker product of two matrices M and N by (see [7])

$$M \otimes N \equiv [M_{ij}N]. \tag{2.19}$$

The Frobenius norm of M is equal to the 2-norm of Vec M:

$$\|M\|_F = \|\text{Vec } M\|. \tag{2.20}$$

Also

$$\text{Vec}\,(MZN) = (N^T \otimes M)\,\text{Vec } Z. \tag{2.21}$$

Apply the Vec operator to the equation $A_C^T H + HA_C = Q$, to obtain

$$(A_C^T \otimes I + I \otimes A_C^T) \operatorname{Vec} H = \operatorname{Vec} Q. \tag{2.22}$$

This may be rewritten as

$$\operatorname{Vec} H = (A_C^T \otimes I + I \otimes A_C^T)^{-1} \operatorname{Vec} Q. \tag{2.23}$$

Since $H = \Omega^{-1}(Q)$, we get

$$\begin{aligned} \|\Omega^{-1}\|_F &\equiv \max \frac{\|\Omega^{-1}(Q)\|_F}{\|Q\|_F} = \max \frac{\|H\|_F}{\|Q\|_F} = \max \frac{\|\operatorname{Vec} H\|}{\|\operatorname{Vec} Q\|} \\ &= \|(A_C^T \otimes I + I \otimes A_C^T)^{-1}\|. \end{aligned} \tag{2.24}$$

Note in (2.24) that $\|\Omega^{-1}\|_F$ denotes the operator norm on Ω^{-1} induced by the Frobenius matrix norm, and is not the same as the Frobenius norm of the associated Kronecker representation of Ω^{-1}. From (2.24) we see that we could evaluate $\|\Omega^{-1}\|_F$ by constructing $(A_C^T \otimes I + I \otimes A_C)^{-1}$ and taking its 2-norm (see [8] or [2]). However, because $A_C^T \otimes I + I \otimes A_C^T$ is of order n^2, this is usually not a practical procedure. Instead, we use the fact that if $M \equiv A_C^T \otimes I + I \otimes A_C^T$ then $\|M^{-1}\| = \sigma_{\max}^{1/2}((M^{-1})^T M^{-1})$.

Thus $\|M^{-1}\|$ can be estimated by the inverse power method [5]. That is, given $v = \operatorname{Vec}(Q) \neq 0$, solve for $\tilde{\omega}$ and ω in

$$M\tilde{\omega} = v, \qquad M^T \omega = \tilde{\omega}.$$

Unless v is poorly chosen, $\|M^{-1}\| \cong \sqrt{\|\omega\|/\|v\|}$. By recycling repeatedly with v reset to ω, this estimate converges to $\|M^{-1}\|$—unless the initial v is orthogonal to the eigenspace E_λ of $(M^T)^{-1}M^{-1}$ corresponding to $\lambda = \|M^{-1}\|^2$ (see [5]).

An equivalent version of this method avoids the use of Kronecker forms: given $Q \neq 0$, solve for $\tilde{H}$ and H in

$$A_C^T \tilde{H} + \tilde{H} A_C = Q, \tag{2.25}$$

$$A_C H + H A_C^T = \tilde{H}. \tag{2.26}$$

Then $\|\Omega^{-1}\|_F \cong \sqrt{\|H\|_F/\|Q\|_F}$ and recycling with Q reset to H improves the estimate [3].

The Frobenius norm of Θ can be found in a similar way. Suppose that $\Theta(Q) = H$, that is, $A_C^T H + HA_C = Q^T X + XQ$. Apply the Vec operator to get

$$(A_C^T \otimes I + I \otimes A_C^T) \operatorname{Vec} H = (I \otimes X) \operatorname{Vec} Q + (X \otimes I) \operatorname{Vec} Q^T.$$

The components of $\operatorname{Vec} Q^T$ are just a permutation of the components of $\operatorname{Vec} Q$:

$$\operatorname{Vec} Q^T = U \operatorname{Vec} Q \tag{2.27}$$

where U is a permutation matrix [7] with $U^T = U$. Then

$$\operatorname{Vec} H = (A_C^T \otimes I + I \otimes A_C^T)^{-1}(I \otimes X + (X \otimes I)U) \operatorname{Vec} Q \tag{2.28}$$

and

$$\|\Theta\|_F = \|(A_C \otimes I + I \otimes A_C^T)^{-1}(I \otimes X + (X \otimes I)U)\|. \tag{2.29}$$

The same type of argument gives

$$\|\Pi\|_F = \|(A_C \otimes I + I \otimes A_C^T)^{-1}(X \otimes X)\|. \tag{2.30}$$

To estimate $\|\Theta\|_F$, the inverse power method takes the following form. Given $\tilde{Q} \neq 0$, set $Q = \tilde{Q}^T X + X\tilde{Q}$, solve (2.25), (2.26), and let $W = 2XH$. Then $\|\Theta\|_F \cong \sqrt{\|W\|_F/\|\tilde{Q}\|_F}$, and we can recycle with $\tilde{Q}$ set equal to W. To estimate $\|\Pi\|_F$, set $Q = X\tilde{Q}X$, solve (2.25), (2.26), and let $Z = XHX$ to get $\|\Pi\|_F \cong \sqrt{\|Z\|_F/\|\tilde{Q}\|_F}$; recycle with $\tilde{Q} = Z$.

These results can be related to the 2-norms of Ω^{-1}, Θ, and Π by exploiting the well-known inequality [18]

$$\|M\| \leqq \|M\|_F \leqq \sqrt{n}\,\|M\|, \tag{2.31}$$

for any $n \times n$ matrix M. If L is either of the operators Ω^{-1}, Θ, or Π, then

$$\frac{1}{\sqrt{n}}\frac{\|L(Q)\|}{\|Q\|} \leqq \frac{\|L(Q)\|_F}{\|Q\|_F} \leqq \sqrt{n}\,\frac{\|L(Q)\|}{\|Q\|}, \tag{2.32}$$

and

$$\frac{\|L\|}{\sqrt{n}} \leqq \|L\|_F \leqq \sqrt{n}\,\|L\|. \tag{2.33}$$

This means that if Q maximizes the 2-norm ratio $\|L(Q)\|/\|Q\|$, then Q will nearly maximize the Frobenius norm ratio $\|L(Q)\|_F/\|Q\|_F$, and vice versa. For example, by Theorem 2.4, $\|\Omega^{-1}(Q)\|/\|Q\|$ is maximized by $Q = I$, so $\|\Omega^{-1}\|_F \cong \|\Omega^{-1}(I)\|_F/\|I\|_F = \|H_0\|_F/\sqrt{n}$. Similarly, $\|\Pi\|_F \cong \|\Pi(I)\|_F/\|I\|_F = \|H_2\|_F/\sqrt{n}$. If better estimates are required then the inverse power method can be used, starting with Q (or $\tilde{Q}$) equal to the identity.

This also suggests a means of estimating the 2-norm of Θ when $\|H_1\| \ll \|H_0\|^{1/2}\|H_2\|^{1/2}$: Use the inverse power method to find $\tilde{Q} \neq 0$ such that $\|\Theta(\tilde{Q})\|_F/\|\tilde{Q}\|_F$ is nearly maximized. Then $\|\Theta(\tilde{Q})\|/\|\tilde{Q}\|$ provides a good estimate for $\|\Theta\|$.

We found that for all the problems we tested, one cycle of the inverse power method, starting with $\tilde{Q} = I$, gave excellent estimates for $\|\Theta\|$. More specifically, set $Q = 2X$, solve (2.25), (2.26), and let $W = 2XH$. Define

$$H_1^{(1)} \equiv \Theta\left(\frac{W}{\|W\|}\right). \tag{2.34}$$

Then $\|H_1^{(1)}\| \cong \|\Theta\|$ and $\|H_1^{(1)}\|$ gives a lower bound on $\|\Theta\|$:

$$\|H_1^{(1)}\| = \frac{\|\Theta(W)\|}{\|W\|} \leqq \max \frac{\|\Theta(Q)\|}{\|Q\|} = \|\Theta\|.$$

If we apply this procedure to Example 1, then we find

$$\sqrt{\lambda/2} \cong \|H_1^{(1)}\| \leqq \|\Theta\| \leqq \sqrt{\|H_0\|\,\|H_2\|} \cong \sqrt{3\lambda/2}.$$

Thus $\|H_1^{(1)}\|$ is within $\sqrt{3}$ of $\|\Theta\|$ for this problem.

The preceding suggests that we define upper and lower condition estimates for the 2-norm as

$$K_U \equiv \frac{\|H_0\|\,\|G\| + 2[\|H_0\|\,\|H_2\|]^{1/2}\|A\| + \|H_2\|\,\|F\|}{\|X\|}, \tag{2.35}$$

$$K_L \equiv \frac{\|H_0\|\,\|G\| + \|H_1^{(1)}\|\,\|A\| + \|H_2\|\,\|F\|}{\|X\|}. \tag{2.36}$$

By Theorem 2.4,

$$K_L \leqq K_B \leqq K_U. \tag{2.37}$$

By Theorem 2.2,

$$\frac{K_L}{3} \leqq K \leqq K_U. \tag{2.38}$$

Numerical tests on a large class of problems (see § 4) show that K_L and K_U are usually very close. If desired, more refined results can be obtained by replacing the term $\|H_1^{(1)}\|$ in (2.36) with the norms of higher inverse power cycle iterates.

We conclude this section by giving a lower bound on $\|H_0\|$ in terms of the stability radius of the closed-loop matrix. For any matrix $M \in R^{m\times m}$, the stability radius of M is the norm of the smallest perturbation ΔM, which makes $M+\Delta M$ unstable (see [11], [14], [21]):

$$\rho_s(M) \equiv \min\{\|\Delta M\| \mid M+\Delta M \text{ has an eigenvalue } \lambda \text{ with } \mathrm{Re}(\lambda) \geqq 0\}. \tag{2.39}$$

LEMMA 2.7. *Let* $A_C^T H_0 + H_0 A_C = -I$. *Then*

$$\frac{1}{2\rho_s(A_C)} \leqq \|H_0\|. \tag{2.40}$$

Proof. See [9] for the proof. □

From this lemma we see that if the closed-loop matrix $A-FX$ can be made unstable by a small perturbation, then $\|H_0\|$ will be large and the problem of finding X is ill-conditioned. This complements a study by Kenney and Laub [14] in which it is shown that for companion systems

$$A = \begin{bmatrix} 0 & 1 & \cdots & 0 \\ & & \ddots & \vdots \\ & & & 1 \\ a_1 & a_2 & \cdots & a_n \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}, \quad C = I \tag{2.41}$$

where a_1 does not grow faster than c^n for some constant $c>1$, we have that $\rho_s(A-BB^TX)$ decays to zero exponentially fast as n increases. We can thus expect that X is very sensitive to small changes in A, B, and C for companion form systems of high dimension.

3. Sensitivity of the differential Riccati equation. We now turn to the sensitivity of the solution to the differential Riccati equation, which although important has apparently not been treated in the literature.

For convenience, we transform the Riccati problem (1.4) with terminal condition into an initial value Riccati problem. Let $X(t) \equiv P(t_1 - t)$; then for $0 \leqq t \leqq t_1$

$$\dot{X}(t) = G + A^T X(t) + X(t)A - X(t)FX(t), \qquad X(0) = P_1 \equiv X_0. \tag{3.1}$$

Under this transformation, $P(t) = X(t_1 - t)$ and the closed-loop dynamical system (1.5) becomes

$$\dot{x}(t) = (A - FX(t_1 - t))x(t), \quad x(0) = x_0, \quad 0 \leqq t \leqq t_1. \tag{3.2}$$

As in the algebraic case, it is convenient to define the damping of the closed-loop dynamical system (3.2) with respect to the weighting matrices X^k for $k = 0, 1, 2$:

$$D_k(t_1) \equiv \max_{\|x_0\|=1} \|x\|_{L_2[0,t_1],X^k} \equiv \max_{\|x_0\|=1} \left[\int_0^{t_1} x^T(t) X^k(t_1 - t) x(t)\, dt\right]^{1/2} \tag{3.3}$$

where the maximum is taken over solutions, x to (3.2).

To avoid confusion, we will use a "+" subscript or superscript to denote quantities related to the algebraic Riccati equation (e.g., X_+ for the solution to (1.6), K_B^+ for (2.8), etc.).

Let $\tilde{X}_0 = \tilde{X}_0^T \geqq 0$ be a perturbation of X_0 and set $\Delta X_0 \equiv \tilde{X}_0 - X_0$. Let $\tilde{A}$, $\tilde{F}$, and $\tilde{G}$ be perturbations of A, F, and G with $\Delta A = \tilde{A} - A$, $\Delta F = \tilde{F} - F$, and $\Delta G = \tilde{G} - G$. As in § 2, we assume that $\tilde{F}$ and $\tilde{G}$ are symmetric and positive definite. Let $\tilde{X} = \tilde{X}(t)$ denote the solution to (3.1) for $\tilde{A}$, $\tilde{F}$, $\tilde{G}$, and $\tilde{X}_0$ and set

$$\Delta X(t) \equiv \tilde{X}(t) - X(t). \tag{3.4}$$

For $0 \leqq t \leqq t_1$, define the differential Riccati condition numbers

$$K_\delta(t) \equiv \sup \left\{ \frac{\|\Delta X(t)\|}{\delta \|X(t)\|} \right\}, \qquad K(t) \equiv \lim_{\delta \to 0} K_\delta(t). \tag{3.5}$$

Here the supremum is taken over the set $\|\Delta W\| \leqq \delta \|W\|$ with $W = A$, F, G, and X_0 such that $F + \Delta F$ and $G + \Delta G$ are symmetric and positive semidefinite. We assume throughout that $\|X(t)\| > 0$; obvious modifications in terms of absolute rather than relative condition numbers apply to the case where $\|X(t)\|$ is very small or zero.

Bounds on $K(t)$ can be found by expanding (3.1) for the perturbed matrices. For $X = X(t)$, let $A_C = A - FX$ and define

$$M_1 \equiv \Delta G + \Delta A^T X + X \Delta A - X \Delta F X, \tag{3.6}$$

$$M_2 \equiv (\Delta A - \Delta F X)^T \Delta X + \Delta X (\Delta A - \Delta F X) - \Delta X (F + \Delta F) \Delta X. \tag{3.7}$$

Using $\tilde{A}$, $\tilde{F}$, $\tilde{G}$, and $\tilde{X}$ in (3.1), we obtain

$$\Delta \dot{X} = A_C^T \Delta X + \Delta X A_C + M_1 + M_2, \quad \Delta X(0) = \Delta X_0, \quad 0 \leqq t \leqq t_1. \tag{3.8}$$

To find the analogue of Ω^{-1} in (2.4), let Φ satisfy

$$\dot{\Phi}(t) = \Phi(t) A_C(t), \quad \Phi(0) = I, \quad 0 \leqq t \leqq t_1. \tag{3.9}$$

Define

$$\Omega_t^{-1}(Z) \equiv -\int_0^t \Phi^T(t) \Phi^{-T}(s) Z(s) \Phi^{-1}(s) \Phi(t)\, ds \tag{3.10}$$

for any continuous matrix function $Z = Z(s)$, $s \in [0, t]$.

By variation of parameters [6], ΔX in (3.8) can be written as

$$\Delta X(t) = \Phi^T(t) \Delta X_0 \Phi(t) - \Omega_t^{-1}(\Delta G) - \Theta_t(\Delta A) + \Pi_t(\Delta F) + \Omega_t^{-1}(M_2) \tag{3.11}$$

where

$$\Theta_t(Z) \equiv \Omega_t^{-1}(Z^T X + XZ), \qquad \Pi_t(Z) \equiv \Omega_t^{-1}(XZX). \tag{3.12}$$

Since the first-order terms in (3.11) depend on the constant matrices ΔA, ΔF, ΔG, and ΔX_0, we define the restricted operator norm, $\|R\| \equiv \max (\|R(Z)\| / \|Z\|)$ for $R = \Omega_t^{-1}$, Θ_t, or Π_t with Z restricted to nonzero constant matrices in $\mathbb{R}^{n \times n}$.

From (3.11),

$$\begin{aligned} \|\Delta X(t)\| \leqq{}& \|\Phi(t)\|^2 \|\Delta X_0\| + \|\Omega_t^{-1}\| \|\Delta G\| + \|\Theta_t\| \|\Delta A\| + \|\Pi_t\| \|\Delta F\| \\ &+ \int_0^t \|\Phi^{-1}(s)\Phi(t)\|^2 \, ds [2(\|\Delta A\| + \|\Delta F\| \|X\|_t) \|\Delta X\|_t \\ &+ (\|F\| + \|\Delta F\|) \|\Delta X\|_t^2] \end{aligned}$$

where $\|\cdot\|_t$ denotes the max norm, $\|Z\|_t \equiv \max_{0\leq s\leq t}\|Z(s)\|$ for any continuous matrix function Z. This inequality suggests that we define the Byers-type approximate condition number

$$K_B(t) \equiv \frac{\|\Phi(t)\|^2\|X_0\| + \|\Omega_t^{-1}\|\,\|G\| + \|\Theta_t\|\,\|A\| + \|\Pi_t\|\,\|F\|}{\|X(t)\|}. \tag{3.13}$$

We then have the analogue of Theorem 2.2.

THEOREM 3.1. *For $0\leq t\leq t_1$, let $K(t)$, $K_B(t)$ be defined by* (3.5) *and* (3.13), *and assume that $X(t)$ satisfies* (3.1) *with $\|X(t)\|\neq 0$. Then*

$$\frac{K_B(t)}{4} \leq K(t) \leq K_B(t). \tag{3.14}$$

Proof. See Appendix 2 for the proof. □

This theorem shows that $K_B(t)$ gives a reasonable estimate of $K(t)$. The connection between conditioning and damping is established by using the analogues of H_k in (2.16): let $H_k = H_k(t)$ be the solution to

$$\dot{H}_k = A_C^T H_k + H_k A_C + X^k, \quad H_k(0) = 0, \quad k = 0, 1, 2. \tag{3.15}$$

LEMMA 3.2. *Let x, D_k, and H_k satisfy* (3.2), (3.3), *and* (3.15), *respectively. Then*

$$x_0^T H_k(t_1) x_0 = \|x\|^2_{L_2[0,t_1],X^k} \equiv \int_0^{t_1} x^T(t) X^k(t_1 - t) x(t)\, dt \tag{3.16}$$

and

$$\|H_k(t_1)\| = D_k^2(t_1) \quad \textit{for } k = 0, 1, 2. \tag{3.17}$$

Proof. Use the fact that $x(t) = \Phi^{-1}(t_1 - t)\Phi(t_1)x_0$ and

$$H_k(t) = \int_0^t \Phi^T(t)\Phi^{-T}(s) X^k(s) \Phi^{-1}(s)\Phi(t)\, ds, \qquad 0\leq t\leq t_1 \tag{3.18}$$

where Φ satisfies (3.9). Now proceed as in the proof of Lemma 2.3. □

From (3.18),

$$\Omega_t^{-1}(I) = -H_0(t), \quad \Theta_t(I) = -2H_1(t), \quad \Pi_t(I) = -H_2(t) \tag{3.19}$$

so that $\|H_0(t)\| \leq \|\Omega_t^{-1}\|$, $2\|H_1(t)\| \leq \|\Theta_t\|$, and $\|H_2(t)\| \leq \|\Pi_t\|$. This suggests the following analogues of Theorem 2.4.

THEOREM 3.3. *For H_k, Ω_t^{-1}, θ_t, and Π_t as in* (3.15), (3.10), *and* (3.12), *respectively,*

$$\|\Omega_t^{-1}\| = \|H_0(t)\|, \tag{3.20}$$

$$\|\Pi_t\| = \|H_2(t)\|, \tag{3.21}$$

$$2\|H_1(t)\| \leq \|\Theta_t\| \leq 2\|H_0(t)\|^{1/2}\|H_2(t)\|^{1/2}. \tag{3.22}$$

Proof. The proof is similar to the proof of Theorem 2.4. □

Because of the parallels between the algebraic and differential problems, the remarks following Theorem 2.4 also apply to Theorem 3.3 with only slight modifications, the main difference arising from the presence of the term $\|\Phi(t)\|^2\|X_0\|$ in (3.13). This term represents the main contribution to the error for t small because $H_k(0) = 0$, but as we will see, $\|\Phi(t)\| \to 0$ as $t\to\infty$ so that its influence is less important for large t. The norm of $\Phi(t)$ can be interpreted as a damping measure for the linear dynamical system (3.9) rather than (3.2).

For $X_0 = X_0^T \geqq 0$, $\lim_{t\to\infty} X(t) = X_+$, (see [4]) and $\lim_{t\to\infty} \dot{X}(t) = 0$. In this case, the differential relation (1.4) for X tends to the algebraic relation (1.6). Thus, it is natural to ask how the sensitivity estimates for the differential problem compare with those of the algebraic problem as $t \to \infty$. The next two lemmas show that the two sensitivity estimates are asymptotically equal, under the assumption that $\|H_0(t)\|$ is uniformly bounded for $0 \leqq t < \infty$.

LEMMA 3.4. *Let $X = X(t)$ satisfy* (3.1) *with $X_0 = X_0^T \geqq 0$. Let Φ satisfy* (3.9). *Then* $\lim_{t\to\infty} \Phi(t) = 0$.

Proof. See Appendix 2 for the proof. □

LEMMA 3.5. *Let Ω^{-1}, Θ, Π, and H_k be given by* (2.4), (2.7), *and* (2.11). *Let Ω_t^{-1}, θ_t, Π_t, and $H_k(t)$ be defined by* (3.10), (3.12), *and* (3.15). *If $\|H_0(t)\|$ is uniformly bounded over $0 \leqq t < \infty$, then*

$$\lim_{t\to\infty} H_k(t) = H_k. \tag{3.23}$$

Moreover, for any constant matrix Z,

$$\lim_{t\to\infty} \Omega_t^{-1}(Z) = \Omega^{-1}(Z), \tag{3.24}$$

$$\lim_{t\to\infty} \Theta_t(Z) = \Theta(Z), \tag{3.25}$$

and

$$\lim_{t\to\infty} \Pi_t(Z) = \Pi(Z). \tag{3.26}$$

Consequently, $\lim_{t\to\infty} K_B(t) = K_B^+$.

Proof. See Appendix 2 for the proof. □

Remark. Since $A_C(t) \to A_C^+$, which is stable, the assumption that $\|H_0(t)\|$ is uniformly bounded for $t \geqq 0$ seems reasonable; however, it is not clear how restrictive this assumption really is.

Just as in the algebraic problem, the possibility exists for $\|H_1(t)\| \ll \|H_0(t)\|^{1/2}\|H_2(t)\|^{1/2}$, in which case (3.22) does not provide much information about $\|\Theta_t\|$. In general this was not found to be a problem, but for Example 1 (2.18) of § 2, the gap increased with λ. For example, if $\lambda = 10^8$ and $X_0 = I$, then $\|H_1(10^{-4})\| = 0.724$, whereas

$$\|H_0(10^{-4})\|^{1/2}\|H_2(10^{-4})\|^{1/2} = 2432.0.$$

This problem can be handled as in § 2 by using the Kronecker forms associated with the Frobenius norm of Θ_t. For a given constant matrix Z,

$$\Theta_t(Z) = -\int_0^t \Phi^T(t)\Phi^{-T}(s)(Z^T X(s) + X(s)Z)\Phi^{-1}(s)\Phi(t)\, ds. \tag{3.27}$$

Using the Vec operator, we obtain

$$\operatorname{Vec}(\Theta_t(Z)) = L(t)\operatorname{Vec}(Z) \tag{3.28}$$

where

$$L(t) \equiv -\Phi^T(t) \otimes \Phi(t) \int_0^t (\Phi^{-T}(s) \otimes \Phi^{-T}(s))(I \otimes X(s) + (X(s) \otimes I)U)\, ds. \tag{3.29}$$

(The permutation matrix U is symmetric [7] and satisfies $U\,\mathrm{Vec}\,(Z^T)=\mathrm{Vec}\,(Z)$.) From (3.28),

$$\|\Theta_t\|_F=\max\frac{\|\Theta_t(Z)\|_F}{\|Z\|_F}=\max\frac{\|\mathrm{Vec}\,\Theta_t(Z)\|}{\|\mathrm{Vec}\,Z\|}=\max\frac{\|L(t)\,\mathrm{Vec}\,Z\|}{\|\mathrm{Vec}\,Z\|}=\|L(t)\|. \tag{3.30}$$

Thus the 2-norm of $L(t)$ is equal to the Frobenius norm (restricted to constant Z) of Θ_t. Moreover, from (3.29)

$$\dot{L}=(A_C^T\otimes I+I\otimes A_C^T)L+I\otimes X+(X\otimes I)U,\qquad L(0)=0. \tag{3.31}$$

We could integrate (3.31) to obtain $L(t)$ and then find $\|L(t)\|$ to get $\|\Theta_t\|_F$. In this case, an estimate of the 2-norm of Θ_t can be found by using the singular vector v of $L(t)$ corresponding to $\sigma_{\max}(L(t))$. Let $V=\mathrm{Unvec}\,(v)$, that is $\mathrm{Vec}\,(V)=v$, then $\|L(t)\|=\|L(t)v\|/\|v\|$ implies that $\|\Theta_t\|_F=\|\Theta_t(V)\|_F/\|V\|_F$. Thus by (2.32), we get the 2-norm estimate $\|\Theta_t\|\cong\|\Theta_t(V)\|/\|V\|$. In fact, by (2.33) we have $\|\Theta_t(V)\|/\|V\|\leqq\|\Theta_t\|\leqq\sqrt{n}(\|\Theta_t(V)\|/\|V\|)$.

This procedure is numerically expensive since $L(t)$ is $n^2\times n^2$. This suggests a power method approach like that of § 2, in which we avoid explicitly constructing $L(t)$. This method is only partially successful, because the nature of $L^T(t)$ makes it hard to avoid using Kronecker forms.

Given $\omega=\mathrm{Vec}\,(W)$, we can form $L(t)\omega$ by integrating the system

$$\dot{H}=A_C^TH+HA_C+W^TX+XW,\qquad H(0)=0 \tag{3.32}$$

and setting $L(t)\omega=\mathrm{Vec}\,(H(t))$. This follows from the (3.31), since $F\equiv L\omega$ satisfies

$$\dot{F}=(A_C^T\otimes I+I\otimes A_C^T)F+(I\otimes X+(X\otimes I)U)\omega.$$

However, $g\equiv L^T\omega$ satisfies $\dot{g}=L^T(A_C\otimes I+I\otimes A_C)\omega+(I\otimes X+U(X\otimes I))\omega$, which does not in general reduce to a simple $n\times n$ matrix differential equation for $\mathrm{Unvec}\,(L^T\omega)$, unless L^T and $(A_C\otimes I+I\otimes A_C)$ commute. In this case $\mathrm{Vec}\,(L^Tq)=H$ where

$$\dot{H}=A_CH+HA_C^T+X(W+W^T),\qquad H(0)=0.$$

This problem needs more research, but fortunately there is a procedure that seems to work well and is much less expensive than evaluating $L(t)$ directly. Let $\tilde{W}$ be given by one cycle of the inverse power method for estimating $\|\Theta\|_F$ as in (2.34). Let $H_1^{(1)}(t)$ satisfy (3.32) with $W=\tilde{W}/\|\tilde{W}\|$. Then $\|H_1^{(1)}(t)\|=\|\Theta_t(\tilde{W})\|/\|\tilde{W}\|\leqq\|\Theta_t\|$, and we have found that $\|H_1^{(1)}(t)\|\cong\|\Theta_t\|$. The rationale for this choice of $\tilde{W}$ is that $\|\Theta(\tilde{W})\|/\|\tilde{W}\|\cong\|\Theta\|$ as discussed in § 2, and that $\Theta_t\to\Theta$ as $t\to\infty$. Thus there is a good possibility that $\tilde{W}$ nearly maximizes the ratio $\|\Theta_t(\tilde{W})\|/\|\tilde{W}\|$, especially for large t.

We now define

$$K_U(t)\equiv\frac{\|\Phi(t)\|^2\|X_0\|+\|H_0(t)\|\,\|G\|+2\|H_0(t)\|^{1/2}\|H_2(t)\|^{1/2}\|A\|+\|H_2(t)\|\,\|F\|}{\|X(t)\|}, \tag{3.33}$$

$$K_L(t)\equiv\frac{\|\Phi(t)\|^2\|X_0\|+\|H_0(t)\|\,\|G\|+\|H_1^{(1)}(t)\|\,\|A\|+\|H_2(t)\|\,\|F\|}{\|X(t)\|}. \tag{3.34}$$

By (3.13) and Theorems 3.1 and 3.3, $K_L(t)\leqq K_B(t)\leqq K_U(t)$, $K_L(t)/4\leqq K(t)\leqq K_U(t)$. The asymptotic convergence results of Lemma 3.5 give $\lim_{t\to\infty}K_U(t)=K_U^+$ and $\lim_{t\to\infty}K_L(t)=K_L^+$.

4. Numerical results. By considering seven basic problems from [1], [9], and [15] with various parameter values, we tested 21 examples for the algebraic equation and seven for the differential equation. A representative subset of our results are presented below in such a way as to illustrate several points.

For example, the upper and lower bounds, K_U in (2.35) and K_L in (2.36) for the true condition number, K in (2.2), were farthest apart for the first example (see Table 1). The same applies to the time-dependent upper and lower bounds, $K_U(t)$ in (3.33) and $K_L(t)$ in (3.34) for $K(t)$ in (3.5), (see Table 2). That these upper and lower bounds are relatively close, even for this rather extreme example, is encouraging.

Another point we want to make with these results is that selective sensitivity can be easily detected. As discussed in § 2, the ratios $\|H_0\|\,\|G\|/\|X\|$, $\|H_1^{(1)}\|\,\|A\|/\|X\|$, and $\|H_2\|\,\|F\|/\|X\|$, (see (2.11) and (2.34)) measure, respectively, the sensitivity of X with respect to perturbations in the sensor matrix G, the state matrix A, and the actuator matrix F. Example 1 below illustrates state matrix sensitivity while Example 2 shows that actuator sensitivity dominates the condition number of companion form systems as the state dimension, n increases. The same example shows that the bound $1/2\rho_s(A_C) < \|H_0\|$, in Lemma 2.7, which relates the closed-loop stability radius to conditioning, can be very conservative. Example 3 shows that a problem can be sensitive in all three coefficient matrices. Lastly, Example 4 has the interesting feature that it is most sensitive with respect to sensor matrix perturbations for the algebraic Riccati problem, but for the differential problem most of the initial sensitivity ($t < 10$) is due to the actuator matrix. Except for Example 4, $F = BB^T$ and $G = C^TC$.

Example 1. Let

$$A = \begin{bmatrix} 0 & \lambda \\ 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}.$$

TABLE 1
Condition measures for Example 1.

System parameter λ	Cond. no. (Frob. norm) K_B	Lower cond. no. (2-norm) K_L	Upper cond. no. (2-norm) K_U	Sensor matrix sensitivity $\frac{\|H_0\|\,\|G\|}{\|X\|}$	State matrix sensitivity $\frac{\|H_1^{(1)}\|\,\|A\|}{\|X\|}$	Actuator matrix sensitivity $\frac{\|H_2\|\,\|F\|}{\|X\|}$
10^0	3.7	3.8	4.2	0.6	1.6	1.6
10^1	7.4	7.3	11	0.3	6.3	0.8

10^4	5×10^3	5×10^3	9×10^3	0.3	5×10^3	0.8
10^8	5×10^7	5×10^7	9×10^7	0.3	5×10^7	0.8

TABLE 2
Convergence of time-dependent condition measures to steady state for $\lambda = 10^8$ *and* $X_0 = I$.

Time t	Lower cond. no. (2-norm) $K_L(t)$	Upper cond. no. (2-norm) $K_U(t)$	Initial matrix sensitivity $\frac{\|\Phi(t)\|^2\|X_0\|}{\|X(t)\|}$	Sensor matrix sensitivity $\frac{\|H_0(t)\|\,\|G\|}{\|X(t)\|}$	State matrix sensitivity $\frac{\|H_1^{(1)}(t)\|\,\|A\|}{\|X(t)\|}$	Actuator matrix sensitivity $\frac{\|H_2(t)\|\,\|F\|}{\|X(t)\|}$
0.0	1.0	1.0	1.0	0.0	0.0	0.0
10^{-7}	29	79	1.0	4×10^{-8}	28	4×10^{-6}
10^{-6}	3×10^3	7×10^3	1.0	3×10^{-7}	3×10^3	3×10^{-3}
10^{-5}	2×10^5	3×10^5	0.2	2×10^{-6}	2×10^5	0.8
10^{-4}	1×10^7	2×10^7	3×10^{-4}	7×10^{-3}	1×10^7	1.0
10^{-3}	5×10^7	9×10^7	4×10^{-10}	0.3	5×10^7	0.8

For this problem the upper and lower condition number bounds, K_U and K_L are relatively more separated than for any other problem we tested. (See also the discussion in § 2 concerning the gap between $\|H_1\|$ and $\|H_0\|^{1/2}\|H_2\|^{1/2}$.) Not surprisingly this problem exhibits sensitivity with respect to the state matrix A (compare column 6 with columns 5 and 7 in Table 1). This carries over to the differential problem. Table 2 shows the asymptotic convergence of the time-dependent condition measures to their steady state (algebraic) values.

Example 2. Let A, B, and C be given by (2.41), with $a_1 = a_2 = \cdots = a_n = 0$. This problem illustrates that high-order companion form systems are subject to actuator sensitivity (compare column 4 with 2 and 3 in Table 3). Columns 5 and 6 in Table 3 show that the bound $1/2\rho_s(A_C) < \|H_0\|$ in (2.40) can be very conservative. For related results, see [14].

Example 3 (Example 2 in [1]). Let A, B, and C be given by

$$A = \begin{bmatrix} -\varepsilon & 1 & 0 & 0 \\ -1 & -\varepsilon & 0 & 0 \\ 0 & 0 & \varepsilon & 1 \\ 0 & 0 & -1 & \varepsilon \end{bmatrix}, \quad B = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}, \quad C = B^T.$$

This problem was designed so that the closed-loop matrix A_C has eigenvalues that approach the imaginary axis as $\varepsilon \to 0$. This forces the stability radius $\rho_s(A_C)$ to go to zero and consequently by (2.40) the norm of H_0 becomes large. From Table 4, we see that X is sensitive to perturbations in A, B, or C.

Example 4 (From [12]). Let A, B, C, F, and G be given by

$$A = \begin{bmatrix} -0.0297 & 0.331 & -1.13 & 0.0 & 0.0 \\ -1.0 & -0.0042 & 0.128 & 0.0 & 1.0 \\ 0.0 & -0.0461 & -0.803 & 1.0 & 0.0 \\ 0.438 & 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 10^3 & 0 \\ 0 & 10^3 \end{bmatrix},$$

$$C = \begin{bmatrix} -0.00297 & 0.0331 & -0.0113 & 0.0 & 0.0 \\ 0.0 & 0.012048 & 0.021187 & 0.0 & 0.0 \\ 0.0 & 0.001265 & 0.05028 & 0.0 & 0.0 \end{bmatrix}, \quad F = BB^T,$$

$$G = C^T \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \varepsilon \end{bmatrix} C.$$

TABLE 3
Sensitivity measures for companion form systems.

10^{-5}	4×10^{10}	2×10^{10}	4×10^6
10^{-7}	4×10^{14}	2×10^{14}	4×10^6

This problem shows increasing sensitivity with respect to the sensor matrix G as ε decreases (see column 1 of Table 5). A very interesting feature of this problem is that for $X_0 = I$ and t near zero, the sensitivity of the differential Riccati equation (Table 6) is mostly due to the actuator matrix, F because of its large norm; $\|F\| = 10^6$. (See row 6, column 4 of Table 6.) Thus the sensitivity of the algebraic problem is not always a reliable guide to the sensitivity of the differential problem.

5. Conclusion. In this paper we have shown that the ideas developed by Byers in [2] for the algebraic Riccati equation can be sharpened and extended to norms other

than the Frobenius norm. This extension is crucial from an interpretive point of view because use of the spectral norm allows an identification of the condition number of the algebraic Riccati equation with the damping properties of the closed-loop dynamical system. The resulting condition numbers are easily computed and provide a simple means of detecting selective sensitivity with respect to the sensor matrix, the open-loop state matrix or the actuator matrix. Moreover, this approach has the pleasant feature that it carries over to a completely parallel theory for the sensitivity of the differential Riccati equation, an area which to our knowledge has not been considered previously.

Appendix 1. Proofs of Theorems 2.2 and 2.4.

Proof of Theorem 2.2. Let $\|\Delta A\| \leqq \delta \|A\|$, $\|\Delta F\| \leqq \delta \|F\|$, and $\|\Delta G\| \leqq \delta \|G\|$ with $F+\Delta F$, $G+\Delta G$ symmetric and positive semidefinite. Then by (2.1), $\|\Delta X\| \leqq \delta \|X\| K_\delta$. Taking norms in (2.5),

$$\|\Delta X\| \leqq \delta(\|\Omega^{-1}\| \|G\| + \|\Theta\| \|A\| + \|\Pi\| \|F\|) + \delta^2 \|\Omega^{-1}\| K_\delta (2(\|A\| + \|F\| \|X\|)\|X\| + (1+\delta)\|F\| \|X\|^2 K_\delta).$$

Divide by $\|X\|\delta$ to get

$$\frac{\|\Delta X\|}{\delta \|X\|} \leqq K_B + \delta \|\Omega^{-1}\| K_\delta (2(\|A\| + \|F\| \|X\|) + (1+\delta)\|F\| \|X\| K_\delta).$$

From (2.1) we then obtain

$$K_\delta \leqq K_B + \delta \|\Omega^{-1}\| K_\delta (2(\|A\| + \|F\| \|X\|) + (1+\delta)\|F\| \|X\| K_\delta).$$

From Theorem 2.1, $K_\delta(A, F, G, \|\cdot\|_F)$ is finite for δ sufficiently small. Since all norms on $\mathbb{R}^{m\times m}$ are equivalent [18], we must have that $K_\delta(A, F, G, \|\cdot\|)$ is finite for δ small for the matrix 2-norm. But $K_\delta(A, F, G, \|\cdot\|)$ is nonincreasing as $\delta \to 0^+$ so

$$K(A, F, G, \|\cdot\|) = \lim_{\delta \to 0} K_\delta(A, F, G, \|\cdot\|) \leqq K_B(A, F, G, \|\cdot\|).$$

We now show that $\|\Omega^{-1}\| \|G\| \leqq K\|X\|$, $\|\Theta\| \|A\| \leqq K\|X\|$, and $\|\Pi\| \|F\| \leqq K\|X\|$; adding these inequalities gives $K_B \leqq 3K$, which completes the proof.

Let $\Delta A = 0$, $\Delta F = 0$, and $\Delta G = \delta \|G\| I$. Then $G+\Delta G$ is symmetric and positive definite as required in (2.1). Using these perturbation matrices in (2.5) gives $\Delta X = -\delta \|G\| \Omega^{-1}(I)$, so $\|\Delta X\| = \delta \|G\| \|\Omega^{-1}(I)\| = \delta \|G\| \|\Omega^{-1}\|$ by (2.12) and (2.13). From (2.1),

$$\|G\| \|\Omega^{-1}\| = \|\Delta X\|/\delta \leqq K_\delta \|X\|.$$

Letting $\delta \to 0$ gives $\|\Omega^{-1}\| \|G\| \leqq K\|X\|$ as desired. Similarly, $\Delta A = 0$, $\Delta F = \delta \|F\| I$, and $\Delta G = 0$ gives $\|\Theta\| \|F\| \leqq K\|X\|$, by (2.12) and (2.14). (Note that $\tilde{F} = F + \Delta F$ is symmetric and positive semidefinite in keeping with (2.1).)

For the operator norm defined by (2.9), standard compactness arguments show that there exists a matrix A_0, satisfying $\|A_0\| = 1$, $\|\Theta(A_0)\| = \|\Theta\|$. Now let $\Delta A = \delta \|A\| A_0$, $\Delta F = 0$, and $\Delta G = 0$ and after an argument similar to the one above we get $\|\Theta\| \|A\| \leqq K\|X\|$. □

Proof of Theorem 2.4. From (2.12), $\|H_0\| \leqq \|\Omega^{-1}\|$, $\|H_2\| \leqq \|\Pi\|$, and $2\|H_1\| \leqq \|\Theta\|$. Now, for $Z \in \mathbb{R}^{m\times m}$, let u and v be unit left and right singular vectors of $\Omega^{-1}(Z)$ such that

$$\|\Omega^{-1}(Z)\| = -u^T \Omega^{-1}(Z) v.$$

Then by (2.4), $\|\Omega^{-1}(Z)\| = \int_0^\infty u^T e^{A_C^T t} Z e^{A_C t} v \, dt \leqq \|Z\| \int_0^\infty \|e^{A_C t} u\| \, \|e^{A_C t} v\| \, dt$. Applying the Cauchy-Schwarz inequality, we obtain $\|\Omega^{-1}(Z)\| \leqq \|Z\| [\int_0^\infty \|e^{A_C t} u\|^2 \, dt]^{1/2} [\int_0^\infty \|e^{A_C t} v\|^2 \, dt]^{1/2}$. But $\int_0^\infty \|e^{A_C t} u\|^2 \, dt = u^T \int_0^\infty e^{A_C^T t} e^{A_C t} \, dt \, u = u^T H_0 u \leqq \|H_0\|$ because u is a unit vector. The same applies to v, so $\|\Omega^{-1}(Z)\| \leqq \|Z\| \, \|H_0\|^{1/2} \|H_0\|^{1/2} = \|Z\| \, \|H_0\|$. Thus $\|\Omega^{-1}\| \leqq \|H_0\|$. Similar arguments establish $\|\Pi\| \leqq \|H_2\|$ and $\|\Theta\| \leqq \|H_0\|^{1/2} \|H_2\|^{1/2}$. □

Appendix 2. Proofs of Theorem 3.1, Lemma 3.4, and Lemma 3.5.

Proof of Theorem 3.1. Let $t \in (0, \infty)$ be given. Because the right-hand side of (3.1) is a smooth function of its arguments, we may appeal to the theory of perturbations of initial conditions and parameters of ordinary differential equations (see [6, Thm. 7.5, Chap. 1]), to conclude that

$$\Delta X = \Delta X(A, F, G, X_0, \Delta A, \Delta F, \Delta G, \Delta X_0, t)$$

is a continuously differentiable function of its arguments. Moreover, for δ sufficiently small, with $\|\Delta A\|/\|A\|, \|\Delta F\|/\|F\|, \|\Delta G\|/\|G\|, \|\Delta X_0\|/\|X_0\| \leqq \delta$, there exists a constant $c < \infty$ such that $\|\Delta X\|_t \leqq \delta c$.

Using this in (3.11), we obtain

$$\|\Delta X(t)\| \leqq \|\Phi(t)\|^2 \delta \|X_0\| + \|\Omega_t^{-1}\| \delta \|G\| + \|\Theta_t\| \delta \|A\| + \|\Pi_t\| \delta \|F\| + \int_0^t \|\Phi^{-1}(s)\Phi(t)\|^2 \, dt [2(\|A\| + \|F\| \, \|X\|_t)c + (1+\delta)\|F\| c^2] \delta^2.$$

Thus $\|\Delta X(t)\|/\delta \|X(t)\| \leqq K_B(t) + N(t)\delta$, where

$$N(t) = \frac{\int_0^t \|\Phi^{-1}(s)\Phi(t)\|^2 \, dt}{\|X(t)\|} [2(\|A\| + \|F\| \, \|X\|_t)c + (1+\delta)\|F\| c^2].$$

So $K_\delta(t) \leqq K_B(t) + N(t)\delta$. Now $N(t)$ is finite by (1.10) and the assumption that $X(t) \neq 0$. Thus letting $\delta \to 0$ gives $K(t) = \lim_{\delta \to 0} K_\delta(t) \leqq K_B(t)$, which proves the right-hand side of (3.14).

Using arguments similar to those in the proof of Theorem 2.2, we can show that

$$\frac{\|\Omega_t^{-1}\| \, \|G\|}{\|X(t)\|} \leqq K(t), \qquad \frac{\|\Theta_t\| \, \|A\|}{\|X(t)\|} \leqq K(t),$$

$$\frac{\|\Pi_t\| \, \|F\|}{\|X(t)\|} \leqq K(t), \qquad \frac{\|\Phi(t)\|^2 \|X_0\|}{\|X(t)\|} \leqq K(t).$$

Adding these inequalities gives $K_B(t) \leqq 4K(t)$ and completes the proof. □

Proof of Lemma 3.4. This lemma has been proved in [13] for the special case $X_0 = 0$. For the general case write (3.9) as $\dot{\Phi}(t) = \Phi(t)(A - FX_+) + \Phi(t)F(X_+ - X(t))$. Since $A_C^+ \equiv A - FX_+ \in \mathbb{R}^{n \times n}$ is stable, the result follows from Theorem 8.1 on p. 92 and Problem 35 on p. 106 of [6], if we can show that for some $t_0 \geqq 0$,

$$\text{(A1)} \qquad \int_{t_0}^\infty t^n \|X_+ - X(t)\| \, dt < \infty.$$

To prove (A1), let $\Phi_+(t) = e^{A_C^+ t}$. Then we can use the representation (see [13])

$$\text{(A2)} \qquad X(t) - X_+ = \Phi_+^T(t - t_0) \left[I + (X(t_0) - X_+) \int_{t_0}^t \Phi_+(s - t_0) F \Phi_+^T(s - t_0) \, ds \right]^{-1} \cdot (X(t_0) - X_+) \Phi_+(t - t_0)$$

for any t_0 such that the inverse in (A2) exists.

Let $\Lambda(A_C^+)$ denote the set of eigenvalues of A_C^+ and define $\alpha(A_C^+) \equiv \max_{\lambda \in \Lambda(A_C^+)} R_e\lambda$. Since A_C^+ is stable, $\alpha = \alpha(A_C^+) < 0$, and there exists a constant c_0 such that $\|\Phi_+(t)\| \leqq c_0 e^{t\alpha/2}$. Hence, $\int_0^\infty \|\Phi_+(t)\|^2\, dt \leqq c_0^2 \int_0^\infty e^{\alpha t}\, dt = c_0^2/|\alpha| < \infty$. Since $\lim_{t\to\infty} X(t) = X_+$, we may find a $t_0 \geqq 0$ such that $\|X(t_0) - X_+\| \|F\| \int_{t_0}^\infty \|\Phi(t)\|^2\, dt < \frac{1}{2}$. This means that for all $t \geqq t_0$, the inverse in (A2) exists and

$$\text{(A3)} \qquad \left\| \left(I + (X(t_0) - X_+) \int_{t_0}^t \Phi_+(s - t_0) F \Phi^T(s - t_0)\, ds \right)^{-1} \right\| < 2.$$

Using (A3) in (A2) gives $\|X(t) - X_+\| \leqq 2c_0^2 \|X(t_0) - X_+\|\, e^{\alpha(t-t_0)}$, which establishes (A1) and completes the proof. □

Remark. The preceding actually shows that the decay rate for $\|\Phi(t)\|$ is asymptotically the same as the decay rate for $\|\Phi_+(t)\|$ (see [10, Thm. 5.4.1]).

Proof of Lemma 2.5. We show that $\lim_{t\to\infty} \Theta_t(Z) = \Theta(Z)$. The other asymptotic convergence proofs are very similar. From the definition of $\Theta_t(Z)$,

$$\dot{\Theta}_t(Z) = A_C^T \Theta_t(Z) + \Theta_t(Z) A_C + Z^T X + XZ, \qquad \Theta_0(Z) = 0.$$

This matrix differential equation can be written as a vector differential system: $\dot{Y}(t) = \mathscr{A}(t) Y(t) + S(t)$, where $Y_t(Z) = \text{Vec}\,(\Theta_t(Z))$, $\mathscr{A}(t) = I \otimes A_C^T + A_C^T \otimes I$, and $S(t) = \text{Vec}\,(Z^T X + XZ)$. Let $\mathscr{A}_+ = I \otimes (A_C^+)^T + (A_C^+)^T \otimes I$, and $S_+ = \text{Vec}\,(Z^T X_+ + X_+ Z)$. By Lemma 2.4, $\lim_{t\to\infty} \mathscr{A}(t) = \mathscr{A}_+$ and $\lim_{t\to\infty} S(t) = S_+$. Moreover, if we set $\alpha = \alpha(A_C^+)$ then there exists constants c_1 and c_2 such that by

$$\|\mathscr{A}(t) - \mathscr{A}_+\| = \|I \otimes (X_+ - X(t))F + F(X_+ - X(t)) \otimes I\| \leqq c_1 e^{t\alpha/2},$$

$$\|S(t) - S_+\| \leqq c_2 e^{t\alpha/2}.$$

Now $\mathscr{A}_+$ has eigenvalues of the form $\lambda = \mu + \nu$ where μ and ν are eigenvalues of A_C^+ (see [17]). Thus $\alpha(\mathscr{A}_+) = 2\alpha(A_C^+) = 2\alpha$. Hence there exists a constant c_3 such that $\|e^{\mathscr{A}_+ t}\| \leqq c_3 e^{\alpha t}$. Let $Y_+ \equiv \text{Vec}\,(\Theta(Z))$ and note that $\mathscr{A}_+ Y_+ = S_+$. Define $\Delta Y(t) \equiv Y(t) - Y_+$. Then $\Delta \dot{Y}(t) = \mathscr{A}_+ \Delta Y(t) + R(t)$, where $R(t) = (\mathscr{A}(t) - \mathscr{A}_+) Y(t) + S(t) - S_+$. The boundness of $\|H_0(t)\|$, together with $\|H_k(t)\| \leqq \|H_0(t)\|\, \|X^k\|_t$ for $k = 1, 2$ and $\|\Theta_t(Z)\| \leqq 2\|H_0(t)\|^{1/2} \|H_2(t)\|^{1/2}, \|Z\|$ ensures that $\|R(t)\| \leqq c_4 e^{t\alpha/2}$ for some constant c_4.

If we write $\Delta Y(t) = e^{\mathscr{A}_0 t} \Delta Y(0) + \int_0^t e^{\mathscr{A}_0(t-s)} R(s)\, ds$, we have

$$\|\Delta Y(t)\| \leqq c_3 e^{\alpha t} \|\Delta Y(0)\| + \int_0^t c_3 c_4 e^{\alpha(t-s)} e^{t\alpha/2}\, ds$$

$$\leqq e^{\alpha t} c_3 \|\Delta Y(0)\| + \frac{c_3 c_4 e^{t\alpha/2}}{|\alpha|} [1 - e^{\alpha t}].$$

Thus $\|\Delta Y(t)\| \to 0$ as $t \to 0$ and we must have $\Theta_t(Z) \to \Theta(Z)$. □

PIECEWISE LINEAR APPROXIMATION FOR HEREDITARY CONTROL PROBLEMS*

GEORG PROPST†

Abstract. This paper presents finite-dimensional approximations for linear retarded functional differential equations by use of discontinuous piecewise linear functions. The approximation scheme is applied to optimal control problems, when a quadratic cost integral must be minimized subject to the controlled retarded system. It is shown that the approximate optimal feedback operators converge to the true ones both in the case where the cost integral ranges over a finite time interval, as well as in the case where it ranges over an infinite time interval. The arguments in the last case rely on the fact that the piecewise linear approximations to stable systems are stable in a uniform sense. This feature is established using a vector-component stability criterion in the state space $\mathbb{R}^n \times L^2$ and the favorable eigenvalue behavior of the piecewise linear approximations.

Key words. hereditary control problem, piecewise linear approximation, uniform stability

AMS(MOS) subject classifications. 34K35, 65L60, 93C15

1. Introduction. Given $\phi^0 \in \mathbb{R}^n$ and $\phi^1 : [-h, 0] \to \mathbb{R}^n$, consider the retarded functional differential equation with constant coefficients

$$\dot{x}(t) = \sum_{k=0}^{p} A_k x(t-h_k) + \int_{-h}^{0} A_{01}(s) x(t+s)\, ds, \qquad t \geqq 0, \tag{1.1}$$
$$x(0) = \phi^0, \quad x = \phi^1 \quad \text{in } L^2(-h, 0; \mathbb{R}^n),$$

where $0 = h_0 < h_1 < \cdots < h_p = h$, $A_k \in \mathbb{R}^{n \times n}$, $k = 0, \cdots, p$, and $A_{01} \in L^2(-h, 0; \mathbb{R}^{n \times n})$. An equivalent abstract Cauchy problem $\dot{z}(t) = Az(t)$, $t \geqq 0$, $z(0) = (\phi^0, \phi^1)$ in the space $M^2 = \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n)$ generates a strongly continuous semigroup. Approximations are constructed by restricting the problem to finite-dimensional subspaces $Z^N = \mathbb{R}^n \times Y^N \subseteq M^2$, defining appropriate generators A^N on Z^N.

Banks and Burns [1] used subspaces Y^N consisting of functions that are piecewise constant on the delay interval $[-h, 0]$. This is the well-known averaging approximation scheme. As an extension, Burns and Cliff [5] enlarged the subspaces to piecewise linear functions. In both papers, the approximating generators were constructed by forward difference methods. In [3] the approximations were obtained by projections onto subspaces of continuous splines being contained in the domain of A. Then Kappel and Salamon [13] introduced δ-type operators to define generators for a spline scheme whose adjoint semigroups converge strongly. These δ-type operators are specially constructed to approximate the differential operator A at the discrete delays, where the splines may be discontinuous, as are the functions in the domain of A^*.

In this paper, a new scheme is presented employing again subspaces of orthogonal piecewise linear functions as in [5], but using δ-type operators for the construction of the approximating generators. These operators are needed at each meshpoint, where the subspace functions may be discontinuous. In fact, the number of discontinuities

increases with the order of the approximation, in contrast to the spline case. The resulting generators are completely different from those given in [5].

An application of the approximation schemes is the optimal control problem, when an integral ranging over $[0, T]$, quadratic in the trajectory and in the control, is to be minimized subject to the controlled delay equation. It was shown by Gibson [9] that, if $T<\infty$, the strong convergence of the semigroups and their adjoints yields convergence in norm of the optimal feedback operators. In this present work, strong convergence of the semigroups and their adjoints is proved using the Trotter–Kato Theorem as in [1] and [9]. Thereby, it is not necessary to assume absolute continuity of A_{01}, as did the proofs in [11]–[13].

In the case of the so-called infinite time horizon $T=\infty$, Gibson's approach relies on the assumption that a stable system is approximated by systems that are stable in a uniform sense. For the averaging scheme, this stability preservation property was established in [19], and in [11] for the Legendre-tau methods. In contrast, the spline schemes do not have this quality (see [14]). This is due to extraneous eigenvalues close to the imaginary axis. It is shown below that the eigenvalues of the present scheme converge to those of the delay equation and that exponential stability of our approximations is dominated by their $\mathbb{R}^n$-components. Thus, uniform preservation of exponential stability is proved with decay rates arbitrarily close to the decay rate of the hereditary system.

The matrices corresponding to the piecewise linear functions are banded and sparse, in contrast to the Legendre and spline methods. While the Legendre schemes [10], [12] exhibit high accuracy even for low-order approximation, the numerical efficiency of the present scheme is about the same as that of the first-order splines in [13], and superior to the averaging methods [1] as well as to those in [5].

Preliminarily, § 2 collects some facts on the semigroup generated by the uncontrolled system and on the linear quadratic hereditary control problem. Section 3 presents an approximation framework suited to § 4, where the piecewise linear scheme is developed. For the sake of transparency and brevity the presentation here is restricted to the one-delay case. The modifications necessary for the treatment of more general cases are briefly described in § 4.6. In § 4.1, the δ-type operators are defined and the projections onto the subspaces of piecewise linear functions are investigated. In § 4.2, the approximating generators and their adjoints are constructed and convergence results for the finite-time horizon problem are proved. In § 4.3, the matrix representations are given and an $\mathbb{R}^n$-component stability criterion is established. Section 4.4 investigates the eigenvalue behavior of the approximate systems when the order of approximation increases. In § 4.5, the uniform stability preservation is proved. Finally, in § 4.7 there is a brief discussion of the numerical tools needed for the implementation of the scheme on a computer and the results of three examples are tabulated.

2. The linear quadratic optimal control problem for hereditary systems. We give a brief outline of known results on the LQR problem. Proofs and a rigorous analysis may be found in [6], [8], and [9]. Consider the linear retarded functional differential equation

$$\dot{x}(t)=A_0x(t)+A_1x(t-r)+B_0u(t), \qquad t\geqq 0 \tag{2.1.1}$$

in $\mathbb{R}^n$, where $r>0$ is a fixed finite delay, A_0, A_1 are real $n\times n$ matrices, B_0 is a real $n\times m$ matrix, and $u(t)\in\mathbb{R}^m$.

Given $\phi=(\phi^0,\phi^1)\in M^2=\mathbb{R}^n\times L^2(-r,0;\mathbb{R}^n)$ and $u\in L^2_{\mathrm{loc}}(0,\infty;\mathbb{R}^m)$, there exists a unique solution $x(t;\phi,u)$ that is absolutely continuous with L^2-derivative on every

interval $[0, T]$ and that satisfies (2.1.1) for almost all $t \geqq 0$, and the initial condition

$$x(0; \phi, u) = \phi^0, \quad x(\cdot; \phi, u) = \phi^1 \quad \text{in } L^2(-r, 0; \mathbb{R}^n). \tag{2.1.2}$$

Defining $x_t: [-r, 0] \to \mathbb{R}^n$ by $x_t(s) = x(t+s)$ and the state at time t by

$$z(t; \phi, u) = (x(t; \phi, u), x_t(\phi, u)) \in M^2, \tag{2.2}$$

system (2.1) is converted to an abstract Cauchy problem in M^2, which is a Hilbert space with the inner product $\langle \phi, \psi \rangle = \phi^{0T}\psi^0 + \langle \phi^1, \psi^1 \rangle_2$. Let $S(t)$, $t \geqq 0$ be the C_0-semigroup corresponding to the free motion of (2.1), i.e.,

$$S(t)\phi = (x(t; \phi, 0), x_t(\phi, 0)), \qquad t \geqq 0, \quad \phi \in M^2.$$

With $B: \mathbb{R}^m \to M^2$ defined by

$$Bu = (B_0 u, 0), \qquad u \in \mathbb{R}^m,$$

the function

$$z(t; \phi, u) = S(t)\phi + \int_0^t S(t-s)Bu(s)\, ds, \qquad t \geqq 0, \tag{2.3}$$

is a mild solution of the abstract system

$$\dot{z}(t) = Az(t) + Bu(t), \qquad t \geqq 0, \quad z(0) = \phi \tag{Σ}$$

where the infinitesimal generator A of $S(\cdot)$ is given by

$$\operatorname{dom} A = \{\phi \in M^2 \mid \phi^1 \in W^{1,2}(-r, 0; \mathbb{R}^n),\ \phi^1(0) = \phi^0\},$$

$$A\phi = (A_0\phi^1(0) + A_1\phi^1(-r), \dot{\phi}^1).$$

The M^2-adjoint of A generates the M^2-adjoint semigroup $S(t)^*$, $t \geqq 0$:

$$\operatorname{dom} A^* = \{\phi \in M^2 \mid \phi^1 \in W^{1,2}(-r, 0; \mathbb{R}^n),\ \phi^1(-r) = A_1^T\phi^0\},$$

$$A^*\phi = (\phi^1(0) + A_0^T\phi^0, -\dot{\phi}^1).$$

The optimal control problem on a finite interval is: given $0 < T < \infty$ and $\phi \in M^2$ find the control $u \in L^2(0, T; \mathbb{R}^m)$ that minimizes the cost functional

$$\begin{aligned} J(u, \phi, T) &= \langle z(T; \phi, u), Gz(T; \phi, u) \rangle \\ &\quad + \int_0^T (\langle z(t; \phi, u), Wz(t; \phi, u) \rangle + u(t)^T Ru(t))\, dt \end{aligned} \tag{2.4}$$

where G, $W: M^2 \to M^2$ are defined by $G\phi = (G_0\phi^0, 0)$, $W\phi = (W_0\phi^0, 0)$ with G_0, W_0 being symmetric nonnegative matrices and $R = R^T$ positive definite. The optimal control $\bar{u}(\cdot)$ is given by the feedback law

$$\bar{u}(t) = -R^{-1}B^*\Pi(t)\bar{z}(t), \qquad 0 \leqq t \leqq T \tag{2.5}$$

where $\Pi(\cdot)$ is the unique, strongly continuous family of nonnegative self-adjoint and bounded operators satisfying the Riccati differential equation

$$\frac{d}{dt}\langle \psi, \Pi(t)\phi \rangle + \langle A\psi, \Pi(t)\phi \rangle + \langle \Pi(t)\psi, A\phi \rangle$$

$$-\langle \Pi(t)\psi, BR^{-1}B^*\Pi(t)\phi \rangle + \langle \psi, W\phi \rangle = 0 \quad \text{for } \phi, \psi \in \operatorname{dom} A, \qquad 0 \leqq t \leqq T,$$

$$\Pi(T) = G$$

and $\bar{z}(t)$ is the mild solution of

$$\dot{z}(t) = (A - BR^{-1}B^*\Pi(t))z(t), \qquad z(0) = \phi,$$

i.e.,

$$\bar{z}(t) = S(t)\phi - \int_0^t S(t-s)BR^{-1}B^*\Pi(s)\bar{z}(s)\, ds.$$

We also consider the infinite time horizon problem, that is the minimization of $J(u, \phi)$ given by (2.4) with $G \equiv 0$ and $T = \infty$, and assume that the system (2.1.1) is stabilizable, i.e., $A - BK$ generates an exponentially stable semigroup for some linear bounded operator $K : M^2 \to \mathbb{R}^m$. Then there exists a nonnegative, self-adjoint operator $\Pi \in \mathscr{L}(M^2)$ that maps dom A into dom A^* and satisfies the algebraic Riccati equation

$$A^*\Pi\phi + \Pi A\phi - \Pi BR^{-1}B^*\Pi\phi + W\phi = 0, \qquad \phi \in \text{dom } A. \tag{2.6}$$

If, in addition, (2.1.1) and W_0 have the property that any admissible control drives the state to zero, that is $J(u, \phi) < \infty$ implies $z(t; \phi, u) \to 0$, as $t \to \infty$, then Π is uniquely determined. This certainly is true if (2.1.1) with output W_0 is observable or if W_0 is simply nonsingular. Using the time-independent solution of (2.6) in the feedback law, (2.5) gives the optimal control and trajectory as in the finite time horizon case.

3. Finite-dimensional approximations. Our goal is to construct systems of ordinary differential equations, such that their solutions approximate the solution to the hereditary control problem in § 2. To this end, let Y^N, $N = 1, 2, \cdots$ be a sequence of finite-dimensional subspaces of $L^2(-r, 0; \mathbb{R}^n)$ with corresponding orthogonal projections p_1^N. Then $Z^N = \mathbb{R}^n \times Y^N$, $N = 1, 2, \cdots$ are finite-dimensional subspaces of M^2 with corresponding orthogonal projections $p^N\phi = (\phi^0, p_1^N\phi^1)$, $\phi \in M^2$. Suppose there is a sequence of linear operators $A^N : Z^N \to Z^N$ and let $S^N(t)$, $t \geqq 0$ be the uniformly continuous semigroups on M^2 generated by the bounded linear operators $A^Np^N : M^2 \to Z^N$, i.e.,

$$S^N(t)\phi = e^{A^Np^Nt}\phi, \qquad \phi \in M^2.$$

Remark. We extend A^N to all of M^2, because we want the semigroup $S^N(\cdot)$ acting on the whole space. Instead of letting the generator $A^Np^N = 0$ on $(Z^N)^\perp$, we could equally well choose another appropriate extension. All that is said about the control problems in Z^N and the corresponding semigroups $S^N(\cdot)$ in M^2 in this section remains valid, if we take the generator of $S^N(\cdot)$ to be $A^Np^N - \alpha(I - p^N)$ with some $\alpha \in \mathbb{R}$. For simplicity of exposition, we will make use of this possibility only at the end of the proof of Theorem 3.3 below.

Observing $B\xi = (B_0\xi, 0) \in Z^N$, $\xi \in \mathbb{R}^m$ for all N, we take the input operators $B^N : \mathbb{R}^m \to Z^N$ as $B^N\xi = B\xi$ to define finite-dimensional control systems on Z^N:

$$\dot{z}(t) = A^Nz(t) + B^Nu(t), \qquad t \geqq 0, \quad z(0) = p^N\phi, \tag{Σ^N}$$

where $u(\cdot) \in L^2_{\text{loc}}(0, \infty; \mathbb{R}^m)$ and $\phi \in M^2$. The optimal control $\bar{u}^N(\cdot)$ minimizing the functional $J^N(u, \phi, T)$, given by (2.4) with $z(\cdot; \phi, u)$ replaced by the solution $z^N(\cdot; \phi, u)$ of (Σ^N), is obtained as feedback by the Nth Riccati operator $\Pi^N(t)$ that satisfies the Riccati differential equation on Z^N with coefficients A^N, $(A^N)^*$, B^N, and W^N and terminal condition $\Pi^N(T) = G^N$ ($G^N = G|_{Z^N}$ and $W^N = W|_{Z^N}$). We write $\bar{z}^N(\cdot)$ for the corresponding optimal trajectory in Z^N.

In applications, the original system (Σ) is controlled by use of the approximate feedback instead of (2.5), i.e., $\bar{u}(t)$ is replaced by the so-called suboptimal control

$$\hat{u}^N(t) = -R^{-1}(B^N)^*\Pi^N(t)p^N\hat{z}^N(t), \qquad 0 \leqq t \leqq T \tag{3.1}$$

where $\hat{z}^N(t)$ is the mild solution of

$$\dot{z}(t) = (A - BR^{-1}(B^N)^*\Pi^N(t)p^N)z(t), \qquad z(0) = \phi.$$

From the uniform dissipativity assumption

(H1) There exists a constant $\omega \in \mathbb{R}$ such that

$$\langle A^N\phi, \phi\rangle \leqq \omega\|\phi\|^2 \quad \text{for all } \phi \in Z^N, \quad N = 1, 2, \cdots$$

follows the existence of a constant $M > 1$ such that

$$\|S^N(t)\phi\| \leqq M e^{\omega t}\|\phi\|, \qquad t \geqq 0, \quad \phi \in M^2. \tag{3.2}$$

Therefore, with

(H2) There exists a subset $D \subseteq \operatorname{dom} A$ and a real number $\lambda > \omega$, such that
(i) $(\lambda I - A)D$ is dense in M^2,
(ii) for all $\phi \in D$, $A^N p^N\phi \to A\phi$ as $N \to \infty$.

(H1), (H2) imply the strong convergence of $S^N(t)$ to $S(t)$ (Trotter–Kato Theorem [16, Chap. III, Thm. 4.5]). The same is true for $S^N{}^*(t)$ if (H2) with A, A^N replaced by A^*, $A^N{}^*$ holds (this will be denoted by (H2*)). Based on this and

(H3) $p^N\phi \to \phi$ for all $\phi \in M^2$

the following assertions were proved in [9] (also [13, Thm. 4.3]).

THEOREM 3.1. *Let* (H1)–(H3) *and* (H2*) *hold. Then, as* $N \to \infty$

(a) $\|\Pi^N(t)p^N - \Pi(t)\|_{\mathscr{L}(M^2)} \to 0.$

(b) $\hat{u}^N(t) \to \bar{u}(t), \quad \bar{u}^N(t) \to \bar{u}(t), \quad \hat{z}^N(t) \to \bar{z}(t), \quad \bar{z}^N(t) \to \bar{z}(t)$

the limits being uniform in t, $0 \leqq t \leqq T$.

(c) $J^N(\hat{u}^N, \phi, T) \to J(\bar{u}, \phi, T), \quad J^N(\bar{u}^N, \phi, T) \to J(\bar{u}, \phi, T).$

In the case of the infinite time horizon, we deal with the algebraic Riccati equations

$$(A^N)^*\Pi^N + \Pi^N A^N - \Pi^N B^N R^{-1}(B^N)^*\Pi^N + W^N = 0 \tag{3.3}$$

on Z^N, $N = 1, 2, \cdots$. If (A^N, B^N) is stabilizable, then there exists a nonnegative, self-adjoint solution Π^N of (3.3), governing the Nth optimal feedback. We will establish convergence of the Riccati operators Π^N using Gibson's arguments in [9] combined with the cross-product structure of the trajectories (see hypothesis (H4) below). This approach needs the assumption that the stabilizability of the hereditary system implies that the systems (A^N, B^N) are stabilizable in a uniform sense with respect to N (see (H5)). As to the investigation of stabilizability or exponential stability we will use a L^2-stability criterion due to Datko [7]. We state here a special version (a proof may also be found in [19]).

LEMMA 3.2. *Let* $S(t)$, $t \geqq 0$ *be a* C_0*-semigroup of bounded linear operators in a Banach space* X *satisfying*

$$\|S(t)\|_{\mathscr{L}(X)} \leqq M_1 e^{\alpha_1 t}, \qquad t \geqq 0$$

and

$$\int_0^\infty \|S(t)x\|_X^2\, dt \leqq c_1\|x\|_X^2, \qquad x \in X \tag{3.4}$$

for some constants M_1, α_1, $c_1 > 0$. *Then there exists an exponent* $\alpha = \alpha(c_1, M_1, \alpha_1) > 0$ *and a constant* $M = M(c_1, M_1, \alpha_1) > 0$ *such that*

$$\|S(t)\|_{\mathcal{L}(X)} \leqq M e^{-\alpha t}, \qquad t \geqq 0. \tag{3.5}$$

Note that if we can prove (3.4) for the semigroups $S^N(\cdot)$ with c_1 independent on N, then, by (3.2), (3.5) yields the exponential stability of $S^N(\cdot)$ uniformly with respect to N. Moreover, observe that the estimate (3.4) is equivalent to

$$\int_0^\infty |(S(t)x)^0|^2_{\mathbb{R}^n}\, dt \leqq c_2 \|x\|^2_{M^2}, \qquad x \in M^2, \tag{3.6}$$

for some constant $c_2 > 0$, if $S(\cdot)$ is the solution semigroup on M^2 as defined in § 2. By Fubini's Theorem, this equivalence follows directly from the state concept (2.2) and is a special feature of the semigroup associated with the retarded functional differential equation.

As far as we want the semigroups $S^N(\cdot)$ to be suitable approximations for $S(\cdot)$, it seems to be natural to demand the equivalence of (3.4) and (3.6) also with regard to $S^N(\cdot)$. We call this the VDP-property of the approximations (meaning the vector-component dominance is preserved). It plays an essential role in our approach to stability questions in context with the infinite time horizon control problem.

Suppose for N sufficiently large there exists a solution Π^N to the Nth algebraic Riccati equation (3.3). Then with

$$\bar{A}^N = A^N - B^N R^{-1} (B^N)^* \Pi^N,$$

$\bar{A}^N p^N$ generates an exponentially stable semigroup $\bar{S}^N(\cdot)$ on M^2. We introduce the projection $V: M^2 \to \mathbb{R}^n$

$$V(\phi^0, \phi^1) = \phi^0$$

and want the following hypothesis to be valid.

(H4) Provided N is sufficiently large, there exists a $c_1 \geqq 0$, independent on N, such that for all $\phi \in Z^N$

$$\int_0^\infty \|\bar{S}^N(t)\phi\|^2_{M^2}\, dt \leqq c_1 \|\phi\|^2_{M^2}$$

if and only if there exists a $c_2 \geqq 0$, independent on N, such that for all $\phi \in Z^N$

$$\int_0^\infty |V\bar{S}^N(t)\phi|^2_{\mathbb{R}^n}\, dt \leqq c_2 \|\phi\|^2_{M^2}.$$

If Π is a nonnegative self-adjoint solution to the algebraic Riccati equation (2.6) for the hereditary control problem, define the operators $\tilde{A}^N : Z^N \to Z^N$, $N = 1, 2, \cdots$ by

$$\tilde{A}^N = A^N - BR^{-1}B^*\Pi$$

and let $\tilde{S}^N(\cdot)$ be the uniformly continuous semigroup on M^2 generated by $\tilde{A}^N p^N$, i.e., $\tilde{S}^N(t) = e^{\tilde{A}^N p^N t}$, $t \geqq 0$.

Intending to provide the existence and uniform boundedness of the operators Π^N, we demand the following.

(H5) If the hereditary system (Σ) is stabilizable, then there exist constants $M, \beta > 0$ such that for N sufficiently large

$$\|\tilde{S}^N(t)|_{Z^N}\| \leqq M e^{-\beta t}, \qquad t \geqq 0.$$

THEOREM 3.3. *Let* (H1)-(H5), (H2*) *hold and assume* W_0 *is nonsingular. If the hereditary system is stabilizable, then*

(a) *For* N *sufficiently large there exists a solution* Π^N *to the* N*th algebraic Riccati equation* (3.3) *and*

$$\|\Pi^N p^N - \Pi\|_{\mathscr{L}(M^2)} \to 0, \qquad N \to \infty.$$

(b) *The optimal and suboptimal controls and trajectories and the corresponding costs converge as in Theorem* 3.1(b),(c).

Proof. As in Theorem 7.4 of [9], we first consider the Nth problem (Σ^N) with initial value $\phi \in M^2$, when it is controlled by the feedback $\tilde{u}^N(t) = -R^{-1}B^*\Pi p^N z(t)$. The evolution of the state in time is then described by $\tilde{z}^N(t) = \tilde{S}^N(t)p^N\phi$ and the corresponding costs can be estimated using (H5):

$$J^N(\tilde{u}^N, \phi) = \int_0^\infty (\langle \tilde{z}^N(t), W\tilde{z}^N(t)\rangle + \tilde{u}^N(t)^T R\tilde{u}^N(t))\, dt$$

$$\leqq \frac{M}{2\beta}(|W_0| + |R^{-1}||B_0|^2\|\Pi\|^2)\|\phi\|^2.$$

Thus, there exists a nonnegative self-adjoint solution Π^N of the Nth algebraic Riccati equation for N sufficiently large and

$$\langle p^N\phi, \Pi^N p^N\phi\rangle = J^N(\tilde{u}^N, \phi) \leqq J^N(\tilde{u}^N, \phi) \leqq c_1\|\phi\|^2$$

with some constant c_1, which does not depend on N. Therefore, there is an index N_0 such that

$$\|\Pi^N p^N\| \leqq c_1, \qquad N \geqq N_0. \tag{3.7}$$

The convergence statement in (a) now follows from Theorem 6.9 of [9], once we have shown

$$\|\bar{S}^N(t)\| \leqq \bar{M}e^{-\alpha t}, \qquad t \geqq 0, \quad N \geqq N_0 \tag{3.8}$$

for some constants $\bar{M}$, $\alpha > 0$.

Since $W_0 > 0$ we have $|\xi|^2 \leqq \mu^{-1}\xi^T W_0 \xi$, $\xi \in \mathbb{R}^n$, where μ is the minimum eigenvalue of W_0. Following the arguments given in [9] (proof of Theorem 7.5) let $\phi \in Z^N$ and define $\bar{z}^N(t) = \bar{S}^N(t)\phi = (x^N(t), y^N(t))$ with $x^N(t) \in \mathbb{R}^n$, $y^N(t) \in Y^N$, $t \geqq 0$. Furthermore, note that $\langle R^{-1}B^*\Pi^N\bar{z}^N(t), B^*\Pi^N\bar{z}^N(t)\rangle_{\mathbb{R}^m} \geqq 0$, so that

$$\int_0^\infty |x^N(t)|^2\, dt \leqq \mu^{-1}\int_0^\infty x^N(t)^T W_0 x^N(t)\, dt$$

$$\leqq \mu^{-1}\int_0^\infty \langle \bar{z}^N(t), (W + \Pi^N BR^{-1}B^*\Pi^N)\bar{z}^N(t)\rangle_{M^2}\, dt$$

$$= \mu^{-1}\left\langle \phi, \int_0^\infty (\bar{S}^N)^*(t)(W + \Pi^N BR^{-1}B^*\Pi^N)\bar{S}^N(t)\phi\, dt \right\rangle$$

$$= \mu^{-1}\langle \phi, \Pi^N\phi\rangle,$$

applying Corollary 4.2 of [9] to the semigroups $S^N(\cdot)$. It follows that $\int_0^\infty |V\bar{S}^N(t)\phi|^2\,dt \leqq \mu^{-1}c_1\|\phi\|^2$, $N \geqq N_0$ and, by hypothesis (H4), $\int_0^\infty \|\bar{S}^N(t)\phi\|^2\,dt \leqq c_2\|\phi\|^2$ with some $c_2 > 0$. Also, because $\bar{S}^N$ is generated by $(A^N - BR^{-1}B^*\Pi^N)p^N$, (3.2) and (3.7) imply (e.g., [16, Chap. III, Thm. 1.1]) the existence of constants M_1, α_1 such that $\|\bar{S}^N(t)\| \leqq M_1 e^{\alpha_1 t}$, $t \geqq 0$, $N \geqq N_0$. Now Lemma 3.2 assures that there are constants M, $\alpha > 0$ such that

$$\|\bar{S}^N(t)|_{Z^N}\| \leqq M e^{-\alpha t}, \qquad t \geqq 0, \quad N \geqq N_0.$$

But this proves (3.8), since, as we mentioned in the remark above, we may replace $A^N p^N$ by $A^N p^N - \alpha(I - p^N)$, so that $\|\bar{S}^N(t)|_{(Z^N)^\perp}\| \leqq e^{-\alpha t}$, while the finite-dimensional control problems on Z^N remain completely unchanged. Statement (b) follows from (a) in a manner similar to that in the finite time horizon case (see [9]). □

4. The piecewise linear approximation scheme. This section presents a special approximation scheme using so-called piecewise linear functions. We prove via several lemmas that this scheme satisfies the hypotheses (H1)-(H3) and (H2*). Then we show that it has the VDP-property, so that (H4) is valid. Furthermore, we investigate the characteristic matrix of the approximate systems to establish results on the eigenvalue behavior when the approximation index increases. This enables us to conclude (H5). Finally, after remarks on the treatment of multiple and distributed delays, we present some of our numerical findings.

4.1. Projection onto spaces of piecewise linear functions. For $N = 1, 2, \cdots$ we subdivide the interval $[-r, 0]$ into the subintervals $I_j^N = [t_j^N, t_{j-1}^N)$, $j = 2, \cdots, N$ and $I_1^N = [t_1^N, 0]$ by defining the meshpoints

$$t_j^N = -\frac{jr}{N}, \quad j = 0, \cdots, N.$$

For each $N \in \mathbb{N}$ the set Y^N of all functions $[-r, 0] \to \mathbb{R}^n$ that are polynomials of degree one on every interval I_j^N is commonly called a space of piecewise linear functions on $[-r, 0]$. A basis of Y^N is given, written in a simplified notation, by the $2N$ matrix functions

$$\begin{aligned} e_{2j-1}^N(s) &= \chi_j^N(s) \cdot I, \\ e_{2j}^N(s) &= \left(\frac{2N}{r} + 2j - 1\right)\chi_j^N(s) \cdot I, \end{aligned} \qquad j = 1, \cdots, N$$

where I denotes the $n \times n$ identity matrix and χ_j^N is the characteristic function of I_j^N. The pairs $\hat{e}_0 = (I, 0)$ and $\hat{e}_j^N = (0, e_j^N)$ are an orthogonal basis of the $n(2N+1)$-dimensional product space $Z^N = \mathbb{R}^n \times Y^N$, $N = 1, 2, \cdots$. The orthogonal projections $p^N : M^2 \to Z^N$ are of the form $p^N(\phi^0, \phi^1) = (\phi^0, p_1^N \phi^1)$, where p_1^N is the L^2-orthogonal projection from L^2 onto Y^N. With

$$Q^N = (\langle \hat{e}_j^N, \hat{e}_k^N \rangle) = \operatorname{diag}\left(1, \frac{r}{N}, \frac{r}{3N}, \cdots, \frac{r}{N}, \frac{r}{3N}\right) \otimes I \tag{4.1}$$

we have

$$\begin{aligned} &\langle \phi, \psi \rangle = \alpha^N(\phi)^T Q^N \alpha^N(\psi), \qquad \phi, \psi \in Z^N, \\ &\alpha^N(p^N\phi) = (Q^N)^{-1} \operatorname{col}\,(\phi^0, \langle e_1^N, \phi^1 \rangle_2, \cdots, \langle e_{2N}^N, \phi^1 \rangle_2), \qquad \phi \in M^2 \end{aligned} \tag{4.2}$$

where the components of the coefficient vector $\alpha^N(p^N\phi)$ are given by $\alpha_0 = \phi^0$ and

$$\begin{aligned} \alpha^N_{2j-1}(p^N\phi) &= \frac{N}{r}\int_{I^N_j} \phi^1(s)\,ds, \\ \alpha^N_{2j}(p^N\phi) &= \frac{3N}{r}\int_{I^N_j} e^N_{2j}(s)\phi^1(s)\,ds, \end{aligned} \qquad j = 1, \cdots, N. \tag{4.3}$$

We frequently will use the abbreviations $\phi^N_j = \alpha^N_j(p^N\phi)$ and $\phi^N = p^N_1\phi^1$. Note that

$$\begin{aligned} |\phi^N_{2j-1}| &\leqq \left(\frac{N}{r}\right)^{1/2} \|\phi^1\|_2 \\ |\phi^N_{2j}| &\leqq \left(\frac{3N}{r}\right)^{1/2} \|\phi^1\|_2, \end{aligned} \qquad j = 1, \cdots, N. \tag{4.4}$$

Obviously, the spaces Z^N are not contained in the domain of the generator A of the hereditary semigroup, since the elements of Y^N are not differentiable on $[-r, 0]$. Nevertheless, the action of A and A^* can be approximated by operators on Z^N imitating, heuristically speaking, the delta distributions in the derivatives of discontinuous functions by operators δ^N in Y^N. Following the ideas developed in [13], we need the operators δ^N for each point, where the piecewise linear functions in Y^N may have jumps.

We define $\delta^{N-}_j, \delta^{N+}_j : \mathbb{R}^n \to Y^N$, $N = 1, 2, \cdots$ by

$$\delta^{N-}_j(\xi) = \left(\frac{N}{r}e^N_{2j+1} + \frac{3N}{r}e^N_{2j+2}\right)\xi, \qquad j = 0, \cdots, N-1$$

and

$$\delta^{N+}_j(\xi) = \left(\frac{N}{r}e^N_{2j-1} - \frac{3N}{r}e^N_{2j}\right)\xi, \qquad j = 1, \cdots, N.$$

PROPOSITION 4.1. (a) *For any $\xi \in \mathbb{R}^n$ and $\phi^1 \in L^2(-h, 0; \mathbb{R}^n)$*

$$\langle \delta^{N-}_j(\xi), \phi^1\rangle_2 = \xi^T\phi^N(t^{N-}_j), \qquad j = 0, \cdots, N-1, \tag{4.5}$$

$$\langle \delta^{N+}_j(\xi), \phi^1\rangle_2 = \xi^T\phi^N(t^N_j), \qquad j = 1, \cdots, N. \tag{4.6}$$

In (4.5) *and throughout the paper, we use the notation $\phi^N(t^{N-}_j)$ for the left side limit of ϕ^N at t^N_j.*

(b) *The norms of the δ-operators are*

$$\|\delta^{N-}_j\| = 2\left(\frac{N}{r}\right)^{1/2}, \qquad j = 0, \cdots, N-1,$$

$$\|\delta^{N+}_j\| = 2\left(\frac{N}{r}\right)^{1/2}, \qquad j = 1, \cdots, N.$$

Proof. (a) Let $1 \leqq j \leqq N-1$. Using (4.3) and observing that

$$e^N_{2j-1}(t^{N-}_{j-1}) = e^N_{2j}(t^{N-}_{j-1}) = I,$$

we get

$$\begin{aligned} \langle \delta^{N-}_j(\xi), \phi^1\rangle_2 &= \int_{-r}^0 \xi^T\left(\frac{N}{r}e^N_{2j+1} + \frac{3N}{r}e^N_{2j+2}\right)(s)\phi^1(s)\,ds \\ &= \xi^T(\phi^N_{2j+1} + \phi^N_{2j+2}) = \xi^T\phi^N(t^{N-}_j). \end{aligned}$$

The proof for δ_0^{N-} is analogous. The statement on δ_j^{N+} follows similarly from the fact that $e_{2j-1}^N(t_j^N) = I$ and $e_{2j}^N(t_j^N) = -I$, $j = 1, \cdots, N$.

(b) Since the elements e_j^N are orthogonal, we have

$$\|\delta_j^{N+}(\xi)\|_2^2 = |\xi|^2\left(\left(\frac{N}{r}\right)^2\|e_{2j-1}^N\|^2 + \left(\frac{3N}{r}\right)^2\|e_{2j}^N\|^2\right)$$

$$= |\xi|^2\left(\frac{N}{r} + \frac{3N}{r}\right) \quad \text{by (4.1).}$$

The proof for δ_j^{N-} is analogous. □

Next we give convergence estimates for the piecewise linear projections of sufficiently smooth functions.

LEMMA 4.2. *For* $\phi^1 \in W^{2,\infty}(-r, 0; \mathbb{R}^n)$

(a) $$\|\phi^N - \phi^1\|_\infty \leqq \frac{c_1}{N^2}\|\ddot{\phi}^1\|_\infty, \qquad N = 1, 2, \cdots.$$

(b) $$\|D^+\phi^N - D\phi^1\|_\infty \leqq \frac{c_2}{N}\|\ddot{\phi}^1\|_\infty,$$

The constants c_1, c_2 *do not depend on* N *or* ϕ^1.

Proof. Applying the Peano Kernel Theorem (see, for instance, Theorem 1.3 of [20]) to the functionals $F_S, G_S : W^{2,\infty}(I_j^N) \to \mathbb{R}^n$, $s \in I_j^N$, given by $F_S(\phi^1) = \phi^1(s) - \phi^N(s)$ and $G_s(\phi^1) = D\phi^1(s) - D\phi^N(s)$, we obtain estimates involving integrals of $\ddot{\phi}^1$ and their projections onto Y^N. These (respectively, their derivatives) are estimated by expansion according to the basis $\{e_j^N\}$ and then using (4.4) and $|e_j^N(s)| \leqq 1$. □

As an immediate consequence from Lemma 4.2(a), we see that the subspaces Z^N defined in this section satisfy hypothesis (H3), since the set $\{(\phi^0, \phi^1) \in M^2 | \phi^0 \in \mathbb{R}^n, \phi^1 \in W^{2,\infty}(-r, 0; \mathbb{R}^n)\}$ is dense in M^2 and $\|p^N\| = 1$ for all N.

4.2. The approximating semigroups and their generators.

DEFINITION 4.3. For $\phi = (\phi^0, \phi^1) \in Z^N$ we define

$$A^N(\phi^0, \phi^1) = \Big(A_0\phi^0 + A_1\phi^1(-r),\ D^+\phi^1 + \delta_0^{N-}(\phi^0 - \phi^1(0)) + \sum_{j=1}^{N-1}\delta_j^{N-}(\phi^1(t_j^N) - \phi^1(t_j^{N-}))\Big).$$

Since $D^+\phi^1 \in Y^N$ for $\phi^1 \in Y^N$ it is clear that A^N is a linear operator $Z^N \to Z^N$.

LEMMA 4.4. *The adjoint of* A^N *is given by*

$$(A^N)^*(\psi^0, \psi^1) = \Big(A_0^T\psi^0 + \psi^1(0),\ -D^+\psi^1 + \sum_{j=1}^{N-1}\delta_j^{N+}(\psi^1(t_j^{N-}) - \psi^1(t_j^N)) + \delta_N^{N+}(A_1^T\psi^0 - \psi^1(-r))\Big)$$

for $(\psi^0, \psi^1) \in Z^N$.

Proof. For $\phi, \psi \in Z^N$, integration by parts of the term in $\langle\psi, A^N\phi\rangle$ involving $D^+\phi^1$ yields

$$\langle\psi^1, D^+\phi^1\rangle_2 = \sum_{j=0}^{N-1}\psi^1(t_j^{N-})^T\phi^1(t_j^{N-}) - \sum_{j=1}^{N}\psi^1(t_j^N)^T\phi^1(t_j^N) - \langle D^+\psi^1, \phi^1\rangle_2.$$

Furthermore, by Proposition 4.1

$$\langle\psi^1, \delta_0^{N-}(\phi^0 - \phi^1(0))\rangle_2 = (\phi^0 - \phi^1(0))^T\psi^1(0^-) = \psi^1(0)^T\phi^0 - \psi^1(0)^T\phi^1(0),$$

and

$$\psi^{0T} A_1 \phi^1(-r) = \langle \delta_N^{N+}(A_1^T \psi^0), \phi^1 \rangle_2,$$

so that

$$\langle (A^N)^*(\psi^0, \psi^1), (\phi^0, \phi^1) \rangle = (A_0^T \psi^0 + \psi^1(0))^T \phi^0 + \langle \delta_N^{N+}(A_1^T \psi^0) - D^+ \psi^1, \phi^1 \rangle_2 + \Delta$$

where Δ is given by

$$\Delta = -\psi^1(0)^T \phi^1(0) + \sum_{j=0}^{N-1} \psi^1(t_j^{N-})^T \phi^1(t_j^{N-}) - \sum_{j=1}^{N} \psi^1(t_j^N)^T \phi^1(t_j^N)$$

$$+ \sum_{j=1}^{N-1} \langle \psi^1, \delta_j^{N-}(\phi^1(t_j^N) - \phi^1(t_j^{N-})) \rangle_2.$$

Here the last sum is transformed using (4.5). By the continuity of ϕ^1, $\psi^1 \in Y^N$ at 0, the first two terms can also be summed up. This yields

$$\Delta = \sum_{j=1}^{N-1} (\psi^1(t_j^{N-}) - \psi^1(t_j^N))^T \phi^1(t_j^N) - \psi^1(-r)^T \phi^1(-r).$$

The result follows by applications of (4.6). □

The next lemma shows that the operators A^N satisfy the uniform dissipativity condition (H1).

LEMMA 4.5. *For all N and all* $\phi \in Z^N$, $\langle A^N \phi, \phi \rangle \leqq \omega \|\phi\|^2$, *with* ω *being the dissipativity constant of A, i.e.,* $\omega = \frac{1}{2} + |A_0| + \frac{1}{2}|A_1|^2$.

Proof. From the definition of A^N and Proposition 4.1, it follows that

$$\langle A^N \phi, \phi \rangle \leqq (A_0 \phi^0)^T \phi^0 + |A_1||\phi^1(-r)||\phi^0| + \sum_{j=1}^{N} \int_{I_j^N} (D^+ \phi^1(s))^T \phi^1(s)\, ds$$

$$+ (\phi^0 - \phi^1(0))^T \phi^1(0^-) + \sum_{j=1}^{N-1} (\phi^1(t_j^N) - \phi^1(t_j^{N-}))^T \phi^1(t_j^{N-})$$

for $\phi \in Z^N$. Using

$$\int_{I_j^N} (D^+ \phi^1(s))^T \phi^1(s)\, ds = \frac{1}{2}(|\phi^1(t_{j-1}^{N-})|^2 - |\phi^1(t_j^N)|^2)$$

and the inequality $\xi^T \eta \leqq \frac{1}{2}(|\xi|^2 + |\eta|^2)$, $\xi, \eta \in \mathbb{R}^n$, we get

$$\langle A^N \phi, \phi \rangle \leqq (A_0 \phi^0)^T \phi^0 + \frac{1}{2}(|A_1|^2 \|\phi\|^2 + |\phi^1(-r)|^2) + \frac{1}{2} \sum_{j=0}^{N-1} |\phi^1(t_j^{N-})|^2$$

$$- \frac{1}{2} \sum_{j=1}^{N} |\phi^1(t_j^N)|^2 + |\phi^0||\phi^1(0)| - |\phi^1(0)|^2$$

$$+ \frac{1}{2} \sum_{j=1}^{N-1} |\phi^1(t_j^N)|^2 - \frac{1}{2} \sum_{j=1}^{N-1} |\phi^1(t_j^{N-})|^2$$

$$\leqq (A_0 \phi^0)^T \phi^0 + \frac{1}{2}|\phi^0|^2 + \frac{1}{2}|A_1|^2 \|\phi\|^2. \qquad \square$$

Looking for appropriate sets to be used in (H2) and (H2*), we define

$$D = \{(\phi^1(0), \phi^1) \in M^2 \,|\, \phi^1 \in W^{2,\infty}(-r, 0; \mathbb{R}^n)\}$$

and

$$D^* = \{(\psi^0, \psi^1) \in \operatorname{dom} A^* \mid \psi^1 \in W^{2,\infty}(-r, 0; \mathbb{R}^n)\}.$$

The following lemma establishes (H2)(ii) and (H2*)(ii).

LEMMA 4.6. (a) *There is a constant $c > 0$, such that for all N and all $\phi \in D$*

$$\|A^N p^N \phi - A\phi\| \leqq \frac{c}{N} \|\ddot{\phi}^1\|_\infty.$$

(b) *For all $\psi \in D^*$*

$$\|(A^N)^* p^N \psi - A^* \psi\| \to 0 \quad \text{as } N \to \infty.$$

Proof. (a) From the definition of A and A^N we have the estimate

$$\begin{aligned}\|A^N p^N \phi - A\phi\| \leqq |A_1||\phi^N(-r) - \phi^1(-r)| + \|D^+\phi^N - D\phi^1\|_2 \\ + \|\delta_0^{N-}(\phi^0 - \phi^N(0))\|_2 \\ + \left\| \sum_{j=1}^{N-1} \delta_j^{N-}(\phi^N(t_j^N) - \phi^N(t_j^{N-})) \right\|_2.\end{aligned}$$

By Proposition 4.1 and Lemma 4.2 for $\phi \in D$ this yields

$$\|A^N p^N \phi - A\phi\| \leqq \left(\frac{c_1}{N^2} + \frac{c_2}{N} + 2\left(\frac{N}{r}\right)^{1/2} \frac{c_3}{N^2}\right) \|\ddot{\phi}^1\|_\infty + \|\Delta^N(\phi^1)\|_2$$

with some constants c_1, c_2, c_3. Taking advantage of the orthogonality of $e_1^N, \cdots, e_{2N}^N$ in L^2, we have for $\xi \in \mathbb{R}^n$

$$\left\| \sum_{j=1}^{N-1} \delta_j^{N-}(\xi) \right\|_2^2 \leqq 4(N-1)\frac{N}{r}|\xi|^2.$$

Hence,

$$\|\Delta^N(\phi^1)\|_2 \leqq 2\left((N-1)\frac{N}{r}\right)^{1/2} \max_{j=1,\cdots,N} |\phi^N(t_j^N) - \phi^N(t_j^{N-})| \leqq \frac{\text{const.}}{N} \|\ddot{\phi}^1\|_\infty.$$

This proves (a). Item (b) follows using similar estimates on the δ_j^{N+} terms and by the fact that $A_1^T \psi^0 = \psi^1(-r)$ for $\psi \in D^*$. □

In order to apply Theorem 3.1 to A^N and $(A^N)^*$ of this section, it remains to show (H2)(i) and (H2*)(i).

LEMMA 4.7. *The sets $(\lambda - A)D$ and $(\lambda - A^*)D^*$ are dense in M^2, if $\lambda > \omega$ as given in Lemma* 4.5.

Proof. We know from semigroup theory that $\{\lambda \in \mathbb{C} \mid \operatorname{Re} \lambda > \omega\}$ is contained in the resolvent sets $\rho(A)$ and $\rho(A^*)$. Hence, given $\psi \in \mathbb{R}^n \times C^1(-h, 0; \mathbb{R}^n)$ the equation $(\lambda - A)\phi = \psi$ has a unique solution $\phi = (\phi^1(0), \phi^1) \in \operatorname{dom} A$, which by the definition of A satisfies $\lambda\phi^1 - \dot{\phi}^1 = \psi^1$. But this implies $\dot{\phi}^1 = \lambda\phi^1 - \psi^1$ is continuous and differentiable. In fact, $\ddot{\phi}^1 = \lambda\dot{\phi}^1 - \dot{\psi}^1$ is continuous, so that $\phi \in \mathbb{R}^n \times C^2(-h, 0; \mathbb{R}^n)$. Hence the dense set $\mathbb{R}^n \times C^1$ is contained in $(\lambda - A)(\mathbb{R}^n \times C^2 \cap \operatorname{dom} A)$, which is a subset of $(\lambda - A)D$. The same arguments can be applied to $(\lambda - A^*)D^*$. □

Summarizing, we can now say that the semigroups $S^N(\cdot)$ and $S^N(\cdot)^*$ generated by $A^N p^N$ and $(A^N)^* p^N$ strongly converge to the hereditary semigroups $S(\cdot)$ and $S(\cdot)^*$ so that for $T < \infty$ we can approximate the Riccati operators and the optimal controls by solving finite-dimensional problems in Z^N.

4.3. Vector dominance preservation. With respect to the basis $\hat{e}_0, \hat{e}_1^N, \cdots, \hat{e}_{2N}^N$ of Z^N and the canonical basis of $\mathbb{R}^n$ the matrices $[A^N]$ and $[A^N*]$ representing A^N and A^N* are given by

$$[A^N]=(Q^N)^{-1}H^N \quad \text{and} \quad [A^N*]=(Q^N)^{-1}H^{NT}$$

with

$$H^N=\begin{bmatrix} \langle \hat{e}_0, A^N\hat{e}_0\rangle & \cdots & \langle \hat{e}_0, A^N\hat{e}_{2N}^N\rangle \\ \vdots & & \vdots \\ \langle \hat{e}_{2N}^N, A^N\hat{e}_0\rangle & \cdots & \langle \hat{e}_{2N}^N, A\hat{e}_{2N}^N\rangle \end{bmatrix}, \qquad N=1,2,\cdots.$$

For the computation of the entries of H^N, observe that the derivatives of the basis elements are given by

$$D^+e_{2j-1}^N=0 \quad \text{and} \quad D^+e_{2j}^N=\frac{2N}{r}e_{2j-1}^N, \quad j=1,\cdots,N.$$

The inner products in H^N are evaluated using the orthogonality of the basis elements and Proposition 4.1. The result is the $n(2N+1)$ square matrix

$$H^N=\begin{bmatrix} A_0 & 0 & \cdots & 0 & A_1 & -A_1 \\ k_0 & h & & & & \\ & k & & 0 & & \\ & & \ddots & & & \\ & 0 & & k & & h \end{bmatrix} \tag{4.7}$$

where $k_0=\begin{pmatrix} I \\ I \end{pmatrix}$ is a $2n\times n$ matrix and

$$h=\begin{pmatrix} -I & I \\ -I & -I \end{pmatrix}, \qquad k=\begin{pmatrix} I & -I \\ I & -I \end{pmatrix}$$

are $2n\times 2n$ matrices. Numerical algorithms solving high-order systems with coefficients $[A^N]$ might take considerable advantage of the fact that H^N has band structure (not the case for the Legendre methods [10]-[12]) and that Q^N is diagonal (not the case for spline methods [13]).

In the following, we exploit the structure of the matrix $[A^N]$ to deduce the VDP property and (H4) for our piecewise linear approximations.

LEMMA 4.8. *If there is a $c_2>0$ independent on N such that for all $\phi\in Z^N$*

$$\int_0^\infty |VS^N(t)\phi|^2\,dt\leqq c_2\|\phi\|^2,$$

then

$$\int_0^\infty \|S^N(t)\phi\|^2\,dt\leqq c_1\|\phi\|^2, \qquad \phi\in Z^N,$$

for some $c_1\geqq 0$ not depending on N or ϕ.

Proof. Let $\phi\in Z^N$ and set $S^N(t)\phi=e^{A^{N_p N_t}}\phi=e^{A^N t}\phi=(w_0^N(t), w_1^N(t))\in Z^N$, $t\geqq 0$. With $w_1^N(t)=\sum_{j=1}^{2N} e_j^N w_j^N(t)$ the coefficient vector $\operatorname{col}(w_0^N(t), w_1^N(t), \cdots, w_{2N}^N(t))$ is the solution of

$$\frac{d}{dt}\begin{bmatrix} w_0^N(t) \\ w_1^N(t) \\ \vdots \\ w_{2N}^N(t) \end{bmatrix}=[A^N]\begin{bmatrix} w_0^N(t) \\ w_1^N(t) \\ \vdots \\ w_{2N}^N(t) \end{bmatrix}, \qquad t\geqq 0, \qquad \begin{matrix} w_0^N(0)=\phi^0, \\ w_j^N(0)=\phi_j^N. \end{matrix} \tag{4.8}$$

A view of the rows of $[A^N]$ reveals that (4.8) implies

$$\dot{v}_1^N(t) = -\frac{N}{r} a v_1^N(t) + \frac{N}{r} v_0^N(t),$$

$$\dot{v}_j^N(t) = -\frac{N}{r} a v_j^N(t) + \frac{N}{r} b v_{j-1}^N(t), \qquad j = 2, \cdots, N, \tag{4.9}$$

$$v_j^N(0) = \operatorname{col}(\phi_{2j-1}^N, \phi_{2j}^N), \qquad j = 1, \cdots, N$$

where $v_j^N(t) = \operatorname{col}(w_{2j-1}^N(t), w_{2j}^N(t)) \in \mathbb{R}^{2n}$, $v_0^N(t) = \operatorname{col}(w_0^N(t), 3w_0^N(t))$ and

$$a = \begin{pmatrix} 1 & -1 \\ 3 & 3 \end{pmatrix} \otimes I, \qquad b = \begin{pmatrix} 1 & -1 \\ 3 & -3 \end{pmatrix} \otimes I.$$

Using (4.4), we get

$$|v_j^N(0)|^2 \leqq \frac{4N}{r} \|\phi\|^2, \qquad j = 1, \cdots, N. \tag{4.10}$$

To estimate the solutions of (4.9), we make use of the fact that, if $f \in L^2(0, \infty; \mathbb{R})$, $\alpha > 0$ and $g(t) = \int_0^t e^{-\alpha(t-s)} f(s)\, ds$, $t \geqq 0$, then $g \in L^2(0, \infty; \mathbb{R})$ and $\int_0^\infty g^2(t)\, dt \leqq 1/\alpha^2 \int_0^\infty f^2(t)\, dt$ (cf. [9, Lemma 7.3]). The first equation in (4.9) yields

$$v_1^N(t) = e^{-(N/r)at} v_1^N(0) + \int_0^t e^{-(N/r)a(t-s)} \frac{N}{r} v_0^N(s)\, ds, \qquad t \geqq 0.$$

With $\tilde{v}_1^N(t) = v_1^N(t) - e^{-(N/r)at} v_1^N(0)$, $t \geqq 0$, we get

$$\begin{aligned} \int_0^\infty |\tilde{v}_1^N(t)|^2\, dt &\leqq \frac{r^2}{N^2} \text{const.} \int_0^\infty \frac{N^2}{r^2} |v_0^N(t)|^2\, dt \\ &\leqq \text{const.} \int_0^\infty |w_0^N(t)|^2\, dt \\ &= \text{const.} \int_0^\infty |VS^N(t)\phi|^2\, dt \\ &\leqq \text{const.} \|\phi\|^2, \end{aligned}$$

by assumption, where the constants do not depend on N. Using (4.10), it follows that

$$\int_0^\infty |v_1^N(t)|^2\, dt \leqq \text{const.} \|\phi\|^2. \tag{4.11}$$

Estimating the solutions of the other equations in (4.9) by the same method, we obtain

$$\int_0^\infty |v_j^N(t)|^2\, dt \leqq \text{const.} \|\phi\|^2 \quad \text{if} \quad \int_0^\infty |v_{j-1}^N(t)|^2\, dt \leqq \text{const.} \|\phi\|^2, \quad j = 2, \cdots, N.$$

So, from (4.11), by induction we get

$$\int_0^\infty |v_j^N(t)|^2\, dt \leqq \text{const.} \|\phi\|^2, \qquad j = 1, \cdots, N.$$

But this proves the assertion of the lemma, because by (4.2)

$$\|S^N(t)\phi\|^2 = |w_0^N(t)|^2 + \sum_{j=1}^{N} \left[\frac{r}{N} |w_{2j-1}^N(t)|^2 + \frac{r}{3N} |w_{2j}^N(t)|^2 \right]$$

$$= |w_0^N(t)|^2 + \sum_{j=1}^{N} \frac{r}{N} |dv_j^N(t)|^2$$

where

$$d = \begin{pmatrix} 1 & 0 \\ 0 & \sqrt{1/3} \end{pmatrix} \otimes I$$

so that

$$\int_0^\infty \|S^N(t)\phi\|^2 \, dt \leqq \int_0^\infty |w_0^N(t)|^2 \, dt + \frac{r}{N} \sum_{j=1}^{N} |d|^2 \int_0^\infty |v_j^N(t)|^2 \, dt$$

$$\leqq \text{const.} \, \|\phi\|^2. \qquad \square$$

COROLLARY 4.9. *The semigroups* $\bar{S}^N(\cdot)$ *generated by* $\bar{A}^N p^N = (A^N - B^N R^{-1} (B^N)^* \Pi^N) p^N$ *satisfy hypothesis* (H4).

Proof. Since $B^N : \mathbb{R}^n \to Z^N$ is represented by the $n(2N+1) \times m$ matrix $[B^N] = \text{col}\,(B_0, 0, \cdots, 0)$, the matrix $[\bar{A}^N]$ differs from $[A^N]$ only in the first n rows. Therefore, (4.8) with $[A^N]$ replaced by $[\bar{A}^N]$ again yields (4.9). The rest of the proof remains unchanged. $\square$

Besides for (H4), the VDP-property of the piecewise linear approximations together with the results of the next section will be used to deduce (H5).

4.4. The eigenvalues of the approximate systems. It is known that the spectrum of the generator A coincides with its point spectrum, namely, $\sigma(A) = \{\lambda \in \mathbb{C} \,|\, \det \Delta(\lambda) = 0\}$, where

$$\Delta(\lambda) = \lambda I - A_0 - A_1 e^{-\lambda r}, \qquad \lambda \in \mathbb{C}.$$

The eigenvalues of the finite-dimensional operators A^N are the zeros of $\det(\lambda I^N - [A^N])$ in $\mathbb{C}$. I^N denotes the $n(2N+1)$-identity matrix. To calculate the determinant of the characteristic matrix $\Delta^N(\lambda) = \lambda I^N - [A^N]$ in terms of rational functions of λ, we transform $\Delta^N(\lambda)$, a square matrix of $n \times n$ blocks numbered from zero to $2N$, by elementary row and column operations.

First, to add the odd numbered columns to their succeeding ones, we multiply $\Delta^N(\lambda)$ from the right by S^N, the identity with $(0, I \text{——} 0, I)$ above the diagonal. Then we multiply from the left with T^N, the identity with $-\lambda(\lambda + 6N/r)^{-1}(0, I \text{——} 0, I)$ above the diagonal, in order to subtract $\lambda(\lambda + 6N/r)^{-1}$ times the even numbered rows from their preceding ones. This yields a matrix whose diagonal $4n \times 4n$ blocks look like

$$\begin{bmatrix} q^N(\lambda) & 0 & 0 & 0 \\ 3N/r & \lambda + (6N/r) & 0 & 0 \\ -p^N(\lambda) & 0 & q^N(\lambda) & 0 \\ -3N/r & 0 & 3N/r & \lambda + (6N/r) \end{bmatrix} \otimes I$$

with

$$p^N(\lambda) = \frac{N}{r} - \frac{3N}{r} \lambda \left(\lambda + \frac{6N}{r} \right)^{-1}, \tag{4.12}$$

$$q^N(\lambda) = \lambda + p^N(\lambda).$$

Its zeroth row of blocks is $(\lambda I - A_0, 0\text{——}0, -A_1, 0)$ and its zeroth column reads $(\lambda I - A_0, p^N(\lambda)\, I, (3N/r)I, 0\text{——}0)$. To transform this matrix into a lower triangular matrix let

$$D_N^N = (q^N(\lambda))^{-1} A_1,$$
$$D_j^N = (q^N(\lambda))^{-1} p^N(\lambda) D_{j+1}^N, \qquad j = 1, \cdots, N-1$$

and multiply from the left with D^N, being the identity with $(I, D_1^N, 0, D_2^N, 0\text{——}D_N^N, 0)$ in the first row. Thus

$$\det \Delta^N(\lambda) = (\det q^N(\lambda) I)^N \left(\det\left(\lambda + \frac{6N}{r}\right) I\right)^N \det \Delta_0^N(\lambda) \tag{4.13}$$

where

$$\Delta_0^N(\lambda) = \lambda I - A_0 - p^N(\lambda) D_1^N = \lambda I - A_0 - (r^N(\lambda))^N A_1$$

with

$$r^N(\lambda) = p^N(\lambda)(q^N(\lambda))^{-1}. \tag{4.14}$$

Note that these transformations are possible, as far as $\lambda + 6N/r \neq 0$ and $q^N(\lambda) \neq 0$, i.e., $\lambda \neq -6N/r$ and $\lambda \neq -2N/r \pm i(N/r)\sqrt{2}$, in particular if $\lambda \in \{\lambda \in \mathbb{C} \mid \operatorname{Re} \lambda \geqq -\rho\}$ and $N > \rho r/2$ for some $\rho > 0$. Furthermore we note that if $\operatorname{Re} \lambda \geqq -\rho$, then $\det \Delta^N(\lambda) = 0$ if and only if $\det \Delta_0^N(\lambda) = 0$, provided $N > \rho r/2$.

LEMMA 4.10. (a) *With the projection* $V: M^2 \to \mathbb{R}^n$ *introduced in* (H4) *we have*

$$[V(\lambda I - A^N)^{-1} V^*] = (\Delta_0^N(\lambda))^{-1}, \qquad \lambda \in \rho(A^N).$$

(b) $\Delta_0^N(\lambda) \to \Delta(\lambda)$ *uniformly in* λ *on bounded subsets of* $\mathbb{C}$.

(c) *For any* $\rho > 0$ *let* $K_\rho = \{\lambda \in \mathbb{C} \mid -\rho \leqq \operatorname{Re} \lambda \leqq |A_0| + |A_1|, |\operatorname{Im} \lambda| \leqq |A_0| + 2e^{\rho r}|A_1|\}$. *There exists an* $N(\rho)$ *such that for* $N \geqq N(\rho)$ *all the roots of* $\det \Delta^N(\lambda) = 0$ *with* $-\rho \leqq \operatorname{Re} \lambda$ *lie within* K_ρ.

Proof. Expanding the determinant of $\Delta^N(\lambda)$ by elementary operations, we have seen that $D^N T^N \Delta^N(\lambda) S^N = U^N(\lambda)$, where $U^N(\lambda)$ is a lower triangular block-matrix with $\Delta_0^N(\lambda)$ in the upper left corner. The first column of blocks in $D^N T^N$ and the first row of blocks in $(S^N)^{-1}$ are of the form $(I\ 0\text{——}0)$. Thus, the application of these transformations to the equation $\Delta^N(\lambda)(\psi^0 *\text{——}*)^T = (\phi^0 0\text{——}0)^T$ yields

$$\begin{aligned} U^N(\lambda)(\psi^0 *\text{——}*)^T &= D^N T^N \Delta^N(\lambda) S^N (S^N)^{-1} (\psi^0 *\text{——}*)^T \\ &= D^N T^N (\phi^0 0\text{——}0)^T = (\phi^0 0\text{——}0)^T \end{aligned}$$

or

$$(\psi^0 *\text{——}*)^T = (U^N(\lambda))^{-1} (\phi^0 0\text{——}0)^T \quad \text{for all } \phi^0, \psi^0 \in \mathbb{R}^n.$$

This implies $\psi^0 = (\Delta_0^N(\lambda))^{-1} \phi^0$. But

$$\begin{aligned} V(\lambda I - A^N)^{-1} V^* \phi^0 &= V(\lambda I - A^N)^{-1} (\phi^0, 0) = [V](\Delta^N(\lambda))^{-1} (\phi^0 0\text{——}0)^T \\ &= [V](\psi^0 *\text{——}*)^T = \psi^0 = (\Delta_0^N(\lambda))^{-1} \phi^0 \end{aligned}$$

for all $\phi^0 \in \mathbb{R}^n$, and this proves (a).

From (4.12), (4.14) we have

$$r^N(\lambda) = \frac{6N^2 - 2Nr\lambda}{6N^2 + 4Nr\lambda + \lambda^2 r^2} = \left(1 + \frac{r\lambda}{N}\right)^{-1} \left(1 + \frac{3r^2\lambda^2}{6N^2 + 4Nr\lambda - 2r^2\lambda^2}\right)^{-1}.$$

As $N \to \infty$

$$\left(1 + \frac{r\lambda}{N}\right)^{-N} \to e^{-r\lambda} \quad \text{and} \quad \left(1 + \frac{3r^2\lambda^2}{6N^2 + 4Nr\lambda - 2r^2\lambda^2}\right)^{-N} \to 1$$

uniformly in λ on bounded subsets of $\mathbb{C}$, and (b) follows. To prove (c) let $\operatorname{Re}\lambda \geqq -\rho$ and $\det \Delta^N(\lambda) = 0$. For $N > \rho r/2$ it follows that $\det \Delta_0^N(\lambda) = 0$. Thus λ is an eigenvalue of $A_0 + (r^N(\lambda))^N A_1$, which implies $|\lambda| \leqq |A_0| + |(r^N(\lambda))^N||A_1|$. For $\operatorname{Re}\lambda \geqq 0$, $|r^N(\lambda)| \leqq 1$. Computing $|r^N(\lambda)|^2$ and its derivative with respect to $\operatorname{Re}\lambda$ shows $|r^N(\lambda)| \leqq |r^N(-\rho)|$ for $\operatorname{Re}\lambda \in [-\rho, 0]$ and N sufficiently large. Hence the bounds in K_ρ are obtained from the convergence $(r^N(-\rho))^N \to e^{\rho r}$. □

Although the estimates in (c) are not tight, they lead to precise results by use of the following consequence of Rouché's Theorem.

PROPOSITION 4.11. *Let f, f^N, $N = 1, 2, \cdots$ be holomorphic inside and on a closed bounded contour $\Gamma \subseteq \mathbb{C}$. If f has no zeros on Γ and if $f^N \to f$ uniformly on Γ, then there exists an $N_0 \in \mathbb{N}$ such that for $N \geqq N_0$, f^N and f have the same number of zeros (counted according to their multiplicities) inside Γ.*

LEMMA 4.12. (a) *If λ_0 is an eigenvalue of A with multiplicity k, then for any $\varepsilon > 0$ (small enough) there is an N_0 such that each A^N, $N \geqq N_0$, possesses k eigenvalues in $B(\lambda_0, \varepsilon) = \{\lambda \in \mathbb{C} \,|\, |\lambda - \lambda_0| < \varepsilon\}$.*

(b) *Let $\rho > 0$, $G_\rho = \{\lambda \in \mathbb{C} \,|\, \operatorname{Re}\lambda \geqq -\rho\}$ and λ_i, $i = 1, \cdots, l$ be the eigenvalues of A in G_ρ. For any $\varepsilon > 0$ (small enough) there exists N_0 such that the operators A^N, $N \geqq N_0$, have no eigenvalues in $G_\rho \setminus \bigcup_{i=1}^l B(\lambda_i, \varepsilon)$.*

Proof. Assume that λ_0 is the only zero of $\det \Delta(\lambda)$ in $\overline{B(\lambda_0, \varepsilon)}$. $\partial B(\lambda_0, \varepsilon)$ is bounded and $\det \Delta_0^N(\lambda) \to \det \Delta(\lambda)$ uniformly on bounded sets. Thus, (a) follows at once from Proposition 4.11.

Choose, without loss of generality, $\varepsilon > 0$ such that $\det \Delta(\lambda)$ has no zero in $\partial G_\rho \setminus \bigcup_{i=1}^l \partial B(\lambda_i, \varepsilon)$. We know from (4.13) that, if $N > \rho r/2$, $\lambda \in G_\rho$ is an eigenvalue of A^N if and only if $\det \Delta_0^N(\lambda) = 0$. Write $G_\rho \setminus \bigcup_{i=1}^l B(\lambda_i, \varepsilon) = G_1 \cup G_2$, where

$$G_1 = (G_\rho \cap K_\rho) \setminus \bigcup_{i=1}^{l} B(\lambda_i, \varepsilon), \qquad G_2 = (G_\rho \cap K_\rho^c) \setminus \bigcup_{i=1}^{l} B(\lambda_i, \varepsilon).$$

G_1 is bounded and ∂G_1 contains no zero of $\det \Delta(\lambda)$. Thus, there is an $N_1 > \rho r/2$ such that for all $N \geqq N_1$ $\det \Delta_0^N(\lambda)$ has as many zeros in G_1 as $\det \Delta(\lambda)$, that is, $\det \Delta_0^N(\lambda)$ has no zero in G_1. Since $G_2 \subseteq K_\rho^c$, there is no eigenvalue of A^N in G_2, if N is sufficiently large. □

This shows that the eigenvalues of A are approximated by the eigenvalues of the operators A^N. Moreover, given $\varepsilon > 0$, let $\rho \in \mathbb{R}$ and λ_i, $i = 1, \cdots, l$, be the eigenvalues of the hereditary system with $\operatorname{Re}\lambda_i \geqq \rho$. Then the piecewise linear approximations do not have eigenvalues in the right halfplane $\operatorname{Re}\lambda \geqq \rho$ outside the balls $B(\lambda_i, \varepsilon)$, $i = 1, \cdots, l$, provided N is sufficiently large.

4.5. Uniform stability. From the results of the previous section, we conclude that if $S(\cdot)$ is stable, i.e., $\|S(t)\| \leqq M e^{-\omega_0 t}$ with some M, $\omega_0 > 0$, then for all $\omega < \omega_0$ there are an N_ω and constants M_N such that for all $N \geqq N_\omega$

$$\|S^N(t)\| \leqq M_N e^{-\omega t}. \tag{4.15}$$

To get uniformity with respect to N on the right-hand side of these estimates, we follow an idea given by Ito [11] in connection with his Legendre-tau approximations. The idea is to establish uniformity in (4.15) for one special no-delay case and to interpret this special case as a perturbation of the general situation.

Let us consider the equation $\dot{x}(t) = -x(t)$, $t \geqq 0$, in $\mathbb{R}^n$ as if it were a functional differential equation with delay, demanding the initial condition $(x(0), x_0) = \phi \in M^2$. We approximate by our piecewise linear scheme, denoting the approximating generators by A_0^N. They are given in Definition 4.3 with $A_0 = -I$, $A_1 = 0$. The representation $[A_0^N]$

is a lower triangular block matrix with $-I$ in the left upper position. Therefore the first row of blocks in $e^{[A_0^N]t}$ is given by $(e^{-t}I\ 0\text{——}0)$. Hence, for all $\phi \in Z^N$

$$|Ve^{A_0^N t}\phi| = |\alpha_0(e^{[A_0^N]t}\alpha^N(\phi))| = |e^{-t}\alpha_0(\phi)| = e^{-t}|\phi^0| \leqq e^{-t}\|\phi\|.$$

Thus, by Lemma 4.8, there is a $c>0$ such that

$$\int_0^\infty \|e^{A_0^N t}\phi\|^2\, dt \leqq c\|\phi\|^2, \qquad \phi \in Z^N \tag{4.16}$$

and by Lemma 3.2 there exist constants M_0, $\alpha_0 > 0$ such that for all $N = 1, 2, \cdots$

$$\|e^{A_0^N t}|_{Z^N}\| \leqq M_0\, e^{-\alpha_0 t}, \qquad t \geqq 0.$$

Remark. Guided by these arguments, we easily see that the spline approximation scheme presented in [13], [14] does not have the VDP-property. Because the first row of blocks of the matrix representing the spline generators ${}^sA_0^N$ is also of type $(-I\ 0\text{——}0)$ we obtain for all ϕ in the spline subspace ${}^sZ^N$, $|(e^{{}^sA_0^N t}\phi)^0| \leqq e^{-t}\|\phi\|$, as above. Thus, if a spline analogue of Lemma 4.8 holds, then by Lemma 3.2 $\|e^{{}^sA_0^N t}|_{{}^sZ^N}\| \leqq K e^{-\varepsilon t}$, for some K, $\varepsilon > 0$, independent of N. But this contradicts the peculiar eigenvalue behavior of the spline scheme (see [14, Prop. 4.6]).

LEMMA 4.13. *If $\|S(t)\| \leqq M e^{-\omega_0 t}$, $t \geqq 0$ for some M, $\omega_0 > 0$ then for all $\omega < \omega_0$ there exist N_ω and $\tilde{M}$ such that for all $N \geqq N_\omega$*

$$\|S^N(t)|_{Z^N}\| \leqq \tilde{M} e^{-\omega t}, \qquad t \geqq 0.$$

Proof. Let $0 < \omega < \omega_0$. We have seen in the proof of Lemma 4.10 that there is a constant c such that $|A_0 + (r^N(-\omega + i\tau))^N A_1| \leqq c$, $\tau \in \mathbb{R}$, if $N \geqq N(\omega)$. It follows that

$$|(\Delta_0^N(-\omega + i\tau))^{-1}| \leqq \frac{1}{|-\omega + i\tau| - c} \quad \text{for } |-\omega + i\tau| > c$$

(det $\Delta_0^N(-\omega + i\tau) \neq 0$ if N is large enough). Thus, from the uniform convergence of $\Delta_0^N(\lambda)$ to $\Delta(\lambda)$ on the set $\{\lambda = -\omega + i\tau \,|\, |\lambda| \leqq c\}$, we have

$$|(\Delta_0^N(-\omega + i\tau))^{-1}| \leqq \gamma, \qquad \tau \in \mathbb{R}, \quad N \geqq N_\omega \tag{4.17}$$

with some $N_\omega \in \mathbb{N}$ and $\gamma > 0$.

Define $A_\omega^N = \omega I + A^N$ and let $\phi \in Z^N$. The trajectory $e^{A_0^N t}\phi$ is the solution of

$$\dot{z}(t) = A_0^N z(t) = A_\omega^N z(t) + (A_0^N - A_\omega^N)z(t), \qquad t \geqq 0, \quad z(0) = \phi.$$

Equivalently,

$$e^{A_0^N t}\phi = e^{A_\omega^N t}\phi + \int_0^t e^{A_\omega^N (t-s)}(A_0^N - A_\omega^N)\, e^{A_0^N s}\phi\, ds;$$

hence

$$e^{A_\omega^N t}\phi = e^{A_0^N t}\phi + \int_0^t e^{A_\omega^N (t-s)} V^* f^N(s, \phi)\, ds$$

where $f^N(\cdot, \phi): \mathbb{R} \to \mathbb{R}^n$ is given by $f^N(s, \phi) = F e^{A_0^N s}\phi$, $s \geqq 0$ with $F: M^2 \to \mathbb{R}^n$:

$$F\psi = (I + \omega I + A_0)\psi^0 + A_1\psi^1(-r) \tag{4.18}$$

because the L^2-component of $(A_\omega^N - A_0^N)\psi$ vanishes for all $\psi \in Z^N$. From (4.18) and (4.16) it is clear that

$$\|f^N(\cdot, \phi)\|_{L^2(0,\infty;\mathbb{R}^n)} \leqq \kappa \|\phi\|_{M^2} \tag{4.19}$$

for some $\kappa > 0$ not depending on N. We write

$$Ve^{A_\omega^N t}\phi = Ve^{A_0^N t}\phi + y(t), \qquad t \geqq 0 \tag{4.20}$$

with

$$y(t) = \int_0^t Ve^{A_\omega^N (t-s)} V^* f^N(s, \phi)\, ds, \qquad t \geqq 0.$$

Letting $f^N(s, \phi) = 0$, $s \leqq 0$ and $e^{A_\omega^N (t-s)} = 0$, $s > t$ or $s \leqq 0$, we have $f^N(\cdot, \phi) \in L^1(\mathbb{R}; \mathbb{R}^n) \cap L^2(\mathbb{R}; \mathbb{R}^n)$ and by (4.15) $e^{A_\omega^N \cdot} \in L^1(\mathbb{R}; \mathscr{L}(Z^N) \cap L^2(\mathbb{R}; \mathscr{L}(Z^N))$, if N is sufficiently large. The calculation of the Fourier-transform $\hat{y}(\cdot)$ of the convolution $y(\cdot)$ yields

$$\begin{aligned}
\hat{y}(\tau) &= (Ve^{A_\omega^N \cdot} V^*)\hat{}(\tau)(f^N(\cdot, \phi))\hat{}(\tau) \\
&= \int_{-\infty}^{\infty} e^{-i\tau t} Ve^{A_\omega^N t} V^*\, dt (f^N(\cdot, \phi))\hat{}(\tau) \\
&= V(-\omega + i\tau - A^N)^{-1} V^* (f^N(\cdot, \phi))\hat{}(\tau), \qquad \tau \in \mathbb{R}.
\end{aligned}$$

By Plancherel's Theorem and (4.19), we get

$$\int_{-\infty}^{\infty} |(f^N(\cdot, \phi))\hat{}(\tau)|^2\, d\tau = \int_0^{\infty} |f^N(t, \phi)|^2\, dt \leqq \kappa^2 \|\phi\|^2.$$

Thus

$$\begin{aligned}
\int_0^{\infty} |y(t)|^2\, dt &= \int_{-\infty}^{\infty} |\hat{y}(\tau)|^2\, d\tau \\
&\leqq \int_{-\infty}^{\infty} |V(-\omega + i\tau - A^N)^{-1} V^*|^2 |(f^N(\cdot, \phi))\hat{}(\tau)|^2\, d\tau \\
&= \int_{-\infty}^{\infty} |(\Delta_0^N(-\omega + i\tau))^{-1}|^2 |(f^N(\cdot, \phi))\hat{}(\tau)|^2\, d\tau
\end{aligned}$$

by Lemma 4.10(a). Therefore, from (4.17)

$$\int_0^{\infty} |y(t)|^2\, dt \leqq \gamma^2 \kappa^2 \|\phi\|^2, \qquad N \geqq N_\omega$$

and, by (4.20), (4.16), and Lemma 4.8,

$$\int_0^{\infty} \|e^{A_\omega^N t}\phi\|^2\, dt \leqq \text{const.}\, \|\phi\|^2, \qquad N \geqq N_\omega, \quad \phi \in Z^N.$$

Lemma 3.2 thus yields constants $\tilde{M}$, $\varepsilon > 0$ not depending on N, such that

$$e^{\omega t} \|e^{A^N t}|_{Z^N}\| = \|e^{A_\omega^N t}|_{Z^N}\| \leqq \tilde{M} e^{-\varepsilon t}, \qquad N \geqq N_\omega. \qquad \square$$

So, if the hereditary semigroup $S(\cdot)$ is exponentially stable with some decay rate ω_0, it is approximated by piecewise linear systems with decay rate arbitrarily close to ω_0.

Another immediate consequence of Lemma 4.13 is the following corollary.

COROLLARY 4.14. *The semigroups* $\tilde{S}^N(\cdot)$ *generated by* $\tilde{A}^N p^N = (A^N - BR^{-1}B^*\Pi)p^N$ *satisfy hypothesis* (H5).

Proof. If the hereditary system is stabilizable, there exists a solution Π of the algebraic Riccati equation, and the closed-loop semigroup $\bar{S}(\cdot)$ generated by $\bar{A} = A - BR^{-1}B^*\Pi$ is exponentially stable. The approximations to $\bar{S}(\cdot)$ are actually given by $\tilde{S}^N(\cdot)$. Thus the previous lemma yields constants $\tilde{M}$, $\omega > 0$ such that

$$\|\tilde{S}^N(t)|_{Z^N}\| \leqq \tilde{M} e^{-\omega t}, \qquad t \geqq 0$$

for all N sufficiently large. □

Summarizing, we have proved that the convergence statements of Theorem 3.3 are valid when the piecewise linear approximation scheme is applied to infinite time horizon hereditary control problems.

4.6. Multiple and distributed delay terms. The piecewise linear approximation scheme can also be used for systems with more than one discrete delay ($p \geqq 2$ in (1.1)) and/or distributed delays ($A_{01}(\cdot) \not\equiv 0$, $A_{01} \in L^2(-h, 0; \mathbb{R}^{n\times n})$ in (1.1)). Then the intervals $I_k = [-h_k, -h_{k-1})$, $I = [-h_1, 0]$ of length $r_k = h_k - h_{k-1}$ are each divided into N subintervals of length r_k/N and the $(2npN)$-dimensional space Y^N consists of functions that are polynomials of degree one on each of these subintervals. In fact, all the results stated above for the single-delay case are valid in the general case. The proofs can be found in [17], which is a previous version of the present paper.

The arguments are essentially the same as above, with the main modifications arising from two facts: in the general case dom A^* contains pairs (ψ^0, ψ^1) with discontinuous functions ψ^1, the jumps at $-h_k$ given by $A_k^T\psi^0$; in order to get dissipativity of A and A^N, an equivalent inner product placing increasing weights on the intervals I_{p-k} is employed (cf. [13, Lemma 5.4]).

The generators A^N have δ^{N-} terms at all the discontinuities in the subspaces Y^N, while the adjoints A^{N*} in addition must reflect the jumps of elements in dom A^* at the points $-h_k$ and so the jump heights $A_k^T\psi^0$ appear in the arguments of the δ^{N+} terms for these points. $A^{N*}\psi \to A^*\psi$ for ψ in an appropriate set $D^* \subseteq$ dom A^* follows from $(A_{01}^T\psi^0)^N \to A_{01}^T\psi^0$ for $A_{01} \in L^2(-h, 0; \mathbb{R}^{n\times n})$; the density of $(\lambda - A^*)D^*$ can be shown by arguments similar to those in the proof of Theorem 7.2 of [9]. This avoids additional smoothness assumptions on A_{01} as it is required in [11]–[13].

The coupling of the intervals I_k as reflected in the matrices $[A^N]$ again yields the VDP-property. Expanding $\det \Delta^N(\lambda)$ for the general case and the determination of bounds on its zeros is laborious but leads to the above stated conclusions on the eigenvalues and the uniform stability of the approximate systems.

For the numerical implementation of a problem with multiple and/or distributed delays we must use the $n(2pN+1)$ matrices:

$$Q^N = \operatorname{diag}\left(1, \frac{r_1}{N}, \frac{r_1}{3N}, \cdots, \frac{r_1}{N}, \frac{r_1}{3N}, \frac{r_2}{N}, \frac{r_2}{3N}, \cdots, \frac{r_p}{N}, \frac{r_p}{3N}\right) \otimes I$$

and H^N, obtained by replacing the first row of $n \times n$ blocks in (4.7) by the row of blocks $(A_0, A_1^N \text{——} A_p^N)$ with

$$A_k^N = (A_{k1}^N, A_{k2}^N \cdots A_{k,2N-2}^N, A_{k,2N-1}^N + A_k, A_{k,2N}^N - A_k),$$

$$A_{kj}^N = \int_{-h}^{0} A_{01}(s)\, e_{kj}^N(s)\, ds, \qquad k = 1, \cdots, p, \quad j = 1, \cdots, 2N,$$

where e_{kj}^N are the basis elements of Y^N, constructed for each interval I_k by analogy to the single-delay case.

4.7. Examples. Testing the numerical performance of the approximation scheme that has been developed in this paper, we have employed it in several examples and

compared the outcomes with the results produced by other schemes. As far as these examples are representative, it turns out that the piecewise linear and the first-order spline approximations [13] are of the same numerical accuracy (for the same approximation index N), but both are inferior to the Legendre methods [10], [12].

In the case of the finite time horizon the Riccati differential equation

$$\frac{d}{dt}[\Pi^N(t)]+[(A^N)^*][\Pi^N(t)]+[\Pi^N(t)][A^N]$$
$$-[\Pi^N(t)][B^N]R^{-1}[B^N]^T[\Pi^N(t)]+[W^N]=0, \qquad 0\leqq t\leqq T,$$
$$[\Pi^N(T)]=[G^N]$$

is transformed, by taking $\Gamma^N(t)=Q^N[\Pi^N(T-t)]$, into a standard Riccati matrix differential equation

$$\frac{d}{dt}\Gamma^N(t)+[A^N]^T\Gamma^N+\Gamma^N[A^N]-\Gamma^N[B^N]R^{-1}[B^N]^T\Gamma^N+[W^N]=0,$$

(4.21) $$0\leqq t\leqq T,$$

$$\Gamma^N(0)=[G^N].$$

Observe that the self-adjointness of $\Pi^N(t)$ implies $[\Pi^N(t)]^TQ^N=Q^N[\Pi^N(t)]$ and hence $\Gamma^N(t)^T=\Gamma^N(t)$. Since B^N, W^N, G^N refer exclusively to the $\mathbb{R}^n$-component of Z^N, we have

$$[B^N]=\operatorname{col}(B_0,0,\cdots,0)\in\mathbb{R}^{n(2pN+1)\times m},$$

$$[W^N]=\begin{bmatrix} W_0 & 0 & \cdots & 0\\ 0 & & & 0\\ \vdots & & & \vdots\\ 0 & & & 0\end{bmatrix}\in\mathbb{R}^{n(2pN+1)\times n(2pN+1)},$$

$$[G^N]=\begin{bmatrix} G_0 & 0 & \cdots & 0\\ 0 & & & 0\\ \vdots & & & \vdots\\ 0 & & & 0\end{bmatrix}\in\mathbb{R}^{n(2pN+1)\times n(2pN+1)}.$$

Thus (if $p=1$, $A_{01}\equiv 0$) we can reduce the dimension of (4.21) introducing the $2n\times n(2N+1)$ matrices

$$F_1^N=\begin{bmatrix} F_0 & 0\cdots 0 & G_0A_1-G_0A_1\\ A_1^TG_0 & 0\cdots\cdots 0\end{bmatrix},\qquad F_2^N=\begin{bmatrix} I & 0\cdots\cdots 0\\ 0\cdots\cdots 0 & I-I\end{bmatrix}$$

where F_0 is given by

$$F_0=A_0^TG_0+G_0A_0-G_0B_0R^{-1}B_0^TG_0+W_0,$$

in order to get the factorization

$$\dot\Gamma(0)=(F_1^N)^T(F_2^N).$$

This implies ([18, p. 304 ff.])

(4.22) $$\Gamma^N(t)=[G^N]+\int_0^t L_1^N(s)^TL_2^N(s)\,ds,$$

$L_i^N(t)$ being the solution of

$$\frac{d}{dt}L_i^N(t) = L_i^N(t)([A^N]-[B^N]R^{-1}[B^N]^T\Gamma^N(t)), \tag{4.23}$$

$$L_i^N(0) = F_i^N, \qquad i=1,2.$$

Multiplying (4.22) from the left with $[B^N]^T$, we obtain

$$[B^N]^T\dot{\Gamma}^N(t) = [B^N]^TL_1^N(t)^TL_2^N(t), \qquad 0 \leqq t \leqq T, \tag{4.24}$$

$$[B^N]^T\Gamma^N(0) = [B^N]^T[G^N].$$

Solving the $n(4n+m)(2N+1)$ differential equations (4.23), (4.24), we get $[B^N]^T\Gamma^N(t)$. But this is all we need for the computation of the suboptimal control $\hat{u}^N(t)$ (see (3.1)). Denoting the $m \times n$ blocks in $[B^N]^T[\Pi^N(t)]$ by $\beta_0^N(t), \cdots, \beta_{2N}^N(t)$, we have

$$\hat{u}^N(t) = -R^{-1}\left\{\beta_0^N(t)\hat{x}^N(t) + \sum_{j=1}^{2N}\int_{-r}^{0}\beta_j^N(t)\, e_{1j}^N(s)\hat{x}^N(t+s)\, ds\right\}, \tag{4.25}$$

$$0 \leqq t \leqq T$$

where $\hat{x}^N(t)$ is the solution of

$$\dot{x}(t) = A_0x(t) + A_1x(t-r) + B_0\hat{u}^N(t) \tag{4.26}$$

in $\mathbb{R}^n$. In each term of the sum in (4.25), the integration ranges only over one of the intervals I_j^N, $j=1, \cdots, N$.

Numerically the systems (4.25), (4.26) were solved simultaneously by an appropriately adjusted fourth-order Runge-Kutta procedure combined with Simpson's rule for the evaluation of the integrals.

Example 4.1. Minimize

$$J(u) = \frac{1}{2}(x_1(2)^2 + x_2(2)^2) + \frac{1}{2}\int_0^2 (u_1(t)^2 + u_2(t)^2)\, dt$$

subject to

$$\dot{x}(t) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} x(t-1) + \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} u(t), \qquad 0 \leqq t \leqq 2,$$

$$x(0) = x_0(t) = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \qquad -1 \leqq t \leqq 0.$$

The true solutions $\bar{u}(t)$, $\bar{x}(t)$ (see [2]) and the piecewise linear approximations with index $N=4$, 8, 16 are presented in Tables 4.1 and 4.2. The relatively greatest errors occur around $t=1$ and $t=2$, where the derivatives of $\bar{x}(t)$ and $\bar{u}(t)$ have jumps, while $\hat{x}^N(t)$ and $\hat{u}^N(t)$ are of course continuously differentiable.

For the infinite time horizon control problem ($p=1$, $A_{01} \equiv 0$) the suboptimal control and trajectory are again calculated via (4.25), (4.26) when $\Pi^N(t)$ is replaced by the stationary operator Π^N, that is, the solution of the algebraic Riccati equation (3.3). The transformation $\Gamma^N = Q^N[\Pi^N]$ yields a standard Riccati matrix equation

$$[A^N]^T\Gamma^N + \Gamma^N[A^N] - \Gamma^N[B^N]R^{-1}[B^N]^T\Gamma^N + [W^N] = 0$$

in $\mathbb{R}^{n(2N+1)\times n(2N+1)}$, which was solved by the Newton-Kleinman Algorithm as presented in [18]. In each step of this algorithm, a Lyapunov matrix equation was solved using

the quadratic procedure given by Smith (see also [18, p. 297]). The time-independent $m \times n$ blocks β_j^N, $j = 0, \cdots, 2N$ were then employed in (4.25). Furthermore, with

$$[\Pi^N] = \begin{bmatrix} \Pi_{00}^N \Pi_{11}^N \cdots \Pi_{1,2N}^N \\ * \text{———} * \\ | \qquad\qquad | \\ * \text{———} * \end{bmatrix}$$

we give some values of the feedback kernel

$$\Pi_1^N(s) = \sum_{j=1}^{2N} \Pi_{1j}^N e_j^N(s),$$

which together with Π_{00}^N determines the feedback law of the Nth approximation. At the meshpoints, we simply have

$$\Pi_1^N(0) = \Pi_{11}^N + \Pi_{12}^N, \quad \Pi_1^N(t_j^N) = \Pi_{1,2j-1}^N - \Pi_{1,2j}^N, \quad j = 1, \cdots, N.$$

Example 4.2. This is the problem of minimizing

$$J(u) = \int_0^\infty [x(t)^2 + u(t)^2]\, dt$$

subject to

$$\dot{x}(t) = x(t) + x(t-1) + u(t), \qquad t \geqq 0,$$
$$x(0) = 0, \quad x_0(t) = \sin \pi t, \quad -1 \leqq t \leqq 0.$$

Table 4.3 gives the optimal costs $J^N = \langle (x(0), x_0), \Pi^N(x(0), x_0) \rangle_{M^2}$ of the approximating systems and the costs $J(\hat{u}^N)$ when the original system is controlled by $\hat{u}^N$. Table 4.4 presents the feedback gains Π_{00}^N and $\Pi_1^N(s)$ at the meshpoints $-j/4$, $j = 0, \cdots, 4$. In Table 4.5, we list the values of $\hat{u}^N(j/4)$, $\hat{x}^N(j/4)$, $j = 0, \cdots, 12$.

Example 4.3. A simplified model for a wind tunnel at the NASA Langley Research Center is given by (see [4])

$$\dot{x}(t)=\begin{bmatrix}-a & 0 & 0\\ 0 & 0 & 1\\ 0 & -\omega^2 & -2\xi\omega\end{bmatrix}x(t)+\begin{bmatrix}0 & ka & 0\\ 0 & 0 & 0\\ 0 & 0 & 0\end{bmatrix}x(t-0.33)+\begin{bmatrix}0\\ 0\\ -\omega^2\end{bmatrix}u(t), \qquad t\geqq 0, \tag{4.27}$$

$x(0)=\operatorname{col}(-0.1, 8.547, 0)\equiv x_0(t)$, $-0.33\leqq t\leqq 0$, where $k=-0.0117$, $\xi=0.8$, $\omega=6.0$, $1/a=1.964$. We want to minimize

$$J(u)=\int_0^\infty [10^4 x_1(t)^2+u(t)^2]\,dt$$

subject to (4.27).

The true solution of the problem has been given in [15]. Note that the matrix W_0 weighting the contribution of the state trajectory to the costs is singular in this example,

in contrast to the assumptions in Theorem 3.3. However, the piecewise linear approximation scheme produces the following values for $J(\hat{u}^N)$ and J^N (Table 4.6).

In Table 4.7, we compare the first block of the Riccati matrix Π^N with the $\mathbb{R}^3$-component of Π. The matrices $\Pi_1(t)$ and $\Pi_1^N(t)$, $-r=-0.33\leqq t\leqq 0$, have nonzero entries only in their second columns, which are shown in Table 4.8 for $t=-jr/4$, $j=0,\cdots,4$.

ON THE OPTIMAL REWARD FUNCTION OF THE CONTINUOUS TIME MULTIARMED BANDIT PROBLEM*

JOSÉ LUIS MENALDI† AND MAURICE ROBIN‡

Abstract. The optimal reward function associated with the so-called "multiarmed bandit problem" for general Markov–Feller processes is considered. It is shown that this optimal reward function has a simple expression (product form) in terms of individual stopping problems, without any smoothness properties of the optimal reward function neither for the global problem nor for the individual stopping problems. Some results relative to a related problem with switching cost are obtained.

Key words. variational inequality, switching problem, bandit problem, dynamic programming, index policy

1. Introduction. This paper deals with the properties of the optimal reward function associated with the so-called "multiarmed bandit problem." Let us recall, formally, the statement of the problem: assume that there are N independent machines. $x_i(t)$, $t \in \mathbb{R}_+$ is the state (for instance the production) of machine i. At each time t, one operates only one machine, the others being frozen. When machine i is operating, $x_i(t)$ evolves as a continuous time Markov process with a given semigroup $\Phi^i(t)$. If $i(t)$ denotes the number of the machine in operation at time t, we want to maximize a global payoff

$$J = E \int_0^\infty e^{-\alpha t} f(i(t), x_{i(t)}(t))\, dt \tag{1.1}$$

where f is a given instantaneous reward.

The multiarmed bandit problem has been studied by Gittins [4] and Whittle [8] in the discrete time case, and more recently by Varaiya, Walrand, and Buyukkoc [7] in a more general setting. Karatzas [5] studied the continuous time case when $x_i(t)$ is a one-dimensional diffusion process. The most general study is done in Mandelbaum [13], [14] who formulated the problem as the control of a multiparameter process. This approach allows, in particular, a strong formulation of the optimal process when $x_i(t)$ is a diffusion process.

In Whittle [9] it is shown that the optimal reward function has a simple expression in terms of an individual stopping problem each involving only one machine. Such an expression is shown to hold true for the diffusion bandit problem in Karatzas [5] thanks to the smoothness of the reward function which allows explicit computations.

In this paper, the main objective is to obtain such an expression when the $x_i(t)$ are general Feller processes, without smoothness properties of the optimal reward function neither for the global problem nor for the individual stopping problem.

Let us describe briefly what expression we are looking for.

‡ Institut National de Recherche en Informatique et en Automatique, Rocquencourt, Domaine de Voluceau, B.P. 105, 78153 Le Chesnay, France.

Following Whittle [9], we will use the variant of the problem where one can decide, at any time, to stop the control problem, with a reward M if this "retirement option" is chosen.

Assume that $x_i(t)$ is for each i, a Markov process with values in some space E_i, with semigroup $\Phi^i(t)$.

If $\underline{x}$ denotes the initial state of the whole set of machines, and if $u(\underline{x}, M)$ is the corresponding optimal reward function, then by applying, formally, the dynamic programming arguments, $u(\underline{x}, M)$ is shown to be the minimum solution of the following inequalities:

$$u(\underline{x}, M) \geqq e^{-\alpha t}\Phi^i(t)u(\underline{x}, M) + \int_0^t e^{-\alpha s}\Phi^i(s)f_i(x_i)\,ds \tag{1.2}$$

$$u(\underline{x}, M) \geqq M.$$

The individual stopping problems have optimal cost functions $(\phi_i(x_i, M), i = 1, N)$, where ϕ_i is the minimum solution of

$$\phi_i(x_i, M) \geqq e^{-\alpha t}\Phi^i(t)\phi_i(x_i, M) + \int_0^t e^{-\alpha s}\Phi^i(s)f_i(x_i)\,ds \tag{1.3}$$

$$\phi_i(x_i, M) \geqq M$$

when $\alpha k \leqq f_i(x_i) \leqq \alpha K, \quad \forall i, \quad \forall x_i$.

The objective is to show that

$$u(\underline{x}, M) = K - \int_M^K \prod_{i=1}^N \frac{\partial \phi_i}{\partial m}\,dm. \tag{1.4}$$

It would be nice to obtain such a formula by analytic methods, as it can be shown that (1.2) and (1.3) have a minimal solution (cf. [1], [2], [3]). However, without smoothness on ϕ_i, we do not know how to show the result by analytic methods.

Here we will use an intermediary control problem (§ 2.1) which is suitable for our objective, although it does not contain a general statement of the multiarmed bandit itself when there is no switching cost.

Using this particular interpretation of the minimal solution of (1.2), we will show (1.4) using an extension to the continuous time case of the Tsitsiklis' lemma [6]. In § 3, we investigate the problem with switching cost, showing a similar lemma; it does not seem possible, however, to obtain an expression of the optimal reward in terms of some individual problems.

2. Problem without switching cost. We start with a control problem which will provide a stochastic interpretation of (1.2).

2.1. An intermediary control problem. Let E_i, $i = 1 \cdots N$ be a family of compact metric spaces endowed with their Borel σ-algebra.

Define $E = E_1 \times \cdots \times E_N$. Throughout the paper,

$\underline{x}$ will denote an element of E, i.e.,

$$\underline{x} = (x_1, \cdots, x_N), \qquad x_i \in E_i.$$

We are given a family of Markov semigroups $\Phi^i(t)$ $i = 1, \cdots, N$, $\Phi^i(t)$ being defined and *continuous* on $C(E_i)$, the Banach space of continuous functions on E_i.[1]

[1] So, Φ^i is a Feller semigroup on $C(E_i)$, cf. Dynkin [10].

If $\Omega_i = D(\mathbb{R}_+, E_i)$, the space of right continuous, left limited functions on $\mathbb{R}_+$ with values in E_i, we denote by $Q^i_{x_i}$ the probability measure on Ω_i corresponding to Φ^1, and we define

$$\Omega = \Omega_1 \times \cdots \times \Omega_N$$

and $\{F_t\}$ the associated canonical σ-algebra.

In order to define the controlled process, we first consider the probability measure corresponding to constant trajectories for the components $j \neq i$ (i being the number of the process which is active, the others being frozen), and which gives the markovian evolution corresponding to $\Phi^i(t)$ for the component i: in other words we define

$$P_{i,\underline{x}} = \delta_{x_1} \times \cdots \times \delta_{x_{i-1}} \times Q^i_{x_i} \times \delta_{x_{i+1}} \cdots \times \delta_{x_N}. \tag{2.1}$$

Notice that, if

$$\underline{x}_t(\omega) = \omega(t) \quad \text{for } \omega \in \Omega,$$

then

$$E_{i,\underline{x}} g(\underline{x}_t) = E^i_{x_i} g(x_1, \cdots, x_{i-1}, x_i(t), x_{i+1}, \cdots, x_N)$$

where $E_{i,\underline{x}}$ (respectively, $E^i_{x_i}$) denotes the expectation with respect to $P_{i,\underline{x}}$, (respectively, $Q^i_{x_i}$).

Assume now that

(2.2) $f_i(x_i)$ is a positive function $f_i \in C(E_i)$, $\forall i$ $\alpha > 0$ a discount factor

(2.3) V will be the set of admissible controls and $v \in V \Leftrightarrow v = (\theta_n, \xi_n)_{n \geqq 0}$, $\theta_0 = 0$, where (θ_n) is an increasing sequence of F_t stopping times, ξ_n a F_{θ_n}-measurable random variable with values in $\{1, \cdots, N\}$ and we assume

(2.4) $\theta_n(\omega) \uparrow +\infty \quad \forall \omega.$

For any $v \in V$, $\underline{x} \in E$, we define, as in [11], the following sequence of probability measures on (Ω, F_∞), if $\xi_0 = i$

$$P^0 = P_{i,\underline{x}}$$

P^1 is the (unique) probability measure on (Ω, F_∞) such that

$$P^1 = P^0 \text{ on } F_{\theta_1}$$

$$P^1(\eta_{\theta_1} B \,|\, F_{\theta_1}) = P_{\xi_1, \underline{x}_{\theta_1}}(B), \quad P^0 \text{ a.s.},$$

$\forall B$ Borel subset of Ω, η_t being the shift operator,

and so on $\cdots$

P^n is similarly defined from P^{n-1}

$$P^n = P^{n-1} \quad \text{on } F_{\theta_n}$$

$$P^n(\eta_{\theta_1} B \,|\, F_{\theta_n}) = P_{\xi_n, \underline{x}_{\theta_n}}(B), \quad P^{n-1} \text{ a.s.}$$

Defining

$$\xi(t) = \xi_n \quad \text{for } t \in [\theta_n, \theta_{n+1}[, \qquad n \geqq 0.$$

We consider the discounted reward

$$J_{\underline{x}}(v) = \lim_{n \uparrow \infty} E^n_{\underline{x}} \int_0^{\theta_{n+1}} e^{-\alpha t} f(\xi(t), \underline{x}_t)\, dt$$

where

$$f(\xi, \underline{x}) = f_i(x_i) \quad \text{iff } \xi = i.$$

Actually, with the assumptions $\theta_n \uparrow +\infty$, one can know that there exists a unique probability measure $P^v_{i,\underline{x}}$ on (Ω, F_∞) such that

$$P^v_{i,\underline{x}} = P^n \quad \text{on } F_{\theta_n} \tag{2.5}$$

and one can also define our total reward by

$$J_{\underline{x}}(v) = E^v_{\underline{x}} \int_0^\infty e^{-\alpha t} f(\xi_t, \underline{x}_t)\, dt. \tag{2.6}$$

We now add another control possibility, namely the "retirement option."

Let T be the set of F_t stopping times, for $v \in V$, $\tau \in T$, and $(i, \underline{x}) \in U \times E$, we define the total reward as

$$J^M_{\underline{x}}(v, \tau) = E^v_{\underline{x}} \left\{ \int_0^\tau e^{-\alpha t} f(\xi_t, \underline{x}_t)\, dt + e^{-\alpha \tau} M \right\} \tag{2.7}$$

where M is a given constant.

We will use, as in Whittle [9], the additional assumption

$$\alpha k \leqq f_j \leqq \alpha K, \quad \forall j \in U, \tag{2.8}$$

where $k < K$ are given nonnegative constants.

The optimal reward function is

$$u(\underline{x}, M) = \operatorname{Sup} (J^M_{\underline{x}}(v, \tau), (v, \tau) \in V \times T). \tag{2.9}$$

Using a *formal* dynamic programming argument, it is easy to check that $u(\underline{x}, M)$ should solve the following inequalities

$$w(\underline{x}, M) \geqq e^{-\alpha t} \Phi^i(t) w + \int_0^t e^{-\alpha s} \Phi^i(s) f_i(x_i)\, ds, \quad \forall t > 0 \quad \forall i \in U,$$

$$w(\underline{x}, M) \geqq M, \tag{2.10}$$

$$w(\cdot, M) \text{ is a bounded measurable function.}$$

In the following section, we will show that u is actually the *minimum* solution of these inequalities (for fixed M).

Let us recall the following result (cf. Bensoussan and Robin [3], Bensoussan [1]):

THEOREM 2.1. *Under the assumption* (2.2) *there exists a minimum solution* $\bar{u}$ *of* (2.10) *in the space of bounded measurable functions. Moreover* $\bar{u}$ *is upper semicontinuous.*

Remark 2.1. In Bensoussan and Robin [3], another kind of interpretation was given for $\bar{u}(\underline{x}, M)$. The present one will be more suitable for the problem we consider.

2.2. Characterization of the optimal reward (2.9). In order to characterize $u(\underline{x}, M)$ as defined in (2.9), we introduce another switching problem, with a switching cost ε. Namely, we consider the same problem as in § 2.1, but now, at each switching time a cost ε (i.e., a reward $-\varepsilon$) is involved. This is in fact a classical switching problem (which can be considered as an impulse control problem where the state is $(\xi_t, \underline{x}_t)$, cf. Bensoussan [1], Bensoussan and Lions [2] for the general theory).

In this context, let

$$V_0 = \{v = (\theta_n, \xi_n)_{n \geqq 1}\}$$

be the set of admissible controls, θ_n, ξ_n being defined as previously.

For $(i, \underline{x}) \in U \times E$, define the reward

$$J_{i,\underline{x}}^{M,\varepsilon}(v, \tau) = E_{i,\underline{x}}^{v}\left\{\int_0^{\tau} e^{-\alpha s} f(\xi(t), \underline{x}_t)\, dt - \varepsilon \sum_{j \geqq 1} e^{-\alpha \theta_j} \chi_{\theta_j < \tau} + e^{-\alpha \tau} M\right\} \tag{2.11}$$

where $E_{i,\underline{x}}^{v}$ is defined as in § 2.1, $(v, \tau) \in V_0 \times T$, and $\chi_B(\omega)$ is the characteristic function of the set B and $\xi_0 = i$ for the construction of $P_{i,\underline{x}}^{n}$.

We also define

$$u_i^{\varepsilon}(\underline{x}, M) = \sup\,(J_{i,\underline{x}}^{M,\varepsilon}(v, \tau), (v, \tau) \in V_0 \times T). \tag{2.12}$$

Let $u^{\varepsilon} = (u_1^{\varepsilon}, \cdots, u_N^{\varepsilon})$.

From impulse control theory (cf. Bensoussan and Lions [2], [11]) we know that, for fixed M, u^{ε} is the minimum element of the set of bounded measurable functions w satisfying

$$\begin{aligned} &w_i(\underline{x}) \geqq e^{-\alpha t}\Phi^i(t) w_i + \int_0^t e^{-\alpha s}\Phi^i(s) f_i(x_i)\, ds, \quad \forall t > 0, \\ &w_i(\underline{x}) \geqq -\varepsilon + \max_j w_j(\underline{x}), \\ &w_i(\underline{x}) \geqq M. \end{aligned} \tag{2.13}$$

Moreover, $u_i^{\varepsilon}(\underline{x}) \in C(E)$, $\forall i = 1, \cdots, N$.

We first establish the following result.

THEOREM 2.2. *Let $\underline{u}(\underline{x}, M)$ be the minimum solution of the inequalities* (2.10), *then*

$$\lim_{\varepsilon \downarrow 0} u_i^{\varepsilon}(\underline{x}, M) = \underline{u}(\underline{x}, M) \tag{2.14}$$

pointwise in $\underline{x}$.

Proof. It is clear that $u_i^{\varepsilon}(\underline{x}, M)$ increases when ε decreases, and that $u_i^{\varepsilon}(\underline{x}, M)$ is bounded (say by $(1/\alpha)\|f\| + M$). Let us define

$$\underline{w}_i = \lim_{\varepsilon \downarrow 0} u_i^{\varepsilon}.$$

From (2.13), we have

$$\underline{w}_i \geqq \max_j w_j(\underline{x}, M), \quad \forall i. \tag{2.15}$$

Hence

$$\underline{w}_i(\underline{x}, M) = \underline{w}(\underline{x}, M) \quad \forall i.$$

But $\underline{u}(\underline{x}, M)$, the minimum solution of (2.10), satisfies obviously (2.13) and therefore

$$u_i^{\varepsilon}(\underline{x}, M) \leqq \underline{u}(\underline{x}, M) \quad \forall \varepsilon, i.$$

So we deduce, when $\varepsilon \to 0$,

$$\underline{w}(\underline{x}, M) \leqq \underline{u}(\underline{x}, M). \tag{2.16}$$

But we see that $\underline{w}(\underline{x}, M)$ will also satisfy (2.10), since this is identical to (2.13) when $\varepsilon = 0$ for a function which does not depend explicitly on i.

Therefore

$$\underline{w}(\underline{x}, M) \geqq \underline{u}(\underline{x}, M).$$

Hence

$$\underline{w}(\underline{x}, M) = \underline{u}(\underline{x}, M)$$

and the theorem is proved. □

Let us define

$$u(\underline{x}, M) = \sup (J_{\underline{x}}^{M}(v, \tau), (v, \tau) \in V \times T). \tag{2.17}$$

Then we have the following Theorem.

THEOREM 2.3.

$$\underline{u}(\underline{x}, M) = u(\underline{x}, M). \tag{2.18}$$

Proof. Since $\varepsilon > 0$, we have

$$u_i^{\varepsilon}(\underline{x}, M) = \sup (J_{i,\underline{x}}^{M,\varepsilon}(v, \tau), (v, \tau) \in V_0 \times T)$$

and

$$J_{i,\underline{x}}^{M,\varepsilon}(v, \tau) \leqq J_{\underline{x}}^{M}(\tilde{v}, \tau)$$

where $\tilde{v} = ((i, 0), v)$, and $(\tilde{v}, \tau) \in V \times T$.

Therefore

$$u_i^{\varepsilon}(\underline{x}, M) \leqq u(\underline{x}, M),$$

hence

$$\underline{u}(\underline{x}, M) \leqq u(\underline{x}, M). \tag{2.19}$$

Now, for any solution w of the inequalities (2.10), one can show as in [11, Thm. VII, § 3.1] or [2b, § 6.4], that

$$w(\underline{x}) \geqq E_x^m \left\{ e^{-\alpha\theta_{m+1}\wedge\tau} w(\underline{x}_{\theta_{m+1}\wedge\tau}) + \int_0^{\theta_{m+1}\wedge\tau} e^{-\alpha t} f(\underline{x}_t, v_t)\, dt \right\}$$

for any admissible control (v, τ), $v = (\theta_i, \xi_i)_{i \geqq 0}$ where E_x^m is the expectation corresponding to the measure P_x^m associate to (v, τ) as in § 1, with $\theta_m \wedge \tau$ instead of θ_m.

From this inequality, we deduce, when $m \to +\infty$, since $w(\underline{x}) \geqq M$ and $\theta_m \wedge \tau \uparrow \tau$, that

$$w(\underline{x}) \geqq J_{\underline{x}}^{M}(v, \tau)$$

and therefore

$$w(\underline{x}) \geqq u(\underline{x}, M).$$

Finally, this gives

$$\underline{u}(\underline{x}, M) \geqq u(\underline{x}, M),$$

which, with (2.19), proves the result. □

2.3. Reduction to write off policies. Following Whittle, a write off policy is defined as a policy such that there exists a family of "write-off" sets $S_i \subset E_i$ with the following properties.

- as soon as x_i (the state of the process i) belongs to S_i, the process i is abandoned;
- one retires as soon as all the processes have been abandoned, and only then;
- before retiring, one works only with those processes which have not been abandoned.

In this section we are going to show a lemma similar to the one obtained by Tsitsiklis [6] for discrete time, showing that we can restrict ourselves to write off policies with write off sets defined by optimal stopping problems for the individual processes.

The individual stopping problems. Let us consider the optimal stopping reward

$$\phi_i(x_i, M) = \sup_{\tau} I^M_{x_i}(\tau) \tag{2.20}$$

$$I^M_{x_i}(\tau) = E^i_{x_i}\left[\int_0^\tau e^{-\alpha t} f_i(x_{it})\, dt + e^{-\alpha\tau} M\right]. \tag{2.21}$$

It is known from standard theory (see Bensoussan [1]) that $\phi_i(x_i, M)$ is the minimum element of the set of functions $w(x_i)$ satisfying

$$\begin{aligned} &w(x_i) \geqq e^{-\alpha t}\Phi^i(t) w + \int_0^t e^{-\alpha s}\Phi^i(s) f_i(x_i)\, ds, \quad \forall t > 0 \\ &w(x_i) \geqq M, \qquad w \in C(E_i). \end{aligned} \tag{2.22}$$

Let us show the following results which extend the discrete time case (cf. Whittle [9]) and the diffusion case (Karatzas [5]).

LEMMA 2.1. *Under the assumptions* (2.2)-(2.8), $\phi(x, M) = \phi_i(x_i, M)$ *has the following properties*:

(i) $\phi(x, M) = M \ \forall M \geqq K$;

(ii) $\phi(x, M) = \int_0^\infty e^{-\alpha t}\Phi^i(t) f_i(x)\, dt, \ \forall M \leqq k$;

(iii) $\forall x \in E_i$, $\phi(x, \cdot)$ *is an increasing convex function*;

(iv) $\phi(x, \cdot)$ *is Lipschitz continuous and in every* M *where the derivative exists*

$$0 \leqq \frac{\partial \phi}{\partial M} \leqq 1;$$

(v) *in every point where the derivative exists*

$$\frac{\partial \phi}{\partial M}(x, M) = E_x\, e^{-\alpha\hat{\tau}}$$

where $\hat{\tau}$ *is optimal for* (2.20), *namely*

$$\hat{\tau} = \inf(t \geqq 0, \phi(x, M) = M).$$

Proof. (i) This shows that $\tau = 0$ is optimal in (2.20) whenever $M \geqq K$. Since $f_i \leqq \alpha K$

$$\begin{aligned} J^M_x(\tau) &\leqq E_x\{(1 - e^{-\alpha\tau})K + e^{-\alpha\tau} M\} \\ &= K + E_x\, e^{-\alpha\tau}(M - K), \end{aligned}$$

clearly if $M \geqq K$, $\tau = 0$ gives the maximum value.

(ii) $f_i \geqq \alpha k$ implies

$$w_o(x) = \int_0^\infty e^{-\alpha t}\Phi^i(t) f_i\, dt \geqq k$$

and since $w_0(x) = e^{-\alpha t}\Phi^i(t) w_0 + \int_0^t e^{-\alpha s}\Phi^i(s) f_i\, ds$, we see that w_0 satisfies (2.22) for $M = k$.

Moreover $t = +\infty$ in (2.22) gives

$$w(x) \geqq w_0(x) \quad \forall w \text{ solution of (2.22)}.$$

(iii) If $0 \leqq \lambda \leqq 1$, then we check that

$$w_\lambda = \lambda\phi(x, m_1) + (1 - \lambda)\phi(x, m_2)$$

satisfies (2.22) for $m = \lambda m_1 + (1-\lambda)m_2$ and therefore

$$w_\lambda \geqq \phi(x, \lambda m_1 + (1-\lambda)m_2).$$

The increasing property is obvious from (2.20).

(iv) From (2.21) one has, for an arbitrary τ

$$I_x^{M+\delta}(\tau) - I_x^M(\tau) = E_x e^{-\alpha\tau}\delta$$

therefore, for $\delta > 0$

$$I_x^{M+\delta}(\tau) \leqq I_x^M(\tau) + \delta \leqq \phi(x, M) + \delta$$

implying

$$\phi(x, M+\delta) \leqq \phi(x, M) + \delta$$

and since $\phi(x, M+\delta) \geqq \phi(x, M)$, we see that

$$0 \leqq \frac{\partial^+\phi}{\partial M}(x, M) \leqq 1.$$

(v) Let $\hat{\tau} = \inf(t \geqq 0, \phi(x, M) = M)$, we know (cf. [1]) that

$$\phi(x, M) = I_x^M(\hat{\tau}).$$

Therefore, if $\delta > 0$,

$$\begin{aligned} I_x^{M+\delta}(\hat{\tau}) &= I_x^M(\hat{\tau}) + \delta E_x e^{-\alpha\hat{\tau}} \\ &= \phi(x, M) + \delta E_x e^{-\alpha\hat{\tau}} \end{aligned}$$

hence

$$\phi(x, M+\delta) - \phi(x, M) \geqq \delta E_x e^{-\alpha\hat{\tau}}$$

$$\frac{\partial^+\phi}{\partial M}(x, M) \geqq E_x e^{-\alpha\hat{\tau}}.$$

Taking $\delta < 0$, we get

$$\frac{\partial^-\phi}{\partial M}(x, M) \leqq E_x e^{-\alpha\hat{\tau}}.$$

Therefore, in M such that the derivative exists, we get the result. □

COROLLARY. *$\partial^+\phi/\partial M$ is a right continuous increasing function such that*

$$0 \leqq \frac{\partial^+\phi}{\partial M} \leqq 1,$$

$$\frac{\partial^+\phi}{\partial M}(x, M) = 1 \quad \forall M \geqq K$$

$$\frac{\partial^+\phi}{\partial M}(x, M) = 0 \quad \forall M < k.$$

Let us now define, for fixed i

$$y_i = (x_1, \cdots, x_{i-1}, x_{i+1}, \cdots, x_N)$$

$U_i(y_i, M)$ the optimal reward function when only the processes different from i are available.

From the previous section, $U_i(y_i, M)$ is the minimum solution of

$$W_i(y_i, M) \geqq e^{-\alpha t}\Phi^j(t)\, W_i + \int_0^t e^{-\alpha s}\Phi^j(s) f_j(x_j)\, ds, \quad \forall t > 0, \quad \forall j \neq i \tag{2.23}$$

$$W_i(y_i, M) \geqq M, \quad W_i(\cdot, M) \text{ bounded and measurable.}$$

We can now state the Tsitsiklis' lemma in continuous time.

LEMMA 2.2. (*Tsitsiklis' lemma in continuous time*). *One has*

$$u(\underline{x}, M) \leqq \phi_i(x_i, M) - M + U_i(y_i, M), \quad \forall i. \tag{2.24}$$

Proof. Let $W_i(\underline{x}, M)$ be the right-hand side of (2.24). We are going to show that W_i satisfies (2.10) and since u is the minimum solution, this will show the lemma. Notice that since $U_i \geqq M$ and $\phi_i \geqq M$, we have

$$W_i(\underline{x}, M) \geqq M.$$

Moreover, since U_i does not depend on x_i,

$$e^{-\alpha t}\Phi^i(t)\, W_i + \int_0^t e^{-\alpha s}\Phi^i(s) f_i\, ds = \left\{ e^{-\alpha t}\Phi^i(t)\phi_i + \int_0^t e^{-\alpha s}\Phi^i(s) f_i\, ds \right\} + e^{-\alpha t}[U_i - M]$$

$$= I + II.$$

We have,

$$I \leqq \phi_i \quad \text{by (2.22)}$$

and, since $U_i - M \geqq 0$,

$$II \leqq U_i - M.$$

Then, for $j \neq i$, since ϕ_i does not depend on x_j, $j \neq i$,

$$e^{-\alpha}\Phi^j(t)\, W_i + \int_0^t e^{-\alpha s}\Phi^j(s) f_j\, ds$$

$$= \left\{ e^{-\alpha t}\Phi^j(t)\, U_i + \int_0^t e^{-\alpha s}\phi^j(s) f_j\, ds \right\} + e^{-\alpha t}[\phi_i - M] = III + IV.$$

Hence, using (2.23)

$$III \leqq U_i,$$

and

$$IV \leqq \phi_i - M \text{ since } \phi_i - M \geqq 0.$$

Therefore the lemma is proved. □

COROLLARY. *Define* $S_i^M = \{x_i \in E_i, \phi_i(x_i, M) = M\}$, *then one can restrict the policies to be write off with respect to* $(S_i^M, i = 1, \cdots, N)$.

Proof. Notice that $U_i(y_i, M) \leqq u(\underline{x}, M)$. If $x_i \in S_i^M$, then (2.24) gives, with the above inequality,

$$u(\underline{x}, M) = U_i(y_i, M)$$

which means that the optimal reward is the same as the one with $N-1$ processes where the i process has been dropped. If there exists i such that, for $\underline{x} = (x_1, \cdots, x_N)$, $x_i \notin S_i^M$, then $u(\underline{x}, M) \geqq \phi_i(x_i, M) > M$ implies that it is not optimal to retire. Finally

if $\underline{x}$ is such that $x_i \in S_i^M$, $\forall i$, then $u(\underline{x}, M) = U_i$ $\forall i$ and we can use the same argument for N-1 processes to show that

$$u(\underline{x}, M) = \phi_j(x_j, M) = M \quad \forall j. \qquad \square$$

Let us denote by V_{off}^M the set of admissible write off policies corresponding to $(S_i^M,\ i = 1, \cdots, N)$. We will use the following lemma due to Whittle (cf. [9]).

LEMMA 2.3. *If (v, τ) is a write off policy, then*

$$E_{\underline{x}}^v e^{-\alpha\tau} = \prod_{i=1}^{N} E_{x_i} e^{-\alpha\tau_i}$$

where τ_i is the retirement times when only the process i is available.

Proof. For the proof see Whittle [9]. $\square$

In our context, this means that, if

$$\tau_i^M = \inf(t \geqq 0,\ \phi_i(x_{it}, M) = M), \tag{2.25}$$

then, for all write off policies,

$$E_x^v e^{-\alpha\tau} = \prod_i E_{x_i} e^{-\alpha\tau_i^M}. \tag{2.26}$$

We can then deduce the product formula for u.

THEOREM 2.4.

$$U(\underline{x}, M) = K - \int_M^K \sum_{i=1}^{N} \frac{\partial \phi_i}{\partial m}(x_i, m)\, dm. \tag{2.27}$$

Proof. Let (v, τ) be an admissible write off policy with respect to $(S_i^M,\ i = 1, \cdots, N)$. We have,

$$J_{\underline{x}}^{M+\delta}(v, \tau) - J_{\underline{x}}^M(v, \tau) = \delta E_{\underline{x}}^v e^{-\alpha\tau}.$$

From the previous lemma

$$J_{\underline{x}}^{M+\delta}(v, \tau) - J_{\underline{x}}^M(v, \tau) = \delta \cdot \prod_{i=1}^{N} E_{x_i} e^{-\alpha\tau_i^M},$$

therefore

$$u(\underline{x}, M+\delta) \geqq J_{\underline{x}}^M(v, \tau) + \delta \prod_{i=1}^{N} E_{x_i} e^{-\alpha\tau_i^M}.$$

Note that the last term is independent from (v, τ) as far as (v, τ) is a write off policy with respect to (S_i^M). Therefore, maximizing with respect to (v, τ)

$$u(\underline{x}, M+\delta) \geqq u(\underline{x}, M) + \delta \prod_i E_{x_i} e^{-\alpha\tau_i^M}$$

which implies, for $\delta > 0$,

$$\frac{\partial^+ u}{\partial M}(\underline{x}, M) \geqq \prod_i E_{x_i} e^{-\alpha\tau_i^M}$$

and for $\delta < 0$

$$\frac{\partial^- u}{\partial M}(\underline{x}, M) \leqq \prod_i E_{x_i} e^{-\alpha\tau_i^M}.$$

Therefore, at every point where the derivatives exist, we have, thanks to the Lemma 2.1,

$$\frac{\partial u}{\partial M}(\underline{x}, M) = \prod_{i=1}^{N} \frac{\partial \phi_i}{\partial M}(x_i, M).$$

Integrating from M to K, using the fact that $u(\underline{x}, K) = K$, we get (2.27). □

Remark. From Bensoussan and Robin [3], we can show that the optimal reward of the discrete time problem converges to the $u(\underline{x}, M)$ when the time step h goes to zero. However, we have not been able to show the product formula in continuous time by letting h go to zero on the product formula of the discrete time case.

2.4. The forward induction lemma. Let us consider the discrete time version of the stopping problems (2.22). Namely, for $h > 0$, we define (dropping the index i)

$$r_h(x) = E_x \int_0^h e^{-\alpha s} f(x_s)\, ds$$

$$Q_h z = \phi(h) z$$

$$\beta = e^{-\alpha h}.$$

Then the optimal reward for the discrete stopping problem $\phi_h(x, m)$ is the unique solution of

$$\phi_h(x, m) = \max\,(r_h + \beta Q_h \phi_h, m).$$

Defining $V_h = \{\tau$, stopping times with values in $N_h = \{nh, n \geqq 0\}\}$, we can write

$$\phi_h(x, m) = \sup_{\tau \in V_h} E_x \left(\int_0^\tau e^{-\alpha s} f(x_s)\, ds + e^{-\alpha \tau} m \right).$$

The *index* is defined, as previously, as

$$M_h(x) = \inf\,(m > k,\ \phi_h(x, m) = m).$$

On the other hand, Whittle [9] shows that $M_h(x)$ has the following representation:

$$M_h(x) = \sup_{\tau \in V_h^*} \frac{E_x \int_0^\tau e^{-\alpha s} f(x_s)\, ds}{1 - E_x e^{-\alpha \tau}} \tag{2.28}$$

with $V_h^* = \{\tau$ stopping times with values in $N_h^* = N_h - \{0\}\}$.

The extension of the formula (2.28) to diffusion processes was done by Karatzas [5] using explicit calculation for one-dimensional processes. We are going to show the same formula in our context; the idea being to approximate the stopping problem (2.22) by a discrete time problem (like in Bensoussan–Robin [3]).

LEMMA 2.4. *Let $\phi(x, m)$ be defined as in* (2.20) (*where we drop the index i*), *and define*

$$M(x) = \inf\,(m > k,\ \phi(x, m) = m), \text{ and } V^* = \bigcup_h V_h^*,$$

then

$$M(x) = \sup_{\tau \in V^*} \frac{E_x \int_0^\tau e^{-\alpha s} f(x_s)\, ds}{1 - E_x e^{-\alpha \tau}}$$

where $V^* = \{\bigcup_h V_h^*\}$.

Proof. Starting with $M_h(x)$ we have

$$k \leqq M_h(x) \leqq K \quad \forall x, \quad \forall h.$$

Clearly, V_h^* is increasing as h decreases to zero and therefore $M_h(x)$ is increasing when $h \downarrow 0$. For fixed x, let

$$v(x) = \lim_{h \downarrow 0} M_h(x)$$

then

$$v(x) = \sup_{\tau \in V^*} Z(\tau), \quad \text{where } Z(\tau) = \frac{E_x \int_0^\tau e^{-\alpha s} f(x_s)\, ds}{1 - E_x e^{-\alpha \tau}}.$$

Indeed, for all ε, there exists h, such that

$$v \geqq M_h > v - \varepsilon \Rightarrow \exists \delta(\varepsilon) \text{ s.t.} \quad M_h - \delta(\varepsilon) > v - \varepsilon$$

and from the definition of M_h, we can find $\tau_h(\delta(\varepsilon))$ such that, $\tau_h \in V_h^*$,

$$M_h \geqq Z(\tau_h) > M_h - \delta(\varepsilon).$$

Therefore for all ε, there exists $\tau \in V^*$ such that $v \geqq Z(\tau) > v - \varepsilon$ proving that $v = \sup (Z(\tau), \tau \in V^*)$.

Let us prove that $v = M(x)$. Assume that $m \geqq v$, then

$$m \geqq v \geqq \frac{E_x \int_0^\tau e^{-\alpha s} f(x_s)\, ds}{1 - E_x e^{-\alpha \tau}} \quad \forall \tau \in V^*$$

$\Rightarrow$

$$m \geqq E_x \left(\int_0^\tau e^{-\alpha s} f(x_s) + e^{-\alpha \tau} m \right) \quad \forall \tau \in V^*$$

(and for $\tau = 0$, we have the equality). Therefore $m \geqq \phi(x, m)$.

But $\phi(x, m) \geqq m$, for all m implies $\phi(x, m) = m$ for all $m \geqq v$. Now assume that $m < v$.

Let us assume that for such m

$$\phi(x, m) = \sup_\tau E_x \int_0^\tau e^{-\alpha s} f(x_s) + e^{-\alpha \tau} m = m.$$

This would imply

$$m \geqq \frac{E_x \int_0^\tau e^{-\alpha s} f(x_s)\, ds}{1 - E_x e^{-\alpha \tau}} \quad \forall \tau \in V^*$$

which contradicts the assumption $m < v$.

Therefore

$$m < v \Rightarrow \phi(x, m) > m, \quad \text{hence } v = M(x). \qquad \square$$

Remark. As it was stressed in Katehakis-Veinott [12] we can also characterize $M_h(x)$ using the "restart in x-problem" for which the optimal reward function $v_h^x(\cdot)$ is given by

$$v_h^x(y) = \max (r_h(y) + \beta Q_h v_h^x, r_h(x) + \beta Q_h v_h)$$

and then (see [12]) we have

$$M_h(x) = v_h^x(x).$$

In continuous time, in order to define a similar problem, we can use the discrete time solution; namely, as in Bensoussan-Robin [3], we could show that for $h = 2^{-N}$

$$v_N^x(y) = v_h^x(y)$$

is increasing when $N \to +\infty$, (and bounded).

Then

$$v^x(y) = \lim_{N \uparrow \infty} v_N^x(y)$$

is the minimum solution of the inequalities

$$v^x(y) \geqq e^{-\alpha t}\phi(t)v^x + \int_0^t e^{-\alpha s}\Phi(s)f\,ds$$

$$v^x(y) \geqq v^x(x), \quad \forall y$$

$v^x(x)$ bounded measurable functions.

This is the continuous time version of the restart in x-problem.

3. The problem with switching cost. We now turn back to the case where there is a switching cost incurred at each time we change the active process. This was already considered in § 2.2 when we constructed the functions u_i^ε. Recall that this is a more or less standard impulse control problem where the underlying state is in fact $(z, \underline{x})$ where $z \in \{1, \cdots, N\}$ is the number of the active process. It would be interesting to know if a product formula like (1.4) holds. We do not know the answer, neither for the question of the optimality of some index rule. However, we can show that the concept of write off policy is still valid in this case and this gives some more information on the optimal policies than the mere interpretation of the dynamic programming condition. The reduction to write off policies will be a consequence of the following simple result, similar to the Tsitsiklis' lemma. Let us make precise some notations: we drop the ε in the optimal reward which is now

$$u(z, \underline{x}, M) = \sup\,(J_{z,\underline{x}}^M(v, \tau), (v, \tau) \in V_0 \times T) \tag{3.1}$$

$J_{z,\underline{x}}^M(v, \tau)$, V_0, T being defined as in (2.11), with $z \in \{1, \cdots, N\}$. We know that u is the minimum element of the set of bounded and measurable functions $w(z, \underline{x})$ satisfying

$$w(z, \underline{x}) \geqq e^{-\alpha t}\Phi^z(t)w + \int_0^t e^{-\alpha s}\Phi^z(s)f_z(x_z)\,ds$$

$$w(z, \underline{x}) \geqq -\varepsilon + \max_j w(j, \underline{x}), \tag{3.2}$$

$$w(z, \underline{x}) \geqq M, \quad \forall z \in \{1, \cdots, N\}.$$

We denote by

$$y_i = (x_j, j \neq i),$$

$U(z, y_i, M)$ the optimal reward when only the processes different from i are available, and when the initial active process is the process number z.

LEMMA 3.1. *We have for arbitrary* $i \in \{1, \cdots, N\}$,

$$u(j, \underline{x}, M) \leqq [\phi_i(x_i, M) - (M + \varepsilon)]^+ + U(j, y_i, M) \quad \forall j \neq i \tag{3.3}$$

$$u(i, \underline{x}, M) \leqq \phi_i(x_i, M) - M + \max\left[M, -\varepsilon + \max_{j \neq i} U(j, y_i, M)\right]. \tag{3.4}$$

Proof. Let us define, for fixed i:

$$w(z,\underline{x})=\begin{cases}[\phi_i(x_i,M)-(M+\varepsilon)]^+ + U(z,y_i,M) & \text{for } z\neq i\\ \phi_i(x_i,M)-M+\max\left[M,-\varepsilon+\max\limits_{j\neq i}U(j,y_i,M)\right] & \text{for } z=i.\end{cases}$$

We are going to show that $w(z,\underline{x})$ satisfies (3.2) and since $u(z,\underline{x},M)$ is the minimum solution, this will prove the lemma. We have,

$$\begin{aligned}&e^{-\alpha t}\Phi^z(t)w(z,\underline{x})+\int_0^t e^{-\alpha s}\Phi^z(s)f_z(x_z)\,ds\\ &=\left\{e^{-\alpha t}\Phi^z(t)U(z,y_i,M)+\int_0^t e^{-\alpha s}\Phi^z(s)f_z(x_z)\,ds\right\}\\ &\quad+e^{-\alpha t}[\phi_i(x_i,M)-(M+\varepsilon)]^+ \quad \text{if } z\neq i\\ &=\left\{e^{-\alpha t}\Phi^i(t)\phi_i+\int_0^t e^{-\alpha s}\Phi^i(s)f_i(x_i)\,ds\right\}\\ &\quad+e^{-\alpha t}\left[\max\left[M,-\varepsilon+\max_{j\neq i}U(j,y_i,M)\right]-M\right] \quad \text{if } z=i.\end{aligned}$$

In the first case, thanks to (3.2), the right-hand side is less than

$$U(z,y_i,M)+e^{-\alpha t}[\phi_i(x_i,M)-(M+\varepsilon)]^+$$

i.e., less than

$$U(z,y_i,M)+[\phi_i(x_i,M)-(M+\varepsilon)]^+=w(z,\underline{x}).$$

In the second one, thanks to (2.22) for ϕ_i, the right-hand side is less than

$$\phi_i(x_i,M)-M+\max\left[M,-\varepsilon+\max_{j\neq i}U(j,y_i,M)\right]=w(z,\underline{x}) \quad \text{if } z=i.$$

Therefore the first inequality of (3.2) is satisfied. It is obvious that $w(z,\underline{x})\geqq M$. Now, for the second inequality of (3.2), we must check that

$$w(i,\underline{x})\geqq -\varepsilon+\max_{j\neq i}([\phi_i(x_i,M)-(M+\varepsilon)]^+ + U(j,y_i,M)) \tag{3.5}$$

and, for $z\neq i$

$$w(z,\underline{x})\geqq -\varepsilon+\max\begin{cases}[\phi_i(x_i,M)-(M+\varepsilon)]^+ + U(j,y_i,M) & \forall j\neq i\\ \phi_i(x_i,M)-M+\max\left[M,-\varepsilon+\max\limits_{j\neq i}U(j,y_i,M)\right].\end{cases} \tag{3.6}$$

But, since $\phi_i(x_i,M)-M\geqq[\phi_i(x_i,M)-(M+\varepsilon)]^+$, (3.5) is obvious from the definition of $w(i,\underline{x})$. For (3.6), since

$$U(z,y_i,M)\geqq -\varepsilon+\max_{j\neq i}U(j,y_i,M)$$

we have

$$w(z,\underline{x})\geqq -\varepsilon+[\phi_i(x_i,M)-(M+\varepsilon)]^+ +\max_{j\neq i}U(j,y_i,M)$$

and since $[\phi_i(x_i, M)-(M+\varepsilon)]^+ \geqq \phi_i(x_i, M)-M-\varepsilon$, we also have

$$w(z, \underline{x}) \geqq -\varepsilon + \phi_i(x_i, M) - M + \max\left[M, -\varepsilon + \max_{j \neq i} U(j, y_i, M)\right].$$

Therefore, the lemma is obtained. □

Let us define the following write off sets:

$$S_i^M = \{(z, \underline{x}) \in \{1, \cdots, N\} \times E_i \text{ such that either } z = i \text{ and } \phi_i(x_i, M) = M, \text{ or } z \neq i \text{ and } \phi_i(x_i, M) \leqq M + \varepsilon\}. \tag{3.7}$$

THEOREM 3.1. *We can restrict the admissible policies to be write off with respect to* $(S_i^M, i = 1, \cdots, N)$, *in other words*

(i) *if* $\exists i$ *s.t.* $(z, \underline{x}) \notin S_i^M$, *we continue* (*i.e., we do not use the retirement option*)

(ii) *if* $\forall i$, $(z, \underline{x}) \in S_i^M$, *we retire*

(iii) *if* $(z, \underline{x}) \in S_i^M$, *the process i is abandoned.*

Proof. (i) Assume that $\exists i$ s.t. $(z, \underline{x}) \notin S_i^M$

then -either $z = i$ and $\phi_i(x_i, M) > M$ hence $u(i, \underline{x}, M) \geqq \phi_i(x_i, M) > M$,

therefore we do not retire;

-or $z \neq i$ and $\phi_i(x_i, M) > M + \varepsilon$

hence $u(z, \underline{x}, M) \geqq -\varepsilon + \max_j u(j, \underline{x}, M) \geqq -\varepsilon + \phi_i > M$.

Therefore we do not retire.

(ii) Assume that

$$\forall i, \quad (z, \underline{x}) \in S_i^M \tag{3.8}$$

and to fix the idea, take $z = N$, then (3.3) implies, since $(z, \underline{x}) \in S_1^M$, and $U(z, y_1, M) \leqq u(z, \underline{x}, M)$,

$$u(z, \underline{x}, M) = U(z, y_1, M).$$

Denote U by $U^{N-1}(z, y_1^{N-1}, M)$ to make explicit that U is the optimal reward of a problem where only the $N-1$ first components are available, i.e., $y_1^{N-1} = (x_2, \cdots, x_N)$.

Then applying again (3.3) to the $N-1$ dimensional bandit problem we get, with $i = 2$

$$u(z, \underline{x}, M) = U^{N-1}(z, y_1^{N-1}, M) = U^{N-2}(z, y_2^{N-2}, M)$$

with $y_2^{N-1} = (x_3, \cdots, x_N)$.

This process goes on until

$$u(z, \underline{x}, M) = U^1(z, x_z, M) = \phi_z(x_z, M)$$

which by the assumption and (3.4) is equal to M. Therefore we must retire if (3.8) holds.

(iii) Assume $(z, \underline{x}) \in S_i^M$

-either $z \neq i$ then (3.3) and $u(z, \underline{x}, M) \geqq U(z, y_i, M)$ implies $u(z, \underline{x}, M) = U(z, y_i, M)$ meaning that we never use again the process i

-or $z = i$ and $\phi_i(x_i, M) = M$, then (3.4) implies that either we retire, or we have

$$u(z, \underline{x}, M) = -\varepsilon + \max_{j \neq z} U(j, y_z, M)$$

meaning that we switch to another process and never use the process $z = i$. This completes the proof of Theorem 3.1. □

THE AUGMENTED LAGRANGIAN METHOD FOR PARAMETER ESTIMATION IN ELLIPTIC SYSTEMS*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. In this paper a new technique for the estimation of parameters in elliptic partial differential equations is developed. It is a hybrid method combining the output-least-squares and the equation error method. The new method is realized by an augmented Lagrangian formulation, and convergence as well as rate of convergence proofs are provided. Technically the critical step is the verification of a coercivity estimate of an appropriately defined Lagrangian functional. To obtain this coercivity estimate a seminorm regularization technique is used.

Key words. augmented Lagrangian method, parameter estimation, least squares, elliptic system

AMS(MOS) subject classifications. 35R30, 49D29

1. Introduction. In this paper we consider the problem of determining the unknown functional coefficient q in the elliptic partial differential equation

$$-\operatorname{div}(q \operatorname{grad} u) = f \quad \text{in } \Omega \qquad u = 0 \quad \text{on } \Gamma, \tag{1.1}$$

from an observation z of the solution u, where Ω is a bounded domain in $\mathbb{R}^n$, $n = 1, 2$, or 3, with piecewise smooth boundary Γ and $f \in H^{-1}$ is given. In applications, the function z might be constructed by interpolation of pointwise measurements. We propose and analyze a hybrid method that combines the output least squares and the equation error formulation [2], [17] within the mathematical framework given by the augmented Lagrangian technique.

The output least squares (OLS) approach is used most commonly and in our example for $n = 2$ or 3, it is stated, for instance, as the minimization problem in H^2:

$$\text{Minimize} \quad \frac{1}{2}|u(q) - z|_H^2 + \frac{\beta}{2} N(q) \tag{1.2}$$

$$\text{over} \quad Q_{\text{ad}} = \{q \in H^2(\Omega) : q \geqq \alpha \text{ and } |q|_{H^2} \leqq \gamma\}$$

where α and γ are positive constants chosen a priori, $u(q)$ is the solution of (1.1), and H is chosen as H^i, $i = 0$ or 1, for example. The second term in the cost functional represents a regularization term and Q_{ad} is chosen so that (1.2) has a solution for every $\beta \geqq 0$. The use of a regularization term guarantees the continuity of the mappings from the observation $z \in H$ ($H = H_0^1$ or L^2, for example) to a solution $q^\beta(z) \in Q_{\text{ad}} \subset \mathrm{H}^2$ for an appropriate choice of N and $\beta > 0$ and, in general, β cannot be taken equal to zero [3], [4], [9], [17]. In this paper we will use a regularization term such that $(N(q))^{1/2}$ is a seminorm on H^2. The use of seminorm regularization is very common for the inversion of linear operators [6], but it is not well studied in nonlinear problems such

as the one presented by estimating q in (1.1). The OLS formulation is quite flexible with regard to the availability of the data. The OLS term in (1.2) can be adjusted in case data are only available over a subset of the domain, or are given as point measurements or as measurements of the flux at the boundary. As its form indicates, the OLS approach is less sensitive with respect to noise in the data when compared to the equation error method to be specified below. However, the minimization in (1.2) is an indirect method to determine the unknown q, and any iterative algorithm for solving (1.2) requires the solution of (1.1) for every update of $q \in Q_{\text{ad}}$.

An alternative to the OLS formulation is the equation error formulation. For our problem it can be stated as follows:

$$\text{(1.3)} \qquad \text{Minimize} \quad \tfrac{1}{2}|\nabla \cdot (q\nabla z) + f|_H^2$$

$$\text{subject to} \quad q \in H^2, \quad q \geqq \alpha$$

where H is either $H^{-1}(=(H_0^1)^*)$ or H^0. Since in computations H^{-1} requires a lesser amount of numerical differentiations of z, it should be preferred. An obvious disadvantage of this formulation is that it needs a fairly accurate observation of z defined over the entire domain Ω and it may be sensitive to noise in the data. On the other hand, it leads to efficient algorithms, since the minimization in (1.3) is quadratic.

The hybrid method that we propose not only combines both these formulations, but it also inherits the flexibility of the OLS approach and the quadratic structure of the equation error approach. This is achieved by viewing (1.2) as the following constrained minimization problem:

$$\text{(1.4)} \qquad \text{minimize} \quad F(q, u) = \frac{1}{2}|u - z|_{H_0^1}^2 + \frac{\beta}{2} N(q)$$

subject to

$$\text{(1.5)} \qquad -\nabla \cdot (q\nabla u) = f \quad \text{in } H^{-1},$$

$$\text{(1.6)} \qquad |q|_{H^2} \leqq \gamma,$$

$$\text{(1.7)} \qquad \alpha \leqq q \quad \text{on } \Omega,$$

in the two independent variables q and u. To solve (1.4)–(1.7) we apply the augmented Lagrangian algorithm (see, e.g., [1], [7], [8], [16]). It essentially involves minimizing a sequence of functionals of the form

$$\text{(1.8)} \qquad L_{c_k}(q, u; \lambda^k) = F(q, u) + \langle \lambda^k, e(q, u) \rangle_{H_0^1} + \frac{c_k}{2}|e(q, u)|_{H_0^1}^2 \quad \text{over } q \in Q_{\text{ad}},$$

and the multiplier sequence $\{\lambda^k\}$ in H_0^1 is given by

$$\text{(1.9)} \qquad \lambda^{k+1} = \lambda^k + c_k e(q_k, u_k),$$

where $\Delta: H_0^1 \to H^{-1}$ is the Laplacian, the function $e: H^2 \times H_0^1 \to H_0^1$ is defined by

$$\text{(1.10)} \qquad e(q, u) = (-\Delta)^{-1}(\nabla \cdot (q\nabla u) + f),$$

and the pair (q_k, u_k) minimizes (1.8). To carry out this iterative scheme a (possibly constant) sequence of positive real numbers $\{c_k\}$ and a startup $\lambda^1 \in H_0^1$ for the Lagrange multiplier need to be chosen. We suggest $\lambda^1 = 0$ but convergence will be guaranteed for any other choice of λ^1 as well. The inequality constraint $|q|_{H^2} \leqq \gamma$ (see (1.6)) can be augmented in a manner similar to the equality constraint $e(q, u) = 0$ (see § 2 for details). Convergence of this algorithm will be shown in Theorem 2.2 by employing

the results of [8], where a general framework for the analysis of the augmented Lagrangian method in infinite-dimensional spaces with equality constraints, as well as inequality constraints with finite-dimensional image space, is given. More precisely, convergence and rate of convergence of the pair (q_k, u_k) to a solution (q^β, u^β) of (1.4)-(1.7) in $H^2 \times H_0^1$, as well as of λ^k to λ^*, the Lagrange multiplier associated with the equality constraint (1.5), in H_0^1 will be proved. This result will be obtained under the assumption that the H^1-error between the data z and the nonregularized OLS-solution u^0 is sufficiently small and that the penalty parameters c_k are sufficiently large. It is not required that $\lim c_k = \infty$ as $k \to \infty$.

A number of remarks are in order.

(1) The minimization of the function in (1.8) requires the solution of a Poisson equation. For the discretized problem several efficient numerical techniques are readily available and any variant can be chosen. As a comparison, in the OLS approach (1.1) must be solved for $u = u(q)$ whenever a change in q occurs.

(2) Note that

$$|\varphi|^2_{H^{-1}} = \langle (-\Delta)^{-1}\varphi, \varphi\rangle = |(-\Delta)^{-1}\varphi|^2_{H_0^1} \quad \text{for all } \varphi \in H^{-1} = (H_0^1)^*.$$

Thus the minimization of the cost functional in (1.8) is a combination of the OLS-problem (1.2) and the equation error problem (1.3) where $H = H^{-1}$, with the aid of the multiplier method. The choice of the H_0^1-topology for the OLS-term and the H^{-1}-topology for the equation error term (equality constraint (1.5)) is natural from the point of view of the second-order sufficient optimality condition for (1.4) that will be used below, and the choice of these topologies leads to a method that requires the same amount of numerical differentiations in both the OLS and the equation error term.

(3) Note that $e(q, u)$ is a bilinear function in q and u. Thus for fixed q (respectively, u) (1.8) becomes quadratic in u (respectively, q) and we can take advantage of this structure numerically (see § 4 for details).

(4) As will be shown the penalty term $(c/2)|e(q, u)|^2_{H_0^1}$ enhances the convexity in the neighborhood of local minima.

(5) There is some arbitrariness in the choice of the topologies for the OLS and the equation error term. We can use $|\nabla(q\nabla u)+f|^2$ instead of $|e(q, u)|^2_{H_0^1}$ while simultaneously $|u-z|^2_{H_0^1}$ is replaced by $|u-z|^2_{H_0^1 \cap H^2}$. This would require a different analysis of the coercivity estimate (see § 3) and would lead to a different numerical implementation. This aspect is not exploited further within this paper.

The paper is organized as follows. In § 2 we describe in detail the augmented Lagrangian algorithm for the estimation of q in (1.1) and state the convergence results in Theorems 2.2 and 2.3. The essential technical tool that guarantees convergence is the positivity of the second Fréchet-derivative of the Lagrange functional (see (2.4) below). This coercivity condition is analyzed for various situations (Propositions 3.4 and 3.5) in § 3. Section 4 is devoted to a brief summary of the numerical experience that has been obtained with the augmented Lagrangian algorithm in parameter estimation. A comprehensive study of our numerical experience will appear elsewhere.

The notation that we use is rather standard. Unless otherwise specified, all function spaces are considered over the domain Ω. We use $\langle \cdot, \cdot \rangle$ to denote the inner product in L^2 and $|\cdot|$ to denote the norm in L^2 and $\mathbb{R}^n$, $n \geqq 1$. For other inner products and norms we use an index, as for instance $|v|_{H^1}$ denotes the common norm in H^1. The space $\mathbb{R}^n$ is endowed with the Euclidean norm. The inner product in H_0^1 is given by $\langle v, w\rangle_{H_0^1} = \langle \nabla v, \nabla w\rangle$ and the associated norm is defined through $|v|^2_{H_0^1} = \langle v, v\rangle_{H_0^1}$.

2. Problem formulation and convergence results. Let us formulate the problem for the multidimensional case ($n = 2$ or 3) first. We consider the constrained minimization

problem in the variables $(q, u) \in H^2 \times H_0^1$:

$$(P^\beta) \qquad \text{Minimize} \quad \frac{1}{2}|u-z|^2_{H_0^1} + \frac{\beta}{2}\left(\sum_{i_1,i_2} |q_{x_{i_1}x_{i_2}}|^2 + |\nabla q|^2\right),$$

$$\text{subject to} \quad e(q,u) = (-\Delta)^{-1}(\nabla \cdot (q\nabla u) + f) = 0 \text{ in } H_0^1, \text{ and}$$

$$|q|_{H^2} \leqq \gamma, q \geqq \alpha \quad \text{on } \Omega$$

where Δ is the Laplacian (considered as operator from H_0^1 onto H^{-1}), $f \in H^{-1}$, $z \in H_0^1$, $\beta \geqq 0$, and α, γ are given constants satisfying $\alpha^2 \int_\Omega dx < \gamma^2$. Note that (q^β, u^β) is a global solution of (P^β) if and only if q^β is a solution of (1.2) with $u(q^\beta) = u^\beta$. To argue existence of a solution q^β of (1.2) observe that Q_{ad} is a bounded, closed, and convex subset of H^2 and hence it is weakly sequentially compact. The parameter-to-solution mapping $q \to u(q)$, $q \in Q_{ad}$, is continuous from the space of continuous functions C to the H_0^1-topology. Moreover, H^2 is compactly embedded in C and norms are weakly lower semicontinuous functionals. Hence it can be shown that for any $\beta \geqq 0$ there exists at least one solution to (1.2) or equivalently (P^β).

Subsequently we will use the closed convex cone $\mathscr{C}$ with vertex at the origin of H^2 defined by

$$\mathscr{C} = \{w \in H^2 : w \leqq 0\}.$$

Let

$$\mathscr{C}^+ = \{\phi \in H^2 : \langle \phi, h \rangle_{H^2} \leqq 0 \text{ for all } h \in \mathscr{C}\}$$

be the positive dual cone and let

$$\mathbb{R}^- = \{x \in \mathbb{R} : x \leqq 0\}.$$

Then (P^β) can be written as follows:

$$(2.1) \qquad \text{Minimize} \quad F(q,u) = \frac{1}{2}|u-z|^2_{H_0^1} + \frac{\beta}{2} N(q)$$

$$\text{subject to} \quad e(q,u) = (-\Delta)^{-1}(\nabla \cdot (q\nabla u) + f) = 0,$$

$$g(q) = \tfrac{1}{2}(|q|^2_{H^2} - \gamma^2) \in \mathbb{R}^-,$$

$$l(q) = \alpha - q \in \mathscr{C}.$$

Henceforth (q^β, u^β) denotes a solution of (2.1). The next theorem (that will be proved in the latter part of this section) shows the existence and the uniqueness of a Lagrange multiplier $(\lambda^*, \mu^*, \eta^*) \in H_0^1 \times R^+ \times \mathscr{C}^+$ associated with a solution (q^β, u^β) of (P^β). We suppress the dependence of $(\lambda^*, \mu^*, \eta^*)$ on β.

THEOREM 2.1. *There exists a Lagrange multiplier* $(\lambda^*, \mu^*, \eta^*) \in H_0^1 \times \mathbb{R}^+ \times \mathscr{C}^+$ *such that*

$$L(q,u;\lambda^*,\mu^*,\eta^*) = F(q,u) + \langle \lambda^*, e(q,u) \rangle_{H_0^1} + \frac{\mu^*}{2}(|q|^2_{H^2} - \gamma^2) + \langle \eta^*, \alpha - q \rangle_{H^2}$$

satisfies

$$(2.2a) \qquad \nabla L(q^\beta, u^\beta; \lambda^*, \mu^*, \eta^*)(h,v) = 0 \quad \text{for all } (h,v) \in H^2 \times H_0^1$$

$$(2.2b) \qquad \mu^*(|q^\beta|^2_{H^2} - \gamma^2) = 0, \qquad \langle \eta^*, \alpha - q^\beta \rangle_{H^2} = 0.$$

Moreover, the Lagrange multiplier is unique and $\lambda^* = \Delta(q^\beta)^{-1}\Delta(u^\beta - z)$ *in* H_0^1 *where* $\Delta(q)u = \nabla \cdot (q\nabla u)$. *Here* $\nabla L(q^\beta, u^\beta; \lambda^*, \mu^*, \eta^*)(h,v)$ *denotes the Fréchet derivative of* $L(\cdot,\cdot;\lambda^*,\mu^*,\eta^*)$ *at* (q^β, u^β) *in direction* $(h,v) \in H^2 \times H_0^1$.

To solve (P^β) (or equivalently (2.1)) we will apply the augmented Lagrangian method. This method, due to Hestenes and Powell, has been studied extensively in the finite-dimensional case and, with equality constraints only, also in the infinite-dimensional case (cf. [1], [5], [7], and [16], for example). The infinite-dimensional case with equality as well as inequality constraints has been studied in [8]. To explain this method we require several reformulations of (P^β). For $c \geqq 0$ consider the augmented problem:

$$
\begin{aligned}
(P)_c \qquad \text{Minimize} \quad & F(q,u)+\frac{c}{2}|e(q,u)|^2_{H_0^1}+\frac{c}{2}|g(q)+w|^2 \\
\text{subject to} \quad & e(q,u)=0 \quad \text{in } H_0^1, \\
& g(q)+w=0, \qquad w\in\mathbb{R}, \\
& w \geqq 0, \\
& \alpha - q \in \mathscr{C}.
\end{aligned}
$$

In the notation of $(P)_c$ as well as F we suppress the dependence on β. We observe that (q^β, u^β) is a solution of (P^β) if and only if $(q^\beta, u^\beta, w^\beta = -g(q^\beta))$ is a solution of $(P)_c$. Moreover, it is simple to verify that $(\lambda^*, \mu^*, \mu^*, \eta^*)$ is a Lagrange multiplier for $(P)_c$, i.e.,

$$
\nabla L_c(q^\beta, u^\beta, w^\beta; \lambda^*, \mu^*, \eta^*)=0 \quad \text{and} \quad \langle \eta^*, \alpha - q^\beta\rangle_{H^2}=0, \quad \mu^* w^\beta = 0
$$

where the Lagrangian $L_c(q, u, w; \lambda^*, \mu^*, \eta^*)$ is given by

$$
\begin{aligned}
L_c(q,u,w;\lambda^*,\mu^*,\eta^*) &= F(q,u)+\langle \lambda^*, e(q,u)\rangle_{H_0^1}+\mu^* g(q) \\
&\quad +\langle \eta^*, \alpha - q\rangle_{H^2}+\frac{c}{2}|e(q,u)|^2_{H_0^1}+\frac{c}{2}|g(q)+w|^2,
\end{aligned} \tag{2.3}
$$

and f, e, g are defined in (2.1). It can also be shown that any solution $(q^\beta, u^\beta, w^\beta)$ of $(P)_c$ is a regular point in the sense of ([14], cf. also Theorem 2.1 and its proof), but since we will not use this fact we do not give its proof here.

Henceforth the following second-order sufficient optimality condition will be used:

There exist constants $\sigma > 0$ and $c_0 \geqq 0$ such that the second Fréchet derivative $\nabla^2 L_{c_0}$ of L_{c_0} satisfies the coercivity condition

$$
\nabla^2 L_{c_0}(q^\beta, u^\beta, w^\beta; \lambda^*, \mu^*, \eta^*)((h,v,y)(h,v,y)) \geqq \sigma(|h|^2_{H^2}+|v|^2_{H_0^1}+|y|^2) \tag{2.4}
$$

for all $(h, v, y) \in H^2 \times H_0^1 \times \mathbb{R}$, where the Lagrangian L_c is defined by (2.3) and $w^\beta = -g(q^\beta)$.

In the next section we will establish this condition for several specific cases. Under (2.4), it can be shown that $(q^\beta, u^\beta, w^\beta)$ is a solution of $(P)_c$ if and only if it is a solution of

$$
\min F(q,u)+\langle \lambda^*, e(q,u)\rangle_{H_0^1}+\mu^*(g(q)+w)+\frac{c}{2}|e(q,u)|^2_{H_0^1}+\frac{c}{2}|g(q)+w|^2, \tag{2.5}
$$

with $w \geqq 0$, $\alpha \leqq q$. In (2.5) the equality constraint and the inequality constraint with finite-dimensional image space are eliminated from the explicit constraints. However, (2.5) contains the unknown Lagrange multipliers (λ^*, μ^*). The augmented Lagrangian

algorithm applied to (P^β) involves solving iteratively for (λ^*, μ^*) and (q^β, u^β) and requires the solution of the following minimization problem:

(2.6) Given $\lambda \in H_0^1$ and $\mu \in \mathbb{R}^+$

$$\text{minimize} \quad F(q,u)+\langle \lambda, e\rangle_{H_0^1}+\mu(g(q)+w)+\frac{c}{2}|e(q,u)|^2_{H_0^1}+\frac{c}{2}|g(q)+w|^2$$

$$\text{subject to} \quad w \geqq 0,\ \alpha \leqq q \text{ and } (q,u,w) \in H^2 \times H_0^1 \times \mathbb{R}.$$

This problem is equivalent to the problem of minimizing

(2.7) $$F(q,u)+\langle \lambda, e\rangle_{H_0^1}+\mu\hat{g}(q,\mu,c)+\frac{c}{2}|e|^2_{H_0^1}+\frac{c}{2}\hat{g}(q,\mu,c)^2$$

$$= F(q,u)+\langle \lambda, e\rangle_{H_0^1}+\frac{c}{2}|e(q,u)|^2_{H_0^1}+\frac{1}{2c}(|\max(0, cg+\mu)|^2-|\mu|^2)$$

subject to $\alpha \leqq q$, where the constraint $w \geqq 0$ is eliminated. Here we put

$$\hat{g}(q,\mu,c)=\max\left(-\frac{\mu}{c}, g(q)\right)$$

and we used the equality

$$c\hat{g}(q,\mu,c)+\mu=\max(-\mu, cg(q))+\mu=\max(0, cg(q)+\mu).$$

Observe that $(q^\beta, u^\beta, w^\beta=\max(0, -g(q^\beta)-\mu/c))$ is a solution of (2.6) if and only if (q^β, u^β) is a solution of (2.7).

We are now prepared to specify the augmented Lagrangian algorithm to solve $(P)^\beta$. Choose a monotonically increasing sequence $\{c_k\}$ of positive real numbers with $c_1 > c_0$ and $(\lambda^1, \mu^1) \in H_0^1 \times \mathbb{R}^+$. In practice we suggest choosing $(\lambda^1, \mu^1)=(0,0)$, where the choice of λ^1 is based on Theorem 2.1: λ^* is close to 0 if u^β is close to z.

For $k \geqq 1$ determine (q_k, u_k) by solving the following:

(2.8) Minimize $\mathscr{L}_k(q,u)$,

$$\text{subject to} \quad (q,u) \in H^2 \times H_0^1,\ \alpha \leqq q,$$

and define

(2.9) $$\lambda^{k+1}=\lambda^k+(c_k-c_0)e(q_k,u_k), \qquad \mu^{k+1}=\mu^k+(c_k-c_0)\hat{g}(q_k,\mu^k,c_k)$$

where

$$\mathscr{L}_k(q,u)=F(q,u)+\langle \lambda^k, e\rangle_{H_0^1}+\frac{c_k}{2}|e|^2_{H^1}+\frac{1}{2c_k}(|\max(0, c_k g(q)+\mu^k)|^2-|\mu^k|^2).$$

In the following result we will ascertain local convexity of the cost functional appearing in (2.7) and (2.8) in a closed ball $\bar{B}$ containing the solution (q^β, u^β) of (P^β). We call (q_k, u_k) a solution of (2.8) in $\bar{B}$ if $\mathscr{L}_k(q_k,u_k) \leqq \mathscr{L}_k(q,u)$ for all $(q,u) \in \bar{B}$ with $\alpha \leqq q$. Existence of a solution of (2.8) in $\bar{B}$ and a Lagrange multiplier η^k associated with the inequality constraint $\alpha \leqq q$ can easily be verified. We will prove convergence of the solutions $(q_k, u_k) \in \bar{B}$ of (2.8) as $k \to \infty$.

It is useful to observe that

$$\mu^{k+1}=\max\left(\frac{\mu^k c_0}{c_k}, \mu^k+(c_k-c_0)g(q_k)\right)$$

and, since $\mu^1 \geqq 0$, this implies that $\mu^k \geqq 0$ for all $k \geqq 1$.

THEOREM 2.2. (a) *Suppose that the coercivity condition* (2.4) *holds. Then for every* $r \geqq \mu^*$ *there exist constants* $\tilde{c} = \tilde{c}(r) > c_0$ *and* $\bar{\sigma} > 0$, *and an open bounded ball* B *in* $H^2 \times H_0^1$ *centered at* (q^β, u^β) *such that*

$$F(q, u) + \langle \lambda^*, e \rangle_{H_0^1} + \mu^* \hat{g}(q, \mu, c) + \langle \eta^*, \alpha - q \rangle_{H^2} + \frac{c_0}{2} |e|_{H_0^1}^2 + \frac{c_0}{2} |\hat{g}(q, \mu, c)|^2 - F(q^\beta, u^\beta)$$

$$\geqq \bar{\sigma}(|q - q^\beta|_{H^2}^2 + |u - u^\beta|_{H_0^1}^2)$$

for all $(q, u) \in \bar{B}$, $c \geqq \tilde{c}$ *and* $\mu \in [0, r]$, *where* $\hat{g}(q, \mu, c) = \max(-\mu/c, g(q))$.

(b) *Suppose that in addition* $r \geqq \mu^* + (|\lambda^1 - \lambda^*|^2 + |\mu^1 - \mu^*|^2)^{1/2}$, *and* $c_1 \geqq \tilde{c}(r)$ *is chosen sufficiently large. Then every solution of* (2.8) *in* $\bar{B}$ *satisfies* $(q_k, u_k) \in B$, $\mu^k \in [0, r]$ *and*

$$\bar{\sigma}(|q_k - q^\beta|_{H^2}^2 + |u_k - u^\beta|_{H_0^1}^2) + \frac{1}{2(c_k - c_0)} (|\lambda^{k+1} - \lambda^*|_{H_0^1}^2 + |\mu^{k+1} - \mu^*|^2)$$

$$\leqq \frac{1}{2(c_k - c_0)} (|\lambda^k - \lambda^*|_{H_0^1}^2 + |\mu^k - \mu^*|^2), \tag{2.10}$$

for every $k \geqq 1$. *Moreover, there exists a constant* $K > 0$ *such that*

$$|q_k - q^\beta|_{H^2}^2 + |u_k - u^\beta|_{H_0^1}^2 \leqq \frac{1}{2\bar{\sigma}(c_k - c_0)} (|\lambda^k - \lambda^*|_{H_0^1}^2 + |\mu^k - \mu^*|^2) \quad \text{for } k \geqq 1,$$

$$|\lambda^k - \lambda^*|_{H_0^1}^2 + |\mu^k - \mu^*|^2 + |\eta^{k-1} - \eta^*|_{H^2}^2$$

$$\leqq \left(\frac{K}{\bar{\sigma}}\right)^{k-1} \prod_{i=1}^{k-1} \frac{1}{c_i - c_0} (|\lambda^1 - \lambda^*|_{H_0^1}^2 + |\mu^1 - \mu^*|^2) \quad \text{for } k \geqq 2. \tag{2.11}$$

The proof of Theorem 2.2 will be given in the latter part of this section.

Next we formulate the problem for the one-dimensional case. Without loss of generality we can assume that $\Omega = (0, 1)$. We take $(q, u) \in H^1 \times H_0^1$ and the regularization term $N(q)$ is chosen as

$$N(q) = \int_0^1 |q_x|^2 \, dx.$$

Thus, for $\beta \geqq 0$, the analogue of (P^β) is defined as follows:

$$\text{Minimize} \quad \frac{1}{2} |u - z|_{H_0^1}^2 + \frac{\beta}{2} |q_x|^2 \tag{2.12}$$

$$\text{subject to} \quad e(q, u) = (-\Delta)^{-1}((qu_x)_x + f) = 0 \quad \text{in } H_0^1,$$

$$|q|_{H^1} \leqq \gamma \quad \text{and} \quad \alpha \leqq q \text{ on } [0, 1]$$

where $\Delta: H_0^1 \to H^{-1}$ is given by $\Delta u = u_{xx}$. The results corresponding to Theorem 2.1 hold with $q \in H^2$ replaced by $q \in H^1$. In particular, if $(q^\beta, u^\beta) \in H^1 \times H_0^1$ is a solution of (2.12), then there exists a unique Lagrange multiplier $(\lambda^*, \mu^*, \eta^*) \in H_0^1 \times R^+ \times \mathscr{C}^+$ such that the Lagrangian

$$L(q; u; \lambda^*, \mu^*, \eta^*) = \tfrac{1}{2}|u - z|_{H_0^1}^2 + \frac{\beta}{2} |q_x|^2 + \langle \lambda^*, e \rangle_{H_0^1} + \frac{\mu}{2} (|q|_{H_0^1}^2 - \gamma^2) + \langle \eta^*, \alpha - q \rangle_{H^1}$$

satisfies $\nabla L(q^\beta, u^\beta; \lambda^*, \mu^*, \eta^*) = 0$ and $\mu^*(|q^\beta|_{H_0^1}^2 - \gamma^2) = \langle \eta^*, \alpha - q^\beta \rangle_{H^1} = 0$, where $\langle \cdot, \cdot \rangle_{H^1}$ is the duality pairing on H^1, $\mathscr{C} = \{h \in H^1 : h \leqq 0\}$ and $\mathscr{C}^+ = \{\varphi \in H^1 : \langle \varphi, h \rangle_{H^1} \leqq 0$

for all $h \in \mathscr{C}\}$ is the positive dual cone of $\mathscr{C}$. The Lagrange multiplier associated with the equality constraint can be expressed as

$$\lambda^* = \Delta(q^\beta)^{-1}\Delta(u^\beta - z) \quad \text{in } H_0^1$$

where $\Delta(q^\beta): H_0^1 \to H^{-1}$ is given by $\Delta(q^\beta)u = (q^\beta u_x)_x$. The Lagrangian for the augmented problem (compare (2.3)) is given by

$$L_c(q, u, w; \lambda^*, \mu^*, \eta^*) = \tfrac{1}{2}|u - z|^2_{H_0^1} + \frac{\beta}{2}|q_x|^2 + \langle \lambda^*, e\rangle_{H_0^1}$$

$$+ \langle \eta^*, \alpha - q\rangle_{H^1} + \mu^* g(q) + \frac{c}{2}|e|^2_{H_0^1} + \frac{1}{2}|g(q) + w|^2 \tag{2.13}$$

where $e = e(q, u)$, and $g(q) = \frac{1}{2}(|q|^2_{H^1} - \gamma^2)$.

The augmented Lagrangian method for the solution of (2.12) now proceeds precisely as in the multidimensional case described in (2.8), (2.9) with $q \in H^2$ replaced by $q \in H^1$, and the regularization term is chosen as $\beta|q_x|^2$. In particular, $\hat{g}(q, \mu, c) = \max(-\mu/c, \frac{1}{2}(|q|^2_{H^1} - \gamma))$ and (2.8) becomes

$$\begin{aligned} &\text{Minimize} \quad \mathscr{L}_k(q, u) \\ &\text{subject to} \quad (q, u) \in H^1 \times H_0^1, \alpha \leqq q, \end{aligned} \tag{2.14}$$

where

$$\mathscr{L}_k(q, u) = \frac{1}{2}|u - z|^2_{H_0^1} + \frac{\beta}{2}|q_x|^2 + \langle \lambda^k, e\rangle_{H_0^1} + \frac{c}{2}|e|^2_{H_0^1}$$

$$+ \frac{1}{2c_k}(|\max(0, c_k g(q) + \mu^k)|^2 - |\mu^k|^2).$$

The following analogue of Theorem 2.2 holds for the one-dimensional case.

THEOREM 2.3. *Suppose that there exist constants $\sigma > 0$ and $c_0 \geqq 0$ such that the second Fréchet derivative $\nabla^2 L_{c_0}$ of L_{c_0} satisfies*

$$\nabla^2 L_{c_0}(q^\beta, u^\beta, w^\beta; \lambda^*, \mu^*, \eta^*)((h, v, y), (h, v, y)) \geqq \sigma(|h|^2_{H^1} + |v|^2_{H_0^1} + |y|^2) \tag{2.15}$$

for all $(h, v, y) \in H^1 \times H_0^1 \times \mathbb{R}$. Then for every $r \geqq \mu^*$ there exist constants $\tilde{c} = \tilde{c}(r) > c_0$ and $\bar{\sigma} > 0$, and an open ball B in $H^1 \times H_0^1$ centered at (q^β, u^β) such that

$$\frac{1}{2}|u - z|^2_{H_0^1} + \frac{\beta}{2}|q_x|^2 + \langle \lambda^*, e\rangle_{H_0^1} + \mu^* \hat{g}(q, \mu, c) + \langle \eta^*, \alpha - q\rangle_{H^1} + \frac{c_0}{2}|e|^2_{H_0^1} + \frac{c_0}{2}|\hat{g}(q, \mu, c)|^2$$

$$\geqq \frac{1}{2}|u^\beta - z|^2_{H_0^1} + \frac{\beta}{2}|q_x^\beta|^2 + \bar{\sigma}(|q - q^\beta|^2_{H^1} + |u - u^\beta|^2_{H_0^1})$$

for all $(q, u) \in \bar{B}$, $c \geqq \tilde{c}$, and $\mu \in [0, r]$. Similarly, the assertions analogous to Theorem 2.2(b) *hold with H^2 replaced by H^1.*

We now come to the proofs of the results of this section.

Proof of Theorem 2.1. Let $\tilde{M}: H^2 \times H_0^1 \to H_0^1 \times \mathbb{R} \times H^2$ be defined by

$$\tilde{M}(h, v) = ((-\Delta)^{-1}(\nabla \cdot (q^\beta \nabla v + h \nabla u^\beta)), \langle q^\beta, h\rangle_{H^2}, -h).$$

The Fréchet derivatives ∇e, ∇g, and ∇l at the minimizer (q^β, u^β) in direction (h, v) are given by

$$\nabla e(q^\beta, u^\beta)(h, v) = (-\Delta)^{-1}(\nabla \cdot (q^\beta \nabla v + h \nabla u^\beta)) \in H_0^1,$$

$$\nabla g(q^\beta, u^\beta)(h, v) = \langle q^\beta, h\rangle_{H^2} \in \mathbb{R}, \qquad \nabla l(q^\beta, u^\beta)(h, v) = -h \in H^2.$$

These are the coordinates of $\tilde{M}$. The existence of a Lagrange multiplier satisfying (2.2) will follow directly from the regular point condition [14, p. 100] that for the problem under consideration is given by

$$\begin{aligned}&\{\tilde{M}(h, v)+(0, r, k)+\lambda(0, \tfrac{1}{2}(|q^\beta|_{H^2}^2-\gamma^2), \alpha-q^\beta):\\ &\qquad (h, v)\in H^2\times H_0^1, r\in\mathbb{R}^+, -k\in\mathscr{C}, \lambda\in\mathbb{R}\}=H_0^1\times\mathbb{R}\times H^2.\end{aligned}\tag{2.16}$$

We thus turn to the verification of (2.16) and choose $(w_1, w_2, w_3)\in H_0^1\times\mathbb{R}\times H^2$ arbitrarily.

Let

$$k=w_3-\min w_3$$

where the minimum is taken over $\bar{\Omega}$ and is well defined since H^2 embeds continuously into C. Observe that $-k\in\mathscr{C}$. Further define

$$h=\lambda(\alpha-q^\beta)-\min w_3,$$

with $\lambda\in\mathbb{R}$ to be fixed below. Clearly, $h\in H^2$ and

$$-h+k+\lambda(\alpha-q^\beta)=w_3,$$

and thus, independently of $\lambda\in\mathbb{R}$, the third coordinate in (2.16) is satisfied for this choice of k and h. Next we consider the second coordinate of (2.16):

$$\langle q^\beta, h\rangle_{H^2}+r+\frac{\lambda}{2}(|q^\beta|_{H^2}^2-\gamma^2)=w_2$$

or by the choice of h

$$r+\lambda(\langle q^\beta, \alpha\rangle-\tfrac{1}{2}|q^\beta|_{H^2}^2-\tfrac{1}{2}\gamma^2)=w_2+\langle q^\beta, \min w_3\rangle.\tag{2.17}$$

Since $\alpha^2\int_\Omega dx<\gamma^2$, the factor $\langle q^\beta, \alpha\rangle-\frac{1}{2}|q^\beta|_{H^2}^2-\frac{1}{2}\gamma^2$ in (2.17) is negative and thus there exist $\lambda\in\mathbb{R}^+$ and $r\in\mathbb{R}^+$ that satisfy (2.17). With $(\lambda, h, -k, r)\in\mathbb{R}\in H^2\times\mathscr{C}\times\mathbb{R}^+$ fixed we turn to the first coordinate in (2.16) that requires solving

$$\nabla(q^\beta\nabla v)=-\Delta w_1-\nabla(h\nabla u^\beta)\quad\text{in } H^{-1},$$

for $v\in H_0^1$. This is clearly possible and hence (2.16) is verified.

Next we will show that

$$\lambda^*=\Delta(q^\beta)^{-1}\Delta(u^\beta-z)\quad\text{in } H_0^1 \text{ where } \Delta(q)u=\nabla(q\nabla u).\tag{2.18}$$

Note that

$$\begin{aligned}&\nabla L(q^\beta, u^\beta; \lambda^*, \mu^*, \eta^*)(h, v)\\ &=\langle\nabla(u^\beta-z), \nabla v\rangle+\beta\Big(\langle\nabla q^\beta, \nabla h\rangle+\sum_{i_1, i_2}\langle(q_k)_{x_{i_1}x_{i_2}}, h_{x_{i_1}x_{i_2}}\rangle\Big)\\ &\quad-\langle\nabla\lambda^*, h\nabla u^\beta+q^\beta\nabla v\rangle+\mu^*\langle q^\beta, h\rangle_{H^2}-\langle\eta^*, h\rangle_{H^2}=0\end{aligned}\tag{2.19}$$

for all $(h, v)\in H^2\times H_0^1$. Let $h=0$ and $v\in H_0^1$ be arbitrary. Then we have

$$\langle\Delta(u^\beta-z), v\rangle-\langle\nabla\cdot(q^\beta\nabla\lambda^*), v\rangle=0$$

for all $v\in H_0^1$. This implies (2.18) and the uniqueness of the Lagrange multiplier λ^*.

To show the uniqueness of Lagrange multipliers μ^* and η^*, assume that $(\lambda^*, \mu_i^*, \eta_i^*)$, $i=1, 2$ are two Lagrange multipliers satisfying (2.2a) and (2.2b). Let $\mu=\mu_1^*-\mu_2^*$ and $\eta=\eta_1^*-\eta_2^*$. By (2.19) and (2.2b) we find

$$\mu\langle q^\beta, h\rangle_{H^2}-\langle\eta, h\rangle_{H^2}=0\quad\text{for all } h\in H^2$$

and moreover

$$\langle \eta, \alpha - q^\beta \rangle_{H^2} = 0.$$

First consider the case of $q^\beta \equiv \alpha$. Since $\alpha^2 \int_\Omega dx < \gamma^2$, the norm constraint is not active and therefore $\mu_1^* = \mu_2^* = 0$ in this case. Moreover, by the first equation we find that $\eta = 0$ so that $\eta_1^* = \eta_2^*$. Next assume that q^β is not identically α. Putting $h = \alpha - q^\beta$ in the first equation and using the second equation, we obtain $\mu \langle q^\beta, \alpha - q^\beta \rangle_{H^2} = 0$ that implies $\mu = 0$. Thus, $\langle \eta, h \rangle_{H^2} = 0$ for all $h \in H^2$. This implies $\eta = 0$ and the proof is completed.

Remark 2.4. If $\mu^* = \beta = 0$ and $\eta^* = 0$, then

$$\langle \nabla(u^\beta - z), \nabla u^\beta \rangle = 0. \tag{2.20}$$

In fact, suppose that $\mu^* = \beta = 0$ and $\eta^* = 0$. Then (2.19) with $v = 0$ implies $\langle \nabla \lambda^*, h \nabla u^\beta \rangle = 0$ for all $h \in H^2$. This equation with $h = q^\beta$ and λ^* expressed as in (2.18) implies

$$\langle \Delta(q^\beta)^{-1} \Delta(u^\beta - z), \Delta(q^\beta) u^\beta \rangle = \langle \nabla(u^\beta - z), \nabla u^\beta \rangle = 0,$$

which is the desired equality.

To prove Theorem 2.2 we need the following lemma.

LEMMA 2.5. *The adjoint operator* $\tilde{M}^*: H_0^1 \times \mathbb{R} \times H^2 \to H^2 \times H_0^1$ *of* $\tilde{M}$ *is surjective. The kernel of* $\tilde{M}^*$ *is one-dimensional and it is characterized by*

$$\ker \tilde{M}^* = \operatorname{span} \{(0, 1, q^\beta)\}.$$

Moreover, $\tilde{M}\tilde{M}^*$ *has a bounded inverse as an operator on range* $\tilde{M}$.

Proof. It is simple to show that the range of $\tilde{M}$ is closed. Next suppose that $\tilde{M}(h, v) = 0$ for some $(h, v) \in H^2 \times H_0^1$. Then $h = 0$ and thus $(-\Delta)^{-1} \nabla \cdot (q^\beta \nabla v) = 0$. Since $(-\Delta)^{-1}: H^{-1} \to H_0^1$ is an isomorphism and since $q^\beta \geqq \alpha$, this implies that $v = 0$. Hence $\tilde{M}$ is injective and by the closed range theorem $\tilde{M}^*$ is surjective. A short calculation shows that the kernel of $\tilde{M}^*$ is given as the set of elements $(x, y, z) \in H^1 \times \mathbb{R} \times H^2$ that satisfy

$$\langle y q^\beta, h \rangle_{H^2} = \langle z, h \rangle_{H^2} \quad \text{for all } h \in H^2.$$

In particular, $\dim (\ker \tilde{M}^*) = 1$. By the closed range theorem, $(\ker \tilde{M}^*)^\perp = \text{range } \tilde{M}$ and

$$H^1 \times R \times H^2 = \ker \tilde{M}^* \oplus \text{range } \tilde{M}.$$

To show that $\tilde{M}\tilde{M}^*$ has a bounded inverse on range $\tilde{M}$, we observe that $\tilde{M}\tilde{M}^*$ is injective and surjective on range $\tilde{M}$. This completes the proof.

Now we turn to a proof of Theorem 2.2.

Proof of Theorem 2.2. The augmentability estimate in (a) follows from the proof of Theorem 2.1 and from Corollary 2.2 of [8] (with (2.4) replacing Theorem 2.1 of [8]). In addition, if the norm constraint is not active, then $\tilde{c}(r)$ and B can be chosen so that

$$g(q) + \frac{\mu}{c} < 0 \tag{2.21}$$

for all $\mu \leqq r$, $c \geqq \tilde{c}(r)$, and all $(q, u) \in \bar{B}$. Estimate (2.10) is a special case of Proposition 4.1 of [8]. We now turn to the proof of (2.11). First observe that by (2.19)

$$\langle \nabla(u^\beta - z), \nabla v \rangle + \beta \left(\langle \nabla q^\beta, \nabla h \rangle + \sum_{i_1, i_2} \langle q^\beta_{x_{i_1} x_{i_2}}, h_{x_{i_1} x_{i_2}} \rangle \right)$$
$$- \langle \nabla \lambda^*, h \nabla u^\beta + q^\beta \nabla v \rangle + \mu^* \langle q^\beta, h \rangle_{H^2} - \langle \eta^*, h \rangle_{H^2} = 0$$

for all $(h, v) \in H^2 \times H_0^1$ and the necessary optimality condition for (q_k, u_k) yields

$$\begin{aligned}(2.22)\qquad &\langle \nabla(u_k - z), \nabla v\rangle + \beta\left(\langle \nabla q_k, \nabla h\rangle + \sum_{i_1,i_2} \langle (q_k)_{x_{i_1}x_{i_2}}, h_{x_{i_1}x_{i_2}}\rangle\right) \\ &\quad - \langle \nabla \tilde{\lambda}^{k+1}, h\nabla u_k + q_k \nabla v\rangle + \tilde{\mu}^{k+1}\langle q^k, h\rangle_{H^2} - \langle \eta^k, h\rangle_{H^2} = 0\end{aligned}$$

for all $(h, v) \in H^2 \times H_0^1$, where

$$\tilde{\lambda}^{k+1} = \lambda^k + c_k e(q_k, u_k) \quad \text{and} \quad \tilde{\mu}^{k+1} = \mu^k + c_k \hat{g}(q_k, \mu^k, c_k).$$

Subtracting these two equalities, rearranging terms, and using the definition of $\tilde{M}$, we obtain

$$\begin{aligned}&\langle (\lambda^* - \tilde{\lambda}^{k+1}, \mu^* - \tilde{\mu}^{k+1}, \eta^* - \eta^k), \tilde{M}(h, v)\rangle_{H_0^1 \times \mathbb{R} \times H^2} \\ (2.23)\qquad &= \langle \nabla(u_k - u^\beta), \nabla v\rangle + \beta\left(\langle \nabla(q_k - q^\beta), \nabla h\rangle + \sum_{i_1,i_2} \langle (q_k)_{x_{i_1}x_{i_2}} - q^\beta_{x_{i_1}x_{i_2}}, h_{x_{i_1}x_{i_2}}\rangle\right) \\ &\quad - \langle \nabla \tilde{\lambda}^{k+1} \cdot \nabla(u^\beta - u_k), h\rangle + \langle (q^\beta - q_k)\nabla \tilde{\lambda}^{k+1}, \nabla v\rangle + \tilde{\mu}^{k+1}\langle q^k - q^\beta, h\rangle_{H^2}.\end{aligned}$$

From (2.10), the sequences $\{\lambda^k, \mu^k\}$ and $\{q_k, u_k\}$ are uniformly bounded in $H_0^1 \times \mathbb{R}$ and $H^2 \times H_0^1$, respectively. This implies uniform boundedness of the sequence $\{\tilde{\lambda}^k, \tilde{\mu}^k\}$ in $H_0^1 \times \mathbb{R}$. By the Riesz Representation Theorem, the right-hand side of (2.23) can be represented by $\langle b_k, (h, v)\rangle_{H^2 \times H_0^1}$ where $b_k \in H^2 \times H_0^1$ and

$$|b_k|_{H^2 \times H_0^1} \leqq K_1 |(q_k, u_k) - (q^\beta, u^\beta)|_{H^2 \times H_0^1}$$

for a constant K_1 independent of k. We find from (2.23) that

$$\tilde{M}^*(\lambda^* - \tilde{\lambda}^{k+1}, \mu^* - \tilde{\mu}^{k+1}, \eta^* - \eta^k) = b_k$$

in $H^2 \times H_0^1$. If P_R denotes the orthogonal projection of $H_0^1 \times R \times H^2$ onto $(\ker \tilde{M}^*)^\perp$, then

$$\tilde{M}\tilde{M}^* P_R(\lambda^* - \tilde{\lambda}^{k+1}, \mu^* - \tilde{\mu}^{k+1}, \eta^* - \eta^k) = \tilde{M} b_k.$$

Since from Lemma 2.5 $\tilde{M}\tilde{M}^*$ is continuously invertible on range $\tilde{M} = (\ker \tilde{M}^*)^\perp$,

$$(2.24)\qquad |P_R(\lambda^* - \tilde{\lambda}^{k+1}, \mu^* - \tilde{\mu}^{k+1}, \eta^* - \eta^k)|_{H_0^1 \times \mathbb{R} \times H^2} \leqq K_2 |(q_k, u_k) - (q^\beta, u^\beta)|_{H^2 \times H_0^1},$$

for a constant K_2 independent of k.

Next the complementarity conditions imply that $\langle \eta^*, \alpha - q^\beta\rangle_{H^2} = 0$ and $\langle \eta^k, \alpha - q_k\rangle_{H^2} = 0$. Since $\{\tilde{\lambda}^k, \tilde{\mu}^k\}$ is uniformly bounded in $H_0^1 \times \mathbb{R}$, it follows from (2.22) that $\{\eta^k\}$ is uniformly bounded. Thus, these equalities yield the estimate

$$(2.25)\qquad |\langle \eta^* - \eta^k, \alpha - q^\beta\rangle_{H^2}| = |\langle \eta^k, q^\beta - q_k\rangle_{H^2}| \leqq K_3 |q^\beta - q_k|_{H^2},$$

for a constant K_3 independent of k. Now let us assume that $q^\beta \not\equiv \alpha$. Then $\langle q^\beta, \alpha - q^\beta\rangle_{H^2} \neq 0$ and it follows from (2.24), (2.25), and the characterization of $\ker \tilde{M}^*$ in Lemma 2.5 that

$$(2.26)\qquad |(\lambda^* - \tilde{\lambda}^{k+1}, \mu^* - \tilde{\mu}^{k+1}, \eta^* - \eta^k)|_{H_0^1 \times \mathbb{R} \times H^1} \leqq K_4 |(q_k, u_k) - (q^\beta, u^\beta)|_{H^2 \times H_0^1},$$

for a constant K_4 independent of k. In the case $q^\beta \equiv \alpha$ the norm constraint is inactive and hence $\mu^* = 0$. By (2.10) we have $\mu^k \leqq r$ for all $k \geqq 1$, and (2.21) then implies that $\tilde{\mu}^k = 0$ for all $k \geqq 2$. Consequently, (2.26) also holds for the case $q^\beta \equiv \alpha$. Next we will show that (2.26) holds when $(\tilde{\lambda}^{k+1}, \tilde{\mu}^{k+1})$ is replaced by $(\lambda^{k+1}, \mu^{k+1})$. Observe that there exists a constant K independent of k such that

$$|\lambda^{k+1} - \tilde{\lambda}^{k+1}|_{H_0^1} \leqq c_0 |\Delta^{-1}\nabla \cdot (q_k \nabla u_k - q^\beta \nabla u^\beta)|_{H_0^1} \leqq K |(q_k, u_k) - (q^\beta, u^\beta)|_{H^2 \times H_0^1},$$

and

$$|\mu^{k+1}-\tilde{\mu}^{k+1}| = c_0\left|\max\left(-\frac{\mu^k}{c_k}, g(q_k)\right)\right| \leqq K|q_k - q^\beta|_{H^2}$$

where for the last estimate we assumed that the norm constraint is active and we used the fact that $\mu^k \geqq 0$. Combining these estimates with (2.26), we obtain

$$|(\lambda^* - \lambda^{k+1}, \mu^* - \mu^{k+1}, \eta^* - \eta^k)|_{H_0^1 \times \mathbb{R} \times H^2} \leqq K_5 |(q_k, u_k) - (q^\beta, u^\beta)|_{H^2 \times H_0^1} \tag{2.27}$$

for a constant K_5 independent of k, provided that $|q^\beta|_{H^2} = \gamma$. If the norm constraint is not active, then by (2.10) we have

$$\mu^{k+1} \leqq \mu^* + (|\lambda^1 - \lambda^*|^2_{H_0^1} + |\mu^1 - \mu^*|^2)^{1/2} \leqq r \quad \text{for all } k \geqq 1$$

and therefore by (2.21)

$$\begin{aligned} \mu^{k+1} &= \max\left(\frac{\mu^k c_0}{c_k}, \mu^k + (c_k - c_0) g(q_k)\right) \\ &\leqq \max\left(\frac{\mu^k c_0}{c_k}, \mu^k - (c_k - c_0)\frac{\mu^k}{c_k}\right) = \frac{\mu^k c_0}{c_k}. \end{aligned} \tag{2.28}$$

The estimates (2.11) now follow from (2.10), (2.27), and (2.28). This completes the proof.

Remark 2.6. The assumption of Theorem 2.2(b) that $c_1 \geqq \tilde{c}(r)$ is sufficiently large is used to guarantee that (q_k, u_k) is in the open ball B for all $k \geqq 1$. If we only assume $c_1 \geqq \tilde{c}(r)$, then the estimates of Theorem 2.2 need to be modified. First (2.10) holds with (q_k, u_k) replaced by $(\tilde{q}_k, \tilde{u}_k)$, where $(\tilde{q}_k, \tilde{u}_k)$ is a solution of (2.8) in $\bar{B}$ (compare [8]). In particular, this implies that $(\tilde{q}_k, \tilde{u}_k) \to (q^\beta, u^\beta)$ and that $\{(\lambda^k, \mu^k)\}_{k=1}^\infty$ is bounded in $H_0^1 \times R$. Let k_0 be chosen such that $(\tilde{q}_k, \tilde{u}_k) \in B$ for all $k \geqq k_0$. Then the analysis of Theorem 2.2 can be repeated to show that for $k \geqq 1$

$$\begin{aligned} &|\lambda^{k+k_0} - \lambda^*|^2_{H_0^1} + |\mu^{k+k_0} - \mu^*|^2 + |\eta^{k+k_0-1} - \eta^*|_{H^2} \\ &\quad \leqq \left(\frac{K}{\bar{\sigma}}\right)^k \prod_{i=k_0}^{k+k_0-1} \frac{1}{c_i - c_0} (|\lambda^{k_0} - \lambda^*|^2_{H_0^1} + |\mu^{k_0} - \mu^*|^2) \end{aligned}$$

The proof of Theorem 2.3 can be given along the lines of that for Theorem 2.2.

3. The coercivity condition. In this section we establish the coercivity condition (2.4) for specific cases. To achieve this goal it is necessary to study the behavior of the solutions (q^β, u^β) to (P^β) as $\beta \to 0^+$. Let

$$N(q) = \sum_{i_1, i_2} |q_{x_{i_1} x_{i_2}}|^2 + |\nabla q|^2, \tag{3.1}$$

representing the seminorm regularization.

LEMMA 3.1. *Let (q^β, u^β) be any solution of (P^β). For $\beta > \beta^0 \geqq 0$, we have*

$$|u^\beta - z|^2_{H_0^1} \leqq |u^{\beta_0} - z|^2_{H_0^1} + \beta(N(q^{\beta_0}) - N(q^\beta)), \tag{3.2}$$

$$\sup_{Q^\beta} N(q^\beta) \leqq \inf_{Q^{\beta_0}} N(q^{\beta_0}), \tag{3.3}$$

$$\sup_{U^{\beta_0}} |u^{\beta_0} - z|_{H_0^1} \leqq \inf_{U^\beta} |u^\beta - z|_{H_0^1} \tag{3.4}$$

where for $\beta \geqq 0$, $Q^\beta = \{q^\beta : (q^\beta, u^\beta)$ is a solution of $(P^\beta)\}$ and $U^\beta = \{u^\beta : (q^\beta, u^\beta)$ is a solution of $(P^\beta)\}$. If $\beta_n \to 0^+$ and $\{q^{\beta_n}\}$ is any sequence of corresponding solution of (P^{β_n}), then $\{q^{\beta_n}\}$ has a weak cluster point, and every weak cluster point is a solution of (P^0), and we have

$$\lim_{n \to \infty} \sup_{Q^{\beta_n}} N(q^{\beta_n}) = \min_{Q^0} N(q^0). \tag{3.5}$$

Moreover, every weak cluster point of a sequence of solutions q^{β_n} is a strong cluster point in H^2 and it is a minimum norm solution of (1.2).

Proof. The proof of (3.2)–(3.5) is a simple consequence of the above remark on the equivalence between (1.2) and (P^β) and the results in § 2 of [4]. In fact, (3.2) follows from (2.2) in [4], (3.3) and (3.4) from Lemma 2.2, and (3.5) from Lemma 2.3 of [4]. Assumption (A2), requiring existence of a minimizer of (P^0) in [4], is guaranteed by the properties of Q_{ad}. The coercivity assumption for N in (A1) of [4] is replaced by the norm constraint. We will show the last statement of the lemma. If q^{β_n} converges weakly to q, then from (3.5) $N(q^{\beta_n}) \to N(q)$ where q is a minimum norm solution of (P^0). Since the embedding from H^2 into L^2 is compact, q^{β_n} converges strongly to q in L^2. Thus we obtain

$$N(q^{\beta_n}) + |q^{\beta_n}|_{L^2} \to N(q) + |q|_{L^2}^2.$$

Since $N(q) + |q|_{L^2}^2$ defines a norm that is equivalent to the common H^2-norm [15, p. 13], this implies $|q^{\beta_n}|_{H^2}^2 \to |q|_{H^2}^2$ so that $\{q^n\}$ converges strongly to q in H^2.

From (3.2), (3.3), (3.5), and observing that $|u^0 - z|_{H_0^1}^2$ is independent of $u^0 \in U^0$, we find the following corollary to Lemma 3.1.

COROLLARY 3.2. *There exists a real-valued monotonically increasing function $\rho(\beta)$ with $\lim \rho(\beta) \to 0$ as $\beta \to 0^+$ such that for $\beta \geqq 0$*

$$\begin{aligned} \sup_{U^\beta} |u^\beta - z|_{H_0^1}^2 &\leqq |u^0 - z|_{H_0^1}^2 + \beta \left(\min_{Q^0} N(q^0) - N(q^\beta)\right) \\ &\leqq |u^0 - z|_{H_0^1}^2 + \beta\rho(\beta). \end{aligned}$$

The second Fréchet derivative of L_c at $(q^\beta, u^\beta, w^\beta)$ in direction $(h, v, y) \in H^2 \times H_0^1 \times \mathbb{R}$ appearing in (2.4) is given by

$$\begin{aligned} &\nabla^2 L_c(q^\beta, u^\beta, w^\beta; \lambda^*, \mu^*, \eta^*)((h, v, y), (h, v, y)) \\ &\quad = |v|_{H_0^1}^2 + \beta N(h) - 2\langle \nabla\lambda^*, h\nabla v\rangle \\ &\qquad + \mu^* |h|_{H^2}^2 + c|(-\Delta)^{-1}\nabla \cdot (q^\beta \nabla v + h\nabla u^\beta)|_{H_0^1}^2 + c|\langle q^\beta, h\rangle_{H^2} + y|^2 \end{aligned} \tag{3.6}$$

where we used

$$|(-\Delta)^{-1}\nabla\varphi|_{H_0^1}^2 = \langle (-\Delta)^{-1}\nabla\varphi, \nabla\varphi\rangle = \langle \nabla\Delta^{-1}\nabla\varphi, \varphi\rangle = \langle P\varphi, \varphi\rangle_{L^2(\Omega, \mathbb{R}^n)} \tag{3.7}$$

for $\varphi \in H^1(\Omega; \mathbb{R}^n)$, which can be verified by Green's formula [15, p. 28]. Here the operator $P = \text{grad}\, \Delta^{-1}\, \text{div}$ defines an orthogonal projection in $L^2(\Omega, \mathbb{R}^n)$.

To prove the coercivity condition (2.4) in Proposition 3.4 we use some well-known estimates [15, pp. 18, 20, 72].

LEMMA 3.3. *There exist positive constants K_i, $i = 1, 2, 3, 4$, depending only on Ω such that*

(a) $|\varphi|_{L^\infty} \leqq K_1 |\varphi|_{H^2}$ *for all* $\varphi \in H^2$,

(b) $|\varphi| \leqq K_2 |\nabla\varphi|$ *for all* $\varphi \in H^1$ *with* $\int_\Omega \varphi\, dx = 0$,

(c) $|\varphi|_{H^2} \leqq K_3 (\sum_{i_1, i_2} |\varphi_{x_{i_1} x_{i_2}}|^2 + |\nabla\varphi|^2)^{1/2}$ *for all* $\varphi \in H^2$ *with* $\int_\Omega \varphi\, dx = 0$.

The proposition also involves the constants α and γ that define Q_{ad}, the function $\rho(\beta)$ from Corollary 3.2, and the constant ω that is defined as follows. For $f \in H^{-1}$ with $f \neq 0$ and $q \in Q_{\text{ad}}$ we have

$$|f|_{H^{-1}} = \sup_{v \in H_0^1} \frac{|\langle q\nabla u, \nabla v\rangle|}{|v|_{H_0^1}} \leqq |q|_{L^\infty} |\nabla u| \leqq K_1 \gamma |u|_{H_0^1}$$

and therefore

$$|u|_{H_0^1} \geqq \frac{|f|_{H^{-1}}}{\gamma K_1} =: \omega > 0. \tag{3.8}$$

PROPOSITION 3.4. *Let $f \in H^{-1}$ satisfy $f \neq 0$ and let $k = (1 + K_2^2 + 4K_1^2K_3^2)^{-1}$. Let (q^0, u^0) be a solution of (P^0) and suppose that for a constant $\beta_0 \in (0, 1)$*

$$|u^0 - z|_{H_0^1}^2 < \beta_0 \left[\frac{\alpha^2 k}{K_1^2} \left(1 - \frac{4k}{\omega} K_1^2 \gamma^2 \beta_0 \right) - \rho(\beta_0) \right]. \tag{3.9}$$

Then there exists a nontrivial compact interval $I = [\underline{\beta}, \beta_0] \subset (0, 1)$ and constants $c_0 > 0$, $\sigma_0 > 0$ such that

$$\nabla^2 L_c(q^\beta, u^\beta, w^\beta; \lambda^*, \mu^*, \eta^*)((h, v, y), (h, v, y)) \geqq \sigma_0(|h|_{H^2}^2 + |v|_{H_0^1}^2 + |y|^2)$$

for all $c \geqq c_0$, $(h, v, y) \in H^2 \times H_0^1 \times \mathbb{R}$ and any solution (q^β, u^β) of (P^β) with $\beta \in I$. Moreover, if $u^0 = z$, then such a constant β_0 always exists and I can be chosen as any compact subset of $(0, \beta_0]$.

We point out that in Proposition 3.4 the solutions (q^0, u^0) and (q^β, u^β) are assumed to be global. This is necessary since the proof requires the estimates of Lemma 3.1 and Corollary 3.2 that are given for (global) solutions. The assumption regarding existence of β_0 such that (3.9) holds represents a smallness condition of the error between z and the nonregularized OLS solution u^0. All quantities appearing on the right-hand side of (3.9) except for $\rho(\beta)$ in principle can be given explicitly.

Proof. Define a quadratic form on $H^2 \times H_0^1$ by

$$\begin{aligned} M_c(h, v) &= |v|_{H_0^1}^2 + \beta N(h) - 2\langle \nabla \lambda^*, h \nabla v \rangle \\ &\quad + c\langle (-\Delta)^{-1} \nabla \cdot (q^\beta \nabla v + h \nabla u^\beta), \nabla (q^\beta \nabla v + h \nabla u^\beta) \rangle \end{aligned} \tag{3.10}$$

where $c \geqq 0$ and the dependence of $M_c(h, v)$ on β is suppressed. For $(h, v, y) \in H^2 \times H_0^1 \times \mathbb{R}$ it follows that

$$\nabla^2 L_c((h, v, y), (h, v, y)) = M_c(h, v) + c(\langle q^\beta, h \rangle_{H^2} + y)^2 + \mu^* |h|_{H^2}^2. \tag{3.11}$$

We first concentrate on M_c. By Theorem 2.1 and Lemma 3.3(a)

$$\begin{aligned} \langle \nabla \lambda^*, h \nabla v \rangle &= -\langle \lambda^*, \nabla \cdot (h \nabla v) \rangle = \langle \nabla \Delta (q^\beta)^{-1} \Delta (u^\beta - z), h \nabla v \rangle \\ &\geqq -|\nabla \Delta (q^\beta)^{-1} \Delta (u^\beta - z)| |h \nabla v| \\ &\geqq -\frac{K_1}{\alpha} |\Delta (u^\beta - z)|_{H^{-1}} |h|_{H^2} |v|_{H_0^1} \\ &= -\frac{K_1}{\alpha} |u^\beta - z|_{H_0^1} |h|_{H^2} |v|_{H_0^1}. \end{aligned} \tag{3.12}$$

By (3.7) and Lemma 3.3 (suppressing the index β)

$$\begin{aligned} \langle (-\Delta)^{-1} \nabla \cdot (q \nabla v + h \nabla u), \nabla \cdot (q \nabla v + h \nabla u) \rangle &= \langle P(q \nabla v + h \nabla u), q \nabla v + h \nabla u \rangle \\ &\geqq \tfrac{1}{2} \langle P(h \nabla u), h \nabla u \rangle - \langle P(q \nabla v), q \nabla v \rangle \\ &\geqq \tfrac{1}{2} \langle P(h \nabla u), h \nabla u \rangle - |q|_{L^\infty}^2 |\nabla v|^2 \\ &\geqq \tfrac{1}{2} \langle P(h \nabla u), h \nabla u \rangle - K_1^2 \gamma^2 |v|_{H_0^1}^2. \end{aligned} \tag{3.13}$$

Here and in (3.14) below we suppress the superscript β. Each $h \in L^2$ can be uniquely decomposed as $h = h_1 + h_2$, where $h_1 = \int_\Omega h(x)\, dx$ and $h_2 \in \{h \in L^2 : \int_\Omega h\, dx = 0\}$. Observe that h_1 and h_2 are orthogonal in L^2 and if $h \in H^2$, then $h_2 \in H^2$. By definition of P and by Lemma 3.3(a) we find

$$\begin{aligned} \langle P(h \nabla u), h \nabla u \rangle &= \langle P(h_1 \nabla u), h_1 \nabla u \rangle + 2\langle P(h_1 \nabla u), h_2 \nabla u \rangle + \langle P(h_2 \nabla u), h_2 \nabla u \rangle \\ &\geqq |h_1|^2 |\nabla u|^2 - 2|h_1| |h_2|_{L^\infty} |\nabla u|^2 \\ &\geqq |h_1|^2 |\nabla u|^2 - 2K_1 |h_1| |h_2|_{H^2} |\nabla u|^2. \end{aligned} \tag{3.14}$$

Let us put $\ell := |u^\beta|^2_{H_0^1}$ and $c = \delta\beta$ with $\delta > 0$ to be chosen below. Then from (3.10), (3.12)–(3.14) we have

$$M_{\delta\beta}(h, v) \geqq (1 - \delta\beta K_1^2\gamma^2)|v|^2_{H_0^1} + \beta\left(N(h) + \frac{\delta\ell}{2}|h_1|^2 - K_1\delta\ell|h_1||h_2|_{H^2}\right)$$

$$- \frac{2K_1}{\alpha}|u^\beta - z|_{H_0^1}|h|_{H^2}|v|_{H_0^1}. \tag{3.15}$$

Next we will show that there exist constants k and δ such that

$$N(h) + \frac{\delta\ell}{2}|h_1|^2 - K_1\delta\ell|h_1||h_2|_{H^2} \geqq k(N(h) + |h|^2) \tag{3.16}$$

for all $h \in H^2$.

From Lemma 3.3 it follows that for any $0 < A < 1$ and $B > 0$

$$N(h) + \frac{\delta\ell}{2}|h_1|^2 - K_1\delta\ell|h_1||h_2|_{H^2}$$

$$\geqq (1 - A)N(h) + \frac{\delta\ell}{2}|h_1|^2 + \frac{A}{K_2^2}|h_2|^2 - \frac{(\delta\ell)^2}{4}B^2K_1^2|h_1|^2 - \frac{1}{B^2}|h_2|^2_{H^2}$$

$$\geqq \left(1 - A - \frac{K_3^2}{B^2}\right)N(h) + \left(\frac{\delta\ell}{2} - \frac{(\delta\ell)^2}{4}B^2K_1^2\right)|h_1|^2 + \frac{A}{K_2^2}|h_2|^2.$$

Since $|h|^2 = |h_1|^2 + |h_1|^2$, inequality (3.16) holds if there exist positive constants δ, k, B, and $A \in (0, 1)$ such that

$$1 - A - \frac{K_3^2}{B^2} \geqq k, \quad \frac{\delta\ell}{2} - \frac{(\delta\ell)^2}{4}B^2K_1^2 \geqq k \quad \text{and} \quad \frac{A}{K_2^2} \geqq k.$$

A calculation shows that these inequalities are satisfied if we take

$$k = (1 + K_2^2 + 4K_1^2K_3^2)^{-1}, \quad A = K_2^2k, \quad B^2 = (4kK_1^2)^{-1}, \quad \delta\ell = 4k.$$

This is the choice of k contained in the statement of the proposition. From (3.15) and (3.16) we have

$$M_c(h, c) \geqq k\beta(N(h) + |h|^2) + \left(1 - \frac{4k}{\ell}\beta K_1^2\gamma^2\right)|v|^2_{H_0^1}$$

$$- \frac{2K_1}{\alpha}|u^\beta - z|_{H_1^0}|h|_{H^2}|v|_{H_0^1}$$

where $c = 4k\beta/\ell$ and $\ell = \ell(\beta) = |u^\beta|^2_{H_0^1}$. By the choice of ω the last inequality implies

$$M_c(h, v) \geqq k\beta|h|^2_{H^2} + \left(1 - \frac{4k}{\omega}\beta K_1^2\gamma^2\right)|v|^2_{H_0^1} - \varepsilon k\beta|h|^2_{H^2} - \frac{K_1^2}{\varepsilon\alpha^2k\beta}|u^\beta - z|^2_{H_0^1}|v|^2_{H_0^1}$$

$$= (1 - \varepsilon)k\beta|h|^2_{H^2} + \left(1 - \frac{4k}{\omega}\beta K_1^2\gamma^2 - \frac{K_1^2}{\varepsilon\beta\alpha^2k}|u^\beta - z|^2_{H_0^1}\right)|v|^2_{H_0^1} \tag{3.17}$$

where $c = 4k\beta/\omega$ and $\varepsilon \in (0, 1)$ is arbitrary. By (3.9) and Corollary 3.2 we find

$$\sup_{U^{\beta_0}} |u^{\beta_0} - z|^2_{H_0^1} < \frac{\varepsilon_1\beta_0\alpha^2k}{K_1^2}\left(1 - \frac{4k}{\omega}K_1^2\gamma^2\beta_0\right)$$

for some $\varepsilon_1 \in (0, 1)$. Furthermore, by (3.4) of Lemma 3.1 there exist constants $\bar{\beta} \in (0, \beta_0)$ and $\eta > 0$ such that

$$\sup_{U^\beta} |u^\beta - z|^2_{H_0^1} \leqq \frac{\varepsilon_1 \beta \alpha^2 k}{K_1^2} \left(1 - \frac{4k}{\omega} K_1^2 \gamma^3 \beta\right) - \eta$$

for all $\beta \in I = [\bar{\beta}, \beta_0]$ and by (3.17) with $\varepsilon = \varepsilon_1$ this implies

$$M_c(h, v) \geqq (1 - \varepsilon_1) k\beta |h|^2_{H^2} + \eta |v|^2_{H_0^1} \quad \text{where } c = \frac{4k\beta}{\omega}$$

for all $\beta \in I$. From the definition of M_c and the last inequality, it follows that there exists a constant $\sigma > 0$ such that

$$M_c(h, v) \geqq \sigma\beta(|h|^2_{H^2} + |v|^2_{H_0^1}) \quad \text{for all } c \geqq \frac{4k\beta}{\omega} \text{ and } \beta \in I. \tag{3.18}$$

If $u^0 = z$ then there always exists $\beta_0 > 0$ such that (3.9) is satisfied, and using Corollary 3.2 we can verify (3.18) with I any compact subset of $(0, \beta_0]$.

Next note that

$$|\langle q^\beta, h\rangle_{H^2} + y|^2 \geqq \tfrac{1}{2}|y|^2 - |\langle q^\beta, h\rangle_{H^2}|^2 \geqq \tfrac{1}{2}|y|^2 - \gamma^2 |h|^2_{H^2}$$

and consequently

$$\begin{aligned} \sigma\beta |h|^2_{H^2} + c_2 |\langle q^\beta, h\rangle_{H^2} + y|^2 &\geqq (\sigma\beta - \gamma^2 c_2)|h|^2_{H^2} + \frac{1}{2} c_2 |y|^2 \\ &= \frac{\sigma\beta}{1 + 2\gamma^2} (|h|^2_{H^2} + |y|^2) \end{aligned} \tag{3.19}$$

where $c_2 = 2\sigma\beta/(1 + 2\gamma^2)$. Hence from (3.11), (3.18), and (3.19) we obtain

$$\nabla^2 L_c(q^\beta, u^\beta, w^\beta; \lambda^*, \mu^*, \eta^*)((h, v, y), (h, v, y)) \geqq \frac{\sigma\beta}{1 + 2\gamma^2} (|h|^2 + |v|^2_{H^1} + |y|^2)$$

for all $(h, v, y) \in H^2 \times H_0^1 \times \mathbb{R}$, $c \geqq \max(4k\beta/\omega, 2\sigma\beta/(1 + 2\gamma^2))$ and $\beta \in I$. This implies the claim.

In special cases the coercivity estimate of Proposition 3.4 can be obtained with $\beta = 0$.

PROPOSITION 3.5. *Let (q^0, u^0) be a local solution of (P_0).*

(a) *If $\mu^* > 0$ and $\operatorname{dist}^2 := |u^0 - z|^2_{H_0^1} < (\alpha / K_1)^2 \mu^*$, then there exist positive constants σ_1 and c_1 such that*

$$\nabla^2 L_c(q^0, u^0, w^0)((h, v, y), (h, v, y)) \geqq \sigma_1 (|h|^2_{H^2} + |v|^2_{H_0^1} + |y|^2)$$

for all $c \geqq c_1$ and $(h, v, y) \in H^2 \times H_0^1 \times \mathbb{R}$.

(b) *Let $\tilde{L}_c$ be given by (1.8) where the norm constraint is not augmented (i.e., $L_c = \tilde{L}_c + (c/2)|g(q) + w|^2$). If $\operatorname{dist} = 0$, then there exist positive constants σ_2 and c_2 such that*

$$\nabla^2 \tilde{L}_c(q^0, u^0)((h, v), (h, v)) \geqq \sigma_2 (|P(h \nabla u^0)|^2_{L^2} + |v|^2_{H_0^1}) \tag{3.20}$$

for all $c \geqq c_2$ and $(h, v) \in H^2 \times H_0^1$.

(c) *Let $\{\varphi_i\}_{i=1}^M$ be (curved) linear elements [19] or indicator functions such that $0 \leqq \varphi_i \leqq 1$ on Ω and let $V^M = \{q = \sum_{i=1}^M q_i \varphi_i : q_i \in \mathbb{R}\} \subset L^\infty$. Let $(P^0)_c^M$ be the problem of minimizing*

$$\frac{1}{2}|u - z|^2_{H_0^1} + \frac{c}{2}|e(q, u)|^2_{H_0^1}$$

subject to $e(q, u) = 0$ *in* H_0^1 *and* $q \in Q_{\mathrm{ad}} = \{q = \sum_{i=1}^M q_i \varphi_i \in V^M : q_i \geqq \alpha$ *and* $q^T W^M q < \gamma^2\}$, *where* $|(W^M)^{1/2}\alpha|^2 < \gamma^2$ *and* W^M *is a symmetric positive definite matrix on* $\mathbb{R}^M$. *Furthermore, assume that* $q \in Q_{\mathrm{ad}}$ *implies* $q(x) \geqq \alpha$ *on* Ω. *Then* $(P^0)_c^M$ *has a solution* $(q^0, u^0) \in V^M \times H_0^1$ *with an associated Lagrange multiplier* $(\lambda^*, \mu^*, \eta^*) \in H_0^1 \times \mathbb{R}_+ \times \mathbb{R}_+^M$ *such that if we define the augmented Lagrangian* (*compare* (2.13))

$$\hat{L}_c(q, u, w; \lambda^*, \mu^*, \eta^*) = \frac{1}{2}|u - z|_{H_0^1}^2 + \langle \lambda^*, e\rangle_{H_0^1} + \frac{\mu^*}{2}(q^T W^M q - \gamma^2) + \sum_{i=1}^M \eta_i^*(\alpha - q_i) + \frac{c}{2}|e|_{H_0^1}^2 + \frac{c}{2}\left(\frac{1}{2}(q^T W^M q - \gamma^2) + w\right)^2,$$

then $\nabla \hat{L}_c(q^0, u^0, w^0; \lambda^*, \mu^*, \eta^*)(h, v, y) = 0$ *for all* $(h, v, y) \in V^M \times H_0^1 \times \mathbb{R}$ *and* $\mu^*(q^{0T} W^M q^0 - \gamma^2) = \sum_{i=1}^M \eta_i^*(\alpha - q_i^0) = 0$. *Moreover, if* $h \to |P(h\nabla u^0)|$ *defines a norm on* V^M *with* $|P(h\nabla u^0)| \geqq b|h|_{L^\infty}$ *for some* $b > 0$ *and all* $h \in V^M$, *and if* $\mathrm{dist} < \alpha b^2 (2|q^0|_{L^\infty}^2 + b^2)^{-1}$, *then there exist positive constants* σ_3 *and* c_3 *such that*

$$\nabla^2 \hat{L}_c(q^0, u^0, w^0; \lambda^*, \mu^*, \eta^*)((h, v, y), (h, v, y)) \geqq \sigma_3(|P(h\nabla u^0)|^2 + |v|_{H_0^1}^2 + y^2)$$

for all $c \geqq c_3$ *and* $(h, v, y) \in V^M \times H_0^1 \times \mathbb{R}$.

We precede the proof with a brief discussion of this proposition. Part (a) presents the most desirable situation. In this case $\mu^* > 0$ takes over the role of the regularization parameter $\beta > 0$ of Proposition 3.4. In general, however, it is difficult to give conditions that guarantee $\mu^* > 0$ (see, however, [13] for the one-dimensional case). Part (b) is not directly applicable for the results of § 2, but it exhibits clearly the difficulties that are involved in obtaining a lower bound on the second derivative of the augmented Lagrangian: First the norm involved in (3.20) is only the L^2 rather than the H^2-norm; second, we obtain an estimate only in terms of $P(h\nabla u^0)$, where the kernel of P is the set of all divergence free vector fields. However, (3.20) also indicates how further assumptions can be made to obtain the desired coercivity estimate. To give an example, let us assume that q is known to be constant a priori, i.e., we take $q \in \{q \in \mathbb{R}: \alpha \leqq q \leqq \gamma(\int_\Omega dx)^{1/2}\}$. Then $h \in \mathbb{R}$ and $P(h\nabla u^0)$ becomes $h\nabla u^0$ and the desired coercivity estimate holds, with the H^2-norm replaced by the norm in $\mathbb{R}$, if $f \neq 0$. A less trivial case is considered in part (c) of the proposition. In the statement of (c) we did not distinguish between a function q and its coordinate expansion q in terms of φ_i. Moreover, we used α to also stand for $\mathrm{col}\,(\alpha, \cdots, \alpha) \in \mathbb{R}^M$ and we recall that $2w^0 = \gamma^2 - q^{0T} W^M q^0$.

Proof of Proposition 3.5. (a) First observe that Theorem 2.1 is applicable for local solutions (q^0, u^0) of (P^0). From (3.10) with $\beta = 0$, (3.12) and (3.13) we conclude that

$$M_c(h, v) + \mu^*|h|_{H^2}^2 = |v|_{H_0^1}^2 - 2\langle \nabla\lambda^*, h\nabla v\rangle + c|P(q^0\nabla v + h\nabla u^0)|^2 + \mu^*|h|_{H^2}^2$$

$$\geqq |v|_{H_0^1}^2 - \frac{2K_1}{\alpha}\,\mathrm{dist}\,|h|_{H^2}|v|_{H_0^1} + \mu^*|h|_{H^2}^2$$

$$\geqq |v|_{H_0^1}^2(1 - \varepsilon) + |h|_{H^2}^2\left(\mu^* - \frac{K_1^2\,\mathrm{dist}^2}{\varepsilon\alpha^2}\right)$$

for any $\varepsilon > 0$. The assumption on dist implies the existence of $\sigma > 0$ such that

$$M(h, v) + \mu^*|h|_{H^2}^2 \geqq \sigma(|h|_{H^2}^2 + |v|_{H_0^1}^2)$$

for all $(h, v) \in H^2 \times H_0^1$. The claim now follows with the same argument as at the end of Proposition 3.4.

(b) Since dist $= 0$, Theorem 2.1 implies that $\lambda^* = 0$, and further

$$\nabla^2 \tilde{L}_c(q^0, u^0)((h, v), (h, v)) = |v|^2_{H_0^1} + c|P(q^0 \nabla v + h \nabla u^0)|^2 + \mu^* |h|^2_{H^2}$$

$$\geqq |v|^2_{H_0^1}(1 - c|q^0|^2_{L^\infty}) + \frac{c}{2}|P(h \nabla u^0)|^2$$

$$\geqq |v|^2_{H_0^1}(1 - cK_1^2 \gamma^2) + \frac{c}{2}|P(h \nabla u^0)|^2.$$

This estimate implies the claim.

(c) The assumptions on α, q, and φ_i imply that Q_{ad} is nonempty and that $q(x) \geqq \alpha$ for every $q \in Q_{\text{ad}}$. It is simple to argue existence of a solution (q^0, u^0) of $(P^0)_c^M$. Moreover, the conclusions of Theorem 2.1 and Lemma 2.5 remain valid if h and $q^\beta \in H^2$ are replaced by h and $q^0 \in \mathbb{R}^M$, if $\mathbb{R}^M$ is endowed with the inner product $\langle h, W^M h \rangle$, and if $\mathscr{C} = \mathbb{R}^M_-$, $\ell(q) = \alpha - q \in \mathbb{R}^M$. In particular, there exists a Lagrange muitiplier $(\lambda^*, \mu^*, \eta^*)$ with the specified properties.

For $h = \sum_{i=1}^M h_i \varphi_i \in V^M$ and $v \in H_0^1$ we find

$$M_c(h, v) := |v|^2_{H_0^1} + 2\langle \nabla \lambda^*, h \nabla u \rangle + c|P(q^0 \nabla v + h \nabla u^0)|^2$$

$$\geqq |v|^2_{H_0^1} - \frac{2}{\alpha} \operatorname{dist} |h|_{L^\infty} |v|_{H_0^1} + \frac{c}{2}|P(h \nabla u^0)|^2 - c|P(q^0 \nabla v)|^2$$

$$\geqq (1 - c|q^0|^2_{L^\infty})|v|^2_{H_0^1} - \frac{2}{\alpha b} \operatorname{dist} |v|_{H_0^1} |P(h \nabla u^0)| + \frac{c}{2}|P(h \nabla u^0)|^2.$$

If $\tilde{c}_3 = 2(b^2 + 2|q^0|_{L^\infty})^{-1}$ then for $c \geqq c_3$ the following inequality holds:

$$M_c(h, v) \geqq \sigma |v|^2_{H_0^1} - \frac{2}{\alpha b} \operatorname{dist} |v|_{H_0^1} |P(h \nabla u^0)| + \frac{\sigma}{b^2}|P(h \nabla u^0)|^2$$

where $\sigma = b^2(b^2 + 2|q^0|^2_{L^\infty})^{-1}$. Thus, if dist $< \sigma\alpha$, then there exists a constant $\tilde{\sigma}_3 > 0$ such that

$$M_c(h, v) \geqq \tilde{\sigma}_3(|v|^2_{H_0^1} + |P(h \nabla u^0)|^2) \tag{3.21}$$

for all $c \geqq \tilde{c}_3$. Since $\nabla \hat{L}_c^2(q^0, u^0, w^0; \lambda^*, \mu^*, \eta^*)((h, v, y)(h, v, y)) = M_c(h, v) + \mu^* h^T W^M h + c(q^{0^T} W^M h + y)^2$, the final claim follows from (3.21) and an argument analogous to the one at the end of Proposition 3.4.

Next we consider the one-dimensional case where we have an explicit formula for the orthogonal projection P and explicit values for the estimates in Lemma 3.3. By D we denote differentiation and the domain Ω is $(0, 1)$.

LEMMA 3.6. *The operator $P = D\Delta^{-1}D$ is an orthogonal projection on L^2. Moreover,* ker P *is the set of all constant functions on* $(0, 1)$ *and* $|P\varphi|^2 = |\varphi|^2 - (\int_0^1 \varphi \, dx)^2$ *for* $\varphi \in L^2$.

Proof. The first part of the lemma is obvious. Next recall that $\{1, \sqrt{2} \cos \pi x, \sqrt{2} \cos 2\pi x, \cdots\}$ is a complete orthonormal system in L^2. For $\varphi \in H^1$ with $\varphi = a_0 + \sum_{k=1}^\infty a_k \sqrt{2} \cos k\pi x$ it is easy to see that $P\varphi = \sum_{k=1}^\infty a_k \sqrt{2} \cos k\pi x$ and $(I - P)\varphi = a_0$. Since H^1 is dense in L^2 this follows for all $\varphi \in L^2$ and, moreover, $|P\varphi|^2 = |\varphi|^2 - |(I - P)\varphi|^2 = |\varphi|^2 - (\int_0^1 \varphi \, dx)^2$.

Lemma 3.7. (a) $|\varphi|_{L^\infty} \leqq \sqrt{2}|\varphi|_{H^1}$ *for all* $\varphi \in H^1$,

(b) $|\varphi|_{L^\infty} \leqq 1/\sqrt{3}|D\varphi|$ *for all* $\varphi \in H^1$ *with* $\int_0^1 \varphi \, dx = 0$,

(c) $\pi|\varphi| \leqq |D\varphi|$ *for all* $\varphi \in H^1$ *with* $\int_0^1 \varphi \, dx = 0$.

Proof. (a) Let $\varphi \in H^1$. By the Mean Value Theorem there exists $\zeta \in [0, 1]$ such that $\varphi(\zeta) = \int_0^1 \varphi(x) \, dx$. For every $x \in [0, 1]$ we have

$$\varphi(x) = \int_\zeta^x D\varphi(s) \, ds + \varphi(\zeta).$$

This implies

$$|\varphi(x)| \leqq \int_0^1 (|D\varphi(s)| + |\varphi(s)|)\, ds \leqq \left(\int_0^1 (|D\varphi(s) + |\varphi(s)|)^2\, ds \right)^{1/2} \leqq \sqrt{2}|\varphi|_{H^1}.$$

(b) By assumption, φ can be expressed as $\varphi = \sum_{k=1}^{\infty} a_k \sqrt{2} \cos k\pi x$. Therefore $|D\varphi|^2 = \pi^2 \sum_{k=1}^{\infty} k^2 a_k^2$, and

$$|\varphi|_{L^\infty} \leqq \sqrt{2} \sum_{k=1}^{\infty} |a_k| = \sqrt{2} \left(\sum_{k=1}^{\infty} k^2 |a_k|^2 \right)^{1/2} (\sum k^{-2})^{1/2}$$

$$= \sqrt{2} \frac{|D\varphi|}{\pi} \cdot \frac{\pi}{\sqrt{6}} = \frac{|D\varphi|}{\sqrt{3}},$$

which was to be proved.

(c) The assertion immediately follows from

$$|\varphi|^2 = \sum_{k=1}^{\infty} |a_k|^2 \quad \text{and} \quad |D\varphi|^2 = \pi^2 \sum_{k=1}^{\infty} k^2 |a_k|^2 \geqq \pi^2 \sum_{k=1}^{\infty} |\alpha_k|^2.$$

Analogously to the multidimensional case we find a lower bound on the solutions of $-D(qDu) = f$ for $q \in Q_{\text{ad}}$:

$$|f|_{H^{-1}} = \sup_{V \in H_0^1} \frac{\langle qDu, Dv \rangle}{|v|_{H_0^1}} \leqq |q|_{L^\infty} |u|_{H_0^1} \leqq \sqrt{2}|q|_{H^1} |u|_{H_0^1} \leqq \sqrt{2}\gamma |u|_{H_0^1},$$

and thus

$$|u(q)|_{H_0^1} \geqq \omega_1 := \frac{|f|_{H^{-1}}}{\sqrt{2}\gamma} \quad \text{for all } q \in Q_{\text{ad}}. \tag{3.22}$$

PROPOSITION 3.8. *Let $f \in H^{-1}$ satisfy $f \neq 0$ and let $k = 3\pi^2/(7\pi^2 + 3)$. Let (q^0, u^0) be a solution of (P^0) and suppose that for a constant $\beta_0 \in (0, 1)$*

$$|u^0 - z|_{H_0^1}^2 < \beta_0 \left[\frac{\alpha^2 k}{2} \left(1 - \frac{8k}{\omega_1} \gamma^2 B_0 \right) - \rho(\beta_0) \right]. \tag{3.23}$$

Then there exists a nontrivial compact interval $I = [\underline{\beta}, \beta_0] \subset (0, 1)$ and constants $c_0 > 0$, $\sigma_0 > 0$ such that

$$\nabla^2 L_c(q^\beta, u^\beta, w^\beta; \lambda^*, \mu^*, \eta^*)((h, v, y), (h, v, y)) \geqq \sigma_0 (|h|_{H^1}^2 + |v|_{H_0^1}^2 + |y|^2)$$

for all $c \geqq c_0$, $(h, v, y) \in H^2 \times H_0^1 \times \mathbb{R}$ and any solution (q^β, u^β) of (P^β) with $\beta \in I$. Moreover, if $u^0 = z$, then such a constant β_0 always exists and I can be chosen as any compact subinterval of $(0, \beta_0]$.

Using Lemmas 3.6 and 3.7 the proof of this proposition is quite analogous to that of Proposition 3.4. In the present case (K_1, K_2, K_3) is replaced by $(\sqrt{2}, 1/\pi, \sqrt{(1/\pi^2) + 1})$.

Special cases in which the coercivity estimate holds with $\beta = 0$ are quite similar to the multidimensional case and hence we will not explicitly state the analogue of Proposition 3.5 in dimension one.

4. Numerical results. In this section we briefly report on our practical experience with the augmented Lagrangian technique (2.8), (2.9) to determine q in (1.1) from data for u. We carried out extensive testing in dimensions one and two. These results will be presented in a forthcoming paper [8*] (see also [10], [11]) and we will therefore give only two typical examples.

Example 1. This is the problem of determining q in

$$-(qu_x)_x = f \quad \text{on } (0,1), \qquad u(0) = u(1) = 0 \tag{4.1}$$

where

$$f(x) = \begin{cases} (18x-6)\dfrac{3\pi}{2}\cos\dfrac{3\pi x}{2} + 18\left(\dfrac{3}{2} + \sin\dfrac{3\pi x}{2}\right) & \text{for } x \in [0, \tfrac{1}{3}), \\ 0 \quad \text{for } x \in (\tfrac{1}{3}, \tfrac{2}{3}), \\ (18x-12)\dfrac{3\pi}{2}\cos\dfrac{3\pi x}{2} + 18\left(\dfrac{3}{2} + \sin\dfrac{3\pi x}{2}\right) & \text{for } x \in [\tfrac{2}{3}, 1], \end{cases}$$

and the "true coefficient" q^* is given by

$$q^*(x) = \frac{3}{2} + \sin\frac{3\pi x}{2}.$$

The corresponding solution $u(q^*) = z$ of (4.1) is

$$u(q^*) = \begin{cases} -9x^2 + 6x & \text{for } x \in [0, \tfrac{1}{3}], \\ 1 \quad \text{for } x \in (\tfrac{1}{3}, \tfrac{2}{3}], \\ -9x^2 + 12x - 3 & \text{for } x \in (\tfrac{2}{3}, 1]. \end{cases}$$

With f and z specified, it is immediately clear that q is not unique within the class of positive H^1 functions that satisfy $u(q) = z$, since its value over the interval $S = (1/3, 2/3)$ does not effect the solution u there. On the other hand, with the techniques of [12] it can easily be argued that $u(q) = u(q^*)$, $q \in H^1$, $q^* \in H^1$ implies $q = q^*$ on $[0,1]\backslash S$. Thus we expect a different behavior of the algorithm over S than over the complement of S.

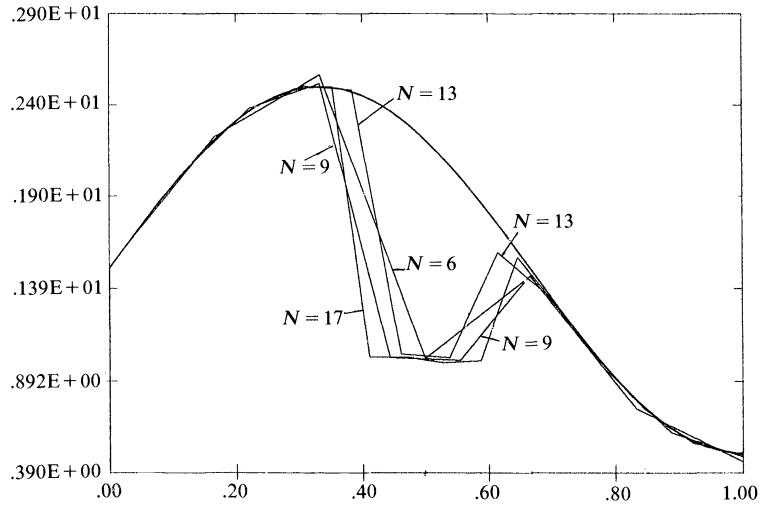
In Fig. 1 we give the numerical results for various values of N. Here N represents the index of discretization of the infinite-dimensional problem (2.8) by finite-dimensional ones involving linear spline subspaces H^N for the statespace H_0^1 and V^N for the parameter space H^1. More precisely we take

$$H^N = \operatorname{span}\{B_i^{2N}\}_{i=1}^{2N-1} \text{ and } V^N = \operatorname{span}\{B_j^N\}_{j=0}^N,$$

where B_i^N is the usual first-order B-spline on the interval $[0,1]$ corresponding to the mesh $\{x_k^N = k/N\}$, $k = 0, \cdots, N$:

$$B_k(x) = \begin{cases} N(x - x_{k-1}^N) & \text{for } x_{k-1}^N \leqq x \leqq x_k^N, \\ N(x_{k+1}^N - x) & \text{for } x_k^N \leqq x \leqq x_{k+1}^N, \\ 0 \quad \text{elsewhere} \end{cases}$$

where $x_{-1}^N = 0$, $x_{N+1}^N = 1$. Figure 1 gives the results after one iteration of the augmented Langrangian algorithm where $\lambda^1 = \mu^1 = 0$, $\gamma^2 = 100{,}000$ and $\beta = 0$. The start-up value for the minimization routine to solve (2.8) was taken as $(q^0, u^0) = (1, 0)$. The corresponding value for u^{17} is indistinguishable from $u(q^*)(= z)$ on all of $(0,1)$. For this example the use of the regularization term did not change the results significantly. In other examples with the same value for z, but with different values for q^* (and thus of f) the use of the regularization term decreased the L^2-error for $q^N - q^*$. The penalty



FUNCTION q METHOD ALG1
$n = 1$, $\gamma^2 = 100{,}000$, $N = 6, 9, 13, 17$, $\lambda_0 = 0$,
$\mu_0 = 0$, L^2-error = 4.134E−1, 5.164E−1, 4.286E−1, 5.514E−1

FIG. 1

parameters c_k were taken to be 1 for all k. The augmented Lagrangian algorithm for this example (as well as for the other examples that we tried) was quite insensitive to the choice of u^0 and q^0 as well as the choice of λ^1 and μ^1 and c_k. However, $\lambda^1 \neq 0$, $\mu^1 \neq 0$ increased the number of iterations that were required before convergence was obtained. We compared the augmented Lagrangian method with the output least squares approach and found that it is less sensitive with respect to the choice of the regularization parameter [10].

Example 2. Here we estimate q in

$$-(qu_x)_x - (qu_y)_y = f \quad \text{on } \Omega \tag{4.2}$$
$$u = 0 \quad \text{on } \Gamma$$

where $\Omega = [0, 1] \times [0, 1]$ and

$$f = 8\pi^2 \sin 2\pi x \sin 2\pi y(1 + 6x^2 y(1-y)) - 24\pi xy(1-y) \cos 2\pi x \sin 2\pi y$$
$$- 12\pi x^2(1-2y) \sin 2\pi x \cos 2\pi y.$$

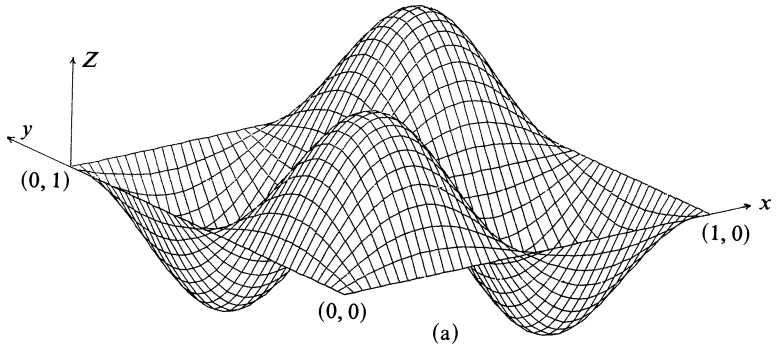
The true solution q^* is

$$q^* = 1 + 6x^2 y(1-y)$$

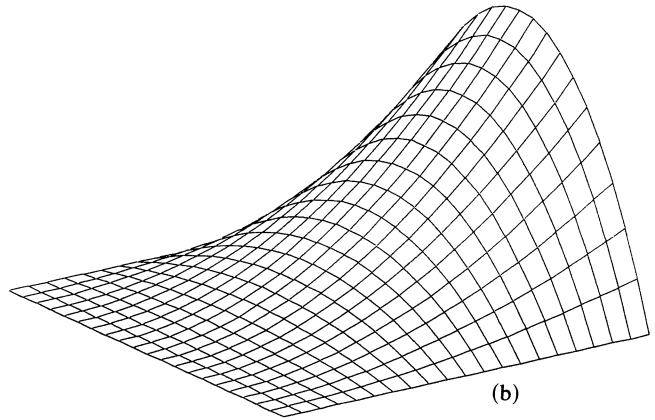
and the corresponding solution $u(q^*) = z$ for (4.2) is given by

$$u(q^*) = \sin 2\pi x \sin 2\pi y.$$

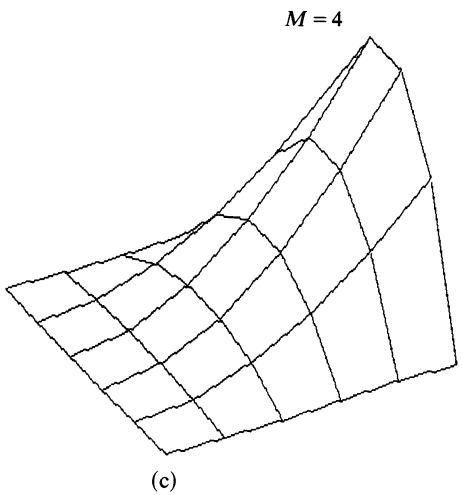
The discretization (4.2) is carried out by taking tensor linear spline subspaces $H^N \otimes H^N$ for the statespace H_0^1 [18], and tensor linear spline subspaces $V^N \otimes V^N$ for the coefficient space. Figures 2(a) and 2(b) give the graphs for z and q^*, respectively. The results after eight iterations of the augmented Lagrangian algorithm with $N = 5$ and $N = 9$ are given in Figs. 2(c) and 2(d). The results after just one iteration are essentially identical. These results are obtained with $\beta = \lambda^1 = \mu^1 = 0$ and $q_0 = 1$. We also carried out calculations where we assumed that only partial observations are available.

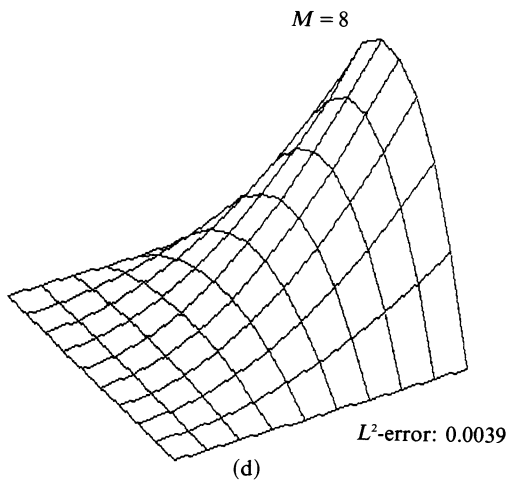


$Z = \sin 2\pi x \cdot \sin 2\pi y$
$q = 1 + 6x^2y(1-y)$



EXAMPLE 4. $q1$, $M = 4$, interpolated data at $(1/3{*}i, 1/3{*}j)$, $i, j = 0, 3$





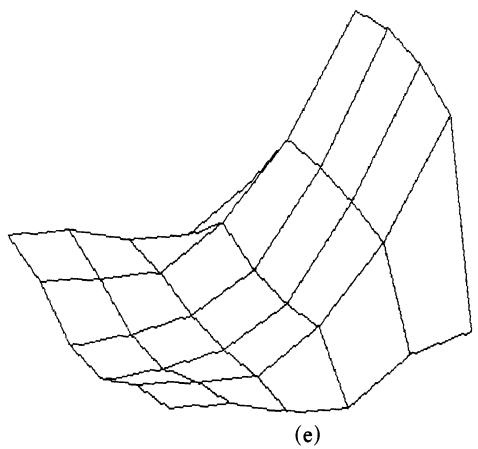


FIG. 2

Specifically, we took the values of $u(q^*)$ at the grid $[(.2i, .2j)\colon i, j = 0, \cdots, 5\}$ and calculated a bicubic interpolation z. Using this z in the augmented Lagrangian algorithm (2.8), (2.9) the resulting plot for q^5 is almost indistinguishable from Fig. 2(c). Then we tried the same procedure with data at $\{(i/3, j/3)\colon i, j = 0, \cdots, 3\}$ and the result for q^5 from these interpolated data is shown in Fig. 2(e).

Overall the augmented Lagrangian approach to estimate q in (1.1) proved to be very effective. This is especially true for the two-dimensional problem, where earlier experiments with the output least squares technique were not very encouraging numerically. Clearly, there is a wide variety of choices for implementing (2.8), (2.9). One variant of (2.8), (2.9) that proved to be effective numerically is the following (we specify it for $n = 2$ or 3).

Step 1. Choose $\lambda^1 = \mu^1 = 0$, $\{c_k\}_{k=1}^{\infty}$ monotonically increasing $c_k > c_0$.

Step 2. Put $k = 1$, $u_0 = z$.

Step 3. Determine q_k from

$$(P_{\text{equ}}) \text{ minimize } \frac{\beta}{2} N(q) + \langle \lambda^k, e(q, u_{k-1}) \rangle_{H_0^1} + \frac{c_k}{2} |e(q, u_{k-1})|_{H_0^1}^2$$

$$+ \mu^k \hat{g}(q, \mu^k, c_k) + \frac{c_k}{2} \hat{g}(q, \mu^k, c_k)^2$$

over $q \in H^2$ subject to $q \geqq \alpha$.

Step 4. Determine u_k from

$$(P_{\text{out}}) \underset{u \in H_0^1}{\text{minimize}} \frac{1}{2} |u - z|_{H_0^1}^2 + \langle \lambda^k, e(q_k, u) \rangle_{H_0^1} + \frac{c_k}{2} |e(q_k, u)|_{H_0^1}^2.$$

Step 5. $\lambda^{k+1} = \lambda^k + c_k e(q_k, u_k)$ and $\mu^{k+1} = \mu^k + c_k \hat{g}(q_k, \mu^k, c_k)$.

Step 6. If convergence is achieved, stop; otherwise put $k = k + 1$ and go to Step 3.

In our implementation for the two-dimensional problem we dropped the second-order derivative terms in the regularization functional of Step 3. This is partially because we used piecewise linear and piecewise constant functions to approximate q and hence second derivatives could only be taken approximately. Moreover, we expect that the second-order derivatives are only required analytically since we choose our coefficients q as H^2 functions, but we expect that this is not essential numerically.

Acknowledgment. We are grateful to Dr. M. Kroller who carried out the numerical calculations that we reported in this section.

OPTIMIZATION WITH AN AUXILIARY CONSTRAINT AND DECOMPOSITION*

GUY COHEN† AND BERNADETTE MIARA‡

Abstract. In the context of decomposition/coordination of a linear quadratic optimal control problem, Takahara's algorithm was an earlier version of the so-called Interaction Prediction Principle that can be examined in the more general framework of infinite-dimensional constrained optimization problems. This principle is both a *decomposition* principle and a *coordination* strategy based on a fixed point scheme. It has been later revisited in the general theory of the Auxiliary Problem Principle and the convergence of corresponding iterative algorithms has been analyzed. In this paper, we keep the same decomposition principle but we propose an alternative coordination strategy. The improvement brought by this new strategy is proved theoretically and illustrated by a numerical example. All of this is based on some manipulation of constrained optimization problems that we call the Auxiliary Constraint Principle.

Key words. optimization algorithms, decomposition, coordination, interaction prediction principle, convergence of algorithms

1. Introduction.

The *Interaction Prediction Principle* (IPP) was first introduced by Takahara [1] (see also Mesarovic et al. [2]) in the context of decomposition/coordination of the classical linear quadratic (LQ) optimal control problem. Later on, Cohen [3], [4] gave a unified theory of decomposition/coordination algorithms in the framework of differentiable[1] mathematical programming in infinite-dimensional Hilbert spaces (in which of course deterministic optimal control problems can be casted). The IPP was shown to fall into the class of so-called *one-level algorithms* [3] for which conditions of convergence were given in [4]. The terminology "*one-level*" was chosen to outline the fact that this class of algorithms is based on a *fixed point* principle, that is, iterated values of primal and dual variables are directly exchanged between subproblems without the intervention of a coordination level.[2] This is in contrast with, e.g., *price coordination* [2], [8] where a coordinator iteratively updates the prices, generally by the Uzawa algorithm, which is indeed a *gradient* algorithm to maximize the dual (coordination objective) function.

At this point, we want to emphasize the difference between *gradient-like* or *variational* algorithms, the purpose of which is to minimize, maximize, or find the saddle-point of some (coordination) objective function, and *fixed point* strategies, the idea of which is to solve first-order optimality conditions. To make this point clearer, let us consider the simple problem of minimizing some real-valued differentiable convex functional f of two variables x and y belonging to the same Hilbert space or to spaces in duality ($\langle \cdot, \cdot \rangle$ denotes either the inner or the duality product). With these assump-

[1] This was later extended to nondifferentiable [5] and stochastic [6] optimization and to variational inequality [7] problems.

[2] Indeed, some coordination task can still be introduced through *under-* or *overrelaxation* strategies which may sometimes improve convergence.

tions, it is equivalent to say that we wish to solve the following system of equations:

$$\frac{\partial f(x, y)}{\partial x} = 0 \tag{1}$$

$$\frac{\partial f(x, y)}{\partial y} = 0. \tag{2}$$

A gradient algorithm uses the left-hand side current value of (1) (respectively, (2)) to update x (respectively, y). Suppose now that $f(x, y) = g(x, y) - \langle x, y \rangle$ so that (1), (2) are, respectively, equivalent to (3), (4) below

$$y = \frac{\partial g(x, y)}{\partial x} \tag{3}$$

$$x = \frac{\partial g(x, y)}{\partial y}, \tag{4}$$

which suggests the following fixed point (parallel) iterations:

$$y^{k+1} = \frac{\partial g(x^k, y^k)}{\partial x} \tag{5}$$

$$x^{k+1} = \frac{\partial g(x^k, y^k)}{\partial y}. \tag{6}$$

It should be noted that now (3) (that is equivalently (1)) is used to update y (and mutatis mutandis for x). Moreover, whereas with the gradient algorithm $f(x^k, y^k)$ should decrease, there is no reason why this should be the case with the fixed point algorithm. A convergence proof for the latter would rely upon an ad hoc Lyapounov function (or upon a contraction argument).

These considerations apply to the class of one-level algorithms as will be shown later on with more details. They largely explain the discrepancy that shows up in [4] between convergence conditions obtained for this class and those for all other classes of algorithms described there, which were of a variational nature. More specifically, there is no equivalent for these latter classes of the *prerequisite* conditions [4, (26-1) or (26-2)] imposed to prove convergence of one-level algorithms (these conditions will be recalled in § 2.4). In all other cases, conditions are only imposed to the step lengths used in these gradient-like algorithms under classical convexity and other technical conditions. Note also that Cohen was able to give a convergence proof for one-level algorithms in the context of linear equality constraints and quadratic cost functions only, whereas, for all the other algorithms, he was able to deal with general convex problems including inequality constraints as well.

The above remarks led us to reconsider the coordination strategy traditionally used in conjunction with the IPP. It is important to distinguish this *decomposition* principle, that is, a way to formulate independent subproblems using some coordination instruments, from the *coordination* strategy itself which is the way of updating these parameters from one iteration to the next. What we are going to do is modify the latter without altering the former. The new coordination strategy will be of a variational rather than of a fixed point nature. Consequently, we shall be able to avoid the prerequisite convergence condition mentioned above, which means that this new approach is more often applicable than the earlier one. Moreover, we shall be able to consider general convex cost functions, but we shall still be limited to affine equality constraints only for technical reasons that will be discussed later.

We first introduce a new way of manipulating a given constrained optimization problem, that is, a way of replacing it by an equivalent one which in this case will have more constraints and more variables. This may seem a rather odd idea, but the interest of this manipulation, which we call the *Auxiliary Constraint Principle* (ACP), will be more apparent later on. We even believe that this interest is broader than the application done here but we shall not elaborate on this. For the time being, let us say that when coupling between potential subproblems arises from constraints, either these constraints are relaxed by appealing to duality (this is what is done in the *Interaction Balance Principle* (IBP) [2] also known as *price decomposition* [8]) or, in one way or another, these coupling constraints must be replaced by uncoupled (auxiliary) ones. In § 2.3, we shall recall how this is achieved in the context of the *Auxiliary Problem Principle* (APP) by a proper choice of the auxiliary function when deriving one-level algorithms. With the ACP, the idea is different in that the auxiliary constraint is introduced by manipulation of the original problem and *before* one appeals to the APP in order to obtain iterative algorithms.

The rest of the paper is organized as follows. The next section is devoted to a summary of the situation starting with Takahara's algorithm later formalized by the IPP, followed by a brief description of the APP framework and the convergence conditions obtained for the so-called one-level algorithm which is directly connected to those earlier algorithms. The ACP is introduced in § 3 and a new coordination strategy is derived from it. Section 4 mixes the ACP and the APP to propose an alternative algorithm to one-level algorithms. A convergence theorem is stated but its proof is given in an appendix. A section is devoted to showing how Takahara's algorithm is modified using the new coordination strategy, and to giving an account of some simple numerical experiments, including a comparison of the traditional fixed point strategy with the new proposed strategy. In these experiments, we study the effect of increasing the interaction magnitude between subproblems. In the conclusion, we discuss open problems and topics of future research.

2. The IPP and its connection with the APP. In order for this paper to be reasonably self-contained, we first recall Takahara's algorithm in its original context of LQ optimal control problems [1]. This was the first appearance of the IPP later developed by Mesarovic and his coauthors [2]. We then abstract this algorithm in a more general context of constrained optimization. On the other hand, we recall the APP framework introduced by Cohen [3], [4], and we show how the IPP can be embedded in this framework (and somewhat extended). Finally, we recall the convergence conditions which result from these considerations.

2.1. Takahara's algorithm. Consider the classical LQ optimal control problem

$$\min \frac{1}{2}\int_0^T x^*Qx + u^*Ru\,dt \tag{7}$$

$$\dot{x} = Fx + Gu, \quad 0 \leqq t \leqq T, \quad x(0) = x_0 \text{ given}, \tag{8}$$

where the star denotes transposition. Moreover, assume that system (8) is made of N interconnected subsystems. With obvious notations, (8) can be rewritten for decomposition purposes as follows

$$i = 1, \cdots, N \begin{cases} F_{ii}x_i + G_{ii}u_i - v_i - \dot{x}_i = 0 \\ \sum_{j \neq i} (F_{ij}x_j + G_{ij}u_j) + v_i = 0 \end{cases} \tag{9}$$

where v_i is the ith interaction variable. In the same way, the necessary Pontryagin optimality conditions (which are also sufficient if Q—respectively R—is nonnegative

definite—respectively, definite positive—which we assume) can be globally written as

$$\begin{aligned} \dot{x} &= Fx + Gu, & x(0) &= x_0 \\ \dot{p} &= -F^*p - Qx, & p(T) &= 0 \\ 0 &= Ru + G^*p \end{aligned}$$

where p is the costate vector. The above conditions can be rewritten as follows

$$(10) \qquad i = 1, \cdots, N \begin{cases} \dot{x}_i = F_{ii}x_i + G_{ii}u_i - v_i \\ \dot{p}_i = -F_{ii}^*p_i - Q_{ii}x_i - \mu_i \\ 0 = R_{ii}u_i + G_{ii}^*p_i + \nu_i \\ v_i = -\sum_{j \neq i} (F_{ij}x_j + G_{ij}u_j) \\ \mu_i = \sum_{j \neq i} (F_{ij}^*p_j + Q_{ij}x_j) \\ \nu_i = \sum_{j \neq i} (G_{ij}^*p_j + R_{ij}u_j) \end{cases}$$

which can be reinterpreted as the optimality conditions of the following LQ problems:

$$(11) \qquad i = 1, \cdots, N \begin{cases} \min \int_0^T \frac{1}{2}(x_i^*Q_{ii}x_i + u_i^*R_{ii}u_i) + \mu_i^*x_i + \nu_i^*u_i \, dt \\ \dot{x}_i = F_{ii}x_i + G_{ii}u_i - v_i. \end{cases}$$

Takahara's algorithm consists of the following fixed point algorithm.

ALGORITHM 1 (Takahara). *At iteration k, knowing x^k, u^k, and p^k, compute the coordination parameters v_i^k, μ_i^k, and ν_i^k using the last three formulas* (10) *and produce the updated values x^{k+1}, u^{k+1}, and p^{k+1} by solving the subproblems* (11).

The fact that the interaction input v_i is "predicted" at some value to decouple the subsystems gave the name IPP to the decomposition method. However, there are also dual variables[3] μ_i and ν_i that must also be "predicted."

2.2. The IPP in the framework of constrained optimization. We now give a simpler view of the IPP by considering optimal control problems as particular instances of constrained optimization problems (in infinite-dimensional spaces). The decision variables are the pair of vector trajectories $\{x(t), u(t)\}_{0 \leq t \leq T}$ and the constraint is the dynamic equation (8) (whose multiplier is p). We shall not discuss the issue of proper topologies in which optimal control problems must be set and we refer the interested reader to [3], [9] for details. Hereafter, constrained optimization problems will be considered in Hilbert spaces only. From now on, let $\mathcal{U}$ denote the Hilbert space of decision variables and $\mathcal{C}$ denote that of constraints, let $J : \mathcal{U} \mapsto \mathbb{R}$ denote the cost function and $\Theta : \mathcal{U} \to \mathcal{C}$ denote the constraint function. We consider the constrained optimization problem

$$(12) \qquad \min J(u) \quad \text{subject to} \quad \Theta(u) = 0.$$

Introducing the Lagrange multiplier p which lies in the dual space $\mathcal{C}^*$ and the Lagrangian $L(u, p) = J(u) + \langle p, \Theta(u) \rangle$, where $\langle \cdot, \cdot \rangle$ denotes the duality product between

[3] These variables should indeed be considered as dual despite the presence of Qx or Ru in their expressions because these latter expressions should be viewed as partial derivatives of the cost function with respect to x and u, respectively.

$\mathscr{C}$ and $\mathscr{C}^*$, under differentiability assumptions and a constraint qualification condition, a necessary condition for some u^* to be a solution of (12) is that there exists some p^* such that $L'_u(u^*, p^*) = 0$ and $L'_p(u^*, p^*) = 0$, where, e.g., L'_u denotes the partial derivative with respect to u. This yields

$$\begin{cases} J'_u(u^*) + [\Theta'_u(u^*)]^* p^* = 0 \\ \Theta(u^*) = 0 \end{cases} \tag{13}$$

where the star over an operator denotes its adjoint operator.

Suppose now that some decompositions of $\mathscr{U}$ and $\mathscr{C}$ into the product of N subspaces are given. Each component $\mathscr{C}_i$ is associated with a corresponding $\mathscr{U}_i$.[4] By J'_i we denote the partial derivative of J with respect to u_i, by Θ_i the mapping from $\mathscr{U}$ to $\mathscr{C}_i$ (that is, the composition of Θ and of the projection to $\mathscr{C}_i$), and finally by Θ'_{ij} the partial derivative of Θ_i with respect to u_j. Equations (13) can be rewritten by blocks, each block corresponding to a problem over the pair of spaces $(\mathscr{U}_i, \mathscr{C}_i^*)$. It is then easy to see that, in this new framework, Takahara's algorithm corresponds to a *relaxation* scheme over this set of equations. In what follows, (u_i^{k+1}, u_{-i}^k) is a shorter notation for $(u_1^k, \cdots, u_{i-1}^k, u_i^{k+1}, u_{i+1}^k, \cdots, u_N^k)$.

ALGORITHM 2 (IPP). *Knowing* (u^k, p^k), *compute* (u^{k+1}, p^{k+1}) *by solving*

$$i = 1, \cdots, N \begin{cases} J'_i(u_i^{k+1}, u_{-i}^k) + [\Theta'_{ii}(u_i^{k+1}, u_{-i}^k)]^* p_i^{k+1} + \sum_{j \neq i} [\Theta'_{ji}(u^k)]^* p_j^k = 0 \\ \Theta_i(u_i^{k+1}, u_{-i}^k) = 0. \end{cases} \tag{14}$$

These equations can again be interpreted as the necessary optimality conditions of the following subproblems

$$i = 1, \cdots, N \begin{cases} \min_{u_i} J_i(u_i, u_{-i}^k) + \sum_{j \neq i} \langle p_j^k, \Theta'_{ji}(u^k) \cdot u_i \rangle \\ \text{subject to } \Theta_i(u_i, u_{-i}^k) = 0. \end{cases} \tag{15}$$

Another version which differs from the above one—only if Θ is nonlinear—would amount to replacing the argument u^k by (u_i^{k+1}, u_{-i}^k) in the terms Θ'_{ji} of (14) and, correspondingly, replacing the last terms in the cost function of (15) by $\langle p_j^k, \Theta_j(u_i, u_{-i}^k) \rangle$.

2.3. The APP and one-level algorithms. Consider first a problem of the form

$$\min_{u \in U^f} J(u) + G(u) \tag{16}$$

where U^f, the feasible set, is a closed convex subset of $\mathscr{U}$, J and G are convex lower semicontinuous mappings from $\mathscr{U}$ to $\mathbb{R}$, and, moreover, J is differentiable. Let K be an auxiliary function of the same type as J. The APP leads to the following basic fixed point algorithm.

ALGORITHM 3 (APP). *Knowing* u^k, *compute* u^{k+1} *as the solution of*

$$\min_{u \in U^f} K(u) + \langle \varepsilon J'(u^k) - K'(u^k), u \rangle + \varepsilon G(u). \tag{17}$$

A justification of this fixed point strategy comes from the fact that if $u^k = u^{k+1}$ (i.e., u^k is a solution of (17)), then u^k is also a solution of (16) (this is proved by

[4] Indeed there is no necessity that the number of component subspaces $\mathscr{C}_i$ be exactly N—it may be smaller without trouble—but it will make our explanations simpler to assume that the two decompositions have the same cardinality.

writing the variational inequality associated to (17)). We refer the reader to [3], [4] for details and also for assumptions on K and conditions on the positive constant ε that guarantee convergence of the above algorithm. As far as decomposition is concerned, if some decomposition of $\mathcal{U}$ into $\mathcal{U}_1 \times \cdots \times \mathcal{U}_N$ is given, if $U^f = U_1^f \times \cdots \times U_N^f$ where $U_i^f \subset \mathcal{U}_i$ for $i = 1, \cdots, N$ (decoupled constraints), if G is additive (that is, $G(u) = \sum_i G_i(u_i)$), and finally if K is also chosen additive, then (17) splits into N independent subproblems.

This APP is generalized to saddle point problems to cope with coupling constraints. The idea is to formulate coupling constraints explicitly as equalities or inequalities and then to appeal to duality in order to relax these constraints. In this paper, we limit ourselves to equality constraints only and we consider (12) again.[5] To solve the saddle point problem of the Lagrangian L with respect to (u, p) in a decomposed way, we introduce an auxiliary saddle function $\Psi(u, p)$. However, the question arises of knowing whether we want to get a decomposition with respect to the variable u only (this is what occurs in price decomposition) or a decomposition with respect to both variables u and p. In the latter case, we have to speak of a decomposition of the space in which p lies, namely here $\mathcal{C}^*$. Hence we assume that a decomposition of $\mathcal{C}$ into N components is given, as we did in the previous section, and we adopt the same notations as previously regarding the components of Θ and Θ'.

Our final purpose is to recover algorithms that look like (15) above, that is, to get subproblems which are initially saddle point problems but which can eventually be interpreted as constrained minimization problems. This is obtained by making a proper choice of the auxiliary function Ψ, namely by giving it the form of a Lagrangian function. Therefore we set

$$\Psi(u, p) = K(u) + \langle p, \Omega(u) \rangle \tag{18}$$

where K is again an auxiliary function of the same type as J and Ω is of the same type as Θ. At iteration k, the auxiliary problem then consists of solving a saddle point problem for the above auxiliary function to which we must add linear corrections analogous to those appearing in (17), namely

$$\Psi(u, p) + \langle \varepsilon L'_u(u^k, p^k) - \Psi'_u(u^k, p^k), u \rangle + \langle \rho L'_p(u^k, p^k) - \Psi'_p(u^k, p^k), p \rangle \tag{19}$$

where ρ is, as ε, a positive constant. Since (19) is affine in p, it looks like a Lagrangian, hence its saddle point may be reinterpreted as an auxiliary constrained optimization problem. We then get the so-called *one-level* algorithm.

ALGORITHM 4 (ONE-LEVEL). *Knowing* (u^k, p^k), *compute* (u^{k+1}, p^{k+1}) *as the primal-dual solution of*

$$\begin{cases} \min\limits_u K(u) + \langle \varepsilon J'(u^k) - K'(u^k), u \rangle + \langle p^k, [\varepsilon \Theta'(u^k) - \Omega'(u^k)] \cdot u \rangle \\ \\ \textit{subject to } \Omega(u) + \rho \Theta(u^k) - \Omega(u^k) = 0. \end{cases} \tag{20}$$

In order for this problem to split into N independent subproblems, one has to choose an *additive* K and a *block-diagonal* Ω. "Block-diagonal" of course means that Ω'_{ij} is identically null whenever $j \neq i$. Note that this condition is necessary and sufficient for the auxiliary function (18) to be additive with respect to the pair (u, p). Now, to precisely recover the subproblems (15), the auxiliary functions K and Ω must depend on the iteration index k, which does not conceptually make any problem, and the

[5] We could have kept uncoupled constraints $u \in U^f$ and an additive part G of the cost function as well.

components K_i^k and Θ_i^k (with obvious notations) must be chosen as follows whereas ε and ρ are set equal to one[6]

$$i = 1, \cdots, N \begin{cases} K_i^k(u_i) = J(u_i, u_{-i}^k) \\ \Omega_i^k(u_i) = \Theta_i(u_i, u_{-i}^k). \end{cases}$$

2.4. Convergence conditions of one-level algorithms. A convergence proof for Algorithm 4 was given only in the case of J and K quadratic and Θ and Ω affine [4]. We recall these convergence conditions.

THEOREM 1. *Let* $J(u) = \frac{1}{2}\langle u, Au\rangle + \langle b, u\rangle$, $K(u) = \frac{1}{2}\langle u, Bu\rangle$, $\Theta(u) = Du - d$, $\Omega(u) = Eu$, *where* A *and* B *are self-adjoint strongly monotone operators over* $\mathcal{U}$ *and* D *and* E *are linear onto operators from* $\mathcal{U}$ *to* $\mathcal{C}$. *Under the following condition (where "strongly monotone" is symbolically denoted by* >0*)*

$$DA^{-1}E^* + EA^{-1}D^* - DA^{-1}BA^{-1}D^* > 0 \text{ over } \mathcal{C}^* \tag{21}$$

it is possible to choose $\rho = \varepsilon$ *and the latter so that*

$$\begin{gathered} B - \varepsilon A/2 > 0 \quad \text{over } \mathcal{U} \\ DA^{-1}E^* + EA^{-1}D^* - DA^{-1}(B + \varepsilon A/2)A^{-1}D^* > 0 \quad \text{over } \mathcal{C}^* \end{gathered} \tag{22}$$

and then Algorithm 4 *converges to the unique solution* (u^*, p^*) *of* (12).

Once (21) is met, (22) can be satisfied for ε small enough. The prerequisite condition (21) can be further simplified into

$$DA^{-1}E^* + EA^{-1}D^* > 0 \quad \text{over } \mathcal{C}^* \tag{23}$$

for, if this latter condition is satisfied, the former can also be satisfied by changing E into αE with α large enough. Hence the problem is to find some auxiliary constraint operator E which is at the same time *block-diagonal* (for decomposition purposes) and which satisfies (23). Indeed, we do not know the answer to the question of existence of such an E in general, but it is clear that this depends heavily on the way the constraint space $\mathcal{C}$ is decomposed into component subspaces (that is, how constraints are grouped in blocks), and then on how these blocks are numbered (that is how subspaces $\mathcal{C}_i$ are paired with subspaces $\mathcal{U}_i$ or else how these blocks of constraints are allocated to subproblems in u_i). This issue is further discussed in [4, Remark 5.1]. However, these considerations will no longer be relevant when using the new coordination strategy introduced hereafter since we will be able to avoid condition (23) to prove convergence.

3. The ACP and a new coordination strategy. As we have just seen, coupling constraints must be handled by appealing to duality. But there are two ways of doing this. In price coordination[7] [8], these constraints no longer appear as constraints in the subproblems but they appear as additional terms in the subproblem objective functions. On the contrary, in the IPP approach, these constraints still appear at the subproblem level as constraints, but of course in a decoupled manner (see (15)), and the additional terms in the subproblem cost functions account for the coupling part

[6] Note that this common value of the convergence parameters ε and ρ may be outside the range of allowed values resulting from the convergence conditions recalled hereafter. But we never claimed that Algorithm 2 would always converge. As far as Takahara's algorithm is concerned, the proof given by the author in [1] was very involved and his convergence conditions were not very clear.

[7] This is also called IBP [2], which is embedded in the so-called family of *two-level* algorithms [3], [4].

only. Alternately in the APP/one-level approach (see (20)), constraints that appear in the subproblems are "auxiliary" constraints, and additional terms in the subproblem cost functions account for the discrepancy between original and auxiliary constraints. These auxiliary constraints, or more exactly the auxiliary operator Ω (or E), have been introduced through the choice of an auxiliary function (18) having a Lagrangian form. Now we are going to introduce this auxiliary operator Ω directly at the level of an equivalent formulation of the original problem (12), that is *prior* to any recourse to the APP, the aim of the latter being to define an iterative algorithm to compute a solution of (12). This way of formulating an equivalent problem to a given constrained optimization problem is referred to as the *Auxiliary Constraint Principle* (ACP).

3.1. The ACP.

THEOREM 2. *In addition to* (12) *and to its Lagrangian introduced earlier, consider the following problem*

$$\text{(24)} \qquad \begin{cases} \min\limits_{u,v} J(u) \\ \text{subject to } \Omega(u) - v = 0 \\ \qquad\qquad \Theta(u) + v - \Omega(u) = 0 \end{cases}$$

(*where v is a new decision variable in $\mathscr{C}$ and Ω maps $\mathscr{U}$ into $\mathscr{C}$*) *and the corresponding Lagrangian*

$$\text{(25)} \qquad \mathscr{L}(u, v; p, q) = J(u) + \langle p, \Omega(u) - v\rangle + \langle q, \Theta(u) + v - \Omega(u)\rangle.$$

Then problems (12) *and* (24) *are equivalent in the following sense*:

(i) *If $(u^*, v^*; p^* q^*)$ is a saddle point of $\mathscr{L}$ over $(\mathscr{U} \times \mathscr{C}) \times (\mathscr{C}^* \times \mathscr{C}^*)$, then $p^* = q^*$ (and of course $v^* = \Omega(u^*)$) and (u^*, p^*) is a saddle point of L.*

(ii) *Conversely, if (u^*, p^*) is a saddle point of L, then $(u^*, \Omega(u^*), p^*, p^*)$ is a saddle point of $\mathscr{L}$.*

Proof.

(i) From the right-hand inequality of the saddle point of $\mathscr{L}$, it is easy to conclude that necessarily $p^* = q^*$ and, of course, from the left-hand inequality that $v^* = \Omega(u^*)$, and then these inequalities reduce to those of the saddle point of L.

(ii) The proof of the converse statement is straightforward. □

Remark 1. This theorem appeals to the *global* theory of duality in that it speaks of saddle points of Lagrangian. Existence of a Lagrangian saddle point is a *sufficient* condition for existence of a solution to problems such as (12) or (24). There are also *necessary* first-order optimality conditions in the framework of a *local* theory of duality (involving Khun-Tucker multipliers in the differentiable case). Obviously, it is possible to state a result similar to Theorem 2 in this context.

3.2. A new coordination strategy for the IPP. Since we consider equality constraints only, and since we wish to remain in the context of convex programming, we deal only with affine constraints and we set $\Theta(u) = Du - d$ and $\Omega(u) = Eu$ as we did in Theorem 1.[8] The stationarity conditions for $\mathscr{L}$ can be expressed in the following way:

$$\text{(26)} \qquad \mathscr{L}'_u(u^*, v^*; p^*, q^*) = 0 \Leftrightarrow J'(u^*) + (D^* - E^*)q^* + E^* p^* = 0$$

$$\text{(27)} \qquad \mathscr{L}'_p(u^*, v^*; p^*, q^*) = 0 \Leftrightarrow Eu^* - v^* = 0$$

$$\text{(28)} \qquad \mathscr{L}'_v(u^*, v^*; p^*, q^*) = 0 \Leftrightarrow q^* - p^* = 0$$

[8] With Algorithm 4, it does not matter if we rather set $\Omega(u) = Eu - d$, as it does not matter if we add a linear function to K. With (24) or (30), that amounts to changing v into $v - d$.

$$\mathscr{L}'_q(u^*, v^*; p^*, q^*) = 0 \Leftrightarrow (D-E)u^* + v^* - d = 0. \tag{29}$$

As far as decomposition is concerned, we shall again assume that decompositions of $\mathscr{U}$ and $\mathscr{C}$ into subspaces are given and that E is block-diagonal with respect to these decompositions. To further simplify this introductory discussion, let us temporarily assume that J is additive. The decomposition idea behind the IPP can be viewed as that of dealing with u and p at the lower (subsystem) level and with v and q at the upper (coordination) level. Indeed, with our assumptions, and if v and q are fixed at some values, say v^k and q^k, the task of solving (26)-(27) splits into N independent tasks which can be interpreted as those of solving the following subproblems

$$i = 1, \cdots, N \begin{cases} \min\limits_{u_i} J_i(u_i) + \sum\limits_{j \neq i} \langle q_j^k, D_{ji}u_i \rangle + \langle q_i^k, (D_{ii} - E_i)u_i \rangle \\ \text{subject to } E_i u_i = v_i^k. \end{cases} \tag{30}$$

Let (u^{k+1}, p^{k+1}) denote an optimal solution. Then, the fixed point coordination strategy usually associated with the IPP uses (28) to update q, namely by setting $q^{k+1} = p^{k+1}$, and (29) to update v, that is, $v^{k+1} = (E-D)u^{k+1} + d$. This strategy may be improved by introducing under- or overrelaxation (according to whether the ρ_i's hereafter are smaller or larger than one)

$$\begin{aligned} v^{k+1} &= (1-\rho_1)v^k + \rho_1((E-D)u^{k+1} + d) \\ &= v^k - \rho_1(Du^{k+1} - d) \end{aligned} \tag{31}$$

$$\begin{aligned} q^{k+1} &= (1-\rho_2)q^k + \rho_2 p^{k+1} \\ &= q^k + \rho_2(p^{k+1} - q^k). \end{aligned} \tag{32}$$

At this point, the reader should remember our discussion of the introduction around (1)-(6). It results from that discussion that we can imagine the following alternative coordination strategy of a gradient or variational nature.

ALGORITHM 5 (ACP). *Knowing* (v^k, q^k), *compute* (u^{k+1}, p^{k+1}) *as a solution of* (30) *and update* (v, q) *by the gradient formulas*

$$v^{k+1} = v^k - \rho_1 \mathscr{L}'_v(u^{k+1}, v^k; p^{k+1}, q^k) = v^k - \rho_1(q^k - p^{k+1}) \tag{33}$$

$$q^{k+1} = q^k + \rho_2 \mathscr{L}'_q(u^{k+1}, v^k; p^{k+1}, q^k) = q^k + \rho_2(Du^{k+1} - d), \tag{34}$$

where ρ_1 *and* ρ_2 *are positive step lengths.*

The comparison of (31), (32) with (33), (34) reveals the important difference between these two strategies.

Remark 2. We have used the fact that $Eu^{k+1} = v^k$ (see (30)) in both (31) and (34). However, it is important to keep the term $-\langle q_i^k, E_i u_i \rangle$ in the cost function (30) even though the value of $E_i u_i$ is a priori known, for, otherwise, the value of p^{k+1} would be changed, and p^{k+1} is used in both (32) and (33).

3.3. The new strategy is a parallel Arrow–Hurwicz algorithm. A justification of the new coordination strategy comes from the study of the following functional

$$\Lambda(v, q) := \inf_u \sup_p \mathscr{L}(u, v; p, q). \tag{35}$$

Note that problem (24) is equivalent to finding $\inf_{u,v} \sup_{p,q} \mathscr{L}(u, v; p, q)$ (without any convexity assumption—this is a classical result in duality theory). Assuming that $\sup_q$ can be inverted with $\inf_u$, the problem reduces to finding $\inf_v \sup_q \Lambda(v, q)$ or the saddle

point of Λ if such a saddle point exists. Then Algorithm 5 is nothing but the Arrow-Hurwicz algorithm [10] in its parallel (rather than sequential) version in that v and q are updated at the same time instead of sequentially. All these facts are precisely stated in the following theorem.

THEOREM 3.

(i) *If there exists a saddle point* $(u^*, v^*; p^*, q^*)$ *of* $\mathscr{L}$, *then* (v^*, q^*) *is a saddle point of* Λ.

(ii) *If* J *is convex and if* Θ *and* Ω *are affine, then* Λ *is a convex-concave (or saddle) function.*

(iii) *If in the definition* (35) *of* Λ, *the* inf sup *is indeed a saddle point, and if the argument* $(\hat{u}(v, q), \hat{p}(v, q))$ *of this saddle point is unique, then* Λ *is differentiable and we have*

$$\begin{aligned}\Lambda'_v(v, q) &= \mathscr{L}'_v(\hat{u}(v, q), v; \hat{p}(v, q), q)\\ &= q - \hat{p}(v, q)\\ \Lambda'_q(v, q) &= \mathscr{L}'_q(\hat{u}(v, q), v; \hat{p}(v, q), q)\\ &= \Theta(\hat{u}(v, q)) + v - \Omega(\hat{u}(v, q)).\end{aligned}$$

Proof.

(i) We have the following general inequalities

$$\begin{aligned}\inf_{u,v}\sup_{p,q}\mathscr{L} &\geqq \inf_{v}\sup_{q}\inf_{u}\sup_{p}\mathscr{L}\\ &\geqq \sup_{q}\inf_{u,v}\sup_{p}\mathscr{L}\\ &\geqq \sup_{p,q}\inf_{u,v}\mathscr{L}.\end{aligned}$$

Since it is assumed that $\mathscr{L}$ does have a saddle point, the two extreme sides are equal. Then, the equality of the two inner sides means that Λ has a saddle point. The rest of the statement is easy to prove.

(ii) Let us introduce the intermediate functional

$$\lambda(u, v, q) := \sup_{p} \mathscr{L}(u, v; p, q).$$

Since $\mathscr{L}$ is *jointly* convex in (u, v), λ is also (jointly) convex in (u, v) as the upper hull of a family of convex functions. Since $\mathscr{L}$ is *jointly* concave in (p, q), λ is concave in q. This is a general result: if a function $f(x, y)$ is *jointly* concave (respectively, convex) in (x, y), the function $\varphi(y) := \sup_x f(x, y)$ (respectively, $\inf_x f(x, y)$) is concave (respectively, convex) in y. Also, for this latter reason, $\Lambda(v, q) = \inf_u \lambda(u, v, q)$ is convex in v. Finally, as the lower hull of a family of concave functions, it is concave in q.

(iii) This is a generalization of a result by Danskin [11] which states a similar result for either of the two functions $\varphi(y)$ introduced above. We skip the proof of this generalization. □

4. Decomposition/coordination algorithms derived from the APP and the ACP. In the same way as Algorithm 4 is an extension of Algorithm 2, we are going to propose an extension of Algorithm 5 above using the APP. We also propose several variants. We then study convergence issues.

4.1. General algorithms. The problem is to compute the saddle point of $\mathscr{L}$. Instead of (18), we choose the following auxiliary function[9]

$$\Phi(u, v; p, q) = K(u) + \frac{1}{2}\|v\|^2 - \frac{1}{2}\|q\|^2 \tag{36}$$

and we make the same kind of linear corrections as in (19). The way we put the superscripts k and $k+1$ hereafter translates the fact that we want to deal with (u, p) at the lower level and *then* with (v, q) at the upper level. Notice also that Φ does not directly depend on p. Actually, the term $\mathscr{N}(u, p) = \langle p, Eu\rangle$ of $\mathscr{L}$ should be considered as "additive" since E will be chosen block-diagonal and (u_i, p_i) will be dealt with simultaneously. Therefore we deal with $\mathscr{N}(u, p)$ as we did with the term $G(u)$ when obtaining (17). We set $\mathscr{M}(u, v; p, q) = \mathscr{L}(u, v; p, q) - \mathscr{N}(u, p)$. Finally, this leads us to calculate

$$\begin{cases} \Phi(u, v; p, q) + \varepsilon\mathscr{N}(u, p) \\ \qquad + \langle \varepsilon\mathscr{M}'_u(u^k, v^k; p^k, q^k) - \Phi'_u(u^k, v^k; p^k, q^k), u\rangle \\ \qquad + \langle \varepsilon\mathscr{M}'_p(u^k, v^k; p^k, q^k) - \Phi'_p(u^k, v^k; p^k, q^k), p\rangle \\ \qquad + \langle \rho_1\mathscr{M}'_v(u^{k+1}, v^k; p^{k+1}, q^k) - \Phi'_v(u^{k+1}, v^k; p^{k+1}, q^k), v\rangle \\ \qquad + \langle \rho_2\mathscr{M}'_q(u^{k+1}, v^k; p^{k+1}, q^k) - \Phi'_q(u^{k+1}, v^k; p^{k+1}, q^k), q\rangle. \end{cases} \tag{37}$$

The algorithm consists of computing the $\max_p \min_u$ of this expression, yielding (u^{k+1}, p^{k+1}), which can be interpreted as the solution of a constrained optimization problem, and then computing (v^{k+1}, q^{k+1}) by solving for the $\max_q \min_v$ which yields (33)-(34). We summarize this as follows.

ALGORITHM 6 (ACP+APP−PARALLEL). *Knowing* (u^k, v^k, p^k, q^k), *compute* (u^{k+1}, p^{k+1}) *as the solution of the following auxiliary problem*

$$\begin{cases} \min\limits_u K(u) + \langle \varepsilon J'(u^k) - K'(u^k), u\rangle + \varepsilon\langle q^k, (D-E)u\rangle \\ \text{subject to } \varepsilon(Eu - v^k) = 0 \end{cases} \tag{38}$$

and then update (v, q) *using formulas* (33)-(34).

Remark 3. It is important not to forget ε in factor of the constraint of (38) since otherwise p^{k+1} used in (33) would be differently scaled. Along the same line, we recall the second part of Remark 2 which still applies here. Finally, comparing (20) and (38), it is seen that Eu in (38) must not be identified with $\Omega(u)$ in (20) but rather with $\varepsilon\Omega(u)$.

As pointed out in Remark 2, we have used the fact that $Eu^{k+1} = v^k$ to simplify the update formula (34) of q.

From the decomposition point of view, whenever decompositions of $\mathscr{U}$ and $\mathscr{C}$ are given, if K—respectively, E—is chosen additive—respectively, block-diagonal—with respect to this (these) decomposition(s), then (38) splits into N independent subproblems.

We can imagine several other versions of the above algorithm. One corresponds to a *sequential* rather than a *parallel* algorithm in v and q, v being updated before q: this amounts to replacing v^k by v^{k+1} in the last term of (37).

[9] This is the usual way to get a gradient algorithm for v and q.

ALGORITHM 7 (ACP+APP−SEQUENTIAL−v BEFORE q). *In Algorithm* 6, *replace the update formula* (34) *for* q *by*

$$q^{k+1} = q^k + \rho_2((D-E)u^{k+1} + v^{k+1} - d). \tag{39}$$

Another sequential version is obtained by updating q before v: this amounts to replacing q^k by q^{k+1} in the next to last term of (37).

ALGORITHM 8 (ACP+APP−SEQUENTIAL−q BEFORE v). *In Algorithm* 6, *replace the update formula* (33) *for* v *by*

$$v^{k+1} = v^k + \rho_1(p^{k+1} - q^{k+1}). \tag{40}$$

See § 5.2 for a comparison of these two sequential versions.

Finally, we can imagine an *implicit* version which results from both modifications indicated above.

ALGORITHM 9 (ACP+APP−IMPLICIT). *In Algorithm* 6, *replace the update formulas* (33)-(34) *for* (v, q) *by the implicit formulas* (40) *and* (39) *which are equivalent to the following explicit form*

$$v^{k+1} = v^k + \frac{\rho_1}{1+\rho_1\rho_2}(p^{k+1} - q^k - \rho_2(Du^{k+1} - d)) \tag{41}$$

$$q^{k+1} = q^k + \frac{\rho_2}{1+\rho_1\rho_2}(Du^{k+1} - d + \rho_1(p^{k+1} - q^k)). \tag{42}$$

Indeed, there is another way to get this implicit algorithm directly. Before we explain this let us make the following remark.

Remark 4. It is equivalent to introduce ε, ρ_1 and ρ_2 as we did in (37), or to set $\varepsilon = \rho_1 = \rho_2 = 1$ in (37) but to redefine Φ (see (36)) as

$$\Phi(u, v; p, q) = \frac{1}{\varepsilon}K(u) + \frac{1}{2\rho_1}\|v\|^2 - \frac{1}{2\rho_2}\|q\|^2. \tag{43}$$

To get the parallel version, we defined $\mathcal{N}(u, p)$ as $\langle p, Eu\rangle$ on the basis of the fact that u and p were dealt with at the same level and thus a nonadditive term appearing in $\mathcal{L}$ could be preserved in the auxiliary problem. The same kind of reason can now be advocated for the pair (v, q) and the term $\langle q, v\rangle$ appearing in $\mathcal{L}$ (see (25)). Therefore, redefining $\mathcal{N}(u, v; p, q)$ as $\langle p, Eu\rangle + \langle q, v\rangle$ and again $\mathcal{M}$ as the complement of $\mathcal{N}$ to $\mathcal{L}$, we can use this observation in conjunction with Remark 4.1 above to get the implicit version directly from (37).

4.2. Convergence.

DEFINITION 1. We say that J is *strongly convex with constant* a if and only if $\exists a > 0$: $\forall u$, $\bar{u}$ and $\alpha \in [0, 1]$,

$$J(\alpha u + (1-\alpha)\bar{u}) \leqq \alpha J(u) + (1-\alpha)J(\bar{u}) - \frac{a}{2}\alpha(1-\alpha)\|u - \bar{u}\|^2. \tag{44}$$

If J is differentiable, it is equivalent to say that J' is strongly monotone with modulus a. Also, this property implies that

$$J(\bar{u}) \geqq J(u) + \langle J'(u), \bar{u} - u\rangle + \frac{a}{2}\|u - \bar{u}\|^2. \tag{45}$$

The Lipschitz property of J' with constant A, namely

$$\exists A > 0 : \|J'(\bar{u}) - J'(u)\| \leqq A\|\bar{u} - u\| \tag{46}$$

implies that

$$J(\bar{u}) \leqq J(u) + \langle J'(u), \bar{u} - u\rangle + \frac{A}{2}\|u - \bar{u}\|^2. \tag{47}$$

THEOREM 4. *We make the foliowing assumptions*:

- *J (respectively, K) is strongly convex with constant a (respectively, b) and differentiable with a Lipschitz derivative with constant A (respectively, B).*
- *D and E are linear continuous operators and E is onto.*

Then there exist a unique primal solution u^* to (12), *and a unique primal-dual solution (u^{k+1}, p^{k+1}) to* (38). *Moreover if ε is chosen in the open interval $(0, b/A)$, there exists an interval $(0, \bar{\rho}_1(\varepsilon))$ in which ρ_1 must be chosen, and then an interval $(0, \bar{\rho}_2(\varepsilon, \rho_1))$ in which ρ_2 must be chosen so that Algorithm 6 generates a sequence $\{u^k\}$ which converges to u^* (and consequently, $\{v^k\}$ converges to Eu^*). The sequences $\{p^k\}$ and $\{q^k\}$ are bounded and have the same cluster points (in the weak topology). Any such cluster point forms with u^* a saddle point of L. Finally, if D is also assumed to be onto, the dual solution p^* of* (12) *is unique and (p^k, q^k) (strongly) converges to (p^*, q^*).*

Comments. The exact expressions of the bounds $\bar{\rho}_1(\varepsilon)$ and $\bar{\rho}_2(\varepsilon, \rho_1)$ would be very involved as shown by the proof given in the appendix, but we can say that if ε tends to either end of its allowed interval, then $\bar{\rho}_1(\varepsilon)$ tends to 0. The same occurs to $\bar{\rho}_2(\varepsilon, \rho_1)$ if ε or ρ_1 approaches its bounds.

Concerning the sequential and the implicit versions (Algorithms 7, 8 and 9), essentially the same convergence theorems as the above can be stated and similarly proved.

5. Applications and numerical results. Before discussing the results of very simple numerical experiments, let us come back for a while to Takahara's algorithm and show how the new coordination strategy looks like in this particular instance.

5.1. Takahara's algorithm revisited. We are not going to make all the calculations, leaving them as an exercise to the reader, but we will only give the main indications. First of all, the variable u of the general theory must be identified with the pair (u, x) of § 2.1, $Du - d = 0$ is (8) (in the form $Fx + Gu - \dot{x} = 0$ with its given initial condition x_0), thus p is p, and of course $J(u)$ is (7). It is natural to choose $K(u)$ as the same integral cost but which retains only the block-diagonal part of Q and R. Finally, $Eu - v = 0$ and $Du - d + v - Eu = 0$ are the pair of equations (9) in that form.

Because of the connection of K with J, it is convenient to set $\varepsilon = 1$ (as we actually did in (30)). But it is not clear that the condition of Theorem 4, namely $\varepsilon < b/A$, does allow this value. Actually, it suffices that b be large enough so that $b > A$. This may be obtained by changing our previous choice of K, adding to it a term of the following form

$$\frac{\gamma}{2}\int_0^T \|u\|^2 + \|x\|^2\, dt \tag{48}$$

with γ large enough. With this at hand, subproblems (11) are unchanged,[10] except for the consequence of (48) which add terms $\gamma/2\int_0^T \|u - u^k\|^2 + \|x - x^k\|^2\, dt$ in the cost

[10] At stage k, set $v_i = v_i^k$ and likewise for μ_i and ν_i.

functions. Let $(u^{k+1}, x^{k+1}, p^{k+1})$ be the resulting solution. Then the new coordination strategy (Algorithm 6) updates μ_i^k and ν_i^k in the following way

$$i=1,\cdots,N\begin{cases} v_i^{k+1}=v_i^k+\rho_1(p_i^{k+1}-q_i^k) \\ q_i^{k+1}=q_i^k+\rho_2\left[\sum_{j\neq i}(F_{ij}x_j^{k+1}+G_{ij}u_j^{k+1})+v_i^k\right] \\ \mu_i^{k+1}=\sum_{j\neq i}(F_{ij}^*q_j^{k+1}+Q_{ij}x_j^{k+1}) \\ \nu_i^{k+1}=\sum_{j\neq i}(G_{ij}^*q_j^{k+1}+R_{ij}u_j^{k+1}). \end{cases}$$

With Algorithm 7, we must change v_i^k in the right-hand side of the second equation above into v_i^{k+1}. We let the reader imagine the other versions (Algorithms 8 and 9).

5.2. Numerical example. The following example is purposedly very simple so that it is possible to have a measure of performance which is independent of the initial conditions of iterations for the various algorithms we are going to compare. This is important since the dimensionality of the "state vector" of the iterations (the number of required initial conditions) is not the same for all of them. We consider quadratic cost functions and linear constraints so that the iterations can be put into the form of a linear system $z^{k+1}=Pz^k$ where z is the state vector, and P is a matrix depending on the convergence parameters ε, and (ρ_1, ρ_2) when appropriate. For all algorithms, we retained the best value of τ we have been able to obtain by the choice of convergence parameters as the measure of performance, where τ is the maximal modulus of eigenvalues of P.

We consider the following problem[11]

$$\min \frac{1}{2}\sum_{i=1}^{2}[\|x_i\|^2+\|u_i\|^2]$$

$$\text{subject to } u_i+\sigma x_j-x_i=0, \quad i,j=1,2, \quad j\neq i$$

where σ will serve us to make the interaction magnitude between the two subsystems more or less important. With respect to the general theory, $u=(u_1, u_2)$ must be identified with $((u_1, x_1), (u_2, x_2))$. We choose $K=J$ (as far as J is additive) and E as the block-diagonal part of D, that is

$$D=\begin{pmatrix}1 & -1 & 0 & \sigma\\ 0 & \sigma & 1 & -1\end{pmatrix} \quad \text{and} \quad E=\begin{pmatrix}1 & -1 & 0 & 0\\ 0 & 0 & 1 & -1\end{pmatrix}.$$

Notice that

$$DA^{-1}E^*+EA^{-1}D^*=\begin{pmatrix}4 & -2\sigma\\ -2\sigma & 4\end{pmatrix}$$

so that the condition (23) is not satisfied for $|\sigma|\geqq 2$.

For this example, we considered Algorithm 4 (fixed point coordination, without under- or overrelaxation scheme since this did not seem to improve things in this instance), Algorithm 6 (parallel Arrow-Hurwicz coordination strategy) and its sequential and implicit versions (Algorithms 7, 8, and 9). To save space, we do not give the expressions of matrix P for all these algorithms; they result from a straightforward application of the general theory. Let us just notice that the state vector z is 8-

[11] The solution is zero for all primal and dual variables but of course this does not matter as far as convergence is concerned.

dimensional with Algorithms 6, 7, 8, and 9 (z is the column vector whose entries are $(u_i, x_i, v_i, q_i)_{i=1,2}$)[12] whereas it is only 6-dimensional with Algorithm 4 (z is $(u_i, x_i, p_i)_{i=1,2}$). The numerical results summarized in Table 1 have been obtained using MATLAB on a Macintosh.

Several comments are in order. First, as predicted by theory, Algorithms 6–9 always converge, even for large interactions, although more and more slowly as interaction magnitude increases, whereas Algorithm 4 fails to converge for $\sigma \geqq 2$. Second, as it might also be expected, the sequential versions appear to be faster than the parallel one and the implicit version is the best of all.[13] Third, the same performance is obtained with both sequential versions whose results have been displayed in the same column of the table. We shall come back to this point later on. Finally, the "one-level" algorithm appears to be better than the other algorithms for small or moderate interaction magnitude, except for the implicit version, at least for the interaction magnitudes investigated above. This confirms our past experience with Algorithm 4 which always performed well for reasonably sized interactions. Indeed, there is a theoretical explanation to this observation. As σ goes to zero, since we chose E as the block-diagonal part of D, E and D tend to be identical. Moreover, since in our example, K and J are also identical, it is obvious that by picking $\varepsilon = \rho = 1$ in (20), Algorithm 4 is immediately stationary, which means that τ tends to zero with σ. A similar statement *cannot* be made for either Algorithm 6 or its sequential or implicit versions. Therefore, the fixed point coordination strategy should be preferred for weakly coupled subproblems. However, in our example, the *implicit* Arrow-Hurwicz coordination strategy is already better for $\sigma = 0.5$ (this is not the case with the other versions).

Let us now come back to the comparison of the two sequential versions (Algorithms 7 and 8). Since τ can be properly defined only when the recurrence is linear, that is, when K and J are quadratic, we limit ourselves to this case. We come back to the notations used in Theorem 1 and we assume that $b = 0$ and $d = 0$ without loss of

TABLE 1.

Each entry of the table reads as

	ε	
	ρ_1	τ
	ρ_2	

σ	Algorithm 4	Algorithm 6	Algorithms 7 & 8	Algorithm 9
0.5	1.00 none 0.3536 none	0.80 1.20 0.8013 0.10	1.00 2.10 0.5462 0.50	1.00 2.50 0.2500 10.00
1.0	1.00 none 0.7071 none	0.50 1.00 0.8716 0.10	0.80 1.70 0.6468 0.40	1.00 2.10 0.4095 1.10
2.0	does not converge	0.50 1.00 0.8851 0.05	0.50 1.10 0.8139 0.20	1.00 1.00 0.5774 0.50
5.0	does not converge	0.50 1.20 0.9148 0.05	1.00 1.20 0.8216 0.05	1.00 1.20 0.7038 0.05

[12] Indeed, $(p_i)_{i=1,2}$ must also be computed at each iteration but need not be stored for the next iteration.

[13] Another advantage of the implicit version which does not appear in the table is that the value of the best τ seems to be less sensitive to those of ε, ρ_1 and ρ_2 than with the other algorithms.

generality (the optimal primal and dual solutions are thus null). The recurrence can be put into the form $My^{k+1} = Ny^k$ where y is the column vector with entries (u, p, v, q). We want to prove that τ (indeed all the eigenvalues) is (are) the same with both sequential versions. An eigenvalue λ and an eigenvector y of $M^{-1}N$ obey the equation $(\lambda M - N)y = 0$. It suffices to prove that the expressions $\det(N - \lambda M)$ are formally identical for both sequential versions. For Algorithm 7, we have

$$\det(N_1 - \lambda M_1) = \begin{pmatrix} (1-\lambda)B - \varepsilon A & -\lambda\varepsilon E^* & 0 & -\varepsilon(D^* - E^*) \\ -\lambda\varepsilon E & 0 & \varepsilon I & 0 \\ 0 & \lambda\rho_1 I & (1-\lambda)I & -\rho_1 I \\ \lambda\rho_2(D-E) & 0 & \lambda\rho_2 I & (1-\lambda)I \end{pmatrix}$$

where I is the identity operator, and for Algorithm 8 we have

$$\det(N_2 - \lambda M_2) = \begin{pmatrix} (1-\lambda)B - \varepsilon A & -\lambda\varepsilon E^* & 0 & -\varepsilon(D^* - E^*) \\ -\lambda\varepsilon E & 0 & \varepsilon I & 0 \\ 0 & \lambda\rho_1 I & (1-\lambda)I & -\lambda\rho_1 I \\ \lambda\rho_2(D-E) & 0 & \rho_2 I & (1-\lambda)I \end{pmatrix}.$$

It is easy to check that, if Q_λ denotes the matrix diag $(I, I, \varepsilon I/\lambda\rho_1, -\varepsilon/\lambda\rho_2)$, $Q_\lambda(N_2 - \lambda M_2)$ is the transpose of $Q_\lambda(N_1 - \lambda M_1)$. Hence both have the same determinant, which proves the desired result since $\det Q_\lambda$ is not identically null.

6. Conclusion. We have proposed a new coordination strategy under several versions (parallel, sequential, implicit) for such decomposition techniques as Takahara's algorithm, the IPP, or one-level algorithms (in the framework of the APP), all these decomposition methods falling into the same category. Because the convergence conditions stated for this new coordination strategy avoid some prerequisite conditions involved in the convergence proof of one-level algorithms, we claim that this new coordination scheme is of broader applicability and that it is particularly suited for subproblems having interactions of large magnitude. This fact has been confirmed by some simple numerical experiments. However, we observed that for weak interactions the fixed point strategy may be competitive. Also, this latter strategy is easier to implement since only one parameter ε has to be tuned instead of three for the new scheme. Some hints are given at the end of the convergence proof in the following appendix concerning the choice of the latter.

The new coordination strategy is indeed an Arrow-Hurwicz algorithm for two auxiliary variables (one primal, the other dual) artificially introduced by some manipulation of the original constrained optimization problem. We called this manipulation "the Auxiliary Constraint Principle" and we believe that the interest of this manipulation is broader than the particular use made here. This will perhaps be shown by future applications. About the Arrow-Hurwicz scheme, we completely studied the parallel version, but the numerical experiments have shown that the sequential version, when the primal variable is updated before the dual, which is more classical, is also more efficient. Another sequential version when the dual variable is first updated yields the same performance, at least in the case of linear iterations (quadratic objective functions and affine constraints). We also proposed an implicit version which seems to be the best of all. For the sequential and implicit versions, we can state convergence theorems and give proofs which are similar to those given for the parallel version. However, these theorems and proofs do not reflect the improvement brought by the sequential and implicit over the parallel version. This point can thus be considered an open problem.

About the directions of future research in this area, we may mention the following. We made assumptions ensuring the differentiability of the saddle function Λ introduced in § 3.3 so that it was natural to use step lengths ρ_1 and ρ_2 that we call "large" as opposed to "small" steps, the latter being steps which must tend to zero as those used in some subgradient algorithms (see [5] for example). Also ε was a "large" step because J and Θ were assumed to be differentiable. The other assumptions that contribute to the differentiability of Λ are the strong convexity of J, the assumption that all the constraints considered are affine *equality* constraints (excluding in particular the presence of a feasible subset U^f which would not be equal to the whole space $\mathcal{U}$ as in (16)) and finally the assumption that E is onto. As a matter of fact, these assumptions all together guarantee uniqueness of $\hat{u}$ and $\hat{p}$ introduced in Theorem 3. Therefore, by relaxing one of these assumptions or another, either $\hat{u}$ or $\hat{p}$ (or both) would not be necessarily unique, meaning that Λ would not be differentiable in either v or q (or both). Then, we should consider algorithms mixing "large" and "small" steps ε, ρ_1 and ρ_2 (see [5] for examples of such algorithms). Forthcoming papers will discuss some of these possibilities.

Appendix: proof of Theorem 4. Existence of a saddle point of the respective Lagrangians associated with (12) and (38) are easily derived from the assumptions. Notice in particular that (45) and the same kind of inequality for K imply that the corresponding cost functions increase at least quadratically at infinity. They also imply that u^* and u^{k+1} are uniquely defined. Uniqueness of p^{k+1} (and similarly of p^*) is derived from the assumption that E (respectively, D) is onto in the following way. Necessary and sufficient optimality conditions for (38)—respectively, (12)—are

$$K'(u^{k+1}) - K'(u^k) + \varepsilon(J'(u^k) + D^*q^k + E^*(p^{k+1} - q^k)) = 0 \tag{49}$$

$$Eu^{k+1} = v^k, \tag{50}$$

respectively,

$$J'(u^*) + D^*p^* = 0 \tag{51}$$

$$Du^* = d. \tag{52}$$

Considering for instance (49), multiply it by E. Since E is onto, EE^* has a continuous inverse. Hence we get

$$p^{k+1} = q^k - (EE^*)^{-1}E\left[\frac{1}{\varepsilon}(K'(u^{k+1}) - K'(u^k)) + J'(u^k) + D^*q^k\right] \tag{53}$$

from which we see that p^{k+1} is uniquely defined since u^{k+1} is. The same applies to p^* using (51) and the inverse of DD^* if D is assumed to be onto.

The principle of the proof consists of studying the behaviour of some "Lyapounov function" along the iterations of the algorithm, from which convergence conclusions will be reached. This Lyapounov function is defined by the following quantity (at stage k)

$$\begin{cases} \phi^k := \underbrace{(1/\varepsilon)(K(u^*) - K(u^k) - \langle K'(u^k), u^* - u^k\rangle) - (a/2)\|u^* - u^k\|^2}_{\phi_1^k} \\ \quad + \underbrace{(1/2\rho_1)\|v^* - v^k\|^2}_{\phi_2^k} + \underbrace{(1/2\rho_2)\|q^* - q^k\|^2}_{\phi_3^k} + \beta(\varepsilon/2\rho_1)\underbrace{\|\hat{p}^k - q^k\|^2}_{\phi_4^k} \end{cases} \tag{54}$$

where β is a positive constant to be chosen later and $\hat{p}^k$ (together with $\hat{u}^k$) is *uniquely* defined by the equations

$$J'(\hat{u}^k) + D^*q^k + E^*(\hat{p}^k - q^k) = 0 \tag{55}$$

$$E\hat{u}^k - v^k = 0. \tag{56}$$

Indeed $\hat{u}$ and $\hat{p}$ are those already encountered in Theorem 3 when defining Λ. Notice that ϕ_1^k is larger than $(b/\varepsilon - a)/2\|u^* - u^k\|^2$ (from (45) applied to K) and this quantity is nonnegative after the condition imposed on ε and the fact that $a \leqq A$. Therefore $\phi^k \geqq 0$.

Let us now calculate the variations $\phi_i^{k+1} - \phi_i^k$ for $i = 1, \cdots, 4$.

$$\phi_1^{k+1} - \phi_1^k = \underbrace{(1/\varepsilon)(K(u^k) - K(u^{k+1}) - \langle K'(u^k), u^k - u^{k+1}\rangle)}_{a_1}$$
$$+ \underbrace{(1/\varepsilon)(\langle K'(u^k) - K'(u^{k+1}), u^* - u^{k+1}\rangle)}_{a_2}$$
$$- \frac{a}{2}(\|u^{k+1} - u^*\|^2 - \|u^k - u^*\|^2).$$

Then $a_1 \leqq -(b/2\varepsilon)\|u^{k+1} - u^k\|^2$ and from (49) and (51)

$$a_2 = \underbrace{\langle J'(u^k) - J'(u^*), u^* - u^{k+1}\rangle}_{b_1}$$
$$+ \underbrace{\langle D^*(q^k - q^*), u^* - u^{k+1}\rangle}_{b_2} + \underbrace{\langle E^*(p^{k+1} - q^k), u^* - u^{k+1}\rangle}_{b_3}.$$

By repeated uses of (45) and (47), we get that

$$b_1 \leqq \frac{A}{2}\|u^{k+1} - u^k\|^2 - \frac{a}{2}(\|u^k - u^*\|^2 + \|u^{k+1} - u^*\|^2).$$

From (33) we get that

$$\phi_2^{k+1} - \phi_2^k = -\langle q^k - p^{k+1}, v^k - v^*\rangle + \frac{1}{2\rho_1}\|v^{k+1} - v^k\|^2$$

and we notice that the first term in the right-hand side is nothing but $-b_3$. Similarly, from (34) we derive that

$$\phi_3^{k+1} - \phi_3^k = \langle q^k - q^*, D(u^{k+1} - u^*)\rangle + \frac{\rho_2}{2}\|D(u^{k+1} - u^*)\|^2$$

and the first term in the right-hand side is equal to $-b_2$. Summarizing the calculations made so far, and setting $d := \|D\|$, we have that

$$\sum_{i=1}^{3}(\phi_i^{k+1} - \phi_i^k) \leqq \left(\frac{A}{2} - \frac{b}{2\varepsilon}\right)\|u^{k+1} - u^k\|^2 + \left(\frac{\rho_2}{2}d^2 - a\right)\|u^{k+1} - u^*\|^2$$
$$+ \underbrace{(1/2\rho_1)\|v^{k+1} - v^k\|^2}_{c}. \tag{57}$$

From (56) and setting $e := \|E\|$, we have that

$$c = \frac{1}{2\rho_1}\|E(\hat{u}^{k+1} - \hat{u}^k)\|^2 \leqq \frac{e^2}{2\rho_1}\|\hat{u}^{k+1} - \hat{u}^k\|^2. \tag{58}$$

Before considering the last variation $\phi_4^{k+1} - \phi_4^k$, let us establish some inequalities that will prove useful. For the sake of brevity, let $r^k := \hat{p}^k - q^k$ (notice that $r^k = -\Lambda_v'(v^k, q^k)$ from Theorem 3). Multiplying (55) by E, we get that

$$r^k = -(EE^*)^{-1}E(J'(\hat{u}^k) + D^*q^k). \tag{59}$$

We set $\omega := \|(EE^*)^{-1}E\|$. Then

$$\begin{aligned}\|r^{k+1}-r^k\| &\leqq \omega(A\|\hat{u}^{k+1}-\hat{u}^k\|+d\|q^{k+1}-q^k\|)\\ &\leqq \omega(A\|\hat{u}^{k+1}-\hat{u}^k\|+\rho_2 d^2\|u^{k+1}-u^*\|)\end{aligned} \tag{60}$$

using (34).

Multiplying the difference of (55) expressed for index $k+1$ and for index k by $\hat{u}^k-\hat{u}^{k+1}$ yields

$$\begin{aligned}\langle r^{k+1}-r^k, v^{k+1}-v^k\rangle &= \langle E^*(r^{k+1}-r^k), \hat{u}^{k+1}-\hat{u}^k\rangle\\ &= \langle J'(\hat{u}^{k+1})-J'(\hat{u}^k)+D^*(q^{k+1}-q^k), \hat{u}^k-\hat{u}^{k+1}\rangle\\ &\leqq -a\|\hat{u}^{k+1}-\hat{u}^k\|^2+\rho_2 d^2\|u^{k+1}-u^*\|\cdot\|\hat{u}^{k+1}-\hat{u}^k\|\end{aligned} \tag{61}$$

using the strong monotony of J' and (34) again.

Consider the difference of (49) and of (55), the latter multiplied by ε. Multiplying this difference by $\hat{u}^k-u^{k+1}$ and noticing that $E\hat{u}^k = Eu^{k+1} = v^k$, it yields

$$\begin{aligned}\varepsilon a\|\hat{u}^k-u^k\|^2 &\leqq \varepsilon\langle J'(u^k)-J'(\hat{u}^k), u^k-\hat{u}^k\rangle+\langle K'(u^{k+1})-K'(u^k), u^{k+1}-u^k\rangle\\ &= \varepsilon\langle J'(u^k)-J'(\hat{u}^k), u^k-u^{k+1}\rangle+\langle K'(u^{k+1})-K'(u^k), \hat{u}^k-u^k\rangle\\ &\leqq (B+\varepsilon A)\|u^{k+1}-u^k\|\cdot\|\hat{u}^k-u^k\|\end{aligned}$$

from which it comes that

$$\|\hat{u}^k-u^k\| \leqq \frac{B+\varepsilon A}{\varepsilon a}\|u^{k+1}-u^k\|. \tag{62}$$

Consider now the difference of (53) and (59). We get that

$$\begin{aligned}\|p^{k+1}-\hat{p}^k\| &= \|p^{k+1}-q^k-r^k\|\\ &= \left\|-(EE^*)^{-1}E\left[\frac{1}{\varepsilon}(K'(u^{k+1})-K'(u^k))+J'(u^k)-J'(\hat{u}^k)\right]\right\|\\ &\leqq \omega\left(\frac{B}{\varepsilon}\|u^{k+1}-u^k\|+A\|\hat{u}^k-u^k\|\right)\\ &\leqq \frac{\omega M_\varepsilon}{\varepsilon}\|u^{k+1}-u^k\|\end{aligned} \tag{63}$$

where we have used (62) and we have set $M_\varepsilon := B+(A/a)(B+\varepsilon A)$.

Now, we calculate the variation

$$\begin{aligned}\phi_4^{k+1}-\phi_4^k &= \|r^{k+1}\|^2-\|r^k\|^2\\ &= \|r^{k+1}-r^k\|^2+2\underbrace{\langle r^k, r^{k+1}-r^k\rangle}_{h}.\end{aligned}$$

But

$$\begin{aligned}h &= \langle\hat{p}^k-p^{k+1}+p^{k+1}-q^k, r^{k+1}-r^k\rangle\\ &= \langle\hat{p}^k-p^{k+1}+\frac{v^{k+1}-v^k}{\rho_1}, r^{k+1}-r^k\rangle\end{aligned}$$

from (33). Now, using (60), (61) and (63), it comes that

$$\phi_4^{k+1}-\phi_4^k \leqq \omega^2(A\|\hat{u}^{k+1}-\hat{u}^k\|+\rho_2 d^2\|u^{k+1}-u^*\|)^2$$
$$+\frac{2\omega^2 M_\varepsilon}{\varepsilon}\|u^{k+1}-u^k\|(A\|\hat{u}^{k+1}-\hat{u}^k\|+\rho_2 d^2\|u^{k+1}-u^*\|)$$
$$+\frac{2}{\rho_1}(-a\|\hat{u}^{k+1}-\hat{u}^k\|^2+\rho_2 d^2\|u^{k+1}-u^*\|\cdot\|\hat{u}^{k+1}-\hat{u}^k\|).$$

Finally, adding inequality (57) to the above multiplied by $\beta(\varepsilon/2\rho_1)$, we can bound the total variation of ϕ^k (see (54)) as follows:

$$\phi^{k+1}-\phi^k \leqq -\tfrac{1}{2}(\vec{V}^k)^* \mathscr{A}(\varepsilon,\rho_1,\rho_2)\vec{V}^k \tag{64}$$

where we have set

$$(\vec{V}^k)^* := (\|u^{k+1}-u^k\|, \|\hat{u}^{k+1}-\hat{u}^k\|, \|u^{k+1}-u^*\|)$$

and

$$\mathscr{A}=\begin{pmatrix} b/\varepsilon-A & -\beta\omega^2 A M_\varepsilon/\rho_1 & -\rho_2\beta\omega^2 d^2 M_\varepsilon/\rho_1 \\ -\beta\omega^2 A M_\varepsilon/\rho_1 & 2\varepsilon\beta a/\rho_1^2-(e^2+\varepsilon\beta\omega^2A^2)/\rho_1 & -\varepsilon\rho_2\beta d^2(1+\rho_1\omega^2 A)/\rho_1^2 \\ -\rho_2\beta\omega^2 d^2 M_\varepsilon/\rho_1 & -\varepsilon\rho_2\beta d^2(1+\rho_1\omega^2 A)/\rho_1^2 & 2a-\rho_2 d^2(1+\varepsilon\rho_2\beta\omega^2 d^2/\rho_1) \end{pmatrix}.$$

Suppose that we can choose ε, ρ_1 and ρ_2 in such a way that $\mathscr{A}$ is positive definite. Then, the sequence $\{\phi^k\}$ is nonincreasing. Since, as shown earlier, it is also bounded from below (by zero), it must converge and the difference of two successive terms must converge to zero. With (64), this proves that $\vec{V}^k$, and in particular $\|u^{k+1}-u^*\|$, also converge to zero. Since E is continuous, v^k converges to v^* and $v^{k+1}-v^k$ converges to zero, hence, from (33), $p^{k+1}-q^k$ also goes to zero. Therefore, a cluster point of the sequence $\{q^k\}$ (in either the strong or the weak topology), if any, is also a cluster point of $\{p^k\}$. Observe that since ϕ^k is nonincreasing, it is bounded, and thus $\{q^k\}$ is bounded and does have weak cluster points. Let $\bar{q}$ be such a cluster point. Considering (49) and passing to the limit, it is not difficult to show that the pair $(u^*, \bar{q})$ satisfies the necessary and sufficient conditions (13).

Finally, if D is onto, hence DD^* is invertible, from the difference of (49) and (51), the latter multiplied by ε, this difference being further multiplied by $(DD^*)^{-1}D$, it is easy to conclude that q^k, and thus p^k, converge to p^* (which is unique).

For the proof to be complete, it remains to show how the convergence parameters can be chosen to ensure the positive definiteness of $\mathscr{A}$. This property translates into the following three conditions:

(i) $m_1(\varepsilon) := b/\varepsilon - A > 0$

(ii) $m_2(\varepsilon,\rho_1) := [m_1(\varepsilon)(2\varepsilon\beta a-\rho_1(e^2+\varepsilon\beta\omega^2A^2))-\beta^2\omega^4A^2M_\varepsilon^2]/\rho_1^2 > 0$

(iii) $\det \mathscr{A}(\varepsilon,\rho_1,\rho_2) > 0$.

Condition (i) is equivalent to the condition imposed to ε in Theorem 4. Condition (ii) first imposes that β be chosen in the open interval $(0, 2\varepsilon m_1(\varepsilon)a/\omega^4A^2M_\varepsilon^2)$, say $\beta = \varepsilon m_1(\varepsilon)a/\omega^4A^2M_\varepsilon^2)$ to fix ideas. Then ρ_1 must belong to the open interval $(0, \bar{\rho}_1(\varepsilon))$ where

$$\bar{\rho}_1(\varepsilon)=\frac{\varepsilon(b-\varepsilon A)a^2}{(\varepsilon(b-\varepsilon A)a+e^2\omega^2M_\varepsilon^2)\omega^2A^2}.$$

Notice that $\bar{\rho}_1(\varepsilon)$ goes to zero if ε tends to either zero or b/A. Finally, once ε and ρ_1 have been fixed at admissible values, observe that $\mathscr{A}$ becomes a block-diagonal positive

definite matrix if $\rho_2 = 0$. Of course this null value is not allowed since we manipulated $1/\rho_2$ in the expression of ϕ. But, by continuity, it is clear that there exists an open interval $(0, \bar{\rho}_2(\varepsilon, \rho_1))$ in which ρ_2 may lie while $\mathscr{A}$ remains positive definite. Unfortunately, the expression of this upper bound yielded by condition (iii) is very involved. But it should be clear that this $\bar{\rho}_2$ tends to zero if either $m_1(\varepsilon)$ or $m_2(\varepsilon, \rho_1)$ does so, that is, if ε or ρ_1 approaches zero or its upper bound.

Acknowledgment. The idea of the Arrow-Hurwicz coordination strategy occurred for the first time during a conversation of the first author with Professor Philippe Mahey of the Catholic University of Rio de Janeiro, Brazil, while the latter was visiting Fontainebleau in February 1984. His contribution is gratefully acknowledged.

POSITIVE PROPER EFFICIENT POINTS AND RELATED CONE RESULTS IN VECTOR OPTIMIZATION THEORY*

JERALD P. DAUER† AND RICHARD J. GALLAGHER‡

Abstract. Positive proper efficient points are defined as solutions of appropriate linear scalar optimization problems. A geometric characterization of positive proper efficient points is given as well as conditions under which the set of positive proper efficient points is dense in the set of all efficient points. It is shown that these results are applicable in the normed vector lattices $C[a, b]$, l^p, and L^p for $1 \leqq p \leqq \infty$, and that previous related results, which required the ordering cone to have a compact or weak-compact base, are not applicable in many normed vector lattices, including $C[a, b]$, l^p, and L^p for $1 \leqq p \leqq \infty$.

Key words. vector optimization, scalarization, positive proper efficient points, normed vector lattice

AMS(MOS) subject classifications. 90C31, 46A55

1. Introduction. One important problem in vector optimization theory is to identify the efficient points of a set A that are solutions of a scalar optimization problem

$$\underset{y \in A}{\text{maximize}} f(y)$$

where f is a continuous linear functional that is strictly positive on the ordering cone. We will refer to such efficient points as positive proper efficient points.

Many authors have obtained results on "proper" efficient points (e.g., see [3]-[5], [9], [14], [16], [22]). An attempt by Hurwicz [16] to give a geometric characterization of positive proper efficient points motivates the approach in § 2, where we first obtain a necessary and sufficient condition that there exists continuous linear functionals that are strictly positive on the ordering cone. We then use this condition to characterize positive proper efficient points. This characterization applies in very general settings. In particular, it does not require the space to be locally convex, and it does not require the ordering cone to have a compact or weak-compact base (assumptions used by earlier authors [4], [5], [9]). In § 3 we examine the restrictiveness of the compactness and weak-compactness assumptions on the base. In particular, we show that the positive cones (i.e., the nonnegative orthants) in the normed vector lattices $C[a, b]$, l^p, and $L^p(\mathbb{R})$, $1 \leqq p \leqq \infty$, do not have compact or weak-compact bases; and moreover, the positive cones in l^p and $L^p(\mathbb{R})$, $1 < p < \infty$, do not even have bounded bases.

A second optimization problem involves the density of the set of positive proper efficient points in the set of all efficient points. This problem has been studied by Arrow, Barankin, and Blackwell [2], Hartley [15], Borwein [5], Dauer and Saleh [9], and Jahn [17]. However, none of these density results are applicable in the normed vector lattices $C[a, b]$, l^p, and L^p, $1 \leqq p \leqq \infty$. Radner [24], in considering the problem of efficient prices for infinite horizon production systems, obtained such a density result for the space l^∞ ordered by the nonnegative orthant. In § 4 we generalize the result of Radner to obtain a density result for many normed vector lattices including the spaces $C[a, b]$, l^p, and L^p, $1 \leqq p \leqq \infty$. Section 5 is devoted to further investigating spaces and cones satisfying the hypotheses of this density theorem. In particular, it is shown that the theorem can be applied in any reflexive normed vector lattice.

Throughout the paper the term topological vector space will mean a real Hausdorff topological vector space and will be denoted by $\mathcal{Y}$. Also, the notation for the spaces $C[a, b]$, $B[a, b]$, c, c_0, l^p, and L^p follow those used in Dunford and Schwartz [10].

2. Positive proper efficient points. Let $\mathcal{Y}$ be a (real Hausdorff) topological vector space. A subset K of $\mathcal{Y}$ is called a *cone* if $\alpha K \subseteq K$ for all $\alpha \geqq 0$. If, in addition, $K \cap (-K) = \{\theta\}$, where θ denotes the zero vector in $\mathcal{Y}$, then K is said to be a *pointed cone*. A pointed convex cone K in $\mathcal{Y}$ induces a partial ordering on $\mathcal{Y}$ by the association

$$x \leqq y \quad \text{if and only if } y - x \in K.$$

An element f in the topological dual $\mathcal{Y}^*$ of $\mathcal{Y}$ is said to be *positive* if $f(k) \geqq 0$ for all $k \in K$ and is said to be *strictly positive* if $f(k) > 0$ for all $k \in K \setminus \{\theta\}$. For convenience we use the notation

$$K^+ = \{f \in \mathcal{Y}^* : f(k) \geqq 0 \text{ for all } k \in K\},$$

$$K^{+i} = \{f \in \mathcal{Y}^* : f(k) > 0 \text{ for all } k \in K \setminus \{\theta\}\}.$$

Note that K^{+i} is not necessarily the interior of K^+. In fact, if K is the nonnegative orthant in l^p, $1 < p < \infty$, then K^+ has empty interior and yet K^{+i} is nonempty. Also note that K^{+i} may be empty. For example, if $\mathcal{Y} = B[a, b]$, the set of all bounded functions on $[a, b]$, and

$$K = \{y \in B[a, b] : y(t) \geqq 0 \text{ for all } t \in [a, b]\},$$

then K^{+i} is empty [23, p. 27]. Proposition 2.1 gives a necessary and sufficient condition for K^{+i} to be nonempty, and Remark 2.2 further discusses conditions for K^{+i} to be nonempty. We first specify some notation and remind the reader of a definition.

If A is a subset of $\mathcal{Y}$, we denote the closure of A by $\operatorname{cl}(A)$ and denote the smallest convex cone containing A by $\operatorname{cone}(A)$. If A is convex, then $\operatorname{cone}(A) = \{\lambda a : \lambda \geqq 0, a \in A\}$. A cone K is said to have a *base* B if B is convex, $\theta \notin \operatorname{cl}(B)$ and $K = \operatorname{cone}(B)$. A based cone is necessarily pointed and convex.

The following proposition characterizes cones with K^{+i} nonempty in terms of an open generator for the cone.

PROPOSITION 2.1. *Let $\mathcal{Y}$ be a topological vector space and let K be a convex cone in $\mathcal{Y}$. Then K^{+i} is nonempty if and only if there exists an open convex set U in $\mathcal{Y}$ satisfying*

(i) $\theta \notin U$; *and*

(ii) $K \subseteq \operatorname{cone}(U)$.

Proof. If K^{+i} is nonempty take any $f \in K^{+i}$ and define $U = \{y \in \mathcal{Y} : f(y) > 0\}$. Then U is an open convex set satisfying (i) and (ii).

Conversely, suppose U is an open convex set satisfying (i) and (ii). Since $\theta \notin U$ there exists $f \in \mathcal{Y}^*$ such that $f(\theta) < f(u)$ for all $u \in U$ (e.g., see [25, p. 58]). Thus $f(u) > 0$ for all $u \in U$. From (ii) it follows that $f(k) > 0$ for all $k \in K \setminus \{\theta\}$. Thus $f \in K^{+i}$. □

Remark 2.2. It is easy to see that if K^{+i} is nonempty, then K must be pointed. Moreover, if K is convex and K^{+i} is nonempty then K is based. Indeed, let $f \in K^{+i}$ and define $B = \{y \in \mathcal{Y} : f(y) = 1\} \cap K$; then B is a base for K. In locally convex spaces the converse is also true. That is, if K is a based cone, then K^{+i} is nonempty. To see this, suppose B is a base for K. Since $\theta \notin \operatorname{cl}(B)$ there exists an open convex neighborhood V of θ such that $\theta \notin B + V$. Thus $B + V$ satisfies (i) and (ii) in Proposition 2.1, and so K^{+i} is nonempty.

It should also be remarked that Krein and Rutman [21, Thm. 2.1] and Klee [20, Thm. 2.7] have shown that if $\mathcal{Y}$ is a separable normed space and K is a closed pointed convex cone then K^{+i} is nonempty.

We now turn our attention to concepts in vector optimization theory. We begin by reviewing the definition of an efficient point and defining a special class of efficient points that are the focus of this work.

DEFINITION 2.3. Let $A \subseteq \mathcal{Y}$. A point $a_0 \in A$ is said to be an *efficient* (maximal, nondominated, Pareto-optimal) *point* of A if $(A - \{a_0\}) \cap K = \{\theta\}$.

DEFINITION 2.4. Let $A \subseteq \mathcal{Y}$. A point $a_0 \in A$ is said to be a *positive proper efficient point* of A if there exists some $f \in K^{+i}$ such that $f(a_0) \geqq f(a)$ for all $a \in A$.

We will denote the efficient points of a set A by $E(A)$ and the positive proper efficient points of A by Pos (A). It is an easy exercise to show that Pos $(A) \subseteq E(A)$. Also note that if A is compact and K^{+i} is nonempty, then Pos (A) is nonempty; hence $E(A)$ is nonempty. Though this fact is easy to show, the proof that $E(A)$ is nonempty for A compact requires a more elaborate argument involving Zorn's Lemma if we do not assume K^{+i} is nonempty [6].

A few remarks concerning the notion of positive proper efficiency are in order. In both finite- and infinite-dimensional spaces many notions of "proper" efficiency have been proposed [3, p. 234], [4, p. 57], [14, p. 618], [16, p. 89], [17, p. 1003], [22, p. 488]. See [5], [9], and [27] for comparisons of the various definitions. In Hurwicz [16], Borwein [4], and Benson [3] these definitions are motivated and defined geometrically, and it is shown that Pos (A) is a subset of the set of "proper" efficient points. Moreover, the notions of proper efficiency introduced by Borwein and Benson are equivalent to positive proper efficiency when A is convex and the ordering cone has a weak-compact base [5, Thm. 1]. Since our interest is in the set Pos (A), we give the following equivalence between positive proper efficient points and certain open generators for the cone. The result is applicable in a very general setting. In particular, it does not require the ordering cone to be weak-compact based, an assumption that will be discussed in § 3.

THEOREM 2.5. *Let $\mathcal{Y}$ be a topological vector space, let K be a pointed convex cone in $\mathcal{Y}$, and let $A \subseteq \mathcal{Y}$. A point $a_0 \in A$ is a positive proper efficient point of A if and only if there exists an open convex set U in $\mathcal{Y}$ such that*

(i) $K \subseteq \text{cone}\,(U)$; *and*

(ii) $\text{cone}\,(A - \{a_0\}) \cap U = \varnothing$.

Proof. Suppose a_0 is a positive proper efficient point of A. Then there exists $f \in K^{+i}$ such that $f(a_0) \geqq f(a)$ for all $a \in A$. Let $U = \{y \in \mathcal{Y}: 1 < f(y) < 2\}$. Then U is an open convex set satisfying $K \subseteq \text{cone}\,(U)$. Now if $a \in A$, then $f(a - a_0) \leqq 0$. Thus

$$A - \{a_0\} \subseteq \{y \in \mathcal{Y}: f(y) \leqq 0\}.$$

Since the latter set is a convex cone, we have that

$$\text{cone}\,(A - \{a_0\}) \subseteq \{y \in \mathcal{Y}: f(y) \leqq 0\}.$$

Hence $\text{cone}\,(A - \{a_0\}) \cap U = \varnothing$.

Conversely, suppose U is an open convex set satisfying (i) and (ii). From (ii) there exists $f \in \mathcal{Y}^*$ and $\gamma \in \mathbb{R}$ such that

$$f(x) \leqq \gamma < f(u)$$

for all $x \in \text{cone}\,(A - \{a_0\})$ and all $u \in U$ (e.g., see [25, p. 58]). Since $\theta \in \text{cone}\,(A - \{a_0\})$ we have $\gamma \geqq 0$. Thus $f(u) > 0$ for all $u \in U$. From (i) it follows that $f \in K^{+i}$. An easy contradiction argument shows that $f(x) \leqq 0$ for all $x \in \text{cone}\,(A - \{a_0\})$. Thus $f(a) \leqq f(a_0)$ for all $a \in A$. Hence a_0 is a positive proper efficient point of A. □

3. Compact and weak-compact based cones in normed vector lattices. Many results in the theory of ordering cones and vector optimization have been proven under the

hypothesis that the cone has a compact or weak-compact base [4], [5], [9], [20]. Thus, since many commonly used normed spaces are, in fact, normed vector lattices, it is of interest to know whether a cone that arises naturally from an existent lattice structure possesses such a base. We begin our study by reviewing the concept of a normed vector lattice. The notions discussed here will be referred to again in § 5. Readers familiar with normed vector lattices may proceed to Theorem 3.1.

If $\mathcal{Y}$ is a partially ordered vector space and $A \subseteq \mathcal{Y}$, we say that $y \in \mathcal{Y}$ is the *supremum* of A, written $\sup(A)$, if y satisfies the following two conditions:

(3.1) $a \leqq y$ for all $a \in A$;

(3.2) if $z \in \mathcal{Y}$ and $a \leqq z$ for all $a \in A$, then $y \leqq z$.

Similarly, we define the *infimum* of A, written $\inf(A)$, except we replace "$\leqq$" by "$\geqq$" in (3.1) and (3.2). A partially ordered vector space $\mathcal{Y}$ is called a *vector lattice* if for every pair $x, y \in \mathcal{Y}$ both $\sup\{x, y\}$ and $\inf\{x, y\}$ exist. If $\mathcal{Y}$ is a vector lattice and if $y \in \mathcal{Y}$, we define

$$y^+ = \sup\{y, \theta\}, \quad y^- = \sup\{-y, \theta\}, \quad |y| = y^+ + y^-.$$

It is clear that y^+, y^-, and $|y|$ are in the set $K := \{y \in \mathcal{Y}: y \geqq \theta\}$, and it is easy to verify that $y = y^+ - y^-$. Thus $\mathcal{Y} = K - K$. The set K is a pointed convex cone called the *positive cone* of $\mathcal{Y}$.

If, in addition to being a vector lattice, $\mathcal{Y}$ is also a topological vector space, we say that the *lattice operations are continuous* in $\mathcal{Y}$ if the maps $y \to y^+$, $y \to y^-$ and $y \to |y|$ of $\mathcal{Y}$ into itself, and the maps $(x, y) \to \sup\{x, y\}$ and $(x, y) \to \inf\{x, y\}$ of $\mathcal{Y} \times \mathcal{Y}$ into $\mathcal{Y}$ are continuous. It can be shown that continuity of any one of the maps implies continuity of all of the maps (e.g., see [26, p. 234]).

A norm $\|\cdot\|$ on a vector lattice $\mathcal{Y}$ is said to be a *lattice norm* if $|x| \leqq |y|$ implies $\|x\| \leqq \|y\|$. A *normed vector lattice* is a vector lattice equipped with a lattice norm. It is easy to check that the lattice operations are continuous in a normed vector lattice.

Some examples of normed vector lattices are $B[a, b]$ and $C[a, b]$ each with pointwise ordering and the supremum norm, L^p for $1 \leqq p \leqq \infty$ with pointwise almost everywhere ordering and the usual norms, and l^p for $1 \leqq p \leqq \infty$ with componentwise ordering and the usual norms. The corresponding positive cones in these spaces are the nonnegative orthants.

THEOREM 3.1. *Let $\mathcal{Y}$ be a normed vector lattice and let K be the positive cone in $\mathcal{Y}$ induced by the lattice order.*

(a) *If K has a compact base, then $\mathcal{Y}$ is finite-dimensional.*

(b) *If K has a weak-compact base, then $\mathcal{Y}$ is reflexive.*

Proof. To show (a) it suffices to show that the closed unit ball is compact. To show (b) it suffices to show that the closed unit ball is weak-compact.

Let B be a compact (weak-compact) base for K. Then there exists $M > 0$ such that $\|b\| \leqq M$ for all $b \in B$ (e.g., see [25, p. 68]). Also, since $\theta \notin \operatorname{cl}(B) = B$, there exists $m > 0$ such that $\|b\| \geqq m$ for all $b \in B$. Thus, $0 < m \leqq \|b\| \leqq M$ for all $b \in B$.

Let $K_M = \{k \in K: \|k\| \leqq M\}$. Then K_M is closed and convex (and hence it is weak-closed). We claim that K_M is compact (weak-compact). To show this, first note that

$$K_M \subseteq \left\{\alpha b: 0 \leqq \alpha \leqq \frac{M}{m}, b \in B\right\}.$$

By Tychonoff's Theorem (e.g., see [10, p. 32]) $[0, M/m] \times B$ is compact in the product topology of $\mathbb{R} \times \mathcal{Y}$ where $\mathbb{R}$ has the usual topology and $\mathcal{Y}$ has the norm (weak) topology.

Also, $\mathcal{Y}$ (with either topology) is a topological vector space, and so multiplication by scalars is a continuous operation from $\mathbb{R} \times \mathcal{Y}$ into $\mathcal{Y}$. Thus, since the continuous image of a compact set is compact, the set $\{\alpha b: 0 \leqq \alpha \leqq M/m, b \in B\}$ is compact (weak-compact). Therefore, the set K_M is a closed (weak-closed) subset of a compact (weak-compact) set, and so K_M is compact (weak-compact).

Now let $\mathcal{Y}_M = \{y \in \mathcal{Y}: \|y\| \leqq M\}$. Then $\mathcal{Y}_M$ is closed (weak-closed) and $\mathcal{Y}_M \subseteq K_M - K_M$. But $K_M - K_M$ is compact (weak-compact) and hence $\mathcal{Y}_M$ is compact (weak-compact). □

COROLLARY 3.2. *The nonnegative orthants in l^1, l^∞, c, c_0, L^1, L^∞, and $C[a, b]$ are not weak-compact based.*

The converse of Theorem 3.1(a) is also true. In fact, any closed pointed convex cone in $\mathbb{R}^n$ has a compact base [20, Prop. 2.4]. However the converse of Theorem 3.1(b) is not true. Corollaries 3.4 and 3.5 show that the nonnegative orthants in the reflexive spaces l^p and $L^p(\mathbb{R})$ for $1 < p < \infty$ do not have bounded bases, and hence are not weak-compact based. We first need the following result, which is due to Johnson [19].

PROPOSITION 3.3. *Let $\mathcal{Y}$ be a normed space and let K be a convex cone in $\mathcal{Y}$. Suppose K contains a sequence $\{y_n\}$ satisfying*

(i) *there exists a constant $m > 0$ such that $\|y_n\| \geqq m$ for all n, and*

(ii) *$\{y_n\}$ converges weakly to zero.*

Then K does not have a bounded base, and hence it does not have a weak-compact base.

Proof. Suppose B is a bounded base for K. Then there exists $M > 0$ such that $\|b\| \leqq M$ for all $b \in B$. Also, for each n there exists $\alpha_n > 0$, $b_n \in B$, such that $y_n = \alpha_n b_n$. Thus $M \geqq \|b_n\| = (1/\alpha_n)\|y_n\| \geqq (1/\alpha_n)m$. Therefore $1/\alpha_n \leqq M/m$. Thus, since $\{y_n\}$ converges weakly to zero, each $f \in \mathcal{Y}^*$ satisfies

$$\lim_{n\to\infty} |f(b_n)| = \lim_{n\to\infty} \frac{1}{\alpha_n} |f(y_n)| = 0.$$

But this says that $\{b_n\}$ converges weakly to zero; that is, $\theta \in \text{wk} - \text{cl}\,(B)$. But since B is convex, $\text{wk} - \text{cl}\,(B) = \text{cl}\,(B)$ and so $\theta \in \text{cl}\,(B)$. This is a contradiction since, by definition of base, $\theta \notin \text{cl}\,(B)$. □

COROLLARY 3.4. *If $1 < p < \infty$, the nonnegative orthant in l^p does not have a bounded base, and hence it does not have a weak-compact base.*

Proof. Let $\{e_n\}$ be the standard basis. That is, $e_n = \langle \delta_{in} \rangle$ where $\delta_{in} = 0$ if $i \neq n$ and $\delta_{nn} = 1$. Then $\|e_n\| = 1$ for all n and $\{e_n\}$ converges weakly to zero. □

COROLLARY 3.5. *If $1 < p < \infty$, the nonnegative orthant in $L^p(\mathbb{R})$ with Lebesgue measure μ does not have a bounded base, and hence it does not have a weak-compact base.*

Proof. Write $\mathbb{R} = \bigcup_{n=1}^{\infty} I_n$ where $\{I_n\}$ is a disjoint collection of measurable sets such that $\mu(I_n) = 1$ for all n. Now define

$$\chi_n(x) = \begin{cases} 1 & \text{if } x \in I_n, \\ 0 & \text{if } x \notin I_n. \end{cases}$$

Then $\|\chi_n\| = 1$ for all n and $\{\chi_n\}$ converges weakly to zero. □

It should be noted that the earlier authors in vector optimization have not indicated any infinite-dimensional reflexive normed vector lattices whose positive cone is weak-compact based. However, we do have the following characterization [18, Thm. 3.8.4].

PROPOSITION 3.6. *Let $\mathcal{Y}$ be a reflexive normed vector lattice and let K be the positive cone induced by the lattice order. Then K has a weak-compact base if and only if K^+ has nonempty interior in the norm topology of $\mathcal{Y}^*$.*

4. Density of Pos (A) in E(A). In § 2 it has been noted that $\text{Pos}\,(A) \subseteq E(A)$. Many authors have given sufficient conditions for the inclusion $E(A) \subseteq \text{cl}\,[\text{Pos}\,(A)]$ to hold.

Arrow, Barankin, and Blackwell [2] seem to have been the first to obtain such a result. They assumed $\mathcal{Y} = \mathbb{R}^n$ with the ordering cone being the nonnegative orthant. Hartley [15] extended this result to arbitrary closed pointed convex ordering cones in $\mathbb{R}^n$. Radner [24] generalized the result of Arrow, Barankin, and Blackwell to the space l^∞ with the nonnegative orthant as the ordering cone. Borwein [5] and Dauer and Saleh [9] obtained density results in normed spaces that are partially ordered by a weak-compact based cone. Jahn [17] provided a density result in normed spaces partially ordered by a Bishop-Phelps cone. (A cone K is said to be a *Bishop-Phelps cone* if $K = \{y \in \mathcal{Y}: \alpha \|y\| \leqq f(y)\}$ for some $\alpha \in (0, 1]$ and some $f \in \mathcal{Y}^*$, $\|f\| = 1$.) Borwein [6, Thm. 5] stated a related density result (the set of "Borwein proper" efficient points is dense in $E(A)$) for normed spaces and required the ordering cone to be closed, convex and admit strictly positive continuous linear functionals.

In this section we give sufficient conditions for the density of Pos (A) in $E(A)$ in the setting of normed spaces without requiring the ordering cone to have a bounded base. (Note that both weak-compact based cones and Bishop-Phelps cones have bounded bases.) Instead we assume the cone satisfies property P defined below. We show that this property is satisfied by the positive cones in many normed vector lattices including $C[a, b]$, l^p, and L^p for $1 \leqq p \leqq \infty$.

For convenience we use the following notation. If $\mathcal{Y}$ is a normed space, the closed unit ball in $\mathcal{Y}^*$ is denoted by

$$\text{Ball}\,(\mathcal{Y}^*) = \{f \in \mathcal{Y}^*: \|f\| \leqq 1\}.$$

If, $g, h \in \mathcal{Y}^*$, we write $h \leqq g$ if $g - h \in K^+$.

PROPERTY P. Let $\mathcal{Y}$ be a normed space and let K be a pointed convex cone in $\mathcal{Y}$. Then K is said to satisfy property P if there exists a nonempty subset D of $K^{+i} \cap \text{Ball}\,(\mathcal{Y}^*)$ satisfying the following two conditions:

P(i) If $f, g \in D$, then there exists $h \in D$ such that $h \leqq f$ and $h \leqq g$.

P(ii) Whenever $y \in \mathcal{Y}$ and $f(y) \geqq 0$ for all $f \in D$, then $y \in K$.

The significance of Property P will become apparent in the proof of the density theorem (Theorem 4.5). First we give some examples.

Example 4.1. Let $\mathcal{Y} = \mathbb{R}^n$ and let

$$K = \{\langle y_1, y_2, \cdots, y_n\rangle: y_i \geqq 0 \text{ for } i = 1, 2, \cdots, n\}.$$

One can easily show that

$$K^{+i} = \{\langle a_1, a_2, \cdots, a_n\rangle: a_i > 0 \text{ for } i = 1, 2, \cdots, n\},$$

and that $D = K^{+i} \cap \text{Ball}\,(\mathcal{Y}^*)$ satisfies P(i) and P(ii). Hence K satisfies property P. □

Example 4.2. Let $\mathcal{Y} = l^p$, $1 \leqq p \leqq \infty$, and let

$$K = \{y := \{y_i\} \in l^p: y_i \geqq 0 \text{ for } i = 1, 2, 3, \cdots\}.$$

Choose

$$D = \{a := \{a_i\} \in l^q: \|a\|_q \leqq 1,\ a_i > 0 \text{ for } i = 1, 2, 3, \cdots\}$$

where $1/p + 1/q = 1$. Then $D \subseteq K^{+i} \cap \text{Ball}\,(\mathcal{Y}^*)$. To show that D satisfies P(i), let $a = \{a_i\}$ and $b = \{b_i\}$ be in D. For $i = 1, 2, 3, \cdots$, define $c_i = \min\{a_i, b_i\}$ and let $c = \{c_i\}$. Then $c \in D$, $c \leqq a$, and $c \leqq b$. Thus D satisfies P(i).

We now show that D satisfies P(ii). Suppose $y = \{y_i\} \in l^p$ and $y \notin K$. It suffices to show that there exists $a = \{a_i\} \in D$ such that $\sum_{i=1}^{\infty} a_i y_i < 0$. Since $y \notin K$ there exists a positive integer m such that $y_m < 0$. Also, since $l^p \subseteq l^\infty$, $\|y\|_\infty < \infty$. Thus, we define

$$a_m = \frac{\|y\|_\infty - \frac{1}{2} y_m}{\|y\|_\infty - y_m}.$$

Note that $0 < a_m < 1$. Now, let a_i, $i \neq m$, be any sequence of positive numbers such that

$$\sum_{i \neq m} a_i = 1 - a_m.$$

Let $a = \{a_i\}$. Then $a \in l^1 \subseteq l^q$ and $\|a\|_q \leqq 1$. Thus $a \in D$. Moreover,

$$\sum_{i=1}^{\infty} a_i y_i \leqq \sum_{\substack{i=1 \\ i \neq m}}^{\infty} a_i \|y\|_\infty + a_m y_m = \frac{1}{2} y_m < 0.$$

Hence, D also satisfies P(ii), and so K satisfies Property P.

Example 4.3. Let $\mathcal{Y} = L^p(\Omega, \mathcal{B}, \mu)$, $1 \leqq p \leqq \infty$, where μ is a σ-finite measure. For convenience, abbreviate $L^p(\Omega, \mathcal{B}, \mu)$ by $L^p(\mu)$. Let

$$K = \{f \in L^p(\mu): f(\omega) \geqq 0 \text{ for } \mu\text{-a.e. } \omega \in \Omega\}.$$

If $g \in L^q(\mu)$, where $1/p + 1/q = 1$, it is well known that the functional F_g, defined by

$$F_g(f) = \int_\Omega fg \, d\mu \quad \text{for all } f \in L^p(\mu), \tag{4.1}$$

is in $(L^p(\mu))^*$; and furthermore, that $\|F_g\| = \|g\|_q$. Using the notation in (4.1), define

$$D = \{F_g \in (L^p(\mu))^*: g \in L^q(\mu), \|g\| \leqq 1, g(\omega) > 0 \text{ for } \mu\text{-a.e. } \omega \in \Omega\}.$$

We show that D is a nonempty subset of $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ satisfying P(i) and P(ii).

To show that D is nonempty it suffices to show that there exists $g \in L^q(\mu)$ such that $g(\omega) > 0$ for μ-a.e. $\omega \in \Omega$. If $p = 1$ or if $\mu(\Omega) < \infty$, this is obvious; and so we assume $p \neq 1$ and $\mu(\Omega) = \infty$. Since μ is σ-finite, $\Omega = \bigcup_{i=1}^{\infty} \Omega_i$, where $0 < \mu(\Omega_i) < \infty$ for $i = 1, 2, 3, \cdots$, and $\Omega_i \cap \Omega_j = \varnothing$ for $i \neq j$. Define $g: \Omega \to \mathbb{R}$ by

$$g(\omega) = \left(\frac{1}{2^i \mu(\Omega_i)}\right)^{1/q} \quad \text{for } \omega \in \Omega_i, \quad i = 1, 2, 3, \cdots.$$

Then $g \in L^q(\mu)$ and $g(\omega) > 0$ for all $\omega \in \Omega$. Hence D is nonempty.

It is clear that $D \subseteq K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$. To show D satisfies P(i), let $F_{g_1}, F_{g_2} \in D$ and define $g \in L^q(\mu)$ by

$$g(\omega) = \min\{g_1(\omega), g_2(\omega)\} \quad \text{for all } \omega \in \Omega.$$

Then F_g, defined by (4.1), is in D, $F_g \leqq F_{g_1}$ and $F_g \leqq F_{g_2}$. Thus D satisfies P(i).

It remains to show that D satisfies P(ii). Let $f \in L^p(\mu)$, $f \notin K$. It suffices to show there exists $F_g \in K^{+i}$ such that $F_g(f) < 0$. Since $f \notin K$, the set

$$\Lambda = \{\omega \in \Omega: f(\omega) < 0\}$$

satisfies $\mu(\Lambda) > 0$. Choose $h \in L^q(\mu)$ satisfying $h(\omega) > 0$ for μ-a.e. $\omega \in \Omega$. Then $fh \in L^1(\mu)$. Let

$$\alpha = \int_\Lambda fh \, d\mu \quad \text{and} \quad \beta = \int_{\Omega \setminus \Lambda} fh \, d\mu.$$

Then $-\infty < \alpha < 0$ and $0 \leqq \beta < \infty$. Choose $\gamma > 0$ such that $\alpha + \beta\gamma < 0$, and define

$$g(\omega) = \begin{cases} h(\omega) & \text{if } \omega \in \Lambda, \\ \gamma h(\omega) & \text{if } \omega \in \Omega \setminus \Lambda. \end{cases}$$

Then F_g, defined by (4.1), is in K^{+i} and $F_g(f) < 0$. Thus, D also satisfies P(ii), and so K satisfies Property P.

Example 4.4. Let $\mathcal{Y} = C[a, b]$, the continuous functions on the interval $[a, b]$, and let

$$K = \{y \in C[a, b]: y(t) \geqq 0 \quad \text{for all } t \in [a, b]\}.$$

Let NBV$[a, b]$ denote the space of normalized functions of bounded variation on $[a, b]$. It is well known that the dual of $C[a, b]$ is isomorphic to NBV$[a, b]$. In particular, if $F \in (C[a, b])^*$, there exists a unique $v \in \text{NBV}[a, b]$ such that

$$F(y) = F_v(y) := \int_a^b y(t)\, dv(t) \quad \text{for all } y \in C[a, b]. \tag{4.2}$$

Furthermore, $\|F_v\| = \text{T.V.}(v)$, where T.V. (v) denotes the total variation of v. We denote elements in $(C[a, b])^*$ by F_v, where the subscript v is understood to be the corresponding element in NBV$[a, b]$ such that (4.2) holds.

Let

$$D = \{F_v \in (C[a, b])^*: \text{T.V.}(v) \leqq 1,\ v \text{ is continuous, piecewise linear with a finite number of linear pieces, and strictly increasing}\}.$$

Then D is a nonempty subset of $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$, and D satisfies P(i) and P(ii) [13]. Hence K satisfies Property P.

The previous examples have illustrated that the positive cones in many common normed vector lattices satisfy Property P. However, this is not always the case. Recall from § 2 that the positive cone in the normed vector lattice $B[a, b]$ does not even admit strictly positive continuous linear functionals, and hence it does not satisfy Property P. Klee [20, pp. 315–316] and Krein and Rutman [21, pp. 21–22] also give examples of pointed convex cones that do not admit strictly positive continuous linear functionals.

Below, in Theorem 4.5, the density theorem is stated. The reader should be aware that the assumption requiring the set A to be compact is more stringent than what is required on the set A by Borwein [5], Dauer and Saleh [9], and Jahn [17], who, on the other hand, place more stringent requirements on the ordering cone.

THEOREM 4.5. *Let $\mathcal{Y}$ be a normed space and let K be a pointed convex cone in $\mathcal{Y}$ satisfying Property* P. *Let A be a nonempty compact convex subset of $\mathcal{Y}$. Then* $E(A) \subseteq \text{cl}[\text{Pos}(A)]$.

Before proving this theorem it will be convenient to introduce some notation and to develop some lemmas that will be used in its proof. For the remainder of this section, let $\mathcal{Y}$ be a normed space, let K be a pointed convex cone in $\mathcal{Y}$ satisfying Property P, and let D be the subset of $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ whose existence is assumed in Property P. For each $p \in D$, define

$$K_1^+(p) = \{f \in K^+: f \geqq p \text{ and } \|f\| \leqq 1\}.$$

LEMMA 4.6. *For each $p \in D$, the set $K_1^+(p)$ is convex and weak-star compact.*

Proof. Let $p \in D$ be given. Note that

$$K_1^+(p) = (K^+ + \{p\}) \cap \text{Ball}(\mathcal{Y}^*).$$

By Alaoglu's Theorem, Ball $(\mathcal{Y}^*)$ is convex and weak-star compact. Thus, it suffices to show that K^+ is convex and weak-star closed.

Clearly, K^+ is convex. Let $\{f_\lambda\}$ be a net in K^+, and suppose that f_λ converges to f weak-star. Then $f_\lambda(y)$ converges to $f(y)$ for all $y \in \mathcal{Y}$. In particular, $f_\lambda(k)$ converges to $f(k)$ for all $k \in K$. Since $f_\lambda(k) \geqq 0$ for all λ and all $k \in K$, we get $f(k) \geqq 0$ for all $k \in K$. Hence $f \in K^+$ and so K^+ is weak-star closed. □

LEMMA 4.7. *For each $p \in D$, define the function $F: \mathcal{Y} \times K_1^+(p) \to \mathbb{R}$ by*

$$F(y,f) = f(y) \quad \text{for all } (y,f) \in \mathcal{Y} \times K_1^+(p).$$

Then F is continuous in the product topology on $\mathcal{Y} \times K_1^+(p)$, where $\mathcal{Y}$ has the norm topology and $K_1^+(p)$ has the weak-star topology.

Proof. Let $(y,f) \in \mathcal{Y} \times K_1^+(p)$ and let $\{(y_\lambda, f_\lambda)\}$ be a net in $\mathcal{Y} \times K_1^+(p)$ converging to (y,f). Then y_λ converges to y in norm and f_λ converges to f weak-star. Let $\varepsilon > 0$ be given. Let the symbol $>$ denote the ordering on the directed set for the net. Then there exists λ_1 such that $\lambda > \lambda_1$ implies that $\|y_\lambda - y\| < \varepsilon/2$, and there exists λ_2 such that $\lambda > \lambda_2$ implies $|f_\lambda(y) - f(y)| < \varepsilon/2$. Choose λ_3 such that $\lambda_3 > \lambda_1$ and $\lambda_3 > \lambda_2$. Then if $\lambda > \lambda_3$ we have

$$\begin{aligned} |F(y,f) - F(y_\lambda, f_\lambda)| &= |f(y) - f_\lambda(y_\lambda)| \\ &\leqq |f(y) - f_\lambda(y)| + |f_\lambda(y) - f_\lambda(y_\lambda)| \\ &\leqq |f(y) - f_\lambda(y)| + \|f_\lambda\| \, \|y - y_\lambda\| \\ &< \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon. \end{aligned}$$

□

The following lemma is due to Fan [12, p. 121].

LEMMA 4.8. *Let A and B be compact convex sets, each in a topological vector space. Let F be a real-valued continuous function on $A \times B$. If for every fixed $b \in B$, $F(a,b)$ is a convex function of a on A, and if for every fixed $a \in A$, $F(a,b)$ is a concave function of b on B, then*

$$\min_{a \in A} \max_{b \in B} F(a,b) = \max_{b \in B} \min_{a \in A} F(a,b).$$

Consequently (e.g., see [11, p. 167]), there exists a pair $(\bar{a}, \bar{b}) \in A \times B$ satisfying

$$F(\bar{a}, b) \leqq F(\bar{a}, \bar{b}) \leqq F(a, \bar{b})$$

for all $a \in A$ and all $b \in B$.

We now have everything needed to prove Theorem 4.5.

Proof of Theorem 4.5. Since $a \in E(A)$ if and only if $\theta \in E(A - \{a\})$ and since A is compact if and only if $A - \{a\}$ is compact, we assume, without loss of generality, that $\theta \in E(A)$. We must show $\theta \in \text{cl}\,[\text{Pos}\,(A)]$.

By Lemmas 4.6 and 4.7, for each $p \in D$, the hypotheses of Lemma 4.8 are satisfied for the function $F: A \times K_1^+(p) \to \mathbb{R}$, defined by

$$F(a,f) = f(a) \quad \text{for all } (a,f) \in A \times K_1^+(p).$$

Hence, there exists $a_p \in A$, $f_p \in K_1^+(p)$ such that

$$F(a_p, f) \geqq F(a_p, f_p) \geqq F(a, f_p) \quad \text{for all } a \in A \text{ and } f \in K_1^+(p).$$

That is,

$$f(a_p) \geqq f_p(a_p) \geqq f_p(a) \quad \text{for all } a \in A \text{ and } f \in K_1^+(p). \tag{4.3}$$

Since $\theta \in A$, inequality (4.3) gives

$$f(a_p) \geqq 0 \quad \text{for all } f \in K_1^+(p). \tag{4.4}$$

Since D satisfies P(i), the pair $(D, \leqq)$ is a directed set. Hence, the set $\{a_p : p \in D\}$ is a net contained in A. Since A is compact, the net has a cluster point, say $\bar{a}$, in A. From (4.3)

$$f_p(a_p) \geqq f_p(a) \quad \text{for all } a \in A.$$

Therefore, since $f_p \in K_1^+(p) \subseteq K^{+i}$, $a_p \in \text{Pos}(A)$. Thus, the net $\{a_p : p \in D\}$ is contained in Pos (A), and so $\bar{a} \in \text{cl}[\text{Pos}(A)]$ (e.g., see [8, p.378]).

We finish the proof by showing that $\bar{a} = \theta$. Since $\theta \in E(A)$, it suffices to show that $\bar{a} \geqq \theta$. By P(ii), it suffices to show that $g(\bar{a}) \geqq 0$ for all $g \in D$. To this end, let $g \in D$ be given and let $\varepsilon > 0$ be given. It suffices to show $g(\bar{a}) > -\varepsilon$. Since $\bar{a}$ is a cluster point of $\{a_p : p \in D\}$ and since g is continuous, $g(\bar{a})$ is a cluster point of $\{g(a_p): p \in D\}$. Thus, there exists $r \in D$, $r \leqq g$, such that

$$|g(\bar{a}) - g(a_r)| < \varepsilon.$$

In particular,

$$g(\bar{a}) > g(a_r) - \varepsilon.$$

Since $r \leqq g$ we have $g \in K_1^+(r)$. Thus, by (4.4), $g(a_r) \geqq 0$. Hence $g(\bar{a}) > -\varepsilon$. □

5. Results concerning Property P. In § 4 we considered some specific examples of spaces and cones satisfying Property P. In this section we give sufficient conditions for a cone to satisfy Property P. We begin with the following proposition.

PROPOSITION 5.1. *Let $\mathcal{Y}$ be a normed vector space and let K be a pointed convex cone in $\mathcal{Y}$ satisfying Property* P. *Let X be a nontrivial subspace of $\mathcal{Y}$ and put $C = K \cap X$. Then C is a pointed convex cone in X that satisfies Property* P *(with respect to X).*

Proof. The fact that C is a pointed convex cone is clear. Let D be the subset of $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$, which satisfies P(i) and P(ii). Define

$$D_X = \{\tilde{f} : \tilde{f} = f|_X \text{ for some } f \in D\}$$

where $f|_X$ denotes the restriction of f to X. Then D_X is a nonempty subset of $C^{+i} \cap \text{Ball}(X^*)$, satisfying P(i) and P(ii) with respect to X. Hence C satisfies Property P. □

As an example of how Proposition 5.1 can be used, note that the space c of all convergent sequences and the space c_0 of all sequences converging to zero are both subspaces of l^∞. Hence, by Example 4.2, the nonnegative orthants in c and c_0 satisfy Property P.

In many of the examples given in § 4 we were able to choose the subset D of $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ satisfying P(i) and P(ii) to be $D = K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$. Specifically, this was done in Example 4.1; Example 4.2 for $1 \leqq p < \infty$; and Example 4.3 for $1 \leqq p < \infty$. Whether or not this can always be done, assuming of course that K^{+i} is nonempty, is an open question. Theorem 5.2 and Corollary 5.3 give sufficient conditions under which such a choice is possible.

The notation $[\theta, k]$ is used to denote the order interval

$$[\theta, k] := \{y \in \mathcal{Y} : \theta \leqq y \leqq k\}.$$

THEOREM 5.2. *Let $\mathcal{Y}$ be a normed vector lattice and let K be the positive cone induced by the lattice order. Suppose that*

(i) *K^{+i} is nonempty, and*

(ii) *$[\theta, k]$ is weak-compact for every $k \in K$.*

Then $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ satisfies P(i) *and* P(ii), *and hence K satisfies Property* P.

COROLLARY 5.3. *Let $\mathcal{Y}$ be a reflexive normed vector lattice and let K be the positive cone induced by the lattice order. If K^{+i} is nonempty, then $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ satisfies* P(i) *and* P(ii), *and hence K satisfies Property* P.

The remainder of this section is devoted to results leading to proofs of Theorem 5.2 and Corollary 5.3. Specifically, Theorem 5.2 follows from Propositions 5.7 and 5.9; and Corollary 5.3 follows from Theorem 5.2 and Proposition 5.11. We begin by giving

sufficient conditions for $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ to satisfy P(ii). The conditions are stated in Proposition 5.7. We first develop some lemmas from which the proposition will follow. The first lemma is well known; its proof uses a standard separation argument (e.g., see [16, p. 66]).

LEMMA 5.4. *Let $\mathcal{Y}$ be a locally convex space and let K be a closed convex cone in $\mathcal{Y}$. If $y \in \mathcal{Y}$ and $f(y) \geqq 0$ for all $f \in K^+$, then $y \in K$.*

LEMMA 5.5. *Let $\mathcal{Y}$ be a locally convex space and let K be a closed pointed convex cone in $\mathcal{Y}$ for which K^{+i} is nonempty. If $y \in \mathcal{Y}$ and $f(y) \geqq 0$ for all $f \in K^{+i}$, then $y \in K$.*

Proof. Suppose $y \notin K$. By Lemma 5.4 there exists $f \in K^+$ such that $f(y) < 0$. Let $g \in K^{+i}$ and choose $\alpha > 0$ such that $f(y) + \alpha g(y) < 0$. Define $F = f + \alpha g$. Then $F \in K^{+i}$ and $F(y) < 0$. □

To apply Lemma 5.5 to the proof of Theorem 5.2, the positive cone in a normed vector lattice must be shown to be closed, pointed, and convex. In § 3, it has been noted that the positive cone is pointed and convex. A proof that the positive cone is closed if the lattice operations are continuous can be found in Schaefer [26, p. 235]. For reference we record these facts in the following lemma.

LEMMA 5.6. *Let $\mathcal{Y}$ be a vector lattice and let $K = \{y \in \mathcal{Y}: y \geqq \theta\}$. Then K is convex and pointed. If, in addition to being a vector lattice, $\mathcal{Y}$ is also a topological vector space such that the lattice operations are continuous, then K is closed.*

Lemmas 5.5 and 5.6 imply the following proposition.

PROPOSITION 5.7. *Let $\mathcal{Y}$ be a normed vector lattice and let K be the positive cone induced by the lattice order. If K^{+i} is nonempty, then $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ satisfies* P(ii).

We now work toward obtaining sufficient conditions for $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ to satisfy P(i). The conditions obtained are stated in Proposition 5.9.

LEMMA 5.8. *Let $\mathcal{Y}$ be a vector lattice and let K be the positive cone induced by the lattice order. Let f and g be positive linear functionals on $\mathcal{Y}$ and define $f \wedge g: K \to \mathbb{R}$ by*

$$(f \wedge g)(k) = g(k) - \sup\{(g-f)(y): \theta \leqq y \leqq k\} \quad \text{for all } k \in K.$$

Define $h: \mathcal{Y} \to \mathbb{R}$ by

$$h(y) = (f \wedge g)(y^+) - (f \wedge g)(y^-) \quad \text{for all } y \in \mathcal{Y}.$$

Then h is a positive linear functional on $\mathcal{Y}$ such that $h \leqq f$ and $h \leqq g$.

If, in addition to being a vector lattice, $\mathcal{Y}$ is also a topological vector space such that the lattice operations are continuous, then h is continuous provided at least one of f or g is continuous.

Proof. The fact that h is a linear functional satisfying $h \leqq f$ and $h \leqq g$ can be found, for example, in Aliprantis and Burkinshaw [1, p. 189] or Schaefer [26, p. 211]. Let $k \in K$. Since $\sup\{(g-f)(y): \theta \leqq y \leqq k\} \leqq g(k)$, we have

$$\begin{aligned} h(k) &= (f \wedge g)(k) \\ &= g(k) - \sup\{(g-f)(y): \theta \leqq y \leqq k\} \\ &\geqq g(k) - g(k) \\ &= 0. \end{aligned}$$

Thus, $h(k) \geqq 0$ for all $k \in K$, and so h is positive.

Now assume that f is continuous. Let $\{y_\lambda\}$ be a net in $\mathcal{Y}$ converging to θ. Since the mapping $T: \mathcal{Y} \to \mathcal{Y}$ defined by $T(y) = |y|$ is continuous, we have that

$$|y_\lambda| = T(y_\lambda) \to T(\theta) = |\theta| = \theta.$$

Also, since $0 \leqq h(|y_\lambda|) \leqq f(|y_\lambda|)$ and since f is continuous, we get that $h(|y_\lambda|) \to 0$. That is,

$$h(y_\lambda^+) + h(y_\lambda^-) = h(y_\lambda^+ + y_\lambda^-) = h(|y_\lambda|) \to 0.$$

But $h(y_\lambda^+) \geqq 0$ and $h(y_\lambda^-) \geqq 0$, and so we have $h(y_\lambda^+) \to 0$ and $h(y_\lambda^-) \to 0$. It follows that $h(y_\lambda) \to 0$, and so h is continuous at θ. Since h is linear, h is continuous everywhere. □

The following proposition uses Lemma 5.8 to obtain sufficient conditions for $K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ to satisfy P(i).

PROPOSITION 5.9. *Let $\mathcal{Y}$ be a normed vector lattice and let K be the positive cone induced by the lattice order. Suppose that*

(i) *K^{+i} is nonempty, and*

(ii) *$[\theta, k]$ is weak-compact for every $k \in K$.*

Then for every pair $f, g \in K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ there exists $h \in K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ such that $h \leqq f$ and $h \leqq g$.

Proof. Let $f, g \in K^{+i} \cap \text{Ball}(\mathcal{Y}^*)$ and define h as in Lemma 5.8. Then $h \in K^+$, $h \leqq f$, and $h \leqq g$. Also, since the normed dual of a normed vector lattice is a Banach lattice [26, p. 238], it follows that $\|h\| \leqq \|f\| \leqq 1$. Hence $h \in \text{Ball}(\mathcal{Y}^*)$.

It remains to show that $h \in K^{+i}$; that is, to show $h(k) > 0$ for all $k \in K \setminus \{\theta\}$. Let $k \in K \setminus \{\theta\}$. Then

$$\begin{aligned} h(k) &= (f \wedge g)(k) \\ &= g(k) - \sup\{(g-f)(y) : \theta \leqq y \leqq k\}. \end{aligned}$$

If $h(k) = 0$, then for every positive integer n there exists $y_n \in [\theta, k]$ such that

$$0 \leqq g(k) - (g-f)(y_n) < \frac{1}{n}.$$

That is,

$$0 \leqq g(k) - g(y_n) + f(y_n) < \frac{1}{n}.$$

Since both f and g are in K^{+i} we have

$$0 \leqq g(k) - g(y_n) < \frac{1}{n} \tag{5.1}$$

and

$$0 \leqq f(y_n) < \frac{1}{n}. \tag{5.2}$$

Now $[\theta, k]$ is weak-compact and so contains a cluster point $\bar{y}$ of $\{y_n\}$. Thus, for every weak open set U containing $\bar{y}$ and for every positive integer N, there exists $n \geqq N$ such that $y_n \in U$.

Let N be a positive integer. Define $U_N = \{y \in \mathcal{Y} : f(\bar{y}) - 1/N < f(y)\}$. Then U_N is a weak-open set and $\bar{y} \in U_N$. Thus there exists $n \geqq N$ such that $y_n \in U_N$. Hence

$$f(\bar{y}) - \frac{1}{N} < f(y_n).$$

Now $f(\bar{y}) \geqq 0$ and $1/n \leqq 1/N$, so the above inequality together with (5.2) yields

$$0 \leqq f(\bar{y}) < \frac{2}{N}.$$

Since N is arbitrary, we get that $f(\bar{y}) = 0$. But $f \in K^{+i}$ and so $\bar{y} = \theta$.

Again let N be a positive integer. Define $G_N = \{y \in \mathcal{Y}: g(y) < 1/N\}$. Then G_N is weak-open and $\bar{y} = \theta \in G_N$. Thus, there exists $n \geqq N$ such that $y_n \in G_N$. From (5.1) we have

$$g(y_n) \leqq g(k) < \frac{1}{n} + g(y_n),$$

which implies that

$$0 \leqq g(k) < \frac{2}{N}.$$

Since N is arbitrary $g(k) = 0$. But this is a contradiction since $g \in K^{+i}$ and $k \in K \setminus \{\theta\}$. □

Note that Propositions 5.7 and 5.9 complete the proof of Theorem 5.2. To complete the proof of Corollary 5.3, it suffices to show that in a reflexive normed vector lattice, the order interval $[\theta, k]$ is weak-compact for every $k \in K$. This fact is proved in Proposition 5.11. We first need the following lemma.

LEMMA 5.10. *Let $\mathcal{Y}$ be a locally convex space and let K be a closed pointed convex cone in $\mathcal{Y}$. Then $[\theta, k]$ is weak-closed for every $k \in K$.*

Proof. Let $k \in K$ and let $\{y_\lambda\}$ be a net in $[\theta, k]$ such that $\{y_\lambda\}$ converges weakly to y. It must be shown that $y \in [\theta, k]$.

Since $\{y_\lambda\}$ converges weakly to y we have that $f(y_\lambda) \to f(y)$ for every $f \in \mathcal{Y}^*$ and, in particular, for every $f \in K^+$. But if $f \in K^+$, then $0 \leqq f(y_\lambda) \leqq f(k)$ for all λ. Hence $0 \leqq f(y) \leqq f(k)$ for all $f \in K^+$. By Lemma 5.4 it follows that $0 \leqq y \leqq k$. □

PROPOSITION 5.11. *Let $\mathcal{Y}$ be a reflexive normed space and let K be a closed pointed convex cone in $\mathcal{Y}$ such that if $k_1, k_2 \in K$ and $k_1 \leqq k_2$, then $\|k_1\| \leqq \|k_2\|$. Then $[\theta, k]$ is weak-compact for every $k \in K$.*

Proof. Since $\mathcal{Y}$ is reflexive, the unit ball $\{y \in \mathcal{Y}: \|y\| \leqq 1\}$ is weak-compact. Thus, the set $\{y \in \mathcal{Y}: \|y\| \leqq \|k\|\}$ is weak-compact for every $k \in K$. The hypotheses of the proposition imply that $[\theta, k] \subseteq \{y \in \mathcal{Y}: \|y\| \leqq \|k\|\}$ and, by Lemma 5.10, that $[\theta, k]$ is weak-closed. Hence $[\theta, k]$ is weak-compact. □

With Proposition 5.9 in mind, we give one final result, which states that $[\theta, k]$ is weak-compact provided K has a weak-compact base. Although the fact itself is interesting, its usefulness in the context of normed vector lattices is somewhat limited since, as seen in § 3, normed vector lattices with weak-compact based positive cones are not abundant. Moreover, by Theorem 3.1, a normed vector lattice with a weak-compact based positive cone is necessarily reflexive; and by Lemma 5.6, Lemma 5.10, and Proposition 5.11, it already follows that in a reflexive normed vector lattice the set $[\theta, k]$ is weak-compact for every k in the positive cone. However, the result is useful if one is interested in cones that do not arise from a lattice structure.

PROPOSITION 5.12. *Let $\mathcal{Y}$ be a normed space and let K be a cone in $\mathcal{Y}$ with a compact (weak-compact) base. Furthermore, suppose that if $k_1, k_2 \in K$ and $k_1 \leqq k_2$, then $\|k_1\| \leqq \|k_2\|$. Then $[\theta, k]$ is compact (weak-compact) for every $k \in K$.*

Proof. Let B be a compact (weak-compact) base for K and let $k \in K$ be given. Since $\theta \notin \mathrm{cl}\,(B) = B$, there exists $m > 0$ such that $\|b\| \geqq m$ for all $b \in B$. Since B is

weak-compact, it follows that K is closed. Thus, by Lemma 5.10, $[\theta, k]$ is weak-closed and hence closed. Also,

$$[\theta, k] \subseteq \{y \in \mathcal{Y}: y = \alpha b \text{ where } 0 \leqq \alpha \leqq \|k\|/m, b \in B\}.$$

Using Tychonoff's Theorem and the fact that scalar multiplication is continuous, it follows that the latter set is compact (weak-compact). Hence $[\theta, k]$ is compact (weak-compact). □

It should be remarked that the above proposition is true in more generality. In particular, it can be shown that if $\mathcal{Y}$ is a locally convex space and K has a compact (bounded) base, then $[\theta, k]$ is compact (bounded) for all $k \in K$ [13, Prop. 5.9]. Also, it is interesting to note that the converse of Proposition 5.12 is not true. Indeed, for l^p, $1 \leqq p < \infty$, the set $[\theta, k]$ is compact for all k in the nonnegative orthant [7, Ex. 2.8], [13, Prop. 5.10]. However, by Theorem 3.1(b) (for $p = 1$) and Corollary 3.4 (for $1 < p < \infty$), the nonnegative orthant in l^p is not weak-compact based.

We refer the reader to Borwein [7] for an excellent summary of many results and examples pertaining to order intervals, based cones, and Banach lattices.

ON A NECESSARY AND SUFFICIENT CONDITION FOR FINITE DIMENSIONALITY OF ESTIMATION ALGEBRAS*

LUEN-FAI TAM†, WING SHING WONG‡, AND STEPHEN S.-T. YAU§

Abstract. Ever since the technique of the Kalman-Bucy filter was popularized, there has been an intense interest in finding new classes of finite dimensional recursive filters. In the late seventies, the concept of the estimation algebra of a filtering system was introduced. It has proven to be an invaluable tool in the study of nonlinear filtering problems. In this paper, a simple algebraic necessary and sufficient condition is established for an estimation algebra of a special class of filtering systems to be finite-dimensional. Also presented is a rigorous proof of the Wei-Norman program which allows one to construct finite-dimensional recursive filters from finite dimensional estimation algebras.

Key words. nonlinear filters, solvable Lie algebra, estimation algebra

AMS(MOS) subject classifications. 17B30, 35K15, 60G35, 93E11

1. Introduction. The idea of using estimation algebras to construct finite-dimensional nonlinear filters was first proposed in Brockett and Clark [1] and Brockett [2]. The motivation came from the following Wei-Norman approach [3] of using Lie algebraic ideas to solve time varying linear differential equations. Consider the equation

$$\frac{d}{dt}X(t) = A(t)X(t) \equiv \sum_{i=1}^{m} a_i(t)A_iX(t), \qquad X(0) = X_0, \tag{1.0}$$

where X and A_i's are n by n matrices and a_i's are scalar-valued functions. Let $B_1, \cdots, B_l$ be a basis of the Lie algebra generated by $A_1, \cdots, A_m$. Then the Wei-Norman Theorem states that locally in t, $X(t)$ has a representation of the form,

$$X(t) = \exp(b_1(t)B_1) \cdots \exp(b_l(t)B_l)X_0, \tag{1.1}$$

where b_i's satisfy an ordinary differential equation of the form

$$\frac{db_i}{dt} = c_i(b_1, \cdots, b_l), \qquad b_i(0) = 0$$

for all i. The function c_i's in the above equation are determined by the structure constants of the Lie algebra generated by the A_i's.

The extension of Wei-Norman's approach to the nonlinear filtering problem is much more complicated. Instead of an ordinary differential equation, we have to solve the Duncan-Mortensen-Zakai (DMZ) equation, which is a stochastic partial differential equation. By working on the robust form of the DMZ equation we can reduce the complexity of the problem to that of solving a time varying partial differential equation. Working independently, Steinberg [4] applied the Wei-Norman approach to solve some partial differential equations that are roughly related to the linear filtering problem. Wong in [5] constructed some new finite-dimensional estimation algebras and used the Wei-Norman approach to synthesize finite-dimensional filters. However, the systems considered in [5] are quite specific and the question whether the Wei-Norman approach works for a general system with finite-dimensional estimation algebra remains open.

In this paper we examine the properties of finite-dimensional estimation algebras and the Wei-Norman approach in detail. We consider here a class of filtering systems having the property that the drift-term f of the state evolution equation is a gradient vector field. In [6], the concept of Ω is introduced, which is defined as the matrix whose i, j-element is $(\partial f_j/\partial x_i)-(\partial f_i/\partial x_j)$. For this class of filtering systems, Ω is zero. Conversely, if $\Omega=0$, then by the Poincaré Lemma, f is a gradient vector field. So, the class of filtering systems considered here is characterized by the fact that $\Omega=0$.

Motivated by the results in Wong [6] and [7], we investigate the algebraic problem of characterizing and classifying finite-dimensional exact estimation algebras. In [6], a sufficient condition of finite dimensionality is derived for certain filtering systems. In [7], a necessary condition and some theorems of the structure of the estimation algebra are demonstrated. In this paper, we derive a simple necessary and sufficient condition for an exact estimation algebra to be finite-dimensional. As an important consequence of these algebraic results, we prove that for a system with finite-dimensional exact estimation algebras, the Wei-Norman approach always leads to finite dimensional filters. The proof will be presented in § 4. The necessary and sufficient theorem presented here also leads us to prove some classification theorems of finite-dimensional exact estimation algebras, which will be presented in a forthcoming paper.

2. Basic concepts. The filtering problem considered here is based on the following signal observation model:

$$\begin{cases} dx(t)=f(x(t))\,dt+g(x(t))\,dv(t) & x(0)=x_0, \\ dy(t)=h(x(t))\,dt+dw(t) & y(0)=0, \end{cases} \tag{2.0}$$

in which x, v, y, and w, are, respectively, $\mathbb{R}^n$, $\mathbb{R}^p$, $\mathbb{R}^m$, and $\mathbb{R}^m$ valued processes, and v and w have components which are independent, standard Brownian processes. We further assume that $n=p$, f, h are C^∞ smooth, and that g is an orthogonal matrix. We will refer to $x(t)$ as the state of the system at time t and $y(t)$ as the observation at time t.

Let $\rho(t, x)$ denote the conditional probability density of the state given the observation $\{y(s)\colon 0\leqq s\leqq t\}$. It is well known (see [8], for example) that $\rho(t, x)$ is given by normalizing a function, $\sigma(t, x)$, which satisfies the following Duncan-Mortensen-Zakai equation:

$$d\sigma(t, x)=L_0\sigma(t, x)\,dt+\sum_{i=1}^{m} L_i\sigma(t, x)\,dy_i(t), \qquad \sigma(0, x)=\sigma_0, \tag{2.1}$$

where

$$L_0=\frac{1}{2}\sum_{i=1}^{n}\frac{\partial^2}{\partial x_i^2}-\sum_{i=1}^{n} f_i\frac{\partial}{\partial x_i}-\sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i}-\frac{1}{2}\sum_{i=1}^{m} h_i^2$$

and for $i=1, \cdots, m$, L_i is the zero degree differential operator of multiplication by h_i.[1] σ_0 is the probability density of the initial point, x_0.

Equation (2.1) is a stochastic partial differential equation. In real applications, we are interested in constructing robust state estimators from observed sample paths with some property of robustness. Davis in [9] studied this problem and proposed some robust algorithms. In our case, his basic idea reduces to defining a new unnormalized density

$$\xi(t, x)=\exp\left(-\sum_{i=1}^{m} h_i(x)y_i(t)\right)\sigma(t, x).$$

[1] If p is a vector, we use the notation p_i to represent the ith component of p.

It is easy to show that $\xi(t, x)$ satisfies the following time varying partial differential equation

$$\frac{d\xi(t,x)}{dt} = L_0\xi(t,x) + \sum_{i=1}^{m} y_i(t)[L_0, L_i]\xi(t,x) + \frac{1}{2}\sum_{i=1}^{m} y_i^2(t)[[L_0, L_i], L_i]\xi(t,x), \tag{2.2}$$

$$\xi(0, x) = \sigma_0$$

where $[\cdot, \cdot]$ is the Lie bracket as described by the following definition.

DEFINITION. If X and Y are differential operators, the Lie bracket of X and Y, $[X, Y]$, is defined by

$$[X, Y]\zeta = X(Y\zeta) - Y(X\zeta),$$

for any C^∞ function ζ.

The objective of constructing a robust finite-dimensional filter to (2.0) is equivalent to finding a smooth manifold M and complete C^∞ vector fields μ_i on M and C^∞ functions ν on $M \times \mathbb{R} \times \mathbb{R}^n$ and ω_i's on $\mathbb{R}^m$, such that $\xi(t, x)$ can be represented in the form:

$$\begin{cases} \dfrac{dz(t)}{dt} = \displaystyle\sum_{i=1}^{k} \mu_i(z(t))\omega_i(y(t)), & z(0) \in M, \qquad \text{(2.3a)} \\ \xi(t, x) = \nu(z(t), t, x). & \qquad \text{(2.3b)} \end{cases}$$

Following [10], we say that system (2.0) has a robust universal finite-dimensional filter if for each initial probability density σ_0 there exists a z_0, such that (2.3a) and (2.3b) hold if $z(0) = z_0$, and μ_i, ω_i are independent of σ_0.

In § 5, we will use the Wei-Norman approach to construct a finite-dimensional filter for (2.0). Before we can achieve that, we need to introduce the concept of the estimation algebra of (2.0) and examine its algebraic structure.

DEFINITION. The estimation algebra $\mathbf{E}$ of a filtering problem (2.0), is defined to be the Lie algebra generated by $\{L_0, L_1, \cdots, L_m\}$, or, $\mathbf{E} = \langle L_0, L_1, \cdots, L_m \rangle_{L.A.}$. If in addition there exists a potential function ϕ such that $f_i = (\partial\phi)/(\partial x_i)$ for all $1 \leqq i \leqq n$, then the estimation algebra is called exact.

From now on, unless stated otherwise, we assume the estimation algebra of (2.0) is exact. We use ∇p to denote the column vector

$$\left(\frac{\partial p}{\partial x_1}, \cdots, \frac{\partial p}{\partial x_n}\right)^T.$$

Hence, $\nabla\phi = f$.

In the case where $n = 1$, all estimation algebras are automatically exact. Note also, all exact estimation algebras are characterized by the fact that $\Omega = 0$.

Define

$$D_i = \frac{\partial}{\partial x_i} - f_i,$$

and

$$\eta = \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2.$$

Then,

$$L_0 = \frac{1}{2}\left(\sum_{i=1}^{n} D_i^2 - \eta\right).$$

Recall that $f_i = (\partial\phi)/(\partial x_i)$. Hence,

$$\eta = \Delta\phi + |\nabla\phi|^2 + \sum_{i=1}^{m} h_i^2. \tag{2.4}$$

We need the following basic results for later discussion.

THEOREM 1. (Ocone). *Let* $\mathbf{E}$ *be a finite-dimensional estimation algebra. If a function* ζ *is in* $\mathbf{E}$, *then* ζ *is a polynomial of degree* $\leqq 2$.

Ocone's theorem ([11], see [12] for an extension) says that $h_1, \cdots, h_m$ in a finite-dimensional estimation algebra are polynomials of degree $\leqq 2$.

LEMMA 1. *Let* ζ *be a* C^∞ *function on* $\mathbb{R}^n$. *Suppose* $E_l(\zeta)$ *is a polynomial of degree at most k where* $E_l = \sum_{i=1}^{l} x_i\, \partial/(\partial x_i)$. *Then* $\zeta = p_k(x_1, \cdots, x_n) + \zeta(0, \cdots, 0, x_{l+1}, \cdots, x_n)$ *where* p_k *is a polynomial of degree k in* $x_1, \cdots, x_n$.

Proof.

$$\begin{aligned}
&\zeta(x_1, x_2, \cdots, x_n) - \zeta(0, \cdots, 0, x_{l+1}, \cdots, x_n) \\
&\quad = \int_0^1 \frac{d}{dt}\,\zeta(tx_1, \cdots, tx_l, x_{l+1}, \cdots, x_n)\, dt \\
&\quad = \int_0^1 \left[x_1 \frac{\partial\zeta}{\partial x_1}(tx_1, \cdots, tx_l, x_{l+1}, \cdots, x_n) + \cdots \right. \\
&\qquad\qquad \left. + x_l \frac{\partial\zeta}{\partial x_l}(tx_1, \cdots, tx_l, x_{l+1}, \cdots, x_n) \right] dt \\
&\quad = \int_0^1 E_l(\zeta)(tx_1, \cdots, tx_l, x_{l+1}, \cdots, x_n)\, dt.
\end{aligned}$$

Since $E_l(\zeta)$ is a polynomial of degree k, we see that $\int_0^1 E_l(\zeta) \times (tx_1, \cdots, tx_l, x_{l+1}, \cdots, x_n)\, dt$ is also a polynomial of degree k. □

LEMMA 2. *Let* ζ *be a* C^∞ *function on* $\mathbb{R}^n$. *Suppose* $E_l\zeta + 2\zeta$ *is a sum of polynomials of degree two and a* C^∞ *function on* $\mathbb{R}^n$ *which depends only on* $x_{l+1}, \cdots, x_n$ *variables. Then for any* $(a_{l+1}, \cdots, a_n) \in \mathbb{R}^{n-l}$, $\zeta(x_1, \cdots, x_l, a_{l+1}, \cdots, a_n)$ *is a polynomial of degree two in* $x_1, \cdots, x_l$ *variables.*

Proof. Let $\tilde{\zeta}(x_1, \cdots, x_l) = \zeta(x_1, \cdots, x_l, a_{l+1}, \cdots, a_n)$. Then

$$\begin{aligned}
E_l(\tilde{\zeta})(x_1, \cdots, x_l) + 2\tilde{\zeta}(x_1, \cdots, x_l) &= E_l(\zeta)(x_1, \cdots, x_l, a_{l+1}, \cdots, a_n) \\
&\quad + 2\zeta(x_1, \cdots, x_l, a_{l+1}, \cdots, a_n)
\end{aligned}$$

is a polynomial of degree two in $x_1, \cdots, x_l$ variables. It is well known that $\tilde{\zeta}$ can be written in the following form

$$\tilde{\zeta}(x_1, \cdots, x_l) = \text{polynomial of degree two} + \sum_{i \leqq j \leqq k} a_{ijk} x_i x_j x_k$$

where a_{ijk} are C^∞ functions on $\mathbb{R}^l$. Clearly $E_l(\tilde{\zeta}) = \text{polynomial of degree two} + \sum_{i \leqq j \leqq k} (E_l(a_{ijk}) + 3a_{ijk}) x_i x_j x_k$ and $E_l(\tilde{\zeta}) + 2\tilde{\zeta} = \text{polynomial of degree two} + \sum_{i \leqq j \leqq k} (E_l(a_{ijk}) + 5a_{ijk}) x_i x_j x_k$. This implies $\sum_{i \leqq j \leqq k} (E_l(a_{ijk}) + 5a_{ijk}) x_i x_j x_k$ is a polynomial of degree two. It follows that for each $i \leqq j \leqq k$, we have $E_l(a_{ijk}) + 5a_{ijk} = 0$. Observe that $E_l(x_1^5 a_{ijk}) = 5x_1^5 a_{ijk} + x_1^5 E_l(a_{ijk}) = 0$. In view of Lemma 1, we know that $x_1^5 a_{ijk}$ is a

polynomial of degree zero, i.e., $x_1^5 a_{ijk} = \text{constant}$. Since a_{ijk} is a C^∞ function on $\mathbb{R}^l$, we conclude that the constant is actually zero. So $\zeta(x_1, \cdots, x_l, a_{l+1}, \cdots, a_n) = \tilde{\zeta}(x_1, \cdots, x_l)$ is a polynomial of degree two in $x_1, \cdots, x_l$ variables. □

3. Structure theorems. The following theorem plays a fundamental role in the classification of exact estimation algebra. It is similar to Theorem 1 in [7], although assuming the estimation algebra is exact allows us to drop certain technical requirements on f, g and h.

THEOREM 2. *Let* **E** *be a finite-dimensional exact estimation algebra. Then* $h_1, \cdots, h_m$ *are polynomials of degree at most one.*

Proof. By Theorem 1, each h_i is a polynomial of degree at most two. Suppose h_1 is of degree two, then by using the affine transformation $\tilde{x} = Ax + b$, where A is orthogonal, we may assume h_1 is of the form

$$\sum_{i=1}^{l} c_i \tilde{x}_i^2 + \sum_{i=l+1}^{n} c_i \tilde{x}_i + c_0,$$

where $c_1, \cdots, c_l$ are nonzero real numbers, and $l \leqq n$. (If $l = n$, the second summation vanishes.) Define $\tilde{f}(\tilde{x}) = Af(x)$ and $\tilde{D}_i = \partial/\partial \tilde{x}_i - \tilde{f}_i$. If $\tilde{\phi}(\tilde{x}) = \phi(x)$, it is easy to see that

$$\tilde{f}(\tilde{x}) = \left(\frac{\partial \tilde{\phi}}{\partial \tilde{x}_1}, \cdots, \frac{\partial \tilde{\phi}}{\partial \tilde{x}_n} \right)^T.$$

Under the transformation, L_0 is mapped into:

$$\tilde{L}_0 = \frac{1}{2} \left(\sum_{i=1}^{n} \tilde{D}_i^2 - \tilde{\eta}(\tilde{x}) \right),$$

where

$$\tilde{\eta}(\tilde{x}) = \left[\sum_{i=1}^{n} \frac{\partial \tilde{f}_i(\tilde{x})}{\partial \tilde{x}_i} + \tilde{f}(\tilde{x})^T \tilde{f}(\tilde{x}) + \sum_{i=1}^{m} \tilde{h}_i(\tilde{x})^2 \right],$$

and h is transformed into

$$\tilde{h}(\tilde{x}) = h(x).$$

E is isomorphic to the Lie algebra generated by $\tilde{L}_0$ and $\tilde{h}_i$. Note that the degree of h_i in x is the same as the degree of $\tilde{h}_i$ in $\tilde{x}$. Without causing any confusion, from now on, we drop the tilde notation.

Since h_1 is not of degree one, then $l \geqq 1$. We shall produce a contradiction. Let $X_0 = h_1$, and define X_i for $i \geqq 1$ recursively by $X_i = [[L_0, X_{i-1}], X_0]$. Since $L_0 = \frac{1}{2}(\sum_{i=1}^{n} D_i^2 - \eta)$, it is easy to see that

$$X_1 = 4 \sum_{i=1}^{l} c_i^2 x_i^2 + \sum_{i=l+1}^{n} c_i^2,$$

and for $j > 1$

$$X_j = 4^j \sum_{i=1}^{l} c_i^{j+1} x_i^2.$$

By the invertibility of the Vandermonde matrix, it follows after some relabeling, if necessary, that

$$p \equiv \frac{1}{2} \sum_{i=1}^{l} x_i^2$$

is an element in **E**. Let Y_0 be the zero degree differential operator defined by multiplication by p. Define

$$Y_1=[L_0, Y_0]=\sum_{i=1}^{l} x_iD_i+l/2,$$

$$Y_2=[L_0, Y_1]=\sum_{i=1}^{l} D_i^2+\frac{1}{2}\sum_{i=1}^{l} x_i\frac{\partial\eta}{\partial x_i}=\sum_{i=1}^{l} D_i^2+\frac{1}{2}E_l(\eta),$$

and

$$Y_3=[Y_2, Y_1]=2\sum_{i=1}^{l} D_i^2-\frac{1}{2}E_l^2(\eta).$$

Then,

$$2Y_2-Y_3=\tfrac{1}{2}E_l^2(\eta)+E_l(\eta)=\tfrac{1}{2}E_l(E_l\eta+2\eta).$$

By Lemma 1, we know that $E_l(\eta)+2\eta$ is a sum of polynomial of degree two and a C^∞ function which depends on $x_{l+1}, \cdots, x_n$ variables. By Lemma 2, it follows that η is a polynomial of degree two in $x_1, \cdots, x_l$, with coefficients which are C^∞ functions in $x_{l+1}, \cdots, x_n$ only. Recall that

$$\Delta\phi+|\nabla\phi|^2=-\sum_{i=1}^{m} h_i^2+\eta. \tag{3.0}$$

Let $\psi\in C_0^\infty$ be any C^∞ function with compact support. Multiply (3.0) with ψ^2 and integrate the equation over $\mathbb{R}^n$.

$$\begin{aligned}-\int_{\mathbb{R}^n}\left(\sum_{i=1}^{m} h_i^2-\eta\right)\psi^2&=\int_{\mathbb{R}^n}\psi^2\Delta\phi+\int_{\mathbb{R}^n}\psi^2|\nabla\phi|^2\\&=-\int_{\mathbb{R}^n}2\psi\langle\nabla\psi, \nabla\phi\rangle+\int_{\mathbb{R}^n}\psi^2|\nabla\phi|^2.\end{aligned} \tag{3.1}$$

By the Schwartz inequality

$$2\int_{\mathbb{R}^n}\psi\langle\nabla\psi, \nabla\phi\rangle\leqq\int_{\mathbb{R}_n}|\nabla\psi|^2+\int_{\mathbb{R}^n}\psi^2|\nabla\phi|^2. \tag{3.2}$$

Putting (3.2) into (3.1), we get

$$\int_{\mathbb{R}^n}|\nabla\psi|^2-\int_{\mathbb{R}^n}\left(\sum_{i=1}^{m} h_i^2-\eta\right)\psi^2\geqq 0, \tag{3.3}$$

which is true for all $\psi\in C_0^\infty$. Take any nonzero C^∞ function θ with compact support. Define ψ to be θ followed by a translation in $x_1, \cdots, x_l$ variables direction. Observe that $\int_{\mathbb{R}^n}|\nabla\psi|^2$ is independent of the translation selected. On the other hand, since η is quadratic in $x_1, \cdots, x_l$ variables and h_1 is of degree four in $x_1, \cdots, x_l$, $\sum_{l=1}^{m} h_i^2-\eta$ becomes very positive when one of the $x_1, \cdots, x_l$ tends to infinity while the other variables remain fixed. We can choose translation in directions, $x_1, \cdots, x_l$, in such a way that

$$\int_{\mathbb{R}^n}\left(\sum_{i=1}^{m} h_i^2-\eta\right)\psi^2$$

is arbitrarily large while $\int_{\mathbb{R}^n} |\nabla\psi|^2$ is bounded. This of course contradicts the inequality (3.3). □

The argument above actually proves the following theorem.

THEOREM 3. *Let $F(x_1, \cdots, x_n)$ be a C^∞ function on $\mathbb{R}^n$. Suppose that there exists a path $C: \mathbb{R} \to \mathbb{R}^n$ and $\delta > 0$ such that $\lim_{t\to\infty} \|C(t)\| = \infty$ and $\lim_{t\to\infty} \sup_{B_\delta(C(t))} F = -\infty$, where $B_\delta(C(t)) = \{x \in \mathbb{R}^n \mid \|x - C(t)\| < \delta\}$. Then there is no C^∞ function ψ on $\mathbb{R}^n$ satisfying the equation*

$$\Delta\psi + |\nabla\psi|^2 = F.$$

COROLLARY. *Let $F(x_1, \cdots, x_n)$ be a polynomial on $\mathbb{R}^n$. Suppose that there exists a polynomial path $C: \mathbb{R} \to \mathbb{R}^n$ such that $\lim_{t\to\infty} \|C(t)\| = \infty$ and $\lim_{t\to\infty} F \circ C(t) = -\infty$. Then there is no C^∞ function ψ on $\mathbb{R}^n$ satisfying the equation*

$$\Delta\psi + |\nabla\psi|^2 = F.$$

Proof. It suffices to prove that $\lim_{t\to\infty} \sup_{B_\delta(C(t))} F(x_1, \cdots, x_n) = -\infty$, where $B_\delta(C(t)) = \{x \in \mathbb{R}^n \mid \|x - C(t)\| < \delta\}$ for some $\delta > 0$. Let $C(t) = (C_1(t), \cdots, C_n(t))$, where

$$\begin{aligned}
C_1(t) &= a_{11}t^k + a_{12}t^{k-1} + \cdots + a_{1k}t + b_1 \\
C_2(t) &= a_{21}t^k + a_{22}t^{k-1} + \cdots + a_{2k}t + b_2 \\
&\vdots \\
C_n(t) &= a_{n1}t^k + a_{n2}t^{k-1} + \cdots + a_{nk}t + b_n.
\end{aligned}$$

Since F is a polynomial, we have

$$(F \circ C)(t) = \gamma_1 t^d + \gamma_2 t^{d-1} + \cdots + \gamma_{d+1},$$

where $\gamma_1, \cdots, \gamma_{d+1}$ are polynomials in a_{ij} and b_i for $i \leqq n$ and $1 \leqq j \leqq k$. γ_1 must be negative since $\lim_{t\to\infty} (F \circ C)(t) = -\infty$. By continuity, we know that there exists a $\delta > 0$, and a sphere center at $(b_1, \cdots, b_n)$ with radius δ, $B_\delta(b)$, such that for any point $(b'_1, \cdots, b'_n)$ in it, the following bounds hold:

$$\begin{aligned}
&\gamma_1(a_{ij}; b'_1, \cdots, b'_n) \leqq \tfrac{1}{2}\gamma_1(a_{ij}; b_1, \cdots, b_n) < 0 \\
&|\gamma_2(a_{ij}; b'_1, \cdots, b'_n) - \gamma_2(a_{ij}; b_1, \cdots, b_n)| \leqq 1 \\
&\vdots \\
&|\gamma_{d+1}(a_{ij}; b'_1, \cdots, b'_n) - \gamma_{d+1}(a_{ij}; b_1, \cdots, b_n)| \leqq 1.
\end{aligned}$$

It follows that for $t > 0$,

$$\begin{aligned}
&\sup_{B_\delta(C(t))} F(x_1, \cdots, x_n) \\
&\quad = \sup_{b' \in B_\delta(b)} F(a_{11}t^k + \cdots + a_{1k} + b'_1, \cdots, a_{n1}t^k + \cdots + a_{nk} + b'_n) \\
&\quad = \sup_{b' \in B_\delta(b)} \{\gamma_1(a_{ij}; b'_1, \cdots, b'_n)t^d + \gamma_2(a_{ij}; b'_1, \cdots, b'_n)t^{d-1} + \cdots \\
&\qquad\qquad + \gamma_{d+1}(a_{ij}; b'_1, \cdots, b'_n)\} \\
&\quad \leqq \tfrac{1}{2}\gamma_1(a_{ij}; b_1, \cdots, b_n)t^d + (1 + \gamma_2(a_{ij}; b_1, \cdots, b_n))t^{d-1} + \cdots \\
&\qquad\qquad + (1 + \gamma_{d+1}(a_{ij}; b_1, \cdots, b_n)).
\end{aligned}$$

As $\gamma_1(a_{ij}; b_1, \cdots, b_n)$ is negative, the right-hand side tends to $-\infty$ as t tends to ∞. The assertion follows immediately. □

The following result provides a simple characterization of when the dimension of an estimation algebra is finite.

THEOREM 4. *Suppose* **E** *is an exact estimation algebra. Then,* **E** *is finite-dimensional if and only if* $\nabla h_i^T J_\eta^j$ *is a constant for* $1 \leqq i \leqq m$ *and all* $j = 0, 1, \cdots$, *where* $J_\eta = (\partial^2 \eta)/(\partial x_i\, \partial x_j)$, *denote the Hessian matrix of* η.

Proof. The sufficiency of the condition follows from the main theorem of [2]. For completeness reason, we provide the proof here. Assume the condition in Theorem 4 holds. Note that **E** is generated by $L_0, L_1, \cdots, L_m$. Recall that for $i = 1, \cdots, m$ we define

$$L_{m+i} = [L_0, L_i] = \nabla h_i^T D,$$

where D denotes the vector

$$(D_1, \cdots, D_n)^T.$$

Define **F** to be the linear space generated by first and zero degree differential operators of the form $\nabla h_i^T J_\eta^j D$ and $\nabla h_i^T J_\eta^j \nabla \eta$, for $i = 1, \cdots, m$, $j = 0, 1, \cdots$. Clearly, $L_{m+1}, \cdots, L_{2m}$ are elements in **F**. Using our stated assumption, it is also straightforward to check that

(i) $[X, Y] =$ constant if $X, Y \in \mathbf{F}$,

(ii) $[L_0, X] \in \mathbf{F}$ if $X \in \mathbf{F}$,

(iii) $[h_i, X] =$ constant for $i = 1, \cdots, m$ and X in **F**.

Conditions (i), (ii), and (iii) imply that

$$\dim \mathbf{E} \leqq \dim \operatorname{span} \{L_0, h_1, \cdots, h_m, 1\} + \dim \mathbf{F}.$$

By our stated assumption,

$$\mathbf{F} \subset \operatorname{span} \{\partial \eta/\partial x_1, \cdots, \partial \eta/\partial x_n, \partial/\partial x_1, \cdots, \partial/\partial x_n\}.$$

It follows that dimension of **E** is finite.

To prove the necessary condition, assume **E** is finite-dimensional and the condition in Theorem 4 does not hold. Without loss of generality, we may assume there is a $k \geqq 0$, such that $\nabla h_1^T, \nabla h_1^T J_\eta, \cdots, \nabla h_1^T J_\eta^k$ are constant vectors, but $\nabla h_1^T J_\eta^{k+1}$ is not. (Notice that ∇h_1 is a constant vector by Theorem 2.) Let $c = \nabla h_1$. Hence, $c^T x$, $c^T \nabla \eta$, $c^T J_\eta \nabla \eta, \cdots, c^T J_\eta^{k-1} \nabla \eta$ all have degrees at most 1. (If $k = 0$, only the first term is present.) It follows that

$$Ad_{L_0}^{2i+1} h_1 = \frac{1}{2^i} c^T J_\eta^i D \qquad i = 0, \cdots, k+1, \tag{3.4a}$$

$$Ad_{L_0}^{2i} h_1 = \frac{1}{2^i} c^T J_\eta^{i-1} \nabla \eta \qquad i = 1, \cdots, k+1. \tag{3.4b}$$

Let $b^T = c^T J_\eta^k$. There exists an orthogonal matrix, Q, such that

$$b^T Q = (d_1, 0, 0, \cdots, 0) \equiv d^T.$$

Define an orthogonal transformation on the state space by $\tilde{x} = Q^T x$. Under this new coordinate, $c^T x$ is mapped to $c^T Q \tilde{x}$, $\eta(x)$ is mapped to $\eta(Q\tilde{x})$, and $c^T J_\eta^k$ is mapped to d^T. So we may assume $b = d$. Equation (3.4) implies that D_1 and $b^T \nabla \eta = d_1(\partial \eta/\partial x_1)$ are both in **E**. By Ocone's Theorem, $(\partial \eta)/(\partial x_1)$ is a polynomial with degree at most 2. By the assumption that $\nabla h_1^T J_\eta^{k+1}$ is not a constant vector, it follows that the degree of $(\partial \eta)/(\partial x_1)$ is exactly 2. So,

$$\eta = x_1 q + r,$$

where q is a polynomial with degree 2, r is independent of x_1. Depending on the degree of q in x_1, we have three possible cases.

(i) *Degree* 2 *case.* Clearly, $\eta - \sum_{i=1}^{m} h_i^2$ can be arbitrarily negative on some polynomial path as the path tends to infinity.

(ii) *Degree* 1 *case.* It follows that $\eta = \sum_{i=2}^{n} \alpha_i x_i x_1^2 + \beta x_1 + r$, where α_i's are constants, at least one of them nonzero, β and r are independent of x_1. Clearly, $\eta - \sum_{i=1}^{m} h_i^2$ can be arbitrarily negative on some polynomial path as the path tends to infinity.

(iii) *Degree* 0 *case.* Since q is independent of x_1, $\eta = sx_1 + t$, where s and t are independent of x_1. If $\sum_{i=1}^{m} h_i^2$ is independent of x_1, then $\eta - \sum_{i=1}^{m} h_i^2$ can be arbitrarily negative. If $\sum_{i=1}^{m} h_i^2$ is dependent on x_1, it must be of degree 2 in x_1. Again, $\eta - \sum_{i=1}^{m} h_i^2$ can be arbitrarily negative on some polynomial path as the path tends to infinity.

In all three cases, there is a contradiction to the Corollary of Theorem 3. □

If $\mathbf{E}$ is finite-dimensional, then $\nabla h_i^T J_\eta^j$ is a constant for $1 \leqq i \leqq n$ and all $j = 0, 1, \cdots$. It is easy to show by inductive argument that the following theorem holds.

THEOREM 5. *Suppose* $\mathbf{E}$ *is an exact finite-dimensional estimation algebra. Then it has a basis consisting of one second degree differential operator* L_0, *first degree differential operator*(*s*) *with constant coefficients, and zero degree differential operator*(*s*) *affine in x. Moreover, if X and Y are in* $\mathbf{E}$ *with degree less than or equal to* 1, *then* $[X, Y]$ *is a constant.*

Theorem 6 follows from Theorem 5.

THEOREM 6. *An exact finite-dimensional estimation algebra is solvable.*

4. The Wei–Norman approach. In this section we will use the structural results of previous sections to derive finite-dimensional filters by the Wei-Norman-Brockett approach. To do this, the first step we have to establish is a representation analogous to (1.1).

Consider the filtering system as defined by (2.0). In the following discussion it is not necessary to assume that the estimation algebra of (2.0) is exact. However, we will retain all the notation introduced earlier. In particular, notice that (2.2) still holds. We assume that the estimation algebra is finite dimensional and has a basis consisting of $E_0 = L_0$, differential operators, $E_1, \cdots, E_p$, (for some p) of the form

$$\sum_{j=1}^{n} \alpha_{ij} D_j + \beta_i,$$

where α_{ij}'s are constants and β_i's are polynomial in x, and zero degree differential operators, $E_{p+1}, \cdots, E_q$, (for some $q > p$) affine in x. Moreover, we assume for $1 \leqq i, j \leqq p$, $[E_i, E_j]$ is a constant and that all zero degree differential operators in the estimation algebra are spanned by $E_{p+1}, \cdots, E_q$.[2]

It follows from Theorem 5 that if the estimation algebra of (2.0) is exact and finite-dimensional then it possesses such a basis. However, the exactness is not always necessary. For example, in [6] sufficient conditions are provided for nonexact systems to possess finite-dimensional estimation algebras.

It is clear that by the assumption on the basis that for $1 \leqq i, j \leqq q$,

$$[E_i, E_j] = \text{constant}.$$

For $p+1 \leqq i, j \leqq q$,

$$[E_i, E_j] = 0,$$

and for $1 \leqq i \leqq q$ the degree of $[E_0, E_i]$ as a differential operator is not greater than one.

[2] Our earlier definition of L_i still holds. Notice that the L_i's may not form a basis of the estimation algebra.

Since $[[L_0, \sum_{i=1}^{l} c_i x_i + d], \sum_{i=1}^{l} c_i x_i + d] = \sum_{i=1}^{l} c_i^2$, if c_i's and d are constants, the constant function is in the estimation algebra. Without loss of generality, we assume that E_q is the constant function 1.

For a filtering system with such a basis, $[[L_0, L_i], L_i] =$ constant for all $i = 1, \cdots, m$. Hence, $\frac{1}{2}\sum_{i=1}^{m} [[L_0, L_i], L_i] y_i^2(t)$, denoted by $u(t)$, is a function of t independent of x. Equation (2.2) becomes

$$\frac{d\xi(t,x)}{dt} = L_0\xi(t,x) + \sum_{i=1}^{m} [L_0, L_i]\xi(t,x)y_i(t) + u(t)\xi(t,x). \tag{4.0}$$

DEFINITION. Suppose X is a differential operator, ζ_0 is in the domain of X, r is a continuous function, and $R(t) = \int_0^t r(s)\,ds$. We denote by $e^{R(t)X}\zeta_0$ the solution at time t of the following equation:

$$\frac{d\zeta(t)}{dt} = r(t)X\zeta(t), \qquad \zeta(0) = \zeta_0,$$

if it is well defined.

For $1 \leqq i \leqq q$, $e^{tE_i}\zeta(x)$ can be expressed in the form $\int k(t,x,r)\zeta(r)\,dr$, for some integrable kernel k. Hence, we can extend the definition of $e^{tE_i}\zeta(x)$ to $e^{tE_i}\zeta(t,x)$, where ζ is also a function of t.

PROPOSITION 1. *If ζ is a C^∞ function in x, then for all $0 \leqq s$, the following Baker-Campbell-Hausdorff type relations hold*:

(1) *For $1 \leqq i < q$,*

$$e^{sE_i}E_0\zeta = \left(E_0 + s\sum_{i=1}^{q} a_{ij}E_j + s^2\delta_i\right)e^{sE_i}\zeta,$$

where a_{ij}'s and δ_i's are constants.

(2) *For $1 \leqq i \leqq p$, $1 \leqq j < q$, or $1 \leqq i < q$, $1 \leqq j \leqq p$,*

$$e^{sE_i}E_j\zeta = (E_j + s\gamma_{ji})e^{sE_i}\zeta,$$

where γ_{ji}'s are constants in x.

(3) *For $p+1 \leqq i, j \leqq q$, or $i = q$, $1 \leqq j \leqq q$, or $j = p$, $1 \leqq i \leqq q$,*

$$e^{sE_i}E_j\zeta = E_j e^{sE_i}\zeta.$$

Proof. If E_i is a zero degree differential operator, e^{sE_i} is simply $\exp(sE_i)$. If it is a first degree differential operator, we may assume it is of the form: $\sum_{j=1}^{n} \alpha_{ij}D_j + \beta_i$. Define α_i to be column nth-dimensional vector whose jth component is α_{ij}. Then, it is well known that

$$\begin{aligned} e^{sE_i}\zeta(x) &= \exp\left(\phi(x) - \phi(x+s\alpha_i) + \int_0^s \beta_i(x+\alpha_i(s-r))\,dr\right)\zeta(x+s\alpha_i) \\ &= \exp\left(\phi(x) - \phi(x+s\alpha_i) + \int_0^s \beta_i(x+\alpha_i r)\,dr\right)\zeta(x+s\alpha_i). \end{aligned} \tag{4.1}$$

Assume first that ϕ and ζ are analytic functions. Let $\tilde{\zeta}$ be an arbitrary analytic function in x. From our discussion, it is clear that $e^{sE_i}\tilde{\zeta}$ is well defined for all real s and $1 \leqq i \leqq q$. Moreover, for any fixed x, $e^{sE_i}E_0e^{-sE_i}\tilde{\zeta}$ is analytic in s. Hence, the classical Baker-Campbell-Hausdorff formula holds from the Taylor series expansion. That is:

$$e^{sE_i}E_0e^{-sE_i}\tilde{\zeta} = \left(E_0 + s[E_i, E_0] + \frac{s^2}{2}[E_i, [E_i, E_0]]\right)\tilde{\zeta}.$$

Now let $\tilde{\zeta} = e^{sE_i}\zeta$. By using the previously stated properties of the basis, it is easy to see that (1) holds under the analytic assumption.

Next, we relax the condition that ϕ is analytic to that it is C^∞. If E_i is a zero degree differential operator, then clearly $e^{sE_i}E_0e^{-sE_i}\tilde{\zeta}$ is still analytic in s and (1) holds as proven before. Hence, we assume that $E_i = \sum_{j=1}^n \alpha_{ij}D_j + \beta_i$. (Recall that β_i is a polynomial in x.) We can find a polynomial sequence, $\{\tilde{\phi}_i\}$, so that $\tilde{\phi}_i$ converges to ϕ and the first and second order derivatives of $\tilde{\phi}_i$ converge to the respective first and second order derivatives of ϕ. Define $\tilde{f}_{j,i}$ to be $(\partial\tilde{\phi}_j)/(\partial x_i)$ and $\tilde{D}_{j,i}$ to be $\partial/(\partial x_i) - \tilde{f}_{j,i}$. Define $\tilde{E}_{j,i}$ to be $\sum_{k=1}^n \alpha_{ik}\tilde{D}_{j,k} + \beta_i$. Finally, define

$$\tilde{E}_{j,0} = \frac{1}{2}\sum_{k=1}^n \frac{\partial^2}{\partial x_k^2} - \sum_{k=1}^n \tilde{f}_{j,k}\frac{\partial}{\partial x_k} - \sum_{k=1}^n \frac{\partial \tilde{f}_{j,k}}{\partial x_k} - \frac{1}{2}\sum_{k=1}^m h_k^2.$$

It is easy to show by (4.1) that there exist functions u and v such that:

$$\begin{aligned} &e^{s\tilde{E}_{j,i}}\tilde{E}_{j,0}e^{-s\tilde{E}_{j,i}}\tilde{\zeta} \\ &= \left(-\frac{1}{2}\sum_{k=1}^n \frac{\partial \tilde{f}_{j,k}(x)}{\partial x_k} + \frac{1}{2}\sum_{k=1}^n \tilde{f}_{j,k}^2(x) - \frac{1}{2}\sum_{k=1}^n \frac{\partial \tilde{f}_{j,k}(x+s\alpha_i)}{\partial x_k}\right. \\ &\quad \left. -\frac{1}{2}\sum_{k=1}^n \tilde{f}_{j,k}^2(x+s\alpha_i)\right)\tilde{\zeta}(x) + \sum_{k=1}^n \tilde{f}_{j,k}(x)u(s,x) + v(s,x), \end{aligned}$$

and

$$\begin{aligned} &e^{sE_i}E_0e^{-sE_i}\tilde{\zeta} \\ &= \left(-\frac{1}{2}\sum_{k=1}^n \frac{\partial f_k(x)}{\partial x_k} + \frac{1}{2}\sum_{k=1}^n f_k^2(x) - \frac{1}{2}\sum_{k=1}^n \frac{\partial f_k(x+s\alpha_i)}{\partial x_k}\right. \\ &\quad \left. -\frac{1}{2}\sum_{k=1}^n f_k^2(x+s\alpha_i)\right)\tilde{\zeta}(x) + \sum_{k=1}^n f_k(x)u(s,x) + v(s,x). \end{aligned}$$

It follows then, that

$$\lim_{j\to\infty} e^{s\tilde{E}_{j,i}}\tilde{E}_{j,0}\, e^{-s\tilde{E}_{j,i}}\tilde{\zeta} = e^{sE_i}E_0\, e^{-sE_i}\tilde{\zeta}.$$

Similarly,

$$\lim_{j\to\infty}\left(\tilde{E}_{j,0} + s[\tilde{E}_{j,i}, \tilde{E}_{j,0}] + \frac{s^2}{2}[\tilde{E}_{j,i}, [\tilde{E}_{j,i}, \tilde{E}_{j,0}]]\right)\tilde{\zeta} = \left(E_0 + s[E_i, E_0] + \frac{s^2}{2}[E_i, [E_i, E_0]]\right)\tilde{\zeta}.$$

Hence, (1) holds in this case also. For the general case, for any given x, construct sequences of analytic functions $\{\tilde{\zeta}_i\}$, so that they converge to ζ. It follows that (1) holds in the general case as well. Statements (2), (3), and (4) can be proved similarly. □

THEOREM 7. *If the estimation algebra of* (2.0) *has a basis as described earlier, then its robust* DMZ *equation* (4.0) *has a solution for all* $t \geqq 0$ *of the form*:

$$\xi(t,x) = e^{r_q(t)E_q}\cdots e^{r_1(t)E_1}\, e^{tE_0}\sigma_0, \tag{4.2}$$

where r_i's satisfy an ordinary differential equation for all t. It follows then that a universal finite-dimensional filter exists for (2.0).

Proof. Since E_0 is elliptic, for any $t>0$, $e^{tE_0}\sigma_0$ is C^∞. By differentiating $\xi(t,x)$ we have

$$\frac{d\xi(t,x)}{dt} = e^{r_qE_q}\cdots e^{r_1E_1}E_0\,e^{tE_0}\sigma_0$$

$$+\frac{dr_1}{dt}\,e^{r_qE_q}\cdots e^{r_2E_2}E_1\,e^{r_1E_1}\,e^{tE_0}\sigma_0+\cdots+\frac{dr_q}{dt}\,E_q\,e^{r_qE_q}\cdots e^{r_1E_1}\,e^{tE_0}\sigma_0.$$

By applying Proposition 1,

$$e^{r_qE_q}\cdots e^{r_1E_1}E_0\,e^{tE_0}\sigma_0 = e^{r_qE_q}\cdots e^{r_2E_2}\left(E_0+r_1\sum_{j=1}^{q}a_{1j}E_j+r_1^2\delta_1\right)e^{r_1E_1}\,e^{tE_0}\sigma_0$$

$$=\left(E_0+\sum_{i=1}^{q-1}\sum_{j=1}^{q}r_ia_{ij}E_j+\kappa_0\right)\xi(t,x),$$

where κ_0 is a polynomial in $r_1,\cdots,r_{q-1}$ and constant in x and r_q.

For $1\leqq i\leqq p$,

$$\frac{dr_i}{dt}\,e^{r_qE_q}\cdots e^{r_{i+1}E_{i+1}}E_i\,e^{r_iE_i}\,e^{r_{i-1}E_{i-1}}\cdots e^{tE_0}\sigma_0$$

$$=\frac{dr_i}{dt}\,e^{r_qE_q}\cdots e^{r_{i+2}E_{i+2}}(E_i+r_{i+1}\gamma_{i+1,i})\,e^{r_{i+1}E_{i+1}}\cdots e^{tE_0}\sigma_0$$

$$=\frac{dr_i}{dt}(E_i+\kappa_i)\xi(t,x),$$

where κ_i is a polynomial with degree 1 in r_j for $i+1\leqq j<q$ and constant in the remaining r_j's and x.

For $p+1\leqq i\leqq q$,

$$\frac{dr_i}{dt}\,e^{r_qE_q}\cdots e^{r_{i+1}E_{i+1}}E_i\,e^{r_iE_i}\,e^{r_{i-1}E_{i-1}}\cdots e^{tE_0}\sigma_0=\frac{dr_i}{dt}\,E_i\xi(t,x).$$

Hence,

$$\frac{d\xi(t,x)}{dt}=\left(E_0+\sum_{i=1}^{q-1}\sum_{j=1}^{q}r_ia_{ij}E_j+\sum_{i=1}^{q}\frac{dr_i}{dt}\,E_i+\sum_{i=1}^{p}\frac{dr_i}{dt}\,\kappa_i+\kappa_0\right)\xi(t,x). \tag{4.3}$$

By substituting (4.3) into (4.0), it is clear that ξ_t is a solution to (4.0), if for $1\leqq j<q$,

$$\frac{dr_j}{dt}=\sum_{i=1}^{m}y_i(t)e_{ij}-\sum_{i=1}^{q-1}r_ia_{ij}, \tag{4.4}$$

and

$$\frac{dr_q}{dt}=u_t+\sum_{i=1}^{m}y_i(t)e_{iq}-\sum_{i=1}^{q-1}r_ia_{iq}-\sum_{i=1}^{p}\frac{dr_i}{dt}\,\kappa_i-\kappa_0, \tag{4.5}$$

where we represent $[L_0, L_i]$ as $\sum_{j=1}^{q}e_{ij}E_j$.

By the aforementioned property of κ_i, it is clear that (4.4) and (4.5) have solutions for all t.

To see that these results lead to a finite-dimensional filter for (2.0), notice that if we let the r_i's play the role of the z_i's in (2.3a), then (4.4) and (4.5) are of the form (2.3a). By using (4.1), it is easy to check that (4.2) is of the form (2.3b). □

Remark. For the Benes systems, the β_i's are all linear. It is well known that finite-dimensional filters exist in those cases [13].

Acknowledgments. The authors thank Dr. Lawrence Ein and the reviewer for their helpful comments.

OPTIMAL CONTROLS FOR STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS*

NORIAKI NAGASE† AND MAKIKO NISIO‡

Abstract. This paper deals with control problems for a state process governed by controlled linear stochastic partial differential equations, whose drift and diffusion coefficients are the second order elliptic and the first order differential operators, respectively. A relaxed system is introduced as a generalization of admissible control and the continuous dependence of state process on a relaxed system, assuming some regularity conditions, is proved. Appealing to the usual compactification method, this continuity result derives the existence of an optimal relaxed system and, under convexity condition of coefficients, an optimal relaxed system provides an optimal admissible control in a wider sense. A relaxed control can be approximated by an admissible control which is Brownian adapted and where Bellman principle holds. As an application, stochastic control of diffusions with partial observation, where the state noise and the observation noise may not be independent, is discussed.

Key words. stochastic partial differential equation, optimal control, relaxed system, weak convergence, convexity condition, Bellman principle, partial observation

1. Introduction.

In this paper we are concerned with control problems of systems governed by the following stochastic partial differential equations (SPDE):

$$\begin{aligned} dq(t,x) = &\sum_{i,j=0}^{d} \frac{\partial}{\partial x_i}\left(a^{ij}(x, y+W(t), U(t)) \frac{\partial}{\partial x_j} q(t,x) + f^i(x, y+W(t), U(t))\right) dt \\ &+ \sum_{k=1}^{d'} \left(\sum_{i=0}^{d} b_k^i(x, y+W(t)) \frac{\partial}{\partial x_i} q(x,t) + g_k(x, y+W(t))\right) dW^k(t) \end{aligned} \tag{1.1}$$

where $W=(W^1, \cdots, W^{d'})$ is a d'-dimensional standard Wiener process and $U(t)$ an admissible control, $0 \leqq t \leqq T$, with T fixed.

The problem is to minimize a given criterion by choosing a suitable admissible control. Namely, we treat stochastic optimal controls for distributed parameter systems. The SPDE (1.1) describes intuitively a physical object governed by a partial differential equation with random perturbation, which has been investigated from various viewpoints (cf. Fujita [5], Krylov and Rozovskii [8], [9], [11], Kunita [12], Pardoux [16], Walsh [20]). But another important example is the Zakai equation for controlled partially observed diffusions (cf. [1], [2], [4], [14], [17]). In this case, inhomogeneous terms f^i and g_k are zero and b_k^i arises from the correlation between system and observation noises. Moreover, the Wiener process W is the observation process and the coefficients a^{ij} and b_k^i depend on W (cf. [4], [21]).

The main aim of this paper is to show the existence of an optimal relaxed control for systems governed by the SPDE (1.1) under the ellipticity condition (see (A.2)); in particular we assume that $(a^{ij}(x,y,u) - \frac{3}{2}\sum_{k=1}^{d'} b_k^i(x,y) b_k^j(x,y))_{i,j=1,\cdots,d}$ is nonnegative definite and some regularity conditions on the coefficients. In particular, if $b_k^i = 0$ for $i=1, \cdots, d$, $k=1, \cdots, d'$, then the matrix $(a^{ij}(x,y,u))_{i,j=1,\cdots,d}$ may be degenerate.

Let Γ be a compact convex subset of $\mathbb{R}^L$. We call it a control region. Λ denotes the set of all measures on $[0, T]\times\Gamma$, such that $\lambda([0, t]\times\Gamma) = t$ for any $t\in[0, T]$. The relaxed control, which is introduced in [2] and [3], is a Λ-valued random variable (see Definition 2.1) and acts linearly on coefficients. Thus a relaxed control μ has a density μ', namely $\mu(dt, du) = \mu'(t, du)\,dt$, and when we apply a relaxed control μ, the coefficients a^{ij} and f^i are replaced by the following $\tilde{a}^{ij}$ and $\tilde{f}^i$, respectively,

$$\tilde{a}^{ij}(t, x, y+W(t), \mu) = \int_\Gamma a^{ij}(x, y+W(t), u)\mu'(t, du)$$

and

$$\tilde{f}^i(t, x, y+W(t), \mu) = \int_\Gamma f^i(x, y+W(t), u)\mu'(t, du).$$

Moreover, the system moves according to the following SPDE:

$$\begin{aligned} dq(t, x) = &\sum_{i,j=0}^{d} \frac{\partial}{\partial x_i}\left(\tilde{a}^{ij}(x, y+W(t), \mu)\frac{\partial}{\partial x_j}q(t, x) + \tilde{f}^i(x, y+W(t), \mu)\right)dt \\ &+ \sum_{k=1}^{d'}\left(\sum_{i=0}^{d} b_k^i(x, y+W(t))\frac{\partial}{\partial x_i}q(x, t) + g_k(x, y+W(t))\right)dW^k(t). \end{aligned} \tag{1.2}$$

Now Λ becomes a compact metric space, by being endowed with the weak convergence topology, and the set of all relaxed controls turns out to be a compact metric space by being endowed with the Prohorov metric. Consequently, for our purposes, it is enough to show that the solution of the SPDE (1.2) depends on the relaxed control continuously. But this is a difficult problem. We overcome this obstacle by using a method similar to that used by Nagase [14] and the evaluations for SPDE given by Krylov and Rozovskii [10]. By this means, we can prove the existence of an optimal relaxed control. Moreover, by applying our existence theorems to the Zakai equation, we can obtain an optimal control for partially observed diffusions with correlated noise (see § 7). This result is new, and is a generalization of [1]–[4] and [14].

In § 2, we will introduce several metric spaces that are appropriate to our control problems and define a relaxed system in a wider sense as a generalization of an admissible control. In § 3, we study the way in which the solution depends on the initial data and the relaxed system. In particular, we will prove the continuous dependence of the solution on the relaxed system, when we endow it with the weak convergence topology on the space of image measures of relaxed systems (Theorems 3.1 and 3.2). Section 4 is concerned with existence theorems (Theorems 4.1 and 4.2). In § 5, we will construct an approximate optimal control which is adapted to a Wiener process. Since the Wiener process in the Zakai equation is nothing but the observation process, we have an approximate optimal control, which is a function of the observed data, for partially observed diffusions. The Bellman principle will be proved in § 6 and some applications will be discussed in § 7.

2. Preliminaries. Let us define the operators L and $M = (M_1, \cdots, M_{d'})$ by

$$L(y, u)\psi(x) = \sum_{i,j=0}^{d} \partial_i(a^{ij}(x, y, u)\partial_j\psi(x) + f^i(x, y, u)) \tag{2.1}$$

and

$$M_k(y)\psi(x) = \sum_{i=0}^{d} b_k^i(x, y)\partial_i\psi(x) + g_k(x, y) \qquad \text{for } x\in\mathbb{R}^d,\ y\in\mathbb{R}^{d'},\ u\in\Gamma, \tag{2.2}$$

respectively, where $\partial_0 =$ identity and $\partial_i = \partial/\partial x_i$, $i = 1, \cdots, d$ and a^{ij}, f^i, b_k^i and g_k are bounded and uniformly continuous.

We denote by L_r^2, $r \geqq 0$, the space of real valued Borel functions on $\mathbb{R}^d$ with the norm defined by:

$$\|f\|_{0,r} = \left(\int_{\mathbb{R}^d} |(1+|x|^2)^{r/2} f(x)|^2 \, dx \right)^{1/2}.$$

Let H_r^m be the subspace of L_r^2 consisting of functions whose generalized derivatives up to the order m belong to L_r^2. Clearly H_r^m becomes a Hilbert space with the inner product

$$(f, g)_{m,r} = \sum_{|\alpha| \leqq m} \frac{|\alpha|!}{\alpha^1! \cdots \alpha^d!} \int_{\mathbb{R}^d} (1+|x|^2)^r D^\alpha f(x) D^\alpha g(x) \, dx,$$

where $\alpha = (\alpha^1, \cdots, \alpha^d)$ is a multi-index with nonnegative integer α^i, $|\alpha| = \alpha^1 + \cdots + \alpha^d$ and $D^\alpha = (\partial/\partial x_1)^{\alpha^1} \cdots (\partial/\partial x_d)^{\alpha^d}$. Let us set $\|f\|_{m,r}^2 = (f, f)_{m,r}$ and, for $r = 0$, $L_0^2 = L^2$, $H_0^m = H^m$, $(\cdot, \cdot)_{m,0} = (\cdot, \cdot)_m$ and $\|\cdot\|_{m,0} = \|\cdot\|_m$, for simplicity, if no confusion occurs.

Now we introduce the following conditions.

(A.1) $D^\alpha a^{ij}$, $D^\alpha b_k^i$ $(0 \leqq |\alpha| \leqq m+1$, $i, j = 0, 1, \cdots, d$, $k = 1, \cdots, d')$ are bounded and uniformly continuous.

(A.2) ellipticity condition: $a^{ij} = a^{ji}$, $i, j = 1, \cdots, d$, and $(a^{ij} - \frac{3}{2} b^i \cdot b^j)_{i,j=1,\cdots,d}$ is a nonnegative definite matrix, where $b^i = (b_1^i, \cdots, b_{d'}^i)$ and "$\cdot$" means the inner product in $\mathbb{R}^{d'}$.

(A.3) $f^i(\cdot, y, u)$, $g_k(\cdot, y) \in H^{m+1}$, $i = 0, \cdots, d$, $k = 1, \cdots, d'$, and their H^{m+1}-norms are bounded in $(y, u) \in \mathbb{R}^{d'} \times \Gamma$.

(A.4)$_{l,r}$ $f^i(\cdot, y, u)$, $g_k(\cdot, y) \in H_r^{l+1}$ and their H_r^{l+1}-norms are bounded in y and u.

(A.4)$_l$ For some $r > 0$, (A.4)$_{l,r}$ holds.

Hereafter we always assume (A.1) $\sim$ (A.3) and, for simplicity, we say

$$\begin{aligned} &|D^\alpha a^{ij}(x, y, u)| \leqq K, \qquad |D^\alpha b_k^i(x, y)| \leqq K, \\ &\|f^i(\cdot, y, u)\|_{m+1} \leqq K, \qquad \|g_k(\cdot, y)\|_{m+1} \leqq K. \end{aligned} \tag{2.3}$$

To study relaxed systems (in a wider sense), we need the following spaces.

By Λ we denote the set of all measures λ on $[0, T] \times \Gamma$ such that

$$\lambda([0, s] \times \Gamma) = s, \quad \text{for } s \leqq T. \tag{2.4}$$

Endowing with the weak convergence topology, we have the following proposition.

PROPOSITION 2.1. *Λ is a compact metric space (cf. [6]).*

Proof. By applying the Prohorov metric, Λ becomes a separable metric space. Suppose $\lambda_n \in \Lambda$ tends to λ weakly as $n \to \infty$. Then $\lambda_n(\cdot \times \Gamma) \to \lambda(\cdot \times \Gamma)$ weakly as a measure on $[0, T]$. Since $\lambda_n(\cdot \times \Gamma)$ is Lebesgue measure by (2.4), $\lambda(\cdot \times \Gamma)$ also satisfies (2.4). Since Λ is tight, by virtue of compactness of $[0, T] \times \Gamma$, this completes the proof. □

Let us set $\mathbf{B}(\Gamma) =$ Borel field on Γ, $\sigma_t(\Lambda) =$ the σ-field generated by $\{\lambda([0, s] \times A); s \leqq t, A \in \mathbf{B}(\Gamma)\}$ and $\sigma(\Lambda) = \sigma_T(\Lambda)$. Let $\mathcal{P} = \mathcal{P}(\Lambda)$ be the space of probabilities on $(\Lambda, \sigma(\Lambda))$, endowed with the weak convergence topology. Then Prohorov's theorem asserts the following proposition.

PROPOSITION 2.2. *$\mathcal{P}$ is a compact metric space.*

By virtue of (2.4), λ has a $\sigma_t(\Lambda)$-adapted kernel λ', namely, $\lambda(dt, du) = \lambda'(t, du)\, dt$, and $\lambda'(t, \cdot)$ is a probability on Γ for almost all t. Moreover, if λ^* is a kernel of λ, then

$\lambda'(t, \cdot) = \lambda^*(t, \cdot)$ for almost all t. Let us set

$$\tilde{h}(t, x, y, \lambda) = \int_\Gamma h(x, y, u)\lambda'(t, du) \quad \text{for } h = a^{ij} \text{ and } f^i$$

and

$$\begin{aligned} \tilde{L}(t, y, \lambda)\psi(x) &= \int_\Gamma L(y, u)\psi(x)\lambda'(t, du) \\ &= \sum_{i,j=0}^{d} \partial_i(\tilde{a}^{ij}(t, x, y, \lambda)\partial_j\psi(x) + \tilde{f}^i(t, x, y, \lambda)). \end{aligned} \tag{2.5}$$

Now we introduce a relaxed system, according to [2] and [3].

DEFINITION 2.1. $\mathcal{R} = (\Omega, \mathcal{F}, \mathcal{F}_t, P, W, \mu)$ is called a relaxed system, if

(2.6) $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$ is a probability space with filteration $\mathcal{F}_t$;

(2.7) W is an $\mathcal{F}_t$-adapted d'-dimensional Wiener process with $W(0) = 0$;

and

(2.8) μ is an $\mathcal{F}_t$-adapted Λ-valued random variable (Λ-r.v. in short). Namely, $\mu(B_1 \times B_2)$ is $\mathcal{F}_t$-measurable whenever $B_1 \in \mathbf{B}[0, t]$ and $B_2 \in \sigma(\Gamma)$ (=topological σ-field on Γ).

For simplicity, we put $\mathcal{R} = (W, \mu)$, if no confusion occurs, and sometimes we call μ a relaxed control.

$\mathcal{A} = (\Omega, \mathcal{F}, \mathcal{F}_t, P, W, U)$ is an admissible system, if (2.8) is replaced by (2.9) below.

(2.9) U is a Γ-valued $\mathcal{F}_t$-adapted process.

Remark. Since $U(t)$ is regarded as $\mu'(t, \cdot) = \delta_{U(t)}$, where δ_x means δ-measure at x, $\mathcal{A}$ is also a relaxed system.

$\mathfrak{R}$ and $\mathfrak{U}$ denote the totalities of relaxed and admissible systems, respectively. Let $\pi(\mathcal{R})$ be the image measure of (W, μ) on $C(0, T; \mathbb{R}^d) \times \Lambda$. Again endowing with the weak convergence topology on the space $\Pi = \{\pi(\mathcal{R}); \mathcal{R} \in \mathfrak{R}\}$, we have the following proposition.

PROPOSITION 2.3. Π *is a compact metric space.*

Proof. The proof is easy, since W is a Wiener process and Λ is a compact metric space. □

DEFINITION 2.2. We say $\mathcal{R}_n$ converges to $\mathcal{R}$, (put $\mathcal{R}_n \to \mathcal{R}$) if, $\pi(\mathcal{R}_n) \to \pi(\mathcal{R})$ weakly.

Consider the SPDE (2.10) for $\mathcal{R} = (\Omega, \mathcal{F}, \mathcal{F}_t, P, W, \mu)$,

$$\begin{aligned} &dq(t) = \tilde{L}(t, y + W(t), \mu)q(t)\, dt + M(y + W(t))q(t)\, dW(t) \\ &q(0) = \phi \ (\in H^m). \end{aligned} \tag{2.10}$$

An H^1-valued $\mathcal{F}_t$-adapted process $q = q(\cdot, \phi, \mathcal{R})$ is called a solution of (2.10) (or a response for $\mathcal{R}$), if (2.11) and (2.12) hold.

$$E\left\{\int_0^T \|q(t)\|_{1,0}^2\, dt\right\} < \infty \tag{2.11}$$

and, for any $\eta \in C_0^\infty$ (smooth function on $\mathbb{R}^d$ with compact support) and almost all t,

$$(q(t), \eta) = (\phi, \eta) + \int_0^t \langle \tilde{L}(s, y + W(s), \mu) q(s), \eta \rangle \, ds + \int_0^t (M(y + W(s)) q(s), \eta) \, dW(s) \cdot \text{w.p. } 1 \tag{2.12}$$

holds, where $(\cdot, \cdot) = L^2(\mathbb{R}^d)$-inner product and $\langle \cdot, \cdot \rangle =$ duality pairing between H^{-1} and H^1 under $H^0 = (H^0)^*$ (= dual space of H^0), namely

$$\langle \tilde{L}(s, y + W(s), \mu) q(s), \eta \rangle = \sum_{i,j=0}^{d} (-1)^{|i|} (\tilde{a}^{ij}(s, \cdot, y + W(s), \mu) \partial_j q(s), \partial_i \eta),$$

where $|i| = 0$ (for $i = 0$), $= 1$ (for $i = 1, \cdots, d$).

Clearly (2.12) does not depend on any special choice of derivative μ'. The SPDE (2.10) can be regarded as an H^{-1}-valued SDE. (See Itô [7] for the general theory of Hilbert space valued SDE.)

According to [10] and [11], we see the following theorem.

THEOREM 2.1 (Krylov and Rozovskii). (I) *Suppose the conditions* (A.1)$\sim$(A.3). *Then, the* SPDE (2.10) *has a unique solution*

$$q \in L^2([0, T] \times \Omega; H^m) \cap L^2(\Omega: C(0, T; H^{m-1})).$$

$q(t)$ *is a Borel function of* $\{\phi, W(s) s \leqq t, \mu([0, s] \times B) \; s \leqq t \; B \in \sigma(\Gamma)\}$ *and there exists a constant* N, *depending only on* T *and* K *in* (2.3), *such that*

$$E\left\{\sup_{t \leqq T} \|q(t)\|_{l,0}^2\right\} \leqq N\left\{\|\phi\|_{l,0}^2 + \sup_{y,u} \sum_{i=0}^{d} \|\partial_i f^i(\cdot, y, u)\|_{l,0}^2 + \sup_y \|g(\cdot, y)\|_{l+1,0}^2\right\}, \tag{2.13}$$

$$l = 0, 1, \cdots, m.$$

(II) *Besides* (A.1)$\sim$(A.3), *we assume* $(A.4)_{l,r}$ *and* $\phi \in H_r^l$. *Then the following evaluation holds.*

$$E\left\{\sup_{t \leqq T} \|q(t)\|_{l,r}^2\right\} \leqq N'\left\{\|\phi\|_{l,r}^2 + \sup_{y,u} \sum_{i=0}^{d} \|\partial_i f^i(\cdot, y, u)\|_{l,r}^2 + \sup_y \|g(\cdot, y)\|_{l+1,r}^2\right\} \tag{2.14}$$

where $N' = N'(T, K, r)$.

(III) *Suppose*

$$F^i : [0, T] \times \mathbb{R}^d \times \Omega \to \mathbb{R}^1, \qquad i = 0, 1, \cdots, d,$$

and

$$G_k : [0, T] \times \mathbb{R}^d \times \Omega \to \mathbb{R}^1, \qquad k = 1, \cdots, d,$$

are $\mathcal{F}_t$*-adapted and*

$$E\left\{\int_0^T \|F^i(t)\|_{m+1,0}^2 \, dt\right\} < \infty, \qquad E\left\{\int_0^T \|G_k(t)\|_{m+1,0}^2 \, dt\right\} < \infty.$$

Let ξ be a solution of the following SPDE:

$$\text{(2.15)}\qquad \begin{cases} d\xi(t) = \sum_{i,j=0}^{d} \partial_i(\tilde{a}^{ij}(t, y+W(t), \mu)\partial_j\xi(t) + F^i(t))\,dt \\ \qquad\qquad + \left(\sum_{i=0}^{d} b^i(t, y+W(t))\partial_i\xi(t) + G(t)\right) dW(t) \\ \xi(0) = \varphi \in H^m. \end{cases}$$

Then, ξ satisfies the following evaluation.

$$\text{(2.16)}\qquad E\left\{\sup_{t\leqq T} \|\xi(t)\|_{l,0}^2\right\} \leqq N\Bigg(\|\varphi\|_{l,0}^2 + E\left\{\int_0^T \left(\sum_{i=0}^{d} \|\partial_i F^i(t)\|_{l,0}^2 + \sum_{k=1}^{d'} \|G_k(t)\|_{l+1,0}^2\right) dt\right\}\Bigg)$$

$(l = 0, 1, \cdots, m)$ *where* $N = N(T, K)$.

Remark. Krylov and Rozovskii proved Theorem 2.1, replacing (A.2) by a weaker condition

$$\text{(A.2')}\qquad a^{ij} = a^{ji}, \qquad i, j = 1, \cdots, d$$

and $(a^{ij} - \frac{1}{2}b^i \cdot b^j)_{i,j=1,\cdots,d}$ is a nonnegative definite matrix.

But we state all of our theorems under the condition (A.2), since we need (A.2) for Proposition 3.1, etc.

3. Continuous dependence of $q(\ , \phi, y, \mathscr{R})$ on ϕ, y, $\mathscr{R}$. Since we are mainly concerned with the probability law $\pi(\mathscr{R})$, we may assume the following canonical form, if necessary:

$\Omega = C(0, T; \mathbb{R}^{d'}) \times \Lambda$, $\mathscr{F} = \sigma(\Omega)$ = the topological σ-field on Ω;

W = the first coordinate function on Ω, $W(t, \omega) = W(\omega)(t)$;

μ = the second coordinate function on Ω,

$\mu(B, \omega) = \mu(\omega)(B)$, $B \in \sigma([0, T] \times \Gamma)$;

$\mathscr{F}_t = \sigma\{W(s), s \leqq t, \mu(B_1 \times B_2), B_1 \in \mathbf{B}[0, t], B_2 \in \sigma(\Gamma)\}$;

$P = \pi(\mathscr{R})$.

First we see the following lemma, which is crucial to the SPDE with ellipticity condition (A.2). It will be proved in the Appendix, according to [10].

LEMMA (*special case of Lemma* 2.1 *of* [10]). *For any $t \in [0, T]$, $y \in \mathbb{R}^{d'}$ and $\lambda \in \Lambda$, put $a^{ij}(\cdot) = a^{ij}(t, \cdot, y, \lambda)$ and $b^i(\cdot) = b^i(\cdot, y)$, for simplicity. Under the conditions* (A.1) *and* (A.2), *there exists a constant N, depending only on K in* (2.3), *T, and l* $(= 0, 1, \cdots, m)$, *such that*

$$(*)\qquad \int \sum_{|\gamma|\leqq l} \left(2\sum_{i,j=0}^{d} (-1)^{|i|} D^\gamma \partial_i u D^\gamma (a^{ij}\partial_j u + \hat{f}^i) + 3\left|D^\gamma\left(\sum_{i=0}^{d} b^i \partial_i u + \hat{g}\right)\right|^2\right) dx \leqq N\left\{\|u\|_l^2 + \sum_{i=0}^{d} \|\partial_i \hat{f}^i\|_l^2 + \sum_{k=0}^{d'} \|\hat{g}_k\|_{l+1}^2\right\}$$

for any fixed three functions u, $\hat{f}^i$, $\hat{g}_k \in H^{l+1}$ and $\hat{g} = (\hat{g}_1, \cdots, \hat{g}_{d'})$.

Remark. (1) When we take $\tilde{f}^i(\cdot, y, \mu)$ and $g(\cdot, y)$ of (2.1) as $\hat{f}^i$ and $\hat{g}$, respectively, (*) turns out to be in the following form:

$$2\langle \tilde{L}(t, y, \mu)u, u\rangle_l + 3|M(y)u|_l^2 \leqq N\left\{\|u\|_l^2 + \sum_{i=0}^{d} \|\partial_i \tilde{f}^i(\cdot, y, \mu)\|_l^2 + \sum_{k=0}^{d'} \|g_k(\cdot, y)\|_{l+1}^2\right\}.$$

(2) Reference [10] says that Lemma holds under conditions (A.1) and (A.2'), if we replace "3" of the integrand of the left-hand side with "1." So a stronger condition (A.2) yields a stronger evaluation (*), which is necessary for Proposition 3.1.

PROPOSITION 3.1. *There is a constant $C = C(T, K, l)$ such that*

$$\sup_{t \leqq T} E\{\|q(t)\|_l^4\} \leqq C\left\{\|\phi\|_l^4 + \sup_{y,u} \sum_{i=0}^{d} \|\partial_i f^i(\cdot, y, u)\|_l^4 + \sup_y \|g(\cdot, y)\|_{l+1}^4\right\}, \tag{3.1}$$

$$l = 0, 1, \cdots, m-1.$$

Proof. For simplicity, we put $\tilde{f}(t) = \tilde{f}(t, y + W(t), \mu)$, $g(t) = g(y + W(t))$, $\tilde{L}(t) = \tilde{L}(t, y + W(t), \mu)$, $M(t) = M(y + W(t))$ and $\langle , \rangle_l =$ duality pairing between H^{l-1} and H^{l+1} under $H^l = (H^l)^*$. Then q satisfies

$$(q(t), \eta)_l = (\phi, \eta)_l + \int_0^t \langle \tilde{L}(s)q(s), \eta\rangle_l \, ds + \int_0^t (M(s)q(s), \eta)_l \, dW(s) \tag{3.2}$$

$$\text{for } \eta \in H^{l+1}, \quad t \leqq T.$$

So Ito's formula derives

$$\begin{aligned} \|q(t)\|_l^2 &= \|\phi\|_l^2 + 2\int_0^t \langle \tilde{L}(s)q(s), q(s)\rangle_l \, ds \\ &\quad + \int_0^t \|M(s)q(s)\|_l^2 \, ds + 2\int_0^t (M(s)q(s), q(s))_l \, dW(s). \end{aligned} \tag{3.3}$$

Thus we see

$$\begin{aligned} &E[\|q(t)\|_l^4] - \|\phi\|_l^4 \\ &= 2E\left\{\int_0^t \|q(s)\|_l^2 \{2\langle \tilde{L}(s)q(s), q(s)\rangle_l + \|M(s)q(s)\|_l^2\} \, ds\right\} \\ &\quad + 4E\left\{\int_0^t (M(s)q(s), q(s))_l^2 \, ds\right\} \\ &\leqq 2E\left\{\int_0^t \|q(s)\|_l^2 \{2\langle \tilde{L}(s)q(s), q(s)\rangle_l + 3\|M(s)q(s)\|_l^2\} \, ds\right\} \\ &\leqq C_1 E\left[\int_0^t \|q(s)\|_l^2 \left\{\|q(s)\|_l^2 + \sum_{i=0}^{d} \|\partial_i \tilde{f}^i(s)\|_l^2 + \|g(s)\|_{l+1}^2\right\} ds\right] \end{aligned} \tag{3.4}$$

appealing to the lemma. Hence we have

$$\begin{aligned} E[\|q(t)\|_l^4] &\leqq C_2\left(E\left[\int_0^t \|q(s)\|_l^4 \, ds\right]\right. \\ &\quad \left. + \|\phi\|_l^4 + E\left[\int_0^t \left(\sum_{i=1}^{d} \|\partial_i \tilde{f}^i(s)\|_l^4 + \|g(s)\|_{l+1}^4\right) ds\right]\right). \end{aligned} \tag{3.5}$$

So Gronwall's inequality completes the proof. □

Now we will study continuous dependence of $q(\cdot, \phi, y, \mathcal{R})$ on $\mathfrak{R}$. For the following Theorem 3.1, we endow with the weak topology on $L^2(0, T; H^m)$ and H^{m-1}. Later Theorem 3.2 is concerned with strong topology on these spaces.

From now on, we always assume $m \geqq 3$.

THEOREM 3.1. *Suppose $\mathcal{R}_n \to \mathcal{R}$. Then, for $\phi \in H^m$ and $y \in \mathbb{R}^d$, we have*

$$(W_n, \mu_n, q(\cdot, \phi, y, \mathcal{R}_n)) \to (W, \mu, q(\cdot, \phi, y, \mathcal{R})) \text{ in law as } C(0, T; \mathbb{R}^{d'}) \times \Lambda \times [w - L^2(0, T; H^m)] - \text{r.v.} \tag{3.6}$$

$$(W_n, \mu_n, q(t, \phi, y, \mathcal{R}_n)) \to (W, \mu, q(t, \phi, y, \mathcal{R})) \text{ in law as } C(0, T; \mathbb{R}^{d'}) \times \Lambda \times [w - H^{m-1}] - \text{r.v.}, \tag{3.7}$$

where $w - X$ denotes the space X carrying the weak topology.

Proof. This theorem is an extension of Theorem 3.1 in [14] to the elliptic case (A.2) and we can apply the same method as [14], using the evaluation (*). First we introduce two spaces $\mathcal{H}_\gamma(D)$ and $\mathcal{H}_\gamma(D, T)$. Let D be a bounded open set of $\mathbb{R}^d$, with smooth boundary. Define $\mathcal{H}_\gamma(D)$ and $\mathcal{H}_\gamma(T, D)$ as follows (cf. [13]).

$$\mathcal{H}_\gamma(D) = \left\{ \varphi \in L^2(-\infty, \infty; H^{m-1}(D)); \int_{-\infty}^{\infty} |\tau|^{2\gamma} \|\hat{\varphi}(\tau)\|_*^2 \, d\tau < \infty \right\} \tag{3.8}$$

with the norm

$$\|\varphi\|_{\mathcal{H}_\gamma(D)}^2 = \int_{-\infty}^{\infty} \|\varphi(t)\|_{H^{m-1}(D)}^2 \, dt + \int_{-\infty}^{\infty} |\tau|^{2\gamma} \|\hat{\varphi}(\tau)\|_*^2 \, d\tau \tag{3.9}$$

where, for simplicity, we put $\hat{\varphi}(\tau) = \int_{-\infty}^{\infty} \exp(-2\pi i \tau t) \varphi(t) \, dt$ in this proof and $\|\cdot\|_* =$ norm of $(H^{m-1}(D))^*$ (= dual space of $H^{m-1}(D)$ under $H^{m-2}(D) = (H^{m-2}(D))^*$) and

$$\mathcal{H}_\gamma(T, D) = \{\varphi|_{[0,T]}; \varphi \in \mathcal{H}_\gamma(D)\} \tag{3.10}$$

with the norm

$$\|\varphi\|_{\mathcal{H}_\gamma(T,D)} = \inf\{\|\psi\|_{\mathcal{H}_\gamma(D)}; \varphi = \psi \text{ a.e. on } [0, T]\}, \tag{3.11}$$

respectively. □

Now we divide the proof into three steps. The first step is the preliminary lemma, which is useful for proving the compactness of space of solutions.

LEMMA 3.1. *For any fixed $\gamma \in (0, \frac{1}{4})$,*

$$q(\ , \phi, y, \mathcal{R}) \in \mathcal{H}_\gamma(T, D), \quad \text{w.p. 1} \tag{3.12}$$

holds, and there is a constant $K_1 = K_1(T, K)$, such that

$$E\{\|q(\ , \phi, y, \mathcal{R})\|_{\mathcal{H}_\gamma(T,D)}^2\} \leqq K_1 I_m(\phi, f, g), \quad \text{for } \forall \mathcal{R} \in \mathfrak{R}, \tag{3.13}$$

where

$$I_m(\phi, f, g) = \|\phi\|_m^2 + \sup_{y,u} \sum_{i=0}^{d} \|\partial_i f^i(\cdot, y, u)\|_m^2 + \sup_y \|g(\cdot, y)\|_{m+1}^2. \tag{3.14}$$

Proof. Put

$$h(t) = \begin{cases} h(t, \mathcal{R}), & t \in [0, T] \\ 0, & t \notin [0, T], \end{cases}$$

for $h(t, \mathcal{R}) = q(t, \phi, y, \mathcal{R})$, $f(\cdot, y + W(t), \mu)$ and $g(\cdot, y + W(t))$. $\tilde{L}(t)$ and $M(t)$, $t \in (-\infty, \infty)$, are defined in the same way as (2.5) and (2.2), respectively. Since q is a solution, the following equality (3.15) holds, for any $\eta \in H^m$,

$$\begin{aligned} (q(t), \eta)_{m-1} &= (\phi, \eta)_{m-1} + \int_0^t \langle \tilde{L}(s) q(s), \eta \rangle_{m-1} \, ds \\ &\quad + \int_0^t (M(s) q(s), \eta)_{m-1} \, dW(s). \end{aligned} \tag{3.15}$$

Therefore, we have

$$2\pi i\tau(\hat{q}(\tau),\eta)_{m-1}=\int_{-\infty}^{\infty}\left(-\frac{d}{dt}\exp(-2\pi i\tau t)\right)(q(t),\eta)_{m-1}\,dt$$

$$=(\phi,\eta)_{m-1}-\exp(-2\pi i\tau T)(q(T),\eta)_{m-1}+\langle\widehat{\tilde{L}q}(\tau),\eta\rangle_{m-1}$$

$$+\int_0^T\exp(-2\pi i\tau t)(M(t)q(t),\eta)_{m-1}\,dW(t). \tag{3.16}$$

Let $\eta_j\in C_0^\infty(\mathbb{R}^d)$, $j=1,2,\cdots$ be a complete orthonormal system of H^m. Then we get

$$4\pi^2\tau^2E[\|\hat{q}(\tau)\|_{m-2}^2]=4\pi^2\tau^2\sum_{j=1}^{\infty}E\{|(\hat{q}(\tau),\eta_j)_{m-1}|^2\}$$

$$\leqq C_1\Big(\|\phi\|_{m-2}^2+E\{\|q(T)\|_{m-2}^2\}+E\{\|\tilde{L}q(\tau)\|_{m-2}^2\}$$

$$+\sum_{k=1}^{d'}\int_0^T\|M_k(t)q(t)\|_{m-2}^2\,dt\Big). \tag{3.17}$$

Since $\|\cdot\|_*\leqq\|\cdot\|_{m-2}\leqq\|\cdot\|_{m-1}$, we see

$$\tau^2E[\|\hat{q}(\tau)\|_*^2]\leqq C_2\Big(\|\phi\|_{m-1}^2+E[\|q(T)\|_{m-1}^2]$$

$$+E\left[\int_0^T(\|q(t)\|_m^2+\|g(t)\|_{m-1}^2)\,dt\right]+E[\|\widehat{\tilde{L}q}(\tau)\|_{m-2}^2]\Big)$$

$$\leqq C_3\left\{I_m(\phi,f,g)+E[\|\widehat{\tilde{L}q}(\tau)\|_{m-2}^2]\right\}.$$

Hence, for any fixed $\kappa\in(1,\frac{3}{2})$,

$$\int_{-\infty}^{\infty}E[|\tau|^{2\gamma}\|\hat{q}(\tau)\|_*^2]\,d\tau$$

$$\leqq\int_{|\tau|\leqq1}E[\|\hat{q}(\tau)\|_*^2]\,d\tau+\int_{|\tau|>1}E\left[\frac{2|\tau|^2}{1+|\tau|^\kappa}\|\hat{q}(\tau)\|_*^2\right]d\tau$$

$$\leqq C_4\Big(\int_{-\infty}^{\infty}E[\|\hat{q}(\tau)\|_{m-2}^2]\,d\tau+I_m(\phi,y,\mathcal{R})\int_{-\infty}^{\infty}\frac{2}{1+|\tau|^\kappa}\,d\tau$$

$$+\int_{-\infty}^{\infty}E[\|\widehat{\tilde{L}q}(\tau)\|_{m-2}^2]\,d\tau\Big)$$

$$\leqq C_5\Big(\int_{-\infty}^{\infty}E\{\|q(t)\|_m^2+\|\tilde{L}q(t)\|_{m-2}^2\}\,dt+I_m(\phi,f,g)\Big)$$

$$\leqq C_6I_m(\phi,f,g)$$

where $C_i=C_i(T,K)$. From this we get

$$E[\|q\|_{\mathcal{H}_\gamma(D)}^2]\leqq K_1I_m(\phi,f,g), \tag{3.18}$$

and complete the proof of Lemma 3.1. □

Second step. Let D_k $(k=1, 2, \cdots)$ be a bounded and open subset of $\mathbb{R}^d$ with smooth boundary, $\bar{D}_k \subset D_{k+1}$ and $\cup_{k=1}^{\infty} D_k = \mathbb{R}^d$. Define a metric d by

$$d(p, q) = \sum_{k=1}^{\infty} \frac{1}{2^k} \min\left(1, \left\{\int_0^T \| p(t) - q(t) \|_{H^{m-2}(D_k)^2} \, dt\right\}^{1/2}\right)$$

for $p, q \in L^2(0, T; H^{m-2})$. $\mathcal{H}^{m-2}(0, T)$ denotes the completion of $L^2(0, T; H^{m-2})$ with respect to the metric d. Put $S_1 = C(0, T; \mathbb{R}^{d'}) \times \Lambda \times \mathcal{H}^{m-2}(0, T)$ and $S_2 = C(0, T; \mathbb{R}^{d'}) \times \Lambda \times [w - L^2(0, T; H^{m-2})]$. For $\mathcal{R} = (W, \mu)$, $m_1(\mathcal{R})$ and $m_2(\mathcal{R})$ denote the image measures of $(W, \mu, q(\cdot, \phi, y, \mathcal{R}))$ on S_1 and S_2, respectively. $B_r = \{q \in L^2(0, T; H^{m-2});\ \|q\|_{\mathcal{H}_\gamma(T, D_k)} \leqq (2^k r)^{1/2},\ k = 1, 2, \cdots\}$ is compact in $\mathcal{H}^{m-2}(0, T)$, because the injection $\mathcal{H}_\gamma(T, D_k) \to L^2(0, T; H^{m-2}(D_k))$ is a compact operator (cf. [13]).

On the other hand, Lemma 3.1 asserts

$$P(q(\cdot, \phi, y, \mathcal{R}) \notin B_r) \leqq K_1 I_m(\phi, f, g)/r.$$

Hence, $\{m_1(\mathcal{R}), \mathcal{R} \in \mathfrak{R}\}$ is relatively compact by Proposition 2.3. Moreover, $\{m_2(\mathcal{R}), \mathcal{R} \in \mathfrak{R}\}$ is also relatively compact by (2.13) and Remark 3.3 in [14].

Third step. Suppose $\mathcal{R}_n \to \mathcal{R}$. Then we can choose a subsequence $\{n_j\}$, such that $m_1(\mathcal{R}_{n_j})$ and $m_2(\mathcal{R}_{n_j})$ converge to some probability measures m_1 and m_2, respectively. So their marginal distributions on $C(0, T; \mathbb{R}^{d'}) \times \Lambda$ coincide with $\pi(\mathcal{R})$ and $i_k(m_1(\mathcal{R}_n)) = j_k(m_2(\mathcal{R}_n))$ and $i_k(m_1) = j_k(m_2)$ $(k = 1, 2, \cdots)$, where

$$i_k : S_1 \to C(0, T; \mathbb{R}^{d'}) \times \Lambda \times L^2(0, T; H^{m-2}(D_k))$$

and

$$j_k : S_2 \to C(0, T; \mathbb{R}^{d'}) \times \Lambda \times L^2(0, T; H^{m-2}(D_k))$$

are the canonical injections.

$$m_1(C(0, T; \mathbb{R}^{d'}) \times \Lambda \times L^2(0, T; H^{m-2})) = 1$$

holds by (2.13).

Endowing with the metric d, we can apply Skorokhod's theorem. Hence, there exist S_1-valued random variables $(\hat{W}_{n_j}, \hat{\mu}_{n_j}, \hat{q}_{n_j})$ and $(\hat{W}, \hat{\mu}, \hat{q})$ on a suitable probability space $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$, such that

(3.19) the law of $(\hat{W}_{n_j}, \hat{\mu}_{n_j}, \hat{q}_{n_j}) = m_1(\mathcal{R}_{n_j})$

The law of $(\hat{W}, \hat{\mu}, \hat{q}) = m_1$ (= limit measure of $m_1(\mathcal{R}_{n_j})$),

(3.20) with probability 1,

(I) $\hat{W}_{n_j} \to \hat{W}$ uniformly on $[0, T]$

(II) $\hat{\mu}_{n_j} \to \hat{\mu}$ weakly

(III) $\hat{q}_{n_j} \to \hat{q}$ in $\mathcal{H}^{m-2}(0, T)$.

Moreover, since (3.1) implies the uniform integrability, we have

(IV) $\hat{q}_{n_j}|_{D_k} \to \hat{q}|_{D_k}$ in $L^2([0, T] \times \Omega; H^{m-2}(D_k))$ for $k = 1, 2, \cdots$.

Hence, from (I) and (II), we see, for all $x \in \mathbb{R}^d$

$$\begin{aligned}
&\int_0^T \psi(t) \tilde{a}(t, x, y + \hat{W}_{n_j}(t), \hat{\mu}_{n_j}) \, dt \\
&\quad = \int_0^T \psi(t) \int_\Gamma a(x, y + \hat{W}_{n_j}(t), u) \hat{\mu}'_{n_j}(t, du) \, dt \\
&\quad \xrightarrow[n_j \to \infty]{} \int_0^T \psi(t) \int_\Gamma a(x, y + \hat{W}(t), u) \hat{\mu}'(t, du) \, dt \\
&\quad = \int_0^T \psi(t) \tilde{a}(t, x, y + \hat{W}(t), \hat{\mu}) \, dt
\end{aligned} \tag{3.21}$$

for any bounded continuous function ψ on $[0, T]$. Namely, we have

$$\tilde{a}(\cdot, x, y+\hat{W}_{n_j}, \hat{\mu}_{n_j}) \to \tilde{a}(\cdot, x, y+\hat{W}, \hat{\mu}) \quad \text{in } [w-L^2(0, T)]. \tag{3.22}$$

Since $\tilde{q}_{n_j}$ is a response for $\mathcal{R}_{n_j}=(\hat{W}_{n_j}, \hat{\mu}_{n_j})$, we see, for any bounded absolutely continuous function ψ with $\psi' \in L^2(0, T)$ and $\psi(T)=0$, and $\eta \in C_0^\infty$,

$$\begin{aligned}
&\int_0^T \psi(t) d(\hat{q}_{n_j}(t), \eta) \\
&\quad = -\psi(0)(\phi, \eta) - \int_0^T (\hat{q}_{n_j}(t), \eta)\psi'(t)\, dt \\
&\quad = \int_0^T \langle \tilde{L}(t, y+\hat{W}_{n_j}(t), \hat{\mu}_{n_j})\hat{q}_{n_j}(t), \eta\rangle \psi(t)\, dt \\
&\qquad + \int_0^T \psi(t)(M(y+\hat{W}_{n_j}(t))\hat{q}_{n_j}(t), \eta)\, d\hat{W}_{n_j}(t).
\end{aligned} \tag{3.23}$$

Hence, we get, as $n_j \to \infty$

$$\begin{aligned}
&-\int_0^T (\hat{q}(t), \eta)\psi'(t)\, dt \\
&\quad = \psi(0)(\phi, \eta) + \int_0^T \langle \tilde{L}(t, y+\hat{W}(t), \hat{\mu})\hat{q}(t), \eta\rangle \psi(t)\, dt \\
&\qquad + \int_0^T \psi(t)(M(y+\hat{W}(t))\hat{q}(t), \eta)\, d\hat{W}(t)
\end{aligned} \tag{3.24}$$

whenever supp $\eta \subset D_k$ for some k.

Equation (3.24) yields that $\hat{q}$ is a response for $(\hat{W}, \hat{\mu})$. Since $\pi(\hat{W}, \hat{\mu}) = \pi(\mathcal{R})$, we obtain

$m_1 =$ the law of $(\hat{W}, \hat{\mu}, \hat{q}) = m_1(\mathcal{R})$ and also $m_2 = m_2(\mathcal{R})$. This fact concludes (3.6).

In the same way we can prove (3.7). □

Now we will deal with $L^2(0, T; H^{m-2})$ and H^{m-2} instead of $[w-L^2(0, T; H^{m-2})]$ and $[w-H^{m-2}]$. Put $\Phi_r = H^m \cap H_r^{m-2}$, $r>0$, with the norm $|\cdot|_r = \|\cdot\|_m + \|\cdot\|_{m-2,r}$. By applying [11], we evaluate $q(t, x)$ for large $|x|$.

THEOREM 3.2. *Suppose* $(A.4)_{m-2,r}$ *besides* (A.1)$\sim$(A.3). *Then for* $\phi \in \Phi_r$, *we have*

$$q(\cdot, \phi, y, \mathcal{R}_n) \to q(\cdot, \phi, y, \mathcal{R}) \quad \textit{in law as } L^2(0, T; H^{m-2}) - \text{r.v.}, \tag{3.25}$$

and for any fixed t

$$q(t, \phi, y, \mathcal{R}_n) \to q(t, \phi, y, \mathcal{R}) \quad \textit{in law as } H^{m-2} - \text{r.v.}, \tag{3.26}$$

whenever $\mathcal{R}_n \to \mathcal{R}$.

Proof. By Theorem 2.1, there exists a constant C depending only on T, K, r, and ϕ such that

$$E\left[\int_{\mathbb{R}^d} (1+|x|^2)^r \{D^\alpha q(t, x, \phi, y, \mathcal{R})\}^2\, dx\right] \leqq C \tag{3.27}$$

for all t, α; $0 \leqq t \leqq T$, $0 \leqq |\alpha| \leqq m-2$, and $\mathcal{R} \in \mathfrak{R}$. Hence, we have

$$E\left[\int_{|x|>\rho} D^\alpha q(t, x)^2\, dx\right] \leqq \frac{C}{(1+\rho^2)^r}. \tag{3.28}$$

By virtue of Skorokhod's theorem, there exist $L^2(0, T; H^{m-2})$-valued random variables $\hat{q}_n$ and $\hat{q}$ on a suitable probability space $(\hat{\Omega}, \hat{\mathcal{F}}, \hat{P})$, such that

(3.29) $\hat{q}_n$ and $\hat{q}$ have the same laws as $q(\ , \phi, y, \mathcal{R}_n)$ and $q(\ , \phi, y, \mathcal{R})$, respectively,

and with probability 1

$$\hat{q}_n \to \hat{q} \text{ in } L^2(0, T; H^{m-2}(D)) \tag{3.30}$$

for any bounded subset D of $\mathbb{R}^d$.

On the other hand, we see from (3.1)

$$E\left[\left(\int_D \{D^\alpha q(t, x)\}^2 \, dx\right)^2\right] \leqq E[\|q(t)\|_{m-2}^4] \leqq C' \qquad \text{for } 0 \leqq |\alpha| \leqq m-2, \tag{3.31}$$

where C' is independent from D, t, and $\mathcal{R}$.

Since this implies the uniform integrability, we get

$$E\left[\int_0^T \int_D \sum_{|\alpha| \leqq m-2} \{D^\alpha \hat{q}_n(t, x) - D^\alpha \hat{q}(t, x)\}^2 \, dx \, dt\right] \to 0. \tag{3.32}$$

Combining (3.32) with (3.28), we obtain

$$E\left[\int_0^T \|\hat{q}_n(t) - \hat{q}(t)\|_{m-2}^2 \, dt\right] \to 0.$$

This concludes (3.25).

For the proof of (3.26), we can apply the same argument. □

Putting

$$\Phi = \bigcup_{r>0} \Phi_r, \tag{3.33}$$

we see the following corollary.

COROLLARY 3.1. *Suppose* $\mathcal{R}_n = (W_n, \mu_n)$ *tends to* $\mathcal{R} = (W, \mu)$. *Then, under the conditions* (A.1) ~ (A.3), $(A.4)_{m-2}$ *and* $\phi \in \Phi$, *there exist* $\hat{\mathcal{R}}_n = (\hat{W}_n, \hat{\mu}_n)$ *and* $\hat{\mathcal{R}} = (\hat{W}, \hat{\mu})$, *on a suitable probability space, such that*

(I) $\pi(W_n, \mu_n) = \pi(\hat{W}, \hat{\mu}_n)$, $\pi(W, \mu) = \pi(\hat{W}, \hat{\mu})$

and with probability 1,

(II) $\hat{W}_n \to \hat{W}$ *uniformly on* $[0, T]$

(III) $\hat{\mu}_n \to \hat{\mu}$ *weakly*

(IV) $\hat{q}_n \to \hat{q}$ *in* $L^2(0, T; H^{m-2})$

(V) $\hat{q}_n(t) \to \hat{q}(t)$ *in* H^{m-2}

where $\hat{q}_n$ *and* $\hat{q}$ *are responses for* $\hat{\mathcal{R}}_n$ *and* $\hat{\mathcal{R}}$, *respectively.*

Next we will study the dependence of q on the initial (ϕ, y).

THEOREM 3.3.

$$E[\sup_{t \leqq T} \|q(t, \phi, y, \mathcal{R}) - q(t, \psi, y, \mathcal{R})\|_l^2] \leqq N \|\phi - \psi\|_l^2 \tag{3.34}$$

$(l = 0, 1, \cdots, m)$, *where* N *is the constant of* (2.13).

$$E[\sup_{t \leqq T} \|q(t, \phi, y_1, \mathcal{R}) - q(t, \phi, y_2, \mathcal{R})\|_l^2] \leqq N_1(1 + I_{l+2}(\phi, f, g))|y_1 - y_2|^2) \tag{3.35}$$

$(l = 0, 1, \cdots, m-2)$, *where* $N_1 = N_1(T, K)$.

Proof. Put $p=q(\cdot, \phi, y, \mathcal{R})-q(\cdot, \psi, y, \mathcal{R})$. Then p satisfies the following SPDE

$$\begin{aligned} dp(t) &= \sum_{i,j=0}^{d} \partial_i(\tilde{a}^{ij}(t, y+W(t), \mu)\partial_j p(t)\, dt \\ &\quad + \sum_{i=0}^{d} b^i(t, y+W(t))\partial_i p(t)\, dW(t) \\ p(0) &= \phi-\psi. \end{aligned} \tag{3.36}$$

Therefore, (2.13) derives (3.34).

Put $\xi=q_1-q_2$ where $q_i=q(\cdot, \phi, y_i, \mathcal{R})$. Then we have

$$\begin{aligned} d\xi(t) &= \{\tilde{L}_1(t)\xi(t)+(\tilde{L}_1(t)-\tilde{L}_2(t))q_2(t)\}\, dt \\ &\quad +\{M_1(t)\xi(t)+(M_1(t)-M_2(t))q_2(t)\}\, dW(t) \\ \xi(0) &= 0 \end{aligned} \tag{3.37}$$

where $\tilde{L}_i(t)=\tilde{L}(t, y_i+W(t), \mu)$ and $M_i(t)=M(t, y_i+W(t))$, $i=1, 2$. So (2.16) asserts

$$\begin{aligned} E\left[\sup_{t\leqq T}\|\xi(t)\|_l^2\right] \leqq NE\Bigg[&\int_0^T \|(\tilde{L}_i(t)-\tilde{L}_2(t))q_2(t)\|_l^2\, dt \\ &+\int_0^T \|(M_1(t)-M_2(t))q_2(t)\|_{l+1}^2\, dt\Bigg]. \end{aligned} \tag{3.38}$$

Thus we see, from (A.1),

$$E\left[\sup_{t\leqq T}\|\xi(t)\|_l^2\right] \leqq N_1|y_1-y_2|^2(1+I_{l+2}(\phi, f, g)) \tag{3.39}$$

$(l=0, 1, \cdots, m-2)$, where $N_1=N_1(T, K)$. □

COROLLARY 3.2. *There is a constant $N_2=N_2(T, K)$ such that*

$$\begin{aligned} &E\left[\sup_{t\leqq T}\|q(t, \phi_1, y_1, \mathcal{R})-q(t, \phi_2, y_2, \mathcal{R})\|_l^2\right] \\ &\leqq N_2\Bigg(|y_1-y_2|^2\Bigg\{1+\min(\|\phi_1\|_{l+2}^2, \|\phi_2\|_{l+2}^2)+\sup_y\|g(\cdot, y)\|_{l+3}^2 \\ &\quad +\sup_{y,u}\sum_{i=0}^{d}\|\partial_i f(\cdot, y, u)\|_{l+2}^2\Bigg\}+\|\phi_1-\phi_2\|_l^2\Bigg) \qquad l=0, 1, \cdots, m-2. \end{aligned} \tag{3.40}$$

4. Optimal relaxed systems. Let $F: L^2(0, T; H^{m-2})\to\mathbb{R}^1$ and $G: H^{m-2}\to\mathbb{R}^1$ be uniformly continuous with linear growth, namely

(4.1) for any $\varepsilon>0$, there is $\delta=\delta(\varepsilon)>0$ such that

$$\begin{aligned} &|F(\psi_1)-F(\psi_2)|<\varepsilon \quad \text{if } \|\psi_1-\psi_2\|_{L^2(0,T;H^{m-2})}<\delta \\ &|G(\varphi_1)-G(\varphi_2)|<\varepsilon \quad \text{if } \|\varphi_1-\varphi_2\|_{m-2}<\delta \end{aligned}$$

and there is $\alpha>0$ such that

$$\begin{aligned} |F(\psi)| &\leqq \alpha(1+\|\psi\|_{L^2(0,T;H^{m-2})}) \\ |G(\varphi)| &\leqq \alpha(1+\|\varphi\|_{m-2}). \end{aligned} \tag{4.2}$$

For $\mathcal{R}\in\mathfrak{R}$, we will define the pay-off function J and the value function V by

$$J(\phi, y, \mathcal{R})=E[F(q(\cdot, \phi, y, \mathcal{R}))+G(q(T, \phi, y, \mathcal{R}))] \tag{4.3}$$

and

$$V(\phi, y) = \inf_{\mathcal{R} \in \mathfrak{R}} J(\phi, y, \mathcal{R}),$$

respectively. Then, Theorem 3.2 and Proposition 2.3 assert the existence of an optimal relaxed system. Now we have Theorem 4.1.

THEOREM 4.1. *Under the conditions* (A.1)$\sim$(A.3) *and* $(A.4)_{m-2}$, *there exists an optimal relaxed system* $\mathcal{R}^* = \mathcal{R}^*(\phi, y)$ *for* $\phi \in \Phi$ (*see* (3.33)), *namely,*

$$V(\phi, y) = J(\phi, y, \mathcal{R}^*) \tag{4.4}$$

holds. Moreover, for any $r > 0$, *we can choose* $\mathcal{R}^*(\phi, y)$, *so that* $\pi(\mathcal{R}^*(\phi, y))$ *is a Borel map from* $\Phi_r \times \mathbb{R}^d$ *into* $\mathcal{P}(C[0, T] \times \Lambda)$.

Proof. Suppose $\mathcal{R}_n \to \mathcal{R}$. Putting $q_n = q(\cdot, \phi, y, \mathcal{R}_n)$ and $q = q(\cdot, \phi, y, \mathcal{R})$, $F(q_n)$ and $G(q_n(T))$ converge to $F(q)$ and $G(q(T))$ in law, respectively. On the other hand, (3.1) derives

$$\sup_n E[F(q_n)^2] \leqq C_1\left(1 + \sup_n E\left[\int_0^T \|q_n(t)\|_{m-2}^2 \, dt\right]\right) < \infty.$$

Thus, the uniform integrability asserts

$$E[F(q_n)] \to E[F(q)].$$

In the same way, we can prove

$$E[G(q_n(T))] \to E[G(q(T))].$$

Hence, $J(\phi, y, \mathcal{R})$ is continuous in $\mathcal{R}$. Thus, Proposition 2.3 concludes (4.4).

For the proof of the latter half, we apply the same arguments as in Chapter 12 of [19]. Putting

$$\mathfrak{X}(\phi, y) = \{\pi(\mathcal{R});\ V(\phi, y) = J(\phi, y, \mathcal{R})\}, \tag{4.5}$$

we show the following lemma.

LEMMA 4.1. $\mathfrak{X}(\phi, y)$ *is nonempty and compact.*

Proof. $\mathfrak{X}(\phi, y)$ is nonempty by (4.4). So we will prove the closedness of $\mathfrak{X}(\phi, y)$. Suppose $\pi(\mathcal{R}_n) \in \mathfrak{X}(\phi, y)$ and converges to $\pi(\mathcal{R})$ weakly. Then $J(\phi, y, \mathcal{R}_n) \to J(\phi, y, \mathcal{R})$.

Hence $J(\phi, y, \mathcal{R}) = V(\phi, y)$, namely, "$\pi(\mathcal{R}) \in \mathfrak{X}(\phi, y)$." □

Let $\phi_n \to \phi$ in Φ_r and $y_n \to y$. Suppose $\pi(\mathcal{R}_n) \in \mathfrak{X}(\phi_n, y_n)$ and $\pi(\mathcal{R}_n) \to \pi(\mathcal{R})$ weakly. Then we will show $\pi(\mathcal{R}) \in \mathfrak{X}(\phi, y)$, which completes the proof.

$$\begin{aligned} &|J(\phi_n, y_n, \mathcal{R}_n) - J(\phi, y, \mathcal{R})| \\ &\quad \leqq |J(\phi_n, y_n, \mathcal{R}_n) - J(\phi, y, \mathcal{R}_n)| + |J(\phi, y, \mathcal{R}_n) - J(\phi, y, \mathcal{R})|. \end{aligned} \tag{4.6}$$

We see, from (3.1), (3.40) and (4.1), the following:

$$\begin{aligned} &\text{1st term of the right-hand side of (4.6)} \\ &\quad \leqq 2\varepsilon + E[|F(q(\phi_n, y_n, \mathcal{R}_n)) - F(q(\phi, y, \mathcal{R}_n))|;\ A_n] \\ &\qquad + E[|G(q(T, \phi_n, y_n, \mathcal{R}_n)) - G(q(T, \phi, y, \mathcal{R}_n))|;\ B_n] \\ &\quad \leqq 2\varepsilon + C_1(1 + \|\phi_n\|_{m-2} + \|\phi\|_{m-2})\{|y_n - y|(1 + \|\phi\|_m) + \|\phi_n - \phi\|_{m-2}\}/\delta \end{aligned} \tag{4.7}$$

with C_1 independent from ε and n, where

$$A_n = \{\|q(\phi_n, y_n, \mathcal{R}_n) - q(\phi, y, \mathcal{R}_n)\|_{L^2(0,T;H^{m-2})} > \delta\}$$

and

$$B_n = \{\|q(T, \phi_n, y_n, \mathcal{R}_n) - q(T, \phi, y, \mathcal{R}_n)\|_{m-2} > \delta\}.$$

Since $J(\phi, y, \mathcal{R})$ is continuous in $\mathcal{R}$, (4.6) and (4.7) yield

$$J(\phi_n, y_n, \mathcal{R}_n) \to J(\phi, y, \mathcal{R}). \tag{4.8}$$

Using $|V(\phi_n, y_n) - V(\phi, y)| \leqq \sup_{\mathcal{R} \in \mathfrak{R}} |J(\phi_n, y_n, \mathcal{R}) - J(\phi, y, \mathcal{R})|$, (4.7) derives

$$V(\phi_n, y_n) \to V(\phi, y). \tag{4.9}$$

Thus, we have

$$J(\phi, y, \mathcal{R}) = \lim_{n\to\infty} J(\phi_n, y_n, \mathcal{R}_n) = \lim_{n\to\infty} V(\phi_n, y_n) = V(\phi, y)$$

Namely, $\pi(\mathcal{R}) \in \mathfrak{X}(\phi, y)$.

Therefore, we can take a Borel selector S_r of $\mathfrak{X}(\phi, y)$, i.e., $S_r : \Phi_r \times \mathbb{R}^{d'} \to \mathcal{P}(C[0, T] \times \Lambda)$, Borel map, such that $S_r(\phi, y) \in \mathfrak{X}(\phi, y)$ ([19, Chap. 12]).

So $S_r(\phi, y) = \pi(\mathcal{R}^*(\phi, y))$ holds. This completes the proof of Theorem 4.1. □

Since a relaxed control turns out to be an admissible control under the Roxin condition, we can get an optimal admissible control. Now we introduce the convexity condition for coefficients of (2.1). Put $c(y, u) = (a^{ij}(\cdot, y, u), f^i(\cdot, y, u); i, j = 0, \cdots, d)$ and $C(y, \Gamma) = \{c(y, u); u \in \Gamma\}$.

CONVEXITY CONDITION (*Roxin condition*). *For any $y \in \mathbb{R}^{d'}$, $C(y, \Gamma)$ is a convex subset of $C(\mathbb{R}^d; \mathbb{R}^{(d+1)(d+2)})$.*

Endowing with the compact uniform topology on $C(\mathbb{R}^d; \mathbb{R}^{(d+1)(d+2)})$ we have Proposition 4.2.

PROPOSITION 4.2. *Under the convexity condition, $C(y, \Gamma)$ is compact and convex.*

Proof. $c(y, \cdot)$ is continuous in Γ. Since Γ is compact, $C(y, \Gamma)$ is compact. □

Let us set $\tilde{c}(\cdot, y, \nu) = \int_\Gamma c(\cdot, y, u)\nu(du)$ for $\nu \in \mathcal{P}(\Gamma)$, namely, $\tilde{c}(\cdot, y, \nu) = (\tilde{a}(\cdot, y, \nu), \tilde{f}(\cdot, y, \nu))$. Putting $\Gamma(y, \nu) = \{u \in \Gamma; \tilde{c}(\cdot, y, \nu) = c(\cdot, y, u)\}$, we see Proposition 4.3.

PROPOSITION 4.3. *$\Gamma(y, \nu)$ is nonempty and compact.*

Proof. Since $C(y, \Gamma)$ is convex and compact, $\tilde{c}(\cdot, y, \nu) \in C(y, \Gamma)$. So $\Gamma(y, \nu) \neq \varnothing$. Now we will show that $\Gamma(y, \nu)$ is closed. Suppose $u_n \in \Gamma(y, \nu)$ and $u_n \to u$. Then $c(\cdot, y, u_n) \to c(\cdot, y, u)$. Thus $c(\cdot, y, u) = \tilde{c}(\cdot, y, \nu)$. This completes the proof. □

Again appealing to [19, Chap. 12], we see Proposition 4.4.

PROPOSITION 4.4. *There exists a Borel selector $\tilde{S}$ of $\Gamma(y, \nu)$, i.e., $\tilde{S} : \mathbb{R}^{d'} \times \mathcal{P}(\Gamma) \to \Gamma$ Borel map, such that $\tilde{S}(y, \nu) \in \Gamma(y, \nu)$.*

Proof. Suppose $\nu_n \to \nu$ weakly and $y_n \to y$. Then

$$\begin{aligned} &|\tilde{c}(x, y_n, \nu_n) - \tilde{c}(x, y, \nu)| \\ &\quad \leqq \int_\Gamma |c(x, y_n, u) - c(x, y, u)| d\nu_n + |\tilde{c}(x, y, \nu_n) - \tilde{c}(x, y, \nu)| \\ &\quad \leqq \sup_{x,u} |c(x, y_n, u) - c(x, y, u)| + |\tilde{c}(x, y, \nu_n) - \tilde{c}(x, y, \nu)| \end{aligned} \tag{4.10}$$

holds. By the uniform continuity of c, the first term tends to 0 as $n \to \infty$. The second term also tends to 0 by the assumption $\nu_n \to \nu$ weakly. Hence, as $n \to \infty$, $|\tilde{c}(\cdot, y, \nu_n) - \tilde{c}(\cdot, y, \nu)| \to 0$ uniformly in any compact set of $\mathbb{R}^d$, by virtue of uniform continuity of c. This derives

$$\tilde{c}(\cdot, y_n, \nu_n) \to \tilde{c}(\cdot, y, \nu), \quad \text{as} \quad n \to \infty. \tag{4.11}$$

Suppose $u_n \in \Gamma(y_n, \nu_n)$ tends to u. Since $c(\cdot, y_n, u_n) \to c(\cdot, y, u)$, (4.11) yields "$u \in \Gamma(y, \nu)$." This concludes the proof of Proposition 4.4. □

For $\mathcal{R} = (\Omega, \mathcal{F}, \mathcal{F}_t, P, W, \mu)$, we define an $\mathcal{F}_t$-adapted process U by

$$U(t) = \tilde{S}(y + W(t), \mu'(t)). \tag{4.12}$$

Then we have

$$\tilde{c}(x, y+W(t), \mu'(t)) = c(x, y+W(t), U(t)) \tag{4.13}$$

and

$$\tilde{L}(t, y+W(t), \mu) = L(y+W(t), U(t)). \tag{4.14}$$

Hence, $q = q(\ , \phi, y, \mathcal{R})$ satisfies

$$\begin{aligned} &dq(t) = L(y+W(t), U(t))q(t)\,dt + M(y+W(t))q(t)\,dW(t) \\ &q(0) = \phi. \end{aligned} \tag{4.15}$$

Since (4.15) has a unique solution, q turns out to be the response for the admissible system $\mathcal{A} = (\Omega, \mathcal{F}, \mathcal{F}_t, P, W, U)$.

Although an admissible system can be regarded as a relaxed system, we denote the pay-off function by $J(\phi, y, \mathcal{A})$, stressing an admissible system $\mathcal{A}$. Recalling Theorem 4.1, we get Theorem 4.2.

THEOREM 4.2. *Supposing* (A.1)$\sim$(A.3), $(A.4)_{m-1}$ *and the convexity condition, there is an optimal admissible system* $\mathcal{A}^*$, *for* $\phi \in \Phi$, *such that*

$$V(\phi, y) = \inf_{\mathcal{A} \in \mathcal{U}} J(\phi, y, \mathcal{A}) = J(\phi, y, \mathcal{A}^*). \tag{4.16}$$

Proof. Put $U^*(t) = \tilde{S}(y+W^*(t), \mu^{*\prime}(t))$ for an optimal relaxed system $\mathcal{R}^* = (\Omega, \mathcal{F}, \mathcal{F}_t, P^*, W^*, \mu^*)$. Then $\mathcal{A}^* = (\Omega, \mathcal{F}, \mathcal{F}_t, P^*, W^*, U^*)$ satisfies

$$V(\phi, y) = J(\phi, y, \mathcal{R}^*) = J(\phi, y, \mathcal{A}^*) \geqq \inf_{\mathcal{A} \in \mathcal{U}} J(\phi, y, \mathcal{A}) \tag{4.17}$$

Since $V(\phi, y) \leqq \inf_{\mathcal{A} \in \mathcal{U}} J(\phi, y, \mathcal{A})$, (4.17) derives (4.16). □

For §§ 5 and 6, we will introduce a subsidiary relaxed system. $\mathcal{R} = (W, \mu)$ is called a constant relaxed system, if $\mu'(t, du, \omega) = \nu(du)$ for any t and ω. In this case, we will call μ a constant relaxed control ν and denote $\mathcal{R} = (W, \nu)$. Stressing the terminal time T, we put

$$\begin{aligned} &\mathcal{J}(T, \phi, y, \nu) = J(T, \phi, y, \mu), \quad \text{if } \mu' = \nu \quad (\in \mathcal{P}(\Gamma)) \\ &v(T, \phi, y) = \inf_{\nu \in \mathcal{P}(\Gamma)} \mathcal{J}(T, \phi, y, \nu) \\ &\mathcal{X}(T, \phi, y) = \{\nu \in \mathcal{P}(\Gamma);\ v(T, \phi, y) = \mathcal{J}(T, \phi, y, \nu)\}. \end{aligned} \tag{4.18}$$

Appealing to the fact "$\mathcal{R}_n = (W_n, \nu_n)$ converges to $\mathcal{R} = (W, \nu)$ if and only if $\nu_n \to \nu$ weakly," we get Theorem 4.3.

THEOREM 4.3. *Under the conditions* (A.1)$\sim$(A.3) *and* $(A.4)_{m-2}$, $\mathcal{X}(T, \phi, y)$ *is nonempty and compact. Moreover, there is a Borel selector* $\mathcal{S}_{T,r}$ *of* $\mathcal{X}(T, \phi, y)$, *for* $(\phi, y) \in \Phi_r \times \mathbb{R}^{d'}$.

We consider the following usual pay-off function for the Bellman principle. Let $h: H^{m-2} \times \mathbb{R}^{d'} \to \mathbb{R}^1$ be quadratic growth and satisfy (4.19), namely,

$$|h(\phi, y)| \leqq C(1 + \|\phi\|_{m-2}^2 + |y|^2)$$

and

$$\begin{aligned} &|h(\phi_1, y_1) - h(\phi_2, y_2)| \\ &\quad \leqq C((\|\phi_1\|_{m-2} + \|\phi_2\|_{m-2})\|\phi_1 - \phi_2\|_{m-2} + (|y_1| + |y_2|)|y_1 - y_2|). \end{aligned} \tag{4.19}$$

By $\mathcal{G}$ we denote the set of functions $g: H^m \times \mathbb{R}^{d'} \to \mathbb{R}^1$, which satisfy (4.20) and (4.21) below,

$$|g(\phi, y)| \leqq C_g(1+\|\phi\|_{m-2}^2+|y|^2) \tag{4.20}$$

and

(4.21) for any $\varepsilon, b>0$, there is $\delta=\delta(\varepsilon, b, g)>0$ such that, for $(\phi_i, y_i)\in B_b$ $(=\{(\phi, y)\in H^m\times\mathbb{R}^{d'};\ \|\phi\|_{m-2}<b,\ |y|<b\})$

$$|g(\phi_1, y_1)-g(\phi_2, y_2)|<\varepsilon$$

holds, whenever $\|\phi_1-\phi_2\|_{m-2}<\delta$ and $|y_1-y_2|<\delta$.

Define J and V by (4.22) and (4.23), respectively,

$$J(t, \phi, y, \mathcal{R}, g)=E\left[\int_0^t h(q(s), y+W(s))\,ds+g(q(t), y+W(t))\right] \tag{4.22}$$

where $q=q(\ \cdot\ , \phi, y, \mathcal{R})$, and

$$V(t, \phi, y, g)=\inf_{\mathcal{R}\in\mathfrak{R}} J(t, \phi, y, \mathcal{R}, g). \tag{4.23}$$

For a constant relaxed system, we define $\mathcal{J}$ and v in the same way.

PROPOSITION 4.5. *$J(t, \cdot, \cdot, \mathcal{R}, g)$, $V(t, \cdot, \cdot, g)$, $\mathcal{J}(t, \cdot, \cdot, \mathcal{R}, g)$ and $v(t, \cdot, \cdot, g)$ belong to $\mathcal{G}$, whenever $g\in\mathcal{G}$.*

Proof. From (2.13), we see

$$\begin{aligned}|J(t, \phi, y, \mathcal{R}, g)| &\leqq E\left[C\int_0^t \{1+\|q(s)\|_{m-2}^2+|y+W(s)|^2\}\right.\\ &\qquad \left.+C_g\{1+\|q(t)\|_{m-2}^2+|y+W(t)|^2\}\right] \qquad (4.24)\\ &\leqq C(t, g)(1+\|\phi\|_{m-2}^2+|y|^2)\end{aligned}$$

where $C(t, g)$ is independent of $\mathcal{R}$. So J, V, $\mathcal{J}$, and v also satisfy the quadratic growth condition (4.20).

Recalling Corollary 3.2, we will show (4.21). Put $q_i=q(\ \cdot\ , \phi_i, y_i, \mathcal{R})$ for $(\phi_i, y_i)\in B_b$. Then we have

$$\begin{aligned}&E\left[\int_0^t |h(q_1(s), y_1+W(s))-h(q_2(s), y_2+W(s))|\,ds\right]\\ &\leqq CE\left[\int_0^t \sum_{i=1}^2 \|q_i(s)\|_{m-2}\|q_1(s)-q_2(s)\|_{m-2}+\sum_{i=1}^2 |y_i+W(s)||y_1-y_2|\,ds\right]\\ &\leqq C\left(\sum_{i=1}^2\left\{E\left[\int_0^t \|q_i(s)\|_{m-2}^2\,ds\right]\right\}^{1/2}\left\{E\left[\int_0^t \|q_1(s)-q_2(s)\|_{m-2}^2\,ds\right]\right\}^{1/2}\right. \qquad (4.25)\\ &\qquad \left.+\sum_{i=1}^2 (|y_i|+\sqrt{t})|y_1-y_2|\right)\\ &\leqq C_1(t)(1+b)(|y_1-y_2|(1+b)+\|\phi_1-\phi_2\|_{m-2})\\ &\leqq C_1(t)(1+b)^2(|y_1-y_2|+\|\phi_1-\phi_2\|_{m-2})\end{aligned}$$

$$
\begin{aligned}
&E[|g(q_i(t), y_i + W(t))|; \|q_i(t)\|_{m-2} > n] \\
&\quad \leqq C_g E[1 + \|q_i(t)\|_{m-2}^2 + |y_i + W(t)|^2; \|q_i(t)\|_{m-2} > n] \\
&\quad \leqq C_g (E[1 + \|q_i(t)\|_{m-2}^4 + |y_i + W(t)|^4])^{1/2} (E[\|q_i(t)\|_{m-2}^2 / n^2])^{1/2} \qquad (4.26) \\
&\quad \leqq C_2(g, t)(1 + \|\phi_i\|_{m-2}^2 + |y_i|^2)(1 + \|\phi_i\|_{m-2} + |y_i|)/n \\
&\quad \leqq C_3(g, t)(1+b)^3/n \\
&E[|g(q_i(t), y_i + W(t))|; |y_i + W(t)| > n] \\
&\quad \leqq C_4(g, t)(1 + \|\phi_i\|^2 + |y_i|^2)(|y_i| + \sqrt{t})/n \qquad (4.27) \\
&\quad \leqq C_5(g, t)(1+b)^3/n.
\end{aligned}
$$

Taking a large enough $n = n(\varepsilon, b, t, g)$ such that

$$
(C_3(g, t) + C_5(g, t))(1+b)^3 < \varepsilon n/4, \qquad (4.28)
$$

we get

$$
\begin{aligned}
&|J(t, \phi_1, y_1, \mathcal{R}, g) - J(t, \phi_2, y_2, \mathcal{R}, g)| \\
&\quad \leqq E\left[C \int_0^t \sum_{i=1}^{2} \|q_i(s)\|_{m-2} \|q_1(s) - q_2(s)\|_{m-2} + \sum_{i=1}^{2} |y_i + W(s)| |y_1 - y_2| \, ds \right] \qquad (4.29) \\
&\qquad + E[|g(q_1(t), y_1 + W(t)) - g(q_2(t), y_2 + W(t))|; \\
&\qquad\qquad \|q_i(t)\|_{m-2} < n, \ |y_i + W(t)| < n, \ i = 1, 2] + \varepsilon.
\end{aligned}
$$

From the continuity condition (4.21) for g, we see

$$
\begin{aligned}
&\text{the middle term of the right-hand side of (4.29)} \\
&\quad < \varepsilon + 2C_g(1 + 2n^2) P\{\|q_1(t) - q_2(t)\|_{m-2} > \delta(\varepsilon, n, g)\} \qquad (4.30) \\
&\quad < \varepsilon + 2C_g(1 + 2n^2) E[\|q_1(t) - q_2(t)\|_{m-2}^2 / \delta^2(\varepsilon, n, g)],
\end{aligned}
$$

whenever $|y_1 - y_2| < \delta(\varepsilon, n, g)$.

Using (3.48), (4.29) and (4.30), we can choose a positive constant $\tilde{\delta} = \tilde{\delta}(t, \varepsilon, b, g)$, independent from $\mathcal{R}$, such that

$$
|J(t, \phi_1, y_1, \mathcal{R}, g) - J(t, \phi_2, y_2, \mathcal{R}, g)| < \varepsilon, \qquad (4.31)
$$

whenever $\|\phi_1 - \phi_2\|_{m-2} < \tilde{\delta}$ and $|y_1 - y_2| < \tilde{\delta}$.

Since

$$
\text{“}|V(t, \phi_1, y_1, g) - V(t, \phi_2, y_2, g)| \leqq \sup_{\mathcal{R} \in \mathfrak{R}} |J(t, \phi_1, y_1, \mathcal{R}, g) - J(t, \phi_2, y_2, \mathcal{R}, g)|,\text{”}
$$

we can complete the proof. □

Now, applying arguments similar to (4.6)-(4.9), we get the following theorem.

THEOREM 4.4. *Under the conditions* (A.1)-(A.3) *and* $(A.4)_{m-2}$, *there exists an optimal relaxed system* $\mathcal{R}^*(\phi, y)$, *such that* $\pi(\mathcal{R}^*(\phi, y))$ *is Borel measurable with respect to* $(\phi, y) \in \Phi_r \times \mathbb{R}^{d'}$, *i.e.*,

$$
J(t, \phi, y, \mathcal{R}^*(\phi, y), g) = \inf_{\mathcal{R} \in \mathfrak{R}} J(t, \phi, y, \mathcal{R}, g).
$$

Example. Quadratic loss. (I) Put $h(\phi, y) = \|\phi\|^2$ $(= \|\phi\|_0^2)$ and $g = 0$. Then h satisfies (4.19). So there exists an optimal relaxed system $\mathcal{R}^* = \mathcal{R}^*(\phi, y)$, i.e.,

$$
\min_{\mathcal{R} \in \mathfrak{R}} E\left[\int_0^T \|q(t, \phi, y, \mathcal{R})\|^2 \, dt \right] = E\left[\int_0^T \|q(t, \phi, y, \mathcal{R}^*)\|^2 \, dt \right]
$$

(II) Put $h=0$ and $g(\phi)=\|\phi\|^2$. Then $g\in\mathcal{G}$. So there exists an optimal relaxed system $\tilde{\mathcal{R}}=\tilde{\mathcal{R}}(\phi, y)$, i.e.,

$$\min_{\mathcal{R}\in\mathfrak{R}} E[\|q(T, \phi, y, \mathcal{R})\|^2]=E[\|q(T, \phi, y, \tilde{\mathcal{R}})\|^2].$$

5. Approximation. In this section, we will show that there exists an approximate optimal control which is adapted to a Wiener process.

We call $\mathcal{R}=(W, \mu)$ a step relaxed system, if $\mu'(t)=\mu'([t/\Delta]\Delta)$ with a positive Δ, where $[\ ]=$Gauss symbol. By $\mathfrak{R}_N$ we denote the totality of step relaxed systems with $\Delta=2^{-N}$. For μ we define an approximate derivative μ'_n as follows:

$$\mu'_n(t, \cdot)=\begin{cases}2^n\mu([t-2^{-n}, t)\times\cdot) & \text{for } t>2^{-n}\\ t^{-1}\mu([0, t)\times\cdot) & \text{for } t\leqq 2^{-n}.\end{cases} \tag{5.1}$$

Put

$$\mu'_{n,k}(t, \cdot)=\mu'_n([2^k t]2^{-k}, \cdot) \tag{5.2}$$

and $\mu_{n,k}([0, t]\times A)=\int_0^t \mu'_{n,k}(s, A)\,ds$. Then, for a suitable sequence $k(n)$, $n=1, 2, \cdots$, we have, with probability 1,

$$\mu_{n,k(n)}\to\mu \text{ weakly.} \tag{5.3}$$

Hereafter, we consider a pay-off function J as (4.22). Therefore, (5.3) yields

$$V(t, \phi, y, g)=\lim_{N\to\infty}\inf_{\mathfrak{R}_N} J(t, \phi, y, \mathcal{R}, g). \tag{5.4}$$

Putting

$$\tilde{\mathfrak{R}}_N=\{\mathcal{R}=(W, \mu)\in\mathfrak{R}_N;\ \mu \text{ is } W\text{-adapted}\}, \tag{5.5}$$

we have the following theorem.

THEOREM 5.1. *Under the conditions* (A.1)-(A.3) *and* $(A.4)_{m-2}$, *we have, for* $\phi\in\Phi$

$$\inf_{\mathfrak{R}_N} J(t, \phi, y, \mathcal{R}, g)=\inf_{\tilde{\mathfrak{R}}_N} J(t, \phi, y, \mathcal{R}, g). \tag{5.6}$$

Proof. Since $\tilde{\mathfrak{R}}_N\subset\mathfrak{R}_N$, it is enough to show

$$J(t, \phi, y, \mathcal{R}, g)\geqq\inf_{\tilde{\mathfrak{R}}_N} J(t, \phi, y, \mathcal{R}, g) \quad \forall\mathcal{R}\in\mathfrak{R}_N. \tag{5.7}$$

Putting $\Delta=2^{-N}$ and $j\Delta<t\leqq(j+1)\Delta$, we will evaluate I, defined by (5.8),

$$I=E\left[\int_{j\Delta}^t h(q(s), y+W(s))\,ds+g(q(t), y+W(t))\,|\,\mathcal{F}_{j\Delta}\right] \tag{5.8}$$

where $q=q(\ , \phi, y, \mathcal{R})$. Under the conditional probability $P(\cdot\,|\,\mathcal{F}_{j\Delta})$, $W^j(\cdot)=W(\cdot+j\Delta)-W(j\Delta)$ becomes a new Wiener process which is independent of $\mathcal{F}_{j\Delta}$ and $\mu'(\theta+j\Delta, \cdot)=\mu'(j\Delta, \cdot)$, $0\leqq\theta\leqq t-j\Delta$, can be regarded as a constant relaxed control. Moreover, the uniqueness of solution derives

$$q(\theta+j\Delta, \phi, y, \mathcal{R})=q(\theta, q(j\Delta, \phi, y, \mathcal{R}), y+W(j\Delta), \mu'(j\Delta)) \quad \text{for } 0\leqq\theta\leqq t-j\Delta. \tag{5.9}$$

Hence, we see

$$\begin{aligned} I&\geqq\inf_{\nu\in\mathcal{P}(\Gamma)}\mathcal{J}(t-j\Delta, q(j\Delta, \phi, y, \mathcal{R}), y+W(j\Delta), \nu, g)\\ &=v(t-j\Delta, q(j\Delta, \phi, y, \mathcal{R}), y+W(j\Delta), g).\end{aligned} \tag{5.10}$$

Defining $v(s): \mathcal{G} \to \mathcal{G}$ by $v(s, \cdot, g) = v(s)g$, we see from (5.10)

$$J(t, \phi, y, \mathcal{R}, g) \geqq E\left[\int_0^{j\Delta} h(q(s), y + W(s))\, ds + v(t - j\Delta)g(q(j\Delta), y + W(j\Delta))\right]. \tag{5.11}$$

By the same argument, we calculate $E[\cdots | \mathcal{F}_{(j-1)\Delta}]$ and obtain

$$J(t, \phi, y, \mathcal{R}, g) \geqq E\left[\int_0^{(j-1)\Delta} h(q(s), y + W(s))\, ds + v(\Delta)v(t - j\Delta)g(q((j-1)\Delta), y + W((j-1)\Delta))\right]. \tag{5.12}$$

Repeating this evaluation, we get

$$J(t, \phi, y, \mathcal{R}, g) \geqq v^j(\Delta)v(t - j\Delta)g(\phi, y). \tag{5.13}$$

We assume that $(A.4)_{m-2, r_0}$ holds. Then (2.14) asserts that $q(t, \phi, y, \mathcal{R}) \in \Phi_r$ with probability 1, whenever $\phi \in \Phi_r$ for $r \leqq r_0$. According to Theorem 4.3, we can take a Borel selector $\mathcal{S}_r(t, g)$ of

$$\mathfrak{X}(t, \phi, y, g) = \{\pi(\mathcal{R}); v(t, \phi, y, g) = J(t, \phi, y, \mathcal{R}, g)\}.$$

Let $(\Omega_i, \mathcal{F}_i, P_i)$, $i = 1, \cdots, (j+1)$ be a probability space and W_i be a Wiener process on it. Let us set

$$\Omega = \prod_{i=1}^{j+1} \Omega_i, \quad \mathcal{F} = \prod_{i=1}^{j+1} \mathcal{F}_i, \quad P = \prod_{i=1}^{j+1} P_i$$

and

$$W(t) = \begin{cases} W_1(t) & \text{for } 0 \leqq t < \Delta \\ W_1(\Delta) + W_2(t - \Delta) & \text{for } \Delta \leqq t < 2\Delta \\ \vdots & \\ \sum_{k=1}^{j} W_k(\Delta) + W_{j+1}(t - j\Delta) & \text{for } j\Delta \leqq t < (j+1)\Delta. \end{cases} \tag{5.14}$$

Then W becomes a Wiener process on $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$, where $\mathcal{F}_t = \sigma_t(W)$. Fix $\nu_1 \in \mathfrak{X}(\Delta, \phi, y, v^{j-1}(\Delta)v(t - j\Delta)g)$ arbitrarily and q_1 denotes the solution of (5.15).

$$\begin{aligned} &dq_1(t) = \tilde{L}(y + W(t), \nu_1)q_1(t)\, dt + M(y + W(t))q_1(t)\, dW(t), \\ &q_1(0) = \phi \qquad 0 < t \leqq \Delta. \end{aligned} \tag{5.15}$$

So q_1 is W-adapted.

Put $\nu_2 = \mathcal{S}_r(\Delta, v^{j-2}(\Delta)v(t - j\Delta)g(q_1(\Delta), y + W(\Delta))$ and q_2 denotes the solution of (5.16).

$$\begin{aligned} &dq_2(t) = \tilde{L}(y + W(t), \nu_2)q_2(t)\, dt + M(y + W(t))q_2(t)\, dW(t), \\ &q_2(\Delta) = q_1(\Delta) \qquad \Delta < t \leqq 2\Delta. \end{aligned} \tag{5.16}$$

Putting $\nu_3 = \mathcal{S}_r(\Delta, v^{j-2}(\Delta)v(t - j\Delta)g(q_2(2\Delta), y + W(2\Delta))$, we repeat the same argument. Now define μ' by

$$\mu'(t) = \nu_k \quad \text{for } t \in [(k-1)\Delta, k\Delta). \tag{5.17}$$

Then μ' is W-adapted and $\tilde{\mathcal{R}} = (\Omega, \mathcal{F}, \mathcal{F}_t, P, W, \mu) \in \tilde{\mathfrak{R}}_N$. Moreover, putting $q = q_k$ on $[(k-1)\Delta, k\Delta)$, we get

$$
\begin{aligned}
&E\left(\int_{j\Delta}^{t} h(q(s), y+W(s))\,ds + g(q(t), y+W(t)) \,\middle|\, \mathcal{F}_{j\Delta}\right) \\
&\quad = E\left(\int_{j\Delta}^{t} h(q_j(s), y+W(s))\,ds + g(q_j(t), y+W(t))\right) \\
&\quad = v(t-j\Delta)g(q(j\Delta), y+W(j\Delta)), \\
&E\left(\int_{(j-1)\Delta}^{j\Delta} h(q(s), y+W(s))\,ds + v(t-j\Delta)g(q(j\Delta), y+W(j\Delta)) \,\middle|\, \mathcal{F}_{(j-1)\Delta}\right) \\
&\quad = v(\Delta)v(t-j\Delta)g(q((j-1)\Delta), y+W((j-1)\Delta)),
\end{aligned} \tag{5.18}
$$

and so on. Thus, we have

$$
\begin{aligned}
&J(t, \phi, y, \tilde{\mathcal{R}}, g) \\
&\quad = E\left[\int_0^t h(q(s), y+W(s))\,ds + g(q(t), y+W(t))\right] \\
&\quad = E\left[E\left(\int_{j\Delta}^{t} h(q(s), y+W(s))\,ds + g(q(t), y+W(t)) \,\middle|\, \mathcal{F}_{j\Delta}\right)\right. \\
&\qquad\qquad \left. + \int_0^{j\Delta} h(q(s), y+W(s))\,ds\right] \\
&\quad = E\left[\int_0^{j\Delta} h(q(s), y+W(s))\,ds + v(t-j\Delta)g(q(j\Delta), y+W(j\Delta))\right] \\
&\quad = E\left[\int_0^{(j-1)\Delta} h(q(s), y+W(s))\,ds\right. \\
&\qquad\qquad \left. + v(\Delta)v(t-j\Delta)g(q((j-1)\Delta), y+W((j-1)\Delta))\right] \\
&\quad = v^j(\Delta)v(t-j\Delta)g(\phi, y).
\end{aligned} \tag{5.19}
$$

From (5.13) and (5.19), we can conclude (5.7). □

Recalling (5.4), we obtain Corollary 5.1.

COROLLARY 5.1. *Under the same condition of Theorem* 5.1,

$$V(t, \phi, y, g) = \lim_{N\to\infty} \inf_{\mathfrak{R}_N} J(t, \phi, y, \mathcal{R}, g) \tag{5.20}$$

holds. In other words, there is an approximate optimal step relaxed system, which is adapted to a Wiener process.

Using the chattering lemma [3], $\mathcal{R} \in \mathfrak{R}_N$ can be approximated by admissible controls which are adapted to a Wiener process. Hence, putting $\tilde{\mathfrak{U}}_N = \mathfrak{U} \cap \tilde{\mathfrak{R}}_N = \{\mathcal{A} = (W, U);\ U \text{ is } W\text{-adapted and } U(t) = U([2^N t]2^{-N})\}$ and $\tilde{\mathfrak{U}} = \bigcup_{N=1}^{\infty} \tilde{\mathfrak{U}}_N$, we have Corollary 5.2.

COROLLARY 5.2. *Under the same condition, there is an approximate optimal step system* $\mathcal{A} \in \tilde{\mathfrak{U}}$.

6. Bellman principle. Now we are ready to prove the Bellman principle. For $\phi \in \Phi_r$ and $\mathscr{A} = (W, U) \in \tilde{\mathfrak{U}}_N$, we will evaluate (6.1):

$$
\begin{aligned}
&J(s+t, \phi, y, \mathscr{A}, g) \\
&\quad = E\left(\int_0^t h(q(\theta), y + W(\theta))\, d\theta \right. \\
&\qquad \left. + E\left[\int_t^{t+s} h(q(\theta), y + W(\theta))\, d\theta + g(q(t+s), y + W(t+s)) \,|\, \mathscr{F}_t \right] \right).
\end{aligned} \tag{6.1}
$$

Since $W^t(\cdot) = W(\cdot + t) - W(t)$ is a Wiener process independent from $\mathscr{F}_t$, we see

(6.2) conditional expectation of 2nd term $\geqq V(s, q(t), y + W(t), g)$ w.p. 1.

This asserts

$$
\begin{aligned}
J(s+t, \phi, y, \mathscr{A}, g) &\geqq J(t, q(t), y + W(t), \mathscr{A}, V(s, \cdot, g)) \\
&\geqq V(t, q(t), y + W(t), V(s, \cdot, g)).
\end{aligned} \tag{6.3}
$$

Now Corollary 5.2 yields

$$
V(s+t, \phi, y, g) \geqq V(t, q(t), y + W(t), V(s, \cdot, g)). \tag{6.4}
$$

Next we will show the converse inequality of (6.4) by a standard argument.

Let $\mathscr{S}_1(\phi, y)$ denote a Borel selector of

$$
\mathfrak{X}(\phi, y) = \{\pi(\mathscr{R});\ V(s, \phi, y, g) = J(s, \phi, y, \mathscr{R}, g)\}.
$$

For any $\mathscr{A} = (\Omega, \mathscr{F}, \mathscr{F}_t, P, W, U) \in \tilde{\mathfrak{U}}_N$, we put $\tilde{\Omega} = C([0, s]; \mathbb{R}^{d'}) \times \Lambda$, $\tilde{W}$ = first coordinate function $\tilde{\mu}$ = second coordinate function, $\tilde{\mathscr{F}} = \sigma(\tilde{W}, \tilde{\mu})$, $\tilde{\mathscr{F}}_\theta = \sigma_\theta(\tilde{W}, \tilde{\mu})$ $\Omega^* = \Omega \times \tilde{\Omega}$, $\mathscr{F}^* = \mathscr{F} \times \tilde{\mathscr{F}}$.

Define P^* by

$$
P^*((\tilde{W}, \tilde{\mu}) \in B \,|\, \mathscr{F}_t) = \mathscr{S}_r(q(t, \phi, y, \mathscr{A}), y + W(t))(B), \tag{6.5}
$$

namely,

$$
P^*((\tilde{W}, \tilde{\mu}) \in B, (W, \mu) \in C) = \int_{\{(W, \mu) \in C\}} \mathscr{S}_r(q(t, \phi, y, \mathscr{A}), y + W(t))(B)\, dP.
$$

Hence, $\tilde{W}$ is a Wiener process on $(\Omega^*, \mathscr{F}^*, P^*)$, independent from W. Thus, putting

$$
W^*(\theta) = \begin{cases} W(\theta), & \theta \leqq t \\ W(t) + \tilde{W}(\theta - t), & t \leqq \theta \leqq s + t \end{cases}
$$

$$
\mu^*(\theta, \cdot) = \begin{cases} \delta_{U(\theta)}(\cdot), & \theta \leqq t \\ \tilde{\mu}(\theta - t, \cdot), & t \leqq \theta \leqq s + t \end{cases}
$$

$$
\mathscr{F}^*_\theta = \sigma_\theta(W^*, \mu^*),
$$

we see $\mathscr{R}^* = (W^*, \mu^*) \in \mathfrak{R}$ and its response q^* satisfies

$$
\begin{aligned}
&E\left[\int_t^{t+s} h(q^*(\theta), y + W^*(\theta))\, d\theta + g(q^*(t+s), y + W(t+s)) \,|\, \mathscr{F}^*_t \right] \\
&\quad = V(s, q(t, \phi, y, \mathscr{A}), y + W(t), g) \\
&\quad = V(s, q(t, \phi, y, \mathscr{R}^*), y + W^*(t), g).
\end{aligned} \tag{6.6}
$$

Therefore,

$$J(s+t, \phi, y, \mathcal{R}^*, g) = J(t, \phi, y, \mathcal{R}^*, V(s, \cdot, g)) \tag{6.7}$$
$$= J(t, \phi, y, \mathcal{A}, V(s, \cdot, g))$$

holds. This asserts

$$V(s+t, \phi, y, g) \leqq J(t, \phi, y, \mathcal{A}, V(s, \cdot, g)).$$

Again, Corollary 5.2 concludes the converse inequality of (6.4).

Thus, we obtain Theorem 6.1.

THEOREM 6.1. *Under the conditions* (A.1)-(A.3) *and* $(A.4)_{m-2}$, *we have*

$$V(t, \cdot, g) \in \mathcal{G} \quad \textit{whenever } g \in \mathcal{G}, \tag{6.8}$$

and the Bellman principle holds, i.e.,

$$V(s+t, \phi, y, g) = V(t, \phi, y, V(s, \cdot, g)) \quad \textit{for } \phi \in \Phi \quad \textit{and} \quad g \in \mathcal{G}. \tag{6.9}$$

Remark. The Bellman principle is formulated by some nonlinear group [1].

7. Applications. (1) Temperature control. Let us consider a heat system in a random medium. The field of temperature $q(t, x)$ is governed by the following SPDE.

$$dq(t, x) = (\Delta q(t, x) + f(x, U(t)))\, dt + g(x)\, dW(t), \qquad t > 0, \quad x \in \mathbb{R}^d,$$

with the initial data $q(0, x) = \phi(x)$, where Δ is the Laplacian operator for x and W a d-dimensional Wiener process. So the temperature is controlled through the external force $f(x, U(t))$. The problem is to minimize the deviation of temperature distribution from the assigned distribution m at a given time T (cf. Sakawa [18]), namely, the pay-off function J is defined by

$$J(U) = E\left[\int_{\mathbb{R}^d} |q(T, x) - m(x)|^2\, dx\right].$$

Hence, Theorem 4.4 concludes the existence of an optimal relaxed control, if f and g satisfy the condition $(A.4)_1$.

(2) Nervous system. In Chapter 3 of [20], Walsh deals with the following SPDE as the dynamics of nervous system,

$$dq(t, x) = \left(\frac{\partial^2}{\partial x^2} q(t, x) - q(t, x)\right) dt + (q(t, x) - g(x))\, dW(t), \qquad 0 < x < L, \quad t > 0,$$

with Neuman boundary condition, where W is a one-dimensional Wiener process, and also considers the barrier problem.

Since a medical treatment acts as an external force, here we will consider the following SPDE as its variant,

$$dq(t, x) = \left(\frac{\partial^2}{\partial x^2} q(t, x) - q(t, x) + f(x, U(t))\right) dt$$
$$+ (q(t, x) - g(x))\, dW(t), \qquad x \in \mathbb{R}^1, \qquad 0 < t \leqq T,$$
$$q(0, x) = \phi(x).$$

Although we want to keep $q(t, x)$ near an assigned level λ at a given spot y, we need some smooth modifications. For given two positive constants b and c, we put

$$p(t) = \frac{1}{2c} \int_{-c}^{c} q(t, y + x)\, dx$$

and

$$h(x)=\begin{cases}1, & x\notin(\lambda-b,\lambda+b)\\ \dfrac{\lambda-x}{b}, & \lambda-b<x<\lambda\\ \dfrac{x-\lambda}{b}, & \lambda<x<\lambda+b.\end{cases}$$

Now the problem is to minimize $E[\int_0^T h(p(t))\,dt]$ and our theorems are applicable.

(3) Stochastic control with partial observation.

Let B and $\hat{B}$ be independent Wiener processes with values in $\mathbb{R}^{d'}$ and $\mathbb{R}^d$, respectively. Suppose that the d-dimensional state process X and the d'-dimensional observation process Y are governed by the following stochastic differential equations (SDE in short) with bounded and smooth coefficients:

$$\begin{aligned}dX(t)&=\gamma(X(t),Y(t),U(t))\,dt+\alpha(X(t),Y(t),U(t))\,d\hat{B}(t)\\&\quad+b(X(t),Y(t))\,dB(t),\qquad 0<t\leqq T\\X(0)&=\xi\end{aligned}\tag{7.1}$$

and

$$dY(t)=f(X(t))\,dt+dB(t),\qquad Y(0)=0,\tag{7.2}$$

where U is an admissible control. So in our model the state and observation noises may not be independent.

Let h and $G:\mathbb{R}^d\times\mathbb{R}^{d'}\to\mathbb{R}^1$, be bounded and Lipschitz continuous. The problem is to minimize the pay-off function J, defined by

$$J(U)=E\left[\int_0^T h(X(t),Y(t))\,dt+G(X(T),Y(T))\right]\tag{7.3}$$

by a suitable choice of U.

In the customary version of stochastic control with partial observation, $U(t)$ is a function of the observation process $Y(s)$, $s\leqq t$, namely, admissible control in the strict sense. Here we treat some wider class of admissible controls, according to [4], as follows:

$A=(\Omega,\mathcal{F},\mathcal{F}_t,\mathring{P},\hat{B},Y,U)$ is called an admissible control system, if

(I) $(\Omega,\mathcal{F},\mathcal{F}_t,\mathring{P})$ is a probability space, with $\mathcal{F}_t=\sigma_t(Y,U)$

(II) Y is a d'-dimensional $\mathcal{F}_t$-Wiener process

(III) U is a Γ-valued process

(IV) $\hat{B}$ is a d-dimensional Wiener process on Ω, independent from (Y,U).

Let ξ be a random variable independent from $(\hat{B},Y,U)$ and ϕ be its probability density. For an admissible system A, we consider SDE,

$$\begin{aligned}dX(t)&=(\gamma(X(t),Y(t),U(t))-b(X(t),Y(t))f(X(t)))\,dt\\&\quad+\alpha(X(t),Y(t),U(t))\,d\hat{B}(t)+b(X(t),Y(t))\,dY(t)\\X(0)&=\xi.\end{aligned}\tag{7.4}$$

Put

$$\rho(t)=\exp\left\{\int_0^t f(X(t))\,dY(t)-\frac{1}{2}\int_0^t|f(X(t))|^2\,dt\right\}\tag{7.5}$$

and define a new probability P by

$$dP = \rho(T)\, d\mathring{P}. \tag{7.6}$$

Then, Girsanov's theorem asserts that, under the probability P, $B(t) = Y(t) - \int_0^t f(X(s))\, ds$, $0 \leqq t \leqq T$, turns out to be a Wiener process independent from $\hat{B}$, and (X, Y) satisfies (7.1).

Moreover, the pay-off function $J(U)$ of (7.3) can be written by

$$J(A) = \mathring{E}\left[\int_0^T h(X(t), Y(t))\rho(t)\, dt + G(X(T), Y(T))\rho(T)\right]$$

where $\mathring{E}$ means the expectation with respect to $\mathring{P}$.

On the other hand, $A = (\Omega, \mathscr{F}, \mathscr{F}_t, \mathring{P}, \hat{B}, Y, U)$ derives an admissible system $\mathscr{A} = (\Omega, \mathscr{F}, \mathscr{F}_t, \mathring{P}, Y, U)$, and an admissible system turns out to be an admissible control system when we add an independent Wiener process $\hat{B}$. For $\mathscr{A} = (\Omega, \mathscr{F}, \mathscr{F}_t, \mathring{P}, Y, U)$, we consider SPDE,

$$\begin{aligned} &dq(t) = L(Y(t), U(t))q(t)\, dt + M(Y(t))q(t)\, dY(t) \\ &q(0) = \phi \ (\in H^3) \end{aligned} \tag{7.7}$$

where

$$\begin{aligned} &L(y, u)q = \sum_{i,j=1}^{d} \frac{\partial}{\partial x_j} a_{ij}(\cdot, y, u) \frac{\partial}{\partial x_i} q - \sum_{j=1}^{d} \frac{\partial}{\partial x_j} (\tilde{a}_j(\cdot, y, u)q), \\ &M^k(y)q = -\sum_{i=1}^{d} b_{ik}(\cdot, y) \frac{\partial}{\partial x_i} q + \tilde{f}_k(\cdot, y)q, \\ &a(x, y, u) = (b(x, y)b^*(x, y) + \alpha(x, y, u)\alpha^*(x, y, u))/2, \\ &\tilde{a}_j(x, y, u) = \gamma_j(x, y, u) - \sum_{i=1}^{d} \frac{\partial a_{ij}}{\partial x_i}(x, y, u), \end{aligned} \tag{7.8}$$

and

$$\tilde{f}_k(x, y) = f_k(x) - \sum_{i=1}^{d} \frac{\partial b_{ik}}{\partial x_i}(x, y).$$

Then, under the conditions (A.1)-(A.3), $J(A)$ can be represented by

$$J(A) = \mathring{E}\left[\int_0^T (h(\cdot, Y(t)), q(t))\, dt + (G(\cdot, Y(T)), q(T))\right]. \tag{7.9}$$

Now we have the following theorem, appealing to Theorems 3.1 and 4.2.

THEOREM 7.1. *Suppose* (A.1)-(A.3), $(A.4)_1$ *and the convexity condition for the coefficients of the* SPDE (7.7). *Then, for* $\phi \in \Phi$, *there is an optimal admissible control system* A^*, *namely*

$$J(A^*) = \inf_A J(A). \tag{7.10}$$

Appendix. Let us prove the lemma in § 3. Here we use the following notation, according to [10]:

For $\alpha = (i_1, \cdots, i_l)$, $D^\alpha = \partial_{i_1} \cdots \partial_{i_l}$, $|\alpha| = l$

$\binom{\alpha}{\gamma} = \binom{i_1}{j_1} \cdots \binom{i_l}{j_l}$ is the binomial coefficient

(for $\gamma = (j_1, \cdots, j_l)$, $0 \leqq j_k \leqq i_k$)

$|i| = 0$ for $i = 0$, $= 1$ for $i = 1, \cdots, d$,

$\int \cdots dx$ stands for $\int_{\mathbb{R}^d} \cdots dx$ and hereafter $N_1, N_2, \cdots$ denote constants depending only on K, T, and l, and repeated indexes are assumed to be summed from 1 (not 0) to d.

We will estimate the principal part of J defined by (1). For $u \in C_0^\infty(\mathbb{R}^d)$, we put

$$
\begin{aligned}
J &= \sum_{|\gamma| \leqq l} \int \{-2D^\gamma(a^{ij}\partial_j u)D^\gamma \partial_i u + 3D^\gamma(b^i \partial_i u)D^\gamma(b^j \partial_j u)\}\, dx \\
&= -2 \int \hat{a}^{ij} \partial_i u \partial_j u\, dx \qquad (1) \\
&\quad + \sum_{1 \leqq |\gamma| \leqq l} \int \{-2D^\gamma(a^{ij}\partial_j u)D^\gamma \partial_i u + 3D^\gamma(b^i \partial_i u)D^\gamma(b^j \partial_j u)\}\, dx,
\end{aligned}
$$

where $\hat{a}^{ij} = a^{ij} - \frac{3}{2} b^i \cdot b^j$.

Using integration by parts, we get

$$
\begin{aligned}
&\int -2D^\gamma(a^{ij}\partial_j u)D^\gamma \partial_i u\, dx \\
&\quad = \int -2a^{ij} D^\gamma \partial_j u D^\gamma \partial_i u\, dx + 2 \sum_{\substack{\alpha+\beta=\gamma \\ |\alpha|=1}} \binom{\gamma}{\alpha} \int D^\alpha a^{ij} D^\beta \partial_i \partial_j u D^\gamma u\, dx \\
&\quad\quad + 2 \sum_{\substack{\alpha+\beta=\gamma \\ |\alpha| \geqq 1}} \binom{\gamma}{\alpha} \int D^\alpha \partial_i a^{ij} D^\beta \partial_j u D^\gamma u\, dx \qquad (2) \\
&\quad\quad + 2 \sum_{\substack{\alpha+\beta=\gamma \\ |\alpha| \geqq 2}} \binom{\gamma}{\alpha} \int D^\alpha a^{ij} D^\beta \partial_i \partial_j u D^\gamma u\, dx.
\end{aligned}
$$

Appealing to $|\beta|+1 \leqq l$ in the third term and $|\beta|+2 \leqq l$ in the fourth term,

$$\leqq \text{first term} + \text{second term} + N_1 \|u\|_l^2.$$

Since $D^\gamma(b^i \partial_i u) - b^i D^\gamma \partial_i u$ is independent of the $(l+1)$th order derivative of u, we obtain, in the same way as (2),

$$
\begin{aligned}
&\int 3D^\gamma(b^i \partial_i u) \cdot D^\gamma(b^j \partial_j u)\, dx \\
&\quad = \int 3|b^i D^\gamma \partial_i u + (D^\gamma(b^i \partial_i u) - b^i D^\gamma \partial_i u)|^2\, dx \\
&\quad = \int 3b^i D^\gamma \partial_i u \cdot b^j D^\gamma \partial_j u\, dx + \int 6 \sum_{\substack{\alpha+\beta=\gamma \\ |\alpha| \geqq 1}} \binom{\gamma}{\alpha} D^\alpha b^i D^\beta \partial_i u \cdot b^j D^\gamma \partial_j u\, dx \\
&\quad\quad + \int 3|D^\gamma(b^i \partial_i u) - b^i D^\gamma \partial_i u|^2\, dx \qquad (3) \\
&\quad \leqq \text{first term} - 6 \sum_{\substack{\alpha+\beta=\gamma \\ |\alpha|=1}} \binom{\gamma}{\alpha} \int (D^\alpha b^i) \cdot b^j D^\beta \partial_i \partial_j u D^\gamma\, dx + N_2 \|u\|_l^2 \\
&\quad = \text{first term} - 3 \sum_{\substack{\alpha+\beta=\gamma \\ |\alpha|=1}} \binom{\gamma}{\alpha} \int D^\alpha (b^i \cdot b^j) D^\beta \partial_i \partial_j u D^\gamma u\, dx + N_2 \|u\|_l^2.
\end{aligned}
$$

(1), (2), and (3) yield

$$J \leqq -2 \sum_{|\gamma| \leqq l} \int \hat{a}^{ij} D^{\gamma} \partial_j u D^{\gamma} \partial_i u \, dx$$

$$+2 \sum_{1 \leqq |\gamma| \leqq l} \sum_{\substack{\alpha+\beta=\gamma \\ |\alpha|=1}} \binom{\gamma}{\alpha} \int D^{\alpha} \hat{a}^{ij} D^{\beta} \partial_i \partial_j u D^{\gamma} u \, dx + N_3 \|u\|_l^2.$$

On the other hand,

$$|D^{\alpha} \hat{a}^{ij} D^{\beta} \partial_i \partial_j u|^2 \leqq N_4 \hat{a}^{ij} D^{\beta} \partial_i \partial_k u D^{\beta} \partial_j \partial_k u$$

$$\leqq N_4 \sum_{|\gamma| \leqq l} \hat{a}^{ij} D^{\gamma} \partial_i u D^{\gamma} \partial_j u$$

holds, by virtue of $\hat{a}^{ij} \in C^2(\mathbb{R}^d)$ and matrix $(\hat{a}^{ij}) \geqq 0$, (see Lemma 1.7.1 of [15]).

Noting $2|ab| \leqq \varepsilon^2 |a|^2 + |b|/\varepsilon^2$, we get

$$J \leqq (N_5 \varepsilon^2 - 2) \sum_{|\gamma| \leqq l} \int \hat{a}^{ij} D^{\gamma} \partial_j u D^{\gamma} \partial_i u \, dx + (N_3 + N_6/\varepsilon^2) \|u\|_l^2.$$

So $J \leqq N_7 \|u\|_l^2$ holds, putting $\varepsilon^2 = 2/N_5$. Applying the same calculation to the other terms, we can prove the lemma for $u \in C_0^{\infty}(\mathbb{R}^d)$. Since $C_0^{\infty}(\mathbb{R}^d)$ is dense in H^{l+1}, we can conclude the proof of the lemma by the routine method. □

DUAL ASCENT METHODS FOR PROBLEMS WITH STRICTLY CONVEX COSTS AND LINEAR CONSTRAINTS: A UNIFIED APPROACH*

PAUL TSENG†

Abstract. Consider problems of the form

$$\text{(P)} \qquad \min \{f(x) \mid Ex \geqq b\},$$

where f is a strictly convex (possibly nondifferentiable) function and E and b are, respectively, a matrix and a vector. A popular method for solving special cases of (P) (e.g., network flow, entropy maximization, quadratic program) is to dualize the constraints $Ex \geqq b$ to obtain a differentiable maximization problem and then apply an iterative ascent method to solve it. This method is simple and can exploit sparsity, thus making it ideal for large-scale optimization and, in certain cases, for parallel computation. Despite its simplicity, however, convergence of this method has been shown only under certain very restrictive conditions and only for certain special cases of (P). In this paper a block coordinate ascent method is presented for solving (P) that contains as special cases both dual coordinate ascent methods and dual gradient methods. It is shown, under certain mild assumptions on f and (P), that this method converges. Also the line searches are allowed to be inexact and, when f is separable, can be done in parallel.

Key words. block coordinate ascent, strict convexity, convex program

AMS(MOS) subject classifications. 49, 90

1. Introduction.

Consider the problem

$$\text{(P)} \qquad \text{Minimize} \quad f(x)$$

$$\text{(1.1)} \qquad \text{subject to} \quad Ex \geqq b,$$

where $f: \Re^m \to (-\infty, +\infty]$, E is an $n \times m$ matrix having no zero row, and b is a vector in $\Re^n$. In our notation all vectors are column vectors and superscript T denotes transpose. We denote by e_{ij} the (i,j)th entry of E and by b_i the ith coordinate of b. We also denote by $\langle \cdot, \cdot \rangle$ the usual Euclidean inner product and by $\| \cdot \|$ its induced norm. On occasion, we will treat in parallel the equality constraint problem

$$(\text{P}^{\text{E}}) \qquad \text{Minimize} \quad f(x)$$

$$\text{subject to} \quad Ex = b.$$

(Extension to the case of mixed equality and inequality constraints is straightforward.)

Denote by S the *effective domain* of f, i.e.,

$$S = \{x \in \Re^m \mid f(x) < +\infty\},$$

by int (S), ri (S) and cl (S), respectively, the *interior*, the *relative interior*, and the *closure* of S, and by X the constraint set for (P), i.e.,

$$X = \{x \in \Re^m \mid Ex \geqq b\}.$$

(For the equality constraint problem (P^{E}), we replace X by $\{x \in \Re^m \mid Ex = b\}$.) We make the following standing assumptions.

Assumption A. f is strictly convex, lower semicontinuous, and continuous within S. Moreover, the *conjugate function* of f defined by

$$f^*(t) = \sup \{\langle t, \xi\rangle - f(\xi) \mid \xi \in \Re^m\} \tag{1.2}$$

is real valued, i.e., $-\infty < f^*(t) < +\infty$ for all $t \in \Re^m$.

Assumption B. $S = S^1 \cap S^2$, where S^1 and S^2 are convex sets in $\Re^m$ such that cl (S^1) is a polyhedral set and $S^1 \cap \text{ri}\,(S^2) \cap X \neq \varnothing$.

Assumption B is the usual feasibility assumption for (P), i.e., $S \cap X \neq \varnothing$, plus an additional constraint qualification. The constraint qualification, which is necessary for establishing the convergence of our algorithm (see § 3), is almost always satisfied. For example, cl (S) (but not necessarily S) is a polyhedral set if f is *separable* [55], [59]. (In this case cl (S) is a box.) Assumption A implies that, for every t, there is some $\xi \in \Re^m$ achieving the supremum in (1.2) and $f(x) \to +\infty$ as $\|x\| \to +\infty$. It follows from the latter that f has bounded level sets. Because f is lower semicontinuous, its level sets are compact. This, together with the feasibility of (P) and the strict convexity of f within S, implies that *there exists a unique optimal solution* to (P), which we denote by x^*.

A dual program of (P), obtained by assigning a Lagrange multiplier p_i to the ith constraint of $Ex \geqq b$, is

$$\text{(D)} \qquad \underset{p \geqq 0}{\text{Maximize}}\ q(p)$$

where

$$\begin{aligned} q(p) &= \min \{f(x) + \langle p, b - Ex\rangle \mid x \in \Re^m\} \\ &= \langle p, b\rangle - f^*(E^T p). \end{aligned} \tag{1.3}$$

(For the equality constraint problem (P^E), the dual program is identical to (D) except that it does not have the nonnegativity constraints on p.) Problem (D) is a concave program with simple nonnegative orthant constraints. Furthermore, strong duality holds for (P) and (D), i.e., the optimal value in (P) equals the optimal value in (D) (see [60, § 1]).

Since f^* is real valued and f is strictly convex, f^* and q are continuously differentiable ([54, Thm. 26.3]). Using the chain rule, we obtain the gradient of q at p, denoted by $d(p)$, to be

$$d(p) = b - E\chi(p), \tag{1.4}$$

where we denote

$$\begin{aligned} \chi(p) &= \nabla f^*(E^T p) \\ &= \arg\max \{\langle p, E\xi\rangle - f(\xi) \mid \xi \in \Re^m\}. \end{aligned} \tag{1.5}$$

We will also denote by $d_i(p)$ the ith coordinate of $d(p)$ and, for any $I \subseteq \{1, \cdots, n\}$, by $d_I(p)$ the vector $(\cdots, d_i(p), \cdots)_{i \in I}$. Note from (1.5) that $\chi(p)$ is also the unique vector x satisfying

$$E^T p \in \partial f(x), \tag{1.6}$$

where $\partial f(x)$ denotes the *subdifferential* of f at x [54].

Note that $p \in \Re^n$ is an optimal solution for (D) if and only if $p = [p + d(p)]^+$, where $[\cdot]^+$ denotes the orthogonal projection onto the nonnegative orthant. However,

(D) is not guaranteed to have an optimal solution. Consider the following example: $n = m = 1$, $E = -1$, $b = 0$, and

$$f(x) = \begin{cases} x^2 - (x)^{1/2} & \text{if } x \geqq 0, \\ +\infty & \text{otherwise.} \end{cases}$$

It can be verified that Assumptions A and B hold, but f does not have a dual support at the optimal primal solution $x^* = 0$.

Differentiability of q motivates a block coordinate ascent method for solving (P) and (D) whereby, given a dual vector p, a block of coordinates are adjusted to increase the dual functional q. Important advantages of such a coordinate ascent method are simplicity, the ability to exploit problem sparsity, and the potential for massive parallelization. As an example, suppose that $f(x)$ is quadratic of the form $\langle x, Qx\rangle/2 + \langle c, x\rangle$, where Q is an $m \times m$ symmetric positive definite matrix and $c \in \Re^m$. Then two coordinates p_i and p_j are uncoupled and can be iterated upon simultaneously if the (i,j)th entry of $EQ^{-1}E^T$ is zero (another example is if f is separable and the (i,j)th entry of EE^T is zero).

Coordinate ascent methods for maximizing general differentiable concave functions have been well studied [5, § 3.2.4], [20], [40], [51], [52], [56], [63], but convergence typically requires compactness of the level sets and some form of strict concavity of the objective function—neither of which holds for q. Coordinate ascent methods for maximizing dual functionals of the form q, on the other hand, have been studied for certain special cases only (e.g., f is differentiable strongly convex, and exact line search is used). More general results are given in [59] and [60], but these results are applicable only for single (not block) coordinate relaxation and for a special type of inexact line search. This lack of a general theory is unfortunate given that dual coordinate ascent methods are among the most popular (and sometimes the only practical) methods for large-scale optimization, e.g., network flow [3], [6], [11], [13], [14], [45], [58], [64], [65], entropy maximization [2], [8], [11], [21], [23], [24], [31]-[33], [37], [41], [48], [57], linear [43] and quadratic programming [12], [15], [18], [27], [28], [38], [39], [42]. Another dual method whose convergence properties are not well understood is the *dual gradient* method [22], [25], [34], [39], [49], [50], [61], [62]. In this method, the dual vector p is moved along the gradient direction (or an approximation of) at each iteration instead of along a coordinate ascent direction. This method can take advantage of second-order derivative information and, in certain cases, is more efficient than dual coordinate ascent methods.

This paper represents an attempt to fill the existing theoretical gaps for the above dual ascent methods. In particular, we (i) propose a general class of (block) coordinate ascent algorithms for maximizing q, (ii) prove various convergence properties for this class, and (iii) show that the dual methods proposed in [2], [6], [8]-[10], [13]-[15], [18], [21], [23], [24], [27], [28], [31]-[33], [37]-[39], [41], [42], [45], [48]-[50], [57]-[60], [62], [64] are in this class. We also present some new algorithms from this class and propose a technique for parallelizing the line search step when f is separable.

This paper is organized as follows: in §§ 2 and 3 we present a coordinate relaxation algorithm and prove that it converges. In § 4 we present an extension of this algorithm for the case where f is strongly convex. In § 5 we consider implementation issues and in § 6 we show that this algorithm contains as special cases a number of known methods. In § 7 we present a technique for parallelizing the line search step in this algorithm when f is separable. In § 8 we give our conclusion and discuss extensions.

We will use the following notation. For any $k \times l$ matrix A, any vector c in $\Re^k$, and any $I \subseteq \{1, \cdots, k\}$, $J \subseteq \{1, \cdots, l\}$, we denote by A_I the matrix $[a_{ij}]_{i \in I, j \in \{1, \cdots, l\}}$, A_{IJ}

the matrix $[a_{ij}]_{i\in I, j\in J}$, and c_I the vector $(\cdots, c_i, \cdots)_{i\in I}$, where a_{ij} is the (i,j)th entry of A and c_i is the ith coordinate of c. For any finite set I and any $J\subseteq I$, we denote by $I\backslash J$ the complement of J relative to I and by $|J|$ the number of elements in J. For any x and z in $\Re^m$, we denote by $f'(x; z)$ the *directional derivative* of f at x along z ([54, pp. 213 and 217]), i.e.,

$$f'(x; z) = \lim_{\lambda\downarrow 0} (f(x+\lambda z) - f(x))/\lambda$$
$$= \max\{\langle z, \eta\rangle \mid \eta \in \partial f(x)\}. \tag{1.7}$$

2. Block coordinate relaxation algorithm. In this section we present our main algorithm, called the *block coordinate relaxation* (BCR) *algorithm*, for solving (P) and (D). In this algorithm, we choose a collection $\mathscr{C}$ of nonempty subsets of $N=\{1, \cdots, n\}$ such that their union equals N and, for each $I\in\mathscr{C}$, we choose continuous functions $\phi_I : \Re^n \times [0, +\infty)^n \to [0, +\infty)$ and $\delta_I : \Re^n \times \Re^n \to [0, +\infty)$ satisfying

(2.1a) $\phi_I(\eta, \pi)$ is bounded away from zero $\Leftrightarrow \pi_I - [\pi_I + \eta_I]^+$ is bounded away from zero,

(2.1b) $\delta_I(\eta, \eta') = 0 \Leftrightarrow \eta_I = \eta'_I$.

We also fix a relaxation parameter $\gamma\in(0, 1]$. Each iteration of the BCR algorithm generates a new dual vector p' from the current dual vector p as follows.

Block Coordinate Relaxation (BCR) *Iteration.*
Given a nonnegative $p\in\Re^n$, choose an $I\in\mathscr{C}$.
Find any nonnegative $p'\in\Re^n$ satisfying

(2.2a) $$p'_i = p_i, \quad \forall i \notin I,$$

(2.2b) $$(\gamma-1)(q(p')-q(p)) \leqq \gamma\langle p'-p, d(p')\rangle,$$

(2.2c) $$\delta_I(d(p'), d(p)) \geqq \phi_I(d(p'), p').$$

Roughly speaking, (2.2a) ensures that only coordinates corresponding to I change value; (2.2b) ensures that a dual ascent occurs; and (2.2c) ensures that the change in the gradient of q, namely $d(p')-d(p)$, is nonzero if p' is not optimal with respect to the coordinates corresponding to I (i.e., $p'_I \neq [p'_I + d_I(p')]^+$). The scalar γ controls the amount of under/over-relaxation in the iteration. ($\gamma>1$ ($\gamma<1$) implies under-relaxation (over-relaxation).)

For solving the equality constraint problem (P^E), we modify the BCR iteration as follows: We replace (2.1a) with "$\phi_I(\eta, \pi)$ is bounded away from zero $\Leftrightarrow$ η is bounded away from zero" and remove the nonnegativity constraints on p and p'. (The extension to mixed equality/inequality constraints is straightforward.)

To ensure that the BCR iteration is well defined (i.e., for any nonnegative $p\in\Re^n$ and $I\in\mathscr{C}$, a p' satisfying (2.2a)-(2.2c) exists), additional assumptions on ϕ_I and δ_I are required. We will see in §§ 5 and 6 that the choice of ϕ_I and δ_I is very important: different choices lead to different methods and, for special cases of (P), the appropriate choice can significantly reduce the work per iteration. We will also see in § 5 that very little needs to be assumed about ϕ_I and δ_I either to make the BCR iteration well defined or to implement it. (For example, if p' is obtained from p by maximizing $q(p)$ over all p_i, $i\in I$, with the other coordinates held fixed, then p' can be shown to satisfy (2.2a)-(2.2c).)

The BCR algorithm that consists of successive applications of the BCR iteration is not guaranteed to converge, unless the coordinates are relaxed in some order. (We

say a coordinate is "relaxed" if the BCR iteration is applied with an $I \in \mathscr{C}$ that contains the index of that coordinate.) We will consider the following two orders of relaxation.

Essentially cyclic order. There exists $T \geqq 1$ such that every coordinate is chosen at least once for relaxation between iterations r and $r+T$, for all $r = 0, 1, \cdots$.

Gauss-Southwell order. At each iteration, choose an $I \in \mathscr{C}$ satisfying

$$\phi_I(d(p), p) \geqq \rho \cdot \max_{J \in \mathscr{C}} \{\phi_J(d(p), p)\},$$

where ρ is a constant in $(0, 1]$.

The above two orders of relaxation are extensions of those discussed in [40, § 7.8] and [56]. We will weaken the essentially cyclic order in § 4. If $\mathscr{C}$ is a partition of N (i.e., the elements of $\mathscr{C}$ are mutually disjoint) and the essentially cyclic order of relaxation is used with $T = |\mathscr{C}| - 1$, then we will say that the order of relaxation is *cyclic.*

3. Main convergence theorem. Let p^r denote the iterate generated by the BCR algorithm at the rth iteration and let $x^r = \chi(p^r)$ $(r = 0, 1, \cdots)$. In this section, we show that, under either the essentially cyclic or the Gauss-Southwell order of relaxation, the BCR algorithm converges, in the sense that $\{x^r\} \to x^*$. We also provide sufficient conditions under which $\{p^r\}$ converges. To simplify the presentation, let I^r denote the set of indexes of the coordinates relaxed at the rth iteration and let $d^r = d(p^r)$ $(r = 0, 1, \cdots)$. Our argument will follow closely that in § 3 of [60] (in fact, to simplify the presentation, we will borrow certain results from [60]).

We precede our proof of convergence with the following four technical lemmas.

LEMMA 1. (a) *For any y in S and any sequence of vectors $\{y^1, y^2, \cdots\}$ in S such that $\{f(y^k) + f'(y^k; y - y^k)\}$ is bounded from below, it holds that both $\{y^k\}$ and $\{f(y^k)\}$ are bounded, and every limit point of $\{y^k\}$ is in S.*

(b) *For any $y \in S$, any $z \in \Re^m$ such that $y + z \in S$, and any sequences $\{y^1, y^2, \cdots\} \to y$ and $\{z^1, z^2, \cdots\} \to z$ such that $y^k \in S$ and $y^k + z^k \in S$ for all k, it holds that*

$$\lim_{k \to +\infty} \sup \{f'(y^k; z^k)\} \leqq f'(y; z).$$

(c) *For any $y \in S$, there exists a positive scalar ε such that $\{x \in S \mid \|x - y\| \leqq \varepsilon\}$ is closed.*

Proof. Parts (a) and (b) follow from, respectively, the proofs of Lemmas 2 and 3 in [60]. Part (c) follows from the proof of Proposition 1(b) in [60]. □

LEMMA 2. *For $r = 0, 1, \cdots$,*

$$q(p^{r+1}) - q(p^r) \geqq \gamma[f(x^{r+1}) - f(x^r) - f'(x^r; x^{r+1} - x^r)], \tag{3.1a}$$

$$f(x^r) + f'(x^r; x^* - x^r) \geqq q(p^r). \tag{3.1b}$$

Proof. We first prove (3.1). From (1.2), (1.3), and (1.5) we have that

$$q(p^r) = \langle p^r, b\rangle + f(x^r) - \langle E^T p^r, x^r\rangle, \quad \forall r = 0, 1, \cdots. \tag{3.2a}$$

Since (cf. (1.4)) $d^r = b - Ex^r$, this implies that, for any r,

$$q(p^{r+1}) - q(p^r) = f(x^{r+1}) - f(x^r) - \langle E^T p^r, x^{r+1} - x^r\rangle + \langle p^{r+1} - p^r, d^{r+1}\rangle. \tag{3.2b}$$

Multiplying both sides by $(\gamma - 1)$ and using (2.2b), we obtain

$$\begin{aligned}\gamma\langle p^{r+1} - p^r, d^{r+1}\rangle &\geqq (\gamma - 1)[q(p^{r+1}) - q(p^r)] \\ &= (\gamma - 1)[f(x^{r+1}) - f(x^r) - \langle E^T p^r, x^{r+1} - x^r\rangle] \\ &\quad + (\gamma - 1)\langle p^{r+1} - p^r, d^{r+1}\rangle.\end{aligned}$$

Hence

$$\langle p^{r+1}-p^r, d^{r+1}\rangle \geqq (\gamma-1)[f(x^{r+1})-f(x^r)-\langle E^T p^r, x^{r+1}-x^r\rangle],$$

which, together with (3.2b), implies that

$$\begin{aligned} q(p^{r+1})-q(p^r) &\geqq \gamma[f(x^{r+1})-f(x^r)-\langle E^T p^r, x^{r+1}-x^r\rangle] \\ &\geqq \gamma[f(x^{r+1})-f(x^r)-f'(x^r; x^{r+1}-x^r)], \end{aligned}$$

where the second inequality follows from (1.7) and the fact (cf. (1.6)) $E^T p^r \in \partial f(x^r)$.

To prove (3.1b), note that since $p^r \geqq 0$ and x^* satisfies (1.1), then

$$\begin{aligned} q(p^r) &\leqq q(p^r)+\langle p^r, Ex^*-b\rangle \\ &= f(x^r)+\langle E^T p^r, x^*-x^r\rangle \\ &\leqq f(x^r)+f'(x^r; x^*-x^r), \end{aligned}$$

where the equality follows from (3.2a) and the second inequality follows from (1.7) and the fact (cf. (1.6)) $E^T p^r \in \partial f(x^r)$. □

Note that, by (3.1a), the sequence $\{q(p^r)\}$ is monotonically increasing. Lemma 1(a), (b) and Lemma 2 imply the following two lemmas.

LEMMA 3. (a) $\{x^r\}$ *and* $\{f(x^r)\}$ *are bounded and each limit point of* $\{x^r\}$ *is in* S.

(b) $\{x^{r+1}-x^r\} \to 0$.

(c) $\{p^r_{I^r}-[p^r_{I^r}+d^r_{I^r}]^+\} \to 0$.

Proof. Since $\{q(p^r)\}$ is monotonically increasing and x^r is in S for all r, (3.1b) and Lemma 1(a) imply part (a). Now, if part (b) does not hold, then there must exist a subsequence R for which $\{x^r\}_{r\in R}$ converges to some point x^∞ and $\{x^{r+1}\}_{r\in R}$ converges to some point $x'' \neq x^\infty$. Let $z = x''-x^\infty$ $(z \neq 0)$. By part (a), both x^∞ and $x^\infty+z$ are in S. Then from (3.1a), the continuity of f on S, and Lemma 1(b), we obtain

$$\lim_{r\to+\infty, r\in R} \inf\{q(p^{r+1})-q(p^r)\} \geqq \gamma[f(x^\infty+z)-f(x^\infty)-f'(x^\infty; z)].$$

Since $q(p^r)$ is nondecreasing with r and f is strictly convex (so the right-hand side of above is a *positive* scalar), it follows that

$$\{q(p^r)\} \to +\infty.$$

This, in view of the strong duality condition

$$\max\{q(p) \mid p \geqq 0\} = \min\{f(x) \mid Ex \geqq b\},$$

contradicts the feasibility of (P), i.e., $S \cap X \neq \emptyset$.

If part (c) does not hold, then there exist scalar $\varepsilon > 0$, coordinate block $I \in \mathscr{C}$, and subsequence R for which

$$I^r = I \quad \text{and} \quad \|p^r_I-[p^r_I+d^r_I]^+\| \geqq \varepsilon, \quad \forall r \in R.$$

Then (2.1a) implies that $\{\phi_I(d^r, p^r)\}_{r\in R}$ is bounded away from zero, i.e., there exists some scalar $\theta > 0$ such that

$$\phi_I(d^r, p^r) \geqq \theta, \quad \forall r \in R.$$

It follows from (2.2c) that

$$\delta_I(d^r, d^{r-1}) \geqq \theta, \quad \forall r \in R. \tag{3.3}$$

Since (cf. (1.4)) $d^r = b - Ex^r$, $\{d^r\}$ is bounded by part (a). This, together with (2.1b), (3.3), and the continuity of δ_I, implies that

$$\|E_I(x^r - x^{r-1})\| = \|d_I^r - d_I^{r-1}\| \geqq \theta', \quad \forall r \in R,$$

for some scalar $\theta' > 0$. This contradicts part (b). □

LEMMA 4. *Under either the essentially cyclic or the Gauss-Southwell order of relaxation, if x^∞ is any limit point of $\{x^r\}$, then $x^\infty \in S \cap X$ and there exists a subsequence $\{x^r\}_{r\in R} \to x^\infty$ satisfying*

$$b_i - E_i x^\infty < 0 \Rightarrow \{p_i^r\}_{r\in R} \to 0. \tag{3.4}$$

Proof. We will first prove that

$$\{p^r - [p^r + d^r]^+\} \to 0. \tag{3.5}$$

Suppose that the essentially cyclic order is used. Fix any coordinate index $i \in N$ and, for each $r \geqq T$, let $\tau(r)$ be the largest integer h not exceeding r such that $i \in I^{h-1}$. Then

$$d_i^r = d_i^{\tau(r)} + \sum_{h=\tau(r)}^{r-1} E_i(x^h - x^{h+1}), \quad \forall r \geqq T.$$

Since $r - \tau(r) \leqq T$ for all $r \geqq T$, this, together with Lemma 3(b), (c) and the fact $p_i^r = p_i^{\tau(r)}$ for all $r \geqq T$, implies (3.5). Now suppose that the Gauss-Southwell order is used. Then (2.1a) and Lemma 3(c) imply that $\{p_I^r - [p_I^r + d_I^r]^+\} \to 0$ for all $I \in \mathscr{C}$. Since the union of the elements of $\mathscr{C}$ equals N, (3.5) holds.

Since $|p_i^r - [p_i^r + d_i^r]^+| = d_i^r$ if $d_i^r \geqq 0$, it follows from (3.5) that $\lim_{r\to+\infty} \sup\{d_i^r\} \leqq 0$ for all i. Hence every limit point of $\{x^r\}$ is in X. This, together with Lemma 3(a), implies that $x^\infty \in S \cap X$.

Next we prove (3.4). Let $d = b - Ex^\infty$. Since $x^\infty \in X$, we have $d_i \leqq 0$ for all i. Consider any i such that $d_i < 0$ (if no such i exists, we are done). Since x^∞ is a limit point of $\{x^r\}$, there exists subsequence R such that $\{x^r\}_{r\in R} \to x^\infty$. Then $\{d_i^r\}_{r\in R} \to d_i < 0$, which, together with (cf. (3.5)) $\{p_i^r - [p_i^r + d_i^r]^+\}_{r\in R} \to 0$, implies that $\{p_i^r\}_{r\in R} \to 0$. □

Lemmas 1 and 4 allow us to prove the main result of this section.

PROPOSITION 1. *If $\{p^r\}$ is a sequence of dual vectors generated by the* BCR *algorithm under either the essentially cyclic or the Gauss-Southwell order of relaxation, then the following hold*:

(a) $\{\chi(p^r)\} \to x^*$.

(b) *If* cl (S) *is a polyhedral set, and there exists a closed ball B around x^* such that $f'(x; (y-x)/\|y-x\|)$ is bounded for all x, y in $B \cap S$, then $\{q(p^r)\} \to f(x^*)$.*

(c) If int $(X) \cap S \neq \varnothing$, *then $\{p^r\}$ is bounded and every one of its limit points is an optimal solution for* (D).

Proof. We prove part (a) only. The proof of parts (b) and (c) is identical to that of Proposition 1 in [60]. Let $x^r = \chi(p^r)$ for all r, let x^∞ be a limit point of $\{x^r\}$, and let R be a subsequence of $\{1, 2, \cdots\}$ satisfying (3.4). Also let $d = b - Ex^\infty$ and $I^- = \{i \in N \mid d_i < 0\}$. By Lemma 4, $x^\infty \in S \cap X$. Suppose that $x^\infty \neq x^*$ and we will reach a contradiction.

Let y be any element of $S^1 \cap \text{ri}\,(S^2) \cap X$ (y exists by Assumption B). Fix any $\lambda \in (0, 1)$ and denote $y(\lambda) = \lambda y + (1-\lambda)x^*$. Then $y(\lambda) \in S^1 \cap \text{ri}\,(S^2) \cap X$. By Lemma 1(c), there exists an $\varepsilon > 0$ such that $\{x \in S \mid \|x - x^\infty\| \leqq \varepsilon\}$ is closed. Since cl (S^1) is a polyhedral set and $y(\lambda) - x^\infty$ belongs to the tangent cone of S^1 at x^∞, this implies that there exists $\delta \in (0, 1)$ such that, for all $r \in R$ sufficiently large,

$$x^r + \delta z \in S^1, \tag{3.6}$$

where $z = y(\lambda) - x^\infty$. On the other hand, since $y(\lambda) \in \text{ri}\,(S^2)$, $x^r \in S^2$ for all r, and $\{x^r\}_{r\in R} \to x^\infty$, we have that, for all $r \in R$ sufficiently large,

$$x^r + \delta z \in S^2. \tag{3.7}$$

Since $y(\lambda) \in X$, $E_i z \geqq 0$ for all $i \notin I^-$. This implies that (since $p^r \geqq 0$)

$$\langle p^r, Ez\rangle \geqq \sum_{i\in I^-} p_i^r (E_i z), \quad \forall r \in R, \quad \text{if } I^- \neq \varnothing,$$

$$\langle p^r, Ez\rangle \geqq 0, \quad \forall r \in R, \quad \text{otherwise.}$$

In either case, we have (cf. (3.4))

$$\lim_{r\to+\infty, r\in R} \inf\{\langle p^r, Ez\rangle\} \geqq 0. \tag{3.8}$$

Since $x^\infty + \delta z \in S$ and (cf. (1.7) and the fact $E^T p^r \in \partial f(x^r))$ $f'(x^r; z) \geqq \langle p^r, Ez\rangle$ for all r, (3.6)-(3.8) and Lemma 1(b) imply that

$$f'(x^\infty; z) \geqq 0.$$

Hence $f(x^\infty) \leqq f(y(\lambda))$. Since the choice of $\lambda \in (0, 1)$ was arbitrary, by taking λ arbitrarily small (and using the continuity of f within S), we obtain that $f(x^\infty) \leqq f(x^*)$. Since f is strictly convex and $x^\infty \in S \cap X$, this contradicts the hypothesis $x^\infty \neq x^*$. □

We remark that a result analogous to Proposition 1 also holds for the BCR algorithm modified to solve the equality constraint problem (P^E).

Extensions.

1. Note from its proof that Proposition 1 still holds if Assumption B is replaced by the following more general assumption: $S \cap X \neq \varnothing$ and, for any $x \in S \cap X$, any $y \in S \cap X$, and any sequence $\{y^k\}$ in S such that $\{y^k\} \to y$, it holds $f'(y; x - y) \geqq \lim_{k\to+\infty} \sup\{f'(y^k; x - y)\}$.

2. Consider a *mixed* algorithm whereby in between BCR iterations are inserted other dual ascent iterations (these other dual ascent iterations need not be convergent on their own). For this mixed algorithm, Proposition 1 can also be shown to hold, provided that (i) there exists a bound $T' \geqq 1$ such that a BCR iteration is executed at least once every T' consecutive iterations (the coordinates are assumed to be relaxed by the BCR iterations in either the essentially cyclic or the Gauss-Southwell order) and that (ii) each inserted dual ascent iteration generates the new dual vector p' from the current dual vector p with the property

$$q(p') - q(p) \geqq \mu[f(\chi(p')) - f(\chi(p)) - f'(\chi(p); \chi(p') - \chi(p))], \tag{3.9}$$

where μ is some fixed positive scalar. (The condition (3.9) is satisfied by most dual ascent iterations. For example, it is satisfied by the BCR iteration (cf. (3.1b)) as well as by any iteration that maximizes exactly q along some direction in $\Re^n$ (cf. (3.2b)).) In such a mixed algorithm, the BCR iteration may be viewed as a *spacer* step to enforce convergence of the iterates. We give an application of this mixed algorithm below. Other applications are discussed in § 6.2. Other extensions of the BCR algorithm are discussed in Proposition 10 and in § 8.

3. It is easily seen that every limit point of the sequence $\{p^r\}$ is an optimal solution of (D). Hence $\{p^r\}$ diverges if (D) does not have an optimal solution. On the other hand if the set of optimal solutions for (D) is nonempty but unbounded, $\{p^r\}$ can still diverge (and thus cause numerical difficulty). To remedy this, we can modify the BCR algorithm by, for example, replacing p with

$$p' = \text{argmin}\{\|\pi\| \mid E^T\pi = E^T p, \langle b, \pi\rangle = \langle b, p\rangle, \pi \geqq 0\} \tag{3.10}$$

at periodic intervals. Because $E^T p' = E^T p$ and $\langle b, p' \rangle = \langle b, p \rangle$, it follows from (1.3) and (1.5) that $q(p') = q(p)$ and $\chi(p') = \chi(p)$. Hence iteration (3.10) satisfies (3.9) and the modified BCR algorithm is convergent. In some cases (e.g., network flow), the minimization (3.10) can be performed quite efficiently.

4. Convergence for strongly convex costs. In this section we consider the special case where f is *strongly convex*, in the sense that there exist scalars $\sigma > 0$ and $\omega > 1$ such that

$$f(y) - f(x) - f'(x; y-x) \geqq \sigma \|y-x\|^{\omega}, \quad \forall x \in S, \quad \forall y \in S. \tag{4.1}$$

We show that, for this special case, the essentially cyclic order of relaxation can be weakened further. (Note that (4.1) is a generalization of the traditional definition of strong convexity (called *uniform convexity* in [47, p. 83]), where ω is taken to be 2. As an example, $f: \Re \to (-\infty, +\infty]$ given by

$$f(x) = \begin{cases} x^4 & \text{if } x \geqq 0, \\ +\infty & \text{otherwise,} \end{cases}$$

satisfies (4.1) with $\omega = 4$, $\sigma = \frac{1}{4}$, but does not satisfy (4.1) with $\omega = 2$ for any positive σ.)

Consider the following order of relaxation that is weaker than the essentially cyclic order.

Quasi-cyclic order. Every coordinate is chosen at least once for relaxation between iterations τ_k and τ_{k+1}, for $k = 1, 2, \cdots$, where $\{\tau_1, \tau_2, \cdots\}$ is a sequence of integers given by

$$\tau_1 = 0 \quad \text{and} \quad \tau_{k+1} = \tau_k + b_k, \qquad k = 1, 2, \cdots,$$

and $\{b_k\}$ is any sequence of integers satisfying

$$b_k \geqq |\mathscr{C}|, \qquad k = 1, 2, \cdots, \quad \text{and} \quad \sum_{k=1}^{\infty} (b_k)^{1-\omega} = +\infty.$$

(For example, $b_k = n \cdot k^{1/(\omega-1)}$ is a valid choice.) The above order of relaxation, first proposed in [59], is similar to the essentially cyclic order but allows the length of the cycle to grow without bound. It is an open question whether this order can be weakened further, say, to one that only assumes that each coordinate is relaxed an infinite number of times.

By using Lemmas 1 and 3 in § 3 and an argument analogous to that for Proposition 2 in [60], we can show the following result that is analogous to Proposition 1 (which, for simplicity, we state without proof).

PROPOSITION 2. *Suppose that* (4.1) *holds and let* $\{p^r\}$ *be a sequence of dual vectors generated by the* BCR *algorithm under the quasi-cyclic order of relaxation. Then the following hold*:

(a) *There exists a subsequence* $R \subseteq \{1, 2, \cdots\}$ *such that* $\{\chi(p^r)\}_{r \in R} \to x^*$.

(b) *If* cl (S) *is a polyhedral set, and there exists a closed ball* B *around* x^* *such that* $f'(x; (y-x)/\|y-x\|)$ *is bounded for all* x, y *in* $B \cap S$, *then* $\{q(p^r)\} \to f(x^*)$ *and* $\{\chi(p^r)\} \to x^*$.

(c) *If* int $(X) \cap S \neq \varnothing$, *then* $\{q(p^r)\} \to f(x^*)$, $\{\chi(p^r)\} \to x^*$, *and* $\{p^r\}$ *is bounded. Moreover, each limit point of* $\{p^r\}$ *is an optimal solution for* (D).

Note that the conclusion of Proposition 2(a) is weaker than that of Proposition 1(a). Only for the special case where f is separable and $\mathscr{C} = \{\{1\}, \cdots, \{n\}\}$ has it been shown that $\{x^r\} \to x^*$, assuming only that (4.1) holds and that the quasi-cyclic order of relaxation is used [59].

5. Choosing ϕ_I and δ_I. We have seen from §§ 3 and 4 that the BCR algorithm converges, provided that each BCR iteration is well defined. In this section we will consider choices of ϕ_I and δ_I that ensure that the BCR iteration is well defined. In particular, we will show that it is well defined if either a certain constraint qualification holds or if ϕ_I and δ_I satisfy a certain growth condition. We will also consider particular implementations of the BCR iteration for, respectively, single coordinate relaxation and gradient ascent.

5.1. Exact coordinate maximization. In this subsection we show that the BCR iteration (2.2a)-(2.2c) is well defined if the dual functional $q(p)$ can be maximized *exactly* with respect to the coordinates p_i, $i \in I$, while the other coordinates are held fixed. To ensure that such an exact maximization is possible, the following constraint qualification on f and X will be considered.

Assumption C. The function f is of the form $f = h + \delta_C$, where $h : \Re^m \to (-\infty, +\infty]$ is a strictly convex function such that $\text{ri}\,(\text{dom}\,(h)) \cap X \neq \varnothing$ and δ_C is the indicator function for a polyhedral set C in $\Re^m$ (i.e., $\delta_C(x) = 0$ if $x \in C$ and $\delta_C(x) = +\infty$ otherwise).

We have the following result.

PROPOSITION 3. *Under Assumption* C (*in addition to Assumptions* A *and* B), *the* BCR *iteration* (2.2a)-(2.2c) *with* $\gamma \in (0, 1]$ *is well defined for any functions* ϕ_I *and* δ_I *satisfying, respectively,* (2.1a) *and* (2.1b).

Proof. Consider any nonnegative vector $p \in \Re^n$ and any $I \in \mathscr{C}$. Let us define the following relaxed problem

$$\begin{aligned} &\text{Minimize} \quad f(x) - \sum_{i \notin I} p_i(E_i x) \\ &\text{subject to} \quad E_I x \geqq b_I. \end{aligned} \tag{5.1}$$

Since (P) is feasible, so is (5.1). Since the cost function of (5.1) has compact level sets (cf. Assumption A), this implies that (5.1) has an optimal solution which we denote by x'. It then follows from Assumption C and Theorem 28.2 in [54] that x', together with some Lagrange multiplier vector associated with the constraints $E_I x \geqq b_I$, satisfies the Kuhn-Tucker conditions for (5.1). Let Δ_i, $i \in I$, denote the coordinate of this Lagrange multiplier vector associated with the constraint $E_i x \geqq b_i$. Define a new dual vector $p' \in \Re^n$ to be the vector whose ith coordinate is

$$p'_i = \begin{cases} \Delta_i & \text{if } i \in I, \\ p_i & \text{otherwise.} \end{cases} \tag{5.2}$$

We claim that $p' \geqq 0$ and satisfies (2.2b) and (2.2c) (clearly p' satisfies (2.2a)). To see this, note from the Kuhn-Tucker conditions for (5.1) that $\Delta_i \geqq 0$, for all $i \in I$, and

$$E_i x' = b_i \quad \text{if } \Delta_i > 0, \qquad i \in I, \tag{5.3a}$$

$$E_i x' \geqq b_i \quad \text{if } \Delta_i = 0, \qquad i \in I, \tag{5.3b}$$

$$\sum_{i \in I} (E_i)^T \Delta_i \in \partial f(x') - \sum_{i \notin I} (E_i)^T p_i. \tag{5.3c}$$

Hence $p' \geqq 0$ and (by (1.6), (5.2), (5.3c)) $\chi(p') = x'$. This, together with (1.4) and (5.2), implies that

$$\begin{aligned} \langle p' - p, d(p') \rangle &= \langle p' - p, b - Ex' \rangle \\ &= \sum_{i \in I} (\Delta_i - p_i)(b_i - E_i x') \\ &\geqq 0, \end{aligned}$$

where the inequality follows from (5.3a), (5.3b). Therefore, $q(p') \geqq q(p)$. Since $\gamma \in (0, 1]$, this implies that (2.2b) holds.

To see that (2.2c) holds, note that (cf. (5.3a), (5.3b) and the fact $d_I(p') = b_I - E_I x'$) $p'_I = [p'_I + d_I(p')]^+$. Hence, by (2.1a), $\phi_I(d(p'), p') = 0$. □

From the proof of Proposition 3 it can be seen that the dual vector p' given by (5.2) is obtained equivalently by maximizing exactly the dual functional $q(p)$ with respect to p_I, while the other coordinates of p are held fixed. If $q(p)$ has bounded level sets and is strictly convex in p_I for all I in $\mathscr{C}$, then the convergence of such a *nonlinear Gauss-Seidel* iteration follows from Proposition 2.5 in [5, § 3.2.4]. However, the conditions under which q has this property are very restrictive.

It is an open question whether the hypothesis in Proposition 3 can be weakened further. For example, would the conclusion of Proposition 3 hold if it is only assumed that (D) has an optimal solution?

5.2. ϕ_I and δ_I satisfy a growth condition. If Assumption C does not hold, then we need to impose some growth conditions on ϕ_I and δ_I to ensure that the BCR iteration is well defined. We state this result in the following proposition.

PROPOSITION 4. *If in the* BCR *iteration, it holds that*

$$\phi_I(\eta, \pi) \leqq \|\pi_I - [\pi_I + \eta_I]^+\|, \quad \forall \eta \in \Re^n, \quad \forall \pi \in [0, +\infty)^n,$$

$$\delta_I(\eta, \eta') \geqq \|\eta_I - \eta'_I\|, \quad \forall \eta, \eta' \in \Re^n,$$

then the BCR *iteration with* $\gamma \in (0, 1]$ *is well defined.*

Proof. Let $p \in \Re^n$ and $I \in \mathscr{C}$ be as in the BCR iteration and let $\beta = \phi_I(d(p), p)$. If $\beta = 0$, then the BCR iteration is well defined (since $p' = p$ satisfies (2.2a)-(2.2c)). Suppose that $\beta > 0$. Let $\theta_i = d_i(p)$ and $I^- = \{i \in I \mid \theta_i < 0\}$, $I^+ = \{i \in I \mid \theta_i > 0\}$. Let μ be any scalar in $(0, \frac{1}{2}]$.

Consider the following relaxed problem

$$\begin{aligned} &\text{maximize} && f(x) - \sum_{i \notin I^-} p_i(E_i x) \\ &\text{subject to} && E_i x \geqq b_i - \theta_i \mu, \quad \forall i \in I^+, \\ & && E_i x \geqq b_i, \quad \forall i \in I^-. \end{aligned} \tag{5.4}$$

First note that the interior of the constraint set for (5.4) intersects S. To see this, let $\zeta(\lambda) = \lambda\chi(p) + (1-\lambda)x^*$. Then (since $\theta_i = b_i - E_i\chi(p)$)

$$E_i\zeta(\lambda) - b_i = \lambda(-\theta_i) + (1-\lambda)(E_i x^* - b_i) \geqq -\lambda\theta_i, \quad \forall i \in I^+,$$

$$E_i\zeta(\lambda) - b_i = \lambda(-\theta_i) + (1-\lambda)(E_i x^* - b_i) \geqq -\lambda\theta_i > 0, \quad \forall i \in I^-,$$

so that, for λ sufficiently small, $\zeta(\lambda)$ is in the interior of the feasible set for (5.4). On the other hand, since $\chi(p)$ and x^* are both in S and S is convex, $\zeta(\lambda) \in S$ for all $\lambda \in [0, 1]$.

Since the interior of the constraint set for (5.4) intersects S, the convex program (5.4) is strictly consistent ([54, p. 300]). It then follows from Assumption A and Corollary 29.1.5 of [54] that there exist an $x' \in \Re^m$ and a Lagrange multiplier vector associated with the constraints in (5.4) that, together, satisfy the Kuhn-Tucker conditions for (5.4). Let Δ_i, $i \in I^+$ ($i \in I^-$), denote the coordinate of this Lagrange multiplier vector associated with the constraint $E_i x \geqq b_i - \theta_i\mu$ ($E_i x \geqq b_i$). Define $p' \in \Re^n$ to be the

vector whose ith coordinate is

$$p_i' = \begin{cases} \Delta_i & \text{if } i \in I^-, \\ p_i + \Delta_i & \text{if } i \in I^+, \\ p_i & \text{otherwise.} \end{cases} \tag{5.5}$$

We claim that $p' \geqq 0$ and satisfies (2.2b) and (2.2c) (clearly p' satisfies (2.2a)). To see this, note from the Kuhn-Tucker conditions for (5.4) that $\Delta_i \geqq 0$, for all $i \in I^+ \cup I^-$, and

$$E_i x' = b_i - \theta_i \mu \quad \text{if } \Delta_i > 0, \qquad i \in I^+, \tag{5.6a}$$

$$E_i x' = b_i \quad \text{if } \Delta_i > 0, \qquad i \in I^-, \tag{5.6a}$$

$$E_i x' \geqq b_i \quad \text{if } \Delta_i = 0, \qquad i \in I^-, \tag{5.6b}$$

$$\sum_{i \in I^+ \cup I^-} (E_i)^T \Delta_i \in \partial f(x') - \sum_{i \notin I^-} (E_i)^T p_i. \tag{5.6c}$$

Hence $p' \geqq 0$ and (by (1.6), (5.5), (5.6c)) $\chi(p') = x'$. The latter implies that (cf. (1.4)) $d_i(p') = b_i - E_i x'$ for all i. This, together with (5.5), (5.6a), (5.6b), and the positivity of $\theta_i \mu$, implies that

$$\begin{aligned} \langle p' - p, d(p') \rangle &= \langle p' - p, b - Ex' \rangle \\ &= \sum_{i \in I^-, \Delta_i = 0} (\Delta_i - p_i)(b_i - E_i x') + \sum_{i \in I^+, \Delta_i > 0} \Delta_i \theta_i \mu \\ &\geqq 0. \end{aligned}$$

Hence $q(p') \geqq q(p)$. Since $\gamma \in (0, 1]$, this implies that (2.2b) holds.

We now show that (2.2c) holds. First note from (5.6a), (5.6b) that $\Delta_i = [\Delta_i + b_i - E_i x']^+$ for all $i \in I^-$. Hence (cf. (5.5))

$$p_i' - [p_i' + d_i(p')]^+ = 0, \quad \forall i \in I^-. \tag{5.7}$$

From the nonexpansive property of $[\cdot]^+$ and $p' \geqq 0$, we also have

$$|p_i' - [p_i' + d_i(p')]^+| \leqq |d_i(p')|, \quad \forall i \in I. \tag{5.8}$$

Since $0 = d_i(p)$ for all $i \in I \setminus (I^- \cup I^+)$, (5.8) implies

$$|p_i' - [p_i' + d_i(p')]^+| \leqq |d_i(p) - d_i(p')|, \quad \forall i \in I \setminus (I^- \cup I^+). \tag{5.9}$$

For each $i \in I^+$, since $d_i(p') \leqq \theta_i \mu$ and $\mu \in (0, \frac{1}{2}]$, we have from $\theta_i = d_i(p)$ that

$$|d_i(p')| \leqq |d_i(p) - d_i(p')|, \quad \forall i \in I^+,$$

and hence (cf. (5.8))

$$|p_i' - [p_i' + d_i(p')]^+| \leqq |d_i(p) - d_i(p')|, \quad \forall i \in I^+. \tag{5.10}$$

Combining (5.7), (5.9), and (5.10), we obtain that $\|p_I' - [p_I' + d_I(p')]^+\| \leqq \|d_I(p) - d_I(p')\|$, which, together with our hypothesis, implies (2.2c). □

The proof of Proposition 4 also suggests an implementation of the BCR iteration—by way of solving (5.4). In fact, from the proof of Proposition 4 we see that (5.4) can be solved *inexactly*, i.e., it suffices to find any nonnegative $p' \in \Re^n$ for which

$$\begin{aligned} &d_i(p') \leqq 0, \quad \forall i \in I^-, \\ &d_i(p') \leqq \delta d_i(p), \quad \forall i \in I^+, \\ &p_i' = p_i, \quad \forall i \notin (I^+ \cup I^-), \end{aligned}$$

where δ is any fixed scalar in $(0, 1)$ (this corresponds to choosing $\phi_I(\eta, \pi) = \|\pi_I - [\pi_I + \eta_I]^+\|$ and $\delta_I(\eta, \eta') = \max\{1, \delta/(1-\delta)\} \cdot \|\eta_I - \eta'_I\|$). With this implementation, the BCR algorithm can be thought of as solving (inexactly) a sequence of subproblems of the form (5.4). The fact that (5.4) can be solved inexactly makes this implementation quite practical.

5.3. Single coordinate relaxation. By choosing the coordinate blocks so that any two coordinates from different blocks are weakly coupled, the BCR algorithm can perform substantially faster than its single coordinate counterpart (the amount of improvement depends on the computational effort per iteration). Nevertheless, for problems that are large and sparse, single coordinate algorithms are often favoured; they are simpler to implement, use less storage, can readily exploit problem sparsity, and converge quite fast. In fact, most of the dual coordinate ascent algorithms are single coordinate algorithms (see § 6).

We will presently consider a specialization of the BCR iteration for the single coordinate case, i.e., $\mathscr{C} = \{\{1\}, \cdots, \{n\}\}$, that is both simple and powerful. For each $i \in N$, let α_i be any scalar in $(0, 1)$ and let $\psi_i : \Re \to \Re$ be any continuous, *strictly increasing* function satisfying $\psi_i(0) = 0$. Consider the following iteration that generates a new dual vector p' from the current dual vector p (e^s denotes the sth coordinate vector in $\Re^n$).

Single Coordinate Relaxation (SCR) *Iteration.*

Given a nonnegative $p \in \Re^n$, choose any $s \in N$ and let $\beta = \psi_s(d_s(p))$.

Set $p' = p + \lambda e^s$, where λ is any scalar satisfying

(5.11a) $\quad \alpha_s\beta \geqq \psi_s(d_s(p')) \geqq 0 \quad$ if $\beta \geqq 0$,

(5.11b) $\quad \alpha_s\beta \leqq \psi_s(d_s(p')) \leqq 0 \quad$ if $\beta < 0 \quad$ and $\quad \psi_s(d_s(p - p_s e^s)) \leqq \alpha_s\beta$,

(5.11c) $\quad \lambda = -p_s \quad$ otherwise.

(For the equality constraint problem (P^E), we modify the SCR iteration as follows: We replace (5.11b), (5.11c) by "$\alpha_s\beta \leqq \psi_s(d_s(p')) \leqq 0$ if $\beta < 0$" and remove the nonnegativity constraint on p.) To see that the stepsize λ is well defined, note that $d_s(p)$ is nondecreasing in p_s (since q is concave and, by (1.4), $d_s(p) = \partial q(p)/\partial p_s$) and ψ_s is strictly increasing. Hence $\lambda > 0$ (< 0) if $\beta > 0$ ($\beta < 0$) and is well defined when it is given by either (5.11b) or (5.11c). If λ is not well defined when it is given by (5.11a), it must be that $\psi_s(d_s(p + \theta e^s)) > \alpha_s\beta$ for all $\theta \geqq 0$. This, together with the properties of ψ_s, implies that $d_s(p + \theta e^s) \geqq \varepsilon$ for all $\theta \geqq 0$, where ε is some positive scalar. Hence

$$\lim_{\theta \to +\infty} q(p + \theta e^s) = +\infty,$$

a contradiction of the feasibility of (P).

Now we show that the SCR iteration is a special case of the BCR iteration with $I = \{s\}$, $\gamma = 1$, $\phi_s(\eta, \pi) = (1/\alpha_s - 1)|[\pi_s + \psi_s(\eta_s)]^+ - \pi_s|$, and $\delta_s(\eta, \eta') = |\psi_s(\eta_s) - \psi_s(\eta'_s)|$. Since $\lambda > 0$ (< 0) if $\beta > 0$ ($\beta < 0$), it follows from (5.11a)-(5.11c) and the properties of ψ_s that $\lambda d_s(p') \geqq 0$. Since $\langle d(p'), p' - p\rangle = \lambda d_s(p')$, this implies that p' satisfies (2.2b) with $\gamma = 1$. Also from (5.11a)-(5.11c) we have that

either $\quad \alpha_s|\beta - \psi_s(d_s(p'))| \geqq (1 - \alpha_s)|\psi_s(d_s(p'))|$

or $\quad p'_s = 0, \quad \psi_s(d_s(p')) < 0,$

which, together with the nonexpansive property of $[\cdot]^+$, implies that

either $\quad \delta_s(d(p'), d(p)) \geqq \phi_s(d(p'), p')$

or $\quad \phi_s(d(p'), p') = 0.$

Hence (2.2c) holds.

Since the SCR iteration is a special case of the BCR iteration, it follows that the algorithm based on successive applications of the SCR iteration converges (in the sense of either Proposition 1 or Proposition 2).

Notes and extensions.

1. If Assumption C holds, then $\alpha_s = 0$ is also allowable (in this case the choice of ψ_s is inconsequential). This is because the SCR iteration with $\alpha_s = 0$ is equivalent to (5.2) with $I = \{s\}$. In this case we obtain that $p'_s = [p'_s + d_s(p')]^+$ and the SCR iteration can be interpreted as an *exact* line search along the sth coordinate direction. We will see in § 6 that most of the single coordinate relaxation methods use exact line search (see [2], [8]-[10], [13], [21], [24], [27], [28], [31]-[33], [39], [41], [45], [48], [50], [57], [58], [64]).

2. In the SCR iteration, λ is always between 0 and the line search stepsize; hence the SCR iteration uses *under-relaxation.* It is possible to also use over-relaxation (i.e., λ exceeding the line search stepsize), if a condition analogous to (2.2b) is imposed.

3. General techniques for computing the stepsize λ in the SCR iteration can be found in [7], [35], [44], [59] (see also [26], [46] for the special case where f is separable and quadratic over a box). In some very special cases, λ can be computed very easily (see § 6.3). If f is separable, then λ can be computed in parallel (see § 7).

5.4. Dual gradient iteration. Consider the equality constrained problem (P^{E}). A classical method for solving this problem is the dual gradient method, whereby at each iteration, the dual vector p is moved along the gradient direction $\nabla q(p)$ (or an approximation of) in order to maximize the dual functional q. This method was one of the first dual methods proposed to solve (P^{E}) [22], [61] (also see [4], [25], [34], [39], [40], [49], [50]) and yet, despite its long history, very little is known about its convergence properties. In this subsection, we show that this method is a special case of the BCR algorithm, from which it immediately follows that this method has the convergence properties stated in Proposition 1.

We describe the dual gradient method below: We fix scalars $\theta_1 \in (0, 1]$ and $\theta_2 \in (0, 1)$. At each iteration, we compute a new dual vector p' from the current dual vector p using the following iteration.

Dual Gradient Iteration.

Given $p \in \Re^n$, choose a vector $u \in \Re^n$ satisfying

$$\langle d(p), u\rangle \geqq \theta_1 \|d(p)\| \cdot \|u\|, \tag{5.12a}$$

and set

$$p' = p + \lambda u, \tag{5.12b}$$

where λ is any positive scalar satisfying

$$0 \leqq \langle d(p + \lambda u), u\rangle \leqq \theta_2 \langle d(p), u\rangle. \tag{5.12c}$$

The stepsize λ can be computed using, say, the Armijo rule [4]. (If Assumption C holds, then exact line search, i.e., $\theta_2 = 0$, is also allowable.)

The above dual gradient method seems to be quite different from the coordinate relaxation methods but, as we show below, it is a special case of the block coordinate relaxation algorithm. (Hence it is convergent in the sense of Proposition 1.)

PROPOSITION 5. *The iteration* (5.12a)-(5.12c) *is well defined and is a special case of the* BCR *iteration for solving* (P^{E}), *with* $\gamma = 1$, $I = N$, $\phi_N(\eta, \pi) = \|\eta\|$, *and* $\delta_N(\eta, \eta') = (1/(1-\theta_2)\theta_1 + 1)\|\eta - \eta'\|$.

Proof. If the iteration (5.12a)-(5.12c) is not well defined, it must be that $\langle d(p+\lambda u), u\rangle$ is bounded away from 0 as $\lambda \to +\infty$. In that case $q(p+\lambda u) \to +\infty$ as $\lambda \to +\infty$, a contradiction of the feasibility of (P^E).

It is clear that p' satisfies (2.2a) and since $\langle d(p'), u\rangle \geqq 0$, p' also satisfies (2.2b) with $\gamma = 1$. To see that p' satisfies (2.2c), note from (5.12a)-(5.12c) that

$$\begin{aligned}\langle d(p)-d(p'), u\rangle &\geqq (1-\theta_2)\langle d(p), u\rangle \\ &\geqq (1-\theta_2)\theta_1 \|d(p)\| \cdot \|u\|.\end{aligned}$$

Hence, by the Cauchy-Schwartz inequality,

$$\|d(p)-d(p')\| \geqq (1-\theta_2)\theta_1 \|d(p)\|.$$

This in turn implies

$$\begin{aligned}\|d(p')\| &\leqq \|d(p)\| + \|d(p)-d(p')\| \\ &\leqq (1/(1-\theta_2)\theta_1 + 1)\|d(p)-d(p')\|.\end{aligned}$$

□

There are a number of choices for the dual ascent direction u. One such choice, proposed in [50] (also see [39, Thm. 4.4.1]), is

$$u = Hd(p), \tag{5.13a}$$

where H is any $n \times n$ symmetric matrix satisfying

$$\mu_1 \|Ey\|^2 \leqq \langle Ey, HEy\rangle \leqq \mu_2 \|Ey\|^2, \quad \forall y \in \Re^m, \tag{5.13b}$$

and μ_1, μ_2 are two positive scalar constants. To see that this choice of u satisfies (5.12a), note that since (P^E) is feasible, there exists $\bar{x} \in \Re^m$ satisfying $b = E\bar{x}$. Hence

$$d(p) = E(\bar{x} - \nabla f^*(E^T p)). \tag{5.14}$$

This, together with (5.13a), (5.13b), implies that

$$\begin{aligned}\langle d(p), u\rangle &= \langle d(p), Hd(p)\rangle \\ &\geqq \mu_1 \|d(p)\|^2 \\ &\geqq \mu_1 \|d(p)\| \, \|u\|/\mu_2,\end{aligned}$$

where the last inequality follows from (cf. (5.13b), (5.14)) $\|Hd(p)\| \leqq \mu_2 \|d(p)\|$. There are a number of choices for the matrix H. For example, H can be computed using a quasi-Newton scheme. Because the matrix E is not assumed to have full row rank, this condition is in general weaker than the requirement that H is positive definite over the entire space.

The identification of the dual gradient method with block coordinate relaxation methods motivates a number of new algorithms. For example, we can consider a block coordinate relaxation algorithm in which each block of coordinates is relaxed either by maximizing the dual functional with respect to all of the coordinates in the block or by performing a one-dimensional line search in the direction given by the partial derivatives of q with respect to these coordinates. The type of relaxation iteration to use for each coordinate block can then be chosen according to the problem structure. As another example, consider the case where the dual functional $q(p)$ has a negative curvature with respect to only a subset of the coordinates of p. In such a case we can take advantage of this structure by alternating between a second-order iteration for these coordinates and a first-order iteration for the remaining coordinates. We illustrate this scheme below.

Suppose that the problem (P^E) has the following separable form

$$\text{Minimize} \quad g(y)+h(z)$$
$$\text{subject to} \quad Ay+Bz=d,$$
$$Cz=e,$$

where $g:\Re^{m_1}\to(-\infty,+\infty]$, $h:\Re^{m_2}\to(-\infty,+\infty]$ are strictly convex functions ($m_1+m_2=m$) and A, B, C, d, e are matrices/vectors of appropriate dimensions. By attaching Lagrange multiplier vectors u and v to, respectively, the constraints $Ay+Bz=d$ and $Cz=e$, we obtain the following dual functional (cf. (1.3)):

$$q(u,v)=\langle d,u\rangle+\langle e,v\rangle-g^*(A^Tu)-h^*(B^Tu+C^Tv),$$

where g^*, h^* denote, respectively, the conjugate function of g and h (cf. (1.2)).

Then, if h^* has a positive curvature, we can use a second-order iteration to update the multiplier vector v. For example, suppose that h is quadratic of the form $h(z)=\langle z,Qz\rangle/2$, where Q is an $m_2\times m_2$ symmetric positive definite matrix. Then $h^*(t)=\langle t,Q^{-1}t\rangle/2$ and

$$\nabla_v q(u,v)=e-CQ^{-1}(B^Tu+C^Tv),$$
$$\nabla_v^2 q(u,v)=-CQ^{-1}C^T,$$

where $\nabla_v q$ and $\nabla_v^2 q$ denote, respectively, the first-order and the second-order partial derivative of q with respect to v. Hence we can update v by moving it along, say, the Newton direction w, given as the solution to the system of linear equations

$$(CQ^{-1}C^T)w=e-CQ^{-1}(B^Tu+C^Tv),$$

to maximize q while u is held fixed. This iteration is a special case of the dual gradient iteration (cf. Proposition 5 and (5.13a), (5.13b)). The other dual vector u can be updated by a different type of BCR iteration.

6. Relation to known methods. In this section, we show that the dual methods proposed in [2], [6], [8]-[10], [13], [15], [18], [21], [23], [24], [27], [28], [31]-[33], [37]-[39], [41], [42], [45], [48]-[50], [57]-[60], [64] are special cases of the BCR algorithm (under the essentially cyclic or the Gauss-Southwell or the quasi-cyclic order of relaxation) and that the conjugate gradient methods in [39], [62] are special cases of the mixed algorithm discussed at the end of § 3. Hence convergence of these methods follow from either Proposition 1 or Proposition 2. We also prove convergence of a general Block S.O.R. algorithm for the solution of the symmetric linear complementarity problem. A mixed version of this algorithm contains as a special case the S.O.R. algorithm proposed in [14].

6.1. General costs and constraints.

PROPOSITION 6. *The methods proposed in* [50] *are special cases of the* BCR *algorithm for solving the special case of* (P^E) *where S is a polyhedral set and f is uniformly convex* (*i.e., satisfies* (4.1) *with* $\omega=2$) *and differentiable on* ri (S).

Proof. The periodic basis ascent method ([50, p. 10]) is a dual single coordinate ascent method that uses exact line search and essentially cyclic order of relaxation. Hence it is a special case of the SCR algorithm with $\alpha_s=0$ for all s. (Although this method allows arbitrary basis vectors to be used for ascent, it can be viewed as a coordinate ascent method, but in a transformed space.) The gradient-type method ([50, p. 11]) is a special case of the gradient method given in § 5.4 where the gradient direction is given by (5.13a), (5.13b) and the line search is exact. (Also see [39], [49] for specialization of this latter method to quadratic programs.) □

PROPOSITION 7. *The methods in* [9] *and* [10] *are special cases of the* SCR *algorithm with* $\alpha_s = 0$ *for all* s.

Proof. Both methods use exact line search. The one in [9] uses cyclic relaxation while the one in [10] uses essentially cyclic relaxation. These methods further require:

(i) S is closed and f is continuously differentiable in ri (S);

(ii) $\{x \in S \mid D(x, y) \leqq \alpha\}$ and $\{y \in \text{ri}\,(S) \mid D(x, y) \leqq \alpha\}$ are bounded for every $y \in \text{ri}\,(S)$ and every $x \in S$, respectively, where $D(x, y) = f(x) - f(y) - \langle \nabla f(y), x - y \rangle$;

(iii) $\text{argmin}\,\{D(z, y) \mid z \in S,\ E_i z = b_i\} \in \text{ri}\,(S)$, $\forall y \in \text{ri}\,(S)$, $\forall i \in N$.

(The conditions (ii), (iii) do not typically hold, except for special cases such as when f is strongly convex and $S = \Re^m$.)

PROPOSITION 8. *The methods in* [59] *and* [60] *are special cases of the* SCR *algorithm with* $\psi_s(\eta) = \eta$ *for all* s.

Proof. The proof is straightforward from the algorithm description in [59] and § 2 of [60]. In [59], f is further assumed to be separable. (However, the convergence results obtained in [59] are stronger than those obtained from Propositions 1 and 2.) □

6.2. Quadratic costs. In this subsection, we consider the special case of (P) where f is quadratic:

$$f(x) = \langle x, Qx \rangle / 2 + \langle c, x \rangle, \tag{6.1}$$

where Q is an $m \times m$ symmetric positive definite matrix and c is a vector in $\Re^m$. It is easily seen that, under the assumption that (P) is feasible, both Assumptions A and B hold (f is in fact uniformly convex). Direct calculation using (6.1) and (1.2)-(1.5) gives

$$q(p) = -\langle p, Mp \rangle / 2 + \langle w, p \rangle, \tag{6.2}$$

$$\chi(p) = Q^{-1}(E^T p - c), \tag{6.3}$$

$$d(p) = w - Mp, \tag{6.4}$$

where we denote $M = EQ^{-1}E^T$ and $w = b + EQ^{-1}c$.

The first dual coordinate ascent method for solving (6.1) was due to Hildreth [28]. He considered the special case where M is positive definite and proposed a single coordinate cyclic relaxation method with exact line search for its solution. This method was later extended to inexact line search [14], [18], [42], essentially cyclic order of relaxation [27], [38], and block coordinate relaxation [14], [15]. In [14], [27], [38], [42], M is not required to be positive definite.

The general form of this method can be stated as follows: We fix a collection $\mathscr{C}$ of nonempty subsets of N such that their union equals N. We also fix two relaxation parameters ω_1 and ω_2 satisfying $\omega_2 \in (0, 2)$ and $\omega_1 \in (0, \min\{1, \omega_2\}]$. At each iteration, we generate a new dual vector p' from the current dual vector p as follows.

Block S.O.R. *Iteration.*

Given $p \in [0, +\infty)^n$, choose an $I \in \mathscr{C}$. Set

$$p' = (1 - \lambda)p + \lambda \Delta, \tag{6.5}$$

where Δ is any vector in $[0, +\infty)^n$ satisfying

$$\Delta_I = [\Delta_I + w_I - M_I \Delta]^+, \tag{6.6a}$$

$$\Delta_{N \setminus I} = p_{N \setminus I}, \tag{6.6b}$$

and λ is any scalar inside $[\omega_1, \omega_2]$ satisfying $(1 - \lambda)p + \lambda \Delta \geqq 0$.

Note that λ is well defined since $\Delta \geqq 0$. (It can be seen that Δ is equivalently a solution of the problem $\max\{q(\pi) \mid \pi \geqq 0,\ \pi_{N\setminus I} = p_{N\setminus I}\}$.) Below we show that the Block S.O.R. iteration, under certain conditions, is a special case of the BCR iteration.

PROPOSITION 9. *If $\omega_1 = \omega_2 = 1$ or if M_{II} is positive definite for all $I \in \mathscr{C}$, then the Block* S.O.R. *iteration is a special case of the* BCR *iteration, with $\gamma = 2/\omega_2 - 1$, $\phi_I(\eta, \pi) = \sum_{i\in I} |\pi_i - [\pi_i + \eta_i]^+|$, and $\delta_I(\eta, \eta') = \rho \|\eta_I - \eta'_I\|$, where ρ is some positive constant depending on M, ω_1, and ω_2 only.*

Proof. We will show that p' given by (6.5)-(6.6b) satisfies (2.2b), (2.2c) ((2.2a) clearly holds). First we prove that (2.2b) holds. From (6.6a), (6.6b) we have

$$\langle w - M\Delta, \Delta - p\rangle \geqq 0, \tag{6.7}$$

and from (6.2) and (6.5) we have

$$\begin{aligned} \langle p' - p, d(p')\rangle &= \langle p' - p, w - Mp'\rangle \\ &= \langle p' - p, M(\Delta - p')\rangle + \langle p' - p, w - M\Delta\rangle \\ &= (1/\lambda - 1)\langle p' - p, M(p' - p)\rangle + \lambda\langle \Delta - p, w - M\Delta\rangle. \end{aligned} \tag{6.8}$$

Also, (6.2) and (6.4) imply

$$\begin{aligned} q(p') - q(p) &= -\langle p', Mp'\rangle/2 + \langle w, p'\rangle + \langle p, Mp\rangle/2 - \langle w, p\rangle \\ &= \langle p' - p, M(p' - p)\rangle/2 + \langle p' - p, w - Mp'\rangle \\ &= \langle p' - p, M(p' - p)\rangle/2 + \langle p' - p, d(p')\rangle. \end{aligned} \tag{6.9}$$

Multiplying both sides by $2(1/\lambda - 1)$ and using (6.7), (6.8), we obtain

$$\begin{aligned} 2(1/\lambda - 1)[q(p') - q(p)] &= (1/\lambda - 1)\langle p' - p, M(p' - p)\rangle + 2(1/\lambda - 1)\langle p' - p, d(p')\rangle \\ &\leqq \langle p' - p, d(p')\rangle + 2(1/\lambda - 1)\langle p' - p, d(p')\rangle \\ &= (2/\lambda - 1)\langle p' - p, d(p')\rangle. \end{aligned}$$

Since $\lambda \leqq \omega_2$ and $2/\lambda - 1$ is a decreasing function of λ, (2.2b) holds with $\gamma = 2/\omega_2 - 1$.

Now we prove that (2.2c) holds. First suppose that $\omega_1 = \omega_2 = 1$. Then $\lambda = 1$ and it follows from (6.5)-(6.6b) that

$$p'_I = [p'_I + w_I - M_I p']^+.$$

Hence $\phi_I(d(p'), p') = 0$ and (2.2c) holds. Next suppose that M_{II} is positive definite. Denote $\tilde{I} = \{i \in I \mid p'_i + w_i - M_i p' < 0\}$ and $\hat{I} = \{i \in I \mid \Delta_i = 0\}$. Then we have

$$p'_i - [p'_i + w_i - M_i p']^+ = p'_i, \quad \forall i \in \tilde{I}, \tag{6.10}$$

$$p'_i - [p'_i + w_i - M_i p']^+ = M_i p' - w_i, \quad \forall i \in I\setminus\tilde{I}. \tag{6.11}$$

Also, using the fact (cf. (6.6a)) $w_i - M_i\Delta = 0$ for all $i \in I\setminus\hat{I}$, we obtain

$$\begin{aligned} p'_i &= (1 - \lambda)p_i, \quad \forall i \in \hat{I}, \\ w_i - M_i p' &= (1 - \lambda)(w_i - M_i p), \quad \forall i \in I\setminus\hat{I}. \end{aligned}$$

This implies

$$\lambda p'_i = (1 - \lambda)(p_i - p'_i), \quad \forall i \in \hat{I}, \tag{6.12}$$

$$\lambda(w_i - M_i p') = (1 - \lambda)M_i(p' - p), \quad \forall i \in I\setminus\hat{I}, \tag{6.13}$$

which, together with the definition of $\tilde{I}$, implies

$$p'_i \leqq M_i p' - w_i = (1 - 1/\lambda)M_i(p' - p), \quad \forall i \in \tilde{I} \cap (I\setminus\hat{I}), \tag{6.14}$$

$$w_i - M_i p' \geqq -p'_i = (1 - 1/\lambda)(p_i - p'_i), \quad \forall i \in (I\setminus\tilde{I}) \cap \hat{I}. \tag{6.15}$$

Also we have that, for all $i \in I$, $w_i - M_i p' \leqq (1-\lambda)(w_i - M_i p)$ (since $w_i - M_i \Delta \leqq 0$ and $p' = (1-\lambda)p + \lambda\Delta$). Hence

$$\lambda(w_i - M_i p') \leqq (1-\lambda) M_i (p' - p), \quad \forall i \in K, \tag{6.16}$$

where we let $K = \{i \in (I \setminus \tilde{I}) \cap \hat{I} \mid w_i - M_i p' > 0\}$. Combining (6.12)-(6.16), we obtain

$$\begin{aligned}
p_i' &= (1-1/\lambda)(p_i' - p_i), && \forall i \in \tilde{I} \cap \hat{I},\\
p_i' &\leqq (1-1/\lambda) M_i (p' - p), && \forall i \in \tilde{I} \cap (I \setminus \hat{I}),\\
w_i - M_i p' &\geqq (1-1/\lambda)(p_i - p_i'), && \forall i \in ((I \setminus \tilde{I}) \cap \hat{I}) \setminus K,\\
w_i - M_i p' &\leqq (1-1/\lambda) M_i (p - p'), && \forall i \in K,\\
w_i - M_i p' &= (1-1/\lambda) M_i (p - p'), && \forall i \in (I \setminus \tilde{I}) \cap (I \setminus \hat{I}).
\end{aligned}$$

Combining the above with (6.10), (6.11) and using (6.4), we obtain

$$\begin{aligned}
\phi_i(d(p'), p') &\leqq |1/\lambda - 1|\,|p_i - p_i'|, && \forall i \in \hat{I} \setminus K,\\
\phi_i(d(p'), p') &\leqq |1/\lambda - 1|\,|M_i (p - p')|, && \forall i \in I \setminus (\hat{I} \setminus K),
\end{aligned}$$

where $\phi_i(\eta, \pi) = |\pi_i - [\pi_i + \eta_i]^+|$. This, together with (6.6b), implies that

$$\sum_{i \in I} \phi_i(d(p'), p') \leqq |1/\lambda - 1| \rho_1 \| p_I - p_I' \|, \tag{6.17}$$

for some positive constant ρ_1 depending on M_{II} only. Since M_{II} is positive definite,

$$\begin{aligned}
\| p_I - p_I' \|^2 &\leqq \rho_2 \cdot \langle p_I - p_I', M_{II}(p_I - p_I') \rangle\\
&\leqq \rho_2 \cdot \| p_I - p_I' \| \cdot \| M_{II}(p_I - p_I') \|\\
&= \rho_2 \cdot \| p_I - p_I' \| \cdot \| d_I(p) - d_I(p') \|,
\end{aligned}$$

where ρ_2 is some positive constant depending on M_{II} only, and the equality follows from (6.4). This and (6.17) imply that

$$\sum_{i \in I} \phi_i(d(p'), p') \leqq |1/\lambda - 1| \rho_1 \cdot \rho_2 \cdot \| d_I(p) - d_I(p') \|.$$

Since $\lambda \in [\omega_1, \omega_2]$, $|1/\lambda - 1| \leqq \max\{1/\omega_1 - 1, 1 - 1/\omega_2\}$. □

COROLLARY 9. *The methods in* [15], [18], [27], [28], [38], [42] *are special cases of the* BCR *algorithm.*

Proof. The methods in [15], [18], [28] require M to be positive definite, in which case M_{II} is positive definite for any $I \subseteq N$. The methods in [27], [38], [42] use single coordinate relaxation, in which case M_{II} is always positive definite (since E has no zero row). Each of the above methods uses either cyclic or essentially cyclic order of relaxation. □

If M_{II} is not positive definite and $\lambda \neq 1$, then it is possible that $d_I(p) = d_I(p')$ and $p_I' \neq [p_I' + d_I(p')]^+$, in which case there is no continuous δ_I and ϕ_I satisfying, respectively, (2.1a) and (2.1b) for which (2.2c) holds. However, the Block S.O.R. algorithm can still be shown to converge by modifying the proofs in § 3 and § 4. To the best of our knowledge, this is the first proof of convergence for this algorithm that makes no assumption on the problem other than that it be feasible.

PROPOSITION 10. *Let p^r be the iterate generated by the Block* S.O.R. *algorithm at the rth iteration. Then, under either the quasi-cyclic (with $\omega = 2$) or the Gauss-Southwell order of relaxation, $\{\chi(p^r)\} \to x^*$ and $\{q(p^r)\} \to f(x^*)$.*

Proof. From the proof of Proposition 9 and Lemma 2 we have that (3.1a) holds with $\gamma = 2/\omega_2 - 1$. Since (3.1b) and Lemma 1 clearly hold and the proof of Lemma 3(a), (b) depends only on Lemmas 1 and 2, it follows that Lemma 3(a), (b) hold. Suppose that Lemma 3(c) also holds. Then since the proof of Proposition 1(a) depends only on Lemmas 1 and 3 and both these lemmas hold, Proposition 1(a) must hold. Similarly, because the hypothesis of Proposition 1(b) is satisfied (f is everywhere differentiable), Proposition 1(b) also holds. Since f is uniformly convex (i.e., f satisfies (4.1) with $\omega = 2$), an analogous argument shows that parts (a), (b) of Proposition 2 also hold. Therefore it suffices to prove that Lemma 3(c) holds.

Suppose that Lemma 3(c) does not hold. Then there exist a scalar $\varepsilon > 0$, a coordinate block $i \in \mathscr{C}$ and a subsequence $R \subseteq \{1, 2, \cdots\}$ for which the coordinates p_i, $i \in I$, are relaxed at the rth iteration, for all $r \in R$, and

$$\| p_I^r - [p_I^r + d_I(p^r)]^+ \| \geqq \varepsilon, \quad \forall r \in R. \tag{6.18a}$$

Let $x^r = \chi(p^r)$. Since (cf. Lemma 3(a)) $\{x^r\}$ is bounded, by further passing into a subsequence if necessary, we will assume that $\{x^{r-1}\}_{r\in R} \to x^\infty$ for some $x^\infty \in \Re^m$. Let $d = b - Ex^\infty$ and let λ^r, Δ^r denote the λ, Δ generated (cf. (6.5)-(6.6b)) at the rth iteration. Then (cf. (1.4), (6.4))

$$w_I - M_I p^r = d_I(p^r) = b_I - E_I x^r, \quad \forall r. \tag{6.18b}$$

Since $\{x^{r-1}\}_{r\in R} \to x^\infty$, this implies that

$$\{w_I - M_I p^{r-1}\}_{r\in R} \to d_I. \tag{6.19a}$$

Since (cf. (6.5), (6.18b)) $E_I(x^r - x^{r-1}) = M_I(p^r - p^{r-1}) = \lambda^r M_I(\Delta^r - p^{r-1})$ and $\lambda^r \geqq \omega_1 > 0$, it follows from (6.19a) and Lemma 3(b) that

$$\{w_I - M_I \Delta^r\}_{r\in R} \to d_I. \tag{6.19b}$$

Now, by (6.6a), $w_I - M_I \Delta^r \leqq 0$ for all $r \in R$. Hence by (6.19b), $d_I \leqq 0$. Let $I^- = \{i \in I \mid d_i < 0\}$. Then

$$d_i = 0, \quad \forall i \in I \setminus I^-, \tag{6.19c}$$

and (cf. (6.6a), (6.19b)), for all $r \in R$ sufficiently large,

$$\Delta_i^r = 0, \quad \forall i \in I^-. \tag{6.19d}$$

Also, from (6.8) we have that, for all $r \in R$,

$$\langle p^r - p^{r-1}, d(p^r)\rangle = (1/\lambda^r - 1)\langle p^r - p^{r-1}, M(p^r - p^{r-1})\rangle + \lambda^r \langle \Delta^r - p^{r-1}, w - M\Delta^r\rangle,$$

which, together with (6.9), (6.6b), and $\lambda^r \in (0, 2)$, implies that

$$\begin{aligned} q(p^r) - q(p^{r-1}) &= \langle p^r - p^{r-1}, M(p^r - p^{r-1})\rangle/2 + \langle p^r - p^{r-1}, d(p^r)\rangle \\ &= (1/\lambda^r - 1/2)\langle p^r - p^{r-1}, M(p^r - p^{r-1})\rangle + \lambda^r \langle \Delta^r - p^{r-1}, w - M\Delta^r\rangle \\ &\geqq \lambda^r \langle \Delta_I^r - p_I^{r-1}, w_I - M_I \Delta^r\rangle. \end{aligned}$$

Since $\lambda^r \geqq \omega_1 > 0$ for all r and the right-hand side of the above is nonnegative by (6.6a), we have $\{\langle \Delta_I^r - p_I^{r-1}, w_I - M_I \Delta^r\rangle\}_{r\in R} \to 0$. This, together with (6.19a)-(6.19d), implies that

$$\{p_i^r\}_{r\in R} \to 0, \quad \forall i \in I^-,$$

$$\{w_i - M_i p^r\}_{r\in R} \to 0, \quad \forall i \in I \setminus I^-.$$

Hence $\{p_I^r - [p_I^r + d_I(p^r)]^+\}_{r\in R} \to 0$, a contradiction of (6.18a). □

Analogous to the mixed algorithm discussed at the end of § 3, we can consider an algorithm whereby other dual ascent iterations are inserted between the Block S.O.R. iterations at regular intervals. It can be shown that Proposition 10 also holds for this mixed algorithm, provided that the inserted dual ascent iterations satisfy the condition (3.9). An interesting special case of this mixed algorithm is the Cottle-Pang algorithm proposed in [14]. This algorithm can be seen to be a special case of the Block S.O.R. algorithm using $\omega_1 = \min\{1, \omega_2\}$ and cyclic order of relaxation. The only difference is that a "reduction" step is inserted at the end of each cycle. This reduction step generates a new iterate p' from the current iterate p by the formula:

$$p' = p - \theta u, \tag{6.20}$$

where u is some nonnegative vector in $\Re^n$ satisfying

$$E^T u = 0, \qquad \langle b, u\rangle = 0, \tag{6.21}$$

and θ is the largest scalar for which p' given by (6.20) is nonnegative (if $u = 0$, θ is set to 0). From (6.20), (6.21) we see that $E^T p = E^T p'$ and $\langle b, p\rangle = \langle b, p'\rangle$. Therefore (cf. (1.3) and (1.5))

$$q(p) = q(p'), \qquad \chi(p) = \chi(p'),$$

and the iteration (6.20), (6.21) satisfies (3.9).

Notes and extensions.

1. For each $I \subseteq N$, the matrix M_{II} is positive definite if and only if E_I has full row rank.

2. The vector Δ satisfying (6.6a), (6.6b) can be computed either approximately using iterative methods [39], [43] or exactly using direct methods [16], [17], [36].

3. If the dual functional q given by (6.2) has bounded level sets on the nonnegative orthant in $\Re^n$ (which can be seen to hold if and only if there exists $z \in \Re^n$ such that $Mz - w > 0$), then the sequence of iterates $\{p^r\}$ generated by the Block S.O.R. iteration is bounded and each of its limit points is an optimal dual solution. If E does not have full row rank, the technique discussed at the end of § 3 may be used to maintain $\{p^r\}$ to be bounded. On the other hand, if $\omega_2 \in (0, 1]$ and b lies in the column space of E, the Block S.O.R. iteration can be implemented working with $E^T p$ instead of p. By (6.3) and Lemma 3(a), $\{E^T p^r\}$ is bounded.

4. Consider the special case of (P^E) where f is the sum of a strictly convex quadratic function and the indicator function for a polyhedral set in $\Re^m$. In [39, § 4] a conjugate gradient method with periodic restart (with a gradient iteration as the spacer step) was proposed to solve this problem, and convergence for this method was established for the Polak-Ribiere-Polyak [4] formula. (Also see [62] for computational results on network flow problems.) However, because each conjugate gradient iteration maximizes exactly the dual functional q along some direction, this method is simply a special case of the mixed algorithm discussed at the end of § 3. Hence it immediately follows that this method converges for any conjugate gradient formula and for the general problem (P^E). Furthermore, instead of the gradient iteration, we can use any BCR iteration as the spacer step.

6.3. Entropy costs. In this subsection we consider the following special case of (P^E):

$$\begin{aligned} &\text{Minimize} && f_1(x) = \sum_j x_j \ln (x_j / u_j) \\ &\text{subject to} && Ex = b,\ x \geqq 0, \end{aligned} \tag{6.22}$$

where E is an $n \times m$ matrix, b is a vector in $\Re^n$, and the u_j's are given positive constants. (Here $\ln(\cdot)$ denotes the natural logarithm.) It is easily verified that Assumptions A and B hold for this problem (assuming that it is feasible). This problem, called the entropy maximization problem ($-f_1$ is the classical entropy function weighted by the u_j's), has applications in matrix balancing [2], [8], [21], [24], [31]-[33], [41], [48], [57], ([5, § 5.5.4]), image reconstruction [11], [12], [23], [37], [53] and maximum likelihood estimation [19].

PROPOSITION 11. *The matrix balancing methods in* [2], [8], [21], [24], [31]-[33], [41], [48], [57] *are special cases of the* SCR *algorithm for solving* (6.22) *with* $\alpha_s = 0$ *for all* s.

Proof. In [33] it was shown that the matrix balancing methods in [1], [21], [24], [31], [32], [41], [48], [57] are special cases of Bregman's method [9], [10] for solving (6.22). The RAS-algorithm considered in [2], [8] can also be seen to be such a special case. (The modified RAS-algorithm in [2] uses essentially cyclic instead of cyclic order of relaxation.) Therefore, by Proposition 7, they are special cases of the SCR algorithm with $\alpha_s = 0$ for all s. □

Consider the following special case of (6.22):

$$\begin{aligned} &\text{Minimize} \quad f_2(x) = \sum_j x_j \ln(x_j) \\ &\text{subject to} \quad Ex = b, \qquad x \geqq 0, \end{aligned} \tag{6.23}$$

where (for each i) $b_i > 0$, $e_{ij} \in [0, 1]$ for all j, and $e_{ij} > 0$ for at least one j. The following method for solving (6.23) was proposed in [23] and [37]. It begins with any $x \in \Re^m$ satisfying $x_j = \exp(\sum_i e_{ij} p_i - 1)$, for all j, for some $p \in \Re^n$. (Here $\exp(\cdot)$ denotes the exponential function.) Given an $x \in \Re^m$, it generates a new estimate x' as follows.

Multiplicative ART *Iteration.*

Choose an index $s \in N$ and set

$$x_j' = x_j \left(b_s \Big/ \left(\sum_k e_{sk} x_k \right) \right)^{e_{sj}}, \quad \forall j = 1, \cdots, m. \tag{6.24}$$

(The index s is chosen by the essentially cyclic order.) The iteration (6.24) is also a special case of the SCR iteration, as we show below.

PROPOSITION 12. *The multiplicative* ART *method is a special case of the* SCR *algorithm with* $\alpha_i = 1 - \min_j \{e_{ij} \mid e_{ij} > 0\}$ *and*

$$\psi_i(\eta) = \begin{cases} \ln(b_i/(b_i - \eta)) & \text{if } b_i - \eta > 0, \\ -\infty & \text{otherwise.} \end{cases}$$

Proof. Straightforward calculation finds the conjugate function of f_2 to be $\sum_j g_j(t_j)$, where $g_j(t_j) = \exp(t_j - 1)$. Hence $\nabla g_j(t_j) = \exp(t_j - 1)$ and (cf. (1.4) and (1.5))

$$\chi_j(p) = \exp(t_j - 1), \tag{6.25a}$$

$$b_i - d_i(p) = \sum_j e_{ij} \exp(t_j - 1), \tag{6.25b}$$

where $t_j = \sum_i e_{ij} p_i$ and $\chi_j(p)$ denotes the jth coordinate of $\chi(p)$.

Given $p \in \Re^n$ and $s \in N$, consider the single coordinate relaxation

$$p' = p + \lambda e^s, \tag{6.26}$$

where e^s denotes the sth coordinate vector in $\Re^n$ and λ is the scalar satisfying

$$b_s/(b_s - d_s(p)) = \exp(\lambda). \tag{6.27}$$

Then (cf. (6.25a))

$$\begin{aligned}\chi_j(p') &= \chi_j(p+\lambda\, e^s)\\ &= \exp\left(\sum_i e_{ij}p_i + e_{sj}\lambda - 1\right)\\ &= \chi_j(p)\exp(\lambda)^{e_{sj}}\\ &= \chi_j(p)(b_s/(b_s-d_s(p)))^{e_{sj}}.\end{aligned}$$

Comparing the above equation with (6.24), we see that the two iterations (6.24) and (6.26), (6.27) are equivalent.

We now show that p' generated by the iteration (6.26), (6.27) satisfies (5.11a)-(5.11c). For simplicity we assume that $d_s(p)\geqq 0$ (the case where $d_s(p)<0$ can be treated analogously). Then, by (6.27), $\exp(\lambda)\geqq 1$. Since (cf. (6.25b))

$$\begin{aligned}b_s - d_s(p') &= b_s - d_s(p+\lambda\, e^s)\\ &= \sum_j e_{sj}\cdot\exp(t_j + e_{sj}\lambda - 1)\\ &= \sum_j e_{sj}\cdot\exp(t_j-1)\cdot\exp(\lambda)^{e_{sj}},\end{aligned}\tag{6.28}$$

we obtain from the facts $\exp(\lambda)\geqq 1$ and $e_{sj}\geqq 1-\alpha_s$ that

$$\begin{aligned}b_s - d_s(p') &\geqq \sum_j e_{sj}\cdot\exp(t_j-1)\cdot\exp(\lambda)^{1-\alpha_s}\\ &= (b_s-d_s(p))\cdot\exp(\lambda)^{1-\alpha_s}.\end{aligned}$$

This, together with (6.27), implies that $1-d_s(p')/b_s \geqq (1-d_s(p)/b_s)^{\alpha_s}$, or, equivalently,

$$\psi_s(d_s(p'))\leqq \alpha_s\psi_s(d_s(p)).$$

On the other hand, since $e_{sj}\in[0,1]$ for all j, we have from (6.28) and the fact $\exp(\lambda)>1$,

$$\begin{aligned}b_s - d_s(p') &= \sum_j e_{sj}\exp(t_j-1)\cdot\exp(\lambda)^{e_{sj}}\\ &\leqq \sum_j e_{sj}\exp(t_j-1)\cdot\exp(\lambda)\\ &= (b_s-d_s(p))\exp(\lambda) = b_s.\end{aligned}$$

Hence $\psi_s(d_s(p'))\geqq 0$ so that λ satisfies (5.11a). □

There is, however, a slight difficulty with the choice of ψ_i given above, namely, that ψ_i is not continuous everywhere. This difficulty can be circumvented by redefining ψ_i on the interval $[b_i-\varepsilon, +\infty)$ to be a continuous (and strictly increasing) extension of itself, for some $\varepsilon>0$. For this choice of ψ_i, the proof of Proposition 12 still goes through, provided that it holds

$$d_{s^r}(p^r)\leqq b_{s^r}-\varepsilon,\quad d_{s^r}(p^{r-1})\leqq b_{s^r}-\varepsilon,\quad \forall r=0,1,\cdots,$$

where p^r denotes the iterate generated by (6.26), (6.27) at the rth iteration and s^r is the index of the coordinate relaxed at the rth iteration. (Hence the value of ε depends on p^0.) To see that this indeed holds, let q denote the dual functional (cf. (1.3)) given by

$$\begin{aligned}q(p) &= \min_{x\geqq 0}\{f_2(x)+\langle p, b-Ex\rangle\}\\ &= \langle b,p\rangle - \sum_j \exp\left(\sum_i e_{ij}p_i - 1\right),\quad \forall p\in\Re^n.\end{aligned}$$

Hence, for any $p \in \Re^n$, any $s \in N$, and any λ given by (6.27), we have

$$\begin{aligned} q(p+\lambda e^s) - q(p) &= b_s\lambda + \sum_j \exp\left(\sum_i e_{ij}p_i - 1\right)(1-\exp(e_{sj}\lambda)) \\ &= b_s\lambda + \sum_j \chi_j(p)(1-\exp(e_{sj}\lambda)) \\ &\geqq b_s\lambda - \sum_j \chi_j(p)e_{sj}(\exp(\lambda)-1) \\ &= b_s(\lambda - 1 + \exp(-\lambda)), \end{aligned}$$

where the second equality follows from (6.25a) and the inequality follows from the fact $\omega^\theta \leqq 1+\theta(\omega-1)$ for all $\omega \geqq 0$ and all $\theta \in [0,1]$. Since the function $\eta \to \eta - 1 + \exp(-\eta)$ is nonnegative for all positive η and attains the value zero at $\eta = 0$ only, this, together with the observation that $\{q(p^r) - q(p^{r-1})\} \to 0$ and $b_s > 0$ for all s, implies (cf. (6.26), (6.27))

$$\{p^r - p^{r-1}\} \to 0, \qquad \{(b_{s^r} - d_{s^r}(p^{r-1}))/b_{s^r}\} \to 1.$$

It then follows from (6.25a), (6.25b) that $\{d(p^r) - d(p^{r-1})\} \to 0$ and $\{d_{s^r}(p^r)/b_{s^r}\} \to 0$. Hence both $\{b_{s^r} - d_{s^r}(p^r)\}$ and $\{b_{s^r} - d_{s^r}(p^{r-1})\}$ are bounded away from zero. (The above argument is based on one given in [37] for Lemma 1 therein.)

6.4. Network flow constraints. In this subsection we consider the special case of (P^E) where E is the node-arc incidence matrix for a generalized network (i.e., each column of E has at most one positive entry and at most one negative entry). An important special case of this problem is the pure network flow problem, for which each positive entry is $+1$ and each negative entry is -1.

PROPOSITION 13. *The network flow methods in* [13], [45], [58], [64] *are special cases of the* SCR *algorithm with* $\alpha_s = 0$ *for all* s.

Proof. These methods are all dual single coordinate relaxation algorithms that use exact line search and cyclic order of relaxation. In [13], [45], [64], the cost function f is further assumed to be separable. In [58] the cost function f is assumed to be strongly convex. (The references [45], [64] do not contain convergence proofs. In [58], to prove convergence, it is also assumed that an optimal dual solution exists and is unique, and that the dual functional q is *twice* differentiable.) □

PROPOSITION 14. *The network flow method in* § 2 *of* [6] *is a special case of the* SCR *algorithm with* $\psi_s(\eta) = \eta$ *for all* s.

Proof. The proof is straightforward from the algorithm description in § 2 of [6]. The cost function f is further assumed to be separable. (However, [6] allows *arbitrary* order of relaxation and further establishes convergence to an optimal dual solution (assuming only that an optimal dual solution exists).) □

Note. By applying the results in §§ 4 and 5, we can readily extend many of the methods discussed in this section. As an example, since (cf. Lemma 3(a)) the sequence of primal vectors generated by the BCR iteration remains in a compact subset of S and the entropy cost f_1 is strongly convex in any compact subset of S, the methods described in [2], [8], [21], [23], [24], [31]-[33], [37], [41], [48], [57] can also be implemented using the quasi-cyclic order of relaxation.

7. A parallel line search procedure. In this section, we present a technique for parallelizing the inexact line search step in the SCR iteration when f has a certain separable structure. This technique is most suited for problems where the constraint matrix E has relatively sparse rows.

Suppose that f is *block separable*, in the sense that

$$f(x) = \sum_{J \in \mathcal{D}} f_J(x_J), \tag{7.1}$$

where $\mathcal{D}$ is a collection of nonempty, pairwise disjoint subsets of $M = \{1, \cdots, m\}$ and each $f_J : \Re^{|J|} \to (-\infty, +\infty]$ is strictly convex function ($\mathcal{D} = \{M\}$ is a valid, but uninteresting choice). We will show that the stepsize λ in the SCR iteration, with $\psi_s(\eta) = \eta$, can be calculated in parallel using at most $|\mathcal{D}|$ processors. (Extensions to arbitrary ψ_s and to the BCR iteration are straightforward, but for simplicity we will not consider them here.)

Denote by f_J^* the conjugate function of f_J and, for each $i \in N$, denote

$$\mathcal{D}(i) = \{J \in \mathcal{D} \mid e_{ij} \neq 0 \text{ for some } j \in J\}.$$

For each $i \in N$, let $\{\rho_{iJ}\}_{J \in \mathcal{D}(i)}$ be any set of positive scalars satisfying

$$\sum_{J \in \mathcal{D}(i)} \rho_{iJ} = 1.$$

Let μ be any scalar in the interval $(0, 1)$. For any nonnegative $p \in \Re^n$ and $s \in N$ satisfying $\beta = d_s(p) \geqq 0$ (the case where $\beta < 0$ may be treated analogously), consider the following procedure for computing an inexact line search stepsize λ.

1. For each $J \in \mathcal{D}(s)$, let $h_J : [0, +\infty) \to [0, +\infty)$ be the function $h_J(\theta) = E_{sJ}(\nabla f_J^*(t_J + \theta(E_{sJ})^T) - \nabla f_J^*(t_J))$, where $t_J = (E_{NJ})^T p$. If $h_J(\theta) \leqq \mu\beta\rho_{sJ}$ for all $\theta \geqq 0$, set $\lambda_J = +\infty$; otherwise, compute a λ_J satisfying

$$\mu\beta\rho_{sJ} \leqq h_J(\lambda_J) \leqq \beta\rho_{sJ}. \tag{7.2}$$

2. Set

$$\lambda = \min_{J \in \mathcal{D}(s)} \{\lambda_J\}. \tag{7.3}$$

(If Assumption C holds, then $\mu = 1$ (i.e., exact line search) is also allowable.) Each step in the above procedure can be seen to be parallelizable among $|\mathcal{D}(s)|$ processors. We have the following main result.

PROPOSITION 15. *For any $p \in [0, +\infty)^n$ and any $s \in N$ such that $\beta = d_s(p) > 0$, the scalar λ given by* (7.2), (7.3) *satisfies*

$$(1 - \mu \min_{J \in \mathcal{D}(s)} \{\rho_{sJ}\})\beta \geqq d_s(p + \lambda e^s) \geqq 0. \tag{7.4}$$

Proof. Since f satisfies (7.1), we obtain from (1.2) that $f^*(t) = \sum_{J \in \mathcal{D}} f_J^*(t_J)$ for all $t \in \Re^m$. Hence (cf. (1.4), (1.5))

$$d_s(p + \theta e^s) = b_s - \sum_{J \in \mathcal{D}(s)} E_{sJ} \nabla f_J^*(t_J + \theta(E_{sJ})^T), \quad \forall \theta \in \Re, \tag{7.5}$$

where $t_J = (E_{NJ})^T p$.

We claim that each λ_J is positive and $\lambda < +\infty$. Each λ_J is positive because $h_J(0) = 0$ and (by convexity of f_J^*) $h_J(\theta)$ is monotonically increasing with θ. To see that $\lambda < +\infty$, suppose the contrary. Then it must be true that

$$E_{sJ}(\nabla f_J^*(t_J + \theta(E_{sJ})^T) - \nabla f_J^*(t_J)) = h_J(\theta) < \mu\beta\rho_{sJ}, \quad \forall \theta \geqq 0,$$

for all $J \in \mathcal{D}(s)$. By summing the above inequality over all $J \in \mathcal{D}(s)$ and using (7.5) and $\sum_{J \in \mathcal{D}(s)} \rho_{sJ} = 1$, we obtain

$$-d_s(p + \theta e^s) + \beta < \mu\beta, \quad \forall \theta \geqq 0,$$

or, equivalently,

$$d_s(p + \theta e^s) > \beta(1 - \mu) > 0, \quad \forall \theta \geqq 0.$$

Hence $q(p+\theta e^s)\to+\infty$ as $\theta\to+\infty$, a contradiction of the assumption that (P) is feasible.

Now we prove (7.4). To prove the second inequality in (7.4), note that (cf. (7.2), (7.3), and the fact that h_J is an increasing function)

$$h_J(\lambda)\leqq\beta\rho_{sJ},\quad\forall J\in\mathcal{D}(s),$$

from which it follows that

$$d_s(p+\lambda e^s)=\beta-\sum_{J\in\mathcal{D}(s)}h_J(\lambda)\geqq 0.$$

To prove the first inequality in (7.4), note that since $\lambda<+\infty$, there exists some $\bar{J}\in\mathcal{D}(s)$ for which

$$\mu\beta\rho_{s\bar{J}}\leqq h_{\bar{J}}(\lambda).$$

Since (cf. $\lambda>0$, $h_J(0)=0$, and $h_J(\theta)$ increases with θ) $h_J(\lambda)\geqq 0$ for all $J\in\mathcal{D}(s)$, this implies that

$$\begin{aligned}d_s(p+\lambda e^s)&=\beta-\sum_{J\in\mathcal{D}(s)}h_J(\lambda)\\&\leqq\beta-\mu\beta\rho_{s\bar{J}}.\end{aligned}$$

□

From Proposition 15 and (5.11a) we see that, for the case $\beta\geqq 0$, the procedure (7.2), (7.3) implements the SCR iteration with $\psi_s(\eta)=\eta$ and $\alpha_s=1-\mu\min_{J\in\mathcal{D}(s)}\{\rho_{sJ}\}$.

To illustrate one computational advantage of the procedure (7.2), (7.3), suppose that $\mathcal{D}=\{\{1\},\cdots,\{m\}\}$ and $f_j^*(t_j)=c_j\exp(t_j)$, where each c_j is a positive scalar. Then, instead of computing λ as an approximate zero of $h(\theta)=\sum_{j\in\mathcal{D}(s)}e_{sj}c_j\exp(t_j+\theta e_{sj})$, say, using an iterative method, we simply set (again assuming that $\beta>0$) $\lambda=\min_{j\in\mathcal{D}(s)}\{\lambda_j\}$, where

$$\lambda_j=(\ln(\exp(t_j)-\mu\beta\rho_{sj}/(e_{sj}c_j)-t_j)/e_{sj},$$

if the quantity inside the ln is positive and $\lambda_j=+\infty$ otherwise.

The line search procedure (7.2), (7.3) is particularly well suited for implementation on fine-grained SIMD (Single Instruction Multiple Data) multiprocessors such as the Connection Machine [29]. To see this, note that this procedure uses the *same* sequence of calculations for all coordinates (this is not true for exact line search). Hence we can execute this procedure *simultaneously* for any subset of coordinates. (In particular, we can choose these coordinates to be pairwise uncoupled.) The communication cost for this procedure depends on the architecture of the machine. On the Connection Machine, by assigning $|\mathcal{D}(s)|$ processors to each $s\in N$ and using an implementation technique similar to that used in [65] for network flow problems, the communication cost can be kept very low.

A potential disadvantage of the procedure (7.2), (7.3) is that the stepsize that it generates is too conservative. Initial computational tests on quadratic cost network flow problems suggest that this is not the case, provided that the row of E operated on is relatively sparse. For dense rows, we can use either exact line search or some refinement of the above procedure. For example, we can dynamically adjust the weights $\{\rho_{sJ}\}$ by giving higher values to those ρ_{sJ} for which h_J has a high growth rate near 0 (ideally the λ_J's would be equal). An interesting research topic is that of finding efficient algorithms for performing this adjustment. Also, instead of choosing λ to be the smallest of the λ_J's, we can choose λ to be the λ_J that yields the largest improvement in the dual cost.

8. Conclusion and extensions. In this paper, we have presented a general algorithmic framework for dual coordinate/gradient ascent and have unified a number of existing methods under this framework. There are many directions in which our results can be extended. For example, we can use a *linear convex combination* of directions generated by the BCR iteration for dual ascent. Such an approach was proposed in [11], [12], [30] in the special cases of single coordinate relaxation for quadratic programming and for entropy maximization, but it also applies to the more general case of the BCR iteration for problems where the cost function is differentiable in the relative interior of its effective domain. Alternatively, we can study specialization of the BCR algorithm to special cases that exploit the structure of the problem. For example, can the conjugate gradient method be efficiently adapted for entropy maximization? It is also worthwhile to implement some of these algorithms (on either a sequential or a parallel machine) in order to test their practical efficiency.

ERRATUM: Optimal Control of Strongly Monotone Variational Inequalities*

SHUZHONG SHI†

I thank Professor V. Barbu for showing me that in my paper entitled "Optimal Control of Strongly Monotone Variational Inequalities" [*SIAM J. Control Optim.*, 26 (1988), pp. 274–290], the inequality (4.10) is wrong (except $K = V$) and the second relation of (4.5) is false. This is a serious error; in fact, I must replace $N_K(\bar{y})$ in (4.5) by a significant "directional derivative" of $N_K(\cdot)$ as in Theorem 3.1 of Barbu's book [2], which, unfortunately, I did not read well enough before.

The corrected second relation of (4.5) is as follows:

$$F'(\bar{y})^*\bar{p} \in -D_P N_K(\bar{y}, -F(\bar{y}) - E(\bar{u}))(\bar{p}) + \partial g(\bar{y}) \tag{1}$$

where $N_K(\cdot)$ is the normal cone to K that, as a set-valued map from K to V^*, has a closed graph for the norm topology of K and the weak topology of V^* and where, for $(y, y^*) \in \text{graph}\,(N)$:

$$\begin{aligned} &q^* \in D_P N_K(y, y^*)(p) \Leftrightarrow \\ &\exists h_k \to 0^+ \quad \exists p_k \xrightarrow{w} p \quad \exists (y_k, y_k^*) \in \text{graph}\,(N_K) \xrightarrow{(n,w)} (y, y^*), \\ &\exists y_k^{*p} \in N_K(y_k + h_k p_k) \quad \text{such that } w - \lim_{k\to\infty} (y_k^{*p} - y_k^*)/h_k = q^*. \end{aligned} \tag{2}$$

Certainly, (1.14), (2.7), (4.42), etc. must also be corrected.

Definition (2) is one "generalized directional derivative" of $N_K(\cdot)$ and it also justifies and states precisely the formal notation $D^2\phi(y^*)p^*$ in Theorem 3.1 of [2] (note that this p^* corresponds to our $-\bar{p}$).

There are two definitions of a derivative of a set-valued map, proposed by [1]. However, they are not suitable for (2). Replacing contingent and Clarke's tangent cones and the norm topology, we adapt the paratingent cone and the weak topology for proposing another definition of a derivative of a set-valued map.

Let X be a Hausdorff topological linear space and $K \subset X$. For any $x \in X$,

$$P_K(x) := \lim_{h\to 0+,\ x'\to x} \sup (K - x')/h \tag{3}$$

is called *paratingent cone* to K at x [3], where lim sup is a Kuratowski limit and

$$\begin{aligned} &v \in P_K(x) \Leftrightarrow \\ &\exists x_\alpha \in K \to x \quad \exists h_\alpha \to 0^+ \quad \exists v_\alpha \to v \quad \forall \alpha,\ x_\alpha + h_\alpha v_\alpha \in K. \end{aligned} \tag{4}$$

Let Y be another Hausdorff topological linear space and F a set-valued map from X to Y. Then, the *paratingent derivative* of F at $(x, y) \in \text{graph}\,(F)$, noted by $PF(x, y)$, is a set-valued map from X to Y, defined by

$$\text{graph}\,(PF(x, y)) = P_{\text{graph}(F)}(x, y). \tag{5}$$

* Received by the editors September 1, 1988; accepted for publication February 6, 1989.
† Nankai Institute of Mathematics, Nankai University, Tianjin, People's Republic of China.

From (3) and (4), it is easy to see that

$$
\begin{aligned}
&v \in PF(x, y)(u) \Leftrightarrow \\
&\exists h_\alpha \to 0^+ \quad \exists u_\alpha \to u \quad \exists (x_\alpha, y_\alpha) \in \text{graph}\,(F), \\
&\exists y_\alpha^v \in F(x_\alpha + h_\alpha u_\alpha) \quad \text{such that } \lim_\alpha (y_\alpha^v - y_\alpha)/h_\alpha = v.
\end{aligned} \tag{6}
$$

Comparing (2) and (6) and letting $X = (V, \sigma(V, V^*))$ and $Y = (V^*, \sigma(V^*, V))$, we obtain that

$$
\begin{aligned}
&D_P N_K(y, y^*) \subset PN_K(y, y^*), \quad \text{i.e.,} \\
&\text{graph}\,(D_P N_K(y, y^*)) \subset \text{graph}\,(PN_K(y, y^*)).
\end{aligned} \tag{7}
$$

However, if $X = (V, \|\cdot\|)$, the inclusions in (7) are inverted.

When $V = V^* = X$ is a Hilbert space, Proposition 7.2.11 of [1] also holds for PN_K or $D_P N_K$, i.e., for instance,

$$q \in D_P N_K(x, p)(u) \Leftrightarrow u \in D_P \pi_K(x + p)(u + q)$$

where $\pi_K : X \to K$ is the projector of best approximation onto K. Furthermore, noting that $\bar{p} \in T_K(\bar{y})$ and $\langle -F(\bar{y}) - E(\bar{u}), \bar{p}\rangle_{V^*, V} = 0$, (1) is quite interesting in this case.

To prove (1), we also need the conception of codifferential for a set-valued map with closed convex graph. According to Definition 4.2.1 of [1], the codifferential $DS(y, x)^*$ of a set-valued map S from Banach space Y to Banach space X with closed convex graph at (y, x) is defined by

$$p \in DS(y, x)^*(q) \Leftrightarrow (p, -q) \in N_{\text{graph}(S)}(y, x). \tag{8}$$

The following proposition is Corollary 4.5.3 of [1].

PROPOSITION 1. *Let X and Y be two Banach spaces, $U : X \to \mathbf{R} \cup \{+\infty\}$ a proper lower semicontinuous, convex function and S a set-valued map from Y to X with closed convex graph. We assume that*

$$0 \in \text{Int}\,(\text{Im}\, S - \text{Dom}\, U).$$

Let $W : Y \to \mathbf{R} \cup \{+\infty\}$ be the marginal function defined by

$$W(y) = \inf_{x \in S(y)} U(x)$$

and let $\bar{x} \in S(\bar{y})$ achieve the minimum of U on $S(\bar{y})$. The subdifferential of the marginal function W is equal to

$$\partial W(\bar{y}) = DS(\bar{y}, \bar{x})^* \, \partial U(\bar{x}).$$

Proof. At first, for simplicity, we assume that $M_n(\cdot, \cdot)$, defined by (4.9), is a continuous single-valued map for the norm topology of $K \times U_{\text{ad}}$ and the weak topology of $N_n B_V$. If K and B_V are strictly convex, this assumption holds. Then, setting

$$p_{nk}^{sw} = M_n(y_n + t_k s, u_n + t_k w),$$

we must replace (4.10) by

$$
\begin{aligned}
&g(y_n + t_k s) + h(u_n + t_k w) - \langle F(y_n + t_k s) + E(u_n + t_k w), p_{nk}^{sw}\rangle_{V^*, V} \\
&\quad > g(y_n) + h(u_n) - \langle F(y_n) + E(u_n), p_{nk}^{sw}\rangle_{V^*, V} - \varepsilon_n t_k (\|s\|_V^2 + \|w\|_U^2)^{1/2} \\
&\quad + \inf_{p \in N_n[(K - y_n - t_k s) \cap B_V]} \langle F(y_n) + E(u_n), p\rangle_{V^*, V} \\
&\quad - \inf_{p \in N_n[(K - y_n) \cap B_V]} \langle F(y_n) + E(u_n), p\rangle_{V^*, V}.
\end{aligned} \tag{9}
$$

Define a set-valued map S_n from V to V by

$$S_n(x) := N_n[(K - y_n - x) \cap B_V], \tag{10}$$

a function $U_n : V \to \mathbf{R}$ by

$$U_n(p) := \langle F(y_n) + E(u_n), p\rangle_{V^*,V}, \tag{11}$$

and a marginal function $W_n : V \to \mathbf{R} \cup \{+\infty\}$ by

$$W_n(x) := \inf_{p \in S_n(x)} U_n(p). \tag{12}$$

Then, (4.15) must be replaced by

$$\begin{aligned} &g^0(y_n; s) + h'(u_n; w) - \langle F'(y_n)s + E'(u_n)w, p_n\rangle_{V^*,V} - W_n'(0; s) \\ &\quad \geqq -\varepsilon_n(\|s\|_V^2 + \|w\|_U^2)^{1/2} \end{aligned} \tag{13}$$

where $p_n = M_n(y_n, u_n)$. Thus, replacing (4.19) and (4.20), we have that

$$\forall s \in K - y_n, \quad g^0(y_n; s) - \langle F'(y_n)^* p_n, s\rangle_{V^*,V} - W_n'(0; s) \geqq -\varepsilon_n \|s\|_V, \tag{14}$$

$$\forall w \in U_{\text{ad}} - u_n, \quad h'(u_n; w) - \langle E'(u_n)^* p_n, w\rangle_{U^*,U} \geqq -\varepsilon_n \|w\|_U. \tag{15}$$

Applying Proposition 1, we have that

$$\partial W_n(0) = DS_n(0, p_b)^*(F(y_n) + E(u_n)). \tag{16}$$

So, from (14) and (16), we obtain that

$$F'(y_n)^* p_n \in N_K(y_n) - DS_n(0, p_n)^*(F(y_n) + E(u_n)) + \partial g(y_n) + \varepsilon_n B_{V^*}. \tag{17}$$

By using the same method as in our paper, we still have (4.29), i.e.,

$$y_n \to \bar{y} \quad \text{in } K \text{ strongly.} \tag{18}$$

We must show that $\{p_n\}$ is bounded and after that, we can assume that

$$p_n \to \bar{p} \quad \text{in } V \text{ weakly,} \tag{19}$$

and deduce (4.34), i.e.,

$$u_n \to \bar{u} \quad \text{in } U_{\text{ad}} \text{ strongly,} \tag{20}$$

provided by extracting a subsequence. In fact, by (14) and (4.31), we have that

$$g^0(y_n; p_n) + \varepsilon_n \|p_n\|_V - W_n'(0, p_n) \geqq \langle F'(y_n)p_n, p_n\rangle_{V^*,V} \geqq C\|p_n\|_V^2. \tag{21}$$

We must show that

$$-W_n'(0; p_n) \leqq O(\|p_n\|_V). \tag{22}$$

Indeed, for $t > 0$ and for any $x \in S_n(tp_n)$, by (10), we have

$$x + tN_n p_n \in N_n(K - y_n)$$

and

$$x + tN_n p_n \in N_n B_V + tN_n p_n \subset N_n(1 + t\|p_n\|_V)B_V$$

and then,

$$\begin{aligned} x + tN_n p_n &\in N_n(K - y_n) \cap N_n(1 + t\|p_n\|_V)B_V \subset N_n(1 + t\|p_n\|_V)\{(K - y_n) \cap B_V\} \\ &= (1 + t\|p_n\|_V)S_n(0). \end{aligned}$$

Hence,

$$S_n(tp_n) \subset (1+t\|p_n\|_V)S_n(0) - tN_n p_n$$

and thus, from (11) and (12), we have that

$$\begin{aligned} W_n'(0, p_n) &= \lim_{t\to 0^+} \frac{\inf_{p\in S_n(tp_n)} U_n(p) - \inf_{p\in S_n(0)} U_n(p)}{t} \\ &\geqq \frac{\inf_{p\in(1+t\|p_n\|_V)S_n(0)} U_n(p) - \inf_{p\in S_n(0)} U_n(p) - tN_n U_n(p_n)}{t} \\ &= -\|p_n\|_V \cdot N_n\| - F(y_n) - E(u_n)\|_{y_n}^K + N_n\langle -F(y_n) - E(u_n), p_n\rangle \\ &\geqq -\|p_n\|_V \cdot N_n\| - F(y_n) - E(u_n)\|_{y_n}^K. \end{aligned}$$

By using (4.22), we deduce (22), and from (21) and (22), it follows that $\{p_n\}$ is bounded.

Now we consider (17). From (18) and (19), we know that $\{F'(y_n)^* p_n\}$ converges weakly. On the other hand, since $\partial g(\cdot)$ is locally bounded, $\{\partial g(y_n)\}$ is relatively weakly compact. Hence, by extracting a subsequence, we can assume that there are two sequences $u_n^* \in N_K(y_n)$ and $v_n^* \in DS_n(0, p_n)^*(F(y_n)+E(u_n))$ such that $w-\lim_{n\to\infty}(u_n^* - v_n^*) = w^*$ exists. We show that for large n,

$$v_n^* \in N_n \cdot N_K\left(y_n + \left(\frac{1}{N_n}\right)p_n\right). \tag{23}$$

In fact, from (8), we have that

$$(v_n^*, F(y_n) - E(u_n)) \in N_{\text{graph}(S_n)}(0, p_n). \tag{24}$$

Set

$$\hat{S}_n(v) := N_n(K - y_n - v) \quad \text{and} \quad B_n(v) \equiv N_n B_V. \tag{25}$$

Then from (10) it follows that

$$S_n(v) = \hat{S}_n(v) \cap B_n(v) \tag{26}$$

and, joining up with (25) and Theorem 4.1.16 of [1],

$$(v_n^*, -F(y_n) - E(u_n)) \in N_{\text{graph}(\hat{S}_n)}(0, p_n) + N_{\text{graph}(B_n)}(0, p_n). \tag{27}$$

But $\{p_n\}$ is bounded, and so for large n

$$(0, p_n) \in \text{Int graph}\,(B_n).$$

Hence,

$$N_{\text{graph}(B_n)}(0, p_n) = \{0\}$$

and thus from (27) we obtain that, for large n,

$$(v_n^*, -F(y_n) - E(u_n)) \in N_{\text{graph}(\hat{S}_n)}(0, p_n). \tag{28}$$

By (25), it means that

$$\forall v \in V \quad \forall w \in N_n(K - y_n - v), \quad \langle v_n^*, v\rangle_{V^*,V} - \langle F(y_n) + E(u_n), w - p_n\rangle_{V^*,V} \leqq 0 \tag{29}$$

and follows that

$$v_n^* = -N_n(F(y_n) + E(u_n)) \tag{30}$$

and

$$(31)\qquad \forall w \in N_n(K - y_n),\quad \langle -(F(y_n) + E(u_n)),\, w - p_n\rangle_{V^*,V} \leqq 0,\quad \text{i.e.,}$$

$$-(F(y_n) + E(u_n)) \in N_K\left(y_n + \frac{1}{N_n} p_n\right),$$

which, indeed, is the definition of p_n. Therefore, from (30) and (31), (23) holds.

Finally, since we also have $u_n^*/N_n \in N_K(y_n)$, by the definition (2), we conclude $w^* \in -D_P N_K(\bar{y}, -F(\bar{y}) - E(\bar{u}))(\bar{p})$, i.e., we complete the proof for the case in which all $M_n(\cdot,\cdot)$ are single-valued.

Now we exclude the singleton assumption of $M_n(\cdot,\cdot)$. Define

$$L_n(y, u) := N_n \| -F(y) - E(u) \|_y^K.$$

Then, by using Proposition 3.2.24 of [1], it is easy to see that $L_n(y, u)$ is locally Lipschitz in a neighborhood of $K \times U_{\text{ad}}$. Hence, (4.15) may be replaced by

$$(32)\qquad g^0(y_n; s) + h'(u_n; w) + L_n^0(y_n, u_n; s, w) \geqq -\varepsilon_n(\|s\|_V^2 + \|w\|_U^2)^{1/2}$$

where $L_n^0(y_n, u_n; s, w)$ is a Clarke directional derivative of L_n, and thus, for any $s \in K - y_n$ and $w \in U_{\text{ad}} - u_n$, there exists $q_n^{sw*} \in \partial L_n(y_n, u_n)$ such that

$$(33)\qquad g^0(y_n; s) + h'(u_n; w) + \langle q_n^{sw*}, (s, w)\rangle_{V^* \times U^*, V \times U} \geqq -\varepsilon_n(\|s\|_V^2 + \|w\|_U^2)^{1/2}.$$

Consider the function $Q : [(K - y_n) \times (U_{\text{ad}} - u_n)] \times \partial L_n(y_n, u_n) \to \mathbf{R}$, defined by

$$(34)\quad Q(s, w; q^*) := g^0(y_n; s) + h'(u_n; w) + \langle q^*, (s, w)\rangle_{V^* \times U^*, V \times U} + \varepsilon_n(\|s\|_V^2 + \|w\|_U^2)^{1/2}.$$

Then, by using the same method as in our paper, we can conclude that there exists $q_n^* \in \partial L_n(y_n, u_n)$ such that

$$\inf_{(s,w)} Q(s, w; q_n^*)$$

$$= \inf_{(s,w)} [g^0(y_n; s) + h'(u_n; w) + \langle q_n^*, (s, w)\rangle_{V^* \times U^*, V \times U} + \varepsilon_n(\|s\|_V^2 + \|w\|_U^2)^{1/2}] \geqq 0,$$

i.e.,

$$(35)\qquad \begin{aligned} &\forall s \in K - y_n \quad \forall w \in U_{\text{ad}} - u_n, \\ &g^0(y_n; s) + h'(u_n; w) + \langle q_n^*, (s, w)\rangle_{V^* \times U^*, V \times U} \geqq -\varepsilon_n(\|s\|_V^2 + \|w\|_U^2)^{1/2}. \end{aligned}$$

We must know what $\partial L_n(y_n, u_n)$ is. We will use a proposition as follows.

PROPOSITION 2. *Let $S_n(\cdot,\cdot)$ be a set-valued map from $V \times V$ to V, defined by*

$$S_n(x, z) := N_n[(K - y_n - z - x) \cap B_V]$$

$$U_n(z, v, p) := \langle F(y_n + z) + E(u_n + v), p\rangle_{V^*,V}$$

and a marginal function

$$W_n(z, v, x) := \inf_{p \in S_n(z,v,x)} U_n(z, v, x).$$

Then W_n is a locally Lipschitz function on a neighborhood of $(K - y_n) \times (U_{\text{ad}} - u_n) \times \{0\}$ and its partial generalized gradient with respect to x at $(z, v, 0)$, $\partial_x W_n(z, v, 0)$, is locally bounded and upper semicontinuous with respect to (z, v) for the norm topology of $(K - y_n) \times (U_{\text{ad}} - u_n)$ and the weak topology of V^*.

The first part of this proposition is also from Proposition 3.2.24 of [1] and its second part is well known.

Now, suppose that for $t_k \to 0^+$, $z_k \in V \to 0$, and $v_k \in U \to 0$,

$$L_n^0(y_n, u_n; s, w) = \lim_{k\to\infty} \{L_n(y_n + z_k + t_k s, u_n + v_k + t_k w) - L_n(y_n + z_k, u_n + v_k)\}/t_k.$$

Since

$$\begin{aligned}
&L_n(y_n + z_k + t_k s, u_n + v_k + t_k w) - L_n(y_n + z_k, u_n + v_k) \\
&\quad \leqq \langle -F(y_n + z_k + t_k s) - E(u_n + v_k + t_k w), \hat{p}_{nk}^{sw} \rangle_{V^*,V} \\
&\qquad - \langle -F(y_n + z_k) - E(u_n + v_k), \hat{p}_{nk}^{sw} \rangle_{V^*,V} \\
&\qquad - \inf_{p \in N_n\{(K - y_n - z_k - t_k s) \cap B_V\}} \langle F(y_n + z_k) + E(u_n + v_k), p \rangle_{V^*,V} \\
&\qquad + \inf_{p \in N_n\{(K - y_n - z_k) \cap B_V\}} \langle F(y_n + z_k) + E(u_n + v_k), p \rangle_{V^*,V} \\
&\quad = \langle -F(y_n + z_k + t_k s) - E(u_n + v_k + t_k w), \hat{p}_{nk}^{sw} \rangle_{V^*,V} \\
&\qquad - \langle -F(y_n + z_k) - E(u_n + v_k), \hat{p}_{nk}^{sw} \rangle_{V^*,V} - W_n(z_k, v_k, t_k s) + W_n(z_k, v_k, 0)
\end{aligned}$$

where $\hat{p}_{nk}^{sw} \in M_n(y_n + z_k + t_k s, u_n + v_k + t_k w)$ and $W_n(\cdot, \cdot, \cdot)$ is defined as in Proposition 2. Obviously,

$$\begin{aligned}
&\lim_{k\to\infty} \{\langle -F(y_n + z_k + t_k s) - E(u_n + v_k + t_k w), \hat{p}_{nk}^{sw} \rangle_{V^*,V} \\
&\qquad - \langle -F(y_n + z_k) - E(u_n + v_k), \hat{p}_{nk}^{sw} \rangle_{V^*,V}\}/t_k = \langle -F'(y_n)s - E'(u_n)w, p_n^{sw} \rangle_{V^*,V}
\end{aligned}$$

where $p_n^{sw} \in M_n(y_n, u_n)$. On the other hand, by the Mean-Value Theorem, there exist $\theta_k \in (0, 1)$ and $r_{nk}^* \in \partial_x W_n(z_k, v_k, \theta_k t_k s)$ such that

$$W_n(z_k, v_k, t_k s) - W_n(z_k, v_k, 0) = \langle r_{nk}^*, t_k s \rangle_{V^*,V}.$$

Using Proposition 2 and extracting a subsequence, we can assume that

$$w - \lim_{k\to\infty} r_{nk}^* = r_n^* \in \partial_x W_n(0, 0, 0) = \partial W_n(0)$$

where $W_n(\cdot)$ is defined as (12) and

$$\lim_{k\to\infty} \{W_n(z_k, v_k, t_k s) - W_n(z_k, v_k, 0)\}/t_k = \langle -r_n^*, s \rangle_{V^*,V} \leqq -W_n'(0; s).$$

Thus, we obtain that

$$L_n^0(y_n, u_n; s, w) \leqq \langle -F'(y_n)s - E'(u_n)w, p_n^{ws} \rangle_{V^*,V} - W_n'(0; s)$$

with $p_n^{ws} \in M_n(y_n, u_n)$, and then, for any s and w,

$$L_n^0(y_n, u_n; s, w) \leqq \sup_{p \in M_n(y_n, u_n)} \{\langle -F'(y_n)^* p, s \rangle_{V^*,V} + \langle -E'(u_n)^* p, w \rangle_{U^*,U}\} - W_n'(0; s).$$

It follows that

$$\partial L_n(y_n, u_n) \subset \bigcup_{p \in M_n(y_n, u_n)} (-F'(y_n)^* p, -E'(u_n)^* p) - (\partial W_n(0), 0).$$

Therefore, for any $q_n^* \in \partial L_n(y_n, u_n)$, there exists a $p_n \in M_n(y_n, u_n)$ such that

$$q_n^* \in (-F'(y_n)^* p_n, -E'(u_n)^* p_n) - (\partial W_n(0), 0).$$

Joining with (35), it deduces that (14) and (15) hold again. Furthermore, by using Proposition 1, (16) holds for every $p_n \in M_n(y_n, u_n)$. Hence, (17) holds also. Thus, it reduces to the first case.

ERRATUM AND ADDENDUM: Positive Semidefinite Matrices: Characterization via Conical Hulls and Least-Squares Solution of a Matrix Equation*

J. C. ALLWRIGHT† AND K. G. WOODGATE‡

Contrary to Theorem 3.1, the optimization problem

$$\text{(P1)} \qquad \min_{A \in S_{\geqq}^n} \|F - AG\|_F$$

does not necessarily have a solution when $\text{rank}\,[G] < n$, where $F, G \in R^{n\times m}$ and $S_{\geqq}^n = \{A \in R^{n\times n}: A' = A \geqq 0\}$. For example, consider Woodgate's counterexample, which initiated this note:

$$F = \begin{bmatrix} -1 \\ 1 \end{bmatrix}, \qquad G = \begin{bmatrix} 1 \\ 0 \end{bmatrix},$$

for which $\inf_{A \in S_{\geqq}^2} \|F - AG\|_F = 1$ but is not achieved by any $A \in S_{\geqq}^2$.

Theorem 3.1 should actually have been as follows.

THEOREM 3.1′. *The minimum in* (P1) *exists when* $\text{rank}\,[G] = n$.

The *error* in the proof of Theorem 3.1 for the case $\text{rank}\,[G] < n$ is caused by the incorrect statement in the penultimate paragraph of page 546 that the set $\text{vec}\,(S_{BC0})$ is closed, where S_{BC0}, of (3.31), is defined by

$$S_{BC0} = \left\{ \begin{bmatrix} B & C \\ C' & 0 \end{bmatrix} : \begin{bmatrix} B & C \\ C' & D \end{bmatrix} \in S_{\geqq}^n \right\}.$$

This set, and hence $\text{vec}\,(S_{BC0})$, is not closed because, for any nonzero C, the matrix $\begin{bmatrix} 0 & C \\ C' & 0 \end{bmatrix}$ is a limit point of S_{BC0} which is not in S_{BC0}.

Suppose now that $\text{rank}\,[G] < n$.

If (P1) actually has a minimum, then the results of § 3 apply. If (P1) does not have a minimum, then it is easy to check that those results, and their proofs, still apply when all occurrences of the nonexistent minimal value $\|F - \hat{A}G\|_F$ are replaced by $\inf\{\|F - AG\|_F: A \in S_{\geqq}^n\}$. Then the methodology of § 3 for finding an $\tilde{A} \in S_{\geqq}^n$ which solves (P1) to prespecified accuracy actually yields an $\tilde{A}$ such that $\|F - \tilde{A}G\|_F$ approximates $\inf\{\|F - AG\|_F: A \in S_{\geqq}^n\}$ to prespecified accuracy—which, from the practical point of view, is just as good.

It is possible to say more for the case when $\text{rank}\,[G] < n$.

From (3.37), for $A \in S_{\geqq}^n$,

$$\text{(A1)} \qquad \|F - AG\|_F^2 = \|F_1 - BG_1\|_F^2 + \|F_2 - C'G_1\|_F^2$$

when A is partitioned as

$$A = Q' \begin{bmatrix} B & C \\ C' & D \end{bmatrix} Q.$$

Since rank $[G_1] = q$ and $B \in S_{\geqq}^q$, it follows from Theorem 3.1′ above that there is a $\hat{B}$ which minimizes $\|F_1 - BG_1\|_F^2$ with respect to $B \in S_{\geqq}^q$. If $\tilde{C} = (F_2 G_1^\dagger)'$ and $R[\tilde{C}] \subset R[\hat{B}]$, then

$$A^* = Q' \begin{bmatrix} \hat{B} & \tilde{C} \\ \tilde{C}' & D \end{bmatrix} Q$$

is optimal for (P1) for any $D \in S_{\geqq}^{n-q}$ such that $D \geqq \tilde{C}' \hat{B}^\dagger \tilde{C}$. This occurs because it follows from (3.36) that $A^* \in S_{\geqq}^n$ and from (A1) above that $\hat{B}$ and $\tilde{C}$ minimize the right-hand side of (A1) with respect to $B \in S_{\geqq}^q$ and $C \in R^{q \times (n-q)}$. Hence (P1) certainly has a minimum when $R[\tilde{C}] \subset R[\hat{B}]$. In fact the following holds.

THEOREM A1. *If* rank $[G] < n$, *then* (P1) *has a minimum if and only if* $R[\tilde{C}] \subset R[\hat{B}]$.

Proof. In view of the above, it just remains to be shown that there is no minimum when $R[\tilde{C}] \not\subset R[\hat{B}]$.

Suppose that $R[\tilde{C}] \not\subset R[\hat{B}]$ and that there is a minimum, say at $A^0 \in S_{\geqq}^n$. Partition A^0 as

$$A^0 = Q' \begin{bmatrix} B^0 & C^0 \\ C^{0\prime} & D^0 \end{bmatrix} Q,$$

where, from (3.36), $B^0 \in S_{\geqq}^q$ and $R[C^0] \subset R[B^0]$.

If $C^0 = \tilde{C}$ then $B^0 \neq \hat{B}$. For suppose $B^0 = \hat{B}$. Then $R[C^0] \subset R[B^0] = R[\hat{B}]$, so that, because the case $C^0 = \tilde{C}$ is being considered, $R[\tilde{C}] \subset R[\hat{B}]$, which contradicts the initial assumption that $R[\tilde{C}] \not\subset R[\hat{B}]$. Since rank $[G_1] = q$, Theorem 3.2 reveals that $\hat{B}$ is the unique global minimizer of $\|F_1 - BG_1\|_F^2$ with respect to $B \in S_{\geqq}^q$ so, since $B^0 \in S_{\geqq}^q$ and $B^0 \neq \hat{B}$, $\|F_1 - B^0 G_1\|_F^2 > \|F_1 - \hat{B} G_1\|_F^2$.

On the other hand, if $C^0 \neq \tilde{C}$ then $\|F_2 - C^{0\prime} G_1\|_F^2 > \|F_2 - \tilde{C}' G_1\|_F^2$, because, since rank $[G_1] = q$, $\tilde{C}$ is the unique minimizer of $\|F_2 - C' G_1\|_F^2$ with respect to $C \in R^{q \times (n-q)}$. Also $\|F_1 - B^0 G_1\|_F^2 \geqq \|F_1 - \hat{B} G_1\|_F^2$ owing to the optimality of $\hat{B}$.

Hence, whether $C^0 = \tilde{C}$ or $C^0 \neq \tilde{C}$,

$$\begin{aligned} \|F - A^0 G\|_F^2 &= \|F_1 - B^0 G_1\|_F^2 + \|F_2 - C^{0\prime} G_1\|_F^2 \\ &> \|F_1 - \hat{B} G_1\|_F^2 + \|F_2 - \tilde{C}' G_1\|_F^2 \\ &= \inf \{\|F - AG\|_F^2 : A \in S_{\geqq}^n\} \end{aligned}$$

where the first equality is from (A1) and the last equality is from (3.12) with $\|F - \hat{A} G\|_F^2$ replaced by $\inf \{\|F - AG\|_F^2 : A \in S_{\geqq}^n\}$, as mentioned earlier in this note. This contradicts the optimality of A^0 and therefore contradicts the existence of a minimum for (P1) when $R[\tilde{C}] \not\subset R[\hat{B}]$, which completes the proof. □

A final point is that it is possible to slightly modify the perturbations made in Theorem 3.5 in order to cause $\tilde{B}$ to be positive definite, as it is only necessary that they cause $\tilde{B}$ to be positive semidefinite with $R[\tilde{C}] \subset R[\tilde{B}]$.

OPTIMAL CONTROL FOR AN INFINITE-DIMENSIONAL PERIODIC PROBLEM UNDER WHITE NOISE PERTURBATIONS*

CONSTANTIN TUDOR†

Abstract. In this paper a result of the type of "law of large numbers" is obtained for the infinite-dimensional version of the linear quadratic cost problem in the periodic case if the deterministic optimal feedback law is used in the presence of white noise perturbations.

Key words. optimal control, periodic problem, law of large numbers

AMS(MOS) subject classifications. 49B, 93E

1. Introduction. In this paper we are concerned with a stochastic linear infinite-dimensional control system of Ito type with periodic coefficients.

We associate an optimization problem, which is natural for the periodic case, with the cost $\int_0^\theta y(t)\,dt$, where θ is the period and y is a process depending quadratically on the control. Now it is clear in the usual deterministic situation that

$$\int_0^\theta y(t)\,dt = \lim_{n\to\infty} \frac{1}{n}\int_0^{n\theta} y(t)\,dt$$

and this suggests that in the stochastic case we use results of the type of the "law of large numbers" by considering cost functions of the form $\overline{\lim}_{n\to\infty}(1/n)\int_0^{n\theta} y(t)\,dt$.

In the finite-dimensional case such results of the "law of large numbers" type have been considered by Mandl [15] for stationary systems and by Halanay, Tudor, and Morozan [11] for almost periodic systems. The periodic infinite-dimensional deterministic case with a cost of the form $\int_0^\theta y(t)\,dt$ has been considered by Da Prato [5]; the periodic infinite-dimensional stochastic case with a cost of the form $E\int_0^\theta y(t)\,dt$ has been considered by Da Prato and Ichikawa [7], [8]; Da Prato and Ichikawa [6] have also considered the case of almost periodic forcing terms, with the cost $\lim_{T\to\infty}(1/T)E\int_0^T y(t)\,dt$. The optimal control has been obtained by Da Prato in [5] as an affine function of the state with the aid of the periodic solution of a Riccati equation and it has been seen that this control is still optimal in the corresponding stochastic setting with expected cost.

The main contribution of the present paper is that it shows that the same control is optimal almost surely with respect to the cost $\overline{\lim}_{n\to\infty}(1/n)\int_0^{n\theta} y(t)\,dt$.

2. Notation and hypotheses. Let M, K, U be real separable Hilbert spaces and let $\theta > 0$. $L(K, H)$ (shortly $L(H)$ if $H = K$) denote the Banach space of all bounded linear operators from K to H. $\Sigma(H) = \{\Pi \in L(H);\ \Pi = \Pi^*\}$, $\Sigma^+(H) = \{\Pi \in \Sigma(H);\ \Pi \geqq 0\}$, where Π^* represents the adjoint of Π. By Ex we denote the expectation of the random variable x, by $\operatorname{Tr}\Pi$ the trace of the operator Π and if X is a topological space we will denote by $\mathcal{B}_X$ the σ-algebra of Borel sets in X. Let $(\Omega, \mathcal{F}, P, (\mathcal{F}_t)_{t\in R})$ be a filtered probability space and let $\{w(t)\}_{t\in R}$ be a K-valued $\mathcal{F}_t$-Wiener process with W as covariance operator ([16]).

DEFINITION. $U(\cdot,\cdot):\{(t, s);\ 0 \leqq s \leqq t\} \to L(H)$ is an evolution operator if

(2.1) $U(t, t) = I$, the idenity operator, for all t,

* Received by the editors December 4, 1987; accepted for publication (in revised form) April 24, 1989.
† Faculty of Mathematics, University of Bucharest, Street Academiei 14, 70109 Bucharest, Romania.

(2.2) $U(t, r)U(r, s) = U(t, s), 0 \leqq s \leqq r \leqq t,$

(2.3) $U(t, s)$ is strongly continuous in s on $[0, t]$ and strongly continuous in t on $[s, \infty)$,

(2.4) For every $T > 0$ there is a constant C_T such that

$$\| U(t, s) \|_{L(H)} \leqq C_T, 0 \leqq s \leqq t \leqq T.$$

It should be noted that (2.4) does not follow from (2.1)-(2.3) as is sometimes supposed (see [10] for a counterexample).

DEFINITION. A strong evolution operator is an evolution operator for which there exists a closed, linear, densely defined operator $A(t)$, $t \geqq 0$, with the domain $D(A(t))$, such that

(2.5) $$U(t, s) : D(A(s)) \to D(A(t)) \quad \text{for } t > s,$$

(2.6) $$\frac{\partial}{\partial t} U(t, s)h = A(t)U(t, s)h \quad \text{for } h \in D(A(s)), \quad t > s.$$

We will assume the following hypotheses (such as Da Prato [5]):

(2.7) (a) For every $t \in R$, $A(t)$ is a closed, linear, densely defined operator and the map $t \to A(t)$ is θ-periodic;
(b) $A(t)$ generates a strong evolution operator $\{U(t, s)\}$;
(c) There exists the Yosida approximation $A_n(t) = n^2[n - A(t)]^{-1} - nI$ for n sufficiently large. Moreover, if $g \in L^2([0, \theta], H)$ and $z(t) = U(t, 0)x + \int_0^t U(t, s)g(s)\, ds$, z_n is the strict solution of $z'(t) = A_n(t)z_n(t) + g(t)$, $z_n(0) = x$, then $\sup_{t \leqq \theta} |z_n(t) - z(t)| \to 0$.

Remark 2.1. From (2.7)(a)-(c) we have that $U(t + \theta, s + \theta) = U(t, s)$ for all $t > s$.

Remark 2.2. Conditions (2.7)(b), (c) are fulfilled if the usual hypotheses of Tanabe and Kato-Tanabe are satisfied [19]:

(2.8) (a) $B : R \to L(U, H)$, $G : R \to L(K, H)$ are θ-periodic and strongly continuous,
(b) $f : R \to H$ is θ-periodic and $f \in L^2([0, \theta], H)$,
(c) $M : R \to \Sigma^+(H)$, $N : R \to \Sigma^+(U)$ are θ-periodic, strongly continuous, and $N(t) \geqq \gamma I$, $\gamma > 0$, for all t.

(2.9) 1 belongs to the resolvent set of $U(\theta, 0)$.

(2.10) *Stabilizability.* There exist a θ-periodic function $C : R \to L(H, U)$ strongly continuous and $\alpha, \beta > 0$ such that $\| U_{A-BC}(t, s) \|_{L(H)} \leqq \alpha \exp\{-\beta(t - s)\}$ for all $s \leqq t$, where U_{A-BC} is the evolution operator relative to $A - BC$.

(2.11) *Detectability.* There exists a θ-periodic function $C_1 : R \to L(H)$ strongly continuous and $\alpha_1, \beta_1 > 0$ such that $\| U_{A-C_1M^{1/2}}(t, s) \|_{L(H)} \leqq \alpha_1 \exp\{-\beta_1(t - s)\}$ for all $s \leqq t$, where $U_{A-C_1M^{1/2}}$ is the evolution operator relative to $A - C_1M^{1/2}$.

3. A class of random processes in Hilbert spaces. Let ξ be a H-valued $\mathcal{F}_a$-measurable random element $(a \in R)$ and let $\{V(t, s)\}$ be an evolution operator that is θ-periodic, i.e., $V(t + \theta, s + \theta) = V(t, s)$ for all $s \leqq t$. Let $g : R \to H$ be continuous, θ-periodic, and let $G : R \to L(K, H)$ be strongly continuous and θ-periodic.

PROPOSITION 3.1. *Under the above assumptions the process*

$$x(t,\xi)=V(t,a)\xi+\int_a^t V(t,s)g(s)\,ds+\int_a^t V(t,s)G(s)\,dw(s),\qquad t\geqq a \tag{3.1}$$

is a Markov process with the transition function $P(s,h,t,A)$ θ*-periodic, i.e.,* $P(s+\theta,h,t+\theta,A)=P(s,h,t,A)$ *for all* $a\leqq s\leqq t$, $h\in H$, $A\in\mathcal{B}_H$. *Moreover, if* V *is exponentially stable, i.e., if there is* α_2, $\beta_2>0$ *such that*

$$\|V(t,s)\|_{L(H)}\leqq\alpha_2\exp\{-\beta_2(t-s)\}\quad \textit{for all } s\leqq t, \tag{3.2}$$

and $E(|\xi|^4)<\infty$, *then* $\sup_{t\geqq a}E(|x(t,\xi)|^4)<\infty$.

Proof. The Markov property of $x(t,\xi)$ is shown in [1]. Let $x(t,s,\xi)_{t\geqq s}$ be the process defined by

$$x(t,s,\xi)=V(t,s)\xi+\int_s^t V(t,u)g(u)\,du+\int_s^t V(t,u)G(u)\,dw(u). \tag{3.3}$$

Then $P(s,h,t,A)=P(x(t,s,h)\in A)$ and the θ-periodicity of the transition function follows at once from the θ-periodicity of V, g, G and the stationarity of w.

Assume now that V is stable and $E(|\xi|^4)<\infty$. We have

$$E(|V(t,a)\xi|^4)\leqq\alpha_2^4E(|\xi|^4),$$

$$\left|\int_0^t V(t,s)g(s)\,ds\right|\leqq\frac{\alpha_2}{\beta_2}\sup_s|g(s)|.$$

Recall that if y is a Gaussian random element with mean zero and covariance Π, then

$$E(|y|^{2n})\leqq(2n-1)!!(\operatorname{Tr}\Pi)^n \tag{3.4}$$

for any integer n, where $(2n-1)!!=(2n-1)(2n-3)\cdots 5.3.1$.

Since the stochastic integral $\int_0^t V(t,s)G(s)\,dw(s)$ is Gaussian with mean zero and covariance

$$\int_0^t V(t,s)G(s)WG^*(s)V^*(t,s)\,ds,$$

then by using (3.4) we obtain

$$\begin{aligned}
&E\left(\left|\int_0^t V(t,s)G(s)\,dw(s)\right|^4\right)\\
&\quad\leqq 3\left\{\int_0^t\operatorname{Tr}[V(t,s)G(s)WG^*(s)V^*(t,s)]\,ds\right\}^2\\
&\quad\leqq 3(\operatorname{Tr}W)^2\sup_s\|G(s)\|^4_{L(K,H)}\left[\int_0^t\|V(t,s)\|^2_{L(H)}\,ds\right]^2\\
&\quad\leqq\frac{3\alpha_2^4(\operatorname{Tr}W)^2}{4\beta_2^2}\sup_s\|G(s)\|^4_{L(K,H)}.
\end{aligned}$$

Now it remains to apply the inequality $|x+y+z|^4\leqq 27(|x|^4+|y|^4+|z|^4)$, x, y, $z\in H$.

PROPOSITION 3.2. *Let* $\{x_n(t)\}_{t\geqq -n}$ *be the process defined by* (3.1) *for* $a=-n$ *and* $\xi=0$. *Then we have the following*:

(a) *For every* t, $x_n(t)$ *converges in* $L^2(\Omega,\mathcal{F},P)$ *to* $x(t)$ *and the process* $\{x(t)\}_{t\in R}$ *is measurable,* $\mathcal{F}_t$*-adapted, and* $t\to x(t):R\to L^2(\Omega,\mathcal{F},P)$ *is continuous.*

(b) *The following inequality holds*:

$$\sup_t E(|x(t)|^4) < \infty. \tag{3.5}$$

(c) $\{x(t)\}$ *is a* θ*-periodic Markov process and for* $t \geqq s$

$$x(t) = V(t, s)x(s) + \int_s^t V(t, r)g(r)\, dr + \int_s^t V(t, r)G(r)\, dw(r) \quad P\text{-a.s.} \tag{3.6}$$

We will denote the process $x(t)$ *by*

$$x(t) = \int_{-\infty}^t V(t, s)g(s)\, ds + \int_{-\infty}^t V(t, s)G(s)\, dw(s). \tag{3.7}$$

We proceed as in [17].

Proof. (a) Recall that

$$\sup_{t \geqq -n} E(|x_n(t)|^4) \leqq \gamma_1 < \infty \quad \text{(see Proposition 3.1).} \tag{3.8}$$

If $t \geqq -n > -m$ we have

$$\begin{aligned} E(|x_m(t) - x_n(t)|^2) &= E(|V(t, -n)x_m(-n)|^2) \\ &\leqq \alpha_2^2 \exp\{-2\beta_2(t+n)\} E(|x_m(-n)|^2) \\ &\leqq \gamma_2 \exp(-2\beta_2 n) \to 0 \end{aligned}$$

as $n \to \infty$, uniformly on every interval $[\alpha, \infty)$, $\alpha \in R$. Then the process $x(t) = \lim_{n\to\infty} x_n(t)$ (L^2-limit) is measurable, adapted and $t \to x(t) : R \to L^2(\Omega, \mathcal{F}, P)$ is continuous.

(b) Inequality (3.5) follows from (3.8).

(c) If $t > s \geqq -n$, then we have

$$x_n(t) = V(t, s)x_n(s) + \int_s^t V(t, r)g(r)\, dr + \int_s^t V(t, r)G(r)\, dw(r)$$

where from letting $n \to \infty$ we obtain (3.6).

The Markov property follows from (3.6) as in [1]. The transition function is given as in Proposition 3.1 and is θ-periodic. Next, for every $t \in R$, $h \in H$, we have

$$\lim_{n\to\infty} E(\exp(i\langle h, x_n(t)\rangle)) = E(\exp(i\langle h, x(t)\rangle)),$$

$$\lim_{n\to\infty} E(\exp(i\langle h, x_{n+\theta}(t+\theta)\rangle)) = E(\exp(i\langle h, x(t+\theta)\rangle)),$$

$$\begin{aligned} E(\exp(i\langle h, x_{n+\theta}(t+\theta)\rangle)) &= \int \exp(i\langle h, z\rangle) P(n+\theta, 0, t+\theta, dz) \\ &= \int \exp(i\langle h, z\rangle) P(n, 0, t, dz) \\ &= E(\exp(i\langle h, x_n(t)\rangle)). \end{aligned}$$

Therefore

$$E(\exp(i\langle h, x(t)\rangle)) = E(\exp(i\langle h, x(t+\theta)\rangle))$$

for all $h \in H$, so that $x(t)$ and $x(t+\theta)$ have the same distribution for every t. This fact, together with the Markov property, implies that $\{x(t)\}$ is θ-periodic.

LEMMA 3.3. *Let* $\{h(t)\}_{t\geqq 0}$ *be an H-valued process such that*

$$\sup_t E(|h(t)|^2) < \infty$$

and let $\{R(t)\}_{t\geqq 0}$ *be an* $L(K, H)$*-valued progressively measurable process such that*

$$\sup_t E(\|R(t)\|^4_{L(K,H)}) < \infty.$$

Then P-almost surely we have

(a) $\lim_{n\to\infty} (1/n)h(n) = 0$.

(b) $\lim_{n\to\infty} (1/n)\int_0^n R(t)\, dw(t) = 0$.

Proof. (a) By Chebyshev's inequality for $\varepsilon > 0$ we have

$$P\left(\frac{1}{n}|h(n)| > \varepsilon\right) \leqq \frac{1}{n^2\varepsilon^2} E(|h(n)|^2) \leqq \frac{\gamma_3}{n^2}.$$

Since $\sum_n 1/n^2 < \infty$, we may apply the Borel-Cantelli Lemma.

(b) By using the inequality (see [13])

$$E\left(\left|\int_0^t \varphi(s)\, dw(s)\right|^4\right) \leqq \gamma_4 t \int_0^t E(\|\varphi(s)\|^4_{L(K,H)})\, ds$$

and the Markov inequality, we obtain

$$\begin{aligned} P\left(\frac{1}{n}\left|\int_0^n R(t)\, dw(t)\right| > \varepsilon\right) &\leqq \frac{1}{n^4\varepsilon^4} E\left(\left|\int_0^n R(t)\, dw(t)\right|^4\right) \\ &\leqq \frac{\gamma_5}{n^3}\int_0^n E(\|R(t)\|^4_{L(K,H)})\, dt \\ &\leqq \frac{\gamma_6}{n^2} \end{aligned}$$

and we use the Borel-Cantelli Lemma again.

4. The deterministic optimization problem. We consider the following Riccati equation:

$$Q' + A^*Q + QA - QBN^{-1}B^*Q + M = 0. \tag{4.1}$$

DEFINITION [5]. A strongly continuous function $Q:[0, \theta] \to \Sigma^+(H)$ is a θ-periodic solution of (4.1) if there is $S \in \Sigma^+(H)$ such that $Q(0) = Q(\theta) = S$ and for every $h \in H$

$$\begin{aligned} Q(t)h = U^*(\theta, t)SU(\theta, t)h \\ -\int_t^\theta U^*(s, t)[Q(s)B(s)N^{-1}(s)B^*(s)Q(s) - M(s)]U(s, t)h\, ds. \end{aligned} \tag{4.2}$$

THEOREM 4.1[5]. (a) *Assume* (2.7), (2.8), (2.10). *Then there exists a* θ*-periodic solution* Q *of* (4.1).

(b) *Assume* (2.7)-(2.10) *and*

(4.3) 1 *belongs to the resolvent set of the evolution operators* $U_{L(Q)}$, $U_{L^*(Q)}$ *generated by* $L(Q) = A - BN^{-1}B^*Q$, $L^*(Q) = A^* - QBN^{-1}B^*$.

Consider the following control problem. Minimize the cost functional

$$\bar{J}(u) = \int_0^\theta [\langle M(t)y(t), y(t)\rangle + \langle N(t)u(t), u(t)\rangle]\, dt \tag{4.4}$$

over all $u \in L^2([0, \theta], H)$ *subject to*

$$y'(t) = A(t)y(t) + B(t)u(t) + f(t), \qquad y(0) = y(\theta). \tag{4.5}$$

Then the optimal control is given by

$$\tilde{u} = -N^{-1}B^*(Qy + r) \tag{4.6}$$

and the optimal cost by

$$\bar{J}(\tilde{u}) = \int_0^\theta [2\langle f(s), r(s)\rangle - \langle N^{-1}(s)B^*(s)r(s), B^*(s)r(s)\rangle]\, ds \tag{4.7}$$

where r is the unique solution of

$$r' + (A^* - QBN^{-1}B^*)r + Qf = 0, \qquad r(0) = r(\theta) \tag{4.8}$$

and y is the unique solution of the equation

$$y' = (A - BN^{-1}B^*Q)y - BN^{-1}B^*r + f, \qquad y(0) = y(\theta). \tag{4.9}$$

THEOREM 4.2. *Assume* (2.7), (2.8) *and either* (2.10), (2.11) *or*

$$M(t) \geqq \alpha I, \qquad \alpha > 0, \tag{4.10}$$

for all t, and for each $s \in R$, $x \in H$ *there is u strongly measurable such that* $\int_s^\infty [\langle M(t)y(t), y(t)\rangle + \langle N(t)u(t), u(t)\rangle]\, dt < \infty$. *Then there exists a unique θ-periodic solution Q of* (4.1) *and the evolution operator* $U_{L(Q)}$ *is exponentially stable.*

Proof. Under (2.7), (2.8), (2.10), and (2.11) the first part of the theorem is proved in [5]. From Lemma 3.5 of [5] it follows that there is $C > 0$ such that for all s

$$\int_s^\infty |U_{L(Q)}(t, s)x|^2\, dt \leqq C|x|^2 \quad \text{for every } x \in H.$$

Therefore by a result due to Datko (see [9] or [14]) $U_{L(Q)}$ is exponentially stable.

Under (2.7), (2.8), and (4.10) the result is proved in Theorem 4.9 of [10].

Remark 4.1. Hypothesis (4.3) in Theorem 4.1 can be replaced by the following:

$$U_{L(Q)},\ U_{L^*(Q)} \text{ are exponentially stable.} \tag{4.11}$$

Indeed (4.3) has been used only to obtain a θ-periodic solution of (4.8) and (4.9). Under (4.11) $r(t) = \int_t^\infty U_{L^*(Q)}(s, t)Q(s)f(s)\, ds$ and $y(t) = \int_{-\infty}^t U_{L(Q)}(t, s) \cdot [f(s) - B(s)N^{-1}(s)B^*(s)r(s)]\, ds$ are the required solutions of (4.8) and (4.9).

Remark 4.2 [3, Lemma 1.2, Thm. 2.4]. Suppose (2.7), (2.8), (2.10) are satisfied. Moreover, assume that $s \to \langle U(t, s)A(s)x, y\rangle$ is integrable for all $y \in H$ and $x \in \mathcal{D} = \bigcap_{0 \leqq t \leqq \theta} D(A(t))$.

If Q is a θ-periodic solution of (4.1), then Q satisfies the following inner product Riccati equation:

$$\frac{d}{dt}\langle Qh, h\rangle + \langle [A^*Q + QA + M - QBN^{-1}B^*Q]h, h\rangle = 0 \quad \text{for all } h \in \mathcal{D}. \tag{4.12}$$

We remark that a sufficient condition for $s \to \langle U(t, s)A(s)x, y\rangle$ to be integrable is that it be measurable and $\sup_{t \leqq \theta} |A(t)x| < \infty$ for each $x \in \mathcal{D}$, and this condition is usually satisfied in the applications.

Remark 4.3. For affine and θ-periodic controls u for which the linear part is stabilizing, existence of periodic dynamics is ensured and we have that $\bar{J}(u)$ given by (4.4) satisfies

$$\bar{J}(u) = \lim_{n \to \infty} \frac{1}{n} \int_0^{n\theta} [\langle M(t)y(t), y(t)\rangle + \langle N(t)u(t), u(t)\rangle]\, dt.$$

This is the reason we consider the cost functional (5.5) in the periodic stochastic case below.

5. Main result. In this section we will consider a stochastic control problem with the cost calculated pathwise.

We consider the controlled stochastic evolution equation

$$dx(t) = [A(t)x(t) + B(t)u(t) + f(t)]\,dt + G(t)\,dw(t). \tag{5.1}$$

DEFINITION. A measurable, adapted process x with values in H is a mild solution of (5.1) on R if for every $t \geqq s$

$$x(t) = U(t,s)x(s) + \int_s^t U(t,r)[B(r)u(r) + f(r)]\,dr + \int_s^t U(t,r)G(r)\,dw(r) \quad P\text{-a.s.} \tag{5.2}$$

We denote by U_{ad} the space of all measurable, adapted, and θ-periodic processes $\{u(t)\}_{t\in R}$ in U with

$$\sup_t E(|u(t)|^4) < \infty \tag{5.3}$$

for which (5.1) has a unique (up to a modification) θ-periodic solution with

$$\sup_t E(|x(t)|^4) < \infty. \tag{5.4}$$

The statement of the control problem is the following. Find $u \in U_{\mathrm{ad}}$ that minimizes over U_{ad} (in the sense of the almost surely inequality) the random cost functional

$$J(u) = \overline{\lim_{n\to\infty}} \frac{1}{n} \int_0^{n\theta} [\langle M(t)x(t), x(t)\rangle + \langle N(t)u(t), u(t)\rangle]\,dt. \tag{5.5}$$

It is not clear if there exist any admissible controls. In this sense we have the following results.

PROPOSITION 5.1. *Suppose that $\{y(t)\}_{t\geqq 0}$ is a real measurable and θ-periodic process with $\sup_t E(|y(t)|) < \infty$. Then $(1/n)\int_0^{n\theta} y(s)\,ds$ converges P-almost surely to a finite random variable.*

PROPOSITION 5.2. *Suppose* (2.10) *is satisfied. Then the feedback control $u(t) = -C(t)x(t) + v(t)$, where $v: R \to U$ is continuous and θ-periodic, is in U_{ad}, and in particular $J(u)$ is finite P-almost surely. Moreover, if $\{x_1(t)\}_{t\geqq 0}$ is any solution of* (5.1) *on R_+ with $E(|x_1(0)|^2) < \infty$ corresponding to the affine control $u_1(t) = -C(t)x_1(t) + v(t)$, then the cost $\overline{\lim}_{n\to\infty}(1/n)\int_0^{n\theta}[\langle M(t)x_1(t), x_1(t)\rangle + \langle N(t)u_1(t), u_1(t)\rangle]\,dt$ is finite P-almost surely and does not depend on the initial condition $x_1(0)$.*

Proof of Proposition 5.1. Define

$$f_k = \int_{(k-1)\theta}^{k\theta} y(s)\,ds = \int_0^{\theta} y(s + (k-1)\theta)\,ds,$$

$$f_k^n = \sum_{i=0}^{n-1} \frac{\theta}{n}\, y\left(\frac{i\theta}{n} + (k-1)\theta\right).$$

It is clear that $\lim_{n\to\infty}(f_{1+p}^n, \cdots, f_{q+p}^n) = (f_{1+p}, \cdots, f_{q+p})$ P-almost surely for all p, q. From periodicity the repartition of $(f_{1+p}^n, \cdots, f_{q+p}^n)$ does not depend on p. Then the repartition of $(f_{1+p}, \cdots, f_{q+p})$ is independent on p, i.e., the sequence (f_k) is stationary. The result is now a consequence of the ergodic theorem (see [2, Thm. 6.28] or [18, Thm. 3]).

Proof of Proposition 5.2. According to Proposition 3.2 the process

$$x(t) = \int_{-\infty}^t U_{A-BC}(t,s)[f(s) + B(s)v(s)]\,ds + \int_{-\infty}^t U_{A-BC}(t,s)G(s)\,dw(s)$$

is θ-periodic and is a mild solution of (5.1), which satisfies (5.4), and in particular, (5.3) also holds.

If y is another θ-periodic mild solution of (5.1), then for fixed t and for all $s<t$ we have

$$\begin{aligned} E[|x(t)-y(t)|^2] &= E[|U_{A-BC}(t,s)(x(s)-y(s))|^2] \\ &\leqq \alpha^2 \exp\{-2\beta(t-s)\}E[|x(s)-y(s)|^2] \\ &\leqq \gamma_7 \exp(2\beta s) \to 0 \quad \text{as } s \to -\infty, \end{aligned}$$

so that $x(t)=y(t)$ P-almost surely.

Next we can write $x_1(t)=x(t)+z(t)$, where $x(t)$ is the θ-periodic solution of (5.1) and $z(t)=U_{A-BC}(t,0)[x_1(0)-x(0)]$.

If $J_1(u_1)$ is the cost defined in Proposition 5.2 then by a simple computation we have

$$J_1(u_1)=\overline{\lim_{n\to\infty}}\left\{\frac{1}{n}\int_0^{n\theta} y_1(t)\,dt+\frac{1}{n}\int_0^{n\theta} y_2(t)\,dt+\frac{1}{n}\int_0^{n\theta} y_3(t)\,dt\right\}$$

where y_1 is a θ-periodic process with $\sup_t E(|y_1(t)|)<\infty$, $y_2(t)\leqq \gamma_8|z(t)|+\gamma_9|z(t)|^2$, and $y_3(t)\leqq y(t)|z(t)|$, with y θ-periodic and $\sup_t E(|y(t)|^2)<\infty$. From Proposition 5.1 we have that $(1/n)\int_0^{n\theta} y_1(t)\,dt \to^{\text{a.s.}} f$. Also it is easily seen that $(1/n)\int_0^{n\theta} y_2(t)\,dt\to 0$.

Define

$$\begin{aligned} g_k &= \int_{(k-1)\theta}^{k\theta} \exp(-\beta t)y(t)\,dt \leqq \exp\{-\beta(k-1)\theta\}\int_0^{\theta} y(t+(k-1)\theta)\,dt \\ &= \exp\{-\beta(k-1)\theta\}h_k. \end{aligned}$$

By Proposition 5.1 we have that (h_k) is stationary with $E(h_1^2)<\infty$. Since

$$\sum_n P(\exp\{-\beta(n-1)\theta\}h_n>\varepsilon)\leqq \sum_n E(h_1)/\varepsilon\exp(\beta(n-1)\theta)<\infty,$$

it follows that $\exp\{-\beta(n-1)\theta\}h_n\to 0$ P-almost surely, where from

$$\frac{1}{n}\left|\int_0^{n\theta} y_3(t)\,dt\right| \leqq \frac{\gamma_{10}}{n}\sum_{k=1}^{n}\exp\{-\beta(k-1)\theta\}h_k\to 0 \quad P\text{-a.s.}$$

The main result is the following theorem.

THEOREM 5.3. *Assume that the hypotheses of Theorem* 4.2 *hold. Moreover, suppose that*

(a) $D(A(t))=D$ *for all* t *and* $\sup_{0\leqq t\leqq\theta}|A(t)h|<\infty$ *for all* $h\in D$;

(b) 1 *belongs to the resolvent set of* $U_{L^*(Q)}$, *where* Q *is the solution of* (4.1).

Then we have the following assertions:

(i) *The optimal control* $\tilde{u}$ *is given by the feedback law*

$$\tilde{u}=-N^{-1}B^*(Q\tilde{x}+r) \tag{5.6}$$

where r *is the solution of* (4.8).

The cost functional (5.5) *satisfies P-almost surely the equality*

$$\begin{aligned} J(\tilde{u}) = \int_0^{\theta} &[2\langle f(s), r(s)\rangle - \langle N^{-1}(s)B^*(s)r(s), B^*(s)r(s)\rangle \\ &+\operatorname{Tr}(G^*(s)Q(s)G(s)W)]\,ds \end{aligned} \tag{5.7}$$

and the optimal dynamics $\tilde{x}(t)$ corresponding to $\tilde{u}$ is given by

$$\begin{aligned}\tilde{x}(t) &= \int_{-\infty}^{t} U_{L(Q)}(t,s)[f(s) - B(s)N^{-1}(s)B^*(s)r(s)]\,ds \\ &\quad + \int_{-\infty}^{t} U_{L(Q)}(t,s)G(s)\,dw(s).\end{aligned} \tag{5.8}$$

(ii) *Let us assume in addition that* (4.10) *holds. If $u \in U_{ad}$ is such that $\lim_{n\to\infty}(1/n)\int_0^{n\theta}|u(t)-\bar{u}(t)|^2\,dt > 0$ P-almost surely, then P-almost surely there exists n' such that for $n \geqq n'$*

$$\begin{aligned}&\int_0^{n\theta}[\langle M(t)x(t), x(t)\rangle + \langle N(t)u(t), u(t)\rangle]\,dt \\ &\quad > \int_0^{n\theta}[\langle M(t)\tilde{x}(t), \tilde{x}(t)\rangle + \langle N(t)\tilde{u}(t), \tilde{u}(t)\rangle]\,dt\end{aligned}$$

where x is the mild solution of (5.1) *corresponding to u.*

We need the following lemma.

LEMMA 5.4. *Assume the hypotheses of Theorem* 5.3 *are satisfied. Let $u \in U_{ad}$, x be the mild solution of* (5.1) *corresponding to u, and define $\bar{u} = -N^{-1}B^*(Qx+r)$. Then the following identity holds*:

$$\begin{aligned}&\int_0^t [\langle M(s)x(s), x(s)\rangle + \langle N(s)u(s), u(s)\rangle\,ds \\ &\quad = \int_0^t \langle N(s)[u(s)-\bar{u}(s)], u(s)-\bar{u}(s)\rangle\,ds \\ &\qquad + \int_0^t [2\langle f(s), r(s)\rangle - \langle N^{-1}(s)B^*(s)r(s), B^*(s)r(s)\rangle \\ &\qquad + \mathrm{Tr}\,(G^*(s)Q(s)G(s)W)]\,ds \\ &\qquad + \langle Q(0)x(0), x(0)\rangle - \langle Q(t)x(t), x(t)\rangle \\ &\qquad + 2\langle r(t), x(t)\rangle - 2\langle r(0)x(0), x(0)\rangle \\ &\qquad + 2\int_0^t \langle Q(s)x(s) - r(s), G(s)\,dw(s)\rangle.\end{aligned} \tag{5.9}$$

Proof of Lemma 5.4. Let $R_\lambda(t)$ be the resolvent of $A(t)$, and let x_λ be the strong solution of

$$\begin{aligned}dx_\lambda(t) &= \{A(t)x_\lambda(t) + \lambda R_\lambda(t)[B(t)u(t)+f(t)]\}\,dt \\ &\quad + \lambda R_\lambda(t)G(t)\,dw(t), \qquad t \geqq 0, \\ x_\lambda(0) &= \lambda R_\lambda(0)x(0).\end{aligned} \tag{5.10}$$

Let $\bar{u}_\lambda = -N^{-1}B^*(Qx_\lambda + r)$. It is known that for every t

$$x_\lambda(t) \to x(t) \text{ in probability, as } \lambda \to \infty \text{ (see [4], [12], [13]).} \tag{5.11}$$

By using Ito's formula we obtain

$$
\begin{aligned}
&\langle Q(t)x_\lambda(t), x_\lambda(t)\rangle \\
&\quad = \langle Q(0)x_\lambda(0), x_\lambda(0)\rangle \\
&\qquad + \int_0^t \Big\{ \frac{d}{ds}\langle Q(s)x_\lambda(s), x_\lambda(s)\rangle + 2\langle Q(s)x_\lambda(s), A(s)x_\lambda(s)\rangle \\
&\qquad\quad + 2\langle Q(s)x_\lambda(s), \lambda R_\lambda(s)[B(s)u(s)+f(s)]\rangle \\
&\qquad\quad + \mathrm{Tr}\,[G^*(s)\lambda R_\lambda^*(s)Q(s)\lambda R_\lambda(s)Q(s)W]\Big\}\, ds \\
&\qquad + 2\int_0^t \langle Q(s)x_\lambda(s), \lambda R_\lambda(s)G(s)\, dw(s)\rangle
\end{aligned} \tag{5.12}
$$

where from substituting $d/ds\langle Q(s)x_\lambda(s), x_\lambda(s)\rangle$ by (4.12) we deduce

$$
\begin{aligned}
&\int_0^t \langle M(s)x_\lambda(s), x_\lambda(s)\rangle\, ds \\
&\quad = \langle Q(0)x_\lambda(0), x_\lambda(0)\rangle - \langle Q(t)x_\lambda(t), x_\lambda(t)\rangle \\
&\qquad + \int_0^t [\langle QBN^{-1}B^*Qx_\lambda, x_\lambda\rangle + 2\langle Qx_\lambda, \lambda R_\lambda(Bu+f)\rangle \\
&\qquad + \mathrm{Tr}\,(G^*\lambda R_\lambda^* Q\lambda R_\lambda GW)]\, ds + 2\int_0^t \langle Qx_\lambda, \lambda R_\lambda G\, dw\rangle.
\end{aligned} \tag{5.13}
$$

Also we have

$$
\begin{aligned}
\langle Nu, u\rangle &= \langle N(u-\bar{u}_\lambda), u-\bar{u}_\lambda\rangle - 2\langle u, B^*Qx_\lambda\rangle - 2\langle u, B^*r\rangle \\
&\quad - \langle N^{-1}B^*Qx_\lambda, B^*Qx_\lambda\rangle - \langle N^{-1}B^*Qx_\lambda, B^*r\rangle \\
&\quad - \langle N^{-1}B^*r, B^*Qx_\lambda\rangle - \langle N^{-1}B^*r, B^*r\rangle.
\end{aligned} \tag{5.14}
$$

Now from (5.13) and (5.14), we obtain

$$
\begin{aligned}
I_\lambda(t) &= \int_0^t [\langle M(s)x_\lambda(s), x_\lambda(s)\rangle + \langle N(s)u(s), u(s)\rangle]\, ds \\
&= \langle Q(0)x_\lambda(0), x_\lambda(0)\rangle - \langle Q(t)x_\lambda(t), x_\lambda(t)\rangle \\
&\quad + \int_0^t [\langle N(u-\bar{u}_\lambda), u-\bar{u}_\lambda\rangle + 2\langle Qx_\lambda, \lambda R_\lambda(Bu+f)\rangle + \mathrm{Tr}\,(G_\lambda^* R_\lambda^* Q\lambda R_\lambda GW) \\
&\quad - 2\langle u, B^*Qx_\lambda\rangle - 2\langle u, B^*r\rangle - 2\langle N^{-1}B^*Qx_\lambda, B^*r\rangle - \langle N^{-1}B^*r, B^*r\rangle]\, ds \\
&\quad + 2\int_0^t \langle Qx_\lambda, \lambda R_\lambda G dw\rangle.
\end{aligned} \tag{5.15}
$$

Next, by using Ito's formula for $\langle r(t)x_\lambda(t), x_\lambda(t)\rangle$ and then substituting r' by (4.8), we arrive at

$$
\begin{aligned}
&\int_0^t \langle QBN^{-1}B^*r, x_\lambda\rangle\, ds \\
&\quad = \langle r(t), x_\lambda(t)\rangle - \langle r(0), x_\lambda(0)\rangle \\
&\qquad + \langle Q(t)f(t), x_\lambda(t)\rangle - \langle r(t), \lambda R_\lambda(t)[B(t)u(t)+f(t)]\rangle \\
&\qquad + \int_0^t \langle r, \lambda R_\lambda G\, dw\rangle.
\end{aligned} \tag{5.16}
$$

Substituting (5.16) in (5.15), we get

$$
\begin{aligned}
I_\lambda(t) = & \int_0^t \langle N(u-\bar{u}_\lambda), u-\bar{u}_\lambda\rangle\, ds \\
& + \int_0^t [\mathrm{Tr}\,(G^*\lambda R_\lambda^* Q \lambda R_\lambda G W) - \langle N^{-1}B^*r, B^*r\rangle + 2\langle r, \lambda R_\lambda f\rangle]\, ds \\
& + \langle Q(0)x_\lambda(0), x_\lambda(0)\rangle - \langle Q(t)x_\lambda(t), x_\lambda(t)\rangle \\
& + 2\langle r(t), x_\lambda(t)\rangle - 2\langle r(0), x_\lambda(0)\rangle \\
& + \int_0^t [2\langle Qx_\lambda, \lambda R_\lambda(Bu+f)\rangle - 2\langle u, B^*Qx_\lambda\rangle - 2(u, B^*r\rangle \\
& - 2\langle Qf, x_\lambda\rangle + 2\langle r, \lambda R_\lambda Bu\rangle]\, ds \\
& + 2\int_0^t \langle Qx_\lambda - r, \lambda R_\lambda G\, dw\rangle.
\end{aligned} \tag{5.17}
$$

Finally, letting $\lambda \to \infty$ and utilizing (5.11), we obtain (5.9).

Proof of Theorem 5.3. (i) If we take $u = \tilde{u}$ $(= \tilde{u})$, $t = n\theta$, we divide by n in (5.9), and then we apply Lemma 3.3; we obtain (5.7). The equality (5.8) follows from Proposition 3.2.

(ii) Part (ii) is a consequence of (5.9) and of Lemma 3.3.

Remark 5.1. The result in (5.7) is of the "limit theorem" type as mentioned in [15] and $\tilde{u}$ can be regarded as optimal with respect to the law of the large numbers.

Example. Consider the stochastic parabolic equation formally described by

$$
\begin{aligned}
& dx(t,z) = \left\{\left[\frac{\partial^2}{\partial z^2} - \varphi(t)\right] x(t,z) + u(t,z) + f(t,z)\right\} dt + G(t,z)\, dw(t), \\
& x(t,0) = x(t,1) = 0
\end{aligned} \tag{5.18}
$$

where φ, f, G are continuous in (t,z), θ-periodic in t, $\varphi \geqq 0$ and w is a real Wiener process.

Let $K = R$, $H = U = L^2((0,1), R)$, $A(t) = \partial^2/\partial z^2 - \varphi(t)$, $D(A(t)) = D = \{h \in H;\ \dot{h}, \ddot{h} \in H,\ h(0) = h(1) = 0\}$.

$A(t)$ generates a strong evolution operator U with $\|U(t,s)\| \leqq 1$ for all $S \leqq t$. The evolution equation corresponding to (5.18) is

$$
dx(t) = [A(t)x(t) + u(t) + f(t)]\, dt + G(t)\, dw(t). \tag{5.19}
$$

THEOREM 5.5. *The cost functional*

$$
J(u) = \overline{\lim_{n\to\infty}} \frac{1}{n} \int_0^{n\theta} [|x(t)|_H^2 + |u(t)|_H^2]\, dt \tag{5.20}
$$

has P-almost surely the minimum value

$$
J(\tilde{u}) = \int_0^\theta [2\langle r(s), f(s)\rangle - |r(s)|_H^2 + \mathrm{Tr}\,(G^*(s)Q(s)G(s))]\, ds \tag{5.21}
$$

corresponding to the optimal control

$$
\tilde{u}(t) = -Q(t)\tilde{x}(t) - r(t) \tag{5.22}
$$

where Q, r are the θ-periodic solutions of

$$\frac{d}{dt}\langle Qh, h\rangle + 2\langle Ah, Qh\rangle - |Qh|_H^2 + |h|_H^2 = 0, \qquad h \in D, \tag{5.23}$$

$$r' + (A - Q)r + Qf = 0, \tag{5.24}$$

and $\tilde{x}$ is the θ-periodic process

$$\tilde{x}(t) = \int_{-\infty}^{t} U_{A-Q}(t, s)[f(s) - r(s)]\, ds + \int_{-\infty}^{t} U_{A-Q}(t, s)G(s)\, dw(s). \tag{5.25}$$

Acknowledgments. I thank the referees for many valuable comments and suggestions and Professor A. Halanay for helpful discussions.

QUADRATIC OPTIMIZATION FOR INFINITE-DIMENSIONAL LINEAR DIFFERENTIAL DIFFERENCE TYPE SYSTEMS: SYNTHESES VIA THE FREDHOLM EQUATION*

E. BRUCE LEE† AND YUNCHENG YOU‡

Abstract. A closed-loop solution for quadratic optimization is presented for control systems whose model is given by infinite-dimensional linear differential difference equations:

$$\frac{dx(t)}{dt} = Ax(t) + \sum_{i=1}^{n} A_i x(t-h_i) + Bu(t) + \sum_{j=1}^{m} B_j u(t-r_j).$$

A nonsemigroup evolution formula for the fundamental solution is given first. The system is then reduced to a Volterra integral system. By the semicausality approach, a new optimality principle is established, and the closed-loop optimal control is given by real-time state feedback plus retarded state integral feedback. The feedback operator is determined by solving a linear Fredholm integral equation. The two crucial methods, semicausal dynamical optimization for Volterra integral systems and nonsemigroup evolution property, are brought together to generalize the syntheses results to infinite-dimensional cases.

Key words. optimal control, infinite-dimensional linear system, differential difference equation, semicausality, Fredholm equation, synthesis solution

1. Optimal control formulation. The quadratic optimization theory of finite-dimensional linear systems with delay in state and/or control variables has been developed by many authors via several different approaches (cf. [1]-[4], [6]-[9], [11]-[15], [18]-[23] and the references therein). Solving a Riccati type equation is a standard way to provide the feedback operator when delays are not involved in the quadratic formulation [10], and also in the finite-dimensional delay cases [8]. The method used to provide the feedback operator for the infinite-dimensional delay type system that is given here is based on the Fredholm resolvent theory. Schumitzky [22] has described the connection between the Riccati equations and the Fredholm resolvent theory. Manitius [20] has used the Fredholm resolvent theory to provide the feedback operator for quadratic optimization for finite-dimensional systems with delays. You [24]-[26] has now generalized this approach to certain infinite-dimensional systems (partial differential equation (PDE) models). Background results on infinite-dimensional systems can be found in [5]. Delfour [8] gives general results in the finite-dimensional case along with associated coupled differential Riccati equations.

However, the methods based on some kind of Riccati equation are quite restrictive for optimization with delayed output appearing in the quadratic criteria (cf. [18]), and also in the infinite-dimensional case there are complications in deriving appropriate Riccati equations, as well as a lack of effective analytic or numerical means to solve the infinite-dimensional differential or integral Riccati equations that will be inherently of the same dimension as the state space. In view of this fact, we have introduced [18] a new approach based on the concepts of a truncation operator and semicausal

trajectory to obtain a synthesis with time delays both in state and in output variables; the latter appears in the cost functional. We have also applied this approach [16], [17] to optimization connected with Volterra integral type systems and two-dimensional systems.

In this paper, this semicausality approach, combined with the nonsemigroup evolution formula of the fundamental solution, is further developed for the infinite-dimensional differential difference type linear systems with delays in state and control variables. A closed-loop synthesis will be presented with the feedback operator determined by solving a linear Fredholm integral equation, which possesses the same dimension as the control variable space (usually finite even though the state space is infinite-dimensional). Therefore, the obtained results will be more applicable theoretically and computationally.

Let X and U be real Hilbert spaces. $T>0$ is finite and fixed. Consider a linear system as represented by infinite-dimensional differential-difference equations:

$$\frac{dx(t)}{dt}=Ax(t)+\sum_{i=1}^{n}A_ix(t-h_i)+Bu(t)+\sum_{j=1}^{m}B_ju(t-r_j),\qquad t\geqq 0, \tag{1.1}$$

$$x(\theta)=\phi(\theta),\quad -h\leqq\theta<0,\quad x(0)=x_0,\quad u(\xi)=\psi(\xi),\quad -r\leqq\xi\leqq 0, \tag{1.2}$$

where $0<h_1<h_2<\cdots<h_n$ and $0<r_1<r_2<\cdots<r_m$ with $h=h_n$ and $r=r_m$, $0<\max(h, r)\ll T$. Denote by $Z=X\times L^2(-h, 0; X)\times L^2(-r, 0; U)$ and assume that initial data $(x_0, \phi, \psi)\in Z$ is arbitrarily given.

Assume that $A:\mathcal{D}(A)(\subset X)\to X$ is a densely defined and closed operator that generates a C_0 semigroup $e^{At}(t\geqq 0)$, besides $A_i\in\mathcal{L}(X)$, $i=1,\cdots,n$, $B\in\mathcal{L}(U; X)$, and $B_j\in\mathcal{L}(U; X)$, $j=1,\cdots,m$.

The state function is the mild solution of (1.1) with the initial data (1.2), i.e.,

$$x(t)=\begin{cases}\phi(t), & -h\leqq t<0,\\ e^{At}x_0+\displaystyle\int_0^t e^{A(t-s)}\left\{\sum_{i=1}^{n}A_ix(s-h_i)+Bu(s)+\sum_{j=1}^{m}B_ju(s-r_j)\right\}ds, & t\geqq 0.\end{cases} \tag{1.3}$$

The admissible control set is given by

$$u(\cdot)\in\mathcal{U}=L^2(0, T; U). \tag{1.4}$$

Set a quadratic cost functional to be

$$J(u)=\langle Q_Tx(T), x(T)\rangle+\int_0^T[\langle Qx(t), x(t)\rangle+\langle Ru(t), u(t)\rangle]\,dt \tag{1.5}$$

where Q_T and $Q\in\mathcal{L}(X)$ are nonnegative and $R\in\mathcal{L}(U)$ is coercively positive.

Optimization involves finding a closed-loop optimal control that minimizes $J(u)$ over $\mathcal{U}$.

Before considering the question of optimal control, it is necessary to make some preparation for the appropriate reformulation of the system in this infinite-dimensional case, as suggested by the following results.

LEMMA 1. *The homogeneous differential-difference equation*

$$\frac{dx(t)}{dt}=Ax(t)+\sum_{i=1}^{n}A_ix(t-h_i),\qquad t\geqq 0, \tag{1.6}$$

$$x(0)=x_0,\quad x(\theta)=\phi(\theta),\quad -h\leqq\theta<0$$

admits a unique mild solution $x(t)$, $t \geqq 0$, *for any given* $(x_0, \phi) \in M^2 = X \times L^2(-h, 0; X)$. *Define* $V(t): (x_0, \phi) \to (x(t), x_t)$, *where* $x_t(\theta) = x(t+\theta)$, *for* $-h \leqq \theta \leqq 0$; *then* $V(t)$ $(t \geqq 0)$ *is a* C_0 *semigroup of bounded linear operators on the* M^2 *space, which is called the solution semigroup associated with* (1.6).

The proof of this lemma is given in Theorem 1 of [25].

Define

$$W^2 = \left\{ \begin{pmatrix} \phi_0 \\ \phi \end{pmatrix} \in M^2 : \phi_0 = \phi(0) \in X, \quad \phi \in AC([-h, 0]; X) \text{ and } \frac{d\phi}{d\theta} \in L^2(-h, 0; X) \right\}$$

with the M^2-induced topology, where AC means strong absolute continuity and $d\phi/d\theta$ is the strong derivative of ϕ.

LEMMA 2. *Let* $\mathcal{A}$ *be the infinitesimal generator of the solution semigroup* $V(t)$ *associated with* (1.6). *Then,* $\mathcal{D}(\mathcal{A}) = \hat{W}^2$ *and*

$$\mathcal{A}\begin{pmatrix} \phi_0 \\ \phi \end{pmatrix} = \begin{pmatrix} A\phi_0 + \sum_{i=1}^{n} A_i \phi(-h_i) \\ E_\phi \end{pmatrix} \quad \forall \begin{pmatrix} \phi_0 \\ \phi \end{pmatrix} \in \mathcal{D}(\mathcal{A}), \tag{1.7}$$

where

$$\hat{W}^2 = \left\{ \begin{pmatrix} \phi_0 \\ \phi \end{pmatrix} \in W^2 : \phi_0 = \phi(0) \in \mathcal{D}(A) \right\},$$

and

$$E_\phi = \frac{d\phi}{d\theta} \quad \text{with } \mathcal{D}(E) = P_{L^2} \hat{W}^2,$$

where $P_{L^2}: M^2 \to L^2(-h, 0; X)$ *is an orthogonal projection.*

The proof of this lemma is also given in Theorem 2 of [25].

By the definition, we see that the mild solution of (1.6) is expressed by

$$x(t) = P_X V(t) \begin{pmatrix} x_0 \\ \phi \end{pmatrix}, \qquad t \geqq 0, \tag{1.8}$$

where $P_X : M^2 \to X$ is an orthogonal projection.

Define the fundamental solution $G(t): [0, \infty) \to \mathcal{L}(X)$ to be the mild solution of the following operator equation:

$$\frac{dG(t)}{dt} = AG(t) + \sum_{i=1}^{n} A_i G(t - h_i), \qquad t \geqq 0, \tag{1.9}$$

$$G(0) = I \quad \text{and} \quad G(t) = 0, \quad t < 0.$$

This mild solution $G(t)$ $(t \geqq 0)$ exists uniquely and is given by

$$G(t) = \begin{cases} e^{At} + \displaystyle\int_0^t e^{A(t-s)} \sum_{i=1}^{n} A_i G(s - h_i)\, ds, & t \geqq 0, \\ 0, & t < 0. \end{cases} \tag{1.10}$$

Since there are multidelays involved in (1.9), the fundamental solution $G(t)$ does not possess the semigroup property, as in the single delay case [8]. However, we need a precise evolutionary property of $G(t)$, which will be used later in the closed-loop syntheses.

LEMMA 3. *Let $G(t)$ be the fundamental solution. Assume that $g(\cdot) \in C^1([0, b]; X)$ with null extension outside $[0, b]$. Then, for any $t \geqq 0$,*

$$\int_0^t G(t-\sigma)g(\sigma)\, d\sigma \in \mathcal{D}(A), \tag{1.11}$$

where $\mathcal{D}(A)$ is the domain of the generator A.

Proof. It is known [5], [23] that for any strongly continuous differentiable $g(\cdot):[0, b] \to X$ (with null extension outside), $\int_0^t e^{A(t-s)}g(s)\, ds \in \mathcal{D}(A)$, and

$$A\int_0^t e^{A(t-s)}g(s)\, ds = e^{At}g(0) - g(t) + \int_0^t e^{A(t-s)}\dot{g}(s)\, ds, \qquad t \geqq 0. \tag{1.12}$$

Since $G(t)$ is given by (1.10), it is enough to show that

$$\int_0^t \int_0^{t-\sigma} e^{A(t-\sigma-s)}A_i G(s-h_i)g(\sigma)\, ds\, d\sigma \in \mathcal{D}(A), \qquad i = 1, \cdots, n. \tag{1.13}$$

Indeed,

$$\begin{aligned} &\int_0^t \int_0^{t-\sigma} e^{A(t-\sigma-s)}A_i G(s-h_i)g(\sigma)\, ds\, d\sigma \\ &= \int_0^t \int_\sigma^t e^{A(t-\xi)}A_i G(\xi-\sigma-h_i)g(\sigma)\, d\xi\, d\sigma \\ &= \int_0^t e^{A(t-\xi)} \int_0^\xi A_i G(\xi-\sigma-h_i)g(\sigma)\, d\sigma\, d\xi. \end{aligned} \tag{1.14}$$

Now we see that $\beta(\xi) \triangleq \int_0^\xi A_i G(\xi-\sigma-h_i)g(\sigma)\, d\sigma = \int_0^\xi A_i G(\eta-h_i)g(\xi-\eta)\, d\eta$ is strongly continuously differentiable (with possible discontinuity in connection with null extension), so that (1.14) implies that (1.13) is true. Moreover, by (1.12) we obtain

$$\begin{aligned} &A\int_0^t \int_0^{t-\sigma} e^{A(t-\sigma-s)}A_i G(s-h_i)g(\sigma)\, ds\, d\sigma \\ &= \int_0^t e^{A(t-\xi)}\left(\frac{d}{d\xi}\int_0^\xi A_i G(\xi-\sigma-h_i)g(\sigma)\, d\sigma\right) d\xi \\ &\quad - A_i \int_0^t G(t-\sigma-h_i)g(\sigma)\, d\sigma. \end{aligned} \tag{1.15}$$

LEMMA 4. *Under the same assumptions as in Lemma 3.*

$$\begin{aligned} \frac{d}{dt}\int_0^t G(t-\sigma)g(\sigma)\, d\sigma &= A\int_0^t G(t-\sigma)g(\sigma)\, d\sigma \\ &\quad + \sum_{i=1}^n A_i \int_0^t G(t-\sigma-h_i)g(\sigma)\, d\sigma + g(t) \end{aligned} \tag{1.16}$$

for $t \geqq 0$ except at the connection point $t = b$ with null extension, where $g(t-0)$ appears for the left derivative.

LEMMA 5. *For any $(x_0, \phi) \in M^2$, the unique mild solution of (1.6) is given by*

$$x(t) = G(t)x_0 + \int_0^t G(t-\sigma) \sum_{i=1}^n A_i \phi(\sigma - h_i)\, d\sigma, \qquad t \geqq 0 \tag{1.17}$$

where it is a convention that $\phi(t) \equiv 0$ whenever $t > 0$.

Proof. First assume that $(x_0, \phi) \in \mathcal{D}(A) \times C^1([-h, 0]; X)$. Let

$$g(\sigma) = \sum_{i=1}^{n} A_i \phi(\sigma - h_i), \qquad \sigma \geqq 0. \tag{1.18}$$

Then we see that $g(\cdot)$ is piecewise strongly continuously differentiable as follows:

$$g(\sigma) = \begin{cases} \sum_{i=1}^{n} A_i \phi(\sigma - h_i), & \sigma \in [0, h_1], \\ \sum_{i=2}^{n} A_i \phi(\sigma - h_i), & \sigma \in (h_1, h_2], \\ \cdots & \cdots \\ A_n \phi(\sigma - h_n), & \sigma \in (h_{n-1}, h_n], \\ 0, & \sigma > h_n. \end{cases} \tag{1.19}$$

Now let

$$y(t) = \begin{cases} G(t)x_0 + \int_0^t G(t-\sigma) \sum_{i=1}^{n} A_i \phi(\sigma - h_i)\, d\sigma, & t \geqq 0, \\ \phi(t), & t < 0. \end{cases} \tag{1.20}$$

By Lemma 4, $y(t)$ is piecewise strongly continuous differentiable on $[0, \infty)$ except for the finite points $t = h_1, \cdots, h_n$, where the left and right strong derivatives still exist. Furthermore, with $g(\cdot)$ defined by (1.18) or (1.19), it follows that for $t \geqq 0$,

$$\begin{aligned} \frac{d}{dt} y(t) &= \frac{d}{dt} G(t)x_0 + \frac{d}{dt} \int_0^t G(t-\sigma) g(\sigma)\, d\sigma \\ &\doteq AG(t)x_0 + \sum_{i=1}^{n} A_i G(t-h_i)x_0 + A \int_0^t G(t-\sigma) g(\sigma)\, d\sigma \\ &\qquad + \sum_{i=1}^{n} A_i \int_0^t G(t-\sigma-h_i) g(\sigma)\, d\sigma + g(t) \\ &= Ay(t) + \left\{ \sum_{i=1}^{n} A_i G(t-h_i)x_0 + \sum_{i=1}^{n} A_i \int_0^t G(t-\sigma-h_i) g(\sigma)\, d\sigma + g(t) \right\} \\ &= Ay(t) + \begin{cases} \sum_{i=1}^{n} A_i \phi(t-h_i), & \text{for } t \in [0, h_1], \\ A_1(G(t-h_1)x_0 + \int_0^t G(t-\sigma-h_1) g(\sigma)\, d\sigma) + \sum_{i=2}^{n} A_i \phi(t-h_1), & \\ & \text{for } t \in (h_1, h_2], \\ \cdots \qquad\qquad \cdots & \\ \sum_{i=1}^{n-1} A_i(G(t-h_i)x_0 + \int_0^t G(t-\sigma-h_i) g(\sigma)\, d\sigma) + A_n \phi(t-h_n), & \\ & \text{for } t \in (h_{n-1}, h_n], \\ \sum_{i=1}^{n} A_i(G(t-h_i)x_0 + \int_0^t G(t-\sigma-h_i) g(\sigma)\, d\sigma), & \text{for } t \in (h_n, \infty), \end{cases} \\ &= Ay(t) + \sum_{i=1}^{n} A_i y(t-h_i) \end{aligned} \tag{1.21}$$

where the first type of discontinuity exists at the points $h_1, \cdots, h_n$.

On the other hand, it can be shown that the mild solution $x(t)$ of (1.6) with the same initial data $(x_0, \phi) \in \mathcal{D}(A) \times C^1([-h, 0]; X)$ is also piecewise strongly continuously differentiable and

$$\frac{dx(t)}{dt} = Ax(t) + \sum_{i=1}^{n} A_i x(t-h_i) \tag{1.22}$$

for $t \geqq 0$ except at $h_1, \cdots, h_n$. Thus $z(t) = x(t) - y(t)$, $t \in [-h, \infty)$, is a strongly absolutely continuous function with its strong derivative $dz/dt = 0$ almost everywhere. This implies that $z(t) \equiv 0$, so that (1.17) is valid for (x_0, ϕ) in $\mathcal{D}(A) \times C^1([-h, 0]; X)$.

Finally, since $\mathcal{D}(A) \times C^1([-h, 0]; X)$ is dense in M^2, we can always use some sequence $\{(x_0^{(k)}, \phi^{(k)})\}_{k=1}^{\infty} \subset \mathcal{D}(A) \times C^1([-h, 0]; X)$ to approximate a given $(x_0, \phi) \in M^2$ so that corresponding sequences $\{x^{(k)}(\cdot)\}_{k=1}^{\infty}$ and $\{y^{(k)}(\cdot)\}_{k=1}^{\infty}$ will converge to $x(\cdot)$ and $y(\cdot)$ with the same (x_0, ϕ) as the initial data, respectively. That is, $\lim_{k\to\infty} y^{(k)}(t) = y(t)$ and $\lim_{k\to\infty} x^{(k)}(t) = x(t)$ for $t \geqq 0$. Since $x^{(k)}(t) \equiv y^{(k)}(t)$ for all $t \geqq 0$, it follows that (1.17) is valid for all $(x_0, \phi) \in M^2$. □

THEOREM 1. *Let $G(t)$ be the fundamental solution. Then it satisfies the following relation*:

$$G(t+s) = G(t)G(s) + \sum_{i=1}^{n} \int_0^{\min(t,h_i)} G(t-\sigma) A_i G(s+\sigma-h_i)\, d\sigma \quad \text{for } t \geqq 0,\ s \geqq 0. \tag{1.23}$$

Proof. By Lemma 5 and the definition of the solution semigroup $V(t)$ associated with (1.6), it follows that

$$\begin{aligned} V(t)\begin{pmatrix} x_0 \\ \phi \end{pmatrix} &= \begin{pmatrix} G(t)x_0 + \displaystyle\int_0^t G(t-\sigma) \sum_{i=1}^{n} A_i \phi(\sigma - h_i)\, d\sigma \\ G(t+\theta)x_0 + \displaystyle\int_0^{t+\theta} G(t+\theta-\sigma) \sum_{i=1}^{n} A_i \phi(\sigma-h_i)\, d\sigma, \quad \theta \in [-h, 0] \end{pmatrix} \\ &= \begin{pmatrix} G(t)x_0 + \displaystyle\sum_{i=1}^{n} \int_0^{\min(t,h_i)} G(t-\sigma) A_i \phi(\sigma-h_i)\, d\sigma \\ G(t+\theta)x_0 + \displaystyle\sum_{i=1}^{n} \int_0^{\min(t+\theta,h_i)} G(t+\theta-\sigma) A_i \phi(\sigma-h_i)\, d\sigma, \quad \theta \in [-h, 0] \end{pmatrix}, \qquad t \geqq 0, \end{aligned} \tag{1.24}$$

where $G(t)$ is the described fundamental solution. In particular,

$$V(t)\begin{pmatrix} x_0 \\ 0 \end{pmatrix} = \begin{pmatrix} G(t)x_0 \\ G(t+\theta)x_0, \quad \theta \in [-h, 0] \end{pmatrix}, \qquad t \geqq 0. \tag{1.25}$$

Now for $t \geqq 0$ and $s \geqq 0$, it follows that

$$\begin{aligned} V(t+s)\begin{pmatrix} x_0 \\ 0 \end{pmatrix} &= \begin{pmatrix} G(t+s)x_0 \\ G(t+s+\theta)x_0, \quad \theta \in [-h, 0] \end{pmatrix} \\ &= V(t)V(s)\begin{pmatrix} x_0 \\ 0 \end{pmatrix} = V(t)\begin{pmatrix} G(s)x_0 \\ G(s+\theta)x_0, \quad \theta \in [-h, 0] \end{pmatrix} \end{aligned} \tag{1.26}$$

$$= \begin{pmatrix} G(t)G(s)x_0 + \sum_{i=1}^{n} \int_0^{\min(t,h_i)} G(t-\sigma)A_iG(s+\sigma-h_i)\,d\sigma\, x_0 \\ G(t+\theta)G(s)x_0 + \sum_{i=1}^{n} \int_0^{\min(t+\theta,h_i)} G(t+\theta-\sigma)A_iG(s+\sigma-h_i)\,d\sigma\, x_0, \quad \theta\in[-h,0] \end{pmatrix}$$

for any $x_0 \in X$.

The equality (1.26) indicates that (1.23) holds. □

For the original linear control system (1.1), (1.2), by an argument similar to that in Lemma 5, it can be proved that the state function of (1.1), (1.2) is expressed by

$$\begin{aligned} x(t) &= G(t)x_0 + \int_0^t G(t-\sigma) \sum_{i=1}^{n} A_i\phi(\sigma-h_i)\,d\sigma \\ &\quad + \int_0^t G(t-\sigma)Bu(\sigma)\,d\sigma + \int_0^t G(t-\sigma) \sum_{j=1}^{m} B_j u(\sigma-r_j)\,d\sigma, \qquad t\in[0,T]. \end{aligned} \tag{1.27}$$

Here and later it will always be a convention that

$$\begin{aligned} &\phi(t)=0 \quad \text{whenever } t>0, \\ &\psi(t)=0 \quad \text{whenever } t>0, \\ &G(t)=0 \quad \text{whenever } t<0. \end{aligned} \tag{1.28}$$

By this convention, the Volterra integrals with time-delayed control can be written as

$$\begin{aligned} \int_0^t G(t-\sigma)B_ju(\sigma-r_j)\,d\sigma &= \int_0^{r_j} G(t-\sigma)B_j\psi(\sigma-r_j)\,d\sigma \\ &\quad + \int_{r_j}^t G(t-\sigma)B_ju(\sigma-r_j)\,d\sigma \\ &= \int_0^t G(t-\sigma)B_j\psi(\sigma-r_j)\,d\sigma + \int_0^t G(t-r_j-\sigma)B_ju(\sigma)\,d\sigma \\ &\quad \text{for } t\geqq r_j, \quad j=1,\cdots,m. \end{aligned} \tag{1.29}$$

If $t<r_j$, then the last term $\int_0^t G(t-r_j-\sigma)B_ju(\sigma)\,d\sigma$ vanishes by (1.28).

Therefore, the state function $x(t)$ is expressed by

$$x(t) = f_{(x_0,\phi,\psi)}(t) + \int_0^t G(t-\sigma)Bu(\sigma)\,d\sigma + \sum_{j=1}^{m} \int_0^t G(t-r_j-\sigma)B_ju(\sigma)\,d\sigma, \tag{1.30}$$

where

$$f_{(x_0,\phi,\psi)}(t) = G(t)x_0 + \int_0^t G(t-\sigma)\left\{ \sum_{i=1}^{n} A_i\phi(\sigma-h_i) + \sum_{j=1}^{m} B_j\psi(\sigma-r_j) \right\} d\sigma. \tag{1.31}$$

Define

$$F(t) = G(t)B + G(t-r_1)B_1 + \cdots + G(t-r_m)B_m, \qquad t\geqq 0; \tag{1.32}$$

then the state function is expressed by the following formula:

$$x(t) = f_{(x_0,\phi,\psi)}(t) + \int_0^t F(t-\sigma)u(\sigma)\,d\sigma, \qquad t\in[0,T], \tag{1.33}$$

where $f_{(x_0,\phi,\psi)}(t)$ and $F(t)$ are defined by (1.31) and (1.32), respectively.

Therefore, the optimal control formulation is to find a closed-loop control function u that minimizes $J(u)$ over $u \in \mathcal{U}$, where $J(u)$ is defined by (1.5) and the state function is given by (1.33).

2. Open-loop optimal control. Denote by $\mathcal{X} = L^2(0, T; X)$ and $C = C([0, T]; X)$. Define operators $\Gamma \in \mathcal{L}(\mathcal{U}; \mathcal{X})$ and $\Gamma_T \in \mathcal{L}(\mathcal{U}; X)$ by

$$(\Gamma u)(t) = \int_0^t F(t-\sigma)u(\sigma)\, d\sigma, \qquad t \in [0, T], \tag{2.1}$$

$$\Gamma_T u = \int_0^T F(T-\sigma)u(\sigma)\, d\sigma. \tag{2.2}$$

Then the state (1.33) can be written as

$$x(\cdot) = f_{(x_0,\phi,\psi)} + \Gamma u, \tag{2.3}$$

with the final value

$$x(T) = f_{(x_0,\phi,\psi)}(T) + \Gamma_T u. \tag{2.4}$$

Substitution of (2.3) and (2.4) into the cost functional (1.5) yields

$$\begin{aligned} J(u) &= \langle Ru, u\rangle_{\mathcal{U}} + \langle Q(\Gamma u + f_{(x_0,\phi,\psi)}), \Gamma u + f_{(x_0,\phi,\psi)}\rangle_{\mathcal{X}} \\ &\quad + \langle Q_T(\Gamma_T u + f_{(x_0,\phi,\psi)}(T)), \Gamma_T u + f_{(x_0,\phi,\psi)}(T)\rangle_X \\ &= \langle \Phi u, u\rangle_{\mathcal{U}} + 2\langle \Gamma^* Q f_{(x_0,\phi,\psi)} + \Gamma_T^* Q_T f_{(x_0,\phi,\psi)}(T), u\rangle_{\mathcal{U}} + \text{const.}\,(x_0, \phi, \psi), \end{aligned} \tag{2.5}$$

where the operator $\Phi \in \mathcal{L}(\mathcal{U})$ is defined by

$$\Phi = RI_{\mathcal{U}} + \Gamma^* Q \Gamma + \Gamma_T^* Q_T \Gamma_T, \tag{2.6}$$

and Φ is coercively positive, and here the same notation Q is used to denote the operator $\tilde{Q} \in \mathcal{L}(\mathcal{X})$ in the sense that

$$(\tilde{Q}y)(t) = Qy(t) \quad \forall y \in \mathcal{X},$$

and const. (x_0, ϕ, ψ) is a constant determined by x_0, ϕ, ψ, i.e.,

$$\text{const.}\,(x_0, \phi, \psi) = \langle Qf_{(x_0,\phi,\psi)}, f_{(x_0,\phi,\psi)}\rangle_{\mathcal{X}} + \langle Q_T f_{(x_0,\phi,\psi)}(T), f_{(x_0,\phi,\psi)}(T)\rangle.$$

THEOREM 2. *For any given $(x_0, \phi, \psi) \in Z \triangleq X \times L^2(-h, 0; X) \times L^2(-r, 0; U)$, there exists a unique optimal control. The control process $(u(\cdot), x(\cdot))$ is optimal if and only if it satisfies the following relation*:

$$u(t) = -R^{-1}\left[F^*(T-t)Q_T x(T) + \int_t^T F^*(\sigma - t)Qx(\sigma)\, d\sigma\right], \qquad t \in [0, T]. \tag{2.7}$$

Proof. From (2.5) with the dominant operator Φ being coercively positive, we obtain that there exists a unique optimal control $u(\cdot) \in \mathcal{U}$ that minimizes $J(u)$ over $\mathcal{U}$. Moreover, $u(\cdot)$ is optimal if and only if

$$\Phi u = -(\Gamma^* Q f_{(x_0,\phi,\psi)} + \Gamma_T^* Q_T f_{(x_0,\phi,\psi)}(T)), \tag{2.8}$$

or equivalently

$$Ru = -\Gamma^* Q x(\cdot) - \Gamma_T^* Q_T x(T). \tag{2.9}$$

Here the adjoint operators Γ^* and Γ_T^* can be given explicitly by

$$(\Gamma^* y)(t) = \int_t^T F^*(\sigma - t) y(\sigma)\, d\sigma, \qquad t \in [0, T] \quad \forall y \in \mathscr{X},$$
$$(\Gamma_T^* y_1)(t) = F^*(T-t) y_1, \qquad t \in [0, T] \quad \forall y_1 \in X. \tag{2.10}$$

Substitute (2.10) into (2.9); then it follows that (2.7) is valid. □

COROLLARY 1. *For any given $(x_0, \phi, \psi) \in Z$, the optimal control $u(\cdot)$ is the unique solution in $\mathscr{U}$ of the following open-loop equation*:

$$Ru(t) + \int_0^T K(t, \sigma) u(\sigma)\, d\sigma = -F^*(T-t) Q_T f_{(x_0, \phi, \psi)}(T) - \int_t^T F^*(\sigma - t) Q f_{(x_0, \phi, \psi)}(\sigma)\, d\sigma, \qquad t \in [0, T], \tag{2.11}$$

where the kernel operator function is defined by

$$K(t, \sigma) = F^*(T-t) Q_T F(T-\sigma) + \int_t^T F^*(s-t) Q F(s-\sigma)\, ds, \qquad (t, \sigma) \in [0, T]^2. \tag{2.12}$$

Here we also use the convention that (*see* (1.32) *and* (1.28))

$$F(t) \equiv 0 \quad \textit{whenever } t < 0.$$

Proof. Since we can deduce that

$$(\Gamma^* Q \Gamma + \Gamma_T^* Q_T \Gamma_T) u = \int_0^T K(\cdot, \sigma) u(\sigma)\, d\sigma,$$

this result is a direct consequence of the optimal control relation (2.8). The uniqueness can be proved by the fact that $\Phi > 0$. □

COROLLARY 2. *The optimum of $J(u)$ on $\mathscr{U}$ is a quadratic form with respect to the initial condition $(x_0, \phi, \psi) \in Z$ and is given by*

$$J^*(x_0, \phi, \psi) = \min_{u \in \mathscr{U}} J(u; x_0, \phi, \psi) = \left\langle P \begin{pmatrix} x_0 \\ \phi \\ \psi \end{pmatrix}, \begin{pmatrix} x_0 \\ \phi \\ \psi \end{pmatrix} \right\rangle_Z, \tag{2.13}$$

where $P \in \mathscr{L}(Z)$ is a nonnegative operator given by

$$P = \tilde{f}^* Q \tilde{f} + \tilde{f}_T^* Q_T \tilde{f}_T - (\Gamma^* Q \tilde{f} + \Gamma_T^* Q_T \tilde{f}_T)^* \Phi^{-1} (\Gamma^* Q \tilde{f} + \Gamma_T^* Q_T \tilde{f}_T), \tag{2.14}$$

where $\tilde{f} \in \mathscr{L}(Z; \mathscr{X})$ and $\tilde{f}_T \in \mathscr{L}(Z; X)$ are defined by

$$\tilde{f} \begin{pmatrix} x_0 \\ \phi \\ \psi \end{pmatrix} = f_{(x_0, \phi, \psi)}(\cdot) \quad \textit{and} \quad \tilde{f}_T \begin{pmatrix} x_0 \\ \phi \\ \psi \end{pmatrix} = f_{(x_0, \phi, \psi)}(T),$$

respectively.

The proof is simply a completion of squares and hence is omitted here.

3. Semicausal optimality principle. To implement the optimal control $u(t)$ by the attainable information involving only the past state $\{x(\sigma): 0 \leqq \sigma \leqq t\}$, we must try to transfer the effect of the future state segment $\{x(\sigma): t < \alpha \leqq T\}$ to the real time optimal control $u(t)$ by seeking appropriate feedback. Similarly, as we have done in [18], there are two important notions to be introduced here.

DEFINITION 1. Define a truncation operator P_ξ by

$$(P_\xi u)(t) = \begin{cases} u(t), & 0 \leqq t \leqq \xi, \\ 0, & \xi < t \leqq T, \end{cases} \tag{3.1}$$

where $0 \leqq \xi \leqq T$ is arbitrarily given.

Then, both P_ξ and $(I - P_\xi) \in \mathscr{L}(\mathscr{U})$ are projections and it is obvious that

$$\begin{aligned} &P_\xi R = RP_\xi, \quad (I - P_\xi)R = R(I - P_\xi), \\ &R^{-1}P_\xi = P_\xi R^{-1}, \quad R^{-1}(I - P_\xi) = (I - P_\xi)R^{-1}. \end{aligned} \tag{3.2}$$

Denote

$$\mathscr{U}_\xi = (I - P_\xi)\mathscr{U} \subset \mathscr{U}.$$

DEFINITION 2. For a given (x_0, ϕ, ψ) and admissible control $u(\cdot)$, define a semicausal trajectory $x_\xi(\cdot)$ with parameter ξ by

$$x_\xi(t) = f_{(x_0,\phi,\psi)}(t) + \int_0^t F(t-\sigma)P_\xi u(\sigma)\, d\sigma, \qquad t \in [0, T]. \tag{3.3}$$

According to these definitions, the following relations are valid:

$$\begin{aligned} &u = P_\xi u + (I - P_\xi)u, \qquad x_\xi = f_{(x_0,\phi,\psi)} + \Gamma P_\xi u, \\ &x = x_\xi + \Gamma(I - P_\xi)u, \qquad x(T) = x_\xi(T) + \Gamma_T(I - P_\xi)u, \end{aligned} \tag{3.4}$$

where $0 \leqq \xi \leqq T$.

Define

$$\Phi_\xi^+ = (I - P_\xi)\Phi \,|\, \mathscr{U}_\xi, \tag{3.5}$$

where $0 \leqq \xi \leqq T$ is a parameter.

Similarly to [18, Lemma 4], $\Phi_\xi^+ \in \mathscr{L}(\mathscr{U}_\xi)$ is self-adjoint and coercively positive, so that Φ_ξ^+ is invertible and, moreover,

$$\|(\Phi_\xi^+)^{-1}\|_{\mathscr{L}(\mathscr{U}_\xi)} \leqq \text{const.} \tag{3.6}$$

where the constant is uniform for $0 \leqq \xi \leqq T$.

Now define another operator $N_\xi \in \mathscr{L}(\mathscr{X} \times X)$ by

$$N_\xi = I_{\mathscr{X}\times X} - \begin{pmatrix} \Gamma \\ \Gamma_T \end{pmatrix} (\Phi_\xi^+)^{-1}(I - P_\xi)(\Gamma^* Q, \Gamma_T^* Q_T). \tag{3.7}$$

LEMMA 6. *Let $\xi \in [0, T]$ be arbitrarily given. The optimal state trajectory $x(\cdot)$ and the corresponding semicausal trajectory $x_\xi(\cdot)$ are related by*

$$\begin{pmatrix} x(\cdot) \\ x(T) \end{pmatrix} = N_\xi \begin{pmatrix} x_\xi(\cdot) \\ x_\xi(T) \end{pmatrix}. \tag{3.8}$$

Proof. For any given initial data $\{x_0, \phi, \psi\}$, let $\{u(\cdot), x(\cdot)\}$ be the optimal control process. From (2.9) and (3.4) it follows that

$$Ru + (\Gamma^* Q \Gamma + \Gamma_T^* Q_T \Gamma_T)(I - P_\xi)u = -(\Gamma^* Q x_\xi + \Gamma_T^* Q_T x_\xi(T)). \tag{3.9}$$

Apply the operator $(I - P_\xi)$ on both sides of (3.9) and use the invertibility of the operator Φ_ξ^+; then

$$(I - P_\xi)u = -(\Phi_\xi^+)^{-1}(I - P_\xi)(\Gamma^* Q, \Gamma_T^* Q_T) \begin{pmatrix} x_\xi(\cdot) \\ x_\xi(T) \end{pmatrix}. \tag{3.10}$$

Substitute (3.10) into the expressions for $x(\cdot)$ and $x(T)$ in (3.4); then (3.8) is obtained. □

Remark 1. If $\xi = 0$, then $x_\xi(t) = f_{(x_0,\phi,\psi)}(t)$, for any $t \in (0, T]$. We have

$$N_{\xi=0} = I_{\mathscr{X}\times X} - \begin{pmatrix} \Gamma \\ \Gamma_T \end{pmatrix} \Phi^{-1}(\Gamma^* Q, \Gamma_T^* Q_T),$$

since $(\Phi_{\xi=0}^+)^{-1} = \Phi^{-1}$ and $I - P_0 = I$. Hence it follows that when $\xi = 0$,

$$N_\xi \begin{pmatrix} x_\xi(\cdot) \\ x_\xi(T) \end{pmatrix} = N_0 \begin{pmatrix} f_{(x_0,\phi,\psi)}(\cdot) \\ f_{(x_0,\phi,\psi)}(T) \end{pmatrix}$$

$$= \begin{pmatrix} f_{(x_0,\phi,\psi)}(\cdot) - \Gamma\Phi^{-1}(\Gamma^* Q f_{(x_0,\phi,\psi)} + \Gamma_T^* Q_T f_{(x_0,\phi,\psi)}(T)) \\ f_{(x_0,\phi,\psi)}(T) - \Gamma_T\Phi^{-1}(\Gamma^* Q f_{(x_0,\phi,\psi)} + \Gamma_T^* Q_T f_{(x_0,\phi,\psi)}(T)) \end{pmatrix}$$

(by the open-loop relation (2.8))

$$= \begin{pmatrix} f_{(x_0,\phi,\psi)}(\cdot) + \Gamma\Phi^{-1}(\Phi u) \\ f_{(x_0,\phi,\psi)}(T) + \Gamma_T\Phi^{-1}(\Phi u) \end{pmatrix}$$

$$= \begin{pmatrix} f_{(x_0,\phi,\psi)}(\cdot) + \Gamma u \\ f_{(x_0,\phi,\psi)}(T) + \Gamma_T u \end{pmatrix} = \begin{pmatrix} x(\cdot) \\ x(T) \end{pmatrix},$$

where u is the optimal control corresponding to the given initial data (x_0, ϕ, ψ), and $x(\cdot)$ is the optimal trajectory corresponding to u.

Therefore, even if $\xi = 0$, Lemma 6 and (3.8) still hold. The reason is that for the optimal process, the optimal control $u(\cdot)$ is uniquely determined by the initial data (x_0, ϕ, ψ), so the optimal trajectory $x(\cdot)$ and its terminal value $x(T)$, in turn, are also uniquely determined by the initial data (x_0, ϕ, ψ) only.

THEOREM 3 (Optimality Principle). *$u(\cdot)$ is an optimal control if and only if*

$$u(t) = -R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T) N_t \begin{pmatrix} x_t(\cdot) \\ x_t(T) \end{pmatrix}, \qquad t \in [0, T], \tag{3.11}$$

where $x_t(\cdot)$ is the corresponding semicausal trajectory with parameter t, N_t is given by (3.7), *and the operators $\Gamma^*(t) \in \mathscr{L}(\mathscr{X}; U)$ and $\Gamma_T^*(t) \in \mathscr{L}(X; U)$ are defined by*

$$\begin{aligned} &\Gamma^*(t)y = \int_t^T F^*(\sigma - t)y(\sigma)\, d\sigma, \quad \forall y \in \mathscr{X}, \\ &\Gamma_T^*(t)y_1 = F^*(T - t)y_1, \quad \forall y_1 \in X, \end{aligned} \tag{3.12}$$

respectively.

Proof. (i) If $u(\cdot)$ is an optimal control, from (2.9) and (3.8) it follows that

$$u = -R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T) N_\xi \begin{pmatrix} x_\xi \\ x_\xi(T) \end{pmatrix}, \tag{3.13}$$

where $\xi \in [0, T]$ is arbitrary. Note (2.10) and (3.12), and take $\xi = t$ for the real time value $u(t)$; then (3.13) reduces to (3.11).

(ii) Conversely, to show that if $u(\cdot)$ satisfies (3.11) then it must be the optimal control, it is enough to show that the control $u(\cdot)$, which satisfies (3.11), is unique. This amounts to showing that $f_{(x_0,\phi,\psi)} = 0$ and $u(\cdot)$ satisfies (3.11) only if $u(t) \equiv 0$ on $[0, T]$.

Indeed, since $f_{(x_0,\phi,\psi)} = 0$, we have $x_t = \Gamma P_t u$. By (3.11), it can be estimated that

$$\|u(t)\| \leqq R^{-1}\| \|(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)\|_{\mathscr{L}(\mathscr{X}\times X; U)} \|N_t\|_{\mathscr{L}(\mathscr{X}\times X)} \left\| \begin{pmatrix} x_t \\ x_t(T) \end{pmatrix} \right\|_{\mathscr{X}\times X} \tag{3.14}$$

Since (1.32) implies $F(t)$ is piecewise strongly continuous and uniformly bounded on the finite interval $[0, T]$, from (3.12), (2.1), (2.2), and (3.7), it follows that

$$\begin{aligned} &\|(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)\|_{\mathscr{L}(\mathscr{X}\times X;U)} \leqq \text{const.},\\ &\|N_t\|_{\mathscr{L}(\mathscr{X}\times X)} \leqq \text{const.}, \end{aligned} \tag{3.15}$$

and

$$\begin{aligned} \left\|\begin{pmatrix} x_t \\ x_t(T)\end{pmatrix}\right\|_{\mathscr{X}\times X} &= \left\|\begin{pmatrix} \Gamma P_t u \\ \Gamma_T P_t u\end{pmatrix}\right\|_{\mathscr{X}\times X} \leqq \text{const.}\,(\|\Gamma\|_{\mathscr{L}(\mathscr{U};\mathscr{X})} + \|\Gamma_T\|_{\mathscr{L}(\mathscr{U};\mathscr{X})})\|P_t u\|_{\mathscr{U}} \\ &= \text{const.}\,\|P_t u\|_{\mathscr{U}}, \end{aligned} \tag{3.16}$$

where all the constants are independent of $t \in [0, T]$. Finally, since

$$\|P_t u\|_{\mathscr{U}} = \left\{\int_0^t \|u(s)\|^2\, ds\right\}^{1/2}, \qquad t \in [0, T], \tag{3.17}$$

all these estimations imply that

$$\|u(t)\|^2 \leqq \text{const.} \int_0^t \|u(s)\|^2\, ds, \qquad t \in [0, T], \tag{3.18}$$

which allows us to use the Gronwall–Bellman inequality to obtain that $u(t) \equiv 0$. □

This optimality principle has qualitatively demonstrated the causal dependence of the optimal control $u(t)$ on the past information $x_t(\cdot)$ or $P_t u$.

4. Fredholm synthesis equation. Let $\xi \in [0, T]$. Define an operator function

$$M_\xi(t, \sigma) = -R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T) N_\xi \begin{pmatrix} F(\cdot - \sigma) \\ F(T - \sigma)\end{pmatrix}, \tag{4.1}$$

where $(t, \sigma) \in [0, T]\times[0, T]$, and $M_\xi(t, \sigma) \in \mathscr{L}(U)$.

LEMMA 7. *The following identities hold*:

$$(\Phi_\xi^+)^{-1}(I - P_\xi)(\Gamma^* Q, \Gamma_T^* Q_T) = (I - P_\xi) R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T) N_\xi : \mathscr{X}\times X \to \mathscr{U}_\xi, \tag{4.2}$$

and

$$\begin{pmatrix} \Gamma \\ \Gamma_T\end{pmatrix} (\Phi_\xi^+)^{-1}(I - P_\xi) = N_\xi \begin{pmatrix} \Gamma \\ \Gamma_T\end{pmatrix} (I - P_\xi) R^{-1} : \mathscr{U} \to \mathscr{X}\times X. \tag{4.3}$$

Proof. The proof is simply a verification with the use of definitions, the idempotent property of $(I - P_\xi)$, and (3.2). Since it is similar to Lemma 6 of [8], it is omitted here.

THEOREM 4 (Synthesis Equation). *For any given $\xi \in [0, T]$, there exists a unique solution $M_\xi(t, \sigma)$ of the following equation*:

$$M_\xi(t, \sigma) + \int_\xi^T R^{-1} K(t, s) M_\xi(s, \sigma)\, ds = -R^{-1} K(t, \sigma), \qquad (t, \sigma) \in [0, T]\times[0, T], \tag{4.4}$$

where $K(t, \sigma)$ is given by (2.12). *The solution is given by* (4.1), *which is strongly continuous in t and piecewise continuous in σ and such that*

$$\|M_\xi(t, \sigma)\| \leqq \text{const.}, \qquad \forall (\xi, t, \sigma) \in [0, T]^3. \tag{4.5}$$

Proof. First we show that $M_\xi(t, \sigma)$ given by (4.1) is a solution of the equation (4.4). Besides, it is easy to see that this $M_\xi(t, \sigma)$ does satisfy the required conditions

of continuity and boundedness from the definition. We check that (4.4) is satisfied by (4.1) as follows:

$$M_\xi(t,\sigma) = -R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)N_\xi \begin{pmatrix} F(\cdot-\sigma) \\ F(T-\sigma) \end{pmatrix}$$

$$= -R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)\left\{ I_{\mathscr{X}\times X} - \begin{pmatrix} \Gamma \\ \Gamma_T \end{pmatrix} (\Phi_\xi^+)^{-1}(I-P_\xi)(\Gamma^*Q, \Gamma_T^*Q_T) \right\}$$

$$\cdot \begin{pmatrix} F(\cdot-\sigma) \\ F(T-\sigma) \end{pmatrix}$$

$$= -R^{-1}(\Gamma^*(t)QF(\cdot-\sigma) + \Gamma_T^*(t)Q_TF(T-\sigma))$$

$$+ R^{-1}(\Gamma^*(t)Q\Gamma + \Gamma_T^*(t)Q_T\Gamma_T)(\Phi_\xi^+)^{-1}(I-P_\xi)(\Gamma^*Q, \Gamma_T^*Q_T)\begin{pmatrix} F(\cdot-\sigma) \\ F(T-\sigma) \end{pmatrix}$$

$$= -R^{-1}(\Gamma^*(t)QF(\cdot-\sigma) + \Gamma_T^*(t)Q_TF(T-\sigma))$$

(by (4.2))

$$+ R^{-1}(\Gamma^*(t)Q\Gamma + \Gamma_T^*(t)Q_T\Gamma_T)(I-P_\xi)R^{-1}(\Gamma^*Q, \Gamma_T^*Q_T)N_\xi \begin{pmatrix} F(\cdot-\sigma) \\ F(T-\sigma) \end{pmatrix}$$

$$= -R^{-1}(\Gamma^*(t)QF(\cdot-\sigma) + \Gamma_T^*(t)Q_TF(T-\sigma))$$

(by (4.1))

$$-R^{-1}(\Gamma^*(t)Q\Gamma + \Gamma_T^*(t)Q_T\Gamma_T)(I-P_\xi)M_\xi(\cdot,\sigma). \tag{4.6}$$

From (3.12), (2.1), (2.2), and (2.12), it follows that

$$R^{-1}(\Gamma^*(t)QF(\cdot-\sigma) + \Gamma_T^*(t)Q_TF(T-\sigma)) = R^{-1}K(t,\sigma), \tag{4.7}$$

and

$$\begin{aligned} &R^{-1}(\Gamma^*(t)Q\Gamma + \Gamma_T^*(t)Q_T\Gamma_T)(I-P_\xi)M_\xi(\cdot,\sigma) \\ &\quad = \int_0^T R^{-1}K(t,s)(I-P_\xi)M_\xi(s,\sigma)\,ds = \int_\xi^T R^{-1}K(t,s)M_\xi(s,\sigma)\,ds. \end{aligned} \tag{4.8}$$

Substitute (4.7) and (4.8) into (4.6); then we obtain

$$M_\xi(t,\sigma) = -R^{-1}K(t,\sigma) - \int_\xi^T R^{-1}K(t,s)M_\xi(s,\sigma)\,ds.$$

This last relation shows that the $M_\xi(t,\sigma)$ given by (4.1) is exactly a solution of the equation (4.4).

Next we prove the uniqueness. This can be done by showing that the corresponding homogeneous equation

$$\tilde{M}_\xi(t,\sigma) + \int_\xi^T R^{-1}K(t,s)\tilde{M}_\xi(s,\sigma)\,ds = 0, \qquad (t,\sigma)\in[0,T]^2 \tag{4.9}$$

admits only the null solution $\tilde{M}_\xi(t,\sigma)\equiv 0$. Indeed, (4.9) restricted on $(t,\sigma)\in[\xi,T]\times[0,T]$ can be rewritten as

$$\Phi_\xi^+\tilde{M}(\cdot,\sigma) = 0 \quad \text{for each } \sigma\in[0,T]. \tag{4.10}$$

Since Φ_ξ^+ is invertible in $\mathscr{L}(\mathscr{U}_\xi)$, we have

$$\tilde{M}_\xi(s,\sigma)\equiv 0 \quad \text{for } s\in[\xi, T] \text{ and } \sigma\in[0, T]. \tag{4.11}$$

Then substitute (4.11) into the integral term of (4.9); we finally obtain

$$\tilde{M}_\xi(t,\sigma)\equiv 0 \quad \text{for } t\in[0, T] \text{ and } \sigma\in[0, T]. \tag{4.12}$$

Thus the proof is completed. □

This result means that the inversion $(\Phi_\xi^+)^{-1}$ has been transferred into solving a linear integral equation (4.4) of Fredholm type. Thus it is possible to obtain the following feedback optimal control by using the semicausal trajectory.

THEOREM 5. *$u(\cdot)$ is the optimal control if and only if*

$$\begin{aligned} u(t) &= -R^{-1}[\Gamma^*(t)Qx_t+\Gamma_T^*(t)Q_Tx_t(T)] \\ &\quad -\int_t^T M_t(t,\sigma)R^{-1}[\Gamma^*(\sigma)Qx_t+\Gamma_T^*(\sigma)Q_Tx_t(T)]\,d\sigma, \qquad t\in[0, T], \end{aligned} \tag{4.13}$$

where $M_\xi(t,\sigma)$ is the unique solution of the linear integral equation (4.4) *of Fredholm type, and $x_t(\cdot)$ is the corresponding semicausal trajectory with real time t as parameter value.*

Proof. If $u(\cdot)$ is the optimal control, by the previous results (3.11), (3.7), and (4.3), it follows that

$$\begin{aligned} u(t) &= -R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)N_t\begin{pmatrix} x_t \\ x_t(T)\end{pmatrix} \\ &= -R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)\begin{pmatrix} x_t \\ x_t(T)\end{pmatrix} + R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)\begin{pmatrix}\Gamma \\ \Gamma_T\end{pmatrix} \\ &\qquad \cdot(\Phi_t^+)^{-1}(I-P_t)(\Gamma^*Q, \Gamma_T^*Q_T)\begin{pmatrix} x_t \\ x_t(T)\end{pmatrix} \\ &= -R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_t)\begin{pmatrix} x_t \\ x_t(T)\end{pmatrix} + R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)N_t\begin{pmatrix}\Gamma \\ \Gamma_T\end{pmatrix} \\ &\qquad \cdot(I-P_t)R^{-1}(\Gamma^*Q, \Gamma_T^*Q_T)\begin{pmatrix} x_t \\ x_t(T)\end{pmatrix} \\ &= -R^{-1}[\Gamma^*(t)Qx_t+\Gamma_T^*(t)Q_Tx_t(T)] \\ &\quad + R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)N_t \\ &\qquad \cdot\begin{pmatrix} \int_t^T F(\cdot-\sigma)R^{-1}[\Gamma^*(\sigma)Qx_t+\Gamma_T^*(\sigma)Q_Tx_t(T)]\,d\sigma \\ \int_t^T F(T-\sigma)R^{-1}[\Gamma^*(\sigma)Qx_t+\Gamma_T^*(\sigma)Q_Tx_t(T)]\,d\sigma\end{pmatrix} \\ &= -R^{-1}[\Gamma^*(t)Qxt+\Gamma_T^*(t)Q_Tx_t(T)] \\ &\qquad + \int_t^T R^{-1}(\Gamma^*(t)Q, \Gamma_T^*(t)Q_T)N_t\begin{pmatrix} F(\cdot-\sigma) \\ F(T-\sigma)\end{pmatrix} \\ &\qquad \cdot R^{-1}[\Gamma^*(\sigma)Qx_t+\Gamma_T^*(\sigma)Q_Tx_t(T)]\,d\sigma \\ &= -R^{-1}[\Gamma^*(t)Qx_t+\Gamma_T^*(t)Q_Tx_t(T)] \\ &\qquad -\int_t^T M_t(t,\sigma)R^{-1}[\Gamma^*(\sigma)Qx_t+\Gamma_T^*(\sigma)Q_Tx_t(T)]\,d\sigma, \end{aligned} \tag{4.14}$$

where we have made use of the convention (1.28). Equation (4.14) shows that the optimal control actually satisfies (4.13).

Conversely, if the initial data (x_0, ϕ, ψ) is given, then there exists only one control $u(\cdot)$, which satisfies the relation (4.13). This can be shown in a similar way by the Gronwall-Bellman inequality, as in the proof of Theorem 4. Thus it is concluded that (4.13) is necessary and sufficient for $u(\cdot)$ to be optimal. □

THEOREM 6 (semicausal trajectory feedback). *$u(\cdot)$ is the optimal control if and only if*

$$u(t) = -\pi(T, t)Q_T x_t(T) - \int_t^T \pi(s, t)Qx_t(s)\,ds, \qquad t \in [0, T], \tag{4.15}$$

where

$$\pi(s, t) = R^{-1}F^*(s-t) + \int_t^s M_t(t, \sigma)R^{-1}F^*(s-\sigma)\,d\sigma, \tag{4.16}$$

and $M_\xi(t, \sigma)$ and $x_t(\cdot)$ are described as in Theorem 5.

Proof. Substitute (3.12) into (4.13), to obtain

$$\begin{aligned} u(t) &= -R^{-1}\left[F^*(T-t)Q_T x_t(T) + \int_t^T F^*(s-t)Qx_t(s)\,ds\right] \\ &\quad - \int_t^T M_t(t, \sigma)R^{-1}\left[F^*(T-\sigma)Q_T x_t(T) + \int_\sigma^T F^*(s-\sigma)Qx_t(s)\,ds\right]d\sigma \\ &= -\left[R^{-1}F^*(T-t) + \int_t^T M_t(t, \sigma)R^{-1}F^*(T-\sigma)\,d\sigma\right]Q_T x_t(T) \\ &\quad - \int_t^T \left[R^{-1}F^*(s-t) + \int_t^s M_t(t, \sigma)R^{-1}F^*(s-\sigma)\,d\sigma\right]Qx_t(s)\,ds \\ &= -\pi(T, t)Q_T x_t(T) - \int_t^T \pi(s, t)Qx_t(s)\,ds, \qquad t \in [0, T]. \end{aligned}$$

Conversely, (4.13) can be deduced from (4.15) so these two relations are equivalent. Thus the conclusion is true. □

Remark 2. Since the semicausal state trajectory $x_t(\cdot)$ with real time t as a running parameter is determined only by the past control $\{u(\sigma): \sigma \leqq t\}$, and the feedback operator function $\pi(s, t)$ is known provided the solution $M_\xi(t, \sigma)$ of the equation (4.4) is available by any means (analytically or numerically), the obtained result (4.15) is justified to be a closed-loop solution of the described optimal control problem.

5. Closed-loop optimal control. In this section, we present an expression for the real time optimal control $u(t)$ by state feedback that involves $\{x(\sigma): \sigma \leqq t\}$, based on the semicausal trajectory feedback given by Theorem 6.

A clarification of the relationship between the state function $x(t)$ and the corresponding semicausal trajectory $x_\xi(t)$ will pave the way to the closed-loop synthesis of the optimal control.

LEMMA 8. *Let $G(t)$ be the fundamental solution associated with* (1.6) *and let $F(t)$ be defined by* (1.32). *Then, the following relation holds*:

$$F(t+s) = G(t)F(s) + \sum_{i=1}^{n} \int_0^{\min(t, h_i)} G(t-\sigma)A_i F(s+\sigma-h_i)\,d\sigma \quad \text{for } t \geqq 0,\ s \geqq 0. \tag{5.1}$$

Proof. The equality can be verified by the use of (1.23) and (1.32). □

LEMMA 9. *Let $x(\cdot)$ be any state function with an initial data $(x_0, \phi, \psi) \in Z$ and an admissible control $u \in \mathcal{U}$, and let $x_\xi(\cdot)$ be the corresponding semicausal trajectory with parameter $\xi \in [0, T]$. Then, the following relation holds:*

$$x_\xi(t) = \begin{cases} x(t) & \text{for } t \leqq \xi, \\ G(t-\xi)x(\xi) + \sum_{i=1}^{n} \int_{\xi}^{\min(t,\xi+h_i)} G(t-\eta)A_i x(\eta - h_i)\, d\eta \end{cases}$$

$$+ \sum_{i=1}^{n} \int_{\min(\xi,h_i)}^{h_i} G(t-\eta)A_i \phi(\eta - h_i)\, d\eta \tag{5.2}$$

$$+ \sum_{j=1}^{m} \int_{\min(\xi,r_j)}^{r_j} G(t-\eta)B_j \psi(\eta - r_j)\, d\eta \quad \text{for } t > \xi.$$

Proof. It is enough to prove (5.2) only for $t > \xi$. In fact, for $t > \xi$,

$$x_\xi(t) \underset{(3.3)}{=} f_{(x_0,\phi,\psi)}(t) + \int_0^\xi F(t-\sigma)u(\sigma)\, d\sigma$$

$$\underset{(1.31)}{=} G(t)x_0 + \int_0^t G(t-\sigma)\left\{ \sum_{i=1}^{n} A_i \phi(\sigma - h_i) + \sum_{j=1}^{m} B_j \psi(\sigma - r_j) \right\} d\sigma$$

$$+ \int_0^\xi F(t-\sigma)u(\sigma)\, d\sigma$$

$$\underset{(5.1)}{\overset{(1.23)}{=}} G(t-\xi)G(\xi)x_0 + \sum_{i=1}^{n} \int_{\xi}^{\min(t-\xi,h_i)} G(t-\xi-s)A_i G(\xi+s-h_i)\, ds\, x_0$$

$$+ G(t-\xi) \int_0^\xi G(\xi-\sigma)\left\{ \sum_{i=1}^{n} A_i \phi(\sigma - h_i) + \sum_{j=1}^{m} B_j \psi(\sigma - r_j) \right\} d\sigma$$

$$+ \sum_{i=1}^{n} \int_0^\xi \int_0^{\min(t-\xi,h_i)} G(t-\xi-s)A_i G(\xi-\sigma+s-h_i)\, ds$$

$$\cdot \left\{ \sum_{i=1}^{n} A_i \phi(\sigma - h_i) + \sum_{j=1}^{m} B_j \psi(\sigma - r_j) \right\} d\sigma$$

$$+ G(t-\xi) \int_0^\xi F(\xi-\sigma)u(\sigma)\, d\sigma$$

$$+ \sum_{i=1}^{n} \int_0^\xi \int_0^{\min(t-\xi,h_i)} G(t-\xi-s)A_i F(\xi-\sigma+s-h_i)\, ds\, u(\sigma)\, d\sigma$$

$$+ \int_\xi^t G(t-\sigma)\left\{ \sum_{i=1}^{n} A_i \phi(\sigma - h_i) + \sum_{j=1}^{m} B_j \psi(\sigma - r_j) \right\} d\sigma$$

$$= G(t-\xi)\left\{ G(\xi)x_0 + \int_0^\xi G(\xi-\sigma)\left\{ \sum_{i=1}^{n} A_i \phi(\sigma - h_i) + \sum_{j=1}^{m} B_j \psi(\sigma - r_j) \right\} d\sigma \right.$$

$$\left. + \int_0^\xi F(\xi-\sigma)u(\sigma)\, d\sigma \right\}$$

$$+\sum_{i=1}^{n}\int_{\xi}^{\min(t,\xi+h_i)} G(t-\eta)A_i\Bigg[G(\eta-h_i)x_0+\int_0^{\xi} G(\eta-\sigma-h_i)\cdot\Bigg\{\sum_{i=1}^{n}A_i\phi(\sigma-h_i)+\sum_{j=1}^{m}B_j\psi(\sigma-r_j)\Bigg\}d\sigma+\int_0^{\xi}F(\eta-\sigma-h_i)u(\sigma)\,d\sigma\Bigg]d\eta$$

$$+\int_{\xi}^{t}G(t-\sigma)\Bigg\{\sum_{i=1}^{n}A_i\phi(\sigma-h_i)+\sum_{j=1}^{m}B_j\psi(\sigma-r_j)\Bigg\}d\sigma$$

(note that $G(t)=0$ and $F(t)=0$ whenever $t<0$)

$$=G(t-\xi)x(\xi)+\sum_{i=1}^{n}\int_{\xi}^{\min(t,\xi+h_i)}G(t-\eta)A_ix(\eta-h_i)\,d\eta+\sum_{i=1}^{n}\int_{\min(\xi,h_i)}^{h_i}G(t-\eta)A_i\phi(\eta-h_i)\,d\eta+\sum_{j=1}^{m}\int_{\min(\xi,r_j)}^{r_j}G(t-\eta)B_j\psi(\eta-r_j)\,d\eta.$$

Therefore, (5.2) is valid. □

Based on these above results, the closed-loop optimal control is achieved as follows.

THEOREM 7 (closed-loop optimal control). *$u(\cdot)$ is the optimal control if and only if it is given by the following linear state feedback*:

$$u(t)=-\Bigg[H(t,t)x(t)+\sum_{i=1}^{n}\int_{t}^{\min(T,t+h_i)}H(t,\eta)A_ix(\eta-h_i)\,d\eta+\sum_{i=1}^{n}\int_{\min(t,h_i)}^{h_i}H(t,\eta)A_ix(\eta-h_i)\,d\eta+\sum_{j=1}^{m}\int_{\min(t,r_j)}^{r_j}H(t,\eta)B_ju(\eta-r_j)\,d\eta\Bigg],\qquad t\in[0,T],\tag{5.3}$$

where $x(\cdot)$ is the corresponding state function, and

(5.4)

$$H(t,\eta)=\pi(T,t)Q_TG(T-\eta)+\int_t^T\pi(s,t)QG(s-\eta)\,ds,\qquad(t,\eta)\in[0,T]\times[0,T]$$

and $\pi(s,t)$ is given by (4.16).

Proof. Substitute (5.2) into (4.15), then the optimal control $u(t)$ is given by

$$u(t)=-\pi(T,t)Q_Tx_t(T)-\int_t^T\pi(s,t)Qx_t(s)\,ds$$

$$=-\pi(T,t)Q_T\Bigg\{G(T-t)x(t)+\sum_{i=1}^{n}\int_t^{\min(T,t+h_i)}G(T-\eta)A_ix(\eta-h_i)\,d\eta+\sum_{i=1}^{n}\int_{\min(t,h_i)}^{h_i}G(T-\eta)A_i\phi(\eta-h_i)\,d\eta+\sum_{j=1}^{m}\int_{\min(t,r_j)}^{r_j}G(T-\eta)B_j\psi(\eta-r_j)\,d\eta\Bigg\}$$

$$-\int_t^T\pi(s,t)Q\Bigg\{G(s-t)x(t)+\sum_{i=1}^{n}\int_t^{\min(s,t+h_i)}G(s-\eta)A_ix(\eta-h_i)\,d\eta$$

$$+\sum_{i=1}^{n}\int_{\min(t,h_i)}^{h_i} G(s-\eta)A_i\phi(\eta-h_i)\,d\eta$$

$$+\sum_{j=1}^{m}\int_{\min(t,r_j)}^{r_j} G(s-\eta)B_j\psi(\eta-r_j)\,d\eta\Bigg\}\,ds$$

$$=-\Bigg[\pi(T,t)Q_TG(T-t)+\int_t^T \pi(s,t)QG(s-t)\,ds\Bigg]x(t)$$

$$-\sum_{i=1}^{n}\int_t^{\min(T,t+h_i)}\Bigg[\pi(T,t)Q_TG(T-\eta)+\int_t^T \pi(s,t)QG(s-\eta)\,ds\Bigg]$$

$$\cdot A_ix(\eta-h_i)\,d\eta$$

$$-\sum_{i=1}^{n}\int_{\min(t,h_i)}^{h_i}\Bigg[\pi(T,t)Q_TG(T-\eta)+\int_t^T \pi(s,t)QG(s-\eta)\,ds\Bigg]$$

$$\cdot A_i\phi(\eta-h_i)\,d\eta$$

$$-\sum_{j=1}^{m}\int_{\min(t,r_j)}^{r_j}\Bigg[\pi(T,t)Q_TG(T-\eta)+\int_t^T \pi(s,t)QG(s-\eta)\,ds\Bigg]$$

$$\cdot B_j\psi(\eta-r_j)\,d\eta$$

$$=-\Bigg[H(t,t)x(t)+\sum_{i=1}^{n}\int_t^{\min(T,t+h_i)} H(t,\eta)A_ix(\eta-h_i)\,d\eta$$

$$+\sum_{i=1}^{n}\int_{\min(t,h_i)}^{h_i} H(t,\eta)A_ix(\eta-h_i)\,d\eta$$

$$+\sum_{j=1}^{m}\int_{\min(t,r_j)}^{r_j} H(t,\eta)B_ju(\eta-r_j)\,d\eta\Bigg],\qquad t\in[0,T],$$

where $\phi(\eta-h_i)=x(\eta-h_i)$ for $\min(t,h_i)\leqq\eta<h_i$ so that $-h_i\leqq\eta-h_i<0$, $i=1,\cdots,n$, and $\psi(\eta-r_j)=u(\eta-r_j)$ for $\min(t,r_j)\leqq\eta<r_j$ so that $-r_j\leqq\eta-r_j\leqq 0$, $j=1,\cdots,m$. This indicates that the optimal control $u(\cdot)$ satisfies the feedback relation (5.3). Conversely, if $u(\cdot)$ satisfies (5.3), we can deduce that $u(\cdot)$ satisfies (4.15). By Theorem 6, this $u(\cdot)$ must be the optimal control. □

COROLLARY 1. *For $t\in[\max(h_n,r_m),T]$, the optimal control is given by*

$$u(t)=-\Bigg[H(t,t)x(t)+\sum_{i=1}^{n}\int_t^{\min(T,t+h_i)} H(t,\eta)A_ix(\eta-h_i)\,d\eta\Bigg]. \tag{5.5}$$

Therefore the last two summation parts depending on the initial data ϕ and ψ have effects only on the small interval $[0,\max(h_n,r_m)]$.

COROLLARY 2. *If $B_1=\cdots=B_m=0$, i.e., there is no time delay in the control variable of the system* (1.1), *then the optimal control is given by*

$$u(t)=-\Bigg[L(t,t)x(t)+\sum_{i=1}^{n}\int_t^{\min(T,t+h_i)} L(t,\eta)A_ix(\eta-h_i)\,d\eta$$

$$+\sum_{i=1}^{n}\int_{\min(t,h_i)}^{h_i} L(t,\eta)A_ix(\eta-h_i)\,d\eta\Bigg],\qquad t\in[0,T], \tag{5.6}$$

where $L(t,\eta)$ is given by

$$L(t,\eta)=R^{-1}B^*\Psi(t,\eta)+\int_t^T M_t(t,\sigma)R^{-1}B^*\Psi(\sigma,\eta)\,d\sigma, \tag{5.7}$$

where

$$\Psi(t,\eta)=G^*(T-t)Q_TG(T-\eta)+\int_t^T G^*(s-t)QG(s-\eta)\,ds \tag{5.8}$$

and $M_\xi(t,\sigma)$ *is the unique solution of the following integral equation*:

$$M_\xi(t,\sigma)+\int_\xi^T R^{-1}B^*\Psi(t,s)BM_\xi(s,\sigma)\,ds=-R^{-1}B^*\Psi(t,\sigma)B, \tag{5.9}$$

$$(t,\sigma)\in[0,T]\times[0,T].$$

Proof. Let $F(t)=G(t)B$ be substituted into (2.12), (4.4), (4.16), and (5.4); then this result is a consequence of the main result described by Theorem 7. □

COROLLARY 3. *If* $A_1=\cdots=A_n=0$, *i.e., there is no time delay in the state variable of the system* (1.1), *then the optimal control is given by*

$$u(t)=-\left[H(t,t)x(t)+\sum_{j=1}^m\int_{\min(t,r_j)}^{r_j}H(t,\eta)B_ju(\eta-r_j)\,d\eta\right], \tag{5.10}$$

where $H(t,\eta)$ *is given by* (5.4) *and* $\pi(s,t)$ *is given by* (4.16), *with*

$$F(t)=e^{At}B+e^{A(t-r_1)}B_1+\cdots+e^{A(t-r_m)}B_m. \tag{5.11}$$

COROLLARY 4. *If* $A_i=0$ $(i=1,\cdots,n)$ *and* $B_j=0$ $(j=1,\cdots,m)$, *then the optimal control is given by*

$$u(t)=-H(t,t)x(t),\qquad t\in[0,T], \tag{5.12}$$

where

$$H(t,t)=\pi(T,t)Q_TG(T-t)+\int_t^T\pi(s,t)QG(s-t)\,ds \tag{5.13}$$

in which

$$G(t)=e^{At}\qquad (G^*(t)=e^{A^*t},\ t\geqq 0,\ \textit{is the dual semigroup}), \tag{5.14}$$

$$\pi(s,t)=R^{-1}B^*\,e^{A^*(s-t)}+\int_t^s M_t(t,\sigma)R^{-1}B^*\,e^{A^*(s-\sigma)}\,d\sigma, \tag{5.15}$$

$M_\xi(t,\sigma)$ *is the unique solution of the equation* (4.4), *in which*

$$K(t,\sigma)=B^*\left\{e^{A^*(T-t)}Q_Te^{A(T-\sigma)}+\int_t^T e^{A^*(s-t)}Qe^{A(s-\sigma)}\,ds\right\}B. \tag{5.16}$$

To show that in this nondelay case ($A_i=0$, $i=1,\cdots,n$, $B_j=0$, $j=1,\cdots,m$), the closed-loop optimal control given by (5.12) does coincide with the standard result by the state feedback with the solution of a Riccati equation, we need the following lemmas.

Later in this section, we denote $G(t)=e^{At}$, $t\geqq 0$, with the previous convention that $G(t)\equiv 0$ whenever $t<0$.

LEMMA 10. *Define an operator function* $W(t,\xi)$ *by*

$$W(t,\xi)=G(t-\xi)-\Gamma(t)(\Phi_\xi^+)^{-1}(I-P_\xi)(\Gamma^*Q,\Gamma_T^*Q_T)\begin{pmatrix}G(\cdot-\xi)\\ G(T-\xi)\end{pmatrix},\qquad 0<\xi\leqq t\leqq T, \tag{5.17}$$

and it is a convention that

$$W(t,\xi)=0\quad \textit{for } t<\xi,$$

where $\Gamma(t)\in\mathscr{L}(\mathscr{U};X)$ *is defined by* (*see* (2.1))

$$\Gamma(t)u=\int_0^t G(t-\sigma)Bu(\sigma)\,d\sigma.$$

Then,

(*i*) *For any given initial condition, the optimal state trajectory* $x(\cdot)$ *satisfies*

$$x(t) = W(t, \xi)x(\xi), \qquad 0 < \xi \leqq t \leqq T. \tag{5.18}$$

(ii) $\sup_{0<\xi\leqq t\leqq T} \| W(t, \xi)\|_{\mathscr{L}(X)} \leqq \text{const.}$

(iii) $W(t, \eta)W(\eta, \xi) = W(t, \xi)$, $0 < \xi \leqq \eta \leqq t \leqq T$.

(iv) $W(t, \xi)$ *is strongly continuous in* $t \in [\xi, T]$ *and in* $\xi \in (0, T]$, *respectively.*

Proof. (i) Since

$$x(t) \overset{(3.4)}{=} x_\xi(t) + \Gamma(t)(I - P_\xi)u, \qquad 0 < \xi \leqq t \leqq T,$$

$$(I - P_\xi)u \overset{(3.10)}{=} -(\Phi_\xi^+)^{-1}(I - P_\xi)(\Gamma^* Q x_\xi + \Gamma_T^* Q_T x_\xi(T)),$$

$$x_\xi(t) \overset{(5.2)}{=} G(t - \xi)x(\xi), \qquad 0 < \xi \leqq t \leqq T,$$

it follows that

$$x(t) = \left(G(t-\xi) - \Gamma(t)(\Phi_\xi^+)^{-1}(I - P_\xi)(\Gamma^* Q, \Gamma_T^* Q_T) \begin{pmatrix} G(\cdot - \xi) \\ G(T - \xi) \end{pmatrix} \right) x(\xi) = W(t, \xi)x(\xi).$$

(ii) By (3.6) and (5.17), $W(t, \xi)$ is uniformly bounded in the $\mathscr{L}(X)$ norm.

(iii) Let $0 < \xi \leqq \eta \leqq t \leqq T$; then it follows from (5.17) and (4.2) that

$$\begin{aligned} W(t, \eta)W(\eta, \xi) &= G(t-\xi) - G(t-\eta)\Gamma(\eta)(\Phi_\xi^+)^{-1}(I - P_\xi)(\Gamma^* Q, \Gamma_T^* Q_T) \begin{pmatrix} G(\cdot - \xi) \\ G(T - \xi) \end{pmatrix} \\ &\quad - \Gamma(t)(\Phi_\eta^+)^{-1}(I - P_\eta)(\Gamma^* Q, \Gamma_T^* Q_T) \begin{pmatrix} G(\cdot - \eta) \\ G(T - \eta) \end{pmatrix} G(\eta - \xi) \\ &\quad + \Gamma(t)(\Phi_\eta^+)^{-1}(I - P_\eta)(\Gamma^* Q, \Gamma_T^* Q_T) \begin{pmatrix} G(\cdot - \eta) \\ G(T - \eta) \end{pmatrix} \cdot \\ &\quad \cdot \Gamma(\eta)(\Phi_\xi^+)^{-1}(I - P_\xi)(\Gamma^* Q, \Gamma_T^* Q_T) \begin{pmatrix} G(\cdot - \xi) \\ G(T - \xi) \end{pmatrix} \\ &= G(t-\xi) - G(t-\eta)\Gamma(\eta)(I - P_\xi)R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T)N_\xi \begin{pmatrix} G(\cdot - \xi) \\ G(T - \xi) \end{pmatrix} \\ &\quad - \Gamma(t)(I - P_\eta)R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T) \\ &\quad \cdot \left\{ N_\eta - N_\eta \begin{pmatrix} G(\cdot - \eta) \\ G(T - \eta) \end{pmatrix} \Gamma(\eta) \right. \\ &\quad \left. \cdot (I - P_\xi)R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T)N_\xi \right\} \begin{pmatrix} G(\cdot - \xi) \\ G(T - \xi) \end{pmatrix}. \end{aligned} \tag{5.19}$$

By (3.7), (4.2), and (4.3), we obtain

$$\begin{aligned} N_\eta - N_\xi &= N_\eta(I - N_\xi) - (I - N_\eta)N_\xi \\ &= N_\eta \begin{pmatrix} \Gamma \\ \Gamma_T \end{pmatrix} (I - P_\xi)R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T)N_\xi - N_\eta \begin{pmatrix} \Gamma \\ \Gamma_T \end{pmatrix} (I - P_\eta)R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T)N_\xi \\ &= N_\eta \begin{pmatrix} \Gamma \\ \Gamma_T \end{pmatrix} (P_\eta - P_\xi)R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T)N_\xi \\ &= N_\eta \begin{pmatrix} G(\cdot - \eta) \\ G(T - \eta) \end{pmatrix} \Gamma(\eta)(I - P_\xi)R^{-1}(\Gamma^* Q, \Gamma_T^* Q_T)N_\xi. \end{aligned} \tag{5.20}$$

Substitute (5.20) into (5.19); then

$$\begin{aligned} W(t,\eta)W(\eta,\xi) &= G(t-\xi)-G(t-\eta)\Gamma(\eta)(I-P_\xi)R^{-1}(\Gamma^*Q,\Gamma_T^*Q_T)N_\xi\begin{pmatrix}G(\cdot-\xi)\\ G(T-\xi)\end{pmatrix}\\ &\quad -\Gamma(t)(I-P_\eta)R^{-1}(\Gamma^*Q,\Gamma_T^*Q_T)N_\xi\begin{pmatrix}G(\cdot-\xi)\\ G(T-\xi)\end{pmatrix}\\ &= G(t-\xi)-\left\{\int_\xi^\eta+\int_\eta^t\right\}G(t-\sigma)BR^{-1}(\Gamma^*(\sigma)Q,\Gamma_T^*(\sigma)Q_T)N_\xi\\ &\quad\cdot\begin{pmatrix}G(\cdot-\xi)\\ G(T-\xi)\end{pmatrix}d\sigma\\ &= G(t-\xi)-\Gamma(t)(I-P_\xi)R^{-1}(\Gamma^*Q,\Gamma_T^*Q_T)N_\xi\begin{pmatrix}G(\cdot-\xi)\\ G(T-\xi)\end{pmatrix}\\ &= G(t-\xi)-\Gamma(t)(\Phi_\xi^+)^{-1}(I-P_\xi)(\Gamma^*Q,\Gamma_T^*Q_T)\begin{pmatrix}G(\cdot-\xi)\\ G(T-\xi)\end{pmatrix}=W(t,\xi). \end{aligned}$$

(iv) By the definition (5.17), it is clear that $W(t,\xi)$ is strongly continuous in $t\in[\xi,T]$. Combination of this continuity with its uniform boundedness (ii) and its evolutionary property (iii) implies that $W(t,\xi)$ is also strongly continuous in $\xi\in(0,t]$. □

LEMMA 11. *Let $H(t,t)$ be given by* (5.13); *then*

$$H(t,t)=R^{-1}B^*P(t),\qquad t\in[0,T], \tag{5.21}$$

where $P(t)$: $[0,T]\to\mathscr{L}(X)$ is given by

$$\begin{aligned} P(t) &= G^*(T-t)Q_TG(T-t)+\int_t^T G^*(s-t)QG(s-t)\,ds\\ &\quad -(\tilde\Gamma^*(t)Q,\tilde\Gamma_T^*(t)Q_T)N_t\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I-P_t)R^{-1}(\Gamma^*Q,\Gamma_T^*Q_T)\begin{pmatrix}G(\cdot-t)\\ G(T-t)\end{pmatrix}, \end{aligned} \tag{5.22}$$

where $\tilde\Gamma^*(t)$ and $\tilde\Gamma_T^*(t)$ are defined by (*cf.* (3.12))

$$\begin{aligned} &\tilde\Gamma^*(t)y=\int_t^T G^*(\sigma-t)y(\sigma)\,d\sigma\quad\forall y\in\mathscr{X},\\ &\tilde\Gamma^*(t)y_1=G^*(T-t)y_1\quad\forall y_1\in X. \end{aligned} \tag{5.23}$$

Proof. From (5.13), (5.15), and (4.1), it follows that

$$\begin{aligned} H(t,t) &= \pi(T,t)Q_TG(T-t)+\int_t^T\pi(s,t)QG(s-t)\,ds\\ &= R^{-1}B^*\left[G^*(T-t)Q_TG(T-t)+\int_t^T G^*(s-t)QG(s-t)\,ds\right]\\ &\quad -R^{-1}B^*\int_t^T(\tilde\Gamma^*(t)Q,\tilde\Gamma_T^*(t)Q_T)N_t\begin{pmatrix}G(\cdot-\sigma)\\ G(T-\sigma)\end{pmatrix}\\ &\quad\cdot BR^{-1}B^*G^*(T-\sigma)\,d\sigma\,Q_TG(T-t)\\ &\quad -R^{-1}B^*\int_t^T\int_t^s(\tilde\Gamma^*(t)Q,\tilde\Gamma_T^*(t)Q_T)N_t\begin{pmatrix}G(\cdot-\sigma)\\ G(T-\sigma)\end{pmatrix}\\ &\quad\cdot BR^{-1}B^*G^*(s-\sigma)\,d\sigma\,QG(s-t)\,ds \end{aligned}$$

$$
\begin{aligned}
&= R^{-1}B^*\Big\{G^*(T-t)Q_TG(T-t)+\int_t^T G^*(s-t)QG(s-t)\,ds \\
&\qquad -(\tilde{\Gamma}^*(t)Q,\tilde{\Gamma}_T^*(t)Q_T)N_t\int_t^T\begin{pmatrix}G(\cdot-\sigma)\\ G(T-\sigma)\end{pmatrix} \\
&\qquad\quad \cdot BR^{-1}\Big[B^*G^*(T-\sigma)Q_TG(T-t) \\
&\qquad\quad +\int_\sigma^T B^*G^*(s-\sigma)QG(s-t)\,ds\Big]\,d\sigma\Big\} \\
&= R^{-1}B^*\Big\{G^*(T-t)Q_TG(T-t)+\int_t^T G^*(s-t)QG(s-t)\,ds \\
&\qquad -(\tilde{\Gamma}^*(t)Q,\tilde{\Gamma}_T^*(t)Q_T)N_t\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix} \\
&\qquad\quad \cdot (I-P_t)R^{-1}(\Gamma^*Q,\Gamma_T^*Q_T)\begin{pmatrix}G(\cdot-t)\\ G(T-t)\end{pmatrix}\Big\}.
\end{aligned}
\tag{5.24}
$$

Formula (5.24) indicates that (5.21) and (5.22) are valid. □

LEMMA 12. *Let $P(t)$ and $W(t,\xi)$ be given by* (5.22) *and* (5.17), *respectively. Then the following relation holds*:

$$
P(t)=G^*(T-t)Q_TW(T,t)+\int_t^T G^*(\sigma-t)QW(\sigma,t)\,d\sigma,\qquad t\in(0,T].
\tag{5.25}
$$

Proof. From (5.17) and (4.3), it follows that

$$
\begin{aligned}
&G^*(T-t)Q_TW(T,t)+\int_t^T G^*(\sigma-t)QW(\sigma,t)\,d\sigma \\
&\quad = G^*(T-t)Q_TG(T-t)+\int_t^T G^*(\sigma-t)QG(\sigma-t)\,d\sigma \\
&\qquad -G^*(T-t)Q_T\Gamma(T)(\Phi_t^+)^{-1}(I-P_t)(\Gamma^*Q,\Gamma_T^*Q_T)\begin{pmatrix}G(\cdot-t)\\ G(T-t)\end{pmatrix} \\
&\qquad -\int_t^T G^*(\sigma-t)Q\Gamma(\sigma)(\Phi_t^+)^{-1}(I-P_t)(\Gamma^*Q,\Gamma_T^*Q_T)\begin{pmatrix}G(\cdot-t)\\ G(T-t)\end{pmatrix}d\sigma \\
&\quad = G^*(T-t)Q_TG(T-t)+\int_t^T G^*(\sigma-t)QG(\sigma-t)\,d\sigma \\
&\qquad -(\tilde{\Gamma}^*(t)Q,\tilde{\Gamma}_T^*(t)Q_T)\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\Phi_t^+)^{-1}(I-P_t)(\Gamma^*Q,\Gamma_T^*Q_T)\begin{pmatrix}G(\cdot-t)\\ G(T-t)\end{pmatrix} \\
&\quad = G^*(T-t)Q_TG(T-t)+\int_t^T G^*(\sigma-t)QG(\sigma-t)\,d\sigma \\
&\qquad -(\tilde{\Gamma}^*(t)Q,\tilde{\Gamma}_T^*(t)Q_T)N_t\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I-P_t)R^{-1}(\Gamma^*Q,\Gamma_T^*Q_T)\begin{pmatrix}G(\cdot-t)\\ G(T-t)\end{pmatrix}=P(t).
\end{aligned}
$$

□

LEMMA 13. *The following relation holds*:

$$
W(t,\xi)=G(t-\xi)-\int_\xi^t W(t,\sigma)BR^{-1}B^*P(\sigma)G(\sigma-\xi)\,d\sigma,\qquad 0<\xi\leqq t\leqq T,
\tag{5.26}
$$

where $W(t,\xi)$ and $P(t)$ are given by (5.17) *and* (5.22), *respectively.*

Proof. Let the function on the right side of (5.26) be denoted by $\lambda(t, \xi)$. It can be verified that for any $y \in X$, both $g_1(t) = W(t, \xi)y$ and $g_2(t) = \lambda(t, \xi)y$, $t \in [\xi, T]$, are strongly continuous solutions of the following Volterra integral equation:

$$g(t) = G(t-\xi)y - \int_{\xi}^{t} G(t-\sigma)BR^{-1}B^*P(\sigma)g(\sigma)\,d\sigma, \qquad t \in [\xi, T]. \tag{5.27}$$

By the uniqueness of the solution, (5.26) is true. □

LEMMA 14. *Let $P(t)$ be defined by* (5.22). *Then, $P(t)$ is the unique strongly continuous and self-adjoint solution of the following integral Riccati equation*:

$$\begin{aligned} P(t) = {} & G^*(T-t)Q_TG(T-t) + \int_t^T G^*(\sigma-t) \\ & \cdot [Q - P(\sigma)BR^{-1}B^*P(\sigma)]G(\sigma-t)\,d\sigma, \qquad t \in [0, T], \end{aligned} \tag{5.28}$$

where $G(t) = e^{At}$ and $G^*(t) = e^{A^*t}$.

Proof. By Lemma 12, $P(t)$ can be expressed by (5.25). Substitute (5.26) into (5.25); then it follows that

$$\begin{aligned} P(t) &= G^*(T-t)Q_TW(T, t) + \int_t^T G^*(\sigma-t)QW(\sigma, t)\,d\sigma \\ &= G^*(T-t)Q_TG(T-t) + \int_t^T G^*(\sigma-t)QG(\sigma-t)\,d\sigma \\ &\quad - G^*(T-t)Q_T\int_t^T W(T, \sigma)BR^{-1}B^*P(\sigma)G(\sigma-t)\,d\sigma \\ &\quad - \int_t^T G^*(\eta-t)Q\int_t^{\eta} W(\eta, \sigma)BR^{-1}B^*P(\sigma)G(\sigma-t)\,d\sigma\,d\eta \\ &= G^*(T-t)Q_TG(T-t) + \int_t^T G^*(\sigma-t)QG(\sigma-t)\,d\sigma \\ &\quad - \int_t^T G^*(\sigma-t)P(\sigma)BR^{-1}B^*P(\sigma)G(\sigma-t)\,d\sigma \\ &= G^*(T-t)Q_TG(T-t) + \int_t^T G^*(\sigma-t) \\ &\quad \cdot [Q - P(\sigma)BR^{-1}B^*P(\sigma)]G(\sigma-t)\,d\sigma, \qquad t \in [0, T]. \end{aligned}$$

Therefore, $P(t)$ is actually a solution of the integral Riccati equation (5.28). By (5.25) and Lemma 10(iv), $P(t)$ is strongly continuous. In [5], it is proved that the strongly continuous solution of (5.28) is unique. Besides, by transposition it can be seen that $P^*(t)$ is also a solution of (5.28), then the uniqueness implies that $P(t) = P^*(t)$, $t \in [0, T]$. □

It is easy to show that the integral Riccati equation (5.28) is equivalent to the following differential Riccati equation:

$$\begin{aligned} \frac{d}{dt}\langle P(t)x, y\rangle = {} & -\langle P(t)x, Ay\rangle - \langle Ax, P(t)y\rangle - \langle Qx, y\rangle + \langle P(t)BR^{-1}B^*P(t)x, y\rangle \\ & \forall x, y \in \mathscr{D}(A), \quad t \in [0, T], \end{aligned} \tag{5.29}$$

with $P(T) = Q_T$.

Thus, we obtain the following result that shows the synthesis via the Fredholm integral equation and the synthesis via the Riccati equation are equivalent in the standard case.

COROLLARY 5. *If* $A_i = 0$ $(i = 1, \cdots, n)$ *and* $B_j = 0$ $(j = 1, \cdots, m)$, *then the optimal control is given by*

$$u(t) = -R^{-1}B^*P(t)x(t), \qquad t \in [0, T], \tag{5.30}$$

where $P(t)$ *is the unique strongly continuous and self-adjoint solution of the differential Riccati equation* (5.29), *and* $x(\cdot)$ *is the corresponding state trajectory.*

If $Q = 0$ in the quadratic cost functional, then the corresponding linear Fredholm integral equation (4.4) can be solved explicitly to provide an explicit formula for the feedback operator $H(t, \eta)$ in (5.4). Note that in this case,

$$K(t, \sigma) = F^*(T - t)Q_TF(T - \sigma). \tag{5.31}$$

Hence the Fredholm equation (4.4) reduces to

$$M_\xi(t, \sigma) + \int_\xi^T R^{-1}F^*(T - t)Q_TF(T - s)M_\xi(s, \sigma)\, ds = -R^{-1}F^*(T - t)Q_TF(T - \sigma). \tag{5.32}$$

It is easy to show that the solution of (5.32) can be given by an explicit form.

LEMMA 15. *The unique solution of the equation* (5.32) *is given by*

$$M_\xi(t, \sigma) = -R^{-1}F^*(T - t)\sqrt{Q_T}[I + \Lambda(\xi)]^{-1}\sqrt{Q_T}\,F(T - \sigma), \tag{5.33}$$

where

$$\Lambda(\xi) = \int_\xi^T \sqrt{Q_T}\,F(T - t)R^{-1}F^*(T - t)\sqrt{Q_T}\, dt. \tag{5.34}$$

LEMMA 16. *Assume that* $Q = 0$; *then the optimal feedback operator is given by*

$$H(t, n) = R^{-1}F^*(T - t)\sqrt{Q_T}(I + \Lambda(t))^{-1}\sqrt{Q_T}\,G(T - \eta), \tag{5.35}$$

where $\Lambda(t)$ *is given by* (5.34).

Proof. Substitute (5.33) into (4.16) then, in turn, into (5.4); it follows that (5.35) holds by an easy rearrangement. □

COROLLARY 6. *Assume that* $Q = 0$ *so that there is no state integral term in the criterion* (1.5). *Then,* $u(\cdot)$ *is the optimal control if and only if*

$$\begin{aligned} u(t) = -R^{-1}\Bigg\{ & F^*(T - t)\sqrt{Q_T}(I + \Lambda(t))^{-1}\sqrt{Q_T}\,G(T - t)x(t) \\ & + \sum_{i=1}^{n} \int_t^{\min(T, t+h_i)} F^*(T - t)\sqrt{Q_T}(I + \Lambda(t))^{-1}\sqrt{Q_T}\,G(T - \eta)A_ix(\eta - h_i)\, d\eta \\ & + \sum_{i=1}^{n} \int_{\min(t, h_i)}^{h_i} F^*(T - t)\sqrt{Q_T}(I + \Lambda(t))^{-1}\sqrt{Q_T}\,G(T - \eta)A_ix(\eta - h_i)\, d\eta \\ & + \sum_{j=1}^{m} \int_{\min(t, r_j)}^{r_j} F^*(T - t)\sqrt{Q_T}(I + \Lambda(t))^{-1}\sqrt{Q_T}\,G(T - \eta)B_ju(\eta - h_i)\, d\eta \Bigg\}, \\ & \qquad t \in [0, T] \end{aligned} \tag{5.36}$$

where $\Lambda(t)$ *is given by* (5.34).

Remark 3. There is an advantage in the above approach and the obtained closed-loop syntheses, i.e., the dimension of the linear Fredholm integral equation (4.4) is

the same as dim U. In many practical control situations, dim U is finite even though dim X is infinite. Therefore the analytic design of the optimal control reduces to solving a finite-dimensional linear integral equation provided dim $U<\infty$, which can be done by standard numerical methods.

Remark 4. The approach taken in this paper can be applied to solve more complicated problems for retarded functional differential systems with distributed delay in control/state/output variables, neutral differential systems and time-variant systems. It can be applied to tackle quadratic differential game problems as well. In all these possible generalizations, the common link is the semicausal dynamical treatment based on the general Volterra systems.

6. An example. As an example, we consider a control system having partial differential equation model with delay:

$$
\begin{aligned}
&u_t(t,x)=u_{xx}(t,x)+u(t-1,x)+b(x)f(t)+b_1(x)f(t-2), \qquad t\geqq 0, \quad x\in[0,1],\\
&u(t,0)=u(t,1)=0, \qquad t\geqq 0,\\
&u(0,x)=u_0(x)\in L^2(0,1)\triangleq X,\\
&u(\theta,x)=\phi(\theta,x)\in L^2(-1,0;X), \qquad -1\leqq\theta<0, \quad x\in[0,1],\\
&f(\xi)=\psi(\xi)\in L^2(-2,0), \qquad -2\leqq\xi\leqq 0,
\end{aligned}
\tag{6.1}
$$

where we assume that $b(x)$ and $b_1(x)$ belong to $L^2(0,1)$. Let $U=\mathbb{R}$ and $f(\cdot)\in L^2(0,T)=L^2(0,T;\mathbb{R})$ where $T>0$ is finite and fixed.

Set a quadratic cost functional as follows:

$$
J(f)=\|u(T,\cdot)\|_X^2+\int_0^T[\|u(t,\cdot)\|_X^2+|f(t)|^2]\,dt,
\tag{6.2}
$$

and the optimization task is to find a control $f*\in L^2(0,T)$ such that

$$
\min_{f\in L^2(0,T)} J(f)=J(f*).
\tag{6.3}
$$

Define the operator $A:\mathscr{D}(A)\to X$ by

$$
\begin{aligned}
&Au=u_{xx}, \qquad u\in\mathscr{D}(A),\\
&\mathscr{D}(A)=\{u\in X:\ u_{xx}\in X \text{ and } u(0)=u(1)=0\}=H^2(0,1)\cap H_0^1(0,1).
\end{aligned}
\tag{6.4}
$$

Then A is the infinitesimal generator of a self-adjoint and compact semigroup e^{At}, which has an expression:

$$
e^{At}u=\sum_{n=1}^{\infty}e^{\lambda_n t}\langle u,\phi_n\rangle_X\phi_n, \qquad t\geqq 0,
\tag{6.5}
$$

where $\{\lambda_n=-n^2\pi^2:\ n=1,2,\cdots\}=\sigma(A)$ and $\{\phi_n(x)=\sqrt{2}\sin(n\pi x);\ n=1,2,\cdots\}$, as the complete eigenvectors of A, forms an orthonormal basis for X.

On the other hand, define

$$
\begin{aligned}
&A_1=I \qquad \text{(identity on } L^2(0,1)=X),\\
&B=b(\cdot)\in\mathscr{L}(\mathbb{R};X) \quad \text{and} \quad B_1=b_1(\cdot)\in\mathscr{L}(\mathbb{R};X).
\end{aligned}
\tag{6.6}
$$

The task can be rewritten in optimal control formulation described in § 1, with the state equation

$$
\frac{du(t)}{dt}=Au(t)+A_1u(t-1)+Bf(t)+B_1f(t-2)
\tag{6.7}
$$

and the cost functional (1.5), where

$$Q_T = I, \quad Q = I, \quad R = 1. \tag{6.8}$$

The following are steps to find the optimal control.

Step 1. Find the fundamental solution $G(t):\mathbb{R}^+ \to \mathscr{L}(X)$ of (1.9). In this case, by the induction and direct calculation, it is not difficult to obtain the following explicit formula for this $G(t)$:

(6.9)

$$G(t) = \begin{cases} e^{At} + e^{A(t-1)}(t-1) + \cdots + e^{A(t-k)}\dfrac{(t-k)^k}{k!}, & t \in [k, k+1], \quad k = 0, 1, \cdots. \\ 0, & t < 0, \end{cases}$$

Note that for $k = 0$, $G(t) = e^{At}$, $t \in [0, 1]$.

Step 2. Write down the expression of the mild solution of (6.7) as the following Volterra integral system:

$$u(t) = p(t) + \int_0^t F(t-\sigma) f(\sigma)\, d\sigma, \qquad t \in [0, T], \tag{6.10}$$

where $p(t)$ and $F(t)$ are given by

$$p(t) = G(t)u_0 + \int_0^t G(t-\sigma)[\phi(\sigma-1) + b_1\psi(\sigma-2)]\, d\sigma$$

where

$$\phi(t) = \begin{cases} \phi(t, \cdot), & -1 \leqq t < 0 \\ 0, & t \geqq 0 \end{cases} \quad \text{and } \psi(t) = 0 \text{ for } t > 0; \quad \text{and}$$

$$F(t) = G(t)B + G(t-2)B_1 = G(t)b(\cdot) + G(t-2)b_1(\cdot), \qquad t \geqq 0. \tag{6.11}$$

The concrete formula for (6.11) can be obtained by substitution of (6.9) and (6.5) into (6.11).

Step 3. Synthesis equation (4.4). Now we can write the kernel operator function $K(t, \sigma)$ in (2.12) as

$$K(t, \sigma) = F^*(T-t)F(T-\sigma) + \int_t^T F^*(s-t)F(s-\sigma)\, ds \quad \text{for } (t, \sigma) \in [0, T]^2, \tag{6.12}$$

where $F(t)$ is given by (6.11), so $K(t, \sigma)$ is known to us. As mentioned in Corollary 1, we have that $F(t) \equiv 0$ whenever $t < 0$. More precisely, since $F(t) \in \mathscr{L}(\mathbb{R}, X)$ for each $t \in \mathbb{R}$, we have

(6.13)

$$K(t, \sigma) = \langle F(T-t), F(t-\sigma)\rangle_X + \int_t^T \langle F(s-t), F(s-\sigma)\rangle_X\, ds, \qquad (t, \sigma) \in [0, T]^2,$$

which is actually a bivariate scalar continuous function.

Since $R = 1$, the synthesis equation (4.4) now becomes

$$M_\xi(t, \sigma) + \int_\xi^T K(t, s) M_\xi(s, \sigma)\, ds = -K(t, \sigma), \qquad t \in [\xi, T], \quad (\xi, \sigma) \in [0, T]^2, \tag{6.14}$$

where $K(t, \sigma)$ is shown by (6.13). Note that (6.14) is a Fredholm integral equation with scalar unknown function $M_\xi(\cdot, \sigma)$ on $[\xi, T]$ where $(\xi, \sigma) \in [0, T]^2$ are two parameters.

The feature of (6.14) is that this is a scalar integral equation. In general, as long as dim $U < \infty$, the synthesis equation is a finite-dimensional integral equation. Thus

we do not need to solve an infinite-dimensional operator equation such as the Riccati equation.

If in the special case $Q=0$, then the solution of (6.14) is given by the following explicit formula:

$$M_\xi(t,\sigma)=-\left\langle F(T-t),\left[I+\int_\xi^T F(T-t)F^*(T-t)\,dt\right]^{-1}F(T-\sigma)\right\rangle. \tag{6.15}$$

If $Q=I$, then (6.14) can be further solved approximately by numerical methods.

Step 4. Feedback operator $H(t,\sigma)$ and the closed-loop optimal control. From (5.4) and (4.16), we have the following expression. For $(t,\sigma)\in[0,T]^2$,

$$\begin{aligned}
H(t,\sigma)&=\Pi(T,t)G(T-\sigma)+\int_t^T \Pi(s,t)G(s-\sigma)\,ds\\
&=\left[F^*(T-t)+\int_t^T M_t(t,\eta)F^*(T-\eta)\,d\eta\right]G(T-\sigma)\\
&\quad+\int_t^T\left[F^*(s-t)+\int_t^s M_t(t,\eta)F^*(s-\eta)\,d\eta\right]G(s-\sigma)\,ds\\
&=\langle F(T-t),G(T-\sigma)\cdot\rangle+\int_t^T M_t(t,\eta)\langle F(T-\eta),G(T-\sigma)\cdot\rangle\,d\eta\\
&\quad+\int_t^T\langle F(s-t),G(s-\sigma)\cdot\rangle\,ds\\
&\quad+\int_t^T M_t(t,\eta)\int_\eta^T\langle F(s-\eta),G(s-\sigma)\cdot\rangle\,ds\,d\eta.
\end{aligned} \tag{6.16}$$

Finally, substitute (6.16) into (5.3) in Theorem 7, to obtain the closed-loop optimal control as follows:

$$\begin{aligned}
f(t)=-\Bigg[&H(t,t)u(t)+\int_t^{\min(T,t+1)}H(t,\xi)u(\xi-1)\,d\xi\\
&+\int_{\min(t,1)}^1 H(t,\xi)\phi(\xi-1)\,d\xi+\int_{\min(t,2)}^2 H(t,\xi)B_1f(\xi-2)\,d\xi\Bigg],\quad t\in[0,T],
\end{aligned} \tag{6.17}$$

where $H(t,\sigma)$ is shown by (6.16).

Especially, for $t\in[2,T]$, we have the optimal control

$$\begin{aligned}
f(t)=-\Bigg[&\langle F(T-t),G(T-t)u(t)\rangle+\int_t^T\langle F(s-t),G(s-t)u(t)\rangle\,ds\\
&+\int_t^T M_t(t,\eta)\Big(\langle F(T-\eta),G(T-t)u(t)\rangle\\
&+\int_\eta^T\langle F(s-\eta),G(s-t)u(t)\rangle\,ds\Big)\,d\eta\Bigg]\\
-\int_t^{\min(T,t+1)}&\Bigg[\langle F(T-t),G(T-\sigma)u(\sigma-1)\rangle+\int_t^T\langle F(s-t),G(s-\sigma)u(\sigma-1)\rangle\,ds\\
&+\int_t^T M_t(t,\eta)\Big(\langle F(T-\eta),G(T-\sigma)u(\sigma-1)\rangle\\
&+\int_\eta^T\langle F(s-\eta),G(s-\sigma)u(\sigma-1)\rangle\,ds\Big)\,d\eta\Bigg]\,d\sigma.
\end{aligned}$$

Therefore we see that for this example (and also for more general delays), the only essential thing in getting the optimal control is to solve the synthesis equation (6.14) for $M_t(t, \sigma)$, which can be done by means of standard computational methods. □

BOUNDARY CONTROLLABILITY OF MAXWELL'S EQUATIONS IN A SPHERICAL REGION*

KATHERINE A. KIME†

Abstract. This paper examines the question of control of electromagnetic fields in a three-dimensional spherical region by means of control currents on the boundary of that region. The necessary theory of divergence-free solutions of the vector wave equation is developed. By use of eigenfunctions of the vector Laplacian in appropriate divergence-free domains and moment problem techniques, sufficient conditions for controllability are set forth.

Key words. control, Maxwell, electromagnetic, boundary control

AMS(MOS) subject classifications. 93C20, 78A40

1. Introduction.

We consider Maxwell's equations

$$\nabla \times H = \frac{\partial E}{\partial t}, \tag{1.1}$$

$$\nabla \times E = -\frac{\partial H}{\partial t}, \tag{1.2}$$

$$\nabla \cdot H = 0, \tag{1.3}$$

$$\nabla \cdot E = 0 \tag{1.4}$$

in Ω the unit ball in R^3, assuming no internal changes or currents. Here $E(x, y, z, t)$ and $H(x, y, z, t)$ are three-dimensional vectors representing the electric and magnetic fields, respectively, $\nabla \times (\ )$ denotes the curl operator, and $\nabla \cdot (\ )$ denotes divergence.

We are interested in the possibility of controlling the fields E, H inside Ω by means of a current $J(\cdot, t)$ flowing tangentially on $\partial\Omega \equiv \Gamma$, the effect of which is described by the boundary condition

$$\bar{n} \times H = -J \quad \text{on} \quad \Gamma \ (\bar{n} \text{ the unit outward normal vector}). \tag{1.5}$$

Thus we may pose the following problem.

CONTROL PROBLEM. Given $T > 0$ and prescribed initial data, find a control current $J(\cdot, t)$ defined on Γ such that the solutions E, H of (1.1)-(1.5) with this initial data also satisfy the terminal condition

$$E(\cdot, T) = H(\cdot, T) = 0.$$

In [15], the control problem for Ω, a circular or rectangular cylinder, was treated, under assumption of invariability of the fields in the axial direction.

Our plan in this paper is as follows. In § 2, we will convert from Maxwell's system to the system of equations for the vector potential associated with the fields, the latter being the vector wave equation with the additional constraint that the solution be divergence-free for all time. It will then be natural to work in certain divergence-free subspaces of

$$\mathscr{L}^2(\Omega) = \{\varphi = (\varphi_1, \varphi_2, \varphi_3) : \varphi_i \in L^2(\Omega),\ i = 1, 2, 3\}.$$

We will introduce necessary definitions and give some known, relevant results concerning these subspaces.

In § 3, we establish existence and uniqueness of a weak solution to the system for the vector potential in the case in which the boundary input is in $L^2[0, T; \mathscr{L}^2(\Gamma)]$, here taken as the admissible control space. This is necessary before taking up the control problem itself, which will be done in § 4. By use of divergence-free eigenfunctions of the vector Laplacian, the "multipole fields" [8], [12], we are able to reduce the control problem to a collection of trigonometric moment problems. In § 5, we establish conditions that allow solution of the moment problems.

2. Conversion to potentials; function spaces.

2.1. Conversion to potentials. Let E, H be smooth solutions of (1.1)-(1.5). Then we may see as in [5], [8], and [12], that there exists a smooth vector W with $H = \nabla \times W$, $E = -\partial W/\partial t$, which satisfies

$$\Box W = 0 \quad \text{in } \Omega, \tag{2.1}$$

$$\nabla \cdot W = 0 \quad \text{in } \Omega, \tag{2.2}$$

$$\bar{n} \times (\nabla \times W) = -J \quad \text{on } \Gamma. \tag{2.3}$$

If $H(\cdot, 0) = H_0$, $E(\cdot, 0) \equiv E_0$, $W(\cdot, 0) \equiv W_0$, $\partial W/\partial t(\cdot, 0) \equiv W_1$ then $\nabla \times W_0 = H_0$, $W_1 = -E_0$.

To proceed without undue complication (due mainly to unwieldly limits of integration), we assume E, H are smooth solutions of (1.1)-(1.4) in $\bar{\Omega}^*$, where Ω^* is a slightly larger ball of radius $\sqrt{2}(1+\varepsilon)+\varepsilon$, $\varepsilon > 0$. We may see by well-known arguments that there exists a smooth vector A such that $H = \nabla \times A$ in $\Omega^* \times [0, T]$. With $f(x)$ any smooth function (with $H = (H_1, H_2, H_3)$), we can define

$$A_1 = f(x),$$

$$A_2 = \int_{-(1+\varepsilon)}^{x} H_3(\xi, y, z, t)\, d\xi + K_1(y, z, t),$$

$$A_3 = \int_{-(1+\varepsilon)}^{x} -H_2(\xi, y, z, t)\, d\xi + K_2(y, z, t)$$

where K_1, K_2 are smooth solutions of

$$\frac{\partial K_1}{\partial y} - \frac{\partial K_1}{\partial z} = H_1(-(1+\varepsilon), y, z, t);$$

we take

$$K_1 = 0, \qquad K_2 = \int_{-(1+\varepsilon)}^{y} H_1(-(1+\varepsilon), \eta, z, t))\, d\eta.$$

We now set $A = (A_1, A_2, A_3)$. By (1.2),

$$\nabla \times E = -\frac{\partial H}{\partial t} = -\frac{\partial}{\partial t}(\nabla \times A) = -\nabla \times \left(\frac{\partial A}{\partial t}\right)$$

or

$$\nabla \times \left(E + \frac{\partial A}{\partial t}\right) = 0, \tag{2.4}$$

which implies the existence of ϕ such that

$$E+\frac{\partial A}{\partial t}=-\nabla\phi.$$

We use $\nabla(\ )$ to denote the gradient. By (1.1),

$$\frac{\partial E}{\partial t}=\nabla\times H=\nabla\times(\nabla\times A)=\text{grad div } A-\Delta A,$$

which implies

$$\text{grad div } A-\Delta A=-\frac{\partial}{\partial t}\left(\nabla\phi+\frac{\partial A}{\partial t}\right)$$

or

$$\frac{\partial^2 A}{\partial t^2}-\Delta A=-\nabla\left(\frac{\partial\phi}{\partial t}+\text{div } A\right). \tag{2.5}$$

By (1.4), (2.4), we have

$$\text{div}\left(\nabla\phi+\frac{\partial A}{\partial t}\right)=0,$$

which implies

$$\Delta\phi=-\frac{\partial}{\partial t}(\text{div } A). \tag{2.6}$$

Observe that if W, ψ are defined by

$$W=A+\nabla\chi,\qquad \psi=\phi-\partial\chi/\partial t \tag{2.7}$$

where χ is any smooth scalar field, then

$$\nabla\times W=(\nabla\times A)+(\nabla\times(\nabla\chi))=H,$$

and

$$-\frac{\partial W}{\partial t}-\nabla\psi=-\frac{\partial A}{\partial t}-\frac{\partial}{\partial t}(\nabla\chi)-\nabla\psi+\nabla\left(\frac{\partial\chi}{\partial t}\right)=E.$$

The fields are thus invariant under such transformations, commonly called gauge transformations. We now choose

$$\chi(x, y, z, t)=\int_0^t \phi(x, y, z, s)\,ds+M(x, y, z)$$

where M is the solution of

$$\Delta M=-\text{div } A(x, y, z, 0)\quad \text{in } \Omega,$$
$$M=0\qquad\qquad\qquad\quad \text{on } \Gamma.$$

If $f\in H^K(\Omega)$, then the solution u of

$$\Delta u=f\quad \text{in } \Omega,$$
$$u=0\quad \text{on } \Gamma$$

belongs to $H_0^1(\Omega) \cap H^{2+K}(\Omega)$. Taking $f = -\text{div } A(x, y, z, 0)$ and applying the Sobolev Lemma, we see that M is smooth. Now

$$\psi = \phi - \frac{\partial}{\partial t} \int_0^t \phi(x, y, z, s)\, ds + \frac{dM}{dt} = 0.$$

We have

$$\nabla \cdot W = \nabla \cdot A + \text{div grad } \chi,$$

and

$$\begin{aligned}
\Delta\chi &= \Delta\left(\int_0^t \phi(x, y, z, s)\, ds + M \right) \\
&= \int_0^t \Delta\phi(x, y, z, s)\, ds + \Delta M \\
&= \int_0^t -\frac{\partial}{\partial s} (\text{div } A(x, y, z, s))\, ds - \text{div } A(x, y, z, 0) \\
&= -\text{div } A(x, y, z, t) + \text{div } A(x, y, z, 0) - \text{div } A(x, y, z, 0) \\
&= -\text{div } A(x, y, z, t),
\end{aligned}$$

the third equality from (2.6). Thus

$$\nabla \cdot W = 0. \tag{2.8}$$

W is said to be in the Colomb gauge. Furthermore, since

$$\begin{aligned}
\Box(\nabla\chi) &= \frac{\partial^2}{\partial t^2} (\nabla\chi) - \Delta(\nabla\chi) \\
&= \nabla\left(\frac{\partial^2 \chi}{\partial t^2} \right) - \nabla(\Delta\chi) \\
&= \nabla\left(\frac{\partial \phi}{\partial t} + \text{div } A \right) \\
&= -\Box A,
\end{aligned}$$

the last equality from (2.5), we have

$$\Box W = \Box A + \Box(\nabla\chi) = 0, \tag{2.9}$$

and thus W satisfies (2.1)-(2.3).

It is a matter of straightforward differentiation to see that if, given W satisfying (2.1)-(2.3), we define $H = \nabla \times W$, $E = -\partial W/\partial t$, then E and H satisfy (1.1)-(1.5). For example,

$$\nabla \times H = \nabla \times (\nabla \times W) = -\Delta W = -\frac{\partial^2 W}{\partial t^2} = \frac{\partial E}{\partial t}.$$

2.2. Function spaces. Considering (2.1)-(2.3), we now wish to work in divergence-free subspaces of $\mathscr{L}^2(\Omega)$, as mentioned above. The inner product on $\mathscr{L}^2(\Omega)$ is given by

$$(u, v) = \int_\Omega u \cdot v\, dV,$$

with norm denoted by $\|u\|$.

Let $\mathscr{H}^\ell(\Omega)$ denote the Hilbert space of vectors that belong to $\mathscr{L}^2(\Omega)$ and have derivatives up to and including the order ℓ belonging to $\mathscr{L}^2(\Omega)$. The inner product is

$$(u, v)_\ell = \sum_{|\alpha| \leqq \ell} (D^\alpha u, D^\alpha v) \quad \text{with norm } \|u\|_\ell.$$

We have [9] the following subspace decomposition of $\mathscr{L}^2(\Omega)$:

$$J(\Omega) = \text{closure in } \mathscr{L}^2(\Omega) \text{ of } \{u: u \in C^\infty(\Omega), \operatorname{div} u = 0\},$$
$$\hat{J}(\Omega) = \text{closure in } \mathscr{L}^2(\Omega) \text{ of } \{u: u \in C_0^\infty(\Omega), \operatorname{div} u = 0\},$$
$$G(\Omega) = \{u: u = \nabla \phi, \phi \in H^1(\Omega)\},$$
$$\hat{G}(\Omega) = \{u: u = \nabla \phi, \phi \in H_0^1(\Omega)\},$$
$$J^\ell(\Omega) = \{J(\Omega) \cap \mathscr{H}^\ell(\Omega)\}.$$

Letting the subscript τ denote tangential component, and the subscript n denote normal component, we define

$$J_n^\ell(\Omega) = \{u \in J^\ell(\Omega): u_n|_\Gamma = 0\},$$
$$J_\tau^\ell(\Omega) = \{u \in J^\ell(\Omega): u_\tau|_\Gamma = 0\},$$
$$J_{n,\tau}^\ell(\Omega) = J_n^\ell(\Omega) \cap J_\tau^\ell(\Omega).$$

By $J_n^0(\Omega)$ and by $J_{n,\tau}^0(\Omega)$, we mean $\hat{J}(\Omega)$, and by $J_\tau^0(\Omega)$ we mean $J(\Omega)$. Note that $J_{n,\tau}^\ell(\Omega)$ is dense in $\hat{J}(\Omega)$, $l \geqq 1$.

The following known theorems, Theorems 2.1–2.3, may be found in [9] or [16], and the references therein (see especially [2] and [3]).

Let $E(\Omega) = \{u \in \mathscr{L}^2(\Omega): \operatorname{div} u \in L^2(\Omega)\}$, where $\operatorname{div} u$ is taken in the distributional sense for $u \in \mathscr{L}^2(\Omega)$. E is a Hilbert space when given the scalar product

$$((u, v))_{E(\Omega)} = (u, v)_{\mathscr{L}^2(\Omega)} + (\operatorname{div} u, \operatorname{div} v)_{L^2(\Omega)}.$$

THEOREM 2.1 [16]. *Let Ω be a bounded open set in R^n, with Lipschitz boundary Γ. Then*

$$(\hat{J}(\Omega))^\perp = G(\Omega),$$
$$\hat{J}(\Omega) = \{u \in L^2(\Omega): \operatorname{div} u = 0, \gamma_\nu u = 0\}$$

where $\operatorname{div} u$ *is taken in the distributional sense. Here $\gamma_\nu: E(\Omega) \to H^{-1/2}(\Gamma)$ is a linear continuous operator (the existence of which may be shown) such that*

$$\gamma_\nu u = \text{the restriction of } u \cdot n \text{ to } \Gamma$$

for every $u \in C_0^\infty(\bar{\Omega})$.

THEOREM 2.2 [16], [17]. *Let Ω be a bounded open set of class C^2. Then $\mathscr{L}^2(\Omega) = \hat{J}(\Omega) \oplus K(\Omega) \oplus \hat{G}(\Omega)$, where*

$$K(\Omega) = \{u \in \mathscr{L}^2(\Omega): u = \nabla \phi, \phi \in H^1(\Omega), \Delta \phi = 0\}. \tag{2.10}$$

THEOREM 2.3 [2], [3], [9]. *If Ω is a bounded open set in R^3, with boundary Γ belonging to $C^{\ell+1}$, $\ell \geqq 1$, then the operator curl establishes a one-to-one correspondence between the spaces $J_\tau^\ell(\Omega)$ and $J_n^{\ell-1}(\Omega)$, and also between $J_n^\ell(\Omega)$ and $J^{\ell-1}(\Omega)$, where for all $u \in J_n^\ell(\Omega)$ and $u \in J_\tau^\ell(\Omega)$, we have the estimates*

$$C_1 \|\nabla \times u\|_{\ell-1} \leqq \|u\|_\ell \leqq C_2 \|\nabla \times u\|_{\ell-1}, \tag{2.11}$$

the constants C_1 and C_2 being independent of u.

We will also have need of two additional facts given in [9] concerning these spaces, which we state here as lemmas, giving proofs as the arguments are short.

LEMMA 2.4 [9]. *Let* $J^*(\Omega) = \{u: u \in J_n^2(\Omega), (\nabla \times u)_\tau|_\Gamma = 0\}$. *Then* $J_n^1(\Omega)$ *is the closure of* $J^*(\Omega)$ *in* $\mathscr{H}^1(\Omega)$.

Proof. The indicated closure is clearly contained in $J_n^1(\Omega)$. It also contains $J_n^1(\Omega)$: if $h \in J_n^1(\Omega)$, there exists $\xi \in J(\Omega)$ such that $h = \operatorname{curl} \xi$. As proved in [2], every vector $\xi \in J(\Omega)$ can be approximated by vectors $\xi^m \in J_\tau^1(\Omega)$ in $\mathscr{L}^2(\Omega)$. Let h^m be the solution of the problem $\operatorname{curl} h^m = \xi^m$. Then

$$\|h^m - h\|_1 \leqq C_2 \|\xi^m - \xi\| \to 0.$$

LEMMA 2.5 [9]. *In the Hilbert space* $\hat{J}(\Omega)$, *the operator* $T = \operatorname{curl}\operatorname{curl}$ *with domain* $D(T) = J^*(\Omega)$ *is self-adjoint and positive definite.*

Proof. As $J_{n,\tau}^2(\Omega) \subset J^*(\Omega)$, $J^*(\Omega)$ is dense in $J(\Omega)$. Let u, v be elements of $J^*(\Omega)$. Then

$$(\nabla \times (\nabla \times u), v) = \int_\Omega (\nabla \times (\nabla \times u)) \cdot v \, dV = \int_\Omega (\nabla \times u) \cdot (\nabla \times v) \, dV$$

$$= \int_\Omega u \cdot (\nabla \times (\nabla \times v)) \, dV = (u, \nabla \times (\nabla \times v)).$$

Thus T is symmetric on $J^*(\Omega)$.

Furthermore, the range of T, $R(T)$, is $\hat{J}(\Omega)$: given v an element of $\hat{J}(\Omega)$, by Theorem 2.3 there exists ψ, an element of $J_\tau^1(\Omega)$, such that $\nabla \times \psi = v$. Applying Theorem 2.3 to ψ, we see that there exists ϕ belonging to $J_n^2(\Omega)$ such that $\nabla \times \phi = \psi$. Thus $\phi \in J^*(\Omega)$, and

$$\nabla \times (\nabla \times \phi) = \nabla \times \psi = v.$$

It is well known [19] that if A is a symmetric operator in a Hilbert space H, and $R(A) = H$, then A is self-adjoint. Thus T is self-adjoint. Again employing Theorem 2.3, we have that T is positive definite:

$$(\nabla \times (\nabla \times u), u) = \int_\Omega (\nabla \times u) \cdot (\nabla \times u) \, dV \geqq \frac{1}{C_2} \|u\|_1.$$

We recall the vector identity

$$\nabla \times (\nabla \times u) = \operatorname{grad} \operatorname{div} u - \Delta u. \tag{2.12}$$

From the fact that $\operatorname{div} u = 0$, for $u \in J^*(\Omega)$, we see that $Tu = -\Delta u$ on $J^*(\Omega)$.

Lemma 2.5, along with the fact that the inclusion $\mathscr{H}^1(\Omega) \to \mathscr{L}^2(\Omega)$ is compact implies that the spectrum of $-\Delta$ is discrete and positive and the eigenfunctions of $-\Delta$ in $J^*(\Omega)$ form bases for $\hat{J}(\Omega)$, $J_n^1(\Omega)$, and $J^*(\Omega)$. From Theorem 2.3, we may show that the eigenfunctions are in $J_n^\ell(\Omega)$, ℓ arbitrarily large, and thus, by the Sobolev Lemma, that the eigenfunctions are smooth.

Remark 2.6. Denote the eigenfunctions of $-\Delta$ in $J^*(\Omega)$ by $\{U_\alpha\}$ (the subscript α will be made precise in § 4). If $u \in C^1(\bar{\Omega})$, $y \in C^2(\bar{\Omega})$, then

$$\operatorname{div}(u \times (\nabla \times v)) = (\nabla \times u) \cdot (\nabla \times v) - u \cdot (\nabla \times (\nabla \times v)).$$

Applying the divergence theorem to the left-hand side, we have the following Green identity for vectors:

$$\int_\Omega (\nabla \times u) \cdot (\nabla \times v) \, dV = \int_\Omega u \cdot (\nabla \times (\nabla \times v)) \, dV - \int_\Gamma u \cdot (\bar{n} \times (\nabla \times v)) \, ds. \tag{2.13}$$

Let S denote the set of all linear combinations of the eigenfunctions U_α; S is dense in $\hat{J}(\Omega)$, $J_n^1(\Omega)$, and $J^*(\Omega)$.

Let $u, v \in S$. Then,

$$\int_\Omega (\nabla \times u) \cdot (\nabla \times v)\, dV = -\int_\Omega u\, \Delta v\, dV. \tag{2.14}$$

For fixed v belonging to S, $L(u) = \int_\Omega (\nabla \times u) \cdot (\nabla \times v) + u\, \Delta v\, dV$ may easily be seen to be a bounded linear functional on $J_n^1(\Omega)$. Since $Lu = 0$ for every u belonging to S, by continuity $Lu = 0$ for every $u \in J_n^1(\Omega)$. Thus (2.14) holds for $v \in S$, $u \in J_n^1(\Omega)$. If $u \in J_n^1(\Omega)$, $L(v) = \int_\Omega (\nabla \times u) \cdot (\nabla \times v) + u\, \Delta v\, dV$ defines a bounded linear functional on $J^*(\Omega)$, and again by continuity (2.14) holds for every u belonging to $J_n^1(\Omega)$, v belonging to $J^*(\Omega)$.

3. Solution with L^2 boundary input. In this section we wish to establish the existence and uniqueness of a solution to (2.1)-(2.3), in the case in which $J \in L^2[0, T; \mathscr{L}^2(\Gamma)]$, $T > 0$. The approach will be based on the method of transposition, as put forth in [10a].

Before proceeding, we show that existence and uniqueness of a solution of the system (2.1), (2.2) with the homogeneous boundary condition

$$n \times (\nabla \times W) = 0 \quad \text{on } \Gamma$$

may be obtained, for appropriate initial data, using semigroup techniques. This is of independent but related interest to our result in the case of inhomogeneous boundary data.

THEOREM 3.1. *Given* $\begin{bmatrix} w_0 \\ w_1 \end{bmatrix} \in J^*(\Omega) \times J_n^1(\Omega)$, *there exists a unique solution* W *of*

$$\begin{aligned} &\Box W = 0 \\ &\nabla \cdot W = 0 \end{aligned} \quad \text{in } \Omega,$$

$$n \times (\nabla \times W) = 0 \quad \text{on } \Gamma, \tag{3.1}$$

$$W(\cdot, 0) = w_0, \qquad \frac{\partial W}{\partial t}(\cdot, 0) = w_1$$

with $W \in C[0, \infty; J^*(\Omega)] \cap C^1[0, \infty; J_n^1(\Omega)]$.

Proof. We define

$$\hat{H} = \left\{ \begin{bmatrix} u \\ v \end{bmatrix} : u \in J_n^1(\Omega),\ v \in \hat{J}(\Omega) \right\}.$$

With inner product

$$\left(\begin{bmatrix} u \\ v \end{bmatrix}, \begin{bmatrix} y \\ z \end{bmatrix} \right)_{\hat{H}} = \int_\Omega (\nabla \times u) \cdot (\nabla \times y) + v \cdot z\, dV$$

$\hat{H}$ is a Hilbert space. Now we define the operator

$$F = \begin{bmatrix} 0 & I \\ \Delta & 0 \end{bmatrix},$$

with $D(F) = J^*(\Omega) \times J_n^1(\Omega)$. Then, using Remark 2.6, we can see that F is skew-symmetric on $D(F)$:

$$\begin{aligned} \left(F \begin{bmatrix} u \\ v \end{bmatrix}, \begin{bmatrix} y \\ z \end{bmatrix} \right)_{\hat{H}} &= \int_\Omega (\nabla \times v) \cdot (\nabla \times y) + \Delta u \cdot z\, dV \\ &= -\int_\Omega v \cdot \Delta y + (\nabla \times z) \cdot (\nabla \times u)\, dV \\ &= \left(\begin{bmatrix} u \\ v \end{bmatrix}, -F \begin{bmatrix} y \\ z \end{bmatrix} \right)_{\hat{H}}. \end{aligned}$$

By definition, Theorems 2.1, 2.3, and Lemma 2.4, $D(F) \subset \hat{H}$ and is dense in $\hat{H}$. Furthermore, the range of F, $R(F)$, is equal to $\hat{H}$: Given $v \in \hat{J}(\Omega)$, by Theorem 2.3, there exists $\phi \in J_\tau^1(\Omega)$ such that $\nabla \times \psi = -v$. Applying Theorem 2.3 to ψ, we see that there exists $\phi \in J_n^2(\Omega)$ such that $\nabla \times \phi = \psi$. Thus $\phi \in J^*(\Omega)$, and $-(\nabla \times (\nabla \times \phi)) = \Delta \phi = v$.

As in the proof of Lemma 2.5, if A is a symmetric operator on a Hilbert space H and $R(A) = H$, then A is self-adjoint. A straightforward adaptation of the proof of this theorem shows that if A is skew-symmetric, and $R(A) = H$, then A is skew-adjoint. Thus we have shown that F is skew-adjoint on $D(F)$. From [13], F generates a C_0 group of unitary operators $S(t)$ and we now have the desired solution W to (3.1).

As implied by the fact that F is skew-adjoint, if the energy of W is defined as $\|W\|_{\hat{H}}^2$, then for smooth solutions W of the above system,

$$\begin{aligned}\frac{d}{dt}(W, W)_{\hat{H}} &= \frac{d}{dt}\int_\Omega (\nabla \times W) \cdot (\nabla \times W) + W \cdot W \, dV \\ &= 2\int_\Omega \left(\nabla \times \frac{\partial W}{\partial t}\right) \cdot (\nabla \times W) + \frac{\partial W}{\partial t} \cdot \frac{\partial^2 W}{\partial t^2} \, dV \\ &= 2\int_\Omega \frac{\partial W}{\partial t} \cdot \left(-\Delta W + \frac{\partial^2 W}{\partial t^2}\right) dV + 2\int_\Gamma \frac{\partial W}{\partial t} \cdot (n \times (\nabla \times W)) \, ds = 0,\end{aligned}$$

i.e., we have conservation of energy. If we define, as is customary, the electromagnetic energy to be $\int_\Omega H \cdot H + E \cdot E \, dV$, then we have conservation of the electromagnetic energy, since $(W, W)_{\hat{H}} = \int_\Omega H \cdot H + E \cdot E \, dV$.

We now turn to the inhomogeneous system (2.1)–(2.3), starting by stating the following general theorem.

THEOREM 3.2 [10a]. *Let V, H be Hilbert spaces, with*

$$V \subset H, \ V \text{ dense in } H, \ V \text{ separable.}$$

Identifying H with its dual and denoting V^* as the dual of V, we have

$$V \subset H \subset V^*.$$

Let $a(\phi, \psi)$ be a bilinear form on V. Let a be symmetric, and continuous, and assume that there exists $\lambda \in R$ such that

$$a(\psi, \psi) + \lambda \|\psi\|_H^2 \geqq \alpha \|\psi\|_V^2, \ \alpha > 0 \quad \text{for every } \psi \in V, \ t \in [0, T].$$

Then, given $f \in L^2[0, T; H]$, $\delta \in V$, $\kappa \in H$, there exists a unique solution ϕ satisfying

$$\frac{d}{dt}(\phi'(t), \psi) + a(\phi(t), \psi) = (f(t), \psi) \quad \forall \psi \in V \tag{3.2}$$

with $\phi(\cdot, T) = \delta$, $\partial\phi/\partial t(\cdot, T) = \kappa$. The unmarked bracket $(\cdot, \cdot)$ denotes the scalar product in H and $d/dt(\phi'(t), \psi)$ is taken in the distributional sense. In addition,

$$\phi \in C([0, T]; V), \qquad \frac{\partial \phi}{\partial t} \in C([0, T]; H)$$

and the map $\{f, \delta, \kappa\} \to \{\phi, \partial\phi/\partial t\}$ is a continuous linear map $L^2[0, T; H] \times V \times H \to L^2[0, T; V] \times L^2[0, T; H]$.

We may now establish the following theorem.

THEOREM 3.3. *Let*

$$a(\phi, \psi) = \int_\Omega (\nabla \times \phi) \cdot (\nabla \times \psi) \, dV \quad \forall \phi, \psi \in J_n^1(\Omega).$$

Then, given $f \in L^2[0, T; \hat{J}(\Omega)] \equiv Y$, *there exists a unique* ϕ *belonging to* $C[0, T; J_n^1(\Omega)]$, *with* $\partial\phi/\partial t$ *belonging to* $C[0, T; \hat{J}(\Omega)]$, *satisfying*

$$\frac{d}{dt}(\phi'(t), \psi) + a(\phi(t), \psi) = (f(t), \psi) \quad \forall \psi \in J_n^1(\Omega), \tag{3.3}$$

with

$$\phi(\cdot, T) = \frac{\partial \phi}{\partial t}(\cdot, T) = 0. \tag{3.4}$$

Proof. $J_n^1(\Omega) \subset \hat{J}(\Omega)$ by Theorem 2.1, and $J_n^1(\Omega)$ is dense in $\hat{J}(\Omega)$ by definition. By Theorem 2.3, the form a is continuous on $J_n^1(\Omega)$, and satisfies the coercive estimate on $J_n^1(\Omega)$; a is clearly symmetric.

Therefore, taking $V = J_n^1(\Omega)$, $H = \hat{J}(\Omega)$, Theorem 3.2 applies and Theorem 3.3 follows.

Remark 3.4. Equation (3.3) may be interpreted further: as before, denote the eigenfunctions of $-\Delta$ in $J^*(\Omega)$ by $\{U_\alpha\}$. Let $g(t)$ belong to $C_0^\infty[0, T]$, and denote the collection of all products of such $g(t)$, U_α by P. The set Q of all linear combinations of elements of P is dense in $L^2[0, T; \hat{J}(\Omega)]$.

Let $f \in P$, i.e., $f(\cdot, t) = g(t) U_\alpha$. The solution of

$$\Box \tilde{\phi} = f, \qquad \tilde{\phi}_n|_\Gamma = 0,$$

$$\tilde{\phi}(\cdot, T) = \frac{\partial \tilde{\phi}}{\partial t}(\cdot, T) = 0$$

may be obtained by separation of variables; $\tilde{\phi}$ is of the form $\beta(t) U_\alpha$, $\beta(t) \in C_0^\infty[0, T]$ (see § 4). Now

$$(\Box \tilde{\phi}, \psi) = (f, \psi) \quad \forall \psi \in J_n^1(\Omega),$$

$$\left(\frac{\partial^2 \tilde{\phi}}{\partial t^2}, \psi\right) + (-\Delta \tilde{\phi}, \psi) = (f, \psi).$$

From Remark 2.6,

$$(-\Delta \tilde{\phi}, \psi) = a(\tilde{\phi}, \psi) \quad \forall \psi \in J_n^1(\Omega).$$

Thus $\tilde{\phi} = \phi$, where ϕ satisfies (3.2) for $f = g(t) U_\alpha$. Now let $f \in Y$. If ϕ is the corresponding solution to (3.3), then $\Box \phi = f$ in the sense of distributions, on the function space $\mathcal{D} = \{\psi: \psi \in C_0^\infty(\Omega \times [0, T]), \nabla \cdot \psi = 0\}$. We may see this as follows. Let $\{f_k\} \subset Q$ be an approximating sequence for f; solve $\Box \phi_k = f_k$. Let $\psi \in \mathcal{D}$. Then

$$(\Box \phi_k, \psi)_Y = (f_k, \psi)_Y.$$

Integrating by parts,

$$(\phi_k, \Box \psi)_Y = (f_k, \psi)_Y.$$

The map $L: f \to \phi$ is continuous from $Y \to L^2[0, T; J_n^1(\Omega)]$. Thus

$$(\phi, \Box \psi)_Y = (f, \psi)_Y.$$

We now apply the method of transposition [10a]. Let X be the collection of ϕ obtained as f runs over Y; from Theorem 3.3, $\phi(\cdot, T) = \partial\phi/\partial t(\cdot, T) = 0$.

Give X the norm $\|\phi\|_X = \|f\|_Y$; then X is a Hilbert space. Let $S: \phi \to f$; we know S is an isomorphism from X to Y, and that $S\phi = \Box\phi$ in the sense of distributions.

Since S is bounded with respect to X norm, S^* is an isomorphism from Y^* to X^*, the duals of Y and X. Identify X and Y with their duals.

Let $L(\phi)$ be any bounded linear functional on X. Then by the Riesz Representation Theorem there exists $g \in X$ such that

$$L(\phi) = (g, \phi)_X \quad \forall \phi \in X.$$

From the above arguments, there exists $W \in Y$ such that $g = S^* W$. Therefore,

$$L(\phi) = (g, \phi)_X = (S^* W, \phi)_X = (W, S\phi)_Y = \int_0^T \int_\Omega W \cdot S\phi \, dV \, dt.$$

Given $J \in L^2[0, T; \mathscr{L}^2(\Gamma)]$ and $\left[\begin{smallmatrix} w_0 \\ w_1 \end{smallmatrix}\right] \in \hat{J}(\Omega) \times (J_n^1(\Omega))^*$,

$$L(\phi) = \int_0^T \int_\Gamma J \cdot \phi \, ds \, dt + \int_\Omega w_1 \cdot \phi(\cdot, 0) - w_0 \cdot \frac{\partial \phi}{\partial t}(\cdot, 0) \, dV$$

defines a bounded linear functional on X, as in [10a]. Thus we have the following theorem.

THEOREM 3.5. *For J, $\left[\begin{smallmatrix} w_0 \\ w_1 \end{smallmatrix}\right]$ given as above, there exists a unique $W \in Y$ satisfying*

$$\int_0^T \int_\Omega W \cdot \Box\phi \, dV \, dt = \int_0^T \int_\Gamma J \cdot \phi \, ds \, dt + \int_\Omega w_1 \cdot \phi_0 - w_0 \cdot \phi_1 \, dV \tag{3.5}$$

for every $\phi \in X$, where $\phi_0 = \phi(\cdot, 0)$, $\phi_1 = \partial\phi/\partial t(\cdot, 0)$.

We take W to be a weak solution of (2.1)-(2.3). Any smooth solution W^* of (2.1)-(2.3) with initial data w_0^*, w_1^*, corresponding to a smooth solution of (1.1)-(1.5), as in § 2.1, would satisfy (3.5). We show this as follows. On X, define

$$L(\phi) = \int_0^T \int_\Omega W^* \cdot \Box\phi \, dV \, dt - \left[\int_0^T \int_\Gamma J \cdot \phi \, ds \, dt + \int_\Omega w_1^* \cdot \phi_0 - w_0^* \cdot \phi_1 \, dV \right].$$

Since

$$\left| \int_0^T \int_\Omega W^* \cdot \Box\phi \, dV \, dt \right| \leqq \| W^* \|_Y \| \Box\phi \|_Y = \| W^* \|_Y \| \phi \|_X,$$

$L(\phi)$ is bounded on X. Let R be the collection of all solutions ϕ obtained by taking $f \in Q$ (Q as in Remark 3.4).

Let $\hat{\phi} \in X$, and let $\hat{f}$ correspond to $\hat{\phi}$ via (3.2). As Q is dense in Y, there exists $\{f_k\} \subset Q$ such that $\| f_k - \hat{f} \|_Y \to 0$. Solve $\Box\phi_k = f_k$; as before, ϕ_k belongs to R. Then

$$\| \phi_k - \hat{\phi} \|_X = \| f_k - \hat{f} \|_Y \to 0;$$

$\{\phi_k\}$ is an approximating sequence for $\hat{\phi}$ in X. Thus R is dense in X.

On R, $L(\phi_k) = 0$:

$$\begin{aligned}
\int_0^T \int_\Omega W^* \cdot \Box\phi_k \, dV \, dt &= \int_0^T \int_\Omega \left(W^* \cdot \frac{\partial^2}{\partial t^2}(\phi_k) - W^* \cdot \Delta\phi_k \right) dV \, dt \\
&= \int_\Omega w_1^* \cdot \phi_{k,0} - w_0^* \cdot \phi_{k,1} \, dV + \int_0^T \int_\Omega \phi_k \cdot \frac{\partial^2 W^*}{\partial t^2} \, dV \, dt \\
&\quad - \int_0^T \int_\Omega \phi_k \cdot \Delta W^* \, dV \, dt \\
&\quad - \int_0^T \int_\Gamma \phi_k \cdot (n \times (\nabla \times W^*)) \, ds \, dt
\end{aligned}$$

(the last equality from integrating by parts, and applying (2.13))

$$= \int_0^T \int_\Gamma J \cdot \phi_k \, ds \, dt + \int_\Omega w_1^* \cdot \phi_{k,0} - w_0^* \cdot \phi_{k,1} \, dV.$$

Thus, by continuity of L, $L(\phi)=0$ for every $\phi \in X$, and W^* satisfies (3.5) for every $\phi \in X$.

We are interested in controls that are L^2 in time, as we will be using moment problem techniques (see (4.23) and so on). We add that Theorems 3.2 and 3.3 may be improved for inhomogeneous terms $f \in L^1[0, T; \hat{J}(\Omega)]$, leading to an improvement of Theorem 3.5 with controls $J \in L^1[0, T; L^2(\Gamma)]$. We first have Theorem 3.6.

THEOREM 3.6 [10b]. *Let V, H be two real Hilbert spaces with V dense in H, the embedding of V into H continuous, and*

$$V \subset H \subset V^*.$$

Let $a(\phi, \psi)$ be a symmetric continuous bilinear form on V, such that

$$a(\psi, \psi) \geqq \alpha \|\psi\|_V^2, \qquad \alpha > 0.$$

We do not restrict generality by taking

$$a(\psi, \psi) = \|\psi\|_V^2. \tag{3.6}$$

We denote by $A \in L(V, V^*)$ the operator defined by

$$(A\phi, \psi) = a(\phi, \psi).$$

Then, given

$$f \in L^1[0, T; V^*], \quad \phi(0) = \delta \in H, \quad \phi'(0) = k \in V^*,$$

there exists a unique solution ϕ satisfying

$$\phi'' + A\phi = f, \tag{3.7}$$

$$\phi \in L^\infty[0, T; H], \qquad \phi' \in L^\infty[0, T; V^*],$$

$$\phi(\cdot, 0) = \delta, \qquad \phi'(\cdot, 0) = \kappa.$$

We may show that, if we take

$$f \in L^1[0, T; H], \quad \delta \in V, \quad \kappa \in H,$$

then the solution satisfies

$$\phi \in L^\infty[0, T; V], \qquad \phi' \in L^\infty[0, T; H].$$

Multiply (3.7) by ϕ'. We make a small modification of the proof of Theorem 3.6 (in which we multiply (3.7) by $A^{-1}\phi'$, approximate f by regular functions, and follow similar arguments). We have

$$\frac{1}{2}\frac{d}{dt}(\|\phi'\|_H^2 + (A\phi, \phi)) = (f, \phi').$$

Define

$$h(t) = \|\phi'\|_H^2 + \|\phi\|_V^2.$$

Now (using 3.6)

$$\frac{1}{2}\frac{dh}{dt} = \frac{1}{2}\frac{d}{dt}(\|\phi'\|_H^2 + (A\phi, \phi)) \leqq \|f\|_H \|\phi'\|_H,$$

or

$$\frac{dh}{dt} \leqq \|f\|_H (h+1).$$

Then, by Gronwall's Lemma,

$$\|\phi\|^2_{L^\infty[0,T;V]} + \|\phi'\|^2_{L^\infty[0,T;H]} \leqq C \left(\exp \int_0^T \|f\|_H \, dt \right) \times \left(\|\phi(0)\|^2_V + \|\phi'(0)\|^2_H + \int_0^T \|f\|_H \, dt \right).$$

We may reverse the direction of time in Theorem 3.6 and arrive at Theorem 3.7.

THEOREM 3.7. *Let*

$$a(\phi, \psi) = \int_\Omega (\nabla x \phi) \cdot (\nabla x \psi) \, dV \quad \forall \phi, \psi \in J^1_n(\Omega)$$

with

$$A(\phi, \psi) = a(\phi, \psi).$$

Then, given $f \in L^1[0, T; \hat{J}(\Omega)]$, *there exists a unique* ϕ *satisfying*

$$\phi'' + A\phi = f,$$

$$\phi \in L^\infty[0, T; J^1_n(\Omega)], \qquad \phi' \in L^\infty[0, T; \hat{J}(\Omega)],$$

$$\phi(\cdot, T) = \frac{\partial \phi}{\partial t}(\cdot, T) = 0.$$

By extension by continuity, ϕ, ϕ' *are continuous in time.*

Again, by transposition, since $L^\infty[0, T; \hat{J}(\Omega)]$ is the dual of $L^1[0, T; \hat{J}(\Omega)]$, and since the map

$$\phi \to \int_0^T \int_\Gamma J \cdot \phi \, ds \, dt$$

with $J \in L^1[0, T; L^2(\Gamma)]$ is bounded, we have Theorem 3.8.

THEOREM 3.8. *Given*

$$J \in L^1[0, T; L^2(\Gamma)], \qquad \begin{bmatrix} w_0 \\ w_1 \end{bmatrix} \in \hat{J}(\Omega) \times (J^1_n(\Omega))^*$$

there exists a unique $W \in L^\infty[0, T; \hat{J}(\Omega)]$ *such that*

$$\int_0^T \int_\Omega W \Box \phi \, dV \, dt = \int_0^T \int_\Gamma J \cdot \phi \, ds \, dt + \int_\Omega (w_1 \cdot \phi_0 - w_0 \cdot \phi_1) \, dV$$

where $\phi_0 = \phi(\cdot, 0)$, $\phi_1 = \partial \phi / \partial t(\cdot, 0)$.

4. Reduction of the control problem to moment problems. Given $\left[\begin{smallmatrix} w_0 \\ w_1 \end{smallmatrix}\right] \in J(\Omega) \times (J^1_n(\Omega))^*$, we now ask if we can find a control J belonging to $L^2[0, T; \mathscr{L}^2(\Gamma)]$ such that the corresponding W given by (3.5) also satisfies

$$W(\cdot, T) = \frac{\partial W}{\partial t}(\cdot, T) = 0.$$

Since W, $\partial W/\partial t$ are not well defined at T, we reformulate: first, take $T_1 > T$, and extend all $J \in L^2[0, T; \mathscr{L}^2(\Gamma)]$ to be identically zero on $[T, T_1]$. This gives a subset $\mathscr{J}$ of $L^2[0, T_1; \mathscr{L}^2(\Gamma)]$. Now replace T by T_1 in Theorem 3.5, and find $J \in \mathscr{J}$ such that the corresponding W, which is thus well-defined on $\Omega \times [T, T_1]$, satisfies $W = 0$ on $[T, T_1]$.

In this section the question of finding the desired control is reduced to the question of finding solutions to a collection of moment problems. Our approach will be similar to that used for the scalar wave equation with L^2 Neumann boundary input [7].

4.1. Equations for J. Now denote the normalized eigenfunctions of $-\Delta$ in $J^*(\Omega)$ by

$$\{U_{nmlk}\}, \quad n = 0, 1, 2, \cdots, \quad m = 0, 1, \cdots, 2n, \quad l = 1, \cdots, \quad k = 1, 2$$

with eigenvalues $(\omega_{nlk})^2$. The U's are basically products of Bessel functions and vector spherical harmonics; they will be given explicitly in § 4.2.

Let $T_1 > T$ and let $h(t)$ be an element of $C_0^\infty[T, T_1]$. Define $h_{nmlk} = h(t) U_{nmlk}$. The set of all such h_{nmlk} is complete in $L^2[T, T_1; \hat{J}(\Omega)]$.

The solution of

$$\Box \phi = h_{nmlk}, \qquad \phi_n|_\Gamma = 0,$$

$$\phi(\cdot, T_1) = \frac{\partial \phi}{\partial t}(\cdot, T_1) = 0$$

is given by

$$\phi(\cdot, t) = \eta(t) U_{nmlk}$$

where $\eta(t)$ satisfies

$$\eta''(t) + (\omega_{nlk})^2 \eta(t) = h(t), \qquad \eta(T_1) = \eta'(T_1) = 0,$$

with $'$ denoting ordinary differentiation. Integrating gives

$$\eta(t) = \frac{1}{\omega_{nlk}} \int_t^{T_1} \sin(\omega_{nlk}(\sigma - t)) h(\sigma)\, d\sigma,$$

$$\eta'(t) = -\int_t^{T_1} \cos(\omega_{nlk}(\sigma - t)) h(\sigma)\, d\sigma;$$

thus

$$\phi(\cdot, t) = \left(\alpha_1 \cos(\omega_{nlk} t) + \frac{1}{\omega_{nlk}} \alpha_2 \sin(\omega_{nlk} t) \right) U_{nmlk}, \tag{4.1}$$

$$\frac{\partial \phi}{\partial t}(\cdot, t) = \left(\alpha_2 \cos(\omega_{nlk} t) - \alpha_1 \omega_{nlk} \sin(\omega_{nlk} t) \right) U_{nmlk} \tag{4.2}$$

where

$$\alpha_1 = \frac{1}{\omega_{nlk}} \int_T^{T_1} \sin(\omega_{nlk} \sigma) h(\sigma)\, d\sigma, \tag{4.3}$$

$$\alpha_2 = -\int_T^{T_1} \cos(\omega_{nlk} \sigma) h(\sigma)\, d\sigma. \tag{4.4}$$

ϕ is clearly in X, and thus for given control J and initial data $\begin{bmatrix} w_0 \\ w_1 \end{bmatrix}$, the corresponding weak solution W must satisfy, for every four-tuple $(nmlk)$:

$$\int_0^{T_1}\int_\Omega W\cdot h_{nmlk}\,dV\,dt=\int_\Omega \alpha_1 U_{nmlk}w_1-\alpha_2 U_{nmlk}w_0\,dV$$

$$+\int_0^{T_1}\int_\Gamma J\cdot\left(\alpha_1\cos(\omega_{nlk}t)+\frac{1}{\omega_{nlk}}\alpha_2\sin(\omega_{nlk}t)\right)U_{nmlk}\,dV\,dt. \tag{4.5}$$

Expand

$$w_0=\sum_{n=0}^{\infty}\sum_{m=0}^{2n}\sum_{l=0}^{\infty}\sum_{k=1}^{2}\xi_{0,nmlk}U_{nmlk}, \tag{4.6}$$

$$w_1=\sum_{n=0}^{\infty}\sum_{m=0}^{2n}\sum_{l=0}^{\infty}\sum_{k=1}^{2}\xi_{1,nmlk}Y_{nmlk} \tag{4.7}$$

(assuming $w_1\in\hat{J}(\Omega)$, which is contained in $(J_n^1(\Omega))^*$). Use of (4.6), (4.7), and the orthogonality of the U's allows simplification of (4.5) to obtain

$$\int_T^{T_1}\int_\Omega W\cdot h_{nmlk}\,dV\,dt=\alpha_1\left\{\int_0^T\int_\Gamma J\cdot[\cos(\omega_{nlk}t)U_{nmlk}]\,ds\,dt+\xi_{1,nmlk}\right\}$$

$$+\alpha_2\left\{\int_0^T\int_\Gamma\frac{J\cdot[\sin(\omega_{nlk}t)U_{nmlk}]}{\omega_{nlk}}\,ds\,dt-\xi_{0,nmlk}\right\}. \tag{4.8}$$

Now, if there exists a J satisfying

$$\int_0^T\int_\Gamma J\cdot[\cos(\omega_{nlk}t)U_{nmlk}]\,ds\,dt=-\xi_{1,nmlk}, \tag{4.9}$$

$$\int_0^T\int_\Gamma\frac{J\cdot[\sin(\omega_{nlk}t)U_{nmlk}]}{\omega_{nlk}}\,ds\,dt=\xi_{0,nmlk} \tag{4.10}$$

for every $(nmlk)$, then the corresponding W will satisfy

$$\int_T^{T_1}\int_\Omega W\cdot h_{nmlk}\,dV\,dt=0$$

for every $(nmlk)$, which implies

$$W=0\quad\text{a.e. on }[T,T_1].$$

4.2. Explicit form of eigenfunctions. First, some necessary terminology will be given. Let (r,θ,ϕ) denote the usual spherical coordinates: r is the radial coordinate, $0\leqq r\leqq 1$; θ is the "longitudinal coordinate," $0\leqq\theta\leqq 2\pi$, and ϕ is the "latitudinal coordinate," $0\leqq\phi\leqq\pi$. Thus

$$\int_\Omega dV=\int_0^{2\pi}\int_0^{\pi}\int_0^1 r^2\sin\phi\,dr\,d\phi\,d\theta.$$

The system of basis vectors corresponding to spherical coordinates will be denoted by $\bar{a}_r$, $\bar{a}_\theta$, $\bar{a}_\phi$. The vector $\bar{a}_r$ is the same as $\bar{n}$, the unit outward normal.

Let $Y_{nm}(\theta,\phi)$ denote the spherical harmonics:

$$Y_{nm}(\theta,\phi)=\begin{Bmatrix}(\cos m\theta)P_n^m(\cos\phi), & m=0,1,\cdots,n\\ (\sin[(m-n)\theta])P_n^{m-n}(\cos\phi), & m=n+1,\cdots,2n\end{Bmatrix},\qquad n=0,1,2,\cdots$$

where the $P_n^m(\cos\phi)$ are the Legendre functions [12].

Let $J_{n+1/2}(z)$ be the cylindrical Bessel function of order $n+(\frac{1}{2})$; $J_{n+(1/2)}(kr)$ satisfies

$$\frac{d^2J}{dr^2}+\frac{1}{r}\frac{dJ}{dr}+\left[k^2-\frac{(n+\frac{1}{2})^2}{r^2}\right]J=0. \tag{4.11}$$

Let $j_n(z)=\sqrt{\pi/2z}\,J_{n+(1/2)}(z)$ be the nth spherical Bessel function,

$$\beta_{nl} \text{ be the } l\text{th root of } j_n(\pi\beta)=0, \quad l=1,2,\cdots, \quad \text{and}$$

$$\gamma_{nl} \text{ the } l\text{th root of } \frac{d}{d\gamma}[\pi\gamma j_n(\pi\gamma)]=0, \qquad l=1,2,\cdots.$$

Now, following (essentially) the notation of [12], define

$$\hat{P}_{nm}=Y_{nm}\bar{a}_r, \quad \hat{C}_{nm}=\operatorname{curl}[Y_{nm}\bar{a}_r], \quad \hat{B}_{nm}=\bar{a}_r\times\hat{C}_{nm}.$$

These are referred to as the vector spherical harmonics [1], [4], [12] and are mutually orthogonal. We have

$$\int_\Gamma \hat{P}_{nm}\cdot\hat{P}_{\mu\nu}\,ds=\int_\Gamma \hat{B}_{nm}\cdot\hat{B}_{\nu\mu}\,ds=\int_\Gamma \hat{C}_{nm}\cdot\hat{C}_{\nu\mu}\,ds$$

$$=\frac{4\pi}{\varepsilon_m(2n+1)}\frac{(n+m)!}{(n-m)!}\delta_{m\mu}\delta_{n\nu}\equiv(\tau_{nm})^2\delta_{m\mu}\delta_{n\nu}.$$

Here $\int_\Gamma ds=\int_0^{2\pi}\int_0^{\pi}\sin\phi\,d\phi\,d\theta$, δ denotes the Kronecker delta, and $\varepsilon_m=1$ when $m=0$, two when $m>0$.

We are now ready to give the explicit eigenfunction expressions. Define

$$\begin{aligned}\hat{M}_{nml}&=\operatorname{curl}[j_n(\pi\gamma_{nl}r)Y_{nm}(\theta,\phi)r\bar{a}_r]\\&=\sqrt{n(n+1)}\,j_n(\pi\gamma_{nl}r)\hat{C}_{nm},\end{aligned} \tag{4.12}$$

$$\begin{aligned}\hat{N}_{nml}&=\operatorname{curl}[\operatorname{curl}[j_n(\pi\beta_{nl}r)Y_{nm}(\theta,\phi)r\bar{a}_r]]\\&=\frac{1}{\pi\beta_{nl}r}\left[n(n+1)j_n(\pi\beta_{nl}r)\hat{P}_{nm}+\sqrt{n(n+1)}\left\{\frac{d}{dr}[rj_n(\pi\beta_{nl}r)]\right\}\hat{B}_{nm}\right].\end{aligned} \tag{4.13}$$

If we define

$$(\lambda_{nl})^2\equiv\int_0^1 n(n+1)[j_n(\pi\gamma_{nl}r)]^2r^2\,dr, \tag{4.14}$$

then

$$\int_\Omega \hat{M}_{nml}\cdot\hat{M}_{nml}\,dV=(\lambda_{nl})^2(\tau_{nm})^2,$$

i.e., $\lambda_{nl}\tau_{nm}$ is the normalization constant for $\hat{M}_{nml}$. Similarly, if we define

$$\int_0^1\frac{[n(n+1)j_n(\pi\beta_{nl}r)]^2+n(n+1)\{d/dr[rj_n(\pi\beta_{nl}r)]\}^2}{(\pi\beta_{nl}r)^2}r^2\,dr\equiv(\rho_{nl})^2, \tag{4.15}$$

then

$$\int_\Omega \hat{N}_{nml}\cdot\hat{N}_{nml}\,dV=(\rho_{nl})^2(\tau_{nm})^2, \tag{4.16}$$

and $\rho_{nl}\tau_{nm}$ is the normalization constant for $\hat{N}_{nml}$. Now let

$$C_{nm} = \frac{\hat{C}_{nm}}{\tau_{nm}}, \quad B_{nm} = \frac{\hat{B}_{nm}}{\tau_{nm}}, \quad P_{nm} = \frac{\hat{P}_{nm}}{\tau_{nm}},$$

$$M_{nml} = \frac{\sqrt{n(n+1)}\, j_n(\pi\gamma_{nl} r)}{\lambda_{nl}} C_{nm},$$

$$N_{nml} = \frac{n(n+1)}{\rho_{nl}(\pi\beta_{nl} r)} \left[j_n(\pi\beta_{nl} r) P_{nm} + \frac{1}{\sqrt{n(n+1)}} \left\{ \frac{d}{dr} [r j_n(\pi\beta_{nl} r)] \right\} B_{nm} \right].$$

The M's and N's are the normalized eigenfunctions; $U_{nml1} = M_{nml}$, $U_{nml2} = N_{nml}$. The M's are sometimes referred to as the transverse magnetic fields, and N's as the transverse electric fields. The collection of M's and N's are referred to as the multipole fields [1], [4], [8]. If we replace $\pi\gamma_{nl}$ and $\pi\beta_{nl}$ by k in the expressions for M_{nml} and N_{nml}, and denote these modified functions by M_{nm} and N_{nm}, then

$$M_{nm} = \left(\frac{1}{k}\right) \operatorname{curl} N_{nm}, \qquad N_{nm} = \left(\frac{1}{k}\right) \operatorname{curl} M_{nm}.$$

We may show

$$\begin{aligned} \nabla \times (\nabla \times M_{nml}) &= -\Delta M_{nml} = (\pi\gamma_{nl})^2 M_{nml}, \\ \nabla \times (\nabla \times N_{nml}) &= -\Delta N_{nml} = (\pi\beta_{nl})^2 N_{nml}. \end{aligned} \tag{4.17}$$

Thus $\omega_{nl1} = \pi\gamma_{nl}$, $\omega_{nl2} = \pi\beta_{nl}$. The M's and N's satisfy the boundary condition of zero normal component and zero tangential curl. They are obtained by constructive techniques [12]. It is apparently assumed that these are all the eigenfunctions of the vector Laplacian that are divergence-free and satisfy

$$u_n|_\Gamma = 0, \qquad (\nabla \times u)_\tau|_\Gamma = 0 \tag{4.18}$$

(boundary conditions of $J^*(\Omega)$). We use a theorem of Lamb [18] to verify this, in Appendix A.

We refer to [18] for further discussion of the multipole fields. Also see [11] for a useful summary.

4.3. Obtaining moment problems. From (4.9), (4.10), the desired J must satisfy

$$\int_0^T \int_\Gamma J \cdot \cos(\pi\gamma_{nl} t) M_{nml}\, ds\, dt = -\xi_{1,nml1}, \tag{4.19}$$

$$\int_0^T \int_\Gamma \frac{J \cdot \sin(\pi\gamma_{nl} t)}{\pi\gamma_{nl}} M_{nml}\, ds\, dt = \xi_{0,nml1}, \tag{4.20}$$

$$\int_0^T \int_\Gamma J \cdot \cos(\pi\beta_{nl} t) N_{nml}\, ds\, dt = -\xi_{1,nml2}, \tag{4.21}$$

$$\int_0^T \int_\Gamma \frac{J \cdot \sin(\pi\beta_{nl} t)}{\pi\beta_{nl}} N_{nml}\, ds\, dt = \xi_{0,nml2}. \tag{4.22}$$

Equations (4.19)-(4.22) constitute a moment problem for J in $L^2[0, T; \mathscr{L}^2(\Gamma)]$. We now derive conditions on the Fourier coefficients of J that must hold if J is to satisfy (4.19)-(4.22). These conditions amount to a collection of moment problems; the Fourier coefficients of J must be solutions to these.

Expand

$$J = \sum_{n=1}^{\infty} \sum_{m=0}^{2n} \sigma_{nm}(t) C_{nm} + \pi_{nm}(t) B_{nm} \tag{4.23}$$

(the C's and B's contain only tangential components). Now fix (nm) in (4.19):

$$\int_0^T \int_\Gamma \left[\sum_{p=1}^{\infty} \sum_{q=0}^{2p} \sigma_{pq} C_{pq} + \pi_{pq} B_{pq} \right] \cdot \cos(\pi\gamma_{nl} t) \frac{j_n(\pi\gamma_{nl} r) C_{nm}}{\lambda_{nl}} \, ds \, dt$$

$$= \frac{j_n(\pi\gamma_{nl})}{\lambda_{nl}} \int_0^T \cos(\pi\gamma_{nl} t) \int_\Gamma \left[\sum_{p=1}^{\infty} \sum_{q=0}^{2n} \sigma_{pq} C_{pq} + \pi_{pq} B_{pq} \right] C_{nm} \, ds \, dt$$

$$= \frac{j_n(\pi\gamma_{nl})}{\lambda_{nl}} \int_0^T \cos(\pi\gamma_{nl} t) \sigma_{nm}(t) \, dt.$$

Thus, for every $l = 0, 1, 2, \cdots$, $\sigma_{nm}(t)$ must satisfy

$$\frac{\sqrt{n(n+1)} j_n(\pi\gamma_{nl})}{\lambda_{nl}} \int_0^T \cos(\pi\gamma_{nl} t) \sigma_{nm}(t) \, dt = -\xi_{1,nml1}. \tag{4.24}$$

Similarly, from (4.20), for every $l = 0, 1, 2, \cdots$, $\sigma_{nm}(t)$ must satisfy

$$\frac{\sqrt{n(n+1)} j_n(\pi\gamma_{nl})}{\lambda_{nl}(\pi\gamma_{nl})} \int_0^T \sin(\pi\gamma_{nl} t) \sigma_{nm}(t) \, dt = \xi_{0,nml1}. \tag{4.25}$$

Now treating the pair (4.21), (4.22) similarly, we have

$$\int_0^T \int_\Gamma J \cdot \frac{\cos(\pi\beta_{nl} t)}{\rho_{nl}(\pi\beta_{nl} r)} \left[j_n(\pi\beta_{nl} r) P_{nm} + \frac{\{d/dr[r j_n(\pi\beta_{nl} r)] B_{nm}\}}{\sqrt{n(n+1)}} \right] ds \, dt$$

$$= \frac{1}{\rho_{nl}} \int_0^T \cos(\pi\beta_{nl} t) \int_\Gamma \left[\sum_{p=1}^{\infty} \sum_{q=1}^{2p} \sigma_{pq} C_{pq} + \pi_{pq} B_{pq} \right] \cdot \frac{j_n'(\pi\beta_{nl}) B_{nm}}{\sqrt{n(n+1)}} \, ds \, dt$$

(since $d/dr[r j_n(\pi\beta_{nl} r)] = j_n(\pi\beta_{nl} r) + \pi\beta_{nl} r j_n'(\pi\beta_{nl} r) = \pi\beta_{nl} j_n'(\pi\beta_{nl})$ at $r = 1$)

$$= \frac{j_n'(\pi\beta_{nl})}{\rho_{nl}\sqrt{n(n+1)}} \int_0^T \cos(\pi\beta_{nl} t) \pi_{nm}(t) \, dt.$$

Thus, for every $l = 0, 1, 2, \cdots$, $\pi_{nm}(t)$ must satisfy

$$\frac{\sqrt{n(n+1)} j_n'(\pi\beta_{nl})}{\rho_{nl}} \int_0^T \cos(\pi\beta_{nl} t) \pi_{nm}(t) \, dt = -\xi_{1,nml2}. \tag{4.26}$$

Similarly, from (4.22), for every $l = 0, 1, 2, \cdots$, $\pi_{nm}(t)$ must satisfy

$$\frac{\sqrt{n(n+1)} j_n'(\pi\beta_{nl})}{\pi\beta_{nl} \cdot \rho_{nl}} \int_0^T \sin(\pi\beta_{nm} t) \pi_{nm}(t) \, dt = \xi_{0,nml2}. \tag{4.27}$$

Equations (4.24) and (4.25) may be put in the equivalent form:

$$\int_0^T \exp[i\pi\gamma_{nl} t] \sigma_{nm}(t) \, dt = \frac{-\xi_{1,nml1} + i\pi\gamma_{nl}\xi_{0,nml1}}{\{\sqrt{n(n+1)} j_n(\pi\gamma_{nl})\}/(\lambda_{nl})} \equiv a_{nml}, \tag{4.28}$$

$$\int_0^T \exp[-i\pi\gamma_{nl} t] \sigma_{nm}(t) \, dt = \frac{-\xi_{1,nml1} - i\pi\gamma_{nl}\xi_{0,nml1}}{\{\sqrt{n(n+1)} j_n(\pi\gamma_{nl})\}/(\lambda_{nl})} \equiv b_{nml}. \tag{4.29}$$

Equations (4.26) and (4.27) may be put in the equivalent form:

$$\int_0^T \exp[i\pi\beta_{nl} t] \pi_{nm}(t) \, dt = \frac{-\xi_{1,nml2} + i\pi\beta_{nl}\xi_{0,nml2}}{\{\sqrt{n(n+1)} j_n'(\pi\beta_{nl})\}/(\rho_{nl})} \equiv c_{nml}, \tag{4.30}$$

$$\int_0^T \exp[-i\pi\beta_{nl} t] \pi_{nm}(t) \, dt = \frac{-\xi_{1,nml2} - i\pi\beta_{nl}\xi_{0,nml2}}{\{\sqrt{n(n+1)} j_n'(\pi\beta_{nl})\}/(\rho_{nl})} \equiv d_{nml}. \tag{4.31}$$

Equations (4.28) and (4.29) constitute a moment problem for $\sigma_{nm}(t)$; (4.30) and (4.31) constitute a moment problem for $\pi_{nm}(t)$ (the reader may refer to, e.g., [7] and [14] for further discussions of moment problems). In § 5, we will show that, under certain conditions, solutions to these moment problems exist.

5. Solutions of moment problems and sufficient conditions on initial data. In § 5.1, we prove that, under summability assumptions on the a's, b's, c's, and d's, the moment problems (4.28), (4.29), and (4.30), (4.31) have solutions. These solutions may be used in the role of the Fourier coefficients of J, and, under additional summability assumptions, the J so defined does belong to $L^2[0, T; \mathscr{L}^2(\Gamma)]$ and satisfies (4.19)-(4.22). In § 5.2, we give sufficient conditions on the initial data w_0, w_1 to ensure satisfaction of all the summability assumptions, culminating in Theorem 5.6.

5.1. Solutions to moment problems.

PROPOSITION 5.1. *For $n = 1, 2, 3, \cdots$, the intervals between the consecutive positive roots of $d/d\gamma[\gamma j_n(\pi\gamma)] = 0$ are bounded below by π, and decrease monotonically to π as $l \to \infty$:*

$$\pi\gamma_{n2} - \pi\gamma_{n1} > \cdots > \pi\gamma_{n,l+1} - \pi\gamma_{n,l} > \cdots \to \pi.$$

Proof. As in § 4.3,

$$\frac{d}{dy}[\gamma j_n(\pi\gamma)] = j_n(\pi\gamma) + \pi\gamma j_n'(\pi\gamma) = 0 \quad \text{for } \gamma = \gamma_{nl}, \quad \text{i.e.,} \tag{5.1}$$

$$j_n(\pi\gamma_{nl}) + \pi\gamma_{nl} j_n'(\pi\gamma_{nl}) = 0.$$

Define

$$f(r) = \frac{d}{dr}[r j_n(\pi\gamma_{nl} r)] = j_n(\pi\gamma_{nl} r) + r\frac{d}{dr}[j_n(\pi\gamma_{nl} r)].$$

From § 4.2,

$$j_n(\pi\gamma_{nl} r) = \frac{1}{\sqrt{2\gamma_{nl} r}} J_{n+(1/2)}(\pi\gamma_{nl} r).$$

Thus,

$$\begin{aligned} f(r) &= \frac{1}{\sqrt{2\gamma_{nl} r}} J_{n+(1/2)}(\pi\gamma_{nl} r) + r \cdot \frac{d}{dr}\left[\frac{1}{\sqrt{2\gamma_{nl} r}} J_{n+(1/2)}(\pi\gamma_{nl} r)\right] \\ &= \frac{1}{\sqrt{2\gamma_{nl}}}\left[\frac{J_{n+(1/2)}(\pi\gamma_{nl} r)}{\sqrt{r}} + r \cdot \left\{-\frac{J_{n+(1/2)}(\pi\gamma_{nl} r)}{2r\sqrt{r}} + \frac{\pi\gamma_{nl}}{\sqrt{r}} J'_{n+(1/2)}(\pi\gamma_{nl} r)\right\}\right] \\ &= \frac{1}{\sqrt{2\gamma_{nl} r}}\left[\frac{1}{2} J_{n+(1/2)}(\pi\gamma_{nl} r) + \pi\gamma_{nl} r J'_{n+(1/2)}(\pi\gamma_{nl} r)\right]. \end{aligned}$$

From (5.1), $f(1) = 0$. Therefore, our equation assumes the form

$$\frac{1}{\sqrt{2\gamma_{nl}}}\left[\frac{1}{2} J_{n+(1/2)}(\pi\gamma_{nl}) + \pi\gamma_{nl} J'_{n+(1/2)}(\pi\gamma_{nl})\right] = 0. \tag{5.2}$$

We now turn to the work of Graham [6], in which he defines, for real x, the positive solutions of

$$\frac{1}{\sqrt{\omega}}\left[\frac{1}{2} J_x(\omega) + \omega J'_x(\omega)\right] = 0 \tag{5.3}$$

as τ_{xl}, $l=1, 2, \cdots$ and the zeros of $J_x(\omega)$ to be g_{xl}, $l=1, 2, \cdots$ (we use g_{xl} for Graham's j_{xl}). Thus from (5.2), and the definition of j_n, we have

$$\pi\gamma_{nl} = \tau_{n+(1/2),l}, \qquad \pi\beta_{nl} = g_{n+(1/2),l}.$$

Reference [6] contains the following result (Lemma 3.1). If $x > \frac{1}{2}$, then the lengths of the intervals between successive elements of the sequence

$$\cdots \tau_{x,l-1} < g_{x,l-1} < \tau_{xl} \cdots$$

decrease monotonically to their asymptotic value of $\pi/2$,

$$g_{x1} - \tau_{x1} > \tau_{x2} - g_{x1} > \cdots \to \pi/2.$$

If $x = \frac{1}{2}$, then all these intervals are exactly $\pi/2$ long.

The proposition follows.

Remarks 5.2. (1) Graham's Lemma 3.1 of [6] and the work of Watson (see [6]) give a lower bound of π on the spacings of the $\pi\beta_{nl}$'s.

(2) Lemma 3.1 of [6] ensures that $d/dr[rj_n(\pi\beta_{nl}r)]$ and $j_n(\pi\gamma_{nl}r)$ do not vanish at $r=1$, a fact that was implicitly assumed true in the derivations of (4.28)-(4.31). We see this as follows. Clearly, $j_n(\pi\gamma_{nl}) \neq 0$. Furthermore, if we let

$$f(r) = \frac{d}{dr}[rj_n(\pi\beta_{nl}r)]$$

then, computing as before, with $x = n + (\frac{1}{2})$,

$$f(r) = \frac{1}{\sqrt{2\beta_{nl}r}}\left[\frac{1}{2}J_x(\pi\beta_{nl}r) + \pi\beta_{nl}rJ'_x(\pi\beta_{nl}r)\right].$$

Since

$$\frac{1}{2}J_x(\omega) + \omega J'_x(\omega) = 0$$

for $\omega = \tau_{xl}$, and τ_{xl} and g_{xl} $(=\pi\beta_{nl})$ are separated by a gap of at least $\pi/2$, we see that $f(1) \neq 0$.

(3) Separation of variables for the scalar Helmholtz equation $\Delta U + \lambda U = 0$, in the unit ball in R^3, with the homogeneous elastic boundary condition $\partial U/\partial n + U = 0$ gives rise to (5.3).

THEOREM 5.3. *Let $n \geqq 1$, $0 \leqq m \leqq 2n$. Assume the sequences $\{a_{nml}\}$, $\{b_{nml}\}$, $\{c_{nml}\}$, and $\{d_{nml}\}$, $l=1, 2, \cdots$, are square summable. Then, given $T > 2$:*

(i) *The moment problem* (4.28), (4.29) *has a solution $\sigma_{nm}(t)$, with*

$$\Lambda_1 \sum_{l=1}^{\infty} (|a_{nml}|^2 + |b_{nml}|^2) \leqq \|\hat{\sigma}_{nm}(t)\|^2_{L^2[0,T]} \leqq \Pi_1 \sum_{l=1}^{\infty} (|a_{nml}|^2 + |b_{nml}|^2) \tag{5.4}$$

where Λ_1, Π_1 are constants independent of nm and the particular sequences a_{nml} and b_{nml}.

(ii) *The moment problem* (4.30), (4.31) *has a solution $\hat{\pi}_{nm}(t)$, with*

$$\Lambda_2 \sum_{l=1}^{\infty} (|c_{nml}|^2 + |d_{nml}|^2) \leqq \|\hat{\pi}_{nm}(t)\|_{L^2[0,T]} \leqq \Pi_2 \sum_{l=1}^{\infty} (|c_{nml}|^2 + |d_{nml}|^2) \tag{5.5}$$

where Λ_2 and Π_2 are constants analogous to Λ_1 and Π_1.

Proof. By Proposition 5.1,

$$\frac{2\pi}{\min_l (\pi\gamma_{n,l+1} - \pi\gamma_{nl})} = 2.$$

Thus, if $T > 2$, a result of Ingham, as in [7], shows that hypotheses of a theorem of Boas may be satisfied. Therefore, the solution $\hat{\sigma}_{nm}(t)$ exists, and (5.4) holds.

Similarly, the lower bound of π on the spacings of the $\pi\beta_{nl}$'s gives the existence of $\hat{\pi}_{nm}(t)$, and (5.5).

THEOREM 5.4. *Assume*

$$\sum_{n=1}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |a_{nml}|^2 < \infty, \qquad \sum_{n=1}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |c_{nml}|^2 < \infty.$$

If we define

$$J = \sum_{n=1}^{\infty} \sum_{m=0}^{2n} \hat{\sigma}_{nm}(t) C_{nm} + \hat{\pi}_{nm}(t) B_{nm},$$

using the solutions $\hat{\sigma}_{nm}(t)$, $\hat{\pi}_{nm}(t)$ *from Theorem* 5.3, *then* $J \in L^2[0, T; \mathscr{L}^2(\Gamma)]$, and J *satisfies* (4.19)-(4.22).

Proof. Note first that $|a_{nml}| = |b_{nml}|$, $|c_{nml}| = |d_{nml}|$:

$$\left\| \sum_{n=n_1}^{n=n_2} \sum_{m=0}^{2n} \{\hat{\sigma}_{nm}(t) C_{nm} + \hat{\pi}_{nm}(t) B_{nm}\} \right\|_{L^2[0,T;\mathscr{L}^2(\Gamma)]}$$

$$= \sum_{n=n_1}^{n=n_2} \sum_{m=0}^{2n} \{\|\hat{\sigma}_{nm}(t)\|_{L^2[0,T]} + \|\hat{\pi}_{nm}(t)\|_{L^2[0,T]}\}$$

$$\leqq 2\Pi_1 \sum_{n=n_1}^{n=n_2} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |a_{nml}|^2 + 2\Pi_2 \sum_{n=n_1}^{n=n_2} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |c_{nml}|^2$$

$$\to 0 \quad \text{as } n_1, n_2 \to 0.$$

The inequality follows from (5.4), (5.5).

The fact that J satisfies (4.19)-(4.22) follows from the discussion preceding (4.28)-(4.31).

5.2. Sufficient conditions on initial data. We first simplify some notation. Let

$$\mu_{nml} \equiv \xi_{0,nml1}, \qquad \zeta_{nml} \equiv \xi_{1,nml1},$$

$$\nu_{nml} \equiv \xi_{0,nml2}, \qquad \eta_{nml} \equiv \xi_{1,nml2}.$$

Thus

$$w_0 = \sum_{n=0}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} \mu_{nml} M_{nml} + \nu_{nml} N_{nml},$$

$$w_1 = \sum_{n=0}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} \zeta_{nml} M_{nml} + \eta_{nml} N_{nml}.$$

We will have need of simplified expressions for the constants λ_{nl} and ρ_{nl}, defined in (4.14), (4.15). These expressions are:

$$(\lambda_{nl})^2 = \frac{n(n+1)}{2}\left[1 - \frac{n(n+1)}{(\pi\gamma_{nl})^2}\right] j_n^2(\pi\gamma_{nl}), \tag{5.6}$$

$$(\rho_{nl})^2 = \frac{n(n+1)}{2} j_{n+1}^2(\pi\beta_{nl}). \tag{5.7}$$

They are derived in Appendix B.

THEOREM 5.5.

(5.8) (i) $$\sum_{l=1}^{\infty} |a_{nml}|^2 < \sum_{l=1}^{\infty} (|\zeta_{nml}|^2 + |\pi\gamma_{nl}\mu_{nml}|^2),$$

(5.9) (ii) $$\sum_{l=1}^{\infty} |c_{nml}|^2 \leqq \sum_{l=1}^{\infty} (|\eta_{nml}|^2 + |\pi\beta_{nl}\nu_{nml}|^2)$$

(*assume the right-hand sides of* (5.8) *and* (5.9) *are finite*; *Theorem* 5.6 *will address this assumption*).

Proof.

$$|a_{nml}|^2 = \left| \frac{-\zeta_{nml} + i\pi\gamma_{nl}\mu_{nml}}{\{\sqrt{n(n+1)}\, j_n(\pi\gamma_{nl})\}/(\lambda_{nl})} \right|^2$$

$$\leqq 2 \frac{\{|\zeta_{nml}|^2 + |\pi\gamma_{nl}\mu_{nml}|^2\}}{R_{nl}^2}$$

where R_{nl} denotes the denominator of a_{nml}.

$$|R_{nl}| = \frac{\sqrt{n(n+1)}\,|j_n(\pi\gamma_{nl})|}{\left(\frac{n(n+1)}{2}\left(1 - \frac{n(n+1)}{(\pi\gamma_{nl})^2}\right) j_n^2(\pi\gamma_{nl})\right)^{1/2}}.$$

As $l \to \infty$, $1 - (n(n+1)/(\pi\gamma_{nl})^2) \to 1$. Therefore,

$$|R_{nl}| > \sqrt{2}, \text{ and (i) follows.}$$

Proceeding similarly for the proof of (ii):

$$|c_{nml}|^2 = \left| \frac{-\eta_{nml} + i\pi\beta_{nl}\nu_{nml}}{\{\sqrt{n(n+1)}\, j_n'(\pi\beta_{nl})\}/(\rho_{nl})} \right|^2$$

$$\leqq 2 \frac{\{|\eta_{nml}|^2 + |\pi\beta_{nl}\nu_{nml}|^2\}}{Q_{nl}^2}$$

where Q_{nl} denotes the denominator of c_{nml}. From identity (2) (Appendix B), for the spherical Bessel functions, we have

$$(2n+1) j_n'(\pi\beta_{nl}) = n j_{n-1}(\pi\beta_{nl}) - (n+1) j_{n+1}(\pi\beta_{nl}).$$

Employing identity (1) (Appendix B), we have

$$(2n+1) j_n'(\pi\beta_{nl}) = n j_{n-1}(\pi\beta_{nl}) + (n+1) j_{n-1}(\pi\beta_{nl}).$$

Therefore

$$j_n'(\pi\beta_{nl}) = j_{n-1}(\pi\beta_{nl}).$$

We now have

$$|Q_{nl}| = \frac{\sqrt{n(n+1)}\,|j_n'(\pi\beta_{nl})|}{\left[\frac{n(n+1)}{2}\right]^{1/2} |j_{n-1}(\pi\beta_{nl})|} = \sqrt{2},$$

and (ii) follows.

THEOREM 5.6. *Let* $T>2$, *and let* $\begin{bmatrix} w_0 \\ w_1 \end{bmatrix} \in J_n^1(\Omega) \times \hat{J}(\Omega)$. *Then*

$$\text{(5.10)} \quad \text{(i)} \qquad \sum_{n=1}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |\pi\gamma_{nl}\mu_{nml}|^2 < \infty,$$

$$\text{(5.11)} \qquad \sum_{n=1}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |\pi\beta_{nl}\nu_{nml}|^2 < \infty.$$

$$\text{(ii)} \qquad \sum_{n=1}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |\zeta_{nml}|^2 < \infty, \qquad \sum_{n=1}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |\eta_{nml}|^2 < \infty.$$

(iii) *There exists* $J \in L^2[0, T, \mathscr{L}^2(\Gamma)]$, *which satisfies* (4.19)-(4.22), *and hence the corresponding* W, *given by Theorem* 3.5, *satisfies* $W=0$ *almost everywhere on* $[T, T_1]$.

Proof. Part (ii) follows directly from the fact that $w_0 \in J(\hat{\Omega})$. Turning to (i), we have

$$\text{(5.12)} \qquad \begin{aligned} \mu_{nml} &= \int_\Omega w_0 \cdot M_{nml}\, dV = \frac{-1}{(\pi\gamma_{nl})^2} \int_\Omega w_0 \cdot \Delta M_{nml}\, dV \\ &= \frac{1}{(\pi\gamma_{nl})^2} \int_\Omega (\nabla \times w_0) \cdot (\nabla \times M_{nml})\, dV. \end{aligned}$$

As may be deduced from remarks in § 4.2,

$$\nabla \times M_{nml} = (\pi\gamma_{nl}) N^*_{nml}$$

where N^*_{nml} denotes the function that results from replacing $\pi\beta_{nl}$ by $\pi\gamma_{nl}$ in N_{nml}. The collection of N^*_{nml} is an orthonormal set in $J(\Omega)$. The "Fourier coefficient" of $(\nabla \times w_0)$ with respect to N^*_{nml} is

$$\int_\Omega (\nabla \times w_0) \cdot \frac{(\nabla \times M_{nml})}{(\pi\gamma_{nl})}\, dV,$$

which we see from (5.12) is equal to $\pi\gamma_{nl}\mu_{nml}$. Since the "Fourier coefficients" of $(\nabla \times w_0)$ with respect to the N^*_{nml}'s must be square summable, by Bessel's inequality,

$$\sum_{n=1}^{\infty} \sum_{m=0}^{2n} \sum_{l=1}^{\infty} |\pi\gamma_{nl}\mu_{nml}|^2 < \infty.$$

Similar arguments apply to the terms $\pi\beta_{nl}\nu_{nml}$. Thus (i) is proved.

Now (i), (ii) and Theorem 5.5 imply that the hypotheses of Theorem 5.4 are satisfied, and (iii) follows.

We remark that, by time reversibility of the wave equation, we are thus able to steer from any given terminal data $\begin{bmatrix} w_0 \\ w_1 \end{bmatrix} \in J_n^1(\Omega) \times J^*(\Omega)$ to any given terminal data $\begin{bmatrix} y_0 \\ y_1 \end{bmatrix}$ in the same space. We also note that the solution W given by Theorem 3.5 belongs to $L^2[0, T; \hat{J}(\Omega)]$ and there is no guarantee that the electromagnetic energy

$$\int_\Omega (\nabla \times W) \cdot (\nabla \times W) + \frac{\partial W}{\partial t} \cdot \frac{\partial W}{\partial t}\, dV = \int_\Omega H \cdot H + E \cdot E\, dV$$

remains finite, even when starting from finite energy states belonging to $J_n^1(\Omega) \times \hat{J}(\Omega)$. An analogous situation occurs in the case of control of the scalar wave equation via L^2 Neumann boundary controls in the unit ball Ω [7].

Appendix A. Here we show that the collection of M_{nml}'s and N_{nml}'s are all the eigenfunctions of the vector Laplacian that are divergence-free and satisfy

$$\text{(A1)} \qquad u_n|_\Gamma = 0, \ (\nabla \times u)_\tau|_\Gamma = 0,$$

i.e., are all the eigenfunctions of $-\Delta$ in $J^*(\Omega)$.

Suppose not, i.e., suppose there exists a smooth P that satisfies

$$-\Delta P = k^2 P, \qquad \operatorname{div} P = 0,$$

and (A1), and that is orthogonal to all M_{nml}, N_{nml}. Let

$$j_n(\pi\gamma_{nl}r)\,Y_{nm} = \psi_{nml}, \qquad j_n(\pi\beta_{nl}r)\,Y_{nm} = \chi_{nml}.$$

Then

$$M_{nml} = \nabla \times (\psi_{nml} r\bar{a}_r), \qquad N_{nml} = \nabla \times (\nabla \times (\chi_{nml} r\bar{a}_r),$$

omitting normalization constants for convenience. By assumption,

$$\begin{aligned} 0 = \int_\Omega P \cdot N_{nml}\, dv &= \int_\Omega P \cdot \nabla \times (\nabla \times (\chi_{nml} r\bar{a}_r))\, dV \\ &= \left\{ \int_\Omega (\nabla \times P) \cdot (\nabla \times (\chi_{nml} r\bar{a}_r)\, dV + \int_\Gamma P \cdot \bar{a}_r \times (\nabla \times \chi_{nml} r\bar{a}_r)\, ds \right\} \\ &= \left\{ \int_\Omega (\chi_{nml} r\bar{a}_r) \cdot (k^2 P)\, dV + \int_\Gamma \chi_{nml} r\bar{a}_r \cdot (\bar{a}_r \times (\nabla \times P))\, ds \right\}. \end{aligned}$$

The last equality follows from the fact that

$$\nabla \times (\chi_{nml} r\bar{a}_r) = \sqrt{n(n+1)}\, \hat{C}_{mn} j_n(\pi\beta_{nl}r) = 0 \quad \text{on } \Gamma.$$

Thus we have

$$\int_\Omega \chi_{nml} r \cdot P_n\, dV = 0 \tag{A2}$$

for every triple (nml). Since the set of χ_{nml} is a complete orthonormal basis in $L^2(\Omega)$ [14], we have $P_n = 0$ in Ω.

Also, by assumption

$$0 = \int_\Omega P \cdot M_{nml}\, dV = \frac{1}{k^2} \int_\Omega (\nabla \times (\nabla \times P)) \cdot (\nabla \times (\psi_{nml} r\bar{a}_r)\, dV.$$

Let $\nabla \times P = R$. Note that

$$\nabla \times (\nabla \times R) = \nabla \times (k^2 P) = k^2 R.$$

Thus

$$\begin{aligned} 0 &= \frac{1}{k^2} \left\{ \int_\Omega (\psi_{nml} r\bar{a}_r) \cdot (\nabla \times (\nabla \times R))\, dV - \int_\Gamma \psi_{nml} r\bar{a}_r \cdot (\bar{a}_r \times (\nabla \times R)\, ds \right\} \\ &= \int_\Omega \psi_{nml} r\bar{a}_r \cdot R\, dV. \end{aligned}$$

Thus we have

$$\int_\Omega \psi_{nml} r R_n\, dV = 0 \tag{A3}$$

for every (nml). Since the set of ψ_{nml} forms an orthonormal basis for $L^2(\Omega)$ (14) we have $R_n = 0$ in Ω. In [18], we have Theorem A.1.

THEOREM A.1 (Lamb). *Let A be a vector field defined and of class C^1 in a domain $a<r<b$, and suppose*

$$\nabla \cdot A = 0, \qquad \bar{a}_r \cdot A = 0,$$
$$\bar{a}_r \cdot (\nabla \times A) = 0 \quad \text{in } a<r<b.$$

Then $A=0$ in $a<r<b$.

Now apply Theorem A.1, taking $A=P$, with $a=0$, $b=1$. Since $P_n=0$, and $(\nabla \times P)_n = 0$, we have $P=0$ in Ω.

Appendix B. Here, the normalization constants λ_{nl} and ρ_{nl}, defined in (4.14), (4.15), will be computed. The following identities for spherical Bessel functions [12] will be needed:

(1) $$\frac{2n+1}{z} j_n(z) = j_{n-1}(z) + j_{n+1}(z),$$

(2) $$(2n+1)\frac{d}{dz} j_n(z) = n j_{n-1}(z) - (n+1) j_{n+1}(z),$$

(3) $$\int [j_n(z)]^2 z^2 \, dz = \frac{z^3}{2}[j_n^2(z) - j_{n-1}(z) j_{n+1}(z)],$$

(4) $$n(n+1) j_n(kr) - \frac{d}{dr}\left[r^2 \frac{d}{dr} j_n(kr) \right] = k^2 r^2 j_n(kr).$$

Computation of $(\lambda_{nl})^2$. We have

$$\begin{aligned}(\lambda_{nl})^2 &= n(n+1)\int_0^1 [j_n(\pi\gamma_{nl} r)]^2 r^2 \, dr \\ &= \frac{n(n+1)}{\pi\gamma_{nl}} \int_0^{\pi\gamma_{nl}} j_n^2(z)\left(\frac{z}{\pi\gamma_{nl}}\right)^2 dz \\ &= \frac{n(n+1)}{2}[j_n^2(\pi\gamma_{nl}) - j_{n-1}(\pi\gamma_{nl}) j_{n+1}(\pi\gamma_{nl})].\end{aligned}$$

Adding (1) and (2) gives

$$j_n(z) + z j_n'(z) = \frac{z}{2n+1}[(n+1) j_{n-1}(z) - n j_{n+1}(z)].$$

From (5.1),

$$0 = (n+1) j_{n-1}(\pi\gamma_{nl}) - n j_{n+1}(\pi\gamma_{nl}).$$

Thus

$$\begin{aligned}(2n+1)^2\left\{\frac{j_n(\pi\gamma_{nl})}{\pi\gamma_{nl}}\right\}^2 &= [j_{n-1}(\pi\gamma_{nl}) + j_{n+1}(\pi\gamma_{nl})]^2 \\ &= j_{n-1}(\pi\gamma_{nl})\left[\frac{n}{n+1}\right] j_{n+1}(\pi\gamma_{nl}) + 2 j_{n-1}(\pi\gamma_{nl}) j_{n+1}(\pi\gamma_{nl}) \\ &\quad + j_{n-1}(\pi\gamma_{nl})\left[\frac{n+1}{n}\right] j_{n+1}(\pi\gamma_{nl}) \\ &= \frac{(2n+1)^2}{n(n+1)} j_{n-1}(\pi\gamma_{nl}) j_{n+1}(\pi\gamma_{nl}).\end{aligned}$$

Therefore,

$$(B1) \qquad (\lambda_{nl})^2 = \frac{n(n+1)}{2}\left[1 - \frac{n(n+1)}{(\pi\gamma_{nl})^2}\right] j_n^2(\pi\gamma_{nl}).$$

Computation of $(\rho_{nl})^2$.

$$\int_0^1 \frac{[n(n+1)j_n(\pi\beta_{nl}r)]^2 + n(n+1)\{d/dr[rj_n(\pi\beta_{nl}r)]\}^2 r^2\, dr}{(\pi\beta_{nl}r)^2} = (\rho_{nl})^2.$$

Now (omitting at times the argument of j_n)

$$\int_0^1 \frac{d}{dr}[rj_n(\pi\beta_{nl}r)] \cdot \frac{d}{dr}[rj_n(\pi\beta_{nl}r)]\, dr$$

$$(*) \qquad = rj_n(\pi\beta_{nl}r)\frac{d}{dr}[rj_n(\pi\beta_{nl}r)]\Big|_0^1 - \int_0^1 rj_n \frac{d^2}{dr^2}[rj_n]\, dr$$

$$= -\int_0^1 rj_n \frac{d^2}{dr^2}[rj_n]\, dr.$$

Since

$$rj_n \frac{d^2}{dr^2}[rj_n] = rj_n \frac{d}{dr}\left(j_n + r\frac{d}{dr}j_n\right)$$

$$= j_n\left(2r\frac{d}{dr}j_n + r^2\frac{d^2}{dr^2}j_n\right)$$

$$= j_n \frac{d}{dr}\left[r^2\frac{d}{dr}j_n\right]$$

we have that

$$(*) = -\int_0^1 j_n(\pi\beta_{nl}r) \cdot \frac{d}{dr}\left[r^2\frac{d}{dr}j_n(\pi\beta_{nl}r)\right] dr$$

$$= \int_0^1 j_n(\pi\beta_{nl}r)((\pi\beta_{nl}r)^2 j_n(\pi\beta_{nl}r) - n(n+1)j_n(\pi\beta_{nl}r))\, dr,$$

the last equality from (4). Thus,

$$(\rho_{nl})^2 = \frac{n(n+1)}{(\pi\beta_{nl})^2}\int_0^1 \{n(n+1)j_n^2(\pi\beta_{nl}r) - n(n+1)j_n^2(\pi\beta_{nl}r) + (\pi\beta_{nl}r)^2 j_n(\pi\beta_{nl}r)\}\, dr$$

$$= (\text{by } 3)\ \frac{n(n+1)}{2}[j_n^2(\pi\beta_{nl}) - j_{n-1}(\pi\beta_{nl})j_{n+1}(\pi\beta_{nl})].$$

By (1), $j_{n-1}(\pi\beta_{nl}) = -j_{n+1}(\pi\beta_{nl})$. Therefore

$$(B2) \qquad (\rho_{nl})^2 = \frac{n(n+1)}{2} j_{n+1}^2(\pi\beta_{nl}).$$

These computations are similar to those in [12] used to compute normalization constants for eigenfunctions that satisfy the "perfect conductor" boundary condition, zero tangential component and zero normal curl on Γ. Interchanging the positions of $\pi\gamma_{nl}$ and $\pi\beta_{nl}$ in our expressions for M and N gives these eigenfunctions. It is advantageous that simple expressions for the normalization constants, which resulted for the "perfect conductor" case, also result in our case.

Acknowledgment. The results in this paper come from my Ph.D. dissertation, University of Wisconsin, Madison, Wisconsin, 1986. I wish to thank my thesis advisor, Professor David Russell, for useful advice and many helpful discussions.

CONVERGENCE OF SUBOPTIMAL CONTROLS: THE POINT TARGET CASE*

H. O. FATTORINI†

Abstract. Sequences of suboptimal controls are considered for arbitrary optimal control problems in the setting of general input-output systems involving a point target condition. A *sequence maximum principle* for these sequences is obtained using Ekeland's variational principle. This sequence maximum principle and other variants are upgraded to *convergence principles* and are applied to show convergence of sequences of suboptimal controls for quasilinear distributed parameter systems, both of parabolic and hyperbolic type. Some of the results apply, without convexity assumptions, on either the systems or on the control set.

Key words. optimal control, maximum principle, approximately optimal control

AMS(MOS) subject classifications. 93E20, 93E25

1. Introduction. Convergence of suboptimal (that is, close-to-optimal) controls for general nonlinear input-output systems was considered in [9] and [10]. The optimal control problems there involve a *set target* condition, that is, trajectories are supposed to hit a *target set* Y. In this paper we continue the study of convergence of sequences of suboptimal controls for general systems (see § 2), this time for the *point target* problem, where trajectories are required to hit a point $\bar{y}$. The strategy is about the same as that in [9] and [10] and consists of three steps. In the first step, using Ekeland's variational principle, we establish a *sequence maximum principle*, that is, an independent approximate maximum principle for each of the suboptimal controls in the sequence. In the second step, we combine these separate maximum principles into a *convergence principle.* The third step consists of translating the convergence principle into actual convergence of optimal controls. Here, we work with particular classes of systems, which we did as well in [9] and [10]. The most notable difference between the treatment of set targets and that of point targets can be roughly summarized as follows. In the set target case, the passage from the weak sequence maximum principle to the convergence principle is automatic; no controllability assumptions are used, although approximate controllability (of the linearized system) plays a role in obtaining convergence of suboptimal controls. In contrast, in the point target case treated here, the convergence principle can only be deduced from the sequence maximum principle via controllability properties of the linearized system and, in fact, may not be true unless controllability is present. The situation here is roughly the same as that in the proof of the maximum principle for general systems in [8] and makes the point target problem much more demanding than the set target problem.

We note that the convergence results in this paper depend only on suboptimality of the controls in question; thus, the particular way in which these controls are constructed is irrelevant. Hence, our results justify existing computations for approximation of optimal controls (usually carried out by penalty methods [9]) rather than proposing specific computational approaches. See also [1], [2], [14].

We note also that the final convergence theorems, when they can be obtained, refer to *strong* convergence (that is, convergence in L^p norms, $1 \leqq p < \infty$). When the control set U is bounded, convergence (of suitable subsequences) in weak topologies

† University of California, Department of Mathematics, Los Angeles, California 90024. This work was supported in part by National Science Foundation grant DMS 82-00645.

follows from weak compactness, but is not very useful from a computational point of view.

Finally, it should be pointed out that the results refer not only to convergence to optimal controls whose existence has been previously established; for instance, constructive existence theorems can be obtained in certain situations without any convexity assumptions (see § 5). The same is true, of course, of the set target problems considered in [9] and [10]. Some results in this paper were announced in [11].

2. Systems. Optimal control problems. We denote by E, F arbitrary Banach spaces, although most of the results in the following sections require both to be Hilbert spaces. U is a subset of F called the *control set.* Given $k \geqq 0$, $T > 0$, we define the *control space* $W(-k, T; U)$ as the set of all (equivalence classes of) strongly measurable F-valued functions $u = u(t)$ defined in $-k \leqq t \leqq T$ such that

$$u(t) \in U \quad \text{a.e.}$$

The space $W(-k, T; U)$ is a complete metric space equipped with the distance

$$d(u, v) = \text{meas}\,\{t: u(t) \neq v(t)\} \tag{2.1}$$

called the *Ekeland distance.*

The *trajectory* or *output* space $C(0, T; E)$ consists of all E-valued continuous functions $y(t)$ defined in $0 \leqq t \leqq T$.

A *system* is, by definition, a map

$$X: W(-k, T; U) \to C(0, T; E) \tag{2.2}$$

that satisfies the following postulates: (a) *Causality.* Let $0 \leqq \bar{t} \leqq T$. Then the *trajectory*

$$y(t, u) = (Xu)(t)$$

in $0 \leqq t \leqq \bar{t}$ depends only on u in $0 \leqq t \leqq \bar{t}$. (b) *Pointwise continuity.* For $\bar{t}$ as in (a), the map

$$u(t) \to y(\bar{t}, u)$$

from $W(-k, \bar{t}; U)$ (endowed with the Ekeland distance) into E (endowed with its original norm) is continuous. (c) *Differentiability* (with respect to spike perturbations). For every $u(t) \in W(-k, \bar{t}; U)$ there exists a set $e = e(u)$ of full measure in $0 \leqq t \leqq \bar{t}$ such that, if $s \in e$, the limit

$$\xi(\bar{t}, s, u, v, u(s)) = \lim_{r \to 0+} r^{-1}(y(\bar{t}, u_{s,r,v}) - y(\bar{t}, u)) \tag{2.3}$$

exists; here $u_{s,r,v}(t)$ is the *spike perturbation* of the control $u(t)$ defined by $u_{s,r,v}(t) = v$ in $s - r < t \leqq s$, $u_{s,r,v}(t) = u(t)$ elsewhere. We call ξ the *derivative* of X.

In this general setting, systems are meant to model (among other things) input-output relationships generated by widely different *state equations* (such as ordinary or delay differential equations, or partial differential equations with distributed or boundary control). The constant k in the control space $W(-k, T; U)$ accounts for possible time delays in the control action (see [8] for systems where $k > 0$). In the examples considered in this paper controls act instantaneously, thus $k = 0$.

We shall consider below the following *optimal control problems.* Let $X: W(-k, T; U) \to C(0, T; E)$ be a system as defined above and consider a second system $X_0: W(-k, T; U) \to C(0, T; \mathbb{R})$ ($\mathbb{R}$ the real numbers) called the *cost functional* of the problem. We denote by $\xi_0(t, s, u, v, w)$ the derivative of X_0. The *augmented system* $\tilde{X}$ is defined by

$$(\tilde{X}u)(t) = ((X_0, X)u)(t) = (y_0(t, u), y(t, u)), \tag{2.4}$$

where $y_0(t, u) = (X_0 u)(t)$. We also use the notation $\tilde{y}(t, u) = (\tilde{X}u)(t)$ for the trajectories of the augmented system in $\mathbb{R} \times E$; in the same fashion, we write $\tilde{\xi}(t, s, u, v, w) = (\xi_0(t, s, u, v, w), \xi(t, s, u, v, w))$.

Let $\bar{y}$ be a point in E (called the *target*). We consider the *optimal control problem* of identifying the times $\bar{t}$ and the controls $\bar{u}$ in $W(-k, \bar{t}; U)$ such that

$$y(\bar{t}, \bar{u}) = \bar{y} \tag{2.5}$$

and

$$y_0(\bar{t}, \bar{u}) = m = \inf y_0(t, u), \tag{2.6}$$

the infimum taken over all times $t > 0$ and all controls $u(t)$ in $W(-k, t; U)$ such that $y(t, u) = \bar{y}$; we *assume* that

$$-\infty < m < \infty. \tag{2.7}$$

A sufficient condition for the first inequality (2.7) to hold is that the cost functional $y_0(t, u)$ be *bounded below* in $W(-k, T; U)$. The second inequality simply means that there exists a control u that hits the target $\bar{y}$ at some time.

A control $u(t)$ in $W(-k, \tilde{t}; U)$ is called $(\tilde{t}, \varepsilon)$-*suboptimal if*

$$\|y(\tilde{t}, u) - \bar{y}\| \leqq \varepsilon, \qquad y_0(\tilde{t}, u) \leqq m + \varepsilon. \tag{2.8}$$

The present theory of convergence of suboptimal controls, be it in the set target or point target case, is based on *weak compactness* properties of the system X; roughly speaking, what is required is that if $\{u^n\}$ is an arbitrary sequence of controls, $u^n \in W(-k, t_n; U)$ then the corresponding sequence of trajectories $\{y(t, u^n)\}$ should have a subsequence convergent (in one sense or another) to a function $y(t)$, not necessary a trajectory of the system. A similar property is required of the variations. This will be satisfied (in different ways) by the systems in § 4 and § 8.

3. The sequence maximum principle. In this and the following sections, E and F are Hilbert spaces.

THEOREM 3.1 (*The sequence maximum principle*). *Let $\{u^n\}$ be a sequence of (t_n, u^n)-suboptimal controls with $\{t_n\}$ bounded, $\varepsilon_n \to 0$. Then there exists a subsequence of $\{u^n\}$ (which we denote by the same symbol) such that*

$$t_n \to \bar{t}, \quad y_0(t_n, u^n) \to m' \leqq m, \quad y(t_n, u^n) \to \bar{y}, \tag{3.1}$$

a second sequence $\{\tilde{u}^n\}$ of controls with $\tilde{u}^n \in W(-k, t_n; U)$ such that

$$d_n(u^n, \tilde{u}^n) \to 0, \tag{3.2}$$

(d_n the Ekeland distance in $W(-k, t_n; U)$), a sequence $\{\tilde{y}^n\} = \{(\mu_n, y^n)\}$ in $\mathbb{R} \times E$ such that $\mu_n \geqq 0$, $\|(\mu_n, y^n)\| = 1$, and a set e_n of full measure in $0 \leqq s \leqq t_n$ such that

$$\begin{aligned} &\mu_n \xi_0(t_n, s, \tilde{u}^n, v, \tilde{u}^n(s)) + \langle y^n, \xi(t_n, s, \tilde{u}^n, v, \tilde{u}^n(s))\rangle \\ &\quad = \langle \tilde{y}^n, \tilde{\xi}(t_n, s, \tilde{u}^n, v, \tilde{u}^n(s))\rangle \geqq -\delta_n \to 0 \quad (v \in U, s \in e_n). \end{aligned} \tag{3.3}$$

Proof. Obviously, we can obtain the first two statements in (3.1) by passing to a subsequence; the third follows from the definition of suboptimal control. To prove (3.2) and (3.3) we consider the function

$$F_n(u) = \{(\max(0, y_0(t_n, u) - m + \varepsilon_n))^2 + \|y(t_n, u) - \bar{y}\|^2\}^{1/2} \tag{3.4}$$

in the space $W(-k, t_n; U)$ (which is complete with respect to the distance (2.1), see [4]). Obviously, $F_n(u) > 0$ (otherwise we could hit $\bar{y}$ with value $m - \varepsilon_n < m$ of y_0). Since $y_0(t_n, u^n) - m < \varepsilon_n$,

$$F_n(u^n) \leqq \{(2\varepsilon_n)^2 + (\varepsilon_n)^2\}^{1/2} = \sqrt{5}\, \varepsilon_n = c\varepsilon_n. \tag{3.5}$$

Applying Ekeland's variational principle [3], [4] we deduce the existence of a control $\tilde{u}^n \in W(-k, t_n; U)$ such that

$$F_n(\tilde{u}^n) \leqq F(u_n) = c\varepsilon_n, \tag{3.6}$$

$$d_n(u^n, \tilde{u}^n) \leqq \sqrt{c\varepsilon_n}, \tag{3.7}$$

$$F_n(w) \geqq F_n(\tilde{u}^n) - \sqrt{c\varepsilon_n}\, d_n(w, \tilde{u}^n). \tag{3.8}$$

We exploit inequality (3.8) for spike variations $w = (\tilde{u}^n)_{s,r,v}$ of $\tilde{u}^n$ using (c) in the definition of system. Note that if g is an arbitrary function, $\max(0, g)^2$ is differentiable if g is differentiable, with derivative $= (\max(0, g))g'$. We consider two alternatives. If we have $y(t_n, \tilde{u}^n) \neq \bar{y}$, then we obtain (3.3) computing the right-sided derivative at $r = 0$ of the function $F_n((u^n)_{s,r,v})$; the vector (μ_n, y^n) is given by $(\mu_n, y^n) = (\lambda_n, x^n)/\|(\lambda_n, x^n)\|$, where

$$(\lambda_n, x^n) = (\max(0, y_0(t_n, \tilde{u}^n) - m + \varepsilon_n), y(t_n, \tilde{u}^n) - y_n). \tag{3.9}$$

On the other hand, if $y(t_n, \tilde{u}^n) = \bar{y}$ we must have $y_0(t_n, \tilde{u}^n) \geqq m$, so the maximum can be omitted from the definition of $F((u^n)_{s,r,v})$ for sufficiently small r. This time we obtain (3.3) with $(\mu_n, y^n) = (1, 0)$.

As usual, a separate theorem is required for the time optimal problem, where, since $\xi_0 = 0$, (3.3) may be empty (in case $\mu_n = 0$).

THEOREM 3.2 (*The sequence maximum principle for the time optimal problem*). *Let* $\{u^n\}$ *be a sequence of* (t_n, u^n)*-suboptimal controls with* $\varepsilon_n \to 0$ *and*

$$t_n < \bar{t}. \tag{3.10}$$

Then there exists a subsequence of $\{u^n\}$ (*denoted by the same symbol*) *such that*

$$t_n \to \tilde{t} \leqq \bar{t}, \quad y(t_n, u^n) \to \bar{y}, \tag{3.11}$$

($\bar{t}$ *the optimal time*), *a second sequence* $\{\tilde{u}^n\}$ *of controls* $\tilde{u}^n \in W(-k, t_n; U)$ *such that*

$$d_n(u^n, \tilde{u}^n) \to 0, \tag{3.12}$$

a sequence $\{y^n\}$ *in* E *such that* $\|y^n\| = 1$ *and a set* e_n *of full measure in* $0 \leqq s \leqq t_n$ *such that*

$$\langle y^n, \xi(t_n, s, \tilde{u}^n, v, \tilde{u}^n(s))\rangle \geqq -\delta_n \to 0 \qquad (v \in U, s \in e_n). \tag{3.13}$$

The proof is entirely similar to that of Theorem 3.1: this time we consider the function

$$F_n(u) = \|y(t_n, u) - \bar{y}\|, \tag{3.14}$$

which satisfies $F_n(u) > 0$, since $\bar{y}$ cannot be hit in time $t_n < \bar{t}$. The vector y^n in (3.13) is $y^n = x^n/\|x^n\|$, where

$$x^n = y(t_n, \tilde{u}^n) - \bar{y}. \tag{3.15}$$

For a similar argument, see [7], [8, § 6].

Remark 3.3. Condition (3.10) (which is indispensable to guarantee positivity of the function (3.14), required for differentiation of the norm) is somewhat inconvenient. In some cases, it can be circumvented by simply replacing the sequence $\{t_n\}$ by a second sequence $\{\tilde{t}_n\}$, with $\tilde{t}_n < \bar{t}$ and

$$\|y(\tilde{t}_n, u^n) - y(t_n, u^n)\| \to 0 \quad \text{as } n \to \infty. \tag{3.16}$$

In fact, if (3.16) holds, the (t_n, ε_n)-suboptimal sequence $\{u^n\}$ will be as well $(\tilde{t}_n, \varepsilon_n)$-suboptimal, and Theorem 3.2 applies. Since $t_n \to \bar{t}$, (3.16) will hold if the set $\{y(t, u)\}$

of all trajectories of X corresponding to all $u \in W(-k, T; U)$ is *equicontinuous.* This is in fact the case, for instance, when X is defined by a finite-dimensional differential system. The sequence maximum principle has to be modified in obvious ways; in (3.12) d_n is the Ekeland distance in $W(-k, \tilde{t}_n; U)$, and (3.13) becomes

$$\langle y^n, \xi(\tilde{t}_n, s, \tilde{u}^n, v, \tilde{u}_n(s))\rangle \geqq -\delta_n \to 0 \qquad (v \in U, s \in e_n). \tag{3.17}$$

4. Systems described by abstract differential equations. Generally speaking, a sequence maximum principle becomes a *convergence principle* if we can show that the sequence $\{(\mu_n, y^n)\}$ in (3.3) has a subsequence (denoted with the same symbol) such that

$$(\mu_n, y^n) \to (\mu, y) \neq 0. \tag{4.1}$$

The convergence principle is *strong* (respectively, *weak*) if the convergence in (4.1) is strong (respectively, weak); note that, since $\|(\mu_n, y^n)\| = 1$, in the first case, the requirement that $(\mu, y) \neq 0$ is unnecessary.

This definition is modified in an obvious way for the time optimal problem, where the sequence maximum principle is (3.13); here, (4.1) becomes

$$y^n \to y \neq 0. \tag{4.2}$$

In some situations (as seen below), the weak convergence principle implies *strong* convergence of sequences of suboptimal controls, usually via compactness properties of the system. The strong convergence principle implies strong convergence of sequences of suboptimal controls without any added compactness properties, but it is much more difficult to prove.

Of course, in case E is finite-dimensional, the passage from the sequence maximum principle to the strong convergence principle is automatic via the Bolzano–Weierstrass theorem.

We consider below systems defined by a semilinear initial value problem

$$y'(t) = Ay(t) + f(t, y(t), u(t)) \qquad (0 \leqq t \leqq T), \tag{4.3}$$

$$y(0) = y^0, \tag{4.4}$$

where A is the infinitesimal generator of a strongly continuous semigroup $\{S(t): t \geqq 0\}$ in the Banach space E. By definition, a *solution* of (4.3)–(4.4) is a continuous solution of the integrated version

$$y(t) = S(t)y^0 + \int_0^t S(t-\sigma) f(\sigma, y(\sigma), u(\sigma))\, d\sigma \qquad (0 \leqq t \leqq T). \tag{4.5}$$

We assume that U is bounded and that $f(t, y, u)$ satisfies the following assumptions:

(F) $f(t, y, u)$ has a Fréchet derivative $\partial_y f(t, y, u)$ with respect to y and f (respectively, $\partial_y f$) is continuous (respectively, strongly continuous) and bounded on bounded subsets of $[0, T] \times E \times U$.

Under these hypotheses, (4.5) can be solved as usual by successive approximations: setting $y^0(t, u) = S(t)y^0$,

$$y^{m+1}(t, u) = S(t)y^0 + \int_0^t S(t-\sigma) f(\sigma, y^m(\sigma, u)), u(\sigma))\, d\sigma \qquad (0 \leqq t \leqq T). \tag{4.6}$$

Since, in general, the approximations $y^m(t, u)$ in (4.6) will not be convergent in the whole interval $[0, T]$, we shall need to construct the solution "in pieces," that is, first in an interval $[0, T_1]$, then in an interval $[T_1, T_2], \cdots$ etc., so that, given T_k in the

interval $[0, T)$ we shall have to examine as well the sequence of successive approximations

$$y^{m+1}(t, u) = S(t-T_k)y(T_k, u) + \int_{T_k}^{t} S(t-\sigma)f(\sigma, y^m(\sigma, u), u(\sigma))\, d\sigma \tag{4.7}$$

in $t \geqq T_k$. Obviously, in order to extend the solution to the whole interval $[0, T]$ it suffices to show that the sequence $\{y^m(t, u)\}$ is convergent in an interval $[T_k, T_{k+1}]$, where $T_{k+1} - T_k$ is bounded away from zero uniformly in k. To insure this, it is enough to have an a priori bound

$$\|y(t)\| \leqq C \qquad (0 \leqq t \leqq T_0) \tag{4.8}$$

for any solution of (4.5) in an arbitrary interval $[0, T_0]$, where C does not depend on T_0 or on $u \in W(0, T; U)$. In fact, assume that (4.8) holds. Let M be a bound for $\|S(t)\|$ in $[0, T]$ and let K be such that

$$\|f(t, y, u)\| \leqq K \qquad (0 \leqq t \leqq T,\ \|y\| \leqq MC+1,\ u \in U).$$

Then we obtain from (4.8) that, if $\|y^m(t, u)\| \leqq MC+1$ in $[T_k, T_{k+1}]$ (which is obviously true for $y_0(t, u) = y(T_k, u)$), we shall have

$$\|y^{m+1}(t, u)\| \leqq MC + MK(t-t_k) \leqq MC+1,$$

if $T_{k+1} - T_k \leqq 1/MK$. Since the approximations defined by (4.8) are bounded in $t_k \leqq t \leqq t_{k+1}$, (by $MC+1$), it is clear that we can estimate $\|y^{m+1}(t, u) - y^m(t, u)\|$ in terms of $\|y^m(t, u) - y^{m-1}(t, u)\|$ using the Lipschitz constant L for $f(t, y, u)$ in $\|y\| \leqq MC+1$, thus the sequence $\{y^m(t, u)\}$ is absolutely and uniformly convergent in $T_k \leqq t \leqq T_{k+1}$ if, in addition, $T_{k+1} - T_k < 1/L$.

The way to establish (4.8) depends on the particular equation under study; see [9] for quasilinear parabolic equations and [10] for the quasilinear hyperbolic case.

Under (4.8) and the rest of the assumptions on $f(t, y, u)$ and A we can prove that the map defined by

$$(Xu)(t) = y(t, u) = y(t), \tag{4.9}$$

where $y(t)$ is the only solution of (4.5), satisfies postulates (a), (b), and (c) in § 2; the derivative $\xi(t, s, u, v, w)$ in (2.3) is

$$\xi(t, s, u, v, w) = S(t, s; u)\{f(s, y(s, u), v) - f(s, y(s, u), w)\} \tag{4.10}$$

where $S(t, s; u)$ is the solution operator of the *linearized equation* $z'(t) = (A + B(t))z(t)$, $B(t; u) = \partial_y f(t, y(t, u), u)$, that is, the only strongly continuous solution of the operator equation

$$S(t, s; u)z = S(t-s)z + \int_s^t S(t-\sigma)B(\sigma; u)S(\sigma, s; u)z\, d\sigma \qquad (0 \leqq s \leqq t \leqq T). \tag{4.11}$$

For complete proofs, see [8]. In particular, we point out that, for u fixed, $S(t, s; u)$ is strongly continuous in its domain of definition (we shall need later in §§ 5 and 6 information on the u-dependence of $S(t, s; u)$). If $S(t)$ is a group, $S(t, s; u)$ of course exists and is strongly continuous in $0 \leqq s, t \leqq T$.

5. Convergence principles and strong convergence of suboptimal controls. We show in this section how convergence principles can be used to establish L^p-convergence of sequences of suboptimal controls $(1 < p < \infty)$ for the system defined by the initial value problem (4.3)-(4.4). We assume from now on that the control set U is bounded and closed and that the nonlinear term $f(t, y, u)$ in (4.3) is of the form

$$f(t, y, u) = f(t, y) + Bu, \tag{5.1}$$

where $B: F \to E$ is a bounded operator. Finally, we assume that either the semigroup $S(t)$ is compact for all $t > 0$ or that B is compact.

The first manipulations do not use compactness of $S(t)$. Noting the computation of the function $\xi(t, s, u, v, w)$ in (4.9), we can write the sequence maximum principle (3.3) in the form

$$\begin{aligned} &\mu_n \xi_0(t_n, s, \tilde{u}^n, v, \tilde{u}^n(s)) \\ &\quad + \langle y^n, S(t_n, s; \tilde{u}^n) B(v - \tilde{u}^n(s)) \rangle \geqq -\delta_n \to 0 \qquad (v \in U, s \in e). \end{aligned} \tag{5.2}$$

The sequence maximum principle (3.13) for the time optimal problem is

$$\langle y^n, S(t_n, s; \tilde{u}^n) B(v - \tilde{u}^n(s)) \rangle \geqq -\delta_n \to 0 \qquad (v \in U, s \in e). \tag{5.3}$$

LEMMA 5.1. *Assume that either B is compact or that $S(t)$ is compact for $t > 0$. Then the operator*

$$(\Pi u)(t) = \int_0^t S(t - \sigma) B u(\sigma)\, d\sigma \tag{5.4}$$

from $L^2(0, T; F)$ into $C(0, T; E)$ (the last space endowed with its usual supremum norm) is compact.

Lemma 5.1 for $S(t)$ compact is Lemma 6.1 in [9]; the proof where B is compact instead is essentially the same, since the kernel $S(t)B$ in the integral (5.4) is compact.

In what follows, we shall consider convergence of sequences $\{u^n\}$ where each control u^n lives in a different space $W(-k, t_n; U)$. Assume that $t_n \to t_0$. We say that $\{u^n\}$ *converges weakly* to $u \in W(-k, t_n; U)$ if u^n, extended to $t \leqq t_n$ (if $t_n < t_0$) by setting $u^n(t) = 0$ there, or chopped off at t_0 (if $t_n > t_0$) converges weakly in $L^2(0, t_0; U)$. A similar meaning will be given to other types of convergence.

We write below

$$V = \overline{\text{conv}}\,(U), \tag{5.5}$$

where $\overline{\text{conv}}$ denotes closed convex hull.

THEOREM 5.2. *Under the same hypotheses of Lemma 5.1, let $\{u^n\}$ be a sequence of controls such that $u^n \in W(0, t_n; U)$. Assume that $t_n \to t_0$. Then there exists a subsequence of $\{u^n\}$ (which we denote by the same symbol) and a $\bar{u} \in W(0, t_0; V)$ such that*

$$u^n(t) \to \bar{u}(t) \quad \textit{weakly in } L^2(0, t_0; F), \tag{5.6}$$

$$y(t, u^n) \to y(t, \bar{u}) \quad \textit{in } C(0, t_0; E). \tag{5.7}$$

Proof. Let $\{u^n\}$ be the sequence in the statement of Theorem 5.2, and let $T > t_n$; extend each u^n to $L^2(0, T; F)$ by setting $u^n(t) = 0$ in $t > t_n$. We may assume, by passing to a subsequence, that $\{u^n\}$ is weakly convergent, so that (5.6) will hold. Since $W(0, T; V)$ is bounded, closed and convex (hence weakly closed) in $L^2(0, T; F)$, the limit $\bar{u}$ belongs to $W(0, T; V)$ as well. We take a look at the approximations $y^m(t, u^n)$, $m = 1, 2, \cdots$ used to compute $y(t, u^n)$ (see (4.6)): these are $y^0(t, u^n) = 0$,

$$\begin{aligned} y^{m+1}(t, u^n) = S(t) y_0 &+ \int_0^t S(t - \sigma) f(\sigma, y^m(\sigma, u^n))\, d\sigma \\ &+ \int_0^t S(t - \sigma) B u^n(\sigma)\, d\sigma. \end{aligned} \tag{5.8}$$

Applying Lemma 5.1 inductively, we deduce that

$$y^m(t, u^n) \to y^m(t, \bar{u}) \tag{5.9}$$

uniformly in $0 \leqq t \leqq T$ as $n \to \infty$, where the $y^m(t, \bar{u})$ are the approximations to $y(t, \bar{u})$ defined by (4.6). On account of the fact that both $\{y^m(t, u)\}$ and $\{y^m(t, u^n)\}$ converge absolutely and uniformly as $m \to \infty$ (independently of n) in an interval $0 \leqq t \leqq T_1$ (see the observations after (4.6)), (5.9) shows that

$$y^m(t, u^n) \to y(t, \bar{u}) \tag{5.10}$$

uniformly in $0 \leqq t \leqq T_1$. Applying the same argument in the intervals $[T_1, T_2]$, $[T_2, T_3], \cdots$ referred to after (4.7) (the lengths of these intervals do not tend to zero in view of the a priori estimate (4.8)), we deduce that the convergence in (5.10) is uniform in the interval $0 \leqq t \leqq T$. This ends the proof of Theorem 5.2.

Remark 5.3. We note that the conclusion of Theorem 5.2 can be made more precise: if $\{u^n\}$ satisfies (5.6), then the same sequence $\{u^n\}$ will satisfy (5.7), without need of passing to a subsequence. The proof uses a standard trick: if the full sequence $\{u^n\}$ fails to satisfy (5.7) there exists a subsequence which stays at a positive distance from $y(t, \bar{u})$. Applying the argument in Theorem 5.2 to this subsequence, a contradiction ensues.

In the following two results, we assume that $S(t)$ is compact for all $t > 0$; recall that this implies that $S(t)$ is continuous in $t > 0$ in the uniform topology of operators.

LEMMA 5.4. *Let $h > 0$. The (E)-valued function*

$$(t, s, u) \to S(t, s; u) \tag{5.11}$$

is uniformly continuous (in the uniform topology of operators) in $0 \leqq s \leqq t - h \leqq T$, $u \in W(0, T; U)$ (u measured in the weak $L^2(0, T; E)$-topology).

LEMMA 5.5. *Let $0 \leqq s < t \leqq T$, $u \in W(0, t; U)$. Then the operator $S(t, s; u): E \to E$ is compact.*

For proofs of Lemmas 5.3 and 5.4, see [9, Thms. 6.3 and 6.4].

We show below how the weak convergence principle can be used to show strong convergence of sequences of suboptimal controls. We note that in their present form, both the weak and the strong convergence principles have been proved only in finite-dimensional spaces. However, slightly modified versions of the sequence maximum principle and of the convergence principles hold in infinite-dimensional spaces (see §§ 6 and 7) and the arguments showing that the convergence principle implies convergence of suboptimal controls are essentially the same, thus we take no advantage below of the finite dimensionality of the space.

All assumptions are in force: the control set U is bounded and closed and the nonlinear term is assumed to be of the form (5.1), with $f(t, y)$ satisfying assumption (F) in § 4; we also suppose that either B is compact or that $S(t)$ is compact for $t > 0$. For simplicity, we consider only the time optimal problem.

Assume that the weak convergence principle (5.3)-(4.2) holds for the sequence $\{\tilde{u}^n\}$ associated by Theorem 3.2 with a sequence $\{u^n\}$ of suboptimal controls. Write

$$B^*S(t_n, s; \tilde{u}^n)^*y^n = (B^*S(t_n, s; \tilde{u}^n)^* - B^*S(\bar{t}, s; \bar{u})^*)y^n + B^*S(\bar{t}, s; \bar{u})^*y^n. \tag{5.12}$$

Since each $B^*S(t, s; \bar{u})^*$ is compact we may assume, passing if necessary to a subsequence, that $B^*S(\bar{t}, s; \bar{u})^*y^n \to B^*S(\bar{t}, s; \bar{u})^*y$ strongly, y the limit in (4.2); on the other hand, using Lemma 5.4 in case $S(t)$ is compact or compactness of B^* when B is compact we deduce that $(B^*S(t_n, s; \tilde{u}^n)^* - B^*S(\bar{t}, s; \bar{u})^*)y^n \to 0$ strongly. In any case,

$$z_n(t) = B^*S(t_n, s; \tilde{u}^n)^*y^n \to z(t) = B^*S(\bar{t}, s; \bar{u})^*y \text{ strongly} \tag{5.13}$$

and we obtain from (5.3) that

$$\langle z(t), v - \tilde{u}^n(s)\rangle \geqq -\delta_n \to 0 \qquad (v \in U, s \in e_n). \tag{5.14}$$

For $z \neq 0$ let $U(z, \delta)$ be the set of all $u \in U$ such that

$$\langle z, v-u\rangle \geqq -\delta \quad \text{for all } v \in U \tag{5.15}$$

(for the geometry of the situation see [9]). Then if the control set U satisfies

$$\operatorname{diam} U(z, \delta) \to 0 \quad \text{as } \delta \to 0 \tag{5.16}$$

for all z with $z \neq 0$, it follows from (5.14) that the sequence $\{\tilde{u}^n(t)\}$ will be pointwise convergent in the set d where

$$z(t) = B^* S(\bar{t}, s; \bar{u})^* y \neq 0. \tag{5.17}$$

Since U is bounded, pointwise convergence in d is equivalent to $L^p(d)$-convergence for any $1 < p < \infty$.

Naturally, no convergence results are obtained outside of d, thus it is important to have conditions that guarantee that d has full measure in $0 \leqq t \leqq \bar{t}$. Conditions to that effect appear hard to come by for general quasilinear equations. In the linear case we have $S(t, s; u) = S(t-s)$ ($S(t)$ the semigroup generated by A). If $S(t)$ is analytic, that d be of full measure in $0 \leqq t \leqq \bar{t}$ is equivalent to *approximate controllability* of the system, one of whose formulations is

(C) if $B^* S(\bar{t}, s; \bar{u})^* y = 0$ in a set of positive measure then $y = 0$.

We note finally that the convergence conclusions are for the auxiliary sequence $\{\tilde{u}^n\}$ rather than for the original sequence $\{u^n\}$ of suboptimal controls. However, this makes no difference since by virtue of (3.2) and the definition of the distance d,

$$\operatorname{meas}\{t: u^n(t) \neq \tilde{u}^n(t)\} \to 0. \tag{5.18}$$

It is easily seen ([9]) that assumption (5.16) implies convexity of U; in fact, (5.16) is equivalent to strict convexity when F is finite-dimensional. However, convergence results can be obtained even in the nonconvex case. Call the vector $z \neq 0$ (that is, the direction z) *improper* with respect to the control set U if (5.16) fails to hold for x, that is, if

$$\limsup_{\delta \to 0} \operatorname{diam} U(z, \delta) > 0. \tag{5.19}$$

Assume that the set of improper directions is finite or at most countable. Then the conclusions will still hold if we can show that the vector $z(t)$ cannot be parallel to any direction except in a null set. As an example, consider the linear case $f = 0$, with $S(t)$ analytic and

$$B = I \tag{5.20}$$

(which insures that the approximate controllability condition (C) is satisfied) and that there exists a vector $z \neq 0$ such that

$$S(\bar{t}-s)^* y = \eta(s) z \tag{5.21}$$

in a set e of positive measure in $0 \leqq s \leqq \bar{t}$. (It is enough to assume that e is an infinite set.) Equality (5.21) means that $S(\bar{t}-s)^* y$ belongs to the one-dimensional subspace $H(z)$ generated by z, thus it follows from analyticity that $S(\bar{t}-s)^* y$ belongs to $H(z)$ for all $s < \bar{t}$. Hence, (5.21) actually holds for all $s < \bar{t}$. If $\eta(\bar{t}) = 0$, $y = 0$, which is impossible. Accordingly, it follows that $z = \eta(\bar{t})^{-1} y \in D(A)$ and

$$A^* S(\bar{t}-s)^* y = -\eta'(s) z = -\eta'(s)/\eta(\bar{t}) y. \tag{5.22}$$

Setting $s = \bar{t}$ we see that y (or, equivalently, z) is an eigenvector of A corresponding to the eigenvalue $-\eta'(\bar{t})/\eta(\bar{t})$. Accordingly, if $y_1, y_2, \cdots$ are the eigenvectors of A corresponding to real eigenvalues, we obtain conversions without the assumption that U is convex; we require instead that none of the y_k be an improper direction with respect to U. This requires knowledge of all the eigenvalues of A and is thus difficult to verify, except when A has no real eigenvalues. We do not know of a characterization of sets U having a finite or countable set of improper directions even in dimension 2. It is possible that a set given by a polar equation

$$\{(r, \theta);\ 0 \leqq r \leqq r(\theta),\ 0 \leqq \theta \leqq 2\pi\}$$

where $r(\theta)$ is sufficiently smooth has that property. That U has a finite set of improper directions can be verified for many choices of $r(\theta)$ (say, functions having a finite number of local maxima).

Remark 5.6. Some obvious simplifications are available in the finite-dimensional case. We may assume that $A = 0$; a condition that guarantees (4.8) is

$$\langle y, f(t, y, u)\rangle \leqq (1 + \|y\|^2) \quad (t \in \mathbb{R},\ y \in E,\ u \in F).$$

It can be easily shown that the set $\{y(t, u)\}$ of all trajectories corresponding to all $u \in W(0, T; U)$ is equi-Lipschitz continuous.

6. The convergence principle: abstract parabolic equations. We show here that for a certain class of quasilinear abstract parabolic equations, a modified convergence principle can be proved that implies L^p-convergence $(1 < p < \infty)$ of sequences of suboptimal controls. However, the definition of suboptimal control will have to be modified as well.

We consider again the system (4.9) defined by the initial value problem (4.3)-(4.4). Translating A if necessary we may assume that

$$\|S(t)\| \leqq C e^{-\beta t} \qquad (t \geqq 0) \tag{6.1}$$

so that fractional powers $(-A)^{\alpha}$ exist for all α and are bounded for $\alpha < 0$. (In particular, A^{-1} is a bounded operator.) We require $S(t)$ to be an analytic semigroup, so that for every $\alpha > 0$ we have a bound of the form

$$\|(-A)^{\alpha} S(t)\| \leqq C t^{-\alpha} e^{-\beta t} \qquad (t > 0). \tag{6.2}$$

We assume the nonlinear term $f(t, y, u)$ is of the form (5.1). Assumptions (F) on $f(t, y)$ will have to be strengthened:

(F_α) For some $\alpha > 0$ $(-A)^{\alpha} f(t, y)$ has a Fréchet derivative $\partial_y(-A)^{\alpha} f(t, y)$ with respect to y and $(-A)^{\alpha} f(t, y)$ (respectively, $\partial_y(-A)^{\alpha} f(t, y)$) is continuous (respectively, strongly continuous) and bounded on bounded subsets of $[0, T] \times E \times U$.

Since $(-A)^{-\alpha}$ is a bounded operator, it is clear that $f(t, y)$ satisfies (F); in particular

$$\partial_y(-A)^{\alpha} f(t, y) = (-A)^{\alpha} \partial_y f(t, y). \tag{6.3}$$

We make some changes in the theory in § 5, beginning with the definition of suboptimal controls. Approximation to the target will have to be measured in a stronger norm, namely the graph norm of A. We *assume* now that the target point $\bar{y}$ belongs to $D(A)$, the domain of A. A control $u(t)$ is $(\tilde{t}, \varepsilon)$-*suboptimal* (or, more precisely, $(A, \tilde{t}, \varepsilon)$-suboptimal) if

$$\|Ay(\tilde{t}, u) - A\bar{y}\| \leqq \varepsilon, \qquad y_0(\tilde{t}, u) \leqq m + \varepsilon. \tag{6.4}$$

The graph norm of A in (6.4) has a simple interpretation when A is a second-order partial differential operator

$$Au(x)=\sum_{j=1}^{m}\sum_{k=1}^{m}D^j(a_{jk}(x)D^k u(x))+\sum_{j=1}^{m}b_j(x)D^j(x)+c(x)u(x) \tag{6.5}$$

in a bounded domain Ω of m-dimensional Euclidean space $\mathbb{R}^m$, defined on functions that satisfy a boundary condition, for instance

$$u(x)=0 \tag{6.6}$$

on the boundary Γ of Ω. Under minimal assumptions on Ω and on the coefficients of $a_{jk}(x)$, $b_j(x)$ and $c(x)$ (see [13] for details), $D(A)$ is just the Sobolev space $H^2(\Omega)_0$ (the subspace of $H^2(\Omega)$ defined by the boundary condition (6.6)) and the graph norm is equivalent to the $H^2(\Omega)$ norm. Thus, the first inequality (6.4) means only approximation in the $H^2(\Omega)$ norm and satisfaction of the boundary condition. The same statement holds for other boundary conditions (see again [13]).

Given a sequence of (A, t_n, ε_n)-suboptimal controls we use instead of (3.4) the function

$$G_n(u)=\{(\max(0, y_0(t_n, u)-m+\varepsilon_n))^2+\|Ay(t_n, u)-A\bar{y}\|^2\}^{1/2} \tag{6.7}$$

in the space $W(0, t_n; U)$; we define $F_n(u)=+\infty$ if $y(t_n, u)$ does not belong to $D(A)$. It is easily shown that the function $F_n(u)$ is lower semicontinuous ([8, Lemma 7.4]), thus Ekeland's theorem can be applied. We obtain in this way the following version of Theorem 3.1.

THEOREM 6.1 (*The modified sequence maximum principle*). *Let* $\{u^n\}$ *be a sequence of* (A, t_n, u^n)*-suboptimal controls with* $\{t_n\}$ *bounded,* $\varepsilon_n\to 0$. *Then there exists a subsequence of* $\{u^n\}$ (*which we denote by the same symbol*) *such that*

$$t_n\to\bar{t}, \qquad y_0(t_n, u^n)\to m'\leqq m, \qquad Ay(t_n, u^n)\to A\bar{y}, \tag{6.8}$$

a second sequence $\{\tilde{u}^n\}$ *of controls with* $\tilde{u}^n\in W(-k, t_n; U)$ *such that*

$$F_n(\tilde{u}^n)<F_n(u^n)<\infty, \tag{6.9}$$

$$d_n(u^n, \tilde{u}^n)\to 0, \tag{6.10}$$

a sequence $\{\tilde{y}^n\}=\{(\mu_n, y^n)\}$ *in* $\mathbb{R}\times D(A)$ *such that* $(\mu_n)^2+\|Ay^n\|^2=1$ *and a set* e_n *of full measure in* $0\leqq s\leqq t_n$ *such that*

$$\begin{aligned}&\mu_n\xi_0(t_n, s, \tilde{u}^n, v, \tilde{u}^n(s))+\langle Ay^n, AS(t_n, s; u)B(v-\tilde{u}^n(s))\rangle\\ &\qquad\geqq -\delta_n\to 0 \quad (v\in U, s\in e_n).\end{aligned} \tag{6.11}$$

An essential ingredient in the proof is the following lemma.

LEMMA 6.2. *Let* $u\in W(0, \bar{t}; u)$, $s<\bar{t}$. *Then* (a) $S(\bar{t}, s; u)E\subseteq D(A)$, (b) *if* $r<\bar{t}-s$ *then* $y(\bar{t}, u_{s,r,v})-y(\bar{t}, u)\in D(A)$, *and*

$$AS(\bar{t}, s; u)(v-u(s))=\lim_{\rho\to 0+}r^{-1}A(y(\bar{t}, u_{s,r,v})-y(\bar{t}, u)) \tag{6.12}$$

in a set e *of full measure in* $0\leqq s<\bar{t}$.

The proof is in [8, § 7]. It is based on the integral equation

$$y(t, u)=S(t)y_0+\int_0^t S(t-\sigma)f(\sigma, y(\sigma, u))\,d\sigma+\int_0^t S(t-\sigma)Bu(\sigma)\,d\sigma \tag{6.13}$$

defining $y(t, u)$; to exploit the assumptions on f, we write the first integrand in the form

$$S(t-\sigma)f(\sigma, y(\sigma, u))=(-A)^{-\alpha}S(t-\sigma)(-A)^{\alpha}f(\sigma, y(\sigma, u)), \tag{6.14}$$

and use the estimate (6.2). We proceed in the same way in the integral equation (4.11) defining $S(t, s; u)$; here the integrand is written in the form

$$\begin{aligned} &S(t-\sigma)\partial_y f(\sigma, y(\sigma, u))S(\sigma, s; u) \\ &\quad = (-A)^{-\alpha}S(t-\sigma)(-A)^{\alpha}\partial_y f(\sigma, y(\sigma, u))S(\sigma, s; u). \end{aligned} \tag{6.15}$$

Once (6.11) has been established we take $v = v(s)$ and integrate in $0 \leqq s \leqq \bar{t}$, assuming that

$$s \to \xi_0(t_n, s, \tilde{u}^n, v(s), \tilde{u}^n(s)) \tag{6.16}$$

is integrable for any $v \in W(0, T; U)$. The result is

$$\begin{aligned} &\mu_n \int_0^{t_n} \xi_0(t_n, s, \tilde{u}^n, v(s), \tilde{u}^n(s))\, ds \\ &\quad + \left\langle Ay_n, A\int_0^{t_n} S(t_n, s; \tilde{u}^n)Bv(s)\, ds - A\int_0^{t_n} S(t_n, s; \tilde{u}^n)B\tilde{u}^n(s)\, ds \right\rangle \\ &\geqq -\delta_n \to 0. \end{aligned} \tag{6.17}$$

However, (6.17) needs some clarification. We must show first that

$$\int_0^{t_n} S(t_n, s; \tilde{u}^n)B\tilde{u}^n(s)\, ds \in D(A). \tag{6.18}$$

To see this, observe that it follows from (6.7) that

$$y(t_n, \tilde{u}^n) \in D(A). \tag{6.19}$$

We use then the integral equation (6.13) and (6.14) to deduce that

$$\int_0^{t_n} S(t-\sigma)B\tilde{u}^n(\sigma)\, d\sigma \in D(A). \tag{6.20}$$

Finally, we exploit the integral equation (4.11) defining $S(t, s; u)$, write the integrand in the form (6.15) and use the assumptions on $f(t, s, u)$ at the beginning of the section.

On the other hand, it is not necessarily true that

$$\int_0^{t_n} S(t_n, s; \tilde{u}^n)Bv(s)\, ds \in D(A), \tag{6.21}$$

thus we only claim (6.17) for those $v \in W(0, t_n; U)$ that satisfy (6.21).

We bring into play some definitions and results of [8]. Let Δ be a set in a Hilbert space H. We say that Δ has *finite codimension* if and only if there exists a closed subspace $K \subseteq H$ of finite codimension (that is, with a finite-dimensional orthogonal complement) such that

$$\Delta_K = \Pi(\overline{\text{conv}}\,(\Delta)) \tag{6.22}$$

has nonempty interior in K, where Π denotes the orthogonal projection from H onto K. A set with nonempty interior (or, more generally such that its closed convex hull has nonempty interior) has finite codimension (take $K = H$). In a finite-dimensional space, any nonempty set has finite codimension, as we see taking $K = \{0\}$.

The definition extends to families of sets. We say that a sequence $\{\Delta_n\}$ *has finite codimension* if there exists a closed subspace $K \subseteq H$ with finite codimension in H such that

$$\Delta_K = \bigcap_{n \geqq 1} \Pi(\overline{\text{conv}}\,(\Delta_n)) \tag{6.23}$$

has nonempty interior. The sequence $\{\Delta_n\}$ is called *bounded* if $\Delta_n \subseteq \Delta$ for all n, where Δ is a bounded set in H.

LEMMA 6.3. *Let $\{\Delta_n\}$ be a bounded sequence of sets in H having finite codimension. Let $\{y_n\}$ be a sequence in H such that*

$$0 < c \leqq \|y_n\| \leqq C. \tag{6.24}$$

Assume that

$$\langle y_n, z\rangle \geqq -\varepsilon_n \to 0 \quad (z \in \Delta_n,\ n = 1, 2, \cdots). \tag{6.25}$$

Then there exists a subsequence of $\{y_n\}$ that converges weakly to an element $y \in H$, $y \neq 0$.

For a proof, see [8, Lemma 5.6].

We denote below by $\Lambda(t)$ the nonlinear operator

$$\Lambda(t)u = \int_0^t S(t, s; u)Bu(s)\, ds \tag{6.26}$$

defined in $W(0, t; U)$.

LEMMA 6.4. *Let $\{\tilde{u}^n\}$ be the sequence in Theorem 6.1. Then $\Lambda(t_n)\tilde{u}^n \in D(A)$ for all n and the sequence $\{A\Lambda(t_n)\tilde{u}^n\}$ is strongly convergent in E.*

Proof. Premultiplying (4.11) by A we obtain

$$\begin{aligned}(-A)S(t, s; u)z &= (-A)S(t-s)z \\ &\quad + \int_s^t (-A)^{1-\alpha} S(t-\sigma)(-A)^{\alpha}\partial_y f(t, y(t, u))S(\sigma, s; u)z\, d\sigma.\end{aligned} \tag{6.27}$$

It follows from (6.27) and (6.2) that

$$\|AS(t, s; u) - AS(t-s)\| \leqq C(t-s)^{\alpha} \tag{6.28}$$

in $0 < s < t < T$. Write now (4.3) in the form

$$\begin{aligned}y'(t, u) &= \{A + \partial_y f(t, y(t, u))\}y(t, u) \\ &\quad + \{f(t, y(t, u)) - \partial_y f(t, y(t, u))y(t, u)\} + Bu(t)\end{aligned} \tag{6.29}$$

and express the solution $y(t, u)$ of (4.3)-(4.4) using the solution operator $S(t, s; u)$ of the linearized equation: the result is

$$\begin{aligned}y(t, u) &= S(t, 0; u)y^0 + \int_0^t S(t, \sigma; u)\{f(\sigma, y(\sigma, u)) - \partial_y f(\sigma, y(\sigma, u))y(\sigma, u)\}\, d\sigma \\ &\quad + \int_0^t S(t, \sigma; u)Bu(\sigma)\, d\sigma.\end{aligned} \tag{6.30}$$

On the left-hand side we use the fact that (6.4) implies

$$Ay(t_n, \tilde{u}^n) \to A\bar{y}. \tag{6.31}$$

On the right-hand side, we use (6.28) to replace (modulo a bounded operator) $AS(t, s; u)$ by $AS(t-s)$ in (6.30), and then write the resulting integrand in the form

$$\begin{aligned}&AS(t-\sigma)\{f(\sigma, y(\sigma, u)) - \partial_y f(\sigma, y(\sigma, u))y(\sigma, u)\} \\ &\quad = (-A)^{1-\alpha} S(t-\sigma)\{(-A)^{\alpha} f(\sigma, u)) - (-A)^{\alpha}\partial_y f(\sigma, y(\sigma, u))y(\sigma, u)\}\end{aligned} \tag{6.32}$$

and use the hypotheses (F_α) on $f(t, y)$ and Theorem 5.2. This ends the proof.

THEOREM 6.5. *Let the semigroup $S(t)$ generated by A be analytic, and let the nonlinearity $f(t, y)$ be of the form* (5.1) *with $B = I$ and $f(t, y)$ satisfying assumptions*

(F_α). *Let the control set U be closed and bounded and have 0 as an interior point. Assume, finally, that* (6.16) *is integrable for any $v \in W(0, T; U)$ and that the set of all elements of the form*

$$\int_0^t \xi_0(t, s, u, v(s), u(s))\, ds \tag{6.33}$$

with $u = \tilde{u}^n$ and $v \in W(0, t; U)$ is bounded, uniformly with respect to n. Then the sequence $\{(\mu_n, y^n)\}$ in Theorem 6.1 *has a subsequence weakly convergent in $\mathbb{R} \times D(A)$ to $(\mu, y) \neq 0$.*

Proof. Given $\bar{t} > 0$ and $u \in W(0, \bar{t}; U)$ we define (following [8]) the set $K(0, \bar{t}, u; U) \subseteq E$ as the set of all elements $z \in E$ of the form

$$z = \Lambda(t)u = \int_0^t S(t, s; u)Bv(s)\, ds. \tag{6.34}$$

The set $\tilde{K}(0, \bar{t}, u; U)$ consists of all elements of the form $(\eta, z) \in \mathbb{R} \times E$ with z given by (6.34) and η given by (6.33).

Making use of the integral equation (4.11) and the assumptions on $S(t)$ and $f(t, y)$, we show that if $y \in D(A)$ then $s \to S(t, s; u)y$ is continuously differentiable in $0 \leqq s < t$ and satisfies

$$(S(t, s; u)y)' = -S(t, s; u)\{A + \partial_y f(s, y(s, u))\}y$$

(see [8] for details). Accordingly, if we define a control by $v_n(s) = \{y - s(A + \partial_y f(s, y(s, \tilde{u}^n)))y\}/t$, then

$$\int_0^{t_n} S(t_n, s; \tilde{u}^n)Bv_n(s)\, ds = y. \tag{6.35}$$

Since $v(s) \in W(0, t_n; U)$ for sufficiently small $\|Ay\|$, it follows that the sequence of sets $A(K(0, t_n, \tilde{u}^n; U) \cap D(A))$ contains a common open set.

The proof ends applying Lemma 6.3 in the space $H = \mathbb{R} \times D(A)$, where $D(A)$ is endowed with the graph norm. The statement just proved above is that the sequence of sets $K(0, t_n, \tilde{u}^n; U) \cap D(A)$ contains a common open set in the space H. On the other hand, the boundedness assumption for elements of the form (6.34) implies that the sequence $\tilde{K}(0, t_n, \tilde{u}^n; U) \cap (\mathbb{R} \times D(A))$ is bounded in $\mathbb{R} \times D(A)$ (that elements of the form (6.33) are bounded is a consequence of the other hypotheses). Hence, $K(0, t_n, \tilde{u}^n; U) \cap (\mathbb{R} \times D(A))$ is of finite codimension there; in view of the convergence relation proved in Lemma (6.3), the same is true of the sequence $K(0, t_n, \tilde{u}^n; U) \cap (\mathbb{R} \times D(A)) - (0, \Lambda(t_n)\tilde{u}^n)$, thus Theorem 6.4 follows from (6.17) and Lemma 6.3.

A separate statement is needed for the time optimal problem. The function under consideration here is not (6.3) but

$$F_n(u) = \|Ay(t_n, u) - A\bar{y}\| \tag{6.36}$$

in the space $W(0, t_n; U)$. Arguing in the same way as with (6.5) we obtain the following theorem.

THEOREM 6.6 (*The modified sequence maximum principle for the time optimal problem*). *Let $\{u^n\}$ be a sequence of (A, t_n, u^n)-suboptimal controls with $t_n < \bar{t}$, $\varepsilon_n \to 0$. Then there exists a subsequence of $\{u^n\}$ (which we denote by the same symbol) such that*

$$t_n \to \tilde{t} \leqq \bar{t}, \qquad Ay(t_n, u^n) \to A\bar{y}, \tag{6.37}$$

a second sequence $\{\tilde{u}^n\}$ of controls with $\tilde{u}^n \in W(-k, t_n; U)$ such that

$$F_n(\tilde{u}^n) < F_n(u^n) < \infty, \tag{6.38}$$

$$d_n(u^n, \tilde{u}^n) \to 0, \tag{6.39}$$

a sequence $\{y^n\} \in D(A)$ *such that* $\|Ay^n\| = 1$ *and a set* e_n *of full measure in* $0 \leqq s \leqq t_n$ *such that*

$$\langle Ay^n, AS(t_n, s; \tilde{u}^n)B(v - \tilde{u}^n(s))\rangle \geqq -\delta_n \to 0 \quad (v \in U, s \in e_n). \tag{6.40}$$

The following analogue of Theorem 6.4 is proved essentially in the same way.

THEOREM 6.7. *Let the semigroup* $S(t)$ *generated by* A *be analytic, and let the nonlinearity be of the form* (5.1), *with* $B = I$ *and* $f(t, y)$ *satisfying assumptions* (F_α). *Let the control set* U *be closed and bounded and have* 0 *as an interior point. Then the sequence* $\{y^n\}$ *in Theorem* 6.5 *has a subsequence weakly convergent in* $D(A)$ *to* $y \neq 0$.

It can be proved (much in the same way as for the convergence principles in § 5) that the generalized convergence principles just established imply strong convergence of sequences of suboptimal controls. Again we consider only the time optimal case.

We will need the following two results, where the assumptions on A and on $f(t, y)$ in Theorem 6.7 are in force.

LEMMA 6.8. *Let* $h > 0$. *The* (E)*-valued function*

$$(t, s, u) \to AS(t, s; u) \tag{6.41}$$

is uniformly continuous (*in the uniform topology of operators*) *in* $0 \leqq s \leqq t - h \leqq T$, $u \in W(0, T; U)$ ($W(0, T; U)$ *endowed with the weak* $L^2(0, T; E)$*-topology.*

LEMMA 6.9. *Let* $0 \leqq s < t \leqq T$, $u \in W(0, t; U)$. *Then the operator* $AS(t, s; u) : E \to E$ *is compact.*

The proofs of both results are consequences of Lemma 5.4 and Lemma 5.5. We use the integral equation (4.11) premultiplied by A:

$$\begin{aligned} AS(t, s; u)z &= AS(t - s)z \\ &+ \int_s^t (-A)^{1-\alpha} S(t - \sigma)(-A)^\alpha \partial_y f(\sigma, y(\sigma, u))S(\sigma, s; u)z \, ds. \end{aligned} \tag{6.42}$$

Lemma 6.8 follows immediately from the estimate (6.2), from the assumptions on $f(t, y)$, from the fact that $AS(t)$ is continuous in the uniform topology of operators in $t > 0$ and from Lemma 5.4, which guarantees that $S(\sigma, s; u)$ is continuous in the uniform topology of operators in $s < \sigma < T$; we divide the domain of integration in (6.42) in three parts, one $s + \delta < t < T - \delta$ where (E)-continuity of the integrand can be exploited, and two residual intervals, $s < s + \delta$ and $T - \delta < T$, which yield an integral as small as desired. To prove Lemma 6.9 we argue in the same way, using the fact that $AS(t) = S'(t)$ is compact for each $t > 0$ and that $S(\sigma, s; u)$ is compact in $s < \sigma < T$ (Lemma 5.5).

We rewrite (6.40) in the form

$$\langle (AS(t_n, s; \tilde{u}^n))^* Ay^n, v - \tilde{u}^n(s)\rangle \geqq -\delta_n \to 0 \quad (v \in U, s \in e_n). \tag{6.43}$$

Consider the following analogue of (5.12):

$$(AS(\bar{t}, s; \tilde{u}^n))^* Ay^n = ((AS(t_n, s; \tilde{u}^n))^* - (AS(\bar{t}, s; \bar{u})))^* y^n + (AS(\bar{t}, s; \bar{u}))^* y^n. \tag{6.44}$$

Using Lemmas 6.7 and 6.8, we deduce that

$$z_n(t) = (AS(t_n, s; \tilde{u}^n))^* Ay^n \to z(t) = (AS(\bar{t}, s; \bar{u}))^* Ay \quad \text{strongly} \tag{6.45}$$

(where $y \neq 0$ is the weak limit of y^n in the space $D(A)$), so that

$$\langle z(t), v - \tilde{u}^n(s)\rangle \geqq -\delta_n \to 0 \quad (v \in U, s \in e_n). \tag{6.46}$$

From then on, all the arguments following (5.14) apply; the only difference is that $z(t)$ was continuous in $0 \leqq t \leqq \bar{t}$ there, while it is only continuous in $0 \leqq t < \bar{t}$ here, but this does not introduce any significant changes.

7. The strong convergence principle: the noncompact case. The weak convergence principle, as defined in § 4, is based on two sets of hypotheses that work in opposite directions. On the one hand, compactness (either of $S(t)$ or of B) is needed; on the other hand, results such as Lemma 6.3 require, roughly speaking, *exact controllability* (of the linearized system), which is unattainable (except in finite-dimensional situations) when $S(t)$ or B are compact (for the latter case, see [6]). Thus, only modified versions of the convergence principle work in very particular situations, such as the one treated in § 6 under the assumption of compactness of $S(t)$. Compactness of B works in the case (not treated in this paper) of hyperbolic equations, where exact controllability to certain (energy) subspaces holds; however, the requirements on B essentially reduce us to the case of one space variable.

A way out may be attempted giving up the compactness properties of $B^*S(t, s; u)^*$ altogether and trying to establish instead a strong convergence principle. However, this only works in very particular situations, as seen in this section and in § 8; on the other hand, compactness in a weakened form is still necessary.

We consider again systems defined by the initial value problem (4.3)-(4.4) in a Hilbert space E. We do not assume that A is compact, but only that $R(\mu; A) = (\mu I - A)^{-1}$ is compact for some μ in the resolvent set $\rho(A)$. The nonlinear term $f(t, y, u)$ is assumed to be of the form (5.1) and satisfy assumptions (F) in § 4.

LEMMA 7.1. *Let $S(t)$ be a strongly continuous semigroup such that $R(\mu; A)$ is compact for some $\mu \in \rho(A)$. Let the operator $\Pi: L^2(0, T; E) \to C(0, T; E)$ be defined by*

$$(\Pi u)(t) = \int_0^t S(t-\sigma)u(\sigma)\, d\sigma. \tag{7.1}$$

Let $\{u^n\}$ be a sequence in $L^2(0, T; E)$ converging weakly to an element $u \in L^2(0, T; E)$. Then (a)

$$\Pi u^n \to \Pi u \quad \textit{strongly in } L^2(0, T; E). \tag{7.2}$$

(b) *If $\{t_n\}$ is a sequence in $[0, T]$ such that $t_n \to t_0$, then*

$$(\Pi u_n)(t_n) \to (\Pi u)(t_0) \quad \textit{weakly in } E. \tag{7.3}$$

A sketch of the proof is in [10, Lemma 5.1]. We can write Π as the convolution $\Pi u = S * u$, where we have set $S(t) = 0$ in $t < 0$. Translating A if necessary, we may assume as well that (6.1) holds for some $\beta > 0$. Denoting by Φ the Fourier transform operator, we have $(\Phi\Pi u)(\sigma) = R(-i\sigma; A)\Phi u(\sigma)$. For $u \in E$ we have

$$\langle \Phi u_n(\sigma), u\rangle = \int_0^T \langle u_n(t), e^{-i\sigma t}u\rangle\, dt \to \int_0^T \langle u(t), e^{-i\sigma t}u\rangle\, dt = \langle \Phi u(\sigma), u\rangle,$$

(where we have set $u(t) = u_n(t)$ in $t > T$) so that $\Phi u_n(\sigma) \to \Phi u(\sigma)$ weakly in E for each σ. Since $R(\mu; A)$ is compact for some μ, it follows from the second resolvent equation that $R(-i\sigma; A)$ is compact for every σ, so that $R(-i\sigma; A)\Phi u_n(\sigma) \to R(-i\sigma; A)\Phi u(\sigma)$ strongly in E for $-\infty < \sigma < \infty$. Noting that by (6.1), $R(-i\sigma; A)$ is uniformly bounded, (a) follows from the dominated convergence theorem and Plancherel's theorem. To prove (b) we only have to observe that, for $u \in E$,

$$\begin{aligned} \langle (\Pi u_n)(t_n), u\rangle &= \int_0^{t_n} \langle u_n(t), S(t_n - t)u\rangle\, dt \to \int_0^{t_n} \langle u(t), S(t-t)u\rangle\, dt \\ &= \langle (\Pi u)(t), u\rangle, \end{aligned} \tag{7.4}$$

noting that $S(t_n - t)u \to S(t-t)u$ strongly in $L^2(0, T; E)$. Of course, in this last step, compactness of the resolvent $R(\mu; A)$ is unnecessary.

The following result is the analogue of Theorem 5.2 for the present hypotheses. As in § 5 we assume that the control set U is closed and bounded, and we denote by $V = \overline{\text{conv}}\,(U)$ the closed convex hull of U.

THEOREM 7.2. *Let the semigroup $S(t)$ generated by A satisfy the assumptions of Lemma 7.1, and suppose $f(t, y, u)$ is of the form (5.1) with $f(t, y)$ satisfying (F). Let $\{u^n\}$ be a sequence of controls with $u^n \in W(0, t_n; U)$. Assume that $t_n \to t_0$. Then there exists a subsequence of $\{u^n\}$ (which we denote by the same symbol) and a $\bar{u} \in W(0, t_0; V)$ such that*

$$u^n(t) \to \bar{u}(t) \quad \textit{weakly in } L^2(0, t_0; F), \tag{7.5}$$

$$y(t, u^n) \to y(t, \bar{u}) \quad \textit{strongly in } L^2(0, T; U), \tag{7.6}$$

$$y(t_n, u^n) \to y(t_0, \bar{u}) \quad \textit{weakly in } E. \tag{7.7}$$

Again, a sketch of the proof can be found in [10, Thm. 5.2]. We use the successive approximation equation (5.8) to compute $y(t, u^n)$ as the limit of the sequence

$$\{y^m(t, u^n);\ m = 1, 2, \cdots\}. \tag{7.8}$$

We have already observed in § 5 that $\{y^m(t, u^n)\}$ converges absolutely and uniformly (with respect to σ and n) as $m \to \infty$ in some interval $[0, T_0]$ independent of n. The (analogously defined) sequence

$$\{y^m(t, \bar{u});\ m = 1, 2, \cdots\} \tag{7.9}$$

used to compute $y(t, \bar{u})$ enjoys the same convergence properties.

Select a subsequence of $\{u^n\}$ (denoted with the same symbol) such that $u^n \to \bar{u} \in L^2(0, T; F)$ weakly; since $W(0, T; V)$ is convex and closed (hence weakly closed) in $L^2(0, T; F)$, $\bar{u} \in W(0, T; V)$. Making use of (5.8) and of Lemma 5.1 and passing to a subsequence, we deduce that $\{y^1(t, u^n)\}$ is strongly convergent in $L^2(0, T_0; F)$ and convergent almost everywhere in $[0, T_0]$. Using then the dominated convergence theorem in the first term, Lemma 5.1 in the second term and passing to a subsequence, we deduce that $y^1(t, u^n)$ converges strongly in $L^2(0, T_0; F)$ and almost everywhere in $[0, T_0]$ to $y^1(t, \bar{u})$. Operating inductively in the same fashion (using at each step the dominated convergence theorem in the first term of (5.8) and Lemma 7.1 in the second term, and taking a diagonal subsequence at the end) we show that each of the terms in the sequence $\{y^m(t, u^n)\}$ converges in $L^2(0, T_0; F)$ to the corresponding term of the sequence $\{y^m(t, \bar{u})\}$. Noting that

$$\begin{aligned} y(t, u^n) - y(t, \bar{u}) = {} & (y(t, u^n) - y^m(t, u^n)) + (y^m(t, u^n) - y^m(t, \bar{u})) \\ & + (y^m(t, \bar{u}) - y(t, \bar{u})) \end{aligned} \tag{7.10}$$

and using the convergence properties just mentioned, (7.6) follows in the interval $[0, T_0]$. To extend the result to all the interval $[0, t_0]$ we proceed as follows. Since $y(t, u^n) \to y(t, \bar{u})$ almost everywhere in $[0, T_0]$, we may assume (if needed shifting T_0 to the left) that $y(T_0, u^n) \to y(T_0, \bar{u})$. To solve in $t \geqq T_0$, we use the approximation scheme (4.6), that is

$$\begin{aligned} y^{m+1}(t, u^n) = {} & S(t)y(T_0, u^n) \\ & + \int_{T_0}^{t} S(t-\sigma) f(\sigma, y^m(\sigma, u^n))\, d\sigma + \int_{T_0}^{t} S(t-\sigma) B u^n(\sigma)\, d\sigma \end{aligned} \tag{7.11}$$

in $t \geqq T_0$. Arguing in the same way (and, of course, passing to a subsequence), we show that $y(t, u^n)$ converges in $L^2([T_0, T_1]; F)$ and almost everywhere in $[T_0, T_1]$ to

$y(t; \bar{u})$. Using the same argument in intervals $[T_1, T_2], [T_2, T_3], \cdots$ whose length does not tend to zero because of (4.8) (see the arguments following (4.8)), we obtain (7.6) in the whole interval $[0, t_0]$.

The proof of (7.7) is similar. We start with the first equation (7.14) ($m = 0$) and use Lemma 7.1(b) in order to show that $y^1(T_0, u^n) \to y^1(T_0, \bar{u})$ weakly in E. We then make use of (7.11) inductively in the interval $[0, T_0]$, combined with the fact that, passing to a subsequence we may assume that each sequence $\{y^m(t, u^n)\}$ converges almost everywhere in $[0, T_0]$ as $n \to \infty$ to $y(t, \bar{u})$ to show that, for each $m = 1, 2, \cdots$

$$y^m(T_0, u^n) \to y^m(T_0, \bar{u}) \quad \text{weakly in } E.$$

This, combined with the convergence properties as $m \to \infty$ of the sequence (7.8), shows that

$$y(T_0, u^n) \to y(T_0, \bar{u}) \quad \text{weakly in } E. \tag{7.12}$$

Using then (7.11) and arguing in the same way, we show (7.7) in the intervals $[T_1, T_2]$, $[T_2, T_3], \cdots$ until the limit t_0 and the sequence $\{t_n\}$ are eventually contained in an interval $[T_k, T_{k+1}]$.

Remark 7.3. Using an argument similar to that in Remark 5.3 we can show that it is unnecessary to take a subsequence in Theorem 7.2.

LEMMA 7.4. *Under the assumptions on $S(t)$ and $f(t, y)$ in Theorem* 7.2 *the (E)-valued functions*

$$(t, s, u) \to S(t, s; u) \tag{7.13}$$

$$(t, s, u) \to S(t, s; u)^* \tag{7.14}$$

are uniformly continuous (in the strong topology of operators) in $0 \leqq s \leqq t \leqq T$, $u \in W(0, T; U)$ ($W(0, T; U)$ endowed with the weak $L^2(0, T; F)$-topology).

The proof (which is also sketched in [10, Thm. 5.3]) uses the integral equation (4.11) defining $S(t, s; u)$, the integral equation

$$S(t, s; u)^* z = S(t-s)^* z + \int_s^t S(\sigma, s; u)^* B(\sigma)^* S(t-\sigma)^* z \, d\sigma \tag{7.15}$$

$$(0 \leqq s \leqq t \leqq T)$$

obtained from (4.11) taking adjoints, the L^2-convergence of $\{y(t, u^n)\}$ and the uniform boundedness of $\|y(t, u^n)\|$. We omit the details.

The following result on the operator $\Lambda(t)u$ defined by (6.26) roughly corresponds to Lemma 6.4.

LEMMA 7.5. *Let $\{\tilde{u}^n\}$ be the sequence in* (5.3). *Then there exists a subsequence (denoted with the same symbol) such that $\{\Lambda(t_n)\tilde{u}^n\}$ is strongly convergent in E.*

The proof is based on (6.30) for $t = t_n$, $u = \tilde{u}^n$. Obviously, the left-hand side and the first term on the right-hand side converge, the latter because of Lemma 7.4. In the integrand we again use Lemma 7.4 for $S(t, \sigma; u)$, uniform boundedness of $\{y(t, u^n)\}$, pointwise convergence of the same sequence (which can be achieved passing to a subsequence) and the dominated convergence theorem.

At this point, there is no difficulty in upgrading the sequence maximum principles in § 5 into weak convergence principles, that is, in establishing the weak convergence of (a subsequence of) the sequence $\{y^n\}$ to a limit $y \neq 0$. However, this would not be useful in the present situation, since the crucial uniform continuity-compactness properties of the operator $S(t, s; u)$, present in the abstract parabolic case, are now lacking. Thus, we need to establish strong convergence of a subsequence of $\{y^n\}$, which we do in the next section.

8. The convergence principle: the noncompact case. Let Δ be an arbitrary set in a Hilbert space H, and let $S(y, \rho)$ be the closed sphere of center y and radius ρ. We say that a point y in the space H is Δ-*regular* if and only if there exists a hyperplane

$$H(y, \bar{y}) = \{v; \langle v - y, \bar{y}\rangle = 0\} \tag{8.1}$$

(where we assume that the *generator* $\bar{y}$ of $H(y, \bar{y})$ satisfies $\|\bar{y}\| = 1$), a number $\rho > 0$ and a map

$$\Pi : S(y, \rho) \cap H(y, \bar{y}) \to \Delta \tag{8.2}$$

such that

$$\|\Pi(z) - z\| \leqq r(\|z - y\|) \quad (\|z - y\| \leqq \rho), \tag{8.3}$$

where the function $r(\mu)$ is defined in $0 < \mu \leqq \rho$ and satisfies

$$r(\mu) = 0(\mu) \quad \text{as } \mu \to 0. \tag{8.4}$$

Example 8.1. Let $\Delta = B(0, R)$ be the sphere of center 0 and radius R in H, and let y be a point in H. If $\|y\| > R$ then it is obvious that y is not Δ-regular. If $\|y\| < R$ then y is Δ-regular (we may take $\rho = R - \|y\|$ and $H(y, \bar{y})$ an arbitrary hyperplane). The only nontrivial situation is that where y belongs to the boundary of Δ, that is, $\|y\| = R$. In this case we take $\bar{u} = y/\|y\|$ and define the map Π by

$$\Pi(z) = (R/\|z\|)z. \tag{8.5}$$

Let $z \in H(y, \bar{y})$. Trigonometry in the two-dimensional subspace generated by y and z reveals that $\|z - y\|/R = \tan\theta$, $\|z - y\|/\|z\| = \sin\theta$, where θ is the angle between y and z. Accordingly,

$$\|\Pi(z) - z\| = \|(R/\|z\|)z - z\| = \|z\| - R = \{(1 - \cos\theta)/\sin\theta\}\|z - y\|, \tag{8.6}$$

and it follows that y is Δ-regular.

LEMMA 8.2. *Let y be a Δ-regular point, and let $\{y^n\}$ be a sequence in H such that* $\|y^n\| = 1$,

$$\langle y^n, z - y\rangle \geqq -\varepsilon_n \to 0 \quad (z \in \Delta). \tag{8.7}$$

Then

$$y^n \to \bar{y} \text{ strongly in } H, \tag{8.8}$$

where $\bar{y}$ is the generator of the hyperplane $H(y, \bar{y})$ in (8.1).

Proof. Let $z \in H(y, \bar{y})$. We have

$$\begin{aligned}\langle y^n, z - y\rangle &= \langle y^n, \Pi(z) - y\rangle - \langle y^n, \Pi(z) - z\rangle \geqq -\varepsilon_n - \|\Pi(z) - z\| \\ &\geqq -\varepsilon_n - r(\|z - y\|).\end{aligned}$$

Let $\delta > 0$. Choose μ so small that $r(\mu)/\mu < \delta/2$ and then n so large that $\varepsilon_m/\mu < \delta/2$ for $m \geqq n$. Taking $\|z - y\| = \mu$ and writing $w = (z - y)/\|z - y\|$ we obtain the relation

$$\langle y^m, w\rangle \geqq -\delta \quad (\|w\| = 1, \langle w, \bar{y}\rangle = 0, m \geqq n).$$

This is easily seen to imply (8.8).

In the following result we consider a sequence $\{\Delta_n\}$ of sets in H and a sequence $\{y_n\}$ in H. We say that $\{y_n\}$ is $\{\Delta_n\}$-*regular* if and only if there exists a sequence $\{H(y_n, \bar{y}_n)\}$ of hyperplanes (with generators $\bar{y}_n$, $\|\bar{y}_n\| = 1$) and a sequence of maps

$$\Pi_n : S(y_n, \rho) \cap H(y_n, \bar{y}_n) \to \Delta_n \tag{8.9}$$

such that

$$\|\Pi_n(z_n) - z_n\| \leqq r(\|z_n - y_n\|)(\|z_n - y_n\| \leqq \rho), \tag{8.10}$$

with

$$r(\mu) = o(\mu) \quad \text{as } \mu \to 0, \tag{8.11}$$

where $r(\mu)$ is defined in $0 < \mu < \rho$. The definition of course implies (but is not equivalent to) the fact that each y_n is Δ_n-regular; note that ρ and $r(\mu)$ are assumed to be independent of n.

LEMMA 8.3. *Let $\{\Delta_n\}$ be a sequence of sets in the Hilbert space H, and let $\{y_n\}$ be a $\{\Delta_n\}$-regular sequence. Assume the sequence $\{\bar{y}_n\}$ of generators of the cones $H(y_n, \bar{y}_n)$ satisfies*

$$\bar{y}_n \to \bar{y} \quad \textit{strongly in } H. \tag{8.12}$$

Let $\{y^n\}$ be a sequence such that $\|y^n\| = 1$ and

$$\langle y^n, z_n - y_n\rangle \geqq -\varepsilon_n \to 0 \quad (z_n \in \Delta_n). \tag{8.13}$$

Then

$$y^n \to \bar{y} \quad \textit{strongly in } H. \tag{8.14}$$

The proof is an obvious generalization of the proof of Lemma 8.2. Let $z_n \in H(y_n, \bar{y}_n)$. Then we have

$$\begin{aligned}\langle y^n, z_n - y_n\rangle &= \langle y^n, \Pi_n(z_n) - y_n\rangle - \langle y^n, \Pi_n(z_n) - z_n\rangle \geqq -\varepsilon_n - \|\Pi_n(z_n) - z_n\| \\ &\geqq -\varepsilon_n - r(\|z_n - y_n\|).\end{aligned}$$

We again take $\delta > 0$ and choose μ so small that $r(\mu)/\mu < \delta/2$ and then n so large that $\varepsilon_m/\mu < \delta/2$ for $m \geqq n$. Taking $\|z_m - y_m\| = \mu$ and writing $w_m = (z_m - y_m)/\|z_m - y_m\|$ we obtain the relation

$$\langle y^m, w_m\rangle \geqq -\delta \,(\|w_m\| = 1, \langle w_m, \bar{y}_m\rangle = 0, m \geqq n), \tag{8.15}$$

which is easily seen to imply (8.14).

In what follows, we work under the assumptions in § 8, that is, we require $R(\mu; A)$ to be compact for some $\mu \in \rho(A)$. We prove a convergence principle pertaining to the time optimal problem.

THEOREM 8.4. *Assume that $R(\mu; A)$ is compact for some $\mu \in \rho(A)$ and that $f(t, y, u)$ is of the form* (5.1) *with $f(t, y)$ satisfying conditions (F) in § 4. Assume that, for every convergent sequence $\{t_n\}$ and every weakly convergent sequence $\{\tilde{u}^n\}$ in $W(0, t_n; U)$ the sequence $\{\Lambda\tilde{u}^n(t_n)\}$ is $\{K(0, t_n, \tilde{u}^n; U)\}$-regular. Assume further that*

$$\bar{y}_n \to \bar{y}, \tag{8.16}$$

where $\bar{y}_n$ is the generator of the hyperplane $H(y_n, \bar{y}_n)$ in (8.9). *Then the sequence $\{y^n\}$ in the sequence maximum principle* (5.3) *is strongly convergent.*

The proof is an immediate consequence of Lemma 8.3.

The $\{K(0, t_n, \tilde{u}^n; U)\}$-regularity assumption in Theorem 8.4 is difficult to verify, since very little is known about reachable sets $\{K(0, t_n, \tilde{u}^n; U)\}$ in infinite-dimensional spaces. An example where $\{K(0, t_n, \tilde{u}^n; U)\}$-regularity holds is the following.

COROLLARY 8.5. *Let A and f satisfy the conditions in Theorem* 8.5. *Assume that*

$$B = I, \quad U = B(0, R) = \{u \in E; \|u\| \leqq R\}. \tag{8.17}$$

Assume in addition that $A + \partial_y f(t, y(t, u))$ is skew adjoint for every t in $0 \leqq t \leqq T$ and every $u \in W(0, T; U)$. Then the sequence $\{y^n\}$ in the sequence maximum principle (5.3) *is strongly convergent.*

Proof. Since each $A+\partial_y f(t, y(t, u))$ is skew adjoint, the solution operator $S(t, s; u)$ is unitary (isometric and invertible) for each s, t. (In particular, $\|S(t, s; u)\| = 1$.) It follows that, for each $\bar{t}$ and each $u \in W(0, \bar{t}; U)$ we have

$$K(0, \bar{t}, u; U) = \bar{t}B(0, R) = B(0, \bar{t}R). \tag{8.18}$$

In fact, it is obvious that every element of $K(0, \bar{t}, u; U)$ has norm $\leqq \bar{t}R$; on the other hand, if $v \in B(0, \bar{t}R)$ then $K(0, \bar{t}, u; U)$, since

$$v = \int_0^{\bar{t}} S(t, s; u)u(s)\, ds$$

with $u(s) = \bar{t}^{-1}S(t, s; u)^{-1}v = \bar{t}^{-1}S(s, t; u)v$.

We show that the sequence $\{\Lambda\tilde{u}^n(t_n)\}$ is $\{K(0, t_n, \tilde{u}^n; U)\}$-regular. We know from Lemma 7.6 that $\{\Lambda\tilde{u}^n(t_n)\} \to y$ strongly; under the present hypotheses $\|\Lambda\tilde{u}^n(t_n)\| \leqq \bar{t}R$, so that $\|y\| \leqq \bar{t}R$. We argue essentially as in Example 8.1. If $\|y\| < \bar{t}R$ then we may use the sequence of hyperplanes $H(y_n, \bar{y})$ with $\bar{y}$ arbitrary and Π the identity map. When $\|y\| = R$ we take $\bar{y}_n = y_n/\|y_n\|$ and we define $\Pi(z) = Rz/\|z\|$. Using (8.6) for $\theta = \theta_n$ the angle between y and z, (8.10) follows. This ends the proof.

By way of conclusion, we note that the difficulties in proving convergence principles (and, through them, strong convergence of optimal controls in the point target case) are essentially the same as those difficulties involved in proving the maximum principle with point target (see [8]). The results available make evident that in infinite-dimensional spaces, either the maximum principle or convergence of suboptimal controls will only hold in very particular situations, two of which were treated in this paper. A way out of this difficulty is to give slackness to the target condition (as done in [8] for the maximum principle and in [9], [10] for convergence of suboptimal controls).

For a different approach to the convergence problem see [12], which covers some cases where the maximum principle does not hold ([5]).

Acknowledgments. The author is grateful to H. Frankowska for many improvements in the presentation, in particular for pointing out the correct function $F_n(u)$ in (3.4). Also, the referee's observations resulted in a much improved paper.

WELL-POSEDNESS OF H^∞ OPTIMAL CONTROL PROBLEMS*

MALCOLM C. SMITH†

Abstract. This paper considers the effect of perturbations of a nominal single-input/single-output linear plant, or a band of uncertainty, on the solution to certain frequency domain optimal control problems. Weighted H^∞ sensitivity minimization, mixed, and robust sensitivity minimization will be considered along with problems of more general type. A brief discussion of H^p optimal control problems will also be given. Typical examples will be presented where optimal sensitivity does not depend continuously on the plant (ill-posedness) and conditions for well-posedness will be given. It is demonstrated that similar discontinuities can occur for more general problems. Also suggested are ways of defining an optimization problem so that continuous dependence of the infimum is ensured.

Key words. feedback, frequency domain design, sensitivity minimization, H^∞-optimization, uncertainty, perturbations, continuity, approximation, delay systems

$\mathbb{R}_{sp}(s)$	the strictly proper (i.e., having a zero at ∞) rational functions

1. Introduction. The H^∞ framework was introduced into control by Zames [16] principally because it is natural for studying problems involving uncertainty. In classical theory, plant uncertainty is represented by a tolerance band on the frequency response, which is exactly a "weighted" ball in H^∞. For the problem of optimal disturbance attenuation there is a natural H^∞ formulation for disturbances whose spectra are not fixed [17], and many other problems involving sensitivity and robustness optimization can be posed in an H^∞ framework [5]. To date, much work on H^∞ optimization has been devoted to obtaining explicit solutions to various classes of control problems. Contributions have been made to understanding the capabilities and limitations of feedback, and new possibilities have opened up for design.

An aspect of H^∞ optimization which has remained unexplored to date is the question of *well-posedness*. By well-posedness we mean roughly that a vanishingly small change in the problem specification will result in a vanishingly small change in the solution. Of course, this has to be defined more precisely in particular cases, but we will mostly be concerned with the effect of perturbations of the nominal plant (or the tolerance band) on the performance measure and the optimal control. After an initial

† Department of Electrical Engineering, Ohio State University, Columbus, Ohio 43210. This work was supported in part by the Science and Engineering Research Council of the United Kingdom and by the Natural Sciences and Engineering Research Council of Canada.

study it seems that the H^∞ formulation is rather susceptible to the phenomena of ill-posedness. It is the purpose of this paper to point out and analyse some of the circumstances when this occurs and to suggest remedies. This paper is an expanded version of [12].

Before proceeding it is worth giving reasons why we consider well-posedness to be an important property. Clearly, well-posedness is not the same as the ordinary notion of robustness, which requires the computed controller to perform satisfactorily for some neighbourhood of the nominal plant. The latter property must be satisfied as a matter of course. First, we can see that well-posedness is desirable purely from a computational point of view. Obviously if the problem solution is critically dependent on small changes in the plant parameters it will be very difficult to obtain satisfactory computational procedures. Second, it is clear that ill-posedness could be caused by neglecting certain constraints in the problem formulation. In this respect a knowledge of how to achieve well-posedness would be a useful guide when selecting a performance criterion. A third motivation is the desire to be able to tune a controller on-line in cases of parameter drift. Assuming that a family of controllers is designed off-line to satisfy certain performance criteria, a successful implementation will undoubtedly require that the mapping from plant to controller defined by the design problem be continuous.

The paper is organized as follows. In § 2 we consider the problem of H^∞ weighted sensitivity minimization for stable plants. In the finite-dimensional case and for delay systems, typical examples are presented showing discontinuity of the infimum with respect to plant perturbations. A general condition is then derived characterizing plants at which we have continuity (Theorem 1). One important requirement is that the optimum for the plant equals the optimum for the inner (all-pass) part of the plant. We give a general condition for this to hold for a wide class of infinite-dimensional plants (Theorem 2). Finally we show continuity of the optimum with respect to perturbations of the weighting function. In § 3 we obtain similar results for the case of H^p weighted sensitivity minimization. In § 4 we present some ways in which the sensitivity minimization problem can be modified to ensure continuity of the infimum (with respect to plant perturbations) for arbitrary plants in H^∞. In § 5 we consider the problem of minimizing the supremal weighted sensitivity over a ball of plants. We show that the optimum does not depend continuously on the radius of the ball, and suggest a modified problem which has continuous dependence. In § 6 we consider a general design problem for (possibly) unstable plants in which the infimum of a weighted combination of closed loop transfer functions is sought. A sufficient condition is obtained for the optimum to depend continuously on the plant (corollary to Theorem 7).

2. H^∞ weighted sensitivity minimization. We begin by recalling the H^∞ optimal sensitivity problem. Consider a plant $P(s) \in \tilde{H}^\infty + \mathbb{R}_{pr}(s)$ in the standard feedback configuration of Fig. 1 where the controller $F(s) \in \tilde{H}^\infty + \mathbb{R}_{pr}(s)$ is to be designed. The feedback loop is defined to be *stable* if all four closed loop transfer functions $x_i \to e_j$ are L^2 bounded-input/bounded-output stable (i.e., elements of $\tilde{H}^\infty$). This is equivalent to

$$P(1+FP)^{-1}, \quad F(1+PF)^{-1} \in \tilde{H}^\infty. \tag{2.1}$$

In this section (and through to § 5) we assume $P(s) \in \tilde{H}^\infty$, in which case (2.1) is equivalent to

$$Q := F(1+PF)^{-1} \in \tilde{H}^\infty. \tag{2.2}$$

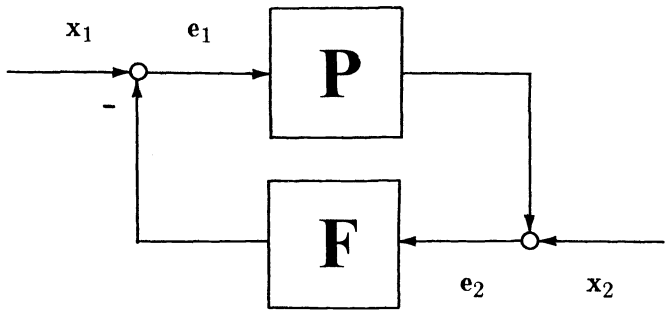

FIG. 1

The H^∞ weighted sensitivity minimization problem is to find

$$\mu(P) := \inf_{F \text{ stablz.}} \| W(1+PF)^{-1} \|_\infty \tag{2.3}$$

where $W(s) \in \tilde{H}^\infty$ is outer and the infimum is taken over all controllers $F(s) \in \tilde{H}^\infty + \mathbb{R}_{pr}(s)$ which stabilize the feedback loop. If $P \in \tilde{H}^\infty$ then (2.3) reduces to

$$\begin{aligned} \mu(P) &= \inf_{\substack{Q \in \tilde{H}^\infty \\ Q/(1-PQ) \in \tilde{H}^\infty + \mathbb{R}_{pr}(s)}} \| W(1-PQ) \|_\infty \\ &\geqq \inf_{Q \in \tilde{H}^\infty} \| W(1-PQ) \|_\infty =: \nu(P). \end{aligned} \tag{2.4}$$

It is usually assumed that (2.4) holds with equality. However, this is not immediate for nonrational P and does not seem to have been established for completely general $P \in H^\infty$. One problem is that $1-PQ$ could have infinitely many $\mathbf{C}_+$ zeros with the consequence that $F = Q/(1-PQ)$ has infinitely many $\mathbf{C}_+$ poles. If W is rational and P is continuous on $\bar{\mathbf{C}}_+$ then equality can be established as in the proof of Theorem 2. For the sake of generality, we will not assume in this paper that (2.4) holds with equality.

We wish to consider the effect of perturbations of P on $\mu(P)$ (and the corresponding optimal F). In particular we want to investigate if the mapping $P \to \mu(P)$ (and $P \to F(P)$) is continuous. Now if $P \in \tilde{H}^\infty$ we have a natural topology on plants defined by the H^∞ norm, which is also physically meaningful (see concluding remarks). In this case our problem reduces to: does $\| P_i - P \|_\infty \to 0$ imply $\mu(P_i) \to \mu(P)$? The answer is clearly no, and the following is a simple example which shows this.

Example 1. Let

$$P(s) = \frac{s}{s+1}, \qquad W(s) = \frac{1}{s+1}.$$

Clearly $\mu(P) \geqq |W(0)| = 1$. In fact $\mu(P) = 1$ and there are a large number of F's which achieve the minimum, e.g., $F = 0$. We note however that $\| P_\varepsilon - P \|_\infty \to 0$ as $\varepsilon \to 0$ where $P_\varepsilon(s) = (s+\varepsilon)/(s+1)$, and that $\mu(P_\varepsilon) = 0$ for all $\varepsilon > 0$. Thus $\mu(\cdot)$ is not continuous at P.

The discontinuity in $\mu(P)$ can be removed in Example 1 by selecting a weighting function $W(s)$ with $W(0) = 0$. However this may be in conflict with a choice which appropriately reflects the spectrum of possible disturbances. There is also no discontinuity if we minimize the 2-norm of the weighted sensitivity rather than the ∞-norm (see § 3). But again there may be strong reasons for preferring a minimax approach. Also, neither of these modifications allows us to choose an optimal F continuously as a function of P. A second instance of discontinuity is the following example.

Example 2. Let

$$P(s)=\frac{e^{-s}}{s+1}, \qquad W(s)=\frac{1}{s+1}.$$

In this case it follows as in [17] (see also Theorem 2) that

$$\mu(P)=\inf_{Q\in\tilde{H}^\infty}\|W-e^{-s}Q\|_\infty.$$

Now from [4] we have $\mu(P)=(1+y_0^2)^{-1/2}$ where y_0 is the unique root of $\tan y+y=0$ lying between $\pi/2$ and π. We note however that $\|P_n-P\|_\infty\to 0$ as $n\to\infty$ where

$$P_n(s)=\frac{1}{(s+1)(1+s/n)^n} \tag{2.5}$$

and clearly $\mu(P_n)=0$ for all n, since P_n is outer (see Theorem 2). Thus $\mu(\cdot)$ is not continuous at P.

Example 2 causes more concern than Example 1 for two reasons. First, there is no obvious way of modifying the weight to ensure even that $\mu(\cdot)$ is continuous. Also the discontinuity in $\mu(\cdot)$ remains when the ∞-norm is replaced by, for example, the 2-norm (see (§ 3). Second, Example 2 represents a plant which is strictly proper and has a delay—this is a very typical situation in practice—whereas a plant which has an imaginary axis zero is more special. Thus Example 2 questions the validity of approximating infinite-dimensional plants by finite-dimensional ones when considering optimal sensitivity (see concluding remarks).

Our first objective is to obtain conditions on P to ensure that $\mu(\cdot)$ is continuous at P. In fact we will show (Theorem 1) that the above examples are the only two types of situations in which $\mu(\cdot)$ can be discontinuous. We begin by establishing the simple fact that $\mu(\cdot)$ is upper semicontinuous on $\tilde{H}^\infty$.

LEMMA 1. *If* P_i, $P\in\tilde{H}^\infty$ *and* $\|P_i-P\|_\infty\to 0$ *as* $i\to\infty$ *then*

$$\limsup \mu(P_i)\leqq\mu(P). \tag{2.6}$$

Proof. Observe that the infimum in $\mu(P)$ can be taken over $Q\in\tilde{H}^\infty$ such that $Q/(1-PQ)\in\tilde{H}^\infty+\mathbb{R}_{pr}(s)$ has no poles on the imaginary axis. For such a Q, $Q/(1-PQ)\in\tilde{H}^\infty+\mathbb{R}_{pr}(s)$ implies that $Q/(1-P_iQ)\in\tilde{H}^\infty+\mathbb{R}_{pr}(s)$ for sufficiently large i. Thus

$$\limsup_i \inf_{\substack{Q\in\tilde{H}^\infty \\ Q/(1-P_iQ)\in\tilde{H}^\infty+\mathbb{R}_{pr}(s)}} \|W(1-P_iQ)\|_\infty \leqq \limsup_i \|W(1-P_i\hat{Q})\|_\infty$$

$$=\|W(1-P\hat{Q})\|_\infty$$

for any $\hat{Q}\in\tilde{H}^\infty$ such that $\hat{Q}/(1-P\hat{Q})\in\tilde{H}^\infty+\mathbb{R}_{pr}(s)$ has no poles on the imaginary axis. The result now follows by taking the infimum over $\hat{Q}$. □

To proceed further we need some standard facts about the factorization of H^∞ functions. We recall that any $P\in\tilde{H}^\infty$ can be written uniquely as $P=BL$ where B, $L\in\tilde{H}^\infty$, B is *inner* or *all-pass* ($|B(j\omega)|=1$ almost everywhere), and L is *outer* or *minimum phase* ($L(s)$ has no zeros in $\mathbf{C}_+$ and $\log|L(s)|$ can be expressed as the Poisson integral of $\log|L(j\omega)|$)—see [6] and [7] for details. Furthermore we can always write $B=B_bB_s$ where B_b, $B_s\in\tilde{H}^\infty$, B_b is a *Blaschke product* and B_s is a *singular inner function.* Transforming the right half plane to the unit disc by setting $z=(s-1)/(s+1)$ we can always write

$$B_b\left(\frac{1+z}{1-z}\right)=\prod_{n=1}^{\infty}\frac{\bar{\alpha}_n}{|\alpha_n|}\left(\frac{\alpha_n-z}{1-\bar{\alpha}_nz}\right)$$

where α_n is a sequence of complex numbers in the disc such that $\Sigma(1-|\alpha_n|)<\infty$. We also have

$$B_s\left(\frac{1+z}{1-z}\right)=\exp\left(-\int\frac{e^{j\theta}+z}{e^{j\theta}-z}\,d\lambda(\theta)\right)$$

where $d\lambda$ is a positive singular measure. We will denote the closed support of the measure by Λ.

Returning to (2.4) we see that

$$\begin{aligned}\nu(P)&=\inf_{Q\in\tilde{H}^\infty}\|W(1-BLQ)\|_\infty\\ &\geqq\inf_{\tilde{Q}\in\tilde{H}^\infty}\|W(1-B\tilde{Q})\|_\infty=\nu(B).\end{aligned}\tag{2.7}$$

Furthermore we can show the following lemma.

LEMMA 2. *For any rational outer* $W(s)\in\tilde{H}^\infty$

$$\nu(B)=\inf_{\hat{Q}\in\tilde{H}^\infty}\|W-B\hat{Q}\|_\infty.\tag{2.8}$$

Proof. This proof generalizes an argument of [17]. Obviously $\nu(B)\geqq\inf\|W-B\hat{Q}\|$. Now if we can find an inverting sequence $L_n\in\tilde{H}^\infty$ such that

$$\|L_nW\|_\infty\leqq 1,\tag{2.9a}$$

$$\|(1-L_nW)W\|_\infty\to 0\quad\text{as } n\to\infty\tag{2.9b}$$

then we can establish (2.8) with equality. To see this observe that for any $\hat{Q}\in\tilde{H}^\infty$

$$W(1-B\hat{Q}L_n)=L_nW(W-B\hat{Q})+(1-L_nW)W$$

and so

$$\|W(1-B\hat{Q}L_n)\|_\infty\leqq\|W-B\hat{Q}\|_\infty+\|(1-L_nW)W\|_\infty,$$

which implies

$$\inf_{\tilde{Q}\in\tilde{H}^\infty}\|W(1-B\tilde{Q})\|_\infty\leqq\inf_{\hat{Q}\in\tilde{H}^\infty}\|W-B\hat{Q}\|_\infty.$$

Now for a rational outer $W(s)$ we can easily find an inverting sequence L_n. Let $W(s)$ have imaginary axis zeros ω_i of multiplicity r_i $(i=1,\cdots,l)$ and r zeros at infinity. Setting

$$L_n(s)=\left(\frac{n}{s+n}\right)^r\prod_{i=1}^{l}\left(\frac{s+j\omega_i}{s+1/n+j\omega_i}\right)^{r_i}W(s)^{-1}$$

we see that $L_n(s)\in\tilde{H}^\infty$ and (2.9a) holds. To verify (2.9b) we note that $L_n(s)W(s)$ tends uniformly to 1 on any compact subset of the imaginary axis not containing any zeros of $W(s)$. □

Remark. This lemma holds for considerably more general outer functions than just rational ones, in fact, for any $W(s)$ for which an inverting sequence satisfying (2.9) exists.

Now (2.8) is a standard mathematical problem which has an extensive literature (see [1], [9], [11]). We can write (2.8) in Nehari problem form as follows:

$$\nu(B)=\inf_{\hat{Q}\in H^\infty}\|WB^*-\hat{Q}\|_\infty=:d(WB^*,H^\infty),$$

where $d(f, H^\infty)$ denotes the distance of the L^∞ function f from H^∞. Now for any $f \in L^\infty$ we can define a multiplication operator $M_f: L^2 \to L^2$ by $M_f x = fx$. If we denote by Π the orthogonal projection from $L^2 \to H^{2\perp}$, the Hankel operator $H_f: H^2 \to H^{2\perp}$ is defined by

$$H_f := \Pi M_{f|H_2}.$$

Now *Nehari's Theorem* [9] says that $d(f, H^\infty) = \|H_f\|$, so $\nu(B) = \|H_{WB^*}\|$. Moreover the infimum in (2.8) is achieved for some $\hat{Q} \in H^\infty$ (not necessarily uniquely).

To date, much work on weighted sensitivity minimization has been concerned with problem (2.8). However it is possible that $\mu(P) > \nu(B)$ and so the optimal sensitivity for P is not obtained by solving (2.8). Example 1 is precisely such a case, since $P(s) = s/(s+1)$ is outer and $\nu(B) = \nu(1) = 0$. Moreover it is clear that the satisfaction of $\mu(P) \geqq \nu(B)$ with equality or inequality is closely tied up with the question of the continuity of $\mu(\cdot)$. In fact, if the outer part L of P is continuous on $\tilde{\mathbf{C}}_+$ then it is easy to see that $\mu(P) > \nu(B)$ implies discontinuity of $\mu(\cdot)$ since L can be uniformly approximated by invertible outer functions. On the other hand it is clear that $\mu(P) = \nu(B)$ is not sufficient for continuity as is shown by Example 2. This example is characterized by the fact that the inner part of the plant is singular *and* $L(s)$ vanishes on the support of the singular measure, namely $s = \infty$. Again $P(s) = e^{-s}/(s+1)$ is continuous on $\tilde{\mathbf{C}}_+$ and can be arbitrarily closely approximated by invertible outer functions. At first sight one might be tempted to conjecture that if e^{-s} is replaced by an infinite Blaschke product B_b then $\mu(\cdot)$ will again be discontinuous, but this is not the case. If $\|P_i - B_b/(s+1)\|_\infty \to 0$ as $i \to \infty$ then the zeros of P_i in $\mathbf{C}_+$ tend to those of B_b by Rouché's theorem. Thus $\liminf \mu(P_i) \geqq \mu(B_{b,T})$ where $B_{b,T}$ is any finite truncation of B_b. But $\sup \mu(B_{b,T}) = \mu(B)$, where the supremum is taken over all truncations (see [15, p. 291, Thm. 9]). Hence $\liminf \mu(P_i) \geqq \mu(B) = \mu(P)$, which together with Lemma 1 establishes continuity.

We are now in a position to derive a general condition for the continuity of $\mu(\cdot)$.

THEOREM 1. *Let $W(s) \in \tilde{H}^\infty$ outer be chosen so that* (2.9) *holds for any B (e.g., $W(s)$ rational). Then $\mu(\cdot)$ is continuous at $P \in \tilde{H}^\infty$ if the following conditions are satisfied*:

$$\mu(P) = \nu(B), \tag{2.10}$$

$$L\left(\frac{1+z}{1-z}\right) \text{ is bounded away from zero on } \Lambda, \tag{2.11}$$

where Λ denotes the closed support of the singular measure of B_s.

Before proving the theorem we introduce some notation and prove a lemma. Let $\Omega \subset \mathbf{C}$ be symmetric with respect to the real axis and define

$$\nu_\Omega(P) := \inf_{Q \in \tilde{H}^\infty(\Omega)} \|W(1 - PQ)\|_{\infty,\Omega}$$

where $\|f(s)\|_{\infty,\Omega} := \sup\{|f(s)|: s \in \Omega\}$.

LEMMA 3. *If $P \in \tilde{H}^\infty(\Omega)$ is bounded away from zero on $\partial\Omega$ then $\nu_\Omega(\cdot)$ is continuous at P.*

Proof. Let $\|P_i - P\|_{\infty,\Omega} \to 0$ as $i \to \infty$. As in Lemma 1 we have $\limsup \nu_\Omega(P_i) \leqq \nu_\Omega(P)$. Write

$$0 < \delta := \inf_{s \in \partial\Omega} |P(s)|$$

and choose n such that $\|P_i - P\|_{\infty,\Omega} < \delta/2$ for all $i \geqq n$. Next take any $Q \in \tilde{H}^\infty(\Omega)$ such that there is an $m \geqq n$ with $\|W(1 - P_m Q)\|_{\infty,\Omega} \leqq \nu_\Omega(P) + 1$. Then $|P_m(s)| > \delta/2$ for $s \in \partial\Omega$

and we deduce that

$$\delta/2\|WQ\|_{\infty,\Omega} \leqq \|WP_mQ\|_{\infty,\Omega}$$
$$\leqq \|W\|_{\infty,\Omega} + \nu_\Omega(P) + 1 =: k$$

i.e., $\|WQ\|_{\infty,\Omega} \leqq 2k/\delta$. Now for any $i \geqq n$

$$\|W(1-P_iQ)\|_{\infty,\Omega} \geqq \|W(1-PQ)\|_{\infty,\Omega} - \|P-P_i\|_\infty \frac{2k}{\delta}$$
$$\geqq \nu_\Omega(P) - \|P-P_i\|_\infty \frac{2k}{\delta}.$$

It thus follows that $\liminf \nu_\Omega(P_i) \geqq \nu_\Omega(P)$ and so $\nu_\Omega(P_i) \to \nu_\Omega(P)$, completing the proof. □

Proof of Theorem 1. Let $P_i \in \tilde{H}^\infty$ be such that $\|P_i - P\|_\infty \to 0$ as $i \to \infty$. We wish to show that $\mu(P_i) \to \mu(P)$ as $i \to \infty$. First we transform to the unit disc using the substitution $z = (s-1)/(s+1)$. Now let $\Delta \subset \partial D$ be the set of points where L is not bounded away from zero. By assumption $\Delta \cap \Lambda = \phi$. Next we construct a sequence of regions $D_1 \subset D_2 \cdots \subset D$ such that P is bounded away from zero on ∂D_j and

$$\bigcup_{j=1}^{\infty} D_j = D - \Delta.$$

From Lemma 3 we have

$$\nu_{D_j}(P_i) \to \nu_{D_j}(P) \text{ as } i \to \infty \tag{2.12}$$

for all j. In a straightforward way we obtain

$$\mu(P_i) \geqq \inf_{Q \in H^\infty(D)} \|W(1-P_iQ)\|_\infty$$
$$\geqq \inf_{Q \in H^\infty(D)} \|W(1-P_iQ)\|_{\infty,D_j}$$
$$\geqq \inf_{Q \in H^\infty(D_j)} \|W(1-P_iQ)\|_{\infty,D_j} = \nu_{D_j}(P_i)$$

for any j. Thus, combining with (2.12) we get

$$\liminf \mu(P_i) \geqq \nu_{D_j}(P) \tag{2.13}$$

for any j. Now let B_k be the inner function obtained from B by dividing out all zeros of B outside D_k. From (2.13) we obviously have

$$\liminf \mu(P_i) \geqq \nu_{D_j}(B_k) \tag{2.14}$$

for any j and k. Our next step is to establish that

$$\sup_j \mu_{D_j}(B_k) = \nu(B_k). \tag{2.15}$$

Suppose to the contrary that we can find a sequence $S_j = W - B_kQ_j$ where $Q_j \in \tilde{H}^\infty(D_j)$ and $\delta > 0$ such that $\|S_j\|_{\infty,D_j} \leqq \nu(B_k) - \delta$ for all j. Then in D_n, the sequence $S_n, S_{n+1}, \cdots$ forms a normal family (see [10, p. 300]). Thus we can find a subsequence converging uniformly on compact subsets of D_n to some $S \in \tilde{H}^\infty(D_n)$. But S can be continued analytically to D_{n+1} since the subsequence is a normal family in D_{n+1}. In fact S can be continued analytically to D and moreover $\|S\|_\infty \leqq \nu(B_k) - \delta$. But we also have that

a subsequence of $Q_j = (W - S_j)B_k^{-1}$ converges uniformly to $Q := (W - S)B_k^{-1}$ on any compact subset of D. Thus $Q \in H(D)$. Moreover

$$\|Q_j\|_{\infty, D_j} \leqq \frac{(\|W\|_\infty + \nu(B_k) - \delta)}{\inf_{z \in \partial D_j} |B_k|}.$$

Since B_k is analytic on Δ we have $\inf_{z \in \partial D_j} |B_k| \to 1$ as $j \to \infty$. Thus $|Q(z) \leqq \|W\|_\infty + \nu(B_k) - \delta$ for all $z \in D$ from which we conclude that $Q \in \tilde{H}^\infty$. This means that $\nu(B_k) \leqq \|S\|_\infty$, which is a contradiction. Hence (2.15) holds and together with (2.14) we get

$$\liminf \mu(P_i) \geqq \nu(B_k) \tag{2.16}$$

for all k. The final step of the proof is to show

$$\sup_k \mu(B_k) = \nu(B). \tag{2.17}$$

We proceed in a similar way to the above. Fist we can find a sequence $S_k = W - B_k Q_k$ where $\|S_k\|_\infty = \nu(B_k) \leqq \nu(B)$, and $Q_k \in \tilde{H}^\infty$. Again the S_k form a normal family in D and there exists an $S \in \tilde{H}^\infty$ with $\|S\|_\infty \leqq \sup_k \nu(B_k) \leqq \nu(B)$ such that (without loss of generality) the sequence S_k converges to S uniformly on compact subsets of D. But $(W - S_k)B_l^{-1}$ converges in the same way to $(W - S)B_l^{-1}$ for any fixed l. Since $(W - S_k)B_l^{-1} \in \tilde{H}^\infty$ with norm less than or equal to $\|W\|_\infty + \nu(B)$ then $(W - S)B_l^{-1} \in \tilde{H}^\infty$. But from (2.11) the singular inner part of B divides B_l for all sufficiently large l. This means that $(W - S)B^{-1} \in \tilde{H}^\infty(D)$. Hence we have $\nu(B) \leqq \|S\|_\infty$ from which (2.17) follows.

Combining (2.16), (2.17), and (2.10) gives

$$\liminf \mu(P_i) \geqq \mu(P)$$

which together with Lemma 1 shows that $\mu(P_i) \to \mu(P)$ as $i \to \infty$. □

To apply Theorem 1 we need to be able to check conditions (2.10) and (2.11) for a given P and W. Condition (2.11) is straightforward. Condition (2.10) can be checked using the following theorem (see Corollary 1) which is a generalization of results of Zames and Francis [17] and Flamm [3].

THEOREM 2. *Let $W(s) \in \tilde{H}^\infty$ be a rational outer function and write $P(s) = B(s)L(s)$ where $B(s)$ is inner and $L(s)$ is outer. Assume that $B(s)$ has no essential singularities on $j\mathbb{R}$ and that $L(s)$ is bounded away from zero on $j\mathbb{R} \cup \{\infty\}$ except at finitely many zeros z_i. Then*

$$\mu(P) = \max\{\nu(B), |W(z_i)|\}. \tag{2.18}$$

Proof. If B is rational the result is straightforward and the methods of [17] apply immediately. So assume B has an essential singularity at ∞. Then $|W(\infty)| \leqq \mu(B)$ since $|W(\infty)|$ is the essential spectral radius of the Hankel H_{WB^*} which is bounded above by $\|H_{WB^*}\| = \mu(B)$. It is also clear that $|W(z_i)| \leqq \mu(P)$ for each i. Thus $\mu(P) \geqq \max\{\nu(B), |W(z_i)|\} =: \lambda$. We first show that

$$\lambda \geqq \inf_{\substack{Q \in R\tilde{H}^\infty \\ Q(\infty) = 0}} \|W - BQ\|_\infty. \tag{2.19}$$

Consider a $Q \in \tilde{H}^\infty$ such that $\|W - BQ\|_\infty = \mu(B) \leqq \lambda$. Following Flamm [3] we let $J_n = [1/(s+1)]^{1/n} \in \tilde{H}^\infty$ (with $J_n(0) = 1$). Then

$$W - BQJ_n = W(1 - J_n) + J_n(W - BQ). \tag{2.20}$$

Since $|W(\infty)| \leqq \lambda$, for any $\varepsilon > 0$ we can find an ω_0 such that $|W(j\omega)| < \lambda + \varepsilon$ for $\omega \geqq \omega_0$. Now for $\omega \in [0, \omega_0]$ it follows from (2.20) that

$$|(W - BQJ_n)(j\omega)| \leqq \|W\|_\infty |1 - J_n(j\omega_0)| + \lambda. \tag{2.21}$$

But $|1 - J_n|$ tends to zero uniformly on $[0, \omega_0]$ so the upper bound in (2.21) tends to λ as $n \to \infty$. Further, for $\omega \in [\omega_0, \infty)$ (2.20) gives

$$\begin{aligned} |(W - BQJ_n)(j\omega)| &\leqq (\lambda + \varepsilon)|1 - J_n(j\omega)| + \lambda |J_n(j\omega)| \\ &\leqq (\lambda + \varepsilon)(1 - |J_n(j\omega)|) + \lambda |J_n(j\omega)| \\ &\quad + (\lambda + \varepsilon)|J_n(j\omega)| - |J_n(j\omega)| \\ &\leqq (\lambda + \varepsilon)\left(1 + \frac{\pi}{2n}|J_n(j\omega)|\right). \end{aligned}$$

Thus,

$$\limsup_{n \to \infty} \|W - BQJ_n\|_\infty \leqq \lambda. \tag{2.22}$$

Now for any n we can find an N such that $|Q(s)J_n(s)| < \delta/2$ for $|s| > N$, $s \in \mathbf{C}_+$ and so

$$|(QJ_n)(j\omega + \varepsilon) - (WB^*)(j\omega)| \leqq |(QJ_n)(j\omega) - (WB^*)(j\omega)| + \delta \tag{2.23}$$

for $|\omega| > N$ and any ε. Also it is clear that

$$|(QJ_n)(j\omega + \varepsilon) - (WB^*)(j\omega + \varepsilon)| \leqq \|W - BQJ_n\|_\infty$$

for $\omega \in [-N, N]$ and any ε. Since WB^* is analytic on $j\mathbb{R}$ then $(WB^*)(j\omega + \varepsilon)$ tends uniformly to $(WB^*)(j\omega)$ on $[-N, N]$, and we deduce

$$\limsup_{\varepsilon \to 0} \sup_{\omega \in [-N, N]} |(QJ_n)(j\omega + \varepsilon) - (WB^*)(j\omega)| \leqq \|W - BQJ_n\|_\infty. \tag{2.24}$$

(2.23) and (2.24) together give

$$\limsup_{\varepsilon \to 0} \|W(s) - B(s)(QJ_n)(s + \varepsilon)\|_\infty \leqq \|W - BQJ_n\|. \tag{2.25}$$

But $(QJ_n)(s + \varepsilon)$ is continuous on $\tilde{\mathbf{C}}_+$ for any ε and can thus be approximated uniformly by rational functions (Mergelyan's Theorem; see [10]). Further we can ensure that the approximants vanish at ∞. This together with (2.25) and (2.22) establishes (2.19).

We next show that (2.19) holds with the additional constraint that $Q(z_i) = 0$ for all i. There are several approaches here (e.g., [17] where $X = W - BQ$ is modified multiplicatively). The above approach for ∞ can also be used. For simplicity assume $z_1 = 0$ and let $J_n = [s/(s+1)]^{1/n}$. Then since $|J_n(j\omega)| - |J_n(j\omega)|$ tends to zero uniformly we again have

$$\limsup_{n \to \infty} \|W - BQJ_n\|_\infty \leqq \|W - BQ\|_\infty$$

for any Q. We can then approximate QJ_n uniformly with rational functions which vanish at both 0 and infinity. Each of the z_i can be dealt with similarly.

Next we observe that (2.19) holds with Q constrained to have zeros at the z_i and ∞ of arbitrary multiplicity. This follows since, for example, if $Q(0) = 0$, then $[s/(s+\varepsilon)]^l Q$ tends to Q uniformly as $\varepsilon \to 0$. We have thus shown that

$$\begin{aligned} \lambda &\geqq \inf_{\substack{Q \in R\tilde{H}^\infty \\ (s+1)Q/WL \in \tilde{H}^\infty}} \|W - BQ\|_\infty \\ &= \inf_{\substack{Q' \in \tilde{H}^\infty \\ Q'L \in \tilde{H}^\infty \cap \mathbb{R}_{sp}(s)}} \|W(1 - PQ')\|_\infty \geqq \mu(P). \end{aligned}$$

The last inequality follows since $Q'L \in \tilde{H}^\infty \cap \mathbb{R}_{sp}(s)$ implies $(1-BLQ')^{-1} \in \tilde{H}^\infty + \mathbb{R}_{pr}(s)$. Together with the obvious inequality $\mu(P) \geqq \lambda$ this completes the proof. □

COROLLARY 1. *For $W(s)$ and $P(s)$ satisfying the conditions of Theorem 2 we have $\mu(P) = \nu(P)$ if and only if $|W(z_i)| \leqq \nu(B)$ at all zeros z_i of $L(s)$ on $j\mathbb{R} \cup \{\infty\}$.*

If we write $\mu(P, W) := \mu(P) = \inf \| W(1+PF)^{-1} \|_\infty$ we can deduce the following.

COROLLARY 2. *If $P(s)$ and $W(s)$ satisfy the conditions of Theorem 2 and W_k is a sequence of rational outer functions such that $\| W_k - W \|_\infty \to 0$ as $k \to \infty$, then $\mu(P, W_k) \to \mu(P, W)$.*

Proof. Certainly $|W_k(z_i)| \to |W(z_i)|$ as $k \to \infty$. Also $\| W_k B^* - WB^* \|_\infty \to 0$ as $k \to \infty$ and so $d(W_k B^*, H^\infty) \to d(WB^*, H^\infty)$. The conclusion now follows from (2.18). □

3. H^p weighted sensitivity minimization. In this section we consider the problem:

$$\hat{\mu}(P) := \inf_{F \text{ stablz.}} \| W(1+PF)^{-1} \|_p \tag{3.1}$$

where $1 \leqq p < \infty$, $P(s) \in \tilde{H}^\infty$ and $F(s) \in \tilde{H}^\infty + \mathbb{R}_{pr}(s)$. We take $W(s)$ to be a rational outer function such that $W \in (s+1)^{-l} \tilde{H}^\infty$ where l is the least integer with $l > 1/p$ (so that $W \in \tilde{H}^p$). We will again consider the question: when does $\| P_i - P \|_\infty \to 0$ as $i \to \infty$ imply that $\hat{\mu}(P_i) \to \hat{\mu}(P)$? As for the case $p = \infty$ it is easy to show $\hat{\mu}(\cdot)$ is upper semicontinuous. Also we have in an obvious way that

$$\begin{aligned} \hat{\mu}(P) &= \inf_{\substack{Q \in \tilde{H}^\infty \\ Q/(1-PQ) \in \tilde{H}^\infty + \mathbb{R}_{pr}(s)}} \| W(1-PQ) \|_p \\ &\geqq \inf_{Q \in \tilde{H}^\infty} \| W(1-PQ) \|_p \\ &\geqq \inf_{Q \in \tilde{H}^\infty} \| W(1-BQ) \|_p =: \hat{\nu}(B). \end{aligned} \tag{3.2}$$

In fact we can prove the following result.

THEOREM 3. *For any $P(s)$ satisfying the conditions of Theorem 2*

$$\hat{\mu}(P) = \hat{\nu}(B) = \inf_{Q \in \tilde{H}^p} \| WB^* - Q \|_p = \inf_{Q \in (s+1)^{-N} \tilde{H}^\infty_-} \| WB^* - Q \|_p \tag{3.3}$$

(where $N > 0$ can be chosen arbitrarily).

Proof. Since $WQ \in \tilde{H}^p$ for any $Q \in \tilde{H}^\infty$ it immediately follows that

$$\hat{\nu}(B) \geqq \inf_{Q \in \tilde{H}^p} \| WB^* - Q) \|_p. \tag{3.4}$$

But $(s+1)^{-N} \tilde{H}^\infty_-$ is dense in $\tilde{H}^p$ for any N (see [6, pp. 59-60]), which shows the third equality in (3.3). Now given any $Q \in (s+1)^{-N} \tilde{H}^\infty_-$ we have $\| [s/(s+\varepsilon)]^r Q - Q \|_p \to 0$ as $\varepsilon \to 0$ by Lebesgue's dominated convergence theorem [10]. Thus

$$\begin{aligned} \inf_{Q \in (s+1)^{-N} \tilde{H}^\infty_-} \| WB^* - Q \|_p &= \inf_{\substack{Q \in (s+1)^{-N} \tilde{H}^\infty_- \\ Q/WL \in \tilde{H}^\infty}} \| WB^* - Q \|_p \\ &= \inf_{\substack{Q' \in \tilde{H}^\infty \\ Q'L \in (s+1)^{-N} \tilde{H}^\infty_-}} \| W(1-BLQ') \|_p \geqq \hat{\mu}(P), \end{aligned}$$

which together with (3.2) and (3.4) completes the proof. □

Theorem 3 shows that, for $1 \leqq p < \infty$, Example 1 is no longer ill-posed. More generally we have the following corollary.

COROLLARY. *If $P(s) \in \mathbb{R}_{pr}(s)$ then $\| P_i - P \|_\infty \to 0$ implies $\hat{\mu}(P_i) \to \hat{\mu}(P)$.*

Proof. Write $P = BL$ where B is inner and L is outer. Now Rouché's Theorem shows that the $\mathbf{C}_+$ zeros of P_i tend to those of P as $i \to \infty$. Thus we can write $P_i = B_i L_i$

where B_i is a finite Blaschke product (L_i not necessarily outer) and $\|B_i - B\|_\infty \to 0$ as $i \to \infty$. Now $\hat{\mu}(P_i) \geqq \hat{\mu}(B_i)$ and, since $\|WB - WB_i\|_p \to 0$ as $i \to \infty$, $\hat{\mu}(B_i) \to \hat{\mu}(B) = \hat{\mu}(P)$. Thus $\liminf \hat{\mu}(P_i) \leqq \hat{\mu}(P)$ from which the result follows by the upper semicontinuity of $\hat{\mu}(\cdot)$. □

However, the ill-posed in Example 2 remains, as we now show.

Example 2 (continued). Assume $1 < p < \infty$, $P = e^{-s}/(s+1)$ and $W = 1/(s+1)$. Then

$$\hat{\mu}(P) = \inf_{Q \in \tilde{H}^p} \left\| \frac{e^s}{s+1} - Q \right\|_p.$$

Since $e^s/(s+1) \notin \tilde{H}^p$, $\hat{\mu}(P) > 0$. In fact, for $p = 2$ we can explicitly compute $\hat{\mu}(P)$ as follows. For any $Q \in \tilde{H}^2$

$$\left\| \frac{e^s}{s+1} - Q \right\|_2^2 = \left\| \frac{e^s - e^{-1}}{s+1} \right\|_2^2 + \left\| \frac{e^{-1}}{s+1} - Q \right\|_2^2$$
$$\geqq (1 + e^{-2})\pi = \hat{\mu}(P)^2.$$

But $\|P_n - P\|_\infty \to 0$ as $n \to \infty$ where $P_n(s)$ is given by (2.5), and moreover, from Theorem 3, $\hat{\mu}(P_n) = 0$ for all n. Thus $\hat{\mu}(\cdot)$ is not continuous at P. □

Once again we can establish a general condition for continuity which parallels Theorem 1.

THEOREM 4. *For any $P \in \tilde{H}^\infty$, $\hat{\mu}(\cdot)$ is continuous at P if* (2.11) *holds.*

Proof (sketch). It is convenient to transform to the disc. This gives

$$\hat{\mu}(P) = \inf_{Q \in \tilde{H}^\infty(D)} \pi^{-1/p} \|(z-1)^{-2/p} \tilde{W}(1 - \tilde{P}\tilde{Q})\|_p$$
$$= \inf_{Q \in \tilde{H}^p(D)} \pi^{-1/p} \|\tilde{W}'(1 - \tilde{P}\tilde{Q})\|_p$$

where $\tilde{W}' = (z-1)^{-2/p}\tilde{W}$. As before, Lemma 3 holds (this time we have to bound $\|\tilde{W}'\tilde{Q}\|_p$). The proof now follows that of Theorem 1 with some modifications. We note that $\|f\|_p \geqq \|f\|_{p,D_j}$ follows from the subharmonicity of $|f|^p$ (see [10]). The two normal family arguments also go through if we work with compact subsets of the disc. □

4. Achieving continuity of performance measure. So far we have considered the problem of sensitivity minimization and have shown that optimal sensitivity is not a continuous function on H^∞. One might expect that this problem would not arise if other terms were included in the objective function, e.g., if a trade-off were sought between sensitivity and complementary sensitivity. However the problem can still occur in the latter case. Consider the following example.

Example 3. Let $P(s) = s/(s+1)$, set

$$\mu(P) = \inf_{F \text{ stablz.}} (\|W_1 PF(1+PF)^{-1}\|_\infty + \|W_2(1+PF)^{-1}\|_\infty)$$
$$= \inf_{Q \in H^\infty} (\|W_1 PQ\|_\infty + \|W_2(1-PQ)\|_\infty)$$

and suppose $\|W_1\|_\infty < |W_2(0)|$. Certainly $\mu(P) \geqq |W_2(0)|$ by considering the second term only. But $\|P_\varepsilon - P\|_\infty \to 0$ as $\varepsilon \to 0$ where $P_\varepsilon = (s+\varepsilon)/(s+1)$, and furthermore $\mu(P_\varepsilon) \leqq \|W_1\|_\infty$ (just by taking $PQ = 1$). Thus we have discontinuity at $P(s)$.

On the other hand, certain optimization problems do behave continuously. By considering the proof of Lemma 3 we can discover a way to force continuity of the performance measure. Consider a problem of the following type:

$$\mu(P) = \inf_{Q \in \mathscr{S}} m(P, Q) \tag{4.1}$$

where $\mathcal{S} \subset \tilde{H}^\infty$ and $m(\cdot,\cdot)$ is a nonnegative function on $\tilde{A}^\infty \times \mathcal{S}$. We remark that many frequency domain optimization problems take the form (4.1). In the theorem below we will show that $\mu(\cdot)$ *is continuous on* $\tilde{A}^\infty$ *at* P *if in some neighbourhood of* P *there are minimizing sequences* Q_i *which are uniformly bounded.*

THEOREM 5. *Let* $P_0 \in \tilde{A}^\infty$ *and suppose for any* $P \in \mathcal{B} := \{P \in \tilde{A}^\infty : \|P - P_0\|_\infty < \varepsilon\}$ *(some* $\varepsilon > 0$*) and* $Q \in \mathcal{S}$ *we can find* $c > 0$ *and* $W \in \tilde{H}^\infty$ *such that*

$$|m(P, Q) - m(P_0, Q)| \leqq c\|P - P_0\|_\infty \|WQ\|_p \tag{4.2}$$

whenever $WQ \in \tilde{H}^p$. *Then if there exists* $M > 0$ *such that for any* $P \in \mathcal{B}$ *we can find a sequence* $Q_i \in \mathcal{S}$ *with* $\|WQ_i\|_p < M$ *and* $m(P, Q_i) \to \mu(P)$, *then* $\mu(\cdot)$ *is continuous at* P_0.

Proof. Let $\|P_n - P_0\|_\infty \to 0$ as $n \to \infty$. Then $m(P_n, Q) \to m(P_0, Q)$ shows that $\limsup \mu(P_n) \leqq \mu(P_0)$. But for any n, we deduce from (4.2) that $\mu(P_n) \geqq \mu(P_0) - cM\|P_0 - P_n\|_\infty$. Hence $\mu(P_n) \to \mu(P)$. □

It is now easy to write down problems which are well-posed in the sense that $\mu(\cdot)$ is continuous on $\tilde{A}^\infty$.

COROLLARY. *Define* $\mu(P)$ *as in* (4.1). *Then* $\mu(\cdot)$ *is continuous on* $\tilde{A}^\infty$ *for the following choices of* $\mathcal{S}$ *and* $m(\cdot,\cdot)$

$$\mathcal{S} = \tilde{H}^\infty,\ m(P, Q) = \left\| \begin{matrix} W_1 Q \\ W_2(1 - PQ) \end{matrix} \right\|_\infty \tag{4.3}$$

$$\mathcal{S} = \{Q \in \tilde{H}^\infty : \|Q\|_\infty < M\},\ m(P, Q) = \|W(1 - PQ)\|_p \tag{4.4}$$

for any $1 \leqq p \leqq \infty$, W_1, $W_1^{-1} \in R\tilde{H}^\infty$ *and* $W \in \tilde{H}^p \cap \mathbb{R}_{sp}(s)$.

For $p = \infty$, problem (4.1+3) represents a desirable choice of design problem since there are procedures for solving this exactly in the rational case (e.g., [5], [8], and [13]). Since we are considering $P \in \tilde{A}^\infty$, it follows as in Theorem 2 that problem (4.1+3) is precisely:

$$\mu(P) = \inf_{F \text{ stablz.}} \left\| \begin{matrix} W_1 F(1 + PF)^{-1} \\ W_2(1 + PF)^{-1} \end{matrix} \right\|_\infty \tag{4.5}$$

(and similarly for (4.1+4)).

Problem (4.1+4) can be viewed as H^p weighted sensitivity minimization with a constraint on $\|Q\|_\infty$. Such a bound does make good physical sense. In the first place, Q as defined in (2.2) is the transfer function from $x_2 \to e_1$. So (4.1+4) represents a disturbance attenuation problem *subject to a disturbance to plant input power limitation.* Second, $\|Q\|_\infty < M$ guarantees a measure of robustness. If $F = Q/(1 - P_0 Q)$ stabilizes P_0 then F stabilizes any P with $\|P - P_0\|_\infty < 1/M$ (since $F(1 + PF)^{-1} = Q(1 - (P - P_0)Q)^{-1}$).

5. The robust sensitivity minimization problem (RSMP). In light of the observation in § 4, that weighted sensitivity minimization subject to a constraint on $\|Q\|_\infty$ is well-posed, it is natural to turn our attention to the problem of robust weighted sensitivity minimization. For stable plants this can be defined as follows. Let $P_0(s) \in \tilde{H}^\infty$ and define

$$\mathcal{B}(\alpha) = \{P(s) \in \tilde{H}^\infty : |(P - P_0)(j\omega)| \leqq \alpha r(j\omega)\} \tag{5.1}$$

where $r(j\omega)$ is a nonnegative L^∞-function. Then we are required to find:

$$\mu(\alpha) = \inf_{\substack{F \text{ which stabilize} \\ \text{all } P \in \mathcal{B}(\alpha)}} \sup_{P \in \mathcal{B}(\alpha)} \|W(1 + PF)^{-1}\|_\infty \tag{5.2}$$

for a given rational outer function W. The question arises whether $\mu(\alpha)$ and the associated optimal control are continuous functions of α. The answer is no, as we now show.

Example 4. Let $P_0(s) = 1/(s+2)$, $r(j\omega) = 1/|1+j\omega|$ and $W(s) = 1/(s+1)$. We claim that $\mu(\alpha)$ is discontinuous and in fact

$$\mu(\alpha) = \begin{cases} 0 & \text{for } \alpha < \frac{1}{2} \\ \geqq 1 & \text{for } \alpha \geqq \frac{1}{2}. \end{cases} \tag{5.3}$$

Clearly if $\alpha \geqq \frac{1}{2}$ then

$$P_1 = \frac{1}{s+2} - \frac{1}{2}\frac{1}{s+1} = \frac{s}{2(s+1)(s+2)} \in \mathcal{B}(\alpha).$$

Therefore for any stabilizing F, $\|W(1+P_1F)^{-1}\|_\infty \geqq |W(0)| = 1$. Thus $\mu(\alpha) \geqq 1$. Now suppose $\alpha < \frac{1}{2}$. We first claim that $F = k$ (for any $k > 0$) is a stabilizing feedback for all $P \in \mathcal{B}(\alpha)$. Write

$$(1+Pk)^{-1} = \left(1+\frac{k}{s+2}\right)^{-1}\left(1+\alpha k\Delta\left(1+\frac{k}{s+2}\right)^{-1}\right)^{-1} \tag{5.4}$$

where $\Delta(s) \in \tilde{H}^\infty$ and $|\Delta(j\omega)| \leqq 1/|1+j\omega|$. Then

$$\left\| \alpha k\Delta\left(1+\frac{k}{s+2}\right)^{-1} \right\|_\infty \leqq \left\| \frac{\alpha k(s+2)}{(s+1)(s+2+k)} \right\|_\infty \leqq 2\alpha \left\| \frac{k}{s+2+k} \right\|_\infty \leqq 2\alpha < 1.$$

Thus from (5.4) we see that $(1+Pk)^{-1} \in \tilde{H}^\infty$. Furthermore

$$\sup_{P\in\mathcal{B}(\alpha)} \|W(1+Pk)^{-1}\|_\infty \leqq \left\| \frac{1}{s+1}\left(1+\frac{k}{s+2}\right)^{-1} \right\|_\infty \cdot \frac{1}{1-2\alpha}. \tag{5.5}$$

But the right-hand side of (5.5) tends to zero as $k \to \infty$. Thus $\mu(\alpha) = 0$.

Owing to the difficulty of solving the RSMP in general a complete analysis of the well-posedness issue here seems rather hard. In the above example

$$\lim_{k\to\infty} \sup_{P\in\mathcal{B}(\alpha)} \|k(1+Pk)^{-1}\|_\infty$$

tends to infinity as $\alpha \uparrow \frac{1}{2}$. This forces a new control strategy to be adopted for $\alpha \geqq \frac{1}{2}$. Once again it turns out that if we keep

$$\sup_{P\in\mathcal{B}(\alpha)} \|F(1+PF)^{-1}\|_\infty$$

bounded then we can ensure continuity. This is the essence of the following result.

THEOREM 6. *Let $\mu(\alpha)$ be defined by*

$$\mu(\alpha) = \inf_{\substack{F \text{ which stabilize} \\ \text{all } P\in\mathcal{B}(\alpha)}} \sup_{P\in\mathcal{B}(\alpha)} m(P, F) \tag{5.6}$$

where

$$m(P, F) = \|W_1(1+PF)^{-1}\|_\infty + \|W_2F(1+PF)^{-1}\|_\infty \tag{5.7}$$

and $W_2W_2^{-1} \in \tilde{H}^\infty$. Then $\mu(\alpha)$ is continuous on $[0, \infty)$.

Proof. It is immediately clear that $\mu(\alpha_1) \leqq \mu(\alpha_2)$ for $\alpha_1 \leqq \alpha_2$. We now show that $\mu(\alpha)$ is upper semicontinuous. Let $\alpha_i \downarrow \alpha_0$. Then $\lim \mu(\alpha_i) \geqq \mu(\alpha_0)$. Now take any F which stabilizes all $P \in \mathcal{B}(\alpha_0)$. Then F stabilizes all $P \in \mathcal{B}(\alpha_i)$ for i sufficiently large since $\mathcal{B}(\alpha)$ is closed. Furthermore, defining

$$\eta(F, \alpha) := \sup_{P\in\mathcal{B}(\alpha)} m(P, F)$$

we see that $\eta(F, \alpha_i) \to \eta(F, \alpha_0)$ as $i \to \infty$, because $m(P, F)$ depends continuously on P. Thus $\lim \mu(\alpha_i) = \mu(\alpha_0)$.

Now the form of (5.7) allows us to show that $\mu(\alpha)$ is lower semicontinuous. First note that if $\hat{\alpha} \leqq \alpha_0$ and F stabilizes all $P \in \mathcal{B}(\hat{\alpha})$ with $\eta(F, \hat{\alpha}) \leqq \mu(\alpha_0)+1$ then

$$\sup_{P \in \mathcal{B}(\hat{\alpha})} \|F(1+PF)^{-1}\|_\infty \leqq \frac{\mu(\alpha_0)+1}{\|W_2^{-1}\|_\infty} =: c. \tag{5.8}$$

We now claim that, for the same F,

$$\sup_{P \in \mathcal{B}(\hat{\alpha}+d)} \|F(1+PF)^{-1}\|_\infty \leqq 2c \tag{5.9}$$

where $d := (2c \sup r(j\omega))^{-1}$. To see this take any $P \in \mathcal{B}(\hat{\alpha}+d)$ and write $P = P_1 + \Delta$ where $P_1 = P_0 + (P-P_0)\hat{\alpha}/(\hat{\alpha}+d) \in \mathcal{B}(\hat{\alpha})$ and $\Delta = (P-P_0)d/(\hat{\alpha}+d) \in \tilde{H}^\infty$, $\|\Delta\|_\infty \leqq (2c)^{-1}$. Then

$$F(1+(P_1+\Delta)F)^{-1} = F(1+P_1F)^{-1}(1+\Delta F(1+P_1F)^{-1})^{-1}$$

and it follows that $\|F(1+PF)^{-1}\|_\infty \leqq c(1-1/2)^{-1}$, which establishes (5.9). Now consider a sequence $\alpha_i \uparrow \alpha_0$ such that $\alpha_i > \alpha_0 - d$ and take a sequence of F_i (stabilizing all $P \in \mathcal{B}(\alpha_i)$) such that $\eta(F_i, \alpha_i) \leqq \mu(\alpha_i) + 1/(i+1)$. Then each F_i stabilizes all $P \in \mathcal{B}(\alpha_0)$ from (5.9). But for any $P_1 \in \mathcal{B}(\alpha_i)$, $P_2 \in \mathcal{B}(\alpha_0)$ and $F = F_i$,

$$\begin{aligned} |m(P_1, F) - m(P_2, F)| &\leqq \|W_1(1+P_1F)^{-1}(P_2-P_1)F(1+P_2F)^{-1}\|_\infty \\ &\quad + \|W_2F(1+P_1F)^{-1}(P_2-P_1)F(1+P_2F)^{-1}\|_\infty \\ &\leqq A\|P_2-P_1\|_\infty \end{aligned}$$

for some positive constant A. This means that

$$\mu(\alpha_0) \leqq \mu(\alpha_i) + 1/(i+1) + B(\alpha_0 - \alpha_i)$$

for some positive constant B, and we conclude, since $\mu(\alpha_i) \leqq \mu(\alpha_0)$ for all i, that $\mu(\alpha_i) \to \mu(\alpha_0)$ as $i \to \infty$. We have thus shown lower semicontinuity, which completes the proof. □

Remark. The theorem holds for any $m(P, F)$ which guarantees a bound of the form (5.8).

6. Unstable plants—continuity of performance measure. We now consider the class $\mathcal{P} = \tilde{A}^\infty + \mathbb{R}_{pr}(s)$. If $P \in \mathcal{P}$ then there exists $A \in \tilde{H}^\infty$, $B \in \tilde{H}^\infty$, and X, $Y \in \tilde{H}^\infty$ with

$$P = \frac{A}{B}, \qquad AX + BY = 1. \tag{6.1}$$

We define a topology on plants $P \in \mathcal{P}$ as follows ([2], [14]). We say $P_n \to P$ if we can find sequences A_n, $B_n \in \tilde{H}^\infty$ such that $P_n = A_n/B_n$ and $\|A_n - A\|_\infty + \|B_n - B\|_\infty \to 0$. It follows that for sufficiently large n there exist X_n, $Y_n \in \tilde{H}^\infty$ such that $A_nX_n + B_nY_n = 1$ and $\|X_n - X\|_\infty + \|Y_n - Y\|_\infty \to 0$ as $n \to \infty$.

It is easy to see that keeping $\|F(1+PF)^{-1}\|_\infty$ bounded is no longer sufficient to ensure continuity of a general optimization problem.

Example 5. Let $P(s) = (s+1)/s$ and consider

$$\mu(P) = \inf_{F \text{ stablz.}} (\|F(1+PF)^{-1}\|_\infty + \|WPF(1+PF)^{-1}\|_\infty)$$

where $W(0) \neq 0$. Considering the second term at $s=0$ shows $\mu(P) \geqq |W(0)|$. But $P_\varepsilon = (s+1)/(s+\varepsilon) \to P$ as $\varepsilon \to 0$ and $\mu(P_\varepsilon) = 0$ since $F = 0$ is a stabilizing feedback. Thus $\mu(\cdot)$ is not continuous at P.

To motivate a sufficient condition for continuity of the performance measure we recall that the feedback system of Fig. 1 is stable if and only if

$$F(1+PF)^{-1} \in \tilde{H}^{\infty} \quad \text{and} \quad P(1+PF)^{-1} \in \tilde{H}^{\infty}. \tag{6.2}$$

We would therefore expect that keeping the norms of both transfer functions in (6.2) bounded would force continuity. This is indeed the case for a very general class of performance criteria. To see this we observe that any stabilizing feedback for P can be written in the form $F = (X + BQ)/(Y - AQ)$ for some $Q \in \tilde{H}^{\infty}$. If we substitute for F we find that any closed loop transfer function is an affine function of Q:

$$T_1 := (1+PF)^{-1} = BY - ABQ, \tag{6.3a}$$

$$T_2 := F(1+PF)^{-1} = BX + B^2Q, \tag{6.3b}$$

$$T_3 := P(1+PF)^{-1} = AY - A^2Q, \tag{6.3c}$$

$$T_4 := PF(1+PF)^{-1} = AX + ABQ. \tag{6.3d}$$

Now define

$$\mu(P) = \inf_{F \text{ stablz.}} m(P, F)$$

where

$$m(P, F) = \sum_{i=1}^{4} \| W_i T_i \|_{\infty} = r(Q)$$

and $W_i \in R\tilde{H}^{\infty}$ are outer functions (possibly zero). Once again, we can show as in Theorem 2 that taking the infimum over *realizable* F's is equivalent to taking the infimum of $r(Q)$ over all $Q \in \tilde{H}^{\infty}$, i.e.,

$$\mu(P) = \inf_{Q \in \tilde{H}^{\infty}} r(Q). \tag{6.4}$$

Now, using the same reasoning as in the proof of Theorem 5 we can show the following result.

THEOREM 7. *Consider any sequence $P_n \to P \in \mathcal{P}$. Then $\mu(P_n) \to \mu(P)$ if for some $k > 0$ and any n sufficiently large there exists a minimizing sequence $Q_{n,i} \in \tilde{H}^{\infty}$ (i.e., $m(P_n, F_{n,i}) \to \mu(P_n)$ as $i \to \infty$ where $F_{n,i} = (X_n + B_n Q_{n,i})/(Y_n - A_n Q_{n,i})$) with $\| Q_{n,i} \|_{\infty} \leqq k$.*

COROLLARY. *If W_2^{-1}, $W_3^{-1} \in \tilde{H}^{\infty}$ then $\mu(\cdot)$ is continuous at all $P \in \mathcal{P}$.*

Proof. Consider any $P \in \mathcal{P}$. Then we can find an ε such that for any $P_1 = A_1/B_1 \in \mathcal{P}$ with $A_1X_1 + B_1Y_1 = 1$ and

$$\| A - A_1 \|_{\infty}, \quad \| B - B_1 \|_{\infty}, \quad \| X - X_1 \|_{\infty}, \quad \| Y - Y_1 \|_{\infty} < \varepsilon,$$

there holds $\mu(P_1) \leqq \mu(P) + 1$. Now if Q_i is any minimizing sequence for P_1 such that $r(Q_i) \leqq \mu(P_1) + 1$, then we certainly have

$$\| A_1 Y_1 - A_1^2 Q_i \|_{\infty} \leqq (\mu(P) + 2) \| W_2^{-1} \|_{\infty}.$$

$$\| B_1 X_1 + B_1^2 Q_i \|_{\infty} \leqq (\mu(P) + 2) / \| W_3^{-1} \|_{\infty}.$$

We therefore deduce that

$$\sup_{s \in \mathbf{C}_+} |Q_i(s)| (|A_1(s)|^2 + |B_1(s)|^2) \leqq M$$

for some constant M. But from (6.1) we have

$$\inf_{s \in \mathbf{C}_+} (|A(s)|^2 + |B(s)|^2) \geqq \delta > 0$$

for some δ. Thus by taking ε sufficiently small we obtain $\|Q_i\|_\infty \leqq 2M/\delta$ for all i. □

7. Concluding remarks.

7.1. Choice of topology. In this paper we have defined two stable plants to be close if the *absolute* error in their frequency responses is uniformly small. Alternatively we could define a stronger topology on plants by requiring that the *relative* error in their frequency responses be uniformly small, i.e., $P_n \to P$ if

$$\sup_\omega \left| \left(\frac{P_n - P}{P} \right)(j\omega) \right| \to 0 \tag{7.1}$$

as $n \to \infty$. From (7.1) it is easy to show that $\mu(P_n) \to \mu(P)$ for H^∞ weighted sensitivity minimization (or any other problem we have considered). To verify this we need to show, as in Lemma 3, that $\liminf \mu(P_n) \geqq \mu(P)$. So take any sequence $Q_n \in \tilde{H}^\infty$ such that $\|W(1-P_nQ_n)\|_\infty \leqq \mu(P_n) + 1/n$. Then clearly $\|WPQ_n\|_\infty \leqq M$ for some positive constant M. But

$$\begin{aligned} |\,\|W(1-P_nQ_n)\|_\infty - \|W(1-PQ_n\|_\infty| &\leqq \|W(P-P_n)Q_n\|_\infty \\ &\leqq \sup_\omega \left| \left(\frac{P-P_n}{P} \right)(j\omega) \right| \|WPQ_n\|_\infty \end{aligned}$$

which implies that $\liminf \|W(1-PQ_n)\|_\infty \leqq \liminf \mu(P_n)$. Hence $\mu(P_n) \to \mu(P)$. However, to strengthen the topology in this way does not really resolve the ill-posedness problem satisfactorily from the engineering point of view since the topology is *too* strong to be relevant in most physical situations. To obtain a close approximation in the sense of (7.1) would require accurate magnitude and phase information at frequencies where the magnitude of the frequency response was arbitrarily small.

7.2. Approximation of delay systems. In Example 2 $\mu(P)$ was shown to be discontinuous at $P(s) = e^{-s}/(s+1)$ by approximating $P(s)$ with a sequence of outer functions. On the other hand, if we have a sequence $P_n = B_n/(s+1)$ such that $\|P_n - P\|_\infty \to 0$ as $n \to \infty$, and further, if B_n is inner and satisfies

$$\|W(B_n^* - e^s)\|_\infty \to 0 \tag{7.2}$$

as $n \to \infty$, then $\mu(P_n) \to \mu(P)$. Thus $\mu(P)$ could be computed by a sequence of (rational) approximants to P, given appropriate choices of B_n. Such a choice is given by $B_n = (1-s/2n)^n/(1+s/2n)^n$ in case $W(s)$ is strictly proper. If $W(\infty) \neq 0$ then (7.2) fails and it is no longer clear how to guarantee $\mu(P_n) \to \mu(P)$.

7.3. Continuous dependence of control on plant. This paper has been concerned with the continuous dependence of the infimum $\mu(P)$, defined by certain minimization problems, on the plant P. A more challenging problem is to arrange for the optimal control F_{opt} to depend continuously on P. Continuity of $\mu(P)$ is by no means sufficient for this. In the H^∞ optimal sensitivity problem it is certainly possible that a rational plant satisfies $\mu(P) = \nu(B)$ and that the infimum in (2.3) is not achieved (e.g., consider a plant which is strictly proper or has a zero on the imaginary axis). In this case the map $P \to F_{\text{opt}}$ is not even well-defined. If we relax the condition that the infimum be achieved exactly, the problem then becomes to select an appropriate F from among infinitely many which are within an arbitrary ε of optimality, and moreover to do this continuously as a function of P. A similar difficulty arises if the infimum to the design problem is not achieved uniquely (which typically occurs, for example, in multivariable H^∞ optimization problems).

Acknowledgment. I would like to thank an anonymous reviewer for some helpful remarks on the manuscript.

QUADRATIC CONTROL FOR LINEAR TIME-VARYING SYSTEMS*

GIUSEPPE DA PRATO† AND AKIRA ICHIKAWA‡

Abstract. An infinite-dimensional linear time-varying system on the interval $(-\infty, \infty)$ is considered. We introduce three quadratic problems: the infinite horizon problem, and one-sided and two-sided average cost problems. A Riccati equation on $(-\infty, \infty)$ is considered first and sufficient conditions for the existence and uniqueness of a bounded solution are given. Then by dynamic programming the quadratic problems are solved. Similar problems in the stochastic case are considered.

Key words. linear quadratic control, time-varying systems

AMS(MOS) subject classifications. 49, 49C20

1. Introduction.

Consider the usual quadratic control problem:

$$y' = A(t)y + B(t)u, \qquad y(t_0) = y_0, \tag{1.1}$$

$$J(u) = \int_{t_0}^{T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \tag{1.2}$$

where A, B, M, and N, are continuous matrices on $(-\infty, \infty)$ of appropriate dimensions and where $|\ |$ and $\langle\ ,\ \rangle$ denote, respectively, the norm and the inner product of vectors. The Riccati equation associated with this problem is the following [28]:

$$Q' + A^*Q + QA + M^*M - QBN^{-1}B^*Q = 0, \tag{1.3}$$

$$Q(T) = 0. \tag{1.4}$$

There exists a unique solution to (1.3), (1.4) on $[t_0, T]$. Since t_0 is fixed but otherwise arbitrary, we can always find a solution on $(-\infty, T]$. Of course Q may not be bounded on $(-\infty, T]$. If we wish to solve the infinite horizon problem (1.1), (1.2) with $T = +\infty$, then it turns out that we need a bounded solution of (1.3) on $[t_0, \infty)$. Since t_0 can vary, we require a bounded solution on $(-\infty, \infty)$. If our system is defined only on a semi-infinite interval $[T_0, \infty)$ (thus, $t_0 \geqq T_0$), then we need a bounded solution of (1.3) on $[T_0, \infty)$ (a semi-infinite interval in the *positive* direction). If all matrices are periodic with a common period θ and if (A, B) is stabilizable and (A, M) detectable, the existence of a θ-periodic solution to (1.3) is known [31], [34]. This result remains true also in infinite dimensions [12], [14]. But the existence problem for general bounded continuous matrices seems to be new.

In this paper we consider (1.3) in infinite dimensions. We assume that $A(t)$ generates an evolution operator in a Hilbert space and that other operators are bounded and continuous. We give a necessary and sufficient condition for the existence of a bounded solution to (1.3). We have uniqueness if (A, M) is detectable. If these two hypotheses are fulfilled, there exists a unique bounded solution Q_∞. We show that the optimal control for (1.1), (1.2) with $T = \infty$ is given by the usual feedback control involving Q_∞. We introduce two quadratic problems of different kind. If (1.1) is replaced by

$$y' = A(t)y + B(t)u + f(t), \tag{1.5}$$

$$y(t_0) = y_0, \tag{1.6}$$

then a more natural cost functional is

$$J_1(u) = \overline{\lim_{T\to\infty}} \frac{1}{T} \int_{t_0}^{t_0+T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt. \tag{1.7}$$

With (1.5) we also associate

$$J_2(u) = \overline{\lim_{T\to\infty}} \frac{1}{2T} \int_{-T}^{T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt. \tag{1.8}$$

We will show that Q_∞ also characterizes optimal control of these problems. This is a generalization of the average cost criterion (usually for time-invariant systems) to time-varying systems.

In § 2 we give basic assumptions on our system (1.1), (1.2).

In § 3 we establish the existence of a bounded solution to the Riccati equation (1.3). We then characterize optimal control using Q_∞. We will show that the optimal closed-loop system for (1.1) is exponentially asymptotically stable. In § 4 we consider the stochastic case and obtain similar results. We also consider the partially observable case and show that the separation principle holds [20], [40].

An important special class of time-varying systems is that of periodic systems. See [7], [8], [22], [35], and [37] for various examples of periodic systems and their optimization problems. We have studied [17] the quadratic problem (1.5)–(1.7) and its stochastic version for periodic systems. We may allow for almost periodic inputs such as in [16].

This paper is an extension of the last two papers. Hence if we assume θ-periodicity of our system, we recover earlier results in [16] and [17].

2. Preliminaries. Let Z be a Hilbert space ($\langle\,,\rangle$ inner product, $|\ |$ norm). We will denote by $\mathscr{L}(Z)$ the Banach space of all linear bounded operators $S: Z \to Z$ endowed with the norm $|S| = \sup\{|Sz|: z \in Z, |z| \leqq 1\}$. If $S \in \mathscr{L}(Z)$ then S^* will represent its adjoint operator. S is called nonnegative ($S \geqq 0$) if S is self-adjoint and $\langle Sz, z\rangle \geqq 0$, for all $z \in Z$. We set $\mathscr{L}^+(Z) = \{S \in \mathscr{L}(Z): S \geqq 0\}$. If $L: D(L) \subset Z \to Z$ is a linear operator we denote by $\sigma(L)$ (respectively, $\rho(L)$) the spectrum (respectively, the resolvent set) of L and by $R(\lambda, L)$, $\lambda \in \rho(L)$ the resolvent operator of L.

For each interval J in $\mathbb{R}^1$ we denote by $C_S(J; \mathscr{L}(Z))$ the set of all mappings $S(t): J \to \mathscr{L}(Z)$ that are strongly continuous, that is, $S(t)z$ is continuous on J for any $z \in Z$. If J is closed and bounded, then due to the Uniform Boundedness Theorem, $C_S(J; \mathscr{L}(Z))$ is a Banach space with respect to the norm:

$$\|S\| = \sup\{|S(t);\ t \in J\}.$$

We set $C_S(J; \mathscr{L}^+(Z)) = \{S \in C_S(J; \mathscr{L}(Z));\ S(t) \geqq 0,\ t \in J\}$. If X is another Hilbert space, we denote by $\mathscr{L}(X, Z)$ the set of all bounded linear operators from X into Z and by $C_S(J; \mathscr{L}(X, Z))$ the set of all strongly continuous mappings from J into $\mathscr{L}(X, Z)$.

Let Y be a Hilbert space. We consider the initial value problem

$$y' = A(t)y + f(t), \quad y(s) = y_0, \quad t \geqq s \tag{2.1}$$

where $y_0 \in Y$ and $f \in L^2_{\text{loc}}(0, \infty; Y)$, the set of locally square integrable functions. We assume the following on $A(t)$:

(H1) (i) For any $t \in \mathbb{R}^1$, $A(t)$ is a linear operator in Y with a constant domain D dense in Y. There exist numbers $\bar{M} > 0$, $\eta \in (\pi/2, \pi)$, $\delta \in \mathbb{R}^1$ such that

$$S_{\delta,\eta} = \{\lambda \in \mathbb{C}: |\arg(\lambda - \delta)| < \eta\} \subset \rho(A(t)) \quad \forall t \in \mathbb{R}^1$$

and the resolvent operator satisfies

$$|R(\lambda, A(t))| \leqq \bar{M}/|\lambda - \delta| \quad \forall \lambda \in S_{\delta,\eta}.$$

(ii) There exist numbers $\alpha \in (0, 1)$ and $\bar{N}$ such that

$$|A(t)x - A(s)x| \leqq \bar{N}|t-s|^{\alpha}|A(0)x| \quad \forall x \in D.$$

Remark 2.1. The hypothesis (H1) has been introduced by Tanabe [36] to study the abstract equation $y' = A(t)y$ where $A(t)$'s are infinitesimal generators of analytic semigroups with constant domains (parabolic equations). In fact, in the sequel we will only need the existence of an evolution operator $U(t, s)$ relative to $A(t)$. Thus our results can be easily arranged to cover hyperbolic equations as well as parabolic equations with nonconstant domains $D(A(t))$. If A is constant, (H1) is interpreted as A being the infinitesimal generator of a C_0-semigroup. Then functional differential equations can be covered [10].

The following result is proved in [36].

PROPOSITION 2.1. *Assume* (H1). *Then there exists a family of operators* $U(t, s) \in \mathscr{L}(Y)$, $t \geqq s$ *such that*

(i) $U(s, s) = I$, $s \in \mathbb{R}^1$,
(ii) $U(\cdot, \cdot)x$ *is continuous for any* $x \in Y$,
(iii) *For* $t > s$, $U(t, s)(Y) \subset D$ *and* $U(t, s)$ *is differentiable in* t *with*

$$\frac{\partial U(t, s)}{\partial t} = A(t)U(t, s).$$

$U(t, s)$ is called the *evolution operator* relative to $A(t)$. It is called (*exponentially*) *stable* if there exist positive numbers $\tilde{M}$, ω such that $|U(t, s)| \leqq \tilde{M} e^{-\omega(t-s)}$ for any $t \geqq s$.

We denote by $A_n(t) = n^2 R(n, A(t)) - nI$ the Yosida approximations of $A(t)$ and by $U_n(t, s)$ the evolution operator relative to $A_n(t)$ (that clearly exists since $A_n(t)$'s are bounded). By using the results in [36] it is easy to prove that

$$\lim_{n\to\infty} U_n(t, s)x = U(t, s)x \quad \forall t \geqq s, \quad \forall x \in Y \tag{2.2}$$

uniformly on the bounded sets of $\mathbb{R}^2$.

We define the *mild solution* of (2.1) by

$$y(t) = U(t, s)y_0 + \int_s^t U(t, r)f(r)\, dr. \tag{2.3}$$

It is continuous on $[s, \infty)$. Let y_n be the classical solution to the problem:

$$y_n' = A_n(t)y_n + f(t), \qquad y_n(s) = y_0. \tag{2.4}$$

Then, by (2.2) $y_n(t) \to y(t)$ uniformly on any bounded subset of $[s, \infty)$.

Assume that $A(t)$ is stable. Then for each $f \in L^{\infty}([s, \infty); Y)$ (the set of bounded measurable functions in Y) $y(t)$ defined by (2.3) is bounded. We now consider for each $f \in L^{\infty}(\mathbb{R}^1; Y)$

$$y' = A(t)y + f(t) \tag{2.4'}$$

on $[-\infty, \infty)$. We say that $y(t)$ is a mild solution on $(-\infty, \infty)$ if it satisfies the integral equation

$$y(t) = U(t, s)y(s) + \int_s^t U(t, r)f(r)\, dr \tag{2.5}$$

for any $t \geqq s$. A mild solution $y(t)$ is called *bounded* if it is bounded on $(-\infty, \infty)$. If $A(t)$ is stable, then there exists a unique bounded mild solution of (2.4'). In fact it is given by

$$y(t) = \int_{-\infty}^{t} U(t, r) f(r)\, dr. \tag{2.6}$$

If A, f are θ-periodic, then y is also θ-periodic. If A is θ-periodic and f is almost periodic, then y is almost periodic [16].

3. Optimal quadratic control in the deterministic case.

3.1. Bounded solutions of a Riccati equation. We consider the usual quadratic control problem.

$$y' = A(t)y + B(t)u, \qquad y(t_0) = y_0, \tag{3.1}$$

$$J_0(u) = \int_{t_0}^{\infty} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \tag{3.2}$$

where $A(t)$ satisfies the condition (H1) and

(H2) (i) $B \in C_S(\mathbb{R}^1, \mathscr{L}(U, Y)) \cap L^\infty(\mathbb{R}^1, \mathscr{L}(U, Y))$, $M \in C_S(\mathbb{R}^1; \mathscr{L}(Y))$, $N \in C_S(\mathbb{R}^1; \mathscr{L}^+(U))$ and there exists an $\varepsilon > 0$ such that $N(t) \geqq \varepsilon$ for any $t \in \mathbb{R}^1$.

(ii) $\sup_{t\in\mathbb{R}} [|M(t)| + |N(t)|] < \infty$.

We wish to minimize $J(u)$ over the set of admissible controls

$$\mathscr{U}_{\text{ad}}^0 = \{u \in L^2([t_0, \infty); U)\text{: the corresponding mild solution } y(t) \to 0 \text{ as } t \to \infty\}. \tag{3.3}$$

To solve this problem the following Riccati equation is useful:

$$Q'(t) + A^*(t)Q(t) + Q(t)A(t) + M^*(t)M(t) - Q(t)B(t)N^{-1}(t)B^*(t)Q(t) = 0. \tag{3.4}$$

We say that Q is a mild solution of (3.4) on the interval $J \subset \mathbb{R}^1$ if $Q \in C_S(J, \mathscr{L}^+(Y))$ and if it satisfies the integral equation

$$\begin{aligned} Q(t)x &= U^*(s, t)Q(s)U(s, t)x \\ &\quad + \int_t^s U^*(r, t)[M^*(r)M(r) - Q(r)B(r)N^{-1}(r)B^*(r)Q(r)]U(r, t)x\, dr \end{aligned} \tag{3.5}$$

for any $x \in Y$ and $t \leqq s$, $t, s \in J$. If $\sup_{t\in\mathbb{R}^1} |Q(t)| < \infty$, we say that Q is a *bounded solution* of (3.4). Even if Q is a solution of the integral equation (3.5) we cannot in general prove that $Q(t)x$ is differentiable for $x \in Y$. Thus Q is not a classical solution to (3.4). Therefore it is useful to introduce approximating systems

$$Q_n' + A_n^* Q_n + Q_n A_n + M^*M - Q_n B N^{-1} B^* Q_n = 0, \tag{3.6}$$

which have classical solutions. The following result is proved in [4].

PROPOSITION 3.1. *Assume* (H1) *and* (H2). *Let* $T \in \mathbb{R}^1$ *and* $Q_0 \in \mathscr{L}^+(Y)$. *Then there exists a unique mild solution* Q *of* (3.4) *on* $(-\infty, T]$ *such that* $Q(T) = Q_0$. *Moreover, there exists a unique classical solution* $Q_n \in C_S((-\infty, T]; \mathscr{L}^+(Y))$ *to* (3.6) *with* $Q_n(T) = Q_0$ *and* $Q_n(t)x \to Q(t)x$ *as* $n \to \infty$ *for any* $x \in Y$ *uniformly on any bounded subset of* $(-\infty, T]$.

In the sequel we set $Q(t) = \Lambda(t; T, Q_0)$, $Q_n(t) = \Lambda_n(t; T, Q_0)$. The following monotonicity property of $\Lambda(\Lambda_n)$ is well known:

$$\begin{aligned} &\Lambda(t; T, Q_0) \leqq \Lambda(t; T, Q_1), \\ &\Lambda_n(t, T, Q_0) \leqq \Lambda_n(t, T, Q_1) \quad \text{if } Q_0 \leqq Q_1. \end{aligned} \tag{3.7}$$

Now we will establish a bounded solution to (3.4). Let $C_b(\mathbb{R}^1; Z)$ be the space of all bounded continuous functions from $\mathbb{R}^1$ to Z. The fundamental hypothesis for the existence of a bounded solution is the following:

(H3) For any $t_0 \in \mathbb{R}$ and $y_0 \in Y$ there exist $u \in C_b(\mathbb{R}^1; U)$ and $C_0 > 0$ such that

$$\int_{t_0}^{\infty} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \leqq C_0 |y_0|^2$$

where y is the mild solution to (3.1).

Hypothesis (H3) is slightly weaker than the existence of an admissible control. It is satisfied, as we will see below, if (A, B) is *stabilizable*, that is, if there exists $K \in C_S(\mathbb{R}^1; \mathscr{L}(Y, U))$ bounded such that the evolution operator relative to $A - BK$ is stable (such an evolution operator does exist since BK is bounded [10]).

Assume that (A, B) is stabilizable so that for some K

$$|U_K(t, s)| \leqq M_0\, e^{-\omega(t-s)}, \qquad t \geqq s \quad \text{for some } M_0 \geqq 1 \text{ and } \omega > 0 \tag{3.8}$$

where U_K is the evolution operator relative to $A - BK$. Now we will show that the hypothesis (H3) is fulfilled. Set

$$y(t) = U_K(t, t_0)y_0, \qquad u(t) = -K(t)U_K(t, t_0)y_0.$$

Then

$$\int_{t_0}^{\infty} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \leqq \frac{M_0^2}{2\omega}(\|M\|^2 + \|N\|\,\|K\|^2)$$

where $\|\cdot\| = \sup_{t \in \mathbb{R}^1} |\cdot|$.

The main result for our Riccati equation is the following theorem.

THEOREM 3.1. *Assume* (H1) *and* (H2). *Then a nonnegative bounded solution to* (3.4) *exists if and only if* (H3) *holds.*

Proof. If. Assume (H3). For any $\alpha \in \mathbb{R}^1$ set $Q_\alpha = \Lambda(\cdot; \alpha, 0)$. By (3.7) we have

$$Q_\alpha(t) \leqq Q_\beta(t) \quad \text{if } t \in (-\infty, \alpha] \text{ and } \alpha \leqq \beta. \tag{3.9}$$

Thus $\{Q_\alpha\}$ is increasing in α. We will now show that $\|Q_\alpha(\cdot)\|$ is bounded. Let $Q_{\alpha,n} = \Lambda_n(\cdot; \alpha, 0)$ and let y_n be the classical solution to the initial value problem:

$$y_n' = A_n(t)y_n + B(t)u, \qquad y_n(t_0) = y_0 \tag{3.10}$$

where u is the control function given in (H3). We then have

$$\begin{aligned} \frac{d}{dt}\langle Q_{\alpha,n}(t)y_n(t), y_n(t)\rangle &= \|N^{1/2}(u + N^{-1}B^*Q_{\alpha,n}y_n)|^2 - |M(t)y_n(t)|^2 \\ &\quad - \langle N(t)u(t), u(t)\rangle. \end{aligned} \tag{3.11}$$

Integrating this from t_0 to α and letting $n \to \infty$, we arrive at

$$\begin{aligned} &\int_{t_0}^{\alpha} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \\ &\quad = \langle Q_{\alpha,n}(t_0)y_0, y_0\rangle + \int_{t_0}^{\alpha} |N^{1/2}(u + N^{-1}B^*Q_{\alpha,n}y_n)|^2\, dt, \end{aligned} \tag{3.12}$$

which yields

$$\langle Q_\alpha(t_0)y_0, y_0\rangle \leqq C_0|y_0|^2 \quad \text{for any } y_0 \in Y. \tag{3.13}$$

By a classical argument we can show that there exists $Q_\infty(t)$ such that

$$\lim_{\alpha\to\infty} Q_\alpha(t_0)y_0 = Q_\infty(t_0)y_0 \quad \text{for any } t_0\in\mathbb{R}^1 \text{ and } y_0\in Y. \tag{3.13'}$$

To prove that Q_∞ is a mild solution of (3.4) on $(-\infty,\infty)$ it suffices to let $\alpha\to\infty$ in the equality:

$$\begin{aligned} Q_\alpha(t)x = {} & U^*(s,t)Q_\alpha(s)U(s,t) \\ & + \int_t^s U^*(r,t)[M^*(r)M(r) \\ & - Q_\alpha(r)BN^{-1}BQ_\alpha(r)]U(r,t)\,dr \end{aligned} \tag{3.14}$$

for $t\leqq s<\alpha$.

Only if. Let Q be a bounded solution to (3.4). For a fixed but otherwise arbitrary $T\in\mathbb{R}^1$, let $Q_n=\Lambda_n(\cdot, T; Q(T))$. Set $K=BN^{-1}B^*$, $L=A-KQ$, $L_n=A_n-KQ_n$ and let U_L and U_{L_n} be evolution operators relative to L and L_n, respectively. Then

$$Q_n'+L_n^*Q_n+Q_nL_n+M^*M+Q_nKQ_n=0, \qquad Q_n(T)=Q(T). \tag{3.15}$$

Hence, for any $t_0\leqq t\leqq T$, we have

$$\begin{aligned} & \frac{d}{dt}\langle Q_n(t)U_{L_n}(t,t_0)y_0,\, U_{L_n}(t,t_0)y_0\rangle \\ & \quad = -|M(t)U_{L_n}(t,t_0)y_0|^2-|\sqrt{K(t)}Q_n(t)U_{L_n}(t,t_0)y_0|^2. \end{aligned} \tag{3.16}$$

Integrating this from t_0 to t_1 and letting $n\to\infty$, we obtain

$$\begin{aligned} & \int_{t_2}^{t_1}[|M(t)U_L(t,t_0)y_0|^2+|\sqrt{K(t)}Q(t)U_L(t,t_0)y_0|^2]\,dt \\ & \quad +\langle Q(t_1)U_L(t_1,t_0)y_0, U_L(t_1,t_0)y_0\rangle = \langle Q(t_0)y_0, y_0\rangle. \end{aligned} \tag{3.17}$$

Now set

$$y(t)=U_L(t,t_0)y_0, \qquad u(t)=-N^{-1}(t)B^*(t)Q(t)U_L(t,t_0)y_0.$$

Then $u\in C_b(\mathbb{R}^1; U)$ and y is a mild solution of (3.1). Moreover,

$$\int_{t_0}^{t_1}[|M(t)y|^2+\langle N(t)u,u\rangle]\,dt \leqq \sup_{t_0\in\mathbb{R}}|Q(t_0)||y_0|^2, \qquad t_0\leqq t_1\leqq T.$$

Since t_1 is arbitrary, we have shown (H3). □

If (H1)-(H3) hold, we will denote by Q_∞ the bounded solution of (3.4) defined by (3.13). We remark that Q_∞ is minimal among all solutions $Q\geqq 0$ of (3.4) on $\mathbb{R}^1$, that is,

$$Q(t)\geqq Q_\infty(t), \qquad t\in\mathbb{R}^1. \tag{3.18}$$

In fact if Q is a solution of (3.4) on $\mathbb{R}^1$, we have

$$Q(\alpha)\geqq Q_\alpha(\alpha)=0$$

so that

$$Q(t)\geqq Q_\alpha(t) \quad \text{for any } t\in(-\infty,\alpha].$$

Letting $\alpha\to\infty$ we obtain (3.18). We will call Q_∞ the *minimal solution* of (3.4) on $\mathbb{R}^1$.

Next we will examine the stability property of a bounded solution Q of (3.4). Set $L = A - KQ$, $K = BN^{-1}B^*$ and for a fixed $T \in \mathbb{R}^1$ let $Q_1(\cdot) = \Lambda(\cdot; T, S)$, where $S \in \mathscr{L}^+(Y)$. Then we can easily check that $Z = Q_1 - Q$ is a mild solution of the equation

$$Z' + L^*Z + ZL - ZKZ = 0, \qquad Z(T) = S - Q(T). \tag{3.19}$$

If U_L is stable, the usual linearization arguments show that Q is uniformly asymptotically stable as $t \to -\infty$ [23]. But as we will see below we can show that Q is attractive from above, and hence it is maximal among all bounded nonnegative solutions of (3.4). This will imply, in particular, the uniqueness of a nonnegative bounded solution for which L is stable. We say that a bounded solution Q of (3.4) is *stable* if $A - KQ$ is stable.

PROPOSITION 3.2. *Assume* (H1) *and* (H2) *and let Q be a stable bounded nonnegative solution to* (3.4). *Let $T \in \mathbb{R}^1$, $S = \mathscr{L}^+(Y)$ be arbitrary and set $Q_1(\cdot) = \Lambda(\cdot; T, S)$. If $S \geqq Q(T)$, then*

$$\lim_{t \to -\infty} (Q_1(t)x - Q(t)x) = 0 \quad \textit{for any } x \in Y.$$

$Q_1(\cdot)$ with arbitrary $S \geqq 0$ is bounded on $(-\infty, T]$.

Moreover, if Q_2 is a bounded solution, then $Q_2(t) \leqq Q(t)$, $t \in \mathbb{R}$.

Proof. Let $Z = Q_1 - Q$, $Q_n = \Lambda_n(\cdot; T, Q(T))$, $Q_{1n} = \Lambda_n(\cdot; T, S)$, and define $Z_n = Q_{1n} - Q_n$, $L_n = A_n - KQ_n$. Then

$$Z_n' + L_n^* Z_n + Z_n L_n - Z_n K Z_n = 0, \tag{3.20}$$

from which follows

$$\frac{d}{dt}\langle Z_n(t) U_{L_n}(t, t_0)y_0, U_{L_n}(t, t_0)y_0\rangle = |\sqrt{K(t)}\, Z_n(t) U_{L_n}(t, t_0)y_0|^2. \tag{3.21}$$

Integrating from t_0 to t and letting $n \to \infty$, we obtain

$$\langle Z(t) U_L(t, t_0)y_0, U_L(t, t_0)y_0\rangle \geqq \langle Z(t_0)y_0, y_0\rangle, \qquad t_0 \leqq t. \tag{3.22}$$

Now, if $S \geqq Q(T)$ then $Z(t_0) \geqq 0$ for any $t_0 \leqq T$. Letting $t_0 \to -\infty$ in (3.22), we obtain $\langle Z(t_0)y_0, y_0\rangle \to 0$ as $t_0 \to -\infty$. Hence $\lim_{t \to -\infty} Z(t)x = 0$ for any $x \in Y$. Assume now that Q_2 is another nonnegative bounded solution of (3.4). Then replacing Q_1 by Q_2 in (3.22) and letting $t \to \infty$ we find $\langle Z(t_0)y_0, y_0\rangle \leqq 0$ so that $Q_2(t) \leqq Q(t)$. □

Now we give a sufficient condition for a bounded nonnegative solution of (3.4) being stable:

(H4) There exists a $K_1 \in C_S(\mathbb{R}^1; \mathscr{L}(Y))$ bounded such that $A - K_1 M$ is stable.

If (H4) holds, we say that (A, M) is *detectable.*

PROPOSITION 3.3. *Assume* (H1), (H2), *and* (H4). *Then any bounded nonnegative solution of* (3.4) *is stable. Thus the Riccati equation* (3.4) *has at most one bounded nonnegative solution.*

Proof. Let $t_0 \in \mathbb{R}$ be fixed and let $y_0 \in Y$. Then by (3.17) we have

$$M(t) U_L(t, t_0)y_0, \qquad \sqrt{K(t)}\, Q(t) U(t, t_0)y_0 \in L^2(t_0, \infty; Y). \tag{3.23}$$

Let $S = A - K_1 M$; then $L = S + K_1 M - KQ$ so that

$$U_L(t, t_0)y_0 = U_S(t, t_0)y_0 - \int_{t_0}^{t} U_S(t, r)(K_1 M - KQ) U_L(r, t_0)y_0\, dr. \tag{3.24}$$

Since U_S is stable, it follows from (3.23), (3.24) that $U_L(t, t_0)y_0 \in L^2(t_0, \infty; Y)$. By Datko [19] U_L is stable.

The uniqueness follows from the fact that a stable solution is maximal. □

In practice it may be more natural to assume that the system (3.1) is defined only on $[T_0, \infty)$ so that $T_0 \geqq T_0 < \infty$. In this case we restrict the hypothesis (H1)-(H4) on $[T_0, \infty)$. We need to modify the definitions.

For example, we say that (A, B) is stabilizable if there exists $K \in C_S([T_0, \infty); L(Y, U))$ bounded such that $|U_{A-BK}(t, s)| \leqq M_0 e^{-\omega(t-s)}$, $t \geqq s \geqq T_0$ for some $M_0 \geqq 1$ and $\omega > 0$. Now all the results restricted on $[T_0, \infty)$ are true. In fact, we have the following corollaries.

COROLLARY 3.1. *Assume* (H1) *and* (H2) *on* $[T_0, \infty)$. *Then a nonnegative bounded solution of* (3.4) *on* $[T_0, \infty)$ *exists if and only if* (H3) *holds on* $[T_0, \infty)$.

COROLLARY 3.2. *Assume* (H1) *and* (H2) *on* $[T_0, \infty)$. *Let* Q *be a stable nonnegative bounded solution of* (3.4) *on* $[T_0, \infty)$. *Then for any bounded solution* $Q_2 \geqq 0$ *of* (3.4), $Q_2(t) \leqq Q(t)$, $t \in [T_0, \infty)$, *that is* Q *is maximal.*

COROLLARY 3.3. *Assume* (H1), (H2), *and* (H4) *on* $[T_0, \infty)$. *Then any nonnegative bounded solution of* (3.4) *is stable. Thus the Riccati equation* (3.4) *has at most one nonnegative bounded solution on* $[T_0, \infty)$.

Finally, we consider two special cases of (3.4): the periodic case and the time invariant case.

In the former we assume (H5).

(H5) There exists a number $\theta > 0$ such that $A(t+\theta) = A(t)$, $B(t+\theta) = B(t)$, $M(t+\theta) = M(t)$, and $N(t+\theta) = N(t)$ for all $t \in \mathbb{R}^1$.

In this case we say that these operators are θ-periodic. We say also that the system (3.1) is θ-periodic. If Q is a bounded solution to (3.4), then $Q_\theta(t)$ defined by

$$Q_\theta(t) = Q(t-\theta), \qquad t \in \mathbb{R}^1$$

is also a bounded solution. Thus if (3.4) has a unique nonnegative bounded solution Q (for example, if (A, M) is detectable) we have $Q(t) = Q(t-\theta)$. In fact, we have Proposition 3.4.

PROPOSITION 3.4. *Assume* (H1), (H3), *and* (H5). *Then the minimal solution* Q_∞ *of* (3.4) *is* θ*-periodic. If, further,* (H4) *holds, then* Q_∞ *is the unique nonnegative* θ*-periodic solution to* (3.4) *and it is uniformly asymptotically stable.*

Proof. Let n be an integer and set

$$V(t) = Q_{n\theta}(t-\theta), \qquad t \in (-\infty, (n+1)\theta] \tag{3.25}$$

where $Q_{n\theta} = \Lambda(\cdot; n\theta, 0)$. Since the coefficients of (3.4) are θ-periodic, V is also a solution of (3.4) on $(-\infty, (n+1)\theta]$. Moreover, $V((n+1)\theta) = Q_{n\theta}(n\theta) = 0$ so that

$$V(t) = Q_{(n+1)\theta}(t) = Q_{n\theta}(t-\theta). \tag{3.26}$$

Now, letting $n \to \infty$ we obtain $Q_\infty(t) = Q_\infty(t-\theta)$. Thus Q_∞ is θ-periodic. Other assertions follow from Proposition 3.2. □

Next we show the global orbital attractiveness of Q_∞.

PROPOSITION 3.5. *Assume* (H1)-(H5). *Let* $S_0 \in \mathscr{L}^+(Y)$ *and set* $Q = \Lambda(\cdot; 0, S_0)$. *Then*

$$\lim_{n\to\infty} Q(t-n\theta)x = Q_\infty(t)x \quad \forall t \in (-\infty, 0]. \tag{3.27}$$

Proof. Let m be an integer such that

$$S_0 \leqq mI \quad \text{and} \quad Q_\infty(0) \leqq mI.$$

Let $V(\cdot) = \Lambda(\cdot; 0, mI)$. Then

$$Q(t) \geqq Q_0(t) \quad \forall t \leqq 0,$$

$$Q(t - n\theta) \geqq Q_0(t - n\theta) = Q_{n\theta}(t) \quad \forall t \leqq n\theta.$$

This implies

$$Q_{n\theta}(t) \leqq Q(t - n\theta) \leqq V(t - n\theta).$$

But $Q_{n\theta}(t)x \to Q_\infty(t)x$ as $n \to \infty$ and $V(t - n\theta)x \to Q_\infty(t)x$ by Proposition 3.2. Thus (3.27) follows. □

Remark 3.1. In Da Prato [12] the existence of a periodic solution to (3.4) is shown under (H1), (H2), (H5), and stabilizability of (A, B). Hence, Proposition 3.4 gives a weaker condition. Proposition 3.5 is also an improvement of Lemma 3.1 [17]. See [31] and [34] for finite-dimensional results.

Now consider the time-invariant case: A, B, M, and N are independent of t. Then (H1) can be replaced by the hypothesis that A is the infinitesimal generator of a C_0-semigroup e^{tA}. Hypothesis (H2) simply implies $B \in \mathscr{L}(U, Y)$, $M \in \mathscr{L}(Y)$, and $N, N^{-1} \in \mathscr{L}^+(U)$. Hypothesis (H4) is the usual detectability condition [39], [41]. Hence we recover the results of Zabczyk [41].

PROPOSITION 3.6. *Suppose that A is the infinitesimal generator of a C_0-semigroup e^{tA} and that $B \in \mathscr{L}(U, Y)$, $M \in \mathscr{L}(Y)$, and $N, N^{-1} \in \mathscr{L}^+(U)$. Suppose (H3) holds. Then $Q_\infty(t) = Q_\infty$ is independent of t and is the minimal solution of the algebraic Riccati equation*

$$A^*Q + QA + M^*M - QBN^{-1}B^*Q = 0. \tag{3.28}$$

If, further, (A, M) is detectable, then Q_∞ is the unique nonnegative solution to (3.20) *in $\mathscr{L}^+(Y)$. Moreover, for each $Q = \Lambda(\cdot, \cdot, S_0)$ with $S_0 \in \mathscr{L}^+(Y)$*

$$\overline{\lim_{t \to -\infty}}\, Q(t)x = Q_\infty x \quad \forall x \in Y.$$

3.2. Quadratic control on the infinite horizon. Let $-\infty \leqq T_0 < \infty$ and let $t_0 \in [T_0, \infty)$ be arbitrary. If $T_0 = -\infty$, we mean by $[T_0, \infty)$, the whole real line $(-\infty, \infty)$. Now consider our control problem

$$y' = A(t)y + B(t)u, \qquad y(t_0) = y_0, \tag{3.1}$$

$$J_0(u) = \int_{t_0}^{\infty} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt. \tag{3.2}$$

We assume (H1)-(H4) on $[T_0, \infty)$ and wish to minimize $J_0(u)$ over

$$\mathscr{U}_{\text{ad}}^0 = \{u \in L^2(t_0, \infty; U)\text{: the corresponding mild solution } y(t) \to 0 \text{ as } t \to \infty\}. \tag{3.3}$$

In view of (H3), (H4), this problem is nontrivial. Let Q_∞ be the unique stable nonnegative bounded solution of (3.4) on $[T_0, \infty)$. The main tool we will use is the following identity.

LEMMA 3.1. *Assume* (H1)-(H3) *on* $[T_0, \infty)$. *Let* $u \in L^2([t_1, t_2]; U)$, $t_0 \leqq t_1 < t_2$ *and let y be the mild solution of* (3.1) *on* $[t_1, t_2]$. *Then*

$$\begin{aligned} &\int_{t_1}^{t_2} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt + \langle Q_\infty(t_2)y(t_2), y(t_2)\rangle \\ &\quad = \int_{t_1}^{t_2} |N^{1/2}(u + N^{-1}B^*Q_\infty y)|^2\, dt + \langle Q_\infty(t_1)y(t_1), y(t_1)\rangle. \end{aligned} \tag{3.29}$$

Proof. Let $Q_n = \Lambda_n(\cdot\,; t_2, Q_\infty(t_2))$ and let y_n be the solution of the initial value problem

$$y_n' = A_n(t)y_n + B(t)u, \qquad y_n(t_1) = y(t_1).$$

Then we have

$$\frac{d}{dt}\langle Q_n(t)y_n(t), y_n(t)\rangle = |N^{1/2}(u + N^{-1}B^*Q_n y_n)|^2 - |M(t)y_n|^2 - \langle N(t)u, u\rangle.$$

Integrating this from t_1 and t_2 and passing to the limit $n \to \infty$, we obtain (3.29).

Now it is easy to solve our control problem.

THEOREM 3.2. *Assume* (H1)-(H4) *on* $[T_0, \infty)$. *Then the optimal control is given by the feedback law*

$$\bar{u} = -N^{-1}B^*Q_\infty \bar{y} \tag{3.30}$$

and the optimal cost by

$$J_0(\bar{u}) = \langle Q_\infty(t_0)y_0, y_0\rangle. \tag{3.31}$$

The optimal closed loop system is stable. If, further, (H5) *holds, then* Q_∞ *is* θ*-periodic. If all operators in* (3.1), (3.2) *are time invariant, then* Q_∞ *is constant.*

Proof. We set $t_1 = t_0$ and pass to the limit $t_2 \to \infty$. Since $y(t_2) \to 0$ as $t_2 \to \infty$ we obtain

$$J_0(u) = \int_{t_0}^{\infty} |N^{1/2}(u + N^{-1}B^*Q_\infty y)|^2\, dt + \langle Q_\infty(t_0)y_0, y_0\rangle.$$

Thus the conclusion follows immediately. □

3.3. The optimal control problem with average cost. Assume (H1), (H2) on $[T_0, \infty)$. Here we are concerned with a more general system

$$y' = A(t)y + B(t)u + f(t), \qquad y(t_0) = y_0 \tag{3.32}$$

where $t_0 \in [T_0, \infty)$ is fixed but otherwise arbitrary and $f \in C_b([T_0, \infty), Y)$. In this case we cannot expect that the cost $J_0(u)$ is finite. Instead we take a more reasonable cost

$$J_1(u) = \overline{\lim_{T\to\infty}} \frac{1}{T} \int_{t_0}^{t_0+T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \tag{3.33}$$

and we wish to minimize it over

$$\mathcal{U}'_{ad} = \left\{ u: \overline{\lim_{T\to\infty}} \frac{1}{T} \int_{t_0}^{t_0+T} |u(t)|^2\, dt < \infty \text{ and the mild solution } y(t) \text{ of (3.32) is bounded on } [t_0, \infty) \right\}. \tag{3.34}$$

We further assume (H3) and let Q_∞ be the minimal bounded solution of (3.4) on $[T_0, \infty)$.

Let $L = A - KQ_\infty$, $K = BN^{-1}B^*$ and consider the following equation:

$$r' + L^*r + Q_\infty f = 0. \tag{3.35}$$

Then we have a similar result to Lemma 3.1.

LEMMA 3.2. *Assume* (H1)-(H3) *on* $[T_0, \infty)$. *Let* $u \in L^2([t_1, t_2]; U)$, $t_0 \leqq t_1 < t_2$, *and let* y *and* r *be mild solutions of* (3.32), (3.35) *on* $|t_1, t_2|$, *respectively. Then*

$$\begin{aligned}\int_{t_1}^{t_2} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt + \langle Q_\infty(t_2)y(t_2), y(t_2)\rangle + 2\langle r(t_2), y(t_2)\rangle \\ = \int_{t_1}^{t_2} |N^{1/2}[u + N^{-1}B^*(Q_\infty y + r)]|^2\, dt \\ + \int_{t_1}^{t_2} [2\langle r, f\rangle - |N^{-1/2}B^* r|^2]\, dt \\ + \langle Q_\infty(t_1)y(t_1), y(t_1)\rangle + 2\langle r(t_1), y(t_1)\rangle.\end{aligned} \tag{3.36}$$

Proof. We take

$$\begin{aligned} &Q_n(\cdot) = \Lambda_n(\cdot\,; t_2, Q_\infty(t_2)), \\ &y_n' = A_n y_n + Bu + f, \qquad y_n(t_1) = y(t_1), \\ &r_n' + (A_n - KQ_n)^* r_n + Q_n f = 0, \qquad r_n(t_2) = r(t_2)\end{aligned}$$

and show

$$\begin{aligned}\frac{d}{dt}[\langle Q_n y_n, y_n\rangle + 2\langle r_n, y_n\rangle] = |N^{1/2}[u + N^{-1}B^*(q_n y_n + r_n)]|^2 \\ - |My_n|^2 - \langle Nu, u\rangle + 2\langle r_n, f_n\rangle - |N^{-1/2}B^* r_n|^2.\end{aligned}$$

Integrating this from t_1 to t_2 and passing to the limit $n \to \infty$, we obtain (3.36).

It we further assume (H4) on $[T_0, \infty)$, then $\mathcal{U}'_{\mathrm{ad}}$ is not empty. To see this, note that there exists a unique bounded solution to (3.35) given by

$$r(t) = \int_t^\infty U_L^*(s, t) Q_\infty(s) f(s)\, ds, \tag{3.37}$$

since L is stable. Now consider the feedback control

$$\bar{u} = -N^{-1}B^*(Q_\infty \bar{y} + r). \tag{3.38}$$

Then the closed-loop system is

$$\bar{y}' = L\bar{y} + f - Kr, \qquad \bar{y}(t_0) = y_0. \tag{3.39}$$

Since L is stable, the mild solution

$$\bar{y}(t) = U_L(t, t_0)y_0 + \int_{t_0}^t U_L(t, s)[f(s) - K(s)r(s)]\, ds \tag{3.40}$$

is bounded on $[t_0, \infty)$. Hence u is admissible.

THEOREM 3.3. *Assume* (H1)-(H4) *on* $[T_0, \infty)$. *Then the optimal control is given by the feedback law* (3.38) *and the optimal cost by*

$$J_1(\bar{u}) = \overline{\lim_{T\to\infty}} \frac{1}{T} \int_{t_0}^{t_0+T} [2\langle r, f\rangle - |N^{-1/2}B^* N|^2]\, dt. \tag{3.41}$$

Proof. We take any $u \in \mathcal{U}'_{\mathrm{ad}}$ and its response y in (3.36). Then, setting $t_1 = t_0$, $t_2 = t_0 + T$ and taking limit supremum as $T \to \infty$, we obtain

$$J_1(\bar{u}) = \overline{\lim_{T\to\infty}} \frac{1}{T} \int_{t_0}^{t_0+T} \{|N^{1/2}[u + N^{-1}B^*(Qy + r)]|^2 + 2\langle r, f\rangle - |N^{-1/2}B^* r|^2\}\, dt. \tag{3.42}$$

Now the assertion follows easily. □

If we assume (H5), then we recover the periodic result in [16].

COROLLARY 3.4. *Assume* (H1)-(H4) *on* $[T_0, \infty)$.

(i) *If* (H5) *holds on* $[T_0, \infty)$ *and if* f *is* θ*-periodic, then* Q_∞ *and* r *are* θ*-periodic and*

$$J_1(\bar{u}) = \frac{1}{\theta}\int_{t_0}^{t_0+\theta} [2\langle r, f\rangle - |N^{-1/2}B^*r|^2]\,dt \quad \text{for any } t_0 \geqq T_0. \tag{3.43}$$

(ii) *If all operators in* (3.32), (3.33), *and* f *are constant, then* Q_∞ *is the unique solution of the algebraic Riccati equation* (3.28) *and*

$$J_1(\bar{u}) = 2\langle r, f\rangle - |N^{-1/2}B^*r|^2 \tag{3.44}$$

where $r = -(L^*)^{-1}Q_\infty f$.

3.4. The optimal control problem with average cost II. Here we assume (H1) and (H2). Our system is

$$y' = A(t)y + B(t)u + f(t) \tag{3.45}$$

where $f \in C_b(\mathbb{R}^1; Y)$. We wish to minimize the average cost

$$J_2(u) = \overline{\lim_{T\to\infty}} \frac{1}{2T}\int_{-T}^{T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\,dt, \tag{3.46}$$

over

$$\mathcal{U}_{\text{ad}}^2 = \left\{ u: \overline{\lim_{T\to\infty}} \frac{1}{2T}\int_{-T}^{T} |u(t)|^2\,dt < \infty \right. \tag{3.47}$$
$$\left. \text{such that there exists a bounded solution to (3.45)} \right\}.$$

If (H3) holds, then Lemma 3.2 is valid. If, further, (H4) holds, then L is stable and there exists a unique bounded solution to (3.35). Thus as in Theorem 3.3 we have Theorem 3.4.

THEOREM 3.4. *Assume* (H1)-(H4). *Then optimal control is given by the feedback law*

$$\bar{u} = -N^{-1}B^*(Q_\infty \bar{y} + r) \tag{3.48}$$

where Q_∞ *is the unique bounded nonnegative stable solution to* (3.4) *and* r *is the unique bounded solution on* $\mathbb{R}^1$ *of the equation*

$$r' + L^*r + Q_\infty f = 0 \tag{3.49}$$

given by

$$r(t) = \int_t^\infty U_L^*(s, t)Q_\infty(s)f(s)\,ds, \qquad t \in \mathbb{R}^1. \tag{3.50}$$

The optimal cost is given by

$$J_2(\bar{u}) = \overline{\lim_{T\to\infty}} \frac{1}{2T}\int_{-T}^{T} [2\langle r, f\rangle - |N^{-1/2}B^*r|^2]\,dt. \tag{3.51}$$

The optimal response $\bar{y}$ *is*

$$\bar{y}(t) = \int_{-\infty}^{t} U_L(t, s)[f(s) - K(s)r(s)]\,ds \tag{3.52}$$

and y is exponentially asymptotically stable (i.e., $y(t; t_0, y_0) - y(t) \to 0$, as $t \to \infty$ where $y(t; t_0, y_0)$ is the solution of (3.39)).

COROLLARY 3.5. *Assume* (H1)-(H4).

(i) *If* (H5) *also holds and if f is θ-periodic, then Q_∞ and r are θ-periodic and*

$$J_2(\bar{u}) = \frac{1}{\theta}\int_0^\theta [2\langle r, f\rangle - |N^{-1/2}B^*r|^2]\,dt = J_1(\bar{u}). \tag{3.53}$$

(ii) *If all operators and f are constant, then Q_∞, r are constant and given as in Corollary* 3.4. *Moreover,*

$$J_2(\bar{u}) = 2\langle r, f\rangle - |N^{-1/2}B^*r|^2 = J_1(\bar{u}). \tag{3.54}$$

Finally, we will consider another special case of Theorem 3.4. Let $AP(\mathbb{R}^1; Z)$ be the Banach space of almost periodic functions in Z [1], [16], [21]. We assume $f \in AP(\mathbb{R}^1; Y)$. We assume (H1)-(H5) so that Q_∞ is the unique nonnegative θ-periodic solution of (3.4). Then L is stable and $r(t)$, given by (3.50), is the unique almost periodic solution of (3.45). Moreover $\bar{y}$, given in (3.52), is also the unique almost periodic solution of the closed system

$$\bar{y}' = L\bar{y} + f - Kr. \tag{3.55}$$

Hence the following problem is meaningful [16]. Minimize

$$J_{\text{ap}}(u) = \lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\,dt \tag{3.56}$$

over the set of admissible controls

$$\begin{aligned}\mathcal{U}_{\text{ap}} = \{u \in AP(\mathbb{R}^1, U)&\text{: there exists } y \in AP(\mathcal{R}^1; Y)\\ &\text{which is a mild solution of (3.45)}\}.\end{aligned} \tag{3.57}$$

Now we find the optimal almost periodic control given in [16].

COROLLARY 3.6. *Assume* (H1)-(H5) *and let $f \in AP(\mathbb{R}^1; Y)$. Then the optimal control is given by the feedback law*

$$\bar{u} = -N^{-1}B^*(Q_\infty\bar{y} + r) \tag{3.58}$$

where Q_∞ is the nonnegative θ-periodic solution to (3.4) *and r is the unique almost periodic solution to*

$$r' + L^*r + Q_\infty f = 0 \tag{3.59}$$

given by

$$r(t) = \int_t^\infty U_L^*(s, t)Q_\infty(s)f(s)\,ds. \tag{3.60}$$

The optimal cost is given by

$$J_{\text{ap}}(\bar{u}) = \lim_{T\to\infty}\frac{1}{2T}\int_{-T}^{T} [2\langle r, f\rangle - |N^{-1/2}B^*r|^2]\,dt \tag{3.61}$$

and the optimal response by

$$\bar{y}(t) = \int_{-\infty}^{t} U_L(t, s)[f(s) - K(s)r(s)]\,ds. \tag{3.62}$$

Remark 3.2. The conclusion of Corollary 3.6 is still valid even if we replace (H4) by a weaker condition:

(H4′) There exist numbers ε_1, $\varepsilon_2 \in (0,1)$ such that $\sigma(U_L(t+\theta,t)) \subset \{\lambda \in C: |\lambda| \leqq 1-\varepsilon_1\} \cup \{\lambda \in C: |\lambda| \geqq 1+\varepsilon_2\}$, for all $t \in \mathbb{R}^1$.

Note that the θ-periodic solution Q_∞ still exists and U_L is well defined. If (H4′) holds, we set

$$\Pi_-(t) = \frac{1}{2\pi i} \int_{C_1} R(\lambda, U_L(t+\theta, t))\, d\lambda, \qquad t \in \mathbb{R}^1, \tag{3.63}$$

$$\Pi_+(t) = I - \Pi_-(t), \qquad t \in \mathbb{R}^1 \tag{3.64}$$

where C_1 is the unit circle in the complex plane. Then (3.55) and (3.59) have unique almost periodic solutions given by

$$\begin{aligned} \bar{y}(t) = &\int_{-\infty}^{t} U_L(t,s)\Pi_-(s)[f(s) - K(s)r(s)]\, ds \\ &- \int_t^{\infty} U_L(t,s)\Pi_+(s)[f(s) - K(s)r(s)]\, ds, \end{aligned} \tag{3.65}$$

$$\begin{aligned} r(t) = &\int_t^{\infty} U_L^*(t,s)\Pi_+^*(s)Q_\infty(s)f(s)\, ds \\ &- \int_{-\infty}^{t} U_L^*(t,s)\Pi_-^*(s)Q_\infty(s)f(s)\, ds. \end{aligned} \tag{3.66}$$

This can be proved by using estimates

$$|U_L(t,s)\Pi_-(s)| \leqq M_-\, e^{-\omega_-(t-s)}, \quad t \geqq s \quad \text{for some } M_- > 0 \text{ and } \omega_- > 0, \tag{3.67}$$

$$|U_L(t,s)\Pi_+(s)| \leqq M_+\, e^{\omega_+(t-s)}, \quad t \leqq s \quad \text{for some } M_+ > 0 \text{ and } \omega_+ > 0. \tag{3.68}$$

For a proof of (3.67) and (3.68) see [23] when $A(t)$ has a special form $A(t) = A + \tilde{L}(t)$ with $\tilde{L}(t)$ dominated by A, and see [29] in the general case.

4. Optimal quadratic control in the stochastic case.

4.1. Quadratic control under complete observation. We can "stochasticize" all results in § 3. Let $(\Omega, F, F_t, -\infty < t < \infty, P)$ be a stochastic basis and let (W_i), $i = 1, 2, \cdots, N_0$ and W be independent Wiener processes in $\mathbb{R}^1$ and H (Hilbert), respectively, with $\mathrm{Cov}[W(t)] = tW$, $W \in \mathscr{L}^+(H)$ nuclear. We replace (3.1), (3.2), (3.32), (3.33), (3.45), and (3.46), respectively, by

$$dy = [A(t)y + B(t)u]\, dt + G_i(t)y\, dW_i, \qquad y(t_0) = y_0, \tag{4.1}$$

$$J_0(u) = E \int_{t_0}^{\infty} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt, \tag{4.2}$$

$$dy = [A(t)y + B(t)u + f(t)]\, dt + G_i(t)y\, dW_i, \qquad y(t_0) = y_0, \tag{4.3}$$

$$J_1(u) = \overline{\lim_{T\to\infty}} \frac{1}{T} E \int_{t_0}^{t_0+T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt, \tag{4.4}$$

$$dy = [A(t)y + B(t)u + f(t)]\, dt + G_i(t)y\, dW_i + G(t)\, dW, \tag{4.5}$$

$$J_2(u) = \overline{\lim_{T\to\infty}} \frac{1}{2T} E \int_{-T}^{T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \tag{4.6}$$

where in (4.1), (4.3), and (4.5) $G_i(t)y\,dW_i$ means the sum over $i=1$ to N_0. The sets of admissible controls are given by

$$\mathcal{U}_{\text{ad}}^0 = \{u \in M^2([t_0, \infty)\times\Omega;\ U)\text{: its response has the property } E|y(t)|^2 \to 0 \text{ as } t\to\infty\}, \tag{4.7}$$

$$\mathcal{U}_{\text{ad}}^1 = \left\{u \in M_{\text{loc}}^2([t_0,\infty)\times\Omega;\ U)\text{: } \overline{\lim_{T\to\infty}}\frac{1}{T}\int_{t_0}^{t_0+T}|u(t)|^2\,dt<\infty,\ E|y(t)|^2 \text{ bounded}\right\}, \tag{4.8}$$

$$\mathcal{U}_{\text{ad}}^2 = \left\{u \in M_{\text{loc}}^2((-\infty,\infty)\times\Omega;\ U)\text{: } \overline{\lim_{T\to\infty}}\frac{1}{2T}\int_{-T}^{T}|u(t)|^2\,dt<\infty, \text{ there exists } y(t) \text{ with } E|y(t)|^2 \text{ bounded}\right\} \tag{4.9}$$

where $M^2([t_1, t_2]\times\Omega;\ U)$ is the subspace of $L_W^2([t_1, t_2]\times\Omega;\ U)$, which consists of F_t-adapted processes and M_{loc}^2 means M^2 for any finite intervals. We remark that it is possible to take an infinite-dimensional $\tilde{W}$ in place of (W_i) as in [25].

The Riccati equations (3.4) and (3.28) are replaced by

$$Q'(t)+A^*(t)Q(t)+Q(t)A(t)+G_i(t)Q(t)G_i^*(t) + M^*(t)M(t)-Q(t)B(t)N^{-1}(t)B^*(t)Q(t)=0, \tag{4.10}$$

$$A^*Q+QA+G_iQG_i^*+M^*M-QBN^{-1}B^*Q=0. \tag{4.11}$$

We keep the hypothesis (H1) as it is and replace (H2), (H3), respectively, by

(S2) (H2) together with
(i) $G_i \in C_S(\mathbb{R}^1;\ \mathcal{L}(Y))$, $G \in C_S(\mathbb{R}^1;\ \mathcal{L}(H, Y))$; and
(ii) $\sup_{t\in\mathbb{R}^1}[|G_i(t)|+|G(t)|]<\infty$.

(S3) For each $t_0\in\mathbb{R}^1$ and $y_0\in L^2(\Omega, F_{t_0}, P)$, there exist $u\in M^2([t_0,\infty)\times\Omega;\ U)$ and C_0 such that

$$E\int_{t_0}^{\infty}[|M(t)y|^2+\langle N(t)u, u\rangle\,dt \leqq C_0E|y_0|^2$$

where y is the mild solution of (4.1).

To replace (H4) by a new one we need to recall some definitions. Consider the homogeneous system

$$dy = A(t)y\,dt + G_i(t)y\,dW_i, \qquad y(t_0)=y_0. \tag{4.12}$$

Since (4.12) is linear, we can easily establish a unique mild solution in $C([t_0, T];\ L_2(\Omega;\ Y))$ that is adapted to F_t: namely, the solution of

$$y(t) = U(t, t_0)y_0 + \int_{t_0}^{t} U(t, s)G_i(s)y(s)\,dW_i(s). \tag{4.13}$$

We say that $(A;\ G_i)$ is (*exponentially*) *stable* if the mild solution of (4.12) satisfies

$$E|y(t)|^2 \leqq M_1\,e^{-\omega(t-t_0)}E|y_0|^2 \quad \forall y_0\in L^2(\Omega, F_{t_0}, P), \quad t\geqq t_0$$

for some $M_1\geqq 1$ and $\omega>0$. Let $V(t, s)$: $L^2(\Omega, F_s, P)\to L^2(\Omega, F_t, P)$ be the stochastic fundamental solution [2], [14], [27] so that $y(t)=V(t, t_0)y_0$. Then (A, G_i) is stable if and only if

$$E|V(t, t_0)y_0|^2 \leqq M_1\,e^{-\omega(t-t_0)}E|y_0|^2, \qquad y_0\in L^2(\Omega, F_{t_0}, P).$$

We say that $(A, B; G_i)$ is *stabilizable* if there exists a $K \in C_s(\mathbb{R}^1; \mathscr{L}(Y, U))$ bounded such that $(A-BK; G_i)$ is stable. Hypothesis (S3) is fulfilled if $(A, B; G_i)$ is stabilizable. Let $D \in C_s(\mathbb{R}^1; \mathscr{L}(Y))$ be bounded. We say that $(A, D; G_i)$ is *detectable* if there exists a $K_1 \in C_S(\mathbb{R}^1; \mathscr{L}(Y))$ bounded such that $(A-K_1D; G_i)$ is stable.

Now we replace (H4) and (H5), respectively, by

(S4) $(A, M; G_i)$ is detectable,

and

(S5) (H5) and $G_i(t+\theta)=G_i(t)$, $G(t+\theta)=G(t)$, $t \in \mathbb{R}^1$.

Now we can stochasticize almost all results in § 3 under our new hypotheses, but below we will give only main results.

THEOREM 4.1. (i) *Assume* (H1) *and* (S2). *Then a nonnegative bounded solution to* (4.10) *exists if and only if* (S3) *holds.*

(ii) *Assume* (H1), (S2), *and* (S4). *Then any bounded nonnegative solution of* (4.10) *is stable, i.e.,* $(A-BN^{-1}B^*Q; G_i)$ *is stable. Hence the Riccati equation* (4.10) *has at most one bounded nonnegative solution in* $\mathscr{L}^+(Y)$.

PROPOSITION 4.1. (i) *Assume* (H1), (S2), (S3), *and* (S5). *Then the minimal solution* Q_∞ *of* (4.10) *is* θ*-periodic. If, further,* (S4) *holds, then* Q_∞ *is the unique* θ*-periodic solution to* (4.10).

(ii) *Suppose all operators are constant. Then* Q_∞ *is constant and is the minimal solution of the Riccati equation* (4.11). *If* $(A, M; G_i)$ *is detectable* [15], *then* Q_∞ *is the unique solution of* (4.11) *in* $\mathscr{L}^+(Y)$ *and* $(A-BN^{-1}BQ_\infty; G_i)$ *is stable.*

Remark 4.1. Results similar to Propositions 3.1, 3.2, 3.5 and Corollaries 3.1–3.3 are also valid.

Now we need a result similar to Lemmas 3.1 and 3.2.

LEMMA 4.1. *Assume* (H1), (S2), *and* (S3). *Let* Q_∞ *be the minimal nonnegative solution of* (4.10). *Let* $u \in M^2([t_1, t_2]\times\Omega; U)$ *and let* y, r *be any mild solutions of* (4.5) *and*

$$r' + L^*r + Q_\infty f = 0, \qquad L^* = A - BN^{-1}B^*Q_\infty, \tag{4.14}$$

respectively, on $[t_1, t_2]$. *Then*

$$\begin{aligned} E\int_{t_1}^{t_2} [|M(t)y|^2 + \langle N(t)u, u\rangle]\,dt + E\langle Q_\infty(t_2)y(t_2), y(t_2)\rangle + 2E\langle r(t_2), y(t_2)\rangle \\ = E\int_{t_1}^{t_2} |N^{1/2}[u + N^{-1}B^*(Q_\infty y + r)]|^2\,dt \\ + \int_{t_1}^{t_2} [2\langle r, f\rangle - |N^{-1/2}B^*r|^2 + \operatorname{tr} GWG^*Q_\infty]\,dt \\ + E\langle Q_\infty(t_1)y(t_1), y(t_1)\rangle + 2E\langle r(t_1), y(t_1)\rangle. \end{aligned} \tag{4.15}$$

Proof. We apply Itô's formula to $\langle Q_n(t)y_n(t), y_n(t)\rangle + 2\langle r_n(t), y_n(t)\rangle$, where Q_n, y_n, r_n are approximations to Q_∞, y, r given by (4.10), (4.5), and (4.14). Then we rearrange terms, take expectations, and finally pass to the limit $n \to \infty$. □

Now we can solve our three problems immediately.

THEOREM 4.2. *Assume* (H1), (S2)–(S4) *and consider the control problems* (4.1), (4.2), (4.7). *The optimal control is given by the feedback law*

$$\bar{u} = -N^{-1}B^*Q_\infty y \tag{4.16}$$

where Q_∞ is the unique bounded nonnegative solution of (4.10) *and the optimal cost is*

$$J_0(\bar{u}) = E\langle Q_\infty(t_0)y_0, y_0\rangle. \tag{4.17}$$

The optimal closed-loop system is stable.

If (S5) *holds, then Q_∞ is θ-periodic. If all operators in* (4.1), (4.2) *are constant, then Q_∞ is constant.*

Proof. We set $f = r = 0$, $t_1 = t_0$, $t_2 = \infty$, and $G = 0$ in (4.15). □

THEOREM 4.3. *Assume* (H1), (S2)-(S4) *and consider the control problems* (4.3), (4.4), (4.8). *The optimal control is given by the feedback law*

$$\bar{u} = -N^{-1}B^*(Q_\infty \bar{y} + r) \tag{4.18}$$

where Q_∞ is the unique bounded nonnegative solution of (4.10) *and r is the unique bounded solution of*

$$r' + L^*r + Q_\infty f = 0, \qquad L = A - BN^{-1}BQ_\infty, \tag{4.19}$$

given by

$$r(t) = \int_t^\infty U_L^*(s, t)Q_\infty(s)f(s)\, ds, \qquad t \geqq t_0. \tag{4.20}$$

The optimal cost is

$$J_1(u) = \overline{\lim_{T\to\infty}} \frac{1}{T}\int_{t_0}^{t_0+T} [2\langle r, f\rangle - |N^{-1/2}B^*r|^2 + \operatorname{tr} GWG^*Q_\infty]\, dt. \tag{4.21}$$

If, further, (S5) *holds, and f is θ-periodic, then Q_∞, r are θ-periodic and*

$$J_1(\bar{u}) = \frac{1}{\theta}\int_{t_0}^{t_0+\theta} [2\langle r, f\rangle - |N^{1/2}B^*r|^2 + \operatorname{tr} GWG^*Q]\, dt. \tag{4.22}$$

THEOREM 4.4. *Assume* (H1), (S2)-(S4) *and consider the control problem* (4.5), (4.6), (4.9). *Then the optimal control is given by*

$$\bar{u} = -N^{-1}B^*(Q_\infty \bar{y} + r) \tag{4.23}$$

where Q_∞ is the unique bounded nonnegative solution of (4.10) *on $\mathbb{R}^1$ and r is the unique bounded solution on $\mathbb{R}^1$ of*

$$r' + L^*r + Q_\infty f = 0, \qquad L = A - BN^{-1}B^*Q \tag{4.24}$$

given by

$$r(t) = \int_t^\infty U_L^*(s, t)Q_\infty(s)f(s)\, ds, \qquad t \in \mathbb{R}^1. \tag{4.25}$$

The optimal cost is given by

$$J_2(\bar{u}) = \overline{\lim_{T\to\infty}} \frac{1}{2T}\int_{-T}^{T} [2\langle r, f\rangle - |N^{-1/2}B^*r|^2 + \operatorname{tr} GWG^*Q_\infty]\, dt \tag{4.26}$$

and the optimal closed-loop system by

$$d\bar{y} = [(A - BN^{-1}B^*Q_\infty)\bar{y} + f - BN^{-1}B^*r]\, dt + G_i\bar{y}\, dw_i + G\, dw. \tag{4.27}$$

It has a unique bounded solution

$$\begin{aligned}\bar{y}(t) = &\int_{-\infty}^t V_Q(t, s)[f(s) - B(s)N^{-1}(s)B^*(s)r(s)]\, ds \\ &+ \int_{-\infty}^t V_Q(t, s)G(s)\, dw(s)\end{aligned} \tag{4.28}$$

where $V_Q(t, s)$ is the stochastic fundamental solution associated with the homogeneous part of (4.27). *$\bar{y}(t)$ is exponentially asymptotically stable, i.e., any solution $y(t)$ of* (4.27) *with $y(0) = y_0$ satisfies: $y(t) - \bar{y}(t) \to 0$ exponentially in mean square as $t \to \infty$.*

If, further, (S5) *holds, and f is θ-periodic, then Q_∞, r are θ-periodic and*

$$J_2(\bar{u}) = \frac{1}{\theta} \int_0^\theta [2\langle r, f\rangle - |N^{-1/2}B^*r|^2 + \operatorname{tr} GWG^*Q_\infty]\, dt \tag{4.29}$$

and $\bar{y}(t)$, given by (4.28), *is the unique θ-periodic solution of* (4.27).

Finally, we consider almost periodic controls. We say that a stochastic process $z(t)$ is (*weakly*) *almost periodic* in Z if $Ez(t)$ and $\operatorname{cov}[z(t)]k$, $k \in Z$ are almost periodic. We assume that all operators except G are θ-periodic and that $G(t)h$, $h \in H$, f are almost periodic. We wish to minimize

$$J_{\mathrm{ap}}(u) = \lim_{T\to\infty} \frac{1}{2T} E \int_{-T}^{T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \tag{4.30}$$

subject to (4.5) over

$$\begin{aligned} \mathcal{U}_{\mathrm{ap}} = \{u:\ &\text{adapted to } F_t, \text{ almost periodic such that there exists} \\ &\text{a mild solution } y \text{ of (4.5) almost periodic}\}. \end{aligned} \tag{4.31}$$

THEOREM 4.5. *Assume* (H1), (S2)-(S4), *and* (S5) *except G. Assume that $G(t)h$, for all $h \in H$ and f are almost periodic. Consider the control problem* (4.5), (4.30), (4.31). *Then the optimal control is given by the feedback law*

$$\bar{u} = -N^{-1}B^*(Q_\infty \bar{y} + r) \tag{4.32}$$

where Q_∞ is the unique stable θ-periodic solution of (4.10) *and r is the unique almost periodic solution of*

$$r' + L^*r + Q_\infty f = 0 \tag{4.33}$$

given by

$$r(t) = \int_t^\infty U_L^*(s, t) Q_\infty(s) f(s)\, ds. \tag{4.34}$$

The optimal cost is

$$J_{\mathrm{ap}}(\bar{u}) = \lim_{T\to\infty} \frac{1}{2T} \int_{-T}^{T} [2\langle r, f\rangle - |N^{-1/2}B^*r|^2 + \operatorname{tr} GWG^*Q_\infty]\, dt. \tag{4.35}$$

The optimal closed-loop system is given by (4.37) *and its unique solution is given by* (4.28).

4.2. Quadratic control under partial observation. Consider a special case of (4.3) and its observation

$$dy = [A(t)y + B(t)u + f(t)]\, dt + G(t)\, dw, \qquad y(t_0) = y_0, \tag{4.36}$$

$$dz = C(t)y\, dt + V(t)\, dv, \qquad z(t_0) = 0 \tag{4.37}$$

where $C(t) \in C_b(\mathbb{R}^1; L(Y, \mathbb{R}^m))$, $V(t) \in C_b(\mathbb{R}^1; \mathbb{R}^{m\times n})$, nonsingular, v is an m-dimensional Wiener process, $y_0 \in L^2(\Omega, F_{t_0}, P)$ is Gaussian with mean $\bar{y}_0$ and covariance P_0, and y_0, w, v are independent. We assume (H1), (S2)-(S4) and wish to minimize

$$J_1(u) = \overline{\lim_{T\to\infty}} \frac{1}{T} E \int_{t_0}^{t_0+T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\, dt \tag{4.38}$$

over all controls u that are adapted to $\sigma\{z(s), t_0 \leqq s \leqq t\}$. We will define the set of admissible controls later. We now recall filtering results of the system:

$$dy = A(t)y\,dt + G(t)\,dw, \qquad y(t_0) = y_0, \tag{4.39}$$

$$dz = C(t)y\,dt + V(t)\,dw, \qquad z(t_0) = 0. \tag{4.40}$$

The optimal filter $\hat{y}(t)$ of $y(t)$ given $Z_t = \sigma\{z(s), t_0 \leqq s \leqq t\}$ is the projection of $y(t)$ onto $L^2(\Omega, Z_t, P)$ [20], [26] and is given by the mild solution of

$$d\hat{y} = A(t)\hat{y}\,dt + P(t)C^*(t)[VV^*(t)]^{-1}\,d\eta, \qquad \hat{y}(t_0) = \bar{y}_0 \tag{4.41}$$

where η is the innovation process given by

$$d\eta = dz - C(t)\hat{y}\,dt \tag{4.42}$$

and $P(t)$, the covariance of the error process $e = y - \hat{y}$, is the mild solution of

$$\begin{aligned} &\text{(a)} \quad P'(t) - A(t)P(t) - P(t)A^*(t) - G(t)WG^*(t) \\ &\qquad + P(t)C^*(t)[VV^*(t)]^{-1}C(t)P(t) = 0, \\ &\text{(b)} \quad P(t_0) = P_0. \end{aligned} \tag{4.43}$$

Following [3], [6], [9], and [17] we define the set of admissible controls

$$\begin{aligned} \mathcal{U}_{\text{pad}} = \Bigg\{ & u \in M^2_{\text{loc}}([t_0, \infty) \times \Omega;\, U)\colon \lim_{T\to\infty} \frac{1}{T} E \int_{t_0}^{t+T_0} |u(t)|^2\,dt \\ & < \infty,\ u(t) \in L^2(\Omega, H_t, P;\, U) \cap L^2(\Omega, Z_t, P;\, U) \\ & \qquad \text{a.e. } t \text{ and } E|y(t)|^2 \text{ is bounded} \Bigg\}, \end{aligned} \tag{4.44}$$

where $H_t = \sigma\{\eta(s), t_0 \leqq s \leqq t\}$.

Now let u be an admissible control and define $\hat{y}$ by

$$d\hat{y} = [A(t)\hat{y} + B(t)u + f(t)]\,dt + P(t)C^*(t)[VV^*(t)]^{-1}\,d\eta, \qquad \hat{y}(0) = \bar{y}_0. \tag{4.45}$$

Then it is well known [3], [6], [9], [17] that

$$\begin{aligned} & E \int_{t_0}^{t_0+T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\,dt \\ & \qquad = E \int_{t_0}^{t_0+T} [|M(t)y|^2 + \langle N(t)u, u\rangle]\,dt + \int_{t_0}^{t_0+T} \operatorname{tr} M(t)P(t)M^*(t)\,dt \end{aligned} \tag{4.46}$$

where y is the response of (4.36). To make our problem nontrivial we assume:

(S6) (a) (A^*, C) is stabilizable,
(b) $(A^*, W^{1/2}G^*)$ is detectable.

PROPOSITION 4.2. *Assume* (H1) *and* (S6). *Then there exists a unique bounded stable solution* P_∞ *to* (4.43a). *The solution* $P(t)$ *of* (4.43) *is bounded on* $[t_0, \infty)$ *for any* $P_0 \geqq 0$. *If, further,* $A(t)$, $C(t)$, *and* $V(t)$ *are* θ*-periodic, then* $P_\infty(t)$ *is* θ*-periodic and* $P(t + n\theta) \to P_\infty(t)$ *strongly for any* $t \geqq T_0$ *as* $n \to \infty$.

Proof. The Riccati equation (4.4) is dual to (3.4). Hence the assertions follow from Propositions 3.2–3.5. □

Remark 4.2. We may replace (S6)(a) by a condition similar to (H3) for the dual control problem. Note that under (S6), P is bounded and

$$\overline{\lim_{T\to\infty}}\frac{1}{T}\int_{t_0}^{t_0+T}\operatorname{tr} M(t)P(t)M^*(t)\,dt<\infty.$$

Now consider an auxiliary problem of minimizing

$$\hat{J}_1(u)=\overline{\lim_{T\to\infty}}\frac{1}{T}\int_{t_0}^{t_0+T}[|M(t)y|^2+\langle N(t)u,u\rangle]\,dt$$

subject to (4.41) over

$$\hat{\mathcal{U}}_{\text{ad}}=\Big\{u:\overline{\lim_{T\to\infty}}\frac{1}{T}E\int_{t_0}^{t_0+T}|u(t)|^2\,dt$$

$$<\infty,\ u \text{ adapted to } H_t \text{ such that } E|\hat{y}(t)|^2 \text{ is bounded}\Big\}.$$

Assume (H1), (H3), (H4), (S2), and (S6). Then in view of Theorem 4.1 the optimal control is given by

$$\bar{u}=-N^{-1}B^*(Q_\infty\hat{y}+r)$$

where Q_∞, r are given as in Theorem 3.4 and

$$J_1(\bar{u})=\overline{\lim_{T\to\infty}}\frac{1}{T}\int_{t_0}^{t_0+T}[2\langle r,f\rangle-|N^{-1/2}B^*r|^2+\operatorname{tr} PC^*[VV^*]^{-1}CPQ_\infty]\,dt.$$

It is well known that this $\bar{u}$ lies in $\mathcal{U}_{\text{pad}}$ [6], [9]. Then we have Theorem 4.6.

THEOREM 4.6. *Assume* (H1), (H3), (H4), (S2), *and* (S6) *and consider the control problem* (4.36)-(4.38), (4.44). *Then the optimal control is given by*

$$\bar{u}=-N^{-1}B^*(Q_\infty\hat{y}+r)$$

where Q_∞ is the unique bounded stable solution of (3.4) *and r is the unique bounded solution of* (3.49) *given by* (3.50). *The optimal cost is given by*

$$J_1(\bar{u})=\overline{\lim_{T\to\infty}}\frac{1}{T}\int_{t_0}^{t_0+T}[2\langle r,f\rangle-|N^{-1/2}B^*r|^2$$

$$+\operatorname{tr} MPM^*+\operatorname{tr} PC^*[VV^*]^{-1}CPQ_\infty]\,dt.$$

If, further, $f(t)$, $C(t)$, and $V(t)$ are θ-periodic and (S5) *holds, then Q_∞, r are θ-periodic and*

$$J_1(\bar{u})=\frac{1}{\theta}\int_0^\theta[2\langle r,f\rangle-|N^{-1/2}B^*r|^2+\operatorname{tr} MP_\infty M^*+\operatorname{tr} P_\infty C^*[VV^*]^{-1}CP_\infty Q_\infty]\,dt$$

where P_∞ is the unique θ-periodic solution of (4.43a).

We may also consider two-sided average cost as J_2 in § 4.1 although the problem becomes a little artificial. We replace the initial conditions of (4.36), (4.37) by $y(-T)=y_0$, $z(-T)=0$ and minimize

$$J_2(u)=\overline{\lim_{T\to\infty}}\frac{1}{2T}\int_{-T}^{T}[|M(t)y|^2+\langle N(t)u,u\rangle]\,dt.$$

We allow only for feedback controls on the filtered process $\hat{y}$ of the form

$$u=-K(t)\hat{y}+h(t)$$

where $K(t)\in C_S(\mathbb{R}^1;\mathcal{L}(Y,U))$ is bounded and $h\in C_b(\mathbb{R}^1;U)$.

THEOREM 4.7. *Assume* (H1), (H3), (H4), (S2), *and* (S6). *The optimal control is given by*

$$\bar{u} = -N^{-1}B^*(Q_\infty \bar{y} + r)$$

and

$$J_2(\bar{u}) = \overline{\lim_{T\to\infty}} \frac{1}{T}\int_{-T} [2\langle r, f\rangle - |N^{-1/2}B^*r|^2 + \operatorname{tr} MP_\infty M^* + \operatorname{tr} P_\infty C^*[VV^*]^{-1}CP_\infty Q_\infty]\, dt$$

where Q_∞, P_∞, *and* r *are unique bounded solutions of* (3.4), (4.43a), *and* (3.49), *respectively. If* f, C, V *are* θ*-periodic and* (S5) *holds, then* Q_∞, P_∞, r *are* θ*-periodic and*

$$J_2(\bar{u}) = \frac{1}{\theta}\int_0^\theta [2\langle r, f\rangle - |N^{-1/2}B^*r|^2 + \operatorname{tr} MP_\infty M^* + \operatorname{tr} P_\infty C^*[VV^*]^{-1}CP_\infty Q_\infty]\, dt.$$

Remark 4.1. We are not able to prove the existence of almost periodic P if the coefficients of (4.43) are almost periodic.

5. An example. Consider the system:

$$\begin{aligned}
&\frac{\partial y}{\partial t} = \sum_{i,j=1}^n \frac{\partial}{\partial x_j} a_{ij}(t,x)\frac{\partial y}{\partial x_i} + \sum_{i=1}^n b_i(t,x)\frac{\partial y}{\partial x_i} \\
&\qquad + c(t,x)y + f(t,x) + u(t,x), \qquad (t,x)\in \mathbb{R}\times\Omega, \quad a_{ij} = a_{ji}, \\
&y(t,x) = 0, \qquad (t,x)\in \mathbb{R}\times\partial\Omega, \\
&y(0,x) = y_0(x), \qquad x\in\Omega
\end{aligned} \tag{5.1}$$

where a_{ij}, b_i, c, f, n are real functions from $\mathbb{R}\times\bar{\Omega}$ to $\mathbb{R}$ and Ω is a bounded set in $\mathbb{R}^n$ with smooth boundary $\partial\Omega$.

We assume the following:

(5.2)
(i) a_{ij}, b, c, and f are continuous and bounded with their first derivatives with respect to $x\in\bar{\Omega}$ and $t\in\mathbb{R}$.
(ii) There exists $\nu > 0$ such that

$$\sum_{i,j=1}^n a_{ij}(t,x)\xi_i\zeta_j \geqq \nu|\zeta|^2, \qquad \xi = (\zeta_1, \cdots, \zeta_n)\in\mathbb{R}^n, \quad x\in\bar{\Omega}, \quad t\in\mathbb{R}.$$

We set $Y = L^2(\Omega)$ and denote by $A(t)$ the linear operator in Y

$$\begin{aligned}
&A(t)y = \sum_{i,j=1}^n \frac{\partial}{\partial x_j} a_{ij}(t,x)\frac{\partial y}{\partial x_i} + \sum_{i=1}^n b_i(t,x)\frac{\partial y}{\partial x_i} + c(t,x)y, \\
&D(A(t)) = H^2(\Omega)\cap H_0^1(\Omega).
\end{aligned} \tag{5.3}$$

Then hypothesis (H1)(i) is fulfilled (see [36]) and (H1)(ii) is easily checked (see, for instance, Tanabe [36]). Moreover, the adjoint operator $A^*(t)$ is given by

$$\begin{aligned}
&A^*(t)y = \sum_{i,j=1}^n \frac{\partial}{\partial x_j} a_{ij}(t,x)\frac{\partial y}{\partial x_i} - \sum_{i=1}^n \frac{\partial}{\partial x_i}(b_i(t,x)y) + c(t,x)y, \\
&D(A^*(t)) = H^2(\Omega)\cap H_0^1(\Omega)
\end{aligned}$$

so that (H1)(ii) holds.

Consider the quadratic control problem. Minimize

$$J_0(u) = \int_0^\infty dt \int_\Omega (|y(t,x)|^2 + |u(t,x)|^2)\, dx \tag{5.4}$$

subject to (5.1) over the set of admissible controls

$$U_{ad}^0 = \{u \in L^2(0, \infty; Y); \text{ the corresponding mild solution to (5.1), } y(t) \to 0 \text{ as } t \to \infty\}. \tag{5.5}$$

We take $U = Y = L^2(\Omega)$, $B = N = M = I$. Then (H2)-(H4) are fulfilled. Thus the Riccati equation (3.4) has a unique bounded solution and the hypotheses of Theorem 3.2 are fulfilled. Then there exists an optimal feedback control for the infinite horizon problem (5.4), (5.5).

Consider now the stochastic system:

$$\begin{aligned} dy = &\Bigg(\sum_{i,j=1}^{n} \frac{\partial}{\partial x_j} a_{ij}(t,x) \frac{\partial y}{\partial x_i} \\ &+ \sum_{i=1}^{n} b_i(t,x) \frac{\partial y}{\partial x_i} + c(t,x)y + u(t,x) + f(t,x) \Bigg) dt \\ &+ \sum_{i=1}^{n} g_i(t,x) y \, dw_i + g(t,x) \, dw, \qquad (t,x) \in [0, +\infty) \times \bar{\Omega}, \\ &y(t,x) = 0, \qquad (t,x) \in [0, +\infty) \times \partial\Omega, \\ &y(0,x) = y_0(x), \qquad x \in \bar{\Omega} \end{aligned} \tag{5.6}$$

where g, g_i are also continuous and bounded with their first derivatives.

Consider the problem. Minimize

$$J_0(u) = E \int_0^\infty dt \int_\Omega (|y(t,x)|^2 + |u(t,x)|^2) \, dt \tag{5.7}$$

over all $u \in U_{ad}^0$ defined by (4.7) where y is the solution of (5.6). Now we can apply Theorem 4.2 and so there exists a feedback for problem (3.9).

APPROXIMATIONS TO STOCHASTIC PROGRAMS WITH COMPLETE RECOURSE*

RIHO LEPP†

Abstract. A two-stage stochastic convex program with relatively complete recourse in L^∞-space is replaced by a mathematical programming problem in a finite-dimensional space. Using discrete convergence of mappings, conditions are presented that guarantee the convergence of the sequence of solutions of approximate problems to the solution of the initial problem.

Key words. stochastic programming, discrete approximation, relatively complete recourse

AMS(MOS) subject classifications. 90C15, 90C31, 65J15

1. Introduction. Let C_1 and C_2 be nonempty, closed convex sets in R^r and R^v, respectively, and let (S, Σ, σ) be a probability space with $S \subset R^k$ and Σ the Borel sigma-field on S. Let f_{1j} be a finite convex function on R^r for $j = 0, 1, \cdots, l_1$ and let $f_{2j}(s, \cdot, \cdot)$ be a finite convex function on $R^r \times R^v$ for $j = 0, 1, \cdots, l_2$ and for almost all $s \in S$.

Consider the stochastic programming problem with recourse: minimize the function

$$f_{10}(x) + \int_S Q(s, x)\sigma(ds) \tag{1.1}$$

over all $x \in R^r$ satisfying

$$x \in C_1 \quad \text{and} \quad f_{1j}(x) \leqq 0, \qquad j = 1, \cdots, l_1, \tag{1.2}$$

where the function $Q(s, x)$ is defined as the value of an "inner" (second stage) subproblem:

$$Q(s, x) = \inf_{y \in C_2} \{f_{20}(s, x, y) | f_{2j}(s, x, y) \leqq 0, \qquad j = 1, \cdots, l_2\}. \tag{1.3}$$

Properties of recourse function $\mathcal{Q}(x)$,

$$\mathcal{Q}(x) = \int_S Q(s, x)\sigma(ds) \tag{1.4}$$

(continuity, convexity) are widely known (see, e.g., [10]). In spite of these promising properties, stochastic programming problems with recourse generally cannot be solved by known methods of mathematical programming because the numerical evaluation of $\mathcal{Q}(x)$ and its gradient is an extremely complicated problem.

Several authors have examined the effect of perturbations in problem data on the optimal value and the solution of the problem (1.1)-(1.3) (see [4], [8], [23] and the cited literature in these references). These results are based, generally speaking, on properties of the value function $Q(s, x)$ and on the weak convergence of a sequence

of discrete probability measures $\{\sigma_n\}$ to measure σ (see, e.g., [3]). Sequence $\{\sigma_n\}$ is determined by partitions $\{\mathcal{S}_n\}$ of S, $\mathcal{S}_n = \{S_{1n}, \cdots, S_{nn}\}$, with properties

(1) $\bigcup_{i=1}^{n} S_{in} = S$;

(2) $S_{in} \cap S_{jn} = \emptyset$, $i \neq j$;

(3) $\mathcal{S}_n \subset \mathcal{S}_{n+1}$;

(4) $\max_{1 \leqq i \leqq n} \sigma(S_{in}) \to 0$, $n \to \infty$.

The partition $\{\mathcal{S}_n\}$ is used in order to get lower and upper bounds for the solution of (1.1)-(1.3). Construction of these bounds rely on the Jensen's inequality and Edmundson-Madansky bound, respectively. In such a partition it is necessary to find the discretization points in the form of conditional mean [4]:

$$\bar{s}_{in} = E\{s \mid S_{in}\}. \tag{1.5}$$

Then the problem reads as follows: minimize the function

$$f_{10}(x) + \sum_{i=1}^{n} Q(\bar{s}_{in}, x) p_{in} \tag{1.6}$$

over all $x \in R^r$ satisfying

$$x \in C_1 \quad \text{and} \quad f_{1j}(x) \leqq 0, \qquad j = 1, \cdots, l_1, \tag{1.7}$$

where

$$Q(\bar{s}_{in}, x) = \inf_{y \in C_2} \{f_{20}(\bar{s}_{in}, x, y) \mid f_{2j}(\bar{s}_{in}, x, y) \leqq 0, \qquad j = 1, \cdots, l_2\} \tag{1.8}$$

and $p_{in} = \sigma(S_{in})$.

Equivalently, if we are able to replace infimum by the minimum for all $\bar{s}_{in}$, then instead of (1.6)-(1.8) we get the following extremum problem (see, e.g., [10]) with activities $y_i \in R^v$, $i = 1, \cdots, n$,: minimize over x and y_i, $i = 1, \cdots, n$, the function

$$f_{10}(x) + \sum_{i=1}^{n} f_{20}(\bar{s}_{in}, x, y_i) p_{in} \tag{1.9}$$

satisfying conditions

$$x \in C_1, \qquad f_{1j}(x) \leqq 0, \qquad j = 1, \cdots, l_1; \tag{1.10}$$

$$y_i \in C_2, \qquad f_{2j}(s_{in}, x, y_i) \leqq 0, \qquad j = 1, \cdots, l_2, \quad i = 1, \cdots, n. \tag{1.11}$$

Roughly speaking, in [4], [9], [23] the approximation scheme is realized via the approximation of an integral by Lebesgue sums.

The aim of this paper is to investigate the behaviour of the sequence of second stage solutions $\{\bar{y}_{in}\}$ of the problems (1.8) as $n \to \infty$. We show that it converges in a certain (weak* discrete) sense to an essentially bounded function $\bar{y}(s)$, $\bar{y} \in L^{\infty}(S, \Sigma, \sigma) \triangleq L^{\infty}(\sigma)$. This $\bar{y}(s)$ is the (second stage) solution of the following "static" formulation of the stochastic programming problem with recourse [16]: minimize over $(x, y(s))$, $x \in R^r$, $y \in L^{\infty}(\sigma)$, the functional

$$f_{10}(x) + \int_S f_{20}(s, x, y(s)) \sigma(ds) \tag{1.12}$$

satisfying conditions

$$x \in C_1, \qquad f_{1j}(x) \leqq 0, \qquad j = 1, \cdots, l_1, \tag{1.13}$$

and almost surely (a.s.)

$$y(s) \in C_2, \qquad f_{2j}(s, x, y(s)) \leqq 0, \qquad j = 1, \cdots, l_2. \tag{1.14}$$

It was shown in [16] that the problems (1.1)-(1.3) and (1.12)-(1.14) are equivalent in the sense that the vector $x \in R^r$ minimizes (1.1)-(1.3) if and only if the pair $(x, y) \in R^r \times L^\infty(\sigma)$ minimizes (1.12)-(1.14), and the optimal values of both problems are equal. Due to this equivalence we can conclude that computational difficulties which arise in numerical solution of stochastic programs with recourse could be in general the same as the difficulties which arise in numerical solution of an extremum problem in a function space with nonlinear operator constraints (constraints (1.14) are just that type). It was pointed out in [15] that "... the static formulation of stochastic programming problems with recourse is computationally more tractable than the dynamic one... and can be solved in some cases by solving a sequence of finite-dimensional discretizations."

In numerical solution of stochastic programming problems with recourse it might be more preferable to use, instead of conditional means $\bar{s}_{in}$, appropriately chosen samples of s. In this purpose we define a convergent quadrature process:

$$\sum_{i=1}^{n} h(s_{in}) m_{in} \to \int_S h(s)\sigma(ds), \quad n \to \infty, \quad \forall h \in C(S). \tag{1.15}$$

It was proved in [21] that for the convergence (1.15) it was necessary and sufficient to have a system of partition $\{\mathscr{A}_n\}$, $\mathscr{A}_n = \{A_{1n}, \cdots, A_{nn}\}$, from Σ with properties

(1) $\sigma(A_{in}) > 0$;
(2) $\bigcup_{i=1}^{n} A_{in} = S$;
(3) $A_{in} \cap A_{jn} = \varnothing, \quad i \neq j$;
(4) $\operatorname{diam} A_{in} \to 0, \quad n \to \infty$;
(5) $\sigma(\partial A_{in}) = 0, \quad i = 1, \cdots, n$;
(6) $\max_{1 \leqq i \leqq n} \dfrac{m_{in}}{\sigma(A_{in})} \to 1, \quad n \to \infty$;
(7) $s_{in} \in A_{in}$,

where ∂A denotes the boundary of a set A and $\operatorname{diam} A = \sup_{s,t \in A} |s - t|$. Our use of the partition $\{\mathscr{A}_n\}$ differs from the use of the partition $\{\mathscr{S}_n\}$ above in the analogous sense as Riemann and Lebesgue integrals differ from each other. Note that the collection of sets $\{\mathscr{A}_n\}$ with properties (1)-(7) generates an algebra $\Sigma_0 \subset \Sigma$ ([21]). Denote the restriction of the measure σ to the algebra Σ_0 by σ_0. Supposing that $S = [0, 1]$ and σ is the Lebesgue measure on $[0, 1]$ then the integrability in the sense of restricted measure σ_0 means simply Riemann integrability.

Suppose that the quadrature process (1.15) converges. Then instead of problem (1.6)-(1.8) we can solve the following mathematical programming problem with a staircase constraint set: minimize over x and y_i, $i = 1, \cdots, n$, the function

$$f_{10}(x) + \sum_{i=1}^{n} f_{20}(s_{in}, x, y_i) m_{in} \tag{1.16}$$

satisfying conditions

$$x \in C_1, \qquad f_{1j}(x) \leqq 0, \qquad j = 1, \cdots, l_1, \tag{1.17}$$

and

$$y_i \in C_2, \qquad f_{2j}(s_{in}, x, y_i) \leqq 0, \qquad j = 1, \cdots, l_2, \quad i = 1, \cdots, n. \tag{1.18}$$

Define by $l_n^\infty(m_n)$ the $v \times n$-dimensional space with norm $\|y_n\|_n = \max_{1 \leqq i \leqq n} |y_{in}|$, where $|\cdot|$ is the Euclidean norm of a v-dimensional vector.

In order to achieve the convergence of $\{\bar{y}_n\}$ to a $\bar{y}(s)$, $\bar{y}_n \in l_n^\infty(m_n)$, $y \in L^\infty(\sigma)$, it is necessary to introduce a system of connection operators $\mathcal{P} = \{p_n\}$, $p_n : L^\infty(\sigma) \to l_n^\infty(m_n)$, $n = 1, 2, \cdots$, between the spaces $l_n^\infty(m_n)$ and $L^\infty(\sigma)$. For the L^P-spaces, $1 \leqq p \leqq \infty$, it is natural to define this system in a piecewise integral form. For any system of connection operators $\mathcal{P} = \{p_n\}$, the following condition should be implemented [20]: for any y

$$\|p_n y\| \to \|y\|, \qquad n \to \infty \tag{1.19}$$

(without (1.19) a discretely converging sequence can have even an infinite number of limits). For any $y \in L^\infty(\sigma)$ the convergence (1.19) takes place [12] and, consequently, makes it possible to solve approximately several problems with a nonlinear operator form $L^\infty(\sigma)$ to $L^\infty(\sigma)$. For example, (1.19) makes it possible to solve approximately continuous programming problems [5], optimal control problems with nonlinear state and control constraints [7] and integral equation [1] in $L^\infty(\sigma)$.

In § 2 we introduce some notions from the theory of discrete convergence necessary for this paper. Since we consider the pair (L^∞, L^1), only discrete and weak* discrete convergences will be used.

In § 3 we deduce conditions that guarantee the convergence of sequence of solutions of discretized problems (1.16)–(1.18) to the solution of the initial problem.

2. Discretization of the problem. Let us introduce some notions from the theory of discrete convergence of mappings (see, e.g., [20], [22]).

Let B and B_n, $n = 1, 2, \cdots$, be Banach spaces with norms $\|\cdot\|$ and $\|\cdot\|_n$, respectively, and let $\mathcal{Q} = \{q_n\}$ be a system of linear connection operators $q_n : B \to B_n$, $n = 1, \cdots$ such that, for every $u \in B$, $\|q_n u\|_n \to \|u\|$ as $n \to \infty$.

DEFINITION 2.1. A sequence $\{u_n\}$ with $u_n \in B_n$ $\mathcal{Q}$-converges (or converges discretely) to $u \in B$ if $\|u_n - q_n u\|_n \to 0$ as $n \to \infty$. We denote this convergence by $u_n \to^{\mathcal{Q}} u$ or simply $u_n \to u$.

DEFINITION 2.2. Connection systems $\mathcal{Q} = \{q_n\}$ and $\mathcal{Q}' = \{q'_n\}$ are called equivalent if for every $u \in B$ $\|q_n u - q'_n u\|_n \to 0$ as $n \to \infty$.

Let B^* and B_n^* be dual spaces to B and B_n, let $\langle u, y \rangle$ denote the value of the linear form $y \in B^*$ at the element $u \in B$ and $\langle u_n, y_n \rangle_n$ denote the value of the linear form $y_n \in B_n^*$ at the element $u_n \in B_n$. Define also a system of linear connection operators $\mathcal{P} = \{p_n\}$, $p_n : B^* \to B_n^*$, $n = 1, \cdots$, such that for every $y \in B^*$ we have

$$\|p_n y\|_n \to \|y\| \quad \text{as } n \to \infty. \tag{2.1}$$

Define (analogously to Definition 2.1) $\mathcal{P}$-convergence of a sequence $\{y_n\}$, $y_n \in B_n^*$, to element $y \in B^*$ and denote this convergence by $y_n \to^{\mathcal{P}} y$ or simply $y_n \to y$.

DEFINITION 2.3. A sequence $\{y_n\}$ with $y_n \in B_n^*$ $\mathcal{Q}$-converges weakly* (or converges weakly* discretely) to $y \in B^*$ if for every discretely converging sequence of elements $u_n \to^{\mathcal{Q}} u$ we have

$$\langle u_n, y_n \rangle_n \to \langle u, y \rangle \quad \text{as } n \to \infty.$$

Denote this convergence by $y_n \dashrightarrow^{\mathcal{Q}} y$ or simply $y_n \dashrightarrow y$.

Denote by $|x_n - x| \to 0$, $n \to \infty$, the convergence in the sense of Euclidean norm.

Define (similarly to the epiconvergence [2], [4]) the discrete epiconvergence of functionals.

Let $(f, \{f_n\})$ be a collection consisting of a functional f and a sequence of functionals $\{f_n\}$. The sequence $\{f_n\}$ is said to $\mathcal{P}$-epiconverge (or epiconverge discretely) to f if for all y we have

$$\liminf_{n\to\infty} f_n(y_n) \geqq f(y) \quad \text{for all } \{y_n\} \ \mathcal{P}\text{-converging to } y; \tag{2.2}$$

there exists $\{y_n\}$ $\mathcal{P}$-converging to y such that

$$\limsup_{n\to\infty} f_n(y_n) \leqq f(y). \tag{2.3}$$

We also need the weak* $\mathcal{Q}$-convergence and a mixture of $\mathcal{P}$- and weak* $\mathcal{Q}$-convergences: if we replace $\mathcal{P}$-convergence of elements by the weak* $\mathcal{Q}$-convergence, the sequence $\{f_n\}$ is said to be $\mathcal{Q}$-weakly* epiconvergent (or epiconvergent weakly* discretely) to f. If we have in (2.2) the $\mathcal{Q}$-weak* convergence and in (2.3) the $\mathcal{P}$-convergence, we say that $\{f_n\}$ epiconverges $\mathcal{Q}\mathcal{P}$-weakly* to f.

Let us be more concrete now about the general notions of discrete convergence to the spaces $L^\infty(\sigma)$ and $L^1(\sigma)$.

Let us restrict the probability measure σ: let the support S of the measure σ be bounded and let

$$\sigma\{s \,|\, |s-t| = \text{const.}\} = 0, \quad \forall t \in S. \tag{A1}$$

For example, the restriction (A1) is fulfilled if the probability measure σ has a density.

For spaces $L^\infty(\sigma)$ and $l_n^\infty(m_n)$, define the system of connection operators $\mathcal{P} = \{p_n\}$, $p_n : L^\infty(\sigma) \to l_n^\infty(m_n)$, $n = 1, \cdots$, in the following way [11]:

$$(p_n y)_{in} = \sigma(A_{in})^{-1} \int_{A_{in}} y(s)\sigma(ds), \qquad i = 1, \cdots, n, \tag{2.4}$$

for an arbitrary fixed collection of sets $\{\mathcal{A}_n\}$, $\mathcal{A}_n = \{A_{1n}, \cdots, A_{nn}\}$ from sigma-field Σ with properties (1)–(7) from the Introduction.

Let $u \in L^1(\sigma)$ and let $\|\cdot\|_1$ denote the norm of an element in $L^1(\sigma)$. Define (analogously to (2.4)) the system $\mathcal{Q}$ of connection operators for spaces $L^1(\sigma)$ and $l_n^1(m_n)$ with a fixed collection of sets $\{\mathcal{B}_n\}$, $\mathcal{B}_n = \{B_{1n}, \cdots, B_{nn}\}$, with properties (1)–(7) (here $l_n^1(m_n)$ is nv-dimensional space with norm

$$\|u_n\|_{n,1} = \sum_{i=1}^{n} |u_{in}| m_{in}.$$

On the set of continuous functions $C(S)$ define (in additon to the system $\mathcal{Q}$) the system of equivalent connection operators $\mathcal{Q}' = \{q_n'\}$:

$$(q_n' z)_{in} = z(s_{in}), \qquad i = 1, \cdots, n, \qquad z \in C(S). \tag{2.4'}$$

Systems of connection operators $\mathcal{Q}$ and $\mathcal{Q}'$ are equivalent according to the Definition 2.2 (see [20, p. 649]). $\mathcal{Q}'$ can be extended onto $L^1(\sigma)$ with preserving linearity of q_n' and property $\|q_n' u\|_{n,1} \to \|u\|_1$ as $n \to \infty$ for every $u \in L^1(\sigma)$.

The system of connection operators $\mathcal{P} = \{p_n\}$ defined by (2.4) satisfies the condition (1.19):

$$\|p_n y\|_n \to \|y\|, \quad n \to \infty, \quad \forall y \in L^\infty(\sigma).$$

The proof of (1.19) for a $y \in L^\infty(\sigma)$ relies on the following two facts:

(1) $\|y\|_p \to \|y\|$, $p \to \infty$ (here $\|y\|_p$ denotes the L^P-norm of $y \in L^\infty(\sigma)$),

(2) $\|\not{p}_n y\|_{n,p} \to \|y\|_p$, $n \to \infty$, for every fixed $p \in [1, \infty)$. The last convergence is equivalent to the following two conditions which can be easily proved:

(2a) $\|\not{p}_n\|_{n,p} \leqq$ const.,

(2a) $\|\not{p}_n y\|_{n,p} \to \|y\|_p$, $n \to \infty$, for any y from $C(S)$ which is dense in $L^p(\sigma)$. The proof of the convergence (2.5) is quite lengthy and is presented in [12].

Remark 2.1. It is easy to see that for the systems of connection operators $\mathcal{P} = \{\not{p}_n\}$ and $\mathcal{Q} = \{\varphi_n\}$ with properties (1)-(7) the compatibility condition [19], $y_n \to^{\mathcal{P}} y$, $u_n \to^{\mathcal{Q}} u \Rightarrow \langle u_n, y_n \rangle_n \to \langle u, y \rangle$ is fulfilled (here $y \in L^\infty(\sigma)$, $y_n \in l_n^\infty(m_n)$, $u \in L^1(\sigma)$, $u_n \in l_n^1(m_n)$).

3. Conditions for convergence of discrete approximations. Let us introduce some notations and assumptions necessary for the discrete approximation of the problem (1.12)-(1.14) by the sequence of problems (1.16)-(1.18). Denote by G and G_n the (nonempty) sets of admissible solutions of problems (1.12)-(1.14) and (1.16)-(1.18), respectively, and by $G_2(s, x)$ the following set:

$$G_2(s, x) = \{y \mid f_{2j}(s, x, y) \leqq 0, j = 1, \cdots, l_2\}.$$

Suppose that

(A2) the functions f_{1j} on R^r, $j = 0, 1, \cdots, l_1$, are convex and differentiable;

(A3) the functions $f_{2j}(s, \cdot, \cdot)$ on $R^r \times R^v$, $j = 0, 1, \cdots, l_2$, are convex and differentiable, for each (x, y) on $R^r \times R^v$ the functions $f_{2j}(\cdot, x, y)$, $j = 0, 1, \cdots, l_2$, are bounded and measurable on S. Moreover, to each bounded set $B \subset R^r \times R^v$ there corresponds a bounded and Σ_0-measurable function $\alpha: S \to R$ and a constant $\beta \in R$ such that $|f_{20}(s, x, y)| \leqq \alpha(s)$ for all $(x, y) \in B$, $|f_{2j}(s, x, y)| \leqq \beta$ for all $(x, y) \in B$, $j = 1, \cdots, l_2$;

(A4) the functions $f'_{2jx}(s, \cdot, \cdot)$, $f'_{2jy}(s, \cdot, \cdot)$ on $R^r \times R^v$, $j = 0, 1, \cdots, l_2$, are continuous, for each (x, y) on $R^r \times R^v$ the functions $f'_{2jy}(\cdot, x, y)$ are bounded and Σ_0-measurable on S. Moreover, to each bounded set $B \subset R^r = R^v$ there correspond bounded and Σ_0-measurable functions $\gamma_j: S \to R$, $\delta_j: S \to R$, such that

$$|f'_{2jx}(s, x, y)| \leqq \gamma_j(s) \quad \text{for all } (x, y) \in B,$$

$$|f'_{2jy}(s, x, y)| \leqq \delta_j(s) \quad \text{for all } (x, y) \in B.$$

Remark 3.1. In order to guarantee the convergence of discrete approximations, more stringent conditions (A3), (A4) compared with [18] are needed. The same is valid about the paper [6].

(A5) The sets $C_1 \subset R^r$ and $C_2 \subset R^v$ are bounded closed and convex with int $C_2 \neq \emptyset$;

(A6) there exists an element $(\tilde{x}, \tilde{y}(s))$ such that for some $\varepsilon > 0$ the constraints (1.2) and (almost surely) (1.3) can be satisfied with $-\varepsilon$ in place of 0 (strict feasibility [17]);

(A7) the support S of the measure σ is bounded; let

$$K_1 = \{x \mid x \in C_1, f_{1j}(x) \leqq 0, j = 1, \cdots, l_1\}.$$

(A8) For all $x \in K_1$ there is bounded region $D \subset R^v$ with $G_2(s, x) \cap D \neq \emptyset$ for all $s \in S$ (relatively complete recourse [17]).

With assumptions (A2), (A3), and (A5), the optimal recourse problem (1.1)-(1.3) is well defined (see, e.g., [18]).

Since the existence conditions do not depend on the properties of the measure σ (discrete measures are not excluded) under the conditions above the problems (1.16)-(1.18) are well defined.

Define together with the connection system $\mathcal{P}$ the following system of piecewise constant restoration operators $\mathcal{R}=\{\imath_n\}$, $\imath_n: l_n^\infty(m_n)\to L^\infty(\sigma)$, of the form

$$(\imath_n y_n)(s)=y_{in} \quad \text{as} \quad s\in A_{in} \tag{3.1}$$

where the sets $\{A_{in}\}_{i=1}^n$ are taken from the system $\mathcal{P}$ with properties (1)-(7) (see (2.4)).

PROPOSITION 3.1. *Let $f_{1j}, j=1,\cdots,l_1$, satisfy the condition* (A2), $f_{2j}, j=1,\cdots,l_2$, *conditions* (A3), (A4), *sets C_1, C_2 the condition* (A5). *If the convergence* (1.15) *holds, then the constraint set G contains all weak* discrete limits of sequences $\{(x_k, y_k)\}$, $(x_k, y_k)\in G_{n_k}$, where $\{G_{n_k}\}$ are arbitrary subsequences of $\{G_n\}$.*

Proof. Let $|x_n - x|\to 0$ and $y_n \to y$ as $n\to\infty$. Consider first constraints (1.18). Let $f_{2j}(s_{in}, x_n, y_{in})\leqq 0$ for all $j=1,\cdots,l_2$ and all $i=1,\cdots,n$, $n=1,2,\cdots$. Let us explain the idea of the proof. On the contrary suppose that there exists a set $D\in\Sigma$ with a positive measure $\sigma(D)>0$, and an index $j\in\{1,\cdots,l_2\}$ such that $f_{2j}(s, x, y(s))\geqq\delta>0$ for all $s\in D$. Then $\delta\sigma(D)\leqq\int_S \chi_D(s) f_{2j}(s, x, y(s))\sigma(ds)$ where

$$\chi_D(s)=\begin{cases}1, & s\in D,\\ 0, & s\notin D.\end{cases}$$

Then the function $\chi_D(s) f_{2j}(s, x, y(s))$ is approximated (as an element of $L^1(\sigma)$) by the function $z(s) f_{2j}(s, x, y_c(s))$, where z, y_c are continuous functions. This enables us to estimate the difference

$$\sum_{i=1}^n |(\wp_n(\chi_D(s) f_{2j}(s, x, y(s)))_{in} - (\wp_n\chi_D(s))_{in} f_{2j}(s_{in}, x, (\wp_n y(s))_{in})| m_{in}. \tag{3.2}$$

If the difference (3.2) is sufficiently small we have the contradiction

$$\begin{aligned} 0\leqq\delta\sigma(D) &\leqq \int_S \chi_D(s) f_{2j}(s, x, y(s))\sigma(ds)\\ &\leqq \sum_{i=1}^n (\wp_n\chi_D(s))_{in} f_{2j}(s_{in}, x_n, y_{in}) m_{in} + \frac{1}{2}\delta\sigma(D) \qquad (3.3)\\ &\leqq \frac{1}{2}\delta\sigma(D) \quad \text{for } n \text{ sufficiently large.}\end{aligned}$$

After these introductory remarks let us now prove Proposition 3.1.

Since $\chi_D(\cdot) f_{2j}(\cdot, x, y(\cdot))\in L^1(\sigma)$ and (definition of $\mathcal{P}$-convergence)

$$\sum_{i=1}^n (\wp_n(\chi_D(s) f_{2j}(s, x, y(s)))_{in} m_{in} \to \int_S \chi_D(s) f_{2j}(s, x, y(s))\sigma(ds), \quad n\to\infty,$$

we have for $n\geqq n_1$

$$\left|\sum_{i=1}^n (\wp_n(\chi_D(s) f_{2j}(s, x, y(s)))_{in} m_{in} - \int_S \chi_D(s) f_{2j}(s, x, y(s))\sigma(ds)\right| \leqq \delta/8\sigma(D).$$

For brevity denote $f_{2j}(x, y)=f_{2j}(s, x, y(s))$ and $(\wp_n\chi_D)_{in} f_{2jn}(x, (\wp_n y)_n)_{in} = (\wp_n\chi_D(s))_{in} f_{2j}(s_{in}, x, (\wp_n y)_{in})$. Consider the difference (3.2):

$$\begin{aligned} &\|(\wp_n(\chi_D f_{2j}(x, y)))_n - (\wp_n\chi_D)_n f_{2jn}(x, (p_n y)_n)\|_n\\ &\leqq \sum_{i=1}^n |(\wp_n(\chi_D f_{2j}(x, y)))_n - (\wp_n(z f_{2j}(x, y_c)))_n| m_{in}\\ &\quad + \sum_{i=1}^n (\wp_n(z f_{2j}(x, y_c)))_n - (\wp_n\chi_D)_n f_{2jn}(x, (\wp_n y)_n)| m_{in}\end{aligned}$$

for some z, $y_c \in C(S)$. Take continuous $z(s)$, $0 \leqq z(s) \leqq 1$, $s \in S$, and $y_c(s)$ such that

$$\int_S |\chi_D(s) - z(s)|\sigma(ds) < \delta \Big/ \left(64 \sup_{s \in S} |f_{2j}(s, x, y_c(s))|\right)$$

and

$$\int_S |f_{2j}(s, x, y(s)) - f_{2j}(s, x, y_c(s))|\sigma(ds) < \delta/64$$

(for any $\nu > 0$ one can choose in $L^1(\sigma)$ such a continuous $z(s)$ that $\int_S |\chi_D(s) - z(s)|\sigma(ds) < \upsilon$). Note that $\sup_{s \in S} |f_{2j}(s, x, y_c(s))|$ is finite since the function $g(s) = |f_{2j}(s, x, y_c(s))|$ is bounded and Σ_0-measurable.

Then for $n \geqq n_2$

$$\sum_{i=1}^{n} |(\not{p}_n(\chi_D f_{2j}(x, y)))_n - (\not{p}_n(z f_{2j}(x, y_c)))_n| m_{in}$$

$$= \sum_{i=1}^{n} |(\not{p}_n(\chi_D f_{2j}(x, y) - z f_{2j}(x, y_c))_n| m_{in}$$

$$\leqq \int_S |\chi_D(s) f_{2j}(s, x, y(s)) - z(s) f_{2j}(s, x, y_c(s))|\sigma(ds)$$

$$+ (\delta/32)\sigma(D) \leqq (\delta/16)\sigma(D).$$

Consider now the difference:

$$\sum_{i=1}^{n} |(\not{p}_n(z f_{2j}(x, y_c)))_{in} - (\not{p}_n \chi_D)_{in} f_{2jn}(x, (\not{p}_n y)_n)| m_{in}$$

$$\leqq \sum_{i=1}^{n} |(\not{p}_n(z f_{2j}(x, y_c)))_{in} - (\not{p}_n z)_{in} f_{2jn}(x, (\not{p}_n y_c)_n))| m_{in}$$

$$+ \sum_{i=1}^{n} |f_{2jn}(x, (\not{p}_n y)_n) - f_{2jn}(x, (\not{p}_n y_c)_n)| m_{in}$$

$$+ \max_{1 \leqq i \leqq n} |f_{2jn}(x, (\not{p}_n y_c)_n)| \sum_{i=1}^{n} |(\not{p}_n(\chi_D - z))_{in}| m_{in}$$

$$\leqq (\delta/16)\sigma(D)$$

as $n \geqq n_3$ (due to the boundedness of $\max_{1 \leqq i \leqq n} |f_{2jn}(x, (\not{p}_n y_c)_n)|$ and the inequality

$$\sum_{i=1}^{n} |(\not{p}_n(\chi_D - z))_{in}| m_{in} \leqq \int |\chi_D(s) - z(s)|\sigma(ds)$$

$$+ \delta \Big/ \left(48 \max_{1 \leqq i \leqq n} |f_{2jn}(x, (\not{p}_n y_c)_n)|\right).$$

Taking $n_4 = \max\{n_2, n_3\}$ we obtain for $n \geqq n_4$ that

$$\|(\not{p}_n(\chi_D f_{2j}(x, y)))_n - (\not{p}_n \chi_D)_n f_{2jn}(x, (\not{p}_n y)_n)\|_n < (\delta/8)\sigma(D).$$

Since $\not\pi_n y \to y$, $n = 1, \cdots, y_{n_k} \dashrightarrow y$, $|x_{n_k} - x| \to 0$, $k = 1, \cdots$, and sequences $\{(\not\pi_n \chi_D)_{in} f'_{2jx}(s_{in}, x, (\not\pi_n y)_{in})\}$, $\{(\not\pi_n \chi_D)_{in} f'_{2jy}(s_{in}, x, (\not\pi_n y)_{in})\}$ converge (analogously to the convergence (3.2)) discretely, then for $n \geqq n_5$ we have

$$\sum_{i=1}^{n} (\not\pi_n \chi_D)_{in} f_{2j}(s_{in}, x, (\not\pi_n y)_{in}) m_{in}$$

$$\leqq \sum_{i=1}^{n} (\not\pi_n \chi_D)_{in} f_{2j}(s_{in}, x_n, y_{in}) m_{in} + (\delta/4)\sigma(D)$$

$$\leqq (\delta/4)\sigma(D)$$

((x_n, y_n) is admissible for (1.16)-(1.18)). Then for $n \geqq n_0 = \max\{n_1, n_4, n_5\}$ we reached the contradiction: $\delta\sigma(D) \leqq \frac{1}{2}\delta\sigma(D)$. So we can conclude that for the limit point $(x, y(s))$ we have $f_{2j}(s, x, y(s)) \leqq 0$ for almost all $s \in S$ and all $j = 1, \cdots, l_2$.

Since $(\imath_n y_n)(s) \in C_2$ for almost all $s \in S$ then due to the closedness of C_2, the limit point $y(s) \in C_2$ for almost all $s \in S$. Conditions (A5) to C_1 and (A2) to $f_{1j}, j = 1, \cdots, l_1$, guarantee that $(x, y(s))$ satisfies all constraints (1.17), (1.18). □

Remark 3.2. Let $C_2 = \{y \mid Dy \geqq d\}$ be a bounded polyhedron with $D - a$ $(k \times v)$-matrix and $d - k$-dimensional vector. Then clearly $(\imath_n y_n)(s) \in C_2$ for almost all $s \in S$ and all $n = 1, 2, \cdots$.

Remark 3.3. The Σ_0-measurability assumption enables us to replace the functions f_{2j}, $j = 0, 1, \cdots, l_2$, and its derivatives in approximation process by their values in discretization points s_{in}. Assuming only Σ-measurability we must use conditional means $\bar{s}_{in}$ instead of s_{in} (see the Introduction). If the functions f_{2j}, $j = 0, 1, \cdots, l_2$, are only Σ-measurable then changing their values on a set of measure zero it is possible that sums in (3.3) are equal to zero for all $n = 1, 2, \cdots$, but the value of the integral does not change. For the same reasons the discrete approximation scheme proposed in [14] may diverge.

Remark 3.4. To make the proof of Proposition 3.1 simpler we could suppose the weak* continuity of $f_{2j}, j = 1, \cdots, l_2$, relative to y. Unfortunately, such a superposition operator is weakly continuous in L^P-spaces, $1 \leqq p < \infty$ (weakly* continuous in L^∞), if and only if it is linear.

Define function F_0 and F_{0n}:

$$F_0 = f_{10}(x) + \int_S f_{20}(s, x, y(s))\sigma(ds),$$

$$F_{0n} = f_{10}(x) + \sum_{i=1}^{n} f_{20}(s_{in}, x, y_{in}) m_{in}.$$

PROPOSITION 3.2. *Let f_{10} satisfy the condition* (A2), *f_{20} conditions* (A2), (A4). *Let the convergence* (1.15) *hold. Then the sequence $\{F_{0n}\}$ $2\mathcal{P}$-weakly* epiconverges to F_0.*

Proof. Let us show that the collection $(F_0, \{F_{0n}\})$ satisfies (2.3). Let $|x_n - x| \to 0$ and $y_n \xrightarrow{\mathcal{P}} y$ as $n \to \infty$. Then

$$f_{10}(x_n) + \sum_{i=1}^{n} f_{20}(s_{in}, x_n, y_{in}) m_{in} - f_{10}(x) - \int f_{20}(s, x, y(s))\sigma(ds)$$

$$\leqq f_{10}(x_n) - f_{10}(x) + |x_n - x| \sum_{i=1}^{n} |f'_{20x}(s_{in}, x_n, y_{in})| m_{in}$$

$$+ \max_{1 \leqq i \leqq n} |y_{in} - (\not\pi_n y)_{in}| \sum_{i=1}^{n} |f'_{20y}(s_{in}, x_n, y_{in})| m_{in} + R_{0n}(x, y)$$

where

$$R_{0n}(x, y) = \left| \sum_{i=1}^{n} f_{20}(s_{in}, x_n, (\not\pi_n y)_{in}) m_{in} - \int f_{20}(s, x, y(s))\sigma(ds) \right|.$$

Since $|x_n - x| \to 0$ and $\not\pi_n y \to^{\mathscr{P}} y$, $n \to \infty$, by the definition, then

$$\left| \sum_{i=1}^{n} (\not\pi_n f_{20}(x, y))_{in} m_{in} - \int f_{20}(s, x, y(s))\sigma(ds) \right| \to 0$$

and

$$\sum_{i=1}^{n} |(\not\pi_n f_{20}(x, y)_{in} - f_{20n}(x_n, (\not\pi_n y)_{in})| m_{in} \to 0, \quad n \to \infty$$

(as in the proof of (3.2) in Proposition 3.1). Consequently, $R_{0n}(x, y) \to 0$ as $n \to \infty$. Due to the convergences $|x_n - x| \to 0$ and $y_n \to^{\mathscr{P}} y$, the collection $(F_0, \{F_{0n}\})$ satisfies (2.3) as $n \to \infty$.

Consider the convergence (2.2). Since a bounded sequence in $L^{\infty}(\sigma)$ is weakly* compact, we have to use the $\mathscr{Q}$-weak* convergence in (2.2). Let $|x_n - x| \to 0$ and $\langle u_n, y_n \rangle_n \to \langle u, y \rangle$ as $n \to \infty$ for every $u_n \to^{\mathscr{Q}} u$, $u_n \in l_n^1(m_n)$, $u \in L^1(\sigma)$. Due to the condition (A4) $f'_{0y} \triangleq f'_{20y}(\cdot, x, y(\cdot)) \in L^1(\sigma)$ also $f'_{0ny} \triangleq f'_{20y}(s_{in}, x, (\not\pi_n y)_{in}) \in l_n^1(m_n))$. Then, analogously to convergence $R_{0n}(x, y) \to 0$, $n \to \infty$, we can show that the sequence $\{f'_{0ny}\}$ converges discretely to $f'_{0y} \in L^1(\sigma)$.

Consider now the difference

$$f_{10}(x) + \int f_{20}(s, x, y(s))\sigma(ds) - f_{10}(x_n) - \sum_{i=1}^{n} f_{20}(s_{in}, x_n, y_{in}) m_{in}$$

$$\leqq f_{10}(x) - f_{10}(x_n) + \sum_{i=1}^{n} (f'_{20x}(s_{in}, x, (\not\pi_n y)_{in}), x - x_n) m_{in}$$

$$+ \sum_{i=1}^{n} (f'_{20y}(s_{in}, x, (\not\pi_n y)_{in}), (\not\pi_n y)_{in} - y_{in}) m_{in} + R_{0n}(x, y).$$

In the last sum all components tend to zero as $n \to \infty$ (by the definition $\not\pi_n y \to^{\mathscr{P}} y$ and by the assumption $y_n \dashrightarrow^{\mathscr{Q}} y$). Hence, the collection $(F_0, \{F_{0n}\})$ satisfies (2.2) as $|x_n - x| \to 0$, $y_n \dashrightarrow^{\mathscr{Q}} y$, $n \to \infty$. □

Let us now formulate and prove the main result of the paper.

Denote by F^* the optimal value of the problem (1.12)-(1.14), by $(\bar{x}_n, \bar{y}_n)$ and F_n^* the solution and optimal value of the problem (1.16)-(1.18), respectively.

THEOREM 3.1. *Let the conditions* (A1)-(A8) *be fulfilled. Let the convergence* (1.15) *hold. Then*

$$\lim_{n \to \infty} F_n^* = F^*$$

and all $\mathscr{Q}$-weak limit points $(\bar{x}, \bar{y})$ of the sequence $\{(\bar{x}_n, \bar{y}_n)\}$ of solutions of the problems* (1.16)-(1.18) *solve the problem* (1.12)-(1.14).

Proof. By admissibility of limit point $(\bar{x}, \bar{y})$ and by Proposition 3.2 we have

$$F^* \leqq f_{10}(\bar{x}) + \int f_{20}(s, \bar{x}, \bar{y}(s))\sigma(ds)$$

$$\leqq \liminf_{n \to \infty} \left\{ f_{10}(\bar{x}_n) + \sum_{i=1}^{n} f_{20}(s_{in}, \bar{x}_n, \bar{y}_{in}) m_{in} \right\}$$

$$= \liminf_{n \to \infty} F_n^*.$$

Let us show that the opposite inequality holds.

Due to the strict feasibility condition (A6) there exists an admissible element $(x_\lambda, y_\lambda(s))$, $x_\lambda = \lambda\tilde{x} + (1-\lambda)\bar{x}$, $y_\lambda = \lambda\tilde{y} + (1-\lambda)\bar{y}$, $0 \leqq \lambda \leqq 1$, such that

(1) $|f_{10}(x_\lambda) + \int f_{20}(s, x_\lambda, y_\lambda(s))\sigma(ds) - f_{10}(\bar{x}) - \int f_{20}(s, \bar{x}, \bar{y}(s))\sigma(ds)| < \varepsilon/2$,

(2) for $n \geqq n_1$ we have $(x_\lambda, \not{p}_n y_\lambda) \in G_n$.

Indeed, consider inequality (1):

$$\left| f_{10}(x_\lambda) + \int f_{20}(s, x_\lambda, y_\lambda(s))\sigma(ds) - f_{10}(\bar{x}) - \int f_{20}(s, \bar{x}, \bar{y}(s))\sigma(ds) \right|$$

$$\leqq \lambda \left| f_{10}(\tilde{x}) + \int f_{20}(s, \tilde{x}, \tilde{y}(s))\sigma(ds) \right.$$

$$\left. - f_{10}(\bar{x}) - \int f_{20}(s, \bar{x}, \bar{y}(s))\sigma(ds) \right|.$$

Take λ so little that

$$\left| f_{10}(x_\lambda) + \int f_{20}(s, x_\lambda, y_\lambda(s))\sigma(ds) - f_{10}(\bar{x}) - \int f_{20}(s, \bar{x}, \bar{y}(s))\sigma(ds) \right| \leqq \varepsilon/2.$$

Now $\lambda = \lambda(\varepsilon)$ is fixed. In order to guarantee the inclusion (2), $(x_\lambda, \not{p}_n y_\lambda) \in G_n$ for all $n \geqq n_1$, n_1-sufficiently large, note that the sequence $\{f_{2j}(s_{in}, x, (\not{p}_n y)_{in})\}$ $\mathcal{P}$-converges to $f_{2j}(s, x, y(s))$, $j = 1, \cdots, l_2$, i.e.,

$$\max_{1 \leqq i \leqq n} |f_{2j}(s_{in}, x, (\not{p}_n y)_{in}) - (\not{p}_n f_{2j}(s, x, y(s)))_{in}| \to 0, \quad n \to \infty. \tag{3.4}$$

This convergence is guaranteed by properties of function f_{2j} (continuity in (x, y) and Σ_0-measurability in (s) and by the definition of $\mathcal{P}$-convergence of the sequence $\{\not{p}_n y\}$ to y. Consequently,

$$\begin{aligned} f_{2j}(s_{in}, x_\lambda, (\not{p}_n y_\lambda)_{in}) \leqq{}& \lambda(f_{2j}(s_{in}, \tilde{x}, (\not{p}_n \tilde{y})_{in}) \\ & - (\not{p}_n f_{2j}(s, \tilde{x}, \tilde{y}(s)))_{in}) + \lambda(\not{p}_n f_{2j}(s, \tilde{x}, \tilde{y}(s)))_{in} \\ & + (1-\lambda)(f_{2j}(s_{in}, \bar{x}, (\not{p}_n \bar{y})_{in}) - (\not{p}_n f_{2j}(s, \bar{x}, \bar{y}(s)))_{in}) \\ & + (1-\lambda)(\not{p}_n f_{2j}(s, \bar{x}, \bar{y}(s)))_{in}. \end{aligned}$$

Since $(\not{p}_n f_{2j}(s, \bar{x}, \bar{y}(s)))_{in} \leqq 0$, $j = 1, \cdots, l_2$, $i = 1, \cdots, n$, $(\not{p}_n f_{2j}(s, \tilde{x}, \tilde{y}(s)))_{in} \leqq -\varepsilon < 0$, $j = 1, \cdots, l_2$, $i = 1, \cdots, n$, and due to $\mathcal{P}$-convergences (3.4) for arguments $(\tilde{x}, \tilde{y}(s))$ and $(\bar{x}, \bar{y}(s))$ we can conclude that there exists a sufficiently large index n_1 such that $(x_\lambda, \not{p}_n y_\lambda) \in G_n$ for all $n \geqq n_1$.

Then from the admissibility of the point $(x_\lambda, \not{p}_n y)$ we obtain the inequality

$$\begin{aligned} & f_{10}(\bar{x}_n) + \sum_{i=1}^{n} f_{20}(s_{in}, \bar{x}_n, \bar{y}_{in}) m_{in} - f_{10}(\bar{x}) - \int f_{20}(s, \bar{x}, \bar{y}(s))\sigma(ds) \\ & \leqq \left\{ f_{10}(x_\lambda) + \sum_{i=1}^{n} f_{20}(s_{in}, x_\lambda, (\not{p}_n y_\lambda)_{in}) m_{in} \right\} \\ & \quad - \left\{ f_{10}(x_\lambda) + \int f_{20}(s, x_\lambda, y_\lambda(s))\sigma(ds) \right\} \\ & \quad + \left| f_{10}(x_\lambda) + \int f_{20}(s, x_\lambda, y_\lambda(s))\sigma(ds) - f_{10}(\bar{x}) - \int f_{20}(s, \bar{x}, \bar{y}(s))\sigma(ds) \right|. \end{aligned}$$

Due to the $\mathcal{P}$-convergence (2.3) of the collection $(F_0, \{F_{0n}\})$ and continuity of f_{10} the first difference in the last sum does not exceed $\varepsilon/2$ as $n \geqq n_2$.

Then for $n \geqq \max\{n_1, n_2\}$ we have

$$f_{10}(\bar{x}_n) + \sum_{i=1}^{n} f_{20}(s_{in}, \bar{x}_n, \bar{y}_{in}) m_{in} \leqq f_{10}(\bar{x}) + \int f_{20}(s, \bar{x}, \bar{y}(s)) \sigma(ds) + \varepsilon.$$

Consequently, $\lim_{n\to\infty} F_n^* = F^*$.

The remaining part of the theorem follows from the $\mathcal{Q}$-weak* convergence of $\{(\bar{x}_{n_k}, \bar{y}_{n_k})\}$, $k = 1, \cdots$, and the admissibility of its limit point $(\bar{x}, \bar{y}(s))$.

Example. Let us illustrate the idea of discrete approximation with a simple example. Consider the Example 2′ (with relatively complete recourse) from [17]: find $x \in R^1$ and $y \in L^\infty[0, 1]$ such that $x \geqq 1$, $y(s) \geqq 0$ and $y(s) - x + s \leqq 0$ for almost all s minimizing the expression

$$2x - \int_0^1 y(s)\, ds.$$

Here $\bar{x} = 1$, $\bar{y}(s) = 1 - s$, $F^* = \frac{3}{2}$.

Consider now the discretized problem: Find $x \in R^1$ and $y_{in} \in R^1$, $i = 1, \cdots, n$, such that $x \geqq 1$, $y_{in} \geqq 0$ and $y_{in} - x + i/n \leqq 0$, $i = 1, \cdots, n$, minimizing the expression

$$2x - \frac{1}{n} \sum_{i=1}^{n} y_{in}.$$

Clearly $\bar{x}_n = 1$, $\bar{y}_{in} = 1 - i/n$, $F_n^* = 3/2 + 1/2n$. Hence, $F_n^* \to F^*$, $\bar{x}_n = \bar{x}$ and $\bar{y}_n \to \bar{y}$ discretely.

4. Concluding remarks. The aim of this paper was to develop an approximation scheme for stochastic convex programs with relatively complete recourse. The problem in the space $R^r \times L^\infty(\sigma)$ was replaced by a mathematical programming problem in a finite-dimensional space. This replacement is justified by the notion of discrete convergence of mappings which describes the convergence of elements in different spaces by a system of connection operators.

Unfortunately, we are not able to solve approximately the general stochastic convex program with recourse. In general the "singular multipliers" [17] in Kuhn-Tucker conditions result from the presence of induced constraints and we have to consider the problem (1.12)-(1.14) in L^∞ in pairing with $(L^\infty)^* \asymp ba(S, \Sigma, \sigma)$—the space of bounded additive set functions which are absolutely continuous with respect to σ. Since for an element $\mu \in ba(S, \Sigma, \sigma)$ the Radon-Nikodym Theorem is formulated under extremely strong conditions [13] (without the Radon-Nikodym Theorem we are not able to discretize the set function μ from $ba(S, \Sigma, \sigma)$), it is quite difficult to define the discrete convergence in $(L^\infty)^*$.

Acknowledgments. The author expresses his gratitude to the referees for the constructive criticism concerning stochastic programming and discrete approximation problems and to the editor for the encouraging attitude.

ON A THEOREM OF ARROW, BARANKIN, AND BLACKWELL*

MARTIN PETSCHKE†

Abstract. A well-known theorem of Arrow, Barankin, and Blackwell states that if $\mathbf{R}^n$ is equipped with the natural ordering, then for every compact convex subset S of $\mathbf{R}^n$ the set of properly minimal elements of S is dense in the set of minimal elements of S.

In this note a result of Jahn is used to show a generalization of the density theorem of Arrow, Barankin, and Blackwell. It will be shown that this theorem holds in a real normed space that is partially ordered by a convex cone with a closed bounded base.

Key words. vector optimization, convex cones

AMS(MOS) subject classifications. 49A27, 46A40, 52A07

1. Introduction. A well-known theorem of Arrow, Barankin, and Blackwell [1] states that if $\mathbf{R}^n$ is equipped with the natural ordering, then for every compact convex subset S of $\mathbf{R}^n$ the set of properly minimal elements of S is dense in the set of minimal elements of S. It was shown by Bitran and Magnanti in [2, Cor. 3.1] that this result remains valid if $\mathbf{R}^n$ is partially ordered by an arbitrary closed convex pointed cone. The Arrow-Barankin-Blackwell Theorem was extended by Borwein [3, Thm. 2] to real normed spaces partially ordered by a convex cone with weakly compact base. In [9, Satz 1] Salz proved the result of Arrow-Barankin-Blackwell in real normed spaces with base norms.

Recently, Jahn [5] has shown that the Arrow-Barankin-Blackwell Theorem remains true in real normed spaces, partially ordered by a Bishop-Phelps cone. What the previously mentioned results have in common is that the ordering cones have closed bounded bases. So we might conjecture that the Arrow-Barankin-Blackwell Theorem is valid for real normed spaces partially ordered by a convex cone with a closed bounded base.

In this note we will answer this conjecture in the affirmative (Theorem 4.1, Corollary 4.2). The idea of our proof is to extend the scope of Jahn's result by means of a characterization lemma concerning Bishop-Phelps cones.

Another problem that arises in this context is the following question. Jahn has shown that the Arrow-Barankin-Blackwell result is valid in L_1 and l_1 spaces, and Borwein has proven it in the case of reflexive spaces. What can be stated for a finite product of some L_1-spaces and some reflexive spaces? In general this product space is neither of L_1 type nor is it reflexive. We will cover this question in an example of a cooperative n player game in § 5.

The result of Corollary 4.2 has an interesting consequence in vector optimization, since it shows that a numerical solution of a convex problem can be computed by solving appropriate scalarized problems.

2. Minimality, proper minimality and Bishop–Phelps cones. Before we present the precise statements, let us recall some basic notions and definitions. In this section let E denote a locally convex Hausdorff space partially ordered by a convex cone C. A subset B of C is called a *base* of C, if B is convex and if each $x \in C\backslash\{0\}$ has a unique

representation $x = \lambda b$ for some $\lambda > 0$ and some $b \in B$. Let us note that if C is a nontrivial cone with basis B then we have $0 \notin B$. We call C *pointed*, if $C \cap -C = \{0\}$. Throughout this paper let E^* denote the topological dual space of E. The *dual cone* C^* of C is defined as

$$C^* := \{l \in E^* : l(x) \geqq 0 \ (x \in C)\}.$$

An important subset of C^* is the *quasi-interior* of C^*, which we denote by $C^{\#}$:

$$C^{\#} := \{l \in E^* : l(x) > 0 \ (x \in C \setminus \{0\})\}.$$

If C has a closed bounded base then C^* has nonempty interior in the strong topology of E^* [7, 3.8.4]. All those interior points are in $C^{\#}$. Now let S be a nonempty subset of E. The convex hull of S will be denoted by conv. (S). We call $\bar{x} \in S$ a *minimal* element of S (with respect to C), if

$$S \cap (\bar{x} - C) = \{\bar{x}\}.$$

An element $\bar{x} \in S$ is called a *properly minimal* element of S (with respect to C) if there is some $l \in C^{\#}$ such that

$$l(\bar{x}) \leqq l(x) \qquad (x \in S).$$

It is obvious that the set of properly minimal elements of S is always contained in the set of minimal elements of S.

Suppose there are two norms $p : E \to \mathbf{R}_+$ and $q : E \to \mathbf{R}_+$. We say that p is *equivalent* to q if there are two positive numbers m and M such that

$$mp(\cdot) \leqq q(\cdot) \leqq Mp(\cdot).$$

Thus p is equivalent to q if and only if p and q induce the same topology on E.

Let $(E, \|\cdot\|)$ be a real normed space, and let S^* denote the unit sphere of the dual space E^*. A subset K of E is called a Bishop-Phelps cone if there is some $l \in S^*$ and $\alpha \in (0, 1]$ such that

$$K = \{x \in E : l(x) \geqq \alpha \|x\|\}.$$

It is easy to see that K is a pointed closed convex cone. If K is not trivial, then K possesses the closed bounded base

$$B := \{x \in K : l(x) = 1\}.$$

But even in $\mathbf{R}^3$ with the Euclidean norm it is not true that every convex cone with a closed bounded base is a Bishop-Phelps cone. The reason for this phenomenon is that every base of a Bishop-Phelps cone in this space must be the convex hull of some ellipse. Thus the natural ordering cone $\mathbf{R}^3_+$ cannot be a Bishop-Phelps cone, since every base of it must be a triangle. On the other hand, $\mathbf{R}^3_+$ is a Bishop-Phelps cone if $\mathbf{R}^n$ is equipped with the l_1-norm. In the next section we will investigate the relation of Bishop-Phelps cones with respect to different norms.

3. Representation of cones as Bishop–Phelps cones.

DEFINITION 3.1. Let $(E, \|\cdot\|)$ be a normed space. Let C be a subset of E. We say that C is *representable* as a Bishop-Phelps cone, if there is some $l \in E^*$ and a norm $p : E \to \mathbf{R}_+$, which is equivalent to $\|\cdot\|$, such that

$$C = \{x \in E : p(x) \leqq l(x)\}.$$

In view of the examples of Bishop-Phelps cones at the end of § 2, we now are able to give a unified characterization of Bishop-Phelps cones generated by different norms.

THEOREM 3.2. *Let $(E, \|\cdot\|)$ be a real normed space. Let C be a nonempty subset of E with $C \neq \{0\}$. Then the following assertions are equivalent*:

(1) *C is representable as a Bishop-Phelps cone.*

(2) *C is a convex cone with a closed bounded base.*

Let us note here that every convex cone with a closed bounded base is closed and pointed [7, Prop. 3.8.3].

Proof. If C is representable as a Bishop-Phelps cone, then there is some $l \in E^*$ and a norm $p: E \to \mathbf{R}_+$, which is equivalent to $\|\cdot\|$ and such that

$$C = \{x \in E: p(x) \leqq l(x)\}.$$

It is easy to see that C is a convex cone. The continuity of l and p imply that C is closed. Let $B := \{x \in C: l(x) = 1\}$. Then B is a base (cf. [6, Lemma 3.3]). We have $p(x) \leqq 1$ for all $x \in B$. Since $\|\cdot\|$ and p are equivalent norms, the set B is bounded. This establishes (1) of Theorem 3.2.

Let C be a convex cone with a closed bounded base B_0. Since $0 \notin B_0$ there is some continuous linear functional, which strictly separates the convex sets $\{0\}$ and B_0. Thus we have some $l \in E^*$ and some $\kappa > 0$ such that

$$0 < \kappa \leqq l(b) \qquad (b \in B_0).$$

Let us consider the set $B := \{x \in C: l(x) = 1\}$. It is easy to verify that B is a closed base of C. Since B_0 is bounded there is some $M > 0$ such that $\|b\| \leqq M$ for all $b \in B_0$. We will show now that B is also bounded. Let x be an element of B. Then there are $\rho > 0$ and $b \in B_0$ such that $x = \rho b$. Thus we have

$$\rho = \rho/1 = \rho/l(x) = 1/l(b) \leqq \kappa^{-1}.$$

From this relation we derive the inequality

$$\|x\| = \rho\|b\| \leqq \kappa^{-1}M,$$

which shows that B is bounded. Now pick $\delta > 0$ such that $l(u) \leqq \frac{1}{2}$ for all $u \in U_\delta := \{x \in E: \|x\| \leqq \delta\}$. Let

$$F := \text{conv.}\,(-B \cup U_\delta \cup B).$$

Then F is convex balanced and absorbing. These properties of F imply that the corresponding *Minkowski* functional

$$p(x) := \inf\{t > 0: x \in tF\} \qquad (x \in E)$$

is a seminorm on E. Furthermore, F is the convex hull of a bounded set. Thus F is also bounded. Consequently, p is a norm on E. Since F is bounded, there is some $m > 0$ with $\|x\| \leqq m$ for all $x \in F$. From the convexity of the sets B, $-B$, and U_δ, it follows that each $x \in F$ has a representation

$$x = \lambda b + \mu u + \nu(-d)$$

for some elements $b, d \in B$, $u \in U_\delta$ and nonnegative numbers λ, μ, ν, that satisfy the condition $\lambda + \mu + \nu = 1$.

Now we will show that $p(\cdot)$ and $\|\cdot\|$ are equivalent. Let $x \in E$ with $\|x\| \leqq \delta$. Then we have $x \in U_\delta \subset F$, and this renders $p(x) \leqq 1$.

Now let $x \in E$ with $p(x) \leqq 1$. Then we get $x \in \bar{F}$. Let $M := \max\{m, \delta\}$. Thus we have $\|x\| \leqq M$. The two preceding conclusions can be summarized in the following inequality:

$$\delta p(x) \leqq \|x\| \leqq Mp(x) \qquad (x \in E).$$

This shows that $p(\cdot)$ and $\|\cdot\|$ are equivalent.

The proof will be complete if we can show that

$$C = \{x \in E : p(x) \leqq l(x)\}. \tag{1}$$

We will denote the right side of (1) by A. First let us show the inclusion $C \subset A$. Let $x \in C$. Then there is some $\lambda \geqq 0$ and some $b \in B$ such that $x = \lambda b$. Thus we have $x \in \lambda B \subset \lambda F$, and this renders $p(x) \leqq \lambda$. Consequently, we get

$$p(x) \leqq \lambda \cdot 1 = \lambda l(b) = l(\lambda b) = l(x)$$

and this implies $x \in A$. It remains to show the inclusion $A \subset C$. We need only to prove that any element $x \in E$ is contained in C if it satisfies the conditions $p(x) = 1$ and $l(x) \geqq 1$. So let $x \in E$ be an element with these properties. Since $p(x) = 1$, we have $x \in \tau F$ for all $\tau > 1$. Now let $(\tau_n)_{n \in \mathbf{N}}$ be a sequence of real numbers with $\tau_n > 1$ for all $n \in \mathbf{N}$ and $\lim_{n \to \infty} \tau_n = 1$. Since $x \in \tau_n F$ for each $n \in \mathbf{N}$ there is some element $b_n \in B$, $d_n \in B$, and $u_n \in U_\delta$ and nonnegative numbers λ_n, μ_n, ν_n with $\lambda_n + \mu_n + \nu_n = 1$ such that

$$x = \tau_n(\lambda_n b_n + \mu_n u_n + \nu_n(-d_n)). \tag{2}$$

We have $0 \leqq \lambda_n \leqq 1$, $0 \leqq \mu_n \leqq 1$, $0 \leqq \nu_n \leqq 1$. Then we can select convergent subsequences $(\lambda_{n_j})_{j \in \mathbf{N}}$, $(\mu_{n_j})_{j \in \mathbf{N}}$, $(\nu_{n_j})_{j \in \mathbf{N}}$. We denote the limits of these subsequences by λ, μ, and ν, respectively. Since $l(x) \geqq 1$ we derive from (2)

$$1 \leqq l(x) \leqq \tau_{n_j}(\lambda_{n_j} + \tfrac{1}{2}\mu_{n_j} - \nu_{n_j}). \tag{3}$$

If we let $j \to \infty$ in (3), we obtain the following inequality:

$$1 \leqq \lambda + \tfrac{1}{2}\mu - \nu. \tag{4}$$

Since $\lambda_{n_j} + \mu_{n_j} + \nu_{n_j} = 1$, as $j \to \infty$ we get

$$1 = \lambda + \mu + \nu. \tag{5}$$

Combining the inequality (4) with (5) leads to the inequality

$$\tfrac{1}{2}\mu + 2\nu \leqq 0.$$

Since μ and ν are nonnegative, we have $\mu = 0$ and $\nu = 0$. From this it follows that $\mu_{n_j} \to 0$, $\nu_{n_j} \to 0$, $\lambda_{n_j} \to 1$. Since U_δ and B are bounded, we have

$$\tau_{n_j}(\mu_{n_j} u_{n_j} + \nu_{n_j}(-d_{n_j})) \to 0 \qquad (j \to \infty).$$

So from (2) it follows that

$$\tau_{n_j} \lambda_{n_j} b_{n_j} \to x \qquad (j \to \infty).$$

Since $\tau_{n_j} \lambda_{n_j} \to 1$, it follows that $b_{n_j} \to x$. But b_{n_j} is contained in B. Consequently, we have $x \in \bar{B} = B \subset C$. Thus $x \in C$ and the desired conclusion has been shown. □

Now we will investigate convex cones in $\mathbf{R}^n$. In the sequel let $\mathbf{R}^n$ be equipped with the Euclidean norm.

LEMMA 3.3. *Every pointed closed convex cone in $\mathbf{R}^n$ admits a compact base.*

Proof. Since $\mathbf{R}^n$ is locally compact, a well-known theorem of Klee [7, Thm. 3.12.8] renders the assertion. □

The next assertion follows directly from Lemma 3.3 and Theorem 3.2.

THEOREM 3.4. *A convex cone in $\mathbf{R}^n$ is representable as a Bishop–Phelps cone if and only if it is closed and pointed.*

4. A generalization of the Arrow–Barankin–Blackwell Theorem. Now we are able to prove the previously announced results.

THEOREM 4.1. *Let $(E, \|\cdot\|)$ be a real normed space, partially ordered by a closed convex cone C with a closed bounded base. Let S be a nonempty convex subset of E, and let $\bar{x} \in S$ be a minimal element of S such that the set*

$$\hat{S} := \{x \in S: \|x - \bar{x}\| \leqq 1\}$$

is weakly compact. Then for every $\varepsilon > 0$ there is some $l_\varepsilon \in C^\#$ and some $x_\varepsilon \in S$ such that

$$l_\varepsilon(x_\varepsilon) = \min_{x \in S} l_\varepsilon(x) \quad \text{and} \quad \|x_\varepsilon - \bar{x}\| \leqq \varepsilon.$$

Proof. Let $\bar{x}$ be some minimal element of S with respect to C and choose $\varepsilon > 0$. Since C is a convex cone with a closed bounded base we can apply Theorem 3.2. Thus there is some $l \in E^*$ and a norm $p: E \to \mathbf{R}_+$ that is equivalent to $\|\cdot\|$ such that

$$C = \{x \in E: p(x) \leqq l(x)\}.$$

Since p is equivalent to $\|\cdot\|$ there are numbers $m > 0$, $M > 0$ with

$$m\|\cdot\| \leqq p(\cdot) \leqq M\|\cdot\|.$$

So $q := (1/m)p$ is also a norm equivalent to $\|\cdot\|$. Let

$$T := \{x \in S: q(x - \bar{x}) \leqq 1\}.$$

It is easy to check that T is a subset of $\hat{S}$. The set T is closed since q is equivalent to $\|\cdot\|$. Thus T is a closed convex subset of the weakly compact set $\hat{S}$, and therefore T is weakly compact also. Then T is also weakly compact in the space (E, q) since the weak topologies of (E, q) and $(E, \|\cdot\|)$ coincide. Another consequence of the equivalence of $\|\cdot\|$ and q is that $C^\#$ remains the same for both spaces $(E, \|\cdot\|)$ and (E, q). Let us define

$$\beta := \sup\left\{\frac{1}{m} l(x): x \in E, q(x) \leqq 1\right\}.$$

Since l is continuous in (E, q) and $C \neq \{0\}$ the inequality $1 \leqq \beta < \infty$ holds. Now we let $\alpha := (1/\beta) \in (0, 1]$ and $l_0 := (\alpha/m)l$. Then l_0 has norm one in the dual space of (E, q) and we have

$$C = \{x \in E: \alpha q(x) \leqq l_0(x)\}.$$

Thus C is a Bishop-Phelps cone in (E, q). Furthermore, T is a weakly compact set in (E, q).

We now may apply Jahn's result [5, Thm. 3.1] to the set S as a subset of the space (E, q): Then for $\varepsilon > 0$ there is some x_ε and some $l_\varepsilon \in C^\#$ such that

$$l_\varepsilon(x_\varepsilon) \leqq l(x) \qquad (x \in S)$$

and $q(\bar{x} - x_\varepsilon) \leqq \varepsilon$. Thus we have

$$\|x_\varepsilon - \bar{x}\| \leqq \frac{1}{m} p(x_\varepsilon - \bar{x}) = q(x_\varepsilon - \bar{x}) \leqq \varepsilon.$$

This completes the proof. □

In the remainder of this section we will present some special cases of Theorem 4.1.

In [3] Borwein has already proved that the set of minimal elements of some weakly compact convex set is contained in the weak closure of the set of properly minimal elements, if the ordering is induced by a cone with a compact base. So in a reflexive space the set of properly minimal elements is dense (with respect to the weak topology) in the set of minimal elements if the cone has a closed bounded base.

Jahn has shown in [5, Cor. 3.5] a result of similar type. He first considered a space ordered by some cone C with a closed bounded base. In this case he has proved that a minimal element of $\bar{x}$ of some weakly compact set can be approximated (with respect to the norm topology) by properly minimal elements, if $\bar{x}$ is also minimal with respect to some Bishop-Phelps cone containing C.

We can obtain both results as immediate consequences of the following corollary, which follows easily from Theorem 4.1.

COROLLARY 4.2. *Let $(E, \|\cdot\|)$ be a real normed space, partially ordered by a convex cone with a closed bounded base, and let S be a weakly compact convex subset of E. Then the set of properly minimal elements of S is dense (with respect to the norm topology) in the set of minimal elements.*

If $E = \mathbf{R}^n$, we derive from Theorem 4.1 and Lemma 3.3 the result of Bitran and Magnanti [2, Cor. 3.1].

COROLLARY 4.3. *Let $\mathbf{R}^n$ be partially ordered by a closed convex pointed cone. Let S be a closed convex subset of $\mathbf{R}^n$. Then the set of properly minimal elements of S is dense in the set of minimal elements of S.*

Since every locally convex Hausdorff space of finite dimensions is isomorphic to $\mathbf{R}^n$ (for a suitable integer n), Corollary 4.3 remains true for such spaces.

5. Example. In this section we will present an application of Corollary 4.2. We will consider an example from [6, Ex. 4.6].

5.1. Cooperative n player game. Let $X, E_1, \cdots, E_n$ be real locally convex Hausdorff spaces. Let each space E_i $(i = 1, \cdots, n)$ be ordered by a closed convex cone C_i $(i = 1, \cdots, n)$. Furthermore, let T be a nonempty subset of X. For each player there is given a mapping $P_i : T \to E_i$, which he tries to minimize on T.

As all players act exclusively cooperative this game can be viewed as a problem of vector optimization.

5.2. Problem of vector optimization. Let $E := E_1 \times E_2 \times \cdots \times E_n$ be the usual product space ordered by the convex cone $C := C_1 \times C_2 \times \cdots \times C_n$. Let $P : T \to E$ be the function $P(t) := (P_1(t), \cdots, P_n(t))$ $(t \in T)$.

In this setting we can reformulate the cooperative n player game: all points of $S := P(T)$, which are minimal with respect to C, must be localized. We now are interested in conditions that assure the Arrow-Barankin-Blackwell Theorem holds in E, if it holds in each E_i. Corollary 4.2 states that this theorem holds in each E_i, if C_i has a closed bounded base.

LEMMA 5.3. *If each of the convex cones $C_1, \cdots, C_n$ has some closed bounded base, then $C := C_1 \times C_2 \times \cdots \times C_n$ also has a closed bounded base.*

Proof. Let $B_1, \cdots, B_n$ be the closed bounded bases of $C_1, \cdots, C_n$, respectively. Consider the set

$$B := \bigcup_{\lambda_1, \cdots, \lambda_n \geq 0; \Sigma \lambda_i = 1} \lambda_1 B_1 \times \cdots \times \lambda_n B_n.$$

We easily check that B is a closed bounded base of C. □

So if $C_1, \cdots, C_n$ all have closed bounded bases, with the aid of Lemma 5.3 we can immediately apply Corollary 4.2 to the setting in § 5.2.

THE EXISTENCE OF CATCHING-UP OPTIMAL SOLUTIONS FOR A CLASS OF INFINITE HORIZON OPTIMAL CONTROL PROBLEMS WITH TIME DELAY*

DEAN A. CARLSON†

Abstract. The optimal control of a system whose states are governed by a nonlinear autonomous Volterra integrodifferential equation with unbounded time interval is considered. Specifically, it is assumed that the delay occurs only in the state variable. The results obtained extend those of Brock and Haurie [*Math. Oper. Res.*, 1 (1976), pp. 337-346] and Leizarowitz [*Math. Oper. Res.*, 10 (1985), pp. 450-461]. In particular, it is shown that (under appropriate hypotheses) catching-up optimal solutions asymptotically approach a unique optimal steady state, and thus enjoy the so-called "turnpike" property found in the economics literature. By combining this result with an associated optimal control problem, the desired existence result is obtained. Furthermore, it is remarked that, in addition to extending these earlier works to the time-delay case, the results presented below utilize convexity, seminormality, and growth hypotheses that in some cases are weaker than those encountered in the above-mentioned papers.

Key words. catching-up solutions, optimal control, integrodifferential equations

1. Introduction. The study of optimal control problems defined on infinite intervals has recently been a rapidly growing area of research. The primary area of application of these problems, although not the only one, concerns models of economic growth in which we search for a path of optimal capital accumulation. In these models it is shown that there exists an optimal asymptotic sustainable consumption in the economy. For a detailed introduction to optimal control problems of this type the reader is referred to the monograph of Carlson and Haurie [6].

It has long been recognized that time delays are important in formulating economic models. Indeed as early as 1935, Kalecki [14] introduced a class of such models described by differential-difference equations. These models were further investigated by Leontief [16] and others. More recently, models with infinite delay were formulated to describe optimal dynamic advertising. In particular, we refer to Hartl [12] for such a model as well as to the article of Hartl and Sethi [13].

In the present paper, we are concerned with the existence of catching-up optimal solutions for a class of models in which the states are governed by a nonlinear autonomous Volterra integrodifferential equation with infinite delay where the delay occurs only with respect to the state variable. The results we obtain extend the original results of Brock and Haurie [5], as well as the generalization given in Leizarowitz [15], for optimal control models whose states are governed by autonomous ordinary differential equations (see also Carlson and Haurie [6]).

With these remarks, the plan of the work presented below is as follows. In § 2, we introduce the model considered and indicate the basic hypotheses assumed throughout our work. Section 3 is devoted to summarizing several technical results concerning linear hereditary operators due to Marcus and Mizel [17] as well as presenting a general lower closure theorem that will be utilized in our presentation. The desired existence results are given in § 4 and we conclude our discussion in § 5

by presenting several examples, including a version of the classical Ramsey model with a distributed time delay.

2. The basic model. We consider a system described by a Volterra integrodifferential equation of the form

$$\dot{x}(t) = f(x(t), u(t)) + \int_{-\infty}^{t} g(t-s)h(x(s))\, ds \quad \text{a.e. } t \geqq 0, \tag{2.1}$$

where $x: (-\infty, \infty) \to E^n$ is a bounded continuous function that is locally absolutely continuous on $[0, \infty)$ and statisfies the prescribed initial condition

$$x(s) = x_0(s) \quad \text{for all } s < 0, \tag{2.2}$$

where $x_0: (-\infty, 0] \to E^n$ is a given bounded continuous function, as well as the state constraints

$$x(t) \in X \quad \text{for } t \in (-\infty, \infty), \tag{2.3}$$

in which X is a closed subset of the n-dimensional Euclidean space E^n. The control function $u: [0, \infty) \to E^m$ is assumed to be Lebesgue measurable and satisfies the feedback control constraints

$$u(t) \in U(x(t)) \quad \text{a.e. } 0 \leqq t, \tag{2.4}$$

where $U: X \to 2^{E^m}$ is a point to set mapping with closed graph $M = \{(x, u): x \in X \text{ and } u \in U(x)\}$.

As regards the functions f, g, and h, we assume that $f: M \to E^n$ and $h: X \to E^p$ are both continuous and that $g = (g_{ij})_{n \times p}$ is an $n \times p$ matrix function defined for $t \geqq 0$ with entries satisfying

$$\begin{aligned} &\text{(i)} \quad \int_0^{\infty} |g_{ij}(t)|\, dt < \infty, \\ &\text{(ii)} \quad \int_0^{\infty} t|g_{ij}(t)|\, dt < \infty, \\ &\text{(iii)} \quad \sum_{m=1}^{\infty} \|g_{ij}\|_m^{\infty} < \infty, \end{aligned} \tag{2.5}$$

where $\|g_{ij}\|_m^{\infty}$ is the essential supremum of g_{ij} restricted to the interval $[m-1, m]$, $m = 1, 2, \cdots$. We remark that the assumption (2.5)(iii) given above implies (2.5)(i), but we have included both for definiteness.

The performance of the above control system is described for any positive time T by the integral functional

$$J_T(x, u) = \int_0^T f^0(x(s), u(s))\, ds, \tag{2.6}$$

where $f^0: M \to E^1$ is a given lower semicontinuous function.

With this notation, we give the following definition.

DEFINITION 2.1. A bounded continuous function $x: (-\infty, \infty) \to E^n$ will be called a *trajectory* if x is locally absolutely continuous on $[0, \infty)$ and if there exists a Lebesgue measurable function (referred to as a control) $u: [0, \infty) \to E^m$ such that the pair $\{x, u\}$ satisfies (2.1), (2.3), (2.4), and the map $t \to f^0(x(t), u(t))$ is locally Lebesgue integrable on $[0, \infty)$. If in addition, the trajectory x satisfies the prescribed initial condition (2.2), we will call x an admissible trajectory and u an admissible control.

For brevity we let A denote the set of all trajectory-control pairs $\{x, u\}$ and let $A_0 \subset A$ be the set of all admissible pairs.

Since the system described above is defined for all $t \geqq 0$, we are primarily concerned with the performance over the entire interval $[0, \infty)$. We do not, however, assume a priori that the performance criterion $J_T(x, u)$ has a finite limit as $T \to \infty$. This necessitates the need to consider a weaker notion of optimality. For our treatment we restrict our attention to the following definitions.

DEFINITION 2.2. An admissible pair $\{x^*, u^*\} \in A_0$ is called

(i) *Strongly optimal* if $J_\infty(x^*, u^*) = \lim_{T\to\infty} J_T(x^*, u^*)$ is finite and if for every $\{x, u\} \in A_0$ we have

$$J_\infty(x^*, u^*) \leqq \lim_{T\to\infty} \inf J_T(x, u); \tag{2.7}$$

(ii) *Catching-up* (or overtaking) *optimal* if for each $\varepsilon > 0$ and pair $\{x, u\} \in A_0$, there exists $\tau = \tau(\varepsilon, x, u) \geqq 0$ such that for all $T \geqq \tau$ we have

$$J_T(x^*, u^*) \leqq J_T(x, u) + \varepsilon. \tag{2.8}$$

Remark 2.1. The notion of strong optimality given above is, of course, the traditional concept of a minimizer. On the other hand, catching-up optimality is a weaker concept that was introduced by von Weiszäcker [20] in 1965. The term overtaking optimality was apparently first used in Brock and Haurie [5]. For a detailed treatment of this concept of optimality as well as several others we refer the reader to [6].

As is usual in discussions of existence of optimal solutions for optimal control problems, it is necessary to place certain convexity and growth hypotheses on the model. These conditions are needed to ensure that appropriate lower semicontinuity and compactness properties hold. The assumptions we require are described as follows.

(A1) For each $x \in X$, the set $\tilde{\mathbb{Q}}(x)$ given by

$$\tilde{\mathbb{Q}}(x) = \{(z^0, z) \in E^{1+n}: z^0 \geqq f^0(x, u), z = f(x, u), u \in U(x)\} \tag{2.9}$$

is a nonempty closed, convex set that satisfies the upper semicontinuity condition property (K) given as

$$\tilde{\mathbb{Q}}(x) = \bigcap_{\delta>0} \operatorname{cl}[\cup \{\tilde{\mathbb{Q}}(y): |y - x| < \delta\}] \tag{2.10}$$

where $|\cdot|$ denotes the usual Euclidean norm on E^n.

(A2) We assume that for each $\varepsilon > 0$ there exists $c_\varepsilon > 0$ such that for all $(x, u) \in M$ we have

$$|f(x, u)| + |h(x)| \leqq c_\varepsilon + \varepsilon f^0(x, u). \tag{2.11}$$

Remark 2.2. The conditions placed on the sets $\tilde{\mathbb{Q}}(x)$ described above are standard and it is well known that for each $T > 0$ they guarantee, in the ordinary case (i.e., $h(x) = 0$), that the functional $(x, u) \to J_T(x, u)$ is lower semicontinuous on A_0 with respect to the weak topology in $\mathrm{AC}([0, T]; E^n)$, the space of absolutely continuous functions, placed on the set of admissible trajectories. (That is, the topology of pointwise convergence of initial conditions and weak L_1-convergence in the derivatives of x.) The growth condition given in (A2) provides for the equi-absolute integrability of the derivatives of the admissible trajectories on $[0, T]$ in a minimizing sequence, and consequently (by the Dunford–Pettis criterion), gives the requisite compactness conditions. We further remark that in the ordinary differential equation case this growth

condition is weaker than the growth condition used in Leizarowitz [15], but it is equivalent to the classical growth hypothesis of Nagumo and Tonelli, which is referred to in Proposition 3.2 of [15]. For a complete discussion of these matters see Cesari [9, § 10.4].

To conclude our description of the model, we introduce the optimal steady-state problem. As is usual in the treatment of autonomous infinite horizon optimal control problems, it will be established that the catching-up optimal solution, which we exhibit, will converge to the optimal steady state. In the economics literature this is commonly called a turnpike property. Such a property was first introduced by Samuelson [18] (see also Cass [8]) in the context of optimal economic growth. We now describe this steady-state problem.

(A3) We assume that the optimal steady-state problem (OSSP) described as

(i) minimize $f^0(x, u)$

subject to

(2.12) (ii) $0 = f(x, u) + \left(\int_0^\infty g(s)\, ds \right) h(x),$

(iii) $x \in X,$

(iv) $u \in U(x)$

has a solution $(\bar{x}, \bar{u}) \in E^{n+m}$, with $\bar{x}$ uniquely determined.

We further assume that there exists $\bar{p} \in E^n$ such that the lower semicontinuous function $L: M \to E^1$ given by

$$L(x, u) = f^0(x, u) - f^0(\bar{x}, \bar{u}) + \left\langle \bar{p}, f(x, u) + \left(\int_0^\infty g(s)\, ds \right) h(x) \right\rangle \tag{2.13}$$

is nonnegative, where $\langle \cdot, \cdot \rangle$ denotes the usual inner product in E^n.

Remark 2.3. The OSSP described above plays an analogous role for the nondelay infinite horizon optimal control problem described by

$$\text{minimize} \int_0^{+\infty} f^0(x(t), u(t))\, dt$$

subject to

$$\dot{x}(t) = f(x(t), u(t)) + \left(\int_0^\infty g(s)\, ds \right) h(x(t)) \quad \text{a.e. } t \geqq 0,$$

$$x(0) = x_0(0),$$

$$x(t) \in X \quad \text{from } t \in (-\infty, \infty),$$

and

$$u(t) \in U(x(t)) \quad \text{a.e. } [0, \infty).$$

In fact, under essentially the same hypotheses as those utilized here, we can establish the existence of a catching-up optimal solution, say $\{\hat{x}, \hat{u}\}$, for the nondelay case (see, e.g., Brock and Haurie [5] and Leizarowitz [15]) by appealing to established results. We refer the reader to these results that are outlined in Carlson and Haurie [6]. In particular, we remark that in all these results it is established that

$$\lim_{t \to \infty} \hat{x}(t) = \bar{x}.$$

As we will see in § 4 this asymptotic convergence property also holds for the delay case considered here. In this way we see that for large $t>0$, the optimal trajectories for both systems are close together.

Concerning the function L we have the following elementary result.

PROPOSITION 2.1. *Under the hypotheses placed on X, U, f^0, f, h, and g, if the sets $\tilde{\mathbb{Q}}(x)$, given by* (2.9), *satisfy the conditions outlined in* (A1) *we have that the sets $\tilde{\mathbb{Q}}_L(x)$ defined for $x \in X$ by*

$$\tilde{\mathbb{Q}}_L(x) = \{(z^0, z): z^0 \geqq L(x, u),\ z = f(x, u),\ u \in U(x)\}$$

enjoy the same properties. Furthermore, if f, h, and f^0 satisfy the growth condition (A2), *the same holds for f, h, and L. That is, for each $\varepsilon > 0$ there exists $c_\varepsilon > 0$ so that*

$$|f(x, u)| + |h(x)| \leqq c_\varepsilon + \varepsilon L(x, u)$$

for all $(x, u) \in M$.

Proof. The convexity and upper semicontinuity properties of the sets $\tilde{\mathbb{Q}}_L(x)$ are an easy consequence of the fact that for each $x \in X$ the affine mapping $\Gamma_x : \tilde{\mathbb{Q}}(x) \to \tilde{\mathbb{Q}}_L(x)$ defined by

$$\Gamma_x(z^0, z) = \left(z^0 - f^0(\bar{x}, \bar{u}) + \left\langle \bar{p}, z + \left(\int_0^\infty g(s)\, ds \right) h(x) \right\rangle, z \right)$$

is one-to-one and onto. We leave the details of this argument to the reader.

To establish the growth condition we let $\varepsilon > 0$ be given, let $K = \max [|\bar{p}|, |\bar{p}| \int_0^\infty g(s)\, ds|]$, and observe that for each $(x, u) \in M$ we have

$$\begin{aligned} f^0(x, u) &= L(x, u) + f^0(\bar{x}, \bar{u}) - \left\langle \bar{p}, f(x, u) + \left(\int_0^\infty g(s)\, ds \right) h(x) \right\rangle \\ &\leqq L(x, u) + f^0(\bar{x}, \bar{u}) + K[|f(x, u)| + |h(x)|]. \end{aligned}$$

Let $\eta > 0$ be chosen so that $\eta < \min [\varepsilon/(1+\varepsilon K), 1/K]$ if $K \neq 0$ and $\eta = \varepsilon$ if $K = 0$. From (A2) there exists $c_\eta > 0$ such that (2.11) holds with $\varepsilon = \eta$. This implies that for all $(x, u) \in M$,

$$|f(x, u)| + |h(x)| \leqq c_\eta + \eta[L(x, u) + f^0(\bar{x}, \bar{u}) + K[|f(x, u)| + |h(x)|]]$$

or, equivalently,

$$(1 - \eta K)[|f(x, u)| + |h(x)|] \leqq [c_\eta + \eta f^0(\bar{x}, \bar{u})] + \eta L(x, u).$$

From our choice of η it follows that $(1 - \eta K)^{-1}\eta < \varepsilon$ and that $1 - \eta K > 0$. Therefore, we obtain

$$\begin{aligned} |f(x, u)| + |h(x)| &\leqq (1 - \eta K)^{-1}(c_\eta + \eta f^0(\bar{x}, \bar{u})) + \frac{\eta}{1 - \eta K} L(x, u) \\ &\leqq (1 - \eta K)^{-1}(c_\eta + \eta f^0(\bar{x}, \bar{u})) + \varepsilon L(x, u). \end{aligned}$$

The desired conclusion follows by choosing $c_\varepsilon > 0$ satisfying

$$c_\varepsilon > (1 - \eta K)^{-1}(c_\eta + \eta f^0(\bar{x}, \bar{u})).$$

3. Linear hereditary operators and a lower closure theorem. To establish our results we will need certain properties of the linear integral operator G defined by

$$(3.1) \qquad (Gy)(t) = \int_{-\infty}^{t} g(t-s)y(s)\, ds = \int_0^\infty g(s)y(t-s)\, ds, \qquad -\infty < t < \infty,$$

in which g is an $n \times p$ matrix function satisfying the condition (2.5)(iii). Clearly, the operator G is not well defined for all choices of functions y. However, operators of

this type have been thoroughly examined in Marcus and Mizel [17], who chose as a domain for this operator the space $N_1((-\infty, \infty); E^p)$ consisting of all locally integrable functions $y \in L^1_{\text{loc}}((-\infty, \infty); E^p)$ with the following property:

$$|||y||| = \sup_{-\infty < s < \infty} \left\{ \int_{s-1}^{s} |y(t)|\, dt \right\} < \infty. \tag{3.2}$$

It is easy to see that $|||\cdot|||$ defines a norm on the space $N_1((-\infty, \infty); E^p)$. With this notation we summarize the results from Marcus and Mizel [17] that we require in the following theorem.

THEOREM 3.1. *Let g be an $n \times p$ matrix function on $[0, \infty)$ satisfying* (2.5)(iii) *and define the operator G on $N_1((-\infty, \infty); E^p)$ by* (3.1). *The following properties hold.*

(A) *For every $y \in N_1((-\infty, \infty); E^p)$ the integral $(Gy)(t)$, defined by* (3.1) *for each $t \in (-\infty, \infty)$, exists as a Lebesgue integral.*

(B) *For every $y \in N_1((-\infty, \infty); E^p)$, the function $G(y): (-\infty, \infty) \to E^n$ is continuous.*

(C) *If $\{y_k\}_{k=1}^{\infty} \subset N_1((-\infty, \infty), E^p)$ is a norm bounded sequence (i.e., there exists $R > 0$ so that $|||y_k||| \leqq R$ for all k) such that for some $y \in N_1((-\infty, \infty); E^p)$ the sequence $\{y_k|_{(\alpha,\beta)}\}_{k=1}^{\infty}$ converges strongly in $L^1(\alpha, \beta)$ to y for all real numbers α, β, $\alpha < \beta$; then the sequence $\{G(y_k)\}_{k=1}^{\infty}$ converges uniformly on compact subsets of $(-\infty, \infty)$ to $G(y)$.*

(D) *If $D \subset N_1((-\infty, \infty): E^p)$ is a norm bounded subset such that D is uniformly integrable on $(-T, T)$ for every $T > 0$, then the set $G(D) = \{G(y): y \in D\}$ is precompact in $C([-T, T]: E^n)$, the space of continuous functions on $[-T, T]$, for all $T > 0$.*

Proof. The proof of the above results are found in Lemmas 7.5 and 7.10 of [17].

Remark 3.1. In [17] the kernel g is assumed to satisfy stronger hypotheses than those indicated above (see [17, p. 21]). However, a careful examination of the proofs for the results given above shows that this additional hypothesis is not required. On the other hand, this additional hypothesis is needed to prove all the results given in [17, Lemma 7.5]. We also note that the proof of part (D) above given in [17, Lemma 7.10] is only concerned with $D \subset N((-\infty, 0); E^p)$ but a straightforward modification of their argument gives the result for the case considered here.

In addition to the above theorem, we will need the following lower closure theorem. For the applications of this result in this paper, the sets G_k below are subsets of the time axis $(-\infty, \infty)$.

THEOREM 3.2. *Let G be a σ-finite measure space, $G = \bigcup_{k=1}^{\infty} G_k$ where $G_k \subset G_{k+1}$ and* meas $(G_k) < \infty$, *let $X \subset E^n$ be closed, and let $R: X \to 2^{E^{1+r}}$ be a given set-valued map that is closed and convex valued and, in addition, satisfies the upper semicontinuity property (K) given by* (2.10). *Furthermore, assume that there exists measurable functions $\eta_k: G_k \to E^1$, $\lambda_k: G_k \to E^1$, $\lambda: G \to E^1$. $\xi_k: G_k \to E^n$, $\xi: G \to E^n$, $x_k: G_k \to E^n$, and $x: G \to E^n$, $k = 1, 2, \cdots$ satisfying the following conditions*:

(i) *For each index k, and almost all $t \in G_k$, $x_k(t) \in X$ and $(\eta_k(t), \xi_k(t)) \in R(x_k(t))$.*

(ii) *$x_k(t) \to x(t)$ pointwise, $\xi_k \to \xi$ weakly in $L^1_{\text{loc}}(G; E^n)$, and $\lambda_k \to \lambda$ weakly in $L^1_{\text{loc}}(G; E^1)$ as $k \to \infty$.*

(iii) *$\lambda \in L^1(G; E^1)$, $\eta_k(t) \geqq \lambda_k(t)$ almost everywhere in G_k, and $-\infty < i = \liminf_{k \to \infty} \int_{G_k} \eta_k(t)\, dt < +\infty$.*

Then there exists $\eta \in L^1(G; E^1)$ such that

$$x(t) \in X \quad \text{and} \quad (\eta(t), \xi(t)) \in R(x(t)) \quad \text{a.e. } t \in G$$

and

$$-\infty < \int_G \eta(t)\, dt \leqq i.$$

Remark 3.2. The above result, in a control-theoretic format, is originally due to Baum [4], in which the upper semicontinuity property (K) is replaced by property (Q). In terms of orientor fields (i.e., the above format) Baum's result was given by Bates [3]. Finally, the assumption property (Q) was replaced by property (K) in Balder [2].

4. Catching-up optimal solutions. With the notation and hypotheses given above we now address the problem of the existence of catching-up optimal solutions. We begin by investigating the asymptotic convergence properties of certain admissible trajectories to the optimal steady state $\bar{x}$. Following Leizarowitz [15], we let $\mathcal{F}$ denote the set of all trajectories $x: E^1 \to E^n$ satisfying

$$L(x(t), u(t)) = 0 \quad \text{a.e. } t > 0 \tag{4.1}$$

where $u: [0, \infty) \to E^n$ is a measurable control function corresponding to the trajectory x (see Definition 2.1). We observe that the optimal steady state $x(t) = \bar{x}$ is a trajectory such that $\mathcal{F}$ is nonempty. As regards to $\mathcal{F}$, we make the following assumption.

(A4) For each $\varepsilon > 0$ there exists $t_\varepsilon > 0$ such that for all $t \geqq t_\varepsilon$ and all $x \in \mathcal{F}$, $|x(t) - \bar{x}| < \varepsilon$.

Concerning Assumption (A4) we remark that it corresponds to property (S) in Leizarowitz [15] and to property $(\mathcal{C})$ of Carlson, Haurie, and Jabrane [7]. As stated, this assumption is difficult to verify and will not hold in general. In the ordinary differential equation case (i.e., $h(x) \equiv 0$) it has been shown in [15] that under suitable convexity conditions this condition is generic. The infinite-dimensional nature of the integrodifferential equation model considered here precludes such a possibility in our situation. Consequently, we content ourselves by presenting explicit conditions that imply this assumption. To this end we introduce the following alternative assumption.

(A4′) For every $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon) > 0$ so that if $x \in X$ satisfies $|x - \bar{x}| > \varepsilon$, then $L(x, u) \geqq \delta$ for all $u \in U(x)$.

LEMMA 4.1. *If* (A4′) *holds, then* (A4) *holds.*

Proof. We assume that (A4′) holds and let $x: E^1 \to E^n$ be a trajectory (see Definition 2.1) so that $L(x(t), u(t)) = 0$ almost everywhere on $[0, \infty)$ (i.e., $x \in \mathcal{F}$). We now show that $x(t) \equiv \bar{x}$ on $[0, \infty)$. Indeed, if there exists $\tau \geqq 0$ for which $x(\tau) \neq \bar{x}$, the continuity of x allows us to assert the existence of an $\varepsilon_0 > 0$ and $\alpha > 0$ so that for all $t \in [\tau, \tau + \alpha)$ we have $|x(t) - \bar{x}| > \varepsilon_0$. However, by (A4′) there exists $\delta_0 > 0$ so that $L(x(t), u) > \delta_0$ for all $u \in U(x(t))$ and almost all $t \in [\tau, \tau + \alpha)$. Clearly, this is a contradiction. Therefore $x(t) \equiv \bar{x}$ on $[0, \infty)$ and thus, since $x \in \mathcal{F}$ was arbitrary, Assumption (A4) holds since for each $\varepsilon > 0$ we can choose $t_\varepsilon = 0$.

The assumption (A4′) appears in earlier works concerning infinite horizon optimal control (see, e.g., Carlson and Haurie [6, Chap. 4] and Brock and Haurie [5]), where its role is analogous to (A4). In fact, it was not until Leizarowitz [15] that (A4′) was replaced by (A4).

A weaker condition than (A4′), which is still sufficient for (A4) to hold, is

(A4″) The optimal steady state $\bar{x}$ is uniquely determined and if $L(x, u) = 0$, then $x = \bar{x}$.

It is easy to see that (A4′) implies (A4″). Moreover, it is also easy to see that Lemma 4.1 holds with (A4″) replacing (A4′).

The implications of (A4′) (or (A4″)) differ slightly from the ordinary differential equation case. In particular, (A4′) (or (A4″)) implies $\mathcal{F} = \{\bar{x}\}$ in the nondelay case. In the delay case considered here it is possible (under (A4′) or (A4″)) that there exists $x \in \mathcal{F}$ that is not identically equal to $\bar{x}$ on $(-\infty, \infty)$. This is demonstrated in the following example. However, we remark that we still essentially have $\mathcal{F}$ as the singleton $\mathcal{F} = \{\bar{x}\}$, since given $x \in \mathcal{F}$ with $x(t) \neq \bar{x}$ for $t < 0$ we must have (under (A4′) or (A4″)) that $x(t) = \bar{x}$ on $[\infty, \infty)$.

Example 4.1. We consider the control system

$$\dot{x}(t) = u(t) + \int_{-\infty}^{t} 2e^{-(t-s)}x(s)\,ds \quad \text{a.e. on } [0, \infty),$$

$$x(s) = \varphi(s) \quad \text{for all } s \leqq 0,$$

$$x(t) \in [-1, 1] \quad \text{on } [0, \infty),$$

$$u(t) \in [-1, 1] \quad \text{a.e. on } [0, \infty).$$

Here we assume that $\varphi : (-\infty, 0] \to [-1, 1]$ is a fixed given initial function. For the objective functional we take

$$J_T(x, u) = \int_0^T [2x(t)(4x(t)^2 + 6x(t) - 9) - 9u(t)]\,dt$$

for $T \geqq 0$. The corresponding optimal steady-state problem becomes

$$\text{minimize } \{2x(4x^2 + 6x - 9) - 9u : 0 = u + 2x,\ x \in [-1, 1],\ u \in [-1, 1]\}.$$

It is a straightforward argument to show that (A3) holds with $\bar{x} = 0$, $\bar{u} = 0$, and $\bar{p} = 9$. Thus,

$$L(x, u) = 2x(4x^2 + 6x - 9) - 9u + 9(2x + u) = 2x(4x^2 + 6x) = 4x^2(2x + 3)$$

and since $(x, u) \in [-1, 1] \times [-1, 1]$ we have

$$L(x, u) \geqq 4x^2,$$

so that if $|x - \bar{x}| = |x| > \varepsilon$ we have, upon choosing $\delta = \varepsilon^2/4$,

$$L(x, u) \geqq \delta.$$

Consequently, the assumption (A4′) holds. Clearly, $x(t) \equiv \bar{x} = 0$ is in $\mathcal{F}$. We now show that $\hat{x} : (-\infty, \infty) \to [-1, 1]$, defined by

$$\hat{x}(t) = \begin{cases} (\frac{1}{2})(e^t - 1) & \text{for } t < 0, \\ 0 & \text{for } t \geqq 0, \end{cases}$$

is also in $\mathcal{F}$. Indeed, we observe that by taking $\hat{u} : [0, \infty) \to [-1, 1]$ to be

$$\hat{u}(t) = \tfrac{1}{2}e^{-t},$$

we have for all $t \geqq 0$ that

$$\hat{u}(t) + \int_{-\infty}^{t} 2e^{-(t-s)}\hat{x}(s)\,ds = \frac{1}{2}e^{-t} + \int_{-\infty}^{0} 2e^{-(t-s)}\left(\frac{1}{2}(e^s - 1)\right) ds$$

$$= \frac{1}{2}e^{-t} - \frac{1}{2}e^{-t} = 0.$$

This implies that $\hat{x}$ is indeed a trajectory with $L(\hat{x}(t), \hat{u}(t)) = 0$ for all $t \geqq 0$ as desired.

Condition (A4′) is finite-dimensional in nature and as a consequence is easier to verify than (A4). To present general conditions that, on the model we consider, are sufficient for (A4′) to hold requires stronger convexity hypotheses. The following proposition gives conditions that permit us to conclude that (A4′) holds.

PROPOSITION 4.1. *Suppose that* $M=\{(x, u): x\in X, u\in U(x)\}$ *is compact and convex with nonempty interior, that* $f^0: M\to E^1$ *is strictly convex, lower semicontinuous and bounded below, and that* $F: M\to E^n$, *defined by*

$$F(x, u)=f(x, u)+\left(\int_0^\infty g(s)\,ds\right)h(x),$$

is continuous and concave (i.e., each component F_i, $F=(F_1, \cdots, F_n)$ *is a concave function). Furthermore, suppose the following*:

(i) *There exists* $(x, u)\in M$ *so that* $F_i(x, u)>0$ *for* $i=1, 2, \cdots, n$; *and*

(ii) *If* $(x, u)\in M$ *is such that* $F_i(x, u)\geqq 0$, $i=1, 2, \cdots, n$, *then there exists* $v\in U(x)$ *so that* $F(x, v)=0$ *and* $f^0(x, v)\leqq f^0(x, u)$.

Then (A3) *and* (A4′) *hold.*

Proof. By the classical Weierstrass Theorem it is clear that the optimization problem

$$\underset{(x,u)\in M}{\text{minimize}}\{f^0(x, u): 0\leqq F_i(x, u), 1\leqq i\leqq n\}$$

has a solution $(\bar{x}, \bar{u})$. Moreover, since f^0 is strictly convex, $(\bar{x}, \bar{u})$ is unique. Condition (i) is Slater's constraint qualification for the above convex program. Consequently, there exists a vector $\bar{p}=(\bar{p}_1, \cdots, \bar{p}_n)\in E^n$, $\bar{p}_i\geqq 0$, so that

$$f^0(x, u)+\langle \bar{p}, F(x, u)\rangle \geqq f^0(\bar{x}, \bar{u}),$$

for all $(x, u)\in M$. Moreover, from (ii) it follows that $F(\bar{x}, \bar{u})=0$ so that we clearly have that (A3) holds. To check (A4′) we proceed by contradiction. That is, we assume there exists $\varepsilon_0>0$ and a sequence of points $\{(x_n, u_n)\}_{n=1}^\infty$ in M so that $|x_n-\bar{x}|>\varepsilon_0$ but

$$\begin{aligned}0&\leqq L(x_n, u_n)\\ &=f^0(x_n, u_n)-f^0(\bar{x}, \bar{u})+\left\langle p, f(x_nu_n)+\left(\int_0^\infty g(s)\,ds\right)h(x_n)\right\rangle<\frac{1}{n}.\end{aligned}$$

The compactness of M allows us to choose a subsequence, say still $\{(x_n, u_n)\}_{n=1}^\infty$, which converges to some point $(\hat{x}, \hat{u})\in M$. This implies

$$0\geqq \liminf_{n\to\infty} L(x_n, u_n)\geqq L(\hat{x}, \hat{u})\geqq 0,$$

giving us $L(\hat{x}, \hat{u})=0$. However, the map $(x, u)\to f^0(x, u)+\langle \bar{p}, F(x, u)\rangle$, $(x, u)\in M$, is strictly convex so that $(\bar{x}, \bar{u})$ is the unique minimizer. Thus we must have $(\hat{x}, \hat{u})=(\bar{x}, \bar{u})$, which is clearly a contradiction since $|\hat{x}-\bar{x}|=\lim_{n\to\infty}|x_n-\bar{x}|>\varepsilon_0$. Thus, (A4′) holds.

Remark 4.1. The above proposition is not new and analogues of this result, for the ordinary differential equation case, appear in earlier works (see, e.g., Carlson and Haurie [6, Lemma 4.4]). While this result requires f^0 to be strictly convex on M we remark that this is only a sufficient condition for (A4′) and is not necessary. Indeed, this convexity condition is not satisfied in Example 4.1. To see this consider the points $(-1, 0)$ and $(-\frac{1}{2}, 0)$ and observe for $\lambda=\frac{1}{2}$ that we have

$$f^0\left(\lambda(-1)+(1-\lambda)\left(-\frac{1}{2}\right), 0\right)=\frac{135}{8}\geqq\frac{1}{2}f^0(-1, 0)+\frac{1}{2}f^0\left(-\frac{1}{2}, 0\right)=\frac{33}{2},$$

which violates the definition of convexity.

With this discussion concerning hypothesis (A4) in hand, we continue our presentation with the following result.

PROPOSITION 4.2. *Let $X \subset E^n$ be closed, let $U: X \to 2^{E^m}$ be a set-valued map with closed graph M, let $f^0: M \to E^1$ be lower semicontinuous, let $f: M \to E^n$ and $h: X \to E^p$ be continuous, and let g be an $n \times p$ matrix function satisfying* (2.5). *Furthermore, assume that* (A1)-(A4) *hold. If $\{x, u\} \in A_0$ is such that*

$$\int_0^\infty L(x(t), u(t))\, dt < \infty, \tag{4.2}$$

then $\lim_{t\to\infty} x(t) = \bar{x}$.

Proof. We proceed by contradiction and suppose that $\{x, u\}$ is as above, but $\lim_{t\to\infty} x(t) \neq \bar{x}$. This implies there exists an $\varepsilon_0 > 0$ and times t_k, $k = 1, 2, \cdots$, increasing to positive infinity such that $|x(t_k) - \bar{x}| > \varepsilon_0$ for all k. As a consequence of (A4) there exists $t_0 > 0$ such that for all $t \geqq t_0$ we have $|s(t) - \bar{x}| < \varepsilon_0/2$ for all trajectories $s \in \mathcal{F}$. Define the sequences of functions $x_k: (-\infty, \infty) \to E^n$ and $u_k: (t_0 - t_k, \infty) \to E^m$ by the formulas

$$x_k(t) = x(t + t_k - t_0), \qquad u_k(t) = u(t + t_k - t_0).$$

Clearly, we have for all $k = 1, 2, \cdots$, and almost all $t \geqq t_0 - t_k$ that

$$\dot{x}_k(t) = f(x_k(t), u_k(t)) + \int_{-\infty}^{t} g(t-s)h(x_k(t))\, ds,$$

$$u_k(t) \in U(x_k(t)), \qquad x_k(t) \in X.$$

We further note that for each $k = 1, 2, \cdots$, x_k satisfies the "initial condition"

$$x_k(s) = x_0(s + t_k - t_0) \quad \text{for all } s \leqq t_0 - t_k.$$

As we will see, since $(t_0 - t_k, \infty)$ tends to $(-\infty, \infty)$ as $k \to \infty$, this fact is not required for our proof. Moreover, since by definition $t \to x(t)$ is bounded, the sequence $\{x_k\}_{k=1}^\infty$ is uniformly bounded and satisfies $x_k(t_0) = x(t_k)$. From the above it is evident that x_k is a trajectory corresponding to the control function u_k (see Definition 2.1). In addition, we observe that for any $T > 0$, and all k sufficiently large

$$\lim_{k\to\infty} \int_{-T}^{T} L(x_k(t), u_k(t)) = \lim_{k\to\infty} \int_{t_k - t_0 - T}^{t_k - t_0 + T} L(x(t), u(t))\, dt = 0,$$

and thus by the growth condition (A2) applied to f, h, and L (see Proposition 2.1) we have that the sequences of functions $z_k(t) = f(x_k(t), u_k(t))$ and $y_k(t) = h(x_k(t))$, $k = 1, 2, \cdots$, are equi-absolutely integrable on $[-T, T]$ for all $T > 0$. Thus, by a standard diagonalization process there exists locally integrable functions $z: (-\infty, \infty) \to E^n$ and $y: (-\infty, \infty) \to E^p$ and subsequences, say still $\{z_k\}$ and $\{y_k\}$, that converge weakly to z and y, respectively, in $L^1_{\text{loc}}((-\infty, \infty), E^n)$ and $L^1_{\text{loc}}((-\infty, \infty), E^p)$. In addition, as the sequence $\{x_k\}$ is bounded and $h: X \to E^p$ is continuous, there exists $K > 0$ so that for all $t \in (-\infty, \infty)$ and all $k = 1, 2, \cdots$

$$|y_k(t)| = |h(x_k(t))| \leqq K.$$

Therefore, as a consequence of Theorem 3.1(D), we can further assume (by extracting another subsequence by diagonalization) that there exists a continuous function

$r:(-\infty,\infty)\to E^n$ such that the sequence $\{G(y_k)\}_{k=1}^{\infty}$, defined for $k=1, 2, \cdots$ by

$$G(y_k)(t)=\int_{-\infty}^{t} g(t-s)y_k(s)\,ds, \qquad t\in(-\infty,\infty),$$

converges uniformly on compact subsets of $(-\infty,\infty)$ to r. That is,

$$r(t)=\lim_{k\to\infty} G(y_k)(t)=\lim_{k\to\infty}\int_{-\infty}^{t}(g(t-s)y_k(s))\,ds. \tag{4.3}$$

Combining the above sequences we observe that for all $k=1, 2, \cdots$

$$\dot{x}_k(t)=z_k(t)+G(y_k)(t) \quad \text{a.e. } t_0-t_k\leqq t;$$

and we conclude that the sequence $\{\dot{x}_k\}_{k=1}^{\infty}$ converges weakly in $L^1_{\text{loc}}((-\infty,\infty);E^n)$ to the locally integrable function $t\mapsto z(t)+r(t)$. Also, since $\{x_k(t_0)\}_{k=1}^{\infty}$ is bounded, we can assume our subsequence has been chosen so that $\lim_{k\to\infty} x_k(t_0)=\hat{x}$, where $\hat{x}\in X$. Define $\hat{x}:(-\infty,\infty)\to E^n$ by the formula

$$\hat{x}(t)=\hat{x}+\int_{t_0}^{t}[z(s)+r(s)]\,ds$$

and observe, since for $t>t_0-t_k$

$$x_k(t)=x_k(t_0)+\int_{t_0}^{t}(z_k(s)+G(y_k)(s))\,ds,$$

that $x_k(t)\to\hat{x}(t)$ pointwise in $(-\infty,\infty)$. Furthermore, we observe that as X is closed we have $\hat{x}(t)\in X$ almost everywhere in $(-\infty,\infty)$ and that $\hat{x}$ is locally absolutely continuous. From these facts, and since $s\to g(t-s)$ is Lebesgue integrable on $(-\infty, t)$ we have, by the Dominated Convergence Theorem,

$$\lim_{k\to\infty}\int_{-\infty}^{t} g(t-s)h(x_k(s))\,ds=\int_{-\infty}^{t} g(t-s)h(\hat{x}(s))\,ds.$$

This implies, for all $t\in(-\infty,\infty)$, as a consequence of (4.3), that

$$r(t)=\int_{-\infty}^{t} g(t-s)h(\hat{x}(s))\,ds.$$

It is now easy to see that for all $t\in(-\infty,\infty)$,

$$\begin{aligned}\hat{x}(t)&=\hat{x}+\int_{t_0}^{t}\left(z(s)+\int_{-\infty}^{s} g(s-\tau)h(\hat{x}(\tau))\,d\tau\right)ds\\&=\hat{x}(0)+\int_{0}^{t}\left(z(s)+\int_{-\infty}^{s} g(s-\tau)h(\hat{x}(\tau))\,d\tau\right)ds.\end{aligned} \tag{4.4}$$

We now wish to show that $\hat{x}$ is a trajectory. To this end we appeal to the Lower Closure Theorem 3.2 using the following notation. For each integer $N=\pm1, \pm2, \cdots$, we let

(i) $G=[N, N+1)$, $G_k=[N, N+1)$, $k=1, 2, \cdots$;

(ii) $\eta_k(t)=L(x_k(t), u_k(t))$, $\xi_k(t)=z_k(t)$, $\xi(t)=z(t)$, $\lambda_k(t)\equiv 0$, $\lambda(t)\equiv 0$, $x_k(t)$ as above and $x(t)=\hat{x}(t)$.

Observe that we also have

$$\begin{aligned}\lim_{k\to\infty}\int_{G_k}\eta_k(t)\,dt&=\lim_{k\to\infty}\int_{N}^{N+1} L(x_k(t), u_k(t))\,dt\\&=\lim_{k\to\infty}\int_{N+t_k-t_0}^{N+1+t_k-t_0} L(x(s), u(s))\,ds=0,\end{aligned}$$

since $L(x, u)$ is nonnegative and (4.2) holds. Thus, all the hypotheses of Theorem 3.2 are satisfied and we can conclude that there exists an integrable function $\eta_N : [N, N+1) \to E^1$ such that

$$\hat{x}(t) \in X \quad \text{and} \quad (\eta_N(t), z(t)) \in \tilde{\mathbb{Q}}(\hat{x}(t)), \quad \text{a.e. } t \in [N, N+1)$$

and

$$\int_N^{N+1} \eta_N(t)\, dt \leqq 0.$$

By standard measurable selection arguments (see Cesari [9, Thm. 11.4i]), there exists a measurable function $u_N : [N, N+1) \to E^m$ such that for almost all $t \in [N, N+1)$ we have $\eta_N(t) \geqq L(\hat{x}(t), u_N(t))$, $z(t) = f(\hat{x}(t), u_N(t))$, and $u_N(t) \in U(\hat{x}(t))$. The desired control generating the trajectory $\hat{x} : (-\infty, \infty) \to E^n$ is now obtained by defining $\hat{u} : (-\infty, \infty) \to E^m$ by

$$\hat{u}(t) \equiv u_N(t), \qquad N \leqq t < N+1,$$

$N = \pm 1, \pm 2, \cdots$. Clearly, $\hat{u}$ is measurable and upon substituting into (4.4) we have for any $t \in E^1$,

$$\hat{x}(t) = \hat{x}(0) + \int_0^t f(\hat{x}(s), \hat{u}(s))\, ds + \int_0^t \int_{-\infty}^s g(s-\tau) h(\hat{x}(\tau))\, d\tau,$$

implying that $\hat{x}$ is a trajectory. Moreover, for any integer N, we have

$$0 \leqq \int_N^{N+1} L(\hat{x}(t), \hat{u}(t))\, dt \leqq \int_N^{N+1} \eta_N(t)\, dt = 0,$$

from which it follows that $L(\hat{x}(t), \hat{u}(t)) = 0$ for almost all $t \in E^1$ since L is nonnegative. Thus we see that $\hat{x} \in \mathcal{F}$. This, however, leads to a contradiction since for all k,

$$\varepsilon_0 \leqq |x_k(t_0) - \bar{x}| \leqq |x_k(t_0) - \hat{x}(t_0)| + |\hat{x}(t_0) - \bar{x}| < |x_k(t_0) - \hat{x}(t_0)| + \frac{\varepsilon_0}{2},$$

giving us the contradiction

$$0 = \lim_{k \to \infty} |x_k(t_0) - \hat{x}(t_0)| > \frac{\varepsilon_0}{2}.$$

Therefore we must have $x(t) \to \bar{x}$ as $t \to \infty$.

Before presenting the desired existence results we require the following technical lemma.

LEMMA 4.2. *Let $X \subset E^n$ be closed, let $h : X \to E^p$ be continuous, and let g be an $n \times p$ matrix function satisfying* (2.5). *Suppose that $\{x_i, u_i\} \in A_0$ for $i = 1, 2$ are such that $\lim_{T \to \infty} x_i(T) = \bar{x}$, $i = 1, 2$. Then we have*

$$\lim_{T \to \infty} \int_0^T \left(\int_{T-t}^{\infty} g(s)\, ds \right) [h(x_1(t)) - h(x_2(t))]\, dt = 0.$$

Proof. Let $\varepsilon > 0$ be given. From the continuity of h and the convergence of $x_i(T)$ to $\bar{x}$ as $T \to \infty$, there exists $\tau > 0$ so that for all $T \geqq \tau$,

$$|h(x_1(T)) - h(x_2(T))| < \varepsilon.$$

For $T > \tau$ we write

$$\left|\int_0^T \left(\int_{T-t}^{\infty} g(s)\,ds\right)[h(x_1(t)) - h(x_2(t))]\,dt\right|$$
$$\leqq \left|\int_0^{\tau} \left(\int_{T-t}^{\infty} g(s)\,ds\right)[h(x_1(t)) - h(x_2(t))]\,dt\right|$$
$$+ \left|\int_{\tau}^{T} \left(\int_{T-t}^{\infty} g(s)\,ds\right)[h(x_1(t)) - h(x_2(t))]\,dt\right|$$
$$= I_1(T) + I_2(T),$$

and estimate $I_1(T)$ and $I_2(T)$ separately. As x_i, $i = 1, 2$, are admissible trajectories, they are bounded. Thus, as h is continuous, there exists $H > 0$ so that for all $t \in [0, \infty)$, $|h(x_1(t)) - h(x_2(t))| \leqq H$. This gives us

$$I_1(T) \leqq \int_0^{\tau} \int_{T-t}^{+\infty} |g(s)|\,ds |h(x_1(t)) - h(x_2(t))|\,dt$$
$$\leqq H \int_0^{\tau} \int_{T-t}^{\infty} |g(s)|\,ds\,dt = H\left[\int_{T-\tau}^{T} \int_t^{\infty} |g(s)|\,ds\,dt\right]$$
$$= H\left[\int_0^T \int_t^{+\infty} |g(s)|\,ds\,dt - \int_0^{T-\tau} \int_t^{\infty} |g(s)|\,ds\,dt\right],$$

which tends to zero as $T \to \infty$ since

$$\lim_{T\to\infty} \int_0^T \int_t^{\infty} |g(s)|\,ds\,dt = \int_0^{\infty} \int_t^{\infty} |g(s)|\,ds\,dt = \int_0^{\infty} t|g(t)|\,dt < \infty.$$

For $I_2(T)$ we observe that

$$I_2(T) \leqq \int_{\tau}^{T} \left(\int_{T-t}^{\infty} |g(s)|\,ds\right)|h(x_1(t)) - h(x_2(t))|\,dt < \varepsilon \int_{\tau}^{T} \int_{T-t}^{\infty} |g(s)|\,ds\,dt$$
$$\leqq \varepsilon \int_0^{\infty} \int_t^{\infty} |g(s)|\,ds\,dt,$$

and since $\varepsilon > 0$ was arbitrary, it follows that for T sufficiently large we have that $I_2(T)$ is as small as desired. Combining these two results, we obtain

$$\lim_{T\to\infty} \int_0^T \left(\int_{T-t}^{+\infty} g(s)\,ds\right)[h(x_1(t)) - h(x_2(t))]\,dt = 0.$$

We now present the following set of sufficient conditions for catching-up optimality.

THEOREM 4.1. *Assume that $X \subset E^n$ is closed, $U : X \to 2^{E^m}$ is a set-valued mapping with closed graph M, $f^0 : M \to E^1$ is lower semicontinuous, $f : M \to E^n$ and $h : X \to E^p$ are continuous, and g is an $n \times p$ matrix function satisfying* (2.5). *In addition, assume that* (A1)-(A4) *hold. If $\{x^*, u^*\} \in A_0$ is such that*

$$\text{(4.5)} \qquad \text{(i)} \quad \int_0^{\infty} L(x^*(t), u^*(t))\,dt < \infty,$$

and

$$\text{(4.6)} \qquad \text{(ii)} \quad \int_0^{\infty} L(x^*(t), u^*(t))\,dt \leqq \lim_{T\to\infty} \int_0^T L(x(t), u(t))\,dt,$$

for all $\{x, u\} \in A_0$, *where the limit on the right is either finite or positive infinity, then the pair* $\{x^*, u^*\}$ *is catching-up optimal.*

Proof. Let $\{x^*, u^*\} \in A_0$ be as above and let $\{x, u\} \in A_0$ be arbitrary. Then for any $T > 0$, we have

$$\begin{aligned} J_T(x, u) - J_T(x^*, u^*) &= \int_0^T L(x(t), u(t))\, dt - \int_0^T L(x^*(t), u^*(t))\, dt \\ &\quad + \left\langle \bar{p}, \int_0^T \left[f(x^*(t), u^*(t)) + \left(\int_0^\infty g(s)\, ds \right) h(x^*(t)) \right] dt \right\rangle \\ &\quad - \left\langle \bar{p}, \int_0^T \left[f(x(t), u(t)) + \left(\int_0^\infty g(s)\, ds \right) h(x(t)) \right] dt \right\rangle \\ &= \int_0^T L(x(t), u(t))\, dt - \int_0^T L(x^*(t), u^*(t))\, dt \\ &\quad + \left\langle \bar{p}, \int_0^T \left[f(x^*(t), u^*(t)) + \left(\int_0^{T-t} g(s)\, ds \right) h(x^*(t)) \right] dt \right\rangle \\ &\quad - \left\langle \bar{p}, \int_0^T \left[f(x(t), u(t)) + \left(\int_0^{T-t} g(s)\, ds \right) h(x(t)) \right] dt \right\rangle \\ &\quad + \left\langle \bar{p}, \int_0^T \left(\int_{T-t}^\infty g(s)\, ds \right) [h(x^*(t)) - h(x(t))]\, dt \right\rangle. \end{aligned}$$

Also, for $T > 0$ and $\{x, u\} \in A_0$, we observe that

$$\begin{aligned} \int_0^T \left(\int_0^{T-t} g(s)\, ds \right) h(x(t))\, dt &= \int_0^T \left(\int_t^T g(s-t)\, ds \right) h(x(t))\, dt \\ &= \int_0^T \int_0^t g(t-s) h(x(s))\, ds\, dt, \end{aligned}$$

so that

$$\begin{aligned} J_T(x, u) - J_T(x^*, u^*) &= \int_0^T [L(x(t), u(t)) - L(x^*(t), u^*(t))]\, dt \\ &\quad + \left\langle \bar{p}, \int_0^T (\dot{x}^*(t) - \dot{x}(t))\, dt \right\rangle \\ &\quad + \left\langle \bar{p}, \int_0^T \left(\int_{T-t}^\infty g(s)\, ds \right) [h(x^*(t)) - h(x(t))]\, dt \right\rangle \\ &= \int_0^T [L(x(t), u(t)) - L(x^*(t), u^*(t))]\, dt + \langle \bar{p}, x^*(T) - x(T) \rangle \\ &\quad + \left\langle \bar{p}, \int_0^T \left(\int_{T-t}^\infty g(s)\, ds \right) [h(x^*(t)) - h(x(t))]\, dt \right\rangle. \end{aligned}$$

We now suppose,

$$\int_0^\infty L(x(t), u(t))\, dt < \infty. \tag{4.7}$$

In this case, as a consequence of Proposition 4.2, $\lim_{T \to \infty} x(T) = \bar{x}$ and we obtain

$$\lim_{T \to \infty} [J_T(x, u) - J_T(x^*, u^*)] = \int_0^{+\infty} L(x(t), u(t))\, dt - \int_0^{+\infty} L(x^*(t), u^*(t))\, dt \geqq 0,$$

where we have used the fact that $x^*(T) \to \bar{x}$ as $T \to \infty$ and applied Lemma 4.1. Thus, it is clear that for any $\varepsilon > 0$ we can find $T_\varepsilon = T(\varepsilon, x, u) \geqq 0$ so that for all $T \geqq T_\varepsilon$

$$J_T(x^*, u^*) < J_T(x, u) + \varepsilon.$$

In the case where the improper integral (4.7) is not finite, the boundedness of both x and x^* imply there exist constants M and K such that for all $T > 0$,

$$|\langle \bar{p}, x^*(T) - x(T) \rangle| < M|\bar{p}|$$

and

$$\begin{aligned}
&\left| \left\langle \bar{p}, \int_0^T \left(\int_{T-t}^{+\infty} g(s)\, ds \right) [h(x^*(t)) - h(x(t))]\, dt \right\rangle \right| \\
&\quad \leqq |\bar{p}| K \int_0^T \left(\int_{T-t}^{\infty} |g(s)|\, ds \right) dt \\
&\quad \leqq |\bar{p}| K \int_0^\infty \left(\int_t^\infty |g(s)|\, ds\, dt \right) \\
&\quad = |\bar{p}| K \int_0^\infty t|g(t)|\, dt.
\end{aligned}$$

Thus,

$$\begin{aligned}
&\liminf_{T \to \infty} [J_T(x, u) - J_T(x^*, u^*)] \\
&\quad \geqq \liminf_{T \to \infty} \left\{ \int_0^T [L(x(t), u(t)) - L(x^*(t), u^*(t))]\, dt - |\bar{p}| M - |\bar{p}| K \int_0^\infty t|g(t)|\, dt \right\} \\
&\quad = +\infty.
\end{aligned}$$

Therefore in each case we arrive at the desired result, and so $\{x^*, u^*\}$ is catching-up optimal.

We are now ready to give the main result of this paper. As a result of the previous theorem, it is clear that a catching up optimal solution exists if we can establish the existence of a strongly optimal solution of the associated problem consisting of minimizing

$$I(x, u) = \int_0^\infty L(x(t), u(t))\, dt \tag{4.8}$$

over all $\{x, u\} \in A_0$. With this brief remark we give the following result.

THEOREM 4.2. *Let $X \subset E^n$ be closed, let $U : X \to 2^{E^m}$ have a closed graph M, let $f^0 : X \to E^1$ be lower semicontinuous, let $f : M \to E^n$ and $h : X \to E^p$ be continuous, and let g be an $n \times p$ matrix valued function satisfying* (2.5). *Furthermore, suppose that* (A1)-(A4) *hold and that there exists an admissible pair $\{\hat{x}, \hat{u}\} \in A_0$ such that* (4.8) *is finite. Under these conditions, the optimal control problem described by* (2.1)-(2.4) *and* (2.6) *has a catching-up optimal solution.*

Proof. By hypothesis, we have

$$0 \leqq \inf_{\{x,u\} \in A} I(x, u) \leqq I(\hat{x}, \hat{u}) < \infty.$$

Thus there exists a minimizing sequence $\{x_k, u_k\}_{k=1}^{\infty}$ for the associated optimal control problem. As a consequence of Proposition 2.1, f, h, and L satisfy the growth condition (A2) with

$$\int_0^T L(x_k(t), u_k(t))\, dt \leqq \int_0^{+\infty} L(\hat{x}(t), \hat{u}(t))\, dt < \infty$$

for all $T > 0$. Therefore, by a standard diagonalization process, there exists a subsequence, say still $\{x_k, u_k\}$, and locally integrable functions $z:[0,\infty) \to E^n$ and $y:[0,\infty) \to E^p$ such that $f(x_k(t), u_k(t)) \to z(t)$ and $h(x_k(t)) \to y(t)$ weakly in $L^1_{\text{loc}}([0,\infty); E^n)$ and $L^1_{\text{loc}}((0,\infty); E^p)$, respectively. This implies that for each $t \geqq 0$ we have

$$\begin{aligned} x_k(t) &= x_0(0) + \int_0^t f(x_k(s), u_k(s))\, ds + \int_0^t \left(\int_{-\infty}^0 g(s-\tau) h(x_0(\tau))\, d\tau \right) dt \\ &\quad + \int_0^t \int_0^s g(s-\tau) h(x_k(\tau))\, d\tau\, dt \\ &= x_0(0) + \int_0^t f(x_k(s), u_k(s))\, ds + \int_0^t \left(\int_{-\infty}^0 g(s-\tau) h(x_0(\tau))\, d\tau \right) ds \\ &\quad + \int_0^t \left(\int_\tau^t g(s-\tau)\, ds \right) h(x_k(\tau))\, d\tau, \end{aligned}$$

which clearly converges pointwise to $x^*:[0,\infty) \to E^n$ given by

$$\begin{aligned} x^*(t) &= x_0(0) + \int_0^t z(s)\, ds + \int_0^t \left(\int_{-\infty}^0 g(s-\tau) h(x_0(\tau))\, d\tau \right) ds \\ &\quad + \int_0^t \left(\int_\tau^t g(s-\tau)\, ds \right) y(\tau)\, d\tau \\ &= x_0(0) + \int_0^t z(s)\, ds + \int_0^t \left(\int_{-\infty}^0 g(s-\tau) h(x_0(\tau))\, d\tau \right) ds \\ &\quad + \int_0^t \left(\int_0^s g(s-\tau) y(\tau)\, d\tau \right) ds. \end{aligned} \tag{4.9}$$

Moreover, this pointwise convergence gives us

$$\lim_{k \to \infty} h(x_k(t)) = h(x^*(t)),$$

so that we have $y(t) = h(x^*(t))$ almost everywhere $t \in E^1$. We now apply the Lower Closure Theorem 3.1 using the following notation:

(i) $G = [0,\infty)$, $G_k = [0, k]$,

(ii) $\eta_k(t) = L(x_k(t), u_k(t))$, $\xi_k(t) = f(x_k(t), u_k(t))$, $x_k(t)$ as above and $\lambda_k(t) \equiv 0$, almost everywhere $t \in G_k$, $k = 1, 2, \cdots$,

(iii) $\lambda(t) \equiv 0$, $\xi(t) = z(t)$, and $x(t) = x^*(t)$ almost everywhere $t \geqq 0$.

(iv) $R(x) = \tilde{\mathbb{Q}}_L(x)$.

It is easy to establish that the hypotheses of Theorem 3.1 are indeed met so that we conclude that there exists $\eta: [0,\infty) \to E^1$, which is integrable and satisfies

$$(\eta(t), \xi(t)) \in \tilde{\mathbb{Q}}_L(x(t)) \quad \text{and} \quad x^*(t) \in X \quad \text{a.e. } t \geqq 0$$

and

$$0 \leqq \int_0^\infty \eta(t)\, dt \leqq \liminf_{k \to \infty} \int_0^k L(x_k(t), u_k(t))\, dt \leqq \inf_{\{x,u\} \in A_0} I(x, u).$$

By appealing to standard measurable selection arguments (see, e.g., Cesari [9; Thm. 11.4i]) there exists a measurable function $u^*:[0,\infty)\to E^m$ such that $\eta(t)\geqq L(x^*(t), u^*(t))$, $z(t)=f(x^*(t), u^*(t))$, and $u^*(t)\in U(x^*(t))$ a.e. $0\leqq t$. Substituting this information into (4.8), we obtain

$$x^*(t)=x_0(0)+\int_0^t f(x^*(s), u^*(s))\,ds+\int_0^t\left(\int_{-\infty}^0 g(s-\tau)h(x_0(\tau))\,d\tau\right)ds$$
$$+\int_0^t\left(\int_0^s g(s-\tau)h(x^*(\tau))\,d\tau\right)ds,$$

which clearly shows the pair $\{x^*, u^*\}$ is an admissible pair (here we have extended x^* to $(-\infty, 0]$ by defining $x^*(s)=x_0(s)$). In addition, we further observe that

$$0\leqq\int_0^{+\infty} L(x^*(t), u^*(t))\,dt\leqq\int_0^{+\infty}\eta(t)\,dt\leqq\inf_{\{x,u\}\in A_0} I(x, u),$$

which shows that $\{x^*, u^*\}$ minimizes $I(x, u)$ over A_0. The desired conclusion now follows by a direct application of Theorem 4.1.

The above existence result generalizes the works of Brock and Haurie [5] and Leizarowitz [15] in two directions. The first of these is the obvious extension to models exhibiting time delay in the state variable. As regards this extension, we also note that our formulation also implies results for a class of problems with finite lag where for some fixed $r>0$ we assume $g(s)\equiv 0$. In such a situation, the hypothesis (2.5) concerning the kernel g are valid if g is essentially bounded on $[0, r]$. The other direction in which we have generalized these earlier results is that we have weakened both the convexity and growth hypotheses. Indeed, in [5] and [15], it is required that the set

$$\Omega=\{(x, z^0, z): x\in X, z^0\geqq f^0(x, u), z=f(x, u), u\in U(x)\}$$

is closed and convex. This condition is stronger than the convexity and upper semicontinuity conditions we require of the sets $\tilde{Q}(x)$. On the other hand, to ensure that assumption (A4′), and hence (A4) hold, we must, in general, assume these stronger convexity hypotheses. However, they need not always be assumed, as is seen in Example 4.1. As regards the growth condition in [15] we have already observed that our growth condition is weaker (see Remark 2.2).

The most difficult hypotheses to be satisfied in the above work concern our condition (A4) and the existence of an admissible pair $\{\hat{x}, \hat{u}\}$ for which $I(\hat{x}, \hat{u})$ is finite. For conditions that ensure (A4) holds we refer the reader to Proposition 4.1. For the existence of $\{\hat{x}, \hat{u}\}$ we note that in the case of finite delay, this condition can be realized by controlling from the initial function $x_0(s)$, $-r\leqq s\leqq 0$, to the terminal function $\bar{x}$, $-r\leqq s\leqq 0$ in finite time. Since the terminal function is a constant function, this problem can be addressed by utilizing known null controllability results for problems with time delay (see, e.g., [1], [10], [11], [19]). For the case of infinite delay such an approach is not applicable and the realization of this hypothesis requires further investigation.

5. Examples.

Example 5.1. In this example we return once more to Example 4.1. As we have already seen, this examples satisfies both assumptions (A3) and (A4). Also as $(x, u)\in[-1, 1]\times[-1, 1]$, a compact set, it is easy to see that the growth condition (A2) is also satisfied. Furthermore, the linearity of $f^0(x, u)=2x(4x^2+6x-9)-9u$ and $f(x, u)=u+2x$ with respect to u easily ensures that the convexity and seminormality hypotheses

of (A1) are also met. Consequently, to apply Theorem 4.2 it is sufficient to ensure that there exists an admissible pair $\{\hat{x}, \hat{u}\}$ for which

$$0 \leqq \int_0^\infty L(\hat{x}(t), \hat{u}(t))\, dt = \int_0^\infty (4x(t)^2(2x(t)+3))\, dt.$$

In this simple example we note that by choosing the control $\hat{u}(t) \equiv 0$, we have that $\hat{x}(t) = \varphi(0)\, e^{-2t}$ is an admissible trajectory for every continuous function $\varphi: (-\infty, 0] \to [-1, 1]$. Clearly, this admissible pair satisfies the desired controllability property. Thus there exists a catching-up optimal solution for this problem.

Example 5.2. The Ramsey model with delay. In this example we present a generalization of the classical Ramsey model of economic growth. Since we deal with minimization problems we use a slightly nonstandard formulation.

For this model we let $x = x(t)$, $-\infty < t < \infty$, denote the stock of capital at time t and $u = u(t)$, $0 \leqq t$, the consumption. We denote the production function by $h = h(x)$ and the utility by $-f^0 = -f^0(u)$. As is standard practice, we assume that $h(0) = 0$ and that h is a smooth increasing strictly concave function satisfying

$$\lim_{x \to 0^+} h'(x) = \infty; \qquad \lim_{x \to \infty} h'(x) = 0,$$

and furthermore, that f^0 is smooth, decreasing, strictly convex with

$$\lim_{u \to 0^+} f^{0\prime}(u) = -\infty \quad \text{and} \quad \lim_{u \to \infty} f^{0\prime}(u) = 0.$$

To introduce the delay we let $g: [0, \infty) \to [0, 1]$ satisfy the hypotheses outlined in (2.5) and assume

$$\int_0^\infty g(s)\, ds = 1. \tag{5.1}$$

This function is introduced to reflect the reduction in production of a plant or factory due to aging equipment. Thus the term $g(t-s)h(x(s))$ represents the rate of production at time t generated by a stock of capital $x(s)$, s time units ago. With this notation we let $\lambda > 0$ be given and consider the optimal control problem

$$\text{minimize} \int_0^\infty f^0(u(t))\, dt \tag{5.2}$$

subject to

$$\dot{x}(t) = \int_{-\infty}^t g(t-s)h(x(s))\, ds - \lambda x(t) - u(t), \tag{5.3}$$

$$x(s) = x_0(s), \qquad s \leqq 0, \tag{5.4}$$

$$0 \leqq x(t) \leqq \hat{x}, \tag{5.5}$$

$$0 \leqq u(t) \leqq h(x(t)). \tag{5.6}$$

The upper bound $\hat{x} > 0$ given in (5.4) is a standard hypothesis in the nondelay case with $\hat{x}$ chosen to be the unique positive solution to

$$h(x) = \lambda x.$$

We remark that in the nondelay case any admissible stock $x(t) > \hat{x}$ is necessarily decreasing. Thus it is reasonable to ask that $x(t) \leqq \hat{x}$, whenever $x_0(s) \in [0, \hat{x}]$; $s \leqq 0$.

As a result of the boundedness of the admissible states it is an easy matter to see that the growth condition (A2) is satisfied. Moreover, the convexity conditions placed on f^0 and the linearity of $f(x, u) = -\lambda x - u$ ensure that the sets $\tilde{\mathbb{Q}}(x)$ are convex and

closed. Furthermore, as f^0 is continuous, these sets also enjoy property (K) so that (A1) is satisfied.

For the optimal steady state we recall that in the nondelay case (see, e.g., Samuelson [18] or Cass [8]) there exists a unique pair $(\bar{x}, \bar{u})$ such that for all (x, u), $x \geqq 0$, $u \geqq 0$ we have

$$L(x, u) = f^0(u) - f^0(\bar{u}) + f^{0\prime}(\bar{u})[h(x) - \lambda x - u] \geqq 0. \tag{5.7}$$

The pair $(\bar{x}, \bar{u})$ is uniquely determined by the system of equations

$$h'(\bar{x}) = \lambda \quad \text{and} \quad \bar{u} = h(\bar{x}) - \lambda \bar{x}.$$

Moreover, the strict concavity of h and the convexity of f^0 imply that for every $\varepsilon > 0$ there exists a $\delta > 0$ so that if $|x - \bar{x}| > \varepsilon$, then

$$L(x, u) > \delta \quad \text{for all } u \in [0, h(x)]. \tag{5.8}$$

As (5.1) holds, it is now easy to see that (A3) is satisfied with L given by (5.7). Finally, (5.8) is simply the verification of (A4′). Thus all the hypotheses, except for the existence of $\{\hat{x}, \hat{u}\}$ admissible so that $I(\hat{x}, \hat{u}) < \infty$, needed in the previous sections are met and so the existence of a catching-up optimal solution is assured whenever $\{\hat{x}, \hat{u}\}$ exists. As remarked earlier, in the nondelay case, or in the finite-delay case, this hypothesis can be met through the application of known controllability results (in particular, see Angell [1; Thm. 5.2]).

Example 5.3. Optimal exploitation of a renewable resource. We conclude our examples with an economic growth model that incorporates a renewable resource into the classical Ramsey model. As in the previous example we let $x = x(t)$, $t \in \mathbb{R}$, denote the stock of capital at time t and $u(t)$, $t \geqq 0$, denote consumer consumption. The production of capital stock depends on a renewable resource (e.g., a forest) and we let $y(t)$, $t \in \mathbb{R}$, denote the amount of the resource available at time t. This resource is harvested at a rate $v(t)$, $t \geqq 0$. With these variables we introduce the following control system:

$$\dot{x}(t) = f(x(t), v(t)) - \lambda x(t) - u(t), \tag{5.9}$$

$$\dot{y}(t) = -v(t) + \int_{-\infty}^{t} g(t-s)h(x(s), y(s))\, ds \quad \text{a.e. } t \geqq 0, \tag{5.10}$$

$$\begin{pmatrix} x(s) \\ y(s) \end{pmatrix} = \begin{pmatrix} x_0(s) \\ y_0(s) \end{pmatrix} \quad \text{for all } s \in (-\infty, 0], \tag{5.11}$$

$$\begin{aligned} 0 \leqq x(t) &\leqq \hat{x} \\ 0 \leqq y(s) &\leqq \hat{y} \end{aligned} \quad \text{for all } t \leqq 0, \tag{5.12}$$

$$\begin{aligned} 0 \leqq u(t) &\leqq f(x(t), v(t)) \\ 0 \leqq v(t) &\leqq h(x(t), y(t)) \end{aligned} \quad \text{a.e. } 0 \leqq t. \tag{5.13}$$

Here we are letting $f: [0, \infty) \times [0, \infty) \to \mathbb{R}$ denote the production function for the capital stock x be a smooth concave function that satisfies

$$\lim_{x \to 0^+} \frac{\partial f}{\partial x}(x, v) = +\infty \quad \text{for each } v \geqq 0,$$

$$\lim_{x \to \infty} \frac{\partial f}{\partial x}(x, v) = 0 \quad \text{for each } v \geqq 0,$$

$$\frac{\partial f}{\partial x}(x, v) > 0 \quad \text{and} \quad \frac{\partial f}{\partial v}(x, v) > 0 \quad \text{for all } (x, v),$$

$$f(0, v) = 0 \quad \text{for each } v \geqq 0.$$

The function $h: [0, \infty) \times [0, \infty) \to \mathbb{R}$ denotes the rate of growth of resource y and we assume that h is concave and satisfies

$$h(x, 0) = 0 \quad \text{for all } x \geqq 0, \qquad \frac{\partial h}{\partial x}(x, y) \geqq 0 \quad \text{for all } (x, y),$$

and

for each $x \in [0, \infty)$ there exists $y_x > 0$ so that on $(0, y_x)$, $h(x, y) > 0$, $h(x, y_x) = 0$ and on (y_x, ∞), $h(x, y) < 0$.

The function $g: [0, \infty) \to [0, 1]$ satisfies the hypotheses outlined in (2.5) and in addition satisfies

$$\int_0^{+\infty} g(s)\, ds = 1.$$

This function is introduced to reflect the fact that the rate of growth of the resource is age-dependent. Finally, the constant $\lambda > 0$ denotes the rate of depreciation of capital, with x_0 and y_0 given initial functions. We observe that the producer influences the rate of growth of the resource through the level of capital stock as well as through the harvest rate v.

As in the previous example, our objective is to maximize the accumulated utility described by a utility function. $-f^0 = -f^0(u)$ where $f^0: [0, \infty) \to \mathbb{R}$ satisfies the same hypotheses as in Example 5.1. Therefore we consider the optimal control problem

$$\text{minimize} \int_0^{\infty} f^0(u(t))\, dt \tag{5.14}$$

over all pairs of functions $\{(x, y), (u, v)\}$ satisfying (5.9)–(5.13).

The associated optimal steady-state problem becomes

$$\text{minimize } f^0(u)$$

over all $(x, y, u, v) \in M$ satisfying

$$0 = f(x, v) - \lambda x - u, \qquad 0 = h(x, y) - v,$$

where

$$M = \{(x, y, u, v): 0 \leqq x \leqq \hat{x}, 0 \leqq y \leqq \hat{y}, 0 \leqq u \leqq f(x, v), 0 \leqq v \leqq h(x, y)\}.$$

It is easy to see that, under the hypotheses placed on the model, the conditions of Proposition 4.1 are satisfied. Indeed we easily see that M is compact convex and int $M \neq \varnothing$, that $F_1(x, y, u, v) = f(x, v) - \lambda x - u$ and $F_2(x, y, u, v) = h(x, y) - v$ are concave, there exists (x, y, u, v) so that $F_i(x, y, u, v) > 0$, $i = 1, 2$, and that $f^0(\cdot)$ is strictly convex. To establish the remaining hypothesis we observe that if $(x, y, u, v) \in M$ is such that $F_i(x, y, u, v) \geqq 0$ for $i = 1, 2$ we may take $(\hat{u}, \hat{v})$ to be given by

$$\hat{v} = h(x, y) \quad \text{and} \quad \hat{u} = f(x, \hat{v}) - \lambda x,$$

and observe that $\hat{v} \geqq v$ so that $f(x, \hat{v}) \geqq f(x, v)$, which implies

$$u \leqq f(x, v) - \lambda x \leqq f(x, \hat{v}) - \lambda x = \hat{u} \leqq f(x, \hat{v}).$$

Clearly, this implies that $(x, y, \hat{u}, \hat{v}) \in M$ and that $f^0(\hat{u}) \leqq f^0(u)$ as observed. Therefore the only remaining hypothesis in Theorem 4.2 concerns the existence of an admissible

pair $\{(\hat{x}, \hat{y}), (\hat{u}, \hat{v})\}$ for which the improper integral $I[(\hat{x}, \hat{y}, \hat{u}, \hat{v})]$ given by (4.7) is finite. Here, as remarked previously, in the case of finite delay, this hypothesis may be met through the application of known controllability results.

Acknowledgment. The author thanks an anonymous referee for several suggestions and comments that enhanced the presentation of the above results.

STABILIZATION OF BEAMS BY POINTWISE FEEDBACK CONTROL*

F. CONRAD†

Abstract. A flexible structure consisting of serially connected Euler-Bernoulli beams with co-located sensors and actuators is considered. Controls are point forces and point bending moments applied at the nodes. It is known that uniform exponential stability can be achieved with linear velocity feedback. A sensitivity analysis of the system's spectrum with respect to feedback coefficients is set up. It is also proved that in a particular case exponential decay rate can be obtained from the spectrum of the system.

Key words. serially connected beams, point control, exponential stabilization

AMS(MOS) subject classifications. 93D15, 73K12, 35P10

1. Introduction. We study the transverse deflection of a system of N serially connected Euler-Bernoulli beams as shown in Fig. 1, where each beam has mass density m_i and flexural rigidity E_iI_i.

The left end $x=0$ is clamped. At the right end and at interior nodes, point control forces U_{0i} and point control bending moments U_{1i} are applied. We assume that at each node, the controls are linear combinations of the transverse and angular velocities; thus sensors and actuators are co-located.

This system has been studied extensively by Chen et al. (see, for instance, [2] where major results can be found). For convenience, we summarize the material of [2], which is useful to us.

Let $y(x, t)$ denote the transverse deflection of the structure at time t. In the sequel, we set $\dot{y}(x, t)=\partial y/\partial t(x, t)$ and $y'(x, t)=\partial y/\partial x(x, t)$.

For the open-loop system we get the following equations:

$$
\begin{aligned}
&m_i\ddot{y}+E_iI_iy''''=0, \quad x_{i-1}<x<x_i, \quad i=1, N,\\
&y(0, t)=y'(0, t)=0,\\
&y(x_i^-, t)=y(x_i^+, t), \qquad i=1, N-1,\\
&y'(x_i^-, t)=y'(x_i^+, t), \qquad i=1, N-1,\\
&E_iI_iy'''(x_i^-, t)-E_{i+1}I_{i+1}y'''(x_i^+, t)=U_{0i}, \qquad i=1, N-1,\\
&-E_iI_iy''(x_i^-, t)+E_{i+1}I_{i+1}y''(x_i^+, t)=U_{1i}, \qquad i=1, N-1,\\
&E_NI_Ny'''(L, t)=U_{0N},\\
&-E_NI_Ny''(L, t)=U_{1N}.
\end{aligned}
\tag{1.1}
$$

For the closed-loop system, we add the feedback law

$$
\begin{pmatrix} U_{0i}(t) \\ U_{1i}(t) \end{pmatrix} = K_i \begin{pmatrix} \dot{y}(x_i, t) \\ \dot{y}'(x_i, t) \end{pmatrix}, \qquad i=1, N \tag{1.2}
$$

where K_i is a 2×2 real matrix.

This system can be written in an abstract form [2]. Let $H=L^2(0, L)$, let $V=\{v\in H^2(0, L)\mid v(0)=v'(0)=0\}$ be the energy space, and let $A\in\mathcal{L}(V, V')$ be defined by

$$
\langle Av, w\rangle=\sum_{i=1}^{N} E_iI_i\int_{x_{i-1}}^{x_i} v''(x)w''(x)\,dx \quad \forall v\in V, \quad w\in V.
$$

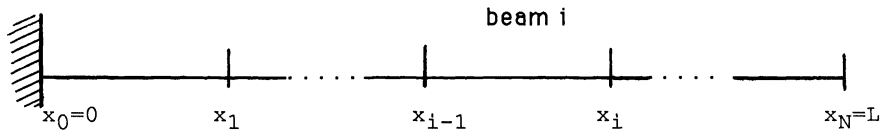

FIG. 1

The observation operator $C \in \mathscr{L}(V, \mathbb{R}^{2N})$ is defined by

$$Cv = (v(x_1), v'(x_1), \cdots, v(x_i), v'(x_i), \cdots, v(x_N), v'(x_N)).$$

The control operator is the transpose $C^* \in \mathscr{L}(\mathbb{R}^{2N}, V')$ of the observation operator.

Let K be the $2N \times 2N$ block-diagonal matrix with entries K_i, $i=1, N$, and M denote the isomorphism $f \to Mf$ on $L^2(0, L)$ where $M(x)$ is the function $M(x) = \sum_{i=1}^{N} m_i 1_{(x_{i-1}, x_i)}(x)$.

In this framework, the equations for the closed-loop system are

$$M\ddot{y} + Ay + C^*KC\dot{y} = 0 \quad \text{in } V'; \quad y \in V. \tag{1.3}$$

THEOREM 1.1 [2]. *Assume K is coercive. Given $(y_0, y_1) \in V \oplus H$, (1.3) admits a unique solution $y \in \mathscr{C}(0, T; V)$; $\dot{y} \in \mathscr{C}(0, T; H)$; $C\dot{y} \in L^2(0, T; \mathbb{R}^{2N})$; $M\ddot{y} \in L^2(0, T; V')$.*

In fact (1.3) defines a $\mathscr{C}^0$ semigroup of contractions on $V \oplus H$ that will be denoted by S_K.

The generator of S_K is

$$\mathscr{A}(K) = \begin{pmatrix} 0 & I \\ -M^{-1}A & -M^{-1}C^*KC \end{pmatrix}.$$

Remark. For a sharp existence result for the open-loop system, we refer the reader to [9].

The main result in [2] concerns stabilization. The elastic energy of the system is defined as

$$E(t) = \sum_{i=1}^{N} \int_{x_{i-1}}^{x_i} [m_i \dot{y}^2(x, t) + E_i I_i y''^2(x, t)]\, dx.$$

THEOREM 1.2 [2]. *Assume the following.*

(i) $m_i \leqq m_{i+1}$ *and* $E_i I_i \geqq E_{i+1} I_{i+1}$, $i = 1, N-1$.

(ii) $K_i = \left(\begin{smallmatrix} \alpha_i & 0 \\ 0 & 0 \end{smallmatrix}\right)$ *with* $\alpha_i \geqq 0$, $i = 1, N-1$.

(iii) *Either* $K_N = \left(\begin{smallmatrix} \alpha_N & 0 \\ 0 & \beta_N \end{smallmatrix}\right)$ *with* $\alpha_N > 0$, $\beta_N \geqq 0$, *or*

$$K_N = \begin{pmatrix} \alpha_N & -\gamma_N \\ \gamma_N & \beta_N \end{pmatrix}, \qquad \alpha_N > 0, \quad \beta_N > 0, \quad \gamma_N \in \mathbb{R}.$$

Then uniform exponential stability holds: there exists $\mu > 0$ such that $E(t) \leqq$ const. $e^{-\mu t} E(0)$, for all $(y_0, y_1) \in V \oplus H$ or else

$$\|S_K(t)\|_{V \oplus H} \leqq \text{const. } e^{-\mu t}. \tag{1.4}$$

Remark 1. Assumptions (ii) and (iii) do not imply that K is coercive. However, the conclusions of Theorem 1.1 are valid provided the estimate on $C\dot{y}$ is replaced by $\dot{y}(x_i, \cdot) \in L^2(0, T)$ whenever $\alpha_i > 0$, $i = 1, \cdots, N$, and $\dot{y}'(x_N, \cdot) \in L^2(0, T)$ whenever $\beta_N > 0$.

Remark 2. Exponential decay for an Euler-Bernoulli beam with rate control on the bending moment only has been obtained in [3] by means of a frequency domain technique. The energy multiplier method used to prove Theorem 1.2 does not seem to work in that case.

The optimal rate of decay μ in (1.4) is of course the spectral radius ω of the semigroup S_K: $\omega = \lim t^{-1} \log \|S_K(t)\|_{V\oplus H}$ as $t \to \infty$.

It was conjectured in [2] that the rate of decay of the energy is given by $\rho(K) = \sup\{\operatorname{Re} \nu_p / p \in \mathbb{N}\}$, where the ν_p are the eigenvalues of the generator $\mathscr{A}(K)$. This cannot result from standard theorems, since, due to the existence of a vertical asymptote for the ν_p in the complex plane (see [3]-[5] and [10]), S_K is neither differentiable nor compact. We prove the conjecture in a particular case: *for a single homogeneous beam with rate control on the shear only, $\rho(K) = \sup\{\operatorname{Re} \nu_p / p \in \mathbb{N}\}$, at least for small K (Corollary 4.5 below).*

Assuming the conjecture holds, the spectrum of the system for a single homogeneous beam has been computed in [2] with respect to feedback coefficients, leading to interesting conclusions. In this paper, *we obtain analytical results concerning the dependence of the spectrum with respect to K, for a general system of connected beams (Theorem 2.2 below).* Applied to a single beam, the results reinforce the conclusions obtained in [2].

Our results are obtained by the following perturbation technique. We consider $\mathscr{A}(K)$ as a perturbation of $\mathscr{A}(0)$ (the free vibrating system) and then get expansions of the eigenvalues and eigenvectors. Therefore, due to the technique, the results, although very precise, are only valid for small K.

The summary of the paper is as follows. In § 2, we set up a sensitivity analysis to get estimates for the eigenvalues of $\mathscr{A}(K)$, for N connected beams. In § 3, we apply the result to a single beam. In § 4, also for a single beam, we improve the estimates on the spectrum, get estimates for the eigenvectors, and then prove the conjecture mentioned previously.

2. Sensitivity analysis of the spectrum of the system. We recall the generator of the semigroup $S_K(t)$:

$$\mathscr{A}(K) = \begin{pmatrix} 0 & I \\ -M^{-1}A & -M^{-1}C^*KC \end{pmatrix}.$$

Let W be the subspace of functions of V that are piecewise H^4 on each interval (x_{i-1}, x_i). Then the domain of the unbounded operator $\mathscr{A}(K)$ on $V \oplus H$ is $\operatorname{dom} \mathscr{A}(K) = \{(u, v) \mid u \in W,\ v \in V;\ Bu = KCv\}$ where

$$Bu = \{\cdots E_i I_i u'''(x_i^-) - E_{i+1} E_{i+1} u'''(x_i^+), -E_i I_i u''(x_i^-) + E_{i+1} I_{i+1} u''(x_i^+), \cdots, E_N I_N u'''(L), -E_N I_N u''(L)\}.$$

The spectrum of $\mathscr{A}(K)$ is purely point spectrum, by classical regularity results (see also [10]).

Obviously, $\nu \in \mathbb{C}$ is an eigenvalue, $\binom{\phi}{\psi} \in \operatorname{dom} \mathscr{A}(K)$ is an eigenvector of $\mathscr{A}(K)$ if and only if

$$\psi = \nu\phi, \tag{2.1}$$

$$A\phi + \nu^2 M\phi + \nu C^* KC\phi = 0. \tag{2.2}$$

Therefore, we only must solve (2.2). This will be achieved by means of the Implicit Function Theorem in an adequate framework, to get the eigenelement as functions of K, near $K = 0$. We now develop the methodology.

2.1. Free vibrations of the structure. In case $K = 0$, (2.2) reduces to

$$A\phi + \nu^2 M\phi = 0, \quad \phi \in W, \qquad B\phi = 0, \tag{2.3}$$

or in strong form, with $\phi \in W$:

$$
\begin{aligned}
&E_iI_i\phi'''' + \nu^2 m_i\phi = 0, \quad x_{i-1} < x < x_i, \quad i = 1, N,\\
&E_iI_i\phi'''(x_i^-) - E_{i+1}I_{i+1}\phi'''(x_i^+) = 0, \qquad i = 1, N-1,\\
&-E_iI_i\phi''(x_i^-) + E_{i+1}I_{i+1}\phi''(x_i^+) = 0, \qquad i = 1, N-1,\\
&E_NI_N\phi'''(L) = 0,\\
&-E_NI_N\phi''(L) = 0.
\end{aligned} \tag{2.4}
$$

As an unbounded operator on H, A is self-adjoint and A^{-1} is compact. Let $(\omega_p^2)_{p\in N}$ be the eigenvalues of $A(\omega_p > 0)$ and ϕ_p the associated eigenfunctions. We assume that the eigenvalues of A are geometrically simple. Then (2.3) has a sequence of solutions (ν_p, ϕ_p) with $\nu_p = \pm i\omega_p$.

2.2. Forced vibrations of the structure. In case $K \neq 0$, we consider solutions (ν, ϕ) of (2.2) near (ν_p, ϕ_p), for any fixed p. Since (2.2) is not well-posed for the eigenfunctions, we must normalize ϕ. Define

$\mathcal{W} = \{\phi_p\}^\perp$ in W, for the H-scalar product, and set $\nu = \nu_p + \mu$, $\mu \in \mathbb{C}$, $\phi = \phi_p + w$, $w \in \mathcal{W}$.

Injecting these expansions into (2.2), we get

$$A w + \nu_p^2 M w + (2\nu_p\mu + \mu^2) M(\phi_p + w) + (\nu_p + \mu) C^* K C(\phi_p + w) = 0$$

or in strong form

$$
\begin{aligned}
&E_iI_iw'''' + \nu_p^2 m_i w + (2\nu_p\mu + \mu^2) m_i(\phi_p + w) = 0, \quad x_{i-1} < x < x_i, \quad i = 1, N,\\
&\begin{bmatrix} E_iI_iw'''(x_i^-) - E_{i+1}I_{i+1}w'''(x_i^+) \\ -E_iI_iw''(x_i^-) + E_{i+1}I_{i+1}w''(x_i^+) \end{bmatrix}\\
&\qquad - (\nu_p + \mu) K_i \begin{pmatrix} \phi_p + w \\ \phi_p' + w' \end{pmatrix}(x_i) = 0, \qquad i = 1, N-1,\\
&\begin{bmatrix} E_NI_Nw'''(L) \\ -E_NI_Nw''(L) \end{bmatrix} - (\nu_p + \mu) K_N \begin{pmatrix} \phi_p + w \\ \phi_p' + w' \end{pmatrix}(L) = 0,
\end{aligned} \tag{2.5}
$$

that is, $\mathcal{F}(\mu, w, K) = 0$ where $\mathcal{F}: \mathbb{C} \times \mathcal{W} \times \mathcal{M}_{2N} \to H \times \mathbb{C}^{2N}$ is the left-hand side of (2.5).

Obviously, $\mathcal{F}(0, 0, 0) = 0$ and $\mathcal{F}$ is regular. We want to apply the Implicit Function Theorem to (2.5). Let $\hat{\mu}$, $\hat{w} \in \mathbb{C} \times \mathcal{W}$. Then

$$
\mathcal{F}_{\mu w}(0,0,0)\hat{\mu}\hat{w} = \begin{cases}
E_iI_i\hat{w}'''' + \nu_p^2 m_i\hat{w} + 2\nu_p\hat{\mu}m_i\phi_p, & x_{i-1} < x < x_i, \quad i = 1, N,\\
E_iI_i\hat{w}'''(x_i^-) - E_{i+1}I_{i+1}\hat{w}'''(x_i^+), & i = 1, N-1,\\
-E_iI_i\hat{w}''(x_i^-) + E_{i+1}I_{i+1}\hat{w}''(x_i^+), & i = 1, N-1,\\
E_NI_N\hat{w}'''(L),\\
-E_NI_N\hat{w}''(L).
\end{cases} \tag{2.6}
$$

LEMMA 2.1. *$\mathcal{F}_{\mu w}(0, 0, 0): \mathbb{C} \times \mathcal{W} \to H \times \mathbb{C}^{2N}$ is an isomorphism.*

Proof. It is enough to establish that for all $f \in H$, and $(\alpha_i, \beta_i) \in \mathbb{C}^2$, $i = 1, N$, the following system

$$
\mathcal{F}_{\mu w}(0,0,0)\hat{\mu}\hat{w} = \begin{pmatrix} f \\ \alpha_i \\ \beta_i \end{pmatrix} \text{ admits a unique solution } \hat{\mu}, \hat{w} \text{ that depends continuously on the data } f, \alpha_i, \beta_i. \tag{2.7}
$$

Consider (2.7), with (2.6) in mind. Let $g \in W$ be the unique solution of

$$
\begin{aligned}
&g'''' = 0, \quad x_{i-1} < x < x_i, \quad i = 1, N, \\
&E_i I_i g'''(x_i^-) - E_{i+1} I_{i+1} g'''(x_i^+) = \alpha_i, \qquad i = 1, N-1, \\
&-E_i I_i g''(x_i^-) + E_{i+1} I_{i+1} g''(x_i^+) = \beta_i, \qquad i = 1, N-1, \\
&E_N I_N g'''(L) = \alpha_N, \\
&-E_N I_N g''(L) = \beta_N.
\end{aligned} \tag{2.8}
$$

g is the minimizer of the strain energy plus the potential energy of the forces α_i and moments β_i:

$$
\frac{1}{2} \sum_{i=1}^{N} \left[E_i I_i \int_{x_{i-1}}^{x_i} v''(x)^2 \, dx + \alpha_i v(x_i) + \beta_i v'(x_i) \right],
$$

g is piecewise cubic and depends continuously on the data α_i and β_i.

We set $\hat{w} = g + \hat{v}$.

Then $\hat{v}$ satisfies

$$
\begin{aligned}
&E_i I_i \hat{v}'''' + \nu_p^2 m_i (g + \hat{v}) + 2\nu_p m_i \hat{\mu} \phi_p = f, \quad x_{i-1} < x < x_i, \quad i = 1, N, \\
&E_i I_i \hat{v}'''(x_i^-) - E_{i+1} I_{i+1} \hat{v}'''(x_i^+) = 0, \qquad i = 1, N-1, \\
&-E_i I_i \hat{v}''(x_i^-) + E_{i+1} I_{i+1} \hat{v}''(x_i^+) = 0, \qquad i = 1, N-1, \\
&E_N I_N \hat{v}'''(L) = 0, \\
&-E_N I_N \hat{v}''(L) = 0;
\end{aligned} \tag{2.9}
$$

equivalently,

$$
A\hat{v} + \nu_p^2 M \hat{v} = f - \nu_p^2 M g - 2\nu_p \hat{\mu} M \phi_p \tag{2.9}
$$

where A is an unbounded self-adjoint operator on H, with A^{-1} compact. By the Fredholm alternative, (2.9) admits a solution if and only if the right-hand side of (2.9) is orthogonal to ϕ_p; this gives a unique $\hat{\mu}$

$$
\hat{\mu} = \frac{(f - \nu_p^2 M g, \phi_p)}{2\nu_p (M\phi_p, \phi_p)}, \tag{2.10}
$$

which is continuous with respect to $f \in H$, $g \in H$.

Denote by $\mathcal{T}$ the pseudoinverse of $A + \nu_p^2 M$; $\mathcal{T}$ is continuous from $\{\phi_p\}^\perp$ onto $\mathcal{W}$. Then the general solution of (2.9) is given by

$$
\hat{v} = \mathcal{T} h + \lambda \phi_p \quad \text{where } h = f - \nu_p^2 M g - 2\nu_p \hat{\mu} M \phi_p, \quad \lambda \in \mathbb{C}.
$$

Since $\hat{w} = \hat{v} + g \in \mathcal{W}$, we have $(\mathcal{T} h + \lambda \phi_p + g, \phi_p) = 0$, which gives a unique $\lambda = -(g, \phi_p)/(\phi_p, \phi_p)$, hence globally, a unique $\hat{w}$ that depends continuously on the data. □

THEOREM 2.2. *For any fixed $p \in \mathbb{N}$, (2.2) has, for K small enough, solutions of the form*

$$
\begin{aligned}
&\nu_{\pm p}(K) = \pm i\omega_p + \hat{\mu}_p(K) + |K| \varepsilon_{\pm p}(K), \\
&\phi_{\pm p}(K) = \phi_p \pm \hat{w}_p(K) + |K| \eta_{\pm p}(K)
\end{aligned}
$$

with

$$
\hat{\mu}_p(K) = -\frac{1}{2} \frac{(KC\phi_p, C\phi_p)}{(M\phi_p, \phi_p)}, \qquad \hat{w}_p(K) \in \mathcal{W}
$$

linear continuous in K and $\varepsilon_{\pm p}(K) \in \mathbb{C}$, $\eta_{\pm p}(K) \in \mathcal{W}$ *regular functions defined for K small enough.*

Proof. The existence of the functions follows from the Implicit Function Theorem applied to $\mathcal{F}$ near $(\pm i\omega_p, \phi_p)$ and valid by Lemma 2.1. We note that $\hat{\mu} = \hat{\mu}_{\pm p}(K)$, $\hat{w} = \hat{w}_{\pm p}(K)$ are solutions of

$$\mathcal{F}_{\hat{\mu}\hat{w}}(0,0,0)\hat{\mu}\hat{w} = -\mathcal{F}_K(0,0,0)K = \begin{cases} 0 \\ \nu_p K_i \begin{pmatrix} \phi_p(x_i) \\ \phi_p'(x_i) \end{pmatrix}, \end{cases} \qquad i = 1, N, \tag{2.11}$$

which is just a special form of (2.7) with $f = 0$. Hence

$$\hat{\mu} = -\frac{\nu_p}{2} \frac{(Mg, \phi_p)}{(M\phi_p, \phi_p)}. \tag{2.12}$$

By (2.11) and (2.12), changing ν_p into $-\nu_p$ gives the opposite sign for g, hence the same $\hat{\mu}$.

On the other hand, since $\hat{w} = \mathcal{T}h + \lambda\phi_p + g$ with $h = -\nu_p^2 Mg - 2\nu_p \hat{\mu} M\phi_p$, the signs of g, h and $\lambda = -(g, \phi_p)/(\phi_p, \phi_p)$ change and so $\hat{w}$ changes sign.

So the only thing not yet established is the expression of $\hat{\mu}_p(K)$ given by the theorem.

We start from (2.12) $(Mg, \phi_p) = (g, M\phi_p) = -(1/\nu_p^2)(g, A\phi_p)$ by (2.3) $= -(1/\nu_p^2)(Ag, \phi_p)$. We note that (2.8) can be written as $Ag + C^*\binom{\alpha_i}{\beta_i} = 0$, thus

$$(Mg, \phi_p) = \frac{1}{\nu_p^2}\left(C^*\begin{pmatrix}\alpha_i \\ \beta_i\end{pmatrix}, \phi_p\right) = \frac{1}{\nu_p^2}\left(\begin{pmatrix}\alpha_i \\ \beta_i\end{pmatrix}, C\phi_p\right)_{\mathbb{R}^{2N}}$$

with

$$\begin{pmatrix}\alpha_i \\ \beta_i\end{pmatrix} = \nu_p K_i \begin{pmatrix}\phi_p(x_i) \\ \phi_p'(x_i)\end{pmatrix},$$

thus $(Mg, \phi_p) = (1/\nu_p)(KC\phi_p, C\phi_p)_{\mathbb{R}^{2N}}$ and the result follows from (2.12). □

Remark. The method also works for a beam with variable mass density and flexural rigidity, clamped at the left end and controlled at the right end. The result is exactly the same.

3. Application to a single beam. We consider a single beam with length L, constant mass density m, and flexural rigidity EI:

$$\begin{aligned} &m\ddot{y} + EIy'''' = 0, \qquad 0 < x < L, \\ &y(0,t) = y'(0,t) = 0, \\ &EI\begin{pmatrix} y'''(L,t) \\ -y''(L,t)\end{pmatrix} = K\begin{pmatrix}\dot{y}(L,t) \\ \dot{y}'(L,T)\end{pmatrix}. \end{aligned} \tag{3.1}$$

It is known [13] that for the uncontrolled system, $\nu_p = \pm i\omega_p$ with

$$\omega_p = \sqrt{EI/mL^4}\,\alpha_p^2 \quad \text{where the } \alpha_p,\ p = 1, 2, \cdots, \text{ are the positive solutions of} \tag{3.2}$$

$$1 + \cos\alpha \operatorname{ch}\alpha = 0. \tag{3.3}$$

Moreover,

$$\alpha_p = (p - \tfrac{1}{2})\pi + \delta_p \quad \text{where} \quad |\delta_p| \leqq 2C_p e^{-(p-1/2)\pi}, \quad C_p < 2 \text{ for } p > 1 \text{ [1]}. \tag{3.4}$$

The $L^2(0, L)$-normalized eigenfunctions are

$$\phi_p(x) = \frac{1}{\sqrt{L}}[\operatorname{ch} z - \cos z - \gamma(\alpha)(\operatorname{sh} z - \sin z)] \tag{3.5}$$

where $\alpha = \alpha_p$, $z = \alpha x/L$ and $\gamma(\alpha) = (\operatorname{ch} \alpha + \cos \alpha)/(\operatorname{sh} \alpha + \sin \alpha)$.

From (3.3) we easily get

$$\phi_p(L) = \frac{2(-1)^{p+1}}{\sqrt{L}}$$

and also

$$\phi_p'(L) = \frac{2\alpha}{L^{3/2}}\left(\operatorname{tg}\frac{\alpha}{2}\right)^{(-1)^p}.$$

With the form of matrix K considered in [2] $K = \begin{pmatrix} k_0 & -\gamma \\ \gamma & k_1 \end{pmatrix}$, the first-order approximations of the eigenvalues of the generator of (3.1) given by Theorem 2.2 are

$$\nu_p(K) = \pm i\sqrt{\frac{EI}{mL^4}}\,\alpha_p^2 - \frac{2}{m}\left[\frac{k_0}{L} + \frac{k_1}{L^3}\,\alpha_p^2\left(\operatorname{tg}^2\frac{\alpha_p}{2}\right)^{(-1)^p}\right] + \cdots. \tag{3.6}$$

Now, if we use (3.4) noting that δ_p is very small as soon as $p \geqq 2$, we have the sharp approximation

$$\nu_p(K) = \pm i\sqrt{\frac{EI}{mL^4}}\,\alpha_p^2 - \frac{2}{m}\left[\frac{k_0}{L} + \frac{k_1}{L^3}\,\alpha_p^2\right] + \cdots,$$

which gives the first-order evolution of the spectrum with respect to K, as shown in Fig. 2.

This is completely consistent with the conclusion obtained in [2] and [10] from a numerical experiment, at least for the first eigenvalues.

Remark. Higher-order expansions are available using a system of formal calculus such as REDUCE to solve the characteristic equation for the feedback system.

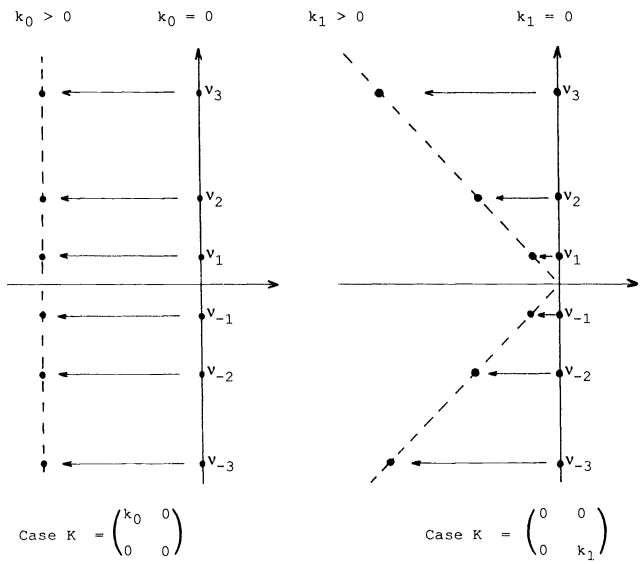

FIG. 2. *Sensitivity of the spectrum with respect to feedback coefficients.*

4. Obtaining an optimal rate of decay. The expansion of the eigenvalue $\nu_p(K)$ with respect to K given in Theorem 2.2 is valid for any fixed $p \in \mathbb{Z}$. In general, the higher-order term in the expansion is not controlled uniformly in p. Consider, for instance, the case of the single beam of § 3, with the matrix

$$K = \begin{pmatrix} k_0 & -\gamma \\ \gamma & k_1 \end{pmatrix}, \qquad k_1 \neq 0.$$

It has been proved that the eigenvalues of large modulus of that system admit a vertical asymptote [3]-[5], [10]. Thus an expansion of the form (3.6), $\nu_p(K) = \pm i(EI/mL^4)^{1/2}\alpha_p^2 - 2/m[k_0/L + k_1\alpha_p^2/L^3] + |K|\varepsilon_p(K)$ with $\varepsilon_p(K) \to 0$ as $K \to 0$ *uniformly in p*, cannot hold if $k_1 \neq 0$.

However, following an idea used in [12], we will get the uniformity, and in fact, very sharp estimates of the higher-order terms, in the particular case of a single beam with control on the shear only ($k_1 = \gamma = 0$). Thus we consider in this section the system

$$\begin{aligned} &m\ddot{y} + EIy'''' = 0, \qquad 0 < x < L, \\ &y(0, t) = y'(0, t) = 0, \\ &EIy'''(L, t) = k_0\dot{y}(L, t), \\ &-EIy''(L, t) = 0. \end{aligned} \tag{4.1}$$

We normalize L and set $a^4 = EI/mL^4$, $k = k_0L^3/EI$; then (4.1) rewrites as

$$\begin{aligned} &\ddot{y} + a^4y'''' = 0, \qquad 0 < x < 1, \\ &y(0, t) = y'(0, t) = 0, \\ &y'''(1, t) = k\dot{y}(1, t), \\ &y''(1, t) = 0. \end{aligned} \tag{4.2}$$

We will even suppose $a = 1$ with a new time scale (keeping the same notation for the new k).

The notation is the same as in §§ 2 and 3: $H = L^2(0, 1)$, $V = \{v \in H^2(0, 1) \mid v(0) = v'(0) = 0\}$, $\langle Au, v\rangle = \int_0^1 u''(x)v''(x)\,dx$, $A \in \mathcal{L}(V, V')$, and, as an unbounded operator on H, $\operatorname{dom} A = W = \{w \in H^4(0, 1) \cap V \mid w''(1) = w'''(1) = 0\}$; here $K = \left(\begin{smallmatrix} k & 0 \\ 0 & 0 \end{smallmatrix}\right)$.

Although not necessary, it is more convenient to work on $H \oplus H$ instead of $V \oplus H$. Since the form $\langle Au, v\rangle$ is V-elliptic, A admits a square root [8], which is a self-adjoint positive unbounded operator $A^{1/2}$ with domain V.

We set $z_1 = A^{1/2}y$, $z_2 = \dot{y}$ and (1.3), and hence (4.2) rewrites as

$$\begin{pmatrix} \dot{z}_1 \\ z_2 \end{pmatrix} = \begin{pmatrix} 0 & A^{1/2} \\ -A^{1/2} & -C^*KC \end{pmatrix} \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} = \mathcal{A}(K) \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \tag{4.3}$$

now with a generator $\mathcal{A}(K)$ (same notation as before, but not same operator) on $H \oplus H$.

For the moment we follow the methodology of § 2. Let $\nu \in \mathbb{C}$ be an eigenvalue of $\mathcal{A}(K)$, $\left(\begin{smallmatrix} \phi \\ \psi \end{smallmatrix}\right) \in \operatorname{dom} \mathcal{A}(K)$ be an eigenvector of $\mathcal{A}(K)$, i.e.,

$$A^{1/2}\psi = \nu\phi, \tag{4.4}$$

$$-A^{1/2}\phi - C^*KC\psi = \nu\psi, \quad \text{or else} \tag{4.5}$$

$$A\psi + \nu C^*KC\psi + \nu^2\psi = 0. \tag{4.6}$$

So we must solve (4.6), the same equation as in § 2, and then $\begin{pmatrix} A^{1/2}\psi \\ \nu\psi \end{pmatrix}$ is an eigenvector of $\mathcal{A}(K)$.

4.1. Uncontrolled system ($K=0$).

$$A\psi + \nu^2\psi = 0. \tag{4.7}$$

According to § 3, we get the sequence of eigenvalues $(\nu_p)_{p\in\mathbb{Z}^*}$ with $\nu_{\pm p} = \pm i\alpha_p^2$, $p>0$ where the α_p are solutions of (3.3) and the sequence of eigenvectors $\psi_{\pm p}(x) = \phi_p(x)$, $p>0$ given by (3.5).

Thus ν_p, $p\in\mathbb{Z}^*$ is the set of eigenvalues of $\mathcal{A}(0)$ and, by (4.4) $\xi_p = 1/\sqrt{2}\begin{pmatrix} \psi_p \\ \varepsilon i\psi_p \end{pmatrix}$, $p\in\mathbb{Z}^*$ ($\varepsilon=\pm 1$ whether $p>0$ or $p<0$) are normalized associated eigenvectors. Moreover, the ξ_p constitute a complete orthonormal basis of $H\oplus H$ (in the sequel, all the spaces are implicitly complexified).

4.2. Feedback system ($K\neq 0$). Now p is fixed, say >0 for convenience in the subsequent computations.

By the results of § 2, we immediately have the following lemma.

LEMMA 4.1. *For any fixed p, and k small enough,* (4.6) *admits solutions of the form*

$$\nu_p(k) = \nu_p - 2k + k\varepsilon_p(k), \qquad p\in\mathbb{Z}^* \tag{4.8}$$

$$\psi_p(k) = \psi_p + kz_p + k\eta_p(k), \qquad p\in\mathbb{Z}^* \tag{4.9}$$

where $\lim_{k\to 0}\varepsilon_p(k) = 0$ *in* $\mathbb{C}$, $z_p\in\mathcal{W}$, *and* $\lim_{k\to 0}\eta_p(k) = 0$ *in* $\mathcal{W}$.

$\mathcal{W}$ is the orthogonal of ψ_p in W for the H-scalar product.

We recall that $\psi_p = \phi_p$ as defined in § 3.

LEMMA 4.2. *$z_p\in\mathcal{W}$ is given by*

$$z_p(x) = \nu_p\psi_p(1)\sum_{q\neq p}\frac{\psi_q(1)}{\nu_q^2-\nu_p^2}\psi_q(x) \tag{4.10}$$

where the series converges uniformly in x. Moreover, $\|z_p\|_{c^0}\leqq M|\log p|/|p|$.

Proof. According to § 2, kz_p is the unique solution of (2.11) that we rewrite here as ($\hat{\mu} = -2k$)

$$\begin{aligned} &z_p'''' + \nu_p^2 z_p - 4\nu_p\psi_p = 0, \qquad z_p\in\mathcal{W}, \\ &z_p'''(1) = \nu_p\psi_p(1), \\ &z_p''(1) = 0. \end{aligned} \tag{4.11}$$

Proceeding as in the proof of Lemma 2.1, we get

$$z_p = g - \frac{(g,\psi_p)}{(\psi_p,\psi_p)}\psi_p + \mathcal{T}(-\nu_p^2 g + 4\nu_p\psi_p)$$

where g is the solution of

$$\begin{aligned} &g'''' = 0, \\ &g(0) = g'(0) = 0, \\ &g'''(1) = \nu_p\psi_p(1), \\ &g''(1) = 0; \end{aligned}$$

therefore $g(x) = \nu_p\psi_p(1)[x^3/6 - x^2/2]$.

$\mathcal{T}$ is the pseudoinverse of $A+\nu_p^2$ defined from $\{\psi_p\}^\perp$ onto $\mathcal{W}$, thus for all $h\in H$, $h\perp\psi_p$:

$$\mathcal{T}h=\sum_{\substack{q=1\\q\neq p}}^{\infty}\frac{(h,\psi_q)}{\nu_p^2-\nu_q^2}\psi_q,$$

so that

$$\begin{aligned}z_p&=\sum_{\substack{q\neq p\\q>0}}(g,\psi_q)\psi_q+\sum_{\substack{q\neq p\\q>0}}\frac{(-\nu_p^2 g+4\nu_p\psi_p,\psi_q)}{\nu_p^2-\nu_q^2}\psi_q\\&=-\sum_{\substack{q\neq p\\q>0}}\frac{\nu_q^2(g,\psi_q)}{\nu_p^2-\nu_q^2}\psi_q=\sum_{\substack{q\neq p\\q>0}}\frac{(g,\psi_q'''')}{\nu_p^2-\nu_q^2}\psi_q\\&=-\sum_{q\neq p}\frac{g'''(1)\psi_q(1)}{\nu_p^2-\nu_q^2}\psi_q\end{aligned}$$

after integration by parts, thus $z_p=\nu_p\psi_p(1)\sum_{q\neq p}\psi_q(1)/(\nu_q^2-\nu_p^2)\psi_q$ with convergence in the sense of $L^2(0,1)$ and (4.10) is established. Since the ψ_q are bounded in L^∞-norm uniformly in p (Lemma 1, Appendix) the convergence is also uniform. From the boundedness of the ψ_q and the estimates on the series $1/(\nu_q^2-\nu_q^2)$ (Lemma 2, Appendix) the estimate on $\|z_p\|_{c^0}$ follows. □

Now we want to get sharp estimates on the higher-order terms in (4.8) and (4.9). So we inject the expressions of $\nu_p(k)$ and $\psi_p(k)$ into (4.6), replacing $\varepsilon_p(k)$ and $\eta_p(k)$ by ε and η for simplicity; after the simplifications due to the first-order approximations, we get

$$\begin{aligned}&A\eta+\nu_p^2\eta+(4k+k\varepsilon^2+2\nu_p\varepsilon-4k\varepsilon)(\psi_p+kz_p+k\eta)\\&\quad-4\nu_pk(z_p+\eta)+(\varepsilon-2)C^*KC(\psi_p+kz_p+k\eta)+\nu_pC^*KC(z_p+\eta)=0\end{aligned}\tag{4.12}$$

or, in strong form:

$$\begin{aligned}&\eta''''+\nu_p^2\eta=4\nu_pk(z_p+\eta)-(4k+k\varepsilon^2+2\nu_p\varepsilon-4k\varepsilon)(\psi_p+kz_p+k\eta),\\&\eta'''(1)=(\varepsilon-2)k(\psi_p(1)+kz_p(1)+k\eta(1))+\nu_pk(z_p(1)+\eta(1)),\\&\eta''(1)=0.\end{aligned}\tag{4.13}$$

We denote the right-hand side of (4.13) by $(f,\alpha,0)$ and apply the same technique as in Lemma 2.1 of § 2.

Let $\eta=\hat\eta+g$ where g absorbs the nonzero boundary condition

$$g(x)=\frac{\alpha}{6}x^3-\frac{\alpha}{2}x^2.$$

Then (4.13) rewrites as

$$\begin{aligned}&\hat\eta''''+\nu_p^2\hat\eta=f-\nu_p^2g,\\&\hat\eta'''(1)=0,\\&\hat\eta''(1)=0,\end{aligned}\tag{4.14}$$

and (4.14) has a solution if and only if $(f-\nu_p^2g,\psi_p)=0$, that is,

$$\nu_p^2(g,\psi_p)=(f,\psi_p)=-4k+k\varepsilon^2+2\nu_p\varepsilon-4k\varepsilon.\tag{4.15}$$

We have already proved in the course of Lemma 4.2 that

$$(g, \psi_p) = \frac{1}{\nu_p^2} g'''(1)\psi_p(1) = \frac{1}{\nu_p^2} \alpha \psi_p(1)$$

so that (4.15) is equivalent to

$$\begin{aligned} &-4k + k\varepsilon^2 + 2\nu_p\varepsilon - 4k\varepsilon \\ &\quad = \psi_p(1)[(\varepsilon - 2)k(\psi_p(1) + kz_p(1) + k\eta(1)) + \nu_p k(z_p(1) + \eta(1))], \end{aligned} \tag{4.16}$$

i.e.,

$$\varepsilon = \frac{k}{2\nu_p}[4\varepsilon + 4 - \varepsilon^2 + \psi_p(1)(\varepsilon - 2)(\psi_p(1) + kz_p(1) + k\eta(1))] + \frac{k}{2}[z_p(1) + \eta(1)]. \tag{4.17}$$

Once (4.17) is satisfied, the unique solution of (4.13) is given by (see again the proof of Lemma 4.2)

$$\eta = g - (g, \psi_p)\psi_p + \mathcal{T}(f - \nu_p^2 g) = \sum_{\substack{q>0 \\ q\neq p}} (g, \psi_q)\psi_q + \sum_{\substack{q>0 \\ q\neq p}} \frac{(f - \nu_p^2 g, \psi_q)}{\nu_p^2 - \nu_q^2} \psi_q$$

$$= \sum_{\substack{q>0 \\ q\neq p}} \frac{-\nu_q^2 (g, \psi_q)}{\nu_p^2 - \nu_q^2} \psi_q + \sum_{\substack{q>0 \\ q\neq p}} \frac{(f, \psi_q)}{\nu_p^2 - \nu_q^2} \psi_q = \sum_{\substack{q>0 \\ q\neq p}} \frac{g'''(1)\psi_q(1)}{\nu_q^2 - \nu_p^2} \psi_q + \sum_{\substack{q>0 \\ q\neq p}} \frac{(f, \psi_q)}{\nu_p^2 - \nu_q^2} \psi_q,$$

$$\begin{aligned} \eta = k \sum_{\substack{q>0 \\ q\neq p}} &\frac{(\varepsilon - 2)(\psi_p(1) + kz_p(1) + k\eta(1)) + \nu_p(z_p(1) + \eta(1))}{\nu_q^2 - \nu_p^2} \psi_q(1)\psi_q \\ &+ k \sum_{\substack{q>0 \\ q\neq p}} \frac{4\nu_p - (4k + k\varepsilon^2 + 2\nu_p\varepsilon - 4k\varepsilon)}{\nu_p^2 - \nu_q^2} (z_p + \eta, \psi_q)\psi_q. \end{aligned} \tag{4.18}$$

Finally, (ε, η) satisfies (4.13) if and only if

$$\varepsilon = kF_p(k, \varepsilon, \eta), \tag{4.19}$$

$$\eta = kG_p(k, \varepsilon, \eta) \tag{4.20}$$

where kF_p and kG_p are the right-hand sides of (4.17) and (4.18), respectively.

THEOREM 4.3. *The functions ε_p and η_p of Lemma 4.1 can be defined on an interval $(-\alpha, \alpha)$ in k independently of p; moreover,*

$$|\varepsilon_p(k)| = \frac{|\log p|}{|p|} O(k), \tag{4.21}$$

$$\|\eta_p(k)\|_{C^0} = \frac{|\log p|^2}{|p|^2} O(k) \tag{4.22}$$

where $O(k)$ is uniform in p.

Proof. We consider (4.19), (4.20) as a fixed-point formulation with parameters k and p

$$(\varepsilon, \eta) = T_p(k, \varepsilon, \eta). \tag{4.23}$$

Let $B = \{k, \varepsilon, \eta: |k| \leqq 1, |\varepsilon| \leqq 1, \|\eta\|_{C^0} \leqq 1\} \subset \mathbb{R} \times \mathbb{C} \times C^0([0, 1])$.

From the expressions of F_p and G_p, Lemma 4.2, and Lemmas 1-3 of the Appendix, we have (M denotes generic constants) on B:

$$\begin{aligned} |F_p(k,\varepsilon,\eta)| &\leqq \frac{M}{|\nu_p|}+M\frac{|\log p|}{|p|}+M\|\eta\|_{c^0} \\ &\leqq M\frac{|\log p|}{|p|}+M\|\eta\|_{c^0}, \end{aligned} \tag{4.24}$$

$$\begin{aligned} \|G_p(k,\varepsilon,\eta)\|_{c^0} &\leqq M\frac{|\log p|}{|p|^3}+M\frac{|\log p|^2}{|p|^2}+M\frac{|\log p|}{|p|}\|\eta\|_{c^0} \\ &\leqq M\frac{|\log p|^2}{|p|^2}+M\frac{|\log p|}{|p|}\|\eta\|_{c^0}, \end{aligned} \tag{4.25}$$

all the constants being independent of p.

Similarly, we get, for the partial derivatives with respect to ε and η:

$$\left|\frac{\partial F_p}{\partial\varepsilon}(k,\varepsilon,\eta)\right| \leqq \frac{M}{|\nu_p|} \leqq M\frac{|\log p|}{|p|}, \tag{4.26}$$

$$\left|\frac{\partial F_p}{\partial\eta}(k,\varepsilon,\eta)\right| \leqq M,$$

$$\left\|\frac{\partial G_p}{\partial\varepsilon}(k,\varepsilon,\eta)\right\|_{c^0} \leqq M\frac{|\log p|}{|p|}, \tag{4.27}$$

$$\left\|\frac{\partial G_p}{\partial\eta}(k,\varepsilon,\eta)\right\|_{c^0} \leqq M\frac{|\log p|}{|p|}.$$

From (4.26) and (4.27) it follows that, for $|k| \leqq \alpha$ small enough, T is a contraction, uniformly in p (and k, for $|k|$ small).

By classical fixed point theory, we get the functions ε and η defined on an interval $(-\alpha, \alpha)$, uniformly in p.

From (4.25), we get $\|\eta_p(k)\|_{c^0} \leqq Mk(|\log p|/|p|)$ and, by bootstrap, we get (4.22).

Finally, (4.21) follows from (4.24) and (4.22). □

Remark. For a general feedback matrix with $k_1 \neq 0$, we must add terms involving $\psi_p'(1)$, which is $O(p)$. Roughly speaking, we lose at least a factor $1/p$ in the series so that estimates (4.21) and (4.22) for ε_p and η_p cannot be better than $\log|p|$ using our technique. This is consistent with the remark concerning uniformity with respect to p at the beginning of this section.

THEOREM 4.4. *For k small enough, $\mathcal{A}(K)$ admits a sequence of eigenvectors that constitute a Riesz basis in $H \oplus H$.*

Proof. We consider the eigenvalues $\nu_p(k)$ and eigenvectors $\psi_p(k)$ given by Lemma 4.1 and Theorem 4.3.

According to (4.4), (4.6), $\binom{A^{1/2}\psi_p(k)}{\nu_p(k)\psi_p(k)}$ is an eigenvector of $\mathcal{A}(K)$. We normalize it by considering

$$\begin{aligned} \xi_p(k) &= \frac{1}{\sqrt{2}\,\omega_p}\begin{pmatrix} A^{1/2}\psi_p + kA^{1/2}(z_p+\eta_p) \\ (\nu_p - 2k + k\varepsilon_p)(\psi_p + k(z_p+\eta_p)) \end{pmatrix} \\ &= \xi_p + \frac{k}{\sqrt{2}\,\omega_p}\begin{pmatrix} A^{1/2}(z_p+\eta_p) \\ (\varepsilon_p - 2)\psi_p + (\nu_p - 2k + k\varepsilon_p)(z_p+\eta_p) \end{pmatrix} \\ &= \xi_p + \frac{k}{\sqrt{2}\,\omega_p}\,h_p. \end{aligned}$$

By Lemma 4.2, $\|z_p\|_{c^0} \leqq M(|\log p|/|p|)$ and by (4.10), $A^{1/2}z_p = \nu_p\psi_p(1)\sum_{q\neq p,q>0}(\psi_q(1)/(\nu_q^2-\nu_p^2))\omega_q\psi_q(x)$, thus by Lemma 3 of the Appendix,

$$\|A^{1/2}z_p\|_{c^0} \leqq M|\nu_p|\frac{|\log p|}{|p|} = M\omega_p\frac{|\log p|}{|p|}.$$

Similarly, using (4.18) and expanding $A^{1/2}\eta$, we obtain the same estimates on $\|\eta_p\|_{c^0}$ and $\|A^{1/2}\eta_p\|_{c^0}$ up to k, which is bounded.

Finally, we obtain that

$$\left\|\frac{k}{\sqrt{2}\,\omega_p}h_p\right\|_{H\oplus H} \leqq \frac{k}{\sqrt{2}}\left\|\frac{h_p}{\omega_p}\right\|_{c^0\times c^0} \leqq Mk\left|\frac{\log p}{p}\right|$$

so that

$$\sum_{p\in\mathbb{Z}^*}|\xi_p(k)-\xi_p|^2_{H\oplus H} \leqq Mk^2\sum_{\mathbb{Z}^*}\left|\frac{\log p}{p}\right|^2 \leqq Mk^2 < 1$$

for k small enough.

According to a theorem of Paley and Wiener [11, p. 206] the $\xi_p(k)$ are a Riesz basis of $H\oplus H$. □

Remark 1. This result also proves that by our perturbation method, we have obtained all the eigenvalues of $\mathcal{A}(K)$.

Remark 2. Alternatively, we have proved that the eigenvectors

$$\frac{1}{\sqrt{2}\,\omega_p}\begin{pmatrix}\psi_p(k)\\ \nu_p\psi_p(k)\end{pmatrix}$$

form a Riesz basis in $V\oplus H$.

COROLLARY 4.5. *For k small enough, the spectral radius of the semigroup* $S_K(t)$ *is given by*

$$\omega(k) = \sup_{p\in\mathbb{Z}^*}\{\operatorname{Re}\nu_p(k)\} = -2k+O(k).$$

Proof. The first equality is a direct consequence of Theorem 4.4 (or Remark 2), the second follows from the uniformity of the estimates of ε_p. □

Remark. A general study of the asymptotic distribution of the eigenfrequencies, either for a single beam with active control at one end, or for two- or N-coupled beams with various dissipative joint conditions, has been carried out in [3]-[5]. Those results and the sensitivity analysis given here in § 2 are mutually complementary. Our results are essentially valid even at low frequencies.

Moreover, the asymptotic gaps for the eigenvalues given in [4] or [5] are one of the general assumptions that make the method of § 4 work, together with boundedness properties of the eigenfunctions.

Thus it seems possible to extend the results of § 4 to systems of coupled beams, provided suitable information on the eigenfunctions is available.

Appendix. Here we prove the technical estimates that are used in the proofs of Lemma 4.2, and Theorems 4.3 and 4.4.

The notation is that of §§ 3 and 4. All the constants m, EI, L are equal to 1, without loss of generality; M denotes constants.

LEMMA 1. $\|\phi_p\|_{c^0} \leqq M$; $\|\phi_p'\|_{c^0} \leqq M\alpha_p$ *where* $\alpha_p > 0$ *is a solution of* (3.3).

Proof. We recall that $\phi_p(x) = \operatorname{ch}\alpha x - \cos\alpha x - \gamma(\alpha)[\operatorname{sh}\alpha x - \sin\alpha x]$

$$\gamma(\alpha) = \frac{-\sin\alpha}{(-1)^p+\cos\alpha}, \qquad \alpha = \alpha_p.$$

By [1] $\alpha=(p-\frac{1}{2})\pi+2c_p(-1)^{p-1}\,e^{-(p-1/2)\pi}=\tilde{\alpha}+\varepsilon$ and $c_p<2$ when $p>1$. Thus for large p

$$\sin\alpha=(-1)^{p-1}+\eta,\qquad |\eta|\leqq\frac{\varepsilon^2}{2},$$

$$|\cos\alpha|\leqq|\varepsilon|\Rightarrow\gamma(\alpha)=1+\xi\quad\text{with } |\xi|\leqq 2\varepsilon\leqq 4c_p\,e^{-\tilde{\alpha}}.$$

Therefore $\phi_p(x)=\operatorname{ch}\alpha x-(1+\xi)\operatorname{sh}\alpha x$

$$-\cos\alpha x+(1+\xi)\sin\alpha x\Rightarrow|\phi_p(x)|\leqq-\xi\frac{e^{\alpha x}}{2}+\left(1+\frac{\xi}{2}\right)e^{-\alpha x}+M\leqq M.$$

For the estimate of the derivative

$$\frac{\phi_p'(x)}{\alpha}=\operatorname{sh}\alpha x+\sin\alpha x-\gamma(\alpha)[\operatorname{ch}\alpha x-\cos\alpha x]$$

$$=\operatorname{sh}\alpha x-(1+\xi)\operatorname{ch}\alpha x+\sin\alpha x+(1-\xi)\cos\alpha x.$$

Then, proceeding as before, we get $|\phi_p'(x)/\alpha|\leqq M$. □

Remark. According to the expressions of $\phi_p(1)$ and $\phi_p'(1)$ given in § 3, the estimates of Lemma 1 are optimal.

LEMMA 2.

$$\sum_{\substack{q>0\\ q\neq p}}\frac{1}{|\nu_p^2-\nu_q^2|}\leqq M\frac{|\log p|}{|p|^3}.$$

Proof.

$$\sum_{\substack{q>0\\ q\neq p}}\frac{1}{|\nu_p^2-\nu_q^2|}=\sum_{\substack{q>0\\ q\neq p}}\frac{1}{|\alpha_q^4-\alpha_p^4|}$$

$$\leqq\frac{1}{\alpha_p^4-\alpha_{p-1}^4}+\frac{1}{\alpha_{p+1}^4-\alpha_p^4}+\int_{\alpha_1}^{\alpha_{p-1}}\frac{dx}{\alpha_p^4-x^4}+\int_{\alpha_{p+1}}^{\infty}\frac{dx}{x^4-\alpha_p^4}$$

$$\leqq\frac{M}{p^3}+\frac{1}{\alpha_p^2}\left[\int_{\alpha_1}^{\alpha_{p-1}}\frac{dx}{\alpha_p^2-x^2}+\int_{\alpha_{p+1}}^{\infty}\frac{dx}{x^2-\alpha_p^2}\right]$$

$$\leqq\frac{M}{p^3}+\frac{M}{p^3}\left(\left[\log\frac{\alpha_p+x}{\alpha_p-x}\right]_{\alpha_1}^{\alpha_{p-1}}-\left[\log\frac{x+\alpha_p}{x-\alpha_p}\right]_{\alpha_{p+1}}^{\infty}\right)$$

$$\leqq\frac{M}{p^3}+\frac{M}{p^3}\log\frac{(\alpha_p+\alpha_{p-1})(\alpha_p-\alpha_1)(\alpha_p+\alpha_{p+1})}{(\alpha_p-\alpha_{p-1})(\alpha_p+\alpha_1)(\alpha_{p+1}-\alpha_p)}\leqq M\frac{|\log p|}{|p|^3}.$$ □

Remark. Using also the comparison of series and integrals, a similar reverse inequality can be established. Therefore, the estimate is optimal.

LEMMA 3.

$$\sum_{\substack{q>0\\ q\neq p}}\frac{|\nu_q|}{|\nu_p^2-\nu_q^2|}\leqq M\frac{|\log p|}{|p|}.$$

Proof.

$$\sum_{\substack{q>0\\ q\neq p}} \frac{|\nu_q|}{|\nu_p^2-\nu_q^2|} = \sum_{\substack{q>0\\ q\neq p}} \frac{\alpha_q^2}{|\alpha_q^4-\alpha_p^4|}$$

$$\leqq \frac{\alpha_{p-1}^2}{\alpha_p^4-\alpha_{p-1}^4} + \frac{\alpha_{p+1}^2}{\alpha_{p+1}^4-\alpha_p^4} + \int_{\alpha_1}^{\alpha_{p-1}} \frac{x^2\,dx}{\alpha_p^4-x^4} + \int_{\alpha_{p+1}}^{\infty} \frac{x^2}{x^4-\alpha_p^4}\,dx$$

$$\leqq \frac{M}{p} + \frac{1}{2}\int_{\alpha_1}^{\alpha_{p-1}} + \int_{\alpha_{p+1}}^{\infty} \left|\frac{1}{\alpha_p^2-x^2} - \frac{1}{\alpha_p^2+x^2}\right| dx$$

$$\leqq \frac{M}{p} + \frac{1}{2\alpha_p}\left[\frac{1}{2}\log\left|\frac{\alpha_p+x}{\alpha_p-x}\right| + \operatorname{arc\,tg}\frac{x}{\alpha_p}\right]_{\alpha_1}^{\alpha_{p-1}}$$

$$+ \frac{1}{2\alpha_p}\left[\frac{1}{2}\log\left|\frac{\alpha_p+x}{\alpha_p-x}\right| + \operatorname{arc\,tg}\frac{x}{\alpha_p}\right]_{\infty}^{\alpha_{p+1}}$$

$$\leqq \frac{M}{p} + M\left|\frac{\log p}{p}\right| \leqq M\frac{|\log p|}{|p|},$$

the estimate being also optimal. □

Acknowledgments. The author wishes to thank the referees who suggested improvements of the paper.

BILINEAR TRANSFORMATION OF INFINITE-DIMENSIONAL STATE-SPACE SYSTEMS AND BALANCED REALIZATIONS OF NONRATIONAL TRANSFER FUNCTIONS*

RAIMUND OBER† AND STEPHEN MONTGOMERY-SMITH‡

Abstract. The bilinear transform maps the open right half plane to the open unit disk and is therefore a suitable tool for carrying over results for continuous-time systems to discrete-time systems and vice versa. Corresponding state-space formulae are widely used and well understood for the case of finite-dimensional systems. In this paper infinite-dimensional generalizations of these formulae are studied for a general class of infinite-dimensional state-space systems. In particular, it is shown that reachability and observability are carried over and that the reachability and observability gramians are preserved under this transformation. Young showed that a wide class of nonrational discrete-time transfer functions admit a balanced state-space representation. It is shown that this result carries over to the continuous-time situation via the bilinear transformation.

Key words. bilinear transformation, infinite-dimensional state-space systems, balanced realizations

AMS(MOS) subject classifications. 93C20, 93B15, 93B20, 93B28

1. Introduction. Balanced realizations for finite-dimensional systems have received a great deal of attention. They were introduced as a means of performing model reduction in an easy fashion [10] and have subsequently been used in H^∞ control theory, for example, to evaluate the Hankel norm of a linear system [5], [3]. Recently, they have been used to study parametrization problems of the set of stable linear systems [11], [13].

The elegant results obtained for finite-dimensional balanced systems brought about some interest in the problem of the extension of the notion of a balanced realization to infinite-dimensional systems. Curtain and Glover [2], as well as Glover, Curtain, and Partington [6] derived continuous-time, balanced realizations for a class of systems with nuclear Hankel operator. Young [20] developed a very general realization theory for infinite-dimensional discrete-time systems.

The motivation for this paper was to show that a large class of systems that includes most H^∞ transfer functions have balanced realizations. Transfer functions in H^∞ are of particular interest since they are precisely the transfer functions of linear systems with L^2 bounded input-output operators. In particular, it is shown here that important systems such as a pure time delay, delayed systems with transfer functions of the form $G(s)\,e^{-sT}$, $G(s)$ nonstrictly proper rational, but also certain transfer functions with singularities on the imaginary axis such as $G(s)=\log(1+1/s)$ admit balanced or, more precisely, parbalanced realizations. These are examples of systems whose corresponding Hankel operator is not nuclear and hence they are not in the class of systems considered by Glover, Curtain, and Partington. The work by Glover, Curtain, and Partington [6] and Ober [12] has shown that balanced realizations can be successfully employed to perform model reduction for certain special classes of infinite-dimensional continuous-time systems. It is hoped that the realization theory for balanced systems developed here is not only of theoretical interest but is also a

step toward the development of model reduction tools for the important class of H^∞ transfer functions.

The realization problem for infinite-dimensional continuous-time systems has been studied by several authors. Shift realizations of infinite-dimensional continuous-time systems have been investigated, for example, by Fuhrmann [4] and Salamon [16]. Other approaches have been taken by Yamamoto [19] and Hegner [12]. The important role the Hankel operator plays in realization theory is well understood (see, e.g., Fuhrmann [4]). From this point of view it is interesting to note that such a connection is also very apparent in the realization of infinite-dimensional systems in terms of balanced realizations. For example, the realizability conditions on a transfer function are in terms of boundedness conditions and compactness conditions on the Hankel operator corresponding to the transfer function. But these can be expressed in terms of analytical properties of the transfer functions.

System theoretic developments often go in parallel for continuous-time and discrete-time systems. In finite-dimensional system theory it is common practice to derive results for one class of systems and then map these over to the other by using a bilinear transformation or the corresponding state space formulae. With this method it is often possible to avoid the repetition of lengthy derivations if results have already been obtained for one class of systems and similar results are needed for the other. The approach taken to the realization problem considered here is based on the same principal. The work by Young [20] contains very general realization results for discrete-time systems in terms of balanced realizations. We will carry these over to the continuous-time case using infinite-dimensional generalizations of the finite-dimensional methods. A major part of this paper is devoted to establishing infinite-dimensional generalizations of these techniques. It is shown that such generalizations are indeed possible and are especially suited to the study of observability and reachability properties, which are of central importance in linear systems theory. In particular, it is shown that these techniques carry over the observability and reachability operators in such a way that the observability (reachability) operator of a continuous-time system and the observability (reachability) operator of its corresponding discrete-time system are unitarily equivalent. It is hoped that such methods will become as useful in an infinite-dimensional setting as they have proved to be for finite-dimensional systems.

In essence, we will prove infinite-dimensional analogues of the following finite-dimensional results. If $C_n^{p,m}$ is the set of minimal asymptotically stable continuous-time systems $(A_c, B_c, C_c, D_c) \in \mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{p\times n} \times \mathbb{R}^{p\times m}$ and $D_n^{p,m}$ is the set of minimal asymptotically stable discrete-time systems $(A_d, B_d, C_d, D_d) \in \mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{p\times n} \times \mathbb{R}^{p\times m}$, then the map $T_n : D_n^{p,m} \to C_n^{p,m}$ defined by

$$T_n((A_d, B_d, C_d, D_d))$$
$$= ((I + A_d)^{-1}(A_d - I), \sqrt{2}(I + A_d)^{-1}B_d, \sqrt{2}\, C_d(I + A_d)^{-1}, D_d - C_d(I + A_d)^{-1}B_d)$$

is a bijection with inverse $T_n^{-1} : C_n^{p,n} \to D_m^{p,n}$ given by

$$T_n^{-1}((A_c, B_c, C_c, D_c))$$
$$= ((I - A_c)^{-1}(I + A_c), \sqrt{2}(I - A_c)^{-1}B_c, \sqrt{2}\, C_c(I - A_c)^{-1}, D_c + C_c(I - A_c)^{-1}B_c).$$

If $(A_c, B_c, C_c, D_c) := T_n((A_d, B_d, C_d, D_d))$, then (A_d, B_d, C_d, D_d) is a realization of the transfer function G_d, i.e., $G_d(z) = C_d(zI - A_d)^{-1}B_d + D_d$, if and only if (A_c, B_c, C_c, D_c) is a realization of the transfer function $G_c(s) := G_d((1+s)/(1-s))$, i.e., $G_c(s) = C_c(sI - A_c)^{-1}B_c + D_c$.

To deal with infinite-dimensional continuous-time systems in their full generality, it is however necessary, in contrast to discrete-time systems, to deal with unbounded input and output operators. This produces serious technical problems, and a careful setup is necessary for the definition of an infinite-dimensional continuous-time system and of the generalization of the transformation T_n.

Our approach to the definition of an infinite-dimensional system is based on the notion of a compatible system, as introduced by Helton [9]. There are, however, several differences in technical details that seem necessary to prove our result. Hedberg [8] used a form of state-space formulae to relate discrete-time shift realizations to continuous-time shift realizations. His method was later reported in the book by Fuhrmann [4]. To derive our results we had to adopt a generalization of the transformation T_n that differs from Hedberg's generalization in several respects.

In § 2 we define the objects of interest to our study, that is, infinite-dimensional discrete- and continuous-time systems. To do this it is necessary to introduce the notion of a rigged Hilbert space, as well as prove several properties of generators of semigroups that are important in our context.

We will need several results from the functional calculus for unbounded functions by Sz.-Nagy and Foias [17]. Section 3 contains a brief introduction to this functional calculus and proves propositions that we will need in later sections. The section can be skipped by readers who are not interested in detailed proofs of the main theorems of the paper.

Section 4 contains our first important results. Here we establish the transformation T relating infinite-dimensional discrete-time systems to continuous-time systems and show that it is a bijection.

State-space systems related by a unitary state-space transformation are studied in § 5. It is established that two discrete-time systems are unitarily equivalent if and only if their corresponding continuous-time systems are unitarily equivalent.

Before § 7, we need to generalize the notion of the dual of a system to infinite-dimensional systems. This is done in § 6.

Section 7 contains one of the main results of this paper. It is shown that the observability operator of a discrete-time system is unitarily equivalent to the observability operator of its corresponding continuous-time system.

Having established all the necessary tools for our treatment of infinite-dimensional state-space systems, we bring them together in § 8 where we prove a general realization result for infinite-dimensional continuous-time transfer functions in terms of balanced systems.

Great emphasis has been placed on a presentation that is as self-contained as possible. It is hoped that this paper might serve some readers as an introduction to infinite-dimensional continuous-time state-space systems.

All Hilbert spaces are assumed to be separable and defined over the complex field. The scalar product $\langle \cdot, \cdot \rangle$ is linear in the first component. The norm of a Hilbert space X is denoted by $\| \cdot \|_X$, or simply by $\| \cdot \|$. The sum of two subsets N and M of a Hilbert space X is defined by $M + N = \{x + y \mid x \in M, y \in N\}$. We denote by $(A, D(A))$ the operator A with domain of definition $D(A)$. The adjoint of the operator $(A, D(A))$ is denoted by $(A^*, D(A^*))$. The space of bounded operators from the Hilbert space X to the Hilbert space Y is denoted by $\mathscr{L}(X, Y)$, whereas $\mathscr{K}(X, Y)$ is the set of compact operators from X to Y. The symbol $\sigma_p(A)$ indicates the point spectrum of the operator A. The abbreviation RHP stands for the open right half plane. The boundary of the open unit disc $\mathbf{D}$ is denoted by $\partial\mathbf{D}$. The real part of a complex number z is denoted by $\mathrm{Re}\,(z)$.

2. Admissible discrete-time and continuous-time systems. In this section we will define the classes of discrete- and continuous-time systems that we will investigate in later parts of the paper. Whereas we can immediately state what we mean by an admissible discrete-time system, we will have to review the notion of a rigged Hilbert-space before we can give the corresponding definition of an admissible continuous-time system.

An admissible discrete-time system is defined as follows.

DEFINITION 2.1. The quadruple of operators (A_d, B_d, C_d, D_d) is called an admissible discrete-time system, with state space X, output space Y and input space U, where X, U, Y are separable Hilbert spaces, if

(i) $A_d \in \mathscr{L}(X)$ is a contraction such that $-1 \notin \sigma_p(A_d)$,
(ii) $B_d \in \mathscr{L}(U, X)$,
(iii) $C_d \in \mathscr{L}(X, Y)$,
(iv) $D_d \in \mathscr{L}(U, Y)$,
(v) A_d, B_d, C_d are such that $\lim_{\lambda \to 1, \lambda > 1} C_d(\lambda I + A_d)^{-1} B_d$ exists in the norm topology.

We write $D_X^{U,Y}$ for the set of admissible discrete-time systems with input space U, output space Y and state space X.

Remark 2.2. The technical condition (v), which is generally not very restrictive, is not necessary to define infinite-dimensional discrete-time systems. It is, however, important to study the connection between continuous-time and discrete-time systems.

We briefly introduce a number of definitions and results on strongly continuous semigroups of contractions. An excellent reference is Pazy [14].

DEFINITION 2.3. Let X be a Hilbert space. A one-parameter family $(T(t))_{t \geqq 0}$ of contractions in $\mathscr{L}(X)$ is a strongly continuous semigroup of contractions if

(i) $T(0) = I$,
(ii) $T(t+s) = T(t)T(s)$ for every $t, s \geqq 0$,
(iii) $\lim_{t \to 0} T(t)x = x$ for all $x \in X$.

The linear operator $(A, D(A))$ given by

$$Ax = \lim_{t \to 0} \frac{T(t)x - x}{t} \quad \text{for } x \in D(A), \qquad D(A) = \left\{ x \in X \;\middle|\; \lim_{t \to 0} \frac{T(t)x - x}{t} \text{ exists} \right\}$$

is called the generator of the semigroup $(T(t))_{t \geqq 0}$.

It can be shown that the generator $(A, D(A))$ uniquely determines the corresponding semigroup $(T(t))_{t \geqq 0}$. Therefore we write $T(t) =: e^{tA}$, $t \geqq 0$. We note that the generator $(A, D(A))$ is a closed linear operator whose domain $D(A)$ is dense in X. A further important property is that it is dissipative, i.e.,

$$\operatorname{Re} \langle Ax, x \rangle \leqq 0 \quad \text{for all } x \in D(A).$$

Moreover, $D(A)$ is a Hilbert space with inner product induced by the graph norm

$$\|x\|_A^2 := \|x\|_X^2 + \|Ax\|_X^2, \qquad x \in D(A).$$

Since $\|x\|_A \geqq \|x\|_X$ for $x \in D(A)$, we can embed X in $D(A)^{(\prime)}$, the set of antilinear continuous functionals on $(D(A), \|\cdot\|_A)$, by

$$E : X \to D(A)^{(\prime)}, \qquad x \mapsto (y \mapsto \langle x, y \rangle).$$

Note that $D(A)^{(\prime)}$ is a Hilbert space with norm $\|f\|' := \sup_{\|x\|_A \leqq 1} |f(x)|$. Since $\langle \cdot, \cdot \rangle$ is linear in the first component, the embedding E is linear. By the above, we have the

rigged structure

$$D(A) \subseteq X \subseteq D(A)^{(\prime)}.$$

It is well known that if $(A, D(A))$ is the generator of a strongly continuous semigroup of contractions $(e^{tA})_{t\geq 0}$ on a Hilbert space, then the adjoint $(A^*, D(A^*))$ of $(A, D(A))$ is the generator of the adjoint semigroup $(e^{tA})^*_{t\geq 0}$. Hence, we have similarly that

$$D(A^*) \subseteq X \subseteq D(A^*)^{(\prime)}.$$

If M is an operator on X such that $D(A^*) \subseteq X$ is invariant under M^*, then M can be extended to an operator $\tilde{M}$ on $D(A^*)^{(\prime)}$ by

$$\tilde{M}: D(A^*)^{(\prime)} \to D(A^*)^{(\prime)}, \qquad f(\cdot) \mapsto f(M^*(\cdot)).$$

Usually we will not distinguish between M and $\tilde{M}$ and we will write M for $\tilde{M}$.

Also, if we have a map $M: Z \to D(A^*)^{(\prime)}$, Z a Hilbert space, such that $M(Z) \subseteq X^{(\prime)} \subseteq D(A^*)^{(\prime)}$, we can consider $M: Z \to X$ using the Riesz Representation Theorem.

We are now in a position to define admissible continuous-time systems.

DEFINITION 2.4. A quadruple of operators (A_c, B_c, C_c, D_c) is called an admissible continuous-time system with state space X, input space U, and output space Y, where X, U, Y are separable Hilbert spaces, if

(i) $(A_c, D(A_c))$ is the generator of a strongly continuous semigroup of contractions on X.

(ii) $B_c: U \to (D(A_c^*)^{(\prime)}, \|\cdot\|')$ is a bounded linear operator.

(iii) $C_c: D(C_c) \to Y$ is linear with $D(C_c) = D(A_c) + (I - A_c)^{-1} B_c U$ and $C_{c|D(A_c)}: (D(A_c), \|\cdot\|_{A_c}) \to Y$ is bounded.

(iv) $C_c(I - A_c)^{-1} B_c \in \mathscr{L}(U, Y)$.

(v) A_c, B_c, C_c are such that $\lim_{s\in\mathbb{R}, s\to\infty} C_c(sI - A_c)^{-1} B_c = 0$ in the norm topology.

(vi) $D_c \in \mathscr{L}(U, Y)$.

We write $C_X^{U,Y}$ for the set of admissible continuous-time systems with input space U, output space Y, and state space X.

Before we continue to prove two lemmas that show admissible continuous-time systems are well defined, let us remark that the state space X of a system in $C_X^{U,Y}$ has the rigged structure $D(A_c) \subseteq X \subseteq D(A_c^*)^{(\prime)}$.

Remark 2.5. In Helton [9] and Fuhrmann [4] a similar definition was given for continuous-time state-space systems. There are, however, several differences between so-called compatible systems and admissible systems as defined here. Our definition of a rigged Hilbert space is slightly different from that used in Helton and Fuhrmann, where X is embedded in the dual spaces $D(A)'$ and $D(A^*)'$, rather than in the spaces of antilinear functionals $D(A)'$ and $D(A^*)'$ as adopted here. The reason for using our definition is that this naturally leads to a definition of the input operator B_c as a linear, rather than an antilinear operator. Most important, however, for the discussion later, is the imposition of (v) in our definition.

To show that the above definition is well defined, we must show that $C_c(sI - A_c)^{-1} B_c$ is well defined for all $s \in \mathbb{R}$ and that $(I - A_c)^{-1} B_c U \subseteq X$. This follows from the following two lemmas, which also contain technical results that are useful in later sections.

LEMMA 2.6. *Let $(A_c, D(A_c))$ be the generator of a strongly continuous semigroup of contractions $(e^{tA_c})_{t\geq 0}$ on the separable Hilbert space X. Then for $s \in$ RHP,*

(i) *$(sI - A_c)^{-1} X \subseteq D(A_c)$ and the map $(sI - A_c)^{-1}: (X, \|\cdot\|_X) \to (D(A_c), \|\cdot\|_{A_c})$ is bounded.*

(ii) *The map $(sI - A_c)^{-1}: (D(A_c), \|\cdot\|_{A_c}) \to (D(A_c), \|\cdot\|_{A_c})$ is bounded.*

(iii) $(sI-A_c)^{-1}D(A_c^*)^{(\prime)} \subseteq X$ *and the map* $(sI-A_c)^{-1}:(D(A_c^*)^{(\prime)}, \|\cdot\|') \to (X, \|\cdot\|_X)$ *is bounded.*

(iv) $e^{tA_c}D(A_c) \subseteq D(A_c)$ *for all* $t \in [0, \infty[$.

Proof. (i) For a proof that $(sI-A_c)^{-1}X \subseteq D(A_c)$, $s \in \mathrm{RHP}$, see Pazy [14, p. 8]. To show that $(sI-A_c)^{-1}:(X, \|\cdot\|_X) \to (D(A_c), \|\cdot\|_{A_c})$ is bounded, $s \in \mathrm{RHP}$, let $x \in X$ and consider

$$\begin{aligned}\|(sI-A_c)^{-1}x\|_{A_c}^2 &= \|(sI-A_c)^{-1}x\|_X^2 + \|A_c(sI-A_c)^{-1}x\|_X^2 \\ &\leqq \|(sI-A_c)^{-1}\|^2\|x\|_X^2 + \|s(sI-A_c)^{-1}x - (sI-A_c)(sI-A_c)^{-1}x\|_X^2 \\ &\leqq \|(sI-A_c)^{-1}\|^2\|x\|_X^2 + (|s|\,\|(sI-A_c)^{-1}\|\,\|x\|_X + \|x\|_X)^2 \\ &= (\|(sI-A_c)^{-1}\|^2 + (|s|\,\|(sI-A_c)^{-1}\|+1)^2)\|x\|_X^2,\end{aligned}$$

which proves the result.

(ii) This follows from (i) since $\|x\|_X \leqq \|x\|_{A_c}$, for $x \in D(A_c)$.

(iii) This follows by duality from (i).

(iv) See Pazy [14, p. 5]. □

By (iii) of the previous lemma and the definition of B_c we have that $(I-A_c)^{-1}B_c \subseteq X$ and so $D(C_c)$ is well defined. The following lemma shows that $C_c(sI-A_c)^{-1}B_c$ is well defined and in $\mathscr{L}(U, Y)$, for all $s \in \mathrm{RHP}$.

LEMMA 2.7. *Let* $A_c: D(A_c) \to X$ *be the generator of a strongly continuous semigroup of contractions. Let* $B_c: U \to (D(A_c^*)^{(\prime)}, \|\cdot\|')$ *be bounded and let* $C_c: D(C_c) \to Y$ *be such that* $C_{c|D(A_c)}: (D(A_c), \|\cdot\|_{A_c}) \to Y$ *is bounded, where* $D(C_c) = D(A_c) + (I-A_c)^{-1}B_cU$. *Then*

(i) $(sI-A_c)^{-1}B_cU \subseteq D(C_c)$ *for all* $s \in \mathrm{RHP}$.

(ii) *If* $C_c(I-A_c)^{-1}B_c \in \mathscr{L}(U, Y)$, *then* $C_c(sI-A_c)^{-1}B_c \in \mathscr{L}(U, Y)$ *for all* $s \in \mathrm{RHP}$.

Proof. Let $s \in \mathrm{RHP}$; then by the resolvent identity we have

$$(sI-A_c)^{-1} = (I-A_c)^{-1} + (1-s)(I-A_c)^{-1}(sI-A_c)^{-1}.$$

Since $(sI-A_c^*)^{-1}D(A_c^*) \subseteq D(A_c^*)$ we can apply B_c and obtain

$$(sI-A_c)^{-1}B_c = (I-A_c)^{-1}B_c + (1-s)(I-A_c)^{-1}(sI-A_c)^{-1}B_c.$$

Since $B_c: U \to (D(A_c^*)^{(\prime)}, \|\cdot\|)$ is bounded, it follows by Lemma 2.6(i), (iii) that

$$(I-A_c)^{-1}(sI-A_c)^{-1}B_c: U \to (D(A_c), \|\cdot\|_{A_c})$$

is continuous. This implies in particular (i), since

$$(sI-A_c)^{-1}B_cU = (I-A_c)^{-1}B_cU + (1-s)(I-A_c)^{-1}(sI-A_c)^{-1}B_cU \subseteq D(C_c).$$

Since $C_{c|D(A_c)}: (D(A_c), \|\cdot\|_{A_c}) \to Y$ is bounded and hence

$$C_c(I-A_c)^{-1}(sI-A_c)^{-1}B_c \in \mathscr{L}(U, Y),$$

we have that

$$C_c(sI-A_c)^{-1}B_c = C_c(I-A_c)^{-1}B_c + (1-s)C_c(I-A_c)^{-1}(sI-A_c)^{-1}B_c \in \mathscr{L}(U, Y). \quad \square$$

Remark 2.8. It is useful to note that using the identification of $X^{(\prime)}$ and X via the Riesz Representation Theorem we have that for $u \in U$ the functional $(sI-A_c)^{-1}B_c(u): D(A_c^*) \to \mathbb{C}$ is given by

$$x \mapsto (sI-A_c)^{-1}B_c(u)[x] = B_c(u)[(\bar{s}I-A_c^*)^{-1}x] = \langle (sI-A_c)^{-1}B_cu, x\rangle.$$

3. The functional calculus by Sz.-Nagy–Foias. In this section we will review some results on the functional calculus by Sz.-Nagy-Foias and prove two technical results that are fundamental to the main results of this paper. This section is, however, only necessary for an understanding of the proofs of some of the theorems presented in later sections. Those theorems themselves are largely formulated without reference to the functional calculus discussed here.

Since we do not assume that the reader is fully familiar with the functional calculus as developed in Sz.-Nagy and Foias [17] we give a brief summary of those results necessary for our applications.

We first consider a standard result of functional calculus. Let $\mathscr{A}$ be the set of functions given by

$$a(z)=\sum_{k=0}^{\infty} c_k z^k \quad \text{such that} \quad \sum_{k=0}^{\infty} |c_k|<\infty.$$

Then $\mathscr{A}$ is an algebra with the involution $a\mapsto a^*$ given by $a^*(z):=\overline{a(\bar{z})}$. Note that a function in $\mathscr{A}$ is analytic on $\mathbf{D}$ and continuous on $\bar{\mathbf{D}}$.

For a contraction T on a Hilbert space X, we define $a(T)=\sum_{k=0}^{\infty} c_k T^k$. The sum converges in the operator norm and hence the operator $a(T)$ is well defined. The following theorem states the fundamental result concerning the functional calculus for functions in $\mathscr{A}$.

THEOREM 3.1. *For a contraction T on a Hilbert space X, the map*

$$\mathscr{A}\to\mathscr{L}(X), \qquad a(z)\mapsto a(T)$$

is an algebra homomorphism. In particular, $a(T)b(T)=b(T)a(T)$, for $a, b\in\mathscr{A}$.

The functions that are important in our context are:

(a) $\phi: z\to(z-1)/(z+1)$,

(b) $\varphi_t: z\mapsto e^{t((z-1)/(z+1))}$, $t\geqq 0$,

(c) $\mu: z\mapsto 1/(1+z)$,

(d) $\delta_t: z\mapsto 1/(1+z)\, e^{t((z-1)/(z+1))}$, $t\geqq 0$.

None of these functions are in $\mathscr{A}$ and hence we must consider extensions of the functional calculus of Theorem 3.1. Note, however, that the functions $z\mapsto\phi(rz)$, $z\mapsto\varphi_t(rz)$, $z\mapsto\mu(rz)$, and $z\mapsto\delta_t(rz)$, $0<r<1$ are in $\mathscr{A}$.

Next we exploit the observation that for each function $u\in H^\infty$ the function $z\mapsto u(rz)$, $0<r<1$, is in $\mathscr{A}$ and discuss functions for which the limit $\lim_{r\to 1-0} u(rT)$ is well defined in the following sense.

DEFINITION 3.2. Let T be a contraction on X. H_T^∞ is the set of those functions $u\in H^\infty$ such that

$$u(T):=\lim_{r\to 1-0} u(rT)$$

exists in the strong operator topology.

Before we can describe a subset of H_T^∞, we must consider contractions in some detail. A subspace Y of a Hilbert space X is called reducing for $T\in\mathscr{L}(X)$ if T maps Y onto itself. A contraction T in $\mathscr{L}(X)$ is called completely nonunitary if there is no nonzero reducing subspace Y of X such that $T_{|Y}$ is unitary. To every contraction T on the space X there corresponds a decomposition $X=X_1\oplus X_2$ into an orthogonal sum of two subspaces X_1 and X_2 reducing T such that $T_1:=T_{|X_1}$ is unitary and $T_2:=T_{|X_2}$ is completely nonunitary. The canonical decomposition of T is denoted by $T=T_1\oplus T_2$. Recall that each unitary operator U has a spectral decomposition $U=\int_0^{2\pi} e^{it}\, dE_t$ for some spectral family $\{E_t\}_{0\leqq t\leqq 2\pi}$ and spectral measure E_U on the unit circle.

THEOREM 3.3. *H_T^∞ contains the functions $u \in H^\infty$ for which the set*

$$C_u = \{z \in \partial \mathbf{D} \mid u(z) \text{ has no nontangential limit at } z\}$$

has measure zero with respect to the spectral measure E_{T_1} corresponding to the unitary part T_1 of T.

Remark 3.4. Now we consider the functions φ_t, $t \geqq 0$, as defined in (b). We clearly have that $\varphi_t \in H^\infty$ and $C_{\varphi_t} \subseteq \{-1\}$. For a contraction T such that -1 is not an eigenvalue of T, -1 is also not an eigenvalue of the unitary part T_1 of T and hence $E_{T_1}(\{-1\}) = 0$, which shows that $\varphi_t \in H_T^\infty$, $t \geqq 0$.

We will not explore the properties of H_T^∞ in general, but consider the special case of the functions φ_t, $t \geqq 0$. These are of importance in connection with semigroup theory. Before we can state the next theorem establishing this role, we need to introduce some additional notation. Let A_c be the generator of a strongly continuous semigroup of contractions $(e^{tA_c})_{t \geqq 0}$; then

$$A_d = (I + A_c)(I - A_c)^{-1}$$

is called the cogenerator of the semigroup $(e^{tA_c})_{t \geqq 0}$ that can be shown to be a contraction such that -1 is not an eigenvalue of A_d. The generator A_c can be expressed by A_d as

$$A_c = (I + A_d)^{-1}(A_d - I).$$

The following theorem states that if given a contraction T such that -1 is not an eigenvalue of T, then $(\varphi_t(T))_{t \geqq 0}$ is a semigroup of contractions with generator $(I+T)^{-1}(T-I)$ and cogenerator T.

THEOREM 3.5. *Let T be a contraction on X. In order that there exists a strongly continuous semigroup of contractions $(T(t))_{t \geqq 0}$ whose cogenerator equals T, it is necessary and sufficient that -1 is not an eigenvalue of T. If this is the case, then $(T(t))_{t \geqq 0}$ is determined by*

$$T(t) = \varphi_t(T), \qquad t \geqq 0$$

with generator $A_c = (I+T)^{-1}(T-I)$.

Proof. The proof follows from Sz.-Nagy and Foias [17, p. 142], replacing T by $-T$. □

We will now consider unbounded functions in order to deal with ϕ, μ, and δ_t. If $T \in \mathcal{L}(X)$ is a contraction such that $-1 \notin \sigma_p(T)$, then it is easily checked that ϕ, μ, and δ_t, $t \geqq 0$ are in the set of functions N_T defined as follows.

DEFINITION 3.6. For a contraction T in $\mathcal{L}(X)$, denote by K_T^∞ the class of functions $v \in H_T^\infty$ for which $v(T)^{-1}$ exists and has dense domain. Let N_T be the class of functions w that admit a representation

$$w = \frac{u}{v}, \quad u \in H_T^\infty, \quad v \in K_T^\infty.$$

For $w \in N_T$, we define $w(T) = v(T)^{-1}u(T)$.

The following proposition states that for a certain subset of N_T we, in fact, have the commutativity property $w(T) = v(T)^{-1}u(T) = u(T)v(T)^{-1}$.

PROPOSITION 3.7. *Let u, v be continuous on $\bar{\mathbf{D}}$, analytic on $\mathbf{D}$ and have no common zeros in $\bar{\mathbf{D}}$. If $v \in K_T^\infty$ for a contraction T, then*

$$v(T)^{-1}u(T) = u(T)v(T)^{-1}.$$

Remark 3.8. Let T be a contraction T such that $-1 \notin \sigma_p(T)$; then, applying the previous proposition to ϕ, we obtain $(I-T)(I+T)^{-1} = (I+T)^{-1}(I-T)$.

The following theorem provides us with techniques to deal with functions in N_T.

THEOREM 3.9. (i) *Let T be a contraction in $\mathscr{L}(X)$ and let $w \in N_T$ be analytic on* $\mathbf{D}$. *If for $x \in X$ we have that*

$$\sup_{0<r<1} \|w(rT)x\| < \infty,$$

it follows that $x \in D(w(T))$ and

$$w(rT)x \to w(T)x$$

weakly as $r \to 1-0$.

(ii) *Suppose the functions u, v are continuous on $\bar{\mathbf{D}}$, analytic on $\mathbf{D}$, and have no common zeros in $\bar{\mathbf{D}}$. We assume that v has no zeros in $\mathbf{D}$ and that it does not vanish on $\partial\mathbf{D}$ except at points of measure zero with respect to the spectral measure E_{T_1} of the unitary part T_1 of T. Moreover, we assume that there exists a constant M such that $|v(\lambda)/v(r\lambda)| \leqq M$ for $\lambda \in \mathbf{D}$, $0<r<1$. Then $w = u/v$ belongs to the class N_T and is analytic in $\mathbf{D}$.*

The condition

$$\sup_{0<r<1} \|w(rT)x\| < \infty$$

characterizes the vectors in $D(w(T))$.

For each $x \in D(w(T))$,

$$w(rT)x \to w(T)x$$

strongly as $r \to 1-0$.

Having reviewed the functional calculus by Sz.-Nagy–Foias, we are now in a position to prove two results that will be a key to results in later sections. Whereas the first proposition deals with the function μ, the second proposition establishes properties of the function δ_t.

PROPOSITION 3.10. *Let T be a contraction on X such that -1 is not an eigenvalue of T. Then*

$$\lim_{\substack{\lambda \to 1 \\ \lambda > 1}} (\lambda I + T)^{-1}x = (I+T)^{-1}x,$$

for $x \in D((I+T)^{-1})$.

Moreover, $x \in D((I+T)^{-1})$ if and only if $\sup_{0<r<1} \|(I+rT)^{-1}x\| < \infty$.

Proof. Let $u = 1$ and $v = 1+z$, so v only vanishes at $z=-1$. Since -1 is not an eigenvalue of T we have that $E_{T_1}(\{-1\}) = 0$. Using $w := u/v$ and $r := 1/\lambda$, the result now follows from Theorem 3.9(ii). □

PROPOSITION 3.11. *Let T be a contraction on X such that -1 is not an eigenvalue of T. If $x \in D((I+T)^{-1})$, then for all $t \geqq 0$,*

(1) $\sup_{0<r<1} \|(I+rT)^{-1} e^{t(rT+I)^{-1}(rT-I)}x\| \leqq \sup_{0<r<1} \|(I+rT)^{-1}x\| < \infty$,

(2) $(I+rT)^{-1} e^{t(rT+I)^{-1}(rT-I)}x \to (I+T)^{-1} e^{t(T+I)^{-1}(T-I)}x$ *weakly as* $r \to 1-0$.

Proof. Write for $\delta_t(z) = 1/(1+z)\, e^{t((z-1)/(z+1))} = \mu(z)\varphi_t(z)$, with $\mu(z) = 1/(z+1)$ and $\varphi_t(z) = e^{t((z-1)/(z+1))}$, $t \geqq 0$. Then we have that $\delta_t \in N_T$, $t \geqq 0$, since $\mu^{-1} \in K_T^\infty$ and since $\varphi_t \in H_T^\infty$, $t \geqq 0$, by Remark 3.4.

As $\varphi_t(rz), \mu(rz) \in \mathscr{A}$, for $0<r<1$, $t \geqq 0$, we have that $\varphi_t(rT)\mu(rT) = \mu(rT)\varphi_t(rT)$. Also note that $\varphi_t(rT)$ is a contraction by Theorem 3.5. Hence we obtain for $t \geqq 0$ and

$x \in D(\mu(T)) = D((I+T)^{-1})$ that

$$\begin{aligned}\sup_{0<r<1} \|\delta_t(rT)x\| &= \sup_{0<r<1} \|\mu(rT)\varphi_t(rT)x\| = \sup_{0<r<1} \|\varphi_t(rT)\mu(rT)x\| \\ &\leqq \sup_{0<r<1} \|\varphi_t(rT)\| \, \|\mu(rT)x\| \leqq \sup_{0<r<1} \|(I+rT)^{-1}x\| \\ &< \infty\end{aligned}$$

where the last inequality follows from Proposition 3.10. The chain of inequalities shows (1).

Thus we have by Theorem 3.9(i) that $D((I+T)^{-1}) \subseteq D(\delta_t(T))$ and that for $x \in D((I+T)^{-1})$ we have,

$$\varphi_t(rT)x \to \varphi_t(T)x$$

weakly as $r \to 1-0$, which proves (2). □

4. A transformation between discrete- and continuous-time systems. We will now introduce a transformation T relating systems in $D_X^{U,Y}$ to systems in $C_X^{U,Y}$ and vice versa. This transformation, which is inspired by a bilinear transformation mapping the unit disk to the right-half plane, is often used for finite-dimensional systems to carry over results from discrete-time systems to continuous-time systems (see, e.g., Glover [5], Ober [11]. Hedberg [8] and Fuhrmann [4] used this approach to prove the existence of state-space realizations for continuous-time systems with transfer function in a certain class of H^∞ functions. The same idea is used here, the specific definitions are, however, somewhat different to avoid certain technical problems.

We first consider the map $T: D_X^{U,Y} \to C_X^{U,Y}$.

THEOREM 4.1. *Let* $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$; *then* $T((A_d, B_d, C_d, D_d)) := (A_c, B_c, C_c, D_c) \in C_X^{U,Y}$, *where*

(i) $A_c := (I+A_d)^{-1}(A_d - I) = (A_d - I)(I+A_d)^{-1}$, $D(A_c) := D((I+A_d)^{-1})$, *and* A_c *generates a strongly continuous semigroup of contractions on* X *given by* $\varphi_t(A_d)$, $t \geqq 0$, *with* $\varphi_t(z) = e^{t((z-1)/(z+1))}$.

(ii) $B_c := \sqrt{2}(I+A_d)^{-1}B_d : U \to D(A_c^*)'$,

$$u \mapsto \sqrt{2}(I+A_d)^{-1}B_d(u)[\,\cdot\,] := \sqrt{2}\langle B_d(u), (I+A_d^*)^{-1}(\,\cdot\,)\rangle_X.$$

(iii) $C_c : D(C_c) \to Y$, $\quad x \mapsto \lim\limits_{\substack{\lambda \to 1 \\ \lambda > 1}} \sqrt{2}\, C_d(\lambda I + A_d)^{-1}x$,

where $D(C_c) = D(A_c) + (I - A_c)^{-1}B_cU$. *On* $D(A_c)$ *we have,*

$$C_{c|D(A_c)} = \sqrt{2}\, C_d(I+A_d)^{-1}.$$

(iv) $D_c := D_d - \lim_{\lambda \to 1, \lambda > 1} C_d(\lambda I + A_d)^{-1}B_d$.

Moreover, let the admissible discrete-time system (A_d, B_d, C_d, D_d) *be a realization of the transfer function*

$$G_d(z) : \mathbb{C} \setminus \bar{\mathbf{D}} \to \mathscr{L}(U, Y),$$

i.e., $G_d(z) = C_d(zI - A_d)^{-1}B_d + D_d$ *for* $z \in \mathbb{C} \setminus \bar{\mathbf{D}}$.

Then, $(A_c, B_c, C_c, D_c) = T((A_d, B_d, C_d, D_d))$ *is an admissible continuous-time realization of the transfer function*

$$G_c(s) := G_d\left(\frac{1+s}{1-s}\right) : \mathrm{RHP} \to \mathscr{L}(U, Y).$$

Proof. We must check that conditions (i)-(vi) of Definition 2.4 are satisfied.

(i) This follows from Theorem 3.5. The fact that $A_c = (A_d - I)(I + A_d)^{-1} = (I + A_d)^{-1}(A_d - I)$ was shown in Remark 3.8.

(ii) Let $u \in U$, $x \in D(A^*)$. Then, since $\frac{1}{2}(I - A_c) = (I + A_d)^{-1}$,

$$\begin{aligned} |B_c(u)[x]| &= |\sqrt{2}\langle B_d(u), (I + A_d^*)^{-1}[x]\rangle_X| \\ &\leqq \frac{1}{\sqrt{2}} \|B_d(u)\|_X \|(I - A_c^*)x\|_X \\ &\leqq \|B_d\|_{\mathscr{L}(U,X)} \|u\|_U (\|x\|_X^2 + \|A_c^* x\|_X^2)^{1/2}. \end{aligned}$$

This implies that $B_c(u) \in D(A_c^*)^{(\prime)}$ and that $B_c: U \to D(A_c^*)^{(\prime)}$ is continuous.

(iii) We first note that, by Proposition 3.10, C_c is defined on $D(A_c) = D((I + A_d)^{-1})$, and that $C_{c|D(A_c)} = \sqrt{2}\, C_d(I + A_d)^{-1}$.

To show that $C_{c|D(A_c)}$ is continuous with respect $\|\cdot\|_{A_c}$, we see that for $x \in D(A_c)$, we have

$$\begin{aligned} \|C_c x\|_Y &= \frac{1}{\sqrt{2}} \|C_d(I - A_c)x\|_Y \\ &\leqq \|C_d\|_{\mathscr{L}(X,Y)} (\|x\|_X^2 + \|A_c x\|_X^2)^{1/2}. \end{aligned}$$

It remains to show that $\lim_{\lambda \to 1, \lambda > 1} C_d(\lambda I + A_d)^{-1} x$ exists for $x \in (I - A_c)^{-1} B_c U$. First note that $(I - A_c)^{-1} B_c = (1/\sqrt{2}) B_d$, for if $x \in D(A_c^*)$, $u \in U$, then

$$\begin{aligned} (I - A_c)^{-1} B_c(u)[x] &= B_c(u)[(I - A_c^*)^{-1} x] \\ &= \sqrt{2}\, \langle B_d(u), (I + A_d^*)^{-1}(I - A_c^*)^{-1} x\rangle \\ &= \frac{1}{\sqrt{2}} \langle B_d(u), x\rangle \end{aligned}$$

where we have used the identity $(I - A_c^*)^{-1} = \frac{1}{2}(I + A_d^*)$. Now we see that

$$\lim_{\substack{\lambda \to 1 \\ \lambda > 1}} \sqrt{2}\, C_d(\lambda I + A_d)^{-1}(I - A_c)^{-1} B_c u = \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} C_d(\lambda I + A_d)^{-1} B_d u$$

exists by the admissibility of (A_d, B_d, C_d, D_d).

(iv) We must show that $C_c(I - A_c)^{-1} B_c \in \mathscr{L}(U, Y)$. But by the proof of (iii), we know that $(I - A_c)^{-1} B_c = (1/\sqrt{2}) B_d$, and hence that

$$C_c(I - A_c)^{-1} B_c = \frac{1}{\sqrt{2}} C_c B_d = \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} C_d(\lambda I + A_d)^{-1} B_d \in \mathscr{L}(U, Y)$$

by the admissibility of (A_d, B_d, C_d, D_d).

(v) This will be shown after the remaining parts of the theorem have been proved.

(vi) The boundedness of D_c follows since $D_d \in \mathscr{L}(U, Y)$ and $\lim_{\lambda \to 1, \lambda > 1} C_d(\lambda I + A_d)^{-1} B_d \in \mathscr{L}(U, Y)$.

We will now prove the statements on the transformation of transfer functions. We have for $s \in \mathrm{RHP}$ that $(1 + s)/(1 - s) \in \mathbb{C} \setminus \bar{\mathbf{D}}$ and hence,

$$\begin{aligned} G_c(s) = G_d\left(\frac{1+s}{1-s}\right) &= C_d\left(\left(\frac{1+s}{1-s}\right) I - A_d\right)^{-1} + D_d \\ &= (1 - s) C_d((I - A_d) + s(I + A_d))^{-1} B_d + D_d \\ &= (1 - s) C_d(I + A_d)^{-1}(sI - (A_d - I)(I + A_d)^{-1})^{-1} B_d + D_d. \end{aligned}$$

The last identity is well defined, since

$$(sI-(A_d-I)(I+A_d)^{-1})^{-1}B_dU=(sI-A_c)^{-1}B_dU\subseteq D(A_c)=D((I+A_d)^{-1}).$$

Hence, $G_c(s)=(1-s)(1/\sqrt{2})C_c(sI-A_c)^{-1}B_d+D_d$.

Now if we extend the range of $(sI-A_c)^{-1}B_d$ to $D(A_c^*)^{(\prime)}$, then we can show that $(sI-A_c)^{-1}B_d=\sqrt{2}/(1-s)(sI-A_c)^{-1}B_c-1/(1-s)B_d$. For if $x\in D(A_c^*)$, then we have, using the resolvent identity, that

$$\begin{aligned}
&\langle (sI-A_c)^{-1}B_d(u),x\rangle_X\\
&\quad=\langle B_d(u),(I-A_c^*)(I-A_c^*)^{-1}(\bar{s}I-A_c^*)^{-1}x\rangle_X\\
&\quad=\left\langle B_d(u),(I-A_c^*)\frac{1}{(1-\bar{s})}[(\bar{s}I-A_c^*)^{-1}-(I-A_c^*)^{-1})]x\right\rangle_X\\
&\quad=\frac{1}{1-s}(\langle B_d(u),(I-A_c^*)(\bar{s}I-A_c^*)^{-1}x\rangle_X-\langle B_d(u),x\rangle_X)\\
&\quad=\frac{\sqrt{2}}{1-s}[(sI-A_c)^{-1}B_c(u)](x)-\frac{1}{1-s}\langle B_d(u),x\rangle_X.
\end{aligned}$$

But we know that $B_dU\subseteq D(C_c)$ and $(sI-A_c)^{-1}B_cU\subseteq D(C_c)$ for $s\in$ RHP. Hence

$$\begin{aligned}
G_c(s)&=(1-s)\frac{1}{\sqrt{2}}C_c(sI-A_c)^{-1}B_d+D_d\\
&=C_c(sI-A_c)^{-1}B_c-\frac{1}{\sqrt{2}}C_cB_d+D_d\\
&=C_c(sI-A_c)^{-1}B_c-\lim_{\substack{\lambda\to 1\\ \lambda>1}}C_d(\lambda I+A_d)^{-1}B_d+D_d\\
&=C_c(sI-A_c)^{-1}B_c+D_c,
\end{aligned}$$

and so (A_c, B_c, C_c, D_c) is a state-space realization of $G_c(s)$.

To finish the proof, it remains to show (v) of Definition 2.4. By the admissibility of (A_d, B_d, C_d, D_d) we obtain

$$\begin{aligned}
\lim_{\substack{s\in\mathbb{R}\\ s\to\infty}}C_c(sI-A_c)^{-1}B_c&=\lim_{\substack{s\in\mathbb{R}\\ s\to\infty}}G_c(s)-D_c\\
&=\lim_{\substack{s\in\mathbb{R}\\ s\to\infty}}C_d\left(\left(\frac{1+s}{1-s}\right)I-A_d\right)^{-1}B_d+D_d-D_c\\
&=-\lim_{\substack{\lambda\to 1\\ \lambda>1}}C_d(\lambda I+A_d)^{-1}B_d+D_d-D_c\\
&=0,
\end{aligned}$$

which completes the proof. □

Before we consider the map $T^{-1}: C_X^{U,Y}\to D_X^{U,Y}$ we need the following lemma, which gives a version of the resolvent identity for not necessarily bounded resolvents.

LEMMA 4.2. *Let $A_d: X\to X$ be a contraction such that $-1\notin\sigma_p(A_d)$. Then for $z\in\mathbb{C}$, such that $|z|>1$ and for $x\in D((I+A_d^*)^{-1})$, we have*

$$(\bar{z}+1)(I+A_d^*)^{-1}(\bar{z}I-A_d^*)^{-1}x=(I+A_d^*)^{-1}x+(\bar{z}I-A_d^*)^{-1}x.$$

Proof. We first must show that if $x \in D((I+A_d^*)^{-1})$, then $(\bar{z}I - A_d^*)^{-1}x \in D((I+A_d^*)^{-1})$. We know by Theorem 4.1 that $A_c = (I+A_d)^{-1}(A_d - I)$ is the generator of a strongly continuous semigroup of contractions, such that $D(A_c^*) = D((I+A_d^*)^{-1})$.

Since $|z| > 1$, we have that $s = (z-1)/(z+1) \in \text{RHP}$. Hence $(\bar{s}I - A_c^*)^{-1}$ is bounded. But

$$(\bar{s}I - A_c^*)^{-1} = (\bar{z}+1)(\bar{z}(I - A_c^*) - (I + A_c^*))^{-1} = (\bar{z}+1)(\bar{z}I - A_d^*)^{-1}(I - A_c^*)^{-1}.$$

Thus $(\bar{s}I - A_c^*)^{-1}(I - A_c^*) = (\bar{z}+1)(\bar{z}I - A_d^*)^{-1}$ and hence, since $(\bar{s}I - A_c^*)^{-1}X \subseteq D(A_c^*)$ by Lemma 2.6, we have that

$$\begin{aligned}(\bar{z}+1)(\bar{z}I - A_d^*)^{-1}D(A_c^*) &= (\bar{s}I - A_c^*)^{-1}(I - A_c^*)D(A_c^*) \\ &\subseteq (\bar{s}I - A_c^*)^{-1}X \subseteq D(A_c^*) = D((I+A_d^*)^{-1}),\end{aligned}$$

which shows the claim.

To prove the statement of the lemma, let $y := (\bar{z}I - A_d^*)^{-1}x \in D((I+A_d^*)^{-1})$. Then,

$$(\bar{z}+1)y = (\bar{z}I - A_d^*)y + (I + A_d^*)y.$$

Since $y \in D((I+A_d^*)^{-1})$, we can apply $(I+A_d^*)^{-1}$ from the left to obtain

$$(\bar{z}+1)(I+A_d^*)^{-1}y = (I+A_d^*)^{-1}(\bar{z}I - A_d^*)y + y,$$

and hence $(\bar{z}+1)(I+A_d^*)^{-1}(\bar{z}I - A_d^*)^{-1}x = (I+A_d^*)^{-1}x + (\bar{z}I - A_d^*)^{-1}x$. □

THEOREM 4.3. *Let* $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$; *then* $T^{-1}((A_c, B_c, C_c, D_c)) := (A_d, B_d, C_d, D_d) \in D_X^{U,Y}$, *where*

(i) $A_d := (I+A_c)(I-A_c)^{-1}$, *and for* $x \in D(A_c)$ *we have that* $A_d x = (I-A_c)^{-1}(I+A_c)x$.

(ii) $B_d := \sqrt{2}(I-A_c)^{-1}B_c$.

(iii) $C_d := \sqrt{2}\, C_c(I-A_c)^{-1}$.

(iv) $D_d := C_c(I-A_c)^{-1}B_c + D_c$.

Moreover, let the admissible continuous-time system (A_c, B_c, C_c, D_c) *be a realization of the transfer function*

$$G_c(s) : \text{RHP} \to \mathscr{L}(U, Y),$$

i.e., $G_c(s) = C_c(sI - A_c)^{-1}B_c + D_c$ *for* $s \in \text{RHP}$.

Then, $(A_d, B_d, C_d, D_d) = T^{-1}((A_c, B_c, C_c, D_c))$ *is an admissible discrete-time realization of the transfer function*

$$G_d(z) := G_c\left(\frac{z-1}{z+1}\right) : \mathbb{C} \setminus \bar{\mathbf{D}} \to \mathscr{L}(\mathbf{U}, \mathbf{Y}).$$

Proof. We must show that (A_d, B_d, C_d, D_d) satisfies conditions (i)-(v) of Definition 2.1.

(i) Let $x \in X$ and define $y = (I-A_c)^{-1}x \in D(A_c)$; then

$$\begin{aligned}\|A_d x\|^2 = \|(I+A_c)y\|^2 &= \langle y, y\rangle + \langle A_c y, A_c y\rangle + 2\,\text{Re}\,\langle A_c y, y\rangle \\ &= \langle (I-A_c)y, (I-A_c)y\rangle + 4\,\text{Re}\,\langle A_c y, y\rangle = \|x\|^2 + 4\,\text{Re}\,\langle A_c y, y\rangle \\ &\leqq \|x\|^2\end{aligned}$$

since $\text{Re}\,\langle A_c y, y\rangle \leqq 0$ as A_c is dissipative, being the generator of a strongly continuous semigroup of contractions. This shows that A_d is a contraction.

It is easily verified that $(I+A_c)(I-A_c)^{-1}x=(I-A_c)^{-1}(I+A_c)x$, $x\in D(A_c)$, as claimed in the theorem and that $-1\notin\sigma_p(A_d)$.

(ii) This follows in a straightforward way from Lemma 2.6.

(iii) Since

$$C_{c|D(A_c)}:(D(A_c),\|\cdot\|_{A_c})\to Y$$

and

$$(I-A_c)^{-1}:(X,\|\cdot\|_X)\to(D(A_c),\|\cdot\|_{A_c})$$

are continuous, we have that

$$C_d=\sqrt{2}\,C_c(I-A_c)^{-1}:(X,\|\cdot\|_X)\to Y$$

is continuous.

(iv) Since by assumption $C_c(I-A_c)^{-1}B_c\in\mathscr{L}(U,Y)$ and $D_c\in\mathscr{L}(U,Y)$, we have that $D_d\in\mathscr{L}(U,Y)$.

(v) Before we prove (v) we first show the last statement of the theorem.

Let $z\in\mathbb{C}$, such that $|z|>1$; then $s=(z-1)/(z+1)\in$ RHP. By definition

$$G_d(z)=C_c\left(\frac{z-1}{z+1}I-A_c\right)^{-1}B_c+D_c.$$

Consider $((z-1)/(z+1)I-A_c)^{-1}B_c$. Let $u\in U$, $x\in D(A_c^*)$; then

$$\begin{aligned}\left(\frac{z-1}{z+1}I-A_c\right)^{-1}B_c(u)[x]&=B_c(u)\left[\left(\frac{\bar z-1}{\bar z+1}I-A_c^*\right)^{-1}x\right]\\&=(z+1)B_c(u)[(\bar z(I-A_c^*)-(I+A_c^*))^{-1}x]\\&=(z+1)B_c(u)[(\bar zI-A_d^*)^{-1}(I-A_c^*)^{-1}x].\end{aligned}$$

But using the fact that $(I-A_c^*)=2(I+A_d^*)^{-1}$ we obtain,

$$\begin{aligned}B_c(u)[x]&=\langle(I-A_c)^{-1}B_c(u),(I-A_c^*)x\rangle\\&=\sqrt{2}\langle B_d(u),(I-A_d^*)^{-1}x\rangle.\end{aligned}$$

Hence

$$\begin{aligned}&\left(\frac{z-1}{z+1}I-A_c\right)^{-1}B_c(u)[x]\\&\quad=(z+1)B_c(u)[(\bar zI-A_d^*)^{-1}(I-A_c^*)^{-1}x]\\&\quad=\sqrt{2}(z+1)\langle B_d(u),(I+A_d^*)^{-1}(\bar zI-A_d^*)^{-1}(I-A_c^*)^{-1}x\rangle\\&\quad=\sqrt{2}\langle B_d(u),(\bar zI-A_d^*)^{-1}(I-A_c^*)^{-1}x\rangle\\&\qquad+\sqrt{2}\langle B_d(u),(I+A_d^*)^{-1}(I-A_c^*)^{-1}x\rangle\\&\quad=\sqrt{2}\langle B_d(u),(\bar zI-A_d^*)^{-1}(I-A_c^*)^{-1}x\rangle+\frac{1}{\sqrt{2}}\langle B_d(u),x\rangle\end{aligned}$$

where the second but last equation uses Lemma 4.2, noting that $(I-A_c^*)^{-1}x\in D(A_c^*)=D((I+A_d^*)^{-1})$. Thus

$$\left(\frac{z-1}{z+1}I-A_c\right)^{-1}B_c(u)=\sqrt{2}(I-A_c)^{-1}(zI-A_d)^{-1}B_d(u)+\frac{1}{\sqrt{2}}B_d(u)\in X.$$

Note that by Lemma 2.6 $(I-A_c)^{-1}X \subseteq D(A_c) \subseteq D(C_c)$ and hence

$$\sqrt{2}(I-A_c)^{-1}(zI-A_d)^{-1}B_dU \subseteq D(C_c).$$

Since $B_dU \subset D(C_c)$ we can apply C_c, and we obtain

$$\begin{aligned} C_c\left(\frac{z-1}{z+1}I-A_c\right)^{-1}B_c+D_c &= \sqrt{2}\,C_c(I-A_c)^{-1}(zI-A_d)^{-1}B_d+\frac{1}{\sqrt{2}}C_cB_d+D_c \\ &= C_d(zI-A_d)^{-1}B_d+C_c(I-A_c)^{-1}B_c+D_c \\ &= C_d(zI-A_d)^{-1}B_d+D_d. \end{aligned}$$

Thus (A_d, B_d, C_d, D_d) is a realization of $G_d(z)$.

We are now in a position to prove (v) of Definition 2.1, i.e., that $\lim_{\lambda>1,\lambda\to 1} C_d(\lambda I+A_d)^{-1}B_d$ exists in the norm topology. By the admissibility of (A_c, B_c, C_c, D_c), we have that

$$\begin{aligned} \lim_{\substack{\lambda\to 1\\ \lambda>1}} C_d(\lambda I+A_d)^{-1}B_d &= -\lim_{\substack{\mu<-1\\ \mu\to -1}} G_d(\mu)+D_d = -\lim_{\substack{\mu<-1\\ \mu\to -1}} G_c\left(\frac{\mu-1}{\mu+1}\right)+D_d \\ &= C_c(I-A_c)^{-1}B_c, \end{aligned}$$

which implies the result. □

Combining the previous two theorems, we can show the following corollary, whose proof is straightforward.

COROLLARY 4.4. *The map* $T: D_X^{U,Y} \to C_X^{U,Y}$ *is a bijection with inverse* $T^{-1}: C_X^{U,Y} \to D_X^{U,Y}$.

Remark 4.5. The following identities that have been used in the above proofs are worthwhile noting for later use:

$$\tfrac{1}{2}(I-A_c)=(I+A_d)^{-1} \quad \text{and} \quad (I-A_c)^{-1}=\tfrac{1}{2}(I+A_d).$$

5. Unitary state-space transformations. In this section we will discuss briefly the effect of a unitary transformation $V: X_1 \to X_2$ of the state space on state-space systems. This discussion will be important in § 8 where we will show that a (par-) balanced realization is unique up to a unitary state-space transformation. The first two propositions show that such an operation is well defined and does not change the transfer function. The last result shows that unitarily equivalent systems are carried over by the map $T: D_X^{U,Y} \to C_X^{U,Y}$ and its inverse.

We first consider unitary state-space transformations for admissible discrete-time systems.

PROPOSITION 5.1. *Let* $(A_d, B_d, C_d, D_d) \in D_{X_1}^{U,Y}$. *If* X_2 *is another Hilbert space and* $V: X_1 \to X_2$ *is a unitary operator, then*

(1) $(VA_dV^*, VB_d, C_dV^*, D_d) \in D_{X_2}^{U,Y}$.

(2) If (A_d, B_d, C_d, D_d) *is a state space realization of the transfer function*

$$G_d(s): \mathbb{C}\backslash\bar{\mathbf{D}} \to L(U, Y),$$

then the $(VA_dV^*, VB_d, C_dV^*, D_d)$ *is a state-space realization of the same transfer function.*

Proof. The proof is straightforward. □

The following proposition, whose proof is straightforward, gives the analogous result for continuous-time systems.

PROPOSITION 5.2. *Let* $((A_c, D(A_c)), B_c, C_c, D_c) \in C_{X_1}^{U,Y}$. *If* X_2 *is another Hilbert space and* $V: X_1 \to X_2$ *is a unitary operator, then*

(1) $((VA_cV^*, VD(A_c)), VB_c, (C_cV^*, VD(C_c)), D_c) \in C_{X_2}^{U,Y}$, *where*

$$(VB_c): U \to ((VD(A_c^*))^{(\prime)}, \|\cdot\|')$$

is given by

$$(VB_c)(u)[x] := B_c(u)[V^*x]$$

$u \in U$, $x \in VD(A_c^*)$.

(2) *If* (A_c, B_c, C_c, D_c) *is a state-space realization of the transfer function*

$$G_c(s): \mathrm{RHP} \to L(U, Y),$$

then $(VA_cV^*, VB_c, C_cV^*, D_c)$ *realizes the same transfer function.*

The following definition introduces the standard notation of unitary equivalence of state-space systems. Note that by the previous two propositions, unitarily equivalent systems have the same transfer function.

DEFINITION 5.3. Two systems $(A_c^i, B_c^i, C_c^i, D_c^i) \in C_{X_i}^{U,Y}$, $i = 1, 2$, are called unitarily equivalent, if there exists a unitary operator $V: X_1 \to X_2$ such that

$$(A_c^2, B_c^2, C_c^2, D_c^2) = (VA_c^1V^*, VB_c^1, C_c^1V^*, D_c^1).$$

An equivalent definition applies to admissible discrete-time systems.

We will now show that the transformation $T: D_X^{U,Y} \to C_X^{U,Y}$ and its inverse preserve the unitary equivalence of systems.

PROPOSITION 5.4. *Let* $(A_d^i, B_d^i, C_d^i, D_d^i) \in D_{X_i}^{U,Y}$, $i = 1, 2$. *Let* $(A_c^i, B_c^i, C_c^i, D_c^i) = T((A_d^i, B_d^i, C_d^i, D_d^i))$, $i = 1, 2$, *be the associated continuous-time systems.*

Then, $(A_c^1, B_c^1, C_c^1, D_c^1)$ *and* $(A_c^2, B_c^2, C_c^2, D_c^2)$ *are unitarily equivalent if and only if* $(A_d^1, B_d^1, C_d^1, D_d^1)$ *and* $(A_d^2, B_d^2, C_d^2, D_d^2)$ *are unitarily equivalent.*

Proof. Assume $(A_d^1, B_d^1, C_d^1, D_d^1)$ and $(A_d^2, B_d^2, C_d^2, D_d^2)$ are unitarily equivalent, i.e., there exists a unitary operator $V: X_1 \to X_2$ such that $(A_d^2, B_d^2, C_d^2, D_d^2) = (VA_d^1V^*, VB_d^1, C_d^1V^*, D_d^1)$.

Since $A_d^2 = VA_d^1V^*$ we have

$$A_c^2 = (I + A_d^2)^{-1}(A_d^2 - I) = (I + VA_d^1V^*)^{-1}(VA_d^1V^* - I) = VA_c^1V^*$$

with $D(A_c^2) = VD(A_c^1)$.

Let $u \in U$, $x_2 \in D((A_c^2)^*)$; then

$$B_c^2(u)[x_2] = \sqrt{2}\langle B_d^2(u), (I + (A_d^2)^*)^{-1}x_2\rangle = \sqrt{2}\langle B_d^1(u), (I + (A_d^1)^*)^{-1}V^*x_2\rangle$$

$$= B_c^1(u)[V^*x_2] = [VB_c^1](u)[x_2]$$

and hence $B_c^2 = VB_c^1$.

$C_c^2 = C_c^1V^*$ since for $x \in D(C_c^2)$, we have

$$C_c^2x = \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} \sqrt{2}\, C_d^2(\lambda I + A_d^2)^{-1}x = \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} \sqrt{2}\, C_d^1(\lambda I + A_d^1)^{-1}V^*x = C_c^1V^*x.$$

The fact that $D_c^1 = D_c^2$ follows, since two unitarily equivalent systems have the same transfer function and thus

$$D_c^2 = D_d^2 - \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} C_d^2(\lambda I + A_d^2)^{-1}B_d^2 = D_d^1 - \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} C_d^1(\lambda I + A_d^1)^{-1}B_d^1 = D_c^1.$$

The converse follows similarly. □

6. Dual systems. If (A, B, C, D) is a finite-dimensional linear system, then (A^T, C^T, B^T, D^T) is called the dual system of (A, B, C, D). It is well known that properties of a system are closely related to those of its dual systems. To examine the reachability operator of an infinite-dimensional system via the observability operator of its dual system, we will now define what we mean by the dual system of an admissible system.

We first consider discrete-time systems.

DEFINITION 6.1. Let $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$; then the dual system $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$ of (A_d, B_d, C_d, D_d) is given by

$$\tilde{A}_d := A_d^* : X \to X, \qquad \tilde{B}_c := C_d^* : Y \to X,$$
$$\tilde{C}_d := B_d^* : X \to U, \qquad \tilde{D}_d := D_d^* : Y \to U.$$

The following lemma shows that the dual system of an admissible system is admissible and shows how the transfer function of a system is related to the transfer function of its dual system.

LEMMA 6.2. *The dual system $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$ of an admissible discrete-time system (A_d, B_d, C_d, D_d) in $D_X^{U,Y}$ is an admissible system in $D_X^{Y,U}$.*

If the discrete-time transfer function $G(s): \mathbb{C}\backslash\bar{\mathbf{D}} \to \mathscr{L}(U, Y)$ has an admissible realization (A_d, B_d, C_d, D_d), then the dual system $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$ is a realization of the transfer function $\tilde{G}(s): \mathbb{C}\backslash\bar{\mathbf{D}} \to \mathscr{L}(Y, U)$, $s \mapsto \tilde{G}(s) := (G(\bar{s}))^*$, i.e., for all $s \in \mathbb{C}\backslash\bar{\mathbf{D}}$,

$$\tilde{G}(s) = (G(\bar{s}))^* = \tilde{C}_d(sI - \tilde{A}_d)^{-1}\tilde{B}_d + \tilde{D}_d.$$

Proof. We must check (i)-(v) in Definition 2.1. To show (i) note that since $\|A_d^*\| = \|A_d\|$, we have that A_d^* is a contraction. Thus we only have to show that $-1 \notin \sigma_p(A_d^*)$. Assume there exists $x \in X$ such that $A_d^* x = -x$; then

$$0 \leqq \|A_d x + x\|^2 = \|A_d x\|^2 + 2\,\mathrm{Re}\,\langle x, A_d^* x\rangle + \|x\|^2$$
$$= \|A_d x\|^2 - 2\|x\|^2 + \|x\|^2 = \|A_d x\| - \|x\|^2 \leqq 0.$$

Thus $\|A_d x + x\|^2 = 0$ and hence $A_c x = -x$, which is a contraction to $-1 \notin \sigma_p(A_d)$.

The remaining parts of the lemma are straightforward to check. □

Next, we are going to define the dual system of an admissible continuous-time system.

DEFINITION 6.3. Let $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$. Then the dual system $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ of (A_c, B_c, C_c, D_c) is given by

$(\tilde{A}_c, D(\tilde{A}_c)) = (A_c^*, D(A_c^*))$, the adjoint operator of $(A_c, D(A_c))$;

$\tilde{B}_c : Y \to D(A_c)^{(\prime)}$, $y \mapsto \tilde{B}_c(y)[\,\cdot\,] := \langle y, C_c(\,\cdot\,)\rangle$;

$\tilde{C}_c : D(\tilde{C}_c) \to U$, $D(\tilde{C}_c) = D(\tilde{A}_c) + (I - \tilde{A}_c)^{-1}\tilde{B}_c Y$, where $\tilde{C}_0 x_0$ is defined by

$$\langle u\tilde{C}_c x_0\rangle = B_c(u)[x_0], \quad \text{for } x_0 \in D(A_c^*),\ u \in U,$$

and by

$$\langle \tilde{C}_c x_0 u\rangle = \langle y_0, C_c(I - A_c)^{-1}B_c u\rangle, \quad \text{for } x_0 = (I - \tilde{A}_c)^{-1}\tilde{B}_c y_0,\ y_0 \in Y,\ u \in U;$$

$\tilde{D}_c := D_c^* : Y \to U$.

The following lemma is the continuous-time equivalent of Lemma 6.2.

LEMMA 6.4. *The dual system $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ of an admissible continuous-time system (A_c, B_c, C_c, D_c) is admissible.*

If the continuous-time transfer function $G(s): \mathrm{RHP} \to \mathscr{L}(U, Y)$ has an admissible realization (A_c, B_c, C_c, D_c), then the dual system $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ is a realization of the transfer function $\tilde{G}(s) := (G(\bar{s}))^*$, i.e., for all $s \in \mathrm{RHP}$,

$$\tilde{G}(s) = (G(\bar{s}))^* = \tilde{C}_c(sI - \tilde{A}_c)^{-1}\tilde{B}_c + \tilde{D}_c.$$

Proof. We must show (i)-(vi) of Definition 2.4. Of these, (i)-(iv) and (vi) are straightforward.

Before we show (v) of Definition 2.4 we show the last statement of the lemma. Let $u \in U$, $y \in Y$, and consider for $G(s) = C_c(sI - A_c)^{-1}B_c + D_c$,

$$\langle y, G(s)u\rangle = \langle y, (C_c(sI - A_c)^{-1}B_c + D_c)u\rangle.$$

Using the resolvent identity we have that

$$\begin{aligned}&\langle y, G(s)u\rangle\\ &\quad = \langle y, C_c(I - A_c)^{-1}B_c u\rangle + \langle y, D_c u\rangle + (1 - \bar{s})\langle y, C_c(I - A_c)^{-1}(sI - A_c)^{-1}B_c u\rangle\\ &\quad = \langle \tilde{C}_c(I - \tilde{A}_c)^{-1}\tilde{B}_c y, u\rangle + \langle \tilde{D}_c y, u\rangle + (1 - \bar{s})\langle y, C_c(I - A_c)^{-1}(sI - A_c)^{-1}B_c u\rangle.\end{aligned}$$

Note that for $x \in X$ we have

$$\langle y, C_c(I - A_c)^{-1}x\rangle = \tilde{B}_c(y)[(I - A_c)^{-1}x] = \langle (I - A_c^*)^{-1}\tilde{B}_c y, x\rangle.$$

Using this identity, we now obtain that

$$\begin{aligned}\langle y, C_c(I - A_c)^{-1}(sI - A_c)^{-1}B_c u\rangle &= \langle (I - A_c^*)^{-1}\tilde{B}_c y, (sI - A_c)^{-1}B_c u\rangle\\ &= \overline{\langle (sI - A_c)^{-1}B_c u, (I - A_c^*)^{-1}\tilde{B}_c y\rangle}\\ &= \overline{B_c(u)[(\bar{s}I - A_c^*)^{-1}(I - A_c^*)^{-1}\tilde{B}_c y]}\\ &= \overline{\langle u, \tilde{C}_c(\bar{s}I - A_c^*)^{-1}(I - A_c^*)^{-1}\tilde{B}_c y\rangle}\\ &= \langle \tilde{C}_c(\bar{s}I - \tilde{A}_c)^{-1}(I - \tilde{A}_c)^{-1}\tilde{B}_c y, u\rangle.\end{aligned}$$

Summarizing and again applying the resolvent identity, we have

$$\begin{aligned}&\langle y, G(s)u\rangle\\ &\quad = \langle \tilde{C}_c(I - \tilde{A}_c)^{-1}\tilde{B}_c y, u\rangle + \langle \tilde{D}_c y, u\rangle + (1 - \bar{s})\langle \tilde{C}_c(\bar{s}I - \tilde{A}_c)^{-1}(I - \tilde{A}_c)^{-1}\tilde{B}_c y, u\rangle\\ &\quad = \langle (\tilde{C}_c(\bar{s}I - \tilde{A}_c)^{-1}\tilde{B}_c + \tilde{D}_c)y, u\rangle\\ &\quad = \langle (G(s))^* y, u\rangle.\end{aligned}$$

Hence $(G(\bar{s}))^* = \tilde{C}_c(sI - \tilde{A}_c)^{-1}\tilde{B}_c + \tilde{D}_c$ for all $s \in \mathrm{RHP}$. Now (v) of Definition 2.4 follows, since

$$\lim_{\substack{s\in\mathbb{R}\\ s\to\infty}} \tilde{C}_c(sI - \tilde{A}_c)^{-1}\tilde{B}_c = \lim_{\substack{s\in\mathbb{R}\\ s\to\infty}} (C_c(sI - A_c)^{-1}B_c)^* = \left(\lim_{\substack{s\in\mathbb{R}\\ s\to\infty}} C_c(sI - A_c)^{-1}B_c\right)^* = 0. \qquad \square$$

We will now show that the notion of duality of two systems is carried over between discrete- and continuous-time systems by the transformation T.

PROPOSITION 6.5. *Let* $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$ *and define* $(A_c, B_c, C_c, D_c) := T((A_d, B_d, C_d, D_d))$. *Let* $(A_d^1, B_d^1, C_d^1, D_d^1) \in D_X^{U,Y}$ *be another discrete-time system and let* $(A_c^1, B_c^1, C_c^1, D_c^1) := T((A_d^1, B_d^1, C_d^1, D_d^1))$ *be its corresponding admissible continuous-time system. Then,*

$$(A_d^1, B_d^1, C_d^1, D_d^1) \text{ is the dual system of } (A_d, B_d, C_d, D_d)$$

if and only if

$$(A_c^1, B_c^1, C_c^1, D_c^1) \text{ is the dual system of } (A_c, B_c, C_c, D_c).$$

Proof. Assume $(A_d^1, B_d^1, C_d^1, D_d^1)$ is the dual system of (A_d, B_d, C_d, D_d). Let $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ be the dual system of (A_c, B_c, C_c, D_c). Then $A_d^1 = \tilde{A}_d = A_d^*$ implies that

$$A_c^1 = (I + A_d^1)^{-1}(A_d^1 - I) = ((A_d - I)(I + A_d)^{-1})^* = A_c^* = \tilde{A}_c.$$

For a justification of the operations with the adjoints, see Weidmann [18, p. 74]. The identity $B_d^1 = \tilde{B}_d = C_d^*$ implies for $y \in Y$, $x \in D(A_c)$, that

$$\begin{aligned} B_c^1(y)[x] &= \sqrt{2}\langle B_d^1 y, (I + (A_d^1)^*)^{-1} x\rangle \\ &= \sqrt{2}\langle y, C_d(I + A_d)^{-1} x\rangle \\ &= \langle y, C_c x\rangle \\ &= \tilde{B}_c(y)[x] \end{aligned}$$

and hence $B_c^1 = \tilde{B}_c$.

To show that $C_c^1 = \tilde{C}_c$, we must consider two cases.

(i) For $x \in D(A_c^1)$ we have $C_c^1 x = \tilde{C}_c x$, since for $u \in U$,

$$\begin{aligned} \langle u, C_c^1 x\rangle &= \sqrt{2}\langle u, C_d^1(I + A_d^1)^{-1} x\rangle = \sqrt{2}\langle B_d u, (I + A_d^*)^{-1} x\rangle \\ &= B_c(u)[x] = \langle u, \tilde{C}_c x\rangle. \end{aligned}$$

(ii) Note that for $y_0 \in Y$, $x_0 := (I - A_c^1)^{-1} B_c^1 y_0 = (I - \tilde{A}_c)^{-1} \tilde{B}_c y_0$, since for $x \in D(A_c)$, we have

$$\begin{aligned} &(I - A_c^1)^{-1} B_c^1(y_0)[x] \\ &= \langle (I - A_c^1)^{-1} B_c^1(y_0), x\rangle = \frac{1}{\sqrt{2}}\langle B_d^1 y_0, x\rangle = \frac{1}{\sqrt{2}}\langle y_0, C_d x\rangle \\ &= \langle y_0, C_c(I - A_c)^{-1} x\rangle = \tilde{B}_c(y_0)[(I - A_c)^{-1} x] \\ &= (I - \tilde{A}_c)^{-1} \tilde{B}_c(y_0)[x]. \end{aligned}$$

Then for $u \in U$,

$$\begin{aligned} \langle C_c^1 x_0, u\rangle &= \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} \langle C_d^1(\lambda I + A_d^1)^{-1} B_d^1 y_0, u\rangle = \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} \langle y_0, C_d(\lambda I + A_d)^{-1} B_d u\rangle \\ &= \langle y_0, C_c(I - A_c)^{-1} B_c u\rangle = \langle \tilde{C}_c x_1, u\rangle \\ &= \langle \tilde{C}_c x_0, u\rangle \end{aligned}$$

where the last equality follows since $x_1 := (I - \tilde{A}_c)^{-1} \tilde{B}_c y_0 = x_0$ and hence $C_c^1 = \tilde{C}_c$.

Since $D_d^1 = \tilde{D}_d = \tilde{D}_d^*$, we have that

$$D_c^1 = D_d^1 - \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} C_d^1(\lambda I + A_d^1)^{-1} B_d^1 = D_d^* - \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} B_d^*(\lambda I + A_d^*)^{-1} C_d^* = D_c^* = \tilde{D}_c.$$

Hence we have that $(A_c^1, B_c^1, C_c^1, D_c^1)$ is the dual system of (A_c, B_c, C_c, D_c).

To show the converse, assume that $(A_c^1, B_c^1, C_c^1, D_c^1)$ is the dual system of (A_c, B_c, C_c, D_c) and let $(\tilde{A}_c, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$ be the dual system of (A_d, B_d, C_d, D_d).

Then

$$A_d^1 = (I + A_c^1)(I - A_c^1)^{-1} = (I + A_c^*)(I - A_c^*)^{-1} = A_d^* = \tilde{A}_d$$

where we apply Theorem 4.19 of Weidmann [18] to justify the manipulations with the adjoints.

The fact that $B_d^1 = \tilde{B}_d$ follows from the following identities, where $y \in Y$, $x \in D(A_c)$,

$$\begin{aligned} \langle B_d^1 y, x\rangle &= \sqrt{2}\langle (I - A_c^1)^{-1} B_c^1 y, x\rangle = \sqrt{2}\, B_c^1(y)[(I - (A_c^1)^*)^{-1} x] \\ &= \sqrt{2}\, \tilde{B}_c(y)[(I - A_c)^{-1} x] = \sqrt{2}\langle y, C_c(I - A_c)^{-1} x\rangle = \langle y, C_d x\rangle \\ &= \langle \tilde{B}_d y, x\rangle. \end{aligned}$$

To show that $C_d^1 = \tilde{C}_d = B_d^*$, let $u \in U$, $x \in D(A_c^*)$,

$$\begin{aligned}\langle u, C_d^1 x\rangle &= \sqrt{2}\langle u, C_c^1(I - A_c^1)^{-1}x\rangle = \sqrt{2}\langle u, \tilde{C}_c(I - A_c^*)^{-1}x\rangle \\ &= \sqrt{2}\, B_c(u)[(I - A_c^*)^{-1}x] = \sqrt{2}\langle (I - A_c)^{-1}B_c u, x\rangle = \langle B_d u, x\rangle \\ &= \langle u, \tilde{C}_d x\rangle.\end{aligned}$$

Since also

$$D_d^1 = C_c^1(I - A_c^1)^{-1}B_c^1 + D_c^1 = (C_c(I - A_c)^{-1}B_c + D_c)^* = D_d^* = \tilde{D}_d,$$

we have the result. □

7. Observability and reachability operators. We are now in a position to discuss some of the central objects of this paper. We define the observability operator for admissible systems. The reachability operator of a system is introduced as the dual of the observability operator of its dual systems.

Having defined observability and controllability gramians of admissible systems, we show one of the main theorems of this paper. It states that the observability operator of a discrete-time system is related by a unitary transformation to the observability operator of its corresponding continuous-time system. This result is the main tool in proving that the transformation T maps discrete-time balanced realizations to continuous-time balanced realizations.

We first define the observability and reachability operators for discrete-time systems.

DEFINITION 7.1. Let $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$; then the operator

$$\begin{aligned}\mathcal{O}_d &: D(\mathcal{O}_d) \to l_Y^2 \\ &x \mapsto (C_d A_d^n x)_{n \geq 0}\end{aligned}$$

is called the observability operator of the system (A_d, B_d, C_d, D_d), where

$$D(\mathcal{O}_d) = \{x \in X \mid (C_d A_d^n x)_{n \geq 0} \in l_Y^2\}.$$

If $\mathcal{O}_d$ is bounded and $\ker(\mathcal{O}_d) = \{0\}$, then the system (A_d, B_d, C_d, D_d) is called observable.

Let $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$ be the dual system of (A_d, B_d, C_d, D_d). If the observability operator $\tilde{\mathcal{O}}_d$ of $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$ is bounded (and hence $D(\tilde{\mathcal{O}}_d) = X$), then the adjoint of $\tilde{\mathcal{O}}_d$ is called the reachability operator $\mathcal{R}_d$ of (A_d, B_d, C_d, D_d), i.e.,

$$\mathcal{R}_d := \tilde{\mathcal{O}}_d^*.$$

If $\mathcal{R}_d$ exists and range $(\mathcal{R}_d)$ is dense in X, the system (A_d, B_d, C_d, D_d) is called reachable.

The analogous definitions for continuous-time systems are now given.

DEFINITION 7.2. Let $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$, then the operator

$$\begin{aligned}\mathcal{O}_c &: D(\mathcal{O}_c) \to L_Y^2([0, \infty[) \\ &x \mapsto C_c e^{tA_c} x\end{aligned}$$

is called the observability operator of the system (A_c, B_c, C_c, D_c), where

$$D(\mathcal{O}_c) = \{x \in X \mid C_c e^{tA_c} x \text{ exists for almost all } t \in [0, \infty[,\ C_c e^{tA_c} x \in L_Y^2([0, \infty[)\}.$$

We say that (A_c, B_c, C_c, D_c) has a bounded observability operator if $D(A_c) \subseteq D(\mathcal{O}_c)$ and $\mathcal{O}_c$ extends to a bounded operator on X. This extension will also be denoted by $\mathcal{O}_c$.

If (A_c, B_c, C_c, D_c) has bounded observability operator $\mathcal{O}_c$ such that $\ker(\mathcal{O}_c) = \{0\}$, then the system (A_c, B_c, C_c, D_c) is called observable.

Let $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ be the dual system of (A_c, B_c, C_c, D_c). If the observability operator $\tilde{\mathcal{O}}_c$ of $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ is a bounded operator on X, the adjoint of $\tilde{\mathcal{O}}_c$ is called the reachability operator $\mathcal{R}_c$ of (A_c, B_c, C_c, D_c), i.e.,

$$\mathcal{R}_c := \tilde{\mathcal{O}}_c^*.$$

If $\mathcal{R}_c$ exists and range $(\mathcal{R}_c)$ is dense in X, the system (A_c, B_c, C_c, D_c) is called reachable.

The notion of reachability and observability gramians as defined below is central in the discussion of balanced realizations in the next section.

DEFINITION 7.3. Let $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$ with bounded reachability operator $\mathcal{R}_d$ and bounded observability operator $\mathcal{O}_d$. Then

$$\mathcal{W}_d := \mathcal{R}_d \mathcal{R}_d^* : X \to X, \qquad \mathcal{M}_d := \mathcal{O}_d^* \mathcal{O}_d : X \to X$$

are called the reachability and the observability gramian, respectively, of the system (A_d, B_d, C_d, D_d). The reachability gramian $\mathcal{W}_c$ and the observability gramian $\mathcal{M}_c$ of a continuous-time system with bounded reachability operator $\mathcal{R}_c$ and observability operator $\mathcal{O}_c$ are similarly defined to be

$$\mathcal{W}_c := \mathcal{R}_c \mathcal{R}_c^* : X \to X, \qquad \mathcal{M}_c := \mathcal{O}_c^* \mathcal{O}_c : X \to X.$$

Before stating the main theorems of this section we present a collection of standard results on Laguerre functions and straightforward modifications thereof. For a reference, see, e.g., Abramowitz and Stegun [1].

PROPOSITION 7.4. *There exists a complete set of orthogonal real-valued functions* $(L_n(t))_{n \geq 0} \subseteq L^2([0, \infty[)$ *such that*

(i) $1/(1+z)\, e^{t((z-1)/(z+1))} = \sum_{n=0}^{\infty} L_n(t) z^n$ *for* $|z| < 1$.

(ii) $\int_0^{\infty} L_n(t) L_m(t)\, dt = \frac{1}{2}\delta_{nm}$ *for all* n, m.

(iii) $|L_n(t)| \leqq 1 \;\; t \in [0, \infty[$, *for* $n \geqq 0$.

(iv) $L_n(t) \in L^1([0, \infty[)$ *for* $n \geqq 0$.

(v) *If* Y *is a separable Hilbert space, then the operator*

$$W : l_Y^2 \to L_Y^2([0, \infty[), \qquad (x_n)_{n \geqq 0} \mapsto \sqrt{2} \sum_{n=0}^{\infty} L_n(t) x_n$$

is unitary, with adjoint

$$W^* : L_Y^2([0, \infty[) \to l_Y^2, \qquad f(t) \mapsto \sqrt{2} \left(\int_0^{\infty} f(t) L_n(t)\, dt \right)_{n \geqq 0}.$$

Now we will state and prove the main theorems of this section. They show that the observability operators of discrete-time systems are related to the observability operators of their corresponding continuous-time systems by a unitary transformation of the input spaces and vice versa. We first consider the case where a discrete-time system is given. Here the connection of its observability operator to the observability operator of its corresponding continuous-time system is investigated.

THEOREM 7.5. *Let* $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$ *and let* $(A_c, B_c, C_c, D_c) := T((A_d, B_d, C_d, D_d))$ *be the corresponding admissible continuous-time system. Then,*

(i) *For* $x \in D((I + A_d)^{-1}) \cap D(\mathcal{O}_d)$, *we have* $x \in D(\mathcal{O}_c)$ *and*

$$\mathcal{O}_c x = W \mathcal{O}_d x$$

where $\mathcal{O}_c$ is the observability operator of (A_c, B_c, C_c, D_c), and W is the unitary operator defined in Proposition 7.4.

(ii) *If $\mathcal{O}_d : X \to l^2_Y$ is bounded, then $\mathcal{O}_c$ extends to a bounded operator given by*

$$\mathcal{O}_c = W\mathcal{O}_d.$$

Proof. (i) Let $x \in D((I+A_d)^{-1}) \cap D(\mathcal{O}_d) = D(A_c) \cap D(\mathcal{O}_d)$. Write

$$F : [0, \infty[\to Y, \qquad t \mapsto F(t) = \sum_{n=0}^{\infty} L_n(t) C_d A_d^n x,$$

$$F_r : [0, \infty[\to Y, \qquad t \mapsto F_r(t) = \sum_{n=0}^{\infty} L_n(t) r^n C_d A_d^n x,$$

$$G : [0, \infty[\to Y, \qquad t \mapsto G(t) = C_c e^{tA_c} x,$$

with $0 < r < 1$. The function $G(t)$, $t \in [0, \infty[$, is well-defined since $e^{tA_c} x \in D(A_c)$ for $x \in D(A_c)$ and hence $e^{tA_c} x \in D(C_c)$.

First note that $F(t)$ is well defined and in $L^2_Y([0, \infty])$, because $(C_d A_d^n x)_{n \geqq 0} \in l^2_Y$ and because $(\sqrt{2}\, L_n(t))_{n \geqq 0}$ forms an orthonormal basis in $L^2([0, \infty[)$.

Now we are going to show that

$$\sqrt{2}\, F_r(t) \to G(t) \quad \text{pointwise weakly as } r \to 1 - 0.$$

Using the notation and results of § 3 we have that $\sum_{n=0}^{\infty} L_n(t) r^n A_d^n = \delta_t(rA_d)$, $0 < r < 1$, since $\delta_t(rz) \in \mathcal{A}$. Hence,

$$F_r(t) = \sum_{n=0}^{\infty} L_n(t) r^n C_d A_d^n x = C_d \left(\sum_{n=0}^{\infty} L_n(t) r^n A_d^n \right)$$

$$= C_d \delta_t(rA_d) = C_d (I + rA_d)^{-1} e^{t(I+rA_d)^{-1}(I-rA_d)} x.$$

Weak convergence now follows from Proposition 3.11.

But $F_r(t) \to F(t)$ in $L^2_Y([0, \infty[)$ as $r \to 1 - 0$, since

$$(r^n C_d A_d^n x)_{n \geqq 0} \to (C_d A_d^n x)_{n \geqq 0} \quad \text{in } l^2_Y \text{ as } r \to 1 - 0.$$

We can now show that these two convergence results imply that for all $y \in Y$

$$\langle y, G(t) \rangle_Y = \langle y, \sqrt{2}\, F(t) \rangle_Y$$

almost everywhere for all $t \in [0, \infty[$. For otherwise, there is an $\varepsilon > 0$ and a measurable set $A \subseteq [0, \infty[$ with Lebesgue measure $\lambda(A) = \varepsilon$ such that

$$\langle y, G(t) \rangle_Y - \langle y, \sqrt{2}\, F(t) \rangle_Y > \varepsilon$$

for $t \in A$. Now, clearly there is an r_0 such that for $r \geqq r_0$

$$\lambda\{t \in A : \langle y, \sqrt{2}\, F_r(t) \rangle - \langle y, \sqrt{2}\, F(t) \rangle > \varepsilon/2\} < \varepsilon/2,$$

and by Egoroff's Theorem, there is an r_1 such that for $r \geqq r_1$

$$\lambda\{t \in A : \langle y, \sqrt{2}\, F_r(t) \rangle - \langle y, G(t) \rangle > \varepsilon/2\} < \varepsilon/2.$$

These three statements together form a contradiction.

Now, since Y is separable we have that

$$C_c e^{tA_c} x = \sqrt{2} \sum_{n=0}^{\infty} L_n(t) C_d A_d^n x$$

almost everywhere for $t \in [0, \infty[$. Thus $\mathcal{O}_c(x) = W\mathcal{O}_d(x)$ for $x \in D(A_c)$.

(ii) Since $\mathcal{O}_d$ is bounded, W is unitary, and $D(A_c)$ is dense in X, $\mathcal{O}_c$ extends to a bounded operator on X. □

The corollary to this theorem shows the equivalent result for reachability operators.

COROLLARY 7.6. *Let* $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$ *and let* $(A_c, B_c, C_c, D_c) := T((A_d, B_d, C_d, D_d))$ *be the corresponding admissible continuous-time system.*

Then, if the reachability operator $\mathcal{R}_d$ *of* (A_d, B_d, C_d, D_d) *exists as a bounded operator, the reachability operator* $\mathcal{R}_c$ *of* (A_c, B_c, C_c, D_c) *exists as a bounded operator and is given by*

$$\mathcal{R}_c = \mathcal{R}_d W^*.$$

Proof. Let $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$ be the dual system of (A_d, B_d, C_d, D_d). By definition $\mathcal{R}_d = \tilde{\mathcal{O}}_d^*$, where $\tilde{\mathcal{O}}_d$ is the observability operator of $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$. Now consider $T((\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)) =: (\tilde{A}_c, \tilde{B}_d, \tilde{C}_c, \tilde{D}_c)$. By Proposition 6.5 we know that $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ is the dual system of (A_c, B_c, C_c, D_c). But the reachability operator $\mathcal{R}_c$ of (A_c, B_c, C_c, D_c) is given by $\mathcal{R}_c = \tilde{\mathcal{O}}_c^*$, where $\tilde{\mathcal{O}}_c$ is the observability operator of $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$. By the previous theorem $\tilde{\mathcal{O}}_c = W\tilde{\mathcal{O}}_d$ and hence $\mathcal{R}_c = \tilde{\mathcal{O}}_c^* = \tilde{\mathcal{O}}_d^* W^* = \mathcal{R}_d W^*$. □

We now show that if a continuous-time system has a bounded observability operator $\mathcal{O}_c$ then the observability operator of its corresponding discrete time system is given by a unitary transformation of $\mathcal{O}_c$.

THEOREM 7.7. *Let* $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$ *and let* $(A_d, B_d, C_d, D_d) = T^{-1}((A_c, B_c, C_c, D_c))$ *be the corresponding admissible discrete time system. Then,*

(i) *For* $x \in D(A_c) \cap D(\mathcal{O}_c)$, *we have* $x \in D(\mathcal{O}_d)$ *and*

$$\mathcal{O}_d x = W^* \mathcal{O}_c x$$

where $\mathcal{O}_d$ *is the observability operator of* (A_d, B_d, C_d, D_d) *and* W^* *is the unitary operator defined in Proposition* 7.4.

(ii) *If* $\mathcal{O}_c$ *is bounded, then* $\mathcal{O}_d$ *extends to a bounded operator on* X *given by*

$$\mathcal{O}_d = W^* \mathcal{O}_c.$$

Proof. (i) Let $x \in D(A_c) \cap D(\mathcal{O}_c)$; then we know that $G(t) := C_c e^{tA_c} x$ exists for all $t \in [0, \infty]$, since $e^{tA_c} x \in D(A_c) \subseteq D(C_c)$, $t \in [0, \infty[$. By assumption $G(t) \in L_Y^2([0, \infty[)$.

Corollary 4.4 implies that

$$G(t) = \sqrt{2}\, C_d (I + A_d)^{-1} e^{t(I+A_d)^{-1}(A_d - I)} x.$$

For $0 < r < 1$, let $G_r(t) = \sqrt{2}\, C_d (I + rA_d)^{-1} e^{t(I+rA_d)^{-1}(rA_d - I)} x$. Since C_d is bounded, we have by Proposition 3.11 that for all $t \in [0, \infty[$,

$$\lim_{r \to 1-0} G_r(t) = G(t) \quad \text{weakly.}$$

Since C_d is bounded and $\delta_t(rz) \in \mathcal{A}$, where δ_t is as defined in § 3, we have that

$$\begin{aligned} G_r(t) &= \sqrt{2}\, C_d (I + rA_d)^{-1} e^{t(I+rA_d)^{-1}(rA_d - I)} x \\ &= \sqrt{2}\, C_d \delta_t(rA_d) x \\ &= \sqrt{2}\, C_d \left(\sum_{n=0}^{\infty} L_n(t) r^n A_d^n x \right) \\ &= \sqrt{2} \sum_{n=0}^{\infty} L_n(t) r^n C_d A_d^n x \in L_Y^2([0, \infty]). \end{aligned}$$

We will now show that there exists $M>0$ such that

$$\|G_r(t)\| \leqq M < \infty \quad \text{for all } 0<r<1, \quad t \in [0, \infty[.$$

Let $t \in [0, \infty[$; then

$$\begin{aligned}\sup_{0<r<1} \|G_r(t)\| &= \sup_{0<r<1} \|\sqrt{2}\, C_d (I+rA_d)^{-1}\, e^{t(I+rA_d)^{-1}(rA_d-I)}x\| \\ &\leqq \sqrt{2}\, \|C_d\| \sup_{0<r<1} \|(I+rA_d)^{-1}\, e^{t(I+rA_d)^{-1}(rA_d-I)}x\| \\ &\leqq M < \infty\end{aligned}$$

where the second to last line follows from Proposition 3.11 noting that $D(A_c) = D((I+A_d)^{-1})$.

Thus for $y \in Y$, we have that

$$|\langle G_r(t), y\rangle \sqrt{2}\, L_n(t)| \leqq \sqrt{2}\, M \|y\|\, |L_n(t)|, \qquad t \in [0, \infty[.$$

Since $L_n(t) \in L^1([0, \infty[)$, we can therefore apply the Dominated Convergence Theorem:

$$\lim_{r \to 1-0} \int_0^\infty \langle G_r(t), y\rangle \sqrt{2}\, L_n(t)\, dt = \int_0^\infty \langle G(t), y\rangle \sqrt{2}\, L_n(t)\, dt.$$

But

$$\begin{aligned}\int_0^\infty \langle G_r(t), y\rangle \sqrt{2}\, L_n(t)\, dt &= \int_0^\infty \left\langle \sum_{i=0}^\infty \sqrt{2}\, L_i(t) r^i C_d A_d^i x, y \right\rangle \sqrt{2}\, L_n(t)\, dt \\ &= 2 \sum_{i=0}^\infty \left(r^i \langle C_d A_d^i x, y\rangle \int_0^\infty L_i(t) L_n(t)\, dt \right) \\ &= r^n \langle C_d A_d^n x, y\rangle.\end{aligned}$$

Thus

$$\begin{aligned}\int_0^\infty \langle G(t), y\rangle \sqrt{2}\, L_n(t)\, dt &= \lim_{r \to 1-0} \int_0^\infty \langle G_r(t), y\rangle \sqrt{2}\, L_n(t)\, dt \\ &= \langle C_d A_d^n x, y\rangle.\end{aligned}$$

Since $G(t) \in L_Y^2([0, \infty[)$, we have an expansion

$$G(t) = \sum_{n=0}^\infty G_n \sqrt{2}\, L_n(t), \qquad G_n \in Y.$$

Thus $\langle G_n, y\rangle = \langle C_d A_d^n x, y\rangle$ for all $y \in Y$ and hence $G_n = C_d A_d^n x$ for $n \geqq 0$. This implies that

$$\mathcal{O}_c(x) = C_c\, e^{tA_c} x = \sqrt{2} \sum_{n=0}^\infty L_n(t) C_d A_d^n x = W \mathcal{O}_d(x)$$

and hence $\mathcal{O}_d(x) = W^* \mathcal{O}_c(x)$.

(ii) This is a straightforward consequence of (i). □

In the following corollary the corresponding result is established for the reachability operators.

COROLLARY 7.8. *Let* $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$ *and let* $(A_d, B_d, C_d, D_d) := T^{-1}((A_c, B_c, C_c, D_c))$ *be the corresponding admissible discrete-time system. Then, if the reachability operator* $\mathcal{R}_c$ *of* (A_c, B_c, C_c, D_c) *exists as bounded operator, the reachability operator* $\mathcal{R}_d$ *of* (A_d, B_d, C_d, D_d) *exists as a bounded operator and is given by*

$$\mathcal{R}_d = \mathcal{R}_c W.$$

Proof. Let $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ be the dual system of (A_c, B_c, C_c, D_c). By definition, $\mathcal{R}_c = \tilde{\mathcal{O}}_c^*$, where $\tilde{\mathcal{O}}_c$ is the observability operator of $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$. Now consider $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d) = T^{-1}((\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c))$. By Proposition 6.5 we know that $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$ is the dual system of (A_d, B_d, C_d, D_d). But the reachability operator $\mathcal{R}_d$ of (A_d, B_d, C_d, D_d) is given by $\mathcal{R}_d = \tilde{\mathcal{O}}_d^*$, where $\tilde{\mathcal{O}}_d$ is the observability operator of $(\tilde{A}_d, \tilde{B}_d, \tilde{C}_d, \tilde{D}_d)$. By the previous theorem $\tilde{\mathcal{O}}_d = W^* \tilde{\mathcal{O}}_c$. Hence $\mathcal{R}_d = \tilde{\mathcal{O}}_d^* = \tilde{\mathcal{O}}_c^* W = \mathcal{R}_c W$. □

The following corollary to the previous two theorems shows that the properties of observability and reachability as well as the observability and reachability gramians are preserved by the transformation T.

COROLLARY 7.9. *Let* $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$ *and* $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$ *such that*

$$(A_c, B_c, C_c, D_c) = T((A_d, B_d, C_d, D_d)).$$

Then,

(1) (A_c, B_c, C_c, D_c) *is observable* (*reachable*) *if and only if* (A_d, B_d, C_d, D_d) *is observable* (*reachable*).

(2) *If the reachability gramians* $\mathcal{W}_c$, $\mathcal{W}_d$ (*observability gramians* $\mathcal{M}_c$, $\mathcal{M}_d$) *of* (A_d, B_d, C_d, D_d) *and* (A_c, B_c, C_c, D_c) *are defined, then*

$$\mathcal{W}_c = \mathcal{W}_d \qquad (\mathcal{M}_c = \mathcal{M}_d).$$

8. Balanced realizations. We will now apply the results on infinite-dimensional state-space systems of the previous sections to tackle the problem that motivated this paper, namely, that of the existence of balanced realizations for continuous-time systems. Our results will allow us to deal with a wider range of transfer functions than previous results; for example, we can handle any transfer function that is bounded in the RHP, and with a limit at infinity along the real axis. This allows us to consider nonstrictly proper delay systems with transfer functions such as $G(s)\, e^{-sT}$, where $G(s)$ is a matrix-valued stable rational transfer function. Previous results were unable to deal with, for example, the pure delay system e^{-sT} because the limits $\lim_{w \to +\infty} e^{-iwt}$ and $\lim_{w \to -\infty} e^{-iwt}$ do not exist and, therefore, the corresponding Hankel operator is not compact. Another example of a function we will be able to deal with is $G(s) = \log(1 + 1/s)$. This function is unusual in that it has a singularity at 0.

The approach taken is to carry over the discrete-time results by Young using the transformation $T: D_X^{U,Y} \to C_X^{U,Y}$. Thus we will first review Young's results before we turn to proving the continuous-time analogue of his discrete-time realization theorem.

The following definition recalls the notion of a balanced system as defined by Moore [10] and the notion of a parbalanced system as introduced by Young [20].

DEFINITION 8.1. Let $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$ $((A_c, B_c, C_c, D_c) \in C_X^{U,Y})$ be such that the observability gramian $\mathcal{M}_d$ $(\mathcal{M}_c)$ and reachability gramian $\mathcal{W}_d$ $(\mathcal{W}_c)$ exist. Then the system is

(i) Parbalanced, if $\mathcal{M}_d = \mathcal{W}_d$ $(\mathcal{M}_c = \mathcal{W}_c)$;

(ii) Balanced, if it is parbalanced and moreover the gramians are diagonal.

Before we state any results, we introduce some notation. Let $H: \mathbf{D} \to \mathcal{L}(U, Y)$ be analytic. We say that $H \in P_+ L^\infty(\mathbf{D}, \mathcal{L}(U, Y))$ if there exists an analytic function $F: \mathbf{D} \to \mathcal{L}(U, Y)$ such that $H + \bar{F}$ is essentially bounded, where $\bar{F}(z) = F(z^{-1})$. Furthermore, if F can be chosen so that $H + \bar{F} \in C(\mathbf{D}, \mathcal{K}(U, Y))$, where $C(\mathbf{D}, \mathcal{K}(U, Y))$ is the set of norm continuous functions on $\partial\mathbf{D}$ with values in the set of compact operators from U to Y, then H is said to be in $P_+ C(\mathbf{D}, \mathcal{K}(U, Y))$.

Similarly, if $H: \mathrm{RHP} \to \mathscr{L}(U, Y)$ is analytic, we say that $H \in P_+L^\infty(\mathrm{RHP}, \mathscr{L}(U, Y))$ ($P_+C(\mathrm{RHP}, \mathscr{K}(U, Y))$) if there is an analytic function $F: \mathrm{RHP} \to \mathscr{L}(U, Y)(\mathscr{K}(U, Y))$ such that $H + \tilde{F}$ is essentially bounded (extends to a norm continuous function on the imaginary axis such that $\lim_{w \in \mathbb{R}, w \to \infty} (H + \tilde{F})(iw) = \lim_{w \in \mathbb{R}, w \to \infty} (H + \tilde{F})(-iw)$), where $\tilde{F}(s) = F(-s)$.

Remark 8.2. If $H \in P_+L^\infty(\mathbf{D}, \mathscr{L}(U, Y))$, then the Hankel operator with symbol H is bounded by an operator-valued version of Nehari's Theorem, whereas by Hartmann's Theorem it is compact if $H \in P_+C(\mathbf{D}, \mathscr{L}(U, Y))$. Note that if U and Y are finite-dimensional, $H \in P_+L^\infty(\mathbf{D}, \mathscr{L}(U, Y))$ ($P_+L^\infty(\mathrm{RHP}, \mathscr{L}(U, Y))$) if and only if H is in $BMOA(\partial\mathbf{D})$ ($BMOA(i\mathbb{R})$) and $H \in P_+C(\mathbf{D}, \mathscr{K}(U, Y))$ ($P_+C(\mathrm{RHP}, \mathscr{K}(U, Y))$) if and only if H is in $VMOA(\partial\mathbf{D})$ ($VMOA(i\mathbb{R})$) (for references, see [15]).

The following theorem by Young [20], gives criteria for a (par-) balanced realization to exist of a discrete-time transfer function.

THEOREM 8.3. *Let $G_d(z): \mathbb{C} \setminus \bar{\mathbf{D}} \to \mathscr{L}(U, Y)$ be analytic with $G_d(\infty) = D_d \in \mathscr{L}(U, Y)$, and write*

$$g(z) := \frac{1}{z}\left(G_d\left(\frac{1}{z}\right) - D_d\right), \qquad z \in \mathbf{D}.$$

(i) *If $g \in P_+L^\infty(\mathbf{D}, \mathscr{L}(U, Y))$, then there exists a separable Hilbert space X and a discrete-time state-space realization (A_d, B_d, C_d, D_d) of $G_d(z)$ with state space X, such that*

$$A_d \in \mathscr{L}(X) \quad \text{is a contraction,}$$

$$B_d \in \mathscr{L}(U, X), \qquad C_d \in \mathscr{L}(X, Y),$$

and (A_d, B_d, C_d, D_d) is reachable and observable with bounded reachability and observability operators, such that (A_d, B_d, C_d, D_d) is parbalanced, i.e., $\mathscr{M}_d = \mathscr{W}_d$. The gramians $\mathscr{M}_d$, $\mathscr{W}_d$ satisfy the Lyapunov equations

$$A_d \mathscr{W}_d A_d^* - \mathscr{W}_d = -B_d^* B_d, \qquad A_d^* \mathscr{M}_d A_d - \mathscr{M}_d = -C_d C_d^*.$$

If $(\bar{A}_d, \bar{B}_d, \bar{C}_d, \bar{D}_d)$ is another parbalanced realization of $G_d(z)$ with state space $\bar{X}$, then (A_d, B_d, C_d, D_d) and $(\bar{A}_d, \bar{B}_d, \bar{C}_d, \bar{D}_d)$ are unitarily equivalent.

(ii) *If, moreover, $g \in P_+C(\mathbf{D}, \mathscr{K}(U, Y))$, there is a basis in X with respect to which (A_d, B_d, C_d, D_d) is balanced.*

To show that for a transfer function G_d such that $\lim_{\lambda < -1, \lambda \to -1} G_d(\lambda) \in \mathscr{L}(U, Y)$, the realization given in the previous theorem is, in fact, admissible, we need to show that -1 is not an eigenvalue of A_d.

LEMMA 8.4. *Let (A_d, B_d, C_d, D_d) be a parbalanced realization of a discrete-time transfer function as given in Theorem* 8.3; *then $-1 \notin \sigma_p(A_d)$.*

Proof. Let $\mathscr{M}_d$ be the observability gramian of (A_d, B_d, C_d, D_d); then

$$A_d^* \mathscr{M}_d A_d - \mathscr{M}_d = -C_d^* C_d.$$

Assume $-1 \in \sigma_p(A_d)$ with eigenvector $x \neq 0$, then

$$\langle x, A_d^* \mathscr{M}_d A_d x \rangle - \langle x, \mathscr{M}_d x \rangle = -\langle x, C_d^* C_d x \rangle$$

and hence

$$\langle A_d x, \mathscr{M}_d A_d x \rangle - \langle x, \mathscr{M}_d x \rangle = 0 = -\| C_d x \|^2,$$

which implies that $C_d x = 0$. Hence for all $n \geqq 0$, $\mathscr{O}_d x = (C_d A_d^n x)_{n \geqq 0} = (-1)^n C_d x = 0$, which is a contradiction to the observability of (A_d, B_d, C_d, D_d). □

We can now apply our results on the transformation T to obtain realization results for continuous-time transfer functions.

THEOREM 8.5. *Let $G_c: \mathrm{RHP} \to \mathscr{L}(U, Y)$ be a continuous-time transfer function that is analytic and such that $\lim_{s\in\mathbb{R}, s\to\infty} G_c(s) \in \mathscr{L}(U, Y)$ exists.*

(i) *If $G_c \in P_+L^\infty(\mathrm{RHP}, \mathscr{L}(U, Y))$, then there exists a separable Hilbert space X and a parbalanced admissible continuous-time state-space realization (A_c, B_c, C_c, D_c) of G_c with state space X. This system is reachable, observable, and has bounded reachability and observability operators.*

If $(\bar{A}_c, \bar{B}_c, \bar{C}_c, \bar{D}_c)$ is another parbalanced realization of $G_c(s)$, then (A_c, B_c, C_c, D_c) and $(\bar{A}_c, \bar{B}_c, \bar{C}_c, \bar{D}_c)$ are unitarily equivalent.

(ii) *If, moreover, $G_c \in P_+C(\mathrm{RHP}, \mathscr{K}(U, Y))$, then there is a basis in X with respect to which (A_c, B_c, C_c, D_c) is balanced.*

Proof. Let $G_d: \mathbb{C}\backslash\bar{\mathbf{D}} \to \mathscr{L}(\mathbf{U}, \mathbf{Y})$ be the associated discrete-time transfer function $G_d(z) = G_c((z-1)/(z+1))$, and write

$$g(z) = \frac{1}{z}\left(G_d\left(\frac{1}{z}\right) - G_c(1)\right), \qquad z \in \mathbf{D}.$$

Then it is easy to see that $G_c \in P_+L^\infty(\mathrm{RHP}, \mathscr{L}(U, Y))(P_+C(\mathrm{RHP}, \mathscr{K}(U, Y)))$ if and only if $g \in P_+L^\infty(\mathbf{D}, \mathscr{L}(U, Y))(P_+C(\mathbf{D}, \mathscr{K}(U, Y)))$.

Hence $G_d(z)$ has a parbalanced realization (A_d, B_d, C_d, D_d) that is admissible since A_d is a contraction, such that $-1 \notin \sigma_p(A_d)$ by Lemma 8.4 and since

$$\lim_{\substack{\lambda<1\\ \lambda\to 1}} C_d(\lambda I + A_d)^{-1}B_d = -\lim_{\substack{\lambda<-1\\ \lambda\to -1}} G_d(\lambda) + D_d = -\lim_{\substack{s\in\mathbb{R}\\ s\to\infty}} G_c(s) + D_d \in \mathscr{L}(U, Y)$$

exists. Then $(A_c, B_c, C_c, D_c) := T((A_d, B_d, C_d, D_d)) \in C_X^{U,Y}$ is a state-space realization of G_c (Theorem 4.1) that is observable and reachable, such that $\mathscr{W}_c = \mathscr{W}_d$ and $\mathscr{M}_c = \mathscr{M}_d$ (Corollary 7.9).

The statement on the uniqueness of the realization follows from Proposition 5.4. □

The following corollary discusses special cases of transfer functions and gives simple criteria for the existence of a parbalanced or balanced realization of a continuous-time transfer function.

COROLLARY 8.6. *Let $G_c(s): \mathrm{RHP} \to \mathscr{L}(U, Y)$ be a continuous-time transfer function, such that $\lim_{s\in\mathbb{R}, s\to\infty} G_c(s) \in \mathscr{L}(U, Y)$ exists and $G_c(s)$ is analytic in* RHP.

(i) *If $G_c(s)$ is bounded in the* RHP, *i.e.*, $\sup_{s\in\mathrm{RHP}} \|G_c(s)\| < \infty$, *then $G_c(s)$ has a parbalanced realization.*

(ii) *If, in particular, $G_c(s): \mathrm{RHP} \mapsto \mathscr{K}(U, Y)$, such that G_c is bounded in the* RHP *and $G_c(s)$ is norm continuous on the imaginary axis including at the points $+\infty$ and $-\infty$, i.e., $w \mapsto G_c(iw)$, $w \in \mathbb{R}$, is norm continuous and $\lim_{w\to-\infty} G_c(iw) = \lim_{w\to+\infty} G_c(iw)$, then $G_c(s)$ has a balanced realization.*

As examples to the previous realization results we can consider delay systems. It follows immediately from the previous corollary that the transfer function e^{-sT} of a pure delay with time constant $T > 0$, has a parbalanced realization. Note that the limits $\lim_{w\to+\infty} e^{-iwT}$ and $\lim_{w\to-\infty} e^{-iwT}$ do not exist. If $G(s)$ is a matrix-valued strictly proper stable rational transfer function, then the transfer function $G(s)\, e^{-sT}$ of the delayed system has a balanced realization.

Another example of a function that has a parbalanced continuous-time state-space realization is the function $G_c(s) = \log(1 + 1/s)$, which is well known to be in $BMOA(i\mathbb{R})$. We note that G_c has a singularity at 0.

UNIFORM STABILIZATION OF THE WAVE EQUATION BY NONLINEAR BOUNDARY FEEDBACK*

ENRIKE ZUAZUA†

Abstract. The question of uniformly stabilizing the solution of the wave equation $y''-\Delta y=0$ in $\Omega\times(0,\infty)$ (Ω is a bounded domain of $\mathbf{R}^n$) by means of a nonlinear feedback law of the following form is studied: $\partial y/\partial v=-k(x)g(y')$ on $\Gamma_0\times(0,\infty)$, $y=0$ on $\Gamma_1\times(0,\infty)$, (Γ_0,Γ_1) being a suitable partition of the boundary of Ω and g a continuous nondecreasing function such that $g(0)=0$. We choose $k(x)\in L^\infty(\Gamma_0)$, $k(x)\geqq 0$ such that $k(x)$ vanishes linearly at the interface points $x\in\bar{\Gamma}_0\cap\bar{\Gamma}_1$. Then, if $g(s)$ behaves like $|s|^{p-1}s$ as $|s|\to 0$ with $p>1$ and linearly as $|s|\to\infty$, it is proved that the energy of every solution decays like $t^{-2/(p-1)}$ as $t\to\infty$. In the case where $p=1$ the exponential decay rate is proved.

Key words. wave equation, boundary damping, nonlinear feedback law, uniform stabilization, decay rate estimate

1. Introduction. Let Ω be a bounded, open, connected set in $\mathbf{R}^n$ ($n\geqq 1$) having a boundary $\Gamma=\partial\Omega$ of class C^2. Given a point $x^0\in\mathbf{R}^n$, let be $m(x)=x-x^0$ and consider the following partition of the boundary:

$$\Gamma(x^0)=\{x\in\Gamma: m(x)\cdot\nu(x)>0\}, \tag{1.1}$$

$$\Gamma_*(x^0)=\{x\in\Gamma: m(x)\cdot\nu(x)\leqq 0\}=\Gamma/\Gamma(x^0) \tag{1.2}$$

where $\nu(x)$ is the unit normal vector to Γ at $x\in\Gamma$ pointing toward the exterior of Ω and " $\cdot$ " denotes the scalar product in $\mathbf{R}^n$. We will denote by $\partial/\partial\nu$ the normal derivative in the direction ν and by $'=\partial^*/\partial t$ the time-derivative.

Let us assume that $\operatorname{int}\Gamma_*(x^0)\neq\varnothing$ and consider the following wave equation:

$$y''-\Delta y=0 \qquad \text{in } \Omega\times(0,\infty), \tag{1.3}$$

$$\frac{\partial y}{\partial\nu}=-\{m(x)\cdot\nu(x)\}g(y') \qquad \text{on } \Gamma(x^0)\times(0,\infty), \tag{1.4}$$

$$y=0 \qquad \text{on } \Gamma_*(x^0)\times(0,\infty), \tag{1.5}$$

$$y(0)=y^0\in V, \qquad y'(0)=y^1\in L^2(\Omega) \tag{1.6}$$

where

$$V=\{\phi\in H^1(\Omega): \phi=0 \text{ on } \Gamma_*(x^0)\} \tag{1.7}$$

and $g\in C(\mathbf{R})$ is a nondecreasing function such that $g(0)=0$ and $g(s)s>0$ for all $s\in\mathbf{R}-\{0\}$.

We define the energy of a solution $y=y(x,t)$ of (1.3)-(1.6) as follows:

$$E(t)=\frac{1}{2}\int_\Omega\{|\nabla y(x,t)|^2+|y'(x,t)|^2\}\,dx \quad \forall t\geqq 0. \tag{1.8}$$

† Departamento de Matemáticas, Universidad del Pais Vasco, Apartado 644, 48080 Bilbao, Spain.

Let us calculate formally (all this will be justified below) the derivative of the energy. By using Green's formula we easily obtain

$$E'(t)=\frac{dE(t)}{dt}=-\int_{\Gamma(x^0)}\{m(x)\cdot\nu(x)\}g(y'(x,t))y'(x,t)\,d\Gamma \tag{1.9}$$

where $d\Gamma$ is the surface measure associated to the boundary Γ. Taking into account the fact that $g(s)s\geqq 0$, for all $s\in\mathbf{R}$ we deduce from (1.9) that the energy $E(t)$ is nonincreasing.

Applying La Salle's invariance principle it is easy to see that the energy goes to zero as t goes to infinity. Indeed, in addition to (1.9) we have

$$\begin{aligned}&\frac{d}{dt}\int_\Omega\{|\nabla(y_1-y_2)(x,t)|^2+|(y_1'-y_2')(x,t)|^2\}\,dx\\ &=-2\int_{\Gamma(x^0)}\{m(x)\cdot\nu(x)\}(g(y_1'(x,t))-g(y_2'(x,t)))(y_1'-y_2')(x,t)\,d\Gamma \qquad (1.10)\\ &\leqq 0\end{aligned}$$

for any two finite energy solutions y_1, y_2 of (1.3)-(1.6).

It is enough to establish the decay for a dense subset of initial data, for instance,

$$W=\{(y^0,y^1)\in V\times V:\Delta y^0\in L^2(\Omega),\frac{\partial y^0}{\partial\nu}=-(m\cdot\nu)g(y^1)\text{ on }\Gamma(x^0)\}.$$

Let us define the higher-order energy

$$F(t)=\frac{1}{2}\int_\Omega(|\Delta y(x,t)|^2+|\nabla y'(x,t)|^2)\,dx. \tag{1.11}$$

We have

$$\frac{dF(t)}{dt}=-\int_{\Gamma(x^0)}\{m\cdot\nu\}g'(y')|y''|^2\,d\Gamma\leqq 0 \tag{1.12}$$

and thus

$$F(t)\leqq F(0)<\infty\quad\forall t\geqq 0. \tag{1.13}$$

Therefore the trajectory $\{y(t),y'(t)\}$ corresponding to the initial data in W is relatively compact in $V\times H$. Applying La Salle's invariance principle we introduce the ω-limit set $\omega\{y^0,y^1\}$ with respect to the strong topology of $V\times H$, and the problem reduces to prove that

$$\omega\{y^0,y^1\}=\{0,0\}. \tag{1.14}$$

From (1.9) we easily deduce that $\omega\{y^0,y^1\}$ is contained in the set of initial data leading to solutions with constant energy, i.e., such that

$$\begin{aligned}&y''-\Delta y=0 && \text{in }\Omega\times(0,\infty),\\ &\frac{\partial y}{\partial\nu}=y'=0 && \text{on }\Gamma(x^0)\times(0,\infty), \qquad (1.15)\\ &y=0 && \text{on }\Gamma_*(x^0)\times(0,\infty).\end{aligned}$$

But Holmgren's Uniqueness Theorem assures that the only function satisfying (1.15) is the trivial one $y=0$, and thus (1.14) holds.

To obtain the compactness of trajectories we have used in (1.12) the fact that g is locally Lipschitz with $g' \geqq 0$ almost everywhere. However, the compactness can be achieved for all nondecreasing continuous function g such that $g(s)s > 0$, for all $s \in \mathbf{R} - \{0\}$ by obtaining uniform energy estimates for the family of functions

$$z_h(x, t) = \frac{y(x, t+h) - y(x, t)}{h}$$

as $h \to 0$.

We note that more general stability results have been recently proven by Chen and Wang in [6] and Lasiecka in [17], [18] in the case where g is a multivalued maximal monotone function.

The aim of this paper is to estimate the rate of decay of the energy and, more precisely, to establish some relations between the rate of the decay and the behavior of the nonlinearity g.

The linear case $g(s) = as$, with $a \in \mathbf{R}$, is well known by now. The first stabilization result is due to Chen [3] (see also [4], [5]). He proved the exponential decay of the energy in this linear case with boundary conditions

$$\frac{\partial y}{\partial \nu} = -k(x)y' \quad \text{on } \Gamma(x^0) \times (0, \infty) \tag{1.16}$$

with $k \in L^\infty(\Gamma(x^0))$, $k \geqq k_0 > 0$ instead of (1.4) but only under the geometrical restriction

$$(x - x^0) \cdot \nu(x) \geqq \gamma > 0 \quad \text{on } \Gamma(x^0). \tag{1.17}$$

Chen's result was later generalized by Lagnese in [13] by considering a more general class of multipliers (other than the radial one $x - x^0$) but always under a geometrical restriction of type (1.17).

An important observation is that condition (1.17) forces

$$\overline{\Gamma(x^0)} \cap \overline{\Gamma_*(x^0)} = \varnothing. \tag{1.18}$$

Thus if $\Gamma(x^0) \neq \varnothing$, the above results cannot apply to regions Ω having a smooth connected boundary. However, in a recent paper by Komornik and Zuazua [11], [12] the geometrical restriction (1.17) has been avoided and the exponential decay has been proved for dimensions $n \leqq 3$ (for some technical reasons that we will discuss in § 2) by taking in (1.16) the weight

$$k(x) = (x - x^0) \cdot \nu(x). \tag{1.19}$$

Subsequently, Lagnese in [15] generalized this result to a larger class of multipliers but always considered weights of type (1.19) in the boundary condition (1.16).

As mentioned above, the first contribution in [11] and [12] was that, for the first time, the geometrical restriction (1.17) was avoided and the second was the method by itself. Indeed, in all preceding works the exponential decay of the energy was obtained from estimates on $\int_0^\infty E(t)\, dt$ by employing a result of Datko [7]. However, in [11] and [12] a different point of view was taken and the exponential decay was obtained by constructing perturbed energy functionals for which differential inequalities leading to the exponential decay were obtained. The advantage of this approach is that it can be easily extended to treat some semilinear problems as in [12]. We note also that Lagnese proved in a recent work [16], inspired by these kinds of methods, stabilization results for von Karman's plate models.

The aim of the present paper is to show how this method can be adapted to obtain decay estimates for wave equations with nonlinear dissipative boundary conditions.

We will consider here functions g satisfying the following conditions:

$$|g(s)| \leqq C_1|s| \quad \forall s \in \mathbf{R}, \tag{1.20}$$

$$|g(s)| \geqq C_2 \inf\{|s|, |s|^p\} \quad \forall s \in \mathbf{R} \tag{1.21}$$

for some C_1, $C_2 > 0$, and $p \geqq 1$.

Under these assumptions, we will prove the following:

(a) When $p = 1$ the energy of every solution decays exponentially;

(b) When $p > 1$ the energy decays as does $t^{-2/(p-1)}$.

It is important to note that the exponential decay rate of the energy may not be expected under the coercivity assumption (1.21) unless $p = 1$. The same phenomena appear in the nonlinear dissipative ordinary differential equation

$$u'' + u + |u'|^{p-1}u' = 0.$$

However, we are not now able to prove that the decay on (b) is optimal.

As mentioned above, the growth assumption (1.20) (which implies that the nonlinearity g is globally majorized by a linear function) is not necessary if we look for stability results asserting that every solution tends to the equilibrium state $\{0, 0\}$ in the energy space as $t \to \infty$ (see also [6] and [17]). However, this assumption will be needed to establish the a priori estimates leading to the decay rates. On the other hand, we note that the coerciveness assumption (1.21) concerns mainly the behavior of g at the origin and that the decay rate (of order $t^{-2/(p-1)}$) is governed by this behavior. This is a natural result since we already know that $\{y(t), y'(t)\} \to 0$, but it must be carefully proved since the decay holds only on the topology of $V \times L^2(\Omega)$.

It is easy to check that the hypotheses (1.20)-(1.21) are satisfied when g is, for instance, as follows:

$$g(s) = \begin{cases} |s|^{p-1}s & \text{when } |s| \leqq 1, \\ s & \text{when } |s| \geqq 1. \end{cases}$$

To handle the case where $p > 1$ in (1.21) we are forced to modify the perturbed energy functional introduced in [11] and [12]. This will be done by following the earlier works of Haraux and Zuazua [10] and Zuazua [23].

We note that in the situation considered above (where $\operatorname{int} \Gamma_*(x^0) \neq \varnothing$), the quantity $(E(t))^{1/2}$ is a norm in $V \times L^2(\Omega)$ equivalent to the one induced by $H^1(\Omega) \times L^2(\Omega)$. Therefore, it is equivalent to study the rate of decay of the energy or the rate of convergence of the solution to the equilibrium state $\{0, 0\}$ in the space $V \times L^2(\Omega)$. The situation is different when $\operatorname{int} \Gamma_*(x^0) = \varnothing$. In this case the quantity $(E(t))^{1/2}$ does not define a norm in $V \times L^2(\Omega) = H^1(\Omega) \times L^2(\Omega)$ and every constant function is a stationary solution of (1.3)-(1.6). In this case to recover the stability properties and the estimates on the rate of decay mentioned above we modify the feedback law and consider, instead of (1.4), (1.5), the following boundary condition:

$$\frac{\partial y}{\partial \nu} + \alpha\{m(x) \cdot \nu(x)\}y = -\{m(x) \cdot \nu(x)\}g(y') \quad \text{on } \Gamma(x^0) \times (0, \infty) \tag{1.22}$$

where $\alpha > 0$.

The rest of the paper is divided in two parts. In § 2 we give and prove our main result concerning the system (1.3)-(1.6) in the case where $\operatorname{int} \Gamma_*(x^0) \neq \varnothing$. In § 3 we give some remarks and discuss some possible extensions of this result and, in particular, the case where $\operatorname{int} \Gamma_*(x^0) = \varnothing$.

2. The main result. The main result of this paper is as follows.

THEOREM 2.1. *Let Ω be a bounded domain of $\mathbf{R}^n$, $n \geqq 3$, with smooth boundary $\Gamma = \partial\Omega$. Assume that $x^0 \in \mathbf{R}^n$ is such that* $\operatorname{int} \Gamma_*(x^0) \neq \varnothing$. *Let g be a continuous nondecreasing function such that $g(0) = 0$ and that (1.20)-(1.21) are satisfied for some positive constants C_1, $C_2 > 0$ and some $p \geqq 1$. Then we have*:

(a) *If $p = 1$, there exist some constants $M > 1$, $\delta > 0$ such that*

$$E(t) \leqq ME(0) \exp\{-\delta t\} \quad \forall t \geqq 0 \tag{2.1}$$

for any solution of (1.3)-(1.6).

(b) *If $p > 1$, there exist some constants $M > 1$ and $\mu > 0$ (with μ depending on $E(0)$) such that*

$$E(t) \leqq ME(0)(1+\mu t)^{-2/(p-1)} \quad \forall t \geqq 0 \tag{2.2}$$

for any solution of (1.3)-(1.6).

Proof. The proof will be carried out in several steps.

Step 1. The well-posedness of the problem is standard. The methods of Brezis [2], Haraux [9], and Lions and Magenes [19] may be applied (see also [17] for the study of this problem) to obtain the following lemma.

LEMMA 2.2. *Let us assume that the hypotheses of Theorem* 2.1 *are satisfied. Then, for any initial data $\{y^0, y^1\} \in V \times L^2(\Omega)$ there exists a uniquely weak solution $y = y(x, t)$ of* (1.3)-(1.6) *such that*

$$y \in C(\mathbf{R}^+, V) \cap C^1(\mathbf{R}^+; L^2(\Omega)), \quad E(t) \leqq E(0) \quad \forall t \geqq 0. \tag{2.3}$$

In addition, the following properties are verified:

(i) *Stability. If $\{y^0, y^1\}$ are replaced by $\{\hat{y}^0, \hat{y}^1\}$, then the corresponding solution $\hat{y}$ is such that*

$$\begin{aligned} &\frac{1}{2}\int_\Omega \{|\nabla y(x,t) - \nabla \hat{y}(x,t)|^2 + |y'(x,t) - \hat{y}'(x,t)|^2\}\, dx \\ &\qquad \leqq \frac{1}{2}\int_\Omega \{|\nabla y^0(x) - \nabla \hat{y}^0(x)|^2 + |y^1(x) - \hat{y}^1(x)|^2\}\, dx \quad \forall t \geqq 0. \end{aligned} \tag{2.4}$$

(ii) *Regularity. If in addition we assume $\{y^0, y^1\} \in W$ where*

$$W = \left\{\{y^0, y^1\} \in V \times V : \Delta y^0 \in L^2(\Omega); \frac{\partial y^0}{\partial \nu} = -\{m \cdot \nu\} g(y^1) \text{ on } \Gamma(x^0)\right\}, \tag{2.5}$$

then we have

$$y \in W^{1,\infty}(\mathbf{R}^+; V); \Delta y \in L^\infty(\mathbf{R}^+; L^2(\Omega)), \tag{2.6}$$

$$\frac{dE(t)}{dt} = E'(t) = -\int_{\Gamma(x^0)} \{m(x) \cdot \nu(x)\} g(y'(x,t)) y'(x,t)\, d\Gamma \quad \forall t \geqq 0. \tag{2.7}$$

From the stability property (2.4) and the fact that the set W is dense in $V \times L^2(\Omega)$ it is enough to prove the estimates (2.1), (2.2) for initial data $\{y^0, y^1\} \in W$, provided the constant μ depends continuously on $E(0)$. Therefore, in what follows we will consider the initial data in in W.

Step 2. We denote by $(\cdot, \cdot)$ (respectively, $|\cdot|$) the scalar product (respectively, the norm) in $L^2(\Omega)$. We introduce the functional

$$\rho(t) = 2(y'(t), m \cdot \nabla y(t)) + (n-1)(y'(t), y(t)). \tag{2.8}$$

We note that

$$|\rho(t)| \leqq C_3 E(t) \tag{2.9}$$

with $C_3 = 2R + (n-1)\alpha$, $\alpha > 0$ being the best constant such that

$$|\psi|_{L^2(\Omega)} \leqq \alpha |\nabla \psi|_{L^2(\Omega)} \quad \forall \psi \in V$$

and $R = \|m(x)\|_{L^\infty(\Omega)}$.

To simplify the notation we will omit the variable x of the functions under the integral sign.

Let us now calculate the derivative of the functional $\rho(t)$. We have (see [11], [12] for the details):

$$\begin{aligned} \rho'(t) &= 2(\Delta y(t), m \cdot \nabla y(t)) - (n-1)|\nabla y(t)|^2 - |y'(t)|^2 \\ &\quad + \int_{\Gamma(x^0)} \left[(n-1) \frac{\partial y(t)}{\partial \nu} y(t) + \{m \cdot v\} |y'(t)|^2 \right] d\Gamma. \end{aligned} \tag{2.10}$$

To estimate the first term of the right-hand side of (2.10) we need the following lemma, which is a slight generalization of an inequality due to Grisvard [8].

LEMMA 2.3. *Under the hypotheses of Theorem* 2.1 *the following inequality holds*:

$$2(\Delta y, m \cdot \nabla y) \leqq (n-2)|\nabla y|^2 + R^2 \int_{\Gamma(x^0)} \{m \cdot \nu\} |v|^2 \, d\Gamma \tag{2.11}$$

for every function $y \in V$ *such that* $\Delta y \in L^2(\Omega)$ *and* $\partial y / \partial \nu = \{m \cdot v\}$ v *with* $v \in L^2(\Gamma(x^0))$.

Proof of Lemma 2.3. In [8] inequality (2.11) has been proved in the case where $v \equiv 0$. Subsequently, in [11] and [12] the following inequality has been proved for $v \in H^{1/2}(\Gamma(x^0))$:

$$2(\Delta y, m \cdot \nabla y) \leqq (n-2)|\nabla y|^2 + 2 \int_\Gamma \frac{\partial y}{\partial \nu} m \cdot \nabla y \, d\Gamma - \int_\Gamma \{m \cdot \nu\} |\nabla y|^2 \, d\Gamma. \tag{2.12}$$

From (2.12) inequality (2.11) may be easily deduced [11], [12]. Let us recall the proof for the sake of completeness. We have

$$\begin{aligned} 2 \int_\Gamma \frac{\partial y}{\partial \nu} m \cdot \nabla y \, d\Gamma - \int_\Gamma \{m \cdot \nu\} |\nabla y|^2 \, d\Gamma &= 2 \int_{\Gamma(x^0)} \frac{\partial y}{\partial \nu} m \cdot \nabla y \, d\Gamma - \int_{\Gamma(x^0)} \{m \cdot \nu\} |\nabla y|^2 \, d\Gamma \\ &\quad + \int_{\Gamma_*(x^0)} \{m \cdot \nu\} |\nabla y|^2 \, d\Gamma \\ &\leqq 2 \int_{\Gamma(x^0)} \frac{\partial y}{\partial \nu} m \cdot \nabla y \, d\Gamma - \int_{\Gamma(x^0)} \{m \cdot \nu\} |\nabla y|^2 \, d\Gamma \\ &\leqq R^2 \int_{\Gamma(x^0)} \frac{1}{\{m \cdot \nu\}} \left| \frac{\partial y}{\partial \nu} \right|^2 d\Gamma \end{aligned}$$

since $y = 0$, $m \cdot \nu \leqq 0$ on $\Gamma_*(x^0)$.

Therefore we have proved (2.11) for $v \in H^{1/2}(\Gamma(x^0))$. This inequality may now be extended for all $v \in L^2(\Gamma(x^0))$ by a standard density argument. □

Combining (2.10) and Lemma 2.3, we deduce

$$\begin{aligned} \rho'(t) \leqq -2E(t) + \int_{\Gamma(x^0)} \{m \cdot \nu\} [R^2 |g(y'(t))|^2 - (n-1) g(y'(t)) y(t) \\ + |y'(t)|^2] \, d\Gamma \quad \forall t \geqq 0 \end{aligned} \tag{2.13}$$

and taking into account that

$$(n-1)\left|\int_{\Gamma(x^0)}\{m\cdot\nu\}g(y'(t))y(t)\,d\Gamma\right|\leqq E(t)+\frac{\beta(n-1)^2}{2}\int_{\Gamma(x^0)}\{m\cdot\nu\}|g(y'(t))|^2\,d\Gamma$$

where $\beta>0$ is the best constant such that

$$\int_{\Gamma(x^0)}\{m\cdot\nu\}|\psi|^2\,d\Gamma\leqq\beta|\nabla\psi|^2\quad\forall\psi\in V$$

and by applying (1.10), we deduce that

$$\rho'(t)\leqq -E(t)+C_4\int_{\Gamma(x^0)}\{m\cdot\nu\}|y'(t)|^2\,d\Gamma\quad\forall t\geqq 0 \tag{2.14}$$

for $C_4=(R^2+(\beta(n-1)^2)/2)C_1^2+1$.

Therefore from (2.3), (2.9), and (2.14) we deduce that

$$\begin{aligned}\frac{d[(E(t))^{(p-1)/2}\rho(t)]}{dt}&=\frac{p-1}{2}(E(t))^{(p-3)/2}E'(t)\rho(t)+(E(t))^{(p-1)/2}\rho'(t)\\ &\leqq -C_5E'(t)-(E(t))^{(p+1)/2}\\ &\quad+C_4(E(t))^{(p-1)/2}\int_{\Gamma(x^0)}\{m\cdot\nu\}|y'(t)|^2\,d\Gamma\quad\forall t\geqq 0\end{aligned} \tag{2.15}$$

with $C_5=((p-1)/2)C_3(E(0))^{(p-1)/2}$.

For $\varepsilon>0$ we introduce the functional

$$E_\varepsilon(t)=(1+\varepsilon C_5)E(t)+\varepsilon[E(t)]^{(p-1)/2}\rho(t). \tag{2.16}$$

The energy $E(t)$ being nonincreasing, we deduce that

$$\tfrac{1}{2}[E_\varepsilon(t)]^{(p+1)/2}\leqq[E(t)]^{(p+1)/2}\leqq 2[E_\varepsilon(t)]^{(p+1)/2}\quad\forall t\geqq 0 \tag{2.17}$$

provided we choose $\varepsilon>0$ such that

$$\varepsilon[E(0)]^{(p-1)/2}\leqq\frac{2}{C_3}\min\left\{\frac{1}{p+1}(2^{2/(p+1)}-1),\frac{1}{|p-3|}\left(1-\frac{1}{2^{2/(p+1)}}\right)\right\}. \tag{2.18}$$

From (2.7), (2.15) we deduce that

$$\begin{aligned}E'_\varepsilon(t)&\leqq -\int_{\Gamma(x^0)}\{m\cdot\nu\}g(y'(t))y'(t)\,d\Gamma\\ &\quad-\varepsilon(E(t))^{(p+1)/2}+\varepsilon C_4(E(t))^{(p-1)/2}\int_{\Gamma(x^0)}\{m\cdot\nu\}|y'(t)|^2\,d\Gamma\quad\forall t\geqq 0.\end{aligned} \tag{2.19}$$

By applying (1.21), we get

$$\begin{aligned}&\varepsilon C_4(E(t))^{(p-1)/2}\int_{\Gamma(x^0)\cap[|y'(t)|\geqq 1]}\{m\cdot\nu\}|y'(t)|^2\,d\Gamma\\ &\leqq\int_{\Gamma(x^0)\cap[|y'(t)|\geqq 1]}\{m\cdot\nu\}g(y'(t))y'(t)\,d\Gamma\quad\forall t\geqq 0\end{aligned} \tag{2.20}$$

for $\varepsilon>0$ such that

$$\varepsilon(E(0))^{(p-1)/2}C_4\leqq C_2. \tag{2.21}$$

Combining (2.19) and (2.20), we obtain

$$E'_\varepsilon(t) \leqq -\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\} g(y'(t))y'(t)\,d\Gamma - \varepsilon(E(t))^{(p+1)/2} + \varepsilon C_4(E(t))^{(p-1)/2}\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\}|y'(t)|^2\,d\Gamma \quad \forall t\geqq 0. \tag{2.22}$$

Step 3. We now distinguish the cases $p=1$ and $p>1$.

(a) Case $p=1$. In this case (1.21), (2.17), (2.21), and (2.22) imply

$$E'_\varepsilon(t) \leqq -\varepsilon E(t) \leqq -\frac{\varepsilon}{2}E_\varepsilon(t) \quad \forall t\geqq 0. \tag{2.23}$$

Solving inequality (2.23), we obtain

$$E_\varepsilon(t) \leqq E_\varepsilon(0)\exp\left\{-\frac{\varepsilon}{2}t\right\} \quad \forall t\geqq 0,$$

which combined with (2.17) yields

$$E(t) \leqq 4E(0)\exp\left\{-\frac{\varepsilon}{2}t\right\} \quad \forall t\geqq 0.$$

Taking into account that in this case the restrictions (2.18), (2.21) do not depend on $E(0)$, we obtain (2.1) with $M=4$ and $\delta=\varepsilon/2$. In fact, (2.1) may be proved for any $M>1$ by taking $\delta>0$ smaller.

(b) Case $p>1$. We apply Young's inequality

$$[E(t)]^{(p-1)/2}\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\}|y'(t)|^2\,d\Gamma \leqq \lambda^{(p+1)/(p-1)}[E(t)]^{(p+1)/2} + \frac{1}{\lambda^{(p+1)/2}}\left(\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\}|y'(t)|^2\,d\Gamma\right)^{(p+1)/2}$$

valid for all $\lambda>0$ with $\lambda=(1/2C_4)^{(p-1)/(p+1)}$, obtaining

$$E'_\varepsilon(t) \leqq -\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\} g(y'(t))y'(t)\,d\Gamma - \frac{\varepsilon}{2}(E(t))^{(p+1)/2} + \varepsilon(2C_4)^{(p-1)/2}\left(\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\}|y'(t)|^2\,d\Gamma\right)^{(p+1)/2} \quad \forall t\geqq 0. \tag{2.24}$$

By applying Hölder's inequality, we deduce

$$\left(\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\}|y'(t)|^2\,d\Gamma\right)^{(p+1)/2} \leqq \left(\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\}\,d\Gamma\right)^{(p-1)/2}\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\}|y'(t)|^{p+1}\,d\Gamma \leqq \left(\int_{\Gamma(x^0)} \{m\cdot\nu\}\,d\Gamma\right)^{(p-1)/2}\int_{\Gamma(x^0)\cap[|y'(t)|\leqq 1]} \{m\cdot\nu\}|y'(t)|^{p+1}\,d\Gamma \quad \forall t\geqq 0,$$

which combined with (1.21), (2.24) for $\varepsilon>0$ small enough verifying

$$\varepsilon(2C_4)^{(p-1)/2}\left(\int_{\Gamma(x^0)} \{m\cdot\nu\}\,d\Gamma\right)^{(p-1)/2} \leqq C_2 \tag{2.25}$$

yields

$$E_\varepsilon'(t) \leqq -\frac{\varepsilon}{2}(E(t))^{(p+1)/2} \leqq -\frac{\varepsilon}{4}(E_\varepsilon(t))^{(p+1)/2} \quad \forall t \geqq 0. \tag{2.26}$$

Finally, solving inequality (2.26), we get

$$E_\varepsilon(t) \leqq E_\varepsilon(0)\left\{1+\frac{\varepsilon(p-1)}{8}[E_\varepsilon(0)]^{(p-1)/2}t\right\}^{-2/(p-1)} \quad \forall t \geqq 0$$

and then, from (2.17),

$$E(t) \leqq 4E(0)\left\{1+\frac{\varepsilon(p-1)}{2^{(4p+2)/p+1}}[E(0)]^{(p-1)/2}t\right\}^{-2/(p-1)} \quad \forall t \geqq 0. \tag{2.27}$$

The restrictions we have made on the choice of ε are (2.18), (2.21), (2.25), which show that, in (2.27), the quantity $\varepsilon[E(0)]^{(p-1)/2}$ may be chosen so that

$$\varepsilon[E(0)]^{(p-1)/2} = \min\,(C_6, C_7[E(0)]^{(p-1)/2}\}$$

for some positive constants C_6, C_7 that do not depend on $E(0)$. We see in particular, that the constant μ of (2.2) depends continuously on $E(0)$. The proof of Theorem 2.1 is now completed. □

Remark 2.4. The hypothesis $n \leqq 3$ has been implicitly used in the proof of Lemma 2.3 since we have applied Grisvard's inequality that has been proved only when $n \leqq 3$. We note that restriction $n \leqq 3$ is not needed when $\overline{\Gamma(x^0)} \cap \overline{\Gamma_*(x^0)} = \varnothing$. Indeed, in this case Lemma 2.3 may be easily proved for every n by applying Green's formula (see, for instance, [3], [13]).

Note also that the method proof of Theorem 2.1 is general and would apply to dimensions $n \geqq 4$ provided the natural generalization of Grisvard's inequality is proved. But it seems this has not been done.

Remark 2.5. The calculations leading to the estimates (2.1), (2.2) do not utilize the assumption that g is nondecreasing. Thus, these estimates also hold for every sufficiently smooth (to carry on the calculations above) solution of (1.3)-(1.6) even if g is not monotone. However, the stability property (2.4) is not satisfied unless g is nondecreasing and then estimates (2.1), (2.2) cannot be extended to weak solutions.

3. Further remarks.

3.1. The case where int $\Gamma_*(x^0) = \varnothing$. As has been pointed out in the Introduction, when int $\Gamma_*(x^0) = \varnothing$ (i.e., Ω is star-shaped with respect to x^0), the system (1.3)-(1.6) reduces to (1.3), (1.4), (1.6) and there exist nontrivial stationary solutions of it (every constant function is a solution). To obtain rates of decay on the $H^1(\Omega) \times L^2(\Omega)$-norm of solutions, we replace the boundary conditions (1.4), (1.5) by (1.22) with $\alpha > 0$. The energy associated to the system is then

$$E_\alpha(t) = \frac{1}{2}\int_\Omega \{|\nabla y(x,t)|^2 + |y'(x,t)|^2\}\,dx + \frac{\alpha}{2}\int_\Gamma \{m(x)\cdot\nu(x)\}|y(x,t)|^2\,d\Gamma. \tag{3.1}$$

We note that since $\alpha > 0$, $(E_\alpha(t))^{1/2}$ defines a norm in $V \times L^2(\Omega) = H^1(\Omega) \times L^2(\Omega)$ equivalent to the usual one. Then it is equivalent to obtain estimates for the rate of decay of $E_\alpha(t)$ or of the $H^1(\Omega) \times L^2(\Omega)$-norm.

We have the following result.

THEOREM 3.1. *Let Ω be a bounded domain of $\mathbf{R}^n$ with smooth boundary $\Gamma = \partial\Omega$ and star-shaped with respect to $x^0 \in \mathbf{R}^n$. Let g be a nondecreasing continuous function such that $g(0) = 0$ and that* (1.20)-(1.21) *are satisfied for some positive constants C_1,*

$C_2 > 0$ and some $p \geqq 1$. Then, if

$$\alpha \in \left(0, \frac{n}{2R^2}\right) \quad \text{with } R = \|x - x^0\|_{L^\infty(\Omega)} \tag{3.2}$$

the conclusions (2.1), (2.2) *of Theorem* 2.1 *hold for the energy $E_\alpha(t)$ defined in* (3.1) *for every solution of the system* (1.3), (1.6), (1.22).

Sketch of proof. First we note that the proof of Theorem 2.1 may also be done by choosing the following functional instead of $\rho(t)$:

$$\rho_\theta(t) = 2(y'(t), m \cdot \nabla y(t)) + \theta(y'(t), y(t)) \tag{3.3}$$

with $\theta \in (n-2, n)$.

Now let us fix $\theta \in (n-2, n)$ such that

$$\alpha < \frac{\theta}{2R^2} \tag{3.4}$$

(which is possible since (3.2) is satisfied) and calculate the derivative of the corresponding functional $\rho_\theta(t)$. By applying Lemma 2.3 we easily get

$$\begin{aligned}\rho_\theta'(t) &\leqq -(\theta - n + 2)|\nabla y(t)|^2 - (n-\theta)|y'(t)|^2 + \int_\Gamma \{m \cdot \nu\} \\ &\quad \times [2R^2|g(y'(t))|^2 - \theta g(y'(t))y(t) + |y'(t)|^2]\, d\Gamma - \alpha(\theta - 2R^2\alpha) \int_\Gamma \{m \cdot \nu\}|y(t)|^2\, d\Gamma \\ &\leqq -2\gamma E_\alpha(t) + \int_\Gamma \{m \cdot \nu\}[2R^2|g(y'(t))|^2 - \theta g(y'(t))y(t) + |y'(t)|^2]\, d\Gamma \quad \forall t \geqq 0\end{aligned}$$

with

$$\gamma = \min\{\theta - n + 2,\ n - \theta,\ \theta - 2R^2\alpha\}.$$

On the other hand, the energy $E_\alpha(t)$ is such that the identity (1.9) holds and the rest of the proof is analogous to that of Theorem 2.1. □

Remark 3.2. In the case where the function g is linear we know that the restriction (3.2) on α is unnecessary (see [21]). It would be interesting to study whether or not this hypothesis is necessary in the nonlinear framework.

Remark 3.3. The feedback law (1.22) with $\alpha > 0$ is more robust than (1.4) with respect to the perturbations of the support $\Gamma(x^0)$ of the boundary damping since the energy (3.1) is always coercive in the space $V \times L^2(\Omega)$ (see [22] for the study of these questions).

Remark 3.4. In the case where $\operatorname{int} \Gamma_*(x^0) \neq \varnothing$ and the boundary condition (1.22) is considered instead of (1.4) on $\Gamma(x^0)$, the conclusions of Theorem 2.1 remain valid provided $|\alpha|$ is sufficiently small. We note that, in this case, the restriction $\alpha > 0$ is not necessary but it is essential that $(E_\alpha(t))^{1/2}$ remains coercive in $V \times L^2(\Omega)$.

3.2. Nonhomogenous wave equation. Assume that $\operatorname{int} \Gamma_*(x^0) \neq \varnothing$ and let us consider the system

$$\begin{aligned} &y'' - \Delta y = h(x) && \text{in } \Omega \times (0, \infty), \\ &\frac{\partial y}{\partial v} = -\{m(x) \cdot \nu(x)\} g(y') && \text{on } \Gamma(x^0) \times (0, \infty), \\ &y = 0 && \text{on } \Gamma_*(x^0) \times (0, \infty), \\ &y(0) = y^0 \in V, \qquad y'(0) = y^1 \in L^2(\Omega) \end{aligned} \tag{3.5}$$

with $h(x) \in L^2(\Omega)$.

There exists a unique stationary solution $y^* \in V$ given by

$$
\begin{aligned}
&-\Delta y^* = h(x) && \text{in } \Omega, \\
&\frac{\partial y^*}{\partial \nu} = 0 && \text{on } \Gamma(x^0), \\
&y^* = 0 && \text{on } \Gamma_*(x^0).
\end{aligned} \tag{3.6}
$$

We observe that when $y = y(x, t)$ solves (3.5), then

$$z(x, t) = y(x, t) - y^*(x)$$

solves (1.3)-(1.5). Thus, Theorem 2.1 provides estimates on the rate of convergence in the space $V \times L^2(\Omega)$ of every solution of (3.5) to the unique rest point y^*. This remark remains valid in the situations considered in § 3.1 above.

It would be interesting to consider problems of type (3.5) with $h = h(x, t)$ periodic or almost-periodic functions (with respect to t) and to study, following [9], [10], and [23], the existence of periodic or almost-periodic solutions and to obtain estimates for the rate of decay of the energy of the difference of two solutions of the problem.

3.3. Semilinear wave equation. Let $f \in W^{1,\infty}_{\text{loc}}(\mathbf{R})$ be a locally Lipschitz continuous function and let us consider the semilinear wave equation

$$y'' - \Delta y + f(y) = 0 \quad \text{in } \Omega \times (0, \infty) \tag{3.7}$$

that we complete with the boundary and initial conditions (1.4)-(1.6) ((1.6), (1.22) when $\operatorname{int} \Gamma_*(x^0) = \varnothing$).

Let us assume that the nonlinear function f satisfies the following sign and growth assumptions:

$$f(s)s \geqq 0 \quad \forall s \in \mathbf{R}, \tag{3.8}$$

$$
\begin{aligned}
&\exists C > 0, \quad p > 1, \quad (n-2)p \leqq n: |f(s) - f(z)| \\
&\qquad \leqq C(1 + |s|^{p-1} + |z|^{p-1})|s - z| \quad \forall s, z \in \mathbf{R},
\end{aligned} \tag{3.9}
$$

$$\exists \delta > 0: f(s)s \geqq (2+\delta)F(s) \quad \forall s \in \mathbf{R} \quad \text{where } F(z) = \int_0^z f(s)\, ds. \tag{3.10}$$

The energy associated to the system is then (if $\alpha = 0$)

$$E(t) = \frac{1}{2} \int_\Omega \{|\nabla y(x, t)|^2 + |y'(x, t)|^2\}\, dx + \int_\Omega F(y(x, t))\, dx. \tag{3.11}$$

All the results of the preceding sections may be generalized (with minor modifications in the proofs) to obtain decay rates of type (2.1), (2.2) for the energy given by (3.11) (see [12] for a detailed proof in the case where g is linear).

3.4. More general partitions of the boundary. Let us return to system (1.3)-(1.6). In the case where g is linear it is well known that other partitions of the boundary (not necessarily of type $(\Gamma(x^0), \Gamma_*(x^0))$) give the exponential decay rate of the energy (see [1], [20] where very general results are proved by microlocal analysis techniques and [15] for a class of multipliers slightly larger than the radial one considered in this paper). It would be interesting to study whether, under those partitions, nonlinear feedback laws may be handled and decay rates of type (2.1), (2.2) obtained.

Acknowledgment. The author thanks Professor J. Lagnese for fruitful discussions and support.

A NEW PROOF OF THE LYAPUNOV CONVEXITY THEOREM*

FABIO TARDELLA†

Abstract. A new proof of the Lyapunov Theorem is given, based on the Shapley-Folkman Theorem, that does not require any tools of functional analysis.

Key words. vector-valued measures, Lyapunov Convexity Theorem, convex analysis, integrals of multifunctions

AMS(MOS) subject classifications. 28B05, 46G10

1. Introduction. The Lyapunov Theorem appeared for the first time in [14]. It states that a nonatomic measure that takes values in $\mathbf{R}^n$ has closed and convex range. Most of its applications are to be found in the theory of optimal control and calculus of variations (see, e.g., [2], [8], [9], [18]). However it has also been fruitfully used in other fields, such as economics [16] and differential equations [19].

Because of its importance, many proofs of the Lyapunov Theorem have been given (see [3]-[5], [10]-[13], [20]). Nevertheless, the proofs appearing in the literature are rather involved or employ sophisticated theorems from functional analysis, such as the Krein-Milman Theorem, or compactness theorems in infinite-dimensional spaces.

Our purpose is to give a short proof of the Lyapunov Theorem that does not digress from measure theory and convex analysis. In fact the burden of the proof is carried by the Shapley-Folkman Theorem, a result of convex analysis (discovered by two economists) whose applications have unfortunately been largely restricted to mathematical economics [1], [17]. See, however, Appendix 1 of [7] for an interesting application to duality in mathematical programming.

SHAPLEY-FOLKMAN THEOREM. *Consider a finite family* $[C_i]_{i\in I}$ *of subsets of* $\mathbf{R}^n$. *If*

$$x \in \operatorname{co} \sum_{i\in I} C_i,$$

then there exists a subset J *of* I, *of cardinality at most* n, *such that*

$$x \in \sum_{i\notin J} C_i + \operatorname{co} \sum_{i\in J} C_i.$$

Here co S *denotes the convex hull of a set* $S \subset \mathbf{R}^n$.

As Blackwell has noted [3], the convexity of the range of a nonatomic vector measure is only a special case of a more general fact, namely, the convexity of the integral of a vector-valued multifunction. Since no extra work is required, we prove the latter statement in Theorem 1. The remaining part of the Lyapunov Theorem, namely, closedness, is established in Theorem 2.

We finally remark that the nonatomicity assumption is not only sufficient but, in a sense, also necessary for a vector measure to have a convex range.

2. The Lyapunov Theorem. Let (T, Σ, μ) be a positive measure space. The measure μ is said to be nonatomic if for every $A \in \Sigma$ with $\mu(A) > 0$, there is $B \in \Sigma$, $B \subset A$, such

* Received by the editors September 1, 1988; accepted for publication April 25, 1989.

† Istituto di Elaborazione dell'Informazione, C.N.R., Via Santa Maria 46, 56100 Pisa, Italy. This paper was written while the author was on leave at the C.R.M., University of Montreal, Canada.

that $0<\mu(B)<\mu(A)$. Since Σ is a σ-algebra, the nonatomicity of μ is easily shown to be equivalent to the following "Darboux property" [6, p. 25]:

$$\forall \alpha \in [0,1], \forall A \in \Sigma, \exists B \in \Sigma, B \subset A, \quad \text{such that } \mu(B) = \alpha\mu(A).$$

A function that associates with every t in T a subset $F(t)$ of $\mathbf{R}^n$ is called a multifunction from T to $\mathbf{R}^n$. An integrable function from T to $\mathbf{R}^n$ such that, for almost every t, $f(t) \in F(t)$ is called an integrable selection of F. The integral of F over T, denoted $\int_T F$, is defined as the set of all points in $\mathbf{R}^n$ of the form $\int_T f(t)\, d\mu$, where f is an integrable selection of F.

THEOREM 1. *If μ is finite and nonatomic, we have*

$$\int_T F = \operatorname{co} \int_T F.$$

Proof. We will show that if x_1 and x_2 belong to $\int_T F$, then the whole segment joining x_1 and x_2 is contained in $\int_T F$. Let $x_1 = \int_T f_1(t)\, d\mu$ and $x_2 = \int_T f_2(t)\, d\mu$, where f_1 and f_2 are integrable selections of F. We consider the multifunction $G(t) = \{f_1(t), f_2(t)\} \subset F(t)$. Because of the nonatomicity of μ, we can find a family $\{A_i\}_{1 \leqq i \leqq 2n}$ of elements of Σ such that $A_i \cap A_j = \varnothing$ for $i \neq j$, $\bigcup_{i=1,2n} A_i = T$, and $\mu(A_i) = (2n)^{-1}\mu(T)$ for $1 \leqq i \leqq 2n$. Given a point

$$x \in \operatorname{co} \int_T G = \operatorname{co} \sum_{i=1}^{2n} \int_{A_i} G$$

the Shapley–Folkman Theorem allows us to find a set I of n indices between 1 and $2n$, such that

$$x \in \sum_{i \notin I} \int_{A_i} G + \operatorname{co} \sum_{i \in I} \int_{A_i} G.$$

The above relation is equivalent to

$$x \in \int_{S_1} G + \operatorname{co} \int_{T \setminus S_1} G$$

where we have set $S_1 = \bigcup_{i \notin I} A_i$. We can therefore assert the existence of two points $x_1 \in \int_{S_1} G$ and $z_1 \in \operatorname{co} \int_{T \setminus S_1} G$ such that

$$x = x_1 + z_1 \quad \text{and} \quad \mu(S_1) = \mu(T \setminus S_1) = 2^{-1}\mu(T).$$

The same argument can be iteratively repeated replacing T by $T \setminus S_1$, so that, by induction, at the mth step we obtain m measurable sets $\{S_i\}_{1 \leqq i \leqq m}$ and $m+1$ points $\{x_i\}_{1 \leqq i \leqq m}$ and z_m, with $x_i \in \int_{S_i} G$ and $z_m \in \operatorname{co} \int_{T \setminus \bigcup_{i=1}^m S_i} G$ such that

$$x = \sum_{i=1}^{m} x_i + z_m \quad \text{and} \quad \mu(S_i) = 2^{-i}\mu(T), \quad 1 \leqq i \leqq m.$$

Observe now that $z_m \to 0$, since $\mu(T \setminus \bigcup_{i=1}^m S_i) = 2^{-m}\mu(T) \to 0$. Therefore we have

$$x = \sum_{i=1}^{\infty} x_i \in \int_{\bigcup_{i=1}^{\infty} S_i} G = \int_T G,$$

with the equality between the integrals holding because $\mu(\bigcup_{i=1}^{\infty} S_i) = \mu(T)$. We have thus shown that $\int_T G$ is convex. To complete the proof it is now sufficient to note that $x_1, x_2 \in \int_T G \subset \int_T F$. □

Let $m=(\mu_1, \mu_2, \cdots, \mu_n)$, where the μ_i are finite signed measures on the measurable space (T, Σ). We say that m is nonatomic if the total variation $|\mu_i|$ of every μ_i is nonatomic.

Remark 1. An equivalent way of defining the nonatomicity of a measure is that of requiring that for every $A\in\Sigma$ there is a $B\subset A$, $B\in\Sigma$, such that $\mu(B)\neq 0$ and $\mu(B)\neq\mu(A)$. This definition can also be applied to the more general case of a measure taking its values in a topological vector space.

We will denote by

$$R(\Sigma)=\{m(A)\colon A\in\Sigma\}$$

the range of the vector measure m, with respect to Σ, and by

$$\Sigma_A=\{A\cap B\colon B\in\Sigma\}$$

the trace of the σ-algebra Σ on a set $A\in\Sigma$.

The dimension of a subset C of $\mathbf{R}^n$, denoted dim C, is defined as the dimension of the smallest affine suspace of $\mathbf{R}^n$ containing C.

THEOREM 2 (Lyapunov Theorem). *If m is nonatomic, $R(\Sigma)$ is closed and convex.*

Proof. The measures $\mu_1, \mu_2, \cdots, \mu_n$ are all absolutely continuous with respect to the nonatomic measure $\mu=|\mu_1|+|\mu_2|+\cdots+|\mu_n|$. Then, by the Radon-Nikodym Theorem, there is an integrable function f from T to $\mathbf{R}^n$ such that $m(A)=\int_A f(t)\,d\mu$ for every $A\in\Sigma$. Let us consider the multifunction $F(t)=\{0, f(t)\}$. It is easy to see that the integrable selections of F are of the form $f\cdot\chi_A$, where χ_A is the characteristic function of $A\in\Sigma$. We then have

$$R(\Sigma)=\int_T F$$

and hence $R(\Sigma)$ is convex by Theorem 1.

Observe now that $R(\Sigma)$ is trivially closed when dim $R(\Sigma)=0$. We assume that it is closed when dim $R(\Sigma)\leqq n-1$ and we will prove that the same thing is true when dim $R(\Sigma)=n$. Assume there is a point $y\in\operatorname{cl} R(\Sigma)\setminus R(\Sigma)$. Then by a standard separation argument, we can find $p\in\mathbf{R}^n$ such that

$$p\cdot y=\sup\{p\cdot x\colon x\in R(\Sigma)\}.$$

Let us consider the sets

$$R_k=\{t\in T\colon p\cdot f(t)<-1/k\},\quad S_k=\{t\in T\colon p\cdot f(t)\geqq -1/k\},\quad k=1,2,\cdots.$$

Obviously,

$$R_k\cap S_k=\varnothing\quad\text{and}\quad R_k\cup S_k=T,\quad k=1,2,\cdots.$$

Let $\{A_n\}$ be a sequence of sets in Σ such that $m(A_n)$ converges to y. We then have

$$\lim_{n\to\infty}\mu(A_n\cap R_k)=0,\qquad k=1,2,\cdots.$$

Hence, for every k, we have

$$y=\lim_{n\to\infty}m(A_n)=\lim_{n\to\infty}\left(\int_{A_n\cap S_k}f(t)\,dt+\int_{A_n\cap R_k}f(t)\,dt\right)=\lim_{n\to\infty}m(A_n\cap S_k).$$

We can then find an increasing function $\sigma\colon\mathbf{N}\to\mathbf{N}$ such that, setting $B_n=A_{\sigma(n)}\cap S_n$, we have

$$\lim_{n\to\infty}m(B_n)=y.$$

Observe now that the sets B_n can be partitioned as follows:

$$B_n = B_n^+ \cup B_n^0 \cup B_n^-$$

where $B_n^+ \subset P = \{t \in T: p \cdot f(t) > 0\}$, $B_n^0 \subset Z = \{t \in T: p \cdot f(t) = 0\}$ and $B_n^- \subset N = \{t \in T: p \cdot f(t) < 0\}$. Since $B_n^- \subset \{t \in T: -1/n \leqq p \cdot f(t) < 0\}$, we have $\lim_{n\to\infty} m(B_n^-) = 0$. Furthermore, $\lim_{n\to\infty} m(B_n^+) = m(P)$. Hence

$$y = m(P) + \lim_{n\to\infty} m(B_n^0)$$

so that $y \in m(P) + \text{cl } R(\Sigma_Z)$. The proof is easily completed observing that dim $R(\Sigma_Z) <$ dim $R(\Sigma)$, and thus $R(\Sigma_Z)$ is closed by the induction hypothesis. □

Remark 2. It has been shown by Halmos [12] that $R(\Sigma)$ is actually closed even without the assumption of nonatomicity of m.

It can be easily observed that the nonatomicity assumption on m implies not only the convexity of $R(\Sigma)$ but also the convexity of $R(\Sigma_A)$ for every $A \in \Sigma$. Conversely, taking into account Remark 1, it is clear that if $R(\Sigma_A)$ is convex for every $A \in \Sigma$, the measure m is nonatomic. These remarks are summarized in the following proposition.

PROPOSITION 3. *The measure m is nonatomic if and only if* $R(\Sigma_A)$ *is convex for every* $A \in \Sigma$.

NECESSARY AND SUFFICIENT CONDITIONS FOR LOCAL OPTIMALITY OF A PERIODIC PROCESS*

QINGHONG WANG† AND JASON L. SPEYER†

Abstract. The accessory minimization problem constructed from the second variation about a periodic extremal path with free period is investigated. Both necessary and sufficient conditions for a periodic path to be a weak local minimum are compactly established through a matrix inequality and the existence of a solution to the Riccati differential equation over the period. Extensions to the optimality conditions for the infinitely-repeated periodic processes are included. The existence of a real symmetric periodic solution to the Riccati differential equation is shown to be necessary for optimality, and this condition, plus some requirements on the eigenvalues of the monodromy matrix, imply sufficiency for optimality.

Key words. optimal control, periodic process, necessary and sufficient condition

AMS(MOS) subject classification. 49B10

1. Introduction. An autonomous optimal periodic control problem consists of minimizing an average cost subject to time-invariant dynamic equations and periodic boundary conditions [13]. In many interesting engineering systems, the solution to this problem is not a steady-state path, but rather a periodic path which gives best performance [9], [11]. In this paper, both necessary and sufficient conditions for weak, local optimality of a periodic path are developed, whereas only sufficiency was obtained in [3], [6], [13]. After formulating the problem in § 2, some second variation properties of the periodic control process are discussed. First, the accessory minimum problem is described in § 3. Then, a necessary condition is derived through the conjugate point condition related to a periodic process. It is shown in § 4 that this necessary condition is equivalent to the existence of a solution to the Riccati differential equation over a period. In § 5, by solving the accessory minimum problem, a necessary condition concerning the optimality, with respect to the period and the initial state, is established where a certain matrix is required to be positive semi-definite. In § 6, the results of previous sections are combined into a set of necessary and sufficient conditions. For sufficiency, the necessity of the nonnegativity of the matrix condition is strengthened to have certain positive definiteness properties. In this sense the difference between the necessary and sufficient conditions is minimal. However, the optimality of a single-period path does not imply that the repeated periodic path, which is obtained by repeating the orbit an arbitrary number of times, is also a minimum. If weak variations around these repeated orbits are considered, the necessary and sufficient conditions need to be strengthened. It is shown in § 7 that, as the number of repeated orbits becomes infinite, the existence of a periodic solution to the Riccati differential equation is necessary for optimality. Furthermore, sufficiency can be proved by requiring that the monodromy matrix has no eigenvalues on the unit circle except for a pair of unit eigenvalues coupled in the same Jordan box. A set of necessary and sufficient conditions for local optimality of an infinitely-repeated periodic process is summarized in § 8. These conditions somewhat weaken the sufficient conditions given in [13] and establish a close relationship between necessary and sufficient conditions. Conclusions are given in § 9.

2. Formulation of the optimal periodic control problem. In this section, the problem of periodic control is formulated and the first-order necessary conditions for optimality are stated.

The optimal periodic control problem consists of minimizing the performance criterion

$$J(u(\cdot), x(0), \tau) = \frac{1}{\tau}\int_0^\tau L(x(t), u(t))\, dt \tag{1}$$

with respect to the period $\tau \in T = (0, \infty)$, the p-vector control function $u(\cdot) \in U = \{u(\cdot): T \to R^p$, piecewise continuous$\}$, and the initial condition of the state variable $x(0) \in R^n$, subject to the time-invariant dynamic constraint

$$\dot{x}(t) = f(x(t), u(t)) \tag{2}$$

and the periodic boundary condition

$$x(\tau) = x(0). \tag{3}$$

It is assumed that τ is the time when the periodic boundary condition is first met. The equilibrium solution, for which the second variational theory of [1], [2] applies, is excluded, and the problem where the periodic boundary conditions are met repeatedly is analyzed in § 7.

The following assumption is made on the problem described in (1) to (3).

Assumption 1. $f(\cdot, \cdot)$ and $L(\cdot, \cdot)$ and their derivatives through second order are continuous with respect to both arguments.

Let $\lambda_0 \in R$ and $\lambda(\cdot): T \to R^n$ be the Lagrange multipliers corresponding to the cost criterion (1) and the dynamics (2), and let H^* be the variational Hamiltonian defined as

$$H^*(x(t), u(t), \lambda(t), \lambda_0) = \lambda_0 L(x(t), u(t)) + \lambda^T(t) f(x(t), u(t)). \tag{4}$$

The minimum principle for an optimal periodic control process is given by the following first-order necessary condition [8].

PROPOSITION 1. *A necessary condition for* $(\tilde{u}(\cdot), \tilde{x}(0), \tau) \in U_{\text{int}} \times R^n \times T$ *being optimal for the problem described in* (1)-(3) *is that there exist Lagrange multipliers* $\lambda_0 \geqq 0$ *and* λ, *not vanishing simultaneously, such that*

$$\dot{\tilde{x}} = f(\tilde{x}, \tilde{u}), \quad \dot{\lambda} = -H_x^{*T}(\tilde{x}, \tilde{u}, \lambda, \lambda_0), \quad 0 = H_u^*(\tilde{x}, \tilde{u}, \lambda, \lambda_0) \tag{5}$$

and

$$\tilde{x}(\tau) = \tilde{x}(0), \quad \lambda(\tau) = \lambda(0), \quad H^*(\tilde{x}(\tau), \tilde{u}(\tau), \lambda(\tau), \lambda_0) = \lambda_0 J(\tilde{u}(\cdot), \tilde{x}(0), \tau) \tag{6}$$

where U_{int} *denotes the interior of the set* U.

Note that subscripts with respect to x and u denote partial differentiations. The explicit arguments of the functions will be dropped when the presentation appears clear. The existence of $(\tilde{u}(\cdot), \tilde{x}(0), \tau) \in U_{\text{int}} \times R^n \times T$ satisfying (5) and (6) is assumed, and the pair $(\tilde{x}(t), \tilde{u}(t))$ is called an extremal of the problem.

Assumption 2. $(\tilde{x}(t), \tilde{u}(t))$ is normal [15], and λ_0 is normalized to unity, i.e., $\lambda_0 = 1$.

The variational Hamiltonian associated with $\lambda_0 = 1$ is defined as

$$H(x(t), u(t), \lambda(t)) \triangleq H^*(x(t), u(t), \lambda(t), 1) \tag{7}$$

and the augmented performance criterion $\bar{J}$ is

$$\bar{J}(u(\cdot), x(0), \tau) = \frac{1}{\tau}\int_0^\tau [H(x, u, \lambda) - \lambda^T \dot{x}]\, dt. \tag{8}$$

The following assumptions on the extremal solutions obtained from (5) and (6) are required for our consideration of the weak second variation.

Assumption 3. The strong form of the Legendre-Clebsch condition, $H_{uu} > 0$, is satisfied along the extremal path.

Assumption 4. (f_x, f_u) is completely controllable along the extremal path.

Remark. Assumption 4 implies Assumption 2 and strong normality as defined in [15].

The following definitions are given in order to simplify the notation:

$$\tilde{f}(t) \triangleq f(\tilde{x}(t), \tilde{u}(t)) \tag{9}$$

$$\tilde{H}(t) \triangleq H(\tilde{x}(t), \tilde{u}(t), \lambda(t)). \tag{10}$$

Similarly, $\tilde{H}_x(t)$, $\tilde{H}_u(t)$, $\tilde{f}_x(t)$, $\tilde{H}_{xx}(t)$, $\tilde{H}_{uu}(t)$, $\tilde{H}_{xu}(t)$, and $\tilde{H}_{ux}(t)$ are partial derivatives of $f(x, u)$ and $H(x, u, \lambda)$ evaluated on the nominal path. For example $\tilde{H}_x(t)$ is defined as

$$\tilde{H}_x(t) \triangleq H_x(\tilde{x}(t), \tilde{u}(t), \lambda(t)). \tag{11}$$

3. Second variation and the accessory minimum problem. The second variational cost associated with perturbations away from an extremal path is derived in [13] as

$$\begin{aligned} d^2\bar{J} = \frac{1}{\tau}\Bigg\{ & [\delta x^T(0) \quad d\tau] \begin{bmatrix} 0 & \tilde{H}_x^T \\ \tilde{H}_x & -\tilde{H}_x\tilde{f} \end{bmatrix}_{t=0} \begin{bmatrix} \delta x(0) \\ d\tau \end{bmatrix} \\ & + \int_0^\tau [\delta x^T \quad \delta u^T] \begin{bmatrix} \tilde{H}_{xx} & \tilde{H}_{xu} \\ \tilde{H}_{ux} & \tilde{H}_{uu} \end{bmatrix} \begin{bmatrix} \delta x \\ \delta u \end{bmatrix} dt \Bigg\} \end{aligned} \tag{12}$$

where $\delta x(t) \triangleq x(t) - \tilde{x}(t)$, $\delta u(t) \triangleq u(t) - \tilde{u}(t)$. The norms of δx and δu are defined as $\|\delta x\| = \max_{t\in[0,T]} (\sum_{i=1}^n (\delta x_i(t))^2)^{1/2}$ and $\|\delta u\| = \max_{t\in[0,T]} (\sum_{i=1}^p (\delta u_i(t))^2)^{1/2}$. Assume that $\|\delta x\|$, $\|\delta u\|$, and $|d\tau|$ are sufficiently small so that the dynamics of the system can be approximated by the linearized differential equation

$$\delta\dot{x} = \tilde{f}_x \delta x + \tilde{f}_u \delta u, \tag{13}$$

and the linearized periodic boundary condition

$$\delta x(\tau) = \delta x(0) - \tilde{f}(\tau)\, d\tau. \tag{14}$$

In the accessory minimum problem, the quadratic cost (12) is minimized subject to the variational constraints (13) and (14). Let $\delta\lambda$ be the Lagrange multiplier associated with the dynamic equation (13), then $\bar{H}$ is the variational Hamiltonian associated with the accessory minimum problem defined as

$$\bar{H} = \frac{1}{2}[\delta x^T \quad \delta u^T] \begin{bmatrix} \tilde{H}_{xx} & \tilde{H}_{xu} \\ \tilde{H}_{ux} & \tilde{H}_{uu} \end{bmatrix} \begin{bmatrix} \delta x \\ \delta u \end{bmatrix} + \delta\lambda^T[\tilde{f}_x \delta x + \tilde{f}_u \delta u]. \tag{15}$$

The first-order necessary conditions, or Euler-Lagrange equations, are

$$0 = \tilde{H}_{ux}\delta x + \tilde{H}_{uu}\delta u + \tilde{f}_u^T \delta\lambda \tag{16}$$

$$\delta\dot{\lambda} = -\tilde{H}_{xx}\delta x - \tilde{H}_{xu}\delta u - \tilde{f}_x^T \delta\lambda. \tag{17}$$

Since $\tilde{H}_{uu} > 0$ by Assumption 3, δu can be solved from (16) in terms of δx and $\delta\lambda$ as

$$\delta u = -\tilde{H}_{uu}^{-1}(\tilde{H}_{ux}\delta x + \tilde{f}_u^T \delta\lambda). \tag{18}$$

By substituting δu of (18) into (13) and (17), the Hamiltonian system of differential equations is obtained as

$$\begin{bmatrix} \delta\dot{x} \\ \delta\dot{\lambda} \end{bmatrix} = \begin{bmatrix} A(t) & -B(t) \\ -C(t) & -A^T(t) \end{bmatrix} \begin{bmatrix} \delta x \\ \delta\lambda \end{bmatrix} \tag{19}$$

where

$$A(t) = \tilde{f}_x(t) - \tilde{f}_u(t)\tilde{H}_{uu}^{-1}(t)\tilde{H}_{ux}(t) \tag{20}$$

$$B(t) = \tilde{f}_u(t)\tilde{H}_{uu}^{-1}(t)\tilde{f}_u^T(t) \tag{21}$$

$$C(t) = \tilde{H}_{xx}(t) - \tilde{H}_{xu}(t)\tilde{H}_{uu}^{-1}(t)\tilde{H}_{ux}(t). \tag{22}$$

The state transition matrix associated with (19) is

$$\phi(t, 0) \triangleq \begin{bmatrix} \phi_{11}(t, 0) & \phi_{12}(t, 0) \\ \phi_{21}(t, 0) & \phi_{22}(t, 0) \end{bmatrix},$$

where $\phi_{ij}(t, 0)$, $i, j = 1, 2$, are $n \times n$ matrices which are partitioned blocks of $\phi(t, 0)$. $\phi(t, 0)$ is propagated by

$$\dot{\phi}(t, 0) = \begin{bmatrix} A(t) & -B(t) \\ -C(t) & -A^T(t) \end{bmatrix} \phi(t, 0), \qquad \phi(0, 0) = I. \tag{23}$$

In the next two sections, the positivity of the second variation with respect to δu, $\delta x(0)$, and $d\tau$ is discussed. The optimality of δu for the accessory minimum problem obtained from (18) is discussed through a conjugate point condition, and then the accessory minimum problem with respect to $\delta x(0)$ and $d\tau$ is considered. Note that the starting point on the path for a periodic process is irrelevant. If the starting point is indexed by t_0, then $t_0 = 0$ in the above formulation can be replaced by any $t_0 \in [0, \tau)$, and the time interval $[0, \tau]$ can be replaced by $[t_0, t_0 + \tau]$.

4. Conjugate point condition of a periodic path. The conjugate point of an extremal path is related to the existence of a nonzero solution to (19) with the zero variations in the initial state and final constraint [4], [10], [15]. If this occurs, a conjugate path can be found which has the same cost as the extremal path. Since the starting point on a periodic path is not unique, the initial and final state variations can be simply written as $\delta x(t_0) = 0$ and $\delta x(t_0 + \tau) = 0$. The conjugate point of a periodic path can be characterized by the property described below.

DEFINITION. t' and t'' are mutually conjugate if there exists a nontrivial solution to (19) on $[t', t'']$ such that $\delta x(t') = \delta x(t'') = 0$, and $\delta x(t) \neq 0$ on $t \in (t', t'')$, where $t' < t'' \leqq t' + \tau$ [10].

By using the state transition matrix defined in (23), $\delta x(t')$ and $\delta x(t'')$ are related by

$$\delta x(t'') = \phi_{11}(t'', t')\delta x(t') + \phi_{12}(t'', t')\delta\lambda(t'). \tag{24}$$

A nontrivial solution exists for $\delta x(t') = \delta x(t'') = 0$ if and only if $\phi_{12}(t'', t')$ is not invertible. Therefore, if $\phi_{12}(t'', t')$ is not invertible, t' and t'' are mutually conjugate. For convenience, let $t' = t_0$ be named as the starting time and $t'' = t_c$ be named as the conjugate time. It will be shown that if there exists a conjugate time $t_c \in (t_0, t_0 + \tau]$, the extremal periodic path is not a minimum. The method to be used is to compare the second variational cost of the conjugate path and that of some nonextremal path. In order to do that, some assumptions are made.

Assumption 5. $\mathcal{N}[\phi_{12}(t_c, t_0)] \cap \mathcal{N}[B^{1/2}(t_c)\phi_{22}(t_c, t_0)] = \{0\}$, where $\mathcal{N}[\cdot]$ represents the null-space of the matrix.

Assumption 6. $\mathcal{N}[\phi_{12}(t_0+\tau, t_0)] \cap \mathcal{N}[B^{1/2}(t_0)(I-\phi_{22}(t_0+\tau, t_0))] = \{0\}$.

Assumption 5 implies that the velocity of the extremal path and the velocity of the conjugate path are different at the conjugate time t_c. Assumption 6 implies that if the conjugate time is at the end of the period, i.e., $t_c = t_0+\tau$, the velocity of the conjugate path at the initial time t_0 is different from the velocity of the conjugate path at the conjugate time $t_0+\tau$. In the following discussion, the initial state variation $\delta x(t_0)$ is assumed to be zero, and the variation of the period $d\tau$ is assumed to be zero as well. The optimality with respect to the variation in the initial state and the period will be discussed in the next section.

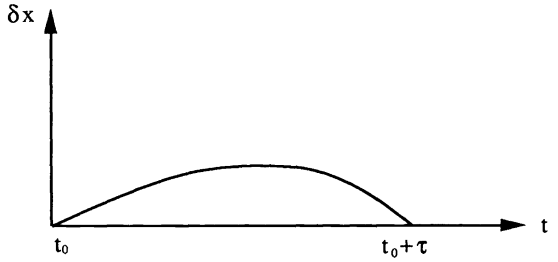
PROPOSITION 2. *If $\phi_{12}(t_c, t_0)$ is not invertible for some $t_c \in (t_0, t_0+\tau]$, then the extremal periodic path is not a minimum.*

Proof. The nonoptimality of the second variation due to a conjugate time $t_c < t_0+\tau$ has been proved elsewhere [4], [15, Thm. 3.1]. Although the case $t_c = t_0+\tau$ is usually excluded, for the periodic control problem, t_0 and t_c can correspond to the same point on the periodic path. By taking advantage of the closure of the path, some δu can be found to make the second variation negative. Let $\delta x(t_0) = 0$ and $\delta\lambda(t_0) = \beta$, where β is a nonzero vector in the null-space of $\phi_{12}(t_0+\tau, t_0)$. Define Path 1 and Path 2 in Fig. 1 to be the paths generated by $\delta u(t) = \delta u^1(t)$ and $\delta u(t) = \delta u^2(t)$, respectively, where

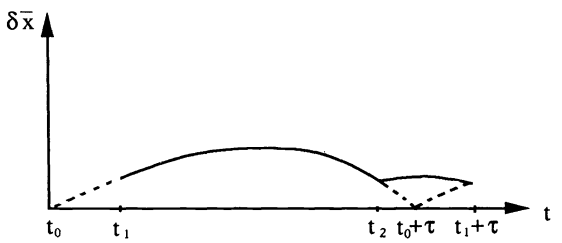
$$\delta u^1(t) = -\tilde{H}_{uu}^{-1}(\tilde{H}_{ux}\delta x + \tilde{f}_u^T \delta\lambda) \qquad t_0 \leqq t < t_0+\tau \tag{25}$$

$$\delta u^2(t) = \begin{cases} -\tilde{H}_{uu}^{-1}(\tilde{H}_{ux}\delta\bar{x} + \tilde{f}_u^T \delta\bar{\lambda}) & t_1 \leqq t \leqq t_2 \\ \text{extremal from} & \\ \delta\bar{x}(t_2) = \delta x(t_2) \text{ to } \delta\bar{x}(t_1+\tau) = \delta x(t_1) & t_2 < t < t_1+\tau \end{cases} \tag{26}$$

where $t_1 = t_0+\varepsilon_1$, $t_2 = t_0+\tau-\varepsilon_2$, and ε_1 and ε_2 are small positive numbers. Path 1 corresponds to the variation of the conjugate path, and Path 2 corresponds to the variation of the nonextremal path.



Path 1: Conjugate Path



Path 2: Nonextremal Path

FIG. 1. *Conjugate path and nonextremal path for $t_c = t_0+\tau$.*

If $\delta x(t)$ and $\delta\lambda(t)$ is a continuous solution of (19) on the interval (t_i, t_j), then by adding the zero term

$$
\begin{aligned}
0 &= -\int_{t_i}^{t_j} \delta\lambda^T[\delta\dot{x} - A(t)\delta x + B(t)\delta\lambda]\,dt \\
&= \delta\lambda^T(t_i)\delta x(t_i) - \delta\lambda^T(t_j)\delta x(t_j) \\
&\quad + \int_{t_i}^{t_j} [\delta\dot{\lambda}^T\delta x + \delta\lambda^T A(t)\delta x - \delta\lambda^T B(t)\delta\lambda]\,dt
\end{aligned} \tag{27}
$$

to the integral term

$$
\int_{t_i}^{t_j} [\delta x^T \quad \delta u^T]\begin{bmatrix} \tilde{H}_{xx} & \tilde{H}_{xu} \\ \tilde{H}_{ux} & \tilde{H}_{uu} \end{bmatrix}\begin{bmatrix} \delta x \\ \delta u \end{bmatrix} dt,
$$

and by substituting δu of (18) into the formulation, the following is obtained:

$$
\int_{t_i}^{t_j} [\delta x^T \quad \delta u^T]\begin{bmatrix} \tilde{H}_{xx} & \tilde{H}_{xu} \\ \tilde{H}_{ux} & \tilde{H}_{uu} \end{bmatrix}\begin{bmatrix} \delta x \\ \delta u \end{bmatrix} dt = \delta x^T(t_i)\delta\lambda(t_i) - \delta x^T(t_j)\delta\lambda(t_j). \tag{28}
$$

Let $J^k(t_i, t_j)$ be the second variational cost of the kth path on the interval (t_i, t_j). The cost of Path 1 is then

$$
J^1(t_0, t_0+\tau) = \frac{1}{\tau}\{\delta x^T(t_0)\delta\lambda(t_0) - \delta x^T(t_0+\tau)\delta\lambda(t_0+\tau)\} = 0. \tag{29}
$$

Our objective is to show that $J^2(t_1, t_1+\tau) < J^1(t_0, t_0+\tau)$. However, only $J^2(t_2, t_1+\tau) < J^1(t_0, t_1) + J^1(t_2, t_0+\tau)$ needs to be shown. $\delta x(t_i)$ and $\delta\lambda(t_i)$, $i = 1, 2$, can be written as

$$
\delta x(t_1) = \phi_{12}(t_1, t_0)\beta = -\varepsilon_1 B(t_0)\beta + o(\varepsilon_1) \tag{30}
$$

$$
\delta\lambda(t_1) = \phi_{22}(t_1, t_0)\beta = [I - \varepsilon_1 A^T(t_0)]\beta + o(\varepsilon_1) \tag{31}
$$

$$
\delta x(t_2) = \phi_{12}(t_2, t_0)\beta = \varepsilon_2 B(t_0)\phi_{22}(t_0+\tau, t_0)\beta + o(\varepsilon_2) \tag{32}
$$

$$
\delta\lambda(t_2) = \phi_{22}(t_2, t_0)\beta = [I + \varepsilon_2 A^T(t_0)]\phi_{22}(t_0+\tau, t_0)\beta + o(\varepsilon_2). \tag{33}
$$

By using (28) along with (30) to (33),

$$
\begin{aligned}
J^1(t_0, t_1) + J^1(t_2, t_0+\tau) &= \frac{1}{\tau}[-\delta x^T(t_1)\delta\lambda(t_1) + \delta x^T(t_2)\delta\lambda(t_2)] \\
&= \frac{1}{\tau}\beta^T[\varepsilon_1 B(t_0) + \varepsilon_2\phi_{22}^T(t_0+\tau, t_0)B(t_0)\phi_{22}(t_0+\tau, t_0)]\beta \\
&\quad + o(\varepsilon_1+\varepsilon_2).
\end{aligned} \tag{34}
$$

By using $\delta\bar{x}(t_2) = \delta x(t_2)$ and $\delta\bar{x}(t_1+\tau) = \delta x(t_1)$, the following can be obtained:

$$
\delta\bar{x}(t_2) = \delta x(t_2) = \varepsilon_2 B(t_0)\phi_{22}(t_0+\tau, t_0)\beta + o(\varepsilon_2) \tag{35}
$$

$$
\delta\bar{x}(t_1+\tau) = \delta x(t_1) = -\varepsilon_1 B(t_0)\beta + o(\varepsilon_1) \tag{36}
$$

$$
\begin{aligned}
\delta\bar{\lambda}(t_1+\tau) &= \phi_{21}(t_1+\tau, t_2)\delta\bar{x}(t_2) + \phi_{22}(t_1+\tau, t_2)\delta\bar{\lambda}(t_2) \\
&= -(\varepsilon_1+\varepsilon_2)C(t_0)\delta\bar{x}(t_2) + [I - (\varepsilon_1+\varepsilon_2)A^T(t_0)]\delta\bar{\lambda}(t_2) + o(\varepsilon_1+\varepsilon_2).
\end{aligned} \tag{37}
$$

$J^2(t_2, t_1+\tau)$ then can be written as

$$
\begin{aligned}
J^2(t_2, t_1+\tau) &= \frac{1}{\tau}[\delta\bar{x}^T(t_2)\delta\bar{\lambda}(t_2) - \delta\bar{x}^T(t_1+\tau)\delta\bar{\lambda}(t_1+\tau)] \\
&= \frac{1}{\tau}\beta^T[\varepsilon_2\phi_{22}^T(t_0+\tau, t_0)B(t_0)\delta\bar{\lambda}(t_2) + \varepsilon_1 B(t_0)\delta\bar{\lambda}(t_2)] + o(\varepsilon_1+\varepsilon_2).
\end{aligned} \tag{38}
$$

Since

$$\begin{aligned}\delta\bar{x}(t_1+\tau) &= \phi_{11}(t_1+\tau, t_2)\delta\bar{x}(t_2)+\phi_{12}(t_1+\tau, t_2)\delta\bar{\lambda}(t_2)\\ &= [I+(\varepsilon_1+\varepsilon_2)A(t_0)]\delta\bar{x}(t_2)-(\varepsilon_1+\varepsilon_2)B(t_0)\delta\bar{\lambda}(t_2)+o(\varepsilon_1+\varepsilon_2),\end{aligned} \tag{39}$$

by combining (35), (36), and (39),

$$(\varepsilon_1+\varepsilon_2)B(t_0)\delta\bar{\lambda}(t_2) = \varepsilon_2 B(t_0)\phi_{22}(t_0+\tau, t_0)\beta+\varepsilon_1 B(t_0)\beta+o(\varepsilon_1+\varepsilon_2). \tag{40}$$

Equation (38) becomes

$$\begin{aligned}J^2(t_2, t_1+\tau) &= \frac{1}{\tau}\frac{\varepsilon_2^2}{\varepsilon_1+\varepsilon_2}\beta^T\phi_{22}^T(t_0+\tau, t_0)B(t_0)\phi_{22}(t_0+\tau, t_0)\beta\\ &\quad+\frac{1}{\tau}\frac{1}{\varepsilon_1+\varepsilon_2}\beta^T[2\varepsilon_1\varepsilon_2 B(t_0)\phi_{22}(t_0+\tau, t_0)+\varepsilon_1^2 B(t_0)]\beta\\ &\quad+o(\varepsilon_1+\varepsilon_2).\end{aligned} \tag{41}$$

From Assumption 5, the first-order terms in (34) and (41) are nonzero. When ε_1 and ε_2 are small enough, the higher-order terms are ignored.

Define

$$\zeta = B^{1/2}(t_0)\beta, \qquad \eta = B^{1/2}(t_0)\phi_{22}(t_0+\tau, t_0)\beta. \tag{42}$$

Equations (34) and (41) can be written as

$$J^1(t_0, t_1)+J^1(t_2, t_0+\tau) = \frac{1}{\tau}(\varepsilon_2\eta^T\eta+\varepsilon_1\zeta^T\zeta) \tag{43}$$

$$J^2(t_2, t_1+\tau) = \frac{1}{\tau}\frac{1}{\varepsilon_1+\varepsilon_2}(\varepsilon_2^2\eta^T\eta+2\varepsilon_1\varepsilon_2\eta^T\zeta+\varepsilon_1^2\zeta^T\zeta). \tag{44}$$

From Assumption 6, $\zeta \neq \eta$. Therefore,

$$\eta^T\eta+\zeta^T\zeta > 2\eta^T\zeta \tag{45}$$

and

$$\begin{aligned}J^1(t_0, t_1)+J^1(t_2, t_0+\tau) &= \frac{1}{\tau}\frac{1}{\varepsilon_1+\varepsilon_2}(\varepsilon_1+\varepsilon_2)(\varepsilon_2\eta^T\eta+\varepsilon_1\zeta^T\zeta)\\ &= \frac{1}{\tau}\frac{1}{\varepsilon_1+\varepsilon_2}[\varepsilon_2^2\eta^T\eta+\varepsilon_1\varepsilon_2(\eta^T\eta+\zeta^T\zeta)+\varepsilon_1^2\zeta^T\zeta]\\ &> \frac{1}{\tau}\frac{1}{\varepsilon_1+\varepsilon_2}[\varepsilon_2^2\eta^T\eta+2\varepsilon_1\varepsilon_2\eta^T\zeta+\varepsilon_1^2\zeta^T\zeta]\\ &= J^2(t_2, t_1+\tau).\end{aligned} \tag{46}$$

This implies that the cost of the nonextremal path is less than the cost of the conjugate path. Therefore, the extremal periodic path is not a minimum. □

The existence of a conjugate point is closely related to the existence of a solution to the Riccati differential equation

$$\dot{P}(t) = -P(t)A(t)-A^T(t)P(t)+P(t)B(t)P(t)-C(t). \tag{47}$$

The following proposition establishes the relationship between these two.

PROPOSITION 3. *Given Assumptions* 1-4, *the necessary and sufficient condition for the absence of a point* $t_c \in (t_0, t_0+\tau]$ *conjugate to* t_0 *is that there exists a continuous real symmetric solution to the Riccati differential equation* (47) *on* $t \in [t_0, t_0+\tau]$.

Proof. For the proof, see the proof of Theorem 7.1 of [10].

COROLLARY 1. *A necessary condition for a periodic path to be a minimum is that there exists a continuous real symmetric solution* $P(t)$ *to the Riccati differential equation* (47) *on* $t \in [t_0, t_0+\tau]$.

COROLLARY 2. *If for every* $t_0 \in [0, \tau)$ *there exists a continuous real symmetric solution* $P(t)$ *to the Riccati differential equation* (47) *on the interval* $t \in [t_0, t_0+\tau]$, *then there are no mutual conjugate points along the extremal single-period path.*

Corollary 1 and Corollary 2 are immediate results of Propositions 2 and 3.

5. A local optimality condition for the initial state and period. If there is no conjugate point along the extremal path (see § 4), the solution to the accessory minimum problem can be determined for a given $\delta x(0)$ and $d\tau$ [5]. Define the quadratic cost $d^2\bar{J}^*(\delta x(0), d\tau)$ to be $\min_{\delta u(\cdot)} d^2\bar{J}$. Then, $d^2\bar{J}^*(\delta x(0), d\tau)$ is the solution to the accessory minimum problem calculated by finding a control $\delta u(\cdot)$ satisfying (13) and (14) which minimizes the second variational cost $d^2\bar{J}$. $d^2\bar{J}^*(\delta x(0), d\tau) \geqq 0$ is a necessary condition for optimality. Otherwise there exists a periodic path with period $\tau + d\tau$ and initial state $\tilde{x}(0) + \delta x(0)$ which gives less cost.

By defining the matrix $\bar{M}$ as

$$\bar{M}(0,\tau) = \begin{bmatrix} \phi_{12}^{-1}(I-\phi_{11}) + \phi_{12}^{-T}(I-\phi_{22}^{T}) & \tilde{H}_x^T + (\phi_{22}-I)\phi_{12}^{-1}\tilde{f} \\ \tilde{H}_x + \tilde{f}^T\phi_{12}^{-T}(\phi_{22}^T - I) & -\tilde{H}_x\tilde{f} - \tilde{f}^T\phi_{22}\phi_{12}^{-1}\tilde{f} \end{bmatrix}_{t=\tau} \tag{48}$$

where ϕ_{ij}, $i,j = 1, 2$, are partitioned blocks of $\phi(\tau, 0)$, and $\tilde{H}_x$ and $\tilde{f}$ are evaluated at $t = \tau$, a necessary condition for the optimality of a periodic process is stated below.

PROPOSITION 4. *Given that* $\phi_{12}(\tau, 0)$ *is invertible, a necessary condition for the periodic path to be a weak local minimum is* $\bar{M}(0, \tau)$ *being positive semi-definite.*

Proof. By using (28) in (12), $d^2\bar{J}^*(\delta x(0), d\tau)$ can be written as

$$\begin{aligned} d^2\bar{J}^*(\delta x(0), d\tau) = \frac{1}{\tau}\Bigg\{ & [\delta x^T(0) \quad d\tau] \begin{bmatrix} 0 & \tilde{H}_x^T \\ \tilde{H}_x & -\tilde{H}_x\tilde{f} \end{bmatrix}_{t=0} \begin{bmatrix} \delta x(0) \\ d\tau \end{bmatrix} \\ & + \delta\lambda^T(0)\delta x(0) - \delta\lambda^T(\tau)\delta x(\tau) \Bigg\}. \end{aligned} \tag{49}$$

To relate $\delta\lambda(0)$ and $\delta\lambda(\tau)$ to the given perturbations $\delta x(0)$ and $d\tau$, (19) is solved by using the state transition matrix:

$$\delta x(t) = \phi_{11}(t, 0)\delta x(0) + \phi_{12}(t, 0)\delta\lambda(0), \tag{50}$$

$$\delta\lambda(t) = \phi_{21}(t, 0)\delta x(0) + \phi_{22}(t, 0)\delta\lambda(0). \tag{51}$$

By substituting the boundary condition (14) into (50), where (50) is evaluated at τ, the following can be obtained:

$$\delta x(0) - \tilde{f}(\tau)\, d\tau = \phi_{11}(\tau, 0)\delta x(0) + \phi_{12}(\tau, 0)\delta\lambda(0). \tag{52}$$

Since $\phi_{12}(\tau, 0)$ is invertible, $\delta\lambda(0)$ can be determined as

$$\delta\lambda(0) = \phi_{12}^{-1}(\tau, 0)[I - \phi_{11}(\tau, 0)]\delta x(0) - \phi_{12}^{-1}(\tau, 0)\tilde{f}(\tau)\, d\tau. \tag{53}$$

Furthermore, by using (51) and (53), $\delta\lambda(\tau)$ is obtained in terms of $\delta x(0)$ and $d\tau$,

$$\begin{aligned} \delta\lambda(\tau) = & -\phi_{22}(\tau, 0)\phi_{12}^{-1}(\tau, 0)\tilde{f}(\tau)\, d\tau \\ & + \{\phi_{21}(\tau, 0) + \phi_{22}(\tau, 0)\phi_{12}^{-1}(\tau, 0)[I - \phi_{11}(\tau, 0)]\}\delta x(0). \end{aligned} \tag{54}$$

If (14), (53), and (54) are used in (49), the second variational cost $d^2\bar{J}^*(\delta x(0), d\tau)$ reduces to

$$d^2\bar{J}^*(\delta x(0), d\tau) = \frac{1}{\tau}[\delta x^T(0)\ d\tau]\bar{M}(0,\tau)\begin{bmatrix}\delta x(0)\\ d\tau\end{bmatrix}. \tag{55}$$

From (55), it follows that a necessary condition for the periodic path to be a minimum is $\bar{M}(0,\tau)\geqq 0$.

Remark. The necessary condition in Proposition 4 applies for all t_0. By replacing $t_0=0$ by any $t_0\in[0,\tau)$, $\bar{M}(t_0, t_0+\tau)$ can be defined the same as (48) except that ϕ_{ij} corresponds to $\phi_{ij}(t_0+\tau, t_0)$, and $\tilde{H}_x$ and $\tilde{f}$ are evaluated at t_0.

Perturbations along the periodic path do not change the orbit, only the part of perturbations perpendicular to the path contributes to a new path. By defining the projection operator $V(t)$ as

$$V = I - \tilde{f}[\tilde{f}^T\tilde{f}]^{-1}\tilde{f}^T, \tag{56}$$

the definition of strong positivity given in [13] is that there exist a positive number k and a positive definite matrix M such that

$$d^2\bar{J} \geqq k\int_0^\tau \delta x^T(t)V^T(t)MV(t)\delta x(t)\,dt. \tag{57}$$

This means that the change in cost from path $\tilde{x}(t)$ to $\tilde{x}(t)+\delta x(t)$ is dominated by the second variational cost for sufficiently small $\|\delta x\|$ [7].

PROPOSITION 5. *If $\xi^T\bar{M}(t, t+\tau)\xi\geqq 0$, for every $n+1$-vector ξ, and the equality is true only if $\xi^T=[\varepsilon\tilde{f}^T(t)\quad 0]$, where ε is an arbitrary real number, then the second variation is strongly positive.*

Proof. Define $\delta y(t)$ to be the component of $\delta x(t)$ in the space orthogonal to the velocity direction of the nominal periodic path,

$$\delta y(t) = V(t)\delta x(t). \tag{58}$$

Let $\sigma_i(t)$, $i=1, 2, \cdots, n+1$ be eigenvalues of $\bar{M}(t, t+\tau)$ such that $\sigma_1(t)=0$ and $\sigma_i(t)>0$, $i=2, \cdots, n+1$. Denote $\underline{\sigma}=\min_{i>1, 0\leqq t\leqq\tau}\sigma_i(t)$. Let L be an $(n+1)\times(n+1)$ orthonormal matrix consisting of the eigenvectors of $\bar{M}(t, t+\tau)$ such that

$$L^T\bar{M}L = \operatorname{diag}[0, \sigma_2, \cdots, \sigma_{n+1}]. \tag{59}$$

Then, L can be written in a partitioned form as

$$L = \begin{bmatrix}\varepsilon\tilde{f} & \bar{V}\\ 0 & \bar{W}\end{bmatrix} \tag{60}$$

where $\bar{V}$ and $\bar{W}$ are $n\times n$ matrix and $1\times n$ matrix, respectively, and ε is a real number which normalizes the velocity vector $\tilde{f}(t)$.

$$\begin{aligned} d^2\bar{J}^*(\delta x(t), d\tau) &= \frac{1}{\tau}[\delta x^T(t)\quad d\tau]\bar{M}(t, t+\tau)\begin{bmatrix}\delta x(t)\\ d\tau\end{bmatrix}\\ &= \frac{1}{\tau}[\delta x^T\quad d\tau]\begin{bmatrix}\bar{V}\\ \bar{W}\end{bmatrix}\operatorname{diag}[\sigma_2, \cdots, \sigma_{n+1}][\bar{V}^T\quad \bar{W}^T]\begin{bmatrix}\delta x\\ d\tau\end{bmatrix}\\ &\geqq \frac{\underline{\sigma}}{\tau}\|\bar{V}^T\delta x + \bar{W}^T d\tau\|^2. \end{aligned} \tag{61}$$

Since L is orthonormal, the column vectors of L are orthogonal. By examining (60), the orthogonality implies that $\tilde{f}$ is orthogonal to the column vectors of $\bar{V}$ and $\bar{W}^T$ is orthogonal to the column vectors of $\bar{V}^T$. Therefore,

$$\bar{V}^T V = \bar{V}^T[I - \tilde{f}(\tilde{f}^T\tilde{f})^{-1}\tilde{f}] = \bar{V}^T, \tag{62}$$

and

$$\|\bar{V}^T\delta x + \bar{W}^T d\tau\|^2 = \|\bar{V}^T\delta x\|^2 + \|\bar{W}^T d\tau\|^2 \geqq \|\bar{V}^T\delta x\|^2. \tag{63}$$

By using (61), (62), and (63), $d^2\bar{J}^*(\delta x(t), d\tau)$ is related to δy as follows:

$$d^2\bar{J}^*(\delta x(t), d\tau) \geqq \frac{\sigma}{\tau}\|\bar{V}^T V\delta x\|^2 = \frac{\sigma}{\tau}\delta y^T\bar{V}\bar{V}^T\delta y. \tag{64}$$

From the orthogonality, $\tilde{f}$ is an eigenvector of $\bar{V}\bar{V}^T$ corresponding to a zero eigenvalue. Furthermore, rank $\bar{V}\bar{V}^T = n-1$. Otherwise, L defined in (60) is not invertible. Let $\mu_1(t), \cdots, \mu_n(t)$ be eigenvalues of $\bar{V}\bar{V}^T$ such that $\mu_1 = 0$ and $\mu_i > 0$, $i = 2, \cdots, n$. Denote $\underline{\mu} = \min_{i>1, t\in[0,\tau]}\mu_i(t)$. Since δy is orthogonal to $\tilde{f}$, then

$$\frac{\sigma}{\tau}\delta y^T\bar{V}\bar{V}^T\delta y \geqq \frac{\sigma\underline{\mu}}{\tau}\|\delta y\|^2. \tag{65}$$

Let $M = I$, $k = (\sigma\underline{\mu})/\tau^2$, then by the mean value theorem, there exists $\theta \in (0, \tau)$ such that

$$k\int_0^\tau \delta x^T(t)V^T(t)MV(t)\delta x(t)\,dt = \frac{\sigma\underline{\mu}}{\tau^2}\int_0^\tau \|\delta y(t)\|^2\,dt = \frac{\sigma\underline{\mu}}{\tau}\|\delta y(\theta)\|^2. \tag{66}$$

Let $\delta x(\theta)$ be the state variation of the perturbed path at $t = \theta$. Then $d^2\bar{J}^*(\delta x(\theta), d\tau)$ is the accessory minimum corresponding to $t_0 = \theta$ with initial perturbation $\delta x(\theta)$ and $d\tau$. Since the neighboring optimal control is used for constructing a closed orbit starting at $\delta x(\theta)$, $d^2\bar{J}^*(\delta x(\theta), d\tau)$ is less than or equal to the cost of an arbitrary perturbed path passing that point. Therefore, by combining (64) with (66),

$$\frac{\sigma\underline{\mu}}{\tau}\|\delta y(\theta)\|^2 \leqq d^2\bar{J}^*(\delta x(\theta), d\tau) \leqq d^2\bar{J}. \tag{67}$$

Remark. The restrictions in [13] that the eigenvalues of the monodromy matrix be distinct except for two unit eigenvalues and the existence of periodic Riccati solution, which are required for the proof of the strongly positive condition, are no longer needed here for a single-period process.

PROPOSITION 6. *If the conditions of Proposition 5 hold, then the two unit eigenvalues of the monodromy matrix are coupled in the same Jordan box.*

Proof. Suppose that $\begin{bmatrix}\alpha\\ \gamma\end{bmatrix}$ is a primary eigenvector of the monodromy matrix corresponding to the unit eigenvalue. By using the symplectic property of $\phi(t, 0)$, the following can be obtained:

$$\alpha^T[\phi_{12}^{-1}(I - \phi_{11}) + \phi_{12}^{-T}(I - \phi_{22}^T)]\alpha = 0. \tag{68}$$

Furthermore, if $\begin{bmatrix}\alpha\\ \gamma\end{bmatrix}$ is an eigenvector which is independent of the one along the velocity direction, i.e.,

$$\begin{bmatrix}\alpha\\ \gamma\end{bmatrix} \neq \varepsilon\begin{bmatrix}\tilde{f}\\ -\tilde{H}_x^T\end{bmatrix},$$

where ε is any real number, then two possible cases may occur:

(i) $\alpha \neq \varepsilon f$. In this case, the strongly positiveness does not hold;

(ii) $\alpha = \varepsilon \tilde{f}$ for some ε, but $\gamma \neq -\varepsilon \tilde{H}_x^T$. In this case, a contradiction to the invertibility of $\phi_{12}(\tau, 0)$ is produced. Since

$$\begin{bmatrix} \phi_{11} & \phi_{12} \\ \phi_{21} & \phi_{22} \end{bmatrix} \begin{bmatrix} \alpha \\ \gamma \end{bmatrix} - \begin{bmatrix} \phi_{11} & \phi_{12} \\ \phi_{21} & \phi_{22} \end{bmatrix} \begin{bmatrix} \varepsilon \tilde{f} \\ -\varepsilon \tilde{H}_x^T \end{bmatrix} = \begin{bmatrix} \phi_{11} & \phi_{12} \\ \phi_{21} & \phi_{22} \end{bmatrix} \begin{bmatrix} 0 \\ \gamma + \varepsilon \tilde{H}_x^T \end{bmatrix} = \begin{bmatrix} 0 \\ \gamma + \varepsilon \tilde{H}_x^T \end{bmatrix}, \tag{69}$$

this indicates that $\phi_{12}(\gamma + \varepsilon \tilde{H}_x^T) = 0$. The result contradicts the invertibility assumption on ϕ_{12}.

Therefore, the unit eigenvalues of the monodromy matrix must be coupled in the same Jordan box. □

The importance of this section has been to establish a second-order necessary condition for the weak local optimality of a periodic process. The condition is derived in a simple algebraic form. From this algebraic condition some properties of the periodic process are determined under weaker assumptions than used in [13].

6. Summary of necessary and sufficient conditions. Based on the discussions in §§ 4 and 5, a set of second variational necessary and sufficient conditions for local optimality of a single-period process are stated.

Sufficient Condition. A second-order sufficient condition for a periodic path to be a weak local minimum given Assumptions 1–6 is that:

(i) For all $t_0 \in [0, \tau)$, there exists a continuous real symmetric solution to the Riccati differential equation (47) on $t \in [t_0, t_0 + \tau]$;

(ii) For all $t_0 \in [0, \tau)$ and $n+1$-vectors ξ, $\xi^T \bar{M}(t_0, t_0 + \tau)\xi \geqq 0$, and the equality is true only if $\xi = [\varepsilon \tilde{f}^T(t_0)\ 0]^T$, where ε is a real number.

Necessary Condition. A second-order necessary condition for a periodic path to be a weak local minimum given Assumptions 1–6 is the same as the sufficient condition, except that condition (ii) is weakened as: For all $t_0 \in [0, \tau)$, $\bar{M}(t_0, t_0 + \tau) \geqq 0$.

The necessary and sufficient conditions given above apply for weak local optimality of a τ-period process called a single periodic process. Condition (i) is a conjugate point condition associated with optimality of the control $u(\cdot)$. Condition (ii) ensures the nonnegativity of the second variation when the period and the initial state are perturbed. The invertibility of ϕ_{12} is insured by condition (i). Note that there is no requirement that the solution of the Riccati equation be periodic as there is in [3], [6], [13]. For the sufficient conditions, the requirement on the eigenvalues of the monodromy matrix is that there are no uncoupled unit eigenvalues, therefore the conditions in [13] are weakened.

7. Second variation analysis for an infinitely-repeated periodic process. In §§ 3–6, the second variation conditions for local optimality of a single periodic process are considered. If a periodic path is an extremal for the optimal periodic control problem with period τ, then for any positive integer k, the $k\tau$-periodic path, which is obtained by repeating the orbit k times, is also an extremal for the same problem, since the necessary conditions of Proposition 1 are satisfied. The optimal control problem for a k-repeated periodic process is defined to minimize the performance criterion

$$J(u(\cdot), x(0), \tau) = \frac{1}{k\tau} \int_0^{k\tau} L(x(t), u(t))\, dt \tag{70}$$

with respect to $u(\cdot)$, $x(0)$, and τ, subject to the dynamic equation (2), and the periodic boundary conditions

$$x(i\tau) = x(0), \quad i = 1, 2, \cdots, k. \tag{71}$$

In the first-order variation analysis, there is no basic difference between the problem described above and the problem stated in (1) to (3). But when small variations around these repeated periodic paths are considered, some interesting phenomena can be revealed. For example, now a comparison path may be closed for the first time at $t = k\tau$ instead of closed around $t = \tau$. In this section, small variations with respect to the k-repeated periodic path are considered. If these repeated periodic processes are included, the second variation conditions summarized in § 6 must be strengthened. In particular, the existence of a periodic solution to the Riccati differential equation is required if k becomes infinite.

If the time interval $(t_0, t_0+\tau]$ is replaced by the time interval $(t_0, t_0+k\tau]$, the conjugate point conditions proved in § 4 apply without modification to each k-repeated τ-periodic process. That is, if $\phi_{12}(t_c, t_0)$ is not invertible for $t_c \in (t_0, t_0+k\tau]$ for some $k>1$, a $k\tau$-periodic path conjugate to the k-repeated τ-periodic extremal path can be found having the same cost as the periodic extremal path. Then, a nonextremal path with period $k\tau$ can be found as shown in § 4, and the cost of this nonextremal path is less than that of the conjugate path. Therefore, the k-repeated τ-periodic path is not a minimum.

The absence of a point $t_c \in (t_0, t_0+k\tau]$ conjugate to t_0 for each t_0 is a necessary condition for the optimality of a k-repeated periodic process. By letting k go to infinity, Proposition 3 and Corollary 1 are modified for the infinitely-repeated periodic process to the following necessary condition.

PROPOSITION 7. *Given Assumptions* 1–4, *a necessary condition for optimality of an infinitely-repeated periodic process is that there exists a continuous real symmetric solution to the Riccati differential equation* (47) *for all t.*

Next, the necessity of existence of a periodic Riccati solution for optimality is shown.

PROPOSITION 8. *Given that* $\phi_{12}(t, t_0)$ *is invertible for* $t > t_0$, *a necessary condition for optimality of an infinitely-repeated periodic process is that the matrix* $-\phi_{12}^{-1}(t, t_0)\phi_{11}(t, t_0)$ *is bounded from below for* $t > t_0$.

Proof. Let the initial state perturbation at t_0 be $\delta x(t_0) = \delta x_0$ and solve the following accessory minimum problem: Minimize the performance criterion

$$J_2(t_0, t_f) = \int_{t_0}^{t_f} [\delta x^T \quad \delta u^T] \begin{bmatrix} \tilde{H}_{xx} & \tilde{H}_{xu} \\ \tilde{H}_{ux} & \tilde{H}_{uu} \end{bmatrix} \begin{bmatrix} \delta x \\ \delta u \end{bmatrix} dt \tag{72}$$

subject to

$$\delta \dot{x} = \tilde{f}_x \delta x + \tilde{f}_u \delta u \tag{73}$$

and

$$\delta x(t_0) = \delta x_0, \quad \delta x(t_f) = 0. \tag{74}$$

According to (28), the cost for this accessory minimum problem is

$$J_2(t_0, t_f) = \delta x^T(t_0) \delta \lambda(t_0). \tag{75}$$

Since

$$\delta x(t_f) = 0 = \phi_{11}(t_f, t_0)\delta x_0 + \phi_{12}(t_f, t_0)\delta \lambda(t_0), \tag{76}$$

$\delta \lambda(t_0)$ can be written as

$$\delta \lambda(t_0) = -\phi_{12}^{-1}(t_f, t_0)\phi_{11}(t_f, t_0)\delta x_0. \tag{77}$$

By substituting (77) into (75),

$$J_2(t_0, t_f) = -\delta x_0^T \phi_{12}^{-1}(t_f, t_0)\phi_{11}(t_f, t_0)\delta x_0. \tag{78}$$

Since the system is controllable, given $t_1 < t_0$, a finite control can be found to take the variation from $\delta x(t_1) = 0$ to $\delta x(t_0) = \delta x_0$, and the corresponding second variational cost is bounded,

$$J_2(t_1, t_0) = \delta x_0^T D \delta x_0 \tag{79}$$

where D is a bounded matrix. If $-\phi_{12}^{-1}(t_f, t_0)\phi_{11}(t_f, t_0)$ is not bounded from below, there exist some δx_0 and t_f in the interval $t_1 < t_f < t_1 + K\tau$ for some K, such that

$$J_2(t_1, t_f) = J_2(t_1, t_0) + J_2(t_0, t_f) < 0, \tag{80}$$

i.e., there exists a $K\tau$-periodic path whose cost is less than that of the K-repeated τ-periodic extremal path. Therefore, the K-repeated τ-periodic path is not a minimum. Clearly this holds for all $k > K$, in particular, as k goes to infinity. □

Note that t_0 represents a particular point on the path which is held fixed. As t_f increases, the cost (78) is shown in the next proposition to monotonically decrease since the terminal state variations are constrained to zero as given in (74).

PROPOSITION 9. *A necessary condition for an infinitely-repeated periodic path to be a minimum is that there exists a continuous real symmetric periodic solution to the Riccati differential equation* (47).

Proof. By differentiating $-\phi_{12}^{-1}(\theta, t)\phi_{11}(\theta, t)$ with respect to θ and manipulating terms using the symplectic property of transition matrix [12], the following matrix differential equation can be obtained:

$$\frac{d}{d\theta}[-\phi_{12}^{-1}(\theta, t)\phi_{11}(\theta, t)] = -\phi_{12}^{-1}(\theta, t)B(\theta)\phi_{12}^{-T}(\theta, t). \tag{81}$$

Since $B(\theta) \geqq 0$, (81) shows that for every t, $-\phi_{12}^{-1}(\theta, t)\phi_{11}(\theta, t)$ is a nonincreasing matrix with respect to θ. According to Proposition 8, $-\phi_{12}^{-1}(\theta, t)\phi_{11}(\theta, t)$ is bounded from below. Therefore, $-\phi_{12}^{-1}(\theta, t)\phi_{11}(\theta, t)$ approaches a limit as θ approaches positive infinity. Denote this limit by $\underline{P}(t)$, then

$$\underline{P}(t) = \lim_{\theta \to \infty} -\phi_{12}^{-1}(\theta, t)\phi_{11}(\theta, t). \tag{82}$$

Since ϕ is the transition matrix of a periodic Hamiltonian system of differential equations, then

$$\phi(\theta, t + \tau) = \phi(\theta - \tau, t) \tag{83}$$

and

$$\underline{P}(t + \tau) = \lim_{\theta \to \infty} -\phi_{12}^{-1}(\theta - \tau, t)\phi_{11}(\theta - \tau, t) = \underline{P}(t). \tag{84}$$

Therefore $\underline{P}(t)$ is periodic.

Finally, $\underline{P}(t)$ satisfying (47) needs to be shown. By differentiating $-\phi_{12}^{-1}(\theta, t)\phi_{11}(\theta, t)$ with respect to t, it is shown that for every θ, $-\phi_{12}^{-1}(\theta, t)\phi_{11}(\theta, t)$ satisfies (47) [12], where $t < \theta$ is assumed. By letting θ go to infinity, it is concluded that $\underline{P}(t)$ is a periodic solution to (47).

PROPOSITION 10. *The controllability assumption and the existence of a continuous real symmetric periodic solution to the Riccati differential equation imply the nonnegativeness of the second variation, or equivalently, imply* $\bar{M}(t_0, t_0 + k\tau) \geqq 0$ *for* $k = 1, 2, \cdots$.

Proof. Only the case $t_0 = 0$ is proved, since the procedure is the same for other t_0. By adding the zero term

$$0 = \frac{1}{k\tau}\int_0^{k\tau} \delta x^T \underline{P}(\tilde{f}_x \delta x + \tilde{f}_u \delta u - \delta \dot{x})\, dt \tag{85}$$

to (12) with τ and $d\tau$ replaced by $k\tau$ and $d(k\tau)$, and following the mathematical manipulation, the second variational cost can be written as

$$d^2\bar{J}=\frac{1}{k\tau}\left\{[\delta x^T(0)\quad d(k\tau)]\begin{bmatrix}0 & (\tilde{H}_x+\tilde{f}^T\underline{P})^T\\ \tilde{H}_x+\tilde{f}^T\underline{P} & (\tilde{H}_x+\tilde{f}^T\underline{P})\tilde{f}\end{bmatrix}_{t=0}\begin{bmatrix}\delta x(0)\\ d(k\tau)\end{bmatrix}\right.$$
$$\left.+\int_0^{k\tau}\|\tilde{H}_{uu}^{-1}(\tilde{f}_u^T\underline{P}+\tilde{H}_{ux})\delta x+\delta u\|_{H_{uu}}^2\,dt\right\}. \tag{86}$$

Consider the following similarity transformation

$$\begin{bmatrix}I & 0\\ -\underline{P}(0) & I\end{bmatrix}\begin{bmatrix}\phi_{11} & \phi_{12}\\ \phi_{21} & \phi_{22}\end{bmatrix}_{t=k\tau}\begin{bmatrix}I & 0\\ \underline{P}(0) & I\end{bmatrix}=\begin{bmatrix}\phi_{11}+\phi_{12}\underline{P} & \phi_{12}\\ 0 & -\underline{P}\phi_{12}+\phi_{22}\end{bmatrix}_{t=k\tau}$$
$$\triangleq\begin{bmatrix}\phi_z & \phi_{12}\\ 0 & \phi_z^{-T}\end{bmatrix}_{t=k\tau} \tag{87}$$

where $Z=A-B\underline{P}$, ϕ_{ij}, $i,j=1,2$, are partitioned blocks of $\phi(k\tau,0)$, and ϕ_Z is the transition matrix associated with Z. Then,

$$\begin{bmatrix}\phi_{11} & \phi_{12}\\ \phi_{21} & \phi_{22}\end{bmatrix}\begin{bmatrix}\tilde{f}\\ -\tilde{H}_x^T\end{bmatrix}=\begin{bmatrix}\tilde{f}\\ -\tilde{H}_x^T\end{bmatrix} \tag{88}$$

implies

$$\phi_z\tilde{f}-\phi_{12}(\underline{P}\tilde{f}+\tilde{H}_x^T)=\tilde{f}. \tag{89}$$

As shown in [14], the controllability assumption and the existence of a real symmetric periodic solution to the Riccati differential equation imply that the monodromy matrix has no uncoupled unit eigenvalues. The eigenvector structure of $\underline{P}$ must include all the primary eigenvectors of the unit eigenvalues. Therefore, $\tilde{f}$ is an eigenvector of unit eigenvalue of the closed-loop matrix ϕ_z, i.e.,

$$\phi_z(k\tau,0)\tilde{f}(0)=\tilde{f}(0). \tag{90}$$

Since ϕ_{12} is invertible, from (89) and (90), the following is obtained:

$$\underline{P}\tilde{f}+\tilde{H}_x^T=0. \tag{91}$$

By using (91) in (86), the first term in the right-hand side of (86) then vanishes, therefore, $d^2\bar{J}\geqq 0$. □

PROPOSITION 11. *If there exists a continuous real symmetric periodic solution to the Riccati differential equation, and the eigenvalues of the monodromy matrix are off the unit circle except for one pair of unit eigenvalues, then the second variation is strongly positive.*

Proof. From (86), the second variation is zero if and only if

$$\delta u=-\tilde{H}_{uu}^{-1}(\tilde{f}_u^T\underline{P}+\tilde{H}_{ux})\delta x. \tag{92}$$

Then

$$\delta\dot{x}=\tilde{f}_x\delta x-\tilde{f}_u\tilde{H}_{uu}^{-1}(\tilde{f}_u^T\underline{P}+\tilde{H}_{ux})\delta x \tag{93}$$

and

$$\delta x(t)=\phi_z(t,0)\delta x(0). \tag{94}$$

By using the periodic boundary condition

$$\delta x(k\tau)=\delta x(0)-\tilde{f}(0)d(k\tau), \tag{95}$$

equation (94) evaluated at $t = k\tau$ can be written as

$$\delta x(0) - \tilde{f}(0)d(k\tau) = \phi_z(k\tau, 0)\delta x(0), \tag{96}$$

or

$$[\phi_z(k\tau, 0) - I\tilde{f}(0)]\begin{bmatrix}\delta x(0)\\ d(k\tau)\end{bmatrix} = 0. \tag{97}$$

It can be shown that $[\delta x^T(0)\ d(k\tau)]^T = [\varepsilon\tilde{f}^T(0)\ 0]^T$ satisfies (97), and it will be shown that it is the only solution. Since $\phi_z(k\tau, 0) = \phi_z^k(\tau, 0)$ has only one unit eigenvalue, therefore

$$\operatorname{rank}[\phi_z(k\tau, 0) - I] = n - 1. \tag{98}$$

Also, $\tilde{f}(0)$ belongs to the null-space of $(\phi_z(k\tau, 0) - I)$. Therefore

$$\operatorname{rank}[\phi_z(k\tau, 0) - I\tilde{f}(0)] = n. \tag{99}$$

This implies that $\bar{M}(0, k\tau)$ has strongly positive property, i.e., $\xi^T\bar{M}\xi = 0$ only if $\xi = [\varepsilon\tilde{f}^T\ 0]^T$. Therefore, the second variation is strongly positive. □

8. New necessary and sufficient conditions. The results of § 7 are summarized into a new set of necessary and sufficient conditions for local weak optimality of an infinitely-repeated periodic process.

PROPOSITION 12. *The necessary condition for local weak optimality of an infinitely-repeated periodic process given Assumptions* 1-6 *is that there exists a continuous real symmetric periodic solution to the Riccati differential equation* (47); *the sufficient condition to the same problem is that in addition, the monodromy matrix has no eigenvalues on the unit circle except for the pair of unit eigenvalues.*

The conditions given in Proposition 12 generalize and extend the previous results.

9. Conclusions. Second variational necessary and sufficient conditions for weak local optimality of a periodic process are discussed. The conditions are derived from two aspects: conjugate point condition and nonnegative condition. The conjugate point condition is related to the existence of a real symmetric solution to the Riccati differential equation over the period, and the nonnegative condition is given in the form of a matrix condition obtained from solving the accessory minimum problem. The weak form of the conditions imply necessity, and the strong form of the conditions imply sufficiency. Some other properties related to a periodic process are also derived under weaker assumptions, such as the strongly positive property (Proposition 5) and the coupling of the two unit eigenvalues of the monodromy matrix (Proposition 6). If the variations around an infinitely-repeated periodic path are considered, the existence of a real symmetric periodic solution to the Riccati differential equation is necessary for optimality and implies nonnegativity of the second variational cost (Propositions 7 to 10). The existence of a periodic solution to the Riccati differential equation and the requirement that no other eigenvalues of the monodromy matrix are on the unit circle except for a pair of unit eigenvalues are shown to be sufficient for optimality (Proposition 11). A new set of necessary and sufficient conditions is given (Proposition 12) which is compact and convenient to use.

Acknowledgment. The authors are grateful to Professor Steven I. Marcus for his helpful comments on this paper.

EXACT CONTROLLABILITY: COEFFICIENT DEPENDING ON THE TIME*

JAIME E. MUÑOZ RIVERA

Abstract. The following is considered: The wave equation $y''-a(t)\Delta y=0$, with initial data given by (y_0, y_1) in $L^2(\Omega)\times H^{-1}(\Omega)$, and the nonhomogeneous condition $y=v$ on the boundary Σ of $Q=\Omega\times]0, T[$. Exact controllability means that there exist a time $T'>0$, and a control v such that $y(T', v)=y'(T', v)=0$. The main result of this paper is to prove that the above system is exactly controllable when $a(\cdot)$ is a monotonic function in some interval of width greater than $R\sqrt{\|a\|_\infty}/a_0$, where $\|a\|_\infty=\sup\{|a(t)|;\ t\in\mathbb{R}\}$, $a_0\leqq a(t)$ for all $t\in\mathbb{R}$ and $R=\sup\{\|x-x_0\|;\ x\in\Omega\}$ for some fixed x_0 in $\mathbb{R}^n$.

Key words. exact controllability, control of distributed systems, wave equation, linear equation

1. Introduction. Let Ω be an open bounded set of $\mathbb{R}^n$ with boundary Γ of class C^2. Let Q be a cylinder defined by $Q=\Omega\times]0, T[$ and Σ be the lateral boundary of Q given by $\Sigma=\Gamma\times]0, T[$. We denote by $(\cdot,\cdot)_\Omega$ and $\|\cdot\|_\Omega$ the inner product and the norm of $L^2(\Omega)$, respectively. In [2], the author has considered the exact controllability problem for the system

$$\begin{aligned} &y''-a(t)\Delta y=0 && \text{in } Q,\\ &y(x,t)=v && \text{on } \Sigma,\\ &y(0)=y_0,\quad y'(0)=y_1 && \text{in } \Omega \end{aligned} \tag{1.1}$$

where a is a function satisfying

$$a, a'\in L^\infty(\mathbb{R}_+),\qquad a(t)\geqq a_0>0. \tag{1.2}$$

We want to find a control v of class $L^2(\Sigma)$, driving the system to rest; that is, we want to find an element v in $L^2(\Sigma)$ satisfying

$$y(v;T)=y'(v,T)=0\quad \text{for } T>0. \tag{1.3}$$

When this is the case, we say that the system is exactly controllable. In [2] it is shown that (1.3) is valid when $a'(t)\geqq 0$ for all $t\geqq 0$. The main result of this paper is to prove that the system (1.1) is exactly controllable when a is a monotonic function in some interval $[T_0, T_1]$ such that

$$T_1-T_0>\frac{R\sqrt{\|a\|_\infty}}{a_0}. \tag{1.4}$$

2. The main result. Let us define ϕ as the solution of the following system:

$$\begin{aligned} &\phi''-a(t)\Delta\phi=0 && \text{in } Q,\\ &\phi(x,t)=0 && \text{on } \Sigma,\\ &\phi(0)=\phi_0,\quad \phi'(0)=\phi_1 && \text{in } \Omega. \end{aligned} \tag{2.1}$$

First, we will prove that there exists a positive constant C satisfying the following inequality:

$$CE(0)\leqq\frac{1}{2}R\|a\|_\infty\int_{\Sigma_0}\left|\frac{\partial\phi}{\partial\nu}\right|^2 d\Sigma. \tag{2.2}$$

* Received by the editors December 19, 1988; accepted for publication May 26, 1989.

† National Laboratory of Scientific Computation, Rua Lauro Muller 455, Botafogo 22290, Rio de Janeiro, Brasil.

Here $R=\sup\{\|x-x_0\|;\, x\in\Omega\}$, where x_0 is a fixed point of $\mathbb{R}^n$, and $\Sigma_0=\Gamma_0\times]0,\, T[$ where $\Gamma_0=\{x\in\Gamma:\,(x-x_0)\cdot\nu(x)\geqq 0\}$. The following remarks are in order.

Remark 2.1. Put $E(t)=\frac{1}{2}\{\|\phi'(t)\|_\Omega^2+a(t)\|\nabla\phi(t)\|_\Omega^2\}$. From (2.1) it follows that

$$E'(t)=\tfrac{1}{2}a'(t)\|\nabla\phi\|_\Omega^2\geqq-\tfrac{1}{2}|a'(t)|\,\|\nabla\phi(t)\|_\Omega^2.$$

From this inequality and by (1.2), we obtain

$$E'(t)\geqq-\frac{|a'(t)|}{2a_0}E(t). \tag{2.3}$$

Remark 2.2. For all $t\in[0,\, T_0]$ we have that

$$E(t)\geqq\exp\left\{-\frac{1}{2a_0}\int_0^{T_0}|a'(s)|\,ds\right\}E(0).$$

In fact, if we multiply (2.3) by $\rho(t)=\exp\{1/2a_0\int_0^t|a'(s)|\,ds\}$, then we have $d/dt\,\{E(t)\rho(t)\}\geqq 0$. Integrating from zero to t, we obtain the result.

Remark 2.3. If a is a monotonic function on $[T_0,\, T_1]$, then we have

$$\sqrt{a_0/\|a\|_\infty}\,E(T_0)\leqq E(t)\leqq E(T_0)\quad\forall t\in[T_0,\, T_1],\text{ when } a'(t)\leqq 0, \tag{2.4}$$

$$E(T_0)\leqq E(t)\leqq\sqrt{\|a\|_\infty/a_0}\,E(T_0)\quad\forall t\in[T_0,\, T_1],\text{ when } a'(t)\geqq 0. \tag{2.5}$$

In fact, let us suppose that a is a nondecreasing function; then we have

$$0\leqq E'(t)=\frac{1}{2}a'(t)\|\nabla\phi(t)\|_\Omega^2\leqq\frac{1}{2}\frac{a'(t)}{a(t)}E(t).$$

From Gronwall's inequality we obtain

$$E(T_0)\leqq E(t)\leqq\sqrt{a(T_1)/a(T_0)}\,E(T_0)\leqq\sqrt{\|a\|_\infty/a_0}\,E(T_0)$$

from which (2.5) follows. Using the same reasoning, we can prove that relation (2.4) is also valid.

Now we are able to prove the following lemma.

LEMMA 2.1. *Let a be a monotonic function on $[T_0,\, T_1]$ satisfying* (1.2). *Then there exists a constant C satisfying condition* (2.2).

Proof. Set $Q'=\Omega\times]T_0,\, T[$, $\Sigma'=\Gamma\times]T_0,\, T[$ and put $m(x)=x-x_0$. Multiplying system (2.1) by $m_k(\partial\phi/\partial x_k)$, we have

$$\begin{aligned}\frac{1}{2}\int_{\Sigma'}a(t)\left|\frac{\partial\phi}{\partial\nu}\right|^2 m_k\nu_k\,d\Sigma&=\left[\left(\phi'(t),\, m_k\frac{\partial\phi}{\partial x_k}(t)\right)_\Omega\right]_{T_0}^{T}-\frac{n}{2}\int_{Q'}\{|\phi'|^2-a(t)|\nabla\phi|^2\}\,dx\,dt\\&\quad+\int_{Q'}a(t)|\nabla\phi|^2\,dx\,dt\end{aligned}$$

where $m(x)=(m_1(x),\cdots,m_k(x),\cdots,m_n(x))$.

But

$$\int_{Q'}\{|\phi'(t)|^2-a(t)|\nabla\phi(t)|^2\}\,dx\,dt=[(\phi'(t),\,\phi(t))_\Omega]_{T_0}^{T}$$

from which we obtain that

$$\frac{1}{2}\int_{\Sigma'} a(t)\left|\frac{\partial\phi}{\partial\nu}\right|^2 m_k\nu_k\,d\Sigma=\left[\left(\phi'(t), m_k\frac{\partial\phi}{\partial x_k}(t)+\frac{n-1}{2}\phi(t)\right)_\Omega\right]_{T_0}^{T}+\int_{T_0}^{T}E(t)\,dt. \tag{2.6}$$

Defining $Z=(\phi'(t), m_k(\partial\phi/\partial x_k)(t)((n-1)/2)\phi(t))_\Omega$, we have

$$|Z|\leqq\|\phi'(t)\|_\Omega\left\|m_k\frac{\partial\phi}{\partial x_k}(t)+\frac{n-1}{2}\phi(t)\right\|_\Omega. \tag{2.7}$$

On the other hand

$$\left\|m_k\frac{\partial\phi}{\partial x_k}(t)+\frac{n-1}{2}\phi(t)\right\|_\Omega^2=\left\|m_k\frac{\partial\phi}{\partial x_k}(t)\right\|_\Omega^2+(n-1)\left(\phi(t), m_k\frac{\partial\phi}{\partial x_k}(t)\right)_\Omega+\frac{(n-1)^2}{4}\|\phi(t)\|_\Omega^2.$$

But

$$\left(\phi(t), m_k\frac{\partial\phi}{\partial x_k}(t)\right)_\Omega=-\frac{n}{2}\|\phi(t)\|_\Omega^2$$

from which we conclude

$$\left\|m_k\frac{\partial\phi}{\partial x_k}(t)+\frac{n-1}{2}\phi(t)\right\|_\Omega\leqq R\|\nabla\phi(t)\|_\Omega. \tag{2.8}$$

By (2.7) and (2.8) we have

$$[|Z|]_{T_0}^{T}\leqq\frac{R}{\sqrt{a_0}}\cdot\sup_{t\in[T_0,T]}E(t). \tag{2.9}$$

Set $\Sigma_0'=\Gamma_0\times]T_0, T[$, and suppose that $a'(t)\leqq 0$ on $[T_0, T_1]$. Now from (2.6), (2.7), (2.9), and Remark 2.3 we have

$$\begin{aligned}\frac{1}{2}R\|a\|_\infty\int_{\Sigma_0}\left|\frac{\partial\phi}{\partial\nu}\right|^2 d\Sigma&\geqq\frac{1}{2}R\|a\|_\infty\int_{\Sigma_0'}\left|\frac{\partial\phi}{\partial\nu}\right|^2 d\Sigma\geqq\frac{1}{2}\int_{\Sigma'}m_k\nu_k\left|\frac{\partial\phi}{\partial\nu}\right|^2 d\Sigma\\&\geqq-\frac{R}{\sqrt{a_0}}E(T_0)+\int_{T_0}^{T}E(t)\,dt\\&\geqq\left\{-\frac{R}{\sqrt{a_0}}+(T_1-T_0)\sqrt{\frac{a_0}{\|a\|_\infty}}\right\}E(T_0)+\int_{T_1}^{T}E(t)\,dt\\&\geqq\frac{1}{\sqrt{a_0}}\left\{-R+(T_1-T_0)\frac{a_0}{\sqrt{\|a\|_\infty}}\right\}E(T_0)\quad\text{for } T\geqq T_1.\end{aligned}$$

Finally the result follows from Remark 2.2. With the same reasoning we can argue the case for $a'(t)\geqq 0$, and the proof is thus complete. □

THEOREM 2.1. *Let $a(\cdot)$ as in Lemma 2.1. Then for all $\{y_0, y_1\}$ in $L^2(\Omega)\times H^{-1}(\Omega)$, there exist v in $L^2(\Sigma)$ such that y, the solution of system (1.1), satisfies (1.3) for $T>T_1$.*

Proof. Let us define ψ as the solution of

$$\begin{aligned}&\psi''-a(t)\Delta\psi=0 && \text{in } Q,\\&\psi(x,t)=w(x,t) && \text{on } \Sigma,\\&\psi(T)=\psi'(T)=0 && \text{in } \Omega,\end{aligned} \tag{2.10}$$

where $w=\partial\phi/\partial\nu$ on Σ_0, and $w=0$ on $\Sigma\backslash\Sigma_0$. It is well known that $\partial\phi/\partial\nu\in L^2(\Sigma)$ when $\{\phi_0, \phi_1\}\in H_0^1(\Omega)\times L^2(\Omega)$ and system (2.10) has only one solution, $\psi\in C([0, T]; L^2(\Omega))$.

Multiplying system (2.1) by ψ and applying Green's formulas, we have

$$\int_{\Sigma_0} a(t)\left|\frac{\partial\phi}{\partial\nu}\right|^2 d\Sigma = \langle\psi'(0), \phi_0\rangle - \langle\psi(0), \phi_1\rangle. \tag{2.11}$$

If we define the operator Λ as

$$\Lambda\{\phi_0, \phi_1\} = \{\psi'(0), -\psi(0)\} \tag{2.12}$$

for $\{\phi_0, \phi_1\}$ in $C_0^\infty(\Omega)\times C_0^\infty(\Omega)$, from Lemma 2.1 we conclude that the functional

$$\{\phi_0, \phi_1\} \mapsto \langle\Lambda\{\phi_0, \phi_1\}, \{\phi_0, \phi_1\}\rangle \tag{2.13}$$

defines a norm in $C_0^\infty(\Omega)\times C_0^\infty(\Omega)$. Let us denote by F the completion space of $C_0^\infty(\Omega)\times C_0^\infty(\Omega)$ with the norm in (2.13). It is clear that F is a Hilbert space. Let us multiply the system (2.1) by $q_k(\partial\phi/\partial x_k)$, where $q=(q_1, \cdots, q_k, \cdots, q_n)$ is a C^2 field of vectors satisfying $q=\nu$ in Γ and ν is the exterior normal of Ω. Then we have the following identity:

$$\begin{aligned}\frac{1}{2}\int_\Sigma a(t)q_k\nu_k\left|\frac{\partial\phi}{\partial\nu}\right|^2 d\Sigma &= \left[\left(\phi'(t), q_k\frac{\partial\phi}{\partial x_k}\right)_\Omega\right]_0^T + \frac{1}{2}\int_Q \frac{\partial q_k}{\partial x_k}\{|\phi'|^2 - a(t)|\nabla\phi|^2\}\,dx\,dt \\ &\quad + \int_Q a(t)\frac{\partial q_k}{\partial x_k}\frac{\partial\phi}{\partial x_k}\frac{\partial\phi}{\partial x_j}\,dx\,dt\end{aligned}$$

from which we have

$$\int_Q \left|\frac{\partial\phi}{\partial\nu}\right|^2 d\Sigma \leqq CE(0) \tag{2.14}$$

where C is a generic constant. From this later inequality we can conclude that the norm of F is equivalent to the norm of the space $H_0^1(\Omega)\times L^2(\Omega)$, and since $C_0^\infty(\Omega)$ is dense in both $H_0^1(\Omega)$ and $L^2(\Omega)$, we obtain that $F = H_0^1(\Omega)\times L^2(\Omega)$. Since Λ is a self-adjoint operator from F to F', from Lemma 2.1 and the relations (2.11) and (2.12), we conclude that Λ is an isomorphism. Finally, if we take $\{y_1, -y_0\}$ *in* F', there exists $\{\phi_0, \phi_1\}$ in F such that

$$\Lambda\{\phi_0, \phi_1\} = \{y_1, y_0\}.$$

From (2.12) we have that the function ψ defined by system (2.10) satisfies $\psi(0)=y_0$, $\psi'(0)=y_1$, taking $v=w$ in system (1.1). By uniqueness of solutions for linear hyperbolic systems, we conclude that $y=\psi$, and from (2.10) the result follows. □

A GENERALIZATION OF THE PROXIMAL POINT ALGORITHM*

CU D. HA†

Abstract. The problem considered in this paper is to find a solution to the generalized equation $0 \in T(x, y)$, where T is a maximal monotone operator on the product $H_1 \times H_2$ of two Hilbert spaces H_1 and H_2. We give a generalization of the proximal map and the proximal point algorithm in which the proposed iterative procedure is based on just one variable. Applying to convex programming problems, instead of adding a quadratic term for all variables as in the proximal point algorithm, a quadratic term for a subset of variables is added. This paper proves that under a mild assumption our algorithm has the same convergence properties as the regular proximal point algorithm.

Key words. monotone operator, convex programming, proximal point algorithm, generalized equation

1. Introduction. Let H be a real Hilbert space with the inner product $\langle \cdot, \cdot \rangle$ and the induced normed $|\cdot|$. Let $T: H \to H$ be a set-valued map. We define its domain, image, and graph, as follows.

$$\text{Dom}(T) := \{z \in H \mid T(z) \neq \phi\},$$

$$\text{Im}(T) := \bigcup_{z \in H} T(z),$$

and

$$\text{Graph}(T) := \{(z, w) \in H \times H \mid w \in T(z)\}.$$

The inverse T^{-1} of T is the set-valued map defined by

$$z \in T^{-1}(w) \quad \text{if and only if } w \in T(z).$$

The set-valued map T is said to be a monotone operator if

$$\langle z - z', w - w' \rangle \geqq 0 \quad \text{for all } (z, w) \text{ and } (z', w') \text{ in Graph}(T).$$

T is said to be a maximal monotone operator if it is monotone and its graph is not properly contained in the graph of any other monotone operator. The theory and applications of monotone operators have been studied extensively; see, for example, Brezis [3], Dolezal [5], and Aubin and Ekeland [1].

The problem that we are interested in is to find a vector z in H such that

$$0 \in T(z). \tag{1.1}$$

Many problems from mathematical programming, complementarity, mathematical economics and other fields can be formulated as generalized equations (1.1) (Robinson [10]). One specific type of such problems that motivates this paper is the convex programming problem

$$\text{minimize } f(z), \tag{1.2}$$

where f is a closed proper convex function.

Let ∂f be the subgradient of f. It is well known that if f is a closed proper convex function, then ∂f is a maximal monotone operator. Furthermore, $\bar{z}$ solves the minimization problem (1.2) if and only if $\bar{z}$ solves the generalized equation (1.1), where $T = \partial f$.

The proximal point algorithm solves (1.1) when T is maximal monotone. Starting at any point z^0 the algorithm generates a sequence $\{z^k\}$ according to the rule

$$z^{k+1} = P_k(z^k), \tag{1.3}$$

where $P_k(z) := (I + c_k T)^{-1}(z)$ and $\{c_k\}$ is a sequence of positive numbers.

The algorithm is based on the fact that the proximal map P_k is single-valued and nonexpansive (Minty [9]). Rockafellar [13] shows that under certain conditions the sequence $\{z^k\}$ converges to a solution $\bar{z}$ to (1.1). The proximal point algorithm has been investigated further by Luque [8] and Spingarn [14], [15]. It also has been applied to decomposition by Spingarn [16], Ha [6], and Kaneko and Ha [7].

Applying to the convex programming problem (1.2), z^{k+1} satisfies the rule (1.3) if and only if it is the unique optimizer of the problem

$$\text{minimize } f(z) + (1/2c_k)|z - z^k|^2. \tag{1.4}$$

The proximal point algorithm solves (1.2) by iteratively solving (1.4). The advantage of (1.4) over (1.2) is that the function $f(\cdot) + (1/2c_k)|\cdot - z^k|^2$ is strongly convex; consequently, (1.4) has a unique optimal solution. Strong convexity of the objective function is a very important feature if we use methods for solving (1.4) that are based on duality. It is especially significant in the decomposition of large scale problems (see Spingarn [16] and Ha [6]).

Suppose now that z consists of two components $z = (x, y)$, then (x^{k+1}, y^{k+1}) is the optimal solution to the problem

$$\underset{(x,y)}{\text{minimize}}\, f(x, y) + (1/2c_k)|(x, y) - (x^k, y^k)|^2. \tag{1.5}$$

However, in some applications we would like to add a quadratic term of just one variable, say y. That means (x^{k+1}, y^{k+1}) would be an optimal solution to the problem

$$\underset{(x,y)}{\text{minimize}}\, f(x, y) + (1/2c_k)|y - y^k|^2. \tag{1.6}$$

The problem (1.6), in general, does not have as attractive features as (1.5); in particular, the objective function in (1.6) is not as strongly convex in (x, y) as that in (1.5). But in the case that either f is already strongly convex in x for all y or f is separable, i.e., $f(x, y) = f_1(x) + f_2(y)$, $f_1(x)$ is linear and the feasible region is bounded, then (1.6) is easier to solve than (1.5). Moreover, in decomposition methods based on duality, for some problems, (1.6) produces simpler subproblems than (1.5). We illustrate these points by an example.

Example. We consider the following quadratic programming problem:

$$\begin{aligned} &\text{minimize } \langle a_1, x\rangle + (1/2)\langle x, Cx\rangle + \langle a_2, y\rangle \\ &\text{subject to } A_1 x \qquad \leqq b_1 \\ &\qquad\qquad A_2 y \leqq b_2 \\ &\qquad B_1 x + B_2 y \leqq b_3, \end{aligned}$$

where a and b are vectors; A, B, and C are matrices having appropriate dimensions. C is assumed to be positive definite.

Let $f(x, y) = \langle a_1, x\rangle + (1/2)\langle x, Cx\rangle + \langle a_2, y\rangle$. Using the regular proximal point algorithm given by (1.5), the problem to be solved is

$$\begin{aligned} &\text{minimize } f(x, y) + (1/2c_k)|(x, y) - (x^k, y^k)|^2 \\ &\text{subject to } A_1 x \qquad \leqq b_1 \\ &\qquad\qquad A_2 y \leqq b_2 \\ &\qquad B_1 x + B_2 y \leqq b_3. \end{aligned}$$

To decompose the problem we put the coupling constraint into the objective function. The dual problem is

$$\text{maximize } g(u).$$

The dual function $g(u)$ is the optimal objective value of the problem

$$\begin{aligned} &\text{minimize } f(x, y) + (1/2c_k)|(x, y) - (x^k, y^k)|^2 + \langle u, b_3 - B_1 x - B_2 y\rangle \\ &\text{subject to } A_1 x \qquad \leqq b_1 \\ &\qquad\qquad A_2 y \leqq b_2. \end{aligned}$$

The above problem consists of two independent subproblems, one in terms of x variable and one in y variable. We are interested in the subproblem in x variable:

$$\begin{aligned} &\text{minimize } \langle a_1, x\rangle + (1/2)\langle x, Cx\rangle + (1/2c_k)|x - x^k|^2 - \langle u, B_1 x\rangle \\ &\text{subject to } A_1 x \leqq b_1. \end{aligned} \tag{1.7}$$

If we use the generalized proximal point algorithm given by (1.6), then the subproblem in x variable is reduced to

$$\begin{aligned} &\text{minimize } \langle a_1, x\rangle + (1/2)\langle x, Cx\rangle - \langle u, B_1 x\rangle \\ &\text{subject to } A_1 x \leqq b_1. \end{aligned} \tag{1.8}$$

For the problem (1.7) we have to update the matrix of the objective function in each iteration of the proximal point algorithm; meanwhile, the matrix of (1.8) remains constant. That advantage of (1.8) is particularly useful if we use a conjugate direction approach for solving the subproblems. Because the matrix of (1.8) is unchanged, the conjugate directions need not be recomputed for any iteration of the generalized proximal point algorithm.

In this paper we propose an algorithm to solve the generalized equation in two variables

$$0 \in T(x, y).$$

The algorithm is a generalization of the proximal point algorithm. Its iterations are based on just one variable—not both as in the proximal point algorithm. Applying to the convex programming problem (1.2) our generalized proximal point algorithm solves iteratively (1.6) instead of (1.5). In § 2 we define the generalized proximal map as

$$P = (\Pi + cT)^{-1}\Pi$$

where Π is the projection on the second space. We show that under a mild condition, namely, $0 \in \operatorname{int} \operatorname{Im}(T)$, the generalized proximal map P has desirable properties. In §§ 3 and 4 we prove the convergence and the rate of convergence of the generalized

proximal point algorithm. Applications to convex programming problems will be reported in a subsequent paper.

2. Properties of the generalized proximal map. Let $H = H_1 \times H_2$, where H_1 and H_2 are two real Hilbert spaces. For convenience we denote the inner products and the norms in H_1 and H_2 by the same notations $\langle \cdot, \cdot \rangle$ and $|\cdot|$, respectively.

The inner product on H is induced from those on H_1 and H_2, i.e.,

$$\langle (x, y), (u, v) \rangle = \langle x, u \rangle + \langle y, v \rangle$$

for $(x, y) \in H_1 \times H_2$ and $(u, v) \in H_1 \times H_2$.

Let Π be the orthogonal projection of H onto $\{0\} \times H_2$, i.e., $\Pi(x, y) = (0, y)$ for $(x, y) \in H_1 \times H_2$. Let $T: H \to H$ be a maximal monotone operator. We consider the problem of finding $(x, y) \in H_1 \times H_2$ satisfying the generalized equation

$$0 \in T(x, y). \tag{2.1}$$

The generalized proximal point algorithm generates from any point $y^0 \in H_2$ a sequence $\{(x^k, y^k)\}$ by the rule

$$(x^{k+1}, y^{k+1}) \in (\Pi + c_k T)^{-1}(0, y^k), \tag{2.2}$$

where $\{c_k\}$ is a sequence of positive numbers.

We denote

$$P := (\Pi + cT)^{-1}\Pi \tag{2.3}$$

for some positive number c and

$$P_k := (\Pi + c_k T)^{-1}\Pi.$$

Then (2.2) is

$$(x^{k+1}, y^{k+1}) \in P_k(x^k, y^k).$$

Note that if Π is substituted by the identity I then P is the regular proximal map $\bar{P}$ of T. That is $\bar{P} = (I + cT)^{-1}$. The proximal map $\bar{P}$ has several familiar properties:

(i) Dom $\bar{P} = H$.

(ii) $\bar{P}$ is single-valued.

(iii) $\bar{P}$ is nonexpansive, i.e.,

$$|P(z) - P(z')| \leqq |z - z'| \quad \text{for } z, z' \in H.$$

(iv) $\bar{P}(z) = z$ if and only if $0 \in T(z)$.

It is easy to see that P defined by (2.3) does not have any property above. However, we will show that under a simple condition P has property (i) and properties similar to (ii)-(iv).

DEFINITION (Aubin and Ekeland [1, p. 392]). Let A be a monotone operator from X to X, a Hilbert space. It satisfies the L property if for all $w \in \text{Im}(A)$ and $y \in \text{Dom}(A)$ there is a number c such that

$$\inf_{(x, u) \in \text{Graph}(A)} \langle u - w, x - y \rangle \geqq c.$$

The following theorem is proved by Brezis and Haraux [4] but its present form is from Aubin and Ekeland [1, p. 393].

THEOREM. *Let A and B be two monotone operators satisfying*

(i) Dom $(A) \subset$ Dom (B),

(ii) *$A + B$ is maximal monotone, and*

(iii) *B satisfies the L property.*

Then

(i) int Im $(A + B) =$ int $(\text{Im}(A) + \text{Im}(B))$ *and*

(ii) cl Im $(A+B) = \text{cl}(\text{Im}(A)+\text{Im}(B))$, *where* int *and* cl *denote the topological interior and closure, respectively.*

PROPOSITION 1. *Suppose* $0 \in \text{int Im}(T)$. *Then*

$$\{0\} \times H_2 \subset \text{int Im}(\Pi + cT) \tag{2.4}$$

and Dom $(P) = H$.

Proof. To use the theorem of Brezis and Haraux with $A = cT$ and $B = \Pi$ we need to verify its three conditions.

Since Dom $(\Pi) = H$ the first condition is trivial. We also have

$$\text{Dom}(cT) \cap \text{int}(\text{Dom}\,\Pi) = \text{Dom}(cT) \neq \phi.$$

Therefore, $cT + \Pi$ is maximal monotone (Rockafellar [12]).

We now show that Π satisfies the L property. Let $x = (x_1, x_2)$, $y = (y_1, y_2)$ and $z = (z_1, z_2)$ be three vectors in $H_1 \times H_2$.

Let

$$u = \Pi(x_1, x_2) = (0, x_2),$$

$$v = \Pi(y_1, y_2) = (0, y_2),$$

and

$$w = \Pi(z_1, z_2) = (0, z_2).$$

We have

$$\begin{aligned}\langle u, x-y\rangle + \langle v, y-z\rangle + \langle w, z-x\rangle &= \langle x_2, x_2-y_2\rangle + \langle y_2, y_2-z_2\rangle + \langle z_2, z_2-x_2\rangle \\ &= \frac{1}{2}(|x_2-y_2|^2 + |y_2-z_2|^2 + |z_2-x_2|^2) \geqq 0.\end{aligned}$$

Define $c := \langle w-v, y-z\rangle$. Then $\langle u-w, x-y\rangle \geqq c$ for all $(x, u) \in \text{graph}(\Pi)$. By the theorem of Brezis and Haraux

$$\begin{aligned}\text{int}(\text{Im}(cT+\Pi)) &= \text{int}(\text{Im}(cT) + \text{Im}(\Pi)) \\ &= \text{int}(\text{Im}(cT) + \{0\} \times H_2).\end{aligned}$$

Some $0 \in \text{int Im}(T) = \text{int Im}(cT)$ we have

$$\{0\} \times H_2 \subset \text{int}(\text{Im}(cT+\Pi)).$$

Let $(x, y) \in H$, then by (2.4) there is $(u, v) \in H$ such that

$$\Pi(x, y) = (0, y) \in (\Pi + cT)(u, v).$$

That implies

$$(u, v) \in (\Pi + cT)^{-1}\Pi(x, y) = P(x, y).$$

Therefore

$$\text{Dom } P = H.$$

PROPOSITION 2.

(i) *If* $(u_i, v_i) \in P(x, y)$ *for* $i = 1, 2$ *then* $v_1 = v_2$.

(ii) *If* $(u_i, v_i) \in P(x_i, y_i)$ *for* $i = 1, 2$ *then* $|v_1 - v_2| \leqq |y_1 - y_2|$.

(iii) $0 \in T(x, y)$ *if and only if* $(x, y) \in P(x, y)$.

Proof.

(i) $(u_i, v_i) \in P(x, y)$
$\Rightarrow (0, y) \in (\Pi + cT)(u_i, v_i)$
$\Rightarrow (0, y - v_i) \in cT(u_i, v_i)$ for $i = 1, 2$.

By monotonicity of cT we have

$$\langle (0, y - v_1) - (0, y - v_2), (u_1, v_1) - (u_2, v_2) \rangle \geqq 0$$
$$\Rightarrow \langle v_2 - v_1, v_1 - v_2 \rangle \geqq 0.$$

Therefore $v_1 = v_2$.

(ii) $(u_i, v_i) \in P(x_i, y_i)$
$\Rightarrow (0, y_i - v_i) \in cT(u_i, v_i)$ for $i = 1, 2$
$\Rightarrow \langle (y_1 - v_1) - (y_2 - v_2), v_1 - v_2 \rangle \geqq 0.$

We have

$$|y_1 - y_2|^2 = |y_1 - y_2 - v_1 + v_2 + v_1 - v_2|^2$$
$$= |y_1 - y_2 - v_1 + v_2|^2 + |v_1 - v_2|^2 + 2\langle y_1 - y_2 - v_1 + v_2, v_1 - v_2 \rangle.$$

Hence

$$|y_1 - y_2|^2 \geqq |y_1 - y_2 - v_1 + v_2|^2 + |v_1 - v_2|^2 \tag{2.5}$$

and

$$|y_1 - y_2| \geqq |v_1 - v_2|.$$

(iii) $(x, y) \in P(x, y)$
$\Leftrightarrow (0, y) \in (\Pi + cT)(x, y)$
$\Leftrightarrow (0, y) - (0, y) \in cT(x, y)$
$\Leftrightarrow 0 \in T(x, y)$.

Although P does not have as good properties as the regular proximal map, from Proposition 2 we observe that P is well behaved enough for our purpose. While P is neither single-valued nor nonexpansive, the second component is uniquely determined and nonexpansive. Moreover, the generalized equation (2.1) can be converted to a fixed point problem.

3. Convergence of the generalized proximal point algorithm. For practical purposes (x^{k+1}, y^{k+1}) should be obtained according to some approximation criteria rather than exactly as in (2.2). Following Rockafellar [13] we consider two approximation criteria

$$|(x^{k+1}, y^{k+1}) - (u^{k+1}, v^{k+1})| \leqq \varepsilon_k, \qquad \sum_{k=0}^{\infty} \varepsilon_k < \infty \tag{A}$$

and

$$|(x^{k+1}, y^{k+1}) - (u^{k+1}, v^{k+1})| \leqq \delta_k |(x^{k+1}, y^{k+1}) - (x^k, y^k)| \tag{B}$$

and

$$|(y^{k+1} - v^{k+1})| \leqq \delta_k |y^{k+1} - y^k|, \qquad \sum_{k=0}^{\infty} \delta_k < \infty,$$

where

$$(u^{k+1}, v^{k+1}) \in P(x^k, y^k). \tag{3.1}$$

Other approximation criteria, as in Auslender [2], will be discussed in a subsequent paper that applies the generalized proximal point algorithm to convex programming problems.

THEOREM 1. *Let* $\{c_k\}$ *be a sequence of positive numbers bounded away from zero. Suppose* $0 \in \operatorname{int} \operatorname{Im}(T)$. *Let* $\{(x^k, y^k)\}$ *be a sequence generated under criterion* (A). *Then* $\{(x^k, y^k)\}$ *is bounded and any of its weak cluster point is a solution to* (2.1). *Moreover,* $\{y^k\}$ *converges weakly to* $\bar{y}$, *a second component of a solution to* (2.1).

Proof. Let $(\bar{x}, \bar{y})$ be a solution to (2.1), then

$$(\bar{x}, \bar{y}) \in P(\bar{x}, \bar{y}).$$

Similarly to (2.5) the relation above and the definition (3.1) of (u^{k+1}, v^{k+1}) yield

$$|y^k - \bar{y}|^2 \geqq |y^k - v^{k+1}|^2 + |v^{k+1} - \bar{y}|^2. \tag{3.2}$$

Hence

$$|v^{k+1} - \bar{y}| \leqq |y^k - \bar{y}|.$$

From

$$|y^{k+1} - \bar{y}| \leqq |y^{k+1} - v^{k+1}| + |v^{k+1} - \bar{y}|$$

it implies that

$$|y^{k+1} - \bar{y}| \leqq \varepsilon_k + |y^k - \bar{y}|.$$

Because $\sum_{k=0}^{\infty} \varepsilon_k < \infty$ the sequence $\{y^k\}$ is bounded and $\lim_{k\to\infty} |y^k - \bar{y}|$ exists and is finite.

We now show that $|y^k - v^{k+1}| \to 0$ as $k \to \infty$. By (3.2) we have

$$\begin{aligned}
|y^k - v^{k+1}|^2 - |y^k - \bar{y}|^2 + |y^{k+1} - \bar{y}|^2 &\leqq |y^{k+1} - \bar{y}|^2 - |v^{k+1} - \bar{y}|^2 \\
&= \langle y^{k+1} - v^{k+1}, (y^{k+1} - \bar{y}) + (v^{k+1} - \bar{y}) \rangle \\
&\leqq |y^{k+1} - v^{k+1}|(|y^{k+1} - \bar{y}| + |v^{k+1} - \bar{y}|) \\
&\leqq \varepsilon_k(|y^{k+1} - \bar{y}| + |y^k - \bar{y}|) \\
&\leqq 2\varepsilon_k(s + |\bar{y}|),
\end{aligned}$$

where s is a positive number such that

$$|y^k| \leqq s \quad \text{for all } k.$$

Consequently

$$|y^k - v^{k+1}|^2 \leqq |y^k - \bar{y}|^2 - |y^{k+1} - \bar{y}|^2 + 2\varepsilon_k(s + |\bar{y}|).$$

Hence

$$|y^k - v^{k+1}| \to 0 \quad \text{as } k \to \infty.$$

Since $\{c_k\}$ is bounded away from zero, we also have

$$(1/c_k)(y^k - v^{k+1}) \to 0 \quad \text{as } k \to \infty. \tag{3.3}$$

The assumption $0 \in \operatorname{int} \operatorname{Im}(T)$ implies that there exist positive numbers α and ε such that

$$|z| \geqq \alpha \Rightarrow |w| \geqq \varepsilon \text{ whenever } w \in T(z)$$

(Rockafellar [13]) or equivalently for any $w \in B(0, \varepsilon)$, $T^{-1}(w) \subset B(0, \alpha)$, where $B(0, \varepsilon)$ and $B(0, \alpha)$ denote the ball of center 0 and radius ε and α, respectively. In other words T^{-1} is locally bounded at 0. By (3.3) there is an integer K such that

$$(0, (1/c_k)(y^k - v^{k+1})) \in B(0, \varepsilon) \text{ for } k \geqq K.$$

That implies

$$(u^{k+1}, v^{k+1}) \in T^{-1}(0, (1/c_k)(y^k - v^{k+1})) \subset B(0, \alpha) \quad \text{for } k \geqq K.$$

Therefore $\{(u^k, v^k)\}$ is bounded and so is $\{(x^k, y^k)\}$.

Let $\{(x^{k_j}, y^{k_j})\}$ be a subsequence that converges weakly to (x^*, y^*). We observe that $\{(u^{k_j}, v^{k_j})\}$ also converges weakly to (x^*, y^*) and

$$(u^{k_j}, v^{k_j}) \in T^{-1}(0, (1/c_{k_j-1})(y^{k_j-1} - v^{k_j})).$$

We know that the graph of a maximal monotone operator is weakly-strongly closed (Aubin and Ekeland [1, p. 379]). Therefore at the limit

$$(x^*, y^*) \in T^{-1}(0, 0)$$

or (x^*, y^*) is a solution to (2.1).

Let $(\tilde{x}, \tilde{y})$ be another weak cluster point of $\{(x^k, y^k)\}$; we will show that $\tilde{y} = y^*$. This proof is similar to the one given by Rockafellar [13, p. 885]. Using the same argument as above, $(\tilde{x}, \tilde{y})$ is a solution to (2.1). Likewise

$$\mu_1 = \lim_{k\to\infty} |y^k - y^*|$$

and

$$\mu_2 = \lim_{k\to\infty} |y^k - \tilde{y}|$$

exist and are finite. From

$$|y^k - \tilde{y}|^2 = |y^k - y^*|^2 + |y^* - \tilde{y}|^2 + 2\langle y^k - y^*, y^* - \tilde{y}\rangle$$

we see that the limit of $\langle y^k - y^*, y^* - \tilde{y}\rangle$ as $k \to \infty$ must exist. That limit has to be zero because y^* is a weak cluster point of $\{y^k\}$. Hence, at the limit

$$\mu_2 = \mu_1 + |y^* - \tilde{y}|^2.$$

Reversing the role of $\tilde{y}$ and y^* we also have

$$\mu_1 = \mu_2 + |y^* - \tilde{y}|^2.$$

That implies $\tilde{y} = y^*$.

4. Rate of convergence. This section follows closely § 3 in Rockafellar [13]. In other words we obtain the same linear rate and if $c_k \uparrow \infty$ the rate is superlinear. Also under certain conditions we have finite convergence.

DEFINITION (Rockafellar [13]). A set-valued map A is said to be Lipschitz continuous at w_0 with modulus $a \geqq 0$ if $A(w_0)$ is single-valued, i.e., $A(w_0) = \{z_0\}$ and for some $\tau > 0$ we have

$$|z - z_0| \leqq a|w - w_0| \quad \text{whenever } z \in A(w) \text{ and } |w - w_0| < \tau.$$

THEOREM 2. *Suppose T^{-1} is Lipschitz continuous at 0 with modulus a. Let $\{(x^k, y^k)\}$ be any sequence generated under Criterion (B) with $\{c_k\}$ nondecreasing ($c_k \uparrow c \leqq \infty$). Assume that $\{(x^k, y^k)\}$ is bounded.*

Let

$$\mu_k := a/(a^2 + c_k^2)^{1/2}.$$

Then $\{(x^k, y^k)\}$ converges strongly to $(\bar{x}, \bar{y})$, the unique solution to (2.1). Moreover, there is an integer K such that

$$|y^{k+1} - \bar{y}| \leqq \theta_k |y^k - \bar{y}| \quad \textit{for all } k \geqq K$$

where $\theta_k := (\mu_k + \delta_k)/(1 - \delta_k)$ for all $k \geqq K$.

Proof. By the definition of Lipschitz continuity, T^{-1} is locally bounded at 0, so $0 \in \operatorname{int} \operatorname{Im}(T)$ (Rockafellar [11]). The boundedness of $\{(x^k, y^k)\}$ allows us to use Theorem 1 with

$$\varepsilon_k = \delta_k |(x^{k+1}, y^{k+1}) - (x^k, y^k)|.$$

By the definition of (u^{k+1}, v^{k+1})

$$(u^{k+1}, v^{k+1}) \in T^{-1}(0, (1/c_k)(y^k - v^{k+1})).$$

By the proof of Theorem 1

$$(1/c_k)(y^k - v^{k+1}) \to 0 \quad \text{as } k \to \infty.$$

Consequently, there is an integer K such that

$$|(1/c_k)(y^k - v^{k+1})| < \tau \quad \text{for all } k \geqq K.$$

That implies

$$|(u^{k+1}, v^{k+1}) - (\bar{x}, \bar{y})| \leqq a|(0, (1/c_k)(y^k - v^{k+1}))|. \tag{4.1}$$

We have

$$\begin{aligned} |(x^{k+1}, y^{k+1}) - (\bar{x}, \bar{y})| &\leqq |(x^{k+1}, y^{k+1}) - (u^{k+1}, v^{k+1})| + |(u^{k+1}, v^{k+1}) - (\bar{x}, \bar{y})| \\ &\leqq 2\delta_k s + a|(0, (1/c_k)(y^k - v^{k+1}))|, \end{aligned}$$

where s is a number such that

$$|(x^k, y^k)| \leqq s \quad \text{for all } k.$$

Hence $\{(x^k, y^k)\}$ converges strongly to $(\bar{x}, \bar{y})$.

We have from (4.1)

$$|v^{k+1} - \bar{y}| \leqq (a/c_k)|y^k - v^{k+1}|$$

and from (3.2)

$$|v^{k+1} - \bar{y}|^2 + |y^k - v^{k+1}|^2 \leqq |y^k - \bar{y}|^2.$$

These imply

$$(1 + (a/c_k)^2)|v^{k+1} - \bar{y}|^2 \leqq (a/c_k)^2 |y^k - \bar{y}|^2$$

or

$$|v^{k+1} - \bar{y}| \leqq (a/(a^2 + c_k^2)^{1/2})|y^k - \bar{y}| = \mu_k |y^k - \bar{y}|.$$

On the other hand,

$$|y^{k+1} - \bar{y}| \leqq |y^{k+1} - v^{k+1}| + |v^{k+1} - \bar{y}|$$

and

$$|v^{k+1} - y^{k+1}| \leqq \delta_k |y^{k+1} - y^k| \leqq \delta_k |y^{k+1} - \bar{y}| + \delta_k |\bar{y} - y^k|.$$

Hence

$$|y^{k+1} - \bar{y}| \leqq \delta_k |y^{k+1} - \bar{y}| + \delta_k |y^k - \bar{y}| + \mu_k |y^k - \bar{y}|$$

or

$$(1 - \delta_k)|y^{k+1} - \bar{y}| \leqq (\delta_k + \mu_k)|y^k - \bar{y}|.$$

That gives

$$|y^{k+1}-\bar{y}| \leqq \theta_k |y^k-\bar{y}| \quad \text{where } \theta_k = (\delta_k+\mu_k)/(1-\delta_k).$$

Theorem 2 shows that the rate of convergence is linear and if $c_k \to \infty$ as $k \to \infty$ then $\mu_k \to 0$ and $\theta_k \to 0$, so the rate is superlinear. In the next theorem we show that for a special case the convergence is finite.

THEOREM 3. *Let $\{(x^k, y^k)\}$ be any sequence generated by the generalized proximal point algorithm under criterion (A) or (B) with $\{c_k\}$ bounded away from zero. We assume that $\{(x^k, y^k)\}$ is bounded if criterion (B) is used. Suppose that there is $(\bar{x}, \bar{y})$ such that $0 \in \operatorname{int} T(\bar{x}, \bar{y})$. Then*

$$(\bar{x}, \bar{y}) = (u^{k+1}, v^{k+1}) \text{ for } k \text{ sufficiently large.}$$

In particular, the generalized proximal point algorithm in its exact form $((x^{k+1}, y^{k+1}) \in P(x^k, y^k))$ gives convergence to $(\bar{x}, \bar{y})$ in a finite number of iterations from any starting point.

Proof. Rockafellar [13] shows that if $0 \in \operatorname{int} T(\bar{x}, \bar{y})$, then T^{-1} is single-valued and constant on a neighborhood of 0, i.e., there exists $\varepsilon > 0$ such that if $|w| < \varepsilon$ then $T^{-1}(w) = (\bar{x}, \bar{y})$. By Theorem 1, $(1/c_k)(y^k - v^{k+1}) \to 0$ as $k \to \infty$ and $(u^{k+1}, v^{k+1}) \in T^{-1}(0, (1/c_k)(y^k - v^{k+1}))$. Therefore for k sufficiently large

$$(0, (1/c_k)(y^k - v^{k+1})) \in B(0, \varepsilon).$$

Consequently $(u^{k+1}, v^{k+1}) = (\bar{x}, \bar{y})$ for k sufficiently large.

Applications of the generalized proximal point algorithm to convex programming problems will be discussed in a subsequent paper.

CONTINUOUS-TIME STOCHASTIC ADAPTIVE TRACKING— ROBUSTNESS AND ASYMPTOTIC PROPERTIES*

HAN-FU CHEN† AND LEI GUO†

Abstract. Adaptive estimation and control problems are considered for continuous-time stochastic systems containing both modeled and unmodeled dynamics. The least squares method is used to estimate unknown parameters included in the modeled part, which are used to update an adaptive control law. It is shown that both the estimation error and the tracking error are bounded, and that the bounds are proportional to constants dominating the unmodeled dynamics. Moreover, convergence rates of the tracking errrors are established in the case where no unmodeled dynamics exist.

Key words. continuous-time stochastic system, adaptive tracking, least squares, robustness, unmodeled dynamics

AMS(MOS) subject classifications. 93C40, 93E12

1. Introduction. In recent years, much attention has been devoted to the analysis of adaptive algorithms when unmodeled dynamics are contained in the system. It is known that (see, e.g., [1]-[3]) unmodeled dynamics or even small disturbances may cause instability in many adaptive algorithms when precautions are not taken. This inspired the study of robust adaptive control where the primary purpose is to maintain stability of the closed-loop system under violations of ideal assumptions. There is already a vast literature on this topic, especially in the deterministic framework (e.g., [4]-[6]).

In the stochastic case, robustness results are much more difficult to obtain. This results from the following "stochastic features": (i) a priori upper bounds for the noise sequence are usually not available, (ii) optimal or at least close to optimal rejection of the noise effects is required, and (iii) traditionally used supermartingale methods fail due to unmodeled dynamics. An initial attempt toward robustness analysis for discrete-time stochastic adaptive systems was made in [7], where an a priori assumption on the input-output data was required. This assumption was later removed in [8] for a large class of stochastic systems represented by a full ARMAX model plus unmodeled dynamics.

While discrete-time adaptive theory is well developed, the corresponding continuous-time analogue becomes a natural concern. There is no doubt that results of this kind are interesting and important in many situations. Unfortunately, it seems that they have received less attention in the literature, and that only some initial works in the adaptive estimation aspect are available (see, e.g., [9]-[12]).

In this paper, we consider both estimation and control problems for stochastic systems described by stochastic differential/integral equations. The adaptive control law is defined based on a continuous-time analogue of the least-squares estimation algorithm. We show the following:

(i) That the least squares method has some degree of robustness when unmodeled dynamics are contained in the model, provided that the system is "persistently excited."

(ii) That the closed-loop adaptive system is stable, with a tracking error upper bound. This bound implies that the tracking error will decrease when upper bounds on the unmodeled dynamics decrease.

* Received by the editors January 21, 1987; accepted for publication (in revised form) August 11, 1989.

† Institute of Systems Science, Academia Sinica, Beijing, People's Republic of China. This project was supported by the National Natural Science Foundation of China and the TWAS research grant 87-43.

(iii) That if there are no unmodeled dynamics, then the least squares estimation results parallel those obtained in the discrete-time case (see, e.g., [13], [14]); furthermore, in the present paper we provide a precise convergence rate for the tracking error, which in the discrete-time case still remains a standing issue.

We state here that the above-mentioned results are established under the assumption that the strong solution of the stochastic differential equations describing the closed-loop system exists. And for the time being, we know of no way to verify or sidestep this assumption. However, we believe that many of the ideas, techniques, and results presented in this paper are necessary preliminaries for future study.

2. The system description. Let $\{F_t\}$ be a family of nondecreasing σ-algebras defined on a probability space (Ω, F, P), and let the system to be considered be described by the following stochastic differential/integral equation:

$$\begin{aligned}(1)\qquad [I+\mu_1 SH_1(S)]A(S)y_t &= [I+\mu_2 H_2(S)]SB(S)u_t + [I+\mu_3 SH_3(S)]C(S)v_t \\ &\quad + \mu_4 S\xi_t(y,u), \qquad t\geqq 0, \quad y_0=0, \quad u_0=0, \quad \xi_0=0\end{aligned}$$

where s denotes the integral operator (e.g., $Sy_t=\int_0^t y_z\,dz$), and y_t and u_t adapted to $\{F_t\}$ are m-dimensional output and l-dimensional input, respectively. The quantities μ_i, $i=1,\cdots,4$, are small constants, $H_i(S)$, $i=1,2,3$, are unmodeled matrix transfer functions, and $\xi_t(y,u)$, dependent on the previous observation $\{y_s, u_2, 0\leqq s\leqq t\}$, is an unknown nonanticipative measurable process characterizing the unmodeled dynamics. Finally, v_t is the system noise that is generated via a known filter $D^{-1}(S)$ from a standard Wiener process (w_t, F_t):

$$(2)\qquad D(S)v_t = w_t, \qquad t\geqq 0.$$

Assume that $A(S)$, $B(S)$, and $C(S)$ are matrix polynomials in S, with unknown coefficients but known upper bounds for the true orders:

$$(3)\qquad A(S)=I+A_1S+\cdots+A_pS^p, \qquad p\geqq 0,$$

$$(4)\qquad B(S)=B_1+B_2S+\cdots+B_qS^{q-1}, \qquad q\geqq 1,$$

$$(5)\qquad C(S)=I+C_1S+\cdots+C_rS^r, \qquad r\geqq 1,$$

$$(6)\qquad D(S)=I+D_1S+\cdots+D_rS^r.$$

Note that (1) may be rewritten in the form

$$(7)\qquad A(S)y_t = SB(S)u_t + C(S)v_t + \eta_t,$$

$$\begin{aligned}(8)\qquad \eta_t &= \mu_4 S\xi_t(y,u) - \mu_1 SH_1(S)A(S)y_t + \mu_2 SH_2(S)B(S)u_t \\ &\quad + \mu_3 SH_3(S)C(S)v_t.\end{aligned}$$

We remark that, if the unmodeled dynamics are removed, i.e., $\eta_t=0$, for all $t\geqq 0$, then the model (7) is reduced to the one considered in [9]-[12]. Clearly, in this case model (7) may be rewritten in the standard linear state space form, and the output process $\{y_t\}$ can be uniquely determined by the process $\{u_t, w_t\}$. In the general case, it is natural to assume that $\{y_t\}$ can also be determined by $\{u_t, w_t\}$ via (7)-(8).

We denote the collection of unknown matrix coefficients of $A(S)$, $B(S)$, and $C(S)$ by θ:

$$(9)\qquad \theta^\tau = [-A_1\cdots -A_p \quad B_1\cdots B_q \quad C_1\cdots C_r].$$

In the sequel, θ is estimated by the continuous-time extended least square algorithm [10]-[12]:

$$d\theta_t = P_t\phi_t D(S)(dy_t^\tau - \phi_t^\tau \theta_t\, dt), \qquad \theta_0 = 0, \tag{10}$$

$$dP_t = -P_t\phi_t\phi_t^\tau P_t\, dt, \quad P_0 = aI \quad (a = \dim \text{ of } \phi_t), \tag{11}$$

$$\phi_t = [y_t^\tau, Sy_t^\tau \cdots S^{p-1}y_t^\tau, u_t^\tau, Su_t^\tau \cdots S^{q-1}u_t^\tau, \hat{v}_t^\tau \cdots S^{r-1}\hat{v}_t^\tau]^\tau, \tag{12}$$

$$\hat{v}_t = y_t - S\theta_t^\tau \phi_t. \tag{13}$$

Obviously, if $r = 0$, then (10) and (11) can be expressed as

$$\theta_t = P_t \int_0^t \phi_s\, dy_s^\tau + P_t(P_0)^{-1}\theta_0, \tag{14}$$

$$P_t = \left(\int_0^t \phi_s\phi_s^\tau\, ds + a^{-1}\right)^{-1}, \tag{15}$$

and the right-hand side of (14) is completely determined by the observations $\{u_s, y_s, s \leqq t\}$.

In the general $r > 0$ case, however, the regressor ϕ_t depends on $\{\theta_s, s \leqq t\}$. Then (10) and (11) constitute a system of nonlinear stochastic differential equations for θ_t. The existence of the solution is far from obvious since the typical Lipschitz condition, which plays a vital role in the standard theory of stochastic differential equations (see, [15, Chap. 4], for example), is hard to verify in the present case. For that study, the introduction of new techniques seems to be necessary, although our differential equations are well motivated.

Henceforth, we assume that the stochastic differential/integral equation (10)-(11) has a unique strong solution $\{\theta_t, t \geqq 0\}$ in the sense of [15, pp. 127].

Set

$$\phi_t^0 = [y_t^\tau, Sy_t^\tau \cdots S^{p-1}y_t^\tau, u_t^\tau, Su_t^\tau \cdots S^{q-1}u_t^\tau, v_t^\tau \cdots S^{r-1}v_t^\tau]^\tau, \tag{16}$$

$$\tilde{\phi}_t = [0 \cdots 0, 0 \cdots 0, \tilde{v}_t^\tau \cdots S^{r-1}\tilde{v}_t^\tau]^\tau \qquad \tilde{v}_t = v_t - \hat{v}_t, \tag{17}$$

$$Y_t = [y_t^\tau \cdots S^{p-1}y_t^\tau]^\tau, \qquad U_t = [u_t^\tau \cdots S^{q-1}u_t^\tau]^\tau, \tag{18}$$

$$V_t = [v_t^\tau \cdots S^{r-1}v_t^\tau]^\tau, \quad \hat{V}_t = [\hat{v}_t^\tau \cdots S^{r-1}\hat{v}_t^\tau]^\tau, \quad \tilde{V}_t = V_t - \hat{V}_t. \tag{19}$$

Then it follows that

$$\phi_t = [Y_t^\tau, U_t^\tau, \hat{V}_t^\tau]^\tau, \quad \phi_t^0 = [Y_t^\tau, U_t^\tau, V_t^\tau]^\tau, \quad \tilde{\phi}_t = [0, 0, \tilde{V}_t^\tau]^\tau. \tag{20}$$

Furthermore, we set

$$F_d = \begin{bmatrix} -D_1 & \cdots & \cdots & -D_r \\ I & 0 & \cdots & 0 \\ 0 & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ 0 & \cdots & I & 0 \end{bmatrix}, \qquad F_c = \begin{bmatrix} -C_1 & \cdots & \cdots & -C_r \\ I & 0 & \cdots & 0 \\ 0 & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ 0 & \cdots & I & 0 \end{bmatrix}. \tag{21}$$

By use of these kinds of matrices it is easy to represent an input-output equation in state space form. For example, from (2) and (19) we may write V_t as

$$dV_t = F_d V_t\, dt + [I, 0 \cdots 0]^\tau\, dw_t. \tag{22}$$

In the sequel, similar representations will be used without additional explanation.

On the unmodeled dynamics η_t, we make an assumption similar to that used for discrete-time systems in [8].

Assumption 1. There is a real number $\varepsilon \geqq 0$ such that

$$\int_0^t \|\dot{\eta}_s\| \, ds \leqq \varepsilon r_t, \qquad t \geqq 0 \tag{23}$$

where

$$\dot{\eta}_t = \mu_4 \xi_t(y, u) - \mu_1 H_1(S)A(S)y_t + \mu_2 H_2(S)B(S)u_t + \mu_3 H_3(S)C(S)v_t \tag{24}$$

and

$$r_t = e + \int_0^t \|\phi_s\|^2 \, ds. \tag{25}$$

We also need the following condition on the noise model, which in the discrete-time case is a standard assumption.

Assumption 2. $D(S)$ is stable and the transfer matrix $D(S)C^{-1}(S) - I/2$ is strictly positive real.

At first sight, Assumption 1 is somewhat hard to understand and rather restrictive. However, the following examples show that there is at least one substantial and important class of dynamical systems that does satisfy this condition.

Example 1. Let the single-input and single-output system be described by the following system with additive noise:

$$y_t = G_0(S)[I + \mu G_1(S)]Su_t + v_t, \tag{26}$$

where $G_0(S) = B(S)/A(S)$ represents the nominal transfer function, whereas $G_1(S)$ is the unmodeled transfer function and is assumed to be stable and proper.

When the additive noise v_t is identically equal to zero, then the system is reduced to the deterministic one, and it coincides with the model considered (e.g., [6]) in the robustness analysis for deterministic systems.

Putting the expression for $G_0(S)$ into (26) leads to

$$A(S)y_t = B(S)u_t + \mu S G_1(S)B(S)u_t + A(S)v_t.$$

Comparing this to (7) shows that in the present case

$$\dot{\eta}_t = \mu G_1(S)B(S)u_t. \tag{27}$$

We now prove that Assumption 1 is satisfied for the system (26). For this the following auxiliary result is needed. We formulate it as a lemma, as it will also be used in the proof of the main results to follow.

LEMMA 1. *Let $E(S)$ and $F(S)$ be matrix polynomials in the integral operator S, such that the transfer matrix $F(S)E^{-1}(s)$ is stable and proper. Then*

$$\int_0^t \|F(S)E^{-1}(S)x_z\|^2 \, dz \leqq c \int_0^t \|x_z\|^2 \, dz$$

for any square integrable function $\{x_t\}$, where c is a constant depending on $E(s)$ and $F(S)$ only.

Proof. Let us write

$$E(S) = I + ES + \cdots + E_d S^d, \qquad F(S) = I + F_1 S + \cdots + F_d S^d$$

and set

$$z_t = E^{-1}(S)x_t, \qquad Z_t = [z_t^\tau \cdots S^{d-1}z_t^\tau]^\tau.$$

Similar to (22) we have

$$Z_t = F_e S Z_t + [x_t^\tau, 0 \cdots 0]^\tau \tag{28}$$

with

$$F_e = \begin{bmatrix} -E_1 & \cdots & \cdots & -E_d \\ I & 0 & \cdots & 0 \\ 0 & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ 0 & \cdots & I & 0 \end{bmatrix}.$$

The above linear differential equation has the solution

$$Z_t = F_e \int_0^t \exp\{F_e(t-s)\}[x_s^\tau, 0 \cdots 0]^\tau \, ds + [x_t^\tau, 0 \cdots 0]^\tau.$$

Since F_e is stable, there are constants $c_1 \geqq 1$ and $\rho > 0$ such that

$$\|\exp\{F_e t\}\| \leqq c_1 e^{-\rho t} \quad \forall t \geqq 0$$

where here and hereafter c_i, $i = 1, 2, \cdots$, denote constants.

It then follows that

$$\begin{aligned} \int_0^t \|Z_z\|^2 \, dz &\leqq 2\|F_e\|^2 \int_0^t \left\{ \left\| \int_0^z \exp[F_e(z-s)][x_s^\tau, 0 \cdots 0]^\tau \, ds \right\|^2 + \|x_z\|^2 \right\} dz \\ &\leqq 2(c_1)^2 \|F_e\|^2 \\ &\quad \cdot \int_0^t \left\{ \int_0^z \exp[-\rho(z-s)] \, ds \int_0^z \exp[-\rho(z-s)] \|x_s\|^2 \, ds + \|x_z\|^2 \right\} dz \\ &\leqq 2(c_1)^2 \rho^{-1} \|F_e\|^2 \int_0^t \left\{ \int_0^z \exp[-\rho(z-s)] \|x_s\|^2 \, ds + \|x_z\|^2 \right\} dz \\ &\leqq 2(c_1)^2 \rho^{-1} \|F_e\|^2 \left\{ \int_0^t \|x_z\|^2 \, dz + \rho^{-1} \int_0^t \|x_s\|^2 \, ds \right\} \\ &\leqq 2(c_1)^2 \rho^{-1} \|F_e\|^2 (1 + \rho^{-1}) \int_0^t \|x_s\|^2 \, ds. \end{aligned} \tag{29}$$

Furthermore, by (28) it follows that

$$SZ_t = (F_e)^{-1} \left\{ Z_t - \begin{bmatrix} x_t \\ 0 \\ \vdots \\ 0 \end{bmatrix} \right\}$$

and

$$\int_0^t \|SZ_z\|^2 \, dz \leqq c_2 \int_0^t \|x_z\|^2 \, dz \tag{30}$$

by (29).

Finally, the lemma follows from (29) and (30):

$$\int_0^t \|F(S)E^{-1}(S)x_s\|^2\,ds = \int_0^t \|z_s + F_1 S z_s + \cdots + F_d S^d z_s\|^2\,ds$$

$$= \int_0^t \|[I, 0 \cdots 0]z_s + [F_1 \cdots F_d]SZ_s\|^2\,ds$$

$$\leqq c\int_0^t \|x_s\|^2\,ds. \qquad \square$$

We now turn back to show that $\dot{\eta}_t$ given by (27) satisfies Assumption 1.
Set

$$x_t = \mu B(S)u_t.$$

We then have

$$\int_0^t \|x_s\|^2\,ds \leqq \mu^2 \int_0^t \|B_1 u_s + \cdots + B_q S^{q-1}u_s\|^2\,ds \leqq \mu^2 c_3 r_t,$$

where r_t is defined by (25) and c_3 is a constant.

Finally, applying Lemma 1 to (27), we find that

$$\int_0^t \|\dot{\eta}_s\|^2\,ds \leqq \int_0^t \|G_1(S)x_s\|^2\,ds \leqq c\int_0^t \|x_s\|^2\,ds \leqq \mu^2 c c_3 r_t,$$

which verifies (23) with $\varepsilon = \mu^2 c c_3$. $\square$

Example 2. Consider the following system:

$$A(S)y_t = SB(S)u_t + C(S)v_t + S\xi_t(y, u).$$

When the last term is identically zero, this model becomes the continuous-time analogue of an ARMAX model (see, e.g., [9]-[12]).

It is clear that Assumption 1 is verified if the nonlinear part $\xi_t(y, u)$ is one of the following forms:

$$\xi_t(y, u) = \varepsilon_1 y_t \sin(t) + \varepsilon_2 u_t \cos(t),$$

$$\xi_t(y, u) = \varepsilon_1 \sin(y_t) + \varepsilon_2 \sin(u_t), \qquad \varepsilon_i \in [0, \varepsilon], \quad i = 1, 2,$$

and so on.

3. Robustness of parameter estimation. We now show that the estimation error is proportional to the constant ε defined in (23) if the input-output data is persistently exciting.

THEOREM 1. *If Assumptions* 1 *and* 2 *are satisfied, then*

$$\limsup_{t\to\infty} \|\theta_t - \theta\| \leqq \alpha k \varepsilon, \quad a.s.$$

where $\alpha \in (0, \infty)$ *is a constant,* ε *is defined in* (23), *and*

$$k = \limsup_{t\to\infty} r_t / \lambda_{\min}(t) < \infty$$

where $\lambda_{\min}(t)$ *denotes the minimum eigenvalue of* P_t^{-1}.

For the proof of this theorem we need the following lemmas.

LEMMA 2. *Under the conditions of Theorem* 1, *there is a constant* $k_0 > 0$ *such that*

$$\operatorname{tr} \tilde{\theta}_t^\tau P_t^{-1} \tilde{\theta}_t \leqq O(1) + O\left(\left\{\int_0^t \|g_s\|^2\, ds\right\}^{(1/2)+\eta}\right) + O(\log r_t)$$
$$+ 2\left\{-\left(k_0 - \frac{c}{2}\right)\int_0^t \|g_s\|^2\, ds + \frac{1}{2c}\int_0^t \|D(S)C^{-1}(S)\dot{\eta}_s\|^2\, ds\right\},$$
$$\forall \eta > 0, \quad c > 0,$$

where $\tilde{\theta}_t = \theta - \theta_t$, $g_t = \tilde{\theta}_t^\tau \phi_t$.

Proof. By (7) and (16) it is easy to see that

$$\begin{aligned} dy_t &= \theta^\tau \phi_t^0\, dt + dv_t + \dot{\eta}_t\, dt \\ &= \theta^\tau \tilde{\phi}_t\, dt + \theta^\tau \phi_t\, dt + dv_t + \dot{\eta}_t\, dt \end{aligned}$$

and hence

$$\begin{aligned} \theta^\tau \tilde{\phi}_t\, dt &= dy_t - \theta_t^\tau \phi_t\, dt + (\theta_t - \theta)^\tau \phi_t\, dt - dv_t - \dot{\eta}_t\, dt \\ &= d\hat{v}_t - \tilde{\theta}_t^\tau \phi_t\, dt - dv_t - \dot{\eta}_t\, dt \\ &= -d\tilde{v}_t - \tilde{\theta}_t^\tau \phi_t\, dt - \dot{\eta}_t\, dt \end{aligned} \tag{31}$$

or

$$C(S)\left(\frac{d\tilde{v}_t}{dt}\right) = -g_t - \dot{\eta}_t \quad \text{or} \quad \left(\frac{d\tilde{v}_t}{dt}\right) = -C^{-1}(S)(g_t + \dot{\eta}_t). \tag{32}$$

Let us now set

$$f_t = \left\{\frac{[C(S) - D(S)]}{S}\right\}\tilde{v}_t + \frac{g_t}{2}; \tag{33}$$

it then follows that

$$f_t = \left[D(S)C^{-1}(S) - \frac{I}{2}\right]g_t + \left\{\frac{[D(S)C^{-1}(S) - I]}{S}\right\}\eta_t. \tag{34}$$

From this and Assumption 2 there are constants $k_0 > 0$, $k_1 > 0$ such that

$$\int_0^t g_s^\tau \{f_s + [I - D(S)C^{-1}(S)]\dot{\eta}_s - k_0 g_s]\, ds + k_1 > 0. \tag{35}$$

From (10), (32), and (33) it follows that

$$\begin{aligned} d\tilde{\theta}_t &= -P_t \phi_t D(S)[dy_t^\tau - \phi_t^\tau \theta_t\, dt] \\ &= -P_t \phi_t D(S)[dv_t - d\tilde{v}_t]^\tau \\ &= -P_t \phi_t [dw_t - d\tilde{v}_t - D_1 \tilde{v}_t\, dt - \cdots - D_r S^{r-1}\tilde{v}_t\, dt]^\tau \\ &= -P_t \phi_t \left[g_t\, dt + \dot{\eta}_t\, dt + \frac{C(S) - D(S)}{S}\,\tilde{v}_t\, dt + dw_t\right]^\tau \\ &= -P_t \phi_t \left(f_t\, dt + \frac{1}{2} g_t\, dt + \dot{\eta}_t\, dt + dw_t\right)^\tau. \end{aligned} \tag{36}$$

Applying Ito's formula, we obtain

$$\begin{aligned} d[\operatorname{tr} \tilde{\theta}_t^\tau P_t^{-1} \tilde{\theta}_t] &= -2g_t^\tau [f_t\,dt + \dot{\eta}_t\,dt + dw_t] + \phi_t^\tau P_t \phi_t\,dt \\ &= -2g_t^\tau \{f_t + [I - D(S)C^{-1}(S)]\dot{\eta}_t - k_0 g_t\}\,dt \\ &\quad + 2g_t^\tau [1 - D(S)C^{-1}(S)]\dot{\eta}_t\,dt - 2k_0 \|g_t\|^2\,dt \\ &\quad - 2g_t^\tau \dot{\eta}_t\,dt - 2g_t^\tau\,dw_t + \phi_t^\tau P_t \phi_t\,dt; \end{aligned}$$

then by (35)

$$\begin{aligned} 0 &\leqq \operatorname{tr} \tilde{\theta}_t^\tau P_t^{-1} \tilde{\theta}_t \\ &\leqq \operatorname{tr} \tilde{\theta}_0^\tau P_0^{-1} \tilde{\theta}_0 + \int_0^t \phi_s^\tau P_s \phi_s\,ds + 2k_1 \\ &\quad + 2\left\{-k_0 \int_0^t \|g_s\|^2\,ds - \int_0^t g_s^\tau D(S)C^{-1}(S)\dot{\eta}_s\,ds - \int_0^t g_s^\tau\,dw_s\right\}. \end{aligned} \tag{37}$$

Noting the following elementary facts:

$$2\int_0^t a_s^\tau b_s\,ds \leqq c\int_0^t \|a_s\|^2\,ds + c^{-1}\int_0^t \|b_s\|^2\,ds \quad \forall c > 0,$$

$$\begin{aligned} \int_0^t \phi_s^\tau P_s \phi_s\,ds &= \int_0^t \operatorname{tr}[P_s \phi_s \phi_s^\tau\,ds] = \int_0^t \operatorname{tr}[P_s\,dP_s^{-1}] \\ &= \int_0^t \frac{d(\det P_s^{-1})}{\det P_s^{-1}} = O(\log r_t), \end{aligned}$$

and applying the following estimate for the Ito integral (see, e.g., [16, Lemma 4]):

$$\int_0^t x_s^\tau\,dw_s = O(1) + o\left(\left\{\int_0^t \|x_s\|^2\,ds\right\}^{1/2+\eta}\right) \quad \text{a.s. } \forall \eta > 0, \tag{38}$$

for any predictable process (x_t, F_t), we can easily conclude the lemma from (37). □

LEMMA 3. *If F_d defined by* (21) *is stable, then*

$$\frac{1}{t}\int_0^t V_s V_s^\tau\,ds \to R \quad \text{a.s. as } t \to \infty \tag{39}$$

where V_t is defined in (19) *and*

$$R \triangleq \int_0^\infty \exp\{F_d \lambda\} \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \exp\{F_d^\tau \lambda\}\,d\lambda.$$

Proof. Since F_d is stable, there exists a positive-definite matrix $P > 0$ such that

$$PF_d + F_d^\tau P = -I.$$

By this and the Ito formula we see from (22) that

$$\begin{aligned} d[V_t^\tau P V_t] &= V_t^\tau (PF_d + F_d^\tau P) V_t\,dt + \operatorname{tr}\left\{\begin{bmatrix} I \\ 0 \\ \vdots \\ 0 \end{bmatrix} [I, 0 \cdots 0] P\,dt + 2V_t^\tau P \begin{bmatrix} I \\ 0 \\ \vdots \\ 0 \end{bmatrix} dw_t \right. \\ &= -\|V_t\|^2\,dt + \operatorname{tr}\begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} P\,dt + 2V_t^\tau P \begin{bmatrix} I \\ 0 \\ \vdots \\ 0 \end{bmatrix} dw_t. \end{aligned}$$

So it follows by applying (38) that

$$V_t^\tau P V_t + \int_0^t \|V_s\|^2\,ds = \operatorname{tr}\begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} Pt + o\left(\left\{\int_0^t \|V_s\|^2\,ds\right\}^{1/2+\eta}\right). \tag{40}$$

Consequently, we conclude that

$$\int_0^t \|V_s\|^2\,ds = O(t), \quad \text{a.s.} \tag{41}$$

Again, by the Ito formula we get

$$V_t V_t^\tau = \left(\int_0^t V_s V_s^\tau\,ds\right) F_d^\tau + F_d\left(\int_0^t V_s V_s^\tau\,ds\right) + \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} t + \int_0^t \begin{bmatrix} I \\ 0 \\ \vdots \\ 0 \end{bmatrix} dw_s V_s^\tau + \int_0^t V_s\,dw_s^\tau [I, 0 \cdots 0]$$

and hence

$$\begin{aligned} &\int_0^t V_s V_s^\tau\,ds \\ &= \int_0^t \exp[F_d(t-z)] \int_0^z \left\{ \begin{bmatrix} I \\ 0 \\ \vdots \\ 0 \end{bmatrix} dw_s V_s^\tau + V_s\,dw_s^\tau [I, 0 \cdots 0] \right\} \exp[F_d^\tau (t-z)]\,dz \\ &\quad + \int_0^t \exp[F_d(t-z)] \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} z \exp[F_d^\tau (t-z)]\,dz. \end{aligned} \tag{42}$$

We now consider the first term on the right-hand side (42). By (38), (41), and the stability of F_d, it is easy to see that there is a constant $\rho > 0$ such that

$$\begin{aligned} &\left\| \int_0^t \exp[F_d(t-z)] \int_0^t \left\{ \begin{bmatrix} I \\ 0 \\ \vdots \\ 0 \end{bmatrix} dw_s V_s^\tau + V_s\,dw_s^\tau [I, 0 \cdots 0] \right\} \exp[F_d^\tau (t-z)]\,dz \right\| \\ &= O\left(\int_0^t \exp[-2\rho(t-z)] \left\{ \int_0^z \|V_s\|^2\,ds \right\}^{1/2+\eta} dz \right) + O(1) \\ &= O\left(\int_0^t \exp[-2\rho(t-z)] z^{1/2+\eta}\,dz \right) = O(t^{1/2+\eta}) \quad \forall \eta > 0. \end{aligned}$$

Hence the lemma follows immediately from this and (42).

Proof of Theorem 1. Since $D(S)C^{-1}(S)$ is strictly positive real, $C(S)$ is stable. Then by Lemma 1 and Assumption 1, it follows that

$$\int_0^t \|D(S)C^{-1}(S)\dot{\eta}_s\|^2\,ds \leqq \varepsilon c_0 r_t \quad \text{for some } c_0 > 0.$$

Taking $c < 2k_0$ in Lemma 2, we see that

$$0 \leqq \operatorname{tr} \tilde{\theta}_t^\tau P_t^{-1} \tilde{\theta}_t \leqq O(1) - \left(k_0 - \frac{c}{2}\right) \int_0^t \|g_s\|^2\,ds + O(\varepsilon r_t) + O(\log r_t). \tag{43}$$

Then for sufficiently large t

$$\begin{aligned}
\operatorname{tr} \tilde{\theta}_t^\tau \tilde{\theta}_t &\leqq \frac{\operatorname{tr}(\tilde{\theta}_t^\tau P_t^{-1} \tilde{\theta}_t)}{\lambda_{\min}(t)} \\
&\leqq \frac{1}{\lambda_{\min}(t)} \left\{ O(1) - \left(k_0 - \frac{c}{2}\right) \int_0^t \|g_s\|^2 \, ds + O(\varepsilon r_t) + O(\log r_t) \right\} \qquad (44) \\
&\leqq O\left(\frac{\log r_t}{r_t}\right) - \frac{k}{r_t}\left(k_0 - \frac{c}{2}\right) \int_0^t \|g_s\|^2 \, ds + O(\varepsilon k).
\end{aligned}$$

Since $c < 2k_0$, the desired result will follow if we can show that $r_t \to \infty$, as $t \to \infty$. We prove this as follows.

From (32) it follows that

$$\tilde{V}_t = -\int_0^t \exp\{F_c(t-s)\}[g_s + \dot{\eta}_s] \, ds.$$

Then by (43) and Assumption 1, we have for some $\rho > 0$ and $c_1 > 0$

$$\begin{aligned}
\int_0^t \|\tilde{V}_z\|^2 \, dz &\leqq \int_0^t \left\| \int_0^z \exp\{F_c(z-s)\}[g_s + \dot{\eta}_s] \, ds \right\|^2 dz \\
&\leqq (c_1)^2 \int_0^t \left\{ \int_0^z \exp[-\rho(z-s)][\|g_s\| + \|\dot{\eta}_s\|] \, ds \right\}^2 dz \\
&\leqq 2(c_1)^2 \int_0^t \int_0^z \exp[-\rho(z-s)] \, ds \int_0^z \exp[-\rho(z-s)][\|g_s\|^2 + \|\dot{\eta}_s\|^2] \, ds \, dz \\
&\leqq 2\rho^{-1}(c_1)^2 \int_0^t \int_z^t \exp[-\rho(z-s)] \, dz \, [\|g_s\|^2 + \|\dot{\eta}_s\|^2] \, ds \qquad (45) \\
&\leqq 2\rho^{-2}(c_1)^2 \int_0^t [\|g_s\|^2 + \|\dot{\eta}_s\|^2] \, ds \\
&\leqq 2\rho^{-2}(c_1)^2 \{O(\log r_t) + O(\varepsilon r_t) + \varepsilon r_t\} \\
&= O(\log r_t) + O(\varepsilon r_t).
\end{aligned}$$

Assume the converse were true, i.e., r_t was bounded in t; then from (45) it would follow that $\int_0^t \|\tilde{V}_z\|^2 \, dz$ would be bounded. But by (20) and (25) it is clear that

$$r_t \geqq \int_0^t \|\hat{V}_z\|^2 \, dz = \int_0^t \|V_z\|^2 \, dz + \int_0^t \|\tilde{V}_z\|^2 \, dz - 2\int_0^t V_z^\tau \tilde{V}_z \, dz.$$

From this and the boundedness of r_t and $\int_0^t \|\tilde{V}_z\|^2 \, dz$, it follows that

$$\int_0^t \|V_z\|^2 \, dz \text{ is bounded.}$$

This contradicts Lemma 3. Hence $r_t \to \infty$, a.s., and Theorem 1 holds. □

Remark 1. If in (7) the unmodeled dynamics $\{\eta_t\}$ are identically zero, then we may take ε as zero in Assumption 1. In this case, it follows from (44) that

$$\|\tilde{\theta}_t\|^2 = O\left(\frac{\log r_t}{\lambda_{\min}(t)}\right) \quad \text{a.s.}$$

This result is the continuous-time version of that obtained in the discrete-time case (see, e.g., [13]-[14]). See also [12] for related results.

4. Robustness of adaptive tracking. Let $\{u_t^*\}$ be a bounded deterministic and differentiable reference signal with $u_0^* = 0$. Our objective here is to design the adaptive control u_t, so that the output $\{y_t\}$ tracks the output of the following reference model:

$$E(S)y_t^* = u_t^*$$

where $E(S) = I + E_1 S + \cdots + E_p S^p$ is a stable matrix polynomial.

Similar to (18), we set

$$Y_t^* = [y_t^* \cdots S^{p-1} y_t^*]^\tau.$$

By a representation similar to (22), it is easy to see that $\{Y_t^*\}$ is a bounded sequence.

From now on, we assume that the upper bound for the order of the polynomial $A(S)$ is equal to that of $C(S)$, i.e., $p = r$.

Similar to the discrete-time case, we need the following standard minimum phase condition.

Assumption 3. $B(S)$ is stable.

Let us define the adaptive control u_t via the following equation:

$$\theta_t^\tau \phi_t = \frac{dy_t^*}{dt}. \tag{46}$$

This together with (1), (10), and (11) form a system of nonlinear stochastic differential equations, for which the existence and uniqueness of the strong solution is assumed.

THEOREM 2. *Consider the system* (1)-(6) *with* $p = r$, *and the estimation algorithm* (10)-(11). *If Assumptions* 1-3 *hold, and the control law is defined from* (46), *then there exists* $\varepsilon_1 > 0$ *such that whenever* ε *in* (23) *lies in the interval* $[0, \varepsilon_1)$, *the following properties hold*:

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T (\| Y_t \|^2 + \| U_t \|^2)\, dt < \infty \quad a.s. \tag{47}$$

and

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T \| Y_t - Y_t^* \|^2\, dt = \operatorname{tr} R + \delta \quad a.s. \tag{48}$$

where $|\delta| = O(\varepsilon^{1/2})$, *and* R *is defined in Lemma* 3.

Proof. From (13) and (46) it is easy to see that

$$y_t - y_t^* = \hat{v}_t, \qquad Y_t^* - Y_t = \tilde{V}_t - V_t. \tag{49}$$

Note that

$$r_T = \int_0^T (\| Y_t \|^2 + \| U_t \|^2 + \| \hat{V}_t \|^2)\, dt + e. \tag{50}$$

We have by (39), (45), and (49) that

$$\int_0^T \| Y_t \|^2\, dt = O(T) + \varepsilon c_3 r_T + O(\log r_T), \qquad c_3 > 0. \tag{51}$$

From this, (7) and the stability of $B(S)$, we have

$$\int_0^T \| U_t \|^2\, dt = O(T) + \varepsilon c_4 r_T + O(\log r_T), \qquad c_4 > 0. \tag{52}$$

Note also that by (45) and Lemma 3, we have

$$\int_0^T \|\hat{V}_t\|^2\,dt \leqq O(T)+2\int_0^T \|\tilde{V}_t\|^2\,dt \leqq O(T)+\varepsilon c_5 r_T + O(\log r_T).$$

Hence, combining (50)-(52), we have

$$r_t \leqq O(t)+\varepsilon c_6 r_t + O(\log r_t), \qquad c_6>0,$$

which yields

$$\limsup_{t\to\infty}\frac{r_t}{t}<\infty \quad \text{for any } \varepsilon\in[0,\varepsilon_1)$$

with $\varepsilon_1 = 1/c_6$. Thus (47) is true.

We now proceed to prove (48). From (45) we have for any $\varepsilon\in[0,\varepsilon_1)$,

$$\frac{1}{T}\int_0^T \|\tilde{V}_t\|^2\,dt = O\left(\frac{\log T}{T}\right)+O(\varepsilon); \tag{53}$$

then by (49)

$$\begin{aligned}
&\frac{1}{T}\int_0^T (Y_t-Y_t^*)(Y_t-Y_t^*)^\tau\,dt\\
&\quad=\frac{1}{T}\int_0^T (V_t-\tilde{V}_t)(V_t-\tilde{V}_t)^\tau\,dt\\
&\quad=\frac{1}{T}\int_0^T V_tV_t^\tau\,dt+\frac{1}{T}\int_0^T \tilde{V}_t\tilde{V}_t^\tau\,dt-\frac{1}{T}\int_0^T (V_t\tilde{V}_t^\tau+\tilde{V}_tV_t^\tau)\,dt,\\
&\quad=R+\left[\frac{1}{T}\int_0^T V_tV_t^\tau\,dt-R\right]+O\left(\frac{\log T}{T}\right)+O(\varepsilon)+O\left(\left\{\frac{\log T}{T}+\varepsilon\right\}^{1/2}\right).
\end{aligned} \tag{54}$$

Hence (48) is also true. □

Remark 2. If the initial value of the reference signal is not zero, i.e., $u_0^*\neq 0$, then we may replace (46) by

$$\theta_t^\tau\phi_t=\frac{dz_t^*}{dt},$$

where $z_t^*=E^{-1}(S)\{u_t^*-\exp(-t^2)u_0^*\}$. In this case, Theorem 2 is true for $\{z_t^*\}$, which approximates $\{y_t^*\}$ exponentially.

5. Asymptotic behavior of adaptive tracking. In this section we assume $\eta_t=0$ in (7). For this ideal case we give the convergence rate for the adaptive tracking errors. It is worth noting that the corresponding discrete-time results have not yet been established (see, e.g., [17], for related discussions).

LEMMA 4. *Let $\{x_t\}$ be any measurable process adapted to $\{F_t\}$, satisfying*

$$\limsup_{T\to\infty}\frac{1}{T}\int_0^T \|x_t\|^2\,dt\leqq k_1<\infty \quad a.s.$$

for some constant k_1. Then

$$\limsup_{T\to\infty}\frac{1}{(T\log\log T)^{1/2}}\left\|\int_0^T x_t\,dw_t^\tau\right\|<\infty \quad a.s. \tag{55}$$

Proof. Without loss of generality, we assume that x_t and w_t are scalars. Taking a constant k_2 so large that

$$(k_2)^2 - k_2 + 2(1-k_2)k_1 > 0, \qquad k_2 > 1,$$

we have

$$\begin{aligned}\int_0^T (k_2 + x_t)^2\, dt &\geqq \int_0^T (x_t)^2\, dt + (k_2)^2 T - 2k_2 \int_0^T |x_t|\, dt \\ &\geqq \int_0^T (x_t)^2\, dt + (k_2)^2 T - k_2 \left[T + \int_0^T (x_t)^2\, dt \right] \\ &\geqq k_2(k_2-1)T + 2(1-k_2)k_1 T.\end{aligned}$$

Consequently,

$$\int_0^\infty (k_2 + x_t)^2\, dt = \infty \quad \text{a.s.}$$

Now, define the following stopping time:

$$\tau(t) = \inf\left\{ s: \int_0^s (k_2 + x_z)^2\, dz = t \right\}.$$

It is known that

$$\int_0^{\tau(t)} (k_2 + x_s)\, dw_s$$

is a Brownian motion (see, e.g., [18, Thm. 4.5]). Then by the law of the iterated logarithm for Wiener processes, we have

$$\frac{1}{(t \log\log t)^{1/2}} \left| \int_0^{\tau(t)} (k_2 + x_s)\, dw_s \right| = O(1) \quad \text{a.s.} \tag{56}$$

Denoting

$$a(t) = \int_0^t (k_2 + x_z)^2\, dz, \tag{57}$$

it is evident that $a(\tau(t)) = t$. Then (56) and (57) imply

$$\frac{1}{[a(T) \log\log a(T)]^{1/2}} \left| \int_0^T (k_2 + x_s)\, dw_s \right| = O(1) \quad \text{a.s.}$$

as $T \to \infty$. From this and the fact that $a(T)/T = O(1)$, it follows that

$$\frac{1}{[T \log\log T]^{1/2}} \left| \int_0^T (k_2 + x_s)\, dw_s \right| = O(1) \quad \text{a.s.}$$

and hence

$$\begin{aligned}&\frac{1}{[T \log\log T]^{1/2}} \left| \int_0^T x_s\, dw_s \right| \\ &\quad \leqq \frac{1}{[T \log\log T]^{1/2}} \left\{ k_2 |w_T| + \left| \int_0^T (k_2 + x_s)\, dw_s \right| \right\} \\ &\quad = O(1) \quad \text{a.s. as } T \to \infty,\end{aligned}$$

completing the proof. □

We are now in a position to prove the following main result of this section.

THEOREM 3. *Consider the system described by* (7) *with* $\eta_t = 0$ *and* $p = r$, *and estimation algorithm* (10)-(11). *If Assumptions* 2 *and* 3 *are satisfied, and if the adaptive control is defined from* (46), *then*

$$\|R_T - R\|^2 = O\left(\frac{\log T}{T}\right) \quad a.s.\ as\ T \to \infty, \tag{58}$$

where R is given in Lemma 3 *and*

$$R_T = \frac{1}{T}\int_0^T (Y_t - Y_t^*)(Y_t - Y_t^*)^\tau\, dt.$$

Proof. We first consider the convergence rate of $1/T\int_0^T V_t V_t^\tau\, dt$.

From (40) it is clear that

$$\limsup_{T\to\infty} \frac{1}{T}\int_0^T \|V_s\|^2\, ds \leqq 2\,\mathrm{tr}\begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} P.$$

Then Lemma 4 implies

$$\limsup_{T\to\infty} \frac{1}{(T\log\log T)^{1/2}} \left\| \int_0^T V_t\, dw_t^\tau \right\| < \infty \quad \text{a.s.},$$

and hence

$$\left\| \int_0^t \exp\left[F_d(t-z)\right] \int_0^z \left\{ \begin{bmatrix} I \\ 0 \\ \vdots \\ 0 \end{bmatrix} dw_s\, V_s^\tau + V_s\, dw_s^\tau [I, 0 \cdots 0] \right\} \exp\left[F_d^\tau (t-z)\right] dz \right\|$$

$$= O(\{t\log\log t\}^{1/2}) \quad \text{a.s.}$$

Consequently, it follows from (42) that

$$\left\| \frac{1}{T}\int_0^T V_s V_s^\tau\, ds - \int_0^\infty \exp\{F_d s\} \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \exp\{F_d^\tau s\}\, ds \right\| = O\left(\left\{\frac{\log\log T}{T}\right\}^{1/2}\right). \tag{59}$$

Setting $\varepsilon = 0$ in (53) and (54), and using (59), we see that

$$R_T = \int_0^\infty \exp\{F_d s\} \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \exp\{F_d^\tau s\}\, ds + O\left(\left\{\frac{\log\log T}{T}\right\}^{1/2}\right) + O\left(\frac{\log T}{T}\right) + O\left(\left\{\frac{\log T}{T}\right\}^{1/2}\right)$$

$$= \int_0^\infty \exp\{F_d s\} \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \exp\{F_d^\tau s\}\, ds + O\left(\left\{\frac{\log T}{T}\right\}^{1/2}\right),$$

which verifies (58). Hence the proof is complete. □

GLOBAL OPTIMIZATION OVER UNBOUNDED DOMAINS*

H. RATSCHEK† AND R. L. VOLLER†

Abstract. Almost all methods for solving the global optimization problem need the assumption that a parallelepiped containing the solution points is known. The boundedness is necessary both for the numerical computation as well as for guaranteeing the convergence properties. In this paper a technique is described that drops this restriction so that the unconstrained problem, in the literal sense of the terms can be solved. The technique is based on the branch-and-bound method and on infinite-interval arithmetic, it is simple to apply, and very robust as examples show.

Key words. global optimization, unconstrained optimization, nonlinear optimization, optimization over unbounded domains

AMS(MOS) subject classifications. 90C30, 65K05, 65K10, 65G10

1. Introduction. Almost all of the well-known methods for solving the global unconstrained optimization problem involve a parallelepiped as bounded subdomain $X \subseteq R^m$ for the function to which the method is applied. Therefore, X must be known a priori or must be determined by means of an analysis of the problem. (A notable exception is [12].)

The technique we provide is destined to solve the global minimization problem for a continuous function $f: R^m \to R$. The search for the global minimizers is accomplished in the whole domain R^m. Bounds of the global minimum f^* are generated, and one or several boxes of prescribed size that include all global minimizers are produced. It can be detected when f has no global minimum at all, and further, whether or not f is bounded from below. If the technique is applied on a computer, the sharpness of these detections is limited by the finite number representation of computers. Although weakened, the detections remain logically valid in this case such that the user can trust them.

The method that we provide to cover the whole space R^m when looking for global minimizers is best demonstrated by applying it to Hansen's Algorithm [3]. Similar algorithms, such as those of Skelboe [17], Moore [10], Asaithambi, Shen, and Moore [1], and Ichida-Fujii [4] may also be used.

Hansen's Algorithm is very sophisticated, hence we discuss a simplified prototype version in § 2. In §§ 3 and 4, the optimization problem and the prototype algorithm are extended and admitted to functions that are defined on R^m. For this reason, a compactification of the space R^m is introduced, $R^m := (\bar{R})^m$ where $\bar{R} := R \cup \{\infty, -\infty\}$. The advantages of this compactification are threefold: (i) The investigation of the convergence properties can make use of compactness principles. (ii) The interpretation in R^m of the results obtained in R^m is straightforward and there is no need to distinguish between the bounded and the unbounded case. (iii) The step from the exact execution of the algorithm in R^m to its numerical execution on a computer is small because the latter operates in $[-L, L]^m$ where L denotes the largest representable number of the machine under consideration. R^m and $[-L, L]^m$ are topologically very similar.

In § 5, the monotonicity test [3], [10] is discussed. This is an extremely effective means for detecting global monotonicity of f in a box such that this box can be

discarded from the search for minimizers. This test is carried over to the unbounded case and the usual assumption for f to be differentiable is weakened. In § 6 an arithmetic for unbounded noncompact intervals is introduced to obtain the inclusion functions required for the extended algorithm. As a consequence, Moore's principle of natural interval extension [9] can be recursively defined for programmable functions over unbounded domains. In § 7, the relationships between the numerical and the exact realization of the extended algorithm are discussed. In § 8, numerical examples show that the practical computation involves no difficulties at all.

Comparing §§ 3, 6, and 7, we are faced with three kinds of infinite intervals:

(i) *Compactified unbounded intervals* such as $[a, \infty] \subseteq \bar{R}$ (cf. § 3). They are needed both for the execution of the algorithm and for the discussion of its convergence properties. Since only topological arguments and no arithmetic are used for this discussion, no arithmetic need be defined for compactified unbounded intervals.

(ii) *Unbounded noncompactified intervals*, such as $[a, \infty) \subseteq R$ (cf. § 6). They occur when the bounds of f over unbounded subdomains are determined. Thus, an arithmetic for such intervals is defined.

(iii) Both kinds of intervals mentioned in (i) and (ii) must be simulated by *machine intervals* when computing on a machine (cf. § 7).

2. The algorithm over bounded domains. We start the discussion with a prototype version of Hansen's Algorithm [3] that is intended to solve optimization problems over parallelepipeds. Hansen's Algorithm differs from the prototype in that it contains many excellent further techniques that speed up the calculation, but do not change the convergence order and the solution set. To have a straightforward discussion we drop these techniques.

Let R be the set of reals, and I be the set of real compact intervals. Right parallelepipeds such as $Y = Y_1 \times \cdots \times Y_m \in I^m$ are called *boxes*. If $D \subseteq R^m$ then $I(D)$ denotes the set of all boxes $Y \subseteq D$. The width of an interval is denoted by $w([a, b]) = b - a$. The *width* of a box Y is defined by $w(Y) = \max_{i=1,\cdots,m} w(Y_i)$. Let $f: D \to R$. The *range* of f over $Y \subseteq D$ is denoted by $\square f(Y) = \{f(y): y \in Y\}$. An interval function $F: I(D) \to I$ is called an *inclusion function* for f if $\square f(Y) \subseteq F(Y)$ for any $Y \in I(D)$. If $A = [a, b]$ is an interval, the lower and upper boundaries of A are denoted by $\operatorname{lb} A = a$ and $\operatorname{ub} A = b$, respectively. The midpoint is denoted by $\operatorname{mid} A = (a + b)/2$, and the midpoint of a box $Y \in I^m$ by $\operatorname{mid} Y = (\operatorname{mid} Y_i)_{i=1}^m$.

The following prototype version of Hansen's Algorithm aims to determine the global minimum and the global minimizers of a function $f: X \to R$ over a bounded box $X \in I^m$ when an inclusion function F for f is given.

Algorithm 1.

(1) Set $Y := X$.
(2) Calculate $F(Y)$, $f(c)$ where $c = \operatorname{mid} Y$.
(3) Set $y := \operatorname{lb} F(Y)$.
(4) Initialize list $L := \{(Y, y)\}$. Set $\tilde{f} := f(c)$.
(5) Choose a coordinate direction k parallel to which Y has an edge of maximum length, that is, $k \in \{i: w(Y_i) = w(Y)\}$.
(6) Bisect Y in direction k getting boxes V_1, V_2 such that $Y = V_1 \cup V_2$.
(7) Calculate $F(V_1)$, $F(V_2)$.
(8) Set $v_i := \min F(V_i)$ for $i = 1, 2$.
(9) Enter the pairs (V_1, v_1), (V_2, v_2) at the end of the list.
(10) (Optional) If f has a generalized gradient in each point of $V_i \cap R^m$ then apply the monotonicity test to V_i for $i = 1, 2$.

(11) Choose a pair $(\tilde{Y}, \tilde{y})$ of the list that satisfies $\tilde{y} \leqq z$ for all pairs (Z, z) of the list.
(12) Discard all pairs (Z, z) from the list that satisfy $\tilde{f} < z$ (*midpoint test*).
(13) If termination criteria hold go to (16).
(14) Denote the first pair of the list by (Y, y). Set $c := \operatorname{mid}(Y)$ and $\tilde{f} := \min(\tilde{f}, f(c))$.
(15) Go to (5).
(16) End

The *monotonicity test* (cf. step (10)) is a means to detect strict monotonicity of f in a box that can then be deleted. The test is a device for accelerating the computation rather than a substantial part of the algorithm since its solution set is independent of the use of the test. The situation, however, changes when unbounded domains are admitted such that the test is highly recommended. The detailed discussion is referred to in §§ 5 and 7.

The midpoint test (cf. step (12)) may operate any $c \in Y$ instead of mid Y. Also ub $F(Y)$ can be used instead of $f(c)$.

A thorough investigation of *termination criteria* can be found in [3] and [11].

Algorithm 1 produces an infinite sequence of lists (L_n) if termination by step (13) is dropped. Furthermore, we get sequences $(\tilde{y}_n)$ and (f_n) according to steps (11) and (14). (We write f_n instead of $\tilde{f}_n$.) Let U_n be the union of all boxes occurring in L_n. It is obvious that (U_n) is a nested sequence. The *convergence properties* of Algorithm 1 are discussed in [11] and [16]. Hints for the construction of inclusion functions and the related order are given in [15].

3. The algorithm over unbounded domains. Algorithm 1 shows very pleasant convergence properties [11], [16]. They depend on the compactness of X. Hence, we will first provide a compactification of R^m, say $\overline{R^m}$. Then both, Algorithm 1 as well as the convergence properties are extended to the compactified unbounded case. For this reason, the objective function f and its inclusion function F must be extended to $\overline{R^m}$. The results gained in $\overline{R^m}$ are then converted into the originally wanted results in R^m. The compactification could be avoided but simplifies matters considerably.

To apply Algorithm 1 to $\overline{R^m}$, the midpoint and the width of boxes in $\overline{R^m}$ must be defined, and further, the given function f and its inclusion function F must be extended. This requires some notation.

Let $\bar{R} := R \cup \{-\infty, \infty\} = [-\infty, \infty]$ be the two-point compactification of R, and let $\overline{R^m} := \bar{R}^m$ be the m-fold topological product of $\bar{R}$. If $A \subseteq R^m$, we denote the compact hull of A with respect to this compactification by $\bar{A}$.

Let I_∞ be the set of all closed (but not necessarily bounded) intervals of R. Thus, the intervals $[a, b]$, $[a, \infty)$, $(-\infty, b]$, and $(-\infty, \infty) = R$ belong to I_∞ where $a, b \in R$. Let $\bar{I}$ be the set of all compact intervals of $\bar{R}$. Thus, $[a, b]$, $[a, \infty]$, $[-\infty, b]$, $[-\infty, \infty] = \bar{R}$, $\infty = [\infty, \infty]$, or $-\infty = [-\infty, -\infty]$ belong to $\bar{I}$ where $a, b \in R$.

Let $A \subseteq \overline{R^m}$; then $I_\infty(A) := \{Y \in I_\infty^m : Y \subseteq A\}$ and $\bar{I}(A) := \{Y \in \bar{I}^m : Y \subseteq A\}$. We note that $I_\infty^m = I_\infty(R^m) = I_\infty(\overline{R^m})$ and $\bar{I}^m = \bar{I}(\overline{R^m})$. Furthermore, $I(A) := \{Y \in I^m : Y \subseteq A\}$.

A width for unbounded boxes may be defined in a variety of ways resulting in formulas of greater or lesser complexity. We do not expect our formula to be either elegant or of theoretical interest (as the chordal-distance on the Riemann sphere), however, it must be appropriate for our purposes, which are the following: (i) If a nested box sequence (Y_n), $Y_n \in \bar{I}^m$ tends to a point of $\overline{R^m}$, the widths of the boxes must tend to zero. (ii) The width must control the bisection process (cf. steps (4) and (5) of Algorithm 1) to generate box sequences contracting to one point; (iii) These

properties of the width should be maintained at the numerical implementation, i.e., the width of the largest machine-infinite interval should be more or less comparable with the width of the smallest machine-finite interval (cf. § 7).

Our width concept depends on a global parameter λ that the user or programmer may choose, such that the global minimizers are suspected to lie in the box $[-\lambda, \lambda]^m$.

If the choice of the user is wrong, the program is still correct but slower. The choice of λ influences the bisection process, and areas outside of this box are treated as nearly infinite areas. For this reason, the width of intervals lying outside of $[-\lambda, \lambda]$ is adapted: If $-\infty < a \leqq b < \infty$, then

$$w([a, b]) := \lambda^2(b-a)/(ab) \quad \text{if } a \geqq \lambda \quad \text{or } b \leqq -\lambda.$$

The width of a box $Y = Y_1 \times \cdots \times Y_m \in \bar{I}^m$ is then defined as follows. Let $0 < \lambda < \infty$ and $a \in R$. Then

$$w([a, \infty]) := \begin{cases} \lambda^2/a & \text{if } a \geqq 10^{-10}, \\ 10^{10} \max(1, \lambda^2) & \text{otherwise,} \end{cases}$$

$$w([-\infty, a]) := w([-a, \infty]),$$

$$w([-\infty, \infty]) := 10^{11} \max(1, \lambda^2), \; w(\pm[\infty, \infty]) = 0,$$

$$w(Y) := \max_{i=1,\cdots,m} w(Y_i).$$

In order not to dissect $[-\lambda, \lambda]^m$ too early, the midpoint of unbounded boxes will also be made dependent on λ. Let $a \in \bar{R}$ and $Y \in \bar{I}^m$. Then we set

$$\operatorname{mid}[a, \infty] := \begin{cases} \lambda & \text{if } a < \lambda, \\ 2a & \text{if } \lambda \leqq a, \end{cases}$$

$$\operatorname{mid}[-\infty, a] := -\operatorname{mid}[-a, \infty] \quad \text{if } a < \infty,$$

$$\operatorname{mid} Y := (\operatorname{mid} Y_i)_{i=1}^m.$$

If, for example, $\lambda = 10$, then the interval $[20, \infty]$ (of width 5) is bisected into $[20, 40]$ and $[40, \infty]$ (both of width $\frac{5}{2}$).

Let $A \in I_\infty^m$ and $f: A \to R$ be given. We want to extend f to a function $f_0: \bar{A} \to \bar{R}$. Let $x \in \bar{A} \backslash A$, then we set

$$f_0(x) := \min \left\{ \lim_{n \to \infty} \inf f(x_n) : x_n \in A, \, x_n \to x \right\} \tag{1}$$

where the convergence of the sequences (x_n) to x is subject to the topology of $\overline{R^m}$. Note that f_0 need not be continuous, even when f is. For example, if $f(x) = e^x$, $x \in R$, then $f_0(-\infty) = 0$ and $f_0(\infty) = \infty$. If $f(x) = \sin x$, $x \in R$, then $f_0(-\infty) = f_0(\infty) = -1$.

Analogously, if $F: I(A) \to I$ is an inclusion function for f, we want to extend F to an inclusion function $F_0: \bar{I}(\bar{A}) \to \bar{I}$ for f_0, that is,

$$\square f_0(\bar{Y}) \subseteq F_0(\bar{Y}) \quad \text{for any } Y \in I_\infty(A). \tag{2}$$

We do not need inclusions of f over boxes $Z = Z_1 \times \cdots \times Z_m$ where any component Z_i is just ∞ or $-\infty$. Such cases are neither considered in (2) nor in the following definition (3), which simplifies matters. Thus we define F_0 by

$$F_0(\bar{Y}) := \overline{F(Y)} \quad \text{for } Y \in I_\infty(A). \tag{3}$$

We call F and also F_0 *nonwasteful* if, given any $Y \in I_\infty(A)$, a partition of A into bounded boxes exists, $A = \bigcup_{i \in J} B_i$, with $B_i \in I(A)$ and some index set J, such that

$$F(Y) \subseteq \overline{\bigcup_{i \in J} F(B_i)}. \tag{4}$$

Condition (4) is necessary for getting reasonable convergence properties. It is a very natural condition, since each programmer would automatically construct nonwasteful inclusions. For example, let $f(x) = x_1^2 + x_2$, $x \in R^2$; then $F(Y) = Y_1^2 + Y_2$, $Y \in I_\infty^2$, is nonwasteful. If $f(x) = \sin x$, $x \in R$, $F(Y) = [-1, 1]$, if $Y \in I$, and $F(Y) = [-2, 2]$ if $Y \in I_\infty \backslash I$ then F is wasteful.

Since there is no danger of misunderstanding we also write f and F instead of f_0 and F_0 in the sequel.

The *global unconstrained optimization problem over unbounded domains* can now be written concisely as follows. Let $X \in I_\infty^m$ and $f: X \to R$ be continuous. The problem to be solved is

$$\min_{x \in X} f(x). \tag{5}$$

Problem (5) is reduced to the *compactified problem*, which is

$$\min_{x \in \bar{X}} f(x). \tag{6}$$

This minimum always exists if the extension of f on $\bar{X}$ is defined via (1). The following algorithm aims to determine the global minimum f^+ and X^+, the set of global minimizers of problem (6).

Algorithm 2 will be syntactically equal to Algorithm 1, but now, unbounded compactified boxes $\bar{X}$ of $X \in I_\infty^m$, functions $f: \bar{X} \to \bar{R}$ and inclusion functions $F: \bar{I}(\bar{X}) \to \bar{I}$ are admitted as input data. We use the formulas for width and midpoint as they have just been introduced.

As Algorithm 1 does, Algorithm 2 produces, at the nth iteration, a list L_n consisting of pairs (Z_{ni}, z_{ni}), $i = 1, \cdots, l_n$, where l_n is the list length and $z_{ni} = \mathrm{lb}\, F(Z_{ni})$. The leading pair of L_n is denoted by (Y_n, y_n), and $(\tilde{Y}_n, \tilde{y}_n)$ denotes a pair of L_n satisfying $\tilde{y}_n \leqq z_{ni}$ for $i = 1, \cdots, l_n$. The function value $f_n \in \bar{R}$ is the lowest value of f produced up to the nth iteration. As before, $U_n = \bigcup_i Z_{ni}$, and (U_n) is a nested sequence.

4. Convergence properties of Algorithm 2. In this section, assumptions are looked for under which Algorithm 2 converges to the solution set of the compactified problem (6). First of all,

$$w(Y_n) \to 0 \quad \text{as } n \to \infty. \tag{7}$$

The proof is similar to the proof of the bounded case in [14] and is suppressed. Also, from the execution of Algorithm 2, we have

$$\tilde{y}_n \leqq f^+ \leqq f_n \quad \text{for all } n. \tag{8}$$

Let $a = (a_1, \cdots, a_m) \in \overline{R^m}$, and A, B be compact subsets of $\overline{R^m}$. We define

$$d_0(a, B) := \min_{b \in B} \left(\sum_{i=1}^{m} w([\min(a_i, b_i), \max(a_i, b_i)]^2 \right)^{1/2},$$

$$d_0(A, B) := \max_{a \in A} d_0(a, B),$$

$$d(A, B) := \max\{d_0(A, B), d_0(B, A)\}.$$

d is some kind of distance and is a means for describing convergence of sequences such as (U_n) to X^+ with respect to the natural topology of $\overline{R^m}$. Within $[-\lambda, \lambda]^m$, d coincides with the usual Hausdorff-metric for compact sets. We write $A_n \to B$ instead of $d(A_n, B) \to 0$ in the sequel. The notation $A_n \to B$ is consistent with the convergence of point sequences, if $A_n, B \in R^m$.

Again let $X \in I_\infty^m$, let $f: \bar{X} \to \bar{R}$ satisfy (1), and let $F: \bar{I}(\bar{X}) \to \bar{I}$ be a nonwasteful inclusion function for f satisfying (3). We consider the assumption

$$w(F(Y)) \to 0 \quad \text{as } w(Y) \to 0 \quad \text{for } Y \in I(X), \tag{9}$$

which implies continuity of f over X such that (6) has a solution, i.e., $X^+ \neq \emptyset$ and f^+ exists. Assumption (9) forced Algorithm 1 to converge if X was bounded [11]. We will see that (9) is also an appropriate convergence condition in the unbounded case. If Algorithm 2 (with or without monotonicity test) is applied to F, f, and $\bar{X}$, then the following theorem holds for the output data.

THEOREM 1. *If* (9) *holds, then as* $n \to \infty$,

(i) $f^+ - \tilde{y}_n \to 0$ *as well as* $f^+ - y_n \to 0$,

(ii) $f_n - f^+ \to 0$ *where* $\tilde{y}_n \leqq f^+ \leqq f_n$,

(iii) $U_n \to X^+$ *where* $X^+ \subseteq U_n$.

Proof. (i) We show that $f^+ - \tilde{y}_n \to 0$. The second assertion, $f^+ - y_n \to 0$ will follow from (ii), since $\tilde{y}_n \leqq y_n \leqq f_n$ holds.

If $f^+ = -\infty$ then $\tilde{y}_n = f^+$ because of (8). Let $f^+ \in R$. We focus on the nth iteration for one moment. Since F is nonwasteful, we have

$$F(\tilde{Y}_n) = \overline{\bigcup_{i \in J_n} F(B_{ni})}$$

for some partition $\tilde{Y} \cap R^m = \bigcup_{i \in J_n} B_{ni}$. Since $\tilde{y}_n = \text{lb } F(\tilde{Y}_n)$ and since $f^+ \in F(B_{ni})$ or $f^+ < \text{lb } F(B_{ni})$ for any $i \in J_n$, the following choice is possible.

If $\tilde{y}_n = -\infty$ we choose B_{ni_n}, $i_n \in J_n$, such that

$$\text{lb } F(B_{ni_n}) < f^+ - 2^n. \tag{10}$$

If $\tilde{y}_n \in R$ we choose B_{ni_n}, $i_n \in J_n$, such that either $\tilde{y}_n \in F(B_{ni_n})$ or both, $\text{lb } F(B_{ni_n}) - \tilde{y}_n < 2^{-n}$ as well as $\text{lb } F(B_{ni_n}) - f^+ < 2^{-n}$ holds.

Now, (7) implies $w(B_{ni_n}) \to 0$ such that $w(F(B_{ni_n})) \to 0$ follows. By (10), $\tilde{y}_n \in R$ holds for sufficiently large n, which means that $\tilde{y}_n \to f^+$.

(ii) We must show that $f_n \searrow f^+$. Let us, however, assume that $f_n \searrow \alpha$ for some $a > f^+$. Since $f^+ = f(x^+)$ for some $x^+ \in X^+$ and since f satisfies (1), there exists a sequence (ξ_k), $\xi_k \in X \subseteq R^m$, such that $\xi_k \to x^+$ and $f(\xi_k) \to f(x^+)$ as $k \to \infty$. Let k be fixed such that $f(x_k) < \alpha$. There exists a sequence (Z'_n) with $\xi_k \in Z'_n$ and Z'_n belonging to L_n, for any n. The existence of (Z'_n) is guaranteed since ξ_k is never excluded by the midpoint test. Condition (7) implies $w(Z'_n) \to 0$, and further $Z'_n \to \xi_k$. Thus, $Z'_n \in I(X)$, for sufficiently large n. We apply (9) and get $w(F(Z'_n)) \to 0$ and $F(Z'_n) \to f(\xi_k)$. For some large n we thus have $\text{ub } F(Z'_n) < \alpha$. Since $f_n \leqq \text{ub } F(Z'_n)$, we have a contradiction.

(iii) Since $X^+ \subseteq U_n$ is obvious, we show that $x \in U_n$, for all n, implies $x \in X^+$. We assume that $f(x) > f^+$ in order to get a contradiction. Since x occurs in every list, a sequence (Z'_n) exists where $x \in Z'_n$ and Z'_n belongs to L_n. Since F is nonwasteful, a partition of $Z'_n \cap R^m$ exists, $Z'_n \cap R^m = \bigcup_{i \in J_n} B_{ni}$. If $Z'_n \in I(X)$, set $B_{ni_n} := Z'_n$. Otherwise choose $i_n \in J_n$ such that $\text{lb } F(B_{ni_n}) \leqq \text{lb } F(Z'_n)$ or that $\text{lb } F(B_{ni_n})$ is asymptotically close to $\text{lb } F(Z'_n)$. Since $w(Z'_n) \to 0$, it follows that $B_{ni_n} \to x$. Let $\xi_n \in B_{ni_n}$; then $f(\xi_n) \to \alpha$ for some $\alpha \geqq f(x)$ due to (1). Now, $w(B_{ni_n}) \to 0$ implies $w(F(B_{ni_n})) \to 0$ and $\text{lb } F(B_{ni_n}) \to \alpha$, and further, $\text{lb } F(Z'_n) \to \alpha$. By (ii), we have $f_n < f(x) \leqq \alpha$ for large n such that Z'_n and thus x is discarded by the midpoint test. This gives the contradiction. □

Condition (9) is too restrictive for functions that have unbounded ranges. Let, for example, $f(x)=x^2$ and $F(Y)=\Box f(Y)$ be the inclusion function. Although the assertions (i)-(iii) of Theorem 1 are satisfied, condition (9) does not hold. In such cases the condition $w(F(Y))-w(\Box f(Y))\to 0$ as $w(Y)\to 0$, for $Y\in I(X)$ could be appropriate. In practice, however, this condition is too difficult to verify. Therefore we establish a condition with which we have obtained the best practical results. It combines theoretical as well as practical requirements where the computer may verify the latter for us.

Let $X\in I_\infty^m$, $f:\bar{X}\to R$, and an inclusion function $F:\bar{I}(\bar{X})\to\bar{I}$ of f be given. We assume that for any given $Z\in I(X)$

$$w(F(Y))\to 0 \quad \text{as } w(Y)\to 0 \quad \text{for } Y\in I(Z). \tag{11}$$

Condition (11) is not at all restrictive. If, for instance, f is continuous and programmable and if F is constructed via natural interval extensions (cf. § 6) then (11) is already satisfied. Then $X^+\neq\varnothing$ and f^+ exists. If Algorithm 2 is applied to F, f, and $\bar{X}$, the following theorem holds for the output data.

THEOREM 2. *If* (11) *holds and if there exists a number n such that the list* L_n *contains only bounded boxes, propositions* (i)-(iii) *of Theorem* 1 *are valid.*

Proof. Let Z be the smallest box of I^m that contains the boxes of L_n, that is, $X^+\subseteq U_n\subseteq Z$. We can now think of L_n as a list created by applying Algorithm 1 to f, F, and Z, such that the assertion of the theorem follows from the properties of Algorithm 1, cf. [11]. □

Example. Let us consider the well-known six-hump-camel-back function, $f(x)=4x_1^2-2.1x_1^4+x_1^6/3+x_1x_2-4x_2^2+4x_2^4$, $x\in X=R^2$. We compare two inclusion functions, F and F_1 of f over $\bar{X}$:

$$F(Y):=4Y_1^2+Y_1^4(Y_1^2/3-2.1)+Y_1Y_2+4Y_2^2(Y_2^2-1)$$

$$F_1(Y):=4Y_1^2-2.1Y_1^4+Y_1^6/3+Y_1Y_2-4Y_2^2+4Y_2^4 \qquad \text{for } Y\in I_\infty(X).$$

$$F(\bar{Y}):=\overline{F(Y)}, \qquad F_1(\bar{Y}):=\overline{F_1(Y)}$$

Neither F nor F_1 satisfy (9). Both F as well as F_1 satisfy (11). If Algorithm 2 is applied to f (using (1)), $\bar{X}$ and F then, after a few iterations, the lists L_n do not contain any unbounded boxes. The assumptions of Theorem 2 are therefore computationally verified for F (cf. Example 1 of § 8 for computational results). This is not the case if F_1 is chosen, since each list will contain unbounded boxes (as long as the monotonicity test is not used). Let, for instance, $\bar{Y}=[a,\infty]\times[b,\infty]$ for $a,b\in R$; then $F_1(\bar{Y})=\bar{R}$ (cf. § 6). Hence $\bar{Y}$ is never discarded by the midpoint test. Nevertheless, the sequence (U_n) will converge to a superset of X^+ that contains the points $(\pm\infty,\pm\infty)$, and we have $\tilde{y}_n=-\infty$ for any n.

Remarks. (1) It is difficult to present precise conditions for F to satisfy the bounded box assumption of Theorem 2. In practice, this assumption was satisfied if F was constructed so that $-\infty\notin F(\bar{Y})$ for all boxes $Y=Y_1\times\cdots\times Y_m\in I_\infty(X)$ where $Y_i=(-\infty,-a]$ or $Y_i=[a,\infty)$, for some arbitrarily large real $a>0$.

(2) The termination criteria known for Algorithm 1 [3], [11] are also appropriate for Algorithm 2 by extending the criteria to infinite boxes and numbers.

Let us return to problem (5) originally posed. Let X^* be the set of global minimizers of problem (5) and f^* the global minimum. Algorithm 2 is appropriate to solve (5) via (6) using the following theorem whose proof is obvious.

THEOREM 3. (i) *If* $f^+=-\infty$, *then* (5) *has no solution, and f is unbounded from below in X.*

(ii) *If* $f^+ \in R$ *and if* $X^* := X^+ \cap R^m$ *is nonempty, then* X^* *and* $f^* = f^+$ *is the solution of* (5). *If* $X^* = \emptyset$ *then* (5) *has no solution but* f *is bounded from below.* □

5. The monotonicity test. The well-known monotonicity test (3), (10) is extended to the unbounded case. This is even more important in the unbounded case, as functions are frequently strictly monotone for large values of the variables, such as polynomials. Such areas contain no minimizers and can be discarded from the lists.

Let $X \in I_\infty^m$, $f: X \to R$, and let $\partial f_i(x)$ be the ith component of the generalized gradient of f at x that is defined as

$$\partial f(x) = \operatorname{conv}\left\{\lim_{n\to\infty} f'(x_n)\colon x_n \to x,\ x_n \in X,\ x_n \notin S \cup \Omega\right\} \tag{12}$$

if at least one limit exists. Here, conv denotes the convex hull, $f'(x_n)$ the gradient of f at x_n, Ω the set of points in some neighbourhood of x at which f is not differentiable, and S any set of Lebesgue measure 0 (cf. Clarke [2]).

Let $Y \in \bar{I}(\bar{X})$, and let $\partial f(x)$ exist for every $x \in Y \cap R^m$ and $G_i(Y) \in \bar{I}$ an inclusion of ∂f_i in Y in the sense that $\partial f_i(x) \in G_i(Y)$ for any $x \in Y \cap R^m$. (In this connection, X cannot be replaced by Y in (12).) We set $Y_i = [a_i, b_i] \in \bar{I}$ and $\bar{X}_i = [c_i, d_i] \in \bar{I}$. Furthermore, let $Y(i/s)$ for $s \in Y_i$ denote that box that arises from Y by replacing Y_i with s. Then the *monotonicity test* (destined to handle the boxes $Y = V_1$, V_2 of step (10) of Algorithm 2) consists of the following two parts:

(I) Test for strictly monotone increasing. For some $i = i, \cdots, m$, if $0 < \operatorname{lb} G_i(Y)$ then

(i) If $c_i < a_i$ then discard (Y, y) from the list.

(ii) If $c_i = a_i \in R$ then replace (Y, y) with the pair (Y', y') where $Y' = Y(i/a_i)$ and $y' = \operatorname{lb} F(Y')$.

(iii) If $a_i = -\infty$ then terminate Algorithm 2 (since $f^+ = -\infty$ such that problem (5) has no solution).

(II) Test for strictly monotone decreasing. Analogous to (I).

Remarks. (1) It is a consequence of a termination by (iii) that only one global minimizer of X^+ is found. But, this is sufficient to guarantee the unsolvability of (5) (cf. Theorem 3).

(2) It is favourable to admit $\pm\infty$ as values of the limits in the definition of the generalized gradient (12). This is shown in the following example where even the bounded case is improved.

Example. Let the semicircle $f(x) = (1-x^2)^{1/2}$ be defined on $X = [-1, 1]$. Then, $X^* = \{-1, 1\}$ and $f^* = 0$. Note that $f'(x) \to \mp\infty$ as $x \to \pm 1$. We applied Algorithm 2 with monotonicity test to this problem, considering Remark (2). We took $F(Y) = (1 - Y^2)^{1/2}$ and $G(Y) = -Y(1 - Y^2)^{1/2}$ as inclusion functions for f and ∂f, respectively, and got the exact result after three iterations. See the next section for the computation of $G(Y)$.

6. How to get inclusion functions. The *simplest* way to get the inclusion functions that are necessary for Algorithm 2 to run is, first, to develop a calculus in I_∞ and to construct inclusion functions with respect to I_∞^m via Moore's principle of natural interval extensions [9], and second, to extend these inclusion functions to $\bar{I}^m$ by means of (3) and (4). We do not use an arithmetic in $\bar{I}$ (cf. [5]), to get the inclusions required since the resulting intervals would be too large in this case.

Let $A, B \in I_\infty$. We expect the arithmetic in I_∞ to satisfy

$$A * B = \{a * b\colon a \in A, b \in B\} \tag{13}$$

if $*$ stands for $+$, $-$, and $\cdot$ (product), and A/B is the smallest interval of I_∞ or is the union of the two smallest intervals of I_∞ such that

$$A/B \supseteq \{a/b\colon a \in A,\ b \in B,\ b \neq 0\}. \tag{14}$$

The case $A/0$ is excluded.

For example, $1/[1, \infty) = [0, 1]$, or $1/[-1, 1] = (-\infty, -1] \cup [1, \infty)$. Hence, I_∞ is not closed with respect to division. We do not worry about that, and we split up the union that occurs into two intervals of I_∞ and process the two intervals separately as long as necessary. For example,

$$\begin{aligned} 1/[-1, 1] + [0, 2]/[1, 2] &= ((-\infty, -1) + [0, 2]) \cup ([1, \infty) + [0, 2]) \\ &= (-\infty, 1] + [1, \infty) = \boldsymbol{R} \in I_\infty. \end{aligned}$$

It is not difficult to establish explicit formulas for the arithmetic defined by (13) and (14) such that we abstain from giving further details. The best way to derive these formulas is to apply limit operations to Moore's formulas for the bounded arithmetic [9], [10]. For instance,

$$[0, 1](-\infty, 0] = \lim_{a \to -\infty} [0, 1][a, 0] = (-\infty, 0].$$

If $f\colon D \to R$, $D \subseteq R^k$ is a function predeclared in the programming language used (such as sin, cos, etc.) and if $Y \in I_\infty^k$, then the *natural interval extension* of f to Y denoted by $f(Y)$ is defined as the smallest interval of I_∞ such that

$$f(Y) \supseteq \square f(Y \cap D). \tag{15}$$

Practically, this definition causes no trouble since the ranges of the functions usually predeclared are well known. For example, if $Y = [-1, \infty)$, then $\sin Y = [-1, 1]$, $\ln Y = R$, and $\exp(-Y) = [0, e]$.

It is necessary to admit boxes Y in (15) that are not necessarily contained in the domain of f since at each step of a recursive evaluation of a natural interval extension, an overestimation of the range is likely. Hence the domain of the function of the next recursive step can be exceeded. Such a superfluous overestimate is prevented by the intersection $Y \cap D$.

Finally, a *natural interval extension* of any programmable function f over $Y \in I_\infty(X)$, $X \in I_\infty^m$ can be defined recursively via (13)-(15), in the same way a function value $f(x)$ is defined recursively via the basic functions (arithmetic operations, predeclared functions), for example, by means of a computer code. The recursive representation of programmable functions is treated in detail in [8], [13], and elsewhere.

Example. If $f(x) = \exp(1/(|\sin x| + |\cos x|))$ and if $Y = R$, then the natural interval extension of f to R is $f(R) = \exp(1/(|\sin R| + |\cos R|)) = [\sqrt{e}, \infty)$.

The result gained in this example depends on the representation for $f(x)$ chosen (cf. also the example after Theorem 2). Thus we can see that it is important to choose appropriate function representations. A procedure to construct them and further details can be found in [14].

7. The realization on the computer. There exist several programming languages and software packages that are able to realize Moore's interval arithmetic on a computer. They also control the rounding errors such that logical flaws cannot occur [3], [6], [9]. Up to now there has not been a general widespread programming language in which an infinite interval arithmetic is incorporated. This is, however, no real problem for a programmer. In our case, we must be aware that both kinds of infinite intervals that we deal with must be simulated by intervals on the computer.

A simple procedure we used is the following. Let R_M be the set of machine representable real numbers. We assume that $\pm L$ is the largest (smallest) number of R_M. Let $I_M = \{[a, b]: a, b \in R_M, a \leqq b\}$ be the set of *machine intervals*. We call $[a, b] \in I_M$ *machine-finite* if $|a|, |b| < L$, otherwise *machine-infinite*. Now, the intervals that occur at the execution of Algorithm 2 on a machine must simulate the intervals that occur at the exact (nonmachine) execution. Hence, a machine-finite interval $[a, b]$ simulates and means $[a, b]$ itself. A machine-infinite interval such as $[A, L]$ means either $[a, \infty)$ if inclusion functions are constructed or $[a, \infty]$ if the execution of Algorithm 2 is addressed. The situation seems involved but is not. It even has the great practical advantage that, when transmitting the inclusion $F(Y)$ to $F(\bar{Y})$, the simulating machine intervals need not be changed.

Width and midpoint of machine intervals are defined as width and midpoint of the corresponding simulated intervals. For instance, $w([1, L]) = \lambda^2$.

An arithmetic $\tilde{*}$ in I_M where $*$ stands for $+$, $-$, $\cdot$, and $/$ is defined as follows. Let $A, B \in I_M$; then $A \tilde{*} B$ is the smallest interval of I_M or the union of the smallest two intervals of I_M such that $A \tilde{*} B \supseteq A * B$ (more precisely, such that $A \tilde{*} B$ is the smallest interval of I_M that *simulates* an inclusion of $A * B$, etc.). In case of division, $B = 0$ is excluded. For instance,

$$[2, L] \tilde{+} [-L, L] = [-L, L] \quad \text{or} \quad [2, L] \tilde{:} [-L, -2] = [-L, -4].$$

Such arithmetics can be fulfilled easily (cf. [6]).

The approximation of the interval values for the functions predeclared by intervals of I_M is done straight, for instance, $\ln [-1, L] = [-L, L]$.

If now Algorithm 2 runs on a machine, then after the computation is terminated either the information $f^+ = -\infty$ (due to the monotonicity test) will be delivered or a machine interval $A \supseteq [\tilde{y}_n, f_n]$ and machine boxes $W_i \supseteq Z_{ni}$, $i = 1, \cdots, l_n$, will be the output data. Here n is the final iteration index and l_n is the length of the list L_n. In general, we get inclusion A and W_i instead of $[\tilde{y}_n, f_n]$ and Z_{ni} because of the common outward rounding when a machine interval arithmetic is used. Due to Theorem 3, the output data of the machine-computation with Algorithm 2 must be interpreted as follows to obtain the required solution of problem (5):

(1) If $f^+ = -\infty$ then f is unbounded from below and (5) has no solution.

(2) If A and W_i, $i = 1, \cdots, l_n$, are machine-finite, then problem (5) has a solution, f^* and X^*, and $f^* \in A$, $X^* \subseteq W := \bigcup_{i=1}^{l_n} W_i$.

(3) If A or if W_{ni} for at least one $i \in \{1, \cdots, l_n\}$ is machine-infinite, then a decision has not been possible whether or not a solution of (5) does exist. However, if a solution exists, f^* and X^*, then $f^* \in A \cap R$ and $X^* \subseteq W \cap R^m$.

8. Numerical results. The following examples were executed in PASCAL-SC.

Example 1. Six-hump-camel-back function, $f(x) = 4x_1^2 - 2.1x_1^4 + x_1^6/3 + x_1 x_2 - 4x_2^2 + 4x_2^4$ for $x \in R^2$. We used the inclusion function F as described in the example after Theorem 2 for larger boxes Y and the mean-value form (cf. [15]) for F if the boxes Y were machine-finite with $w(Y) \leqq 1$. Starting box was $\bar{R}^2$, respectively, $[-L, L]^2$. We needed 211 iterations of Algorithm 2 with monotonicity test (which is about 422 interval function evaluations of $F(Y)$) to obtain the intended absolute accuracy of 10^{-6} for the solution, $f^* \in -1.03162\,84535\,8 + [0, 5]10^{-11}$, $X^* \subseteq W_1 \cup W_2$, where

$$W_1 = [-8.98426\,8, -8.98414\,8]10^{-2} \times [7.12655\,78, 7.12656\,98]10^{-1},$$

$$W_2 = -W_1.$$

By contrast, when we applied Algorithm 1 (also with monotonicity test) with starting box $[-2.5, 2.5]^2$ we needed 163 iterations (about 326 evaluations of $F(Y)$).

Example 2. Wolfe's [18] function modified by Zowe [19] is defined as follows:

$$f(x)=\begin{cases}5(9x_1^2+16x_2^2)^{1/2} & \text{if } x_1 \geqq |x_2|,\\ 9x_1+16|x_2| & \text{if } 0<x_1<|x_2|,\\ 9x_1+16|x_2|-x_1^9 & \text{if } x_1 \leqq 0,\end{cases}$$

where $x \in R^2$. The only global minimizer of f with respect to R^2 is $x^*=(-1,0)$ and $f^*=-8$. The function is convex, and f fails to be differentiable only on the ray $x_1 \leqq 0$, $x_2=0$. As inclusion functions we used natural interval extensions and their unions (if Y was assigned to more than one function branch) for larger and unbounded boxes, otherwise we used the mean value form of f on Y (cf. [14]) where inclusions of the generalized gradient, instead of inclusion of the derivative, were taken if no derivative was available.

When we applied Algorithm 2 (with monotonicity test) to f, F, and $\bar{X}=\bar{R}^2$, 106 iterations (about 212 evaluations of $F(Y)$) were needed to determine the solutions x^* and f^* within an absolute accuracy of $2 \cdot 10^{-6}$.

Example 3. Let $X=[-1,1]\times[-1,1]\times[0,\infty) \subseteq R^3$ and $f: X \to R$ be defined by

$$f(x)=(1-x_1^2)^{1/2}\cos x_3+(1-x_2^2)^{1/2}/(1+x_3^2)+2x_3\, e^{-x_1}.$$

There exist four global minimizers of f in X having the coordinates $x_1=\pm 1$, $x_2=\pm 1$, $x_3=0$. The objective function f is differentiable in the interior of X, continuous—but not Lipschitz—on X. However, f is generalized differentiable (when infinite values are admitted) on the edge of X that contains the four minimizers. As inclusion functions we used the plain natural interval extension as well as the mean-value form. Algorithm 2 (with monotonicity test) needed 31 iterations (which makes about 62 evaluations of $F(Y)$) to achieve the intended absolute accuracy of about 10^{-6} for X^* and of 10^{-10} for f^*.

Example 4. One of the unknown referees suggested considering the function $f(x)=(x_1-x_2)^2$. The set of global minimizers X^* consists of the whole line $x_1=x_2$. When we applied Algorithm 2 (with monotonicity test) to f, $F(Y)=(Y_1-Y_2)^2$, $\bar{X}=\bar{R}^2$, and $\lambda=10$, we needed 733 iterations to obtain an intended maximum box width of one (which was chosen to avoid a too long computer run). The final list contained 313 bounded and five unbounded boxes that were covering the line $x_1=x_2$. The final inclusion for the minimum value $f^*=f^+$ was $[0,0]$.

Acknowledgments. The authors are greatly indebted to Tom Heilandt and R. Ernemann for programming and computing the examples in § 8.

GLOBAL CONTROLLABILITY OF LOCALLY LINEARIZABLE SYSTEMS*

R. M. HIRSCHORN†

Abstract. A nonlinear control system that is locally feedback linearizable usually will not have the global controllability properties of a linear system. The purpose of this paper is to study the reachable set for such systems and to generate controls to accomplish desired state transfers.

Key words. controllability, affine systems

AMS(MOS) subject classification. 93B05

1. Introduction. There has been considerable interest in classifying those nonlinear systems that are locally feedback linearizable (cf. Brockett [1], Jakubczyk and Respondek [2], and [3]-[6]). These ideas have recently been employed to control the motion of robot manipulators (cf. [7]-[9]). The purpose of this paper is to study the global controllability of such systems.

A nonlinear control system is locally feedback linearizable if, replacing u by $(\beta(x)u+k(x))$ and changing coordinates in some open neighbourhood of the initial state, we can obtain a controllable time-invariant linear system. For the nonlinear system $\dot{x}=f(x)+ug(x)$; $x(0)=x_0$ with $f(x_0)=0$, necessary and sufficient conditions for feedback linearization have been derived based on the way f and g generate a Lie algebra of vector fields (cf. [1]-[3]). It is natural to suppose that systems which satisfy these Lie algebraic criteria exhibit some of the standard controllability properties associated with linear control systems, for example, the reachable set of states includes an open neighbourhood of the initial state. The following example shows that this is not always the case if $f(x_0)\neq 0$.

Example 1.1. Consider the system model

$$\dot{x}_1(t)=u(t), \qquad \dot{x}_2(t)=e^{x_1(t)} \tag{1.1}$$

with $\underline{x}(0)=\underline{x}_0=(0,0)$ and $\underline{x}\in M=R^2$. This system is affine with $f(x_1,x_2)=(0,e^{x_1})$, and $g(x_1,x_2)=(1,0)$ and $\{f,g\}$ satisfy the Lie algebraic criteria for local feedback linearization, although $f(x_0)\neq(0,0)$. Note that rescaling u by $\tilde{u}=e^{x_1}u$ followed by the change in coordinates $z_1=e^{x_1}$, $z_2=x_2$ we obtain the *controllable* linear system

$$\begin{bmatrix}\dot{z}_1\\ z_2\end{bmatrix}=\begin{bmatrix}0 & 0\\ 1 & 0\end{bmatrix}\begin{bmatrix}z_1\\ z_2\end{bmatrix}+\begin{bmatrix}1\\ 0\end{bmatrix}\tilde{u}, \qquad \underline{z}(0)=\underline{z}_0=(1,0). \tag{1.2}$$

Unfortunately the original system (1.1) is not even locally controllable about $\underline{x}_0$ since at any time $t>0$ the reachable set of states is

$$\mathcal{R}_t(\underline{x}_0)=R\times(0,\infty)$$

and thus $\underline{x}_0$ is on the boundary of the reachable set.

This example illustrates that, for systems with the Lie algebraic properties for feedback linearization operating from a point where $f(x_0)\neq 0$, controllability depends on more than the structure of the Lie algebra of vector fields generated by f and g. The geometry of the state manifold and the integral curves of f and g also play a role.

In § 2 a globally defined output map h is associated with systems that satisfy the Lie algebraic criteria for local feedback linearization. A set $\mathcal{Y}_h(x_0)$ of admissible C^∞ output functions is described. This set includes all outputs that result from C^∞ inputs. In § 3 the set of reachable states is deduced from $\mathcal{Y}_h(x_0)$, and output tracking is used to explicitly define a control u to transfer the state of the system from $x(t_0)=x_0$ to $x(t_1)=x_1$. A class of systems that are globally controllable is identified.

2. State transfers using output tracking. For linear control systems the variation of constants formula can be utilized to explicitly find a control function u that will transfer the state from $x(t_0)=x_0$ to $x(t_1)=x_1$ $(t_1>t_0)$ (cf. Brockett [10]). Another approach to generating u is to use output tracking. For example, consider the linear system

$$\dot{x}(t)=Ax(t)+bu(t), \qquad x\in R^n. \tag{2.1}$$

Let $\alpha=\operatorname{rank}[b, Ab, \cdots, A^{n-1}b]$ and choose c to be any $1\times n$ matrix over R with

$$cb=cAb=\cdots=cA^{\alpha-2}b=0$$

and $cA^{\alpha-1}b\neq 0$.

If $y(t)=cx(t)$ is considered to be an output for (2.1), then

$$\begin{aligned}
&y^{(1)}(t)=\dot{y}(t)=c\dot{x}(t)=cAx(t),\\
&y^{(2)}(t)=cA^2x(t),\\
&\vdots\\
&y^{(\alpha-1)}(t)=cA^{\alpha-1}x(t),\\
&y^{(\alpha)}(t)=cA^{\alpha}x(t)+cA^{\alpha-1}bu(t).
\end{aligned} \tag{2.2}$$

Let

$$c^\alpha(x)=\begin{bmatrix} cx\\ cAx\\ \vdots\\ cA^{\alpha-1}x\end{bmatrix} \quad\text{and}\quad y^\alpha(t)=\begin{bmatrix} y(t)\\ y^{(1)}(t)\\ \vdots\\ y^{(\alpha-1)}(t)\end{bmatrix}$$

so that when $x(t)$ is a trajectory for (2.1) then $y^\alpha(t)=c^\alpha(x(t))$. It is easy to check that c^α is a 1-1 map of Range $[b, Ab, \cdots, A^{\alpha-1}b]$ onto R^α. Thus, to transfer the state of (2.1) from $x(t_0)=0$ to $x(t_1)=x_1\in$ Range $[b, Ab, \cdots, A^{\alpha-1}b]$ is equivalent to transferring the output $y(\cdot)$ from $y^\alpha(t_0)=c^\alpha(x_0)=c^\alpha(0)=\underline{0}$ to $y^\alpha(t_1)=c^\alpha(x(t_1))=c^\alpha(x_1)$.

Now choose any function $y_d(t)$ with $y_d^\alpha(t_0)=0$ and $y_d^\alpha(t_1)=c^\alpha(x_1)$. From (2.2)

$$y_d^{(\alpha)}(t)=cA^\alpha x(t)+cA^{\alpha-1}bu(t),$$

and thus using the control

$$u_d(x,t)=\frac{y_d^{(\alpha)}(t)-cA^\alpha x}{cA^{\alpha-1}b},$$

the output $y(t)$ has $y^\alpha(t_0)=0$, $y^\alpha(t_1)=c^\alpha(x_1)$. In particular, using u_d it follows that $x(t_0)=0$ and $x(t_1)=x_1$. This method of achieving state transfers will be generalized to nonlinear systems that, in essence, are locally feedback linearizable.

Consider the single-input nonlinear system model

$$\dot{x}(t) = f(x(t)) + u(t)g(x(t)); \qquad x(t_0) = x_0 \in M \tag{2.3}$$

where M is a C^∞ (smooth) n-dimensional manifold, f, g are C^∞ vector fields on M and $u:[t_0, \infty) \to R$ is continuous.

Suppose $f(x_0) = 0$. Then the system (2.3) will be called *locally state linearizable on an open neighbourhood $\mathcal{U}_0$ of x_0* if the system can be transformed into a linear controllable system via a change of coordinates in $\mathcal{U}_0$ (cf. [6]). Suppose that (2.3) is modified on U_0 by replacing $u(t)$ by $(\beta(x(t))u(t) + k(x(t)))$ where $k(x)$ is a smooth feedback law defined on $\mathcal{U}_0$ with $k(x_0) = 0$ and $\beta(x)$ is a smooth change of coordinates in the input space with $\beta(x) \neq 0$ for all $x \in \mathcal{U}_0$. If the resulting system is locally state linearizable on $\mathcal{U}_0$ we say that (2.3) is *feedback linearizable on $\mathcal{U}_0$*.

If $f(x_0) = 0$ then a necessary and sufficient condition for the system (2.3) to be feedback linearizable on an open neighborhood $\mathcal{U}_0$ of x_0 in M is that the set of vectors

$$\{g(x), \operatorname{ad}_f g(x), \operatorname{ad}_f^2 g(x), \cdots, \operatorname{ad}_f^{n-1} g(x)\} \tag{2.4}$$

are linearly independent at each x in $\mathcal{U}_0$ and the distribution

$$\mathcal{D}(x) = \operatorname{span}\{g(x), \cdots, \operatorname{ad}_f^{n-2} g(x)\}$$

is involutive (cf. [1]-[3]). To study the structure of the reachable set for systems that satisfy (2.4) some global condition must be added. Note that when $f(x_0) \neq 0$ the system is not locally feedback linearizable. In this paper the existence of an output map $y = h(x)$ with relative order $\alpha_h = n$ (cf. [11]-[13]) will be assumed.

If $h \in C^\infty(M)$ is an output map $y = h(x)$ for (2.3), then the *relative order* α_h is the least nonnegative integer k such that $gf^{k-1}h \not\equiv 0$ on M, and $\alpha_h = \infty$ if $gf^k h \equiv 0$ for all $k \geqq 0$ (if X is a vector field and h is a function, then $Xh = dhX$). Thus for the linear system (2.1) with the output $y = h(x) = cx$ the relative order $\alpha_h = \alpha = \operatorname{rank}[b, Ab, \cdots, A^{n-1}b]$. If this system is controllable then $\alpha_h = n$. That is, for a controllable time-invariant linear system there are linear outputs with relative order $\alpha_h = n$. The following lemma shows that for nonlinear systems that satisfy condition (2.4) there are locally defined outputs with $\alpha_h = n$.

LEMMA 2.1. *Suppose that the nonlinear system* (2.3) *satisfies the Lie algebraic criteria* (2.4). *Then there exists an open neighborhood $\mathcal{U}_0$ of x_0 in M and a C^∞ output $y = h(x)$ defined on $\mathcal{U}_0$ with $\alpha_h = n (= \dim M)$.*

Proof. From (2.4) the distribution $\mathcal{D}(x) = \operatorname{span}\{g(x), \cdots, \operatorname{ad}_f^{n-2} g(x)\}$ is involutive on some open neighborhood $\mathcal{U}_{x_0}$ of x_0 in M, and $\operatorname{ad}_f^{n-1} g(x) \notin \mathcal{D}(x)$ for all $x \in \mathcal{U}_{x_0}$. The Frobenius Theorem (cf. [14]) asserts that there exist an open set $\mathcal{U}_0$ such that $x_0 \in \mathcal{U}_0 \subset \mathcal{U}_{x_0}$ and a coordinate system $(\mathcal{U}_0, x_1, \cdots, x_n)$ such that the slices $x_n = c$, c constant, are the integral manifolds of $\mathcal{D}$ around x_0. Define $h \in C^\infty(\mathcal{U}_0)$ to the function $h(x) = x_n$. Thus for all vector fields $X \in \mathcal{D}$, $Xh \equiv 0$. In particular, $gh = 0$,

$$\operatorname{ad}_f gh = (fg - gf)h = f(gh) - gfh = -gfh \equiv 0, \cdots, \operatorname{ad}_f^{n-2} gh$$

$$= (-1)^{n-3} gf^{n-2} h \equiv 0$$

and since $\operatorname{ad}_f^{n-1} g \notin \mathcal{D}$, $\operatorname{ad}_f^{n-1} gh = (-1)^{n-2} gf^{n-1} h \not\equiv 0$. This means that the relative order of h is $\alpha_h = n$, as required.

There can be obstructions to obtaining a global version of Lemma 2.1. The following (somewhat pathological) example illustrates this point.

Example 2.2. Consider the system (2.3) where $M = T^2$, the two-torus, and $f(x_1, x_2) = (1+2\cos 2\pi x_1, 0)$, $g(x_1, x_2) = (1, \sqrt{2})$, $x_0 = (0.5, 0.5)$, T^2 is modeled as the square $[0,1]\times[0,1]$ with the usual identifications. Since $\mathrm{ad}_f g(x_1, x_2) = (4\pi \sin 2\pi x_1, 0)$, it follows that (2.4) is satisfied and Lemma 2.1 applies. Thus locally there exist outputs h with $\alpha_h = 2$—for example, $\mathcal{U}_0 = (0,1)\times(0,1)$ and $h(x_1, x_2) = \sqrt{2}x_1 - x_2$ will suffice—but there is no $h \in C^\infty(T^2)$ with $\alpha_h = 2$! Suppose such an h exists. Then $gh \equiv 0$ implies that h is constant on the integral curves of g. Since each g-integral curve is a dense submanifold of T^2 (a skew line), h must be constant on T^2 by the continuity of h. In that case $gf^i h \equiv 0$ for all i so that $\alpha_h = \infty$, a contradiction.

In practice it is not unreasonable to expect the existence of a globally defined output function $y = h(x)$ with $\alpha_h = n$ when (2.4) holds.

As in the linear case the existence of outputs $y = h(x)$ with $\alpha_h = n$ gives a useful type of observability.

DEFINITION. Let $y = h(x)$ be a C^∞ output map for the system (2.3) with relative order α_h. Then define

$$y^\alpha(t) = \begin{bmatrix} y(t) \\ y^{(1)}(t) \\ \vdots \\ y^{(\alpha_h - 1)}(t) \end{bmatrix}$$

and

$$h^\alpha(x) = \begin{bmatrix} h(x) \\ fh(x) \\ f^2h(x) \\ \vdots \\ f^{\alpha_h - 1}h(x) \end{bmatrix}.$$

Since $y(t) = h(x(t))$,

$$\begin{aligned} y^{(1)}(t) &= dh_{x(t)}\dot{x}(t) \\ &= dh_{x(t)}(f(x(t)) + u(t)g(x(t))) \\ &= fh(x(t)) + u(t)gh(x(t)) \\ &= fh(x(t)) \\ &\vdots \\ y^{(\alpha_h - 1)}(t) &= f^{\alpha_h - 1}h(x(t)) \\ y^{(\alpha_h)}(t) &= f^{\alpha_h}(x(t)) + u(t)gf^{\alpha_h - 1}h(x(t)) \end{aligned}$$

we see that $y^\alpha(t) = h^\alpha(x(t))$. Thus if we observe $y^\alpha(t_1)$ we know $h^\alpha(x(t_1))$ which, in turn, implies some knowledge of the state $x(t_1)$.

LEMMA 2.2. *Suppose the system* (2.3) *satisfies the linearization condition* (2.4). *Then there exists an open neighborhood* $\mathcal{U}$ *of* x_0 *and a* C^∞ *output* $y = h(x)$ *defined on* $\mathcal{U}$ *with* $\alpha_h = n$, *and the map* $x \mapsto h^\alpha(x)$ *is a diffeomorphism of* $\mathcal{U}$ *into* R^n.

Proof (compare with [2], [3]). Lemma 2.1 implies the existence of an output h with $\alpha_h = n$ on $\mathcal{U}$. To complete the proof we need only show that $dh^\alpha_{x_0}$ is a linear

isomorphism—the Inverse Function Theorem then applies. Suppose $dh^{\alpha}_{x_0}v = \underline{0}$ for $v \in T_{x_0}(M)$. From (2.4), $v = a_0 g(x_0) + a_1 \operatorname{ad}_f g(x_0) + \cdots + a_{n-1} \operatorname{ad}_f^{n-1} g(x_0)$, and thus $dh^{\alpha}_{x_0}v = \underline{0}$ means that $dh_{x_0}v = 0$, $d(fh)_{x_0}v = 0, \cdots, d(f^{n-1}h)_{x_0}v = 0$. Using the first of these equalities, we have that $dh_{x_0}v = a_0 gh(x_0) + a_1 \operatorname{ad}_f gh(x_0) + \cdots + a_{n-1} \operatorname{ad}_f^{n-1} gh(x_0) = 0$ as $\alpha_h = n$, $gh \equiv \operatorname{ad}_f gh \equiv \cdots \equiv \operatorname{ad}_f^{n-2} gh \equiv 0$. From the proof of Lemma 2.1 we have $\operatorname{ad}_f^{n-1} gh(x_0) \neq 0$, so that $dh^{\alpha}_{x_0}v = 0$ implies $a_{n-1} = 0$. Similarly, $d(fh)_{x_0}v = 0$ implies $a_{n-2} = 0$, and continuing we can conclude that $v = 0$. Thus $dh^{\alpha}_{x_0}$ is a linear isomorphism and the proof is complete.

Remark. The output $y = h(x)$ described in Lemma 2.2 results in a realization that is *locally observable.* That is, if $x(t_1) \in \mathcal{U}$ and we observe $y^{\alpha}(t_1)(= h^{\alpha}(x(t_1)))$, then we can recover the state $x(t_1)$ via $x(t_1) = (h^{\alpha}|_{\mathcal{U}})^{-1}(y^{\alpha}(t_1))$. Knowing y and its derivatives at a fixed time enables us to deduce the state when $x \in \mathcal{U}$.

To study the structure of the reachable set for the system (2.3) a global version of Lemma 2.2 will be required.

DEFINITION. The system (2.3) can be *globally observed using the output* $y = h(x)$ if there exists a C^{∞} output $h(x)$ defined on M with $\alpha_h = n$, and the map $x \mapsto h^{\alpha}(x)$ is a diffeomorphism of M *into* R^n.

Suppose the system (2.3) can be globally observed using the output $y = h(x)$. To transfer the state from $x(t_0) = x_0$ to $x(t_1) = x_1$ $(t_1 > t_0)$ we can employ output tracking. If $x(t)$ is a trajectory for (2.3) then $y^{\alpha}(t) = h^{\alpha}(x(t))$. Thus to achieve the desired state transfer the output function $y(t)$ must satisfy

$$y^{\alpha}(t_0) = h^{\alpha}(x(t_0)) = h^{\alpha}(x_0), \qquad y^{\alpha}(t_1) = h^{\alpha}(x(t_1)) = h^{\alpha}(x_1). \tag{2.5}$$

From equation (2.4)

$$y^{(\alpha)}(t) = f^{\alpha}h(x(t)) + u(t) g f^{\alpha-1} h(x(t)), \tag{2.6}$$

where $\alpha = \alpha_h$. Thus, if y_d is any C^{∞} function that satisfies (2.5) and

$$u(x, t) = \frac{y_d^{(\alpha)}(t) - f^{\alpha}h(x)}{g f^{\alpha-1} h(x)}, \tag{2.7}$$

then

$$\begin{aligned} y^{(\alpha)}(t) &= f^{\alpha}h(x(t)) + u(x(t), t) g f^{\alpha-1} h(x(t)) \\ &= y_d^{(\alpha)}(t). \end{aligned}$$

Since $y^{\alpha}(t_0) = y_d^{\alpha}(t_0)$ it follows that $y \equiv y_d$. In particular, $y^{\alpha}(t_1) = y_d^{\alpha}(t_1) = h^{\alpha}(x_1)$ so that $x(t_1) = x_1$, as required.

This is a generalization of the technique used at the beginning of this section to transfer states for linear systems, where $g f^{\alpha-1} h(x) = cA^{\alpha-1}b$, a nonzero constant. Here $g f^{\alpha-1} h(x)$ can vanish.

DEFINITION. A state x is a *singular point for an output* $y = h(x)$ if $g f^{\alpha-1} h(x) = 0$. Let M_h^s denote the set of singular points for h in M.

The following results examine the behaviour of the system around singular points.

LEMMA 2.3. *Suppose that the system* (2.3) *is locally feedback linearizable and can be globally observed using the output* $y = h(x)$. *Then there exist* C^{∞} *functions* a_k, b_k : Range $h^{\alpha} \to R$ *with the following property*:

If $x(t)$ *is a trajectory then* $f^{\alpha}h(x(t)) = a_0(y^{\alpha}(t))$, $g f^{\alpha-1} h(x(t)) = b_0(y^{\alpha}(t))$,

and for each time t_s such that $x(t_s) \in M_h^s$ (i.e., $x(t_s)$ is a singular point),

$$\frac{d^k}{dt^k} f^\alpha h(x(t_s)) = a_k(y^\alpha(t_s)),$$

$$\frac{d^k}{dt^k} g f^{\alpha-1} h(x(t_s)) = b_k(y^\alpha(t_s))$$

for $k = 0, 1, 2, \cdots$ where $\alpha = \alpha_h$.

In particular, $x(t_s) \in M_h^s$ if and only if $b_0(h^\alpha(x(t_s))) = b_0(y^\alpha(t_s)) = 0$.

Proof. By definition $y^\alpha(t) = h^\alpha(x(t))$ so that $x(t) = (h^\alpha)^{-1}(y^\alpha(t))$ and thus $f^\alpha h(x(t)) = f^\alpha h((h^\alpha)^{-1}(y^\alpha(t))) = a_0(y^\alpha(t))$ where $a_0(z) = f^\alpha h((h^\alpha)^{-1}(z))$.

Similarly, if $b_0(z) = g f^{\alpha-1} h((h^\alpha)^{-1}(z))$ then $g f^{\alpha-1} h(x(t)) = b_0(y^\alpha(t))$. Now setting $\alpha = \alpha_h$, we have

$$\begin{aligned}
\frac{d}{dt} f^\alpha h(x)(t)) &= \frac{d}{dt} a_0(y^\alpha(t)) \\
&= \frac{d}{dt} a_0(y(t), y^{(1)}(t), \cdots, y^{(\alpha-1)}(t)) \\
&= \sum_{i=0}^{\alpha-1} \frac{\partial a_0}{\partial y^{(i)}} y^{(i+1)}(t) \\
&= (da_0)_{y^\alpha(t)}(y^{(1)}(t), y^{(2)}(t), \cdots, y^{(\alpha-1)}(t), y^{(\alpha)}(t)) \\
&= (da_0)_{y^\alpha(t)}(y^{(1)}(t), \cdots, y^{(\alpha-1)}(t), a_0(y^\alpha(t)) + u(t) b_0(y^\alpha(t))),
\end{aligned}$$

and at time t_s, $b_0(y^\alpha(t_s)) = 0$ so that

$$\frac{d}{dt} f^\alpha h(x(t_s)) = a_1(y^\alpha(t_s)) \quad \text{where } a_1(z) = (da_0)_z(z_1, \cdots, z_\alpha, a_0(z)).$$

Similarly, $d/dt\, g f^{\alpha-1} h(x(t_s)) = b_1(y^\alpha(t_s))$ and a simple induction argument completes the proof.

COROLLARY. *Suppose that the system* (2.3) *satisfies the hypotheses of Lemma* 2.3. *Then the functions a_k, b_k are defined inductively by*

$$a_{k+1}(z) = (da_k)_z(z_2, \cdots, z_\alpha, a_0(z)),$$

$$b_{k+1}(z) = (db_k)_z(z_2, \cdots, z_\alpha, a_0(z))$$

where $\alpha = \alpha_h$ and

$$a_0(z) = f^\alpha h((h^\alpha)^{-1}(z)),$$

$$b_0(z) = g f^{\alpha-1} h((h^\alpha)^{-1}(z))$$

for $z \in$ Range $h^\alpha \subseteq R^\alpha$.

Proof. These are the functions constructed in the proof of Lemma 2.3.

As in [12] we can define the *degree of singularity* $\beta(x_0)$ of a singular point x_0 that is connected with the number of extra restrictions placed on $y(t)$ when a trajectory

$x(t)$ passes through x_0 at time t. When (2.3) can be globally observed using the output $y=h(x)$, then $\beta(x)$ is simply the least positive integer k such that $b_k(h^\alpha(x_0))\neq 0$ and $\beta(x_0)=\infty$ if $b_k(h^\alpha(x_0))=0$ for all k. Note that if $x_0\notin M_h^s$ then $\beta(x_0)=0$.

LEMMA 2.4. *Suppose that the system* (2.3) *can be globally observed using the output* $y=h(x)$, *and* M, f, g, h *are real analytic. Then* $\beta(x_0)<\infty$ *for all* $x_0\in M$.

Proof. Suppose $\beta(x_0)=\infty$ for some $x_0\in M_h^s$. Then $b_k(h^\alpha(x_0))=0$ for all $k>0$. If $x(t)$ is any trajectory for (2.3) with $x(t_0)=x_0$, then from Lemma 2.3,

$$\frac{d^k}{dt^k} gf^{\alpha-1}h(x(t_0)) = b_k(y^\alpha(t_0)) = b_k(h^\alpha(x(t_0))) = 0$$

for $k=0, 1, 2, \cdots$, where $\alpha=\alpha_h$. Thus the Taylor coefficients in the Taylor series expansion of $gf^{\alpha-1}h(x(t))$ about $t=t_0$ are zero and hence $gf^{\alpha-1}h(x(t))=0$ for all $t\in R$. This, in turn, implies that $gf^{\alpha-1}h\equiv 0$ on M, which contradicts the definition of α (i.e., $gf^{\alpha-1}h\not\equiv 0$). Thus $\beta(x_0)<\infty$ and the proof is complete.

In light of Lemma 2.4 we can reasonably assume that $\beta(x)<\infty$ for all $x\in M$. If, in addition, the system (2.3) can be globally observed using the output $y=h(x)$, then the degree of a singularity can be expressed in terms of the outputs. That is, define

$$\hat{\beta}(z)=\beta((h^\alpha)^{-1}(z)),$$

a function defined on Range h^α. Thus when $x(t)$ is a trajectory for (2.3) with output $y(t)$ then $\beta(x(t))=\beta((h^\alpha)^{-1}h^\alpha(x(t)))=\hat{\beta}(y^\alpha(t))$, Now we can associate with this system the functions $a_0, a_1, \cdots, b_0, b_1, \cdots$ from Lemma 2.3 as well as the function $\hat{\beta}$.

DEFINITION. Let $\mathcal{Y}_h(x_0)$ denote the set of all C^∞ functions on R with the following properties:

(i) $y^\alpha(t)\in$ Range h^α for all t;

(ii) $y^\alpha(t_0)=h^\alpha(x_0)$;

(iii) If $b_0(y^\alpha(t_s))=0$ at time t_s, then $y^{(\alpha_h+k)}(t_s)=a_k(y^\alpha(t_s))$ for $0\leqq k<\hat{\beta}(y^\alpha(t_s))$.

THEOREM 2.5. *Suppose that the system* (2.3) *can be globally observed using the output* $y=h(x)$. *Then each function in* $\mathcal{Y}_h(x_0)$ *is an output for the system resulting from a continuous input. Furthermore,* $\mathcal{Y}_h(x_0)$ *contains all output functions which result from* C^∞ *inputs.*

Proof. Let u be a C^∞ input to the system (2.3) that results in the trajectory $x(t)$ and the output function $y(t)=h(x(t))$. Then $y^\alpha(t)=h^\alpha(x(t))$, and thus $y^\alpha(t)\in$ Range h^α for $t\geqq t_0$. Also $y^\alpha(t_0)=h^\alpha(x(t_0))=h^\alpha(x_0)$. Finally, suppose that $b_0(y^\alpha(t_s))=0$ for some time t_s. Let $\alpha=\alpha_h$. From Lemma 2.3 $y^{(\alpha)}(t)=a_0(y^\alpha(t))+u(t)b_0(y^\alpha(t))$. Thus if $\beta=\hat{\beta}(y^\alpha(t_s))$ then $b_0(y^\alpha(t_s))=(d/dt)b_0(y^\alpha(t_s))=\cdots=(d^{\beta-1}/dt^{\beta-1})b_0(y^\alpha(t_s))=0$ and $(d^\beta/dt^\beta)b_0(y^\alpha(t_s))\neq 0$. This means that

$$y^{(\alpha+1)}(t)=\frac{d}{dt}a_0(y^\alpha(t))+u^{(1)}(t)b_0(y^\alpha(t))+u(t)\frac{d}{dt}b_0(y^\alpha(t))$$

so at time t_s

$$y^{(\alpha+1)}(t_s)=\frac{d}{dt}a_0(y^\alpha(t_s))+u^{(1)}(t_s)\cdot 0+u(t_s)\cdot 0$$

$$=a_1(y^\alpha(t_s)).$$

Similarly, $y^{(\alpha+k)}(t_s)=a_k(y^\alpha(t_s))$ for $0\leqq k<\beta$. Thus if u is C^∞ then $y\in\mathcal{Y}_h(x_0)$.

Finally, suppose that $y_d \in \mathcal{Y}_h(x_0)$. Define the feedback control

$$u_d(t,x)=\begin{cases}\dfrac{y_d^{(\alpha)}(t)-a_0(h^\alpha(x))}{b_0(h^\alpha(x))} & \text{when } b_0(y_d^{(\alpha)}(t_s))\neq 0,\\ r(t_s) \quad \text{when } b_0(y_d^\alpha(t_s))=0\end{cases}$$

where $r(t_s)=(y_d^{(\alpha+\beta)}(t_s)-a_\beta(y_d^\alpha(t_s)))/b_\beta(y_d^\alpha(t_s))$. The proof will be complete if it can be shown that using u_d results in a trajectory $x(t)$ with the property that $t\mapsto u_d(t,x(t))$ is continuous and $y(t)=h(x(t))=y_d(t)$. Of course $y_d^\alpha(t_0)=h^\alpha(x_0)=y^\alpha(t_0)$ so that $y\equiv y_d$ if $y^{(\alpha)}\equiv y_d^{(\alpha)}$. If $t\neq t_s$, then

$$\begin{aligned}y^{(\alpha)}(t)&=a_0(y^\alpha(t))+u_d(t,x(t))b_0(y^\alpha(t))\\&=a_0(y^\alpha(t))+\frac{y_d^{(\alpha)}(t)-a_0(y^\alpha(t))}{b_0(y^\alpha(t))}\cdot b_0(y^\alpha(t))\\&=y_d^{(\alpha)}(t),\end{aligned}$$

so that $y\equiv y_d$ for $t_0\leqq t<t_s$. At time t_s, $b_0(y_d^\alpha(t_s))=0$ and $u_d(t_s,x(t_s))=r(t_s)$. Now

$$\begin{aligned}\lim_{t\to t_s^-}u_d(t,x(t))&=\lim_{t\to t_s^-}\frac{y_d^{(\alpha)}(t)-a_0(y_d^\alpha(t))}{b_0(y_d^\alpha(t))}\\&=\lim_{t\to t_s^-}\frac{y_d^{(\alpha+1)}(t)-(d/dt)a_0(y_d^\alpha(t))}{(d/dt)b_0(y_d^\alpha(t))}\end{aligned}$$

using l'Hôpital's rule—note that $y_d^{(\alpha)}(t_s)=a_0(y_d^\alpha(t_s))$ since $y\in\mathcal{Y}_h(x_0)$. Now if $\beta>1$, then $(d/dt)b_0(y_d^\alpha(t_s))=b_1(y_d^\alpha(t_s))=0$ and $y_d^{(\alpha+1)}(t_s)=(d/dt)a_0(y_d^\alpha(t_s))=a_1(y_d^\alpha(t_s))$ since $y\in\mathcal{Y}_h(x_0)$, so using l'Hôpital's rule

$$\lim_{t\to t_s^-}u_d(t,x(t))=\lim_{t\to t_s^-}\frac{y_d^{(\alpha+2)}(t)-(d^2/dt^2)a_0(y_d^\alpha(t))}{(d^2/dt^2)b_0(y_d^\alpha(t))}$$

and continuing this process

$$\begin{aligned}\lim_{t\to t_s^-}u_d(t,x(t))&=\lim_{t\to t_s}\frac{y_d^{(\alpha+\beta)}(t)-(d^\beta/dt^\beta)a_0(y_d^\alpha(t))}{(d^\beta/dt^\beta)b_0(y_d^\alpha(t))}\\&=\frac{y_d^{(\alpha+\beta)}(t_s)-a_\beta(y_d^\alpha(t_s))}{b_\beta(y_d^\alpha(t_s))}\\&=r(t_s)\\&=u_d(t_s,x(t_s))\end{aligned}$$

and it follows that u_d is continuous and the proof is complete. Note that in open-loop form the control corresponding to y_d is

$$u_d(t)=\begin{cases}\dfrac{y_d^{(\alpha)}(t)-a_0(y_d^\alpha(t))}{b_0(y_d^\alpha(t))} & \text{when } b_0(y_d^\alpha(t))\neq 0,\\ r(t_s) \quad \text{when } b_0(y_d^\alpha(t_s))=0\end{cases}\tag{2.8}$$

where $r(t_s)=(y_d^{(\alpha+\beta)}(t_s)-a_\beta(y_d^\alpha(t_s)))/b_\beta(y_d^\alpha(t_s))$.

In § 3 the set $\mathcal{Y}_h(x_0)$ of output functions is used to deduce the reachable set and perform state transfers using inputs derived from output tracking. This section ends with a number of examples.

Example 2.3 (Example 1.1 continued). Here $M = R^2$, $f(x) = (0, e^{x_1})$, $g(x) = (1, 0)$, and $x(0) = x_0 = (a, b)$. To find an output $h(x)$ with $\alpha_h = \dim M = 2$ requires $gh \equiv 0$. Thus h is a function of x_2. We are led to try $h(x_1, x_2) = x_2$. Thus $gh \equiv 0$, $gfh(x_1, x_2) = e^{x_1}$ so that $\alpha_h = 2$, and since $h^\alpha(x_1, x_2) = (x_2, e^{x_1})$, a diffeomorphism of M into R^2, this system can be globally observed using the output $y = h(x)$. Since $gf^{\alpha-1}(x_1, x_2) = e^{x_1} \neq 0$ there are no singular points, i.e., $\beta(x) = 0$ for all $x \in M$, and thus $\mathcal{Y}_h(x_0)$ consists of C^∞ functions y with

(i) $(y(t), \dot{y}(t)) \in \text{Range } h^\alpha = R \times R^+ \qquad (R^+ = (0, \infty))$,

(ii) $(y(0), \dot{y}(0)) = h^\alpha(x_0) = (b, e^a)$.

That is, $\mathcal{Y}_h(x_0) = \{y \in C^\infty(R) \mid y(0) = b,\ \dot{y}(0) = e^a \text{ and } y \text{ increasing}\}$.

Example 2.4. Consider the system model where $f(x_1, x_2) = (0, x_1 + x_2 + 1)$, $g(x_1, x_2) = (x_1 + x_2, 0)$ and $x(0) = x_0 = (a, b) \in M = R^2$. Here $\text{ad}_f g(x_1, x_2) = (x_1 + x_2 + 1, -(x_1 + x_2))$ so that condition (2.4) is satisfied (when $a + b \neq 0$). To find an output $h : M \to R^2$ such that the system is globally observed we require $\alpha_h = \dim M = 2$. Since this means $gh = (\partial h/\partial x_1)(x_1 + x_2) \equiv 0$, h must be a function of x_2 alone. Trying $h(x_1, x_2) = x_2$ we have $fh(x_1, x_2) = x_1 + x_2 + 1$ so that $h^\alpha(x_1, x_2) = (x_2, x_1 + x_2 + 1)$ is a diffeomorphism of $M = R^2$ into R^2 (in fact, Range $h^\alpha = R^2$), and h will suffice. Since

$$\begin{aligned} y &= h(x_1, x_2) = x_2, \\ \dot{y} &= fh(x_1, x_2) = x_1 + x_2 + 1, \\ \ddot{y} &= f^2 h(x_1, x_2) + ugfh(x_1, x_2) \\ &= (x_1 + x_2 + 1) + u(x_1 + x_2) \\ &= \dot{y} + u(\dot{y} - 1) \end{aligned}$$

it follows that $a_0(y, \dot{y}) = \dot{y}$ and $b_0(y, \dot{y}) = \dot{y} - 1$. Here the singular set is $M_h^s = \{(x_1, x_2) \mid x_1 + x_2 = 0\}$, and from the corollary to Lemma 2.3,

$$\begin{aligned} a_1(y, \dot{y}) &= da_{0_{(y,\dot{y})}}(\dot{y}, \dot{y}) = \dot{y} \\ b_1(y, \dot{y}) &= db_{0_{(y,\dot{y})}}(\dot{y}, \dot{y}) = \dot{y}. \end{aligned}$$

Thus if $b_0(y^\alpha(t_s)) = b_0(y(t_s), \dot{y}(t_s)) = \dot{y}(t_s) - 1 = 0$ at time t_s (i.e., $\dot{y}(t_s) = 1$), then $b_1(y^\alpha(t_s)) = \dot{y}(t_s) = 1 \neq 0$, hence $\beta = 1$. Since Range $h^\alpha = R^2$, it follows that $\mathcal{Y}_h(x_0)$ consists of all C^∞ functions with the property that

$y^\alpha(0) = (y(0), \dot{y}(0)) = h^\alpha(x_0) = (b, a + b + 1)$ and if $b_0(y^\alpha(t_s)) = \dot{y}(t_s) - 1 = 0$ then $\ddot{y}(t_s) = a_1(y^\alpha(t_s)) = \dot{y}(t_s) = 1$.

That is, $\mathcal{Y}_h(x_0) = \{y \in C^\infty(R) \mid y(0) = b,\ \dot{y}(0) = a + b + 1$, and when $\dot{y}(t_2) = 1$ then $\ddot{y}(t_s) = 1\}$.

Example 2.5. Consider the system

$$\begin{aligned} \dot{x}_1 &= x_1 u, & x_1(0) &= a, \\ \dot{x}_2 &= \ln x_1, & x_2(0) &= b \end{aligned}$$

where $M = R^+ \times R$. This system can be globally observed using $h(x) = x_2$ (or e^{x_2}, etc.). Here $h^\alpha(x_1, x_2) = (x_2, \ln x_1) : M \to R^2$ is a diffeomorphism onto R^2, and $\ddot{y} = u$ so that $gfh(x_1, x_2) = 1$ and there are *no* singular states. Thus

$$\mathcal{Y}_h(x_0) = \{y \in C^\infty(R) \mid y(0) = b,\ \dot{y}(0) = \ln a\}.$$

3. The set of reachable states. Let $x(t, u, x_0)$ denote the solution to the differential equation (2.3) where u is a continuous control. A state $x \in M$ is said to be *reachable*

from x_0 at time t if $x = x(t, y, x_0)$ for some (continuous) control u. The collection of all states reachable from x_0 at time t is denoted by $\mathcal{R}_t(x_0)$, the *reachable set at time t.* The system (2.3) is called *strongly controllable* if $\mathcal{R}_t(x_0) = M$ for all $t > t_0$.

For systems that can be globally observed using an output h we can essentially determine $\mathcal{R}_t(x_0)$ from the collection of output functions $\mathcal{Y}_h(x_0)$. Define $\mathcal{Q}_t^h(x_0)$ to be the subset

$$\mathcal{Q}_t^h(x_0) = \{(h^\alpha)^{-1} y^\alpha(t) \,|\, y \in \mathcal{Y}_h(x_0)\} \subseteq M.$$

THEOREM 3.1. *Suppose that the system* (2.3) *can be globally observed using the output $y = h(x)$. Then*

(i) $\mathcal{R}_t(x_0) \supseteq \mathcal{Q}_t^h(x_0)$ *for all* $t > t_0$;

(ii) $\mathcal{Q}_t^h(x_0)$ *is dense in* $\mathcal{R}_t(x_0)$, *in fact* $\operatorname{cl}(\operatorname{int} \mathcal{Q}_t^h(x_0)) = \operatorname{cl}(\operatorname{int} \mathcal{R}_t(x_0))$ *for all* $t > t_0$; *and*

(iii) $\mathcal{R}_t(x_0) = M$ *if and only if* $\mathcal{Q}_t^h(x_0) = M$.

COROLLARY. *Suppose that the system* (2.3) *can be globally observed using the output $y = h(x)$. Then we can transfer the state of the system from $x(t_0) = x_0$ to $x(t_1) = x_1 \in \mathcal{Q}_t^h(x_0)$ as follows*:

(i) *Choose $y \in \mathcal{Y}_h(x_0)$ such that $y(t_1) = h^\alpha(x_1)$.*

(ii) *Set $u_d(t) = (y^{(\alpha)}(t) - a_0(y^\alpha(t)))/b_0(y^\alpha(t))$ for all t such that $b_0(y^\alpha(t)) \neq 0$ $(\alpha = \alpha_h)$.*

(iii) *If $b_0(y^\alpha(t_s)) = 0$ set $u_d(t_s) = (y^{(\alpha+\beta)}(t_s) - a_\beta(y^\alpha(t_s)))/b_\beta(y^\alpha(t_s))$ where $\beta = \hat{\beta}(y^\alpha(t_s))$.*

Then u_d is a continuous control that steers the system from $x(t_0) = x_0$ to $x(t_1) = x_1$.

Proof of Theorem 3.1. From Theorem 2.5 $\mathcal{Y}_h(x_0)$ contains all outputs that result from C^∞ inputs, and each $y \in \mathcal{Y}_h(x_0)$ is an output $y(t) = h(x(t))$ for the system corresponding to a continuous input $u(t)$. Thus $y^\alpha(t) = h^\alpha(x(t))$ and $(h^\alpha)^{-1} y^\alpha(\cdot) = x(\cdot)$ is a system trajectory so that (i) follows. Since the set of states we can reach at time t using C^∞ inputs has an interior that is dense in $\mathcal{R}_t(x_0)$ (cf. [15]), (ii) follows. Of course $\mathcal{R}_t(x_0) = M$ if and only if $\operatorname{int} \mathcal{R}_t(x_0) = M$, if and only if $\mathcal{Q}_t^h(x_0) = M$, and the proof is complete.

Proof of the corollary. This result is proved in § 2. In particular, $u(t)$ is described in (2.8).

Example 3.1. Consider the system from Example 2.3. Here $y \in \mathcal{Y}_h(x_0)$ if and only if $y(0) = b$, $\dot{y}(0) = e^a$ and y is increasing $(x(0) = (a, b))$. Thus $y(t) > b$ and $\dot{y}(t) > 0$ for any $t > 0$, so that

$$\mathcal{Q}_t^h(x_0) = (h^\alpha)^{-1}\{(y_1, y_2) \,|\, y_1 > b, y_2 > 0\}.$$

Furthermore, $h^\alpha(x_1, x_2) = (x_2, e^{x_1})$ so that $(h^\alpha)^{-1}(y_1, y_2) = (\ln y_2, y_1)$, and thus

$$\begin{aligned} \mathcal{Q}_t^h(x_0) &= \{(\ln y_2, y_1) \,|\, y_1 > b, y_2 > 0\} \\ &= R \times (b, \infty). \end{aligned}$$

Since $\mathcal{Q}_t^h(x_0)$ is a dense subset of $\mathcal{R}_t(x_0)$, and $M = R^2$, clearly the system is not strongly controllable. In fact,

$$\operatorname{cl} \mathcal{R}_t(x_0) = \operatorname{cl} \mathcal{Q}_t^h(x_0) = R \times [b, \infty) \neq R^2.$$

Example 3.2. Consider the system from Example 2.4. Here $M = R^2$, $h^\alpha(x_1, x_2) = (x_2, x_1 + x_2 + 1)$ so that $(h^\alpha)^{-1}(y_1, y_2) = (y_2 - y_1 - 1, y_1)$, and $x(0) = (a, b)$. Suppose $x(0) = (1, 1)$. Then $y \in \mathcal{Y}_h(x_0)$ if and only if $y(0) = 1$, $\dot{y}(0) = 3$ and whenever $\dot{y}(t_s) = 1$

then $\ddot{y}(t_s)=1$. This means that $\dot{y}$ is increasing when $\dot{y}(t_s)=1$, and hence if $y\in\mathcal{Y}_h(x_0)$ then $\dot{y}(t)$ will always be greater than one. Thus $y(t)>y(0)+t=t+1$ and

$$\begin{aligned}\mathcal{Q}_t^h(x_0)&=(h^\alpha)^{-1}\{(y_1,y_2)\,|\,y_1>t+1,\,y_2>1\}\\&=\{(y_2-y_1-1,y_1)\,|\,y_1>t+1,\,y_2>1\}\\&=\{(x_1,x_2)\,|\,x_2>t+1,\,x_1>-x_2\}.\end{aligned}$$

Thus $\operatorname{cl}\mathcal{R}_t(x_0)=\operatorname{cl}\mathcal{Q}_t^h(x_0)=\{x_2\geqq t+1,\,x_1\geqq -x_2\}\neq R^2=M$, and the system is far from being strongly controllable.

Example 3.3. From Example 2.5, $y\in\mathcal{Y}_h(x_0)$ if and only if $y(0)=b$, $\dot{y}(0)=\ln a$ where $x(0)=(a,b)$ so that $y(t)$ and $\dot{y}(t)$ are unrestricted. Here $h^\alpha(x_1,x_2)=(x_2,\ln x_1)$ so that $(h^\alpha)^{-1}(y_1,y_2)=(e^{y_2},y_1)$ and

$$\begin{aligned}Q_t^h(x_0)&=(h^\alpha)^{-1}(R^2)\\&=M.\end{aligned}$$

Thus $\mathcal{R}_t(x_0)=M$ and the system is strongly controllable.

In Example 3.1 there are no singular states but the range of $h^\alpha\neq R^2$ and the system is not strongly controllable. In Example 3.1 Range $h^\alpha=R^2$ but there are singular states, i.e., $M_h^s=\varnothing$, and this system also failed to be strongly controllable. Example 3.3 is a strongly controllable system with $M_h^s=\varnothing$ and Range $h^\alpha=R^2$. The connections between $\mathcal{R}_t(x_0)$ and Range h^α are not explored, but when Range $h^\alpha=R^n$ ($n=\dim M$) strong controllability is related to the existence of singular states.

THEOREM 3.2. *Suppose that the system* (2.3) *can be globally observed using the output* $y=h(x)$ *with* Range $h^\alpha=R^n$. *If* $M_h^s=\varnothing$ *then the system* (2.3) *is strongly controllable. If* $M_h^s\neq\varnothing$ *and* $b_1(h^\alpha(x))>0$ (*or* <0) *on* M_h^s (*e.g.*, $\beta=1$ *on* M_h^s *and* M_h^s *is connected*) *then* (2.3) *is not strongly controllable.*

Proof. Suppose that the above system has $M_h^s=\varnothing$. Then

$$\begin{aligned}&\mathcal{Y}_h(x_0)=\{y\in C^\infty(R)\,|\,y^\alpha(t_0)=h^\alpha(x_0)\},\quad\text{and}\\&\mathcal{Q}_t^h(x_0)=\{(h^\alpha)^{-1}y^\alpha(t)\,|\,y\in\mathcal{Y}_h(x_0)\}\\&\qquad=\{(h^\alpha)^{-1}z\,|\,z\in R^n\}\\&\qquad=M.\end{aligned}$$

Thus using Theorem 3.1 we conclude that $\mathcal{R}_t(x_0)=M$ for any $x_0\in M$ and $t>t_0$.

Now suppose $b_1(h^\alpha(x))>0$ on M_h^s, $M_h^s\neq\varnothing$, and the system (2.3) is strongly controllable. Choose $x_1\in M_h^s$. Then there exist a control u and trajectory $t\mapsto x(t)$ such that $x(t_0)=x_0$, $x(t_s)=x_1$ and $x(2t_s)=x_1$ where $t_s>t_0$. Here $x(t_s)\in M_h^s$ so that

$$b_0(h^\alpha(x(t_s)))=b_0(y^\alpha(t_s))=0$$

$$\frac{d}{dt}b_0(h^\alpha(x(t_s))=\frac{d}{dt}b_0(y^\alpha(t_s))=b_1(y^\alpha(t_s))>0$$

by assumption. This means that $b_0(y^\alpha(t))$ is increasing at time t_s. Also $x(2t_s)\in M_h^s$ so that $b_0(y^\alpha(2t_s))=0$, and hence $b_0(y^\alpha(t))$ must become zero on $(t_s,2t_s]$. If $b_0(y^\alpha(t_1))=0$ for some $t_1\in(t_s,2t_s]$ then $(d/dt)b_0(y^\alpha(t_1))\leqq 0$, which contradicts $b_1(h^\alpha(x))>0$ for all $x\in M_h^s$. Thus (2.3) cannot be strongly controllable.

Acknowledgment. The author thanks the anonymous referee for constructive criticism and helpful suggestions.

AN APPROXIMATION THEORY FOR THE IDENTIFICATION OF NONLINEAR DISTRIBUTED PARAMETER SYSTEMS*

H. T. BANKS†, SIMEON REICH‡, AND I. G. ROSEN§

Abstract. An abstract approximation framework for the identification of nonlinear distributed parameter systems is developed. Inverse problems for nonlinear systems governed by strongly maximal monotone operators (satisfying a mild continuous dependence condition with respect to the unknown parameters to be identified) are treated. Convergence of Galerkin approximations and the corresponding solutions of finite-dimensional approximating identification problems to a solution of the original infinite-dimensional identification problem is demonstrated, using the theory of nonlinear evolution systems and a nonlinear analogue of the Trotter–Kato approximation result for semigroups of bounded linear operators. The nonlinear theory developed here is shown to subsume an existing linear theory as a special case. It is also shown to be applicable to a broad class of nonlinear elliptic operators and the corresponding nonlinear parabolic partial differential equations to which they lead. An application of the theory to a quasilinear model for heat conduction or mass transfer is discussed.

1. Introduction.

In this paper we develop a general abstract approximation framework for the identification of nonlinear distributed parameter evolution systems. Our intent is to define relatively straightforward and easily verified criteria that are applicable to broad classes of nonlinear systems; these criteria will guarantee the convergence of solutions to a sequence of finite-dimensional Galerkin approximation based parameter estimation problems to a solution of the original, underlying, infinite-dimensional identification problem. The results that we present below generalize and extend the theory recently developed by Banks and Ito in [2] and [3] for regularly dissipative or abstract parabolic, linear systems. It is, to the best of our knowledge, the first such general approximation theory for inverse problems involving nonlinear distributed systems.

The sufficient conditions set down in our framework include a relatively weak continuity assumption with respect to the unknown parameters to be identified, an equiboundedness and an equistrong monotonicity assumption on the nonlinear operator describing the system dynamics. In addition our theory requires a standard approximation assumption on the Galerkin subspaces used to effect the finite-dimensional, or finite-element, approximations. We demonstrate that solutions to the

finite-dimensional identification problems approximate a solution to the infinite-dimensional identification problem via a convergence result for solutions to the forward problems. This result is obtained using the theory of nonlinear evolution systems and a nonlinear analog of the well-known Trotter–Kato approximation result for linear semigroups.

In the present paper, we are concerned only with theory; implementation questions and conclusions drawn from our numerical or computational studies will be reported on elsewhere. Also, while we have tried to make our framework as versatile as possible, the treatment below does have limitations. For example, our theory can handle quasi-autonomous systems but it is not applicable in the fully nonautonomous case. The development of a general theory that can handle nonlinear systems involving time-dependent operators requires additional effort and is currently the focus of our ongoing investigations. The particular difficulties inherent in the time-dependent case will be described in greater detail in our discussions below.

We provide a brief outline of the remainder of the paper. In § 2 we state a fundamental existence and uniqueness result for infinite-dimensional nonlinear systems and prove a general approximation result that is especially well suited for application in the context of the inverse problems which are the central focus of our study. In § 3 we define a class of nonlinear distributed systems and the associated parameter identification problems. We define the Galerkin approximations and prove the general convergence result. Section 4 contains some examples. We show that our nonlinear theory subsumes the linear theory presented in [2] and [3] as a special case; we also consider the application of our framework to a class of nonlinear elliptic operators and the corresponding nonlinear parabolic partial differential equations to which they lead. In particular, we look at the application of our results to a well-known quasilinear model for heat conduction or mass transfer. In § 5 we summarize our findings and provide some concluding remarks.

2. An approximation result for nonlinear evolution systems. Let X_0 be a Banach space with norm $|\cdot|_0$. We consider the nonlinear, quasi-autonomous initial value problem in X_0 given by

$$\dot{x}_0(t) + A_0 x_0(t) \ni f_0(t), \qquad 0 < t \leqq T, \tag{2.1}$$

$$x_0(0) = x_0^0 \tag{2.2}$$

where $x_0^0 \in X_0$, $f_0 : [0, T] \to X_0$ and the nonlinear operator $A_0 : X_0 \to 2^{X_0}$ is in general multivalued, not everywhere defined, and not continuous. The existence of solutions to the initial value problem (2.1), (2.2) and the subsequent approximation result to follow, are both consequences of Theorem 2.1 to be given below.

We require the following definitions. Let X be a Banach space with norm $|\cdot|_X$. For $A : X \to 2^X$, a nonlinear, multivalued operator, the domain and range of A are defined by $\mathrm{Dom}(A) = \{x \in X : Ax \neq \emptyset\}$ and $\mathcal{R}(A) = \bigcup_{x \in \mathrm{dom}(A)} Ax$, respectively. We say that the operator A is accretive if for every $\lambda > 0$, $x_1, x_2 \in \mathrm{Dom}(A)$ and $y_1 \in Ax_1$, $y_2 \in Ax_2$, we have

$$|x_1 - x_2|_X \leqq |x_1 - x_2 + \lambda(y_1 - y_2)|_X.$$

We say that A is m-accretive if A is accretive and $\mathcal{R}(I + \lambda A) = X$ for some $\lambda > 0$. We note that if A is m-accretive, then $\mathcal{R}(I + \lambda A) = X$ for every $\lambda > 0$ and for each $\lambda > 0$ the resolvent of A at λ, $J(\lambda; A) : X \to X$, a single-valued, everywhere defined, nonlinear operator on X can be defined as $J(\lambda; A) = (I + \lambda A)^{-1}$.

A two-parameter family of nonlinear operators $\{U(t, s)\colon 0 \leqq s \leqq t \leqq T\}$ defined on a subset $\Omega \subset X$ is called a nonlinear evolution system on Ω if for each $x \in \Omega$ we have $U(t, s)x \in \Omega$, $U(s, s)x = x$, and $U(t, r)U(r, s)x = U(t, s)x$ for $0 \leqq s \leqq r \leqq t \leqq T$, and $U(t, s)x$ is continuous from the triangle $\triangle = \{[s, t]\colon 0 \leqq s \leqq t \leqq T\}$ into X.

A strongly continuous function $x\colon [0, T] \to X$ is called a strong solution to the quasi-autonomous initial value problem

$$\dot{x}(t) + Ax(t) \ni f(t), \qquad 0 < t \leqq T, \tag{2.3}$$

$$x(0) = x^0 \tag{2.4}$$

where $f\colon [0, T] \to X$ and $x^0 \in X$ if x is absolutely continuous on compact subintervals of $(0, T)$, differentiable almost everywhere and satisfies $f(t) - \dot{x}(t) \in Ax(t)$ for almost every $t \in [0, T]$ and $x(0) = x^0$.

THEOREM 2.1. *Let X be a Banach space with norm $|\cdot|_X$ and suppose that $A\colon X \to 2^X$ and $f\colon [0, T] \to X$ appearing in* (2.3) *satisfy*

(1) *That there exists an $\omega \in R$ for which the operator $A + \omega I$ is m-accretive,*

(2) *$f \in L_1(0, T; X)$.*

Then a unique, nonlinear evolution system $\{U(t, s)\colon 0 \leqq s \leqq t \leqq T\}$ on $\overline{\mathrm{Dom}(A)}$ can be constructed that satisfies

(i) $|U(t, s)\phi - U(t, s)\psi|_X \leqq e^{\omega(t-s)}|\phi - \psi|_X$, *for* $\phi, \psi \in \overline{\mathrm{Dom}(A)}$ *and* $0 \leqq s \leqq t \leqq T$,

(ii) $|U(s+t, s)\phi - U(r+t, r)\phi|_X \leqq 2\int_0^t e^{\omega(t-\tau)}|f(\tau+s) - f(\tau+r)|_X \, d\tau$, *for all* $\phi \in \overline{\mathrm{Dom}(A)}$ *and all* $t > 0$ *such that* $s + t$, $r + t \leqq T$.

(iii) *If* $x^0 \in \overline{\mathrm{Dom}(A)}$ *and the initial value problem* (2.3), (2.4) *has a strong solution x, then*

$$x(t) = U(t, s)x(s) \quad \text{for } 0 \leqq s \leqq t \leqq T.$$

When $x^0 \in \overline{\mathrm{Dom}(A)}$, the strongly continuous function $x\colon [0, T] \to X$ given by $x(t) = U(t, 0)x^0$ is referred to as a mild or generalized solution to (2.3), (2.4).

Theorem 2.1 is a direct consequence of results given by Crandall and Evans in [7] and [9]. Henceforth, we will assume that $A_0\colon X_0 \to 2^{X_0}$ and $f_0\colon [0, T] \to X$, satisfy (1) and (2) in the statement of Theorem 2.1 and that $x_0 \in \overline{\mathrm{Dom}(A_0)}$. We then let $\{U_0(t, s)\colon 0 \leqq s \leqq t \leqq T\}$ denote the corresponding nonlinear evolution system on $\overline{\mathrm{Dom}(A_0)}$ and consider the approximation of mild solutions to the initial value problem (2.1), (2.2).

Our approximation result is in the spirit of those given for nonlinear semigroups and evolution systems by Crandall and Pazy in [8] and Goldstein in [10]. However, our theorem differs from these earlier treatments in two ways. First, we require that the time-dependent perturbation f_0 be only L_1 as opposed to it being continuous as in [8] and satisfying a Lipschitz-like condition in [10]. This distinction is especially relevant in the case of control systems where discontinuous input is common. The second difference is that we give our result in a form that is most appropriate for application to the development of a general approximation theory or framework and computational schemes for the parameter identification problems to be discussed in the next section.

We require some set theoretic notation. For sets H_n, $n = 0, 1, 2, \cdots$, by $\lim H_n \supset H_0$ we mean: given $x_0 \in H_0$, there exist $x_n \in H_n$ such that $x_n \to x_0$ as $n \to \infty$.

THEOREM 2.2. *For each $n \in Z^+ = \{1, 2, 3, \cdots\}$ let X_n be a closed linear subspace of X_0. For $n = 0, 1, \cdots$, let $A_n\colon X_n \to 2^{X_n}$ be a possibly multivalued nonlinear operator on X_n, and let $f_n\colon [0, T] \to X_n$ be an X_n-valued measurable function defined on $[0, T]$. Suppose that there exists an $\omega_0 \in R$, independent of n, for which the operators $A_n + \omega_0 I$ are m-accretive, that there exists a function $g \in L_1(0, T; X_0)$ for which $|f_n(t)| \leqq g(t)$, for*

almost every $t \in [0, T]$, *and that* $\lim \bar{D}_n \supset \bar{D}_0$ *where* $D_n = \mathrm{Dom}(A_n)$ *and* $D_0 = \mathrm{Dom}(A_0)$. *Suppose further that for some* $\lambda_0 > 0$, *we have*

$$\lim_{n\to\infty} J(\lambda_0; A_n + \omega_0 I)\phi_n = J(\lambda_0; A + \omega_0 I)\phi_0 \tag{2.5}$$

whenever $\phi_n \in X_n$ *with* $\lim_{n\to\infty} \phi_n = \phi_0 \in X_0$, *and that*

$$\lim_{n\to\infty} f_n(t) = f_0(t) \quad \textit{for a.e. } t \in [0, T].$$

Then for each $n \in Z^+$ *there exists a unique nonlinear evolution system* $\{U_n(t, s): 0 \leqq s \leqq t \leqq T\}$ *on* $\bar{D}_n$ *corresponding (in the sense of Theorem* 2.1) *to* A_n *and* f_n *and for* $\phi_n \in \bar{D}_n$ *with* $\lim_{n\to\infty} \phi_n = \phi_0 \in \bar{D}_0$ *we have*

$$\lim_{n\to\infty} U_n(t, s)\phi_n = U_0(t, s)\phi_0, \qquad 0 \leqq s \leqq t \leqq T, \tag{2.6}$$

with the limit being uniform in t *for* $t \in [s, T]$.

Proof. We follow Goldstein (see [10], [11]) and use an approach first suggested by Kisynski [13] for demonstrating the convergence of approximations to linear semigroups, to prove the theorem via an application of our existence result, Theorem 2.1.

Let $\chi = \{\hat{x} = \{x_n\}_{n=0}^{\infty}: x_n \in X_n,\ n = 0, 1, 2, \cdots,$ and $\lim_{n\to\infty} x_n = x_0\}$ and for $\hat{x} \in \chi$ set $\|\hat{x}\| = \sup_n |x_n|_0$. Then $\|\cdot\|$ defines a norm on the linear vector space χ, and the space χ together with the norm $\|\cdot\|$ is a Banach space. Define the operator $A: \chi \to 2^{\chi}$ by

$$\begin{aligned}\mathrm{dom}(A) = \{\hat{x} = \{x_n\}_{n=0}^{\infty} \in \chi: {} & x_n \in \mathrm{Dom}(A_n), \text{ and for each } n = 1, 2, \cdots \text{ there} \\ & \text{exists a } y_n \in A_n x_n \text{ such that } \lim_{n\to\infty} y_n = y_0 \in A_0 x_0\},\end{aligned}$$

for $\hat{x} \in \mathrm{Dom}(A)$, $\hat{y} = \{y_n\}_{n=0}^{\infty} \in A\hat{x}$ if and only if $y_n \in A_n x_n$, $n = 0, 1, \cdots$ and $\lim_{n\to\infty} y_n = y_0$.

Define an essentially χ-valued function f on the interval $[0, T]$ by $f(t) = \{f_n(t)\}_{n=0}^{\infty}$. The assumptions on the f_n are such that $f_n(t) \to f_0(t)$ for almost every $t \in [0, T]$. However, by appropriately redefining on a set of measure zero, we may infer from the assumptions on the functions f_n that $f: [0, T] \to \chi$ with $f \in L_1(0, T; \chi)$.

It is readily seen that the operator $A + \omega_0 I$ is m-accretive. Let $\hat{x}^1 = \{x_n^1\}_{n=0}^{\infty}$, $\hat{x}^2 = \{x_n^2\}_{n=0}^{\infty} \in \mathrm{Dom}(A)$, and let $\hat{y}^1 = \{y_n^1\}_{n=0}^{\infty} \in A\hat{x}^1$ and $\hat{y}^2 = \{y_n^2\}_{n=0}^{\infty} \in A\hat{x}^2$. Since for each $n = 0, 1, 2, \cdots$, $A_n + \omega_0 I$ is assumed to be m-accretive, for $\lambda > 0$, we have

$$\begin{aligned}\|\hat{x}^1 - \hat{x}^2\| &= \sup_n |x_n^1 - x_n^2|_0 \leqq \sup_n |x_n^1 - x_n^2 + \lambda(y_n^1 + \omega_0 x_n^1 - (y_n^2 + \omega_0 x_n^2))|_0 \\ &= \|\hat{x}^1 - \hat{x}^2 + \lambda(\hat{y}^1 + \omega_0 \hat{x}^1 - (\hat{y}^2 + \omega_0 \hat{x}^2))\|,\end{aligned}$$

and therefore that $A + \omega_0 I$ is accretive. Now let $\hat{y} = \{y_n\}_{n=0}^{\infty} \in \chi$ and set $\hat{x} = \{x_n\}_{n=0}^{\infty}$ with $x_n = J(\lambda_0; A_n + \omega_0 I)y_n$, $n = 0, 1, 2, \cdots$ where λ_0 is chosen as in (2.5). It is immediately clear that for each $n = 0, 1, 2, \cdots$, $x_n \in \mathrm{Dom}(A_n) \subset X_n$. Since $\hat{y} \in \chi$ we have $\lim_{n\to\infty} y_n = y_0$ and therefore, by assumption (2.5), that $\lim_{n\to\infty} x_n = x_0$ or $\hat{x} \in \chi$. Setting $z_n = (y_n - (1 + \lambda_0\omega_0)x_n)/\lambda_0$, $n = 0, 1, 2, \cdots$, it follows that $z_n \in A_n x_n$ and $\lim_{n\to\infty} z_n = z_0 \in A_0 x_0$. We conclude that $\hat{x} \in \mathrm{Dom}(A)$, $(I + \lambda_0(A + \omega_0 I))\hat{x} \ni \hat{y}$, and that $\mathcal{R}(I + \lambda_0(A + \omega_0 I)) = \chi$.

We have shown that the operator A and the function f satisfy conditions (1) and (2) given in the statement of Theorem 2.1. Therefore, a unique nonlinear evolution system $\{U(t, s): 0 \leqq s \leqq t \leqq T\}$ on $\overline{\mathrm{Dom}(A)}$ corresponding to A and f can be constructed with $U(t, s) = \{U_n(t, s)\}_{n=0}^{\infty}$. Using assumption (2.5) it can be shown that $\overline{\mathrm{Dom}(A)} = \{\hat{x} = \{x_n\}_{n=0}^{\infty} \in \chi: x_n \in \bar{D}_n,\ n = 0, 1, 2, \cdots$ and $\lim_{n\to\infty} x_n = x_0\}$. Since $\mathcal{R}(U(t, s)) \subset \chi$, it

follows that

$$\lim_{n\to\infty} U_n(t,s)\phi_n = U_0(t,s)\phi_0, \qquad 0 \leqq s \leqq t \leqq T \tag{2.7}$$

whenever $\phi_n \in \bar{D}_n$ and $\lim_{n\to\infty} \phi_n = \phi_0 \in \bar{D}_0$. Since each of the operators A_n and the functions f_n satisfy conditions (1) and (2) of Theorem 2.1, unique nonlinear evolution systems $\{U_n(t,s): 0 \leqq s \leqq t \leqq T\}$ on $\bar{D}_n$ corresponding to A_n and f_n can be constructed. Recalling that $\overline{\mathrm{Dom}(A)} \subset \bigtimes_{n=0}^{\infty} \bar{D}_n$, we may define the family of operators $\{V(t,s): 0 \leqq s \leqq t \leqq T\}$ on $\overline{\mathrm{Dom}(A)}$ by

$$V(t,s)\hat{x} = \{V_n(t,s)x_n\}_{n=0}^{\infty} \equiv \{U_n(t,s)x_n\}_{n=0}^{\infty} \tag{2.8}$$

for $\hat{x} = \{x_n\}_{n=0}^{\infty} \in \overline{\mathrm{Dom}(A)}$. Uniqueness (see [9]) dictates that for each $n = 0, 1, 2, \cdots$, $U_n(t,s)x_n = V_n(t,s)x_n$ whenever $\{x_n\}_{n=0}^{\infty} \in \overline{\mathrm{Dom}(A)}$. This together with (2.7) and (2.8) establish (2.6). The fact that the convergence in (2.6) is uniform in t for $t \in [s, T]$ is argued exactly as it was for the convergence of approximations to nonlinear semigroups in the proof of Theorem 3.2 in [10].

We note that (2.5) is also a necessary condition for the conclusion to hold (see, for example, Theorem 1 of [14]).

3. An approximation theory for identification problems. Let H be a real Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and corresponding norm $|\cdot|$. Let V be a reflexive real Banach space with norm $\|\cdot\|$ and let V^* be its dual. (Our entire theory can be developed in complex spaces if necessary; see [6].) We denote the usual dual norm on V^* by $\|\cdot\|_*$ and assume that V is densely and continuously embedded in H with $|v| \leqq \mu\|v\|$, $v \in V$, for some positive constant μ. Identifying H with its dual, we obtain $V \subset H = H^* \subset V^*$. For $\phi \in V^*$ and $v \in V$ the duality pairing between ϕ and v is denoted by $\langle \phi, v \rangle$. When $\phi \in H$, its pairing with $v \in V$ agrees with the inner product of ϕ with v. It follows for $u \in H$ and $v \in V$ that $\|u\|_* \leqq \mu|u|$ and $\|v\|_* \leqq \mu^2\|v\|$. Let $\mathcal{Q}$ and Z be metric spaces and let Q be a nonempty, compact, subset of $\mathcal{Q}$. The spaces $\mathcal{Q}$ and Z, and the set Q are referred to as the parameter space, the observation space, and the admissible parameter set, respectively.

We recall that a single-valued operator $A: V \to V^*$ is hemicontinuous if $\lim_{t\to 0} A(u+tv) = Au$ for all $u, v \in V$ where the limit is taken in the weak sense.

For each $q \in Q$ let $A(q): V \to V^*$ be a single-valued, hemicontinuous (in general, nonlinear) operator satisfying:

(A) (Continuity): For each $v \in V$, the map $q \to A(q)v$ is continuous from $Q \subset \mathcal{Q}$ into V^*.

(B) (Equi V-monotonicity): There exist an $\omega \in R$ and an $\alpha > 0$, both independent of $q \in Q$, such that

$$\langle A(q)u - A(q)v, u - v \rangle + \omega|u - v|^2 \geqq \alpha\|u - v\|^2,$$

for every $u, v \in V$.

(C) (Equiboundedness): The operator $A(q)$ maps V bounded sets into V^* bounded sets, uniformly in $q \in \mathcal{Q}$. That is, if S is V bounded, then there exists M_S depending on S such that

$$\sup\{\|A(q)v\|_*: v \in S, q \in \mathcal{Q}\} \leqq M_S.$$

For each $q \in Q$, let $f(\cdot; q) \in L_1(0, T; H)$ and $u^0(q) \in H$, and assume that the mapping $q \to u^0(q)$ is continuous from $Q \subset \mathcal{Q}$ into H and that the mapping $q \to f(t; q)$ is continuous from $Q \subset \mathcal{Q}$ into H for almost every $t \in [0, T]$. Also, for every $z \in Z$, let $u \to \Phi(u; z)$ be a continuous map from $C(0, T; H)$ into R^+.

We consider parameter identification or inverse problems of the following form:

(ID) Given observations $z \in Z$, determine parameters $\bar{q} \in Q$ that minimize

$$\phi(q) = \Phi(u_0(q); z)$$

where $u_0(q) = u_0(\cdot\,; q)$ is a mild solution to the initial value problem

$$\dot{u}(t) + A(q)u(t) = f(t; q), \qquad 0 < t \leqq T, \tag{3.1}$$

$$u(0) = u^0(q) \tag{3.2}$$

corresponding to $q \in Q$.

By a mild solution to (3.1), (3.2) we mean a solution in the sense of Theorem 2.1. To be more precise, for each $q \in Q$ we define the operator $A_0(q)$: Dom $(A_p(q)) \subset H \to H$ to be the restriction of the operator $A(q)$ to the subset of V given by Dom $(A_0(q)) = \{v \in V\colon A(q) \in H\}$, and prove the following theorem.

THEOREM 3.1. *For each $q \in Q$ the operator $A_0(q)$: Dom $(A_0(q)) \subset H \to H$ is densely defined and the operator $A_0(q) + \omega I$ is m-accretive.*

Proof. We first show that for each $q \in Q$ the operator $A(q) + \omega I : V \to V^*$ is coercive. If $\{v_n\} \subset V$ with $\lim_{n\to\infty} \|v_n\| = \infty$, then from assumptions (B) and (C) we obtain

$$\begin{aligned}
&\lim_{n\to\infty} \langle (A(q) + \omega I)v_n, v_n\rangle / \|v_n\| \\
&\quad = \lim_{n\to\infty} \{(\langle A(q)v_n - A(q)\theta, v_n\rangle + \omega |v_n|^2)/\|v_n\| + \langle A(q)\theta, v_n\rangle/\|v_n\|\} \\
&\quad \geqq \lim_{n\to\infty} \{\alpha \|v_n\|^2/\|v_n\| - |\langle A(q)\theta, v_n\rangle|/\|v_n\|\} \\
&\quad \geqq \lim_{n\to\infty} \{\alpha \|v_n\| - \|A(q)\theta\|_*\} \geqq \lim_{n\to\infty} \alpha \|v_n\| - \beta = \infty
\end{aligned}$$

where θ denotes the zero vector in V and $\beta > \sup_{q\in Q} \|A(q)\theta\|_*$. It follows that for each $\lambda > 0$, the operator $I + \lambda(A(q) + \omega I)\colon V \to V^*$ is monotone, everywhere defined on V, hemicontinuous, and coercive. Consequently, $\mathcal{R}(I + \lambda(A(q) + \omega I)) = V^*$ (see Barbu [6, Thm. II.1.3]) and therefore $\mathcal{R}(I + \lambda(A_0(q) + \omega I)) = H$. Also, for $u, v \in$ Dom $(A_0(q))$, we may use assumption (B) to conclude that

$$\begin{aligned}
\left(1 + \frac{\lambda\alpha}{\mu^2}\right)|u - v|^2 &\leqq |u - v|^2 + \lambda\alpha \|u - v\|^2 \\
&\leqq |u - v|^2 + \lambda\langle (A(q) + \omega I)u - (A(q) + \omega I)v, u - v\rangle \\
&= \langle (I + \lambda(A(q) + \omega I))u - (I + \lambda(A(q) + \omega I))v, u - v\rangle \\
&\leqq |(I + \lambda(A_0(q) + \omega I))u - (I + \lambda(A_0(q) + \omega I))v|\,|u - v|
\end{aligned}$$

or

$$|u - v| \leqq |u - v + \lambda((A_0(q) + \omega I)u - (A_0(q) + \omega I)v)|,$$

which proves that $A_0(q) + \omega I$ is m-accretive on Dom $(A_0(q)) \subset H$.

In light of Theorem 3.1, we may apply Theorem 2.1 with $X = H$, $A = A_0(q)$ and $f = f(\cdot, q)$. We conclude that there exists a unique nonlinear evolution system $\{U_0(t, s; q)\colon 0 \leqq s \leqq t \leqq T\}$ on $\overline{\text{Dom}\,(A_p(q))} \subset H$ satisfying (i)-(iii) of Theorem 2.1. The mild solution $u_0(\cdot\,; q)\colon [0, T] \to H$ to the initial value problem (3.1), (3.2) is given by $u_0(t; q) = U_0(t, 0; q)u^0(q)$ for $t \in [0, T]$.

While it is not true in general that $\overline{\text{Dom}\,(A_0(q))} = H$, we can, in several special cases of importance, argue this equality. We present two such cases.

LEMMA 3.1. *If the operator $A(q)$ satisfies, in addition to* (A), (B), (C), *the following condition, then* $\overline{\text{Dom}(A_0(q))} = H$: *$A(q)$ takes H bounded sets into V^* bounded sets.*

Proof. To show $\overline{\text{Dom}(A_0(q))} = H$, we let $u \in H$ and for each $n = 1, 2, \cdots$, we set $u_n = J(1/n; A_0(q) + \omega I)u \in \text{Dom}(A_0(q))$. Then, arguing as we have above, we find that

$$|u_n|^2 + (1/n)\alpha\|u_n\|^2 \leqq \langle u - (1/n)A(q)\theta, u_n\rangle$$
$$\leqq |u||u_n| + (1/n)\|A(q)\theta\|_*\|u_n\|$$

where θ is again the zero vector in V. But then

$$\left(\frac{1}{2}\right)|u_n|^2 + \left(\frac{1}{n}\right)\left(\frac{\alpha}{2}\right)\|u_n\|^2 \leqq \left(\frac{1}{2}\right)|u|^2 + \left(\frac{1}{n}\right)\left(\frac{1}{2\alpha}\right)\|A(q)\theta\|_*^2 \tag{3.3}$$
$$\leqq \left(\frac{1}{2}\right)|u|^2 + \left(\frac{1}{n}\right)\left(\frac{\beta^2}{2\alpha}\right),$$

from which it immediately follows that the u_n are uniformly bounded in H. Indeed, from (3.3) we see that $(1/n)\|u_n\|^2$, and hence $\|u_n\|/\sqrt{n}$ is bounded so that $\|u_n\|/n \to 0$ as $n \to \infty$.

Thus we find that (using the fact that $\{A_0(q)u_n\}$ is V^* bounded)

$$\|u_n - u\|_* = \left(\frac{1}{n}\right)\|(A_0(q) + \omega I)u_n\|_*$$
$$\leqq \frac{1}{n}\{\|(A_0(q)u_n\|_* + \mu^2\omega\|u_n\|\} \tag{3.3a}$$
$$\leqq \frac{1}{n}\{K + \mu^2\omega\|u_n\|\}.$$

Since the last term in the estimate above tends to zero as $n \to \infty$, we find $u_n \to u$ in V^* as $n \to \infty$. This, together with the fact that V is dense in H imply that $u_n \to u$ weakly in H as $n \to \infty$. Since $A_0(q) + \omega I$ is m-accretive, $\overline{\text{Dom } A_0(q)}$ is convex from which $\overline{\text{Dom}(A_0(q))} = H$ immediately follows.

We note that the additional condition ($A(q)$ takes H bounded sets into V^* bounded sets) of Lemma 3.1 allows for a number of nonlinearities that arise in applications. For example, in a typical case ($H = L_2(0, 1)$, $V = H^2(0, 1)$) this condition is satisfied by A given by $(Av)(x) = |v(x)|^\alpha \operatorname{sgn} v(x)$ for $0 \leqq \alpha \leqq 2$.

We can also establish the results of Lemma 3.1 by strengthening condition (C).

LEMMA 3.2. *If the operator $A(q)$ satisfies* (A), (B), *and the following condition, then* $\overline{\text{Dom}(A_0(q))} = H$:

($\tilde{\text{C}}$) *There exists a constant $\beta > 0$, independent of $q \in Q$ such that $\|A(q)v\|_* \leqq \beta\{\|v\| + 1\}$ for every $v \in V$.*

Proof. The arguments are exactly the same as those for Lemma 3.1 except that (3.3a) must be replaced by

$$\|u_n - u\|_* \leqq \frac{1}{n}\|(A_0(q) + \omega I)u_n\|_* \leqq \frac{1}{n}\{(\beta + \omega\mu^*)\|u_n\| + \beta\}.$$

Remark. Under additional hypotheses on $f(\cdot; q)$ and $u^0(q)$ other existence results can be applied to obtain somewhat different notions of a solution to the initial value problem (3.1), (3.2). For example (see [6, pp. 140–144]), if $f(\cdot; q) \in W^{1,1}(0, T; H)$ and $u^0(q) \in \text{Dom}(A_0(q))$, then there exists a unique $u(\cdot, q): [0, T] \to V$ satisfying $u(\cdot; q) \in W^{1,\infty}(0, T; H)$, $A(q)u(\cdot; q) \in L_\infty(0, T; H)$ and $\dot{u}(t; q) + A(q)u(t; q) = f(t; q)$ for

almost every $t \in [0, T]$. Or, if $u^0(q) \in H$ and $f(\cdot; q) \in L_2(0, T; V^*)$ then there exists a unique $u(\cdot; q)$ that is V^*-valued absolutely continuous almost everywhere on $[0, T]$, $u(\cdot; q) \in C(0, T; H) \cap L_2(0, T; V)$, $\dot{u}(\cdot; q) \in L_2(0, T; V^*)$ and $\dot{u}(t; q) + A(q)u(t; q) = f(t; q)$, for almost every $t \in [0, T]$. If, in addition, the mapping $t \to t^\gamma f'(t; q)$ is an element in $L_2(0, T; V^*)$ for some $\gamma \geqq 1$, then the mapping $t \to t^\gamma \dot{u}(t; q)$ is in $L_2(0, T; V) \cap L_\infty(0, T; H)$. In particular, when $f(\cdot; q) = 0$, the nonlinear semigroup $\{S_0(t; q)\colon 0 \leqq t \leqq T\}$ on H defined by $S_0(t; q) = U_0(t; 0; q)$, $t \in [0, T]$, with generator $-A_0(q)$ behaves as does a holomorphic linear semigroup in that it smooths. That is, $S_0(t; q)u^0(q) \in \text{Dom}\,(A_0(q))$, $t \in (0, T]$, and the mapping $t \to t(d/dt)S(t; q)u^0(q)$ is an element in $L_\infty(0, T; H)$ for every $u^0(q) \in H$. Also, some generalizations are possible. For example, in assumption (B), the term $\alpha\|u - v\|^2$ can be replaced by a term of the form $\alpha(\|u - v\|)\|u - v\|$ where $\alpha(\cdot)$ is a continuous, strictly increasing function on $[0, \infty)$ satisfying $\alpha(0) = 0$ and $\lim_{x \to \infty} \alpha(x) = \infty$. Or, the terms $\|u - v\|^2$ in (B) and $\|v\|$ in ($\tilde{C}$) can be replaced by $\|u - v\|^p$ and $\|v\|^{p-1}$, respectively, for any $p \geqq 2$.

The development of computational methods for the solution of the infinite-dimensional optimization problem (ID) requires the finite-dimensional approximation of the abstract initial value problem (3.1), (3.2). The general framework that we are proposing is based on a classical Galerkin approach. For each $n = 1, 2, \cdots$ let H_n denote a finite-dimensional subspace of H that is a subset of V. Let $P_n : H \to H_n$ denote the orthogonal projection of H onto H_n with respect to the $\langle \cdot, \cdot \rangle$ inner product. We assume that the approximating subspaces H_n, and the projections P_n satisfy

(D) For each $v \in V$, $\lim_{n \to \infty} \|P_n v - v\| = 0$.

Note that assumption (D) and V densely and continuously embedded in H imply that $\lim_{n \to \infty} |P_n u - u| = 0$ for each $u \in H$.

For each $q \in Q$ and $n = 1, 2, \cdots$ we define the single-valued operator $A_n(q)\colon H_n \to H_n$ by $A_n(q)u_n = v_n$ for $u_n \in H_n$ where v_n satisfies

$$\langle A(q)u_n, w_n \rangle = \langle v_n, w_n \rangle, \qquad w_n \in H_n.$$

That $A_n(q)$ is a well-defined operator from H_n into H_n follows from the Riesz Representation Theorem applied to the Hilbert space H_n and the bounded linear functional $\langle A(q)u_n, \cdot \rangle$ on H_n. Also, define $f_n(\cdot; q)\colon [0, T] \to H_n$ and $u_n^0(q) \in H_n$ by $f_n(t; q) = P_n f(t; q)$, $0 \leqq t \leqq T$, and $u_n^0(q) = P_n u^0(q)$, respectively. Note that $f_n(\cdot; q) \in L_1(0, T; H_n) \subset L_1(0, T; H)$ and that $|f_n(t; q)| \leqq |f(t; q)|$ for $q \in Q$ and almost every $t \in [0, T]$.

We consider the sequence of approximating identification problems given by the following:

(ID_n) Given observations $z \in Z$, determine parameters $\bar{q}_n \in Q$ that minimize

$$\phi_n(q) = \Phi(u_n(q); z)$$

where $u_n(q) = u_n(\cdot; q)$ is a mild solution to the initial value problem in H_n

$$\dot{u}_n(t) + A_n(q)u_n(t) = f_n(t; q), \qquad 0 < t \leqq T, \tag{3.4}$$

$$u_n(0) = u_n^0(q) \tag{3.5}$$

corresponding to $q \in Q$.

From the definition of the $A_n(q)$ and the assumptions (B) and (C) on $A(q)$, using arguments analogous to those used to prove Theorem 3.1, it can be shown that the operators $A_n(q) + \omega I$ are m-accretive on H_n. It then follows from Theorem 2.1 that

for each $n = 1, 2, \cdots$ there exists a unique nonlinear evolution system $\{U_n(t, s; q): 0 \leqq s \leqq t \leqq T\}$ on H_n satisfying (i)-(iii) in the statement of that theorem with $X = H_n$, $f(t) = f_n(t; q)$, and $x^0 = u_n^0(q)$. The mild solution to the initial value problem (3.4), (3.5) is given by $u_n(t; q) = U_n(t, 0; q)u_n^0(q)$, $t \in [0, T]$.

If we assume for the moment that the approximating identification problems (ID_n) have solutions $\bar{q}_n \in Q$, then it is desirable that they in some sense approximate a solution $\bar{q}$ to the original identification problem (ID). This is in fact the case. For suppose that it can be shown that for any sequence $\{q_n\} \subset Q$ with $\lim_{n\to\infty} q_n = q \in Q$, we have

$$\lim_{n\to\infty} u_n(q_n) = u_0(q_0) \quad \text{in } C(0, T; H). \tag{3.6}$$

Then $\{\bar{q}_n\} \subset Q$ and Q a compact subset of the metric space $\mathcal{Q}$ imply that there exist a subsequence $\{\bar{q}_{n_j}\} \subset \{\bar{q}_n\}$ and a $\bar{q} \in Q$ such that $\lim_{j\to\infty} \bar{q}_{n_j} = \bar{q}$. For any $q \in Q$ the continuity of Φ implies

$$\begin{aligned}
\phi(\bar{q}) &= \Phi(u_0(\bar{q}); z) = \Phi\left(\lim_{j\to\infty} u_{n_j}(\bar{q}_{n_j}); z\right) \\
&= \lim_{j\to\infty} \Phi(u_{n_j}(\bar{q}_{n_j}); z) = \lim_{j\to\infty} \phi_{n_j}(\bar{q}_{n_j}) \\
&\leqq \lim_{j\to\infty} \phi_{n_j}(q) = \lim_{j\to\infty} \Phi(u_{n_j}(q); z) \\
&= \Phi\left(\lim_{j\to\infty} u_{n_j}(q); z\right) = \Phi(u_0(q); z) \\
&= \phi(q).
\end{aligned}$$

Note that in the discussion above we did not assume that a solution to problem (ID) exists. But rather we have shown that the existence of solutions $\bar{q}_n$ to the approximating problems (ID_n) and (3.6) imply the existence of a solution $\bar{q}$ to problem (ID). When the solution to problem (ID) is unique, the sequence $\{\bar{q}_n\}$ itself converges to $\bar{q}$.

The existence of a solution $\bar{q}_n$ to problem (ID_n) for each $n = 1, 2, \cdots$ will follow from the compactness of Q and the continuity of Φ once the following continuous dependence result has been established: $\lim_{m\to\infty} u_n(q_m) = u_n(q_0)$ in $C(0, T; H_n)$ whenever $\{q_m\} \subset Q$ with $\lim_{m\to\infty} q_m = q_0$. Although continuous dependence for the finite-dimensional systems (3.4), (3.5) could be demonstrated via a modification to any one of a number of familiar continuous dependence results for ordinary differential equations (see, for example, Hale [12, Thm. I.3.4]), it is also easily handled with the approximation theory developed in the previous section. This and the convergence in (3.6) are addressed in the following theorem.

THEOREM 3.2. *If assumptions* (A)-(D) *hold, then*

(a) *If* $\{q_n\} \subset Q$ *with* $\lim_{n\to\infty} q_n = q_0$ *then* $\lim_{n\to\infty} u_n(q_n) = u_0(q_0)$ *in* $C(0, T; H)$; *and*

(b) *If* $\{q_m\} \subset Q$ *with* $\lim_{m\to\infty} q_m = q_0$ *then* $\lim_{m\to\infty} u_n(q_m) = u_n(q_0)$ *for each* $n \in Z^+$.

Proof. Assumption (D) and the continuity of the map $q \to u^0(q)$ from Q into H imply $\lim_{n\to\infty} u_n^0(q_n) = u^0(q_0)$ in H. Hence, we will have verified (a) if we can show that $\lim_{n\to\infty} U_n(t, s; q_n)w_n = U_0(t, s; q_0)w_0$, $0 \leqq s \leqq t \leqq T$, uniformly in t for $t \in [s, T]$ whenever $w_n \in H_n$ with $\lim_{n\to\infty} w_n = w_0 \in H$. We argue this using Theorem 2.2. Note that assumption (D) implies $\lim_{n\to\infty} H_n \supset H$ and assumption (D) together with the assumed continuity of the map $q \to f(t; q)$ from $Q \subset \mathcal{Q}$ into H for almost every $t \in [0, T]$ imply $\lim_{n\to\infty} f_n(t; q_n) = f(t; q_0)$ in H for almost every $t \in [0, T]$ with the $f_n(\cdot; q_n)$

dominated by a function $g \in L_1(0, T; H)$, which is independent of n. Thus, we need only to demonstrate that for some $\lambda_0 > 0$, we have

$$\lim_{n\to\infty} J(\lambda_0; A_n(q_n)+\omega I)w_n = J(\lambda_0; A_0(q_0)+\omega I)w_0 \tag{3.7}$$

in H whenever $w_n \in H_n$, $n \in Z^+$ with $\lim_{n\to\infty} w_n = w_0$.

Let $\lambda_0 > 0$ and set $v_n = J(\lambda_0; A_n(q_n)+\omega I)w_n$ and $v_0 = J(\lambda_0; A_0(q)+\omega I)w_0$. We first show that $\|v_n\|$ is uniformly bounded in n. From assumption (B) we obtain

$$\begin{aligned}
\lambda_0\alpha\|v_n\|^2 &\leqq \lambda_0\omega|v_n|^2 + \lambda_0\langle A(q_n)v_n - A(q_n)\theta, v_n\rangle \\
&= \langle (I+\lambda_0(A_n(q_n)+\omega I))v_n, v_n\rangle - |v_n|^2 \\
&\quad + \lambda_0\langle A(q_0)\theta - A(q_n)\theta, v_n\rangle - \lambda_0\langle A(q_0)\theta, v_n\rangle \\
&= \langle w_n, v_n\rangle - |v_n|^2 + \lambda_0\langle A(q_0)\theta - A(q_n)\theta, v_n\rangle - \lambda_0\langle A(q_0)\theta, v_n\rangle \\
&\leqq \|w_n\|_*\|v_n\| + \lambda_0\|A(q_0)\theta - A(q_n)\theta\|_*\|v_n\| + \lambda_0\|A(q_0)\theta\|_*\|v_n\|
\end{aligned}$$

where θ denotes the zero vector in V. This estimate together with assumption (C) yields

$$\|v_n\| \leqq (\lambda_0\alpha)^{-1}\mu|w_n| + \alpha^{-1}\|A(q_n)\theta - A(q_0)\theta\|_* + \alpha^{-1}M_{\{\theta\}}.$$

Recalling assumption (A) and that $\lim_{n\to\infty} w_n = w_0$ in H, we find that the desired uniform bound on $\|v_n\|$ has been established.

Once again, from assumption (B), we find

$$\begin{aligned}
\lambda_0\alpha\|v_n - v_0\|^2 &\leqq \lambda_0\omega|v_n - v_0|^2 + \lambda_0\langle A(q_n)v_n - A(q_n)v_0, v_n - v_0\rangle \\
&= \lambda_0\omega|v_n - v_0|^2 + \lambda_0\langle A(q_n)v_n - A(q_0)v_0, v_n - P_nv_0\rangle \\
&\quad + \lambda_0\langle A(q_n)v_n - A(q_0)v_0, P_nv_0 - v_0\rangle \\
&\quad + \lambda_0\langle A(q_0)v_0 - A(q_n)v_0, v_n - v_0\rangle \\
&= \lambda_0\omega\langle P_nv_0 - v_0, v_n - v_0\rangle + \langle (I+\lambda_0(A_n(q_n)+\omega I))v_n \\
&\quad - (I+\lambda_0(A_0(q_0)+\omega I))v_0, v_n - P_nv_0\rangle + \langle v_0 - v_n, v_n - P_nv_0\rangle \\
&\quad + \lambda_0\langle A(q_n)v_n - A(q_0)v_0, P_nv_0 - v_0\rangle \\
&\quad + \lambda_0\langle A(q_0)v_0 - A(q_n)v_0, v_n - v_0\rangle \\
&= \lambda_0\omega\langle P_nv_0 - v_0, v_n - v_0\rangle + \langle w_n - w_0, v_n - P_nv_0\rangle - |v_n - P_nv_0|^2 \\
&\quad + \lambda_0\langle A(q_n)v_n - A(q_0)v_0, P_nv_0 - v_0\rangle \\
&\quad + \lambda_0\langle A(q_0)v_0 - A(q_n)v_0, v_n - v_0\rangle \\
&\leqq \lambda_0\omega\|P_nv_0 - v_0\|_*\|v_n - v_0\| + \|w_n - w_0\|_*\|v_n - v_0\| \\
&\quad + \|w_n - w_0\|_*\|P_nv_0 - v_0\| + \lambda_0\|A(q_n)v_n - A(q_0)v_0\|_*\|P_nv_0 - v_0\| \\
&\quad + \lambda_0\|A(q_0)v_0 - A(q_n)v_0\|_*\|v_n - v_0\|.
\end{aligned}$$

The estimate $ab \leqq (1/2\eta)a^2 + (\eta/2)b^2$ for any $\eta > 0$ and assumption (C) allow us to argue that (here we let M_S be the bound of (C) for $S = \{\|v_n\|, \|V_0\|\}$)

$$\begin{aligned}
\frac{\lambda_0\alpha}{2}\|v_n - v_0\|^2 &\leqq \frac{3\omega^2\lambda_0}{2\omega}\|P_nv_0 - v_0\|_*^2 + \frac{3}{2\lambda_0\alpha}\|w_n - w_0\|_*^2 + \|w_n - w_0\|_*\|P_nv_0 - v_0\| \\
&\quad + \lambda_0\|A(q_n)v_n - A(q_0)v_0\|_*\|P_nv_0 - v_0\| + \frac{3\lambda_0}{2\alpha}\|A(q_0)v_0 - A(q_n)v_0\|_*^2 \\
&\leqq \left\{\frac{3\omega^2\lambda_0\mu^4}{2\alpha} + \frac{(\lambda_0+1)}{2}\right\}\|P_nv_0 - v_0\|^2 + \left\{\frac{3\mu^2}{2\lambda_0\alpha} + \frac{\mu^2}{2}\right\}|w_n - w_0|^2 \\
&\quad + \lambda_0 2M_S\|P_nv_0 - v_0\| + \frac{3\lambda_0}{2\alpha}\|A(q_0)v_0 - A(q_n)v_0\|_*^2.
\end{aligned}$$

From this, $\lim_{n\to\infty} w_n = w_0$ in H, and assumptions (A) and (D), we can conclude, that $\lim_{n\to\infty} v_n = v_0$ in V and that (3.7) holds.

An analogous, but somewhat simpler argument can be used to verify (b). We use Theorem 2.2 to show that for $n \in Z^+$ fixed, $\lim_{m\to\infty} U_n(t, s; q_m)w_m = U_n(t, s; q_0)w_0$, $0 \leqq s \leqq t \leqq T$, uniformly in t for $t \in [s, T]$ whenever $w_m, w_0 \in H_n$ with $\lim_{m\to\infty} w_m = w_0$ in H. Clearly, $\lim_{m\to\infty} f_n(\cdot; q_m) = f_n(\cdot; q_0)$ in $L_1(0, T; H_n)$ so that we need only to show that for some $\lambda_0 > 0$,

$$\lim_{m\to\infty} J(\lambda_0; A_n(q_m) + \omega I)w_m = J(\lambda_0; A_n(q_0) + \omega I)w_0$$

in H whenever $\lim_{m\to\infty} w_m = w_0$ in H. Let $v_m = J(\lambda_0; A_n(q_m) + \omega I)w_m$ and $v_0 = J(\lambda_0; A_n(q_0) + \omega I)w_0$. Then from assumption (B)

$$\begin{aligned}
\lambda_0\alpha \|v_m - v_0\|^2 &\leqq \lambda_0\omega |v_m - v_0|^2 + \lambda_0\langle A(q_m)v_m - A(q_m)v_0, v_m - v_0\rangle \\
&= \langle (I + \lambda_0(A_n(q_m) + \omega I))v_m - (I + \lambda_0(A_n(q_0) + \omega I))v_0, v_m - v_0\rangle \\
&\quad - |v_m - v_0|^2 + \lambda_0\langle A(q_0)v_0 - A(q_m)v_0, v_m - v_0\rangle \\
&= \langle w_m - w_0, v_m - v_0\rangle - |v_m - v_0|^2 + \lambda_0\langle A(q_0)v_0 - A(q_m)v_0, v_m - v_0\rangle \\
&\leqq \|w_m - w_0\|_* \|v_m - v_0\| + \lambda_0 \|A(q_0)v_0 - A(q_m)v_0\|_* \|v_m - v_0\|
\end{aligned}$$

or

$$\|v_m - v_0\| \leqq \frac{\mu}{\lambda_0\alpha} |w_m - w_0| + \frac{1}{\alpha} \|A(q_0)v_0 - A(q_m)v_0\|_*.$$

Assumption (A) and $\lim_{m\to\infty} w_m = w_0$ in H yield the desired result and the theorem is proved.

Remark. In practice, the approximating identification problems (ID_n) are solved using standard iterative search techniques (for example, steepest descent, Newton's method, etc.) requiring the evaluation of $\phi_n(q)$ for $q \in Q$ at each step. This in turn requires the integration of the finite-dimensional initial value problem (3.4), (3.5). Once a basis for H_n has been chosen, the solution to (3.4), (3.5) can be computed using any standard numerical integrator for ordinary differential systems. Also, the parameter space $\mathcal{Q}$ and the admissible parameter set Q are frequently functional in nature and are infinite-dimensional. When this is the case, the set Q must also be discretized. Suppose that for each $m = 1, 2, \cdots$, $I^m : Q \subset \mathcal{Q} \to \mathcal{Q}$ is a continuous map with finite-dimensional range and that $\lim_{m\to\infty} I^m(q) = q$ with the convergence uniform in q for $q \in Q$. Set $Q^m = I^m(Q)$ (note that Q^m is a compact subset of $\mathcal{Q}$) and consider the identification problems (ID_n^m) defined to be the problems (ID_n) with Q replaced by Q^m. It is clear that each of these problems admits a solution $\bar{q}_n^m$ and it is not difficult to argue that there exists a subsequence $\{\bar{q}_{n_k}^{m_j}\} \subset \{\bar{q}_n^m\}$ with $\lim_{j,k\to\infty} \bar{q}_{n_k}^{m_j} = \bar{q}$, $\bar{q}$ a solution to problem (ID) (see, for example, [4]). Once bases for H_n and the range of I^m have been chosen, problem (ID_n^m) involves the minimization of a functional over a compact subset of Euclidean space subject to finite-dimensional constraints.

Remark (Nonautonomous systems). Theorems 2.1 and 2.2 remain valid for certain classes of temporally inhomogeneous or time-dependent operators $A = A(t)$. To be more precise, the family of operators $A(t) : X \to 2^X$ must be m-accretive on X for almost every $t \in [0, T]$ and must satisfy

$$|J(\lambda; A(t))x - J(\lambda; A(s))x|_X \leqq \lambda |h(t) - h(s)|_X L(|x|_X) \tag{3.8}$$

for each $x \in X$, every λ satisfying $0 < \lambda \leqq \lambda_0$ for some $\lambda_0 > 0$, some $h \in L_1(0, T; X)$, some continuous, nondecreasing function $L: [0, \infty) \to [0, \infty)$ and almost every $t, s \in [0, T]$ (see [8], [9]). (Note that for simplicity we have taken $\omega = 0$; however, the discussion to follow remains valid for any $\omega \in R$.) The primary motivation for developing the framework outlined above was to define readily verifiable conditions on the operators $A(q): V \to V^*$ that, if satisfied, would (i) also automatically be satisfied by the Galerkin approximation $A_n(q)$ and (ii) lead to the desired convergence of solutions to the approximating identification problems to a solution to problem (ID). The natural assumption to add to (A)-(C) that certainly satisfies criterion (i) and that could conceivably lead to an estimate of the form (3.8) in H is that

$$\|A(t; q)v - A(s; q)v\|_* \leqq |h(t) - h(s)|\tilde{L}(|v|) \tag{3.9}$$

for each $v \in V$, almost every $s, t \in [0, T]$ and some $h \in L_1(0, T; H)$ and some continuous nondecreasing $\tilde{L}: [0, \infty) \to [0, \infty)$, both of which do not depend on $q \in Q$. Unfortunately, however, we can only show that (3.9) leads to an estimate of the form

$$|J(\lambda; A_0(t; q))u - J(\lambda; A_0(s; q))u| \leqq \sqrt{\lambda}\, |h(t) - h(s)| L(|u|) \tag{3.10}$$

for each $u \in H$. Moreover, it is not clear to us how, or if, the proof of the fundamental Theorem 2.1 given in [9] could be modified so that (3.10) would suffice. We have explored alternative approaches and developed other techniques for treating the nonautonomous case (for example, in the linear case, based on some ideas in Tanabe [18], and in the strongly monotone case, via a variational formulation which can be found in Barbu [6]). These results will appear soon in forthcoming papers.

4. Applications and examples. We briefly describe some classes of systems to which the general framework developed in the previous section applies. In our discussion below we consider theoretical aspects only. Implementation questions will be treated and the results of our numerical studies will be reported on elsewhere.

Example 4.1 (Linear regularly dissipative operators). The approximation theory for inverse problems for systems involving linear regularly dissipative operators was treated in detail by Banks and Ito in, and is the central focus of, [2] and [3]. We show here that the linear theory is a special case of the nonlinear theory given in § 3.

Let the spaces H, V, V^*, and $\mathcal{Q}$ and the set Q be as they have been defined above. For each $q \in Q$ let $a(q)(\cdot, \cdot)$ be a sesquilinear form defined on $V \times V$, which satisfies the following conditions:

(A′) For each $v \in V$ the mapping $q \to a(q)(\cdot, v)$ is continuous from $Q \subset \mathcal{Q}$ into V^*. That is, given $\varepsilon > 0$, there exists a $\delta > 0$ such that

$$\sup_{\substack{u \in V \\ \|u\| = 1}} |a(q_0)(u, v) - a(q)(u, v)| < \varepsilon$$

whenever $d(q_0, q) < \delta$ where d denotes the metric on $\mathcal{Q}$.

(B′) There exist an $\omega \in R$ and an $\alpha > 0$, both independent of $q \in Q$, for which $a(q)(v, v) + \omega |v|^2 \geqq \alpha \|v\|^2$ for every $v \in V$.

(C′) There exists a constant $\beta > 0$, independent of $q \in Q$, such that

$$|a(q)(u, v)| \leqq \beta \|u\| \, \|v\| \quad \text{for every } u, v \in V.$$

When conditions (A′)-(C′) are satisfied it is not difficult to argue that for each $q \in Q$ an operator $A(q) \in \mathcal{L}(V, V^*)$ can be defined by

$$[A(q)v](u) = \langle A(q)v, u \rangle = a(q)(u, v),$$

$u, v \in V$ and that $A(q): V \to V^*$ satisfies (A)-(C). It then follows from Theorems 2.1 and 3.1 that there exists a unique nonlinear evolution system $\{U_0(t, s; q): 0 \leqq s \leqq t \leqq T\}$ on H corresponding to the initial value problem

$$\dot{u}(t) + A_0(q)u(t) = f(t; q), \qquad 0 < t \leqq T,$$
$$u(0) = u^0(q)$$

where for each $q \in Q$, $f(\cdot; q) \in L_1(0, T; H)$, $u^0(q) \in H$, and $A_0(q)$: Dom $(A_0(q)) \subset H \to H$ is the restriction of $A(q)$ to the set Dom $(A_0(q)) = \{v \in V: A(q)v \in H\}$. The operator $-A_0(q)$ is the infinitesimal generator of an analytic semigroup $\{T_0(t; q): t \geqq 0\}$ on H (see [18]) and for $\phi \in H$

$$U_0(t, s; q)\phi = T_0(t-s; q)\phi + \int_s^t T_0(t-\tau; q)f(\tau; q)\, d\tau. \tag{4.1}$$

It can be shown that the semigroup $\{T_0(t; q): t \geqq 0\}$ admits an extension $\{T(t; q): t \geqq 0\}$, which is an analytic semigroup on V^* with generator $A(q): V \subset V^* \to V^*$. Also the restriction of $\{T_0(t; q): t \geqq 0\}$ to V, call it $\{\tilde{T}(t; q): t \geqq 0\}$, is an analytic semigroup on V with generator $\tilde{A}(q)$: Dom $(\tilde{A}(q)) \subset V \to V$, the restriction of $A(q)$ to the set Dom $(\tilde{A}(q)) = \{v \in V: A(q)v \in V\}$ (see [3], [18]). Consequently, with appropriate assumptions on $f(\cdot; q)$, the evolution system $\{U_0(t, s; q): 0 \leqq s \leqq t \leqq T\}$ admits an extension $\{U(t, s; q): 0 \leqq s \leqq t \leqq T\}$, which is an evolution system on V^* and a restriction $\{\tilde{U}(t, s; q): 0 \leqq s \leqq t \leqq T\}$, which is an evolution system on V.

It is clear from (4.1) that when $A(q)$ is linear, we may take $f(\cdot; q) \equiv 0$ and consider only the approximation of the semigroup $\{T_0(t; q): t \geqq 0\}$. For each $n = 1, 2, \cdots$ let the finite-dimensional subspaces H_n of H and the corresponding orthogonal projections P_n be as they were defined in § 3 and assume that condition (D) is satisfied. Denote the Galerkin approximations to $A(q)$ (i.e., the restriction of $A(q)$ to an operator from H_n into $H_n^* = H_n$) by $A_n(q)$ and set $T_n(t; q) = \exp(-tA_n(q))$, $t \geqq 0$. Theorem 3.2 then implies that

$$\lim_{n\to\infty} |T_n(t; q_n)P_n u^0(q_n) - T_0(t; q_0)u^0(q_0)| = 0 \tag{4.2}$$

uniformly in t, for $t \in [0, T]$ whenever $\{q_n\} \subset Q$ with $\lim_{n\to\infty} q_n = q_0 \in Q$, and the mapping $q \to u^0(q)$ is continuous from $Q \subset \mathcal{Q}$ into H. In addition, recalling that we required that $H_n \subset V$ for all $n = 1, 2, \cdots$, an inspection of the proof of Theorem 3.2 reveals that in the linear case with the existence of the semigroup $\{\tilde{T}(t; q): t \geqq 0\}$ on V, we may apply Theorem 2.2 with $X = V$ and conclude that

$$\lim_{n\to\infty} \|T_n(t; q_n)P_n u^0(q_n) - \tilde{T}(t; q_0)u^0(q_0)\| = 0 \tag{4.3}$$

uniformly in t for $t \in [0, T]$ whenever $\lim_{n\to\infty} q_n = q_0$, $u^0(q) \in V$ and the map $q \to u^0(q)$ is continuous from Q into V (see also [3]). Then for $\phi \in H$, setting

$$U_n(t, s; q)P_n\phi = T_n(t-s; q)P_n\phi + \int_s^t T_n(t-\tau; q)P_n f(\tau; q)\, d\tau$$

under appropriate assumptions on $f(\cdot; q)$, (4.2) and (4.3) continue to hold with $T_n(t; q)$, $T_0(t; q)$, and $\tilde{T}(t; q)$ replaced by $U_n(t, s; q)$, $U_0(t, s; q)$, and $\tilde{U}(t, s; q)$, respectively, with the convergence being uniform in t, for $t \in [s, T]$. Hence the linear theory and results of [3] are a special case of the nonlinear theory of § 3.

We note that in the context of the identification problem, the fact that the stronger V-convergence given in (4.3) can be obtained is significant. Indeed, (4.3) permits the

relaxation of the continuity assumption on the performance index Φ to the requirement that for each $z \in Z$, the mapping $u \to \Phi(u, z)$ be continuous from $C([0, T]; V)$ into R^+. This can have the effect of significantly enlarging the class of allowable observations (e.g., see [1]). For example, in the case of a one-dimensional parabolic system formulated in $H = L_2$ with V in H^1, spatially discrete (i.e., pointwise, as opposed to distributed in space) measurements will suffice (see [3] and [5]).

Among the class of linear regularly dissipative operators that arise from a form satisfying (A')-(C') are the familiar elliptic partial differential operators on L_2. Briefly, let Ω be a region in R^l and let $\mathcal{Q} = \times_{n=1}^{l^2+l+1} L_\infty(\Omega)$. Let Q be a compact subset of $\mathcal{Q}$ with the property that if $q = \{(a_{ij}, b_i, c): i, j = 1, \cdots, l\} \in Q$, then for some $\alpha > 0$ independent of $q \in Q$,

$$\sum_{i,j=1}^{l} a_{ij}(x)\zeta_i\zeta_j \geqq \alpha|\zeta|^2$$

for every $x \in \Omega$, and every $\zeta \in R^l$. For $q \in Q$ and $u, v \in H^1(\Omega)$ set

$$a(q)(u, v) = \int_\Omega \left\{ \sum_{i,j=1}^{l} a_{ij}(x) \frac{\partial u(x)}{\partial x_i} \frac{\partial v(x)}{\partial x_j} + \sum_{i=1}^{l} b_i(x) \frac{\partial u(x)}{\partial x_i} v(x) + c(x)u(x)v(x) \right\} dx$$

with $H = L_2(\Omega)$ and V any closed subspace of $H^1(\Omega)$ containing $H_0^1(\Omega)$, it can be shown (see, e.g., [18, p. 29]) that $a(q)(\cdot, \cdot)$ satisfies (A')-(C'). The operator $A(q)$ is given formally by

$$A(q) = -\sum_{i,j=1}^{l} \frac{\partial}{\partial x_j} a_{ij}(x) \frac{\partial}{\partial x_i} + \sum_{i=1}^{l} b_i(x) \frac{\partial}{\partial x_i} + c(x). \tag{4.4}$$

When $\partial\Omega$ is sufficiently smooth, $A(q)$ is the elliptic operator given by (4.4), V is chosen to be either $H_0^1(\Omega)$ or $H^1(\Omega)$, and (3.1) becomes a parabolic partial differential equation with either Dirichlet or Neumann boundary conditions.

For $H = L_2(\Omega)$ and V a subspace of $H^1(\Omega)$, choosing the approximating subspaces to be the span of an appropriate collection of first-order spline functions will typically satisfy assumption (D) (see [15, Chaps. 2, 6] and Example 4.2 below).

Example 4.2 (Nonlinear elliptic operators). Let Ω be a bounded region in R^l with smooth boundary $\Gamma = \partial\Omega$. For $\alpha = (\alpha_1, \cdots, \alpha_l)$ a multi-index, let $|\alpha| = \alpha_1 + \alpha_2 + \cdots + \alpha_l$ and denote the αth order generalized, or distributional derivative of a function u by $D^\alpha u$; that is,

$$D^\alpha u(x) = \frac{\partial^{\alpha_1}}{\partial x_1^{\alpha_1}} \cdots \frac{\partial^{\alpha_l}}{\partial x_l^{\alpha_l}} u(x), \qquad x \in \Omega.$$

Let m be a nonnegative integer and let δu denote the vector-valued function of length $N = \binom{l+m}{l}$ whose components are all of the partial derivatives of u of order greater than or equal to zero and less than or equal to m.

For each multi-index α with $|\alpha| \leqq m$, let $(x, \zeta) \to a_\alpha(x, \zeta)$ be a real-valued function defined on $\Omega \times R^N$ that is measurable in x and continuous in ζ. We assume that

(1) There exist a $g \in L_2(\Omega)$ and a positive constant γ such that

$$|a_\alpha(x, \zeta)| \leqq \gamma(|p(\zeta)| + g(x)) \quad \text{where } p(\zeta) \text{ is any polynomial,} \tag{4.5}$$

for almost every $x \in \Omega$, each $\zeta \in R^N$, and all α with $|\alpha| \leqq m$; and

(2) There exists a positive constant λ such that

$$\sum_{|\alpha| \leqq m} (a_\alpha(x, \zeta) - a_\alpha(x, \eta))(\zeta_\alpha - \eta_\alpha) \geqq \lambda \sum_{|\alpha| \leqq m} |\zeta_\alpha - \eta_\alpha|^2 \tag{4.6}$$

for almost every $x \in \Omega$ and all $\zeta, \eta \in R^N$.

Let $H = L_2(\Omega)$ and let V be any closed subspace of $H^m(\Omega)$ that contains $H_0^m(\Omega)$. Define the operator $A: V \to V^*$ by

$$(Au)(v) = \sum_{|\alpha| \leqq m} \int_\Omega a_\alpha(x, \delta u(x)) D^\alpha v(x)\, dx, \tag{4.7}$$

for $u, v \in V$. The operator A given by (4.7) is the distributional form of the formal differential operator

$$(Au)(x) = \sum_{|\alpha| \leqq m} (-1)^\alpha D^\alpha a_\alpha(x, \delta u(x)). \tag{4.8}$$

A differential operator of the form (4.8) is referred to as a nonlinear elliptic operator and the partial differential equation

$$\frac{\partial u}{\partial t}(t, x) + \sum_{|\alpha| \leqq m} (-1)^\alpha D^\alpha a_\alpha(x, \delta u(t, x)) = f(t, x) \tag{4.9}$$

is said to be of nonlinear parabolic type. When $V = H_0^m(\Omega)$, a solution in V^* to the abstract equation

$$\dot{u}(t) + Au(t) = f(t),$$

with A given by (4.7), corresponds to a variational solution to (4.9) which satisfies Dirichlet boundary conditions. When $V = H^m(\Omega)$, a variational solution to the Neumann problem is obtained. Note that in the linear case we have

$$a_\alpha(x, \delta u(x)) = \sum_{|\beta| \leqq m} a^{\alpha,\beta}(x) D^\beta u(x).$$

Under the assumptions above, it is not difficult to show that A given by (4.7) is hemicontinuous and satisfies conditions (B) and (C) given in § 3. With an appropriate choice of the space $\mathcal{Q}$ and the set Q, condition (A) can be satisfied as well.

A quasilinear model for heat conduction or mass transfer, in which the heat or mass flux is a function of the temperature or mass fraction gradient discussed in [16] and [17], leads to a nonlinear elliptic operator and a nonlinear parabolic partial differential equation of the forms (4.8) and (4.9), respectively, with $m = 1$. Let Ω be a bounded region in R^l with smooth boundary and let $\mathcal{Q} = L_\infty(\Omega \times R^l)$. Let Q be a compact subset of $\mathcal{Q}$ with the property that $q \in Q$ if and only if the mapping $\zeta \to q(x, \zeta)$ is C^1 on R^l for almost every $x \in \Omega$, and there exists a $\lambda > 0$ (which does not depend on q) such that

$$(q(x, \zeta)\zeta - q(x, \eta)\eta) \cdot (\zeta - \eta) \geqq \lambda |\zeta - \eta|^2 \tag{4.10}$$

for almost every $x \in \Omega$ and all $\zeta, \eta \in R^l$. (When $l = 1$, the function $q(x, \xi) = q(\xi) = (1 - 0.5\, e^{-\xi^2})$ satisfies (4.10).)

Let $H = L_2(\Omega)$ and let V be any closed subspace of $H^1(\Omega)$ that contains $H_0^1(\Omega)$. Then $V \subset H \subset V^*$, and for each $q \in Q$ define $A(q): V \to V^*$ by

$$(A(q)u)(v) = \int_\Omega q(x, \nabla u(x)) \nabla u(x) \cdot \nabla v(x)\, dx \tag{4.11}$$

for $u, v \in V$. Note that for each $q \in Q$ the operator given by (4.11) is of the form (4.7) with

$$a_\alpha(x, \delta u(x)) = q(x, \nabla u(x)) D^\alpha u(x) \tag{4.12}$$

for $x \in \Omega$ and all α with $|\alpha| = 1$ and $a_\alpha = 0$ for $|\alpha| = 0$. The nonlinear parabolic partial differential equation (4.9) takes the form

$$\frac{\partial u}{\partial t}(t, x) - \nabla \cdot q(x, \nabla u(t, x)) \nabla u(t, x) = f(t, x), \qquad t > 0, \quad x \in \Omega.$$

Taking $\| \cdot \|$ to be the usual norm on $H^1(\Omega)$, it follows that

$$\| A(q_0)u - A(q_1)u \|_* \leqq |q_0 - q_1|_{L_\infty} \| u \|$$

for each $u \in V$ and $q_0, q_1 \in Q$. Since Q is a compact subset of $L_\infty(\Omega \times R^l)$, it is easily verified that a_α given by (4.12) satisfies a growth condition of the form (4.5) with p linear and γ and g independent of $q \in Q$. An application of the Mean Value Theorem together with assumption (4.10) implies the existence of a $\lambda > 0$, independent of $q \in Q$, for which (4.6) holds. Consequently, (A), (B), and ($\tilde{\text{C}}$) given in § 3 are satisfied, and our general theory (including Lemma 3.2) can be applied.

With regard to approximation, polynomial spline function based Galerkin subspaces can often be shown to satisfy condition (D). For example, when $l = 1$ and $\Omega = (0, 1)$ in the nonlinear heat conduction/mass transfer example discussed above, the subspaces H_n can be chosen as the span of the linear B-spline ("hat") functions with respect to the uniform mesh $\{0, 1/n, 2/n, \cdots, 1\}$ appropriately modified to satisfy stable, or geometric, boundary conditions. Familiar error estimates for interpolation and the Schmidt inequality can then be used to verify that condition (D) is satisfied (see, e.g., [15, Chap. 6.3]). Generalization to higher dimensions is possible, and can often be achieved via tensor products of one-dimensional elements (again, see [15, Chap. 6]).

5. Concluding remarks. We have developed a general abstract approximation framework for the identification of nonlinear distributed parameter evolution systems. The class of systems to which our theory applies are those whose dynamics can be described by a nonlinear operator that satisfies conditions that are the natural nonlinear extensions, or analogues, of the properties of regularly dissipative, or abstract parabolic, linear operators. The approach we have taken is based on the defining of a sequence of approximating finite-dimensional identification problems in which the systems to be identified are Galerkin approximations to the original, underlying, infinite-dimensional nonlinear dynamics. Under a weak continuity assumption with respect to the unknown parameters to be identified, equiboundedness and equimonotonicity conditions, and an approximation assumption on the Galerkin subspaces (all of which are readily verified for wide classes of nonlinear distributed systems and finite-element subspaces), we are able to demonstrate that solutions to the approximating problems exist, and, in some sense, approximate (i.e., subsequential convergence) solutions to the original infinite-dimensional identification problem. We have shown that the linear theory presented in [2] and [3] is a special case of our nonlinear framework and that our results are applicable to a reasonably wide class of nonlinear elliptic operators and corresponding nonlinear parabolic partial differential equations. In particular, we have considered application of our theoretical framework to a quasilinear model for heat conduction or mass transport.

The general approximation result for nonlinear evolution systems discussed in § 2 is applicable to a much broader class of nonlinear dynamical systems than we subsequently treated in § 3. For example, this class of systems would include those with dynamics described by set-valued maps or multifunctions, and (after nontrivial modification to the general theory) time-dependent or nonautonomous operators. We

are currently investigating these features of the general approximation theory in the context of parameter estimation problems. (In this connection, see the last remark in § 3.) Also, we would like to be able to weaken the somewhat restrictive strong monotonicity condition. Any progress that we might make in these efforts would have the potential to significantly enlarge the class of nonlinear systems to which our theory and framework would apply. Finally, extensive numerical or computational studies designed to demonstrate the feasibility and point out the limitations of our schemes and general approach are currently underway and will be reported on in a forthcoming paper.

After this paper was accepted for publication, related efforts by Kluge and Langmach were called to the authors' attention. Some of these efforts are related in that those authors used monotonicity concepts to treat several specific estimation problems for nonlinear partial differential equations. Motivated by problems involving flow of viscous liquids through porous media [H. Langmach, *On the determination of functional parameters in some parabolic differential equations*, in Theory of Nonlinear Operators (Proc. Summer School Berlin 1977), Abh. Akad. Wiss. DDR, 6 (1978), pp. 174-184], Langmach discusses conditions to guarantee existence and convergence of approximations to best fit parameters in first-order parabolic systems where the unknown coefficients are monotone functions of the gradient of the system solution. His approach is in the spirit of the efforts on inverse problems for elliptic systems by Kluge and Langmach [*On some problems of determination of functional parameters in partial differential equations*, in Modeling and Identification of Distributed Parameter Systems, Lecture Notes in Control and Information Science 1, Springer-Verlag, Berlin, New York, 1977, pp. 298-309] and differs substantially from the approach taken in §§ 2 and 3 of this paper.

OBSERVABILITY OF SYSTEMS ON LIE GROUPS AND COSET SPACES*

D. CHENG†, W. P. DAYAWANSA‡, AND C. F. MARTIN§

Abstract. The purpose of this paper is to study the observability of a class of systems for which the state space is a Lie group and the output space is a coset space. The study of this type of system was initiated by Brockett [*SIAM J. Control*, 10 (1972), pp. 265-284]. In this paper, Brockett's observability results are generalized and necessary and sufficient conditions for observability are obtained. Effective algorithms are established to verify such conditions. Finally, as an application, some disturbance decoupling problems are considered.

Key words. observability, global observability, Lie groups, analytic systems

AMS(MOS) subject classification. 93B

1. Introduction. In this paper, we study the observability properties of systems that are described by a state equation that evolves on a Lie group G and an output equation that takes values in a coset space of G. These equations are assumed to be of the form

$$\dot{x} = A(x) + \sum_{i=1}^{m} B_i(x)u_i, \qquad x \in G, \tag{1.1}$$

$$y = Cx \tag{1.2}$$

where $A(x)$, $B_1(x), \cdots, B_m(x)$ are right-invariant vector fields on G, C is a closed subgroup of G, and the notation Cx is to be interpreted as the right coset of C in G that contains x.

This system model has been studied by Brockett [1] where G was assumed to be a group of matrices. Brockett has shown [1] that there are many important applications in engineering and in physics that have models of this form. Jurdjevic and Sussmann [2] have extended (1.1) to an abstract Lie group G and have obtained a set of basic controllability properties of (1.1). Our work is related to and extends the work of [1].

The observability properties are discussed by Brockett [1]. To describe Brockett's observability result, we need a preliminary definition.

DEFINITION 1.1. Two points x_1 and x_2 are distinguishable if there exists some control that gives rise to different outputs for the two starting points.

Let S be a subset of G. We denote by $\{S\}_G$ the subgroup generated by S, i.e., the smallest subgroup of G containing S. Let $\mathcal{H}$ be a set of right invariant vector fields of G. We denote by $\{\mathcal{H}\}_{\mathrm{LA}}$ the Lie subalgebra generated by $\mathcal{H}$, and

$$\exp(\{\mathcal{H}\}_{\mathrm{LA}}) = \{\exp X \mid X \in \{\mathcal{H}\}_{\mathrm{LA}}\}.$$

The main observability result of [1] is Theorem 1.1.

THEOREM 1.1 [1]. *Let $\mathscr{H}$ and $\mathscr{L}$ be Lie algebras in* $\mathrm{gl}\{n, \mathbb{R}\}$, *and suppose that all the points reachable from the identity for matrix system*

$$\dot{x} = \left(A + \sum_{i=1}^{m} u_i B_i\right)x, \qquad y = (\{\exp \mathscr{H}\}_G)x$$

are $\{\exp \mathscr{L}\}_G$. *Then the set of initial states $\mathscr{S}$, which are indistinguishable from the identity, contains* $\{\exp \mathscr{K}\}_G$ *if and only if* $\{\mathrm{ad}_{\mathscr{L}} \mathscr{K}\}_{\mathrm{LA}} \subset \mathscr{H}$. *Therefore a necessary condition for all states to be distinguishable from the identity is that $\mathscr{H}$ contains no subalgebra $\mathscr{K}$ such that* $\{\mathrm{ad}_{\mathscr{L}} \mathscr{K}\}_{\mathrm{LA}} \subset \mathscr{H}$.

It is shown by example in Brockett [1] that the preceding theorem is not sufficient. An important point in this theorem is that the "unobservable" part is related to an $\mathscr{L}$-invariant subalgebra $\{\mathrm{ad}_{\mathscr{L}} \mathscr{K}\}_{\mathrm{LA}}$, which is contained in the Lie subalgebra of the output subgroup.

Motivated by this fact, we investigate the "unobservable" part in more detail. The results of Jurdjevic and Sussmann [2] enable us to describe the controllable set, which corresponds to $\{\exp \mathscr{L}\}_G$ of Theorem 1.1. Based on [1] and [2], we give necessary and sufficient conditions for the system (1.1), (1.2) to be observable.

The paper is organized in the following way. Section 2 contains two main results—local observability conditions and global observability conditions. In § 3, we develop algorithms that are useful for studying groups of matrices. In § 4, we give some examples. Finally, in § 5 the input-output decoupling problem is discussed as an application.

2. Observability results. To avoid unnecessary complexity, we assume throughout this paper that the controls are piecewise constant. In fact, this is not essential. For instance, if we replace the set of piecewise constant functions by the set of the piecewise continuous functions, all of the arguments remain valid.

Let $R(x)$ be the reachable set starting from x, i.e., $R(x)$ is the set of points y such that there exist a piecewise constant control u and a time $T \geqq 0$, such that the solution of (1.1) satisfies $x(0) = x$, $x(T) = y$. We denote by $R(x, t)$ the reachable set at time t, starting from x.

It is proved in Jurdjevic and Sussmann [2] that for the right-invariant system (1.1), the reachable set of x is related to the reachable set of the identity e by

$$R(x) = R(e)x. \tag{2.1}$$

Using this fact, we prove the following elementary result, which shows that distinguishing two arbitrary points is equivalent to distinguishing a point from the identity.

LEMMA 2.1. *Two points p and q are indistinguishable if and only if for each* $r \in R(e)$

$$\mathrm{Ad}\,(r)pq^{-1} \in C. \tag{2.2}$$

Proof. By the structure of the output (1.2) it is clear that p and q are indistinguishable if and only if for all t, $R(p, t)$ and $R(q, t)$ are in the same coset of C. From (2.1), it follows that

$$Crp = Crq \quad \text{for all } r \in R(e), \tag{2.3}$$

that is,

$$rpq^{-1}r^{-1} = \mathrm{Ad}\,(r)pq^{-1} \in C. \qquad \square$$

Now we may define an unobservable state as follows. (It is similar to the linear case: x_1 and x_2 are indistinguishable if and only if $x_1 - x_2$ belongs to an unobservable subspace.)

DEFINITION 2.1. A point h is called unobservable if there exist p and q such that $pq^{-1} = h$ and p and q are indistinguishable.

Remark 1. Let h be unobservable. Then it follows from Lemma 2.1 that for any pair (p^1, q^1) if $p^1(q^1)^{-1} = h$, then p^1 and q^1 are indistinguishable.

Let

$$H = \{h \in G \mid h \text{ is unobservable}\}.$$

By definition of unobservable state and equation (2.2), it is clear that

$$H \subset C. \tag{2.4}$$

In fact, H has a subgroup structure that is shown in the following lemma.

LEMMA 2.2. *Assume C is closed. Then the unobservable set H is a closed Lie subgroup of G.*

Proof. By definition and Lemma 2.1,

$$H = \{h \in G \mid rhr^{-1} \in C \text{ for all } r \in R(e)\}. \tag{2.5}$$

Let $h_1, h_2 \in H$. Then,

$$rh_1h_2^{-1}r^{-1} = rh_1r^{-1}rh_2^{-1}r^{-1} = (rh_1r^{-1})(rh_2r^{-1})^{-1} \in C.$$

Thus, H is a subgroup of G.

Since C is closed, if for a sequence $\{h_n\} \subset H$, $h_n \to h$, as $n \to \infty$, then

$$rh_nr^{-1} \to rhr^{-1} \in C.$$

Thus, $h \in H$, and hence H is closed. Now the result follows from the well-known fact (see for example, Hausner and Schwartz [4]) that a closed subgroup of a Lie group is a Lie subgroup. □

If C is closed, the output mapping has an analytic structure that is described by the following well-known theorem.

THEOREM 2.1 [3]. *Let G be a Lie group and C a closed subgroup of G. Then the quotient space $C\backslash G$ admits the structure of real analytic manifold in such a way that the action of G on $C\backslash G$ is real analytic, that is, the mapping $G \times C\backslash G \to C\backslash G$, which maps (p, Cq) into Cpq, is real analytic. In particular, the projection $G \to C\backslash G$ is real analytic.*

Let $\{R(e)\}_G$ be the subgroup of G generated by $R(e)$ and let $\overline{\{R(e)\}_G}$ denote the closure of $\{R(e)\}_G$. For convenience denote the vector fields $A(x), B_1(x), \cdots, B_m(x)$ by $A, B_1, \cdots, B_m$, respectively, where A and B_i are elements in $\mathcal{G}(G)$, the Lie algebra of G. Then we have the following lemma.

LEMMA 2.3. *Assume $h \in H$. Then*

$$\text{Ad}\,(r)h \in H \quad \textit{for all } r \in \overline{\{G(e)\}_G}. \tag{2.6}$$

Proof. First, we claim that

$$\text{Ad}\,(r)h \in H \quad \text{for all } r \in G(e). \tag{2.7}$$

Since $R(e)$ is a semigroup [2], for any $\tilde{r} \in R(e)$ we have $\tilde{r}r \in R(e)$. Thus,

$$(\tilde{r}r)h(\tilde{r}r)^{-1} = \tilde{r}(rhr^{-1})\tilde{r}^{-1} \in C \quad \text{for all } \tilde{r} \in R(e).$$

It follows that $rhr^{-1} \in H$.

From its defining properties, it is clear that

$$\{R(e)\}_G = \left\{ \exp(t_sX_s) \cdots \exp(t_1X_1) \mid t_i \in \mathbb{R}, s \in Z^+, \right.$$
$$\left. X_i \in \left\{ A + \sum_{j=1}^{m} u_jB_j \;\middle|\; u_j \in \mathbb{R} \right\}, i = 1, \cdots, s \right\}. \tag{2.8}$$

Set

$$E_s = \{(t_1, \cdots, t_s) \in \mathbb{R}^s \,|\, \mathrm{Ad}\,(\exp(t_s X_s) \cdots \exp(t_1 X_1))h \in C\}.$$

Then, to prove (2.6) for $r \in \{R(e)\}_G$ it is enough to show that $E_s = \mathbb{R}^s$, $s = 1, 2, \cdots$. We proceed by induction. For $s = 1$, if $\mathrm{Ad}\,(\exp t_1 X_1)h \not\subset C$, then there exists $\tilde{t}_1$ such that

$$\left.\frac{d}{dt_1}\right|_{\tilde{t}_1} \mathrm{Ad}\,(\exp t_1 X_1)h \notin (R_p)_* \mathcal{G}(C)$$

where $p = \mathrm{Ad}\,(\exp \tilde{t}_1 X_1)h$, $\mathcal{G}(C)$ is the Lie algebra of C and R_p is the right translation, i.e., $R_p : G \to G$ is defined as $x \to xp$. In other words, there exists a right-invariant one-form $w(x)$ generated by $w \in (\mathcal{G}(C))^{\perp}$ such that

$$\left\langle w_{(p)}, \left.\frac{d}{dt_1}\right|_{\tilde{t}_1} \mathrm{Ad}\,(\exp t_1 X_1)h \right\rangle \neq 0. \tag{2.9}$$

By analyticity, (2.9) holds in an open dense subset of $\mathbb{R}$. But according to (2.7), for $\tilde{t}_1 \in \mathbb{R}_+ = \{t \in \mathbb{R},\ t \geqq 0\}$ the left-hand side of (2.9) is zero; this leads to a contradiction. Now, assume that

$$\mathrm{Ad}\,(\exp(t_{s-1} X_{s-1}) \cdots \exp(t_1 X_1))h \in C, \qquad t_i \in \mathbb{R}$$

and

$$\{\mathrm{Ad}\,(\exp(t_s X_s) \cdots \exp(t_1 X_1))h \,|\, (t_1, \cdots, t_s) \in \mathbb{R}^s\} \not\subset C.$$

Then there exists $\tilde{t} = (\tilde{t}_1, \cdots, \tilde{t}_s)$ such that

$$\left.\frac{d}{dt}\right|_{\tilde{t}_s} \mathrm{Ad}\,(\exp(tX_s) \exp(\tilde{t}_{s-1} X_{s-1}) \cdots \exp(\tilde{t}_1 X_1))h \in \mathcal{G}(C).$$

Similar to the case when $s = 1$, we have a contradiction.

Thus, we have shown that (2.6) holds for all $r \in \{R(e)\}_G$. By continuity, it holds for all $r \in \overline{\{R(e)\}_G}$. □

Remark 2.[1] It is clear by (2.8) that $\{R(e)\}_G$ is a path-connected group, hence a Lie subgroup [5]. Now since $\{R(e)\}_G$ is a connected Lie group, and $A, B_1, B_2, \cdots, B_m$ generate $\mathcal{G}(\{R(e)\}_G)$, then [2, Lemma 6.2]

$$\begin{aligned} \{R(e)\}_G = \{&\exp(t_x X_s) \cdots \exp(t_1 X_1) \,|\, t_i \in \mathbb{R},\ s \in Z^+, \\ &X_i \in \{A, B_1, \cdots, B_m\},\ i = 1, \cdots, s\}. \end{aligned} \tag{2.10}$$

□

Next, we investigate the relations among the Lie algebras $\mathcal{G}(H)$, $\mathcal{G}(C)$, and $\mathcal{G}(G)$, which are the Lie algebras of H, C, and G, respectively.

Let $\{X_1(x), \cdots, X_s(x)\}$ be a set of right-invariant vector fields generated by $X_i \in \mathcal{G}(G)$, $i = 1, \cdots, s$, respectively. Let Δ denote the subspace of $\mathcal{G}(G)$ spanned by $\{x_1, \cdots, x_5\}$. A subspace Δ of $\mathcal{G}(G)$ is called $Y \in \mathcal{G}(G)$ invariant if

$$\{[Y, X] \,|\, X \in \Delta\} \subset \Delta.$$

Likewise, for right-invariant we form $w_1(x), \cdots, w_s(x)$ generated by $w_i \in \mathcal{G}^*(G)$, the cotangent space of G at the identity e, we have a right-invariant subspace

$$\Omega = \mathrm{span}\,\{w_1, \cdots, w_s\}.$$

[1] This remark was suggested by an anonymous reviewer.

Ω is Y invariant if

$$\{L_Y w \mid w \in \Omega\} \subset \Omega.$$

The following two lemmas are generalizations of Theorem 1.1.

LEMMA 2.4. *$\mathcal{G}(H)$ is A and B_i, $i = 1, \cdots, m$, invariant.*

Proof. Let $X = A$ or B_i, $t \in \mathbb{R}$, $p = \exp(tX)$. According to Lemma 2.3 and (2.10), $(\operatorname{Ad} \exp(tX))_* \mathcal{G}(H) \subset \mathcal{G}(H)$. Now let $Y \in \mathcal{G}(H)$. Then

$$[X, Y] = \frac{d}{dt}\bigg|_{t=0} \operatorname{Ad} \exp(tX)_* Y \in \mathcal{G}(H). \qquad \square$$

LEMMA 2.5. *$\mathcal{G}(H)$ is the largest A and B_i, $i = 1, \cdots, m$, invariant Lie subalgebra contained in $\mathcal{G}(C)$.*

Proof. We claim that

$$\mathcal{G}(H) = \bigcap_{\substack{X_1, \cdots, X_p \in \{A, B_1, \cdots, B_m\} \\ p \in Z^+}} \operatorname{ad}_{X_1}^{-1} \cdots \operatorname{ad}_{X_p}^{-1} \mathcal{G}(C). \tag{2.11}$$

First, we show that (2.11) implies $\mathcal{G}(H)$ is the largest A and B_i invariant Lie subalgebra contained in $\mathcal{G}(C)$. Assume $\mathcal{G}(\tilde{H}) \subset \mathcal{G}(C)$ is also A and B_i invariant. Then, for any $X_1, \cdots, X_p \in \{A, B_1, \cdots, B_m\}$,

$$\operatorname{ad}_{X_1} \cdots \operatorname{ad}_{X_p} \mathcal{G}(\tilde{H}) \subset \mathcal{G}(\tilde{H}) \subset \mathcal{G}(C).$$

Thus,

$$\mathcal{G}(\tilde{H}) \subset \operatorname{ad}_{X_1}^{-1} \cdots \operatorname{ad}_{X_p}^{-1} \mathcal{G}(C).$$

Since $X_1, \cdots, X_p$ are chosen arbitrarily, we have that

$$\mathcal{G}(\tilde{H}) \subset \mathcal{G}(H).$$

Next, we prove (2.11).

($\subseteq$) Lemma 2.4 shows that $\mathcal{G}(H)$ is A and B_i invariant. The inclusion follows by an argument similar to the above.

($\supseteq$) Let

$$Y \in \bigcap_{\substack{X_1, \cdots, X_p \in \{A, B_1, \cdots, B_m\} \\ P \in Z^+}} \operatorname{ad}_{X_1}^{-1} \cdots \operatorname{ad}_{X_p}^{-1} \mathcal{G}(C).$$

To show that $Y \in \mathcal{G}(H)$, it is enough to show that

$$\exp(\tau Y) \in H \quad \text{for all } \tau \in \mathbb{R}.$$

Using (2.10), it suffices to show that for any

$$\begin{aligned} &X_1, \cdots, X_p \in \{A, B_1, \cdots, B_m\}, \qquad (t_1, \cdots, t_p) \in \mathbb{R}^p, \\ &\operatorname{Ad}(\exp(t_p X_p) \cdots \exp(t_1 X_1)) \exp \tau Y \in C. \end{aligned} \tag{2.12}$$

Since $\operatorname{Ad}(\exp(t_p X_p) \cdots \exp(t_1 X_1))$ is a diffeomorphism, we have

$$\operatorname{Ad}(\exp(t_p X_p) \cdots \exp(t_1 X_1)) \exp \tau Y = \exp(\operatorname{Ad}(\exp(t_p X_p) \cdots \exp(t_1 X_1) \tau Y)).$$

Now to prove (2.12), it suffices to show that

$$\operatorname{Ad}(\exp(t_p X_p) \cdots \exp(t_1 X_1)) \tau Y \in \mathcal{G}(C). \tag{2.13}$$

Let us denote the right-hand side of (2.11) by $\mathcal{J}$. Now since

$$\begin{aligned} &\operatorname{Ad}(\exp(t_p X_p) \cdots \exp(t_1 X_1) \tau Y) \\ &\qquad = \operatorname{Ad}(\exp t_p X_p) \operatorname{Ad}(\exp t_{p-1} X_{p-1}) \cdots \operatorname{Ad}(\exp(t_1 X_1)) \tau Y, \end{aligned}$$

it suffices to prove that

$$\operatorname{Ad}(\exp(t_1X_1)\tau Y)\in\mathscr{J}.$$

But

$$\operatorname{Ad}(\exp(t_1x_1)\tau y)=\exp(\operatorname{ad}(t_1x_1))\tau y$$
$$=\sum_{n=0}^{\infty}\frac{(\operatorname{ad}(t_1x_1))^n}{n!}(\tau y).$$

Therefore, obviously, $\operatorname{Ad}(\exp(t_1x_1)\tau y)\in\mathscr{J}$. □

We are now ready to discuss the observability properties of (1.1), (1.2).

DEFINITION 2.2. System (1.1), (1.2) is locally observable at x if there exists a neighborhood V_x of x such that

$$I_x\cap V_x=\{x\},$$

where I_x is the set of points that are indistinguishable from x. System (1.1), (1.2) is locally observable if it is locally observable everywhere. System (1.1), (1.2) is (globally) observable if

$$I_x=\{x\}.$$

In fact, Lemma 2.5 leads to the following local observability result, which is now obvious.

THEOREM 2.2. *System* (1.1), (1.2) *is locally observable if and only if the largest* A *and* B_i, $i=1,\cdots,m$, *invariant subalgebra contained in* $\mathscr{G}(C)$ *is zero. Moreover, if* V_e *is a neighborhood of* e *such that* $I_e\cap V_e=\{e\}$, *then* $V_x=R_x(V_e)$ *is a neighborhood of* x *such that* $I_x\cap V_x=\{x\}$.

Let S be the centralizer of $\{R(e)\}_G$, i.e.,

$$S=\{x\in G\,|\,rx=xr \text{ for all } r\in\{R(e)\}_G\}. \tag{2.14}$$

According to (2.10), we may express S in an easily verifiable form as

$$S=\{x\in G\,|\,x\exp(tX)=\exp(tX)x,\ X\in\{A,B_1,\cdots,B_m\}\}. \tag{2.15}$$

We will use S to establish a global result.

It is obvious that S is a closed subgroup of G, and hence is a Lie subgroup. Moreover, by the construction of $\{R(e)\}_G$ we see that to verify that $x\in S$ it is enough to verify that

$$\operatorname{Ad}(x)\exp(tY)=\exp tY$$

for

$$Y\in\{A,B_1,\cdots,B_m\},\qquad t\in\mathbb{R}.$$

Now we state our global observability theorem.

THEOREM 2.3. *System* (1.1), (1.2) *is globally observable if and only if the following two conditions are satisfied*:

(a) $\mathscr{G}(H)=\{0\}$,

(b) $S\cap C=\{e\}$.

Proof. Necessity. The necessity of (a) has been proved in Theorem 2.2. The necessity of (b) is obvious, because if $e\neq h\in S\cap C$, then $h\in H$, i.e., h is indistinguishable from e.

Sufficiency. From (a) we see that H is a discrete subgroup of G. Now for each $h \in H$, we define a mapping $\phi : \{R(e)\}_G \to H$ as

$$\phi(r) = \mathrm{Ad}\,(r)h.$$

According to Lemma 2.3, ϕ maps $\{R(e)\}_G$ into H. Now, since $\{R(e)\}_G$ is connected and ϕ is continuous, $\{\mathrm{Ad}\,(r)h \,|\, r \in \{R(e)\}_G\} \subset H$ is connected, but since

$$h \in \{\mathrm{Ad}\,(r)h \,|\, r \in \{R(e)\}_G\}$$

it follows that

$$\{h\} = \{\mathrm{Ad}\,(r)h \,|\, r \in \{R(e)\}_G\},$$

i.e.,

$$\mathrm{Ad}\,(r)h = h \quad \text{for all } r \in \{R(e)\}_G.$$

In other words, $h \in S$. Now using condition (b), we see that $h = e$, i.e., $H = \{e\}$. □

3. Algorithm. In the previous section, we saw that the Lie subalgebra $\mathcal{G}(H)$ of the unobservable Lie group H plays an important role in investigating the observability of the system (1.1), (1.2). The following algorithm gives a method to compute it.

ALGORITHM 3.1.

$$\Omega_0 \triangleq \mathcal{G}(C)^{\perp},$$

$$\Omega_{k+1} \triangleq \Omega_k + L_A\Omega_k + \sum_{i=1}^{m} L_{B_i}\Omega_k, \qquad k \geqq 1.$$

Algorithm 3.1 produces an increasing sequence of right-invariant subspaces. To see that it provides $\mathcal{G}(H)$, we need the following theorem. The proof may be found in Isidori [6].

THEOREM 3.1. *In Algorithm* 3.1 *if* $\Omega_{k^*+1} = \Omega_{k^*}$ *then*

$$\mathcal{G}(H) = \Omega_{k^*}^{\perp}. \tag{3.1}$$

Note that the algorithm converges since the sequence of subspace $\{\Omega_K\}$ is increasing.

Since every Lie algebra over the field of real numbers $\mathbb{R}$ is isomorphic to some matrix algebra, we may consider further algorithmic details for the Lie algebras of groups of matrices.

First, let $\omega(x) \in V^*(G)$ be a right-invariant covector field (one-form) generated by $\omega \in \mathcal{G}^*(G)$, and let $A(x)$, $B(x) \in V(G)$ be the right-invariant vector fields generated by A, $B \in \mathcal{G}(G)$, respectively. Then,

$$\begin{aligned} \langle L_A\omega, B\rangle &= \langle L_{A(x)}\omega(x), B(x)\rangle \\ &= L_{A(x)}\langle \omega(x), B(x)\rangle - \langle \omega(x), [A(x), B(x)]\rangle. \end{aligned} \tag{3.2}$$

Since $\langle \omega(x), B(x)\rangle$ is constant, the first term of the right-hand side of (3.2) is zero. Thus, we have

$$\langle L_A\omega, B\rangle = -\langle \omega, [A, B]\rangle. \tag{3.3}$$

Now we consider a group of matrices. Assume the group considered is $\mathrm{GL}\,(n, \mathbb{R})$ (or a subgroup of it). Then, A, $B \in \mathrm{gl}\,(n, \mathbb{R})$ may be considered as matrices $A = (a_{ij})$

and $B = (b_{ij})$, respectively. Let $\omega \in \mathrm{gl}^*(n, \mathbb{R})$. We may assume ω is also expressed as a matrix $\omega = (\omega_{ij})$ and define

$$\langle \omega, A \rangle = \sum_{i=1}^{n} \sum_{j=1}^{n} \omega_{ij} a_{ij}. \tag{3.4}$$

Now,

$$\begin{aligned} \langle L_A \omega, B \rangle &= -\langle \omega, [A, B] \rangle \\ &= \sum_{i=1}^{n} \sum_{j=1}^{n} \sum_{k=1}^{n} (a_{kj} \omega_{ij} b_{ik} - a_{ik} \omega_{ij} b_{kj}) \\ &= \sum_{p=1}^{n} \sum_{q=1}^{n} \left(\sum_{k=1}^{n} \omega_{pk} a_{qk} - a_{kp} \omega_{kq} \right) b_{pq}. \end{aligned}$$

Thus

$$L_A \omega = [\omega, A^T] = \omega A^T - A^T \omega, \tag{3.5}$$

where T stands for transpose. To apply Algorithm 3.1, formula (3.5) is helpful.

Remark 3. As shown in Brockett [1], a right-invariant vector field on $\mathcal{G}(n, \mathbb{R})$ may be written as

$$A(x) = Ax,$$

where $A = A(e)$ and $A(x) = (R_x)_* A(e) = Ax$. Similarly, a right-invariant covector field may be written as

$$\omega(x) = \omega(x^T)^{-1}$$

where $\omega = \omega(e)$ and $\omega(x) = (R_{x^{-1}})^* \omega(e) = \omega(x^T)^{-1}$.

To see this, we only have to show that

$$\langle \omega(x), A(x) \rangle = \langle \omega, A \rangle.$$

In fact, if we denote $y = x^{-1}$, $x = (x_{ij})$, and $y = (y_{ij})$, then

$$\begin{aligned} \langle \omega(x), A(x) \rangle &= \sum_i \sum_j \left(\sum_p \omega_{ip} y_{jp} \right) \left(\sum_q a_{iq} x_{qj} \right) \\ &= \sum_i \sum_p \sum_q \omega_{ip} a_{iq} \left(\sum_j x_{qj} y_{jp} \right) \\ &= \sum_i \sum_p \sum_q \omega_{ip} a_{iq} \delta_{qp} \\ &= \sum_i \sum_p \omega_{ip} a_{ip} = \langle \omega, A \rangle. \end{aligned}$$

In fact, if we rewrite $A(x)$ in the "usual fashion" as a vector

$$A(e) = (a_{11}, \cdots, a_{1n}, a_{21}, \cdots, a_{2n}, \cdots, a_{n1}, \cdots, a_{nn})^T,$$

then

$$A(x) = \underbrace{(x^T \dotplus x^T \dotplus \cdots \dotplus x^T)}_{n \text{ terms.}} A(e)$$

Similarly,

$$\omega(x) = \omega(e)((x^T)^{-1} \dotplus (x^T)^{-1} \dotplus \cdots \dotplus (x^T)^{-1})$$

where "$\dotplus$" denotes the direct sum of matrices, and $(x^T \dotplus x^T \dotplus \cdots \dotplus x^T)$ and $((x^T)^{-1} \dotplus (x^T)^{-1} \dotplus \cdots \dotplus (x^T)^{-1})$ are the Jacobian matrices of R_x and $R_{x^{-1}}$, respectively.

4. Examples. In this section, we present some examples to demonstrate our results and algorithms.

Example 4.1. Consider a system

$$\dot{x} = uBx, \tag{4.1}$$

$$y = Cx \tag{4.2}$$

where $x \in \mathrm{GL}(3, \mathbb{R})$, $C = \mathrm{SO}(3)$, and

$$B = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

Now $\mathcal{G}(C)$ is the following set of skew-symmetric matrices:

$$\mathcal{G}(C) = \mathrm{span}\left\{\begin{bmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}\right\}.$$

According to Algorithm 3.1, we set

$$\Omega_0 = \mathrm{span}\left\{\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}\right\}$$

$$\triangleq \mathrm{span}\{\omega_1, \omega_2, \omega_3, \omega_4, \omega_5, \omega_6\}.$$

Using formula (3.5), we see that

$$L_B\omega_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad L_B\omega_5 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \quad L_B\omega_6 = \begin{bmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

Thus, $\Omega_1 = \mathcal{G}^*(G)$ and $k_* = 1$. Therefore,

$$\mathcal{G}(H) = \Omega_1^{\perp} = \{0\}.$$

Next, let us consider

$$S \cap C = \{x \in C \mid x \exp tB = \exp(tB)x, \text{ for all } t \in \mathbb{R}\}.$$

Let $x = (x_{ij}) \in C$. Since

$$\exp tB = \begin{bmatrix} 1 & 0 & 0 \\ t & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix},$$

we set

$$x \exp tB = \begin{bmatrix} x_{11} + x_{12} & x_{12} & x_{13} \\ x_{21} + tx_{22} & x_{22} & x_{23} \\ x_{31} + tx_{32} & x_{32} & x_{33} \end{bmatrix} = \exp(tB)x = \begin{bmatrix} x_{11} & x_{12} & x_{13} \\ tx_{11} + x_{21} & tx_{12} + x_{22} & tx_{13} + x_{23} \\ x_{31} & x_{32} & x_{33} \end{bmatrix}.$$

It follows that

$$x_{12} = 0, \quad x_{11} = x_{22}, \quad x_{13} = 0, \quad x_{32} = 0. \tag{4.3}$$

Since $x \in C = \mathrm{SO}(3)$, the only solutions of (4.3) are

$$x_1 = e, \qquad x_2 = \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \tag{4.4}$$

According to Theorem 2.3, system (4.1), (4.2) is not globally observable. □

Example 4.2. Consider the following system:

$$\dot{x} = Ax + uBx, \tag{4.5}$$

$$y = Cx \tag{4.6}$$

where B and C are as in Example 4.1, and

$$A = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

As in the previous example, we see that $\mathscr{G}(H) = \{0\}$. So the system is locally observable. Now

$$e^{At} = \begin{bmatrix} 1 & 0 & t \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

According to (2.15), we have only to check the commutativity of both x_1 and x_2 of (4.4) with $\exp(tA)$. For x_2 the answer is "no." Therefore, $x_1 = e = I_3$ is the only element in $S \cap C$. It follows that system (4.5), (4.6) is globally observable.

Remark 4. In Example 4.2, if we consider e^{At}, e^{Bt}, $e^{-Bt}e^{-At}e^{Bt}e^{At}$ and their products, it is easy to see that

$$\{R_{(e)}\}_G = \left\{ \begin{pmatrix} 1 & 0 & a \\ b & 1 & c \\ 0 & 0 & 1 \end{pmatrix} \middle| \, a, b, c \in \mathbb{R} \right\}.$$

It follows that

$$S = \left\{ \begin{pmatrix} x & 0 & 0 \\ 0 & x & y \\ 0 & 0 & x \end{pmatrix} \middle| \, x, y \in \mathbb{R}, x \neq 0 \right\}$$

and therefore,

$$S \cap C = I_3.$$

But in general, it is difficult to calculate $\{R(e)\}_G$ and S. In fact, Example 4.2 shows that to use Theorem 2.3 it is not necessary to construct $\{R(e)\}_G$ and S directly. We may check the global observability by the following rule, which may be considered as a corollary of Theorem 2.3.

COROLLARY 4.1. *System* (1.1), (1.2) *is globally observable, if and only if,*

(a) $\mathscr{G}(H) = \{0\}$,

(b) $\{x \in C \mid \exp(tX)x = x \exp(tX),\ X \in \{A, B_1, \cdots, B_m\},\ t \in \mathbb{R}\} = \{e\}$.

5. Decoupling problems. As an application, we consider a decoupling problem. To keep the right-invariance of $A(x)$ and $B_i(x)$, we consider only a constant feedback

$$u = \alpha + \beta u \tag{5.1}$$

where $\alpha \in \mathbb{R}^m$ and $\beta \in \mathrm{GL}(m, \mathbb{R})$.

Now assume

$$\dot{x} = A(x) + \sum_{i=1}^{m} u_i B_i(x) + \omega W(x), \tag{5.2}$$

$$y = Cx \tag{5.3}$$

where ω is a disturbance.

LEMMA 5.1. *The disturbance ω does not affect the output y if and only if*

$$W \in \mathcal{G}(H). \tag{5.4}$$

Proof. In fact, we may choose a local coordinate chart (ϕ, U) around e, say $x = (x^1, x^2)$, such that

$$C \cap U = \{p \in U \mid x_p^2 = 0\}.$$

Thus,

$$y = x^2(q), \qquad q \in U.$$

Now, it is easy to see that on U, $\mathcal{G}(H)$ is the largest A and B_i invariant distribution contained in the $\ker(y_*)$. Note that constant feedback does not affect $\mathcal{G}(H)$. Thus, the canonical decoupling result shows that (Isidori et al. [7]) (5.4) is a necessary and sufficient condition that ω does not affect y on V. By the analyticity, it is also true globally. □

Next, we consider the input-output decoupling problem. Assume $C_1, \cdots, C_k$ are Lie subgroups of G. Let $C = C_1 \cap \cdots \cap C_k$. Then it is easy to see that

$$y = Cx \tag{5.5}$$

is equivalent to

$$\begin{aligned} y_1 &= C_1 x \\ &\vdots \\ y_k &= C_k x \end{aligned} \tag{5.6}$$

in the sense that p and q are indistinguishable in (5.5) if and only if they are indistinguishable in (5.6).

Let $\mathcal{G}(H^i)$ be the largest A and B_i invariant Lie subalgebra contained in $\mathcal{G}(C_1 \cap \cdots C_{i-1} \cap C_{i+1} \cdots \cap C_k)$. Consider the system

$$\begin{aligned} \dot{x} &= A(x) + \sum_{i=1}^{m} u_i B_i(x), \\ y_j &= C_j x, \qquad j = 1, \cdots, k. \end{aligned} \tag{5.7}$$

We say that the input-output decoupling problem is solvable if there exists $\beta = (\beta_{ij}) \in \mathrm{GL}(m, \mathbb{R})$, such that for

$$u = v\beta$$

there exists a partition of v, namely $v = (v^1, \cdots, v^k)$, such that v^i affects only the corresponding y_i, $i = 1, \cdots, k$.

THEOREM 5.1. *For the system described by* (5.7) *the input-output decoupling problem is solvable if and only if*

$$B = B \cap \mathcal{G}(H^1) + \cdots + B \cap \mathcal{G}(H^k)$$

where $B = \operatorname{span}\{B_1, \cdots, B_m\}$. *Moreover, if the system* (5.7) *satisfies the controllability rank condition (i.e.,* $\mathcal{G}(\{R_e\}_G) = \mathcal{G}(G)$*), then* v^i *controls* y^i *completely.*

Proof. The proof is immediate from Lemma 5.1 and the well-known decoupling results of Nijmeijer and Schumacher [8] and Cheng [9].

6. Conclusion. We have considered a system defined on a Lie group with outputs in a coset space as described in Brockett [1]. The main results of this paper are two observability theorems, Theorems 2.2 and 2.3, that give necessary and sufficient conditions for local and global observability, respectively. Algorithm 3.1 calculates the A and B_i invariant Lie subalgebra contained in a given Lie subalgebra, which makes the condition in the above two theorems computably verifiable. Some examples are included. Finally, we have briefly discussed the input-output decoupling problem of a system on a Lie group with output in a coset space.

OPTIMAL CONTROL OF TWO-DIMENSIONAL SYSTEMS*

MAURO BISIACCO† AND ETTORE FORNASINI‡

Abstract. Necessary and sufficient conditions for the existence and the uniqueness of the solution of the optimal control problem of discrete-time linear time invariant two-dimensional systems are determined. Given a system that satisfies these conditions, the optimal control law is obtained using an algebraic Riccati equation with coefficients in the polynomial ring $R[z]$. Since the feedback implementation of this law does not preserve the causal structure of the system, suboptimal control laws are also discussed that lead to a weakly causal two-dimensional system.

Finally, some important connections between optimal control in an l_2 setting and l_∞ stabilization are investigated.

Key words. two-dimensional systems, linear quadratic optimal control, Riccati equation, l_2 stabilizability, l_∞ stability

1. Introduction.

Underlying a study of a two-dimensional system is often a motivation to improve its dynamical behaviour.

Recently, some authors [1]-[3] concentrated their efforts in two-dimensional state space models stabilization by means of feedback compensators. Their synthesis objective being to obtain a prescribed stable closed-loop characteristic polynomial, the approach they followed is reminiscent of the classical one-dimensional pole placement method. However, the pole placement design usually exhibits a poor control on the short-term system response, since it essentially affects the asymptotic evolution.

In this paper we take a different approach and concentrate our study on design procedures that are based on the minimization of a quadratic cost functional J. The two-dimensional system, which is the end result of this optimal design, is not merely internally stable, but satisfies additional requirements on the state and input evolutions that are summarized by the structure of J.

The class of discrete time two-dimensional systems we will consider has as a prototype the linear model described by the state updating equation [4]

$$(1.1)\quad x(h+1, k+1) = A_1 x(h, k+1) + A_2 x(h+1, k) + B_1 u(h, k+1) + B_2 u(h+1, k)$$

where $x(h, k) \in R^n$ and $u(h, k) \in R^m$ are the local state and the input value at (h, k) and A_1, A_2, B_1, B_2 are real matrices of suitable dimensions.

Assuming that the initial local states $x(i, -i)$ have been assigned, the state dynamics is completely determined by the input function $u(\cdot, \cdot)$. Our prime concern in the next section will be to pose in precise terms the optimum LQ problem for the system above. In fact, if no constraint is imposed on the structure of the infinite set of initial local states we might expect that initial conditions contribute *per se* an infinite value to the corresponding cost functional. It turns out that a satisfactory theory requires us to assume that both the space of allowed initial conditions and the space of input functions are l_2.

Within this framework, a fundamental property is the one that reduces the existence and the uniqueness of two-dimensional optimal control to a pair of rank conditions on two-dimensional polynomial matrices. This result constitutes a nontrivial extension

of the corresponding one-dimensional polynomial criteria based on PBH controllability and reconstructibility matrices.

One further point of contact with the one-dimensional theory is that the optimal control can be expressed in a linear feedback form, so that the resulting closed-loop system is also a linear dynamic system. In this respect, however, a deep difference arises, since one-dimensional optimal control law preserves the original causality structure of the system, while two-dimensional causality is completely lost. This is essentially due to the fact that the optimal control value at (h, k) depends on an infinite number of local states that are not located in the past of (h, k).

The main tool for solving the problem is a special extension of the algebraic Riccati equation, whose coefficients are polynomial matrices in one variable. When the solvability conditions are satisfied, this equation admits a unique stabilizing solution, which induces a feedback matrix analytic in an open neighbourhood of the unit circle.

The analyticity property is extremely important in two respects. First, it allows us to obtain the optimal feedback law using the coefficients of a Laurent series expansion. Second, it naturally calls for an approximation procedure that provides a suboptimal control through the truncation of the above series.

A noteworthy advantage is that this suboptimal control stabilizes the closed-loop system while preserving a weakly causal two-dimensional structure, that recursively generates the feedback input values.

The l_2 approach followed in the paper is mainly motivated by the necessity of guaranteeing that the optimal control problem is a meaningful one. Usually, when dealing with the internal stability of two-dimensional systems, a more general approach is taken into account [5], since an l_∞ constraint is the only requirement imposed on the set of initial conditions. The control law we obtained by solving the l_2 optimal control problem still holds in an l_∞ setting and, interestingly enough, the l_2 stabilizability criterion, based on the rank of a two-dimensional polynomial matrix, provides a necessary and sufficient condition for l_∞ stabilizability also.

2. Problem formulation. Denote by

$$\mathscr{C}_k = \{(i, j): i+j = k\}, \qquad k = 0, 1, 2, \cdots$$

the kth *separation set* in $Z \times Z$. For purposes of future manipulation, it is useful to single out the restrictions of the input function $u(\cdot, \cdot)$ and the state evolution $x(\cdot, \cdot)$ to the separation sets and to consider such restrictions either as bilateral sequences or as Laurent formal power series in one variable. So, the restrictions of $u(\cdot, \cdot)$ and $x(\cdot, \cdot)$ to $\mathscr{C}_k$ will be denoted by the sequences

$$\mathfrak{U}_k := \{u(-i, k+i);\ i \in Z\}, \tag{2.1}$$

$$\mathfrak{X}_k := \{x(-i, k+i);\ i \in Z\}, \tag{2.2}$$

or by the series

$$\mathfrak{U}_k(\xi) := \sum_{i=\infty}^{+\infty} u(-i, k+i)\xi^i, \tag{2.3}$$

$$\mathfrak{X}_i(\xi) := \sum_{i=-\infty}^{+\infty} x(-i, k+i)\xi^i. \tag{2.4}$$

In the following, sequences (2.2) will be called *global states.*

For each initial global state $\mathfrak{X}_0$ on the separation set $\mathscr{C}_0$ and each input function $u(\cdot,\cdot)$, we introduce the quadratic *cost functional*[1]

$$J(u,\mathfrak{X}_0) := \sum_{h+k\geqq 0} [x^T(h,k)Qx(h,k)+u^T(h,k)Ru(h,k)] \tag{2.5}$$

with $R>0$ and $Q\geqq 0$. The optimal control problems we aim to solve are the following:

(i) Given $\mathfrak{X}_0$, derive conditions for the existence and the uniqueness of an input $u(\cdot,\cdot)$ that minimizes the cost J.

(ii) Whenever these conditions are satisfied, explicitly compute the optimal input and the corresponding value of J.

It is apparent from the structure of J that admissible input functions must belong to the space $l_2^{2D}(R^m)$ of R^m-valued functions $u(\cdot,\cdot)$ defined on

$$Z_+^2 := \{(h,k)\in Z\times Z: h+k\geqq 0\} = \bigcup_{k\geqq 0} \mathscr{C}_k$$

and satisfying the finite norm condition

$$\|u(\cdot,\cdot)\|_2^2 := \sum_{h+k\geqq 0} u^T(h,k)u(h,k) < \infty.$$

Furthermore, we are only interested in state dynamics $x(\cdot,\cdot)$ that belong to $l_2^{2D}(R^n)$. Although this condition is not necessary for guaranteeing the finiteness of J in case Q is singular, it fulfills the natural requirement of imposing a stable pattern on the admissible state evolutions. In fact, $x(\cdot,\cdot)\in l_2^{2D}$ implies that the associated global states $\mathfrak{X}_t$ satisfy

$$\|\mathfrak{X}_t\|_2^2 := \sum_{i=-\infty}^{+\infty} x^T(-i,t+i)x(-i,t+i) < \infty, \tag{2.6}$$

$$\sum_{t=0}^{\infty} \|\mathfrak{X}_t\|_2^2 = \|x(\cdot,\cdot)\|_2^2 \tag{2.7}$$

showing that $\|\mathfrak{X}_t\|\to 0$ as $t\to\infty$.

Just putting $t=0$ in (2.6), we argue that the allowable bilateral sequences of initial conditions must belong to $l_2(R^n)$. In this way, the optimization problem we aim to solve is completely couched in an l_2 setting.

It is well known that the infinite time least squares problem for stationary linear one-dimensional dynamical systems may be treated analytically via the algebraic Riccati equation. The questions of the existence and uniqueness of a stabilizing optimal solution, however, can be settled a priori, without explicitly solving the equation. In fact, a necessary and sufficient condition for both properties is that the polynomial matrix

$$[I-Aw \quad Bw] \tag{2.8}$$

has full rank for any w in the closed unit disk and the polynomial matrix

$$\begin{bmatrix} Q \\ I-Aw \end{bmatrix} \tag{2.9}$$

has full rank for any complex w in the unit cirle [6], [7]:

$$\gamma_1 := \{w\in C: |w|=1\}.$$

[1] Throughout the paper, ^{T} means transpose, ^{V} conjugate, and $*$ conjugate transpose.

In two-dimensional optimal control problems, the existence and uniqueness properties of a two-dimensional stabilizing control still reduce to rank conditions on polynomial matrices in two variables and the optimal control law is obtained via an algebraic Riccati equation whose coefficients are polynomial matrices in one variable. A precise statement of the main results is given by Theorem 1.

THEOREM 1. *The following facts are equivalent*:

(1) OS (*optimal solution*). *For each global state* $\mathfrak{X}_0$ *in* $l_2(R^n)$ *there exists an* l_2^{2D} *solution of the optimal control problem, i.e., there exists an input* $u(\cdot,\cdot)$ *in* $l_2^{2D}(R^m)$ *such that* $x(\cdot,\cdot)$ *belongs to* $l_2^{2D}(R^n)$ *and the corresponding value of* J *is minimized.*

(2) RC (*rank conditions*). *The two-dimensional polynomial matrix*

$$[I - A_1 z_1 - A_2 z_2 \quad B_1 z_1 + B_2 z_2] \tag{2.10}$$

has full rank on the set

$$\mathcal{M} = \{(z_1, z_2) \in C \times C : |z_1| = |z_2| \leqq 1\}$$

and the two-dimensional polynomial matrix

$$\begin{bmatrix} Q \\ I - A_1 z_1 - A_2 z_2 \end{bmatrix} \tag{2.11}$$

has full rank on the unit torus

$$\mathcal{T} = \{(z_1, z_2) \in C \times C : |z_1| = |z_2| = 1\}.$$

(3) AREz (*algebraic Riccati equation*). *The following polynomial algebraic Riccati equation*:

$$\begin{aligned} P(z) = Q &+ (A_1^T + A_2^T z^{-1}) P(z)(A_1 + A_2 z) \\ &- (A_1^T + A_2^T z^{-1}) P(z)(B_1 + B_2 z)[R + (B_1^T + B_2^T z^{-1}) P(z)(B_1 + B_2 z)]^{-1} \\ &\times (B_1^T + B_2^T z^{-1}) P(z)(A_1 + A_2 z) \end{aligned} \tag{2.12}$$

in the unknown matrix $P(z)$ *admits a unique solution in an open annulus that includes* γ_1, *with the following properties*:

(i) $P(e^{j\omega}) = P^*(e^{j\omega}) \geqq 0$, *for all* $\omega \in [0, 2\pi]$.

(ii) *The matrix*

$$K(z) := -[R + (B_1^T + B_2^T z^{-1}) P(z)(B_1 + B_2 z)]^{-1} (B_1^T + B_2^T z^{-1}) P(z)(A_1 + A_2 z) \tag{2.13}$$

is analytic in an open annulus that includes γ_1.

(iii) *The matrix*

$$\hat{\Gamma}(\omega) := (A_1 + A_2 e^{j\omega}) + (B_1 + B_2 e^{j\omega}) K(e^{j\omega}) \tag{2.14}$$

is asymptotically stable for all ω *in* $[0, 2\pi]$.

Moreover, whenever the above conditions are fulfilled, the input $u(\cdot,\cdot)$ considered in OS is uniquely determined by the stabilizing feedback law

$$u(h, k) = \sum_{i=-\infty}^{+\infty} K_i x(h + i, k - i) \tag{2.15}$$

where the matrices K_i are the coefficients of the Laurent series expansion

$$K(z) = \sum_{i=-\infty}^{+\infty} K_i z^i. \tag{2.16}$$

The implications OS→RC of the above theorem will be proved in § 3 and the implications RC→AREz→OS in § 4. In § 5 an l_∞ extension of some results will be given, while in § 6 a suboptimal solution is discussed, which seems quite attractive from the implementation point of view.

3. Necessary conditions for l_2 solvability. An obvious necessary solvability condition of the l_2 optimal control problem is that for any initial global state $\mathcal{X}_0$ in l_2, there exists some input $u(\cdot,\cdot)$ in l_2^{2D} that provides an l_2^{2D} state evolution.

Denoting by $\mathcal{V}(\mathcal{X}_0)$ the affine variety of all inputs in l_2^{2D} with this property, the above requirement is formally restated as

$$\mathcal{V}(\mathcal{X}_0) \neq \varnothing \qquad \forall \mathcal{X}_0 \in l_2. \tag{3.1}$$

It is intuitively clear, however, that the existence of input functions inducing finite values in the cost functional does not necessarily imply that the infimum of $J(\mathcal{X}_0,\cdot)$ is effectively attained for some input function in $\mathcal{V}(\mathcal{X}_0)$. So we expect that additional conditions, besides (3.1), must be fulfilled to guarantee the existence of an optimal control in $\mathcal{V}(\mathcal{X}_0)$.

The following theorem shows that in some sense it is meaningful to discuss separately the existence of l_2^{2D} state evolutions and that of optimal controls. Actually, the first problem is connected with the rank of the matrix (2.10), whereas the second depends on the rank of both (2.10) and (2.11).

The results of the theorem that provide necessary conditions for solving these problems will be supplemented by those of § 4, showing that the same conditions are also sufficient. Thus an elegant check is available for the feasibility of two-dimensional optimal control which constitutes a nontrivial extension of the results already available in the one-dimensional case.

THEOREM 2. *If $\mathcal{V}(\mathcal{X}_0) \neq \varnothing$ for all initial global states $\mathcal{X}_0 \in l_2$, the polynomial matrix* (2.10) *has full rank for all (z_1, z_2) in $\mathcal{M}$. If moreover, for each $\mathcal{X}_0 \in l_2$, there exists an input $u_{\text{opt}} \in \mathcal{V}(\mathcal{X}_0)$ such that*

$$J(\mathcal{X}_0, u) \geqq J(\mathcal{X}_0, u_{\text{opt}}) \quad \forall u \in \mathcal{V}(\mathcal{X}_0), \tag{3.2}$$

then the polynomial matrix (2.11) *has full rank for all (z_1, z_2) in $\mathcal{T}$.*

Proof. Suppose that (2.10) is not full rank at $(z_1^0, z_2^0) = (b\, e^{j\vartheta_1^0}, b\, e^{j\vartheta_2^0}) \in \mathcal{M}$.

Then there exists a nonzero vector $v \in C^n$ such that

$$v^T(I - A_1 z_1^0 - A_2 z_2^0) = 0, \qquad v^T(B_1 z_1^0 + B_2 z_2^0) = 0. \tag{3.3}$$

We now introduce the following initial global state $\mathcal{X}_0 \in l_2$:

$$\mathcal{X}_0 := \{x(i,-i) = 0 \quad \text{for } i \neq 0;\ x(0,0) = v\}$$

and suppose that there exists an input $u(\cdot,\cdot) \in l_2^{2D}$ whose corresponding state evolution $x(\cdot,\cdot)$ is in l_2^{2D}. Since $0 < b \leqq 1$, the functions u_b and x_b defined by

$$u_b(h,k) = u(h,k) b^{h+k}, \qquad h+k \geqq 0, \tag{3.4}$$

$$x_b(h,k) = x(h,k) b^{h+k}, \qquad h+k \geqq 0, \tag{3.5}$$

are in l_2^{2D} and x_b represents the state evolution determined by $\mathcal{X}_0$ and u when A_1, A_2, B_1, B_2 in (1.1) are replaced by bA_1, bA_2, bB_1, bB_2. Therefore, taking the double Fourier transforms of u_b and x_b

$$\hat{u}_b(\omega_1,\omega_2) := \sum_{h+k\geqq 0} u_b(h,k)\, e^{-ih\omega_1} e^{-ik\omega_2}, \tag{3.6}$$

$$\hat{x}_b(\omega_1,\omega_2) := \sum_{h+k\geqq 0} x_b(h,k)\, e^{-ih\omega_1} e^{-ik\omega_2}, \tag{3.7}$$

it is easy to prove that

$$v=[I-bA_1\,e^{-j\omega_1}-bA_2\,e^{-j\omega_2}]\hat{x}_b(\omega_1,\omega_2)-[bB_1\,e^{-j\omega_1}+bB_2\,e^{-j\omega_2}]\hat{u}_b(\omega_1,\omega_2) \tag{3.8}$$

holds almost everywhere in $[0,2\pi)\times[0,2\pi)$. Letting

$$a(\omega_1,\omega_2):=\begin{bmatrix}(I-bA_1^T\,e^{j\omega_1}-bA_2^T\,e^{j\omega_2})v\\(-bB_1^T\,e^{j\omega_1}-bB_2^T\,e^{j\omega_2})v\end{bmatrix}, \tag{3.9}$$

premultiplication of (3.8) by v^* gives

$$\|v\|_2^2=\left\langle a(\omega_1,\omega_2),\begin{bmatrix}\hat{u}_b(\omega_1,\omega_2)\\\hat{x}_b(\omega_1,\omega_2)\end{bmatrix}\right\rangle\leqq\|a(\omega_1,\omega_2)\|_2\cdot\left\|\begin{bmatrix}\hat{u}(\omega_1,\omega_2)\\\hat{x}(\omega_1,\omega_2)\end{bmatrix}\right\|_2$$

which in turn implies that

$$\|\hat{u}_b(\omega_1,\omega_2)\|_2^2+\|\hat{x}_b(\omega_1,\omega_2)\|_2^2\geqq\|v\|_2^4/\|a(\omega_1,\omega_2)\|_2^2. \tag{3.10}$$

Since $a(\vartheta_1^0,\vartheta_2^0)=0$, it is easy to obtain a quadratic upper bound of the following form:

$$\|a(\omega_1,\omega_2)\|_2^2\leqq M[(\omega_1-\vartheta_1^0)^2+(\omega_2-\vartheta_2^0)^2]$$

and inequality (3.10) can be replaced by

$$\|\hat{u}_b(\omega_1,\omega_2)\|_2^2+\|\hat{x}_b(\omega_1,\omega_2)\|_2^2\geqq\|v\|_2^4/M[(\omega_1-\vartheta_1^0)^2+(\omega_2-\vartheta_2^0)^2]. \tag{3.11}$$

The right-hand side of the above inequality being not summable on $[0,2\pi)\times[0,2\pi)$, we have that the same is a fortiori true for the left-hand side. This contradicts the original assumption that $u_b(\cdot,\cdot)$ and $x_b(\cdot,\cdot)$ were l_2^{2D} functions. In fact that assumption implied, by Parseval's Theorem, the summability of both $\hat{u}_b$ and $\hat{x}_b$ on $[0,2\pi)\times[0,2\pi)$.

Note that in the above proof a complex valued global state $\mathfrak{X}_0$ was considered. However the conclusion of the theorem is correct even when only real global states are allowed: we have just to analyze the dynamics that correspond to the real or imaginary part of $\mathfrak{X}_0$.

The proof of the second part of the theorem is quite long and will be omitted for sake of brevity. It may be found in [8]. □

4. A Riccati equation for two-dimensional systems. It is very well known that the algebraic Riccati equation plays a crucial role in the solution of one-dimensional optimal control problems. In this section we will derive a Riccati equation for two-dimensional systems that provides a closed-loop optimal solution to the problem of minimizing the quadratic cost functional J defined in (2.5).

As a matter of fact, the actual evaluation of the minimum cost and the explicit computation of the optimal input function lead us to study the existence of a particular solution of the Riccati equation, which we characterize in terms of positive definiteness and analyticity.

Let us first start with a preliminary analysis of the open-loop system dynamics in terms of Fourier transforms. We assume that $\mathfrak{X}_0$ and $\mathfrak{U}_t$ belong to l_2. Then, by equation (1.1) all global states $\mathfrak{X}_t$, $t=1,2,\cdots$ are in l_2 and the Fourier transforms

$$\begin{aligned}\hat{\mathfrak{U}}_1(\omega)&=\sum_{h=-\infty}^{+\infty}u(t+h,-h)\,e^{-ih\omega},\\ \hat{\mathfrak{X}}_t(\omega)&=\sum_{h=-\infty}^{+\infty}x(t+h,-h)\,e^{-ih\omega}\end{aligned} \tag{4.1}$$

have components in $L_2[0, 2\pi]$. Letting

$$\hat{A}(\omega) = A_1 + e^{j\omega}A_2, \qquad \hat{B}(\omega) = B_t + e^{j\omega}B_2,$$

equation (1.1) can be rewritten as a first-order recursive equation

$$\hat{\mathfrak{X}}_{t+1}(\omega) = \hat{A}(\omega)\hat{\mathfrak{X}}_t(\omega) + \hat{B}(\omega)\hat{\mathfrak{U}}_t(\omega), \tag{4.2}$$

whereas Parseval's and Beppo Levi's Theorems allow us to express the cost functional in the following form:

$$\begin{aligned} J &= \sum_{t=0}^{\infty} (2\pi)^{-1} \int_0^{2\pi} \mathfrak{X}_t^*(\omega) Q \hat{\mathfrak{X}}_t(\omega) + \hat{\mathfrak{U}}_t^*(\omega) R \hat{\mathfrak{U}}_t(\omega)\, d\omega \\ &= (2\pi)^{-1} \int_0^{2\pi} \sum_{t=0}^{\infty} [\hat{\mathfrak{U}}_t^*(\omega) \quad \hat{\mathfrak{X}}_t^*(\omega)] \begin{bmatrix} R & 0 \\ 0 & Q \end{bmatrix} \begin{bmatrix} \hat{\mathfrak{U}}_t(\omega) \\ \hat{\mathfrak{X}}_t(\omega) \end{bmatrix} d\omega. \end{aligned} \tag{4.3}$$

Suppose that the l_2^{2D} norms of the input function $u(\cdot, \cdot)$ and of the state dynamics $x(\cdot, \cdot)$ are both finite, i.e.,

$$\begin{aligned} \|u(\cdot, \cdot)\|_2^2 &= (2\pi)^{-1} \int_0^{2\pi} \sum_{t=0}^{\infty} \hat{\mathfrak{U}}_t^*(\omega) \hat{\mathfrak{U}}_t(\omega)\, d\omega < \infty, \\ \|x(\cdot, \cdot)\|_2^2 &= (2\pi)^{-1} \int_0^{2\pi} \sum_{t=0}^{\infty} \hat{\mathfrak{X}}_t^*(\omega) \hat{\mathfrak{X}}_t(\omega)\, d\omega < \infty. \end{aligned} \tag{4.4}$$

Then, for every Hermitian matrix $\hat{P}(\omega) = \hat{P}^*(\omega)$ with elements in $L_\infty[0, 2\pi]$, we obtain the following identity:

(4.5)

$$\begin{aligned} 0 &= \hat{\mathfrak{X}}_0^*(\omega)\hat{P}(\omega)\hat{\mathfrak{X}}_0(\omega) - \sum_{t=0}^{\infty} \hat{\mathfrak{X}}_t^*(\omega)\hat{P}(\omega)\hat{\mathfrak{X}}_t(\omega) \\ &\quad + \sum_{t=0}^{\infty} [\hat{\mathfrak{U}}_t^*(\omega)\hat{B}^*(\omega) + \hat{\mathfrak{X}}_t^*(\omega)\hat{A}^*(\omega)]\hat{P}(\omega)[\hat{A}(\omega)\hat{\mathfrak{X}}_t(\omega) + \hat{B}(\omega)\hat{\mathfrak{U}}_t(\omega)] \\ &= \hat{\mathfrak{X}}_0^*(\omega)\hat{P}(\omega)\hat{\mathfrak{X}}_0(\omega) \\ &\quad + \sum_{t=0}^{\infty} [\hat{\mathfrak{U}}_t^*(\omega)\hat{\mathfrak{X}}_t^*(\omega)] \begin{bmatrix} \hat{B}^*(\omega)\hat{P}(\omega)\hat{B}(\omega) & \hat{B}^*(\omega)\hat{P}(\omega)\hat{A}(\omega) \\ \hat{A}^*(\omega)\hat{P}(\omega)\hat{B}(\omega) & \hat{A}^*(\omega)\hat{P}(\omega)\hat{A}(\omega) - \hat{P}(\omega) \end{bmatrix} \begin{bmatrix} \hat{\mathfrak{U}}_t(\omega) \\ \hat{\mathfrak{X}}_t(\omega) \end{bmatrix}. \end{aligned}$$

Integrating (4.5) between zero and 2π and adding the resulting identity to J, we obtain

$$\begin{aligned} J &= (2\pi)^{-1} \int_0^{2\pi} \hat{\mathfrak{X}}_0^*(\omega)\hat{P}(\omega)\hat{\mathfrak{X}}_0(\omega)\, d\omega \\ &\quad + (2\pi)^{-1} \int_0^{2\pi} \sum_{t=0}^{\infty} [\hat{\mathfrak{s}}_t^*(\omega) \quad \hat{\mathfrak{X}}_t^*(\omega)] \\ &\qquad \times \begin{bmatrix} R + \hat{B}^*(\omega)\hat{P}(\omega)\hat{B}(\omega) & 0 \\ 0 & \hat{E}(\omega) \end{bmatrix} \begin{bmatrix} \hat{\mathfrak{s}}_t(\omega) \\ \hat{\mathfrak{X}}_t(\omega) \end{bmatrix} \end{aligned} \tag{4.6}$$

where

$$\hat{K}(\omega) := -[R + \hat{B}^*(\omega)\hat{P}(\omega)\hat{B}(\omega)]^{-1}\hat{B}^*(\omega)\hat{P}(\omega)\hat{A}(\omega), \tag{4.7}$$

$$\hat{\mathfrak{s}}_t(\omega) := \hat{\mathfrak{U}}_t(\omega) - \hat{K}(\omega)\hat{\mathfrak{X}}_t(\omega), \tag{4.8}$$

$$\begin{aligned} \hat{E}(\omega) &= -\hat{P}(\omega) + Q + \hat{A}^*(\omega)\hat{P}(\omega)\hat{A}(\omega) - \hat{A}^*(\omega)\hat{P}(\omega)\hat{B}(\omega) \\ &\quad \times [R + \hat{B}^*(\omega)\hat{P}(\omega)\hat{B}(\omega)]^{-1}\hat{B}^*(\omega)\hat{P}(\omega)\hat{A}(\omega). \end{aligned} \tag{4.9}$$

Clearly, if we are able to choose $\hat{P}(\omega)$ in such a way that $\hat{E}(\omega)$ is zero almost everywhere in $[0, 2\pi]$, then (4.6) reduces to

$$J = (2\pi)^{-1} \int_0^{2\pi} \hat{\mathfrak{X}}_0^*(\omega)\hat{P}(\omega)\hat{\mathfrak{X}}_0(\omega)\, d\omega + (2\pi)^{-1} \int_0^{2\pi} \sum_{t=0}^{\infty} \hat{\mathfrak{s}}_t^*(\omega) \times [R + \hat{B}^*(\omega)\hat{P}(\omega)\hat{B}(\omega)]\hat{\mathfrak{s}}_t(\omega)\, d\omega$$

and the minimum value of J

$$J_{\min} = (2\pi)^{-1} \int_0^{2\pi} \hat{\mathfrak{X}}_0^*(\omega)\hat{P}(\omega)\hat{\mathfrak{X}}_0(\omega)\, d\omega \tag{4.10}$$

is attained using the closed-loop control given by

$$\hat{\mathfrak{U}}_t(\omega) = \hat{K}(\omega)\hat{\mathfrak{X}}_t(\omega). \tag{4.11}$$

The conclusion we have drawn so far depicts the situation in a way that may convince us of the intuitive reasonableness of the result. However, some caveats are in order, since the validity of the procedure depends heavily on the existence of $\hat{P}(\omega)$ and on the fact that both the input and the state dynamics given by (4.11) and (4.2) belong to l_2^{2D}.

More precisely, the solution of the optimal control problem outlined above makes sense if we are able to give a positive answer to the following questions:

(i) Is there any solution $\hat{P}(\omega) = \hat{P}^*(\omega)$ of the equation $\hat{E}(\omega) = 0$, i.e., of the ω-dependent Riccati equation (AREω)

$$\hat{P}(\omega) = Q + \hat{A}^*(\omega)\hat{P}(\omega)\hat{A}(\omega) - \hat{A}^*(\omega)\hat{P}(\omega)\hat{B}(\omega) \times [R + \hat{B}^*(\omega)\hat{P}(\omega)\hat{B}(\omega)]^{-1}\hat{B}^*(\omega)\hat{P}(\omega)\hat{A}(\omega)?$$

(ii) Among these solutions, is there any solution $\hat{P}(\omega)$ that provides, through (4.7), a feedback matrix $\hat{K}(\omega)$ mapping $L_2[0, 2\pi]$ into $L_2[0, 2\pi]$? This requirement is necessary for guaranteeing that the feedback law (4.11) (reinterpreted in the time domain) always transforms an l_2 global state $\mathfrak{X}_t$ into an l_2 input sequence $\mathfrak{U}_t$.

(iii) In particular, does (AREω) possess any (Hermitian) solution that ensures asymptotic stability of the closed-loop system, in the sense that, for any $\mathfrak{X}_0 \in \mathrm{l}_2$, the resulting global states sequence $\{\mathfrak{X}_t\}$ can be viewed as an element of l_2^{2D}? Note that this condition is needed in order to have a feedback input (4.11) that belongs to $\mathscr{V}(\mathfrak{X}_0)$.

For every fixed ω in $[0, 2\pi]$, (AREω) is the algebraic Riccati equation of a one-dimensional system over the complex field. So, if the rank conditions of Theorem 1 are fulfilled, for each ω in $[0, 2\pi]$ the equation has a unique positive semidefinite solution $\hat{P}(\omega) = \hat{P}^*(\omega)$, that makes the one-dimensional closed-loop system matrix

$$\hat{\Gamma}(\omega) = \hat{A}(\omega) + \hat{B}(\omega)\hat{K}(\omega) \tag{4.12}$$

asymptotically stable [7].

Clearly $P(\omega)$, viewed as a matrix function of ω, satisfies the first question we raised above. Actually, it provides a solution that also satisfies questions (ii) and (iii). However showing this property deserves an accurate investigation of the analytic structure of $\hat{P}(\omega)$. A first result in this direction is provided by Theorem 3, which shows that the map

$$P: \gamma_1 \to C^{n\times n}: e^{j\omega} \to \hat{P}(\omega) \tag{4.13}$$

admits an analytic extension to a suitable open annulus including γ_1, and the extension $P(z)$ satisfies (2.12).

THEOREM 3. *Assume that the matrices* (2.10) *and* (2.11) *are full rank for any* (z_1, z_2) *in* $\mathcal{M}$ *and in* $\mathcal{T}$, *respectively. Then the equation* (2.12) *admits a* (*unique*) *solution* $P(z)$ *that fulfills the following conditions*:

(i) $P(z)$ *is analytic in an open annulus that includes the unit circle* γ_1.

(ii) *For all* ω *in* $[0, 2\pi]$, $P(e^{j\omega})$ *coincides with the unique Hermitian positive-semidefinite stabilizing solution* $\hat{P}(\omega)$ *of* (AREω).

For the proof, see the Appendix.

To completely answer questions (ii) and (iii), we need to discuss certain important properties of the solution $P(z)$ obtained in Theorem 3 that shed some light on the structure of the optimal feedback law and on its stabilizing character.

(1) Because of the analytic nature of $P(z)$, there exists a Laurent series expansion

$$P(z) = \sum_{h=-\infty}^{+\infty} P_h z^h \tag{4.14}$$

that converges in an open annulus including γ_1. The coefficients P_h of (4.14) are real matrices that satisfy the conditions

$$P_h = P_{-h}^T, \qquad h = 0, 1, 2, \cdots. \tag{4.15}$$

The proof of this property depends on the following lemma.

LEMMA 1. *Let* $P(z)$ *be the solution of* (AREz) *considered in Theorem* 3. *Then*

$$P(z) = P^T(z^{-1})$$

in a suitable open annulus that includes γ_1.

Proof. For all $\omega \in [0, 2\pi]$, the matrix $P(e^{j\omega}) = \hat{P}(\omega)$ is a solution of (AREω). On the other hand, taking the transpose of both sides of (AREω) and substituting ω with $-\omega$ we check easily that $P^T(e^{-j\omega})$ is still a solution of (AREω). So $P(e^{j\omega})$ and $P^T(e^{-j\omega})$ are both Hermitian positive-semidefinite solutions of (AREω) for any ω in $[0, 2\pi]$. Because of the uniqueness of the stabilizing solution, proving that these solutions coincide reduces to show that the matrix

$$\hat{A}(\omega) - \hat{B}(\omega)[R + \hat{B}^*(\omega)P^T(^{-j\omega})\hat{B}(\omega)]^{-1}\hat{B}^*(\omega)P^T(e^{-j\omega})\hat{A}(\omega) \tag{4.16}$$

is asymptotically stable for any ω in $[0, 2\pi]$. This is again obvious, since the conjugate of (4.16) is $\hat{\Gamma}(-\omega)$, which is asymptotically stable by hypothesis.

Thus $P(z)$ and $P^T(z^{-1})$ are analytical in an open annulus that includes γ_1 and assume the same values on γ_1. By the identity principle of analytic functions, this implies $P(z) = P^T(z^{-1})$ for any z in the annulus. □

We therefore have (4.15), as an immediate consequence of the lemma. Moreover, in (4.14) the Hermiticity of $P(e^{j\omega})$ gives $P_h = P_{-h}^*$, $h = 0, 1, 2, \cdots$.

The above equalities and (4.15) imply $P_{-h}^* = P_{-h}^T$, which proves the realness of all matrices P_h.

(2) The coefficients P_h in the expansion of $P(z)$ decay exponentially as $|h|$ increases, i.e., there exist $M > 0$ and $\lambda \in (0, 1)$ such that

$$\|P_h\| < M\lambda^{|h|}, \qquad h \in Z. \tag{4.17}$$

(3) Since $P(e^{j\omega})$ is positive semidefinite for any ω in $[0, 2\pi]$,

$$R + (B_1^T + B_2^T z^{-1})P(z)(B_1 + B_2 z)$$

is invertible for every $z \in \gamma_1$ and, by a continuity argument, for every z in an open annulus that includes γ_1. Hence the matrix

$$K(z) = -[R + (B_1^T + B_2^T z^{-1})P(z)(B_1 + B_2 z)]^{-1}(B_1^T + B_2^T z^{-1})P(z)(A_1 + A_2 z)$$

extends analytically $\hat{K}(\omega)$ in the annulus and therefore admits a Laurent power series expansion

$$K(z) = \sum_{h=-\infty}^{\infty} K_h z^h. \tag{4.18}$$

Clearly, the feedback law (4.11) is well defined, since it associates an input $\hat{\mathfrak{U}}_t(\omega) \in L_2[0, 2\pi]$ to every global state $\hat{\mathfrak{X}}_t(\omega) \in L_2[0, 2\pi]$. This provides a positive answer to question (ii).

We conclude at once from these properties that the state dynamics $x(\cdot, \cdot)$ and the corresponding input function $u(\cdot, \cdot)$ are, for any initial global state $\mathfrak{X}_0$ in $\mathfrak{l}_2$, elements of $\mathfrak{l}_2^{2D}$, which is all we need to answer question (iii). Actually, the Lyapunov equation

$$\hat{V}(\omega) = I + \hat{\Gamma}^*(\omega)\hat{V}(\omega)\hat{\Gamma}(\omega) \tag{4.19}$$

admits a unique positive-definite solution, given by the sum of the following pointwise convergent series:

$$\hat{V}(\omega) = \sum_{h=0}^{\infty} \hat{\Gamma}^*(\omega)^h \hat{\Gamma}(\omega)^h.$$

Furthermore, the linearity of (4.19) and the uniqueness of its solution for every ω in $[0, 2\pi]$ imply that the matrix $\hat{V}(\omega)$ is a continuous function of ω and hence its spectral radius $\rho(\omega)$ is uniformly bounded by some positive ρ.

Combining all these properties and applying Beppo Levi's and Parseval's Theorems, we obtain

$$\|x(\cdot, \cdot)\|_2^2 = \sum_{t=0}^{\infty} \|\mathfrak{X}_t\|_2^2 = (2\pi)^{-1} \sum_{t=0}^{\infty} \int_0^{2\pi} \hat{\mathfrak{X}}_0^*(\omega)\hat{\Gamma}^*(\omega)^t \hat{\Gamma}(\omega)^t \hat{\mathfrak{X}}_0(\omega)\, d\omega$$

$$= (2\pi)^{-1} \int_0^{2\pi} \mathfrak{X}_0^*(\omega)\hat{V}(\omega)\mathfrak{X}_0(\omega)\, d\omega \leqq \rho \|\mathfrak{X}_0\|_2^2.$$

So $x(\cdot, \cdot)$ and, obviously, $u(\cdot, \cdot)$ belong to $\mathfrak{l}_2^{2D}$.

Tying together the results of Theorem 3 and its consequences, discussed at points (1)-(3), we have that the implications RC $\rightarrow$ ARE $\rightarrow$ OS in Theorem 1 are completely proved.

To conclude this section, we wish to investigate some important consequences of the time domain structure of the optimal control law

$$u(h, k) = \sum_{i=-\infty}^{+\infty} K_i x(h+i, k-i). \tag{4.20}$$

Clearly the input value at (h, k) linearly depends on the whole sequence of local states on the separation set including (h, k). So, the quarter plane causality is completely lost in the closed-loop system.

As the coefficients K_i decay to zero exponentially, it is reasonable to expect that a suboptimal control law could be achieved by truncating the infinite series (4.18) and hence by using a finite number of local states in the feedback law (4.20). This will be discussed in detail in the sequel. Here we only remark that the input (4.20) actually minimizes the cost functional, whose value is given by

$$
\begin{aligned}
J_{\min}(\mathfrak{X}_0) &= (2\pi)^{-1} \int_0^{2\pi} \hat{\mathfrak{X}}_0^*(\omega)\hat{P}(\omega)\hat{\mathfrak{X}}_0(\omega)\, d\omega \\
&= \sum_{h,k=-\infty}^{+\infty} x^T(h,-h)P_{h-k}x(k,-k) \\
&= [\cdots x^T(1,-1)x^T(0,0)x^T(-1,1)\cdots] \\
&\qquad \begin{bmatrix} \ddots & \ddots & \ddots & \\ \ddots P_0 & P_1 & P_2 \ddots & \\ \ddots P_{-1} & P_0 & P_1 \ddots & \\ \ddots P_{-2} & P_{-1} & P_0 & \\ & \ddots & \ddots & \ddots \end{bmatrix} \begin{bmatrix} \vdots \\ x(1,-1) \\ x(0,0) \\ x(-1,1) \\ \vdots \end{bmatrix}.
\end{aligned} \tag{4.21}
$$

Remark. In case the system is autonomous (i.e., $B_1 = B_2 = 0$), the stabilizability condition (2.10) reduces to

$$\det(I - A_1 z_1 - A_2 z_2) \neq 0 \tag{4.22}$$

for $|z_1| = |z_2| \leqq 1$ or, equivalently, to the internal stability of the one-dimensional matrices $A_1 + A_2 e^{j\omega}$ for all ω in $[0, 2\pi]$. Note that the stability of $A_1 + A_2 e^{j\omega}$ for all ω is equivalent to two-dimensional internal stability [5] and hence to $\det(I - A_1 z_1 - A_2 z_2) \neq 0$ in the unit closed polydisk $\mathscr{P}_1 = \{(z_1, z_2): |z_1| \leqq 1, |z_2| \leqq 1\}$.

Under the same hypothesis, (AREω) reduces to the ω-independent Lyapunov equation for two-dimensional systems and (4.21) gives the Lyapunov function associated with its free dynamical evolution [5].

5. l_∞ stabilization. The feedback law (4.20) we obtained in the previous section, using an l_2 spaces approach, is well defined even when the initial global state $\mathfrak{X}_0$ belongs to an l_∞ space

$$\|\mathfrak{X}_0\|_\infty := \sup_{h \in Z} \|x(h,-h)\|_2 < \infty. \tag{5.1}$$

Actually, the exponential decay of the matrix sequence $\{K_i\}$ as $i \to \pm\infty$ implies that (4.20) converges for all bounded sequences of local states, which shows that $\mathfrak{U}_t$ and $\mathfrak{X}_t$ are in l_∞ for any $t \geqq 0$. Now it seems quite natural to ask whether the closed-loop asymptotic stability (4.20) realized in the l_2 case is preserved when l_∞ initial global states are allowed.

Here asymptotic stability means that $x(h,k)$ converges to zero uniformly as $h + k \to \infty$.

We first note that there exist positive constants M and λ, $0 < \lambda < 1$, such that

$$\|\hat{\Gamma}^t(\omega)\|_2 < M\lambda^t, \qquad t = 0, 1, 2, \cdots$$

for any ω in $[0, 2\pi]$ (for a proof, see Theorem 5 in the Appendix). Let us assume that all local states of $\mathfrak{X}_0$ are zero except for a single local state x. Then we have

$$\|\mathfrak{X}_t\|_\infty \leqq \|\mathfrak{X}_t\|_2 < M\lambda^t \|x\|_2. \tag{5.2}$$

In case $\mathfrak{X}_0$ is an arbitrary l_∞ sequence, any local $x(h, t-h) \in \mathfrak{X}_t$ is the superposition of $t+1$ contributions determined by the initial local states $x(h,-h)$, $x(h-1,-h+1), \cdots, x(h-t,-h+t)$. Consequently,

$$\|\mathfrak{X}_t\|_\infty = \sup_{h \in Z} \|x(h,-h+t)\|_2 < (t+1)M\lambda^t \|\mathfrak{X}_0\|_\infty \tag{5.3}$$

shows that the global states converge uniformly to zero.

Note that the above discussion implies that an l_∞ stabilizing control does exist as soon as matrix (2.10) is full rank on $\mathcal{M}$. In fact, assuming $Q = I_n$ in the cost functional, an l_2 optimal feedback law is computable through the solution of (2.12) and, as the above discussion shows, the same law provides an l_∞ stabilizing control.

It turns out that the rank condition on (2.10) is not only sufficient but also necessary for the existence of l_∞ input functions that drive any initial global state $\mathfrak{X}_0 \in l_\infty$ uniformly to zero. This is proved in the following theorem.

THEOREM 4. *Assume that the matrix* $[I - A_1 z_1 - A_2 z_2 \;\; B_1 z_1 + B_2 z_2]$ *is not full rank for some* $(z_1^0, z_2^0) \in \mathcal{M}$. *Then there exists an initial global state* $\mathfrak{X}_0 \in l_\infty$, *with* $\|\mathfrak{X}_0\|_\infty = 1$, *having the following property. For any sequence* $\{\mathfrak{U}_t\}$ *with elements in* l_∞, *the corresponding sequence of global states* $\{\mathfrak{X}_t\}$ *satisfies*

$$\|\mathfrak{X}_t\|_\infty \geqq 1, \qquad t = 1, 2, \cdots. \tag{5.4}$$

Proof. Let $(z_1^0, z_2^0) = (\rho e^{j\vartheta_1}, \rho e^{j\vartheta_2})$, $0 < \rho \leqq 1$ and define

$$\mu := e^{j(\vartheta_2 - \vartheta_1)}, \quad F := A_1 + \mu A_2, \quad G := B_1 + \mu B_2.$$

Since the one-dimensional polynomial matrix $[I - Fz \;\; G]$ is not full rank at $z = \rho e^{j\vartheta_1}$, the one-dimensional system (F, G) is not stabilizable. This implies that, modulo a change of basis in the state space, the matrices F and G have the following block structure:

$$F = \begin{bmatrix} F_{11} & F_{12} \\ 0 & F_{22} \end{bmatrix}, \qquad G = \begin{bmatrix} G_1 \\ 0 \end{bmatrix}$$

and the spectrum of F_{22} includes the eigenvalue $\gamma = \rho^{-1} e^{-j\vartheta_1}$.

Referring the local state space of the original two-dimensional system to the same basis and partitioning its matrices conformably with the partition of F and G

$$A_i = \begin{bmatrix} A_{11}^{(i)} & A_{12}^{(i)} \\ A_{21}^{(i)} & A_{22}^{(i)} \end{bmatrix}, \quad B_i = \begin{bmatrix} B_1^{(i)} \\ B_2^{(i)} \end{bmatrix}, \quad i = 1, 2,$$

we have

$$A_{21}^{(1)} + \mu A_{21}^{(2)} = 0, \qquad B_2^{(1)} + \mu B_2^{(2)} = 0. \tag{5.5}$$

An easy inductive argument shows that the polynomial matrices $(A_1 + A_2\xi)^r$ and $(A_1 + A_2\xi)^{r-1}(B_1 + B_2\xi)$, $r = 1, 2, \cdots$ have the following form:

$$(A_i + A_2\xi)^r = \begin{bmatrix} (*) & (*) \\ M_{21}^{(r)}(\xi)(\xi - \mu) & M_{22}^{(r)}(\xi)(\xi - \mu) + F_{22}^r \end{bmatrix}, \tag{5.6}$$

$$(A_1 + A_2\xi)^{r-1}(B_1 + B_2\xi) = \begin{bmatrix} (*) \\ N_{r-1}(\xi)(\xi - \mu) \end{bmatrix} \tag{5.7}$$

where $M_{21}^{(r)}(\xi)$, $M_{22}^{(r)}(\xi)$, $N_{r-1}(\xi)$, and $(*)$ denote polynomial matrices with elements in $C[\xi]$.

We now introduce the r-steps reachability matrix

$$\mathcal{R}_r = [(B_1 + B_2\xi) \;\; (A_1 + A_2\xi)(B_1 + B_2\xi) \cdots (A_1 + A_2\xi)^{r-1}(B_1 + B_2\xi)]. \tag{5.8}$$

Then the global state $\mathfrak{X}_r(\xi)$ that corresponds to an initial global state $\mathfrak{X}_0(\xi)$, and to inputs $\mathfrak{U}_0(\xi), \mathfrak{U}_1(\xi) \cdots \mathfrak{U}_{r-1}(\xi)$, is expressed as [9]

$$\mathfrak{X}_r(\xi) = (A_1 + A_2\xi)^r \mathfrak{X}_0(\xi) + \mathcal{R}_r(\xi) \begin{bmatrix} \mathfrak{U}_{r-1}(\xi) \\ \vdots \\ \mathfrak{U}_0(\xi) \end{bmatrix}. \tag{5.9}$$

Using (5.7), we rewrite the reachability matrix as

$$\mathscr{R}_r(\xi)=\begin{bmatrix} I & 0 \\ 0 & (\xi-\mu)I \end{bmatrix}\begin{bmatrix} (*) & (*) & (*) \\ N_0(\xi) & N_1(\xi)\cdots N_{r-1}(\xi) \end{bmatrix},$$

which shows that the forced state evolution in (5.9) has the following structure:

$$\begin{bmatrix} (*) \\ (\xi-\mu)\sum_{i=0}^{r-1} N_i(\xi)\mathfrak{U}_{r-1-i}(\xi) \end{bmatrix} := \begin{bmatrix} (*) \\ (\xi-\mu)q(\xi) \end{bmatrix}. \tag{5.10}$$

To satisfy (5.4), we introduce an initial global state

$$\mathfrak{X}_0(\xi)=\begin{bmatrix} 0 \\ v \end{bmatrix}\sum_{h=-\infty}^{+\infty}\mu^{-h}\xi^h \tag{5.11}$$

where v is a unitary eigenvector of F_{22} associated to the eigenvalue γ. Since $\mathfrak{X}_0(\xi)(\xi-\mu)=0$, it is easy to see that the corresponding free state evolution in (5.9) is

$$(A_1+A_2\xi)^r\mathfrak{X}_0(\xi)=\gamma^r\mathfrak{X}_0(\xi)+\begin{bmatrix} (*) \\ 0 \end{bmatrix}. \tag{5.12}$$

Here (*) denotes some arbitrary bilateral formal power series.

Since $\mathfrak{U}_0(\xi)$, $\mathfrak{U}_1(\xi)\cdots\mathfrak{U}_{r-1}(\xi)$ are bounded (i.e., $\|\mathfrak{U}_i\|_\infty<\infty$, $i=0,1,\cdots,r-1$), $\mathfrak{X}_r(\xi)$ is also bounded. So, we combine (5.10) and (5.12) and get the inequality

$$\begin{aligned}\|\mathfrak{X}_r(\xi)\|_\infty &= \left\|\begin{bmatrix} [*] \\ \gamma^r v\sum_k \mu^{-k}\xi^k+(\xi-\mu)q(\xi) \end{bmatrix}\right\|_\infty \\ &\geqq \|\gamma^r v\textstyle\sum_k \mu^{-k}\xi^k+(\xi-\mu)q(\xi)\|_\infty.\end{aligned} \tag{5.13}$$

One additional consequence of the boundedness of $\mathfrak{U}_i(\xi)$ is that the series $q(\xi)=\sum_k q_k\xi^k$ we introduced in (5.10) is l_∞ and therefore there exists a positive M such that $\|q_k\|<M$ for all k in Z.

Now consider in (5.13) the coefficients of the series

$$\gamma^r v\sum_{k=-\infty}^{+\infty}\mu^{-k}\xi^k+(\xi-\mu)q(\xi):=\sum_{k=-\infty}^{+\infty}g_k\xi^k.$$

It is immediate that $\mu^k g_k=v\gamma^r+\mu^k q_{k-1}-\mu^{k+1}q_k$, and summing over k yields

$$\sum_{k=0}^{N-1}g_k\mu^k=Nv\gamma^r+q_{-1}-\mu^N q_{N-1} \tag{5.14}$$

where N is an arbitrary positive integer. We therefore have

$$\begin{aligned}\|\mathfrak{X}_r(\xi)\|_\infty &\geqq \sup_{k\in Z}\|g_k\|\geqq\left(\frac{1}{N}\right)[\|g_0\|+\|g_1\|+\cdots\|g_{N-1}\|] \\ &=\left(\frac{1}{N}\right)[\|g_0\|+\|\mu g_1\|+\cdots\|\mu^{N-1}g_{N-1}\|] \\ &\geqq\left(\frac{1}{N}\right)\left\|\sum_{k=0}^{N-1}g_k\mu^k\right\|\geqq\rho^{-r}\|v\|-N^{-1}\|q_{-1}+\mu^N q_{N-1}\|\geqq\rho^{-r}-\frac{2M}{N}\end{aligned} \tag{5.15}$$

and since $N\geqq 1$ was arbitrary, $\|\mathfrak{X}_r(\xi)\|_\infty\geqq\rho^{-r}\geqq 1$. This shows that (5.4) holds independently of the choice of the inputs $\mathfrak{U}_i$ in l_∞.

By the argument used in the conclusion of Theorem 2, the statement of the theorem is correct even when only real global states are allowed. □

Remark 1. When dealing with globally reachable two-dimensional systems, i.e., systems whose reachability matrix $\mathcal{R}_n(\xi)$ is right invertible in $R(\xi)$, it has been proved in [9] that every initial global state $\mathfrak{X}_0$ can be driven to zero in a finite number of steps, irrespective of the rank condition of Theorem 4. Actually this does not involve a contradiction, since the finite-time control considered in [9] was not restricted to use only l_∞ inputs. For instance, assuming in (1.1) $A_1 = A_2 = 1$, $B_1 = -B_2 = 1$ gives a globally reachable two-dimensional system whose PBH matrix (2.10) is zero at $(z_1^0, z_2^0) = (1, 1) \in \mathcal{M}$. The global state

$$\mathfrak{X}_0(\xi) = \sum_{-\infty}^{+\infty}{}_k \xi^k$$

is controlled to zero in one step by the unbounded input

$$\mathfrak{U}_0(\xi) = -\sum_{-\infty}^{+\infty}{}_k k\xi^k.$$

Remark 2. A sufficient stabilizability condition based on the rank of (2.10) has been proved in [10] using different techniques and referring to dynamical models where the local state at (h, k) linearly depends on all local states and input values of the separation set $\mathcal{C}_{h+k-1}$.

In Kamen's paper, however, stabilizability means by definition the existence of a stabilizing state feedback, whereas the stabilizability definition considered in the present paper is essentially open loop. Actually, no a priori hypothesis has been assumed here on the way the stabilizing input functions could be generated, and the possibility of implementing the stabilizing control by a state feedback law is a theorem rather than an assumption.

The major consequence of this approach is that open-loop stabilizability, closed-loop stabilizability, and the full rank of (2.10) on $\mathcal{M}$ are equivalent properties.

6. Weakly causal suboptimal feedback. The control law (4.20), we obtained through the solution of (AREz), provides a state feedback that stabilizes (1.1) both in the l_2 and in the l_∞ settings.

Although this approach is conceptually appealing, the difficulties when no approximation is used can be very great. We already noted that, in general, the input value at (h, k) depends on the (infinitely many) local states $x(h-i, k+i)$, $i \in Z$. So, implementing (4.20) completely destroys the quarter plane causality of the original system and produces a half plane causal two-dimensional system, whose updating equation is required in principle to cope with an infinite-dimensional state vector. Moreover, to determine the solution of (2.12) is by no means a trivial task. In particular, a difficult problem that has no one-dimensional counterpart is that of obtaining the analytic structure of the feedback matrix $K(z)$ and computing the coefficients K_i that provide, in the time domain, the optimal feedback law.

We will give here two examples. The first shows how the solvability conditions based on the rank of (2.10) and (2.11) reflect into the analytic structure of $\hat{P}(\omega)$. The second gives an idea of some difficulties involved in the computation of K_is even in dimension one.

Example 1. Assume as in (1.1) $m = n = 1$ and $A_1 = B_1 = B_2 = 1$ and $A_2 = -1$. Furthermore, let $R = Q = 1$ be the weighting matrices of J.

In this case the solution of AREz can be obtained in closed form as

$$P(z) = \frac{1 \pm \sqrt{5 + 2z + 2z^{-1}}}{2(2 + z + z^{-1})}.$$

Letting $z = e^{jw}$, we obtain a negative solution and the solution

$$\hat{P}(\omega) = \frac{1}{-1+\sqrt{5+4\cos\omega}}.$$

The first cannot be taken into account, since we are looking for nonnegative solutions only; the second is positive for all ω in $[0, 2\pi]$, except at $\omega = \pi$, where $\hat{P}(\omega)$ diverges. Actually this is not surprising, because (2.10) is not full rank at $(\frac{1}{2}, -\frac{1}{2}) \in \mathcal{M}$. Hence a stabilizing optimal feedback law does not exist for some initial global state in $\mathfrak{l}_2$.

Example 2. Let us change only the sign of A_2 in the previous example. In this case the unique positive-definite solution of (AREω) is given by

$$\hat{P}(\omega) = \frac{2}{\sqrt{1+16(1+\cos\omega)^2}-(3+4\cos\omega)}$$

and the corresponding feedback matrix is

$$\hat{K}(\omega) = \frac{4(1+\cos\omega)}{1+\sqrt{1+16(1+\cos\omega)^2}}.$$

A plot of $\hat{P}(\omega)$ is given in Fig.1.

Since $\hat{P}(\omega)$ attains its minimum value at $\omega = \pi$, we have

$$J_{\min}(\mathfrak{X}_0) = (2\pi)^{-1}\int_0^{2\pi} \hat{P}(\omega)|\hat{\mathfrak{X}}_0(\omega)|^2\, d\omega \geqq \|\mathfrak{X}_0\|_2^2 \hat{P}(\pi)$$

and $J_{\min}$ can be made arbitrarily close to the lower bound if we consider initial global states whose spectral content is concentrated in a narrow neighbourhood of π.

The computation of the K_h's depends on the evaluation of the following integrals:

$$K_h = (2\pi)^{-1}\int_0^{2\pi} \frac{4(1+\cos\omega)\cos(\omega h)}{1+\sqrt{1+16(1+\cos\omega)^2}}\, d\omega.$$

Since infinitely many K_h's are different from zero, the optimal feedback law (2.15) cannot be implemented by a finite-dimensional device, and the resulting closed-loop system is a half-plane causal two-dimensional system.

To overcome the storage and computation problems, it seems natural to investigate whether, in the case (1.1) satisfying the rank condition of Theorem 3, the stabilizing feedback matrix could be constrained to have all elements in the bilateral polynomials ring $R[z, z^{-1}]$. An obvious advantage of this control law is that $u(h, k)$ would only

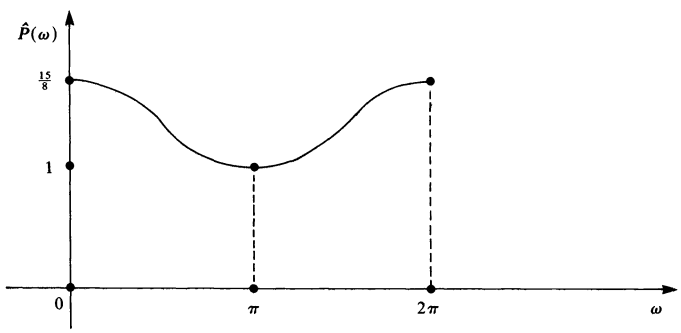

FIG. 1

depend on a finite number of local states, which makes the closed-loop system weakly causal [11].

The question above can be positively answered. Actually, we will prove that the bilateral polynomial matrix

$$K_N(z) := \sum_{i=-N}^{N} K_i z^i$$

obtained by truncation of the Laurent series (4.18) gives an (l_2 and l_∞) stabilizing state feedback, provided that N is large enough. Furthermore, when N diverges and l_2 initial states are considered, the corresponding cost functional J_N asymptotically converges to the minimum value $J_{\min}$.

To prove the first statement, recall that the coefficients K_i exponentially decay as $|i| \to \infty$. This implies that $K_N(e^{j\omega})$ and the corresponding closed-loop matrix $\Gamma_N(e^{j\omega})$ uniformly converge to $K(e^{j\omega})$ and $\Gamma(e^{j\omega})$, respectively.

Denoting by $\rho < 1$ the maximum spectral radius of $\Gamma(e^{j\omega})$ as ω varies in $[0, 2\pi]$, it will suffice to prove that for every ω the spectral radius of $\Gamma_N(e^{j\omega})$ does not exceed $(1+\rho)/2$ for large values of N. It even suffices to prove that for every ω the distance between the eigenvalues of $\Gamma_N(e^{j\omega})$ and those of $\Gamma(e^{j\omega})$ is less than $(1-\rho)/2$ for large values of N.

By the Ostrowski Theorem [12], there exists a positive real δ such that the distance between the eigenvalues of $\Gamma_N(e^{j\omega})$ and those of $\Gamma(e^{j\omega})$ is less than $(1-\rho)/2$ if

$$\|\Gamma(e^{j\omega}) - \Gamma_N(e^{j\omega})\| < \delta \tag{6.1}$$

for every ω in $[0, 2\pi]$. But the uniform convergence of $\Gamma_N(e^{j\omega})$ to $\Gamma(e^{j\omega})$ guarantees that (6.1) becomes true as N diverges.

To prove that J_N converges to $J_{\min}$ we introduce a frequency-dependent quadratic Lyapunov function that provides a very convenient integral representation of the cost functional J.

LEMMA 2. *Assume that the feedback law* $\hat{U}_t(\omega) = \hat{K}(\omega)\hat{X}_t(\omega)$ *stabilizes the system* (1.1) *in the usual* l_2 *sense and denote by* $\hat{\Gamma}(\omega)$ *the corresponding closed-loop matrix. The cost functional associated to an initial global state* $\hat{X}_0(\omega)$ *is given by*

$$J = (2\pi)^{-1} \int_0^{2\pi} \hat{X}_0^*(\omega)\hat{P}(\omega)n\hat{X}_0(\omega)\, d\omega \tag{6.2}$$

where $\hat{P}(\omega)$ *is the (unique) solution of the following Lyapunov equation*:

$$\hat{P}(\omega) = \hat{\Gamma}^*(\omega)\hat{P}(\omega)\hat{\Gamma}(\omega) + [Q + \hat{K}^*(\omega)R\hat{K}(\omega)]. \tag{6.3}$$

Proof. By Parseval's and Beppo Levi's Theorems, the cost functional can be represented as

$$J = (2\pi)^{-1} \sum_{h=0}^{\infty} \int_0^{2\pi} [\hat{X}_h^*(\omega)Q\hat{X}_h(\omega) + \hat{U}_h^*(\omega)R\hat{U}_h(\omega)]\, d\omega$$

$$= (2\pi)^{-1} \int_0^{2\pi} \hat{X}_0^*(\omega) \sum_{h=0}^{\infty} \hat{\Gamma}^*(\omega)^h [Q + \hat{K}^*(\omega)R\hat{K}(\omega)]\hat{\Gamma}(\omega)^h \hat{X}_0(\omega)\, d\omega.$$

Since $\hat{\Gamma}(\omega)$ is asymptotically stable for every ω in $[0, 2\pi]$, it is easy to check that the series

$$\sum_{h=0}^{\infty} \hat{\Gamma}^*(\omega)^h [Q + \hat{K}^*(\omega)R\hat{K}(\omega)]\hat{\Gamma}(\omega)^h$$

converges pointwise for every ω to the unique (positive-definite) solution of (6.3).

As a consequence of the above lemma, we have

$$J_N - J_{\min} = (2\pi)^{-1} \int_0^{2\pi} \hat{\mathfrak{X}}_0^*(\omega)[\hat{P}_N(\omega) - \hat{P}(\omega)]\hat{\mathfrak{X}}_0(\omega)\, d\omega. \tag{6.4}$$

Here $\hat{P}(\omega)$ is both the stabilizing solution of (AREω) and the solution of the Lyapunov equation (6.3) that includes the optimal feedback law $\hat{K}(\omega)$ and the corresponding closed-loop system matrix $\hat{\Gamma}(\omega)$. $\hat{P}_N(\omega)$ is the solution of a Lyapunov equation that includes the truncation $\hat{K}_N(\omega)$ of the optimal feedback law and the corresponding closed-loop system matrix $\hat{\Gamma}_N(\omega)$.

The matrix solution $\hat{P}(\omega)$ of (6.3), associated with the optimal feedback law, is unique and its elements $\hat{p}_{ij}(\omega)$ continuously depend on the elements of $\hat{\Gamma}(\omega)$ and $\hat{K}(\omega)$. Therefore the uniform convergence of $\hat{K}_N(\omega)$ and $\hat{\Gamma}_N(\omega)$ to $\hat{K}(\omega)$ and $\hat{\Gamma}(\omega)$ implies that $\hat{P}_N(\omega)$ uniformly converges to $\hat{P}(\omega)$. Using (6.4) we conclude that J_N converges to $J_{\min}$. □

The stabilizability condition we referred to in this paper

$$[I - A_1 z_1 - A_2 z_2 \quad B_1 z_1 + B_2 z_2] \quad \text{full rank in } \mathcal{M} \tag{6.5}$$

is weaker than the condition

$$[I - A_1 z_1 - A_2 z_2 \quad B_1 z_1 + B_2 z_2] \quad \text{full rank in } P_1, \tag{6.6}$$

which is necessary and sufficient [1] for the existence of a stabilizing state feedback law that preserves the quarter plane causality of the closed-loop system.

Clearly, in the case where (6.5) holds and (6.6) does not, losing quarter plane causality is the price we pay for achieving the closed-loop stabilization.

Although condition (6.5) is in general weaker than (6.6), if we assume $B_1 = B_2 = 0$ both conditions collapse. Actually, in this case neither causal nor noncausal feedback can stabilize the system, unless it is originally stable.

Appendix.

Proof of Theorem 3. Let $P = [p_{ij}]$ belong to $C^{n\times n}$ and introduce the map $f: C \times C^{n\times n} \to C^{n\times n}$ given by

$$\begin{aligned} f(z, P) = {} & P - Q - (A_1^T + A_2^T z^{-1})P(A_1 + A_2 z) \\ & + (A_1^T + A_2^T z^{-1})P(B_1 + B_2 z)[R + (B_1^T + B_2^T z^{-1})P(B_1 + B_2 z)]^{-1} \\ & \times (B_1^T + B_2^T z^{-1})P(A_1 + A_2 z). \end{aligned} \tag{A1}$$

We therefore have that the problem of obtaining the solutions of (2.12) reduces to that of solving, with respect to the matrix variable P, the implicit equation

$$f(z, P) = 0. \tag{A2}$$

The proof will break up into two parts. The first is devoted to a local solution of the implicit equation on the neighbourhood of an arbitrary point of the unit circle. It will be shown that, given $e^{j\bar{\omega}}$, there exists a unique analytic matrix $P_{\bar{\omega}}(\cdot)$, defined on an open disk centered in $e^{j\bar{\omega}}$, that solves (A2) and satisfies the condition

$$P_{\bar{\omega}}(e^{j\omega}) = \hat{P}(\omega).$$

The second part is concerned with the existence of a global solution of (A2). An analytic continuation $P(z)$ of the local solution will be provided on an open neighbourhood of γ_1 in such a way that the condition

$$P(e^{j\omega}) = \hat{P}(\omega)$$

holds for any $\omega \in [0, 2\pi]$.

As far as the local solution of (A2) is concerned, the definition of $\hat{P}(\omega)$ implies $f(e^{i\bar{\omega}}, \hat{P}(\bar{\omega})) = 0$, so that, to apply the Implicit Function Theorem, we must check that the Jacobian matrix of f with respect to the variables p_{ij} is nonsingular at $(e^{j\bar{\omega}}, \hat{P}(\bar{\omega}))$. Assume that the entries of P and the components of $f(z, P)$ have been lexicographically ordered, so that equation (A2) takes the following form;

$$\begin{aligned} &f_{11}(z, p_{11}, p_{12}, \cdots, p_{1n}, p_{21}, \cdots, p_{2n}, \cdots, p_{nn}) = 0, \\ &f_{12}(z, p_{11}, p_{12}, \cdots, p_{1n}, p_{21}, \cdots, p_{2n}, \cdots, p_{nn}) = 0, \\ &\cdots \\ &f_{nn}(z, p_{11}, p_{12}, \cdots, p_{1n}, p_{21}, \cdots, p_{2n}, \cdots, p_{nn}) = 0. \end{aligned} \tag{A3}$$

Letting

$$\begin{aligned} \Gamma(z, P) = (A_1 + A_2 z) - (B_1 + B_2 z)[R + (B_1^T + B_2^T z^{-1}) P (B_1 + B_2 z)]^{-1} \\ \times (B_1^T + B_2^T z^{-1}) P (A_1 + A_2 z), \end{aligned}$$

some elementary algebraic manipulations on (A1) yield the (i, j)th indexed columns of the Jacobian matrix

$$\frac{\partial f}{\partial p_{ij}} = \frac{\partial P}{\partial p_{ij}} - \Gamma^T(z^{-1}, P^T)\left(\frac{\partial P}{\partial p_{ij}}\right)\Gamma(z, P). \tag{A4}$$

In particular, if (A4) is evaluated at $(e^{j\bar{\omega}}, \hat{P}(\bar{\omega}))$, we obtain

$$\frac{\partial f}{\partial p_{ij}} = e_i e_j^T - \hat{\Gamma}^*(\bar{\omega}) e_i e_j^T \hat{\Gamma}(\bar{\omega}) \tag{A5}$$

where e_i denotes the ith column of the $n \times n$ identity matrix and $\hat{\Gamma}(\omega)$ has been defined in (4.12).

Thus, for $i, j, r, s = 1, 2, \ldots, n$, the entries of the Jacobian matrix are

$$\frac{\partial f_{rs}}{\partial p_{ij}} = \delta_{(r,s)(i,j)} - \hat{\Gamma}^V_{i,r}(\bar{\omega}) \hat{\Gamma}_{j,s}(\bar{\omega})$$

and its (r, s)th row can be expressed as

$$e_r^T \otimes e_s^T - (e_r^T \hat{\Gamma}^*(\bar{\omega})) \otimes (e_s^T \hat{\Gamma}^T(\bar{\omega})) = (e_r^T \otimes e_s^T)[I - \hat{\Gamma}^*(\bar{\omega}) \otimes \hat{\Gamma}^T(\bar{\omega})].$$

This shows that the Jacobian matrix of f with respect to P is given by

$$I - \hat{\Gamma}^*(\bar{\omega}) \otimes \hat{\Gamma}^T(\bar{\omega}) \tag{A6}$$

and is a nonsingular matrix because of the asymptotic stability of $\hat{\Gamma}(\bar{\omega})$.

Before beginning with the "global part" of the proof, we need to investigate some properties of the local solution. Since the closed-loop matrix

$$\hat{\Gamma}(\bar{\omega}) = \Gamma(e^{j\bar{\omega}}, P_{\bar{\omega}}(e^{j\bar{\omega}}))$$

is asymptotically stable, by a continuity argument $P_{\bar{\omega}}(e^{j\omega})$ is a stabilizing solution of (AREω) for any $e^{j\omega}$ in a suitable open arc $\alpha(\bar{\omega})$ of γ_1 centered in $e^{j\bar{\omega}}$.

Thus both $P_{\bar{\omega}}(e^{j\omega})$ and $\hat{P}(\omega)$ provide a stabilizing solution of (AREω) in $\alpha(\bar{\omega})$ and, by the uniqueness of the Hermitian stabilizing solution of (AREω), it suffices to prove that $P_{\bar{\omega}}(e^{j\omega})$, $e^{j\omega}$ in $\alpha(\bar{\omega})$, is an Hermitian matrix for concluding that

$$\hat{P}(\omega) = P_{\bar{\omega}}(e^{j\omega}) \quad \forall\, e^{j\omega} \in \alpha(\bar{\omega}). \tag{A7}$$

Actually, taking the conjugate transpose of the identity $f(e^{j\omega}, P_{\bar\omega}(e^{j\omega}))=0$, $e^{j\omega}$ in $\alpha(\bar\omega)$, we obtain $f(e^{j\omega}, P^*_{\bar\omega}(e^{j\omega}))=0$, $e^{j\omega}\in\alpha(\bar\omega)$. On the other hand, we have

$$P^*_{\bar\omega}(e^{j\bar\omega})=\hat P^*(\bar\omega)=\hat P(\bar\omega)=P_{\bar\omega}(e^{j\bar\omega})$$

so that the uniqueness of the solution of (A2) in a neighbourhood of $(e^{j\bar\omega}, \hat P(\bar\omega))$ implies

$$P_{\bar\omega}(e^{j\omega})=P^*_{\bar\omega}(e^{j\omega}), \qquad e^{j\omega}\in\alpha(\bar\omega)\cap D(\bar\omega)$$

where $D(\bar\omega)$ is a suitable open disk centered at $e^{j\bar\omega}$.

This last result has really been our main goal. We use it to associate with each point $e^{j\bar\omega}\in\gamma_1$ an open disk $D(\bar\omega)$, centered in $e^{j\bar\omega}$ and an analytic function $P_{\bar\omega}(z)$, defined in $D(\bar\omega)$ and satisfying $P_{\bar\omega}(e^{j\omega})=\hat P(\omega)$ on $\gamma_1\cap D(\bar\omega)$.

Extracting from the infinite open covering $\{D(\omega)\}_{\omega}\in[0,2\pi]$ a finite subcovering of γ_1 and piecing together all functions that correspond to it, we obtain a function $P(z)$ that is analytical in an open annulus including γ_1 and that fulfills the condition

(A8) $$P(e^{j\omega})=\hat P(\omega) \quad \forall\omega\in[0,2\pi].$$ □

THEOREM 5. *Let $\hat A(\cdot):[0,2\pi]\to C^{n\times n}$ be a continuous function and assume that $\hat A(\omega)$ is asymptotically stable for any ω in $[0,2\pi]$. Then there exist $M>0$ and $\lambda\in(0,1)$ such that*

$$\|\hat A^t(\omega)\|_2\leqq M\lambda^t.$$

Proof. By the continuity assumption, there exists a real $\delta>0$ such that $\hat A(\omega)(1+\delta)$ is asymptotically stable for every ω.

Then the Lyapunov equation

$$\hat P(\omega)=I+\hat A^*(\omega)\hat P(\omega)\hat A(\omega)(1+\delta)^2$$

admits a unique positive-definite solution

$$\hat P(\omega)=\sum_{t=0}^{+\infty}\hat A^*(\omega)^t\hat A(\omega)^t(1+\delta)^{2t},$$

which is continuous in $[0,2\pi]$.

Let M^2 denote the maximum spectral radius of $\hat P(\omega)$ in $[0,2\pi]$ and $\lambda:=(1+\delta)^{-1}$. Then, for every v in C^n we have

$$v^*M^2v\geqq v^*\hat P(\omega)v=\sum_{t=0}^{\infty}\|(1+\delta)^t\hat A(\omega)^tv\|_2^2\geqq\lambda^{-2t}\|\hat A(\omega)^tv\|_2^2,$$

which proves our assertion. □

A COMPLETE CHARACTERIZATION OF ORBIT CLOSURES OF CONTROLLABLE SINGULAR SYSTEMS UNDER RESTRICTED SYSTEM EQUIVALENCE*

D. HINRICHSEN† AND J. O'HALLORAN‡

Abstract. In this paper properties of the orbit space of controllable generalized state-space systems modulo restricted system equivalence are derived. In particular, it is shown that this space is a smooth quasiprojective variety of dimension *nm*. Then the possible degenerations of controllable systems under transformations of restricted system equivalence are characterized and it is proved that every noncontrollable system can be approximated by a family of controllable systems that belong to a single equivalence class. In the single input case, this class is uniquely determined, whereas in the multivariable case a noncontrollable system may lie in the boundary of finitely or even infinitely many equivalence classes.

Key words. singular system, restricted system equivalence, pencils, algebraic group actions, orbit spaces, orbit closures

AMS(MOS) subject classifications. 93B27, 14D20

0. Introduction.

Consider the system of differential equations

$$\dot{x} = \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix} x + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u$$

and the family of systems resulting from high-gain state feedback via $F_\varepsilon = [\varepsilon \quad 0]$:

$$\dot{x} = \begin{bmatrix} 0 & 1 \\ \varepsilon & 1 \end{bmatrix} x + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u$$

(i.e., there are entries of $A + BF_\varepsilon$ that become arbitrarily large as $\varepsilon \to \infty$). Generalizing the approach of Young, Kokotovic, and Utkin in [20], we may obtain a "limit" of this family of systems by replacing each system Σ_ε with an equivalent one in such a way that a limit exists as $\varepsilon \to \infty$. "Equivalence" in this case means *restricted system equivalence* that consists of: (1) left multiplication by a nonsingular matrix L, and (2) change of coordinates in the state space via a nonsingular matrix R. Specifically, we have

$$\dot{x} = Ax + Bu \text{ is equivalent to } LR\dot{x} = LARx + LBu.$$

In the example above, we could transform each system Σ_ε by

$$L_\varepsilon = \begin{bmatrix} 1 & -1 \\ \varepsilon & 1 \end{bmatrix} \quad \text{and} \quad R_\varepsilon = \begin{bmatrix} 1/\varepsilon & 0 \\ 0 & 1/\varepsilon \end{bmatrix}$$

resulting in the family

$$\begin{bmatrix} 1/\varepsilon & -1/\varepsilon \\ 1 & 1/\varepsilon \end{bmatrix} \dot{x} = \begin{bmatrix} -1 & -1/\varepsilon \\ 1 & (\varepsilon+1)/\varepsilon \end{bmatrix} x + \begin{bmatrix} -1 \\ 1 \end{bmatrix} u.$$

Taking the limit as $\varepsilon \to \infty$, we obtain the system

$$\begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \dot{x} = \begin{bmatrix} -1 & 0 \\ 1 & 1 \end{bmatrix} x + \begin{bmatrix} -1 \\ 1 \end{bmatrix} u.$$

Note that different choices of equivalence transformations $(L_\varepsilon, R_\varepsilon)$ may result in different limits.

In general, a limit of a high-gain feedback family

$$\dot{x} = (A + BF_\varepsilon)x + Bu$$

may be given by the limit as $\varepsilon \to \infty$ of

$$L_\varepsilon R_\varepsilon \dot{x} = L_\varepsilon (A + BF_\varepsilon) R_\varepsilon x + L_\varepsilon B u$$

for some choice of equivalence transformations $(L_\varepsilon, R_\varepsilon)$. As in the example above, there is no guarantee that $\lim_{\varepsilon\to\infty} L_\varepsilon R_\varepsilon$ is nonsingular. Hence a natural setting for limits under high-gain feedback is that of *generalized state-space systems* (or semistate systems), i.e., linear systems of differential equations of the form

$$(0.1) \quad E\dot{x}(t) = Ax(t) + Bu(t), \qquad E, A \in K^{n\times n}, \quad B \in K^{n\times m} \quad (K = \mathbb{R} \text{ or } K = \mathbb{C}).$$

To secure unique solvability of (0.1) on $\mathbb{R}^+$ we always assume

$$(0.2) \qquad \det(sE - A) \not\equiv 0.$$

If E is singular, the system is called *singular*, otherwise it is called *regular*. Besides arising naturally as limits under high-gain feedback, generalized state-space systems are of interest in their own right and have received growing attention in control theory (see [16], [18], [1]–[3], [19], [15], [21]).

To provide a mathematical basis for a systematic analysis of high-gain state feedback, we must first understand limits of generalized state-space systems under transformations by restricted system equivalence. This is the basic question we address in this paper.

Besides being central to any analysis of high-gain state feedback, the determination of limits under equivalence transformations is an important part of the basic theory of generalized state-space systems. Basic system properties like controllability, observability, and stability are invariant with respect to equivalence transformations. However, every asymptotically stable system $\dot{x} = Ax$ is equivalent to a system that is arbitrarily close to an unstable system (see [10]). An analogous statement holds true for controllability. Thus, although these structural properties are invariant with respect to equivalence, they may be lost in the limit under equivalence transformations. In this paper we show that, in the case of generalized state-space systems, the limit of a controllable system under restricted system equivalence transformations is not controllable unless it is equivalent to the original system. Moreover, we characterize these uncontrollable systems that occur as limits of a given controllable system under transformations of restricted system equivalence.

This characterization of limits under equivalence transformations generalizes the results of Khadr and Martin [13] on regular systems. The natural concept of equivalence for regular state-space systems is *similarity*, which is the restriction of restricted system equivalence to the set of regular systems. Two regular state-space systems of the form

$$(0.3) \qquad \dot{x} = Ax + Bu, \qquad (A, B) \in L(n, m) := K^{n\times(n+m)} \quad (K = \mathbb{R} \text{ or } K = \mathbb{C})$$

are said to be *similar* if one can be transformed to the other via a linear change of basis in the state space K^n. In geometrical terms, this means that both systems lie in the same orbit under the *similarity action* of the general linear group $Gl_n(K)$ on $L(n, m)$:

$$(0.4) \qquad \begin{aligned} \sigma: \quad & \mathrm{Gl}_n(K) \times L(n, m) \to L(n, m), \\ & (S, (A, B)) \to S \cdot (A, B) = (SAS^{-1}, SB). \end{aligned}$$

The geometric structure of the orbit space of state-space systems under similarity has been analyzed in detail (see, for instance, [7], [8], [13], [17]). In both the case of singular systems and that of regular systems, equivalent systems may be viewed as different representations of the same physical system. Thus the set of equivalence classes may be considered as the true space of linear systems. We describe the geometry of this space, extending the theory for regular systems to singular systems.

For singular systems, the nondegeneracy condition (0.2) guarantees that the system (0.1) admits a unique distributional solution $x_{x_0,u}$ for arbitrary initial values $x(0-) = x_0 \in K^n$ and control functions $u(\cdot) \in C^\infty(\mathbb{R}_+, K^m)$. If E is singular, the solution formula for $x_{x_0,u}$ will contain the Dirac impulse and some of its derivatives for certain $x_0 \in K^n$ (see [2]). It is to this ability of the system (0.1) to produce impulsive solutions that the term "infinite-frequency behaviour" refers (see [18], [15]).

Restricted system equivalence preserves both the finite- and the infinite-frequency behaviour. It was for this reason that restricted system equivalence was introduced by Rosenbrock [16] as the natural equivalence relation on the set of generalized state-space systems. The concept of restricted system equivalence was adopted from the theory of matrix pencils (cf. [4], [16], [15]). The equivalence classes are orbits under the group action of restricted system equivalence

$$\begin{aligned} \eta: \quad & (\mathrm{Gl}_n(K) \times \mathrm{Gl}_n(K)) \times K^{n\times(2n+m)} \to K^{n\times(2n+m)}, \\ & ((L, R), (E, A, B)) \to (LER^{-1}, LAR^{-1}, LB). \end{aligned} \tag{0.5}$$

We restrict our attention to the case of singular systems of the form (0.1), i.e., without an output equation $y = Cx$. The same questions that we address in this paper can certainly be asked about singular systems with output and we could try, for example, to extend the results in [17, IV.5]. This would, however, require an additional careful analysis. Due to limitation of space, we do not consider the output question in the present paper. To provide a mathematical basis for a systematic analysis of high-gain state feedback, it suffices to pursue the above questions for systems of the form (0.1) (without an output equation).

In § 1, we develop tools and preliminary results to be used in the rest of the paper. In particular, we establish basic properties of the space of equivalence classes under left equivalence:

$$(E, A, B) \sim (LE, LA, LB), \qquad L \in \mathrm{Gl}_n(K). \tag{0.6}$$

We also discuss the concept of controllability for semistate systems and study, for any $\alpha \in K$, the map ρ_α that associates with any system (E, A, B) satisfying $\det(\alpha E - A) \neq 0$ the state-space system

$$(A_\alpha, B_\alpha) = ((\alpha E - A)^{-1}E, (\alpha E - A)^{-1}B) \in L(n, m). \tag{0.7}$$

This correspondence is obtained from a standard reparameterization of matrix pencils [4, XII, § 2] that transforms a given regular pencil (E, A) into a pencil $(\alpha E - A, E)$ in which the first matrix is nonsingular. The transformation (0.7) has been used in the context of singular systems before (see, for example, [21]).

In § 2, we study the space $S^c(n, m)/\eta$ of restricted equivalence classes of controllable systems. In particular, we show that $S^c(n, m)/\eta$ is a smooth quasiprojective variety of dimension nm.

Restricting attention to the first two components of the action (0.5), it is obvious that, in order to characterize the orbit closures of η, we must first describe the orbit closures of regular pencils under strict equivalence. In § 3 we obtain such a description by using the results of Gerstenhaber [5] about orbit closures under the conjugation

action on single matrices. As a consequence of the characterization, we see that there are only finitely many orbits contained in the orbit closure of a regular pencil.

Finally, in § 4, we obtain a complete characterization of the systems that lie in the boundary of a controllable orbit and we show that every noncontrollable system can be approximated by a family of controllable systems that all belong to a single restricted equivalence class. In the single input case ($m = 1$), this equivalence class is uniquely determined. Hasse diagrams are used to illustrate the results.

1. Preliminaries. The space of all generalized state-space equations with m input and n semistate variables is

$$S(n, m) = \{(E, A, B) \in K^{n\times(2n+m)}: \det(sE - A) \not\equiv 0\}. \tag{1.1}$$

The set $S(n, m)$ is an open dense subset of $K^{n\times(2n+m)}$ with respect to both the Zariski topology and the standard topology. In the following, we provide $S(n, m)$ with the topology induced by the standard topology on $K^{n\times(2n+m)}$. However, we will make use of the fact that $S(n, m)$ is a (Zariski) open subset of an affine variety. The space $L(n, m) = K^{n\times(n+m)}$ of systems of the form (0.3) may be embedded in the space $S(n, m)$ via the map

$$i: \quad (A, B) \to (I, A, B). \tag{1.2}$$

For $L \in \mathrm{Gl}_n(K)$, we say that (E, A, B) is left-equivalent to (LE, LA, LB). Clearly, two left-equivalent system equations $E\dot{x} = Ax + Bu$ and $LE\dot{x} = LAx + LBu$ have the same set of solutions $(x(\cdot), u(\cdot))$. Conversely, two system equations that have the same solution set are left-equivalent (see [2, Thm. 3]). Identifying in $S(n, m)$ all triples that determine the same solution set, we obtain the orbit space of the algebraic $\mathrm{Gl}_n(K)$-action:

$$\begin{aligned} \lambda: \quad & \mathrm{Gl}_n(K) \times S(n, m) \to S(n, m), \\ & (L, (E, A, B)) \to L \cdot (E, A, B) = (LE, LA, LB). \end{aligned} \tag{1.3}$$

The orbit space $\hat{S}(n, m) = S(n, m)/\lambda$ is canonically provided with the quotient topology, i.e., the finest topology for which the projection

$$\begin{aligned} \pi_\lambda: \quad & S(n, m) \to \hat{S}(n, m), \\ & (E, A, B) \to O_\lambda(E, A, B) = \{(LE, LA, LB): L \in \mathrm{Gl}_n(K)\} \end{aligned} \tag{1.4}$$

is continuous. Since $rk[E, A] = n$ by (0.2), λ is a free action of $\mathrm{Gl}_n(K)$, i.e., all the stabilizers of points in $S(n, m)$ are trivial:

$$\mathrm{Stab}_\lambda(E, A, B) = \{L \in \mathrm{Gl}_n(K): L \cdot (E, A, B) = (E, A, B)\} = \{I_n\}. \tag{1.5}$$

Because $\mathrm{Stab}_\lambda(E, A, B)$ is trivial, $O_\lambda(E, A, B)$ is isomorphic (as a variety) to $\mathrm{Gl}_n(K)$. It follows from the Closed Orbit Lemma [11, Lemma 8.3] that all the orbits $O_\lambda(E, A, B)$ are closed in $S(n, m)$.

In the following, we will embed $\hat{S}(n, m)$ into the Grassmanian $\mathrm{Grass}_n(V)$, where $V = K^{2n+m}$. The set $\mathrm{Grass}_n(V)$ of n-dimensional linear subspaces of V is endowed with the structure of a compact analytic manifold and of a projective variety. To see that $\mathrm{Grass}_n(V)$ is in fact a projective variety, consider the Plücker embedding

$$\begin{aligned} p: \quad & \mathrm{Grass}_n(V) \to \mathbb{P}(\Lambda^n V), \\ & \mathrm{span}\{v_1, \cdots, v_n\} \to v_1 \wedge \cdots \wedge v_n. \end{aligned}$$

(For more details, see [17, p. 15].) If we associate with every element (E, A, B) in $S(n, m)$ the n-dimensional linear subspace $v[E, A, B]$ of V spanned by the row vectors

of the compound matrix $[E, A, B]$, we obtain a map from the space $S(n, m)$ to $\mathrm{Grass}_n(V)$:

$$\zeta: \quad S(n, m) \to \mathrm{Grass}_n(V), \qquad (E, A, B) \to v[E, A, B]. \tag{1.6}$$

To realize the map ζ in terms of the Plücker embedding, let $I = (i_1, \cdots, i_n)$ with $1 \leqq i_1 < i_2 < \cdots < i_n \leqq 2n+m$ determine a choice of n columns of $[E, A, B]$ and let $|E, A, B|_I$ be the determinant of the $n \times n$ matrix consisting of those columns. Let $\mathcal{I}$ be the set of all subsets of $\{1, 2, \cdots, 2n+m\}$ with n elements:

$$\mathcal{I} = \{(i_1, \cdots, i_n): 1 \leqq i_1 < i_2 < \cdots < i_n \leqq 2n+m\}.$$

Then we have

$$p \circ \zeta(E, A, B) = (|E, A, B|_I)_{I \in \mathcal{I}}.$$

Thus, under the Plücker embedding of $\mathrm{Grass}_n(V)$ into $\mathbb{P}(\Lambda^n V)$, we see that ζ is a regular (polynomial) map. The induced injection

$$\hat{\zeta}: \quad \hat{S}(n, m) \to \mathrm{Grass}_n(V), \qquad O_\lambda(E, A, B) \to v[E, A, B] \tag{1.7}$$

is a homeomorphism that maps $\hat{S}(n, m)$ onto an open dense subset of the compact analytic manifold $\mathrm{Grass}_n(V)$. As such, $\hat{S}(n, m)$ is provided with the structure of a K-analytic manifold itself, and $\dim_K \hat{S}(n, m) = n(n+m)$. Since $\mathrm{Grass}_n(V)$ is a projective variety, the embedding $\hat{\zeta}$ also provides $\hat{S}(n, m)$ with the structure of a quasi-projective variety.

Of special importance in our context is the subset $S^c(n, m)$ of controllable systems (E, A, B) in $S(n, m)$. Controllability of a singular system (0.1) is usually defined via a decomposition $K^n = X_1 \oplus X_2$ of the semistate space that decomposes (0.1) into the standard form (see [4, p. 28])

$$\dot{x}_1 = A_1 x_1 + B_1 u, \qquad A_2 \dot{x}_2 = x_2 + B_2 u \tag{1.8}$$

where $\dim X_1 = \deg \det (sE - A)$, $x_1 \in X_1$, $x_2 \in X_2$, and A_2 is nilpotent. The pairs (A_1, B_1), (A_2, B_2) are uniquely determined up to similarity [6]. Following [19], we call a system (0.1) *controllable* if for any $t_1 > 0$ and all $x_0 \in X_1$, $z \in K^n$, there exists a smooth control function $u(\cdot)$ such that the solution $x(\cdot)$ of (1.1) with $x(0) = x_0$ satisfies $x(t_1) = z$. Various necessary and sufficient criteria for controllability can be found in the literature (see [16], [19], [3], [21]). In particular,

(1.9) (E, A, B) is controllable $\Leftrightarrow$ (A_1, B_1) and (A_2, B_2) are both controllable.

The following two conditions are particularly useful for our purpose.

PROPOSITION 1.1. *The system* (0.1) *is controllable if and only if it satisfies one of the following equivalent conditions*:

(a) $\mathrm{Im}\,(\alpha E - A) + \mathrm{Im}\, B = K^n$ *for all* $\alpha \in K$, *and* $\mathrm{Im}\, E + \mathrm{Im}\, B = K^n$.

(b) $\sum_{i=0}^{n-1} \mathrm{Im}\,(((\alpha E - A)^{-1} E)^i (\alpha E - A)^{-1} B) = K^n$ *for some (or all)* $\alpha \in K$ *such that* $\det(\alpha E - A) \neq 0$. □

For a proof, see [19] and [21], respectively.

It is easy to verify that controllability is invariant with respect to the group action λ. Moreover, Proposition 1.1 implies that the following subsets are open and dense in $S(n, m)$ and in $\hat{S}(n, m)$, respectively,

$$S^c(n, m) = \{(E, A, B) \in S(n, m): (E, A, B) \text{ is controllable}\},$$

$$\hat{S}^c(n, m) = \pi_\lambda(S^c(n, m)).$$

Proposition 1.1 leads us to consider the correspondence between (E, A, B) and $(A_\alpha, B_\alpha) := ((\alpha E - A)^{-1}E, (\alpha E - A)^{-1}B)$. For any $\alpha \in K$, let

$$S_\alpha(n, m) = \{(E, A, B) \in S(n, m): \det(\alpha E - A) \neq 0\}.$$

$S_\alpha(n, m)$ is an open dense subset of $S(n, m)$ for each $\alpha \in K$. Furthermore, $S_\alpha(n, m)$ is a principal open subset of $K^{n\times(2n+m)}$ (the nonzero set of a single polynomial), and so it is an affine variety (see [11, p. 10]). Because $\mathrm{Gl}_n(K)$ acts on $S_\alpha(n, m)$ with closed orbits, we conclude from a theorem of Mumford and Fogarty [14, p. 30] that the quotient $\hat{S}_\alpha(n, m)$ is an affine variety. In fact, we will see in Proposition 1.2 that $\hat{S}_\alpha(n, m)$ is isomorphic to $L(n, m)$. Because $\deg \det(sE - A) \leqq n$ for every (E, A, B) in $S(n, m)$, it follows that, for any $n+1$ distinct numbers $\alpha_1, \cdots, \alpha_{n+1}$, we have

$$S(n, m) = \bigcup_{i=1}^{n+1} S_{\alpha_i}(n, m). \tag{1.10}$$

The correspondence motivated by Proposition 1.1 results in the λ-invariant mappings

$$\rho_\alpha: \quad S_\alpha(n, m) \to L(n, m), \qquad (E, A, B) \to (A_\alpha, B_\alpha) \tag{1.11}$$

and the induced maps on the quotient sets

$$\hat{\rho}_\alpha: \quad \hat{S}_\alpha(n, m) \to L(n, m), \qquad O_\lambda(E, A, B) \to (A_\alpha, B_\alpha). \tag{1.12}$$

The following proposition, together with (1.10), establishes that, for any set of $n+1$ distinct numbers $\alpha_1, \cdots, \alpha_{n+1}$, the family $(\hat{S}_{\alpha_i}(n, m), \hat{\rho}_{\alpha_i})_{1\leqq i\leqq n+1}$ forms an atlas of analytic charts on $\hat{S}(n, m)$.

PROPOSITION 1.2. *For any $\alpha \in K$, the mapping $\rho_\alpha: S_\alpha(n, m) \to L(n, m)$ is regular, surjective, and invariant on λ-orbits, and the induced map on the quotient set*

$$\hat{\rho}_\alpha: \quad \hat{S}_\alpha(n, m) \to L(n, m)$$

is an isomorphism of varieties, which preserves controllability:

$$\hat{\rho}_\alpha(\hat{S}_\alpha^c(n, m)) = L^c(n, m). \tag{1.13}$$

Proof. The mapping ρ_α is clearly regular and λ-invariant. For any pair $(\hat{A}, \hat{B}) \in L(n, m)$, let

$$E = \hat{A}, \quad A = \alpha\hat{A} - I, \quad B = \hat{B}. \tag{1.14}$$

Then $\alpha E - A = I$ and hence $(E, A, B) \in S_\alpha(n, m)$, and we have $\rho_\alpha(E, A, B) = (\hat{A}, \hat{B})$. Therefore, the mapping ρ_α is surjective.

Now assume that $(E_i, A_i, B_i) \in S_\alpha(n, m)$, $i = 1, 2$, and that $(\alpha E_1 - A_1)^{-1}E_1 = (\alpha E_2 - A_2)^{-1}E_2$ and $(\alpha E_1 - A_1)^{-1}B_1 = (\alpha E_2 - A_2)^{-1}B_2$. If we set $L = (\alpha E_1 - A_1)(\alpha E_2 - A_2)^{-1}$, then $LB_2 = B_1$, $LE_2 = E_1$, and $L(\alpha E_2 - A_2) = \alpha E_1 - A_1$. It follows that $LA_2 = A_1$ and so $(E_1, A_1, B_1) \in O_\lambda(E_2, A_2, B_2)$. Thus the mapping $\hat{\rho}_\alpha$ is a continuous bijection. The first part of this proof shows that the mapping ρ_α has a regular right inverse, and so the inverse mapping $\hat{\rho}_\alpha^{-1}$ is regular. Finally, we see from Proposition 1.2 that the isomorphism $\hat{\rho}_\alpha$ respects controllability. □

Remark 1.3. The Liusternik–Schnirelmann category $\mathrm{cat}\, X$ of a topological space X is, by definition, the smallest cardinality of any open covering of X consisting only of subsets contractible in X (see [12] for a survey). As a consequence of the proposition, we have

$$\mathrm{cat}\, \hat{S}(n, m) \leqq n + 1. \tag{1.15}$$

2. The orbit space of semistate systems under restricted system equivalence. The group action of restricted system equivalence η described by (0.5) is an extension of the action λ to a larger transformation group. The space $S(n, m)$ is invariant with respect to η, and η induces the following algebraic $\mathrm{Gl}_n(K)$-action $\hat{\eta}$ on the quotient $\hat{S}(n, m)$:

$$\begin{aligned} \hat{\eta}: \quad & \mathrm{Gl}_n(K) \times \hat{S}(n, m) \to \hat{S}(n, m), \\ & (R, O_\lambda(E, A, B)) \to O_\lambda(ER^{-1}, AR^{-1}, B). \end{aligned} \tag{2.1}$$

The action $\hat{\eta}$ is the restriction to $\hat{S}(n, m)$ of the following algebraic action $\bar{\eta}$ on the Grassmannian:

$$\begin{aligned} \bar{\eta}: \quad & \mathrm{Gl}_n(K) \times \mathrm{Grass}_n(V) \to \mathrm{Grass}_n(V), \\ & (R, v(E, A, B)) \to v(ER^{-1}, AR^{-1}, B). \end{aligned} \tag{2.2}$$

Under the variety isomorphisms $\hat{\rho}_\alpha$ defined by (1.12), the orbits of the group action $\hat{\eta}$ are mapped onto the orbits of the similarity action (0.4). The following proposition exhibits the precise relationship between the $\hat{\eta}$-action restricted to $\hat{S}_\alpha(n, m)$

$$\hat{\eta}_\alpha = \hat{\eta} \,|\, \mathrm{Gl}_n(K) \times \hat{S}_\alpha(n, m) \tag{2.3}$$

and the similarity action σ on $L(n, m)$ defined by (0.4).

PROPOSITION 2.1. *For any $\alpha \in K$, the map $\hat{\rho}_\alpha : \hat{S}_\alpha(n, m) \to L(n, m)$ is an equivariant isomorphism of varieties with respect to the $\mathrm{Gl}_n(K)$-action $\hat{\eta}_\alpha$ on $\hat{S}_\alpha(n, m)$ and the $\mathrm{Gl}_n(K)$-action σ on $L(n, m)$.*

Proof. The fact that the map $\hat{\rho}_\alpha$ is an isomorphism was established in Proposition 1.2. It only remains to show that $\hat{\rho}_\alpha$ satisfies, for any $R \in \mathrm{Gl}_n(K)$,

$$\hat{\rho}_\alpha(\hat{\eta}_\alpha(R, O_\lambda(E, A, B))) = \sigma(R, \hat{\rho}_\alpha(O_\lambda(E, A, B))). \tag{2.4}$$

But this is a direct consequence of the following equality that is obtained directly from the definition of $\hat{\rho}_\alpha$ (see (1.3) and (1.12)):

$$\hat{\rho}_\alpha(O_\lambda(LER^{-1}, LAR^{-1}, LB)) = (RA_\alpha R^{-1}, RB_\alpha), \qquad L, R \in \mathrm{Gl}_n(K). \tag{2.5}$$

□

DEFINITION. Let G be a reductive algebraic group acting on a variety X with orbits $O(x)$, $x \in X$. A point $x \in X$ is *regular* if there is a Zariski open neighborhood U of x for which $\dim O(x) = \dim O(y)$ for all $y \in U$ (see [14, p. 10]). A point $x \in X$ is *pre-stable* if there is a G-invariant Zariski open neighborhood U of x such that the action of G on U is closed.

The following proposition characterizes the regular points of the actions η and $\hat{\eta}$.

PROPOSITION 2.2. *An element (E, A, B) of $S(n, m)$ (respectively, an element $O_\lambda(E, A, B)$ of $\hat{S}(n, m)$) has a trivial stabilizer with respect to η (respectively, $\hat{\eta}$) if and only if (E, A, B) is controllable. Furthermore, every noncontrollable system has a stabilizer of dimension greater than zero.*

Proof. If $(E, A, B) \in S_\alpha(n, m)$ is controllable and $(LER, LAR, LB) = (E, A, B)$ for some L, $R \in \mathrm{Gl}_n(K)$, then by Proposition 1.1, (A_α, B_α) is controllable, and by Proposition 2.1, $(RA_\alpha R^{-1}, RB_\alpha) = (A_\alpha, B_\alpha)$. For controllable state-space systems, the stabilizer, with respect to the similarity action, is trivial (see, for instance, [17, IV.1.4]). Therefore $R = I_n$ and $L[E, A] = [E, A]$. Since $[E, A]$ is of full rank, it follows that $L = I_n$. Thus the stabilizer of (E, A, B) (respectively, $O_\lambda(E, A, B)$) with respect to η (respectively, $\hat{\eta}$) is trivial.

Suppose (E, A, B) is not controllable. Then (A_α, B_α) is not controllable and so its controllability subspace X_1 has dimension $r < n$. Then $K^n = X_1 \oplus X_2$ and, for some $R \in \mathrm{Gl}_n(K)$, we have

$$RA_\alpha R^{-1} = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix} \quad \text{and} \quad RB_\alpha = \begin{bmatrix} B_1 \\ 0 \end{bmatrix}.$$

But the pair $(RA_\alpha R^{-1}, RB_\alpha)$ is stabilized by the family $(I_r \oplus aI_{n-r})_{a \in K^*}$. Therefore, the stabilizer of (A_α, B_α) has dimension greater than zero. If $S \in \mathrm{Gl}_n(K)$ stabilizes (A_α, B_α), it follows from Proposition 2.1 that $((\alpha E - A)S(\alpha E - A)^{-1}, S)$ stabilizes (E, A, B). Therefore, the stabilizers of (E, A, B) and of $O_\lambda(E, A, B)$ have dimension greater than zero. □

It follows from Proposition 2.2 that the η-orbits in $S^c(n, m)$ (respectively, the $\hat{\eta}$-orbits in $\hat{S}^c(n, m)$) are the orbits in $S(n, m)$ of maximal dimension. Thus the open set $S^c(n, m)$ (respectively, $\hat{S}^c(n, m)$) is the set of regular points relative to the action η (respectively, $\hat{\eta}$). Because the orbits in $S^c(n, m)$ (respectively, $\hat{S}^c(n, m)$) are all of the same dimension, it follows from the Closed Orbit Lemma [11, Lemma 8.3] that $\mathrm{Gl}_n(K) \times \mathrm{Gl}_n(K)$ (respectively, $\mathrm{Gl}_n(K)$) acts on $S^c(n, m)(\hat{S}(n, m))$ with closed orbits. Therefore the set of prestable points in $S(n, m)$ $(\hat{S}(n, m))$ relative to $n(\hat{\eta})$ is the set $S^c(n, m)$ $(\hat{S}^c(n, m))$. From the definition of $S^c(n, m)/\eta$ and of $\hat{S}^c(n, m)/\hat{\eta}$, it follows that they are homeomorphic.

We conclude this section by proving that the quotient $S^c(n, m)/\eta$ is a smooth quasiprojective variety. For this we need the following terminology. An increasing sequence $I = (i_1, \cdots, i_n)$ of n integers, $1 \leqq i_1 < i_2 < \cdots < i_n \leqq (n+1)m$, is called a *selection* of (n, m). Let $\mathcal{I}$ be the set of all selections of (n, m) and order $\mathcal{I}$ lexicographically. If $C(A, B) = [B, AB, \cdots, A^nB]$ is the extended controllability matrix for a controllable state-space system $(A, B) \in L^c(n, m)$ and $I \in \mathcal{I}$, we let $|C(A, B)|_I$ denote the determinant of the $n \times n$ matrix consisting of the columns of $C(A, B)$ selected by I. Let $(|C(A, B)|_I)_{I \in \mathcal{I}}$ be the sequence, ordered by the lexicographic ordering on $\mathcal{I}$, of these determinants. We say that I is a *nice selection* if, whenever the jth column of A^iB is selected by I, then the jth column of A^rB is selected by I for all r, $0 \leqq r < i$. Note that in this case i is necessarily strictly less than n.

Let $s = |\mathcal{I}| = \binom{(n+1)m}{n}$ and define a map from the σ-orbit space of $L^c(n, m)$ to projective $(s-1)$-space:

$$\psi: \quad L^c(n, m)/\sigma \to \mathbb{P}^{(s-1)}(K), \qquad O_\sigma(A, B) \to (|C(A, B)|_I)_{I \in \mathcal{I}}. \tag{2.6}$$

The map ψ is well defined because

$$|C(RAR^{-1}, RB)|_I = |RC(A, B)|_I = (\det R)|C(A, B)|_I$$

for any $R \in \mathrm{Gl}_n(K)$.

LEMMA 2.3. *The map $\psi: L^c(n, m)/\sigma \to \mathbb{P}^{(s-1)}(K)$ is injective.*

Proof. For any $(A, B) \in L^c(n, m)$, let

$$g(A, B) = \text{row span}_K\, C(A, B).$$

Then it is easy to verify that, for arbitrary $(A_i, B_i) \in L^c(n, m)$, $i = 1, 2$,

$$g(A_1, B_1) = g(A_2, B_2) \Leftrightarrow C(A_2, B_2) = RC(A_1, B_1) \text{ for some } R \in \mathrm{Gl}_n(K)$$

$$\Leftrightarrow A_2 = RA_1R^{-1} \text{ and } B_2 = RB_1 \text{ for some } R \in \mathrm{Gl}_n(K).$$

Thus the map

$$g: \quad L^c(n, m)/\sigma \to \mathrm{Grass}_n(K^{(n+1)m})$$

is injective (an algebraic embedding). Now, if $p: \mathrm{Grass}_n(K^{(n+1)m}) \to \mathbb{P}^{(s-1)}(K)$ denotes the Plücker embedding of $\mathrm{Grass}_n(K^{(n+1)m})$ (see § 1), then $\psi = p \circ g$. Hence the map ψ is injective. □

THEOREM 2.4. *The geometric quotient $\hat{S}^c(n, m)/\hat{\eta}$ is a smooth quasiprojective variety of dimension nm over K.*

Proof. We begin by showing that the quotient $\hat{S}^c(n, m)/\hat{\eta}$ is a variety. (For a general definition of variety, see [11].) In § 1 we found that, for distinct $\alpha_1, \cdots, \alpha_{n+1} \in K$, the set $\{\hat{S}_{\alpha_i}(n, m)\}_{1 \leqq i \leqq n+1}$ is an open affine cover of $\hat{S}(n, m)$. For each α_i, the map $\hat{\rho}_{\alpha_i}$ defines an isomorphism between the affine varieties $\hat{S}_{\alpha_i}(n, m)$ and $L(n, m)$ (Proposition 1.2).

Let $\{U_I\}_{I \text{ nice}}$ be the finite open affine cover of $L^c(n, m)$ described by [17, p. 52], i.e., for each nice selection I define

$$U_I = \{(A, B) \in L^c(n, m): |C(A, B)|_I \neq 0\}.$$

Let $U_i^I = \hat{\rho}_{\alpha_i}^{-1}(U_I)$. Since U_i^I is a principal open subset of the affine variety $\hat{S}_{\alpha_i}(n, m)$, it is an affine variety. Thus the set $\{U_i^I\}_{1 \leqq i \leqq n+1, I \text{ nice}}$ is a finite open affine cover of $\hat{S}^c(n, m)$. Let

$$\pi_{\hat{\eta}}: \hat{S}^c(n, m) \to \hat{S}^c(n, m)/\hat{\eta} \tag{2.7}$$

be the quotient map. The sets $V_i^I = \pi_{\hat{\eta}}(U_i^I)$, $1 \leqq i \leqq n+1$, I a nice selection, form an open cover of $\hat{S}^c(n, m)/\hat{\eta}$. Because $\mathrm{Gl}_n(K)$ acts on the affine variety U_i^I with closed orbits, the geometric quotient V_i^I is affine [14, p. 27], i.e., there is an isomorphism $\xi_i^I: V_i^I \to A_i^I$ onto an affine variety A_i^I for each index (i, I).

For each index (i, I), $1 \leqq i \leqq n+1$, $I \in \mathcal{I}$, define a map $\sigma_i^I: S^c(n, m) \to K$ by

$$\sigma_i^I(E, A, B) = |C(A_{\alpha_i}, B_{\alpha_i})|_I \det(\alpha_i E - A)^{m+1}, \tag{2.8}$$

where m is chosen so that $|C(A_{\alpha_i}, B_{\alpha_i})|_I \det(\alpha_i E - A)^m$ is a polynomial in the entries of (E, A, B) for all (i, I). For each pair of indices $((i, I), (j, J))$, $1 \leqq i, j \leqq n+1$, I, J nice selections, define a map $\sigma_{ij}^{IJ}: V_i^I \to K$ by

$$\sigma_{ij}^{IJ}(O_{\hat{\eta}}(O_\lambda(E, A, B))) = \frac{\sigma_j^J(E, A, B)}{\sigma_i^I(E, A, B)}.$$

If we let

$$A_{ij}^{IJ} = \{a \in A_i^I: \sigma_{ij}^{IJ}(\xi_i^{I^{-1}}(a)) \neq 0\},$$

then $\pi_{\hat{\eta}}^{-1}(\xi_i^{I^{-1}}(A_{ij}^{IJ})) = U_i^I \cap U_j^J = \pi_{\hat{\eta}}^{-1}(\xi_j^{J^{-1}}(A_{ji}^{JI}))$. Thus A_{ij}^{IJ} and A_{ji}^{JI} are both quotients of $U_i^I \cap U_j^J$ under the action $\hat{\eta}$. By the uniqueness of quotients, it follows that there is an isomorphism $\varphi_{ij}^{IJ}: A_{ij}^{IJ} \to A_{ji}^{JI}$ such that $\varphi_{ij}^{IJ} \circ \xi_i^I \circ \pi_{\hat{\eta}} = \xi_j^J \circ \pi_{\hat{\eta}}$ on $U_i^I \cap U_j^J$. Thus the open cover $\{V_i^I\}_{1 \leqq i \leqq n+1, I \text{ nice}}$ patches together to form a prevariety structure on $\hat{S}^c(n, m)/\hat{\eta}$. To see that $\hat{S}^c(n, m)/\hat{\eta}$ is in fact a variety, we use the fact that a prevariety is a variety if any two points lie in an affine open set [11, p. 23]. For any two elements (E_i, A_i, B_i), $i = 1, 2$, of $S^c(n, m)$, choose $\alpha \in K$ such that $(E_i, A_i, B_i) \in S_\alpha(n, m)$, $i = 1, 2$. Choose coefficients $\{a_I\}_{I \text{ nice}}$ so that the following map f is nonzero on $O_\lambda(E_i, A_i, B_i)$ for $i = 1, 2$:

$$f: \quad \hat{S}_\alpha(n, m) \to K, \qquad O_\lambda(E, A, B) \to \Sigma_{I \text{ nice}}\, a_I |C(A_\alpha, B_\alpha)|_I.$$

(To see that the map f is well defined, see equation (4.6) in § 4.) The set

$$\hat{S}_\alpha(n, m)_f = \{O_\lambda(E, A, B) \in \hat{S}_\alpha(n, m): f(O_\lambda(E, A, B)) \neq 0\}$$

is a principal open subset of $\hat{S}_\alpha(n, m)$ and so it is affine. Because $\hat{S}_\alpha(n, m)_f \subset \hat{S}^c(n, m)$ and $\mathrm{Gl}_n(K)$ acts on $\hat{S}^c(n, m)$ with closed orbits, it follows that $\pi_{\hat{\eta}}(\hat{S}_\alpha(n, m)_f)$ is an open affine set containing the two points $\pi_{\hat{\eta}}(E_i, A_i, B_i)$, $i = 1, 2$. Therefore, $\hat{S}^c(n, m)/\hat{\eta}$ is a variety.

The variety $L^c(n, m)/\sigma$ is smooth and and has dimension nm (see [7]). It follows from Proposition 2.1 that $\pi_{\hat{\eta}}(\hat{S}^c_\alpha(n, m) = \hat{S}^c_\alpha(n, m)/\hat{\eta}$ is smooth and has dimension nm. Since the open sets $\hat{S}^c_\alpha(n, m)/\hat{\eta}$ cover $\hat{S}^c(n, m)/\hat{\eta}$, the same holds true for $\hat{S}^c(n, m/\hat{\eta}$.

To show that $\hat{S}^c(n, m)/\hat{\eta}$ is quasiprojective, we embed it in projective space $\mathbb{P}^{r-1}(K)$. Let $r = \binom{(n+1)m}{n}(n+1)$, corresponding to the pairs (i, I), ordered lexicographically, where $1 \leqq i \leqq n+1$ and $I \in \mathscr{I}$. We define

$$\begin{aligned} \varphi\colon\quad & \hat{S}^c(n, m)/\hat{\eta} \to \mathbb{P}^{r-1}(K), \\ & O_{\hat{\eta}}(O_\lambda(E, A, B)) \to (\sigma_i^I(E, A, B))_{1 \leqq i \leqq n+1, I \in \mathscr{I}}, \end{aligned} \tag{2.9}$$

where the maps σ_i^I are those defined by (2.8). Clearly, φ is a polynomial map.

To see that φ is injective, we first show that φ is injective on each open set $\hat{S}^c_{\alpha_i}(n, m)/\hat{\eta}$, $1 \leqq i \leqq n+1$ (where the elements $\alpha_i \in \mathrm{K}$ are those chosen for the definition of the maps σ_i^I). It follows from Proposition 2.1 that $\hat{S}^c_{\alpha_i}(n, m)/\hat{\eta}$ and $L^c(n, m)/\sigma$ are isomorphic as varieties via

$$\hat{\hat{\rho}}_{\alpha_i}\colon\quad \hat{S}^c_{\alpha_i}(n, m)/\hat{\eta} \underset{\to}{\cong} L^c(n, m)/\sigma, \qquad O_{\hat{\eta}}(O_\lambda(E, A, B)) \to O_\sigma(A_{\alpha_i}, B_{\alpha_i}).$$

From the definitions of the maps φ, $\hat{\hat{\rho}}_{\alpha_i}$, and ψ (from Lemma 2.3), we see that $\psi \circ \hat{\hat{\rho}}_{\alpha_i} = \varphi$ on $\hat{S}^c_{\alpha_i}(n, m)/\hat{\eta}$. It follows from Lemma 2.3 that φ is injective on $\hat{S}^c_{\alpha_i}(n, m)/\hat{\eta}$.

If $\varphi(O_{\hat{\eta}}(O_\lambda(E_1, A_1, B_1))) = \varphi(O_{\hat{\eta}}(O_\lambda(E_2, A_2, B_2)))$ for some $(E_i, A_i, B_i) \in S^c(n, m)$, then choose j, $1 \leqq j \leqq n+1$, such that $\sigma_j^I(E_1, A_1, B_1) \neq 0$ for some $I \in \mathscr{I}$. It follows that the orbits $O_{\hat{\eta}}(O_\lambda(E_i, A_i, B_i))$ lie in $\hat{S}^c_{\alpha_j}(n, m)/\hat{\eta}$, $i = 1, 2$. Since φ is injective on $\hat{S}^c_{\alpha_j}(n, m)/\hat{\eta}$, we have $O_{\hat{\eta}}(O_\lambda(E_1, A_1, B_1)) = O_{\hat{\eta}}(O_\lambda(E_2, A_2, B_2))$. Thus the map φ is an embedding of $\hat{S}^c(n, m)/\hat{\eta}$ into $\mathbb{P}^{r-1}(K)$ and so the quotient $\hat{S}^c(n, m)/\hat{\eta}$ is quasiprojective. □

Remark 2.5. In [9], Helmke and Shayman show that the quotient $\hat{S}^c(n, m)/\hat{\eta}$ is compact with respect to the standard topology. This fact, along with quasi-projectivity, establishes that $\hat{S}^c(n, m)/\hat{\eta}$ is a projective variety. □

The analytic structure of the quotient $\hat{S}^c(n, m)/\hat{\eta}$ is described in the following proposition.

PROPOSITION 2.6. *$\hat{S}^c(n, m)/\hat{\eta}$ is a connected analytic manifold of dimension nm.*

Proof. The fact that $\hat{S}^c(n, m)/\hat{\eta}$ is an analytic manifold of dimension nm follows from the proof of Theorem 2.4. The fact that this manifold is connected was established in Proposition 4.4 of [6]. □

3. Orbit closures of regular pencils. We say that a system $\Sigma = (E, A, B)$ *degenerates* to a system $\bar{\Sigma} = (\bar{E}, \bar{A}, \bar{B})$ (with respect to the group action η) if $(\bar{E}, \bar{A}, \bar{B})$ is contained in the boundary of (E, A, B), i.e.,

$$(\bar{E}, \bar{A}, \bar{B}) \in \partial O_\eta(E, A, B) := \overline{O_\eta(E, A, B)} \backslash O_\eta(E, A, B)$$

where the closure is taken in the space $S(n, m)$. (Because an orbit under an algebraic group action is a constructible set [11, Lemma 8.3], the Zariski closure of an orbit is the same as closure in the standard topology.) The main goal of this paper is to characterize the orbit closures of *controllable* systems with respect to the group action η. Thus we want to determine those systems to which a given controllable system can degenerate.

For any continuous group action on a Hausdorff space, the closure of an orbit is a union of orbits. Thus we see that if Σ degenerates to $\bar{\Sigma}$, then any system in the orbit of Σ degenerates to any system in the orbit of $\bar{\Sigma}$:

$$(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\eta(E, A, B)} \Leftrightarrow O_\eta(\bar{E}, \bar{A}, \bar{B}) \subset \overline{O_\eta(E, A, B)}.$$

By restricting our attention to orbit closure within the open subsets $S_\alpha(n, m)$, we see that η-orbit closure in $S_\alpha(n, m)$ corresponds to σ-orbit closure in $L(n, m)$.

LEMMA 3.1. *If* $(\bar{E}, \bar{A}, \bar{B})$ *and* (E, A, B) *are in* $S_\alpha(n, m)$, *then*

$$(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\eta(E, A, B)} \Leftrightarrow \rho_\alpha(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\sigma(\rho_\alpha(E, A, B))}. \tag{3.1}$$

Proof. It is easy to show that η-orbit closures in $S(n, m)$ are projected by π_λ onto $\hat{\eta}$-orbit closures in $\hat{S}(n, m)$. Thus the statement (3.1) is equivalent to

$$\begin{aligned} &\pi_\lambda(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_{\hat{\eta}}(\pi_\lambda(E, A, B))} \\ &\quad \Leftrightarrow \hat{\rho}_\alpha(\pi_\lambda(\bar{E}, \bar{A}, \bar{B})) \in \overline{O_\sigma(\hat{\rho}_\alpha(\pi_\lambda(E, A, B)))}. \end{aligned} \tag{3.2}$$

Since the mapping $\hat{\rho}_\alpha$ is an orbit-preserving isomorphism of varieties (Proposition 2.1), we have

$$\begin{aligned} \overline{O_\sigma(\hat{\rho}_\alpha(\pi_\lambda(E, A, B)))} &= \overline{\hat{\rho}_\alpha(O_{\hat{\eta}}(\pi_\lambda(E, A, B)))} \\ &= \hat{\rho}_\alpha[\overline{O_{\hat{\eta}}(\pi_\lambda(E, A, B))}]. \end{aligned}$$

The result (3.2) follows. □

Let $P(n)$ be the set of regular $n \times n$ matrix pencils

$$P(n) = \{(E, A) \in K^{n \times 2n} : \det(sE - A) \not\equiv 0\},$$

provided with the standard topology induced from $K^{n \times 2n}$. The open covering $\{S_\alpha(n, m)\}$ of the space $S(n, m)$ induces an open covering of the space $P(n)$: for any $\alpha \in K$, define

$$P_\alpha(n) = \{(E, A) \in P(n) : \det(\alpha E - A) \neq 0\}.$$

If $(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\eta(E, A, B)}$, then it is clear that $(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)}$, where ε is the $\mathrm{Gl}_n(K) \times \mathrm{Gl}_n(K)$-action on the first two components:

$$\varepsilon: \quad \mathrm{Gl}_n(K) \times \mathrm{Gl}_n(K) \times P(n) \to P(n), \qquad ((L, R), (E, A)) \to (LER^{-1}, LAR^{-1}).$$

Thus any characterization of η-orbit closure in $S(n, m)$ involves a characterization of ε-orbit closure in $P(n)$. In this section we give such a characterization. The following lemma allows us to reduce the problem of ε-orbit closure to that of orbit closure under the conjugation action γ on the space $K^{n \times n}$ of single matrices, a well-known result that appears in [5].

LEMMA 3.2. *If* (E, A) *and* $(\bar{E}, \bar{A})$ *are in* $P_\alpha(n)$, *then*

$$(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)} \Leftrightarrow \bar{A}_\alpha \in \overline{O_\gamma(A_\alpha)}. \tag{3.3}$$

Proof. If we embed $P(n)$ in $S(n, m)$ via $(E, A) \to (E, A, 0)$, then $P_\alpha(n)$ is embedded (as a closed η-invariant subset) in $S_\alpha(n, m)$. Since $(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)}$ if and only if $(\bar{E}, \bar{A}, 0) \in \overline{O_\eta(E, A, 0)}$, it follows that (3.3) is a direct consequence of Lemma 3.1. □

LEMMA 3.3. *If* (E, A), $(\bar{E}, \bar{A}) \in P(n)$ *and* $(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)}$, *then* $\det(s\bar{E} - \bar{A})$ *is a nonzero scalar multiple of* $\det(sE - A)$.

Proof. Suppose $\lim_{k \to \infty} L_k E R_k^{-1} = \bar{E}$ and $\lim_{k \to \infty} L_k A R_k^{-1} = \bar{A}$. Then we have

$$\begin{aligned} \det(s\bar{E} - \bar{A}) &= \lim_{k \to \infty} \det(L_k(sE - A)R_k^{-1}) \\ &= \lim_{k \to \infty} \det(L_k R_k^{-1}) \det(sE - A). \end{aligned}$$

Since $\det(\alpha\bar{E}-\bar{A})\neq 0$ for some $\alpha\in K$, it follows that $\lim_{k\to\infty}\det(L_kR_k^{-1})$ exists and

$$\lim_{k\to\infty}\det(L_kR_k^{-1})=c\neq 0.$$

The conclusion follows. □

A consequence of this lemma is

$$(E,A)\in P_\alpha(n)\Rightarrow\overline{O_\varepsilon(E,A)}\subset P_\alpha(n). \tag{3.4}$$

A necessary and sufficient condition for two regular matrix pencils to be in the same ε-orbit was first established by Weierstrass. We follow [4, XII.2] in the following presentation. In describing conjugacy classes of single matrices via the associated invariant polynomials or the elementary divisors, we consider the matrix pencil $sI-A$. To extend these ideas to strict equivalence (i.e., ε-equivalence) of pairs of matrices (E, A), we consider the homogeneous matrix pencil $sE+tA$. The $j\times j$ minors of $sE+tA$ are homogeneous polynomials of degree j in the variables s and t, with coefficients in K. Let $D_j(E, A)$ be the greatest common divisor of all of the $j\times j$ minors of $sE+tA$ (with the coefficient of the highest power of s equal to one) and let $D_0(E, A)=1$. In particular, the polynomial $D_n(E, A)=c\det(sE+tA)$, for some $c\neq 0$, is the normalized "characteristic polynomial" of the pencil (E, A). It is easy to see that

$$D_j(E,A)\,|\,D_{j+1}(E,A)\quad\text{for } 0\leqq j\leqq n-1.$$

The invariant polynomials of the matrix pencil (E, A) are defined by

$$i_k(E,A)=\frac{D_{n-k+1}(E,A)}{D_{n-k}(E,A)},\qquad 1\leqq k\leqq n. \tag{3.5}$$

The following result is an easy consequence of the criterion of Weierstrass (see [4, XII.2]).

PROPOSITION 3.4 (Weierstrass). *Two regular matrix pencils (E_1, A_1) and (E_2, A_2) are in the same ε-orbit, i.e., there exist L, $R\in \mathrm{Gl}(n, K)$ such that*

$$LE_1R=E_2\quad\text{and}\quad LA_1R=A_2,$$

if and only if both matrix pencils have the same invariant polynomials. □

The elementary divisors of a matrix pencil (E, A) are the powers of the irreducible factors obtained by decomposition of the invariant polynomials. It follows from Proposition 3.4 that the elementary divisors, up to scalar multiple (equivalently the invariant polynomials or the polynomials $D_j(E, A)$) parameterize the ε-orbits in $P(n)$.

For each irreducible homogeneous polynomial F in $K[s, t]$ and each pencil of matrices (E, A), define

$$d_{j,F}(E,A)=\text{the multiplicity of } F \text{ in } D_j(E,A),$$

$$m_{k,F}(E,A)=\text{the multiplicity of } F \text{ in } i_k(E,A).$$

Note that $d_{0,F}(E, A)=0$ and that $m_{k,F}(E, A)=d_{n-k+1,F}(E, A)-d_{n-k,F}(E, A)$, $1\leqq k\leqq n$, so that

$$\sum_{k=1}^{j} m_{k,F}(E,A)=d_{n,F}(E,A)-d_{n-j,F}(E,A),\qquad j=1,\cdots,n. \tag{3.6}$$

In particular, for each irreducible factor F of $\det(sE+tA)$, the (nonincreasing) family

$$m_F(E,A):=(m_{1,F}(E,A),\cdots,m_{n,F}(E,A))$$

is a *partition* of $d_{n,F}(E, A)$, i.e., $d_{n,F}(E,A)=\sum_{k=1}^{n} m_{k,F}(E,A)$.

Using the standard form for matrix pencils described in [4, XII.2], it can be seen that, given any homogeneous polynomial $D(s, t) = \prod_{i=0}^{h} F_i^{r_i}$ with distinct irreducible factors $F_0, \cdots, F_h$ and given a partition $p_i = (p_{i1}, \cdots, p_{in})$, $p_{i1} \geqq \cdots \geqq p_{in}$, of each r_i, $i = 0, \cdots, h$, there is a matrix pencil (E, A) in $P(n)$ with

$$m_{F_i}(E, A) = p_i \quad \text{for each } i,\ 0 \leqq i \leqq h. \tag{3.7}$$

More specifically, if $D(s, t)$ is decomposed over the field $\mathbb{C}$,

$$D(s, t) = ct^{r_0} \prod_{i=1}^{h} (s + t\lambda_i)^{r_i}, \qquad \lambda_1, \cdots, \lambda_h \text{ distinct}, \tag{3.8}$$

then a pencil satisfying (3.7) is given by

$$E = \begin{bmatrix} I_r & 0 \\ 0 & J(0, p_0) \end{bmatrix}, \qquad A = \begin{bmatrix} J(\lambda_1, p_1) & & 0 \\ & \ddots & \\ & & J(\lambda_h, p_h) \\ 0 & & & I_{n-r} \end{bmatrix}, \tag{3.9}$$

where $r = \sum_{i=1}^{h} r_i$ and $J(\lambda_i, p_i)$ is the $r_i \times r_i$ Jordan matrix with eigenvalue λ_i and block structure given by p_i.

In the sequel, we will use the following ordering on partitions of a positive integer.

DEFINITION 3.5. If $a_1 \geqq a_2 \geqq \cdots \geqq a_n \geqq 0$ and $b_1 \geqq b_2 \geqq \cdots \geqq b_n \geqq 0$ are partitions of n (i.e., $\sum_{i=1}^{n} a_i = \sum_{i=1}^{n} b_i = n$), then we say that

$$(a_1, a_2, \cdots, a_n) \leqq (b_1, b_2, \cdots, b_n) \text{ in the } \textit{dominance order} \text{ if}$$

$$\sum_{k=1}^{j} a_k \leqq \sum_{k=1}^{j} b_k \text{ for all } j = 1, \cdots, n. \qquad \square$$

In the space $K^{n \times n}$ of single matrices, orbits under the conjugation action γ are classified by the Jordan form. It follows from the proof of Lemma 3.3 (with $E = I$ and $L_k = R_k$) that orbit closure under the conjugation action γ preserves the characteristic polynomial $\det(sI - M)$. Therefore, the orbits in the boundary of a given γ-orbit $O_\gamma(M)$ are completely described by the partitions specifying the block structure of the associated Jordan form. In fact, Gerstenhaber has shown in [5] that, for a given matrix M in $K^{n \times n}$, a matrix $\bar{M}$ is in $\overline{O_\gamma(M)}$ if and only if

$$\operatorname{rank}(\lambda I - \bar{M})^i \leqq \operatorname{rank}(\lambda I - M)^i \quad \text{for all } i \in N \text{ and all } \lambda \in \mathbb{C}. \tag{3.10}$$

In terms of the complex Jordan forms

$${}^J\bar{M} = \bigoplus_{i=1}^{h} J(\lambda_i, \bar{p}_i) \quad \text{and} \quad {}^JM = \bigoplus_{i=1}^{h} J(\lambda_i, p_i)$$

of $\bar{M}$ and M, respectively, (3.10) is equivalent to

$$\det(sI - \bar{M}) = \det(sI - M) \quad \text{and} \quad \bar{p}_i \leqq p_i, \quad i = 1, \cdots, h. \tag{3.11}$$

Since $\bar{p}_{ik}$, respectively p_{ik}, is the multiplicity of the irreducible factor $(s - \lambda_i)$ in the invariant polynomial $i_k(I, \bar{M})$, respectively, $i_k(I, M)$, we obtain from (3.6) and (3.11) that

$$\bar{M} \in \overline{O_\gamma(M)} \Leftrightarrow D_j(I, M) \mid D_j(I, \bar{M}) \quad \text{for all } j, \quad 1 \leqq j \leqq n. \tag{3.12}$$

To carry the characterization of γ-orbit closure over to the setting of matrix pencils, we consider the following degree-preserving automorphism of $K[s, t]$:

$$F(s, t) \to \tilde{F}(s, t) = F(\alpha s + t, -s), \tag{3.13}$$

where $\alpha \in K$. Given a pencil (E, A), choose α such that $(E, A) \in P_\alpha(n)$. Then this automorphism maps any $j \times j$ minor of $sE + tA$ onto the corresponding minor of $(\alpha s + t)E - sA = s(\alpha E - A) + tE$. Hence

$$\tilde{D}_j(E, A) = D_j(\alpha E - A, E). \tag{3.14}$$

A consequence of Proposition 3.4 is that the polynomials $D_j(E, A)$ are invariant on ε-orbits. In particular, we have

$$D_j(\alpha E - A, E) = D_j(I, (\alpha E - A)^{-1}E) = D_j(I, A_\alpha), \qquad (E, A) \in P_\alpha(n). \tag{3.15}$$

Remark 3.6. For a given homogeneous polynomial $D(s, t)$ of degree n, define

$$P_D = \{(E, A): \det(sE + tA) = cD(s, t) \text{ for some } 0 \neq c \in K\}.$$

Replacing $sE - A$ (respectively, $s\bar{E} - \bar{A}$) with $sE + tA$ (respectively, $s\bar{E} + t\bar{A}$) in the proof of Lemma 3.3, we see that

$$(E, A) \in P_D \quad \text{and} \quad (\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)} \Rightarrow (\bar{E}, \bar{A}) \in P_D. \tag{3.16}$$

Because the correspondence (3.13) is a degree-preserving automorphism of $K[s, t]$, we obtain from (3.14) and Proposition 3.4 that the map $(E, A) \to (\alpha E - A, E)$ induces a bijective correspondence between the ε-orbits in P_D and the ε-orbits in $P_{\tilde{D}}$.

The following result characterizes the ε-orbit closures in the pencil space $P(n)$.

THEOREM 3.7. *Let* $(\bar{E}, \bar{A})$, $(E, A) \in P(n)$. $(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)}$ *if and only if one of the following equivalent conditions is satisfied*:

(i) $D_j(E, A) \mid D_j(\bar{E}, \bar{A})$ *for all* j, $1 \leqq j \leqq n$.

(ii) $m_F(\bar{E}, \bar{A}) \leqq m_F(E, A)$ *for all irreducible factors* F *of* $\det(sE + tA)$.

Proof. It follows from (3.16) that we need only consider the set P_D for a fixed homogeneous polynomial D. Choose $\alpha \in K$ so that $D(\alpha, -1) \neq 0$, i.e., $P_D \subset P_\alpha(n)$. By Lemma 3.2, we have

$$(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)} \Leftrightarrow \bar{A}_\alpha \in \overline{O_\gamma(A_\alpha)}.$$

From (3.12), we have

$$\bar{A}_\alpha \in \overline{O_\gamma(A_\alpha)} \Leftrightarrow D_j(I, A_\alpha) \mid D_j(I, \bar{A}_\alpha) \quad \text{for all } j, \quad 1 \leqq j \leqq n.$$

From (3.14), (3.15), and the fact that the correspondence (3.13) is a degree-preserving automorphism of $K[s, t]$, it follows that

$$D_j(I, A_\alpha) \mid D_j(I, \bar{A}_\alpha) \Leftrightarrow D_j(E, A) \mid D_j(\bar{E}, \bar{A}).$$

Therefore, $(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)}$ if and only if condition (i) is satisfied. To see that conditions (i) and (ii) are equivalent, we note that condition (i) is equivalent to

$$\begin{aligned} &d_{j,F}(E, A) \leqq d_{j,F}(\bar{E}, \bar{A}) \quad \text{for all } j, \quad 1 \leqq j \leqq n, \\ &\text{and for all irreducible factors } F \text{ of } \det(sE + tA), \end{aligned} \tag{3.17}$$

hence by equation (3.6), to condition (ii). □

In the case $E = \bar{E} = I$, Theorem 3.7 coincides with Gerstenhaber's Theorem in [5].

The following is a direct consequence of the theorem.

COROLLARY 3.8. *Let* $(E, A) \in P(n)$. *Then*

(i) $\overline{O_\varepsilon(E, A)}$ *contains only finitely many orbits,*

(ii) $O_\varepsilon(E, A)$ *is closed in* $P(n)$ *if and only if* $m_{k,F}(E, A) \leqq 1$ *for all* k, $1 \leqq k \leqq n$, *and for all irreducible factors* F *of* $\det(sE + tA)$.

Remark 3.9. Using the standard form (3.9), it is clear from part (ii) of the corollary that every closed orbit contains a pencil of the form

$$\left[\begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} S & 0 \\ 0 & I_{n-r} \end{bmatrix}\right] \tag{3.18}$$

where S is semisimple (diagonalizable over $\mathbb{C}$).

To better understand the consequences of Theorem 3.7, we introduce the concept of Hasse diagrams for orbit closures. A Hasse diagram is a directed graph whose vertices represent orbits and whose directed edges represent orbit closures. More precisely, the orbit at the terminal node of an arrow is in the closure of the orbit at the initial node of the arrow. Of course the diagram is transitive. It follows from (3.16) that there are an infinite number of disjoint components in the Hasse diagram of ε-orbits, each component consisting of ε-orbits in P_D for a fixed homogeneous polynomial $D(s, t)$ of degree n in $K[s, t]$. Because ε-orbits are classified by partitions of the multiplicities of the irreducible factors of D, P_D contains only finitely many orbits. For any positive integer m, $m \leqq n$, there is a unique largest partition of m (with respect to the dominance order) $p^* = (m, 0, \cdots, 0) \in \mathbb{N}^n$ and a unique smallest one $p_* = (1, \cdots, 1, 0, \cdot, 0) \in \mathbb{N}^n$. It follows that there are unique ε-orbits O^* and O_* in P_D such that $P_D = \overline{O^*}$ and every ε-orbit in P_D has O_* in its closure. In particular, the Hasse diagram for P_D is connected and has unique maximal and minimal vertices. These smallest orbits O_* (of minimal dimension within P_D) are the closed ε-orbits, which we described in Remark 3.9. From Theorem 3.7(ii), we see that the maximal orbit O^* in P_D must be the set of pencils (E, A) in P_D that satisfy the following:

$$m_{k,F}(E, A) = 0 \text{ for } k > 1 \text{ and for all irreducible factors } F \text{ of } \det(sE + tA). \tag{3.19}$$

Using the standard form (3.9), we see that the pencils which satisfy (3.19) are those that are equivalent to pencils of the form

$$\left[\begin{bmatrix} I_r & 0 \\ 0 & N \end{bmatrix}, \begin{bmatrix} J & 0 \\ 0 & I_{n-r} \end{bmatrix}\right] \tag{3.20}$$

where N is a nilpotent matrix with one Jordan block and J has one Jordan block for each eigenvalue. We illustrate these ideas with the following example.

Example 3.10. In the case $D = s^2t^2$, the set P_D consists of pencils of 4×4 matrices (E, A) such that $\det(sE + tA) = cs^2t^2$ for some $0 \neq c \in K$. Figure 1 is the Hasse diagram for P_D, where each vertex is given by a representative from an ε-orbit. We denote the 2×2 Jordan block with eigenvalue 0 by J_2 and the 2×2 identity matrix by I_2.

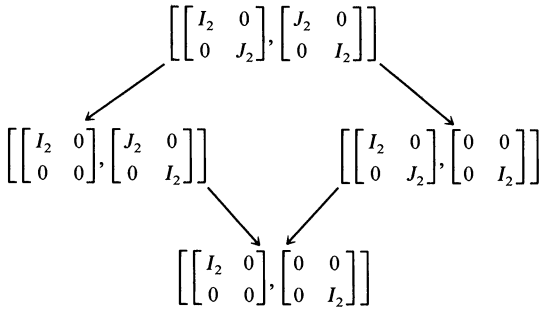

FIG. 1.

4. Orbit closures of controllable semistate systems. In this section, we describe orbit closures of controllable systems (E, A, B) under the restricted equivalence action η given by

$$(L, R) \cdot (E, A, B) = (LER^{-1}, LAR^{-1}, LB).$$

We will denote the triple (LER^{-1}, LAR^{-1}, LB) by $L(E, A, B)R^{-1}$.

Analogous to the case of regular pencils that was studied in § 3, we can restrict our attention to $S_\alpha(n, m)$; it follows from (3.4) that

$$(E, A, B) \in S_\alpha(n, m) \Rightarrow \overline{O_\eta(E, A, B)} \subset S_\alpha(n, m). \tag{4.1}$$

Thus we can reduce the problem of η-orbit closures in $S(n, m)$ to that of η-orbit closures in $S_\alpha(n, m)$, $\alpha \in K$. From Lemma 3.1, we see that η-orbit closures in $S_\alpha(n, m)$ correspond to σ-orbit closures in $L(n, m)$ via the map ρ_α defined by (1.11).

LEMMA 4.1. *Suppose that* $(\bar{E}, \bar{A}, \bar{B})$ *and* (E, A, B) *are in* $S(n, m)$ *and that* (L_k) *and* (R_k) *are sequences in* $\mathrm{Gl}_n(K)$ *such that*

$$\lim_{k\to\infty} L_k(E, A, B)R_k^{-1} = (\bar{E}, \bar{A}, \bar{B}). \tag{4.2}$$

If (E, A, B) *is controllable, then*

$$Y = \lim_{k\to\infty} L_k \quad \textit{and} \quad X = \lim_{k\to\infty} R_k \tag{4.3}$$

exist in $K^{n\times n}$ *and*

$$YE = \bar{E}X, \quad YA = \bar{A}X, \quad \bar{B} = YB. \tag{4.4}$$

Proof. Choose any $\alpha \in K$ such that $\det(\alpha E - A) \neq 0$. Then, by (4.1), $\det(\alpha\bar{E} - \bar{A}) \neq 0$. The α-controllability matrix of $(E, A, B) \in S_\alpha(n, m)$ is, by definition, the controllability matrix of $\rho_\alpha(E, A, B) = (A_\alpha, B_\alpha)$:

$$C_\alpha(E, A, B) = [B_\alpha, A_\alpha B_\alpha, \cdots, A_\alpha^{n-1}B_\alpha]. \tag{4.5}$$

By direct computation, we obtain

$$C_\alpha(L_k(E, A, B)R_k^{-1}) = R_k C_\alpha(E, A, B), \tag{4.6}$$

and from (4.2) it follows that

$$\lim_{k\to\infty} R_k C_\alpha(E, A, B) = C_\alpha(\bar{E}, \bar{A}, \bar{B}) \tag{4.7}$$

because the mapping $C_\alpha : (E, A, B) \to C_\alpha(E, A, B)$ is continuous on $S_\alpha(n, m)$. Since (E, A, B) is controllable, it follows from Proposition 1.1 that $C_\alpha(E, A, B)$ has rank n and hence $X = \lim_{k\to\infty} R_k$ exists. By the hypothesis (4.2), we have

$$\lim_{k\to\infty} L_k(\alpha E - A)R_k^{-1} = \alpha\bar{E} - \bar{A}, \tag{4.8}$$

hence

$$\lim_{k\to\infty} L_k(\alpha E - A) = (\alpha\bar{E} - \bar{A})X. \tag{4.9}$$

Since $\det(\alpha E - A) \neq 0$, it follows that $Y = \lim_{k\to\infty} L_k$ exists and we have

$$Y(\alpha E - A) = (\alpha\bar{E} - \bar{A})X, \qquad YB = \bar{B}. \tag{4.10}$$

Since (4.10) holds for every α such that $\det(\alpha\bar{E} - \bar{A}) \neq 0$, the equalities (4.4) follow. □

Remark 4.2. Let $(\bar{E}, \bar{A}, \bar{B}), (E, A, B) \in S_\alpha(n, m)$ and suppose that they satisfy (4.4). Then

$$Y = (\alpha\bar{E} - \bar{A})X(\alpha E - A)^{-1} \tag{4.11}$$

and we can rewrite (4.4) in terms of A_α and B_α:

$$\begin{aligned} &XA_\alpha = \bar{A}_\alpha X, \qquad X(\alpha E - A)^{-1}A = (\alpha\bar{E} - \bar{A})^{-1}\bar{A}X, \\ &XB_\alpha = \bar{B}_\alpha. \end{aligned} \tag{4.12}$$

Conversely, the existence of $X \in K^{n\times n}$ satisfying (4.12) implies the equalities (4.4) where Y is defined by (4.11). Using the equalities (4.12) and induction, it is straightforward to show that

$$XC_\alpha(E, A, B) = C_\alpha(\bar{E}, \bar{A}, \bar{B}). \tag{4.13}$$

If the system (E, A, B) is controllable, then $C_\alpha(E, A, B)$ has full rank and it follows that X is unique. It then follows from (4.11) that Y is unique.

We are now in a position to describe the η-orbit closures of controllable systems in $S(n, m)$.

THEOREM 4.3. *Let* $(\bar{E}, \bar{A}, \bar{B}), (E, A, B) \in S(n, m)$ *and suppose that* (E, A, B) *is controllable. Then* $(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\eta(E, A, B)}$ *if and only if the following two conditions are satisfied*:

(i) *There exists a unique pair of matrices* $X, Y \in K^{n\times n}$ *such that* $YE = \bar{E}X$, $YA = \bar{A}X$, *and* $\bar{B} = YB$.

(ii) $D_j(E, A)$ *divides* $D_j(\bar{E}, \bar{A})$ *for all* j, $1 \leqq j \leqq n$.

Proof. First, suppose that $(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\eta(E, A, B)}$. The existence of matrices X, Y satisfying condition (i) follows from Lemma 4.1, and the uniqueness was established in Remark 4.2. Clearly, $(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)}$, and so condition (ii) follows from Theorem 3.7.

Conversely, suppose that conditions (i) and (ii) are satisfied. By Theorem 3.7, condition (ii) implies that $(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)}$. Then it follows from Lemma 3.2 that $\bar{A}_\alpha \in \overline{O_\gamma(A_\alpha)}$ for any $\alpha \in K$ such that $\det(\alpha E - A) \neq 0$. (Recall that γ denotes the conjugation action on $K^{n\times n}$.) Moreover, it follows from Remark 4.2 that $XA_\alpha = \bar{A}_\alpha X$ and $XB_\alpha = \bar{B}_\alpha$. By Lemma 4.4 of [13], there exists a sequence (R_k) in $\mathrm{Gl}_n(K)$ such that

$$\lim_{k\to\infty} R_k A_\alpha R_k^{-1} = \bar{A}_\alpha \quad \text{and} \quad \lim_{k\to\infty} R_k = X. \tag{4.14}$$

Define $L_k \in \mathrm{Gl}_n(K)$ by

$$L_k = (\alpha\bar{E} - \bar{A})R_k(\alpha E - A)^{-1}. \tag{4.15}$$

It follows from (4.14) that

$$\lim_{k\to\infty} L_k E R_k^{-1} = \bar{E}. \tag{4.16}$$

On the other hand, the definition (4.15) of L_k implies that

$$L_k(\alpha E - A)R_k^{-1} = \alpha\bar{E} - \bar{A}. \tag{4.17}$$

This, together with (4.16), implies that

$$\lim_{k\to\infty} L_k A R_k^{-1} = \bar{A}. \tag{4.18}$$

Because $\lim_{k\to\infty} R_k = X$ and, by (4.12), $XB_\alpha = \bar{B}_\alpha$, we have

$$\lim_{k\to\infty} R_k(\alpha E - A)^{-1}B = (\alpha\bar{E} - \bar{A})^{-1}\bar{B}.$$

It follows from (4.15) that

$$\lim_{k\to\infty} L_k B = \lim_{k\to\infty} (\alpha\bar{E} - \bar{A}) R_k (\alpha E - A)^{-1} B = \bar{B}.$$

Therefore $(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\eta(E, A, B)}$. □

By duality, we obtain an analogous result for systems of the form

$$E\dot{x} = Ax,$$
$$y = Cx \quad \text{where } \det(sE - A) \not\equiv 0.$$

By [19], we see that such a system is observable if and only if the system

$$E^t\dot{x} = A^t x + C^t u$$

is controllable. Applying Theorem 4.3 to the system (E^t, A^t, C^t), we obtain Corollary 4.4.

COROLLARY 4.4. *Suppose that $(\bar{E}, \bar{A})$ and (E, A) are regular pencils and suppose that (E, A, C) is observable. Let ψ be the action of $\mathrm{Gl}_n(K) \times \mathrm{Gl}_n(K)$ on matrix triples given by*

$$(L, R) \cdot (E, A, C) = (LER^{-1}, LAR^{-1}, CR^{-1}).$$

Then $(\bar{E}, \bar{A}, \bar{C}) \in \overline{O_\psi(E, A, C)}$ if and only if the following two conditions are satisfied:

(i) *There exists a unique pair of matrices U, $W \in K^{n\times n}$ such that $EW = U\bar{E}$, $AW = U\bar{A}$, and $\bar{C} = CW$.*

(ii) *$D_j(E, A)$ divides $D_j(\bar{E}, \bar{A})$ for all j, $1 \leqq j \leqq n$.*

In the regular case where $E = \bar{E} = I_n$, condition (i) coincides with the conclusion of Theorem 4.1 in [13]. Thus Theorem 4.3 yields a straight generalization of the main result of Khadr and Martin. The following corollary characterizes those systems $(E, A, B) \in S(n, m)$ that have a closed η-orbit, i.e., those that degenerate only to equivalent systems.

COROLLARY 4.5. *For any $(E, A, B) \in S(n, m)$, the orbit $O_\eta(E, A, B)$ is closed in $S(n, m)$ if and only if (E, A, B) is equivalent to a system $(\hat{E}, \hat{A}, 0)$ with*

$$\hat{E} = \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix} \quad \text{and} \quad \hat{A} = \begin{bmatrix} S & 0 \\ 0 & I_{n-r} \end{bmatrix}$$

where S is semisimple.

Proof. If $O_\eta(E, A, B)$ is closed, then B is necessarily zero since every system degenerates to one with $B = 0$ via

$$\lim_{\varepsilon\to 0} \varepsilon I \cdot (E, A, B) \cdot (\varepsilon I)^{-1} = (E, A, 0).$$

A system $(E, A, 0) \in S(n, m)$ has a closed η-orbit if and only if $O_\varepsilon(E, A)$ is closed. Thus the corollary follows from Remark 3.9. □

In the following proposition we prove that every noncontrollable system in $S(n, m)$ is the degeneration of a controllable system, i.e.,

$$S(n, m) = \bigcup_{(E,A,B)\in S^c(n,m)} \overline{O_\eta(E, A, B)},$$

whereas a controllable system cannot degenerate to a controllable system.

PROPOSITION 4.6.

$$S(n, m) \setminus S^c(n, m) = \bigcup_{(E,A,B)\in S^c(n,m)} \partial O_\eta(E, A, B). \tag{4.19}$$

Proof. Since η is an algebraic $\mathrm{Gl}_n(K)$-action, orbits in the boundary of $O_\eta(E, A, B)$ have dimension strictly less than dim $O_\eta(E, A, B)$; see [11, Lemma 8.3]. But we have seen in Proposition 2.2 that orbits of controllable systems all have the same dimension. Therefore

$$S(n, m)\backslash S^c(n, m) \supset \bigcup_{(E,A,B)\in S^c(n,m)} \partial O_\eta(E, A, B).$$

To prove the opposite inclusion, let $(\bar{E}, \bar{A}, \bar{B})$ be an arbitrary element of $S(n, m)\backslash S^c(n, m)$ and choose $\alpha \in K$ such that $\det(\alpha\bar{E} - \bar{A}) \neq 0$. By Theorem 5.1 of [13] there exists a state-space system $(\hat{A}, \hat{B}) \in L^c(n, m)$ such that

$$\rho_\alpha(\bar{E}, \bar{A}, \bar{B}) = (\bar{A}_\alpha, \bar{B}_\alpha) \in \overline{O_\sigma(\hat{A}, \hat{B})}.$$

By Proposition 1.2, there exists a system (E, A, B) in $S^c_\alpha(n, m)$ with $\rho_\alpha(E, A, B) = (A_\alpha, B_\alpha) = (\hat{A}, \hat{B})$, and by Lemma 3.1 the η-orbit of the system (E, A, B) contains $(\bar{E}, \bar{A}, \bar{B})$ in its closure. □

Note that this result is stronger than the statement that $S^c(n, m)$ is dense in $S(n, m)$. The closures of orbits of an η-invariant open and dense subset of $S(n, m)$ do not necessarily cover $S(n, m)$. For instance, the open and dense subset $S_{\mathrm{reg}}(n, m)$ of all regular systems is closed with respect to orbit closure, since no regular system can degenerate to a singular system in $S(n, m)$ (a consequence of (3.16)). For a given noncontrollable system $(\bar{E}, \bar{A}, \bar{B})$ in $S(n, m)$, there will, in general, exist more than one orbit $O_\eta(E, A, B) \subset S^c(n, m)$ that contains $(\bar{E}, \bar{A}, \bar{B})$ in its closure. However, in the single input case $(m = 1)$, this orbit is uniquely determined. A proof of this fact is indicated in the following example.

Example 4.7. Let $m = 1$ and suppose (without loss of generality) that the pencil $(\bar{E}, \bar{A})$ is in standard form:

$$\bar{E} = \begin{bmatrix} I_r & 0 \\ 0 & \bar{N} \end{bmatrix}, \quad \bar{A} = \begin{bmatrix} \bar{J} & 0 \\ 0 & I_{n-r} \end{bmatrix}, \quad \bar{B} = \begin{bmatrix} \bar{b}_1 \\ \bar{b}_2 \end{bmatrix} \begin{matrix} \}r \\ \}n-r \end{matrix}$$

where $r = \deg \det(s\bar{E} - \bar{A})$ and $\bar{N}$, $\bar{J}$ are in Jordan normal form and $\bar{N}$ is nilpotent. Let

$$\bar{J} = \bigoplus_{i=1}^{s} J(\lambda_i, p_i)$$

where $J(\lambda_i, p_i)$ is an $r_i \times r_i$ Jordan matrix with eigenvalue λ_i and block structure p_i; (see (3.9)). Let $O_\eta(E, A, B)$ be an orbit in $S^c(n, 1)$ that contains $(\bar{E}, \bar{A}, \bar{B})$ in its closure. Again we may assume that (E, A) is in standard form with N and J in Jordan normal form. Since (N, b_2) and (J, b_1) are both controllable (1.9), it follows that N has only one nilpotent Jordan block $J(0, (n-r))$ and J has only one Jordan block $J(\lambda_i, (r_i))$ for each eigenvalue λ_i (for ease of notation, we let (a) denote the partition $(a, 0, \cdots, 0)$). Thus the orbit $O_\varepsilon(E, A)$ is uniquely determined by $(\bar{E}, \bar{A})$.

Using [4, VIII.2], it is not difficult to show that any two controllable systems (E, A, B) and (E, A, B') are η-equivalent. Thus we may choose B to be the column matrix with every entry equal to one. Thus, for any $(\bar{E}, \bar{A}, \bar{B}) \in S(n, 1)$, there exists a unique (and easily constructible) orbit $O_\eta(E, A, B)$ in $S^c(n, 1)$ with $(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\eta(E, A, B)}$.

In the multi-input case, the determination of all η-orbits whose closure contains a given noncontrollable system $(\bar{E}, \bar{A}, \bar{B})$ is an open problem. It is not even known under which conditions the number of such orbits is finite.

In the following examples, we consider the reverse situation: for a given controllable system (E, A, B), we seek to determine all the η-orbits in the closure of $O_\eta(E, A, B)$.

Example 4.8. Consider $\overline{O_\eta(E, A, B)}$, where

$$E = \begin{bmatrix} I_2 & 0 \\ 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} J_2 & 0 \\ 0 & I_2 \end{bmatrix}, \quad B = \begin{bmatrix} I_2 \\ I_2 \end{bmatrix}.$$

If $(\bar{E}, \bar{A}, \bar{B}) \in \overline{O_\eta(E, A, B)}$, then $(\bar{E}, \bar{A}) \in \overline{O_\varepsilon(E, A)}$. Thus, from Fig. 1, we see that, up to equivalence, there are two choices for $(\bar{E}, \bar{A})$:

(a) $(\bar{E}, \bar{A}) = (E, A)$.

(b) $(\bar{E}, \bar{A})$ is the pair at the bottom of Fig. 1.

Since (E, A, B) is controllable, the possibilities for $\bar{B}$ will be determined by the matrices $X, Y \in K^{n\times n}$ satisfying $YE = \bar{E}X$ and $YA = \bar{A}X$. In case (a), a straightforward computation shows that X and Y must be of the form:

$$X = Y = \left[\begin{array}{cc|c} a & b & 0 \\ 0 & a & \\ \hline & 0 & s \quad t \\ & & u \quad v \end{array}\right], \qquad a, b, s, t, u, v \in K. \tag{4.20}$$

Hence the systems $(E, A, \bar{B})$ in $\overline{O_\eta(E, A, B)}$ are those for which $\bar{b}_{21} = 0$ and $\bar{b}_{11} = \bar{b}_{22}$. Since left multiplication of $\bar{B}$ by nonsingular matrices Y of the form (4.20) yields a system $(E, A, Y\bar{B})$ in the same η-orbit, we find that exactly 12 η-orbits of the form $O_\eta(E, A, \bar{B})$ lie in $\overline{O_\eta(E, A, B)}$, namely, those determined by

$$\bar{B} = \begin{bmatrix} \bar{B}_1 \\ \bar{B}_2 \end{bmatrix}$$

with

$$\bar{B}_1 = I_2, J_2, \text{or } 0 \quad \text{and} \quad \bar{B}_2 = I_2, J_2, 0, \text{or} \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}. \tag{4.21}$$

Now consider case (b), where $\bar{B} = YB$ and

$$YE = \bar{E}X \quad \text{and} \quad YA = \bar{A}X. \tag{4.22}$$

Then X, Y must be of the form

$$X = Y = \left[\begin{array}{cc|c} 0 & a & 0 \\ 0 & b & \\ \hline & 0 & s \quad t \\ & & u \quad v \end{array}\right], \qquad a, b, s, t, u, v \in K. \tag{4.23}$$

It follows that $\bar{B}$ may be any matrix in $K^{4\times 2}$ satisfying $b_{11} = b_{21} = 0$. Two such systems $(\bar{E}, \bar{A}, \bar{B})$ and $(\bar{E}, \bar{A}, \bar{B}')$ are equivalent if and only if there are nonsingular matrices L, R such that

$$L\bar{E} = \bar{E}R, \quad L\bar{A} = \bar{A}R, \quad \bar{B}' = L\bar{B}. \tag{4.24}$$

It follows that

$$L = R = \begin{bmatrix} S & 0 \\ 0 & T \end{bmatrix} \quad \text{for some } S, T \in \mathrm{Gl}_2(K). \tag{4.25}$$

Then there are eight orbits of the form $O_\eta(\bar{E}, \bar{A}, \bar{B})$ in $\overline{O_\eta(E, A, B)}$: those for which

$$\bar{B} = \begin{bmatrix} \bar{B}_1 \\ \bar{B}_2 \end{bmatrix},$$

where

$$\bar{B}_1 = J_2 \text{ or } 0 \quad \text{and} \quad \bar{B}_2 = I_2, J_2, 0, \quad \text{or} \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}. \tag{4.26}$$

Although there are only 20 orbits in the closure of the η-orbits in Example 4.8, we see in the next example that there can be infinitely many orbits in the closure of an η-orbit, at least in the case $m \geqq 2$.

Example 4.9. Suppose $n \geqq 1$ and $m \geqq 2$. Let $E = I_n$, let $A = \operatorname{diag}(\alpha_1, \cdots, \alpha_n)$ such that $\alpha_1 = \alpha_2 \in K$ and $\alpha_i \neq \alpha_j$ for all $i \neq j$, $i, j \geqq 2$, and let

$$B = \begin{bmatrix} B_1 \\ \vdots \\ B_n \end{bmatrix}$$

where $B \in K^{n \times m}$ is any matrix such that (I, A, B) is controllable (i.e., all rows B_i of B are nonzero and B_1 and B_2 are independent). By Theorem 4.3, we know that $(I, A, \bar{B}) \in \overline{O_\eta(I, A, B)}$ if there is a matrix $X \in K^{n \times n}$ such that $XA = AX$ and $\bar{B} = XB$. Consider the family of $n \times n$ matrices

$$X(\varepsilon) = \left[\begin{array}{cc|c} 1 & \varepsilon & 0 \\ 0 & 0 & \\ \hline & 0 & 0 \end{array}\right], \qquad \varepsilon \in K,$$

and the resulting family of systems $(I, A, B(\varepsilon))$, $B(\varepsilon) = X(\varepsilon)B$, in $\overline{O_\eta(I, A, B)}$. Two of these systems, $(I, A, B(\varepsilon))$ and $(I, A, B(\varepsilon'))$, are η-equivalent if and only if there exists $T \in \mathrm{Gl}_n(k)$ such that $TA = AT$ and $B(\varepsilon') = TB(\varepsilon)$. If $TA = AT$, then T is of the form

$$T = T_2 \oplus D \text{ where } T_2 \in \mathrm{Gl}_2(K) \text{ and } D \in \mathrm{Gl}_{n-2}(K) \text{ is diagonal.}$$

Hence

$$TB(\varepsilon) = \begin{bmatrix} t_{11}(B_1 + \varepsilon B_2) \\ t_{21}(B_1 + \varepsilon B_2) \\ 0 \\ \vdots \\ 0 \end{bmatrix}.$$

If $TB(\varepsilon) = B(\varepsilon')$, then $t_{21} = 0$ and

$$t_{11}(B_1 + \varepsilon B_2) = B_1 + \varepsilon' B_2.$$

Since B_1 and B_2 are independent, it follows that $t_{11} = 1$ and $\varepsilon = \varepsilon'$. Therefore, the orbits $\{O_\eta(I, A, B(\varepsilon))\}_{\varepsilon} \in K$ are distinct and so $O_\eta(I, A, B)$ contains an infinite number of orbits.

To date, there is no general description of the η-orbit boundaries that contain only finitely many orbits.

ON DIFFERENTIAL GAMES OF FIXED DURATION WITH PHASE COORDINATE RESTRICTIONS ON ONE PLAYER*

K. HAJI-GHASSEMI†

Abstract. This paper considers differential games of fixed duration in which state constraints described by a given closed set **E** are imposed on one of the players. Using Berkovitz's definition of a game, the existence of the value is obtained first and, under mild conditions, the existence of saddle points. Sufficient conditions are then given for the value to be continuous or Lipschitz continuous.

Key words. differential games, phase restrictions, value, saddle point

AMS(MOS) subject classification. 90D25

Introduction. Consider a differential game of fixed duration with terminal time T, and dynamics:

$$\begin{aligned} &\dot{x} = f(t, x, y, z), \\ &x \in \mathbb{R}^n, \qquad y \in Y, \qquad z \in Z, \end{aligned} \tag{0.1}$$

where Y and Z are compact subsects of $\mathbb{R}^p$ and $\mathbb{R}^q$, respectively. Using the definition of a game according to Berkovitz, [1], the set-valued payoff, for a game with initial point (t_0, x_0), is defined by

$$\mathbf{P}[t_0, x_0, \Gamma, \Delta] = \{g(\varphi[\mathbf{T}]) \colon \varphi \in \Phi[\cdot, t_0, x_0, \Gamma, \Delta]\},$$

where Γ and Δ are strategies of the first and the second player, respectively, and $\Phi[\cdot, t_0, x_0, \Gamma, \Delta]$ is the set of all motions resulting from (Γ, Δ) (see [1] for definitions), and $g : \mathbb{R}^n \to \mathbb{R}$ is a given function.

Let **E** be a given closed set in $\mathbb{R}^n$. Suppose that in the above game we impose the additional restriction that one of the players, say the first player (maximizer), must choose his strategies in such a way that all resulting motions lie in **E**. Such restrictions can be imposed by defining the payoff through, in place of g, an extended real valued function $V(\cdot)$ defined by

$$V(\varphi) = \begin{cases} g(\varphi[T]) & \text{if } \varphi[t] \in \mathbf{E}\ \forall t \in [t_0, T] \\ -\infty & \text{otherwise.} \end{cases} \tag{0.2}$$

Note. If player II (minimizer) were chosen as the restricted player, one would replace "$-\infty$" by "$+\infty$" in the definition of $V(\varphi)$.

Games with phase coordinate restrictions as above have been considered previously by Friedman ([4], [5]), Scalzo ([8]), Subbotin [9], and Zaremba ([10], [11]). Each author, using a particular definition of a game, establishes the existence ([4], [5], [8], [9], [10], [11]) and continuity (or Lipschitz continuity) ([4], [5], [8]) of the value. In [4] and [5] it is also shown, under assumptions which guarantee the existence and the continuity of the value, that saddle points exist if one restricts the class of strategies appropriately. These are termed "X-saddle points." In this paper, using Berkovitz's definition of a game, introduced in [1], we obtain sharper results on the existence of value and saddle points and the regularity of the value for the games described above.

During the preparation of this work, the author was supported by a David Ross grant from Purdue University and, in part, by National Science Foundation grant DMS-8700813.

It is shown, in § 1, that the techniques of [1], slightly extended, give the existence of value in games where the restricted phase set is any closed subset of $\mathbb{R}^n$. In § 2, we show that, in general, saddle points exist in such games if the strategies of player I are limited to a smaller class. But, if the value is assumed to be always finite (but not necessarily continuous), then saddle points do exist without restricting the class of strategies. In § 3, which comprises a large part of the paper, first the regularity properties of the value are examined for an especially simple type of phase set, namely, a half-space: $\{x \in \mathbb{R}^n: x^n \geqq 0\}$. This case occurs frequently in examples. Conditions are given ensuring that the value is always greater than $-\infty$, continuous, or Lipschitz continuous. Here Theorem 3.1 is of the same nature as the existing results of Friedman and Scalzo ([4], [5], [8]), but with much less restrictive hypotheses (cf., for example, [5, Thms. 8.1 and 8.3]). Then extensions to more general sets are briefly commented on. We conclude by showing that if $\mathbf{E}$ is any closed set, continuity of the value of $\partial\mathbf{E}$ implies continuity on $\mathbf{E}$.

Throughout this work, unless otherwise stated, we assume the following concerning the data of the problems.

H1. (i) The function f in (0.1) is continuous on $[0, \mathbf{T}] \times \mathbb{R}^n \times Y \times Z$.

(ii) There is a constant $K > 0$ such that

$$|f(t, x, y, z) - f(t, \bar{x}, y, z)| \leqq K|x - \bar{x}|$$

for all $t \in [0, T]$, $x, \bar{x} \in \mathbb{R}^n$, $y \in Y$, $z \in Z$.

(iii) The function g, used to define the payoff, is continuous.

(iv) (Isaacs' condition). For any $(t, x) \in [0, \mathbf{T}] \times \mathbf{E}$, and $s \in \mathbb{R}^n$

$$\max_y \min_z \langle s, f(t, x, y, z)\rangle = \min_z \max_y \langle s, f(t, x, y, z)\rangle.$$

(v) The phase set $\mathbf{E}$ is closed.

Remarks. 1. For a discussion of the Isaacs' condition, see [1, § 9]. 2. In (ii), it suffices, for our results, that f be locally Lipschitz in x.

We use the concepts and notations introduced in [1] throughout the paper. We assume, therefore, that the reader is familiar with them. We will denote the Euclidean norm of $x \in \mathbb{R}^n$ by $|x|$, $\{x \in \mathbb{R}^n: |x - a| \leqq R\}$ by $B_R(a)$, and if $\mathbf{F} \subset \mathbb{R}^n$, $\inf\{|x - f|: f \in \mathbf{F}\}$ by $d(x, \mathbf{F})$.

1. Existence of the value. The main result of this section is Theorem 1.1. It asserts the existence of the value in games described by (0.1) and (0.2). We lead to it through several lemmas. We assume **H1** throughout this section.

LEMMA 1.1. *Let Δ be a strategy of the second player defined on $[t_0, \mathbf{T}]$, $t_0 \in [0, \mathbf{T}]$, such that for some $c \in \mathbb{R}$, and X, a compact subset of $\mathbf{E}$,*

$$\varphi \in \Phi[\cdot, t_0, x_0, \Delta], \quad x_0 \in X \Rightarrow V(\varphi) < c. \tag{1.1}$$

Then there exists an $\varepsilon > 0$ such that for any $x_0 \in X$ and $\Phi \in \Phi[\cdot, t_0, x_0, \Delta]$,

$$g(\varphi[\mathbf{T}]) \geqq c \Rightarrow \exists \hat{t} \in [t_0, \mathbf{T}] \quad \text{such that } d(\varphi[\hat{t}], \mathbf{E}) \geqq \varepsilon. \tag{1.2}$$

Proof. If the conclusion were false, then there would exist sequences $\{x_n\}$ in X, $\varepsilon_n \to 0$, and $\varphi_n \in \Phi[\cdot, t_0, x_n, \Delta]$ such that

$$g(\varphi_n[\mathbf{T}]) \geqq c \quad \text{and} \quad d(\varphi_n[t], \mathbf{E}) < \varepsilon_n, \quad \forall t \in [t_0, \mathbf{T}].$$

Since by [1, Lemma 6.2] $\cup\{\Phi[\cdot, t_0, x_n, \Delta]: n = 1, 2, \cdots\}$ is compact in the space of continuous functions on $[t_0, \mathbf{T}]$ with the uniform topology, we may assume, by taking

a subsequence, that there exist an $x_0 \in X$, and a motion $\varphi \in \Phi[\cdot, t_0, x_0, \Delta]$ such that as $n \to \infty$, $x_n \to x_0$, and $\varphi_n \to \varphi$, uniformly on $[t_0, T]$. Hence, for any $t \in [t_0, T]$,

$$d(\varphi[t], \mathbf{E}) = \lim_{n\to\infty} d(\varphi_n[t], \mathbf{E}) = 0.$$

Since $\mathbf{E}$ is closed, this gives $\varphi[t] \in \mathbf{E}$ for all $t \in [t_0, T]$. Therefore, by the definition of V and the continuity of g,

$$V(\varphi) = g(\varphi[T]) = \lim_{n\to\infty} g(\varphi_n[T]) \geqq c.$$

This contradicts (1.1). □

LEMMA 1.2. *Let $\alpha \in \mathbb{R}$. The set $D(\alpha) = \{(t, x): w^+(t, x) < \alpha\}$ is open. (In particular, $w^+(\cdot, \cdot)$ is upper semicontinuous.)*

Proof. Let $(t_0, x_0) \in D(\alpha)$ and $0 < \delta < (\alpha - w^+(t_0, x_0))/2$. Take $c = \alpha - \delta$. Then $w^+(t_0, x_0) < c$. Hence, by the definition of $w^+(t_0, x_0)$, there exists a strategy Δ such that for any $\varphi \in \Phi[\cdot, t_0, x_0, \Delta]$, we have $V(\varphi) < c$. Let $\varepsilon > 0$ be as in Lemma 1.1. Let $t_1 \in [0, \mathbf{T}]$, and define $s: [t_1, \mathbf{T}] \to [t_0, \mathbf{T}]$ by $s(t) = t_0 + (\mathbf{T} - t_0)(t - t_1)/(\mathbf{T} - t_1)$. Let $x_1 \in E$. Let $\Theta = \Theta(t_0, x_0, t_1, x_1)$ be the one-one onto map from the set of all strategies in the game with initial point (t_1, x_1) to those with initial point (t_0, x_0) defined using $s(\cdot)$ as in [1, p. 181]. By [1, Lemma 6.5], for every motion $\varphi \in \Phi[\cdot, t_1, x_1, \Theta^{-1}\Delta]$, there exists a motion $\bar{\varphi} \in \Phi[\cdot, t_0, x_0, \Delta]$ such that

$$\max \{|\varphi[t] - \bar{\varphi}[s(t)]|: t \in [t_1, T]\} \leqq \eta(\rho) \tag{1.3}$$

where $\rho \equiv |t_0 - t_1| + |x_0 - x_1|$, and $\eta(\rho) \to 0$ as $\rho \to 0$.

Let G be a bounded neighborhood of (t_0, x_0). It follows from **H1** that there exists an $R > 0$ such that any motion φ with its initial point in G satisfies $|\varphi[t]| \leqq R$. By the continuity of $g(\cdot)$, there exists $\sigma_1 > 0$ such that

$$0 < \sigma_1 < \varepsilon/2, \quad \text{and } |g(x) - g(x')| < \delta/2, \quad \forall x, x' \in B_R(0), |x - x'| < \sigma_1. \tag{1.4}$$

Let $\sigma_2 > 0$ be such that $\rho < \sigma_2 \Rightarrow \eta(\rho) < \sigma_1$. Now suppose $\rho < \sigma_2$, and let $\varphi \in \Phi[\cdot, t_1, x_1, \Theta^{-1}\Delta]$. Let $\bar{\varphi} \in \Phi[\cdot, t_0, x_0, \Delta]$ such that (1.3) holds. Then either there exists a $\bar{t} \in [t_1, \mathbf{T}]$ with $\varphi[\bar{t}] \notin \mathbf{E}$, in which case, $V(\varphi) = -\infty$, or $\varphi[t] \in \mathbf{E}$ for all $t \in [t_1, \mathbf{T}]$, in which case, by (1.3) and (1.4), $d(\bar{\varphi}[t], \mathbf{E}) < \varepsilon/2$, for all $t \in [t_1, \mathbf{T}]$. Hence, by the choice of ε, $g(\bar{\varphi}[T]) < c$. Now, by (1.4) and the choice of δ, $g(\varphi[T]) < c + \delta/2 < \alpha$. Thus in either case, $V(\varphi) < \alpha - \delta/2$. Since $\varphi \in \Phi[\cdot, t_1, x_1, \Theta^{-1}\Delta]$ was chosen arbitrarily, we have

$$w^+(t_1, x_1) \leqq \sup_{\Gamma} P[t_1, x_1, \Gamma, \Delta] < \alpha.$$

We have shown that $|t_0 - t_1| + |x_0 - x_1| < \sigma_2 \Rightarrow (t_1, x_1) \in D(\alpha)$. Therefore $D(\alpha)$ is open. □

COROLLARY. *Let $(t_0, x_0) \in [0, T] \times E$, $v^0 = w^+(t_0, x_0)$, and*

$$C^+(v^0) = \{(t, x): w^+(t, x) \geqq v^0\}.$$

Then $C^+(v^0) \neq \varnothing$, and is closed. Moreover if $v^0 \neq -\infty$, then any $(t, x) \in C^+(v^0)$ has $x \in \mathbf{E}$.

Proof. $C^+(v^0) \neq \varnothing$ since $(t_0, x_0) \in C^+(v^0)$. The last statement is clear. Closure follows from Lemma 1.2. □

Lemma 1.4, below, is the analogue of [1, Lemma 8.3]; i.e., it states that the sets $C^+(\alpha)$, above are "u-stable"; see Remark 1 below. For future reference, we separate out the main argument of its proof in the next lemma. The proof is essentially the same as that given in [3]. We will therefore omit some of the details.

LEMMA 1.3. *Let* $t_1 \in [0, T]$, *and* $X \subset \mathbf{E}$ *be a compact set such that for some real number* c,

$$w^+(t_1, x) < c, \quad \forall x \in X.$$

Then there exists a strategy Δ^*, *defined on* $[t_1, \mathbf{T}]$, *such that*

$$V(\varphi) < c \quad \textit{for all } \varphi \in \cup\{\Phi[\cdot, t_1, x, \Delta^*]: x \in X\}.$$

Proof. Since X is compact and, by Lemma 1.2, w^+ is upper semicontinuous, there exists an $x^* \in X$ such that $w^+(t_1, x^*) = \max\{w^+(t_1, x): x \in X\}$. By assumption $c - w^+(t_1, x^*) > 0$. Let $\sigma \in (0, c - w^-(t_1, x^*))$. Then $w^+(t_1, x) < c - \sigma$ for all $x \in X$. Therefore, by the definition of w^+, for every $x \in X$, there exists a strategy $\Delta(x)$ such that

$$\varphi \in \Phi[\cdot, t_1, x, \Delta(x)] \Rightarrow V(\varphi) < c - \sigma. \tag{1.5}$$

Now, by Lemma 1.1, there exists an $\varepsilon > 0$ such that for any $\varphi \in \Phi[\cdot, t_1, x, \Delta(x)]$,

$$g(\varphi[\mathbf{T}]) \geqq c - \sigma \Rightarrow d(\varphi[\bar{t}], \mathbf{E}) \geqq \varepsilon. \tag{1.6}$$

It follows from [1, Lemma 6.5] and the continuity of g that there exists a $\delta(x)$ such that if $\bar{x} \in X$, $|x - \bar{x}| < \delta(x)$ then for all $\bar{\varphi} \in \Phi[\cdot, t_1, \bar{x}, \Theta\Delta(x)]$, there exits a $\varphi \in \Phi[\cdot, t_1, x, \Delta(x)]$ (with $\Theta = \Theta(t_1, \bar{x}, t_1, x)$ as in Lemma 1.2) such that

$$\text{(a)} \quad |\varphi[t] - \bar{\varphi}[t]| < \varepsilon/2, \quad \forall t \in [t_1, \mathbf{T}], \tag{1.7}$$

$$\text{(b)} \quad |g(\varphi[\mathbf{T}]) - g(\bar{\varphi}[\mathbf{T}])| < \sigma/2.$$

By (1.5), (1.6), and (1.7), either $g(\bar{\varphi}[\mathbf{T}]) < c - \sigma/2$ or for some $\bar{t} \in [t_1, T]$, $d(\bar{\varphi}[\bar{t}], \mathbf{E}) \geqq \varepsilon/2$. In either case $V(\bar{\varphi}) < c - \sigma/2$. Thus if $|x - \bar{x}| < \delta(x)$, then

$$V(\bar{\varphi}) < c - \sigma/2, \quad \forall \bar{\varphi} \in \Phi[\cdot, t_1, \bar{x}, \Theta\Delta(x)]. \tag{1.8}$$

Let $B(x)$ be the ball of radius $\delta(x)$ centered at x. Then $X \subset \cup\{B(x): x \in X\}$. Since X is compact, there exist $x_1, \cdots, x_k$ such that $X \subset \cup\{B(x_i): i = 1, \cdots, k\}$. Now we define a strategy Δ^* as follows (see [3] for a more formal definition): if $\Pi_{n,i}$ denotes the nth-stage partition of $\Delta(x_i)$, $i = 1, \cdots, k$, let the nth-stage partition of Δ^* be $\Pi_n = \cup\{\Pi_{n,i}: i = 1, \cdots, k\}$. Given the initial point $x \in X$, let $j = j(x) = \min\{i: 1 \leqq i \leqq k$ and $|x - x_i| < \delta(x_i)\}$. Then Δ^*, at the nth-stage, plays the nth-stage of $\Theta\Delta(x_j)$. Note that this is possible since the partition points of $\Pi_{n,j}$ are among those of Π_n. It follows that if $\varphi \in \cup\{\Phi[\cdot, t_1, x, \Delta^*]: x \in X\}$ then $\varphi \in \Phi[\cdot, t_1, x, \Theta\Delta(x_{j(x)})]$. Therefore, by (1.8), $V(\varphi) < c - \sigma/2 < c$ for all $\varphi \in \cup\{\Phi[\cdot, t_1, x, \Delta^*]: x \in X\}$ as desired. □

LEMMA 1.4. *Let* $\alpha \in \mathbb{R}$, *and* $C^+(\alpha) = \{(t, x): w^+(t, x) \geqq \alpha\}$. *Let* $(\tau, \xi) \in C^+(\alpha)$ *and let* $\tau < t_1 < \mathbf{T}$. *Let* $v(\cdot)$ *be any control of the second player on* $[\tau, \mathbf{T}]$. *Then there exists a relaxed control* η *such that the corresponding relaxed trajectory* $\psi(\cdot)$, *with initial point* (τ, ξ) *satisfies* $(t_1, \psi(t_1)) \in C^+(\alpha)$.

Remark 1. The property described above will be referred to as the "u-stability" (or simply "stability") of the set $C^+(\alpha)$.

Proof. Suppose the assertion were false, then there would exist $t_1 \in (\tau, T)$ and $v(\cdot)$, a control function for player II, defined on $[\tau, \mathbf{T}]$ such that if $\psi(\cdot)$ is a relaxed trajectory corresponding to a relaxed control η, then $(t_1, \psi(t_1)) \notin C^+(\alpha)$. Let Ψ be the set consisting of all points $\psi(t_1)$ for all such ψ. Then Ψ is compact ([1, Lemmas 6.1, 6.2]). Set $X = \Psi \cap \mathbf{E}$. X is compact since $\mathbf{E}$ is closed and Ψ is compact. Also, for all $x \in X$, $(t_1, x) \notin C^+(\alpha)$. Therefore, by the definition of $C^+(\alpha)$, $w^+(t_1, x) < \alpha$ for all $x \in X$. Since w^+ is upper semicontinuous and X is compact, there exists $\alpha' < \alpha$ such that $w^+(t_1, x) < \alpha' < \alpha$, for all $x \in X$. Hence, by Lemma 1.3, there exists a strategy Δ^*, defined on $[\tau, \mathbf{T}]$, such that

$$V(\varphi) < \alpha', \quad \forall \varphi \in \cup\{\Phi[\cdot, t_1, x, \Delta^*]: x \in X\}. \tag{1.9}$$

Let $\hat{\Delta}$ be the concatenation of $v(\cdot)$, on $[\tau, t_1]$, and Δ^*, on $[t_1, \mathbf{T}]$. Then for every $\bar{\varphi} \in \Phi[\cdot, \tau, \xi, \hat{\Delta}]$, there exists a motion $\varphi \in \Phi[\cdot, t_1, \bar{\varphi}[t_1], \Delta^*]$ such that

$$\bar{\varphi}[t] = \varphi[t], \quad \forall t \in [t_1, \mathbf{T}]. \tag{1.10}$$

Hence $V(\bar{\varphi}) \leqq V(\varphi)$. By the definition of $\hat{\Delta}$, and [1, Lemma 6.1], there exists a relaxed trajectory ψ such that $\psi(t) = \bar{\varphi}[t]$ for all $t \in [\tau, t_1]$. Therefore if $\bar{\varphi}[t] \in E$ for all $t \in [\tau, t_1]$, then $\bar{\varphi}[t_1] \in X$. By (1.9), $V(\varphi) < \alpha'$. Using (1.10), we have $V(\bar{\varphi}) < \alpha' < \alpha$. Since $\bar{\varphi} \in \Phi[\cdot, t_1, \xi, \hat{\Delta}]$ was chosen arbitrarily, we conclude

$$w^+(\tau, \xi) \leqq \sup\{V(\bar{\varphi}): \bar{\varphi} \in \Phi[\cdot, \tau, \xi, \hat{\Delta}]\} \leqq \alpha' < \alpha.$$

This contradicts the assumption that $(\tau, \xi) \in C^+(\alpha)$, proving the lemma. □

Remark 2. Lemmas 1.2 and 1.4 have shown that if $C^+(\alpha)$, $\alpha \in \mathbb{R}$ is nonempty, then it is closed and "u-stable." Hence we may define extremal strategies, $\Gamma_e = \Gamma_e(C^+(\alpha))$, as in [1, p. 189].

The next lemma is the analogue of [1, Lemma 10.1]. Note that Lemma 9.1 of [1] is valid in our setting since it is independent of the pay-off. Therefore, using the closure and the u-stability of $C^+(\alpha)$, the same arguments as in [1, Lemma 10.1] prove the next lemma.

LEMMA 1.5. *Let* **H1** *hold and let* $(t_0, x_0) \in [0, \mathbf{T}] \times \mathbf{E}$. *Let* $v^0 = w^+(t_0, x_0)$, *and* $\Gamma_e = \Gamma_e(C^+(v^0))$. *Then for every motion* $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma_e]$,

$$(t, \varphi[t]) \in C^+(v^0), \quad \forall t \in [t_0, \mathbf{T}].$$

It follows from this lemma, therefore, that $V(\varphi) = g(\varphi[\mathbf{T}]) \geqq v^0$, for all $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma_e]$. Now the existence of the value follows easily.

THEOREM 1.1. *Let* **H1** *hold and let* $(t_0, x_0) \in [0, \mathbf{T}] \times \mathbf{E}$. *Then the differential game described by* (0.1), *and* (0.2) *has value* $w(t_0, x_0)$.

Proof. Let $v^0 = w^+(t_0, x_0)$. If $v^0 = -\infty$ then clearly $w^-(t_0, x_0) = -\infty$ also, and the value exists trivially. Suppose $v^0 \neq -\infty$, and let $\Gamma_e = \Gamma_e(C^+(v^0))$. Then by Lemma 1.5, for every motion $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma_e]$, $V(\varphi) \geqq v^0$. Hence,

$$w^-(t_0, x_0) \geqq \inf_{\Delta} P[t_0, x_0, \Gamma_e, \Delta] \geqq v^0 = w^+(t_0, x_0).$$

Since the reverse inequality always holds, we are done. □

Remark 3. It is clear that games with phase restrictions on the minimizer, player II, can be treated similarly. Thus games with phase restrictions on only one of the players, in the sense described above, have value.

We conclude this section with a discussion of the set

$$C^-(\alpha) = \{(t, x): t \in [0, T], x \in E, \text{ and } w^-(t, x) \leqq \alpha\}, \quad \alpha \in \mathbb{R},$$

in games with phase restrictions only on the maximizer. Let $(\tau, \xi) \in C^-(\alpha)$ (some $\alpha \in \mathbb{R}$), and $t_1 \in [\tau, T]$. Let $u(\cdot)$ be a control function of the first player, defined on $[\tau, t_1]$, with the property that for any control function, $v(\cdot)$, of the second player and a solution, φ, of

$$\dot{x}(t) = f(t, x, u(t), v(t)), \quad \text{a.e. } t \in [\tau, t_1], \qquad x(\tau) = \xi, \tag{1.11}$$

φ satisfies $\varphi(t) \in E$ for all $t \in [\tau, t_1]$. Then by arguments similar to those of Lemma 1.4, we can show that there exists a relaxed control ζ such that the corresponding relaxed trajectory ψ satisfies

$$(t_1, \psi(t_1)) \in C^-(\alpha). \tag{1.12}$$

Now if $\xi \in \text{int}(E)$, it follows from **H1** that there is a $\delta = \delta(\xi) > 0$ such that for any control function $v(\cdot)$ and solution φ of (1.11) $\varphi(t) \in E$, $t \in [\tau, \tau + \delta]$. Hence we have the following lemma.

LEMMA 1.6. *Let* $(\tau, \xi) \in C^{-}(\alpha)$, *some* $\alpha \in \mathbb{R}$. *Let* $\xi \in \text{int}(E)$. *Then there exists a* $\delta = \delta(\xi) > 0$ *such that for any* $t_1 \in (\tau, \tau + \delta)$, *and any* $u(\cdot)$, *a control of the first player, defined on* $[\tau, t_1]$, *there exists a relaxed control* ζ *such that* ψ, *the corresponding relaxed trajectory, satisfies* (1.12).

2. Saddle points. In this section, we consider the question of the existence of saddle points in a game of § 1 with initial point (t_0, x_0). If $w(t_0, x_0) = -\infty$, then there exists a Δ^* such that $V(\varphi) = -\infty$ for all $\varphi \in \Phi[\cdot, t_0, x_0, \Delta^*]$. Hence for any Γ, the pair (Γ, Δ^*) forms a saddle point trivially. Hence we will assume, below, that $w(t_0, x_0) > -\infty$. We will first show, in Theorem 2.1, that, in general, saddle points exist if we restrict the class of strategies of the first player, appropriately. We will then prove the main theorem of this section, Theorem 2.2, which states that if $w(t, x) > -\infty$ for all $(t, x) \in [0, \mathbf{T}] \times \mathbf{E}$, (but not necessarily continuous there), then saddle points exist without any restrictions on the class of strategies.

We will use the following notation in this and later sections. For a pair of strategies (Γ, Δ),

1. $\Phi_m(\cdot, t_0, x_0, \Gamma, \Delta)$ will denote the set of all mth-stage trajectories resulting from (Γ, Δ) with initial point (t_0, x_0).
2. $\Phi_m(\cdot, t_0, x_0, \Gamma) = \cup \{\Phi_m(\cdot, t_0, x_0, \Gamma, \Delta): \Delta\}$.
3. $\delta_m(\Gamma) = \sup \{\max_{t \in [t_0, T]} d(\varphi_m(t), E): \varphi_m \in \Phi_m(\cdot, t_0, x_0, \Gamma)\}$.
4. $H_t = \{(t, x): x \in \mathbb{R}^n\}$.

DEFINITION. Let us call a class $\mathbb{\Gamma}$ of strategies Γ of the first player, "*restricted*" if $\delta_m(\Gamma) \to 0$ as $m \to \infty$, *uniformly* in $\Gamma \in \mathbb{\Gamma}$.

THEOREM 2.1. *Let* $(t_0, x_0) \in [0, \mathbf{T}] \times \mathbf{E}$, *with* $w(t_0, x_0) > -\infty$, *and* Γ_0 *be the extremal pointing strategy defined with respect to* $C^{+}(w(t_0, x_0))$. *Then for any restricted class* $\mathbb{\Gamma}$ *of strategies of player I, there exists* Δ_0 *such that*

$$\text{(2.1)} \qquad \text{(a)} \quad P[t_0, x_0, \Gamma_0, \Delta_0] = \{w(t_0, x_0)\},$$

$$\text{(b)} \quad \textit{For all } \Delta \textit{ and all } \Gamma \in \mathbb{\Gamma},$$

$$P[t_0, x_0, \Gamma, \Delta_0] \subseteqq P[t_0, x_0, \Gamma_0, \Delta_0] \subseteqq P[t_0, x_0, \Gamma_0, \Delta].$$

The theorem follows easily from Propositions 2.1 and 2.2 below. We first prove these propositions.

PROPOSITION 2.1. *Let* $\mathbb{\Gamma}^*$ *be the set of all strategies,* Γ, *of player I such that for any* $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma]$, $\varphi[t] \in E$, *for all* $t \in [t_0, \mathbf{T}]$. *Then for any* $\Gamma \in \mathbb{\Gamma}^*$, *we have* $\delta_m(\Gamma) \to 0$ *as* $m \to \infty$.

Proof. Suppose that for some Γ the conclusion were false. Then, by taking a subsequence, we may assume that there exists an $\varepsilon > 0$ such that $\delta_m(\Gamma) > \varepsilon$ for all m. By the definition of $\delta_m(\Gamma)$, there exists a $\varphi_m \in \Phi_m(\cdot, t_0, x_0, \Gamma)$ such that

$$\text{(2.2)} \qquad d(\varphi_m(t_m), \mathbf{E}) > \varepsilon \quad \text{for some } t_m \in [t_0, \mathbf{T}].$$

We may assume, by taking another subsequence if necessary, that there exist a $\bar{t} \in [t_0, T]$ and a $\bar{\varphi} \in \Phi[\cdot, t_0, x_0, \Gamma_0]$ such that

$$\text{(2.3)} \qquad \begin{aligned} &t_m \to \bar{t}, \quad \text{as } m \to \infty, \text{ and} \\ &\varphi_m \to \bar{\varphi}, \quad \text{uniformly on } [t_0, T], \text{ as } m \to \infty. \end{aligned}$$

Assumptions **H1** ensure that $\{\varphi_m\}$ is an equicontinuous sequence. Hence, it follows from (2.2) and (2.3) that $d(\bar{\varphi}[\bar{t}], E) \geqq \varepsilon$, contradicting the hypothesis. □

Remark. In particular, by Lemma 1.5, $\delta_m(\Gamma_0) \to 0$ as $m \to \infty$. It follows that if $\mathbb{\Gamma}$ is a restricted class then $\mathbb{\Gamma} \cup \{\Gamma_0\}$ is also a restricted class. *Hence we will always assume from now on that a restricted class contains* Γ_0. Note that, in a similar way, if $\Gamma \in \mathbb{\Gamma}^*$ and $\mathbb{\Gamma}$ is restricted, then $\mathbb{\Gamma} \cup \{\Gamma\}$ is also restricted.

PROPOSITION 2.2. *Let* $\mathbb{\Gamma}$ *be a restricted class. Then there exists a* Δ_0 *such that*

$$P[t_0, x_0, \Gamma, \Delta_0] \leqq w(t_0, x_0) \text{ for all } \Gamma \in \mathbb{\Gamma},$$

and

$$P[t_0, x_0, \Gamma_0, \Delta_0] = w(t_0, x_0).$$

Proof. The second assertion follows from the first and from Lemma 1.5. We now prove the first assertion. Let $v_0 = w(t_0, x_0) > -\infty$. By definition,

$$v_0 = \inf_{\Delta} \sup_{\Gamma} P[t_0, x_0, \Gamma, \Delta].$$

Hence for every n there exists a Δ_n such that, for every $\Gamma \in \mathbb{\Gamma}$,

$$P[t_0, x_0, \Gamma, \Delta_n] \leqq \sup_{\Gamma} P[t_0, x_0, \Gamma, \Delta_n] < v_0 + 1/n. \tag{2.4}$$

Claim. For every n, there exists an $m(n)$ such that if $m \geqq m(n)$, then for any $\varphi_m \in \bigcup \{\Phi_m(\cdot, t_0, x_0, \Gamma, \Delta_n) : \Gamma \in \mathbb{\Gamma}\}$, we have $g(\varphi_m(T)) < v_0 + 1/n$.

Verification. From (2.4) we have that for all $\varphi \in \Phi[\cdot, t_0, x_0, \Delta_n]$, $V(\varphi) < v_0 + 1/n$. By Lemma 1.1, there exists an $\varepsilon_n > 0$ such that for all $\varphi \in \Phi[\cdot, t_0, x_0, \Delta_n]$,

$$g(\varphi[\mathbf{T}]) \geqq v_0 + 1/n \Rightarrow \exists \bar{t} \in [t_0, \mathbf{T}] \text{ satisfying } d(\varphi[\bar{t}], \mathbf{E}) \geqq \varepsilon_n. \tag{2.5}$$

Since $\mathbb{\Gamma}$ *is restricted, there exists an* $m(n)$ such that

$$m \geqq m(n) \Rightarrow \delta_m(\Gamma) < \varepsilon_n/2, \quad \forall \Gamma \in \mathbb{\Gamma}. \tag{2.6}$$

Hence if $m \geqq m(n)$ and $\varphi_m \in \bigcup \{\Phi_m(\cdot, t_0, x_0, \Gamma, \Delta_n) : \Gamma \in \mathbb{\Gamma}\}$ then,

$$\max \{d(\varphi_m(t), \mathbf{E}) : t \in [t_0, \mathbf{T}]\} \leqq \delta_m(\Gamma) < \varepsilon_n/2. \tag{2.7}$$

Now suppose that the claim is false. Then there exists an n and a sequence $m(i) \to \infty$ as $i \to \infty$, and $\{\varphi_{m(i)}\} \subset \bigcup \{\Phi_{m(i)}(\cdot, t_0, x_0, \Gamma, \Delta_n) : \Gamma \in \mathbb{\Gamma}\}$ such that $g(\varphi_{m(i)}(T)) \geqq v_0 + 1/n$. Since $\{\varphi_{m(i)}\}$ is a sequence of $m(i)$th-stage trajectories of Δ_n, there exists a motion $\varphi \in \Phi[\cdot, t_0, x_0, \Delta_n]$ such that $\varphi_{m(i)} \to \varphi$ uniformly on $[t_0, \mathbf{T}]$, as $i \to \infty$. Hence by the continuity of g, $g(\varphi[\mathbf{T}]) \geqq v_0 + 1/n$. Therefore, by (2.5), there exists a $\bar{t} \in [t_0, T]$ such that $d(\varphi[\bar{t}], \mathbf{E}) \geqq \varepsilon_n$. Since $\varphi_{m(i)}$ converges to φ uniformly, we have

$$d(\varphi_{m(i)}(\bar{t}), \mathbf{E}) \geqq \varepsilon_n/2,$$

for all i sufficiently large. This contradicts (2.7), proving the claim.

Now define Δ_0 as $\{\Delta_{n,m(n)}, \Pi_{n,m(n)}\}$ where $\Pi_{n,i}$ is the ith-stage partition of Δ_n. That is, the nth-stage of Δ_0 is the $m(n)$th-stage of Δ_n. Hence if $\Gamma \in \mathbb{\Gamma}$, $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma, \Delta_0]$ and $\{\varphi_n\}$ is the sequence of nth-stage trajectories converging to φ, then, by the definition of Δ_0, $\varphi_n \in \Phi_{m(n)}(\cdot, t_0, x_0, \Gamma, \Delta_n)$. Therefore, by the above claim, $g(\varphi_n(T)) < v_0 + 1/n$. Hence $V(\varphi) \leqq g(\varphi[T]) \leqq v_0$. Since Γ in $\mathbb{\Gamma}$ and $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma, \Delta_0]$ were chosen arbitrarily, we conclude:

$$P[t_0, x_0, \Gamma, \Delta_0] \leqq v_0 \quad \text{for all } \Gamma \in \mathbb{\Gamma}, \tag{2.8}$$

as desired. □

Proof of Theorem 2.1. As noted above,

$$P[t_0, x_0, \Gamma_0, \Delta_0] = w(t_0, x_0). \tag{2.9}$$

On the other hand, by Lemma 1.5, $w(t_0, x_0) \leqq P[t_0, x_0, \Gamma_0, \Delta]$ for any Δ. Hence, using (2.8) and (2.9), we have

$$P[t_0, x_0, \Gamma, \Delta_0] \leqq P[t_0, x_0, \Gamma_0, \Delta_0] \leqq P[t_0, x_0, \Gamma_0, \Delta]$$

for all strategies Δ and all $\Gamma \in \mathbb{\Gamma}$, as was claimed. □

Before we state and prove Theorem 2.2, let us note that if $\Omega \subset [0, \mathbf{T}] \times \mathbf{E}$ is closed and "u-stable," then Lemmas 9.1 and 10.1 of [1] prove the following lemma.

LEMMA 2.1. *Suppose Ω is closed and u-stable. Let X be a compact subset of $\mathbf{E}$ and let $t \in [0, \mathbf{T}]$ be such that $\Omega \cap H_t \neq \varnothing$. Let Γ_e be the strategy defined extremally with respect to Ω. Then there exists a constant $C > 0$, independent of Ω, such that for any $\varphi \in \cup \{\Phi[\cdot, t, x, \Gamma_e]: x \in X\}$ we have*

$$d((\tau, \varphi[\tau]), \Omega \cap H_\tau) \leqq C d((t, x), \Omega \cap H_t).$$

Proof. If $(t, x) \in \Omega$ then the proof is exactly the same as that of [1, Lemma 10.1]. Otherwise, using the same notation as in [1, Lemma 10.1], we have $k = k(m) = 1$, and

$$\lim_{m \to \infty} \varepsilon_m(\tau_k) = d((t, x), C^+(\alpha) \cap H_t),$$

where $\varepsilon_m(\tau) \equiv d((\tau, \varphi_m(\tau)), C^+(\alpha) \cap H_\tau)$. As in that Lemma, we obtain

$$\varepsilon_m^2(t) \leqq \varepsilon_m^2(\tau_k)\, e^{\beta K} + \mathbf{E}(\delta_m)(e^{\beta K} - 1)/\beta, \quad \forall \tau \in [\tau_k, T],$$

where $\mathbf{E}(\cdot)$ is a function, depending on X and the modulus of continuity of f, such that $\mathbf{E}(r) \to 0$ as $r \to 0$, $K =$ Lipschitz constant of f and β is a constant, which in our setting depends only on f and X. Letting $m \to \infty$, we obtain the desired conclusion with $C = e^{\beta K/2}$. □

We are now ready to state and prove Theorem 2.2.

THEOREM 2.2. *Suppose that $w(t, x) > -\infty$ for all $(t, x) \in [0, \mathbf{T}] \times \mathbf{E}$. Then saddle points exist; i.e., for every $(t_0, x_0) \in [0, T] \times \mathbf{E}$, there exists Δ_0 such that for any Γ and Δ,*

$$P[t_0, x_0, \Gamma, \Delta_0] \leqq P[t_0, x_0, \Gamma_0, \Delta_0] \leqq P[t_0, x_0, \Gamma_0, \Delta],$$

where Γ_0 is the extremal strategy with respect to $C^+(t_0, x_0)$.

Remark. Conditions which guarantee $w(t, x) > -\infty$ for all $(t, x) \in [0, \mathbf{T}] \times \mathbf{E}$ can be given when more information is known about $\mathbf{E}$; see, for example, Proposition 3.1 below.

Proof. It can be easily verified that $w(t, x) > -\infty$ for all $(t, x) \in [0, \mathbf{T}] \times \mathbf{E}$ if and only if $[0, \mathbf{T}] \times \mathbf{E}$ is u-stable. Now, let $(t_0, x_0) \in [0, \mathbf{T}] \times \mathbf{E}$. Let $R > 0$ be such that all trajectories with initial point (t_0, x), x in a bounded neighborhood of x_0, remain in $B_R(0)$ on $[t_0, T]$. Let $M = \max\{|f(t, x, y, z)|: t \in [t_0, T], |x| \leqq R, y \in Y, z \in Z\}$. Let Γ_e denote the extremal strategy defined with respect to $[0, \mathbf{T}] \times \mathbf{E}$. By Lemma 2.1, there exists a constant $C > 0$ such that for all $\varphi \in \cup \{\Phi[\cdot, t_0, x, \Gamma_e]: |x| \leqq R\}$, we have $d(\varphi[t], \mathbf{E}) \leqq C d(x, \mathbf{E})$. Fix $\mathcal{K} > C$. Then it follows from the compactness of $\cup \{\Phi[\cdot, t_0, x, \Gamma_e]: |x| \leqq R\}$ (cf., [1, Lemma 6.1]) that there exists an m^* such that if $m \geqq m^*$ then

$$d(\varphi_m(t), \mathbf{E}) \leqq \mathcal{K} d(x, \mathbf{E}), \quad \text{for all } \varphi_m \in \cup \{\Phi_m(\cdot, t_0, x, \Gamma_e): |x| \leqq R\}. \tag{2.10}$$

Without loss of generality, we will assume that $m^* = 1$.

Now let $\mathbb{\Gamma} = \{\Gamma: \delta_m(\Gamma) \leqq C[\delta_m(\Gamma_0) + M(T - t_0)/m]\}$. Then, by Proposition 2.2, there exists a Δ_0 such that

$$P[t_0, x_0, \Gamma, \Delta_0] \leqq P[t_0, x_0, \Gamma_0, \Delta_0], \quad \text{for all } \Gamma \in \mathbb{\Gamma}. \tag{2.11}$$

Claim. Δ_0 has the desired property; i.e., (2.11) holds for any Γ.

Verification. Suppose that the claim is false. Then there exists a strategy Γ and a motion $\varphi \in \Phi[\cdot\, t_0, x_0, \Gamma, \Delta_0]$ such that $V(\varphi) > v_0$. In particular, $\varphi[t] \in \mathbf{E}$, for all $t \in [t_0, T]$. Let $\{\varphi_m(\cdot)\}$ be the sequence of mth-stage trajectories converging to φ. Let (u_m, v_m) denote the controls of φ_m. We will show that there exists a $\bar{\Gamma} \in \mathbb{\Gamma}$ such that $\varphi \in \Phi[\cdot, t_0, x_0, \bar{\Gamma}, \Delta_0]$. This contradicts (2.11), proving the claim.

Before defining $\bar{\Gamma}$, observe that since $\varphi[t] \in E$, for all $t \in [t_0, T]$, then

$$\max\{d(\varphi_m(t), \mathbf{E}): t \in [t_0, T]\} \to 0 \quad \text{as } m \to \infty.$$

Hence for every m, there exists $n(m) \geqq m$ such that

$$\max\{d(\varphi_n(t), \mathbf{E}): t \in [t_0, \mathbf{T}]\} \leqq \delta_m(\Gamma_0), \quad \textit{if } n \geqq n(m).$$

Let $N = \{n(i): i = 1, 2, \cdots\}$, and define $\bar{\Gamma}$ as follows. $\bar{\Gamma} = (\bar{\Gamma}_m, \Pi_m)$ where $\Pi_m = \{t_0 < \tau_1 < \cdots < \tau_m = T\}$ is a uniform partition of $[t_0, T]$ into m subintervals of length $(T - t_0)/m$. Now if $m \notin N$, then let $\bar{\Gamma}_m$ be the mth-stage of the extremal strategy Γ_0. If $m \in N$, then $\bar{\Gamma}_{m,i} = u_m \restriction [t_0, \tau_i)$, for $i = 1, \cdots, k(m)$, where u_m is as defined above, and $k = k(m) \geqq 1$ is the smallest index such that

$$\max\{d(\bar{\varphi}_m(\tau), \mathbf{E}): \tau \in [\tau_{k-1}, \tau_k]\} > \delta_m(\Gamma_0), \tag{2.12}$$

and $\bar{\varphi}_m$ is the trajectory, with initial point (t_0, x_0), resulting from $\bar{\Gamma}_m$ versus some Δ_m on $[t_0, \tau_k]$. Note that if (2.12) never occurs or if $k = m$ then $\bar{\Gamma}_m$ has been defined completely. If $k < m$, then for every $j \geqq k+1$, define $\bar{\Gamma}_{m,j}$ extremally with respect to $[0, \mathbf{T}] \times \mathbf{E}$. Observe that,

$$d(\bar{\varphi}_m(\tau_k), \mathbf{E}) \leqq d(\bar{\varphi}_m(\tau_{k-1}), \mathbf{E}) + M(\mathbf{T} - t_0)/m \leqq \delta_m(\Gamma_0) + M(\mathbf{T} - t_0)/m,$$

where the second inequality follows from the definition of k. Therefore, if $m \in N$, using (2.10), we have that for all $\tau \in [\tau_k, T]$,

$$d(\bar{\varphi}_m(\tau), \mathbf{E}) \leqq \mathcal{K} d(\bar{\varphi}_m(\tau_k), \mathbf{E}) \leqq \mathcal{K}(\delta_m(\Gamma_0) + M(\mathbf{T} - t_0)/m).$$

By the definition of $\bar{\Gamma}$, if $m \notin N$, then $d(\bar{\varphi}_m(\tau), \mathbf{E}) \leqq \delta_m(\Gamma_0)$. Thus, $\bar{\Gamma} \in \mathbb{\Gamma}$. Furthermore, for $m \in N$, (u_m, v_m) is the mth-stage outcome of $\bar{\Gamma}$ and Δ_0. Therefore, $\varphi_m \in \Phi_m(\cdot, t_0, x_0, \bar{\Gamma}, \Delta_0)$ if $m \in N$. Since $\varphi_m \to \varphi$, we have $\varphi \in \Phi[\cdot, t_0, x_0, \bar{\Gamma}, \Delta_0]$. This proves the claim and the theorem. □

3. Regularity of the value. Although by Lemma 1.2, the value of the game considered in § 1 (i.e., with phase restrictions on only the maximizing player) is upper semicontinuous, it can easily fail to be continuous or even finite valued in general, as shown in the following example.

Example 1. Consider the game with dynamics

$$\dot{x} = y - z - \varepsilon$$

with $\varepsilon > 0$, $Y = [0, 1]$, $Z = [0, 1]$, $\mathbf{E} = \{x \in \mathbb{R}: x \geqq 0\}$, and $g(x) = x$. It is clear that $w(t, x) = -\infty$ for any initial point (t, x) with $0 \leqq x < (T - t)\varepsilon$, $\mathbf{T}$ = final time.

In this section we will discuss conditions which imply the finiteness, continuity, or Lipschitz continuity, of the value.

To avoid cumbersome notation, for our first two results (i.e., up to Theorem 3.3) we will assume that the phase set $\mathbf{E}$ is of a particularly simple type, namely:

$$\mathbf{E} = \{x \in \mathbb{R}^n: x^n \geqq 0\}. \tag{3.1}$$

These results extend easily to more general types of sets, as remarked below.

Clearly, the difficulty with Example 1, above, is that, for some initial values (t, x), the second player can always force the first player to violate his phase constraint. The

following condition will prevent such situations, ensuring the finiteness of the value.

H2. For any $(t, x) \in [0, \mathbf{T}] \times \partial \mathbf{E}$,

$$\max_{y} \min_{z} f^n(t, x, y, z) \geqq 0.$$

PROPOSITION 3.1. *If* **H1** *and* **H2** *holds then* $w(t, x)$ *is finite for all* $(t, x) \in [0, \mathbf{T}] \times \mathbf{E}$.

Proof. $w(t_0, x_0) = \sup_{\Gamma} \inf_{\Delta} P[t_0, x_0, \Gamma, \Delta]$ is finite valued if and only if there exists a strategy Γ such that for any $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma]$, $\varphi[t] \in \mathbf{E}$ for all $t \in [t_0, T]$; i.e., $\varphi^n[t] \geqq 0$, for all $t \in [t_0, \mathbf{T}]$. Let

$$\Omega(t, x) = \{y \in Y: \min_{z} f^n(t, x, y, z) \geqq 0\}.$$

Then, by **H2**, $\Omega(t, x) \neq \varnothing$, if $x^n = 0$. Consider the strategy $\Gamma = \{\Gamma_m, \Pi_m\}$ where the mth-stage partition $\Pi_m = \{t_0 < \tau_1 < \tau_2 < \cdots < \tau_m = \mathbf{T}\}$ is a uniform partition of $[t_0, \mathbf{T}]$ into m intervals. *Let* $\delta_m \equiv \|\Pi_m\| = (\mathbf{T} - t_0)/m$. Let Γ_m be defined as in [1, p. 189] using a positional strategy $U(t, x)$ satisfying $U(t, x) \in \Omega(t, x^1, \cdots, x^{n-1}, 0)$. Let $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma]$ with $\{\varphi_m(\cdot)\}$ as the sequence of mth-stage trajectories converging uniformly to φ.

Claim. $\varphi^n[t] \geqq 0$ for all $t \in [t_0, T]$. If not, then there exists a $\acute{t} \in [t_0, T]$ such that $\varphi^n[\acute{t}] < 0$. Let $\bar{t} = \inf\{t < \acute{t}: \varphi^n[\tau] < 0 \text{ for all } \tau \in (t, \acute{t}]\}$ and $\sigma = \acute{t} - \bar{t}$. We will arrive at a contradiction. By the definition of $\bar{t}$ and the continuity of φ, we have $\varphi^n[\bar{t}] = 0$, and $\varphi^n[t] < 0$ for all $t \in (\bar{t}, \bar{t} + \sigma]$. For each m, let $k = k(m)$ and $j = j(m)$ be the smallest integers satisfying

$$\text{(i)} \quad \bar{t} \in [t_0, \tau_k) \quad \text{and} \quad \text{(ii)} \quad \bar{t} + \sigma \in [\tau_j, \tau_{j+1})$$

Then,

$$\text{(3.2)} \qquad \text{(a)} \quad \tau_k \to \bar{t} \text{ and } \tau_j \to \bar{t} + \sigma \quad \text{as } m \to \infty.$$

$$\text{(b)} \quad \varphi^n_m(\tau_k) \to \varphi^n[\bar{t}] = 0 \quad \text{as } m \to \infty.$$

$$\text{(c)} \quad \varphi^n_m(t) < 0, \quad \forall t \in [\tau_k, \tau_j], \quad \text{for } m \text{ sufficiently large.}$$

Define $h(t, x, y) = \min\{f^n(t, x, y, z): z \in Z\}$. It follows from **H1** that

$$\text{(3.3)} \qquad \text{(a)} \quad |h(t, x, y) - h(t, \bar{x}, y)| \leqq K|x - \bar{x}|, \quad \forall t \in [0, T]; \ y \in Y; \quad x, \bar{x} \in \mathbb{R}^n,$$

$$\text{(b)} \quad h(t, x, U(t, x)) \geqq 0 \quad \text{if } x^n = 0,$$

where K = Lipschitz constant of f as a function of x. Statement (b) follows from the definition of $U(t, x)$. Let $R > 0$ be large enough so that $\max\{|\varphi_m(t)|: t \in [t_0, T]\} \leqq R$ for all m. Define $M = \max\{|f(t, x, y, z)|: t \in [0, T], |x| \leqq R, y \in Y, z \in Z\}$ and

$$\omega(r) = \sup\{|f^n(t, x, y, z) - f^n(t', x', y', z')|: |(t, x, y, z) - (t', x', y', z')| \leqq r, |x| \leqq R, |x'| \leqq R\},$$

then $\omega(r) \to 0$ as $r \to 0$. Now if $t \in [\tau_i, \tau_{i+1}]$, then

$$f^n(t, \varphi_m(t), y_i, v_m(t)) \geqq f^n(\tau_i, \varphi_m(\tau_i), y_i, v_m(t)) - \omega((M+1)\delta_m),$$

where $y_i \equiv U(\tau_i, \varphi_m(\tau_i))$. Hence

$$\text{(3.4)} \qquad \varphi^n_m(t) \geqq \varphi^n_m(\tau_i) - \delta_m \omega((M+1)\delta_m) + \int_{\tau_i}^{t} f^n(\tau_i, \varphi_m(\tau_i), y_i, v_m(\tau))\, d\tau.$$

By the definition of h, for almost every $\tau \in [\tau_i, t]$, we have

$$f^n(\tau_i, \varphi_m(\tau_i), y_i, v_m(\tau)) \geqq h(\tau_i, \varphi_m(\tau_i), y_i).$$

Let $\hat{\varphi}_m(t) \equiv (\varphi_m^1(t), \cdots, \varphi_m^{n-1}(t), 0)$, then by (3.3),

$$h(\tau_i, \varphi_m(\tau_i), y_i) \geqq h(\tau_i, \hat{\varphi}_m(\tau_i), y_i) - K|\varphi_m^n(\tau_i)| \geqq -K|\varphi_m^n(\tau_i)|.$$

Therefore, from (3.4), we get:

$$\varphi_m^n(t) \geqq \varphi_m^n(\tau_i) - \delta_m K|\varphi_m^n(\tau_i)| - \delta_m \omega((M+1)\delta_m), \quad \forall t \in [\tau_i, \tau_{i+1}).$$

Using (3.2.c), we obtain that if $k \leqq i \leqq j$ then

$$\varphi_m^n(t) \geqq \varphi_m^n(\tau_i)(1+\delta_m K) - \delta_m \omega((M+1)\delta_m). \tag{3.5}$$

It follows, using $\varphi_m^n(\tau_k) < 0$, that for any $t \in [\tau_k, \tau_j)$,

$$\varphi_m^n(t) \geqq \varphi_m^n(\tau_k)(1+\delta_m K)^{k-j} - \delta_m \omega((M+1)\delta_m)(1+\cdots+(1+\delta_m K)^{k-j-1}).$$

Since $k-j \leqq m$, we may replace $k-j$ by m (note that $\varphi_m^n(\tau_k) < 0$):

$$\varphi_m^n(t) \geqq \varphi_m^n(\tau_k)(1+\delta_k K)^m - \delta_m \omega((M+1)\delta_m)(1+\cdots+(1+\delta_m K)^m).$$

This gives, after summing the last expression on the right and regrouping, that for every $t \in [\tau_k, \tau_j]$,

$$\varphi_m^n(t) \geqq [\varphi_m^n(\tau_k) - \delta_m \omega((M+1)\delta_m)](1+\delta_m K)^m - \omega((M+1)\delta_m)/K.$$

Letting $m \to \infty$ and using (3.2.a), (3.2.b), the fact that $\delta_m = (T-t_0)/m$ and $\omega((M+1)\delta_m) \to 0$, we get $\varphi^n[t] \geqq 0$ for all $t \in [\bar{t}, \bar{t}+\sigma]$, contradicting the choice of $\bar{t}$ and σ, and proving the proposition. □

COROLLARY. *If E is as in* (3.1) *and* **H2** *holds, then for any $(t_0, x_0) \in [0, T] \times E$ the game with initial point (t_0, x_0) has a saddle point.*

Proof. To obtain the proof, combine Theorem 2.2 and Proposition 3.1. □

That condition **H2** is not sufficient in itself for the continuity of the value can be seen in the following example.

Example 2. Consider the game with dynamics:

$$\dot{x}^1 = 0, \qquad \dot{x}^2 = y - z, \qquad \dot{x}^3 = x^1 y,$$

control sets $Y = Z = [0, 1]$, $g(x) = x^2$, where $x = (x^1, x^2, x^3)$, and some $T > 0$ as the fixed final time. The phase set is $E = \{x \in \mathbb{R}^3 : x^3 \geqq 0\}$. Consider $x_0 \in \partial E$ (i.e., $x_0^3 = 0$) and some initial time $t_0 < T$. If $x_0^1 = 0$ then the optimal plays are $y^* \equiv 1$ and $z^* \equiv 1$ and $w(t_0, x_0) = x_0^2$. However if $x_0^1 < 0$ then the only admissible choice for player I is $y^* \equiv 0$. Hence, $w(t_0, x_0) = x_0^2 - (T - t_0)$. Therefore, on ∂E, w is discontinuous.

Remark. It is not difficult to find examples of games where w is discontinuous in the interior of $[0, T] \times E$. However, as will be shown in Theorem 3.3, if the value w is discontinuous on $[0, T] \times E$ then it is also discontinuous on $[0, T] \times \partial E$.

Let us also observe that the value in the following variant of the above example is continuous:

Example 3. In Example 2, let us change $\dot{x}^3$ to

$$\dot{x}^3 = x^1 y + \varepsilon$$

for some $\varepsilon > 0$. Consider the resulting game. For (t_0, x_0) (with $x_0 \in E$), the value is given by:

$$w(t_0, x_0) = \begin{cases} x_0^2 & \text{if } x_0^1 \geqq -\varepsilon \\ x_0^2 + ((\varepsilon/|x_0^1|) - 1)(T - \bar{t}) & \text{if } x_0^1 < -\varepsilon, \end{cases}$$

where $\bar{t} = \min(T, t_0 + x_0^3/(|x_0^1| - \varepsilon))$. Hence w is continuous.

Note. The existing results ([4], [5], and [8]) do not apply to this example because of their restrictive hypotheses.

We will show, in Theorem 3.1, that, in fact, the following strengthened versions of **H2** and **H1** ensure the continuity of the value:

H3. For every $t \in [0, T]$, $x \in \partial E$ (i.e., $x^n = 0$),

$$\max_y \min_z f^n(t, x, y, z) > 0.$$

H1′. Same as **H1** except for **H1**-(ii) which is changed to the following.

(ii) There exists a constant $K > 0$ such that

$$|f(t, x, y, z) - f(t', x', y, z)| \leqq K(|t - t'| + |x - x'|)$$

for all $t, t' \in [0, T]$, $x, x' \in E$, $y \in Y$, $z \in Z$.

We begin the discussion leading to Theorem 3.1 by introducing some of the parameters to be used in the proofs below.

Note 1. **H3** and our continuity assumptions on f imply that for any $R > 0$, there exist $\beta = \beta(R) > 0$ and $\varepsilon_0 = \varepsilon_0(R) > 0$ such that

$$\max_y \min_z f^n(t, x, y, z) \geqq \beta \tag{3.6}$$

for all $(t, x) \in [0, T] \times \{x \in \mathbb{R}^n : |x| \leqq R : |x| \leqq R, |x^n| \leqq \varepsilon_0\}$. We will denote by $\tilde{y}(t, x)$ any element of Y which attains the maximum in (3.6).

Note 2. Let $(\bar{t}, \bar{x}) \in [0, T] \times \{x \in \mathbb{R}^n : |x| \leqq R, |x^n| \leqq \varepsilon_0\}$, and let φ_v be a solution of

$$\dot{x} = f(t, x, \tilde{y}(\bar{t}, \bar{x}), v(t)), \quad \text{a.e. } t \in [\bar{t}, T], \qquad x(\bar{t}) = \bar{x},$$

where $v(\cdot)$ is some control function of player II. We will denote by $h_1 = h_1(R)$ a positive number such that

$$f^n(t, \varphi_v(t), \tilde{y}(\bar{t}, \bar{x}), v(t)) \geqq \beta/2, \quad \text{a.e. } t \in [\bar{t}, \bar{t} + h_1] \tag{3.7}$$

for any choice of $v(\cdot)$. That such an h_1 exists follows easily from (3.6) and the continuity assumptions on f.

Note 3. Let (t_0, x_0), (t_1, x_1) be given in $[0, T) \times X$, where X is a bounded subset of E. Let $s : [t_1, T] \mapsto [t_0, T]$ be defined by $s(\tau) = t_0 + (\tau - t_1)(T - t_0)/(T - t_1)$. Recall from [1, Lemma 6.4] that if **H1′** holds then there exists a constant $\tilde{K}$, independent of the initial points (t_i, x_i), such that if φ, φ' are solutions to

$$\dot{x} = f(t, x, u(t), v(t)), \quad \text{a.e. } t \in [t_1, T], \quad x(t_1) = x_1, \tag{3.8}$$

and

$$\dot{x} = f(t, x, u(s^{-1}(t)), v(s^{-1}(t))), \quad \text{a.e. } t \in [t_0, T], \qquad x(t_0) = x_0, \tag{3.9}$$

respectively, for some pair of controls $(u(\cdot), v(\cdot))$, then

$$\max \{|\bar{\varphi}(t) - \varphi(s(t))| : t \in [t_1, T]\} \leqq \tilde{K}(|t_0 - t_1| + |x_0 - x_1|). \tag{3.10}$$

We can now state and prove the main lemma leading to Theorem 3.1.

LEMMA 3.1. *Suppose* **H1′** *and* **H3** *hold. Then for every compact subset X of E, there exist $\mu > 0$, $\delta > 0$, and $C > 0$, depending on X, such that given a pair of points (t_0, x_0) and (t_1, x_1) in $[0, T) \times X$ with*

$$|t_0 - t_1| + |x_0 - x_1| < \delta, \tag{3.11}$$

there exists a strategy Γ^* on $[t_1, T]$ with the following property. If $\varphi^* \in \Phi[\cdot, t_1, x_1, \Gamma^*]$ and $t^* = \min(t_1 + \mu, T)$, then

$$\varphi^*[t] \in E, \quad \forall t \in [t_1, t^*]. \tag{3.12}$$

Moreover, there exists a motion $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma_0]$, *where* Γ_0 *is the extremal strategy defined with respect to* $C^+(w(t_0, x_0))$, *such that*

$$|\varphi^*[t] - \varphi[s(t)]| < C(|t_0 - t_1| + |x_0 - x_1|), \quad \forall t \in [t_1, t^*], \tag{3.13}$$

where $s(\cdot)$ *is as defined above.*

Proof. Let $R > 0$ be large enough so that all motions with initial points in $[0, T] \times X$ always remain in $B_R(0)$. This is possible using **H1'** and the compactness of X. Let β, h_1, ε_0, and $\tilde{K}$ be defined as in Notes 1-3 above with respect to this R. Let

$$\delta = \min(\varepsilon_0/2\tilde{K}, \beta h_1/4\tilde{K}). \tag{3.14}$$

To define Γ^*, note that, by the remark following Proposition 2.1, there exists an integer m^* such that any mth-stage trajectory resulting from Γ_0 satisfies

$$\max\{d(\varphi_m(t), E): t \in [t_0, T]\} < \varepsilon_0/2, \quad \text{if } m \geqq m^*. \tag{3.15}$$

We define Γ^*_m, the mth-stage of Γ^*, for $m \geqq m^*$. Let $\Pi_m = \{t_0 < \tau_1 < \cdots < \tau_m = T\}$ be a uniform partition of $[t_0, T]$, with norm $\|\Pi_m\| = (T - t_0)/m$. Set $\sigma_i = s^{-1}(\tau_i)$, $i = 1, \cdots, m$, and take Π^*_m, the mth-stage partition of Γ^*, to be $\{\sigma_0 < \sigma_1 < \cdots < \sigma_m\}$. Note that Π^*_m is also a uniform partition. Let Δ be any strategy of the second player. We will now describe how Γ^*_m chooses a control function on $[\sigma_i, \sigma_{i+1})$ playing against Δ_m.

To facilitate the description of Γ^*_m, let us denote by $u^*_{m,i}(\cdot)$, the choice of Γ^*_m on $[\sigma_i, \sigma_{i+1})$, and by $u^*_m(\cdot)$ the concatenation of $u^*_{m,i}$'s. Similarly, $v^*_{m,i}(\cdot)$ will be the choice of Δ_m on $[\sigma_i, \sigma_{i+1})$ and v^*_m their concatenation. Let u_m be the choice of $\Gamma_{0,m}$ on $[\tau_i, \tau_{i+1})$ playing against a control function v_m, which will be constructed using v^*_m. Once u^*_m and v^*_m are determined on an interval $[t_1, \sigma_i)$, we will denote by $\varphi^*_m(\cdot)$ the trajectory determined by (3.8) on $[t_1, \sigma_i]$ using u^*_m and v^*_m. Similarly, $\varphi_m(\cdot)$ will denote the trajectory on $[t_0, \tau_i]$ resulting from (u_m, v_m) with initial point (t_0, x_0).

We are now ready to define $\Gamma^*_{m,i}$, $i = 0, \cdots, m-1$. For $i = 0$, set $\Gamma^*_{m,0} = \Gamma_{0,m,0}(s(t))$, $t \in [t_1, \sigma_1)$. For $i > 0$, if $\varphi^*_m(\sigma_i) \in E$ then define

$$u^*_{m,i}(t) = u_{m,i}(s(t)), \qquad t \in [\sigma_i, \sigma_{i+1})$$

where $u_{m,i}$, defined on $[\tau_i, \tau_{i+1})$, is the choice of $\Gamma_{0,m}$ on $[\tau_i, \tau_{i+1})$ playing against v_m defined by

$$v_m(\tau) = v^*_m(s^{-1}(\tau)), \qquad \tau \in [t_0, \tau_{i-1}).$$

Let $k = k(m) > 1$ be the smallest integer such that $\varphi^*_m(\sigma_k) \notin E$. Define $h = (4\tilde{K}/\beta)(|t_0 - t_1| + |x_0 - x_1|)$. Note that $h < h_1$ by (3.11) and (3.14). Let $\nu = \nu(m)$ be determined as the smallest integer such that

$$[\sigma_k, \sigma_k + h) \subset \cup\{[\sigma_{k+i}, \sigma_{k+i+1}): i = 0, \cdots, \nu\}. \tag{3.16}$$

Note that $\sigma_k + h \in [\sigma_{k+\nu}, \sigma_{k+\nu+1}]$, and therefore

$$|\sigma_{k+\nu} - (\sigma_k + h)| \leqq \|\Pi^*_m\| \to 0, \quad \text{as } m \to \infty. \tag{3.17}$$

Now on the intervals $[\sigma_{k+i}, \sigma_{k+i+1})$, $i = 0, \cdots, \nu - 1$, define

$$u^*_{m,k+i}(t) \equiv \tilde{y}(\sigma_k, \varphi^*_m(\sigma_k)),$$

where $\tilde{y}(\cdot, \cdot)$ is as in Note 1 above. Observe that $\tilde{y}(\sigma_k, \varphi^*_m(\sigma_k))$ is defined since, by (3.15), $|\varphi^*_m(\sigma_k)| < \varepsilon_0$. Define $h_m \equiv \nu\|\Pi^*_m\|$. Then, since Π^*_m is a uniform partition, we have $\sigma_{k+\nu} = \sigma_k + h_m$. Let

$$u^*_{m,k+\nu}(t) = u_{m,k}(s(t - h_m)), \quad \text{for } t \in [\sigma_{k+\nu}, \sigma_{k+\nu+1}).$$

Note that $u_{m,k}(\cdot)$ is defined on $[\tau_k, \tau_{k+1})$ and depends only on the restrictions of u_m and v_m to $[t_0, \tau_k)$.

For $i \geqq \nu+1$, define $v_m(\cdot)$ on $[t_0, \tau_{k+i-\nu})$ by

$$v_m(\tau) = \begin{cases} v_m^*(s^{-1}(\tau)) & \text{if } \tau \in [t_0, \tau_k) \\ v_m^*(s^{-1}(\tau)+h_m) & \text{if } \tau \in [t_0, \tau_k) \\ z_0 & \text{if } \tau \in [\tau_k, \tau_{k+i-\nu}) \text{ and } s^{-1}(\tau)+h_m \geqq T, \end{cases}$$

where $z_0 \in Z$ is some arbitrarily chosen fixed element. Now, let $u_{m,k+i-\nu}$ be the outcome of $\Gamma_{0,m}$ against v_m, and for $i \geqq \nu+1$, define

$$u_{m,k+i}^*(t) = u_{m,k+i-\nu}(s(t-h_m)), \qquad t \in [\sigma_{k+i}, \sigma_{k+i+1}).$$

This completes the definition of Γ^*.

From the above constructions it follows that u_m^*, v_m^*, u_m, and v_m satisfy the following relationships:

$$u_m^*(t) = \begin{cases} u_m(s(t)) & t \in [t_1, \sigma_k) \\ \tilde{y}(\sigma_k, \varphi_m^*(\sigma_k)) & t \in [\sigma_k, \sigma_{k+\nu}) \\ u_m(s(t-h_m)) & t \in [\sigma_{k+\nu}, T], \end{cases} \tag{3.18}$$

and

$$v_m(\tau) = \begin{cases} v_m^*(s^{-1}(\tau)) & t \in [t_0, \tau_k) \\ v_m^*(s^{-1}(\tau)+hm) & t \in [\tau_k, s^{-1}(T-h_m)) \\ z_0 & t \in [s^{-1}(T-h_m), T]. \end{cases} \tag{3.19}$$

Let us also observe that since u_m is an outcome of Γ_0 (by its construction), φ_m is an mth-stage trajectory resulting from Γ_0.

For the analysis that follows we will need a third trajectory, $\bar{\varphi}_m(\cdot)$, defined on $[t_1, T]$ with controls $(\bar{u}_m, \bar{v}_m)$ and initial point (t_1, x_1), where

$$\text{(a)} \quad \bar{u}_m(t) = u_m(s(t)), \qquad t \in [t_1, T], \tag{3.20}$$

$$\text{(b)} \quad \bar{v}_m(t) = v_m(s(t)), \qquad t \in [t_1, T].$$

Observe that $\bar{\varphi}_m$ is an mth-stage trajectory resulting from $\Theta\Gamma_0$, where Θ is the map defined using $s(\cdot)$ as in [1] (or see Lemma 1.2 above).

We now verify that Γ^* has the desired properties. Let $\varphi^* \in \Phi[\cdot, t_1, x_1, \Gamma^*, \Delta]$, for some Δ. Let $\{\varphi_m^*\}$ be the sequence of mth-stage trajectories converging to φ^*. We may assume, without loss of generality, that $\varphi_m^*(t_1) = x_1$. Let $\varphi_m(\cdot) = \varphi_m(\cdot, t_0, x_0, u_m, v_m)$ and $\bar{\varphi}_m(\cdot) = \varphi_m(\cdot, t_1, x_1, \bar{u}_m, \bar{v}_m)$ where (u_m, v_m) and $(\bar{u}_m, \bar{v}_m)$ are related to (u_m^*, v_m^*) through (3.18)–(3.20). We claim that there exist constants $\mu > 0$ and $C > 0$, independent of φ^* and (t_i, x_i), $i = 0, 1$, such that

$$\text{(i)} \quad \max\{d(\varphi_m^*(t), E): t \in [t_1, t^*]\} \to 0, \quad \text{as } m \to \infty. \tag{3.21}$$

$$\text{(ii)} \quad \lim_{m\to\infty} |\varphi_m^*(t) - \varphi_m(s(t))| \leqq C(|t_0 - t_1| + |x_0 - x_1|).$$

Before proving (3.21) we finish the proof of the lemma using (3.21). It is clear that (3.21(i)) implies (3.12). As for (3.13), consider the sequence $\{\varphi_m\}$. Extracting a subsequence, if necessary, we may assume that, for some $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma_0, \Delta]$, $\varphi_m \to \varphi$, uniformly on $[t_0, T]$. Therefore, by (3.21(ii)), we have

$$|\varphi^*[t] - \varphi[s(t)]| < C(|t_0 - t_1| + |x_0 - x_1|).$$

Thus the lemma is proved once we establish (3.21). The proof of (3.21) is similar to that given by Soner, in a different context, in [11, Lemma 3.2].

Verification of (3.21(i)). Note that, by the definition of σ_k, $\varphi_m^*(t) \in E$ for all $t \in [t_1, \sigma_{k-1}]$, and all $m \geqq m^*$. Also, since $|\sigma_k - \sigma_{k-1}| = \|\Pi_m^*\| \to 0$ as $m \to \infty$, we get

$$d(\varphi_m^*(\sigma_k), E) \to 0, \quad \text{as } m \to \infty. \tag{3.22}$$

Recall that an $[\sigma_k, \sigma_{k+\nu}]$, $u_m^* \equiv \tilde{y}(\sigma_k, \varphi_m^*(\sigma_k))$. Hence, by (3.7),

$$f^n(t, \varphi_m^*(t), \tilde{y}(\sigma_k, \varphi_m^*(\sigma_k)), v_m^*(t)) \geqq \beta/2 > 0, \quad \forall t \in [\sigma_k, \sigma_{k+\nu}].$$

Therefore, $\max\{d(\varphi_m^*(t), E): t \in [\sigma_k, \sigma_{k+\nu}]\} = d(\varphi_m^*(\sigma_k), E)$. Hence, by (3.22), we always have

$$\max\{d(\varphi_m^*(t), E): t \in [t_1, \sigma_{k+\nu}]\} \to 0, \quad \text{as } m \to \infty. \tag{3.23}$$

Let $\mu > 0$ be such that

$$\gamma(\mu) \equiv K\mu\, e^{K\mu} + M(e^{K\mu} - 1) \leqq \beta/4, \tag{3.24}$$

where K is the Lipschitz constant of f (see **H1'**), and $M = \max\{|f(t, x, y, z)|: t \in [0, T], |x| \leqq R, y \in Y, z \in Z\}$. Now suppose $\sigma_{k+\nu} < t^*$ (otherwise we are done by (3.23)). Define $\tilde{t} = t^* - h_m$ (recall $h_m = \nu\|\Pi\|_m^*\|$), and $\psi(\cdot)$ by

$$\psi(t) = (\varphi_m^*)^n(t + h_m) - (\bar{\varphi}_m)^n(t), \quad \text{for } t \in [\sigma_k, \tilde{t}],$$

where $\bar{\varphi}_m$ is related to φ_m^* as explained before. Then, for $t \in [\sigma_k, \tilde{t}]$,

$$\begin{aligned} \psi(t) = \psi(\sigma_k) + \int_{\sigma_k}^{t} [&f^n(s + h_m, \varphi_m^*(s + h_m), u_m^*(s + h_m), v_m^*(s + h_m)) \\ &- f^n(s, \bar{\varphi}_m(s), \bar{u}_m(s), \bar{v}_m(s))]\, ds. \end{aligned} \tag{3.25}$$

Let I denote the integral on the right, then, by (3.18) and (3.19),

$$I = \int_{\sigma_k}^{t} [f^n(s + h_m, \varphi_m^*(s + h_m), \bar{u}_m(s), \bar{v}_m(s)) - f^n(s, \bar{\varphi}_m(s), \bar{u}_m(s), \bar{v}_m(s))]\, ds.$$

By the Lipschitz continuity of f,

$$|I| \leqq \int_{\sigma_k}^{t} K[h_m + |\varphi_m^*(s + h) - \bar{\varphi}_m(s)|]\, ds, \qquad t \in [\sigma_k, \tilde{t}]. \tag{3.26}$$

In a similar way, for $s \in [\sigma_k, \tilde{t}]$,

$$|\varphi_m^*(s + h_m) - \bar{\varphi}_m(s)| \leqq |\varphi_m^*(\sigma_k + h_m) - \bar{\varphi}_m(\sigma_k)| + \int_{\sigma_k}^{s} K[h_m + |\varphi_m^*(\tau + h_m) - \bar{\varphi}_m(\tau)|]\, ds.$$

Using Gronwall's lemma, we get, for $s \in [\sigma_k, \tilde{t}]$,

$$|\varphi_m^*(s + h_m) - \bar{\varphi}_m(s)| \leqq [|\varphi_m^*(\sigma_k + h_m) - \bar{\varphi}_m(\sigma_k)| + Kh_m\mu]\, e^{K(s - \sigma_k)}. \tag{3.27}$$

Also, since $\varphi_m^*(\sigma_k) = \bar{\varphi}_m(\sigma_k)$, we have

$$|\varphi_m^*(\sigma_k + h_m) - \bar{\varphi}_m(\sigma_k)| \leqq \int_{\sigma_k + h_m}^{\sigma_k} |f(s, \varphi_m^*(s), u_m^*(s), v_m^*(s))|\, ds \leqq Mh_m.$$

Together with (3.27) we obtain

$$|\varphi_m^*(s + h_m) - \bar{\varphi}_m(s)| \leqq (M + K\mu)h_m\, e^{K(s - \sigma_k)}, \qquad s \in [\sigma_k, \tilde{t}]. \tag{3.28}$$

Substituting in (3.26) and integrating we get

$$|I| \leqq h_m(K\mu\, e^{K\mu} + M(e^{K\mu} - 1)) \equiv h_m\gamma(\mu), \tag{3.29}$$

(where $\gamma(\cdot)$ was defined in (3.24)). Thus, from (3.25) and (3.29), we obtain

$$\psi(t) \geqq \psi(\sigma_k) - h_m \gamma(\mu), \qquad t \in [\sigma_k, \tilde{t}]. \tag{3.30}$$

On the other hand,

$$\psi(\sigma_k) = \varphi_m^{*n}(\sigma_k + h_m) - \bar{\varphi}_m^n(\sigma_k) = \int_{\sigma_k}^{\sigma_k + h_m} f^n(s, \varphi_m^*(s), u_m^*(s), v_m^*(s))\, ds. \tag{3.31}$$

Recall that $\sigma_k + h \in [\sigma_{k+\nu}, \sigma_{k+\nu+1}]$. Since, by definition, $\sigma_k + h_m = \sigma_{k+\nu}$, we have, using (3.17),

$$|h_m - h| \leqq \|\Pi_m^*\| \to 0, \quad \text{as } m \to \infty.$$

Since $h < h_1$, there exists an m_1 such that $h_m < h_1$ if $m > m_1$. Hence, by (3.7) and (3.31),

$$\psi(\sigma_k) \geqq \beta h_m / 2, \quad \text{for } m > m_1.$$

Substituting into (3.30), we obtain

$$\psi(t) \geqq h_m[\beta/2 - \gamma(\mu)], \qquad t \in [\sigma_k, \tilde{t}], \qquad m > m_1. \tag{3.32}$$

By the choice of μ (see (3.20)),

$$\psi(t) \geqq h_m \beta / 4. \tag{3.33}$$

Next, noting the relationship between φ_m and $\bar{\varphi}_m$, we have from (3.10),

$$\max\{|\bar{\varphi}_m(t) - \varphi_m(s(t))| : t \in [t_1, T]\} \leqq \tilde{K}(|t_0 - t_1| + |x_0 - x_1|). \tag{3.34}$$

Hence if $\rho_m = \max\{d(\varphi_m(t), E) : t \in [t_0, T]\}$, then, using (3.34), we get

$$\max\{d(\bar{\varphi}_m(t), E) : t \in [t_0, \tilde{t}]\} \leqq \rho_m + \tilde{K}(|t_0 - t_1| + |x_0 - x_1|). \tag{3.35}$$

Observe that $\varphi_m(\cdot)$ is an mth-stage trajectory resulting from Γ_0. By Lemma 1.5, $\rho_m \to 0$, as $m \to \infty$. From (3.33) and the definition of $\psi(\cdot)$, we have

$$\begin{aligned} \varphi_m^{*n}(t + h_m) &\geqq \beta h_m / 4 + \bar{\varphi}_m^n(t) \\ &\geqq \beta h_m / 4 - \max\{d(\bar{\varphi}_m(t), E) : t \in [t_0, \tilde{t}]\}. \end{aligned}$$

Taking the minimum of the left side on $[\sigma_k, \tilde{t}]$, and using (3.35), we get

$$\min\{\varphi_m^{*n}(t + h_m) : t \in [\sigma_k, \tilde{t}]\} \geqq \beta h_m / 4 - \tilde{K}(|t_0 - t_1| + |x_0 - x_1|) - \rho_m.$$

Since $h_m \to h$ $(= 4\tilde{K}(|t_0 - t_1| + |x_0 - x_1|)/\beta)$ and $\rho_m \to 0$ as $m \to \infty$, we conclude

$$\lim_{m \to \infty} \min\{\varphi_m^{*n}(t + h_m) : t \in [\sigma_k, \bar{t}]\} \geqq 0.$$

This is the desired conclusion since $\sigma_k + h_m = \sigma_{k+\nu}$ and $\tilde{t} + h_m = t^*$.

Verification of (3.21(ii)). By the triangle inequality,

$$|\varphi_m^*(t) - \varphi_m(s(t))| \leqq |\varphi_m^*(t) - \bar{\varphi}_m(t)| + |\bar{\varphi}_m(t) - \varphi_m(s(t))|. \tag{3.36}$$

We already have an estimate of the second term on the right, namely (3.34). Let us consider the first term.

Case 1. $\sigma_{k+\nu} \leqq t^*$. Recall that for any $t \in [t_1, \sigma_k]$, $\varphi_m^*(t) = \bar{\varphi}_m(t)$. Now, if $t \in (\sigma_k, \tilde{t}]$, then

$$\begin{aligned} |\varphi_m^*(t) - \bar{\varphi}_m(t)| &\leqq |\varphi_m^*(t + h_m) - \bar{\varphi}_m(t)| + |\varphi_m^*(t + h_m) - \varphi_m^*(t)| \\ &\leqq (M + k\mu) h_m e^{K(t - \sigma_k)} + M h_m \qquad \text{(using (3.28))} \\ &\leqq h_m[(M + k\mu) e^{K\mu} + M]. \end{aligned}$$

If $t \in [\tilde{t}, t^*]$, then

$$|\varphi_m^*(t) - \bar{\varphi}_m(t)| \leqq |\varphi_m^*(t-h_m) - \varphi_m^*(t)| + |\varphi_m^*(t-h_m) - \bar{\varphi}_m(t-h_m)| + |\bar{\varphi}_m(t-h_m) - \bar{\varphi}_m(t)|$$

$$\leqq \int_{t-h_m}^{t} |f(\tau, \varphi_m^*(\tau), u_m^*(\tau), v_m^*(\tau))|\, d\tau + h_m[(M+k\mu)\, e^{K\mu} + M] + \int_{t-h_m}^{t} |f(\tau, \bar{\varphi}_m(\tau), \bar{u}_m(\tau), \bar{v}(\tau))|\, d\tau$$

$$\leqq 2h_m M + h_m[(M+k\mu)\, e^{K\mu} + M] = h_m[3M + (M+k\mu)\, e^{K\mu}].$$

Case 2. $\sigma_{k+\nu} > t^*$. Here, since $\varphi_m^*(\sigma_k) = \bar{\varphi}_m(\sigma_k)$, we have, for $t \in [\sigma_k, t^*]$,

$$|\varphi_m^*(t) - \bar{\varphi}_m(t)| \leqq \int_{\sigma_k}^{t} |f(\tau, \varphi_m^*(\tau), u_m^*(\tau), v_m^*(\tau)) - f(\tau, \bar{\varphi}_m(\tau), \bar{u}_m(\tau), \bar{v}(\tau))|\, d\tau$$

$$\leqq 2M(t-\sigma_k) \leqq 2Mh_m,$$

where the last inequality holds since $(t-\sigma_k) \leqq (t^*-\sigma_k) \leqq \sigma_{k-\nu} - \sigma_k \leqq h_m$. Hence in both cases

$$|\varphi_m^*(t) - \bar{\varphi}_m(t)| \leqq h_m[3M + (M+K\mu)\, e^{K\mu}], \quad \forall t \in [\sigma_k, t^*].$$

Now, using this and the fact that $h_m \to h = (4/\beta)\tilde{K}(|t_0 - t_1| + |x_0 - x_1|)$, we have

$$\lim_{m\to\infty} |\varphi_m^*(t) - \bar{\varphi}_m(t)| \leqq \tilde{C}(|t_0 - t_1| + |x_0 - x_1|), \quad \forall t \geqq \sigma_k, \tag{3.37}$$

where $\tilde{C} = (4/\beta)\tilde{K}((M+K\mu)\, e^{K\mu} + M)$.

Combining (3.37), (3.34), and using (3.36), we obtain (3.21(ii)) with $C = \tilde{C} + \tilde{K}$. Note that C depends only on $R > 0$ and f. This completes the proof of Lemma 3.1. □

Before stating Theorem 3.1, we make some technical notes which will be used in the proof of the theorem.

Note i. For the assertion of Lemma 3.1 to be applicable to a pair of points (t_0, x_0), (t_1, x_1), we need $|t_0 - t_1| + |x_0 - x_1| < \min(\beta h_1/4\tilde{K}, \varepsilon_0/2\tilde{K})$. It would be convenient, below, to also assume $|t_0 - t_1| < \mu/2$. Since μ depends only on $R > 0$ and f, this causes no problem. Hence, assume for Lemma 3.1 that

$$|t_0 - t_1| + |x_0 - x_1| < \delta^* \triangleq \min(\beta h_1/4\tilde{K}, \varepsilon_0/2\tilde{K}, \mu/2). \tag{3.38}$$

Note ii. Assume (3.38) holds. Note that if $t_0, t_1 \in [T-\mu, T]$ then

$$s(t_1 + \mu) \geqq T, \tag{3.39}$$

since $t_1 + \mu \geqq T$, $s(T) = T$, and $s(\cdot)$ is nondecreasing on $[t_1, T]$. If $t_0, t_1 \in [0, T-\mu]$, then

$$s(t_1 + \mu) \geqq t_0 + \mu/2. \tag{3.40}$$

To see this, recall that $s(t) = m(t - t_1) + t_0$, with $m = (T - t_0)/(T - t_1)$. Now if $t_1 \geqq t_0$, then $m \geqq 1$ and $s(t_1 + \mu) \geqq t_0 + \mu$. If $t_1 < t_0$, then

$$0 < t_0 - t_1 < \mu/2 < (T - t_1)/2.$$

Now $2(t_0 - t_1) < T - t_1$ is equivalent to $m \geqq 1/2$. Hence (3.40) holds.

Note iii. Let $\alpha(t) = t - s(t) = (1-m)t + (mt_1 - t_0)$, $t \in [t_1, T]$. Since $\alpha(\cdot)$ is a linear function, $\max\{|\alpha(t)|: t \in [t_1, T]\}$ occurs either at t_1 or at T. But $\alpha(T) = 0$. Hence, $|\alpha(t_1)| \geqq |\alpha(t)|$, for all $t \in [t_1, T]$. That is,

$$|t_1 - t_0| \geqq |t - s(t)| \quad \forall t \in [t_1, T]. \tag{3.41}$$

Note iv. In the proof of Theorem 3.1, as well as some other results in the later sections, we will use inductive arguments. The following device will be useful in these arguments. Let $R>0$ and denote by $S(R)$ the set of all initial points $(t_0, x_0)\in[0, T]\times E$ such that any solution $\varphi(\cdot)$ of the dynamics (0.1) with $\varphi(t_0)=x_0$ satisfies $|\varphi(t)|\leqq R$ for all $t\in[t_0, T]$. It follows from **H1** that given any $(t_0, x_0)\in[0, T]\times E$, there exists $R_0>0$ such that $(t_0, x_0)\in S(R_0)$. Hence $[0, T]\times E=\cup\{S(R): R>0\}$. Furthermore the following two properties hold.

P1. Let $(t_0, x_0)\in S(R_0)$. Then for every motion $\varphi[\cdot, t_0, x_0, \Gamma, \Delta]$, resulting from some pair of strategies Γ and Δ, and for every $t\in[t_0, T]$, we have

$$(t, \varphi[t, t_0, x_0, \Gamma, \Delta])\in S(R).$$

P2. $S(R)$ is closed (hence compact).

We prove **P1**. Property **P2** can be proved along similar lines.

Proof of **P1**. Let $t_1\in[t_0, T]$ and $\varphi\in\Phi[\cdot, t_0, x_0, \Gamma, \Delta]$ for some Γ and Δ. Set $x_1=\varphi[t_1]$. Let $\{\varphi_m(\cdot, t_0, x_{0m}, u_m(\cdot), v_m(\cdot))\}$ (we will write $\varphi_m(\cdot)$ for convenience) be a sequence of mth-stage trajectories converging to φ. We need to show that if, for some pair of controls $(u(\cdot), v(\cdot))$, $\eta(\cdot)$ satisfies

$$\dot\eta(t)=f(t, \eta(t), u(t), v(t)), \quad \text{a.e. } t\in[t_1, T], \eta(t_1)=x_1,$$

then $|\eta(t)|\leqq R$. Define $\tilde u_m$ and $\tilde v_m$ by

$$\tilde u_m(t)=\begin{cases} u_m(t) & \text{if } t\in[t_0, t_1)\\ u(t) & \text{if } t\in[t_1, T]\end{cases} \quad\text{and}\quad \tilde v_m(t)=\begin{cases} v_m(t) & \text{if } t\in[t_0, t_1)\\ v(t) & \text{if } t\in[t_1, T],\end{cases}$$

and let $\tilde\varphi_m(\cdot)=\tilde\varphi_m(\cdot, t_0, x_0, \tilde u_m(\cdot), \tilde v_m(\cdot))$. Since $(t_0, x_0)\in S(R)$, $|\tilde\varphi_m(t)|\leqq R$ for all $t\in[t_0, T]$. By the continuous dependence of solutions of differential equations on their initial values, we have

$$\eta(t)=\lim_{m\to\infty}\tilde\varphi_m(t), \quad \text{for } t\in[t_1, T].$$

Hence $|\eta(t)|\leqq R$ for all $t\in[t_1, T]$. □

In what follows we will use the following notation. If Ω is a subset of $\mathbb{R}\times\mathbb{R}^n$, let $\Omega_t\equiv\{(s, x)\in\Omega: s=t\}$, and $\Omega_{[\tau,t]}\equiv\{(s, x)\in\Omega: s\in[\tau, t]\}$. We now state and prove the following theorem.

THEOREM 3.1. *If* **H1′** *and* **H3** *hold then* $w(\cdot,\cdot)$ *is continuous (or locally Lipschitz continuous) on* $[0, T]\times E$ *if* $g(\cdot)$ *is.*

Proof. We will prove that if g is locally Lipschitz then so is w; that is, for every compact set $X\subset E$, there exists a constant C^* such that for every (t_0, x_0), $(t_1, x_1)\in[0, T]\times X$,

$$|w(t_0, x_0)-w(t_1, x_1)|\leqq C^*(|t_0-t_1|+|x_0-x_1|).$$

The modifications needed for the other statement are straightforward.

Let $R>0$ be such that $S(R)$ contains $[0, T]\times X$. Since by **P2**, above, $S(R)$ is compact, we obtain from Lemma 3.1 the constants $\mu>0$, $C>0$, $\tilde K>0$, $h_1>0$, $\delta^*>0$, etc. Now, for some positive integer σ,

$$S(R)\subset\bigcup_{k=1}^{\sigma} S(R)_{[T-k\mu/2, T]}.$$

We will show, by induction, that for each $k=2, \cdots, \sigma$ there exist constants $\bar\delta_k$, $\bar C_k$ such that for every (t_0, x_0), and (t_1, x_1) in $S(R)_{[T-k\mu/2, T]}$, we have

$$|t_0-t_1|+|x_0-x_1|<\bar\delta_k\Rightarrow|w(t_0, x_0)-w(t_1, x_1)|\leqq\bar C_k(|t_0-t_1|+|x_0-x_1|). \tag{3.42}$$

Then, since $S(R) \supset [0, T] \times X$, it follows that (3.42), with $k = \sigma$, holds for every (t_0, x_0), $(t_1, x_1) \in [0, T] \times X$. We then show that this gives the desired conclusion. We now proceed with the proof of (3.42).

Case $k = 2$ (i.e., $t_i \in [T - \mu, T]$). If $t_0 = T$, then we let Γ^* be the extremal strategy with respect to $C^+(w(t_1, x_1))$. Note that for all $\varphi \in \Phi[\cdot, t_1, x_1, \Gamma^*]$, $\varphi[t] \in E$ for all $t \in [t_1, T]$ and since φ is a Lipschitz function with constant M—where M is as defined following (3.2)—we obtain,

$$|\varphi[T] - x_0| \leqq |\varphi[T] - \varphi[t_1]| + |x_1 - x_0| \leqq M\{|t_0 - t_1| + |x_1 - x_0|\},$$

where we assumed, without loss of generality, that $M \geqq 1$ and used $T = t_0$ in the last inequality. Therefore, by the Lipschitz continuity of $g(\cdot)$, we obtain

$$w(t_1, x_1) \geqq w(t_0, x_0) - C_g M\{|t_0 - t_1| + |x_1 - x_0|\},$$

where C_g is the Lipschitz constant of g. The case $t_1 = T$ leads to the same inequality in a similar way using Γ_0, the strategy extremal to $C^+(w(t_0, x_0))$, in place of Γ^*, and noting that $w(t_1, x_1) = g(x_1)$.

Now let us assume $t_0, t_1 \in [T - \mu, T)$. Take $\bar{\delta}_2 = \delta^*$ (see (3.38)). Let Δ be any strategy of the second player on $[t_1, T]$ and Γ^* be as in Lemma 3.1. If $\varphi^* \in \Phi[\cdot, t_1, x_1, \Gamma^*, \Delta]$ then, since $t_1 + \mu \geqq T$, by that lemma we have

$$\varphi^*[t] \in E \quad \text{for every } t \in [t_1, T]. \tag{3.43}$$

Moreover, there exists $\varphi \in \Phi[\cdot, t_1, x_1, \Gamma_0]$, where Γ_0 is as defined above, such that

$$|\varphi^*[t] - \varphi[s(t)]| \leqq C(|t_0 - t_1| + |x_0 - x_1|) \quad \forall t \in [t_1, T]. \tag{3.44}$$

Since $s(T) = T$, and Γ_0 is extremal with respect to $C^+(w(t_0, x_0))$, we have $g(\varphi[s(T)]) \geqq w(t_0, x_0)$. Using (3.43), (3.44) and the Lipschitz continuity of g, we get

$$V(\varphi^*) = g(\varphi^*[T]) \geqq w(t_0, x_0) - \bar{C}_2(|t_0 - t_1| + |x_0 - x_1|) \tag{3.45}$$

with $\bar{C}_2 = C_g C$. Hence, taking sup over all strategies Γ, we obtain

$$\sup_{\Gamma} P[t_1, x_1, \Gamma, \Delta] \geqq w(t_0, x_0) - \bar{C}_2(|t_0 - t_1| + |x_0 - x_1|).$$

Since Δ was chosen arbitrarily, taking the infimum over all Δ on the left, we get

$$w(t_1, x_1) \geqq w(t_0, x_0) - \bar{C}_2(|t_0 - t_1| + |x_0 - x_1|).$$

We may assume that $\bar{C}_2 \geqq C_g M$ so that the above inequality holds for all $t_0, t_1 \in [T - \mu, T]$. Switching the roles of (t_0, x_0) and (t_1, x_1), we obtain the same inequality with (t_0, x_0) and (t_1, x_1) interchanged. This proves (3.42) in this case.

Now assume (3.42) holds for k, and consider the case for $k+1$; i.e., $t_i \in [T - (k+1)\mu/2, T]$, $i = 0, 1$. We distinguish two possibilities:

First. t_0, t_1 are both in $[T - (k+1)\mu/2, T - k\mu/2]$. Then we take

$$\bar{\delta}_{k+1} = \min(\delta^*, \bar{\delta}_k/2C, \bar{\delta}_k/2)$$

and suppose $|t_0 - t_1| + |x_0 - x_1| < \bar{\delta}_{k+1}$. As before, let Δ be an arbitrary strategy of the second player on $[t_1, T]$ and $\varphi^* \in \Phi[\cdot, t_1, x_1, \Gamma^*, \Delta]$. Then

$$\varphi^*[t] \in E \quad \text{for every } t \in [t_1, t_1 + \mu], \tag{3.46}$$

and there is a motion $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma_0]$ such that

$$|\varphi^*[t] - \varphi[s(t)]| \leqq C(|t_0 - t_1| + |x_0 - x_1|) < \bar{\delta}_k/2, \quad \forall t \in [t_1, t_1 + \mu]. \tag{3.47}$$

Now note that $s(t_1+\mu)\in[T-k\mu/2, T]$, by (3.40). Clearly $t_1+\mu\in[T-k\mu/2, T]$, also. Moreover, it follows from (3.41), and the definition of $\bar{\delta}_{k+1}$, that

$$|t_1+\mu-s(t_1+\mu)|\leqq|t_1-t_0|<\bar{\delta}_{k+1}\leqq\bar{\delta}_k/2. \tag{3.48}$$

Thus, by (3.47) and (3.48), we have

$$|t_1+\mu-s(t_1+\mu)|+|\varphi^*[t_1+\mu]-\varphi[s(t_1+\mu)]|<\bar{\delta}_k.$$

Using our induction hypothesis, and property **P1** of $S(R)$, we have:

$$\begin{aligned}
&|w(t_1+\mu, \varphi^*[t_1+\mu])-w(s(t_1+\mu), \varphi[s(t_1+\mu)])|\\
&\qquad\leqq\bar{C}_k(|t_1+\mu-s(t_1+\mu)|+|\varphi^*[t_1+\mu]-\varphi[s(t_1+\mu)]|)\\
&\qquad\leqq\bar{C}_k(|t_0-t_1|+C(|t_0-t_1|+|x_0-x_1|)) \quad \text{by (3.47)}\\
&\qquad\leqq\bar{C}_k(C+1)(|t_0-t_1|+|x_0-x_1|).
\end{aligned} \tag{3.49}$$

Let Γ_e be defined on $[t_1+\mu, T]$ extremally with respect to $C^+(w(t_1+\mu, \varphi^*[t_1+\mu]))$. Define $\bar{\Gamma}$ as the concatenation of Γ^* on $[t_1, t_1+\mu]$ with Γ_e on $[t_1+\mu, T]$. Then there exists a motion $\bar{\varphi}\in\Phi[\cdot, t_1, x_1, \bar{\Gamma}, \Delta]$ such that

$$\varphi[t]=\varphi^*[t]\in E \quad \forall t\in[t_1, t_1+\mu]$$

and

$$\bar{\varphi}\restriction[t_1+\mu, T]\in\Phi[\cdot, t_1+\mu, \varphi^*[t_1+\mu], \Gamma_e].$$

Therefore, by the properties of extremal strategies,

$$V(\bar{\varphi})=g(\bar{\varphi}[T])\geqq w(t_1+\mu, \varphi^*[t_1+\mu]).$$

Using (3.49) and the fact that $w(s(t_1+\mu), \varphi[s(t_1+\mu)])\geqq w(t_0, x_0)$, we obtain

$$V(\bar{\varphi})\geqq w(t_0, x_0)-C_k(C+1)(|t_0-t_1|+|x_0-x_1|).$$

Taking the sup over all Γ's and the inf over all Δ's, as in case $k=2$, we get $w(t_1, x_2)\geqq w(t_0, x_0)-C_k(C+1)(|t_0-t_1|+|x_0-x_1|)$. Switching the roles of (t_0, x_0) and (t_1, x_1), we obtain

$$|w(t_0, x_0)-w(t_1, x_1)|\leqq C_k(C+1)(t_0-t_1|+|x_0-x_1|).$$

Second. One of t_0, t_1, say t_1, is in $(T-k\mu/2, T]$. Let us define $(t_2, x_2)\equiv(T-k\mu/2, x_1)$. Then, with $\bar{\delta}_{k+1}$ as before,

$$|t_2-t_1|+|x_2-x_1|\leqq|t_2-t_1|\leqq|t_1-t_0|\leqq\bar{\delta}_k/2,$$

and

$$|t_2-t_0|+|x_2-x_0|\leqq|t_0-t_1|+|x_0-x_1|\leqq\bar{\delta}_{k+1}.$$

Therefore, using the first case and our induction hypothesis,

$$\begin{aligned}
|w(t_0, x_0)-w(t_1, x_1)|&\leqq|w(t_0, x_0)-w(t_2, x_2)|+|w(t_2, x_2)-w(t_1, x_1)|\\
&\leqq\bar{C}_k(C+1)(|t_0-t_1|+|x_0-x_1|)+\bar{C}_k(|t_1-t_0|)\\
&\leqq\bar{C}_{k+1}(|t_0-t_1|+|x_0-x_1|),
\end{aligned}$$

with $\bar{C}_{k+1}=\bar{C}_k(C+2)$. Hence in either case, (3.42) is satisfied with $\bar{C}_{k+1}$ and $\bar{\delta}_{k+1}$.

This concludes our induction, proving (3.42). It remains to show that the conclusion of the theorem follows from (3.42). Note that it follows from (3.42) that $w(\cdot, \cdot)$ is continuous on $[0, T]\times X\subset S(R)$. In particular, there exists a constant $L>0$ such that

$$|w(t, x)|\leqq L \quad \forall(t, x)=[0, T]\times X.$$

Let $C^*=\max(\bar{C}_\sigma, 2L/\bar{\delta}_\sigma)$. Then given a pair of points (t_0, x_0) and (t_1, x_1) in $[0, T]\times X$,

$$|t_0-t_1|+|x_0-x_1|<\bar{\delta}_\sigma\Rightarrow|w(t_0, x_0)-w(t_1, x_1)|\leqq C^*(|t_0-t_1|+|x_0-x_1|),$$

(using (3.42)) and

$$|t_0-t_1|+|x_0-x_1|\geqq\bar{\delta}_\sigma \Rightarrow |w(t_0,x_0)-w(t_1,x_1)|\leqq 2L\leqq C^*(|t_0-t_1|+|x_0-x_1|).$$

That is, $w(\cdot,\cdot)$ is Lipschitz on $[0,T]\times X$ with constant C^*. The proof of the theorem is now complete. □

Condition **H3** is not necessary for the continuity of the value. This can be seen from the following example:

Example 4. Consider Example 2, again:

$$\dot{x}^1=0$$
$$\dot{x}^2=y-z$$
$$\dot{x}^3=x^1y,$$

$Y=Z=[0,1]$, $E=\{x: x^3\geqq 0\}$. Here, however, we change the payoff function, $g(\cdot)$, to $g(x)=-x^2$. It can easily be verified that for any $(t_0,x_0)\in[0,t]\times E$, $w(t_0,x_0)=-x_0^2$. Thus w is continuous on $[0,T]\times E$.

Note that **H3** is not satisfied here but the optimal play, $y^*\equiv 0$, automatically gives $\dot{x}^3\geqq 0$. In some examples, such as the above, it can be directly verified that the extremal strategies automatically respect the given state constraints. Condition **H4**, below, says just this. We will show in Theorem 3.2 that **H1** and **H4** ensure that the value is continuous (or Lipschitz continuous) if g is continuous (Lipschitz continuous).

H4. (i) $\exists x\in E$ such that $w(0,x)>-\infty$,

(ii) If $t\in[0,T]$, $x\notin E$ and $\alpha\in\mathbb{R}$ are such that $U^\alpha(t,x)$, the extremal strategy with respect to $C^+(\alpha)$, is defined then

$$\min_z f^n(t,x,y^*(t,x),z)\geqq 0,$$

where $y^*(t,x)$ is the outcome of $U^\alpha(t,x)$.

Remarks. 1. By Proposition 3.1, **H2** implies **H4**-(i).

2. **H4** implies **H2**; in particular, $w(t,x)\in\mathbb{R}$, for all (t,x) in $[0,T]\times E$. To see this, note that, by **H4**-(i), there exists an $x_0\in E$ such that $w(0,x_0)\in\mathbb{R}$. Let $\alpha=w(0,x_0)$. Then $U^\alpha(t,x)$ is defined for all (t,x) in $[0,T]\times E$ since for all $t\in[0,T]$, $C^+(\alpha)\cap\{(t,x): x\in R^n\}\neq\varnothing$. Now given (t,x) with $x^n=0$, let $x_\kappa=(x^1,x^2,\cdots,x^{n-1},1/k)$.Then, using **H4**-(ii),

$$\max_y\min_z f^n(t,x_\kappa,y,z)\geqq\min_z f^n(t,x_\kappa,y^*(t,x_\kappa),z)\geqq 0.$$

Since $(t,x)\to\max_y\min_z f^n(t,x,y,z)$ is continuous, **H2** follows.

3. **H4**-(ii) is always satisfied if the following conditions (a), (b) hold:

(a) $Y=Y_1\times Y_2$, and $Z=Z_1\times Z_2$, for some compact sets Y_i and Z_i, such that

$$f^i(t,x,y,z)=f^i(t,x,y_1,z_1),\quad \text{for } i=1,\cdots,n-1,$$

and

$$f^n(t,x,y,z)=f^n(t,x,y_1,y_2,z_2);$$

i.e., f^n has controls distinct from the controls of $f^1,\cdots,f^{n-1}$.

(b) For every (t,x,y_1,z_2), if $x\notin E$ then $\exists y_2\in Y_2$ such that $f^n(t,x,y_2,z_2)\geqq 0$.

Proof. Suppose $y^*(t,x)=(y_1^*,y_2^*)$ is the outcome of an extremal strategy $U^\alpha(t,x)$ at (t,x), $x\notin E$. Then, by the definition of extremal strategies, there exist some $z^*=(z_1^*,z_2^*)\in Z$ and $w\in C^+(\alpha)$ such that for all $z\in Z$, $y\in Y$,

$$\langle s,f(t,x,y^*,z)\rangle\geqq\langle s,f(t,x,y^*,z^*)\rangle\geqq\langle s,f(t,x,y,z^*)\rangle,$$

where $s = w - x$. Note that $w^n \geqq 0$, since $C^+(\alpha) \subset [0, T] \times E$, and $x^n < 0$. Hence, $s^n > 0$. Let $\hat{v}$ denote the first $n-1$ components of a vector v in $\mathbb{R}^n$. Then we have

$$\langle \hat{s}, \hat{f}(t, x, y_1^*, z_1)\rangle + s^n f^n(t, x, y^*, z_2) \geqq \langle s, f(t, x, y^*, z^*)\rangle$$
$$\geqq \langle \hat{s}, \hat{f}(t, x, y_1, z_1^*)\rangle + s^n f^n(t, x, y, z_2^*).$$

Taking $z = (z_1^*, z_2)$, in the first inequality, $y = (y_1^*, y_2)$, in the second, and using $s^n > 0$, we obtain

$$f^n(t, x, y^*, z_2) \geqq f^n(t, x, y^*, z_2^*) \geqq f^n(t, x, y_1^*, y_2, z_2^*), \quad \text{for all } z_2 \in Z_2, \text{ and } y_2 \in Y_2.$$

By assumption (b), the right side can be made nonnegative by an appropriate choice of y_2. Therefore, we have $f^n(t, x, y^*, z_2) \geqq 0$ for all $z_2 \in Z_2$, as desired. □

Let $(t_0, x_0) \in [0, T] \times E$, and $v_0 = w(t_0, x_0)$. Then $v_0 \in \mathbb{R}$ by Remark 2 above. Let $U_0(t, x)$ be the extremal pointing strategy defined with respect to $C^+(v_0)$. Note that U_0 can be used to define an extremal strategy Γ_0 in a game with initial point (t_1, x_1) as long as $t_1 \geqq t_0$. Since $C^+(v_0) \subset [0, T] \times E$, it follows from Lemma 1.5, that, for any motion $\varphi \in \Phi[\cdot, t_1, x_1, \Gamma_0]$, $\varphi[t] \in E$ for all $t \in [t_1, T]$. If **H4** holds, then more is true, namely the following lemma.

LEMMA 3.2. *Let (t_0, x_0) and v_0 be as above. If* **H4** *holds and $(t_1, x_1) \in [t_0, T] \times E$, not necessarily in $C^+(v_0)$, then for any motion $\varphi \in \Phi[\cdot, t_1, x_1, \Gamma_0]$, we have $\varphi[t] \in E$ for $t \in [t_1, T]$.*

Proof. Let $\varphi \in \Phi[\cdot, t_1, x_1, \Gamma_e]$ with $\{\varphi_m\}$ as the mth-stage trajectories converging to φ. Suppose there exists a $\acute{t} \in [t_1, T]$ such that $\varphi^n[\acute{t}] < 0$. Then, as in Proposition 3.1, letting $\bar{t} = \inf\{t < \acute{t}: \varphi^n[\tau] < 0 \text{ for all } \tau \in (t, \acute{t}]\}$ and $\sigma = \acute{t} - \bar{t}$ we have

$$\varphi^n[\bar{t}] = 0, \qquad \varphi^n[\tau] < 0 \quad \forall \tau \in [\bar{t}, \bar{t} + \sigma]. \tag{3.50}$$

Let $R > 0$ be such that $|\varphi_m(t)| \leqq R$ for all $t \in [t_1, T]$ and all m. For each m, let τ_k and τ_j be defined as in Proposition 3.1, with $\bar{t} + \sigma$ in place of $\bar{t} + \delta$. Then, just as in that proof,

$$\tau_k \to \bar{t}, \ \tau_j \to \bar{t} + \sigma \quad \text{as } m \to \infty,$$
$$\varphi_m^n(\tau_k) \to 0 \quad \text{as } m \to \infty,$$
$$\varphi_m^n(t) < 0 \quad \forall t \in [\tau_k, \tau_j], \quad \text{for } m \text{ sufficiently large.}$$

Let $\omega(r)$ and the constant M be defined as in Proposition 3.1. Now, for $t \in [\tau_i, \tau_{i+1})$, $k \leqq i < j$,

$$f^n(t, \varphi_m(t), y_i, v_m(t)) \geqq f^n(\tau_i, \varphi_m(\tau_i), y_i, v_m(t)) - \omega((M+1)\delta_m),$$

where $\delta_m = (T - t_0)/m$ and $y_i = U^\alpha(\tau_i, \varphi_m(\tau_i))$, $\alpha = w(t_1, x_1)$. Hence, by **H4**-(ii)

$$f^n(\tau_i, \varphi_m(\tau_i), y_i, z) \geqq 0 \quad \forall z \in Z.$$

Therefore,

$$\varphi_m^n(t) \geqq \varphi_m^n(\tau_i) - \delta_m \omega((M+1)\delta_m), \quad \forall t \in [\tau_i, \tau_{i+1}).$$

Using this, we obtain for $t \in [\tau_k, \tau_j]$,

$$\varphi_m^n(t) \geqq \varphi_m^n(\tau_k) - (j-k)\delta_m \omega((M+1)\delta_m)$$
$$\geqq \varphi_m^n(\tau_k) - m\delta_m \omega((M+1)\delta_m).$$

Letting $m \to \infty$, we get

$$\varphi^m[t] \geqq 0 \quad \forall t \in [\bar{t}, \bar{t} + \sigma],$$

contradicting (3.50). □

THEOREM 3.2. *Let* **H1** *and* **H4** *hold. Then* $w(\cdot,\cdot)$ *is continuous on* $[0, T]\times E$ *if* $g(\cdot)$ *is continuous on* E, *and* $w(\cdot,\cdot)$ *is locally Lipschitz continuous on* $[0, T]\times E$ *if* $g(\cdot)$ *is locally Lipschitz on* E.

Proof. We consider the assertion about Lipschitz continuity. The modifications needed for the other statement are straightforward. Let $X \subset E$ be compact. We show that there exists a constant $K>0$ such that for all (t_0, x_0) and (t_1, x_1) in $[0, T]\times X$,

$$|w(t_0, x_0) - w(t_1, x_1)| \leqq K(|t_0 - t_1| + |x_0 - x_1|).$$

Let $v_0 = w(t_0, x_0)$, $v_1 = w(t_1, x_1)$. Suppose $t_1 \geqq t_0$. Let $\bar{\Gamma}_0, \Gamma_1$ be defined on $[t_1, T]$ extremally with respect to $C^+(v_0)$ and $C^+(v_1)$, respectively. Note that because of **H4**, v_0 and v_1 are finite (see Remark 2). Define

$$d_1 \equiv d((t_1, x_1), C^+(v_0) \cap H_{t_1}).$$

Then, by Lemma 2.1 with $\Omega = C^+(v_0)$, there exists a $C>0$ such that for any $\varphi \in \Phi[\cdot, t_1, x_1, \bar{\Gamma}_0]$,

$$d((t, \varphi[t]), C^+(v_0) \cap H_t) \leqq Cd_1 \quad \forall t \in [t_1, T]. \tag{3.51}$$

Specializing to $t = T$, we have that for any $\varphi \in \Phi[\cdot, t_1, x_1, \bar{\Gamma}_0]$ there exists x_φ such that $(T, x_\varphi) \in C^+(v_0)$ and $|x_\varphi - \varphi[T]| \leqq Cd_1$. It is easily verified (see end of proof) that there exists a constant $\mu>0$, independent of (t_i, x_i) $(i=0, 1)$, for which we have

$$d_1 \leqq \mu(|t_0 - t_1| + |x_0 - x_1|). \tag{3.52}$$

Hence

$$|x_\varphi - \varphi[T]| \leqq C\mu(|t_0 - t_1| + |x_0 - x_1|).$$

It follows that

$$|g(x_\varphi) - g(\varphi[T])| \leqq C_g C\mu(|t_0 - t_1| + |x_0 - x_1|),$$

where C_g is the Lipschitz constant of g on a sufficiently large compact set. Since $g(x_\varphi) \geqq v_0$, we have

$$g(\varphi[T]) \geqq v_0 - C_g C\mu(|t_0 - t_1| + |x_0 - x_1|).$$

By Lemma 3.2, $\varphi[t] \in E$ for all $t \in [t_1, T]$. Therefore, $V(\varphi) = g(\varphi[T])$. Since $\varphi \in \Phi[\cdot, t_1, x_1, \bar{\Gamma}_0]$ was arbitrary, we obtain

$$\inf_{\Delta} P[t_1, x_1, \bar{\Gamma}_0, \Delta] \geqq v_0 - C_g C\mu(|t_0 - t_1| + |x_0 - x_1|).$$

Hence, taking the sup over all Γ's on the left, we have

$$w(t_1, x_1) \geqq v_0 - C_g C\mu(|t_0 - t_1| + |x_0 - x_1|). \tag{3.53}$$

To obtain a similar relation with (t_0, x_0) and (t_1, x_1) interchanged, we proceed as follows. Note that we may not be able to define a strategy over $[t_0, T]$ extremally with respect to $C^+(v_1)$ since $t_1 \geqq t_0$. Instead, let Γ_0 be defined on $[t_0, T]$ extremally with respect to $C^+(v_0)$. Define $\bar{\Gamma}_1$ as the concatenation of Γ_0 on $[t_0, t_1]$ and Γ_1 on $[t_1, T]$. Then given a motion $\bar{\varphi} \in \Phi[\cdot, t_0, x_0, \bar{\Gamma}_1]$; there exists $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma_0]$ such that

$$\text{(a)} \quad \bar{\varphi} \restriction [t_0, t_1] \equiv \varphi \restriction [t_0, t_1] \tag{3.54}$$

$$\text{(b)} \quad \bar{\varphi} \restriction [t_1, T] \in \Phi[\cdot, t_1, \bar{\varphi}[t_1], \Gamma_1].$$

Applying Lemma 3.2 to φ, we have that $\varphi[t] \in E$ for $t \in [t_0, t_1]$. In particular, by (3.54(a)), $\bar{\varphi}[t_1] \in E$. Also, again using Lemma 3.2 and (3.54(b)), $\bar{\varphi}[t] \in E$ for all

$t \in [t_1, T]$. Thus, we have $\bar{\varphi}[t] \in E$, for all $t \in [t_0, T]$. Now define $d_2 = d((t_1, \bar{\varphi}[t_1]), C^+(v_1) \cap H_{t_1})$. It can be shown (see end of proof) that regardless of the choice of $\bar{\varphi}$,

$$d_2 \leqq \mu(|t_0 - t_1| + |x_0 - x_1|). \tag{3.55}$$

Using (3.54(b)), it follows from Lemma 2.1, with $\Omega = C^+(v_1)$, that there exists $x_{\bar{\varphi}}$ such that $(T, x_{\bar{\varphi}}) \in C^+(v_1)$ and

$$|\bar{\varphi}[T] - x_{\bar{\varphi}}| \leqq C d_2 \leqq C\mu(|t_0 - t_1| + |x_0 - x_1|).$$

Hence

$$|g(\bar{\varphi}[T]) - g(x_{\bar{\varphi}})| \leqq C_g C\mu(|t_0 - t_1| + |x_0 - x_1|).$$

Since $g(x_{\bar{\varphi}}) \geqq v_1$,

$$g(\bar{\varphi}[T]) \geqq v_1 - C_g C\mu(|t_0 - t_1| + |x_0 - x_1|).$$

Since the choice of $\bar{\varphi}$ was arbitrary, we get, as before,

$$w(t_0, x_0) \geqq v_1 - C_g C\mu(|t_0 - t_1| + |x_0 - x_1|). \tag{3.56}$$

Let $K = C_g C\mu$. Then, from (3.53) and (3.56), we have the desired conclusion. It remains to verify (3.52) and (3.55).

Proof of (3.52). Take $\varphi \in \Phi[\cdot, t_0, x_0, \Gamma_0]$ and let $\{\varphi_m(\cdot)\}$ be the sequence of mth-stage trajectories converging to φ. Since by Lemma 1.5, $(t_1, \varphi[t_1]) \in C^+(v_0)$, we have

$$\begin{aligned} d_1 &\leqq |(t_1, x_1) - (t_1, \varphi[t_1])| = \lim_{m \to \infty} |(t_1, x_1) - (t_1, \varphi_m(t_1))| \\ &\leqq \lim_{m \to \infty} \{|(t_1, x_1) - (t_0, x_{0_m})| + |(t_0, x_{0_m}) - (t_1, \varphi_m(t_1))|\}, \end{aligned} \tag{3.57}$$

where $x_{0_m} = \varphi_m(t_0)$. Then, for any m,

$$|\varphi_m(t_1) - x_{0_m}| \leqq \int_{t_0}^{t_1} |f(t, \varphi_m(t), u_m(t), v_m(t))|\, dt \leqq M|t_1 - t_0|,$$

where $M = \max\{|f(t, x, y, z)|: t \in [0, T], |x| \leqq R, y \in Y, z \in Z\}$, and $R > 0$ is sufficiently large so that any trajectory with initial point in $[0, T] \times X$ lies in $B_R(0)$. Hence, together with (3.57), we have

$$d_1 \leqq |(t_0, x_0) - (t_1, x_1)| + \sqrt{M^2 + 1}|t_0 - t_1| \leqq \mu(|t_0 - t_1| + |x_0 + x_1|),$$

where $\mu = 1 + \sqrt{M^2 + 1}$. Note that μ depends on X (through M) but not on the initial points (t_0, x_0) and (t_1, x_1).

Proof of (3.56). Since $(t_1, x_1) \in C^+(v_1)$,

$$d_2 \leqq |(t_1, \bar{\varphi}[t_1]) - (t_1, x_1)| \leqq \lim_{m \to \infty} |(t_1, \bar{\varphi}_m(t_1)) - (t_1, x_1)|,$$

where $\{\bar{\varphi}_m\}$ is the sequence of mth-stage trajectories converging to $\bar{\varphi}$. As in the proof of (3.52), above, if $x_{0_m} = \bar{\varphi}_m(t_0)$,

$$\begin{aligned} d_2 &\leqq \lim_{m \to \infty} \{|(t_1, \bar{\varphi}_m(t_1)) - (t_0, x_{0_m})| + |(t_0, x_{0_m}) - (t_1, x_1)|\} \\ &\leqq \sqrt{M^2 + 1}|t_1 - t_0| + |(t_0, x_0) - (t_1, x_1)| \\ &\leqq \mu(|t_0 - t_1| + |x_0 - x_1|). \end{aligned}$$

This completes the proof of Theorem 3.2. □

Remark 4. (Restrictions on the minimizer). If the phase restriction $x^n \geqq 0$ is placed on the minimizer rather than the maximizer, then we clearly need to adjust conditions **H2**, **H3**, and **H4** accordingly. We record these changes here for later reference:
H2 (for minimizer): for all $t \in [0, T]$, $x \in \partial E$

$$\max_z \min_y f^n(t, x, y, z) \geqq 0.$$

H3 (for minimizer) is the same as **H2** with strict inequality.
H4 (for minimizer):

(i) There exists an $x \in E$ such that $w(0, x) > -\infty$.

(ii) If $t \in [0, T)$, $x \notin E$ and $\alpha \in \mathbb{R}$ are such that $V^\alpha(t, x)$, the extremal strategy with respect to $C^-(\alpha)$, is defined then

$$\min_y f^n(t, x, y, z^*(t, x)) \geqq 0,$$

where $z^*(t, x)$ is the outcome of $V^\alpha(t, x)$.

Remark 5 (More general sets E). The arguments used to prove Proposition 3.1, and Theorems 3.1 and 3.2 are essentially of a local nature. Using this fact, we can extend these theorems to the setting where E is a closed set with nonempty interior and C^2 boundary. In doing so, it is only necessary to extend Lemmas 3.1 and 3.2 to the new setting. Now, through a change of coordinates, E can be locally mapped onto a subset of $\{x: x^n \geqq 0\}$. We then apply the results obtained above the problem in the new coordinates.

Clearly assumptions **H2**, **H3**, and **H4** have to be expressed in terms different from before. Such adjustments are straightforward; for example, **H3** would read:
H3': If $t \in [0, T]$, $x \in \partial E$ and $n(x)$ is the inward normal to ∂E at x, then

$$\max_y \min_z \langle n(x), f(t, x, y, z)\rangle > 0.$$

In a similar manner, these theorems extend to sets E of form $E = E_1 \cap E_2 \cap \cdots \cap E_k$, where each of the E_i's is a closed set with $\operatorname{int}(E_i) \neq \varnothing$ and C^2 boundary with the further restriction that if $x \in E_1 \cap E_2 \cap \cdots \cap E_k$, and $n_i(x) =$ the (inward) normal to ∂E_i at x, then the set $\{n_i(x): 1 \leqq i \leqq k\}$ is a linearly independent set of vectors. This covers, for example, the case of $E = \{x \in \mathbb{R}^n: x^1 \geqq 0, \cdots, x^k \geqq 0\}$. We refer the interested reader to § 4 of [6] for the details.

Our last result differs from Theorems 3.1 and 3.2 in that we make no assumptions on the shape or smoothness of the phase set E.

THEOREM 3.3. *Suppose w is continuous on $[0, T] \times \partial E$, then w is continuous on $[0, T] \times E$.*

Before starting the proof, we make an observation. Suppose $(t_0, x_0) \in C^+(\alpha)$, for some $\alpha \in \mathbb{R}$, and $t_1 \geqq t_0$. Referring to the proof of Lemma 2.1, we note that given a compact set $X \subset E$ containing x_0, if Γ_e is the strategy defined on $[t_1, T]$, extremally with respect to $C^+(\alpha)$, then there exist constants β, K and a function $E(\cdot)$, all depending only on f and X, such that for any $\varphi_m \in \Phi_m(\cdot, t_1, x_1, \Gamma_e)$, $x_1 \in X$, we have, for all $t \in [t_1, T]$,

$$d^2((t, \varphi[t]), C^+(\alpha) \cap H_t) \leqq e^{\beta K} d^2((t_1, x_1), C^+(\alpha) \cap H_{t_1}) + E(\delta_m)(e^{\beta K - 1}/\beta),$$

where $\delta_m = (T - t_1)/m$. It follows that if $C > e^{(\beta K)/2}$ then there exists an m^*, independent of the set $C^+(\alpha)$, such that for any $\varphi_m \in \Phi_m(\cdot, t_1, x_1, \Gamma_e)$, if $m \geqq m^*$, then

$$d((t, \varphi_m(t)), C^+(\alpha) \cap H_t) \leqq C d((t_1, x_1), C^+(\alpha) \cap H_{t_1}), \quad \forall t \in [t_1, T].$$

Proof of the Theorem. Let $(t_0, x_0) \in [0, T] \times E$. By Lemma 1.2, we only need to show that w is lower semicontinuous; i.e., $\forall \varepsilon > 0$, $\exists \delta > 0$ such that

$$|t_0 - t_1| + |x_0 - x_1| < \delta \Rightarrow w(t_1, x_1) > w(t_0, x_0) - \varepsilon. \tag{3.58}$$

Let G be a bounded neighborhood of x_0 and $R > 0$ be such that any trajectory with initial point in $[0, T] \times \bar{G}$ is contained in $B_R(0)$. Since w is, by hypothesis, continuous on $[0, T] \times \partial E$, there exists a $\sigma > 0$ such that for any t, $t' \in [0, T]$ and x, $x' \in \partial E \cap B_R(0)$,

$$|t - t'| + |x - x'| < \sigma \Rightarrow \| w(t, x) - w(t', x')| < \varepsilon/2. \tag{3.59}$$

Case 1. $t_1 \geqq t_0$. Define, for any $x_1 \in \bar{G}$, a strategy $\Gamma(t_1, x_1)$ as follows. The mth-partition is a uniform subdivision $\{t_1 < \tau_1 < \cdots < \tau_m = T\}$ of $[t_1, T]$. The mth-stage strategy is defined positionally as follows. Let $\Gamma_{m,0} = U_0(t_1, x_1)$ where $U_0 = U_e(C^+(v_0))$, and $v_0 = w(t_0, x_0)$. Suppose $u_m(\cdot)$, the outcome of Γ_m versus some Δ_m, has been defined on $[t_1, \tau_i)$ and φ_m is the corresponding trajectory on $[t_1, \tau_i]$. Let $v_m(\cdot)$ be the outcome of Δ_m on $[t_1, \tau_i)$. Then if $\varphi_m(\tau_i) \in E$ define $\Gamma_{m,i+1}(u_m, v_m) = U_0(\tau_i, \varphi_m(\tau_i))$. Suppose $\kappa = \kappa(m)$ is the smallest index such that $\varphi_m(\tau_k) \notin E$. Define $t_m = \inf\{t' < \tau_k : \varphi_m(\tau) \notin E$, for all $\tau \in (t', \tau_\kappa]\}$. Note that $t_m \in [\tau_{\kappa-1}, \tau_\kappa)$, by its definition, and $\varphi_m(t_m) \in \partial E$. Let $v_m = w(t_m, \varphi_m(t_m))$ and $U_m = U_e(C^+(v_m))$. Now, define $\Gamma_{m,i+1}(u_m, v_m) = U_m(\tau_i, \varphi_m(\tau_i))$, for all $i \geqq \kappa$.

It follows from the above observation, with $X = \bar{G}$, that if φ_m is an mth-stage trajectory of $\Gamma(t_1, x_1)$, then

$$d((t, \varphi_m(t)), C^+(v_0) \cap H_t) \leqq C d((t_1, x_1), C^+(v_0) \cap H_{t_1}), \quad \forall t \in [t_1, \tau_\kappa], \tag{3.60}$$

and

$$d((t, \varphi_m(t)), C^+(v_m) \cap H_t) \leqq C d((\tau_\kappa, \varphi_m(\tau_k)), C^+(v_m) \cap H_{\tau_\kappa}), \quad \forall t \in [\tau_\kappa, T]. \tag{3.61}$$

Now recall that, as observed in the proof of Theorem 3.2 (cf. (3.52)), there exists a constant μ, depending on X, such that

$$d((t_1, x_1), C^+(v_0) \cap H_{t_1}) \leqq \mu\{|t_0 - t_1| + |x_0 + x_1|\}, \tag{3.62}$$

$$d((\tau_\kappa, \varphi_m(\tau_\kappa)), C^+(v_m) \cap H_{\tau_\kappa}) \leqq \mu\{|\tau_\kappa - t_m| + |\varphi_m(t_m) - \varphi_m(\tau_\kappa)|\}. \tag{3.63}$$

From (3.62) and (3.63), we have that for all $m \geqq m^*$,

$$d((t, \varphi_m(t)), C^+(v_0) \cap H_t) \leqq C\{|t_0 - t_1| + |x_0 - x_1|\}, \quad \forall t \in [t_1, \tau_\kappa]. \tag{3.64}$$

Let $\mathcal{F} = C^+(v_0) \cap [t_0, T] \times (\partial E \cap \bar{B}_R(0))$. $\mathcal{F}$ is compact, being bounded and closed. For each m, define $\rho_m \in \mathbb{R}$ as follows. If $\mathcal{F} = \varnothing$ or if $\varphi_m(t) \in E$, for all $t \in [t_1, T]$ and all $\varphi_m(t) \in \Phi_m(\cdot, t_1, x_1, \Gamma(t_1, x_1))$ then $\rho_m = 0$. Otherwise $\rho_m = \sup\{d((t_m, \varphi_m(t_m)), \mathcal{F})$: $\varphi_m \in \Phi_m(\cdot, t_1, x_1, \Gamma(t_1, x_1))\}$, where t_m is as defined above.

Claim. For every positive number σ, there exists a $\delta > 0$ such that if $|t_0 - t_1| + |x_0 - x_1| \leqq \delta$, $t_1 \geqq t_0$, then $\rho_m \leqq \sigma$ for all $m \geqq m^*$. To prove this statement suppose, on the contrary, that there exist $\sigma > 0$, sequences $(t_n, x_n) \to (t_0, x_0)$, $t_n \geqq t_0$, and $\{m(n)\}$ such that $\rho_{m(n)} > \sigma$ for every n. By the definition of ρ_m, we obtain a sequence $\{\varphi_{m(n)}\}$ with

$$d((t_{m(n)}, \varphi_{m(n)}(t_{m(n)})), \mathcal{F}) \geqq \sigma, \quad \forall n. \tag{3.65}$$

Applying (3.64) with $t = t_{m(n)}$, we have that $\exists z_n$ such that $(t_{m(n)}, z_n) \in C^+(v_0)$ and

$$|z_n - \varphi_{m(n)}(t_{m(n)})| \leqq C(|t_n - t_0| + |x_0 - x_n|). \tag{3.66}$$

It follows that $\{z_n\}$ is bounded. Hence, by taking a subsequence, we may assume that there exist t^* and z^* such that $t_{m(n)} \to t^*$ and $z_n \to z^*$. Therefore, from (3.66) we get that $\varphi_{m(n)}(t_{m(n)}) \to z^*$, as $n \to \infty$. Since $\varphi_{m(n)}(t_{m(n)}) \in \partial E$ for all n, we conclude that $z^* \in \partial E$. Also, since $C^+(v_0)$ is closed, we have $(t^*, z^*) \in C^+(v_0)$. Therefore $(t^*, z^*) \in \mathcal{F}$. But now $\varphi_{m(n)}(t_{m(n)}) \to z^*$ and $t_{m(n)} \to t^*$ contradict (3.65).

We now prove (3.58) for this case. Let σ be as chosen in (3.59). By the above claim there exists $\delta_1 > 0$ such that if $|t_0 - t_1| + |x_0 - x_1| \leqq \delta_1$ then $\rho_m \leqq \sigma$. Now let φ be any motion in $\Phi[\cdot, t_1, x_1, \Gamma(t_1, x_1)]$ with $\{\varphi_m\}$ as its mth-stage trajectories. Without loss of generality, we may assume that $\varphi_m(t_1) = x_1$ (i.e., $\varphi_m \in \Phi_m(\cdot, t_1, x_1, \Gamma(t_1, x_1))$). We claim that $\varphi[t] \in E$, for all $t \in [t_1, T]$ and $g(\varphi[T]) \geqq v_0 - \varepsilon$.

Verification. Suppose that for all m sufficiently large, $\kappa = \kappa(m) < m$ (κ as defined above); otherwise the desired conclusion follows from (3.64) and the continuity of g. Recall that $t_m \in [\tau_{\kappa-1}, \tau_\kappa)$. Hence, since the norm of the partition tends to zero as $m \to \infty$, we get

$$|\tau_\kappa - t_m| + |\varphi_m(t_m) - \varphi_m(\tau_k)| \to 0 \quad \text{as } m \to \infty. \tag{3.67}$$

It follows from (3.61), (3.63), (3.67) and the fact that, by the definition of v_m, $(t_m, \varphi_m(t_m)) \in C^+(v_m)$, that

$$\lim_{m\to\infty} \max_{t\in[\tau_\kappa, T]} d((t, \varphi_m(t)), C^+(v_m) \cap H_t) = 0. \tag{3.68}$$

Hence, by the continuity of $g(\cdot)$, for all m sufficiently large,

$$g(\varphi_m(T) \geqq v_m - \varepsilon/4. \tag{3.69}$$

Note also that by the definition of τ_κ, and since $t_m \in [\tau_{\kappa-1}, \tau_\kappa)$,

$$\max_{t\in[t_1, \tau_\kappa]} d(\varphi_m(\tau), E) = \max_{t\in[t_m, \tau_\kappa]} d(\varphi_m(\tau), E) \to 0, \quad \text{as } m \to \infty.$$

Furthermore, since $C^+(v_m) \subset [0, T] \times E$, we get from (3.68), that

$$\max_{t\in[\tau_\kappa, T]} d(\varphi_m(t), E) \to 0, \quad \text{as } m \to \infty.$$

Hence, $\varphi[t] \in E$, for all $t \in [t_1, T]$. Therefore, $V(\varphi) = g(\varphi[T])$, and using (3.69),

$$V(\varphi) = g(\varphi[T]) \geqq v_m - \varepsilon/2, \tag{3.70}$$

for all m sufficiently large. Now, by the choice of δ_1, for every m, there exists $(\bar{t}_m, \bar{x}_m) \in \mathscr{F}$ such that $|\bar{t}_m - t_m| + |\varphi_m(t_m) - \bar{x}_m| \leqq \sigma$. Therefore, by (3.59) and the fact that $\mathscr{F} \subset C^+(v_0)$, we have

$$v_m = w(t_m, \varphi_m(t_m)) \geqq w(\bar{t}_m, \bar{x}_m) - \varepsilon/2 \geqq v_0 - \varepsilon/2. \tag{3.71}$$

Thus, by (3.70), $V(\varphi) \geqq v_0 - \varepsilon$. Since $\varphi \in \Phi[\cdot, t_1, x_1, \Gamma(t_1, x_1)]$ was arbitrary, taking inf over all φ's and sup over all Γ's, we have $w(t_1, x_1) \geqq w(t_0, x_0) - \varepsilon$, as desired. This completes Case 1.

Let us note that we have actually shown, above, that for an initial point (t_1, x_1), with $t_1 \geqq t_0$, if the first player plays that mth-stage of $\Gamma(t_1, x_1)$ at the mth-stage, then any for $\varphi_m \in \Phi_m(\cdot, t_1, x_1, \Gamma(t_1, x_1))$, we have

$$g(\varphi_m(T)) \geqq v_0 - 3\varepsilon/4, \tag{3.72}$$

(cf., (3.69) and (3.71)) for all m sufficiently large, provided $|t_0 - t_1| + |x_0 - x_1| < \delta_1$.

Case 2. $t_1 < t_0$. Let $M = \max\{1, |f(t, x, y, z)|: t \in [0, T], |x| \leqq R, y \in Y, z \in Z\}$. Let $\delta_2 = \min\{\delta_1, \sigma\}/(M+1)$. Suppose that $|t_0 - t_1||x_0 - x_1| < \delta_2$. Define a strategy $\Gamma(t_1, x_1)$ as follows. The mth-stage partition is $\Pi = \{t_1 < \tau_1 < \cdots < \tau_m = t_0 < \cdots < \tau_{2m} = T\}$ where $|\tau_i - \tau_{i-1}| = (t_0 - t_1)/m$ if $i \leqq m$ and $|\tau_i - \tau_{i-1}| = (T - t_0)/m$ if $i > m$. For the mth-stage strategy, take $\Gamma_{m,0} = U_1(t_1, x_1)$, where $U_1 = U_e(C^+(w(t_1, x_1)))$. Suppose $u_m(\cdot)$ is the outcome of $\Gamma_m(t_1, x_1)$ versus some Δ_m defined on $[t_1, \tau_i)$ and $\varphi_m(\cdot) = \varphi_m(\cdot, t_1, x_1, u_m, v_m)$ defined on $[t_1, \tau_i]$. If $\varphi_m(\tau_i) \in E$, then

$$\Gamma_{m,i+1}(u_m, v_m) = \begin{cases} U_1(\tau_i, \varphi_m(\tau_i)) & \text{if } i < m \\ U_0(\tau_i, \varphi_m(\tau_i)) & \text{if } i \geqq m. \end{cases}$$

Let $\kappa = \kappa(m)$ be the smallest index such that $\varphi_m(\tau_\kappa) \notin E$. Then define $t_m \in [\tau_{\kappa-1}, \tau_\kappa)$ as before, let $v_m = w(t_m, \varphi_m(t_m))$ and $U_m = U_e(C^+(v_m))$. Now, define $\Gamma_{m,i+1}(u_m, v_m) = U_m(\tau_i, \varphi_m(\tau_i))$, for all $i \geqq \kappa$. Note that if $\varphi_m \in \Phi_m(\cdot, t_1, x_1, \Gamma(t_1, x_1))$, then

$$
\begin{aligned}
|t - t_0| + |\varphi_m(t) - x_0| &\leqq |t - t_0| + |\varphi_m(t) - \varphi_m(t_1)| + |\varphi_m(t_1) - x_0| \\
&\leqq (M+1)(|t_0 - t_1| + |x_0 - x_1|) < \delta_2, \quad \text{for all } t \in [t_1, t_0].
\end{aligned} \tag{3.73}
$$

Now if $\varphi_m(t) \in E$ for all $t \in [t_1, t_0]$, then, because of the definition of $\Gamma(t_1, x_1)$, we have that (3.72) holds. On the other hand, suppose that for some $t \in [t_1, t_0]$, $\varphi_m(t) \notin E$, then $k \leqq m$. We may assume, in this case, that $x_0 \in \partial E$, for if $x_0 \in \operatorname{int}(E)$ then, by shrinking δ_2, if necessary, we can arrange to have $\varphi_m(t) \in \operatorname{int}(E)$ for all $t \in [t_1, t_0]$. Now, by arguments similar to those of Case 1, we have $g(\varphi_m(T) \geqq v_m - 3\varepsilon/4$, (cf., (3.69)), for all m sufficiently large. But, by (3.73), $|t_m - t_0| + |\varphi_m(t) - x_0| < \delta_2 < \sigma$. Hence, by (3.59), we have

$$
v_m = w(t_m, \varphi_m(t_m)) \geqq w(t_0, x_0) - \varepsilon/2.
$$

Thus, (3.72) holds in this case also. Note that, just as in Case 1, using the fact that sets $C^+(\alpha) \subset [0, T] \times E$ for any $\alpha \in \mathbb{R}$, we have that if $\varphi \in \Phi[\cdot, t_1, x_1, \Gamma(t_1, x_1))$ then $\varphi[t] \in E$ for all $t \in [t_1, T]$. Hence it follows from (3.72) and the continuity of $g(\cdot)$ that

$$
V(\varphi) = g(\varphi[T]) \geqq v_0 - \varepsilon.
$$

Taking inf over all φ's and sup over all Γ's we obtain $w(t_1, x_1) \geqq w(t_0, x_0) - \varepsilon$ in this case. Therefore if $\delta = \min(\delta_1, \delta_2)$, we have (3.58) as desired. This completes the proof of the Theorem. □

Example (Battle of Bunker Hill). The dynamics are:

$$
\begin{aligned}
\dot{x}^1 &= -c_1 p_1 x^3 z \\
\dot{x}^2 &= -c_1 z \\
\dot{x}^3 &= -c_2 p_2 x^1 y \\
\dot{x}^4 &= -c_2 y
\end{aligned}
$$

where the c_i's and p_i's are positive constants. The control sets are $Y = Z = [0, 1]$, and $T =$ some given final time. The terminal payoff is defined through either of the following functions: $g_1(x) = x^1 - x^3$ and $g_2(x) = x^1 x^4 - x^3 x^2$. This game was studied heuristically by Isaacs in [7] (cf. [7] for an interpretation of the game). One of the players, say player I, is restricted to $E = \{x: x^3 \geqq 0, x^4 \geqq 0\}$. It is assumed further that the initial point of the game is such that $x^1 \geqq 0$ and $x^2 \geqq 0$ are automatically satisfied throughout the game. It is then easy to check that if $x_0 \in \partial E$, then the only admissible control for player I is $y \equiv 0$. Hence, for $x_0 \in \partial E$ the game reduces to an optimal control problem for player II. Its value is easily seen to be continuous. Therefore, by Theorem 3.3, the value of the original game, which exists by Theorem 1.1, is also continuous.

Remark 6 (Hamilton-Jacobi-Isaacs' equation). In Theorems 3.1, 3.2, and 3.3, we have given conditions under which $w(\cdot, \cdot)$ will be continuous. By essentially the same arguments as those of [2], but not using a Lipschitz continuity assumption on W, it follows (cf. [6]) from the stability of $C^+(\alpha)$ and Lemma 1.6 that w satisfies the following.

(1) If φ is continuously differentiable on a neighborhood of $[0, T] \times E$ and $w - \varphi$ has a local max at $(t_0, x_0) \in (0, T) \times E$, then

$$
\varphi_t(t_0, x_0) + H(t_0, x_0, D\varphi(t_0, x_0)) \geqq 0;
$$

(2) If φ is continuously differentiable on a neighborhood of $[0, T]\times E$ and $w-\varphi$ has a local min at $(t_0, x_0)\in(0, T)\times \underline{\text{int}(E)}$, then

$$\varphi_t(t_0, x_0)+H(t_0, x_0, D\varphi(t_0, x_0))\leqq 0,$$

where $H(t, x, p)=\max_y \min_z \langle p, f(t, x, y, z)\rangle$ and $D\varphi=(\partial\varphi/\partial x^1, \cdots, \partial\varphi/\partial x^n)$.

Let us note that conditions (1) and (2) are precisely the ones proposed by Soner in [12] as defining "constrained viscosity solutions" of the Hamilton-Jacobi equation. Under a mild restriction on ∂E, by combining the methods of Ishii ([13]) and Soner ([12]), we can show (cf., [6]) that (1), (2), and the terminal condition $w(T, x)=g(x)$, for all $x\in E$, determine w uniquely on $[0, T]\times E$. We note that this type of uniqueness theorem is not new. The first such result was obtained by Soner (cf., [12]). More recently, Capuzzo-Dolcetta and Lions have given a detailed treatment of viscosity solutions for problems with state contraints in [15] (see also [14]). In this paper they obtain, in addition to many other interesting results, uniqueness theorems of the type mentioned above for more general functions H (cf., [15, Thms. III.1-III.4]).

Acknowledgment. This work comprises parts of the author's Ph.D. thesis. The author would like to thank his major advisor, Professor L. D. Berkovitz, for suggesting the problem and for his subsequent, invaluable suggestions and guidance.

A SKEW TOEPLITZ APPROACH TO THE H^∞ OPTIMAL CONTROL OF MULTIVARIABLE DISTRIBUTED SYSTEMS*

HITAY ÖZBAY† AND ALLEN TANNENBAUM‡

Abstract. In this paper the problem of the H^∞ optimization of multivariable distributed systems in the four block setting is studied. This work is based on several previous papers and employs the skew Toeplitz framework developed in [*Operator Theory: Adv. Appl.*, 32 (1988), pp. 21-43], [*Operator Theory: Adv. Appl.*, 32 (1988), pp. 93-112], [*Operator Theory and Integral Equations*, 11 (1988), pp. 726-767], [*J. Functional Anal.*, 74 (1987), pp. 146-159], [SIAM J. Math. Anal., 19 (1988), pp. 1081-1091].

Key words. H^∞-optimal control, distributed system, four block problem, skew Toeplitz operator

AMS(MOS) subject classifications. 93B35, 93C05

1. Introduction. In the past few years, there has been a major research effort devoted to the study of the H^∞ optimization of linear systems. We refer the reader to [13] for an extensive set of references. In this paper we consider the problem of the H^∞-optimization for multivariable distributed systems.

Motivations leading to the H^∞ optimization in systems theory lie in the most natural problems of control engineering such as robust stabilization, sensitivity minimization, and model matching. It can be shown that, in the sense of H^∞ optimality, these problems are equivalent, and can be stated (see [13]) as one *standard problem.* Consider the setup shown in Fig. 1. In this configuration w, u, y, and z are vector-valued signals with w the exogenous input representing the disturbances, measurement noises, etc., u the command signal, z the output to be controlled, and y the measured output. G represents a combination of the plant and the weights in the control system. The standard H^∞ problem is to find a stabilizing controller K such that the H^∞ norm of the transfer function from w to z is minimized. For finite-dimensional systems an expression for a suboptimal controller is given in [2] and [4] using a state-space approach.

Now it is quite well known that an optimal solution of the standard problem can be reduced to finding the singular values of a certain operator (the so-called **four block operator**) that will be defined below. For details we refer the reader to [5]–[7]. Depending on the specific problem considered, the corresponding four block operator can be simplified to a 2-block or a 1-block operator.

This paper is based on several previous papers [6]–[12], [21], and basically employs the skew Toeplitz framework of [3] to study the standard problem. We should note that software for the implementation of the techniques used in this paper has already been written at the Systems Research Center of Honeywell, Minneapolis in collaboration with Blaise Morton, and has been applied to several distributed systems including a flexible beam problem. We plan to write a paper with several such "benchmark" examples with Blaise Morton in the near future.

The present paper is organized as follows. In the next section we set up some notation and give some background on the ideas taken from previous work. In § 3 we derive our main result which is a rank type formula for the singular values of the four block operator. We illustrate a special case of our main result by considering SISO plants in § 4, and by giving an explicit example in § 5. Finally, in § 6 we summarize our results and make some comments.

2. Problem definition and preliminary remarks. We will now state the standard H^∞ problem and define the four block operator. We will also present some preliminary results from earlier work [3], [6], [7]. Throughout the paper all Hardy spaces are defined on the unit disc D in the standard way. For an integer m we denote the canonical unilateral shift (defined by multiplication by z) on $H^2(\mathbf{C}^m)$ by $S: H^2(\mathbf{C}^m) \to H^2(\mathbf{C}^m)$ and the bilateral shift on $L^2(\mathbf{C}^m)$ by $U: L^2(\mathbf{C}^m) \to L^2(\mathbf{C}^m)$. Let W, F, G, J, and M be H^∞ matrices, of sizes $p \times m$, $p \times l$, $q \times m$, $q \times l$, and $p \times p$, respectively, with $p \leqq \max\{m, l\}$, where W, F, G, J have rational entries, and M is a nonconstant inner matrix. These matrices are associated with the weighting matrices and the plant in the usual way of transforming the standard problem to the 4-block framework (i.e., via Youla parametrization and some inner outer factorizations; see, e.g., [13] and [20]). It is important to note that for many problems of interest, in the case of rational weights and distributed stable plants, this reduces to the kind of problem described below. See [15] for all the details. The standard H^∞ problem amounts to finding

$$\mu := \inf\left\{ \left\| \begin{bmatrix} W - MQ & F \\ G & J \end{bmatrix} \right\|_\infty : Q \in H^\infty p \times m \right\},$$

where for a $k \times n$ matrix of the form $\left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right]$, ($A$, B, C, D having appropriate sizes with entries in L^∞), we set

$$\left\| \begin{bmatrix} A & B \\ C & D \end{bmatrix} \right\|_\infty = \operatorname{ess\,sup}\left\{ \left\| \begin{bmatrix} A(\zeta) & B(\zeta) \\ C(\zeta) & D(\zeta) \end{bmatrix} \right\| : |\zeta| = 1 \right\}.$$

(For the norm on the right-hand side the $k \times n$ matrix is taken as a linear operator from $\mathbf{C}^n$ to $\mathbf{C}^k$ for each fixed ζ in ∂D, the unit circle.) Note that if $F = G = J = 0$ then this problem reduces to the classical Nehari problem, which is also known as the *1-block problem.* For $F = J = 0$ we have the *2-block problem.*

To the $p \times p$ inner matrix M, we associate the spaces $H(M) := H^2(\mathbf{C}^p) \ominus MH^2(\mathbf{C}^p)$ and $L(M) := L^2(\mathbf{C}^p) \ominus MH^2(\mathbf{C}^p)$. Let $P_{H(M)}: H^2(\mathbf{C}^p) \to H(M)$, $P_{L(M)}: L^2(\mathbf{C}^p) \to L(M)$, $P_{H^2}: L^2(\mathbf{C}^p) \to H^2(\mathbf{C}^p)$, and $P_{L^2 \ominus H^2}: L^2(\mathbf{C}^p) \to L^2(\mathbf{C}^p) \ominus H^2(\mathbf{C}^p)$ be orthogonal projections.

We now define the 4-block operator (see [5] and [7]):

$$A := \begin{bmatrix} P_{H(M)}W(S) & P_{L(M)}F(U) \\ G(S) & J(U) \end{bmatrix}.$$

Note that $A: H^2(\mathbf{C}^m) \oplus L^2(\mathbf{C}^l) \to L(M) \oplus L^2(\mathbf{C}^q)$.

In the paper, by a slight abuse of notation, ζ will denote a complex variable as well as an element of ∂D. The context will make the meaning clear. Note that $W(S)$ can be seen as the operator defined by multiplication by $W(\zeta)$, and similarly for $G(S)$, $F(U)$, and $J(U)$. Using the commutant lifting theorem [18, pp. 257-259], we can show that μ is equal to $\|A\|$. (See [5] and [7] for the details.) Note that $\|A\|^2$ is the largest element of $\sigma(A^*A)$, the spectrum of A^*A. $\sigma(A^*A)$ consists of the discrete spectrum (i.e., eigenvalues with finite multiplicity), which we denote by $\sigma_d(A^*A)$, and its complement $\sigma_e(A^*A)$, the essential spectrum. The essential spectrum of A^*A consists of those $\lambda \in \mathbf{C}$ for which there exists

$$\begin{bmatrix} x_n \\ y_n \end{bmatrix} \in H^2(\mathbf{C}^m) \oplus L^2(\mathbf{C}^l) \quad \text{with} \quad \left\| \begin{bmatrix} x_n \\ y_n \end{bmatrix} \right\|_2 = 1 \quad \forall n \geqq 1,$$

and $\left[\begin{smallmatrix} x_n \\ y_n \end{smallmatrix}\right] \to 0$ weakly as $n \to \infty$, such that

$$(\lambda I - A^*A) \begin{bmatrix} x_n \\ y_n \end{bmatrix} \to 0 \quad \text{as } n \to \infty.$$

The essential norm, denoted by $\|A\|_e$, is defined as

$$\|A\|_e^2 = \max \{\lambda : \lambda \in \sigma_e(A^*A)\}.$$

In the SISO case we have that (see [7, Thm. 3.2])

$$\|A\|_e = \max(\alpha, \beta, \gamma),$$

where

$$\alpha = \max \left\{ \left\| \begin{bmatrix} W(\zeta) & F(\zeta) \\ G(\zeta) & J(\zeta) \end{bmatrix} \right\| : \zeta \in \sigma_e(T) \right\},$$

$$\beta = \max \{ \| [G(\zeta) \quad J(\zeta)] \| : \zeta \in \partial D \},$$

$$\gamma = \max \left\{ \left\| \begin{bmatrix} F(\zeta) \\ J(\zeta) \end{bmatrix} \right\| : \zeta \in \partial D \right\}.$$

$\sigma_e(T)$ denotes the essential spectrum of the operator $T := P_{H(M)}S|_{H(M)}$. We let $\mathcal{R}$ be the set of all $\lambda \in \partial D$ that do not lie on any of the open arcs of ∂D on which $M(\zeta)$ is a unitary operator-valued analytic function. Then from [17] and [18], we have that

$$\sigma_e(T) = \mathcal{R}.$$

In the case of infinite-dimensional MIMO systems it may be difficult to find the essential norm of A. Nevertheless, upper and lower bounds can be obtained in terms of α, β, γ. This is discussed in detail in § 3.2.

Note that when $\|A\| > \|A\|_e$, $\|A\|^2$ is an eigenvalue of A^*A. Here we are going to develop a rank type formula for the eigenvalues of A^*A. We will show that this formula is obtained by a certain linear system of equations (called the *singular system* in [7]). These equations are derived from the inversion of two Toeplitz operators and the essential inversion of a skew Toeplitz operator. It is important to note that in the

2-block problem, one of the Toeplitz operator inversions disappears, and in the 1-block case the same is true for both of the Toeplitz operator inversions. The Fredholm conditions on the invertibility of the skew Toeplitz operator (which is essentially invertible) and the coupling between various systems of equations constitute the singular system. See also [3] and [7].

3. Main results.

3.1. Discrete spectrum. Let us begin with the following assumption $W = B/k$, $F = C/k$, $G = D/k$, and $J = E/k$, where B, C, D, E are polynomial matrices and k is a scalar polynomial. We denote by n an upper bound for the degree of the entries of all polynomial matrices appearing throughout the paper.

Now it is easy to see that ρ^2 is an eigenvalue of A^*A if and only if there exists a nonzero

$$\begin{bmatrix} x \\ y \end{bmatrix} \in H^2(\mathbf{C}^m) \oplus L^2(\mathbf{C}^l),$$

such that

$$\begin{aligned} &(\rho^2 k(S)^* k(S) I - B(S)^* P_{H(M)} B(S) - D(S)^* D(S))x \\ &\quad -(P_{H^2}(B(U)^* P_{L(M)} C(U) + D(U)^* E(U)))y = 0, \end{aligned} \tag{1a}$$

and

$$\begin{aligned} &-((C(U)^* P_{H(M)} B(S) + E(U)^* D(S)))x \\ &\quad +(\rho^2 k(U)^* k(U) I - C(U)^* P_{L(M)} C(U) - E(U)^* E(U))y = 0. \end{aligned} \tag{1b}$$

Note that $P_{H(M)} B(S)x = B(\zeta)x - M(\zeta) P_{H^2} M(\zeta)^* B(\zeta)x$. Following the techniques used in [3], we make the factorization

$$M(\zeta)^* B(\zeta) = \Omega_b(\zeta) M_b(\zeta)^*, \tag{f1}$$

where $\Omega_b(\zeta)$ is a polynomial matrix of size $p \times m$ and $M_b(\zeta)$ is an inner matrix of size $m \times m$. We now decompose the space $H^2(\mathbf{C}^m)$ as $H(M_b) \oplus M_b H^2(\mathbf{C}^m)$, and express $x = x_b + M_b x_b'$ where $x_b \in H(M_b)$ and $x_b' \in H^2(\mathbf{C}^m)$. Then we have

$$P_{H^2} M(\zeta)^* B(\zeta)x = P_{H^2} \Omega_b(\zeta) M_b(\zeta)^* (x_b + M_b x_b').$$

Since M_b is inner,

$$P_{H^2} M(\zeta)^* B(\zeta)x = \Omega_b(\zeta) x_b' + P_{H^2} \Omega_b(\zeta) M_b(\zeta)^* x_b.$$

By (f1) we see that the right-hand side of this last equality is equal to

$$M(\zeta)^* B(\zeta) M_b(\zeta) x_b' + P_{H^2} \Omega_b(\zeta) M_b(\zeta)^* x_b.$$

We can write $\Omega_b(\zeta) = \Omega_{b0} + \Omega_{b1}\zeta + \cdots + \Omega_{bn}\zeta^n$. The fact that $x_b \in H(M_b)$ implies

$$M_b(\zeta)^* x_b = \zeta^{-1} u_{-1} + \zeta^{-2} u_{-2} + \cdots$$

for some $u_{-i} \in \mathbf{C}^m$, $i \geqq 1$. Therefore,

$$P_{H^2} \Omega_b(\zeta) M_b(\zeta)^* x_b = \sum_{i=1}^{n} \sum_{j=i}^{n} \Omega_{bj} \zeta^{j-i} u_{-i} =: x_{\omega b}.$$

Combining the above computations we get

$$P_{H(M)} B(S)x = B(S)x_b - M x_{\omega b}.$$

Similarly, for the computation of

$$P_{L(M)}C(U)y = C(U)y - MP_{H^2}M^*Cy,$$

we use the factorization

$$M(\zeta)^*C(\zeta) = \Omega_c(\zeta)M_c(\zeta)^*, \tag{f2}$$

where $\Omega_c(\zeta)$ is a polynomial matrix of size $p \times l$ and M_c is an inner matrix of size $l \times l$. As before we write $y = y_c + M_c y_c'$ where $y_c \in L(M)$ and $y_c' \in H^2(\mathbf{C}^l)$. Let $\Omega_c(\zeta) = \Omega_{c0} + \Omega_{c1}\zeta + \cdots + \Omega_{cn}\zeta^n$. Then

$$P_{H^2}\Omega_c M_c^* y_c = \sum_{i=1}^{n}\sum_{j=i}^{n} \Omega_{cj}\zeta^{j-i}v_{-i} =: y_{wc}$$

for some $v_{-i} \in \mathbf{C}^l$, $i = 1, \cdots, n$. This leads us to

$$P_{L(M)}C(U)y = C(U)y_c - My_{wc}.$$

Now we see that, with the above factorizations and decompositions, (1a), (1b) are equivalent to

$$\begin{aligned}&(\rho^2 k(S)^*k(S)I - D(S)^*D(S) - B(S)^*B(S))x_b\\ &-P_{H^2}((B(U)^*C(U) + D(U)^*E(U))y_c + D(U)^*E(U)M_c y_c')\\ &+(\rho^2 k(S)^*k(S)I - D(S)^*D(S))M_b x_b' = -B(S)^*Mx_{wb} - P_{H^2}B(U)^*My_{wc},\end{aligned} \tag{2a}$$

and

$$\begin{aligned}&(\rho^2 k(U)^*k(U)I - E(U)^*E(U) - C(U)^*C(U))y_c\\ &-(C(U)^*B(S) + E(U)^*D(S))x_b - E(U)^*D(S)M_b x_b'\\ &+(\rho^2 k(U)^*k(U)I - E(U)^*E(U))M_c y_c' = -C(U)^*My_{wc} - C(U)^*Mx_{wb}.\end{aligned} \tag{2b}$$

Now we will compute $P_{H^2}(B(U)^*C(U) + D(U)^*E(U))y_c$. First write

$$B(U)^*C(U) + D(U)^*E(U) = Q_{-n}^1 U^{*n} + \cdots + Q_0^1 + \cdots + Q_n^1 U^n.$$

Then,

$$P_{H^2}Q_{-i}^1 U^{*i}y_c = Q_{-i}^1 P_{H^2}U^{*i}y_c = Q_{-i}^1 S^{*i}(P_{H^2}y_c).$$

Let $y_c = \cdots + y_{c(-1)}\zeta^{-1} + y_{c(0)} + y_{c(1)}\zeta + \cdots$. Then

$$P_{H^2}Q_i^1 U^i y_c = Q_i^1 S^i(P_{H^2}y_c) + Q_i^1(\zeta^{i-1}y_{c(-1)} + \cdots + y_{c(-i)}).$$

Therefore,

$$\begin{aligned}&P_{H^2}(B(U)^*C(U) + D(U)^*E(U))y_c\\ &= (B(S)^*C(S) + D(S)^*E(S))(P_{H^2}y_c) + \sum_{i=1}^{n} Q_i^1(\zeta^{i-1}y_{c(-1)} + \cdots + y_{c(-i)}).\end{aligned}$$

Similarly, we have

$$P_{H^2}D(U)^*E(U)M_c y_c' = D(S)^*E(S)M_c y_c'.$$

Hence (2a) is equivalent to

$$\begin{aligned}&(\rho^2 k(S)^*k(S)I - D(S)^*D(S) - B(S)^*B(S))x_b + (\rho^2 k(S)^*k(S)I - D(S)^*D(S))M_b x_b'\\ &-((B(S)^*C(S) + D(S)^*E(S))y_c^+ + D(S)^*E(S)M_c y_c')\\ &= -B(S)^*Mx_{wb} - B(S)^*My_{wc} + \sum_{i=1}^{n} Q_i^1(\zeta^{i-1}y_{c(-1)} + \cdots + y_{c(-i)}),\end{aligned} \tag{3a}$$

where $y_c^+ := P_{H^2}y_c$. Note that we have $y = y_c^- + y_c^+ + M_c y_c'$, where $y_c^- \in L(M_c) \ominus H(M_c)$, $y_c^+ \in H(M_c)$, and $y_c' \in H^2(\mathbf{C}^l)$.

We will separate the equation (2b) into two parts by taking the orthogonal projections on $H^2(\mathbf{C}^l)$ and $L^2(\mathbf{C}^l)\ominus H^2(\mathbf{C}^l)$. As in the above discussion, if

$$\rho^2 k(U)^* k(U) I - E(U)^* E(U) - C(U)^* C(U) =: Q^2_{-n} U^{*n} + \cdots + Q^2_0 + \cdots + Q^2_n U^n,$$

then we have

$$P_{H^2}(\rho^2 k(U)^* k(U) I - E(U)^* E(U) - C(U)^* C(U)) y_c$$

$$= (\rho^2 k(S)^* k(S) I - E(S)^* E(S) - C(S)^* C(S)) y_c^+ + \sum_{i=1}^{n} Q_i^2(\zeta^{i-1} y_{c(-1)} + \cdots + y_{c(-i)}).$$

Hence the projection of (2b) on $H^2(\mathbf{C}^l)$ gives

$$(\rho^2 k(S)^* k(S) I - E(S)^* E(S) - C(S)^* C(S)) y_c^+ + (\rho^2 k(S)^* k(S) I - E(S)^* E(S)) M_c y_c'$$

$$-(C(S)^* B(S) + E(S)^* D(S)) x_b - E(S)^* D(S) M_b x_b' \tag{3b}$$

$$= -C(S)^* M y_{wc} - C(S)^* M x_{wb} - \sum_{i=1}^{n} Q_i^2(\zeta^{i-1} y_{c(-1)} + \cdots + y_{c(-i)}).$$

We now study the projection of (2b) on $L^2(\mathbf{C}^l)\ominus H^2(\mathbf{C}^l)$. First note that

$$P_{L^2\ominus H^2} Q^2_{-i} U^{*i} y_c = Q^2_{-i} U^{*i} y_c^- + Q^2_{-i}(\zeta^{-i} y_{c0} + \cdots + \zeta^{-1} y_{c(i-1)}),$$

and

$$P_{L^2\ominus H^2} Q_i^2 U^i y_c = Q_i^2 U^i y_c^- - Q_i^2(\zeta^{i-1} y_{c(-1)} + \cdots + y_{c(-i)}).$$

Hence

$$P_{L^2\ominus H^2}(\rho^2 k(U)^* k(U) I - E(U)^* E(U) - C(U)^* C(U)) y_c$$

$$= (\rho^2 k(U)^* k(U) I - E(U)^* E(U) - C(U)^* C(U)) y_c^-$$

$$+ \sum_{i=1}^{n} Q^2_{-i}(\zeta^{-i} y_{c0} + \cdots + \zeta^{-1} y_{c(i-1)})$$

$$- \sum_{i=1}^{n} Q_i^2(\zeta^{i-1} y_{c(-1)} + \cdots + y_{c(-i)}).$$

This takes care of the first term in (2b). For the projections of the other terms we use the following notation:

$$\rho^2 k(U)^* k(U) I - E(U)^* E(U) =: Q^3_{-n} U^{*n} + \cdots + Q^3_0 + \cdots + Q^3_n U^n,$$

$$C(U)^* B(U) + E(U)^* D(U) =: Q^4_{-n} U^{*n} + \cdots + Q^4_0 + \cdots + Q^4_n U^n,$$

$$E(U)^* D(U) =: Q^5_{-n} U^{*n} + \cdots + Q^5_0 + \cdots + Q^5_n U^n,$$

$$M_b(\zeta) =: M_{b0} + M_{b1}\zeta^1 + M_{b2}\zeta^2 + \cdots,$$

$$M_c(\zeta) =: M_{c0} + M_{c1}\zeta^1 + M_{c2}\zeta^2 + \cdots,$$

$$M(\zeta) =: M_0 + M_1\zeta^1 + M_2\zeta^2 + \cdots,$$

$$C(U)^* =: C_0^* + C_1^* U^* + \cdots + C_n^* U^{*n},$$

$$x_b'(\zeta) =: x_{b0}' + x_{b1}'\zeta^1 + \cdots,$$

$$y_c'(\zeta) =: y_{c0}' + y_{c1}'\zeta^1 + \cdots,$$

$$x_b(\zeta) =: x_{b0} + x_{b1}\zeta^1 + \cdots.$$

With this notation, taking the projection of (2b) on $L^2(\mathbf{C}^l)\ominus H^2(\mathbf{C}^l)$, and then multiplying both sides of the resulting equation by ζ^{-n} (this is equivalent to the operation U^{*n}, which is left invertible on $L^2(\mathbf{C}^l)\ominus H^2(\mathbf{C}^l)$) will give us

$$X_3(\zeta^{-1})y_c^- := F_3(\zeta^{-1}), \tag{4a}$$

where $X_3(\zeta^{-1}) = Q^2_{-n}\zeta^{-2n} + \cdots + Q^2_0\zeta^{-n} + \cdots + Q^2_n$, and

$$\begin{aligned} F_3(\zeta^{-1}) := {} & \sum_{i=1}^{n} Q_i^2 \sum_{j=1}^{i} \zeta^{-n+i-j} y_{c(-j)} - \sum_{i=1}^{n} Q^2_{-i} \sum_{j=0}^{i-1} \zeta^{-n+i-j} y_{c(j)} \\ & - \sum_{i=1}^{n} C_i^* \sum_{j=0}^{i-1} \zeta^{-n+j-i} \sum_{k=0}^{j} M_{j-k} \sum_{s=1}^{n-k} \Omega_{c(s+k)} v_{-s} \\ & + \sum_{i=1}^{n} Q^4_{-i} \sum_{j=0}^{i-1} \zeta^{-n-i+j} x_{bj} + \sum_{i=1}^{n} Q^5_{-i} \sum_{j=1}^{i} \zeta^{-n-j} \sum_{k=0}^{i-j} M_{b(i-j-k)} x'_{bk} \\ & - \sum_{i=0}^{n} Q^3_{-i} \sum_{j=1}^{i} \zeta^{-n-j} \sum_{k=0}^{i-j} M_{c(i-j-k)} y'_{ck} \\ & - \sum_{i=1}^{n} C_i^* \sum_{j=0}^{i-1} \zeta^{-n+j-i} \sum_{k=0}^{j} M_{j-k} \sum_{s=1}^{n-k} \Omega_{b(s+k)} u_{-s}. \end{aligned}$$

We now play the same game with (3a) and (3b). Indeed, we multiply both sides of these equations by ζ^n. (This is equivalent to the application of the operator S^n, which is left invertible on $H^2(\mathbf{C}^l)$ and $H^2(\mathbf{C}^m)$.) Set

$$\begin{aligned} \rho^2 k(S)^* k(S) I - D(S)^* D(S) - B(S)^* B(S) &=: Q^6_{-n} S^{*n} + \cdots + Q^6_0 + \cdots + Q^6_n S^n, \\ \rho^2 k(S)^* k(S) I - D(S)^* D(S) &=: Q^7_{-n} S^{*n} + \cdots + Q^7_0 + \cdots + Q^7_n S^n, \\ D(S)^* E(S) &=: Q^8_{-n} S^{*n} + \cdots + Q^8_0 + \cdots + Q^8_n S^n, \\ B(S)^* &=: B_0^* + \cdots + B_n^* S^{*n}. \end{aligned}$$

For any polynomial of degree $\leqq n$, $P(\zeta)$, we define $\hat{P}(\zeta) := \zeta^n P^*(\zeta^{-1})$. Then it is easy to see that (3a) combined with (3b) is equivalent to

$$X_1(\zeta)\begin{bmatrix} x_b \\ y_c^+ \end{bmatrix} + X_2(\zeta)\begin{bmatrix} M_b & 0 \\ 0 & M_c \end{bmatrix}\begin{bmatrix} x'_b \\ y'_c \end{bmatrix} = \begin{bmatrix} F_1(\zeta) \\ F_2(\zeta) \end{bmatrix}, \tag{4b}$$

where

$$X_1(\zeta) := \begin{bmatrix} (\rho^2 \hat{k}kI - \hat{D}D - \hat{B}B) & -(\hat{B}C + \hat{D}E) \\ -(\hat{C}B + \hat{E}D) & (\rho^2 \hat{k}kI - \hat{E}E - \hat{C}C) \end{bmatrix},$$

$$X_2(\zeta) := \begin{bmatrix} (\rho^2 \hat{k}kI - \hat{D}D) & -\hat{D}E \\ -\hat{E}D & (\rho^2 \hat{k}kI - \hat{E}E) \end{bmatrix},$$

$$\begin{aligned} F_1(\zeta) := {} & \sum_{i=1}^{n} Q^6_{-i} \sum_{j=0}^{i-1} \zeta^{n-i+j} x_{bj} + \sum_{i=1}^{n} Q^7_{-i} \sum_{j=0}^{i-1} \zeta^{n-i+j} \sum_{k=0}^{j} M_{b(j-k)} x'_{bk} \\ & + \sum_{i=1}^{n} Q_i^1 \sum_{j=1}^{i} \zeta^{n+i-j} y_{c(-j)} - \sum_{i=1}^{n} Q^1_{-i} \sum_{j=0}^{i-1} \zeta^{n-i+j} y_{cj} \\ & - \sum_{i=1}^{n} Q^8_{-i} \sum_{j=0}^{i-1} \zeta^{n-i+j} \sum_{k=0}^{j} M_{c(j-k)} y'_{ck} - \hat{B}(\zeta) M(\zeta) \sum_{i=1}^{n} \sum_{j=1}^{i} \Omega_{bi} \zeta^{i-j} u_{-j} \\ & + \sum_{i=1}^{n} B_i^* \sum_{j=0}^{i-1} \zeta^{n-i+j} \sum_{k=0}^{j} M_{j-k} \sum_{s=1}^{n-k} \Omega_{b(s+k)} u_{-s} - \hat{B}(\zeta) M(\zeta) \sum_{i=1}^{n} \sum_{j=1}^{i} \Omega_{ci} \zeta^{i-j} v_{-j} \\ & + \sum_{i=1}^{n} B_i^* \sum_{j=0}^{i-1} \zeta^{n-i+j} \sum_{k=0}^{j} M_{j-k} \sum_{s=1}^{n-k} \Omega_{c(s+k)} v_{-s}, \end{aligned}$$

and

$$F_2(\zeta) = \sum_{i=1}^{n} Q_{-i}^2 \sum_{j=0}^{i-1} \zeta^{n-i+j} y_{cj} + \sum_{i=1}^{n} Q_{-i}^3 \sum_{j=0}^{i-1} \zeta^{n-i+j} \sum_{k=0}^{j} M_{c(j-k)} y'_{ck}$$

$$- \sum_{i=1}^{n} Q_i^2 \sum_{j=1}^{i} \zeta^{n+i-j} y_{c(-j)} - \sum_{i=1}^{n} Q_{-i}^4 \sum_{j=0}^{i-1} \zeta^{n-i+j} x_{bj}$$

$$- \sum_{i=1}^{n} Q_{-i}^5 \sum_{j=0}^{i-1} \zeta^{n-i+j} \sum_{k=0}^{j} M_{b(j-k)} x'_{bk} - \hat{C}(\zeta) M(\zeta) \sum_{i=1}^{n} \sum_{j=1}^{i} \Omega_{bi} \zeta^{i-j} u_{-j}$$

$$+ \sum_{i=1}^{n} C_i^* \sum_{j=0}^{i-1} \zeta^{n-i+j} \sum_{k=0}^{j} M_{j-k} \sum_{s=1}^{n-k} \Omega_{b(s+k)} u_{-s} - \hat{C}(\zeta) M(\zeta) \sum_{i=1}^{n} \sum_{j=1}^{i} \Omega_{ci} \zeta^{i-j} v_{-j}$$

$$+ \sum_{i=1}^{n} C_i^* \sum_{j=0}^{i-1} \zeta^{n-i+j} \sum_{k=0}^{j} M_{j-k} \sum_{s=1}^{n-k} \Omega_{c(s+k)} v_{-s}.$$

Let us summarize the above results in the following:

PROPOSITION 1. *ρ^2 is an eigenvalue of A^*A if and only if there exists $x_b \in H(M_b)$, $x'_b \in H^2(\mathbf{C}^m)$, $y_c^+ \in H(M_c)$, $y_c^- \in L(M_c) \ominus H(M_c)$, $y'_2 \in H^2(\mathbf{C}^l)$, not all zero, such that* (4a) *and* (4b) *hold.*

Defining

$$M_0 := \begin{bmatrix} M_b & 0 \\ 0 & M_c \end{bmatrix},$$

we see that

$$\begin{bmatrix} x_b \\ y_c^+ \end{bmatrix} \in H(M_0) = H^2(\mathbf{C}^N) \ominus M_0 H^2(\mathbf{C}^N), \qquad N = m + l.$$

Now set

$$x_0 := \begin{bmatrix} x_b \\ y_c^+ \end{bmatrix}, \quad x'_0 := \begin{bmatrix} x'_b \\ y'_c \end{bmatrix}, \quad F'_0 := \begin{bmatrix} F_1 \\ F_2 \end{bmatrix} \cdot p.$$

Then (4b) can be rewritten as

$$X_1(\zeta) x_0 + X_2(\zeta) M_0 x'_0 = F'_0(\zeta). \tag{5}$$

Remark. Equation (5) is exactly the same type of equation that we obtained in [12] for the 2-block problem. In the 1-block case, we get a similar equation with $X_2(\zeta)$, a scalar. In fact, if we assume that $d_b(\zeta) := \det X_2(\zeta)$ is not identically equal to zero, then (5) can be put in the form

$$X_0(\zeta) x_0 + d_b(\zeta) M_0 x'_0 = F_0(\zeta), \tag{6}$$

where $X_0 = X_2^a X_1$, $F_0 = X_2^a F'_0$, and $X_2^a(\zeta)$ is the algebraic adjoint of $X_2(\zeta)$, i.e.,

$$X_2^a(\zeta) X_2(\zeta) = X_2(\zeta) X_2^a(\zeta) = d_b(\zeta) I.$$

For (6), we make the factorization

$$X_0(\zeta) M_1(\zeta) = M_0(\zeta) \Omega_0(\zeta), \tag{f3}$$

where $M_1(\zeta)$ is $N \times N$ inner and $\Omega_0(\zeta)$ is $N \times N$ polynomial. Then, as shown using skew Toeplitz theory in [3], there exists $X_0^{(-1)}$, an $N \times N$ H^∞-matrix, such that

$$X_0^{(-1)} X_0 = I + M_1 E_0 \quad \text{and} \quad X_0^{(-1)} M_0 = M_1 E_1$$

for some E_0 and E_1, $N \times N$ H^∞-matrices. Multiplying both sides of (6) by $X_0^{(-1)}$ and taking the orthogonal projection, of the resulting equation, on $H(M_1)$ we obtain

$$P_{H(M_1)} x_0 = P_{H(M_1)} X_0^{(-1)} F_0(\zeta).$$

Now we make our first assumption of genericity.

Assumption (a1). The operator $\tau := P_{H(M_1)}|_{H(M_0)}$ is invertible.

With this assumption we obtain

$$x_0 = \tau^{-1} P_{H(M_1)} X_0^{(-1)} F_0, \tag{7a}$$

and

$$d_b(\zeta) x_0' = P_{H^2}(M_0(\zeta)^*(I - X_0 \tau^{-1} P_{H(M_1)} X_0^{(-1)}) F_0). \tag{7b}$$

Next, applying the algebraic adjoint of $X_3(\zeta^{-1})$, $X_3^a(\zeta^{-1})$ to both sides of (4a) we get

$$d_d(\zeta^{-1}) y_c^- = X_3^a(\zeta^{-1}) F_3(\zeta^{-1}), \tag{7c}$$

where $d_d(\zeta^{-1}) = \det X_3(\zeta^{-1})$. Equation (7a) gives the conditions for invertibility of a certain skew Toeplitz operator. See also [3]. We see that it is coupled, via F_0, to (7b) and (7c), which give the invertibility conditions of two Toeplitz operators.

We will now show that (7a)-(7c) give finitely many interpolation conditions for ρ^2 to be an eigenvalue of A^*A. From this we will derive the finite matricial rank condition for the determination of the singular values of A. First note that there exists $y_c^- \in L(M_c) \ominus H(M_c)$ satisfying (7c) if and only if there exists $\hat{y}_c^- \in H^2(\mathbf{C}^l)$ satisfying

$$d_d(\zeta) \hat{y}_c^- = P_{H^2}(\zeta^{-1} X_3^a(\zeta) F_3(\zeta)). \tag{7d}$$

Indeed, this follows since $L^2(\mathbf{C}^l) \ominus H^2(\mathbf{C}^l)$ is isomorphic to $SH^2(\mathbf{C}^l) = \zeta H^2(\mathbf{C}^l)$ and the natural isomorphism is given by the reflection operator: $\zeta^{-1} \to \zeta$.

Next it is easy to see that the right-hand sides of (7a), (7b), and (7d) can be put into the form

$$\tau^{-1} P_{H(M_1)} X_0^{(-1)}(\zeta) F_0(\zeta) = K_a(\zeta)\Phi,$$

$$P_{H^2}(M_0(\zeta)^*(I - X_0(\zeta)\tau^{-1} P_{H(M_1)} X_0^{(-1)}(\zeta)) F_0(\zeta)) = K_b(\zeta)\Phi,$$

$$P_{H^2}(\zeta^{-1} X_3^a(\zeta) F_3(\zeta)) = K_d(\zeta)\Phi,$$

where $K_a(\zeta)$, $K_b(\zeta)$ are H^∞ matrices of sizes $N \times r$ and $K_d(\zeta)$ is an $l \times r$ polynomial in ζ (these all can be explicitly computed from M_0, M_1, X_0, $X_0^{(-1)}$, X_3, F_0, and F_3),

$$\Phi^T = [x_{b0}^T \cdots x_{b(n-1)}^T x_{b0}'^T \cdots x_{b(n-1)}'^T y_{c0}^T \cdots y_{c(n-1)}^T y_{c0}'^T$$
$$\cdots y_{c(n-1)}'^T u_{-1}^T \cdots u_{-n}^T v_{-1}^T \cdots v_{-n}^T y_{c(-1)}^T \cdots y_{c(-n)}^T],$$

and $r = 2n(m+l) + n(m+2l)$. With this notation we immediately get the following identities:

$$K_{ai}\Phi = x_{0i}, \tag{8a}$$

$$K_{bi}\Phi = \sum_{j=0}^{i} d_{bj} x_{0(i-j)}', \tag{8b}$$

$$K_{di}\Phi = \sum_{j=0}^{i} d_{dj} \hat{y}_{c(i-j)}^-, \tag{8d}$$

for all $i=0,\cdots,n$, where

$$K_a(\zeta)=:K_{a0}+K_{a1}\zeta+K_{a2}\zeta^2+\cdots,$$
$$K_b(\zeta)=:K_{b0}+K_{b1}\zeta+K_{b2}\zeta^2+\cdots,$$
$$K_d(\zeta)=:K_{d0}+K_{d1}\zeta+K_{d2}\zeta^2+\cdots,$$
$$x_0(\zeta)=:x_{00}+x_{01}\zeta+x_{02}\zeta^2+\cdots,$$
$$x_0'(\zeta)=:x_{00}'+x_{01}'\zeta+x_{02}'+\cdots,$$
$$\hat{y}_c^-(\zeta)=:\hat{y}_{c0}^-+\hat{y}_{c1}^-\zeta+\hat{y}_{c2}^-\zeta^2+\cdots,$$
$$d_b(\zeta)=:d_{b0}+\cdots+d_{b2nN}\zeta^{2nN},$$
$$d_d(\zeta)=:d_{d0}+\cdots+d_{d2nl}\zeta^{2nl}.$$

Rearranging terms in (8a), (8b), (8d) and combining them into one equation we obtain,

$$K\Phi=0, \tag{9}$$

where K is a constant matrix that can be computed from the K_{ai}, K_{bi}, K_{di}, d_{bi}, and d_{di}, $i=0,\cdots,n$.

We now make our second assumption of genericity.

Assumption (a2). $d_b(\zeta)$ and $d_d(\zeta)$ have distinct roots, all of which are nonzero.

Then, as in [6], [7], and [10], we see that d_b has roots $\alpha_1,\cdots,\alpha_{r_b}$ inside D, $\alpha_{r_b+1},\cdots,\alpha_{(2nN-r_b)}$ on ∂D and $1/\bar{\alpha}_1,\cdots,1/\bar{\alpha}_{r_b}$ outside $\bar{D}$. Similarly, d_d has roots $\beta_1,\cdots,\beta_{r_d}$ inside D, $\beta_{r_d+1},\cdots,\beta_{(2nl-r_d)}$ on ∂D and $1/\bar{\beta}_1,\cdots,1/\bar{\beta}_{r_d}$ outside $\bar{D}$.

We are ready to state our main result.

THEOREM 1. *Assume* (a1) *and* (a2). *Then,* $\rho^2>\|A\|_e^2$ *is an eigenvalue of* A^*A *if and only if*

$$\operatorname{rank} R<r,$$

where

$$R:=\begin{bmatrix} K \\ K_b(\alpha_1) \\ \vdots \\ K_b(\alpha_{(2nN-r_b)}) \\ K_d(\beta_1) \\ \vdots \\ K_d(\beta_{(2nl-r_d)}) \end{bmatrix}. \tag{9a}$$

Proof. By Proposition 1, ρ^2 is an eigenvalue of A^*A if and only if there exists $x_0\in H(M_0)$, $x_0'\in H^2(\mathbf{C}^N)$ and $\hat{y}_c^-\in H^2(\mathbf{C}^l)$, not zero, such that (7a), (7b), (7d) are satisfied. By an argument similar to the one used in [3], [6], [7], and [11], we see that the existence of such x_0, x_0', $\hat{y}_c^-$ is equivalent to finding a nonzero Φ such that

$$K_b(\alpha_i)\Phi=0, \qquad i=1,\cdots,2nN-r_b,$$
$$K_d(\beta_i)\Phi=0, \qquad i=1,\cdots,2nl-r_d,$$

and (9) holds. This completes the proof. □

Remark. In the absence of the genericity assumptions, the matrix (9a) takes on a certain degenerate form exactly as in [11]. We see from Theorem 1 that the largest value of ρ that gives a solution for the equation

$$\det R^*R=0$$

is the norm of the 4-block operator A. From R, we can determine the singular values and singular vectors of the 4-block operator A.

3.2. Essential spectrum. We now give a sufficient condition for ρ to be strictly greater than the essential norm of A; in order to do this we study the essential spectrum of A^*A.

PROPOSITION 2. *Suppose that*

(a3) *the Toeplitz operator* $\tau_2 := P_{H^2} M_1^* M_0|_{H^2}$ *is invertible,*

(a4) $\{z: \det X_1(z) = 0\} \cap \sigma_e(T_0) = \varnothing$,

where $T_0 := P_{H(M_0)} S|_{H(M_0)}$. *Then,* $\rho > \max\{\beta, \gamma\}$ *implies* $\rho^2 \notin \sigma_e(A^*A)$, *where* β *and* γ *are defined as in* § 2.

Proof. Let $\rho > \max\{\beta, \gamma\}$. If ρ^2 were in $\sigma_e(A^*A)$, then there would exist

$$\begin{bmatrix} x^{(n)} \\ y^{(n)} \end{bmatrix} \in H^2(\mathbf{C}^m) \oplus L^2(\mathbf{C}^l) \quad \text{with} \quad \left\| \begin{bmatrix} x^{(n)} \\ y^{(n)} \end{bmatrix} \right\|_2 = 1 \quad \forall n \geq 1,$$

and $\left[\begin{smallmatrix} x^{(n)} \\ y^{(n)} \end{smallmatrix}\right] \to 0$ weakly as $n \to \infty$, satisfying

$$(4b)_e \qquad X_1(\zeta) \begin{bmatrix} x_b^{(n)} \\ y_c^{+(n)} \end{bmatrix} + X_2(\zeta) \begin{bmatrix} M_b & 0 \\ 0 & M_c \end{bmatrix} \begin{bmatrix} x_b'^{(n)} \\ y_c'^{(n)} \end{bmatrix} \to 0 \quad \text{strongly,}$$

and

$$(7d)_e \qquad X_3(\zeta) \hat{y}_c^{-(n)} \to 0 \quad \text{strongly.}$$

(These conditions for $\rho^2 \in \sigma_e(A^*A)$ are sufficient as well.) This follows from Proposition 1 and equations (4b) and (7d). Note that $F_1(\zeta)$, $F_2(\zeta)$, and $F_3(\zeta)$ converge to zero strongly as $x^{(n)}$ and $y^{(n)}$ converge to zero weakly. In the above we have, as before,

$$x^{(n)} = x_b^{(n)} + M_b x_b'^{(n)},$$

$$y^{(n)} = y_c^{-(n)} + y_c^{+(n)} + M_c y_c'^{(n)},$$

with

$$\hat{y}_c^{-(n)}(\zeta) := y_c^{-(n)}(\zeta^{-1}),$$

$$\begin{bmatrix} x_b^{(n)} \\ y_c^{+(n)} \end{bmatrix} =: x_0^{(n)} \in H(M_0),$$

$$\begin{bmatrix} x_b'^{(n)} \\ y_c'^{(n)} \end{bmatrix} =: x_0'^{(n)} \in H^2(\mathbf{C}^m) \oplus H^2(\mathbf{C}^l),$$

and $y_c^{-(n)} \in L^2(\mathbf{C}^l) \ominus H^2(\mathbf{C}^l)$. They all converge to zero weakly as $n \to \infty$.

Note that $(7d)_e$ means that

$$\left(\rho^2 I - [F(S)^* \quad J(S)^*] \begin{bmatrix} F(S) \\ J(S) \end{bmatrix} \right) \hat{y}_c^{-(n)} \to 0 \quad \text{strongly.}$$

Since $\rho > \gamma$, we see that

$$\left(\rho^2 I - [F(S)^* \quad J(S)^*] \begin{bmatrix} F(S) \\ J(S) \end{bmatrix} \right)$$

is invertible, and so $\hat{y}_c^{-(n)}$ converges to zero strongly.

Next from $(4b)_e$ we get that

$$(6)_e \qquad X_0(\zeta) x_0^{(n)} + d_b(\zeta) M_0 x_0'^{(n)} \to 0 \quad \text{strongly.}$$

Taking orthogonal projections on $M_1 H^2(\mathbf{C}^N)$ we see that

$$P_{H^2} M_1^* X_0 x_0^{(n)} + P_{H^2} M_1^* M_0 d_b(\zeta) x_0'^{(n)} \to 0 \quad \text{strongly.}$$

Recall that $P_{H^2} M_1^* X_0 x_0^{(n)} = P_{H^2} \Omega_0 M_0^* x_0^{(n)}$, so it converges to zero strongly as $x_0^{(n)} \in H(M_0)$ converges to zero weakly. Hence using Assumption (a3) we have that

$$(7)_e \qquad d_b(\zeta) x_0'^{(n)} \to 0 \quad \text{strongly.}$$

This implies, by $(6)_e$, that

$$(8)_e \qquad d_b(\zeta) \det X_1(\zeta) x_0^{(n)} \to 0 \quad \text{strongly.}$$

It is easy to see, by definition of β, that for $\rho > \beta$, $d_b(\zeta)$ has no roots on ∂D. Then we can write

$$d_b(\zeta) = (\zeta - \alpha_1)\left(\zeta - \frac{1}{\bar{\alpha}_1}\right) \cdots (\zeta - \alpha_{nN})\left(\zeta - \frac{1}{\bar{\alpha}_{nN}}\right),$$

for some $\alpha_1, \cdots, \alpha_{nN} \in D$. Multiplying $(7)_e$ by

$$\prod_{i=1}^{nN} \frac{\bar{\alpha}_i}{(1 - \zeta \bar{\alpha}_i)^2},$$

which is in H^∞ (because all α_i's are in D), we obtain

$$m_1(\zeta) x_0'^{(n)} \to 0 \quad \text{strongly,}$$

where

$$m_1(\zeta) = \prod_{i=1}^{nN} \frac{\zeta - \alpha_i}{(1 - \zeta \bar{\alpha}_i)}.$$

This implies that $x_0'^{(n)} \to 0$ strongly, because $m_1(S)^* m_1(S)$ is equal to the identity.

From $(8)_e$, a similar argument gives that

$$(9)_e \qquad \det X_1(\zeta) x_0^{(n)} \to 0 \quad \text{strongly.}$$

Let us assume now that $d_1(\zeta) := \det X_1(\zeta)$ has nonzero distinct roots. So $d_1(\zeta) = 0$ at points $z_1, \cdots, z_{n_1}$ inside D, $1/\bar{z}_1, \cdots, 1/\bar{z}_{n_1}$ outside $\bar{D}$, and $z_{n_1+1}, \bar{z}_{n_1+1}, \cdots, z_{nN}, \bar{z}_{nN}$ on ∂D. Using a similar trick as before, we obtain

$$m_2(\zeta) \prod_{i=n_1+1}^{nN} (\zeta - z_i)(\zeta - \bar{z}_i) x_0^{(n)} \to 0 \quad \text{strongly,}$$

where
