THEOREM 2.4. *Let $\sigma_0\in\mathcal{S}^{\#}$ be such that $\hat{h}(\hat{y}(\sigma_0\otimes\pi)(t_1))\leqq 0$ for all $\pi\in\mathcal{S}^{\#}_P$, and let*

$$y_0(t):=y(\sigma_0)(t),\qquad \hat{y}_0(\pi)(t):=\hat{y}(\sigma_0\otimes\pi)(t).$$

Let Assumption 2.3 be satisfied and Λh and $\Lambda\hat{h}$ be derivate containers for h and $\hat{h}$. Then either

(a) *there exists $\beta>0$ such that*

$$h(y_0(t_1))+\beta\bar{B}_m\subset\{h(y(\sigma)(t_1))\,|\,\sigma\in\mathcal{S}^{\#},\ \hat{h}(\hat{y}(\sigma\otimes\pi)(t_1))\leqq-\beta\ \ \forall\pi\in\mathcal{S}^{\#}_P\}$$

or

(b) *there exist*

$$\ell^1\in\mathbb{R}^m,\quad \omega\in\mathrm{frm}^+(\mathcal{S}^{\#}_P),\quad z\in AC(T,\mathbb{R}^n),\quad \hat{z}:\mathcal{S}^{\#}_P\to AC(T,\mathbb{R}^{n+p})$$

such that

(b1)
$$0<|\ell^1|+\omega(\mathcal{S}^{\#}_P)\leqq 1$$

$$z(t)^T\in\ell^{1T}\Lambda h(y_0(t_1))+\int_t^{t_1}z(s)^T\,\partial f(s,y_0(s),\sigma_0(s))\,ds\quad\forall t\in T$$

$$\hat{z}(\pi)\in\overline{\mathrm{co}}\Big\{\zeta\in AC(T,\mathbb{R}^{n+p})\,|\,\zeta(t)^T\in\Lambda\hat{h}(\hat{y}_0(\pi)(t_1))+\int_t^{t_1}\zeta(s)^T\,\partial\hat{f}(s,\hat{y}_0(\pi)(s),\sigma_0\otimes\pi(s))\,ds\ \forall t\in T\Big\}$$

(b2) (*the maximum principles*).

(b2.1) (*the maximum principle in integral form*).

$$\int_{t_0}^{t_1}z(s)^Tf(s,y_0(s),(\sigma-\sigma_0)(s))\,ds+\int\omega(d\pi)\int_{t_0}^{t_1}\hat{z}(\pi)(s)^T\hat{f}(s,\hat{y}_0(\pi)(s),(\sigma-\sigma_0)(s),\pi(s))\,ds\geqq 0\quad\forall\sigma\in\mathcal{S}^{\#}$$

(b2.2) (*a "pointwise" maximum principle*). *If $R^\#(t)=R$ for all $t\in T$ then, for all $r\in R$,*

$$z(t)^T f(t, y_0(t), r)+\left[\int_W \hat{z}(\pi)(\cdot)^T\hat{f}(\cdot, \hat{y}_0(\pi)(\cdot), r, \pi(\cdot))\omega(d\pi)\right](t)$$

$$\geqq z(t)^T f(t, y_0(t), \sigma_0(t))$$

$$+\left[\int_W \hat{z}(\pi)(\cdot)^T\hat{f}(\cdot, \hat{y}_0(\pi)(\cdot), \sigma_0(\cdot), \pi(\cdot))\omega(d\pi)\right](t) \quad \mu\text{-a.e.}$$

(b2.3) (*a pointwise maximum principle*).

(i) *If the compact set on which the continuous function*

$$\pi\to\hat{h}(\hat{y}_0(\pi)(t_1)) : \mathscr{S}^\#_P\to\mathbb{R}$$

achieves its upper bound 0 *is at most denumerable then, for μ-almost all $t\in T$, $\sigma_0(t)$ has its support on the compact set on which the continuous function*

$$r\to z(t)^T f(t, y_0(t), r)+\int \hat{z}(\pi)(t)^T\hat{f}(t, \hat{y}_0(\pi)(t), r, \pi(t))\omega(d\pi)$$

achieves its minimum over $R^\#(t)$;

(ii) *if the function $\not{f}_2$ of assumption* (2.3.5) *is independent of r then, for μ-almost all $t\in T$, $\sigma_0(t)$ has its support on the compact set on which the continuous function*

$$r\to z(t)^T f(t, y_0(t), r)+\int \hat{z}(\pi)(t)^T\hat{\not{f}}_1(t, \hat{y}_0(\pi)(t), r)\omega(d\pi)$$

achieves its minimum over $R^\#(t)$.

(b3) (*the transversality condition*).

$$\hat{h}(\hat{y}_0(\pi^*)(t_1))=\max\{\hat{h}(\hat{y}_0(\pi)(t_1))\mid \pi\in\mathscr{S}^\#_P\}=0 \quad \textit{for } \omega\textit{-almost all } \pi^*.$$

THEOREM 2.5. *Let $\sigma_0\in\mathscr{S}^\#$, and let $\mathscr{S}'$ be an arbitrary denumerable subset of $\mathscr{S}^\#$ containing σ_0, with $\tilde{\mathscr{P}}$ defined accordingly. Assume that*

$$\hat{h}(\hat{y}(\sigma_0\otimes\pi)(t_1))\leqq 0 \quad \forall\pi\in\tilde{\mathscr{P}},$$

and let

$$y_0(t):=y(\sigma_0)(t), \qquad \hat{y}_0(\pi)(t):=\hat{y}(\sigma_0\otimes\pi)(t).$$

Let Assumption 2.3 *be satisfied and Λh and $\Lambda\hat{h}$ be derivate containers for h and $\hat{h}$. Then either*

(a) *there exists $\beta>0$ such that*

$$h(y_0(t_1))+\beta\bar{B}_m\subset\{h(y(\sigma)(t_1))\mid\sigma\in\operatorname{co}\mathscr{S}', \hat{h}(\hat{y}(\sigma\otimes\pi)(t_1))\leqq-\beta\ \forall\pi\in\tilde{\mathscr{P}}\}$$

or

(b) *there exist*

$$\ell^1\in\mathbb{R}^m, \quad \omega\in\operatorname{frm}^+(\tilde{\mathscr{P}}), \quad z\in AC(T,\mathbb{R}^n), \quad \hat{z}:\tilde{\mathscr{P}}\to AC(T,\mathbb{R}^{n+p})$$

such that

(b1)
$$0<|\ell^1|+\omega(\tilde{\mathcal{P}})\leqq 1$$

$$z(t)^T\in \ell^{1T}\Lambda h(y_0(t_1))+\int_t^{t_1} z(s)^T\,\partial f(s,y_0(s),\sigma_0(s))\,ds\quad \forall t\in T$$

$$\hat{z}(\pi)\in\overline{\mathrm{co}}\Big\{\zeta\in AC(T,\mathbb{R}^{n+p})\,|$$
$$\zeta(t)^T\in\Lambda\hat{h}(\hat{y}_0(\pi)(t_1))+\int_t^{t_1}\zeta(s)^T\,\partial\hat{f}(s,\hat{y}_0(\pi)(s),\sigma_0\otimes\pi(s))\,ds\ \forall t\in T\Big\}.$$

(b2) (*maximum principles*).

(b2.1) (*a weak maximum principle in integral form*).

$$\int_{t_0}^{t_1} z(s)^T f(s,y_0(s),(\sigma-\sigma_0)(s))\,ds$$
$$+\int\omega(d\pi)\int_{t_0}^{t_1}\hat{z}(\pi)(s)^T\hat{f}(s,\hat{y}_0(\pi)(s),(\sigma-\sigma_0)\otimes\pi(s))\,ds\geqq 0\quad\forall\sigma\in\mathcal{S}'.$$

(b2.2) (*a weak pointwise maximum principle*). *If $\mathcal{S}'$ is closed under concatenations with σ_0 on rational intervals, i.e., if, for every subinterval I of T with rational endpoints and every $\sigma\in\mathcal{S}'$, we have $\sigma'\in\mathcal{S}'$ whenever $\sigma'(t)=\sigma(t)$ for $t\in I$, $\sigma'(t)=\sigma_0(t)$, elsewhere, then, for all $\sigma\in\mathcal{S}'$,*

$$z(t)^T f(t,y_0(t),\sigma(t))+\left[\int_W \hat{z}(\pi)(\cdot)^T\hat{f}(\cdot,\hat{y}_0(\pi)(\cdot),\sigma\otimes\pi(\cdot))\omega(d\pi)\right](t)$$
$$\geqq z(t)^T f(t,y_0(t),\sigma_0(t))+\left[\int_W \hat{z}(\pi)(\cdot)^T\hat{f}(\cdot,\hat{y}_0(\pi)(\cdot),\sigma_0\otimes\pi(\cdot))\omega(d\pi)\right](t)$$
$$\mu\text{-a.e.}$$

(b3) (*the transversality condition*).
$$\hat{h}(\hat{y}_0(\pi^*)(t_1))=\max_{\pi\in\tilde{\mathcal{P}}}\hat{h}(\hat{y}_0(\pi)(t_1))=0\quad \textit{for } \omega\textit{-almost all } \pi^*.$$

Let
$$\mathcal{T}_i:=\Big\{\theta=(\theta^1,\cdots,\theta^i)\in\mathbb{R}^i\,|\,\theta^j\geqq 0,\ \sum_{j=1}^i\theta^j\leqq 1\Big\}.$$

If E and F are normed vector spaces, $A\subset E$ convex, $A^\circ\neq\emptyset$, $a\in A$, and $g:A\to F$, we define the (Fréchet) derivative $g'(a)$ (even if $a\in\partial A$) as the continuous linear operator on E to F such that
$$\lim|b-a|^{-1}[g(b)-g(a)-g'(a)(b-a)]=0\quad\text{as } b\to a,\quad b\in A\backslash\{a\}.$$

A basic tool in proving Theorems 2.4 and 2.5 will be a special case of the following general result that we expect to apply in other contexts as well. In proving Theorems 2.4 and 2.5 we will use Theorem 2.6 below with $\mathcal{U}=K$. However, in other applications that we have in mind, the set K may represent $\mathcal{S}^{\#}$ and the set $\mathcal{U}$ an "abundant" subset of $\mathcal{S}^{\#}$ such as the set of ordinary (unrelaxed) controls.

THEOREM 2.6. *Let K be a convex subset of a real vector space, $q_j\in K$ for $j=0,1,2,\cdots$, $\mathcal{Y}$ a normed vector space, C a convex subset of $\mathcal{Y}$ with a nonempty interior, $(\varphi,\Phi):K\to\mathbb{R}^m\times\mathcal{Y}$, $\Phi(q_0)\in C$, and e_j^i the jth column of the unit $i\times i$ matrix. Let $\mathcal{U}\subset K$ be such that, for each $i=1,2,\cdots$ and $\theta\in\mathcal{T}_i$, there exists a sequence $(u_k(\theta))$ in $\mathcal{U}$ such that, for each i,*

$$\lim_k(\varphi,\Phi)(u_k(\theta))=(\varphi,\Phi)\Big(q_0+\sum_{j=1}^i\theta^j(q_j-q_0)\Big)\quad\textit{uniformly on }\mathcal{T}_i$$

and

$$\theta \to (\varphi, \Phi)(u_k(\theta)) : \mathcal{T}_i \to \mathbb{R}^m \times \mathcal{Y} \quad \textit{is continuous for every } k.$$

Assume that there exist $\delta > 0$ *and functions* $(\varphi_i, \Phi_i) : K \to \mathbb{R}^m \times \mathcal{Y}$ *for* $i = 1, 2, \cdots$ *such that*

$$\lim_i (\varphi_i, \Phi_i) = (\varphi, \Phi) \quad \textit{uniformly}$$

and, for every $i = 1, 2, \cdots$, *the function*

$$\theta \to (g_i, G_i)(\theta) := (\varphi_i, \Phi_i)\left(q_0 + \sum_{j=1}^{i} \theta^j (q_j - q_0) \right) : \delta\mathcal{T}_i \to \mathbb{R}^m \times \mathcal{Y}$$

is continuously differentiable.

Then either

(a) *there exists* $\beta > 0$ *such that*

$$\varphi(q_0) + \beta \bar{B}_m \subset \{\varphi(u) \mid u \in \mathcal{U},\ \Phi(u) + \beta \bar{B}_{\mathcal{Y}} \subset C\}$$

or

(b) *there exist sequences* $(\ell_i) = (\ell_i^1, \ell_i^2)$ *in* $\mathbb{R}^m \times \mathcal{Y}^*$, (γ_i) *in* $(0, \infty)$, *and* (θ_i), *with* $|\ell_i| = |\ell_i^1| + |\ell_i^2| = 1$, $\lim_i \gamma_i = 0$, *and* $\theta_i \in \gamma_i \mathcal{T}_i$, *such that*

(b1) $\liminf_i \ell_i(g_i'(\theta_i), G_i'(\theta_i)) e_j^i \geqq 0$ *for all* $j = 1, 2, \cdots$,

and, for every weak cluster point* $\ell = (\ell^1, \ell^2)$ *of* (ℓ_i), *we have*

(b2) $0 < |\ell| = |\ell^1| + |\ell^2| \leqq 1$;

(b3) $\ell^2 \Phi(q_0) = \sup_{c \in C} \ell^2 c$.

3. Comments.

3.1. Maximum principles. Heuristically, one might "derive" the pointwise maximum principle 2.4(b2.3(i)) without the special assumption made there by interchanging the order of integration in the double integral in 2.4(b2.1) and then choosing various $\sigma \in \mathcal{S}^*$ to coincide with σ_0 except on small subintervals of T containing a given point t. This method—which works effectively for many other problems—fails in our case. The reason is that we have no way of showing, and no reason to expect, that the integrand of this double integral is $\omega \times \mu$-measurable. In fact, if we denote this integrand by $\chi(\pi, s)$, then we can think of the family $\{\chi(\pi, \cdot) \mid \pi \in \mathcal{P}\}$ as a stochastic process, and an analogous interchange of the order of integration in the context of stochastic processes appears to require rather strong assumptions (see, e.g., [3, Thm. 3A, p. 79]) that are not satisfied in our case. In our study of conflicting control problems with data that are C^1 with respect to the state variables [4, Chap. IX, § X.3.7] we were able to avoid this difficulty and to obtain improved results (both for relaxed and unrelaxed adverse controls) by proceeding essentially as follows. Let

$$\psi(\pi, t, r, r_P) := \hat{z}(\pi)(t)^T \hat{f}(t, \hat{y}(\sigma_0 \otimes \pi)(t), r, r_P),$$
$$\mathfrak{h}(\pi, t, r) = \max\{\psi(\pi, t, r, r_P) \mid r_P \in R_P^\#(t)\}.$$

We showed that relations 2.4(b3) and 2.5(b3) of Theorems 2.4 and 2.5, and specifically

$$\hat{h}(\hat{y}(\sigma_0 \otimes \pi^*)(t_1)) \geqq \hat{h}(\hat{y}(\sigma_0 \otimes \pi)(t_1)) \tag{3.1.1}$$

for ω-almost all π^* and all $\pi \in \mathcal{P}$, imply that, for μ-almost all t and $\sigma_0(t)$-almost all r, we have

$$\psi(\pi, t, r, \pi^*(t)) = \mathfrak{h}(\pi, t, r). \tag{3.1.2}$$

This last relation enabled us to replace the integrand of the double integral with $\mathfrak{h}(\pi, t, (\sigma - \sigma_0)(t))$ that is $\omega \times \mu$-measurable because $\pi \to \hat{y}(\sigma_0 \otimes \pi)(t_1)$ is continuous and $\pi \to \hat{z}(\pi)(\cdot): \mathcal{P} \to (C(T, \mathbb{R}^{n+p}), |\cdot|_{\sup})$ is ω-measurable so that $(\pi, s) \to \hat{z}(\pi)(s)$ is $\omega \times \mu$-measurable.

The reason that the above method is effective in the C^1 case is because $\hat{z}(\pi)$ is then uniquely defined by the differential equation to which the differential inclusions of 2.4(b1) and 2.5(b1) reduce themselves. Relation (3.1.1) then implies that

$$\int_{t_0}^{t_1} \psi(\pi, s, \sigma_0(s), \pi'(s) - \pi^*(s))\, ds,$$

which is the directional derivative of $\pi \to \hat{h}(\hat{y}(\sigma_0 \otimes \pi)(t_1))$ at π^* in the direction of $\pi' - \pi^*$, must be nonpositive for all $\pi' \in \mathcal{P}$, and this yields relation (3.1.2). Unfortunately, in our present context, the function $\hat{z}(\pi)$ that "corresponds" to relation (3.1.1) and the function $\hat{z}(\pi)$ that appears in 2.4(b2), respectively, 2.5(b2) may be different solutions of the inclusion in (b1).

The "pointwise" maximum principles 2.4(b2.2) and 2.4(b2.3(i)) appear to be both theoretically and computationally much weaker than the corresponding C^1 results involving the function $\mathfrak{h}$. It remains to be seen whether, and to what extent, these results can be strengthened. The maximum principles of Theorem 2.5 are much weaker than the corresponding relations 2.4(b2.1) and 2.4(b2.2) of Theorem 2.4 and, for this reason, Theorem 2.5 must be viewed as a preliminary result marking only the first step in the study of nonsmooth problems with hyperrelaxed adverse controls. On the other hand, Theorem 2.5 "comes cheaply" because it is derived along with Theorem 2.4 without causing any complications or requiring any additions.

3.2. Assumption (2.3.5). For all $\pi \in \mathcal{P}$, let

$$Z(\pi) = \Big\{ \zeta \in AC(T, \mathbb{R}^{n+p}) \,|\, \zeta(t)^T \in \Lambda \hat{h}(\hat{y}_0(\pi)(t_1)) + \int_t^{t_1} \zeta(s)^T\, \partial \hat{f}(s, \hat{y}_0(\pi)(s), \sigma_0 \otimes \pi(s))\, ds \ \forall t \in T \Big\}.$$

Assumption (2.3.5) is explicitly used only in Lemma 4.4 below to prove that the set-valued function $\pi \to Z(\pi)$ has a closed graph. The latter property is later used to prove the relation $\hat{z}(\pi) \in \overline{\text{co}}\, Z(\pi)$ ω-almost everywhere of statements 2.4(b1) and 2.5(b1). In view of the transversality relations 2.4(b3) and 2.5(b3), this last relation involves only the adverse controls π in the set $\mathcal{H}$ of those that maximize $\hat{h}(\hat{y}(\sigma_0 \otimes \pi)(t_1))$. For a given σ_0, the determination of $\mathcal{H}$ represents an unrestricted optimal control problem (at least in the case of relaxed adverse controls), a problem that is reasonably well understood and often computationally manageable. On the other hand, without Assumption (2.3.5), we can only assert that $\hat{z}(\pi) \in \overline{\text{co}}\, \mathfrak{Z}(\pi)$ ω-almost everywhere, where $\mathfrak{Z}(\cdot)$ is the set-valued mapping whose graph is the closure of graph $(Z(\cdot))$. The use of $\mathfrak{Z}(\cdot)$ would generally require the determination of lim-sup $Z(\pi)$ as π approaches $\mathcal{H}$ (a problem for which we know no practicable methods of attack) except for special problems, such as evasion problems [4, § IX.3], where $\hat{f}$ has a special structure.

4. Proofs. We denote by $\mathcal{Y}$ a normed vector space. If A and B are subsets of a real vector space, we write

$$A \ominus B := \{z \in A \,|\, z + B \subset A\}.$$

LEMMA 4.1. *If $A \subset \mathcal{Y}$ and $W \subset \mathbb{R}^m \times \mathcal{Y}$ are convex, $A^\circ \neq \varnothing$, $z \in \mathbb{R}^m$, and $W \cap \{z\} \times A = \varnothing$ then there exists $\ell = (\ell^1, \ell^2) \in \mathbb{R}^m \times \mathcal{Y}^*$ such that*

$$|\ell| = 1, \qquad \ell w \geqq \ell^1 z + \ell^2 a \quad \forall w \in W, \quad a \in A.$$

Proof. Let $V:=\{v\,|\,(z,v)\in W\}$. Then $V\cap A=\emptyset$ and there exists $\ell'^2\in\mathcal{Y}^*$ such that $\ell'^2\neq 0$ and

$$\ell'^2 v \geqq \ell'^2 a \quad \forall v\in V, \quad a\in A.$$

Thus

$$\{(\ell'^2 w^2, w^1)\,|\,(w^1,w^2)\in W\} \quad \text{and} \quad \{(\ell'^2 a-\alpha, z)\,|\,\alpha>0,\ a\in A\}$$

are disjoint and convex subsets of $\mathbb{R}\times\mathbb{R}^m$ and there exists $(\ell^0,\ell^1)\neq 0$ in $\mathbb{R}\times\mathbb{R}^m$ such that

$$\ell^0\ell'^2 w^2+\ell^1 w^1 \geqq \ell^0\ell'^2 a-\ell^0\alpha+\ell^1 z \quad \forall\alpha>0, \quad (w_1,w_2)\in W, \quad a\in A.$$

Set $\ell^2=\ell^0\ell'^2$. If $\ell^1=0$ then $\ell^0\neq 0$, hence $\ell^2\neq 0$. Thus $\ell:=(\ell^1,\ell^2)\neq 0$ and

$$\ell w\geqq \ell^1 z+\ell^2 a \quad \forall w\in W, \quad a\in A.$$

We may assume that $|\ell|=1$, otherwise replacing ℓ with $\ell/|\ell|$. □

LEMMA 4.2. *Let W be a nonempty convex subset of $\mathbb{R}^m\times\mathcal{Y}$, $r>\gamma>0$, C_0 a convex subset of $\mathcal{Y}$ containing $y+rB_{\mathcal{Y}}$, $0\in W$, $0\in\bar{C}_0$, and $C_\gamma:=C_0\ominus\gamma\bar{B}_{\mathcal{Y}}$. Then either*

(a) $\gamma\bar{B}_m\subset\{w^1\,|\,(w^1,w^2)\in W,\ w^2\in C_\gamma\}$

or

(b) *there exists $\ell=(\ell^1,\ell^2)\in\mathbb{R}^m\times\mathcal{Y}^*$ such that $|\ell|=|\ell^1|+|\ell^2|=1$ and*

$$\ell w\geqq-\gamma(1+|y|/r) \quad \forall w\in W, \qquad \ell^2 c_\gamma\leqq\gamma \quad \forall c_\gamma\in C_\gamma.$$

Proof. Since $r>\gamma$, the set C_γ° is nonempty. If (a) does not hold then there exists a point $z\in\gamma\bar{B}_m$ such that $W\cap\{z\}\times C_\gamma=\emptyset$. Then, by Lemma 4.1, there exists $\ell\in\mathbb{R}^m\times\mathcal{Y}^*$ such that $|\ell|=1$ and

$$\ell^1 z+\ell^2 c_\gamma\leqq\ell w \quad \forall c_\gamma\in C_\gamma, \qquad w\in W.$$

Since $0\in W$, this implies that

$$\ell^2 c_\gamma\leqq-\ell^1 z\leqq|\ell|\,|z|\leqq\gamma \quad \forall c_\gamma\in C_\gamma.$$

Since $(\gamma/r)y\in C_\gamma$, we have

$$\ell w\geqq\ell^1 z+\frac{\gamma}{r}\ell^2 y\geqq-|\ell^1|\gamma-\frac{\gamma}{r}|\ell^2|\,|y|\geqq-\gamma(1+|y|/r) \quad \forall w\in W. \qquad \square$$

4.3. Proof of Theorem 2.6. Let

$$A_i(\theta,\alpha):=\{g_i'(\theta)\omega\,|\,\omega\in\mathcal{T}_i,\ G_i'(\theta)\omega+\alpha\bar{B}_{\mathcal{Y}}\subset C-\Phi(q_0)\}$$

$$\gamma_i':=\sup\{\alpha\in[0,\delta]\,|\,\alpha\bar{B}_m\subset A_i(\theta,\alpha)\ \forall\theta\in\alpha\mathcal{T}_i\}.$$

Then either $\gamma=\frac{1}{2}\limsup_i\gamma_i'>0$, and then

(i) there exist $\gamma\in(0,\delta]$ and $\mathcal{I}_1\subset(1,2,\cdots)$ such that

$$\gamma\bar{B}_m\subset A_i(\theta,\gamma) \quad \forall i\in\mathcal{I}_1, \qquad \theta\in\gamma\mathcal{T}_i$$

or $\lim_i\gamma_i'=0$, and then

(ii) there exist i_0, $\gamma_i=\gamma_i'+1/i>0$, and $\theta_i\in\gamma_i\mathcal{T}_i$ such that $\lim_i\gamma_i=0$ and $\gamma_i\bar{B}_m$ is not contained in $A_i(\theta_i,\gamma_i)$ for $i\geqq i_0$.

First assume that (i) holds, and let $(u_k(\theta))$ be as defined in the statement of the theorem. Let $I, N \in \{1, 2, \cdots\}$ be sufficiently large so that

$$\sup_{\theta \in \gamma \mathcal{T}_I} |g_I(\theta) - \varphi(u_N(\theta))| \leqq \gamma^2/32, \tag{4.3.1}$$

$$\sup_{\theta \in \gamma \mathcal{T}_I} |G_I(\theta) - \Phi(u_N(\theta))| \leqq \gamma^2/128, \tag{4.3.2}$$

$$|G_I(0) - \Phi(q_0)| \leqq \gamma^2/128, \tag{4.3.3}$$

and let

$$G_I^{\#}(\theta) := G_I(\theta) + [\Phi(q_0) - G_I(0)].$$

Since $\Phi(q_0) \in C$, we have $G_I^{\#}(0) \in C$. Furthermore, by (4.3.2) and (4.3.3),

$$\sup_{\theta \in \gamma \mathcal{T}_I} |G_I^{\#}(\theta) - \Phi(u_N(\theta))| \leqq \gamma^2/64. \tag{4.3.4}$$

Let $\beta = \gamma^2/64$. Since $G_I^{\#\prime}(\theta) = G_I'(\theta)$ for all $\theta \in \delta \mathcal{T}_I$, it follows from (4.3.1), (4.3.4), and [7, Thm. 3.4, p. 848], that

$$\begin{aligned}\varphi(q_0) + \beta \bar{B}_m &\subset \{\varphi(u_N(\theta)) \mid \theta \in \gamma \mathcal{T}_I,\ \Phi(u_N(\theta)) + \beta \bar{B}_{\mathcal{Y}} \subset C\} \\ &\subset \{\varphi(u) \mid u \in \mathcal{U},\ \Phi(u) + \beta \bar{B}_{\mathcal{Y}} \subset C\},\end{aligned}$$

showing that alternative (a) is valid.

Next assume that (ii) holds. Since $C^\circ \neq \emptyset$, there exist $y \in C$ and $r > 0$ such that $y + r\bar{B}_{\mathcal{Y}} \subset C$, and we may assume that $r > \gamma_i$ for all sufficiently large i, say $i \geqq i_1$. By Lemma 4.2, with

$$W := \{(g_i'(\theta_i), G_i'(\theta_i))\omega \mid \omega \in \mathcal{T}_i\}, \qquad C_0 := C - \Phi(q_0),$$

for each $i \geqq i_1$ there exists $\ell_i = (\ell_i^1, \ell_i^2) \in \mathbb{R}^m \times \mathcal{Y}^*$ such that $|\ell_i| = 1$,

$$\ell_i^1 g_i'(\theta_i)\omega + \ell_i^2 G_i'(\theta_i)\omega \geqq -\gamma_i(1 + |y|/r) \quad \forall \omega \in \mathcal{T}_i, \tag{4.3.5}$$

$$\ell_i^2 c_i \leqq \gamma_i \quad \forall c_i \in C - \Phi(q_0) \ominus \gamma_i \bar{B}_{\mathcal{Y}}. \tag{4.3.6}$$

Relation (b1) now follows directly from (4.3.5).

Let $\ell = (\ell^1, \ell^2)$ be the weak* limit of some subsequence $(\ell_i)_{i \in \mathcal{I}}$ of (ℓ_i), with $\mathcal{I} \subset (i_1, i_1 + 1, \cdots)$, and let $c \in C^\circ$. Then, for all sufficiently large $i \in \mathcal{I}$,

$$c - \Phi(q_0) \in C - \Phi(q_0) \ominus \gamma_i \bar{B}_{\mathcal{Y}}$$

and by (4.3.6) $\ell^2(c - \Phi(q_0)) \leqq 0$. Since ℓ^2 is continuous, this implies that

$$\ell^2(c - \Phi(q_0)) \leqq 0 \quad \forall c \in C,$$

thus proving (b3). Thus it remains to prove that $0 < |\ell| \leqq 1$. The inequality $|\ell| \leqq 1$ follows from $|\ell_i| = 1$ for all i. The inequality $|\ell| > 0$ follows directly from (4.3.6) and the assumption that $C^\circ \neq \emptyset$. Indeed, there exist y_0 and $r_0 > 0$ such that

$$y_0 + r_0 \bar{B}_{\mathcal{Y}} \subset C - \Phi(q_0) \ominus \gamma_i \bar{B}_{\mathcal{Y}}$$

for all large $i \in \mathcal{I}$. It follows by (4.3.6) that

$$\ell_i^2 y_0 + r_0 \ell_i^2 z \leqq \gamma_i \quad \forall z \in \bar{B}_{\mathcal{Y}};$$

hence

$$\ell_i^2 y_0 \leqq \gamma_i - r_0 |\ell_i^2| = \gamma_i - r_0(1 - |\ell_i^1|)$$

and therefore

$$\ell^2 y_0 \leqq -r_0(1-|\ell^1|),$$

thus proving that $\ell = (\ell^1, \ell^2) \neq 0$. □

We will henceforth use the notation of § 2 (and, in particular, the symbol $\mathcal{P}$ to denote either $\mathcal{S}^\#_P$ or $\tilde{\mathcal{P}}$) and the known result (proven in the arguments of [4, Thm. VI.1.1]) that the functions

$$\sigma \to y(\sigma) : \mathcal{S}^\# \to C(T, \mathbb{R}^n) \quad \text{and} \quad \hat{\sigma} \to \hat{y}(\hat{\sigma}) : \hat{\mathcal{S}}^\# \to C(T, \mathbb{R}^{n+p})$$

are continuous. We also observe that the μ-integrable function ψ of assumption (2.3.3) may be assumed to be a constant. This can be accomplished by replacing the independent variable t in the differential equation

$$\hat{y}(t) = \int_{t_0}^{t} \hat{f}(s, \hat{y}(s), \sigma \otimes \pi(s))\, ds \quad \forall t \in T$$

by $\tau := \int_{t_0}^{t} [1+\psi(s)]\, ds$ that effectively divides $\hat{f}$ by $1+\psi(t)$ and does not affect the statement of Theorems 2.4 and 2.5. Furthermore, since Assumption 2.3 guarantees that all the solutions of the above equations are uniformly bounded, we denote by c the common bound and Lipschitz constant of $f(t, \cdot, r)$, $\hat{f}(t, \cdot, r, r_P)$, $\hat{f}_1(t, \cdot, r)$, $\hat{f}_2(t, \cdot, r, r_P)$, h, $\hat{h}$, $y(\sigma)$, and $\hat{y}(\sigma \otimes \pi)$.

LEMMA 4.4. *Let $c^* := c \exp(c(t_1 - t_0))$ and X be the compact subset of $C(T, \mathbb{R}^{n+p})$ whose elements have c^* as a common bound and a common Lipschitz constant. For each $\pi \in \mathcal{P}$, let $Z(\pi)$ be the collection of all $\zeta \in AC(T, \mathbb{R}^{n+p})$ satisfying*

$$\zeta(t)^T \in \Lambda \hat{h}(\hat{y}_0(\pi)(t_1)) + \int_t^{t_1} \zeta(s)^T\, \partial \hat{f}(s, \hat{y}_0(\pi)(s), \sigma_0 \otimes \pi(s))\, ds \quad \forall t \in T.$$

Then $Z(\pi) \subset X$ for all $\pi \in \mathcal{P}$ and the function

$$\pi \to Z(\pi) : \mathcal{P} \to 2^{AC(T, \mathbb{R}^{n+p})}$$

has a closed graph.

Proof. Let $\lim_k \pi_k = \pi^*$ in $\mathcal{P}$. Since $\partial \hat{f}$ and $\Lambda \hat{h}$ are bounded by c for all $\pi \in \mathcal{P}$ and $\partial \hat{f}$ has values that are compact and convex, the sets $Z(\pi)$ are compact and contained in X. If, for each $k = 1, 2, \cdots$, we choose $\zeta_k \in Z(\pi_k)$ and set

$$\hat{y}_k := \hat{y}(\sigma_0 \otimes \pi_k) = \hat{y}_0(\pi_k), \qquad \hat{\sigma}_k := \sigma_0 \otimes \pi_k$$

then, by Assumption (2.3.5),

$$\partial \hat{f}(t, \hat{y}_k(t), \hat{\sigma}_k(t)) = \partial \hat{f}_1(t, \hat{y}_k(t), \sigma_0(t)) + \mathcal{D}_2 \hat{f}_2(t, \hat{y}_k(t), \hat{\sigma}_k(t))$$

and there exist μ-measurable selections M_k of

$$t \to \partial \hat{f}_1(t, \hat{y}_k(t), \sigma_0(t))$$

such that, for all $t \in T$,

$$\zeta_k(t)^T = \zeta_k(t_1)^T + \int_t^{t_1} \zeta_k(s)^T [M_k(s) + \mathcal{D}_2 \hat{f}_2(s, \hat{y}_k(s), \hat{\sigma}_k(s))]\, ds. \tag{4.4.1}$$

Now assume, by way of contradiction, that there exist $\mathcal{K} \subset (1, 2, \cdots)$ and $\varepsilon_0 > 0$ such that

$$\operatorname{dist}(\zeta_k, Z(\pi^*)) := \inf\{|\zeta_k - x|_{\sup} \mid x \in Z(\pi^*)\} > \varepsilon_0 \quad \forall k \in \mathcal{K}. \tag{4.4.2}$$

We may choose a subsequence $\mathscr{K}_1$ of $\mathscr{K}$ such that the functions ζ_k converge uniformly to some ζ^* as k ranges over $\mathscr{K}_1$. Since $\lim_k \pi_k = \pi^*$ in $\mathscr{P}$, hence $\lim_k \sigma_0 \otimes \pi_k = \sigma_0 \otimes \pi^*$ in $\hat{\mathscr{S}}^*$, we have

$$\lim_k \hat{y}(\sigma_0 \otimes \pi_k) = \hat{y}(\sigma_0 \otimes \pi^*) \text{ in } C(T, \mathbb{R}^{n+p}).$$

Let $\bar{B}_{n+p,n+p}$ denote $\bar{B}_{\mathscr{Y}}$ for $\mathscr{Y} = \mathscr{L}(\mathbb{R}^{n+p}, \mathbb{R}^{n+p})$, $c_1 = 2c(t_1 - t_0)$,

$$c' = (3cc^* + 1)[1 + c_1 \exp(c_1)], \qquad 0 < \eta < \varepsilon_0/c', \quad \hat{y}^* = \hat{y}(\sigma_0 \otimes \pi^*)$$

and let $\mathscr{K}_2 \subset \mathscr{K}_1$ be such that, for all $k \in \mathscr{K}_2$, $r \in R$, $r_P \in R_P$, $t \in T$,

$$\begin{gathered} |\mathscr{D}_2 \hat{f}_2(t, \hat{y}_k(t), r, r_P) - \mathscr{D}_2 \hat{f}_2(t, \hat{y}^*(t), r, r_P)| \leqq \eta \\ \partial \hat{f}_1(t, \hat{y}_k(t), \sigma_0(t)) \subset \partial \hat{f}_1(t, \hat{y}^*(t), \sigma_0(t)) + \eta \bar{B}_{n+p,n+p} \\ |\zeta_k - \zeta^*|_{\sup} \leqq \eta, \qquad \zeta_k(t_1) \in \Lambda \hat{h}(\hat{y}^*(t_1)) + \eta \bar{B}_p. \end{gathered} \tag{4.4.3}$$

Then, for $k \in \mathscr{K}_2$,

$$\begin{aligned} \lim_{j \in \mathscr{K}_2} \int_t^{t_1} & \zeta_j(s)^T \mathscr{D}_2 \hat{f}_2(s, \hat{y}_j(s), \hat{\sigma}_j(s))\, ds \\ &= \int_t^{t_1} \zeta^*(s)^T \mathscr{D}_2 \hat{f}_2(s, \hat{y}^*(s), \sigma_0 \otimes \pi^*(s))\, ds \\ &\in \int_t^{t_1} \zeta_k(s)^T \mathscr{D}_2 \hat{f}_2(s, \hat{y}^*(s), \sigma_0 \otimes \pi^*(s))\, ds + c\eta \bar{B}_p \end{aligned}$$

and therefore

$$\begin{aligned} \int_t^{t_1} & \zeta_k(s)^T \mathscr{D}_2 \hat{f}_2(s, \hat{y}_k(s), \sigma_0 \otimes \pi_k(s))\, ds \\ &\in \int_t^{t_1} \zeta_k(s)^T \mathscr{D}_2 \hat{f}_2(s, \hat{y}^*(s), \sigma_0 \otimes \pi^*(s))\, ds + 2c\eta \bar{B}_p \end{aligned} \tag{4.4.4}$$

for all sufficiently large $k \in \mathscr{K}_2$, say for $k \in \mathscr{K}_3$.

Let $M_k^*(t)$ be the closest point in the compact convex set $\partial \hat{f}_1(t, \hat{y}^*(t), \sigma_0(t))$ to $M_k(t)$ and $\mathfrak{z}_k$ a closest point in $\Lambda \hat{h}(\hat{y}^*(t_1))$ to $\zeta_k(t_1)$. The point $M_k^*(t)$ is unique because we have chosen a strictly convex norm for $\mathscr{L}(\mathbb{R}^{n+p}, \mathbb{R}^{n+p})$. By Lusin's theorem, the μ-measurable functions $t \to M_k(t)$ and $t \to \partial \hat{f}_1(t, \hat{y}^*(t), \sigma_0(t))$ have continuous restrictions to sets of nearly full μ-measure, and $M_k^*(\cdot)$ is continuous when restricted to these sets. Thus $M_k^*(\cdot)$ is μ-measurable and, by (4.4.1), (4.4.3), and (4.4.4), for all $k \in \mathscr{K}_3$ and $t \in T$, we have

$$\zeta_k(t)^T = \mathfrak{z}_k + \int_t^{t_1} \zeta_k(s)^T [M_k^*(s) + \mathscr{D}_2 \hat{f}_2(s, \hat{y}^*(s), \sigma_0 \otimes \pi^*(s))]\, ds + e_k(t)^T,$$

where $|e_k(t)| \leqq (3cc^* + 1)\eta$. If we denote by $\zeta_k^*(\cdot)$ the solution ζ of

$$\zeta(t)^T = \mathfrak{z}_k + \int_t^{t_1} \zeta(s)^T [M_k^*(s) + \mathscr{D}_2 \hat{f}_2(s, \hat{y}^*(s), \sigma_0 \otimes \pi^*(s))]\, ds,$$

then we observe that $\zeta_k^* \in Z(\pi^*)$ for all $k \in \mathscr{K}_3$ and that $\Delta_k := \zeta_k - \zeta_k^*$ satisfies

$$\Delta_k(t) = \int_t^{t_1} \Delta_k(s)^T [M_k^*(s) + \mathscr{D}_2 \hat{f}_2(s, \hat{y}^*(s), \sigma_0 \otimes \pi^*(s))]\, ds + e_k(t).$$

Thus, by Gronwall's inequality,

$$|\Delta_k(t)| \leqq (3cc^*+1)[1+2c(t_1-t_0)\exp(2c(t_1-t_0))]\eta = c'\eta$$

and therefore

$$\zeta_k \in Z(\pi^*) + c'\eta \bar{B}_{C(T,\mathbb{R}^{n+p})} \subset Z(\pi^*) + \varepsilon_0 \bar{B}_{C(T,\mathbb{R}^{n+p})} \quad \forall k \in \mathscr{K}_3.$$

Thus $\operatorname{dist}(\zeta_k, Z(\pi^*)) \leqq \varepsilon_0$, which contradicts (4.4.2).

We conclude that the function $\pi \to Z(\pi) : \mathscr{P} \to 2^{AC(T,\mathbb{R}^{n+p})}$ is upper semicontinuous and has compact values. Thus, by Berge's theorem, it has a closed graph. □

The following lemma is partly patterned on Lemma 3.2 of [5, p. 30].

LEMMA 4.5. *Let* $\mathscr{X} = C(T, \mathbb{R}^{n+p})$, $\omega_i \in \operatorname{frm}^+(\mathscr{P})$, $\omega_i(\mathscr{P}) \leqq 1$, $\lim_i \omega_i = \omega$ *weakly*, X *and* $Z(\pi)$ *be as defined in Lemma* 4.4, $\hat{z}_i : \mathscr{P} \to X$ ω_i*-measurable for all* $i = 1, 2, \cdots$, *and assume that for every* $\varepsilon > 0$ *there exists* $i_0(\varepsilon)$ *such that*

$$\hat{z}_i(\pi) \in \Gamma_\varepsilon(\pi) := (Z(\pi) + \varepsilon \bar{B}_{\mathscr{X}}) \cap X \quad \forall i \geqq i_0(\varepsilon), \qquad \pi \in \mathscr{P}.$$

Then there exist an ω*-measurable* $\hat{z} : \mathscr{P} \to C(T, \mathbb{R}^{n+p})$ *and* $\mathscr{I} \subset (1, 2, \cdots)$ *such that*

$$\hat{z}(\pi) \in \overline{\operatorname{co}}\, Z(\pi) \quad \forall \pi \in \mathscr{P}$$

and

$$\lim_{i \in \mathscr{I}} \int \omega_i(d\pi) \int_{t_0}^{t_1} \hat{z}_i(\pi)(s)^T \chi(s, \pi)\, ds = \int \omega(d\pi) \int_{t_0}^{t_1} \hat{z}(\pi)(s)^T \chi(s, \pi)\, ds$$

for all bounded $\chi : T \times \mathscr{P} \to \mathbb{R}^{n+p}$ *such that* $s \to \chi(s, \pi)$ *is* μ*-measurable for each* $\pi \in \mathscr{P}$ *and the function*

$$\pi \to \int_{t_0}^{t_1} x(s)^T \chi(s, \pi)\, ds : \mathscr{P} \to \mathbb{R}$$

is continuous for each $x \in X$.

Proof. For $i = 1, 2, \cdots$, let

$$\mathscr{L}_i(\varphi) = \int \varphi(\pi, \hat{z}_i(\pi))\omega_i(d\pi) \quad \forall \varphi \in C(\mathscr{P} \times X).$$

Then there exists $\nu_i \in \operatorname{frm}^+(\mathscr{P} \times X)$ such that

$$\text{(4.5.1)} \qquad \mathscr{L}_i(\varphi) = \int \varphi(\pi, x)\nu_i(d(\pi, x)), \qquad |\mathscr{L}_i| = \nu_i(\mathscr{P} \times X) = \omega_i(\mathscr{P}) \leqq 1$$

for all $\varphi \in C(\mathscr{P} \times X)$, and there exist $\mathscr{I} \subset (1, 2, \cdots)$ and $\nu \in \operatorname{frm}^+(\mathscr{P} \times X)$ such that

$$\lim_{i \in \mathscr{I}} \nu_i = \nu \quad \text{weakly.}$$

Let n_ω denote the (conventional) norm of $L^1(\omega, C(\mathscr{P}))$. Then, for all $\varphi \in C(\mathscr{P} \times X) = C(\mathscr{P}, C(X))$, we have

$$\left| \int \varphi(\pi, x)\nu(d(\pi, x)) \right| \leqq \int |\varphi(\pi, \cdot)|_{\sup} \nu(d(\pi, x))$$

$$= \lim_{i \in \mathscr{I}} \int |\varphi(\pi, \cdot)|_{\sup} \nu_i(d(\pi, x)) = \lim_{i \in \mathscr{I}} \int |\varphi(\pi, \cdot)|_{\sup} \omega_i(d\pi)$$

$$= \int |\varphi(\pi, \cdot)|_{\sup} \omega(d\pi) = n_\omega(\varphi).$$

Thus ν is a continuous linear functional on the normed vector space $(C(\mathcal{P}, C(X)), n_\omega)$ and, by the Hahn-Banach theorem, can be extended to $(L^1(\omega, C(X)), n_\omega)$. It follows, by a variant of the Dunford-Pettis theorem (the proof being the same as in [4, Thm. IV.1.8]), that there exists an ω-measurable $\lambda : \mathcal{P} \to \operatorname{frm}(X)$ such that $\operatorname{ess\,sup}_{t\in T} |\lambda(t)|(X) < \infty$ and

$$(4.5.2) \int \varphi(\pi, x)\nu(d(\pi, x)) = \int \omega(d\pi) \int \varphi(\pi, x)\lambda(\pi)(dx) \quad \forall \varphi \in L^1(\omega, C(X)).$$

We verify that $\lambda(\pi)$ is a nonnegative measure ω-almost everywhere.

Let $\varepsilon > 0$. By Lemma 4.4, Graph (Z) is closed and therefore Graph (Γ_ε) is closed. Since $\hat{z}_i(\pi) \in \Gamma_\varepsilon(\pi)$ for all $\pi \in \mathcal{P}$ and all sufficiently large i, relation (4.5.1) implies that ν_i has its support on Graph (Γ_ε) for sufficiently large i and therefore ν has its support on Graph (Γ_ε). It follows thus from relation (4.5.2) that $\lambda(\pi)$ is supported ω-almost everywhere on $\Gamma_\varepsilon(\pi)$. Therefore, by (4.5.1) and (4.5.2), for every $u \in C(\mathcal{P})$,

$$\begin{aligned}\lim_{i\in\mathcal{I}} \mathcal{L}_i(u) = \int u(\pi)\omega(d\pi) &= \int u(\pi)\nu(d(\pi, x)) \\ &= \int \omega(d\pi) \int u(\pi)\lambda(\pi)(dx) \\ &= \int u(\pi)\lambda(\pi)(\Gamma_\varepsilon(\pi))\omega(d\pi);\end{aligned}$$

hence $\lambda(\pi)(\Gamma_\varepsilon(\pi)) = 1$ ω-almost everywhere.

Now set

$$\hat{z}(\pi) := \int x\lambda(\pi)(dx) \quad \forall \pi \in \mathcal{P}$$

and let $\chi : T \times \mathcal{P} \to \mathbb{R}^{n+p}$ be as described in the statement of the lemma. Then $\pi \to \hat{z}(\pi)$ is ω-measurable and

$$\hat{z}(\pi) \in \overline{\text{co}}\, \Gamma_\varepsilon(\pi) := \overline{\text{co}}\, [(Z(\pi) + \varepsilon \bar{B}_{\mathcal{X}}) \cap X] \quad \forall \varepsilon > 0;$$

hence $\hat{z}(\pi) \in \overline{\text{co}}\, Z(\pi)$. Furthermore, the function

$$(\pi, x) \to \varphi(\pi, x) = \int_{t_0}^{t_1} x(s)^T \chi(s, \pi)\, ds$$

being continuous in π for each x and continuous in x uniformly for all π, belongs to $C(\mathcal{P} \times X)$. Thus, by (4.5.1) and (4.5.2),

$$\begin{aligned}\mathcal{H}(\chi) := \lim_{i\in\mathcal{I}} \int \omega_i(d\pi) \int_{t_0}^{t_1} \hat{z}_i(\pi)(s)^T \chi(s, \pi)\, ds \\ = \int \nu(d(\pi, x)) \int_{t_0}^{t_1} x(s)^T \chi(s, \pi)\, ds \\ = \int \omega(d\pi) \int \left[\int_{t_0}^{t_1} x(s)^T \chi(s, \pi)\, ds\right] \lambda(\pi)(dx).\end{aligned}$$

We observe that, for every $\pi \in \mathcal{P}$, the function $s \to x(s)^T \chi(s, \pi)$ is μ-integrable for all $x \in X$ and the function $x \to x(s)^T \chi(s, \pi)$ is continuous on X uniformly for all s and

π. Thus the function $(s, x)\to x(s)^T\chi(s, \pi)$ is $\mu\times\lambda(\pi)$-integrable and, by Fubini's theorem,

$$\int\left[\int_{t_0}^{t_1} x(s)^T\chi(s, \pi)\, ds\right]\lambda(\pi)(dx)=\int_{t_0}^{t_1}\left[\int x(s)^T\lambda(\pi)(dx)\right]\chi(s, \pi)\, ds$$

$$=\int_{t_0}^{t_1}\left[\int x\lambda(\pi)(dx)\right](s)^T\chi(s, \pi)\, ds$$

$$=\int_{t_0}^{t_1}\hat{z}(\pi)(s)^T\chi(s, \pi)\, ds.$$

Thus $\mathcal{H}(\chi)=\int\omega(d\pi)\int_{t_0}^{t_1}\hat{z}(\pi)(s)^T\chi(s, \pi)\, ds.$ □

LEMMA 4.6. *Let ω and $\hat{z}$ be as in Lemma* 4.5 *and*

$$\hat{\mathcal{A}}_j(\pi, t):=\hat{z}(\pi)(t)^T\hat{f}(t, \hat{y}_0(\pi)(t), (\sigma_j-\sigma_0)\otimes\pi(t)).$$

Then

$$\int\omega(d\pi)\int_{t_0}^{t_1}\hat{\mathcal{A}}_j(\pi, s)\, ds=\int_{t_0}^{t_1}\left[\int_w\hat{\mathcal{A}}_j(\pi, \cdot)\omega(d\pi)\right](s)\, ds\quad\forall j=1, 2, \cdots.$$

Proof. We first prove that the bounded function

$$\pi\to\hat{\mathcal{A}}_j(\pi, \cdot):\mathcal{P}\to(L^2(\mu, \mathbb{R}), |\cdot|_w)$$

is ω-measurable and therefore also ω-integrable. Since

$$\pi\to\hat{z}(\pi):\mathcal{P}\to(C(T, \mathbb{R}^{n+p}), |\cdot|_{\sup})$$

is ω-measurable, for every $\varepsilon>0$ there exists a closed set $F_\varepsilon\subset\mathcal{P}$ such that $\omega(\mathcal{P}\backslash F_\varepsilon)<\varepsilon$ and $\hat{z}|_{F_\varepsilon}$ is continuous, so that

$$\lim_i\hat{z}(\pi_i)(t)=\hat{z}(\pi)(t)\quad\text{uniformly for } t\in T$$

if $\pi, \pi_i\in F_\varepsilon$ and $\lim_i\pi_i=\pi$. The bounded function

$$\pi\to\hat{f}(\cdot, \hat{y}_0(\pi)(\cdot), (\sigma_j-\sigma_0)\otimes\pi(\cdot)):\mathcal{P}\to(L^2(\mu, \mathbb{R}), |\cdot|_w)$$

is continuous because

$$\pi\to\hat{y}_0(\pi):\mathcal{P}\to(C(T, \mathbb{R}^{n+p}), |\cdot|_{\sup})$$

is continuous and therefore

$$\pi\to\int_{t_0}^{t_1} g(s)^T\hat{f}(s, \hat{y}_0(\pi)(s), (\sigma_j-\sigma_0)\otimes\pi(s))\, ds$$

is continuous for every $g\in L^2(\mu, \mathbb{R}^{n+p})$. Therefore, if $\lim_i\pi_i=\pi$ in F_ε then

$$\lim_i\int_{t_0}^{t_1} g(s)\mathcal{A}_j(\pi_i, s)\, ds=\int_{t_0}^{t_1} g(s)\mathcal{A}_j(\pi, s)\, ds\quad\forall g\in L^2(\mu, \mathbb{R}).$$

Thus $\pi\to\mathcal{A}_j(\pi, \cdot):F_\varepsilon\to(L^2(\mu, \mathbb{R}), |\cdot|_w)$ is continuous for every $\varepsilon>0$, and therefore the bounded function

$$\pi\to\hat{\mathcal{A}}_j(\pi, \cdot):\mathcal{P}\to(L^2(\mu, \mathbb{R}), |\cdot|_w)$$

is ω-integrable.

Let $\mathscr{L}(\psi) := \int_{t_0}^{t_1} \psi(s)\, ds$ for all $\psi \in L^2(\mu, \mathbb{R})$. Then $\mathscr{L}$ is a bounded linear functional on $(L^2(\mu, \mathbb{R}), |\cdot|_w)$ and therefore

$$\begin{aligned}\int \omega(d\pi) \int_{t_0}^{t_1} \hat{\mathscr{A}}_j(\pi, s)\, ds &= \int \mathscr{L}(\hat{\mathscr{A}}_j(\pi, \cdot))\omega(d\pi)\\ &= \mathscr{L}\left(\int_w \hat{\mathscr{A}}_j(\pi, \cdot)\omega(d\pi)\right)\\ &= \int_{t_0}^{t_1} \left[\int_w \hat{\mathscr{A}}(\pi, \cdot)\omega(d\pi)\right](s)\, ds \quad \forall j = 1, 2, \cdots \qquad \square\end{aligned}$$

LEMMA 4.7. *Let $\mathscr{P} = \mathscr{S}_P^{\#}$, let ω and $\hat{z}$ be as in Lemma* 4.5, *and let*

$$\hat{\mathscr{A}}(r, \pi, t) := \hat{z}(\pi)(t)^T \hat{f}(t, \hat{y}_0(\pi)(t), r, \pi(t)), \qquad I(r) := \int_w \hat{\mathscr{A}}(r, \pi, \cdot)\omega(d\pi).$$

Then

$$\lim_i I(r_i)(t) = I(r)(t) \ \mu\text{-a.e.} \quad \text{if } \lim_i r_i = r \text{ in } R.$$

Proof. Let $F \subset T$ be measurable, $\alpha > 0$, and $\psi: \mathscr{S}_P^{\#} \times T \to \mathbb{R}$ such that

$$\psi(\pi, \cdot) \in L^2(\mu, \mathbb{R}), \qquad |\psi(\pi, t)| \leqq \alpha \quad \forall \pi \in \mathscr{S}_P^{\#},\ t \in F$$

and $\pi \to \psi(\pi, \cdot): \mathscr{S}_P^{\#} \to (L^2(\mu, \mathbb{R}), |\cdot|_w)$ is ω-measurable. Set

$$J(\cdot) = \int_w \psi(\pi, \cdot)\omega(d\pi).$$

Then we have

$$(4.7.1) \qquad |J(t)| \leqq \alpha\omega(\mathscr{S}_P^{\#}) \ \mu\text{-a.e.} \quad \text{in } F.$$

Indeed, assume, by way of contradiction, that there exists $H \subset F$ such that $\mu(H) > 0$ and $|J(t)| > \alpha\omega(\mathscr{S}_P^{\#})$ for all $t \in H$. Set

$$g(t) = 1/J(t) \quad \forall t \in H, \qquad g(t) = 0 \quad \forall t \in T \backslash H,$$

$$\mathscr{L}_g(\chi) = \int_{t_0}^{t_1} g(t)\chi(t)\, dt \quad \forall \chi \in L^2(\mu, \mathbb{R}).$$

Then $\mathscr{L}_g$ is a bounded linear functional on $(L^2(\mu, \mathbb{R}), |\cdot|_w)$ and therefore

$$\begin{aligned}0 < \mu(H) = \int_{t_0}^{t_1} g(t)J(t)\, dt &= \mathscr{L}_g\left(\int_w \psi(\pi, \cdot)\omega(d\pi)\right)\\ &= \int \mathscr{L}_g(\psi(\pi, \cdot))\omega(d\pi) = \int \omega(d\pi) \int_{t_0}^{t_1} g(t)\psi(\pi, t)\, dt\\ &\leqq \alpha \int \omega(d\pi) \int_{t_0}^{t_1} |g(t)|\, dt < \mu(H),\end{aligned}$$

a contradiction.

Let

$$\alpha_i(\pi)(t) := \sup \{|\hat{\mathscr{A}}(r, \pi, t) - \hat{\mathscr{A}}(r', \pi, t)| \mid \text{dist}(r, r') \leqq 1/i\}.$$

Then, for all $t \in T$, $\lim_i \alpha_i(\pi)(t) = 0$ uniformly for $\pi \in \mathcal{S}_P^\#$, and the argument used in proving Egoroff's theorem shows that for all $\varepsilon > 0$ there exist a subset A_ε of T and numbers $k(m, \varepsilon)$ such that

$$\mu(T \backslash A_\varepsilon) < \varepsilon, \qquad \alpha_i(\pi)(t) \leqq 1/m \quad \forall i \geqq k(\varepsilon, m), \quad \pi \in \mathcal{S}_P^\#, \quad t \in A_\varepsilon.$$

Thus

$$|\hat{\mathscr{A}}(r, \pi, t) - \hat{\mathscr{A}}(r', \pi, t)| \leqq 1/m \quad \forall t \in A_\varepsilon, \ \pi \in \mathcal{S}_P^\#$$

if dist $(r, r') \leqq 1/k(\varepsilon, m)$, and therefore, for each $\varepsilon > 0$, $m \in \{1, 2, \cdots\}$, and $i \geqq k(m, \varepsilon)$, the function

$$(\pi, t) \rightarrow \psi(\pi, t) := \alpha_i(\pi)(t)$$

satisfies our assumptions, with $F = A_\varepsilon$ and $\alpha = 1/m$. It follows thus, by (4.7.1), that

$$|I(r_i)(t) - I(r)(t)| = \left| \left[\int_W (\hat{\mathscr{A}}(r, \pi, \cdot) - \hat{\mathscr{A}}(r_i, \pi, \cdot)) \omega(d\pi) \right](t) \right| \leqq \frac{1}{m} \omega(\mathcal{S}_P^\#)$$

$$\mu\text{-a.e. in } A_\varepsilon$$

if dist $(r, r_i) \leqq 1/k(m, \varepsilon)$. This implies that

$$\lim_i I(r_i)(t) = I(r)(t) \ \ \mu\text{-a.e.} \quad \text{if } \lim_i r_i = r. \qquad \square$$

4.8. Proof of Theorems 2.4 and 2.5. *Step* 1. We define a subset $\mathcal{S}_\infty$ of $\mathcal{S}^\#$ in the following manner. For purposes of Theorem 2.5, we enumerate $\mathcal{S}'$ as $\{\sigma_0, \sigma_1, \cdots\}$ and set $\mathcal{S}_\infty = \text{co } S'$. For purposes of Theorem 2.4, we observe that, by Castaing's theorem [1, Thm. 5.3], there exists an at most denumerable collection $\mathcal{R}_\infty^\#$ of μ-measurable selections of $R^\#$ such that the set $\{\rho(t) \mid \rho \in \mathcal{R}_\infty^\#\}$ is dense in $R^\#(t)$ μ-almost everywhere. Let $\mathcal{I}_\infty$ be the collection of all closed subintervals of T with rational endpoints. Then the set $\mathcal{R}_\infty^\# \times \mathcal{I}_\infty$ is denumerable. For each $(\rho, I) \in \mathcal{R}_\infty^\# \times \mathcal{I}_\infty$ we define a corresponding element $\sigma \in \mathcal{S}^\#$ by

$$\sigma(t) = \delta_{\rho(t)} \quad \forall t \in I, \qquad \sigma(t) = \sigma_0(t) \quad \forall t \in T \backslash I.$$

We then adjoin to the denumerable set of such σ a denumerable dense subset of the compact metric space $\mathcal{S}^\#$ and the given point σ_0, and enumerate the entire set as $\{\sigma_0, \sigma_1, \sigma_2, \cdots\}$. We then set

$$\mathcal{S}_\infty = \text{co } \{\sigma_0, \sigma_1, \sigma_2, \cdots\}.$$

Step 2. Let $p_i : \mathbb{R}^{n+p} \rightarrow [0, \infty)$ be C^1 for $i = 1, 2, \cdots$ and such that

$$p_i(\hat{y}) = 0 \quad \text{if } |\hat{y}| \geqq 1/i \quad \text{or} \quad \hat{y} \notin \hat{V}, \qquad \int p_i(\hat{y}) \, d\hat{y} = 1,$$

where $d\hat{y}$ refers to the Lebesgue measure on $\mathbb{R}^{n+p}$. We set

$$\hat{f}_i(t, \hat{y}, r, r_P) = \int \hat{f}(t, \hat{y} - \hat{y}_1, r, r_P) p_i(\hat{y}_1) \, d\hat{y}_1.$$

We recall [6, Proof of Thm. 2.5] that the functions $\hat{f}_i(t, \cdot, \cdot, \cdot)$ and $\mathscr{D}_2 \hat{f}_i(t, \cdot, \cdot, \cdot)$ exist and are continuous, that

$$\mathscr{D}_2 \hat{f}_i(t, \hat{y}, r, r_P) \in \partial^{1/i} \hat{f}(t, \hat{y}, r, r_P) \quad \text{if } \hat{y} + \frac{1}{i} \bar{B}_{n+p} \subset \hat{V},$$

and that $\lim_i \hat{f}_i = \hat{f}$ uniformly when $\hat{y}$ is restricted to a compact set. Thus, for all sufficiently large i and each $\sigma \in \mathcal{S}_\infty$ and $\pi \in \mathcal{P}$, the differential equation

$$\hat{y}(t) = \int_{t_0}^{t} \hat{f}_i(s, \hat{y}(s), \sigma \otimes \pi(s))\, ds \quad \forall t \in T$$

has a unique solution $\hat{y}_i(\sigma \otimes \pi)$. For all such i, σ, and π, and for $\theta \in \mathcal{T}_i$, we set

$$\hat{y}_i(\sigma \otimes \pi) = (y_i(\sigma), \tilde{y}_i(\sigma \otimes \pi)), \quad \varphi(\sigma) = h(y(\sigma)(t_1)), \quad \varphi_i(\sigma) = h_i(y_i(\sigma)(t_1)),$$

$$\Phi(\sigma)(\pi) = \hat{h}(\hat{y}(\sigma \otimes \pi)(t_1)), \qquad \Phi_i(\sigma)(\pi) = \hat{h}_i(\hat{y}_i(\sigma \otimes \pi)(t_1)),$$

$$\sigma^*(\theta) = \sigma_0 + \sum_{j=1}^{i} \theta^j(\sigma_j - \sigma_0),$$

$$g_i(\theta) = \varphi_i(\sigma^*(\theta)), \qquad G_i(\theta)(\pi) = \Phi_i(\sigma^*(\theta))(\pi),$$

where (h_i), $(\hat{h}_i)$ are the sequences that define Λh, $\Lambda \hat{h}$. We easily verify (using the uniform boundedness and uniform Lipschitz continuity with respect to $\hat{v}$ of $\hat{f}$, $\hat{f}_i$, h, h_i, $\hat{h}$, $\hat{h}_i$) that

$$\lim_i y_i(\sigma) = y(\sigma), \qquad \lim_i \hat{y}_i(\sigma \otimes \pi) = \hat{y}(\sigma \otimes \pi),$$

$$\lim_i \varphi_i(\sigma) = \varphi(\sigma), \qquad \lim_i \Phi_i(\sigma)(\pi) = \Phi(\sigma)(\pi)$$

uniformly for all $\sigma \in \mathcal{S}_\infty$ and $\pi \in \mathcal{S}_P^{\#}$, and that the functions

$$\pi \to \Phi(\sigma)(\pi) : \mathcal{P} \to \mathbb{R}, \qquad \pi \to \Phi_i(\sigma)(\pi) : \mathcal{P} \to \mathbb{R}$$

are continuous (because, as previously observed, $\pi \to \sigma \otimes \pi$ and $\pi \to \hat{y}(\sigma \otimes \pi)$ are continuous for each $\sigma \in \mathcal{S}_\infty$). Thus the values of (φ, Φ) and (φ_i, Φ_i) are in $\mathbb{R}^m \times C(\mathcal{P})$. We also observe that $\hat{f}_i(t, \cdot, r, r_P)$, h_i, $\hat{h}_i$, and $\hat{y}_i$ have a common bound and Lipschitz constant that we continue to denote by c. The arguments of [4, Thms. X.3.2 and X.3.4] show that (g_i, G_i) are C^1, the functions

$$\theta \to y_i(\sigma^*(\theta)) \quad \text{and} \quad \theta \to \hat{y}_i(\sigma^*(\theta) \otimes \pi)$$

are continuous, uniformly for all θ and π, and

$$(4.8.1) \quad \begin{aligned} g_i'(\theta)e_j^i &= \int_{t_0}^{t_1} \zeta_i(\theta)(s)^T f_i(s, y_i(\sigma^*(\theta))(s), [\sigma_j - \sigma^*(\theta)](s))\, ds \\ G_i'(\theta)(\pi)e_j^i &= \int_{t_0}^{t_1} \mathfrak{z}_i(\theta)(\pi)(s)^T \hat{f}_i(s, \hat{y}_i(\sigma^*(\theta) \otimes \pi)(s), [\sigma_j - \sigma^*(\theta)] \otimes \pi(s))\, ds \end{aligned}$$

for all $\theta \in \mathcal{T}_i$ and $\pi \in \mathcal{P}$, where

$$\zeta_i(\theta) \in AC(T, \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)) \quad \text{and} \quad \mathfrak{z}_i(\theta)(\pi) \in AC(T, \mathbb{R}^{n+p})$$

are solutions of the differential equations

$$(4.8.2) \quad \begin{aligned} \zeta(t)^T &= h_i'(y_i(\sigma^*(\theta))(t_1)) + \int_t^{t_1} \zeta(s)^T \mathcal{D}_2 f_i(s, y_i(\sigma^*(\theta))(s), \sigma^*(\theta)(s))\, ds, \\ \mathfrak{z}(t)^T &= \hat{h}_i'(\hat{y}_i(\sigma^*(\theta) \otimes \pi)(t_1)) + \int_t^{t_1} \mathfrak{z}(s)^T \mathcal{D}_2 \hat{f}_i(s, \hat{y}_i(\sigma^*(\theta) \otimes \pi)(s), \sigma^*(\theta) \otimes \pi(s))\, ds. \end{aligned}$$

Furthermore, the arguments of [4, Thm. X.3.4] show that $\pi \to \mathfrak{z}_i(\theta)(\pi)$ is continuous for each i and θ.

Step 3. Let

$$\mathscr{U} = K = \mathscr{S}_\infty = \text{co}\,\{\sigma_0, \sigma_1, \sigma_2, \cdots\}, \qquad q_j = \sigma_j, \quad \delta = 1,$$
$$\mathscr{Y} = C(\mathscr{P}), \qquad C = \{g \in \mathscr{Y} \mid g(\pi) \leqq 0 \ \ \forall \pi \in \mathscr{P}\},$$
$$u_k(\theta) = \sigma^*(\theta) \quad \forall i, k = 1, 2, \cdots, \qquad \theta \in \mathscr{T}_i.$$

Then Theorem 2.6 is applicable. Alternative (a) of Theorem 2.6 yields directly alternatives (a) of Theorems 2.4 and 2.5. We will assume, therefore, that alternative (b) of Theorem 2.6 holds and will seek to derive alternatives (b) of Theorems 2.4 and 2.5.

The functionals $\ell_i^2 \in \mathscr{Y}^* = C(\mathscr{P})^*$ are represented by measures $\omega_i \in \text{frm}\,(\mathscr{P})$ and, being uniformly bounded, have a subsequence $(\ell_i^2)_{i\in\mathscr{I}}$ converging in the weak* topology to some ℓ^2 represented by some $\omega \in \text{frm}\,(\mathscr{P})$. By 2.6(b3),

$$\ell^2\Phi(\sigma_0) = \int \hat{h}(\hat{y}_0(\pi)(t_1))\omega(d\pi) = \sup\left\{\int g(\pi)\omega(d\pi) \mid g(\pi) \leqq 0 \ \ \forall \pi \in \mathscr{P}\right\}.$$

Since $\pi \to \hat{h}(\hat{y}_0(\pi)(t_1))$ is nonpositive and bounded, this implies that $\omega \in \text{frm}^+\,(\mathscr{P})$ and therefore $\ell^2\Phi(\sigma_0) = 0$ and the transversality conditions (b3) of Theorems 2.4 and 2.5 are satisfied. Furthermore, the bounded sequence $(\ell_i^1)_{i\in\mathscr{I}}$ has a subsequence $(\ell_i^1)_{i\in\mathscr{I}_1}$ converging to some $\ell^1 \in \mathbb{R}^m$. Thus the relation $0 < |\ell^1| + |\ell^2| \leqq 1$ of Theorem 2.6 yields the relation $0 < |\ell^1| + \omega(\mathscr{P}) \leqq 1$ of Theorems 2.4 and 2.5.

We next consider the terms in relation 2.6(b1). Let

$$z_i^T := \ell_i^{1T}\zeta_i(\theta_i), \quad \hat{z}_i(\pi) := \hat{\mathfrak{z}}_i(\theta_i)(\pi), \quad \sigma_i^\# := \sigma^*(\theta_i).$$

Then the sequence $(z_i)_{i\in\mathscr{I}_1}$, whose elements are uniformly bounded and have a common Lipschitz constant, has a subsequence $(z_i)_{i\in\mathscr{I}_2}$ converging uniformly to some $z \in AC(T, \mathbb{R}^n)$. Furthermore,

$$|\hat{f}_i(s, \hat{v}, (\sigma_i^\# - \sigma_0) \otimes \pi(s))| \leqq 2c \sum_{j=1}^{i} \theta_i^j \leqq 2c\gamma_i$$

for all i, s, $\hat{v}$, and π. It follows now from the first equation of (4.8.2) that z is a solution of the corresponding differential inclusions in 2.4(b1) and 2.5(b1) and, by (4.8.1),

$$\text{(4.8.3)} \qquad \lim_{i\in\mathscr{I}_2} \ell_i^1 g_i'(\theta_i)e_j^i = \int_{t_0}^{t_1} z(s)^T f(s, y_0(s), (\sigma_j - \sigma_0)(s))\, ds \quad \forall j = 1, 2, \cdots.$$

We also have, by (4.8.1) and (4.8.2),

$$\ell_i^2 G_i'(\theta_i)e_j^i = \int \omega_i(d\pi) \int_{t_0}^{t_1} \hat{z}_i(\pi)(s)^T \hat{f}_i(s, \hat{y}_i(\sigma_i^\# \otimes \pi)(s), (\sigma_j - \sigma_i^\#) \otimes \pi(s))\, ds;$$

hence

$$\text{(4.8.4)} \qquad \begin{aligned} &\lim_{i\in\mathscr{I}_2} \ell_i^2 G_i'(\theta_i)e_j^i \\ &= \lim_{i\in\mathscr{I}_2} \int \omega_i(d\pi) \int_{t_0}^{t_1} \hat{z}_i(\pi)(s)^T \hat{f}(s, \hat{y}_0(\pi)(s), (\sigma_j - \sigma_0) \otimes \pi(s))\, ds. \end{aligned}$$

Let X and $Z(\pi)$ be as defined in Lemma 4.4. We observe that the function

$$s \to \chi(s, \pi) := \hat{f}(s, \hat{y}_0(\pi)(s), (\sigma_j - \sigma_0) \otimes \pi(s))\, ds$$

is bounded, uniformly for all $\pi \in \mathcal{P}$ and $j = 1, 2, \cdots$, and it is μ-measurable. Furthermore, the function

$$\pi \to \int_{t_0}^{t_1} x(s)^T \chi(s, \pi)\, ds$$

is continuous on $\mathcal{P}$ for every $x \in X$ (since $\pi \to \sigma \otimes \pi$ is continuous for each $\sigma \in \mathcal{S}_\infty$). It follows therefore from (4.8.4) and Lemma 4.5 that there exists $\hat{z}(\pi) \in \overline{\text{co}}\, Z(\pi)$ for all $\pi \in \mathcal{P}$ such that $\pi \to \hat{z}(\pi)$ is ω-measurable and

$$\lim_{i \in \mathcal{I}_2} \ell_i^2 G_i'(\theta_i) e_j^i$$
$$= \int \omega(d\pi) \int_{t_0}^{t_1} \hat{z}(\pi)(s)^T \hat{f}(s, \hat{y}_0(\pi)(s), (\sigma_j - \sigma_0) \otimes \pi(s))\, ds \quad \forall j = 1, 2, \cdots.$$

This last statement and (4.8.3), together with relation 2.6(b1), now yield 2.4(b1), 2.5(b1), and the inequality

$$\int_{t_0}^{t_1} z(s)^T f(s, y_0(s), (\sigma_j - \sigma_0)(s))\, ds$$
$$+ \int \omega(d\pi) \int_{t_0}^{t_1} \hat{z}(\pi)(s)^T \hat{f}(s, \hat{y}_0(\pi)(s), (\sigma_j - \sigma_0) \otimes \pi(s))\, ds \geqq 0 \tag{4.8.5}$$
$$\forall j = 1, 2, \cdots,$$

which yields, in particular, statement 2.5(b2.1).

Step 4. Let

$$\mathcal{A}(r, t) := z(t)^T f(t, y_0(t), r), \qquad \mathcal{A}_j(t) = \mathcal{A}((\sigma_j - \sigma_0)(t), t),$$

$\hat{\mathcal{A}}_j(\pi, t)$ be as defined in Lemma 4.6, and

$$\mathcal{B}_j := \int_w \hat{\mathcal{A}}_j(\pi, \cdot)\, \omega(d\pi).$$

By (4.8.5) and Lemma 4.6, we have

$$\int_{t_0}^{t_1} [\mathcal{A}_j(s) + B_j(s)]\, ds \geqq 0 \quad \forall j = 1, 2, \cdots.$$

Let L be the set of the common Lebesgue points of $\mathcal{A}_j + \mathcal{B}_j$ for all j that is of full μ-measure, let $t \in L \cap (t_0, t_1)$, and let (a_k) and (b_k) be sequences of rational numbers in T such that

$$a_k < t < b_k, \qquad \lim_k (b_k - a_k) = 0.$$

Then, for all $j = 1, 2, \cdots$,

$$\lim_k \frac{1}{b_k - a_k} \int_{a_k}^{b_k} [\mathcal{A}_j(s) + \mathcal{B}_j(s)]\, ds = \mathcal{A}_j(t) + B_j(t). \tag{4.8.6}$$

We observe that, for purposes of Theorem 2.4, for each $\rho \in \mathcal{R}_\infty^\#$ and k there exists some j such that

$$\sigma_j(s) = \delta_{\rho(s)} \ \text{ if } a_k \leqq s \leqq b_k, \qquad \sigma_j(s) = \sigma_0(s) \ \text{ if } s \in T \backslash [a_k, b_k].$$

For purposes of Theorem 2.5, and under the assumption of 2.5(b2.2), for each $\sigma' \in \mathscr{S}'$ and k there exists some j such that

$$\sigma_j(s) = \sigma'(s) \quad \text{if } a_k \leqq s \leqq b_k, \qquad \sigma_j(s) = \sigma_0(s) \quad \text{if } s \in T \backslash [a_k, b_k].$$

Since $\mathscr{A}_j(s) = \mathscr{B}_j(s) = 0$ for $s \in T\backslash[a_k, b_k]$, it follows from (4.8.5) and (4.8.6) that, for all $\sigma \in \mathscr{R}^\#_\infty$, respectively, $\sigma \in \mathscr{S}'$ and all $t \in L$, we have

$$\begin{aligned} &z(t)^T f(t, y_0(t), \sigma(t)) + \left[\int_W \hat{z}(\pi)(\cdot)^T \hat{f}(\cdot, \hat{y}_0(\pi)(\cdot), \sigma \otimes \pi(\cdot))\omega(d\pi)\right](t) \\ &\qquad \geqq z(t)^T f(t, y_0(t), \sigma_0(t)) + \left[\int_W \hat{z}(\pi)(\cdot)^T \hat{f}(\cdot, \hat{y}(\pi)(\cdot), \sigma_0 \otimes \pi(\cdot))\omega(d\pi)\right](t). \end{aligned} \tag{4.8.7}$$

Within the context of Theorem 2.5, this proves statement 2.5(b2.2) and completes the proof of Theorem 2.5.

Step 5. We henceforth consider statement (b2) of Theorem 2.4 and set $\mathscr{P} = \mathscr{S}^\#_P$. By choice, the set $\{\sigma_1, \sigma_2, \cdots\}$ is dense in $\mathscr{S}^\#$, and the function $\sigma \to \sigma \otimes \pi : \mathscr{S}^\# \to \hat{\mathscr{S}}^\#$ is continuous for each $\pi \in \mathscr{S}^\#_P$. Thus both integrals over T that appear in (4.8.5) are continuous functions of σ over $\mathscr{S}^\#$ if σ_j is replaced by σ. Therefore, inequality (4.8.5) remains valid when σ_j is replaced by any $\sigma \in \mathscr{S}^\#$. This proves relation 2.4(b2.1). It follows from (4.8.7) and Lemma 4.7 that, if $R^\#(t) = R$ for all $t \in T$ then, for all $r \in R$,

$$\begin{aligned} &z(t)^T f(t, y_0(t), r) + \left[\int_W \hat{z}(\pi)(\cdot)^T \hat{f}(\cdot, \hat{y}_0(\pi)(\cdot), r, \pi(\cdot))\omega(d\pi)\right](t) \\ &\qquad \geqq z(t)^T f(t, y_0(t), \sigma_0(t)) + \left[\int_W \hat{z}(\pi)(\cdot)^T \hat{f}(\cdot, \hat{y}(\pi)(\cdot), \sigma_0(\cdot), \pi(\cdot))\omega(d\pi)\right](t) \\ &\qquad\qquad \mu\text{-a.e.} \end{aligned}$$

This proves statement 2.4(b2.2).

We next derive the pointwise maximum principle (b2.3(i)) of Theorem 2.4. As before, let

$$\mathscr{A}(r, t) := z(t)^T f(t, y_0(t), r), \qquad \hat{\mathscr{A}}(r, \pi, t) := \hat{z}(\pi)(t)^T \hat{f}(t, \hat{y}_0(\pi)(t), r, \pi(t)).$$

For each $\rho \in \mathscr{R}^\#_\infty$ and $\pi \in \operatorname{supp}(\omega)$, the functions

$$t \to \mathscr{A}(\delta_{\rho(t)} - \sigma_0(t), t) \quad \text{and} \quad t \to \hat{\mathscr{A}}(\delta_{\rho(t)} - \sigma_0(t), \pi, t)$$

are μ-integrable and, therefore, the set of their common Lebesgue points is of full μ-measure. Since $\mathscr{R}^\#_\infty$ and (by 2.4(b3)) $\operatorname{supp}(\omega)$ are at most denumerable, the set L of their common Lebesgue points for all $\rho \in \mathscr{R}^\#_\infty$ and $\pi \in \operatorname{supp}(\omega)$ is also of full μ-measure. Now let $t \in L \cap (t_0, t_1)$, and let (a_k) and (b_k) be sequences of rational numbers in T such that

$$a_k < t < b_k, \qquad \lim_k (b_k - a_k) = 0.$$

Then, for all $\sigma \in \{\sigma_0, \sigma_1, \cdots\}$ and $\pi \in \operatorname{supp}(\omega)$,

$$\lim_k \frac{1}{b_k - a_k} \int_{a_k}^{b_k} \mathscr{A}(\sigma(s), s)\, ds = \mathscr{A}(\sigma(t), t)$$

$$\lim_k \frac{1}{b_k - a_k} \int_{a_k}^{b_k} \hat{\mathscr{A}}(\sigma(s), \pi, s)\, ds = \hat{\mathscr{A}}(\sigma(t), \pi, t).$$

We observe that for each $\rho \in \mathcal{R}^{\#}_{\infty}$ and k there exists some j such that

$$\sigma_j(s) = \delta_{\rho(s)} \quad \text{if } a_k \leqq s \leqq b_k, \qquad \sigma_j(s) = \sigma_0(s) \quad \text{if } s \in T \backslash [a_k, b_k].$$

It follows therefore from (4.8.5) that, for all $\rho \in \mathcal{R}^{\#}_{\infty}$ and $t \in L$,

$$(4.8.8) \quad \mathcal{A}(\rho(t), t) + \int \hat{\mathcal{A}}(\rho(t), \pi, t)\omega(d\pi) \geqq \mathcal{A}(\sigma_0(t), t) + \int \hat{\mathcal{A}}(\sigma_0(t), \pi, t)\omega(d\pi).$$

The functions $f(t, \mathbf{y}, \cdot)$ and $\hat{f}(t, \hat{\mathbf{y}}, \cdot, r_P)$ are equicontinuous and $\pi(t)$ are probability measures. Thus, for each $t \in L$, the functions

$$r \to \mathcal{A}(r, t) \quad \text{and} \quad r \to \int \hat{\mathcal{A}}(r, \pi, t)\omega(d\pi)$$

are continuous. Since the set $\{\rho(t) \mid \rho \in \mathcal{R}^{\#}_{\infty}\}$ is dense in $R^{\#}(t)$ μ-almost everywhere and $\sigma_0(t)$ is supported on $R^{\#}(t)$, we conclude from (4.8.8) that, for μ-almost all t and for all $r \in R^{\#}(t)$,

$$\mathcal{A}(\sigma_0(t), t) + \int \hat{\mathcal{A}}(\sigma_0(t), \pi, t)\omega(d\pi) \leqq \mathcal{A}(r, t) + \int \hat{\mathcal{A}}(r, \pi, t)\omega(d\pi).$$

This proves statement (b2.3(i)) of Theorem 2.4.

We finally derive the maximum principle (b2.3(ii)) of Theorem 2.4. Since $\hat{f}(t, \hat{\mathbf{y}}, r, r_P) = \not{f}_1(t, \hat{\mathbf{y}}, r) + \not{f}_2(t, \hat{\mathbf{y}}, r_P)$, the maximum principle (b2.1) yields

$$\int_{t_0}^{t_1} z(s)^T f(s, y_0(s), (\sigma - \sigma_0)(s))\, ds$$
$$+ \int \omega(d\pi) \int_{t_0}^{t_1} \hat{z}(\pi)(s)^T \hat{\not{f}}_1(s, \hat{\mathbf{y}}_0(\pi)(s), (\sigma - \sigma_0)(s))\, ds \geqq 0 \quad \forall \sigma \in \mathcal{S}^{\#}.$$

The function $(s, \pi) \to \hat{z}(\pi)(s)$, ω-measurable in π and continuous in s, and the function $(s, \pi) \to \hat{\not{f}}_1(s, \hat{y}_0(\pi)(s), (\sigma - \sigma_0)(s))$, μ-measurable in s and continuous in π, are both $\mu \times \omega$-measurable. We may therefore apply Fubini's theorem to the double integral above and obtain

$$(4.8.9) \qquad \int_{t_0}^{t_1} E(s, (\sigma - \sigma_0)(s))\, ds \geqq 0 \quad \forall \sigma \in \mathcal{S}^{\#},$$

where

$$E(s, (\sigma - \sigma_0)(s))$$
$$= z(s)^T f(s, y_0(s), (\sigma - \sigma_0)(s)) + \int \hat{z}(\pi)(s)^T \hat{\not{f}}_1(s, \hat{y}_0(\pi)(s), (\sigma - \sigma_0)(s))\omega(d\pi).$$

If we choose $\rho \in \mathcal{R}^{\#}_{\infty}$ then, for any μ-measurable set F and

$$\sigma(s) = \delta_{\rho(s)} \quad \forall s \in F, \qquad \sigma(s) = \sigma_0(s) \quad \forall s \in T \backslash F,$$

relation (4.8.9) yields $\int_F [E(s, \rho(s)) - E(s, \sigma_0(s))\, ds \geqq 0$, hence

$$E(t, \rho(t)) - E(s, \sigma_0(t)) \geqq 0 \quad \mu\text{-a.e.}$$

Since $\mathcal{R}^{\#}_{\infty}$ is denumerable and $\{\rho(t) \mid \rho \in \mathcal{R}^{\#}_{\infty}\}$ dense in $R^{\#}(t)$ μ-almost everywhere, we conclude that the maximum principle 2.4(b2.3(ii)) is valid. This concludes the proof of Theorem 2.4. □

MARTINGALE AND DUALITY METHODS FOR UTILITY MAXIMIZATION IN AN INCOMPLETE MARKET*

IOANNIS KARATZAS†, JOHN P. LEHOCZKY‡, STEVEN E. SHREVE§, AND GAN-LIN XU¶

Abstract. The problem of maximizing the expected utility from terminal wealth is well understood in the context of a complete financial market. This paper studies the same problem in an *incomplete market* containing a bond and a finite number of stocks whose prices are driven by a multidimensional Brownian motion process W. The coefficients of the bond and stock processes are adapted to the filtration (history) of W, and incompleteness arises when the number of stocks is *strictly smaller* than the dimension of W. It is shown that there is a way to complete the market by introducing additional "fictitious" stocks so that the optimal portfolio for the thus completed market *coincides* with the optimal portfolio for the original incomplete market. The notion of a "least favorable" completion is introduced and is shown to be closely related to the existence question for an optimal portfolio in the incomplete market. This notion is expounded upon using martingale techniques; several equivalent characterizations are provided for it, examples are studied in detail, and a fairly general existence result for an optimal portfolio is established based on convex duality theory.

Key words. incomplete markets, portfolio processes, stochastic control, convex duality, utility maximization

1. Introduction.

This paper studies the problem of an agent who receives a deterministic initial capital, which he must then invest in an incomplete market so as to maximize the expected utility of his wealth at a prespecified final time. The market consists of a bond and m stocks, the latter being driven by a d-dimensional Brownian motion. In such a model, *incompleteness arises when m is strictly smaller than d.* The market coefficients, i.e., the interest rate, the rates of stock appreciation, and the stock volatility coefficients, are random processes adapted to the full d-dimensional Brownian motion. When $m < d$, it is typically not possible to construct a portfolio consisting of the bond and the m available stocks, so as to completely hedge the risk associated with these coefficient processes.

Our model is not Markov, and so the Bellman equation of dynamic programming is inadequate for its analysis. Using the Bellman equation, Svensson [21] has treated an infinite-horizon, incomplete, Markov model with an income process. He derives first-order conditions and obtains explicit solutions when the utility for consumption has constant absolute risk aversion. Duffie and Jackson [4] provide a similar analysis of a finite-horizon, incomplete, Markov model.

The principal result of this paper, Theorem 12.5, provides conditions under which an optimal portfolio exists in an incomplete market, and characterizes this optimal portfolio in terms of the solution to a dual optimization problem.

In § § 2–5, we define the utility maximization problem faced by the agent. In § 6 we present the solution when the market is complete $(m = d)$, and complete hedging is possible. This solution proceeds in three steps. First, on the underlying probability space we determine a new measure which discounts the growth inherent in the market; under this measure, the expected value of the final wealth attained by any reasonable portfolio is equal to the initial endowment. Second, among all random variables whose expectation under the new measure is equal to the initial endowment, a most desirable one is determined. Third, it is shown that a portfolio can be constructed that attains this most desirable random variable as its terminal wealth; this portfolio is optimal. A *complete market* is one in which the agent can construct a portfolio that attains as final wealth any random variable with expectation under the new measure equal to the initial endowment. Because such a construction is possible, it is said that the agent can *hedge against the risk* associated with this market. Mathematically, the construction of a portfolio uses the fact that any martingale with respect to a Brownian filtration can be represented as a stochastic integral with respect to the Brownian motion; the integrand in this representation leads to the portfolio we are seeking. However, if there are fewer than d stocks, this line of argument fails.

In § 7 we introduce a convenient way of thinking about an incomplete market: *fictitious completion.* When there are fewer than d stocks, then we augment the stocks with certain fictitious ones so as to create a complete market. If the fictitious stocks have a high appreciation rate, then under an optimal portfolio the agent will hold a long position in them, but if they have a low (even negative) appreciation rate, then he will hold a short position. Thus we would expect to be able to adjust the appreciation rates of the fictitious stocks so that the agent, by optimal choice, does not invest in them at all. These judiciously chosen fictitious stocks allow us to write down the complete market solution for the utility maximization problem but are superfluous in the actual implementation of the optimal portfolio, which must then also be optimal for the original incomplete market. The fictitious completion with the above property is the least advantageous to the agent, because the portfolio which is optimal under this completion is available to him under every other fictitious completion. We thus have the notion of a *least favorable fictitious completion*: for every fictitious completion we compute the portfolio which maximizes the expected utility of final wealth, and then we choose the completion which makes this maximum expected utility as small as possible.

As explained in § 7, a convenient way to parametrize fictitious completions of an incomplete market is by a certain space of continuous local martingales, each local martingale being the Radon–Nikodym derivative process of the new measure alluded to in the earlier discussion of complete markets. This kind of parametrization is studied in § 8, and several pertinent results are established. It is also desirable to characterize the local martingale corresponding to the least favorable fictitious completion, and to show that it gives rise to an optimal portfolio in the original incomplete problem; this program is carried out in § 9, where various such equivalent characterizations are provided. Section 10 studies two examples in which the least favorable fictitious completion can be computed fairly explicitly. In the first example the utility function is logarithmic, and it is discovered that the fictitious stocks in the least favorable completion should have rates of appreciation equal to the interest rate of the bond. This is a very general result, insensitive to the nature of the dependence of market coefficients on the driving Brownian motion. In the second example it is assumed that the utility function is of the power form, and that the driving Brownian motion splits into two independent parts; the first part drives the stock processes, whose coefficients are adapted solely to the second part. The least favorable local martingale is exhibited as the solution to a martingale representation problem, and the optimal portfolio is found to be given by the formula already known to be correct for deterministic model coefficients.

In § 11 we introduce an auxiliary optimization problem involving the family of local martingales which characterize fictitious completions; this problem is "dual" to the "primal" utility maximization question of § 5, in the sense of convex duality. We study the relation between the primal and dual problems, and explain how a solution to the latter induces one for the former. The question of existence in the dual problem is tantamount to the existence of a least favorable fictitious completion; it is dealt with in § 12, by the use of methods from convex analysis.

Our model for the financial market can be traced back to Merton [16], [17] and Samuelson [20]. The modern mathematical approach to portfolio management in complete markets, built around the ideas of equivalent martingale measures and the creation of portfolios from martingale representation theorems, began with Harrison and Kreps [6] and was further developed by Harrison and Pliska [7], [8], in the context of option pricing. Pliska [19], Cox and Huang [2], [3], and Karatzas, Lehoczky, and Shreve [13] adapted the martingale ideas to problems of utility maximization. Much of this development appears in § 5.8 of Karatzas and Shreve [14], from which § 6 of the present paper is drawn (see also the review article of Karatzas [12] for a survey of financial economics problems in complete markets). An extension of the papers above to infinite horizon problems is reported by Huang and Pagès [11].

A first step toward a martingale analysis of incomplete markets was taken by Pagès [18], who considered a Brownian model in which the number of stocks was strictly less than the dimension of the driving Brownian motion. However, the coefficients of the bond and stock prices in this model were allowed to depend on the underlying Brownian model only through the bond and stock prices themselves. Thus, the vector of bond and stock prices formed a Markov process. This specialization created an essentially complete market, and thus it avoided the more interesting case of a market with genuinely unhedgeable risk. However, Pagès did characterize the class of equivalent martingale measures which could arise in an incomplete model, and this laid the groundwork for further developments (e.g., Lemma 8.2 in this paper). A more substantial step was taken by He and Pearson [9] in a discrete-time, finite probability space model, where the authors proposed finding the optimal intermediate consumption and terminal wealth corresponding to each of the equivalent martingale measures, and then searching over those policies to find a pair yielding the minimum expected total utility. Using separating hyperplane arguments, they were able to show that the total utility obtained by this two-step "minimax" process is the optimal total value for the incomplete problem.

He and Pearson have also studied the incomplete problem in a continuous-time, Brownian model. In an early version of He and Pearson [10], the authors consider Pagès's characterization of the family of equivalent martingale measures and search over this family for a "minimax" equivalent martingale measure, which would lead them to the optimal consumption and portfolio processes just as in a complete market. The martingale associated with this measure would create the "Arrow–Debreu" state prices in the incomplete model. However, the continuous-time model is more subtle than one might expect, and although it is now clear that Arrow–Debreu state prices exist for the incomplete model under some assumptions, it is not clear that they are associated with a martingale.

The present paper uses local martingales rather than martingales to address the issue of market incompleteness in continuous-time models. This work was motivated by the aforementioned previous version of He and Pearson [10], and by the use of local martingale methods introduced by Xu [22] in the study of incompleteness induced by a prohibition on the short-selling of stocks. Using the stochastic duality theory of Bismut [1], Xu formulated a dual problem whose solution could be shown to exist and could then be used to obtain existence and characterization of the solution of the original problem. As this paper shows, such duality methods can also be used in the traditional incomplete Brownian market model. While we still do not know if the minimax equivalent martingale measure sought by He and Pearson exists in any generality (see, however, the note following the references), we show here that the solution to Bismut's dual problem is a "least favorable local martingale" which can be used to generate a sequence of equivalent measures. The existence of this least favorable local martingale is sufficient for the study of many models. A notable exception is the incomplete market model in which the agent's endowment is a stochastic process; we do not know how to obtain the existence and a characterization of the optimal policy for such a model in terms of a least favorable local martingale, unless it is actually a martingale.

He and Pearson [10] have incorporated Xu's local martingale techniques into their original work. They report the existence of an optimal portfolio for the terminal wealth utility maximization problem when the index of relative risk aversion is everywhere greater than or equal to one, and they report similar results for the problem with intermediate consumption and consumption at the terminal time when the index of relative risk aversion is everywhere less than or equal to one. Our paper deals only with the case of terminal wealth utility maximization when the index of relative risk aversion is everywhere less than or equal to one; the generalization to also allow for intermediate consumption is straightforward. Whereas He and Pearson [10] assume that some augmentation of the market model will result in Markov prices, we allow general Itô price processes. He and Pearson [10] do not provide the full set of equivalent conditions contained in our Theorem 9.4, nor do they use our assumption (4.8). This assumption and the introduction of the set $K_1(\sigma)$ play a fundamental role in our proof of Theorem 9.4.

Remark on Notation: We denote by "standing assumption" those conditions that are always in force; they will not be cited in the theorems. The Standing Assumptions are 2.1, 2.2, 2.3, 4.1, and 5.1. We denote by "assumption" those conditions which are in force only when theorems specifically cite them.

2. The market model. We adopt a model for the financial market consisting of one bond with price $P_0(t)$ given by

$$dP_0(t) = r(t)P_0(t)\,dt, \qquad P_0(0) = 1, \tag{2.1}$$

and m stocks with prices per share $P_i(t)$, $i = 1, \cdots, m$, satisfying the equations

$$dP_i(t) = P_i(t)\left[b_i(t)\,dt + \sum_{j=1}^{d} \sigma_{ij}(t)\,dW_j(t)\right], \qquad i = 1, \cdots, m. \tag{2.2}$$

Here $W = (W_1, \cdots, W_d)^*$ is a d-dimensional Brownian motion on a probability space $(\Omega, \mathscr{F}, P)$, and we denote by $\{\mathscr{F}_t\}$ the P-augmentation of the filtration generated by W. It is assumed throughout that $d \geqq m$, i.e., the number of sources of uncertainty in the model is at least as large as the number of stocks available for investment.

The *interest rate* $r(t)$, the vector $b(t)=(b_1(t),\cdots,b_m(t))^*$ of *stock appreciation rates*, and the *volatility matrix* $\sigma(t)=\{\sigma_{ij}(t)\}_{1\leqq i\leqq m,\,1\leqq j\leqq d}$ are the *coefficients of the model.* They are taken to be progressively measurable with respect to $\{\mathcal{F}_t\}$.

Standing Assumption 2.1. *$\int_0^T \|b(t)\|\,dt<\infty$, $\int_0^T |r(t)|\,dt\leqq L$ hold almost surely, for some given real constant $L>0$.*

The positive constant T in Standing Assumption 2.1 is the *terminal time* for the problem. All processes are defined on $[0, T]$.

Standing Assumption 2.2. *The matrix $\sigma(t)$ has full rank for every t.*

As a result of Standing Assumption 2.2, the matrix $(\sigma(t)\sigma^*(t))^{-1}$ and the *relative risk* process

$$\theta(t)\triangleq\sigma^*(t)(\sigma(t)\sigma^*(t))^{-1}[b(t)-r(t)\mathbf{1}_m] \tag{2.3}$$

are defined. Throughout this paper, we denote by $\mathbf{1}_k$ the k-dimensional vector whose every component is one. In addition to Standing Assumptions 2.1 and 2.2, the following assumption will be made throughout.

Standing Assumption 2.3. *$\int_0^T \|\theta(t)\|^2\,dt<\infty$, almost surely P.*

We shall have occasion to use the so-called *discount process*

$$\beta(t)\triangleq\frac{1}{P_0(t)}=\exp\left\{-\int_0^t r(s)\,ds\right\}, \tag{2.4}$$

as well as the process

$$W_0(t)\triangleq W(t)+\int_0^t \theta(s)\,ds \tag{2.5}$$

and the exponential local martingale

$$Z_0(t)\triangleq\exp\left\{-\int_0^t \theta^*(s)\,dW(s)-\frac{1}{2}\int_0^t \|\theta(s)\|^2\,ds\right\}. \tag{2.6}$$

DEFINITION 2.4. A financial market as above will be called *complete* if $m=d$, and *incomplete* if $m<d$.

3. Portfolio and wealth processes. A *portfolio process* $\pi(t)=(\pi_1(t),\cdots,\pi_m(t))^*$ is an $\mathbb{R}^m$-valued, $\{\mathcal{F}_t\}$-adapted process satisfying

$$\int_0^T \|\sigma^*(t)\pi(t)\|^2\,dt<\infty \quad \text{a.s. } P. \tag{3.1}$$

We regard $\pi_i(t)$ as the proportion of an agent's wealth invested in stock i at time t; the remaining proportion $1-\pi^*(t)\mathbf{1}_m=1-\sum_{i=1}^m \pi_i(t)$ is invested in the bond. We do *not* constrain these proportions to take values in the interval $[0, 1]$; in other words, we allow both short-selling of stocks, and borrowing at the interest rate of the bond. For a given, nonrandom, initial wealth $x>0$, let $X^{x,\pi}$ denote the *wealth process* corresponding to a portfolio π defined by $X^{x,\pi}(0)=x$ and

$$\begin{aligned} dX^{x,\pi}(t)&=r(t)X^{x,\pi}(t)\,dt+X^{x,\pi}(t)\pi^*(t)[(b(t)-r(t)\mathbf{1}_m)\,dt+\sigma(t)dW(t)] \\ &=r(t)X^{x,\pi}(t)\,dt+X^{x,\pi}(t)\pi^*(t)\sigma(t)dW_0(t). \end{aligned} \tag{3.2}$$

In other words,

$$\begin{aligned} \beta(t)X^{x,\pi}(t)&=x\exp\left\{\int_0^t \pi^*(s)\sigma(s)\,dW_0(s)-\frac{1}{2}\int_0^t \|\sigma^*(s)\pi(s)\|^2\,ds\right\} \\ &=x+\int_0^t \beta(s)X^{x,\pi}(s)\pi^*(s)\sigma(s)\,dW_0(s), \qquad 0\leqq t\leqq T. \end{aligned} \tag{3.3}$$

Remark 3.1. An application of Itô's rule to the product of the processes Z_0 and $\beta X^{x,\pi}$ of (2.6), (3.3) leads to

$$\beta(t)Z_0(t)X^{x,\pi}(t)=x+\int_0^t \beta(s)Z_0(s)X^{x,\pi}(s)(\sigma^*(s)\pi(s)-\theta(s))^*\,dW(s). \tag{3.4}$$

This shows, in particular, that the process $\beta Z_0 X^{x,\pi}$ is a nonnegative local martingale, hence a supermartingale.

4. Utility functions. The agent in our model has a utility function $U:(0,\infty)\to\mathbb{R}$ for wealth. We make the following assumption throughout.

Standing Assumption 4.1. *U is strictly increasing, strictly concave, continuous and continuously differentiable, and satisfies*

$$U'(0)\triangleq\lim_{x\downarrow 0}U'(x)=\infty,\qquad U'(\infty)\triangleq\lim_{x\to\infty}U'(x)=0. \tag{4.1}$$

The (continuous, strictly decreasing) inverse of the function U' will be denoted by $I:(0,\infty)\to(0,\infty)$; by analogy with (4.1), it satisfies

$$I(0)\triangleq\lim_{y\downarrow 0}I(y)=\infty,\qquad I(\infty)\triangleq\lim_{y\to\infty}I(y)=0. \tag{4.2}$$

We introduce also the function

$$\tilde U(y)\triangleq\max_{x>0}[U(x)-xy]=U(I(y))-yI(y),\qquad 0<y<\infty, \tag{4.3}$$

which is the Legendre transform of $-U(-x)$, with U extended to be $-\infty$ on the negative real axis. The function $\tilde U$ is strictly decreasing, strictly convex, and satisfies

$$\tilde U'(y)=-I(y),\qquad 0<y<\infty, \tag{4.4}$$

$$U(x)=\min_{y>0}[\tilde U(y)+xy]=\tilde U(U'(x))+xU'(x),\qquad 0<x<\infty. \tag{4.5}$$

The useful inequalities

$$U(I(y))\geqq U(x)+y[I(y)-x]\qquad \forall x>0, y>0, \tag{4.6}$$

$$\tilde U(U'(x))\leqq \tilde U(y)-x[U'(x)-y]\quad \forall x>0, y>0 \tag{4.7}$$

then follow directly from (4.3), (4.5).

The monotonicity of U and $\tilde U$ guarantees that the limits

$$U(0)\triangleq\lim_{x\downarrow 0}U(x),\qquad U(\infty)\triangleq\lim_{x\to\infty}U(x),$$

$$\tilde U(0)\triangleq\lim_{y\downarrow 0}\tilde U(y),\qquad \tilde U(\infty)\triangleq\lim_{y\to\infty}\tilde U(y)$$

exist in the extended real-number system.

LEMMA 4.2. $U(0)=\tilde U(\infty)$, $\tilde U(0)=U(\infty)$.

Proof. It follows from (4.3) that $\tilde U(\infty)\leqq\lim_{y\to\infty}U(I(y))=U(0)$, as well as

$$\tilde U(\infty)\geqq\lim_{z\to\infty}\left[U\left(\frac{\varepsilon}{z}\right)-\varepsilon\right]=U(0)-\varepsilon\quad \forall\varepsilon>0,$$

whence $\tilde U(\infty)=U(0)$. Similarly, it follows from (4.5) that $U(\infty)\geqq\lim_{x\to\infty}\tilde U(U'(x))=\tilde U(0)$, as well as

$$U(\infty)\leqq\lim_{\xi\to\infty}\left[\tilde U\left(\frac{\varepsilon}{\xi}\right)+\varepsilon\right]=\tilde U(0)+\varepsilon\quad \forall\varepsilon>0,$$

whence $U(\infty)=\tilde U(0)$. □

We will sometimes impose the following condition on the utility function U.

Assumption 4.3. For some $\alpha \in (0,1)$, $\gamma \in (1,\infty)$, we have

$$\alpha U'(x) \geqq U'(\gamma x) \quad \forall x \in (0,\infty). \tag{4.8}$$

Quite obviously, Assumption 4.3 is satisfied by the utility functions $U(x) = \log x$ and $U(x) = x^\delta/\delta$, with $\delta < 1$, $\delta \neq 0$. Upon replacing x by $I(y)$ in (4.8), and then applying I to both sides of the resulting inequality, we see that Assumption 4.3 is equivalent to the condition

$$I(\alpha y) \leqq \gamma I(y) \quad \forall y \in (0,\infty), \tag*{(4.8)$'$}$$

for some $\alpha \in (0,1)$, $\gamma \in (1,\infty)$. By iterating (4.8)$'$, we obtain the apparently stronger statement

$$\forall \alpha \in (0,1), \quad \exists \gamma \in (1,\infty), \quad \text{such that} \quad I(\alpha y) \leqq \gamma I(y) \quad \forall y \in (0,\infty). \tag{4.9}$$

5. The utility maximization problem. For a given utility function U and a given initial capital $x > 0$, the stochastic control problem considered in this paper is the following: *to maximize the expected utility from terminal wealth* $EU(X^{x,\pi}(T))$, over the class $\mathscr{A}(x)$ of portfolio processes π that satisfy

$$E(U(X^{x,\pi}(T)))^- < \infty, \tag{5.1}$$

where $a^- \triangleq \max\{-a, 0\}$. The value function of this problem is denoted by

$$V(x) \triangleq \sup_{\pi \in \mathscr{A}(x)} EU(X^{x,\pi}(T)). \tag{5.2}$$

To be sure this problem is meaningful, we make the following assumption throughout.

Standing Assumption 5.1. $V(x) < \infty$, *for all* $x \in (0,\infty)$.

A portfolio process $\pi \in \mathscr{A}(x)$ which attains the supremum in (5.2) is called *optimal*. In §§ 9, 11, and 12 we provide conditions that ensure the existence of optimal portfolios, as well as various characterizations of optimality. Some examples, in which optimal portfolios can be computed explicitly, appear in § 10.

Remark 5.2. In the case of a market model for which the relative risk process $\theta(\cdot)$ of (2.4) satisfies the condition

$$\int_0^T \|\theta(t)\|^2 \, dt \leqq C \quad \text{a.s.} \tag{5.3}$$

for some given real constant $C > 0$, a sufficient condition for Standing Assumption 5.1 is

$$U(x) \leqq k_1 + k_2 x^\delta \quad \forall x \in (0,\infty) \tag{5.4}$$

for some $k_1 > 0$, $k_2 > 0$, $\delta \in (0,1)$.

Indeed, the process Z_0 of (2.6) is then a martingale, and $W_0(\cdot)$ is a Brownian motion under the probability measure $P_0(A) = E[Z_0(T)1_A]$ on $\mathscr{F}_T$ (the Girsanov theorem; cf. Karatzas and Shreve [14, § 3.5]). For any $p \in (1, 1/\delta]$ and suitable constants $c_1 > 0$, $c_2 > 0$, we have

$$U_+^p(x) \leqq c_1 + c_2 x^{\delta p} \quad \forall x \in (0,\infty) \tag{5.5}$$

from (5.4), where $U_+(x) \triangleq \max\{U(x), 0\}$. Also, we have

$$\begin{aligned}(X^{x,\pi}(T))^{\delta p} &= x^{\delta p} \cdot \exp\left[\delta p \int_0^T r(s)\,ds - \frac{\delta p(1-\delta p)}{2}\int_0^T \|\sigma^*(s)\pi(s)\|^2\,ds\right] \\ &\quad \cdot \exp\left[\delta p \int_0^T \pi^*(s)\sigma(s)\,dW_0(s) - \frac{\delta^2 p^2}{2}\int_0^T \|\sigma^*(s)\pi(s)\|^2\,ds\right] \\ &\leqq (e^L x)^{\delta p} \cdot \exp\left[\delta p \int_0^T \pi^*(s)\sigma(s)\,dW_0(s)\right. \\ &\quad \left. -\frac{1}{2}\delta^2 p^2 \int_0^T \|\sigma^*(s)\pi(s)\|^2\,ds\right]\end{aligned} \tag{5.6}$$

from (3.3), and

$$\begin{aligned}E_0 Z^{-q}(t) &= E_0\left[\exp\left\{q\int_0^T \theta^*(s)\,dW_0(s) - \frac{q^2}{2}\int_0^T \|\theta(s)\|^2\,ds\right\}\right. \\ &\qquad\qquad \left. \cdot \exp\left\{\frac{q(q-1)}{2}\int_0^T \|\theta(s)\|^2\,ds\right\}\right] \\ &\leqq \exp\left\{\frac{q(q-1)}{2}C\right\}\end{aligned} \tag{5.7}$$

from (2.6) with $1/p + 1/q = 1$. Now (5.5)-(5.7), in conjunction with the Hölder inequality, give

$$\begin{aligned}EU(X^{x,\pi}(T)) &= E_0[Z_0^{-1}(T)U(X^{x,\pi}(T))] \\ &\leqq (E_0 Z_0^{-q}(T))^{1/q}(E_0 U_+^p(X^{x,\pi}(T)))^{1/p} \\ &\leqq \exp\left\{\frac{(q-1)}{2}C\right\}(c_1 + c_2(e^L x)^{\delta p})^{1/p} < \infty\end{aligned}$$

for every $\pi \in \mathcal{A}(x)$, justifying Standing Assumption 5.1.

6. The complete market solution. The utility maximization problem of § 5 admits a simple solution in the case $m = d$ of a complete market; this solution was derived by Karatzas, Lehoczky, and Shreve [13] and independently by Cox and Huang [2], [3]. In this section we briefly review the pertinent results, both for easy reference and for later usage in the treatment of the incomplete market case.

For the purposes of this discussion, we need the following assumption.

Assumption 6.1. $E[\beta(T)Z_0(T)I(y\beta(T)Z_0(T))] < \infty$, for all $y \in (0, \infty)$.

Under it, the function $\mathcal{X}_0 : (0, \infty) \to (0, \infty)$ defined by

$$\mathcal{X}_0(y) \triangleq E[\beta(T)Z_0(T)I(y\beta(T)Z_0(T))], \qquad 0 < y < \infty \tag{6.1}$$

inherits from I the property of being a continuous, strictly decreasing mapping of $(0, \infty)$ onto itself, and so $\mathcal{X}_0$ has a (continuous, strictly decreasing) inverse $\mathcal{Y}_0$ from $(0, \infty)$ onto itself. We define

$$\xi_0^x \triangleq I(\mathcal{Y}_0(x)\beta(T)Z_0(T)). \tag{6.2}$$

Note that for every portfolio process $\pi \in \mathcal{A}(x)$, the supermartingale $\beta Z_0 X^{x,\pi}$ of (3.4) satisfies

$$E[\beta(T)Z_0(T)X^{x,\pi}(T)] \leqq x. \tag{6.3}$$

LEMMA 6.2. *The random variable* ξ_0^x *satisfies*

$$E[\beta(T)Z_0(T)\xi_0^x] = x, \tag{6.4}$$

$$E(U(\xi_0^x))^- < \infty, \tag{6.5}$$

and for every portfolio $\pi \in \mathscr{A}(x)$, *we have*

$$EU(X^{x,\pi}(T)) \leqq EU(\xi_0^x). \tag{6.6}$$

Proof. Equation (6.4) follows directly from the definitions of ξ_0^x and $\mathscr{Y}_0$. From (4.6) we have

$$\begin{aligned} U(\xi_0^x) &\geqq U(1) + \mathscr{Y}_0(x)\beta(T)Z_0(T)[\xi_0^x - 1] \\ &\geqq -|U(1)| - \mathscr{Y}_0(x)\beta(T)Z_0(T). \end{aligned} \tag{6.7}$$

But β is nonnegative and bounded almost surely and Z_0 is a nonnegative local martingale, thus a supermartingale. Therefore $E[\beta(T)Z_0(T)] < \infty$, and (6.5) follows. Now let π be a portfolio satisfying (5.1). From (4.6), (6.3), and (6.4) we have

$$\begin{aligned} EU(\xi_0^x) &\geqq E\{U(X^{x,\pi}(T)) + \mathscr{Y}_0(x)\beta(T)Z_0(T)[\xi_0^x - X^{x,\pi}(T)]\} \\ &\geqq EU(X^{x,\pi}(T)). \end{aligned}$$

□

From Lemma 6.2 it develops that if there exists a portfolio $\hat{\pi}$ such that $\xi_0^x = X^{x,\hat{\pi}}(T)$, then $\hat{\pi}$ is optimal. So far we have not used the assumption of market completeness; this assumption is used only in the *construction of the portfolio* $\hat{\pi}$ which finances ξ_0^x, a question that we now broach.

We begin with the positive martingale

$$M(t) \triangleq E[\beta(T)Z_0(T)\xi_0^x | \mathscr{F}_t]. \tag{6.8}$$

Being adapted to the Brownian filtration $\{\mathscr{F}_t\}$, M admits the stochastic integral representation

$$M(t) = x + \int_0^t \psi^*(s)\, dW(s) \tag{6.9}$$

for some $\{\mathscr{F}_t\}$-adapted process ψ satisfying $\int_0^T \|\psi(s)\|^2\, ds < \infty$ almost surely (e.g., Karatzas and Shreve [14, p. 184]). According to Itô's lemma

$$d\left(\frac{M(t)}{Z_0(t)}\right) = \frac{1}{Z_0(t)}(\psi(t) + M(t)\theta(t))^*\, dW_0(t),$$

and thus

$$\beta(T)\xi_0^x = \frac{M(T)}{Z_0(T)} = x + \int_0^T \frac{1}{Z_0(t)}(\psi(t) + M(t)\theta(t))^*\, dW_0(t).$$

We define

$$\hat{X}(t) \triangleq \frac{M(t)}{\beta(t)Z_0(t)} = \frac{1}{\beta(t)}\left[x + \int_0^t \frac{1}{Z_0(s)}(\psi(s) + M(s)\theta(s))^*\, dW_0(s)\right], \tag{6.10}$$

$$\hat{\pi}(t) \triangleq \frac{1}{\beta(t)Z_0(t)\hat{X}(t)}(\sigma^*(t))^{-1}(\psi(t) + M(t)\theta(t)), \tag{6.11}$$

and verify that $\hat{X}(0) = x$, $\hat{X}(T) = \xi_0^x$ as well as $d(\beta(t)\hat{X}(t)) = \beta(t)\hat{X}(t)\hat{\pi}^*(t)\sigma(t)\, dW_0(t)$ hold. A comparison with (3.3) shows that $\hat{X}(\cdot)$ is the wealth process corresponding to the portfolio $\hat{\pi}$: $\hat{X}(\cdot) \equiv X^{x,\hat{\pi}}(\cdot)$.

We have proved the following result.

THEOREM 6.3. *Let an initial wealth $x > 0$ be given. In a complete market* ($d = m$) *under Assumption* 6.1, *the portfolio $\hat{\pi}$ given by* (6.11) *is optimal. The resulting optimal terminal wealth is given by* (6.2).

Example 6.4 (*Logarithmic utility function*). Suppose $U(x) = \log x$. Then $\mathscr{X}_0(y) = 1/y$, $\mathscr{Y}_0(x) = 1/x$ and

$$\xi_0^x = x \exp\left\{\int_0^T \left(r(t) + \frac{1}{2}\|\theta(t)\|^2\right) dt + \int_0^T \theta^*(t)\, dW(t)\right\}. \tag{6.12}$$

Let $\hat{\pi}$ be given by

$$\hat{\pi}(t) \triangleq (\sigma(t)\sigma^*(t))^{-1}[b(t) - r(t)\mathbf{1}_m]. \tag{6.13}$$

From (3.4) we have $X^{x,\hat{\pi}}(T) = x/\beta(T)Z_0(T) = \xi_0^x$, so $\hat{\pi}$ is optimal and

$$V(x) = E[\log X^{x,\hat{\pi}}(T)] = \log x + E\int_0^T \left(r(t) + \frac{1}{2}\|\theta(t)\|^2\right) dt, \tag{6.14}$$

provided that this last expectation is finite (cf. Karatzas [12, §§ 9.3, 9.6]).

Example 6.5 (*Power utility function and deterministic model coefficients*). Suppose that $U(x) = x^\delta/\delta$, where $\delta < 1$, $\delta \neq 0$, and suppose that the processes r and θ are deterministic. Then $\exp\{(\delta/(1-\delta)) \int_0^t \theta^*(s)\, dW(s) - (\delta^2/2(1-\delta)^2) \int_0^t \|\theta(s)\|^2\, ds\}$ is a martingale with expectation equal to one (Karatzas and Shreve [14, Cor. 5.13, p. 199]), and from (6.1)

$$\begin{aligned}\mathscr{X}_0(y) &= y^{1/(\delta-1)} \exp\left\{\frac{\delta}{1-\delta}\int_0^T \left(r(s) + \frac{1}{2}\|\theta(s)\|^2\right) ds \cdot E \exp\left\{\frac{\delta}{1-\delta}\int_0^T \theta^*(s)\, dW(s)\right\}\right.\\ &= y^{1/(\delta-1)} \exp\left\{\frac{\delta}{1-\delta}\int_0^T m(s)\, ds\right\},\end{aligned}$$

where

$$m(t) \triangleq r(t) + \frac{1}{2(1-\delta)}\|\theta(t)\|^2. \tag{6.15}$$

It follows that $\mathscr{Y}_0(x) = x^{\delta-1} \exp\{\delta \int_0^T m(s)\, ds\}$, and

$$\xi_0^x = x \exp\left\{\int_0^T \left(r(t) + \frac{1-2\delta}{2(1-\delta)^2}\|\theta(t)\|^2\right) dt + \frac{1}{1-\delta}\int_0^T \theta^*(t)\, dW(t)\right\}. \tag{6.16}$$

Taking

$$\hat{\pi}(t) \triangleq \frac{1}{1-\delta}(\sigma(t)\sigma^*(t))^{-1}[b(t) - r(t)\mathbf{1}_m] \tag{6.17}$$

in (3.4), we obtain

$$\beta(t)Z_0(t)X^{x,\hat{\pi}}(t) = x \exp\left\{-\frac{\delta^2}{2(1-\delta)^2}\int_0^t \|\theta(s)\|^2\, ds + \frac{\delta}{1-\delta}\int_0^t \theta^*(s)\, dW(s)\right\},$$

from which follows $X^{x,\hat{\pi}}(T) = \xi_0^x$ and thereby the optimality of $\hat{\pi}$.

7. Fictitious completions of an incomplete market. The utility maximization problem of § 5 for an *incomplete market* ($d > m$) will be studied by the method of "fictitious completion." We will perform, in other words, the thought experiment of introducing $d - m$ additional stocks driven by the d-dimensional Brownian motion W, thus creating a fictitious complete market in which the utility maximization problem can be solved as in § 6. We will then try to determine appreciation rates for these additional stocks, so that the optimal portfolio in the resulting complete market *does not invest in the additional stocks at all,* i.e., is in $\mathscr{A}(x)$.

Following this program, we introduce an $\{\mathscr{F}_t\}$-progressively measurable, uniformly bounded, $(d-m)\times d$ matrix-valued process $\rho(t)$ whose rows, thought of as vectors in $\mathbb{R}^d$, are orthonormal and in the kernel of $\sigma(t)$, i.e., $\sigma(t)\rho^*(t)=0$. We also introduce an $\{\mathscr{F}_t\}$-progressively measurable, $(d-m)$-dimensional vector process $\mathscr{a}$ satisfying

$$\int_0^T \|\mathscr{a}(t)\|\,dt<\infty \quad \text{a.s.} \tag{7.1}$$

We create fictitious stocks with prices $S_i(t)$ governed by

$$dS_i(t)=S_i(t)\left[\mathscr{a}_i(t)\,dt+\sum_{j=1}^{d}\rho_{ij}(t)\,dW_j\,(t)\right], \qquad i=1,\cdots,d-m. \tag{7.2}$$

The matrix-valued process ρ will be held fixed throughout the remainder of the paper, but the process $\mathscr{a}$ will be considered as a parameter.

For the augmented stock appreciation rate vector $\tilde{b}\triangleq\left[\begin{smallmatrix} b \\ \mathscr{a}\end{smallmatrix}\right]$ and the augmented volatility matrix $\tilde{\sigma}\triangleq\left[\begin{smallmatrix} \sigma \\ \rho\end{smallmatrix}\right]$ we can define an augmented *relative risk* process

$$\tilde{\theta}(t)\triangleq\tilde{\sigma}^*(t)(\tilde{\sigma}(t)\tilde{\sigma}^*(t))^{-1}[\tilde{b}(t)-r(t)\mathbf{1}_m]=\theta(t)+\nu(t) \tag{7.3}$$

by analogy with (2.3), where

$$\nu(t)\triangleq\rho^*(t)[\mathscr{a}(t)-r(t)\mathbf{1}_{d-m}]. \tag{7.4}$$

Note that $\theta^*(t)\nu(t)=0$, and thus $\|\tilde{\theta}(t)\|^2=\|\theta(t)\|^2+\|\nu(t)\|^2$. It will be assumed that

$$\int_0^T \|\nu(t)\|^2\,dt<\infty \tag{7.5}$$

holds almost surely, so that (by analogy with (2.6) and (6.1)) we may define the exponential local martingale

$$\begin{aligned} Z_\nu(t)&\triangleq\exp\left\{-\int_0^t(\theta^*(s)+\nu^*(s))\,dW\,(s)-\frac{1}{2}\int_0^t(\|\theta(s)\|^2+\|\nu(s)\|^2)\,ds\right\}\\ &=1-\int_0^t Z_\nu(s)(\theta(s)+\nu(s))^*\,dW\,(s)\end{aligned} \tag{7.6}$$

and the function

$$\mathscr{X}_\nu(y)\triangleq E[\beta(T)Z_\nu(T)I(y\beta(T)Z_\nu(T))], \qquad 0<y<\infty. \tag{7.7}$$

If the condition

$$\mathscr{X}_\nu(y)<\infty \quad \forall y\in(0,\infty) \tag{7.8}$$

prevails, we may define $\mathscr{Y}_\nu$ to be the inverse of $\mathscr{X}_\nu$ and set

$$\xi_\nu^x\triangleq I(\mathscr{Y}_\nu(x)\beta(T)Z_\nu(T)) \tag{7.9}$$

by analogy with (6.2).

Remark 7.1. If the fictitious stocks introduced in this section were really available, then $EU(\xi_\nu^x)$ would be the maximal expected utility of final wealth (Theorem 6.3). Since these stocks are *not* available, we have

$$V(x)\triangleq\sup_{\pi\in\mathscr{A}(x)}EU(X^{x,\pi}(T))\leqq EU(\xi_\nu^x), \tag{7.10}$$

and equality holds if there exists a portfolio process $\pi\in\mathscr{A}(x)$ such that

$$X^{x,\pi}(T)=\xi_\nu^x \quad \text{a.s.}, \tag{7.11}$$

i.e., if the terminal wealth ξ_ν^x can be financed without investment in the fictitious stocks. In light of (7.10), such a π would be optimal for the problem of utility maximization in the incomplete market. In § 9 we shall discuss properties which π and ν must have in order to be related by (7.11).

8. A family of exponential local martingales. Let us denote by $S[0, T]$ the class of $\{\mathscr{F}_t\}$-adapted, $\mathbb{R}^d$-valued processes ψ satisfying

$$\int_0^T \|\psi(t)\|^2 \, dt < \infty \tag{8.1}$$

almost surely, and decompose $S[0, T]$ into the orthogonal subspaces

$$K(\sigma) \triangleq \{\nu \in S[0, T];\ \sigma(t)\nu(t) = 0, \quad \forall t \in [0, T], \text{a.s.}\}, \tag{8.2}$$

$$K^\perp(\sigma) \triangleq \{\varphi \in S[0, T];\ \varphi(t) \in \text{Range}\,(\sigma^*(t)), \forall t \in [0, T], \text{a.s.}\}. \tag{8.3}$$

Remark 8.1. The process θ of (2.3) belongs to $K^\perp(\sigma)$, whereas the process ν of (7.4) belongs to $K(\sigma)$. On the other hand, if $\nu \in K(\sigma)$ is given, then (7.4) can be solved for the appreciation rate vector α of the fictitious stocks, by taking this vector equal to

$$\alpha_\nu(t) \triangleq \rho(t)\nu(t) + r(t)\mathbf{1}_{d-m}. \tag{8.4}$$

Thus, the class $K(\sigma)$ provides a parameter space for fictitious completions of the incomplete market.

We will denote by $\mathfrak{M}_\nu$ the fictitious completion of the financial market by the additional stocks of (7.2), with $\rho(\cdot)$ fixed and $\alpha(\cdot) \equiv \alpha_\nu(\cdot)$, $\nu \in K(\sigma)$.

The associated family of exponential local martingales $\{Z_\nu\}_{\nu \in K(\sigma)}$, given by (7.6), will play a fundamental role in what follows.

LEMMA 8.2. *Consider the discounted stock price processes*

$$Q_i(t) \triangleq \beta(t)P_i(t), \qquad i = 1, \cdots, m.$$

Then for every $\nu \in K(\sigma)$, the processes $Z_\nu Q_i$ are local martingales under P.

Proof. It is seen from (2.2), (2.4) that

$$dQ_i(t) = Q_i(t)[(b_i(t) - r(t))\,dt + \sigma_i(t)\,dW(t)],$$

where $\sigma_i(t)$ is the ith row vector of the matrix $\sigma(t)$. It follows from this, (7.6), Itô's rule, and $\sigma(t)\nu(t) = 0$, that

$$d(Z_\nu(t)Q_i(t)) = Z_\nu(t)Q_i(t)[\sigma_i(t) - (\theta(t) + \nu(t))^*]\,dW(t). \qquad \square$$

PROPOSITION 8.3. *For any given $\pi \in \mathscr{A}(x)$, $\beta Z_\nu X^{x,\pi}$ is a local martingale under P for every $\nu \in K(\sigma)$; in particular,*

$$E[\beta(T)Z_\nu(T)X^{x,\pi}(T)] \leqq x \quad \forall \nu \in K(\sigma). \tag{8.5}$$

Proof. From (3.3), (2.5), and (7.6) follows the analogue

$$\beta(t)Z_\nu(t)X(t) = x + \int_0^t \beta(s)Z_\nu(s)X(s)[\sigma^*(s)\pi(s) - (\theta(s) + \nu(s))]^*\,dW(s) \tag{8.6}$$

of (3.4) for the process $X \equiv X^{x,\pi}$. This representation shows that $\beta Z_\nu X^{x,\pi}$ is a positive local martingale, hence a supermartingale, and (8.5) follows. $\square$

Remark 8.4. Suppose that π is a portfolio process, and that X is a continuous, $\{\mathscr{F}_t\}$-adapted process which satisfies (8.6) almost surely, *for some* $\nu \in K(\sigma)$. Then X is the wealth process corresponding to the initial endowment x and the portfolio process π, i.e., $X = X^{x,\pi}$. Indeed, apply Itô's rule to the product of the processes $\beta Z_\nu X$ and Λ_ν, where $\Lambda_\nu = Z_\nu^{-1}$ is easily seen from (7.6) to satisfy

$$d\Lambda_\nu(t) = \Lambda_\nu(t)[(\theta(t)+\nu(t))^* \, dW(t) + (\|\theta(t)\|^2 + \|\nu(t)\|^2)\, dt],$$

and obtain (3.3).

The following result provides a kind of "converse" to Proposition 8.3.

THEOREM 8.5. *Consider a positive, $\mathcal{F}_T$-measurable random variable B, for which there exists a process $\lambda \in K(\sigma)$ with*

$$E[\beta(T)Z_\nu(T)B] \leqq x = E[\beta(T)Z_\lambda(T)B] \quad \forall \nu \in K(\sigma). \tag{8.7}$$

Then there exists a portfolio $\pi \in \mathcal{A}(x)$, such that $X^{x,\pi}(T) = B$, almost surely.

Proof. Define a positive, $\{\mathcal{F}_t\}$-adapted process X via

$$\beta(t)Z_\lambda(t)X(t) = M(t) \triangleq E[\beta(T)Z_\lambda(T)B|\mathcal{F}_t], \qquad 0 \leqq t \leqq T. \tag{8.8}$$

Certainly $X(0) = x$, $X(T) = B$ almost surely, and the positive martingale M in (8.8) has $M(0) = x$. From the martingale representation theorem (Karatzas and Shreve [14, Problem 3.4.16, p. 184]), $M(t) = x + \int_0^t \varphi(s)\, dW(s)$ for some $\{\mathcal{F}_t\}$-adapted process φ satisfying $\int_0^T \|\varphi(t)\|^2\, dt < \infty$ almost surely. Since M is continuous and $M(t) > 0$ for all $t \in [0, T]$, we may define $\psi \in S[0, T]$ by $\psi(t) = -\varphi(t)/M(t)$. Then

$$\begin{aligned} M(t) &= x \exp\left\{ -\int_0^t \psi^*(s)\, dW(s) - \frac{1}{2}\int_0^t \|\psi(s)\|^2\, ds \right\} \\ &= x - \int_0^t M(s)\psi^*(s)\, dW(s), \qquad 0 \leqq t \leqq T. \end{aligned} \tag{8.9}$$

Decomposing ψ as $\psi = \psi_1 + \psi_2$ with $\psi_1 \in K^\perp(\sigma)$, $\psi_2 \in K(\sigma)$ and comparing (8.8), (8.9) with (8.6), it transpires that proving the theorem amounts to finding a portfolio π such that

$$-M(t)(\psi_1(t)+\psi_2(t)) = \beta(t)Z_\lambda(t)X(t)[\sigma^*(t)\pi(t) - (\theta(t)+\lambda(t))]. \tag{8.10}$$

This will certainly be possible, provided that

$$\psi_2(t) = \lambda(t) \quad dt \times dP \text{ a.e. on } [0, T] \times \Omega, \tag{8.11}$$

because we can take then π to satisfy $\sigma^*\pi = \theta - \psi_1 \in K^\perp(\sigma)$. Consequently, *we have to show that* (8.7) *implies* (8.11).

To this end, consider an arbitrary but fixed $\nu \in K(\sigma)$ and introduce the sequence of stopping times $\{\tau_n\}_{n=1}^\infty$ given by

$$\begin{aligned} \tau_n \triangleq T \wedge \inf\Big\{ t \in [0, T];\ M(t) \geqq n, \text{ or } &\int_0^t (\|\psi_1(s)\|^2 + \|\psi_2(s)\|^2 + \|\lambda(s)\|^2)\, ds \geqq n, \\ \text{or } \int_0^t \|\nu(s)\|^2\, ds \geqq n, &\text{ or } \left|\int_0^t \nu^*(s)\, dW(s)\right| \geqq n \Big\} \end{aligned} \tag{8.12}$$

for every $n \geqq 1$. Obviously, $\lim_{n\to\infty} \tau_n = T$ almost surely, and we denote $\nu_n(t) \triangleq \nu(t)1_{[0,\tau_n]}(t)$. Clearly, $\lambda + \varepsilon\nu_n \in K(\sigma)$ and

$$Z_{\lambda+\varepsilon\nu_n}(t) = Z_\lambda(t) \exp\left\{ -\varepsilon \int_0^{t\wedge\tau_n} \nu^*(s)(dW(s) + \lambda(s)\, ds) - \frac{\varepsilon^2}{2}\int_0^{t\wedge\tau_n} \|\nu(s)\|^2\, ds \right\}, \tag{8.13}$$

for every $\varepsilon \in (-1, 1)$, $n \geqq 1$. On the other hand, the definition of τ_n in (8.12) gives

$$e^{-3n|\varepsilon|} \leqq \frac{Z_{\lambda+\varepsilon\nu_n}(T)}{Z_\lambda(T)} \leqq e^{3n|\varepsilon|}, \qquad -1 < \varepsilon < 1. \tag{8.14}$$

It follows then quite easily (from (8.12)-(8.14) and the dominated convergence theorem) that (8.7) implies

$$0=\frac{\partial}{\partial\varepsilon}E\left[\beta(T)Z_{\lambda+\varepsilon\nu_n}(T)B\right]\bigg|_{\varepsilon=0}=E\left[\beta(T)\cdot\frac{\partial}{\partial\varepsilon}Z_{\lambda+\varepsilon\nu_n}(T)\bigg|_{\varepsilon=0}\cdot B\right] \tag{8.15}$$
$$=-E\left[\beta(T)Z_\lambda(T)B\int_0^{\tau_n}\nu^*(s)(dW(s)+\lambda(s)\,ds)\right],$$

or equivalently, in the notation of (8.8):

$$E\left[M(\tau_n)\int_0^{\tau_n}\nu^*(s)(dW(s)+\lambda(s)\,ds)\right]=0\quad\forall n\geqq 1. \tag{8.16}$$

Now Itô's rule, in conjunction with (8.9), gives

$$M(\tau_n)\int_0^{\tau_n}\nu^*(s)(dW(s)+\lambda(s)\,ds)$$
$$=\int_0^{\tau_n}M(t)\nu^*(t)(\lambda(t)-\psi_2(t))\,dt+\int_0^{\tau_n}M(t)\nu^*(t)\,dW(t) \tag{8.17}$$
$$-\int_0^{\tau_n}M(t)\left\{\int_0^t\nu^*(s)(dW(s)+\lambda(s)\,ds)\right\}(\psi_1(t)+\psi_2(t))^*\,dW(t).$$

From the definition of τ_n in (8.12) we see that the expectations of the two stochastic integrals in (8.17) are equal to zero. Substituting back into (8.16), we obtain

$$E\int_0^{\tau_n}M(t)\nu^*(t)(\lambda(t)-\psi_2(t))\,dt=0\quad\forall n\geqq 1. \tag{8.18}$$

The arbitrariness of $\nu\in K(\sigma)$ in (8.18) leads to (8.11). □

9. Equivalent optimality conditions in an incomplete market. The conclusions of § 7 were predicated on the assumption

$$\mathcal{X}_\nu(y)<\infty\quad\forall y\in(0,\infty), \tag{7.8}$$

but this condition often will not hold for all $\nu\in K(\sigma)$ (cf. § 13 (Appendix)). Accordingly, we restrict ourselves to the class

$$K_1(\sigma)\triangleq\{\nu\in K(\sigma);\ \nu\text{ satisfies (7.8)}\} \tag{9.1}$$

in what follows.

Remark 9.1. If Assumption 4.3 holds, and $\nu\in K(\sigma)$ satisfies $\mathcal{X}_\nu(y)<\infty$ for *some* $y\in(0,\infty)$, then $\nu\in K_1(\sigma)$. This can be verified easily, using (4.9).

For a fixed initial capital $x>0$, let $\hat\pi\in\mathcal{A}(x)$ be given, and consider the statement that $\hat\pi$ is optimal for the incomplete market maximization problem of § 5:

(A) OPTIMALITY OF $\hat\pi$. $EU(X^{x,\pi}(T))\leqq EU(X^{x,\hat\pi}(T))$, *for all* $\pi\in\mathcal{A}(x)$.

We will characterize condition (A) with the help of the following conditions (B)-(E). For a given $\lambda\in K_1(\sigma)$ recall the notation of (4.3), (7.9) and consider the following statements.

(B) FINANCIBILITY OF ξ^x_λ. *There exists a portfolio* $\hat\pi\in\mathcal{A}(x)$ *such that* $X^{x,\hat\pi}(T)\equiv\xi^x_\lambda$, *almost surely.*

(C) LEAST-FAVORABILITY OF λ. $EU(\xi^x_\lambda)\leqq EU(\xi^x_\nu)$, *for all* $\nu\in K_1(\sigma)$.

(D) DUAL OPTIMALITY OF λ. *For all* $\nu\in K_1(\sigma)$,

$$E\tilde U(\mathcal{Y}_\lambda(x)\beta(T)Z_\lambda(T))\leqq E\tilde U(\mathcal{Y}_\lambda(x)\beta(T)Z_\nu(T)).$$

(E) PARSIMONY OF λ. $E[\beta(T)Z_\nu(T)\xi^x_\lambda]\leqq x$, *for all* $\nu\in K_1(\sigma)$.

Our principal result of this section, Theorem 9.4, states that conditions (B)-(E) on λ are *equivalent* and they imply the existence of $\hat{\pi}$ satisfying (A), provided that Assumption 4.3 and $U(0)>-\infty$ hold. This latter restriction is rather severe, for it excludes the important special case of the logarithmic utility function $U(x)=\log x$. For this reason we also develop a somewhat more modest result, Theorem 9.3, which suffices for a complete treatment of the logarithmic case (Example 10.1).

But first, let us try to motivate the developments that follow by discussing the significance of conditions (B)-(E). While we do not present any proofs for the claimed equivalences in the discussion that follows, we offer some plausible arguments to the effect that conditions (A)-(E) are connected to one another.

Discussion 9.2. For any given $\lambda \in K_1(\sigma)$, ξ_λ^x is the optimal level of terminal wealth in the fictitiously completed market $\mathfrak{M}_\lambda$. When will it also be optimal in the original, incomplete market? Presumably, only when there exists a portfolio $\hat{\pi}$ *which invests in the original m stocks only* (i.e., $\hat{\pi} \in \mathcal{A}(x)$), such that $X^{x,\hat{\pi}} = \xi_\lambda^x$. In other words, condition (B) has then to hold, and condition (E) follows directly from (8.5). In particular, (E) says that the value of the contingent claim ξ_λ^x is at least as large in the fictitiously completed market $\mathfrak{M}_\lambda$ as in any other market $\mathfrak{M}_\nu$, $\nu \in K_1(\sigma)$. Note in this connection that, according to the definitions, $E[\beta(T)Z_\lambda(T)\xi_\lambda^x]=x$, for all $\lambda \in K_1(\sigma)$.

Furthermore, the terminal wealth ξ_λ^x can be financed by investing in the stocks of *any* other market $\mathfrak{M}_\nu$ (since, in fact, it can be financed by investing in the original m stocks). Thus we obtain the condition (C), which captures the "least favorable" character of λ.

Let us derive finally the condition (D), at least in the case $U(0)>-\infty$ (in which $\tilde{U}$ is bounded from below, thanks to Lemma 4.2, and thus the expectations in (D) are well defined). Indeed, by writing (4.7) with x replaced by ξ_λ^x and y replaced by $\mathcal{Y}_\lambda(x)\beta(T)Z_\nu(T)$, and taking expectations, we obtain

$$\begin{aligned} E\tilde{U}(\mathcal{Y}_\lambda(x)\beta(T)Z_\nu(T)) &\geqq E\tilde{U}(\mathcal{Y}_\lambda(x)\beta(T)Z_\lambda(T))+\mathcal{Y}_\lambda(x)\\ &\quad\cdot\{E[\beta(T)Z_\lambda(T)\xi_\lambda^x]-E[\beta(T)Z_\nu(T)\xi_\lambda^x]\}\\ &\geqq E\tilde{U}(\mathcal{Y}_\lambda(x)\beta(T)Z_\lambda(T)) \end{aligned}$$

from condition (E).

THEOREM 9.3. *Conditions* (B) *and* (E) *are equivalent, and imply* (C). *Furthermore, if* (B) *holds, then the portfolio* $\hat{\pi}$ *in* (B) *satisfies* (A).

Proof. (B)$\Rightarrow$(E) follows from Proposition 8.3.

(E)$\Rightarrow$(B) follows by letting $B\equiv\xi_\lambda^x$ in Theorem 8.5. Note that this theorem remains valid if in it $K(\sigma)$ is replaced by $K_1(\sigma)$. In order to see this, it suffices to observe that the processes $\lambda+\varepsilon\nu_n$ (appearing in (8.13)) belongs to $K_1(\sigma)$ for every $\varepsilon\in(-1,1)$, $n\geqq 1$, because from (8.14) and the fact that $\lambda \in K_1(\sigma)$:

$$\mathcal{X}_{\lambda+\varepsilon\nu_n}(y)\leqq e^{3n|\varepsilon|}\mathcal{X}_\lambda(y\,e^{-3n|\varepsilon|})<\infty \quad \forall y\in(0,\infty).$$

The last statement of the theorem follows from Remark 7.1.

(B)$\Rightarrow$(C) holds because the previous implication and (7.10) imply

$$EU(\xi_\lambda^x)=V(x)\leqq EU(\xi_\nu^x) \quad \forall \nu \in K_1(\sigma). \qquad \square$$

THEOREM 9.4. *Assume that* $U(0)>-\infty$ *holds. Then*

(i) *Conditions* (B)-(E) *are equivalent, and if* (B) *holds, then the portfolio* $\hat{\pi}$ *in* (B) *satisfies* (A);

(ii) *Conversely, if* $\hat{\pi}\in\mathcal{A}(x)$ *satisfies* (A), *then there exists a* $\lambda\in K_1(\sigma)$ *for which* (B)-(E) *hold, provided that Assumption* 4.3 *is also in force.*

Proof. In view of Theorem 9.3, we need discuss only the implications (C)⇒(D)⇒(B) and assertion (ii) under the appropriate conditions.

(C)⇒(D) For any given $y>0$ and $\nu\in K_1(\sigma)$, the convexity of $\tilde U$ yields

$$\frac{1}{|\varepsilon|}|\tilde U((y+\varepsilon)\beta(T)Z_\nu(T))-\tilde U(y\beta(T)Z_\nu(T))|\leqq\beta(T)Z_\nu(T)I\left(\frac{y}{2}\beta(T)Z_\nu(T)\right)\tag{9.2}$$

in conjunction with (4.4), for $\varepsilon>-y/2$, $\varepsilon\neq 0$. From the assumption $\nu\in K_1(\sigma)$, the random variable on the right-hand side of (9.2) has expectation equal to $\mathscr{X}_\nu(y/2)<\infty$, and the dominated convergence theorem shows that

$$\frac{d}{dy}E\tilde U(y\beta(T)Z_\nu(T))=-E[\beta(T)Z_\nu(T)I(y\beta(T)Z_\nu(T))]=-\mathscr{X}_\nu(y).\tag{9.3}$$

Therefore, for any given $x>0$, $\nu\in K_1(\sigma)$, the convex function

$$f_\nu(y)\triangleq E\tilde U(y\beta(T)Z_\nu(T))+xy,\qquad 0<y<\infty,\tag{9.4}$$

attains its minimum at $\mathscr{Y}_\nu(x)$, since $f'_\nu(y)=x-\mathscr{X}_\nu(y)$. But thanks to (C) and (4.3), we now have for any $y>0$ that

$$\begin{aligned}f_\nu(y)&\geqq f_\nu(\mathscr{Y}_\nu(x))=E[\tilde U(\mathscr{Y}_\nu(x)\beta(T)Z_\nu(T))\\&\quad+\mathscr{Y}_\nu(x)\beta(T)Z_\nu(T)\cdot I(\mathscr{Y}_\nu(x)\beta(T)Z_\nu(T))]\\&=EU(I(\mathscr{Y}_\nu(x)\beta(T)Z_\nu(T)))=EU(\xi^x_\nu)\geqq EU(\xi^x_\lambda)\\&=\cdots=f_\lambda(\mathscr{Y}_\lambda(x))\quad\forall\nu\in K_1(\sigma)\end{aligned}\tag{9.5}$$

and thus,

$$\begin{aligned}E\tilde U(\mathscr{Y}_\lambda(x)\beta(T)Z_\lambda(T))&=E[U(\xi^x_\lambda)-\mathscr{Y}_\lambda(x)\beta(T)Z_\lambda(T)\xi^x_\lambda]\\&=f_\lambda(\mathscr{Y}_\lambda(x))-x\mathscr{Y}_\lambda(x)\leqq f_\nu(\mathscr{Y}_\lambda(x))-x\mathscr{Y}_\lambda(x)\\&=E\tilde U(\mathscr{Y}_\lambda(x)\beta(T)Z_\nu(T)).\end{aligned}$$

(D)⇒(B) Repeat the proof of Theorem 8.5 up to (8.14), with $K(\sigma)$ replaced by $K_1(\sigma)$, (8.7) by (D), and B by ξ^x_λ. Everything then boils down to showing that the analogue

$$E\left[\beta(T)Z_\lambda(T)\xi^x_\lambda\int_0^{\tau_n}\nu^*(s)(dW(s)+\lambda(s)\,ds)\right]=0\tag{9.6}$$

of (8.15) can be obtained from the consequence of (D)

$$\frac{\partial}{\partial\varepsilon}E[\tilde U(\mathscr{Y}_\lambda(x)\beta(T)Z_{\lambda+\varepsilon\nu_n}(T))]|_{\varepsilon=0}=0,\tag{9.7}$$

since $\lambda+\varepsilon\nu_n\in K_1(\sigma)$ for every $\varepsilon\in(-1,1)$, $n\geqq 1$ (recall the argument in the proof of implication (E)⇒(B) in Theorem 9.3). Indeed, (9.6) follows formally from (9.7) by differentiating inside the expectation sign, and using (4.4), (7.9), (8.13).

For a rigorous justification, recall (8.12) and use the convexity of $\tilde U$ to obtain, for any given $y>0$:

$$\begin{aligned}&|\tilde U(y\beta(T)Z_{\lambda+\varepsilon\nu_n}(T))-\tilde U(y\beta(T)Z_\lambda(T))|\\&\quad\leqq y\beta(T)I(y\beta(T)\min\{Z_\lambda(T),Z_{\lambda+\varepsilon\nu_n}(T)\})\,|Z_{\lambda+\varepsilon\nu_n}(T)-Z_\lambda(T)|\\&\quad\leqq y\beta(T)(e^{3n|\varepsilon|}-1)Z_\lambda(T)I(y\beta(T)\,e^{-3n}Z_\lambda(T))\\&\quad\leqq K_n|\varepsilon|\cdot y\beta(T)Z_\lambda(T)I(y\beta(T)\,e^{-3n}Z_\lambda(T)),\end{aligned}\tag{9.8}$$

where $K_n \triangleq \sup_{0<\varepsilon<1}(e^{3n\varepsilon}-1)/\varepsilon$. The expectation of the right-hand side of (9.8) is equal to $yK_n|\varepsilon|$ times $E[\beta(T)Z_\lambda(T)I(ye^{-3n}\beta(T)Z_\lambda(T)] = \mathscr{X}_\lambda(ye^{-3n})$, a finite quantity by the assumption $\lambda \in K_l(\sigma)$.

On the other hand, the mean-value theorem implies that for each $\varepsilon \in (-1, 1)\backslash\{0\}$ there is a random variable γ_ε with values in $[0, 1]$, such that

$$\begin{aligned}
&\frac{1}{\varepsilon}[\tilde{U}(y\beta(T)Z_{\lambda+\varepsilon\nu_n}(T)) - \tilde{U}(y\beta(T)Z_\lambda(T))]\\
&\quad = y\beta(T)\frac{Z_{\lambda+\varepsilon\nu_n}(T)-Z_\lambda(T)}{\varepsilon}\cdot(\tilde{U}'(y\beta(T)\{Z_\lambda(T)+\gamma_\varepsilon(Z_{\lambda+\varepsilon\nu_n}(T)-Z_\lambda(T)\}))\\
&\quad = -I(y\beta(T)\{Z_\lambda(T)+\gamma_\varepsilon(Z_{\lambda+\varepsilon\nu_n}(T)-Z_\lambda(T))\})\cdot y\beta(T)Z_\lambda(T)\\
&\qquad \cdot\frac{1}{\varepsilon}\left[\exp\left\{-\varepsilon\int_0^{\tau_n}\nu^*(s)(dW(s)+\lambda(s)\,ds)-\frac{\varepsilon^2}{2}\int_0^{\tau_n}\|\nu(s)\|^2\,ds\right\}-1\right].
\end{aligned}$$

From this and (9.7), the conclusion (9.6) follows, thanks to the dominated convergence theorem, by letting $\varepsilon\downarrow 0$.

Proof of (ii). *Step* 1. Let $\hat{X}$ be the wealth process corresponding to the optimal portfolio $\hat{\pi}$. We have from (3.3)

$$\begin{aligned}
\beta(t)\hat{X}(t) &= x+\int_0^t \beta(s)\hat{X}(s)(\sigma^*(s)\hat{\pi}(s))^*\,dW_0(s)\\
&= x\exp\left\{\int_0^t \hat{\pi}^*(s)\sigma(s)\,dW_0(s)-\frac{1}{2}\int_0^t\|\sigma^*(s)\hat{\pi}(s)\|^2\,ds\right\}.
\end{aligned}\tag{9.9}$$

Now take a *bounded*, $\{\mathscr{F}_t\}$-progressively measurable portfolio process η with values in $\mathbb{R}^m$, and perform a small random perturbation of $\hat{\pi}$ according to

$$\pi_\varepsilon(t) \triangleq \hat{\pi}(t)+\varepsilon\eta(t)1_{\{t\leqq\tau_n\}},\tag{9.10}$$

where $-1<\varepsilon<1$, $\varepsilon\neq 0$, and

$$\begin{aligned}
\tau_n = T\wedge\inf\Big\{t\in[0, T];\ &\left|\int_0^t \eta(s)\sigma(s)\,dW_0(s)\right|\geqq n,\text{ or }\int_0^t\|\sigma^*(s)\hat{\pi}(s)\|^2\,ds\geqq n,\text{ or}\\
&\int_0^t\|\sigma^*(s)\eta(s)\|^2\,ds\geqq n,\text{ or }\int_0^t\|\theta(s)\|^2\,ds\geqq n,\text{ or }N(t)\geqq n,\text{ or}\\
&|A(t)|\geqq n,\text{ or }\int_0^t\|\psi(s)\|^2\,ds\geqq n\Big\}
\end{aligned}\tag{9.11}$$

(see (9.19), (9.20) below for the definitions of the processes N, A, and ψ). We also define the process $X_\varepsilon(\cdot)$ via

$$\begin{aligned}
\beta(t)X_\varepsilon(t) &\triangleq x\exp\left\{\int_0^t \pi_\varepsilon^*(s)\sigma(s)\,dW_0(s)-\frac{1}{2}\int_0^t\|\sigma^*(s)\pi_\varepsilon(s)\|^2\,ds\right\}\\
&= x+\int_0^t \beta(s)X_\varepsilon(s)\pi_\varepsilon^*(s)\sigma(s)\,dW_0(s),
\end{aligned}\tag{9.12}$$

and note that $X_\varepsilon(\cdot)\equiv X^{x,\pi_\varepsilon}(\cdot)$. Consequently, (A) gives

$$\frac{\partial}{\partial\varepsilon}EU(X_\varepsilon(T))|_{\varepsilon=0}=0.\tag{9.13}$$

A comparison of (9.9), (9.12) yields

$$X_\varepsilon(t)=\hat{X}(t)\exp\left\{\varepsilon\int_0^{t\wedge\tau_n}\eta^*(s)\sigma(s)\,d\hat{W}(s)-\frac{\varepsilon^2}{2}\int_0^{t\wedge\tau_n}\|\sigma^*(s)\eta(s)\|^2\,ds\right\},\tag{9.14}$$

where

$$\hat{W}(t)\triangleq W_0(t)-\int_0^t\sigma^*(s)\hat{\pi}(s)\,ds=W(t)+\int_0^t(\theta(s)-\sigma^*(s)\hat{\pi}(s))\,ds.\tag{9.15}$$

Then, at least formally, (9.13) and (9.14) lead to

$$E\left[U'(\hat{X}(T))\hat{X}(T)\int_0^{\tau_n}\eta^*(s)\sigma(s)\,d\hat{W}(s)\right]=0\quad\forall n\geqq 1.\tag{9.16}$$

Step 2. In order to justify (9.16) rigorously, observe from (9.14) and (9.11) that $e^{-3n|\varepsilon|}\leqq X_\varepsilon(T)/\hat{X}(T)\leqq e^{3n|\varepsilon|}$, almost surely, and from the concavity of U

$$\begin{aligned}\frac{1}{|\varepsilon|}|U(X_\varepsilon(T))-U(\hat{X}(T))|&\leqq U'(\min\{X_\varepsilon(T),\hat{X}(T)\})\left|\frac{X_\varepsilon(T)-\hat{X}(T)}{\varepsilon}\right|\\ &\leqq U'(e^{-3n|\varepsilon|}\hat{X}(T))\hat{X}(T)\frac{e^{3n|\varepsilon|}-1}{|\varepsilon|}\\ &\leqq[U(e^{-3n|\varepsilon|}\hat{X}(T))-U(0)]\,e^{3n}K_n\\ &\leqq e^{3n}K_n\cdot[U(\hat{X}(T))-U(0)],\end{aligned}\tag{9.17}$$

with K_n as in (9.8). The right-hand side of (9.17) has finite expectation, namely, $e^{3n}K_n(V(x)-U(0))$. On the other hand, the mean value theorem implies the existence of a random variable γ_ε with values in $[0, 1]$, such that

$$\begin{aligned}\frac{1}{\varepsilon}[U(X_\varepsilon(T))-U(\hat{X}(T))]&=\frac{1}{\varepsilon}(X_\varepsilon(T)-\hat{X}(T))\cdot U'(\hat{X}(T)+\gamma_\varepsilon\{X_\varepsilon(T)-\hat{X}(T)\})\\ &=U'(\hat{X}(T)+\gamma_\varepsilon\{X_\varepsilon(T)-\hat{X}(T)\})\hat{X}(T)\\ &\quad\cdot\frac{1}{\varepsilon}\left[\exp\left\{\varepsilon\int_0^{\tau_n}\eta^*(s)\sigma(s)\,d\hat{W}(s)\right.\right.\\ &\quad\left.\left.-\frac{\varepsilon^2}{2}\int_0^{\tau_n}\|\sigma^*(s)\eta(s)\|^2\,ds\right\}-1\right].\end{aligned}$$

It is clear now that (9.16) follows from this expansion, (9.13), and the dominated convergence theorem, by letting $\varepsilon\downarrow 0$.

Step 3. Now proving (B) amounts to finding $\lambda\in K_1(\sigma)$ such that $\hat{X}(T)=I(\mathcal{Y}_\lambda(x)\beta(T)Z_\lambda(T))$, or equivalently

$$U'(\hat{X}(T))=\mathcal{Y}_\lambda(x)\beta(T)Z_\lambda(T).\tag{9.18}$$

We will show that (9.16) leads to a "natural" candidate process $\lambda\in K(\sigma)$, which is actually in $K_1(\sigma)$ and for which (9.18) is then shown to hold (Step 4).

Consider the process

$$\begin{aligned}A(t)&\triangleq\int_0^t\eta^*(s)\sigma(s)\,d\hat{W}(s)\\ &=\int_0^t\eta^*(s)\sigma(s)\,dW(s)+\int_0^t\eta^*(s)\sigma(s)[\theta(s)-\sigma(s)\hat{\pi}(s)]\,ds,\end{aligned}\tag{9.19}$$

as well as the positive martingale

$$N(t) \triangleq E[U'(\hat{X}(T))\hat{X}(T)|\mathcal{F}_t] = y_0 + \int_0^t N(s)\psi^*(s)\,dW(s), \tag{9.20}$$

where $y_0 = EN(T)$ and ψ is some process in $S[0, T]$, constructed by the argument preceding (8.9). Using Standing Assumption 5.1 and $U(0) > -\infty$, note that $y_0 = EN(T) \leqq E[U(\hat{X}(T)) - U(0)] < \infty$. Obviously (9.16) amounts to $E[N(\tau_n)A(\tau_n)] = 0$; on the other hand, we have from (9.19) and (9.20) that

$$\begin{aligned} N(\tau_n)A(\tau_n) = \int_0^{\tau_n} & N(t)\eta^*(t)\sigma(t)[\psi(t) + \theta(t) - \sigma^*(t)\hat{\pi}(t)]\,dt \\ & + \int_0^{\tau_n} N(t)[\sigma^*(t)\eta(t) + A(t)\psi(t)]^*\,dW(t). \end{aligned}$$

From the definition of τ_n in (9.11), the stochastic integral has zero expectation, and thus $E[N(\tau_n)A(\tau_n)] = 0$ leads to

$$E\int_0^{\tau_n} N(t)\eta^*(t)\sigma(t)[\psi(t) + \theta(t) - \sigma^*(t)\hat{\pi}(t)]\,dt = 0 \quad \forall n \geqq 1 \tag{9.21}$$

for arbitrary η as described above. Because $\tau_n \nearrow T$ almost surely as $n \to \infty$, we obtain that

$$\lambda \triangleq \sigma^*\hat{\pi} - (\psi + \theta) \tag{9.22}$$

belongs to $K(\sigma)$. For this choice of λ, the exponential local martingale Z_λ of (7.6) becomes

$$\begin{aligned} Z_\lambda(t) &= \exp\left\{-\int_0^t (\theta(s) + \lambda(s))^*\,dW(s) - \frac{1}{2}\int_0^t \|\theta(s) + \lambda(s)\|^2\,ds\right\} \\ &= \exp\left\{\int_0^t (\psi(s) - \sigma^*(s)\hat{\pi}(s))^*\,dW(s) - \frac{1}{2}\int_0^t \|\psi(s) - \sigma^*(s)\hat{\pi}(s)\|^2\,ds\right\}. \end{aligned} \tag{9.23}$$

Step 4. Finally, we justify $\lambda \in K_1(\sigma)$ and (9.18). From (9.20) and (9.9) and $\sigma\lambda = 0$, it follows that

$$\begin{aligned} U'(\hat{X}(T)) &= \beta(T)\frac{N(T)}{\beta(T)\hat{X}(T)} \\ &= \beta(T)\frac{y_0}{x}\frac{\exp\{\int_0^T \psi^*(s)\,dW(s) - \frac{1}{2}\int_0^T \|\psi(s)\|^2\,ds\}}{\exp\{\int_0^T (\sigma^*(s)\hat{\pi}(s))^*\,dW_0(s) - \frac{1}{2}\int_0^T \|\sigma^*(s)\hat{\pi}(s)\|^2\,ds\}} \\ &= \frac{y_0}{x}\beta(T)Z_\lambda(T), \end{aligned} \tag{9.24}$$

thanks to (9.23) and (9.22). It remains to show that $\lambda \in K_1(\sigma)$ and $y_0 = x\mathcal{Y}_\lambda(x)$. In order to see this, apply $I(\cdot)$ to both sides of (9.24), take expectations, and use (9.24) again to obtain

$$\begin{aligned} \mathcal{X}_\lambda\left(\frac{y_0}{x}\right) &= E\left[\beta(T)Z_\lambda(T)I\left(\frac{y_0}{x}\beta(T)Z_\lambda(T)\right)\right] = E[\beta(T)Z_\lambda(T)\hat{X}(T)] \\ &= \frac{x}{y_0}E[U'(\hat{X}(T))\hat{X}(T)] = \frac{x}{y_0}EN(T) = x < \infty. \end{aligned}$$

From Remark 9.1 we have $\lambda \in K_1(\sigma)$, and $y_0 = x\mathcal{Y}_\lambda(x)$ follows. □

10. Examples in an incomplete market. In the examples of this section, we assume $m<d$ and produce the optimal portfolio $\hat{\pi}$ and the process $\lambda \in K_1(\sigma)$ satisfying conditions (B), (C), and (E). In Example 10.2, λ also satisfies (D).

Example 10.1 (*Logarithmic utility function*). Suppose $U(x)=\log x$. Then $\mathscr{X}_\nu(y)=1/y$, $\mathscr{Y}_\nu(x)=1/x$, for all $\nu \in K(\sigma)$, and $\xi_\nu^x = x/\beta(T)Z_\nu(T)$. The process $\lambda \equiv 0$ satisfies (E), because

$$E[\beta(T)Z_\nu(T)\xi_0^x]=xE\left[\exp\left\{-\int_0^T \nu^*(s)\,dw\,(s)-\frac{1}{2}\int_0^T \|\nu(s)\|^2\,ds\right\}\right] \leqq x \quad \forall \nu \in K(\sigma).$$

The last inequality follows from the fact that $\exp\{-\int_0^t \nu^*(s)\,dW\,(s)-\frac{1}{2}\int_0^t \|\nu(s)\|^2\,ds\}$, being a nonnegative local martingale, must be a supermartingale. According to Theorem 9.3, the optimal portfolio process $\hat{\pi}$ must satisfy $X^{x,\hat{\pi}}(T)=\xi_0^x$, and this $\hat{\pi}$ was determined in (6.13) of Example 6.4. The value function $V(x)$ is given by the expression (6.14), and it is finite for every $x \in (0,\infty)$ if $E\int_0^T \|\theta(t)\|^2\,dt<\infty$ (recall Standing Assumption 5.1). From (7.4) we see that $\lambda \equiv 0$ corresponds to completion of the market by stocks whose appreciation rates are equal to the interest rate. *With a logarithmic utility function, the agent will not use such stocks even for hedging purposes.*

Example 10.2 (*Power utility function and totally unhedgeable market coefficients*). Suppose $U(x)=x^\delta/\delta$, where $\delta<1$, $\delta \neq 0$. Suppose that the volatility matrix $\sigma(t)$ has the form $\sigma(t)=[\check{\sigma}(t), 0]$, where $\check{\sigma}(t)$ is an $m \times m$, nonsingular matrix for all $t \in [0, T]$, almost surely. Decompose W into $\check{W}(t)=(W_1(t),\cdots, W_m(t))^*$ and $\mathring{W}(t)=(W_{m+1}(t),\cdots, W_d(t))^*$, and let $\{\check{\mathscr{F}}_t\}$ and $\{\mathring{\mathscr{F}}_t\}$ be the augmentations under P of the (independent) filtrations generated by $\check{W}$ and $\mathring{W}$, respectively. Assume that the processes r, b, and $\check{\sigma}$ are adapted to $\{\mathring{\mathscr{F}}_t\}$, a situation we refer to as *totally unhedgeable market coefficients* because the stock prices are driven solely by $\check{W}$:

$$dP_i(t)=P_i(t)\left[b_i(t)\,dt+\sum_{j=1}^m \check{\sigma}_{ij}(t)d\check{W}_j(t)\right], \qquad i=1,\cdots, m.$$

We show that under these conditions, the portfolio process given by (6.17) is optimal. In the present context, this process is random and $\{\mathring{\mathscr{F}}_t\}$-adapted, rather than deterministic as in Example 6.5.

To verify the above assertion, we note first that $\theta^*(t)=[\check{\theta}^*(t), 0]$, where

$$\check{\theta}(t) \triangleq \check{\sigma}(t)(\sigma(t)\check{\sigma}^*(t))^{-1}[b(t)-r(t)\mathbf{1}].$$

We note also that the processes $\lambda \in K(\sigma)$ are of the form $\lambda^*(t)=[0, \mathring{\lambda}^*(t)]$, where $\mathring{\lambda}(t)$ is $(d-m)$-dimensional. With $m(\cdot)$ given by (6.15), we define

$$A \triangleq E\exp\left\{\delta\int_0^T m(t)\,dt\right\}.$$

The differential of the positive $\{\mathring{\mathscr{F}}_t\}$-martingale $N(t) \triangleq E[\exp\{\delta\int_0^T m(s)\,ds\}|\mathring{\mathscr{F}}_t\}$ has a representation as $dN(t)=-N(t)\mathring{\lambda}^*(t)\,d\mathring{W}\,(t)$, where $\lambda=\begin{bmatrix} 0 \\ \mathring{\lambda} \end{bmatrix} \in K(\sigma)$ (see the argument leading to (8.9) for a justification). Therefore

$$\exp\left\{\delta\int_0^T m(t)\,dt\right\}=N(T)=A\exp\left\{-\int_0^T \mathring{\lambda}^*(t)\,d\mathring{W}\,(t)-\frac{1}{2}\int_0^T \|\mathring{\lambda}(t)\|^2\,dt\right\}. \tag{10.1}$$

We may assume without loss of generality that $\check{W}$ is the coordinate mapping process $\check{W}(t, \check{\omega})=\check{\omega}(t)$ defined on $\check{\Omega} \triangleq C([0, T], \mathbb{R}^m)$, the space of continuous functions from $[0, T]$ to $\mathbb{R}^m$, and $\mathring{W}$ is the coordinate mapping process on $\mathring{\Omega} \triangleq C([0, T], \mathbb{R}^{d-m})$. Then $\Omega = \check{\Omega} \times \mathring{\Omega}$, and P is the product of m-dimensional Wiener measure $\check{P}$ on $\check{\Omega}$ and $(d-m)$-dimensional Wiener measure $\mathring{P}$ on $\mathring{\Omega}$. Abusing notation slightly, we regard the $\{\mathring{\mathscr{F}}_t\}$-adapted process $\check{\theta}$ as a process on $\mathring{\Omega}$. For $\mathring{P}$-almost every $\mathring{\omega} \in \mathring{\Omega}$, we have $\int_0^T \|\check{\theta}^*(s, \mathring{\omega})\|^2\, ds < \infty$, and thus for fixed $\mathring{\omega}$, the process

$$(t, \check{w}) \mapsto \exp\left\{\frac{\delta}{1-\delta} \int_0^t \check{\theta}(s, \mathring{\omega})\, d\check{W}(s, \check{\omega}) - \frac{\delta^2}{2(1-\delta)^2} \int_0^t \|\check{\theta}(s, \mathring{\omega})\|^2\, ds\right\}$$

is an $\{\check{\mathscr{F}}_t\}$-martingale on $\check{\Omega}$ under $\check{P}$, with expectation equal to one (Karatzas and Shreve [14, Cor. 5.13, p. 199]). Consequently,

$$\begin{aligned} &E\left[\exp\left\{\frac{\delta}{1-\delta} \int_0^T \check{\theta}^*(s)\, d\check{W}(s)\right\} \middle| \mathring{\mathscr{F}}_T\right](\check{\omega}, \mathring{\omega}) \\ (10.2) \qquad &= \int_{\check{\Omega}} \exp\left\{\frac{\delta}{1-\delta} \int_0^T \check{\theta}^*(s, \mathring{\omega})\, d\check{W}(s, \check{\omega})\right\} P(d\check{\omega}) \\ &= \exp\left\{\frac{\delta^2}{2(1-\delta)^2} \int_0^T \|\check{\theta}(s, \mathring{\omega})\|^2\, ds\right\}. \end{aligned}$$

From (10.2) and (10.1) we have

$$\begin{aligned} \mathscr{X}_\lambda(y) = y^{1/(\delta-1)} E\Bigg[\exp\Bigg\{&\frac{\delta}{1-\delta} \int_0^T \left(r(s) + \frac{1}{2}\|\check{\theta}(s)\|^2 + \frac{1}{2}\|\mathring{\lambda}(s)\|^2\right) ds \\ &+ \frac{\delta}{1-\delta} \int_0^T \mathring{\lambda}^*(s)\, d\mathring{W}(s)\Bigg\} E\left[\exp\left\{\frac{\delta}{1-\delta} \int_0^T \check{\theta}^*(s)\, d\check{W}(s)\right\} \middle| \mathring{\mathscr{F}}_T\right]\Bigg] \\ = y^{1/(\delta-1)} E\Bigg[&\exp\left\{\frac{\delta}{1-\delta} \int_0^T \left(m(s)\, ds + \frac{1}{2}\|\mathring{\lambda}(s)\|^2\right) ds + \frac{\delta}{1-\delta} \int_0^T \mathring{\lambda}^*(s)\, d\mathring{W}(s)\right\}\Bigg] \\ = A^{\delta/(1-\delta)} y^{1/(\delta-1)} &E\left[\exp\left\{\delta \int_0^T m(s)\, ds\right\}\right] = \left(\frac{y}{A}\right)^{1/(\delta-1)} \end{aligned}$$

It follows that $\lambda \in K_1(\sigma)$, $\mathscr{Y}_\lambda(x) = Ax^{\delta-1}$, and using (10.1) we obtain

$$\begin{aligned} \xi_\lambda^x = (\mathscr{Y}_\lambda(x)\beta(T)Z_\lambda(T))^{1/(\delta-1)} = x \exp\Bigg\{&\int_0^T \left(r(t) + \frac{1-2\delta}{2(\delta-1)^2}\|\theta(t)\|^2\right) dt \\ &+ \frac{1}{1-\delta} \int_0^T \theta^*(t)\, dW(t)\Bigg\}. \end{aligned}$$

Just as in Example 6.5, we conclude from (3.4) that $X^{x,\hat{\pi}}(T) = \xi_\lambda^x$, where $\hat{\pi}$ is given by (6.17).

Remark 10.3. An important unresolved question is whether there are simple, widely applicable conditions that guarantee that for the process λ satisfying conditions (B)-(E) of § 9, the nonnegative local martingale Z_λ is actually a martingale. (See, however, the note following the references.) In Example 10.1 we have

$$Z_\lambda(t) = Z_0(t) = \exp\left\{-\int_0^t \theta^*(s)\, dW(s) - \frac{1}{2}\int_0^t \|\theta(s)\|^2\, ds\right\},$$

so we must assume at least that Z_0 is a martingale in order to conclude that Z_λ is. In Example 10.2 a computation similar to (10.2) reveals that

$$\begin{aligned} EZ_\lambda(T) &= E\bigg[\exp\bigg\{-\int_0^T \mathring{\lambda}^*(t)\,d\mathring{W}(t) - \frac{1}{2}\int_0^T (\|\check{\theta}(t)\|^2 + \|\mathring{\lambda}(t)\|^2)\,dt\bigg\} \\ &\qquad \cdot E\bigg[\exp\bigg\{-\int_0^T \check{\theta}^*(t)\,d\check{W}(t)\bigg\}\bigg|\mathring{\mathcal{F}}_T\bigg]\bigg] \\ &= E\bigg[\exp\bigg\{-\int_0^T \mathring{\lambda}^*(t)\,d\mathring{W}(t) - \frac{1}{2}\int_0^T \|\mathring{\lambda}(t)\|^2\,dt\bigg\}\bigg]. \end{aligned}$$

Taking expectations in (10.1) and recalling the definition of A, we see that $EZ_\lambda(T) = 1$. This is enough to ensure that Z_λ is a martingale (Karatzas and Shreve [14, p. 198]). We have so far been unable to produce an example in which Z_0 is a martingale but Z_λ is not.

11. Duality. We henceforth impose the following assumption.

Assumption 11.1. $U(0) > -\infty$.

In addition to the original, or "primal," optimization problem

$$V(x) = \sup_{\pi \in \mathcal{A}(x)} J(x; \pi), \qquad J(x; \pi) \triangleq EU(X^{x,\pi}(T)) \tag{11.1}$$

of § 5, we shall consider in what follows the *dual optimization problem* for $y \in (0, \infty)$, namely,

$$\tilde{V}(y) = \inf_{\nu \in K(\sigma)} \tilde{J}(y; \nu), \qquad \tilde{J}(y; \nu) \triangleq E\tilde{U}(y\beta(T)Z_\nu(T)). \tag{11.2}$$

This problem will have a value function $\tilde{V}: (0, \infty) \to \mathbb{R}$ under the following assumption, which will also remain in force for the remainder of the paper.

Assumption 11.2. For every $y \in (0, \infty)$, there exists $\nu \in K(\sigma)$ such that

$$\tilde{J}(y; \nu) < \infty. \tag{11.3}$$

See Remark 11.9 in connection with this assumption.

For arbitrary $x > 0$, $y > 0$, $\pi \in \mathcal{A}(x)$, and $\nu \in K(\sigma)$ it follows from (4.3) that

$$U(X^{x,\pi}(T)) \leqq \tilde{U}(y\beta(T)Z_\nu(T)) + y\beta(T)Z_\nu(T)X^{x,\pi}(T), \tag{11.4}$$

with equality if and only if

$$X^{x,\pi}(T) = I(y\beta(T)Z_\nu(T)). \tag{11.5}$$

By taking expectations in (11.4) and recalling Proposition 8.3, we obtain

$$J(x; \pi) \leqq \tilde{J}(y; \nu) + xy, \tag{11.6}$$

with equality prevailing if and only if (11.5) and $x = \mathcal{X}_\nu(y)$ hold. In particular, it follows from (11.6) that

$$V(x) \leqq \tilde{V}(y) + xy \quad \forall x > 0,\ y > 0. \tag{11.7}$$

Remark 11.3. Suppose that for some given $x > 0$ and $y > 0$, there exist $\hat{\pi}_x \in \mathcal{A}(x)$ and $\lambda_y \in K(\sigma)$ such that

$$J(x; \hat{\pi}_x) = \tilde{J}(y; \lambda_y) + xy. \tag{11.8}$$

Then $\hat{\pi}_x$ achieves the supremum in (11.1), and λ_y achieves the infimum in (11.2).

PROPOSITION 11.4. *Under Assumptions* 11.1 *and* 11.2, *suppose that, for a given* $y>0$, *there is an optimal process* $\lambda_y \in K_1(\sigma)$ *for the dual problem of* (11.2). *Then there exists an optimal portfolio* $\hat{\pi}_x \in \mathcal{A}(x)$ *for the primal problem of* (11.1) *with* $x=\mathcal{X}_{\lambda_y}(y)$, *and we have*

$$\tilde{V}(y)=\sup_{\xi>0}[V(\xi)-y\xi]. \tag{11.9}$$

In particular, $\tilde{V}(\cdot)$ *is convex.*

Proof. The optimality of λ_y gives

$$E[\tilde{U}(\mathcal{Y}_{\lambda_y}(x)\beta(T)Z_{\lambda_y}(T))]\leqq E[\tilde{U}(\mathcal{Y}_{\lambda_y}(x)\beta(T)Z_\nu(T))] \quad \forall \nu\in K(\sigma) \tag{11.10}$$

for this particular $x=\mathcal{X}_{\lambda_y}(y)$. This is Condition (D) of § 9. Theorem 9.4(i) shows the existence of a portfolio $\hat{\pi}_x \in \mathcal{A}(x)$, which is optimal for the primal problem and satisfies

$$X^{x,\hat{\pi}_x}(T)=I(y\beta(T)Z_{\lambda_y}(T)).$$

We conclude that (11.8) prevails (i.e., (11.6) holds as an equality with $\pi=\hat{\pi}_x$, $\nu=\lambda_y$), and thus

$$\tilde{V}(y)=\tilde{J}(y;\lambda_y)=J(x;\hat{\pi}_x)-xy=V(x)-xy\leqq\sup_{\xi>0}[V(\xi)-y\xi].$$

The inequality in the opposite direction follows directly from (11.7), and the duality relationship (11.9) is established. □

Assumption 11.5. Suppose that the dual problem of (11.2) admits an optimal process $\lambda_y\in K_1(\sigma)$, *for every* $y>0$.

A sufficient condition (Theorem 12.3) for the fulfillment of Assumption 11.5 will be given in the next section. Under the Assumption 11.5, (11.9) holds for all $y>0$, and the following question arises. *Under what conditions can we guarantee that, for every given* $x>0$, *there exists an optimal portfolio* $\hat{\pi}_x$ *for* (11.1)? According to Proposition 11.4, this will happen if for every $x>0$ we can find a real number $y(x)>0$ such that

$$x=\mathcal{X}_{\lambda_{y(x)}}(y(x)). \tag{11.11}$$

PROPOSITION 11.6. *Suppose that the conditions of Proposition* 11.4 *hold, as well as Assumptions* 11.5 *and* 4.3 *and* $U(\infty)=\infty$. *Then for every* $x>0$, *there exists a real number* $y(x)>0$ *that achieves* $\inf_{y>0}[\tilde{V}(y)+xy]$; *this number satisfies* (11.11) *as well.*

Proof. From (11.3), Jensen's inequality, the supermartingale property of Z_ν, and the decrease of $\tilde{U}$, we have

$$\tilde{J}(y;\nu)\geqq\tilde{U}(yE[\beta(T)Z_\nu(T)])\geqq\tilde{U}(ye^L EZ_\nu(T))\geqq\tilde{U}(ye^L) \quad \forall\nu\in K(\sigma) \tag{11.12}$$

for the constant $L>0$ of Standing Assumption 2.1. Therefore, $\tilde{V}(y)\geqq\tilde{U}(ye^L)$ holds for every $y\in(0,\infty)$, and $\tilde{V}(0)\triangleq\lim_{y\downarrow 0}\tilde{V}(y)\geqq\tilde{U}(0)=U(\infty)=\infty$ (Lemma 4.2).

Consequently, for any given $x>0$, the convex function $f_x(y)=\tilde{V}(y)+xy$, $0<y<\infty$ satisfies $f_x(0+)=f_x(\infty)=\infty$, and thus attains its infimum on $(0,\infty)$ at some point $y(x)>0$. Now by the Assumption 11.5, there exists a process $\lambda_{y(x)}\in K_1(\sigma)$ such that $\tilde{V}(y(x))=\tilde{J}(y(x);\lambda_{y(x)})$, and we have

$$\begin{aligned}\inf_{\eta>0}[\eta y(x)x+\tilde{J}(\eta y(x);\lambda_{y(x)})]&=\inf_{y>0}[xy+\tilde{J}(y;\lambda_{y(x)})]\\&\geqq\inf_{y>0}[xy+\tilde{V}(y)]=xy(x)+\tilde{V}(y(x)).\end{aligned}$$

In other words, with the notation

$$G_y(u)\triangleq\tilde{J}(uy;\lambda_y)=E\tilde{U}(uy\beta(T)Z_{\lambda_y}(T)), \qquad 0<u<\infty, \tag{11.13}$$

the function

$$D_x(u) \triangleq uxy(x) + G_{y(x)}(u), \qquad 0 < u < \infty \tag{11.14}$$

achieves its infimum at $u = 1$.

From these considerations and Lemma 11.7 below, it transpires that

$$D'_x(1) = xy(x) + G'_{y(x)}(1) = xy(x) - y(x)\mathscr{X}_{\lambda_{y(x)}}(y(x))$$

is equal to zero, and thus (11.11) holds. □

LEMMA 11.7. *Under the conditions of Proposition* 11.6, *the function* $G_y(\cdot)$ *of* (11.13) *is well defined and finite on* $(0, \infty)$ *for any given* $0 < y < \infty$, *and satisfies*

$$G'_y(1) = -y\mathscr{X}_{\lambda_y}(y). \tag{11.15}$$

Proof. Since $\tilde{U}(\infty) = U(0) > -\infty$ by assumption and by Lemma 4.2, we have from (4.4) that

$$\tilde{U}(y) - \tilde{U}(\infty) = -\int_y^\infty \tilde{U}'(\xi)\, d\xi = \int_y^\infty I(\xi)\, d\xi, \qquad 0 < y < \infty.$$

Thus, for any given $\alpha \in (0, 1)$, it follows with the help of (4.9) that

$$\tilde{U}(\alpha y) - \tilde{U}(\infty) = \int_{\alpha y}^\infty I(\xi)\, d\xi = \alpha \int_y^\infty I(\alpha\eta)\, d\eta$$

$$\leqq \alpha\gamma \int_y^\infty I(\eta)\, d\eta = \alpha\gamma[\tilde{U}(y) - \tilde{U}(\infty)], \qquad 0 < y < \infty$$

for a suitable constant $\gamma \in (1, \infty)$. Consequently, for any given $y \in (0, \infty)$,

$$E\tilde{U}(\alpha y\beta(T)Z_{\lambda_y}(T)) \leqq \alpha\gamma E\tilde{U}(y\beta(T)Z_{\lambda_y}(T)) + (1 - \alpha\gamma)\tilde{U}(\infty)$$

$$= \alpha\gamma\tilde{J}(y; \lambda_y) + (1 - \alpha\gamma)U(0) < \infty.$$

Since $\alpha \in (0, 1)$ is arbitrary,

$$E\tilde{U}(uy\beta(T)Z_{\lambda_y}(T)) < \infty \tag{11.16}$$

holds for every $u \in (0, 1]$. But the function $\tilde{U}(\cdot)$ is decreasing, so (11.16) also holds for every $u > 1$.

Now use the convexity of $\tilde{U}$, the dominated convergence theorem, (4.4), and the fact that $\lambda_y \in K_1(\sigma)$, to justify the computations

$$G'_y(1) = yE[\beta(T)Z_{\lambda_y}(T)\tilde{U}'(y\beta(T)Z_{\lambda_y}(T))]$$

$$= -yE[\beta(T)Z_{\lambda_y}(T)I(y\beta(T)Z_{\lambda_y}(T))] = -y\mathscr{X}_{\lambda_y}(y),$$

which leads to (11.15). □

It just remains now to put Propositions 11.4 and 11.6 together, in order to obtain the following existence result for the primal problem (11.1).

THEOREM 11.8. *Suppose that Assumptions* 4.3, 11.1, 11.2, *and* 11.5 *hold and* $U(\infty) = \infty$. *Then for any given level* $x > 0$ *of initial capital, there exists an optimal portfolio* $\hat{\pi}_x \in \mathscr{A}(x)$ *for the utility maximization problem of* § 5.

In other words, under appropriate conditions, in order to obtain the existence of an optimal portfolio it is sufficient to deal with the existence of a solution $\lambda_y \in K_1(\sigma)$ for the dual problem (11.2). We will do that in the next section.

Remark 11.9. Assumption 11.2 is satisfied if (5.3) and (5.4) hold. Indeed, it is not hard to check that condition (5.4) and definition (4.3) lead to

$$\tilde{U}(y) \leqq k_1 + k_3 y^{-\alpha} \quad \forall 0 < y < \infty \tag{11.17}$$

with $\alpha = \delta/(1-\delta)$, $k_3 = (1-\delta)(k_2\delta^{\delta})^{1/(1-\delta)}$, and thus

$$\tilde{J}(y;\nu) \leqq k_1 + k_3 y^{-\alpha} e^{\alpha L} EZ_\nu^{\alpha}(T), \tag{11.18}$$

where L is the constant of Standing Assumption 2.1. But now

$$Z_\nu^{\alpha}(T) = \exp\left\{\alpha \int_0^T (\theta(t)+\nu(t))^* \, dW(t) - \frac{\alpha^2}{2}\int_0^T (\|\theta(t)\|^2 + \|\nu(t)\|^2)\, dt\right\}$$
$$\cdot \exp\left[\frac{\alpha(\alpha+1)}{2}\int_0^T (\|\theta(s)\|^2 + \|\nu(s)\|^2)\, ds\right],$$

and if we take $\nu \in K(\sigma)$ to satisfy

$$\int_0^T \|\nu(s)\|^2 \, ds \leqq C \quad \text{a.s.}$$

(by analogy with (5.3)) we obtain $EZ_\nu^{\alpha}(T) \leqq e^{\alpha(1+\alpha)C}$. Back into (11.18), this estimate shows that (11.3) is satisfied.

12. Existence in the dual problem. We will establish here the following existence result for the dual optimization problem of (11.2). This theorem is the final step in the solution to the problem of optimal investment in an incomplete market; see Theorem 12.5.

Assumption 12.1. $E\int_0^T \|\theta(t)\|^2 \, dt < \infty$.

Assumption 12.2. $x \mapsto xU'(x)$ is nondecreasing on $(0,\infty)$.

THEOREM 12.3. *Suppose that Assumptions* 4.3, 11.1, 11.2, 12.1, *and* 12.2 *hold. Then for every* $y \in (0,\infty)$, *there exists a process* $\lambda_y \in K_1(\sigma)$ *which achieves the infimum in* (11.2). □

Remark 12.4. Assumption 12.2 is equivalent to

$$y \mapsto yI(y) \quad \text{is nonincreasing on } (0,\infty). \tag{12.1}$$

If U is of class $C^2(0,\infty)$, Assumption 12.2 amounts to the statement that the Arrow–Pratt measure of relative risk aversion does not exceed one:

$$-\frac{xU''(x)}{U'(x)} \leqq 1 \quad \forall x \in (0,\infty). \tag{12.2}$$

On the other hand, it follows from Assumption 12.2 that $U'(x) \geqq U'(1)/x$ for all $x \geqq 1$, whence $U(x) \geqq U(1) + U'(1)\log x$. Consequently,

$$U(\infty) = \infty. \tag{12.3}$$

From this remark and Theorems 12.3, 11.8, and 9.4, we deduce then the fundamental result of §§ 11 and 12 as follows.

THEOREM 12.5. *Under the assumptions of Theorem* 12.3, *corresponding to every* $x > 0$, *there exist*:

(i) *An optimal portfolio* $\hat{\pi}_x \in \mathscr{A}(x)$ *for the utility maximization problem of* § 5; *and*

(ii) *A process* $\lambda \in K_1(\sigma)$ (λ *depending on* x) *which achieves the infimum in* (11.2) *with* $y = \mathscr{Y}_\lambda(x)$; *this* λ *satisfies the equivalent conditions* (B)-(E) *of* § 9, *and the* $\hat{\pi}$ *appearing in* (B) *is* $\hat{\pi}_x$.

We carry out the proof of Theorem 12.3 in a series of lemmas that take up much of the remainder of the section. Let us start with a rather simple observation.

LEMMA 12.6. *Under Assumptions* 11.1 *and* 12.2, *we have* $\tilde{U}(0)=\infty$, $\tilde{U}(\infty)>-\infty$, *and*

$$z\mapsto\tilde{U}(e^z)\quad \textit{is convex on } \mathbb{R}. \tag{12.4}$$

Proof. The first two claims follow directly from Lemma 4.2 and (12.3). As for (12.4), observe from (4.4) and (12.1) that $(d/dz)\tilde{U}(e^z)=-e^zI(e^z)$ is a nondecreasing function of z. □

Introduce now the Hilbert space

$$H(\sigma)\triangleq\left\{\nu\in K(\sigma);\, E\int_0^T\|\nu(s)\|^2\,ds<\infty\right\} \tag{12.5}$$

with inner product $\langle\mu,\nu\rangle\triangleq E\int_0^T\mu^*(s)\nu(s)\,ds$ and norm $[\nu]\triangleq\sqrt{\langle\nu,\nu\rangle}$. For a fixed $y>0$, we consider the functional $\tilde{J}_y: H(\sigma)\to\mathbb{R}\cup\{+\infty\}$ given by (11.2), namely,

$$\tilde{J}_y(\nu)\triangleq E\tilde{U}(y\beta(T)\,e^{-\zeta_\nu(T)}) \tag{12.6}$$

with the notation

$$\zeta_\nu(t)\triangleq\int_0^t(\theta(s)+\nu(s))^*\,dW(s)+\frac{1}{2}\int_0^t(\|\theta(s)\|^2+\|\nu(s)\|^2)\,ds,\qquad \nu\in K(\sigma). \tag{12.7}$$

LEMMA 12.7. *Under Assumptions* 11.1, 12.1, *and* 12.2, $\tilde{J}_y(\cdot)$ *is a convex functional on* $H(\sigma)$, *which satisfies*

$$\lim_{[\nu]\to\infty}\tilde{J}_y(\nu)=\infty, \tag{12.8}$$

for every $y\in(0,\infty)$.

Proof. From the convexity of the Euclidean norm in $\mathbb{R}^d$, the decrease of $\tilde{U}$ and (12.4), we have

$$\begin{aligned}\tilde{J}_y(\lambda_1\nu_1+\lambda_2\nu_2)&\leqq E\tilde{U}\left(\exp\left[\log y-\int_0^T r(s)\,ds-\lambda_1\zeta_{\nu_1}(T)-\lambda_2\zeta_{\nu_2}(T)\right]\right)\\&=E\tilde{U}\left(\exp\left\{\lambda_1\left[\log y-\int_0^T r(s)\,ds-\zeta_{\nu_1}(T)\right]\right.\right.\\&\qquad\left.\left.+\lambda_2\left[\log y-\int_0^T r(s)\,ds-\zeta_{\nu_2}(T)\right]\right\}\right)\\&\leqq\lambda_1\tilde{J}_y(\nu_1)+\lambda_2\tilde{J}_y(\nu_2)\end{aligned} \tag{12.9}$$

for any ν_1, ν_2 in $H(\sigma)$ and $\lambda_1\geqq 0$, $\lambda_2\geqq 0$ with $\lambda_1+\lambda_2=1$. On the other hand, with L as in Standing Assumption 2.1, we obtain from (12.4) and Jensen's inequality

$$\begin{aligned}\tilde{J}_y(\nu)&\geqq E\tilde{U}(\exp[\log y+L-\zeta_\nu(T)])\\&\geqq\tilde{U}(\exp[\log y+L-E\zeta_\nu(T)])\\&=\tilde{U}(\exp[\log y+L-\tfrac{1}{2}[\theta]^2-\tfrac{1}{2}[\nu]^2)\xrightarrow[{[\nu]\to\infty}]{}\infty.\end{aligned} \tag{12.10}$$

□

LEMMA 12.8. *Under Assumptions* 11.1, 12.1, *and* 12.2, *we have* $\tilde{J}_y(\nu)=\infty$, *for every* $\nu\in K(\sigma)\backslash H(\sigma)$ *and* $y\in(0,\infty)$.

Proof. Fix $y\in(0,\infty)$, $\nu\in K(\sigma)\backslash H(\sigma)$ and define stopping times

$$\tau_n \triangleq T\wedge \inf\left\{t\in[0,T];\ \int_0^t \|\nu(s)\|^2\,ds=n\right\}$$

for $n=1,2,\cdots$. With L as in Standing Assumption 2.1, it follows from Jensen's inequality, the supermartingale property of Z_ν, and the decrease of $\tilde{U}$, that

$$\begin{aligned}\tilde{J}_y(\nu)&=E\tilde{U}(y\beta(T)Z_\nu(T))=E[E\{\tilde{U}(y\beta(T)Z_\nu(T))|\mathcal{F}_{\tau_n}\}]\\&\geqq E[\tilde{U}(ye^LE\{Z_\nu(T)|\mathcal{F}_{\tau_n}\})]\geqq E\tilde{U}(ye^LZ_\nu(\tau_n))\\&\geqq \tilde{U}\left(y\exp\left\{L-\frac{1}{2}E\int_0^{\tau_n}(\|\theta(s)\|^2+\|\nu(s)\|^2)\,ds\right\}\right),\end{aligned}$$

for every $n\geqq 1$. The conclusion follows by letting $n\to\infty$. □

Proof of Theorem 12.3. Fix $y\in(0,\infty)$. The convex functional $\tilde{J}_y(\cdot)$ of (12.6) is lower-semicontinuous in the strong topology of $H(\sigma)$, by Fatou's Lemma. Therefore, it is also lower-semicontinuous in the weak topology (Ekeland and Temam [5, Cor. 2.2, Chap. 1]). Thanks to the coercivity property (12.8) of Lemma 12.7, $\tilde{J}_y(\cdot)$ attains its infimum over $H(\sigma)$ at some $\lambda_y\in H(\sigma)$ [5, Prop. 1.2, Chap. 2]. In light of Lemma 12.8 and Assumption 11.2,

$$\inf_{y\in K(\sigma)}\tilde{J}_y(\nu)=\tilde{J}_y(\lambda_y)<\infty. \tag{12.11}$$

It remains to show that $\lambda_y\in K_1(\sigma)$. From the decrease of $\tilde{U}$ and I, (4.4) and (4.8)$'$, we obtain for some $\alpha\in(0,1)$, $\gamma\in(1,\infty)$:

$$\begin{aligned}\tilde{U}(\xi)-\tilde{U}(\infty)&\geqq\tilde{U}(\xi)-\tilde{U}\left(\frac{\xi}{\alpha}\right)=\int_\xi^{\xi/\alpha}I(u)\,du\geqq\xi\left(\frac{1}{\alpha}-1\right)I\left(\frac{\xi}{\alpha}\right)\\&\geqq\frac{1-\alpha}{\alpha\gamma}\,\xi I(\xi)\quad\forall\xi\in(0,\infty).\end{aligned}\tag{12.12}$$

Replacing ξ by $y\beta(T)Z_{\lambda_y}(T)$ in (12.12) and taking expectations, we obtain

$$\mathcal{X}_{\lambda_y}(y)=E[\beta(T)Z_{\lambda_y}(T)I(y\beta(T)Z_{\lambda_y}(T))]\leqq\frac{\alpha y}{y(1-\alpha)}[E\tilde{U}(y\beta(T)Z_{\lambda_y}(T))-\tilde{U}(\infty)]<\infty,$$

thanks to (12.11), and thus $\lambda_y\in K_1(\sigma)$ by Remark 9.1. □

13. Appendix. We provide in this section an example with a well-behaved utility function U for which we do not have $\mathcal{X}_\nu(y)<\infty$ for all $y\in(0,\infty)$ and $\nu\in K(\sigma)$. The existence of such an example necessitates the introduction of the set $K_1(\sigma)$ in § 9.

In the setting of § 2, take $m=1$, $d=2$, $\sigma(t)\equiv(0,1)$, $r(t)\equiv 0$, $b(t)\equiv 0$, $T=1$, $B=W_1$, and define the stopping time $\tau\triangleq\inf\{t\in[0,1];\ t+B^2(t)=1\}$ and the process

$$\varphi(t)\triangleq\left\{\begin{matrix}\dfrac{-2B(t)}{(1-t)^2}1_{\{t\leqq\tau\}} & 0\leqq t<1\\ 0; & t=1\end{matrix}\right\},\tag{13.1}$$

$\nu(t) \triangleq (\varphi(t), 0)^*$. For the utility function $U(x) = 2\sqrt{x}$ we have $I(y) = y^{-2}$, and (7.6), (7.7) give

$$Z_\nu(t) = \exp\left\{ -\int_0^t \varphi(s)\, dB(s) - \frac{1}{2}\int_0^t \varphi^2(s)\, ds \right\}, \tag{13.2}$$

$$\mathscr{X}_\nu(y) = y^{-2} E\left[\exp\left\{ \int_0^1 \varphi(s)\, dB(s) + \frac{1}{2}\int_0^1 \varphi^2(s)\, ds \right\} \right]. \tag{13.3}$$

It is shown in Liptser and Shiryaev [15, p. 224] (see also Karatzas and Shreve [14, p. 201]) that the process Z_ν of (13.2) is *not* a martingale; in fact, the construction (13.1) is made with this property in mind. This implies, in particular, that

$$E\left[\exp\left\{ \frac{1}{2}\int_0^1 \varphi^2(s)\, ds \right\} \right] = \infty; \tag{13.4}$$

for otherwise Z_ν would be a martingale, by Novikov's theorem (Karatzas and Shreve [14, p. 199]). According to Liptser and Shiryaev [14, p. 225]:

$$\int_0^1 \varphi(s)\, dB(s) - \frac{1}{2}\int_0^1 \varphi^2(s)\, ds = -1 - 2\int_0^\tau [(1-t)^{-4} - (1-t)^{-3}] B^2(t)\, dt,$$

whence

$$\mathscr{X}_\nu(y) = \frac{1}{ey^2} E\left[\exp\left\{ 2\int_0^\tau [(1-t)^{-4} + (1-t)^{-3}] B^2(t)\, dt \right\} \right].$$

If this last expectation were finite, then so would be

$$E\left[\exp\left\{ \frac{1}{2}\int_0^1 \varphi^2(s)\, ds \right\} \right] = E\left[\exp\left\{ 2\int_0^\tau (1-t)^{-4} B^2(t)\, dt \right\} \right],$$

contradicting (13.4).

Acknowledgment. We are grateful to an anonymous referee for carefully reading this paper and offering helpful advice on exposition.

Note added in proof. It has recently been discovered that, under quite general conditions, the local martingale Z_λ is actually a martingale, where λ is the process whose existence is proved in Theorem 12.5. This result is reported in [23].

INVARIANCE OF THE APPROXIMATELY REACHABLE SET UNDER NONLINEAR PERTURBATIONS *

KOICHIRO NAITO † AND THOMAS I. SEIDMAN ‡

Abstract. This paper considers nonlinear perturbations of control systems with linear dynamics and seeks to analyze whether the approximately reachable set may be left unchanged by this perturbation. Under suitable conditions it is shown that this analysis may be reduced to the presumably simpler analysis of such invariance for a family of affine perturbations. Interest centers on the context of infinite-dimensional state spaces so the system may, for example, correspond to a hyperbolic or parabolic partial differential equation.

Key words. approximate reachability, control, distributed parameter system, nonlinear, perturbation, invariance

AMS(MOS) subject classifications. 49E25, 35B37, 93B05, 93C20

1. Introduction.

Reachability results for distributed parameter systems are hard to come by since, when the state space $\mathcal{X}$ is infinite-dimensional, the "standard" approaches (typically based on such implicit assumptions as local compactness, etc.) may no longer be applicable. This is especially true for nonlinear systems in a setting for which the information available relates only to the *approximately* reachable sets for related linear problems. Our concern here is with the extension to this more general context of a mode of analysis treated in a sequence of earlier papers [11], [12], [15], [16].

We consider a nonlinear control system given by

$$\dot{x} = \mathbf{A}x + \mathbf{F}x + \mathbf{B}u, \qquad u \in \boldsymbol{\mathcal{U}}_{ad} \tag{1.1}$$

with $\mathbf{A}$ linear and $\mathbf{F}$ a nonlinear operator satisfying some suitable growth condition. The control operator $\mathbf{B}$ need not be linear and we may occasionally write $\mathbf{B}(u)$ to emphasize this; we set $\boldsymbol{\mathcal{W}}_{ad} := \{w = \mathbf{B}(u) : u \in \boldsymbol{\mathcal{U}}_{ad}\}$.

We wish to consider (1.1) as a "perturbation" of the control problem

$$\dot{z} = \mathbf{A}z + \mathbf{B}u, \qquad u \in \boldsymbol{\mathcal{U}}_{ad} \tag{1.2}$$

omitting the nonlinearity $\mathbf{F}$. For the moment we require only that (1.2) should have a meaningful solution for each $u \in \boldsymbol{\mathcal{U}}_{ad}$ and we will consistently denote this solution by z_u. Setting

$$\boldsymbol{\mathcal{Z}}_{ad} := \{z_u \text{ satisfying (1.2) for some } u \in \boldsymbol{\mathcal{U}}_{ad}\}, \tag{1.3}$$

part of our interpretation of "meaningful" is that $\boldsymbol{\mathcal{Z}}_{ad}$ is to be considered in some[1] Banach space $\boldsymbol{\mathcal{X}}$ of functions on $[0,T]$ with continuity to $\mathcal{X}$ for the evaluation map

[1] In general we take $\boldsymbol{\mathcal{X}}$ to be $C([0,T] \to \mathcal{X})$, which certainly ensures that the evaluation map $\mathbf{E}$ will be continuous. We do note that lesser regularity could be permitted away from the terminal time — in particular, to allow for the effect of "rough" initial data.

$\mathbf{E} : z \mapsto z(T) : \boldsymbol{\mathcal{X}} \to \mathcal{X}$ so that we can speak about the *reachable set*

$$\mathcal{K}_0 := \mathbf{E}\boldsymbol{\mathcal{Z}}_{ad} := \{\mathbf{E}z : z \in \boldsymbol{\mathcal{Z}}_{ad}\}$$

as a subset of the state space $\mathcal{X}$.

In considering (1.1), we observe that: for any *particular* solution $x = x_u$, the nonlinearity gives $\mathbf{F}x$ as some specific function g. This solution is then also a solution of an alternate perturbation of the system (1.2):

$$(1.4) \qquad \dot{x} = \mathbf{A}x + g + \mathbf{B}u, \qquad u \in \boldsymbol{\mathcal{U}}_{ad}$$

using the same control u. We will consider the family of *affine perturbations* (1.4) with g taken from some given subset $\boldsymbol{\mathcal{G}}$ of a function space $\boldsymbol{\mathcal{V}}$. The relation, of course, is that $\boldsymbol{\mathcal{G}}$ is to contain each $\mathbf{F}[x(\cdot)]$ as u ranges over $\boldsymbol{\mathcal{U}}_{ad}$ in (1.1). Presumably the reachability analysis for (each of) the affinely perturbed problems (1.4) should be simpler than that for the original nonlinearly perturbed problem (1.1). For (1.4), (1.1) we will again be considering solutions in the same space $\boldsymbol{\mathcal{X}}$ of $\mathcal{X}$-valued functions as we use for the "unperturbed" equation (1.2).

It will be important for us to consider the relation of (1.1) to (1.2) from the viewpoint of (1.4). Given a solution $z = z_u$ for (1.2), we may write (1.1) as an equation for $y = x - z$:

$$(1.5) \qquad \mathbf{G} : z \mapsto \mathbf{F}(y + z) =: g \ \text{ such that } \dot{y} = \mathbf{A}y + g.$$

For the moment this specification of a "map" $\mathbf{G} = \mathbf{G}_{\mathrm{F}}$ is purely formal but, of course, we will eventually want to have $\mathbf{G} : \boldsymbol{\mathcal{Z}}_{ad} \to \boldsymbol{\mathcal{G}}$.

The question we wish to consider is:

(Q) When must a state ξ which is approximately reachable for (1.2) also be approximately reachable for the nonlinear system (1.1)?

Letting $\mathcal{K}_{\mathrm{F}} \subset \mathcal{X}$ denote the reachable set for (1.1) — i.e., the set of values for $\xi = x(T)$ as x ranges over solutions of (1.1) with $u \in \boldsymbol{\mathcal{U}}_{ad}$ — this asks whether $\mathcal{K}_0 \subset \bar{\mathcal{K}}_{\mathrm{F}}$; we note that the complementary inclusion is, in general, much easier to analyze. More precisely, we are asking:

> When can the question (**Q**) above be analyzed (answered affirmatively) by considering the *family* of (presumably simpler) related questions for the affine problems (1.4) as g ranges over $\boldsymbol{\mathcal{G}}$?

In this form it should be clear that our concern is with the *validation of a mode of analysis.* We are, for example, seeking conditions on (1.4) for $g \in \boldsymbol{\mathcal{G}}$ ensuring that $\bar{\mathcal{K}}$ is invariant under the perturbation: (1.2) $\longmapsto$ (1.1). The essential requirement will be a certain uniformity (over suitable bounded subsets of $\boldsymbol{\mathcal{G}}$) for a measure of the approximate reachability; see (3.23) et seq.

We have already investigated the corresponding invariance of the (exactly) reachable set in a sequence of papers [11], [12], [15], [16]. The work presented here represents an extension of this work in two directions: the consideration of *approximate* rather than exact reachability and *the consideration of control sets which do not form a linear space with linear* **B**.

We further note that our present approach to (**Q**) is "one ξ at a time" and so, with minor modification, lends itself to an analysis of approximate controllability for (1.1) in a less "global" context than the invariance of the title. The arguments used here put this work in the setting of "the fixed point approach to controllability" and we refer, e.g., to [5] and its references for further historical discussion of this approach.

2. Some examples. In this section, before beginning the analysis of reachability, we wish to provide some representative examples for which one can verify certain general hypotheses, $(\mathbf{H}_1)$ below, as to the settings to which our analysis applies. As previously noted, our concern is with settings for which the state space $\mathcal{X}$ is infinite-dimensional so that (1.2) may itself be an abstract formulation of a partial differential equation. We emphasize that our hypotheses do *not* restrict consideration to parabolic equations (compact, analytic semigroups). The analysis here could, in principle, be applied also to hyperbolic systems — although one expects that considerations of *approximate* reachability (compare [15], [17]) might then only be of interest if $\{\mathbf{B}(u) : u \in \boldsymbol{\mathcal{U}}_{ad}\}$ is not itself a linear space.

We turn now to some specific examples of systems governed by partial differential equations whose dynamics will satisfy the general hypotheses $(\mathbf{H}_1)$ below — but only indicate briefly the verifications. In §6 we will provide, following [15], some results which are sufficient to provide such verification for more general classes of problems. For each of these examples the spatial domain will be a bounded region $\Omega \subset \mathbb{R}^m$ with "smooth enough" boundary $\partial\Omega$; we set $\mathcal{Q} := (0,T) \times \Omega$ and $\Sigma := (0,T) \times \partial\Omega$.

Example 1. Our first example already exhibits many of our concerns for application. Consider boundary control of the nonlinear heat equation:

$$\dot{x} = \Delta x + \varphi(\cdot, x, \nabla x) \text{ on } \mathcal{Q}, \qquad x_n = e^u \text{ on } \Sigma \tag{2.6}$$

as (1.1). The corresponding "linear" control problem is then

$$\dot{z} = \Delta z \text{ on } \mathcal{Q}, \qquad z_n = w \text{ on } \Sigma \tag{2.7}$$

where $w := e^u$. (Note that x_n, z_n denote normal derivatives at $\partial\Omega$.)

We wish to take $\mathcal{X} := L^2(\Omega)$ as state space. Note that the function $f(\xi) := \varphi(\cdot, \xi(\cdot), [\nabla\xi](\cdot))$ is not well defined for general $\xi \in \mathcal{X}$ since the argument $\nabla\xi$ would then only be in $H^{-1}(\Omega)$ and so need not be a function at all for pointwise composition with φ. This is a situation for which the considerations of Lemma 3 below are important. If we assume that the scalar function φ is (uniformly) Lipschitzian in its variables $\xi, \nabla\xi$, then we can introduce the auxiliary space $\boldsymbol{\mathcal{Y}} := L^2([0,T] \to H^1(\Omega))$ and have Lipschitz continuity from $\boldsymbol{\mathcal{Y}}$ to $\boldsymbol{\mathcal{V}} := L^2(\mathcal{Q})$ for the Nemytsky operator $\mathbf{F} : x \mapsto \varphi(\cdot, x, \nabla x)$. Fairly standard methods show that $\mathbf{L}$ is well defined and continuous from this $\boldsymbol{\mathcal{V}}$ to $\boldsymbol{\mathcal{X}}$ and to $\boldsymbol{\mathcal{Y}}$. Further, if one uses a suitable weighting (exponential in t) for the norms of $\boldsymbol{\mathcal{Y}}$ and $\boldsymbol{\mathcal{V}}$, then one can arrange that $\vartheta < 1$ so Lemma 3 will apply (provided we can take $\boldsymbol{\mathcal{Z}} \hookrightarrow \boldsymbol{\mathcal{X}} \cap \boldsymbol{\mathcal{Y}}$).

Note that these considerations do not yet involve $\boldsymbol{\mathcal{U}}_{ad}$ or $\boldsymbol{\mathcal{Z}}_{ad}$ as $\mathbf{L}$ relates only to the problem with *homogeneous* boundary conditions (and, of course, homogeneous initial conditions).

Suppose we would wish to consider $\boldsymbol{\mathcal{U}}_{ad} = \{u \in L^2(\Sigma) : u > 0 \text{ ae}\}$. Clearly we must begin by restricting this further, to those u (and corresponding $w = e^u$) for which (2.7) and (2.6) have solutions in some satisfactory sense. If we take $w \in \boldsymbol{\mathcal{W}} := L^2(\Sigma)$, then it is standard that the solution map $\mathbf{S}$ defined by (2.7) is continuous and, indeed, compact from $\boldsymbol{\mathcal{W}}$ to $\boldsymbol{\mathcal{X}} \cap \boldsymbol{\mathcal{Y}}$. One can then take, e.g., $\boldsymbol{\mathcal{Z}} := \mathbf{S}\boldsymbol{\mathcal{W}}$, normed so that $\mathbf{S}$ is an isometry. By suitable density arguments one can show that the $\boldsymbol{\mathcal{X}}$-closures of the sets of solutions for (2.6), (2.7), and the corresponding equation affinely perturbed by arbitrary $g \in \boldsymbol{\mathcal{V}}$ will be the same whether one works with $\boldsymbol{\mathcal{W}}_{ad} := \{w \in \boldsymbol{\mathcal{W}} : w \geq 1 \text{ ae}\}$ or with the original $\boldsymbol{\mathcal{U}}_{ad}$, restricted to u giving solutions in $\boldsymbol{\mathcal{X}}$. Thus one has equivalence in the sense of (3.17), below. This, together with Lemma 3, gives $(\mathbf{H}_1)$.

We note also that this $\boldsymbol{\mathcal{Z}}_{ad}$ is convex and closed in $\boldsymbol{\mathcal{Z}}$ since we obviously have $\boldsymbol{\mathcal{W}}_{ad}$ convex and closed in $\boldsymbol{\mathcal{W}}$.

Example 2. We next consider distributed control of the equation

$$\dot{x} = \Delta x + \varphi(\cdot, x, \nabla x) + w \text{ on } \mathcal{Q}, \qquad x = 0 \text{ on } \Sigma, \tag{2.8}$$

assuming that $\varphi : \mathcal{Q} \times \mathbb{R}^{m+1} \to \mathbb{R}$ is a "nice" function (i.e., with uniform bounds on enough derivatives). Again, (2.8) can be put into the abstract form (3.15) by taking the state space $\mathcal{X}$ to be $\mathcal{X}_0 = L^2(\Omega)$ and then introducing $\mathbf{A}$ as the Laplacian on Ω with domain $\mathcal{D}(\mathbf{A}) := \{\xi \in H^2(\Omega) \subset \mathcal{X}_0 : \xi|_{\partial\Omega} = 0\}$. Since $-\mathbf{A}$ is self-adjoint and positive, there is no difficulty (e.g., through the rate of decay of the eigenfunction expansion coefficients) in defining $[-\mathbf{A}]^r$ for all $r \geq 0$ and we set $\mathcal{X}_\mu := \mathcal{D}([-\mathbf{A}]^{\mu/2})$; it is known [7], [8] that $\mathcal{X}_\mu = H^\mu(\Omega)$ for $0 \leq \mu < \frac{1}{2}$, that $\mathcal{X}_\mu = \{\xi \in H^\mu(\Omega) : \xi|_{\partial\Omega} = 0\}$ for $\frac{1}{2} < \mu < \frac{5}{2}$, etc.

Consider controls $w \in \boldsymbol{\mathcal{W}} = \boldsymbol{\mathcal{W}}_m := L^2([0,T] \to \mathcal{X}_m)$ for (fixed) $m \geq 0$. A standard semigroup estimate[2] gives continuity for $\mathbf{L}_t$ from $\boldsymbol{\mathcal{W}}_m$ to $\mathcal{X}_\mu$ for each $\mu < m+1$ and a convolution estimate shows that $\mathbf{L}w =: x(\cdot)$ will be in $L^2([0,T] \to \mathcal{X}_\mu$ for $\mu < m+2$. We get

$$x(\cdot) \in \boldsymbol{\mathcal{X}}_\mu := C([0,T] \to \mathcal{X}_\mu) \cap L^2([0,T] \to \mathcal{X}_{\mu+1})$$

for each $\mu < m+1$. On the other hand, for any $\xi \in \mathcal{X}_{m+2}$ we can set $w_*(t) := (\xi - t\mathbf{A}\xi)/T$ to get $w_* \in \boldsymbol{\mathcal{W}}_m$ and $\mathbf{L}_t w_* = (t/T)\xi$. Hence, $\mathcal{X}_{m+2} \subset \mathcal{K}_0(\boldsymbol{\mathcal{W}}_m) \subset \cap_{\mu<m+1}\mathcal{X}_m$. Any *more* precise estimate of $\mathcal{K}_0(\boldsymbol{\mathcal{W}}_m)$ would be much more difficult to obtain — even in this "simple" setting.

In considering the nonlinear partial differential equation (2.8), our assumptions make φ uniformly Lipschitzian in $x, \nabla x$, so a standard (Picard iteration) argument gives existence of a (unique) solution of the nonlinear equation (2.8) in $\boldsymbol{\mathcal{X}}_0$ for, say, any control $w \in \boldsymbol{\mathcal{W}}_0 = L^2(\mathcal{Q})$; compare the proof of Lemma 3 below and the proof of Lemma 4 in [15]. This then gives $\varphi(\cdot, x, \nabla x) =: \mathbf{F}x =: \mathbf{G}_\mathbf{F} w =: g$ again in $L^2(\mathcal{Q})$ so $[g + w] \in \boldsymbol{\mathcal{W}}_0$ and by the analysis above, we then have $x \in \boldsymbol{\mathcal{X}}_\mu$ for arbitrary $\mu < 1$ and this gives $\mathcal{K}_\mathbf{F} \subset \cap_{\mu<1}\mathcal{X}_\mu$. For smoother controls one can similarly obtain the regularity result: $\mathcal{K}_\mathbf{F}(\boldsymbol{\mathcal{W}}_m) \subset \cap_{\mu<m+1}\mathcal{X}_\mu$ provided one has an estimate of the form:

$$\|(-\mathbf{A})^{\mu/2}\mathbf{F}x\| \leq C[1 + \|(-\mathbf{A})^{(\mu+1)/2}x\|] \tag{2.10}$$

for such μ. The estimate (2.10) follows from the assumed regularity of φ while $\mu < \frac{1}{2}$ but the boundary conditions then intervene; one will only continue to have (2.10), at least while $\mu < \frac{5}{2}$, provided that, in addition to the bounds on derivatives for φ, one were to require that $\varphi(\cdot, 0, \cdot) = 0$ on $\partial\Omega$ so $x|_{\partial\Omega} = 0$ also implies $[\mathbf{F}x]|_{\partial\Omega} = 0$.

For the nonlinear equation (2.8) there is no longer a simple explicit calculation to give a useful *lower* bound for $\bar{\mathcal{K}}_\mathbf{F}(\boldsymbol{\mathcal{W}}_m)$. Taking $\mathcal{X} = \mathcal{X}_0$, for example, we have $\mathcal{X}_{m+2}$ dense in $\mathcal{X}$ for arbitrary m so $\bar{\mathcal{K}}_0(\boldsymbol{\mathcal{W}}_m) = \mathcal{X}$ and we would similarly like to show that $\bar{\mathcal{K}}_\mathbf{F}(\boldsymbol{\mathcal{W}}_m) = \mathcal{X}$. Under the assumptions we are now imposing, we can consider, e.g., $1 < m < \frac{3}{2}$ and get

$$\mathbf{L}_{[T]}g \in \mathcal{D}(\mathbf{A}) = [\mathcal{D}([-\mathbf{A}]^{m+1}), \mathcal{X}]_\vartheta \subset [\mathcal{K}_0(\boldsymbol{\mathcal{W}}_m, \mathcal{X}]_\vartheta$$

[2] Since $\mathbf{A}$ generates an analytic semigroup on $\mathcal{X}_0$ one has

$$\|(-\mathbf{A})^r\mathbf{S}(\tau)\| \leq C\tau^{-r} \tag{2.9}$$

on bounded intervals for $r \geq 0$ and with C depending on r and the interval.

with $\vartheta = m/(m+1)$ as parameter for the interpolation spaces, corresponding to (5.41). Thus, looking ahead, we note that the assumptions of Theorem 5 will then be satisfied if one further imposes a growth condition on φ to strengthen (2.10) so as to get (6.48) with $r < 1/(m+1)$.

Example 3. For our next example we take $\Omega = (0,1) \subset \mathbb{R}^1$ and consider

$$\begin{aligned} &\dot{x} = x'' + \varphi(x, x') &&\text{on} \quad \mathcal{Q} := (0,T) \times (0,1), \\ &x(\cdot, 0) = u(\cdot), \ x(\cdot, 1) = 0 &&\text{on} \quad (0,T). \end{aligned} \tag{2.11}$$

As above we assume φ is uniformly Lipschitzian and take $\mathcal{X} := L^2(0,1)$; we now wish to take

$$\boldsymbol{\mathcal{W}}_{ad} = \boldsymbol{\mathcal{U}}_{ad} := \{\text{integer-valued step functions on } (0,T)\}.$$

We again take $\boldsymbol{\mathcal{Y}} := L^2([0,T] \to H^1(0,1))$ and $\boldsymbol{\mathcal{V}} := L^2(\mathcal{Q})$. Since we can "restart" the equations at each of the (finitely many) jumps of $u \in \boldsymbol{\mathcal{U}}_{ad}$, there is no difficulty with the solvability, for each such u, of the various equations: solutions will be piecewise smooth. Our difficulty is now with the continuity of the maps and with the desired convexity of $\boldsymbol{\mathcal{Z}}_{ad}$.

Suppose the scalar function φ also satisfies a growth condition $\varphi(r,s) \le a_0 + a_1|r|$ so the Nemytsky operator $\mathbf{F}$ satisfies $|[\mathbf{F}x](t)|_{\mathcal{X}} \le C_0 + C_1|x(t)|_{\mathcal{X}}$, independent of x'. In this case, a bound on u in, say, $L^2(0,T)$ gives solutions, for (2.11) and for the corresponding linear equations, in a compact subset of $\boldsymbol{\mathcal{X}}$ and, using interior regularity, such that the corresponding gradients are in a compact subset of, say, $L^2((0,T)\times(a,b))$ for any $0 < a < b < 1$. It follows, extracting suitable convergent subsequences for which the gradients are converging pointwise ae, that if one considers any bounded set in $L^2(0,T)$ then all limits of the solutions will again be solutions in $\boldsymbol{\mathcal{X}}$. We now observe (compare Lemma 5) that the set $\boldsymbol{\mathcal{U}}_{ad}$ above and the set $\boldsymbol{\mathcal{W}} := H_0^1(0,T)$ have the same (sequential) weak closure in $L^2(0,T)$, i.e., all of $L^2(0,T)$, so the $\boldsymbol{\mathcal{X}}$-closures of the sets of solutions (and so the corresponding approximately reachable sets) will be the same for each of these as for $L^2(0,T)$ — restricted to those u for which there are, indeed, solutions in $\boldsymbol{\mathcal{X}}$ satisfying the boundary conditions in a meaningful sense. It follows that we can take $\boldsymbol{\mathcal{W}}'_{ad} := \boldsymbol{\mathcal{W}}$ and $\boldsymbol{\mathcal{Z}}'_{ad} = \boldsymbol{\mathcal{Z}} := \mathbf{S}\boldsymbol{\mathcal{W}}'_{ad}$ (noting that we do have continuity and compactness for $\mathbf{S} : \boldsymbol{\mathcal{W}} \to \boldsymbol{\mathcal{X}} \cap \boldsymbol{\mathcal{Y}}$) with equivalence in the sense of (3.17). We will have $(\mathbf{H}_1)$ and the needed convexity if we work with this $\boldsymbol{\mathcal{Z}}_{ad}$.

Example 4. For our final example we consider a quasi-linear wave equation

$$\ddot{x} = \Delta x + \varphi(\cdot, x) \text{ on } \mathcal{Q}, \qquad x|_{\Sigma} = u \tag{2.12}$$

where we assume φ is smooth, uniformly Lipschitzian and with a growth condition $|\varphi| \le C(1 + |x|)^{\bar{r}}$ with $\bar{r} < 1$. We assume homogeneous initial conditions: $x(0) = 0 = \dot{x}(0)$ and that the controls $u \in \boldsymbol{\mathcal{U}}_{ad}$ are to be taken smooth enough to have an extension to $\mathcal{Q}$, again denoted by u, with, say, $q := [\ddot{u} - \Delta u] \in L^2(\mathcal{Q})$. This will ensure that the solution $z = z_u$ of the corresponding form of (1.2)

$$\ddot{z} = \Delta z \text{ on } \mathcal{Q}, \qquad z|_{\Sigma} = u \tag{2.13}$$

will be in $\boldsymbol{\mathcal{Z}} := C^1([0,T] \to L^2(\Omega) \cap C([0,T] \to H^1(\Omega))$, using an estimate obtained by multiplying (2.13) by $[z - u]$, integrating, and applying the Gronwall Inequality. If we take $\boldsymbol{\mathcal{V}} := L^2(\mathcal{Q})$, then a similar estimate shows the continuity of $\mathbf{L} : \boldsymbol{\mathcal{V}} \to \boldsymbol{\mathcal{Z}}$. Finally, we note that (1.5) becomes

$$\ddot{y} = \Delta y + \varphi(\cdot, y + z) \text{ on } \mathcal{Q}, \qquad y|_{\Sigma} = 0$$

and a standard contraction mapping argument gives existence of a solution $y \in \boldsymbol{\mathcal{Z}}$, using the Lipschitz property of φ, with an estimate $|y| = \mathcal{O}(|z|^{\bar{r}})$ where $|y|$ is the $\boldsymbol{\mathcal{Z}}$-norm and $|z|$ is the $\boldsymbol{\mathcal{V}}$-norm. The compactness of the embedding $\boldsymbol{\mathcal{Z}} \hookrightarrow \boldsymbol{\mathcal{V}}$ then completes the verification of the general hypotheses $(\mathbf{H}_1)$ with the growth condition (4.28).

We note two particular cases of interest from the viewpoint of reachability: (1) in the one-dimensional case with $\boldsymbol{\mathcal{U}}_{ad}$ consisting of functions vanishing at one end of Ω and nonnegative at the other, it is known [13] that $\mathcal{K}_0$ is dense in, say, $\mathcal{X} = L^2(\Omega)$ for T large enough; (2) for $\Omega \subset \mathbb{R}^m$ with $u \in \boldsymbol{\mathcal{U}}_{ad}$ having support in some small fixed subset $\Gamma \subset \partial\Omega$ and/or with T not too large, then the reachable set will only be some (small) part of $\mathcal{X}$ and it is interesting to ask whether a geometric restriction on the support in $\mathcal{Q}$ for φ could provide the hypotheses for invariance.

3. Formulation and notation. We have already introduced the set $\boldsymbol{\mathcal{Z}}_{ad}$ of solutions of (1.2) (in some fixed sense) as the control u ranges over $\boldsymbol{\mathcal{U}}_{ad}$ and the (formal) operator $\mathbf{E} : x \mapsto x(T)$. We now also introduce the linear solution operator $\mathbf{L}$:

$$\mathbf{L} : v \mapsto x \text{ such that } \dot{x} = \mathbf{A}x + v \tag{3.14}$$

(with homogeneous initial conditions) for suitable $v(\cdot)$. Note that (1.2) and (1.4) have linear dynamics (i.e., linear in z or x although not necessarily in u) while the dynamics given by the perturbed equation (1.1) are quasi-linear.

We have already made our *first basic observation*: neither $\mathbf{B}$ nor $u \in \boldsymbol{\mathcal{U}}_{ad}$ (nor their individual properties) can be relevant to any of (1.2), (1.1), (1.4), but only $w := \mathbf{B}(u)$, considered as an element of some space $\boldsymbol{\mathcal{W}}$. Indeed, we have seen that the only *really* relevant entity is $z = z_u$, the corresponding solution of (1.2). Thus, the effects of control are entirely determined by the set $\boldsymbol{\mathcal{Z}}_{ad}$.

Expressed in terms of this (formal) operator $\mathbf{L}$, the differential equations (1.1) and (1.4) then take the abstract forms:

$$x = \mathbf{LF}x + z \qquad (z \in \boldsymbol{\mathcal{Z}}_{ad}), \tag{3.15}$$

$$x = \mathbf{L}g + z \qquad (z \in \boldsymbol{\mathcal{Z}}_{ad},\ g \in \boldsymbol{\mathcal{G}}), \tag{3.16}$$

where $\boldsymbol{\mathcal{Z}}_{ad}$ is now simply a (specified) subset of some function space $\boldsymbol{\mathcal{Z}}$ and $\boldsymbol{\mathcal{G}}$ is a specified subset of another function space $\boldsymbol{\mathcal{V}}$. Until one specifies the spaces involved this is purely formal but we note here that, although we refer for convenience to (1.1), (1.2), (1.4), we will always be interpreting "solution" in the present sense: through the *abstract operator equations* (3.15), (3.16) with any hypotheses and interpretations to be attached to these. Except for this section, the (motivating) earlier examples, and the final section, our considerations are independent of any interpretation of (3.15) and (3.16) as differential equations.

Note that, since we consider the equations (1.2), etc., with fixed initial conditions, it is always possible, with no loss of generality, to translate the problem by some fixed trajectory z_0, correspondingly modifying $\mathbf{F}$, $\boldsymbol{\mathcal{Z}}_{ad}$, and all reachable sets. Henceforth, for expository simplicity, we do assume that, ab initio, the problem has been formulated with homogeneous initial conditions so that one has $z_u = \mathbf{L}w$ where $w = \mathbf{B}(u)$. At the same time, once one has avoided consideration of any (essentially irrelevant) problems with regularity near the initial time, it is convenient to assume that all our solutions are elements of the fixed space $\boldsymbol{\mathcal{X}} := C([0,T] \to \mathcal{X})$ so that, in particular, the operator $\mathbf{E} : \boldsymbol{\mathcal{X}} \to \mathcal{X}$ is always well defined and continuous. We also assume that $\boldsymbol{\mathcal{Z}}_{ad} \subset \boldsymbol{\mathcal{X}}$ set-theoretically, but may find it convenient to topologize it somewhat differently: as $\boldsymbol{\mathcal{Z}}_{ad} \subset \boldsymbol{\mathcal{Z}}$; e.g., if there is a continuous embedding $\boldsymbol{\mathcal{Z}} \hookrightarrow \boldsymbol{\mathcal{X}}$.

Our underlying set of "solvability hypotheses" is:

($\mathbf{H}_1$) Let *each* of the following hold:

(i) Equation (3.14) has a (unique) solution $x = \mathbf{L}v \in \boldsymbol{\mathcal{X}}$ for each $v \in \boldsymbol{\mathcal{V}}$; the linear map $\mathbf{L}$ is well-defined and continuous from $\boldsymbol{\mathcal{V}}$ to $\boldsymbol{\mathcal{X}}$.

(ii) For each $z \in \boldsymbol{\mathcal{Z}}_{ad}$ there is a unique solution x of (3.15) and we assume that $g = \mathbf{F}x$ is in $\boldsymbol{\mathcal{V}}$, i.e., there is a well-defined (nonlinear) map $\mathbf{G} = \mathbf{G}_{\mathrm{F}} : \boldsymbol{\mathcal{Z}}_{ad} \to \boldsymbol{\mathcal{V}} : z \mapsto g$ which we assume is continuous. By ([illegible]) we then have $x \in \boldsymbol{\mathcal{X}}$ for the solution x of (3.15).

(iii) The map $\mathbf{G} : \boldsymbol{\mathcal{Z}}_{ad} \to \boldsymbol{\mathcal{V}}$ is *compact*.

Compare (1.5) for the definition of the map $\mathbf{G}$. In §4 we will consider some specific examples involving partial differential equations and some classes of settings for which these abstract hypotheses can be verified.

Having formulated the "dynamics" of the problem — introducing the relevant spaces and the operators $\mathbf{L}$ and $\mathbf{G}_{\mathrm{F}}$ to obtain (3.15), (3.16) — we next wish to consider the various reachable and approximately reachable sets. We now define $\mathbf{L}_{[t]} : v \mapsto [\mathbf{L}v](t)$ (so, in particular, $\mathbf{EL} = \mathbf{L}_{[\mathrm{T}]}$) and set

$$\mathbf{T} = \mathbf{T}_{\mathrm{F}} := \mathbf{L}_{[\mathrm{T}]}\mathbf{G} + \mathbf{E} : \boldsymbol{\mathcal{Z}}_{ad} \to \mathcal{X} : z \mapsto \xi := \mathbf{E}x \text{ such that (3.15).}$$

Clearly, in view of ($\mathbf{H}_1$), the operator $\mathbf{T}$ is continuous. If, for arbitrary $\boldsymbol{\mathcal{Z}}_* \subset \boldsymbol{\mathcal{Z}}$, we define:

$$\begin{aligned}
\mathcal{K}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}_*) &:= \{\mathbf{E}x : \text{(3.15) for } z \in \boldsymbol{\mathcal{Z}}_*\} = \{\mathbf{T}_{\mathrm{F}}z : z \in \boldsymbol{\mathcal{Z}}_*\},\\
\mathcal{K}_0(\boldsymbol{\mathcal{Z}}_*) &:= \mathbf{E}\boldsymbol{\mathcal{Z}}_* := \{\mathbf{E}z : z \in \boldsymbol{\mathcal{Z}}_*\},\\
\mathcal{K}_g(\boldsymbol{\mathcal{Z}}_*) &:= \{(\mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}z) : z \in \boldsymbol{\mathcal{Z}}_*\} = \mathbf{L}_{[\mathrm{T}]}g + \mathcal{K}_0(\boldsymbol{\mathcal{Z}}_*),
\end{aligned}$$

then the (exactly) *reachable sets* for (1.2), (1.1), and (1.4) will be $\mathcal{K}_0 = \mathcal{K}_0(\boldsymbol{\mathcal{Z}}_{ad})$, $\mathcal{K}_{\mathrm{F}} = \mathcal{K}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}_{ad})$, and $\mathcal{K}_g = \mathcal{K}_g(\boldsymbol{\mathcal{Z}}_{ad})$, respectively. The corresponding approximately reachable sets are then the $\mathcal{X}$-closures: $\bar{\mathcal{K}}_0$, $\bar{\mathcal{K}}_{\mathrm{F}}$, $\bar{\mathcal{K}}_g$, respectively (i.e., $\overline{\mathcal{K}_0(\boldsymbol{\mathcal{Z}}_{ad})}$, etc.). We make here our *second basic observation*: for present purposes we may always replace the "original" $\boldsymbol{\mathcal{Z}}_{ad}$ at our convenience with any other set $\boldsymbol{\mathcal{Z}}'_{ad}$ for which the approximately reachable sets are the same:

$$\bar{\mathcal{K}}_0(\boldsymbol{\mathcal{Z}}'_{ad}) = \bar{\mathcal{K}}_0(\boldsymbol{\mathcal{Z}}_{ad}),\ \bar{\mathcal{K}}_g(\boldsymbol{\mathcal{Z}}'_{ad}) = \bar{\mathcal{K}}_g(\boldsymbol{\mathcal{Z}}_{ad}),\ \bar{\mathcal{K}}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}'_{ad}) = \bar{\mathcal{K}}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}_{ad}). \tag{3.17}$$

In particular, the continuity of $\mathbf{G}$ assumed in ($\mathbf{H}_1$)(ii) will mean that we can always take $\boldsymbol{\mathcal{Z}}_{ad}$ closed, i.e., replacing it by its closure with no loss of generality. As part of this observation we also note that $\boldsymbol{\mathcal{Z}}_{ad}$ — or, equivalently, $\boldsymbol{\mathcal{Z}}'_{ad}$ satisfying (3.17) — is of purely set-theoretic significance so the relevant topology is at our convenience.

It is sometimes convenient to introduce explicitly the intermediate space $\boldsymbol{\mathcal{W}}$ such that $\mathbf{B}(u) \in \boldsymbol{\mathcal{W}}_{ad} \subset \boldsymbol{\mathcal{W}}$ so $\boldsymbol{\mathcal{Z}}_{ad} = \mathbf{S}\boldsymbol{\mathcal{W}}_{ad}$ and to consider the map: $u \mapsto w := \mathbf{B}(u) \mapsto z = z_u$ defined by (1.2). The second "factor" of this is the (linear) solution map for (1.2):

$$\mathbf{S} : \boldsymbol{\mathcal{W}} \to \boldsymbol{\mathcal{Z}} : w \mapsto z \tag{3.18}$$

and we now write $\boldsymbol{\mathcal{W}}_{ad} \equiv \boldsymbol{\mathcal{W}}'_{ad}$ if $\boldsymbol{\mathcal{Z}}_{ad} := \mathbf{S}\boldsymbol{\mathcal{W}}_{ad}$ and $\boldsymbol{\mathcal{Z}}'_{ad} := \mathbf{S}\boldsymbol{\mathcal{W}}'_{ad}$ are equivalent in the sense of (3.17).

In our previous work we assumed, with $\boldsymbol{\mathcal{G}}_* = \boldsymbol{\mathcal{V}}$, that the *exactly* reachable set for (1.2) was invariant under all the affine perturbations (1.4) for $g \in \boldsymbol{\mathcal{V}}$, i.e., that

$$\mathcal{K}_g = \mathcal{K}_0 \text{ for each } g \in \boldsymbol{\mathcal{G}}_*. \tag{3.19}$$

The natural reachability condition for us to consider in attempting a corresponding treatment of approximate controllability would seem to be

$$\bar{\mathcal{K}}_g = \bar{\mathcal{K}}_0 \text{ for each } g \in \boldsymbol{\mathcal{G}}_* \tag{3.20}$$

but we will need to strengthen half of this, the inclusion

$$\mathcal{K}_0 \subset \bar{\mathcal{K}}_g, \tag{3.21}$$

to obtain the desired result. Suppose, given $\xi \in \mathcal{X}$ and $\varepsilon > 0$, we introduce the set-valued function $\mathcal{C}(\cdot) = \mathcal{C}(\cdot;\xi,\varepsilon)$ defined on $\boldsymbol{\mathcal{V}}$ by

$$\mathcal{C}(g;\xi,\varepsilon) := \{z \in \boldsymbol{\mathcal{Z}}_{ad} : |\xi - [\mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}z]|_{\mathcal{X}} \le \varepsilon\}. \tag{3.22}$$

Then (3.21) just means that $\mathcal{C}(g;\xi,\varepsilon)$ is nonempty for each $\xi \in \mathcal{K}_0$ and each $\varepsilon > 0$. Fixing $\xi \in \mathcal{K}_0$ and $\varepsilon > 0$, we now set

$$\nu(g) = \nu(g;\xi,\varepsilon) := \inf\{|z|_{\boldsymbol{\mathcal{Z}}} : z \in \mathcal{C}(g;\xi,\varepsilon)\} \tag{3.23}$$

for $g \in \boldsymbol{\mathcal{V}}$ and then, for $R > 0$, define

$$\beta(R) = \beta(R;\xi,\varepsilon) := \sup\{\nu(\mathbf{G}z;\xi,\varepsilon) : z \in \boldsymbol{\mathcal{Z}}_{ad},\ |z|_{\boldsymbol{\mathcal{Z}}} \le R\} \tag{3.24}$$

To have each $\nu(g)$ finite (for $\varepsilon > 0$ and $g \in \boldsymbol{\mathcal{G}}_*$) just means that $\xi \in \bar{\mathcal{K}}_g$ (for each $g \in \boldsymbol{\mathcal{G}}_*$) so (3.21) means that $\nu(g;\xi,\varepsilon) < \infty$ for each $\varepsilon > 0$ and every $\xi \in \mathcal{K}_0$. This does not yet mean that β will be finite and we will express the desired strengthening of (3.21) quantitatively in terms of $\nu(\cdot)$ and $\beta(\cdot)$.

Returning to the condition (3.20), we finish this section with some observations about the structure of the set $\boldsymbol{\mathcal{V}}_a = \boldsymbol{\mathcal{V}}_a(\boldsymbol{\mathcal{Z}}_{ad})$ given by

$$\boldsymbol{\mathcal{V}}_a := \{g \in \boldsymbol{\mathcal{V}} : \bar{\mathcal{K}}_g = \bar{\mathcal{K}}_0\} = \{g \in \boldsymbol{\mathcal{V}} : \mathbf{L}_{[\mathrm{T}]}g + \bar{\mathcal{K}}_0 = \bar{\mathcal{K}}_0\}, \tag{3.25}$$

noting that (3.20) just asserts that $\boldsymbol{\mathcal{G}}_* \subset \boldsymbol{\mathcal{V}}_a$. Since we always assume $\mathbf{L}_{[\mathrm{T}]}$ is continuous, we always have $\boldsymbol{\mathcal{V}}_a$ closed in $\boldsymbol{\mathcal{V}}$.

LEMMA 1. *$\boldsymbol{\mathcal{V}}_a$ is closed under addition and subtraction. If $\bar{\mathcal{K}}_0$ is convex, then $\boldsymbol{\mathcal{V}}_a$ is a* (*closed*) *subspace of $\boldsymbol{\mathcal{V}}$.*

Proof. Suppose $g, g' \in \boldsymbol{\mathcal{V}}_a$. We first wish to show that $\mathcal{K}_{\bar{g}} \subset \bar{\mathcal{K}}_0$ where $\bar{g} := g - g'$, i.e., for any $\bar{\xi} \in \mathcal{K}_{\bar{g}}$ and $\varepsilon > 0$ that there exists $\bar{z} \in \boldsymbol{\mathcal{Z}}_{ad}$ with $|\bar{\xi} - \mathbf{E}\bar{z}| \le \varepsilon$. To start, we have $\bar{\xi} = \mathbf{L}_{[\mathrm{T}]}\bar{g} + \mathbf{E}z_0 = \xi_1 - \mathbf{L}_{[\mathrm{T}]}g'$ with $\xi_1 := \mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}z_0$. Since $\xi_1 \in \mathcal{K}_g$ and $g \in \boldsymbol{\mathcal{V}}_a$ gives $\mathcal{K}_g \subset \bar{\mathcal{K}}_0$, there must be $z_1 \in \boldsymbol{\mathcal{Z}}_{ad}$ such that $|\xi_1 - \mathbf{E}z_1| \le \varepsilon/2$. Now $\mathbf{E}z_1 \in \mathcal{K}_0$ and $g' \in \boldsymbol{\mathcal{V}}_a$ gives $\mathcal{K}_0 \subset \bar{\mathcal{K}}_{g'} = \mathbf{L}_{[\mathrm{T}]}g' + \bar{\mathcal{K}}_0$ so $(\mathbf{E}z_1 - \mathbf{L}_{[\mathrm{T}]}g') \in \bar{\mathcal{K}}_0$ and there must be $\bar{z} \in \boldsymbol{\mathcal{Z}}_{ad}$ with $|[\mathbf{E}z_1 - \mathbf{L}_{[\mathrm{T}]}g'] - \mathbf{E}\bar{z}| \le \varepsilon/2$. Since $\bar{\xi} - \mathbf{E}\bar{z} = (\xi_1 - \mathbf{E}z_1) + (\mathbf{E}z_1 - [\mathbf{L}_{[\mathrm{T}]}g' + \mathbf{E}\bar{z}])$, this gives $|\bar{\xi} - \mathbf{E}\bar{z}| \le \varepsilon$ as desired so $\bar{\xi} \in \bar{\mathcal{K}}_0$. This shows $\mathbf{L}_{[\mathrm{T}]}\bar{g} + \mathcal{K}_0 \subset \bar{\mathcal{K}}_0$ for $\bar{g} = g - g'$. Reversing the roles of g, g' gives $-\mathbf{L}_{[\mathrm{T}]}\bar{g} + \mathcal{K}_0 \subset \bar{\mathcal{K}}_0$ or $\mathcal{K}_0 \subset \bar{\mathcal{K}}_{\bar{g}}$. Combining gives $\bar{\mathcal{K}}_0 = \bar{\mathcal{K}}_{\bar{g}}$ so $\bar{g} \in \boldsymbol{\mathcal{V}}_a$ for $\bar{g} = g - g' \in \boldsymbol{\mathcal{V}}_a - \boldsymbol{\mathcal{V}}_a$, i.e., $\boldsymbol{\mathcal{V}}_a$ is closed under subtraction. Trivially, $0 \in \boldsymbol{\mathcal{V}}_a$ so $g' \in \boldsymbol{\mathcal{V}}_a$ gives $-g' \in \boldsymbol{\mathcal{V}}_a$ whence $\bar{g} = g - (-g') = g + g'$ is in $\boldsymbol{\mathcal{V}}_a$ for $g, g' \in \boldsymbol{\mathcal{V}}_a$, i.e., $\boldsymbol{\mathcal{V}}_a$ closed under addition also.

If we only show that convexity of $\bar{\mathcal{K}}_0$ implies that of $\boldsymbol{\mathcal{V}}_a$, then the algebraic closure above shows that $\boldsymbol{\mathcal{V}}_a$ is a subspace. Suppose, then, $\bar{g}$ is any convex combination of $\boldsymbol{\mathcal{V}}_a$ so $\bar{g} = \sum c_j g_j$ with $c_j > 0, \sum c_j = 1, g_j \in \boldsymbol{\mathcal{V}}_a$. For any $\xi \in \mathcal{K}_0$ we have $\mathbf{L}_{[\mathrm{T}]}\bar{g} + \xi = \sum c_j(\mathbf{L}_{[\mathrm{T}]}g_j + \xi)$. As each $g_j \in \boldsymbol{\mathcal{V}}_a$ we have each $(\mathbf{L}_{[\mathrm{T}]}g_j + \xi) \in \bar{\mathcal{K}}_0$ so convexity of $\bar{\mathcal{K}}_0$ gives $(\mathbf{L}_{[\mathrm{T}]}\bar{g} + \xi) \in \bar{\mathcal{K}}_0$. This, for each $\xi \in \mathcal{K}_0$, gives $\mathcal{K}_{\bar{g}} \subset \bar{\mathcal{K}}_0$. By Lemma 1 we have also $-\bar{g} = \sum c_j(-g_j)$ a convex combination of $\boldsymbol{\mathcal{V}}_a$ so $[\mathbf{L}_{[\mathrm{T}]}(-\bar{g}) + \xi] \in \bar{\mathcal{K}}_0$ for each $\xi \in \mathcal{K}_0$, i.e., $\xi \in [\mathbf{L}_{[\mathrm{T}]}\bar{g} + \bar{\mathcal{K}}_0] = \bar{\mathcal{K}}_{\bar{g}}$. Combining gives $\bar{\mathcal{K}}_0 = \bar{\mathcal{K}}_{\bar{g}}$ so $\bar{g} \in \boldsymbol{\mathcal{V}}_a$. □

Note that closure under addition shows that $\boldsymbol{\mathcal{V}}_a$ is always unbounded (except for the trivial case: $\boldsymbol{\mathcal{V}}_a = \{0\}$), so $\boldsymbol{\mathcal{Z}}_{ad}$ must then also be unbounded. Note that $\bar{\mathcal{K}}_0$ will certainly be convex if $\boldsymbol{\mathcal{Z}}_{ad}$ is convex.

4. Reachability. At this point we begin our analysis of approximate reachability by proving the trivial part of invariance: if, *for each affine perturbation* by $g \in \boldsymbol{\mathcal{G}}_* := \mathbf{G}\boldsymbol{\mathcal{Z}}_{ad}$ in (1.4), one can reach no state which is not already approximately reachable for (1.2), then the nonlinear perturbation (1.1) can also produce no new reachable states.

LEMMA 2. *Assume* $(\mathbf{H}_1)$(ii) *and the reachability inclusion*

$$\mathcal{K}_g \subset \bar{\mathcal{K}}_0 \textit{ for each } g \in \boldsymbol{\mathcal{G}}_*, \tag{4.26}$$

i.e., $\xi + \mathbf{L}_{[\mathrm{T}]}g \in \bar{\mathcal{K}}_0$ *for* $\xi \in \mathcal{K}_0$, $g \in \boldsymbol{\mathcal{G}}_*$. *Then* $\bar{\mathcal{K}}_\mathrm{F} \subset \bar{\mathcal{K}}_0$.

Proof. Since $\bar{\mathcal{K}}_\mathrm{F} = \bigcap_{\varepsilon>0}[\mathcal{K}_\mathrm{F} + \mathcal{B}_\varepsilon]$ with $\mathcal{B}_\varepsilon := \{\xi \in \mathcal{X} : |\xi| < \varepsilon\}$, we have $\xi \in \bar{\mathcal{K}}_\mathrm{F}$ if and only if for each $\varepsilon > 0$ there is some $\xi_\varepsilon = \mathbf{T}z_\varepsilon \in \mathcal{K}_\mathrm{F}$ with $|\xi_\varepsilon - \xi| < \varepsilon$. Setting $g_\varepsilon := \mathbf{G}z_\varepsilon$, we then have $\mathbf{T}z_\varepsilon = \mathbf{L}_{[\mathrm{T}]}g_\varepsilon + \mathbf{E}z_\varepsilon$ so $\xi_\varepsilon \in \mathcal{K}_{g_\varepsilon}$. This shows that we always have

$$\bar{\mathcal{K}}_\mathrm{F} \subset \bigcap_{\varepsilon>0} \bigcup_{g\in\boldsymbol{\mathcal{G}}_*} [\mathcal{K}_g + \mathcal{B}_\varepsilon] = \bigcap_{\varepsilon>0} \left[\left(\bigcup_{g\in\boldsymbol{\mathcal{G}}_*} \mathcal{K}_g \right) + \mathcal{B}_\varepsilon \right]. \tag{4.27}$$

Now, if one has (4.26), then the right side of (4.27) will be in $\bigcap_{\varepsilon>0}[\bar{\mathcal{K}}_0 + \mathcal{B}_\varepsilon] = \bar{\mathcal{K}}_0$ as asserted. □

For comparison we note that our previous work [11], [12], [15], [16] obtained essentially the following result.

THEOREM 1. *Let* $\boldsymbol{\mathcal{Z}}_{ad} = \boldsymbol{\mathcal{Z}}$ *be a Banach space* [3] *and assume* $(\mathbf{H}_1)$ *together with the growth condition*

$$|\mathbf{G}_\mathrm{F}z|_{\boldsymbol{\mathcal{V}}} \leq C_0 + C_1|z|^{\bar{r}}_{\boldsymbol{\mathcal{Z}}}. \tag{4.28}$$

for some $\bar{r} < 1$. *Assume the reachability invariance* (3.19): $\mathcal{K}_g = \mathcal{K}_0$ *for each* $g \in \boldsymbol{\mathcal{V}}$. *Then* $\mathcal{K}_\mathrm{F} = \mathcal{K}_0$, *i.e., the* exactly *reachable set is then invariant under the perturbation by* $\mathbf{F}$.

(*Of course this implies invariance of the approximately reachable set: we also have* $\bar{\mathcal{K}}_\mathrm{F} = \bar{\mathcal{K}}_0$.)

Proof. We only sketch the proof here to fix the ideas; for details, see [15]. From the inclusion $\mathcal{K}_g \subset \mathcal{K}_0$, we can argue as in Lemma 2 to have $\mathcal{K}_\mathrm{F} \subset \mathcal{K}_0$. The principal effort must go into showing that one also has the reverse inclusion $\mathcal{K}_0 \subset \mathcal{K}_\mathrm{F}$.

[3] In the previous papers $\boldsymbol{\mathcal{U}}_{ad} = \boldsymbol{\mathcal{U}}$ was a Banach space with $\mathbf{B}$ linear. The modification to the present formulation requires no essential change in the ideas at this point since we can topologize $\boldsymbol{\mathcal{Z}}$ by identification with $\boldsymbol{\mathcal{U}}/\mathcal{N}(\mathbf{B})$ when $\mathbf{B}$ is linear.

The proof begins by noting equivalence of (3.19) to the range condition

$$\mathbf{L}_{[\mathrm{T}]}\boldsymbol{\mathcal{V}} \subset \mathbf{E}\boldsymbol{\mathcal{Z}}. \tag{4.29}$$

Then the nullspace of the continuous linear map:

$$[g, \{z\}] \mapsto \mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}z : \boldsymbol{\mathcal{V}} \times [\boldsymbol{\mathcal{Z}}/\mathcal{N}(\mathbf{E})] \to \mathcal{X}$$

will be the graph of a linear operator: $g \mapsto \{z\}$ which is bounded by the Closed Graph Theorem. By the Michael Selection Theorem [10], there is a continuous right inverse to the canonical projection: $z \mapsto \{z\} : \boldsymbol{\mathcal{Z}} \to [\boldsymbol{\mathcal{Z}}/\mathcal{N}(\mathbf{E})]$ which may be taken to be of linear growth.

Composing, for any fixed $\xi \in \mathcal{K}_0$, there is a continuous selection $\mathbf{C} = \mathbf{C}_\xi : \boldsymbol{\mathcal{V}} \to \boldsymbol{\mathcal{Z}}$ satisfying

$$\mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}[\mathbf{C}g] = \xi \tag{4.30}$$

and a linear growth condition: $|\mathbf{C}g|_{\boldsymbol{\mathcal{Z}}} = \mathcal{O}(|g|_{\boldsymbol{\mathcal{V}}})$. It is an important point that $\mathbf{C}$ depends only on the range inclusion (4.29) and not at all on $\mathbf{F}$.

We then consider the map: $\boldsymbol{\mathcal{Z}} \to \boldsymbol{\mathcal{Z}}$ given by

$$\mathbf{C}\mathbf{G}_{\mathrm{F}} : z \mapsto g := \mathbf{G}_{\mathrm{F}}z \mapsto \hat{z} := \mathbf{C}g \tag{4.31}$$

and note that this can be restricted to an invariant ball by using the linear growth of $\mathbf{C}$ and the sublinear growth condition in (4.28). Using $(\mathbf{H}_1)$(iii), the Schauder Fixpoint Theorem applies to give the desired result since using a fixpoint $\hat{z}$ of $\mathbf{C}_\xi\mathbf{G}$ in (3.15) just gives $\mathbf{T}_{\mathrm{F}}\hat{z} = \xi$. □

Our intention here is to use, for the analysis of the approximately reachable set, a modified version of the argument used above for the exactly reachable set. We already have Lemma 2 and have noted that the real problem is to determine when $\bar{\mathcal{K}}_0 \subset \bar{\mathcal{K}}_{\mathrm{F}}$, which is just the question (**Q**) of the Introduction. It is not difficult to see, much as for (4.27), that we have

$$\bar{\mathcal{K}}_{\mathrm{F}} = \bigcap_{\varepsilon>0} \{\xi \in \mathcal{X} : \Phi(\xi,\varepsilon) \neq \emptyset\} \tag{4.32}$$

where $\Phi(\xi,\varepsilon) := \{z \in \boldsymbol{\mathcal{Z}}_{ad} : z \in \mathcal{C}(\mathbf{G}z;\xi,\varepsilon)\}$. Our argument, then, is to show that the set-valued map: $z \mapsto \mathcal{C}(\mathbf{G}z;\xi,\varepsilon)$ has a fixpoint (so $\Phi(\xi,\varepsilon)$ is nonempty) for $\xi \in \mathcal{K}_0$ and all $\varepsilon > 0$. We take the inclusion $\mathcal{K}_0 \subset \bar{\mathcal{K}}_g$ of (3.20) as a starting point but, again as noted, we will be forced to strengthen this.

The critical difficulty with this program is that (4.29), with $\boldsymbol{\mathcal{Z}}_{ad}$ a Banach space, was essential for the applicability of the theorems used above to obtain the essential continuity and linear growth for $\mathbf{C}_\xi$ and so, with the growth condition (4.28), existence of an invariant ball for the mapping $\mathbf{C}_\xi\mathbf{G}_{\mathrm{F}}$. The various results in this paper correspond to ways of handling this difficulty.

We have already made our *third basic observation*: for present purposes we may not only fix ξ (arbitrary $\xi \in \mathcal{K}_0$) but also ε (arbitrary $\varepsilon > 0$): now considering $\mathbf{C} = \mathbf{C}_{\xi,\varepsilon} : \boldsymbol{\mathcal{G}} \to \boldsymbol{\mathcal{Z}}_{ad}$, we weaken (4.30) to require only that

$$\mathbf{C}_{\xi,\varepsilon}(g) \in \mathcal{C}(g;\xi,\varepsilon) \text{ so } |\xi - (\mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}[\mathbf{C}g])|_{\mathcal{X}} \leq \varepsilon. \tag{4.33}$$

One easily sees that having $\mathcal{C}(g;\xi,\varepsilon)$ nonempty (for each $\xi \in \mathcal{K}_0$ and each $\varepsilon > 0$) is precisely equivalent to the inclusion $\mathcal{K}_0 \subset \bar{\mathcal{K}}_g$. Given this and the compactness of $\mathbf{G}_{\mathrm{F}}$, it is not too difficult to construct $\mathbf{C} = \mathbf{C}_{\xi,\varepsilon}$ continuous giving (4.33) for each $g \in \boldsymbol{\mathcal{G}}_*$. Unfortunately, without strengthening this condition we cannot obtain a growth rate for $\mathbf{C} = \mathbf{C}_{\xi,\varepsilon}$ which, with (4.28), would give a bounded invariant set. (Under the strong assumption that $\mathbf{E}\boldsymbol{\mathcal{G}}_*$ is known to be precompact in $\mathcal{X}$, we do, however, have Theorem 6, below.) Our basic approach is embodied in the following theorems.

THEOREM 2. *Assume* $(\mathbf{H}_1)$. *Let* $\boldsymbol{\mathcal{Z}}_{ad}$ *be convex and, for some* $\xi \in \mathcal{X}$ *and* $\varepsilon > 0$, *assume that there is some* $R = R(\xi, \varepsilon)$ *such that*

$$\beta(R; \xi, \varepsilon) < R. \tag{4.34}$$

Then there is some $\bar{z} \in \boldsymbol{\mathcal{Z}}_{ad}$ *(with* $|\bar{z}| \leq R$*) such that* $|\xi - \mathbf{T}_{\mathrm{F}}\bar{z}| \leq 2\varepsilon$.

Proof. By $(\mathbf{H}_1)$ we have $\mathbf{G}$, $\mathbf{L}$, $\mathbf{T}_{\mathrm{F}}$ continuous so there is no loss of generality in taking $\boldsymbol{\mathcal{Z}}_{ad}$ closed in $\boldsymbol{\mathcal{Z}}$ (i.e., replacing it by its closure). Now define

$$\boldsymbol{\mathcal{Z}}_R := \{z \in \boldsymbol{\mathcal{Z}}_{ad} : |z| \leq R\}, \quad \boldsymbol{\mathcal{G}}_R := \mathbf{G}\boldsymbol{\mathcal{Z}}_R = \{\mathbf{G}z : z \in \boldsymbol{\mathcal{Z}}_R\}. \tag{4.35}$$

Note that (i) $\boldsymbol{\mathcal{Z}}_R$ is closed and convex in $\boldsymbol{\mathcal{Z}}$, (ii) $\boldsymbol{\mathcal{G}}_R$ is precompact in $\boldsymbol{\mathcal{V}}$ by $(\mathbf{H}_1)$(iii), and (iii) $\mathcal{C}_R(g) := \boldsymbol{\mathcal{Z}}_R \cap \mathcal{C}(g; \xi, \varepsilon)$ is nonempty for each $g \in \boldsymbol{\mathcal{G}}_R$ since $\nu(g) \leq \beta(R) < R$. By (ii), we can find a finite set of "centers" $\{g_j : j = 1, \cdots, J\}$ such that

$$\min_j\{|g - g_j|\} \leq \delta := \varepsilon/2\|\mathbf{L}_{[\mathrm{T}]}\| \text{ for each } g \in \boldsymbol{\mathcal{G}}_R \tag{4.36}$$

and by (iii), we can find $z_j \in \mathcal{C}_R(g_j)$ for each j. A standard construction gives a continuous partition of unity subordinate to the covering of $\boldsymbol{\mathcal{G}}_R$ by 2δ-balls centered at $\{g_j\}$, i.e., continuous scalar functions φ_j on $\boldsymbol{\mathcal{V}}$ such that

$$\varphi_j \geq 0, \ \sum \varphi_j(g) = 1 \text{ for } g \in \boldsymbol{\mathcal{G}}_R, \quad \varphi_j(g) > 0 \Longrightarrow |g - g_j| \leq 2\delta.$$

We now define $\mathbf{C} = \mathbf{C}_{\xi,\varepsilon}$ by

$$\mathbf{C}g := \sum \varphi_j(g) z_j$$

and note that this gives $\mathbf{C} : \boldsymbol{\mathcal{G}}_R \to \boldsymbol{\mathcal{Z}}_R$ since $\boldsymbol{\mathcal{Z}}_R$ is convex. Clearly $\mathbf{C}$ is continuous and, as each $z_j \in \mathcal{C}(g_j)$, a simple computation from (3.22) gives

$$|\xi - [\mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}\mathbf{C}g]|_{\mathcal{X}} \leq 2\varepsilon \quad \text{for each } g \in \boldsymbol{\mathcal{G}}_R. \tag{4.37}$$

From $(\mathbf{H}_1)$ we have $\mathbf{C}\mathbf{G} : \boldsymbol{\mathcal{Z}}_R \to \boldsymbol{\mathcal{Z}}_R$ continuous and compact so, applying the Schauder Fixpoint Theorem, there is a fixpoint $\bar{z} \in \boldsymbol{\mathcal{Z}}_R$, i.e., we have $\mathbf{C}\bar{g} = \bar{z}$ for $\bar{g} = \mathbf{G}\bar{z}$. Putting $g = \bar{g}$ gives $\mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}\mathbf{C}g = \mathbf{L}_{[\mathrm{T}]}\mathbf{G}\bar{z} + \mathbf{E}\bar{z} =: \mathbf{T}_{\mathrm{F}}\bar{z}$ so (4.37) gives $|\xi - \mathbf{T}_{\mathrm{F}}\bar{z}| \leq 2\varepsilon$ as desired. □

THEOREM 3. *Assume* $(\mathbf{H}_1)$ *with* (4.28) *and that* $\boldsymbol{\mathcal{Z}}_{ad}$ *is convex. Now suppose, for some* $\xi \in \mathcal{K}_0$ *and each* $\varepsilon > 0$, *that one has a growth rate*

$$\nu(g) \leq \tilde{C}_0 + \tilde{C}_1|g|_{\boldsymbol{\mathcal{V}}}^{\tilde{r}} \quad \textit{for } g \in \boldsymbol{\mathcal{G}}_* \tag{4.38}$$

with $\tilde{r} < 1/\bar{r}$. *(Here,* ν *is defined as in* (3.23)*; the numbers* $\tilde{C}_0, \tilde{C}_1, \tilde{r}$ *may depend on* ξ, ε.*) Then one has* $\xi \in \bar{\mathcal{K}}_{\mathrm{F}}$.

Proof. Substituting (4.28) in (4.38) gives

$$\beta(R) \leq \tilde{C}_0 + \tilde{C}_1[C_0 + C_1 R^{\bar{r}}]^{\tilde{r}} = \mathcal{O}(R^{\bar{r}\tilde{r}}) = o(R)$$

as $\bar{r}\tilde{r} < 1$. Hence one can always find $R = R(\xi, \varepsilon)$ for which $\beta(R) < R$ so Theorem 2 applies. □

Note that if we have this for *every* $\xi \in \mathcal{K}_0$ and also have the hypotheses of Lemma 2, then we have shown, as in the title, *invariance of the approximately reachable set* under the nonlinear perturbation $\mathbf{F}$, i.e., $\bar{\mathcal{K}}_{\mathrm{F}} = \bar{\mathcal{K}}_0$.

The condition (4.28) is the same growth condition for the nonlinearity as was imposed in Theorem 1. Note also that the condition (4.38) implies, in particular, that ν is finite and so quantitatively strengthens the simple requirement of approximate reachability for each (1.4):

$$\xi \subset \bar{\mathcal{K}}_g = \mathbf{L}_{[\mathrm{T}]}g + \bar{\mathcal{K}}_0 \text{ for each } g \in \boldsymbol{\mathcal{G}}_* := \{\mathbf{G}_{\mathrm{F}}z : z \in \boldsymbol{\mathcal{Z}}_{ad}\} \tag{4.39}$$

which, for every $\xi \in \mathcal{K}_0$, would just be (3.21). We can also use this approach — more-or-less unchanged, with proper formulation — in a somewhat more complicated nonlinear setting in which the linear operator $\mathbf{A}$ is also taken to depend on x, u. Without developing this further at the present time, we provide the formulation here in the hope that it will also add to the reader's insight into the essential aspects of the original argument above. Clearly one might continue to extend the same basic ideas.

We now suppose that we wish to analyze approximate reachability for an equation of the form

$$\dot{x} = \mathbf{A}(x, u)x + f(x, u) + \mathbf{B}u, \qquad u \in \boldsymbol{\mathcal{U}}_{ad} \tag{4.40}$$

by comparison with similar considerations for the family of (presumably simpler) equations (1.4); now, $\mathbf{A}$ ranges over a suitable set $\boldsymbol{\mathcal{A}}$ of linear operators and g ranges over $\boldsymbol{\mathcal{G}}$. As above, we assume that $\mathbf{A}(x_u, u) \in \boldsymbol{\mathcal{A}}$ and $f(x_u, u) \in \boldsymbol{\mathcal{G}}$ for each solution x_u of (4.40) as u ranges over $\boldsymbol{\mathcal{U}}_{ad}$ and that that solutions are here also taken in $\boldsymbol{\mathcal{X}} := C([0,T] \to \mathcal{X})$ where $\mathcal{X}$ is the state space. We assume that there are well-defined maps

$$\begin{array}{rccl} \mathbf{M}: & \boldsymbol{\mathcal{U}}_{ad} \to \boldsymbol{\mathcal{A}} & : & u \mapsto \mathbf{A}(x_u, u), \\ \mathbf{L}_{[\mathrm{T}]}: & \boldsymbol{\mathcal{U}}_{ad} \times \boldsymbol{\mathcal{A}} \times \boldsymbol{\mathcal{G}} \to \mathcal{X} & : & [u, \mathbf{A}, g] \mapsto x_u(T) \end{array}$$

given by (4.40) and (1.4), respectively. We will take $\boldsymbol{\mathcal{U}}_{ad}$ to be a convex subset of a suitable Banach space and take $\boldsymbol{\mathcal{A}}$, $\boldsymbol{\mathcal{G}}$ to be compact Hausdorff spaces; we assume the topologies can be taken so that $\mathbf{L}_{[\mathrm{T}]}$ and $\mathbf{M}$ are continuous. Much as before, we then introduce

$$\begin{aligned} \mathcal{C}(\mathbf{A}, g; \xi, \varepsilon) &= \{u \in \boldsymbol{\mathcal{U}}_{ad} : |\xi - \mathbf{L}_{[\mathrm{T}]}[u, \mathbf{A}, g]| < \varepsilon\}, \\ \nu(\mathbf{A}, g; \xi, \varepsilon) &= \inf\{|u| : u \in \mathcal{C}(\mathbf{A}, g; \xi, \varepsilon)\}, \\ R(\xi, \varepsilon) &= \sup\{\nu(\mathbf{A}, g; \xi, \varepsilon) : \mathbf{A} \in \boldsymbol{\mathcal{A}},\ g \in \boldsymbol{\mathcal{G}}\}. \end{aligned}$$

For $\nu(\mathbf{A}, g; \xi, \varepsilon)$ to be finite just means that $\mathcal{C}(\mathbf{A}, g; \xi, \varepsilon)$ is nonempty and this will be the case, for the given $\xi \in \mathcal{X}$ and every $\varepsilon > 0$, if and only if this ξ is approximately reachable for (1.4) using this $\mathbf{A} \in \boldsymbol{\mathcal{A}}$. This, of course, would not be sufficient in itself to ensure finiteness of $R(\xi, \varepsilon)$ unless, for example, one were to know that $\nu(\cdot; \xi, \varepsilon)$ would be upper semicontinuous on the (assumed) compact set $\boldsymbol{\mathcal{A}} \times \boldsymbol{\mathcal{G}}$.

THEOREM 4. *Let the setting be as assumed above and suppose, for some fixed $\xi \in \mathcal{X}$, that we have $R(\xi, \varepsilon) < \infty$ for each $\varepsilon > 0$. Then this ξ is approximately reachable for* (4.40).

Proof. Choose some $R > R(\xi, \varepsilon)$ and restrict attention to the ball $\boldsymbol{\mathcal{U}}_R := \{u \in \boldsymbol{\mathcal{U}}_{ad} : |u| \le R\}$. We can then construct a continuous map $\mathbf{C} = \mathbf{C}_{\xi,\varepsilon} : [\boldsymbol{\mathcal{A}} \times \boldsymbol{\mathcal{G}}] \to \boldsymbol{\mathcal{U}}_R$ such that, corresponding to (4.33), we have

$$|\xi - \mathbf{L}_{[\mathrm{T}]}[\mathbf{C}(\mathbf{A}, g), \mathbf{A}, g]|_{\mathcal{X}} \le 2\varepsilon$$

for each $[\mathbf{A}, g] \in \boldsymbol{\mathcal{A}} \times \boldsymbol{\mathcal{G}}$. We omit detail since this is much as in the proof of Theorem 2 — what corresponds to (4.36) is that we can find, for each $[\mathbf{A}, g]$, a control $\tilde{u} \in \boldsymbol{\mathcal{U}}_R \cap \mathcal{C}(\mathbf{A}, g; \xi, \varepsilon)$ and then a neighborhood $\mathcal{N} = \mathcal{N}(\mathbf{A}, g)$ on which the continuous function $\mathbf{L}_{[\mathrm{T}]}[\tilde{u}, \cdot]$ varies by no more than ε in $\mathcal{X}$-norm; there is then a finite subcovering by such neighborhoods, and one can find a corresponding partition of unity.

Note that the continuity of $\mathbf{G}$ and the compactness of $\boldsymbol{\mathcal{A}} \times \boldsymbol{\mathcal{G}}$ make the composition $\mathbf{CG}$ a continuous, compact selfmap of the bounded convex set $\boldsymbol{\mathcal{U}}_R$. The Schauder Fixpoint Theorem applies to ensure a fixpoint $\hat{u}$ for which (4.40) gives $|\xi - x_{\hat{u}}(T)| \le 2\varepsilon$. This, for each $\varepsilon > 0$, ensures the approximate reachability of this ξ for (4.40). □

5. Further results. Having verified $(\mathbf{H}_1)$, the principal problem in applying the general results above is, of course, the difficulty in verifying a condition such as (4.38) to enable one to restrict attention to some $\boldsymbol{\mathcal{Z}}_R$. There are, however, certain cases in which one can proceed. We note one in which $\boldsymbol{\mathcal{Z}}_{ad}$ is the whole Banach space $\boldsymbol{\mathcal{Z}}$ and another in which the nonlinearity $\mathbf{F}$ gives only a compactly restricted perturbation of the final value.

Since we only consider $\nu(g; \xi_0, \varepsilon)$ for $\xi_0 \in \mathcal{K}_0$ so $\xi_0 = \mathbf{T}z_0$, we can introduce

$$\bar{\nu}(\bar{\xi}; \varepsilon) := \inf\{|z'| : z' \in [z_0 - \boldsymbol{\mathcal{Z}}_{ad}],\ |\bar{\xi} - \mathbf{T}z'| \le \varepsilon\}$$

and have $\nu(g; \mathbf{T}z_0, \varepsilon) = \bar{\nu}(\mathbf{L}_{[\mathrm{T}]}g, \varepsilon)$. Observe that if we consider $\boldsymbol{\mathcal{Z}}_{ad} = \boldsymbol{\mathcal{Z}}$, then scaling gives $\bar{\nu}(\lambda\bar{\xi}, \varepsilon) = \lambda\bar{\nu}(\bar{\xi}, \varepsilon/\lambda)$ so (4.38) is equivalent to requiring that

$$\nu_*^{\vartheta}(\bar{\xi}) := \limsup_{\varepsilon \to 0} \{\inf_{z} \{\varepsilon^{-(1-\vartheta)}|z| : z \in \boldsymbol{\mathcal{Z}} \text{ and } |\bar{\xi} - \mathbf{E}z|_{\mathcal{X}} \le \varepsilon\}\}$$

should be bounded for $\bar{\xi} \in \{\mathbf{L}_{[\mathrm{T}]}g : g$ in some $\boldsymbol{\mathcal{V}}$-bounded subset of $\boldsymbol{\mathcal{G}}_*\}$. It is possible to show that ν_*^{ϑ} is actually a norm intermediate between the $\mathcal{X}$-norm on $\bar{\mathcal{K}}_0$ ($\vartheta = 0$) and the obvious induced norm: $|\xi|_1 := \inf\{|z| : \mathbf{T}z = \xi\}$ on $\mathcal{K}_0$ ($\vartheta = 1$). Thus, finiteness of $\nu_*^{\vartheta}(\mathbf{L}_{[\mathrm{T}]}g)$ is a stronger condition than just requiring $\mathbf{L}_{[\mathrm{T}]}g \in \bar{\mathcal{K}}_0$ but is weaker than the exact reachability condition of Theorem 2, i.e., that $\mathbf{L}_{[\mathrm{T}]}g \in \mathcal{K}_0$. We will not analyze ν_*^{ϑ} directly but will, instead, use the established theory Banach space interpolation (cf., e.g., [4]).

THEOREM 5. *Suppose* $\boldsymbol{\mathcal{Z}}_{ad} = \boldsymbol{\mathcal{Z}}$ *so* $\bar{\mathcal{K}}_0 =: \mathcal{X}_0$ *is a* (*closed*) *subspace of* $\mathcal{X}$. *Assume* $(\mathbf{H}_1)$ *and suppose*[4] *that, for some* $\vartheta > 0$, *one has*

$$\mathbf{L}_{[\mathrm{T}]}g \in \mathcal{X}_{\vartheta} \quad \textit{for each } g \in \boldsymbol{\mathcal{V}} \tag{5.41}$$

where $\mathcal{X}_{\vartheta}$ *is an interpolation space* $[\mathcal{X}_0, \mathcal{X}_1]_{\vartheta}$ *with* $\mathcal{X}_1 := \mathcal{K}_0$ (*taken with the norm:* $|\xi|_1 := \inf\{|z| : \mathbf{E}z = \xi$ *for* $\xi \in \mathcal{X}_1 = \mathcal{K}_0\}$*; note that here* $|z|$ *is the* $\boldsymbol{\mathcal{Z}}$-*norm*) *and* $\mathcal{X}_0 := \bar{\mathcal{K}}_0$ *with the* $\mathcal{X}$-*norm. Let* $\mathbf{F}$ *be a nonlinearity satisfying the growth condition* (4.28) *for some* $\bar{r} < \vartheta$. *Then the approximately reachable set* $\bar{\mathcal{K}}_{\mathrm{F}}$ *is precisely* $\bar{\mathcal{K}}_0$.

[4] Given $\mathbf{F}$, the hypothesis (5.41) with $\vartheta > \bar{r}$ is somewhere between taking $\vartheta = 0$, which just reduces to the (inadequate) hypothesis (4.39), and taking $\vartheta = 1$ which is equivalent to the exact reachability inclusion (4.29) used in Theorem 1. Note that it is easiest to obtain (5.41) if one takes $\boldsymbol{\mathcal{V}}$ as small as possible consistent with $(\mathbf{H}_1)$.

Proof. Since (5.41) gives $\mathbf{L}_{[\mathrm{T}]}\boldsymbol{\mathcal{V}} \subset \mathcal{X}_1 \subset \mathcal{X}_0$ and these are subspaces, we have (4.26) so $\bar{\mathcal{K}}_{\mathrm{F}} \subset \bar{\mathcal{K}}_0$ by Lemma 2. As usual, we are primarily concerned with the complementary inclusion.

While there are various possible interpolation functors, the extremal property of the K-functor (see, e.g., Theorem 3.9.1 of [4]) gives a uniform estimate:

$$s^{-\vartheta}K(s;\xi) \leq C|\xi|_\vartheta \quad (s > 0,\ \xi \in \mathcal{X}_\vartheta) \tag{5.42}$$

(C depending on the choice of $|\cdot|_\vartheta$) where the function $K(\cdot)$ is defined by

$$\begin{aligned} K(s;\xi) &:= \inf\{|\xi_0|_{\mathcal{X}} + s|\xi_1|_1 : \ \xi_0 + \xi_1 = \xi,\ \xi_1 \in \mathcal{X}_1\} \\ &= \inf\{s|z| + |\xi - \mathbf{E}z| : \ z \in \boldsymbol{\mathcal{Z}}\}. \end{aligned} \tag{5.43}$$

Fixing $\varepsilon > 0$, define

$$\omega(\nu) = \omega(\nu;\varepsilon) := [C\,\varepsilon^{-(1-\vartheta)}]^{1/\vartheta}\ \nu^{1/\vartheta}.$$

For any $\xi \in \mathcal{X}_\vartheta$ set $\nu := |\xi|_\vartheta$ and consider $s = \varepsilon/\omega$ in (5.42), (5.43) with $\omega > \omega(\nu)$.

From (5.42) this gives $K(s;\xi) < \varepsilon$ so, from (5.43), there exists $z \in \boldsymbol{\mathcal{Z}}$ such that

$$|\xi - \mathbf{E}z| < \varepsilon, \qquad |z| < \omega.$$

(Here the first is the $\mathcal{X}$-norm while the second is the $\boldsymbol{\mathcal{Z}}$-norm.) Since we may take ω arbitrarily close to $\omega(\nu)$, this shows:

$$\inf\{|z| : |\xi - \mathbf{E}z| \leq \varepsilon\} \leq [C\varepsilon^{-(1-\vartheta)}]^{1/\vartheta}|\xi|_\vartheta^{1/\vartheta} \tag{5.44}$$

for $\xi \in \mathcal{X}_\vartheta$.

Note that (5.41) implies, by the Closed Graph Theorem, continuity of $\mathbf{L}_{[\mathrm{T}]}$ as a linear operator from $\boldsymbol{\mathcal{V}}$ to $\mathcal{X}_\vartheta$, i.e., existence of a constant $\bar{C}$ such that $|\mathbf{L}_{[\mathrm{T}]}g|_\vartheta \leq \bar{C}|g|$ ($|g|$ is the $\boldsymbol{\mathcal{V}}$-norm). Now fix $\xi_0 = \mathbf{E}z_0 \in \mathcal{K}_0 = \mathcal{X}_1$ and, letting $\xi = \mathbf{L}_{[\mathrm{T}]}g$ in (5.44), note that $|\xi - \mathbf{E}z| \leq \varepsilon$ if and only if

$$|\xi_0 - [\mathbf{L}_{[\mathrm{T}]}g + \mathbf{E}(z_0 - z)]|_{\mathcal{X}} \leq \varepsilon \ \text{ so } z_0 - z =: z' \in \mathcal{C}(g;\xi_0,\varepsilon).$$

From (5.44), any $\omega > \omega(|\mathbf{L}_{[\mathrm{T}]}g|_\vartheta)$ can be used to estimate z' so

$$\begin{aligned} \nu(g;\xi_0,\varepsilon) &= \inf\{|z'| : z' = z_0 - z \in \mathcal{C}(g;\xi_0,\varepsilon)\} \\ &\leq |z_0| + \inf\{|z| : z_0 - z \in \mathcal{C}(g;\xi_0,\varepsilon)\} \\ &\leq |z_0| + [C\varepsilon^{-(1-\vartheta)}]^{1/\vartheta}[\bar{C}|g|]^{1/\vartheta} \end{aligned} \tag{5.45}$$

We recognize this as (4.38) with $\tilde{r} = 1/\vartheta$; the assumption $\vartheta > \bar{r}$ gives $\tilde{r} < 1/\bar{r}$. Thus Theorem 3 applies to show $\mathcal{K}_0 \subset \bar{\mathcal{K}}_{\mathrm{F}}$ and one has the desired invariance: $\bar{\mathcal{K}}_{\mathrm{F}} = \bar{\mathcal{K}}_0$. □

COROLLARY. *Suppose* $\boldsymbol{\mathcal{V}}_0$ *is any space for which* $\mathbf{L}_{[\mathrm{T}]} : \boldsymbol{\mathcal{V}}_0 \to \mathcal{X}$ *is continuous and* $\boldsymbol{\mathcal{V}}_1$ *is any space for which the exact reachability condition holds:* $\{\mathbf{L}_{[\mathrm{T}]}g : g \in \boldsymbol{\mathcal{V}}_1\} \subset \mathcal{K}_0$. *Assume* ($\mathbf{H}_1$) *with* $\boldsymbol{\mathcal{V}}$ *taken as* $\boldsymbol{\mathcal{V}}_\vartheta := [\boldsymbol{\mathcal{V}}_0, \boldsymbol{\mathcal{V}}_1]_\vartheta$ *for some* $\vartheta > \bar{r}$; *assume* (4.26) *and* (4.28). *Then one has* $\bar{\mathcal{K}}_{\mathrm{F}} = \bar{\mathcal{K}}_0$.

Proof. Let $\mathbf{L}^0_{[\mathrm{T}]}$ be $\mathbf{L}_{[\mathrm{T}]} : \boldsymbol{\mathcal{V}}_0 \to \mathcal{X}_0 := \bar{\mathcal{K}}_0$ and let $\mathbf{L}^1_{[\mathrm{T}]}$ be $\mathbf{L}_{[\mathrm{T}]} : \boldsymbol{\mathcal{V}}_1 \to \mathcal{X}_1 := \mathcal{K}_0$; the latter is bounded by the Closed Graph Theorem since $\mathbf{L}_{[\mathrm{T}]}\boldsymbol{\mathcal{V}}_1 \subset \mathcal{X}_1$. Then boundedness of $\mathbf{T}^\vartheta : \boldsymbol{\mathcal{V}}_\vartheta \to \mathcal{X}_\vartheta := [\mathcal{X}_0, \mathcal{X}_1]_\vartheta$ follows from interpolation theory [4] and Theorem 5 applies. □

A somewhat modified fixpoint argument provides our final result.

THEOREM 6. *Assume* $(\mathbf{H}_1)$(i),(ii) *and* (4.26). *Let* $\boldsymbol{\mathcal{Z}}_{ad}$ *be convex and closed in* $\boldsymbol{\mathcal{Z}}$ *and assume we have* (3.21) *for each* $g \in \boldsymbol{\mathcal{G}}_* := \{\mathbf{G}_F z : z \in \boldsymbol{\mathcal{Z}}_{ad}\}$. *Finally, we assume that* $\mathbf{L}_{[T]}\boldsymbol{\mathcal{G}}_* := \{\mathbf{L}_{[T]}\mathbf{G}_F z : z \in \boldsymbol{\mathcal{Z}}_{ad}\}$ *is precompact in* $\mathcal{X}$. *Then, one has* $\bar{\mathcal{K}}_F = \bar{\mathcal{K}}_0$.

Proof. By Lemma 2 we have $\bar{\mathcal{K}}_F \subset \bar{\mathcal{K}}_0$ and, as earlier, need only show $\xi \in \bar{\mathcal{K}}_F$ for each fixed $\xi = \xi_0 \in \bar{\mathcal{K}}_0$.

Note that (3.21) just means that $[\xi_0 - \mathbf{L}_{[T]}g] \in \bar{\mathcal{K}}_0$ and this, for each $g \in \mathbf{G}_*$, means $[\xi_0 - \mathbf{L}_{[T]}\mathbf{G}_*] \subset \bar{\mathcal{K}}_0$. As $\bar{\mathcal{K}}_0 := \overline{\mathbf{E}\boldsymbol{\mathcal{Z}}_{ad}}$ is convex, since $\boldsymbol{\mathcal{Z}}_{ad}$ is and $\mathbf{E}$ is linear, we have $\mathcal{X}_* := \overline{co}(\xi_0 - \mathbf{L}_{[T]}\boldsymbol{\mathcal{G}}_*) \subset \bar{\mathcal{K}}_0$. On the other hand, we note that $\mathcal{X}_0 := \overline{co}(\mathbf{L}_{[T]}\boldsymbol{\mathcal{G}}_*)$ is convex and is compact by the precompactness assumption so $\mathcal{X}_*$ is compact since we easily see $\mathcal{X}_* := \xi_0 - \mathcal{X}_0$.

Given any $\varepsilon > 0$, one can then find a finite covering of $\mathcal{X}_*$ by ε-balls which may be taken centered at $\{\xi_j : j = 1, \cdots, J\}$ with each $\xi_j \in \mathcal{K}_0 \cap \mathcal{X}_*$ so there exist $z_j \in \boldsymbol{\mathcal{Z}}_{ad}$ such that $\mathbf{E}z_j = \xi_j$. As in the proof of Theorem 2,we can find a continuous partition of unity subordinate to this covering:

$$\varphi_j \geq 0, \quad \sum \varphi_j \equiv 1 \text{ on } \mathcal{X}_*, \quad \varphi_j(\xi) \neq 0 \Longrightarrow |\xi - \xi_j| < \varepsilon.$$

and then define $\mathbf{C} = \mathbf{C}_\varepsilon$ by

$$\mathbf{C}\xi := \sum \varphi_j(\xi) z_j,$$

noting that $\mathbf{C}\xi \in \boldsymbol{\mathcal{Z}}_{ad}$ for $\xi \in \mathcal{X}_*$ by the assumed convexity of $\boldsymbol{\mathcal{Z}}_{ad}$. Clearly $\mathbf{C} : \mathcal{X}_* \to \boldsymbol{\mathcal{Z}}_{ad}$ is continuous and, as earlier, a simple computation shows that

$$|\xi - \mathbf{EC}\xi| \leq \varepsilon \quad \text{for } \xi \in \mathcal{X}_*. \tag{5.46}$$

As already noted, for any $z \in \boldsymbol{\mathcal{Z}}_{ad}$ we have $[\xi - \mathbf{L}_{[T]}\mathbf{G}z] \in \mathcal{X}_*$ so the map:

$$\xi \mapsto z := \mathbf{C}\xi \mapsto [\xi - \mathbf{L}_{[T]}\mathbf{G}z] \tag{5.47}$$

is a continuous selfmap of the compact, convex set $\mathcal{X}_*$.

By the Schauder Fixpoint Theorem this map has a fixpoint $\bar{\xi}$ so, setting $\bar{z} := \mathbf{C}\bar{\xi} \in \boldsymbol{\mathcal{Z}}_{ad}$ we have $\bar{\xi} = \xi - \mathbf{L}_{[T]}\mathbf{G}\bar{z}$. Using (5.46), we have $|\xi - \mathbf{T}_F\bar{z}|_{\mathcal{X}} = |\xi - [\mathbf{L}_{[T]}\mathbf{G}\bar{z} + \mathbf{T}\bar{z}]|_{\mathcal{X}} = |\bar{\xi} - \mathbf{E}\bar{z}|_{\mathcal{X}} \leq \varepsilon$. Since this is possible for each $\varepsilon > 0$, we have $\xi \in \bar{\mathcal{K}}_F \subset \bar{\mathcal{K}}_F$. Since that holds for each $\xi \in \bar{\mathcal{K}}_0$, we have $\bar{\mathcal{K}}_0 \subset \bar{\mathcal{K}}_F$. □

6. Approaches to the hypotheses.

Finally, we consider the verification of the abstract hypothesis $(\mathbf{H}_1)$ for more concrete settings — e.g., such as those presented in §2. We begin by noting that in connection with $(\mathbf{H}_1)$ (ii), (iii) there may be an advantage in introducing an auxiliary function space $\boldsymbol{\mathcal{Y}}$.

LEMMA 3. *Suppose* $\boldsymbol{\mathcal{Z}}$ *embeds continuously in a space* $\boldsymbol{\mathcal{Y}}$ *which is compatible with* $\boldsymbol{\mathcal{X}}$ *in the sense that the set* $\boldsymbol{\mathcal{Y}} \cap \boldsymbol{\mathcal{X}}$ *is dense both in* $\boldsymbol{\mathcal{Y}}$ *and in* $\boldsymbol{\mathcal{X}}$ *with*

$$y_k \in \boldsymbol{\mathcal{Y}} \cap \boldsymbol{\mathcal{X}}, \quad y_k \xrightarrow{\boldsymbol{\mathcal{Y}}} \hat{y}, \quad y_k \xrightarrow{\boldsymbol{\mathcal{X}}} \hat{x} \Longrightarrow \hat{y} = \hat{x} \in \boldsymbol{\mathcal{Y}} \cap \boldsymbol{\mathcal{X}}.$$

Assume that, in addition to $(\mathbf{H}_1)$(i), *the linear operator* $\mathbf{L}$ *is continuous from* $\boldsymbol{\mathcal{V}}$ *to* $\boldsymbol{\mathcal{Y}}$ *and that the nonlinear map* $\mathbf{F}$ *is Lipschitzian from* $\boldsymbol{\mathcal{Y}}$ *to* $\boldsymbol{\mathcal{V}}$ *with Lipschitz constant* C *such that* $C\|\mathbf{L}\|_{\boldsymbol{\mathcal{V}}\to\boldsymbol{\mathcal{Y}}} =: \vartheta < 1$. *Then:*

(i) *One has* $(\mathbf{H}_1)$(ii) *with* $\mathbf{G}_F$ *Lipschitzian.*

(ii) *If* (*in addition to the original hypotheses*) *one has a growth condition*

$$|\mathbf{F}y|_{\boldsymbol{\mathcal{V}}} \leq a_0 + a_1|y|^{\bar{r}}_{\boldsymbol{\mathcal{Y}}} \tag{6.48}$$

for $\mathbf{F}$, *then* $\mathbf{G}_{\mathrm{F}}$ *satisfies the growth condition* (4.28).

(iii) *If* (*in addition to the original hypotheses*) *one has*

$$\{\mathbf{F}(\mathbf{L}g + z) : g \in \boldsymbol{\mathcal{G}}_0,\ z \in \boldsymbol{\mathcal{Z}}_0\} \text{ precompact in } \boldsymbol{\mathcal{V}} \quad \text{for each compact subset } \boldsymbol{\mathcal{G}}_0 \subset \boldsymbol{\mathcal{V}}, \tag{6.49}$$

then $\mathbf{G}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}_0)$ *is precompact in* $\boldsymbol{\mathcal{V}}$. (*Note that if* (6.49) *holds for each bounded subset* $\boldsymbol{\mathcal{Z}}_0$ *of* $\boldsymbol{\mathcal{Z}}$, *then* (iii) *gives* $(\mathbf{H}_1)$(iii); *a sufficient condition for this, in view of* (i), *is that the embedding* $\boldsymbol{\mathcal{Z}} \hookrightarrow \boldsymbol{\mathcal{Y}}$ *is compact.*)

Proof. Under the assumption $\vartheta < 1$, the map: $y \mapsto [\mathbf{LF}y + z]$ is a contraction on $\boldsymbol{\mathcal{Y}}$ so there is a unique fixpoint $y = Y(z)$, the solution of (3.15). One easily obtains the Lipschitz constant $1/(1-\vartheta)$ for the solution map $Y(\cdot) : z \mapsto y : \boldsymbol{\mathcal{Y}} \to \boldsymbol{\mathcal{Y}}$ and composing this with the Lipschitzian maps $\boldsymbol{\mathcal{Z}} \hookrightarrow \boldsymbol{\mathcal{Y}}$ on one side and $\mathbf{F}$ on the other gives the desired Lipschitz continuity for $\mathbf{G}_{\mathrm{F}} : z \mapsto \mathbf{F}y : \boldsymbol{\mathcal{Z}} \to \boldsymbol{\mathcal{V}}$. This gives linear growth for $Y(\cdot) : \boldsymbol{\mathcal{Z}} \to \boldsymbol{\mathcal{Y}}$ and composing that with (6.48) gives (4.28). The compactness assertion (iii) is an immediate consequence of Lemma 2 in [14], applied to the uniformly contractive family of maps: $g \mapsto \mathbf{F}(\mathbf{L}g + z)$ $(z \in \boldsymbol{\mathcal{Z}}_0)$ whose fixpoints give $\mathbf{G}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}_0)$. □

Note that our treatment of these problems presupposes well-posedness for the equations and, for our application of fixed-point arguments, convexity of $\boldsymbol{\mathcal{Z}}_{ad}$ and suitable compactness.

We now turn to a somewhat more general consideration of abstract settings giving $(\mathbf{H}_1)$. For this consideration our present concerns are essentially identical with those of [15] and we recall the relevant discussion there in providing classes of settings for which the relevant well-posedness and compactness can be verified. For this we suppose $\mathbf{A}(\cdot)$ generates a *fundamental solution* (evolution system) $\mathbf{S}$ — i.e.,

$$\begin{array}{lll} (6.50) & \text{(i)} & \mathbf{S}(t,s) \text{ is a bounded linear operator on } \mathcal{X} \text{ with} \\ & & \|\mathbf{S}(t,s)\| \leq M \text{ for } 0 \leq s \leq t \leq T; \\ & \text{(ii)} & \mathbf{S}(t,s)\mathbf{S}(s,r) = \mathbf{S}(t,r) \text{ for } 0 \leq r \leq s \leq t \leq T; \\ & \text{(iii)} & \mathbf{S}(t,s)\xi \longrightarrow \xi \text{ as } t \to s+ \text{ for } \xi \in \mathcal{X}; \\ & \text{(iv)} & \partial\mathbf{S}(t,s)\xi/\partial t = \mathbf{A}(s)\xi \text{ for } t = s \text{ and } \xi \in \mathcal{D} = \mathcal{D}(\mathbf{A}(s)). \end{array}$$

This permits us to introduce the notion of a *mild solution* [9] of (1.2) or (1.4): the linear map $\mathbf{L}$ will be given, in terms of $\mathbf{S}(\cdot)$, by

$$[\mathbf{L}v](t) = \mathbf{L}_t v := \int_0^t \mathbf{S}(t,s)v(s)\,ds \text{ for } 0 \leq t \leq T \tag{6.51}$$

for suitable $v(\cdot)$. In this formulation, (1.1) corresponds to the nonlinear integral equation[5] (abstract Volterra equation of second kind):

$$x(t) = \bar{z}(t) + \int_0^t \mathbf{S}(t,s)[f(s,x(s)) + [\mathbf{B}(u)](s)]\,ds$$

[5] Here $\bar{z}(t)$ is the solution of the equation $\dot{z} = \mathbf{A}z$ with the original initial conditions. With our assumption that the problem has been formulated so as to have homogeneous initial conditions, this term vanishes: $\bar{z} = 0$.

This is, of course, just the operator equation (3.15).

Now introduce (reflexive) Banach spaces $\mathcal{V}$, $\mathcal{W}$ and spaces $\boldsymbol{\mathcal{V}}$ and $\boldsymbol{\mathcal{W}}$ of $\mathcal{V}$- and $\mathcal{W}$-valued functions, respectively, on $[0,T]$. We assume $\boldsymbol{\mathcal{V}}$, $\boldsymbol{\mathcal{W}}$ are compatible with $\mathcal{X}$ in the sense that the set $\mathcal{V} \cap \mathcal{X}$ is dense both in $\mathcal{V}$ and in $\mathcal{X}$ with

$$v_k \in \mathcal{V} \cap \mathcal{X}, \quad v_k \xrightarrow{\mathcal{V}} \hat{v}, \quad v_k \xrightarrow{\mathcal{X}} \hat{x} \Longrightarrow \hat{v} = \hat{x} \in \mathcal{V} \cap \mathcal{X}$$

and similarly for $[\mathcal{W}, \mathcal{X}]$. It will thus be possible to make suitable extensions or restrictions of $\mathbf{S}(t,s)$ so, e.g., the formal definition (3.14) may make sense for v in $\boldsymbol{\mathcal{V}}$ or in $\boldsymbol{\mathcal{W}}$.

We note that [15] provides four alternate sets of more concrete conditions on $\mathcal{X}, \mathcal{W}, \mathcal{V}, \mathbf{S}(\cdot\cdot), f(\cdot\cdot)$ under which one can verify $(\mathbf{H}_1)$. For convenience of reference we present these here, converted to our present notation. For this, we take $\boldsymbol{\mathcal{V}}, \boldsymbol{\mathcal{W}}$ to have the form

$$\boldsymbol{\mathcal{V}} := L^p([0,T] \to \mathcal{V}), \qquad \boldsymbol{\mathcal{W}} := L^{p'}([0,T] \to \mathcal{W}) \tag{6.52}$$

and introduce another possible space $\mathcal{Y}$ compatible with $\mathcal{X}$. We assume:

$(\mathbf{C}_1)$ Let *each* of the following hold:

(i) $\|\mathbf{S}(t,s)\|_{\mathcal{V}\to\mathcal{X}} \le \rho_{\mathcal{V}}(t-s)$, $\|\mathbf{S}(t,s)\|_{\mathcal{W}\to\mathcal{X}} \le \rho_{\mathcal{W}}(t-s)$,
$\|\mathbf{S}(t,s)\|_{\mathcal{V}\to\mathcal{Y}} \le \hat{\rho}_{\mathcal{V}}(t-s)$, $\|\mathbf{S}(t,s)\|_{\mathcal{W}\to\mathcal{Y}} \le \hat{\rho}_{\mathcal{W}}(t-s)$;

(ii) $\|\mathbf{S}(t,s) - \mathbf{S}(t',s)\|_{\mathcal{Y}\to\mathcal{X}}$, $\|\mathbf{S}(t,s) - \mathbf{S}(t',s)\|_{\mathcal{W}\to\mathcal{X}} \le \varepsilon$
for $0 \le s \le t' - \varepsilon$, $t' < t \le T$ with $\varepsilon = \varepsilon(h) \to 0$ as $h := t - t' \to 0$;

(iii) $|f(t,\eta)|_{\mathcal{V}} \le \alpha(t) + \beta|\eta|_{\mathcal{Y}}^{\bar{r}}$ $\quad (\bar{r} := \bar{p}/p < 1)$
$|\mathbf{S}(t,s)[f(s,\eta) - f(s,\eta')]|_{\mathcal{Y}} \le \rho_{\mathcal{Y}}(t-s)|\eta - \eta'|_{\mathcal{Y}}$

where

$$\rho_{\mathcal{V}} \in L^q, \quad \rho_{\mathcal{W}} \in L^{q'} \quad \hat{\rho}_{\mathcal{V}} \in L^{\bar{q}}, \quad \hat{\rho}_{\mathcal{W}} \in L^{\bar{q}'}, \quad \alpha \in L^p, \quad \rho_{\mathcal{Y}} \in L^1,$$

with $1 < p$, $p' < \infty$, $1 \le \bar{p} < p$, and

$$1/p + 1/q = 1/p' + 1/q' = 1; \;\; 1/p + 1/\bar{q}, 1/p' + 1/\bar{q}' \le 1 + 1/\bar{p}.$$

To the set of conditions $(\mathbf{C}_1)$ we may adjoin any of four *alternative* conditions:

$(\mathbf{C}_2)$ Let *any one* of the following hold:

(i) For some Banach space $\hat{\mathcal{Y}} = \hat{\mathcal{Y}}_i$ such that the embedding: $\mathcal{Y} \hookrightarrow \hat{\mathcal{Y}}$ is compact, assume that for small $\delta > 0$ there exists M_δ such that
$\|\mathbf{S}(t, t-\delta)\|_{\hat{\mathcal{Y}}\to\mathcal{Y}} \le M_\delta \qquad$ for $\delta \le t \le T$.

(ii) For some Banach space $\hat{\mathcal{Y}} = \hat{\mathcal{Y}}_{ii}$ such that the embedding $\hat{\mathcal{Y}} \hookrightarrow \mathcal{Y}$ is compact, strengthen $(\mathbf{C}_1)$(i) by requiring:
$\|\mathbf{S}(t,s)\|_{\mathcal{W}\to\hat{\mathcal{Y}}} \le \hat{\rho}_{\mathcal{W}}(t-s) \qquad$ ($\hat{\mathcal{Y}}$ replacing $\mathcal{Y}$).

(iii) For some Banach space $\hat{\mathcal{Y}} = \hat{\mathcal{Y}}_{iii}$ such that the embedding: $\mathcal{Y} \hookrightarrow \hat{\mathcal{Y}}$ is compact, strengthen the growth condition in $(\mathbf{C}_1)$(iii) by requiring
$|f(t,\zeta)|_{\mathcal{V}} \le \alpha(t) + \beta|\zeta|_{\hat{\mathcal{Y}}}^{\bar{r}}$.
with $\bar{r} := \bar{p}/p < 1$ ($\hat{\mathcal{Y}}$ replacing $\mathcal{Y}$).

(iv) Take $\mathcal{Y} = \mathcal{X}$ reflexive in $(\mathbf{C}_1)$ and, for some Banach space $\hat{\mathcal{Y}} = \hat{\mathcal{Y}}_{iv}$ such that $\mathcal{X} = \mathcal{Y} \hookrightarrow \hat{\mathcal{Y}}$ is a compact embedding, assume that for each $\mu > 0$ there exists $\alpha_\mu \in L^p$ for which
$|\zeta|_{\hat{\mathcal{Y}}} \le \mu \Longrightarrow |f(t,\zeta)|_{\mathcal{V}} \le \alpha_\mu(t)$.

LEMMA 4. *Let $\mathcal{X}, \mathcal{W}, \mathcal{V}$, etc., be as above and assume* $(\mathbf{C}_1)$; *we will norm* $\boldsymbol{\mathcal{Z}} := \mathbf{L}\boldsymbol{\mathcal{W}}$ *so* $\mathbf{L}$ *is an isometry. Then one has* $(\mathbf{H}_1)$(i) *and* $(\mathbf{H}_1)$(ii) *as well as the growth condition* (4.28). *If in addition, we assume* $(\mathbf{C}_2)$ (*i.e., any one of the four alternative conditions presented*), *then* $\mathbf{G}$ *is also compact:*

$$(\mathbf{C}_1) + (\mathbf{C}_2) \Longrightarrow (H_1) + (4.28).$$

Proof. See [15] for details. We note here that only $(\mathbf{C}_1)$(ii) is used to give $(\mathbf{H}_1)$(i) and that $(\mathbf{C}_1)$(i),(iii) give a solution of (3.15) initially in $\boldsymbol{\mathcal{Y}} := L^{\bar{p}}([0,T] \to \mathcal{Y})$ from which one obtains $g := f(\cdot, x(\cdot)) \in \boldsymbol{\mathcal{V}}$ by Krasnoselskii's Theorem (cf., e.g., [2]). One then has $x \in \boldsymbol{\mathcal{X}}$ from $x = \mathbf{L}g + \mathbf{L}w$ and $(\mathbf{H}_1)$(i). The four alternative arguments for compactness of $\mathbf{G}$ from $(\mathbf{C}_2)$ use, among them, the Aubin Compactness Theorem [1], the Arzela–Ascoli Theorem, and an argument from [14]. □

Remark. The conditions above do not apply directly to boundary control (as in Examples 2 and 3) but the arguments in [15] may be easily modifiable to treat this situation. Indeed, the arguments in [15] are fairly standard, using convolution estimates from the form of $(\mathbf{C}_1)$(i) as applied to the representation (6.51) and the modification simply amounts to the corresponding use of a rather similar representation [3]

$$z(t) = [\mathbf{L}w](t) = \int_0^t [(-\mathbf{A})^{\vartheta}\mathbf{S}(t-s)][(-\mathbf{A})^{1-\vartheta}\Gamma]w(s)\,ds \tag{6.53}$$

for the solution of

$$\dot{z} = \mathbf{A}z, \qquad \mathbf{M}z = w := \mathbf{B}(u) \in \boldsymbol{\mathcal{W}}_{ad}. \tag{6.54}$$

Here, $\mathbf{A}$ (whose domain formally involves imposition of homogeneous boundary conditions) is the infinitesimal generator of an analytic semigroup $\mathbf{S}$ on $\mathcal{X}$ and $\mathbf{M}$ is the appropriate boundary operator; we have introduced the so-called "Green's operator" $\Gamma : \omega \mapsto v$ by

$$-\mathbf{A}v = 0, \qquad \mathbf{M}v = \omega.$$

We then use regularity theory for the problem defining Γ, the relation of the Sobolev spaces $H^{2\vartheta} := [L^2, H^1]_{2\vartheta}$ to the domain of $(-\mathbf{A})^{\vartheta}$ (e.g., [7] or [8]) when $\mathbf{A}$ is a second order elliptic operator, and the estimate (2.9).

We now turn to consideration of the convexity of $\boldsymbol{\mathcal{Z}}_{ad}$ and ask: How restrictive an assumption is this? We have already noted that we may replace $\boldsymbol{\mathcal{Z}}_{ad}$ by any *equivalent* set $\boldsymbol{\mathcal{Z}}'_{ad}$ satisfying (3.17) and we shall now see that we may quite reasonably expect to find such a closed convex set $\boldsymbol{\mathcal{Z}}'_{ad}$. We will actually work with $\boldsymbol{\mathcal{W}}_{ad}$ (cf. (3.18)) and will find a natural setting for which $\boldsymbol{\mathcal{W}}_{ad} \equiv \boldsymbol{\mathcal{W}}'_{ad} := \overline{co}\boldsymbol{\mathcal{W}}_{ad}$ ($\overline{co}$ = closed convex hull in $\boldsymbol{\mathcal{W}}$). We first need a preparatory result, which we "dignify" as a theorem.

THEOREM 7. *Let* $\boldsymbol{\mathcal{W}}$ *have the form* $L^p([0,T] \to \mathcal{W})$ $[1 \le p < \infty]$ *with* $\mathcal{W}$ *satisfying the technical hypothesis that*[6]

$$\boldsymbol{\mathcal{W}}_* := L^{\infty}([0,T] \to \mathcal{W}^*) \quad \textit{is dense in } \boldsymbol{\mathcal{W}}^*. \tag{6.55}$$

Suppose a subset $\boldsymbol{\mathcal{W}}_0 \subset \boldsymbol{\mathcal{W}}$ *has*[7] *the* segment property*:*

[6] It is known to be sufficient for this that $\mathcal{W}$ be reflexive or, somewhat more generally, that $\mathcal{W}$ have the Radon-Nikodym Property; cf., e.g., [6].

[7] Typically, $\boldsymbol{\mathcal{U}}_{ad}$ has the form: $\boldsymbol{\mathcal{U}}_{ad} = \{u \in \boldsymbol{\mathcal{U}} : u(t) \in \mathcal{U}_{ad}(t) \subset \mathcal{U} \text{ a.e.}\}$ and so satisfies (SP) if, say, $\boldsymbol{\mathcal{U}} := L^p([0,T] \to \mathcal{U})$. In this case, if $\mathbf{B}$ is defined pointwise in t for (1.2), etc., then (SP) is immediate for $\boldsymbol{\mathcal{W}}_{ad}$.

(SP) $\qquad w_0, w_1 \in \boldsymbol{\mathcal{W}}_0 \Longrightarrow w_s \in \boldsymbol{\mathcal{W}}_0 \quad (s \in \mathcal{S} = \{\textit{dense in } [0,T]\})$
where, given w_0 *and* w_1, *we set*

$$w_s(t) := \{w_1(t) \textit{ for } 0 \le t < s; \quad w_0(t) \textit{ for } s \le t \le T\}.$$

Then $\boldsymbol{\mathcal{W}}_1$, *the sequential weak closure of* $\boldsymbol{\mathcal{W}}_0$ *in* $\boldsymbol{\mathcal{W}}$, *is just the closed convex hull* $\overline{co}\boldsymbol{\mathcal{W}}_0$.

Proof. We set $\Sigma_{\mathcal{S}} :=$ {finite unions of intervals in $[0,T]$ with endpoints in $\mathcal{S}$}; for $\sigma \in \Sigma_{\mathcal{S}}$, let χ_σ be its characteristic function and then for $w_0, w_1 \in \boldsymbol{\mathcal{W}}_0$ set

$$w_\sigma = \{w_1 \text{ on } \sigma; \quad w_0 \text{ on } [0,T]\backslash\sigma\} = (1-\chi_\sigma)w_0 + \chi_\sigma w_1$$

so, e.g., w_s — as defined for (SP) — is now $w_{[0,s)}$. Note that repeated application of (SP) shows that each such w_σ must also be in $\boldsymbol{\mathcal{W}}_0$. Note, also, that (SP) for $\boldsymbol{\mathcal{W}}_0$ immediately gives (SP) for its sequential weak closure $\boldsymbol{\mathcal{W}}'$: just consider approximating sequences from $\boldsymbol{\mathcal{W}}_0$. Since $\overline{co}\boldsymbol{\mathcal{W}}_1 = \overline{co}\boldsymbol{\mathcal{W}}_0$, we may assume, with no loss of generality, that $\boldsymbol{\mathcal{W}}_0$ is already (sequentially weakly) closed and only show that (SP) then implies its convexity.

Now observe that for any constant $\vartheta \in (0,1)$ there is a sequence $\{\sigma_n\} \subset \Sigma_{\mathcal{S}}$ such that $\{\chi_\sigma\}$ is weak-* convergent to the constant function ϑ in $L^\infty(0,T)$. To see this, just partition $[0,T]$ into n equal subintervals and (noting the assumed density of $\mathcal{S}$) choose a sub-subinterval in each with endpoints in $\mathcal{S}$ and having length approximately $\vartheta T/n$; this gives σ_n. The weak-* convergence to ϑ is then an easy computation.

Given any w_0, $w_1 \in \boldsymbol{\mathcal{W}}_0$ and $\vartheta \in (0,1)$, we note, by repeated application of (SP), that each $w_\sigma = [\chi_\sigma w_1 + (1-\chi_\sigma)w_0]$ is also in $\boldsymbol{\mathcal{W}}_0$. For any $\psi \in \boldsymbol{\mathcal{W}}_*$ the $\mathcal{W}$-duality product $\langle \psi, w_1 - w_0\rangle$ (taken pointwise in t) is a function in $L^p(0,T) \subset L^1(0,T)$ so for the $\boldsymbol{\mathcal{W}}$-duality we have

$$\begin{aligned} \langle \psi, w_\sigma \rangle &= \int_0^T \langle \psi, \chi_\sigma w_1 + (1-\chi_\sigma)w_0\rangle\, dt \\ &= \int_0^T \chi_\sigma \langle \psi, w_1 - w_0\rangle\, dt + \langle \psi, w_0\rangle \\ &= \langle \chi_\sigma, \langle \psi, w_1 - w_0\rangle\rangle_{L^1(0,T)} + \langle \psi, w_0 \rangle \\ &\longrightarrow \langle \vartheta, \langle \psi, w_1 - w_0\rangle\rangle_{L^1(0,T)} + \langle \psi, w_0 \rangle \\ &= \langle \psi, \vartheta w_1 + (1-\vartheta)w_0\rangle. \end{aligned}$$

Since this holds for each ψ in the dense subset $\boldsymbol{\mathcal{W}}_* \subset \boldsymbol{\mathcal{W}}^*$, it follows that $w_\sigma \rightharpoonup [\vartheta w_1 + (1-\vartheta)w_0]$ (weak convergence in $\boldsymbol{\mathcal{W}}$) so this is in $\boldsymbol{\mathcal{W}}_0$. This, for each such w_0, w_1, ϑ, is just the desired convexity of $\boldsymbol{\mathcal{W}}_0$. □

COROLLARY. *Assume* $(\mathbf{H}_1)$. *Let* $\boldsymbol{\mathcal{W}}$, $\boldsymbol{\mathcal{W}}_{ad}$ *be as in Theorem* 7. *Suppose* $\mathbf{S} : w \mapsto z : \boldsymbol{\mathcal{W}} \to \boldsymbol{\mathcal{Z}}$, *as in* (3.18), *is continuous with* $\mathbf{ES} : \boldsymbol{\mathcal{W}} \to \mathcal{X}$ *compact and the graph of* $\mathbf{G}_{\mathrm{F}} \circ \mathbf{S}$ *is closed in* $\boldsymbol{\mathcal{W}}_{sw} \times \boldsymbol{\mathcal{V}}$ ($\cdot_{sw}$ *indicates the sequential weak topology*). *Then* $\boldsymbol{\mathcal{W}}_{ad} \equiv \boldsymbol{\mathcal{W}}'_{ad} := \overline{co}\boldsymbol{\mathcal{W}}_{ad}$ *in the sense of* (3.17).

Proof. Since $\boldsymbol{\mathcal{W}}_{ad} \subset \boldsymbol{\mathcal{W}}'_{ad}$, we automatically have similar inclusions in (3.17). It is the converse which is effectively a corollary to Theorem 7.

Fix $\xi \in \bar{\mathcal{K}}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}'_{ad})$ where $\boldsymbol{\mathcal{Z}}'_{ad} := \mathbf{S}[\overline{co}\boldsymbol{\mathcal{W}}_{ad}]$ so for each (fixed) $\varepsilon > 0$ there is some $w = w_\varepsilon \in \overline{co}\boldsymbol{\mathcal{W}}_{ad}$ such that $|\xi - \mathbf{TS}w| < \varepsilon$; set $z = \mathbf{S}w$ and $g = \mathbf{G}z$. By Theorem 7 there is then a sequence w_k in $\boldsymbol{\mathcal{W}}_{ad}$ with $w_k \rightharpoonup w$. Since $\{z_k := \mathbf{S}w_k\}$ is bounded we may, by $(\mathbf{H}_1)$(iii), extract a subsequence (still denoted by w_k) with $g_k = \mathbf{G}z_k \to \hat{g}$ in $\boldsymbol{\mathcal{V}}$. The closed graph requirement then ensures that $\hat{g} = g$ so, in particular, $\mathbf{L}_{[\mathrm{T}]}g_k \to \mathbf{L}_{[\mathrm{T}]}g$ in $\boldsymbol{\mathcal{X}}$. Since we also have $\mathbf{ES}w_k \to \mathbf{ES}w$ by the assumed compactness, this gives $\mathbf{TS}w_k \to \mathbf{TS}w$. This shows that for some $w_k \in \boldsymbol{\mathcal{W}}_{ad}$ we have $|\xi - \mathbf{TS}w_k| < 2\varepsilon$ and that, for each $\varepsilon > 0$, proves that we have $\xi \in \bar{\mathcal{K}}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}_{ad})$. Of course this applies for each $\xi \in \bar{\mathcal{K}}_{\mathrm{F}}(\boldsymbol{\mathcal{Z}}'_{ad})$. The arguments for $\bar{\mathcal{K}}_0$ and $\bar{\mathcal{K}}_g$ are similar but simpler. □

Note that, with only a small modification of the hypotheses here, one can show that the closures (say, in $\boldsymbol{\mathcal{X}}$) of the solution sets for (1.2), (1.4), (1.1) will be the same for $\boldsymbol{\mathcal{W}}_{ad}$ as for its (closed) convex hull $\boldsymbol{\mathcal{W}}'_{ad}$.

SOME RESULTS FOR AN OPTIMAL CONTROL PROBLEM WITH SEMILINEAR STATE EQUATION*

FAUSTO GOZZI†

Abstract. A control problem governed by a semilinear state eqution depending on a small parameter ε is considered. It is proven that, for ε sufficiently small, the associated Hamilton-Jacobi equation has a unique strict solution; consequently, the control problem can be solved by dynamic programming method.

Key words. optimal control, semilinear state equation, Hamilton-Jacobi equation

AMS(MOS) subject classifications. 93C, 49B

1. Introduction. We are concerned with a dynamical system governed by the following semilinear state equation:

$$\text{(SE)}\qquad \begin{aligned} &y' = Ay + f(\varepsilon, y) + u \quad \text{on } [0, T],\\ &y(0) = x, \qquad x \in H, \end{aligned}$$

where $A: D(A) \subset H \to H$ is the infinitesimal generator of a strongly continuous semigroup in a Hilbert space H, ε is a real parameter, and f is a smooth function from H to H which goes uniformly to zero (with its derivatives) when $\varepsilon \to 0$; T is a fixed positive constant.

We consider then the following optimal control problem (P):

Minimize the functional

$$\text{(P)}\quad (1.1)\qquad J(x, u) = \int_0^T \left[g(y(s)) + \frac{1}{2}|u(s)|^2 \right] ds + \phi_0(y(T))$$

over all controls $u \in L^2(0, T; U)$,
where y is subject to the state equation (SE).

Here g and ϕ_0 are smooth convex functions from H to H.

We treat this problem by the dynamic programming method studying the corresponding Hamilton-Jacobi equation:

$$\text{(HJ)}\qquad \begin{aligned} &\phi_t(t, x) - \tfrac{1}{2}|\phi_x(t, x)|^2 + \langle Ax + f(\varepsilon, x), \phi_x(t, x)\rangle + g(x) = 0 \\ &\qquad\qquad \forall (t, x) \in [0, T] \times D(A),\\ &\phi(T, x) = \phi_0(x) \quad \forall x \in H. \end{aligned}$$

If we set $\varepsilon = 0$, $g(x) = \frac{1}{2}\langle Mx, x\rangle$, and $\phi_0(x) = \frac{1}{2}\langle P_0 x, x\rangle$, then the problem (P) reduces to the well-known linear regulator problem, which has been extensively studied (see, for instance, [7]). However, for the applications, the use of a linear state equation is very restrictive.

Moreover, if g and ϕ_0 are general convex functions and $\varepsilon = 0$, the cost J is a convex function on $L^2(0, T; H)$ and (HJ) admits a unique strict solution on $[0, T]$ (see [2] and [3]). We remark that if $\varepsilon \neq 0$ then J is generally not convex and the method used in [4] only gives the existence of a local solution of (HJ) in some interval $[0, \delta]$.

† Dipartimento di Matematica, Scuola Normale Superiore, Via F. Buonarroti, 56127 Pisa, Italy.

The viscosity solutions approach has recently been generalized by Crandall and Lions (see [5]) to cover infinite-dimensional problems. They can prove, under suitable hypotheses, existence and uniqueness of a viscosity solution ϕ of (HJ). However, ϕ is not regular, and the classical method of dynamic programming based on the solution of the closed-loop equation,

$$\text{(1.2)}\qquad \begin{aligned} &y'(s) = Ay(s) + f(\varepsilon, y(s)) - \phi_x(T-s, y(s)) \quad \text{on } [0, T],\\ &y(0) = x, \qquad x \in H, \end{aligned}$$

cannot be used.

When the semigroup $\{e^{tA}\}_{t \geqq 0}$ is compact it is possible to study (HJ) by variational methods (see [1], for instance). In this case the existence of a feedback optimal control can be proved; however, the solution ϕ is still not regular and the closed-loop equation (1.2) cannot be directly solved. For other results in this direction see [9].

The aim of this paper is to find, for $|\varepsilon|$ sufficiently small, global regular solutions of the Hamilton-Jacobi equation (HJ) *and then to solve the control problem* (P) *by* using the classical argument of dynamic programming.

More precisely, under suitable hypotheses, for every given $R > 0$ we prove that there exists $\bar{\varepsilon}(R) > 0$ such that for $|\varepsilon| \leqq \bar{\varepsilon}(R)$ equation (HJ) has a unique solution ϕ_ε in $[0, T] \times \Sigma_R$, where Σ_R is the closed ball in H with radius R.

Then we fix an upper bound r_0 for the norm of the initial state x, and we can show that, if ε is sufficiently small, the closed-loop equation (1.2) has a unique strong solution y_ε with $\sup_{t \in [0,T]} |y_\varepsilon(t)| \leqq Cr_0$ for a constant $C \geqq 1$ and that there exists a unique optimal control u_ε such that $\sup_{t \in [0,T]} |u_\varepsilon(t)| \leqq M(r_0)$ where M is a given function $(0, +\infty) \to (0, +\infty)$ depending only on the data. Moreover, we prove that the optimal pair $(u_\varepsilon, y_\varepsilon)$ is a regular function of the parameter ε and we give an expansion in a neighbourhood of $\varepsilon = 0$ in a special case.

Our hypotheses are that g and ϕ_0 are convex and sufficiently regular (two times differentiable), g is strictly convex, and $A - \omega \mathrm{I}$ is strictly dissipative for some $\omega > 0$.

We sketch briefly the idea of the proof of the main theorem. We consider the approximating equation:

$$\text{(HJ)}_\alpha \qquad \begin{aligned} &\phi_t(t, x) = -\frac{1}{\alpha}(\phi(t, x) - \phi_\alpha(t, x)) + \langle Ax + f(\varepsilon, x), \phi_x(t, x)\rangle + g(x)\\ &\hspace{20em} \forall (t, x) \in [0, T] \times D(A),\\ &\phi(0, x) = \phi_0(x) \quad \forall x \in H, \end{aligned}$$

where ϕ_α is the convex regularization of ϕ (see next section). Here the "bad" term $|\phi_x(t, x)|^2/2$ is replaced by $(\phi(t, x) - \phi_\alpha(t, x))/\alpha$ (see § 2).

When $\varepsilon = 0$ the solution ϕ_ε^α of (HJ)_α is convex and it is possible to show that ϕ_ε^α converges to the solution of (HJ) as $\alpha \to 0$ (see [2] and [3]). We are able to prove that if ε is sufficiently small, then the solution ϕ_ε^α still exists globally and it is convex. Thus it is possible to show the existence of the limit as $\alpha \to 0$.

2. Notation and preliminary results. We begin by specifying the notation we will use throughout this paper. Let H be a real Hilbert space with norm $|\cdot|_H$ and scalar product $\langle \cdot, \cdot \rangle_H$. With obvious modifications all the results of this paper can be adapted to complex Hilbert spaces. We denote by $\mathscr{L}(H)$ the Banach algebra of the linear bounded operators from H into H. By $\Sigma(H)$ we denote the set of all Hermitian operators in $\mathscr{L}(H)$, and we set

$$\Sigma^+ = \{T \in \mathscr{L}(H); \langle Tx, x \rangle \geqq 0, \forall x \in H\}.$$

Now let X, Y be two Hilbert spaces. If $f: X \to Y$ is a k-times Fréchet differentiable function, we set, for every $r > 0$,

$$|f|_{h,r} = \sup \{|f^{(h)}(x)|: |x| \leqq r\}, \qquad h = 0, \cdots, k \tag{2.1}$$

$$\|f\|_{h,r} = \sup \left\{ \frac{|f^{(h)}(x) - f^{(h)}(y)|}{|x-y|}: |x|, |y| \leqq r, x \neq y \right\}, \qquad h = 0, \cdots, k. \tag{2.2}$$

Note that if f is an $(n+1)$-times Fréchet differentiable function we have

$$\|f\|_{n,r} = |f|_{n+1,r}. \tag{2.3}$$

For $k \in \mathbf{N}$ we define

$$C^k(X, Y) = \{f: X \to Y, k\text{-times continuously Fréchet differentiable: } |f|_{h,r} < +\infty, \forall h = 0, \cdots, k, \forall r > 0\}, \tag{2.4}$$

$$C^k_{\text{Lip}}(X, Y) = \{f \in C^k(X, Y): \|f\|_{k,r} < +\infty, \forall r > 0\}. \tag{2.5}$$

If $Y = \mathbf{R}$ we write $C^k(X)$ instead of $C^k(X, \mathbf{R})$.

We remark that $C^k(X, Y)$ and $C^k_{\text{Lip}}(X, Y)$ are Fréchet spaces with the seminorms $\sum_{h=0}^k |f|_{h,r}$ and $\|f\|_{k,r} + \sum_{h=0}^k |f|_{h,r}$ $(r \in \mathbf{N})$, respectively, and we say that $f_n \to f$ in $C^k(X, Y)$ if $|f_n - f|_{i,r} \to 0$ for $i = 0, \cdots, k$ and for every $r > 0$.

Now let $\phi: [0, T] \times H \to \mathbf{R}$ and $k \geqq 1$. We say that $\phi \in B([0, T]; C^k(H))$ if ϕ satisfies the following conditions:

(i) $\sup_{t \in [0,T]} |\phi(t, \cdot)|_{h,r} < +\infty$, for $h = 0, \cdots, k$, for all $r > 0$,

(ii) $\phi: [0, T] \times H \to \mathbf{R}$ is continuous,

(iii) $\phi_x: [0, T] \times H \to H$ is continuous;

and, if $k \geqq 2$,

(iv) $\partial^h \phi / \partial x^h$ is strongly continuous for $h = 2, \cdots, k$, that is, the map

$$[0, T] \times H \to H, \qquad (t, x) \to \frac{\partial^h \phi}{\partial x^h}(y_1, \cdots, y_{h-1})$$

is continous for all $(y_1, \cdots, y_{h-1}) \in H^{h-1}$.

Analogously we say that $\phi \in B([0, T]; C^k_{\text{Lip}}(H))$ if $\phi \in B([0, T]; C^k(H))$ and

$$\sup_{t \in [0,T]} \|\phi(t, \cdot)\|_{k,r} < +\infty \quad \forall r > 0.$$

Moreover, we say that $\phi_n \to \phi$ in $B([0, T]; C^k(H))$ if

$$\sup_{t \in [0,T]} |\phi(t, \cdot) - \phi_n(t, \cdot)|_{i,r} \to 0 \quad \text{for } i = 0, \cdots, k, \quad \forall r > 0. \tag{2.6}$$

Finally, setting $\Sigma_r = \{x \in H, |x| \leqq r\}$, we similarly define the spaces $C^k(\Sigma_r)$, $C^k_{\text{Lip}}(\Sigma_r)$, $B([0, T]; C^k(\Sigma_r))$, $B([0, T]; C^k_{\text{Lip}}(\Sigma_r))$, and we set $|\phi|_{C^k(\Sigma_r)} = \sum_{i=0}^k |\phi|_{i,r}$, and $|\phi|_{C^k_{\text{Lip}}(\Sigma_r)} = |\phi|_{C^k(\Sigma_r)} + \|\phi\|_{k,r}$, for $\phi \in C^k(\Sigma_r)$ and $\phi \in C^k_{\text{Lip}}(\Sigma_r)$, respectively.

Now we consider the regularization of a convex function (see [2, p. 5]) and we recall its fundamental properties, which we will use in the following.

We denote by K (respectively, K_R) the set of all convex functions $\phi \in C^1(H)$ (respectively, $C^1(\Sigma_R)$) such that $\phi'(0) = 0$.

For $\phi \in K$ we set

$$\phi_\alpha(x) = \min \left\{ \phi(y) + \frac{1}{2\alpha} |x-y|^2; y \in H \right\}, \qquad \alpha \in \mathbf{R} - \{0\}, \quad x \in H. \tag{2.7}$$

We remark that the minimum exists and it is unique, due to the convexity of ϕ.

Moreover, setting

$$x_\alpha = (1+\alpha\phi')^{-1}(x), \qquad \alpha \in \mathbf{R}, \quad x \in H \tag{2.8}$$

we have

$$\phi_\alpha(x) = \phi(x_\alpha) + \frac{\alpha}{2}|\phi'(x_\alpha)|^2. \tag{2.9}$$

We now collect the properties of ϕ_α we need, which are proved in [2, pp. 35, 42].

LEMMA 2.1. *Let ϕ, $\bar\phi \in K \cap C^2_{\mathrm{Lip}}(H)$; then ϕ_α, $\bar\phi_\alpha \in K \cap C^2_{\mathrm{Lip}}(H)$ and the following estimates hold for every $R > 0$:*

(a) $|\phi_\alpha|_{i,R} \leqq |\phi|_{i,R}$, *for* $i = 0, 1, 2$;

(b) $\|\phi_\alpha\|_{2,R} \leqq \|\phi\|_{2,R}$;

(c) $|\phi_\alpha - \bar\phi_\alpha|_{i,R} \leqq |\phi - \bar\phi|_{i,R}$, *for* $i = 0, 1$;

(d) $|\phi_\alpha - \bar\phi_\alpha|_{2,R} \leqq |\phi - \bar\phi|_{2,R} + \alpha\|\bar\phi\|_{2,R}|\phi - \bar\phi|_{1,R}$;

LEMMA 2.2. *Let $\phi \in K \cap C^2_{\mathrm{Lip}}(H)$, and set*

$$R_{\alpha,\phi}(x) = \frac{1}{\alpha}(\phi(x) - \phi_\alpha(x)) - \frac{1}{2}|\phi'(x)|^2. \tag{2.10}$$

Then for $R > 0$ we have

(i) $|R_{\alpha,\phi}|_{0,R} \leqq \alpha|\phi|^2_{1,R}|\phi|_{2,R}$;

(ii) $|R_{\alpha,\phi}|_{1,R} \leqq \alpha(|\phi|^2_{1,R}\|\phi\|_{2,R} + |\phi|_{2,R}|\phi|_{1,R})$.

We observe that the same statements hold if K is replaced by K_R.

Remark 2.3. It is not difficult to show that if ϕ, $\bar\phi \in K \cap C^k_{\mathrm{Lip}}(H)$ ($k \geqq 3$), then analogous estimates hold true for $|\phi_\alpha|_{i,R}$, $|\phi_\alpha - \bar\phi_\alpha|_{i,R}$, and $|R_{\alpha,\phi}|_{i-1,R}$, $i = 3, \cdots, k$.

3. Global existence and uniqueness for the Hamilton–Jacobi equation. Consider the following Cauchy problem:

$$\text{(HJ)} \quad \begin{aligned} &\phi_t(t,x) = -\tfrac{1}{2}|\phi_x(t,x)|^2 + \langle Ax + f(\varepsilon,x), \phi_x(t,x)\rangle + g(x) \quad \forall (t,x) \in [0,T] \times D(A), \\ &\phi(0,x) = \phi_0(x) \quad \forall x \in H. \end{aligned}$$

Our hypotheses (as we said in the Introduction) are the following:

(i) $A: D(A) \subset H \to H$ is the infinitesimal generator of a strongly continuous semi-group in H and there exists $w \in \mathbf{R}$ subject to

$$\langle Ax, x\rangle \leqq \omega|x|^2 \quad \forall x \in D(A).$$

(ii) $f(\varepsilon, \cdot) \in C^2_{\mathrm{Lip}}(H, H)$, for all $\varepsilon \in \mathbf{R}$; $f(\varepsilon, 0) = 0$, $(\partial f/\partial x) f(\varepsilon, 0) = 0$, for all $\varepsilon \in \mathbf{R}$; $f(\varepsilon, x) \to_{\varepsilon \to 0} 0$ uniformly on $C^2_{\mathrm{Lip}}(H, H)$.

(iii) g, $\phi_0 \in C^2_{\mathrm{Lip}}(H) \cap K$; $\langle g''(x)z, z\rangle \geqq \mu|z|^2$, for all x, $z \in H$, for $\mu > 0$ fixed; that is, g is strictly convex on H.

We recall this result about (SE).

PROPOSITION 3.1. *Let $x \in H$, $u \in L^2(0, T; H)$; let $\bar\omega = \max\{\omega, 0\}$. Assume that* (i)–(iii) *hold true. We define*

$$r = 2\,e^{\bar\omega T}(|x|_H + \sqrt{T}\,|u|_{L^2(0,T;H)}) = r(|x|, |u|).$$

Then there exists $\varepsilon_0(r) > 0$ such that, for $|\varepsilon| \leqq \varepsilon_0$, (SE) *has a unique mild solution $y \in C([0, T]; H)$, and we have*

$$|y(t)| \leqq r \qquad \textit{and, if } \omega > 0 \qquad |y(t)| \leqq |x| + \sqrt{T}\,|u|_{L^2(0,T;H)}. \tag{3.1}$$

Sketch of proof. It is a standard application of contraction principle and Gronwall lemma (for similar arguments see [6] and [8, Chapter 6]). We consider (SE) in the following integral form:

$$\text{(SEI)} \qquad y(t)=e^{tA}x+\int_0^t e^{(t-s)A}[u(s)+f(\varepsilon, y(s))]\,ds \overset{\text{def}}{=} (\Lambda y)(t).$$

Let $B_r=\{y\in C([0,T];H);\ |y|\leqq r\}$. By simple estimates it follows that for ε sufficiently small, Λ defined in (SEI) is a contraction map on B_r. So there exists a unique solution of (SE) on B_r. From the Gronwall inequality we easily obtain that the solution y is unique also on $C([0,T];H)$ and that the estimates (3.1) hold. □

In the following for every fixed $r>0$ we will suppose that $|\varepsilon|\leqq\varepsilon_0(r)$.

We say that a function $\phi\in B([0,T];C^1_{\text{Lip}}(\Sigma_R)\cap K_R)$ is a strict solution of (HJ) if $\phi(\cdot,x)\in C^1([0,T])$ for all $x\in D(A)$, and satisfy (HJ).

More generally, if ϕ is defined only on $[0,T]\times\Sigma_R$ we say that ϕ is a strict solution on Σ_R if the conditions above hold true on this ball.

THEOREM 3.2. *Under assumptions* (i)–(iii), *for every* $R>0$ *there exists* $\bar\varepsilon(R)>0$ *such that, if* $|\varepsilon|\leqq\bar\varepsilon(R)$, *then the Hamilton–Jacobi equation* (HJ) *has a unique strict solution* $\phi_\varepsilon:[0,T]\times\Sigma_R\to\mathbf{R}$ *and we have*

$$\phi_\varepsilon(t,\cdot)\in C^2_{\text{Lip}}(\Sigma_R)\cap K_R \quad \forall t\in[0,T],$$

$$\sup_{t\in[0,T]} |\phi_\varepsilon(t,\cdot)|_{C^2_{\text{Lip}}(\Sigma_R)}<+\infty.$$

4. Proof of Theorem 3.2. First we prove, by the method of successive approximations, the existence of a solution ϕ^α_ε for the integral form of the approximating problem $(\text{HJ})_\alpha$. Afterwards we show that ϕ^α_ε converges to a strict solution ϕ_ε of the Cauchy problem (HJ) for $\alpha\to 0$.

The uniqueness is easily shown by standard methods.

At the moment we assume that hypothesis (i) holds with $\omega<0$, that is, A is a strictly dissipative operator on H. We will explain later (see Remark 4.8) the generalization of the proof to the case where $\omega\geqq 0$.

4.1. The integral approximating problem. Using the characteristics method we can write the approximating problem $(\text{HJ})_\alpha$ in the following integral form (see [4]):

$$\text{(4.1)} \qquad \begin{aligned}\phi(t,x)&=e^{-t/\alpha}\phi_0(\zeta_\varepsilon(0,t,x))\\ &\quad+\int_0^t e^{-(t-s)/\alpha}\left[g(\zeta_\varepsilon(s,t,x))+\frac{1}{\alpha}\phi_\alpha(s,\zeta_\varepsilon(s,t,x))\right]ds\end{aligned}$$

where $\zeta_\varepsilon(s,t,x)$ is the solution of the Cauchy problem:

$$\text{(4.2)} \qquad \begin{aligned}&\zeta'_\varepsilon(s)=-A\zeta_\varepsilon(s)-f(\varepsilon,\zeta_\varepsilon(s)) \quad \text{for } s\in[0,t],\\ &\zeta_\varepsilon(t)=x, \qquad x\in H, \quad t\in[0,T],\end{aligned}$$

that is, ζ_ε is the family of characteristic curves for $(\text{HJ})_\alpha$ linearized.

4.2. Characteristics estimate. We show some fundamental estimates for the characteristic curves.

PROPOSITION 4.1. *Let* (i), (ii) *be true. We fix* $R>0$. *Let* $t\in[0,T]$, $x\in H$ *with* $|x|\leqq R$. *There exists* $\varepsilon_1(R)>0$ *such that, if* $|\varepsilon|\leqq\varepsilon_1(R)$, *then the Cauchy problem* (4.2) *has a unique mild solution* $\zeta_\varepsilon(\cdot, t, x)$ *on* $[0, t]$ *and we have*

$$\zeta_\varepsilon(s, t, \cdot) \in C^2_{\mathrm{Lip}}(H, H) \quad \forall s, t \in [0, T], \quad s \leqq t.$$

Moreover, the following estimates hold:

$$|\zeta_\varepsilon(s, t, x)| \leqq |x|\, e^{+\omega(t-s)/2}, \tag{4.3}$$

$$|\zeta_\varepsilon(s, t, \cdot)|_{1,R} \leqq e^{+\omega(t-s)/2}, \tag{4.4}$$

$$|\zeta_{\varepsilon xx}(s, t, x)(z, z)|_H \leqq |f(\varepsilon, \cdot)|_{2,R} \int_s^t |\zeta_{\varepsilon x}(\sigma, t, x)z|_H^2\, e^{+\omega(\sigma-s)/2}\, d\sigma, \tag{4.5}$$

$$\|\zeta_\varepsilon(s, t, \cdot)\|_{2,R} \leqq \int_s^t e^{+\omega(\sigma-s)/2}[3|f(\varepsilon, \cdot)|_{2,R} + \|f(\varepsilon, \cdot)\|_{2,R}]|\zeta_\varepsilon(\sigma, t, \cdot)|_{1,R}\, d\sigma. \tag{4.6}$$

Proof. The proof of existence and uniqueness follows from Proposition 3.1. The regularity with respect to x follows from the parameter-dependent contraction principle. For the estimates it is sufficient to choose $\varepsilon_1(R)$ such that

$$\langle Ax + f(\varepsilon, x), x\rangle \leqq \frac{\omega}{2}|x|^2 \quad \forall x \in \Sigma_{2R} \quad \forall |\varepsilon| \leqq \varepsilon_1(R), \tag{4.7}$$

and it is possible due to hypothesis (ii). Now by (4.7) the operator $A + f(\varepsilon, \cdot)$ is strictly dissipative on Σ_{2R}.

If $|x| \leqq R$, then $|\zeta_\varepsilon(s, t, x)| \leqq 2R$ (see Proposition 3.1), and by applying Gronwall's inequality we obtain (4.3).

Analogously, $\zeta_{\varepsilon x}$ satisfies the Cauchy problem:

$$\begin{aligned} &\zeta'_{\varepsilon x}(s) = -A\zeta_{\varepsilon x}(x) - f_x(\varepsilon, \zeta_\varepsilon(s))\zeta_{\varepsilon x}(s) \quad \text{for } s \in [0, T], \\ &\zeta_{\varepsilon x}(s) = I, \qquad I \in \mathscr{L}(H) \end{aligned} \tag{4.8}$$

and again

$$\langle (A + f_x(\varepsilon, x))z, z\rangle \leqq \frac{\omega}{2}|z|^2 \quad \forall x \in \Sigma_R, \quad \forall z \in H.$$

From Gronwall's inequality (4.4) follows.

For the other estimates we observe that for every $z \in H$ we have

$$\begin{aligned} &\zeta'_{\varepsilon xx}(s)(z, z) = -A\zeta_{\varepsilon xx}(s)(z, z) - [f_x(\varepsilon, \zeta_\varepsilon(s))\zeta_{\varepsilon xx}(s)(z, z) \\ &\qquad\qquad + f_{xx}(\varepsilon, \zeta_\varepsilon(s))(\zeta_{\varepsilon x}(s)z, \zeta_{\varepsilon x}(s)z)] \quad \text{for } s \in [0, T], \\ &\xi_{\varepsilon xx}(t) = 0 \end{aligned} \tag{4.9}$$

and from Gronwall's inequality (4.5) and (4.6) follow.

4.3. Convexity estimates. We now consider the application

$$\Gamma^\varepsilon_\alpha : B([0, T]; C^2_{\mathrm{Lip}}(\Sigma_R)) \to B([0, T]; C^2_{\mathrm{Lip}}(\Sigma_R)) \tag{4.10}$$

defined by (see (4.1))

$$\begin{aligned} \Gamma^\varepsilon_\alpha \phi(t, x) &= e^{-t/\alpha}\phi_0(\zeta_\varepsilon(0, t, x)) \\ &\quad + \int_0^t e^{-(t-s)/\alpha}\left[g(\zeta_\varepsilon(s, t, x)) + \frac{1}{\alpha}\,\phi_\alpha(s, \zeta_\varepsilon(s, t, x))\right] ds. \end{aligned} \tag{4.11}$$

Clearly, $\Gamma^\varepsilon_\alpha$ is well defined and (4.10) holds. We prove that, for ε, α sufficiently small, $\Gamma^\varepsilon_\alpha$ is a convexity-preserving map.

LEMMA 4.2. *Let $R>0$, $C>0$ be fixed, and $\alpha\in[0,1]$. Let* (i)-(iii) *hold true. We consider*

$$\mathscr{F}_C^R=\left\{\phi\in B([0,T]);\ C^2_{\mathrm{Lip}}(\Sigma_R)\cap K_R)\ \textit{such that}\ \sup_{t\in[0,T]}|\phi(t,\cdot)|_{1,R}\leqq C\right\}.$$

Then there exists $\varepsilon(R,C)>0$ such that, for $|\varepsilon|\leqq\varepsilon(R,C)$, $\Gamma_\alpha^\varepsilon$ is a convexity-preserving map, that is,

$$\Gamma_\alpha^\varepsilon(\mathscr{F}_C^R)\subset B([0,T];\ C^2_{\mathrm{Lip}}(\Sigma_R)\cap K_R).$$

Proof. First we remark that, for $\phi\in C^2_{\mathrm{Lip}}(\Sigma_R)$, we have $\phi\in K_R$ if and only if

$$\langle\phi''(x)z,z\rangle\geqq 0\quad\forall x\in\Sigma_R,\quad\forall z\in H,\quad\phi'(0)=0.\tag{4.12}$$

Therefore we have to show that there exists $\varepsilon(R,C)>0$ such that for $|\varepsilon|\leqq\varepsilon(R,C)$

$$\langle(\Gamma_\alpha^\varepsilon\phi)_{xx}(t,x)z,z\rangle\geqq 0\quad\forall\phi\in\mathscr{F}_C^R,\quad\forall x\in\Sigma_R,\quad\forall z\in H,\quad\text{and}$$
$$(\Gamma_\alpha^\varepsilon\phi)_x(t,0)=0\quad\forall t\in[0,T].$$

Let $\phi\in B([0,T];\ C^2_{\mathrm{Lip}}(\Sigma_R))$ be such that $\sup_{t\in[0,T]}|\phi(t,\cdot)|_{1,R}\leqq C$. By differentiating twice (4.11) with respect to x we obtain

$$\begin{aligned}(\Gamma_\alpha^\varepsilon\phi)_x(t,x)&=e^{-t/\alpha}\zeta_{\varepsilon x}^*(0,t,x)\phi_0'(\zeta_\varepsilon(0,t,x))\\&\quad+\int_0^t e^{-(t-s)/\alpha}\zeta_{\varepsilon x}^*(s,t,x)\left[g'(\zeta_\varepsilon(s,t,x))+\frac{1}{\alpha}\phi_{\alpha x}(s,\zeta_\varepsilon(s,t,x))\right]ds,\end{aligned}\tag{4.13}$$

$$\begin{aligned}(\Gamma_\alpha^\varepsilon\phi)_{xx}(t,x)&=e^{-t/\alpha}\zeta_{\varepsilon x}^*(0,t,x)\phi_0''(\zeta_\varepsilon(0,t,x))\zeta_{\varepsilon x}(0,t,x)\\&\quad+\int_0^t e^{-(t-s)/\alpha}\zeta_{\varepsilon x}^*(s,t,x)\\&\quad\cdot\left[g''(\zeta_\varepsilon(s,t,x))+\frac{1}{\alpha}\phi_{\alpha xx}(s,\zeta_\varepsilon(s,t,x))\right]\zeta_{\varepsilon x}(s,t,x)\,ds\\&\quad+e^{-t/\alpha}\zeta_{\varepsilon xx}^*(0,t,x)\phi_0'(\zeta_\varepsilon(0,t,x))\\&\quad+\int_0^t e^{-(t-s)/\alpha}\zeta_{\varepsilon xx}^*(s,t,x)\left[g'(\zeta_\varepsilon(s,t,x))+\frac{1}{\alpha}\phi_{\alpha x}(s,\zeta_\varepsilon(s,t,x))\right]ds,\end{aligned}\tag{4.14}$$

and therefore

$$\begin{aligned}\langle(\Gamma_\alpha^\varepsilon\phi)_{xx}(t,x)z,z\rangle&=e^{-t/\alpha}\langle\phi_0''(\zeta_\varepsilon(0,t,x))\zeta_{\varepsilon x}(0,t,x)z,\zeta_{\varepsilon x}(0,t,x)z\rangle\\&\quad+\int_0^t e^{-(t-s)/\alpha}\left\langle\left[g''(\zeta_\varepsilon(s,t,x))+\frac{1}{\alpha}\phi_{\alpha xx}(s,\zeta_\varepsilon(s,t,x))\right]\right.\\&\qquad\left.\zeta_{\varepsilon x}(s,t,x)z,\zeta_{\varepsilon x}(s,t,x)z\right\rangle ds\\&\quad+e^{-t/\alpha}\langle\zeta_{\varepsilon xx}(0,t,x)(z,z),\phi_0'(\zeta_\varepsilon(0,t,x))\rangle+\int_0^t e^{-(t-s)/\alpha}\\&\quad\cdot\left\langle\zeta_{\varepsilon xx}(s,t,x)(z,z),\left[g'(\zeta_\varepsilon(s,t,x))+\frac{1}{\alpha}\phi_{\alpha x}(s,\zeta_\varepsilon(s,t,x))\right]\right\rangle ds.\end{aligned}\tag{4.15}$$

By assumption (iii) the first two terms of (4.15) are positive. Concerning the last two terms we show that they are smaller than the second one. We have by the inequalities (4.3)-(4.6):

$$\begin{aligned}&|e^{-t/\alpha}\langle \zeta_{\varepsilon xx}(0,t,x)(z,z), \phi_0'(\zeta_\varepsilon(0,t,x))\rangle| \\ &\qquad \leqq e^{-t/\alpha}|\phi_0|_{1,R}|f(\varepsilon,\cdot)|_{2,R}\int_0^t |\zeta_{\varepsilon x}(s,t,x)z|^2\,ds \overset{\text{def}}{=} A_{\varepsilon,R}\end{aligned}$$

and

$$\begin{aligned}&\left|\int_0^t e^{-(t-s)/\alpha}\left\langle \zeta_{\varepsilon xx}(s,t,x)(z,z), \left[g'(\zeta_\varepsilon(s,t,x))+\frac{1}{\alpha}\,\phi_{\alpha x}(s,t,x))\right]\right\rangle ds\right| \\ &\qquad \leqq e^{-t/\alpha}\int_0^t e^{s/\alpha}\varepsilon\left(|g|_{1,R}+\frac{1}{\alpha}\,C\right)|f(\varepsilon,\cdot)|_{2,R}\left(\int_s^t |\zeta_{\varepsilon x}(\sigma,t,x)z|^2\,dx\right)ds \\ &\qquad \leqq e^{-t/\alpha}\left(|g|_{1,R}+\frac{1}{\alpha}\,C\right)|f(\varepsilon,\cdot)|_{2,R}\int_0^t |\zeta_{\varepsilon x}(\sigma,t,x)z|^2\left(\int_0^\sigma e^{s/\alpha}\,ds\right)d\sigma \\ &\qquad \leqq e^{-t/\alpha}(\alpha|g|_{1,R}+C)|f(\varepsilon,\cdot)|_{2,R}\int_0^t e^{s/\alpha}|\zeta_{\varepsilon x}(s,t,x)z|^2\,ds \overset{\text{def}}{=} B_{\varepsilon,R}.\end{aligned}$$

It follows that

$$A_{\varepsilon,R}+B_{\varepsilon,R}\leqq |f(\varepsilon,\cdot)|_{2,R}(|\phi_0|_{1,R}+|g|_{1,R}+C)\int_0^t e^{-(t-s)/\alpha}|\zeta_{\varepsilon x}(s,t,x)z|^2\,ds.$$

Set $\varepsilon(R,C)$ such that for all $|\varepsilon|\leqq\varepsilon(R,C)$, we have

$$|f(\varepsilon,\cdot)|_{2,R}\leqq\frac{\mu}{|\phi_0|_{1,R}+|g|_{1,R}+C}, \tag{4.16}$$

then by assumption (iii) it follows:

$$\langle(\Gamma_\alpha^\varepsilon\phi)_{xx}(t,x)z,z\rangle\geqq 0.$$

Finally, by (4.13) we immediately get

$$(\Gamma_\alpha^\varepsilon\phi)_x(t,0)=0 \quad \forall t\in[0,T]$$

and the proof is complete. □

4.4. Successive approximations.

LEMMA 4.3. *Let* (i)-(iii) *hold true. Fix* $R>0$, *and set*

$$L=L(R)=|\phi_0|_{C^2_{\text{Lip}}(\Sigma_r)}+T|g|_{C^2_{\text{Lip}}(\Sigma_R)}.$$

Let $|\varepsilon|\leqq\varepsilon(R,L)$. *Consider the sequence* $\{\phi^n\}_{n\in\mathbf{N}}\subset B([0,T];C^2_{\text{Lip}}(\Sigma_R)\cap K_R)$ *defined by*

$$\phi^0=\Gamma_\alpha^\varepsilon(0), \qquad \phi^n=\Gamma_\alpha^\varepsilon(\phi^{n-1}),$$

Then there exists $\varepsilon_2(R)\in(0,\varepsilon(R,L))$ *such that for* $|\varepsilon|\leqq\varepsilon_2(R)$, *we have*:

(I) $\phi\in\mathscr{F}_C^R$ *and also* $\sup_{t\in[0,T]}|\phi^n(t,\cdot)|_{C^2_{\text{Lip}}(\Sigma_R)}\leqq L(R)$, *for all* $n\in\mathbf{N}$;
(II) $|\phi^n(t,\cdot)-\phi^{n-1}(t,\cdot)|_{C^2(\Sigma_R)}\leqq(L(R)+1)^{n+1}t^n/\alpha^n n!$, *for all* $n\in\mathbf{N}$;
(III) $\Gamma_\alpha^\varepsilon$ *is continuous on* $B([0,T];C^2(\Sigma_R))$.

Remark 4.4. This implies that there exists $\phi_\varepsilon^\alpha\in B([0,T];C^2_{\text{Lip}}(\Sigma_R)\cap K_R)$ such that

$$\phi^n\xrightarrow{n\to\infty}\phi_\varepsilon^\alpha \quad \text{in } B([0,T];C^2(\Sigma_R))$$

and therefore (by (III))

$$\phi^\alpha_\varepsilon(t,x)=(\Gamma^\varepsilon_\alpha\phi^\alpha_\varepsilon)(t,x)\quad \text{on } [0,T]\times\Sigma_R$$

and ϕ^α_ε is also a strict solution of $(\mathrm{HJ})_\alpha$.

We also remark that estimate (I) does not depend on α. This fact will be used to prove the convergence of ϕ^α as $\alpha\to 0$ in the next section.

Proof of (I). We use a recurrence argument. First we have that (I) holds true for the function $0\in B([0,T]; C^2_{\mathrm{Lip}}(\Sigma_R))$. After we suppose that (I) holds true for $\phi^0,\cdots,\phi^{n-1}$. Then by using (4.12)-(4.14), and Lemma 2.1, we obtain

$$|\phi^n(t,\cdot)|_{C^2_{\mathrm{Lip}}(\Sigma_R)}\leqq e^{-t/\alpha}|\phi_0|_{C^2_{\mathrm{Lip}}(\Sigma_R)}\gamma(0,t)+|g|_{C^2_{\mathrm{Lip}}(\Sigma_R)}\int_0^t e^{-(t-s)/\alpha}\gamma(s,t)\,ds$$
$$+\frac{1}{\alpha}\int_0^t e^{-(t-s)/\alpha}|\phi^{n-1}(s,\cdot)|_{C^2_{\mathrm{Lip}}(\Sigma_R)}\gamma(s,t)\,ds,$$

where

$$\gamma(s,t)\leqq e^{+\omega(t-s)/2}+(|f(\varepsilon,\cdot)|_{2,R}+|f(\varepsilon,\cdot)|^2_{2,R}T+\|f(\varepsilon,\cdot)\|_{2,R})(t-s).$$

It is easy to see that, if we set $E_R=|f(\varepsilon,\cdot)|_{2,R}+|f(\varepsilon,\cdot)|^2_{2,R}T+\|f(\varepsilon,\cdot)\|_{2,R}$, then for ε sufficiently small we have $E_R\leqq(-\omega/2)\,e^{T\omega/2}$ and hence $\gamma(s,t)\leqq 1$, for all s, $t\in[0,T]$. Now by iterating the above estimate we obtain

$$|\phi^n(t,\cdot)|_{C^2_{\mathrm{Lip}}(\Sigma_R)}\leqq e^{-t/\alpha}|\phi_0|_{C^2_{\mathrm{Lip}}(\Sigma_R)}\sum_{k=0}^n\frac{1}{k!}\frac{t^k}{\alpha^k}$$
$$+|g|_{C^2_{\mathrm{Lip}}(\Sigma_R)}\int_0^t e^{-(t-s)/\alpha}\sum_{k=0}^n\frac{1}{k!}\frac{(t-s)^k}{\alpha^k}\,ds\leqq L(R).$$

Proof of (II). Using the same method as (I) we get

$$|\phi^n(t,\cdot)-\phi^{n-1}(t,\cdot)|_{C^2(\Sigma_R)}\leqq\frac{1}{\alpha}\int_0^t e^{-(t-s)/\alpha}\gamma_1(s,t)|\phi^{n-1}(s,\cdot)-\phi^{n-2}(s,\cdot)|_{C^2(\Sigma_R)}\,ds$$

and it is easy to prove that

$$\gamma_1(s,t)\leqq L(R)+1.$$

By iterating we get

$$|\phi^n(t,\cdot)-\phi^{n-1}(t,\cdot)|_{C^2(\Sigma_R)}\leqq\frac{L(R)}{\alpha}\int_0^T e^{-(t-s)/\alpha}\frac{(L(R)+1)^n}{(n-1)!}\frac{(t-s)^{n-1}}{\alpha^{n-1}}\,ds$$

from which (II) follows.

Proof of (III). Let ϕ, $\bar\phi\in B([0,T]; C^2_{\mathrm{Lip}}(\Sigma_R)\cap K_R)$, and let

$$D=\sup_{t\in[0,T]}\{|\phi(t,\cdot)|_{C^2(\Sigma_R)},|\bar\phi(t,\cdot)|_{C^2(\Sigma_R)}\}.$$

Then we have

$$\sup_{t\in[0,T]}\{|\Gamma^\varepsilon_\alpha\phi(t,\cdot)-\Gamma^\varepsilon_\alpha\bar\phi(t,\cdot)|_{C^2(\Sigma_R)}\}$$
$$\leqq\frac{1}{\alpha}\int_0^t e^{-(t-s)/\alpha}(D+1)|\phi(s,\cdot)-\bar\phi(s,\cdot)|_{C^2(\Sigma_R)}\,ds$$
$$\leqq\frac{(D+1)T}{\alpha}\sup_{t\in[0,T]}|\phi(t,\cdot)-\bar\phi(t,\cdot)|_{C^2(\Sigma_R)}$$

and (III) is proved. □

Remark 4.5. If $f(\varepsilon,\cdot)\in C^k_{\mathrm{Lip}}(H,H)$ and g, $\phi_0\in C^k(H)$ $(k\geqq 3)$ it is possible to prove (by reducing the limit for $|\varepsilon|$) that $\phi^n\in B([0,T];\ C^k_{\mathrm{Lip}}(\Sigma_R)\cap K_R)$ and

$$\phi^n \xrightarrow{n-\infty} \phi^\alpha_\varepsilon \quad \text{in } B[0,T];\ C^k(\Sigma_R)).$$

4.5. Convergence of ϕ^α_ε as $\alpha\to 0$.

LEMMA 4.6. *We assume that* (i)–(iii) *hold. Let $R>0$ be fixed and let $\varepsilon_2(R)$ be as in* § 4.4. *Let $\phi^\alpha_\varepsilon\in B([0,T];\ C^2(\Sigma_R)\cap K_R)$ be the strict solution of* $(\mathrm{HJ})_\alpha$.

Then there exists $\phi_\varepsilon\in B([0,T];\ C^1_{\mathrm{Lip}}(\Sigma_R)\cap K_R)$ such that:

(a) $\phi^\alpha_\varepsilon \xrightarrow{\alpha\to 0} \phi_\varepsilon$ *in* $B([0,T];\ C^1(\Sigma_R))$,

(b) ϕ_ε *is a strict solution of the Hamilton-Jacobi equation* (HJ),

(c) *for all* $t\in[0,T]$, $\phi_\varepsilon(t,\cdot)\in C^2_{\mathrm{Lip}}(\Sigma_R)\cap K_R)$.

Proof. Due to the estimates in § 4.4 (see Remark 4.4) the proof is completely analogous to the one of [2, pp. 38–41, 98–99]; thus it will be only sketched.

Let $\alpha>0$, $\beta>0$. Then ϕ^β_ε (we write ϕ^β for simplicity) fulfills the equation

$$\phi^\beta_t(t,x)+\frac{1}{\alpha}(\phi^\beta-\phi^\beta_\alpha)-\langle Ax+f(\varepsilon,x),\ \phi^\beta_x\rangle=g(x)+R_{\alpha,\phi^\beta}+R_{\beta,\phi^\beta} \tag{4.17}$$

$$\forall(t,x)\in[0,T]\times D(A)\cap\Sigma_R,$$

$$\phi^\beta(0,x)=\phi_0(x)\quad \forall x\in H.$$

It follows, by using the integral form, that

$$|\phi^\beta(t,\cdot)-\phi^\alpha(t,\cdot)|_{C^1(\Sigma_R)}\leqq\frac{1}{\alpha}\int_0^t e^{-(t-s)/\alpha}|\phi^\beta(s,\cdot)-\phi^\alpha(s,\cdot)|_{C^1(\Sigma_R)}\,ds$$

$$+\int_0^t e^{-(t-s)/\alpha}(|R_{\alpha,\phi^\beta(s,\cdot)}|_{C^1(\Sigma_R)}+|R_{\beta,\phi^\beta(s,\cdot)}|_{C^1(\Sigma_R)}\,ds.$$

Now by Lemma 2.2 and Gronwall's inequality we get

$$|\phi^\beta(t,\cdot)-\phi^\alpha(t,\cdot)|_{C^1(\Sigma_R)}\leqq(\alpha+\beta)3L^3(R)T,$$

so (a) is proved.

To show (b) we remark that, if $x\in D(A)$, then $\phi^\alpha(\cdot,x)\in C^1([0,T])$, and

$$\phi^\alpha_t(t,x)=g(x)+R_{\alpha,\phi^\alpha(t,\cdot)}(x)-\tfrac{1}{2}|\phi^\alpha_x(t,x)|^2+\langle Ax+f(\varepsilon,x),\ \phi^\alpha_x(t,x)\rangle,$$

so $\phi^\alpha_t(\cdot,x)\xrightarrow{\alpha\to 0}\phi_{\varepsilon t}$ in $C([0,T])$, and ϕ_ε is a strict solution.

To show (c) we apply Ascoli's theorem exactly as in [2, pp. 40–41]. □

Remark 4.7. As in the previous section, if $f(\varepsilon,\cdot)\in C^k_{\mathrm{Lip}}(H,H)$, g, $\phi_0\in C^k(H)$ and $|\varepsilon|$ is sufficiently small, then it is possible to prove that

$$\phi^\alpha_\varepsilon\xrightarrow{\alpha\to 0}\phi_\varepsilon\quad\text{in } B([0,T];\ C^{k-1}(\Sigma_R))$$

and

$$\phi_\varepsilon(t,\cdot)\in C^k_{\mathrm{Lip}}(\Sigma_R)\cap K_R\quad\forall t\in[0,T].$$

4.6. Uniqueness. This also is standard and we only sketch the proof (see [2, pp. 39, 99], [4] for more details). Let ϕ_1, ϕ_2 be two strict solutions of (3.1). Then for $\alpha>0$ we have

$$\phi_{i,t}(t,x)=-\frac{1}{\alpha}(\phi_i-\phi_{i,\alpha})+\langle Ax+f(\varepsilon,x),\ \phi_{i,x}\rangle+g(x)+R_{\alpha,\phi_i}$$

$$\forall(t,x)\in[0,T]\times D(A)\cap\Sigma_R,\quad i=1,2,$$

$$\phi_i(0,x)=\phi_0(x)\quad\forall x\in H.$$

By using the integral form (4.1) and applying Gronwall's inequality we obtain

$$|\phi_1(t,\cdot)-\phi_2(t,\cdot)|_{C^1(\Sigma_R)}\leqq 5\alpha L^3(R)T$$

and the uniqueness follows from the arbitrariness of α.

Now Theorem 3.2 is proved and we may set $\bar{\varepsilon}(R)=\varepsilon_2(R)$ as in § 4.4.

Remark 4.8. At this point, as we said in the beginning of this section, we show that the result of Theorem 3.2 also holds true when the operator A is not strictly dissipative. In this case we have, by the hypothesis (i):

$$\langle Ax, x\rangle \leqq \omega|x|^2 \quad \forall x\in H \quad \text{for some } \omega\geqq 0.$$

We proceed in this way (see [2, Remark 5, p. 46]. Set $\eta(t,x)=\phi(t, e^{-2\omega t}x)$. Then (HJ) reduces to

$$(\overline{\text{HJ}})\qquad \begin{aligned}&\eta_t(t,x)=-\tfrac{1}{2}b(t)|\eta_x(t,x)|^2+\langle A_1x+f_1(\varepsilon,x,t),\eta_x(t,x)\rangle+g_1(t,x)\\ &\qquad\qquad\qquad\qquad\qquad\qquad \forall (t,x)\in[0,T]\times D(A),\\ &\eta(0,x)=\phi_0(x)\quad \forall x\in H,\end{aligned}$$

where we posed

$$b(t)=e^{4\omega t},\qquad A_1=A-2\omega,$$

$$f_1(\varepsilon,x,t)=e^{2\omega t}f(\varepsilon, x\,e^{-2\omega t}),\qquad g_1(t,x)=g(x\,e^{-2\omega t}).$$

Now we can write $(\overline{\text{HJ}})$ in approximating integral form as follows:

$$(4.18)\qquad \begin{aligned}\eta(t,x)=e^{-B(t)}\phi_0(\zeta_\varepsilon^1(0,t,x))&+\int_0^t e^{-(B(t)-B(s))}\\ &\cdot\left[g_1(s,\zeta_\varepsilon^1(s,t,x))+\frac{1}{\alpha}b(s)\eta_\alpha(s,\zeta_\varepsilon^1(s,t,x))\right]ds,\end{aligned}$$

where

$$B(t)=\frac{1}{\alpha}\int_0^t b(s)\,ds$$

and $\zeta_\varepsilon^1(s,t,x)$ is the solution of the Cauchy problem,

$$(4.19)\qquad \begin{aligned}&(\zeta_\varepsilon^1)'(s)=-A_1\zeta_\varepsilon^1(s)-f_1(\varepsilon,\zeta_\varepsilon^1(s),s)\quad \text{for } s\in[0,T],\\ &\zeta_\varepsilon^1(s)=x,\qquad x\in H.\end{aligned}$$

Now we can solve this approximating problem using the same method seen in §§ 4.2, 4.3, and 4.4. The only differences are:

(1) The functions g_1, f_1 are time-dependent, but this dependence is uniform on $[0,T]\times\Sigma_R$ for all $R>0$ (also for the derivatives), so it is sufficient to change the value of the constants which appear in the proof. In this case all these constants depend on T and they blow up when T goes to $+\infty$.

(2) The factor $1/\alpha$ is replaced by $b(t)/\alpha$ and t/α by $B(t)=(1/\alpha)\int_0^t b(s)\,ds$. However, we can repeat all of our estimates using that $b(t)$ is bounded on $[0,T]$ and $b(t)b(s)=b(t+s)$.

Finally, the proofs of §§ 4.5 and 4.6 are completely analogous by arranging the constants.

5. Solution of the control problem. In this section we apply the results of Theorem 3.2 to the solution of the control problem (P). We assume (i)-(iii) and for simplicity we discuss only the case in which the operator A is strictly dissipative (that is, $\omega < 0$ in the hypothesis (i)). Anyway, all the results of this section also hold true in the general case. The proof for the general case is the same: we have only to arrange the constants. Let r, $M > 0$ be fixed. Suppose $|x| \leqq r$, $|u|_{L^2(0,T;H)} \leqq L(r)$. Now set $R = r + \sqrt{T}M$ and $|\varepsilon| \leqq \bar{\varepsilon}$.

Then, as seen in § 3, the following statements hold true:

(1) The state equation (1) has a unique mild solution

$$y \in C([0, T]; H) \quad \text{with } |y(t)| \leqq R.$$

(2) The Hamilton-Jacobi equation (HJ) has a unique strict solution

$$\phi_\varepsilon \in B([0, T]; C^1_{\mathrm{Lip}}(\Sigma_R) \cap K_R).$$

Using these results we can solve the control problem (P) in a standard way.

LEMMA 5.1. *Let r, $M > 0$ be fixed. Let $x \in \Sigma_r$, $u \in L^2(0, T; H)$, with $|u|_{L^2} \leqq M$. Let $R = r + \sqrt{T}M$ and $|\varepsilon| \leqq \bar{\varepsilon}(R)$. Let y be the mild solution of the Cauchy problem*:

$$(5.1) \qquad \begin{aligned} &y' = Ay + f(\varepsilon, y) + u \quad \text{on } [0, T], \\ &y(t) = x. \end{aligned}$$

Then the following fundamental identity holds for every $(t, x) \in [0, T] \times \Sigma_r$:

$$(5.2) \qquad \begin{aligned} &\phi_\varepsilon(T - t, x) + \frac{1}{2}\int_t^T |u + \phi_{\varepsilon x}(T - s, y(s))|^2 \, ds \\ &= \phi_0(y(T)) + \int_t^T \left[g(y(s)) + \frac{1}{2}|u(s)|^2 \right] ds \\ &= J(x, u) \quad \text{if } t = 0. \end{aligned}$$

The proof is standard (see, for instance, [2, pp. 51-52], [7]). We only recall that for $|\varepsilon| < \bar{\varepsilon}(r + \sqrt{T}M)$, expression (5.2) makes sense, due to statements (1) and (2).

Now we consider the closed-loop equation:

$$(5.3) \qquad \begin{aligned} &y'(s) = Ay(s) + f(\varepsilon, y(s)) - \phi_{\varepsilon x}(T - s, y(s)) \quad \text{on } [0, T], \\ &y(t) = x, \qquad x \in \Sigma_r. \end{aligned}$$

We remark that, since $\phi_{\varepsilon x}(T - t, \cdot)$ is a locally Lipschitz monotone operator on H, then (5.3) has a unique mild solution $y_\varepsilon \in C([t, T]; H)$. Furthermore, due to the monotonicity of $\phi_{\varepsilon x}(T - t, \cdot)$ we have that

$$(5.4) \qquad |y_\varepsilon(s)| \leqq |x| \leqq r \quad \forall s \in [t, T].$$

Hence we can state the following theorem.

THEOREM 5.2. *Let $r_0 > 0$ be fixed. There exists $\varepsilon_3(r_0) > 0$ such that for $|x| \leqq r_0$, $|\varepsilon| \leqq \varepsilon_3(r_0)$, problem* (P) *has a unique optimal control u_ε. Moreover, u_ε is given by the feedback formula*

$$(5.5) \qquad u_\varepsilon(s) = -\phi_{\varepsilon x}(T - s, y_\varepsilon(s)),$$

where $y_\varepsilon(s)$ is the solution of the closed-loop equation (5.3) *for $t = 0$.*

Proof. Let

$$M_0 = M_0(r_0) = \max \{\sqrt{T}L(r_0), L(r_0), \sqrt{2L(r_0)}\}$$

as in Lemma 4.3. First we observe that if $|u|_{L^2} > M_0$, then $J(u) > J(0)$, in fact,

$$J(x, 0) = \int_0^T g(y_1(s))\,ds + \phi_0(y_1)(T)),$$

where

$$y_1' = Ay_1 + f(\varepsilon, y_1). \qquad y_1(0) = x,$$

which implies

$$|y_1(s)| \leqq |x|\, e^{+\omega s/2} \quad \forall |\varepsilon| \leqq \varepsilon_1(r_0)$$

and

$$J(x, 0) \leqq |g|_{0,r_0} T + |\phi_0|_{0,r_0} \leqq L(r_0).$$

But

$$J(x, u) \geqq |u|_{L^2}^2 - |\phi_0(0)| - T|g(0)| \geqq M_0^2 - L(r_0)$$
$$\geqq J(x, 0) \quad \text{as } |u|_{L^2(0,T;H)} > M_0.$$

So we only have to minimize J for $u \in L^2(0, T; H)$, $|u|_{L^2} \leqq M_0$.

Now set $\varepsilon_3(r_0) = \bar{\varepsilon}(r_0 + \sqrt{T}\, M_0)$ and let $|\varepsilon| \leqq \varepsilon_3(r_0)$. At this point we need only to show that u_ε given by (5.5) is such that $|u_\varepsilon|_{L^2} \leqq M_0(r_0)$. In fact, in this case it easily follows by Lemma 5.1 that u_ε is the unique optimal control for (P) (see [2], pp. 50–54].

We have by (5.4)

$$|\phi_{\varepsilon x}(T - s, y_\varepsilon(s))| \leqq \sup_{t \in [0,T]} |\phi_\varepsilon(T - s, \cdot)|_{1,r_0} \leqq L(r_0).$$

It follows that

$$|u_\varepsilon|_{L^2} \leqq \sqrt{T} L(r_0) \leqq M_0(r_0). \qquad \square$$

6. Regularity with respect to the parameter ε. In this section we give a regularity result for the solution of our control problem.

First of all we remark that if $f \in C^k_{\text{Lip}}(H, H)$, then it is not difficult to prove that the solution ϕ_ε of the Hamilton–Jacobi equation (HJ) and its spatial derivative $\phi_{\varepsilon x}$ are $(k-1)$-times differentiable with respect to ε (see Remarks 4.5 and 4.7).

For simplicity we assume that, for every $x \in H$,

$$\text{(iv)} \quad \begin{aligned} &\phi_0(x) = \tfrac{1}{2}\langle P_0 x, x\rangle, \\ &g(x) = \tfrac{1}{2}\langle Mx, x\rangle, \\ &f(\varepsilon, x) = \varepsilon f(x), \\ &\omega < 0 \quad \text{in hypothesis (i)} \end{aligned}$$

with P_0, $M \in \Sigma^+(H)$, $f \in C^2_{\text{Lip}}(H, H)$, and $\langle Mx, x\rangle \geqq \mu |x|^2$, for all $x \in H$. Then if $\varepsilon = 0$, the solution of Hamilton–Jacobi equation (HJ) is the quadratic form $x \to \frac{1}{2}\langle P(t)x, x\rangle$, where $P(t)$ is the solution of the Riccati operator equation

$$\text{(6.1)} \quad \begin{aligned} &P' = A^*P + PA - P^2 + M \quad \text{on } [0, T], \\ &P(0) = P_0. \end{aligned}$$

PROPOSITION 6.1. *Let* (i)-(iv) *hold. Fix any* $R>0$, *and let* $|\varepsilon|\leqq\bar{\varepsilon}(R)$. *Then, for every* $n\in\mathbf{N}$ *and for every* $x\in\Sigma_R$ *there exist the derivatives*:

$$\frac{\partial^n}{\partial\varepsilon^n}\phi_\varepsilon(t,x)|_{\varepsilon=0},\qquad \frac{\partial^n}{\partial\varepsilon^n}\phi_{\varepsilon x}(t,x)|_{\varepsilon=0},$$

and we have

$$\frac{1}{n!}\frac{\partial^n}{\partial\varepsilon^n}\phi_\varepsilon(t,x)|_{\varepsilon=0}=\phi_n(t,x),$$

$$\frac{1}{n!}\frac{\partial^n}{\partial\varepsilon^n}\phi_{\varepsilon x}(t,x)|_{\varepsilon=0}=\phi_{n,x}(t,x),$$

where $\phi_0(t,x)=\frac{1}{2}\langle P(t)x,x\rangle$, *and for* $n\geqq1$, ϕ_n *is the strict solution of the equation*

$$\begin{aligned}&\phi_{nt}=\langle(A-P(t))x,\phi_{n,x}\rangle+\langle f(x),\phi_{(n-1),x}\rangle-\sum_{h=1}^{n-1}\langle\phi_{h,x},\phi_{(n-h),x}\rangle,\\&\phi_n(0,x)=0.\end{aligned}\tag{6.2}$$

Moreover, the following recursive formula holds:

$$\begin{aligned}\phi_n(t,x)=&\int_0^t\langle f(U(t-s,0)x),\phi_{(n-1),x}(s,U(t-s,0)x)\rangle\,ds\\&-\int_0^t\sum_{h=1}^{n-1}\langle\phi_{h,x}(s,U(t-s,0)x),\phi_{(n-h),x}(s,U(t-s,0)x)\rangle\,ds,\end{aligned}\tag{6.3}$$

where $U(t,s)$ *is the evolution operator associated to* $A-P(t)$. *Similar formulas hold true for the derivatives with respect to* ε *of the function* $\phi_{\varepsilon x}$ (*obtained by differentiating with respect to* x *the corresponding formulas for* ϕ_ε).

Proof. For every $n\in\mathbf{N}$ we consider the function

$$\delta_n=\frac{1}{\varepsilon^n}\left(\phi_\varepsilon-\frac{1}{2}\langle P(t)x,x\rangle-\varepsilon\phi_1-\cdots-\varepsilon^n\phi_n\right)$$

and we show that recursively

$$\left.\begin{aligned}&\lim_{\varepsilon\to0}\delta_n(t,x)=0\\&\lim_{\varepsilon\to0}\delta_{n,x}(t,x)=0\end{aligned}\right\}\text{uniformly on }[0,T]\times\Sigma_R.\tag{6.4}$$

For instance, in the case where $n=0$, we have that the function $\delta_0(t,x)=\phi_\varepsilon(t,x)-\frac{1}{2}\langle P(t)x,x\rangle$ satisfies the following Cauchy problem in H:

$$\begin{aligned}&\delta_{0t}(t,x)=\langle F(t,x),\delta_{0x}(t,x)\rangle+\varepsilon G(t,x)\quad\forall(t,x)\in[0,T]\times(D(A)\cap\Sigma_R),\\&\delta(0,x)=0\quad\forall x\in\Sigma_R,\end{aligned}\tag{6.5}$$

where

$$F(t,x)=Ax-\tfrac{1}{2}[P(t)x-\phi_{\varepsilon x}(t,x)]$$

and

$$G(t,x)=\langle f(x),P(t)x\rangle.$$

Using the classical argument of characteristics, we obtain that

$$\delta_0(t,x)=\varepsilon\int_0^t G(s,\xi(s,t,x))\,ds\quad\forall(t,x)\in[0,T]\times\Sigma_R,\tag{6.6}$$

where $\xi(s, t, x)$ is the solution of the Cauchy problem in H:

$$\begin{aligned}&\frac{\partial \xi}{\partial s}(s, t, x) = -F(s, \xi(s, t, x)) \quad \text{for } s \in [0, t],\\ &\xi(t, t, x) = x \quad \text{for } x \in \Sigma_R.\end{aligned} \tag{6.7}$$

We observe that, due to the hypothesis (iv) and the monotonicity of $\phi_{\varepsilon x}$ the Cauchy problem (6.7) has a unique mild solution $\xi(s, t, x) \in C([0, T]; H)$ for every $x \in \Sigma_R$, and that

$$|\xi(s, t, x)| \leqq |x|.$$

This enables us to write (6.6) for every $x \in \Sigma_R$. Now by (6.6) and boundedness of G on $[0, T] \times \Sigma_R$ it follows that

$$\lim_{\varepsilon \to 0} \delta_0(t, x) = 0 \quad \text{uniformly on } [0, T] \times \Sigma_R.$$

A similar argument can be repeated for the spatial derivative of δ_0 using that the function $E(t, x) = \phi_{\varepsilon x}(t, x)$ satisfies the quasi-linear operator equation (see [2, p. 100]

$$\begin{aligned}&E_t(t, x) = [A + \varepsilon f'(x)]^* E(t, x) + E_x(t, x)[Ax + \varepsilon f(x) - E(t, x)] + M\\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{on } [0, T] \times (D(A) \cap \Sigma_R)\\ &E(0, x) = P_0.\end{aligned} \tag{6.8}$$

Finally, we can recursively repeat the same argument also for every $n \in \mathbf{N}$. □

REMARK 6.2. Proposition 6.1 also holds if we have

$$\phi_0(x) = \tfrac{1}{2}\langle P_0 x, x\rangle + \theta_\varepsilon(x), \qquad g(x) = \tfrac{1}{2}\langle Mx, x\rangle + \eta_\varepsilon(x),$$

where θ, η are smooth function with respect to ε, vanishing for $\varepsilon = 0$. Moreover, θ, η must belong to $C^2_{\text{Lip}}(H, H)$ with respect to x.

Note also that we have not used any additional regularity hypothesis on f.

Finally, we have Proposition 6.3.

PROPOSITION 6.3. *Let* (i)–(iv) *hold and let* $f \in C^k_{\text{Lip}}(H, H)$ $(k \geqq 2)$. *Then for* $\varepsilon \in [-\bar{\varepsilon}(R), \bar{\varepsilon}(R)]$, *and* $h = 1, \cdots, k-1$ *there exist* $(\partial^h/\partial \varepsilon^h)u_\varepsilon$, $(\partial^h/\partial \varepsilon^h)y_\varepsilon$ *and*

$$\frac{1}{h!}\frac{\partial^h}{\partial \varepsilon^h} u_\varepsilon(s) = u_h(s), \qquad \frac{1}{h!} = \frac{\partial^h}{\partial \varepsilon^h} y_\varepsilon(s) = y_h(s),$$

where we have

$$y_0'(s) = (A - P(T-s))y_0(s), \qquad y_0(0) = x,$$

$$y_1'(s) = (A - P(T-s))y_1(s) + f(y_0(s)) - \psi_{1,x}(s, y_0(s)), \qquad y_1(0) = 0,$$

and, for $h > 1$,

$$\begin{aligned} y_h'(s) = (A - P(T-s))y_h(s) &- \phi_{h,x}(s, y_0(s))\\ &+ \sum_{r=1}^{h-1} \sum_{\substack{i_1 + \cdots + i_r = h-1\\ i_j \geqq 1}} \frac{1}{r!}\frac{\partial^r}{\partial x^r} f(y_0(s))(y_{i_1}(s), \cdots, y_{i_r}(s))\\ &+ \sum_{q=1}^{h} \sum_{r=1}^{h-q} \sum_{\substack{i_1 + \cdots + i_r = h-q\\ i_j \geqq 1}} \frac{1}{r!}\frac{\partial^r}{\partial x^r} \psi_{q,x}(s, y_0(s))(y_{i_1}(s), \cdots, y_{i_r}(s))\end{aligned}$$

$$y_h(0) = 0.$$

Moreover,

$$u_0(s) = -P(T-s)y_0(s),$$

and, for $h>0$,

$$u_h(s) = -\phi_{h,x}(s, y_0(s)) - \sum_{q=1}^{h} \sum_{r=1}^{h-q} \sum_{\substack{i_1+\cdots+i_r=h-q \\ i_j \geqq 1}} \frac{1}{r!} \frac{\partial^r}{\partial x^r} \psi_{q,x}(s, y_0(s))(y_{i_1}(s), \cdots, y_{i_r}(s))$$

For the proof we argue as in Proposition 6.1.

7. Examples. We give two examples.

Parabolic systems. Let $H = H^1(0, 1)$. We consider the parabolic state equation:

$$\text{(7.1)} \quad \begin{aligned} &y_t(t, x) = \Delta_x y(t, x) + \varepsilon f(y(t, x)) + u(t, x), \qquad t \in [0, T], \quad x \in (0, 1), \\ &y(0, x) = y_0(x) \in H^1(0, 1), \quad y(t, 0) = 0 = y(t, 1) \quad \forall t \in [0, T]. \end{aligned}$$

We denote by A the operator on H defined by

$$D(A) = H^3(0, 1) \cap H_0^1(0, 1), \qquad Ay = \Delta y.$$

The control u is any element of $L^2(0, T; H)$, and f is a smooth function $\mathbf{R} \to \mathbf{R}$ such that, if we define

$$F: H \to H, \quad F(y)(x) = f(y(x)) \quad \forall x \in (0, 1),$$

then we have $f \in C^2_{\text{Lip}}(H, H)$. For example, we can take $f(z) = z^2$ and use the fact that $H^1(0, 1)$ is an algebra.

We want to minimize the cost

$$\text{(72)} \qquad J(y_0, u) = \int_0^T \left[\frac{1}{2}|y(s)|_H^2 + \frac{1}{2}|u(s)|_H^2\right] ds + \frac{1}{2}|y(T)|_H^2$$

over all controls $u \in L^2(0, T; H)$, where y is the mild solution of (7.1).

Now assumptions (i)-(iv) are verified. In particular,

$$\langle Ay, y\rangle_H \leqq -C_0|y|_H^2 \quad \forall y \in D(A),$$

where $C_0 > 0$.

If r_0 is the supremum of the norm of the initial state y_0, we take M_0 as in § 5, and we set $|\varepsilon| \leqq \varepsilon_3(r_0)$.

Then by the Theorems 3.2 and 5.2 there exists a unique optimal pair $(u_\varepsilon, y_\varepsilon)$ for problem (P), and the following feedback formula holds:

$$u_\varepsilon(s) = -\phi_{\varepsilon x}(T-s, y_\varepsilon(s)),$$

where ϕ_ε is the strict solution of the Hamilton-Jacobi equation (HJ).

Furthermore, if $F \in C^k_{\text{Lip}}(H, H)$ (which is true if $f(z) = z^2$), then the optimal pair is k-times differentiable with respect to ε and the expansion given in Proposition 6.3 holds.

We can repeat the same example in higher dimensions by setting $H = H^k(\Omega)$, where Ω is an open bounded subset of $\mathbf{R}^n$ with sufficiently smooth boundary $\partial\Omega$ and $k > n/2$ (so H is an algebra).

Hyperbolic systems. Consider the following optimization problem:

Minimize

$$J(y_0, y_1, u) = \int_0^T \left[g(y(s), y'(s)) + \frac{1}{2}|u(s)|^2\right] ds + \phi_0(y(T), y'(T))$$

subject to

$$y''(s)+A_0(y)(s)+\varepsilon f(y(s))=u(s), \qquad s\in[0,T],$$
$$y(0)=y_0, \quad y'(0)=y_1, \quad y_0\in V, \quad y_1\in E,$$

where V, E are real Hilbert spaces such that $V\subset E\subset V'$ and the inclusion $V\to E$ is continuous and densely defined (V' is the dual of V and E is identified with its own dual). Moreover, $u\in L^2(0,T;E)$.

$A_0\colon V\to V'$ is a linear continuous symmetric operator, and denoting by $\langle\cdot,\cdot\rangle_0$ the duality between V and V', there exists $\omega>0$ such that

$$\langle A_0y,y\rangle_0\geqq\omega|y|^2 \quad \forall y\in V.$$

$f\colon V\to E$ is a twice Fréchet differentiable mapping with $f^{(k)}$ $(k=0,1,2)$ locally bounded and locally Lipschitz continuous. Finally, concerning the functions g and ϕ_0 we assume that

$$g,\phi_0\in C^2_{\mathrm{Lip}}(V\times E), \quad \phi \text{ is convex}, \quad g \text{ is strictly convex}.$$

We set $H=V\times E$ and we endow H of the usual Hilbert structure:

$$\langle(v_1,e_1),(v_2,e_2)\rangle=\langle A_0v_1,v_2\rangle+\langle e_1,e_2\rangle \quad \text{for } v_1,v_2\in V, \quad e_1,e_2\in E.$$

Setting $Y(s)=(y(s),y'(s))$ and $Y_0=(y_0,y_1)$, we can write our state equation as

$$Y'(s)+AY(s)+\varepsilon F(Y(s))=U(s) \quad \text{for } s\in[0,T],$$
$$Y(0)=Y_0, \qquad Y_0\in H,$$

where

$$A=\begin{pmatrix}0 & -1\\ A_0 & 0\end{pmatrix}, \quad U=(0,u), \quad F(y,z)=(0,f(y)) \quad \forall(y,z)\in V\times E=H.$$

Now, our problem is expressed in the form (1.2) in terms of the operators A and F, and (i)-(iii) hold. We can proceed as in the previous example to solve the control problem.

We recall a typical example of this situation. Let $E=L^2(\Omega)$, where Ω is an open bounded subset of $\mathbf{R}^3$ with sufficiently smooth boundary $\partial\Omega$. Moreover, let

$$V=H^1_0(\Omega), \qquad A_0=-\Delta,$$

and $f(y)(z)=h(y(z))$ for every $z\in\Omega$, where h is a smooth (C^2_{Lip} at least) function $\mathbf{R}\to\mathbf{R}$ such that for some constants a, $b>0$ we have

$$\left|\frac{d^ih(w)}{dw^i}\right|\leqq a|w|^{3-i}+b \quad \text{for } i=0,1,2$$

($h(w)=w^3$, for instance). Finally let J be as in (7.2). Thus all our fundamental assumptions are verified. In particular, $f\in C^2_{\mathrm{Lip}}(H,H)$, because $H^1_0(\Omega)\subset L^6(\Omega)$.

MODEL MATCHING AND FACTORIZATION FOR NONLINEAR SYSTEMS: A STRUCTURAL APPROACH*

C. H. MOOG†, A. M. PERDON‡, AND G. CONTE§

Abstract. The model matching and the left factorization problems for nonlinear systems are investigated using an approach based on the structural algorithm. Sufficient conditions for the solvability of the first and necessary conditions, which in some cases and from a local point of view are also sufficient, for that of the second problem are found in terms of equalities between ranks or structures at infinity.

Key words. nonlinear systems, model matching, factorization, structure algorithm

1. Introduction.

The problem of matching the input/output behavior of a model by precompensating a given system has been studied in the linear case by various authors and many results on the existence and the construction of general or special solutions are, by now, available (see [8], [9], [12], [20], [22], [23], and [32]). In the framework of nonlinear systems, the model matching problem was first considered in a general form in [7]. In that paper, the desired precompensator was required to be proper and the problem was tackled by reducing it to an equivalent disturbance decoupling problem. Two conditions that are respectively sufficient and necessary for the existence of solutions were obtained by using differential geometric techniques (see [15]). Then, extending the results of [20] such conditions were expressed in terms of equality of the structure at infinity, in the sense of [26], of the system and of a suitable composition of the system and the model. The case in which the model is a linear system was investigated in [16] and more recently in [4]. Necessary and sufficient conditions for a restricted class of nonlinear systems have recently been given in [14]. Other contributions are found in [27] and, from a differential algebraic point of view, in [28]. Remaining in a linear context, the model matching problem can be assimilated to that of factoring the transfer function of the model through that of the system, viewed as a left factor. The problem of factoring through a given right factor, which is called left factorization problem, can therefore be viewed as a sort of dual of the model matching one and, although less relevant in control theory, has received some attention. Results, which parallel those concerning the matching, are found in [1], [2], [12], [19], and [32].

In this paper we consider the model matching and the left factorization problems for affine nonlinear systems in a general formulation, which does not demand the compensator or the left factor to be proper, as well as in a stronger one, in which the properness is required. Our approach is based on the structure algorithm that is described in [18] and [31]. The algorithm is used as a tool both for defining the

structural invariants, rank, and structure at infinity, which allow us to state conditions for the existence of solutions, and for constructing such solutions. The results we obtain can be summarized as follows. The model matching problem admits a solution, respectively, a proper one, if the rank of the system and that of a suitable composition of the system and the model are equal, respectively, if their structure at infinity are equal. Note that the structure at infinity we refer to is that derived in [21] from the structure algorithm and does not coincide with that defined, in a geometric way, in [26] and considered in [7]. The sufficient condition we obtain is weaker than that of [7], however it is not necessary, as shown by an example due to Huijberts [13]. A nonstructural weaker condition is briefly discussed. The proof of the existence of a solution, when the sufficient condition is verified, is constructive. The results holding for the left factorization problem are the following. The problem admits a solution, respectively, a proper one, only if the rank of the factor system and that of the parallel composition of the same and the system to be factored are equal, respectively, if their structure at infinity are equal. Conversely, the rank equality is not in general sufficient and additional technical conditions are required to show, only locally and making use of the implicit function theorem, the existence of solutions.

The paper is organized as follows. Section 2 contains some preliminaries concerning the structure algorithm, the structure invariants defined by it, and their characterization in terms of vector spaces of differentials [5], [6]. Section 3 contains the statement and a discussion of the model matching problem, the related results that we already mentioned, and some examples. Section 4 deals with the left factorization problem, presenting and discussing its statement, the related results, and one example.

2. Notation and preliminaries. Consider a nonlinear control system of the form

$$\Sigma=\begin{cases}\dot{x}=f(x)+g(x)u, & \text{(2.1a)}\\ y=h(x), & \text{(2.1b)}\end{cases}$$

where $x(t)\in\mathbb{R}^n$, $u(t)\in\mathbb{R}^m$, $y(t)\in\mathbb{R}^p$, and $f(\cdot)$, the columns of $g(\cdot)$ and $h(\cdot)$, are *meromorphic* functions of x; that is, they are elements of the fraction field $\mathcal{F}$ of the ring of functions of the variable x, which are analytic on a domain $\mathcal{D}\subset\mathbb{R}^n$.

Following [5] and [6], we associate to $\sum$ a chain of vector spaces over the field $\mathcal{K}$ of meromorphic functions of $x, u, \cdots, u^{(n-1)}$ defined as follows. Recall, first, that denoting by $\nu=(\nu_1,\cdots,\nu_j)$ the components of $(x, u, \cdots, u^{(n-1)})$, the action of the partial derivative operator $\partial/\partial\nu_i$ on a meromorphic function $\eta(\nu)=\pi(\nu)/\theta(\nu)$, where $\pi(\cdot)$ and $\theta(\cdot)$ are analytic, is defined, by the usual rule of calculus, as

$$\frac{\partial}{\partial\nu_i}\frac{\pi(\nu)}{\theta(\nu)}:=\left(\theta(\nu)\frac{\partial}{\partial\nu_i}\pi(\nu)-\pi(\nu)\frac{\partial}{\partial\nu_i}\theta(\nu)\right)\Big/\theta^2(\nu). \tag{2.2}$$

Then, the differential of η is given by

$$d\eta(\nu):=\frac{\partial\eta}{\partial\nu}d\nu. \tag{2.3}$$

Returning to the system $\sum$, we view the time derivatives of the output y

$$\dot{y}=\dot{y}(x,u)=\frac{\partial y}{\partial x}[f(x)+g(x)u], \tag{2.4a}$$

$$\vdots$$

$$y^{(k+1)}=y^{(k+1)}(x,u,\cdots,u^{(k)})$$

$$=\frac{\partial y^{(k)}}{\partial x}[f(x)+g(x)u]+\sum_{i=0}^{k-1}\frac{\partial y^{(k)}}{\partial u^{(i)}}u^{(i+1)} \tag{2.4b}$$

as functions of x, $u, \cdots, u^{(k)}$, whose components are elements of $\mathcal{K}$. Now we can introduce the vector space $\mathscr{E}$ spanned over $\mathcal{K}$ by $\{dx, du, \cdots, du^{(n-1)}\}$ and we consider the chain of subspaces $\mathscr{E}_0 \subset \mathscr{E}_1 \subset \cdots \subset \mathscr{E}_n$ of $\mathscr{E}$ defined by

$$\begin{aligned} &\mathscr{E}_0 = \operatorname{span}\{dx\}, \\ &\qquad\vdots \\ &\mathscr{E}_n = \operatorname{span}\{dx, d\dot{y}, \cdots, dy^{(n)}\}. \end{aligned} \tag{2.5}$$

The notation dx stands for $dx_1, \cdots, dx_n$; du stands for $du_1, \cdots, du_m$, and $dy^{(k)}$ stands for $dy_1^{(k)}, \cdots, dy_p^{(k)}$ for any $k \geqq 0$.

Associated with the chain $\mathscr{E}_0 \subset \mathscr{E}_1 \subset \cdots \subset \mathscr{E}_n$ we have the list of integers $\sigma_1 \leqq \cdots \leqq \sigma_n$ given by

$$\sigma_k = \dim_{\mathcal{K}} \frac{\mathscr{E}_k}{\mathscr{E}_{k-1}}. \tag{2.6}$$

It has been shown in [5] and [6] that σ_1 equals the integer ρ_1, and $(\sigma_i - \sigma_{i-1})$ equals the integer ρ_i for $i \geqq 1$, where ρ_i is obtained from the ith step of the structure algorithm, or Singh's inversion algorithm [18], [31]. In particular, σ_n equals the rank ρ of $\sum$ as well as, in a suitable context, the differential output rank [10], [11]. It is useful, for completeness, to recall here Singh's inversion algorithm in a special form that will be employed in the sequel. Given the system $\sum$ we may consider its input u as divided into two subsets $u = (v, w)$, where v is viewed as a set of controls and w as a set of parameters. In this case, we apply to $\sum$ the following algorithm, denoted by Singh$_v$

Step 1. Calculate

$$\dot{y} = \frac{\partial h}{\partial x}[f(x) + g_v(x)v + g_w(x)w] =: f_1(x, w) + g_1(x)v \tag{2.7}$$

and set $G_1(x) := g_1(x)$ and $s_1 := \operatorname{rank} G_1(x)$. Permute, if necessary, the rows of the output so that the first s_1 rows of $G_1(x)$ are linearly independent and decompose $\dot{y}$ as

$$\dot{y} = \begin{pmatrix} \tilde{y}_1 \\ \hat{y}_1 \end{pmatrix}, \tag{2.8}$$

where $\dim \tilde{y}_1 = s_1 =: \rho_{1v}$. Then, eliminating v in the last rows, write

$$\begin{pmatrix} \tilde{y}_1 \\ \hat{y}_1 \end{pmatrix} = \begin{pmatrix} \tilde{f}_1(x, w) + \tilde{g}_1(x)v \\ \hat{y}_1(x, w, \tilde{y}_1) \end{pmatrix}$$

and set $\tilde{G}_1(x) =: \tilde{g}_1(x)$.

Step $k+1$. Suppose that from Steps 1 through k we have

$$\begin{aligned} \tilde{y}_1 &= \tilde{f}_1(x, w) + \tilde{g}_1(x)v, \\ &\ \ \vdots \\ \tilde{y}_k &= \tilde{f}_k(x, w, \cdots, w^{(k-1)}, \tilde{y}_1, \cdots, \tilde{y}_1^{(k-1)}, \cdots, \tilde{y}_{k-1}, \dot{\tilde{y}}_{k-1}) \\ &\qquad + \tilde{g}_k(x, w, \cdots, w^{(k-2)}, \tilde{y}_1, \cdots, \tilde{y}_1^{(k-2)}, \cdots, \tilde{y}_{k-1})v, \\ \hat{y}_k &= \hat{y}_k(x, w, \cdots, w^{(k-1)}, \tilde{y}_1, \cdots, \tilde{y}_1^{(k-1)}, \cdots, \tilde{y}_k), \end{aligned}$$

where

$$\tilde{G}_k = \begin{pmatrix} \tilde{g}_1 \\ \vdots \\ \tilde{g}_k \end{pmatrix}$$

has full rank s_k. Then

$$\begin{aligned}\dot{\hat{y}}_k = & f_{k+1}(x, w, \cdots, w^{(k)}, \tilde{y}_1, \cdots, \tilde{y}_1^{(k)}, \cdots, \tilde{y}_k, \dot{\tilde{y}}_k) \\ & + g_{k+1}(x, w, \cdots, w^{(k-1)}, \tilde{y}_1, \cdots, \tilde{y}_1^{(k-1)}, \cdots, \tilde{y}_k)v.\end{aligned}$$

Define $G_{k+1} := \left(\begin{smallmatrix}\tilde{G}_k \\ g_{k+1}\end{smallmatrix}\right)$ and $s_{k+1} := \text{rank } G_{k+1}(x)$. Decompose $\dot{\hat{y}}_k$ as

$$\dot{\hat{y}}_k = \begin{pmatrix}\tilde{y}_{k+1} \\ \hat{y}_{k+1}\end{pmatrix},$$

where $\dim \tilde{y}_{k+1} = s_{k+1} - s_k =: \rho_{k+1v}$. Then, eliminating v in the last rows, write

$$\begin{aligned}\tilde{y}_{k+1} = & \tilde{f}_{k+1}(x, w, \cdots, w^{(k)}, \tilde{y}_1, \cdots, \tilde{y}_1^{(k)}, \cdots, \tilde{y}_k, \dot{\tilde{y}}_k) \\ & + \tilde{g}_{k+1}(x, w, \cdots, w^{(k-1)}, \tilde{y}_1, \cdots, \tilde{y}_1^{(k-1)}, \cdots, \tilde{y}_k)v, \\ \hat{y}_{k+1} = & \hat{y}_{k+1}(x, w, \cdots, w^{(k)}, \tilde{y}_1, \cdots, \tilde{y}_1^{(k)}, \cdots, \tilde{y}_{k+1})\end{aligned}$$

and set

$$\tilde{G}_{k+1} := \begin{pmatrix}\tilde{g}_1 \\ \vdots \\ \tilde{g}_k\end{pmatrix}.$$

The above algorithm performs the inversion of $\sum$, viewed as a system depending on the parameter w, with respect to the input v when $\rho_v := s_n$ equals the dimension of v. When w is empty Singh$_v$ reduces to the usual Singh's inversion algorithm.

The indices σ_i, s_i, and ρ_i contain essentially the same information and each of them could be used in the following. We choose to state the next results in terms of the ρ_i, which have a direct interpretation as numbers of zeros at infinity of order i (see [21]), although the other indices are often used in proofs and calculations.

LEMMA 2.1. *Let the systems*

$$T = \begin{cases}\dot{x} = f(x) + g(x)u, \\ y_T = h(x) + h'(x)u\end{cases} \tag{2.9}$$

and

$$G = \begin{cases}\dot{z} = f_G(z) + g_G(z)v, \\ y_G = h_G(z)\end{cases} \tag{2.10}$$

with outputs of the same dimension, be given, and let (GT) *denote the composite system*

$$(GT) = \begin{cases}\dot{x} = f(x) + g(x)u, \\ \dot{z} = f_G(z) + g_G(z)v, \\ y_{GT} = h(x) - h_G(z) + h'(x)u.\end{cases} \tag{2.11}$$

Then we have $\rho_{iv}(GT) = \rho_i(G)$ *for all i and, in particular,* $\rho_v(GT) = \rho(G)$.

Proof. Let $\mathscr{K}'$ denote the field of meromorphic functions in the variables x, z, $v, \cdots, v^{(N-1)}$ and the parameters $u, \cdots, u^{(N)}$, where $N = \dim x + \dim z$. We denote by $\mathscr{E}_i^{GT}$ the vector space spanned over $\mathscr{K}'$ by $\{dx, dz, d\dot{y}_{GT}, \cdots, dy_{GT}^{(i)}\}$. Note that to consider $u, \cdots, u^{(N)}$ as parameters instead of variables means that the differential $d(\cdot)$ is given by $d(\cdot) = (\partial(\cdot)/\partial x)\, dx + (\partial(\cdot)/\partial z)\, dz + \sum_{i=0}^{N-1} (\partial(\cdot)/\partial v^{(i)})\, dv^{(i)}$. Following the proof given in Theorem 2.3 of [7] we can show that $\rho_{iv}(GT) = \dim_{\mathscr{K}'} \mathscr{E}_i^{GT}/\mathscr{E}_{i-1}^{GT}$. From this, since $dy_{GT}^{(j)} = dy_T^{(j)} - dy_G^{(j)} = \varphi_j(x, u, \cdots, u^{(j)})\, dx - dy_G^{(j)}$ with $\varphi_j \in \mathscr{K}'$, it follows that $\rho_{iv}(GT) = \dim \text{span}_{\mathscr{K}'} \{dx, dz, d\dot{y}_G, \cdots, dy_G^{(i)}\} - \dim \text{span}_{\mathscr{K}'} \{dx, dz, d\dot{y}_G,$

$\cdots, dy_G^{(i-1)}\}$, and hence $\rho_{iv}(GT) = \dim \operatorname{span}_{\mathcal{K}'}\{dz, d\dot{y}_G, \cdots, dy_G^{(i)}\} - \dim \operatorname{span}_{\mathcal{K}'}\{dz, d\dot{y}_G, \cdots, dy_G^{(i-1)}\}$. Now, let $\{\omega_1, \cdots, \omega_{r_i}\} \subset \{dz, d\dot{y}_G, \cdots, dy_G^{(i)}\}$ be a basis over $\mathcal{K}'$ of $\mathcal{E}_i^{GT}$, and let $\bar{\omega}$ be an element of $\{dz, d\dot{y}_G, \cdots, dy_G^{(i)}\} \backslash \{\omega_1, \cdots, \omega_{r_i}\}$. We write $\bar{\omega} = \sum \gamma_j(x, z, v, \cdots, v^{(N-1)}, u, \cdots, u^{(N)})\omega_j$ with $\gamma_j \in \mathcal{K}'$ and, computing the derivatives with respect to $x, u, \cdots, u^{(N)}$, we get

$$\frac{\partial \bar{\omega}}{\partial x} = \sum \frac{\partial \gamma_j}{\partial x} \omega_j = 0,$$

$$\frac{\partial \bar{\omega}}{\partial u} = \sum \frac{\partial \gamma_j}{\partial u} \omega_j = 0,$$

$$\vdots$$

$$\frac{\partial \bar{\omega}}{\partial u^{(N)}} = \sum \frac{\partial \gamma_j}{\partial u^{(N)}} \omega_j = 0.$$

Therefore $\partial\gamma_j/\partial x = 0$ and $\partial\gamma_j/\partial u = \cdots = \partial\gamma_j/\partial u^{(N)} = 0$ for all j, or, equivalently, $\gamma_j = \gamma_j(z, v, \cdots, v^{(N-1)})$. This says that $\{\omega_1, \cdots, \omega_{r_i}\}$ is a set of generators over the field $\mathcal{K}$ of meromorphic functions in the variables $z, v, \cdots, v^{(N-1)}$ of $\operatorname{span}_{\mathcal{K}}\{dz, d\dot{y}_G, \cdots, dy_G^{(i)}\} = \mathcal{E}_i^G$. Moreover, since $\mathcal{K} \subset \mathcal{K}'$, $\dim_{\mathcal{K}'} \mathcal{E}_i^{GT} = \dim_{\mathcal{K}} \mathcal{E}_i^G$ for all i and the result follows.

3. Model matching problem.

3. Model matching problem. In the nonlinear framework, the model matching problem was considered in [7] and, in the case of a linear model, in [4] and [16]. Some further contributions are made in [27]. The formulation of the model matching problem we give in the following differs slightly from that of [7].

3.1. Problem formulation. Let us now state the model matching problem (M.M.P.) in the formulation that will be used in the sequel.

MODEL MATCHING PROBLEM (M.M.P.). Given a model

$$T = \begin{cases} \dot{x} = f(x) + g(x)u, \\ y_T = h(x) \end{cases} \tag{3.1}$$

and a system G as in (2.10), find a proper compensator

$$H = \begin{cases} \dot{\xi} = f_H(\xi, z, u), \\ v = h_H(\xi, z, u) \end{cases}$$

with state space $\mathbb{R}^q$ and a map $\varphi: \mathbb{R}^n \to \mathbb{R}^q$ such that, denoting by y_{GH} the output of the composite system GH, we have that $y_T(u, x) - y_{GH}(u, \varphi(x), z)$; that is, the difference between the output of the model, viewed as a function of u and of the initial state x, and the output of the composite system, viewed as a function of u and of the initial states z and $\xi = \varphi(x)$, does not depend on u.

In order to gain a better insight into the model matching problem we are considering, we now state it in a generalized form (G.M.M.P.), which includes in particular the left inversion problem. Specializing such formulation by requiring a proper compensator we get the most interesting case from the point of view of control theory.

GENERALIZED MODEL MATCHING PROBLEM (G.M.M.P.). Given a model T as in (2.9) and a system G as in (2.10) find an integer $\nu \geqq 0$, a possibly nonproper compensator

$$H=\begin{cases}\dot{\xi}=f_H(\xi,z,u,\cdots,u^{(\nu)}),\\ v=h_H(\xi,z,u,\cdots,u^{(\nu)})\end{cases}\tag{3.2}$$

with state space $\mathbb{R}^q$ and a map $\varphi:\mathbb{R}^n\to\mathbb{R}^q$ such that, denoting by y_{GH} the output of the composite system GH, we have that $y_T(u,x)-y_{GH}(u,\varphi(x),z)$; that is, the difference between the output of the model, viewed as a function of u and of the initial state x, and the output of the composite system, viewed as a function of u and of the initial states z and $\xi=\varphi(x)$, does not depend on $u^{(\nu)}$.

The M.M.P. is the special case of the G.M.M.P. for $\nu=0$.

Remark 3.2. (i) In the M.M.P. the requirement that $y_T(u,x)-y_{GH}(u,\varphi(x),z)$ does not depend on u amounts, in the linear case, to the equality of the transfer functions of the model and of the composite systems. From this point of view, therefore, our formulation represents the natural extension of the one currently understood for the linear model matching problem (compare with the references quoted in the Introduction and with [15] and [16]).

We recall that a stronger formulation of the M.M.P., requiring the equality of y_T and y_{GH}, has been considered, only for a linear model, in [4]. Note that the problem we stated qualifies as an exact M.M.P., as opposed to an approximate or an asymptotic M.M.P., which could also be considered (see, e.g., [14]).

Let us consider the left inversion problem in the linear framework. The solution provided by the Silverman algorithm [30] has the form (3.2), where ν is the inherent integration order of the system [29], [25]. In the simple example given by $T=\{y_T=y$ and by

$$G=\begin{cases}\dot{z}=v,\\ y=z,\end{cases}$$

we obtain

$$H=G^{-1}=\begin{cases}\dot{\xi}=\dot{y},\\ v=\dot{y}.\end{cases}$$

The difference between the outputs of the identity model T and of GH is $y_T-y_{GH}=y-z$; the latter depends on the input y and is independent on the first derivative $\dot{y}$.

(ii) Roughly speaking, our formulation of the G.M.M.P. amounts to requiring that $y_T(u,x)-y_{GH}(u,\varphi(x),z)$ depend only on a finite number of derivatives of the input. In our framework, the independence of $y_T(u,x)-y_{GH}(u,\varphi(x),z)$ on $u^{(\nu)}$ is technically expressed by the following condition:

$$d(y_T(u,x)-y_{GH}(u,\varphi(x),z))^{(k)}\in\operatorname{span}_{\mathcal{K}}\{dx,dz,d\xi,du,\cdots,du^{(\nu-1)}\}\quad\text{for } k\geqq 0,\tag{3.3}$$

which says, in other terms, that $u^{(\nu)}$ does not appear in any time derivative of $y_T(u,x)-y_{GH}(u,\varphi(x),z)$. In (3.3), $\mathcal{K}$ denotes the field of meromorphic functions in the variables $x, z, \xi, u, \cdots, u^{(\nu+N)}$ with $N=\dim x+\dim z+\dim\xi$.

(iii) In dealing with nonlinear systems of the form (2.1), we must take into account the presence of possible singularities. To cope with them, we will say that the M.M.P. is solvable if there exists a compensator H of the form (3.2) and a map φ, which achieve (3.3) for all initial states x and z in an open and dense subset of the state spaces and for all (sufficiently many times differentiable) input functions $u(t)$, assuming values in an open dense subset of $\mathbb{R}^n$, while the system evolve on a time interval $[0, t)$, whose length may depend on the chosen initial conditions and on the input. In such a case the pair (H,φ) is called a solution of the M.M.P. The next examples will illustrate our point of view.

Example 3.3. (i) Let

$$T = \begin{cases} \dot{x} = u, \\ y_T = x \end{cases} \quad \text{and} \quad G = \begin{cases} \dot{z} = v, \\ y_G = z^2 \end{cases}$$

be the data of a M.M.P. The pair consisting of the compensator $H = \{v = u/2z$ and of the empty function is a solution in the sense of Remark 3.2. In fact, for $z_0 \neq 0$, we obtain $y_{GH}(u, z_0) = \int_0^t u(\tau)\, d\tau + z_0^2$ for all input functions $u(\tau)$ and for all $t > 0$ such that $\int_0^t u(\tau)\, d\tau + z_0^2 > 0$. Then, we have $y_T(u, x) - y_{GH}(u, z) = x - z^2$ and $d(y_T(u, x) - y_{GH}(u, z))^{(k)} \in \operatorname{span}_{\mathcal{K}} \{dx, dz\}$. In particular, if, for example, the input is bounded by $|u(\tau)| \leqq M$, and the initial conditions $x_0, z_0 \neq 0$, are chosen, $y_T - y_{GH}$ is independent from u over the time interval $[0, z_0^2/M)$. It may be useful to note that $v = u/2z$ is a solution of the M.M.P. in the same way, that is with the same limitations, in which it is a solution, in the sense of [17], of the disturbance decoupling problem with disturbance measurement described by $\dot{x} = u$, $\dot{z} = v$, $y = x - z^2$, where u is the disturbance and v is the control.

(ii) Note that taking, for instance,

$$T = \begin{cases} \dot{x} = xu, \\ y_T = x \end{cases} \quad \text{and} \quad G = \begin{cases} \dot{z} = zv, \\ y_G = z, \end{cases}$$

contrary to what happens in the linear case, the identity compensator $H = \{v = u$ does not give a solution of the M.M.P. In fact, $y_T - y_{GH} = (x_0 - z_0) \exp (\int_0^t u(\tau)\, d\tau)$ is independent from u only if the initial states of the model and of the system coincide. In this case a solution is given by the compensator

$$H = \begin{cases} \dot{\xi} = \xi u, \\ v = (\xi/z) u, \end{cases} \quad \text{where } \xi(t) \in \mathbb{R}^n,$$

and by $\varphi = \mathrm{id}$.

A structural condition under which a compensator exists and a procedure to compute it are given in the following theorem.

THEOREM 3.4. *The generalized model matching problem is solvable if*

$$\rho(GT) = \rho(G), \tag{3.4}$$

where (GT) *is the composite system* (2.11).

Proof. Applying Singh$_v$ to (GT), we obtain

$$\begin{aligned} \begin{pmatrix} \tilde{Y}_1 \\ \tilde{Y}_2 \\ \vdots \\ \tilde{Y}_N \\ \hat{Y}_N \end{pmatrix} &= \begin{pmatrix} \tilde{F}_1(x, z, u, \dot{u}) \\ \tilde{F}_2(x, z, u, \dot{u}, \ddot{u}, \tilde{Y}_1, \dot{\tilde{Y}}_1) \\ \vdots \\ \tilde{F}_N(x, z, u, \cdots, u^{(N)}, \tilde{Y}_1, \cdots, \tilde{Y}_1^{(N-1)}, \cdots, \tilde{Y}_{N-1}, \dot{\tilde{Y}}_{N-1}) \\ \hat{F}_N(x, z, u, \cdots, u^{(N)}, \tilde{Y}_1, \cdots, \tilde{Y}_1^{(N-1)}, \cdots, \tilde{Y}_{N-1}, \dot{\tilde{Y}}_{N-1}, \tilde{Y}_N) \end{pmatrix} \\ &\quad + \begin{pmatrix} \tilde{G}_1(z) \\ \tilde{G}_2(x, z, u, \tilde{Y}_1) \\ \vdots \\ \tilde{G}_N(x, z, u, \cdots, u^{(N-2)}, \tilde{Y}_1, \cdots, \tilde{Y}_1^{(N-2)}, \cdots, \tilde{Y}_{N-1}) \\ 0 \end{pmatrix} v \\ &= \begin{pmatrix} \tilde{F} \\ \hat{F}_N \end{pmatrix} + \begin{pmatrix} \tilde{G} \\ 0 \end{pmatrix} v \end{aligned} \tag{3.5}$$

with rank $\tilde{G} = \#$ rows $\tilde{G} = \rho_v(GT)$ and where $\tilde{Y}_i$ represents a suitable subset of rows of $y^{(i)}_{GT}$, which will be useful to denote also as $y^{(i)}_{T.i} - y^{(i)}_{G.i}$. We can choose constant values

$$Y = \begin{pmatrix} Y_1 \\ \vdots \\ Y_{N-1} \\ 0 \end{pmatrix} \quad \text{for } \tilde{Y} = \begin{pmatrix} \tilde{Y}_1^{(N-2)} \\ \vdots \\ \tilde{Y}_{N-1} \\ \tilde{Y}_N \end{pmatrix}$$

such that the generic rank of $\tilde{G}$ evaluated at Y is equal to the number of rows of $\tilde{G}$. Then, solving for v the system

$$\begin{pmatrix} \tilde{Y}_1 \\ \vdots \\ \tilde{Y}_N \end{pmatrix}_{|Y} = \tilde{F}_{|Y} + \tilde{G}_{|Y} v,$$

obtained by replacing $\tilde{Y}$ with Y in (3.5), we get

$$v = \phi(x, z, u, \cdots, u^{(N)}, \tilde{Y}_1, \cdots, \tilde{Y}_1^{(N-3)}, Y_1, \cdots, \tilde{Y}_{N-2}, Y_{N-2}, Y_{N-1}).$$

Now, denoting by w_0 a vector of same dimension as x and by w_i a vector of dimension $(N-i)\cdot \dim \tilde{Y}_i$, we set $\nu = N$ and we construct the compensator

$$(3.6) \qquad H = \begin{cases} \dot{w}_0 = f(w_0) + g(w_0)u \\ \dot{w}_i = \begin{pmatrix} 0 & 1 & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & 1 \\ 0 & \cdot & \cdot & 0 \end{pmatrix} w_i + \begin{pmatrix} 0 \\ \vdots \\ 0 \\ Y_i \end{pmatrix} & \text{for } 1 \leqq i \leqq N-2, \\ v = \phi(w_0, z, u, \cdots, u^{(N)}, w_1, \cdots, w_{N-2}, Y_{N-1}) \end{cases}$$

and, letting $\varphi(x) = (x, 0, \cdots, 0)$, we claim that (H, φ) is a solution of the G.M.M.P. In order to show this, let us first remark that, in (3.5), $\hat{Y}_N$ is actually independent from $u^{(k)}$, for all k. In fact, by Lemma 2.1 and the rank equality (3.4) it follows that $\rho(GT) = \rho_v(GT)$ and we know from Theorem 2.3 of [7], that the dx, dz, $d\tilde{Y}_1, \cdots, d\tilde{Y}_1^{(N-1)}, \cdots, d\tilde{Y}_N$ are independent over the field $\mathcal{K}$. So, if $\partial \hat{F}_N / \partial u^{(k)} \neq 0$, for some $k \geqq 0$, $d\hat{Y}_N$ does not belong to $\text{span}_{\mathcal{K}}\{dx, dz, d\tilde{Y}_1, \cdots, d\tilde{Y}_1^{(N-1)}, \cdots, d\tilde{Y}_N\}$, then $\rho(GT) > \rho_v(GT)$, contradicting the assumption.

Now let us consider the composite system (GH):

$$(GH) = \begin{cases} \dot{w} = F(w) + G(w)u, \\ \dot{z} = f_G(z) + g_G(z)\phi(w, z, u, \cdots, u^{(N)}), \\ y_{GH} = h_G(z) \end{cases}$$

initialized at $\varphi(x_0) = (x_0, 0, \cdots, 0)$, and the difference $y_T - y_{GH}$ between the output of the model and that of (GH). Recalling the notation $\tilde{Y}_i = y^{(i)}_{T.i} - y^{(i)}_{G.i}$, by substituting the output of H to v in (3.5) and taking derivatives, we get

$$y^{(N-1)}_{T.i} - y^{(N-1)}_{GH.i} = Y_i \quad \text{for } 1 \leqq i \leqq N-1,$$
$$y^{(N)}_{T.N} - y^{(N)}_{GH.N} = 0.$$

Therefore $d(y_T - y_{GH})^{(k)} \in \text{span}_{\mathcal{K}}\{dx, dz, dw, du, \cdots, du^{(N-1)}\}$ for all k. □

It is worthwhile to note that, although in § 3.1 the compensator H is described in a very general form, the construction illustrated in the proof of Theorem 3.4 always produces a system whose state equations have the same form of those of the model.

In particular, the derivatives of the input appear only in the output function $h_H(\xi, z, u, \cdots, u^{(\nu)})$. A structural condition under which there exists a proper compensator H, that is, one that does not depend on the derivatives of the input u, is given in the next theorem.

THEOREM 3.5. *The* M.M.P. *is solvable with a proper compensator H of the form*

$$H=\begin{cases}\dot{\xi}=f_H(\xi, z, u),\\ v=h_H(\xi, z, u)\end{cases}$$

if

$$\rho_i(GT)=\rho_i(G) \tag{3.7}$$

for all $i \geqq 1$.

Proof. Assume that (3.7) holds; then, for all i, we have by Lemma 2.1 $\rho_{iv}(GT)=\rho_i(GT)$. In particular, this implies that at the first step of the algorithm Singh$_v$ applied to (GT) we have

$$\begin{pmatrix}\tilde{Y}_1\\ \hat{Y}_1\end{pmatrix}=\begin{pmatrix}\tilde{F}_1(x, z, u)\\ \hat{F}_1(x, z, u, \tilde{Y}_1)\end{pmatrix}+\begin{pmatrix}\tilde{G}_1(z)\\ 0\end{pmatrix}v,$$

where actually $\partial\hat{F}_1/\partial u=0$, since otherwise $\rho_1(GT)$ would be strictly greater than $\rho_{1v}(GT)$. Repeatedly applying the same argument, we get at the last step N

$$\begin{pmatrix}\tilde{Y}\\ \hat{Y}_N\end{pmatrix}=\begin{pmatrix}\tilde{F}(x, z, u, \tilde{Y}, \cdots, \tilde{Y}^{(N-1)})\\ \hat{F}_N(x, z, u, \tilde{Y}, \cdots, \tilde{Y}^{(N)})\end{pmatrix}+\begin{pmatrix}\tilde{G}(x, z, \tilde{Y}, \cdots, \tilde{Y}^{(N-2)})\\ 0\end{pmatrix}v$$

and, hence, $v=\phi(x, z, u, \tilde{Y}, \cdots, \tilde{Y}^{(N-3)})$. Therefore the compensator obtained following the construction described in the proof of Theorem 3.4 is, in this case, proper. □

Example 3.6. (i) The M.M.P. concerning the model

$$T=\begin{cases}\dot{x}=\begin{pmatrix}x_2\\ 0\\ x_4\\ 0\end{pmatrix}+\begin{pmatrix}0&0\\ 1&0\\ 0&0\\ 0&1\end{pmatrix}u,\\ y_T=\begin{pmatrix}x_1\\ x_3\end{pmatrix}\end{cases}$$

and the system

$$G=\begin{cases}\dot{z}=\begin{pmatrix}0\\ z_4\\ 0\\ 0\end{pmatrix}+\begin{pmatrix}z_3&0\\ 0&1\\ 1&1\\ 0&1\end{pmatrix}v,\\ y_G=\begin{pmatrix}z_2-z_3\\ z_1\end{pmatrix}\end{cases}$$

was considered in [7]. It was shown that the geometric necessary condition given in the same paper is not verified, although the compensator

$$H=\begin{cases}\dot{\zeta}=\dfrac{\zeta^2}{\zeta+z_3}+\dfrac{1}{\zeta+z_3}(-\zeta\quad 1)u,\\ v=\begin{pmatrix}\zeta\\ \zeta^2/(\zeta+z_3)\end{pmatrix}+\dfrac{1}{\zeta+z_3}\begin{pmatrix}0&0\\ z_3&1\end{pmatrix}u\end{cases}$$

provides a solution of the problem (see [7, Ex. 5.4]). It can be easily checked that (3.7) is verified, that is, $\rho_i(GT)=\rho_i(G)$. Then, applying the procedure illustrated in the proof of Theorem 3.4, we get the proper compensator

$$H'=\begin{cases} \dot{\xi}=\begin{pmatrix}\xi_2\\0\\\xi_4\\0\end{pmatrix}+\begin{pmatrix}0&0\\1&0\\0&0\\0&1\end{pmatrix}u,\\ v=\begin{pmatrix} z_4-\xi_2\\ (z_4-\xi_2-u_1z_3-u_2)/(\xi_2-z_3-z_4)\end{pmatrix}.\end{cases}$$

Clearly, by removing the unnecessary equations $\dot{\xi}_1=\xi_2$, $\dot{\xi}_3=\xi_4$, and $\dot{\xi}_4=u_2$, we obtain another compensator, say H'', which solves the problem. Now, the change of variables $\zeta=z_4-\xi_2$ transforms H'' into H.

(ii) Consider the model

$$T=\begin{cases}\dot{x}=\begin{pmatrix}x_2\\0\end{pmatrix}+\begin{pmatrix}0\\1\end{pmatrix}u,\\ y_T=\begin{pmatrix}0\\x_1\end{pmatrix}\end{cases}$$

and the system

$$G=\begin{cases}\dot{z}=\begin{pmatrix}1&0\\0&1\\z_3&1\end{pmatrix}v,\\ y_G=\begin{pmatrix}z_1\\z_2-z_3\end{pmatrix},\end{cases}$$

for which $\rho(GT)=\rho(G)$. Note that, since

$$y_G=\begin{pmatrix}\displaystyle\int_0^t v_1(\tau)\,d\tau+z_1(0)\\ \displaystyle\int_0^t v_2(\tau)\,d\tau-\exp\left(\int_0^t v_1(\tau)\,d\tau\right)\int_0^t \exp\left(\int_0^\tau v_1(\sigma)\,d\sigma\right)v_2(\tau)\,d\tau\\ \displaystyle +z_2(0)+z_3(0)\exp\left(\int_0^t v_1(\tau)\,d\tau\right)\end{pmatrix}$$

and $y_{T.1}=0$, contrary to what happens in the linear case, it is not possible to find a compensator H such that $y_T-y_{GH}=0$ for $u\neq 0$, also when we are allowed to choose the initial condition $z(0)$. Applying Singh$_v$ to (GT), we get

$$\tilde{Y}=\begin{pmatrix}\dot{Y}_1\\\ddot{Y}_2\end{pmatrix}=\begin{pmatrix}0\\u-z_3\ddot{Y}_1\end{pmatrix}-\begin{pmatrix}1&0\\z_3\dot{Y}_1&\dot{Y}_1\end{pmatrix}v=\tilde{F}+\tilde{G}v,$$

and then, in fixing constant values Y for $\tilde{Y}$, we are obliged to choose $\dot{Y}_1\neq 0$. Taking, for instance, $Y=\binom{1}{0}$, we get $v=\binom{-1}{u+z_3}$, which represents by itself a compensator H that solves the problem.

Remark 3.7. The conditions of Theorems 3.4 and 3.5 are not necessary for the existence of solutions to the G.M.M.P. and the M.M.P. as pointed out by the following example due to Huijberts [13]. Let

$$T=\begin{cases} \dot{x}=\begin{pmatrix} x_2\\ x_3\\ 0\\ x_4 \end{pmatrix}+\begin{pmatrix} 0 & 0\\ 1 & 0\\ 0 & 1\\ 0 & 0 \end{pmatrix}\begin{pmatrix} u_1\\ u_2 \end{pmatrix},\\ y_T=\begin{pmatrix} x_2\\ x_4\\ x_1 \end{pmatrix} \end{cases}$$

and

$$G=\begin{cases} \dot{z}=\begin{pmatrix} z_2\\ 0\\ 0 \end{pmatrix}+\begin{pmatrix} 0 & z_2\\ 1 & 0\\ 0 & 1 \end{pmatrix}\begin{pmatrix} v_1\\ v_2 \end{pmatrix},\\ y_G=\begin{pmatrix} z_2\\ z_3\\ z_1 \end{pmatrix}. \end{cases}$$

By applying Singh's algorithm to G, we get $\rho_1(G)=\rho_2(G)=\rho_3(G)=2$. The same procedure applied to (GT) gives

$$\begin{aligned} \dot{y}_{GT1}&=x_3+u_1-v_1,\\ \dot{y}_{GT2}&=x_4-v_2,\\ \dot{y}_{GT3}&=x_2+z_2(\dot{y}_{GT2}-x_4-1), \end{aligned}$$

and then

$$\ddot{y}_{GT3}=\dot{y}_{GT1}+z_2(\ddot{y}_{GT2}-x_4)-(\dot{y}_{GT1}-x_3-u_1)(\dot{y}_{GT2}-x_4).$$

So $\rho_1(GT)=2$, $\rho_2(GT)=3$ and the sufficient conditions of Theorems 3.4 and 3.5 are not satisfied. However, the compensator

$$H=\begin{cases} \dot{\xi}=\begin{pmatrix} \xi_2\\ \xi_3\\ 0 \end{pmatrix}+\begin{pmatrix} 0 & 0\\ 1 & 0\\ 0 & 1 \end{pmatrix}\begin{pmatrix} u_1\\ u_2 \end{pmatrix},\\ v_1=\xi_3+u_1,\\ v_2=0, \end{cases}$$

and $\varphi=\mathrm{id}$ give a solution to the M.M.P.

From (3.5) we get the equality

$$\begin{aligned} \tilde{Y}=\tilde{F}(x,z,u,\cdots,u^{(N)},\tilde{Y}_1,\cdots,\tilde{Y}_1^{(N-1)},\cdots,\tilde{Y}_{N-1},\dot{\tilde{Y}}_{N-1})&\\ +\tilde{G}_N(x,z,u,\cdots,u^{(N-2)},\tilde{Y}_1,\cdots,\tilde{Y}_1^{(N-2)},\cdots,\tilde{Y}_{N-1})v& \end{aligned}\tag{3.8}$$

and, by derivation of $\hat{Y}_N$, the equalities

$$\begin{aligned} \hat{Y}_N&=\hat{F}_N(x,z,u,\cdots,u^{(N)},\tilde{Y}_1,\cdots,\tilde{Y}_1^{(N-1)},\cdots,\tilde{Y}_{N-1},\dot{\tilde{Y}}_{N-1},\tilde{Y}_N),\\ \hat{Y}_N^{(n+q-N)}&=\hat{F}_{n+q}(x,z,u,\cdots,u^{(n+q)},\tilde{Y}_1,\cdots,\tilde{Y}_1^{(n+q-1)},\\ &\qquad\cdots,\tilde{Y}_{N-1},\cdots,\tilde{Y}_{N-1}^{(n+q-N+1)},\tilde{Y}_N,\cdots,\tilde{Y}_N^{(n+q-N)}), \end{aligned}\tag{3.9}$$

from which it can be understood that a weaker condition for the existence of solutions to the M.M.P. is, in particular, that there exists a vector of functions

$$Y(x, z) = \begin{pmatrix} Y_1(x, z) \\ \vdots \\ Y_N(x, z) \end{pmatrix}$$

such that

(i) $\partial Y^{(k)}/\partial u = 0$ for all k;

(ii) Substituting $Y(x, z)$ and its derivatives for

$$\tilde{Y} = \begin{pmatrix} \tilde{Y}_1 \\ \vdots \\ \tilde{Y}_N \end{pmatrix}$$

and its derivatives in $\tilde{G}$, the generic rank is equal to the number of rows;

(iii) Substituting $Y(x, z)$ and its derivatives for

$$\tilde{Y} = \begin{pmatrix} \tilde{Y}_1 \\ \vdots \\ \tilde{Y}_N \end{pmatrix}$$

and its derivatives in $\hat{F}_N, \cdots, \hat{F}_{n+q}$, respectively in $\tilde{F}$, all the coefficients of the monomials in $u, \cdots, u^{(n+q)}$, and respectively, all the coefficients of the monomials in $\dot{u}, \cdots, u^{(N)}$, are zero. Such a condition is verified in the example above for $Y(x, z) = \binom{0}{x_4}$.

4. Left factorization problem. It is well known [2], [12] that in the linear case (3.4) and (3.7) are necessary and sufficient conditions for solving the G.M.M.P. or the M.M.P., and also when no feedback connection between the state of the system G and the precompensator H is allowed. In such formulation, the linear G.M.M.P. amounts to the problem of factoring the transfer function of the model T through a possible left factor, represented by the transfer function of G. It is then, natural, from an abstract point of view, to also consider the dual problem, which consists of factoring the transfer function of T through a possible given right factor (see [1], [2], [12], and [19]). In the more general case we are considering, this leads to the following formulation for what we call the left factorization problem.

4.1. Problem formulation.

Left Factorization Problem (L.F.P.). Given a model T as in (3.1) and a system

$$(4.1) \qquad H = \begin{cases} \dot{z} = f_H(z) + g_H(z)u, \\ v = h_H(z), \end{cases}$$

find a proper compensator

$$G = \begin{cases} \dot{\xi} = f_G(\xi, v), \\ y_G = h_G(\xi, v) \end{cases}$$

with state space $\mathbb{R}^q$ and a map $\varphi : \mathbb{R}^n \to \mathbb{R}^q$ such that, denoting by Y_{GH} the output of the cascade GH, we have $y_T(u, x_0) - y_{GH}(u, \varphi(x_0), z_0) = 0$ for any initial states x_0, z_0.

Generalized Left Factorization Problem (G.L.F.P.). Given a model T as in (2.9) and a system H as in (4.1), find an integer $\nu \geqq 0$, a possibly nonproper compensator

$$(4.2) \qquad G = \begin{cases} \dot{\xi} = f_G(\xi, v, \cdots, v^{(\nu)}), \\ y_G = h_G(\xi, v, \cdots, v^{(\nu)}), \end{cases}$$

with state space $\mathbb{R}^q$, and a map $\varphi:\mathbb{R}^n\to\mathbb{R}^q$, such that, denoting by Y_{GH} the output of the cascade GH, we have

$$y_T(u, x_0)-y_{GH}(u, \varphi(x_0), z_0)=0 \tag{4.3}$$

for any initial states x_0, z_0.

Remark 4.2. The same considerations as in Remark 3.2 apply to the present situation. Therefore a solution (G, φ) will be one that achieves (4.3) for all initial states x_0 and z_0 in an open and dense subset of the state spaces.

The first result we have in this framework is the following theorem.

THEOREM 4.3. *The* G.L.F.P. *is solvable only if*

$$\rho\begin{pmatrix}T\\ H\end{pmatrix}=\rho(H), \tag{4.4}$$

where $\left(\begin{smallmatrix}T\\ H\end{smallmatrix}\right)$ *is the system consisting of the state and output equations of T and H.*

Proof. We start by proving the theorem under an additional technical assumption on the system H. Assume that the maximal regular controllability distribution $\mathcal{R}^*_H$ of H contained in ker dh_H is locally well defined, i.e., that the regularity conditions of [15, § 6.4] are satisfied. Denoting by $\mathcal{G}$ the distribution spanned by $g_H(z)$, we assume that the following holds:

$$\dim(\mathcal{G}\cap\mathcal{R}^*_H)=m-\rho(H). \tag{4.5}$$

Now, let the regular feedback $u=\alpha(z)+\beta(z)w$ be a "friend" of $\mathcal{R}^*_H$, and let us denote by $\left(\begin{smallmatrix}\tilde T\\ \tilde H\end{smallmatrix}\right)$ the system obtained by compensating $\left(\begin{smallmatrix}T\\ H\end{smallmatrix}\right)$ with $u=\alpha(z)+\beta(z)w$. By (4.5), the action of the feedback $u=\alpha(z)+\beta(z)w$ transforms H into the system $\tilde H$ that, up to a change of coordinates, is of the form [15] $\dot z_1=f_1(z_1)+g_1(z_1)\bar w_1$, $\dot z_2=f_2(z_1, z_2)+g_2(z_1, z_2)w$, $v=h_{\tilde H}(z_1)$, where $w=(\bar w_1, \bar w_2)$, $\bar w_1=(w_1,\cdots, w_\rho)$ and $\rho=\rho(H)$. Hence we have

$$\frac{\partial v^{(k)}(w, z_0)}{\partial w_i}=0 \tag{4.6}$$

for all $i\geqq\rho+1$ and all k. Moreover, if (G, φ) is a solution of the G.L.F.P., we have that the output trajectory $\bar Y(w, x_0, \varphi(x_0), z_0)$ of the cascade composition between $\left(\begin{smallmatrix}\tilde T\\ \tilde H\end{smallmatrix}\right)$ and the system

$$\tilde G=\begin{cases}\dot\xi=f_G(\xi, v,\cdots, v^{(\nu)}),\\ y=y_{\tilde T}-h_G(\xi, v,\cdots, v^{(\nu)}),\end{cases}$$

initialized at $(x_0, \varphi(x_0), z_0)$, is identically zero. This, together with (4.5), implies

$$\begin{aligned}\frac{\partial y^{(k)}(w, x_0, \varphi(x_0), z_0)}{\partial w_i}&=\frac{\partial y^{(k)}_{\tilde T}(w, x_0, z_0)}{\partial w_i}-\frac{\partial y^{(k)}_{G\tilde H}(w, x_0, \varphi(x_0), z_0)}{\partial w_i}\\ &=\frac{\partial y^{(k)}_{\tilde T}(w, x_0, z_0)}{\partial w_i}-\frac{\partial y^{(k)}_{G}(y_{\tilde H}(w, z_0), \varphi(x_0))}{\partial w_i}\\ &=\frac{\partial y^{(k)}_{\tilde T}(w, x_0, z_0)}{\partial w_i}-\frac{\partial y^{(k)}_{G}(y_{\tilde H}(w, z_0), \varphi(x_0))}{\partial y_{\tilde H}}\cdot\frac{\partial y_{\tilde H}(w, z_0)}{\partial w_i}\\ &=\frac{\partial y^{(k)}_{\tilde T}(w, x_0, z_0)}{\partial w_i}\\ &=0\quad\text{for all } i\geqq\rho+1 \text{ and all } k.\end{aligned}$$

Therefore, $\rho\left(\begin{smallmatrix}\tilde T\\ \tilde H\end{smallmatrix}\right)$ is not greater than $\rho(H)$ and, as a consequence, $\rho\left(\begin{smallmatrix}T\\ H\end{smallmatrix}\right)=\rho\left(\begin{smallmatrix}\tilde T\\ \tilde H\end{smallmatrix}\right)=\rho(H)$.

The general case can always be reduced to the previous one. In fact, if (4.5) does not hold, we can pick $\rho(H)$ independent output components of H that can be decoupled with a regular dynamic state feedback [10], [3], [24]. Then, the extended system H_E verifies $\dim(\mathcal{G}_E \cap \mathcal{R}^*_{H_E}) = m - \rho(H_E)$. Since any solution of the G.L.F.P. concerning T and H also solves that concerning T_E and H_E, and since the regular dynamic state feedback does not affect the rank of the systems, the conclusion follows from the first part. □

In general, (4.4) is not sufficient for the solvability of the G.L.F.P. However, under (4.5) and an additional technical condition, which essentially assures the possibility of locally expressing z as a function of the output and its derivatives, it is possible to get a local result. More precisely, it is possible, for any z_0 in an open and dense subset of the state space, to find a neighborhood $\mathcal{D}_0$ and to show the existence of a compensator G and a map φ that achieve (4.3) for $z \in \mathcal{D}_0$. In this case, we will say, that the L.F.P. is locally solvable.

THEOREM 4.4. *The* G.L.F.P. *is locally solvable if the following conditions hold*:

(i) $\rho\binom{T}{H} = \rho(H)$;

(ii) $\dim(\mathcal{G} \cap \mathcal{R}^*_H) = m - \rho(H)$;

(iii) $\sum_{i \geqq 0} (\rho(H) - s_i) = n$, *where* $n = \dim z$, $s_0 = 0$, *and the* s_i *are obtained by applying Singh's inversion algorithm to H.*

Proof. We consider a friend of $\mathcal{R}^*_H$, $u = \alpha(z) + \beta(z)w$, as in the proof of Theorem 4.3 and we use the notation introduced there. By the rank equality $\rho\binom{\tilde{T}}{\tilde{H}} = \rho\binom{T}{H} = \rho(H)$, since (4.6) holds, the input components w_i, with $i \geqq \rho + 1$, do not affect the output of $\binom{\tilde{T}}{\tilde{H}}$. By applying Singh's inversion algorithm to $\tilde{H}$ we get

$$\bar{w}_1 = \psi(z, v, \dot{v}, \cdots, v^{(\nu)}), \tag{4.7}$$

where ψ is a meromorphic function of its arguments and, in particular, it is defined for all z in an open dense subset of the state space. Moreover, using arguments such as those in [17, § 4], we can show that, by (iii), the Jacobian matrix

$$\frac{\partial}{\partial z} \begin{pmatrix} v - h_{\tilde{H}}(z) \\ \hat{v}_1 - \hat{v}_1(z, \tilde{v}_1) \\ \vdots \\ \hat{v}_N - \hat{v}_N(z, \tilde{v}_1, \cdots, \tilde{v}_1^{(N-1)}, \cdots, \tilde{v}_N) \end{pmatrix},$$

whose elements are obtained by applying Singh's algorithm to $\tilde{H}$, has rank n. Then, for any z_0 in an open and dense subset of the state space, there exists a neighborhood $\mathcal{D}_0$ of z_0 such that $z = \chi(v, \dot{v}, \cdots, v^{(\nu)})$ for $z \in \mathcal{D}_0$. By substituting in (4.7), we then get, $\bar{w}_1 = \bar{\psi}(v, \dot{v}, \cdots, v^{(\nu)})$. Now, writing the state equation of $\binom{\tilde{T}}{\tilde{H}}$ as $\dot{x} = f_1(x, z) + g_1(x, z)\bar{w}_1 + g_2(x, z)\bar{w}_2$, $\dot{z} = f_2(z) + g_3(z)w$, we can consider the system

$$G = \begin{cases} \dot{\xi} = f_1(\xi, \chi(v, \dot{v}, \cdots, v^{(\nu)})) + g_1(\xi, \chi(v, \dot{v}, \cdots, v^{(\nu)}))\bar{\psi}(v, \dot{v}, \cdots, v^{(\nu)}), \\ y_G = h(\xi), \end{cases}$$

$$= \begin{cases} \dot{\xi} = f_G(\xi, v, \dot{v}, \cdots, v^{(\nu)}), \\ y_G = h(\xi), \end{cases}$$

and we claim that (G, φ), where φ is the identity map, is a solution of the G.L.F.P. relatively to $\mathcal{D}_0$. In fact, by inspection, we see that the output trajectory

$Y(w, x_0, \varphi(x_0), z_0)$ of the system

$$\begin{aligned}
\dot{x} &= f_1(x, z) + g_1(x, z)\bar{w}_1 + g_2(x, z)\bar{w}_2,\\
\dot{z} &= f_2(z) + g_3(z)w,\\
\dot{\xi} &= f_1(\xi, z) + g_1(\xi, z)\bar{w}_1,\\
y &= h(x) - h(\xi)
\end{aligned}$$

is identically zero for all w. Inverting the feedback $u = \alpha(z) + \beta(z)w$, we obtain $y_T(u, x_0) = y_{GH}(u, \varphi(x_0), z_0)$. □

Example 4.5. Let the systems

$$T = \begin{cases} \dot{x} = u, \\ y_T = x \end{cases} \quad \text{and} \quad H = \begin{cases} \dot{z}_1 = z_2, \\ \dot{z}_2 = u, \\ v = z_1^2, \end{cases}$$

be given. Conditions (i) and (ii) of Theorem 4.4 are clearly verified as well as (iii) is, since $\rho(H) = 1$, $\dim z = 2$, $s_1 = 0$, $s_2 = 1$. In this case there is no need to apply any feedback. By Singh's inversion algorithm we get $u = \psi(z, v, \dot{v}, \ddot{v}) = (\ddot{v} - 2z_2^2)/2z_1$ and $v - z_1^2 = 0$, $\dot{v} - 2z_1z_2 = 0$. Since

$$\frac{\partial}{\partial z}\begin{pmatrix} v - z_1^2 \\ \dot{v} - 2z_1z_2 \end{pmatrix} = \begin{pmatrix} -2z_1 & 0 \\ z_2 & z_1 \end{pmatrix}$$

has rank 2 for $z_1 \neq 0$, we can express z as a function of v, $\dot{v}$ in the neighborhood of any point for which $z_1 \neq 0$. In particular, here we have

$$\begin{pmatrix} z_1 \\ z_2 \end{pmatrix} = \chi(v, \dot{v}) = \begin{pmatrix} \sqrt{v} \\ \dot{v}/2\sqrt{v} \end{pmatrix} \quad \text{for } z_1 > 0.$$

Then, the compensators

$$G_1 = \begin{cases} \dot{\xi} = \dfrac{\ddot{v} - \dot{v}^2/2v}{2\sqrt{v}} \\ y_G = \xi \end{cases} \quad \text{and} \quad G_2 = \begin{cases} \dot{\xi} = -\dfrac{\ddot{v} - \dot{v}^2/2v}{2\sqrt{v}} \\ y_G = \xi \end{cases},$$

together with the identity map, are local solutions of the G.L.F.P., respectively for $z_1 > 0$ and for $z_1 < 0$.

When a proper compensator is sought, the necessary condition (4.4) must be strengthened into the equality of structures at infinity, and we obtain the following result.

THEOREM 4.6. *The* L.F.P. *is solvable with a proper compensator*

$$G = \begin{cases} \dot{\xi} = f_G(\xi, v), \\ y_G = h_G(\xi, v) \end{cases}$$

only if

$$\rho_i\begin{pmatrix} T \\ H \end{pmatrix} = \rho_i(H) \tag{4.8}$$

for all $i \geqq 1$.

Proof. Let $\mathcal{K}$ denote the field of meromorphic functions in the variables $(x, z, u, \cdots, u^{(N-1)})$, where $N = \dim x + \dim z$. By definition $\rho_i(\begin{smallmatrix} T \\ H \end{smallmatrix}) = \dim \operatorname{span}_{\mathcal{K}} \{dx, dz, d\dot{y}_T, d\dot{v}, \cdots, dy_T^{(i)}, dv^{(i)}\} - \dim \operatorname{span}_{\mathcal{K}} \{dx, dz, d\dot{y}_T, d\dot{v}, \cdots, dy_T^{(i-1)}, dv^{(i-1)}\}$. Denoting by $\mathcal{K}'$ the field of meromorphic functions in the variables $(x, z, \xi, u, \cdots, u^{(N-1)})$, since neither T nor H depend on ξ we have $\rho_i\binom{T}{H} = \dim \operatorname{span}_{\mathscr{K}'}\{dx, dz, d\xi, d\dot{y}_T, d\dot{v}, \cdots, dy_T^{(i)}, dv^{(i)}\} - \dim \operatorname{span}_{\mathscr{K}'}\{dx, dz, d\xi, d\dot{y}_T, d\dot{v}, \cdots, dy_T^{(i-1)}, dv^{(i-1)}\}$. Since $y_{GH} = y_T$, we can substitute $dy_{GH}^{(k)}$ into $dy_T^{(k)}$ for all k in the equation above, thus $\rho_i\binom{T}{H} = \dim \operatorname{span}_{\mathscr{K}'}\{dx, dz, d\xi, d\dot{y}_{GH}, d\dot{v}, \cdots, dy_{GH}^{(i)}, dv^{(i)}\} - \dim \operatorname{span}_{\mathscr{K}'}\{dx, dz, d\xi, d\dot{y}_{GH}, d\dot{v}, \cdots, dy_{GH}^{(i-1)}, dv^{(i-1)}\}$. Moreover, by the properness of (GH), we also have that $dy_{GH}^{(k)} \in \operatorname{span}_{\mathscr{K}'}\{dx, dz, d\xi, d\dot{v}, \cdots, dv^{(k)}\}$, thus $\rho_i\binom{T}{H} = \dim \operatorname{span}_{\mathscr{K}'}\{dx, dz, d\xi, d\dot{v}, \cdots, dv^{(i)}\} - \dim \operatorname{span}_{\mathscr{K}'}\{dx, dz, d\xi, d\dot{v}, \cdots, dv^{(i-1)}\}$. Let $\mathscr{K}''$ denote the field of meromorphic functions in the variables $(z, u, \cdots, u^{(n-1)})$, where $n = \dim z$. Since $dv^{(k)} \in \operatorname{span}_{\mathscr{K}''}\{dz, du, d\dot{u}, \cdots, du^{(k-1)}\}$ for all $k \leqq n$, we finally get

$$\rho_i\binom{T}{H} = \dim \operatorname{span}_{\mathscr{K}''}\{dz, d\dot{v}, \cdots, dv^{(i)}\} - \dim \operatorname{span}_{\mathscr{K}''}\{dz, d\dot{v}, \cdots, dv^{(i-1)}\} = \rho_i(H).$$

5. Conclusion. The model matching and the left factorization problems for nonlinear systems have been considered in the framework of a structural approach based on Singh's inversion algorithm. The result obtained on the model matching problem consists of a computable sufficient condition that also allows us to derive a procedure for constructing a solution, if any.

Necessary computable conditions for the existence of solutions of the left factorization problem have also been found. Under additional technical assumptions, one of the previous conditions has also been shown to be sufficient for assuring the existence of local solutions. However, in this case, the proof is not entirely constructive, since it makes use of the implicit function theorem.

Note added in proof. Further results on the problem have recently been obtained by Huijberts in "A nonregular solution of the nonlinear dynamic disturbance decoupling problem with an application to a complete solution of the nonlinear model matching problem," Memorandum No. 862, University of Twente, 1990.

MARKOV DECISION PROBLEMS AND STATE-ACTION FREQUENCIES*

EITAN ALTMAN† AND ADAM SHWARTZ†‡

Abstract. Consider a controlled Markov chain with countable state and action spaces. Basic quantities that determine the values of average cost functionals are identified. Under some regularity conditions, these turn out to be a collection of numbers, one for each state-action pair, describing for each state the relative number of uses of each action. These "conditional frequencies," which are defined *pathwise*, are shown to determine the "state-action frequencies" that, in the finite case, are known to determine the costs. This is extended to the countable case, allowing for unbounded costs. The space of frequencies is shown to be compact and convex, and the extreme points are identified with stationary deterministic policies.

Conditions under which the search for optimality in several optimization problems may be restricted to stationary policies are given. These problems include the standard Markov decision process, as well as constrained optimization (both in terms of average cost functionals) and variability-sensitive optimization. An application to a queueing problem is given, where these results imply the existence and explicit computation of optimal policies in constrained optimization problems.

The pathwise definition of the conditional frequencies implies that their values can be controlled directly; moreover, they depend only on the limiting behavior of the control. This has immediate application to adaptive control of Markov chains, including adaptive control under constraints.

Key words. Markov decision process, average cost, constrained optimization, state-action frequencies, nonstationary control

AMS(MOS) subject classifications. 90B50, 60G17, 60J10, 93E20

Introduction. An important issue in optimization problems is the reduction of the space of policies over which we optimize. This is motivated by the need to reduce the complexity of the search for optimal policies, and by the desire to restrict attention to those policies that are easy to implement. Indeed, in many optimization problems we first show that it is possible to restrict the optimization to the class of stationary policies. This simplifies the search, since many computational methods are available in the stationary case. Furthermore, the implementation requires relatively little memory. Conditions that ensure that we may indeed restrict the search of optimal policies for Markov decision processes to stationary policies (or even to deterministic stationary policies) are an active area of research (see, e.g., Borkar [9], [10], Cavazos-Cadena [12], Dekker and Hordijk [14], Sennott [28], [29] and references therein).

On the other hand, it is of interest to know how flexible we can be in the choice of policies, in a way that does not change the values of average cost criteria. This is the case in adaptive optimization, where we often use on-line estimation schemes to generate an approximation of the optimal control (the certainty equivalence approach). The goal in this case is to achieve the same performance as in the case of full information.

These two issues are treated in this paper in the framework of the following question. For a given policy, what are the quantities that determine the values of average cost functionals? Fix a state x and an action a. For each t, consider the (random) number of times the process visited state x and action a was used by time t. It turns out that in many cases average costs are determined by the limits (in time) of the expectations of such "state-action frequencies." For each time t, consider the (random) ratio of the number of uses of action a while in state x, to the number of

‡ The research of this author was performed in part while he was visiting the Mathematical Sciences Research Center, AT&T Bell Laboratories.

visits to state x. Below we show that the pathwise limits of these "conditional frequencies" are the more basic quantity, in that they determine the expected state action frequencies.

We deal with countable state and action spaces, and obtain classes of policies that achieve every possible state action frequency; we term such classes "complete." In the finite case, some questions of completeness are investigated in [2], [15], and [22]; Derman [15] gives conditions for the completeness of Markov policies. Hordijk and Kallenberg [22] strengthen this result to Markov policies having just one accumulation point of the "matrix" of frequencies. Derman [15] and, later, Hordijk and Kallenberg [22] give conditions for the completeness of stationary policies. Two time sharing policies were introduced by Altman and Shwartz [1]-[3], who show that under the conditions of Derman [15], completeness depends on pathwise limit properties only, and in particular may be achieved using deterministic (but nonstationary) policies. In this paper we show that in the countable case the space of achievable frequencies is a compact convex set whose extreme points are frequencies obtained by deterministic (stationary) policies. This extends the geometric characterization given in the finite case by Derman [15], Hordijk and Kallenberg [22], and Altman and Shwartz [2].

We give conditions under which some classes of policies (such as the stationaries) are "sufficient" in the countable case for several optimization problems, including optimization under several constraints. These results allow the use of steady-state analysis of systems, which simplifies the search for optimal policies considerably. It becomes possible to translate results on performance, which in many cases deal with "steady state," into results concerning optimization (see, e.g., Altman and Shwartz [1], [3]). Previous results on the sufficiency of stationary policies in the case of countable state space dealt only with the minimization (or maximization) of a single criterion.

Then, we introduce a larger family of "sufficient" policies—the action time sharing (*ats*) policies—which is characterized by the existence of a with probability one limit to the conditional frequencies. In contrast with the standard "small" classes of policies such as the stationary policies, these policies are flexible enough to be useful for adaptive problems, as they have the following important property: the expected frequencies (and thus the cost) achieved by any policy depends only on the (pathwise) limiting behavior of the control mechanism. More precisely, it depends only on the limit of the conditional frequencies, described above. Therefore it is possible to use nonstationary algorithms based on real-time estimation of unknown parameters, and still obtain optimality. Moreover, whereas existing results on adaptive control of Markov chains consider only the optimization of a single criterion, the present results can be used to obtain adaptive controls under more general criteria, such as constrained optimization. An application of these ideas in the case of *finite* state and action spaces is given in Altman and Shwartz [2, § 5], [4]. The computation of optimal policies of the *ats* type is equivalent to the computation over the more restricted class of stationary policies, and the implementation is just as simple.

After introducing the model and some notation, § 1 provides the basic motivation by introducing the standard Markov decision problem and a constrained optimization problem. In § 2 we derive conditions under which the frequencies determine the value of optimization criteria, and under which stationary policies or other complete classes of policies are sufficient for the two optimization problems. In § 3 the basic results concerning the completeness of the stationary policies and the role of the conditional frequencies in determining the behavior of the process are derived. Since the state and action spaces are countable (and thus not compact), a tightness condition is used. The literature concerning the tightness problem is extensive; in § 4 we adapt some applicable results. The case where tightness does not hold is treated by imposing conditions on the cost, under which tight policies are "better" than nontight ones. In § 5 it is shown that the space of frequencies is compact, and has the geometric characterization as the convex hull of the frequencies of stationary deterministic policies. This has implications to the existence of optimal policies in constrained optimization problems. Finally, we apply and extend the results of the previous sections. In § 6 we treat a queueing network, and in § 7 an equivalence between the constrained optimization problem and an associated linear program (which is well known in the finite case [15], [22]) is extended to the countable case. Section 8 treats some lesser known optimization problems involving variance.

1. The model and the problems. Let $\{X_t\}_{t=1}^{\infty}$ be a discrete time process defined on the countable *state space* $\mathbf{X}=\{0, 1, \cdots\}$. At time t an action A_t from the countable *action space* $\mathbf{A}$ is taken. Denote by $A(x)$ the set of actions available when in state x. $h_n := (X_1, A_1, X_2, A_2, \cdots, X_n, A_n)$ is the *history* of $\{X_t\}$. Denote the transition probabilities for the controlled Markov chain by

$$(1.1)\quad P_{xay} := P(X_{n+1}=y\,|\,X_n=x;\ A_n=a)=P(X_{n+1}=y\,|\,h_{n-1}=h,\ X_n=x;\ A_n=a).$$

A policy u in the *policy space* U is defined by $u=\{u_1, u_2, \cdots\}$, where u_t is applied at time epoch t, and $u_t(\cdot\,|\,h_{t-1}, X_t)$ is a conditional probability measure over $\mathbf{A}$. Each policy u induces a probability measure P^u on the space of paths (which serves as the canonical sample space Ω). The corresponding expectation operator is denoted by E_u.

A *Markov policy* $f\in U(M)$ is characterized by the dependence of $u_t(\cdot\,|\,h_{t-1}, X_t)$ on X_t only; i.e., $u_t(\cdot\,|\,h_{t-1}, X_t)=u_t(\cdot\,|\,X_t)$. A *stationary policy* $g\in U(S)$ is characterized by a single conditional probability measure $u(\cdot\,|\,X_t)=p^g_{\cdot|X_t}$ over $\mathbf{A}$, so that $p^g_{A(x)|x}=1$; under g, $\{X_t\}$ becomes a Markov chain with stationary transition probabilities, given by $P^g_{xy}=\sum_{a\in A(x)} p^g_{a|x}P_{xay}$. The class of stationary deterministic policies $U(SD)$ is a subclass of $U(S)$, and every $g\in U(SD)$ is identified with a mapping $g:\mathbf{X}\to\mathbf{A}$, so that for each x, $p^g_{\cdot|x}=\delta_{g(x)}(\cdot)$ is concentrated at one point $a\in A(x)$.

Let $c(x, a)$ be a real valued function on $\mathbf{X}\times\mathbf{A}$, possibly unbounded, and let

$$C^t_x(u)=\frac{1}{t}E_u\left[\sum_{s=1}^{t} c(X_s, A_s)\,|\,X_1=x\right].$$

We assume throughout that for each u, the cost $C^t_x(u)$ is well defined. This will usually follow from uniform integrability assumptions on $c(X_t, A_t)$, or from a condition that $c(\cdot,\cdot)$ is bounded below. The optimization problem OP involves the minimization of average cost functionals:

$$(1.2\text{a})\qquad \bar{C}_x(u)=\overline{\lim_{t\to\infty}}\, C^t_x(u),$$

$$(1.2\text{b})\qquad \underline{C}_x(u)=\underline{\lim}_{t\to\infty}\, C^t_x(u).$$

These include the standard "positive" and "negative" Markov decision problems. Given the constants V_k, $1\leqq k\leqq K$, the constrained optimization problem COP is defined as

$$(1.3\text{a})\qquad \text{minimize}\quad \bar{C}_x(u)\qquad \text{subject to}\quad \bar{D}^k_x(u)\leqq V_k,\quad 1\leqq k\leqq K,$$

$$(1.3\text{b})\qquad \text{minimize}\quad \underline{C}_x(u)\qquad \text{subject to}\quad \bar{D}^k_x(u)\leqq V_k,\quad 1\leqq k\leqq K,$$

where $\bar{D}^k_x(u)$ is defined similarly to $\bar{C}_x(u)$ with $c(x, a)$ replaced by $d^k(x, a)$, and both $c(x, a)$ and $d^k(x, a)$ may be unbounded. For finite state and action spaces, a solution to the constrained optimization problem based on linear programming was already obtained by Derman [15] and Hordijk and Kallenberg [22], and some variables of this linear program are limits of the state-action frequencies (1.4).

These *expected state-action frequencies* (Derman [15]) and *expected state frequencies*

$$\text{(1.4)}\qquad \begin{aligned} \bar f^T_{x,u}(y,a) &:= \frac{1}{T}\sum_{s=1}^{T} P^u(X_s=y, A_s=a \mid X_1=x), \\ \bar f^t_{x,u}(y) &:= \frac{1}{t}\sum_{s=1}^{t} P^u(X_s=y \mid X_1=x) \end{aligned}$$

are key quantities in the analysis below. Let the "matrix" $\{\bar f_{x,u}(y,a)\}_{y,a}$ denote a generic accumulation point of the infinite "matrix" $\{\bar f^T_{x,u}(y,a)\}_{y,a}$ as $T\to\infty$ (i.e., an accumulation point in a countable-dimensional space with one coordinate for each state action pair), and let $\{\bar f_{x,u}(y)\}_y$ denote any accumulation point of the infinite vector $\{\bar f^t_{x,u}(y)\}_y$. Let $\bar F_{x,u}$ denote the set of all limit matrices $\bar f_{x,u}(\cdot,\cdot)$. Any class of policies U' determines a set of accumulation points $L_x(U') := \bigcup_{u\in U'} \bar F_{x,u}$ and the set of all such limits is denoted by $L_x := \bigcup_{u\in U} \bar F_{x,u}$. We use the abbreviations $L_x(S) := L_x(U(S))$ and $L_x(D) := L_x(U(SD))$.

The following definitions are useful for the sample-path analysis of § 3. Let $f^T(y,a) := (1/T)\sum_{s=1}^T 1\{X_s=y, A_s=a\}$ denote the sample-path frequency at which the event of being at state y and choosing action a occurs till time T. The expectation of the random variable $f^T(y,a)$ under u starting at x is thus $\bar f^T_{x,u}(y,a)$. The frequency at which the event of being at state y occurs till time T is denoted by $f^T(y) = (1/T)\sum_{s=1}^T 1\{X_s=y\}$. Finally, $f^T(a\mid y) := f^T(y,a)[f^T(y)]^{-1}$ is the frequency at which action a is chosen conditioned on being in state y, until time T. If $f^T(y)=0$ define $f^T(a\mid y) := 0$. Denote by $f(y,a)$ (respectively, $f(y)$) any accumulation point of $f^T(y,a)$ (respectively, $f^T(y)$) as $T\to\infty$.

Let g be a stationary policy. The following standard result will be frequently used.

LEMMA 1.1. *Assume that under g the process $\{X_t\}_{t=1}^\infty$ has one positive recurrent class, and that from any transient state, absorption into the recurrent class occurs in finite expected time. Then*

$$\bar f_{x,g}(y,a) = \pi^g(y)p^g_{a|y} = \lim_{t\to\infty} f^t(y,a) \quad P^g \textit{ a.s.}$$

For the last equality to hold, it suffices that absorption occurs with probability one.

A class of policies U' is called *complete* if $L_x = \bigcup\{\bar F_{x,u'}\colon u'\in U'$ and $\bar F_{x,u'}$ *is a singleton*$\}$. U' is called *weakly complete* if

$$L_x \cap \left\{\zeta\colon \sum_{y,a}\zeta(y,a)=1\right\} \subset \bigcup\{\bar F_{x,u'}\colon u'\in U' \text{ and } \bar F_{x,u'} \textit{ is a singleton}\}.$$

Note that for each t, $\bar f^t_{x,u}(y,a)$ can be considered as a probability measure over $\mathbf{X}\times\mathbf{A}$. The condition $\sum_{y,a}\bar f_{x,u}(y,a)=1$ for every limit point $\bar f_{x,u}(y,a)$ of a subsequence $\{\bar f^{t_n}_{x,u}(y,a)\}_n$ is equivalent to tightness of this set of measures [8]. Thus weak completeness considers only tight frequencies.

A class of policies U' is called *sufficient* for an optimization problem if for any policy u there is a policy $u'\in U'$ that performs at least as well. The motivation for studying questions of completeness and the spaces of frequencies is provided in § 2 below, where the connection between completeness and sufficiency is established. Note that sufficiency does not imply existence of an optimal policy, but rather that the search for "good" policies can be restricted to any subclass that is sufficient.

The following assumptions are used frequently in the paper:

(A0) At each state x, the set of available actions $A(x)$ is finite.

(A1) Under any policy $g \in U(S)$ the state space contains a single *positive* recurrent class, and absorption into the positive recurrent class takes place in finite expected time.

It follows from Fisher [18] that under (A0) and (A1), if there are no transient states under any policy in $U(SD)$ then the chain is ergodic under each policy in $U(S)$ if and only if it is ergodic under each policy in $U(SD)$ (see also § 5, Corollary 5.3).

(A2(u)) Given a policy u, the expected frequencies $\{\bar{f}^{t}_{x,u}(y, a)\}_t$ are tight.

(A2) Assumption (A2(u)) holds for all policies $u \in U$.

(A2*) The family of stationary probabilities corresponding to policies in $U(SD)$ is tight.

Remarks. (i) The issue of tightness is treated in § 4. In Lemma 4.1 we show that under the appropriate conditions, (A2) is equivalent to (A2*). We give simple verifiable sufficient conditions for (A2*), and develop some methods for the nontight case.

(ii) Assumption (A2(u)) depends on the initial state x, even when (A1) holds. For example, let u' be a policy that violates (A2(u')) (e.g., the policy constructed in [17]). Let g be a policy for which (A2(g)) holds (under (A1), this holds for any stationary policy). If u equals u' whenever $X_0 = x$ and otherwise uses g, then clearly (A2(u)) holds for all initial states except x. Throughout the paper, reference to (A2(u)) will implicitly assume a fixed initial state, which is omitted from the notation.

To make the discussion more concrete, we cite Theorem 3.2, whose proof is given in § 3.

THEOREM 3.2. *Under* (A1) *the class of stationary policies is weakly complete.*

As will become clear in § 3, the property of completeness does not depend on stationarity; it is more naturally defined through conditional frequencies. This will be seen to provide a large degree of flexibility, which can be applied in a straightforward manner to adaptive optimization problems [4].

2. Sufficiency and completeness. The aim of this section is to establish the relation between optimization problems and state-action frequencies, and in particular between sufficiency and completeness. In the case of finite state and action spaces it is known that the time average expected cost has a representation as a linear function of the expected state-action frequencies (e.g., [15]). We extend this result to the countable case, and establish sufficient conditions under which the costs (1.2a) and (1.2b) can be represented as linear functionals (2.4) of the frequencies. The advantage of this approach is that it deals directly with the cost functionals, and therefore applies to many classes of optimization problems. In the following sections we investigate the optimization problems OP and COP, and show the connection between completeness and sufficiency. In particular, we present conditions under which the search for solutions of OP and COP can be restricted to those policies for which the costs have the linear representation (2.4) in terms of the frequencies. Similar results are obtained in § 8 for other optimization problems. These results motivate the further investigation of the achievable frequencies under various classes of policies, which is carried out in § 5. We will be especially interested in finding out which classes of policies are complete. This will indicate when a class of policies is sufficient for the optimization problems OP and COP, or, in other words, whether we may restrict the search for optimal policies to smaller classes of policies. Moreover, as will become clear is § 3, this approach identifies the key quantities that determine the costs, and allows for a flexible choice of controls while keeping the cost fixed.

The results of this section concerning optimization problems are given under condition (A2), which is a rather strong "uniform stability" assumption. In § 4 we provide natural sufficient conditions for (A2), and also show how the results can be extended when tightness does not hold.

2.1. Representation of costs through frequencies. Unlike the case of finite state and action spaces, the time average expected cost in the countable case need not even have a representation as a function of the expected state-action frequencies.

Counterexample 2.1. The deterministic case. Let $P_{xy} = 1\{x+1=y\}$ and $c(x, a) = 1$ for all states and actions. The action is thus irrelevant to both the dynamics and cost and we may assume that there is just one possible action. Under any policy u we clearly have $\bar{f}_{x,u}(y, a) = 0$, while $C_x(u) = 1$.

In this example (A1) does not hold. Counterexample 3.5 in § 3 presents a case where (A1) holds but (A2) does not, and which exhibits similar behavior.

Lemmas 2.2 and 2.3 provide conditions under which a linear representation (2.4) holds. Fix an initial state x and a policy u. Since by assumption $C_x^t(u)$ is well defined, the definitions imply

$$\bar{C}_x(u) = \overline{\lim_{t\to\infty}} \sum_{y,a} \bar{f}^t_{x,u}(y, a) c(y, a). \tag{2.1}$$

Let $\{s_n\}_n$ be a subsequence along which the limit is obtained, i.e.,

$$\bar{C}_x(u) = \lim_{n\to\infty} \sum_{y,a} \bar{f}^{s_n}_{x,u}(y, a) c(y, a). \tag{2.2}$$

Using diagonalization, choose a further subsequence $\{t_n\}_n$ so that $\bar{f}^{t_n}_{x,u}(y, a) \to \bar{f}_{x,u}(y, a)$, for all y and a.

LEMMA 2.2. *Assume* (A1) *and let* $\{c(X_s, A_s)\}_s$ *be uniformly integrable under* P^u. *If* (A2(u)) *holds then the costs* (1.2) *are a function* (2.4) *of the* $\bar{f}_{x,u}$ *defined above. If* v *is a policy such that* $\bar{F}_{x,v} = \{\bar{f}_{x,u}\}$ *and* $\{c(X_s, A_s)\}_s$ *are also uniformly integrable under* P^v, *then* $\bar{C}_x(u) = \bar{C}_x(v)$ *and* $\underline{C}_x(u) = \underline{C}_x(v)$.

Proof. Consider first the cost function defined through (1.2a). Note that for each t, $\bar{f}^t_{x,u}(\cdot, \cdot)$ can be considered as a probability measure over $\mathbf{X} \times \mathbf{A}$, and the cost $c(\cdot, \cdot)$ can then be viewed as a random variable over $\mathbf{X} \times \mathbf{A}$. The convergence $\bar{f}^{t_n}_{x,u}(y, a) \to \bar{f}_{x,u}(y, a)$ for all y and a thus translates under (A2(u)) into weak convergence of probability measures along t_n. As $\{c(X_s, A_s)\}_s$ is uniformly integrable with respect to P^u, $c(\cdot, \cdot)$ is also uniformly integrable with respect to $\{\bar{f}^t_{x,u}\}_t$; this follows from the fact that for every function h,

$$\sum_{y,a} \bar{f}^t_{x,u}(y, a) h[c(y, a)] = E_u \frac{1}{t} \sum_{s=1}^{t} [h[c(X_s, A_s)] \mid X_1 = x]. \tag{2.3}$$

This weak convergence of $\bar{f}^t_{x,u}$ implies the convergence of $c(\cdot, \cdot)$ in distribution, and combining this to the uniform integrability of $c(\cdot, \cdot)$ we finally obtain [8]

$$\bar{C}_x(u) = \sum_{y,a} \bar{f}_{x,u}(y, a) c(y, a). \tag{2.4}$$

The argument for (1.2b) is identical. The last claim is now immediate since $\bar{f}_{x,u} = \bar{f}_{x,v}$. □

It is not difficult to establish the following converse to Lemma 2.2. If (2.4) holds for each limit point $\bar{f}_{x,u}$ in $\bar{F}_{x,u}$ and c satisfies $\infty > \bar{c} > c(y, a) > \varepsilon > 0$, for all y, a, then (A2(u)) holds. But for an arbitrary c (2.4) may not imply (A2(u)) (for example, $c = 0$ provides no information).

Next, we discuss the representation (2.4) for stationary policies. Fix $g \in U(S)$ and an initial state x, and let $0 \in \mathbf{X}$ be recurrent under g. With the standard convention that $\inf \varnothing := \infty$, define $\eta(1) := \inf\{t \geqq 1: X_t = 0\}$, $\eta(k+1) := \inf\{t > \eta(k): X_t = 0\}$, where $\eta(k) = \infty$ implies $\eta(k+1) = \infty$.

LEMMA 2.3. *Assume* (A1) *and let* $g \in U(S)$. *Then* (A2(g)) *holds, and the representation* (2.4) *for the costs* (1.2) *holds whenever one of the following is true*: (i) $\{c(X_s, A_s)\}_s$ *are uniformly integrable with respect to* P^g; (ii) *c is bounded from below and* (A3(g)) *holds*; (iii) *c is bounded from above and* (A3(g)) *holds, where*

$$\text{(A3}(g)\text{)} \qquad \begin{aligned} &E_g\left[\sum_{s=1}^{\eta(1)-1} |c(X_s, A_s)| \,|X_1 = x\right] = \infty \\ &\textit{implies } E_g\left[\sum_{\eta(1)}^{\eta(2)-1} |c(X_s, A_s)| \,|X_1 = x\right] = \infty. \end{aligned}$$

Note that if, under g, x belongs to the recurrent class then (A3(g)) always holds (see the proof below). In particular, when there are no transient states under g, (A3(g)) holds.

Proof. The first claim follows from Lemma 1.1, and (i) is obtained by combining this with Lemma 2.2.

To prove (ii), consider first a cost of the form $c(x, a) = c(x)$. Recall that the initial condition is fixed, and is omitted from the notation below. Denote by $\tau_k := E_g[\eta(k+1) - \eta(k)]$ the expected time between consecutive visits to state zero under g. (We call such a period a cycle.) From Chung [13], under (A1), $\tau := \tau_k$ is independent of k. Denote the (sample) cost over the kth cycle by $Y(k) := \sum_{t=\eta(k)}^{\eta(k+1)-1} c(X_t)$. If $\eta(k) = \infty$ set $Y(k) := 0$. Assume that

$$(*) \qquad E_g\left[\sum_{\eta(1)}^{\eta(2)-1} |c(X_s)|\right] < \infty.$$

Denote by $W := E_g[Y(1)]$ the total expected cost during the first cycle. Since c is bounded below, (A1) implies that (*) is equivalent to W being finite. From Chung [13] it follows that under (A1), (*), and (A3(g)),

$$(2.5) \qquad \bar{C}_x(g) = \underline{C}_x(g) = C(g) = \frac{W}{\tau} = \sum_{y \in \mathbf{X}} \pi_y^g c(y).$$

But as g is stationary, $\bar{f}_{x,g}(y) = \pi_y^g$ whereas the tightness impliess $\sum_{a \in \mathbf{A}} \bar{f}_{x,g}(y, a) = \bar{f}_{x,g}(y)$. Hence

$$(2.6) \qquad C(g) = \sum_{y \in \mathbf{X}} \bar{f}_{x,g}(y) c(y) = \sum_{y,a} \bar{f}_{x,u}(y, a) c(y).$$

Next, if (*) does not hold then $W = \infty$. Denote $c^M(x) := c(x) 1\{c(x) \leqq M\}$, and define W^M, $Y^M(k)$, and $C_x^M(u)$ as before, but with $c^M(x)$ replacing $c(x)$. The following monotone convergence holds pathwise:

$$Y(1) = \sum_{s=\eta(1)}^{\eta(2)-1} c(X_s) = \lim_{M \to \infty} \sum_{s=\eta(1)}^{\eta(2)-1} c^M(X_s) = \lim_{M \to \infty} Y^M(1).$$

Clearly, $C(g) \geqq \overline{\lim}_{M \to \infty} C_x^M(g) = \overline{\lim}_{M \to \infty} W^M/\tau = W/\tau$ by (2.5) and the monotone convergence theorem. Thus $C(g) = W/\tau$, i.e., all but the last equality in (2.5) hold independently of (*). It then follows from (2.5) that

$$(2.7) \qquad \infty = \lim_{M \to \infty} \frac{W^M}{\tau} = \lim_{M \to \infty} \sum_{y \in \mathbf{X}} \pi_y^g c^M(y) = \sum_{y \in \mathbf{X}} \pi_y^g c(y)$$

using the monotone convergence theorem. The argument leading to (2.6) now implies (2.4).

Finally, we allow the cost to depend on the action. Let $\hat{c}(x) := \sum_{a\in A(x)} p^g_{a|x} c(a, x)$. Note that

$$C_x(g) = \overline{\lim_{t\to\infty}} \frac{1}{t} E_u\left[\sum_{s=1}^{t} \hat{c}(X_s) \,|\, X_1 = x\right] = \sum_{y\in\mathbf{X}} \bar{f}_{x,g}(y)\hat{c}(y)$$

$$= \sum_{y\in\mathbf{X}} \sum_{a\in\mathbf{A}} \bar{f}_{x,g}(y) p^g_{a|y} c(y, a) = \sum_{y,a} \bar{f}_{x,g}(y, a) c(y, a),$$

since $\bar{f}_{x,g}(y) p^g_{a|y} = \bar{f}_{x,g}(y, a)$, and where changes of order of summation are justified since c is bounded below. The proof in the case the cost bounded from above is identical. □

That (A3(g)) is necessary can be seen through the following example. Let $\mathbf{X}$ be the positive integers and let $\mathbf{A} := \{a\}$. Let $P_{0a0} = 1$, and $P_{xa0} = 0.5$, $P_{xa(x+1)} = 0.5$ for $x > 0$. With $c(y, a) = b^y$, (A3(g)) is violated and (2.4) fails to hold whenever $b \geqq 2$.

2.2. Optimization and frequencies.

Using the previous lemmas we next discuss optimization under the expected average cost criterion.

LEMMA 2.4. *Assume $c(x, a)$ is bounded below, and let $C_x(u)$ denote either of the costs* (1.2). *If*

$$C_x(u) = \lim_{n\to\infty} \sum_{y,a} \bar{f}^{t_n}_{x,u}(y, a) c(y, a) \tag{2.8}$$

for some u and sequence $\{t_n\}$, then for any accumulation point $\bar{f}_{x,u}$ of $\{\bar{f}^{t_n}_{x,u}\}$, $C_x(u) \geqq \sum_{y,a} \bar{f}_{x,u}(y, a) c(y, a)$.

Proof. Assume first that c is positive and let $\{s_n\}$ be a subsequence of $\{t_n\}$ such that $\bar{f}^{s_n}_{x,u} \to \bar{f}_{x,u}$ for all (a, y). An application of Fatou's lemma, where c is considered as a σ-finite measure yields

$$C_x(u) = \lim_{n\to\infty} \sum_{y,a} \bar{f}^{s_n}_{x,u}(y, a) c(y, a) \geqq \sum_{y,a} \underline{\lim}_{n\to\infty} \bar{f}^{s_n}_{x,u}(y, a) c(y, a) = \sum_{y,a} \bar{f}_{x,u}(y, a) c(y, a). \tag{2.9}$$

In general, shifting c to obtain such a measure, the same argument applies. □

COROLLARY 2.5. *Let u and v be two policies such that $\bar{F}_{x,v} = \{\bar{f}_{x,v}\}$, and $\bar{f}_{x,u} = \bar{f}_{x,v}$, for some accumulation point $\bar{f}_{x,u} \in \bar{F}_{x,u}$. Assume that under v the representation* (2.4) *holds and $c(x, a)$ is bounded below. Then $C_x(v) \leqq C_x(u)$, where $C_x(u)$ stands for either of the costs* (1.2).

The following theorem gives conditions under which the search for optimal (or ε optimal) policies can be restricted to a subclass of policies.

THEOREM 2.6. *Consider the problem of minimizing $\bar{C}_x(u)$ (or minimizing $\underline{C}_x(u)$). Assume* (A1) and (A2) *and let U' be complete. Then U' is sufficient if one of the following assumptions holds*:

(i) *$\{c(X_s, A_s)\}_s$ is uniformly integrable with respect to P^u for each $u \in U$.*

(ii) *For each $u' \in U'$* (2.4) *holds and $c(x, a)$ is bounded below.*

Proof. (i). For any $u \in U$, there exists a $v \in U'$ satisfying the hypotheses of Lemma 2.2, and sufficiency follows. The proof of (ii) follows from Lemma 2.4 and Corollary 2.5. □

Note that the question of existence of optimal policies is not raised here.

2.3. Constrained optimization.

The reason for restricting problem COP to cost functionals D^k defined through (1.2a) is that, when the constraints are defined through (1.2b), a complete class of policies may not be sufficient, even if the state and action spaces are finite. For example:

Counterexample 2.7. Optimization under a constraint. Let $\mathbf{X}=\{x\}$, and $\mathbf{A}=\{p, q\}$. Set $c(x,p)=d(x,q)=-1$, $d(x,p)=c(x,q)=0$. Define $\underline{C}$ and $\underline{D}$ through (1.2b). The objective is to minimize $\underline{C}_x(u)$ under the constraint $\underline{D}_x(u)\leqq -0.5$.

In the finite, single class case, it is well known that the class of stationary policies achieves all possible frequencies. It is easy to see that the best stationary policy g chooses p or q with equal probability, and $\underline{C}_x(g)=-0.5=\underline{D}_x(g)$. Consider the policy u that uses p at times $(2n)^2\leqq t<(2n+1)^2$ $n=1,2,\cdots$ and action q at the remaining epochs. Then $\underline{C}_x(u)=\underline{D}_x(u)=-1$, and we conclude that there is no stationary optimal policy.

THEOREM 2.8. *Consider problem* COP (1.3a) *and* (1.3b). *Under* (A1) *and* (A2) *the stationary policies are sufficient if one of the following holds*;

(i) $\{c(X_s, A_s)\}_s$ *and* $\{d^k(X_s, A_s)\}_s$, $1\leqq k\leqq K$ *are uniformly integrable with respect to* P^u *for each u, or*

(ii) $c(x, a)$ *and* $d^k(x, a)$, $1\leqq k\leqq K$ *are bounded below and* (A3(g)) *holds for all* $g\in U(S)$, *with respect to c and* d^k, $1\leqq k\leqq K$.

Remark. It clearly suffices to check (A3(g)) for those policies that satisfy the constraints (see also § 4).

Proof. Consider first (1.3a). Fix an arbitrary policy u. Let t_n be a subsequence such that $\bar{C}_x(u)=\lim_{n\to\infty}\sum_{y,a}\bar{f}^{t_n}_{x,u}(y,a)c(y,a)$, and such that the limits $\bar{f}^{t_n}_{x,u}(y,a)\to \bar{f}_{x,u}(y,a)$ for all y and a, and $\lim_{n\to\infty}\sum_{y,a}\bar{f}^{t_n}_{x,u}(y,a)d^k(y,a)$ exist. According to Corollary 3.3 the class of stationary policies $U(S)$ is complete, hence there exists a stationary policy g such that $\bar{f}_{x,g}=\bar{f}_{x,u}$. Under assumption (i), Lemma 2.3 implies that (A2(g)) holds, and so Lemma 2.2 implies $\bar{C}_x(g)=\bar{C}_x(u)$. Finally,

$$\bar{D}^k_x(u)=\overline{\lim_{t\to\infty}}\sum_{y,a}\bar{f}^{t}_{x,u}(y,a)d^k(y,a)\geqq\overline{\lim_{n\to\infty}}\sum_{y,a}\bar{f}^{t_n}_{x,u}(y,a)d^k(y,a)$$

$$=\sum_{y,a}\bar{f}_{x,u}(y,a)d^k(y,a)=\bar{D}^k_x(g),$$

where the next to last equality is validated by the arguments of the proof of Lemma 2.2. This proves the theorem under assumption (i).

Under (ii), since (A1) implies that $\bar{f}_{x,g}$ is a singleton, Lemma 2.3 and Corollary 2.5 can be invoked to conclude $\bar{C}_x(g)\leqq\bar{C}_x(u)$ and $\bar{D}^k_x(g)\leqq\bar{D}^k_x(u)$ for each k, and the proof for (1.3a) is concluded. The proof for (1.3b) is identical. □

Finally, we consider an arbitrary complete class.

COROLLARY 2.9. *Assume* (A1) *and* (A2) *and consider* COP (1.3). *Let* U' *be any complete class of policies. Assume* (2.4) *holds for all* $u'\in U'$ *and for c and* d^k. *Then* U' *is sufficient if one of the following holds*;

(i) $\{c(X_s, A_s)\}_s$ *and* $\{d^k(X_s, A_s)\}_s$, $1\leqq k\leqq K$ *are uniformly integrable with respect to* P^u *for each u, or*

(ii) $C(x, a)$ *and* $d^k(x, a)$, $1\leqq k\leqq K$ *are bounded below.*

Proof. Stationarity is used in the proof of Theorem 2.8 solely to guarantee that $\bar{F}$ is a singleton and the representation (2.4) holds. □

3. Completeness: action time sharing. In Theorem 3.2 we prove that the class of stationary policies is weakly complete under (A1), and complete (Corollary 3.3) under the additional assumption (A2). This and the results of § 2 allow us to recover and extend classical results, concerning optimality of stationary policies.

The classical approach to Markov optimization problems relies on the specific class of stationary policies, and on their statistical properties. In contrast, the point of view taken here is to find weak sufficient conditions for a class of policies to be complete. The class of "action time sharing" policies introduced below includes the stationary policies. However, the novelty of this approach is expressed in Theorem 3.6, which states that the frequencies achieved by "*ats*" policies depend only on their **pathwise** conditional frequencies. This implies (Theorem 3.7) that completeness can be achieved within subclasses other than stationaries: for example, using deterministic, nonstationary policies.

Fix $\alpha := \{\alpha_y^a, y \in \mathbf{X}, a \in A(y)\}$, where $\alpha_y^a \geqq 0$, and $\sum_{a \in A(y)} \alpha_y^a = 1$ for each $y \in \mathbf{X}$.

DEFINITION. A policy u is an "action time sharing" (*ats*) policy with parameter α, and is denoted as $\hat{\alpha}$ if for every state y that is visited infinitely often P^u almost surely and any action a,

$$f^T(a \mid y) \to \alpha_y^a \quad \text{as } T \to \infty \quad P^u \text{ a.s.}$$

Thus an *ats* policy $\hat{\alpha}$ alternates between several actions at each state so as to achieve a prescribed (state dependent) limiting relative frequency for each action. There are no restrictions as to how the limiting frequencies $f^T(a \mid y)$, are achieved, and there are many ways such a policy can be realized.

A realization of an *ats* policy with parameter α is a mapping h from the space S_α of all possible collections α to the space of all policies U. Given such a mapping h, let $U^h(ats) := h(S_\alpha)$ denote the subclass of *ats* policies of the form $\hat{\alpha} = h(\alpha)$ for some $\alpha \in S_\alpha$. For example, setting $p_{a|y} = \alpha_y^a$ defines a stationary policy, where $p_{a|y}$ are the conditional distributions. We thus recover the class of stationary policies, where the realization is by randomly choosing the actions using unfair dice. Another possible realization of *ats* policies is through the use of a counter for each $y \in \mathbf{X}$, $a \in A(y)$. We then choose in a *deterministic way* which action to use for every state, so that the appropriate conditional frequencies are achieved.

The main result of this section, Theorem 3.7, states that under (A1) and (A2), $U^h(ats)$ is complete for any h (see the definition of completeness in § 1). Moreover, the frequencies $\bar{f}_{x,\hat{\alpha}}(y, a)$ depend only on the parameter α, and not on the realization $\hat{\alpha} = h(\alpha)$ (Theorem 3.6). We proceed to investigate the completeness of stationary policies, and will then turn to *ats* policies. But first we need a technical lemma.

LEMMA 3.1. *Under* (A1) *for any transition matrix* P^g, $g \in U(S)$ *there exists a measure* π *such that*

$$\pi(y) \geqq \sum_{z \in \mathbf{X}} \pi(z)[P^g]_{zy}. \tag{3.1}$$

The measure π *is finite, is unique up to a multiplicative constant, and in fact* $\pi(y) = \sum_{z \in \mathbf{X}} \pi(z)[P^g]_{zy}$.

Remark. This result is well known when there are no transient states (see, e.g., [27, Thm. 1.10, p. 67]).

Proof. Existence. Let R and T denote the recurrent and transient classes under g. By Theorem 1.10 of [27, p. 67], there exists a finite measure $\tilde{\pi}$, unique up to a multiplicative constant, such that

$$\tilde{\pi}(y) = \sum_{z \in R} \tilde{\pi}(z)[P^g]_{zy}.$$

Define the measure π on $\mathbf{X}$ by $\pi(y) = \tilde{\pi}(y)$ for $y \in R$ and $\pi(y) = 0$ otherwise. Then it is easy to check that π solves (3.1), in fact with equality. To prove uniqueness, let π be a solution of (3.1). Iterating (3.1), we obtain for every $n > 0$

$$\pi(y) \geqq \sum_{z \in \mathbf{X}} \pi(z)[(P^g)^n]_{zy} \geqq \sum_{z \in R} \pi(z)[(P^g)^n]_{zy}. \tag{3.2}$$

Again, by Theorem 1.10 of [27, p. 67], there exists $\{\pi(y), y\in R\}$, unique up to a multiplicative constant and independent of n, such that for all $y\in R$, $\pi(y)=\sum_{z\in R}\pi(z)[(P^g)^n]_{zy}$. But this and (3.2) imply that π satisfies $\sum_{z\in T}\pi(z)[(P^g)^n]_{zy}=0$ for all $y\in R$ and all n. Fix some $y\in R$; by (A1), for each $z\in T$ there exists a finite n such that $[(P^g)^n]_{zy}>0$. Thus we conclude $\pi(z)=0$ and the uniqueness is established. □

THEOREM 3.2. *Under* (A1) *the class of stationary policies is weakly complete.*

Proof. First note that $\bar{F}_{x,g}$ is a singleton for any stationary policy g. This follows from the existence of a unique stationary probability, under (A1). Pick any frequency matrix $\zeta\in L_x$ that is achieved, say, by a policy $u\in U$. To establish the theorem we need to show that whenever $\{\bar{f}^t_{x,u}\}_t$ is tight, there exists a policy $g\in U(S)$ so that $\bar{f}_{x,g}=\zeta$. Thus let u be a policy such that $\{\bar{f}^t_{x,u}\}_t$ is tight. Let $\{t_n\}_n$ be an increasing sequence of times (chosen by diagonalization) along which $\lim_{n\to\infty}\bar{f}^{t_n}_{x,u}(y,a):=\bar{f}_{x,u}(y,a)=\zeta(y,a)$ and $\lim_{n\to\infty}\bar{f}^{t_n}_{x,u}(y):=\bar{f}_{x,u}(y)$ exist for all y and $a\in A(y)$. Note that for each y,

$$\bar{f}_{x,u}(y)=\lim_{n\to\infty}\bar{f}^{t_n}_{x,u}(y)=\lim_{n\to\infty}\sum_{a\in A(y)}\bar{f}^{t_n}_{x,u}(y,a) \tag{3.3}$$

and by tightness and the convergence $\bar{f}^{t_n}_{x,u}(y,a)\to\bar{f}_{x,u}(y,a)$, the probability measures $\bar{f}^{t_n}_{x,u}$, $n=1,2,\cdots$ converge weakly (see the Portmanteau theorem in [8]), so that

$$\bar{f}_{x,u}(y)=\lim_{n\to\infty}\sum_{a\in A(y)}\bar{f}^{t_n}_{x,u}(y,a)=\sum_{a\in A(y)}\lim_{n\to\infty}\bar{f}^{t_n}_{x,u}(y,a)=\sum_{a\in A(y)}\bar{f}_{x,u}(y,a). \tag{3.4}$$

Set $\beta^a_y:=\bar{f}_{x,u}(y,a)[\bar{f}_{x,u}(y)]^{-1}$ whenever $\bar{f}_{x,u}(y)\neq 0$. If $\bar{f}_{x,u}(y)=0$ then the β^a_y are chosen arbitrarily but such that $0\leqq\beta^a_y\leqq 1$ for all a, and $\sum_{a\in A(y)}\beta^a_y=1$. By (3.4), $\sum_{a\in A(y)}\beta^a_y=1$ for every y. Define the stationary policy g by $p^g_{a|y}=\beta^a_y$. Then

$$P^g_{xy}=\sum_{a\in A(x)}\beta^a_x P_{xay}. \tag{3.5}$$

Since for every $s>1$ we have $P^u_x\{X_s=y\}=\sum_{z,a}P^u_x\{X_{s-1}=z, A_{s-1}=a\}P_{zay}$, we get after some algebra

$$\bar{f}^t_{x,u}(y)-\frac{1}{t}P^u_x\{X_1=y\}=\sum_{z,a}\bar{f}^t_{x,u}(z,a)P_{zay}-\frac{1}{t}\sum_{z,a}P^u_x\{X_t=z, A_t=a\}P_{zay}. \tag{3.6}$$

Since the left side of (3.6) converges along the sequence t_n to $\bar{f}_{x,u}(y)$, so does the right. Fix y and consider P_{zay} as a σ-finite measure on $\mathbf{X}\times\mathbf{A}$. Applying Fatou's lemma we obtain using (3.6)

$$\bar{f}_{x,u}(y)=\lim_{n\to\infty}\sum_{z,a}\bar{f}^{t_n}_{x,u}(z,a)P_{zay}\geqq\sum_{z,a}\bar{f}_{x,u}(z,a)P_{zay} \tag{3.7}$$

since the last term in (3.6) is bounded by t^{-1}. From (3.5), (3.7) and from the definition of β^a_y we obtain

$$\bar{f}_{x,u}(y)\geqq\sum_z\bar{f}_{x,u}(z)\cdot P^g_{zy}. \tag{3.8}$$

From (3.8) we conclude that $\bar{f}_{x,u}(\cdot)$ is an excessive measure with respect to the transition matrix P^g. It follows from (3.4) that $\{\bar{f}^{t_n}_{x,u}(\cdot)\}_{t_n}$ are tight, and hence $\bar{f}_{x,u}(\cdot)$ is in fact a probability measure. But under (A1), Lemma 3.1 implies that $\bar{f}_{x,u}=\pi^g$. Using the definition of β and g this finally implies that

$$\zeta(y,a)=\bar{f}_{x,u}(y,a)=\bar{f}_{x,u}(y)\cdot\beta^a_y=\pi^g(y)p^g_{a|y}=\bar{f}_{x,g}(y,a) \tag{3.9}$$

by Lemma 1.1. □

From Theorem 3.2 we immediately obtain Corollary 3.3.

COROLLARY 3.3. *Under* (A1) *and* (A2) *the class of stationary policies is complete.*

Combining this with the theorems of § 2 we thus conclude that, under the relevant assumptions, the stationary policies are sufficient for problems OP and COP.

Assumption (A2) is used to guarantee that $\sum_{y,a} \bar{f}_{x,u}(y, a) = 1$ and that $\sum_{a \in A(y)} \beta_y^a = 1$ for every y. Assumption (A0) guarantees the latter; note that it does not imply that $\mathbf{A}$ is finite.

COROLLARY 3.4. *Under* (A1) *and* (A0), *for every policy u and a matrix $\bar{f}_{x,u}(\cdot, \cdot)$, there exists a stationary policy g and a constant $0 \leqq \delta \leqq 1$ such that $\bar{f}_{x,u}(y, a) = \delta \cdot \bar{f}_{x,g}(y, a)$, $y \in \mathbf{X}$, $a \in A(y)$. Under* (A2), $\delta = 1$.

Proof. Following the proof of Theorem 3.2, observe that $\bar{f}_{x,u}(\cdot)$ is an excessive measure due to (3.8) and is thus, by Lemma 3.1, proportional to π^g. But $\bar{f}_{x,u}(\cdot, \cdot)$ is clearly a subprobability measure, i.e., $\sum_{y,a} \bar{f}_{x,u}(y, a) \leqq 1$. Thus by the argument of (3.9), $\bar{f}_{x,u}(y, a) = \delta \cdot \bar{f}_{x,g}(y, a)$, $y \in \mathbf{X}$, $a \in A(y)$. If (A2) holds then it is a probability measure, and $\delta = 1$ by Theorem 3.2. □

Remark. If under every $u \in U(SD)$ there are no transient states then δ in Corollary 3.4 is always strictly positive; moreover, $\bar{f}_{x,u}(y) > \varepsilon(y)$ uniformly in $u \in U$ (see, e.g., [18]).

Before we show that $\bar{f}_{x,\hat{\alpha}}$ depends only on α, we present a simple example that demonstrates the importance of (A2), and shows that a condition such as (A0) is necessary for (A2).

Counterexample 3.5. Countable action space. Consider problem OP with $\mathbf{X} = \{x\}$ and $\mathbf{A} = \{1, 2, \cdots\}$, and let $c(x, a) = 1 + a^{-1}$. Clearly, $X_t = x$ for all t. Under any stationary policy g, $\bar{C}_x(g) > 1$ and $\sum_{a \in A(x)} \bar{f}_{x,g}(x, a) = \bar{f}_{x,g}(x) = 1$. Let u be the nonstationary policy that chooses action $a = t$ at time t. Clearly, we have $\bar{C}_x(u) = 1$, $\bar{f}_{x,u}(x, a) = 0$, $\bar{f}_{x,u}(x) = 1$.

This example demonstrates that even under the unichain assumption, the expected state-action frequencies may not be tight while the expected state frequencies are, and the average expected cost is not necessarily a function of the expected state action frequencies. Moreover, the stationary policies are not complete, and due to the noncompactness of the action space, the cost achieved by some nonstationary policy can be strictly smaller than the cost of any stationary policy. This is in contrast with the case of finite state and action spaces (see Derman [15]).

A counterexample where both (A1) and (A0) hold yet (A2) is not satisfied is presented in Fisher and Ross [17]. They show that indeed without (A2) the stationary policies may be incomplete.

THEOREM 3.6. *Under* (A1) *and* (A2), *$\bar{F}_{x,\hat{\alpha}} = \{\bar{f}_{x,\hat{\alpha}}\}$ is a singleton. Moreover, $\bar{f}_{x,\hat{\alpha}}$ depends only on α and is independent of the realization h.*

Proof. Let $v = \hat{\alpha} = h(\alpha)$ be some *ats* policy with parameter α. Define the stationary policy g by $p^g_{a|y} = \alpha_y^a$. By the strong law of large numbers, g is also an *ats* policy with parameter α. The proof is concluded by showing that $\bar{f}_{x,v}(y, a) = \bar{f}_{x,g}(y, a)$. Since the initial state is fixed, we suppress it in the notation of P and E. Let

$$M_t := \sum_{s=2}^{t} 1\{X_s = y\} - \sum_{s=2}^{t} \sum_{x,a} 1\{X_{s-1} = x, A_{s-1} = a\} P_{xay}.$$

Then for any u, M_t is a P^u martingale and by the stability theorem (e.g., [20, Thm. 2.22])

$$\text{(3.10)} \qquad \lim_{t \to \infty} \frac{1}{t} \left[\sum_{s=2}^{t} 1\{X_s = y\} - \sum_{s=2}^{t} \sum_{x,a} 1\{X_{s-1} = x, A_{s-1} = a\} P_{xay} \right] = 0 \quad P^u \text{ a.s.}$$

Let N be the P^v-null set of ω for which either (3.10) or the convergence in the definition of the *ats* policy v do not hold. Fix $\omega \in \Omega - N$ and an arbitrary increasing sequence of times t_n. Using diagonalization, construct a subsequence s_n to t_n along which for all y and a, $f^{s_n}(y, a)$, $f^{s_n}(y)$ and $f^{s_n}(a|y)$ converge to some limits $f(y, a)$, $f(y)$, and

$f(a\,|\,y)$, respectively. Note that from the definition of the *ats* policy v it follows that $f(y)=\sum_a f(y,a)$ P^v almost surely. For that ω we have from (3.10) for all $y\in\mathbf{X}$:

$$f(y)=\lim_{n\to\infty}\sum_{x,a} f^{(s_n-1)}(x,a)P_{xay}. \tag{3.11}$$

An argument as in (3.7) and (3.8) implies

$$f(y)\geqq\sum_{x,a} f(x,a)P_{xay}. \tag{3.12}$$

From the definition of the *ats* policy v it is easy to see that

$$\alpha_x^a f(x)=f(a\,|\,x)f(x)=f(x,a). \tag{3.13}$$

From (3.12) and (3.13) we obtain, since all terms are nonnegative

$$f(y)\geqq\sum_{x\in\mathbf{X}} f(x)\left[\sum_{a\in A(x)}\alpha_x^a P_{xay}\right]=\sum_{x\in\mathbf{X}} f(x)P_{xy}^g. \tag{3.14}$$

Using the same argument that followed the proof of Corollary 3.4 we obtain for all $y\in\mathbf{X}$:

$$f(y)=\delta(\omega,\{s_n\})\cdot\pi_y^g \tag{3.15}$$

for some constant δ satisfying $0\leqq\delta\leqq 1$. Thus, for all y, z in $\mathbf{X}$,

$$\lim_n\,[f^{s_n}(y)\pi^g(z)-f^{s_n}(z)\pi^g(y)]=0.$$

Since the sequence $\{t_n\}_n$ was arbitrary, we conclude that in fact

$$\lim_t\,[f^t(y)\pi^g(z)-f^t(z)\pi^g(y)]=0$$

and this holds for P^v almost surely. But by the bounded convergence theorem,

$$\lim_t\,[E_v f^t(y)\pi^g(z)-E_v f^t(z)\pi^g(y)]=\lim_t\,[\bar f^t_{x,v}(y)\pi^g(z)-\bar f^t_{x,v}(z)\pi^g(y)]=0.$$

By assumption $\{\bar f^t_{x,v}\}_t$ is tight. Fix any subsequence $\{r_n\}_n$ such that $\bar f^{r_n}_{x,v}\to\bar f_{x,v}$. Then $\bar f_{x,v}(y)\pi^g(z)=\bar f_{x,v}(z)\pi^g(y)$. However, the only probability measure that solves this equation is $\bar f_{x,v}=\pi^g$, and we conclude that $\bar f^t_{x,v}\to\pi^g$. From the definition of the *ats* policy v and the bounded convergence theorem, we have

$$\overline{\lim_{t\to\infty}}\,E_v|\alpha_y^a-f^t(y,a)[f^t(y)]^{-1}|=0.$$

Thus, using the bounded convergence theorem and the tightness (A2),

$$\lim_{t\to\infty}\bar f^t_{x,v}(y,a)=\lim_{t\to\infty}E_v f^t(y)\cdot\frac{f^t(y,a)}{f^t(y)}=\lim_{t\to\infty}\bar f^t_{x,v}(y)\cdot\alpha_y^a=\alpha_y^a\pi^g(y) \tag{3.16}$$

for all a, y. Finally, Lemma 1.1 implies $\bar f_{x,g}(y,a)=\alpha_y^a\cdot\pi^g(y)=\bar f_{x,v}(y,a)$. Since π^g depends only on α and not on $\hat\alpha$ this concludes the proof. □

Combining Theorem 3.2 and Theorem 3.6 it follows that the completeness is determined by the α only, so that complete classes can be easily generated.

THEOREM 3.7. *Under* (A1) *and* (A2), *for any realization* $h:S_\alpha\to U$, $U^h(ats)$ *is complete.*

4. Tightness. The issue of tightness for Markov decision processes has been investigated extensively. It is easy to see that, in general, unless the sets $A(x)$ are finite (compact), (A2) need not hold. In the compact case, Lemma 4.1 provides a simple sufficient condition for (A2). We describe briefly several approaches that provide sufficient conditions for tightness in this compact case (i.e., under (A0)).

If compactness of the actions is not assumed, we can usually construct a policy u for which (A2(u)) does not hold, so that (A2) will not hold. However, since the tightness appears in connection with the optimization problems, we derive conditions on the cost functions that guarantee that the search for optimal policy can be restricted to policies satisfying (A2(u)). This extends the results of §§ 2.2 and 2.3 to cases where (A2) does not hold.

LEMMA 4.1. *Under* (A0) *and* (A1), (A2) *implies* (A2*). *If in addition there are no transient states, then* A2 *is equivalent to* (A2*).

Proof. It is shown in the proof of Lemma 7.3 of [10] that, under (A0) and (A1) and when there are no transient states, (A2*) implies that for each state x and policy u the expected frequencies $\{\bar f^t_{x,u}(y)\}_t$ are tight. To see that the converse holds, assume (A0) and (A1) and let g_i be a sequence of policies in $U(SD)$ such that the sequence of corresponding invariant distributions π_i is not tight. Clearly, $\bar f^t_{x,g_i}(y)\rightarrow\pi_i(y)$ for all x, y. Thus we can find an increasing sequence $\{t_i\}$ and construct a policy u where $u_t(\cdot\,|\,H_{t-1},X_t)=g_i(x_t)$ for $t_i<t\leqq t_{i+1}$ such that $\bar f^{t_i}_{x,u}\rightarrow\bar f_{x,u}$, and $\sum_y\bar f_{x,u}(y)<1$. Thus it suffices to show that $\{\bar f^t_{x,u}(y)\}_t$ is tight if and only if $\{\bar f^t_{x,u}(y,a)\}_t$ is tight.

By definition, $\{\bar f^t_{x,u}(y)\}_t$ is tight if and only if for any $\varepsilon>0$ there exists a compact (finite) set $K(\varepsilon)\subset\mathbf{X}$ such that $\sum_{y\in K(\varepsilon)}\bar f^t_{x,u}(y)>1-\varepsilon$, and similarly for $\{\bar f^t_{x,u}(y,a)\}_t$. Given $K(\varepsilon)$, let $K'(\varepsilon):=\{(y,a)\colon y\in K(\varepsilon),\,a\in A(y)\}$. Then $K'(\varepsilon)$ is compact and since

$$\bar f^t_{x,u}(y)=\sum_{a\in A(y)}\bar f^t_{x,u}(y,a) \tag{4.1}$$

we have $\sum_{(y,a)\in K'(\varepsilon)}\bar f^t_{x,u}(y,a)=\sum_{(y)\in K(\varepsilon)}\bar f^t_{x,u}(y)>1-\varepsilon$. To prove the converse, given $K'(\varepsilon)\subset\mathbf{X}\times\mathbf{A}$ let $K(\varepsilon):=\{y\colon(y,a)\in K'(\varepsilon)$ for *some* $a\in A(y)\}$. The same argument now concludes the proof. □

Assumption (A2*) is quite common in the literature on controlled Markov chains with a countable state space, and sufficient conditions are available. Borkar [10, § III] shows that (A2*) is equivalent to the time between visits to some recurrent state being uniformly integrable under all $u\in U(SD)$. The whole § IX in [10] is then devoted to different sufficient conditions for that uniform integrability. Hordijk [21] presents several sufficient conditions for (A2*), in terms of the measures $P^g_{x,K}:=\sum_{y\in K}P^g_{xy}$;

(i) The set of probability measures $\{P(X_2=\cdot\,|\,X_1=x)\colon x\in\mathbf{X},\,g\in U(S)\}$ is tight [21, Lemma 10.3, § 10].

(ii) Given any $\varepsilon>0$ there exist a finite set $K(\varepsilon)$ and an integer $N(\varepsilon)$ such that for all $x\in\mathbf{X}$ and $g\in U(S)$,

$$[(P^g)^{N(\varepsilon)}]_{x,K(\varepsilon)}\geqq 1-\varepsilon.$$

(iii) The simultaneous Doeblin condition. There exist a finite set K, a positive integer n, and a positive real number c such that $[P^g]^n_{x,K}\geqq c$ for all $x\in\mathbf{X}$ and all $g\in U(S)$ [21, § 11.1].

Two other assumptions that are equivalent to (iii) above (and are thus sufficient for (A2*)) are presented in Theorem 11.3 of [21]. To formulate these conditions, denote

$${}_AP^{g,t}_{x,B}:=P^g\{X_t\in B,\,X_s\notin A,\,1<s<t\,|\,X_1=x\},\qquad m_g(x,A):=\sum_{t=2}^{\infty}{}_AP^{g,t}_{x,\mathbf{X}}.$$

(iv) There exist a finite set K, $c>0$, and n such that $\sum_{s=2}^{n}{}_KP^{g,s}_{x,K}\geqq c$ for all $x\in\mathbf{X}$ and $g\in U(S)$.

(v) There exist a finite set K and a real number b such that for all $x\in\mathbf{X}$ and $g\in U(S)$, $m_g(x,K)\leqq b$.

In the absence of tightness, it may be possible to restrict the optimization problem to a subclass of policies under which tightness holds, if the structure of the costs makes it unprofitable to use nontight policies (see also Borkar [10]).

LEMMA 4.2. *Assume there exists a sequence of increasing compact (i.e., finite) subsets* K_i *of* $\mathbf{X}\times\mathbf{A}$ *such that* $\bigcup_i K_i=\mathbf{X}\times\mathbf{A}$, *and such that the cost function* $c(y, a)$ *satisfies*

$$\liminf_{i\to\infty}\{c(y, a);\ (y, a)\notin K_i\}=\infty. \tag{4.2}$$

Then for any policy u *such that* $\bar{C}_x(u)<\infty$ (*or* $\underline{C}_x(u)<\infty$), *the frequencies* $\{\bar{f}^{t}_{x,u}(\cdot,\cdot)\}_t$ *are tight.*

Proof. By (4.2), $c(x, a)$ is bounded below, say by B. Assume $\{\bar{f}^{t}_{x,u}(\cdot,\cdot)\}$ is not tight. Then there exists some $\varepsilon>0$ and an increasing sequence $\{t_l\}$ such that $\sum_{(y,a)\notin K_l}\bar{f}^{t_l}_{x,u}(y, a)>\varepsilon$. Let $c_j:=\inf\{c(y, a);\ (y, a)\notin K_j\}$. Clearly, $\bar{C}^{t_l}_x(u)\geqq c_j\varepsilon-|B|$. But by (4.2) $\lim_{j\to\infty}c_j=\infty$, and hence $\bar{C}_x(u)=\infty$, contradicting the hypotheses. The proof using $\underline{C}$ is identical. □

A complete class of policies (or even a weakly complete class of policies) may thus be sufficient even when the tightness assumption (A2) does not hold.

THEOREM 4.3. *Assume* (A1) *and consider the problem of minimizing* $\bar{C}_x(u)$. *Let* U' *be a weakly complete class such that* (2.4) *holds for each* $v\in U'$. *If* $c(\cdot,\cdot)$ *satisfies the conditions of Lemma* 4.2, *then* U' *is sufficient for* OP.

Note that the stationary policies are in fact weakly complete (Corollary 3.4) and, under (A3(g)), satisfy (2.4).

Proof. From Lemma 4.2 we conclude that if $\{\bar{f}^{t}_{x,u}\}_t$ is not tight (so that for some limit point $\sum_{y,a}\bar{f}_{x,u}(y, a)<1$), then necessarily $C_x(u)=\infty$. Thus we may limit the optimization to policies u for which $\{\bar{f}^{t}_{x,u}\}_t$ is tight, so that $\sum_{y,a}\bar{f}_{x,u}(y, a)=1$. By (4.2) $c(\cdot,\cdot)$ is bounded from below, and hence by Corollary 2.5 U' is sufficient. □

Similarly for the constrained problem COP, we may relax (A2) in Theorem 2.8.

THEOREM 4.4. *Assume* (A1) *and consider problem* COP. *Let* U' *be a weakly complete class such that* (2.4) *holds for each* $v\in U'$. *If either* $c(\cdot,\cdot)$ *or* $d^k(\cdot,\cdot)$, *some* k *satisfies the conditions of Lemma* 4.2, *then* U' *is sufficient for* COP.

Proof. The proof is similar to that of Theorem 4.3. □

Next we present another method that provides conditions for sufficiency in cases that the tightness does not hold. It is a generalization of conditions that Borkar [9] introduced for the case of instantaneous cost that depends only on the state. Following [9], $c(\cdot,\cdot)$ is said to be "V-almost monotone" if there exists a collection of compact sets $\{K_i\}_i$ as in Lemma 4.2 such that $\liminf_{i\to\infty}\{c(y, a);\ (y, a)\notin K_i\}\geqq V$.

LEMMA 4.5. *Assume* (A0) *and* (A1) *and let* U' *be a weakly complete class of policies such that every* $u\in U'$ *satisfies* (2.4). *If* $c(\cdot,\cdot)$ *is V-almost monotone and* $C_x(u')\leqq V$, *some* $u'\in U'$, *then* U' *is sufficient for* OP.

Proof. Note that $c(\cdot,\cdot)$ is bounded below. Consider first the minimization of $\bar{C}_x$, fix an arbitrary v, and note that if $C_x(v)\geqq V$ then we are done. Thus assume $C_x(v)<V$ and let t_n be a subsequence such that $C_x(v)=\lim_{n\to\infty}\sum_{y,a}\bar{f}^{t_n}_{x,v}(y, a)c(y, a)$ and $\bar{f}^{t_n}_{x,v}$ converges to some $\bar{f}_{x,v}$. By Corollary 3.4, there exists a $g\in U(S)$ such that $\delta\bar{f}_{x,g}=\bar{f}_{x,v}$ for some $0\leqq\delta\leqq 1$. By completeness there exists a $u\in U'$ such that $\delta\bar{f}_{x,u}=\bar{f}_{x,v}$. Let ε_i be such that $\inf\{c(y, a);\ (y, a)\notin K_i\}\geqq V-\varepsilon_i$. For every i we have

$$\begin{aligned} C_x(v) &= \lim_{n\to\infty}\left[\sum_{(y,a)\in K_i}\bar{f}^{t_n}_{x,v}(y, a)c(y, a)+\sum_{(y,a)\notin K_i}\bar{f}^{t_n}_{x,v}(y, a)c(y, a)\right] \\ &\geqq \sum_{(y,a)\in K_i}\bar{f}_{x,v}(y, a)c(y, a)+\underline{\lim}_{n\to\infty}\sum_{(y,a)\notin K_i}\bar{f}^{t_n}_{x,v}(y, a)c(y, a), \end{aligned}$$

$$\underline{\lim}_{n\to\infty} \sum_{(y,a)\notin K_i} \bar{f}^{t_n}_{x,v}(y,a)c(y,a) \geqq (V-\varepsilon_i) \underline{\lim}_{n\to\infty} \sum_{(y,a)\notin K_i} \bar{f}^{t_n}_{x,v}(y,a)$$

$$= (V-\varepsilon_i) \underline{\lim}_{n\to\infty} \left[1 - \sum_{(y,a)\in K_i} \bar{f}^{t_n}_{x,v}(y,a)\right].$$

Using the fact that each term on the right converges to $\bar{f}_{x,v}(y,a)$ and that $\bar{f}_{x,v} = \delta \bar{f}_{x,u}$, we get

$$C_x(v) \geqq \delta \sum_{(y,a)\in K_i} \bar{f}_{x,u}(y,a)c(y,a) + (V-\varepsilon_i)\left[1 - \delta \sum_{(y,a)\in K_i} \bar{f}_{x,u}(y,a)\right].$$

By taking $i\to\infty$ we obtain $C_x(v) \geqq \delta C_x(u) + V(1-\delta)$ or $\delta C_x(v) \geqq \delta C_x(u) + (1-\delta)\times (V - C_x(v))$. Since the last term is positive, $C_x(v) \geqq C_x(u)$ that establishes the proof. The proof for $\underline{C}$ is identical. □

In the following lemma we apply the method of Lemma 4.5 in order to generalize Theorem 4.4.

LEMMA 4.6. *Assume* (A0) *and* (A1). *Let U' be a weakly complete class of policies such that every $u \in U'$ satisfies* (2.4) *for c and d^k, $1 \leqq k \leqq K$. Assume $c(\cdot,\cdot)$ is V_0-monotone and $d^k(\cdot,\cdot)$ is V_k-monotone, $1\leqq k \leqq K$. If there exists a policy $u' \in U'$ such that $C_x(u') \leqq V_0$ and $D^k_x(u') \leqq V_k$, $1 \leqq k \leqq K$, then U' is sufficient for* COP.

Proof. The proof is the same for both $\bar{C}$ and $\underline{C}$. Note that without loss of generality, we may take the sets K_i to be the same for all costs c and d^k. Fix $v \in U'$ and note that if $C_x(v) \geqq V_0$ or for some k $D^k_x(v) > V_k$ then we are done. Thus assume $D^k_x(v) \leqq V_k$ for $k = 1, \cdots, K$ and $C_x(v) \leqq V_0$. Choose a subsequence $\{t_n\}_n$ such that $C_x(v) = \lim_{n\to\infty} \sum_{y,a} \bar{f}^{t_n}_{x,v}(y,a)c(y,a)$ and such that $\lim_{n\to\infty} \sum_{y,a} \bar{f}^{t_n}_{x,v}(y,a)d^k(y,a)$, $1 \leqq k \leqq K$, and $\lim_{n\to\infty} \bar{f}^{t_n}_{x,v}$ exist. Then for $1 \leqq k \leqq K$, $D^k_x(v) \geqq \overline{\lim}_{n\to\infty} \sum_{y,a} \bar{f}^{t_n}_{x,v}(y,a)d^k(y,a)$ and by choosing u as in Lemma 4.5 we obtain by the same argument $\delta C_x(v) \geqq \delta C_x(u) + (1-\delta)(V_0 - C_x(v))$ and $\delta D^k_x(v) \geqq \delta D^k_x(u) + (1-\delta)(V_k - D^k_x(v))$. Hence $C_x(v) \geqq C_x(u)$ and $V_k \geqq D^k_x(v) \geqq D^k_x(u)$ that concludes the proof. □

5. Achievable frequencies. In this section we describe the geometry of L_x. For the case of finite state and action spaces Derman [15] has shown that under (A1), L_x is closed and convex, and its extreme points correspond to policies in $U(SD)$. In Theorem 5.1 we extend this result to the countable space. Let co B denote the convex hull of the set B, and $\overline{\text{co}}$ B, its closed convex hull. Let η be a function from the integers onto all pairs (x,a) and fix $0 < \mu < 1$. Define a metric d on the set of subprobability measures on $\mathbf{X}\times\mathbf{A}$.

$$d(\zeta_1,\zeta_2) := \sum_{j=1}^{\infty} |\zeta_1(\eta[j]) - \zeta_2(\eta[j])|\mu^j. \tag{5.1}$$

We will use henceforth the product topology induced by this metric. Throughout this section we assume that

(A1′) The state space forms a single *positive* recurrent class under any policy $g \in U(S)$.

To prove Theorem 5.1, we need to introduce PTS ("policy time sharing") policies [2]. A PTS policy is specified through the stationary policies u_i, $i = 1, 2, \cdots, l$, a state z, and by an l-dimensional vector parameter $\alpha = \{\alpha_1, \alpha_2, \cdots, \alpha_l\}$, where $\alpha_i \geqq 0$ and $\sum_i \alpha_i = 1$. Fix a state z that, due to (A1′) is positive recurrent under each u_i. Call the period between two consecutive visits to states z a cycle. A PTS policy v with parameter α is any policy that uses a fixed u_i during each cycle, and for which the relative number of cycles during which u_i is used converges to α_i, P^v almost surely, $i=1, 2, \cdots, l$. Such a policy is denoted $\hat{\alpha}$. It follows immediately from the results of [1] and [3] that for any initial state x, $\bar{F}_{x,\hat{\alpha}}$ is a singleton, and

$$\bar{f}_{x,\hat{\alpha}} = \sum_{i=1}^{l} \gamma_i(\alpha)\bar{f}_{x,u_i}, \tag{5.2}$$

where $\gamma_i = \alpha_i\tau_i[\sum_{j=1}^{l} \alpha_j\tau_j]^{-1}$ and τ_i is the mean recurrence time of state z under u_i.

THEOREM 5.1. *Under* (A1′) *and* (A2), $L_x = L_x(S)$ *is compact. Moreover,* $L_x = \mathrm{co}\,\{L_x(D)\} = \overline{\mathrm{co}}\,\{L_x(D)\}$.

Proof. By Corollary 3.3, $L_x(S) = L_x$. To prove compactness, let $\{\xi_n\}_n \subset L_x$. Using diagonalization, choose a subsequence $\{\xi_{n_i}\}_i$ that (for notational convenience) is denoted $\{\zeta_n\}_n$, such that $\zeta_n(x, a) \to \zeta(x, a)$ for some ζ, for all x, a. ζ_n may all be considered measures over $\mathbf{X} \times \mathbf{A}$, and $\zeta_n(x, a) \to \zeta(x, a)$, where ζ is (possibly subprobability) measure. Our aim is to find a policy u that achieves ζ. By (A2) this implies that ζ is a probability measure.

By Corollary 3.3 there exists a stationary policy g_i that achieves ζ_i. Let $\varepsilon_i := d(\zeta, \zeta_i)$, so that $\lim_{n\to\infty} \varepsilon_n = 0$. Consider the nonstationary policy u, that uses g_1 until the time $t_1 := \min\{t\colon d(\zeta_1, \bar{f}^{\,t}_{u,x}) \leqq \varepsilon_1\}$, and uses g_i until between t_{i-1} and $t_i := \min\{t > t_{i-1}\colon d(\zeta_i, \bar{f}^{\,t}_{u,x}) \leqq \varepsilon_i\}$. The fact that $t_n < \infty$ can be proved by induction using the following fact. Suppose the policy u uses g_n from time s onward, and let $\chi_s(z) = P^u(X_s = z \mid X_1 = x)$. Then

$$\bar{f}^{\,t}_{x,u}(y, a) = \frac{s}{t}\bar{f}^{\,s}_{x,u}(y, a) + p^{g_n}_{a|y}\frac{t-s}{t}\sum_{z\in\mathbf{X}} \chi_s(z)\left(\sum_{r=1}^{t-s} [P^{g_n}]^r_{zy}\right),$$

where P^{g_n} is the transition matrix under g_n. It then follows easily that $\lim_{t\to\infty} \bar{f}^{\,t}_{x,u}(y, a) = \zeta_n$.

Thus $d(\zeta, \bar{f}^{\,t_n}_{x,u}) \leqq d(\zeta, \zeta_n) + d(\zeta_n, \bar{f}^{\,t_n}_{x,u}) \leqq 2\varepsilon_n$ and we obtain along the subsequence $\{t_n\}_n$, $\bar{f}_{x,u} = \zeta$. By (A2) ζ is a probability measure, so that L_x is closed and sequentially compact, hence compact.

To prove the convexity, recall (the first part of the proof) that $L_x = L_x(S)$. Suppose $\zeta = \beta\bar{f}_{x,u_1} + (1-\beta)\bar{f}_{x,u_2}$ for u_1, $u_2 \in U(S)$. A PTS policy u such that $\bar{f}_{x,u} = \zeta$ is obtained by setting $\alpha_1 := (\beta/\tau_1)(\beta/\tau_1 + (1-\beta)/\tau_2)^{-1}$, and $\alpha_2 = 1 - \alpha_1$ (this follows from (5.2)).

Since L_x is compact and convex in $\mathbb{R}^\infty$, by the Krein–Milman theorem it is the convex hull of its extreme points. Next we show that all extreme points of L_x correspond to deterministic stationary policies. Let g bé a stationary nondeterministic policy. Then for some state $z \in \mathbf{X}$ and actions a_1 and a_2 in $A(z)$, the probability α_i to use action a_i under the policy g is strictly positive. Consider the stationary policies u_i that coincide with g in all states except for state z. In state z policy u_i uses action a_i with probability $\alpha_1 + \alpha_2$. Then according to (5.2), the PTS policy $\hat{\alpha}$ that switches in state z between u_1 and u_2 achieves $\bar{f}_{x,g} = \gamma\bar{f}_{x,u_1} + (1-\gamma)\bar{f}_{x,u_2}$. Therefore $\bar{f}_{x,g}$ is not an extreme point in L_x, and since for every policy u there is a $g \in U(S)$ with $\bar{f}_{x,u} = \bar{f}_{x,g}$ this concludes the proof. □

Theorem 5.1 enables us to strengthen theorem 2.6 as follows.

COROLLARY 5.2. *Assume* (A1′) *and* (A2) *under the uniform integrability assumption, or under the assumption that c is bounded from below, the class of deterministic policies is sufficient for problem* OP (*with C defined through either* (1.2a) *or* (1.2b)).

Proof. By Lemma 2.3, the cost of a stationary policies has the representation (2.4). An argument as in the proof of Theorem 5.1 then shows that the cost of any nondeterministic policy is a convex combination of the costs of two other stationary policies. □

Another conclusion from Theorem 5.1 is that under (A1′) and (A2) the state frequencies are bounded from below by a positive (state dependent) constant, uniformly in the policy.

COROLLARY 5.3. *Under* (A1′) *and* (A2), *for each* $y \in \mathbf{X}$ *there exists a constant* $\Delta(y) > 0$ *such that* $\bar{f}_{x,u}(y) > \Delta(y)$ *for all policies* $u \in U$.

Proof. Suppose the claim does not hold. Then there exists a sequence g_n of stationary policies and some state z such that $\lim_{n\to\infty} \bar{f}_{x,g_n}(z) = 0$. We can then construct a subsequence n_k along which $\lim_{n\to\infty} \bar{f}_{x,g_n}(y)$ exists for all $y \in \mathbf{X}$. Using Theorem 5.1 and (3.3), (3.4) there exists some stationary policy g achieving this limit, hence $\bar{f}_{x,g}(z) = 0$, which contradicts (A1). □

Remark. Fisher [18] showed that if the state space forms a single *positive* recurrent class when using any deterministic policy $g \in U(SD)$ then (A1′) holds. He then obtained the same result as in Corollary 5.3 using only the weaker condition (A0) instead of (A2).

Finally, we use Theorem 5.1 to strengthen Theorem 2.8. Theorem 2.8 states that we may restrict our search for optimal policy for COP to the stationary policies. But it does not say that an optimal policy exists. We show that this is indeed the case.

COROLLARY 5.4. *Consider problem* COP. *Assume* (A1′) *and* (A2) *and either*

(i) *Both* $c(y, a)$ *and* $d^k(y, a)$ *are bounded from below*; *or*

(ii) *Both* $c(y, a)$ *and* $d^k(y, a)$ *are uniformly integrable with respect to* $\{\bar{f}_{x,g}\}$, $g \in U(S)$.

If there is any feasible policy then there exists an optimal stationary policy.

Proof. According to Theorem 2.8 we may restrict to the stationary policies in searching for optimality. We first show that $C_x(\cdot)$ and $D_x^k(\cdot)$ are lower semicontinuous functions of the frequencies $\bar{f}_{x,g}$. Let $\{\zeta_n\}$ be a sequence of frequencies, achieved, say, by the stationary policies $\{g_n\}$ (i.e., $\zeta_n(\cdot,\cdot) = \bar{f}_{x,g_n}(\cdot,\cdot)$) converging to ζ. According to Theorem 5.1 there exists a stationary policy g such that $\zeta = \bar{f}_{x,g}$. Under (i) this implies by Fatou's lemma (using $c(\cdot,\cdot)$ as a measure) that the cost function $C_x(g)$ satisfies

$$\begin{aligned} C_x(g) &= \sum_{y,a} \zeta(y, a)c(x, a) = \sum_{y,a} \lim_{n\to\infty} \zeta_n(y, a)c(y, a) \\ &\leqq \lim_{n\to\infty} \sum_{y,a} \zeta_n(y, a)c(y, a) = \lim_{n\to\infty} C_x(g_n) \end{aligned} \tag{5.3}$$

and similarly

$$D_x^k(g) = \sum_{y,a} \lim_{n\to\infty} \zeta_n(y, a)d^k(y, a) \leqq \lim_{n\to\infty} D_x^k(g_n), \tag{5.4}$$

which establishes the lower semicontinuity for the case (i). If (ii) is assumed, then in fact we have continuity. To see that, note that the compactness of $L_x(S)$ (Theorem 5.1) implies by Prohorov's theorem that $\{\zeta_n\}$ are tight, hence converge weakly. As in the proof of Lemma 2.2, consider now $c(y, a)$ and $d^k(y, a)$ as "random variables" on the space $\mathbf{X} \times \mathbf{A}$. The weak convergence of $\{\zeta_n\}$ implies the convergence of $c(\cdot,\cdot)$ and $d^k(\cdot,\cdot)$ in distribution, and combining it with (ii) we obtain $C_x(g) = \lim_{n\to\infty} C_x(g_n)$ and $D_x^k(g) = \lim_{n\to\infty} C_x^k(g_n)$.

We thus have lower semicontinuity under either (i) or (ii). This implies that the set $\Pi_V := \{\mu\colon \mu \in L(S), D_x^k(\mu) \leqq V^k, 1 \leqq k \leqq K\}$ is compact, since it is obtained as the intersection of the compact set $L(S)$ and the inverse map of the closed sets $(-\infty, V_k]$. Finally, by the lower semicontinuity of $C_x(\cdot)$ on Π_V we conclude that $C_x(\cdot)$ achieves its minimum on Π_V, i.e. there exists an optimal stationary policy for COP. □

6. Application to a queueing system. In this section we apply Theorems 2.6 and 3.2 to investigate a constrained problem in the following discrete-time queueing model. At time t, M_t^k customers arrive to queue k, $1 \leqq k \leqq K$. Each input stream is received in an infinite capacity buffer. Arrival vectors $M_t = \{M_t^1, \cdots, M_t^K\}$ are independent from slot to slot, form a renewal sequence with finite means λ_k. During a time slot $(t, t+1)$ a customer from any class k, $1 \leqq k \leqq K$ may be served, according to some policy, which is a prespecified dynamic priority assignment. If served, with probability μ_k it completes its service and leaves the system; otherwise it remains in its queue. A generic element of the state is given by $x = \{x^1, x^2, \cdots, x^K\}$ and it represents a K-dimensional vector of the different queue sizes. Altman and Shwartz [1], [3] solve a problem with constraints on the average sizes of several queues. They find an optimal nonstationary time sharing policy, using a linear program. The recurrence properties of this system as well as bounds and representations for average cost functionals for general cost functions are obtained in Makowski and Shwartz [25].

Below we present conditions for the completeness of stationary policies , and the existence of optimal stationary policies for COP with several constraints. Sufficiency is proved for costs that are nonlinear in the queue sizes. We then solve the general constrained problem with linear costs (generalizing [1], [3], [26]). Throughout we restrict to nonidling policies; using coupling (as in [11]) it can be shown that when the costs are positive and increasing (in the number of customers), idling leads to no improvement.

6.1. Completeness and sufficiency of stationary policies. We first show that (A1) and (A2) hold. We assume the standard stability condition on the traffic intensity $\rho := \sum_{k=1}^K \lambda_k/\mu_k < 1$. This is a sufficient condition for (A1) (see [25] or [26]). In order to show that (A2) is satisfied, we use Lemma 4.2. Let $c(x, a) = \sum_{k=1}^K x^k/\mu_k$. The average cost is then finite and does not depend on the policy (this follows from the μc rule [5], [6], [11]). Therefore (with the obvious choice of K_i) all conditions of Lemma 4.2 are satisfied, and (A2) holds. Hence we obtain, using Theorem 2.8, Corollary 3.3, and Corollary 6.1.

COROLLARY 6.1. *Under the foregoing assumptions on the queueing model, the stationary policies are complete. If $c(x, a)$ and $d^k(x, a)$ are bounded below then the stationary policies are sufficient for* COP.

If $c(x, a)$ and $d^k(x, a)$ are not bounded from below then the stationary policies are still sufficient for COP, provided $\{c(X_s, A_s)\}_s$ and $\{d^k(X_s, A_s)\}_s$ are uniformly integrable with respect to P^u for each policy u (Theorem 2.8). In [25], Makowski and Shwartz give the following sufficient conditions (P1) and (P2) for the uniform integrability. For any K-dimensional vector x let $|x|$ denote $\sum_{k=1}^K |x^k|$:

(P1) There exists an integer $\gamma > 1$ such that $E[|M_t|^\gamma] < \infty$ and $E[|X_1|^\gamma] < \infty$.

Note that both expectations are independent of the policy.

(P2) There exist $0 < \delta < \gamma - 1$ and L such that $|c(x, a)| \leqq L(1 + |x|^\delta)$.

These results establish that the search for optimal, or ε-optimal policies may be restricted to the stationary policies. This allows the application of steady-state analysis, of the type used in queueing theory, to problems OP and COP.

6.2. Solving COP with linear cost functions. Consider the linear cost function $c(x, a) := \sum_{k=1}^K c_k x^k$ and $d^i(x, a) = \sum_{k=1}^K d_k^i x^k$ for $1 \leqq i \leqq M$, where c_k and d_k^i are nonnegative constants. This COP problem was solved in [1] and [3] for the case $M = 1$, and for the case $d_k^i = \delta_i(k)$ and $M < K$ using "PTS" policies over the set of $l = K!$ priority policies g_i. It is shown [1] and [3] that under the condition $\rho < 1$ and $E|X_1| < \infty$, all the τ_i (defined below (5.2)) are equal, and the cost under $\hat{\alpha}$ is given by

$$C_x(\hat{\alpha}) = \sum_{i=1}^{l} \alpha_i C(g_i) \qquad (6.1)$$

with a similar linear expression for $D_x^k(\hat{\alpha})$. Denote by $\hat{\beta}$ the optimal policy among all PTS policies for problem COP. From (6.1) it follows that $\hat{\beta}$ can be obtained by solving the following linear program:

$$(6.2)\quad \text{(LP)}\qquad \text{Find } \alpha \text{ that minimizes } \sum_{i=l}^{l} \alpha_i C(g_i)$$

$$\text{subject to } \sum_{i=1}^{l} \alpha_i D^k(g_i) \leqq V_k, \quad 1 \leqq k \leqq K, \quad \sum_{i=1}^{l} \alpha_i = 1, \quad \alpha_i \geqq 0$$

$$\text{for } 1 \leqq i \leqq l.$$

Based on Theorem 2.8(ii) we show in the following theorem that $\hat{\beta}$ is in fact overall optimal.

THEOREM 6.2. *The* PTS *policy obtained by solving* LP *is optimal for* COP.

Proof. Following [3] we define the average size of queue k by

$$(6.3)\qquad \bar{X}_x^k(u) := \overline{\lim_{t\to\infty}} \frac{1}{t} E_u\left[\sum_{s=1}^{t} X_t^k \,|\, X_1 = x\right].$$

Consider the class U' of all policies satisfying

$$(6.4)\qquad C_x(u) = \sum_{k=1}^{K} c_k \bar{X}_x^k(u) \quad \text{and} \quad D_x^j(u) = \sum_{k=1}^{K} d_k^j \bar{X}_x^k(u), \quad 1 \leqq j \leqq M.$$

Note that $U(S) \subset U'$ and $U(PTS) \subset U'$ (this is obtained by applying Lemma 2.3 to compute $\bar{X}_x^k(u)$). According to Theorem 2.8(ii) $U(S)$ is sufficient hence U' must be sufficient. Reference [3] shows that PTS policies are "Pareto optimal" in the following sense. For any policy u there exists a PTS policy w such that $\bar{X}_x^k(w) \leqq \bar{X}_x^k(u)$, $1 \leqq k \leqq K$. This implies that $\hat{\beta}$ is optimal over U', and since U' is sufficient, this implies that $\hat{\beta}$ is overall optimal. □

This result illustrates the usefulness of the present approach. There are several results reducing optimization problems for queues to computable problems (such as linear programs). However, the optimization is usually carried out over a class of policies that is smaller than U' above (e.g., in [19] the optimization is carried out over the class of "steady state" policies). Results on sufficiency then allow to conclude optimality over the class U of *all* policies.

7. Second application: a linear program formulation for COP. Below we present a linear program that we show to be equivalent to COP. Such linear programs have been introduced for the case of finite state and action spaces (e.g., Derman [15] and Hordijk and Kallenberg [22]). In the finite case these are the most important method to compute optimal policies for COP (an alternative linear program is described in [2]). We use a different approach by which we obtain a similar linear program for the countable case. Naturally, we cannot expect to find explicit solutions for COP using an infinite-dimensional linear program, but this approach can be used to shed some light on the structure of optimal solutions for COP. Consider the LP.

Find $\{z^*(y, a)\}_{y,a}$ that minimizes $C(z) := \sum_{y,a} c(y, a) z(y, a)$ subject to

$$(7.1a)\qquad \sum_{y,a} z(y, a) P_{yav} \leqq \sum_a z(v, a), \qquad v \in \mathbf{X},$$

$$(7.1b)\qquad \sum_{y,a} d^k(y, a) z(y, a) \leqq V_k, \qquad 1 \leqq k \leqq K,$$

$$(7.1c)\qquad \sum_{y,a} z(y, a) = 1, \qquad z(y, a) \geqq 0.$$

THEOREM 7.1. *Assume* (A1) *and* (A2) *and assume either that* (i) *c and* d^k *are bounded below, and* (A3(*g*)) *holds for all stationary g, with respect to both c and* d^k, $1 \leqq k \leqq K$, *or that* (ii) $\{c(X_s, A_s)\}_s$ *and* $\{d^k(X_s, A_s)\}_s$, $1 \leqq k \leqq K$ *are uniformly integrable under* P^u *for all* $u \in U$.

(i) *If the stationary policy w is feasible for* COP, *then* $\{z(y, a)\}$ *satisfies* (7.1), *where*

$$z(y, a) = \pi_y^w \cdot p_{a|y}^w. \tag{7.2}$$

(ii) *If g is an optimal stationary policy for* COP *then there exists an optimal solution for* LP *satisfying*

$$z^*(y, a) = \pi_y^g \cdot p_{a|y}^g. \tag{7.3}$$

(iii) *Conversely, let* $\{z(y, a)\}$ *satisfy* (7.1). *Then the policy w is feasible for* COP, *where*

$$p_{a|y}^w = \frac{z(y, a)}{\sum_{a \in A(y)} z(y, a)} \tag{7.4}$$

whenever the denominator is nonzero, and otherwise $p_{a|y}^w$ *are chosen arbitrarily but such that* $p_{\cdot|y}^w$ *is a probability measure.*

(iv) *If* z^* *solves* LP, *then the stationary policy g is optimal for* COP, *where*

$$p_{a|y}^g = \frac{z^*(y, a)}{\sum_{a \in A(y)} z^*(y, a)} \tag{7.5}$$

whenever the denominator is nonzero, and otherwise $p_{a|y}^g$ *are chosen arbitrarily but such that* $p_{\cdot|y}^g$ *is a probability measure.*

Proof. To prove (i) we note that $z(y, a)$ as defined in (7.2) satisfies (7.1c) since π^w and $p_{\cdot|y}^w$ are probability measures. Next we note that $z(a, y) = \bar{f}_{x,w}(a, y)$, thus (7.1b) is satisfied since its left side is equal to $D^k(g)$ by Lemma 2.3. Similarly, (7.1a) is satisfied since by definition π_y^w is invariant under the transition $P_{yv}^w = \sum_a P_{yav} p_{a|y}^w$.

To prove (iii), let $z(y) := \sum_{a \in A(y)} z(y, a)$ and substitute (7.4) in (7.1a) to obtain

$$z(y) \geqq \sum_{v \in \mathbf{X}} z(v) P_{vy}^w. \tag{7.6}$$

Following Lemma 3.1 and using (7.1c) we obtain $z(y) = \pi^w(y) = \bar{f}_{x,w}(y)$. By (7.4) and by the fact that $\bar{f}_{x,w}(y, a) = \bar{f}_{x,w}(y) \cdot p_{a|y}^w$ we obtain $z(y, a) = \pi^w(y) p_{a|y}^w = \bar{f}_{x,w}(y, a)$. It then follows by Lemma 2.3 and (7.1b) that $D^k(w) \leqq V_k$, $1 \leqq k \leqq K$, and therefore w is feasible for COP.

Parts (ii) and (iv) follow from the fact established above that (7.1) and (7.4) define a one-to-one correspondence between the z's that are feasible to LP and the stationary policies w's that are feasible to COP. Moreover, under this correspondence, it follows from Lemma 2.3 that the value $C(z)$ of LP is equal to $C_x(w)$, which establishes the proof. □

8. Extensions. In this section we outline some applications of our methods to lesser-known optimization criteria, involving variance minimization.

8.1. Variability sensitive optimization. The variability sensitive optimization problem VSOP was studied in the finite case by Filar, Kallenberg, and Lee [16] and later by Bayal-Gursoy and Ross [7];

$$\text{Maximize } R_x(u) := \varliminf_{t \to \infty} \frac{1}{t} \sum_{s=1}^{t} E_u[r(c(X_s, A_s), C_x^t(u))], \tag{8.1}$$

where $r(\cdot,\cdot)$ is called the variability function. Taking $r(x,y)=x-\lambda(x-y)^2$ the VSOP obtains the interpretation of finding a policy u that has high expected average reward but low expected variance. Other variability criteria and other variability functions are treated in the finite state-action space in [7] and [16].

In Theorem 8.1 we present conditions that ensure the sufficiency of classes of policies for problem VSOP. We will use $r(x,y)=x-\lambda(x-y)^2$. Note that when $\lambda=0$ this reduces to problem OP.

THEOREM 8.1. *Consider problem* VSOP. *Assume* (A1) *and* (A2) *and let U' be complete. If $\{c^2(X_s, A_s)\}_s$ is uniformly integrable with respect to P^u for each u, then U' is sufficient.*

Proof. First note that $R_x(u)$ is equal to

$$\underline{\lim}_{t\to\infty}\left[\sum_{y,a}\bar{f}^{\,t}_{x,u}(y,a)[c(y,a)-\lambda c^2(y,a)]+\lambda\left[\sum_{y,a}\bar{f}^{\,t}_{x,u}(y,a)c(y,a)\right]^2\right]. \tag{8.2}$$

Let t_n be any subsequence of t that achieves the $\underline{\lim}$ in the expression above, and along which $\bar{f}^{\,t_n}_{x,u}(y,a)\to\bar{f}_{x,u}(y,a)$ for all y and a. Following the same weak convergence arguments that were used in § 2.1, we obtain from the uniform integrability

$$R_x(u)=\sum_{y,a}\bar{f}_{x,u}(y,a)[c(y,a)-\lambda c^2(y,a)]+\lambda\left[\sum_{y,a}\bar{f}_{x,u}(y,a)c(y,a)\right]^2. \tag{8.3}$$

Thus $R_x(u)$ can be represented as a function of the expected state-action frequency, so completeness implies sufficiency. □

As a simple corollary, for bounded cost completeness implies sufficiency.

8.2. The problem with constraints. VSOP can also be considered in the framework of optimization under constraints. Kawai [23] introduced the problem of minimizing the variance of some cost subject to a single constraint on the expected average cost. He treats the case of finite state and action spaces, and restricting to the stationary policies he finds an optimal solution. Kurano [24] finds a policy that is optimal among the stationary deterministic policies for the same problem as Kawai yet with general state and action spaces.

Using similar arguments as above, we show below that any complete family of policies (e.g., the stationary policies) is sufficient for the problem of Kawai; hence the solution that Kawai finds is overall optimal. Moreover, using the same kind of assumptions as in Theorem 8.1 we show (using arguments as in the proof of Theorem 2.8) that these are sufficient for the case of countable state and action spaces, and for more than one constraint on expected average cost functionals.

Denote the variance under a policy u with initial state x by $R_x(u)$ through (8.1) with $r(x,y):=(x-y)^2$. Given K real numbers $V_1,\cdots,V_K$, define the following constrained problem:

$$\text{(CVSOP)}\qquad \text{minimize}\quad R_x(u)$$
$$\text{subject to}\quad \bar{D}^k_x(u)\leqq V_k,\qquad 1\leqq k\leqq K.$$

References [23] and [24] consider the case $V=V_1$ that is (ε) close to the supremum of the optimal expected average cost. The meaning of CVSOP is then to find a policy that minimizes the variance among all policies that are ε-optimal for OP.

THEOREM 8.2. *Consider problem* CVSOP. *Assume* (A1) *and* (A2) *and let U' be complete. If $\{c^2(X_s, A_s)\}_s$ and $\{d^k(X_s, A_s)\}_s$ $1\leqq k\leqq K$ are uniformly integrable with respect to P^u for each u, then U' is sufficient.*

Proof. The variance is given by

$$R_x(u)=\overline{\lim_{t\to\infty}}\left(\left[\sum_{y,a}\bar{f}^{t}_{x,u}(y,a)c(y,a)\right]^2-\sum_{y,a}\bar{f}^{t}_{x,u}(y,a)c^2(y,a)\right).$$

By diagonalization, there exists some subsequence t_n along which $\lim_{n\to\infty}\bar{f}^{t_n}_{x,u}(y,a)=\bar{f}_{x,u}(y,a)$ for all y and a, such that

$$R_x(u)=\left[\sum_{y,a}\bar{f}_{x,u}(y,a)c(y,a)\right]^2-\sum_{y,a}\bar{f}_{x,u}(y,a)c^2(y,a).$$

(similarly to the way (8.3) is obtained).

The rest of the proof now follows the same lines as the proof of Theorem 2.8. □

STABILIZABILITY OF TIME-PERIODIC PARABOLIC EQUATIONS*

ALESSANDRA LUNARDI†

Abstract. Second-order parabolic equations with time-periodic coefficients in $[0, +\infty[\times \Omega$($\Omega$ is a regular bounded domain in $\mathbf{R}^n$) are considered, with input acting either in the interior or on the boundary of Ω. Stabilizability results that are similar to some of the known results concerning the autonomous case are given. Abstract evolution equations techniques are employed.

Key words. asymptotic behavior, stabilizability, evolution operator in periodic parabolic problems

AMS(MOS) subject classifications. 35K20, 35B35, 34G10, 49E20, 93D20, 93D99

1. Introduction. We consider nonautonomous parabolic problems defined on a bounded domain Ω in $\mathbf{R}^n$ with regular boundary $\partial\Omega$ and exterior unit normal vector $\nu(x) = (\nu_1(x), \cdots, \nu_n(x))$:

$$\begin{aligned} &u_t(t,x) = \mathscr{A}(t,x,\partial)u(t,x) + \phi(t,x), \qquad t>0, \quad x\in\Omega,\\ &u(0,x) = u_0(x), \qquad x\in\Omega,\\ &\mathscr{B}(x,\partial)u(t,x) = 0, \qquad t>0, \quad x\in\partial\Omega, \end{aligned} \tag{1.1}$$

$$\begin{aligned} &v_t(t,x) = \mathscr{A}(t,x,\partial)v(t,x), \qquad t>0, \quad x\in\Omega,\\ &v(0,x) = v_0(x), \qquad x\in\Omega,\\ &\mathscr{B}(x,\partial)v(t,x) = \psi(t,x), \qquad t>0, \quad x\in\partial\Omega. \end{aligned} \tag{1.2}$$

Here $\mathscr{A}(t,x,\partial) = a_{ij}(t,x)D_{ij} + b_i(t,x)D_i + c(t,x)\mathbf{I}$ is any elliptic operator with smooth coefficients, T-periodic with respect to time, and $\mathscr{B}(x,\partial)$ is either the trace operator on $\partial\Omega$ or any mixed nontangential boundary operator with smooth coefficients: $\mathscr{B}(x,\partial)u = \beta_i(\cdot)D_iu + \gamma(\cdot)u$ (the summation convention is used throughout). The inputs ϕ, ψ are of the form

$$\phi(t,x) = (\Phi(t)f(t))(x), \qquad \psi(t,x) = (\Psi(t)g(t))(x), \tag{1.3}$$

where f, g have values in general Banach spaces Y, Z, respectively, and $\Phi(t)$, $\Psi(t)$ are linear T-periodic operators belonging to $L(Y, L^p(\Omega))$, $L(Z, L^p(\partial\Omega))$, respectively.

The stabilizability problem consists in finding sufficient conditions on the data in order that for each u_0, $v_0 \in L^p(\Omega)$ there are $f:[0,+\infty[\to Y$, $g:[0,+\infty[\to Z$ such that the solutions u, v of problems (1.1), (1.2) decay asymptotically to zero as $t\to+\infty$, in the strongest possible norm. Obviously, for such a problem to be significant, we assume that the free systems (with $f\equiv 0$, $g\equiv 0$) are not asymptotically stable.

Systems of the type (1.1), (1.2) arise in several fields, like heat conduction and diffusion problems (see, e.g., [23, Chaps. 3, 5]).

We work in a L^p space setting ($1<p<+\infty$) to avoid technical difficulties. However, since we employ an abstract evolution equations approach, other topologies could, in principle, be considered. In fact, our analysis is based on the representation formulas

for the solutions of (1.1), (1.2):

$$U(t,\cdot)=G(t,0)u_0+\int_0^t G(t,s)\phi(s,\cdot)\,ds,\qquad t\geqq 0, \tag{1.4}$$

$$v(t,\cdot)=G(t,0)v_0+\int_0^t G_s(t,s)H(s)\psi(s,\cdot)\,ds,\qquad t\geqq 0, \tag{1.5}$$

where $G(t,s)\in L(L^p(\Omega), W^{2,p}(\Omega))$ is the evolution operator of the free system, $G_s(t,s)=\partial/\partial s\; G(t,s)$ and $H(s)$ is either the Dirichlet mapping $D(s)$ or the mixed mapping $M(s)$ relevant to the elliptic operator $\mathcal{A}(s,\cdot,\partial)$, i.e., $H(s)g$ is the solution z of the problem

$$\mathcal{A}(s,\cdot,\partial)z\equiv 0\quad\text{in }\Omega,\qquad \mathcal{B}(\cdot,\partial)z=g\quad\text{in }\partial\Omega \tag{1.6}$$

(see [17] for formula (1.5)). Therefore, throughout the paper we consider a more general situation: we are given a couple of Banach spaces X, D (D being continuously embedded in X), and a family of generators of analytic semigroups $A(t): D\to X$ with $A(t+T)=A(t)$, such that there exists an evolution operator $G(t,s)$ for the linear problem $u'(t)=A(t)u(t)$.

In § 2 we state some asymptotic behavior properties (in the X-norm and in the D-norm) of the functions u, v defined in (1.4), (1.5). Such properties are consequences of results in [16] (where a Floquet theory for abstract parabolic equations has been developed) and [17] (where differentiability of $G(t,s)$ with respect to s has been shown, together with formula (1.5)). Floquet theory deals with asymptotic behavior of the evolution operator: as in ordinary differential equations, an essential role is played by the spectra of the linear operators

$$V(s)=G(s+T,s),\qquad s\in\mathbf{R}. \tag{1.7}$$

In particular, in our examples (1.1), (1.2), the free systems are not asymptotically stable if and only if some eigenvalues of $V(s)$ have modulus greater or equal to one (we recall that the nonzero eigenvalues of $V(s)$ are independent of s, whereas the corresponding eigenvectors may depend explicitly on s).

In § 3 we study stabilizability of abstract parabolic equations:

$$u'(t)=A(t)u(t)+\Phi(t)f(t),\qquad t>0;\quad u(0)=u_0, \tag{1.8}$$

where $\Phi(t)\in L(Y,X)$ and $\Phi(t+T)=\Phi(t)$, Y being any Banach space. We find a stabilizability result that generalizes the well-known results concerning ordinary differential equations (see [11]). Precisely, we fix $\omega\geqq 0$ such that no element of the spectrum of $V(s)$ has modulus $e^{-\omega T}$, and we show that the following conditions are equivalent:

(i) For every u_0 in the closure of D there is a continuous $f:[0,+\infty[\to Y$, with $\|e^{\omega t}f(t)\|_Y$ bounded, such that $\limsup_{t\to+\infty}\|e^{\omega t}u(t)\|_D<+\infty$.

(ii) For every $\lambda\in\mathbf{C}$ with $|\lambda|>e^{-\omega T}$ we have (denoting, as usual, adjoint operators by *)

$$(\lambda-V(0)^*)x^*=0,\quad s\to\Phi(s)^*G(T,s)^*x^*\equiv 0\quad\text{in }[0,T]\Rightarrow x^*=0.$$

In § 3.2 we apply the result of (1.1), with

$$Y=\mathbf{R}^k,\qquad \Phi(t)(y_1,\cdots,y_k)=\phi_i(t,\cdot)y_i, \tag{1.9}$$

where $t\to\phi_i(t,\cdot)$ belongs to $C^\alpha(\mathbf{R};L^p(\Omega))$, $\phi_i(t+T,\cdot)=\phi_i(t,\cdot)$, $i=1,\cdots,k$, and $\phi_1,\cdots,\phi_k$ are linearly independent. We find that system (1.1) is stabilizable in the

$W^{2,p}$-norm if an algebraic condition, involving the functions ϕ_i and the eigenfunctions of $V(s)^*$, holds. Precisely, we require that for each eigenvalue λ of $V(0)$ with $|\lambda| \geqq 1$ there is $s \in [0, T[$ such that, denoting by $\{\xi_1^*, \cdots, \xi_{N(\lambda)}^*\}$ any system of generators of $\ker(\lambda - V(s)^*)$, we have $k \geqq N(\lambda)$, and the matrix

$$[A_{ji}(s)] = [\langle \phi_i(s, \cdot), \xi_j^* \rangle]_{i=1,\cdots,k; j=1,\cdots,N(\lambda)} \tag{1.10}$$

has rank $N(\lambda)$ (we identify, as usual, $(L^p(\Omega))^*$ and $L^{p^*}(\Omega)(1/p + 1/p^* = 1)$, setting $\langle f, g^* \rangle = \int_\Omega f(x) g^*(x)\, dx$). In the particular case of the one-dimensional heat equation with time-periodic coefficients (see [23, Chap. 5]):

$$\begin{aligned} &u_t(t, x) = a(t) u_{xx}(t, x) + c(t) u(t, x) + y(t)\phi(x), \qquad 0 < x < l, \quad t > 0, \\ &u(0, x) = u_0(x), \qquad 0 < x < l, \\ &u(t, 0) = u(t, l) = 0, \qquad t > 0, \end{aligned} \tag{1.11}$$

with $a(t)$, $c(t) > 0$, $\phi \in L^p(0, l)$, the evolution operator is $G(t, s) = \exp[A \int_s^t a(s)\, ds + \int_s^t c(s)\, ds]$ (where e^{At} is the semigroup generated by the second derivative operator with zero boundary condition), and the stabilizability condition is the following: For each $k \in \mathbf{N}$ such that $\int_0^T c(s)\, ds - \pi^2 k^2 l^{-2} \int_0^T a(s)\, ds > 0$, we have $\int_0^l \phi(x) \sin(\pi k x / l)\, dx \neq 0$.

In § 4 we consider boundary stabilizability. Formally, the results are similar to the previous ones. In the case of Dirichlet boundary condition (§ 4.1) we fix $\omega \geqq 0$ such that no eigenvalue of $V(0)$ has modulus $e^{-\omega T}$, and we show that the following conditions are equivalent:

(i) For every $u_0 \in L^p(\Omega)$ there is a regular function $g : [0, +\infty[\to Z$ (with $\|e^{\omega t} g(t)\|_Z$ bounded) such that $\limsup_{t \to +\infty} \|e^{\omega t} u(t)\|_{W^{2,p}(\Omega)} < +\infty$,

(ii) For every $\lambda \in \mathbf{C}$ with $|\lambda| > e^{-\omega T}$ we have

$$(\lambda - V(0)^*)x^* = 0, \quad s \to \Psi(s)^* \left[\frac{\partial}{\partial \nu_s} (G(T, s)^* x^*) \right] \equiv 0 \quad \text{in } [0, T] \Rightarrow x^* = 0.$$

Here $\partial/\partial \nu_s$ denotes the conormal derivative (at the boundary) at the time s: $\partial/\partial \nu_s f = a_{ij}(s, \cdot) D_i f(\cdot) \nu_j(\cdot)$.

In particular, in the case where $Z = W^{2-1/p,p}(\partial\Omega)$, $\Psi(s) \equiv 1$, condition (ii) is fulfilled (at least in the self-adjoint, C^∞ case) thanks to a result in [19]. In the case where $Z = \mathbf{R}^k$, $\Psi(t)(z_1, \cdots, z_k) = \psi_i(t, \cdot) z_i$ (where $\psi_i(t, \cdot)$ are regular, T-periodic, linearly independent functions with values in $W^{2-1/p,p}(\partial\Omega)$), (ii) is fulfilled provided a full rank condition holds, i.e., there is $s \in \mathbf{R}$ such that $k \geqq N(\lambda)$ and the matrix

$$[B_{ij}] = \left[\left\langle \psi_i(s, \cdot), \frac{\partial}{\partial \nu_s} \xi_j^* \right\rangle \right]_{i=1,\cdots,k; j=1,\cdots,N(\lambda)} \tag{1.12}$$

has rank $N(\lambda)$ (again, we identify $(L^p(\partial\Omega))^*$ and $L^{p^*}(\partial\Omega)$, setting $\langle f, g^* \rangle = \int_{\partial\Omega} f(x) g^*(x)\, d\sigma_x$, and, as before, $\{\xi_1^*, \cdots, \xi_{N(\lambda)}^*\}$ is any system of generators of $\ker(\lambda - V(s)^*)$).

In the case of mixed boundary condition (§ 4.2) we find quite similar results, with $\partial/\partial \nu_s$ replaced by the trace operator. For instance, in the case of the time-periodic heat equation with Neumann boundary condition,

$$\begin{aligned} &u_t(t, x) = a(t) \Delta u(t, x), \qquad x \in \Omega, \quad t > 0, \\ &u(0, x) = u_0(x), \qquad x \in \Omega, \\ &\frac{\partial}{\partial \nu} u(t, x) = z(t) \psi(t, x), \qquad t > 0, \end{aligned} \tag{1.13}$$

the unique eigenvalue of $G(T, 0)$ with modulus greater than or equal to one is one and the corresponding eigenspace is one-dimensional (it consists of the constant functions), so that the system is exponentially stabilizable provided there is s such that $\int_{\partial\Omega} \psi(s, x)\, d\sigma_x \neq 0$.

Concerning the literature on the subject, a considerable amount of papers have been devoted to stabilizability (in fact, feedback stabilizability) in autonomous problems, both in the case of distributed and boundary inputs (see, for instance, [5], [18], [21], [12], [13], [4], and the references quoted there). To the author's knowledge, stabilizability in nonautonomous parabolic problems has not yet been studied.

We remark that abstract and concrete feedback stabilizability results could be obtained from ours (at least, in the case where X, Y are Hilbert spaces, i.e., $p=2$) using the theories developed in [7] and [8]. Concerning problem (1.8), it has been shown in [7] that if the system is stabilizable then there is an optimal pair (u_0^*, f^*) minimizing the cost functional

$$J(u_0, f) = \int_0^{+\infty} (\|u(t)\|_X^2 + \|f(t)\|_Y^2)\, dt, \tag{1.14}$$

and, denoting by u^* the solution of (1.8) with data (u_0^*, f^*) we have $f^*(t) = -\Phi(t)^* Q(t) u^*(t)$, where $Q(t) \in L(X)$ is the unique positive T-periodic solution of the Riccati equation

$$Q'(t) + A(t)^* Q(t) + Q(t)A(t) - Q(t)\Phi(t)\Phi(t)^* Q(t) + \mathbf{I} = 0, \qquad t \in \mathbf{R}. \tag{1.15}$$

From [6] it follows that the evolution operator generated by $A - \Phi\Phi^* Q$ is exponentially stable (see § 3 of [7]): therefore we get the feedback $F(t) = -\Phi(t)^* Q(t)$.

A similar procedure may be employed in problem (1.2): in this case, the study of the corresponding Riccati equation is much more complicated. Solvability of initial value problems for such equations was shown in [1], where the existing results for the autonomous case ([13], [9]) were extended to a larger class of nonautonomous equations. The result of [1] also implies, as remarked in [8], the existence of a unique positive T-periodic solution of the Riccati equation. Arguing as before, we can construct a feedback operator.

2. Asymptotic behavior in abstract parabolic Cauchy problems.

Let X, D be Banach spaces, with norms $\|\cdot\|$, $\|\cdot\|_D$, respectively, D being continuously embedded in X. We consider a time-periodic initial value problem:

$$u'(t) = A(t)u(t) + f(t), \qquad t > 0, \quad u(0) = x. \tag{2.1}$$

The linear operators $A(t)$ are subject to the following assumptions ($0 < \alpha < 1$, $T > 0$):

(2.2)
(i) $t \to A(t) \in C^\alpha(\mathbf{R}; L(D, X))$,
(ii) $A(t+T) = A(t)$, $\quad t \in \mathbf{R}$,
(iii) For each $t \in \mathbf{R}$, $A(t)$ generates an analytic semigroup $e^{sA(t)}$ in X and there is $c \geqq 1$ such that $c^{-1}\|x\|_D \leqq \|x\| + \|A(t)x\| \leqq c\|x\|_D$ for every $x \in D$, $t \in \mathbf{R}$.

Then there is an evolution operator $G(t, s) \in L(X, D)(t \geqq s)$, such that for every locally α-Hölder continuous function $f: [0, +\infty[\to X$ and for every x in the closure of D, problem (2.1) has a unique solution $u \in C[0, +\infty[; X) \cap C^1(]0, +\infty[; X) \cap$

$C(]0, +\infty[; D)$, given by the variation of constants formula:

$$u(t) = G(t, 0)x + \int_0^t G(t, s)f(s)\, ds, \qquad t \geqq 0. \tag{2.3}$$

If f is continuous in $[0, +\infty[$, then the function u defined in (2.3) is the unique strong solution of (2.1). For this and other properties of $G(t, s)$ we refer to [20] for the dense domain case, and to [15] for the nondense domain case.

Some regularity properties will be described through the interpolation spaces X_θ $(0 < \theta < 1)$ defined by

$$X_\theta = (X, D)_{\theta,\infty} \tag{2.4}$$

(see, e.g., [22]). To treat asymptotic behavior as $t \to +\infty$, we introduce certain functional spaces consisting of exponentially decaying functions: for any Banach space B, $\omega \geqq 0$ and $0 < \alpha < 1$, we set

$$\begin{aligned} &C_\omega([0, +\infty[; B) = \{u \in C([0, +\infty[; B); \sup_{t>0} \|u(t)\, e^{\omega t}\|_B < +\infty\}, \\ &\|u\|_{C_\omega([0,+\infty[; B)} = \sup_{t>0} \|u(t)\, e^{\omega t}\|_B, \end{aligned} \tag{2.5}$$

$$\begin{aligned} &C^\alpha_\omega([0, +\infty[; B) \\ &\qquad = \left\{u \in C_\omega([0, +\infty[; B); \sup_{0<s<t} \|u(t)\, e^{\omega t} - u(s)\, e^{\omega s}\|_B (t-s)^{-\alpha} < +\infty\right\}, \\ &\|u\|_{C^\alpha_\omega([0,+\infty[; B)} \\ &\qquad = \sup_{t>0} \|u(t)\, e^{\omega t}\|_B + \sup_{t>s>0} \|u(t)\, e^{\omega t} - u(s)\, e^{\omega s}\|_B (t-s)^{-\alpha}, \end{aligned} \tag{2.6}$$

$$\begin{aligned} &C^1_\omega([0, +\infty[; B) = \{u \in C^1([0, +\infty[; B); u, u' \in C_\omega([0, +\infty[; B))\}; \\ &\|u\|_{C^1_\omega([0,+\infty[; B)} = \|u\|_{C_\omega([0,+\infty[; B)} + \|u'\|_{C_\omega([0,+\infty[; B)}. \end{aligned} \tag{2.7}$$

In the limiting case $\omega = 0$, $C_0([0, +\infty[; B)$ consists of bounded functions, and $C^\alpha_0([0, +\infty[; B)$ consists of uniformly Hölder continuous functions. It is easy to see that if u belongs to $C^\alpha_\omega([0, +\infty[; B)$, then

$$\sup_{0<s<t} e^{\omega s} \|u(t) - u(s)\|_B (t-s)^{-\alpha} \leqq \gamma(\omega) \|u\|_{C^\alpha_\omega([0,+\infty[; B)}. \tag{2.8}$$

We now recall some results of [16], which generalize to the infinite-dimensional case the known asymptotic behavior properties of the evolution operator for ordinary differential equations. We define the period map (Poincaré map) by

$$V(s) = G(s + T, s), \qquad s \in \mathbf{R}. \tag{2.9}$$

Denote by $\sigma(V(s))$ the spectrum of $V(s)$, and fix $\omega \geqq 0$ such that

$$\sigma(V(s)) \cap \{\lambda \in \mathbf{C}; |\lambda| = e^{-\omega T}\} = \varnothing, \qquad s \in \mathbf{R}. \tag{2.10}$$

Since $s \to V(s)$ is uniformly continuous (in fact, α-Hölder continuous due to [15, Prop. 3.6]) with values in $L(X)$ and $\sigma(V(s))$ is closed for every s, then, setting

$$\begin{aligned} &\sigma(V(s)) = \sigma_1(V(s)) \cup \sigma_2(V(s)), \qquad s \in \mathbf{R}, \\ &\sigma_1(V(s)) \subset \{\lambda \in \mathbf{C}; |\lambda| < e^{-\omega T}\}, \quad \sigma_2(V(s)) \subset \{\lambda \in \mathbf{C}; |\lambda| > e^{-\omega T}\} \quad \forall s \in \mathbf{R}, \end{aligned} \tag{2.11}$$

we have

$$(2.12)\qquad \rho_1=\sup\{|\lambda|;\ \lambda\in\sigma_1(V(s)),\ s\in\mathbf{R}\}<e^{-\omega T}<\rho_2=\inf\{|\lambda|;\ \lambda\in\sigma_2(V(s)),\ s\in\mathbf{R}\}.$$

Two families of projections may be defined as follows:

$$(2.13)\qquad P_1(t)=\frac{1}{2\pi i}\int_{C(0,e^{-\omega T})}(\lambda-V(t))^{-1}\,d\lambda,\quad P_2(t)=(\mathbf{I}-P_1(t)),\quad t\in\mathbf{R},$$

where $C(0,r)$ is the circle centered at $0\in\mathbf{C}$ with radius $r>0$. The restriction of the evolution operator $G(t,s)$ to the subspace $P_2(s)(X)$ is well defined also for $t<s$, and we have, for every $\varepsilon>0$ sufficiently small ($\varepsilon<T^{-1}\log(e^{-\omega T}/\rho_1)$, $\varepsilon<T^{-1}\log(\rho_2/e^{-\omega T})$):

$$(2.14)\qquad \begin{aligned}&\text{(i)}\quad \|G(t,s)P_1(s)\|_{L(X)}\leqq k_1(\varepsilon)\,e^{-(\omega+\varepsilon)(t-s)},\quad t>s,\\ &\text{(ii)}\quad \|G(t,s)P_1(s)\|_{L(X,D)}\leqq k_1(\varepsilon)(t-s)^{-1}\,e^{-(\omega+\varepsilon)(t-s)},\quad t>s,\\ &\text{(iii)}\quad \|G(t,s)P_2(s)\|_{L(X,D)}\leqq k_2(\varepsilon)\,e^{(\omega+\varepsilon)(t-s)},\quad t<s\end{aligned}$$

(see [16, Props. 2.3(i), 2.7(i)]).

PROPOSITION 2.1. *Let* (2.2), (2.10) *hold, let f belong to $C_\omega([0,+\infty[;X)$, and let x belong to the closure of D in X. Then the function u defined in* (2.3) *belongs to $C_\omega([0,+\infty[;X)$ if and only if*

$$(2.15)\qquad P_2(0)x=-\int_0^{+\infty}G(0,s)P_2(s)f(s)\,ds.$$

If (2.15) *holds, and, in addition, f belongs to $C_\omega^\alpha([0,+\infty[;X)$, then u belongs to $C_\omega([a,+\infty[;D)$ for every $a>0$; in particular,*

$$(2.16)\qquad \sup_{t\geqq a}\|u(t)\,e^{\omega t}\|_D<+\infty\quad \textit{for each } a>0.$$

If (2.15) *holds, and, in addition, f belongs to $C_\omega([0,+\infty[;X_\theta)$ for some $\theta\in\,]0,1[$, then u' and $A(\cdot)u(\cdot)$ belong to $C_\omega([a,+\infty[;X)$ for every $a>0$; in particular* (2.16) *holds.*

Proof. The first part of the proposition was proved in Proposition 3.10 of [16]. Moreover, if f belongs to $C_\omega^\alpha([0,+\infty[;X)$, in particular, it belongs to $C^\alpha([0,a];X)$ for every $a>0$, so that, by Propostions 3.5(ii) and 2.6(i) of [15], u belongs to $C^\alpha([a/2,a];D)\cap C^{\alpha+1}([a/2,a];X)$. Consequently, by Lemma 1.1 of [15], $u'(a)=A(a)u(a)+f(a)$ belongs to X_α. Analogously, if f belongs to $C_\omega([0,+\infty[;X_\theta)$, then it belongs to $C([0,a];X_\theta)$ for every $a>0$, so that, by Propositions 2.5 and 3.5(iii) of [15], $A(t)u(t)$ belongs to X_θ for $0<t\leqq a$; in particular, $A(a)u(a)$ belongs to X_θ. Moreover, condition (2.15) implies easily

$$(2.17)\qquad P_2(a)u(a)=-\int_a^{+\infty}G(a,s)P_2(s)f(s)\,ds,$$

so that we can apply Proposition 3.10 of [16] to show the last part of the statement. □

Under some more regularity assumptions on $A(\cdot)$, i.e.,

$$(2.18)\qquad t\to A(t)\in C^{1+\alpha}(\mathbf{R},L(D,X))\quad\text{for some }\alpha\in\,]0,1[,$$

we can show that $s\to G(t,s)$ is differentiable for $t>s$ with values in $L(X,D)$. In the sequel, together with the function u defined in (2.3), we will be concerned also with the function

$$(2.19)\qquad v(t)=G(t,0)x+\int_0^t G_s(t,s)f(s)\,ds,\qquad t\geqq 0,$$

where f has values in some interpolation space X_θ, $0<\theta<1$. v is well defined, since (see [17]) for every $a>0$ there is $M_a>0$ such that

$$\|G_s(t,s)\|_{L(X_\theta,X)}\leqq M_a(t-s)^{\theta-1},\qquad 0\leqq s<t\leqq a. \tag{2.20}$$

In order to deal with asymptotic behavior of $v(t)$, we establish some estimates for $P_i(t)G_s(t,s)$, $i=1,2$.

LEMMA 2.2. *Let* (2.2), (2.10), (2.18) *hold. Then*:

(i) *For every* $t\in\mathbf{R}$, *the function* $s\to G(t,s)P_1(s)$ *is differentiable in* $]-\infty,t[$ *with values in* $L(X,D)$, *and*

$$\frac{\partial}{\partial s}(G(t,s)P_1(s))=P_1(t)G_s(t,s),\qquad t>s. \tag{2.21}$$

Moreover, for every $\varepsilon\in[0,T^{-1}\log(e^{-\omega T}/\rho_1)[$ *there is* $C_1(\varepsilon)>0$ *such that*

$$\begin{aligned}
&\text{(i)}\quad \left\|\frac{\partial}{\partial s}(G(t,s)P_1(s))x\right\|\\
&\qquad\leqq C_1(\varepsilon)(t-s)^{\theta-1}\,e^{-(\omega+\varepsilon)(t-s)}\|x\|_\theta,\qquad t>s,\quad x\in X_\theta,\\
&\text{(ii)}\quad \left\|\frac{\partial}{\partial s}(G(t,s)P_1(s))x\right\|_D\\
&\qquad\leqq C_1(\varepsilon)(t-s)^{\theta-2}\,e^{-(\omega+\varepsilon)(t-s)}\|x\|_\theta,\qquad t>s,\quad x\in X_\theta.
\end{aligned} \tag{2.22}$$

(ii) *For every* $t\in\mathbf{R}$, *the function* $s\to G(t,s)P_2(s)$ *is differentiable in* $\mathbf{R}$ *with values in* $L(X,D)$, *and*

$$\begin{aligned}
&\frac{\partial}{\partial s}(G(t,s)P_2(s))=P_2(t)G_s(t,s),\qquad t\geqq s,\\
&\frac{\partial}{\partial s}(G(t,s)P_2(s))=G(t,r)P_2(r)G_s(r,s)=G(t,r)G_s(r,s),\qquad t\leqq s<r.
\end{aligned} \tag{2.23}$$

Moreover, for every $\varepsilon\in[0,T^{-1}\log(\rho_2/e^{-\omega T})[$ *there is* $C_2(\varepsilon)>0$ *such that*

$$\left\|\frac{\partial}{\partial s}(G(t,s)P_2(s))x\right\|_D\leqq C_2(\varepsilon)\,e^{(\omega+\varepsilon)(t-s)}\|x\|_\theta,\qquad t\leqq s,\quad x\in X_\theta. \tag{2.24}$$

Proof. (i) Since $G(t,s)P_1(s)=P_1(t)G(t,s)$ for every $t>s$, we have, for $t>s$, $t>s+h$:

$$h^{-1}[G(t,s+h)P_1(s+h)-G(t,s)P_1(s)]=P_1(t)h^{-1}[G(t,s+h)-G(t,s)].$$

Therefore $G(t,\cdot)P_1(\cdot)$ is differentiable in $]-\infty,t[$ with values in $L(X)$, and (2.21) holds. Since $G(t,s)=G(t,r)G(r,s)$ for $t>r>s$, then $G_s(t,s)=G(t,r)G_s(r,s)$, so that $G(t,\cdot)P_1(\cdot)$ is differentiable in $]-\infty,t[$ with values in $L(X,D)$, and

$$P_1(t)G_s(t,s)=P_1(t)G(t,r)G_s(r,s)=G(t,r)P_1(r)G_s(r,s),\qquad t>r>s. \tag{2.25}$$

If $t\geqq s+2$ we get, choosing $r=s+1$ and using estimates (2.14) and (2.20) with $a=1$,

$$\left\|\frac{\partial}{\partial s}(G(t,s)P_1(s))x\right\|+\left\|\frac{\partial}{\partial s}(G(t,s)P_1(s))x\right\|_D\leqq 2M_1k_1(\varepsilon)\,e^{-(\omega+\varepsilon)(t-s)}\|x\|_\theta.$$

If $t\leqq s+2$ we choose $r=(t+s)/2$ in (2.25), and, again using (2.14) and (2.20) we find

$$\begin{aligned}
&\left\|\frac{\partial}{\partial s}(G(t,s)P_1(s))x\right\|\leqq k_1(\varepsilon)\,e^{-2(\omega+\varepsilon)}M_2\left[\frac{t-s}{2}\right]^{\theta-1}\|x\|_\theta,\\
&\left\|\frac{\partial}{\partial s}(G(t,s)P_1(s))x\right\|_D\leqq\left[\frac{t-s}{2}\right]^{-1}k_1(\varepsilon)\,e^{-2(\omega+\varepsilon)}M_2\left[\frac{t-s}{2}\right]^{\theta-1}\|x\|_\theta.
\end{aligned}$$

By the arbitrariness of ε we get estimates (2.22).

The proof of (ii) is analogous; to show (2.24) we can use the second equality in (2.23) with $r=1+s$, and estimate (2.14)(iii). □

Now we are ready to prove a result similar to Proposition 2.1.

PROPOSITION 2.3. *Let* (2.2), (2.10), (2.18) *hold, and let x belong to the closure of D, f belong to $C_\omega([0,+\infty[;X_\theta)$ for some $\theta\in\,]0,1[$. Then the function v defined in* (2.19) *belongs to $C_\omega([0,+\infty[;X)$ if and only if*

$$P_2(0)x=-\int_0^{+\infty}\frac{\partial}{\partial s}(G(0,s)P_2(s))f(s)\,ds. \tag{2.26}$$

If (2.26) *holds, and, in addition, f belongs to $C_\omega^\beta([0,+\infty[;X_\theta)$ with $\theta+\beta>1$, then v is differentiable for $t>0$, $v(t)-f(t)$ belongs to D for $t>0$, and*

$$v'(t)=A(t)[v(t)-f(t)],\qquad t>0. \tag{2.27}$$

Moreover, v', $A(\cdot)[v(\cdot)-f(\cdot)]$ belong to $C_\omega([a,+\infty[;X)$ for every $a>0$, and we have

$$\sup_{t\geqq a}\|(v(t)-f(t))\,e^{\omega t}\|_D\leqq C(a,\omega,\theta)(\|x\|+\|f\|_{C_\omega^\beta([0,+\infty[;X_\theta)}). \tag{2.28}$$

Proof. First of all, we note that, due to estimates (2.22) and (2.24), the functions

$$v_1(t)=P_1(t)v(t)=G(t,0)P_1(0)x+\int_0^t\left[\frac{\partial}{\partial s}(G(t,s)P_1(s))\right]f(s)\,ds,\qquad t>0,$$

$$v_2(t)=-\int_t^{+\infty}\left[\frac{\partial}{\partial s}(G(t,s)P_2(s))\right]f(s)\,ds,\qquad t\geqq 0,$$

belong both to $C_\omega([0,+\infty[;X)$ (in fact, v_2 belongs to $C_\omega([0,+\infty[;D))$.

For every $t\geqq 0$ we have $v(t)=P_1(t)v(t)+P_2(t)v(t)$. Hence, using (2.23) we get

$$\begin{aligned}v(t)-v_1(t)-v_2(t)&=G(t,0)P_2(0)x+\int_0^{+\infty}\left[\frac{\partial}{\partial s}(G(t,s)P_2(s))\right]f(s)\,ds\\&=G(t,0)\left\{P_2(0)x+\int_0^{+\infty}\left[\frac{\partial}{\partial s}(G(0,s)P_2(s))\right]f(s)\,ds\right\}\overset{\text{def}}{=}G(t,0)y,\end{aligned}$$

where y belongs to $P_2(0)(X)$. Since $\sup_{t>0}\|e^{\omega t}G(t,0)y\|=+\infty$ for every $y\in P_2(0)\times(X)\backslash\{0\}$, then v belongs to $C_\omega([0,+\infty[;X)$ if and only if $y=0$, i.e., (2.26) holds.

Let now (2.26) hold, and let f belong to $C_\omega^\beta([0,+\infty[;X_\theta)$, with $\theta+\beta>1$. For every $t>0$ we have, by Corollary 2.6 of [17] and equality (2.21),

$$\begin{aligned}&\int_0^t\frac{\partial}{\partial s}[G(t,s)P_1(s)]f(s)\,ds\\&\quad=\int_0^t P_1(t)G_s(t,s)[f(s)-f(t)]\,ds+P_1(t)\int_0^t G_s(t,s)f(t)\,ds\\&\quad=\int_0^t\frac{\partial}{\partial s}[G(t,s)P_1(s)][f(s)-f(t)]\,ds+P_1(t)[f(t)-G(t,0)f(t)],\qquad t\geqq 0,\end{aligned}$$

so that

$$v_1(t)=G(t,0)P_1(0)(x-f(t))+\int_0^t\frac{\partial}{\partial s}(G(t,s)P_1(s))[f(s)-f(t)]\,ds+P_1(t)f(t),\qquad t\geqq 0.$$

Therefore, by estimate (2.22)(ii), $v_1(t)-P_1(t)f(t)$ belongs to D for every $t>0$ and also using estimates (2.14)(ii) and (2.8) we get, for $t \geqq a > 0$,

$$\begin{aligned}\|[v_1(t) - P_1(t)f(t)]\, e^{\omega t}\|_D &\leqq t^{-1}k_1(0)\Big(\|x\| + \sup_{t>0} \|f(t)\|\Big) \\ &\quad + C_1(\varepsilon) \int_0^t \varepsilon^{-\varepsilon(t-s)}(\tau - s)^{\theta+\beta-2}\, ds \|f\|_{C^\beta_\omega([0,+\infty[;X_\theta)} \\ &\leqq a^{-1}k_1(0)\|x\| + [a^{-1}k_1(0) \\ &\quad + C_1(\varepsilon)\gamma(\beta,\omega)\varepsilon^{1-\theta-\beta}\Gamma(\theta+\beta-1)]\|f\|_{C^\beta_\omega([0,+\infty[;X_\theta)}\end{aligned}$$

so that $v_1 - P_1 f$ belongs to $C_\omega([0, +\infty[; D)$. Since v_2 also belongs to $C_\omega([0, +\infty[; D)$, and P_2 is bounded with values in $L(X, D)$ (see (2.13)), then $v_2 - P_2 f$ belongs to $C_\omega([0, +\infty[; D)$. Therefore $v - f = v_1 + v_2 - (P_1 + P_2)f$ belongs to $C_\omega([0, +\infty[; D)$. Moreover, by Remark 2.8 of [17], $v - G(\cdot, 0)x$ belongs to $C^1(]0, +\infty[; X)$, and $d/dt(v(t) - G(t, 0)x) = A(t)[v(t) - G(t, 0)x - f(t)]$ for $t > 0$. Since $G(\cdot, 0)x$ also belongs to $C^1(]0, +\infty[; X)$, then v belongs to $C^1(]0, +\infty[; X)$, and (2.27) holds. Formula (2.28) now follows easily. □

3. Stabilizability for distributed parameters systems. Here we apply the asymptotic behavior results of the previous section to prove some stabilizability theorems. We begin (§ 3.1) with an abstract stabilizability result generalizing the well-known one [11] concerning ordinary differential systems. We apply such a result to a distributed interior control problem (§ 3.2).

3.1. Stabilizability in abstract parabolic periodic problems. Throughout the section we use notation from § 2 and we assume that (2.2), (2.8) hold. We denote by Y another Banach space, with norm $\|\cdot\|_Y$, and consider the problem

$$u'(t) = A(t)u(t) + \Phi(t)f(t), \quad t > 0, \quad u(0) = x, \tag{3.1}$$

under the following assumptions on the linear operators $\Phi(t): Y \to X$ $(0 < \alpha < 1)$:

$$t \to \Phi(t) \in C^\alpha(\mathbf{R}; L(Y, X)), \quad \Phi(t + T) = \Phi(t) \quad \forall t \in \mathbf{R}. \tag{3.2}$$

For every x in the closure of D and $f \in C([0, +\infty[; Y)$, problem (3.1) has a unique strong solution u, given by the variation of constants formula,

$$u(t) = G(t, 0)x + \int_0^t G(t, s)\Phi(s)f(s)\, ds, \qquad t \geqq 0. \tag{3.3}$$

We want to find necessary and sufficient conditions on the family $\{\Phi(t); t \in \mathbf{R}\}$ in order that for every x belonging to the closure of D there is $f: [0, +\infty[\to Y$ such that the (strong) solution of (3.1) decays exponentially as $t \to +\infty$. Due to Proposition 2.1, the problem is not trivial if

$$\sigma(V(s)) \cap \{\lambda \in \mathbf{C}; |\lambda| \geqq 1\} \neq \emptyset \quad \text{for some } s \in \mathbf{R}. \tag{3.4}$$

We fix, once and for all, a number $\omega \geqq 0$ satisfying (2.10), and we assume (see (2.11)):

(3.5) For every $s \in \mathbf{R}$, $\sigma_2(V(s))$ consists of a finite number of eigenvalues with finite algebraic multiplicity.

It can be easily shown that the nonzero eigenvalues of $V(s)$ do not depend on s. Therefore we can set

$$\sigma_2 \overset{\text{def}}{=} \sigma_2(V(s)) \quad \forall s \in \mathbf{R}. \tag{3.6}$$

Again, it is easy to see that λ belongs to σ_2 if and only if the problem

$$v'(t)=A(t)v(t)+\kappa v(t), \qquad t\in\mathbf{R}, \tag{3.7}$$

with $\kappa=e^{-\lambda T}$ has a nontrivial T-periodic solution.

THEOREM 3.1. *Let* (2.2), (2.10), (3.3)-(3.5) *hold. The following conditions are equivalent*:

(i) *For every x in the closure of D there is $f\in C_\omega([0,+\infty[;\ Y)$ such that the solution u of* (3.1) *belongs to $C_\omega([0,+\infty[;\ X)$*;

(ii) *For every $\lambda\in\mathbf{C}$ with $|\lambda|>e^{-\omega T}$ we have*

$$(\lambda-V(0)^*)x^*=0,\quad \Phi(s)^*G(T,s)^*x^*=0 \quad \textit{for each } s\in[0,T]\Rightarrow x^*=0.$$

If one of the equivalent conditions (i) *or* (ii) *holds, then for each x belonging to the closure of D there is f belonging to $C^\alpha_\omega([0,+\infty[;\ Y)$, such that u belongs to $C_\omega([a,+\infty[;\ D)$ for every $a>0$.*

Proof. (i)$\Rightarrow$(ii) Assume by contradiction that (ii) does not hold. Choose $\lambda\in\mathbf{C}$ with $|\lambda|>e^{-\omega T}$ and $x^*\neq 0$ such that $\lambda x^*=V(0)^*x^*$, $\Phi(s)^*G(T,s)^*x^*\equiv 0$ in $[0,T]$. Let $x\in P_2(0)(X)$ be such that $\langle x,x^*\rangle=1$. By assumption there is $f\in C_\omega([0,+\infty[;\ Y)$ such that u belongs to $C_\omega([0,+\infty[;\ X)$. Taking $t=nT$, $n\in\mathbf{N}$, we have

$$\begin{aligned}\langle u(nT),x^*\rangle&=\langle G(nT,0)x,x^*\rangle+\int_0^{nT}\langle G(nT,s)\Phi(s)f(s),x^*\rangle\,ds\\&=\langle x,(V(0)^*)^nx^*\rangle\\&\quad+\sum_{k=0}^{n-1}\int_0^T\langle f(s+kT),\Phi(s)^*G(T,s)^*(V(0)^*)^{n-k-1}x^*\rangle\,ds\\&=\lambda^n\,e^{n\omega T}.\end{aligned}$$

Since $|\lambda^n e^{n\omega T}|=(|\lambda|\,e^{\omega T})^n\to+\infty$ as $n\to+\infty$, then $\sup_{t>0}\|u(t)\,e^{\omega t}\|=+\infty$, so that u does not belong to $C_\omega([0,+\infty[;\ X)$. By contradiction, (ii) holds.

(ii)$\Rightarrow$(i). Assume by contradiction that (i) does not hold. Due to Proposition 2.1, this means that the map

$$\gamma: C_\omega([0,+\infty[;\ Y)\to P_2(0)(X), \qquad \gamma f=\int_0^{+\infty}G(0,s)P_2(s)\Phi(s)f(s)\,ds,$$

is not onto. Since $P_2(0)(X)$ is finite-dimensional (by assumption (3.5)), γ is not onto if and only if

$$\gamma^*:(P_2(0)(X))^*\to(C_\omega([0,+\infty[;\ Y))^*$$

is not one to one, i.e., there is $x^*\in P_2(0)^*(X^*)\backslash\{0\}$ such that $\Phi(s)^*P_2(s)^*\times G(0,s)^*x^*=\Phi(s)^*G(0,s)^*x^*=0$ for $s\geqq 0$. Setting $s=\sigma+nT$, we get $\Phi(\sigma)^*G(0,\sigma)^*\times(V(0)^*)^{-n}x^*=0$, for $0\leqq\sigma\leqq T$ and $n\in\mathbf{N}$, and hence, for every $\xi\in\mathbf{C}$ with $|\xi|>\|(V(0)^*_{|P_2(0)^*(x^*)})^{-1}\|_{L(P_2(0)^*(X^*))}$ we have

$$\Phi(\sigma)^*G(0,\sigma)^*(\xi-(V(0)^*_{|P_2(0)^*(X^*)})^{-1})^{-1}x^*=0, \qquad 0\leqq\sigma\leqq T. \tag{3.8}$$

By assumption (3.5), the set $\{\xi\in\sigma(V(0)^*_{|P_2(0)^*(X^*)})^{-1};\ |\xi|>e^{-\omega T}\}$ is finite. Since $\xi\to(\xi-V(0)^*_{|P_2(0)^*(X^*)})^{-1}$ is holomorphic in its domain of definition, then (3.8) holds for every ξ in the resolvent set of $(V(0)^*_{|P_2(0)^*(X^*)})^{-1}$, with $|\xi|>e^{-\omega T}$. Then by (3.8) we get, for $\lambda\in\rho(V(0)^*)$, $|\lambda|<e^{-\omega T}$:

$$\Phi(\sigma)^*G(0,\sigma)^*(\lambda-V(0)^*)^{-1}(V(0)^*_{|P_2(0)^*(X^*)})^{-1}x^*=0, \qquad 0\leqq\sigma\leqq T. \tag{3.9}$$

Again using assumption (3.5), we find that (3.9) holds for every $\lambda\in\rho(V(0)^*)$. Let $\sigma_2=\{\lambda_1,\cdots,\lambda_N\}$. Then, since $x^*\in P_2(0)^*(X^*)$, we have $x^*=P_2(0)^*x=\sum_{i=1}^N P_{\lambda_i}(0)^*x^*$, where $P_{\lambda_i}(s)=1/2\pi i\int_{C(\lambda_i,\varepsilon)}(\lambda-V(s))^{-1}\,d\lambda$, $i=1,\cdots,N$, and $\varepsilon>0$ is sufficiently small. Since $x^*\neq 0$, there is $i\in\{1,\cdots,N\}$ such that $P_{\lambda_i}(0)^*x^*\neq 0$. Since λ_i is an eigenvalue with finite algebraic multiplicity, there is $m\in\mathbf{N}$ such that $(\lambda_i-V(0)^*)^mP^*_{\lambda_i}x^*=0$ and $y^*\overset{\text{def}}{=}(\lambda_i-V(0)^*)^{m-1}P^*_{\lambda_i}x^*\neq 0$. y^* belongs obviously to ker $(\lambda_i-V(0)^*)$, and from (3.9) we get, multiplying by λ^k $(k\in\mathbf{Z})$ and integrating over $C(\lambda_i,\varepsilon)$,

$$\Phi(\sigma)^*G(0,\sigma)^*(V(0)^*)^kP^*_{\lambda_i}x^*=0\quad\text{for each } k\in\mathbf{Z}$$

so that

$$\Phi(\sigma)^*G(0,\sigma)^*y^*=\Phi(\sigma)^*G(0,\sigma)^*(\lambda_i-V(0)^*)^{m-1}P^*_{\lambda_i}x^*=0.$$

This contradicts assumption (ii). Therefore (ii) implies (i).

Now let one of the equivalent conditions (i) or (ii) hold. Arguing as in the proof of (ii)⇒(i), we can see that the mapping

$$\Gamma: C^\alpha_\omega([0,+\infty[;\,Y)\to P_2(0)(X),\quad \Gamma f=\int_0^{+\infty}G(0,s)P_2(s)\Phi(s)f(s)\,ds,$$

is onto. The statement now follows applying Proposition 2.1. □

3.2. Applications to distributed control problems. Here we consider the problem

$$\begin{aligned} &u_t(t,x)=\mathscr{A}(t,x,\partial)u(t,x)+y_k(t)\phi_k(t,x), && t>0,\quad x\in\Omega,\\ &u(0,x)=u_0(x), && x\in\Omega, \\ &\mathscr{B}u(t,x)=0, && \end{aligned}\tag{3.10}$$

where the linear operator $\mathscr{A}(t,x,\partial)$ is given by

$$\mathscr{A}(t,\cdot,\partial)f=a_{ij}(t,\cdot)D_{ij}f+b_i(t,\cdot)D_if+c(t,\cdot)f,\tag{3.11}$$

and

$$\begin{aligned} &\text{(a)}\quad a_{ij}(t,x)=a_{ji}(t,x),\qquad a_{ij}(t,x)\xi_i\xi_j\geqq\nu|\xi|^2,\\ &\text{(b)}\quad a_{ij}(t+T,x)=a_{ij}(t,x),\quad b_i(t+T,x)=b_i(t,x),\quad c(t+T,x)=c(t,x),\\ &\text{(c)}\quad t\to a_{ij}(t,\cdot),\quad t\to b_i(t,\cdot),\quad t\to c(t,\cdot)\in C^\alpha(\mathbf{R};\,C(\bar\Omega)). \end{aligned}\tag{3.12}$$

The boundary operator $\mathscr{B}$ is either the trace operator on $\partial\Omega$ or else any mixed nontangential differential operator:

$$(\mathscr{B}g)(x)=\beta_i(x)D_ig(x)+\gamma(x)g(x),\qquad x\in\partial\Omega,\tag{3.13}$$

with

$$\beta_i,\ \gamma\in C^1(\partial\Omega),\quad \beta_i(x)\nu_i(x)\neq 0,\quad x\in\partial\Omega.\tag{3.14}$$

We choose $p>1$ and we set

$$X=L^p(\Omega),\qquad D=\{\phi\in W^{2,p}(\Omega);\ \mathscr{B}\phi=0\}.\tag{3.15}$$

Then the operators

$$A(t): D\to X,\qquad A(t)\phi=\mathscr{A}(t,x,\partial)\phi\tag{3.16}$$

satisfy assumption (2.2) due to [3] and [2]. The evolution operator $G(t,s)$ generated by $\{A(t);\,t\in\mathbf{R}\}$ is compact because D is compactly embedded in X; therefore the spectrum of $V(s)$ consists of isolated eigenvalues (except the point $z=0$) with finite algebraic multiplicity, and it is independent of s. Hence, assumptions (2.10), (3.5) are satisfied by any $\omega \geqq 0$ such that no complex number with modulus $e^{-\omega T}$ is an eigenvalue of $V(0)$.

We choose

$$Y=\mathbf{R}^k, \qquad \Phi(t)(y_1,\cdots,y_k)=\phi_i(t,\cdot)y_i, \tag{3.17}$$

and we assume that $\phi_1,\cdots,\phi_k$ are linearly independent and such that

$$t\to\phi_i(t,\cdot)\in C^\alpha(\mathbf{R};X), \quad \phi_i(t+T,\cdot)=\phi_i(t,\cdot) \quad \forall t\in\mathbf{R}. \tag{3.18}$$

For every $\lambda\in\sigma(V(0)^*)$ let $\xi_1^*,\cdots,\xi_{N(\lambda)}^*$ be linearly independent functions in $L^{p^*}(\Omega)$ $(1/p+1/p^*=1)$ spanning the eigenspace of $V(0)^*$ with eigenvalue λ. Then for every $s\in[0,T]$ the mapping $\Phi(s)^*G(T,s)^*:\ker(\lambda-V(0)^*)\to(\mathbf{R}^k)^*=\mathbf{R}^k$ may be represented (with respect to such a basis) by the matrix

$$[A_{ji}(s)]=[\langle G(T,s)\phi_j(s,\cdot),\xi_i^*\rangle]_{i=1,\cdots,N(\lambda),j=1,\cdots,k}. \tag{3.19}$$

Hence, the result of Theorem 3.1 can be reformulated as follows.

PROPOSITION 3.2. *Fix any $\omega\geqq 0$ such that no eigenvalue of $V(0)$ has modulus $e^{-\omega T}$. Then the following statements are equivalent:*

(i) *For each $u_0\in L^p(\Omega)$ there are $y_1,\cdots,y_k\in C_\omega^\alpha([0,+\infty[;\mathbf{R})$ such that the solution u of* (3.10) *satisfies*

$$\sup_{t\geqq 0}\|e^{\omega t}u(t,\cdot)\|_{L^p(\Omega)}<+\infty, \quad \sup_{t\geqq a}\|e^{\omega t}u(t,\cdot)\|_{W^{2,p}(\Omega)}<+\infty \quad \forall a>0;$$

(ii) *For each $\lambda\in\sigma(V(0))$ with $|\lambda|>e^{-\omega T}$, and for each $y\in\mathbf{R}^{N(\lambda)}\backslash\{0\}$ there is $s\in[0,T]$ such that $[A_{ji}(s)]y\neq 0$, where $[A_{ji}(s)]$ is the matrix defined in* (3.19). □

From Proposition 3.2 we get the following sufficient condition for the stabilizability of system (3.10).

COROLLARY 3.3. *The following conditions are equivalent:*

(i) *For each $\lambda\in\sigma(V(0))$ with $|\lambda|>e^{-\omega T}$, we have $N(\lambda)\leqq k$, and there is $\bar{s}\in[0,T]$ such that the rank of the matrix $[A_{ji}(\bar{s})]$ defined in* (3.19) *is $N(\lambda)$;*

(ii) *For each $\lambda\in\sigma(V(0))$ with $|\lambda|>e^{-\omega T}$ we have $N(\lambda)\leqq k$, and there is $\bar{s}\in[0,T]$ such that, denoting by $\{\chi_1^*,\cdots,\chi_{N(\lambda)}^*\}$ any system of generators of* $\ker(\lambda-V(\bar{s})^*)$, *the rank of the matrix*

$$[B_{ji}]=[\langle\phi_j(\bar{s},\cdot),\chi_i^*\rangle]_{i=1,\cdots,N(\lambda),j=1,\cdots,k}$$

is $N(\lambda)$.

If either (i) *or* (ii) *holds, then conditions* (i) *and* (ii) *of Proposition* 3.2 *hold, so that system* (3.10) *is stabilizable.*

Proof. Since $G(T,s)^*:\ker(\lambda-V(0)^*)\to\ker(\lambda-V(s)^*)$ is an isomorphism, then $\{\xi_1^*,\cdots,\xi_{N(\lambda)}^*\}$ is a basis of $\ker(\lambda-V(0)^*)$ if and only if $\{G(T,s)^*\xi_1^*,\cdots,G(T,s)^*\xi_{N(\lambda)}^*\}$ is a basis of $\ker(\lambda-V(s)^*)$. Therefore, conditions (i) and (ii) are clearly equivalent. Moreover, if (i) holds, then for every $y\in\mathbf{R}^{N(\lambda)}\backslash\{0\}$ we have $[A_{ji}(\bar{s})]y\neq 0$, so that (ii) of Proposition 3.2 holds. □

4. Stabilizability in boundary control problems. Here we consider a parabolic initial value problem nonhomogeneous at the boundary,

$$\begin{aligned} &v_t(t,x)=\mathscr{A}(t,x,\partial)v(t,x), && t>0, \quad x\in\Omega,\\ &v(0,x)=v_0(x), && x\in\Omega,\\ &\mathscr{B}(x,\partial)v(t,x)=\Psi(t)g(t)(x), && t>0, \quad x\in\partial\Omega, \end{aligned} \tag{4.1}$$

where, as before, Ω is a bounded open set in $\mathbf{R}^n$ with C^2 boundary $\partial\Omega$, the linear operator $\mathscr{A}(t, x, \partial)$ is defined in (3.11) and its coefficients satisfy assumption (3.12), and $\mathscr{B}(x, \partial)$ is either the trace operator on $\partial\Omega$ or the differential operator defined in (3.13), with coefficients satisfying (3.14), $g(\cdot)$ is a function with values in a Banach space Z, and $\Psi(t)$ is a linear (time periodic) operator in $L(Z, L^p(\partial\Omega))$, for some $p > 1$.

$$(4.2)\quad \begin{aligned} &\text{(a)}\quad t \to a_{ij}(t, \cdot),\ t \to b_i(t, \cdot), \qquad t \to c(t, \cdot) \in C^{1+\alpha}(\mathbf{R};\ C(\bar{\Omega})),\\ &\text{(b)}\quad x \to a_{ij}(t, x) \in C^2(\bar{\Omega}),\quad x \to b_i(t, x) \in C^1(\bar{\Omega}),\quad x \to c(t, x) \in C(\bar{\Omega}),\quad \forall t \in \mathbf{R},\\ &\text{(c)}\quad \sup_{t\in\mathbf{R}} \|a_{ij}(t, \cdot)\|_{C^2(\bar{\Omega})} + \sup_{t\in\mathbf{R}} \|b_i(t, \cdot)\|_{C^1(\bar{\Omega})} + \sup_{t\in\mathbf{R}, x\in\bar{\Omega}} |c(t, x)| < +\infty, \end{aligned}$$

and we choose, as before, $X = L^p(\Omega)$, $D = \{\phi \in W^{2,p}(\Omega);\ \mathscr{B}\phi = 0\}$. Due to assumption (4.2)(a), the function $t \to A(t)$ (defined in (3.16)) belongs to $C^{1+\alpha}(\mathbf{R};\ L(D, X))$, so that there exists $G_s(t, s) \in L(X, D)$ for $t > s$ (see [17]).

4.1. The Dirichlet boundary condition. In this case, D is the space $W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega)$. We assume that

$$(4.3)\qquad 0 \in \rho(A(t)) \quad \forall t \in \mathbf{R},$$

so that for each $t \in \mathbf{R}$ the Dirichlet mapping $D(t) \in L(W^{2-1/p,p}(\partial\Omega), W^{2,p}(\Omega))$ is well defined by $D(t)y = z$, where z is the unique solution of the elliptic boundary value problem

$$(4.4)\qquad \mathscr{A}(t, x, \partial)z = 0 \quad \text{in } \Omega, \qquad z|_{\partial\Omega} = y$$

(see [3]). Concerning the linear operators $\Psi(t)$, we assume that

$$(4.5)\qquad \begin{aligned} &t \to \Psi(t) \in C^1(\mathbf{R}, L(Z, L^p(\partial\Omega))) \cap C(\mathbf{R}, L(Z, W^{2-1/p,p}(\partial\Omega))),\\ &\hspace{16em}\Psi(t + T) = \Psi(t), \quad t \in \mathbf{R}. \end{aligned}$$

In [17] we showed that for every $\xi \in C^1([0, +\infty[;\ L^p(\partial\Omega)) \cap C([0, +\infty[;\ W^{2-1/p,p}(\partial\Omega))$ the function $D(\cdot)\xi(\cdot)$ belongs to $C^1([0, +\infty[;\ X_\theta)$ for each $\theta < 1/2p$, and, if v_0 belongs to $L^p(\Omega)$, then problem

$$w'(t) = \mathscr{A}(t, \cdot, \partial)w, \quad t > 0, \quad w(0, \cdot) = w_0, \quad \mathscr{B}w(t) = \xi(t), \quad t > 0$$

has a unique solution $w \in C([0, +\infty[;\ L^p(\Omega)) \cap C^1(]0, +\infty[;\ L^p(\Omega)) \cap C(]0, +\infty[;\ W^{2,p}(\Omega))$, given by the representation formula

$$\begin{aligned} W(t) &= G(t, 0)w_0 + \int_0^t G_s(t, s)D(s)\xi(s)\, ds\\ &= G(t, 0)(w_0 - D(0)\xi(0)) - \int_0^t G(t, s)\frac{\partial}{\partial s}[D(s)\xi(s)]\, ds + D(t)\xi(t), \qquad t \geqq 0. \end{aligned}$$

Therefore, if g belongs to $C^1([0, +\infty[;\ Z)$, problem (4.1) has a unique solution v such that $t \to v(t, \cdot)$ belongs to $C([0, +\infty[;\ L^p(\Omega)) \cap C^1(]0, +\infty[;\ L^p(\Omega)) \cap C(]0, +\infty[;\ W^{2,p}(\Omega))$, and v is given by

$$\begin{aligned} v(t, \cdot) &= G(t, 0)v_0 + \int_0^t G_s(t, s)D(s)\Psi(s)g(s, \cdot)\, ds\\ (4.6)\qquad &= G(t, 0)(v_0 - D(0)\Psi(0)g(0, \cdot)) - \int_0^t G(t, s)\frac{\partial}{\partial s}[D(s)\psi(s)g(s, \cdot)]\, ds\\ &\quad + D(t)\Psi(t)g(t, \cdot), \qquad t \geqq 0. \end{aligned}$$

We want to find sufficient conditions on the data to ensure that for every $v_0 \in X$ there is $g \in C^1([0, +\infty[; Z)$ such that $v(t, \cdot)$ decays exponentially as $t \to +\infty$ in the $W^{2,p}$ norm. We use notation from § 2.

THEOREM 4.1. *Let* (4.2), $\cdots$, (4.5), (3.12)(*a*) *hold, and let* $\omega \geqq 0$ *be such that* $\sigma(V(s)) \cap \{\lambda \in \mathbf{C}; |\lambda| = e^{-\omega T}\} = \varnothing$ *for each* $s \in \mathbf{R}$. *Then the following statements are equivalent*:

(i) *For every* $v_0 \in L^p(\Omega)$ *there is* $g \in C^1_\omega([0, +\infty[; Z)$ *such that* $t \to v(t, \cdot)$ (*where* v *is the solution of* (4.1)) *belongs to* $C_\omega([0, +\infty[; L^p(\Omega))$;

(ii) *For every* $\lambda \in \mathbf{C}$ *with* $|\lambda| > e^{-\omega T}$ *we have*

$$(\lambda - V(0)^*)x^* = 0, \quad \Psi(s)^*\left[\frac{\partial}{\partial \nu_s}(G(T, s)^*x^*)\right] = 0 \quad \textit{for each } s \in [0, T] \Rightarrow x^* = 0,$$

where $\partial/\partial \nu_s \psi = a_{ij}(s, \cdot)D_i\psi(\cdot)\nu_j(\cdot)$ *and we identify* $G(T, s)^*x^*$ *with the function* $f \in W^{2,p^*}(\Omega)$ *such that* $(G(T, s)^*x^*)(y) = \int_\Omega y(x)f(x)\,dx$ *for each* $y \in L^p(\Omega)$.

If one of the equivalent conditions (i) *or* (ii) *holds, then for every* $v_0 \in L^p(\Omega)$ *there is* $g \in C^1_\omega([0, +\infty[; Z)$ *such that* $t \to v(t, \cdot)$ *belongs to* $C_\omega([a, +\infty[; W^{2,p}(\Omega))$ *for each* $a > 0$.

Proof. The proof is quite analogous to that of Theorem 3.1, therefore some steps will be only sketched.

First, from [17] it follows that if $t > s$, then $G(t, s)^*x^*$ belongs to $D(A(s)^*) \overset{\text{def}}{=} \{y^* \in X^*$: the mapping $D \to C$, $x \to \langle A(s)x, y^*\rangle$ has a continuous extension to $X\}$, and

$$G_s(t, s)^*x^* = -A(s)^*G(t, s)^*x^*.$$

Moreover, a simple integration by parts argument shows that for each $y^* \in D(A(s)^*) = W^{2,p^*}(\Omega) \cap W_0^{1,p^*}(\Omega)$ we have $A(s)^*y^* = D_{ij}(a_{ij}(s, \cdot)y^*(\cdot)) - D_j(b_j(\cdot)y^*(\cdot)) + c(\cdot)y^*(\cdot)$, and

$$D(s)^*A(s)^*y^* = \frac{\partial}{\partial \nu_s} y^*.$$

Therefore

$$D(s)^*(G_s(t, s)^*x^* = -\frac{\partial}{\partial \nu_s}(G(t, s)^*x^*), \qquad t > s. \tag{4.7}$$

Due to equality (4.7) and the first representation formula in (4.6), the proof of (i)$\Leftrightarrow$(ii) is the same (with obvious modifications) as the corresponding one in Theorem 3.1.

Now let one of the equivalent conditions (i) or (ii) hold; then for every $u_0 \in L^p(\Omega)$ there is $g \in C^1_\omega([0, +\infty[; Z)$ such that $\limsup_{t \to +\infty} \|e^{\omega t}u(t, \cdot)\|_{L^p(\Omega)} < +\infty$. We show that also $\limsup_{t \to +\infty} \|e^{\omega t}u(t, \cdot)\|_{W^{2,p}(\Omega)} < +\infty$.

Since $t \to v(t, \cdot)$ belongs to $C_\omega([0, +\infty[; L^p(\Omega))$, then by Proposition 2.3 we have

$$P_2(0)v_0 = -\int_0^{+\infty} \frac{\partial}{\partial s}[G(0, s)P_2(s)]D(s)\Psi(s)g(s)\,ds.$$

As remarked before, $s \to D(s)\Psi(s)g(s)$ belongs to $C^1([0, +\infty[; X_\theta)$ for each $\theta < 1/2p$; therefore, by Corollary 2.6 of [17], we can integrate by parts to get

$$P_2(0)[v_0 - D(0)\Psi(0)g(0)] = \int_0^{+\infty} G(0, s)P_2(s)\frac{\partial}{\partial s}[D(s)\Psi(s)g(s)]\,ds. \tag{4.8}$$

Since $s \to \Psi(s)g(s)$ belongs to $C^1([0, +\infty[; L^p(\partial\Omega)) \cap C([0, +\infty[; W^{2-1/p,p}(\partial\Omega))$, then, by using Proposition 3.1 of [17], we can see easily that $v \to v(t, \cdot)$ belongs to

$C([0,+\infty[;\ L^p(\Omega))\cap C^1(]0,+\infty[;\ L^p(\Omega))\cap C(]0,+\infty[;\ W^{2,p}(\Omega))$, and it may be represented by the second formula in (4.6). Since $s\to D(t)\Psi(t)g(t)$ belongs to $C_\omega([0,+\infty[;\ W^{2,p}(\Omega))$, then $t\to v(t,\cdot)$ is in $C_\omega([a,+\infty[;\ W^{2,p}(\Omega))$ for every $a>0$ if and only if the function

$$z(t)=G(t,0)[v_0-D(0)\Psi(0)g(0)]-\int_0^t G(t,s)\frac{\partial}{\partial s}[D(s)\Psi(s)g(s)]\,ds,\qquad t\geqq 0,$$

does. Since $d/ds\, D(s)\Psi(s)g(s)$ belongs to $C_\omega([0,+\infty[;\ X_\theta)$ with $\theta>0$ and (4.8) holds, the last statement of Proposition 2.1 implies $z\in C_\omega([a,+\infty[;\ W^{2,p}(\Omega))$ for every $a>0$. □

THEOREM 4.2. *Under the previous assumptions and notation, let* $Z=W^{2-1/p,p}(\partial\Omega)$, $\Psi(s)=\mathbf{I}$ *for each* s. *Then system* (4.1) *is stabilizable, provided* $\mathscr{A}(t,\cdot,\partial)$ *is formally self-adjoint, and* $\partial\Omega$ *and the coefficients of* $\mathscr{A}(t,\cdot,\partial)$ *are of class* C^∞ *for every* t.

Proof. For each $x^*\in X^*$, $G(T,s)^*x^*$ is the solution of

$$u'(s)=-A(s)^*u(s),\quad s<T,\qquad u(T)=x^*,$$

so that, setting $t=T-s$, we have $G(T,s)^*x^*=v(T-s)$, where v satisfies

$$v'(t)=A(T-t)^*v(t),\quad t>0,\qquad v(0)=x^*.$$

Now, a result of [19] ensures that the set $\{(t,x)\in[0,T]\times\partial\Omega;\ v(t,x)=\partial/\partial\nu\, v(t,x)=0\}$ has Lebesgue measure zero. Therefore $s\to\partial/\partial\nu_s(G(T,s)^*x^*)$ cannot vanish identically in $[0,T]$, and we can apply Theorem 4.1, which implies the statement. □

4.2. Applications to boundary control problems (I). Under the previous assumptions and notation, we consider in particular the case where

$$Z=\mathbf{R}^k,\qquad \Psi(t)(y_1,\cdots,y_k)=\psi_i(t,\cdot)y_i,\tag{4.9}$$

and

$$t\to\psi_i(t,\cdot)\in C^1(\mathbf{R};\ L^p(\partial\Omega))\cap C(\mathbf{R};\ W^{2-1/p,p}(\partial\Omega)),\qquad \psi_i(t+T,\cdot)=\psi_i(t,\cdot)\quad\forall t\in\mathbf{R}.\tag{4.10}$$

Applying Theorem 4.1 we get results similar to the ones of Proposition 3.2 and Corollary 3.3; the proof is also similar and it is omitted.

PROPOSITION 4.3. *Let* (4.2), (4.3), (4.9), (4.10) *hold, and let* $\omega\geqq 0$ *be such that no eigenvalue of* $V(0)$ *has modulus* $e^{-\omega T}$. *Then the following statements are equivalent*:

(i) *For each* $v_0\in L^p(\Omega)$ *there are* $y_1,\cdots,y_k\in C^1_\omega([0,+\infty[;\ \mathbf{R})$ *such that the solution* v *of* (4.1) *satisfies*

$$\sup_{t\geqq 0}\|e^{\omega t}v(t,\cdot)\|_{L^p(\Omega)}<+\infty,\quad \sup_{t\geqq a}\|e^{\omega t}v(t,\cdot)\|_{W^{2,p}(\Omega)}<+\infty\quad\forall a>0;$$

(ii) *For each* $\lambda\in\sigma(V(0))$ *with* $|\lambda|>e^{-\omega T}$, *denote by* $\{\xi_1^*,\cdots,\xi_{N(\lambda)}^*\}$ *any basis of* $\ker(\lambda-V(0)^*)$ *and set*

$$[A_{ji}(s)]=\left[\left\langle\psi_j(s,\cdot),\frac{\partial}{\partial\nu_s}G(T,s)^*\xi_i^*\right\rangle\right]_{i=1,\cdots,N(\lambda),j=1,\cdots,k}.\tag{4.11}$$

Then for every $y\in\mathbf{R}^{N(\lambda)}\backslash\{0\}$, *there is* $s\in[0,T]$ *such that* $[A_{ji}(s)]y\neq 0$.

Condition (i) *and* (ii) *hold if one of the following equivalent conditions is satisfied*:

(iii) *For each* $\lambda\in\sigma(V(0))$ *with* $|\lambda|>e^{-\omega T}$ *we have* $N(\lambda)\leqq k$, *and there is* $\bar{s}\in[0,T]$ *such that the rank of the matrix* $[A_{ji}(\bar{s})]$ *is* $N(\lambda)$;

(iv) *For each* $\lambda \in \sigma(V(0))$ *with* $|\lambda| > e^{-\omega T}$ *we have* $N(\lambda) \leqq k$, *and there is* $\bar{s} \in [0, T]$ *such that, denoting by* $\{\chi_1^*, \cdots, \chi_{N(\lambda)}^*\}$ *any system of generators of* $\ker(\lambda - V(\bar{s})^*)$, *the rank of the matrix*

$$[B_{ji}] = \left[\left\langle \psi_j(\bar{s}, \cdot), \frac{\partial}{\partial \nu_s} \chi_i^* \right\rangle\right]_{i=1,\cdots,N(\lambda), j=1,\cdots,k}$$

is $N(\lambda)$. □

4.3. The mixed boundary condition. The space D is now $D = \{g \in W^{2,p}(\Omega); \mathscr{B}(x, \partial)g = 0\}$, where $\mathscr{B}$ is the differential operator defined in (3.13). Assuming again that (4.3) holds, we may define the mixed mapping $M(t)$ by $M(t)g = z$, where z is the unique solution of the elliptic boundary value problem (1.6).

The assumptions on the linear operators $\Psi(t)$ are the following:

$$\text{(4.12)} \qquad \begin{aligned} &t \to \Psi(t) \in C^\beta(\mathbf{R}, L(Z, L^p(\partial\Omega))) \cap C(\mathbf{R}, L(Z, W^{1-1/p,p}(\partial\Omega))), \\ &\Psi(t+T) = \Psi(t), \quad t \in \mathbf{R}, \end{aligned}$$

where

$$\text{(4.13)} \qquad \beta > \frac{1}{2} + \frac{1}{2p}.$$

The linear mapping $M(t)$ belongs to $L(L^p(\partial\Omega), W^{1-1/p-\varepsilon,p}(\Omega)) \cap L(W^{1-1/p,p}(\partial\Omega), W^{2,p}(\Omega))$ for each $t \in \mathbf{R}$ and $\varepsilon > 0$ (see [3] and [14]; in fact, in [14] more regularity assumptions are made in order to treat a larger class of boundary value problems, but the reader can check that in this regularity problem our hypotheses are sufficient). Moreover, assumption (4.2) implies also that $t \to M(t)$ belongs to $C^1(\mathbf{R}; L(L^p(\partial\Omega), W^{1-1/p-\varepsilon,p}(\Omega))) \cap C^1(\mathbf{R}; L(W^{1-1/p,p}(\partial\Omega), W^{2,p}(\Omega)))$. On the other hand, by [10] we have

$$X_\theta = B_\infty^{2\theta,p}(\Omega) \quad \text{for } \theta < \frac{1}{2} - \frac{1}{2p},$$

with equivalence of the respective norms, so that, recalling that $W^{1-1/p-\varepsilon,p}(\Omega)$ is continuously embedded in $B_\infty^{1-1/p-\varepsilon,p}(\Omega)$, we also get

$$t \to M(t) \in C^1(\mathbf{R}; L(Z, X_\theta)).$$

Therefore, for every $\psi \in C^\beta([0, +\infty[; L^p(\partial(\Omega)) \cap C([0, +\infty[; W^{1-1/p,p}(\partial\Omega))$, we have

$$t \to M(t)\psi(t) \in C^\beta([0, +\infty[; X_\theta) \cap C([0, +\infty[; W^{2,p}(\Omega)), \qquad \theta < \frac{1}{2} - \frac{1}{2p}.$$

Under such regularity assumptions, it can be deduced from [17] that, for every $w_0 \in L^p(\Omega)$, the problem

$$w'(t) = \mathscr{A}(t, \cdot, \partial)w, \quad t > 0, \quad w(0, \cdot) = w_0, \quad \mathscr{B}w(t) = \psi(t), \quad t > 0,$$

has a unique solution $w \in C([0, +\infty[; L^p(\Omega)) \cap C^1(]0, +\infty[; L^p(\Omega)) \cap C([0, +\infty[; W^{2,p}(\Omega))$, given by the representation formula

$$w(t) = G(t, 0)w_0 + \int_0^t G_s(t, s)M(s)\psi(s)\, ds, \qquad t \geqq 0.$$

Therefore, if $g:[0,+\infty[\to Z$ is locally β-Hölder continuous, then problem (4.1) has a unique solution v such that $t\to v(t,\cdot)\in C([0,+\infty[;\ L^p(\Omega))\cap\ C^1(]0,+\infty[;\ L^p(\Omega))\cap C([0,+\infty[;\ W^{2,p}(\Omega))$, given by

$$v(t,\cdot)=G(t,0)v_0+\int_0^t G_s(t,s)M(s)\Psi(s)g(s,\cdot)\,ds,\qquad t\geqq 0.$$

The following result, concerning stabilizability for problem (4.1), is quite similar to the one of Theorem 4.1.

THEOREM 4.4. *Let* (4.2), (4.3), (4.12), (4.13), (3.12)(a) *hold, and let* $\omega\geqq 0$ *be such that* $\sigma(V(s))\cap\{\lambda\in\mathbf{C};\ |\lambda|=e^{-\omega T}\}=\emptyset$ *for each* $s\in\mathbf{R}$. *Then the following statements are equivalent*:

(i) *For every* $v_0\in L^p(\Omega)$ *there is* $g\in C^\beta_\omega([0,+\infty[;\ Z)$ *such that* $t\to v(t,\cdot)$ (*where* v *is the solution of* (4.1)) *belongs to* $C_\omega([0,+\infty[;\ L^p(\Omega))$;

(ii) *For every* $\lambda\in\mathbf{C}$ *with* $|\lambda|>e^{-\omega T}$ *we have*

$$(\lambda-V(0)^*)x^*=0,\quad \Psi(s)^*[(G(T,s)^*x^*)_{|\partial\Omega}]=0\quad \textit{for each } s\in[0,T]\Rightarrow x^*=0,$$

where we identify $G(T,s)^*x^*$ *with the function* $f\in W^{2,p^*}(\Omega)$ *such that* $(G(T,s)^*x^*)(y)=\int_\Omega y(x)f(x)\,dx$ *for each* $y\in L^p(\Omega)$.

If one of the equivalent conditions (i) *or* (ii) *holds, then for every* $v_0\in L^p(\Omega)$ *there is* $g\in C^\beta_\omega([0,+\infty[;Z)$ *such that* $t\to v(t,\cdot)$ *belongs to* $C_\omega([a,+\infty[;\ W^{2,p}(\Omega))$ *for each* $a>0$.

Proof. It is similar to the one of Theorem 4.1. Concerning $D(A(s)^*)$, it is well known (see [14]) that there are a first-order boundary operator $\mathscr{B}^*=\mathscr{B}^*(s,\cdot,\partial)$, and a zero order boundary operator $\mathscr{C}^*$ (with $\mathscr{C}^*\phi=c^*(s,x)\phi(x)$, $c^*(s,x)\neq 0$ for any $x\in\partial\Omega$) such that for every couple of regular functions u, v we have

$$\int_\Omega [v(x)(\mathscr{A}(s,x,\partial)u)(x)-u(x)(\mathscr{A}^*(s,x,\partial)v)(x)]\,dx$$

$$=\int_{\partial\Omega}[u(\cdot)\mathscr{B}^*v(\cdot)-\mathscr{B}u(\cdot)\mathscr{C}^*v(\cdot)]\,d\sigma_x,$$

where $\mathscr{A}^*(s,\cdot,\partial)$ is defined in (4.7). Then $D(A(s)^*)=\{y^*\in W^{2,p^*}(\Omega):\ \mathscr{B}^*y^*=0\}$, and $A(s^*)y^*=\mathscr{A}^*(s,\cdot,\partial)y^*$. Integrating by parts we easily get

$$(M(s)^*A(s)^*y^*)(x)=-c^*(s,x)y^*(x),\quad s\in\mathbf{R},\quad x\in\partial\Omega,\quad y^*\in D(A(s)^*),$$

so that

$$M(s)^*G_s(t,s)^*x^*=c^*(s,\cdot)G(t,s)^*x^*_{|\partial\Omega},\quad \forall x^*\in X^*=L^{p^*}(\Omega),\quad t>s,$$

and we have to apply Proposition 2.3 instead of Proposition 2.1. □

4.4. Applications to boundary control problems (II). We again consider the case where

$$Z=\mathbf{R}^k,\qquad \Psi(t)(y_1,\cdots,y_k)=\psi_i(t,\cdot)y_i,\tag{4.14}$$

and, for some $\beta\in]\frac{1}{2},1[$

$$\begin{aligned}&t\to\psi_i(t,\cdot)\in C^\beta(\mathbf{R};\ L^p(\partial\Omega))\cap C(\mathbf{R};\ W^{2-1/p,p}(\partial\Omega)),\\ &\qquad\qquad\qquad\qquad\qquad\phi_i(t+T,\cdot)=\phi_i(t,\cdot)\quad\forall t\in\mathbf{R}.\end{aligned}\tag{4.15}$$

Applying Theorem 4.1 we get a result similar to the one of Proposition 3.2.

PROPOSITION 4.5. *Let* (3.12)(a), (4.2), (4.3), (4.14), (4.15) *hold, and let* $\omega\geqq 0$ *be such that no eigenvalue of* $V(0)$ *has modulus* $e^{-\omega T}$. *Then the following statements are equivalent*:

(i) *For each* $v_0 \in L^p(\Omega)$ *there are* $y_1, \cdots, y_k \in C^\beta_\omega([0, +\infty[; \mathbf{R})$ *such that the solution* v *of* (4.1) *satisfies*

$$\sup_{t \geqq 0} \|e^{\omega t} v(t, \cdot)\|_{L^p(\Omega)} < +\infty, \quad \sup_{t \geqq a} \|e^{\omega t} v(t, \cdot)\|_{W^{2,p}(\Omega)} < +\infty \quad \forall a > 0;$$

(ii) *For each* $\lambda \in \sigma(V(0))$ *with* $|\lambda| > e^{-\omega T}$, *denote by* $\{\xi_1^*, \cdots, \xi_{N(\lambda)}^*\}$ *any basis of* $\ker(\lambda - V(0)^*)$ *and set*

$$[A_{ji}(s)] = [\langle \psi_j(s, \cdot), (G(T, s)^* \xi_i^*)_{|\partial\Omega} \rangle]_{i=1,\cdots,N(\lambda), j=1,\cdots,k}. \tag{4.16}$$

Then for every $y \in \mathbf{R}^{N(\lambda)} \backslash \{0\}$, *there is* $s \in [0, T]$ *such that* $[A_{ji}(s)] y \neq 0$.

Conditions (i) *and* (ii) *hold if one of the following equivalent conditions is satisfied*:

(iii) *For each* $\lambda \in \sigma(V(0))$ *with* $|\lambda| > e^{-\omega T}$ *we have* $N(\lambda) \leqq k$, *and there is* $\bar{s} \in [0, T]$ *such that the rank of the matrix* $[A_{ji}(\bar{s})]$ *defined in* (4.16) *is* $N(\lambda)$;

(iv) *For each* $\lambda \in \sigma(V(0))$ *with* $|\lambda| > e^{-\omega T}$ *we have* $N(\lambda) \leqq k$, *and there is* $\bar{s} \in [0, T]$ *such that, denoting by* $\{\chi_1^*, \cdots, \chi_{N(\lambda)}^*\}$ *any system of generators of* $\ker(\lambda - V(\bar{s})^*$, *the rank of the matrix*

$$[B_{ji}] = [\langle \psi_j, \chi_{i|\partial\Omega} \rangle]_{i=1,\cdots,N(\lambda), j=1,\cdots,k}$$

is $N(\lambda)$. □

A PERTURBED PARALLEL DECOMPOSITION METHOD FOR A CLASS OF NONSMOOTH CONVEX MINIMIZATION PROBLEMS*

KHALIL MOUALLIF†, VAN HIEN NGUYEN‡, AND JEAN-JACQUES STRODIOT‡

Abstract. A perturbed parallel decomposition method for solving the following model problem is presented: minimize $f_0(x)+\sum_{i=1}^m f_i(x)$ over all x in $\mathbb{R}^n$, where f_0 is differentiable and strongly convex, and the f_i's are closed, proper, and convex (but not necessarily differentiable). An important feature of the proposed method is the ability to split the given problem into independent subproblems that contain only individual functions; in that way the algorithm is suitable for parallel computation. The approach also allows for inaccuracies and duality gaps during the iterative process. Furthermore, convergence is established under perturbations on the f_i's in the epiconvergence sense (and under inexact minimizations at each iteration). Relations of the method with the recent work of Han and Lou on the same model problem are also discussed. From the theoretical point of view, this paper represents a significant improvement on the parallel decomposition algorithms of Han and Lou.

Key words. decomposition technique, parallel optimization algorithm, nonsmooth convex programming, variational convergence

1. Introduction.

This paper presents a general perturbed parallel decomposition method for solving the following nondifferentiable convex optimization problem:

$$\text{(P)} \qquad \text{minimize}\, f_0(x)+\sum_{i=1}^{m} f_i(x) \quad \text{over all } x\in\mathbb{R}^n$$

where $f_0:\mathbb{R}^n\to\mathbb{R}$ is differentiable and strongly convex with modulus α (see, for example, Rockafellar [23]) and for all $i=1,\cdots,m$, each f_i is a closed proper convex function from $\mathbb{R}^n$ into the extended real line $\mathbb{R}\cup\{+\infty\}$ (see Rockafellar [22]). We do not assume the f_i's to be differentiable. Note that the f_i's are allowed to take the value $+\infty$; this fact is important since it permits us to model implicitly the constraints that may be imposed on the choice of x. For consistency, we assume that

$$\bigcap_{i=1}^{m} \operatorname{dom} f_i \neq \emptyset,$$

where $\operatorname{dom} f_i$ is the effective domain of f_i defined by

$$\operatorname{dom} f_i=\{x\in\mathbb{R}^n \mid f_i(x)<+\infty\}.$$

In the method we propose here, the problem (P) is first perturbed (that is, the f_i's are replaced by functions f_i^k, which approximate the f_i's in the sense of epiconvergence; see, for example, Attouch and Wets [3], [5]) and is then dualized in the sense of convex analysis (see [22]) to obtain a problem that is a nonsmooth unconstrained convex problem, which in turn is solved by applying the so-called auxiliary problem principle (see, for example, Cohen [10]). An important feature of our method is that the problem (P) (or rather, its perturbed form) is decomposed into independent subproblems that contain only individual functions f_i (or rather f_i^k); in this way the algorithm is suitable for parallel computation. In our approach we also allow the solutions of the perturbed "primal" and "dual" programs, which are alternately and

repeatedly solved during the parallel iterative process, to be inaccurate. Note that this property is very important, especially as far as applications and computations are concerned; exact solutions—if they do exist—may be difficult, if not impossible, to find. In the general framework that we work with in this paper (that is, under perturbations and with inexact minimizations) we are able to show that, under fairly mild conditions, the method has attractive convergence properties both in the "primal" space and in the "dual" space.

The motivation for this paper comes from the observation that the model problem (P) represents a fairly broad class of problems that may arise in various situations. For example, the present method can be applied to the following constrained optimization problem (although we are mainly concerned with the unconstrained problem (P)):

$$(\bar{\mathrm{P}}) \qquad \begin{aligned} &\text{minimize} && f_0(x) \\ &\text{subject to} && x \in C_1 \cap \cdots \cap C_m, \end{aligned}$$

where f_0 is as above, and for all $i = 1, \cdots, m$, each C_i is a nonempty closed convex set of $\mathbb{R}^n$. For consistency, we assume that the set $C_1 \cap \cdots \cap C_m$ is nonempty. Then, the problem $(\bar{\mathrm{P}})$ may be rewritten in the equivalent form

$$(1.1) \qquad \text{minimize} f_0(x) + \sum_{i=1}^{m} \delta(x|C_i) \quad \text{over all } x \in \mathbb{R}^n,$$

where $\delta(\cdot|C_i)$ is the indicator function of C_i defined by

$$\delta(x|C_i) = \begin{cases} 0 & \text{if } x \in C_i, \\ +\infty & \text{otherwise.} \end{cases}$$

Clearly, the problem (1.1) (therefore, the problem $(\bar{\mathrm{P}})$) is a problem of the form (P) since the functions $\delta(\cdot|C_i) = f_i$ are obviously closed, proper, and convex. Note that this example $(\bar{\mathrm{P}})$ includes as a special case the well-known projection problem of a given point in $\mathbb{R}^n$ onto the intersection of a finite number of convex sets of $\mathbb{R}^n$ (see [14]).

Another instance where the model problem (P) arises is when we want to

$$(1.2) \qquad \begin{aligned} &\text{minimize} && f_0(x) + \sum_{i=1}^{m} \langle c^i, z^i \rangle \\ &\text{subject to} && A_i x + B_i z^i \le b^i \quad \text{for } i = 1, \cdots, m \\ & && x \in \mathbb{R}^n, \quad z^i \in \mathbb{R}^{n_i}, \end{aligned}$$

where f_0 is as above, $c^i \in \mathbb{R}^{n_i}$, $b^i \in \mathbb{R}^{m_i}$, A_i, and B_i are $m_i \times n$ and $m_i \times n_i$ matrices, respectively, whereas $\langle \cdot, \cdot \rangle$ denotes the Euclidean inner product in $\mathbb{R}^{n_i}$ (for all $i = 1, \cdots, m$). Then, it is known (see, for example, Lasdon [16]) that, under reasonable assumptions, the functions

$$f_i(x) = \min \{\langle c^i, z^i \rangle | z^i \in \mathbb{R}^{n_i}, B_i z^i \le b^i - A_i x\}$$

are finite real-valued, convex, and piecewise linear (polyhedral). Then, the problem (1.2) can be restated as the model problem (P). Similar ideas are also encountered for other decomposable problems in stochastic programming (see, for example, the state-of-the-art tutorials of Wets [27] and Varaiya and Wets [26]) and in structural optimization (see, for example, Barthelemy [8] for a useful survey).

Our method is closely related to—but is different from—that proposed by Han and Lou [13] for the model problem (P) ("Algorithm II for (B)"). The main differences with this recent work are twofold. First of all, the derivation of the method is entirely different here from that described in [13]. Roughly speaking, in [13] Han and Lou begin by presenting a basic decomposition method for solving the following optimization problem ("Algorithm I for (A)"):

$$\text{(A)} \qquad \text{minimize}\, p(y_1, \cdots, y_m) + \sum_{i=1}^{m} g_i(y_i) \quad \text{over all } y_1 \in \mathbb{R}^{n_1}, \cdots, y_m \in \mathbb{R}^{n_m},$$

where $p:\mathbb{R}^{n_1+\cdots+n_m} \to \mathbb{R}$ is a convex, differentiable function whose gradient mapping is Lipschitz continuous, and $g_i:\mathbb{R}^{n_i} \to \mathbb{R} \cup \{+\infty\}$ is closed, proper, and convex for all $i = 1, \cdots, m$. Then, through duality theory, they transform the model problem (P) into a dual problem that has the form of (A), and apply their basic decomposition technique to the dual so that they can also decompose the model problem (P) and solve it in parallel.

A second difference between our approach and the one of Han and Lou [13] is that we allow for inaccuracies and variational perturbations during the parallel iterative process. Our development therefore encompasses that of Han and Lou for the case of the model problem (P). One of the implications of our development is that an additional regularity assumption made in [13] is proven to be superfluous. This arises from the fact that they did need a duality theorem for the dual programs they had to consider. As a consequence, our convergence results are more general. Details are discussed in § 4.

Note that our method is also related to the proximal point algorithm in convex programming (for a survey, see Lemaire [17]), but with a simultaneous utilization of a gradient method for the differentiable part of the objective function.

The remainder of the paper is organized as follows. The method is derived and stated in § 2. Its connections with Han and Lou's "Algorithm II for (B)" [13] are established in § 3. There we show that the "Algorithm I for (A)" of Han and Lou [13] can also be derived in the same way as in § 2, that is, by applying the auxiliary problem principle. Convergence results for the method are presented in § 4. Finally, we end the paper with a conclusion section.

We use the following notation and terminology. $\mathbb{R}^n$ denotes the n-dimensional Euclidean space with the ordinary inner product $\langle \cdot, \cdot \rangle$ and the associated two-norm $\|\cdot\|$. All vectors are column vectors. However, for convenience, a column vector in $\mathbb{R}^{n_1+n_2}$ is denoted by (x_1, x_2), even though x_1 and x_2 are column vectors in $\mathbb{R}^{n_1}$ and $\mathbb{R}^{n_2}$, respectively.

All the definitions and most of the notation concerning convex analysis are those of Rockafellar [22]. For instance, the conjugate of a convex function f, denoted by f^*, is given by

$$f^*(y) = \sup_{x \in \mathbb{R}^n} \{\langle x, y\rangle - f(x)\}$$

and the subdifferential of f at $\bar{x}$ is given by

$$\partial f(\bar{x}) = \{y \in \mathbb{R}^n \mid f(z) \geq f(\bar{x}) + \langle z - \bar{x}, y\rangle \text{ for all } z \in \mathbb{R}^n\}.$$

2. Derivation of the method. In this section, the general perturbed parallel decomposition method will be proposed for solving the model problem (P). Before doing this it is necessary to recall (see Wijsman [29]) the following definition of epiconvergence of a sequence of closed proper convex functions. Epigraphical analysis provides a very rich and unified tool to study a broad class of problems that includes variational problems, generalized equations, and mathematical programs, and has received much attention during the last decade (see, for example, Attouch [2], Attouch and Wets [3], [5], and Rockafellar and Wets [24]).

Let $\{\phi^k\}$ be a sequence of closed proper convex functions from $\mathbb{R}^n$ into $\mathbb{R} \cup \{+\infty\}$ and suppose ϕ is a function satisfying the same hypotheses. Epiconvergence of $\{\phi^k\}$ to ϕ may be characterized by the conjunction of these very tangible local conditions: At each $x \in \mathbb{R}^n$,

(i) Whenever $\{x^k\} \to x$, then $\liminf \phi^k(x^k) \geq \phi(x)$;

(ii) There exists a sequence $\{x^k\}$ convergent to x for which $\lim \phi^k(x^k) = \phi(x)$. We will write

$$\phi = \text{epi-lim } \phi^k$$

for "$\{\phi^k\}$ is epi-convergent to ϕ."

As in Lemaire [18], the model problem (P) is embedded in a family of parametrized problems by perturbing the functions f_i (for $i = 1, \cdots, m$) in replacing them by the functions f_i^k (for $i = 1, \cdots, m$, and $k \in \mathbb{N}$) satisfying the following condition:

$$f_i = \underset{k \to +\infty}{\text{epi-lim}} f_i^k \qquad (i = 1, \cdots, m), \tag{2.1}$$

where, of course, the functions f_i^k are also closed, proper, and convex. Thus, we are led to consider the approximating problems

$$\text{minimize } f_0(x) + \sum_{i=1}^{m} f_i^k(x) \quad \text{over all } x \in \mathbb{R}^n. \tag{P$_k$}$$

For illustration purposes, we consider the problem ($\bar{\text{P}}$) here again. It was shown in § 1 that the problem ($\bar{\text{P}}$) is equivalent to the problem (1.1), which is of the form (P) with

$$f_i = \delta(\cdot | C_i) \quad \text{for } i = 1, \cdots, m.$$

For each $i = 1, \cdots, m$, we consider penalty functions f_i^k (where $k \in \mathbb{N}$) satisfying the following conditions (compare with Auslender, Crouzeix, and Fédit [7]):

$$f_i^k : \mathbb{R}^n \to \mathbb{R} \quad \text{is convex for all } k \in \mathbb{N}; \tag{H1}$$

$$f_i^k \leq f_i^{k+1} \quad \text{for all } k \in \mathbb{N}; \tag{H2}$$

$$\begin{aligned} &\lim_{k \to +\infty} f_i^k(x) = 0 && \text{if } x \in C_i, \\ &\lim_{k \to +\infty} f_i^k(x) = +\infty && \text{otherwise.} \end{aligned} \tag{H3}$$

Then, it follows immediately from Attouch [2, Thm. 3.20] that

$$\underset{k \to +\infty}{\text{epi-lim}} f_i^k = \delta(\cdot | C_i) = f_i \quad \text{for all } i = 1, \cdots, m.$$

Note that if the constraint set C_i, for $i = 1, \cdots, m$ is defined by

$$C_i = \{x \in \mathbb{R}^n | g_i(x) \leq 0\},$$

where $g_i : \mathbb{R}^n \to \mathbb{R}$ is convex, then we can take f_i^k as the classical exterior penalty function

$$f_i^k = r_i^k(\max\{0, g_i\})^2$$

or as the exact penalty function

$$f_i^k = r_i^k \max\{0, g_i\},$$

where

$$0 < r_i^k \leq r_i^{k+1} \quad \text{and} \quad \lim_{k \to +\infty} r_i^k = +\infty.$$

In these conditions, it is easy to see that the functions f_i^k satisfy the above assumptions (H1)-(H3); that is, they are perturbations of f_i in our sense.

For discussion of other examples of f_i^k verifying (2.1), we refer to Attouch and Wets [3], Mine and Fukushima [21], Attouch [2], and Alart and Lemaire [1].

We now turn to the perturbed problem (P_k). We take the Fenchel dual (see [22, Thm. 31.1]) of (P_k) to obtain a nonsmooth dual convex problem, namely,

$$(\mathrm{P}_k^*) \qquad \text{minimize} f_0^*(y)+\left(\sum_{i=1}^m f_i^k\right)^*(-y) \quad \text{over all } y\in\mathbb{R}^n.$$

By Theorem 16.4 of Rockafellar [22], if

$$(2.2) \qquad \bigcap_{i=1}^m \operatorname{ri}(\operatorname{dom} f_i^k)\neq\varnothing$$

(ri stands for the relative interior) then the second term of the objective function of (P_k^*) is such that

$$\left(\sum_{i=1}^m f_i^k\right)^*(y)=\inf\left\{\sum_{i=1}^m (f_i^k)^*(y_i)|y_1,\cdots,y_m\in\mathbb{R}^n,\ \sum_{i=1}^m y_i=y\right\}.$$

Because of this equality, we consider from now on (even in the cases where the hypothesis (2.2) does not hold) as the Fenchel dual program of (P_k) the following problem:

$$(\mathrm{D}_k) \qquad \text{minimize} f_0^*\left(\sum_{i=1}^m y_i\right)+\sum_{i=1}^m (f_i^k)^*(-y_i) \quad \text{over all } y_1\in\mathbb{R}^n,\cdots,y_m\in\mathbb{R}^n.$$

It should be pointed out that, in this paper, we *do not* assume that the regularity condition (2.2) (or a similar condition on ri (dom f_i)) holds. As a consequence of this, we do not necessarily have a duality theorem for the dual pair (P_k) and (D_k). Another way of expressing this is to say that our approach allows for duality gaps between these primal and dual programs during the parallel iterative process. This property is important because it may not always be possible or desirable to generate dual solutions that close the duality gap.

The following result is the key to the derivation of the method. To state it some new terminology must first be introduced.

Let $F_0:\mathbb{R}^N\to\mathbb{R}$ be a differentiable convex function and let $G^k:\mathbb{R}^N\to\mathbb{R}\cup\{+\infty\}$ be a closed proper convex function depending on a natural integer k. We are concerned with the following (master) problem for each fixed k in $\mathbb{N}$:

$$(\mathrm{MP}_k) \qquad \text{minimize } F_0(y)+G^k(y) \quad \text{over all } y\in\mathbb{R}^N.$$

Now let $K^k:\mathbb{R}^n\to\mathbb{R}$ be a differentiable and strongly convex function depending on k and consider the following function $J_{\bar{y}}^k:\mathbb{R}^N\to\mathbb{R}\cup\{+\infty\}$ depending on some $\bar{y}\in\mathbb{R}^N$ and $\varepsilon_k>0$ defined by

$$(2.3) \qquad J_{\bar{y}}^k(y)=K^k(y)+\langle\varepsilon_k\nabla F_0(\bar{y})-\nabla K^k(\bar{y}),y\rangle+\varepsilon_k G^k(y) \quad \text{for all } y\in\mathbb{R}^N.$$

Then we have the following fundamental lemma that Cohen [10, Lemma 2.2] called the auxiliary problem principle.

LEMMA 1. *For each fixed $k\in\mathbb{N}$, we have that $\bar{y}\in\mathbb{R}^N$ solves the (auxiliary) problem*

$$(\mathrm{AP}_k) \qquad \textit{minimize } J_{\bar{y}}^k(y) \quad \textit{over all } y\in\mathbb{R}^N$$

if and only if $\bar{y}$ solves the master problem (MP_k).

Proof. The following statements are equivalent:

$\bar{y}$ is an optimal solution of $(\mathrm{AP}_k) \Leftrightarrow 0 \in \partial J_{\bar{y}}^k(\bar{y})$

$\Leftrightarrow 0 \in \nabla F_0(\bar{y}) + \partial G^k(\bar{y})$ by [22, Thm. 23.8])

$\Leftrightarrow \bar{y}$ is an optimal solution of (MP_k). □

To find such a $\bar{y} \in \mathbb{R}^N$ (whose existence is ensured under reasonable conditions) Cohen [10] proposed to use, for each fixed $k \in \mathbb{N}$, a kind of fixed-point algorithm.

Let a sequence of differentiable and strongly convex functions $\{K^{kj}\}_{j \in \mathbb{N}}$ and a sequence of positive numbers $\{\varepsilon_{kj}\}_{j \in \mathbb{N}}$ be chosen. The index j denotes the iteration index. Cohen's algorithm [10] can be described as follows:

Initialization Step
Choose a point $y^0 \in \mathbb{R}^N$, let $j = 0$, and go to the main step.
Main Step
Let y^{j+1} be an optimal solution to the following auxiliary problem:

(AP_{kj}) minimize $K^{kj}(y) + \langle \varepsilon_{kj} \nabla F_0(y^j) - \nabla K^{kj}(y^j), y \rangle + \varepsilon_{kj} G^k(y)$ for all $y \in \mathbb{R}^N$.

If $\|y^{j+1} - y^j\|$ or $|F_0(y^{j+1}) + G^k(y^{j+1}) - F_0(y^j) - G^k(y^j)|$ is below some desired tolerance, then stop; otherwise, replace j by $j+1$, and repeat.

Set for each fixed $k \in \mathbb{N}$

$$F_0(y) = f_0^*\left(\sum_{i=1}^m y_i\right) \tag{2.4}$$

and

$$G^k(y) = \sum_{i=1}^m (f_i^k)^*(-y_i) \tag{2.5}$$

for all $y = (y_1, \ldots, y_m) \in \mathbb{R}^{m \cdot n}$. Also we set $m \cdot n = N$. Then, clearly, the Fenchel dual problem (D_k) is of the form of the master problem (MP_k), to which Lemma 1 applies. Indeed, because $f_0 : \mathbb{R}^n \to \mathbb{R}$ was supposed to be differentiable and strongly convex with modulus α, it is known (see, for example, Han and Lou [12, § 2] or [13, § 3]) that the conjugate function $f_0^* : \mathbb{R}^n \to \mathbb{R}$ of f_0 is also differentiable everywhere, strictly convex, co-finite, and

$$\nabla f_0^* = (\nabla f_0)^{-1}. \tag{2.6}$$

Thus, the function $F_0 : \mathbb{R}^N \to \mathbb{R}$, as defined by (2.4), is differentiable and convex. On the other hand, because the functions $f_i^k : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ were assumed to be closed, proper, and convex, it is easy to see (by Rockafellar [22, Thm. 12.2]) that the conjugate functions $(f_i^k)^* : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\}$ of f_i^k also have the same properties. For each $k \in \mathbb{N}$, the function $G^k : \mathbb{R}^N \to \mathbb{R} \cup \{+\infty\}$, as defined by (2.5), is thus obviously a closed proper convex function.

However, for obvious reasons, we do not want to solve each dual problem (D_k). So it is natural to consider a diagonal process to generate the sequence $\{y^k\}_{k \in \mathbb{N}}$: At the kth iteration, in order to compute y^{k+1} from y^k, we only solve the auxiliary problem (AP_{kj}) with $j = k$. Moreover, for each $k \in \mathbb{N}$, we suppose that $\varepsilon_{kk} = 1$ and $K^{kk}(y) = (1/2\lambda_k)\|y\|^2$ for all $y \in \mathbb{R}^N$, where $\lambda_k > 0$. This kind of quadratic core K^{kk} has often been used to ensure convergence; in particular, it is akin to the proximal point algorithm; for example, see Rockafellar [23] and Lemaire [17].

In other words, from a starting point $y^0 \in \mathbb{R}^N$, a sequence $\{y^k\}_{k\in\mathbb{N}}$ will be generated step by step as follows: for each $k \in \mathbb{N}$, y^{k+1} is the optimal solution to the problem

$$(\mathrm{AD}_k) \quad \text{minimize } (1/2\lambda_k)\|y\|^2 + \langle \nabla F_0(y^k) - (1/\lambda_k)y^k, y\rangle + G^k(y) \quad \text{for all } y \in \mathbb{R}^N.$$

Then we can write

$$y^{k+1} = \arg\min_{y\in\mathbb{R}^N} \{(1/2\lambda_k)\|y - y^k + \lambda_k \nabla F_0(y^k)\|^2 + G^k(y)\} \tag{2.7}$$

because

$$(1/2\lambda_k)\|y - y^k + \lambda_k \nabla F_0(y^k)\|^2 + G^k(y) = (1/2\lambda_k)\|y\|^2 + \langle \nabla F_0(y^k) - (1/\lambda_k)y^k, y\rangle + G^k(y) + \text{term independent of } y.$$

Now remember from (2.4) and (2.5) that

$$\nabla F_0(y) = \nabla F_0(y_1, \cdots, y_m) = \left(\nabla f_0^*\left(\sum_{i=1}^m y_i\right), \cdots, \nabla f_0^*\left(\sum_{i=1}^m y_i\right)\right)$$

and

$$G^k(y) = \sum_{i=1}^m (f_i^k)^*(-y_i),$$

and that $\|\cdot\|$ denotes the Euclidean norm in $\mathbb{R}^{m\cdot n}$, in such a way that we can get the following splitting of y^{k+1}, as defined by (2.7), into individual components ($i = 1, \cdots, m$):

$$y_i^{k+1} = \arg\min_{y_i\in\mathbb{R}^n} \left\{(1/2\lambda_k)\left\| y_i - y_i^k + \lambda_k \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right\|^2 + (f_i^k)^*(-y_i)\right\}.$$

Thus, we easily obtain that

$$y_i^{k+1} = \arg\min_{y_i\in\mathbb{R}^n} \left\{(1/2\lambda_k)\|y_i - y_i^k\|^2 + \left\langle y_i - y_i^k, \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right\rangle + (f_i^k)^*(-y_i)\right\}. \tag{2.8}$$

Consequently, the characterization of optimality says that

$$0 \in \partial\left((1/2\lambda_k)\|\cdot - y_i^k\|^2 + \left\langle \cdot - y_i^k, \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right\rangle + (f_i^k)^*(-\cdot)\right)(y_i^{k+1}).$$

Convex analysis calculus then gives

$$0 \in (1/\lambda_k)(y_i^{k+1} - y_i^k) + \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right) - \partial(f_i^k)^*(-y_i^{k+1}).$$

Equivalently, we have

$$(1/\lambda_k)(y_i^{k+1} - y_i^k) + \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right) \in \partial(f_i^k)^*(-y_i^{k+1}).$$

By Rockafellar [22, Thm. 23.5], this is in turn equivalent to

$$-y_i^{k+1} \in \partial f_i^k\left((1/\lambda_k)(y_i^{k+1} - y_i^k) + \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right);$$

that is,

$$0 \in y_i^{k+1} + \partial f_i^k\left((1/\lambda_k)(y_i^{k+1} - y_i^k) + \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right).$$

We can then express this differential inclusion as

$$y_i^{k+1} = \arg\min_{y_i \in \mathbb{R}^n} \left\{(1/2\lambda_k)\|y_i\|^2 + f_i^k\left((1/\lambda_k)(y_i - y_i^k) + \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right)\right\}. \tag{2.9}$$

To evaluate $\nabla f_0^*(\sum_{i=1}^m y_i^k)$ in (2.9), we want to avoid the conjugate function f_0^* in computation. For this purpose, we may calculate $\nabla f_0^*(\sum_{i=1}^m y_i^k)$ by solving the following problem:

$$\text{minimize } f_0(x) - \left\langle x, \sum_{i=1}^m y_i^k \right\rangle \quad \text{over all } x \in \mathbb{R}^n. \tag{F}$$

To see this, let x^k be a solution of (F). Then we have the following equivalence:

$$\nabla f_0(x^k) - \sum_{i=1}^m y_i^k = 0 \Leftrightarrow x^k = (\nabla f_0)^{-1}\left(\sum_{i=1}^m y_i^k\right).$$

From (2.6), we obtain

$$x^k = \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right), \tag{2.10}$$

which was what we wanted.

Until now, we have been dealing with the method in its perturbed form involving exact minimizations. Now we will take inexact minimizations into consideration. To this end, let us introduce $m+1$ sequences of nonnegative numbers: $\{\varepsilon_i^k\}_{k\in\mathbb{N}}$ for $i = 0, 1, \cdots, m$. Also let $\{\lambda_k\}_{k\in\mathbb{N}}$ be a sequence of positive numbers.

To make our notation simpler, we set

$$(1/\lambda_k)(y_i - y_i^k) + \nabla f_0^*\left(\sum_{i=1}^m y_i^k\right) = z_i.$$

This and (2.10) give that (2.9) is equivalent to

$$\begin{aligned} z_i^{k+1} &= \arg\min_{z_i \in \mathbb{R}^n} \{(1/2\lambda_k)\|y_i^k + \lambda_k(z_i - x^k)\|^2 + f_i^k(z_i)\}, \\ y_i^{k+1} &= y_i^k + \lambda_k(z_i^{k+1} - x^k). \end{aligned} \tag{2.11}$$

Taking all these into account, we are now in a position to state our general perturbed parallel decomposition method as follows.

THE METHOD (in its general form). Let $\lambda_k > 0$ and $\varepsilon_i^k \geq 0$ for $i = 0, 1, \cdots, m$ and $k = 0, 1, 2, \cdots$. We start with any point $y^0 = (y_1^0, \cdots, y_m^0) \in \mathbb{R}^{m\cdot n}$. We then calculate $x^0 \in \mathbb{R}^n$, then $y^1 = (y_1^1, \cdots, y_m^1) \in \mathbb{R}^{m\cdot n}$, $x^1 \in \mathbb{R}^n, \cdots$ by doing the following computation:

(a) Compute x^k by

$$x^k \in \varepsilon_0^k - \arg\min_{x \in \mathbb{R}^n} \left\{f_0(x) - \left\langle x, \sum_{i=1}^m y_i^k \right\rangle\right\}. \tag{2.12}$$

(b) For $i = 1, \cdots, m$, we compute y_i^{k+1} by

$$\begin{aligned} z_i^{k+1} &\in \varepsilon_i^k - \arg\min_{z_i \in \mathbb{R}^n} \{(1/2\lambda_k)\|y_i^k + \lambda_k(z_i - x^k)\|^2 + f_i^k(z_i)\}, \\ y_i^{k+1} &= y_i^k + \lambda_k(z_i^{k+1} - x^k). \end{aligned} \tag{2.13}$$

As usual we let

$$\varepsilon - \arg\min_{x\in\mathbb{R}^n} \phi(x) = \{\bar{x}\in\mathbb{R}^n | \phi(\bar{x}) \le \inf \phi + \varepsilon\}$$

for any function $\phi:\mathbb{R}^n \to \mathbb{R}\cup\{+\infty\}$.

At this point, a few remarks are of interest. Steps (a) *and* (b) of the method are realized with only approximate minimization in the subproblems. The subproblem in Step (a) contains only the (differentiable strongly convex) function f_0. Each of the m subproblems in step (b) contains only one (nondifferentiable convex) function f_i^k. These m subproblems in step (b) are independent of each other and can be solved in parallel by using any nonsmooth convex minimization algorithm (see especially Auslender [6]; see also Fukushima [11], Kiwiel [15], Strodiot and Nguyen [25] and the references cited therein). Therefore, in the proposed method, the parallel decomposition takes place with respect to the set of "constraints" f_i or rather f_i^k (as opposed to with respect to the set of varaibles x). Note that the objective function of each subproblem in step (b) (which is defined by an approximation f_i^k of f_i) is not only approximately solved but also depends on an approximate solution to the subproblem in step (a).

3. Connections with the work of Han and Lou. In [13] Han and Lou give a parallel decomposition algorithm to solve the model problem (P). Because in the present paper we are concerned with the same problem (P) (with the same assumptions on the problem functions f_0 and f_i ($i=1,\cdots,m$)), it is natural to establish here the relationship between our method and the one proposed by Han and Lou. In order to facilitate the understanding of the analysis of this section we first briefly recall Han and Lou's algorithm ("Algorithm II for (B)") in [13].

HAN AND LOU'S ALGORITHM. Start from a point $y^0=(y_1^0,\cdots,y_m^0)$ in $\mathbb{R}^{m\cdot n}$ and a sufficiently large number a (>0). Having $y^k=(y_1^k,\cdots,y_m^k)$ at the kth iteration, we do the following:

(a) Compute x^k by solving the problem

$$\text{(3.1)}\qquad \text{minimize}\, f_0(x) - \left\langle x, \sum_{i=1}^{m} y_i^k \right\rangle \quad \text{over all } x\in\mathbb{R}^n.$$

(b) For $i=1,\cdots,m$, we solve the problem

$$\text{(3.2)}\qquad \text{minimize}\, a\|y_i\|^2 + f_i(2ay_i - 2ay_i^k + x^k) \quad \text{over all } y_i\in\mathbb{R}^n$$

to obtain the optimal solution y_i^{k+1} (ith component of $y^{k+1}=(y_1^{k+1},\cdots,y_m^{k+1})$).

Now, the relationship we just mentioned above can be laid out as in the next result.

PROPOSITION 1. *For the model problem* (P), *Han and Lou's algorithm as defined by* (3.1)-(3.2) *is a particular case of our method as defined by* (2.12)-(2.13) *with the following special choices*:

$$f_i^k = f_i \quad \textit{for all } i=1,\cdots,m \textit{ and all } k\in\mathbb{N},$$

$$\varepsilon_i^k = 0 \textit{ for all } i=0,1,\cdots,m \textit{ and all } k\in\mathbb{N}.$$

Proof. The proof is immediate from the derivation of our method in the previous section (see (2.9), (2.10), and (F)) in taking $1/2\lambda_k = a$ for all $k\in\mathbb{N}$. □

On the other hand, recall that in [13], the authors started with a basic decomposition method optimization problem they called problem (A) ("Algorithm I for (A)"); see § 1 for the definition of (A). The algorithm that they proposed for solving this problem (A) (and from which they derived, through duality, their "Algorithm II for (B)") can be stated as follows.

Start from a point $y^0=(y_1^0,\cdots,y_m^0)$ in $\mathbb{R}^{n_1+\cdots+n_m}$ and a real number $a>0$. At the kth iteration, having $y^k=(y_1^k,\cdots,y_m^k)\in\mathbb{R}^{n_1+\cdots+n_m}$, we compute $y^{k+1}=(y_1^{k+1},\ldots,y_m^{k+1})\in\mathbb{R}^{n_1+\cdots+n_m}$ in doing the following:

(a) Calculate

$$z^k=(z_1^k,\cdots,z_m^k)=\nabla p(y^k)\in\mathbb{R}^{n_1+\cdots+n_m}. \tag{3.3}$$

(b) For $i=1,\cdots,m$, find $y_i^{k+1}\in\mathbb{R}^{n_i}$ by solving the problem

$$\text{minimize } a\|y_i-y_i^k\|^2+\langle y_i-y_i^k, z_i^k\rangle+g_i(y_i) \quad \text{over all } y_i\in\mathbb{R}^{n_i}. \tag{3.4}$$

Then, it is not difficult to see that Han and Lou's "Algorithm I for (A)" as defined by (3.3)-(3.4) can also be viewed as a particular case of our method as defined by (2.7), or equivalently (2.8). Indeed, it suffices to take

$$F_0(y)=p(y),\quad G^k(y)=\sum_{i=1}^m g_i(y_i),\quad y=(y_1,\cdots,y_m)\in\mathbb{R}^{n_1+\cdots+n_m}=\mathbb{R}^N$$

and

$$\frac{1}{2\lambda_k}=a \quad \text{for all } k\in\mathbb{N}.$$

We conclude this section with the following remark. As Han and Lou [13, § 4] point out, their "Algorithm II for (B)" is the one considered in [12] for the case of minimizing the constrained problem ($\bar{\text{P}}$). Consequently, our method may also be viewed as generalizing the first parallel algorithm of Han and Lou [12] to solve ($\bar{\text{P}}$).

4. Convergence of the general method. This section presents our analysis of convergence for the general method as defined by (2.12)-(2.13) to solve the model problem (P). We begin by studying an estimate on the distance between the solution and an epsilon-solution for a problem of minimizing a strongly convex function (see also Auslender [6] and Auslender, Crouzeix, and Fédit [7, Lemma 2.2]).

LEMMA 2. *Let $\phi:\mathbb{R}^n\to\mathbb{R}\cup\{+\infty\}$ be a closed proper strongly convex function (with modulus $\beta>0$) and let $\varepsilon>0$. Let $\bar{x}$ be the exact solution to the problem of minimizing ϕ over $\mathbb{R}^n$ and suppose that $\bar{x}_\varepsilon$ is an ε-minimizer of the same optimization problem. Then*

$$\|\bar{x}-\bar{x}_\varepsilon\|\le\sqrt{2\varepsilon/\beta}. \tag{4.1}$$

Proof. By Proposition 6 of [23] we have

$$\phi(\bar{x}_\varepsilon)\ge\phi(\bar{x})+(\beta/2)\|\bar{x}-\bar{x}_\varepsilon\|^2.$$

On the other hand, from the definition of $\bar{x}_\varepsilon$,

$$\phi(\bar{x}_\varepsilon)\le\phi(\bar{x})+\varepsilon.$$

Combining this with the preceding inequality yields (4.1). □

For any closed proper convex function $\phi:\mathbb{R}^n\to\mathbb{R}\cup\{+\infty\}$ and any real number $\lambda>0$, we set

$$\phi_\lambda(x)=\inf_{z\in\mathbb{R}^n}\{\phi(z)+(1/2\lambda)\|x-z\|^2\}. \tag{4.2}$$

These functions ϕ_λ, for $\lambda>0$, play a fundamental role in optimization theory and are called Moreau-Yosida approximates (of index λ of ϕ). It is well known that $\phi_\lambda:\mathbb{R}^n\to\mathbb{R}$ is a closed convex function. The unique $\bar{z}\in\mathbb{R}^n$ for which the infimum in (4.2) is attained, is denoted by prox $(x|\lambda\phi)$ and is characterized by

$$(1/\lambda)(x-\text{prox}\,(x|\lambda\phi))\in\partial\phi(\text{prox}\,(x|\lambda\phi)). \tag{4.3}$$

This point $\operatorname{prox}(x|\lambda\phi)$ is called the proximal point, and the mapping $\operatorname{prox}(\cdot|\lambda\phi)$ the proximal mapping associated with $\lambda\phi$. It is nonexpansive, as shown below:

$$\|\operatorname{prox}(x|\lambda\phi)-\operatorname{prox}(x'|\lambda\phi)\| \le \|x-x'\| \quad \text{for all } x, x' \in \mathbb{R}^n. \tag{4.4}$$

More detailed information on this can be found in Brézis [9], Attouch [2], and Rockafellar [22], [23].

For subsequent use, define the functions g_i and g_i^k (for all $i=1,\cdots,m$ and all $k\in\mathbb{N}$) by letting

$$g_i(y_i)=f_i^*(-y_i) \quad \text{and} \quad g_i^k(y_i)=(f_i^k)^*(-y_i) \quad \text{for all } y_i\in\mathbb{R}^n. \tag{4.5}$$

The next theorem provides the first important step in obtaining results of convergence for our general method for the model problem (P).

THEOREM 1. *Under the same assumptions and with the same notation as above, there exists a sequence* $\{e_0^k\}_{k\in\mathbb{N}}$ *of points in* $\mathbb{R}^n$ *and a sequence* $\{e^k\}_{k\in\mathbb{N}}$ *of points in* $\mathbb{R}^{m\cdot n}$, *where* $e^k=(e_1^k,\cdots,e_m^k)$ *for all* $k\in\mathbb{N}$, *such that*

$$x^k=\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)+e_0^k \quad \textit{for all } k\in\mathbb{N}, \tag{4.6}$$

$$y_i^{k+1}=\operatorname{prox}\left(y_i^k-\lambda_k\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\middle|\lambda_k g_i^k\right)+e_i^k \quad \textit{for all } i=1,\cdots,m \textit{ and all } k\in\mathbb{N}, \tag{4.7}$$

where the errors e_0^k *and* e_i^k *satisfy the following estimates*:

$$\|e_0^k\|\le\sqrt{2\varepsilon_0^k/\alpha} \quad \textit{for all } k\in\mathbb{N}, \tag{4.8}$$

$$\|e_i^k\|\le\sqrt{2\lambda_k\varepsilon_i^k}+\lambda_k\sqrt{2\varepsilon_0^k/\alpha} \quad \textit{for all } i=1,\cdots,m \textit{ and all } k\in\mathbb{N}. \tag{4.9}$$

Proof. It follows from (2.10) that

$$\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)=\arg\min_{x\in\mathbb{R}^n}\left\{f_0(x)-\left\langle x, \sum_{i=1}^m y_i^k\right\rangle\right\}. \tag{4.10}$$

So, using (4.10), (2.12), and Lemma 2, we obtain

$$\left\|x^k-\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right\|\le\sqrt{2\varepsilon_0^k/\alpha} \tag{4.11}$$

because the function $f_0(\cdot)-\langle\cdot,\sum_{i=1}^m y_i^k\rangle:\mathbb{R}^n\to\mathbb{R}$ is strongly convex with modulus α. Then, it suffices to set

$$e_0^k=x^k-\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)$$

in order to get the desired results (4.6) and (4.8).

To show that we have (4.7) and (4.9) let us define, for $i=1,\cdots,m$ and $k\in\mathbb{N}$, the points $\bar{y}_i^{k+1}$ and $\tilde{y}_i^{k+1}$ as follows:

$$\bar{y}_i^{k+1}=\arg\min_{y_i\in\mathbb{R}^n}\{(1/2\lambda_k)\|y_i\|^2+f_i^k((1/\lambda_k)(y_i-y_i^k)+x^k)\} \tag{4.12}$$

and

$$\tilde{y}_i^{k+1}=\operatorname{prox}\left(y_i^k-\lambda_k\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\middle|\lambda_k g_i^k\right). \tag{4.13}$$

Now, recall that y_i^{k+1}, which was defined by (2.13), can be written as

$$y_i^{k+1}\in\varepsilon_i^k-\arg\min_{y_i\in\mathbb{R}^n}\{(1/2\lambda_k)\|y_i\|^2+f_i^k((1/\lambda_k)(y_i-y_i^k)+x^k)\}\tag{4.14}$$

(to see this, it suffices to set $y_i=y_i^k+\lambda_k(z_i-x^k)$).

Let

$$e_i^k=y_i^{k+1}-\tilde{y}_i^{k+1}.$$

Then we have immediately (4.7). Let us prove that we have the estimate (4.9) for e_i^k. We have

$$\|e_i^k\|\le\|y_i^{k+1}-\bar{y}_i^{k+1}\|+\|\bar{y}_i^{k+1}-\tilde{y}_i^{k+1}\|.\tag{4.15}$$

Because the function $(1/2\lambda_k)\|\cdot\|^2+f_i^k((1/\lambda_k)(\cdot-y_i^k)+x^k):\mathbb{R}^n\to\mathbb{R}\cup\{+\infty\}$ is strongly convex with modulus $1/\lambda_k$, we deduce from Lemma 2 and the definition of $\bar{y}_i^{k+1}$ (see (4.12)) and of y_i^{k+1} (see (4.14)) that

$$\|y_i^{k+1}-\bar{y}_i^{k+1}\|\le\sqrt{2\lambda_k\varepsilon_i^k}.\tag{4.16}$$

It remains to estimate the second term of the right-hand side of (4.15) in order to finish the proof of the theorem. For this purpose, let us write the following equivalent statements:

$$\begin{aligned}(4.12)&\Leftrightarrow 0\in\bar{y}_i^{k+1}+\partial f_i^k((1/\lambda_k)(\bar{y}_i^{k+1}-y_i^k)+x^k)\\&\Leftrightarrow(1/\lambda_k)(\bar{y}_i^{k+1}-y_i^k)+x^k\in\partial(f_i^k)^*(-\bar{y}_i^{k+1})\\&\Leftrightarrow 0\in(1/\lambda_k)(\bar{y}_i^{k+1}-y_i^k)+x^k-\partial(f_i^k)^*(-\bar{y}_i^{k+1})\\&\Leftrightarrow 0\in(1/\lambda_k)(\bar{y}_i^{k+1}-y_i^k)+x^k+\partial g_i^k(\bar{y}_i^{k+1})\quad\text{(see (4.5))}\\&\Leftrightarrow\bar{y}_i^{k+1}=\arg\min_{y_i\in\mathbb{R}^n}\{(1/2\lambda_k)\|y_i-y_i^k+\lambda_kx^k\|^2+g_i^k(y_i)\}.\end{aligned}$$

That is, we have

$$\bar{y}_i^{k+1}=\operatorname{prox}(y_i^k-\lambda_kx^k|\lambda_kg_i^k).\tag{4.17}$$

Because the proximal mapping is nonexpansive (see (4.4)), it follows from (4.13), (4.17), and (4.11) that

$$\begin{aligned}\|\bar{y}_i^{k+1}-\tilde{y}_i^{k+1}\|&\le\lambda_k\left\|x^k-\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right\|\\&\le\lambda_k\sqrt{2\varepsilon_0^k/\alpha}.\end{aligned}$$

This inequality together with (4.16) and (4.15) gives the desired result (4.9), and the proof is finished. □

Before stating the next corollary, we recall that the functions F_0 and G^k, defined for all $y=(y_1,\cdots,y_m)\in\mathbb{R}^{m\cdot n}$, were introduced in § 2 by (2.4) and (2.5), respectively (see also (4.5)).

COROLLARY 1. *For all* $k\in\mathbb{N}$, *we have*

$$y^{k+1}=\operatorname{prox}(y^k-\lambda_k\nabla F_0(y^k)|\lambda_kG^k)+e^k,\tag{4.18}$$

where the error e^k *satisfies the following estimate*:

$$\|e^k\|\le\sqrt{m}\,(\sqrt{2\lambda_k\varepsilon_k}+\lambda_k\sqrt{2\varepsilon_0^k/\alpha})\tag{4.19}$$

where $\varepsilon_k=\max\{\varepsilon_1^k,\cdots,\varepsilon_m^k\}$.

To prove Corollary 1 the following lemma is used.

LEMMA 3. *For each $i=1,\cdots,m$, let $\phi_i:\mathbb{R}^{n_i}\to\mathbb{R}\cup\{+\infty\}$ be a closed proper convex function. For $N=n_1+\cdots+n_m$ define the function $\Phi:\mathbb{R}^N\to\mathbb{R}\cup\{+\infty\}$ by letting*

$$\Phi(y)=\sum_{i=1}^m \phi_i(y_i) \quad \textit{for all } y=(y_1,\cdots,y_m)\in\mathbb{R}^N. \tag{4.20}$$

Then Φ is a closed proper convex function, and we have, for all $\lambda>0$,

$$\Phi_\lambda(y)=\sum_{i=1}^m (\phi_i)_\lambda(y_i) \tag{4.21}$$

and

$$\operatorname{prox}(y|\lambda\Phi)=(\operatorname{prox}(y_1|\lambda\phi_1),\cdots,\operatorname{prox}(y_m|\lambda\phi_m)). \tag{4.22}$$

Proof. The proof of the fact that Φ is closed, proper, and convex is omitted here because it is easy. To prove (4.21) note that, for $\lambda>0$, we successively have

$$\begin{aligned}\Phi_\lambda(y)&=\inf\{(1/2\lambda)\|z-y\|^2+\Phi(z)|z=(z_1,\cdots,z_m)\in\mathbb{R}^N\}\\&=\inf\left\{\sum_{i=1}^m[(1/2\lambda)\|z_i-y_i\|^2+\phi_i(z_i)]|z\in\mathbb{R}^N\right\}\\&=\sum_{i=1}^m\inf\{(1/2\lambda)\|z_i-y_i\|^2+\phi_i(z_i)|z_i\in\mathbb{R}^{n_i}\}\\&=\sum_{i=1}^m(\phi_i)_\lambda(y_i),\end{aligned}$$

where $(\phi_i)_\lambda$ denotes the Moreau-Yosida approximate of index λ of ϕ_i.

On the other hand, to prove (4.22), let us set

$$z=\operatorname{prox}(y|\lambda\Phi)=(z_1,\cdots,z_m)\in\mathbb{R}^N.$$

Because of the characterization (4.3) of the proximal point, we have

$$(1/\lambda)(y-z)\in\partial\Phi(z).$$

By virtue of Lemma 4.3 of McLinden [19], this inclusion is equivalent to

$$(1/\lambda)(y_i-z_i)\in\partial\phi_i(z_i)\quad\text{for all } i=1,\cdots,m;$$

this means that

$$z_i=\operatorname{prox}(y_i|\lambda\phi_i)\quad\text{for all } i=1,\cdots,m,$$

and the lemma is proved. □

Proof of Corollary 1. The formulation (4.18) is a direct consequence of (4.22), (4.7), and the fact that

$$\nabla F_0(y^k)=\nabla F_0(y_1^k,\cdots,y_m^k)=\left(\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right),\cdots,\nabla f_0^*\left(\sum_{i=1}^m y_i^k\right)\right).$$

On the other hand, the estimate (4.19) is immediate from (4.9). □

We now give a first convergence theorem of the general method. To state this we introduce the following Fenchel dual program of (P):

$$\text{(D)}\qquad \text{minimize} f_0^*\left(\sum_{i=1}^m y_i\right)+\sum_{i=1}^m f_i^*(-y_i)\quad\text{over all } y_1\in\mathbb{R}^n,\cdots,y_m\in\mathbb{R}^n.$$

THEOREM 2. *Consider the general method as defined by* (2.12)–(2.13). *Let* $\{x^k\}_{k\geq 0}$ *and* $\{y^k\}_{k\geq 1}$ *be the sequences it generates from an arbitrary initial point* $y^0 \in \mathbb{R}^{m\cdot n}$. *Suppose the following*:

(a) $0<\underline{\lambda}\leq \lambda_k \leq \bar{\lambda} < 2\alpha/m$ *for all* $k\in\mathbb{N}$;

(b) $f_i = \text{epi-lim}_{k\to+\infty} f_i^k$ *for each* $i=1,\cdots,m$;

(c) $\lim_{k\to+\infty}\varepsilon_i^k=0$ *for each* $i=0,1,\cdots,m$;

(d) *The sequence* $\{y^k\}_{k\geq 0}$ *is bounded.*

Then the sequence $\{x^k\}_{k\geq 0}$ *converges to the unique solution of* (P) *and any accumulation point of the sequence* $\{y^k\}_{k\geq 0}$ *is a solution of the Fenchel dual program* (D) *of* (P). □

Before giving the proof, let us notice that under the hypotheses of Theorem 2, the Fenchel dual program (D) of (P) admits a solution.

Proof. By hypothesis (b), for each $i=1,\cdots,m$, $\{f_i^k\}_{k\geq 0}$ is a sequence of closed proper convex functions epiconvergent to f_i. Then, by virtue of a theorem of Wijsman [29] (see, for example, Attouch [2, Thm. 3.18]), epiconvergence of their conjugate functions to that of f_i also occurs:

$$f_i^* = \underset{k\to+\infty}{\text{epi-lim}}\,(f_i^k)^* \quad \text{for each } i=1,\cdots,m.$$

But this is equivalent to (see (4.5))

$$g_i = \underset{k\to+\infty}{\text{epi-lim}}\, g_i^k \quad \text{for each } i=1,\cdots,m.$$

Using Theorem 6 of McLinden and Bergstrom [20], we obtain

$$G=\underset{k\to+\infty}{\text{epi-lim}}\, G^k, \tag{4.23}$$

where, of course,

$$G(y)=\sum_{i=1}^m g_i(y_i) \quad\text{and}\quad G^k(y)=\sum_{i=1}^m g_i^k(y_i) \quad \text{for all } y=(y_1,\cdots,y_m)\in\mathbb{R}^{m\cdot n}.$$

On the other hand, combining assumptions (c), (a), and the estimate (4.19) of Corollary 1 gives

$$\lim_{k\to+\infty}\|e^k\|=0. \tag{4.24}$$

Because f_0 is strongly convex with modulus α, it follows from (2.6) by a simple computation, that ∇f_0^* is Lipschitz continuous with constant $1/\alpha$, and consequently ∇F_0 is Lipschitz continuous with constant m/α. This fact, together with hypothesis (a), (4.18), (4.23), (4.24), and hypothesis (d) allow us to invoke Theorem 2 of Lemaire [18] to conclude that the Fenchel dual program (D) has at least one solution and that any accumulation point of $\{y^k\}_{k\geq 0}$ (its existence is guaranteed by hypothesis (d)) is a solution of (D). This proves the second part of the theorem.

To prove the first part of the theorem, let us begin by showing that the sequence $\{x^k\}_{k\geq 0}$ is bounded. To see this, note that the sequence $\{\sum_{i=1}^m y_i^k\}_{k\geq 0}$ is also bounded in $\mathbb{R}^n$ because $\|\sum_{i=1}^m y_i^k\|\leq\sqrt{m}\,\|y^k\|$ and $\{y^k\}_{k\geq 0}$ is bounded by assumption (d). Since ∇f_0^* is Lipschitz continuous with constant $1/\alpha$, we deduce that the sequence $\{\nabla f_0^*(\sum_{i=1}^m y_i^k)\}_{k\geq 0}$ is bounded. Hence, it follows from (4.6), (4.8) of Theorem 1, and hypothesis (c) that the sequence $\{x^k\}_{k\geq 0}$ is also bounded.

If it can be shown that any accumulation point of $\{x^k\}_{k\geq 0}$ solves (P), the first part of the theorem will be proven since (P) has a unique solution.

We therefore consider a subsequence $\{x^{k_j}\}_{j\geq 0}$ of $\{x^k\}_{k\geq 0}$ converging to $\bar{x}\in\mathbb{R}^n$. Since $\{y^k\}_{k\geq 0}$ is bounded, by taking a further subsequence, if necessary, we can find a point $\bar{y}=(\bar{y}_1,\cdots,\bar{y}_m)\in\mathbb{R}^{m\cdot n}$ such that $y^{k_j}=(y_1^{k_j},\cdots,y_m^{k_j})\rightarrow\bar{y}$. On the other hand,by (4.6) and (4.8) of Theorem 1, we have, for all $j\in\mathbb{N}$,

$$x^{k_j}=\nabla f_0^*(y_1^{k_j}+\cdots+y_m^{k_j})+e_0^{k_j} \tag{4.25}$$

with

$$\|e_0^{k_j}\|\leq\sqrt{2\varepsilon_0^{k_j}/\alpha}. \tag{4.26}$$

By passing to the limit $j\rightarrow+\infty$ in (4.25) and (4.26), we see that

$$\bar{x}=\nabla f_0^*\left(\sum_{i=1}^m \bar{y}_i\right) \tag{4.27}$$

because ∇f_0^* is continuous and $\varepsilon_0^{k_j}\rightarrow 0$ as $j\rightarrow+\infty$ (hypothesis (c)). It follows that

$$\sum_{i=1}^m \bar{y}_i=\nabla f_0(\bar{x}). \tag{4.28}$$

Now, by the first part of the proof, we know that $\bar{y}$ is a solution of (D). Therefore, we have the following characterization of optimality:

$$0\in\nabla F_0(\bar{y})+\partial G(\bar{y}).$$

This implies immediately that

$$0\in\nabla f_0^*\left(\sum_{i=1}^m \bar{y}_i\right)+\partial g_i(\bar{y}_i)\quad\text{for all } i=1,\cdots,m,$$

or equivalently (see (4.27)),

$$0\in\bar{x}-\partial f_i^*(-\bar{y}_i)\quad\text{for all } i=1,\cdots,m.$$

Thus (see [22, Thm. 23.5]),

$$-\bar{y}_i\in\partial f_i(\bar{x})\quad\text{for all } i=1,\cdots,m.$$

Hence we have

$$-\sum_{i=1}^m \bar{y}_i\in\sum_{i=1}^m \partial f_i(\bar{x})$$

so that (see (4.28))

$$0\in\nabla f_0(\bar{x})+\partial\left(\sum_{i=1}^m f_i\right)(\bar{x})$$

because $\sum_{i=1}^m \partial f_i(\bar{x})\subset\partial(\sum_{i=1}^m f_i)(\bar{x})$. This completes the proof of the theorem. □

In connection with the work of Han and Lou [13], it is worth mentioning that our Theorem 2 is a generalization and an improvement of Theorem 3.2 of [13]. It is a generalization because it suffices to take, in the theorem above: $\lambda_k=1/2a$ for all $k\in\mathbb{N}$, $f_i^k=f_i$ for all $i=1,\cdots,m$ and all $k\in\mathbb{N}$, and $\varepsilon_i^k=0$ for all $i=0,1,\cdots,m$ and all $k\in\mathbb{N}$, in order to obtain the convergence of the sequence $\{x^k\}_{k\in\mathbb{N}}$ to the optimal solution of (P). It is also an improvement because, not as in [13], the theorem above holds true without any regularity condition. Moreover, not as here, there are no convergence results in Theorem 3.2 of [13] concerning the sequence $\{y^k\}_{k\in\mathbb{N}}$.

Note that hypothesis (d) of Theorem 2 is crucial, and must be checked in each particular case. Nevertheless, we have the following convergence result.

THEOREM 3. *Under the same notation as in the preceding theorem, suppose the following*:

(a) $0<\underline{\lambda}\le\lambda_k\le\bar{\lambda}<2\alpha/m$ *for all* $k\in\mathbb{N}$;

(b) $f_i^k\le f_i^{k+1}$ *for each* $i=1,\cdots,m$ *and all* $k\in\mathbb{N}$, *and* $f_i=\sup_{k\in\mathbb{N}}f_i^k$ *for each* $i=1,\cdots,m$;

(c) $\lim_{k\to+\infty}\varepsilon_i^k=0$ *for each* $i=0,1,\cdots,m$;

(d) *the solution set of the Fenchel dual program* (D) *is a nonempty bounded set.*

Then any accumulation point of the sequence $\{y^k\}_{k\in\mathbb{N}}$ *is a solution of* (D) *and the sequence* $\{x^k\}_{k\in\mathbb{N}}$ *converges to the unique solution of* (P).

Proof. In view of Theorem 3.20 of Attouch [2], hypothesis (b) implies

$$f_i=\operatorname*{epi-lim}_{k\to+\infty}f_i^k\quad\text{for all } i=1,\cdots,m.$$

Consequently, as in the first part of the proof of Theorem 2, we have

$$G=\operatorname*{epi-lim}_{k\to+\infty}G^k.$$

On the other hand, as the sequence $\{f_i^k\}_{k\in\mathbb{N}}$ is monotone increasing, the sequence of their conjugates $\{(f_i^k)^*\}_{k\in\mathbb{N}}$ is monotone decreasing, so that the sequence $\{g_i^k\}_{k\in\mathbb{N}}$ is also monotone decreasing. Hence, from the definition of G^k, we have that

$$\{G^k\}_{k\in\mathbb{N}}\quad\text{is monotone decreasing.}\tag{4.29}$$

According to Theorem 3.20 of Attouch [2] again, we get

$$G=\operatorname{cl}\left(\inf_{k\in\mathbb{N}}G^k\right),\tag{4.30}$$

where cl denotes the closure (of the convex function $\inf_{k\in\mathbb{N}}G^k$).

Now, to show the theorem, it suffices to show that the sequence $\{y^k\}_{k\in\mathbb{N}}$ is bounded, because of Theorem 2. But first we deduce from assumption (d) that the problem (D) has a finite optimal value $\inf(\mathrm{D})\in\mathbb{R}$. Note that the solution set of (D) is also the level set

$$L=\{y\in\mathbb{R}^N\,|\,F_0(y)+G(y)\le\inf(D)\}.$$

As it is nonempty and bounded by hypothesis, it follows from Corollary 8.7.1 of [22] that the set

$$S_\gamma=\{y\in\mathbb{R}^N\,|\,F_0(y)+G(y)\le\gamma\}$$

is bounded for every $\gamma\in\mathbb{R}$. As a consequence, the function F_0+G is coercive; that is, we have

$$\lim_{\|y\|\to+\infty}(F_0(y)+G(y))=+\infty.\tag{4.31}$$

From Corollary 1, the fact that ∇F_0 is Lipschitz continuous and (4.29)-(4.31), we can conclude, by using Proposition 4(iii) of Lemaire [18], that the sequence $\{y^k\}_{k\in\mathbb{N}}$ is bounded, which completes the proof of the theorem. □

An example of functions f_i^k (for $i=1,\cdots,m$, and $k\in\mathbb{N}$) that satisfy assumption (b) of Theorem 3 has been given in § 2 (see (H1)-(H3)). Another instance is provided by the class of casting functions due to Wets [28, § 6].

In view of Theorem 3, it is important from a practical standpoint, to study when the solution set of the Fenchel dual program (D) is nonempty and bounded. To ensure this, we use the Fenchel duality theory. More precisely, we conclude this section on this matter with the following result.

THEOREM 4. *The notation being the same as above, if the condition*

$$\operatorname{int}(\operatorname{dom} f_1) \cap \cdots \cap \operatorname{int}(\operatorname{dom} f_m) \neq \emptyset \tag{4.32}$$

is satisfied, then the solution set of the Fenchel dual program (D) *of* (P) *is a nonempty bounded set.*

Before giving the proof, let us note that condition (4.32) holds true automatically if the functions f_i are finite real valued (for an example, see (1.2)).

Proof. By Theorem 27.1 of [22], we know that the solution set of the Fenchel dual program (D) of (P) is a nonempty bounded set if and only if

$$0 \in \operatorname{int}(\operatorname{dom}(F_0 + G)^*). \tag{4.33}$$

Therefore, to prove the theorem we need only to establish that hypothesis (4.32) implies that (4.33) holds true. Using Theorem 16.4 of [22], we have

$$\operatorname{dom}(F_0 + G)^* = \operatorname{dom} F_0^* + \operatorname{dom} G^* \tag{4.34}$$

because

$$\operatorname{ri}(\operatorname{dom} F_0) \cap \operatorname{ri}(\operatorname{dom} G) = \operatorname{ri}(\operatorname{dom} G) \neq \emptyset.$$

Start by determining the set dom F_0^*. To do this recall that

$$F_0(y) = F_0(y_1, \cdots, y_m) = f_0^*\left(\sum_{i=1}^m y_i\right).$$

So, using Theorem 16.3 of [22] and the fact that dom $f_0^* = \mathbb{R}^n$, we get

$$\operatorname{dom} F_0^* = \{(x_1, \cdots, x_m) \in \mathbb{R}^{m \cdot n} | x_1 = \cdots = x_m\}. \tag{4.35}$$

We now use hypothesis (4.32) to determine the set dom G^*. Let $\bar{x} \in \mathbb{R}^n$ be such that

$$\bar{x} \in \bigcap_{i=1}^m \operatorname{int}(\operatorname{dom} f_i).$$

This gives

$$0 \in -(\bar{x}, \cdots, \bar{x}) + \prod_{i=1}^m \operatorname{int}(\operatorname{dom} f_i). \tag{4.36}$$

Because $g_i(y_i) = f_i^*(-y_i)$ by definition, we have $g_i^*(x_i) = f_i(-x_i)$ for $i = 1, \cdots, m$. It now follows that dom $g_i^* = -\operatorname{dom} f_i$. Thus, from (4.36), we obtain

$$0 \in (\bar{x}, \cdots, \bar{x}) + \operatorname{int}\left(\prod_{i=1}^m \operatorname{dom} g_i^*\right).$$

Hence,

$$0 \in (\bar{x}, \cdots, \bar{x}) + \operatorname{int}(\operatorname{dom} G^*) \tag{4.37}$$

because

$$G^*(x_1, \cdots, x_m) = \sum_{i=1}^m g_i^*(x_i)$$

and

$$\operatorname{dom} G^* = \prod_{i=1}^{m} \operatorname{dom} g_i^*$$

(see McLinden [19, Lemma 4.3]).

On the other hand, the set $(\bar{x}, \cdots, \bar{x}) + \operatorname{int}(\operatorname{dom} G^*)$ is an open set. It follows from (4.37) and (4.35) that

$$0 \in (\bar{x}, \cdots, \bar{x}) + \operatorname{int}(\operatorname{dom} G^*) \subset \operatorname{dom} F_0^* + \operatorname{dom} G^*.$$

Hence, we deduce from (4.34) that

$$0 \in \operatorname{int}(\operatorname{dom}(F_0 + G)^*),$$

which is precisely (4.33) and this completes the proof. □

Note that condition (4.32) holds true automatically if the functions f_i are finite real valued (for an example, see (1.2)).

5. Conclusions. We have presented a convergent perturbed parallel decomposition method for minimizing the model objective function $f_0 + \sum_{i=1}^{m} f_i$. The method allows for approximate minimizations, duality gaps, and epigraphical perturbations during the iterative process.

At the present time, there are no rate-of-convergence results relating to our decomposition method. With respect to this topic the notion of variational semidistance due to Attouch and Wets [4] seems to be the main technical tool to employ. This is a subject for further research.

ON EIGENSTRUCTURE ASSIGNMENT BY GAIN OUTPUT FEEDBACK*

CALIXTE CHAMPETIER† AND JEAN-FRANCOIS MAGNI‡

Abstract. In this paper, the eigenstructure assignment of linear multivariable control systems is studied from a geometric point of view. For the class of systems in which the number of outputs plus the number of inputs exceeds the number of states, genericity properties relative to this problem are derived. It is shown, without any assumption on the genericity of the system, that the pole assignment can be carried out by choosing some closed-loop *eigenvectors* almost freely. The crucial point is that all the expected degrees of freedom in pole assignment are so described without redundancy, which fully justifies the practical interest of such techniques. Despite the technicality required for the derivation of intermediate results, the main result, which is an eigenstructure assignment algorithm, is very easy to implement because it is only based on the computation of certain sums and intersections of characteristic subspaces. Furthermore, it is shown how the basic tools developed here can be used to tackle the problem of finding a necessary and sufficient condition for exact pole assignment.

Key words. linear systems, multivariable control, output feedback, pole assignment, eigenvector assignment

AMS(MOS) subject classification. 93B

1. Introduction. Since the fundamental paper of Kimura [7], the pole assignment problem for systems satisfying $m+p>n$ (where n, m, p stand, respectively, for the numbers of states, inputs, and outputs), has received much investigation. It was shown in this paper that for a given triple satisfying the above condition, an *almost arbitrary* set of distinct closed-loop poles was assignable by gain output feedback. The use of the *characteristic subspaces*, which were introduced in this reference, enlightened various problems in linear system theory and was at the origin of the eigenvector assignment techniques as in Moore [13]. Simultaneously, a similar result appeared in Davison and Wang [2]. This result is less general because it is based on genericity assumptions with respect to the input and output matrices—therefore on the controllability and observability indices—of the considered system. In fact, as we will demonstrate in the present paper, the difficulties that arise for pole assignment are closely related to these indices (these difficulties are even more severe when it is not assumed that $m+p>n$). As the indices of practical systems do not often satisfy generic properties, this kind of assumption is to be avoided as far as possible. Among the various contributions that followed the fundamental work of Kimura, let us mention more specifically that of Fletcher [4] in which are discussed the proofs given in [7].

The simultaneous assignment of both eigenvalues and eigenvectors has also received much attention. In the specific case where the assumption $m+p>n$ is satisfied, Mielke and Liberty [12] proposed an algorithm based on the approach of [2] for freely assigning $p-1$ eigenvectors while the remaining degrees of freedom were used for assigning the $n-p+1$ other eigenvalues. It is worth noting that in this work as well as in the work of various other authors, only descriptions of eigenstructure assignment procedures are given, the cases in which the corresponding algorithms may fail are not studied.

‡ Centre d'Etude et de Recherche de Toulouse, BP 4025, F31055 Toulouse Cedex, France.

Another domain of interest which followed the contribution of Kimura is the problem of *exact* pole assignment. The first result obtained in this field is due to Fletcher [3], who proved that a set of n distinct real eigenvalues or a set of n distinct, nonreal, self-conjugate eigenvalues could exactly be assigned. The first result concerning the pathologies when a mixture of real and nonreal numbers are to be assigned is given in Magni [8] in terms of a necessary condition. It is shown in Magni [9] that this necessary condition is as well sufficient. This proof is given in the self-contained set of papers: [5], [6], [10].

In this paper we first study, from a geometric point of view, the properties of the characteristic subspaces. Some of the results obtained are also useful for more general pole assignment problems as, for instance, those presented in Magni and Champetier [11]. Our main result concerns the genericity relative to the choice of the eigenvalues within their corresponding characteristic subspaces. We prove that the eigenvalues/eigenvectors assignment can be performed iteratively, almost any choice at each step of the algorithm being such that the algorithm will not fail until $p-1$ eigenvectors and n eigenvalues are assigned. We show as well that the set of pathologic eigenvalues is finite and the cardinal of this set is estimated from above. A numerical example shows that this set may not be empty. It is in this study of the genericity of the choice of the degrees of freedom exhibited by the proposed algorithm that our contribution with respect to previous results of the literature lies. An advantage of the approach adopted here is that, despite some difficulties arising in some proofs, the final assignment procedure is extremely simple to implement and only the computation of certain intersections and sums of characteristic subspaces is required. The intermediate result concerning the number of pathological eigenvalues which might appear during the assignment of the $p-1$ eigenvectors allows us to provide an alternative proof of the above-mentioned necessary and sufficient condition for exact pole assignment.

2. Characteristic subspaces. In this section, the definitions and various properties of the (A, B) and (C, A)-characteristic subspaces are recalled. We shall consider a complete (i.e., controllable and observable) triple (A, B, C), where the matrices B and C are assumed to be of full rank:

$$\mathcal{U} \xrightarrow{B} \mathcal{X} \xrightarrow{A} \mathcal{X} \xrightarrow{C} \mathcal{Y}.$$

First, let us recall the definition of these subspaces.

DEFINITION 2.1. For any complex number λ, the *(A, B)-characteristic subspaces* $\mathcal{S}(\lambda)$ is defined by $\mathcal{S}(\lambda) \triangleq (A-\lambda I)^{-1} \operatorname{Im} B$ and the *(C, A)-characteristic subspaces* $\mathcal{T}(\lambda)$ by $\mathcal{T}(\lambda) \triangleq (A-\lambda I) \operatorname{Ker} C$.

(Note that with "$(A-\lambda I)^{-1}$" being applied to a vector space, it is not necessary that the matrix $(A-\lambda I)$ be invertible to define $\mathcal{S}(\lambda)$ as above.) For notational conveniences, we shall denote $\bar{\mathbb{C}}$ the following set $\{\mathbb{C} \cup \{\infty\}\}$. $\mathcal{S}(\infty)$ will stand for $\operatorname{Im} \beta$ and $\mathcal{T}(\infty)$ for $\operatorname{Ker} C$. Note that for any vector $s \in \mathcal{S}(\lambda)$ it is clear that there exists a unique vector w called the *input direction corresponding to s* defined by $(A-\lambda I)s = -Bw$. In this paper, the *input directions* will be used only for explicit computations of gain feedback matrices.

Elementary properties of the characteristic subspaces will be needed in this paper. Their proofs (scattered in various papers, see, for instance, [3], [8], [11], [18]) can be derived in a straightforward way by considering the Brunovski canonical form. Let us state some of them. If $m<n$, $\mathcal{S}(\lambda) \neq \mathcal{S}(\lambda')$ for any $(\lambda, \lambda') \in \bar{\mathbb{C}}^2$ such that $\lambda \neq \lambda'$. The dimension of $\mathcal{S}(\lambda) \cap \mathcal{S}(\lambda')$ is equal to the number or controllability indices equal to one and the dimension of $\mathcal{S}(\lambda)+\mathcal{S}(\lambda')$ follows easily. If $p<n$, $\mathcal{T}(\lambda) \neq \mathcal{T}(\lambda')$ for any

$(\lambda, \lambda') \in \bar{\mathbb{C}}^2$ such that $\lambda \neq \lambda'$. Within some proofs given in this paper (Lemma 3.5, Lemma 4.3 third case), the knowledge of the characteristic subspaces on the Brunovski canonical form will be required and the reader will be referred to the literature cited above.

Both subspaces defined below will play a key role in the sequel:

$$(1)\qquad \mathscr{B}_0 = \bigcap_{\lambda \in \bar{\mathbb{C}}} \mathscr{S}(\lambda), \qquad \mathscr{C}_0 = \sum_{\lambda \in \bar{\mathbb{C}}} \mathscr{T}(\lambda).$$

Let p_0 and m_0 denote, respectively, the numbers of observability and controllability indices that are equal to one. The following properties of these subspaces are well known.

LEMMA 2.2.

$$\dim \mathscr{B}_0 = m_0 \textit{ and } \mathscr{B}_0 = \mathscr{S}(\lambda) \cap \mathscr{S}(\lambda') \textit{ for any } (\lambda, \lambda') \in \bar{\mathbb{C}}^2 \textit{ s.t. } \lambda \neq \lambda';$$

$$\dim \mathscr{C}_0 = n - p_0 \textit{ and } \mathscr{C}_0 = \mathscr{T}(\lambda) + \mathscr{T}(\lambda') \textit{ for any } (\lambda, \lambda') \in \bar{\mathbb{C}}^2 \textit{ s.t. } \lambda \neq \lambda'.$$

Note that for $\lambda = \infty$ and $\lambda' = 0$, we have $\mathscr{B}_0 = \operatorname{Im} B \cap A^{-1} \operatorname{Im} B$ and $\mathscr{C}_0 = \operatorname{Ker} C + A \operatorname{Ker} C$. Finally, we recall two lemmas, the proofs of which can be found in [8] or [10].

LEMMA 2.3. *If $n = m + p - 1$ with $m < n$ and $p < n$, then, there exists no more than one real number $\tilde{\lambda}$ such that*

$$\mathscr{C}_0 \subset \mathscr{S}(\tilde{\lambda}).$$

LEMMA 2.4. *If $p_0 = p - 1$, then $\mathscr{C}_0 = \bigcup_{\lambda \in \bar{\mathbb{C}}} \mathscr{T}(\lambda)$.*

The vocabulary and the classical notations of the geometric approach will be extensively used. The reader is referred to the basic literature in this field [17], [16]. Let us first recall the definition of the *induced* and *restricted* subsystems. If $\mathscr{S}$ is (A, B)-invariant and (C, A)-invariant, we can define the subsystem *induced modulo* $\mathscr{S}$: $(A(\operatorname{mod} \mathscr{S}), B(\operatorname{mod} \mathscr{S}), C(\operatorname{mod} \mathscr{S}))$ and the subsystem *restricted to* $\mathscr{S}$: $(A|\mathscr{S}, B|\mathscr{S}, C|\mathscr{S})$ by the commutative diagram of Fig. 2.1. Following [1] and [14] we can state the following property. Let (A, B, C) be a complete triple and $\mathscr{S}$ an (A, B)-invariant and (C, A)-invariant subspace. Then, there exists at least one output feedback K which satisfies $(A + BKC)\mathscr{S} \subset \mathscr{S}$ (such a feedback will be said to be *admissible*).

$$\begin{tikzcd}
B^{-1}\mathcal{S} \arrow[r, "B|\mathcal{S}"] \arrow[d, "\iota'"] & \mathcal{S} \arrow[r, "A|\mathcal{S}"] \arrow[d, "\iota"] & \mathcal{S} \arrow[d, "\iota"] \arrow[dr, "C|\mathcal{S}"] & \\
\mathcal{U} \arrow[r, "B"] \arrow[dr, "B(\mathrm{mod}\,\mathcal{S})"'] & \mathcal{X} \arrow[r, "A"] \arrow[d, "\pi"] & \mathcal{X} \arrow[r, "C"] \arrow[d, "\pi"] & \mathcal{Y} \arrow[d, "\pi'"] \\
 & \mathcal{X}/\mathcal{S} \arrow[r, "A(\mathrm{mod}\,\mathcal{S})"] & \mathcal{X}/\mathcal{S} \arrow[r, "C(\mathrm{mod}\,\mathcal{S})"] & \mathcal{Y}/C\mathcal{S}
\end{tikzcd}$$

FIG. 2.1. *Definition of the induced and restricted subsystems.*

Moreover, for any admissible feedback K, we have $\Lambda_F \cup \Lambda'_F \subset \sigma(A+BKC)$ where Λ_F and Λ'_F are the fixed spectra defined by the following lattice:

$$(2) \qquad 0 \longrightarrow \mathcal{R}^*_{\mathcal{S}} \xrightarrow{\Lambda_F} \mathcal{S} \xrightarrow{\Lambda'_F} \mathcal{N}^*_{\mathcal{S}} \longrightarrow \mathcal{X}.$$

Furthermore, Λ_F is the set of the invariant zeros of the triple (A, S, C) where S is any mapping such that $\operatorname{Im} S = \mathcal{S}$ and Λ'_F is the set of the invariant zeros of the triple (A, B, E) where E is any mapping such that $\operatorname{Ker} E = \mathcal{S}$. In fact, it is a more specific version of this result which will be used.

PROPOSITION 2.5. *Let $\Lambda = \{\lambda_1, \cdots, \lambda_n\}$ be a set of complex numbers. Assume that there exists a subspace $\mathcal{S}$ satisfying the following properties*:

(i) $\dim \mathcal{S} = p$;

(ii) $\mathcal{S} = \operatorname{Span}\{s_1, \cdots, s_p\}$ *with* $s_i \in \mathcal{S}(\lambda_i)$ *for* $i = 1, \cdots, p$;

(iii) $\mathcal{N}^*_{\mathcal{S}} = \mathcal{X}$ *with* $\Lambda'_F = \{\lambda_{p+1}, \cdots, \lambda_n\}$ (*cf. lattice* (2)).

Then, there exists a unique output feedback gain K satisfying

$$\sigma(A+BKC) = \Lambda \quad \textit{and} \quad (A+BKC)s_i = \lambda_i s_i \quad \textit{for } i = 1, \cdots, p.$$

This gain is given by $K = [w_1, \cdots, w_p](C[s_1, \cdots, s_p])^{-1}$ where the vectors w_i are the input directions corresponding to the vectors s_i.

Proof. It is straightforward to show that $\mathcal{N}^*_{\mathcal{S}} = \mathcal{X}$ is equivalent to $S + \operatorname{Ker} C = \mathcal{X}$. Since $\dim \mathcal{S} = p$, we have $\mathcal{S} \cap \operatorname{Ker} C = 0$. So, $\mathcal{S}$ is (C, A)-invariant. Consider the input directions w_i corresponding to s_i. As $\mathcal{S} \cap \operatorname{Ker} C = 0$, there exists a unique gain K such that $[w_1, \cdots, w_p] = KC[s_1, \cdots, s_p]$ which is equivalent to $(A+BKC)s_i = \lambda_i s_i$ for $i = 1, \cdots, p$. Therefore, this gain is admissible, and $\Lambda'_F \subset \sigma(A+BKC)$. Hence, $\sigma(A+BKC) = \Lambda$. □

The construction of the subspace $\mathcal{S}$ given in Proposition 2.5 can be used in order to assign the whole spectrum. But the third condition on $\mathcal{S}$ remains to be clarified.

THEOREM 2.6. *Let (C, A) be an observable pair, $\mathcal{S}$ a (C, A)-invariant subspace defining the lattice*

$$0 \longrightarrow \mathcal{S} \xrightarrow{\Lambda'_F} \mathcal{N}^*_{\mathcal{S}} \longrightarrow \mathcal{X}.$$

The following properties are equivalent:

(i) $\beta \in \Lambda'_F$;

(ii) $\dim \mathcal{S} \cap \mathcal{T}(\beta) \neq \dim \mathcal{S} \cap \operatorname{Ker} C$;

(iii) $\dim \mathcal{S} \cap \mathcal{T}(\beta) > \dim \mathcal{S} \cap \operatorname{Ker} C$.

More precisely, if $\beta \in \Lambda'_F$, then $\dim \mathcal{S} \cap \mathcal{T}(\beta) = \dim \mathcal{S} \cap \operatorname{Ker} C + r(\beta)$, where $r(\beta)$ is the geometrical multiplicity of the eigenvalue β.

Proof. Let $P(\beta)$ be the polynomial matrix defined by

$$P(\beta) = \begin{bmatrix} A - \beta I & S \\ C & 0 \end{bmatrix}.$$

Let us consider, for a given complex number β, the mapping F_β defined by

$$F_\beta: \quad \mathcal{S} \cap \mathcal{T}(\beta) \longrightarrow \operatorname{Ker} P(\beta),$$

$$x \longrightarrow \begin{bmatrix} v \\ w \end{bmatrix}$$

where $v \in \operatorname{Ker} C$, $x = (A - \beta I)v$, $x = -Sw$. As $x \in \mathcal{S}$ and $\mathcal{S}$ is of full rank, w exists and is unique; as $x \in \mathcal{T}(\beta)$, there exists a vector $v \in \operatorname{Ker} C$ such that $x = (A - \beta I)v$. This vector is unique since the pair (A, C) is observable. Then the mapping F_β is well defined. Furthermore, it is clear that $F_\beta(x) \in \operatorname{Ker} P(\beta)$. It is straightforward to show that F_β is linear and bijective. So,

$$\text{for all } \beta \in \mathbb{C}, \quad \dim \mathcal{S} \cap \mathcal{T}(\beta) = \dim \operatorname{Ker} P(\beta).$$

The rank property of $P(\beta)$ allows us to state that, if β_0 is an invariant zero of the triple (A, S, C), for all β which is not such a zero we have

$$\dim \mathcal{S} \cap \mathcal{T}(\beta_0) = \dim \mathcal{S} \cap \mathcal{T}(\beta) + r(\beta_0)$$

where $r(\beta_0)$ is the geometric multiplicity of β_0. As $r(\beta_0) > 0 \Leftrightarrow \beta_0 \in \Lambda'_F$, it suffices to show that $\dim \mathcal{S} \cap \operatorname{Ker} C = \dim \mathcal{S} \cap \mathcal{T}(\beta)$ to prove the proposition. $\mathcal{S}$ being (C, A)-invariant, there exists an input injection G such that $(A + GC)\mathcal{S} \subset \mathcal{S}$. For any complex number $\beta \notin \sigma(A + GC)(\Rightarrow \notin \Lambda'_F)$, $(A + GC - \beta I)$ is bijective and $(A + GC - \beta I)\mathcal{S} = \mathcal{S}$. Furthermore, the (C, A)-characteristic subspaces being invariant by input injection, $(A + GC - \beta I)\mathcal{T}(\beta) = \mathcal{T}(\beta)$. It follows that $(A + GC - \beta I)(\mathcal{S} \cap \operatorname{Ker} C) = \mathcal{S} \cap \mathcal{T}(\beta)$. □

Comment 1. From Theorem 2.6 and its dual counter part, it is easy to *characterize controllability and complementary observability subspaces in terms of characteristic subspaces.* Clearly, if (C, A) is an observable pair and $\mathcal{S}$ is (C, A)-invariant, $\mathcal{S}$ is a complementary observability subspace if and only if for all $\beta \in \mathbb{C}$, $\dim \mathcal{S} \cap \mathcal{T}(\beta) = \dim \mathcal{S} \cap \operatorname{Ker} C$. If (A, B) is a controllable pair and $\mathcal{S}$ is (A, B)-invariant, $\mathcal{S}$ is a controllability subspace if and only if for all $\lambda \in \mathbb{C}$, $\dim \mathcal{S} \cap \mathcal{S}(\lambda) = \dim \mathcal{S} \cap \operatorname{Im} B$. Note that this result can be viewed as a corollary of Theorem 7.1 of [15].

Finally, we will need the following results.

LEMMA 2.7. *Let $\mathcal{S}$ be (C, A) and (A, B)-invariant, $\tilde{\mathcal{S}}(\lambda)$ and $\tilde{\mathcal{T}}(\beta)$ denote the characteristic subspaces of $(A + BKC, B, C)$ induced modulo $\mathcal{S}$ (where K is an admissible feedback), and Λ_F denote the fixed spectrum corresponding to the lattice* (2).

(i) $\operatorname{Im}(B(\operatorname{mod} \mathcal{S})) = \pi(\operatorname{Im} B)$;

(ii) $\operatorname{Ker}(C(\operatorname{mod} \mathcal{S})) = \pi(\operatorname{Ker} C)$;

(iii) $\tilde{\mathcal{S}}(\lambda) = \pi(\mathcal{S}(\lambda))$ *for all* $\lambda \in \mathbb{C} \backslash \Lambda_F$;

(iv) $\tilde{\mathcal{T}}(\beta) = \pi(\mathcal{T}(\beta))$ *for all* $\beta \in \mathbb{C}$.

Proof. Let us denote $\tilde{B} = B(\operatorname{mod} \mathcal{S})$ and $\tilde{C} = C(\operatorname{mod} \mathcal{S})$. $\tilde{B} = \pi B$ yields (i). From the commutativity of the diagram of Fig. 2.1, we have

$$\operatorname{Ker} \tilde{C} = \pi \operatorname{Ker}(\tilde{C}\pi) = \pi \operatorname{Ker}(\pi' C) = \pi(\mathcal{S} + \operatorname{Ker} C) = \pi(\operatorname{Ker} C),$$

hence (ii) is satisfied. Moreover, it is easy to see that $\pi(\mathcal{S}(\lambda)) \subset \tilde{\mathcal{S}}(\lambda)$. In view of the dual counterpart of Theorem 2.6 from the relation

$$\dim \pi(\mathcal{S}(\lambda)) = \dim \mathcal{S}(\lambda) - \dim \mathcal{S} \cap \mathcal{S}(\lambda),$$

we have

$$\dim \pi(\mathcal{S}(\lambda)) = \dim \operatorname{Im} B - \dim \mathcal{S} \cap \operatorname{Im} B,$$

that is,

$$\dim \pi(\mathcal{S}(\lambda)) = \dim \pi(\operatorname{Im} B) = \dim \operatorname{Im} \tilde{B} = \dim \tilde{\mathcal{S}}(\lambda).$$

Part (iv) can be proved in the same manner by using (ii). □

3. Degrees of freedom in pole assignment by output feedback. Our main result concerning the available freedom for eigenvalue/eigenvector assignment is stated in Theorem 3.1 below. The whole section is devoted to its proof. To describe our results, a notion of iterative genericity is required. A property *depending on an iterative choice* in linear spaces will be said *iteratively generic* if it is generic at the first step in the sense where it is true except perhaps on a *thin* subset (i.e., a semialgebraic subset of nonmaximal dimension) of the first linear subspace, then, a nonpathologic choice being performed, the property remains generic with respect to the choice of a second vector in the second space, and so on.

3.1. Statement of the main result and description of the algorithm. The eigenstructure assignment procedure presented here requires a special treatment for the assignment of the pth eigenvector. This is considerably simplified if it is assumed that this special eigenvector corresponds to a real eigenvalue. Otherwise polynomial approaches must be used. So, it will be assumed that the set of eigenvalues to be assigned satisfies a slightly restrictive condition of admissibility. A finite set $\Lambda = \{\lambda_1, \cdots, \lambda_n\} \subset \mathbb{C}$ is said to be *admissible* if $\lambda_i \neq \lambda_j$ for $i \neq j$ and if there exists a partition of Λ consisting of three self-conjugate disjoint subsets of the form $\Lambda_1 = \{\lambda_1, \cdots, \lambda_{p-1}\}$, $\{\lambda_p\}$ and $\Lambda_2 = \{\lambda_{p+1}, \cdots, \lambda_n\}$. Now we can state our main result.

THEOREM 3.1. *Let (A, B, C) be a complete triple in $\mathbb{R}^{n\times n} \times \mathbb{R}^{n\times m} \times \mathbb{R}^{p\times n}$ satisfying $m+p>n$ and Λ be an admissible set of n complex numbers. Then (except perhaps for a finite subset of values of $\lambda_1, \cdots, \lambda_{p-1}$) the property*

$$\dim \mathcal{S}'(\lambda_p) = m+p-n$$

is iteratively generic with respect to the selection of vectors $s_i \in \mathcal{S}(\lambda_i)$, $i = 1, \cdots, p-1$ such that $s_i = \overline{s_j}$ if $\lambda_i = \overline{\lambda_j}$, where $\mathcal{S}'(\lambda_p) \triangleq \mathcal{S}(\lambda_p) \cap (\mathcal{T}(\lambda_{p+1}) + \mathcal{S}_{p-1}) \cap \cdots \cap (\mathcal{T}(\lambda_n) + \mathcal{S}_{p-1})$ with $\mathcal{S}_{p-1} \triangleq \langle s_1, \cdots, s_{p-1}\rangle$. Furthermore, given a generic vector s_p in $\mathcal{S}'(\lambda_p)$, we have $\langle s_1, \cdots, s_p\rangle \cap \operatorname{Ker} C \neq 0$ and the output feedback K given by

$$K = [w_1 \cdots w_p](C[s_1, \cdots, s_p])^{-1}$$

(where w_i is the input direction associated to s_i) is the unique real gain such that $\sigma(A+BKC) = \Lambda$ with $s_1, \cdots, s_p$ as eigenvectors associated to $\lambda_1, \cdots, \lambda_p$.

For synthesizing modal control laws, it is very important to have at one's disposal, without redundancy, all the degrees of freedom remaining after having chosen the pole to be assigned. Note that various pole assignment methods given in the literature waste degrees of freedom in "linearizing" the problem. Here the problem considered is naturally "linear." Let us check that all the degrees of freedom appearing in Theorem 3.1 are available without redundancy. There are mp entries in the gain matrix. Therefore after pole assignment it must remain exactly $mp-n$ free parameters. The choice of the $p-1$ first eigenvectors performed in m-dimensional subspaces, uses $(p-1)(m-1)$ degrees of freedom. Furthermore, the choice of the pth eigenvector being performed in an $(m+p-n)$-dimensional subspace, $m+p-n-1$ additional degrees of freedom are used. It is easy to check that $mp-n = (p-1)(m-1)+(m+p-n-1)$.

The eigenvectors s_i appearing in the above theorem are recursively chosen in order to construct the lattice given in Fig. 3.1 (in this lattice, $\mathcal{S}_i$ denotes the subspace Span $\{s_1, \cdots, s_i\}$; if λ_i is complex, we take $\lambda_{i+1} = \overline{\lambda_i}$ and $s_{i+1} = \overline{s_i}$). From Proposition 2.5, it is clear'that Theorem 3.1 will be proved if we can construct a subspace $\mathcal{S}_p$ satisfying the lattice of Fig. 3.1 for a generic choice of the vectors $s_1, \cdots, s_{p-1}$. The proof of such a result is the object of the sequel of this section. The lattice diagram (2) suggests that when $\mathcal{S}_i$ is made invariant, the set of assigned poles is exactly "$\Lambda_F \cup \Lambda'_F$." Note that in Fig. 3.1 the maximal controllability subspaces are not specified. It will appear in the proof given below (see (5)) that for $i = 1, \cdots, n-p$ we have $\mathcal{R}^*_{\mathcal{S}_i} = 0$. For $i > n-p$, $\mathcal{R}^*_{\mathcal{S}_i}$ is no longer equal to zero. But in view of Proposition 2.5, the spectrum of the subsystem restricted to $\mathcal{S}_i$ is nevertheless freely assignable by choosing a *special* gain feedback instead of considering *any* admissible gain feedback.

$$\begin{tikzcd}
0 \arrow[r, "\{\lambda_1\}"] & \mathcal{S}_1 = \mathcal{N}^*_{\mathcal{S}_1} \arrow[r] \arrow[d] & \mathcal{X} \\
0 \arrow[r, "\{\lambda_1, \lambda_2\}"] & \mathcal{S}_2 = \mathcal{N}^*_{\mathcal{S}_2} \arrow[r] \arrow[d] & \mathcal{X} \\
0 \arrow[r, "\{\lambda_1, \cdots, \lambda_{p-1}\}"] & \mathcal{S}_{p-1} = \mathcal{N}^*_{\mathcal{S}_{p-1}} \arrow[r] \arrow[d] & \mathcal{X} \\
0 \arrow[r, "\{\lambda_1, \cdots, \lambda_p\}"] & \mathcal{S}_p \arrow[r, "\{\lambda_{p+1}, \cdots, \lambda_n\}"] & \mathcal{X} = \mathcal{N}^*_{\mathcal{S}_p}
\end{tikzcd}$$

FIG. 3.1. *Illustration of the algorithm by a lattice diagram.*

3.2. Initialization of the construction of the lattice. The subspaces $\mathcal{S}_i$, $i = 1, \cdots, p-1$ appearing in Fig. 3.1 will be iteratively constructed. The main difficulty lies in the initialization of the procedure. The construction of $\mathcal{S}_{i+1}$ from $\mathcal{S}_i$ is easier and will be treated later. The following proposition deals with the initialization of the procedure in the case where the involved eigenvalue is real.

PROPOSITION 3.2. *Let (A, B, C) be a complete triple satisfying $m+p>n$. There exists no more than one real number $\tilde{\lambda}$ such that for any $\lambda \in \mathbb{R} \backslash \{\tilde{\lambda}\}$, for almost every vector $s \in \mathcal{S}(\lambda)$, the subspace $\mathcal{S} = \langle s \rangle$ satisfies*

(3) $$\mathcal{S} \cap \operatorname{Ker} C = 0,$$

(4) $$\textit{for all } \beta \in \mathbb{C}, \quad \mathcal{S} \cap \mathcal{T}(\beta) = 0,$$

(5) $$\textit{if } m < n, \quad \mathcal{S} \cap \operatorname{Im} B = 0.$$

Proof. Clearly, if $m<n$, $\mathcal{S}(\lambda) \neq \operatorname{Im} B$ for all $\lambda \in \mathbb{C}$. So, $\mathcal{S}(\lambda) \cap \operatorname{Im} B$ is a proper subspace of $\mathcal{S}(\lambda)$. In view of the dimensions of $\mathcal{S}(\lambda)$ and $\operatorname{Ker} C$, it is clear that $\mathcal{S}(\lambda) \cap \operatorname{Ker} C$ is a proper subspace of $\mathcal{S}(\lambda)$. The proposition will be demonstrated if we show that the set

$$\mathcal{S}(\lambda) \cap \bigcup_{\beta \in \mathbb{C}} \mathcal{T}(\beta)$$

is thin in $\mathcal{S}(\lambda)$. Let p_0 be the number of observability indices equal to one. Two cases must be considered.

1) $p - p_0 = 1$. Then, from Lemma 2.4

$$\operatorname{Ker} C \cup \bigcup_{\beta \in \mathbb{C}} \mathcal{T}(\beta) = \mathcal{C}_0.$$

It remains to show that $\mathcal{C}_0 \cap \mathcal{S}(\lambda)$ is a proper subspace of $\mathcal{S}$. Assume that $\mathcal{S}(\lambda) \subset \mathcal{C}_0$. As $n \leqq m+p-1$, we have $n - p_0 \leqq m$, i.e., dim $\mathcal{C}_0 \leqq$ dim $\mathcal{S}(\lambda)$. Hence,

(6) $$\mathcal{C}_0 = \mathcal{S}(\lambda).$$

So necessarily $n = m+p-1$. From Lemma 2.3, there exists no more than one value $\tilde{\lambda}$ of λ such that (6) is satisfied.

2) $p-p_0>1$. From now on, λ is assumed to be different from $\tilde{\lambda}$. From the definition of the (C, A)-characteristic subspaces, there exist p polynomials P_i, $i=1, \cdots, p$ in $n+1$ complex variables such that

$$(7) \qquad x=(x_1, \cdots, x_n)^T \in \mathcal{T}(\beta) \quad \text{iff } P_i(x_1, \cdots, x_n, \beta)=0 \quad \text{for } i=1, \cdots, p.$$

Consider the set $\mathcal{S}(\lambda, \beta) \subset \mathbb{C}^{n+1}$ consisting of the points $(x_1, \cdots, x_n, \beta)$ satisfying

$$x=(x_1, \cdots, x_n)^T \in \mathcal{S}(\lambda) \cap \mathcal{T}(\beta).$$

This set is a closed algebraic subset in $\mathbb{C}^{n+1}$ defined by the $n-m+p$ polynomial equations: those appearing in (7) together with the linear equations in $x_1, \cdots, x_n$ satisfied by any vector x belonging to $\mathcal{S}(\lambda)$. Let r be the algebraic dimension of this subset and assume that $r>m-1$. This means that there exists no more than $n+1-m$ algebraically independent polynomials P_i', $i=1, \cdots, n+1-m$ such that

$$(x, \beta) \in \mathcal{S}(\lambda, \beta) \quad \text{iff } P_i'(x, \beta)=0.$$

Then, for any $\beta_0 \in \mathbb{C}$, the subspace $\mathcal{S}(\lambda) \cap \mathcal{T}(\beta_0)$ is of dimension $\geqq m-1$ (this subspace is described by the equations $\beta=\beta_0$, $P_i'(x, \beta_0)=0$ for $i=1, \cdots, n-m+1$). As $\dim \mathcal{T}(\beta_0)=n-p<m=\dim \mathcal{S}(\lambda)$, we must have $\mathcal{T}(\beta_0) \subset \mathcal{S}(\lambda)$ for all β_0, i.e. from Lemma 2.2, $\mathcal{C}_0 \subset \mathcal{S}(\lambda)$. From Lemma 2.3, $\lambda=\tilde{\lambda}$ which contradicts the hypothesis. So $\dim \mathcal{S}(\lambda, \beta) \leqq m-1$, and the set $\mathcal{S}(\lambda) \cap \bigcup_{\beta \in \mathbb{C}} \mathcal{T}(\beta)$, which is the projection of $\mathcal{S}(\lambda, \beta)$ on $\mathcal{S}(\lambda)$, is contained in a semialgebraic subset of dimension $\leqq m-1$. □

The complex case is much more intricate.

PROPOSITION 3.3. *Let (A, B, C) be a complete triple satisfying $m+p>n$. There exists a finite subset $\Xi \subset \mathbb{C}$ such that for all $\lambda \in \mathbb{C} \backslash (\mathbb{R} \cup \Xi)$, for almost every vector $s \in \mathcal{S}(\lambda)$, the subspace $\mathcal{S}=\langle s, \bar{s} \rangle$ satisfies*

$$(8) \qquad \dim \mathcal{S}=2,$$

$$(9) \qquad \mathcal{S} \cap \operatorname{Ker} C=0,$$

$$(10) \qquad \mathcal{S} \cap \mathcal{T}(\beta)=0 \quad \textit{for all } \beta \in \mathbb{C},$$

$$(11) \qquad \textit{if } m<n-1, \quad \mathcal{S} \cap \operatorname{Im} B=0,$$

$$(12) \qquad \textit{if } m \geqq n-1, \quad \mathcal{S}+\operatorname{Im} B=\mathcal{X}.$$

The cardinal of Ξ can be estimated from above as follows:

$$\textit{if } p \geqq 4, \quad \operatorname{Card} \Xi \leqq 2(n-p),$$

$$\textit{if } p=3, \quad \operatorname{Card} \Xi \leqq 4(n-p).$$

Proof. In a first step, a vector in $\mathcal{S}(\lambda)$ such that (10) is satisfied will be constructed (such a vector will be called *admissible*) and an estimation of Card Ξ will be given. In a second step, we will show that almost every vector in $\mathcal{S}(\lambda)$ is admissible.

Step 1. Construction of an admissible vector and estimation of Card Ξ. The basic idea for constructing an admissible vector consists in decreasing the order of the system to deal with. This artifice is needed to avoid the treatment of numerous special cases. In fact, in that way, only three cases (see Lemma 3.5) are to be considered. To decrease the order, we are going to use a result (Proposition 3.10) which will be proved in the next section. This proposition is used here in a case where only real eigenvalues are assigned; in this case its proof is independent of the results stated in Proposition 3.3 (it depends only on Proposition 3.2). As $n-p \leqq m-1$, from Proposition 3.2 and 3.10, $n-p$ distinct *real* eigenvalues of the triple (A^T, C^T, B^T) can be assigned by output feedback. More precisely, this pole assignment can be achieved by choosing a subspace $\mathcal{Q}$ satisfying

- $\dim \mathcal{Q} = n-p$, $\mathcal{Q}=\bar{\mathcal{Q}}$;
- $\mathcal{Q}$ is a complementary observability subspace of the pair (A^T, B^T);
- $\mathcal{Q} \cap \operatorname{Im} C^T = 0$;
- $\mathcal{Q} \cap \operatorname{Ker} B^T = 0$;
- There exists a feedback K such that the spectrum of $(A^T + C^T K^T B^T)|\mathcal{Q}$ is a set, denoted by Λ'_F, of $n-p$ distinct real numbers arbitrarily chosen.

With respect to the triple (A, B, C), the subspace $\mathcal{S}=\mathcal{Q}^{\perp}$ satisfies

- $\dim \mathcal{S} = p$, $\mathcal{S}=\bar{\mathcal{S}}$;
- $\mathcal{S}$ is a controllability subspace;
- $\mathcal{S} + \operatorname{Ker} C = \mathbb{C}^n$ (hence $\mathcal{S} \cap \operatorname{Ker} C = 0$);
- $\mathcal{S} + \operatorname{Im} B = \mathbb{C}^n$ (hence $\dim \mathcal{S} \cap \operatorname{Im} B = m+p-n$);
- $\sigma(A+BKC)(\operatorname{mod} \mathcal{S}) = \Lambda'_F$;
- Λ'_F corresponds to the fixed spectrum of the lattice (2) defined by $\mathcal{S}$.

From now on, the spectrum Λ'_F and the gain K will be fixed. Consider the triple $(\hat{A}, \hat{B}, \hat{C})$, restriction of the triple $(A+BKC, B, C)$ to $\mathcal{S}$. The number of states, outputs, inputs of this system are, respectively, $n'=p$, $p'=p$ (because $\mathcal{S} \cap \operatorname{Ker} C = 0$), $m' = m+p-n$. Obviously, the characteristic subspaces of the triples $(A+BKC, B, C)$ and (A, B, C) are equal and so, the characteristic subspaces $\hat{\mathcal{S}}(\lambda)$ of the triple $(\hat{A}, \hat{B}, \hat{C})$ are given by the dual counterpart of Lemma 2.7:

$$\hat{S}(\lambda) = \mathcal{S}(\lambda) \cap \mathcal{S}. \tag{13}$$

An admissible vector will be searched in the subspace $\hat{S}(\lambda)$.

LEMMA 3.4. *There exists a finite set* $\Phi \subset \mathbb{R}$ *with* $\operatorname{Card} \Phi \leqq n-p$ *such that for all* $\lambda \in \mathbb{C}\backslash\mathbb{R}$, *for all* $s \in \hat{\mathcal{S}}(\lambda)$, *we have*

$$\textit{for all } \beta \in \mathbb{C}\backslash\Phi, \quad \langle s, \bar{s}\rangle \cap \mathcal{T}(\beta) = 0,$$

$$\textit{for all } \beta \in \Phi, \quad \dim \langle s, \bar{s}\rangle \cap \mathcal{T}(\beta) = 1.$$

Proof. From Theorem 2.6, as $\mathcal{S} \cap \operatorname{Ker} C = 0$ and the fact that the elements of Λ'_F are distinct, we have

$$\text{for all } \beta \in \mathbb{C}\backslash\Lambda'_F, \quad \langle s, \bar{s}\rangle \cap \mathcal{T}(\beta) = 0, \tag{14}$$

$$\text{for all } \beta \in \Lambda'_F, \quad \dim \langle s, \bar{s}\rangle \cap \mathcal{T}(\beta) \leqq 1. \tag{15}$$

As $\hat{\mathcal{S}}(\lambda) \subset \mathcal{S}$ and $\mathcal{S} = \bar{\mathcal{S}}$, the lemma is proved (necessarily $\Phi \subset \Lambda'_F$). □

The proof of the following technical lemma is straightforward by using the Brunovski canonical form.

LEMMA 3.5. (i) *Assume that* $n' \geqq 3$, $m' \geqq 2$. Let $\theta \in \mathbb{C}\backslash\mathbb{R}$ *and* s_1, s_2 *be two independent vectors in* $\hat{S}(\theta)$. *Then, for almost any vector* $s_3 \in \hat{\mathcal{S}}(\theta)$, *we have*

$$\langle s_1, \bar{s}_1\rangle \cap \langle s_2, \bar{s}_2\rangle \neq \langle s_1, \bar{s}_1\rangle \cap \langle s_3, \bar{s}_3\rangle.$$

(ii) *Assume that* $n' \geqq 4$, $m'=1$. *Let* $\theta_1 \in \mathbb{C}\backslash\mathbb{R}$. *Then, for all* $\theta_2 \in \mathbb{C}\backslash(\mathbb{R} \cup \{\theta_1, \bar{\theta}_1\})$, *for all* $s_1 \in \hat{\mathcal{S}}(\theta_1)$, *for all* $s_2 \in \hat{\mathcal{S}}(\theta_2) (s_1 \neq 0, s_2 \neq 0)$, *we have*

$$\langle s_1, \bar{s}_1\rangle \cap \langle s_2, \bar{s}_2\rangle = 0.$$

(iii) *Assume that* $n'=3$, $m'=1$. *Let* $\theta_1, \theta_2 \in \mathbb{C}\backslash\mathbb{R}$ *such that* $\theta_2 \notin \{\theta_1, \bar{\theta}_1\}$. *Then, for any* $\theta_3 \in \mathbb{C}\backslash\mathbb{R}$ *such that* $\theta_3 \notin \{\theta_1, \bar{\theta}_1, \theta_2, \bar{\theta}_2\}$, *for any* $s_i \in \hat{\mathcal{S}}(\theta_i)$ $(i=1,2,3)$ *such that* $s_i \neq 0$, *we have*

$$\langle s_1, \bar{s}_1\rangle \cap \langle s_2, \bar{s}_2\rangle \neq \langle s_1, \bar{s}_1\rangle \cap \langle s_3, \bar{s}_3\rangle.$$

The following lemma gives more information about the number of pathological λ for a given β in the set Φ of Lemma 3.4.

LEMMA 3.6. *For any $\beta \in \Phi$, there exists a finite subset $\Xi(\beta)$ of $\mathbb{C}\backslash\mathbb{R}$ satisfying*

- *If $n' \geqq 4$,* Card $\Xi(\beta) \leqq 2$;
- *If $n' = 3$,* Card $\Xi(\beta) \leqq 4$;
- *For any $\lambda \notin \Xi(\beta)$, for almost any $s \in \hat{\mathscr{S}}(\lambda)$, $\langle s, \bar{s}\rangle \cap \mathscr{T}(\beta) = 0$.*

Proof. Let $\beta \in \Phi$. Three cases are to be considered.

(a) $n' \geqq 3$; $m' \geqq 2$. Let $\theta \in \mathbb{C}\backslash\mathbb{R}$; assume that there exist two independent vectors $s_1, s_2 \in \hat{\mathscr{S}}(\theta)$ such that $\langle s_1, \bar{s}_1\rangle \cap \mathscr{T}(\beta) \neq 0$ and $\langle s_2, \bar{s}_2\rangle \cap \mathscr{T}(\beta) \neq 0$. Then, from Lemma 3.4, $\dim \langle s_1, \bar{s}_1\rangle \cap \mathscr{T}(\beta) = 1$ and $\dim \langle s_2, \bar{s}_2\rangle \cap \mathscr{T}(\beta) = 1$. From (15), this means that $\langle s_1, \bar{s}_1\rangle \cap \mathscr{T}(\beta) = \langle s_2, \bar{s}_2\rangle \cap \mathscr{T}(\beta)$, which is equivalent to $\langle s_1, \bar{s}_1\rangle \cap \langle s_2, \bar{s}_2\rangle \cap \mathscr{T}(\beta) \neq 0$. So, from Lemma 3.5(i), for almost all vectors $s_3 \in \hat{\mathscr{S}}(\theta)$, we have $\langle s_3, \bar{s}_3\rangle \cap \mathscr{T}(\beta) = 0$ (otherwise we would have $\langle s_1, \bar{s}_1\rangle \cap \mathscr{T}(\beta) \neq \langle s_3, \bar{s}_3\rangle \cap \mathscr{T}(\beta)$, that is $\dim \mathscr{S} \cap \mathscr{T}(\beta) = 2$). So, in this case, Card $\Xi(\beta) = 0$.

(b) $n' \geqq 4$; $m' = 1$. In this case, the above argument used with Lemma 3.5(ii) leads to Card $\Xi(\beta) \leqq 2$.

(c) $n' = 3$; $m' = 1$. In this case, from Lemma 3.5(iii), Card $\Xi(\beta) \leqq 4$. □

The previous technical results can be summarized in the following lemma.

LEMMA 3.7. *There exists a finite subset $\Xi \in \mathbb{C}\backslash\mathbb{R}$ such that*

- *If $n' = p \geqq 4$,* Card $\Xi \leqq 2(n-p)$;
- *If $p = 3$,* Card $\Xi \leqq 4(n-p)$;
- *For any $\lambda \in \mathbb{C}\backslash\mathbb{R} \cup \Xi$, there exists $s \in \mathscr{S}(\lambda)$ such that for any $\beta \in \mathbb{C}$, $\langle s, \bar{s}\rangle \cap \mathscr{T}(\beta) = 0$.*

Proof. From Lemmas 3.4 and 3.6, we can take $\Xi = \bigcup_{\beta \in \Phi} \Xi(\beta)$ and choose s generically in $\hat{\mathscr{S}}(\lambda)$ for any $\lambda \notin \Xi$. □

Step 2. Genericity of admissible vectors. We will show now that if there exists one admissible vector in $\mathscr{S}(\lambda)$, almost every vector in $\mathscr{S}(\lambda)$ will be admissible as well. The following supporting lemma will be used.

LEMMA 3.8. *Let $P_1(x, \beta), \cdots, P_n(x, \beta)$ be polynomials in the complex variables $x \in \mathbb{C}^m$ and $\beta \in \mathbb{C}$ such that there exists x_0 satisfying*

$$\textit{for any } \beta \in \mathbb{C}, \textit{ there exists } i \in [1, n] \textit{ such that } P_i(x_0, \beta) \neq 0.$$

Then, the algebraic set

$$\mathscr{V} = \{x \textit{ s.t. there exists } \beta \textit{ s.t. } P_1(x, \beta) = 0, \cdots, P_n(x, \beta) = 0\}$$

is thin in $\mathbb{C}^m$.

Proof. If at least one of the considered polynomials is constant with respect to β but is not identically equal to zero, it is clear that $\mathscr{V}$ is thin. Otherwise, it is clear that there exists at least two polynomials that depend on β. Assume that P_1 is such a polynomial. So its leading coefficient is not identically equal to zero ($Ldc_\beta P_1(x) \neq 0$). It is straightforward to construct another polynomial $P_1'(x, \beta)$ as a linear combination of $P_2, \cdots, P_n$ such that $P_1(x_0, \beta)$ and $P_1'(x_0, \beta)$ have no common root and with $Ldc_\beta P_1'(x) \neq 0$. By a continuity argument, the property relative to the common roots is true in a neighbourhood of x_0. As the leading coefficients are not identically equal to zero, there exists x_1 arbitrarily close to x_0 satisfying:

- $P_1(x_1, \beta)$ and $P_1'(x_1, \beta)$ have no common root,
- $Ldc_\beta(P_1(x_1)) \neq 0$,

- $Ldc_\beta(P_1'(x_1)) \neq 0$,

i.e., $Res_\beta(P_1, P_1')(x_1) \neq 0$. So, $Res_\beta(P_1, P_1')(x) \neq 0$. Therefore, as

$$\mathcal{V} \subset \{x \text{ s.t. } Res_\beta(P_1, P_1')(x) = 0\}, \ \mathcal{V} \text{ is thin.} \qquad \square$$

The fact that admissibility is a generic condition can now be proved.

LEMMA 3.9. *Let $\lambda \in \mathbb{C}\backslash(\mathbb{R} \cap \Xi)$. Then, for almost every $s \in \mathcal{S}(\lambda)$, we have*

$$\textit{for all } \beta \in \mathbb{C}, \quad \langle s, \bar{s}\rangle \cap \mathcal{T}(\beta) = 0.$$

Proof. Let $\mathcal{T}(\beta)$ be the rational matrix such that $\mathcal{T}(\beta) = \operatorname{Im} T(\beta)$. Let λ be a given complex number in $\mathbb{C}\backslash(\mathbb{R} \cap \Xi)$ and S be a matrix such that $\mathcal{S}(\lambda) = \operatorname{Im} S$. We have to prove that the set

$$\mathcal{V}(\lambda) = \{x \in \mathbb{C}^m \text{ such that there exists } \beta \in \mathbb{C} \text{ s.t. } \langle Sx, \overline{Sx}\rangle \cap \mathcal{T}(\beta) \neq 0\}$$

is thin in $\mathbb{C}^m$. We have

$$x \in \mathcal{V}(\lambda) \text{ iff there exists } \beta \in \mathbb{C} \text{ s.t. rank}\,[Sx\,\overline{Sx}\;\, T(\beta)] \leqq n - p + 1.$$

Let $(P_i)_{i \in I}$ be the minors of order $n-p+2$ of the matrix $[Sx\,\overline{Sx}\;\, T(\beta)]$. Clearly, the P_i's are polynomials in x, $\bar{x}$, β and

$$x \in \mathcal{V}(\lambda) \text{ iff there exists } \beta \in \mathbb{C} \text{ s.t. } P_i(x, \bar{x}, \beta) = 0.$$

From Lemma 3.7, there exists at least one admissible vector, i.e.,

$$\text{there exists } x_0 \in \mathbb{C}^m \text{ such that for all } \beta \in \mathbb{C}, \text{ there exists } i \in I \text{ s.t. } P_i(x_0, \bar{x}_0, \beta) \neq 0.$$

Lemma 3.8 concludes the proof. □

Step 3. *End of the proof of Proposition* 3.3. Consider the restricted system constructed in Step 1. By construction, for any $s \in \hat{\mathcal{S}}(\lambda) \cap \mathcal{S}$, we have $\langle s, \bar{s}\rangle \cap \operatorname{Ker} C = 0$. So,

$$\dim(\operatorname{Ker} C + \mathcal{S}(\lambda)) \geqq \dim \operatorname{Ker} C + 1,$$

$$\dim(\operatorname{Ker} C + \mathcal{S}(\lambda) + \overline{\mathcal{S}(\lambda)}) \geqq \dim \operatorname{Ker} C + 2.$$

From the Kimura lemma (see Lemma 1 of [7]), for almost any vector $s \in \mathcal{S}(\lambda)$, we have that $\langle s, \bar{s}\rangle \cap \operatorname{Ker} C = 0$. Furthermore, using the Brunovski canonical form, it is clear that almost any vector $s \in \mathcal{S}(\lambda)$ satisfies the properties (11) and (12). So, the properties (8) to (12) are independently satisfied by almost any vector $s \in \mathcal{S}(\lambda)$. As a finite union of thin subsets is thin, almost every vector of $\mathcal{S}(\lambda)$ satisfies all of them. □

3.3. Recursive construction of the lattice. To construct $\mathcal{S}_{i+1}$ from $\mathcal{S}_i$, the proposed approach consists in applying the results of the previous section to the subsystem induced modulo $\mathcal{S}_i$. The genericity of the properties obtained relative to this subsystem will be recovered for the subsystem induced modulo $\mathcal{S}_{i+1}$ and so on.

PROPOSITION 3.10. *Let (A, B, C) be a complete triple satisfying $m + p > n$. Consider an (A, B)-invariant subspace $\mathcal{S}_i$ with the following properties.*

(i) *There exists a self-conjugate set of distinct complex numbers $\{\lambda_1, \cdots, \lambda_i\}$ such that*

$$\mathcal{S}_i = \langle s_1, \cdots, s_i\rangle \textit{ with } s_i \in \mathcal{S}(\lambda_i) \textit{ and } s_k = \bar{s}_j \textit{ if } \lambda_k = \bar{\lambda}_j;$$

(ii) $\mathcal{S}_i \cap \operatorname{Ker} C = 0$;

(iii) $\mathcal{S}_i \cap \mathcal{T}(\beta) = 0$ *for any* $\beta \in \mathbb{C}$;

(iv) $\mathcal{S}_i \cap Im\, B = 0$ *if* $i \leqq n - m$.

Let λ_i be a real number (respectively, a complex nonreal number) and assume that $i \leqq p - 1$ (respectively, $i < p - 1$). Then, there exists a finite set $\Xi_{i+1} \subset \mathbb{C}$ (cf. Propositions 3.2 *and*

3.3 *for a majoration of* Card Ξ_{i+1}) *such that if* $\lambda_{i+1} \notin \{\lambda_1, \cdots, \lambda_i\} \cup \Xi_{i+1}$, *then, for almost any* $s_{i+1} \in \mathcal{S}(\lambda_{i+1})$, *the subspace* $\mathcal{S}_{i+1} = \langle s_1, \cdots, s_i, s_{i+1}\rangle$ (*respectively,* $\mathcal{S}_{i+2} = \langle s_1, \cdots, s_i, s_{i+1}, \bar{s}_{i+1}\rangle$) *satisfies the same properties* (i)–(iv) *than* $\mathcal{S}_i$. *Furthermore,* $\Xi_i \subset \Xi_{i+1}$.

Proof. This result will be proved only in the case where λ_{i+1} is real, the demonstration in the complex case being identical. Let $\mathcal{S}_i$ be a subspace satisfying the properties (i)–(iv). As $\mathcal{S}_i \cap \operatorname{Ker} C = 0$, there exists an output feedback gain K_i such that $\mathcal{S}_i$ is $(A + BK_iC)$-invariant. Let us consider the system $(\tilde{A}, \tilde{B}, \tilde{C})$ induced by $(A + BK_iC, B, C)$ modulo $\mathcal{S}_i$. Let $\tilde{\mathcal{S}}(\lambda)$ and $\tilde{\mathcal{T}}(\beta)$ denote the characteristic subspaces of the induced system. It is well known that the pair $(\tilde{A}, \tilde{B})$ is controllable (cf. [17]). As $\mathcal{S}_i \cap \operatorname{Ker} C = 0$ and $\mathcal{S}_i \cap \mathcal{T}(\beta) = 0$ for any $\beta \in \mathbb{C}$, the pair $(\tilde{A}, \tilde{C})$ is observable (cf. Comment 1). Furthermore, if $\tilde{n} \triangleq \dim \mathcal{X}/\mathcal{S}_i$, $\tilde{p} \triangleq \dim \operatorname{Im} \tilde{C}$, $\tilde{m} \triangleq \dim \operatorname{Im} \tilde{B}$, we have

$$\begin{aligned}
&\tilde{n} = n - i,\\
&\tilde{p} = p - i \quad (\text{as } \mathcal{S}_i \cap \operatorname{Ker} C = 0),\\
&\tilde{m} = m \quad \text{for } i \leqq n - m \quad (\text{as then } \mathcal{S}_i \cap \operatorname{Im} B = 0),\\
&\quad = n - i \quad \text{for } i > n - m.
\end{aligned} \tag{16}$$

So, in any case, the induced system satisfies the condition $\tilde{n} < \tilde{m} + \tilde{p}$ and Proposition 3.2 may be applied to the induced system. Thus, there exists no more than one real number $\tilde{\lambda}$ such that for any $\lambda_{i+1} \in \mathbb{R}\backslash\{\tilde{\lambda}\}$, for almost any vector $\tilde{s}_{i+1} \in \tilde{\mathcal{S}}(\lambda_{i+1})$, we have

$$\begin{aligned}
&\langle \tilde{s}_{i+1}\rangle \cap \operatorname{Ker} \tilde{C} = 0,\\
&\langle \tilde{s}_{i+1}\rangle \cap \tilde{\mathcal{T}}(\beta) = 0 \quad \text{for all } \beta \in \mathbb{C},\\
&\langle \tilde{s}_{i+1}\rangle \cap \operatorname{Im} \tilde{B} = 0 \quad \text{if } i < n - m.
\end{aligned} \tag{17}$$

In the sequel, we will assume that $\lambda_{i+1} \notin \{\lambda_1, \cdots, \lambda_i\} \cup \{\tilde{\lambda}\}$. The two following lemmas will achieve the proof of the proposition.

LEMMA 3.11. *For almost any vector* $s_{i+1} \in \mathcal{S}(\lambda_{i+1})$, *the subspace* $\mathcal{S}_{i+1} = \mathcal{S}_i + \langle s_{i+1}\rangle$ *satisfies the conditions* (i)–(iv) *of Proposition* 3.10.

Proof. From Lemma 2.7, we have

$$\pi(\operatorname{Im} B) = \operatorname{Im} \tilde{B}, \tag{18}$$

$$\pi(\operatorname{Ker} C) = \operatorname{Ker} \tilde{C}, \tag{19}$$

$$\pi(\mathcal{S}(\lambda)) = \tilde{\mathcal{S}}(\lambda) \quad \text{for all } \lambda \notin \{\lambda_1, \cdots, \lambda_i\}, \tag{20}$$

$$\pi(\mathcal{T}(\beta)) = \tilde{\mathcal{T}}(\beta) \quad \text{for all } \beta \in \mathbb{C}. \tag{21}$$

Now, consider a vector $\tilde{s}_{i+1} \in \tilde{\mathcal{S}}(\lambda_{i+1})$ satisfying (17). From (20), we can associate to $\tilde{s}_{i+1}$ a vector $s_{i+1} \in \mathcal{S}(\lambda_{i+1})$ such that $\pi(\mathcal{S}_{i+1}) = \langle \tilde{s}_{i+1}\rangle$. Using the fact that if $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$ *are three subspaces in a space* $\mathcal{X}$ *such that* $\mathcal{B} \subset \mathcal{A}$, $\mathcal{B} \cap \mathcal{C} = 0$ *and* $\pi(\mathcal{A}) \cap \pi(\mathcal{C}) = 0$, *where* π *is the canonical surjection from* $\mathcal{X}$ *onto* $\mathcal{X}/\mathcal{B}$, *then* $\mathcal{A} \cap \mathcal{C} = 0$. Equations (18)–(21), $\mathcal{S}_{i+1}$ satisfy properties (i)–(iv) of the proposition. Furthermore, the genericity of $\tilde{s}_{i+1}$ in $\tilde{\mathcal{S}}(\lambda_{i+1})$ corresponds obviously to the genericity of s_{i+1} in $\mathcal{S}(\lambda_{i+1})$. □

LEMMA 3.12. *Let* Ξ_k *be the set of the eigenvalues which cannot be assigned at the kth step of the algorithm. Then* $\Xi_i \subset \Xi_{i+1}$ *for* $i = 1, \cdots, p - 2$.

Proof. Assume that λ is a "pathological" eigenvalue at the first step of the algorithm. This means that for any $s \in \mathcal{S}(\lambda)$, there exists $\beta \in \mathbb{C}$ such that $\langle s, \bar{s}\rangle \cap \mathcal{T}(\beta) \neq 0$. Let π be the projection from $\mathcal{X}$ onto $\mathcal{X}/\mathcal{S}_1$ and let $\tilde{s} \triangleq \pi(s)$. In view of (21), we have

$$\pi(\langle s, \bar{s}\rangle \cap \mathcal{T}(\beta)) \subset \langle \tilde{s}, \bar{\tilde{s}}\rangle \cap \tilde{\mathcal{T}}(\beta).$$

As $\mathcal{S}_1 \cap \mathcal{T}(\beta) = 0$ by construction, we have

$$\langle s, \bar{s}\rangle \cap \mathcal{T}(\beta) \neq 0 \Rightarrow \langle \tilde{s}, \bar{\tilde{s}}\rangle \cap \tilde{\mathcal{T}}(\beta) \neq 0.$$

So, if λ is pathological at the first step, it is still pathological at the second step. Therefore it remains pathological all along the algorithm. □

Note that the subspaces $\mathcal{S}_i$, $i = 1, \cdots, p-1$ so constructed from a generic choice of vectors $s_i \in \mathcal{S}(\lambda_i)$ satisfy the lattice given in Fig. 3.1:

1. $\mathcal{S}_i$ is (A, B)-invariant (from (i));
2. $\mathcal{S}_i$ is (C, A)-invariant (from (ii));
3. $\mathcal{N}^*_{\mathcal{S}_i} = \mathcal{S}_i$ (from (iii) and Comment 1);
4. $\mathcal{R}^*_{\mathcal{S}_i} = 0$ if $i \leqq n - m$ (from (iv));
5. By construction, the eigenvalues are assigned as desired.

3.4. Final step of the construction of the lattice. Now, the subspace $\mathcal{S}_p$ of the lattice must be constructed. In the following proposition are pointed out the degrees of freedom appearing in this construction.

PROPOSITION 3.13. *Consider a subspace* $\mathcal{S}_{p-1} = \langle s_1, \cdots, s_{p-1}\rangle$ *satisfying conditions* (i)–(iv) *of Proposition* 3.10. *Let* λ_p *be a real number and let* $\Lambda_2 = \{\lambda_{p+1}, \cdots, \lambda_n\}$ *be a self-conjugate set of complex numbers, so that* $\Lambda = \{\lambda_1, \cdots, \lambda_n\}$ *is admissible. Then the subspace*

$$\mathcal{S}'(\lambda_p) = \mathcal{S}(\lambda_p) \cap (\mathcal{T}(\lambda_{p+1}) \oplus \mathcal{S}_{p-1}) \cap \cdots \cap (\mathcal{T}(\lambda_n) \oplus \mathcal{S}_{p-1})$$

satisfies

1. $\dim \mathcal{S}'(\lambda_p) = m + p - n > 0$;
2. *For almost every vector* $s_p \in \mathcal{S}'(\lambda_p)$, *the subspace* $\mathcal{S}_p = \langle s_1, \cdots, s_p\rangle$ *satisfies* $\mathcal{S}_p \cap \operatorname{Ker} C = 0$ *and the spectrum induced modulo* $\mathcal{S}_p$ *is* Λ_2.

Proof. Consider the system induced modulo $\mathcal{S}_{p-1}$ (the related canonical surjection is denoted by π). For this system, we have (cf. (16)) $\tilde{n} = n - p + 1$, $\tilde{m} = n - p + 1$, $\tilde{p} = 1$. Thus, for all $\lambda \in \mathbb{C}$, $\tilde{\mathcal{S}}(\lambda) = \tilde{\mathcal{X}}$. Furthermore, as $\mathcal{S}_{p-1} \cap \operatorname{Ker} C = 0$ and $\lambda_p \notin \{\lambda_1, \cdots, \lambda_{p-1}\}$, the relations (18) to (21) are satisfied. So, as $\operatorname{Ker} \pi = \mathcal{S}_{p-1}$, we have

$$\pi(\mathcal{S}'(\lambda_p)) = \tilde{\mathcal{T}}(\lambda_{p+1}) \cap \cdots \cap \tilde{\mathcal{T}}(\lambda_n). \tag{22}$$

Considering the special form of the characteristic subspaces on the Brunovski canonical form, it is straightforward to see that $\dim \tilde{\mathcal{T}}(\lambda_{p+1}) \cap \cdots \cap \tilde{\mathcal{T}}(\lambda_n) = 1$ and $\tilde{\mathcal{T}}(\lambda_{p+1}) \cap \cdots \cap \tilde{\mathcal{T}}(\lambda_n) \cap \operatorname{Ker} \tilde{C} = 0$. Therefore from (22),

$$\dim \pi(\mathcal{S}'(\lambda_p)) = 1 \tag{23}$$

and

$$\pi(\mathcal{S}'(\lambda_p) \cap (\operatorname{Ker} C \oplus \mathcal{S}_{p-1})) = 0. \tag{24}$$

Furthermore, as $\mathcal{S}(\lambda_p) \cap \mathcal{S}_{p-1} = \operatorname{Ker} \pi | \mathcal{S}(\lambda_p)$, we have

$$\dim \mathcal{S}(\lambda_p) \cap \mathcal{S}_{p-1} = \dim \mathcal{S}(\lambda_p) - \dim \operatorname{Im} \pi | \mathcal{S}(\lambda_p) \tag{25}$$

$$= \dim \mathcal{S}(\lambda_p) - \dim \tilde{\mathcal{X}} \tag{26}$$

so

$$\dim \mathcal{S}(\lambda_p) \cap \mathcal{S}_{p-1} = m + p - n - 1. \tag{27}$$

From (23) and the fact that $\mathcal{S}'(\lambda_p) \cap \mathcal{S}_{p-1} = \mathcal{S}(\lambda_p) \cap \mathcal{S}_{p-1}$, we have

$$\dim \mathcal{S}'(\lambda_p) = \dim \mathcal{S}'(\lambda_p) \cap \mathcal{S}_{p-1} + \dim \pi(\mathcal{S}'(\lambda_p)) = m + p - n.$$

Hence (i) holds. Furthermore, (24) leads to

$$\mathcal{S}'(\lambda_p)\cap(\operatorname{Ker} C\oplus\mathcal{S}_{p-1})\subset\mathcal{S}_{p-1}.$$

Therefore, $\mathcal{S}'(\lambda_p)\cap(\operatorname{Ker} C\oplus\mathcal{S}_{p-1})$ is contained in $\mathcal{S}(\lambda_p)\cap\mathcal{S}_{p-1}$. As this subspace is a hyperplane of $\mathcal{S}'(\lambda_p)$ (from (27)), we deduce that for almost any vector $s_p\in\mathcal{S}'(\lambda_p)$, the subspace $\mathcal{S}_p=\langle s_1,\cdots,s_p\rangle$ satisfies $\mathcal{S}_p\cap\operatorname{Ker} C=0$. Moreover, by construction, $\mathcal{S}_p\cap\mathcal{T}(\lambda_i)\neq 0$ for $i=p+1,\cdots,n$. From Theorem 2.6, this means that the spectrum induced modulo $\mathcal{S}_p$ is $\{\lambda_{p+1},\cdots,\lambda_n\}$.

The construction of the subspace $\mathcal{S}_p=\langle s_1,\cdots,s_p\rangle$ from a generic choice of vectors $s_i\in\mathcal{S}(\lambda_i)$, $i=1,\cdots,p-1$ and $s_p\in\mathcal{S}'(\lambda_p)$ completes that of the lattice given in Fig. 3.1. So, Theorem 3.1 is demonstrated. □

3.5. Illustrative example. Let us consider the following numerical example:

$$A=\begin{bmatrix}0&1&0&0\\0&0&1&0\\0&0&0&1\\0&0&0&0\end{bmatrix},\qquad B=\begin{bmatrix}2&1\\5&3\\6&4\\2&2\end{bmatrix},$$

$$C=\begin{bmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\end{bmatrix}$$

(i) *The generic case.* Assume that $\{\lambda_1=-2+2i,\ \lambda_2=-2-2i,\ \lambda_3=-2,\ \lambda_4=-1\}$. We have to choose a vector in $\mathcal{S}(-2+2i)$. It is straightforward to check that

$$\mathcal{S}(-2+2i)=\begin{bmatrix}5&0\\0&1\\-12+4i&2\\-28-4i&2\end{bmatrix}.$$

Assume that $s_1=[5+5i,10,4-8i,-4-32i]^T$. The vector s_2 is fixed as being equal to $\bar{s}_1$. It remains to find s_3 in the subspace $\mathcal{S}'(-2)=\mathcal{S}(-2)\cap(\mathcal{T}(-1)+\langle s_1,s_2\rangle)$. As $\mathcal{T}(-1)=\operatorname{Im}[0,0,1,1]^T$, we obtain $s_3=[-1,-0.5,-1,3]^T$. Now the input directions w_i are given by solving $(A-\lambda_i I)s_i=-Bw_i$ for $i=1,3$. The following numerical values are obtained:

$$w_1=\begin{bmatrix}-66-28i\\102+56i\end{bmatrix},\qquad w_3=\begin{bmatrix}5.5\\-8.5\end{bmatrix}.$$

Finally, the feedback gain is given by $K=[w_1,\bar{w}_1,w_3](C[s_1,\bar{s}_1,s_3])^{-1}$:

$$K=\begin{bmatrix}-4&-5&1\\7.2&7.6&-2.5\end{bmatrix}.$$

We are now going to illustrate the pathologies that may occur (but which are avoided by choosing generic eigenvalues and eigenvectors).

(ii) *First class of pathologies.* Assume that the same eigenvalues are to be assigned. If the vector s_1 is selected as being equal to $[5,0,-12+4i,-28-4i]^T$, then as $\mathcal{T}(\beta)=\operatorname{Im}[0,0,1,-\beta]^T$, there exists obviously a value of β for which $\langle s_1,\bar{s}_1\rangle\cap\mathcal{T}(\beta)\neq 0$ (this value is $\beta=1$). It is the pathology corresponding to equation (10). Now if s_1 is selected as being equal to $[5,-2,-12,-28-8i]^T$, clearly $\langle s_1,\bar{s}_1\rangle\cap\operatorname{Ker} C\neq 0$ (see (9)). Note that it is clear that almost any other choice of s_1 does not induce such pathologies provided that the vector of the first and the second entries of s_1 is not colinear to a real vector.

(iii) *Second class of pathologies.* This numerical example has been especially worked out in order to exhibit another kind of pathology which does not appear generally. If $\lambda_1 = -1+i$, we have

$$\mathcal{S}(-1+i)=\begin{bmatrix} 0 & 0 \\ 1-i & 1 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}.$$

Clearly, for all choice of s_1 in this subspace, it is clear that there exists a value of β denoted $\beta(s_1)$ such that $\langle s_1, \overline{s_1}\rangle \cap \mathcal{T}(\beta(s_1)) \neq 0$. The set of such complex numbers was denoted Ξ. Its cardinal was only estimated from above in Proposition 3.3, this numerical example shows that it is not empty for some system. (Note that similar pathologies have already been pointed out [8], [10] but only for real numbers.)

4. A necessary and sufficient condition for exact pole assignment by output feedback. In the case where $m+p>n$, Kimura [7] and Davison and Wang [2] have shown that it was possible by using output feedback to assign the poles of a complete triple arbitrarily close to any prescribed set of eigenvalues. The algorithm developed in § 3 also deals with this kind of approximative assignment. Nevertheless, our results are much more precise since we have shown that only a *finite* number of eigenvalues cannot be assigned (and that it is possible to assign up to $p-1$ eigenvectors arbitrarily closed to prescribed vectors in (A, B)-characteristic subspaces). The preciseness of Propositions 3.2 and 3.3 can be used, furthermore, to improve these results by deriving a shortened proof of the necessary and sufficient condition for *exact* pole assignment given in Magni [9], [10]. At each step of the algorithm used in the previous section, the eigenstructure assignment was relative to *induced* subsystems (see Fig. 3.1). Here, as we are not concerned any more with eigenvector assignment, we have, as an additional freedom, the possibility of considering at each step, either *induced* or *restricted* subsystems. It is this additional freedom which permits us to cope with exact assignability. Let us recall the main result of [9] or [10].

THEOREM 4.1. *Let (A, B, C) be a complete triple satisfying $m+p>n$. A self-conjugate set Λ of n distinct eigenvalues being given, here exists an output feedback gain K such that $\sigma(A+BKC)=\Lambda$ if and only if the three following conditions do not hold simultaneously*:

1. $n=m+p-1$, *p and m are even*;
2. *Λ contains exactly one real eigenvalue denoted by $\tilde{\lambda}$*;
3. $\mathcal{C}_0=\mathcal{S}(\tilde{\lambda})$ *or* $\mathcal{B}_0=\mathcal{T}(\tilde{\lambda})$.

Note that the real number denoted $\tilde{\lambda}$ in Theorem 4.1 is the one defined by Lemma 2.3 and that both conditions $\mathcal{C}_0=\mathcal{S}(\tilde{\lambda})$ and $\mathcal{B}_0=\mathcal{T}(\tilde{\lambda})$ are equivalent (see [8]). The proof of the necessity of this theorem can be found in [8]. The sufficiency was proved in two steps. The first step [3], [6] is relative to the case where $\Lambda \cap \mathbb{R} = \emptyset$. The second step deals with the general case [9], [10]. The preciseness of Proposition 3.3 allows us to derive shortened proof of the first step. Let us state the result which corresponds to this first step.

PROPOSITION 4.2. *We have a complete triple (A, B, C) such that $m+p>n$ with n even. For all self-conjugate set Λ of n distinct complex nonreal numbers, there exists a gain output feedback K such that $\sigma(A+BKC)=\Lambda$.*

This result will be proved by downwards recursion. The following lemma concerns the final step of the recursion.

LEMMA 4.3. *If $m+p>n$ with $m \leqq 3$ and $p \leqq 3$, Proposition 4.2 is true.*

Proof. If $m=n$ or $p=n$, we can conclude by using state feedback or output injection. So, we have only to consider the following cases (n being even):

1. $m=3$, $p=3$, $n=4$;
2. $m=2$, $p=3$, $n=4$ with controllability indices $\{2,2\}$;
3. $m=2$, $p=3$, $n=4$ with controllability indices $\{3,1\}$.

First case. The sets of controllability and observability indices are both $\{2,1,1\}$. Considering the Brunovski canonical form for $\mathcal{S}(\lambda)$, we have (see § 2)

$$\dim \mathcal{C}_0=2,\quad \dim \mathcal{S}(\lambda)=3,\quad \dim \mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda})=4.$$

So, from the Kimura lemma [7, Lemma 1], almost all vector $s\in\mathcal{S}(\lambda)$ will satisfy

$$\langle s,\bar{s}\rangle\cap\mathcal{C}_0=0, \tag{28}$$

hence from (1)

$$\langle s,\bar{s}\rangle\cap\mathcal{T}(\beta)=0\quad\text{for all }\beta\in\bar{\mathbb{C}}.$$

Furthermore, from the fact that $\mathcal{S}(\lambda)\neq \operatorname{Im} B$, it is clear that almost all vector $s\in\mathcal{S}(\lambda)$ satisfies

$$\dim(\langle s,\bar{s}\rangle+\operatorname{Im} B)=4. \tag{29}$$

So, from Comment 1, the system $(A(\operatorname{mod}\langle s,\bar{s}\rangle), B(\operatorname{mod}\langle s,\bar{s}\rangle), C(\operatorname{mod}\langle s,\bar{s}\rangle))$ is controllable and observable. As it has two states, one output, and two inputs, it is pole assignable by output injection. □

Second case. The observability indices being $\{2,1,1\}$, we have

$$\dim \mathcal{C}_0=2.$$

If $\mathcal{S}(\lambda)\subset\mathcal{C}_0$, we have $\mathcal{S}(\bar{\lambda})\subset\mathcal{C}_0$, hence $\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda})\subset\mathcal{C}_0$, which is nonsense since $\dim\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda})=4$ (obvious considering the Brunovsky canonical form). So, $\dim\mathcal{C}_0+\mathcal{S}(\lambda)\geqq 3$ and $\dim\mathcal{C}_0+\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda})=4$. From the Kimura lemma [7, Lemma 1], it follows that almost any $s\in\mathcal{S}(\lambda)$ satisfies (28). Furthermore, it is clear that $\dim\operatorname{Im} B+\mathcal{S}(\lambda)=3$ and $\dim\operatorname{Im} B+\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda})=4$, therefore, as above, almost any $s\in\mathcal{S}(\lambda)$ satisfies (29). Considering the subsystem induces modulo $\langle s,\bar{s}\rangle$, we can conclude as above. □

Third case. To conclude as in the above case, it suffices to prove that

$$\dim(\mathcal{C}_0+\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda}))=4.$$

If this condition is not satisfied, we have

$$\mathcal{C}_0\subset\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda})$$

because $\dim(\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda}))=3$ (still considering the Brunovski canonical form). Let λ' be another eigenvalue of Λ, so, $\Lambda=\{\lambda,\bar{\lambda},\lambda',\bar{\lambda}'\}$. Now, we will show that we cannot have simultaneously

$$\mathcal{C}_0\subset\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda})\quad\text{and}\quad\mathcal{C}_0\subset\mathcal{S}(\lambda')+\mathcal{S}(\bar{\lambda}'),$$

which concludes the proof since either λ or λ' can be assigned. Now, assume that the above conditions are satisfied. Then

$$\mathcal{C}_0=(\mathcal{S}(\lambda)+\mathcal{S}(\bar{\lambda}))\cap(\mathcal{S}(\lambda')+\mathcal{S}(\bar{\lambda}')). \tag{30}$$

This relation will be written on the controllability canonical basis. In this basis, A, B, $\mathcal{S}(\lambda)$ take the form

$$(31)\qquad A=\begin{bmatrix}0&1&0&0\\0&0&1&0\\ *&*&*&*\\ *&*&*&*\end{bmatrix},\quad B=\begin{bmatrix}0&0\\0&0\\1&0\\0&1\end{bmatrix},\quad \mathcal{S}(\lambda)=\begin{bmatrix}1&0\\ \lambda&0\\ \lambda^2&0\\0&1\end{bmatrix}.$$

Let us define $x_1x_2x_3x_4$ as follows:

$$\operatorname{Ker} C \triangleq \operatorname{Im}[x_1, x_2, x_3, x_4]^T.$$

From (30), the vector $[0, 0, 0, 1]^T$ lies in $\mathscr{C}_0$. As $\mathscr{C}_0=\operatorname{Ker} C + A \operatorname{Ker} C$ and as $\dim \mathscr{C}_0=2$, we must have

$$\operatorname{rank}\begin{bmatrix}x_1&x_2&0\\x_2&x_3&0\\x_3&*&0\\x_4&*&1\end{bmatrix}=2.$$

If $x_1=0$, then necessarily $x_2=0$, hence $x_3=0$, so $\mathscr{C}_0=\operatorname{Im} B$ which, in view of (30) and (31) is a nonsense. If $x_1\neq 0$, take $x_1=1$ and $x_2=\varepsilon$. Then, $x_3=\varepsilon^2$ and $[1, \varepsilon, \varepsilon^2, 0]^T\in(\mathcal{S}(\lambda)+\mathcal{S}(\bar\lambda))\cap(\mathcal{S}(\lambda')+\mathcal{S}(\bar\lambda'))$. Hence, $\varepsilon=\lambda$ or $\bar\lambda$ and $\varepsilon=\lambda'$ or $\bar\lambda'$ which contradicts the fact that the elements of Λ are distinct. □

Proof of Proposition 4.2. The proof is performed by downwards recursion until conditions of Lemma 4.3 are encountered. Three initial configurations are to be considered.

Case 1. $p\geqq m$ and $p\geqq 4$. In this case, since n is even, $n<m+p\Rightarrow n<2p\Rightarrow n\leqq 2p-2\Rightarrow 2(n-p)\leqq n-2$. From Proposition 3.3, the number Ξ of complex eigenvalues which cannot be assigned satisfies Card $\Xi\leqq 2(n-p)$. So, there exists a complex number in Λ which can be assigned. Let s, $\bar s$ be the assigned right eigenvectors. At the next step, the system $(A(\text{mod}\langle s,\bar s\rangle), B(\text{mod}\langle s,\bar s\rangle), C(\text{mod}\langle s,\bar s\rangle))$ will be considered. This system has $n-2$ states, $p-2$ outputs, $\min(n-2, m)$ inputs. If $n-2=\min(n-2, m)$, the algorithm stops by the use of an output injection. Otherwise, it reduces to one of the three cases considered here.

Case 2. $m\geqq p$ and $m\geqq 4$. This is the dual case of the previous one. A pair of left eigenvectors is assigned; the next step is relative to a restricted system.

Case 3. $m\leqq 3$ and $p\leqq 3$. In this case, Lemma 4.3 can be used to conclude. □

5. Conclusion. In this paper we have studied the genericity of eigenvalue/eigenvector assignment for control systems in which the number of outputs (p) plus the number of inputs (m) exceeds the number of states (n). Intermediate results occurring in this proof have permitted us to obtain a necessary and sufficient condition for the exact assignability of a set of distinct poles. Maximal controllability subspaces and minimal complementary observability subspaces have been characterized in terms of the dimension of their intersections with the characteristic subspaces. It is this characterization that is the key to all results we have obtained here. It is worth noting that the main difference between the work presented in this paper and the work that is to be done for dealing with more general systems $(m+p\leqq n)$ lies in the fact that here (except in the proof of Theorem 4.1 relative to a very special case which is detailed in [10]) it was possible to construct *complementary observability subspaces* at each step of our algorithm. When $m+p\leqq n$ the property of complementary observability must be released. The fact that some eigenvalues might be induced by constructing noncomplementary observability subspaces must be viewed as a positive fact as far as these induced eigenvalues can be almost arbitrarily chosen. While some of the results obtained in this paper are sufficiently general so as to cope with these problems, some others are to be amended for instance by introducing degeneracy conditions on systems. In this field, numerous problems are still open (see Magni and Champetier [11] for further discussions).

STRUCTURE AND CLASSIFICATION THEOREMS OF FINITE-DIMENSIONAL EXACT ESTIMATION ALGEBRAS*

RUI-TAO DONG†, LUEN-FAI TAM‡, WING SHING WONG§, AND STEPHEN S.-T. YAU¶

Abstract. Estimation algebra turns out to be a crucial concept in the investigation of finite-dimensional nonlinear filters. In an earlier paper by the authors, a necessary and sufficient algebraic condition was derived for an exact estimation algebra to be finite-dimensional. In this paper, the investigation of the properties of finite-dimensional exact estimation algebras is continued, and some structure and partial classification theorems for such algebras are proved.

Key words. nonlinear filters, solvable Lie algebra, estimation algebra, elliptic partial differential equation

AMS(MOS) subject classifications. 17B30, 35J15, 60G35, 93E11

1. Introduction. In a previous paper [1], we introduced the concept of an exact estimation algebra. A simple algebraic necessary and sufficient condition was proved for an exact estimation algebra to be finite-dimensional. We also provided a detailed examination of the relationship between finite-dimensional exact estimation algebras and finite-dimensional nonlinear filters. This paper is in essence a continuation of our earlier study of exact estimation algebra, and we strongly recommend that the readers familiarize themselves with the results in [1]. However, every effort will be made to make this paper as self-contained as possible without too much duplication of the previous paper.

In this paper, we will prove some structure and partial classification theorems of exact finite-dimensional estimation algebras. The class of nonlinear filtering systems with an exact estimation algebra can be characterized by the solutions of some family of Riccati partial differential equations. These equations are the focal point of this study. We will provide two alternative existence proofs of these equations and examine their uniqueness properties.

2. Basic concepts. In this section, we will recall some basic concepts and results from [1]. The idea of using estimation algebras to construct finite-dimensional nonlinear filters was first proposed in Brockett and Clark [2], Brockett [3], and Mitter [4].[1] The motivation came from the Wei–Norman approach [5] of using Lie algebraic ideas to solve linear time-varying differential equations.

Consider a filtering problem based on the following signal observation model:

$$\begin{aligned} dx(t) &= f(x(t))\,dt + g(x(t))\,dv(t), \qquad x(0) = x_0, \\ dy(t) &= h(x(t))\,dt + dw(t), \qquad y(0) = 0, \end{aligned} \tag{2.0}$$

in which x, v, y, and w, are respectively, $\mathbb{R}^n$, $\mathbb{R}^p$, $\mathbb{R}^m$, and $\mathbb{R}^m$-valued processes, and v and w have components that are independent, standard Brownian processes. We further

assume that $n=p$, f, h are C^∞ smooth, and that g is an orthogonal matrix. We will refer to $x(t)$ as the state of the system at time t and to $y(t)$ as the observation at time t.

Let $\rho(t,x)$ denote the conditional probability density of the state given the observation $\{y(s): 0\leqq s\leqq t\}$. It is well known (see [6], for example) that $\rho(t,x)$ is given by normalizing a function $\sigma(t,x)$, which satisfies the following Duncan-Mortensen-Zakai equation:

$$d\sigma(t,x)=L_0\sigma(t,x)\,dt+\sum_{i=1}^m L_i\sigma(t,x)\,dy_i(t),\qquad \sigma(0,x)=\sigma_0, \tag{2.1}$$

where

$$L_0=\frac{1}{2}\sum_{i=1}^n\frac{\partial^2}{\partial x_i^2}-\sum_{i=1}^n f_i\frac{\partial}{\partial x_i}-\sum_{i=1}^n\frac{\partial f_i}{\partial x_i}-\frac{1}{2}\sum_{i=1}^m h_i^2$$

and for $i=1,\cdots,m$, L_i is the zero-degree differential operator of multiplication by h_i.[2] σ_0 is the probability density of the initial point x_0. In this paper, we will assume that σ_0 is a C^∞ function.

Equation (2.1) is a stochastic partial differential equation. In real applications, we are interested in constructing state estimators from observed sample paths with some property of robustness. In [7] Davis studied this problem and proposed some robust algorithms. In our case, his basic idea reduces to defining a new unnormalized density

$$\xi(t,x)=\exp\left(-\sum_{i=1}^m h(x)_i y_i(t)\right)\sigma(t,x).$$

It is easy to show that $\xi(t,x)$ satisfies the following time-varying partial differential equation

$$\begin{aligned}\frac{d\xi(t,x)}{dt}&=L_0\xi(t,x)+\sum_{i=1}^m y_i(t)[L_0,L_i]\xi(t,x)\\&\quad+\frac{1}{2}\sum_{i=1}^m y_i^2(t)[[L_0,L_i],L_i]\xi(t,x),\qquad \xi(0,x)=\sigma_0,\end{aligned}\tag{2.2}$$

where $[\cdot,\cdot]$ is the Lie bracket defined as follows.

Definition. If X and Y are differential operators, the Lie bracket of X and Y, $[X,Y]$, is defined by

$$[X,Y]\zeta=X(Y\zeta)-Y(X\zeta)$$

for any C^∞ function ζ.

Definition. The estimation algebra $\mathbf{E}$ of a filtering problem (2.0), is defined to be the Lie algebra generated by $\{L_0,L_1,\cdots,L_m\}$, or $\mathbf{E}=\langle L_0,L_1,\cdots,L_m\rangle_{L.A.}$. If in addition there exists a potential function ϕ such that $f_i=\partial\phi/\partial x_i$, for all $1\leqq i\leqq n$, then the estimation algebra is called exact.

From now on, unless stated otherwise, we assume the estimation algebra of (2.0) is exact. We use ∇p to denote the column vector $(\partial p/\partial x_1,\cdots,\partial p/\partial x_n)^T$. Hence, $\nabla\phi=f$.

[2] If p is a vector, we use the notation p_i to represent the ith component of p.

Define $D_i = \partial/\partial x_i - f_i$, and $\eta = \sum_{i=1}^n \partial f_i/\partial x_i + \sum_{i=1}^n f_i^2 + \sum_{i=1}^m h_i^2$. Then,

$$L_0 = \frac{1}{2}\left(\sum_{i=1}^n D_i^2 - \eta\right). \tag{2.3}$$

Recall that $f_i = \partial\phi/\partial x_i$. Hence,

$$\eta = \Delta\phi + |\nabla\phi|^2 + \sum_{i=1}^m h_i^2. \tag{2.4}$$

In [8] the two matrices Ω and J_η were introduced. Ω is the matrix whose i, j element is $\partial f_j/\partial x_i - \partial f_i/\partial x_j$. Note that all exact estimation algebras are characterized by the fact that $\Omega = 0$. $J_\eta = [\partial^2\eta/\partial x_i\, \partial x_j]$ is the Hessian matrix of η.

In [1], we proved the following structure theorems.

THEOREM 1. *Let* **E** *be a finite-dimensional exact estimation algebra. Then* $h_1, \cdots, h_m$ *are polynomials of degree at most one.*

THEOREM 2. *Let* $F(x_1, \cdots, x_n)$ *be a* C^∞ *function on* $\mathbb{R}^n$. *Suppose that there exists a path* $C: \mathbb{R} \to \mathbb{R}^n$ *and* $\delta > 0$ *such that* $\lim_{t\to\infty} \|C(t)\| = \infty$ *and* $\lim_{t\to\infty} \sup_{B_\delta(C(t))} F = -\infty$, *where* $B_\delta(C(t)) = \{x \in \mathbb{R}^n \mid \|x - C(t)\| < \delta\}$. *Then there is no* C^∞ *function* ψ *on* $\mathbb{R}^n$ *satisfying*

$$\Delta\psi + |\nabla\psi|^2 = F.$$

COROLLARY 1. *Let* $F(x_1, \cdots, x_n)$ *be a polynomial on* $\mathbb{R}^n$. *Suppose that there exists a polynomial path* $C: \mathbb{R} \to \mathbb{R}^n$ *such that* $\lim_{t\to\infty} \|C(t)\| = \infty$ *and* $\lim_{t\to\infty} F \circ C(t) = -\infty$. *Then there is no* C^∞ *function* ψ *on* $\mathbb{R}^n$ *satisfying*

$$\Delta\psi + |\nabla\psi|^2 = F. \tag{2.5}$$

THEOREM 3. *Suppose* **E** *is an exact estimation algebra. Then,* **E** *is finite-dimensional if and only if* $\nabla h_i^T J_\eta^j$ *is a constant for* $1 \leqq i \leqq m$ *and all* $j = 0, 1, \cdots$.

THEOREM 4. *Suppose* **E** *is an exact finite-dimensional estimation algebra. Then it has a basis consisting of one second-degree differential operator* L_0, *first-degree differential operator(s) with constant coefficients for the* $\partial/\partial x_i$ *terms,*[3] *and zero-degree differential operator(s) affine in x. Moreover, if X and Y are in* **E** *with degree less than or equal to one, then* $[X, Y]$ *is a constant.*

Theorem 5 follows from Theorem 4.

THEOREM 5. *An exact finite-dimensional estimation algebra is solvable.*

To show the relevancy of studying finite-dimensional exact estimation algebra in nonlinear filtering problems, we proved in [1] that a system defined by (2.0) with a finite-dimensional exact estimation algebra admits a universal finite-dimensional filter and provided an explicit Lie-algebraic method to construct such a filter.

Given the importance of the estimation algebra, a natural question arises as to whether we can classify all finite-dimensional exact estimation algebras up to Lie-algebraic isomorphism. Theorems 4 and 5 provide a starting point for solving this problem. In Theorem 6, we provide a more explicit structure theorem for an important subclass of finite-dimensional exact estimation algebras. A second question that arises naturally is whether we can classify all filtering systems with finite-dimensional exact estimation algebras up to state-space diffeomorphism. This is apparently a very difficult problem and requires a careful study of partial differential equations of the type (2.4).

[3] This clarifies the original statement of Theorem 5 of [1].

The connection between these types of equations and the nonlinear filtering problem was first noted by Benes (see [9]). The properties of these equations, however, are not well known. In Theorems 9 and 12, we provide some answers in regard to the existence and uniqueness of the solutions of these types of equations. Our result here is far from providing a reasonable classification theory of systems with finite-dimensional exact estimation algebras, but it may be viewed as a necessary first step.

3. Classification theorems. If **E** is finite-dimensional, then the matrix

$$M=[\nabla h_1,\cdots,\nabla h_m,J_\eta\nabla h_1,\cdots,J_\eta\nabla h_m,J_\eta^2\nabla h_1,\cdots,J_\eta^2\nabla h_m,\cdots]\tag{3.0}$$

is a constant matrix and

$$h_1,\cdots,h_m,\nabla h_1^T\nabla\eta,\cdots,\nabla h_m^T\nabla\eta,\nabla h_1^TJ_\eta\nabla\eta,\cdots,\nabla h_m^TJ_\eta\nabla\eta,\cdots$$

are all linear functions in **E**. If the rank of M is n, we say that the corresponding estimation algebra has full rank. In this case, it is easy to describe the Lie algebra structure of the estimation algebra.

THEOREM 6. *Suppose* **E** *is of maximal rank. Then it is a real vector space of dimension* $2n+2$ *with basis given by* 1, x_1, $x_2,\cdots,x_n$, $D_1,\cdots,D_n$, *and* L_0. *Moreover,* η *is a polynomial of degree at most two and the quadratic part of* $\eta-\sum_{i=1}^m h_i^2$ *is positive semidefinite.*

Proof. Since the columns of M represent gradient vectors of functions in **E** and M is a constant matrix with rank n, there are constants c_i's such that x_i+c_i is in **E** for $i=1,\cdots,m$. It is easy to show the following relations:

$$[L_0,x_i+c_i]=\frac{1}{2}\left[\sum_{j=1}^n D_j^2,x_i+c_i\right]=D_i,$$

$$[D_i,x_j+c_j]=\begin{cases}1 & \text{if } i=j,\\ 0 & \text{if } i\neq j,\end{cases}$$

$$[L_0,D_i]=\frac{1}{2}\left[\sum_{j=1}^n D_j^2,D_i\right]+\frac{1}{2}[D_i,\eta]=\frac{1}{2}\frac{\partial\eta}{\partial x_i}.$$

$\partial\eta/\partial x_i$ is a polynomial of degree at most one, for all $1\leqq i\leqq n$. Hence **E** is a real vector space spanned by 1, $x_1,\cdots,x_n$, $D_1,\cdots,D_n$ and L_0. The fact that the quadratic part of $\eta-\sum_{i=1}^m h_i^2$ is positive semidefinite again follows from Theorem 2. □

Theorem 6 implies that all exact finite-dimensional estimation algebras with maximal rank come from Benes filters (see [9] for details concerning Benes filters).

For any filtering system defined in (2.0) with an exact estimation algebra, (2.4) assigns a characteristic η. Theorem 6 implies that if the estimation algebra is finite-dimensional with maximal rank, then this mapping maps the given system to a quadratic polynomial. In order to develop a classification of systems with finite-dimensional estimation algebras, we need to know the range of this mapping restricted to such systems. We also need to understand the properties of the inverse of this mapping. In the following, we will provide some partial results to these questions. The key to these questions is a complete understanding of the existence and uniqueness properties of (2.5).

Let q be a C^∞ function defined on $\mathbb{R}^n$. Extend $-\Delta+q$ in the standard way to act on a closed subspace of $L^2(\mathbb{R}^n)$. It follows from the definition that the first eigenvalue λ_1 of the operator $-\Delta+q$ is equal to

$$\lambda_1=\inf_\phi\frac{\int|\nabla\phi|^2\,dx+\int q\phi^2\,dx}{\int\phi^2\,dx},\tag{3.1}$$

where infimum is taken on all nonzero C^∞ functions with compact support. The following theorem by Fischer-Colbrie and Schoen is well known (see [10]).

THEOREM 7 [10]. *Let q be a C^∞ function defined on $\mathbb{R}^n$. Then there exists a positive function ζ satisfying the equation $\Delta\zeta - q\zeta = 0$ on $\mathbb{R}^n$ if and only if the first eigenvalue λ_1 of $-\Delta + q$ on $\mathbb{R}^n$ is nonnegative.*

Assume now that the estimation algebra is finite-dimensional and has maximal rank. Then by Theorem 6, we know that

$$\eta - \sum_{i=1}^{m} h_i^2 = q, \tag{3.2}$$

where q is a polynomial of degree two with quadratic part positive semidefinite. Recall that

$$\begin{aligned}\eta &= \sum_{i=1}^{m} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2 \\ &= \Delta\phi + |\nabla\phi|^2 + \sum_{i=1}^{m} h_i^2.\end{aligned}$$

Putting this into (3.2), we have

$$\Delta\phi + |\nabla\phi|^2 = q. \tag{3.3}$$

Let $u = e^\phi$. Then $\partial u/\partial x_i = (\partial\phi/\partial x_i)\, e^\phi$ and $\partial^2 u/\partial x_i^2 = (\partial^2\phi/\partial x_i^2 + (\partial\phi/\partial x_i)^2)\, e^\phi$, hence

$$\Delta u - qu = 0. \tag{3.4}$$

We observe that (3.3) has a C^∞-solution ϕ if and only if (3.4) has a C^∞ positive solution u.

THEOREM 8. *Let q be a quadratic polynomial in $x_1, \cdots, x_n$. Let λ_1 be the first eigenvalue of the operator $-\Delta + q$. Then λ_1 is nonnegative if and only if under an orthogonal transformation and a translation, q can be written in the form*

$$\sum_{i=1}^{n} a_i x_i^2 - c,$$

where a_i and c are constants, $a_i \geqq 0$, and $c \leqq \sum_{i=1}^{n} \sqrt{a_i}$.

Proof. Suppose that $x = (x_1, \cdots, x_n)^T = Ay - y_0$, where A is an orthogonal matrix and y_0 is a constant vector. Then $\Delta_y = \Delta_x$, and the first eigenvalue of the operator $-\Delta_x + q$ is nonnegative if and only if the first eigenvalue of $-\Delta_y + \tilde{\eta}$ is nonnegative where $\tilde{\eta}(y) = \eta(x(y))$. Hence after an orthogonal transformation and a translation, we may assume that

$$q(x) = \sum_{i=1}^{l} a_i x_i^2 + \sum_{i=l+1}^{n} b_i x_i - c,$$

where a_i, b_i, and c are constants, $a_i \neq 0$, for $i = 1, \cdots, l$.

By Theorem 7, we know that $\lambda_1 \geqq 0$ if and only if (3.4) has C^∞ positive solution if and only if (3.3) has C^∞ solution. In view of Theorem 2, this implies that $b_i = 0$ and we have that $a_i \geqq 0$ for $i = 1, \cdots, n$. Hence it remains to prove that the first eigenvalue of the operator $-\Delta + r - c$ is nonnegative if and only if $c \leqq \sum_{i=1}^{n} \sqrt{a_i}$, where $r = \sum_{i=1}^{n} a_i x_i^2$. This is equivalent to proving that the first eigenvalue λ_1' of the operator $-\Delta + r$ is $\sum_{i=1}^{n} \sqrt{a_i}$.

Denote $c_0 = \sum_{i=1}^n \sqrt{a_i}$. Let ξ be a C^∞ function with compact support. Then

$$\begin{aligned}
\int |\nabla \xi|^2\, dx + \int r\xi^2\, dx &= \int \sum_{i=1}^n \left(\left(\frac{\partial \xi}{\partial x_i} \right)^2 + a_i x_i^2 \xi^2 \right) dx \\
&= \int \sum_{i=1}^n \left(\frac{\partial \xi}{\partial x_i} + \sqrt{a_i}\, x_i \xi \right)^2 dx - 2 \int \left(\sum_{i=1}^n \sqrt{a_i}\, x_i \xi \frac{\partial \xi}{\partial x_i} \right) dx \\
&= \int \sum_{i=1}^n \left(\frac{\partial \xi}{\partial x_i} + \sqrt{a_i}\, x_i \xi \right)^2 dx \\
&\qquad - \int \sum_{i=1}^n \frac{\partial}{\partial x_i} (\sqrt{a_i}\, x_i \xi^2)\, dx + \int \left(\sum_{i=1}^n \sqrt{a_i} \right) \xi^2\, dx \\
&= \int \sum_{i=1}^n \left(\frac{\partial \xi}{\partial x_i} + \sqrt{a_i}\, x_i \xi \right)^2 dx + c_0 \int \xi^2\, dx \\
&\geqq c_0 \int \xi^2\, dx.
\end{aligned}$$

Hence $\lambda_1' \geqq c_0$. On the other hand,

$$\chi(x) = \prod_{i=1}^n \exp\left(-\frac{\sqrt{a_i}\, x_i^2}{2} \right)$$

is an eigenfunction of $-\Delta + r$ with eigenvalue c_0, so $c_0 \geqq \lambda_1'$. Hence $c_0 = \lambda_1'$. □

THEOREM 9. *Suppose* $\mathbf{E}$ *is a finite estimation algebra of maximal rank. Then under an orthogonal transformation and a translation,* η *can be written in the form*

$$\sum_{i=1}^m h_i^2 + \sum_{i=1}^n a_i x_i^2 - c,$$

where a_i *and* c *are constants,* $a_i \geqq 0$, *and* $c \leqq \sum_{i=1}^n \sqrt{a_i}$.

Proof. This result follows from Theorems 7 and 8. □

4. Alternative proof. Theorem 9 provides a constraint that the coefficients of (2.0) must satisfy so that the system has a finite-dimensional estimation algebra of maximal rank. It is a first step in providing some classification results of all finite-dimensional exact estimation algebras. In the following, we provide an alternative proof of these results by applying a technique pioneered by Li and Yau [11]. In fact, Theorem 12 sharpens the results stated in Theorem 9.

THEOREM 10. *Consider the following equation*:

$$\Delta \xi + |\nabla \xi|^2 = \sum_{ij=1}^n a_{ij} x_i x_j - c, \tag{4.0}$$

where $(x_1, \cdots, x_n) \in \mathbb{R}^n$, $c \in \mathbb{R}$ *and the constant matrix* $A = (a_{ij})$ *is positive semidefinite. Then for any smooth solution* ξ *of* (4.0) *defined on* $\mathbb{R}^n$, $|\nabla \xi|$ *has at most linear growth, namely,*

$$|\nabla \xi(x)| \leqq C(1 + |x|), \qquad x \in \mathbb{R}^n$$

for some constant C.

Proof. Let $u = -\xi$. After orthogonal change of coordinates, (4.0) becomes

$$-\Delta u + |\nabla u|^2 = \sum_{i=1}^n \lambda_i x_i^2 - c. \tag{4.1}$$

Let $v=\sum_{i=1}^n \frac{1}{2}\sqrt{\lambda_i}\, x_i^2$. It is easy to see that

$$-\Delta v+|\nabla v|^2=\sum_{i=1}^n \lambda_i x_i^2-c_0, \tag{4.2}$$

where $c_0=\sum_{i=1}^n \sqrt{\lambda_i}$. Let $w=u-v$. Then subtracting (4.2) from (4.1), we get

$$\begin{aligned} c_0-c&=-\Delta u+\Delta v+|\nabla u|^2-|\nabla v|^2\\ &=-\Delta(u-v)+\nabla(u-v)\cdot\nabla(u-v)+2\nabla(u-v)\cdot\nabla v\\ &=-\Delta w+|\nabla w|^2+2\nabla w\cdot\nabla v, \end{aligned} \tag{4.3}$$

where $x\cdot y$ represents the standard inner product between vectors x and y. Denote $F=|\nabla w|^2$. Direct computation yields

$$\begin{aligned} \Delta F&=\Delta(\nabla w\cdot\nabla w)\\ &=2\sum_{i,j=1}^n\left(\frac{\partial^2 w}{\partial x_i\,\partial x_j}\right)^2+2(\nabla\Delta w)\cdot\nabla w\\ &\geqq\frac{2}{n}|\Delta w|^2+2\nabla(F+2\nabla v\cdot\nabla w+c-c_0)\cdot\nabla w. \end{aligned} \tag{4.4}$$

If $\nabla^2 v$ and $\nabla^2 w$ represent the Hessian of v and w, respectively, then

$$\begin{aligned} 4\nabla(\nabla v\cdot\nabla w)\cdot\nabla w&=4[\nabla^2 v\nabla w+\nabla^2 w\nabla v]\cdot\nabla w\\ &\geqq 4[\nabla^2 w\nabla v]\cdot\nabla w=4[\nabla^2 w\nabla w]\cdot\nabla v\\ &=2\nabla(\nabla w\cdot\nabla w)\cdot\nabla v=2\nabla F\cdot\nabla v. \end{aligned} \tag{4.5}$$

Putting (4.5) into (4.4), we have

$$\begin{aligned} \Delta F&\geqq\frac{2}{n}(F+2\nabla v\cdot\nabla w+c-c_0)^2+2\nabla F\cdot\nabla w+2\nabla F\cdot\nabla v\\ &\geqq\frac{2}{n}F^2+\frac{4}{n}F(2\nabla v\cdot\nabla w+c-c_0)+2\nabla F\cdot\nabla(v+w)\\ &\geqq\frac{2}{n}F^2-\frac{8}{n}F^{3/2}|\nabla v|+2\nabla F\cdot\nabla(v+w)+\frac{4(c-c_0)}{n}F. \end{aligned} \tag{4.6}$$

Denote $r^2=\sum_{i=1}^n x_i^2$. For $a>0$, the function $(a^2-r^2)^2F$ achieves its maximum at $x_0\in B_a(0)=\{x\in\mathbb{R}^n:|x|<a\}$. At that point,

$$\nabla[(a^2-r^2)^2F]=0,$$

which implies

$$4rF\nabla r=(a^2-r^2)\nabla F. \tag{4.7}$$

Also at the point x_0,

$$\begin{aligned} 0&\geqq\Delta[(a^2-r^2)^2F]\\ &=(a^2-r^2)^2\Delta F+2\nabla(a^2-r^2)^2\cdot\nabla F+F\Delta(a^2-r^2)^2\\ &=(a^2-r^2)^2\Delta F-8(a^2-r^2)r\nabla r\cdot\nabla F+[8r^2-4n(a^2-r^2)]F. \end{aligned} \tag{4.8}$$

Using (4.7), we get

$$(a^2-r^2)^2\Delta F-24r^2F-4n(a^2-r^2)F\leqq 0. \tag{4.9}$$

Using (4.6), we have

$$\begin{aligned}(a^2-r^2)^2\left[\frac{2}{n}F^2-\frac{8}{n}F^{3/2}|\nabla v|+2\nabla F\cdot\nabla(v+w)+\frac{4(c-c_0)}{n}F\right]&\\ -[24r^2+4n(a^2-r^2)]F\leqq 0.&\end{aligned} \tag{4.10}$$

Dotting (4.7) with $\nabla(v+w)$, we get

$$\begin{aligned}(a^2-r^2)\nabla(v+w)\cdot\nabla F&=4rF\nabla r\cdot(\nabla v+\nabla w)\\ &\geqq -4rF|\nabla v|-4rF^{3/2}.\end{aligned} \tag{4.11}$$

Putting (4.11) back into (4.10) and dividing it by F, we have

$$\begin{aligned}\frac{2}{n}(a^2-r^2)^2F-\frac{8}{n}(a^2-r^2)^2F^{1/2}|\nabla v|-(a^2-r^2)[8r|\nabla v|+8rF^{1/2}]&\\ +4(a^2-r^2)^2\frac{c-c_0}{n}-[24r^2+4n(a^2-r^2)]\leqq 0.&\end{aligned} \tag{4.12}$$

By denoting $M=(a^2-r^2)F^{1/2}$, (4.12) becomes

$$\begin{aligned}&\frac{2}{n}M^2-\left[\frac{8}{n}(a^2-r^2)|\nabla v|+8r\right]M\\ &\quad+\left[4(a^2-r^2)^2\frac{c-c_0}{n}-4n(a^2-r^2)-8r(a^2-r^2)|\nabla v|-24r^2\right]\leqq 0.\end{aligned}$$

Noting the fact that $|\nabla v|\leqq c_1r$ and $r\leqq a$, we can see that

$$M\leqq c_2a^3,$$

where c_1 and c_2 are constants. The inequality

$$\begin{aligned}M&=\max_{|x|\leqq a}(a^2-r^2(x))F^{1/2}(x)\\ &\geqq\max_{|x|\leqq a/2}(a^2-|x|^2)F^{1/2}(x)\\ &\geqq\max_{|x|\leqq a/2}\left[a^2-\left(\frac{a}{2}\right)^2\right]F^{1/2}(x)\\ &=\frac{3}{4}a^2\max_{|x|\leqq a/2}|\nabla w|\end{aligned}$$

yields the estimate

$$\max_{|x|\leqq a/2}|\nabla w|\leqq C_3a. \tag{4.13}$$

Combining (4.13) with the relation $w=u-v$, we can conclude that $|\nabla u|$ has at most linear growth. □

Remark. We can also deduce the above theorem by making use of Theorem 1.3 of [11].

THEOREM 11. *If $c<\sqrt{\lambda}$, and $\lambda>0$, then*

$$-u''+(u')^2=\lambda x^2-c, \quad u(0)=a, \quad u'(0)=b, \tag{4.14}$$

has a global solution for any a and small $|b|$.

Proof. Let $v=u'$. We have

$$v'=v^2-\lambda x^2+c, \qquad v(0)=b.$$

Suppose (A, B) is the maximum open interval containing zero, such that v exists. Define two auxiliary functions:

$$v_+(x)=\varepsilon x+k, \qquad v_-(x)=-\delta x-l.$$

We have that

$$\begin{aligned} v'_+-v_+^2+\lambda x^2-c&=\varepsilon-(\varepsilon x+k)^2+\lambda x^2-c\\ &=(\lambda-\varepsilon^2)x^2-2k\varepsilon x+(\varepsilon-c-k^2). \end{aligned}$$

Choose $\varepsilon>0$, such that

$$\lambda-\varepsilon^2>0 \quad\text{and}\quad \varepsilon-c>0.$$

This is possible because $\sqrt{\lambda}>c$. Choose $k>0$ small enough, so that

$$(\lambda-\varepsilon^2)x^2-2k\varepsilon x+(\varepsilon-c-k^2)>0, \qquad x\in[0, B].$$

By the standard comparison theorem [12], we have

$$v(x)<v_+(x) \quad \text{for } x\in[0, B),$$

as long as $v(0)=b<k=v_+(0)$.

Similarly, we can show that if δ is sufficiently large, so that

$$\lambda-\delta^2<0 \quad\text{and}\quad \delta+c>0,$$

then

$$v'_--v_-^2+\lambda x^2-c=(\lambda-\delta^2)x^2-2l\delta x-(\delta+c+l^2)<0$$

for all $x\in[0, B]$ and $l\geqq 0$.

The comparison theorem again implies that

$$v(x)>v_-(x) \quad \text{for } x\in[0, B),$$

if $v(0)=b>-l=v_-(0)$.

This implies that when $-l<b<k$, $B=\infty$. Otherwise, as $v(B)$ is bounded, we can extend v beyond B, a contradiction to the hypothesis that (A, B) is the maximal interval on which v is defined.

Similar arguments show that $A=-\infty$ when $|b|$ is sufficiently small. □

Remark. If $\lambda=0$, then we can prove by direct integration that there is a global solution to (4.14) if $|b|$ is small enough.

THEOREM 12. *Consider the following equation:*

$$\Delta\xi+|\nabla\xi|^2=\sum_{i,j=1}^{n} a_{ij}x_ix_j-c, \tag{4.15}$$

where $(x_1, \cdots, x_n)\in\mathbb{R}^n$, $c\in\mathbb{R}$ and the constant matrix $A=(a_{ij})$ is positive semidefinite. Let $\{\lambda_1, \cdots, \lambda_n\}$ be the eigenvalues of A and $c_0=\sum_{i=1}^n\sqrt{\lambda_i}$. Then we have the following:

(I) (*Existence*). *When* $c < c_0$, *there is a family of* C^∞ *solution of* (4.15) *with* $2n$ *parameters such that* $|\nabla \xi|$ *has at most linear growth at* ∞, *namely,*

$$|\nabla \xi(x)| \leqq C(1+|x|),$$

for some constant C.

(II) (*Uniqueness*). *When* $c = c_0$, *there is a quadratic polynomial, uniquely determined up to a constant, which satisfies* (4.15). *Moreover, this is the unique solution up to a constant if either one of the following conditions holds*:

(i) rank $A = 0$ (*namely,* $A = 0$), *or*

(ii) rank $A \geqq n-2$.

(III) (*Nonexistence*). *When* $c > c_0$, *there is no smooth solution to* (4.15).

Proof. Let $u = -\xi$. After an orthogonal change of coordinates, (4.15) becomes

$$-\Delta u + |\nabla u|^2 = \sum_{i=1}^{n} \lambda_i x_i^2 - c. \tag{4.16}$$

For part (I), let $c = \sum_{i=1}^n c_i$ with $c_i < \sqrt{\lambda_i}$. By Theorem 11, there is a 2-parameter family of solution of the

$$-u_i'' + (u_i')^2 = \lambda_i x_i^2 - c_i. \tag{4.17}$$

It is easy to see that $u(x) = \sum_{i=1}^n u_i(x_i)$ satisfies (4.15) and that $|\nabla u|$ has at most linear growth at ∞. To see that there is a $2n$-parameter family of such solutions to (4.16), note that $n-1$ parameters come from the different ways of decomposing c into c_i's so that $c = \sum_{i=1}^n c_i$, n parameters come from $u_i'(0)$, and the last parameter comes from the arbitrary constant added to the whole solution.

For part (II), it is clear that there exists a uniquely determined quadratic polynomial solution. If in addition the first rank condition is satisfied, we need only to prove that the only solutions of

$$-\Delta u + |\nabla u|^2 = 0 \tag{4.18}$$

are constants. Taking $\Phi = e^{-u}$, (4.18) can be written as

$$\Delta \Phi = 0. \tag{4.19}$$

It is equivalent to prove that (4.19) has no positive solutions other than constants. However, this is well known to be the case.

Next, assume the second rank condition is satisfied, that is, rank $A \geqq n-2$. Let $v(x) = \sum_{i=1}^n \frac{1}{2}\sqrt{\lambda_i}\, x_i^2$. Note that $v(x)$ satisfies

$$-\Delta v + |\nabla v|^2 = \sum_{i=1}^{n} \lambda_i x_i^2 - c_0. \tag{4.20}$$

Subtracting (4.20) from (4.16) and letting $w = u - v$, we get

$$-\Delta w + 2\nabla v \cdot \nabla w + |\nabla w|^2 = 0. \tag{4.21}$$

Define $B(r) = \{x : |x_i| \leqq r, i = 1, 2, \cdots, n\}$. Multiplying by e^{-2v} and integrating on both sides of (4.21), we get

$$\begin{aligned} 0 &= \int_{B(r)} e^{-2v}(-\Delta w + 2\nabla v \cdot \nabla w) + \int_{B(r)} e^{-2v}|\nabla w|^2 \\ &= \int_{B(r)} -\nabla \cdot (e^{-2v}\nabla w) + \int_{B(r)} e^{-2v}|\nabla w|^2 \\ &= -\int_{\partial B(r)} e^{-2v}\nabla w \cdot \vec{n} + \int_{B(r)} e^{-2v}|\nabla w|^2, \end{aligned}$$

where $\vec{n}$ is the unit outward normal of $\partial B(r)$. By the Schwartz inequality, we get

$$\int_{B(r)} e^{-2v}|\nabla w|^2 = \int_{\partial B(r)} e^{-2v}\nabla w \cdot \vec{n} \leqq \int_{\partial B(r)} e^{-2v}|\nabla w| \leqq \sqrt{\left(\int_{\partial B(r)} e^{-2v}|\nabla w|^2\right)\left(\int_{\partial B(r)} e^{-2v}\right)}. \tag{4.22}$$

Denoting $f(r) = \int_{B(r)} e^{-2v}|\nabla w|^2$, $g(r) = \int_{B(r)} e^{-2v}$, (4.22) becomes

$$(f(r))^2 \leqq f'(r) \cdot g'(r). \tag{4.23}$$

Supposing $f(r_0) > 0$ for some r_0, we have

$$\frac{f'}{f^2} \geqq \frac{1}{g'}. \tag{4.24}$$

Integrating (4.24) over $(r_0, +\infty)$, we have

$$\infty > \frac{1}{f(r_0)} - \frac{1}{f(\infty)} = \int_{r_0}^{\infty} \frac{f'}{f^2}\, dr \geqq \int_{r_0}^{\infty} \frac{1}{g'}\, dr. \tag{4.25}$$

Other the other hand,

$$g(r) = \int_{B(r)} e^{-2v} = \prod_{i=1}^{n} \left(\int_{-r}^{r} \exp\left(-\sqrt{\lambda_i}\, x_i^2\right) dx_i\right).$$

It is easy to see that

(i) If rank $A = n$, $g'(r) \to 0$ as $r \to \infty$.

(ii) If rank $A = n - 1$, $g'(r) \to c > 0$ as $r \to \infty$.

(iii) If rank $A = n - 2$, $g'(r) \approx cr$ as $r \to \infty$.

In all of the above three cases, the right-hand side of (4.25) is divergent. The contradiction says that $f(r) \equiv 0$, namely, w is a constant. So $u = v + \text{const}$.

For part (III), the statement holds even if A is degenerate. Since $c_0 = \sum_{i=1}^{n} \sqrt{\lambda_i} < c$, we can find δ small such that $\sum_{i=1}^{n} (\sqrt{\lambda_i} + \delta) < c$. Let $v = \sum_{i=1}^{n} \frac{1}{2}(\sqrt{\lambda_i} + \delta)x_i^2$. v satisfies

$$-\Delta v + |\nabla v|^2 = \sum_{i=1}^{n} (\sqrt{\lambda_i} + \delta)^2 x_i^2 - \sum_{i=1}^{n} (\sqrt{\lambda_i} + \delta). \tag{4.26}$$

Subtracting (4.26) from (4.16) and letting $w = u - v$, we get

$$-\Delta w + 2\nabla v \cdot \nabla w \leqq 0.$$

Using the same argument as before, but without assuming the rank condition on A, we can show that $u = v + \text{const}$. So u cannot be a solution to (4.16). A contradiction and no smooth solution to (4.16) exists. □

Remark. Equation (4.15) may have other solutions in addition to those listed in part (I). Some examples are given on page 86 of [9].

STRUCTURE AT INFINITY OF STRUCTURED DESCRIPTOR SYSTEMS AND ITS APPLICATIONS*

KAZUO MUROTA† AND JACOB W. VAN DER WOUDE‡

Abstract. The generic structure at infinity of the transfer matrix of a descriptor system is investigated under the physically reasonable assumption that the coefficients in the equations are classified into independent physical parameters and dimensionless constants. For such a structured descriptor system, the generic structure at infinity is characterized in terms of an independent assignment (or weighted matroid intersection) problem. This leads to necessary and sufficient conditions for the generic solvability of the exact matching problem for a (singular) descriptor system and for the generic solvability of the disturbance decoupling problem for a nonsingular descriptor system. The obtained conditions can be checked by efficient matroid-theoretic algorithms.

1. Introduction. In this paper we present a structural approach to the structure at infinity of the transfer matrix of a general class of physical systems that have a so-called descriptor representation. This research is also motivated by the disturbance decoupling problem (DDP) and the exact model matching problem (EMMP), which are counted among the fundamental problems in control theory.

To introduce the DDP for the general class of descriptor systems, we first consider the well-known linear finite-dimensional time-invariant system described by

$$\dot{\mathbf{x}}(t)=A\mathbf{x}(t)+B\mathbf{u}(t)+G\mathbf{d}(t), \qquad \mathbf{y}(t)=C\mathbf{x}(t) \tag{1}$$

with state $\mathbf{x}(t)\in\mathbf{R}^n$, input $\mathbf{u}(t)\in\mathbf{R}^m$, disturbance $\mathbf{d}(t)\in\mathbf{R}^l$ and output $\mathbf{y}(t)\in\mathbf{R}^p$. The DDP for system (1) consists of finding a constant matrix K such that with the feedback $\mathbf{u}(t)=K\mathbf{x}(t)$ the transfer matrix of the closed-loop system satisfies

$$C(sI-A-BK)^{-1}G=0. \tag{2}$$

A geometric condition for the solvability of DDP is given by Wonham [31] in terms of (A, B)-invariant subspaces. Furthermore, it is shown in Emre and Hautus [5] (see also Bhattacharyya, Gomes, and Howze [3, Thm. 3]) that DDP is equivalent to EMMP, that is, that DDP is solvable if and only if there exists a strictly proper rational matrix $X(s)$ such that

$$C(sI-A)^{-1}BX(s)=C(sI-A)^{-1}G. \tag{3}$$

In the spirit of the structural or generic approach initiated by Lin [15], the generic solvability of DDP is considered by van der Woude [32], and independently by Commault, Dion, and Perez [4], under the assumption that the nonzero entries in the coefficient matrices in (1) are independent parameters. A graph-theoretic necessary and sufficient condition for the generic solvability of DDP is then derived on the basis of two observations. One is that the solvability of EMMP can be expressed in terms

of the structure at infinity of the two transfer matrices in (3), and the other is that the generic structure at infinity of a transfer matrix can be characterized in terms of linkings in a signal-flow type of graph associated with the system. Similar graph-theoretic characterizations of the generic structure at infinity are obtained by Suda, Wan, and Ueno [27], and for a restricted case by Kobayashi and Nakamizo [12]. Other investigations on the generic number of zeros are made by Reinschke [25], Söte [26], and Svaricek [28].

It has been gradually recognized, however, that the standard form (1) is not very suitable for representing the structure of a system in that the entries of the matrices in (1) are usually not independent but are algebraically related to one another. In this respect, the so-called descriptor form

$$F\dot{\mathbf{x}}(t)=A\mathbf{x}(t)+B\mathbf{u}(t)+G\mathbf{d}(t), \qquad \mathbf{y}(t)=C\mathbf{x}(t), \tag{4}$$

considered in this paper, is more suitable, where we assume throughout that $A-sF$ is nonsingular.

In this paper we adopt the physically plausible framework introduced by Murota [17]-[20], in which the notion of mixed matrices is used to obtain results concerning the generic or structural controllability and the fixed modes of physical systems. Here, we also use the notion of mixed matrices, but now we are interested in the generic structure at infinity of the transfer matrix of physical systems. Therefore, inspired by the previous works, we derive a characterization for the structure at infinity of the transfer matrix of a descriptor system and we present an algorithm by which the structure at infinity can be computed in an efficient way. In addition, we indicate how the algorithm can be used to check the solvability of two versions of DDP for descriptor systems.

Rephrasing the above, we discuss in this paper the structure at infinity and the solvability of DDP under the assumption that the entries of the coefficient matrices in the descriptor equations (4) are classified into independent physical parameters and dimensionless fixed constants. We develop a combinatorial characterization of matroid-theoretic nature for the structure at infinity, based on the characterization of dynamical degree given by Murota [17], [18] using the structural framework mentioned above. As an application of the obtained characterization we give a necessary and sufficient condition for the generic solvability of DDP for the descriptor system (4) with nonsingular F. This condition can be checked efficiently by a matroid-theoretic algorithm that is guaranteed to run in polynomial time in the size of the control system.

This paper is organized as follows. In § 2 we present some known facts about rational function matrices and mixed matrices. In § 3 we summarize some results on the solvability of DDP. In particular, the solvability of DDP is expressed in terms of the maximum degrees of minors of polynomial matrices associated with the system. In § 4 we describe a physically plausible mathematical model in which mixed matrices are used and on the basis of which a method of structural analysis is developed. In § 5 we show that the problem of determining the maximum degrees of minors of a polynomial mixed matrix is reduced to an independent assignment (or weighted matroid intersection) problem. Finally in § 6 we give an illustrative example.

2. Preliminaries.

2.1. Rational function matrix. Let $\mathbf{F}$ be a field, and denote by $\mathbf{F}[s]$ and $\mathbf{F}(s)$, respectively, the ring of polynomials and the field of rational functions in s over $\mathbf{F}$. A rational function $f(s)=p(s)/q(s)\in\mathbf{F}(s)$ with $p(s), q(s)\in\mathbf{F}[s]$ is called *proper* (respectively, *strictly proper*) if $\deg f(s)\leqq 0$ (respectively, $\deg f(s)<0$), where $\deg f(s)=\deg p(s)-\deg q(s)$ and $\deg(0)=-\infty$.

We call a matrix a *proper* (respectively, *strictly proper*) *rational matrix* if its entries are proper (respectively, strictly proper) rational functions. A square proper rational matrix is called *bicausal* if it is invertible and its inverse is a proper rational matrix. Since the proper rational functions form a Euclidean ring, any proper rational matrix can be brought into the Smith form [24], which in control literature is sometimes referred to as the *structure at infinity*. From this we see further that any rational matrix can be brought into the Smith-McMillan form at infinity, as stated below.

LEMMA 2.1. *Let $P(s)$ be a rational matrix. Then there exist bicausal matrices $U(s)$ and $V(s)$ such that*

$$P(s)=V(s)\begin{pmatrix}\Gamma(s) & O\\ O & O\end{pmatrix}U(s),$$

where

$$\Gamma(s)=\mathrm{diag}\,(s^{-t_1},\cdots,s^{-t_r}),$$

$r=\mathrm{rank}\,P(s)$, *and* t_k $(k=1,\cdots,r)$ *are integers with* $t_1\leqq\cdots\leqq t_r$. □

The integers t_k $(k=1,\cdots,r)$ are uniquely determined, and are referred to as the *orders of the zeros at infinity* of $P(s)$ when $P(s)$ is proper. In this paper we use the notation

$$\mathrm{ord}_k\,P=t_k \qquad (1\leqq k\leqq r)$$

and

$$\mathrm{ord}\,P=(t_1,\cdots,t_r).$$

An alternative characterization of ord P can be given in terms of the degrees of minors of the matrix P. Let R and C denote the row set and the column set of P, and $P[I,J]$ be the submatrix of P with row set $I\subseteq R$ and column set $J\subseteq C$. For a square rational matrix $P(s)$ we define

$$\delta(P)=\deg_s\det P(s).$$

Furthermore, for a (possibly nonsquare) rational matrix $P(s)$ and for $I_0\subseteq R$, $J_0\subseteq C$ and $k\geqq\max\,(|I_0|,|J_0|)$ we define

$$\delta_k(P;I_0,J_0)=\max\,\{\delta(P[I,J])\,|\,I\supseteq I_0,J\supseteq J_0,|I|=|J|=k\} \tag{5}$$

and

$$\delta_k(P)=\delta_k(P,\emptyset,\emptyset).$$

Using the Cauchy-Binet formula, the following can be shown from Lemma 2.1.

LEMMA 2.2. *For* $1\leqq k\leqq r$,

$$\sum_{j=1}^{k}\mathrm{ord}_j\,P=-\delta_k(P). \qquad \square$$

In the particular case where $P(s)$ is given as

$$P(s)=C(sF-A)^{-1}B$$

with nonsingular $sF-A$, the above lemma can be formulated as follows.

LEMMA 2.3. *For* $1\leqq k\leqq r$,

$$\sum_{j=1}^{k}\mathrm{ord}_j\,(C(sF-A)^{-1}B)=-\delta_{n+k}\left(\begin{pmatrix}A-sF & B\\ C & O\end{pmatrix};I_0,J_0\right)+\delta(A-sF),$$

where I_0 and J_0 are, respectively, the row and column sets corresponding to the $n\times n$ nonsingular submatrix $A-sF$. □

The following lemma can be shown using Lemma 2.1 and Lemma 2.2 (see, e.g., [5], [24], [32]).

LEMMA 2.4. *Let $P(s)$ and $R(s)$ be proper rational matrices with the same number of rows. There exists a proper rational matrix $X(s)$ such that $P(s)X(s)=R(s)$ if and only if*

$$\operatorname{ord} P(s)=\operatorname{ord}(P(s)\,|\,R(s)). \tag{6}$$ □

Note that (6) implies

$$\operatorname{rank} P(s)=\operatorname{rank}(P(s)\,|\,R(s)).$$

2.2. Mixed matrices. Let $\mathbf{K}$ be a subfield of a field $\mathbf{F}$. A matrix D is called a *mixed matrix* with respect to $\mathbf{F}/\mathbf{K}$ if

$$D=Q+T,$$

where

(i) $Q=(Q_{ij})$ is a matrix over $\mathbf{K}$, and

(ii) $T=(T_{ij})$ is a matrix over $\mathbf{F}$ such that the set of its nonzero entries is algebraically independent over $\mathbf{K}$.

(In this paper, the entries of the matrix Q will represent fixed constants, whereas the entries of T will denote independent system parameters. A concrete example of mixed matrix is given in § 6. See Murota [18], [21] for more background about this section.)

The following identity due to Murota and Iri [23] is fundamental. It can be translated nicely into the matroid-theoretic language and enables us to compute the rank of D by an efficient matroid-theoretic algorithm using arithmetic operations in the subfield $\mathbf{K}$ only. Recall that the term-rank of T is defined as the maximum size of a submatrix $T[I,J]$ for which there exists a one-to-one correspondence (permutation) $\pi: I\to J$ such that $T_{i\pi(i)}\neq 0$ for all $i\in I$, i.e.,

$$\text{term-rank } T=\max\{\tau\,|\,\tau=|I|=|J|,\ \exists\pi(\text{one-to-one}): I\to J, \forall i\in I,\ T_{i\pi(i)}\neq 0\}.$$

LEMMA 2.5. *For a mixed matrix $D=Q+T$,*

$$\operatorname{rank} D=\max\{\operatorname{rank} Q[R-I, C-J]+\text{term-rank } T[I,J]\,|\,I\subseteq R, J\subseteq C\},$$

where R and C are the row set and the column set of D. □

Let $\mathbf{K}_0\subseteq \mathbf{F}_0$ be fields, and

$$D(s)=Q(s)+T(s) \tag{7}$$

be a polynomial matrix such that

(i) $Q(s)$ is a polynomial matrix with coefficients from $\mathbf{K}_0$, and

(ii) The set of nonzero coefficients of the entries of $T(s)$ is algebraically independent over $\mathbf{K}_0$.

Then $D(s)$ is a mixed matrix with respect to $\mathbf{F}_0(s)/\mathbf{K}_0(s)$. The following identity, noted by Murota [17], [18], is an extension of Lemma 2.5. Recall that $\delta(\cdot)$ is defined as in § 2.1.

LEMMA 2.6. *Let $D(s)=Q(s)+T(s)$ be a square polynomial mixed matrix as above. Then*

$$\delta(D)=\max\{\delta(Q[R-I, C-J])+\delta(T[I,J])\,|\,|I|=|J|, I\subseteq R, J\subseteq C\},$$

where R and C are the row set and the column set of D.

Proof. The expansion

$$\det(D) = \sum \{\pm \det Q[R-I, C-J] \cdot \det T[I, J] \,|\, |I| = |J|\}$$

shows that

$$\delta(D) \leqq \max \{\delta(Q[R-I, C-J]) + \delta(T[I, J]) \,|\, |I| = |J|\}.$$

Conversely, let $(I, J) = (I^*, J^*)$ yield the maximum on the right-hand side, and consider a term (monomial in the nonzero coefficients in $T[I^*, J^*]$) in $\det T[I^*, J^*]$. The algebraic independence of the nonzero coefficients in T guarantees that this term is not cancelled out but remains in $\det D$. Hence, the above inequality is in fact an equality. □

2.3. Independent assignment. Let $G = (V, E)$ be a directed graph with vertex set V and edge set E. The initial and the terminal vertex of an edge $e \in E$ are denoted by $\partial^+ e$ and $\partial^- e$. $G = (V, E)$ is called a (directed) *bipartite graph* if the vertex set V is partitioned into two disjoint parts as $V = V^+ \cup V^-$ in such a way that all edges are directed from V^+ to V^- (i.e., $\partial^+ e \in V^+$ and $\partial^- e \in V^-$). A *matching* is a subset M of E such that $|M| = |\partial^+ M| = |\partial^- M|$, where $\partial^+ M = \{\partial^+ e \,|\, e \in M\}$, etc. See, e.g., [16] for more about matchings.

A *matroid* is a pair $\mathbf{M} = (U, \mathcal{B})$ of a finite set U and a nonempty collection $\mathcal{B}$ of subsets of U such that:

> If $B_1, B_2 \in \mathcal{B}$ and $b_1 \in B_1 - B_2$, then there exists $b_2 \in B_2 - B_1$ such that $(B_1 \cup \{b_2\}) - \{b_1\} \in \mathcal{B}$.

A subset of U is called a *base* if it belongs to $\mathcal{B}$. All bases of $\mathbf{M}$ have an equal cardinality, which is called the *rank* of $\mathbf{M}$. A subset of U is said to be *independent* if it is contained in a base. See, e.g., [14] and [29] for more about matroids.

Suppose that a bipartite graph $G = (V, E)$ is given and, furthermore, that two matroids, say $\mathbf{M}^+$ and $\mathbf{M}^-$, are defined on V^+ and V^- in terms of the families of bases $\mathcal{B}^+$ and $\mathcal{B}^-$. A matching M is an *independent matching* if $\partial^+ M$ and $\partial^- M$ are independent in $\mathbf{M}^+$ and $\mathbf{M}^-$, respectively. A matching M is an *independent assignment* if $\partial^+ M \in \mathcal{B}^+$ and $\partial^- M \in \mathcal{B}^-$.

Suppose further that an integer weight $\zeta(e)$ is given for each edge $e \in E$, i.e., $\zeta: E \to \mathbf{Z}$. The weight of a matching M is defined by $\zeta(M) = \sum_{e \in M} \zeta(e)$. The independent assignment problem (IAP) is to find an independent assignment M with maximum weight. It is known that IAP is equivalent to the weighted matroid intersection problem. There are a number of very efficient algorithms for finding a maximum independent assignment. See, e.g., [7], [8], [11], [13], [14], and [29] for more about IAP (or weighted matroid intersection problem) and algorithms, and [10], [18] for its applications to engineering problems.

3. Solvability of disturbance decoupling. In this section we summarize some of the standard results on the solvability of DDP. We start by considering a problem that is very much related to DDP. This problem, called the modified disturbance decoupling problem (MDDP), for system (1) consists of finding matrices K and H such that with the feedback $\mathbf{u}(t) = K\mathbf{x}(t) + H\mathbf{d}(t)$ the closed-loop system satisfies

$$C(sI - A - BK)^{-1}(G + BH) = 0. \tag{8}$$

For a descriptor system (4) with nonsingular F, versions of the two decoupling problems DDP and MDDP can be formulated in a straightforward way by observing that descriptor systems (4) with nonsingular F can be transformed into systems of type (1) by a premultiplication with F^{-1}. In that case, DDP for (4) amounts to finding a matrix K such that

$$C(sF-A-BK)^{-1}G=0 \tag{9}$$

and MDDP to finding matrices K and H such that

$$C(sF-A-BK)^{-1}(G+BH)=0. \tag{10}$$

It can be shown with the results of Emre and Hautus [5] (see also Bhattacharyya, Gomes, and Howze [3, Thm. 3], Hautus [9]) that DDP (respectively, MDDP) then is solvable if and only if there exists a strictly proper (respectively, proper) rational matrix $X(s)$ such that

$$C(sF-A)^{-1}BX(s)=C(sF-A)^{-1}G. \tag{11}$$

It then also follows from Lemma 2.4 that MDDP is solvable if and only if

$$\operatorname{ord} C(sF-A)^{-1}B=\operatorname{ord} C(sF-A)^{-1}(B\,|\,G). \tag{12}$$

Noting that

$$\operatorname{rank} C(sF-A)^{-1}B=\operatorname{rank} C(sF-A)^{-1}(B\,|\,G) \tag{13}$$

is equivalent to

$$\operatorname{rank}\begin{pmatrix} A-sF & B\\ C & O\end{pmatrix}=\operatorname{rank}\begin{pmatrix} A-sF & B & G\\ C & O & O\end{pmatrix}, \tag{14}$$

and using Lemma 2.3, we see that (12) holds if and only if

$$\delta_{n+k}\left(\begin{pmatrix} A-sF & B\\ C & O\end{pmatrix}; I_0, J_0\right)=\delta_{n+k}\left(\begin{pmatrix} A-sF & B & G\\ C & O & O\end{pmatrix}; I_0, J_0\right) \tag{15}$$

for $k=1,\cdots,\min(m,p)$, where I_0 and J_0 are, respectively, the rows and columns corresponding to the $n\times n$ submatrix $A-sF$. For later reference we define

$$D(s)=\begin{pmatrix} A-sF & B & G\\ C & O & O\end{pmatrix}. \tag{16}$$

The solvability condition for DDP is obtained from the observation that there exists a strictly proper rational matrix $X(s)$ satisfying (11) if and only if there exists a proper rational matrix $X(s)$ satisfying (11) with G replaced by sG. That is, DDP is solvable if and only if

$$\delta_{n+k}\left(\begin{pmatrix} A-sF & B\\ C & O\end{pmatrix}; I_0, J_0\right)=\delta_{n+k}\left(\begin{pmatrix} A-sF & B & sG\\ C & O & O\end{pmatrix}; I_0, J_0\right) \tag{17}$$

for $k=1,\cdots,\min(m,p)$.

As an extension of (3) we will say that EMMP is solvable for (4) (possibly with singular F) if there exists a strictly proper rational matrix $X(s)$ such that (11) holds.

Summarizing, we can state the following.

LEMMA 3.1. (1) *The* MDDP *for* (4) *with nonsingular F is solvable if and only if* (15) *holds true for* $k=1,\cdots,\min(m,p)$.

(2) *The* DDP *for* (4) *with nonsingular F is solvable if and only if* (17) *holds true for* $k=1,\cdots,\min(m,p)$.

(3) *The* EMMP *for* (4) (*possibly with singular F*) *is solvable if and only if* (17) *holds true for* $k=1,\cdots,\min(m,p)$. □

In this paper we restrict ourselves to nonsingular descriptor systems when we consider DDP or MDDP. DDP for singular systems (with singular F) has been investigated recently by Banaszuk [1], Banaszuk, Kociecki, and Przyluski [2], and Fletcher and Aasaraai [6].

4. Structured system. In this section we give a mathematical formulation for the generic solvability of DDP and the generic structure at infinity for descriptor systems (4) using the structural framework of Murota [17], [18]. First, we briefly summarize two physical observations relevant to analysis of combinatorial structures and describe a mathematical model that represents the combinatorial structure of a system fairly well.

The standard state space representation (1) of a dynamical system has been useful for investigating analytical and algebraic properties of linear systems. Also the investigations of structural properties of linear systems until recently have been mainly based on systems of the type (1). However, as mentioned before in § 1, it has been gradually recognized that systems of type (1) are not powerful enough for the modeling of general physical systems. The reason for this is that due to the incidence structure of a physical system, some of the variables describing the system may be algebraically related to one another. Such relations cannot be incorporated in system descriptions of the form (1), but can be incorporated in those of the form (4). Therefore, systems of the type (4) form a more general framework for the investigation of structural properties of physical systems.

The mathematical model adopted here is based on two different physical observations. One is the distinction between "accurate" and "inaccurate" numbers, and the other is the consistency with respect to physical dimensions.

The first observation, due to Murota and Iri [23], is concerned with how we recognize the structure of a system. When a system is written in the form of (4) in terms of elementary variables, it is often justified to assume that the nonzero entries of the matrices F, A, etc., are classified into two groups. One group of generic parameters and the other group of fixed constants. In other words, we can distinguish the following two kinds of numbers, together characterizing a physical system:

1) Inaccurate numbers. Numbers representing independent physical parameters such as resistances in electrical networks, which, being contaminated with noise and other errors, take values independent of one another, and therefore can be modeled as algebraically independent numbers; and
2) Accurate numbers. Numbers accounting for various sorts of conservation laws such as Kirchhoff's laws, which, stemming from topological incidence relations, are precise in value (often ±1), and therefore cause no serious numerical difficulty in arithmetic operations on them.

We may also refer to the numbers of the first kind as "system parameters" and to those of the second kind as "fixed constants."

This observation can be translated into a mathematical assumption using the notion of mixed matrices. That is, we assume that the matrices F, A, etc., in (4) are mixed matrices with respect to $\mathbf{F}_0/\mathbf{Q}$ (where $\mathbf{F}_0$ is a sufficiently large field and $\mathbf{Q}$ the field of rational numbers) expressed as

$$F = Q_F + T_F, \qquad A = Q_A + T_A, \quad \text{etc.},$$

where Q_F, Q_A, etc., are matrices over $\mathbf{Q}$, and, furthermore, we assume that

(A1) The collection of nonzero entries of T_F, T_A, etc., are algebraically independent over $\mathbf{Q}$.

Then $D(s)$ of (16) is a mixed matrix with respect to $\mathbf{F}_0(s)/\mathbf{Q}(s)$, accordingly expressed as

$$D(s)=Q_D(s)+T_D(s) \tag{18}$$

with

$$Q_D(s)=\begin{pmatrix} Q_A-sQ_F & Q_B & Q_G \\ Q_C & O & O \end{pmatrix}, \qquad T_D(s)=\begin{pmatrix} T_A-sT_F & T_B & T_G \\ T_C & O & O \end{pmatrix}.$$

The second observation, due to Murota [17], is concerned with the "accurate numbers," i.e., with $Q_D(s)$ in (18). The "accurate numbers" usually represent topological and/or geometrical incidence coefficients, which have no physical dimensions, so that it is natural to expect that the entries of Q_F, Q_A, etc., are dimensionless constants. On the other hand, the indeterminate s should have the physical dimension of the inverse of time, since it corresponds to the differentiation with respect to time.

Since the system (4) is to represent a physical system, relevant physical dimensions are associated with both the variables and the equations, or alternatively, with the columns and the rows of $D(s)$. Choosing time as one of the fundamental dimensions, we denote by $-c_j$ and $-r_i$ the exponent to the dimension of time associated, respectively, with the jth column and the ith row. The principle of dimensional homogeneity then requires that the (i,j) entry of $D(s)$ should have the dimension of time with exponent c_j-r_i.

Combining this fact with the observations on the nondimensionality of Q_F, Q_A, etc., and on the dimension of s, we obtain

$$Q_D(s)=\operatorname{diag}(s^{r_1},\cdots,s^{r_{n+p}})\cdot Q_D(1)\cdot\operatorname{diag}(s^{-c_1},\cdots,s^{-c_{n+m+l}}). \tag{19}$$

It can be shown by purely linear-algebraic arguments without reference to physical dimensions (cf. [17], [18]) that a polynomial matrix $Q_D(s)$ can be represented as (19) with some (nonunique) r_i and c_j if and only if

(A2) Every nonzero subdeterminant of $Q_D(s)$ is a monomial in s over $\mathbf{Q}$.

Hence, the principle of dimensional homogeneity comes down to assuming (A2). It should be emphasized that this algebraic assumption (A2) expresses the physical-dimensional consistency among the "accurate numbers" or "fixed constants."

The mathematical model used here for structural analysis consists of (4) or (16), which satisfy (A1) and (A2). Adopting this model, we will give combinatorial characterizations of the following:

1) The properness of the transfer matrix of a descriptor system (possibly with singular F), i.e., $\delta_1(C(sF-A)^{-1}B)$;
2) The structure at infinity of the transfer matrix of a descriptor system (possibly with singular F), i.e., $\operatorname{ord}(C(sF-A)^{-1}B)$;
3) The solvability of DDP and MDDP for a descriptor system with nonsingular F;
4) The solvability of EMMP for a descriptor system (possibly with singular F).

It should be obvious that the special case of the present model with $Q_D(s)=0$ reduces to the conventional framework of a structured descriptor system in which all the nonzero entries are assumed to be independent parameters; note that (A2) is satisfied trivially when $Q_D(s)=0$.

From Lemma 2.3 and Lemma 3.1 it follows that the characterizations above can be obtained by solving the problem below. Note that a combinatorial characterization (cf. [18, § 19]) derived from Lemma 2.5 for the rank of a mixed matrix is already available.

PROBLEM. Find a combinatorial characterization to $\delta_k(D; I_0, J_0)$ for a mixed matrix $D(s)$ of the form (7) (not necessarily of the form (16)) such that $Q(s)$ satisfies (A2), where I_0 and J_0 are specified row and column subsets, and $k \geqq \max(|I_0|, |J_0|)$.

Remark 4.1. In this paper we consider models for which among others, assumption (A1) is satisfied. Denoting by $\mathcal{T}$ the collection of the nonzero entries of T_F, T_A, etc., it is clear that assumption (A1) on algebraic independence of $\mathcal{T}$ is introduced to investigate "generic properties" of the family of descriptor systems parametrized by $\mathcal{T}$.

The four properties listed above are in fact generic properties with respect to this parametrization $\mathcal{T}$. For example, the solvability of DDP is characterized in terms of the degrees of minors in s, as stated in Lemma 3.1(2), and the degree of each minor remains constant outside an algebraic variety in the space of $\mathcal{T}$. This shows that the solvability of DDP is a generic property.

Hence, our combinatorial characterizations to be obtained are valid for almost all parameter values of $\mathcal{T}$, and can fail only for "combinations" of the values of $\mathcal{T}$ that are algebraically dependent over $\mathbf{Q}$. To reiterate, our results yield "generic" conditions for the system-theoretic properties, where the "genericity" is defined with respect to $\mathcal{T}$.

There is another point to be noted about the significance of the generic solvability of DDP and MDDP. Even though Lemma 3.1(2) may hold for a particular system, this does not mean that the generic value of the left-hand side of (17) is equal to the generic value of the right-hand side of (17), for $k = 1, \cdots, \min(m, p)$. This is because the equalities may be satisfied, and hence DDP may be solvable, for a special combination of the parameter values of $\mathcal{T}$ that are algebraically dependent over $\mathbf{Q}$, while generically at least one of the equalities is violated. Thus, the usual solvability of DDP does not imply the generic solvability of DDP. The same holds of course for the solvability of MDDP. Note that this stands in sharp contrast to the structural controllability. Namely, if a system is controllable in the usual sense, then the system must be structurally controllable.

5. Combinatorial characterization.

In this section we give a solution of the following problem.

PROBLEM. Find a combinatorial characterization to $\delta_k(D; I_0, J_0)$ (cf. (5) for notation) for a mixed matrix $D(s) = Q(s) + T(s)$ as in (7) such that $Q(s)$ satisfies (A2), i.e.,

$$Q(s) = \operatorname{diag}(s^{r_i} \mid i \in R) \cdot Q(1) \cdot \operatorname{diag}(s^{-c_j} \mid j \in C), \tag{20}$$

for some $r_i \in \mathbf{Z}$ and $c_j \in \mathbf{Z}$, where R and C denote the row and the column set of D, and where $I_0 \subseteq R$, $J_0 \subseteq C$ and $k \geqq \max(|I_0|, |J_0|)$ are specified. □

Before considering the general case we explain our approach for the special case that $I_0 = J_0 = \emptyset$. That is, we will first consider a combinatorial characterization for $\delta_k(D) = \delta_k(D; \emptyset, \emptyset)$. After that we indicate how the obtained result can be extended to the general case.

First note that Lemma 2.6 for $\delta(D)$ can be extended for $\delta_k(D)$ as follows.

LEMMA 5.1. *Let $D(s) = Q(s) + T(s)$ be a polynomial mixed matrix as above. Then*

$$\begin{aligned}\delta_k(D) = \max\{\delta(Q[I_1, J_1]) + \delta(T[I_2, J_2]) \mid\ & |I_i| = |J_i|, I_i \subseteq R, J_i \subseteq C\ (i = 1, 2); \\ & |I_1| + |I_2| = k, I_1 \cap I_2 = J_1 \cap J_2 = \emptyset\},\end{aligned}$$

where R and C are the row set and the column set of D.

Proof. By definition,

$$\delta_k(D) = \max\{\delta(D[I,J]) \mid |I| = |J| = k\}.$$

The claim follows immediately from Lemma 2.6 applied to $\delta(D[I,J])$. □

We will reformulate Lemma 5.1 above as an independent assignment problem (IAP). Note for $k \leqq \operatorname{rank} D$ there exists a tuple $(I_1, J_1; I_2, J_2)$ as above such that $Q[I_1, J_1]$ and $T[I_2, J_2]$ are nonsingular, where, for example, $Q[\emptyset, \emptyset]$ is assumed to be nonsingular. Suppose the maximum in Lemma 5.1 is attained by $(I_1, J_1; I_2, J_2)$.

We associate with D a bipartite graph $G = G(D) = (V, E)$ having vertex bipartition $V = V^+ \cup V^-$ with

$$V^+ = R_T \cup R_Q \cup C_Q, \qquad V^- = R \cup C,$$

where R_T and R_Q are disjoint copies of R, and C_Q is a disjoint copy of C. By $\varphi_Q : R \cup C \to R_Q \cup C_Q$ and $\varphi_T : R \to R_T$ will denote the natural correspondences between the copies. The edge set E is defined by

$$\begin{aligned} E = &\{(\varphi_Q(i), i) \mid i \in R\} \cup \{(\varphi_Q(j), j) \mid j \in C\} \\ &\cup \{(\varphi_T(i), i) \mid i \in R\} \cup \{(\varphi_T(i), j) \mid T_{ij} \neq 0, i \in R, j \in C\}. \end{aligned}$$

Since $T[I_2, J_2]$ is nonsingular, we may associate with $(I_1, J_1; I_2, J_2)$ a matching M in G defined by

$$\begin{aligned} M = &\{(\varphi_Q(i), i) \mid i \in R - I_1\} \cup \{(\varphi_Q(j), j) \mid j \in J_1\} \\ &\cup \{(\varphi_T(i), i) \mid i \in I_1\} \cup \{(\varphi_T(i), j) \mid i \in I_2, j \in J_2, j = \pi(i)\}, \end{aligned} \tag{21}$$

where π is a permutation $\pi : I_2 \to J_2$ such that $T_{i\pi(i)} \neq 0$ (for all $i \in I_2$). Then

$$\begin{aligned} \partial^+ M &= (R_Q - \varphi_Q(I_1)) \cup \varphi_Q(J_1) \cup \varphi_T(I_1 \cup I_2), \\ \partial^- M &= R \cup J_1 \cup J_2. \end{aligned}$$

We now show that M is an independent assignment in G with respect to matroids appropriately defined on V^+ and V^-. First we define

$$\mathscr{L} = \{(I_1, J_1) \mid Q[I_1, J_1] \text{ is nonsingular}, I_1 \subseteq R, J_1 \subseteq C\},$$
$$\mathscr{L}_Q = \{(\varphi_Q(I_1), \varphi_Q(J_1)) \mid (I_1, J_1) \in \mathscr{L}\}$$

and next we consider two families of subsets of V^+ and V^-, respectively, defined as

$$\mathscr{B}^+ = \mathscr{B}_k^+ = \{U^+ \subseteq V^+ \mid (R_Q - U^+, C_Q \cap U^+) \in \mathscr{L}_Q, |U^+| = |R| + k\},$$
$$\mathscr{B}^- = \mathscr{B}_k^- = \{U^- \subseteq V^- \mid U^- \supseteq R, |U^-| = |R| + k\}.$$

These two families, $\mathscr{B}^+$ and $\mathscr{B}^-$, define matroids, as claimed below.

LEMMA 5.2. (1) *$\mathscr{B}_k^+$ forms a base of a matroid, say $\mathbf{M}^+ = \mathbf{M}_k^+$, of rank $|R| + k$; $\mathbf{M}^+$ is the direct sum of a linear matroid of rank $|R|$ representable over $\mathbf{K}_0$ and a uniform matroid of rank k.*

(2) *$\mathscr{B}_k^-$ forms a base family of a matroid, say $\mathbf{M}^- = \mathbf{M}_k^-$, of rank $|R| + k$; $\mathbf{M}^-$ is the direct sum of a uniform matroid of rank k and a free matroid of rank $|R|$.*

Proof. (1) Put $I_1 = \varphi_Q^{-1}(R_Q - U^+)$ and $J_1 = \varphi_Q^{-1}(C_Q \cap U^+)$ and note that $Q[I_1, J_1]$ is nonsingular if and only if the column vectors of the compound matrix $\tilde{Q}(s) = (I \mid Q(s))$ corresponding to $(R - I_1) \cup J_1$ form a basis, where the column set of $\tilde{Q}(s)$ is identified with $R \cup C$. Observe further that the assumption (A2) implies that columns of $\tilde{Q}(s)$ are independent if and only if the corresponding columns of $\tilde{Q}(1)$, which is a matrix over $\mathbf{K}_0$, are also independent. This shows that the condition $(R_Q - U^+, C_Q \cap U^+) \in \mathscr{L}_Q$ in the definition of $\mathscr{B}^+$ defines a linear matroid on $R_Q \cup C_Q$ that is representable over $\mathbf{K}_0$. The second condition, being equivalent to $|R_T \cap U^+| = k$, defines a uniform matroid on R_T of rank k. Hence, $\mathbf{M}^+$ is the direct sum of the two matroids as claimed.

(2) Similarly, $\mathbf{M}^-$ is the direct sum of a free matroid on R and a uniform matroid of rank k on C. □

Since $\partial^+ M \in \mathcal{B}^+$ and $\partial^- M \in \mathcal{B}^-$ by the construction, we see that the matching M associated with $(I_1, J_1; I_2, J_2)$ is in fact an independent assignment in G with respect to $\mathbf{M}^+$ and $\mathbf{M}^-$.

Conversely, an independent assignment M determines a tuple $(I_1, J_1; I_2, J_2)$ such that $I_1 \cap I_2 = \emptyset$, $J_1 \cap J_2 = \emptyset$, and both $Q[I_1, J_1]$ and $T[I_2, J_2]$ are nonsingular. In fact, these subsets are determined by the following relations:

$$I_1 = \varphi_Q^{-1}(R_Q - \partial^+ M), \qquad J_1 = \varphi_Q^{-1}(C_Q \cap \partial^+ M),$$
$$I_2 = \varphi_T^{-1}(R_T \cap \partial^+ M) - I_1, \qquad J_2 = (C \cap \partial^- M) - J_1.$$

Next we will introduce a weight function $\zeta : E \to \mathbf{Z}$ with reference to the degrees of the entries of $Q(s)$ and $T(s)$. Using the numbers r_i and c_j in (20), we define, for $e \in E$,

$$\zeta(e) = \begin{cases} -r_i & \text{if } e = (\varphi_Q(i), i), \quad i \in R, \\ -c_j & \text{if } e = (\varphi_Q(j), j), \quad j \in C, \\ \deg_s T_{ij} & \text{if } e = (\varphi_T(i), j), \quad i \in R, \quad j \in C, \\ 0 & \text{if } e = (\varphi_T(i), i), \quad i \in R. \end{cases} \tag{22}$$

Then from (20)-(22), we see that

$$\begin{aligned} \zeta(M) &= -\sum_{i \in R - I_1} r_i - \sum_{j \in J_1} c_j + \sum_{i \in I_2} \deg_s T_{i\pi(i)} \\ &= \delta(Q[I_1, J_1]) - r_0 + \sum_{i \in I_2} \deg_s T_{i\pi(i)}, \end{aligned}$$

where

$$r_0 = \sum_{i \in R} r_i. \tag{23}$$

In addition we have

$$\sum_{i \in I_2} \deg_s T_{i\pi(i)} = \delta(T[I_2, J_2])$$

for an appropriate choice of π. Therefore, we have the relation

$$\max_M \zeta(M) = \max_{(I_1, J_1; I_2, J_2)} \{\delta(Q[I_1, J_1]) + \delta(T[I_2, J_2])\} - r_0,$$

where the maximum on the left-hand side is taken over all independent assignments M, and that on the right-hand side is over all tuples $(I_1, J_1; I_2, J_2)$ having the properties stated before. Combining the above identity with Lemma 5.1, we obtain the combinatorial characterization for $\delta_k(D)$. In the case where $k = |R| = |C|$, this result reduces (essentially) to the result for $\delta(D)$ obtained by Murota [17], [18].

THEOREM 5.1. *For $D(s)$ of* (7) *having property* (20) *and for $k \geqq 0$,*

$$\delta_k(D) = \max_M \zeta(M) + r_0,$$

where the maximum on the right-hand side is taken over all independent assignments M in the bipartite graph $G(D)$ with matroids defined by $\mathcal{B}_k^+$ and $\mathcal{B}_k^-$, and r_0 is defined by (23). □

The ideas expounded above for the case that $I_0 = J_0 = \emptyset$ can be extended to the general case. To this end, we consider an IAP on the same graph $G(D)$ but with slightly different matroids $\mathbf{M}^+ = \mathbf{M}_k^+(I_0)$ and $\mathbf{M}^- = \mathbf{M}_k^-(J_0)$ defined by

$$\begin{aligned} \mathcal{B}^+ = \mathcal{B}_k^+(I_0) = \{U^+ \subseteq V^+ \mid (R_Q - U^+, C_Q \cap U^+) \in \mathcal{L}_Q, \\ R_T \cap U^+ \supseteq \varphi_T(I_0), |U^+| = |R| + k\}, \end{aligned}$$
$$\mathcal{B}^- = \mathcal{B}_k^-(J_0) = \{U^- \subseteq V^- \mid U^- \supseteq R \cup J_0, |U^-| = |R| + k\}.$$

In the spirit of Lemma 5.2 we can prove that $\mathbf{M}^+$ is the direct sum of a linear matroid of rank $|R|$ representable over $\mathbf{K}_0$, a uniform matroid of rank $k-|I_0|$ and a free matroid of rank $|I_0|$, whereas $\mathbf{M}^-$ is the direct sum of a uniform matroid of rank $k-|J_0|$ and a free matroid of rank $|R|+|J_0|$. The weight function ζ remains unchanged. The main result of this paper is now stated.

THEOREM 5.2. *For* $D(s)$ *of* (7) *having property* (20) *and for* $I_0 \subseteq R$, $J_0 \subseteq C$ *and* $k \geqq \max(|I_0|, |J_0|)$ *as specified before,*

$$\delta_k(D; I_0, J_0) = \max_M \zeta(M) + r_0,$$

where the maximum on the right-hand side is taken over all independent assignments M *in the bipartite graph* $G(D)$ *with matroids defined by* $\mathcal{B}_k^+(I_0)$ *and* $\mathcal{B}_k^-(J_0)$, *and* r_0 *is defined by* (23). □

The established characterization provides us with an efficient and practical way of computing $\delta_k(D; I_0, J_0)$ by means of well-established algorithms for the independent assignment problem (see [7], [8], [11], [13], and [14] for algorithms). It then follows from the arguments in § 4 that we have efficient algorithms for checking the properness of a transfer function matrix, for computing the structure at infinity of a transfer function matrix, and for testing for the solvability of EMMP, DDP, and MDDP. Remember, however, that the algorithms yield "generic" results for descriptor systems, where the "genericity" is defined with respect to the parametrization by the nonzero entries of the T-part (cf. Remark 4.1).

In an application of the above result to the structure at infinity, we have to compute $\delta_k(D; I_0, J_0)$ for $k = n+1, \cdots, n+r$ with D, I_0, and J_0 fixed (see Lemma 2.3). This means that we have to solve r problems in the same bipartite graph, but with different matroids $\mathbf{M}_k^+(I_0)$ and $\mathbf{M}_k^-(J_0)$ for $k = n+1, \cdots, n+r$. However, these matroids are closely related to one another in the sense that an independent matching for $k = k_1$ is also an independent matching for $k = k_1 + 1$. In the standard augmenting algorithm for IAP, we can therefore use the maximum weight independent assignment M for $k = k_1$ as the starting independent matching for the problem with $k = k_1 + 1$; M is to be increased by one in size.

In another application of the above result to the solvability of EMMP, DDP, or MDDP we have to compare $\delta_k(D_1; I_0, J_0)$ with $\delta_k((D_1|D_2); I_0, J_0)$ for each k (see [15] and [17]). Here we may regard the graph $G(D_1)$ as a subgraph of $G((D_1|D_2))$ and an independent assignment in $G(D_1)$ is also an independent assignment in $G((D_1|D_2))$. This means that, once a maximum weight independent assignment is found in $G(D_1)$, the test for the equality $\delta_k(D_1; I_0, J_0) = \delta_k((D_1|D_2); I_0, J_0)$ can be done simply by detecting a negative-length cycle in the auxiliary graph used in standard implementations of the algorithms for IAP.

A special case of Theorem 5.1 is used in van der Woude [33] in the computation of a splitting of the external variable of a linear structured system in AR-form into an input and an output in such a way that the output depends on the input in a nonanticipative way (cf. Willems [30]).

A variant of Theorem 5.2 is used by Murota [22] in designing an efficient algorithm for computing the Smith normal form of a polynomial matrix $D(s)$ of (7) having property (20).

6. Example. This section presents an example that illustrates the method proposed in § 5 in comparison with the graph-theoretic method of van der Woude [32] (and also Commault, Dion, and Perez [4] and Suda, Wan, and Ueno [27]). We will compute the structure at infinity of the transfer matrix $P(s) = C(sF-A)^{-1}B$ of a descriptor system (4) ($n=6$, $m=2$, $p=2$) defined by

$$A-sF=\begin{pmatrix} -s & 0 & 1 & 0 & 0 & 0 \\ 0 & -s & 0 & 1 & 0 & 0 \\ -k_1 & 0 & -sm_1 & 0 & -1 & 0 \\ 0 & -k_2 & 0 & -sm_2 & 1 & 0 \\ 0 & 0 & 0 & 0 & -1 & f \\ -s & s & 0 & 0 & 0 & 1 \end{pmatrix},$$

$$B=\begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}, \qquad C=\begin{pmatrix} 1 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 \end{pmatrix}.$$

We regard $\{m_1, m_2, k_1, k_2, f\}$ as independent free parameters. (This example represents a small mechanical system consisting of two masses m_1 and m_2, two springs k_1 and k_2, and one damper f (see [18, § 18]).) We have the mixed matrix

$$D(s)=\begin{pmatrix} -s & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -s & 0 & 1 & 0 & 0 & 0 & 0 \\ -k_1 & 0 & -sm_1 & 0 & -1 & 0 & 1 & 0 \\ 0 & -k_2 & 0 & -sm_2 & 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & f & 0 & 0 \\ -s & s & 0 & 0 & 0 & 1 & 0 & 0 \\ 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \end{pmatrix},$$

which can be decomposed as (18) with

$$Q_D(s)=\begin{pmatrix} -s & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -s & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ -s & s & 0 & 0 & 0 & 1 & 0 & 0 \\ 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \end{pmatrix}$$

and

$$T_D(s)=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -k_1 & 0 & -sm_1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -k_2 & 0 & -sm_2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & f & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

Note that $Q_D(s)$ admits an expression of the form (20) with

$$r_1=r_2=1,\quad r_3=r_4=r_5=2,\quad r_6=1,\quad r_7=0,\quad r_8=1,$$
$$c_1=c_2=0,\quad c_3=c_4=1,\quad c_5=2,\quad c_6=1,\quad c_7=c_8=2.$$

(These numbers are determined from the physical dimensions associated with variables and equations, although they are not unique from the mathematical point of view (see [18, § 18]).)

We denote the rows of D by w_i $(i=1,\cdots,6)$ and y_i $(i=1,2)$, and the columns by x_j $(j=1,\cdots,6)$ and u_j $(j=1,2)$. That is,

$$R=\{w_i\,|\,i=1,\cdots,6\}\cup\{y_1,y_2\},$$
$$C=\{x_j\,|\,j=1,\cdots,6\}\cup\{u_1,u_2\}.$$

The subsets I_0 and J_0 specified in Lemma 2.3 are given by

$$I_0=\{w_i\,|\,i=1,\cdots,6\},\qquad J_0=\{x_j\,|\,j=1,\cdots,6\}.$$

The associated graph $G(D)=(V,E)$ has 40 vertices ($|V^+|=24$, $|V^-|=16$) and 29 edges with weight ζ of (22) (see Fig. 1). Among those edges, 24 edges represent the correspondence between copies, and the remaining 5 edges denote the independent parameters as listed below, where we use the short-hand notation $\varphi_T(w_i)=w_i^T$:

parameters:	m_1	m_2	k_1	k_2	f
edges:	(w_3^T,x_3)	(w_4^T,x_4)	(w_3^T,x_1)	(w_4^T,x_2)	(w_5^T,x_6).
weights:	1	1	0	0	0

By Lemma 2.5 we see that $A-sF$ is in fact nonsingular with rank equal to 6, and, furthermore, by Lemma 2.6 that $\delta(A-sF)=4$. On the other hand, Lemma 2.5 reveals that $D(s)$ is singular with rank $D(s)=7$ although term-rank $D(s)=8$. Hence,

$$\text{rank } P(s)=\text{rank } D(s)-\text{rank }(A-sF)=1.$$

By solving the IAP with matroids $\mathbf{M}_7^+(I_0)$ and $\mathbf{M}_7^-(J_0)$, we find an independent assignment M with maximum weight $\zeta(M)=-7$; for example, such M is given by (21) with $I_1=\{w_1,w_2,w_3,w_5,w_6,y_2\}$, $J_1=\{x_1,x_2,x_3,x_5,x_6,u_1\}$, $I_2=\{w_4\}$, $J_2=\{x_4\}$. Since $r_0=10$, we obtain

$$\delta_7(D(s);\,I_0,J_0)=\zeta(M)+r_0=3.$$

It then follows from Lemma 2.3 that

$$\text{ord}_1\,P(s)=-3+4=1.$$

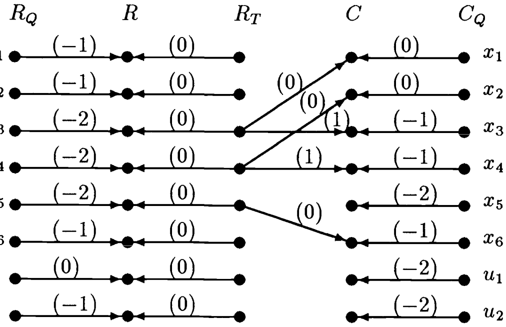

FIG. 1. *Graph $G(D)$ of example* ((·): *weight*).

For comparison let us apply the graph-theoretic method of van der Woude [32] to this example. We first transform this system into the standard state space form (1) to obtain a fourth-order system ($n=4$) with

$$\hat{A}=\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -k_1/m_1 & 0 & -f/m_1 & f/m_1 \\ 0 & -k_2/m_2 & f/m_2 & -f/m_2 \end{pmatrix},$$

$$\hat{B}=\begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 1/m_1 & 0 \\ 0 & 1/m_2 \end{pmatrix}, \qquad \hat{C}=\begin{pmatrix} 1 & -1 & 0 & 0 \\ 0 & 0 & 1 & -1 \end{pmatrix}.$$

We denote the transfer matrix of this system by

$$\hat{P}(s)=\hat{C}(sI-\hat{A})^{-1}\hat{B}.$$

Note that $P(s)=\hat{P}(s)$.

The associated digraph $\hat{G}$ is depicted in Fig. 2. As is easily seen, $\hat{G}$ admits a Menger-type vertex-disjoint complete linking (of size 2) from $\{u_1, u_2\}$ to $\{y_1, y_2\}$. This means (see, for instance, [18, Thm. 7.2] and [32, Thm. 6.2]) that if the nonzero entries of $\hat{A}$, $\hat{B}$ and $\hat{C}$ were algebraically independent, then

$$\operatorname{rank} \hat{P}(s)=2.$$

Furthermore, the graph-theoretic criterion of van der Woude [32] tells us that

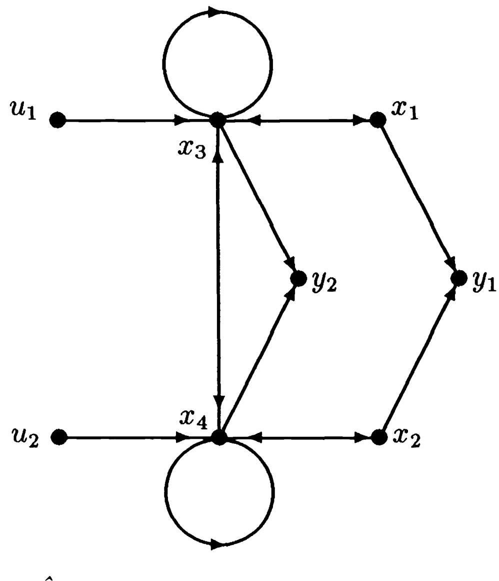

FIG. 2. *Graph $\hat{G}$ of example (↔ stands for a pair of edges in opposite directions).*

$\sum_{j=1}^{k} \operatorname{ord}_j \hat{P}(s)$ is equal to the minimum number of vertices x_j contained in a vertex-disjoint linking of size k from $\{u_1, u_2\}$ to $\{y_1, y_2\}$, and hence that

$$\operatorname{ord}_1 \hat{P}(s) = 1, \qquad \operatorname{ord}_2 \hat{P}(s) = 2,$$

provided again that the nonzero entries of $\hat{A}$, $\hat{B}$, and $\hat{C}$ were algebraically independent. However, in the present example the conclusion that rank $\hat{P}(s) = 2$, and $\operatorname{ord}_1 \hat{P}(s) = 1$, $\operatorname{ord}_2 \hat{P}(s) = 2$, is incorrect because the entries of the matrices are not algebraically independent.

From the previous it is clear that the correct conclusion is that rank $\hat{P}(s) = 1$ and $\operatorname{ord}_1 \hat{P}(s) = 1$. Therefore, in the case of algebraically related entries the structure at infinity of a physical system can be determined better by the matroid-theoretic method developed in this paper than by the graph-theoretic method of [4], [27], or [32].

Acknowledgments. The comments of the anonymous referees were helpful in revision.

NECESSARY CONDITIONS FOR OPTIMAL CONTROL OF DISTRIBUTED PARAMETER SYSTEMS*

XUNJING LI† AND JIONGMIN YONG†

Abstract. The Ekeland variational principle is used to prove a maximum principle for the optimal controls of a general semilinear evolutionary control system in a Banach space with strictly convex dual. The boundary constraint is of general type which includes the optimal periodic control problem as a special case.

Key words. maximum principle, Ekeland's variational principle, optimal control, distributed parameter system

AMS(MOS) subject classifications. 49B27, 93C25

1. Introduction. Necessary conditions for optimal control of lumped parameter systems were derived by Pontryagin et al. [29] (see also [6]-[9], [28], [30]). Butkovskii [7] was the first to discuss the optimal control problems for distributed parameter systems. The maximum principle as a set of necessary conditions for optimal control of distributed parameter systems has been studied by many authors. Since it is well known that the maximum principle may be false for distributed parameter systems (see [4]), there are many papers that give some conditions ensuring that the maximum principle remains true. We refer the readers to [1], [4], [5], [11], and [26] for some results of this aspect. We note that the above-mentioned references discuss the cases for distributed parameter systems or functional differential systems with no end constraints and/or with the control domain being convex. Thus, they do not include the Pontryagin original result as a special case. It was Li and Yao [25] who proved a maximum principle, for distributed parameter systems in some Banach spaces with finite-codimensional target set, which covered the Pontryagin result. Fattorini [18], [19] proved a maximum principle for distributed parameter systems in some Hilbert spaces under the condition that the reachable set of the variational system is of finite codimension. Xu [31] proved a similar result in a uniformly convex Banach space.

Problems with general end constraints (meaning that the initial and the terminal states of the system belong to some subset of the product space of the state space; see § 2 for details) for lumped parameter systems were formulated by Berkovitz [6] and he pointed out that, by increasing the dimension of the state space, such problems can be reduced to the one with separated end constraints, studied by Pontryagin et al.

Colonius [10], Li [23], and Li and Chow [24] considered the optimal periodic control problems for functional differential systems. They proved the maximum principle under some technical assumptions. Li and Chow [24] and Jin and Li [22] studied the problems with general end constraints for functional differential systems and derived the necessary conditions for the optimal controls.

In this paper, we use Ekeland's variational principle to prove a maximum principle for the optimal controls of a general semilinear evolutionary control system in some Banach space with general end constraints which contains the periodic optimal control problem as a special case. We should note that unlike the finite-dimensional case, we

† Department of Mathematics, Fudan University, Shanghai 200433, China.

could not simply use the argument of [6] to reduce such a problem to the one with separated end constraints.

2. Optimal control problem, maximum principle. In this section, we give the basic framework of our optimal control problem. We will also state the main result of this paper—the maximum principle, the proof of which will be given in § 4.

Let X and Y be Banach spaces with the embedding $X \hookrightarrow Y$ being dense and continuous. We denote the dual spaces of X and Y by X^* and Y^*, respectively. We assume the following:

(H0) X^* is strictly convex.

By [2] and [3] (see also [15]), we know that if X is reflexive, then, by changing the norm to an equivalent one, we may assume that X^* is strictly convex. Also, if X is separable, we may also do the above (see the proof of Theorem 4 of [12], see also [13], [14]). Thus, we see that (H0) is general enough to cover almost all cases that interest us (e.g., $X = C([-r, 0]; \mathbb{R}^n)$, $L^1(\mathbb{R}^n)$, etc.). Next, let U be a given metric space. For $T > 0$, the admissible control set is the following:

$$\mathcal{U}_{\text{ad}} = L^\infty(0, T; U).$$

We let

$$\Delta = \{(t, s) \in [0, T] \times [0, T] \| 0 \leqq s < t \leqq T\},$$
$$\bar{\Delta} = \{(t, s) \in [0, T] \times [0, T] \| 0 \leqq s \leqq t \leqq T\}.$$

Now, our optimal control problem can be stated as follows.

PROBLEM C. Minimize

$$J(u(\cdot)) = \int_0^T f^0(t, x(t; u), u(t))\, dt, \tag{2.1}$$

subject to the evolutionary distributed parameter system with the constraints on the initial and terminal states and the control:

$$x(t; u) = G(t, 0)x(0; u) + \int_0^t G(t, s)f(s, x(s; u), u(s))\, ds, \qquad 0 \leqq t \leqq T, \tag{2.2}$$

$$(x(0; u), x(T; u)) \in S \subset X \times X, \tag{2.3}$$

$$u(\cdot) \in \mathcal{U}_{\text{ad}}. \tag{2.4}$$

To understand our problem, let us make the following hypotheses.

(H1) The evolution operator $G: \Delta \to \mathcal{L}(Y, X)$ is strongly continuous in Δ and there exist constants $M > 0$ and $0 \leqq \alpha < 1$, such that

$$\|G(t, s)\|_{\mathcal{L}(Y,X)} \leqq \frac{M}{(t-s)^\alpha} \quad \forall (t, s) \in \Delta. \tag{2.5}$$

Moreover, the operator $G: \bar{\Delta} \to \mathcal{L}(X, X)$ is also strongly continuous and

$$G(s, s) = I \quad \forall s \in [0, T], \tag{2.6}$$

where I is the identity operator on X.

(H2) The mappings $f: [0, T] \times X \times U \to Y, f^0: [0, T] \times X \times U \to \mathbb{R}$ and their Fréchet derivatives f_x and f_x^0 are strongly continuous.

(H3) The set $S \subset X \times X$ is convex and closed.

Remark 2.1. By general end constraint, we mean that the initial and the terminal states of the system satisfy (2.3). In [25], Li and Yao considered the case of

$$S=\{x_0\}\times Q,$$

with $x_0\in X$ given and $Q\subset X$ being of finite codimension. On the other hand, Li and Chow [24] studied the optimal periodic control problems, which corresponds to the case where

$$S=\{(x,x)|x\in X\}.$$

Now, we let $\bar{u}(\cdot)$ be an optimal control and $\bar{x}(\cdot)\equiv x(\cdot\,;\bar{x}_0,\bar{u}(\cdot))$ be the corresponding optimal trajectory of the system (2.2) with the (optimal) initial state $\bar{x}_0$. We denote

$$B(t)=f_x(t,\bar{x}(t),\bar{u}(t))\quad \forall t\in[0,T], \tag{2.7}$$

and for any $y\in Y$, we define an operator $G_1(t,s)$ through the following equation:

$$G_1(t,s)y=G(t,s)y+\int_s^t G(t,r)B(r)G_1(r,s)y\,dr,\qquad 0\leqq s<t\leqq T. \tag{2.8}$$

It is not hard to show that $G_1(\cdot,\cdot)$ is well defined and that it satisfies [11]

$$G_1(t,s)y=G(t,s)y+\int_s^t G_1(t,r)B(r)G(r,s)y\,dr\quad \forall x\in X,\quad 0\leqq s<t\leqq T. \tag{2.9}$$

Moreover, for any $\eta\in X$ and $h(\cdot)\in L^1(0,T;Y)$, the solution $\xi(\cdot)$ of

$$\xi(t)=G(t,0)\eta+\int_0^t G(t,s)B(s)\xi(s)\,ds+\int_0^t G(t,s)h(s)\,ds,\qquad t\in[0,T] \tag{2.10}$$

can be written as

$$\xi(t)=G_1(t,0)\eta+\int_0^t G_1(t,s)h(s)\,ds,\qquad t\in[0,T]. \tag{2.11}$$

Next, let us denote

$$\mathcal{R}=\left\{\xi\in X|\xi=\int_0^T G_1(T,t)[f(t,\bar{x}(t),u(t))-f(t,\bar{x}(t),\bar{u}(t))]\,dt,\ u(\cdot)\in\mathcal{U}_{\text{ad}}\right\}, \tag{2.12}$$

$$Q=\{\eta\in X|\eta=x_1-G_1(T,0)x_0,(x_0,x_1)\in S\}. \tag{2.13}$$

DEFINITION 2.2. Let Ω be a subset of some topological vector space Z. We say that Ω is of finite codimension in Z, if there exists a point $z_0\in\overline{\text{co}}\,\Omega$, such that

$$\text{span}\,\{\Omega-z_0\}\equiv\text{the closed subspace spanned by }\{z-z_0|z\in\Omega\}$$

is a finite-codimensional closed subspace of Z and $\Omega-z_0$ has a nonempty interior in span $\{\Omega-z_0\}$.

It is not hard to see that if $\Omega\subset Z$ is of finite codimension in Z, then for any $z\in\overline{\text{co}}\,\Omega$, span $\{\Omega-z\}$ is a finite-codimensional closed subspace of Z. We will use this fact in sequel.

Before we state our main result, let us introduce the following Hamiltonian for our Problem C. For all $(t,x,\psi,\psi^0,u)\in[0,T]\times X\times X^*\times\mathbb{R}\times U$,

$$H(t,x,\psi,\psi^0,u)=\langle\psi,f(t,x,u)\rangle+\psi^0f^0(t,x,u). \tag{2.14}$$

Now, let us state our main result of this paper.

THEOREM 2.3 (maximum principle). *Let* (H0)-(H3) *hold. Let* $(\bar{x}(\cdot),\bar{u}(\cdot))$ *be a solution of Problem* C. *Let* $\mathcal{R}-Q$ *be of finite codimension in X. Then, there exists a* $(\psi(\cdot),\psi^0)\neq 0$, *such that*

$$\psi^0\leqq 0, \tag{2.15}$$

$$(2.16)\quad \begin{aligned}\psi(t)=G^*(T,t)\psi(T)&+\int_t^T G^*(s,t)f_x^*(s,\bar{x}(s),\bar{u}(s))\psi(s)\,ds\\ &+\psi^0\int_t^T G^*(s,t)f_x^{0*}(s,\bar{x}(s),\bar{u}(s))\,ds,\qquad t\in[0,T],\end{aligned}$$

$$(2.17)\quad H(t,\bar{x}(t),\psi(t),\psi^0,\bar{u}(t))=\max_{u\in U}H(t,\bar{x}(t),\psi(t),\psi^0,u)\quad \text{a.e. } t\in[0,T],$$

and

$$(2.18)\quad \langle\psi(0),x_0-\bar{x}(0)\rangle-\langle\psi(T),x_1-\bar{x}(T)\rangle\leqq 0\quad \forall(x_0,x_1)\in S.$$

3. Some preliminary results. In this section, we give several lemmas which will play crucial roles in the proof of the maximum principle.

LEMMA 3.1. *Let $x(\cdot)$ be the solution of* (2.2) *corresponding to $(x_0,v(\cdot))\in X\times\mathcal{U}_{\text{ad}}$. Then, for any $\rho\in(0,1]$, $\eta\in X$ and $w(\cdot)\in\mathcal{U}_{\text{ad}}$, there exists a measurable set $E_\rho\subseteq[0,T]$ with*

$$(3.1)\quad \text{meas}\,(E_\rho)=\rho T,$$

such that the solution $x_\rho(\cdot)$ of (2.2) *corresponding to $x_0+\rho\eta$ and*

$$(3.2)\quad v_\rho(t)=\begin{cases}v(t), & t\in[0,T]\backslash E_\rho,\\ w(t), & t\in E_\rho,\end{cases}$$

satisfies

$$(3.3)\quad x_\rho(t)=x(t)+\rho\delta x(t)+o(\rho)\quad \text{as } \rho\downarrow 0,$$

uniformly in $t\in[0,T]$, $w(\cdot)\in\mathcal{U}_{\text{ad}}$ and η in bounded sets of X, where $\delta x(\cdot)$ satisfies the following variational equation:

$$(3.4)\quad \begin{aligned}\delta x(t)=G(t,0)\eta&+\int_0^t G(t,s)f_x(s,x(s),v(s))\delta x(s)\,ds\\ &+\int_0^t G(t,s)[f(s,x(s),w(s))-f(s,x(s),v(s))]\,ds,\qquad t\in[0,T].\end{aligned}$$

The proof can be found in [25].

LEMMA 3.2. *Let Z be a locally convex topological vector space. Let Q be a finite-codimensional subset of Z with the property that*

$$(3.5)\quad 0\in\overline{\text{co}}\,Q.$$

Suppose $\{f_n\}$ is a sequence of continuous linear functionals on Z satisfying the following:

(i) *There exists a convex neighborhood N of zero and there exist constants c, $C>0$, such that*

$$(3.6)\quad c\leqq\sup_{z\in N}f_n(z)\leqq C\quad \forall n\geqq 1;$$

(ii) *There exists a sequence of positive numbers $\varepsilon_n\downarrow 0$, such that*

$$(3.7)\quad f_n(z)\geqq-\varepsilon_n\quad \forall n\geqq 1,\quad z\in Q;$$

(iii) *There exists a continuous linear functional f, such that*

$$(3.8)\quad f_n\to f\quad \textit{weakly}^*.$$

Then, we have

$$(3.9)\quad f\neq 0.$$

Proof. First of all, from (3.7), we see that

$$f_n(z) \geqq -\varepsilon_n \quad \forall n \geqq 1, \quad z \in \overline{\text{co}}\, Q. \tag{3.10}$$

Next, from our assumptions on Q, we can find closed subspaces Z_0 and Z_1 of Z, such that

$$Z = Z_0 \oplus Z_1, \qquad \dim Z_1 < \infty, \tag{3.11}$$

and for some $\bar{z}_0 \in \overline{\text{co}}\, Q$ and some convex neighborhood $N(\bar{z}_0)$ of $\bar{z}_0$ (in Z), it holds (note (3.5)) that

$$N(\bar{z}_0) \cap Z_0 \subset \overline{\text{co}}\, Q. \tag{3.12}$$

Without loss of generality, we may assume that the neighborhood N appearing in (i) is symmetric and bounded (in the sense that for any continuous linear functional g, we have $\sup_{z \in N} g(z) < \infty$), and

$$N(\bar{z}_0) = N + \bar{z}_0. \tag{3.13}$$

Now, suppose $f = 0$; we will obtain a contradiction. For any $z \in N$, by (3.13), we have $z + \bar{z}_0 \in N(\bar{z}_0)$. On the other hand, we have the decomposition

$$z + \bar{z}_0 = z_0 + z_1, \qquad z_0 \in Z_0, \quad z_1 \in Z_1.$$

By (3.12), we know that $z_0 \in \overline{\text{co}}\, Q$. Thus,

$$\begin{aligned} f_n(z) &= f_n(z_0) + f_n(z_1) - f_n(\bar{z}_0) \\ &\geqq -\varepsilon_n + f_n(z_1) - f_n(\bar{z}_0). \end{aligned}$$

Then, by (3.8), the assumption $f = 0$, and (3.11), we obtain

$$\delta_n \equiv |f_n(\bar{z}_0)| + |f_n(z_1)| \to 0 \quad \text{as } n \to \infty,$$

uniformly in $z \in N$ (note that z_1 depending on z). Thus, we have

$$f_n(z) \leqq \varepsilon_n + \delta_n \quad \forall z \in N, \quad n \geqq 1.$$

This leads to a contradiction to (3.6). Hence (3.9) follows. □

A result similar to Lemma 3.2 was proved by Fattorini [19] in the case where Z is a Hilbert space and by Xu [31] in the case where Z is a Banach space. Our argument is a little different from theirs and looks simpler. In § 4, we will use this result for the case where Z is a Banach space.

LEMMA 3.3. *Let Z be a Banach space and let Z_1 and Z_2 be closed subspaces of Z such that $Z = Z_1 \oplus Z_2$. Let $G_1 \in \mathscr{L}(Z)$ and set*

$$Y = \{(z, G_1 z + z_1) | z \in Z, z_1 \in Z_1\}.$$

Then, Y is a closed subspace of $Z \times Z$ and

$$Z \times Z = Y \oplus (\{0\} \times Z_2). \tag{3.14}$$

In particular, Y is of finite codimension in $Z \times Z$ if and only if Z_1 is of finite codimension in Z.

Proof. First of all, it is easy to see that Y is closed in $Z \times Z$. Next, for any $(x, y) \in Z \times Z$, there exist $z_1 \in Z_1$ and $z_2 \in Z_2$, such that

$$y - G_1 x = z_1 + z_2. \tag{3.15}$$

Thus,

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x \\ G_1 x + z_1 \end{pmatrix} + \begin{pmatrix} 0 \\ z_2 \end{pmatrix} \in Y + (\{0\} \times Z_2). \tag{3.16}$$

On the other hand, if $\binom{0}{z} \in Y \cap (\{0\} \times Z_2)$, then we have some $z_1 \in Z_1$ such that

$$\begin{pmatrix} 0 \\ z \end{pmatrix} = \begin{pmatrix} x \\ G_1 x + z_1 \end{pmatrix}.$$

Thus, $x = 0$ and

$$z = z_1 \in Z_1 \cap Z_2 = \{0\}.$$

Hence, (3.14) follows. The last conclusion is obvious. □

The next result involves the Clarke's generalized gradient. Thus, let us recall some relevant material, which can be found in [9].

Let Z be a Banach space. Let $g: Z \to \mathbb{R}$ be a Lipschitz continuous function. We define

$$g^0(z; \xi) = \overline{\lim_{z' \to z, \rho \downarrow 0}} \frac{g(z' + \rho \xi) - g(z')}{\rho} \quad \forall z, \xi \in Z, \tag{3.17}$$

$$\partial g(z) = \{\zeta \in Z^* | g^0(z; \xi) \geqq \langle \zeta, \xi \rangle, \forall \xi \in Z\} \quad \forall z \in Z. \tag{3.18}$$

It holds that

$$g^0(z; \xi) = \max \{\langle \zeta, \xi \rangle | \zeta \in \partial g(z)\} \quad \forall z, \xi \in Z. \tag{3.19}$$

Now, if Q is a convex and closed subset of Z, we can define

$$d_Q(z) = \inf_{z' \in Q} |z - z'|_Z.$$

We know that $d_Q(\cdot)$ is a convex function and

$$|d_Q(z) - d_Q(z')| \leqq |z - z'|_Z. \tag{3.20}$$

Furthermore, by Proposition 2.2.7 of [9], we have

$$\lim_{\rho \downarrow 0} \frac{d_Q(z + \rho \xi) - d_Q(z)}{\rho} = d_Q^0(z; \xi), \tag{3.21}$$

and

$$\begin{aligned} \partial d_Q(z) &\equiv \{\zeta \in Z^* | d_Q^0(z; \xi) \geqq \langle \zeta, \xi \rangle, \forall \xi \in Z\} \\ &= \{\zeta \in Z^* | d_Q(z') - d_Q(z) \geqq \langle \zeta, z' - z \rangle, \forall z' \in Z\}. \end{aligned} \tag{3.22}$$

In addition, we have the following lemma.

LEMMA 3.4. *Let Q be a convex and closed subset of some Banach space Z. Then, for any $z \notin Q$,*

$$|\zeta|_{Z^*} = 1 \quad \forall \zeta \in \partial d_Q(z). \tag{3.23}$$

Proof. By (3.20) and Proposition 2.1.2 of [9], we know that

$$|\zeta|_{Z^*} \leqq 1 \quad \forall \zeta \in \partial d_Q(z). \tag{3.24}$$

Now, since $z \notin Q$, for any $0 < \delta < 1$, there exists a $q_\delta \in Q$, such that

$$d_Q(z) \geqq (1 - \delta) |z - q_\delta|_Z > 0. \tag{3.25}$$

Thus, for any $\zeta \in \partial d_Q(z)$, by (3.22), we have

$$-d_Q(z) \geqq \langle \zeta, q_\delta - z \rangle.$$

Then,

$$(1-\delta)|z-q_\delta|_Z \leqq d_Q(z) \leqq -\langle \zeta, q_\delta - z\rangle \leqq |\zeta|_{Z^*}|z-q_\delta|_Z.$$

Hence, by (3.25),

$$|\zeta|_{Z^*} \geqq 1-\delta.$$

Then, (3.23) follows (see (3.24)). □

COROLLARY 3.5. *Let Z be a Banach space with strictly convex dual Z^*. Let Q be a convex and closed subset of Z. Then, for any $z \notin Q$, $\partial d_Q(z)$ is a singleton.*

Proof. By Proposition 2.1.2 of [9], we know that $\partial d_Q(z)$ is convex in Z^*. Thus, our assertion follows from Lemma 3.4 and the strict convexity of Z^*. □

4. Proof of the maximum principle. This section is devoted to proving the maximum principle stated in § 2. For any $(x_0, u(\cdot)) \in X \times \mathcal{U}_{ad}$, we denote the unique solution of (2.2) with $x(0)=x_0$ by $x(\cdot\,; x_0, u)$. Then, let us introduce the following

$$x^0(t; x_0, u) = \int_0^t f^0(s, x(s; x_0, u), u(s))\, ds \quad \forall t \in [0, T]. \tag{4.1}$$

It is clear that

$$x^0(T; x_0, u) = J(u(\cdot)). \tag{4.2}$$

As in § 2, we let $\bar{u}(\cdot)$ be an optimal control, $\bar{x}(\cdot)$ be the optimal trajectory of the system (2.2) corresponding to $\bar{u}(\cdot)$ and the (optimal) initial state $\bar{x}_0$ and $\bar{x}^0(\cdot)$ be the corresponding function obtained through (4.1). Then, for any $\varepsilon > 0$, we define

$$F_\varepsilon(x_0, u) = \{d_S(x_0, x(T; x_0, u))^2 + d_{S_\varepsilon^0}(x^0(T; x_0, u))^2\}^{1/2} \quad \forall (x_0, u) \in X \times \mathcal{U}_{ad}, \tag{4.3}$$

where

$$\begin{aligned} d_S(x_0, x_1) &= d((x_0, x_1), S) \\ &\equiv \inf\{(|x_0-y_0|^2 + |x_1-y_1|^2)^{1/2} | (y_0, y_1) \in S\} \quad \forall (x_0, x_1) \in X \times X, \\ S_\varepsilon^0 &= (-\infty, -\varepsilon + \bar{x}^0(T)], \\ d_{S_\varepsilon^0}(x^0) &= d(x^0, S_\varepsilon^0) \quad \forall x^0 \in \mathbb{R}. \end{aligned}$$

In the space $X \times \mathcal{U}_{ad}$, we introduce the following metric. For all $x, \hat{x} \in X$, $u(\cdot), \hat{u}(\cdot) \in \mathcal{U}_{ad}$,

$$\bar{d}((x, u(\cdot)), (\hat{x}, \hat{u}(\cdot))) = \{|x-\hat{x}|_X^2 + d(u(\cdot), \hat{u}(\cdot))^2\}^{1/2},$$

where

$$d(u(\cdot), \hat{u}(\cdot)) = \text{meas}\,\{t \in [0, T] | u(t) \neq \hat{u}(t)\}.$$

Then, it is not hard to see that $(X \times \mathcal{U}_{ad}, \bar{d})$ is a complete metric space (see [16], [19], [31]). Also, it is easy to see that $F_\varepsilon(\cdot, \cdot)$ is continuous on $X \times \mathcal{U}_{ad}$. Next, we see that

$$F_\varepsilon(x_0, u(\cdot)) > 0 \quad \forall (x_0, u(\cdot)) \in X \times \mathcal{U}_{ad}, \tag{4.4}$$

$$F_\varepsilon(\bar{x}_0, \bar{u}(\cdot)) = \varepsilon \leqq \inf F_\varepsilon(x_0, u(\cdot)) + \varepsilon. \tag{4.5}$$

Thus, by Ekeland's variational principle [16], [17], there exists a pair $(x_0^\varepsilon, u^\varepsilon(\cdot)) \in X \times \mathcal{U}_{ad}$, such that

$$\bar{d}((x_0^\varepsilon, u^\varepsilon(\cdot)), (\bar{x}_0, \bar{u}(\cdot))) \leqq \sqrt{\varepsilon}, \tag{4.6}$$

$$F_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot)) \leqq F_\varepsilon(\bar{x}_0, \bar{u}(\cdot)), \tag{4.7}$$

$$\begin{aligned} F_\varepsilon(x_0, u(\cdot)) \geqq F_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot)) - \sqrt{\varepsilon}\, \bar{d}((x_0^\varepsilon, u^\varepsilon(\cdot)), (x_0, u(\cdot))), \\ \forall (x_0, u(\cdot)) \in X \times \mathcal{U}_{ad}. \end{aligned} \tag{4.8}$$

Now, take any $(\eta, u(\cdot)) \in X \times \mathcal{U}_{\text{ad}}$ and $\rho \in (0, 1]$, by Lemma 3.1, we know that there exists a measurable set $E_\rho \subset [0, T]$, with meas $E_\rho = \rho T$, such that if we let

$$u_\rho^\varepsilon(t) = \begin{cases} u^\varepsilon(t), & t \in [0, T] \backslash E_\rho, \\ u(t), & t \in E_\rho, \end{cases} \tag{4.9}$$

and let $x^\varepsilon(\cdot)$, $x^{0,\varepsilon}(\cdot)$ and $x_\rho^\varepsilon(\cdot)$, $x_\rho^{0,\varepsilon}(\cdot)$ be the solutions of (2.2) and (4.1) corresponding to $(x_0^\varepsilon, u^\varepsilon(\cdot))$ and $(x_0^\varepsilon + \rho\eta, u_\rho^\varepsilon(\cdot))$, respectively; then, for any $t \in [0, T]$, as $\rho \downarrow 0$,

$$x_\rho^\varepsilon(t) = x^\varepsilon(t) + \rho\xi_\varepsilon(t) + o(\rho), \tag{4.10}$$

$$x_\rho^{0,\varepsilon}(t) = x^{0,\varepsilon}(t) + \rho\xi_\varepsilon^0(t) + o(\rho), \tag{4.11}$$

where

$$\begin{aligned} \xi_\varepsilon(t) = G(t, 0)\eta &+ \int_0^t G(t, s) f_x(s, x^\varepsilon(s), u^\varepsilon(s))\xi_\varepsilon(s)\, ds \\ &+ \int_0^t G(t, s)[f(s, x^\varepsilon(s), u(s)) - f(s, x^\varepsilon(s), u^\varepsilon(s))]\, ds, \qquad t \in [0, T], \end{aligned} \tag{4.12}$$

$$\begin{aligned} \xi_\varepsilon^0(t) = &\int_0^t f_x^0(s, x^\varepsilon(s), u^\varepsilon(s))\xi_\varepsilon(s)\, ds \\ &+ \int_0^t [f^0(s, x^\varepsilon(s), u(s)) - f^0(s, x^\varepsilon(s), u^\varepsilon(s))]\, ds, \qquad t \in [0, T]. \end{aligned} \tag{4.13}$$

Now, let us separate several cases.

Case 1. For all small enough $\varepsilon > 0$, we have

$$d_S(x_0^\varepsilon, x^\varepsilon(T)),\ d_{S_\varepsilon^0}(x^{0,\varepsilon}(T)) > 0. \tag{4.14}$$

Then, we see that for all small enough $\rho > 0$,

$$d_{S_\varepsilon^0}(x_\rho^{0,\varepsilon}(T)) > 0. \tag{4.15}$$

Thus, we have

$$d_{S_\varepsilon^0}(x_\rho^{0,\varepsilon}(T)) - d_{S_\varepsilon^0}(x^{0,\varepsilon}(T)) = \rho\xi_\varepsilon^0(T) + o(\rho). \tag{4.16}$$

On the other hand, since S is convex and closed in $X \times X$, by (3.19) and (3.21), we have

$$\begin{aligned} &\lim_{\rho\downarrow 0} \frac{d_S(x_0^\varepsilon + \rho\eta, x_\rho^\varepsilon(T)) - d_S(x_0^\varepsilon, x^\varepsilon(T))}{\rho} \\ &= d_S^0((x_0^\varepsilon, x^\varepsilon(T)); (\eta, \xi_\varepsilon(T))) \\ &= \max\{\langle a, \eta\rangle + \langle b, \xi_\varepsilon(T)\rangle | (a, b) \in \partial d_S(x_0^\varepsilon, x^\varepsilon(T))\} \\ &= \langle a_\varepsilon, \eta\rangle + \langle b_\varepsilon, \xi_\varepsilon(T)\rangle, \end{aligned} \tag{4.17}$$

where $\langle \cdot, \cdot \rangle$ is the duality between X and X^* and $\partial d_S(x_0^\varepsilon, x^\varepsilon(T))$ is the singleton $\{(a_\varepsilon, b_\varepsilon)\}$ (see Corollary 3.5). By (4.14) and Lemma 3.4, we know that

$$|a_\varepsilon|_{X^*}^2 + |b_\varepsilon|_{X^*}^2 = 1. \tag{4.18}$$

Here, we take $\{|\cdot|_X^2 + |\cdot|_X^2\}^{1/2}$ as the norm of $X \times X$. Then, in (4.8), by letting $x_0 = x_0^\varepsilon + \rho\eta$ and $u(\cdot) = u_\rho^\varepsilon(\cdot)$, we have

$$-\sqrt{\varepsilon}\,(|\eta|^2 + T^2)^{1/2} \leqq \frac{F_\varepsilon(x_0^\varepsilon + \rho\eta, u_\rho^\varepsilon(\cdot)) - F_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot))}{\rho}. \tag{4.19}$$

Letting $\rho \to 0$ and by (4.16)-(4.17), we obtain

$$-\sqrt{\varepsilon}\,(|\eta|^2+T^2)^{1/2} \leqq \langle \bar{\varphi}_\varepsilon, \eta\rangle + \langle \bar{\psi}_\varepsilon, \xi_\varepsilon(T)\rangle + \bar{\psi}^0_\varepsilon \xi^0_\varepsilon(T), \tag{4.20}$$

where

$$\bar{\varphi}_\varepsilon = \frac{d_S(x_0^\varepsilon, x^\varepsilon(T))}{F_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot))} a_\varepsilon, \tag{4.21}$$

$$\bar{\psi}_\varepsilon = \frac{d_S(x_0^\varepsilon, x^\varepsilon(T))}{F_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot))} b_\varepsilon, \tag{4.22}$$

$$\bar{\psi}^0_\varepsilon = \frac{d_{S^0_\varepsilon}(x^{0,\varepsilon}(T))}{F_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot))}. \tag{4.23}$$

Thus, by (4.18), we have

$$|\bar{\varphi}_\varepsilon|^2_{X^*} + |\bar{\psi}_\varepsilon|^2_{X^*} + (\bar{\psi}^0_\varepsilon)^2 = 1. \tag{4.24}$$

From (4.6), we know that as $\varepsilon \downarrow 0$, we have

$$\begin{gathered} x_0^\varepsilon \to \bar{x}_0, \qquad \xi_\varepsilon(t) \to \xi(t), \\ \xi^0_\varepsilon(t) \to \xi^0(t), \end{gathered} \tag{4.25}$$

uniformly in $t \in [0, T]$, where $\xi(\cdot)$ and $\xi^0(\cdot)$ satisfy the following equations:

$$\begin{aligned} \xi(t) = G(t, 0)\eta &+ \int_0^t G(t, s) f_x(s, \bar{x}(s), \bar{u}(s))\xi(s)\, ds \\ &+ \int_0^t G(t, s)[f(s, \bar{x}(s), u(s)) - f(s, \bar{x}(s), \bar{u}(s))]\, ds, \qquad t \in [0, T], \end{aligned} \tag{4.26}$$

$$\begin{aligned} \xi^0(t) = &\int_0^t f^0_x(s, \bar{x}(s), \bar{u}(s))\xi(s)\, ds \\ &+ \int_0^t [f^0(s, \bar{x}(s), u(s)) - f^0(s, \bar{x}(s), \bar{u}(s))]\, ds, \qquad t \in [0, T]. \end{aligned} \tag{4.27}$$

On the other hand, by (3.22), we have

$$\langle a_\varepsilon, x_0 - x_0^\varepsilon\rangle + \langle b_\varepsilon, x_1 - x^\varepsilon(T)\rangle \leqq -d_S(x_0^\varepsilon, x^\varepsilon(T)) \leqq 0 \quad \forall (x_0, x_1) \in S. \tag{4.28}$$

Thus,

$$\begin{aligned} &\langle \bar{\varphi}_\varepsilon, x_0 - \bar{x}_0\rangle + \langle \bar{\psi}_\varepsilon, x_1 - \bar{x}(T)\rangle \\ &\leqq (|x_0^\varepsilon - \bar{x}_0|^2_X + |x^\varepsilon(T) - \bar{x}(T)|^2_X)^{1/2} \equiv \delta_\varepsilon \to 0 \quad \text{as } \varepsilon \to 0. \end{aligned} \tag{4.29}$$

Then, by (4.20), we have

$$\begin{aligned} &\langle \bar{\varphi}_\varepsilon, \eta - (x_0 - \bar{x}_0)\rangle + \langle \bar{\psi}_\varepsilon, \xi(T) - (x_1 - \bar{x}(T))\rangle + \bar{\psi}^0_\varepsilon \xi^0(T) \\ &\geqq -\sqrt{\varepsilon}\,(|\eta|^2+T^2)^{1/2} - \delta_\varepsilon - |\xi_\varepsilon(T) - \xi(T)| - |\xi^0_\varepsilon(T) - \xi^0(T)| \\ &\geqq -\theta_\varepsilon \quad \forall (x_0, x_1) \in S. \end{aligned} \tag{4.30}$$

Here, we can see that θ_ε is uniform in $u(\cdot) \in \mathscr{U}_{\mathrm{ad}}$ and η in bounded sets of X. Now, we let

$$\hat{\mathscr{R}} = \left\{ \begin{pmatrix} \hat{\eta} \\ \hat{\xi} \end{pmatrix} \in X \times X \,\middle|\, \hat{\xi} = G_1(T, 0)\hat{\eta} + \xi,\ \xi \in \mathscr{R},\ \hat{\eta} \in X \right\},$$

and let

$$X_1 = \operatorname{span}\,(\mathcal{R} - Q + \bar{x}(T) - G_1(T, 0)\bar{x}_0).$$

Then, by our assumption, we know that X_1 is finite-codimensional in X. On the other hand, it is not hard to see that

$$\operatorname{span}\left(\hat{\mathcal{R}} - S + \begin{pmatrix} \bar{x}_0 \\ \bar{x}(T) \end{pmatrix}\right) = Y \equiv \left\{ \begin{pmatrix} x \\ G_1(T, 0)x + x_1 \end{pmatrix} \middle| x \in X, x_1 \in X_1 \right\}.$$

Thus, by Lemma 3.3, we know that Y is finite-codimensional in $X \times X$. Equivalently, we have that $\hat{\mathcal{R}} - S + \binom{\bar{x}_0}{\bar{x}(T)}$ is finite-codimensional in $X \times X$. Also, this set contains the element zero of $X \times X$. Thus, by Lemma 3.2 and (4.24), (4.30), we have a subsequence (denoted in the same way) such that

$$(\bar{\varphi}_\varepsilon, \bar{\psi}_\varepsilon, \bar{\psi}^0_\varepsilon) \xrightarrow{*} (\bar{\varphi}, \bar{\psi}, \bar{\psi}^0) \neq 0. \tag{4.31}$$

Then, from (4.20) and (4.23), we obtain

$$\langle \bar{\varphi}, \eta \rangle + \langle \bar{\psi}, \xi(T) \rangle + \bar{\psi}^0 \xi^0(T) \geqq 0, \tag{4.32}$$

$$\bar{\psi}^0 \geqq 0. \tag{4.33}$$

Case 2. There exists a sequence $\varepsilon \downarrow 0$, such that

$$d_S(x_0^\varepsilon, x^\varepsilon(T)) = 0. \tag{4.34}$$

Then, by (4.4), we must have

$$d_{S^0_\varepsilon}(x^{0,\varepsilon}(T)) > 0. \tag{4.35}$$

Thus, (4.20) and (4.21)-(4.23) read

$$-\sqrt{\varepsilon}\,(|\eta|^2 + T^2)^{1/2} \leqq \xi^0_\varepsilon(T), \tag{4.36}$$

$$\bar{\varphi}_\varepsilon = 0, \quad \bar{\psi}_\varepsilon = 0, \quad \bar{\psi}^0_\varepsilon = 1. \tag{4.37}$$

Letting $\varepsilon \to 0$, we get (trivially)

$$\xi^0(T) \geqq 0, \tag{4.38}$$

and

$$\bar{\varphi} = 0, \quad \bar{\psi} = 0, \quad \bar{\psi}^0 = 1. \tag{4.39}$$

Case 3. There exists a sequence $\varepsilon \downarrow 0$, such that

$$d_{S^0_\varepsilon}(x^{0,\varepsilon}(T)) = 0. \tag{4.40}$$

Then, by (4.4), we have

$$d_S(x_0^\varepsilon, x^\varepsilon(T)) > 0. \tag{4.41}$$

Then, by the arguments used in Cases 1 and 2, we can show that (4.32)-(4.33) hold with $\bar{\psi}^0 = 0$. Thus, in any case, we always have (4.32)-(4.33). On the other hand, from (4.28) (which is true for all of these three cases), we obtain that

$$\langle \bar{\varphi}, x_0 - \bar{x}_0 \rangle + \langle \psi, x_1 - \bar{x}(T) \rangle \leqq 0 \quad \forall (x_0, x_1) \in S. \tag{4.42}$$

Now, let $\psi(\cdot)$ be the unique solution of (2.16). Then, by (2.8) and (2.9), we have

$$\psi(t) = -G_1^*(T, t)\bar{\psi} + \psi^0 \int_t^T G_1^*(s, t) g(s)\, ds, \qquad t \in [0, T], \tag{4.43}$$

where

$$g(s)=f_x^0(s,\bar{x}(s),\bar{u}(s))^*, \qquad s\in[0,T], \tag{4.44}$$

and

$$\psi^0=-\bar{\psi}^0\leqq 0. \tag{4.45}$$

From (2.11) and (4.26)-(4.27), we know that

$$\xi(t)=G_1(t,0)\eta+\int_0^t G_1(t,s)h(s)\,ds, \qquad t\in[0,T], \tag{4.46}$$

$$\xi^0(t)=\int_0^t [\langle g(s),\xi(s)\rangle+h^0(s)]\,ds, \qquad t\in[0,T], \tag{4.47}$$

where

$$h(s)=f(s,\bar{x}(s),u(s))-f(s,\bar{x}(s),\bar{u}(s)), \qquad t\in[0,T],$$
$$h^0(s)=f^0(s,\bar{x}(s),u(s))-f^0(s,\bar{x}(s),\bar{u}(s)), \qquad t\in[0,T].$$

Thus, we have the following duality equality (note (2.14)):

$$\begin{aligned}&\langle\psi(T),\xi(T)\rangle-\langle\psi(0),\eta\rangle+\psi^0\xi^0(T)\\ &=\int_0^T [\langle\psi(t),h(t)\rangle+\psi^0h^0(t)]\,dt,\\ &=\int_0^T [H(t,\bar{x}(t),\psi(t),\psi^0,u(t))-H(t,\bar{x}(t),\psi(t),\psi^0,\bar{u}(t))]\,dt,\end{aligned} \tag{4.48}$$

for all $\eta\in X$, $u(\cdot)\in\mathscr{U}_{\mathrm{ad}}$ and $(\psi(\cdot),\psi^0,\xi(\cdot),\xi^0(\cdot))$ satisfy (4.4), (4.45)-(4.47). Hence, by setting $\eta=0$, we obtain (note (4.32))

$$\int_0^T [H(t,\bar{x}(t),\psi(t),\psi^0,u(t))-H(t,\bar{x}(t),\psi(t),\psi^0,\bar{u}(t))]\,dt\leqq 0 \quad \forall u(\cdot)\in\mathscr{U}_{\mathrm{ad}}. \tag{4.49}$$

Thus, (2.17) follows. By taking $u(\cdot)=\bar{u}(\cdot)$, we get (see (4.32) and (4.48))

$$\langle\bar{\varphi},\eta\rangle\geqq\langle\psi(0),\eta\rangle \quad \forall\eta\in X.$$

Thus, $\bar{\varphi}=\psi(0)$ and (2.18) follows. Finally, by (4.31) and (4.43), we see that $(\psi(\cdot),\psi^0)\neq 0$. The proof of the maximum principle is completed. □

Remark 4.1. At the present time it is an open question whether the strict convexity of X^* could be removed.

5. Applications. This section discusses some interesting and important cases covered by our result.

(1) The control problem with fixed endpoints. The constraint of this problem is $S=\{(x_0,x_1)\}$. Thus, we have $Q=\{x_1-G_1(T,0)x_0\}$. Hence, provided (H0)-(H3) hold and $\mathscr{R}$ is finite-codimensional in X, the maximum principle holds. This is the result of Fattorini [19].

(2) The control problem with a terminal end constraint. In this problem, we have $S=\{x_0\}\times Q_1$. Thus, $Q=Q_1-G_1(T,0)x_0$ is finite-codimensional in X is the same as Q_1 is so. Hence, provided (H0)-(H3) hold and Q_1 is finite-codimensional in X, the maximum principle holds. This is the result of Li and Yao [25]. The difference is that they did not assume the strict convexity of X^*.

(3) The control problem with separated end constraints. For this problem, $S = Q_0 \times Q_1$. We have that the maximum principle holds if (H0)-(H3) hold and $Q = Q_1 - G_1(T, 0)Q_0$ is finite-codimensional in X. This result is new.

(4) The optimal periodic control problem. The periodicity of the problem gives $S = \{(x, x) | x \in X\}$. In addition to (H0)-(H3), let us assume that $G(\cdot, \cdot)$, f^0 and f satisfy the periodic conditions:

(H4) For any $0 \leqq s \leqq t$, $x \in X$, and $u \in U$,

$$G(t+T, s+T) = G(t, s), \tag{5.1}$$

$$f(t+T, x, u) = f(t, x, u), \tag{5.2}$$

$$f^0(t+T, x, u) = f^0(t, x, u). \tag{5.3}$$

From Theorem 2.3, we have the following theorem.

THEOREM 5.1. *Let* (H0)-(H4) *hold, and let* $\mathcal{R}$ – Range $(I - G_1(T, 0))$ *be finite-codimensional in X. Then, the maximum principle holds for the periodic optimal control problem, i.e., there exist* $\psi^0 \leqq 0$ *and* $\psi(\cdot)$ *satisfying* (2.16) *with the periodic condition* $\psi(T) = \psi(0)$, *such that the maximum condition* (2.17) *holds and* $(\psi^0, \psi(\cdot)) \neq 0$.

COROLLARY 5.2. *Assume that* (H0)-(H4) *hold and* $G_1(T, 0)$ *is a compact operator on X. Then, the maximum principle holds for the optimal periodic control problem.*

Here we only need to note that when $G_1(T, 0)$ is compact, then $I - G_1(T, 0)$ is a Fredholm operator on X and thus it has a finite-codimensional range. Then, Theorem 5.1 applies.

Finally, let us give two interesting examples.

Example 5.3. Let $r > 0$, $X = C([-r, 0]; \mathbb{R}^n)$. Then, X is separable. Thus, we may endow a new norm to X so that X^* is strictly convex (see [12]-[14]). Consider the following functional differential system

$$\frac{dx(t)}{dt} = f(t, x_t, u(t)), \tag{5.4}$$

where $f: \mathbb{R} \times X \times \mathbb{R}^m \to \mathbb{R}^n$ is a given map and $x_t \in X$ is defined by

$$x_t(\theta) = x(t+\theta) \quad \forall \theta \in [-r, 0],$$

whenever $x(\cdot)$ is continuous. Furthermore, we let $f^0: \mathbb{R} \times X \times \mathbb{R}^m \to \mathbb{R}$ be given. We assume that (H2) and (5.2)-(5.3) hold for the maps f and f^0. Now, we let $G_1(\cdot, \cdot)$ be the solution operator of the variational equation

$$\frac{d\delta x(t)}{dt} = f_y(t, x_t, u(t))\delta x_t, \tag{5.5}$$

where $f_y(t, x_t, u)$ is the Fréchet derivative of $f(t, x_t, u)$ in x_t. From Hale [21], we know that $G_1(T, 0)$ is compact for $T > r$. Thus, by Corollary 5.2, if the period $T > r$, then the maximum principle holds for the periodic optimal control problem of functional differential system (5.4) without any additional condition. Here, we eliminate the conditions imposed by Colonius [10], Li [23], or Li and Chow [24] in proving the similar result. In this example, we may also take $X = W^{1,p}([-r, 0]; \mathbb{R}^n)$ with $1 \leqq p < \infty$.

Example 5.4. Let $\Omega \subset \mathbb{R}^n$ be a bounded region with smooth boundary Γ. Let $a_{ij} \in C^2(\Omega)$ such that for some constant $\alpha > 0$,

$$\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geqq \alpha \sum_{i=1}^{n} \xi_i^2 \quad \forall \xi = (\xi_1, \cdots, \xi_n) \in \mathbb{R}^n, \quad x \in \Omega. \tag{5.6}$$

Consider the parabolic system

$$\begin{aligned} &\frac{\partial y}{\partial t}=\sum_{i,j=1}^{n} a_{ij}(x)\frac{\partial^2 y}{\partial x_i\,\partial x_j}+f(t,x,y,u(x,t)), \qquad (t,x)\in\mathbb{R}\times\Omega,\\ &y(T,x)=y(0,x), \qquad x\in\Omega,\\ &y(t,x)=0, \qquad (t,x)\in\mathbb{R}\times\Gamma, \end{aligned} \tag{5.7}$$

where $f:\mathbb{R}\times\Omega\times\mathbb{R}\times\mathbb{R}^m\to\mathbb{R}$ is a continuous function such that f_y is continuous and

$$f(t+T,\cdot,\cdot,\cdot)=f(t\cdot,\cdot,\cdot).$$

If we let

$$Ay=-\sum_{i,j=1}^{n} a_{ij}(x)\frac{\partial^2 y}{\partial x_i\,\partial x_j},$$

with the Dirichlet boundary condition, then e^{-At} is an analytic semigroup on $X\equiv L^2(\Omega)$ which is compact for all $t>0$ [20], [27]. Now, let

$$J(u(\cdot))=\int_0^T\int_\Omega f^0(t,x,y(t,x),u(t,x))\,dx\,dt. \tag{5.8}$$

We consider the following periodic optimal control problem.

Minimize $J(\cdot)$ subject to the parabolic system (5.7), with

$$\begin{aligned} &u(t,\cdot)\in\mathcal{U}_{\mathrm{ad}}\subseteq L^\infty(\Omega) \quad \text{a.e. } t\in[0,T],\\ &u(t+T,\cdot)=u(t,\cdot). \end{aligned} \tag{5.9}$$

Now, if $(\bar y(\cdot,\cdot),\bar u(\cdot,\cdot))$ is optimal, then it is not hard to show that the evolution operator $G_1(t,s)$ of the variational equation:

$$\begin{aligned} &\frac{\partial(\delta y)}{\partial t}=\sum_{i,j=1}^{n} a_{ij}(x)\frac{\partial^2(\delta y)}{\partial x_i\,\partial x_j}+f_y(t,x,\bar y(t,x),\bar u(x,t))\delta y, \qquad (t,x)\in\mathbb{R}\times\Omega,\\ &y(0,x)=y_0(x), \qquad x\in\Omega,\\ &y(t,x)=0, \qquad (t,x)\in\mathbb{R}\times\Gamma, \end{aligned} \tag{5.10}$$

has the property that $G_1(T,0)$ is compact. Thus, the maximum principle holds for this periodic optimal control problem.

Acknowledgments. The authors thank the referees for pointing out a mistake in the original version of the paper.

OPTIMAL CONTROL WITH INFINITE HORIZON FOR DISTRIBUTED PARAMETER SYSTEMS WITH CONSTRAINED CONTROLS*

G. DI BLASIO†

Abstract. Optimal control problems for systems governed by linear partial differential state equations with constrained controls are studied. If the dynamics are stabilizable with respect to the cost, it is proved that the value function is a generalized solution for the associated stationary Hamilton-Jacobi equation. Moreover, the feedback formula and uniqueness are proved under suitable assumptions.

Key words. Hamilton-Jacobi equations, optimal control problem, constrained controls

AMS(MOS) subject classifications. 49C20, 34G20

1. Introduction and statement of results. Let X and U be real separable Hilbert spaces with inner product $\langle\,,\rangle_X$ and $\langle\,,\rangle_U$, respectively. We will be concerned with the following problem. Minimize the functional

$$J_\infty(u,x)=\int_0^{+\infty}[h(u(t))+g(y(t))]\,dt \tag{1}$$

over all measurable $u: R_+\to U$ and $y: R_+\to X$ satisfying the state equation (in the mild sense)

$$y'(t)=Ay(t)+Bu(t),\quad t\geqq 0,\qquad y(0)=x \tag{2}$$

and the control constraint

$$u(t)\in C,\qquad t\geqq 0. \tag{3}$$

Here

(i) $h: U\to R$ is defined as $h(u)=\frac{1}{2}\|u\|_U^2$ if $u\in C$, whereas $h(u)=+\infty$ if $u\notin C$;

(ii) $g: X\to R_+$ is a lower semicontinuous (l.s.c.) convex function;

(iii) $A: D(A)\subseteq X\to X$ is the infinitesimal generator of a C_0-semigroup $S(t)$ satisfying $\|S(t)x\|_X\leqq \exp(\omega t)\|x\|_X$, for some $\omega\in R$;

(iv) $B\in L(U,X)$;

(v) $C\subseteq U$ is a closed, convex, and bounded set containing the origin.

We will follow the dynamic programming approach, which exploits the connection of (1)-(3) with the following stationary Hamilton-Jacobi equation:

$$H(B^*\varphi_x(x))-\langle\varphi_x(x),Ax\rangle_X=g(x), \tag{4}$$

where B^* is the adjoint of B and $H: U\to R$ is defined as

$$H(u)=\tfrac{1}{2}[\|u\|_U^2-\|u+P_C(-u)\|_U^2]$$

(here $P_C(u)$ denotes the projection of u on C).

In the case where $g(\cdot)=\frac{1}{2}\|\cdot\|_X^2$ and $C=U$ problem (1)-(3) reduces to the well-known linear-quadratic optimal control problem and (4) is replaced by the algebraic Riccati equation. For this problem and the connection with the algebraic Riccati equation there is an almost complete theory (see, e.g., the review paper of Pritchard and Zabczyk [12] and the references therein).

In this paper we prove that there exists an optimal pair for (1)-(3) if and only if (4) admits a solution. Moreover, we will give sufficient conditions for the existence of solutions of (4). These solutions will be obtained as

$$\varphi(x) = \lim_{t\to\infty} \underline{\varphi}(t, x),$$

where $\underline{\varphi}$ is the solution of the Hamilton-Jacobi equation

$$\varphi_t(t, x) + H(B^*\varphi_x(t, x)) - \langle \varphi_x(t, x), Ax\rangle_X = g(x) \tag{5}$$

satisfying

$$\varphi(0, x) = 0.$$

Stationary Hamilton-Jacobi equations have been studied by Crandall and Lions [5]-[7] in the case where the equations contain an additional term $\varepsilon\varphi$ with $\varepsilon > 0$. This regularization does not allow for the study of problem (1)-(3). We also recall the results of Cannarsa and Da Prato [4] who have studied (1)-(3) and the corresponding Hamilton-Jacobi equation in the case where h and g are locally Lipschitz and convex functions and the operator A is replaced by $A_1 + F$, where A_1 generates an analytic semigroup and F is nonlinear.

The plan of the paper is as follows. In § 2 we recall some results concerning an approximated version of (5). In §§ 3-4 we prove existence and establish some properties of solutions of (5). Furthermore, in § 5 we study the existence of solutions of (4) together with the connection with problem (1)-(3). Moreover, we give sufficient conditions for the feedback formula and for uniqueness. Finally in § 6 we consider an application to a partial differential state equation.

2. Preliminaries. The approximating Hamilton–Jacobi equation. In this section we recall some results of [8], which will be needed in the sequel. We use the following notation for functions $\varphi: X \to R$:

$$C_2(X) = \{\varphi \text{ is continuous}, \sup\,(|\varphi(x)|/(1+\|x\|^2)) < +\infty\},$$

$$|\varphi(\cdot)|_R = \sup_{\|x\|\leqq R} |\varphi(x)|,$$

$$C^1_{\mathrm{Lip}}(X) = \{\varphi \text{ is Fréchet-differentiable}, \sup_{x\neq y}((\|\varphi'(x)-\varphi'(y)\|)/(\|x-y\|)) < +\infty\}$$

(here and in the following the subscripts X and U in the scalar products are omitted for simplicity in notation).

Let $F: X \to R$ be the function defined as $F(x) = H(B^*x)$

$$F(x) = \tfrac{1}{2}(\|B^*x\|^2 - \|B^*x + P_C(-B^*x)\|^2); \tag{6}$$

then it can be proved (see [8, § 2]) that F is convex, Fréchet differentiable and

$$F'(x) = -BP_C(-B^*x). \tag{7}$$

Furthermore, we denote by F^* the conjugate function of F

$$F^*(x) = \sup_{y\in X}\{\langle x, y\rangle - F(y)\}. \tag{8}$$

Hence F^* satisfies the property

$$\langle x, y\rangle \leqq F^*(x) + F(y) \quad \text{with equality holding iff } x = F'(y). \tag{9}$$

Now let K_0 be the subset of $C^1_{\mathrm{Lip}}(X)$ defined as

$$K_0 = \{\varphi \in C^1_{\mathrm{Lip}}(X): \varphi \text{ is convex}, \varphi(0) = \varphi'(0) = 0\}. \tag{10}$$

For given $\varphi \in K_0$ and $\lambda > 0$ we set

$$\varphi_\lambda(x) = \inf_{y \in X} \left\{ \varphi(y) + \lambda F^*\left(\frac{x-y}{\lambda}\right)\right\}. \tag{11}$$

It can be proved that the infimum is attained at $y = J_\lambda(x)$, where

$$J_\lambda(x) = (1 + \lambda F'\varphi')^{-1}(x). \tag{12}$$

Therefore

$$\varphi_\lambda(x) = \varphi(J_\lambda(x)) + \lambda F^*\left(\frac{x - J_\lambda(x)}{\lambda}\right). \tag{13}$$

In the case where $F(x) = \frac{1}{2}\|x\|^2$, (i.e., when $B = I$ and $C = U$), the functions φ_λ given by (11) reduce to the well-known regularization of convex functions. In the present context it can be proved that φ_λ satisfy the following properties (see [8, § 3]):

(i) $\varphi_\lambda \in K_0$, $\varphi_\lambda(x) \leqq \varphi(x)$,

(ii) $\lim_{\lambda \downarrow 0} \varphi_\lambda(x) = \varphi(x)$,

(iii) $\lim_{\lambda \downarrow 0} (\varphi(x) - \varphi_\lambda(x))/\lambda = F(\varphi'(x))$.

In view of (iii) we will replace the Hamilton-Jacobi equation (5) by the following approximating equation:

$$\varphi_t(t, x) + 1/\lambda(\varphi(t, x) - \varphi_\lambda(t, x)) - \langle Ax, \varphi_x(t, x)\rangle = g(x). \tag{14}$$

Equation (14) and the initial condition

$$\varphi(0, x) = f(x) \tag{15}$$

yield to the integral equation

$$\begin{aligned} \varphi(t, x) = \exp\left(-\frac{t}{\lambda}\right) f(S(t)x) + \int_0^t \exp\left(\frac{s-t}{\lambda}\right) \\ \cdot \left[\frac{1}{\lambda}\varphi_\lambda(s, S(t-s)x) + g(S(t-s)x)\right] ds, \end{aligned} \tag{16}$$

where $S(t)$ is the semigroup generated by A. Conversely, if φ satisfy (16), then it is easy to see that for each $x \in D(A)$ the function $t \to \varphi(t, x)$ is continuously differentiable and satisfies (14)-(15).

We have the following lemma (see [8, Thm. 3]).

LEMMA 1. *Let $f, g \in K_0$. Then there exists a unique $\varphi^\lambda \in C(0, T; C_2(X))$ such that $\varphi^\lambda(t, \cdot) \in K_0$, $t \to \varphi(t, x)$ is continuously differentiable for $x \in D(A)$, and φ^λ is a solution of* (16). *Moreover, for each $R > 0$ we have*

$$|\varphi^\lambda(t, \cdot)|_R \leqq |f(\cdot)|_{R\exp(\omega t)} + t|g(\cdot)|_{R\exp(\omega t)}, \tag{17}$$

where ω satisfies $\|S(t)\| \leqq \exp(\omega t)$.

Proof. The existence of a unique solution of (16) is proved in Theorem 3 of [7]. To prove (17) set

$$\psi(t, x) = \varphi^\lambda(t, \exp(-\omega t)x). \tag{18}$$

Then ψ satisfies

$$\psi_t(t, x) + \frac{1}{\lambda}[\psi(t, x) - (\varphi^\lambda)_\lambda(t, \exp(-\omega t)x)] - \langle A_1 x, \psi_x(t, x)\rangle = g(\exp(-\omega t)x),$$

where $A_1 = A - \omega I$. Therefore

$$\psi(t, x) = \exp\left(-\frac{t}{\lambda}\right) f(S_1(t)x) + \int_0^t \exp\left(\frac{s-t}{\lambda}\right)$$
$$\cdot \left[\frac{1}{\lambda}(\varphi^\lambda)_\lambda(s, S_1(t-s)\exp(-\omega s)x) + g(S_1(t-s)\exp(-\omega s)x)\right] ds,$$

where S_1 is the semigroup generated by A_1. Now from property (i) we have

$$(\varphi^\lambda)_\lambda(s, S_1(t-s)\exp(-\omega s)x) \leqq \varphi^\lambda(s, S_1(t-s)\exp(-\omega s)x) = \psi(s, S_1(t-s)x)$$

so that

$$|\psi(t, \cdot)|_R \leqq \exp\left(-\frac{t}{\lambda}\right)|f(\cdot)|_R + \int_0^t \exp((s-t)/\lambda)\left[\frac{1}{\lambda}|\psi(s, \cdot)|_R + |g(\cdot)|_R\right] ds$$

and hence

$$\exp\left(\frac{t}{\lambda}\right)|\psi(t, \cdot)|_R \leqq |f(\cdot)|_R + \int_0^t \exp\left(\frac{s}{\lambda}\right)|g(\cdot)|_R\, ds + \int_0^t \exp\left(\frac{s}{\lambda}\right)\frac{1}{\lambda}|\psi(s, \cdot)|_R\, ds.$$

Therefore from the Gronwall inequality we get

$$\exp\left(\frac{t}{\lambda}\right)|\psi(t, \cdot)|_R \leqq |f(\cdot)|_R + \lambda\left[\exp\left(\frac{t}{\lambda}\right) - 1\right]|g(\cdot)|_R$$
$$+ \int_0^t \exp\left(\frac{t-s}{\lambda}\right)\frac{1}{\lambda}\left[|f(\cdot)|_R + \lambda\left(\exp\left(\frac{s}{\lambda}\right) - 1\right)|g(\cdot)|_R\right] ds$$

so that (17) follows from (18). □

The following lemma establishes a monotonicity result for the solutions of (16).

LEMMA 2. *Let φ and $\tilde\varphi$ be the solutions of* (16) *with data* (f, g) *and* $(\tilde f, \tilde g)$, *respectively. If $\tilde f \leqq f$ and $\tilde g \leqq g$, then $\tilde\varphi \leqq \varphi$.*

Proof. The existence of solutions of (16) can be proved by a fixed point argument (see [8, Thm. 3]). Therefore the assertion $\tilde\varphi \leqq \varphi$ is a consequence of the fact that $\tilde\varphi \leqq \varphi$ imply $\tilde\varphi_\lambda \leqq \varphi_\lambda$, where φ_λ is defined by (11). □

3. Solutions to the Hamilton–Jacobi equation.

DEFINITION 1. Let $f, g \in K_0$ (where K_0 is defined by (10)). We say that a continuous function $\varphi: [0, T] \times X \to R$ is a *strong solution* of the problem

$$\begin{aligned} &\varphi_t(t, x) + H(B^*\varphi_x(t, x)) - \langle Ax, \varphi_x(t, x)\rangle = g(x), \\ &\varphi(0, x) = f(x), \end{aligned} \tag{19}$$

if

(i) $\varphi(t, \cdot) \in K_0$; $\varphi(\cdot, x) \in \text{Lip}(0, T)$, for each $x \in D(A)$,

(ii) there exist $\{f_n\}, \{g_n\} \subseteq K_0$ and $\{\varphi_n\} \subseteq C(0, T; C_2(X))$ verifying $\varphi_n(t, \cdot) \in K_0$; for each $x \in D(A)$ $t \to \varphi_n(t, x)$ is continuously differentiable. Moreover,

$$f_n \to f, \quad \text{in } C_2(X), \quad g_n \to g \quad \text{in } C_2(X), \quad \varphi_n \to \varphi \quad \text{in } C(0, T; C_2(X)),$$

and

$$\frac{\partial}{\partial t}\varphi_n(t, x) + H(B^*\varphi_{nx}(t, x)) - \langle Ax, \varphi_{nx}(t, x)\rangle = g_n(x),$$

$$\varphi_n(0, x) = f(x).$$

We have the following existence result.

THEOREM 1. *For each $f, g \in K_0$ there exists a unique strong solution of problem* (19) *and we have*

(i) $\varphi = \lim_{\lambda \downarrow 0} \varphi^\lambda$ *in* $C(0, T; C_2(X))$, *where* φ^λ *is the solution of* (16).

Moreover, we have

(ii) $|\varphi(t, \cdot)|_R \leqq |f(\cdot)|_{R\exp(\omega t)} + t|g(\cdot)|_{R\exp(\omega t)}$.

Furthermore, if φ and $\tilde{\varphi}$ are strong solutions of (19) *with data (f, g) and $(\tilde{f}, \tilde{g})$, respectively, and $\tilde{f} \leqq f$, $\tilde{g} \leqq g$, then*

(iii) $\tilde{\varphi}(t, \cdot) \leqq \varphi(t, \cdot)$.

Proof. Assertion (i) is proved in Theorem 4 of [8]. Assertions (ii) and (iii) are consequences of property (i), (17), and Lemma 2. □

Now set

$$J(u, x) = f(y(T)) + \int_t^T [h(u(s)) + g(y(s))]\, ds \tag{20}$$

and consider the problem of minimizing $J(u, x)$ over all (y, u) satisfying

$$y'(s) = Ay(s) + Bu(s), \quad t \leqq s \leqq T, \qquad y(t) = x. \tag{21}$$

The following theorem concerns the connection between strong solutions of (19) and problems (20)-(21).

THEOREM 2. *Let φ be the strong solution of* (19). *Then for each (y, u) satisfying* (21) (*in the mild sense*) *we have*

$$\varphi(T-t, x) + \int_t^T \frac{1}{2} \|P_C(-B^*\varphi_x(T-s, y(s))) - u(s)\|^2\, ds \leqq J(u, x). \tag{22}$$

If in addition (y^*, u^*) in (21) *satisfies*

$$u^*(s) = P_C(-B^*\varphi_x(T-s, y^*(s)),$$

then

$$\varphi(T-t, x) = f(y^*(T)) + \int_t^T [h(u^*(s)) + g(y^*(s))]\, ds. \tag{23}$$

Proof. Using (31) of [7], we have

$$\varphi(T-t, x) + \int_t^T [H(B^*\varphi_x(T-s, y(s))) + \langle \varphi_x(T-s, y(s)), Bu(s)\rangle + \tfrac{1}{2}\|u\|^2]\, ds \leqq J(u, x).$$

Furthermore, from the convexity of C we have

$$\langle B^*\varphi_x(T-s, y(s)) + P_C(-B^*\varphi_x(T-s, y(s))), u(s) - P_C(-B^*\varphi_x(T-s, y(s)))\rangle \geqq 0$$

so that from (6)

$$\begin{aligned} &H(B^*\varphi_x(T-s, y(s))) + \langle \varphi_x(T-s, y(s)), Bu(s)\rangle \\ &\quad = -\tfrac{1}{2}\|P_C(-B^*\varphi_x(T-s, y(s)))\|^2 - \langle B^*\varphi_x(T-s, y(s)), P_C(-B^*\varphi_x(T-s, y(s)))\rangle \\ &\qquad + \langle B^*\varphi_x(T-s, y(s)), u(s)\rangle \\ &\quad \geqq \tfrac{1}{2}\|P_C(-B^*\varphi_x(T-s, y(s)))\|^2 - \langle P_C(-B^*\varphi_x(T-s, y(s))), u(s)\rangle \end{aligned}$$

and (22) is proved. Assertion (23) is proved in Theorem 5 of [8]. □

In the following we need existence for solutions of (19) with more general data (f, g). To this end we introduce the subset K_0'' defined as

$$K_0'' = \{\varphi : X \to R\colon \varphi \text{ is convex and l.s.c., } 0 \in \operatorname{Int} D(\varphi),\ \varphi(0) = 0, 0 \in \partial\varphi(0)\}. \tag{24}$$

As usual, we denote by $D(\varphi)$ the effective domain of φ

$$D(\varphi)=\{x\in X\colon \varphi(x)<+\infty\}$$

and by $\partial\varphi$ the subdifferential of φ

$$\partial\varphi(x)=\{x'\in X\colon \varphi(x+y)\geqq \varphi(x)+\langle y, x'\rangle, \forall y\in X\}.$$

DEFINITION 2. Let $f, g\in K_0''$. We say that a function φ from $[0, T]\times X$ into R is a *generalized solution* of (19) if

(i) $\varphi(t,\cdot)\in K_0''$,

(ii) there exist $\{f_\varepsilon\}, \{g_\varepsilon\}\subseteq K_0$ and $\{\varphi_\varepsilon\}$ such that

$$f_\varepsilon\uparrow f,\quad g_\varepsilon\uparrow g,\quad \varphi_\varepsilon(t,x)\to\varphi(t,x),$$

moreover, φ_ε is the strong solution of the problem

$$\begin{aligned}&\varphi_t(t,x)+H(B^*\varphi_x(t,x))-\langle Ax, \varphi_x(t,x)\rangle=g_\varepsilon,\\ &\varphi(0,x)=f_\varepsilon(x).\end{aligned}\tag{25}$$

We have the following existence result.

THEOREM 3. *For each $f, g\in K_0''$ there exists a generalized solution of* (19).

Proof. For each $\varepsilon>0$ set

$$\begin{aligned}f_\varepsilon(x)&=\min_{y\in X}\left[\frac{1}{2\varepsilon}\|x-y\|^2+f(y)\right],\\ g_\varepsilon(x)&=\min_{y\in X}\left[\frac{1}{2\varepsilon}\|x-y\|^2+g(y)\right].\end{aligned}\tag{26}$$

We have $f_\varepsilon, g_\varepsilon\in K_0$ and moreover

$$f_\varepsilon(x)\uparrow f(x),\qquad g_\varepsilon(x)\uparrow g(x).\tag{27}$$

Using Theorem 1(ii) and (iii) and (27) we have that there exists φ_ε strong solution of (25) and moreover

$$|\varphi_\varepsilon(t,\cdot)|_R\leqq|f_\varepsilon(\cdot)|_{R\exp(\omega t)}+t|g_\varepsilon(\cdot)|_{R\exp(\omega t)}\tag{28}$$

and

$$\varphi_\varepsilon(t,x)\leqq\varphi_{\varepsilon'}(t,x),\qquad 0<\varepsilon'<\varepsilon.$$

Therefore there exists φ such that

$$\varphi_\varepsilon(t,x)\uparrow\varphi(t,x).$$

Moreover, we have that $\varphi(t,\cdot)$ is convex and l.s.c. To accomplish the proof it suffices to show that $0\in\operatorname{Int}D(\varphi(t,\cdot))$. Since $0\in\operatorname{Int}D(f)$, $\operatorname{Int}D(g)$ and f and g are convex we have that there exists R' such that $B(0,R')\subseteq D(f), D(g)$ (here $B(0,r)=\{x\in X\colon \|x\|\leqq r\}$). Therefore using (27) and (28), we have that $B(0, R'/\exp(\omega T))\subseteq D(\varphi(t,\cdot))$ so that $0\subseteq\operatorname{Int}D(\varphi(t,\cdot))$. □

We now investigate the connection between the generalized solutions of (19) and the optimal control problem (20)-(21). To this end we set for (y, u) satisfying (21)

$$J_\varepsilon(u,x)=f_\varepsilon(y(T))+\int_t^T[h(u(s))+g_\varepsilon(y(s))]\,ds.$$

We have the following theorem.

THEOREM 4. *Let φ be a generalized solution of* (19). *Then we have*

$$\varphi(T-t,x)=\inf J(u,x).\tag{29}$$

Moreover, if $x \in D(\varphi(T-t, \cdot))$ *then there exists the optimal pair* (y^*, u^*) *for* $J(u, x)$ *and we have*

$$y^* = w - \lim y_\varepsilon, \qquad u^* = w - \lim u_\varepsilon, \tag{30}$$

where $(y_\varepsilon, u_\varepsilon)$ *is optimal for* $J_\varepsilon(u, x)$.

Proof. Let $\{\varphi_\varepsilon\}$, $\{f_\varepsilon\}$, and $\{g_\varepsilon\}$ be given by Definition 2(ii). By (22) we have

$$\varphi_\varepsilon(T-t, x) + \int_t^T \frac{1}{2} \|P_C(-B^*\varphi_{\varepsilon,x}(T-s, y(s))) - u(s)\|^2 \, ds \leqq J_\varepsilon(u, x) \leqq J(u, x). \tag{31}$$

Therefore letting $\varepsilon \to 0$ we get

$$\varphi(T-t, x) \leqq J(u, x). \tag{32}$$

To accomplish the proof of (29) let $(y_\varepsilon, u_\varepsilon)$ in (21) be given by

$$u_\varepsilon(s) = P_C(-B^*\varphi_{\varepsilon,x}(T-s, y_\varepsilon(s))).$$

By (23) we have

$$\varphi_\varepsilon(T-t, x) = J_\varepsilon(u, x). \tag{33}$$

Moreover, since $u_\varepsilon \in C$ and C is bounded we have, for $s \in [t, T]$, $\|u_\varepsilon(s)\| \leqq \text{const}$, so that $\|y_\varepsilon(s)\| \leqq \text{const}$. Therefore there exists a subsequence $\varepsilon_k \to 0$ satisfying, for almost every $s \in [t, T]$,

$$u_{\varepsilon_k}(s) \to u^*(s), \qquad y_{\varepsilon_k}(s) \to y^*(s), \quad \text{weakly} \tag{34}$$

and moreover (y^*, u^*) satisfies (21) (in the mild sense). Now let $\varepsilon' > 0$; since $\{f_\varepsilon\}$ is monotone we have for $\varepsilon_k < \varepsilon'$

$$f_{\varepsilon_k}(y_{\varepsilon_k}(T)) \geqq f_{\varepsilon'}(y_{\varepsilon_k}(T))$$

so that

$$\liminf f_{\varepsilon_k}(y_{\varepsilon_k}(T)) \geqq f_{\varepsilon'}(y^*(T)),$$

which in turn implies

$$\liminf f_{\varepsilon_k}(y_{\varepsilon_k}(T)) \geqq f(y^*(T)).$$

In the same way we find

$$\liminf g_{\varepsilon_k}(y_{\varepsilon_k}(s)) \geqq g(y^*(s)).$$

Hence we get from (33)

$$\varphi(T-t, x) \geqq J(u^*, x) \tag{35}$$

so that from (32)

$$\varphi(T-t, x) = J(u^*, x)$$

and (29) is proved. Moreover, if $x \in D(\varphi(T-t, \cdot))$, then (y^*, u^*) is optimal. Since the optimal pair is unique, by the same argument used above we prove that each subsequence of $(y_\varepsilon, u_\varepsilon)$ contains a subsequence that converges weakly to (y^*, u^*). □

4. Properties of the solutions of the Hamilton–Jacobi equation. In this section we establish a number of properties of the solutions of (19). We begin with the following result.

THEOREM 5. *For each $f, g \in K_0''$ there exists a unique generalized solution of* (19). *If, in addition, $D(f) = D(g) = X$, then we have*

(i) $D(\varphi(t, \cdot)) = X$,

(ii) *$\varphi(t, \cdot)$ is locally Lipschitz continuous on X, uniformly for $t \in [0, T]$,*

(iii) *$\varphi(\cdot, x)$ is Lipschitz continuous on $[0, T]$ for each $x \in D(A)$,*

(iv) *φ is continuous on $[0, T] \times X$,*

(v) *the optimal pair (y^*, u^*) satisfies the feedback formula $u^*(s) \in P_C(-B^* \partial_x \varphi(T - s, y^*(s)))$, for a.e. $s \in [0, T]$ (where $\partial_x \varphi(t, x)$ denotes the subdifferential of $x \to \varphi(t, x)$).*

Proof. The existence and the uniqueness of φ are proved in Theorem 3 and in (29). To prove (i) and (ii) let us use (29) with $u = 0$

$$\varphi(T - t, x) \leqq f(\exp(A(T - t))x + \int_t^T g(\exp(A(s - t))x)\, ds.$$

Since $D(f) = D(g) = X$ we have, by well-known properties of l.s.c. and convex functions, that f and g are continuous on X. Therefore the functions $F_1(x) = \sup_{s \in [0, T]} f(\exp(As)x)$ and $G_1(x) = \sup_{s \in [0, T]} g(\exp(As)x)$ are finite for each $x \in X$. Since they are l.s.c. and convex functions, we have that F_1 and G_1 are continuous on X. Thus for each $x \in X$ there exist r_x and M_x such that

$$\varphi(T - t, y) \leqq M_x, \quad y \in B(x, 2r_x), \quad t \in [0, T] \tag{36}$$

and (i) is proved. Moreover, we have (see, e.g., [9, Cor. 1.2.4]) that $\varphi(t, \cdot)$ is Lipschitz continuous on $B(x, r_x)$ with Lipschitz constant $M_x r_x^{-1}$, which proves (ii). To prove (iii) fix $t_1, t_2 \in [0, T]$ with $t_1 < t_2$ and let (y_1^*, u_1^*) be optimal at (t_1, x), we have

$$\begin{aligned} |\varphi(T - t_1, x) - \varphi(T - t_2, x)| &\leqq |\varphi(T - t_1, x) - \varphi(T - t_2, y_1^*(t_2))| \\ &\quad + |\varphi(T - t_2, y_1^*(t_2)) - \varphi(T - t_2, x)| = I_1 + I_2. \end{aligned}$$

Since the restriction of (y_1^*, u_1^*) to $[t_2, T]$ is optimal at $(t_2, y_1^*(t_2))$, we have

$$I_1 = \int_{t_1}^{t_2} h(u_1^*(s)) + g(y_1^*(s))\, ds = I_1' + I_1''.$$

Since $u_1^*(s) \in C$, and C is bounded, we have $\|u_1^*(s)\| \leqq$ const. so that

$$I_1' \leqq c(t_2 - t_1).$$

Moreover, if $x \in D(A)$

$$\begin{aligned} \|y_1^*(s) - x\| &\leqq \|\exp((s - t_1)A)x - x\| + \left\| \int_{t_1}^{s} Bu_1^*(\sigma)\, d\sigma \right\| \\ &\leqq \left\| \int_0^{s - t_1} A \exp(\sigma A)x\, d\sigma \right\| + c(t_2 - t_1) \\ &\leqq (\exp(\omega T)\|Ax\| + c)(t_2 - t_1). \end{aligned}$$

Since g is continuous at x there exist r_x and M_x such that if $y \in B(x, r_x)$, then $g(y) \leqq M_x$. Therefore if $t_2 - t_1 \leqq r_x' = r_x(\exp(\omega T)\|Ax\| + c) - 1$ we have

$$I_1'' \leqq M_x(t_2 - t_1)$$

so that if $t_2 - t_1 \leqq r_x'$

$$I_1 \leqq I_1' + I_1'' \leqq c_1(x)(t_2 - t_1).$$

Furthermore, using (ii) we have that there exist r''_x and $c_2(x)$ such that for $t_2-t_1 \leqq r''_x$ we get

$$I_2 \leqq c_2(x)(t_2-t_1),$$

which achieves the proof of (iii). Moreover, (iv) follows from (ii) and (36). To prove (v) let us use (31) with (y, u) replaced by (y^*, u^*)

$$\varphi_\varepsilon(T-t, x)+\int_t^T \frac{1}{2}\|P_C(-B^*\varphi_{\varepsilon,x}(T-s, y^*(s)))-u^*(s)\|^2\, ds \leqq J(u, x).$$

Since (y^*, u^*) is optimal we have $\varphi(T-t, x)=J(u^*, x)$; hence there exists $\{\varepsilon_k\}$ such that, for almost every $s\in[0, T]$,

$$\lim P_C(-B^*\varphi_{\varepsilon_k,x}(T-s, y^*(s)))=u^*(s). \tag{37}$$

Now fix $t_0\in[0, T]$. From (36) there exist r_0 and M_0 such that if $s\in[0, T]$ and $\|x-y^*(t_0)\|\leqq r_0$, then $\varphi(T-s, x)\leqq M_0$, so that $\varphi_\varepsilon(T-s, x)\leqq M_0$; moreover, there exists σ_0 such that $|s-t_0|\leqq\sigma_0$ implies $|y^*(s)-y^*(t_0)|\leqq r_0/4$. Therefore using the abovementioned property of convex functions (see [9]) we have that for $s\in[t_0-\sigma_0, t_0+\sigma_0]$ the function $\varphi_\varepsilon(T-s, \cdot)$ is Lipschitz continuous on the ball $B(y^*(s), r_0/4)$ and the Lipschitz constant $c=c(M_0, r_0)$ is independent of ε. Therefore for $s\in[t_0-\sigma_0, t_0-\sigma_0]$ we have

$$\|\varphi_{\varepsilon,x}(T-s, y^*(s))\|\leqq c(M_0, r_0).$$

Since $[0, T]$ is compact we have that there exists c such that for $s\in[0, T]$ we have

$$\|\varphi_{\varepsilon,x}(T-s, y^*(s))\|\leqq c;$$

therefore there exists a subsequence (again denoted by $\{\varepsilon_k\}$) such that

$$w-\lim \varphi_{\varepsilon_k,x}(T-s, y^*(s))=z(s)\in\partial\varphi_x(T-s, y^*(s))$$

so that by (37)

$$u^*(s)=P_C(-B^*z(s))$$

and (v) is proved. □

Remark 1. Due to Asplund's theorem [1] (see also [10, Thm. 2.12]) we have that if $D(f)=D(g)=X$, then the generalized solution of (19) is Fréchet differentiable on a dense subset of X.

The following result concerns monotonicity of the solutions of (19).

THEOREM 6. *Let φ and $\tilde{\varphi}$ be the generalized solutions of* (19) *with data* (f, g) *and* $(\tilde{f}, \tilde{g})$, *respectively. If $\tilde{f}\leqq f$ and $\tilde{g}\leqq g$, then*

$$\tilde{\varphi}(t, x)\leqq\varphi(t, x).$$

Proof. From Theorem 3 and from uniqueness we have that $\varphi=\lim\varphi_\varepsilon$, where φ_ε is the strong solution of (25) with data $(f_\varepsilon, g_\varepsilon)$ given by (26), and similarly for $\tilde{\varphi}$. Hence the assertion follows from Theorem 1(iii) and from the fact that $\tilde{f}_\varepsilon\leqq f_\varepsilon$ and $\tilde{g}_\varepsilon\leqq g_\varepsilon$. □

The following result concerns continuous dependence upon the data.

THEOREM 7. *Let φ and φ_n be the generalized solutions of* (19) *with data* (f, g) *and* (f_n, g_n), *respectively. If $f_n\uparrow f$ and $g_n\uparrow g$, then*

$$\varphi_n(t, x)\uparrow\varphi(t, x).$$

Proof. From Theorem 6 we have that $\{\varphi_n\}$ is nondecreasing. Therefore for each (t, x) there exists

$$\psi(t, x) = \lim \varphi_n(t, x). \tag{38}$$

Furthermore, from (29) we have

$$\varphi_n(T-t, x) \leqq f_n(y(T)) + \int_t^T [h(u(s)) + g_n(y(s))]\, ds \tag{39}$$

over all (y, u) satisfying (21), whereas we have

$$\varphi_n(T-t, x) = f_n(y_n(T)) + \int_t^T [h(u_n(s)) + g_n(y_n(s))]\, ds \tag{40}$$

if $x \in D(\varphi_n(T-t, \cdot))$ and (y_n, u_n) is optimal. Now (38) and (39) imply

$$\psi(T-t, x) \leqq f(y(T)) + \int_t^T [h(u(s)) + g(y(s))]\, ds$$

and hence if φ denotes the generalized solution of (19)

$$\psi(t, x) \leqq \varphi(t, x).$$

Moreover, let $x \in D(\psi(T-t, \cdot))$; using (40) and a computation similar to the one used in proving (34) we get that there exists a subsequence (y_{n_k}, u_{n_k}) such that $y_{n_k} \to y^*$ and $u_{n_k} \to u^*$, weakly, and that

$$\psi(T-t, x) \geqq f(y^*(T)) + \int_t^T [h(u^*(s)) + g(y^*(s))]\, ds.$$

Therefore we have

$$\psi(T-t, x) = \inf J(u, x), \tag{41}$$

where the infimum is taken over all (y, u) satisfying (21). Hence using (29) and (41) we get $\varphi = \psi$ and the assertion is proved. □

Remark 2. Without essential modifications it can be proved that the assertion of Theorem 7 remains true if the assumptions $f_n \uparrow f$ and $g_n \uparrow g$ are replaced by $f_n \downarrow f$ and $g_n \downarrow g$.

The following lemmas are a consequence of Theorem 6.

LEMMA 3. *Let* $\underline{\varphi}$ *be the generalized solution of problem* (19) *with* $f = 0$. *Then* $\underline{\varphi}(\cdot, x)$ *is nondecreasing, for each* $x \in X$.

Proof. For each $t_0 > 0$ we have that $\underline{\varphi}(t + t_0, x)$ is the generalized solution of (19) with $f(x) = \underline{\varphi}(t_0, x) \geqq 0$. Therefore using Theorem 6 we get $\underline{\varphi}(t, x) \leqq \underline{\varphi}(t + t_0, x)$ and the assertion is proved. □

LEMMA 4. *Let* φ *be the generalized solution of* (19), *and let* $\underline{\varphi}$ *be the generalized solution of* (19) *with* $f = 0$. *Then we have*

$$\underline{\varphi}(t, x) \leqq \varphi(t, x).$$

Proof. The assertion is a consequence of Theorem 6. □

We conclude this section with the following definition which is suggested by Lemma 4.

DEFINITION 3. We say that $\underline{\varphi}$ is the minimal solution of

$$\varphi_t(t, x) + H(B^* \varphi_x(t, x)) - \langle Ax, \varphi_x(t, x) \rangle = g(x) \tag{42}$$

if $\underline{\varphi}$ is the generalized solution of (19) with $f = 0$.

5. The stationary Hamilton–Jacobi equation and the infinite horizon problem.

DEFINITION 4. We say that a function $\varphi \in K_0''$ is a *stationary solution* of equation (42) if φ is a generalized solution of (19) with $f(x) = \varphi(x)$.

A stationary solution of (42) will be also called a solution of the equation

$$H(B^*\varphi_x(x)) + \langle Ax, \varphi_x(x)\rangle = g(x). \tag{43}$$

Moreover (43) will be called the *stationary* Hamilton-Jacobi *equation.* Equation (43) generalizes the well-known algebraic Riccati equation. For this equation uniqueness is false in general. Hence we do not expect to have uniqueness for solutions of (43). Therefore it is convenient to introduce the following notation.

DEFINITION 5. We say that $\underline{\varphi}_\infty$ is the *minimal solution* of the stationary Hamilton-Jacobi equation (43) if $\underline{\varphi}_\infty$ is a solution of (43) and for every solution φ of (43) we have

$$\underline{\varphi}_\infty(x) \leqq \varphi(x).$$

The *maximal solution* $\bar{\varphi}_\infty$ is similarly defined.

The following theorem gives sufficient and necessary conditions for the existence of the minimal solution of (43).

THEOREM 8. *Let* $\underline{\varphi}(t, x)$ *be the minimal solution of* (42). *Then* (43) *admits a minimal solution if and only if there exist* $r > 0$ *and* M_x *such that for each* $\|x\| \leqq r$

$$\underline{\varphi}(t, x) \leqq M_x. \tag{44}$$

Moreover, the minimal solution $\underline{\varphi}_\infty$ *is given by*

$$\underline{\varphi}_\infty(x) = \lim_{t\to+\infty} \underline{\varphi}(t, x). \tag{45}$$

Furthermore, we have

$$\underline{\varphi}_\infty(x) = \inf\left\{\underline{\varphi}_\infty(y(T)) + \int_0^T [h(u(s)) + g(y(s))]\, ds\right\}, \tag{46}$$

where the infimum is taken over all (y, u) *satisfying* (21) *with* $t = 0$.

Proof. By Lemma 3 we have that $\underline{\varphi}(\cdot, x)$ is nondecreasing, so that there exists $\underline{\varphi}_\infty$ given by (45). Now let φ be a solution of (43); from Lemma 4 we have $\underline{\varphi}(t, x) \leqq \varphi(x)$ so that $\underline{\varphi}_\infty \leqq \varphi$. Therefore if (43) has a solution, then (44) is satisfied. Conversely, let (44) hold; then we have that $0 \in \operatorname{Int} D(\underline{\varphi}_\infty)$ so that $\underline{\varphi}_\infty \in K_0''$. Furthermore, set $f_n(x) = \underline{\varphi}(n, x)$ and denote by φ_n the generalized solution of (19) with $f = f_n$. Then we have $f_n \uparrow \underline{\varphi}_\infty$ and $\varphi_n(t, x) \uparrow \underline{\varphi}_\infty(x)$ so that by Theorem 7 the function $\underline{\varphi}_\infty$ is a stationary solution of (42). Finally, assertion (46) is a consequence of (29). □

The following theorem establishes a monotonicity result for the minimal solutions of (43).

THEOREM 9. *Let* $\underline{\varphi}_\infty$ *and* $\tilde{\underline{\varphi}}_\infty$ *be the minimal solutions of* (43) *with data g and* $\tilde{g}$, *respectively, and let* $\tilde{g} \leqq g$. *Then we have*

$$\tilde{\underline{\varphi}}_\infty(x) \leqq \underline{\varphi}_\infty(x).$$

Proof. From Lemma 4 we have that $\tilde{\underline{\varphi}}(t, x) \leqq \underline{\varphi}(t, x)$ so that the assertion follows by a passage to the limit. □

Furthermore, the following result concerns continuous dependence upon the data.

THEOREM 10. *Let* $\underline{\varphi}_\infty$ *and* $\underline{\varphi}_{n,\infty}$ *be the minimal solutions of* (43) *with data g and* g_n, *respectively. If* $g_n \uparrow g$, *then*

$$\underline{\varphi}_{n,\infty} \uparrow \underline{\varphi}.$$

Proof. By Theorem 9 we have that $\{\varphi_{n,\infty}\}$ is nondecreasing so that there exists $\psi = \lim \varphi_{n,\infty}$. Moreover, from Theorem 7, ψ is a solution of (43). Furthermore, from Theorem 9 we have $\psi \leqq \underline{\varphi}_\infty$ so that $\psi = \underline{\varphi}_\infty$. □

We now investigate the connection between the minimal solution of (43) and the infinite horizon problem introduced in § 1.

Set

$$J_\infty(u, x) = \int_0^{+\infty} [h(u(s)) + g(y(s))]\, ds,$$

where (y, u) satisfies

$$y'(t) = Ay(t) + Bu(t), \quad t \geqq 0, \qquad y(0) = x. \tag{47}$$

DEFINITION 6. Given $x \in X$ we say that a control $u \in L^2(R_+; U)$ is *admissible* if $J_\infty(u, x) < +\infty$. Moreover, we say that $x \in X$ is *admissible* if there exists an admissible control at x. We denote the set of all admissible initial data by X_0. Moreover, if u is admissible and y verifies (47), we say that (y, u) is an *admissible pair.*

DEFINITION 7. We say that (A, B) is *locally C-stabilizable* with respect to the observation g if $0 \in \operatorname{Int} X_0$. We say that (A, B) is *C-stabilizable* (with respect to g) if $X_0 = X$.

The notion of stabilizability introduced in Definition 7 is a generalization of the one given in the linear quadratic optimal control problem (i.e., in the case where $C = U$ and $g(\cdot) = \frac{1}{2}\|\cdot\|^2$). In this case the stabilizability problem and the connection with the algebraic Riccati equation (which replaces the stationary Hamilton–Jacobi equation (43)) is widely investigated (see, e.g., the review paper [12] and the references therein).

To our knowledge there is no general theory concerning C-stabilizability. In the following we give some sufficient conditions which may be applied to some situations.

We assume that there exist c, γ, and r such that if $\|x\| \leqq r$, then $g(x) \leqq c\|x\|^\gamma$.

Example 1. The simplest example of stabilizability is the case where A is exponentially stable, i.e.,

$$\|\exp(tA)\| \leqq \exp(\omega t) \tag{48}$$

with $\omega < 0$. In this case the control $u = 0$ is admissible for each $\|x\| \leqq r$ so that $B(0, r) \subseteq X_0$. If in addition $D(g) = X$ (i.e., $g(x) < +\infty$ for each x), then $X_0 = X$ and (A, B) is C-stabilizable for each B and C.

Example 2. If the control constraint C is given by

$$C = \{u \in U: \|u\| \leqq K\}, \tag{49}$$

then if A satisfies (48) with $\omega = 0$ and $B^{-1} \in L(X, U)$, we have that (A, B) is locally C-stabilizable. In this case for fixed $x \in B(0, r)$ it suffices to take

$$u(t) = -\varepsilon B^{-1} \exp[t(A - \varepsilon I)]x,$$

where I is the identity operator, and

$$y(t) = \exp[t(A - \varepsilon I)]x,$$

where $\varepsilon \leqq K(\|B^{-1}\| r)^{-1}$. Therefore we have $B(0, r) \subseteq X_0$; moreover, if $D(g) = X$ we have $X_0 = X$ and (A, B) is C-stabilizable.

Example 3. Finally, another example of a C-stabilizable pair (A, B) (with C given by (49)) is the case where (A, B) is stabilizable with respect to I in the sense of linear quadratic optimal control problem. In this case there exists $L \in L(X, U)$ such that

$A-BL$ is exponentially stable, i.e., there exists constants M, $\alpha>0$ verifying $\|\exp[t(A-BL)]\|\leqq M\exp(-\alpha t)$. Now define $r^*=\min(rM^{-1}, KM^{-1}\|L\|^{-1})$; then for each $x\in B(0, r^*)$ it suffices to take

$$u(t)=L\exp[t(A-BL)]x, \qquad y(t)=\exp[t(A-BL)]x$$

so that we have $B(0, r^*)\subseteq X_0$.

We now investigate the connection between the stabilizability of (A, B) and the existence of solutions of (43).

THEOREM 11. *Let there exist the minimal solution of* (43). *Then* (A, B) *is locally C-stabilizable with respect to g and we have* $D(\underline{\varphi}_\infty)=X_0$.

Moreover, for each $x\in X_0$ *there exists an optimal pair* (y^*, u^*) *and we have*

$$\underline{\varphi}_\infty(x)=J_\infty(u^*, x). \tag{50}$$

If in addition $X_0=X$ *and* $D(g)=X$, *then*

$$u^*(t)\in P_C(-B^*\,\partial\underline{\varphi}_\infty(y^*(t))). \tag{51}$$

Proof. Let $\underline{\varphi}$ be the minimal solution of (42); by (29) we have

$$\underline{\varphi}(T, x)=\inf\left\{\int_0^T [h(u(s))+g(y(s))]\,ds\right\} \tag{52}$$

over all (y, u) satisfying

$$y'(s)=Ay(s)+Bu(s), \quad 0\leqq s\leqq T, \qquad y(0)=x. \tag{53}$$

Now let $x\in D(\underline{\varphi}_\infty)$ and let (y_n, u_n) be optimal on $[0, n]$; we have

$$\underline{\varphi}(n, x)=\int_0^n [h(u_n(s))+g(y_n(s))]\,ds. \tag{54}$$

Moreover, let u_n^* be defined as

$$u_n^*(s)=\begin{cases} u_n(s) & \text{if } 0\leqq s\leqq n,\\ 0 & \text{if } n<s\end{cases}$$

and let y_n^* be the solution of (53) with u replaced by u_n^*. Since $\underline{\varphi}(n, x)\leqq\underline{\varphi}_\infty(x)$ we have by (54) that $\{u_n^*\}$ is bounded on $L^2(R_+; U)$. Hence there exists $\{u_{n_k}^*\}$ such that

$$u_{n_k}^*\to u^* \quad \text{weakly in } L^2(R_+; U).$$

Therefore for each $T>0$ we have

$$y_{n_k}^*\to y^* \quad \text{weakly in } L^2(0, T; X).$$

Moreover y^* is the solution of (53) with u replaced by u^*. Furthermore, for $n_k>T$ we have

$$\underline{\varphi}_\infty(x)\geqq\underline{\varphi}(n_k, x)\geqq\int_0^T [h(u_{n_k}^*(s))+g(y_{n_k}^*(s))]\,ds$$

so that

$$\underline{\varphi}_\infty(x)\geqq\int_0^T [h(u(s^*))+g(y^*(s))]\,ds.$$

Since T is arbitrary we get

$$\underline{\varphi}_\infty(x)\geqq\int_0^{+\infty} [h(u^*(s))+g(y^*s)]\,ds \tag{55}$$

so that (y^*, u^*) is admissible and $x \in X_0$. Hence (A, B) is locally C-stabilizable and $D(\underline{\varphi}_\infty) \subseteq X_0$. Conversely if $x \in X_0$ and (y, u) is admissible at x, we have by (52)

$$\underline{\varphi}(T, x) \leqq \int_0^T [h(u(s)) + g(y(s))]\, ds \leqq J_\infty(u, x) \tag{56}$$

so that $x \in D(\underline{\varphi}_\infty)$ and hence $X_0 = D(\underline{\varphi}_\infty)$. Moreover, from (55) and (56) we have

$$\underline{\varphi}_\infty(x) = J_\infty(u^*, x).$$

Finally, (51) follows from (v) of Theorem 5. □

COROLLARY 1. *The following properties are equivalent*:

(i) (A, B) *is locally C-stabilizable with respect to* g;

(ii) *There exists a solution of* (43).

Proof. (I)⇒(ii) Let $x \in X_0$ and let (y, u) be an admissible pair at x. If $\underline{\varphi}$ is the minimal solution of (41) we have, by (29),

$$\underline{\varphi}(T, x) \leqq \int_0^T [h(u(s)) + g(y(s))]\, ds \leqq J_\infty(u, x)$$

so that the assertion follows from Theorem 8. Assertion (ii)⇒(i) is proved in Theorem 11. □

We now give sufficient conditions for the existence of the maximal solution of (43). We begin with the following result.

THEOREM 12. *Let g be coercive, that is, $g(x) \geqq \gamma\|x\|^p$, for some $p \geqq 1$. Moreover, let (A, B) be locally C-stabilizable with respect to g. Then there exists the maximal solution $\bar{\varphi}_\infty$ of* (43) *and we have $\bar{\varphi}_\infty = \underline{\varphi}_\infty$, that is, there exists a unique solution of* (43).

Proof. Let (y^*, u^*) be optimal for $J_\infty(u, x)$ and let φ be a solution of (43). Since φ is a solution of (42) with initial datum φ we have by (29)

$$\varphi(x) \leqq \varphi(y^*(t)) + \int_0^t [h(u^*(s)) + g(y^*(s))]\, ds,$$

hence by (50)

$$\varphi(x) \leqq \varphi(y^*(t)) + \int_0^{+\infty} [h(u^*(s)) + g(y^*(s))]\, ds = \varphi(y^*(t)) + \underline{\varphi}_\infty(x). \tag{57}$$

Since g is coercive we have that $y^* \in L^p(R_+; X)$ for some $p \geqq 1$. This, in turn, implies that there exists $\{t_n\} \uparrow +\infty$ such that $y^*(t_n) \to 0$. Therefore by a passage to the limit we get $\varphi(x) \leqq \underline{\varphi}_\infty(x)$, so that $\underline{\varphi}_\infty$ is maximal. □

Now let us introduce the following notation:

$$g_{(\varepsilon)}(x) = g(x) + \tfrac{1}{2}\varepsilon\|x\|^p,$$

$$J_{\varepsilon,\infty}(u, x) = \int_0^{+\infty} [h(u(s)) + g_{(\varepsilon)}(y(s))]\, ds.$$

We have the following existence result.

THEOREM 13. *Assume that (A, B) is locally C-stabilizable with respect to $g_{(1)}$, for some $p \geqq 1$. Then there exists the maximal solution of* (43) *and we have*

$$\varphi_{\varepsilon,\infty} \downarrow \bar{\varphi}_\infty, \tag{58}$$

where $\varphi_{\varepsilon,\infty}$ is the (*unique*) *solution of*

$$H(B^*\varphi_x(x)) + \langle Ax, \varphi_x(x)\rangle = g_{(\varepsilon)}(x).$$

Proof. By Theorem 9 we have that $\{\varphi_{\varepsilon,\infty}\}$ is nonincreasing so that there exists $\bar{\varphi}_\infty$ given by (58). Moreover, from Remark 2 it follows that $\bar{\varphi}_\infty$ is a solution of (43). To prove that $\bar{\varphi}_\infty$ is maximal let φ be a solution of (43) and let $(y_\varepsilon^*, u_\varepsilon^*)$ be optimal for $J_{\varepsilon,\infty}$. Using (57) with g replaced by $g_{(\varepsilon)}$ we get, since $g_{(\varepsilon)}$ is coercive, $\varphi(x) \leqq \varphi_{\varepsilon,\infty}(x)$. Therefore the conclusion follows by a passage to the limit. □

The following result concerns the connection between the maximal solution of (43) and the infinite horizon problem. We have the following theorem.

THEOREM 14. *Let (A, B) be locally C-stabilizable with respect to $g_{(1)}$ and let $\bar{\varphi}_\infty$ be the maximal solution of* (43). *Moreover, set*

$$Y = \{(y, u) \colon y \in L^2(R_+; X) \text{ and } u \in L^2(R_+; U)\}.$$

Then we have

$$\bar{\varphi}_\infty(x) = \inf J_\infty(u, x),$$

where the infimum is taken over all $(y, u) \in Y$ satisfying (47).

Proof. Let $(y, u) \in Y$ and let $\varphi_{\varepsilon,\infty}$ be defined as in the proof of Theorem 13. By (50) we have

$$\varphi_{\varepsilon,\infty} \leqq J_{\varepsilon,\infty}(u, x)$$

so that by (58) we get $\bar{\varphi}_\infty \leqq J_\infty(u, x)$ and hence $\bar{\varphi}_\infty \leqq \inf_Y J_\infty(u, x)$. Furthermore, let $(y_\varepsilon, u_\varepsilon)$ be optimal for $J_{\varepsilon,\infty}$; we have

$$\varphi_{\varepsilon,\infty}(x) = J_{\varepsilon,\infty}(u_\varepsilon, x) \geqq J_\infty(u_\varepsilon, x) \geqq \inf_Y J_\infty(u, x)$$

and the conclusion follows by a passage to the limit.

The following result concerns monotonicity of the maximal solutions of (43).

THEOREM 15. *Assume that (A, B) is locally C-stabilizable with respect to $g_{(1)}$. Moreover, let $\tilde{g} \leqq g$ and let $\tilde{\bar{\varphi}}_\infty$ and $\bar{\varphi}_\infty$ be the maximal solutions of* (43) *with data $\tilde{g}$ and g, respectively. Then we have*

$$\tilde{\bar{\varphi}}_\infty \leqq \bar{\varphi}_\infty.$$

Proof. The result follows from (58) and from Theorem 9. □

Finally, the following result concerns continuous dependence upon the data.

THEOREM 16. *Let g and g_n be such that $g_n \downarrow g$, and let (A, B) be locally C-stabilizable with respect to $g_{1,(1)}$. Moreover, let φ and $\bar{\varphi}_n$ be the maximal solutions of* (43) *with data g and g_n, respectively. Then $\bar{\varphi}_n \downarrow \bar{\varphi}$.*

Proof. The result follows from (58) and from Theorem 9. □

6. Applications.

In this section we give some examples of optimal control problems which can be studied by means of the results of § 5.

Let Ω be an open bounded set of R^n with smooth boundary $\partial\Omega$ and set $X = L^2(\Omega)$. We denote by A the operator defined as

$$D(A) = \left\{ y \in W^{2,2}(\Omega) \colon \frac{\partial y}{\partial \nu} = 0 \right\},$$

$$Ay = \Delta y, \tag{59}$$

where Δ is the Laplacian operator. Then it is known that A generates a semigroup $\exp(tA)$ verifying

$$\|\exp(tA)y\|_X \leqq \|y\|_X. \tag{60}$$

Moreover, $\sigma(A)$ consists of isolated nonpositive eigenvalues. We denote by X_1 and X_2 the subspaces corresponding to the spectral sets $\sigma_1=\{0\}$ and $\sigma_2=\sigma(A)\backslash\{0\}$. Then

$$X=X_1\oplus X_2 \tag{61}$$

and X_1, X_2 are invariant under A. Moreover, if A_i is the restriction of A to X_i, then $\exp(tA_2)$ is exponentially stable, i.e.,

$$\|\exp(tA_2)y\|_X \leqq M\exp(\omega t)\|y\|_X \tag{62}$$

for some $\omega<0$. Now let U be a real separable Hilbert space and let $B\in L(U,X)$. If $B^{-1}\in L(X,U)$ using (60) and the results of Example 2 of § 5 we have that (A,B) is C-stabilizable with respect to $\frac{1}{2}\|\cdot\|^2$ for any C of the form (49). Therefore we get the following theorem.

THEOREM 17. *Consider the problem of minimizing the functional*

$$J_\infty(u,y_0)=\frac{1}{2}\int_0^{+\infty}dt\int_\Omega [|y(t,x)|^2+|u(t,x)|^2]\,dx \tag{63}$$

over all (y,u) *verifying*

$$\begin{aligned} &y_t(t,x)=\Delta y(t,x)+(Bu)(t,x), \qquad t>0,\quad x\in\Omega,\\ &\frac{\partial}{\partial v}y(t,x)=0, \qquad t>0,\quad x\in\partial\Omega,\\ &y(0,x)=y_0(x), \qquad x\in\Omega,\\ &\int_\Omega |u(t,x)|^2\,dx\leqq K, \qquad t>0, \end{aligned} \tag{64}$$

where $B\in L(X)$. *Then if* $B^{-1}\in L(X)$ *we have*

(i) *For each* $y_0\in L^2(\Omega)$ *there exists an optimal pair* (y^*,u^*) *at* y_0 *for problem* (63), (64). *Moreover we have* $\varphi_\infty(x)=J_\infty(u^*,y_0)$, *where* φ_∞ *is the solution of*

$$\tfrac{1}{2}(\|B^*\,\partial\varphi(y)\|^2-\|B^*\,\partial\varphi(y)+P_C(-B^*\,\partial\varphi(y))\|^2)-\langle\Delta y,\partial\varphi(y)\rangle=\tfrac{1}{2}\|y\|^2$$

and

$$P_C(y)=\begin{cases} y & \text{if } \|y\|\leqq K,\\ \|y\|/K & \text{if } \|y\|>K.\end{cases}$$

Moreover the following feedback formula holds:

(ii) $u^*(t,\cdot)\in P_C(-B^*\,\partial\varphi_\infty(y^*(t,\cdot)))$.

Proof. The result is a consequence of Theorems 11 and 12 and Corollary 1. □

Now let $\psi\in L_\infty(\Omega)$ and let $B\in L(R,X)$ be given by

$$(Bu)(x)=u\cdot\psi(x). \tag{65}$$

We consider the following problem. Minimize the functional

$$J_\infty(u,y_0)=\frac{1}{2}\int_0^{+\infty}dt\left[\int_\Omega |y(t,x)|^2\,dx+|u(t)|^2\right] \tag{66}$$

over all (y,u) satisfying

$$\begin{aligned} &y_t(t,x)=\Delta y(t,x)+u(t)\psi(x), \qquad t>0,\quad x\in\Omega,\\ &\frac{\partial}{\partial \nu}y(t,x)=0, \qquad t>0,\quad x\in\partial\Omega,\\ &y(0,x)=y_0(x), \qquad x\in\Omega,\\ &|u(t)|\leqq K. \end{aligned} \tag{67}$$

To study problem (66), (67) we use the results of Example 3 of § 5 and look for conditions guaranteeing stabilizability in the sense of linear quadratic optimal control (with respect to I) for the pair (A, B) given by (59) and (65). To this end we use (61) and set $\psi=\psi_1+\psi_2$, with $\psi_i \in X_i$; moreover, we denote by $B_i \in L(R, X_i)$ the operator given by

$$(B_i u)(x)=u\psi_i(x). \tag{68}$$

By (62) we have that (A_2, B_2) is stabilizable. Therefore using a result of [11] we have that if (A_1, B_1) is stabilizable then so is (A, B). Finally, it is easy to see that (A_1, B_1) is stabilizable if and only if $\psi_1 \neq 0$, i.e.,

$$\int_\Omega \psi(x)\,dx \neq 0. \tag{69}$$

Therefore using the results of Example 3, Theorems 11 and 12 and Corollary 1, we get the following theorem.

THEOREM 18. *Let ψ satisfy* (69). *Then for each $y_0 \in L^2(\Omega)$ such that $\|y_0\|$ is suitably small there exists an optimal pair (y^*, u^*) at y_0 for problem* (66), (67), *and we have*

$$J_\infty(u^*, y_0)=\varphi_\infty(y_0),$$

where φ_∞ is the minimal solution of

$$\tfrac{1}{2}(\langle\psi, \partial\varphi(y)\rangle)^2-|\langle\psi, \partial\varphi(y)\rangle+P_C(-\langle\psi, \partial\varphi(y)\rangle)|^2-\langle\Delta y, \partial\varphi(y)\rangle=\tfrac{1}{2}\|y\|^2$$

and

$$P_C(u)=\begin{cases} u & \text{if } |u| \leqq K, \\ |u|/K & \text{if } |u|>K. \end{cases}$$

ON OUTPUT FEEDBACK VIA GRASSMANNIANS*

XIAOCHANG WANG†

Abstract. The output feedback pole placement map χ has been studied by using the central projection model. Necessary and sufficient conditions for χ being dominant are given. 2×2 systems of McMillan degree 4 and 2×3 systems of McMillan degree 6 are studied intensively.

Key words. pole placement of linear multivariable systems, Grassmannians, central projection

AMS(MOS) subject classification. 93D15

1. Introduction. Consider a linear system

$$\dot{x} = Ax + Bu, \qquad y = Cx,$$

where x, u, y, are n, m, p, vectors, respectively. The poles of the system are the eigenvalues of A. If an output feedback

$$u = Ky$$

is applied to the system, the closed-loop system becomes

$$\dot{x} = (A + BKC)x.$$

The closed-loop poles became the eigenvalues of $A+BKC$. Identifying a characteristic polynomial with a point in affine n-space $\mathbf{A}^n$, we can define pole placement map $\chi : \mathbf{A}^{mp} \rightarrow \mathbf{A}^n$ by

$$\chi(K) = \det(sI - A - BKC).$$

The output pole placement problem has been studied by many authors. In 1975, Kimura [10] and Davison and Wang [5] proved independently that $m+p-1 \geqq n$ implies the generic pole assignability for generic systems. In 1977, by using the dominant morphism theorem, Hermann and Martin [8] proved that if $[A, X]=0$ and $CXB=0$ implies $X=0$, then the system has the generic pole-assignability by complex feedbacks. They also showed that $mp \geqq n$ implies the generic pole-assignability by complex feedbacks for generic systems. About a decade ago, inspired by a profound geometric construction due to Martin and Hermann [12] and by the questions raised by Willems and Hesslink [18], a geometric framework using Grassmannian variety was developed by Brockett and Byrnes [1], [3]. Since then, many new results have been proved using this framework. In 1981, Brockett and Byrnes [2] proved that when $mp = n$, if a system is nondegenerate, then the system has arbitrary pole-assignability by complex feedback and there are

$$d(m, p) = \frac{1! \cdots (p-1)!(mp)!}{m! \cdots (mp-1)!}$$

such feedback laws to assign each set of n poles. In 1983, by using the Ljusternik-Šnirel'mann category of real Grassmannians, Byrnes [4] proved that L-S$-$ $cat(\text{Grass}_R\ (p, m+p)) \geqq n+1$ implies generic pole assignability by real feedback that, when combined with the new results of L-S category of real Grassmannian, improved

Kimura's result. Recently, a new result that improved Kimura's result was proved by Rosenthal [14] using a very simple argument based on this framework.

One problem in feedback pole placement is to determine whether the pole placement map χ is dominant (see § 2). Note that χ is dominant over **C** if and only if it is dominant over **R**. When χ is dominant, it is almost onto over **C** by the dominant morphism theorem, and its image has nonempty interior over **R**.

Two necessary and sufficient conditions can be deduced from [8] and [18]. They are:

(a) χ is dominant if and only if there exists a K such that $[A+BKC, X]=0$ and $CXB=0$ implies that $X=0$.

(b) χ is dominant if and only if there exists a K such that $\{CB, C(A+BKC)B, \cdots, C(A+BKC)^{n-1}B\}$ are linearly independent.

In both conditions, the K must be determined before the conditions can be used.

In this paper, the dominant morphism theorem is applied to the central projection model of the pole placement map introduced by Byrnes [3]. The main result is that χ is dominant if and only if $mp \geqq n$, $\dim sp\{\text{minors of } G(s)\}=n$ and Grass $(p, m+p)$ is not contained in the Schubert variety $\sigma(E)$ under the embedding induced by the map $i: x \to C(T_x)$, where E is the center of χ. In the cases of 2×2 and 2×3 systems, if $mp=n$, the conditions become very simple: χ is dominant if and only if $\dim sp\{\text{minors of } G(s)\}=n$.

2. Preliminaries. Let X and Y be varieties, a morphism $\varphi: Y \to Y$ is called dominant if $\varphi(X)$ is Zariski-dense in Y. Let $k(X)$ and $k(Y)$ be the function fields of X and Y, then φ induces a homomorphism $\varphi: k(Y)\to k(X)$ by

$$\varphi^*(f(y))=f(y(x)).$$

It is easy to show that φ is dominant if and only if φ^* is one to one [7], [13], [15]. So if φ is dominant, $k(Y)$ can be considered as a subfield of $k(X)$.

PROPOSITION 2.1. *Let X and Y be affine varieties of the same dimensions over an algebraically closed field of characteristic* 0 *and $\varphi: X\to Y$ be a dominant morphism, then there is a Zariski-open set $Y_0 \subset Y$ such that $\#\varphi^{-1}(y)=[k(X): k(Y)]$ for all $y \in Y_0$.*

This is Proposition 3.17 of [13], except we are working over an arbitrary algebraically closed field of characteristic zero. The proof is the same.

The number $[k(X): k(Y)]$ is called the degree of φ.

PROPOSITION 2.2 (dominant morphism theorem). *Let $\varphi: X\to Y$ be a morphism of affine varieties over an algebraically closed field*; *then the following are equivalent*:

(i) *φ is dominant.*

(ii) *$\varphi(X)$ contains a nonempty Zariski open set of Y.*

(iii) *$d\varphi_x$ is onto for some smooth point x of X.*

(i)$\Rightarrow$(ii) is Theorem 6 of [15, § 5, Chap. I]. (i)$\Rightarrow$(iii) is Proposition 3.6 of [13]. (ii)$\Rightarrow$(i) is obvious. To prove (iii)$\Rightarrow$(i), suppose φ is not dominant. Let $Z=\overline{\varphi(X)}$; then $\dim Z < \dim Y$. So $\dim \operatorname{Im} d\varphi_x \leqq \dim Z < \dim Y$, $d\varphi_x$ cannot be onto for any x.

Let k be an algebraically closed field. A dominant morphism $\varphi: Y\to Y$ of affine varieties is called finite if $k[X]$ is integral over $k[Y]$. A finite morphism is epimorphic and it carries closed sets into closed sets of the same dimension [15]. A morphism $\varphi: X\to Y$ of quasi-projective varieties is called finite if every point $y\in Y$ has an affine neighborhood V such that the set $U=f^{-1}(V)$ is affine and $\varphi: U\to V$ is finite.

An example of finite morphism is the central projection. Let E be a d-dimensional subspace of a projective space $\mathbf{P}^n$, determined by $n-d$ linearly independent linear equations $L_1=L_2=\cdots=L_{n-d}=0$. The mapping $\pi(x)=(L_1(x), \cdots, L_{n-d}(x))$ is called a projection with the center at E; π is a morphism $\mathbf{P}^N - E \to \mathbf{P}^{n-d-1}$.

PROPOSITION 2.3. *If X is closed in $\mathbf{P}^n$ and $X \subset \mathbf{P}^n - E$, where E is a d-dimensional subspace, then the projection $\pi: X \to \mathbf{P}^{n-d-1}$ with the center at E determines a finite morphism $X \to \pi(X)$.*

The proof can be found in [15]. The geometrical meaning of the central projection is the following. As a model $\mathbf{P}^{n-d-1}$ we take any $(n-d-1)$-dimensional subspace $H \subset \mathbf{P}^m$ disjoint from E. Through any point $x \in \mathbf{P}^n - E$ and E there passes a unique $(d+1)$-dimensional subspace E_x. This subspace intersects H in a unique point, namely, $\pi(x)$. On the other hand, through any $y \in H$ and E there passes a unique $(d+1)$-dimensional subspace E_y. Then for all $x \in E_y \cap X - E$, $\pi(x) = y$. When $X \cap E = \emptyset$, π is finite, so $E_y \cap X$ has finite many points for all y. By Bezout's theorem (see [16, Prop. 3.26]) we have Proposition 2.4.

PROPOSITION 2.4. *If X is an $(n-d-1)$-dimensional subvariety of $\mathbf{P}^n$ and E is a d-dimensional subspace, $X \subset \mathbf{P}^n - E$, then the projection $\pi: X \to \mathbf{P}^{n-d-1}$with the center at E is onto and for any $y \in \mathbf{P}^{n-d-1}$,*

$$\# \pi^{-1}(y) = \deg X$$

counting multiplicity.

Now we introduce a projective variety, the Grassmannian Grass (m, n). Grass (m, n) is the variety of all *m-dimensional* subspaces in a *n-dimensional* vector space V^n. For each *m-space* $H \subset V^n$, if we choose a basis $\{\alpha_1, \cdots, \alpha_m\}$ and write each α_1 as column vector, then we have an $n \times m$ full rank matrix, $M_\alpha = [\alpha_1, \cdots, \alpha_m]$. For any $n \times m$ full rank matrix M, *col. sp* $M = H$ if and only if $M = M_\alpha T$ for some $T \in \mathrm{GL}(m)$. So we can say that Grass (m, n) is the variety of all $n \times m$ full rank matrices modulo $\mathrm{GL}(m)$. For any $n \times m$ matrix M of rank m, let $x_{i_1, \ldots, i_m}$ be the $m \times m$ minor of M by taking $i_1, \ldots, i_m$ rows of M. Since $x_{i_1, \ldots i_m}(MT) = x_{i_1, \cdots, i_m}(M) \det T$ for any $T \in \mathrm{GL}(m)$, we have an imbedding

$$p: \text{Grass}(m, n) \to \mathbf{P}^N,$$

where $N = \binom{n}{m} - 1$. This imbedding is called the Plücker imbedding. The imbedded Grassmannian is determined by a system of quadratic equations (see [6]).

3. Central projection and output feedback pole placement. Consider the closed-loop characteristic polynomial $\det(sI - A - BKC)$ of a linear system (A, B, C). It is well known that

$$\det(sI - A - BKC) = \det \begin{bmatrix} I & N(s) \\ K & D(s) \end{bmatrix},$$

where $G(s) = N(s) D^{-1}(s)$ is a right coprime factorization of the open-loop transfer function $G(s)$ [2], [3]. Since rank $\left[\begin{smallmatrix} I \\ K \end{smallmatrix}\right] = p$ and rank $\left[\begin{smallmatrix} N(s) \\ D(s) \end{smallmatrix}\right] = m$ for all s, $sp\left[\begin{smallmatrix} I \\ K \end{smallmatrix}\right]$ is a point in Grass $(p, m+p)$ and $sp\left[\begin{smallmatrix} N(s) \\ D(s) \end{smallmatrix}\right]$ is a curve in Grass $(m, m+p)$. We define the Plücker coordinates of Grass $(p, m+p)$ and Grass $(m, m+p)$ in the following way. Put all multiple index $(i_1, \cdots, i_p)$, $1 \leqq i_1 < \cdots < i_p \leqq m+p$ in order such that $(i_1, \cdots, i_p) < (j_1, \ldots, j_p)$ if there exists an s such that $i_t = j_t$ for all $t < s$ and $i_s < j_s$. For an ith index $(i_1, \cdots, i_p)$, let x_i be the $p \times p$ minor of $\left[\begin{smallmatrix} I \\ K \end{smallmatrix}\right]$ by using $i_1, \cdots, i_p$ rows and $p_i(s)$ be the $m \times m$ minor of $\left[\begin{smallmatrix} N(s) \\ D(s) \end{smallmatrix}\right]$ by eliminating $i_1, \cdots, i_p$ rows. Then

$$\det(sI - A - BKC) = \det \begin{bmatrix} I & N(s) \\ K & D(s) \end{bmatrix} \tag{1}$$

$$= \sum_{i=0}^{N} \theta(i) p_i(s) x_i, \tag{2}$$

where

$$N=\binom{m+p}{p}-1 \quad \text{and} \quad \theta(i)=(-1)^{p(p+1)/2+i_1+\cdots+i_p}$$

for the ith index $(i_1,\cdots,i_p)$. Note that $x_0=1$ and $p_0(s)=\det D(s)$. Let $\det(sI-A-BKC)=b_0+b_1s+\cdots+b_ns^n$ and $\theta(i)p_i(s)=a_{0i}+a_{1i}s+\cdots+a_{ni}s^n$. Then by equating coefficients of (1), we have

$$\begin{bmatrix} a_{00} & a_{01} & \cdots & a_{0N} \\ a_{10} & a_{11} & \cdots & a_{1N} \\ \vdots & \vdots & & \\ a_{n0} & a_{n1} & \cdots & a_{nN} \end{bmatrix}\begin{bmatrix} x_0 \\ x_1 \\ \vdots \\ x_N \end{bmatrix}=\begin{bmatrix} b_0 \\ b_1 \\ \vdots \\ b_n \end{bmatrix} \tag{3}$$

or

$$Lx=b. \tag{4}$$

Let $E=\{x\in \mathbf{P}^N \mid Lx=0\}$; then (4) defines a central projection $\chi:\text{Grass}(p,m+p)-E\to \mathbf{P}^{r-1}$, where $r=\operatorname{rank} L$. So the pole placement map is the projection $\chi:\text{Grass}(p,m+p)-E\to\mathbf{P}^{r-1}$.

The geometrical meaning of χ is the following. Let $\mathbf{P}^n$ be the space of all polynomials of degree less than or equal to n with the equivalent relation $f\sim g$ if and only if $f=ag$ for some nonzero number α. Extending (4) to $\mathbf{P}^N$, we have $\tilde{\chi}:\mathbf{P}^N\to\mathbf{P}^n$ such that $\tilde{\chi}|_{\text{Grass}(p,m+p)}=\chi$, $\tilde{\chi}$ is a rational mapping and $\tilde{\chi}(\mathbf{P}^N)=\mathbf{P}^{r-1}\subseteq\mathbf{P}^n$. When we take any $(r-1)$-dimensional subspace $H\subset\mathbf{P}^N$ disjoint from E, $\tilde{\chi}|_H$ is one to one and $\tilde{\chi}(H)=\mathbf{P}^{r-1}$, so $H\cong\operatorname{Im}\tilde{\chi}$. We can identify the points in H with the points in $\operatorname{Im}\tilde{\chi}$. Through any point $x\in\text{Grass}(p,m+p)-E$ and E, there passes a unique $(N-r+1)$-dimensional subspace E_x. This subspace intersects H in a unique point, which is $\chi(x)$.

LEMMA 3.1.

$$\operatorname{rank} L=\dim sp\{\textit{minors of}\, G(s)\}+1,$$

where $sp\{minors\ of\, G(s)\}$ is a subspace spanned over $\mathbf{R}$ in $\mathbf{R}(s)$.

Proof. Since

$$\begin{bmatrix} N(s) \\ D(s)\end{bmatrix}=\begin{bmatrix} G(s) \\ I\end{bmatrix}D(s),$$

comparing the corresponding minors of each side, we have that

$$p_i(s)=m_i(s)\det D(s), \qquad i=1,2,\cdots,N,$$

where $\{m_i, i=1,2,\cdots,N\}$ are all minors of $G(s)$. So

$$\dim sp\{\text{minors of } G(s)\}=\dim sp\{p_i(s), i=1,2,\cdots,N\}.$$

Note that only $p_0(s)$ is a polynomial of degree n; all the other $p_i(s)$'s are polynomials of degree less than n. So

$$\begin{aligned}\dim sp\{p_i(s), i=1,2,\cdots,N\} &\\ &=\dim sp\{p_i(s), i=0,1,2,\cdots,N\}-1\\ &=\operatorname{rank} L-1.\end{aligned}$$

Recall the concept of nondegeneracy introduced by Brockett and Byrnes [2]: $G(s)$ is nondegenerate if and only if no hypersurface $\sigma(\omega)$ in Grass $(m, m+p)$ contains the curve

$$\begin{bmatrix} N(s) \\ D(s) \end{bmatrix},$$

where $\omega \in \text{Grass}\,(p, m+p)$ and

$$\sigma(\omega)=\{\nu \in \text{Grass}\,(m, m+p) \mid \dim\,(\omega \cap \nu) \geqq 1\}.$$

Now from the definition of E we can see that $G(s)$ is nondegenerate if and only if

$$E \cap \text{Grass}\,(p, m+p)=\phi.$$

When $G(s)$ is nondegenerate, the central projection χ is a finite morphism Grass $(p, m+p) \rightarrow \mathbf{P}^n$, since the degree of Grass $(p, m+p)$ is (see [9]):

$$d(m, p)=\frac{1!2!\cdots(p-1)!(mp)!}{m!(m+1)!\cdots(m+p-1)!}.$$

By Proposition 2.4, we have the Brockett-Byrnes theorem [3].

BROCKETT-BYRNES' THEOREM. *Let $G(s)$ be a nondegenerate $p \times m$ transfer function of McMillan degree $n=mp$. For all choices $(s_1, \cdots, s_n)$, we can find*

$$d(m, p)=\frac{1!2!\cdots(p-1)!(mp)!}{m!(m+1)!\cdots(m+p-1)!}$$

feedback laws over the complex field such that the closed-loop poles are exactly $(s_1, \cdots, s_n)$.

Actually, we have proved a more general result.

THEOREM 3.1. *If $G(s)$ is nondegenerate, then the image of χ : Grass $(p, m+p) \rightarrow \mathbf{P}^n$ is an irreducible projective variety of dimension mp. For each $p \in \operatorname{Im} \chi$, there are finite many feedback laws over the complex field such that the closed-loop characteristic polynomial is p.*

When $G(s)$ is degenerate, Grass $(p, m+p)-E$ is a quasi-projective variety and χ : Grass $(p, m+p) \rightarrow \mathbf{P}^n$ is a rational mapping. In this case, χ is almost onto over $\mathbf{C}$ if and only if χ is dominant. Here "almost onto" means that $\operatorname{Im} \chi$ contains a nonempty Zariski open set. We first prove a general result. Recall the concept of affine cone over a projective variety $X \subseteq \mathbf{P}^N$: For any nonempty algebraic set $X \subseteq \mathbf{P}^N$, let $\theta: \mathbf{A}^{N+1}-\{0\} \rightarrow \mathbf{P}^N$ be the mapping that sends the point with affine coordinates $(a_0, \cdots, a_N)$ to the point with homogeneous coordinates $(a_0, \cdots, a_N)$. The affine cone over X is defined as

$$C(X)=\theta^{-1}(X) \cup \{0\},$$

$$\dim C(X)=\dim X+1.$$

The tangent space $T_{x,X}$ of a projective variety X at x is defined as the projective closure of the tangent space of $X \cap U$ at x for any affine piece U of $\mathbf{P}^N$ that contains x.

PROPOSITION 3.1. *Let E be an $(N-n-1)$-dimension subspace of $\mathbf{P}^N$ over an algebraically closed field. For any projective variety $X \subset \mathbf{P}^N$, the central projection $\pi: X-E \rightarrow \mathbf{P}^n$ is almost onto if and only if $\dim X \geqq n$ and there exists a smooth point x of X such that*

$$\dim\,(T_{x,X} \cap E)=\dim X-n-1,$$

where the left-hand side equals -1 means that $T_{x,X} \cap E=\varnothing$.

Proof. Assume that E is defined by linear independent equations $L_0 = L_1 = \cdots = L_n = 0$. Define $\tilde{\pi}: C(\mathbf{P}^N) \to \mathbf{A}^{n+1}$ as

$$\tilde{\pi}(x) = (L_0(x), \cdots, L_n(x));$$

then $\theta(\tilde{\pi}(x)) = \pi(\theta(x))$ if $x \neq 0$ and $\tilde{\pi}(x) \neq 0$. $\pi: X - E \to \mathbf{P}^n$ is almost onto if and only if $\tilde{\pi}: C(X) \to \mathbf{A}^{n+1}$ is almost onto. By the dominant morphism theorem, $\tilde{\pi}: C(X) \to \mathbf{A}^{n+1}$ is almost onto if and only if $d\tilde{\pi}: T_{y,C(X)} \to \mathbf{A}^{n+1}$ is onto at some smooth point y of $C(X)$. Since $\tilde{\pi}$ is linear, $d\tilde{\pi}(T_{y,C(X)}) = \tilde{\pi}(T_{y,C(X)})$. Note that $y \neq 0$. Let $x = \theta(y)$; then

$$C(T_{x,X}) = T_{y,C(X)}.$$

Restrict $\tilde{\pi}$ on $C(T_{x,X})$,

$$\dim \operatorname{Im} \tilde{\pi} + \dim \ker \tilde{\pi} = \dim C(T_{x,X}) = \dim X + 1.$$

So $\tilde{\pi}: C(T_{x,X}) \to \mathbf{A}^{n+1}$ is onto if and only if

$$\dim \ker \tilde{\pi} = \dim X - n.$$

When $\dim X > n$, $\ker \tilde{\pi} \neq \{0\}$, $\theta(\ker \tilde{\pi} - \{0\}) = T_{x,X} \cap E$, so $\dim \ker \tilde{\pi} = n$ if and only if

$$\dim T_{x,X} \cap E = \dim X - n - 1.$$

When $\dim X = n$, $\ker \tilde{\pi} = \{0\}$ if and only if

$$T_{x,X} \cap E = \varnothing.$$

The theorem is proved.

Applying Proposition 3.1 to χ: Grass $(p, m+p) - E \to \mathbf{P}^n$, we have the following corollary.

COROLLARY 3.1. *If* $\dim E = \binom{m+p}{p} - n - 2 = N - n - 1$, *then* χ: Grass $(p, m+p) - E \to \mathbf{P}^n$ *is almost onto if and only if* $mp \geqq n$ *and there is an* $x \in$ Grass $(p, m+p)$ *such that*

$$\dim T_x \cap E = mp - n - 1 \quad \text{if } mp > n,$$

$$T_x \cap E = \varnothing \quad \text{if } mp = n.$$

For each x, T_x is an mp-dimensional subspace of $\mathbf{P}^N$, where $N = \binom{m+p}{p} - 1$, and $C(T_x)$ is an $(mp+1)$-dimensional linear subspace of $\mathbf{A}^{N+1}$. The map $i: x \to C(T_x)$ induces an embedding:

$$(5) \qquad i: \text{Grass}\,(p, m+p) \subset \text{Grass}\,(mp+1, N+1).$$

If $\dim E = \binom{m+p}{p} - n - 2 = N - n - 1$, $C(E)$ is an $(N-n)$-dimensional linear subspace of $\mathbf{A}^{N+1}$, so it is a point in Grass $(N-n, N+1)$.

Let

$$(6) \qquad \sigma(E) = \{T \in \text{Grass}\,(mp+1, N+1) \mid \dim (T \cap C(E)) \geqq mp - n + 1\}.$$

$\sigma(E)$ is a Schubert variety of codimension $mp - n + 1$ of Grass $(mp+1, N+1)$. It is the intersection of Grass $(mp+1, N+1)$ with a subspace of codimension $mp - n + 1$ of $\mathbf{P}^M$, where $M = \binom{N+1}{mp+1} - 1$ and Grass $(mp+1, N+1) \subset \mathbf{P}^M$ by Plücker embedding (see [11]), so we have Theorem 3.2.

THEOREM 3.2. *Let* $G(s)$ *be an* $m \times p$ *transfer function of McMillan degree* n, *then the output feedback pole placement map* χ: Grass $(p, m+p) - E \to \mathbf{P}^n$ *is dominant if and only if* $mp \geqq n$, $\dim$ *sp*$\{$*minors of* $G(s)\} = n$ *and* Grass $(p, m+p)$ *is not contained in the Schubert variety* $\sigma(E)$ *defined by* (6) *under the embedding induced by the mapping* $i: x \to C(T_x)$.

Proof. By Lemma 3.1, the condition of

$$\dim sp\{\text{minors of } G(s)\} = n$$

is equivalent to the condition of

$$\operatorname{rank} L = n+1$$

for the L defined in (4), which is equivalent to the condition of

$$\dim E = N - n - 1 = \binom{m+p}{p} - n - 2. \tag{7}$$

Note that (7) is a necessary condition. By Corollary 3.1, χ is almost onto if and only if $mp \geqq n$, $\dim sp\{\text{minors of } G(s)\} = n$ and there exists an $x \in \text{Grass}\,(m, m+p)$ such that

$$\dim C(T_x) \cap C(E) = mp - n.$$

Then by the definition of $\sigma(E)$, (6), the theorem is proved.

4. 2 × 2 systems of McMillan degree 4. We use our results to examine some systems. The simplest Grassmannian that is not a projective space is Grass (2, 4), which corresponds to the 2×2 systems of McMillan degree 4. The degree of Grass (2, 4) is 2, so if $G(s)$ is nondegenerate, χ is onto and 2 to 1 over **C**. For general cases, we have the following result.

THEOREM 4.1. *Let $G(s)$ be a 2×2 transfer function of McMillan degree 4. Then for almost all choices $(s_1, \cdots, s_4)$, we can find output feedback law over* **C** *such that the closed-loop poles are $(s_1, \cdots s_4)$ if and only if*

$$\dim sp\{\textit{minors of}\, G(s)\} = 4.$$

Proof. By Theorem 3.2, if we can prove

$$\text{Grass}\,(2,4) \not\subset \sigma(E)$$

for any E of dimension zero, then the theorem is proved. Grass (2, 4) is embedded in Grass (5, 6) and $\sigma(E)$ is a hyperplane section of Grass (5, 6). Since Grass $(5, 6) = \mathbf{P}^5$,

$$i: \text{Grass}\,(2,4) \subset \text{Grass}\,(5,6)$$

is the Plücker embedding, $\sigma(E)$ is a hyperplane so Grass $(2, 4) \not\subset \sigma(E)$ for any E of dimension zero.

Example 4.1. Let

$$G(s) = \frac{1}{s^4-1}\begin{bmatrix} s^3 & s \\ s & s^3 \end{bmatrix}.$$

The minors of $G(s)$ are $\{s^3/(s^4-1),\ s/(s^4-1),\ s^2/(s^4-1)\}$, so χ is not almost onto.

Example 4.2. Let

$$G(s) = \begin{bmatrix} 1/s & 1/s^2 \\ 0 & 1/s^3 \end{bmatrix}.$$

Then $G(s)$ is degenerate and the minors of $G(s)$ are $\{1/s,\ 1/s^2,\ 1/s^3,\ 1/s^4\}$,

$$\dim sp\{\text{minors of } G(s)\} = 4.$$

So we can place the poles of $G(s)$ to almost all choices $(s_1, \cdots, s_4)$ by complex output feedback. We can also place the poles to almost all self-conjugate $(s_1, \cdots, s_4)$ by real output feedback (see Theorem 4.2).

Now we consider the real field. Willems and Hesslink [18] proved that χ cannot be almost onto over $\mathbf{R}$ for generic system. Brockett and Byrnes [2] proved that if $G(s)$ is nondegenerate, χ is not almost onto over $\mathbf{R}$. So we consider the case when $G(s)$ is degenerate.

LEMMA 4.1. *If $G(s)$ is degenerate and χ is dominant, the degree of χ is one.*

Proof. Note that

$$\dim E = 0.$$

So if $G(s)$ is degenerate,

$$E \subset \text{Grass}\,(2, 4).$$

Let L be any line through E. If $L \not\subset \text{Grass}\,(2, 4)$, then L can intersect Grass $(2, 4)$ in at most one other point because

$$\deg \text{Grass}\,(2, 4) = 2.$$

Hence by Proposition 2.1,

$$\deg \chi = 1.$$

THEOREM 4.2. *Let $G(s)$ be a 2×2 transfer function of McMillan degree 4. Then for almost all self-conjugate $(s_1, \cdots, s_4)$ we can find a real output feedback law such that the closed-loop poles are $(s_1, \cdots, s_4)$ if and only if $G(s)$ is degenerate and*

$$\dim sp\{\textit{minors of}\, G(s)\} = 4.$$

Proof. χ is almost onto over $\mathbf{R}$ if χ is dominant and degree of χ is an odd number.

Brockett and Byrnes [2] proved that χ is onto over $\mathbf{R}$ if and only if $\det G(s) \equiv 0$ and

$$\dim sp\{g_1(s), g_2(s), g_3(s), g_4(s)\} = 4,$$

where $\{g_i\}$ are entries of $G(s)$. Note that $\det G(s) = 0$ is one of the cases of $G(s)$ being degenerate, so Brockett–Byrnes' result is included in Theorem 4.2.

5. 2×3 systems of McMillan degree 6. The next Grassmannian we will consider is the Grass $(2, 5)$. The degree of Grass $(2, 5)$ is 5, which is an odd number. So for a nondegenerate system, we can place poles arbitrarily over both the complex and the real fields.

For Grass $(2, 4)$, we have the property that Grass $(p, m+p) \not\subset \sigma(E)$ for any codimension $mp+1$ subspace E of $\mathbf{P}^N$, where $N = \binom{m+p}{p} - 1$ and Grass $(p, m+p)$ is embedded in Grass $(mp+1, N+1)$ (see § 3 and the proof of Theorem 4.1). For Grass $(2, 5)$, unfortunately, we do not have such a property. It is not difficult to find a subspace E of dimension two such that Grass $(2, 5) \subset \sigma(E)$, but, if we restrict such E to be the center of the projection χ for some system, it is not easy. After trying to construct such a system, we finally find that it is impossible. We have the same result as in Grass $(2, 4)$ as follows.

THEOREM 5.1. *Let $G(s)$ be a 2×3 transfer function of McMillan degree 6. Then χ is dominant if and only if*

$$\dim sp\{\textit{minors of}\, G(s)\} = 6.$$

We only give the ideal of the proof here. Please refer to [17] for details. The ideal is to find the forms of E such that Grass $(2, 5) \subset \sigma(E)$, then show that such E cannot be the center of χ for any transfer function $G(s)$.

Theorems 4.1 and 5.1 tempt us to conjecture that

$$\dim sp\{\text{minors of } G(s)\} = mp$$

might be the necessary and sufficient condition for χ being dominant for any $p\times m$ system of McMillan degree mp. However, this is not true. It is a necessary condition, but it is not sufficient; we must add the condition that Grass $(p, m+p)$ is not contained in the Schubert variety $\sigma(E)$ (see Theorem 3.2). We give an example of 3×3 transfer function $G(s)$ of McMillan degree 9 here.

Example 5.1. Let

$$G(s)=\frac{1}{s^4(s^3+1)(s-1)^2}\begin{bmatrix} s^6(s-1)^2 & -s^3(s-1)^2 & 0 \\ s^2(s-1)^2(s^2+1) & -s(s-1)^2(s^4+1) & 0 \\ s^4 & -s^5+s^4-s^2 & 0 \end{bmatrix}.$$

The dimension of $sp\{\text{minors of } G(s)\}$ equals 9, but the last column of $G(s)$ is zero. For any feedback law $u=Ky$, let

$$K=\begin{bmatrix} k_{11} & k_{12} & k_{13} \\ k_{21} & k_{22} & k_{23} \\ k_{31} & k_{32} & k_{33} \end{bmatrix}.$$

The values of k_{31}, k_{32}, k_{33} do not influence the closed-loop transfer function. So χ actually maps $\mathbf{A}^6$ into $\mathbf{A}^9$, it cannot be almost onto.

6. Conclusions. The output pole placement map χ has been studied by using a central projection model. It is proved that χ is dominant if and only if $mp\geqq n$, $\dim sp\{\text{minors of } G(s)\}=n$ and Grass $(p, m+p)\not\subset\sigma(E)$, where Grass $(p, m+p)$ is embedded in Grass $(mp+1, N+1)$ and $\sigma(E)$ is a Schubert variety of codimension $mp-n+1$ of Grass $(mp+1, N+1)$. In the cases of the 2×2 system of McMillan degree 4 and the 2×3 system of McMillan degree 6, it is proved that

$$\dim sp\{\text{minors of } G(s)\}=n$$

is a necessary and sufficient condition for χ being dominant, but this condition is not sufficient generally. It is also proved that for a 2×2 system of degree 4, χ is almost onto over the real field if and only if $G(s)$ is degenerate and

$$\dim sp\{\text{minors of } G(s)\}=4.$$

Acknowledgment. The author thanks C. I. Byrnes for his help and advice.

OPTIMAL CONTROL OF THE RUNNING MAX *

ARTHUR C. HEINRICHER† AND RICHARD H. STOCKBRIDGE‡

Abstract. A class of stochastic control problems where the payoff depends on the running maximum of a diffusion process is described. Such processes are appealing models for physical processes that evolve in a *continuous* and *increasing* manner. Dynamic programming conditions of optimality for these nonstandard problems are investigated and applied to particular examples.

Key words. controlled diffusion, running maximum, dynamic programming

AMS(MOS) subject classification. 93E20

1. Introduction.

This paper is devoted to the analysis of some nonstandard stochastic control problems which are derived from applications in which the state of the system is naturally monotone. They are closely related to standard controlled diffusion problems except that the payoff is allowed to depend on the *running maximum* of the diffusion. Our basic problem is of the following form.

The objective is to choose a control u_t to maximize

$$J(x,y;u) := E_{xy} \int_0^{\tau(B)} h(x_t, y_t, u_t)dt, \tag{1}$$

where the state is the pair (x_t, y_t) defined by the system

$$dx_t = f(x_t,u_t)dt + \sigma(x_t,u_t)dw_t, \quad x_0 = x, \tag{2}$$

$$y_t = \max\{x_s : 0 \leqq s \leqq t\} \vee y, \quad y_0 = y \geqq x. \tag{3}$$

We take $B \geqq y \geqq x$ and define $\tau(B)$ as the hitting time for x_t at level B. Here and throughout the paper, $w = (w_t,\ 0 \leqq t < \infty)$ denotes a standard, one-dimensional, Brownian motion.

To apply dynamic programming techniques to this problem, we consider the pair (x_t, y_t) as the *state.* (The process y_t alone is not a Markov process, but the pair (x_t, y_t) *is* a (strong) Markov process.) Pictured in the plane, the trajectories move on $y =$ const. lines while $x < y$, and there is motion in the y-direction only along the diagonal $x = y$.

The *value function V* reflects this picture of the state. It is defined in the half-plane $\{(x,y) : x \leqq y\}$. It satisfies a standard dynamic programming partial differential equation involving only derivatives with respect to x in the region $x < y$. The dependence on y_t in (1) becomes important only on the diagonal $x = y$ and adds a boundary condition to the dynamic programming equation. This picture also motivates the decomposition of the running max problem into a family of auxiliary control problems.

There is a large literature on optimal control for Markov processes, and diffusion processes in particular [13], [18], but it is impossible to model a *monotone* process via a (nondegenerate) diffusion because of the violent fluctuations of the Brownian

motion. There is also a large literature working with monotone stochastic models in reliability theory and the statistics of lifetime distributions. Much of the work refers to the seminal paper of Esary, Marshall, and Proschan [12] on so-called *shock models.* These provide monotone models, but the paths increase in jumps and so are not suitable as models for phenomena that evolve in a *continuous* manner.

There is no literature on continuous, monotone stochastic processes simply because no nontrivial examples exist. In fact, Çinlar [7] has shown that the only *scalar* stochastic processes that are continuous, monotone, and strong Markov are *deterministic* functions of the initial state (up to a random killing). We can obtain a *vector* stochastic process that is continuous and strong Markov with one monotone component. By taking a diffusion and its running maximum, we obtain perhaps the simplest example of such a vector stochastic process.

One important application that requires a continuous and monotone stochastic process model is the optimal control of *wear*; tires, drill bits, and jet engines do not "unwear." Çinlar [5] has analyzed perhaps the most general class of stochastic processes suitable as models for wear (see [6], [8], [9]). In these *semi-Markov* processes, one component of a two-component process is monotone and assumed to model wear, while the second component is a Markov process referred to as the "excitation process." However, the generality of these processes detracts from their usefulness in certain control applications.

Baxter and Lee [3], [4] describe repair policies for a diffusion wear model. Conrad and McClamroch [10] use a controlled diffusion model for wear and describe applications to automated manufacturing. In both of these, the monotonicity of wear is surrendered to obtain a tractable control model.

The objective function (1) can be viewed with an interpretation similar to Conrad and McClamroch's [10] application in mind. Consider a control problem in which the state of a system is related to the level of wear in a machine and the control u can be interpreted as a *rate of working.* Profit is accrued while the machine is working, with an increase in the work rate providing an increase in the rate of income. The machine, however, will eventually deteriorate and fail (at level B in (1)), with increased wear decreasing the rate of income, and failure ending the process. (For such applications, the integrand $h(x, y, u)$ in (1) should be increasing as a function of u and decreasing as a function of x and y.) The controller is faced with competing objectives: he should work fast to maximize the rate of income, but working too fast will increase wear and will speed the failure of the machine.

1.1. Summary. We begin by describing sufficient conditions for optimality in terms of the Hamilton–Jacobi–Bellman (HJB) partial differential equation. In particular, we show that the appearance of the running maximum in the objective function is manifest only in the addition of an oblique derivative condition on the boundary of the halfplane $x \leqq y$.

We then describe how the running max problem can be solved by first solving a family of auxiliary problems. These are standard stochastic control problems and we give a simple formula for the running max value in terms of these auxiliary value functions.

One class of running max problems is particularly easy to solve. When the payoff depends *only* on the control and the running max, the optimal feedback control is constant for each of the auxiliary problems. This gives a simple formula for the auxiliary value function and hence for the running max value.

As an application, in §3 we solve a control problem in which the running profit depends in a linear way on the diffusion and its running maximum. The policy runs the gamut from a pure x-threshold policy when the payoff depends only on the diffusion process x to a pure y-threshold when the payoff depends only on the running max y. We investigate the regularity properties of this value function.

2. Dynamic programming conditions for optimality. We describe sufficient conditions for optimality in terms of the Hamilton–Jacobi–Bellman (HJB) partial differential equation. Our formulation is based on the standard verification theory as presented in Chapter VI of [13].

For a standard controlled diffusion problem, where the integrand in (1) does not depend on y_t and the state is given by (2), the (HJB) equation takes the form

$$\max_{u \in U}\left\{\frac{1}{2}\sigma(x,u)^2\, V''(x) + f(x,u)V'(x) + h(x,u)\right\} = 0 \tag{4}$$

for $x < B$ with the terminal condition

$$V(B) = 0. \tag{5}$$

If we can find a solution (in some appropriate sense) for this partial differential equation, then this solution will be the value function:

$$V(x) = \sup_{u \in \mathcal{A}} J(x;u).$$

We assume that controls take values in a compact set U and that the coefficients of the problem satisfy the following:

(A1) h is continuous and satisfies the polynomial growth condition

$$0 \leqq h(x,y,u) \leqq C\,(1 + |x|^p + |y|^p + |u|^p) \qquad (x \leqq y \leqq B,\ u \in U),$$

for suitable constants C and p;

(A2) f and σ are C^1 functions with

$$|f_x(x,u)| + |f_u(x,u)| \leqq K,\ |\sigma_x(x,u)| + |\sigma_u(x,u)| \leqq K\ (x \leqq B,\ u \in U),$$

and

$$|\sigma(x,u)| \leqq M\ (x \leqq B,\ u \in U),$$

for suitable constants K and M.

For the admissible controls, take the collection of *nonanticipative controls* as defined in Chapter VI of [13, p. 162]. Let $\mathcal{A}$ denote the collection of admissible controls.

The following example shows that the problem may be ill posed without a positive lower bound on $f(x,u)$. Consider a problem with control set $U = [0,1]$ and reward function

$$J(u) = E\int_0^{\tau(1)} \sqrt{u_t}\, dt,$$

where

$$dx_t = u_t dt + dw_t, \; x_0 = 0,$$

and $\tau(1)$ is the hitting time for level one. A maximizing sequence is obtained by taking constant controls $u_t^{(n)} \equiv 1/n$ for $n \geqq 1$. The state process is a drifted Brownian motion, with constant drift $1/n$, and so the expected time to reach level 1 is n. The expected reward is

$$J\left(u^{(n)}\right) = E\left[\int_0^{\tau(1)} \frac{1}{\sqrt{n}}\, dt\right] = \frac{1}{\sqrt{n}}\, E\left[\tau(1)\right] = \sqrt{n}.$$

There is no optimal policy; the controller can obtain arbitrarily large rewards by working arbitrarily slowly. We impose the following condition to preclude this behavior.

(A3) There is a constant α such that

$$0 < \alpha \leqq f(x,u) \; (x \leqq B, u \in U).$$

Our assumptions provide an exponential estimate on the probability that the diffusion exits the strip (A,B) at the lower boundary A. Let

$$\tau := \inf\left\{t \geqq 0 : x_t \notin (A,B)\right\}.$$

LEMMA 2.1. *Assume that $f(\cdot)$ and $\sigma(\cdot)$ satisfy assumptions* (A2) *and* (A3), *that $(x_t,\ 0 \leqq t)$ is a solution for* (2), *and that τ is defined as above. Then*

$$P_x\left(x_\tau = A\right) \leqq C \exp\left(kA\right), \tag{6}$$

where $k := 2\alpha/M^2 > 0$, and C depends on x, B, α, and M.

Proof. Define $\Phi(\cdot) : [A,B] \to [0,1]$ by

$$\Phi(x) = \frac{e^{-kx} - e^{-kB}}{e^{-kA} - e^{-kB}} \tag{7}$$

with k defined as above. Observe that

$$\Phi'(x) \leqq 0, \quad \Phi''(x) \geqq 0 \; (x \in (A,B)), \tag{8}$$

and that $\Phi(\cdot)$ satisfies the boundary value problem

$$\begin{gathered}\frac{1}{2}M^2\Phi''(x) + \alpha\Phi'(x) = 0, \; (x \in (A,B)), \\ \Phi(A) = 1, \; \Phi(B) = 0,\end{gathered} \tag{9}$$

By Itô's formula, taking expectations and using the fact that $\sigma(\cdot)$ and $\Phi'(\cdot)$ are bounded as well as the sign condition (8), we have

$$\begin{aligned} E_x\left[\Phi(x_\tau)\right] - \Phi(x) &= E_x \int_0^\tau \left[\frac{1}{2}\sigma^2(x_t,u_t)\Phi''(x_t) + f(x_t,u_t)\Phi'(x_t)\right] dt \\ &\leqq E_x \int_0^\tau \left[\frac{1}{2}M^2\Phi''(x_t) + \alpha\Phi'(x_t)\right] dt \\ &= 0. \end{aligned}$$

Therefore,

$$P_x(x_\tau = A) = E_x\left[\Phi(x_\tau)\right] \leqq \Phi(x) \leqq \left[\frac{e^{-kx} - e^{-kB}}{1 - e^{-kB}}\right] \exp(kA),$$

and the proof is compete. □

The following theorem is a direct extension of the standard sufficient condition for optimality.

THEOREM 2.2. *Let $V(x,y)$ be a solution of the dynamic programming equation*

$$\max_{u \in U}\left\{\frac{1}{2}\sigma(x,u)^2\, V_{xx}(x,y) + f(x,u)V_x(x,y) + h(x,y,u)\right\} = 0, \tag{10}$$

in the region $x < y < B$ satisfying the terminal condition

$$V(B,B) = 0, \tag{11}$$

as well as the boundary condition

$$V_y(y,y) = 0 \qquad (y \leqq B). \tag{12}$$

In addition, suppose $V(x,y)$ is continuous, twice continuously differentiable with respect to x, and satisfies a polynomial growth condition

$$|V(x,y)| \leqq C(1 + |x|^p + |y|^p) \qquad (x \leqq y,\ y \leqq B), \tag{13}$$

for appropriate constants C and p. Then:

(a) *$V(x,y) \geq J(x,y;u)$ for any admissible control u and any $x \leqq y$;*

(b) *If u^* is an admissible control that attains the maximum in* (10), *then u^* is optimal and $V(x,y) = J(x,y;u^*)$ is the value function.*

Proof. The proof is an application of the Itô formula. Assume that $V(x,y)$ satisfies (10)–(13). Let u be an admissible control and let (x_t, y_t) be the corresponding state process. Let T and N be positive constants and define

$$\tau_N := \inf\{t \geq 0 : x_t \leqq -N\}.$$

Then applying the Itô formula to $V(x_t, y_t)$, we have

$$\begin{aligned} V(x,y) \;&=\; -\int_0^{\tau(B)\wedge\tau_N\wedge T}\left[f(x_t,u_t)V_x(x_t,y_t) + \frac{1}{2}\sigma^2(x_t,u_t)V_{xx}(x_t,y_t)\right] dt \\ &\quad - \int_0^{\tau(B)\wedge\tau_N\wedge T} V_y(x_t,y_t)dy_t - \int_0^{\tau(B)\wedge\tau_N\wedge T} \sigma(x_t,u_t)V_x(x_t,y_t)dw_t \\ &\quad + \; V(x_{\tau(B)\wedge\tau_N\wedge T}, y_{\tau(B)\wedge\tau_N\wedge T}), \end{aligned}$$

where dy is the measure associated with the monotone increasing process y. Since the process $(y_t,\ 0 \leq t < \infty)$ increases only on the set $\{t : x_t = y_t\}$, the measure dy assigns mass only on this set. Hence the boundary condition (12) implies that the second integral is zero. Taking expectations and using (10) and the fact that the stochastic integral has zero expectation (the integrand is bounded), we obtain

$$\begin{aligned} V(x,y) &= -E_{xy}\int_0^{\tau(B)\wedge\tau_N\wedge T}\left[f(x_t,u_t)V_x(x_t,y_t)+\frac{1}{2}\sigma^2(x_t,u_t)V_{xx}(x_t,y_t)\right]dt \\ &\quad + E_{xy}V(x_{\tau(B)\wedge\tau_N\wedge T},y_{\tau(B)\wedge\tau_N\wedge T}) \\ &\geqq E_{xy}\int_0^{\tau(B)\wedge\tau_N\wedge T} h(x_t,y_t,u_t)dt + E_{xy}V(x_{\tau(B)\wedge\tau_N\wedge T},y_{\tau(B)\wedge\tau_N\wedge T}). \end{aligned}$$

The monotone convergence theorem implies that the integral term converges to the reward function $J(x,y;u)$ as T and $N\to\infty$. It follows from the continuity of V and the bounded convergence theorem that

$$\lim_{T\to\infty} E_{xy}V(x_{\tau(B)\wedge\tau_N\wedge T},y_{\tau(B)\wedge\tau_N\wedge T}) = E_{xy}V(x_{\tau(B)\wedge\tau_N},y_{\tau(B)\wedge\tau_N}).$$

To conclude, we must show that

$$(14)\qquad \lim_{N\to\infty} E_{xy}V(x_{\tau(B)\wedge\tau_N},y_{\tau(B)\wedge\tau_N}) = E_{xy}V(B,B)=0.$$

This will follow from the bound

$$(15)\qquad \sup_N E_{xy}\left[V^2(x_{\tau(B)\wedge\tau_N},y_{\tau(B)\wedge\tau_N})\right]<\infty,$$

because this implies uniform integrability.

The polynomial growth condition (13) provides the estimate

$$(16)\qquad E_{xy}\left[V^2(x_{\tau(B)\wedge\tau_N},y_{\tau(B)\wedge\tau_N})\right]\leqq C_1+C_2E_{xy}\left[x^{2p}_{\tau(B)\wedge\tau_N}\right],$$

where C_1 and C_2 depend on B, C, p, and the initial data. Because

$$E_{xy}\left[x^{2p}_{\tau(B)\wedge\tau_N}\right]\leqq B^{2p}+N^{2p}P_{xy}\left(\tau_N<\tau(B)\right),$$

Lemma 2.1, with $A=-N$, provides a bound for the right-hand side of (16) that is independent of N. Hence the family $V(x_{\tau(B)\wedge\tau_N},y_{\tau(B)\wedge\tau_N})$ is uniformly integrable. Equation (14) follows and we have

$$V(x,y)\geqq J(x,y;u)$$

for an arbitrary admissible control policy.

When u^* is an admissible control that attains the maximum in (10), the above argument holds with equality. □

Remark 2.3. If x_t is a Brownian motion, then the computations in [16, p. 95] can be modified to determine the transition densities for the Brownian motion and its running max (allowing arbitrary initial positions $x\leqq y$). We can then show that this process has infinitesimal generator

$$A\phi(x,y)=\frac{1}{2}\phi_{xx}(x,y)$$

with domain all functions defined in the halfplane $x \leqq y$, which are twice continuously differentiable with respect to x, continuously differentiable on the diagonal, and satisfy the boundary condition

$$\phi_y(x,y) = 0 \text{ when } x = y.$$

This derivation helps to explain, from another point of view, the origin of the boundary condition (12).

2.1. The auxiliary problem. The running max problem can be solved by first solving an *auxiliary problem.* In this problem y is a fixed parameter, the process starts at some $x \leqq y$, and the controller seeks to maximize the payoff obtained up to the first time the diffusion x_t reaches level y. This is a standard stochastic control problem for each $y \leqq B$.

In particular, let $x \leqq y$, define

$$\tau_1 = \tau_1(x,y;u) := \inf\{t \geq 0 : \ x_t = y\}, \tag{17}$$

and seek to maximize

$$J_1(x,y;u) := E_{xy} \int_0^{\tau_1} h(x_t, y, u_t)dt. \tag{18}$$

Let $W(x,y)$ denote the value function for this auxiliary problem:

$$W(x,y) := \sup_{u \in \mathcal{A}} J_1(x,y;u).$$

The HJB equation satisfied by $W(x,y)$ is of the standard form (4):

$$\max_{u \in U} \left\{ \frac{1}{2}\sigma(x,u)^2 \, W_{xx}(x,y) + f(x,u)W_x(x,y) + h(x,y,u) \right\} = 0 \tag{19}$$

on the halfline $x < y$ with the terminal condition

$$W(y,y) = 0. \tag{20}$$

There is a simple relationship between the value functions for the auxiliary problem and the running max problem. Using the *principle of optimality* (as presented in Lions [20, Thm. B]), we can show that the payoff starting at (x,y) consists of the auxiliary payoff $W(x,y)$ plus the payoff on the diagonal $V(y,y)$. Indeed, the principle of optimality says that for any admissible control and any stopping time θ,

$$V(x,y) = \sup_{u \in \mathcal{A}} E_{xy} \left[\int_0^{\theta \wedge \tau(B)} h(x_t, y_t, u_t)dt + V(x_{\theta\wedge\tau(B)}, y_{\theta\wedge\tau(B)}) \right].$$

Taking $\theta = \tau_1$, noting that $\tau_1 \leqq \tau(B)$ and $(x_{\tau_1}, y_{\tau_1}) = (y,y)$, this becomes

$$V(x,y) = \sup_{u \in \mathcal{A}} E_{xy}\left[J_1(x,y;u) + V(y,y)\right] = W(x,y) + V(y,y).$$

Thus we have the following proposition.

PROPOSITION 2.4. *The value functions for the running max problem and the auxiliary problem satisfy*

$$V(x,y) = W(x,y) + V(y,y) \qquad (x \leqq y, \ y \leqq B). \tag{21}$$

If we formally differentiate (21) with respect to y, evaluate on $x = y$, and use the boundary condition (12), we obtain

$$0 = V_y(y, y) = W_y(y, y) + \frac{d}{dy} V(y, y).$$

This indicates that the value for the running max problem can be represented entirely in terms of the value for the auxiliary problem.

THEOREM 2.5. *Let $W(x, y)$ be a solution of the dynamic programming equation* (19) *on the halfline $x < y$ satisfying the terminal condition* (20). *Suppose that $W(x, y)$ is twice continuously differentiable with respect to x and satisfies the polynomial growth condition*

$$|W(x, y)| \leqq C(1 + |x|^p + |y|^p) \qquad (x \leqq y),$$

for appropriate constants C and p. Then $W(x, y)$ is the value function for the auxiliary problem (18), *and if $u^*(x, y)$ is an admissible control that attains the maximum in* (19), *then $u^*(x, y)$ is an optimal control.*

In addition, assume that $W(x, y)$ is continuous with respect to (x, y) and differentiable along $x = y$. Then the running max value function is given by

$$V(x, y) = W(x, y) + \int_y^B W_y(z, z) dz \qquad (x \leqq y,\ y \leqq B). \tag{22}$$

The optimal control $u^*(x, y)$ for the auxiliary problem is also optimal for the running max problem (1).

Proof. The proof that $W(x, y)$ is the value function and that $u^*(x, y)$ is optimal for the auxiliary problem follows the standard verification theorem for a controlled diffusion (as in [13, Chap. VI]). (The proof is almost identical to that of Theorem 2.2, except that there is no integral with respect to dy_t to consider.)

Defining $V(x, y)$ as in (22), $V(x, y)$ inherits exactly the smoothness of $W(x, y)$; in particular, we have

$$V_x(x, y) = W_x(x, y),\ V_{xx}(x, y) = W_{xx}(x, y),$$

as well as

$$V(B, B) = W(B, B) = 0,$$

and

$$V_y(y, y) = W_y(y, y) - W_y(y, y) = 0.$$

Since $W(x, y)$ satisfies (19), $V(x, y)$ satisfies (10) as well as the terminal and boundary conditions (11) and (12). Theorem 2.2 identifies $V(x, y)$ as the value function and $u^*(x, y)$ as the optimal control policy for the running max problem. □

Remark 2.6. We have obtained *sufficient* conditions for optimality in terms of smooth, classical solutions to the (HJB) equation. The value function need not be a smooth classical solution, however. Recent work on existence and uniqueness in the class of generalized solutions known as *viscosity solutions* includes [11], [14], [15], [20], and [21]. In particular, Lions [20], [21] has developed dynamic programming conditions for standard control problems that do not require the smoothness hypothesized in Theorems 2.2 and 2.5. Barron [2] has applied these techniques and shown that the running max value function is the unique continuous viscosity solution for the boundary value problem (10)–(12).

2.2. The pure running max problem. When the payoff depends only on the control and the running max, and the drift and diffusion coefficients depend only on the control, the problem turns out to be remarkably simple. The reason for the simplification is that the optimal control is constant for fixed y and so the form of $W(x,y)$ is easy to derive.

Consider the following special running max problem. The objective is to choose a control u_t to maximize

$$J(x,y;u) := E_{xy}\int_0^{\tau(B)} h(y_t,u_t)dt, \tag{23}$$

where the state is given by

$$dx_t = f(u_t)dt + \sigma(u_t)dw_t,\ x_0 = x, \tag{24}$$

$$y_t = \max\{x_s : 0 \leqq s \leqq t\} \vee y. \tag{25}$$

Note that h depends only on y and u and the coefficients in the diffusion depend only on u.

When we consider the auxiliary objective function

$$J_1(x,y;u) = E_{xy}\int_0^{\tau_1} h(y,u_t)dt,$$

and restrict our attention to constant controls $u \in U$, the integrand is constant and thus

$$J_1(x,y;u) = h(y,u)E_{xy}\tau_1(x,y;u).$$

Furthermore, because the coefficients in (24) are constant, the expected value of the hitting time is known (see, for example, [17, §5, Chap. 7]):

$$E_{xy}\tau_1(x,y;u) = \frac{(y-x)}{f(u)}.$$

For a choice of $u \in U$, call it $u^*(y)$, which maximizes the ratio

$$u \mapsto \frac{h(y,u)}{f(u)}, \tag{26}$$

the payoff $J_1(x,y;u^*(y))$ satisfies the (HJB) equation (19) and the terminal condition (20). The standard verification theorem (as in [13, Chap. VI]) then identifies $J_1(x,y;u^*(y))$ as the value function $W(x,y)$ of the auxiliary problem and $u^*(y)$ as the optimal policy. The pair $(W(x,y),u^*(y))$ also satisfies the conditions of Theorem 2.5 and so $u^*(y)$ is the optimal policy for the pure running max problem and the value is given by (22). Summarizing, we have the following proposition.

PROPOSITION 2.7. *The value function for the auxiliary pure running max problem is*

$$W(x,y) = \frac{h(y,u^*(y))}{f(u^*(y))}(y-x), \tag{27}$$

where $u^*(y)$ maximizes the ratio (26). *The value function for the pure running max problem* (23) *is then*

$$V(x,y) = \frac{h(y,u^*(y))}{f(u^*(y))}(y-x) + \int_y^B \frac{h(z,u^*(z))}{f(u^*(z))}dz. \tag{28}$$

This explicit expression for $W(x,y)$ allows us to investigate its smoothness with respect to y. Clearly, if f, h, and u^* are twice continuously differentiable, $W(x,y)$ will be, also. The more interesting situation is when there is a jump in the optimal control $u^*(y)$.

Even if $u^*(y)$ is discontinuous, $W(x,y)$ will be continuous. To see this, assume that the optimal control $u^*(y)$ is identically α in a left-neighborhood of $\overline{y}$ and $u^*(y)$ is identically β in a right-neighborhood of $\overline{y}$. Then

$$\frac{h(\overline{y}^-,\beta)}{f(\beta)} \leqq \frac{h(\overline{y}^-,\alpha)}{f(\alpha)} = \frac{h(\overline{y}^+,\alpha)}{f(\alpha)} \leqq \frac{h(\overline{y}^+,\beta)}{f(\beta)} = \frac{h(\overline{y}^-,\beta)}{f(\beta)}.$$

(The inequalities follow from the optimality of α for $y < \overline{y}$ and of β for $y > \overline{y}$, and the equalities follow from the continuity of h.) As a result, equality holds throughout and continuity of h gives

$$\frac{h(\overline{y},\alpha)}{f(\alpha)} = \frac{h(\overline{y},\beta)}{f(\beta)} = \max_{u\in U}\frac{h(\overline{y},u)}{f(u)}. \tag{29}$$

So a switch occurs at an *indifference level*, a level $\overline{y}$ where the return obtained from control α is exactly the same as the return from control β. This is another way of saying that the value function (either the running max or the auxiliary value function) is continuous across the switching level.

When the optimal control does switch, there could be a jump in $W_y(x,y)$ at the switching level and we have a simple expression for the size of the jump. Let $\overline{y}$, α, and β be as above and assume that h is twice differentiable with respect to y. Then

$$\begin{aligned} \Delta W_y(x,\overline{y}) &:= W_y(x,\overline{y}^+) - W_y(x,\overline{y}^-) \\ &= h_y(\overline{y},\beta)E_{x\overline{y}}\,\tau_1(x,\overline{y};\beta) - h_y(\overline{y},\alpha)E_{x\overline{y}}\,\tau_1(x,\overline{y};\alpha) \qquad (30) \\ &= \left[\frac{h_y(\overline{y},\beta)}{f(\beta)} - \frac{h_y(\overline{y},\alpha)}{f(\alpha)}\right](\overline{y}-x). \end{aligned}$$

Note in particular the size of the jump decreases to zero at $x = \overline{y}$. In addition, the jump in W_{yy} is given by

$$\Delta W_{yy}(x,\overline{y}) = 2\left[\frac{h_y(\overline{y},\beta)}{f(\beta)} - \frac{h_y(\overline{y},\alpha)}{f(\alpha)}\right] + \left[\frac{h_{yy}(\overline{y},\beta)}{f(\beta)} - \frac{h_{yy}(\overline{y},\alpha)}{f(\alpha)}\right](\overline{y}-x). \tag{31}$$

The jumps in $W_y(x,y)$ and $W_{yy}(x,y)$ are inherited by $V_y(x,y)$ and $V_{yy}(x,y)$. For example,

$$\begin{aligned} \Delta V_y(x,\overline{y}) &:= V_y(x,\overline{y}^+) - V_y(x,\overline{y}^-) \\ &= \Delta W_y(x,\overline{y}) - \Delta W_y(\overline{y},\overline{y}) \\ &= \Delta W_y(x,\overline{y}). \end{aligned}$$

Remark 2.8. If we assume that

(a) $u \mapsto f(u)$ is positive, increasing, and concave on U; and

(b) $u \mapsto h(y,u)$ is positive, increasing, and convex for fixed y;

then for fixed x and y,

$$u \mapsto f(u)W_x(x,y) + h(y,u) \text{ is convex,}$$

and hence the maximum in the (HJB) equation is attained at the extreme values of the control set U. In other words, the optimal control is a *bang-bang* control.

3. The linear mixed problem. Consider now a control problem in which the control, the diffusion, and the running max enter the payoff in a linear way. Take

$$f(x,u) = u^\delta \text{ with } \delta \in (0,1], \text{ and } \sigma(x,u) \equiv 1,$$

so that the state is the pair (x_t, y_t) defined by the system

$$dx_t = (u_t)^\delta dt + dw_t,\ x_0 = x, \tag{32}$$

$$y_t = \max\{x_s : 0 \leqq s \leqq t\} \vee y, \tag{33}$$

with $x \leqq y$. The stopping time $\tau(B)$ is defined as before.

The admissible control processes $u = (u_t; 0 \leqq t < \infty)$ take values in

$$U := [\alpha, \beta] \text{ with } 0 < \alpha < \beta,$$

and the objective is to maximize the payoff

$$J(x,y;u) := E_{xy} \int_0^{\tau(B)} [cu_t - k_1 x_t - k_2 y_t] dt. \tag{34}$$

The parameters c, k_1, and k_2 are positive and we require that

$$c\beta - k_1 B - k_2 B \geqq 0. \tag{35}$$

This is sufficient to guarantee that the running profit can always be made positive. Alternatively, we can think of this last condition as *defining* the destruction level B as the maximum level at which it is possible to still make a profit.

We will construct the value function using the auxiliary problems described in §2 and show that the optimal control is a bang-bang control that switches between α and β at a switching line given by

$$k_1 x + k_2 y = \text{const.}$$

(see (41) below).

Remark 3.1. The restriction to the case $0 < \delta \leqq 1$ is made to give an optimal policy of the bang-bang form (recall Remark 2.8). When $\delta > 1$, the optimal policy is no longer simply α or β, but makes a smooth transition between these two values as x increases to y.

3.1. The auxiliary problem.

As described in §2.1, this running max problem can be solved by solving a family of simpler, standard control problems. Recall that the objective in the auxiliary problem is to maximize

$$J_1(x,y;u) := E_{xy} \int_0^{\tau_1} [cu_t - k_1 x_t - k_2 y] dt, \tag{36}$$

where $\tau_1 = \tau_1(x,y;u) := \inf\{t \geq 0 : \; x_t = y\}$, x_t is defined as in (32), and $y \geqq x$ is fixed.

The (HJB) equation (19) reduces to

$$\max_{\alpha \leqq u \leqq \beta} \left\{ \frac{1}{2} W_{xx}(x,y) + u^\delta W_x(x,y) + cu - k_1 x - k_2 y \right\} = 0 \tag{37}$$

on the halfline $x < y$ with the terminal condition

$$W(y,y) = 0. \tag{38}$$

We construct a solution $W(x,y)$ to (37) by first solving the equation with $u \equiv \alpha$ and then with $u \equiv \beta$, and patching these solutions together at a switching point $x = \overline{x}\,(y)$. (We are using the heuristic "principle of smooth fit." See Lehoczky and Shreve [19] for a discussion of this principle in singular and absolutely continuous control.)

The general solution for the (HJB) equation (37) with constant control (ignoring the maximization condition for a moment) is

$$\varphi(x,y;u) - \frac{c_1(u,y)}{2u^\delta} \exp\left(-2u^\delta x\right) + c_2(u,y), \tag{39}$$

where

$$\varphi(x,y;u) := \frac{k_1}{2u^\delta} x^2 - \left(\frac{cu}{u^\delta} + \frac{k_1}{2u^{2\delta}} \right) x + \frac{k_2}{u^\delta} xy. \tag{40}$$

We have one solution for $u = \alpha$ and one for $u = \beta$. The five parameters: $c_1(\alpha, y)$, $c_1(\beta, y)$, $c_2(\alpha, y)$, $c_2(\beta, y)$, and the switching point $\overline{x}\,(y)$, are at our disposal. These five parameters are fixed by the terminal condition (38), continuity of the function and its first two derivatives, and a growth condition for x large and negative.

Standard techniques provide the following estimate for the growth of $W(x,y)$.

LEMMA 3.2. *There is a positive constant $C = C(\alpha, \beta, \delta, c, k_1, k_2)$ such that*

$$0 \leqq \sup_{u \in \mathcal{A}} J_1(x,y;u) \leqq C\left(1 + |x|^2 + |y|^2\right) \; (x \leqq y).$$

In particular, the polynomial growth condition (13) *is satisfied with $p = 2$.*

This lemma rules out exponential growth for x large and negative. The fact that $\varphi(x,y;\alpha) > \varphi(x,y;\beta)$ for x large and negative indicates that the optimal control must be $u = \alpha$ for such x, and so $c_1(\alpha, y) \equiv 0$. Hence

$$W_x(x,y) = \frac{k_1}{\alpha^\delta} x - \left(\frac{c\alpha}{\alpha^\delta} + \frac{k_1}{2\alpha^{2\delta}} \right) + \frac{k_2}{\alpha^\delta} y \; (x < \overline{x}\,(y)).$$

For $x > \overline{x}\,(y)$, we use $u = \beta$, so

$$W_x(x,y) = \frac{k_1}{\beta^\delta} x - \left(\frac{c\beta}{\beta^\delta} + \frac{k_1}{2\beta^{2\delta}} \right) + \frac{k_2}{\beta^\delta} y + c_1(\beta, y) \exp\left(-2\beta^\delta x\right) \; (\overline{x}\,(y) < x < B).$$

If we require that $W_x(x,y)$ be continuous across $x = \overline{x}\,(y)$, we have one restriction:

$$\begin{aligned}&\tfrac{k_1}{\alpha^\delta}\overline{x}\,(y) - \left(\tfrac{c\alpha}{\alpha^\delta} + \tfrac{k_1}{2\alpha^{2\delta}}\right) + \tfrac{k_2}{\alpha^\delta}y \\ &\quad = \tfrac{k_1}{\beta^\delta}\overline{x}\,(y) - \left(\tfrac{c\beta}{\beta^\delta} + \tfrac{k_1}{2\beta^{2\delta}}\right) + \tfrac{k_2}{\beta^\delta}y + c_1(\beta,y)\exp\left(-2\beta^\delta\overline{x}\,(y)\right).\end{aligned}$$

Continuity of $W_{xx}(x,y)$ across $x = \overline{x}\,(y)$ provides a second restriction:

$$\frac{k_1}{\beta^\delta} - 2\beta^\delta c_1(\beta,y)\exp\left(-2\beta^\delta\overline{x}\,(y)\right) = \frac{k_1}{\alpha^\delta}.$$

Combining these we obtain the switching line

$$\overline{x}\,(y) = \frac{1}{2\alpha^\delta} + \frac{c}{k_1}\left(\frac{\alpha\beta^\delta - \alpha^\delta\beta}{\beta^\delta - \alpha^\delta}\right) - \frac{k_2}{k_1}y, \tag{41}$$

as well as

$$c_1(\beta,y) = -\frac{k_1}{2\beta^\delta}\left(\frac{\beta^\delta - \alpha^\delta}{\alpha^\delta\beta^\delta}\right)e^{2\beta^\delta\overline{x}\,(y)}. \tag{42}$$

Note that there is a switch (i.e., $\overline{x}\,(y) < y$) if and only if

$$y > \hat{y} := \frac{1}{2\alpha^\delta}\left(\frac{k_1}{k_1+k_2}\right) + \frac{c}{k_1+k_2}\left(\frac{\alpha\beta^\delta - \alpha^\delta\beta}{\beta^\delta - \alpha^\delta}\right). \tag{43}$$

The constants $c_2(\beta,y)$ and $c_2(\alpha,y)$ are determined by requiring $W(y,y) = 0$ and continuity across $\overline{x}\,(y)$ for $y > \hat{y}$. In particular, for $y \leqq \hat{y}$ there is no switch and so

$$c_2(\alpha,y) = -\varphi(y,y;\alpha)\ (y \leqq \hat{y}). \tag{44}$$

For $y > \hat{y}$, the control is β for $\overline{x}\,(y) < x \leqq y$ and $W(y,y) = 0$ provides

$$c_2(\beta,y) = -\frac{k_1}{4\beta^{2\delta}}\left(\frac{1}{\alpha^\delta} - \frac{1}{\beta^\delta}\right)\exp\left(-2\beta^\delta(y - \overline{x}\,(y))\right) - \varphi(y,y;\beta). \tag{45}$$

Continuity at $x = \overline{x}\,(y)$ requires

$$c_2(\alpha,y) = -\varphi(\overline{x}\,(y),y;\alpha) + \varphi(\overline{x}\,(y),y;\beta) + \frac{k_1}{4\beta^{2\delta}}\left(\frac{1}{\alpha^\delta} - \frac{1}{\beta^\delta}\right) + c_2(\beta,y). \tag{46}$$

This construction provides a solution to (37), which is twice continuously differentiable (with respect to x) and also satisfies the growth condition of Lemma 3.2. The standard verification theorem for controlled diffusions provides the following proposition.

PROPOSITION 3.3. *The optimal control for the auxiliary problem* (36) *is*

$$u^*(x,y) = \begin{cases} \alpha, & x < y,\ y \leqq \hat{y}, \\ \alpha, & x < \overline{x}\,(y),\ y > \hat{y}, \\ \beta, & \overline{x}\,(y) < x \leqq y,\ y > \hat{y}, \end{cases} \tag{47}$$

where $\overline{x}\,(y)$ is defined in (41) *and $\hat{y}$ is defined in* (43). *The value function is given by*

$$
(48)W(x,y)=\begin{cases}\varphi(x,y;\alpha)-\varphi(y,y;\alpha),\ x\leqq y,\ y\leqq\hat{y},\\[2ex] \varphi(x,y;\alpha)+c_2(\alpha,y),\ x\leqq\overline{x}\,(y),\ y>\hat{y},\\[2ex] \varphi(x,y;\beta)-\dfrac{c_1(\beta,y)}{2\beta^\delta}\,e^{(-2\beta^\delta x)}+c_2(\beta,y),\ \overline{x}\,(y)<x\leqq y,\ y>\hat{y},\end{cases}
$$

where $\varphi(x,y;u)$ is defined in (40) *and the parameters $c_2(\alpha,y)$, $c_1(\beta,y)$, and $c_2(\beta,y)$ are defined in* (46), (42), *and* (45), *respectively.*

By construction, $W(x,y)$ is twice continuously differentiable with respect to x. As a function of y, $W(x,y)$ is equally well behaved *as long as* $k_1>0$. In particular, for fixed x, the control switches from α to β at

$$
(49)\qquad \overline{y}\,(x):=\frac{1}{2\alpha^\delta}\frac{k_1}{k_2}+\frac{c}{k_2}\left(\frac{\alpha\beta^\delta-\alpha^\delta\beta}{\beta^\delta-\alpha^\delta}\right)-\frac{k_1}{k_2}x.
$$

We verify that $W_y(x,y)$ is continuous across $y=\overline{y}\,(x)$; the computations to verify the continuity of $W(x,y)$ and $W_{yy}(x,y)$ are similar. Looking at $W_y(x,y)$ above and below $y=\overline{y}\,(x)$ (letting "$'$" denote differentiation with respect to y), we obtain

$$
\begin{aligned}
\Delta W_y(x,\overline{y}\,(x)) &:= W_y(x,\overline{y}\,(x)^+)-W_y(x,\overline{y}\,(x)^-)\\
&= \varphi_y(x,\overline{y}\,(x);\beta)-\left(c_1'(\beta,\overline{y}\,(x))\frac{1}{2\beta^\delta}\right)e^{-2\beta^\delta x}\\
&\quad+c_2'(\beta,\overline{y}\,(x))-\varphi_y(x,\overline{y}\,(x);\alpha)-c_2'(\alpha,\overline{y}\,(x))\\
&= \left[\frac{k_1}{2\beta^\delta}\left(\frac{\beta^\delta-\alpha^\delta}{\beta^\delta\alpha^\delta}\right)+\varphi_x(x,\overline{y}\,(x);\alpha)-\varphi_x(x,\overline{y}\,(x);\beta)\right]\overline{x}\,'(y)\\
&= \left[\frac{k_1}{2\beta^\delta}\left(\frac{\beta^\delta-\alpha^\delta}{\beta^\delta\alpha^\delta}\right)-\frac{k_1}{2\beta^\delta}\left(\frac{\beta^\delta-\alpha^\delta}{\beta^\delta\alpha^\delta}\right)\right]\overline{x}\,'(y)\\
&= 0.
\end{aligned}
$$

We have used the definitions of $c_1(\beta,y)$, $c_2(\alpha,y)$, $c_2(\beta,y)$ given above as well as $\overline{x}\,(\overline{y}\,(x))=x$ and

$$
\left[c_1(\beta,\overline{y}\,(x))e^{-2\beta^\delta x}+\varphi_x(x,\overline{y}\,(x);\beta)-\varphi_x(x,\overline{y}\,(x);\alpha)\right]=W_x(x,\overline{y}\,(x)^+)-W_x(x,\overline{y}\,(x)^-)=0.
$$

Note that

$$
\overline{x}\,'(y)=-\frac{k_2}{k_1}
$$

becomes infinite as $k_1\to 0$. This corresponds with the appearance of the jump in $W_y(x,y)$ at $y=\overline{y}$ (recall (30)) for the pure running max problem ($k_1=0$).

Since $W(x,y)$ is continuous in the region $\{(x,y)\,:\,x\leqq y\}$, twice continuously differentiable with respect to x, continuously differentiable on the diagonal $x=y$, and has polynomial growth, Theorem 2.5 can be applied to construct the value function for the running max problem. The optimal policy for the running max problem is the same as the policy described in Proposition 3.3.

PROPOSITION 3.4. *The optimal feedback control for the linear mixed problem* (34) *is given in* (47). *The value function is given by*

$$V(x,y) = W(x,y) + \int_y^B W_y(z,z)dz, \tag{50}$$

with $W(x,y)$ *defined in Proposition* 3.3, (48).

As long as $k_1 > 0$, $V(x,y)$ is also twice continuously differentiable in both x and y. In fact, $V(x,y)$ inherits its smoothness from $W(x,y)$ since

$$V_y(x,y) = W_y(x,y) - W_y(y,y),$$

and

$$V_{yy}(x,y) = W_{yy}(x,y) - W_{xy}(y,y) - W_{yy}(y,y).$$

3.2. Two special cases. We now discuss two limiting cases for the mixed problem.

3.2.1. The standard problem: $\mathbf{k_2 = 0}$. If the running maximum y_t does not enter the objective function, then the control problem is reduced to a standard optimal stochastic control problem.

The switching level defined in (41) becomes constant:

$$\overline{x} = \frac{1}{2\alpha^\delta} + \frac{c}{k_1}\left(\frac{\alpha\beta^\delta - \alpha^\delta\beta}{\beta^\delta - \alpha^\delta}\right) = \frac{1}{2\alpha^\delta} + \frac{c\alpha}{k_1}\left[1 - \left(\frac{(\beta/\alpha) - 1}{(\beta/\alpha)^\delta - 1}\right)\right]. \tag{51}$$

Note that the term in parentheses is negative when $0 < \alpha < \beta$ and $0 < \delta < 1$.

The switching level $\overline{x}$ defined in (51) is decreased if the ratio c/k_1 is increased. That is, if the coefficient of u is increased in the running cost, then it is optimal to use the maximum work rate longer. Similarly, if c/k_1 is small, so the coefficient of x in the running cost dominates, then $\overline{x}$ approaches the maximum switching level $1/2\alpha^\delta$. Finally, in the case where $\delta = 1$, the switching level becomes independent of the cost parameters c and k_1, since $\overline{x} = 1/(2\alpha)$.

3.2.2. The pure running max version: $\mathbf{k_1 = 0}$. If the diffusion x_t does not enter the objective function, then this is a pure running max problem, so we know that the optimal policy will be a y-threshold policy. In particular, the switching point $\overline{x}(y)$ defined in (41) becomes $-\infty$ and $\overline{y}(x)$ defined in (49) becomes constant:

$$\overline{y} = \frac{c}{k_2}\left(\frac{\alpha\beta^\delta - \alpha^\delta\beta}{\beta^\delta - \alpha^\delta}\right) = \frac{c\alpha}{k_2}\left[1 - \left(\frac{(\beta/\alpha) - 1}{(\beta/\alpha)^\delta - 1}\right)\right]. \tag{52}$$

The optimal policy is

$$u^*(x,y) = \begin{cases} \alpha, & y \leqq \overline{y}; \\ \beta, & \overline{y} < y \leqq B. \end{cases} \tag{53}$$

Note that $\overline{y}$ is negative for $0 < \delta < 1$, increasing to zero when $\delta = 1$, hence it is never optimal to use the slow work rate if the initial state y is nonnegative.

Remark 3.5. One of the original motivations for this research was to determine what happens when the objective for a controlled diffusion problem depends on the running maximum instead of the diffusion. For the linear example, we have shown that the policy changes from an x-threshold to a y-threshold policy and the switching level for the running max problem is *lower* than the switching level for the standard problem. That is, let $\overline{x}$ denote the optimal switching level for the payoff

$$J(x;u) := E_x \int_0^{\tau(B)} [cu_t - kx_t]dt$$

and let $\overline{y}$ denote the switching level for

$$J_{\max}(x,y;u) := E_{xy} \int_0^{\tau(B)} [cu_t - ky_t]dt.$$

Then

$$\overline{y} = \overline{x} - \frac{1}{2\alpha^\delta} < \overline{x}.$$

As noted in §2.2, the value function for a pure running max problem does not retain the smoothness (with respect to y) demonstrated after Proposition 3.3. The value function is given by

$$V(x,y) = W(x,y) + \int_y^B W_y(z,z)dz,$$

where, recalling (27),

$$W(x,y) = \begin{cases} (c\alpha - k_2 y)\dfrac{(y-x)}{\alpha^\delta}, & y \leqq \overline{y}, \ x \leqq y, \\ (c\beta - k_2 y)\dfrac{(y-x)}{\beta^\delta}, & \overline{y} < y \leqq B, \ x \leqq y. \end{cases} \tag{54}$$

Note that $W(x,y)$ satisfies the the hypotheses of Theorem 2.5.

The value function $V(x,y)$ is not continuously differentiable with respect to y; there is a "corner" at $\overline{y}$. Recalling (30), $V_y(x,y)$ has a positive jump at $\overline{y}$ of magnitude

$$\begin{aligned} \Delta V_y(x,\overline{y}) &= \Delta W_y(x,\overline{y}) \\ &= k_2 \left[E_{x\overline{y}}\, \tau_1(x,\overline{y}\,;\beta) - E_{x\overline{y}}\, \tau_1(x,\overline{y}\,;\alpha)\right] \\ &= k_2 \left(\frac{\beta^\delta - \alpha^\delta}{\alpha^\delta \beta^\delta}\right)(\overline{y} - x). \end{aligned}$$

The jump in $V_y(x,y)$ is just k_2 times the jump in the expected hitting time when the control switches.

Finally, there is a jump in $V_{yy}(x,y)$ at $y = \overline{y}$ of magnitude

$$\Delta V_{yy}(x,\overline{y}) = 2k_2 \left(\frac{\beta^\delta - \alpha^\delta}{\beta^\delta \alpha^\delta}\right).$$

4. Concluding remarks. The running max provides a continuous, monotone stochastic process model with the advantages of all the machinery of the Itô calculus for applications. The theory of controlled diffusions extends to handle problems in controlling the running max. It remains to be seen in applications whether a running max model will provide results fundamentally different from results for standard controlled diffusions.

One important application for running max problems is in optimal control and replacement problems for systems subject to deterioration and wear. If we take the linear mixed problems considered in §3 and consider it as such a problem, we obtain a quite counterintuitive policy: work cautiously ($u = \alpha$) when the machine is new and work the machine very hard ($u = \beta$) as the machine ages and wears. This behavior is an artifact of the form of the objective function and not the running max model for the state. In particular, there is a large penalty for working with a worn machine and there is no penalty for failure while working, hence there is no reward for working conservatively with a worn machine. There is also no option to quit before failure and there is no reward for doing so. Thus, the linear payoff does not fit the form usually studied in optimal repair and replacement problems (see [1], [10], [12], and [22] for example). In future work, we will consider running max control problems where the objective function is closer to the types of objectives usually considered in these applications.

There are interesting and difficult estimation and identification problems introduced in applications of the running max model. Recall that it was not possible to simply *replace* the diffusion with the running max; the running max alone is not a Markov process. It was necessary to assume that the controller could observe *both* the diffusion $(x_t; 0 \leqq t < \infty)$ *and* the running maximum $(y_t; 0 \leqq t < \infty)$. How is the problem changed, indeed is it solvable in any sense, if only the values of the running maximum are available to the controller? As shown in §2.2, if the diffusion does not enter the payoff function directly, then the optimal policy depends only on the observed values of y_t. However, if both the diffusion and its running maximum enter the payoff, the optimal policy depends on the observed value of x_t, and then we are faced with a *partially observed* stochastic control problem, and the problems become much more difficult.

Acknowledgments. We thank Professors Kurt Helmes and Raymond Rishel for helpful comments and criticisms during the development of this research. We also thank Professors Steve Shreve and Tom Kurtz for many helpful discussions.

FINITE TIME OBSERVER DESIGN BY PROBABILISTIC-VARIATIONAL METHODS*

MATTHEW R. JAMES†

Abstract. A notion of finite time observer for partially observed deterministic control systems is introduced; it is shown how such observers are obtained by probabilistic-variational methods. Observability plays an essential role. The procedure is carried out for finite-state discrete-time systems and continuous-time nonlinear systems, and the observers obtained are respectively finite and infinite dimensional. A simple algorithm implementing the observer for finite-state systems is described. An observability grammian for nonlinear systems is introduced and is used to study the time evolution of sets of indistinguishable points, as well as local properties of the function satisfying the observer equation. Finally, the results are specialized to bilinear systems.

Key words. nonlinear control systems, observers, filters, observability

AMS(MOS) subject classifications. 93B07, 93E11

1. Introduction.

In this paper we introduce a notion of *finite time observer* for partially observed deterministic control systems and show how such observers are obtained by probabilistic-variational methods. A finite time observer is a dynamical system that uses observations from a control system to compute an estimate $\hat{x}(t)$ of the state $x(t)$ of the control system; and after a finite time has elapsed, the estimate is exact: for any *universal* input defined on $[0,T]$, $\hat{x}(t) = x(t)$, $t \geq T$. Most existing observer designs are *asymptotic*: $\text{dist}(\hat{x}(t), x(t)) \to 0$ as $t \to \infty$.

In [3], Baras and Krishnaprasad proposed that observers for nonlinear control systems might be obtained as asymptotic limits of recursive filters. Their idea was to add noise, scaled by a small parameter $\epsilon > 0$, to the equations defining the system, construct the corresponding family of filters parameterized by $\epsilon > 0$, and then pass to the limit as $\epsilon \to 0$. The limiting filter that results is a candidate observer for the original deterministic system. Finally, we must determine whether the candidate is, in fact, an observer. Baras [1] conjectured that, in general, an "infinite-dimensional" observer would result, under appropriate hypotheses (such as observability). The rationale behind this idea was to achieve an observer design by exploiting both the additional structure obtained by randomizing the problem, and the power of asymptotic methods.

To date, work on this approach has been primarily concerned with studying the asymptotic filtering problem (James and Baras [17], James [15]) and using the limiting filter to motivate asymptotic observer designs (Baras, Bensoussan, and James [2]; James [15]). Such designs were obtained by approximating the limiting filter, in the spirit of extended Kalman filtering, and required the system to satisfy a *detectability* condition. The purpose of this paper is to show that the approach of Baras and

Krishnaprasad is successful in theory by carrying it out in two general settings: finite-state machines and nonlinear control systems.

The underlying asymptotic nonlinear filtering problem is connected with the theory of large deviations, which provides a link between asymptotic probabilities and variational problems. This problem has been studied by Hijab [12], [13], who characterized the limiting filter in terms of Mortensen's [24] method of deterministic minimum energy estimation. In the observer problem, the initial state is unknown, so we construct nonlinear filters for the randomized systems that reflect this lack of knowledge. If the system input is universal, then these filters are are consistent as $\epsilon \rightarrow 0$ (Theorems 3.1 and 4.1). The limiting filters so obtained are also consistent: they compute the state exactly (Theorems 3.2 and 4.2).

In §2 we review the concept of observability and define the term "finite time observer." In §3 we study in detail the method as it applies to finite-state machines. The observer obtained is finite-dimensional, and we describe how it can be implemented by a simplified parallel algorithm or circuit. These results might be useful for approximating more complex systems and developing numerical algorithms. In §4 we turn to continuous-time nonlinear control systems. The observers are, in general, infinite-dimensional (with dynamics given by Hamilton–Jacobi equations), a disadvantage shared with nonlinear stochastic filters. Because observability is so important, we study this concept further in §5 by characterizing the change in local structure of the sets of indistinguishable points as time increases, and relating this to certain properties of the value function, which solves the Hamilton-Jacobi equation. To do so, we introduce an observability grammian for nonlinear systems (a 2-form) and use it to define a time-dependent distribution, which we call the observability grammian distribution. This develops well-known results on local observability based on the observability codistribution introduced by Hermann and Krener [11]. We specialize our results to bilinear systems in §6.

2. Preliminaries. In this section we recall some definitions concerned with the concepts of observability and observers. We begin by introducing the models to be used.

We consider discrete-time finite-state machines defined by

$$\begin{aligned} &x(t+1) = f(x(t), u(t)); \quad t = 0, 1, 2, \cdots; \quad x(0) = x_0; \\ &y(t) = h(x(t)); \qquad t = 0, 1, 2, \cdots. \end{aligned} \tag{2.1}$$

The state $x(t)$ evolves in a finite set $\mathbf{X}$, and the control $u(t)$ and observation $y(t)$ take values in finite sets $\mathbf{U}$ and $\mathbf{Y}$, respectively. These sets have n, m, and p elements, respectively. The machine is described by a state transition map $f : \mathbf{X} \times \mathbf{U} \rightarrow \mathbf{X}$ and an output map $h : \mathbf{X} \rightarrow \mathbf{Y}$. Denote by $[0, T\,]$ the time interval $\{0, 1, 2, \cdots, T\}$ and define the sequence spaces $\mathcal{U}^T = \{u : [0, T\,] \rightarrow \mathbf{U}\}$, $\mathcal{U} = \bigcup_{T \geq 0} \mathcal{U}^T$, $\mathcal{X}^T = \{x : [0, T\,] \rightarrow \mathbf{X}\}$, $\mathcal{Y}^T = \{y : [0, T\,] \rightarrow \mathbf{Y}\}$. Let γ_u denote the flow for system (2.1); that is, $x(t) = \gamma_u(t)x_0 \in \mathbf{X}$ is the state at time t of (2.1) corresponding to the control $u \in \mathcal{U}$ with initial condition $x_0 \in \mathbf{X}$. We also write $x^T = (x(0), x(1), \cdots, x(T)) \in \mathcal{X}^T$ for an entire trajectory over the time interval $[0, T\,]$. Similarly, $y(t) = h(\gamma_u(t)x_0) \in \mathbf{Y}$ and $y^T = (y(0), y(1), \cdots, y(T)) \in \mathcal{Y}^T$.

The continuous-time nonlinear control systems we consider are defined by

$$\begin{aligned} &\dot{x}(t) = f(x(t), u(t)), \quad t > 0, \quad x(0) = x_0; \\ &y(t) = h(x(t)), \qquad t \geq 0. \end{aligned} \tag{2.2}$$

Here, $x(t) \in \mathbf{X}$, $u(t) \in \mathbf{U}$, and $y(t) \in \mathbf{Y}$; where $\mathbf{X} = \Re^n$, $\mathbf{Y} = \Re^p$ and $\mathbf{U} \subset \Re^m$. We assume that $f \in C^\infty(\Re^n \times \Re^m, \Re^n)$ and $h \in C^\infty(\Re^n, \Re^p)$ satisfy

$$\begin{aligned} |f(x,u) - f(z,u)| &\leq C|x-z|, \\ |f(x,u)|| &\leq C\,(1 + |x| + |u|)\,, \\ |h(x) - h(z)| &\leq C|x-z|, \end{aligned}$$

where $C > 0$ is independent of $x, z \in \Re^n$, $u \in \mathbf{U}$. Let $\mathcal{U}^T = C([0,T\,], \mathbf{U})$, $\mathcal{X}^T = C([0,T\,], \mathbf{X})$, $\mathcal{Y}^T = C([0,T\,], \mathbf{Y})$, denote the respective path spaces, equipped with the uniform norms, and write $\mathcal{U} = \bigcup_{T \geq 0} \mathcal{U}^T$. Our observer design (given in §4) is also valid for piecewise continuous controls, although we do not treat this extension here. The flow is again written $x(t) = \gamma_u(t)x_0$, etc.

In what follows, all time instants t and intervals $[0,T\,]$ are assumed to be within the domain of definition dom(u) of the relevant control $u \in \mathcal{U}$. In §3.2 and §4.2, the controls may be either open or closed loop. We turn now to the concept of observability. A system Σ will mean either (2.1) or (2.2). The definitions are the same for both.

DEFINITION 2.1 (a) A system Σ is observable on $[0,T\,]$ if for all $x_0^1 \neq x_0^2$ in $\mathbf{X}$ there exists $u \in \mathcal{U}$ such that

$$h(\gamma_u(t)x_0^1) \neq h(\gamma_u(t)x_0^2) \quad \text{for some} \quad t \in [0,T\,]. \tag{2.3}$$

(b) We say that Σ is reconstructable on $[0,T\,]$ if for all $x_0^1 \neq x_0^2$ in $\mathbf{X}$ there exists $u \in \mathcal{U}$ such that

$$\begin{aligned} h(\gamma_u(t)x_0^1) = h(\gamma_u(t)x_0^2) \quad &\text{for all} \quad t \in [0,T\,] \\ \text{implies} \quad \gamma_u(T)x_0^1 = \gamma_u(T)x_0^2&. \end{aligned} \tag{2.4}$$

(c) A control u for which (2.4) holds for all states $x_0^1 \neq x_0^2$ is termed *universal* on $[0,T\,]$.

For continuous-time systems, if u is universal on $[0,T\,]$, then (2.3) holds for all $x_0^1 \neq x_0^2$. The existence and genericity of universal controls is discussed by Sontag [26] and Sussmann [27]. A related discussion of observers is given by Sontag [26].

The observer problem is a deterministic state estimation problem: we wish to design a deterministic dynamical system that takes as inputs $u \in \mathcal{U}^t$ and $y \in \mathcal{Y}^t$ and produces an estimate $\hat{x}(t) \in \mathbf{X}$ of the state $x(t) \in \mathbf{X}$; the initial condition $x_0 \in \mathbf{X}$ being unknown. This problem was first solved for observable linear systems by Luenberger [22], in an asymptotic sense: $\lim_{t\to\infty} \operatorname{dist}(\hat{x}(t), x(t)) = 0$. Later, Wonham extended this result to *detectable* linear systems [31], which are not necessarily observable. Asymptotic observers for nonlinear systems have been obtained by numerous authors, for instance: Williamson [30], Kuo, Elliott, and Tarn [21], Bestle and Zeitz [4], Krener and Respondek [20], Isidori [14], Baras, Bensoussan, and James [2], Celle et al. [6]. These observers are defined by ordinary differential equations, are finite-dimensional, and either assume a local observability condition or involve a stability condition for the equation satisfied by the error (detectability). Each design has a number of advantages and disadvantages (Walcott, Corless, and Zak [29]), and many require precise knowledge of the system model.

In this paper we introduce observers that compute the state *exactly* after a finite time has elapsed:

$$\hat{x}(t) \;=\; x(t) \quad \text{for all} \quad t \geq T. \tag{2.5}$$

An important requirement is that the estimate be computed recursively; thus we want the observer to be realizable as a dynamical system, of the general form

$$\begin{aligned} \dot{m}(t) &= F(m(t), u(t), y(t)), \quad t > 0, \quad m(0) = m_0; \\ \hat{x}(t) &= G(m(t)), \qquad t \geq 0; \end{aligned} \tag{2.6}$$

for continuous-time systems, and

$$\begin{cases} m(t+1) = F(m(t), u(t), y(t)), \quad t = 0, 1, 2, \cdots; \quad m(0) = m_0; \\ \hat{x}(t) = G(m(t)), \qquad t = 0, 1, 2, \cdots; \end{cases} \tag{2.7}$$

for discrete-time systems. Equations (2.6) and (2.7) are interpreted as defining dynamical systems with state $m(t)$ taking values in a space $\mathbf{M}$, and producing an output $\hat{x}(t) \in \mathbf{X}$. This output is the state estimate. The space $\mathbf{M}$ need not be finite-dimensional.

DEFINITION 2.2 A dynamical system $\mathcal{O}_\Sigma$ of the form (2.6) or (2.7) is called a finite time observer for the system Σ provided (2.5) holds for any control $u \in \mathcal{U}$ that is universal on $[0, T]$.

The task of observer design, then, is to somehow obtain from the given data a system of the form (2.6) or (2.7) that fulfills the requirements of the definition. In the following we achieve this goal in some generality using ideas from nonlinear filtering and large deviations.

3. Finite-state machines.

3.1. Asymptotic filtering. We regard system (2.1) as a deterministic Markov chain and define a random perturbation as follows. Let $N(x)$ denote a set of points "neighboring" $x \in \mathbf{X}$, defined so that $N(x)$ contains $f(x, u)$ for every $u \in \mathbf{U}$, and every point z for which $x = f(z, u)$ for some $u \in \mathbf{U}$. Define for $z, x \in \mathbf{X}$ and $u \in \mathbf{U}$

$$U(z, x; u) = \begin{cases} 0 & \text{if} \quad x = f(z, u), \\ 1 & \text{if} \quad x \neq f(z, u) \quad \text{and} \quad x \in N(z), \\ +\infty & \text{if} \quad x \neq f(z, u) \quad \text{and} \quad x \notin N(z), \end{cases}$$

and for $\epsilon > 0$,

$$A^\epsilon(u)_{xz} = \frac{1}{Z} \exp\left(-\frac{1}{\epsilon} U(z, x; u)\right),$$

where Z is a normalization constant: $\sum_{x \in N(z)} A^\epsilon(u)_{xz} = 1$ for each $z \in \mathbf{X}$. (Throughout, Z denotes an appropriate normalization constant.) A random perturbation of the state $\{x(t);\ t = 0, 1, 2, \cdots\}$ is an $\mathbf{X}$-valued Markov chain $\{x^\epsilon(t);\ t = 0, 1, 2, \cdots\}$ whose probabilities $p^\epsilon_x(t) = \text{Prob}\,(x^\epsilon(t) = x \mid u, x^\epsilon(0) = x_0)$ evolve according to

$$p^\epsilon(t+1) = A^\epsilon(u(t)) p^\epsilon(t); \quad t = 0, 1, 2, \cdots; \quad p^\epsilon(0) = p_0. \tag{3.1}$$

Note that $A^\epsilon(u) \to A(u)$ and thus $x^\epsilon(t) \Rightarrow x(t)$ as $\epsilon \to 0$.

Denoting by θ an element of $\mathcal{X}^T$, we have, using the Markov property,

$$\begin{aligned} P^\epsilon_{u, x_0}(\theta) &= \text{Prob}\,(x^{\epsilon, T} = \theta \mid u, x^\epsilon(0) = x_0), \\ &= \frac{1}{Z} \exp\left(-\frac{1}{\epsilon} \sum_{t=0}^{T-1} U(\theta(t), \theta(t+1); u(t))\right) I_{\{\theta(0) = x_0\}}. \end{aligned} \tag{3.2}$$

This is a probability measure on $\mathcal{X}^T$ corresponding to the process $x^{\epsilon, T}$ (a Gibbs distribution). From this explicit formula, we readily obtain a large deviation result for these measures (cf. Theorem 3.1 below).

The noisy observation is a $\mathbf{Y}$-valued process $\{y^\epsilon(t);\ t = 0, 1, 2, \cdots\}$ distributed according to the conditional probability

$$\text{Prob}\,(y^\epsilon(t) = y \mid x^\epsilon(t) = x) = \frac{1}{Z} \exp\left(-\frac{1}{\epsilon} V(x, y)\right), \tag{3.3}$$

where

$$V(x, y) = \begin{cases} 0 & \text{if} \quad y = h(x), \\ 1 & \text{if} \quad y \neq h(x). \end{cases}$$

Let us now define a filter, assuming instead that the initial condition x_0^ϵ is random and has the uniform distribution μ on $\mathbf{X}$. This is done because in the observer problem the initial condition is completely unknown. For $\theta \in \mathcal{X}^T$ and $\eta \in \mathcal{Y}^T$, Bayes' rule gives

$$\begin{aligned} \Pi^\epsilon_{u,\mu}(\theta \mid \eta) &= \text{Prob}\,(x^{\epsilon,T} = \theta \mid y^{\epsilon,T} = \eta, u, \mu) \\ &= \frac{1}{Z} \exp\left(-\frac{1}{\epsilon}\left[\sum_{t=0}^{T-1} U(\theta(t), \theta(t+1); u(t)) + \sum_{t=0}^{T} V(\theta(t), \eta(t))\right]\right), \end{aligned} \tag{3.4}$$

where the averaging with respect to μ is absorbed into the normalization constant Z.

Let x_0^* denote the actual initial condition of (2.1), and let x_*^ϵ, x_*, y_*^ϵ, y_* denote the corresponding state and observation trajectories produced by (2.1) and its random perturbation, under the action of a control $u \in \mathcal{U}$. We are interested in the asymptotic behaviour of this filter evaluated using the actual noisy observations y_*^ϵ. Define the *action function* for the filters by

$$I_u(\theta \mid \eta) = \sum_{t=0}^{T-1} U(\theta(t), \theta(t+1); u(t)) + \sum_{t=0}^{T} V(\theta(t), \eta(t)). \tag{3.5}$$

We then have the following large deviations and consistency result.

THEOREM 3.1. *The family of filters* $\{\Pi^\epsilon_{u,\mu}\}$ *obey the large deviation principle in probability* (LDPP) *with action function* $I_u(\theta \mid y_*)$. *In particular, if* $A \subset \mathcal{X}^T$, *then*

$$\lim_{\epsilon \to 0} \epsilon \log \Pi^\epsilon_{u,\mu}(A \mid y_*^\epsilon) = -\min_{\theta \in A} I_u(\theta \mid y_*) \quad \textit{in probability.}$$

Furthermore, if $u \in \mathcal{U}^T$ *is a control for which* (2.3) *holds for all* $x_0^1 \neq x_0^2$, *then*

$$\Pi^\epsilon_{u,\mu}(\cdot \mid y_*^\epsilon) \Rightarrow \delta_{x_*} \quad \textit{in probability as } \epsilon \to 0.$$

The proof of this theorem is straightforward and employs the explicit formula (3.4). The weak convergence statement depends on the fact that the assumed observability condition implies that the functional $I_u(\cdot \mid y_*)$ has a *unique* minimizer, namely, x_*. Indeed, $I(x_* \mid y_*) = 0$, and also if $I(\theta \mid y_*) = 0$, then θ is a solution of (2.1) producing the output y_*. If for the given control (2.3) holds for all $x_0^1 \neq x_0^2$, then this implies that $\theta(0) = x_*(0)$, and hence $\theta = x_*$ (cf. Theorem 3.2 below). Thus if A is a subset of $\mathcal{X}^T$ not containing x_*, then the large deviation limit result implies (Varadhan [28]) that $\Pi^\epsilon_{u,\mu}(A \mid y_*^\epsilon)$ decays exponentially to zero as $\epsilon \to 0$. This theorem is interpreted as saying that the filters $\Pi^\epsilon_{u,\mu}$, when applied to the actual noisy observations, concentrate on the desired state trajectory x_* as $\epsilon \to 0$, provided the observability condition holds.

3.2. Observer design. It is clear from the above that the state trajectory can be determined by solving a variational problem: find the unique minimizer of $I_u(\cdot \mid y_*)$. We solve this problem using the dynamic programming method, and obtain a recursive system that becomes our finite time observer for the machine (2.1). For each $t = 0, 1, 2, \cdots$ define a function

$$m(\cdot, t) : \mathbf{X} \to [0, \infty)$$

by

$$m(x,t) = \min \{ I_u(\theta \mid y_*) : \theta(t) = x, \theta \in \mathcal{X}^t \} . \tag{3.6}$$

The function $I_u(\cdot \mid y_*)$ is taken to be defined on the interval $\{0, 1, \cdots, t\}$ rather than the interval $\{0, 1, \cdots, T\}$. The dynamic programming method gives

$$\begin{aligned} m(x,t) &= \min_{z \in N(x)} \{ m(z, t-1) + U(z, x; u(t-1)) + V(x, y_*(t)) \} ; \ t \geq 1; \\ m(x, 0) &= V(x, y_*(0)). \end{aligned} \tag{3.7}$$

Define also the "deterministic estimate" [24], [12]:

$$\hat{x}(t) = \operatorname*{argmin}_{x \in \mathbf{X}} m(x,t) \equiv \{ x \in \mathbf{X} : m(x,t) = 0 \} . \tag{3.8}$$

This quantity is set-valued, since $m(\cdot, t)$ may have many minima. For example, $\hat{x}(0) = \{ x \in \mathbf{X} : h(x) = y_*(0) \}$. Equations (3.7) and (3.8) define the limiting filter; in fact, $\lim_{\epsilon \to 0} \epsilon \log P(x^\epsilon(t) = x \mid y_*^{\epsilon,t}, u, \mu) = -m(x,t)$ in probability. Our main result concerning observers for the finite-state machine (2.1) is the following theorem.

THEOREM 3.2. *The recursive system* (3.7), (3.8) *is a* finite time observer *for the finite-state machine* (2.1). *In particular, if* u *is a* universal *control on* $[0, T]$, *then*

$$\hat{x}(t) = \{ x_*(t) \} \quad \textit{for all} \quad t \geq T. \tag{3.9}$$

Proof. For all $t = 0, 1, 2, \cdots$, $m(x_*(t), t) = 0$ and $m(x,t) \geq 0$ for all $x \in \mathbf{X}$. Suppose that $t \geq T$ and $\tilde{x} \in \mathbf{X}$ is such that $m(\tilde{x}, t) = 0$. Then there exists $\tilde{\theta} \in \mathcal{X}^t$ such that $\tilde{\theta}(t) = \tilde{x}$ and $I_u(\tilde{\theta} \mid y_*) = 0$. This implies that

$$\begin{aligned} \tilde{\theta}(s+1) &= f(\tilde{\theta}(s), u(s)); \qquad s = 0, 1, \cdots, T-1; \\ y_*(s) &= h(\tilde{\theta}(s)); \qquad s = 0, 1, \cdots, T. \end{aligned}$$

(In fact, these relations also hold for $s = T, \cdots, t-1$; $s = T+1, \cdots, t$, respectively.) If u is a universal control on $[0, T]$, this forces $\tilde{\theta}(T) = x_*(T)$. From this, it follows that $\tilde{\theta}(s) = x_*(s)$, $s = T+1, \cdots, t$, and so $\tilde{x} = \tilde{\theta}(t) = x_*(t)$. □

Computing $\hat{x}(t)$ requires the determination of those $x \in \mathbf{X}$ satisfying $m(x,t) = 0$. For each x, the computation of $m(x,t)$ involves up to n minimizations. This procedure can be simplified by setting

$$\tilde{m}(x,t) = \begin{cases} 0 & \text{if } m(x,t) = 0, \\ 1 & \text{if } m(x,t) > 0. \end{cases}$$

Regard 1 and 0 as the logical values TRUE and FALSE. Then $\tilde{m}(x,t)$ is given by the logical expression

$$\begin{aligned} \tilde{m}(x,t) &= V(x, y_*(t)) \vee \bigwedge_{z \in N(x) : x = f(z, u(t-1))} \tilde{m}(z, t-1) \quad \text{if } t \geq 1, \\ \tilde{m}(x, 0) &= V(x, y_*(0)), \end{aligned} \tag{3.10}$$

where the symbols $\vee$ and $\wedge$ denote OR and AND, respectively. If the set $\{ z \in N(x) : x = f(z, u(t-1)) \}$ is empty, we set $\tilde{m}(x,t) = 1$. Note that $\hat{x}(t) = \{ x : \tilde{m}(x,t) = 0 \}$. A digital circuit or parallel algorithm can readily be designed to realize (3.10).

4. Nonlinear control systems.

4.1. Asymptotic filtering. On a probability space $(\Omega, \mathcal{F}, P)$ we consider a family of diffusion processes $\{x^\epsilon(t), t \geq 0\}$ together with observation processes $\{\xi^\epsilon(t), t \geq 0\}$, satisfying the stochastic differential equations

$$\begin{aligned} dx^\epsilon(t) &= f(x^\epsilon(t), u(t))dt + \sqrt{\epsilon}dw(t), \qquad x^\epsilon(0) = x_0, \\ d\xi^\epsilon(t) &= h(x^\epsilon(t))dt + \sqrt{\epsilon}dv(t), \qquad \xi^\epsilon(0) = 0. \end{aligned} \tag{4.1}$$

Here, $\{w(t), t \geq 0\}$ and $\{v(t), t \geq 0\}$ are independent Wiener processes in $\mathbf{X} = \Re^n$ and $\mathbf{Y} = \Re^p$, respectively, and $x_0 \in \Re^n$. This defines the perturbed state and observation equations for the continuous-time nonlinear control system (2.2). As is well known (Freidlin and Wentzell [10]), $x^{\epsilon,T} \to x^T$ and $\xi^{\epsilon,T} \to \xi^T$ in probability as $\epsilon \to 0$, where $\xi(t) = \int_0^t y(s)ds$, and the distributions P^ϵ_{u,x_0} of $x^{\epsilon,T}$ on $\mathcal{X}^T$ obey the large deviation principle (uniformly in $x_0 \in \Re^n$).

We use the well-known robust filter (Davis [8]) for (4.1), defined assuming that the distribution of the initial condition x^ϵ_0 is a probability measure μ on $\Re^n$ such that $\mu(B(x,r)) > 0$ for every ball $B(x,r)$. This filter is a continuous map

$$\Pi^\epsilon_{u,\mu} : \mathcal{Y}^T \to \mathcal{P}(\mathcal{X}^T)$$

such that

$$\Pi^\epsilon_{u,\mu}(A \mid \xi^\epsilon_*) = P\left(x^{\epsilon,T} \in A \mid \xi^\epsilon_*,\ u, \mu\right) \ \text{ a.s.} \qquad (A \in \mathcal{B}(\mathcal{X}^T)).$$

An explicit formula for the filter corresponding to a bilinear system is given in §6. For $\theta \in \mathcal{X}^T$ and absolutely continuous $\eta \in \mathcal{Y}^T$, define the action function for these filters by

$$I_u(\theta \mid \eta) = \begin{cases} \frac{1}{2}\int_0^T |\dot\theta(s) - f(\theta(s), u(s))|^2 + |\dot\eta(s) - h(\theta(s))|^2 ds \\ \qquad\qquad\qquad\qquad \text{if } \theta \text{ is absolutely continuous,} \\ +\infty \qquad\qquad\qquad \text{otherwise.} \end{cases} \tag{4.2}$$

The $(*)$ notation of the preceding section is again used to indicate a distinguished initial condition and the corresponding state and observation paths. Parallel to Theorem 3.1 we have the following result, which refines the large deviation results of Hijab [12], [13], and James [15]; see also [18], [17].

THEOREM 4.1. *The filters* $\{\Pi^\epsilon_{u,\mu}\}$ *obey the* LDPP *with action function* $I_u(\theta \mid \xi_*)$. *In particular, if* $A \subset \mathcal{X}^T$, *then*

$$\Pi^\epsilon_{u,\mu}(A \mid \xi^\epsilon_*) \asymp \exp\left(-\frac{1}{\epsilon}\inf_{\theta \in A} I_u(\theta \mid \xi_*)\right) \quad \textit{in probability as} \quad \epsilon \to 0.$$

Furthermore, if u is a universal *control on* $[0, T]$, *then*

$$\Pi^\epsilon_{u,\mu}(\cdot \mid \xi^\epsilon_*) \Rightarrow \delta_{x_*} \ \textit{ in probability as } \epsilon \to 0.$$

Here, the symbol $\asymp$ denotes asymptotic equivalence. The proof of this theorem is omitted and is based on a generalization of the well-known Varadhan–Laplace asymptotic method (Varadhan [28]), and the fact that if u is universal on $[0, T]$, then the unique minimizer of $I_u(\cdot \mid \xi_*)$ is x_* (cf. Theorem 4.2 below). The convergence of the measures is with respect to the Prohorov metric on the space $\mathcal{P}(\mathcal{X}^T)$ of probability measures.

4.2. Observer design. As for finite-state machines, the state trajectory can be obtained in principle by finding the minimizer of $I_u(\cdot \mid \xi_*)$. For $t \geq 0$ define a function

$$m(\cdot, t) : \Re^n \to [0, \infty)$$

by

$$m(x,t) = \inf \left\{ \tfrac{1}{2}|h(\theta(0)) - y_*(0)|^2 + I_u(\theta \mid \xi_*) : \theta(t) = x, \theta \in \mathcal{X}^t \right\}, \tag{4.3}$$

where $I_u(\cdot \mid \xi_*)$ is defined for the time interval $[0,t]$. The cost term for the initial condition does not appear in the limiting filter. It is added here to include the information that is available at time $t = 0$ in the deterministic limit. The value function $m(x,t)$ is continuous and is the unique viscosity solution of the Hamilton–Jacobi (HJ) equation (Crandall, Evans, and Lions [7])

$$\begin{cases} \dfrac{\partial}{\partial t} m(x,t) + \frac{1}{2}|Dm(x,t)|^2 + f(x,u(t)) \cdot Dm(x,t) \\ \qquad\qquad\qquad -\frac{1}{2}|y_*(t) - h(x)|^2 = 0 \quad \text{in } \Re^n \times (0,\infty), \\ \qquad m(x,0) = \frac{1}{2}|y_*(0) - h(x)|^2 \qquad \text{in } \Re^n. \end{cases} \tag{4.4}$$

Also define

$$\hat{x}(t) = \operatorname*{argmin}_{x \in \Re^n} m(x,t). \tag{4.5}$$

The limiting filter satisfies (4.4), (4.5), except with $m(\cdot, 0) = 0$; if $\pi^\epsilon_{u,\mu}(x, t \mid \xi^{\epsilon,t}_*)$ denotes the conditional density, then $\lim_{\epsilon \to 0} \epsilon \log \pi^\epsilon_{u,\mu}(x,t \mid \xi^{\epsilon,t}_*) = -m(x,t)$ in probability [17], [15]. We have the following result concerning the existence of observers for the nonlinear system (2.2).

THEOREM 4.2. *The dynamical system* (4.4), (4.5) *is a* finite time observer *for the nonlinear system* (2.2). *In particular, if u is a* universal *control on* $[0, T]$, *then*

$$\hat{x}(t) = \{x_*(t)\} \quad \textit{for all} \quad t \geq T. \tag{4.6}$$

Proof. Now $m(x,t) \geq 0$ for every $x \in \Re^n$, and also $m(x_*(t), t) = 0$ for $t \geq 0$. Let $t \geq T$ and suppose that u is universal on $[0, T]$. If $z \in \Re^n$ is such that $m(z,t) = 0$, then, thanks to the lower semicontinuity of $I_u(\cdot \mid \xi_*)$, there exists $\theta \in \mathcal{X}^t$ such that $\frac{1}{2}|h(\theta(0)) - y_*(0)|^2 + I_u(\theta \mid \xi_*) = 0$ and $\theta(t) = z$. Hence $\dot{\theta}(s) = f(\theta(s), u(s))$ and $y_*(s) = h(\theta(s))$ for each $s \in [0,t]$. Thus θ is a state trajectory, and produces the output y_*. Since u is universal on $[0, T]$, we must have $\theta(T) = x_*(T)$, and therefore $z = x_*(t)$. □

Remarks. (i) Note that this observer is *infinite-dimensional*, with state space $\mathbf{M} = C(\Re^n)$.

(ii) Theorem 4.2 does not require all the smoothness assumed for the data f and h in §2. The Lipschitz continuity and growth conditions suffice.

(iii) What is important is the computation of $\hat{x}(t) = \{x \in \Re^n : m(x,t) = 0\}$, and, as noted in §3.2, it may be possible numerically to compute $\hat{x}(t)$ without computing the complete solution of (4.4) (James [16]).

5. Observability and the value function. In this section we study the time evolution of the sets of indistinguishable points and certain properties of the value function $m(x,t)$. This provides some insight into how an observer can aquire information and determine the state trajectory. We consider system (2.2) and drop the $(*)$ notation used in previous sections. Most of the results below remain valid if the class of admissible controls $\mathcal{U}$ is expanded to include all measurable controls $u : [0, T] \to \mathbf{U}$.

For each $t \geq 0$, define the set of points *indistinguishable* from x_0 on $[0,t]$ with respect to the control $u \in \mathcal{U}^t$ by

$$\mathbf{I}_t^u(x_0) = \{x \in \Re^n : h(\gamma_u(s)x) = h(\gamma_u(s)x_0) \text{ for all } 0 \leq s \leq t\}, \tag{5.1}$$

and the set of points indistinguishable from x_0 on $[0,t]$ with respect to the class of controls $\mathcal{U}^t$ by

$$\mathbf{I}_t(x_0) = \bigcap_{u \in \mathcal{U}^t} \mathbf{I}_t^u(x_0). \tag{5.2}$$

As time t increases, these sets can decrease in both size and dimension. For instance, $\mathbf{I}_0(x_0)$ is generically the submanifold $h^{-1}(h(x_0))$, whereas if the control system is observable on $[0,T]$, then, for all $t \geq T$, $\mathbf{I}_t(x_0) = \{x_0\}$. Below, we study the local structure of the sets $\mathbf{I}_t(x_0)$ for times t between these extremes.

We define the *observability grammian* $\mathcal{O}^u$ for system (2.2) given the control $u \in \mathcal{U}$ to be a map assigning to each $t \in \operatorname{dom}(u)$ a field $\mathcal{O}^u(t)$ of symmetric bilinear forms defined for $X_1, X_2 \in T_x\Re^n$ by

$$\begin{aligned}\mathcal{O}_x^u(t)(X_1,X_2) &= \langle dh(x), X_1\rangle \cdot \langle dh(x), X_2\rangle \\ &\quad + \int_0^t \langle dh(\gamma_u(s)x), \gamma_{u*x}(s)X_1\rangle \cdot \langle dh(\gamma_u(s)x), \gamma_{u*x}(s)X_2\rangle ds.\end{aligned} \tag{5.3}$$

Here, $\gamma_{u*x}(s)$ denotes the differential of the flow, $\langle\cdot,\cdot\rangle$ denotes the pairing between vectors and covectors, and the dot is the usual inner product in $\Re^p$.

Remark. This grammian is "dual" to the deterministic Malliavin covariance matrix defined by Bismut [5]. The observability grammian for linear systems was introduced by Kalman [19].

The rank of $\mathcal{O}_x^u(t)$ is a left-continuous nondecreasing function of time t for each fixed $x \in \Re^n$. The kernel of this grammian is defined by

$$\Delta_t^u(x) = \ker \mathcal{O}_x^u(t) \tag{5.4}$$

for $x \in \Re^n$. Define the *observability grammian distribution* Δ_t for $t \geq 0$, $x \in \Re^n$ by

$$\Delta_t(x) = \bigcap_{u \in \mathcal{U}^t} \Delta_t^u(x). \tag{5.5}$$

The set $\mathcal{M}_t$ of nonsingular points of Δ_t is an open dense subset of $\Re^n$. This distribution characterizes the local structure of the sets of indistinguishable points.

THEOREM 5.1. *Fix $t \geq 0$ and let $x_0 \in \Re^n$ be a nonsingular point for Δ_t,; $d = \dim \Delta_t(x_0)$. Then there exists a neighborhood U of x_0 such that $\mathbf{I}_t(x_0) \cap U$ is a d-dimensional integral submanifold of Δ_t.*

Proof. Since $\dim \Delta_t$ is constant near x_0, and the $\mathcal{O}_x^u(t)$ are continuous functions of x, there exists controls $u_1, \cdots, u_\ell \in \mathcal{U}^t$ such that

$$\Delta_t(x) = \bigcap_{i=1}^{\ell} \Delta_t^{u_i}(x)$$

for all x near x_0. Write $H = L^2([0,t], \Re^p)$ and define $Y_t : \Re^n \to H^\ell$ by

$$Y_t(x) = \begin{Bmatrix} Y_t^1(x_0) \\ \vdots \\ Y_t^\ell(x_0) \end{Bmatrix},$$

where $Y_t^i(x) = \{h(\gamma_{u_i}(s)x),\ 0 \le s \le t\}$. Now $dY_t^i(x) = \{\langle dh(\gamma_{u_i}(s)x), \gamma_{u_i *}(s)\cdot\rangle,\ 0 \le s \le t\}$, and so

$$\ker dY_t(x) = \Delta_t(x)$$

for all x near x_0. By the rank theorem (Rudin [25]), there is a neighborhood V of x_0 such that $Y_t(V)$ is an $(n-d)$-dimensional submanifold of H^ℓ. By the implicit function theorem, there exists a neighborhood U of x_0 contained in V such that $Y_t^{-1}(Y_t(x_0))\cap U$ is a d-dimensional submanifold of $\Re^n$. This submanifold is an integral submanifold of Δ_t through x_0. By construction, $\mathbf{I}_t(x_0) \cap U \subset Y_t^{-1}(Y_t(x_0)) \cap U$.

Now let $u \in \mathcal{U}^t$, and $x \in Y_t^{-1}(Y_t(x_0)) \cap U$. Reducing U if necessary, there exists a piecewise smooth curve $\alpha : [0,1] \to Y_t^{-1}(Y_t(x_0)) \cap U$ such that $\alpha(0) = x_0$, $\alpha(1) = x$ and

$$\dot\alpha(r) \in \Delta_t(\alpha(r)) \subset \Delta_t^u(\alpha(r)) \ \text{ a.e. } r \in [0,1].$$

This implies

$$\langle dh(\gamma_u(s)\alpha(r)), \gamma_{u*}(s)\dot\alpha(r)\rangle = 0$$

for $0 \le s \le t$, almost everywhere $r \in [0,1]$. Then $h(\gamma_u(s)\alpha(r)) = h(\gamma_u(s)x_0)$ for all $0 \le s \le t$, $r \in [0,1]$, and hence $h(\gamma_u(s)x) = h(\gamma_u(s)x_0)$ for all $0 \le s \le t$. Therefore $Y_t^{-1}(Y_t(x_0)) \cap U \subset \mathbf{I}_t(x_0) \cap U$, completing the proof. □

Let us say that system (2.2) is *locally observable* on $[0,T\,]$ if every point $x_0 \in \Re^n$ has a neighborhood U_{x_0} such that $I_T(x_0) \cap U_{x_0} = \{x_0\}$.

COROLLARY 5.1. *If* $\Delta_T \equiv \{0\}$ *in* $\Re^n$, *then system* (2.2) *is locally observable on* $[0,T\,]$. *Conversely, if* (2.2) *is* (*locally*) *observable on* $[0,T\,]$, *then* $\Delta_T = \{0\}$ *generically.*

Proof. The first statement follows immediately from Theorem 5.1. The dimension of Δ_T is constant on the open dense set $\mathcal{M}_T$, and Theorem 5.1 implies that this dimension must be zero there if (2.2) is locally observable on $[0,T\,]$; hence the second claim. □

In [11], Hermann and Krener introduced the *observability codistribution* Ω defined for $x \in \Re^n$ by

$$\Omega(x) = \operatorname{span}_\Re \left\{dh(x), L_{f^u} dh(x), L_{f^u}^2 dh(x), \cdots \ :\ u \in \mathbf{U}\right\},$$

where $L_{f^u}^k dh$, $k = 0,1,2,\cdots$, denotes the kth Lie derivative of the 1-form dh with respect to the vector field with constant control $f^u = f(\cdot,u)$. The annihilator of Ω is denoted $\Omega^\perp$.

PROPOSITION 5.1. *For all* $t > 0$ *we have*

$$\Delta_t(x) \subset \Omega^\perp(x) \ \text{ for all } x \in \Re^n.$$

Furthermore, if $\mathcal{R}$ *denotes the open dense subset of nonsingular points for* Ω *and if* $\mathbf{U}$ *is compact, then for each* $x_0 \in \mathcal{R}$ *there exists* $t_0 > 0$ *and a neighborhood* $V_{x_0} \subset \mathcal{R}$ *of* x_0 *such that*

$$\Delta_t(x) = \Omega^\perp(x) \ \text{ for all } x \in V_{x_0}, \ \text{ and all } t \in (0,t_0].$$

Proof. 1. Let $X \in \Delta_t(x)$ and let $u(s) = u \in \mathbf{U}$ for $s \in [0,t]$. Then $X \in \Delta_t^u(x)$ and so $\langle dh(\gamma_u(s)x), \gamma_{u*x}(s)X\rangle = 0$, $0 \le s \le t$. Repeatedly differentiating with respect to s gives for $k = 0,1,2,\cdots$ $\langle L_{f^u}^k dh(x), X\rangle = 0$. This holds for each fixed $u \in \mathbf{U}$, and hence $X \in \Omega^\perp(x)$.

2. Since $\mathbf{U}$ is compact, there exits $t_0 > 0$ and a neighborhood $V_{x_0} \subset \mathcal{R}$ of x_0 such that if $x \in V_{x_0}$ and $t \in [0,t_0]$ then $\gamma_u(s)x \in \mathcal{R}$, $0 \le s \le t$, for any $u \in \mathcal{U}^t$. Let $X \in \Omega^\perp(x)$, $x \in V_{x_0}$, and $0 < t \le t_0$. By approximation, it is enough to show that if $u \in \mathcal{U}^t$ is piecewise constant, then $X \in \Delta_t^u(x)$. Select points $t^0 = 0 < t^1 < \cdots < t^k = t$ and

$u^i \in \mathbf{U}$ and define $u(s) = u^i$ if $s \in [t^i, t^{i-1})$, $i = 1, \cdots, k$. The invariance of $\Omega^\perp$ under the action of f^{u^i} (Isidori [14]) implies that $\gamma_{u^i * x^{i-1}}(s)\Omega^\perp(x^{i-1}) \subset \Omega^\perp(\gamma_{u^i}(s)x^{i-1})$ for $s \in [t^i, t^{i-1}]$, where $x^i = \gamma_{u^i}(t^i)x^{i-1}$, $x^0 = x$. Then $\langle dh(\gamma_u(s)x), \gamma_{u*x}(s)X\rangle = 0$ for $0 \leq s \leq t$; i.e., $X \in \Delta_t^u(x)$. □

Thus, generically, the leaves of Ω consist of points that are not *instantaneously* distinguishable. System (2.2) satisfies the *observability rank condition* (ORC), provided that $\dim \Omega(x) = n$ for all $x \in \Re^n$. Hermann and Krener prove that if the control system satisfies the ORC, then it is locally weakly observable; i.e., every point can instantaneously be distinguished from it neighbors; conversely, if this property holds, then the ORC holds generically. Note that if the ORC holds, then necessarily $\Delta_t \equiv \{0\}$ in $\Re^n$ for all $t > 0$. Also, note that $\Omega^\perp(x) \subset \Delta_0(x)$ for all $x \in \Re^n$.

A control $u \in \mathcal{U}^T$ is called a *local universal control* on $[0, T]$ if every $x_0 \in \Re^n$ has a neighborhood V_{x_0} such that $\mathbf{I}_T^u(x_0) \cap V_{x_0} = \{x_0\}$. The observability grammian $\mathcal{O}^u$ is related to the system obtained by linearizing (2.2) along a trajectory.

COROLLARY 5.2. *If u is a local universal control on $[0, T]$, then the linearized system*

$$\begin{cases} \dot{X}(t) = Df(\gamma_u(t)x, u(t))X(t), & t > 0, \quad X(0) = X_0 \in T_x\Re^n; \\ Y(t) = \langle dh(\gamma_u(s)x), X(t)\rangle, & t \geq 0 \end{cases} \tag{5.6}$$

is observable on $[0, T]$ for all x belonging to an open dense subset of $\Re^n$. Conversely, if (5.6) is observable on $[0, T]$ for every $x \in \Re^n$, then u is a local universal control.

Proof. Specializing Theorem 5.1 to the case of a single control, it follows that if u is a (local) universal control on $[0, T]$, then Δ_T^u is zero on an open dense subset of $\Re^n$; that is, the observability grammian $\mathcal{O}_x^u(T)$ is strictly positive definite for all x in this set. This implies that the linear system (5.6) is observable on $[0, T]$, for all such x. The converse statement also follows from Theorem 5.1. □

These results give information on the sets of points $\hat{x}(t)$ on which the value function $m(\cdot, t)$ vanishes.

THEOREM 5.2. *Let $u \in \mathcal{U}$. Then we have:w*

(a) *There exists a neighborhood $S(x_0)$ of $\Gamma(x_0) = \{\gamma_u(t)x_0;\ t \geq 0\}$ on which the value function m is of class $C^{\infty,1}$, and $P(t) = D^2m(\gamma_u(t)x_0, t)$ satisfies the Riccati equation*

$$\begin{cases} \dot{P}(t) = -P(t)Df(\gamma_u(t)x_0, u(t)) - Df(\gamma_u(t)x_0, u(t))'P(t) - P(t)^2 \\ \qquad\qquad + Dh(\gamma_u(t)x_0)'Dh(\gamma_u(t)x_0), \qquad t > 0; \\ P(0) = Dh(x_0)'Dh(x_0); \end{cases} \tag{5.7}$$

(b) *If x_0 is a nonsingular point for Δ_t^u, then there exists a neighborhood W of $\gamma_u(t)x_0$ such that $\hat{x}(t; x_0, u) \cap W$ is a submanifold of dimension $\dim \Delta_t^u(x_0)$;*

(c) *If u is a (local) universal control on $[0, T]$, then for $t \geq T$ we have*

$$D^2m(\gamma_u(t)x_0, t) > 0, \tag{5.8}$$

for all x_0 belonging to an open dense subset of $\Re^n$.

Proof. Part (a). For any $t \geq 0$, there exists a minimizer $\tilde{\theta} \in \mathcal{X}^t$ such that $\tilde{\theta}(t) = \gamma(t)x_0$, $m(\gamma(t)x_0, t) = 0$. This implies that $\tilde{\theta}(s) = \gamma(s)x_0$, $0 \leq s \leq t$, and so the minimizer is unique. Therefore $m(\cdot, \cdot)$ is differentiable at $(\gamma(t)x_0, t)$ and it also follows that $(\gamma(t)x_0, t)$ is not conjugate to $\Gamma(x_0)$ (Fleming [9]). The method of characteristics then provides a unique smooth solution $\tilde{m}$ to the HJ equation (9.2) in a neighborhood $S(x_0)$ of $\Gamma(x_0)$; this solution coincides with m in $S(x_0)$.

The Riccati equation (5.7) is obtained by differentiating $D^2m(\gamma(s)x_0, s)$ with respect to s and combining the resulting expression with the equation obtained by differentiating the HJ equation (4.4) twice with respect to x. Note that the adjoint variable $\lambda(s) = Dm(\gamma(s)x_0, s)$ equals zero and $y(s) = h(\gamma(s)x_0)$ on $[0, t]$.

Part (b). We have $\hat{x}(t; x_0, u) = \gamma_u(t)\mathbf{I}_t^u(x_0)$, and so the result of Theorem 5.1 specialized to a single control can be carried over by the flow to establish (b).

Part (c). Corollary 5.2 implies that if u is a (local) universal control on $[0, T\,]$, then for $t \geq T$ we have $\mathcal{O}^u_{x_0}(t) > 0$ for x_0 belonging to an open dense subset of $\Re^n$. From linear systems theory (Kalman [19]), if $\mathcal{O}^u_{x_0}(T) > 0$ then the solution of the Riccati equation $P(t)$ is also strictly positive definite for $t \geq T$. □

Remark. In the context of stochastic nonlinear filtering, Mitter [23] mentions that the invertibility of the Hessian of an analogous value function is related to observability. In his derivation of the extended Kalman filter, Mitter needs to invert this Hessian. Theorem 5.2 establishes this relationship in the deterministic case. Note that (5.8) is true for all $x_0 \in \Re^n$ and $t \geq T$ if $\Delta^u_T \equiv \{0\}$ in $\Re^n$.

6. Bilinear systems.

Consider the bilinear control system

$$\begin{aligned} &\dot{x}(t) = \left(A_0 + \sum_{i=1}^{m} u_i(t)A_i\right) x(t), \quad t > 0, \;\; x(0) = x_0; \\ &y(t) = Cx(t), \qquad t \geq 0, \end{aligned} \tag{6.1}$$

where A_i and C are appropriately sized matrices. For $u \in \mathcal{U}$ write $A^u(t) = A_0 + \sum_{i=1}^m u_i(t)A_i$. With $\mu(dx) = (2\pi)^{-n/2}\exp(-\frac{1}{2}|x|^2)dx$, the robust filter for the random perturbation of (6.1) has conditional density

(6.2)
$$\pi^{\epsilon}_{u,\mu}(x, t \mid \xi^{\epsilon}) = (2\pi \det(P^{\epsilon}(t)/\epsilon)^{-1})^{-n/2} \exp\left(-\frac{1}{2\epsilon}(x - \hat{x}^{\epsilon}(t))'P^{\epsilon}(t)(x - \hat{x}^{\epsilon}(t))\right),$$

where

$$\begin{aligned} &d\hat{x}^{\epsilon}(t) = A^u(t)\hat{x}^{\epsilon}(t)dt + (P^{\epsilon}(t))^{-1}C'(d\xi^{\epsilon}(t) - C\hat{x}^{\epsilon}(t)dt), \; t > 0, \;\; \hat{x}^{\epsilon}(0) = 0, \\ &\dot{P}^{\epsilon}(t) = -P^{\epsilon}(t)A^u(t) - A^u(t)'P^{\epsilon}(t) - P^{\epsilon}(t)^2 + C'C, \; t > 0, \;\; P^{\epsilon}(0) = \epsilon I. \end{aligned} \tag{6.3}$$

Note that $P^{\epsilon}(t) > 0$ for all $t \geq 0$. The observer equation (4.4) has the explicit solution

$$m(x, t) \;=\; \tfrac{1}{2}x'P(t)x + M(t)x + \tfrac{1}{2}N(t), \tag{6.4}$$

where

$$\begin{aligned} &\dot{P}(t) = -P(t)A^u(t) - A^u(t)'P(t) - P(t)^2 + C'C, \quad t > 0, \; P(0) = C'C; \\ &\dot{M}(t) = -M(t)\left(A^u(t) + P(t)\right) - y(t)'C, \quad t > 0, \quad M(0) = -y(0)'C; \\ &\dot{N}(t) = -M(t)M(t)' + \mid y(t) \mid^2, \quad t > 0, \; N(0) = \mid y(0) \mid^2 . \end{aligned} \tag{6.5}$$

If u is universal on $[0, T\,]$, then if $t \geq T$ we have $P(t) > 0$ and

$$\hat{x}(t) = \{-P(t)^{-1}M(t)'\} = \{x(t)\}. \tag{6.6}$$

In general, if $0 \leq t \leq T$, $P(t)$ need not be invertible, and $\hat{x}(t) = x(t) + \ker P(t)$, an affine subspace of $\Re^n$. Also, $\mathbf{I}_t^u(x_0) = x_0 + \ker \mathcal{O}^u(t)$, where $\mathcal{O}^u$ is the observability grammian of the time-varying pair (C, A^u). The ORC will be satisfied provided (Isidori [14])

$$\Omega^{\perp} = \bigcap_{k=0}^{n-1} \bigcap_{j_1,\dots,j_k=0}^{m} \ker(CA_{j_1}\dots A_{j_k}) = \{0\}, \tag{6.7}$$

in which case (6.1) will be observable and the finite-dimensional observer (6.5), (6.6) will compute the state exactly for any universal control (such controls are generic; Sussmann [27]).

7. Conclusion. We have shown that a finite time observer exists and computes the state exactly (if a universal input is used) for any control system satisfying minor technical conditions. The major disadvantage is that the observers are in general infinite-dimensional when the state space has infinitely many points. This is similar to the situation for stochastic nonlinear filtering theory. Our design is simple and general, but it is computationally difficult. From an engineering point of view, computational and practical questions need to be addressed and resolved to yield usable designs. We note that computational methods are currently under development, and they promise to be robust with respect to modeling uncertainties (James [16]). In addition, since the observer is the limit of a family of nonlinear filters, the consistency results suggest that the observer should tolerate system noise fairly well.

Acknowledgments. I wish to thank Professor J. S. Baras for providing the initial inspiration for this work and for encouraging me to work on this topic, and Professors L. C. Evans and W. H. Fleming for several helpful discussions.

AN EXACT PENALIZATION VIEWPOINT OF CONSTRAINED OPTIMIZATION*

JAMES V. BURKE†

Abstract. In their seminal papers Eremin [*Soviet Mathematics Doklady*, 8 (1966), pp. 459–462] and Zangwill [*Management Science*, 13 (1967), pp. 344–358] introduce a notion of exact penalization for use in the development of algorithms for constrained optimization. Since that time, exact penalty functions have continued to play a key role in the theory of mathematical programming. In the present paper, this theory is unified by showing how the Eremin–Zangwill exact penalty functions can be used to develop the foundations of the theory of constrained optimization for finite dimensions in an elementary and straightforward way. Regularity conditions, multiplier rules, second-order optimality conditions, and convex programming are all given interpretations relative to the Eremin–Zangwill exact penalty functions. In conclusion, a historical review of those results associated with the existence of an exact penalty parameter is provided.

Key words. exact penalty functions, calmness, constraint qualification, optimality conditions, convex programming

1. Introduction.

In their seminal papers Eremin [23] and Zangwill [75] introduced a notion of exact penalization for use in the development of algorithms for nonlinear constrained optimization. This notion of exact penalization is the natural extension of the so-called big-M method of linear programming (see Charnes, Cooper, and Henderson [14, §4] for the earliest reference known to us) to nonlinear programming. Since that time, exact penalty functions have continued to play a key role in the theory of mathematical programming. Within the algorithmic sphere, the history of these functions is quite rich, even though their use has been, and still is, a topic of controversy. The root of this controversy is the nondifferentiable nature of these functions. From an algorithmic viewpoint, this nondifferentiability can induce the so-called Maratos effect (a phenomenon that prevents rapid local convergence). A great deal of effort has been devoted to overcoming this difficulty, leading to the development of the so-called watchdog technique [12] and second-order correction techniques [19], [28], [26], [29], and others. Other authors, in an effort to avoid the problems associated with nondifferentiability, have introduced entirely different classes of exact penalty functions that are differentiable [5], [30], [34], [60], and [69]. The research in this area continues at a rapid pace and the controversies over the use of nondifferentiable exact penalty functions in algorithms are far from nearing resolution. This paper can, in many ways, be viewed as a contribution to this discussion. However, our approach is from a rather different perspective. We do not discuss algorithms at all, rather we demonstrate how the Eremin–Zangwill exact penalty functions can be used to develop the foundations of the theory of constrained optimization in an elementary and straightforward way. In doing so, we show how all of the fundamental notions and results in constrained optimization can be derived from the Eremin–Zangwill exact penalty functions, from regularity conditions such as calmness [15], [66], to the

*Received by the editors September 16, 1986; accepted for publication (in revised form) June 1, 1990.

†Mathematics Department, GN-50, University of Washington, Seattle, Washington 98195. The work of the author was supported in part by National Science Foundation grant DMS–8803206 and by Air Force Office of Scientific Research grant AFOSR–860080.

existence of Lagrange multipliers, to second-order necessary and sufficient conditions for optimality. The derivation of these results by means of the Eremin–Zangwill exact penalty functions is by no means strained or artificial, quite the contrary, the proofs are often simplified at the expense of obtaining a more powerful result. Thus, our goal in this endeavor is not to demonstrate the viability of these penalty functions for use in algorithmic development, but rather to demonstrate their role vis-á-vis the foundations of the theory and to provide an interpretation for many of the familiar objects in this theory in terms of the corresponding objects associated with these penalty functions. Hopefully, one consequence of these investigations is that the practical significance of these penalty functions can be more accurately assessed.

We begin §2 by reviewing some of the fundamental results and concepts associated with constrained optimization. We discuss calmness, regularity, constraint qualifications, and their relationships vis-á-vis exact penalization. This section contains all of the first-order results related to the existence of Kuhn–Tucker [43] multipliers. In §3 we show how exact penalization techniques can be used to derive a multiplier theorem in the absence of a constraint qualification. This multiplier rule is reminiscent of the one given by John [42]. Second-order results are obtained in §4. The case of convex programming is studied in §5, and in §6 we provide a historical review of the literature on the existence of a finite exact penalty parameter. The approach to the theory of constrained optimization from the viewpoint of exact penalization is also the theme of Fletcher [29, §14.3], Garcia-Palomares [31], and Rockafellar [64]. A very nice survey of exact penalization techniques in general is given by Fletcher [27]. The present paper is based on Burke [9], wherein several further results and generalizations are obtained.

The notation that we employ is for the most part standard; however, a partial list is provided for the reader's convenience. Let X be a real normal linear space and let X^* be its topological dual. The spaces X and X^* are paired in duality by the continuous bilinear form

$$\langle x^*, x\rangle := x^*(x)$$

defined on $X^* \times X$. Given $x_1, x_2 \in X$ the line segment joining them is denoted by

$$[x_1, x_2] := \{\lambda x_1 + (1-\lambda)x_2 : \lambda \in [0,1]\}.$$

Let C be a subset of X. Then cl(C) is the closure of C, int(C) is the interior of C, and ri(C) is the interior of C relative to its affine hull, i.e., the smallest closed affine set containing C. The core of C, denoted core(C), is the set of all point $z \in C$ such that every line through z contains a line segment $[z_1, z_2]$ with $z \in [z_1, z_2] \subset C$ and $z_1 \neq z \neq z_2$. In finite dimensions, we have core$(C) =$ int(C). The *polar* of C is given by

$$C^0 := \{x^* \in X^* : \langle x^*, x\rangle \leq 1 \text{ for all } x \in C\}$$

and the *positive conjugate* of C is $C^* := -C^0$. The *recession cone* of C is

$$\text{rec}(C) := \{y \in X : C + y \subset cl(C)\}$$

and the cone generated by C is

$$\text{cone}(C) := \cup_{\lambda \geq 0} \lambda C,$$

where for any two subsets S_1 and S_2 of X and any two scalars $\alpha, \beta \in \mathbb{R}$ we have

$$\alpha S_1 + \beta S_2 := \{\alpha s_1 + \beta s_2 : s_1 \in S_1, s_2 \in S_2\}.$$

The *support* and *indicator* functions for C are given, respectively, as

$$\psi^*(x^*|C) := \sup\{\langle x^*, y\rangle : y \in C\}$$

and

$$\psi(x|C) := \begin{cases} 0, & \text{if } x \in C \\ +\infty, & \text{otherwise.} \end{cases}$$

The *barrier cone* of C is

$$\text{bar}(C) := \{x^* \in X^* : \psi^*(x^*|C) < \infty\}$$

and the relation

$$\text{rec}(C) = [\text{bar}(C)]^0$$

holds if X is reflexive.

A *multifunction* T mapping X into Y where Y is another real normal linear space, written $T : X \rightrightarrows Y$, is a mapping of X whose values are subsets of Y. The *domain* of T is the set $\text{dom}(T) := \{x \in X : T(x) \neq \emptyset\}$ and the *graph* of T is graph $(T) := \{(x, y) | y \in T(x)\}$. T is said to be *upper semicontinuous* if graph (T) is closed in $X \times Y$ under the product topology. The space $\mathcal{L}(X, Y)$ is the space of continuous linear maps from X to Y. Given $T \in \mathcal{L}(X, Y)$ we write

$$\text{ran}(T) := \{y \in Y : \exists x \in X \text{ with } y = Tx\}$$

and

$$\ker(T) := \{x \in X : Tx = 0\}.$$

If X and Y are finite-dimensional, then, with respect to fixed bases for X and Y, one can identify $\mathcal{L}(X, Y)$ with $\mathbb{R}^{m \times n}$ the set of $m \times n$ matrices, where $\dim(X) = n$ and $\dim(Y) = m$. The *adjoint* of $A \in \mathcal{L}(X, Y)$ is the uniquely defined mapping $A^* \in \mathcal{L}(Y^*, X^*)$ for which

$$\langle A^* y^*, x\rangle = \langle y^*, Ax\rangle$$

for all $(y^*, x) \in Y^* \times X$. In finite dimensions we have $A^* = A^T$.

Let $f : X \to \overline{\mathbb{R}}$ where $\overline{\mathbb{R}} := \mathbb{R} \cup \{+\infty\}$, we write

$$\begin{aligned} \text{dom}(f) &:= \{x \in X : f(x) < +\infty\}, \\ \text{lev}_f(x) &:= \{y \in X : f(y) \leq f(x)\}, \text{ and} \\ \text{epi}(f) &:= \{(\mu, x) : f(x) \leq \mu\}. \end{aligned}$$

We say that f is *lower semicontinuous* if $\text{epi}(f)$ is a closed set. If f is Lipschitz near a point $x \in X$, then the *Clarke generalized directional derivative*,

$$f^0(x; d) := \limsup_{\substack{y \to x \\ t \downarrow 0}} \frac{f(y + tv) - f(y)}{t},$$

exists at x for every $d \in X$.

The norm on X is denoted $\|\cdot\|$ and its unit ball is $\mathbb{B} := \{x : \|x\| \leq 1\}$. The dual norm is given by $\|x^*\|_0 := \psi^*(x^*|\mathbb{B})$ and its unit ball is $\mathbb{B}^0$. The distance function for a set $C \subset X$ is given by

$$\text{dist}(y|C) := \inf\{\|y - x\| : x \in C\}.$$

For $C \subset X^*$, the dual distance function is denoted

$$\mathrm{dist}_0(y|C) := \inf\{\|y - x\|_0 : x \in C\}.$$

In finite dimensions the Euclidean norm plays a special role and is denoted by $\|\cdot\|_2$ with corresponding distance function $\mathrm{dist}_2(\cdot|C)$. The distance function for a set $C \subset X$ is Lipschitz with Lipschitz constant 1, and so its Clarke generalized directional derivative exists at every point in all directions. Based on this observation we define the *tangent cone* to a point $x \in C$ by

$$T(x|C) := \{d \in X : \mathrm{dist}(\cdot|C)^0(x; d) = 0\}$$

with the *normal cone* defined via polarity

$$N(x|C) := T(x|C)^0.$$

For convex sets, these objects reduce to the usual notions of tangent and normal cone. In finite dimensions one can also define the *limiting proximal normal cone* at a point $x \in C$ by $\widehat{N}(x|C) := \{\lambda \lim v_i/\|v_i\| : \lambda \geq 0, v_i \perp C \text{ at } x_i \to x,\ v_i \to 0\}$, where one writes $v \perp C$ at y to mean that $y \in \mathrm{cl}(C)$ and $v = y^1 - y$ with $\|y^1 - y\|_2 = \mathrm{dist}_2(y|C)$. One has that $N(x|C)$ is the closed convex hull of $\widehat{N}(x|C)$.

Given $f : X \to \overline{\mathbb{R}}$ the *generalized subdifferential* of f at $x \in \mathrm{dom}(f)$ is given by

$$\partial f(x) := \{x^* \in X^* : (-1, x^*) \in N((f(x), x)|\mathrm{epi}(f))\},$$

the *asymptotic subdifferential* is

$$\partial^\infty f(x) := \{x^* \in X^* : (0, x^*) \in N((f(x), x)|\mathrm{epi}(f))\},$$

the *limiting proximal subdifferential* is

$$\widehat{\partial} f(x) := \{x^* \in X^* : (-1, x^*) \in \widehat{N}((f(x), x)|\mathrm{epi}(f))\},$$

and the *asymptotic limiting proximal subdifferential* is

$$\widehat{\partial}^\infty f(x) := \{x^* \in X : (0, x^*) \in \widehat{N}((f(x), x)|\mathrm{epi}(f))\}.$$

Clearly, $\partial^\infty f(x) = \mathrm{rec}(\partial f(x))$ whenever $\partial f(x) \neq \emptyset$. The *generalized directional derivative* of f is then defined to be

$$f^0(x; v) := \psi^*(v|\partial f(x))$$

with $f^0(x; v) := -\infty$ if $\partial f(x) = \emptyset$. This notation is consistent with that of the Clarke subdifferential for locally Lipschitz functions.

The function f is said to be *subdifferentially regular* at a point $x \in \mathrm{dom}(f)$ if

$$\liminf_{\substack{u \to v \\ t \downarrow 0}} \frac{f(x + tu) - f(x)}{t} = f^0(x; v)$$

for all $v \in X$, in which case

$$f^0(x; v) = f'(x; v) := \lim_{t \downarrow 0} \frac{f(x + tv) - f(x)}{t}.$$

A function $F : X \to Y$ has *Frechet derivative* $F'(x) \in \mathcal{L}(X,Y)$ at $x \in X$ if

$$F(y) = F(x) + F'(x)(y - x) + o(\|y - x\|),$$

where $\lim_{y \to x} o(\|y - x\|)/\|y - x\| = 0$. The mapping F is *strictly differentiable* at $x \in X$ if there exists $F_s'(x) \subset \mathcal{L}(X,Y)$ such that

$$\lim_{\substack{x' \to x \\ t \downarrow 0}} \frac{F(x' + tv) - F(x')}{t} = F_s'(x)v$$

for all v in X. If $f : X \to \overline{R}$ is strictly differentiable at a point $x \in \mathrm{dom}(f)$, then $\partial f(x) = \{f_s'(x)\}$.

If both X and Y are finite-dimensional and $F : X \to Y$ is locally Lipschitz, then F is almost everywhere differentiable in the sense of Lebesgue measure. The *generalized Jacobian* of F at a point $x \in X$, denoted $\partial F(x)$, is the convex hull of all operators in $\mathcal{L}(X,Y)$ obtained as the limit of sequences of the form $\{F'(x_i)\}$ where $x_i \to x$ and $F'(x_i)$ exists at each x_i. Again, if F is strictly differentiable at x, then $\partial F(x) := \{F_s'(x)\}$.

Let $f : X \to \overline{\mathbb{R}}$ and $C \subset X$. We write

$$\arg\min\{f(x) : x \in C\} := \{x \in C : f(x) = \min\{f(x) : x \in C\}\}$$

and define $\arg\max\{f : x \in C\}$ similarly. A local minimum of *radius* ε for the problem $\min\{f(x) : x \in C\}$ is any point $x \in C$ such that $f(x) \leq f(y)$ for all $y \in C \cap (x + \varepsilon\mathbb{B})$.

For more information about the objects defined above see [15]–[17], [54], and [65]–[68].

2. The fundamentals: calmness, regularity, and exact penalization. Let X and Y be normal linear spaces and consider the problem

$$(\mathcal{P}) \qquad \begin{array}{l} \text{minimize } f(x) \\ \text{subject to } g(x) \in C, \end{array}$$

where $f : X \to \overline{\mathbb{R}} := \mathbb{R} \cup \{+\infty\}$, $g : X \to Y$, and C is a closed subset of Y. We begin with a discussion of regularity conditions that allow the development of general multiplier rules for $\mathcal{P}$. One of the weakest such conditions was proposed by Rockafellar and is known as calmness.

DEFINITION 2.1. Let f, g, X, Y, and C be as in the statement of $\mathcal{P}$ and consider the perturbed problems

$$(\mathcal{P}_u) \qquad \begin{array}{l} \text{minimize } f(x) \\ \text{subject to } g(x) \in C + u. \end{array}$$

Let $\overline{x} \in X$ and $\overline{u} \in Y$ be such that $g(\overline{x}) \in C + \overline{u}$ and $\overline{x} \in \mathrm{dom}(f) := \{x \in X : f(x) < +\infty\}$. The problem $\mathcal{P}_{\overline{u}}$ is said to be *calm* at $\overline{x}$ if there are constants $\overline{\alpha} \geq 0$ and $\varepsilon > 0$ such that for every pair $(x, u) \in X \times Y$ with $\|x - \overline{x}\| \leq \varepsilon$ and $g(x) \in C + u$ we have

$$f(x) + \overline{\alpha}\|u - \overline{u}\| \geq f(\overline{x}). \tag{2.1}$$

The constants $\overline{\alpha}$ and ε are called the *modulus* and *radius* of calmness for $\mathcal{P}_{\overline{u}}$ at $\overline{x}$, respectively.

The family of perturbed problems $\mathcal{P}_u$ is said to be calm at $\overline{u}$ if

$$\liminf_{u \to \overline{u}} \frac{V(u) - V(\overline{u})}{\|u - \overline{u}\|} > -\infty, \tag{2.2}$$

where

$$V(u) := \begin{cases} +\infty, & \text{if } \{x : g(x) \in C + u\} = \emptyset \\ \min\{f(x) : g(x) \in C + u\}, & \text{otherwise} \end{cases}$$

is the value function for the family $\mathcal{P}_u$.

Remarks. (1) This definition for $\mathcal{P}_{\overline{u}}$ to be calm at $\overline{x}$ varies from the definition that is usually given (eg., see Clarke [15, Def. 6.4.1]); however, in Burke [8, §2], it is shown that they are equivalent when g is continuous at $\overline{x}$.

(2) Observe that if $\mathcal{P}_{\overline{u}}$ is calm at $\overline{x}$, then $\overline{x}$ is necessarily a local solution to $\mathcal{P}_{\overline{u}}$, and if $\mathcal{P}_u$ is calm at $\overline{u}$, then for any solution $\overline{x}$ to $\mathcal{P}_{\overline{u}}, \mathcal{P}_{\overline{u}}$ is calm at $\overline{x}$.

(3) The notion of calmness is closely related to the notion of a Φ_1-subdifferential introduced in Dolecki and Rolewicz [20].

The calmness hypothesis is quite weak and in many situations is easily verified. In finite dimensions, calmness holds on a dense subset of the perturbations.

PROPOSITION 2.1. (1) (Clarke [15, Prop. 6.4.5]) *Suppose that* $Y := \mathbb{R}^m, C := \mathbb{R}^m_-$, *and* $f := f_0 + \psi(\cdot|S)$ *with* $S \subset X$ *nonempty and closed, and* $f_0 : X \to \mathbb{R}$ *and* $g : X \to \mathbb{R}^m$ *locally Lipschitzian. If* $V(u)$ *is finite for all* u *near* 0, *then for almost all* u *in a neighborhood of the origin the problem* $\mathcal{P}_u$ *is calm.*

(2) (Burke [8, Prop. 3.1]) *Suppose that* Y *is finite-dimensional,* f *is lower semicontinuous, and* g *is continuous. If* $\overline{u} \in Y$ *and* $\gamma > 0$ *are such that* V *is bounded on* $\overline{u} + \gamma\mathbb{B}$, *then* $\mathcal{P}_u$ *is calm on a dense subset of* $\overline{u} + \gamma\mathbb{B}$.

From (2.2) it is clear that calmness is a weak variational property of the value function V. A condition of this type is always required for establishing the existence of multipliers. It is remarkable that the notion of calmness at a solution to $\mathcal{P}_{\overline{u}}$ is equivalent to the existence of a finite exact penalty parameter.

THEOREM 2.1 (Burke [8, Thm. 1.1]). *Let* $\overline{x} \in X$ *and* $\overline{u} \in Y$ *be such that*

$$g(\overline{x}) \in C + \overline{u} \quad \text{and} \quad \overline{x} \in \operatorname{dom}(f).$$

Then $\mathcal{P}_{\overline{u}}$ *is calm at* $\overline{x}$ *with modulus* $\overline{\alpha} \geq 0$ *and radius* $\varepsilon > 0$ *if and only if* $\overline{x}$ *is a local minimum of radius* ε *for*

$$P_{\overline{u},\alpha}(x) := f(x) + \alpha \operatorname{dist}(g(x)|C + \overline{u})$$

for all $\alpha \geq \overline{\alpha}$, *that is,*

$$P_{\overline{u},\alpha}(\overline{x}) \leq P_{\overline{u},\alpha}(x)$$

for all $x \in \overline{x} + \varepsilon\mathbb{B}$ *and* $\alpha \geq \overline{\alpha}$.

Remark. The fact that calmness implies the existence of an exact penalty parameter is also established in Clarke [15] and Dolecki and Rolewicz [20]. However, the reverse implication and the precision of this correspondence is first established in [8].

Thus, at this early juncture we see that the Eremin–Zangwill exact penalty functions play a fundamental role in the theory. Under the calmness hypothesis we can obtain multiplier rules for $\mathcal{P}$ by first invoking Theorem 2.1 and then applying the pertinent calculus rules of an appropriate subdifferential (e.g., the Clarke subdifferential [15]–[17], the Michel–Penot subdifferential [53], the limiting proximal subdifferential [65]–[66], etc.)

We present two sample results based on the subdifferential calculus developed in Clarke [15] and Rockafellar [66], [68].

THEOREM 2.2. (1) *Suppose* $\mathcal{P}$ *is calm at* $\overline{x} \in X$, g *is strictly differentiable at* $\overline{x}$ *with strict derivative* $g_s'(\overline{x})$, *and* $\partial f(\overline{x}) \neq \emptyset$. *Then there is a* $y \in N(g(\overline{x})|C)$ *such that*

$$0 \in \partial f(\overline{x}) + g_s'(\overline{x})^* y.$$

(2) *If* X *and* Y *are finite-dimensional,* $\mathcal{P}$ *is calm at* $\overline{x} \in X$, f *is lower semicontinuous near* $\overline{x}$, *and* g *is Lipschitzian near* $\overline{x}$, *then there exists* $y \in N(g(\overline{x})|C)$ *such that*

$$0 \in \partial f(\overline{x}) + \partial g(\overline{x})^* y.$$

Proof. (1) By Theorem 2.1, $\overline{x}$ is a local minimum for $P_\alpha(x) := f(x) + \alpha \operatorname{dist}(g(x)|C)$ for all α sufficiently large. Hence $0 \in \partial P_\alpha(\overline{x})$ for all $\alpha \geq \overline{\alpha}$ for some $\overline{\alpha} \geq 0$. By [68, Cor. 2],

$$\partial P_\alpha(\overline{x}) \subset \partial f(\overline{x}) + \alpha\partial\,[\operatorname{dist}(g(\cdot)|C)](\overline{x}).$$

From [15, Prop. 2.4.2],

$$N(g(\overline{x})|C) = cl[\cup_{\lambda \geq 0} \lambda\partial\,[\operatorname{dist}(\cdot|C)](g(\overline{x}))]. \tag{2.3}$$

Consequently, by the chain rule [15, Thm. 2.3.10],

$$0 \in \partial f(\overline{x}) + g_s'(\overline{x})^* N(g(\overline{x})|C),$$

from which the result follows.

(2) This is an immediate consequence of Rockafellar [66, Cor. 5.2.3] and inclusion (2.3). □

Remarks. (1) To incorporate an abstract constraint of the form $x \in S \subset X$ we simply replace f by $f + \psi(\cdot|S)$.

(2) We do not claim that the results in Theorem 2.2 are original. Results similar to these can be found elsewhere in the literature, e.g., [1], [3], [15]–[17], [39]–[41], [45], [54], [63]–[66]. However, the proofs that we provide are different from those that are usually provided, due to the explicit dependence on Theorem 2.1.

Various conditions can be found in the literature that ensure that the calmness hypothesis is satisfied. All of these conditions are related to the regularity of the constraint systems of the form

$$g(x) \in C \quad \text{and} \quad x \in S \subset X. \tag{2.4}$$

DEFINITION 2.2. System (2.4) is said to be *regular* at a solution x_0 if there exist constants $\kappa > 0$ and $\varepsilon > 0$ such that

$$\operatorname{dist}(x|\Omega(u)) \leq \kappa \operatorname{dist}(g(x)|C + u)$$

for all $x \in (x_0 + \varepsilon\mathbb{B}) \cap S$ and $u \in \varepsilon\mathbb{B}$ where

$$\Omega(u) := \{x \in X : g(x) \in C + u, x \in S\}.$$

The constant κ is called the *modulus of regularity* for (2.4) at x_0.

Remark. This and more general notions of regularity for (2.4) are studied by several authors, e.g., [1], [4], [7], [15], [20], [48], [49], [51], [52], [61], [62], [66]–[68], [73].

Calmness and regularity are related via Clarke's elementary exact penalization theorem.

THEOREM 2.3 (Clarke [15, Prop. 2.4.3]). *Let $f : X \to \overline{\mathbb{R}}$ be Lipschitz of rank κ on a set $T \subset X$. Let $\overline{x}$ belong to a set $\Omega \subset T$ and suppose that f attains a minimum over Ω at $\overline{x}$. Then for any $\widehat{\kappa} \geq \kappa$, the function $\pi_{\widehat{\kappa}}(x) := f(x) + \widehat{\kappa}\ \mathrm{dist}(x|\Omega)$ attains a minimum over T at $\overline{x}$. If $\widehat{\kappa} > \kappa$ and Ω is closed, then any other point minimizing $\pi_{\widehat{\kappa}}$ over T must also lie in Ω.*

We have the following elementary corollaries to Theorem 2.3.

COROLLARY 2.3.1. *Consider the problem $\mathcal{P}$ with g continuous and $f := f_0 + \psi(\cdot|S)$ for some $f_0 : X \to \mathbb{R}$ and some $S \subset X$ closed and nonempty. Suppose that $\overline{x} \in S$ is a local solution to $\mathcal{P}$ at which the system (2.4) is regular with modulus κ_1 and near which f_0 is Lipschitz of rank κ_2, then $\overline{x}$ is a local minimum of $P_\alpha(x) := f(x) + \alpha\ \mathrm{dist}(g(x)|C)$ for all $\alpha \geq \kappa_1\kappa_2$. If $\alpha > \kappa_1\kappa_2$, then there is a neighborhood of $\overline{x}$ such that any other local minimum $\widehat{x}$ of $P_\alpha(x)$ within this neighborhood is such that $f(\overline{x}) = f(\widehat{x})$ and $g(\widehat{x}) \in C$.*

Proof. Let $\varepsilon > 0$ be such that f_0 is Lipschitz of rank κ_2 on $\overline{x} + \varepsilon\mathbb{B}$, the defining inequality for regularity holds for all $x \in (\overline{x} + \varepsilon\mathbb{B}) \cap S$ and $u \in \varepsilon\mathbb{B}$, and $f(\overline{x}) \leq f(x)$ for all $x \in \{z : g(z) \in C\} \cap (\overline{x} + \varepsilon\mathbb{B})$. Set $\Omega := \Omega(0) \cap (\overline{x} + \varepsilon\mathbb{B})$ and note that since g is continuous, the set Ω is closed. By Theorem 2.3, $\pi_{\widehat{\kappa}}(x)$ attains a minimum over $\overline{x} + \varepsilon\mathbb{B}$ at $\overline{x}$ for $\widehat{\kappa} \geq \kappa_2$, and if $\widehat{\kappa} > \kappa_2$, then any other minimum of $\pi_{\widehat{\kappa}}$ over $\overline{x} + \varepsilon\mathbb{B}$ must also lie in Ω. Then, for every $\delta \in (0, \frac{1}{3}\varepsilon)$ and $y \in \overline{x} + \frac{1}{3}\varepsilon\mathbb{B}$, there is a $z_\delta \in \Omega(0)$ such that $\|y - z_\delta\| \leq \mathrm{dist}(y|\Omega(0)) + \delta \leq \frac{2}{3}\varepsilon$. Hence $\|z_\delta - \overline{x}\| \leq \|y - z_\delta\| + \|y - \overline{x}\| \leq \varepsilon$ so that $\mathrm{dist}(y|\Omega) \leq \mathrm{dist}(y|\Omega(0)) + \delta$. Letting $\delta \downarrow 0$ we find that $\mathrm{dist}(y|\Omega) = \mathrm{dist}(y|\Omega(0))$ for all $y \in \overline{x} + \frac{1}{3}\varepsilon\mathbb{B}$. The result now follows from the definition of regularity with the neighborhood of $\overline{x}$ being $\overline{x} + \frac{1}{3}\varepsilon\mathbb{B}$. □

COROLLARY 2.3.2. *Consider the problem $\mathcal{P}$ and let f, g, and $\overline{x}$ be as in Corollary 2.3.1. Then $\mathcal{P}$ is calm at $\overline{x}$.*

Proof. This is an immediate consequence of Corollary 2.3.1 and Theorem 2.1. □

Remark. Dolecki and Rolewicz [20] obtain a result similar to Corollary 2.3.1 in a more general setting by using somewhat different techniques. Their result is based upon the notion of an upper Hausdorff semicontinuous multifunction.

Conditions yielding the regularity of the constraint system (2.4) have been studied by many authors [1], [4], [7], [15], [20], [48], [49], [51], [52], [61], [62], [66]–[68], [73]. The first and most famous of these results is the Lyusternik theorem [48]. An excellent discussion of a variety of these regularity results is given in Borwein [7]. In the mathematical programming literature such conditions are often called constraint qualifications, e.g., the Mangasarian–Fromovitz constraint qualification [51], [52]. In his thesis, Maguregui [49, Chap. 2], introduced the constraint qualification

$$0 \in \mathrm{core}(g(x_0) + g'(x_0)(S - x_0) - C). \tag{2.5}$$

THEOREM 2.4 (Maguregui [49, Chap. 2]). *Suppose that X and Y are Banach spaces, the sets $S \subset X$ and $C \subset Y$ are nonempty, closed, and convex, and $g : X \to Y$ is strictly differentiable at $\overline{x} \in S$. If $g(\overline{x}) \in C$ and (2.5) is satisfied, then system (2.4) is regular at $\overline{x}$.*

Remarks. (1) Using the constraint qualification

$$g_s'(x_0)T(x_0|S) - T(g(x_0)|C) = Y, \tag{2.6}$$

Borwein [7, Thm. 4.3] show that the convexity assumption on the sets C and S can be removed if we instead assume that the sets S and C are epi-Lipschitzian (in the sense of Rockafellar [68]) at x_0 and $g(x_0)$, respectively.

(2) If X and Y are finite-dimensional or if C and S are convex, then the conditions (2.5), (2.6), and

$$\ker([g_s'(x_0)^T, I]) \cap [N(g(x_0)|C) \times N(x_0|S)] = \{0\} \tag{2.7}$$

are all equivalent. Moreover, if $S = \mathbb{R}^n$, and $C := \mathbb{R}^s \times \{0\}_{R^{m-s}}$, all of the conditions (2.5)–(2.7) are equivalent to the Mangasarian–Fromovitz constraint qualification.

(3) In the finite-dimensional case, Borwein [7, Thm. 3.2] has shown that we can generalize (2.7) to

$$\ker([\partial g(x_0)^T, I]) \cap [N(g(x_0)|C) \times N(x_0|S)] = \{0\}, \tag{2.8}$$

where

$$\ker([\partial g(x_0)^T, I]) := \{(y, z) \in \mathbb{R}^m \times \mathbb{R}^n : 0 \in \partial g(x_0)^T y + z\},$$

and still guarantee the regularity of system (2.4).

COROLLARY 2.4.1. *Let the hypotheses of Theorem* 2.4 *hold and consider the problem $\mathcal{P}$ with g continuous and $f := f_0 + \psi(\cdot|S)$, where $f_0 : X \to \mathbb{R}$ Lipschitz near $\overline{x}$. Then $\mathcal{P}$ is calm at $\overline{x}$, or equivalently, $\overline{x}$ is a local minimum for P_α for all α sufficiently large. Moreover, there is a threshold value of α, say $\overline{\alpha}$, and a neighborhood U of $\overline{x}$ such that if $\alpha > \overline{\alpha}$, then any other local minimum of P_α, $\widehat{x} \in U$, must satisfy $f(\overline{x}) = f(\widehat{x})$ and $g(\widehat{x}) \in C$.*

Proof. This is an immediate consequence of Theorem 2.1, Corollary 2.3.1, and Theorem 2.4. □

Remarks. (1) Corollary 2.4.1 extends Han and Mangasarian [33, Thm. 4.4] where it is assumed that $X = \mathbb{R}^n, Y = \mathbb{R}^m$, $S = \mathbb{R}^n$, and $Y := \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$, f_0 and g are continuously differentiable and $\overline{x}$ is a strict local solution to $\mathcal{P}$.

(2) Dolecki and Rolewicz [20, Thm. 2.1] obtain a result similar to Corollary 2.4.1 in a somewhat more general setting. Their result is based upon the notion of locally controllable image nearly inner approximations (inia).

In finite dimensions it is possible to strengthen the result in Corollary 2.4.1 by dropping the requirement that S be convex. Clarke establishes this in [15, Cor. 5, p. 244]. It can also be established by methods that place exact penalty techniques within a broader context of convex composite optimization. In convex composite optimization one studies the problem

$$(\mathcal{Q}) \qquad \text{minimize} \quad q(x)$$

with $q := f + h \circ g$ where $f : X \to \overline{\mathbb{R}}$ and $g : X \to Y$ are as in the statement of $\mathcal{P}$, and $h : Y \to \overline{\mathbb{R}}$ is convex. If C is convex, then $P_\alpha(x) := f(x) + \alpha \operatorname{dist}(g(x)|C)$ is an example of a convex composite function. The following result concerning $\mathcal{Q}$ is a modest extension of a result originally due to Burke and Poliquin [11, Thm. 3.1].

THEOREM 2.5. *Consider the problem $\mathcal{Q}$ where $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ is lower semicontinuous, $g : \mathbb{R}^n \to \mathbb{R}^m$ is locally Lipschitz, and $h : \mathbb{R}^m \to \overline{\mathbb{R}}$ is lower semicontinuous and convex.*

Let $\overline{x} \in \operatorname{dom}(q)$ and suppose that

$$\begin{bmatrix} 0 \in \partial^\infty f(\overline{x}) + \partial g(\overline{x})^* y \\ y \in N(g(\overline{x})|\operatorname{dom}(h)) \end{bmatrix} \Longrightarrow y = 0. \tag{2.9}$$

Define

$$q_\alpha(x) := f(x) + h_\alpha(g(x)) \tag{2.10}$$

with

$$h_\alpha(y) := \inf\{h(z) + \alpha\|y - z\| : z \in \mathbb{R}^m\}. \tag{2.11}$$

If $\overline{x} \in \mathrm{dom}(q)$ *is a local solution to* $\mathcal{Q}$, *then there is an* $\overline{\alpha} > 0$ *such that* $\overline{x}$ *is a local minimizer for* $q_\alpha(x)$ *for all* $\alpha \geq \overline{\alpha}$.

Remarks. (1) The proof of Theorem 2.5 is rather technical, and so is relegated to Appendix A.

(2) The operation employed in (2.11) is known as the infimal convolution of h and $\alpha\|\cdot\|$, and is written $h \,\square\, \alpha\|\cdot\|$. In general, we have

$$\mathrm{epi}[h_1 \,\square\, h_2] = \mathrm{epi}(h_1) + \mathrm{epi}(h_2)$$

for any two convex functions h_1 and h_2. Consequently, $h_1 \,\square\, h_2$ is always convex.

(3) Note that $\mathrm{dom}(h_\alpha) = \mathbb{R}^m$ even if $\mathrm{dom}(h) \neq \mathbb{R}^m$. Hence $\mathrm{dom}(q_\alpha) = \mathrm{dom}(f)$.

If the set C in problem $\mathcal{P}$ is convex, then $\mathcal{P}$ can be seen as an instance of $\mathcal{Q}$ by taking $h := \psi(\cdot|C)$. In this case we have

$$\begin{aligned} h_\alpha(y) :&= \inf\{\psi(z|C) + \alpha\|y - z\| : z \in \mathbb{R}^m\} \\ &= \alpha \ \mathrm{dist}(y|C), \end{aligned}$$

and so

$$q_\alpha(x) = P_\alpha(x) := f(x) + \alpha \ \mathrm{dist}(g(x)|C).$$

Thus Theorem 2.5 can be used to provide conditions under which a finite exact penalty parameter α exists. Condition (2.9) is just another constraint qualification. In particular, if $f := f_0 + \psi(\cdot|S)$ with f_0 locally Lipschitz and S closed, then (2.8) and (2.9) are equivalent and we recover Clarke's result [15, Cor. 5, p. 244] as a special case. Constraint qualifications of the type (2.9) were originally formulated by Rockafellar in [66] and [68]. These comments yield the following corollary to Theorem 2.5.

COROLLARY 2.5.1. *Let* $f : \mathbb{R}^n \to \overline{\mathbb{R}}$, $g : \mathbb{R}^n \to \mathbb{R}^m$, *and* $\overline{x} \in \mathbb{R}^n$ *be as in the statement of Theorem* 2.5 *and consider problem* $\mathcal{P}$. *If* (2.9) *holds with* $h := \psi(\cdot|C)$ *where is* C *nonempty closed and convex, then* $\mathcal{P}$ *is calm at* $\overline{x}$, *or equivalently,* $\overline{x}$ *is a local minimum for* P_α *for all* α *sufficiently large. Moreover, there is a threshold value of* α, *say* $\overline{\alpha}$, *and a neighborhood* U *of* $\overline{x}$ *such that if* $\alpha > \overline{\alpha}$, *then any minimum* $\widehat{x}$ *of* P_α *on* U *must satisfy* $f(\overline{x}) = f(\widehat{x})$ *and* $g(\widehat{x}) \in C$.

Proof. In light of the comments preceding the statement of the result, we need only prove the last part of the result. To this end let $\overline{\alpha}$ be any value of α for which $\overline{x}$ is a local minimum of P_α, and let U be any neighborhood of $\overline{x}$ such that $P_{\overline{\alpha}}(\overline{x}) \leq P_{\overline{\alpha}}(x)$ for all $x \in U$. If $\widehat{\alpha} > \overline{\alpha}$, then $P_{\overline{\alpha}}(\overline{x}) \leq P_{\widehat{\alpha}}(x)$ for all $x \in U$. If $\widehat{x}$ is any other minimum of $P_{\widehat{\alpha}}$ on U, then

$$P_{\widehat{\alpha}}(\widehat{x}) = f(\overline{x}) \leq f(\widehat{x}) + \frac{\overline{\alpha} + \widehat{\alpha}}{2} \ \mathrm{dist}(g(\widehat{x})|C).$$

Consequently, $\mathrm{dist}(g(\widehat{x})|C) = 0$ and $f(\overline{x}) = f(\widehat{x})$. □

Remark. For the case in which $C := \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$ and both f and g are continuously differentiable, this result was first obtained by Han and Mangasarian in [33, Thm. 4.4]. Rosenberg [71, Prop. 1] later generalized Han and Mangasarian's result to the case in which $C := \mathbb{R}^s_- \times \{0\}_{R^{m-s}}$, $f := f_0 + \psi(\cdot|S)$, where f_0 and g are locally Lipschitz and S is nonempty and closed.

In this section we have obtained multiplier rules for $\mathcal{P}$ via the exact penalty function P_α and the calmness hypothesis. We call these multipliers Kuhn–Tucker multipliers. Given $x \in \Omega := \{x \in \mathrm{dom}(f) : g(x) \in C\}$, we denote these multipliers by

$$\text{K-T}(x) := \{y \in N(g(x)|C) : 0 \in \partial f(x) + \partial g(x)^* y\}, \tag{2.12}$$

where $\partial g(x)$ is always taken to be $g_s'(x)$ in the infinite-dimensional setting. This set is always closed and may be empty. It should be noted that this is an extension of the usual theory of Kuhn–Tucker multipliers; that is, if f and g are continuously differential and $C := \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$, then K-T (x) consists precisely of the usual Kuhn–Tucker multipliers for $\mathcal{P}$ at x [43], [51], [70].

PROPOSITION 2.6. *Suppose X and Y are normed linear spaces, C is a closed subset of Y, $f : X \to \overline{\mathbb{R}}$, and $g : X \to Y$. Let $\bar x \in \mathrm{dom}(P_\alpha)$ be such that $g(\bar x) \in C$.*

(1) *If g is strictly differentiable at $\bar x$ and $0 \in \partial P_\alpha(\bar x)$ for some $\alpha \geq 0$, then K-T $(\bar x) \neq \emptyset$.*

(2) *If X and Y are finite-dimensional, g is Lipschitz near $\bar x$, and $0 \in \partial P_\alpha(x)$ for some $\alpha \geq 0$, then K-T $(\bar x) \neq \emptyset$.*

(3) *If f is subdifferentially regular at $\bar x$, g is strictly differentiable at $\bar x$, C is convex, and K-T $(\bar x) \neq \emptyset$, then $0 \in \partial P_\alpha(\bar x)$ for all $\alpha >$ $\mathrm{dist}_0(0|K\text{-}T(\bar x))$ (or $\alpha \geq$ $\mathrm{dist}_0(0|K\text{-}T(\bar x))$ if Y^* is separable).*

Proof. (1) This follows directly from [68, Thms. 2 and 3] and inclusion (2.3).

(2) This follows from [66, Cor. 5.2.3].

(3) The proof is by [68, Thms. 2 and 3],

$$\alpha\partial P_\alpha(\bar x) = \partial f(\bar x) + \alpha g_s'(\bar x)^*\partial\ [\mathrm{dist}(\cdot|C)](g(\bar x)).$$

Let $y \in K - T(\bar x)$ be such that $\|y\|_0 < \alpha$. If Y^* is separable we can choose $\|y\|_0 = \alpha$ [21], [74]. Then $0 \in \partial P_\alpha(\bar x)$ since, by (3.5),

$$\partial\ [\mathrm{dist}(\cdot|C)](g(\bar x)) = \mathbb{B}^0 \cap N(g(\bar x)|C).$$

Remark. Proposition 2.6 extends similar results found in Garcia-Palomares [31, §4], Han and Mangasarian [33, §4], Lasserre [44], Polak, Mayne, and Wardi [59, §3], and Rosenberg [71]. All of these results apply to the finite-dimensional case with $C := \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$. They obtain results for other norms by appealing to the equivalence of norms in finite-dimensions.

It is well known that K-T $(\bar x)$ may be empty even if $\bar x$ is a local solution to $\mathcal{P}$. Nevertheless, more general multiplier rules can be established in this case. The such result is attributed to John [42]. In the next section, we generalize this result to $\mathcal{P}$.

3. A John type multiplier rule for $\mathcal{P}$. In this section we consider the problem $\mathcal{P}$ with $f := f_0 + \psi(\cdot|S)$, $f_0 : \mathbb{R}^n \to \mathbb{R}$ and $g : \mathbb{R}^n \to \mathbb{R}^m$ locally Lipschitz, $S \subset \mathbb{R}^n$ nonempty and closed, and $C \subset \mathbb{R}^m$ nonempty, closed, and convex, and derive a multiplier rule that does not depend on calmness. For this purpose let $\bar x$ be a local solution of radius ε to $\mathcal{P}$, and for each $\delta \geq 0$, consider the function $\theta_\delta : \mathbb{R} \times \mathbb{R}^n \to \overline{\mathbb{R}}$ given by

$$\theta_\delta(x) := \mathrm{dist}[(f_0(x), g(x))|C_{\bar x,\delta}] + \psi(\cdot|S \cap (\bar x + \varepsilon\mathbb{B})), \tag{3.1}$$

where

$$C_{\overline{x},\delta} := (f_0(\overline{x}) - \delta + \mathbb{R}_-) \times C \subset \mathbb{R} \times \mathbb{R}^m. \tag{3.2}$$

It is assumed that the norm chosen for $\mathbb{R} \times \mathbb{R}^m$ is such that $\|(\xi, 0)\| = |\xi|$. Observe that for each $\delta \geq 0$ we have

$$\theta_\delta(\overline{x}) \leq \delta + \inf\theta_\delta(x) \tag{3.3}$$

and if $\delta > 0$, then

$$0 < \inf\theta_\delta(x) < +\infty. \tag{3.4}$$

Thus, in particular, $\overline{x}$ is a global minimum for θ_0. The function θ_0 is a kind of exact penalty function for $\mathcal{P}$. It is similar to the Eremin–Zangwill penalty functions except that no a priori assumptions are required for $\overline{x}$ to be a global minimum for θ_0. Exact penalty functions of this type were considered by Morrison [55] in the case where $C = \{0\}$, $S = \mathbb{R}^n$, and where $\mathbb{R}^m$ is given the Euclidean norm. In this setting, Morrison showed how we can apply the methods of nonlinear least squares to solve $\mathcal{P}$. Further discussion of these penalty functions is given in Fletcher [27].

By applying the appropriate rules of the subdifferential calculus to θ_0, we can obtain a multiplier rule for $\mathcal{P}$. Unfortunately, such a direct application yields a rather uninteresting multiplier rule because of the nature of the subdifferential of the distance function $\text{dist}[\cdot|C_{\overline{x},\varepsilon}]$.

PROPOSITION 3.1. *Let Γ be a nonempty, closed, convex subset of a normed linear space X. Then* $\text{dist}(y|\Gamma)$ *is a convex function whose subdifferential is*

$$\partial \text{ dist}(y|\Gamma) := \begin{cases} \mathbb{B}^0 \cap N(y|\Gamma), & \textit{if } y \in \Gamma \\ (\text{bdry } \mathbb{B}^0) \cap N(y|\Gamma + \text{ dist}(y|\Gamma)\mathbb{B}), & \textit{otherwise.} \end{cases} \tag{3.5}$$

If Γ is not assumed to be convex, then

$$N(y|\Gamma) = \text{cl}[\cup_{\lambda \geq 0} \lambda\partial \text{ dist}(y|\Gamma)]. \tag{3.6}$$

Proof. In the convex case with $y \in \Gamma$, the formula $\partial \text{ dist}(y|\Gamma) = \mathbb{B}^0 \cap N(y|\Gamma)$ is elementary and well known. When Γ is convex and $y \notin \Gamma$, the formula is derived in Burke [9, §2]. The final formula (3.6) is due to Clarke [15, Prop. 2.4.2]. □

Thus a direct application of the chain rule [15, Thm. 2.3.10] to θ_0 would yield, according to Proposition 3.1, the trivial inclusion

$$0 \in \mathbb{R}_+ \partial f_0(\overline{x}) + \partial g(\overline{x})^* N(g(\overline{x})|C) + N(\overline{x}|S).$$

This is the reason for including the perturbation δ in definition (3.1). Due to inequality (3.3) we can apply Ekeland's variational principle [22] to obtain, for each $\delta > 0$, the existence of an $x_\delta \in (\overline{x} + \varepsilon\mathbb{B}) \cap S$ satisfying

$$\|\overline{x} - x_\delta\| \leq \sqrt{\delta},$$

and

$$\theta_\delta(x) + \sqrt{\delta}\|x - x_\delta\| > \theta_\delta(x_\delta)$$

for all $x \neq x_\delta$. Hence $\overline{x}$ is a strict global minimum of the function

$$\widehat{\theta}_\delta(x) := \theta_\delta(x) + \sqrt{\delta}\|x - x_\delta\|.$$

Now, by (3.4), we have $\theta_\delta(x_\delta) > 0$ and so $(f_0(x_\delta), g(x_\delta)) \notin C_{\overline{x},\delta}$. Thus, when we apply the appropriate rules of the subdifferential calculus (Rockafellar [66, Cor. 5.2.3]) to the inclusion $0 \in \partial\widehat{\theta}_\delta(x_\delta)$, we obtain the existence of an $x_\delta \geq 0$ and

$$y_\delta \in N(g(x_\delta)|C + \text{ dist}(g(x_\delta)|C)\mathbb{B})$$

with $\|(\lambda_\delta, y_\delta)\|_0 = 1$ such that

$$0 \in \lambda_\delta\partial f_0(x_\delta) + \partial g(x_\delta)^* y_\delta + N(x_\delta|S) + \sqrt{\delta}\mathbb{B}^0$$

for all δ with $\sqrt{\delta} < \varepsilon$. Consequently, any cluster point $(\overline{\lambda}, \overline{y})$ of $\{(\lambda_\delta, y_\delta)\}$ as $\delta \downarrow 0$ must satisfy

$$\|(\overline{\lambda}, \overline{y})\|_0 = 1, \tag{3.7}$$

$$\overline{\lambda} \geq 0,\ \overline{y} \in N(g(\overline{x})|C), \tag{3.8}$$

and

$$0 \in \overline{\lambda}\partial f_0(\overline{x}) + \partial g(\overline{x})^*\overline{y} + N(\overline{x}|S). \tag{3.9}$$

We have just proved the following theorem.

THEOREM 3.1. *Let f, g, s, C, and $\overline{x}$ be as given at the beginning of this section. Then there exist multipliers $\overline{\lambda} \geq 0$ and $\overline{y} \in N(g(\overline{x})|C)$ such that* (3.7)–(3.9) *hold.*

With a bit of work this result can be obtained from Clarke [15, Thm. 6.1.1]. Moreover, the proof that we provide has a certain similarity to Clarke's proof. We included this proof since it is simpler and more direct. Furthermore, it illustrates the intimate relationship between the multipliers and the subgradient of the distance function at $(f_0(\overline{x}), g(\overline{x}))$.

Note that if the multiplier $\overline{\lambda}$ in (3.7) is nonzero, then $\overline{\lambda}^{-1}\overline{y} \in \text{K-T}(\overline{x})$, i.e.,

$$\text{K-T}(\overline{x}) := \{\overline{\lambda}^{-1}\overline{y} : (\overline{\lambda}, \overline{y}) \text{ satisfy } (3.7)\text{–}(3.9) \text{ with } \overline{\lambda} \neq 0\}. \tag{3.10}$$

Moreover, if f and g satisfy the conditions of part (2) of Proposition 2.6, then

$$0 \in \partial P_{\overline{\lambda}^{-1}}(\overline{x}).$$

Thus the magnitude of $\overline{\lambda}$ is inversely related to the magnitude of an exact penalty parameter for $\mathcal{P}$. The multipliers $(\overline{\lambda}, \overline{y})$, for which $\overline{\lambda} = 0$, are of great significance in the analysis of $\mathcal{P}$. We call these multipliers *Fritz John multipliers* and denote them by

$$\begin{aligned} FJ(x) : &= \{\mu\overline{y} : \mu \geq 0, (0, \overline{y}) \text{ satisfies } (3.7)\text{—}(3.9)\ \} \\ &= \ker([\partial g(x)^T, I]) \cap (N(g(x)|C) \times N(x|S)), \end{aligned}$$

where

$$\ker([\partial g(x)^T, I]) := \{(y, z) \in \mathbb{R}^m \times \mathbb{R}^n : 0 \in \partial g(x)^T y + z\}.$$

Observe that $FJ(x)$ is a nonempty, closed, and convex cone for every $x \in S$ with $g(x) \in C$. Moreover, if K-T $(x) \neq \emptyset$, and g is strictly differentiable at x, then $FJ(x) = \text{rec}(\text{K-T}(x))$. Clarke [15] refers to the Kuhn–Tucker and Fritz John multipliers as the normal and abnormal multipliers, respectively.

According to Theorem 3.1, one is guaranteed of the existence of Kuhn–Tucker multipliers at a local solution $\overline{x}$ to $\mathcal{P}$ if $FJ(\overline{x}) = \{0\}$, or equivalently, if

$$\ker[\partial g(\overline{x})^T, I] \cap (N(g(x)|C) \times N(x(S)) = \{0\}.$$

This condition is precisely the constraint qualification (2.8) and (2.9) of the previous section. Thus we see that condition (2.8) is truly a fundamental property for constrained optimization. It is a natural condition under which we obtain both constraint regularity and the the existence of Kuhn–Tucker multipliers. For this reason, we will refer to (2.8) as the *basic constraint qualification* throughout the remainder of the paper.

PROPOSITION 3.2. *Let f, g, and C be as given in the beginning of this section and let $x \in S$ be such that $g(x) \in C$ and K-T $(x) \neq \emptyset$.*

(1) *If the basic constraint qualification* (2.8) *is satisfied at x, then K-T (x) is compact.*

(2) *If g is strictly differentiable at x, then* K-T (x) *is convex and* $\text{rec}(K\text{-}T(x)) = FJ(x)$, *in which case* K-T (x) *is compact if and only if the basic constraint qualification* (2.8) *is satisfied at x.*

(3) *If $\overline{x}$ is a local solution to $\mathcal{P}$ at which the basic constraint qualification* (2.8) *is satisfied, then* K-T $(\overline{x})$ *is nonempty.*

Proof. (1) If K-T (x) is not compact, then it contains an unbounded sequence $\{y_i\} \subset N(g(x)|C)$. For each $i = 1, 2, \cdots$, there exists vectors $v_i \in \partial f_0(x)$ and $z_i \in N(x|S)$ and a matrix $J_i \in \partial g(x)$ such that

$$0 = v_i + J_i^T y_i + z_i.$$

With no loss in generality, we can assume that $(y_i, z_i)(\|y_i\| + \|z_i\|)^{-1} \to (\overline{y}, \overline{z})$ and $J_i \to \overline{J}$ with $\|\overline{y}\| + \|\overline{z}\| = 1$, $\overline{y} \in N(g(x)|C), \overline{z} \in N(x|S)$, and $\overline{J} \in \partial g(x)$. But then $0 = \overline{J}^T \overline{y} + \overline{z}$ so that $FJ(x) \neq \{0\}$, a contradiction. Hence K-T (x) is compact.

(2) The convexity of K-T (x) and the equivalence $\text{rec}(\text{K-T}(x)) = FJ(x)$ follow directly from the definitions. Thus the equivalence of (2.8) with the compactness of K-T (x) follows immediately from [70, Thm. 8.4].

(3) This follows from the preceding discussion. □

Remark. Proposition 3.2 extends a well-known result of Gauvin [32]. Another generalization of Gauvin's result is obtained in Nguyen, Strodiot, and Mifflin [56], where it is assumed that $C := \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$ and that the s components of g are Lipschitz.

4. Second-order optimality conditions for $\mathcal{P}$. The second-order results of this section are based on the second-order theory for convex composite optimization developed in Burke [10] and Burke and Poliquin [11]. If $f := f_0 + \psi(\cdot|S)$ with $f_0 : \mathbb{R}^n \to \mathbb{R}$ and the sets $S \subset \mathbb{R}^n$ and $C \subset \mathbb{R}^m$ are taken to be nonempty, closed and convex, then the exact penalty functions P_α and θ_0 defined in §§2 and 3, respectively, are convex composite functions. Thus we can apply the results of [10], [11] directly to these functions. The theorems obtained in this way are very much in the spirit of those established in Levitin, Miljutin, and Osinolovski [45], Ioffe [39]–[41], Ben–Isreal, Ben-Tal, and Zlobec [4], and Rockafellar [63]–[64]. These results are distinguished by their use of the entire set of multipliers rather than a single vector of multipliers as is the case in the classical theory of second-order optimality conditions (e.g., see Hestenes [35]–[36], Pennisi [57], and Fiacco and McCormick [25]). Let us begin by reviewing the pertinent results in [66] and [11].

THEOREM 4.1 (Rockafellar [66, Cor. 5.2.3]). *Suppose $f : \mathbb{R}^n \to \mathbb{R}$ is lower semicontinuous, $g : \mathbb{R}^n \to \mathbb{R}^n$ is locally Lipschitz, and $\overline{x} \in \mathrm{dom}(q)$, where $q(x) := f(x) + h(g(x))$, is such that* (2.9) *holds. If $\overline{x}$ is a local minimum of q, then the set of multipliers*

$$(4.1)\qquad M_Q(\overline{x}) := \{y \in \partial h(\cdot)(g(\overline{x})) : 0 \in \partial f(\overline{x}) + \partial g(\overline{x})^* y\}$$

is nonempty.

THEOREM 4.2 (Burke and Poliquin [11, Thm. 4.2]). *Let $\overline{x} \in S \subset \mathbb{R}^n$ be such that $f_0 : \mathbb{R}^n \to \mathbb{R}$ and $g : \mathbb{R}^n \to \mathbb{R}^m$ are twice continuously differentiable near $\overline{x}$. Moreover, let $h : \mathbb{R}^n \to \overline{\mathbb{R}}$ be lower semicontinuous and convex with $g(\overline{x}) \in \mathrm{dom}(h)$, and suppose that S is closed and convex. Set $q := f_0 + \psi(\cdot|S) + h \circ g$.*

(1) *If $\overline{x}$ is a local minimum for q at which the basic constraint qualification* (2.7) *is satisfied, then $M_Q(\overline{x}) \neq \emptyset$ and*

$$(4.2)\qquad \max\{d^T(\nabla^2 f_0(\overline{x}) + \nabla^2_{xx}(\langle y, g(\overline{x})\rangle))d : y \in M_Q(\overline{x})\} \geq 0$$

for all $d \in \mathrm{cl}(K_Q(\overline{x})) \cap T(\overline{x}|S)$

$$(4.3)\qquad K_Q(x) := \{d \in \mathbb{R}^n : \exists \overline{t} > 0 \quad \textit{such that } h(g(x) + tg'(x)d) \leq h(g(x)) \forall t \in (0, \overline{t})\}.$$

(2) *If $M_Q(\overline{x}) \neq \emptyset$ and*

$$(4.4)\qquad \sup\{d^T(\nabla^2 f_0(\overline{x}) + \nabla^2_{xx}(\langle y, g(\overline{x})\rangle))d : y \in M_Q(\overline{x})\} > 0$$

for all $d \in D_Q(\overline{x})\backslash\{0\}$ where

$$(4.5)\qquad D_Q(x) := \{d \in \mathbb{R}^n : q'(x; d) \leq 0\},$$

then there is a $\gamma > 0$ such that

$$q(x) \geq q(\overline{x}) + \gamma\|x - \overline{x}\|^2$$

for all x near $\overline{x}$.

PROPOSITION 4.3. *Let $\overline{x} \in S \subset \mathbb{R}^n$ be such that $f_0 : \mathbb{R}^n \to \mathbb{R}$ and $g : \mathbb{R}^n \to \mathbb{R}^m$ are continuously differentiable near $\overline{x}$. Moreover, let $h : \mathbb{R}^n \to \overline{\mathbb{R}}$ be lower semicontinuous and convex with $g(\overline{x}) \in \mathrm{dom}(h)$, suppose that S is closed, and set $q := f_0 + \varphi(\cdot|S) + h \circ g$. If*

$$(4.6)\qquad \mathrm{ran}\begin{bmatrix} g'(\overline{x}) \\ I \end{bmatrix} \bigcap \mathrm{ri}[T(g(\overline{x})|\mathrm{lev}_h(g(x))) \times T(\overline{x}|S)] \neq \emptyset$$

and

$$(4.7)\qquad \mathrm{cone}(\partial h(\cdot)(g(\overline{x}))) = N(g(\overline{x})|\mathrm{lev}_h(g(\overline{x}))),$$

then $D_Q(\overline{x}) = \overline{K_Q(\overline{x})} \cap T(\overline{x}|S)$. *Moreover, if* $0 \notin \partial h(\cdot)(g(\overline{x}))$, *then* (4.7) *is satisfied, and if the basic constraint qualification* (2.8) *holds, then* (4.6) *is satisfied.*

Proof. All but the very last statement is established in [11, Prop. 5.1]. For the last statement, we take polars in (2.7) to obtain

$$\operatorname{ran}\begin{bmatrix} g'(\overline{x}) \\ I \end{bmatrix} + (T(g(\overline{x})|\mathrm{lev}_h(g(\overline{x}))) \times T(\overline{x}|S)) = \mathbb{R}^m.$$

Now, for any subspace W and closed convex cone K the condition $W + K = \mathbb{R}^m$ implies that $W \cap \mathrm{ri}(K) \neq \emptyset$ by a simple separation argument. This establishes the result. □

We now apply these results to $\mathcal{P}$. The result is a sufficiency theorem which does not require a constraint qualification. The result is obtained by applying Theorem 4.2 to the function θ_0.

THEOREM 4.4. *Let* S *and* C *be nonempty closed convex subsets of* $\mathbb{R}^n$ *and* $\mathbb{R}^m$, *respectively, and let* $\overline{x} \in S$ *be such that* $f_0 : \mathbb{R}^n \to \mathbb{R}$ *and* $g : \mathbb{R}^n \to \mathbb{R}^m$ *are twice continuously differentiable near* $\overline{x}$ *and* $g(\overline{x}) \in C$. *Set* $f := f_0 + \psi(\cdot|S)$ *and consider the problem* $\mathcal{P}$. *If the set of multipliers*

$$M_{\mathcal{P}}(\overline{x}) := \{(\lambda, y) \in \mathbb{R} \times \mathbb{R}^m : (3.7)\text{–}(3.9) \textit{ are satisfied}\} \tag{4.8}$$

is nonempty and

$$\max\{d^T(\lambda\nabla^2 f_0(\overline{x}) + \nabla^2_{xx}(\langle y, g(\overline{x})\rangle))d : (\lambda, y) \in M_{\mathcal{P}}(\overline{x})\} > 0 \tag{4.9}$$

for every $d \in D_{\mathcal{P}}(\overline{x})$ *where*

$$D_{\mathcal{P}}(\overline{x}) := \{d \in T(\overline{x}|S) : \nabla f_0(\overline{x})^T d \leq 0, g'(\overline{x})d \in T(g(\overline{x})|C)\}, \tag{4.10}$$

then there is a $\gamma > 0$ *such that*

$$f_0(x) \geq f_0(\overline{x}) + \gamma\|x - \overline{x}\|^2 \tag{4.11}$$

for every $x \in \Omega := \{x \in S : g(x) \in C\}$ *near* $\overline{x}$.

Proof. Consider part (2) of Theorem 4.2 as it applies to the function θ_0 defined in (3.1). We begin by defining the functions f_0, g, and h and the set S that appear in Theorem 4.2. For the sake of clarity, we denote these functions and set as $f_{0_{(4.2)}}$, $g_{(4.2)}$, $h_{(4.2)}$, and $S_{(4.2)}$, respectively. For the remainder of the proof the functions f_0 and g, and the set S, will refer to those that are given in the statement of Theorem 4.4. With this notation we define $f_{0_{(4.2)}} \equiv 0$, $g_{(4.2)} := (f_0, g)$, $h_{(4.2)} :=$ $\mathrm{dist}[\cdot|C_{\overline{x},0}]$, and $S_{(4.2)} := S \cap (\overline{x} + \varepsilon\mathbb{B})$. The set $M_Q(\overline{x})$ is given by

$$\{(\lambda, y) : \|(\lambda, y)\|_0 \leq 1 \text{ and } (3.8)\text{–}(3.9) \text{ hold for } f_{0_{(4.2)}} \text{ and } g_{(4.2)}\} \supset M_{\mathcal{P}}(\overline{x}),$$

and the set $D_Q(\overline{x})$ is given by

$$\begin{aligned}
&\{d : \psi^*(d|N(\overline{x}|S)) + \psi^*(d|[0,1]\nabla f_0(x) + g'(x)^T(\mathbb{B}^0 \cap N(g(x)|C))) \leq 0\} \\
=&\{d \in T(\overline{x}|S) : \lambda\nabla f_0(\overline{x})^T d + y^T g'(\overline{x})d \leq 0 \ \forall\lambda \in [0,1], y \in \mathbb{B}^0 \cap N(g(\overline{x})|C)\} \\
=&\{d \in T(\overline{x}|S) : \nabla f_0(\overline{x})^T d \leq 0, g'(\overline{x})d \in T(g(\overline{x})|C)\} \\
=&D_{\mathcal{P}}(\overline{x}),
\end{aligned}$$

where the line follows by choosing the norm on $\mathbb{R} \times \mathbb{R}^m$ to be $|\xi| + \|y\|_0$ for every $(\xi, y) \in \mathbb{R} \times \mathbb{R}^m$. Since inequality (4.9) implies inequality (4.4), we have the existence of $\gamma > 0$ such that

$$\theta_0(x) \geq \theta_0(\overline{x}) + \gamma\|x - \overline{x}\|^2 \tag{4.12}$$

for all x near $\overline{x}$, where by the theorem is proved. □

Remarks. (1) The theorem actually establishes inequality (4.12), which is stronger than inequality (4.11).

(2) We could just as well have used the multiplier set $M_{\mathcal{Q}}(\overline{x})$ in (4.9), but, since the maximum is positive, both of these multiplier sets yield the same value in (4.9).

Unfortunately, without a constraint qualification, the same trick cannot be applied to obtain a second-order necessary condition for $\mathcal{P}$. The problem is that $M_{\mathcal{P}}(\overline{x}) \subsetneq M_{\mathcal{Q}}(\overline{x})$ with $(0,0) \in M_{\mathcal{Q}}(\overline{x})$. Consequently (4.2) is valid for all $d \in \mathbb{R}^n$ and it does not imply (4.9) with the weak inequality. On the other hand, if the sets C and S are polyhedral convex, then such a result can be established (e.g., see [35] and [36] or [25]).

If one is willing to assume the basic constraint qualification (2.7), then, by applying Theorem 4.2 to P_α both second-order necessary and sufficient conditions for $\mathcal{P}$ can be obtained. To establish this result, we require the following lemma.

LEMMA 4.5. *Let X and Y be normed linear spaces and let C be a nonempty closed convex subset of Y. Moreover, let $\overline{x} \in X$, $f : X \to \overline{\mathbb{R}}$, and $g : X \to Y$ be such that $\partial f(\overline{x}) \neq \emptyset$, f is subdifferentially regular at $\overline{x}$, $g(\overline{x}) \in C$, and g is strictly differentiable at $\overline{x}$. If the set* K-T $(\overline{x})$ *is nonempty, then*

$$\begin{aligned}\{d \in X : P_\alpha^0(\overline{x}; d) \leq 0\} &= \{d \in X : f^0(\overline{x}; d) = 0, g_s'(\overline{x})d \in T(g(\overline{x})|C)\} \\ &=: D_{\mathcal{P}}(\overline{x})\end{aligned}$$

for all $\alpha >$ $\operatorname{dist}_0(0|K\text{-}T(\overline{x}))$.

Proof. The hypotheses and Rockafellar [68, Thms. 2 and 3] imply that

$$\partial P_\alpha(\overline{x}) = \partial f(\overline{x}) + \alpha g_s'(\overline{x})^*(\mathbb{B}^0 \cap N(g(\overline{x})|C)).$$

Thus, if $\alpha >$ $\operatorname{dist}_0(0|\text{K-T}(\overline{x}))$, then clearly

$$D_{\mathcal{P}}(\overline{x}) \subset \{d \in X : P_\alpha^0(\overline{x}; d) \leq 0\}.$$

On the other hand, let $d \in \{d : P_\alpha^0(\overline{x}; d) \leq 0\}$. Then for each $y \in$ K-T $(\overline{x})$ with $\|y\|_0 < \alpha$ there is a $z \in \partial f(\overline{x})$ such that $0 = z + g_s'(\overline{x})^* y$. Hence,

$$\begin{aligned}0 &\geq P_\alpha^0(\overline{x}; d) \\ &\geq \langle z + \alpha g_s'(\overline{x})^* \frac{y}{\|y\|_0}, d\rangle \\ &= (1 - \frac{\alpha}{\|y\|_0})\langle z, d\rangle,\end{aligned}$$

and so $f^0(\overline{x}; d) \geq \langle z, d\rangle \geq 0$. But $0 \in N(g(\overline{x})|C) \cap \mathbb{B}^0$ so that $f^0(\overline{x}; d) \leq 0$. Consequently, $f^0(\overline{x}; d) = 0$ and $g_s'(\overline{x})d \in T(g(\overline{x})|\mathbb{B})$. □

Remark. The set $D_{\mathcal{P}}(\overline{x})$ given above is the obvious generalization of the set defined in (4.10) to which it reduces under the hypotheses of Theorem 4.4.

THEOREM 4.6. *Let S and C be nonempty closed convex subsets of $\mathbb{R}^n$ and $\mathbb{R}^m$, respectively, and let $\overline{x} \in S$ be such that $f_0 : \mathbb{R}^n \to \mathbb{R}$ and $g : \mathbb{R}^n \to \mathbb{R}^m$ are twice continuously differentiable near $\overline{x}$, $g(\overline{x}) \in C$, and the basic constraint qualification (2.7) holds. Set $f := f_0 + \psi(\cdot|S)$ and consider the problem $\mathcal{P}$.*

(1) *If $\overline{x}$ is a local solution to $\mathcal{P}$, then*

$$\max\{d^T(\nabla^2 f_0(\overline{x}) + \nabla^2_{xx}(\langle y, g(\overline{x})\rangle))d : y \in K\text{-}T(\overline{x})\} \geq 0 \tag{4.13}$$

for all $d \in D_{\mathcal{P}}(\overline{x})$.

(2) *If K-T $(\overline{x}) \neq \emptyset$ and*

$$\max\{d^T(\nabla^2 f_0(x) + \nabla^2_{xx}(\langle y, g(\overline{x})\rangle)))d : y \in K\text{-}T(\overline{x})\} > 0 \tag{4.14}$$

for all $d \in D_{\mathcal{P}}(\overline{x})\backslash\{0\}$, then for each

$$\alpha > \overline{\alpha} := \max\{\|y\|_0 : y \in K\text{-}T(\overline{x})\} \tag{4.15}$$

there are scalars $\varepsilon > 0$ and $\gamma > 0$ such that

$$P_\alpha(x) \geq P_\alpha(\overline{x}) + \gamma\|x - \overline{x}\|^2$$

for all $x \in \overline{x} + \varepsilon\mathbb{B}$, and

$$f_0(x) \geq f_0(\overline{x}) + \gamma\|x - \overline{x}\|^2$$

for all $x \in \Omega \cap (\overline{x} + \varepsilon\mathbb{R})$ where

$$\Omega := \{x \in S : g(x) \in C\}.$$

Proof. In $\mathcal{Q}$ take $h := \alpha \operatorname{dist}(\cdot|C)$. Then, by Proposition 4.3 and Lemma 4.5,

$$D_{\mathcal{Q}}(\overline{x}) = \operatorname{cl}(K_{\mathcal{Q}}(\overline{x})) \cap T(\overline{x}|S) = D_{\mathcal{P}}(\overline{x}) \tag{4.16}$$

as long as $\alpha > \|y\|_0$ for some $y \in$ K-T$(\overline{x})$. Moreover, by part (1) of Proposition 3.2, the set K-T $(\overline{x})$ is compact. Hence if K-T $(\overline{x}) \neq \emptyset$, then $\overline{\alpha}$ is finite and for any $\alpha \geq \overline{\alpha}$ one has

$$M_{\mathcal{Q}}(\overline{x}) = \text{K-T}(\overline{x}). \tag{4.17}$$

(1) By Corollary 2.5.1, there is an $\alpha > 0$ such that $\overline{x}$ is a local minimum for P_α. Taking $h := \alpha \operatorname{dist}(\cdot|C)$ in $\mathcal{Q}$, we get $M_{\mathcal{Q}}(\overline{x}) \subset$ K-T$(\overline{x})$, where α is chosen so that $\alpha >$ $\operatorname{dist}_0(0|\text{K-T}(\overline{x}))$. The result then follows from (4.16) and part (1) of Theorem 4.2.

(2) By taking $\alpha > 0$ to satisfy (4.15) and by observing (4.16) and (4.17), the result is an immediate consequence of part (2) of Theorem 4.2 with $h := \alpha \operatorname{dist}(\cdot|C)$. □

Remark. For the case in which C and S are polyhedral convex, Theorem 4.6 is also obtained by Ioffe [39]–[41], Ben–Israel, Ben–Tal, and Zlobec [4], and Rockafellar [63]–[64].

In Theorem 4.6 we obtain second-order necessary and sufficient conditions for $\mathcal{P}$ from the corresponding second-order conditions for P_α. This approach is the reverse of that which is usually taken in the literature. In particular, Charalambous [13, Thm. 2], Han and Mangasarian [33, Thm. 4.6], and Lasserre [44, Thm. 2] essentially show that if K-T $(\bar{x}) \neq \emptyset$ and the second-order sufficiency condition of Pennisi [57, Thm. 3.3] holds for some $y \in$ K-T$(\bar{x})$, then $\bar{x}$ is a strict local minimum for P_α for all $\alpha > \|y\|_0$. These results do not require the imposition of the basic constraint qualification (2.7). On the other hand, they do require the application of a stronger second-order sufficiency condition. In the next result, we obtain a result, paralleling those of Charalambous, Han and Mangasarian, and Lasserre.

THEOREM 4.7. *Let S, C, $\bar{x}$, f_0, and g be as in the statement of Theorem* 4.6, *except that the basic constraint qualification may fail to hold at $\bar{x}$. If there exists $\bar{y} \in K\text{-}T(\bar{x})$ such that*

$$d^T(\nabla^2 f_0(\bar{x}) + \nabla^2_{xx}(\langle \bar{y}, g(\bar{x})\rangle))d > 0$$

for every $d \in D_{\mathcal{P}}(\bar{x})\backslash\{0\}$, then for each $\alpha > \|y\|_0$ there are scalars $\varepsilon > 0$ and $\gamma > 0$ such that

$$P_\alpha(x) \geq P_\alpha(\bar{x}) + \gamma\|x - \bar{x}\|^2$$

for all $x \in \bar{x} + \varepsilon\mathbb{B}$ and

$$f_0(x) \geq f_0(\bar{x}) + \gamma\|x - \bar{x}\|^2$$

for all $x \in \Omega \cap (\bar{x} + \varepsilon\mathbb{B})$.

Proof. For this choice of α (4.16) holds and by part (3) of Proposition 2.6, $0 \in \partial P_\alpha(\bar{x})$ with $y \in M_{\mathcal{Q}}(\bar{x})$ where $h := \alpha \operatorname{dist}(\cdot|C)$. Hence, the result again follows directly from part (2) of Theorem 4.2. □

Before leaving this section we obtain yet another sufficiency result for $\mathcal{P}$. It is a first-order sufficiency result and is a direct consequence of Lemma 4.5. The result is similar to results by Howe [37], Rosenberg [71, Thm. 3], and Bazaraa and Goode [3, Thms. 2.1, 2.2, 3.1, and 4.1].

THEOREM 4.8. *Let X, Y, $\bar{x}$, f, and g be as in the statement of Lemma* 4.5 *where it is further assumed that X is finite-dimensional. If the set $K\text{-}T$ $(\bar{x})$ is nonempty and $D_{\mathcal{P}}(\bar{x}) = \{0\}$, then there are scalars $\varepsilon > 0$ and $\gamma > 0$ such that*

$$P_\alpha(x) \geq P_\alpha(\bar{x}) + \gamma\|x - \bar{x}\|$$

for all $x \in (\bar{x} + \varepsilon\mathbb{B})$ and $\alpha >$ $\operatorname{dist}_0(0|K\text{-}T(\bar{x}))$, and

$$f(x) \geq f(\bar{x}) + \gamma\|x - \bar{x}\|$$

for all $x \in \{x : g(x) \in C\} \cap (\bar{x} + \varepsilon\mathbb{B})$.

Proof. From Lemma 4.5, $P^0_\alpha(\bar{x}; d) > 0$ for all $d \neq 0$. By Rockafellar [68, Thms. 2 and 3], $P^0_\alpha(\bar{x}; d) = P'_\alpha(\bar{x}; d)$. The result now easily follows with $\gamma = \inf\{P'_\alpha(\bar{x}; d) : \|d\| = 1\} > 0$. □

5. Convex programming. Eremin and Zangwill originated the study of exact penalization in the context of convex programming. In this section, we extend this theory to the problem $\mathcal{P}$. The step in this process is to establish an equivalence between the problem $\mathcal{P}$ and a problem $\widetilde{\mathcal{P}}$ to which the classical theory of convex programming applies [35], [36], [38], [43], [46], [48], [51], [70], [72]. To this end, let X be a real normed linear space, Y a real reflexive Banach space, $C \subset X$ and $S \subset X$ be nonempty, closed, and convex, and set

$$\widetilde{C} := \operatorname{cl}\{(\lambda, \lambda y) : \lambda \geq 0, y \in C\},$$

where the closure is taken with respect to the product topology on $\mathbb{R} \times Y$.

Given $g : X \to Y$ we define $G : X \to \mathbb{R} \times Y$ by

$$G(x) := (-1, -g(x))$$

for all $x \in X$. Consider the constrained optimization problem

$$(\widetilde{\mathcal{P}}) \qquad \begin{array}{l} \text{minimize } f(x) \\ \text{subject to } G(x) \le 0, \end{array}$$

where $f := f_0 + \psi(\cdot|S)$ with $f_0 : X \to \mathbb{R}$ a convex function and where "$\le$" denotes the partial order induced on $\mathbb{R} \times Y$ by $\widetilde{C}$, i.e., $\underset{\sim}{y_1} \le y_2$ if and only if $y_2 - y_1 \in \widetilde{C}$. Observe that $x \in X$ solves $\mathcal{P}$ if and only if x solves $\widetilde{\mathcal{P}}$. We now develop a purely convex theory for $\mathcal{P}$ based upon that which already exists for $\widetilde{\mathcal{P}}$.

LEMMA 5.1. *Let $G : X \to \mathbb{R} \times Y$ and $\widetilde{C} \subset \mathbb{R} \times Y$ be as given above. Then the following conditions are equivalent.*

(1) *G is convex with respect to $\widetilde{C}$; i.e., $G(\lambda x + (1 - \lambda)y) \le \lambda G(x) + (1 - \lambda)G(y)$ for every $x, y \in X$ and $\lambda \in [0, 1]$.*

(2) *g is concave with respect to $\operatorname{rec}(C)$; i.e., $g(\lambda x + (1-\lambda)y) - [\lambda g(x) + (1-\lambda)g(y)] \in \operatorname{rec}(C)$ for every $x, y \in X$ and $\lambda \in [0, 1]$.*

(3) *For each $y \in \operatorname{bar}(C)$ the mapping $g_y : X \to \mathbb{R}$, given by $g_y(\cdot) := \langle y, g(\cdot)\rangle$, is convex.*

Moreover, each of the above conditions imply that the distance function $\operatorname{dist}(g(\cdot)|C)$ is convex.

Proof. (1) $\iff$ (2): Let $x_1, x_2 \in X$ and choose $\lambda \in [0, 1]$. Then G is convex with respect to $\widetilde{C}$ if and only if

$$\lambda(-1, -g(x_1)) + (1 - \lambda)(-1, -g(x_2)) - (-1, -g(\lambda x_1 + (1 - \lambda)x_2)) \in \widetilde{C},$$

or equivalently

$$g(\lambda x_1 + (1 - \lambda)x_2) - [\lambda g(x_1) + (1 - \lambda)g(x_2)] \in \operatorname{rec}(C)$$

since $\operatorname{rec}(C) = \{y : (0, y) \in \widetilde{C}\}$. This is equivalent to saying that g is concave with respect to $\operatorname{rec}(C)$.

(2) $\iff$ (3): The mapping g is concave with respect to $\operatorname{rec}(C)$ if and only if for every $x_1, x_2 \in X$ and $\lambda \in [0, 1]$

$$g(\lambda x_1 + (1 - \lambda)x_2) - [\lambda g(x_1) + (1 - \lambda)g(x_2)] \in (\operatorname{bar}(C))^0$$

since $[\operatorname{bar}(C)]^0 = \operatorname{rec}(C)$. This is equivalent to saying that

$$\langle y, g(\lambda x_1 + (1 - \lambda)x_2)\rangle \le \langle y, \lambda g(x_1) + (1 - \lambda)g(x_2)\rangle$$

for every $x_1, x_2 \in X$, $\lambda \in [0, 1]$, and $y \in \operatorname{bar}(C)$; i.e., $\langle y, g(\cdot)\rangle$ is convex for every $y \in \operatorname{bar}(C)$.

Finally, if any one of (1)–(3) hold, then clearly (3) is valid. Hence, for every $y \in \operatorname{bar}(C) = \operatorname{dom}(\psi^*(\cdot|C))$ the function

$$\langle y, g(\cdot)\rangle - \psi^*(y|C)$$

is convex. Therefore,

$$\operatorname{dist}(g(\cdot)|C) := \sup\{\langle y, g(\cdot)\rangle - \psi^*(y|C) : y \in \mathbb{B}^0\}$$

is convex since it is the supremum of a collection of convex functions. □

Remark. If C is bounded, then g is concave with respect to the $\operatorname{rec}(C)$ if and only if g is affine, and if $C := \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$, then g is concave with respect to $\operatorname{rec}(C)$ if and only if g_i is convex for $i = 1, \cdots, s$ and g_i is affine for $i = s+1, \cdots, m$.

LEMMA 5.2. *Let $\widetilde{L} : S \times \widetilde{C}^* \to \mathbb{R}$ be the standard Lagrangian for $\widetilde{\mathcal{P}}$ where $\widetilde{C}^* := -\widetilde{C}^0$, i.e.,*

$$\widetilde{L}(x, z) := f(x) + \langle z, G(x)\rangle,$$

and define $L : S \times Y^* \to \mathbb{R}$ by

$$L(x, y) := f(x) + \langle y, g(x)\rangle - \psi^*(y|C).$$

Suppose that $f := f_0 + \psi(\cdot|S)$ with $f_0 : X \to \mathbb{R}$ convex and $g : X \to Y$ is concave with respect to $\operatorname{rec}(C)$ so that both $\widetilde{L}$ and L are convex–concave saddle functions by the previous lemma. Then $(x_0, (\xi_0, -y_0)) \in S \times \widetilde{C}^*$ is a saddle point for $\widetilde{L}$ if and only if (x_0, y_0) is a saddle point for L in which case $\xi_0 = \psi^*(y_0|C)$, $y_0 \in N(g(x_0)|C)$, and $g(x_0) \in C$.

Proof. By direct computation we verify that

$$\widetilde{C}^* := \{(\xi, -y) | (\xi, y) \in \operatorname{epi}(\psi^*(\cdot|C))\}.$$

If $(x_0, (\xi_0, -y_0))$ is a saddle point for $\widetilde{L}$, then, in particular, $x_0 \in S$ and

$$\langle(\xi, -y), (-1, -g(x_0))\rangle \le \langle(\xi_0, -y_0), (-1, -g(x_0))\rangle$$

for every $(\xi, y) \in \operatorname{epi}(\psi^*(\cdot|C))$, or equivalently,

$$\langle y, g(x_0)\rangle - \xi \le \langle y_0, g(x_0)\rangle - \xi_0 \tag{5.1}$$

for every $(\xi, y) \in \operatorname{epi}(\psi^*(\cdot|C))$. But this can occur if and only if

$$\xi_0 = \psi^*(y_0|C), g(x_0) \in C, \langle y_0, g(x_0)\rangle = \psi^*(y_0|C),$$

and

$$L(x_0, y) \le L(x_0, y_0)$$

for every $y \in \operatorname{bar}(C)$. To see this, set $y = y_0$ in (5.1) to get $\xi_0 = \psi^*(y_0|C)$, next set $y = y_0 + z$ in (5.1) to get $\langle z, g(x_0)\rangle \le \psi^*(z|C)$ for all $z \in \operatorname{bar}(C)$, and so $g(x_0) \in C$. Finally, having $g(x_0) \in C$ we obtain from (5.1) that

$$0 \le \langle y_0, g(x_0)\rangle - \psi^*(y_0|C) \le 0.$$

The reverse implication is obvious.

By employing the fact that $\xi_0 = \psi^*(y_0|C)$, $g(x_0) \in C$, and $\psi^*(y_0|C) = \langle y_0, g(x_0)\rangle$, we obtain from the other half of the saddle point inequalities for $\widetilde{L}$ that

$$L(x_0, y_0) = \widetilde{L}(x_0, (\xi_0, -y_0)) \le f(x) + \langle y_0, g(x)\rangle - \psi^*(y_0|C)$$

for every $x \in S$, or equivalently,

$$L(x_0, y_0) \le L(x, y_0)$$

for all $x \in S$ whereby the lemma is established. □

Having obtained the equivalence of the saddle point conditions for $\widetilde{L}$ and L, we can now simply translate the saddle point results for $\widetilde{\mathcal{P}}$ into similar results for $\mathcal{P}$. In this way, we obtain the following two results from [46, Cor. 1, p. 219] and [46, Thm. 2, p. 221], respectively.

THEOREM 5.3. *Let X be a real normed linear space and Y a real reflexive Banach space, let $S \subset X$ and $C \subset Y$ be nonempty, closed, and convex, and suppose that $f := f_0 + \psi(\cdot|S)$ with $f_0 : X \to \mathbb{R}$ convex, and $g : X \to Y$ is concave with respect to* $\mathrm{rec}(C)$, *and there is an $x \in S$ such that $g(x) \in \mathrm{int}(C)$. If $\overline{x}$ solves $\mathcal{P}$, then there is a $\overline{y} \in N(g(\overline{x})|C)$ such that $(\overline{x}, \overline{y})$ is a saddle point for $L(x, y)$.*

Remark. If X and Y are finite-dimensional, then we need only assume that there is an $x \in S$ such that $g(x) \in \mathrm{ri}(C)$.

THEOREM 5.4. *Let X, Y, S, C, g, and f be as in the statement of Theorem* 5.3. *If there exists an $\overline{x} \in S$ and $\overline{y} \in \mathrm{bar}(C)$ such that $(\overline{x}, \overline{y})$ is a saddle point for $L(x, y)$, then $\overline{x}$ solves $\mathcal{P}$.*

Further results of this type can also be obtained. Theorems 5.3 and 5.4 are presented only to give the flavor of what can be said in the convex case. In this setting, the most natural notion of a Kuhn–Tucker multiplier is derived from that of a saddle point of L. Thus, for the convex case, we extend the definition of K-T (x) as follows;

$$\text{K-T}(x) := \{y \in \mathrm{bar}(C) : (x, y) \text{ is a saddle point for } L\}.$$

Our primary result on exact penalization in the convex case now follows.

THEOREM 5.5. *Let X, Y, S, C, f, and g be as in the statement of Theorem* 5.3, *let $\overline{x} \in S$, and consider the following two conditions:*

(A) *f is continuous near $\overline{x}$ and g is strictly differentiable at $\overline{x}$.*

(B) *X and Y are finite-dimensional and g is Lipschitz near $\overline{x}$.*

The following statements are equivalent:

(1) *$\mathcal{P}$ is calm at $\overline{x}$.*

(2) *$\overline{x}$ is a global minimum of P_α for all α sufficiently large.*

Moreover, if either (A) *or* (B) *holds, then* (1) *and* (2) *are equivalent to*

(3) *K-T $(\overline{x}) \neq \emptyset$.*

Furthermore, given $\overline{y} \in$ K-T$(\overline{x})$, then $\overline{x}$ is a global minimum for P_α for all $\alpha \ge \|\overline{y}\|_0$ and if $\alpha >$ $\mathrm{dist}_0(0|\text{K-T}(\overline{x}))$, then

$$\arg\min\{P_\alpha(x) : x \in X\} \subset \arg\min\{f(x) : g(x) \in C\}.$$

Proof. By Lemma 5.1, P_α is a convex function for all $\alpha \ge 0$; consequently, any local minimum of P_α is a global minimum of P_α. Therefore, the equivalence of (1) and (2) is a consequence of Theorem 2.1.

The proof that (3) is equivalent to (1) and (2) is essentially identical under the two hypotheses (A) and (B), except that we use [66, Cor. 5.2.3] in the finite-dimensional case and [68, Thms. 2 and 3] in the infinite-dimensional case. Hence, we provide the proof only when (A) is assumed.

We begin by assuming (2) and showing that (3) holds. From (2) there is a $\overline{y} \in \partial\ \mathrm{dist}(\cdot|C)(g(\overline{x}))$ with $0 \in \partial f(\overline{x}) + \alpha g_s'(\overline{x})^*\overline{y}$, or equivalently, there is a $\overline{y} \in N(g(\overline{x})|C)$ such that

$$0 \in \partial_x L(\overline{x}, \overline{y}),$$

since $\partial\ \mathrm{dist}(\cdot|C)(y(\overline{x})) = \mathbb{B}^0 \cap N(g(\overline{x})|C)$ by Proposition 3.1. Consequently,

$$L(\overline{x}, \overline{y}) \leq L(x, \overline{y})$$

for all $x \in X$, since $L(x, \overline{y})$ is convex in x by Lemma 5.1. Finally, since

$$\begin{aligned}\psi(g(\overline{x})|C) &= \langle \overline{y}, g(\overline{x})\rangle - \psi^*(\overline{y}|C)\\ &= \sup\{\langle y, g(\overline{x})\rangle - \psi^*(y|C) : y \in Y\},\end{aligned}$$

we have that

$$L(\overline{x}, y) \leq L(\overline{x}, \overline{y})$$

for all $y \in Y$.

Next we assume that (3) holds and establish (2). Since $L(\overline{x}, y) \leq L(\overline{x}, \overline{y})$ for all $y \in Y$ we know that

$$0 = \psi(g(\overline{x})|C) = \langle \overline{y}, g(\overline{x})\rangle - \psi^*(\overline{y}|C).$$

Next, let $x \in S$ and choose $\alpha \geq \|\overline{y}\|_0$, then

$$\begin{aligned}P_\alpha(\overline{x}) &= L(\overline{x}, \overline{y})\\ &\leq L(x, \overline{y})\\ &\leq \sup\{L(x, y) : y \in \alpha\mathbb{B}\}\\ &= f(x) + \alpha\sup\{\langle y, g(x)\rangle - \psi^*(y|C) | y \in \mathbb{B}^0\}\\ &= P_\alpha(x).\end{aligned}$$

Hence $\overline{x}$ is a global minimum for $P_\alpha(x)$ for all $\alpha \geq \|\overline{y}\|_0$.

To prove the last statement of the theorem choose $\overline{y} \in$ K-T$(\overline{x})$ such that $\alpha > \|\overline{y}\|_0$. Setting $\overline{\alpha} = \|\overline{y}\|_0$, we know that $0 \in \partial P_{\overline{\alpha}}(\overline{x})$ and $0 \in \partial P_\alpha(\overline{x})$ so that $\overline{x}$ is a global minimum for both $P_{\overline{\alpha}}$ and P_α. Thus, in particular, arg $\min\{P_\alpha(x) : x \in X\} \neq \emptyset$. Let $\widetilde{x} \in$ arg $\min\{P_\alpha(x) : x \in X\}$, we need to show that $\widetilde{x} \in$ arg $\min\{f(x) : g(x) \in C\}$. For this, it is sufficient to show that $f(\widetilde{x}) \leq f(\overline{x})$ and $g(\widetilde{x}) \in C$. Due to the nature of $\overline{x}$ and $\widetilde{x}$ we have

$$f(\widetilde{x}) + \alpha\ \mathrm{dist}(g(\widetilde{x})|C) \leq f(\overline{x}) + \alpha\ \mathrm{dist}(g(\overline{x})|C)$$

and

$$f(\overline{x}) + \overline{\alpha}\ \mathrm{dist}(g(\overline{x})|C) \leq f(\widetilde{x}) + \overline{\alpha}\ \mathrm{dist}(g(\widetilde{x})|C).$$

By adding these inequalities we find that

$$(\alpha - \overline{\alpha})\ \mathrm{dist}(g(\widetilde{x})|C) \leq (\alpha - \overline{\alpha})\ \mathrm{dist}(g(\overline{x})|C).$$

Hence $g(\widetilde{x}) \in C$ and $f(\widetilde{x}) \leq f(\overline{x})$. □

Remark. The form of Theorem 5.5 is based on Rosenberg [71, Thm. 2]. This result extends similar results appearing in Eremin [23], Zangwill [75], Pietrzykowski

[58], Luenberger [47], Charalambous [13], Han and Mangasarian [33], Lasserre [44], Garcia-Palomares [31], Rosenberg [71], and Bertsekas [6].

6. Historical review.

In this section we attempt to provide a chronology of those results that establish the existence of an exact penalty parameter. We apologize for any omission or oversight.

It seems apparent that the big-M method for linear programming is the precursor of exact penalization techniques for nonlinear programming, especially since the initial results were obtained for the convex programming case. However, we are uncertain that this was indeed the motivation. Our earliest reference for the big-M method is Charnes, Cooper, and Anderson [14, §4]. The precise origins of the method are unknown to us. Our earliest reference for exact penalization in nonlinear programming is Eremin [23]. In this paper, Eremin considers the case of convex programming with $C = \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$ and $S = \mathbb{R}^n$. In [23, Thm. 2], he shows that if $\bar{y} \in \text{K-T}(\bar{x})$, then $\bar{x}$ is a global minimum for P_α whenever $\alpha > \|y\|_0$ when $\mathbb{R}^m$ is endowed with the ℓ_1 norm. At essentially the same time, Zangwill [75] published his well-known paper. Zangwill considered the case of convex programming with $C = \mathbb{R}^m_-$ and $S = \mathbb{R}^n$ and showed that if $\bar{x}$ solved $\mathcal{P}$ and $g(x_0) \in \text{int}(C)$, then $\bar{x}$ minimized P_α for all $\alpha > (f(x_0) - f(\bar{x}) + 1)(\max[g_i(x_0) : i = 1, \cdots, m])^{-1}$. This result can be used to show that K-T $(\bar{x}) \neq \emptyset$, and so is somewhat deeper than Eremin's result.

Pietrzykowski [58] provides the result for the nonconvex case. He considers the instance of $\mathcal{P}$ where $C = \mathbb{R}^s \times \{0\}_{\mathbb{R}^{m-s}}$ and $S = \mathbb{R}^n$. The analysis that Pietrzykowski gives a reminiscent of Zangwill's. He shows that if $\bar{x}$ is a strict local minimum for $\mathcal{P}$, near which f and g are differentiable and at which $g'(\bar{x})$ is surjective, then $\bar{x}$ is a strict local minimum for P_α for all α sufficiently large. Pietrzykowski's result can be used to show that K-T $(\bar{x}) \neq \emptyset$ under these hypotheses.

Luenberger [47] considers exact penalization in the setting of optimal control. We interpret his result as it applies to $\mathcal{P}$. In this context, Luenberger has $C = \mathbb{R}^m_-$ and $S = \mathbb{R}^n$ and assumes that $\bar{x}$ is a local minimum for $\mathcal{P}$ at which there exists a $\bar{y} \in N(g(\bar{x})|C)$ such that $\bar{x}$ is a local minimum for $L(x, \bar{y})$. Under these circumstances Luenberger shows that $\bar{x}$ is a local minimum for P_α for all $\alpha \geq \|\bar{y}\|_0$ where $\mathbb{R}^m$ is endowed with the ℓ_1 norm. Luenberger's proof is the same as that provided by Eremin. Clearly, Luenberger's result applies in the convex case subject to the appropriate constraint qualification, but it can also be applied to cases in which the second-order sufficiency condition of Pennisi [57] holds. Luenberger himself only states that this result applies "under standard regularity conditions."

Evans, Gould, and Tolle [24] consider the case where $C = \mathbb{R}^m_-$, $S = \mathbb{R}^n$, and f and g are continuously differentiable. In this context, their nondifferentiable exact penalty functions are quite different from the Eremin–Zangwill exact penalty functions. For these new functions they provide some exactness results that are similar in spirit to those of Eremin, Zangwill, and Pietrzykowski.

Howe [37] considers the case in which $C = \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$, $S = \mathbb{R}^n$, and f and g are continuously differentiable. His result is the appearance of the type of sufficiency result given in Theorem 4.8. He shows that if $D_{\mathcal{P}}(\bar{x}) = \{0\}$, then $\bar{x}$ is a local minimum for P_α for all α sufficiently large.

Bandler and Charalambous [2] consider the same case as Evans, Gould, and Tolle [24] and derive yet another type of nondifferentiable exact penalty function. For this exact penalty function they provide an exactness result that is similar in spirit to those of Eremin, Zangwill, and Pietrzykowski.

Bertsekas [6] investigates the case of convex programming with $C = \mathbb{R}^m_-$ and

$X = \mathbb{R}^n$, and establishes necessary and sufficient conditions for a function of the form

$$\pi(x) = f(x) + \sum_{i=1}^{m} p_i(g_i(x))$$

to be exact for $\mathcal{P}$. If $(\overline{x}, \overline{y})$ is a saddle point for $L(x, y)$ he shows that

$$\lim_{t \to 0^+} \frac{p_i(t)}{t} \geq \overline{y}^{(i)} \quad i = 1, \cdots, m,$$

with

$$\arg\min\{\pi(x)\} = \arg\min\{f(x) : g(x) \in C\},$$

if

$$\lim_{t \to 0^+} \frac{p_i(t)}{t} > \overline{y}^{(i)}.$$

We obtain Eremin's result as a special case. Bertsekas also applies his result to the exact penalty functions of Evans, Gould, and Tolle.

Charalambous [13] is the first to consider more general norms in the construction of P_α. Specifically, Charalambous considers the case $C = \mathbb{R}^m_-, S = \mathbb{R}^n$ where f and g are continuously differentiable. He then utilizes the ℓ_p-norms to form P_α. Charalambous establishes two key results. In the result, he considers the convex programming case and shows that if $(\overline{x}, \overline{y})$ is a saddle point for $L(x, y)$, then $\overline{x}$ is a global minimum for P_α for all $\alpha > \|\overline{y}\|_0$. The proof is similar to those of Eremin and Luenberger. Charalambous' second result is the instance of an exact penalization theorem employing Pennisi's [57] second-order sufficiency conditions. He shows that if the second-order sufficiency condition of Theorem 4.7 is satisfied, then $\overline{x}$ is a local minimum for P_α for all $\alpha > \|\overline{y}\|_0$.

Dolecki and Rolewicz [20] present the deepest first-order results for exact penalization currently available in the literature. They consider a model problem that is somewhat more general than the problem $\mathcal{P}$ and obtain exact penalty results based on a more general notion of subdifferential. In this context, they obtain one of the implications in Theorem 2.1 and a version of Corollary 2.3.1. The Dolecki–Rolewicz paper represents the attempt to extend exact penalization techniques to the nondifferentiable case in infinite-dimensions.

Perhaps the most widely referenced paper on exact penalization is by Han and Mangasarian [33]. Their paper is the most comprehensive and comprehensible study of the subject available in the literature. Han and Mangasarian consider the case in which $C = \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$, $S = \mathbb{R}^n$, and f and g are continuously differentiable. One of the most significant contributions of their paper is the relaxation of the first-order conditions under which an exact penalty parameter for $\mathcal{P}$ exists. Specifically, they show that if the Mangasarian–Fromovitz constraint qualification is satisfied at a strict local solution $\overline{x}$ to $\mathcal{P}$, then there exists an $\overline{\alpha} \geq 0$ such that $\overline{x}$ is a local solution to P_α for all $\alpha \geq \overline{\alpha}$. They establish this result for an arbitrary norm by appealing to the equivalence of norms in finite dimensions. This result is an instance of Corollary 2.4.1 (however, Corollary 2.4.1 does not require that $\overline{x}$ be a strict local solution). They also provide a second-order result that is similar to that of Charalambous. Moreover, they establish the equivalence of stationarity conditions for $\mathcal{P}$ and the minimization of P_α, as is done in Proposition 6.2. They conclude by again establishing Eremin's result for the case of convex programming. The penalty functions they consider are a generalization of the Eremin–Zangwill penalty functions and are based on the work of Bertsekas.

The work of Lasserre [44] appears soon after that of Han and Mangasarian. He considers the case in which $C := \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$, $S = \mathbb{R}^n$, f and g are continuously differentiable, and $\mathbb{R}^m$ is endowed with a weighted ℓ_1 norm. In this case, he establishes a second-order result similar to that of Charalambous. Moreover, he shows that if the active constraint gradients are linearly independent at a local solution to $\mathcal{P}$, then an exact penalty parameter exists for $\mathcal{P}$. This result is different from the corresponding result of Han and Mangasarian, and Pietrzykowski since Lasserre does not assume that the solution is a strict local minimum. Nonetheless, it appears that both of these results are subsumed in the work of Dolecki and Rolewicz. Lasserre also recaptures and extends the result of Luenberger by recognizing the relationship between saddle points of the Lagrangian and local minimum of the exact penalty function.

Fletcher [29, §14.3] considers the same situation as Lasserre. Under the hypothesis that the active constraint gradients are linearly independent, Fletcher [29] is the to recognize the actual equivalence of the first- and second-order optimality conditions for $\mathcal{P}$ and the exact penalty function P_α. Consequently, Fletcher's work is a direct precursor of the results presented in this paper.

Bazaraa and Goode [3] consider the case where $C = \mathbb{R}^m_-$, S is closed, and f_0 and g are continuously differentiable. They establish some extensions to Howe's result using some of the modern techniques of nonsmooth analysis. Moreover, by assuming that S is compact, they obtain global versions of Howe's theorem and give estimates for the value of an exact penalty parameter that are reminiscent of those established by Zangwill.

In [15] Clarke establishes his elementary exact penalization result for the case in which the inclusion constraint $g(x) \in C$ is absent. This result is one of the corner stones of §2 and appears as Theorem 2.3. Clarke's proof should be reviewed by every student of this subject. It is very elementary, requiring only seven short sentences. Clarke also shows that calmness implies the existence of an exact penalty parameter for $\mathcal{P}$ when $C := \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$.

In [59], Polak, Mayne, and Wardi consider the case where $C = \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$, $S = \mathbb{R}^n$, f and g_i, $i = 1, \cdots, s$ are locally Lipschitz, and g_i, $i = s+1, \cdots, m$ are continuously differentiable. In this setting, they establish the equivalence of the stationarity conditions for $\mathcal{P}$ and the minimization of P_α for all α sufficiently large. This result is generalized in Proposition 2.6.

Rosenberg [71] considers the case in which $C = \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$, $S = \mathbb{R}^n$, and f and g are locally Lipschitz functions. He begins by providing local and strict local versions of Clarke's result that calmness implies the existence of an exact penalty parameter. He then reviews the convex programming case and establishes the version of Theorem 4.8, upon which our treatment is based. Rosenberg concludes his study by extending Howe's result to the Lipschitzian case where he provides results that are substantially more general than those of Bazaraa and Goode. For problems of this type he also provides a sharp lower bound for the value of an exact penalty parameter.

Garcia-Palomares [31] examines the case in which $C = \mathbb{R}^s_- \times \{0\}_{\mathbb{R}^{m-s}}$ $S = \mathbb{R}^n$, f and g are continuously differentiable, and $\mathbb{R}^m$ is endowed with the ℓ_∞ norm. The perspective in this paper is quite similar to the one we have taken. His goal is to establish the equivalence between the first- and second-order optimality conditions for $\mathcal{P}$ and P_α. In this regard, he provides versions of some of the results presented in the latter half of §2 and §3. His approach allows a great deal of further insight in the case of the ℓ_∞-norm.

In [50] Mangasarian considers the convex programming case with $C = \mathbb{R}^s_-$, $S = \mathbb{R}^n$, and f and g continuously differentiable. He extends the analysis of Zangwill to provide lower bounds for the value of an exact penalty function under weaker hypotheses.

Recently Conn and Gould [18, 1987] have generalized the ℓ_1 exact penalty function to obtain an exact penalty function for a class of semi-infinite programming problems. They consider both the convex and nonconvex cases, and their results are not covered by those presented in this paper. These new exact penalty functions for semi-infinite programming are quite interesting and deserve much further study.

In [64] Rockafellar studies the case in which $C \subset \mathbb{R}^m$ is the product of intervals, $X \subset \mathbb{R}^n$ is polyhedral convex, and $f_0(x) := \max\{f_{0_j}(x) : j = 1, \cdots, s\}$ where $f_{0_j}, j = 1, \cdots, s$ and g are all continuously differentiable. As in our study, Rockafellar derives the equivalence of first- and second-order optimality conditions for $\mathcal{P}$ and P_α via similar results for convex composite optimization. However, Rockafellar's results rely on the piecewise linear–quadratic case, the theory that he develops in [63].

We conclude by offering our apologies to the many authors we have not mentioned, especially to those who have made significant contributions in the domain of algorithmic development.

A. Appendix.

We proceed to establish Theorem 2.5. For this purpose we will need the following lemmas from Burke and Poliquin [11].

LEMMA A1. *Let $q : \mathbb{R}^n \to \overline{\mathbb{R}}$ be as given in Theorem 2.5. If $\overline{x} \in \operatorname{dom}(q)$ is such that (2.9) holds, then there is a neighborhood U of $\overline{x}$ such that (2.9) is satisfied at every point of $\operatorname{dom}(q) \cap U$.*

Proof. This is a direct consequence of the upper semicontinuity of $\partial f, \partial f^\infty$, ∂g, and $N(\cdot|\operatorname{dom}(h))$. □

LEMMA A2. *Let $h : \mathbb{R}^m \to \overline{\mathbb{R}}$ be as in Theorem 2.5 and let $\{(y_i, z_i)\} \subset$ graph (∂h) be such that $y_i \to y \in \operatorname{dom}(h)$ and $\|z_i\| \uparrow \infty$. Then every cluster point of the sequence $\{z_i/\|z_i\|\}$ is an element of the normal cone to $\operatorname{dom}(h)$ at y.*

LEMMA A3. *Let $h : \mathbb{R}^m \to \overline{\mathbb{R}}$ and $h_\alpha : \mathbb{R}^m \to \mathbb{R}$ be as in Theorem 2.5. If $h_\alpha(\overline{y}) = h(\overline{z}) + \alpha\|\overline{y} - \overline{z}\|$, where $\overline{z} \in \operatorname{dom}(h)$, then $u \in \partial h_\alpha(\overline{y})$ if and only if $u \in \partial h(\overline{z}) \cap (\alpha\mathbb{B}^0)$ and $(\overline{y} - \overline{z}) \in N(u|\alpha\mathbb{B}^0)$.*

The proof of Theorem 2.5 now follows.

Proof. Let ε, $\delta > 0$ be such that $f(x) \geq f(\overline{x})$ for all $x \in \overline{x} + \varepsilon\mathbb{B}$ and (2.9) is satisfied on $\operatorname{dom}(q) \cap (\overline{x} + \delta\mathbb{B})$. Set

$$\xi := 1 + \max\{\|g(x) - g(\overline{x})\| : x \in \overline{x} + \varepsilon\mathbb{B}\},$$

and define

$$\widetilde{h}_\alpha(y) := \inf\{h(z) + \psi(z|g(\overline{x}) + \xi\mathbb{B}) + \alpha\|y - z\| : z \in \mathbb{R}^m\}.$$

Consider the function

$$\widehat{q}_\alpha(x) := \widetilde{q}_\alpha(x) + \varphi(x) + \psi(x|\overline{x} + \varepsilon\mathbb{B}),$$

where $\widetilde{q}_\alpha := f + \widetilde{h}_\alpha \circ g$ and $\varphi(x) := \operatorname{dist}_2^2(x|\overline{x} + \delta\mathbb{B})$. Observe that arg min$\widehat{q}_\alpha$ is nonempty as $\widehat{q}_\alpha$ is lower semicontinuous and $\overline{x} + \varepsilon\mathbb{B}$ is compact. Hence, there is a sequence $\alpha_i \uparrow \infty$ for which there is a corresponding sequence $\{x_i\} \subset \overline{x} + \varepsilon\mathbb{B}$ converging to some element $\widehat{x}$ of $\overline{x} + \varepsilon\mathbb{B}$ such that

$$x_i \in \arg\min \widehat{q}_{\alpha_i}$$

for each $i = 1, 2, \cdots$. Also, from the lower semicontinuity of h and the compactness of $g(\overline{x}) + \xi\mathbb{B}$, there exists for each $i = 1, 2, \cdots$ a y_i in $\mathrm{dom}(h) \cap (g(\overline{x}) + \xi\mathbb{B})$ such that

$$\widetilde{h}_{\alpha_i}(x_i) = h(y_i) + \alpha_i \|y_i - g(x_i)\|.$$

Clearly,

$$q(\overline{x}) \geq \widehat{q}_{\alpha_i}(x_i) \geq \widetilde{q}_{\alpha_i}(x_i). \tag{A.1}$$

Therefore, as $\alpha_i \uparrow \infty$ we have $\|y_i - g(x_i)\| \to 0$ so that $y_i \to g(\widehat{x})$, and thus eventually $y_i \in \mathrm{int}(g(\overline{x}) + \xi\mathbb{B})$, which implies that $\widetilde{q}_{\alpha_i}(x_i) = q_{\alpha_i}(x_i)$. From (A.1) we also obtain that $g(\widehat{x}) \in \mathrm{dom}(h) \cap (g(\overline{x}) + \xi B)$, $\widehat{x} \in \overline{x} + \varepsilon\mathbb{B}$, and

$$q(\overline{x}) \geq q(\widehat{x}) + \varphi(\widehat{x}) \geq q(\widehat{x}).$$

But since $\widehat{x} \in \overline{x} + \varepsilon\mathbb{B}$, the hypotheses imply that $q(\overline{x}) = q(\widehat{x})$ and $\widehat{x} \in \overline{x} + \delta\mathbb{B}$.

We now show that eventually $g(x_i) \in \mathrm{dom}(h)$. Since $x_i \in \arg\min \widehat{q}_{\alpha_i}$ and $x_i \to \widehat{x} \in \overline{x} + \delta\mathbb{B}$, we know that eventually

$$0 \in \partial\widetilde{q}_{\alpha_i}(x_i) + \nabla\varphi(x_i).$$

Hence, by Rockafellar [66, Cor. 5.2.3] and Lemma A.3, eventually there exist $v_i \in \partial f(x_i)$ and $w_i \in \partial\widetilde{h}_{\alpha_i}(g(x_i))$ with

$$w_i \in \partial h(y_i) \text{ and } (g(x_i) - y_i) \in N(w_i | \alpha_i \mathbb{B}^0)$$

(since $N(y_i | g(\overline{x}) + \xi\mathbb{B}) = \{0\}$ as eventually $y_i \in \mathrm{int}(F(\overline{x}) + \xi\mathbb{B})$) such that

$$0 \in v_i + \partial g(x_i)^T w_i + \nabla\varphi(x_i). \tag{A.2}$$

If the sequence $\{(v_i, w_i)\}$ possesses a divergent subsequence $\{(v_i, w_i)\}_J$, then, by Lemma A.2, the sequence $\{(v_i, w_i)/\|(v_i, w_i)\|\}_J$ possesses a cluster point $(\overline{v}, \overline{w})$ with $\overline{v} \in \partial^\infty f(\widehat{x})$, $\overline{w} \in N(g(\widehat{x}) | \mathrm{dom}(h))$, and $\|(\overline{v}, \overline{w})\| = 1$. But for such a cluster point $(\overline{v}, \overline{w})$ we obtain from (3.5) that $0 \in \partial^\infty f(\widehat{x}) + \partial g(\widehat{x})^T w$ which contradicts the choice of δ. Thus the sequence $\{(v_i, w_i)\}$ is bounded. Hence for $\overline{\alpha}$ sufficiently large $\{w_i\} \subset \overline{\alpha}\mathbb{B}^0$ so that $N(w_i | \alpha_i \mathbb{B}^0) = \{0\}$ for all i such that $\alpha_i > \overline{\alpha}$. But then $y_i = g(x_i)$ so that $g(x_i) \in \mathrm{dom}(h)$ whenever $\alpha_i > \overline{\alpha}$. Therefore, for all $\alpha_i > \overline{\alpha}$,

$$q(\overline{x}) \geq \widehat{q}_{\alpha_i}(x_i) \geq \widetilde{q}_{\alpha_i}(x_i) = q_{\alpha_i}(x_i) = q(x_i) \geq q(\overline{x}),$$

so that $\overline{x} \in \arg\min \widehat{q}_{\alpha_i}$. Consequently, $\overline{x}$ is also a local minimizer of q_{α_i} for all $\alpha_i > \overline{\alpha}$. □

Remark. The method of proof also shows that if $\overline{x}$ is a strict local minimizer of q, then it is also a strict local minimizer of q_α.

Abstract. An algorithm of the form $X_{k+1} = X_k - a_k(\nabla U(X_k) + \xi_k) + b_k W_k$, where $U(\cdot)$ is a smooth function on $\mathbb{R}^d$, $\{\xi_k\}$ is a sequence of $\mathbb{R}^d$-valued random variables, $\{W_k\}$ is a sequence of independent standard d-dimensional Gaussian random variables, $a_k = A/k$ and $b_k = \sqrt{B}/\sqrt{k \log\log k}$ for k large, is considered. An algorithm of this type arises by adding slowly decreasing white Gaussian noise to a stochastic gradient algorithm. It is shown, under suitable conditions on $U(\cdot)$, $\{\xi_k\}$, A, and B, that X_k converges in probability to the set of global minima of $U(\cdot)$. No prior information is assumed as to what bounded region contains a global minimum. The analysis is based on the asymptotic behavior of the related diffusion process $dY(t) = -\nabla U(Y(t))dt + c(t)dW(t)$, where $W(\cdot)$ is a standard d-dimensional Wiener process and $c(t) = \sqrt{C}/\sqrt{\log t}$ for t large.

1. Introduction. In this paper we consider a class of algorithms for finding a global minimum of a smooth function $U(x)$, $x \in \mathbb{R}^d$. Specifically, we analyze the convergence of a modified stochastic gradient algorithm

$$X_{k+1} = X_k - a_k(\nabla U(X_k) + \xi_k) + b_k W_k, \tag{1.1}$$

where $\{\xi_k\}$ is a sequence of $\mathbb{R}^d$-valued random variables, $\{W_k\}$ is a sequence of standard d-dimensional independent Gaussian random variables, and $\{a_k\}$, $\{b_k\}$ are sequences of positive numbers with $a_k, b_k \to 0$. An algorithm of this type arises by artificially adding the $b_k W_k$ term (via a Monte Carlo simulation) to a standard stochastic gradient algorithm,

$$Z_{k+1} = Z_k - a_k(\nabla U(Z_k) + \xi_k). \tag{1.2}$$

Algorithms like (1.2) arise in a variety of optimization problems including adaptive filtering, identification, and control; here the sequence $\{\xi_k\}$ is due to noisy or imprecise measurements of $\nabla U(\cdot)$ (cf. [1]). The asymptotic behavior of $\{Z_k\}$ has been extensively studied. Let S and S^* be the set of local and global minima of $U(\cdot)$, respectively. It can be shown, for example, that if $U(\cdot)$ and $\{\xi_k\}$ are suitably behaved, $a_k = A/k$ for k large, and $\{Z_k\}$ is bounded, then $Z_k \to S$ as $k \to \infty$ with probability one. However, in general, $Z_k \not\to S^*$ (unless of course $S = S^*$). The idea behind the additional $b_k W_k$ term in (1.1) compared with (1.2) is that if b_k tends to zero slowly enough, then possibly $\{X_k\}$ (unlike $\{Z_k\}$) will avoid getting trapped in a strictly local minimum of $U(\cdot)$. In fact, we will show that if $U(\cdot)$ and $\{\xi_k\}$ are suitably behaved, $a_k = A/k$ and $b_k^2 = B/k \log\log k$ for k large with $B/A > C_0$ (where C_0 is a positive constant that depends only on $U(\cdot)$), and $\{X_k\}$ is tight, then $X_k \to S^*$ as $k \to \infty$ in probability. We also give a condition for the tightness of $\{X_k\}$. We remark that in [1] both probability one and

weak convergence of $\{Z_k\}$ are treated. Furthermore, convergence of Z_k to S is established under very weak conditions on $\{\xi_k\}$ assuming that $\{Z_k\}$ is bounded. Here the convergence of X_k to S^* is established under somewhat stronger conditions on $\{\xi_k\}$ assuming that $\{X_k\}$ is tight (which is weaker than boundedness).

An algorithm like (1.1) was first proposed and analyzed by Kushner [2]. However, the analysis in [2] required that the trajectories of $\{X_k\}$ lie within a fixed ball (which was achieved by modifying (1.1) near the boundary of the ball). Hence, the version of (1.1) in [2] is only suitable for optimizing $U(\cdot)$ over a compact set. Some other differences between the results presented here and in [2] include conditions on $\{a_k\}$, $\{b_k\}$, and $\{\xi_k\}$, and also the method of analysis; these are discussed below.

The analysis of the convergence of $\{Z_k\}$ is usually based on the asymptotic behavior of the *associated ordinary differential equation* (ODE)

$$\dot{z}(t) = -\nabla U(z(t)) \tag{1.3}$$

(cf. [1], [3]). This motivates our analysis of the convergence of $\{X_k\}$ based on the asymptotic behavior of the *associated stochastic differential equation* (SDE)

$$dY(t) = -\nabla U(Y(t))\,dt + c(t)\,dW(t), \tag{1.4}$$

where $W(\cdot)$ is a standard d-dimensional Wiener process and $c(\cdot)$ is a positive function with $c(t)\to 0$ as $t\to\infty$. The diffusion $Y(\cdot)$ has been called continuous simulated annealing. In this context, $U(x)$ is called the energy of state x and $T(t) = c^2(t)/2$ is called the temperature at time t. Continuous simulated annealing was first suggested in [4] and [5] for global optimization problems that arise in image processing applications with continuous grey levels. Now the asymptotic behavior of $Y(t)$ as $t\to\infty$ has been studied intensively by a number of researchers. In [2] and [5], convergence results were obtained by considering a version of (1.4) with a reflecting boundary; in [6] and [7] the reflecting boundary was removed. Our analysis of $\{X_k\}$ is based on the analysis of $Y(\cdot)$ developed by Chiang, Hwang, and Sheu [7] who prove the following result: if $U(\cdot)$ is well behaved and $c^2(t) = C/\log t$ for t large with $C > C_0$ then $Y(t)\to S^*$ as $t\to\infty$ in probability. The main difficulty associated with using $Y(\cdot)$ to analyze $\{X_k\}$ is that we must deal with long time intervals and slowly decreasing (unbounded) Gaussian noise.

We make some further remarks on the differences between the results and methods in this paper as compared with [2]. We first note that in [2] the modified version of (1.1), which constrains the trajectories of $\{X_k\}$ to lie within a fixed ball, is analyzed for $a_k = b_k = A/\log k$, k large. Although a detailed asymptotic description of $\{X_k\}$ is obtained for this case, in general, $X_k \not\to S^*$ unless $\xi_k = 0$. The reason for this is intuitively clear: even if $\{\xi_k\}$ is bounded, $a_k\xi_k$ and $a_k W_k$ can be of the same order, and hence can interfere with each other. On the other hand, here we allow $\{\xi_k\}$ with unbounded variance, in particular, $E\{|\xi_k|^2\} = O(k^\gamma)$ and $\gamma < 1$. This has important implications when $\nabla U(\cdot)$ is not measured exactly. We also note that the analysis in [2] is different from that done here, in that in [2] the behavior of $\{X_k\}$ is obtained by deriving various large deviations estimates of Donsker–Varadhan type, whereas here we obtain the behavior of $\{X_k\}$ directly from the corresponding behavior of $Y(\cdot)$. It should be pointed out that in a certain sense the results in [2] are also stronger than those presented here, because the large deviation approach in [2] treats the whole tail of the process $\{X_k\}$, while only "local" type results are discussed here. However, from our point of view the most significant difference between our work and that done in [2] (and more generally in other work on global optimization such as [8]) is that we deal with unbounded processes and establish the convergence of an algorithm that finds a global minimum of a function when it is not known a priori what bounded region contains such a point.

The paper is organized as follows. In § 2 we state our assumptions and main result. In § 3 we take up the proof of this result. In § 4 we prove a general tightness criterion, which is then used in § 5 to establish tightness and ultimately convergence for two example algorithms.

2. Main result. In this section we present our main result on the convergence of the discrete time algorithm

$$X_{k+1}=X_k-a_k(\nabla U(X_k)+\xi_k)+b_kW_k, \qquad k\geqq 0, \tag{2.1}$$

which is closely related to the continuous time algorithm

$$dY(t)=-\nabla U(Y(t))\,dt+c(t)\,dW(t), \qquad t\geqq 0. \tag{2.2}$$

Here $U(\cdot)$ is a smooth function on $\mathbb{R}^d$, $\{\xi_k\}$ is a sequence of $\mathbb{R}^d$-valued random variables, $\{W_k\}$ is a sequence of independent d-dimensional Gaussian random variables with $E\{W_k\}=0$ and $E\{W_k\otimes W_k\}=I$ (the identity matrix), $W(\cdot)$ is a standard d-dimensional Wiener process, and

$$a_k=\frac{A}{k},\quad b_k^2=\frac{B}{k\log\log k},\quad k \text{ large},$$

$$c^2(t)=\frac{C}{\log t},\quad t \text{ large},$$

where A, B, and C are positive constants with $C=B/A$. Further conditions on $U(\cdot)$, $\{\xi_k\}$, and $\{W_k\}$ will be discussed below. It will be useful to define a continuous-time interpolation of $\{X_k\}$. Let

$$t_k=\sum_{n=0}^{k-1}a_n, \qquad k\geqq 0,$$

and

$$X(t)=X_k, \quad t\in[t_k,t_{k+1}), \quad k\geqq 0.$$

In the sequel we assume some or all of the following conditions (α and β are constants whose values will be specified later):

(A1) $U(\cdot)$ is a C^2 function from $\mathbb{R}^d$ to $[0,\infty)$ such that

$$\min U(x)=0,$$

$$U(x)\to\infty \quad\text{and}\quad |\nabla U(x)|\to\infty \quad \text{as } |x|\to\infty,$$

$$\inf\,(|\nabla U(x)|^2-\Delta U(x))>-\infty.$$

(A2) For $\varepsilon>0$ let

$$d\pi^\varepsilon(x)=\frac{1}{Z^\varepsilon}\exp\left(-\frac{2U(x)}{\varepsilon^2}\right)dx, \qquad Z^\varepsilon=\int\exp\left(-\frac{2U(x)}{\varepsilon^2}\right)dx<\infty.$$

π^ε has a unique weak limit π as $\varepsilon\to 0$.

(A3) $$\varliminf_{|x|\to\infty}\left\langle\frac{\nabla U(x)}{|\nabla U(x)|},\frac{x}{|x|}\right\rangle>L(d), \qquad L(d)=\left(\frac{4d-4}{4d-3}\right)^{1/2}.$$

(A4) For $k=0,1,\cdots$ let $\mathscr{F}_k=\sigma(X_0, W_0,\cdots, W_{k-1}, \xi_0,\cdots,\xi_{k-1})$. Let K be a compact subset of $\mathbb{R}^d$. There exists $L>0$ such that

$$E\{|\xi_k|^2|\mathscr{F}_k\}\leqq La_k^\alpha, \quad |E\{\xi_k|\mathscr{F}_k\}|\leqq La_k^\beta, \quad \forall X_k\in K, \quad \text{w.p.1.}$$

W_k is independent of $\mathscr{F}_k$.

We note that the measure π concentrates on S^*, the global minima of $U(\cdot)$. The existence of π and a simple characterization in terms of the Hessian of $U(\cdot)$ is discussed in [9]. In [7], (A1) and (A2) were needed for the analysis of $Y(t)$ as $t\to\infty$; here we also need (A3) and (A4) for the analysis of X_k as $k\to\infty$. Assumption (A3) asserts that $\nabla U(x)$ has a sufficiently large radial component for $|x|$ large. This condition will be used to extend an escape time estimate for $\{X_k\}$ from a bounded region in the $d=1$ case to the $d>1$ case (see Lemma 4). It may be possible to replace $L(d)$ by 0 in (A3) but we have not been able to do so (except of course for $d=1$). Note that (A3) is implied by (A1) when $d=1$.

For a process $Z(\cdot)$ and a function $f(\cdot)$, let $E_{t_1,z_1}\{f(Z(t))\}$ denote conditional expectation given $Z(t_1)=z_1$, and let $E_{t_1,z_1;t_2,z_2}\{f(Z(t))\}$ denote conditional expectation given $Z(t_1)=z_1$ and $Z(t_2)=z_2$ (more precisely, these are suitable fixed versions of conditional expectations). Also for a measure $\mu(\cdot)$ and a function $f(\cdot)$ let $\mu(f)=\int f\,d\mu$.

In [7] it was shown that there exists a constant C_0 (denoted there by c_0) that plays a critical role in the convergence of $Y(t)$ as $t\to\infty$. C_0 has an interpretation in terms of the action functional [10] for the perturbed dynamical systems

$$dY^\varepsilon(t)=-\nabla U(Y^\varepsilon(t))\,dt+\varepsilon\,dW(t). \tag{2.3}$$

Now for $\phi(\cdot)$ an absolutely continuous function on $\mathbb{R}^d$, the (normalized) action functional for (2.3) is given by

$$I(t,x,y)=\inf_{\substack{\phi(0)=x\\ \phi(t)=y}}\frac{1}{2}\int_0^t|\dot\phi(s)+\nabla U(\phi(s))|^2\,ds.$$

According to [7]

$$C_0=\tfrac{3}{2}\sup_{x,y\in S_0}(V(x,y)-2U(y)),$$

where $V(x,y)=\lim_{t\to\infty}I(t,x,y)$ and S_0 is the set of all the stationary points of $U(\cdot)$, i.e., $S_0=\{x\colon \nabla U(x)=0\}$; see [7] for a further discussion of C_0 including some examples. Here is the Chiang–Hwang–Sheu theorem on the convergence of $Y(t)$ as $t\to\infty$.

THEOREM 1 [7]. *Assume* (A1) *and* (A2) *hold. Then for $C>C_0$ and any bounded continuous function $f(\cdot)$ on $\mathbb{R}^d$*

$$\lim_{t\to\infty}E_{0,y_0}\{f(Y(t))\}=\pi(f) \tag{2.4}$$

uniformly for y_0 in a compact set.

Let $K_1\subset\mathbb{R}^d$ and let $\{X_k^{x_0}\}$ denote the solution of (2.1) with $X_0=x_0$. We say that $\{X_k^{x_0}\colon k\geqq 0, x_0\in K_1\}$ is tight if given $\varepsilon>0$ there exists a compact $K_2\subset\mathbb{R}^d$ such that $P_{0,x_0}\{X_k\in K_2\}>1-\varepsilon$ for all $k\geqq 0$ and $x_0\in K_1$. Here is our theorem on the convergence of X_k as $k\to\infty$.

THEOREM 2. *Assume* (A1)-(A4) *hold with $\alpha>-1$ and $\beta>0$. Also assume that $\{X_k^{x_0}\colon k\geqq 0, x_0\in K\}$ is tight for K a compact set. Then for $B/A>C_0$ and any bounded* *continuous function* $f(\cdot)$ *on* $\mathbb{R}^d$

$$\lim_{k\to\infty} E_{0,x_0}\{f(X_k)\}=\pi(f) \tag{2.5}$$

uniformly for x_0 *in a compact set.*

Remark. We specifically separate the question of tightness from convergence in Theorem 2. It is appropriate to do this because sometimes it is convenient to first prove tightness and then to put an algorithm into the form of (2.1) to prove convergence. In § 4, we actually give a condition for tightness of a class of algorithms somewhat more general than (2.1), and then use it in § 5 to prove tightness and ultimately convergence for two example algorithms.

Since π concentrates on S^*, we have, of course, that (2.4) and (2.5) imply $Y(t)\to S^*$ as $t\to\infty$ and $X_k\to S^*$ as $k\to\infty$ in probability, respectively.

The proof of Theorem 2 requires the following two lemmas. Let $\beta(\cdot)$ be defined by

$$\int_s^{\beta(s)} \frac{\log s}{\log u}\,du=s^{2/3}, \qquad s>1.$$

Note that $s+s^{2/3}\leqq\beta(s)\leqq s+2s^{2/3}$ for s large.

LEMMA 1 [7]. *Assume the conditions of Theorem* 1. *Then for any bounded continuous function* $f(\cdot)$ *on* $\mathbb{R}^d$

$$\lim_{s\to\infty}(E_{s,x}\{f(Y(\beta(s)))\}-\pi^{c(s)}(f))=0$$

uniformly for x *in a compact set.*

LEMMA 2. *Assume the conditions of Theorem* 2. *Then for any bounded continuous function* $f(\cdot)$ *on* $\mathbb{R}^d$

$$\lim_{s\to\infty}(E_{0,x_0;s,x}\{f(X(\beta(s)))\}-E_{s,x}\{f(Y(\beta(s)))\})=0$$

uniformly for x_0 *in a compact set and all* x.

Lemma 1 is proved in Lemmas 1–3 of [7]. Lemma 2 is proved in § 3. Note that these lemmas involve approximation on increasingly large time intervals: $\beta(s)-s\geqq s^{2/3}\to\infty$ as $s\to\infty$. We now show how these lemmas may be combined to prove Theorem 2.

Proof of Theorem 2. Since $\beta(s)$ is continuous and $\beta(s)\to\infty$ as $s\to\infty$, it is enough to show that

$$\lim_{s\to\infty} E_{0,x_0}\{f(X(\beta(s)))\}=\pi(f) \tag{2.6}$$

uniformly for x_0 in a compact set. We have for $r>0$

$$\begin{aligned}
&|E_{0,x_0}\{f(X(\beta(s)))\}-\pi(f)|\\
&\leqq\int P_{0,x_0}\{X(s)\in dx\}|E_{0,x_0;s,x}\{f(X(\beta(s)))\}-\pi(f)| \qquad (2.7)\\
&\leqq\int_{|x|\leqq r} P_{0,x_0}\{X(s)\in dx\}|E_{0,x_0;s,x}\{f(X(\beta(s)))\}-\pi(f)|+2\|f\|P_{0,x_0}\{|X(s)|>r\}.
\end{aligned}$$

Now by the tightness assumption

$$\sup_{s\geqq0} P_{0,x_0}\{|X(s)|>r\}\to0 \quad \text{as } r\to\infty. \tag{2.8}$$

Also by Lemmas 1 and 2 and assumption (A2)

$$\tag{2.9}\begin{aligned}&\sup_{|x|\leqq r}|E_{0,x_0;s,x}\{f(X(\beta(s)))\}-\pi(f)|\\ &\quad\leqq \sup_{|x|\leqq r}|E_{0,x_0;s,x}\{f(X(\beta(s)))\}-E_{s,x}\{f(Y(\beta(s)))\}|\\ &\qquad+\sup_{|x|\leqq r}|E_{s,x}\{f(Y(\beta(s)))\}-\pi^{c(s)}(f)|\\ &\qquad+|\pi^{c(s)}(f)-\pi(f)|\to 0\quad \text{as } s\to\infty.\end{aligned}$$

Combining (2.7)-(2.9) and letting $s\to\infty$ and then $r\to\infty$ gives (2.6) and hence the theorem. □

3. Proof of Lemma 2. Before proceeding with the proof of Lemma 2 we address the following technical issue. Observe that Lemma 2 is not concerned with the joint probability law of $X(\cdot)$ and $Y(\cdot)$. Hence without loss of generality we can and will assume that

$$W_k=a_k^{-1/2}(W(t_{k+1})-W(t_k)),$$

and that the following assumption holds in place of (A4):

(A4′) For $k=0,1,\cdots$ let $\mathscr{F}_k=\sigma(X_0, Y_0, \xi_0,\cdots,\xi_{k-1}, W(s), 0\leqq s\leqq t_k)$. Let K be a compact subset of $\mathbb{R}^d$. There exists $L>0$ such that

$$E\{|\xi_k|^2|\mathscr{F}_k\}\leqq La_k^\alpha,\quad |E\{\xi_k|\mathscr{F}_k\}|\leqq La_k^\beta\quad \forall X_k\in K,\quad \text{w.p.1.}$$

$W(t)-W(t_k)$ is independent of $\mathscr{F}_k$ for $t>t_k$.

It will also be convenient to define

$$c^2(t_k)=\frac{C}{\log\log k},\quad k \text{ large},$$

and to let $c^2(\cdot)$ be a piecewise linear interpolation of $\{c^2(t_k)\}$. Note that $c^2(t)\sim C/\log t$, and since $C=B/A$ we have $\sqrt{a_k}c(t_k)=b_k$.

In the sequel, $c_1, c_2,\cdots$ denote positive constants whose value may change from proof to proof.

The proof of Lemma 2 is based on the following three lemmas. For s, $R>0$ define the exit times

$$\sigma(s,R)=\inf\{t\geqq s\colon |X(t)|>R\},$$

$$\tau(s,R)=\inf\{t\geqq s\colon |Y(t)|>R\}.$$

LEMMA 3 [7, p. 745]. *Assume the conditions of Theorem* 1. *Then given* $r>0$ *there exists* $R>r$ *such that*

$$\lim_{s\to\infty}P_{s,x}(\tau(s,R)>\beta(s)\}=1$$

uniformly for $|x|\leqq r$.

LEMMA 4. *Assume the conditions of Theorem* 2. *Then given* $r>0$ *there exists* $R>r$ *such that*

$$\lim_{s\to\infty}P_{0,x_0;s,x}\{\sigma(s,R)>\beta(s)\}=1$$

uniformly for $|x|\leqq r$ *and all* x_0.

LEMMA 5. *Assume the conditions of Theorem* 2. *Then for* $0<r<R$

$$\lim_{s\to\infty} E_{0,x_0;s,x}\{|X(\beta(s))-Y(\beta(s))|^2, \sigma(s,R)\wedge\tau(s,R)>\beta(s)\}=0$$

uniformly for $|x|\leqq r$ *and all* x_0.

The proofs of Lemmas 4 and 5 are given below. We now show how these lemmas may be combined to prove Lemma 2.

Proof of Lemma 2. Given $r>0$, choose $R>r$ as in Lemmas 3 and 4. Fix $s>0$ for the moment and let $\sigma=\sigma(s,R)$ and $\tau=\tau(s,R)$. Henceforth assume all quantities are conditioned on $X(0)=x_0$, $X(s)=Y(s)=x$, and $|x|\leqq r$. We have

$$\begin{aligned}&|E(\{f(X(\beta(s)))\}-E\{f(Y(\beta(s)))\}|\\ &\quad\leqq E\{|f(X(\beta(s)))-f(Y(\beta(s)))|, \sigma\wedge\tau>\beta(s)\}+2\|f\|P\{\sigma\wedge\tau\leqq\beta(s)\}.\end{aligned}\tag{3.1}$$

Now by Lemmas 3 and 4

$$P\{\sigma\wedge\tau\leqq\beta(s)\}\to 0 \quad \text{as } s\to\infty.\tag{3.2}$$

Also, since $f(\cdot)$ is uniformly continuous on a compact, given $\varepsilon>0$ there exists $\delta>0$ such that $|f(u)-f(v)|<\varepsilon$ whenever $|u-v|<\delta$ and $|u|,|v|\leqq R$. Hence using the Chebyshev inequality and Lemma 5

$$\begin{aligned}&E\{|f(X(\beta(s)))-f(Y(\beta(s)))|, \sigma\wedge\tau>\beta(s)\}\\ &\quad\leqq 2\|f\|P\{|X(\beta(s))-Y(\beta(s))|\geqq\delta, \sigma\wedge\tau>\beta(s)\}+\varepsilon\\ &\quad\leqq\frac{2\|f\|}{\delta^2}E\{|X(\beta(s))-Y(\beta(s))|^2, \sigma\wedge\tau>\beta(s)\}+\varepsilon\to\varepsilon \quad \text{as } s\to\infty.\end{aligned}\tag{3.3}$$

Combining (3.1)-(3.3) and letting $s\to\infty$ and then $\varepsilon\to 0$ gives the lemma. □

The proofs of Lemmas 4 and 5 involve comparisons between $X(\cdot)$ and $Y(\cdot)$. Define $\zeta(\cdot,\cdot)$ by

$$Y(t)=Y(s)-(t-s)(\nabla U(Y(s))+\zeta(s,t))+c(s)(W(t)-W(s))$$

for $t\geqq s\geqq 0$. To compare $X(\cdot)$ and $Y(\cdot)$ we will need statistics for $\zeta(\cdot,\cdot)$.

PROPOSITION 1. *For every* $R>0$

$$E_{s,y}\{|\zeta(s,t\wedge\tau(s,R))|^2\}=O(|t-s|)$$

as $t\downarrow s$, *uniformly for* $s\geqq 0$ *and all* y.

Proof. In this proof we can and will assume that $\nabla U(\cdot)$ is a bounded and Lipschitz function on $\mathbb{R}^d$ (since $|Y(u)|\leqq R$ for $s\leqq u\leqq t\wedge\tau(s,R)$ we can modify $U(x)$ for $|x|>R$ without loss of generality). Fix $s\geqq 0$ and let $\tau=\tau(s,R)$. Henceforth assume all quantities are conditioned on $Y(s)=y$. Now for $t\geqq s$ we can write

$$(t-s)\zeta(s,t\wedge\tau)=\int_s^{t\wedge\tau}(\nabla U(Y(u))-\nabla U(Y(s)))\,du-\int_s^{t\wedge\tau}(c(u)-c(s))\,dW(u).\tag{3.4}$$

Let d_1 and d_2 be Lipschitz constants for $\nabla U(\cdot)$, $c(\cdot)$, respectively. Under our assumptions on $\nabla U(\cdot)$ and $c(\cdot)$ it is well known (cf. [11]) that $E\{|Y(u)-Y(s)|^2\}=O(|u-s|)$ as $u\downarrow s$, uniformly for $s\geqq 0$ and all y. Hence

$$\begin{aligned}E\left\{\left|\int_s^{t\wedge\tau}(\nabla U(Y(u))-\nabla U(Y(s)))\,du\right|^2\right\}&\leqq d_1^2E\left\{\left(\int_s^t|Y(u)-Y(s)|\,du\right)^2\right\}\\ &\leqq 2d_1^2(t-s)\int_s^t E\{|Y(u)-Y(s)|^2\}\,du\\ &=O((t-s)^3)\end{aligned}\tag{3.5}$$

and

$$\begin{aligned} E\left\{\left|\int_s^{t\wedge\tau} (c(u)-c(s))\,dW(u)\right|^2\right\} &\leqq \int_s^t (c(u)-c(s))^2\,du \\ &\leqq d_2^2\int_s^t (u-s)^2\,du = O((t-s)^3) \end{aligned} \tag{3.6}$$

as $t\downarrow s$, uniformly for $s\geqq 0$ and all y. The proposition follows from (3.4)-(3.6). □

COROLLARY 1. *Given $R>0$, let $\zeta_k=\zeta(t_k, t_{k+1}\wedge\tau(t_k, R))$. Then there exists $M>0$ such that*

$$E\{|\zeta_k|^2|\mathscr{F}_k\}\leqq Ma_k, \quad |E\{\zeta_k|\mathscr{F}_k\}|\leqq Ma_k^{1/2} \quad \text{w.p.1.}$$

Proof. Observe that ζ_k is $\{Y(t_k), W(t)-W(t_k), t_k<t\leqq t_{k+1}\}$ measurable. Since $Y(t_k)$ is $\mathscr{F}_k$ measurable and $\{W(t)-W(t_k), t_k<t\leqq t_{k+1}\}$ is independent of $\mathscr{F}_k$, we must have $P\{\zeta_k\in\cdot\,|\mathscr{F}_k\}=P\{\zeta_k\in\cdot\,|Y(t_k)\}$ w.p.1. The corollary now follows from Proposition 1 and Holder's inequality. □

3.1. Proof of Lemma 4. The idea behind this proof is to compare $X(t)$ and $Y(t)$ in such a way as to eliminate the slowly decreasing Gaussian noise (i.e., the b_kW_k term) between them. Once the decreasing Gaussian noise is eliminated, we can control the deviation of $X(t)$ from $Y(t)$ over increasingly large time intervals and ultimately obtain the escape time estimate for $X(t)$ from a bounded region from that for $Y(t)$ in Lemma 3. It seems very difficult to work directly with the continuous-time interpolation $X(t)$.

For each n let k_n be the integer that satisfies $\beta(t_n)\in[t_{k_n}, t_{k_{n+1}})$. We show there exists $R>r$ such that

$$\lim_{n\to\infty} P_{0,x_0;t_n,x}\{\sigma(t_n, R)>t_{k_n}\}=1 \tag{3.7}$$

uniformly for $|x|\leqq r$ and all x_0. The lemma then follows by some minor details that are omitted.

By Lemma 3 there exists $R_1>r$ such that

$$\lim_{n\to\infty} P_{t_n,x}\{\tau(t_n, R_1)>t_{k_n}\}=1$$

uniformly for $|x|\leqq r$. Hence (3.7) will follow if we can show that there exists $R>r$ such that

$$\lim_{n\to\infty} P_{0,x_0;t_n,x}\{\sigma(t_n, R)\leqq t_{k_n}, \tau(t_n, R_1)>t_{k_n}\}=0 \tag{3.8}$$

uniformly for $|x|\leqq r$ and all x_0. We first assume $d=1$ (the scalar case) and then generalize to $d>1$. The generalization to $d>1$ requires (A3).

Proof for $d=1$. In view of (A1) there exists $R_2>R_1$ such that

$$\sup_{x\leqq -R_2} U'(x)<\inf_{|x|\leqq R_1} U'(x), \qquad \inf_{x\geqq R_2} U'(x)>\sup_{|x|\leqq R_1} U'(x).$$

Let $R_3=R_2+1$ and $R_4=2R_3+3R_1$. We show that (3.8) holds with $R=R_4$.

Fix n for the moment and let $\sigma=\sigma(t_n, R_4)$, $\tau=\tau(t_n, R_1)$. Let

$$\zeta_k=\zeta(t_k, t_{k+1}\wedge\tau(t_k, R_1))$$

and

$$Y_{k+1}=Y_k-a_k(\nabla U(Y_k)+\zeta_k)+b_kW_k.$$

Note that if $Y(t_n)=Y_n$ and $\tau\geqq t_k\geqq t_n$, then $Y(t_k)=Y_k$. Henceforth assume all quantities are conditioned on $X(0)=X_0=x_0$, $X(t_n)=X_n=Y(t_n)=Y_n=x$, $|x|\leqq r$.

We proceed by observing that if the event $\{\sigma\leqq t_{k_n}\}$ occurs then either

- At some time k, $n\leqq k<k_n$, X_k jumps from $[-R_4, R_2]$ to (R_3,∞), or from $[-R_2, R_4]$ to $(-\infty,-R_3)$;
- At some time k, $n\leqq k<k_n$, X_k jumps from $[-R_4, R_2]$ to $(R_2, R_3]$, and exits from $(R_2, R_4]$ to (R_4,∞) at some time l, $k<l\leqq k_n$;
- At some time k, $n\leqq k<k_n$, X_k jumps from $[-R_2, R_4]$ to $[-R_3,-R_2)$, and exits from $[-R_4,-R_2)$ to $(-\infty,-R_4)$ at some time l, $k<l\leqq k_n$.

Now define $\mathscr{F}_k$-stopping times:

$$\begin{aligned}
\mu_1^+&=\inf\{k>n\colon X_{k-1}\leqq R_2,\ R_2<X_k\leqq R_3\},\\
\nu_1^+&=\inf\{k>\mu_1^+\colon X_k\leqq R_2\},\\
\mu_2^+&=\inf\{k>\nu_1^+\colon X_{k-1}\leqq R_2,\ R_2<X_k\leqq R_3\},\\
\nu_2^+&=\inf\{k>\mu_2^+\colon X_k\leqq R_2\},\\
&\ \vdots
\end{aligned}$$

and

$$\begin{aligned}
\mu_1^-&=\inf\{k>n\colon X_{k-1}\geqq -R_2,\ -R_3\leqq X_k<-R_2\},\\
\nu_1^-&=\inf\{k>\mu_1^-\colon X_k\geqq -R_2\},\\
\mu_2^-&=\inf\{k>\nu_1^-\colon X_{k-1}\geqq -R_2,\ -R_3\leqq X_k<-R_2\},\\
\nu_2^-&=\inf\{k>\mu_2^-\colon X_k\geqq -R_2\},\\
&\ \vdots\,.
\end{aligned}$$

Note that if $\mu_m^+, \mu_m^-<k_n$, then we must have $m\leqq m_n$ (where $m_n\leqq(k_n-n)/2$). Hence if we let

$$D_n=\bigcup_{k=n}^{k_n-1}\{-R_4\leqq X_k\leqq R_2,\ X_{k+1}>R_3\}\cup\{-R_2\leqq X_k\leqq R_4,\ X_{k+1}<-R_3\},$$

$$E_n^+=\bigcup_{m=1}^{m_n}\{t_{\mu_m^+}<\sigma<t_{\nu_m^+},\ \sigma\leqq t_{k_n},\ \tau>t_{k_n}\},$$

$$E_n^-=\bigcup_{m=1}^{m_n}\{t_{\mu_m^-}<\sigma<t_{\nu_m^-},\ \sigma\leqq t_{k_n},\ \tau>t_{k_n}\},$$

then

$$P\{\sigma\leqq t_{k_n},\ \tau>t_{k_n}\}\leqq P\{D_n\}+P\{E_n^+\}+P\{E_n^-\}.$$

CLAIM 1. $\lim_{n\to\infty}P\{D_n\}=0$ *uniformly for* $|x|\leqq r$ *and all* x_0.

CLAIM 2. $\lim_{n\to\infty}P\{E_n^\pm\}=0$ *uniformly for* $|x|\leqq r$ *and all* x_0.

Assuming that Claims 1 and 2 hold, we have $P\{\sigma\leqq t_{k_n},\ \tau>t_{k_n}\}\to 0$ as $n\to\infty$. And the convergence is uniform for $|x|\leqq r$ and all x_0. This proves (3.8) and hence Lemma 4 when $d=1$.

Proof of Claim 1. Using the Chebyshev inequality and a standard estimate for the tail probability of a Gaussian random variable we have

$$
\begin{aligned}
P\{D_n\} &\leqq \sum_{k=n}^{k_n-1} P\{-R_4 \leqq X_k \leqq R_2,\, X_{k+1}-X_k > R_3-R_2\} \\
&\qquad \cup \{-R_2 \leqq X_k \leqq R_4,\, X_{k+1}-X_k < -(R_3-R_2)\} \\
&\leqq \sum_{k=n}^{k_n-1} P\{|X_k| \leqq R_4,\, |X_{k+1}-X_k| > R_3-R_2\} \\
&= \sum_{k=n}^{k_n-1} P\{|X_k| \leqq R_4,\, |-a_k(U'(X_k)+\xi_k)+b_k W_k| > R_3-R_2\} \\
&\leqq \sum_{k=n}^{k_n-1} \left(P\left\{|X_k| \leqq R_4,\, a_k|\xi_k| > \frac{R_3-R_2}{3}\right\} + P\left\{b_k|W_k| > \frac{R_3-R_2}{3}\right\}\right), \quad n \text{ large} \\
&\leqq c_1 \sum_{k=n}^{k_n-1} \left(a_k^2 E\{|\xi_k|^2,\, |X_k| \leqq R_4\} + \exp\left(-\frac{c_2}{b_k^2}\right)\right) \\
&\leqq c_3 \sum_{k=n}^{k_n-1} \left(a_k^{2+\alpha} + \exp\left(-\frac{c_2}{b_k^2}\right)\right) \\
&\leqq c_5 \sum_{k=n}^{\infty} \left(\frac{1}{k^{2+\alpha}} + \exp(-c_4 k)\right) \to 0 \quad \text{as } n \to \infty,
\end{aligned}
$$

since $\alpha > -1$. This completes the proof of Claim 1. □

Proof of Claim 2. Since the proofs for E_n^+ and E_n^- are symmetric, we only consider E_n^+. For convenience we suppress the + sign throughout, i.e., $E_n \triangleq E_n^+$, $\mu_m \triangleq \mu_m^+$, $\nu_m \triangleq \nu_m^+$.

For $1 \leqq m \leqq m_n$ let

$$E_{n,m} = \{t_{\mu_m} < \sigma < t_{\nu_m},\, \sigma \leqq t_{k_n},\, \tau > t_{k_n}\}.$$

We have

$$
\begin{aligned}
P\{E_{n,m}\} &= P \bigcup_{k=n+2}^{k_n} \{t_{\mu_m} < t_k < t_{\nu_m},\, \sigma = t_k,\, \tau > t_{k_n}\} \\
&= P \bigcup_{k=n+2}^{k_n} \{X_k - Y_k > R_4 - R_1,\, t_{\mu_m} < t_k < t_{\nu_m},\, \sigma = t_k,\, \tau > t_{k_n}\} \\
&\leqq P \bigcup_{k=n+2}^{k_n} \{X_k - Y_k > R_4 - R_1,\, t_{\mu_m} < t_k \leqq t_{\nu_m} \wedge \sigma \wedge \tau\} \\
&= P\left\{ \max_{k:\, t_{\mu_m} < t_k \leqq t_{\nu_m} \wedge \sigma \wedge \tau \wedge t_{k_n}} [X_k - Y_k] > R_4 - R_1 \right\} \\
&= P\left\{ \max_{k:\, t_{\mu_m} < t_k \leqq t_{\nu_m} \wedge \sigma \wedge \tau \wedge t_{k_n}} \left[X_{\mu_m} - Y_{\mu_m} - \sum_{l=\mu_m}^{k-1} a_l(U'(X_l) - U'(Y_l)) \right.\right. \\
&\qquad\qquad \left.\left. - \sum_{l=\mu_m}^{k-1} a_l(\xi_l - \zeta_l) \right] > R_4 - R_1 \right\}.
\end{aligned}
$$

Note that the $b_k W_k$ terms have been eliminated at this point; it is here we see the utility of comparing $X(t)$ and $Y(t)$. Now suppose $t_{\mu_m} < t_k \leqq t_{\nu_m} \wedge \sigma \wedge \tau \wedge t_{k_n}$. Then $X_{\mu_m} \in (R_2, R_3]$, $Y_{\mu_m} \in (-R_1, R_1)$, which implies $X_{\mu_m} - Y_{\mu_m} \leqq R_3 + R_1 = (R_4 - R_1)/2$.

Also $X_l \in (R_2, R_4]$, $Y_l \in (-R_1, R_1)$ for all l such that $\mu_m \leqq l < k$, which implies $U'(X_l) - U'(Y_l) > 0$ for all l such that $\mu_m \leqq l < k$. Now let

$$\eta_k = (\xi_k - \zeta_k)\mathbf{1}_{\{|X_k| \leqq R_4\}}.$$

Note that by (A4′) and Corollary 1

$$E\{|\eta_k|^2 | \mathscr{F}_k\} \leqq c_1 a_k^{\alpha \wedge 1}, \quad |E\{\eta_k | \mathscr{F}_k\}| \leqq c_1 a_k^{\beta \wedge (1/2)} \quad \text{w.p.1.}$$

Hence

$$\begin{aligned}
P\{E_{n,m}\} &\leqq P\left\{ \max_{k: t_{\mu_m} < t_k \leqq t_{\nu_m} \wedge \sigma \wedge \tau \wedge t_{k_n}} \sum_{l=\mu_m}^{k-1} a_l \eta_l > \frac{R_4 - R_1}{2} \right\} \\
&\leqq P\left\{ \max_{\mu_m < k \leqq \nu_m \wedge k_n} \sum_{l=\mu_m}^{k-1} a_l \eta_l > \frac{R_4 - R_1}{2} \right\} \\
&= P\left\{ \max_{n+1 \leqq k \leqq k_n - 1} \sum_{l=n+1}^{k} a_l \eta_l \mathbf{1}_{\{\mu_m \leqq l < \nu_m\}} > \frac{R_4 - R_1}{2} \right\} \\
&\leqq P\left\{ \max_{n+1 \leqq k \leqq k_n - 1} \sum_{l=n+1}^{k} a_l (\eta_l - E\{\eta_l | \mathscr{F}_l\}) \mathbf{1}_{\{\mu_m \leqq l < \nu_m\}} \right. \\
&\qquad \left. + \max_{n+1 \leqq k \leqq k_n - 1} \sum_{l=n+1}^{k} a_l E\{\eta_l | \mathscr{F}_l\} \mathbf{1}_{\{\mu_m \leqq l < \nu_m\}} > \frac{R_4 - R_1}{2} \right\}.
\end{aligned} \tag{3.9}$$

But

$$\begin{aligned}
\max_{n+1 \leqq k \leqq k_n - 1} &\left| \sum_{l=n+1}^{k} a_l E\{\eta_l | \mathscr{F}_l\} \mathbf{1}_{\{\mu_m \leqq l < \nu_m\}} \right| \\
&\leqq \sum_{l=n+1}^{k_n - 1} a_l |E\{\eta_l | \mathscr{F}_l\}| \\
&\leqq c_1 \sum_{l=n+1}^{k_n - 1} a_l^{(3/2) \wedge (1+\beta)} \\
&\leqq c_2 \sum_{l=n+1}^{\infty} \frac{1}{k^{(3/2) \wedge (1+\beta)}} \to 0 \quad \text{as } n \to \infty
\end{aligned} \tag{3.10}$$

since $\beta > 0$. Combining (3.9) and (3.10) gives for n large enough

$$P\{E_{n,m}\} \leqq P\left\{ \max_{n+1 \leqq k \leqq k_n - 1} \sum_{l=n+1}^{k} a_l (\eta_l - E\{\eta_l | \mathscr{F}_l\}) \mathbf{1}_{\{\mu_m \leqq l < \nu_m\}} > \frac{R_4 - R_1}{4} \right\}. \tag{3.11}$$

Let $\tilde{\eta}_k = \eta_k - E\{\eta_k | \mathscr{F}_k\}$ and

$$S_{m,k} = \sum_{l=n+1}^{k} a_l \tilde{\eta}_l \mathbf{1}_{\{\mu_m \leqq l < \nu_m\}}, \qquad k \geqq n+1.$$

Since $\tilde{\eta}_l$ is $\mathscr{F}_{l+1}$-measurable and $\{\mu_m \leqq l < \nu_m\} \in \mathscr{F}_l$, $\{S_{m,k}, \mathscr{F}_{k+1}\}_{k \geqq n+1}$ is a martingale. Hence applying Doob's inequality to (3.11) gives for n large enough

$$\begin{aligned}
P\{E_{n,m}\} &\leqq P\left\{ \max_{n+1 \leqq k \leqq k_n - 1} S_{m,k} > \frac{R_4 - R_1}{4} \right\} \\
&\leqq c_3 E\{S_{m,k_n - 1}^2\} \\
&= c_3 \sum_{k=n+1}^{k_n - 1} a_k^2 E\{|\tilde{\eta}_k|^2 \mathbf{1}_{\{\mu_m \leqq k < \nu_m\}}\}.
\end{aligned}$$

Finally,

$$
\begin{aligned}
P\{E_n\} &\leqq \sum_{m=1}^{m_n} P\{E_{n,m}\} \\
&\leqq c_3 \sum_{k=n+1}^{k_n-1} a_k^2 E\left\{|\tilde{\eta}_k|^2 \sum_{m=1}^{m_n} \mathbf{1}_{\{\mu_m \leqq k < \nu_m\}}\right\} \\
&\leqq c_3 \sum_{k=n+1}^{k_n-1} a_k^2 E\{|\tilde{\eta}_k|^2\} \\
&\leqq c_3 \sum_{k=n+1}^{k_n-1} a_k^2 E\{|\eta_k|^2\} \\
&\leqq c_4 \sum_{k=n+1}^{k_n-1} a_k^{3\wedge(2+\alpha)} \\
&\leqq c_5 \sum_{k=n+1}^{\infty} \frac{1}{k^{3\wedge(2+\alpha)}} \to 0 \quad \text{as } n \to \infty
\end{aligned}
$$

since $\alpha > -1$. This completes the proof of Claim 2.

Proof for $d > 1$. We now show how the above proof for $d = 1$ can be extended to $d > 1$.

Let u^i denote the ith component of a vector u. Suppose for the moment that there exists $R_2 > R_1$ such that for $R_3 = R_2 + 1$ and $R_4 = 2R_3 + 3R_1$, we have

$$
\sup_{\substack{x^i \leqq -R_2 \\ |x^j| \leqq R_4 \forall j \neq i}} \frac{\partial U}{\partial x^i}(x) < \inf_{|x^j| \leqq R_1 \forall j} \frac{\partial U}{\partial x^i}(x), \tag{3.12}
$$

$$
\inf_{\substack{x^i \geqq R_2 \\ |x^j| \leqq R_4 \forall j \neq i}} \frac{\partial U}{\partial x^i}(x) > \sup_{|x^j| \leqq R_1 \forall j} \frac{\partial U}{\partial x^i}(x). \tag{3.13}
$$

For $s > 0$, $R_0 > 0$, and $i = 1, \cdots, d$ let

$$
\sigma_i(s, R_0) = \inf\{t \geqq s \colon |X^i(t)| > R_0\}.
$$

Then we can show that as $n \to \infty$

$$
\begin{aligned}
&P_{0,x_0;t_n,x}\{\sigma(t_n, \sqrt{d}\, R_4) \leqq t_{k_n}, \tau(t_n, R_1) > t_{k_n}\} \\
&\qquad \leqq \sum_{i=1}^{d} P_{0,x_0;t_n,x}\{\sigma_i(t_n, R_4) \leqq t_{k_n}, \sigma_i(t_n, R_4) \leqq \sigma_j(t_n, R_4)\ \forall j \neq i, \tau(t_n, R_1) > t_{k_n}\} \to 0
\end{aligned}
$$

similarly to the proof given above that

$$
P_{0,x_0;t_n,x}\{\sigma(t_n, R_4) \leqq t_{k_n}, \tau(t_n, R_1) > t_{k_n}\} \to 0
$$

in the scalar case $d = 1$. So (3.8) and hence Lemma 4 holds for $R = \sqrt{d}\, R_4$.

It remains to establish (3.12) and (3.13). We only consider (3.13). Let $D(R_2) = \{x \colon x^i \geqq R_2, |x^j| \leqq R_4\ \forall j \neq i\}$. Since R_1 is fixed here, there will exist R_2 such that (3.13) holds if we can show

$$
\lim_{R_2 \to \infty} \inf_{x \in D(R_2)} \frac{\partial U}{\partial x^i}(x) = \infty.
$$

We proceed by breaking $\nabla U(x)$ into radial and tangential components and comparing the projection of these components on e^i, the ith standard basis element in $\mathbb{R}^d$. So let

$$\begin{aligned}
\hat{x} &= \frac{x}{|x|}, && |x| > 0, \\
\hat{\theta} &= \frac{\nabla U(x) - \langle \nabla U(x), \hat{x} \rangle \hat{x}}{|\nabla U(x) - \langle \nabla U(x), \hat{x} \rangle \hat{x}|}, && |\nabla U(x) - \langle \nabla U(x), \hat{x} \rangle \hat{x}| > 0 \\
&= 0, && |\nabla U(x) - \langle \nabla U(x), \hat{x} \rangle \hat{x}| = 0
\end{aligned}$$

and

$$g(x) = \frac{\langle \nabla U(x), \hat{\theta} \rangle \langle \hat{\theta}, e^i \rangle}{\langle \nabla U(x), \hat{x} \rangle \langle \hat{x}, e^i \rangle}, \quad x^i \text{ large.}$$

Of course $\langle \hat{x}, \hat{\theta} \rangle = 0$. Then

$$\begin{aligned}
\overline{\lim_{R_2 \to \infty}} \sup_{x \in D(R_2)} g^2(x) &\leqq \overline{\lim_{R_2 \to \infty}} \sup_{x \in D(R_2)} \frac{|\nabla U(x)|^2 - \langle \nabla U(x), \hat{x} \rangle^2}{\langle \nabla U(x), \hat{x} \rangle^2} \cdot \frac{1 - \langle \hat{x}, e^i \rangle^2}{\langle \hat{x}, e^i \rangle^2} \\
&= \overline{\lim_{R_2 \to \infty}} \sup_{x \in D(R_2)} \left[\left\langle \frac{\nabla U(x)}{|\nabla U(x)|}, \frac{x}{|x|} \right\rangle^{-2} - 1 \right] \cdot \frac{|x|^2 - (x^i)^2}{(x^i)^2} \\
&< (L(d)^{-2} - 1) 4(d-1) = 1,
\end{aligned}$$

where the first inequality follows from Bessel's inequality (applied to $\nabla U(x)$ and to e^i), and the last inequality follows from (A3) and the fact that if $x \in D(R_2)$ then $|x|^2 - (x^i)^2 \leqq (d-1) R_4^2$ and $(x^i)^2 \geqq R_2^2$ (and also $R_4 \sim 2R_2$ as $R_2 \to \infty$). Hence

$$\begin{aligned}
\underline{\lim_{R_2 \to \infty}} \inf_{x \in D(R_2)} \frac{\partial U}{\partial x^i}(x) &= \underline{\lim_{R_2 \to \infty}} \inf_{x \in D(R_2)} [\langle \nabla U(x), \hat{x} \rangle \langle \hat{x}, e^i \rangle + \langle \nabla U(x), \hat{\theta} \rangle \langle \hat{\theta}, e^i \rangle] \\
&= \underline{\lim_{R_2 \to \infty}} \inf_{x \in D(R_2)} \langle \nabla U(x), \hat{x} \rangle \langle \hat{x}, e^i \rangle (1 + g(x)) \\
&= \underline{\lim_{R_2 \to \infty}} \inf_{x \in D(R_2)} |\nabla U(x)| \left\langle \frac{\nabla U(x)}{|\nabla U(x)|}, \frac{x}{|x|} \right\rangle \frac{x^i}{|x|} (1 + g(x)) = \infty.
\end{aligned}$$

Hence (3.13) and similarly (3.12) follows. This completes the proof of Lemma 4.

3.2. Proof of Lemma 5. The idea behind this proof is that if $X(s) = Y(s)$ and $X(t)$ and $Y(t)$ remain in a fixed bounded set on large time intervals $t \in [s, \beta(s)]$ (and they do by Lemmas 3 and 4), then we can develop a recursion for estimating $E\{|X(\beta(s)) - Y(\beta(s))|^2\}$, and from the recursion we can show that $E\{|X(\beta(s)) - Y(\beta(s))|^2\} \to 0$ as $s \to \infty$. This is true even though the interval length $\beta(s) - s \to \infty$ as $s \to \infty$.

For each n let k_n be the integer that satisfies $\beta(t_n) \in [t_{k_n}, t_{k_{n+1}})$. We show that

$$(3.14) \qquad \lim_{n \to \infty} E_{0, x_0; t_n, x} \{|X(t_{k_n}) - Y(t_{k_n})|^2, \sigma(t_n, R) \wedge \tau(t_n, R) > t_{k_n}\} = 0.$$

The lemma then follows by some minor details, which are omitted.

In this proof we can and will assume that $\nabla U(\cdot)$ is bounded and Lipschitz function on $\mathbb{R}^d$, and ξ_k satisfies (A4′) with $K = \mathbb{R}^d$ (instead of K a compact subset of $\mathbb{R}^d$), i.e.,

$$(3.15) \qquad E\{|\xi_k|^2 | \mathscr{F}_k\} \leqq L a_k^\alpha, \quad |E\{\xi_k | \mathscr{F}_k\}| \leqq L a_k^\beta \quad \text{w.p.1}$$

(if $\sigma(t_n, R) \wedge \tau(t_n, R) > t_{k_n}$ then $|X(t)|$, $|Y(t)| \leqq R$ for $t_n \leqq t \leqq t_{k_n}$, and so $U(x)$ can be modified for $|x| > R$ and we can set $\xi_k = 0$ for $|X_k| > R$ without loss of generality).

Fix n for the moment and let $\sigma = \sigma(t_n, R)$, $\tau = \tau(t_n, R)$. Let

$$\zeta_k = \zeta(t_k, t_{k+1} \wedge \tau(t_k, R))$$

and

$$Y_{k+1} = Y_k - a_k(\nabla U(Y_k) + \zeta_k) + b_k W_k.$$

Note that if $Y(t_n) = Y_n$ and $\tau > t_{k_n}$, then $Y(t_{k_n}) = Y_{k_n}$. Henceforth assume all quantities are conditioned on $X(0) = X_0 = x_0$, $X(t_n) = X_n = Y(t_n) = Y_n = x$, $|x| \leqq r$. Then

$$\begin{aligned} E\{|X(t_{k_n}) - Y(t_{k_n})|^2, \sigma \wedge \tau > t_{k_n}\} &= E\{|X_{k_n} - Y_{k_n}|^2, \sigma \wedge \tau > t_{k_n}\} \\ &\leqq E\{|X_{k_n} - Y_{k_n}|^2\}. \end{aligned} \tag{3.16}$$

We proceed to show that the right side of (3.16) tends to zero as $n \to \infty$. Let

$$\Delta_k = X_k - Y_k, \qquad \eta_k = \xi_k - \zeta_k.$$

Note that by (3.15) and Corollary 1

$$E\{|\eta_k|^2 | \mathcal{F}_k\} \leqq c_1 a_k^{\alpha \wedge 1}, \quad |E\{\eta_k | \mathcal{F}_k\}| \leqq c_1 a_k^{\beta \wedge (1/2)} \quad \text{w.p.1.}$$

Now using Holder's inequality and the fact that X_k, Y_k, and hence Δ_k are $\mathcal{F}_k$ measurable we have

$$\begin{aligned} E\{|\Delta_{k+1}|^2\} &= E\{|\Delta_k - a_k(\nabla U(X_k + \Delta_k) - \nabla U(X_k) + \eta_k)|^2\} \\ &= E\{|\Delta_k|^2\} - 2a_k E\{\langle \Delta_k, \nabla U(X_k + \Delta_k) - \nabla U(X_k)\rangle\} \\ &\quad -2a_k E\{\langle \Delta_k, \eta_k\rangle\} + a_k^2 E\{|\nabla U(X_k + \Delta_k) - \nabla U(X_k)|^2\} \\ &\quad + 2a_k^2 E\{\langle \nabla U(X_k + \Delta_k) - \nabla U(X_k), \eta_k\rangle\} + a_k^2 E\{|\eta_k^2|\} \\ &\leqq E\{|\Delta_k|^2\} + 2d_1 a_k E\{|\Delta_k|^2\} \\ &\quad + 2a_k E\{|\Delta_k|^2\}^{1/2} E\{|E\{\eta_k|\mathcal{F}_k\}|^2\}^{1/2} + 2d_1^2 a_k^2 E\{|\Delta_k|^2\} \\ &\quad + 2d_1 a_k^2 E\{|\Delta_k|^2\}^{1/2} E\{|E\{\eta_k|\mathcal{F}_k\}|^2\}^{1/2} + a_k^2 E\{E\{|\eta_k|^2|\mathcal{F}_k\}\} \\ &\leqq (1 + c_2 a_k) E\{|\Delta_k|^2\} + c_2 a_k^\delta, \end{aligned}$$

where d_1 is a Lipschitz constant for $\nabla U(\cdot)$ and $\delta = \min[\frac{3}{2}, 2 + \alpha, 1 + \beta]$. Using the assumptions that $\alpha > -1$ and $\beta > 0$ we have $\delta > 1$. Now for each n

$$\begin{gathered} E\{|\Delta_{k+1}|^2\} \leqq (1 + c_2 a_k) E\{|\Delta_k|^2\} + c_2 a_k^\delta, \qquad k \geqq n, \\ E\{|\Delta_n|^2\} = 0, \end{gathered}$$

and if we replace the inequality with equality, the resulting difference equation is unstable as $k \to \infty$ (recall that $a_k = A/k$, k large). Nonetheless, we make the following claim.

CLAIM 3. *There exists $\gamma > 1$ such that*

$$\lim_{n \to \infty} \sup_{k: t_n \leqq t_k \leqq \gamma t_n} E\{|\Delta_k|^2\} = 0.$$

Assume the claim holds. Since $t_{k_n} \leqq \beta(t_n) \leqq t_n + 2t_n^{2/3} < \gamma t_n$ for n large, it follows that

$$\lim_{n \to \infty} E\{|\Delta_{k_n}|^2\} = 0.$$

This proves (3.14) and hence Lemma 5. It remains to prove the claim.

Proof of Claim 3. For each n let $\{u_{n,k}\}_{k\geqq n}$ be a sequence of nonnegative numbers such that

$$u_{n,k+1}\leqq(1+a_k)u_{n,k}+a_k^\delta,\qquad k\geqq n,$$
$$u_{n,n}=0,$$

where $\delta>1$. Now

$$u_{n,k}\leqq\sum_{m=n}^{k-1}a_m^\delta\prod_{l=m+1}^{k-1}(1+a_l)\leqq\left(\sum_{m=n}^{k-1}a_m^\delta\right)\cdot\exp\left(\sum_{m=n}^{k-1}a_m\right),$$

since $1+x\leqq e^x$. Also $\sum_n^{k-1}a_m\leqq A(\log(k/n)+1/n)$ and $\sum_n^{k-1}a_m^\delta\leqq A(1/(\delta-1)n^{\delta-1}+1/n^\delta)$, and if $t_k\leqq\gamma t_n$ then $k\leqq c_1n^\gamma$. Choose γ such that $1<\gamma<1+(\delta-1)/A$. It follows that

$$\sup_{k:t_n\leqq t_k\leqq\gamma t_n}u_{n,k}\leqq c_2n^{(\gamma-1)A-(\delta-1)}\to0\quad\text{as }n\to\infty.$$

The claim follows by setting $u_{n,k}=E\{|\Delta_k|^2\}$.

Remark. The proof of Claim 3 does *not* work if $a_k=A/k^\eta$ for any $\eta<1$.

4. General tightness criterion. In this section we consider the tightness of an algorithm of the form

$$X_{k+1}=X_k-a_k(\psi_k(X_k)+\xi_k)+b_kW_k,\qquad k\geqq0 \tag{4.1}$$

where $\{a_k\}$, $\{b_k\}$, $\{\xi_k\}$, and $\{W_k\}$ are defined as in § 2, and $\{\psi_k(x): x\in\mathbb{R}^d\}$ is an $\mathbb{R}^d$-valued random vector field for $k=0,1,\cdots$. We will deal with the following conditions in this section (α, β, γ_1, and γ_2 are constants whose values will be specified later).

(B1) For $k=0,1,\cdots$, let $\mathcal{F}_k=\sigma(X_0,W_0,\cdots,W_{k-1},\xi_0,\cdots,\xi_{k-1})$. There exists $L_1>0$ such that

$$E\{|\xi_k|^2|\mathcal{F}_k\}\leqq L_1a_k^\alpha,\quad|E\{\xi_k|\mathcal{F}_k\}|\leqq L_1a_k^\beta\quad\text{w.p.1}$$

W_k is independent of $\mathcal{F}_k$.

(B2) Let K be a compact subset of $\mathbb{R}^d$. There exists $L_2>0$ such that

$$E\{|\psi_k(x)|^2|\mathcal{F}_k\}\leqq L_2\quad\forall x\in K,\quad\text{w.p.1.}$$

(B3) There exists $L_3, R>0$ such that

$$E\{|\psi_k(x)||\mathcal{F}_k\}^2\geqq L_3\frac{|x|^2}{a_k^{\gamma_1}}\quad\forall|x|>R,\quad\text{w.p.1.}$$

(B4) There exists $L_4, R>0$ such that

$$E\{|\psi_k(x)|^2|\mathcal{F}_k\}\leqq L_4\frac{|x|^2}{a_k^{\gamma_2}}\quad\forall|x|>R,\quad\text{w.p.1.}$$

(B5) There exists $L_5, R>0$ such that

$$E\{\langle\psi_k(x),x\rangle|\mathcal{F}_k\}\geqq L_5E\{|\psi_k(x)||x||\mathcal{F}_k\}\quad\forall|x|>R,\quad\text{w.p.1.}$$

THEOREM 3. *Assume that* (B1)-(B5) *hold with* $\alpha>-1,\beta>0$, *and* $0\leqq\gamma_1\leqq\gamma_2<1$. *Let* $\{X_k\}$ *be given by* (4.1) *and* K *be a compact subset of* $\mathbb{R}^d$. *Then* $\{X_k^{x_0}: k\geqq0, x_0\in K\}$ *is a tight family of random variables.*

The proof of Theorem 3 will require the following lemmas.

LEMMA 6. *Assume the conditions of Theorem* 3. *Then there exist an integer* k_0 *and an* $M_1>0$ *such that*

$$E_{0,x_0}\{|X_{k+1}|^2\}-E_{0,x_0}\{|X_k|^2\}\leqq0\quad\textit{if } E_{0,x_0}\{|X_k|^2\}\geqq M_1,$$

for $k\geqq k_0$ *and all* x_0.

Proof. Assume all quantities are conditioned on $X_0 = x_0$. Now it follows from (B2)–(B5) and the fact that X_k is $\mathcal{F}_k$-measurable that

$$\begin{aligned}
&E\{|\psi_k(X_k)|^2, |X_k| \leqq R\} \leqq L_2,\\
&E\{|\psi_k(X_k)|^2, |X_k| > R\} \geqq L_3 a_k^{-\gamma_1} E\{|X_k|^2, |X_k| > R\},\\
&E\{|\psi_k(X_k)|^2, |X_k| > R\} \leqq L_4 a_k^{-\gamma_2} E\{|X_k|^2, |X_k| > R\},\\
&E\{\langle \psi_k(X_k), X_k\rangle, |X_k| > R\} \geqq L_5 L_3^{1/2} a_k^{-\gamma_1/2} E\{|X_k|^2, |X_k| > R\}.
\end{aligned}$$

Let $D \in \mathcal{F}_k$. Then using Holder's inequality and the fact that X_k is $\mathcal{F}_k$-measurable and W_k is independent of $\mathcal{F}_k$ we have

$$\begin{aligned}
&E\{|X_{k+1}|^2, D\} - E\{|X_k|^2, D\}\\
&\quad = E\{|X_k - a_k(\psi_k(X_k) + \xi_k) + b_k W_k|^2, D\} - E\{|X_k|^2, D\}\\
&\quad = -2a_k E\{\langle X_k, \psi_k(X_k)\rangle, D\} - 2a_k E\{\langle X_k, \xi_k\rangle, D\}\\
&\qquad + 2b_k E\{\langle X_k, W_k\rangle, D\} + a_k^2 E\{|\psi_k(X_k)|^2, D\}\\
&\qquad + 2a_k^2 E\{\langle \psi_k(X_k), \xi_k\rangle, D\} - 2a_k b_k E\{\langle \psi_k(X_k), W_k\rangle, D\}\\
&\qquad + a_k^2 E\{|\xi_k|^2, D\} - 2a_k b_k E\{\langle \xi_k, W_k\rangle, D\} + b_k^2 E\{|W_k|^2, D\}
\end{aligned}$$

$$\begin{aligned}
&\quad \leqq -2a_k E\{\langle X_k, \psi_k(X_k)\rangle, D\}\\
&\qquad + 2a_k E\{|X_k|^2, D\}^{1/2} E\{|E\{\xi_k | \mathcal{F}_k\}|^2\}^{1/2}\\
&\qquad + 2b_k E\{\langle X_k, E\{W_k\}\rangle, D\} + a_k^2 E\{|\psi_k(X_k)|^2, D\}\\
&\qquad + 2a_k^2 E\{|\psi_k(X_k)|^2, D\}^{1/2} E\{E\{|\xi_k|^2 | \mathcal{F}_k\}\}^{1/2}\\
&\qquad + 2a_k b_k E\{|\psi_k(X_k)|^2, D\}^{1/2} E\{|W_k|^2\}^{1/2}\\
&\qquad + a_k^2 E\{E\{|\xi_k|^2 | \mathcal{F}_k\}\}\\
&\qquad + 2a_k b_k E\{E\{|\xi_k|^2 | \mathcal{F}_k\}\}^{1/2} E\{|W_k|^2\}^{1/2} + b_k^2 E\{|W_k|^2\}.
\end{aligned} \tag{4.2}$$

Let $D = \{X_k > R\}$. Then using (4.2) we have

$$\begin{aligned}
&E\{|X_{k+1}|^2, |X_k| > R\} - E\{|X_k|^2, |X_k| > R\}\\
&\quad \leqq -c_1 a_k^{1-\gamma_1/2} E\{|X_k|^2, |X_k| > R\}\\
&\qquad + c_2((a_k^{\delta_1} + a_k^{1-\gamma_2/2} b_k) E\{|X_k|^2, |X_k| > R\} + a_k^{\delta_2} + a_k^{\delta_3} b_k + b_k^2),
\end{aligned}$$

where $\delta_1 = \min[1+\beta, 2-\gamma_2, 2+(\alpha-\gamma_2)/2]$, $\delta_2 = \min[1+\beta, 2+(\alpha-\gamma_2)/2, 2+\alpha]$, and $\delta_3 = \min[1-\gamma_2/2, 1+\alpha/2]$. Using the assumptions that $\alpha > -1$, $\beta > 0$, and $0 \leqq \gamma_1 \leqq \gamma_2 < 1$, we have $\delta_1 > 1$, $\delta_2 > 1$, and $\delta_3 > \frac{1}{2}$, and since $b_k = o(a_k^{1/2})$ we get

$$\begin{aligned}
&E\{|X_{k+1}|^2, |X_k| > R\} - E\{|X_k|^2, |X_k| > R\}\\
&\quad \leqq (-c_3 a_k^{1-\gamma_1/2} + o(a_k^{1-\gamma_1/2})) E\{|X_k|^2, |X_k| > R\} + o(a_k^{1-\gamma_1/2})\\
&\quad \leqq -c_4 a_k^{1-\gamma_1/2} (E\{|X_k|^2\} - R - 1)
\end{aligned} \tag{4.3}$$

for all $k \geqq k_0$, if we choose k_0 large enough.

Let $D = \{X_k \leqq R\}$. Then using (4.2) we have

$$E\{|X_{k+1}|^2, |X_k| \leqq R\} - E\{|X_k|^2, |X_k| \leqq R\} \leqq c_5(a_k^{\delta_4} + a_k^{\delta_5} b_k + b_k^2),$$

where $\delta_4 = \min[1, 1+\beta, 2+\alpha/2, 2+\alpha]$ and $\delta_5 = \min(1, 1+\alpha/2]$. Using the assumptions that $\alpha > -1$ and $\beta > 0$ we have $\delta_4 = 1$ and $\delta_5 > \frac{1}{2}$, and since $b_k = o(a_k^{1/2})$ we get

$$(4.4) \qquad E\{|X_{k+1}|^2, |X_k| \leqq R\} - E\{|X_k|^2, |X_k| \leqq R\} \leqq c_6 a_k \leqq c_6 a_k^{1-\gamma_1/2}$$

for all $k \geqq 0$.

Finally, let $M_1 = c_6/c_4 + R + 1$. Then combining (4.3) and (4.4) gives the lemma. □

LEMMA 7. *Assume the conditions of Theorem* 3. *Then there exists an* $M_2 > 0$ *such that*

$$E_{0,x_0}\{|X_{k+1}|^2\} - E_{0,x_0}\{|X_k|^2\} \leqq M_2(E_{0,x_0}\{|X_k|^2\} + 1)$$

for $k \geqq 0$ *and all* x_0.

Proof. Similarly to the proof of Lemma 6 we can show that conditioned on $X_0 = x_0$

$$E\{|X_{k+1}|^2, |X_k| > R\} - E\{|X_k|^2, |X_k| > R\} \leqq c_1 a_k^{1/2}(E\{|X_k|^2\} + 1)$$

and

$$E\{|X_{k+1}|^2, |X_k| \leqq R\} - E\{|X_k|^2, |X_k| \leqq R\} \leqq c_1 a_k.$$

Combining these equations gives the lemma. □

Proof of Theorem 3. Let M_1, M_2, and k_0 be as in Lemmas 6 and 7. By Lemma 7 there exists $c_1 \geqq M_1$ such that

$$E_{0,x_0}\{|X_k|^2\} \leqq c_1, \quad \forall k \leqq k_0, \quad x_0 \in K,$$

and by Lemmas 6 and 7 we also have

$$E_{0,x_0}\{|X_{k+1}|^2\} - E_{0,x_0}\{|X_k|^2\} \leqq 0 \quad \text{if } E_{0,x_0}\{|X_k|^2\} \geqq M_1$$

and

$$E_{0,x_0}\{|X_{k+1}|^2\} - E_{0,x_0}\{|X_k|^2\} \leqq M_2(E_{0,x_0}\{|X_k|^2\} + 1)$$

for $k \geqq k_0$ and all x_0. Let $c_2 = c_1 + M_2(M_1 + 1)$. Then by induction we get

$$E_{0,x_0}\{|X_k|^2\} \leqq c_2 \quad \forall k \geqq 0, \quad x_0 \in K,$$

and the tightness of $\{X_k^{x_0}: k \geqq 0, x_0 \in K\}$ follows from this. □

5. Tightness and convergence for two example algorithms. In this section we apply Theorems 2 and 3 to establish the tightness and ultimately the convergence of two example algorithms. Define $U(\cdot)$, $\{a_k\}$, $\{b_k\}$, $\{\xi_k\}$, and $\{W_k\}$ as in § 2. We will need to consider one or both of the following conditions:

$$(\text{A5}) \qquad \underline{\lim}_{|x| \to \infty} |\nabla U(x)|/|x| > 0.$$

$$(\text{A6}) \qquad \overline{\lim}_{|x| \to \infty} |\nabla U(x)|/|x| < \infty.$$

Example 1. Here we consider the following algorithm:

$$(5.1) \qquad X_{k+1} = X_k - a_k(\nabla U(X_k) + \xi_k) + b_k W_k, \qquad k \geqq 0.$$

THEOREM 4. *Assume* (A1)-(A3), (B1), (A5), and (A6) *hold with* $\alpha > -1, \beta > 0$. *Let* $\{X_k\}$ *be given by* (5.1). *Then for* $B/A > C_0$ *and any bounded continuous function* $f(\cdot)$ *on* $\mathbb{R}^d$

$$\lim_{k \to \infty} E_{0,x_0}\{f(X_k)\} = \pi(f)$$

uniformly for x_0 *in a compact set.*

Proof. The assumptions of Theorem 2 and Theorem 3 (with $\psi_k(x) = \nabla U(x)$ and $\gamma_1 = \gamma_2 = 0$) are satisfied. □

Observe that the proof of tightness of $\{X_k^{x_0}\}$ using Theorem 3 requires that (A5) and (A6) hold, i.e., there exists M_1 and M_2 such that

$$M_1|x| \leqq |\nabla U(x)| \leqq M_2|x|, \quad |x| \text{ large.}$$

Intuitively, the upper bound on $|\nabla U(x)|$ is needed to prevent potentially unbounded oscillations of $\{X_k\}$ around the origin. It is possible to modify (5.1) in such a way that only the lower bound on $|\nabla U(x)|$ (i.e., (A5)) but not the upper bound on $|\nabla U(x)|$ (i.e., (A6)) is needed. Since we still want convergence to a global minimum of $U(\cdot)$, which is not known to lie in a specified bounded domain, standard multiplier and projection methods [1] are precluded. The next example gives a modification of (5.1), which has the desired properties.

Example 2. Here we consider the following algorithm:

$$(5.2) \qquad \begin{aligned} X_{k+1} &= X_k - a_k(\nabla U(X_k) + \xi_k) + b_k W_k \quad && \text{if} \quad |\nabla U(X_k) + \xi_k| \leqq \frac{|X_k| \vee 1}{a_k^\gamma} \\ &= X_k - a_k^{1-\gamma} X_k + b_k W_k && \text{if} \quad |\nabla U(X_k) + \xi_k| > \frac{|X_k| \vee 1}{a_k^\gamma}, \end{aligned}$$

where $\gamma > 0$. Intuitively, note that if K is a fixed compact set, $X_k \in K$, ξ_k is not too large, and k is very large, then X_k is updated to X_{k+1} as in (5.1). Also note that in (5.2) (like (5.1)), $\nabla U(X_k)$ and ξ_k only appear as the sum $\nabla U(X_k) + \xi_k$. This means that we can use noisy or imprecise measurements of $\nabla U(\cdot)$ in (5.2) in exactly the same way as in (5.1).

THEOREM 5. *Assume* (A1)-(A3), (B1), *and* (A5) (*but not necessarily* (A6)) *hold with* $\alpha > 0$. *Let* $\{X_k\}$ *be given by* (5.2) *with* $0 < \gamma < \frac{1}{2}$. *Then for* $B/A > C_0$ *and any bounded continuous function* $f(\cdot)$ *on* $\mathbb{R}^d$

$$(5.3) \qquad \lim_{k \to \infty} E_{0,x_0}\{f(X_k)\} = \pi(f)$$

uniformly for x_0 *in a compact set.*

Proof. Let

$$(5.4) \qquad X_{k+1} = X_k - a_k(\nabla U(X_k) + \xi_k') + b_k W_k$$

(this defines ξ_k') and $\mathscr{F}_k' = \sigma(X_0, \xi_0', \cdots, \xi_{k-1}', W_0, \cdots, W_{k-1})$. We show that $(\xi_k', W_k, \mathscr{F}_k')$ satisfies (A4). Hence by Theorem 2 if $\{X_k^{x_0}: k \geqq 0, x_0 \in K\}$ is tight for K compact then (5.3) holds.

Let

$$\begin{aligned} \psi_k(x) &= \nabla U(x) \quad && \text{if} \quad |\nabla U(x) + \xi_k| \leqq \frac{|x| \vee 1}{a_k^\gamma} \\ &= \frac{x}{a_k^\gamma} && \text{if} \quad |\nabla U(x) + \xi_k| > \frac{|x| \vee 1}{a_k^\gamma}. \end{aligned}$$

Let

$$(5.5) \qquad X_{k+1} = X_k - a_k(\psi_k(X_k) + \xi_k'') + b_k W_k$$

(this defines ξ_k'') and $\mathscr{F}_k'' = \sigma(X_0, \xi_0'', \cdots, \xi_{k-1}'', W_0, \cdots, W_{k-1})$. We show that $(\xi_k'', W_k, \mathscr{F}_k'')$ satisfies (B1) and $(\psi_k(x), \mathscr{F}_k'')$ satisfies (B2)-(B5) with $\gamma_1 = 0$, $\gamma_2 = 2\gamma$. Hence by Theorem 3 $\{X_k^{x_0}: k \geqq 0, x_0 \in K\}$ is tight for K compact and (5.3) does hold. These assertions are proved in Claims 4 and 5 below.

Remark. The proof shows the importance of separating the tightness and convergence issues. Even though we can write algorithm (5.2) in the form of algorithm (5.4), we cannot apply Theorem 3 to (5.4) to prove tightness because $U(\cdot)$ may not satisfy (A6), and ξ'_k may not satisfy (B1) even though ξ_k satisfies (B1).

CLAIM 4. *Let K be a compact subset of $\mathbb{R}^d$. Then there exists $M_1 > 0$ such that*

$$E\{|\xi'_k|^2|\mathcal{F}'_k\} \leqq M_1 a_k^\alpha \quad \forall X_k \in K, \quad w.p.1.$$

Also, W_k is independent of $\mathcal{F}'_k$.

Proof. Clearly,

$$\begin{aligned} \xi'_k &= \xi_k && \text{if} \quad |\nabla U(X_k) + \xi_k| \leqq \frac{|X_k| \vee 1}{a_k^\gamma} \\ &= \frac{X_k}{a_k^\gamma} - \nabla U(X_k) && \text{if} \quad |\nabla U(X_k) + \xi_k| > \frac{|X_k| \vee 1}{a_k^\gamma}. \end{aligned}$$

Hence for $X_k \in K$ and k large enough

$$\begin{aligned} E\{|\xi'_k|^2|\mathcal{F}_k\} &\leqq E\{|\xi_k|^2|\mathcal{F}_k\} + E\left\{\left|\frac{X_k}{a_k^\gamma} - \nabla U(X_k)\right|^2, |\nabla U(X_k) + \xi_k| > \frac{|X_k| \vee 1}{a_k^\gamma} \,\middle|\, \mathcal{F}_k\right\} \\ &\leqq L_1 a_k^\alpha + \frac{c_1}{a_k^{2\gamma}} \Pr\left\{|\nabla U(X_k) + \xi_k| > \frac{|X_k| \vee 1}{a_k^\gamma} \,\middle|\, \mathcal{F}_k\right\} \\ &\leqq L_1 a_k^\alpha + \frac{c_1}{a_k^{2\gamma}} \Pr\left\{|\xi_k| > \frac{c_2}{a_k^\gamma} \,\middle|\, \mathcal{F}_k\right\} \\ &\leqq L_1 a_k^\alpha + c_3 E\{|\xi_k|^2|\mathcal{F}_k\} \leqq M_1 a_k^\alpha \quad \text{w.p.1}, \end{aligned}$$

where we have used the assumption that $\gamma > 0$ and the Chebyshev inequality. It is easy to see that the inequality actually holds for all $k \geqq 0$. Since $\mathcal{F}'_k \subset \mathcal{F}_k$, the claim follows.

CLAIM 5. *Let K be a compact subset of $\mathbb{R}^d$. Then there exists M_1, M_2, M_3, M_4, and M_5, $R > 0$ such that*

(i) *$E\{|\xi''_k|^2|\mathcal{F}''_k\} \leqq M_1 a_k^\alpha$ w.p.1. Also W_k is independent of $\mathcal{F}''_k$,*

(ii) *$E\{|\psi_k(x)|^2|\mathcal{F}''_k\} \leqq M_2$ for all $x \in K$, w.p.1,*

(iii) *$E\{|\psi_k(x)||\mathcal{F}''_k\}^2 \geqq M_3|x|^2$ for all $|x| > R$, w.p.1,*

(iv) *$E\{|\psi_k(x)|^2|\mathcal{F}''_k\} \leqq M_4(|x|^2/a_k^{2\gamma})$ for all $|x| > R$, w.p.1,*

(v) *$E\{\langle\psi_k(x), x\rangle|\mathcal{F}''_k\} \geqq M_5 E\{|\psi_k(x)||x||\mathcal{F}''_k\}$ for all $|x| > R$, w.p.1.*

Proof. First observe that (iii) and (v) follow immediately from (A3) and (A5).

(i) Clearly,

$$\begin{aligned} \xi''_k &= \xi_k \quad \text{if} \quad |\nabla U(X_k) + \xi_k| \leqq \frac{|X_k| \vee 1}{a_k^\gamma} \\ &= 0 \quad \text{if} \quad |\nabla U(X_k) + \xi_k| > \frac{|X_k| \vee 1}{a_k^\gamma}. \end{aligned}$$

Hence

$$E\{|\xi''_k|^2|\mathcal{F}_k\} \leqq E\{|\xi_k|^2|\mathcal{F}_k\} \leqq M_1 a_k^\alpha \quad \text{w.p.1}.$$

Since $\mathcal{F}''_k \subset \mathcal{F}_k$, (i) must hold.

(ii) For $x \in K$ and k large enough

$$\begin{aligned} E\{|\psi_k(x)|^2|\mathscr{F}_k\} &\leqq |\nabla U(x)|^2 + \frac{|x|^2}{a_k^{2\gamma}} \Pr\left\{|\nabla U(x)+\xi_k| > \frac{|x| \vee 1}{a_k^{\gamma}} \,\middle|\, \mathscr{F}_k\right\} \\ &\leqq c_1 + \frac{c_1}{a_k^{2\gamma}} \Pr\left\{|\xi_k| > \frac{c_2}{a_k^{\gamma}} \,\middle|\, \mathscr{F}_k\right\} \\ &\leqq c_1 + c_3 E\{|\xi_k|^2|\mathscr{F}_k\} \leqq M_2 \quad \text{w.p.1}, \end{aligned}$$

where we have used the assumption that $\gamma > 0$ and the Chebyshev inequality. It is easy to see that the inequality actually holds for $x \in K$ and all $k \geqq 0$. Since $\mathscr{F}_k'' \subset \mathscr{F}_k$, (ii) must hold.

(iv) For $|x|$ large enough and $k \geqq 0$

$$\begin{aligned} E\{|\psi_k(x)|^2|\mathscr{F}_k\} &\leqq \frac{|x|^2}{a_k^{2\gamma}} + |\nabla U(x)|^2 P\left\{|\nabla U(x)+\xi_k| \leqq \frac{|x| \vee 1}{a_k^{\gamma}} \,\middle|\, \mathscr{F}_k\right\} \\ &\leqq \frac{|x|^2}{a_k^{2\gamma}} + E\left\{|\nabla U(x)|^2, |\nabla U(x)| \leqq \frac{|x|}{a_k^{\gamma}} + |\xi_k| \,\middle|\, \mathscr{F}_k\right\} \\ &\leqq 4\frac{|x|^2}{a_k^{2\gamma}} + 3E\{|\xi_k|^2|\mathscr{F}_k\} \leqq M_4 \frac{|x|^2}{a_k^{2\gamma}} \quad \text{w.p.1}. \end{aligned}$$

Since $\mathscr{F}_k'' \subset \mathscr{F}_k$, (iv) must hold. This completes the proof of the claim and hence the theorem. □

As a final note observe that the algorithm (5.1) does require (A6), and also (B1) with $\alpha > -1$, $\beta > 0$. On the other hand, the algorithm (5.2) does not require (A6), but does require (B1) with $\alpha > 0$ (and hence $\beta > 0$ by Holder's inequality). It may be possible to allow $\{\xi_k\}$ with unbounded variance in (5.2) but this would require some additional assumptions on $\{\xi_k\}$ and we do not pursue this.

ON SUBDIFFERENTIALS OF OPTIMAL VALUE FUNCTIONS*

LIONEL THIBAULT†

Abstract. A general mathematical programming problem in which the constraints are defined by multifunctions and depend on a parameter u, and the resulting value function $m(u)$ are considered. In the context of Banach spaces admitting equivalent Fréchet differentiable norms estimates for the generalized gradient ∂m of m are established. A special study is made of problems in which the multifunctions defining the constraints take convex values. For these problems, estimates for ∂m are given in terms of the generalized gradients of the support functions of these multifunctions.

Key words. optimal value function, subdifferential, generalized gradient, ε-Fréchet subgradient, singular subdifferential, support function, regular multifunction

AMS(MOS) subject classifications. 90C30, 90C31, 90C48

Introduction. The study of the behaviour of an optimal value function is known to be very important for the interpretation of marginal values for resources in an economic framework and for its direct significance in stability and sensitivity analysis. A useful tool that furnishes information about the behaviour of the optimal value function is its Clarke subdifferential. So, many authors have studied the Clarke subdifferential of the optimal value function of a problem depending on a parameter and some have proved that this subdifferential is related to the Lagrange multipliers (relative to necessary optimality conditions in terms of Clarke generalized gradients) of the concerned problem. In the case of problems with explicit constraints, this was probably begun with the paper of Gauvin [14]. Recently, a great deal of progress has been realized in this domain by Rockafellar. Indeed, in a series of papers [28]-[32], Rockafellar considered the following general finite-dimensional problem:

$$(O_u) \qquad \underset{x\in\mathbb{R}^n}{\text{minimize}}\ \{f(x,u): (x,u)\in D,\ g(x,u)\in C\},$$

where $D\subset\mathbb{R}^n\times\mathbb{R}^m$ and $C\subset\mathbb{R}^k$, f is an extended real-valued lower semicontinuous function, and g is a locally Lipschitz mapping (not necessarily differentiable). For this general problem, Rockafellar established estimates for the Clarke subdifferential of the value function in terms of Lagrange multipliers vectors that satisfy necessary conditions for (O_u) in terms of Clarke subdifferentials. He also proved that the already-known bounds on Dini derivatives of the value function follow from his subgradient estimates, without the restrictions on (O_u), which were often made in the past. All the results of Rockafellar in these papers are strongly related to the notion of proximal subgradients that he introduced in [28] and the exact formula giving the Clarke subdifferential of a function in terms of its limiting proximal subgradients in finite dimension. Let us note that Clarke [7] also furnished other proofs of estimates of subdifferentials of some general value functions in finite dimension by using the expression of the Clarke normal cones in terms of limiting perpendicular vectors in finite dimension and that with Clarke [7] and Clarke and Loewen [8], a great deal of progress has also been made in perturbed optimal control problems.

The present paper studies the Clarke subdifferential of the optimal value function of a general perturbed problem with a constraint defined by a multifunction:

$$m(u)=\min_x\{f(x,u): u\in M(x), x\in A\}.$$

* Received by the editors December 7, 1988; accepted for publication (in revised form) August 10, 1990.

In fact, we are interested in finding estimates for the Clarke subdifferential $\partial m(u)$ of m in terms of the coderivative of M (and the subdifferential of Δ_M, where $\Delta_M(x, y) = d(y, M(x))$) and the subdifferential of f, on the one hand, and mainly (whenever M takes convex values) in terms of the subdifferential of f and the subdifferential of the support function of M, on the other hand. To this end we follow the work begun by Rockafellar [31]. The nice result of Treiman [34], [35], giving an exact expression of the Clarke subdifferential in terms of limiting ε-Fréchet subgradients, and the general and no less deep calculus rules established by Kruger [20] and Kruger and Mordukhovich [21] for the generalized differentials introduced in [21], allow us to work in the context of Banach spaces admitting an equivalent norm that is Fréchet differentiable off zero (for example, any reflexive Banach space). By this method, at the same time we obtain estimates for the subdifferential $\delta m(u)$ in the sense of Kruger and Mordukhovich.

Sections 1 and 2 are devoted to recalling and to establishing some results that will be used throughout the paper. In § § 3 and 4 we give estimates for the Kruger-Mordukhovich subdifferentials and singular subdifferentials of m in terms of the subdifferential of f and the coderivative of M. By the result of Treiman estimates of the Clarke subdifferential of m can easily be derived. The particular and important case where M takes convex values is considered in the last section. Following Clarke [6], [7] we prove, for unperturbed problems with constraints defined by convex-valued multifunctions, first-order necessary optimality conditions (complementary to those of Dien [10], [11]) in terms of the subdifferentials of the support functions of these multifunctions. Then we give estimates for the subdifferential of m in terms of the subdifferentials of f and the support function of M.

Before closing this Introduction, let us indicate that two extensive lists of references on directional derivatives or subdifferentials of optimal value functions can be found in [7] and [29].

1. Distance function associated with a multifunction. Let M be a multifunction from a metric space E into a metric space F. We consider the function Δ_M defined on $E \times F$ by

$$\Delta_M(x, y) = d(y, M(x)),$$

where the right term is $-\infty$ whenever $M(x) = \varnothing$. As several estimates in this paper will be given in terms of subdifferentials of Δ_M, we show in this section the importance of this function in Clarke subdifferential theory.

Obviously,

$$d((x, y), GrM) \leqq \Delta_M(x, y) \quad \text{for all } (x, y) \in E \times F,$$

where $GrM = \{(x, y) \in E \times F : y \in M(x)\}$ and the distance on $E \times F$ is defined by

$$d((x, y), (x', y')) = (d(x, x')^2 + d(y, y')^2)^{1/2}.$$

In order to give a type of reverse inequality, let us recall the notion of pseudo-Lipschitz multifunction (see Aubin and Ekeland [1], [2]).

DEFINITION 1.1. Let $l \geqq 0$. M is said to be *l-pseudo-Lipschitz at* $(\bar{x}, \bar{y}) \in GrM$ if there are $X \in \mathcal{N}(\bar{x})$, $Y \in \mathcal{N}(\bar{y})$, such that

$$(1.1) \qquad Y \cap M(x) \subset \bigcup_{y \in M(x')} B(y, l d(x, x')) \quad \text{for all } x, x' \in X$$

(here $\mathcal{N}(\bar{x})$ denotes the filter of neighbourhoods of $\bar{x}$).

Remark. Rockafellar [32] has proved that M is l-pseudo-Lipschitz at $(\bar{x}, \bar{y})$ if and only if there are $X \in \mathcal{N}(\bar{x})$ and $Y \in \mathcal{N}(\bar{y})$ such that

$$(1.2) \qquad d(y, M(x)) \leqq d(y', M(x')) + d(y, y') + ld(x, x')$$

for all $(x, y), (x', y') \in (X \times Y)$.

The following result has already been obtained by Clarke [5] for Lipschitz multifunctions. Here we extend it to pseudo-Lipschitz multifunctions. Throughout the paper $B(x, r)$ will be the closed ball centered at x.

PROPOSITION 1.2. *If M is l-pseudo-Lipschitz at $(\bar{x}, \bar{y}) \in GrM$, then there exist $X \in \mathcal{N}(\bar{x})$, $Y \in N(\bar{y})$ such that*

$$\Delta_M(x, y) \leqq Kd((x, y), GrM) \quad \textit{for all } (x, y) \in X \times Y,$$

where $K = 2 \max(1, l)$.

Proof. Choose $\varepsilon > 0$ such that $B((\bar{x}, \bar{y}), 3\varepsilon) \subset X \times Y$, where X and Y are given by (1.2). Fix $(x, y) \in B((\bar{x}, \bar{y}), \varepsilon)$. For any $(x', y') \in E \times F$ with $d((x', y'), (\bar{x}, \bar{y})) > 3\varepsilon$ we have

$$\begin{aligned} d((x, y), (x', y')) &\geqq d((\bar{x}, \bar{y}), (x', y')) - d((\bar{x}, \bar{y}), (x, y)) \\ &\geqq 3\varepsilon - d((\bar{x}, \bar{y}), (x, y)) \\ &\geqq \varepsilon + d((x, y), (\bar{x}, \bar{y})) \geqq \varepsilon + d((x, y), GrM). \end{aligned}$$

So we have

$$d((x, y), GrM) = \inf \{(d((x, y), (x', y')) \colon (x', y') \in B((\bar{x}, \bar{y}), 3\varepsilon) \cap GrM\}.$$

But for any $(x', y') \in B((\bar{x}, \bar{y}), 3\varepsilon) \cap GrM$

$$\begin{aligned} d(y, M(x)) &\leqq d(y, M(x')) + ld(x, x') \\ &\leqq d(y, y') + ld(x, x') \\ &\leqq Kd((x, y), (x', y')), \end{aligned}$$

where $K = 2 \max(1, l)$ and hence

$$\Delta_M(x, y) \leqq Kd((x, y), GrM). \qquad \square$$

In the sequel E and F will be two real *normed vector spaces.* Let f be a function from E into $\mathbb{R} \cup \{-\infty, +\infty\}$ with $|f(\bar{x})| < \infty$. The generalized directional derivative $f^{\uparrow}(\bar{x}; \cdot)$ is defined (see Rockafellar [27]) by

$$\begin{aligned} f^{\uparrow}(\bar{x}; h) &= \limsup_{\substack{(x,\alpha)\downarrow_f \bar{x} \\ t \downarrow 0}} \inf_{h' \to h} t^{-1}[f(x + th') - \alpha] \\ &:= \sup_{H \in \mathcal{N}(h)} \left[\limsup_{\substack{(x,\alpha)\downarrow_f \bar{x} \\ t \downarrow 0}} \left(\inf_{h' \in H} t^{-1}(f(x + th') - \alpha) \right) \right] \end{aligned}$$

and the directional hyperderivative $f^0(\bar{x}; \cdot)$ by

$$f^0(\bar{x}; h) = \limsup_{\substack{(x,\alpha)\downarrow_f \bar{x} \\ t \downarrow 0}} t^{-1}[f(x + th) - \alpha],$$

where $(x, \alpha)\downarrow_f \bar{x}$ means

$$(x, \alpha) \in \operatorname{epi} f := \{(z, \beta) \in E \times \mathbb{R} \colon f(x) \leqq \beta\} \quad \text{and} \quad (x, \alpha) \to (\bar{x}, f(\bar{x})).$$

If f is Lipschitz around $\bar{x}$, then

$$f^{\uparrow}(\bar{x}; h) = f^0(\bar{x}; h) = \limsup_{\substack{x \to \bar{x} \\ t \downarrow 0}} t^{-1}[f(x+th) - f(x)].$$

Using a technique inspired by a method introduced by Hiriart-Urruty in [16] we have Proposition 1.3.

PROPOSITION 1.3. *Let M be any multifunction from E into F with $(\bar{x}, \bar{y}) \in GrM$. Then for all $(h, k) \in E \times F$*

$$\Delta_M^{\uparrow}(\bar{x}, \bar{y}; h, k) = \limsup_{\substack{(x,y) \xrightarrow[t \downarrow 0]{M} (\bar{x},\bar{y})}} \inf_{(h',k') \to (h,k)} t^{-1}[\Delta_M(x+th', y+tk')]$$

and

$$\Delta_M^0(\bar{x}, \bar{y}; h, k) = \limsup_{\substack{(x,y) \xrightarrow[t \downarrow 0]{M} (\bar{x},\bar{y})}} t^{-1}[\Delta_M(x+th, y+tk)],$$

where $(x, y) \xrightarrow{M} (\bar{x}, \bar{y})$ means $(x, y) \in GrM$ and $(x, y) \to (\bar{x}, \bar{y})$.

Proof. We only show the first equality (the second one is obtained with $H \times K = \{(h, k)\}$ in the proof below). It is enough to prove that the left-hand side of this equality is not greater than the other one (which we denote by β) since the reverse inequality is obviously true. Consider $\gamma > 0$ and $H \times K \in \mathcal{N}(h, k)$. There exists $X \times Y' \in N(\bar{x}, \bar{y})$, $\varepsilon' \in]0, 1[$ such that for all $t \in]0, \varepsilon'[$, $(x, y) \in (X \times Y') \cap GrM$ there is $(h', k') \in H \times K$ with (we suppose $\beta < +\infty$)

$$(1.3) \qquad t^{-1}\Delta_M(x+th', y+tk') < \beta + \gamma.$$

Choose $\varepsilon \in]0, \min(\varepsilon', \gamma)[$ and $Y \in \mathcal{N}(\bar{y})$ such that $Y + B(0, 2\varepsilon) \subset Y'$ and fix any $t \in]0, \varepsilon[$ and any $(x, y, \alpha) \in \operatorname{epi} \Delta_M \cap X \times Y \times]-\varepsilon, \varepsilon[$. As $\alpha \geqq \Delta_M(x, y) = d(y, M(x))$ we have $M(x) \neq \emptyset$ and hence we can choose $y' \in M(x)$

$$\|y - y'\| < t^2 + d(y, M(x)) < \varepsilon^2 + \alpha < 2\varepsilon,$$

and hence $y' \in y + B(0, 2\varepsilon) \subset Y'$, which ensures that $(x, y') \in (X \times Y') \cap GrM$. Therefore by (1.3) there exists $(h', k') \in H \times K$ such that

$$\begin{aligned} \beta + 2\gamma &> t^{-1}[\Delta_M(x+th', y'+tk')] + t \\ &\geqq t^{-1}[\Delta_M(x+th', y'+tk') + \|y - y'\| - \Delta_M(x, y)] \\ &\geqq t^{-1}[\Delta_M(x+th', y+tk') - \alpha], \end{aligned}$$

which proves that

$$\beta \geqq \Delta_M^{\uparrow}(\bar{x}, \bar{y}; h, k). \qquad \square$$

The function Δ_M has been sucessfully used by Clarke [5], [7] for Lipschitz multifunctions in optimal control theory. The following corollary makes clear that Δ_M can also be a powerful tool in optimization theory even for M not necessarily Lipschitz.

Before stating this corollary let us recall that the Clarke tangent cone $T(A; \bar{x})$ to a subset $A \subset E$ at a point $\bar{x} \in A$ is the set of all vectors $h \in E$ such that for all $x_n \xrightarrow{A} \bar{x}$, $t_n \downarrow 0$ there exists $h_n \to h$ in E with $x_n + t_n h_n \in A$ for all n. We know (see [7] and [27]) that

$$d_A^0(\bar{x}; h) = 0 \Leftrightarrow h \in T(A; \bar{x}) \Leftrightarrow \psi_A^{\uparrow}(\bar{x}; h) = 0,$$

where $d_A(x) := d(x, A)$ and $\psi_A(x) = 0$ if $x \in A$ and $+\infty$ otherwise.

The polar cone $N(A;\bar{x})$ of $T(A;\bar{x})$ is called the normal cone. We have $N(A;\bar{x})=\partial\psi_A(\bar{x})$, where for $f: E\to\mathbb{R}\cup\{-\infty,+\infty\}$ with $|f(\bar{x})|<\infty$ $\partial f(\bar{x})$ denotes the Clarke generalized gradient of f at $\bar{x}$ given by

$$\partial f(\bar{x})=\{y^*\in E^*: \langle y^*, h\rangle\leqq f^\uparrow(\bar{x};h)\forall hE\}.$$

COROLLARY 1.4. *Let M be any multifunction from E into F with $(\bar{x},\bar{y})\in GrM$. Then*:

(i) $d^0_{GrM}(\bar{x},\bar{y};h,k)\leqq\Delta^\uparrow_M(\bar{x},\bar{y};h,k)\leqq\psi^\uparrow_{GrM}(\bar{x},\bar{y};h,k)$;

(ii) $\partial d_{GrM}(\bar{x},\bar{y})\subset\partial\Delta_M(\bar{x},\bar{y})\subset N(GrM;\bar{x},\bar{y})$;

(iii) *If M is pseudo-Lipschitz at $(\bar{x},\bar{y})$ then $\Delta^\uparrow(\bar{x},\bar{y};h,k)=\Delta^0(\bar{x},\bar{y};h,k)\leqq 2K\,d^0_{GrM}(\bar{x},\bar{y};h,k)$, where K is the constant given by Proposition* 1.2.

Proof. We know (by what precedes with $M'(x,y)=GrM$, $E'=E\times F$ and $F'=E\times F$) that

$$d^0_{GrM}(\bar{x},\bar{y};h,k)=\limsup_{(x,y)\xrightarrow[t\downarrow 0]{M}(\bar{x},\bar{y})} t^{-1}\,d_{GrM}(x+th,y+tk),$$

and we easily see that

$$d_{GrM}(x,y)\leqq\Delta_M(x,y)\leqq\psi_{GrM}(x,y).$$

So the results are direct consequences of Propositions 1.3 and 1.2. □

We close this section by recalling a result of Clarke on distance functions that will be often used in the sequel of this paper.

PROPOSITION 1.5 (Clarke [7]). *Let $f: E\to\mathbb{R}$ be a function that is k-Lipschitz around $\bar{x}$. Assume that $\bar{x}$ gives a local minimum of f relative to a subset A of the metric space E. Then $\bar{x}$ gives a local unconstrained minimum of $f+kd_A$ (where $d_A(x)=d(x,A)$).*

2. Subdifferentials and singular subdifferentials.

Throughout this section E will be a *Banach space*.

The important notion of ε-Fréchet subgradient will be crucial in the sequel (see [20], [21], [34], and [35]). An element $x^*\in E^*$ is said to be an *F_ε-subgradient* to an extended real-valued function $f: E\to\bar{\mathbb{R}}:=\mathbb{R}\cup\{-\infty,+\infty\}$ at a point $\bar{x}$ where $|f(\bar{x})|<\infty$ if there exists a neighbourhood X of $\bar{x}$ such that

$$\langle x^*, x-\bar{x}\rangle\leqq f(x)-f(\bar{x})+\varepsilon\|x-\bar{x}\|\quad\text{for every } x\in X;$$

equivalently $\bar{x}$ gives a local minimum of the function

$$x\to f(x)-\langle x^*, x-\bar{x}\rangle+\varepsilon\|x-\bar{x}\|.$$

Let $\delta_\varepsilon f(\bar{x})$ the set of all F_ε-subgradients to f at $\bar{x}$.

The *subdifferential in the sense of Kruger-Mordukhovich* [20], [21] is the set $\delta f(\bar{x})$ of all $x^*\in E^*$ for which there exist $\varepsilon_n\downarrow 0$, $x_n\to\bar{x}$ with $f(x_n)\to f(\bar{x})$, $x^*_n\in\delta_{\varepsilon_n}f(\bar{x})$ with $x^*_n\xrightarrow{w^*}x^*$.

The singular subdifferential (see Treiman [34], [35]) associated with $\delta f(\bar{x})$ is the set $\delta^\infty f(\bar{x})$ of all $x^*\in F^*$ for which there exist $\varepsilon_n\downarrow 0$, $s_n\downarrow 0$, $x_n\to\bar{x}$ with $f(x_n)\to f(\bar{x})$, $x^*_n\in\delta_{\varepsilon_n}(s_nf)(x_n)$ with $x^*_n\xrightarrow{w^*}x^*$.

If A is a subset of E and $x\in A$, $\mathcal{N}(A,x)=\delta\Psi_A(x)$ is the Kruger-Mordukhovich normal cone to A at x.

The following deep result is due to Treiman [34], [35].

PROPOSITION 2.1. [34], [35]. *If E admits an equivalent norm that is Fréchet-differentiable off zero and f is lower semicontinuous, then*

$$\partial f(\bar{x})=\text{cl co}\,[\delta f(\bar{x})+\delta^\infty f(\bar{x})]$$

with the convention $\varnothing+A=\varnothing$.

Let us recall (Kruger [20]) a formula that gives an upper estimate of $\delta(f+g)$ in terms of δf and δg. Here we state Kruger's result in its less general form.

PROPOSITION 2.2. [20]. *Assume that $f: E \to \bar{\mathbb{R}}$ is lower semicontinuous with $|f(\bar{x})| < \infty$ and that $g: E \to \bar{\mathbb{R}}$ is locally Lipschitz around $\bar{x}$. If E admits an equivalent norm that is Fréchet differentiable off zero then*

$$\delta(f+g)(\bar{x}) \subset \delta f(\bar{x}) + \delta g(\bar{x}).$$

The following result will be needed in the search of estimates of subdifferentials of optimal value functions.

PROPOSITION 2.3. *Let f and g be two functions from E into $\bar{\mathbb{R}}$ with $|f(\bar{x})| < \infty$ and $|g(\bar{x})| < \infty$. If g is locally Lipschitz around $\bar{x}$, then*

$$\delta^{\infty}(f+g)(\bar{x}) = \delta^{\infty} f(\bar{x}).$$

Proof. Let $x^* \in \delta^{\infty}(f+g)(\bar{x})$. There exist $x_n \to \bar{x}$ with $(f+g)(x_n) \to (f+g)(\bar{x})$, $\varepsilon_n \downarrow 0$, $s_n \downarrow 0$ and $x_n^* \xrightarrow{w^*} x^*$ such that $x_n^* \in \delta_{\varepsilon_n}(s_n f + s_n g)(x_n)$. Consider an open neighbourhood X of $\bar{x}$ over which g is Lipschitz and denote by k a Lipschitz constant. We may assume that all $x_n \in X$. Choose for each $n \in \mathbb{N}$ a neighbourhood $X_n \subset X$ of x_n with

$$\langle x_n^*, x - x_n \rangle \leqq s_n(f+g)(x) - s_n(f+g)(x_n) + \varepsilon_n \|x - x_n\| \quad \text{for all } x \in X_n.$$

By Lipschitz continuity of g we have

$$\langle x_n^*, x - x_n \rangle \leqq s_n f(x) - s_n f(x_n) + \eta_n \|x - x_n\| \quad \text{for all } x \in X_n,$$

where $\eta_n := (\varepsilon_n + k s_n) \downarrow 0$. So $x_n^* \in \delta_{\eta_n} f(x_n)$ and $f(x_n) \to f(\bar{x})$ since $g(x_n) \to g(\bar{x})$ and this implies $x^* \in \delta^{\infty} f(\bar{x})$. Therefore we have

$$\delta^{\infty}(f+g)(\bar{x}) \subset \delta^{\infty} f(\bar{x}). \tag{2.1}$$

Writing $f = (f+g) + (-g)$ we also have by Lipschitz continuity of $(-g)$ and by relation (2.1),

$$\delta^{\infty} f(\bar{x}) \subset \delta^{\infty}(f+g)(\bar{x}),$$

and the proof is complete. □

COROLLARY 2.4. *Let $g: E \to \bar{\mathbb{R}}$ be locally Lipschitz around $\bar{x}$. Then*

$$\delta^{\infty} g(\bar{x}) = \{0\}.$$

Proof. It suffices to write $g = 0 + g$. □

In the same vein we have the following result.

PROPOSITION 2.5. *Let f and g be two functions from E into $\bar{\mathbb{R}}$ with $|f(\bar{x})| < \infty$ and $|g(\bar{x})| < \infty$. Assume that g is locally Lipschitz around $\bar{x}$. Then if $x_n \to \bar{x}$ with $f(x_n) \to f(\bar{x})$, $\varepsilon_n \downarrow 0$, $s_n \downarrow 0$, $x_n^* \xrightarrow{w^*} x^*$, $x_n^* \in \delta_{\varepsilon_n}(f + s_n g)(x_n)$, then*

$$x^* \in \delta f(\bar{x}).$$

Proof. For x in some neighbourhood X_n of x_n we have

$$\begin{aligned} \langle x_n^*, x - x_n \rangle &\leqq f(x) - f(x_n) + s_n(g(x) - g(x_n)) + \varepsilon_n \|x - x_n\| \\ &\leqq f(x) - f(x_n) + \eta_n \|x - x_n\|, \end{aligned}$$

where $\eta_n := (\varepsilon_n + k s_n) \downarrow 0$ and k is a Lipschitz constant for g around the point $\bar{x}$. Then $x_n^* \in \delta_{\eta_n} f(x_n)$ and hence $x^* \in \delta f(\bar{x})$. □

We need to consider the *Clarke singular generalized gradient* $\partial^\infty f(\bar{x})$, which is the set of all $x^* \in E^*$ for which there exist $s_n \downarrow 0$, $x_n \to x$ with $f(x_n) \to f(\bar{x})$, $x_n^* \in s_n\, \partial f(x_n)$ with $x_n^* \xrightarrow{w^*} x^*$. (Recall that the set of points $(x, f(x))$ where $\partial f(x) \neq \varnothing$ is dense in $Gr(f)$ whenever f is lower semicontinuous; see McLinden [22].)

PROPOSITION 2.6. $\partial^\infty f(\bar{x}) \subset \partial^\infty f(\bar{x})$.

Proof. Let $x^* \in \delta^\infty f(\bar{x})$. There exist $\varepsilon_n \downarrow 0$, $s_n \downarrow 0$, $x_n \to \bar{x}$ with $f(x_n) \to f(\bar{x})$, $x_n^* \in \delta_{\varepsilon_n} s_n f(x_n)$ with $x_n^* \xrightarrow{w^*} x^*$. Using the definition of $\delta_{\varepsilon_n} f(x_n)$ it is not difficult to see that

$$\langle x_n^*, h\rangle \leqq s_n f^\uparrow(x_n; h) + \varepsilon_n \|h\| \quad \text{for all } h \in E,$$

and hence by subdifferential calculus (see [27]) we have

$$x_n^* \in s_n\, \partial f(x_n) + \varepsilon_n B^*,$$

where B^* is the closed unit ball with center zero of E^*. So we can conclude that $x^* \in \partial^\infty f(\bar{x})$. □

Let us show that Δ_M also allows us to describe $\mathcal{N}(M; \bar{x}, \bar{y})$.

PROPOSITION 2.7. *Let F be a Banach space, $M: E \rightrightarrows F$ a multifunction with closed graph, and $(\bar{x}, \bar{y}) \in GrM$. Then*

$$\mathcal{N}(M; \bar{x}, \bar{y}) = \bigcup_{s \geqq 0} s\delta\Delta_M(\bar{x}, \bar{y}).$$

Proof. (i) Let $(x^*, y^*) \in \delta\Delta_M(\bar{x}, \bar{y})$. There exist $(x_n^*, y_n^*) \xrightarrow{w^*} (x^*, y^*)$, $(x_n, y_n) \xrightarrow{\Delta_M} (\bar{x}, \bar{y})$, $\varepsilon_n \downarrow 0$ and $\rho_n > 0$ such that

$$\langle x_n^*, v\rangle + \langle y_n^*, w\rangle \leqq \Delta_M(x_n + v, y_n + w) - \Delta_M(x_n, y_n) + \varepsilon_n(\|v\| + \|w\|)$$

for each (v, w) with $\|v\| + \|w\| \leqq \rho_n$. We may suppose $y_n \notin M(x_n)$ since otherwise the proof is finished. Choose $r_n > 0$ with $r_n^2 < \min(\rho_n^2, (1/n)\Delta_M(x_n, y_n))$. There exist $s_n \downarrow 1$ such that $(s_n - 1)\Delta_M(x_n, y_n) < r_n^2$. If we choose $y_n' \in M(x_n)$ satisfying $\|y_n - y_n'\| \leqq s_n \Delta_M(x_n, y_n)$ we get

$$\begin{aligned}\langle x_n^*, v\rangle + \langle y_n^*, w\rangle &\leqq \Delta_M(x_n + v, y_n + w) - s_n^{-1}\|y_n - y_n'\| + \varepsilon_n(\|v\| + \|w\|)\\ &\leqq \Delta_M(x_n + v, y_n' + w) + (1 - s_n^{-1})\|y_n - y_n'\| + \varepsilon_n(\|v\| + \|w\|)\end{aligned}$$

for all v, w with $\|v\| + \|w\| \leqq \rho_n$. Then for all $(x, y) \in M \cap B((x_n, y_n'), \rho_n)$ we have

$$\langle x_n^*, x - x_n\rangle + \langle y_n^*, y - y_n'\rangle \leqq (1 - s_n^{-1})\|y_n - y_n'\| + \varepsilon_n(\|x - x_n\| + \|y - y_n'\|),$$

and hence for $\gamma_n^2 := (1 - s_n^{-1})\|y_n - y_n'\|$ we get

$$0 \leqq \langle -x_n^*, x - x_n\rangle + \langle -y_n^*, y - y_n'\rangle + \varepsilon_n(\|x - x_n\| + \|y - y_n'\|) + \gamma_n^2.$$

By the Ekeland variational principle [2] there exist $(x_n'', y_n'') \in M \cap B((x_n, y_n'), \rho_n)$ satisfying $\|x_n'' - x_n\| + \|y_n'' - y_n'\| \leqq \gamma_n$ and such that for $(x, y) \in M \cap B((x_n, y_n'), \rho_n)$

$$\begin{aligned}\langle -x_n^*, x_n'' - x_n\rangle + \langle -y_n^*, y_n'' - y_n'\rangle + \varepsilon_n(\|x_n'' - x_n\| + \|y_n'' - y_n'\|) &\leqq \langle -x_n^*, x - x_n\rangle\\ &\quad + \langle -y_n^*, y - y_n'\rangle + \varepsilon_n(\|x - x_n\| + \|y - y_n'\|)\\ &\quad + \gamma_n(\|x - x_n''\| + \|y - y_n''\|),\end{aligned}$$

and hence

$$\langle x_n^*, x - x_n''\rangle + \langle y_n^*, y - y_n''\rangle \leqq (\varepsilon_n + \gamma_n)(\|x - x_n''\| + \|y - y_n''\|). \tag{2.2}$$

As $\gamma_n^2 = (1 - s_n^{-1})\|y_n - y_n'\| \leqq s_n(1 - s_n^{-1})\Delta_M(x_n, y_n) < r_n^2$ we have $\alpha_n := r_n - \gamma_n > 0$. Moreover,

$$\|x - x_n''\| + \|y - y_n''\| \leqq \alpha_n \Rightarrow \|x - x_n\| + \|y - y_n'\| \leqq \|x - x_n''\| + \|y - y_n''\| + \gamma_n \leqq r_n \leqq \rho_n.$$

Therefore for all $(x,y)\in M\cap B((x''_n,y''_n),\alpha_n)$ we have by (2.2)

$$\langle x^*_n, x-x''_n\rangle+\langle y^*_n, y-y''_n\rangle\leqq(\varepsilon_n+\gamma_n)(\|x-x''_n\|+\|y-y''_n\|),$$

and hence $(x^*_n,y^*_n)\in\delta_{\varepsilon_n+\gamma_n}\psi_M(x''_n,y''_n)$. So $(x^*,y^*)\in\delta\psi_M(\bar{x},\bar{y})=\mathcal{N}(M;\bar{x},\bar{y})$.

(ii) Consider now $(x^*,y^*)\in\mathcal{N}(M;\bar{x},\bar{y})$. Choose $(x^*_n,y^*_n)\xrightarrow{w^*}(x^*,y^*)$, $(x_n,y_n)\xrightarrow{M}(\bar{x},\bar{y})$, $\varepsilon_n\downarrow 0$ and $r_n>0$ such that

$$\langle x^*_n, x-x_n\rangle+\langle y^*_n, y-y_n\rangle\leqq\varepsilon_n(\|x-x_n\|+\|y-y_n\|)$$

for every $(x,y)\in M\cap B((x_n,y_n),3r_n)$. Choose $k>0$ with $\|x^*_n\|+\|y^*_n\|\leqq k$ and $\varepsilon_n\leqq k$ for all $n\in\mathbb{N}$. By Proposition 1.5 for $B_n:=B((x_n,y_n),3r_n)$ we have

$$\langle x^*_n, x-x_n\rangle+\langle y^*_n, y-y_n\rangle\leqq 2kd((x,y),M\cap B_n)+\varepsilon_n(\|x-x_n\|+\|y-y_n\|)$$

for every $(x,y)\in B_n$ and hence

$$\langle x^*_n, x-x_n\rangle+\langle y^*_n, y-y_n\rangle\leqq 2k\Delta_M(x,y)+\varepsilon_n(\|x-x_n\|+\|y-y_n\|)$$

for every $(x,y)\in B((x_n,y_n),r_n)$. Therefore $(x^*_n,y^*_n)\in 2k\delta_{\varepsilon' n}\Delta_M(x_n,y_n)$ with $\varepsilon'_n=(2k)^{-1}\varepsilon_n$, which ensures that $(x^*,y^*)\in 2k\delta\Delta_M(\bar{x},\bar{y})$. So the proof is complete. □

3. Subdifferentials of optimal value functions. Let $f:E\times F\to\bar{\mathbb{R}}$ be lower semicontinuous and let C be a closed subset of $E\times F$ where E and F are two Banach spaces. We consider the perturbed problem $\mathcal{P}_u$, which consists in minimizing for u the function $f(\cdot,u)$ over all x satisfying $(x,u)\in C$, and we define the function $m:F\to\bar{\mathbb{R}}$ and the multifunction $S:F\rightrightarrows E$ by

$$m(u)=\inf_{x\in C_u}f(x,u)\quad\text{and}\quad S(u)=\{x\in C_u : m(u)=f(x,u\},$$

where $C_u=\{x\in E\colon (x,u)\in C\}$.

We say that the family of problems $\mathcal{P}_u$ satisfies *condition* (K) at $\bar{u}$ if m is lower semicontinuous around $\bar{u}$ with $m(\bar{u})$ finite, S takes nonempty values on some neighbourhood of $\bar{u}$, and for every sequence $(\varepsilon_n,u_n)\to(0_+,\bar{u})$ with $m(u_n)\to m(\bar{u})$ and $\delta_{\varepsilon_n}(u_n)\neq\emptyset$ there exist some sequence $(x_n)_n$ admitting a cluster point and such that $x_n\in S(u_n)$ for n sufficiently large.

Note that such a cluster point necessarily belongs to $S(\bar{u})$.

General assumptions ensuring condition (K) can be found in [7], [13], [29], and [31]. Condition (K) is, for example, satisfied whenever the projection of C on E is compact or whenever the multifunction S admits a local selection that is continuous at $\bar{u}$. It also holds if there is a mapping $h:F\to E$ continuous at $\bar{u}$ and a compact $H\subset E$ such that $C_u\subset h(u)+H$ for u near $\bar{u}$.

All the results in the rest of the paper will justify, each in its own situation, the intuitively clear fact: for f convex in both variables $u^*\in\partial m(\bar{u})$, $m(u)=\inf_x f(x,u)$ and $m(\bar{u})=f(\bar{x},\bar{u})$ we have $(0,u^*)\in\partial f(\bar{x},\bar{u})$.

In the same vein it is also clear that for $u^*\in\delta_\varepsilon m(\bar{u})$ we have $(0,u^*)\in\delta_\varepsilon f(\bar{x},\bar{u})$. This illustrates how the Kruger–Mordukhovich subdifferential can be useful in obtaining estimates of subdifferentials of optimal value functions.

Our aim in this section and the following ones is to give estimates for the Clarke subdifferential of m. In light of the important result of Treiman recalled in Proposition 2.1 it will be enough to establish estimates for $\delta m(\bar{u})$ and $\delta^\infty m(\bar{u})$.

Throughout this section (because of Propositions 2.1 and 2.2) we assume that E and F admit *equivalent norms that are Fréchet-differentiable* off zero. By [15] the closed balls of E^* and F^* are w^*-sequentially compact.

PROPOSITION 3.1. *Let $f: E \times F \to \mathbb{R}$ be locally Lipschitz, let $M: E \rightrightarrows F$ be a multifunction with closed graph, and let A be a closed subset of E. Let*

$$m(u) = \inf_x f(x, u)\colon u \in M(x), x \in A\}.$$

Assume that condition (K) is satisfied at $\bar{u}$ and that M is pseudo-Lipschitz at each point in $S(\bar{u}) \times \{\bar{u}\}$. Then:

(i) *For each $u^* \in \delta m(\bar{u})$ there exist $\bar{x} \in S(\bar{u})$ and $\lambda > 0$ such that $(0, u^*) \in \delta(f + \lambda\Delta_M + \lambda d_{A\times F})(\bar{x}, \bar{u}) \subset \delta f(\bar{x}, \bar{u}) + \lambda\delta\Delta_M(\bar{x}, \bar{u}) + \lambda\delta d_A(\bar{x}) \times \{0\}$;*

(ii) *For each $u^* \in \delta^\infty m(\bar{u})$ there exist $\bar{x} \in S(\bar{u})$ and $\gamma > 0$ such that $(0, u^*) \in \gamma\delta(\Delta_M + d_{A\times F})(\bar{x}, \bar{u}) \subset \gamma\delta\Delta_M(\bar{x}, \bar{u}) + \gamma\delta_A(\bar{x}) \times \{0\}$.*

Proof. (i) Let $u^* \in \delta m(\bar{u})$. There exist $\varepsilon_n \downarrow 0$, $u_n \to \bar{u}$ with $m(u_n) \to m(\bar{u})$, $u_n^* \xrightarrow{w^*} u^*$ such that the function

$$u \to m(u) - \langle u_n^*, u - u_n\rangle + \varepsilon_n \|u - u_n\|$$

attains a local minimum at u_n. By assumption (K) we may suppose that there exists $x_n \in S(u_n)$ with (x_n) converging to some $\bar{x} \in S(\bar{u})$. Then if we consider the multifunction T defined by $T(x) = M(x)$ if $x \in A$ and $T(x) = \emptyset$ otherwise, we have for every $(x, u) \in GrT$ and u near u_n

$$\begin{aligned} -\langle u_n^*, u_n\rangle + f(x_n, u_n) &\leqq \varepsilon_n \|u - u_n\| - \langle u_n^*, u\rangle + m(u) \\ &\leqq \varepsilon_n \|u - u_n\| - \langle u_n^*, u\rangle + f(x, u). \end{aligned}$$

Therefore for n sufficiently large, by Proposition 1.5, (x_n, u_n) gives a local minimum of the function

$$(x, u) \to \varepsilon_n \|u - u_n\| - \langle u_n^*, u\rangle + f(x, u) + (\varepsilon_n + k + \|u_n^*\|) d(x, u; GrT),$$

where k is a Lipschitz constant for f around $(\bar{x}, \bar{u})$ and hence (x_n, u_n) also gives a local minimum relative to $A \times F$ for the function

$$(x, u) \to \varepsilon_n \|u - u_n\| - \langle u_n^*, u\rangle + f(x, u) + (\varepsilon_n + k + \|u_n^*\|)\Delta_M(x, u).$$

Denoting by l a pseudo-Lipschitz constant for M around $(\bar{x}, \bar{u})$ we obtain that (x_n, u_n) gives a local minimum of the function

$$\begin{aligned} (x, u) \to \varepsilon_n \|u - u_n\| - \langle u_n^*, u\rangle + f(x, u) + (\varepsilon_n + \|u_n^*\| + k)\Delta_M(x, u) \\ + 3(1 + l)(\varepsilon_n + \|u_n^*\| + k) d_A(x). \end{aligned}$$

Choose a real number $\lambda \geqq 3(1 + l) \sup_n (\varepsilon_n + \|u_n^*\| + k)$. Then

$$(0, u_n^*) \in \delta_{\varepsilon_n}(f + \lambda\Delta_M + \lambda d_{A\times F})(x_n, u_n) \tag{3.1}$$

and, as $(f + \lambda\Delta_M + \lambda d_{A\times F})(x_n, u_n) \to (f + \lambda\Delta_M + \lambda d_{A\times F})(\bar{x}, \bar{u})$, this yields

$$(0, u^*) \in \delta(f + \lambda\Delta_M + \lambda d_{A\times F})(\bar{x}, \bar{u}) \subset \delta f(\bar{x}, \bar{u}) + \lambda\delta\Delta_M(\bar{x}, \bar{u}) + \lambda\delta d_A(\bar{x}) \times \{0\}.$$

(ii) As in part (i) for some $s_n \downarrow 0$ and $\gamma \geqq 3(1 + l) \sup_n (\varepsilon_n + \|u_n^*\| + s_n k)$ the function

$$(x, u) \to \varepsilon_n \|u - u_n\| - \langle u_n^*, u\rangle + s_n f(x, u) + \gamma\Delta_M(x, u) + \gamma d_{A\times F}(x, u)$$

attains a local minimum at (x_n, u_n) and hence

$$(0, u_n^*) \in \delta_{\varepsilon_n}(s_n f + \gamma\Delta_M + \gamma d_{A\times F})(x_n, u_n).$$

Proposition 2.5 ensures that

$$(0, u^*) \in \gamma\delta(\Delta_M + d_{A\times F})(\bar{x}, \bar{u}) \subset \gamma\delta\Delta_M(\bar{x}, \bar{u}) + \gamma\delta d_A(\bar{x}) \times \{0\},$$

which completes the proof. □

Remark. By (3.1) we see that it is enough to require instead of condition (K) the convergence of $(x_n)_n$ to some $\bar{x}$ with respect to some topology for which we can pass to the limit in (3.1). This condition holds in the perturbed control problems considered by Clarke [7] and Clarke and Loewen [8]. Also, for

$$m(u)=\inf_x\{(f(Jx)\colon u\in M(x), J_0(x)\in A_0\}$$

whenever M is a convex multifunction, A_0 is a subset of some finite-dimensional space X_0, J and J_0 are two continuous surjective linear mappings from X into the finite-dimensional spaces X' and X_0, respectively, and the projection of $\{(x, u)\colon u\in M(x), J_0(x)\in A_0\}$ on X is weakly compact.

If M is a multifunction from E into F with $(\bar{x}, \bar{y})\in GrM$, we define the Kruger-Mordukhovich co-derivative of M at (x, y) as the multifunction from F^* into E^* satisfying

$$x^*\in D^*M(\bar{x}, \bar{y})(y^*)\Leftrightarrow(x^*, -y^*)\in\mathcal{N}(GrM; \bar{x}, \bar{y}),$$

where $\mathcal{N}(GrM; \bar{x}, \bar{y})$ denotes the Kruger-Mordukhovich normal cone to GrM.

COROLLARY 3.2. *Let $f\colon E\to\mathbb{R}$ be locally Lipschitz, let $M\colon E\rightrightarrows F$ be a multifunction with closed graph, and let A be a closed subset of E. Let*

$$m(u)=\inf_x\{f(x)\colon u\in M(x), x\in A\}.$$

Assume that condition (K) is satisfied at $\bar{u}$ and that M is pseudo-Lipschitz at each point in $S(\bar{u})\times\{\bar{u}\}$. Then

$$\delta m(\bar{u})\subset\bigcup_{\bar{x}\in S(\bar{u})}\{u^*\in F^*\colon 0\in\partial f(x)+D^*M(\bar{x})(-u^*)+N(A; \bar{x})\}$$

and

$$\delta^\infty m(\bar{u})\subset\bigcup_{\bar{x}\in S(\bar{u})}\{u^*\in F^*\colon 0\in D^*M(\bar{x})(-u^*)+N(A; \bar{x})\}.$$

Proof. Let $u^*\in\delta m(\bar{u})$. Then by Proposition 3.1 there exist $\bar{x}\in S(\bar{u})$, $\lambda>0$ such that

$$(0, u^*)\in\delta f(\bar{x})\times\{0\}+\lambda\delta\Delta_M(\bar{x}, \bar{u})+\lambda\delta d_\Delta(\bar{x})\times\{0\},$$

and hence by Proposition 2.7 there are

$$x_1^*\in\delta f(\bar{x}),\quad (x_2^*, u_2^*)\in\mathcal{N}(M; \bar{x}, \bar{u}),\quad x_3^*\in N(A; \bar{x})$$

satisfying

$$x_1^*+x_2^*+x_3^*=0\quad\text{and}\quad u^*=u_2^*.$$

Therefore

$$0\in\partial f(\bar{x})+D^*M(\bar{x})(-u^*)+N(A; \bar{x}),$$

and this proves the first inclusion. The proof of the second inclusion is similar. □

Before stating the next corollary let us give another description of D^*G when G is a locally Lipschitz single-valued mapping.

PROPOSITION 3.3. *Let $G\colon E\to F$ be a mapping that is k-Lipschitz around $\bar{x}$. For $\bar{y}:=G(\bar{x})$ we have $D^*G(\bar{x}, \bar{y})(y^*)=\hat{\delta}(y^*\circ G)(\bar{x})$, where $\hat{\delta}(y^*\circ G)(\bar{x})$ is the set of $x^*\in E^*$ for which there exist $y_n^*\xrightarrow{w^*}y^*$, $\varepsilon_n\downarrow 0$, $x_n\to\bar{x}$, $x_n^*\xrightarrow{w^*}x^*$ satisfying $x_n^*\in\delta_{\varepsilon_n}(y_n^*\circ G)(x_n)$.*

Proof. Let $(x^*, -y^*) \in \mathcal{N}(GrG; \bar{x}, \bar{y})$. There exist $x_n^* \xrightarrow{w^*} x^*$, $y_n^* \xrightarrow{w^*} y^*$, $\varepsilon_n \downarrow 0$, $x_n \to \bar{x}$, and $r_n > 0$ such that for any $x \in B(x_n, r_n)$

$$\langle x_n^*, x - x_n\rangle - \langle y_n^*, G(x) - G(x_n)\rangle \leqq \varepsilon_n(\|x - x_n\| + \|G(x) - G(x_n)\|) \leqq \varepsilon_n(1+k)\|x - x_n\|,$$

and hence $x_n^* \in \partial_{\varepsilon_n'}(y_n^* \circ G)(x_n)$ for $\varepsilon_n' = \varepsilon_n(1+k)$. So $x^* \in \hat{\partial}(y^* \circ G)(\bar{x})$.

The converse implication is similar. □

PROPOSITION 3.4 (Kruger [20]). *Let E and F be two Banach spaces that admit equivalent Fréchet differentiable (off zero) norms. Let $G: E \to F$ and $g: F \to \mathbb{R}$ be two locally Lipschitz mappings and $\bar{y} := G(\bar{x})$.*

Then $\partial(g \circ G)(\bar{x}) \subset \bigcup \{\hat{\partial}(y^* \circ G)(\bar{x}): y^* \in \partial g(\bar{y})\}$.

Remark. $\hat{\partial}(y^* \circ G)(\bar{x}) = \partial(y^* \circ G)(\bar{x})$ whenever F is finite-dimensional.

COROLLARY 3.5. *Let $f: E \to \mathbb{R}$ and $G: E \to F$ be two locally Lipschitz mappings, and let A and B be two closed subsets in E and F, respectively. Let*

$$m(u) = \inf_x \{f(x): G(x) + u \in B, x \in A\}.$$

Assume that condition (K) is satisfied at $\bar{u}$. Then

(i) $$\partial m(\bar{u}) \subset \bigcup_{\bar{x} \in S(\bar{u})} \{u^* \in \mathcal{N}(B; G(\bar{x}) + \bar{u}): 0 \in \partial f(\bar{x}) + \hat{\partial}(u^* \circ G)(\bar{x}) + \mathcal{N}(A; \bar{x})\}$$

and

$$\partial^\infty m(\bar{u}) \subset \bigcup_{\bar{x} \in S(\bar{u})} \{u^* \in \mathcal{N}(B; G(\bar{x}) + \bar{u}): 0 \in \hat{\partial}(u^* \circ G)(\bar{x}) + \mathcal{N}(A; \bar{x})\}.$$

(ii) *If F is finite-dimensional, both inclusions above hold with $\partial(u^* \circ G)(\bar{x})$ replacing $\hat{\partial}(u^* \circ G)(\bar{x})$.*

Proof. Put $M(x) = -G(x) + B$. Then M is locally Lipschitz and

$$\Delta_M(x, u) = d(u, -G(x) + B) = d_B \circ H(x, u),$$

where $H(x, u) = G(x) + u$. Let $u^* \in \partial m(\bar{u})$. By Proposition 3.1 there exist $\bar{x} \in S(\bar{u})$, $\lambda > 0$ such that

$$(0, u^*) \in \partial f(\bar{x}) \times \{0\} + \lambda \partial \Delta_M(\bar{x}, \bar{u}) + \lambda \partial d_A(\bar{x}) \times \{0\}$$

and hence putting $\bar{z} = G(\bar{x}) + \bar{u}$ we obtain by Proposition 3.4 that there are $x_1^* \in \partial f(\bar{x})$, $y^* \in \lambda \partial d_B(\bar{z}) \subset \mathcal{N}(B; \bar{z})$, $(x_2^*, u_2^*) \in \hat{\partial}(y^* \circ G)(\bar{x}) \times \{y^*\}$, $x_3^* \in \lambda \partial d_A(\bar{x}) \subset \mathcal{N}(A; \bar{x})$ satisfying

$$x_1^* + x_2^* + x_3^* = 0, \qquad u_2^* = y^* = u^*.$$

Therefore $u^* \in \mathcal{N}(B; \bar{z})$ and

$$0 \in \partial f(\bar{x}) + \hat{\partial}(u^* \circ G)(\bar{x}) + \mathcal{N}(A; \bar{x}).$$

The first inclusion (i) is then proved and the proof of the second one is the same. So the proof is complete since (ii) is a direct consequence of (i) for $\hat{\partial}(u^* \circ G)(\bar{x}) = \partial(u^* \circ G)(\bar{x})$ whenever F is finite-dimensional. □

4. Perturbed problems with metrically regular constraints. In this section we consider the perturbed problem $\mathcal{P}_u$

$$m(u) = \inf_x \{f(x, u): 0 \in M(x, u), (x, u) \in A\},$$

where A is a closed subset in $E \times F$, $M: E \times F \rightrightarrows G$ is a multifunction of closed graph from $E \times F$ into a Banach space G.

Let us recall that M is *metrically regular* at $(\bar{x}, \bar{u}, 0) \in GrM$ with respect to A if there exist $\gamma > 0$, $X \times U$ a neighbourhood of $(\bar{x}, \bar{u})$ such that

$$(4.1) \qquad d((x, u), A \cap M^{-1}(0)) \leqq \gamma d(0, M(x, u)) \quad \text{for all } (x, u) \in (X \times U) \cap A.$$

Actually, many results on verifiable conditions ensuring metric regularity are known (see [1], [16], [17], [19], [25], [26], and the references therein).

LEMMA 4.1. *Assume that f is locally Lipschitz. Let $u^* \in \partial_\varepsilon m(\bar{u})$, $\bar{x} \in S(\bar{u})$, and $\alpha > (\varepsilon + \|u^*\| + k)$ (where k is a Lipschitz constant for f around $(\bar{x}, \bar{u})$). If M is metrically regular at $(\bar{x}, \bar{u}, 0)$, then the point $(\bar{x}, \bar{u})$ is a local minimum for the function*

$$(x, u) \to \varepsilon \|u - \bar{u}\| - \langle u^*, u\rangle + f(x, u) + \alpha\gamma d(0, M(x, u)) + q(x, u),$$

where $q := \alpha(1 + \gamma l)d_A$ if M is l-pseudo-Lipschitz at $(\bar{x}, \bar{u}, 0)$ and ψ_A otherwise.

Proof. By assumption there exists a neighbourhood U_0 of $\bar{u}$ over which $\bar{u}$ gives a minimum of the function

$$u \to \varepsilon \|u - \bar{u}\| - \langle u^*, u\rangle + m(u).$$

Choose a neighbourhood $X \times U$ of $(\bar{x}, \bar{u})$ with $U \subset U_0$ and over which (4.1) is satisfied. Then for $(x, u) \in (X \times U) \cap A \cap M^{-1}(0)$ we have

$$\begin{aligned} -\langle u^*, \bar{u}\rangle + f(\bar{x}, \bar{u}) &\leqq \varepsilon \|u - \bar{u}\| - \langle u^*, u\rangle + m(u) \\ &\leqq \varepsilon \|u - \bar{u}\| - \langle u^*, u\rangle + f(x, u), \end{aligned}$$

and hence, by Proposition 1.5, $(\bar{x}, \bar{u})$ gives a local minimum of the function

$$(x, u) \to \varepsilon \|u - \bar{u}\| - \langle u^*, u\rangle + f(x, u) + \alpha d((x, u), A \cap M^{-1}(0)).$$

By metrical regularity $(\bar{x}, \bar{u})$ gives a local minimum relative to A of the function

$$(x, u) \to \varepsilon \|u - \bar{u}\| - \langle u^*, u\rangle + f(x, u) + \alpha\gamma d(0, M(x, u)),$$

and hence, by Proposition 1.5 again, $(\bar{x}, \bar{u})$ gives a local minimum of the function

$$(x, u) \to \varepsilon \|u - \bar{u}\| - \langle u^*, u\rangle + f(x, u) + \alpha\gamma d(0, M(x, u)) + q(x, u). \qquad \square$$

We denote by p_M the function defined by

$$p_M(x, u) = d(0, M(x, u))$$

and we assume in the rest of this section that E and F admit equivalent *Fréchet differentiable norms.*

PROPOSITION 4.2. *Assume f is locally Lipschitz, M is regular with respect to A at each point in $S(\bar{u}) \times \{\bar{u}\} \times \{0\}$, and condition (K) is satisfied at $\bar{u}$. Let $u^* \in \delta m(\bar{u})$:*

(i) *There exist $\bar{x} \in S(\bar{u})$ and $\alpha > 0$ such that*

$$(0, u^*) \in \delta(f + \alpha\gamma p_M + \psi_A)(\bar{x}, \bar{u}).$$

(ii) *If in addition M is pseudo-Lipschitz at each point in $S(\bar{u}) \times \{\bar{u}\} \times \{0\}$, then there exist $\bar{x} \in S(\bar{u})$, $\alpha > 0$, and $l > 0$ such that*

$$(0, u^*) \in \delta(f + \alpha\gamma p_M + \alpha(1 + \gamma l)d_A)(\bar{x}, \bar{u}).$$

Proof. Choose $u_n \to \bar{u}$ with $m(u_n) \to m(\bar{u})$, $\varepsilon_n \downarrow 0$, $u_n^* \xrightarrow{w^*} u^*$ with $u_n^* \in \partial_{\varepsilon_n} m(u_n)$ and choose also $x_n \in S(u_n)$. By condition (K) we may suppose $x_n \to \bar{x} \in S(\bar{u})$. If we denote by k a Lipschitz constant for f around $(\bar{x}, \bar{u})$ and we choose $\alpha > (1 + \|u^*\| + k)$, Lemma 4.1 ensures that (for n sufficiently large) the point (x_n, u_n) gives a local minimum of the function

$$(x, u) \to \varepsilon_n \|u - u_n\| - \langle u_n^*, u\rangle + f(x, u) + \alpha\gamma p_M(x, u) + \psi_A(x, u).$$

As

$$(f+\alpha\gamma p_M+\psi_A)(x_n, u_n)\to(f+\alpha\gamma p_M+\psi_A)(\bar{x}, \bar{u})$$

we obtain

$$(0, u^*)\in\delta(f+\alpha\gamma+\psi_A)(\bar{x}, \bar{u})$$

and this proves (i). The proof of (ii) is exactly the same. □

PROPOSITION 4.3. *Assume f is locally Lipschitz, M is regular with respect to A at each point in $S(\bar{u})\times\{\bar{u}\}\times\{0\}$, and condition (K) is satisfied at $\bar{u}$. Let $u^*\in\delta^\infty(\bar{u})$:*

(i) *There exist $\bar{x}\in S(\bar{u})$ and $\alpha>0$ such that*

$$(0, u^*)\in\delta(\alpha\gamma p_M+\psi_A)(\bar{x}, \bar{u}).$$

(ii) *If in addition M is pseudo-Lipschitz at each point in $S(\bar{u})\times\{\bar{u}\}\times\{0\}$, then there exist $\bar{x}\in S(\bar{u})$, $\alpha>0$, and $l>0$ such that*

$$(0, u^*)\in\delta(\alpha\gamma p_M+\alpha(1+\gamma l)d_A)(\bar{x}, \bar{u}).$$

Proof. The proof is similar to that of Proposition 4.2. □

5. Estimates in terms of subdifferentials of support functions. In this section M is still a multifunction from a Banach space E into a Banach space F. For $x\in E$ and $y^*\in F^*$ we put

$$h(x, y^*)=\sup\{\langle y^*, y\rangle: y\in M(x)\}.$$

In all the sequel we assume that $M(x)$ is a *closed convex* subset in F for each $x\in E$ and that F is *reflexive.* So there exists an equivalent norm on F that is Fréchet differentiable off zero and throughout this section F will always be endowed with *such a norm.* Moreover, by the lopsided minimax theorem (see [2]) or by the Hahn–Banach theorem, it is not difficult to see that whenever $M(x)\neq\emptyset$

$$\Delta_M(x, y)=\max_{y^*\in B_{F^*}}(\langle y^*, y\rangle-h(x, y^*)), \tag{5.1}$$

where B_{F^*} denotes the closed unit ball centered at the origin of F^*.

In order to give a relationship between $\partial\Delta$ and ∂h let us begin with the following result, which is a variant of Theorem 2.8.2 of Clarke [6].

PROPOSITION 5.1. *Let G be a Banach space with B_{G^*} w^*-sequentially compact, and let S be a sequentially compact space and $\bar{x}\in G$. Let $g_s: G\to\bar{\mathbb{R}}$ for each $s\in S$. Assume that there exists a neighbourhood X of $\bar{x}$ in G and a real number $k\geqq 0$ such that for each $s\in S$ the function g_s is finite on X and k-Lipschitz on X. Assume also that the supremum in*

$$g(x):=\sup\{g_s(x): s\in S\}$$

is attained for each $x\in X$. Then g is finite and k-Lipschitz on X and

$$\partial g(\bar{x})\subset\operatorname{cl}\operatorname{co}\bigcup\{\hat{\partial}g_s(\bar{x}): s\in S(\bar{x})\},$$

where $S(\bar{x})=\{s\in S: g(\bar{x})=g_s(\bar{x})\}$ and

$$\hat{\partial}g_s(\bar{x})=\{\lim x_n^*: x_n^*\in\partial g_{s_n}(x_n), s_n\to s, x_n\to\bar{x}'\}.$$

Proof. It suffices to repeat (with very slight modification) the arguments of the first part of the proof of Theorem 2.8.2 in Clarke [7]. □

Remarks. (1) If G admits an equivalent Gateaux-differentiable norm, then (see [15]) B_{G^*} is w^*-sequentially compact.

(2) If $g_s^\Box(\bar{x}; \bar{v})$ denotes the following "lim sup" of the difference quotient

$$g_s^\Box(x; v) = \limsup_{\substack{(x,r)\to(\bar{x},s)\\ t\downarrow 0}} t^{-1}[g_r(x+tv) - g_r(x)],$$

then $g_s^\Box(\bar{x}; \cdot)$ is k-Lipschitz on G and hence the set

$$\partial^\Box g_s(\bar{x}) := \{x^* \in G^*: \langle x^*, v\rangle \leqq g_s^\Box(\bar{x}; v) \forall v \in G\}$$

is nonempty, w^*-compact and convex, and moreover it is not difficult to verify that

$$\hat{\partial} g_s(\bar{x}) \subset \partial^\Box g_s(\bar{x})$$

and that the relations

$$x_n^* \in \partial^\Box g_{s_n}(x_n), \quad x_n \to \bar{x}, \quad s_n \to s, \quad x_n^* \xrightarrow{w^*} x^*$$

ensure that $x^* \in \partial^\Box g_s(\bar{x})$.

Furthermore $\partial^\Box g_s(\bar{x}) = \operatorname{cl} \operatorname{co} \hat{\partial} g_s(\bar{x})$ whenever S is metrizable and G is separable.

Let $r > 0$, $M_r(x) = M(x) + rB_F$, and $h_r(x, y^*) = \sup \{\langle y^*, y\rangle: y \in M_r(x)\} = h(x, y^*) + r\|y^*\|_*$. As the dual norm of F^* is strictly convex (since the norm of F is Gateaux-differentiable off zero; see [12]), then for each $x \in E$ the function $y^* \to h_r(x, y^*)$ is strictly convex on its domain.

If M is locally Lipschitz around $\bar{x}$ in the sense that there exists $l > 0$ and a neighbourhood X of $\bar{x}$ in E such that

$$M(x') \subset M(x) + l\|x - x'\| B_F \quad \text{for all } x, x' \in X$$

and $M(\bar{x}) \neq \varnothing$, then for any $x \in X$

$$h(x, y^*) < \infty \Leftrightarrow h(\bar{x}, y^*) < \infty \Leftrightarrow h_r(\bar{x}, y^*) < \infty.$$

We set as in [10] (see also [2])

$$F_M^* = \{y^* \in F^*: h(\bar{x}, y^*) < \infty\}$$

and we easily see that F_M^* is a convex cone (the barrier cone of M see [2]).

PROPOSITION 5.2. *Assume that F is reflexive and endowed with a norm that is differentiable off zero, that $B_{F^*} \cap F_M^*$ is w^*-sequentially closed, and that M is locally Lipschitz around $\bar{x}$ (with $M(\bar{x}) \neq \varnothing$). Then, for $\Delta_r := \Delta_{M_r}$,*

$$(-x^*, y^*) \in \partial \Delta_r(\bar{x}, \bar{y}) \Rightarrow x^* \in \partial^\Box h_r(\cdot, y^*)(\bar{x}).$$

Proof. The set $S := B_{F^*} \cap F_M^*$ is w^*-sequentially compact and by (5.1)

$$\Delta_r(x, y) = \sup_{u^* \in S} (\langle u^*, y\rangle - h_r(x, u^*)).$$

Now, on the one hand, by Proposition 1.5 we have for any $u^* \in B_{F^*}$

$$\begin{aligned} h_r(\bar{x}, u^*) &= \sup \{\langle u^*, y'\rangle: y' \in M_r(\bar{x})\} \\ &= \sup \{\langle u^*, y'\rangle - d(y', M_r(\bar{x})): y' \in F\} \\ &= \sup \{\langle u^*, y'\rangle - \Delta_r(\bar{x}, y'): y' \in F\}. \end{aligned}$$

On the other hand, the function $\langle u^*, \cdot\rangle - \Delta_r(\bar{x}, \cdot)$ is concave (because $M(\bar{x})$ is convex) and $y^* \in \partial_2 \Delta_r(\bar{x}, \bar{y}) = \partial(d_{M_r(\bar{x})})(\bar{y})$ (see Proposition 5.3). So we obtain

$$0 \in \partial(\langle y^*, \cdot\rangle - \Delta_r(\bar{x}, \cdot))(\bar{y})$$

and

$$h_r(\bar{x}, y^*) = \langle y^*, \bar{y}\rangle - \Delta_r(\bar{x}, \bar{y}).$$

Therefore we have

$$h_r(\bar{x}, y^*) < \infty \quad \text{and} \quad y^* \in S(\bar{x}, \bar{y}),$$

which implies by the strict convexity of $h_r(\bar{x}, \cdot)$

$$S(\bar{x}, \bar{y}) = \{y^*\}.$$

Applying Proposition 5.1 and setting $q_{u^*}(x, y) = \langle u^*, y\rangle - h_r(x, u^*)$, we get

$$(-x^*, y^*) \in \partial^{\square} q_{y^*}(\bar{x}, \bar{y}) = (0, y^*) - \partial^{\square} h_r(\cdot, y^*)(\bar{x}) \times \{0\}$$

and hence

$$x^* \in \partial^{\square} h_r(\cdot, y^*)(\bar{x}). \qquad \square$$

Remark. If M is given by $M(x) = N(x) + Q$ where N is a multifunction which takes closed, convex, and bounded values and which is Lipschitz around $\bar{x}$ with $N(\bar{x}) \neq \emptyset$ and where Q is a closed convex cone in F, then it is not difficult to see that

$$F_M^* = Q^0 := \{y^* \in F^* : \langle y^*, y\rangle \leqq 0 \; \forall y \in Q\}.$$

Thus F_M^* is w^*-closed, which ensures that $B_{F^*} \cap F_M^*$ is w^*-sequentially compact whenever F is reflexive. $\square$

The following result, which is used in the proof of the proposition above, will also be needed in the sequel.

PROPOSITION 5.3. *Let $k \geqq 0$, and let $P: G \rightrightarrows H$ be a multifunction from a normed vector space G into the convex subsets of a normed space H. Assume that P is pseudo-Lipschitz at $(\bar{x}, \bar{y}) \in GrP$. Then there exists a neighbourhood $X \times Y$ of $(\bar{x}, \bar{y})$ such that for each $(x, y) \in X \times Y$ and $(x^*, y^*) \in t\, \partial\Delta_p(x, y)$ with $t > 0$, we have*

$$y^* \in t\, \partial d_{P(x)}(y).$$

Proof. Choose an open neighbourhood $X \times Y$ of $(\bar{x}, \bar{y})$ in $G \times H$ and a real number $\alpha > 0$ such that Δ_P is α-Lipschitz over $X \times Y$. As $\Delta_P(x, \cdot)$ is convex we obtain, by Proposition 4.4 of [9],

$$y^* \in \partial_2(t\Delta_P)(x, y) = t\partial d_{P(x)}(y). \qquad \square$$

The following proposition is an adaptation of the techniques introduced by Clarke [7] in order to give necessary conditions for optimal control problems in terms of the Hamiltonian (see also Clarke [6]).

PROPOSITION 5.4. *Let $(\bar{x}, \bar{u})$ be a local minimum point for the problem*

$$\min\{f(x, u) : u \in M(x), x \in A\}.$$

If f and the multifunction M are k-Lipschitz around $\bar{x}$, then for ε small enough and $0 < r < k^{-1}\varepsilon^2$ there exist $x_\varepsilon \in A$ and $u_\varepsilon \in M_r(x_\varepsilon)$ with

$$\|x_\varepsilon - \bar{x}\| \leqq \varepsilon, \quad \|u - \bar{u}\| \leqq \varepsilon, \quad f(\bar{x}, \bar{u}) \leqq f(x_\varepsilon, u_\varepsilon) \leqq f(\bar{x}, \bar{u}) + \varepsilon^2$$

such that $(x_\varepsilon, u_\varepsilon)$ is a local minimum of the function

$$(x, u) \to f(x, u) + \varepsilon d((x, u), (x_\varepsilon, u_\varepsilon)) + K d_A(x) + K\Delta_r(x, u),$$

where K is a constant independent of (ε, x, u).

Proof. Suppose that $(\bar{x} + sB) \times (\bar{u} + 2sB)$ is a neighbourhood over which $(\bar{x}, \bar{u})$ is a minimum for the above problem and over which f and M are k-Lipschitz. Consider

$\varepsilon < \min(s, (ks)^{1/2})$. Then for $x \in A \cap (\bar{x} + sB)$ and $u \in M_r(x) \cap (\bar{u} + sB)$ there exists $b \in B$ with $u - rb \in M(x) \cap (\bar{u} + 2sB)$ and hence

$$f(x, u) - f(\bar{x}, \bar{u}) - \varepsilon^2 \geqq f(x, u - rb) - f(\bar{x}, \bar{u}) + \varepsilon^2 - kr\|b\| \geqq \varepsilon^2 - kr > 0.$$

Therefore by Ekeland's variational principle (see [2]) there exists $x_\varepsilon \in A \cap (\bar{x} + sB)$ and $u_\varepsilon \in M_r(x_\varepsilon) \cap (\bar{u} + sB)$ such that

$$\|x_\varepsilon - \bar{x}\| \leqq \varepsilon, \quad \|u - \bar{u}\| \leqq \varepsilon, \quad f(\bar{x}, \bar{u}) \leqq f(x_\varepsilon, u_\varepsilon) \leqq f(\bar{x}, \bar{u}) + \varepsilon^2$$

and $(x_\varepsilon, u_\varepsilon)$ is a minimum point of the function

$$(x, u) \to f(x, u) - f(\bar{x}, \bar{u}) + \varepsilon d((x, u), (x_\varepsilon, u_\varepsilon))$$

over the set $\{(x, u) \colon u \in M_r(x) \cap (\bar{u} + sB), x \in A \cap (\bar{x} + sB)\}$. So it suffices to apply Proposition 1.5 to get the conclusion of the proposition. □

We can now give estimates of the subdifferential of the optimal value function in terms of the support function of M.

PROPOSITION 5.5. *Let $f \colon E \times F \to \mathbb{R}$ be locally Lipschitz, let $M \colon E \rightrightarrows F$ be a locally Lipschitz multifunction with closed convex values, and let A be a closed subset of E. Let*

$$m(u) = \inf_x \{f(x, u) \colon u \in M(x), x \in A\}.$$

Assume E admits an equivalent Fréchet differentiable norm (off zero), condition (K) is satisfied at $\bar{u}$, and $B_F^* \cap F_M^*$ is w^*-sequentially compact. Then for each $u^* \in \delta m(\bar{u})$ (respectively, $\delta^\infty m(\bar{u})$) there exists $\bar{x} \in S(\bar{u})$, $\lambda > 0$, and $(x^*, y^*) \in E^* \times F^*$ such that

$$(x^*, u^* - y^*) \in \delta(f + \lambda d_{A \times F})(\bar{x}, \bar{u}), \quad -x^* \in \partial^\square h(\cdot, y^*)(\bar{x}), \quad y^* \in \lambda \delta d_{M(\bar{x})}(\bar{u})$$

(respectively, $0 \in \partial^\square h(\cdot, u^*)(\bar{x}) + \gamma \delta d_A(\bar{x})$ and $u^* \in \lambda \partial \delta_{M(\bar{x})}(\bar{u})$).

Proof. Let $u^* \in \delta m(\bar{u})$. There exists $\varepsilon_n \downarrow 0$, $u_n \to \bar{u}$ with $m(u_n) \to m(\bar{u})$, $u_n^* \xrightarrow{w} \bar{u}$ such that the function

$$u \to m(u) - \langle u_n^*, u - u_n \rangle + \varepsilon_n \|u - u_n\|$$

attains a local minimum at u_n. By assumption (K) we may suppose that there exists $x_n \in S(u_n)$ with (x_n) converging to some $\bar{x} \in S(\bar{u})$. Then for all $x \in A$ and $u \in M(x)$ with u near u_n

$$\begin{aligned} -\langle u_n^*, u_n \rangle + f(x_n, u_n) &\leqq \varepsilon_n \|u - u_n\| - \langle u_n^*, u \rangle + m(u) \\ &\leqq \varepsilon_n \|u - u_n\| - \langle u_n^*, u \rangle + f(x, u). \end{aligned}$$

Therefore by Proposition 5.4 there exist a constant $\lambda > 0$ and $(x_n', u_n') \in (x_n, u_n) + \varepsilon_n B$, which is a local minimum of the function

$$(x, u) \to \varepsilon_n \|u - u_n\| - \langle u_n^*, u \rangle + f(x, u) + \varepsilon_n \|u - u_n'\| + \varepsilon_n \|x - x_n'\| + \lambda d_A(x) + \lambda \Delta_{r_n}(x, u),$$

and hence

$$(0, 0) \in 2\varepsilon_n B - (0, u_n^*) + \delta(f + \lambda d_{A \times F})(x_n', u_n') + \lambda \partial \Delta_{r_n}(x_n', u_n'),$$

which implies there exist $(z_n^*, v_n^*) \in \partial \Delta_{r_n}(x_n', u_n')$ satisfying

$$(-\lambda z_n^*, u_n^* - \lambda v_n^*) \in 2\varepsilon_n B + \delta(f + \lambda d_{A \times F})(x_n', u_n').$$

Extracting a subsequence if necessary we may suppose that $-\lambda z_n^* \xrightarrow{w} x^*$ and $\lambda v_n^* \xrightarrow{w} y^*$, which ensures $(x^*, u^* - y^*) \in \delta(f + \lambda d_{A \times F})(\bar{x}, \bar{u})$ and $x^* \in \partial^\square h(\cdot, y^*)(\bar{x})$, since by Proposition 5.2, we have $-\lambda z_n^* \in \partial^\square h_{r_n}(\cdot, \lambda v_n^*)(x_n')$.

Moreover, by Proposition 5.3 we have $v_n^* \in \partial d_{M_{r_n(x'_n)}}(u'_n)$ and by l-Lipschitz continuity of M around $\bar{x}$ we have

$$M_{r_n}(x'_n) \subset M(\bar{x}) + r_n B + l\|x'_n - \bar{x}\| B \quad \text{and} \quad M(\bar{x}) \subset M_{r_n}(\bar{x}) \subset N_{r_n}(x'_n) + l\|x'_n - \bar{x}\| B,$$

and hence for every $u \in F$

$$d_{M_{r_n}}(x'_n)(u) \geqq d_{M(\bar{x})}(u) - r - l\|x'_n - \bar{x}\| \quad \text{and} \quad d_{M(\bar{x})}(u) \geqq d_{M_{r_n}}(x'_n)(u) - l\|x'_n - \bar{x}\|.$$

Therefore for any $u \in F$ we have

$$\begin{aligned}\langle v_n^*, u - u'_n \rangle &\leqq d_{M_{r_n}}(x'_n)(u) - d_{M_{r_n}}(x'_n)(u'_n) \\ &\leqq d_{M(\bar{x})}(u) + l\|x'_n - \bar{x}\| - (d_{M(\bar{x})}(u'_n) - r_n - l\|x'_n - \bar{x}\|)\end{aligned}$$

and hence

$$\langle \lambda^{-1} y^*, u - \bar{u} \rangle \leqq d_{M(\bar{x})}(u) - d_{M(\bar{x})}(\bar{u}),$$

which ensures $y^* \in \lambda \partial d_{M(\bar{x})}(\bar{u}) = \lambda \delta_{M(\bar{x})}(\bar{u})$ and completes the proof for $u^* \in \delta m(\bar{u})$.

For $u^* \in \delta^\infty m(\bar{u})$ the proof is similar. □

ON THE CONVERGENCE OF A MATRIX SPLITTING ALGORITHM FOR THE SYMMETRIC MONOTONE LINEAR COMPLEMENTARITY PROBLEM*

ZHI-QUAN LUO†‡ AND PAUL TSENG†

Abstract. A matrix splitting algorithm for the linear complementarity problem is considered, where the matrix is symmetric positive semidefinite. It is shown that if the splitting is regular, then the iterates generated by the algorithm are well defined and converge to a solution. This result resolves in the affirmative a long standing question about the convergence of the point successive overrelaxation (SOR) method for solving this problem. This result is also extended to related iterative methods. As direct consequences, convergence of the methods of, respectively, Aganagic, Cottle et al., Mangasarian, Pang, and others, is obtained, without making any additional assumptions on the problem.

Key words. convergence, iterative methods, convex quadratic program, linear complementarity, matrix splitting, gradient projection, SOR

AMS(MOS) subject classifications. 49, 90

1. Introduction.

Let M be an $n \times n$ symmetric positive semidefinite matrix and let q be an element of $\Re^n$ (the n-dimensional Euclidean space). Consider the following convex quadratic program:

$$\text{(P)} \qquad \begin{array}{ll} \text{minimize} & f(x) = \tfrac{1}{2}\langle x, Mx\rangle + \langle q, x\rangle \\ \text{subject to} & x \geqq 0. \end{array}$$

In our notation, all vectors are column vectors, $\langle \cdot, \cdot \rangle$ denotes the usual Euclidean inner product, and, for any vector x, x_i denotes its ith coordinate. We note that all our results can be extended in a straightforward manner to problems with general box constraints of the form

$$l \leqq x \leqq c,$$

where l is any element of $[-\infty, \infty)^n$ and c is any element of $(-\infty, \infty]^n$ (e.g., unconstrained problems). However, in order to simplify the presentation, we will not treat the more general problems here.

The problem (P), commonly referred to as the *symmetric monotone linear complementarity* problem, has a number of important applications to, for example, linear/quadratic programming [BeT89], [Man77], [MaD87], [LiP87] and the solution of certain boundary value problems [CoG78], [CGS78], [DeT84].

We make the following standing assumption on (P):

Assumption A. f is bounded from below on the feasible set $X = [0, \infty)^n$.

Since f is convex quadratic and X is a polyhedral set, it follows from a standard result in quadratic programming (see, e.g., [Eav71], [FrW57]) that (P) has a finite optimal value and the set of optimal solutions for (P), denoted by X^*, is nonempty. However, because M is only positive semidefinite, X^* may be unbounded.

‡ Present address, Department of Electrical and Computer Engineering, McMaster University, Room 225/CRL, Hamilton, Ontario, Canada L8S 4L7.

From the Kuhn-Tucker conditions for (P) it is easily seen that an x belongs to X^* if and only if the orthogonal projection of $x-\nabla f(x)$ onto the feasible set X is x itself, i.e.,

$$x=[x-(Mx+q)]^+, \tag{1.1}$$

where $[y]^+$ denotes the orthogonal projection of y onto X. Now, let us write M as

$$M=B+C, \tag{1.2}$$

for some $n\times n$ matrices B and C. In the terminology of numerical analysis [OrR70], such a pair (B, C) is called a *splitting* of M. If in addition $B-C$ is positive definite (not necessarily symmetric), then (B, C) is called a *regular* splitting of M (cf. [LiP87]).

Suppose that, instead of solving the nonlinear equation (1.1) directly, we fix a solution estimate $x\in X$ and solve the following approximation to (1.1)

$$y=[y-(By+Cx+q)]^+, \tag{1.3}$$

to obtain a solution y. We can then set x to y and repeat the procedure. We formalize this procedure with the following iterative scheme. Let (B, C) be a regular splitting of M. Define a corresponding point-to-point mapping $\mathcal{A}_B: X\mapsto X$ by (cf. (1.3))

$$\mathcal{A}_B(x)=\{y\in\Re^n \mid y=[y-(By+Cx+q)]^+\} \quad \forall x\in X. \tag{1.4}$$

We show in § 2 that $\mathcal{A}_B$ is well defined (see Lemma 2(a)). Note that an x is an optimal solution of (P) if and only if $x=\mathcal{A}_B(x)$. Consider the following algorithm for solving (P).

MATRIX SPLITTING ALGORITHM. Choose an $x^0\in X$. Generate a sequence of vectors $\{x^0, x^1, \cdots\}$ in X by the formula

$$x^{r+1}=\mathcal{A}_B(x^r), \qquad r=0,1,\cdots. \tag{1.5}$$

In order for the algorithm (1.4)-(1.5) to be practical, the splitting (B, C) should be chosen so that (1.3) is easily solvable. We will discuss such choices in § 5.

The first matrix splitting algorithm for solving the problem (P) is the cyclic coordinate descent method of Hildreth [Hil57]. This method is simple, uses little storage, can exploit problem sparsity, and is practical for solving large scale problems. The method of Hildreth was subsequently extended by Cryer [Cry71] to a (point) SOR method, which in turn was extended by Cottle, Golub, and Sacher [CGS78] and Cottle and Pang [CoP82] to block successive overrelaxation (SOR) methods. Cottle and Goheen [CoG78] further extended the Cottle-Golub-Sacher method to solve problems with box constraints. An extension of Cryer's method along a different direction was proposed by Mangasarian [Man77], which is also closely related to a gradient projection algorithm of Aganagic [Aga78]. (Applications of Mangasarian's method to solving strictly convex quadratic programs and linear programs are discussed in [Man84] and [MaD87]. Parallel implementation of the method is discussed in [MaD87].) Pang [Pan82] showed that the above methods (with the possible exception of the block SOR methods) can be viewed as special cases of the matrix splitting algorithm (1.4)-(1.5). Pang then proceeded to give an extensive analysis of this algorithm [Pan82], [Pan84], [Pan86]. Yet, despite their long history and practical advantages, convergence of these iterative methods remained largely unresolved. (A summary of the current knowledge is given in [LiP87, § 2-3]. See [BeT89, Chap. 3] and [Che84] for discussions on gradient projection algorithms.) In particular, none of the above methods has been shown to be convergent (in the sense that the iterates converge to an optimal solution) if the optimal solution is not unique. Convergence typically requires additional assumptions on the problem, all of which lead to the compactness of the solution set X^*, in which case the proof becomes rather routine (i.e., checking that each limit point is an optimal solution). In the absence of any such assumption, it was only known that the gradient of the iterates converge and that each limit point of the iterates, if it exists, is an optimal solution. The method of Cottle and Pang [CoP82] does generate a limit point, but this method includes, in addition to the standard block SOR iteration, a projection step to ensure that the iterates stay bounded and, moreover, it is applicable only to problems with a network structure. It is the aim of this paper to resolve this fundamental question of convergence by showing that the above methods are indeed convergent without making any additional assumptions on the problem. In fact, we prove a more general result that, if the splitting is regular, then the corresponding matrix splitting algorithm (1.4)–(1.5) is well defined and convergent, and the same conclusion holds for certain SOR extensions of the algorithm. (To the best of our knowledge, the only other matrix splitting algorithm that is known to be convergent in the same strong sense is one considered in Tseng [Tse89].[1]) Our proof is of some interest in itself as it uses certain (new) contraction properties of regular splitting and gives a detailed analysis of the trajectory of the iterates near the boundary of the feasible set X.

We remark that even for the simplest instance of the matrix splitting algorithm (1.4)–(1.5), such as the cyclic coordinate descent method, convergence is very difficult to establish when the cost function has unbounded level sets. The only other nontrivial problem having unbounded level sets in the cost function, and for which the cyclic coordinate descent method is known to be convergent in our strong sense, is a certain dual problem arising in nonlinear network optimization [BHT87].

This paper proceeds as follows. In § 2 we derive a number of properties of the solutions of (P) and of regular splitting. In § 3 we use these properties to prove that, when the splitting is regular, the iterates generated by the algorithm (1.4)–(1.5) converge to an optimal solution of (P). In § 4 we propose SOR extensions of this algorithm. In § 5 we apply the above results to a number of known methods.

In our notation, superscript T will denote matrix transpose and $\|\cdot\|$, $\|\cdot\|_\infty$ will denote, respectively, the L_2-norm and the L_∞-norm in some Euclidean space. If A is a square matrix, $\|A\|$ will denote the matrix norm of A induced by the vector norm $\|\cdot\|$, i.e., $\|A\|=\max_{\|x\|=1}\|Ax\|$. For any $k\times m$ matrix A, we will denote by A_i the ith row of A and, for any nonempty $I\subseteq\{1,\cdots,k\}$ and $J\subseteq\{1,\cdots,m\}$, by A_I the submatrix of A obtained by removing all rows i of A such that $i\notin I$, and by A_{IJ} the submatrix of A_I obtained by removing all columns j of A_I such that $j\notin J$. We will also denote by Span (A) the space spanned by the columns of A. Analogously, for any k-vector x and any nonempty subset $J\subseteq\{1,\cdots,k\}$, we denote by x_J the vector with components x_i, $i\in J$. For any finite set J, we denote by Card (J) the cardinality of J. Finally, for any $J\subseteq\{1,\cdots,n\}$, we denote by $\tilde{J}$ the complement of J with respect to $\{1,\cdots,n\}$.

2. Characterization of optimal solutions and regular splittings. In this section we derive various properties of the elements of X^* and the mapping $\mathcal{A}_B$ given by regular splittings (B, C) of M. These properties will be used in the following section to prove convergence of the algorithm (1.4)–(1.5).

The first result, which is well known (see [AdG75] or [Man88]), states that ∇f is invariant over the solution set X^*.

[1] When the splitting is regular and *symmetric*, a simpler proof of convergence for the matrix splitting algorithm with inexact subproblem solution was recently found by Mangasarian (see [Man90]).

Lemma 1. *There exists a $d^* \in \Re^n$ such that $Mx^* + q = d^*$ for all $x^* \in X^*$.*

The next result shows that, if (B, C) is a regular splitting of M, then $\mathcal{A}_B$ is a well-defined point-to-point mapping and possesses a certain descent property.

Lemma 2. *Let (B, C) be a regular splitting of M. Then the following hold:*

(a) *$\mathcal{A}_B : X \mapsto X$ is a well-defined point-to-point mapping.*

(b) *For any $x \in X$,*

$$f(y) - f(x) \leqq \langle y - x, (C - B)(y - x)\rangle / 2,$$

where $y = \mathcal{A}_B(x)$.

Proof. We first prove part (a). Since $B - C$ is positive definite, it follows from $2B = M + (B - C)$ (cf. $M = B + C$) and the positive semidefinite property of M that B is positive definite. Hence, by a well-known result on variational inequality [BeT89, p. 271], [KiS80, § 2], we have that, for any $x \in X$, the nonlinear equation

$$y = [y - (By + Cx + q)]^+,$$

has a unique solution y. This proves part (a).

Now we prove part (b). It can be seen by using $M = B + C$ that, for any x and y in $\Re^n$,

$$f(y) - f(x) = \langle y - x, By + Cx + q\rangle + \langle y - x, (C - B)(y - x)\rangle / 2.$$

On the other hand, we see from (1.4) that $y = \mathcal{A}_B(x)$ if and only if $y \in X$ and

$$B_i y + C_i x + q_i \geqq 0, \quad B_i y + C_i x + q_i > 0 \Rightarrow y_i = 0 \quad \forall i.$$

Hence if in addition $x \in X$ (so that $x \geqq 0$), then $\langle y - x, By + Cx + q\rangle \leqq 0$. □

(The results of Lemma 2 are quite well known (e.g., [LiP87]). The proof of part (b) is based on one given in Lemma 4.1 of [Pan84].)

It can be seen that if the nonnegativity constraints $x \in X$ are removed, then, for any splitting (B, C) of M, $y = \mathcal{A}_B(x)$ if and only if $By + Cx + q = 0$, or equivalently (assuming that B is invertible)

$$y = -B^{-1}(Cx + q) = (I - B^{-1}M)x - B^{-1}q.$$

We next study an important contractive property of the iteration matrix $I - B^{-1}M$ when the splitting is regular.

Definition 1. Let Q be an $n \times n$ real symmetric matrix and let Null (Q) be the null space of Q. (Clearly, $\Re^n$ is the direct sum of Null (Q) and Span (Q).) A matrix T of size $n \times n$ is said to be *convergent* for Q if T, when viewed as a linear transformation from $\Re^n$ to $\Re^n$, is equal to identity in Null (Q) *and* is contractive in Span (Q). In other words, T satisfies

(1) $Tz = z$ for all $z \in$ Null (Q);

(2) For any $z \in$ Span (Q), the sequence $\{\|T^k z\|\}$ converges to zero geometrically, as $k \to \infty$ (with a convergence ratio that depends on T only).

The following important result is due to Keller [Kel65, Thm. 2] (see also [BeP79, p. 201]).

Proposition 1. *Let Q be a real symmetric matrix and let N be a nonsingular matrix for which the matrix*

$$N + N^T - Q \tag{2.1}$$

is positive definite. Then $T = I - N^{-1}Q$ is convergent for Q if and only if Q is positive semidefinite.

As a direct consequence of Keller's result, we have the following contractive properties of the iteration matrix $I - B^{-1}M$, for any regular splitting (B, C) of M.

LEMMA 3. *Let Q be an $m \times m$ symmetric positive semidefinite matrix and let (N, H) be a regular splitting of Q. Then N is positive definite and the following hold:*

(a) *There exist $\rho \in (0, 1)$ and $\tau > 0$ such that*

$$\left\| \prod_{h=1}^{k} (I - \theta^h Q N^{-1}) z \right\| \leqq \tau(1 - \underline{\theta}(1-\rho))^k \|z\| \quad \forall k \geqq 1, \forall z \in \operatorname{Span}(Q),$$

for any $\underline{\theta} \in (0, 1]$ and any sequence of scalars $\{\theta^1, \theta^2, \cdots\}$ in the interval $[\underline{\theta}, 1]$.

(b) *There exists $\Delta \geqq 1$ such that*

$$\left\| \prod_{h=1}^{k} (I - \theta^h N^{-1} Q) z \right\| \leqq \Delta \|z\| \quad \forall k \geqq 1, \quad \forall z \in \mathfrak{R}^m,$$

for any $\underline{\theta} \in (0, 1]$ and any sequence of scalars $\{\theta^1, \theta^2, \cdots\}$ in the interval $[\underline{\theta}, 1]$.

Proof. From $Q = N + H$ we have $N - H = 2N - Q$, so the symmetric part of $N - H$ is $N + N^T - Q$. Since $N - H$ is positive definite so its symmetric part is also positive definite, then Proposition 1 yields that $I - N^{-1}Q$ is convergent for Q. This implies

$$(2.2) \qquad (I - N^{-1}Q) z \in \operatorname{Span}(Q) \quad \forall z \in \operatorname{Span}(Q),$$

and that there exists a $\rho \in (0, 1)$ depending on N and Q only such that

$$(2.3) \qquad \|(I - N^{-1}Q) z\| \leqq \rho \|z\| \quad \forall z \in \operatorname{Span}(Q).$$

(a) Consider any $z \in \operatorname{Span}(Q)$, any integer $k \geqq 1$, any $\underline{\theta} \in (0, 1]$, and any sequence of scalars $\{\theta^1, \theta^2, \cdots\}$ in the interval $[\underline{\theta}, 1]$. Since Q is symmetric positive semidefinite, then there exists a w satisfying $z = Qw$ and

$$(2.4) \qquad \|w\| \leqq \frac{1}{\sigma} \|z\|,$$

where σ denotes the smallest nonzero eigenvalue of Q. Let w^0 denote the orthogonal projection of w onto $\operatorname{Span}(Q)$ and let $w^1, \cdots, w^k$ be given by the formula

$$(2.5) \qquad w^h = (I - \theta^h N^{-1} Q) w^{h-1}, \qquad h = 1, \cdots, k.$$

Then, $z = Qw^0$, $w^0 \in \operatorname{Span}(Q)$, and it is easily seen by using induction on h (together with (2.2), (2.5)) that

$$w^h \in \operatorname{Span}(Q) \quad \forall h = 0, 1, \cdots, k.$$

Then, for each $h \in \{1, \cdots, k\}$, since $w^{h-1} \in \operatorname{Span}(Q)$, we have from (2.3) and (2.5) that

$$\begin{aligned}
\|w^h\| &= \|(I - \theta^h N^{-1} Q) w^{h-1}\| \\
&= \|(1 - \theta^h) w^{h-1} + \theta^h (I - N^{-1} Q) w^{h-1}\| \\
(2.6) \qquad &\leqq (1 - \theta^h) \|w^{h-1}\| + \theta^h \|(I - N^{-1} Q) w^{h-1}\| \\
&\leqq (1 - \theta^h) \|w^{h-1}\| + \theta^h \rho \|w^{h-1}\| \\
&\leqq (1 - \underline{\theta}(1 - \rho)) \|w^{h-1}\|,
\end{aligned}$$

where the last inequality follows from $\theta^h \geqq \underline{\theta}$, and hence

$$\|w^k\| \leqq (1 - \underline{\theta}(1-\rho))^k \|w^0\| \leqq (1 - \underline{\theta}(1-\rho))^k \|w\|.$$

This combined with the observation $\prod_{h=1}^{k}(I-\theta^h QN^{-1})z = Qw^k$ (cf. (2.5) and $z=Qw^0$) and (2.4) then yields

$$\begin{aligned}\left\|\prod_{h=1}^{k}(I-\theta^h QN^{-1})z\right\| &= \|Qw^k\| \\ &\leqq \|Q\|(1-\underline{\theta}(1-\rho))^k\|w\| \\ &\leqq \frac{\|Q\|}{\sigma}(1-\underline{\theta}(1-\rho))^k\|z\|.\end{aligned} \tag{2.7}$$

By setting $\tau=\|Q\|/\sigma$, we complete the proof of part (a).

(b) Consider any $z\in\Re^n$, any integer $k\geqq 1$, any $\underline{\theta}\in(0,1]$, and any sequence of scalars $\{\theta^1,\theta^2,\cdots\}$ in the interval $[\underline{\theta},1]$. Let us decompose z into the sum of z' and z'', for some $z'\in\operatorname{Span}(Q)$ and some $z''\in\operatorname{Null}(Q)$. Since $I-N^{-1}Q$ is convergent for Q we have $(I-N^{-1}Q)z''=z''$, so that

$$(I-\theta^h N^{-1}Q)z''=(1-\theta^h)z''+\theta^h(I-N^{-1}Q)z''=z'',\qquad h=1,\cdots,k.$$

Hence

$$\prod_{h=1}^{k}(I-\theta^h N^{-1}Q)z''=z''. \tag{2.8}$$

Let $z^0=z'$ and let $z^1,\cdots,z^k$ be given by the formula

$$z^h=(I-\theta^h N^{-1}Q)z^{h-1},\qquad h=1,\cdots,k.$$

Then, $z^0\in\operatorname{Span}(Q)$ and it is easily seen by using induction on h (together with (2.2)) that $z^h\in\operatorname{Span}(Q)$ for all h, so (2.3) yields

$$\begin{aligned}\|z^h\| &= \|(I-\theta^h N^{-1}Q)z^{h-1}\| \\ &\leqq (1-\theta^h)\|z^{h-1}\|+\theta^h\|(I-N^{-1}Q)z^{h-1}\| \\ &\leqq (1-\underline{\theta}(1-\rho))\|z^{h-1}\|,\qquad h=1,\cdots,k.\end{aligned} \tag{2.9}$$

Hence

$$\left\|\prod_{h=1}^{k}(I-\theta^h N^{-1}Q)z'\right\| = \|z^k\|\leqq(1-\underline{\theta}(1-\rho))^k\|z^0\|=(1-\underline{\theta}(1-\rho))^k\|z'\|.$$

By combining the above relation with (2.8) and using the obvious facts $\|z'\|\leqq\|z\|$, $\|z''\|\leqq\|z\|$, we obtain

$$\begin{aligned}\left\|\prod_{h=1}^{k}(I-\theta^h N^{-1}Q)z\right\| &\leqq \left\|\prod_{h=1}^{k}(I-\theta^h N^{-1}Q)z'\right\|+\|z''\| \\ &\leqq (1-\underline{\theta}(1-\rho))^k\|z\|+\|z\|\leqq 2\|z\|.\end{aligned}$$

□

Remark 1. Since $I-N^{-1}Q=N^{-1}(I-QN^{-1})N$, the two matrices $I-N^{-1}Q$ and $I-QN^{-1}$ are similar and therefore have identical eigenvalues. Hence part (b) of Lemma 3 implies that the eigenvalues of $I-QN^{-1}$ are also either inside or on the unit circle.

Remark 2. The relaxation parameters $\theta^1,\theta^2,\cdots$ are not needed for establishing our main result (Theorem 1), but they will be used in § 4 when we introduce under/over-relaxation to the mapping $\mathcal{A}_B$.

Remark 3. It can be seen by using Lemma 3(a) that, for any $b \in \operatorname{Span}(Q)$ and any $y^0 \in \Re^m$, the sequence of points $\{y^r\}$ generated according to

$$y^{r+1} = (I - N^{-1}Q)y^r - N^{-1}b, \qquad r = 0, 1, \cdots$$

converges geometrically.

Consider the coordinate descent method for solving the unconstrained version of (P) (i.e., find an x satisfying $Mx + q = 0$)

$$y^{r+1} = (I - (E+L)^{-1}M)y^r - (E+L)^{-1}q,$$

where E and L denote, respectively, the diagonal and the strictly lower triangular part of M. We assume that $q \in \operatorname{Span}(M)$ so the problem has a solution and that E has positive diagonal entries so the above iterations are well defined. (Since M is symmetric positive semidefinite, then a diagonal entry of M is zero if and only if the entire row (column) of M containing that entry is zero, so the second assumption is really not restrictive.) As an immediate consequence of Remark 3, we have that the iterates $\{y^r\}$ converge at a geometric rate. This is because the splitting $(E + L, L^T)$ is easily verified to be regular, so since $q \in \operatorname{Span}(M)$, Remark 3 then implies the geometric rate of convergence of $\{y^r\}$ to some x satisfying $Mx + q = 0$.

Lemma 3 in turn implies the following facts.

LEMMA 4. *Let (B, C) be a regular splitting of M. Then the following hold*:

(a) *For any nonempty $J \subseteq \{1, \cdots, n\}$, there exist $\rho_J \in (0, 1)$ and $\tau_J > 0$ such that*

$$\|(I - M_{JJ}(B_{JJ})^{-1})^k z\| \leqq \tau_J(\rho_J)^k\|z\| \quad \forall k \geqq 1, \quad \forall z \in \operatorname{Span}(M_{JJ}).$$

(b) *There exists a $\Delta \geqq 1$ such that, for any nonempty $J \subseteq \{1, \cdots, n\}$,*

$$\|(I - (B_{JJ})^{-1}M_{JJ})^k z\| \leqq \Delta\|z\| \quad \forall k \geqq 1, \quad \forall z.$$

Proof. Since $B - C$ is positive definite, $B_{JJ} - C_{JJ}$ is positive definite. Parts (a) and (b) then follow immediately from, respectively, parts (a) and (b) of Lemma 3. □

Let

$$I^* = \{i \in \{1, \cdots, n\} \mid d_i^* = 0\}.$$

Then, for each $x^* \in X^*$, we have $M_{I^*}x^* + q_{I^*} = 0$ (cf. Lemma 1), so that

$$q_{I^*} \in \operatorname{Span}(M_{I^*}). \tag{2.10}$$

Moreover, from (1.1) and Lemma 1 we have that $x^* = [x^* - d^*]^+$ for all $x^* \in X^*$. Since $[\cdot]^+$ is the orthogonal projection onto the nonnegative orthant, this shows that, for all $i \notin I^*$,

$$d_i^* > 0 \quad \text{and} \quad x_i^* = 0 \quad \forall x^* \in X^*. \tag{2.11}$$

In the remainder of this paper, we assume that $I^* \neq \emptyset$ for otherwise it is well known that the matrix splitting algorithm terminates finitely. The submatrix of M indexed by I^* has a number of interesting properties, which we show below.

LEMMA 5. *For any $J \subseteq I^*$,* $\operatorname{Span}(M_{J\tilde{J}}) \subseteq \operatorname{Span}(M_{JJ})$ *and* $q_J \in \operatorname{Span}(M_{JJ})$. (*Recall that $\tilde{J}$ denotes the complement of J with respect to* $\{1, \cdots, n\}$.)

Proof. The proof is by contradiction. Suppose that for some $i \notin J$, $M_{Ji} \notin \operatorname{Span}(M_{JJ})$. It then follows that there exists some vector $u \in \Re^{\operatorname{Card}(J)}$ such that

$$\langle u, M_{Ji}\rangle < 0, \qquad M_{JJ}u = 0. \tag{2.12}$$

Let x be the n-dimensional vector given by $x_J = u$, $x_i = 1$ and $x_j = 0$ for all $j \notin J$ with $j \neq i$. Then

$$\langle x, Mx\rangle = \langle u, M_{JJ}u\rangle + 2\langle u, M_{Ji}\rangle,$$

and it follows from (2.12) that

$$\langle x, Mx\rangle < 0,$$

a contradiction of the positive semidefinite property of M. Thus, Span $(M_{J\bar{J}}) \subseteq$ Span (M_{JJ}). This, together with the fact $q_J \in$ Span (M_J) (cf. (2.10) and $J \subseteq I^*$), implies $q_J \in$ Span (M_{JJ}). □

3. A general convergence theorem. Let $\{x^r\}$ be a sequence of iterates generated by the algorithm (1.4)-(1.5), i.e.,

$$x^{r+1} = \mathcal{A}_B(x^r), \qquad r = 0, 1, \cdots,$$

where (B, C) is some regular splitting of M. By Lemma 2(a), $\{x^r\}$ is well defined. We will show that $\{x^r\}$ converges to an element of X^*.

To motivate our proof, note from Lemma 2(b) that, for all r,

$$\begin{aligned} f(x^{r+1}) &\leqq f(x^r) - \langle x^{r+1} - x^r, (B - C)(x^{r+1} - x^r)\rangle/2 \\ &\leqq f(x^r) - \gamma\|x^{r+1} - x^r\|^2/2, \end{aligned} \tag{3.1}$$

where $\gamma > 0$ denotes the smallest eigenvalue of the symmetric part of $(B - C)$. Upon summing this inequality over all r and using the fact that $f(x^r)$ is bounded from below for all r (cf. Assumption A) and the fact that $\gamma > 0$, we obtain

$$\sum_{r=0}^{\infty} \|x^{r+1} - x^r\|^2 < \infty. \tag{3.2}$$

Hence $x^{r+1} - x^r \to 0$, which together with

$$x^{r+1} = [x^{r+1} - (Bx^{r+1} + Cx^r + q)]^+ \tag{3.3}$$

(cf. $x^{r+1} = \mathcal{A}_B(x^r)$), the Lipschitz continuity of $[\cdot]^+$, and the fact $B + C = M$, establishes the following lemma.

LEMMA 6. (a) $x^{r+1} - x^r \to 0$.

(b) $x^r - [x^r - Mx^r - q]^+ \to 0$.

Hence any limit point x^∞ of $\{x^r\}$ satisfies $x^\infty = [x^\infty - Mx^\infty - q]^+$ and is therefore in X^*. This result is quite well known (e.g., [Pan86], [LiP87]) and, as we just saw, is relatively easy to prove. The difficulty lies in showing that $\{x^r\}$ indeed has a limit point. This is a highly nontrivial task to which the remainder of this section will be devoted.

Remark 4. Equation (3.2) gives an estimate of the rate at which $x^{r+1} - x^r \to 0$, but technically speaking, it is not enough for us to claim the convergence of $\{x^r\}$ since it does not prevent $x^{r+1} - x^r$ to decrease like $1/r$, in which case $\|x^r\| \to \infty$. Intuitively, it seems unlikely that such a sequence of iterates can be generated by the matrix splitting algorithm, but to show this rigorously is very difficult, as indicated by the complexity of the proof given below.

For each $x \in \mathfrak{R}^n$, let $\phi(x)$ denote the distance from x to X^*, i.e.,

$$\phi(x) = \min_{x^* \in X^*} \|x - x^*\|.$$

The next lemma, which shows that $\{Mx^r\}$ converges and that $\{x^r\}$ comes arbitrarily close to X^*, follows as a direct consequence of Lemma 6.

LEMMA 7. (a) $Mx^r + q \to d^*$.

(b) $\phi(x^r) \to 0$.

Proof. Part (a) is shown in Theorem 3.1 of [Pan86]. Part (b) is a direct consequence of part (a) and the upper-Lipschitzian property of the solution set of a monotone linear complementarity problem (see [Rob81]). □

Now let us map out the directions for the most intricate part of our proof. By Lemma 7(b), we know that $\{x^r\}$ comes arbitrarily close to X^*, but we do not know if it is bounded. Now, it is easily seen from Lemmas 6(b) and 7(a) that those coordinates x_i^r, $i \notin I^*$, stay fixed to the boundary point 0 for all r sufficiently large; so we need to consider only those coordinates of x^r indexed by I^*. If these coordinates all stay strictly away from zero (which, for example, holds if every element x^* of X^* is *nondegenerate* in the sense that $x_i^* > 0$ for all $i \in I^*$), then the problem effectively becomes unconstrained and it immediately follows from Keller's result (see Remark 3) that all coordinates of x^r converge at a geometric rate. Hence the difficulty lies with those coordinates x_i^r $(i \in I^*)$ that bounce around the boundary point zero, possibly causing one of the remaining coordinates to sail off to infinity. To resolve this difficulty, we will show that these coordinates perturb the movement of the remaining coordinates only (additively) by their own maximum deviation from the boundary. This fact, shown in Lemma 8 below, is based on the contraction property of the algorithmic mapping for the unconstrained case (cf. Lemma 4) and Lemma 5. Then those coordinates of x^r that start out far from the boundary will stay far from the boundary (cf. geometric convergence for the unconstrained case), unless one of the remaining coordinates also moves far from the boundary, so that, eventually, each coordinate of x^r either stays close to the boundary or stays far from the boundary. Those coordinates that stay close to the boundary are clearly bounded; those coordinates that stay far from the boundary are also bounded because perturbation by the other coordinates is bounded and, within themselves, the convergence is geometric (since they are effectively unconstrained). We now proceed with the actual proof.

Let

$$\beta = 1 + \max_{J \subseteq I^*} \sqrt{\operatorname{Card}(\tilde{J})} \left\{ \left(\frac{\tau_J \|(B_{JJ})^{-1}\| \, \|M_{JJ}\|}{1-\rho_J} + \Delta + 1 \right) \|(B_{JJ})^{-1} B_{J\tilde{J}}\| + \frac{\tau_J \|(B_{JJ})^{-1}\| \, \|M_{J\tilde{J}}\|}{1-\rho_J} \right\}.$$

The following lemma, based on Lemmas 1, 4, and 5, shows that those coordinates of x^r that stay away from the boundary of X are influenced by the remaining coordinates only through the distance, scaled by β, of these remaining coordinates from the boundary of X. This result allows us to separate the effect of these two sets of coordinates on each other.

LEMMA 8 (coordinate separation). *Consider any $J \subseteq I^*$. If for some two integers $s \geqq t \geqq 0$ we have $x_i^r > 0$ for all $i \in J$ and all $r = t+1, t+2, \cdots, s$, then, for any $x^* \in X^*$,*

$$\|x_J^s - x_J^*\| \leqq \Delta \|x_J^t - x_J^*\| + \beta \max_{r \in \{t, \cdots, s\}} \|x_{\tilde{J}}^r - x_{\tilde{J}}^*\|_\infty .$$

Proof. The claim clearly holds if $s = t$ (since $\Delta \geqq 1$). Suppose that $s > t$. Since $x_i^r > 0$ for all $i \in J$ and all $r = t+1, \cdots, s$, it follows from the fact $x^{r+1} = [x^{r+1} - (Bx^{r+1} + Cx^r + q)]^+$ for all r (cf. (3.3)) that

$$B_J x^{r+1} + C_J x^r + q_J = 0, \qquad r = t, \cdots, s-1,$$

or equivalently (using $M_J = B_J + C_J$),

$$B_J(x^{r+1} - x^r) + M_J x^r + q_J = 0, \qquad r = t, \cdots, s-1.$$

Since $J \subseteq I^*$, we also have (using Lemma 1 and the definition of I^*)

$$M_J x^* + q_J = 0.$$

Combining the above two equalities and multiplying by $(B_{JJ})^{-1}$ yields

$$(B_{JJ})^{-1}B_J(x^{r+1}-x^r)+(B_{JJ})^{-1}M_J(x^r-x^*)=0, \qquad r=t,\cdots,s-1.$$

This in turn implies, after some rearrangement of terms, that

$$\begin{aligned} x_J^{r+1}-x_J^* &= (I-(B_{JJ})^{-1}M_{JJ})(x_J^r-x_J^*)-(B_{JJ})^{-1}M_{J\tilde{J}}(x_{\tilde{J}}^r-x_{\tilde{J}}^*) \\ &\quad -(B_{JJ})^{-1}B_{J\tilde{J}}(x_{\tilde{J}}^{r+1}-x_{\tilde{J}}^r), \qquad r=t,\cdots,s-1. \end{aligned}$$

By letting $G=I-(B_{JJ})^{-1}M_{JJ}$ and successively applying the above recursion for $r=t,\cdots,s-1$, we obtain

$$\begin{aligned} x_J^s-x_J^* &= (G)^h(x_J^t-x_J^*)-\sum_{k=0}^{h-1}(G)^{h-k-1}(B_{JJ})^{-1}M_{J\tilde{J}}(x_{\tilde{J}}^{t+k}-x_{\tilde{J}}^*) \\ &\quad -\sum_{k=0}^{h-1}(G)^{h-k-1}(B_{JJ})^{-1}B_{J\tilde{J}}(x_{\tilde{J}}^{t+k+1}-x_{\tilde{J}}^{t+k}), \end{aligned} \tag{3.4}$$

where we denote $h=s-t$. Now we estimate the last sum in (3.4). Let

$$y^k=(B_{JJ})^{-1}B_{J\tilde{J}}(x_{\tilde{J}}^{t+k}-x_{\tilde{J}}^*), \qquad k=0,1,\cdots,h.$$

Then the last sum in (3.4) can be rewritten as $\sum_{k=0}^{h-1}(G)^{h-k-1}(y^{k+1}-y^k)$. By rearranging the terms within the summation sign, we obtain an alternative form for this sum:

$$\begin{aligned} \sum_{k=0}^{h-1}(G)^{h-k-1}(y^{k+1}-y^k) &= \sum_{k=0}^{h-1}(G)^{h-k-1}y^{k+1}-\sum_{k=0}^{h-1}(G)^{h-k-1}y^k \\ &= \sum_{k=1}^{h-1}(G)^{h-k-1}(G)y^k+y^h-(G)^{h-1}y^0-\sum_{k=1}^{h-1}(G)^{h-k-1}y^k \\ &= \sum_{k=1}^{h-1}(G)^{h-k-1}(G-I)y^k+y^h-(G)^{h-1}y^0. \end{aligned}$$

Since $G-I=-(B_{JJ})^{-1}M_{JJ}$, this together with (3.4) implies that

$$\begin{aligned} x_J^s-x_J^* &= (G)^h(x_J^t-x_J^*)-\sum_{k=0}^{h-1}(G)^{h-k-1}(B_{JJ})^{-1}M_{J\tilde{J}}(x_{\tilde{J}}^{t+k}-x_{\tilde{J}}^*) \\ &\quad +\sum_{k=1}^{h-1}(G)^{h-k-1}(B_{JJ})^{-1}M_{JJ}y^k-y^h+(G)^{h-1}y^0. \end{aligned}$$

Let $H=I-M_{JJ}(B_{JJ})^{-1}$. Then $G=(B_{JJ})^{-1}HB_{JJ}$, so that $(G)^{h-k-1}=(B_{JJ})^{-1}(H)^{h-k-1}B_{JJ}$ for all k. This together with the above equation yields

$$\begin{aligned} x_J^s-x_J^* &= (G)^h(x_J^t-x_J^*)-\sum_{k=0}^{h-1}(B_{JJ})^{-1}(H)^{h-k-1}M_{J\tilde{J}}(x_{\tilde{J}}^{t+k}-x_{\tilde{J}}^*) \\ &\quad +\sum_{k=1}^{h-1}(B_{JJ})^{-1}(H)^{h-k-1}M_{JJ}y^k-y^h+(G)^{h-1}y^0. \end{aligned}$$

Also, since $J\subseteq I^*$, we have from Lemma 4 that $\|(H)^{h-k-1}z\|\leqq\tau_J(\rho_J)^{h-k-1}\|z\|$ for any $z\in\operatorname{Span}(M_{JJ})$ and $\|(G)^hz\|\leqq\Delta\|z\|$ for any z. This, together with the above equation and the fact Span $(M_{J\tilde{J}}) \subseteq$ Span (M_{JJ}) (cf. Lemma 5), implies

$$\begin{aligned}
\|x^s_J - x^*_J\| &\leqq \|(G)^b(x^t_J - x^*_J)\| + \sum_{k=0}^{h-1} \|(B_{JJ})^{-1}\| \, \|(H)^{h-k-1} M_{J\tilde{J}}(x^{t+k}_{\tilde{J}} - x^*_{\tilde{J}})\| \\
&\quad + \sum_{k=1}^{h-1} \|(B_{JJ})^{-1}\| \, \|(H)^{h-k-1} M_{JJ} y^k\| + \|y^h\| + \|(G)^{h-1} y^0\| \\
&\leqq \Delta \|x^t_J - x^*_J\| + \sum_{k=0}^{h-1} \|(B_{JJ})^{-1}\| \tau_J (\rho_J)^{h-k-1} \|M_{J\tilde{J}}(x^{t+k}_{\tilde{J}} - x^*_{\tilde{J}})\| \\
&\quad + \sum_{k=1}^{h-1} \|(B_{JJ})^{-1}\| \tau_J (\rho_J)^{h-k-1} \|M_{JJ} y^k\| + \|y^h\| + \Delta \|y^0\| \\
&\leqq \Delta \|x^t_J - x^*_J\| + \tau_J \|(B_{JJ})^{-1}\| \, \|M_{J\tilde{J}}\| \sum_{k=0}^{h-1} (\rho_J)^{h-k-1} \max_{r \in \{t, \cdots, s-1\}} \|x^r_{\tilde{J}} - x^*_{\tilde{J}}\| \\
&\quad + \tau_J \|(B_{JJ})^{-1}\| \, \|M_{JJ}\| \sum_{k=1}^{h-1} (\rho_J)^{h-k-1} \max_{k \in \{1, \cdots, h-1\}} \|y^k\| + \|y^h\| + \Delta \|y^0\| \\
&\leqq \Delta \|x^t_J - x^*_J\| + \tau_J \|(B_{JJ})^{-1}\| \, \|M_{J\tilde{J}}\| (1 - \rho_J)^{-1} \max_{r \in \{t, \cdots, s-1\}} \|x^t_{\tilde{J}} - x^*_{\tilde{J}}\| \\
&\quad + \tau_J \|(B_{JJ})^{-1}\| \, \|M_{JJ}\| (1 - \rho_J)^{-1} \max_{k \in \{1, \cdots, h-1\}} \|y^k\| + \|y^h\| + \Delta \|y^0\|.
\end{aligned}$$

Since $y^k = (B_{JJ})^{-1} B_{J\tilde{J}}(x^{t+k}_{\tilde{J}} - x^*_{\tilde{J}})$, we also have $\|y^k\| \leqq \|(B_{JJ})^{-1} B_{J\tilde{J}}\| \, \|x^{t+k}_{\tilde{J}} - x^*_{\tilde{J}}\|$ for every k, and the lemma is proved. □

By using Lemmas 6–8, we can now prove our main result that $\{x^r\}$ converges (see Theorem 1). The basic idea of the proof is to show that those coordinates of x^r that are bounded sufficiently far away from the boundary of X are essentially unaffected by the rest. This then allows us to treat these coordinates as if they are unconstrained and by using the contraction property of $\mathcal{A}_B$ on them, we conclude convergence for these coordinates.

In our proof, we will make frequent use of the following scalars:

$$\begin{aligned}
&\sigma_0 = 1, \\
&\sigma_k = \Delta + 3 + \beta + (\beta + 1)\sigma_{k-1}, \qquad k = 1, 2, \cdots, n.
\end{aligned}$$

(Note that $\sigma_k \geqq 1$ for all k and is monotonically increasing with k.) We will also use the fact (cf. Lemmas 6(a) and 7(b)) that, for any $\delta > 0$, there exists a scalar r_δ such that

$$\phi(x^r) \leqq \delta \quad \forall r \geqq r_\delta, \tag{3.5}$$

$$\|x^{r+1} - x^r\| \leqq \delta \quad \forall r \geqq r_\delta. \tag{3.6}$$

Since $x^*_i = 0$ for all $i \notin I^*$ and all $x^* \in X^*$ (cf. (2.11)), it immediately follows from (3.5) that

$$x^r_i \leqq \delta \quad \forall r \geqq r_\delta, \quad \forall i \notin I^*. \tag{3.7}$$

Our proof comprises a sequence of three lemmas. The first lemma roughly shows that if those coordinates of x^r which start near the boundary of X stay near the boundary while the remaining coordinates start far from the boundary, then x^r will stay close to the optimal solution set.

LEMMA 9. *Fix any $\delta > 0$ and let r_δ be a scalar such that* (3.5)-(3.6) *hold. If for some $k \in \{1, \cdots, n\}$, some nonempty $J \subseteq I^*$ and some two integers $t' > t \geqq r_\delta$ we have*

$$x_i^t > \sigma_k \delta \quad \forall i \in J, \tag{3.8}$$

$$x_i^r \leqq \sigma_{k-1} \delta \quad \forall i \notin J, \quad \forall r = t, t+1, \cdots, t'-1, \tag{3.9}$$

then the following hold:

(a) $x_i^{t'} > \sigma_{k-1}\delta$, *for all* $i \in J$.

(b) *There exists an $x^* \in X^*$ such that*

$$\|x^r - x^*\|_\infty \leqq \sigma_k \delta \quad \forall r = t, t+1, \cdots, t'-1.$$

Proof. Let x^* be any element of X^* satisfying $\phi(x^t) = \|x^t - x^*\|$. Then we have from (3.5) that

$$\|x^t - x^*\| \leqq \delta. \tag{3.10}$$

Also we have from (3.9) that, for all $i \notin J$, $x_i^* \leqq x_i^t + \|x^t - x^*\| \leqq \sigma_{k-1}\delta + \|x^t - x^*\|$, which together with (3.10) implies $0 \leqq x_i^* \leqq \sigma_{k-1}\delta + \delta$. Since $0 \leqq x_i^r \leqq \sigma_{k-1}\delta$ for $r = t, t+1, \cdots, t'-1$ (cf. (3.9)), this in turn implies that

$$|x_i^r - x_i^*| \leqq \sigma_{k-1}\delta + \delta \quad \forall i \notin J, \quad \forall r = t, t+1, \cdots, t'-1. \tag{3.11}$$

Next we prove by induction that, for $r = t, t+1, \cdots, t'-1$,

$$x_i^r > \sigma_{k-1}\delta + \delta \quad \forall i \in J. \tag{3.12}$$

Equation (3.12) clearly holds for $r = t$ (cf. (3.8) and $\sigma_k \geqq \sigma_{k-1} + 1$). Suppose that (3.12) holds for $r = t, t+1, \cdots, s$, for some $s \in \{t, t+1, \cdots, t'-2\}$. We will prove that it also holds for $r = s+1$. Since $x_i^r > 0$ for all $i \in J$ and all $r = t+1, \cdots, s$ (cf. (3.12)), we have from Lemma 8 that

$$\|x_J^s - x_J^*\| \leqq \Delta \|x_J^t - x_J^*\| + \beta \max_{r \in \{t, \cdots, s\}} \|x_{\bar{J}}^r - x_{\bar{J}}^*\|_\infty,$$

which together with (3.10) and (3.11) implies

$$\|x_J^s - x_J^*\| \leqq \Delta\delta + \beta(\sigma_{k-1}\delta + \delta). \tag{3.13}$$

Then we have that, for any $i \in J$,

$$\begin{aligned} x_i^{s+1} &\geqq x_i^t - \|x_J^t - x_J^{s+1}\| \\ &\geqq x_i^t - (\|x_J^t - x_J^*\| + \|x_J^* - x_J^s\| + \|x_J^s - x_J^{s+1}\|) \\ &> \sigma_k\delta - (\delta + \|x_J^* - x_J^s\| + \delta) \\ &\geqq \sigma_k\delta - (\delta + (\Delta\delta + \beta\sigma_{k-1}\delta + \beta\delta) + \delta) \\ &= \sigma_{k-1}\delta + \delta, \end{aligned}$$

where the strict inequality follows from (3.6), (3.8), and (3.10). This completes the induction and proves that (3.12) holds for $r = t, t+1, \cdots, t'-1$. Since (3.12) holds for $r = t, t+1, \cdots, t'-1$, it can be seen from the argument above that (3.13) holds for $s = t, t+1, \cdots, t'-1$, which when combined with (3.11) (and using the facts $\beta > 1$ and $\|z\|_\infty \leqq \|z\|$ for all z) yields

$$\|x^r - x^*\|_\infty \leqq (\Delta + \beta\sigma_{k-1} + \beta)\delta \quad \forall r = t, t+1, \cdots, t'-1.$$

Since $\Delta+\beta\sigma_{k-1}+\beta\leqq\sigma_k$, this proves part (b). From (3.12) with $r=t'-1$, we have that, for all $i\in J$,

$$\begin{aligned} x_i^{t'} &\geqq x_i^{t'-1}-\|x^{t'-1}-x^{t'}\| \\ &>\sigma_{k-1}\delta+\delta-\|x^{t'-1}-x^{t'}\|. \end{aligned}$$

Since $\|x^{t'-1}-x^{t'}\|\leqq\delta$ (cf. (3.6)), this proves part (a). □

The following lemma extends Lemma 9 by removing the assumption that the coordinates that start near the boundary of X remain near the boundary (while still assuming that the remaining coordinates start far from the boundary).

LEMMA 10. *Fix any $\delta>0$ and let r_δ be a scalar such that* (3.5)-(3.6) *hold. If for some $k\in\{1,\cdots,n\}$, some $J\subseteq I^*$ with* Card $(J)\geqq$ Card $(I^*)-k+1$ *and some integer $t\geqq r_\delta$ we have*

$$x_i^t>\sigma_k\delta\quad\forall i\in J,\qquad x_i^t\leqq\sigma_{k-1}\delta\quad\forall i\notin J;$$

then there exist an $x^*\in X^*$ and a $\bar{t}\geqq t$ satisfying

$$\|x^r-x^*\|_\infty\leqq\sigma_k\delta\quad\forall r\geqq\bar{t}. \tag{3.14}$$

Proof. Our proof is by induction on k. By Lemma 9(b), we see that the claim holds for $k=1$. (Since in this case $J=I^*$, then, by (3.7), condition (3.9) is satisfied for all $t'\geqq t$, so Lemma 9(b) yields that there exists an $x^*\in X^*$ such that $\|x^r-x^*\|_\infty\leqq\sigma_k\delta$ for all $r\geqq t$.) Suppose that the claim holds for $k=1,2,\cdots,h-1$, for some $h\geqq2$. We show below that it also holds for $k=h$.

Fix any $J\subseteq I^*$ with Card $(J)\geqq$ Card $(I^*)-h+1$ and any integer t for which

$$x_i^t>\sigma_h\delta\quad\forall i\in J, \tag{3.15}$$

$$x_i^t\leqq\sigma_{h-1}\delta\quad\forall i\notin J. \tag{3.16}$$

We consider two cases.

Case 1. $x_i^r\leqq\sigma_{h-1}\delta$, for all $i\notin J$ and all $r\geqq t$. Since $x_i^t>\sigma_h\delta$, for all $i\in J$ (cf. (3.15)), it immediately follows from Lemma 9(b) that there exists an $x^*\in X^*$ such that

$$\|x^r-x^*\|_\infty\leqq\sigma_h\delta\quad\forall r\geqq t.$$

This shows that (3.14) holds for $k=h$ (with $\bar{t}=t$ and with the above choice of x^*).

Case 2. There exists an $r>t$ and an $i\notin J$ such that $x_i^r>\sigma_{h-1}\delta$. Let

$$t'=\text{smallest } r\ (r>t) \text{ such that } x_i^r>\sigma_{h-1}\delta \text{ for some } i\notin J.$$

Then, by (3.16), $x_i^r\leqq\sigma_{h-1}\delta$ for all $i\notin J$ and all $r=t,t+1,\cdots,t'-1$. Since $x_i^t>\sigma_h\delta$, for all $i\in J$ (cf. (3.15)), Lemma 9(a) yields that

$$x_i^{t'}>\sigma_{h-1}\delta\quad\forall i\in J. \tag{3.17}$$

Consider the $h+1$ intervals

$$[0,\sigma_0\delta],\quad(\sigma_0\delta,\sigma_1\delta],\quad(\sigma_1\delta,\sigma_2\delta],\quad\cdots,\quad(\sigma_{h-2}\delta,\sigma_{h-1}\delta],\quad(\sigma_{h-1}\delta,\infty). \tag{3.18}$$

We have from (3.17) and the fact $x_i^{t'}>\sigma_{h-1}\delta$ for some $i\notin J$ that the $(h+1)$st interval contains at least Card $(J)+1$ elements from the set $\{x_1^{t'},x_2^{t'},\cdots,x_n^{t'}\}$. Also, (3.7) and $\sigma_0=1$ imply that the first interval contains at least $n-$Card (I^*) elements from the same set. Since Card $(J)\geqq$ Card $(I^*)-h+1$, this leaves at most $h-2$ elements from that set to go into the remaining $h-1$ intervals. Hence, by the pigeon hole principle, there must exist some $j\in\{1,2,\cdots,h-1\}$ such that

$$x_i^{t'}\notin(\sigma_{j-1}\delta,\sigma_j\delta]\quad\forall i.$$

Let h' be the largest j for which this occurs. Then the interval $(\sigma_{h'}\delta, \infty)$ contains at least Card $(J)+h-h'$ elements from the set $\{x_1^{t'}, x_2^{t'}, \cdots, x_n^{t'}\}$. Let J' be the index set for these elements, i.e., $J'=\{i \mid x_i^{t'} > \sigma_{h'}\delta\}$. Then we have

$$x_i^{t'} > \sigma_{h'}\delta \quad \forall i \in J', \qquad x_i^{t'} \leqq \sigma_{h'-1}\delta \quad \forall i \notin J',$$

and

$$\begin{aligned} \text{Card}\,(J') &\geqq \text{Card}\,(J)+h-h' \\ &\geqq \text{Card}\,(I^*)+1-h'. \end{aligned}$$

Moreover, by (3.7), we have $J' \subseteq I^*$. Since $h' < h$, we can apply our induction hypothesis to h', J', and t' to conclude that there exists an $x^* \in X^*$ and a $\bar{t} \geqq t'$ satisfying

$$\|x^r - x^*\|_\infty \leqq \sigma_{h'}\delta \quad \forall r \geqq \bar{t}.$$

Since $\sigma_{h'} \leqq \sigma_h$, this shows that (3.14) holds for $k=h$ (with the given $\bar{t}$ and x^*).

Hence in either case the claim holds for $k=h$. This then completes the induction on k and proves the lemma. □

We are now ready to prove the following key lemma.

LEMMA 11. *For any $\delta > 0$, there exists an $x^* \in X^*$ and an $\hat{r} > 0$ such that*

$$\|x^r - x^*\|_\infty \leqq \sigma_n\delta + \delta \quad \forall r \geqq \hat{r}. \tag{3.19}$$

Proof. The proof is based on Lemma 10. Fix any $\delta > 0$ and let r_δ be a scalar such that (3.5)-(3.6) hold. Choose any integer $\bar{r} \geqq r_\delta$ and consider the two possible cases: either (i) $x_i^r \leqq \sigma_n\delta$ for all i and all $r \geqq \bar{r}$, or (ii) there exists a $t \geqq \bar{r}$ and an i such that $x_i^t > \sigma_n\delta$. In case (i), let x^* be an element of X^* such that $\phi(x^{\bar{r}}) = \|x^{\bar{r}} - x^*\|$. Then we have from (3.5) that, for all i,

$$0 \leqq x_i^* \leqq x_i^{\bar{r}} + \|x^{\bar{r}} - x^*\| \leqq \sigma_n\delta + \delta.$$

Since $0 \leqq x_i^r \leqq \sigma_n\delta$ for all i and all $r \geqq \bar{r}$, this implies that

$$\|x^r - x^*\|_\infty \leqq \sigma_n\delta + \delta \quad \forall r \geqq \bar{r}.$$

Hence (3.19) holds with $\hat{r} = \bar{r}$ and with the above choice of x^*. Now consider case (ii). In this case, by the pigeon hole principle, one of the following n intervals

$$(\sigma_0\delta, \sigma_1\delta], \quad (\sigma_1\delta, \sigma_2\delta], \quad \cdots, \quad (\sigma_{n-1}\delta, \sigma_n\delta]$$

does not contain any element from $\{x_1^t, x_2^t, \cdots, x_n^t\}$, i.e., there exists $j \in \{1, 2, \cdots, n\}$ such that

$$x_i^t \notin (\sigma_{j-1}\delta, \sigma_j\delta] \quad \forall i.$$

Choose k to be the *largest* such j and let $J = \{i \mid x_i^t > \sigma_k\delta\}$. Then Card $(J) \geqq n-k+1$ and

$$x_i^t > \sigma_k\delta \quad \forall i \in J, \qquad x_i^t \leqq \sigma_{k-1}\delta \quad \forall i \notin J.$$

Moreover, by (3.7) and $\sigma_k \geqq 1$, we see that $J \subseteq I^*$. Hence the assumptions of Lemma 10 are satisfied by k, J, and t, and it follows from Lemma 10 that there exists an $x^* \in X^*$ and a $\bar{t} \geqq t$ satisfying

$$\|x^r - x^*\|_\infty \leqq \sigma_k\delta \quad \forall r \geqq \bar{t}.$$

Since $\sigma_k \leqq \sigma_n$, this shows that (3.19) holds (with the given x^* and with $\hat{r} = \bar{t}$). □

The following main convergence result then follows as a corollary of Lemma 11.

THEOREM 1. *The matrix splitting algorithm* (1.4)-(1.5) *is well defined and it generates a sequence of iterates* $\{x^r\}$ *converging to an element of* X^*.

Proof. The algorithm is well defined by Lemma 2(a). Now, for any $\varepsilon > 0$, Lemma 11 shows that there exists an $x^* \in X^*$ and an $\hat{r} > 0$ such that

$$\|x^r - x^*\|_\infty < \varepsilon/2 \quad \forall r \geqq \hat{r}.$$

Hence, for all $r_1, r_2 > \hat{r}$, there holds

$$\begin{aligned}\|x^{r_1} - x^{r_2}\|_\infty &\leqq \|x^{r_1} - x^*\|_\infty + \|x^* - x^{r_2}\|_\infty \\ &\leqq \varepsilon/2 + \varepsilon/2 = \varepsilon.\end{aligned}$$

This implies that $\{x^r\}$ is a Cauchy sequence so that it converges. By Lemma 7(b), it converges to an element of X^*. □

4. SOR matrix splitting algorithms. In this section we consider three extensions of the basic algorithm (1.4)-(1.5). First, we consider one that adds an under/overrelaxation parameter to the algorithm. This extension is motivated by the block SOR methods of Cottle, Golub, and Sacher [CGS78], of Cottle and Goheen [CoG78], and of Cottle and Pang [CoP82] (which introduced a mechanism for overrelaxation) and the methods of Mangasarian [Man77] and of Aganagic [Aga78] (which introduced a mechanism for underrelaxation). Second, we consider a Gauss-Seidel extension of the basic algorithm. In this algorithm, only a subset of the coordinates are relaxed at each iteration while the other coordinates are held fixed. Last, we consider an SOR extension of the basic algorithm which allows noncyclic order of relaxation. This third algorithm contains the previous two as special cases but is shown to be convergent only in a certain weak sense.

We first describe the under/overrelaxation extension. In the algorithm, we choose a splitting (B, C) of M and a relaxation parameter $\bar{\omega}$ satisfying

$$0 < \bar{\omega}, \qquad B - C + (1 - \bar{\omega})M \text{ is positive definite.} \tag{4.1}$$

We also choose a second relaxation parameter $\underline{\omega}$ satisfying

$$0 < \underline{\omega} \leqq \min\{1, \bar{\omega}\}, \tag{4.2}$$

and an $n \times n$ positive *diagonal* matrix D. Then, for any chosen $x^0 \in X$, we generate a sequence of vectors $\{x^0, x^1, \cdots\}$ in X by the formula

$$x^{r+1} = (1 - \omega^r)x^r + \omega^r \hat{x}^r, \tag{4.3}$$

where $\hat{x}^r$ is a solution of the equation

$$y = [y - D(By + Cx^r + q)]^+, \tag{4.4}$$

and ω^r is *any* scalar in $[\underline{\omega}, \bar{\omega}]$ such that x^{r+1} given by (4.3) is in X.

Note that if (B, C) is a regular splitting and

$$0 < \bar{\omega} < 1 + \frac{1}{\|Q^{-1/2}MQ^{-1/2}\|},$$

where Q denotes the symmetric part of $B - C$, i.e., $Q = ((B - C) + (B - C)^T)/2$, then (4.1) is satisfied. Hence, the algorithm above contains as a special case the algorithm (1.4)-(1.5) (let $\underline{\omega} = \bar{\omega} = 1$ and D be the $n \times n$ identity matrix). The relaxation parameter we introduced in (4.3) is useful mainly when $\omega^r > 1$ (i.e., *overrelaxation* [OrR70]), which in some cases can significantly improve the convergence. Nonetheless, the case of *underrelaxation*, i.e., $\omega^r < 1$, is also of some practical interest since, in this case, it is only required that $B-C$ be positive definite on the null space of M (instead of on the entire space) in order for (4.1) to hold. The purpose for introducing the matrix D in (4.4) is, from the point of view of convergence, largely cosmetic as the presence of D does not change the sequence of iterates generated. (To see this, note that since D is a diagonal matrix, y is a solution of (4.4) if and only if $y \in X$ and $y_i = 0$ for all i such that $D_{ii}(B_i y + C_i x^r + q_i) > 0$. Since $D_{ii} > 0$ for all i, this set of conditions is equivalent to $y \in X$ and $y_i = 0$ for all i such that $B_i y + C_i x^r + q_i > 0$, which in turn is equivalent to $y = [y - (By + Cx^r + q)]^+$ or, by (1.4), $y = \mathcal{A}_B(x^r)$.) However, by choosing D to match the structure of B and C, we can in some cases simplify the form of the iteration (see § 5 for examples). Note that since the sequence of iterates generated is independent of D, we can also allow D to be time-varying.

By modifying the argument used in §§ 2 and 3, we can show that the algorithm (4.1)-(4.4) is convergent.

THEOREM 2. *For any splitting* (B, C) *of* M *and any scalars* $\underline{\omega}$, $\bar{\omega}$ *satisfying* (4.1)-(4.2), *any* $n \times n$ *positive diagonal matrix* D *and any* $x^0 \in X$, *the sequence of iterates* $\{x^r\}$ *generated by* (4.3)-(4.4) *is well defined and converges to an element of* X^*.

Sketch of proof. Since $2B = (B - C + (1-\bar{\omega})M) + \bar{\omega}M$ (cf. $M = B + C$) and $\bar{\omega}M$ is positive semidefinite, we have from (4.1) that B is positive definite. The proof of Lemma 2(a) then shows that $\mathcal{A}_B$ is a well-defined point-to-point mapping. For $r = 0, 1, \cdots$, let $\hat{x}^r$ be a solution of (4.4). Then from the preceding discussion we have that

$$\hat{x}^r = \mathcal{A}_B(x^r), \qquad r = 0, 1, \cdots,$$

so that $\{\hat{x}^r\}$ is well defined. Since $x^{r+1} = (1-\omega^r)x^r + \omega^r \hat{x}^r$ for all r (cf. (4.3)), $\{x^r\}$ is well defined.

It remains to show that $\{x^r\}$ is convergent. The proof of this is analogous to that of Theorem 1, with Lemmas 4, 6, and 8 replaced by more general versions of themselves that take into account the relaxation parameters. More precisely, by applying Lemma 3 with the identifications $Q \leftrightarrow M_{JJ}$, $N \leftrightarrow B_{JJ}/\omega$, $\underline{\theta} \leftrightarrow \underline{\omega}/\bar{\omega}$, it is easily seen that the following generalization of Lemma 4 holds:

(a) For any nonempty $J \subseteq \{1, \cdots, n\}$, there exist $\rho_J \in (0, 1)$ and $\tau_J > 0$ such that

$$\left\| \prod_{h=s}^{s+k-1} (I - \omega^h M_{JJ}(B_{JJ})^{-1}) z \right\| \leqq \tau_J (\rho_J)^k \|z\| \quad \forall k \geqq 1, \quad \forall s \geqq 0, \quad \forall z \in \operatorname{Span}(M_{JJ}).$$

(b) There exists a $\Delta > 0$ such that, for any nonempty $J \subseteq \{1, \cdots, n\}$,

$$\left\| \prod_{h=s}^{s+k-1} (I - \omega^h (B_{JJ})^{-1} M_{JJ}) z \right\| \leqq \Delta \|z\| \quad \forall k \geqq 1, \quad \forall s \geqq 0, \quad \forall z.$$

By using the above generalized version of Lemma 4 in place of Lemma 4, it can be verified that Lemma 8, with "$x_i^r > 0$ for all $i \in J$ and all $r = t+1, \cdots, s$" replaced by "$\hat{x}_i^r > 0$ for all $i \in J$ and all $r = t+1, \cdots, s$," still holds (possibly with a different constant β that depends not only on M and B, but also on $\underline{\omega}$ and $\bar{\omega}$). Also, it can be verified by using (4.1), (4.3), (4.4), and $\omega^r \in [\underline{\omega}, \bar{\omega}]$, for all r, that relation (3.1) still holds (with a slightly different γ given by $\gamma =$ smallest eigenvalue of the symmetric part of $((1-\bar{\omega})M + B - C)/\underline{\omega})$, so it readily follows that Lemmas 6 and 7 also hold.

Now, we have from (4.3) that, for all r, $x^{r+1} - \hat{x}^r = (1 - 1/\omega^r)(x^{r+1} - x^r)$, so

$$\|x^{r+1} - \hat{x}^r\| \leqq \max\{1, 1/\underline{\omega}\} \|x^{r+1} - x^r\|.$$

Then, by redefining the scalar σ_0 to be $1 + \max\{1, 1/\underline{\omega}\}$ with the other scalars $\sigma_1, \cdots, \sigma_n$ recursively defined as before, the proof of Lemma 9 (which depends on Lemmas 6-8 only) still goes through. Lemmas 10 and 11 then follow from Lemmas 6, 7, and 9 as before. □

Remark 5. We can also use *different relaxation parameters for different coordinates* provided that the relaxation parameters are *fixed.* More precisely, let us consider the following underrelaxed algorithm:

$$x^{r+1}=\begin{bmatrix}1-\bar{\omega}_1 & & \\ & \ddots & \\ & & 1-\bar{\omega}_n\end{bmatrix}x^r+\begin{bmatrix}\bar{\omega}_1 & & \\ & \ddots & \\ & & \bar{\omega}_n\end{bmatrix}\mathscr{A}_B(x^r), \qquad r=0,1,\cdots,$$

where $x^0\in X$, $\bar{\omega}_1,\cdots,\bar{\omega}_n$ are fixed scalars in the interval $(0,1]$, and (B, C) is a splitting of M for which the matrix

$$2B\begin{bmatrix}1/\bar{\omega}_1 & & \\ & \ddots & \\ & & 1/\bar{\omega}_n\end{bmatrix}-M$$

is positive definite. In the special case where $\bar{\omega}_1=\cdots=\bar{\omega}_n$, this algorithm reduces to the algorithm (4.1)-(4.4) using fixed underrelaxation. By suitably modifying the proof of Theorem 2, it can be shown that this underrelaxed algorithm is convergent.

Now we consider a Gauss-Seidel type algorithm. Let $\{1,\cdots,n\}$ be partitioned into m nonempty, mutually disjoint subsets $I_1, I_2,\cdots,I_m$ (i.e., $I_i\cap I_j=\varnothing$ if $i\neq j$ and $I_1\cup\cdots\cup I_m=\{1,\cdots,n\}$). For $j=1,\cdots,m$, we choose a regular splitting $(B_{I_jI_j}, C_{I_jI_j})$ of $M_{I_jI_j}$ and define a corresponding mapping $\mathscr{A}_j: X\mapsto X$ by

$$\text{(4.5)}\qquad \mathscr{A}_j(x)=\{y\in\Re^n\,|\,y_{I_j}=[y_{I_j}-(B_{I_jI_j}y_{I_j}+C_{I_jI_j}x_{I_j}+M_{I_j\tilde{I}_j}x_{\tilde{I}_j}+q_{I_j})]_j^+,\ y_{\tilde{I}_j}=x_{\tilde{I}_j}\},$$

where $[\cdot]_j^+$ denotes the orthogonal projection onto the box $[0,\infty)^{\mathrm{Card}(I_j)}$. By Lemma 2(a), $\mathscr{A}_j$ is a well-defined point-to-point mapping. The mapping $\mathscr{A}_j$ has the effect of applying a matrix splitting iteration to the subset of coordinates indexed by I_j, while the other coordinates are held fixed. The Gauss-Seidel matrix splitting (GS-MS) algorithm generates a sequence of iterates by applying cyclically the mappings $\mathscr{A}_1,\cdots,\mathscr{A}_m$:

GS-MS ALGORITHM. Choose an $x^0\in X$. Generate a sequence of vectors $\{x^0, x^1,\cdots\}$ in X by the formula

$$\text{(4.6)}\qquad x^{r+1}=(\mathscr{A}_m\circ\cdots\circ\mathscr{A}_2\circ\mathscr{A}_1)(x^r), \qquad r=0,1,\cdots.$$

It is easily seen that in the special case where $m=1$, this algorithm reduces to the algorithm (4.1)-(4.4) with relaxation parameters $\underline{\omega}=\bar{\omega}=1$.

By extending the proof of Theorem 2, we can show that the GS-MS algorithm is convergent.

THEOREM 3. *The sequence of iterates generated by the* GS-MS *algorithm* (4.5)-(4.6) *converges to an element of* X^*.

Sketch of proof. Similar to the proof of Theorem 2, it suffices to show that Lemmas 6-8 still hold.

We first show that Lemmas 6 and 7 still hold. Since the I_j's are disjoint, we have from (4.6) that

$$\text{(4.7)}\qquad x_{I_j}^{r+1}=\mathscr{A}_j(x_{I_1}^{r+1},\cdots,x_{I_j}^{r+1},x_{I_{j+1}}^r,\cdots,x_{I_m}^r), \qquad j=1,\cdots,m, \quad \forall r.$$

Then, by using (4.5) and an argument analogous to that for (3.1), we obtain that

$$f(x_{I_1}^{r+1},\cdots,x_{I_j}^{r+1},x_{I_{j+1}}^r,\cdots,x_{I_m}^r)\leqq f(x_{I_1}^{r+1},\cdots,x_{I_{j-1}}^{r+1},x_{I_j}^r,\cdots,x_{I_m}^r)-\gamma\|x_{I_j}^{r+1}-x_{I_j}^r\|^2,$$

for all r and all j, where $\gamma > 0$ denotes the smallest eigenvalue of the symmetric part of $B_{I_jI_j} - C_{I_jI_j}$, minimized over all j. By applying the above inequality recursively for all j, we obtain that

$$f(x^{r+1}) \leqq f(x^r) - \gamma \sum_{j=1}^{m} \|x_{I_j}^{r+1} - x_{I_j}^r\|^2 = f(x^r) - \gamma \|x^{r+1} - x^r\|^2 \quad \forall r,$$

and it readily follows that Lemmas 6 and 7 hold.

Now we show that Lemma 8 still holds (possibly with a different β). Consider any $J \subseteq I^*$ and suppose that for some two integers $s \geqq t \geqq 0$ we have $x_i^r > 0$ for all $i \in J$ and all $r = t+1, t+2, \cdots, s$. Let $J_j = J \cap I_j$ and $\hat{J}_j = \tilde{J} \cap I_j$. Then $I_j = J_j \cup \hat{J}_j$ for all j, and we have from (4.5) and (4.7) that, for any $r \in \{t, \cdots, s-1\}$, there holds

$$\begin{aligned} 0 &= B_{J_jI_j} x_{I_j}^{r+1} + C_{J_jI_j} x_{I_j}^r + \sum_{k<j} M_{J_jI_k} x_{I_k}^{r+1} + \sum_{k>j} M_{J_jI_k} x_{I_k}^r + q_{J_j} \\ &= B_{J_jJ_j} x_{J_j}^{r+1} + C_{J_jJ_j} x_{J_j}^r + \sum_{k<j} M_{J_jJ_k} x_{J_k}^{r+1} + \sum_{k>j} M_{J_jJ_k} x_{J_k}^r \\ &\qquad + B_{J_j\hat{J}_j} x_{\hat{J}_j}^{r+1} + C_{J_j\hat{J}_j} x_{\hat{J}_j}^r + \sum_{k<j} M_{J_j\hat{J}_k} x_{\hat{J}_k}^{r+1} + \sum_{k>j} M_{J_j\hat{J}_k} x_{\hat{J}_k}^r + q_{J_j}, \qquad j = 1, \cdots, m. \end{aligned}$$

By rewriting the fifth to the eighth terms in the above expression as

$$B_{J_j\hat{J}_j}(x_{\hat{J}_j}^{r+1} - x_{\hat{J}_j}^r) + \sum_{k<j} M_{J_j\hat{J}_k}(x_{\hat{J}_k}^{r+1} - x_{\hat{J}_k}^r) + \sum_{k=1}^{m} M_{J_j\hat{J}_k} x_{\hat{J}_k}^r,$$

we can express the above set of equations using a single matrix splitting as follows:

$$\begin{aligned} &\begin{bmatrix} B_{J_1J_1} & & & & & \\ M_{J_2J_1} & B_{J_2J_2} & & & & \\ \vdots & \ddots & \ddots & & & \\ M_{J_jJ_1} & \cdots & M_{J_jJ_{j-1}} & B_{J_jJ_j} & & \\ \vdots & & & \ddots & \ddots & \\ M_{J_mJ_1} & & \cdots & & M_{J_mJ_{m-1}} & B_{J_mJ_m} \end{bmatrix} x_J^{r+1} \\ &\quad + \begin{bmatrix} C_{J_1J_1} & M_{J_1J_2} & & \cdots & & M_{J_1J_m} \\ & \ddots & \ddots & & & \vdots \\ & & C_{J_iJ_i} & M_{J_jJ_{j+1}} & \cdots & M_{J_jJ_m} \\ & & & \ddots & \ddots & \vdots \\ & & & & C_{J_{m-1}J_{m-1}} & M_{J_{m-1}J_m} \\ & & & & & C_{J_mJ_m} \end{bmatrix} x_J^r \\ &\quad + \begin{bmatrix} B_{J_1\hat{J}_1} & & & & & \\ M_{J_2\hat{J}_1} & B_{J_2\hat{J}_2} & & & & \\ \vdots & \ddots & \ddots & & & \\ M_{J_j\hat{J}_1} & \cdots & M_{J_j\hat{J}_{j-1}} & B_{J_j\hat{J}_j} & & \\ \vdots & & & \ddots & \ddots & \\ M_{J_m\hat{J}_1} & & \cdots & & M_{J_m\hat{J}_{m-1}} & B_{J_m\hat{J}_m} \end{bmatrix} \cdot (x_{\tilde{J}}^{r+1} - x_{\tilde{J}}^r) \\ &\quad + M_{J\tilde{J}} x_{\tilde{J}}^r + q_J = 0, \end{aligned}$$

or equivalently,

$$0 = Fx_J^{r+1} + Gx_J^r + H(x_{\tilde{J}}^{r+1} - x_{\tilde{J}}^r) + M_{J\tilde{J}} x_{\tilde{J}}^r + q_J,$$

for suitably defined matrices F and H, with $G = M_{JJ} - F$. Fix any $x^* \in X^*$. By subtracting the identity $0 = M_J x^* + q_J$ (cf. $J \subseteq I^*$ and Lemma 1) from the above equation and rearranging terms, we obtain

$$x_J^{r+1} - x_J^* = (I - F^{-1}M_{JJ})(x_J^r - x_J^*) - F^{-1}M_{J\bar{J}}(x_{\bar{J}}^r - x_{\bar{J}}^*) - F^{-1}H(x_{\bar{J}}^{r+1} - x_{\bar{J}}^r),$$

for $r = t, \cdots, s-1$. Now the matrix difference $F - G$ can be seen to have the form $L + E - L^T$, where L is a certain strictly (block) lower triangular part of M_{JJ} and E is a block diagonal matrix whose jth diagonal block is $B_{J_jJ_j} - C_{J_jJ_j}$. Therefore $\langle z, (F-G)z\rangle = \langle z, Ez\rangle > 0$ for all $z \neq 0$, where the strict inequality follows from the positive definite property of the $B_{J_jJ_j} - C_{J_jJ_j}$'s. This shows that (F, G) is a regular splitting of M_{JJ}. The rest of the proof then proceeds as in the proof of Lemma 8. □

Remark 6. We can also introduce under/overrelaxation in the GS-MS algorithm. More precisely, for each $j \in \{1, \cdots, m\}$, let $(B_{I_jI_j}, C_{I_jI_j})$ be a splitting of $M_{I_jI_j}$ and $\bar{\omega}_j$ be a scalar in $(0, 1]$ satisfying

$$B_{I_jI_j} - C_{I_jI_j} + (1 - \bar{\omega}_j)M_{I_jI_j} \quad \text{is positive definite.}$$

We define $\mathcal{A}_j$ as in (4.5) (but with the above splitting) and let $\mathcal{R}_j : X \mapsto X$ be the *underrelaxation* mapping corresponding to $\mathcal{A}_j$:

$$\mathcal{R}_j(x) = (1 - \bar{\omega}_j)x + \bar{\omega}_j\mathcal{A}_j(x).$$

Then the underrelaxed GS-MS algorithm comprises applications of the mappings $\mathcal{R}_1, \cdots, \mathcal{R}_m$ in a cyclical manner:

$$x^{r+1} = (\mathcal{R}_m \circ \cdots \circ \mathcal{R}_2 \circ \mathcal{R}_1)(x^r), \qquad r = 0, 1, \cdots.$$

In the special case where $\bar{\omega}_1 = \cdots = \bar{\omega}_m = 1$, the above algorithm reduces to the GS-MS algorithm. Furthermore, we can introduce an overrelaxation mechanism at the end of each iteration,

$$x^{r+1} = (1 - \omega^r)x^r + \omega^r(\mathcal{R}_m \circ \cdots \circ \mathcal{R}_2 \circ \mathcal{R}_1)(x^r), \qquad r = 0, 1, \cdots,$$

where each ω^r is chosen such that $x^{r+1} \in X$ and $\underline{\omega} < \omega^r \leqq \bar{\omega}$. The relaxation parameters $\underline{\omega}$ and $\bar{\omega}$ are chosen such that $0 < \underline{\omega} \leqq \min\{1, \bar{\omega}\}$ and $K + (1 - \bar{\omega})M$ is positive definite, where K is the $n \times n$ block diagonal matrix whose diagonal blocks comprise the positive definite matrices $(B_{I_jI_j} - C_{I_jI_j} + (1 - \bar{\omega}_j)M_{I_jI_j})/\bar{\omega}_j$, $j = 1, \cdots, m$. We can also introduce a positive diagonal matrix in the definition of $\mathcal{A}_j$ as in (4.4). In the special case where $m = 1$ and $\bar{\omega}_1 = 1$, this latter algorithm reduces to the algorithm (4.1)-(4.4). Convergence of the above algorithms can be shown by modifying the proof of Theorems 2 and 3.

We can alternatively extend the GS-MS algorithm to allow under/overrelaxation (during the updating of each subset of coordinates), nondisjoint subsets I_j, and noncyclic order of relaxation. This leads to the following SOR type algorithm, which we call the SOR-MS algorithm. Let $I_1, \cdots, I_m$ be a finite collection of nonempty (not necessarily disjoint) subsets of $\{1, \cdots, n\}$ whose union equals $\{1, \cdots, n\}$. For each $j = 1, \cdots, m$, we choose a splitting $(B_{I_jI_j}, C_{I_jI_j})$ of $M_{I_jI_j}$ and a $\bar{\omega}_j > 0$ satisfying

$$(4.8) \qquad B_{I_jI_j} - C_{I_jI_j} + (1 - \bar{\omega}_j)M_{I_jI_j} \quad \text{is positive definite.}$$

We also choose a second relaxation parameter $\underline{\omega}_j$ satisfying

$$(4.9) \qquad 0 < \underline{\omega}_j \leqq \min\{1, \bar{\omega}_j\},$$

and define $\mathcal{P}_j : X \mapsto X$ to be the point-to-set mapping

$$(4.10) \qquad \mathcal{P}_j(x) = \{z \mid z = (1 - \omega)x + \omega\mathcal{A}_j(x),\ z \in X, \text{ for some } \underline{\omega}_j \leqq \omega \leqq \bar{\omega}_j\},$$

where $\mathcal{A}_j : X \mapsto X$ is the point-to-point mapping given by (4.5). The SOR-MS algorithm generates a sequence of iterates by successively applying the mappings $\mathcal{P}_1, \cdots, \mathcal{P}_m$ (but not necessarily in any fixed order):

SOR-MS ALGORITHM. Choose an $x^0 \in X$. Generate a sequence of vectors $x^0, x^1, \cdots$ in X by the formula

$$x^{r+1} \in \mathcal{P}_{j^r}(x^r), \qquad r = 0, 1, \cdots, \tag{4.11}$$

where $j^0, j^1, \cdots$ is some sequence of indices in $\{1, \cdots, m\}$.

We will impose the following rule on the order of coordinate relaxation (see, e.g., [SaS73], [HeL78]):

ALMOST CYCLIC RULE. There exists an integer $\bar{r}$ such that $\{1, \cdots, m\} \subseteq \{j^{r+1}, j^{r+2}, \cdots, j^{r+\bar{r}}\}$ for all r.

The SOR-MS algorithm can be seen to contain most of the earlier algorithms as special cases. For example, if $m = 1$, then it reduces to the algorithm (4.1)-(4.4). If the I_j's are disjoint, $\omega_j = \bar{\omega}_j = 1$ for all j, and $\{j^0, j^1, \cdots\} = \{1, \cdots, m, 1, \cdots, m, \cdots\}$, then it reduces to the GS-MS algorithm. It also contains other methods as special cases. For example, if the $M_{I_jI_j}$'s are positive definite and we choose $B_{I_jI_j} = M_{I_jI_j}$ for all j, then (4.8) is equivalent to $\bar{\omega}_j < 2$ and the SOR-MS algorithm reduces to a block SOR method considered in [Tse88, § 6.2]. Furthermore, if the I_j's are disjoint and $\{j^0, j^1, \cdots\} = \{1, \cdots, m, 1, \cdots, m, \cdots\}$, then it reduces to the block SOR methods considered in [CGS78], [CoG78]; and if $m = n$ and $I_j = \{j\}$ for all j, then it reduces to the point SOR methods of Herman and Lent [HeL78] and of Lent and Censor [LeC80]. For a final example, if $I_j = \{1, \cdots, n\}$ for all j, then it reduces to a matrix splitting algorithm that alternates amongst m matrix splittings.

We have not been able to show that the SOR-MS algorithm is convergent in the sense of Theorems 1-3. (The difficulty lies in the proof of Lemma 8, which no longer goes through when the index subsets $I_1, \cdots, I_m$ overlap or when different *and* time varying relaxation parameters are placed on different coordinates.) However, by combining the second half of the proof of Theorem 2 with the first half of the proof of Theorem 3, we can show that it is convergent in the weaker sense of Lemma 7.

THEOREM 4. *Let* $x^0, x^1, \cdots$ *denote the iterates generated by the* SOR-MS *algorithm* (4.5), (4.8)-(4.11) *under the almost cyclic rule. Then* $Mx^r + q \to d^*$ *and* $\phi(x^r) \to 0$. *Moreover,* $f(x^r)$ *tends to the optimal value of* (P) *and every limit point of* $\{x^r\}$ *is a solution of* (P).

Although the above result is not the strongest one possible, it nonetheless improves upon those existing. For example, it shows, for the first time, that the algorithms considered in [Tse88, § 6.2], [HeL78], [LeC80], [CGS78], and [CoG78] generate iterates that come arbitrarily close to the solution set X^*.

5. Application to known methods. In this section we apply the results developed in §§ 3 and 4 to a number of well-known methods and show, for the first time, that these methods are convergent without making any additional assumption on the problem. We also extend some of these methods to incorporate overrelaxation.

Example 1 (point SOR method). Suppose that M has positive diagonal entries. Consider the following well-known point SOR method [Hil57], [Cry71], [Man84] for solving (P):

$$x_i^{r+1} = \left[x_i^r - \frac{\alpha}{M_{ii}} \left(\sum_{j<i} M_{ij} x_j^{r+1} + \sum_{j \geq i} M_{ij} x_j^r + q_i \right) \right]^+, \qquad i = 1, \cdots, n,$$

where α is a relaxation parameter in $(0, 2)$ and $[\,\cdot\,]^+$ denotes the orthogonal projection onto the interval $[0, \infty)$. (This method can be viewed alternatively as a (cyclic) coordinate descent method with inexact line search [Tse88, § 6.2].) It is easily seen that this method is a special case of the algorithm (4.1)-(4.4) with $\underline{\omega} = \bar{\omega} = 1$ and the following choices of (B, C) and D:

$$B = \alpha^{-1}E + L, \quad C = (1 - \alpha^{-1})E + L^T, \quad D = \alpha E^{-1},$$

where E and L are, respectively, the diagonal and the strictly lower triangular part of M. Since $B - C = (2\alpha^{-1} - 1)E + L - L^T$, which is positive definite for all $\alpha \in (0, 2)$, it follows from Theorem 2 that this method is convergent. This improves upon existing results (e.g., [Cry71], [Man84], [LiP87]), which require for convergence either M be *strictly copositive* or that a certain Slater condition hold (all of which lead to the compactness of X^*).

Example 2 (gradient projection algorithms). Consider the well-known gradient projection algorithm [Gol64], [LeP65] (also see [Ber82], [BeT89], [Che84], [Lue73]) applied to solve (P),

$$x^{r+1} = [x^r - \alpha(Mx^r + q)]^+,$$

where α is a positive stepsize. It is easily seen that this is a special case of the algorithm (4.1)-(4.4) with $\underline{\omega} = \bar{\omega} = 1$ and the following choices of (B, C) and D:

$$B = \frac{1}{\alpha} I, \quad C = M - \frac{1}{\alpha} I, \quad D = \alpha I.$$

In this case $B - C$ can be seen to be positive definite for all $\alpha < 2/\|M\|$. Hence by Theorem 1, the algorithm is convergent for all $\alpha \in (0, 2/\|M\|)$. (This result was first established by Cheng [Che84] for the more general problem of minimizing a pseudoconvex differentiable function over a closed convex set.) Aganagic [Aga78] proposed a modification of the above algorithm by adding a relaxation parameter $\omega \in (0, 1]$:

$$x^{r+1} = (1 - \omega)x^r + \omega[x^r - \alpha(Mx^r + q)]^+.$$

This algorithm is also a special case of the algorithm (4.1)-(4.4) with $\underline{\omega} = \bar{\omega} = \omega$ and with (B, C) and D given as above. Hence, by Theorem 2, this algorithm is also convergent for all $\alpha \in (0, 2/\|M\|)$. (This improves on the result of Aganagic which requires M to be positive definite for convergence. Furthermore, from Theorem 2 we see that overrelaxation (i.e., $\omega > 1$) is also permissible, as long as $\alpha\omega \in (0, 2/\|M\|)$.)

Example 3 (Mangasarian's algorithm). Consider the following iterative algorithm proposed by Mangasarian [Man77] (also see [Man84], [MaD87] for applications)

$$x^{r+1} = (1 - \omega)x^r + \omega[x^r - \alpha E(Mx^r + q + K(x^{r+1} - x^r))]^+,$$

where $\omega \in (0, 1]$, E is an $n \times n$ positive diagonal matrix, K is an $n \times n$ matrix, and α is a positive scalar. It can be seen that the above algorithm is a special case of the algorithm (4.1)-(4.4) with $\underline{\omega} = \bar{\omega} = \omega$ and the following choices of (B, C) and D:

$$B = (\alpha E)^{-1} + \omega K, \quad C = M - (\alpha E)^{-1} - \omega K, \quad D = \alpha E.$$

Since $B - C + (1 - \omega)M = 2(\alpha E)^{-1} + 2\omega K - \omega M$, it follows from Theorem 2 that the above algorithm is well defined and convergent if $2(\alpha E)^{-1} + 2\omega K - \omega M$ is positive definite, which is exactly the condition given by Mangasarian [Man77, (6)]. (Mangasarian proved that the algorithm itself is well defined for all choices of the matrix K satisfying either his assumption [Man77, (6)], or the assumption that K is strictly lower triangular, which was the case of principal concern in [Man77]. He also showed that each limit point of the iterates generated by the algorithm is a solution, but the question of whether such a limit point exists was left open.)

Example 4 (block SOR method). Consider the following block SOR method of Cottle, Golub, and Sacher [CGS78] and of Cottle and Goheen [CoG78] (also see [CoP82]). Partition the index set $\{1, \cdots, n\}$ into m nonempty, mutually disjoint subsets $I_1, \cdots, I_m$ and assume that $M_{I_jI_j}$ is positive definite for all j. Choose a relaxation parameter $\bar{\omega} \in (0, 2)$. Then, for any given $x^0 \in X$, the method generates a sequence of iterates $\{x^0, x^1, \cdots\}$ whereby, given x^r, a new iterate x^{r+1} is generated as follows.

Let $z^0 = x^r$. For $j = 1, \cdots, m$, compute $\hat{z}^j$ to be the (unique) solution to the following system of nonlinear equations ($[\cdot]^+$ denotes the orthogonal projection onto the interval $[0, \infty)$)

$$z_i = [z_i - (M_i z + q_i)]^+ \quad \forall i \in I_j,$$
$$z_i = z_i^{j-1} \quad \forall i \notin I_j,$$

and let $z^j = (1-\omega)z^{j-1} + \omega \hat{z}^j$, where ω is the largest scalar in $(0, \bar{\omega}]$ such that $z^j \in X$. Then set $x^{r+1} = z^m$. (This method essentially replaces the strictly lower triangular (diagonal) part of M in the point SOR method by strictly lower triangular (diagonal) blocks.) In the case where $\bar{\omega} = 1$, this method can be seen to be a special case of the GS-MS algorithm (4.5)-(4.6) with

$$B_{I_jI_j} = M_{I_jI_j}, \qquad C_{I_jI_j} = 0,$$

so that by Theorem 3 it is convergent. If $0 < \bar{\omega} \leqq 1$, then by Remark 6 it is also convergent. (This improves upon the results of [CGS78] and [CoG78] which require M to be positive definite for convergence. It also obviates the need for the projection step employed in [CoP82] to ensure the existence of a limit point.) In the case where $1 < \bar{\omega} < 2$, however, the convergence of this method remains unresolved. It is known to be convergent only in the weak sense of Theorem 4.

6. Discussions and extensions. In this paper, we have established the iterate convergence of matrix splitting algorithms for solving the symmetric monotone linear complementarity problem when the splitting is regular. Our result improves on the earlier convergence results in that it does not make any assumption on the boundedness of the optimal solution set. Our proof makes essential use of linearity of the problem and certain contractive properties of the iteration matrices. In particular, these contractive properties enable us to carefully estimate the behaviors of the algorithm near the boundary of the feasible set.

There are several directions in which our results can be improved. For example, we may consider solving each of the subproblems (1.5) *inexactly*. Specifically, consider the sequence of iterates $\{x^1, x^2, \cdots,\}$ generated by

$$x^{r+1} = \mathcal{A}_B(x^r + e^r),$$

where e^r denotes the "error" vector at the rth iteration. Recently, Mangasarian [Man90] established the convergence of $\{x^r\}$ under (essentially) the assumption that B is symmetric and that the error vectors $\{e^r\}$ satisfy

$$\sum_{r=0}^{\infty} \|e^r\| < \infty, \tag{6.1}$$

$$\sum_{r=0}^{\infty} \|e^r\| \, \|x^{r+1} - x^r\| < \infty. \tag{6.2}$$

We remark that our proof (Lemmas 8-11) can be modified to establish the convergence of $\{x^r\}$ for any regular splitting (B, C) (not necessarily symmetric) under the same set of assumptions (6.1) and (6.2). This is because each error vector e^r contributes additively an $O(\|e^r\|)$ perturbation to all future iterates (cf. Lemma 4(b)), so the perturbation contributed by all of the error vectors after the rth iteration is only $O(\sum_{i=r}^{\infty} \|e^i\|)$, which, by (6.1), tends to zero as $r \to \infty$. (Condition (6.2) is needed to ensure that Lemma 6 still holds (see [Man90]).)

Another interesting extension of the results obtained here is to analyze the *rate* of convergence of the matrix splitting algorithms. Such an analysis has been obtained by Luo and Tseng [LuT89] for the special case of the coordinate descent method (but for the more general problem of minimizing, over a box, a function which is the composition of an affine mapping with a strictly convex essentially smooth function) and only recently we have been able to extend their analysis to matrix splitting algorithms.

Acknowledgments. We express our deep gratitude to the referees for providing many valuable comments and for bringing the work of Keller [Kel65] to our attention. We also thank Professor O. L. Mangasarian for his helpful suggestions.

RECURSIVE IDENTIFICATION AND ADAPTIVE PREDICTION IN LINEAR STOCHASTIC SYSTEMS*

TZE LEUNG LAI† AND ZHILIANG YING‡

Abstract. By making use of extended stochastic Lyapunov functions and martingale limit theorems, established herein are certain basic properties of adaptive d-step ahead predictors associated with the extended least squares, stochastic gradient (without interlacing), and monitored recursive maximum likelihood algorithms for recursive identification of an ARMAX system. Both the direct (or implicit) and indirect (or explicit) approaches to adaptive prediction are considered within a unified framework involving stochastic regression models. Applications to adaptive control of ARMAX systems are also discussed.

Key words. adaptive prediction, global convergence, stochastic gradient algorithm, AML, recursive MLE, stochastic adaptive control, certainty equivalence, asymptotic efficiency

AMS(MOS) subject classifications. 93E12, 93C40, 60G42

1. Introduction and background. Consider the ARMAX system (autoregressive moving average system with exogenous inputs) defined by the linear stochastic difference equation

$$A(q^{-1})y_n = q^{-\Delta}B(q^{-1})u_n + C(q^{-1})\varepsilon_n, \tag{1.1}$$

where $\{y_n\}$, $\{u_n\}$, and $\{\varepsilon_n\}$ denote the output, input, and disturbance sequences, respectively, $\Delta \geqq 1$ represents the delay, and

$$\begin{aligned} &A(q^{-1}) = 1 + a_1 a^{-1} + \cdots + a_p q^{-p}, \qquad B(q^{-1} = b_1 + \cdots + b_k q^{-(k-1)}, \\ &C(q^{-1}) = 1 + c_1 q^{-1} + \cdots + c_h q^{-h} \end{aligned} \tag{1.2}$$

are scalar polynomials in the backward shift operator q^{-1}. Throughout the sequel we will assume that the sequence $\{\varepsilon_n\}$ is a martingale difference sequence with respect to an increasing sequence of σ-fields $\mathscr{F}_n$ such that

$$\sup_n E(|\varepsilon_n|^\alpha \mid \mathscr{F}_{n-1}) < \infty \quad \text{a.s. for some } \alpha > 2. \tag{1.3}$$

Moreover, the input u_t at stage t is assumed to be $\mathscr{F}_t$-measurable (i.e., involving only the current and past observations $y_t, y_{t-1}, u_{t-1}, \cdots$, but no future observations). Letting $x_0 = (y_0, \cdots, y_{1-p}, u_0, \cdots, u_{2-\Delta-k}, \varepsilon_0, \cdots, \varepsilon_{1-h})$ denote the "initial condition" of (1.1), it is also assumed that x_0 is $\mathscr{F}_0$-measurable.

Let $1 \leqq d \leqq \Delta$. When the system parameters $a_1, \cdots, a_p, b_1, \cdots, b_k, c_1, \cdots, c_h$ and the initial condition x_0 are known, the minimum variance d-step ahead predictor $\tilde{y}_{n+d} \triangleq E(y_{n+d} \mid \mathscr{F}_n)$ of the output y_{n+d} can be determined recursively by the Åström predictor identity (1.6) below (cf. [1]-[4]). By the division algorithm, there exist polynomials $F(z) = 1 + f_1 z + \cdots + f_{d-1} z^{d-1}$ and $G(z) = g_1 + \cdots + g_{p(d)} z^{p(d)-1}$ with $p(d) = p \vee (h - d + 1)$ such that

$$C(z) = F(z)A(z) + z^d G(z), \tag{1.4}$$

and therefore (1.1) can be rewritten in the form

$$C(q^{-1})\{y_{n+d}-F(q^{-1})\varepsilon_{n+d}\}=G(q^{-1})y_n+q^{-(\Delta-d)}F(q^{-1})B(q^{-1})u_n. \tag{1.5}$$

This implies that the minimum variance predictor $\tilde{y}_{n+d}$ is given recursively by

$$C(q^{-1})\tilde{y}_{n+d}=G(q^{-1})y_n+q^{-(\Delta-d)}F(q^{-1})B(q^{-1})u_n. \tag{1.6}$$

The prediction error of the predictor $\tilde{y}_{n+d}$ is

$$\eta_{n+d}\overset{\Delta}{=}y_{n+d}-\tilde{y}_{n+d}=F(q^{-1})\varepsilon_{n+d}. \tag{1.7}$$

In practice, the system parameters and initial condition are usually unknown, and we must "adapt" the optimal predictor (1.6) by substituting the unknown entities in (1.6) by their estimates. The so-called *explicit* (or *indirect*) approach of adaptive prediction is to first estimate the parameters $a_1,\cdots,a_p, b_1,\cdots,b_k, c_1,\cdots,c_h$ of the explicit dynamical system (1.1) and then to substitute these parameter values that appear in the polynomials $C(q^{-1})$, $B(q^{-1})$, $F(q^{-1})$, and $G(q^{-1})$ of (1.6) by their estimates. In contrast, the *implicit* (or *direct*) approach of adaptive prediction is to first develop recursive estimates θ_n of the parameter vector

$$\begin{gathered}\theta=(g_1,\cdots,g_{p(d)},b_1,(fb)_2,\cdots,(fb)_{k+d-1},-c_1,\cdots,-c_h)', \quad \text{where}\\ \sum_{i=1}^{k+d-1}(fb)_i z^{i-1}=F(z)B(z), \quad \text{so that } (fb)_1=b_1,\end{gathered} \tag{1.8}$$

of the system's implicit representation that combines (1.5) and (1.7) into the form

$$\begin{gathered}y_{n+d}=\theta'\psi_n+\eta_{n+d}, \quad \text{where}\\ \psi_n=(y_n,\cdots,y_{n-p(d)+1},u_{n-\Delta+d},\cdots,u_{n-k-\Delta+2},\tilde{y}_{n+d-1},\cdots,\tilde{y}_{n+d-h})',\end{gathered} \tag{1.9}$$

noting that $\tilde{y}_{n+d}=\theta'\psi_n$ by (1.6). Letting $\hat{y}_{n+d}$ denote the adaptive predictor of y_{n+d}, this implicit approach generates $\hat{y}_{n+d}$ recursively by

$$\begin{gathered}\hat{y}_{n+d}=\theta_n'\phi_n, \quad \text{where}\\ \phi_n=(y_n,\cdots,y_{n-p(d)+1},u_{n-\Delta+d},\cdots,u_{n-k-\Delta+2},\hat{y}_{n+d-1},\cdots,\hat{y}_{n+d-h})'.\end{gathered} \tag{1.10}$$

For the explicit approach, there is a large literature on recursive estimation of the parameter vector

$$\Theta=(-a_1,\cdots,-a_p,b_1,\cdots,b_k,c_1,\cdots,c_h)' \tag{1.11}$$

of the dynamical system (1.1), which can be written in the regression form

$$\begin{gathered}y_n=\Theta'\Psi_{n-1}+\varepsilon_n, \quad \text{where}\\ \Psi_t=(y_t,\cdots,y_{t-p+1},u_{t-\Delta+1},\cdots,u_{t-\Delta-k+2},\varepsilon_t,\cdots,\varepsilon_{t-h+1})'.\end{gathered} \tag{1.12}$$

The recent monographs [2]-[4] provide excellent unified overviews of various recursive estimation algorithms in the literature. In particular, an important and widely studied problem concerning, these recursive estimators is under what conditions they converge. In the seminal papers [5], [6], Ljung developed the ODE (ordinary differential equation) method for the convergence analysis of recursive estimators Θ_n of Θ. Under certain a priori boundedness and recurrence assumptions on Θ_n, this method introduces a space-time renormalization into the recursion for $\Theta_n-\Theta$ to obtain a nonrandom ODE as a limit point and studies the limiting behavior of Θ_n via the stability properties of the associated ODE. Such stability analysis is often conveniently carried out by making use of a Lyapunov function. Instead of working with a Lyapunov function associated with the limiting ODE, an obvious alternative is to develop an analogue for the original recursions defining Θ_n. This is the idea behind the "stochastic Lyapunov function" approach introduced by Moore and Ledwich [7] and Solo [8]. A basic ingredient of this approach is to use the underlying system dynamics to develop recursive inequalities for a suitably chosen nonnegative random function of Θ_n and to normalize and transform this function into a nonnegative almost supermartingale (stochastic Lyapunov function) to which the martingale convergence theorem can be applied. In particular, for the AML algorithm

$$\Theta_n=\Theta_{n-1}+P_{n-1}\Phi_{n-1}(y_n-\Theta_{n-1}'\Phi_{n-1}),\qquad P_n^{-1}=P_{n-1}^{-1}+\Phi_n\Phi_n', \tag{1.13a}$$

$$\Phi_n=(y_n,\cdots,y_{n-p+1},u_{n-\Delta+1},\cdots,u_{n-\Delta-k+2},\hat{\varepsilon}_n,\cdots,\hat{\varepsilon}_{n-h+1})', \tag{1.13b}$$

$$\hat{\varepsilon}_n=y_n-\Theta_n'\Phi_{n-1}, \tag{1.13c}$$

Solo [8] used this approach to prove the strong consistency of Θ_n under both the "persistent excitation" condition

$$n^{-1}\sum_{i=1}^{n}\Psi_i\Psi_i' \quad \text{converges a.s. to a positive-definite matrix} \tag{1.14}$$

and the "positive real" condition

$$\min_{|z|=1}\operatorname{Re}\left(\frac{1}{C(z)}-\frac{1}{2}\right)>0. \tag{1.15}$$

For the AML algorithm, by using martingale limit theorems (not restricted to convergence) to analyze directly Solo's recursive inequalities for the quadratic form

$$Q_n\triangleq(\Theta_n-\Theta)'P_{n-1}^{-1}(\Theta_n-\Theta), \tag{1.16}$$

instead of following Solo [8] to transform Q_n into a nonnegative almost supermartingale that converges almost surely by the martingale convergence theorem, Lai and Wei [9] established the strong consistency of Θ_n under (1.15) and the much weaker excitation condition

$$\lambda_{\min}\left(\sum_{i=1}^{n}\Psi_i\Psi_i'\right)\to\infty \quad\text{and}\quad \log\lambda_{\max}\left(\sum_{i=1}^{n}\Psi_i\Psi_i'\right)=o\left(\lambda_{\min}\left(\sum_{i=1}^{n}\Psi_i\Psi_i'\right)\right)\quad\text{a.s.} \tag{1.17}$$

Here and in the sequel we use $\lambda_{\max}(A)$ and $\lambda_{\min}(A)$ to denote the maximum and minimum eigenvalues of a symmetric matrix A. Because of the Lyapunov-type recursive inequalities satisfied by Q_n which, however, need not be convergent, we will call such functions "extended stochastic Lyapunov functions" as in [10], where it is shown that stronger results can often be obtained by applying martingale theory directly to such functions without transforming them into (convergent) stochastic Lyapunov functions.

In the explicit approach to adaptive prediction, for a recursive algorithm Θ_n estimating the unknown parameter vector Θ defined in (1.11), we first use Θ_n at stage n to estimate the unknown coefficients of the polynomials $C(q^{-1})$, $B(q^{-1})$, $F(q^{-1})$, and $G(q^{-1})$ in (1.6), leading to the estimated polynomials $\hat{C}_n(q^{-1})$, $\hat{B}_n(q^{-1})$, $\hat{F}_n(q^{-1})$, and $\hat{G}_n(q^{-1})$ at stage n, and then define the predictor $\hat{y}_{n+d}$ of y_{n+d} by the recursive relation

$$\hat{C}_n(q^{-1})\hat{y}_{n+d}=\hat{G}_n(q^{-1})y_n+q^{-(\Delta-d)}\hat{F}_n(q^{-1})\hat{B}_n(q^{-1})u_n, \tag{1.18}$$

noting that the coefficients of $F(q^{-1})$ and $G(q^{-1})$ are polynomial functions of the components of Θ by (1.4). Hence, if Θ_n converges almost surely to Θ and $C(z)$ is stable (i.e., all its zeros lie outside the unit circle), then it follows from (1.16) and (1.18) that

$$\sum_{i=1}^{n} (\tilde{y}_{i+d} - \hat{y}_{i+d})^2 = o\left(\sum_{i=1}^{n} (y_i^2 + u_i^2)\right) \quad \text{a.s.} \tag{1.19}$$

(cf. Lemma 5 of § 2). In most applications, we typically have sample mean square boundedness for the input-output data, i.e.,

$$\limsup_{n\to\infty} n^{-1} \sum_{i=1}^{n} (y_i^2 + u_i^2) < \infty \quad \text{a.s.,} \tag{1.20}$$

in which case (1.19) implies that

$$n^{-1} \sum_{i=1}^{n} (\tilde{y}_{i+d} - \hat{y}_{i+d})^2 \to 0 \quad \text{a.s.} \tag{1.21}$$

A sequence of d-step ahead predictors $\{\hat{y}_{n+d}\}$ is said to be "globally convergent" if (1.21) holds (cf. [11]). We have pointed out above that if a consistent estimator Θ_n of the parameter vector Θ of the explicit system (1.11) can be found and if $C(z)$ is stable and (1.20) holds, then globally convergent adaptive predictors can be constructed by the recursive relation (1.18). However, the requirement of consistency in parameter estimation is often not needed in the construction of globally convergent adaptive predictors, particularly if we use an implicit approach. Extending the AML algorithm to the implicit model (1.9), Sin, Goodwin, and Bitmead [12] constructed d-step ahead adaptive predictors based on an interlaced AML algorithm and showed that such predictors are globally convergent under assumption (1.20) and an assumption analogous to (1.15). As pointed out by Zhang [13], however, their proof uses Solo's [8] result (A6) whose proof contains a gap. In § 3, where Solo's result (A6) is shown to be incorrect without additional assumptions, we prove a stronger result than the Sin-Goodwin-Bitmead theorem under the additional assumption that $\limsup_{n\to\infty} \phi_n'(\sum_1^n \phi_i\phi_i')^{-1}\phi_n < 1$ almost surely, where the ϕ_n are the pseudoregression vectors in their algorithm.

The global convergence property (1.21) for adaptive predictors is of particular interest in the adaptive control problem of setting the input u_t at stage t so that the output $y_{t+\Delta}$ is as close as possible to some target value $y_{t+\Delta}^*$. When the system parameters and the initial condition x_0 are known and $b_1 \neq 0$, the minimum variance controller is to set u_t such that $\tilde{y}_{t+\Delta} = y_{t+\Delta}^*$. In ignorance of x_0 and the system parameters, it is therefore natural to set u_t such that $\hat{y}_{t+\Delta} = y_{t+\Delta}^*$, where $\hat{y}_{t+\Delta}$ is a globally convergent adaptive Δ-step ahead predictor of $y_{t+\Delta}$. Since $\tilde{y}_{t+\Delta} = y_{t+\Delta} - \eta_{t+\Delta}$, (1.21) implies the so-called "self-optimizing" property that

$$n^{-1} \sum_{i=\Delta+1}^{n} (y_i - y_i^* - \eta_i)^2 \to 0 \quad \text{a.s.,} \tag{1.22}$$

for the adaptive controller defined by $\hat{y}_{t+\Delta} = y_{t+\Delta}^*$.

In the case where unit delay $\Delta = 1$, Goodwin, Ramadge, and Caines [14] used this approach in conjunction with the stochastic gradient algorithm

$$\theta_n = \theta_{n-1} + (a/r_{n-1})\phi_{n-1}(y_n - \hat{y}_n), \qquad r_n = r_{n-1} + \|\phi_n\|^2, \tag{1.23}$$

where ϕ_t and $\hat{y}_t$ are defined in (1.10) (with $d = 1$) and $a > 0$, to establish the self-optimizing property (1.22) for the adaptive controller that chooses the input u_t so that

$$\hat{y}_{t+1} = y_{t+1}^*, \tag{1.24}$$

under the assumptions

$$\min_{|z|=1} \operatorname{Re}\left(C(z)-\frac{a}{2}\right)>0, \tag{1.25}$$

$$B(z) \text{ is stable and } b_1 \neq 0, \tag{1.26}$$

(1.27) $(x_0, \varepsilon_1, \cdots, \varepsilon_n)$ is absolutely continuous with respect to Lebesgue measure for every $n \geqq 1$.

Assumption (1.27) ensures that the component of θ_n estimating the component b_1 of θ is nonzero almost surely and therefore we can indeed define u_t by $\theta_t' \phi_t = y_{t+1}^*$, i.e., by (1.24). As shown in [11] for general delay Δ but still for $d=1$, (1.25) and (1.20) are sufficient conditions for the global convergence of adaptive one-step ahead predictors based on the stochastic gradient algorithm (1.23). Assumption (1.26) is needed to ensure that (1.20) holds for the adaptive controller (1.24).

For general delay Δ and $d=\Delta$, Goodwin, Sin, and Saluja [15] extended (1.23) to the form

$$\theta_n = \theta_{n-d} + (a/r_{n-d})\phi_{n-d}(y_n - \theta_{n-d}'\phi_{n-d}), \qquad r_n = r_{n-1} + \|\phi_n\|^2, \tag{1.28}$$

in which ϕ_n is given by (1.10). Under assumptions (1.25) and (1.20), they showed that the adaptive d-step head predictors $\hat{y}_{n+d} = \theta_n' \phi_n$ are globally convergent. By using the explicit instead of the implicit approach, Fuchs [16], [17] also constructed globally convergent adaptive d-step ahead predictors of the form (1.18), in which the coefficients of the polynomials $\hat{C}_n(q^{-1})$, $\hat{B}_n(q^{-1})$, $\hat{F}_n(q^{-1})$, and $\hat{G}_n(q^{-1})$ are determined from the stochastic gradient algorithm Θ_n estimating (1.11), defined by

$$\Theta_n = \Theta_{n-1} + (a/r_{n-1})\Phi_{n-1}\, e_n, \tag{1.29a}$$

$$e_n = y_n - \Theta_{n-1}'\Phi_{n-1}, \tag{1.29b}$$

$$\begin{aligned} &r_n = r_{n-1} + \|\Phi_n\|^2, \\ &\text{where } \Phi_n = (y_n, \cdots, y_{n-p+1}, u_{n-\Delta+1}, \cdots, u_{n-\Delta-k+2}, e_n, \cdots, e_{n-h+1})'. \end{aligned} \tag{1.29c}$$

Unlike the single recursion in (1.29), the algorithm (1.28) interlaces d recursions $\theta_{j+d(t+1)} = \theta_{j+dt} + (a/r_{j+dt})\phi_{j+dt}(y_{j+d(t+1)} - \theta_{j+dt}'\phi_{j+dt})$, $j=0, \cdots, d-1$. It has been an open problem concerning whether such multiple recursions are indeed necessary and not just dictated by the stochastic Lyapunov function method of convergence analysis (cf. [16, p. 219]). By using the extended stochastic Lyapunov function approach instead, we show in § 4 that interlacing is not needed to establish global convergence of adaptive d-step ahead predictors based on the stochastic gradient algorithm for the implicit model (1.9), giving a positive answer to this long-standing open problem.

Although the stochastic gradient algorithm (with a scalar gain a/r_t) leads to globally convergent adaptive predictors by either the explicit or implicit approach under assumptions (1.20) and (1.25), the rate of convergence in (1.21) of such adaptive predictors is usually inferior to that associated with recursive identification algorithms using matrix gains, as noted by Lai, Wei, and Zhang [18] who illustrated this point by the following simple example. Consider one-step ahead prediction in the ARX system

$$y_{n+1} = \alpha y_n + \beta u_n + \varepsilon_{n+1}, \tag{1.30}$$

where $|\alpha|<1$, the ε_n are independent normal random variables with mean 0 and variance $\sigma^2>0$, and the inputs u_n are also independent normal random variables with mean 0 and variance $\sigma_n^2 \sim n^{-2\gamma}$ for some $0<\gamma<\frac{1}{2}$ and such that $\{u_n\}$ and $\{\varepsilon_n\}$ are independent sequences. In this case, for the adaptive predictor $\hat{y}_{n+1}^G = \Theta_n'\Phi_n$ defined by the stochastic gradient algorithm (1.29) with $a=1$ and $\Phi_n=(y_n, u_n)'$, the convergence rate in (1.21) cannot be faster than $n^{-2\gamma}$ since

$$P\left\{\liminf_{n\to\infty} n^{-(1-2\gamma)} \sum_{i=1}^{n} (\tilde{y}_{i+1}-\hat{y}_{i+1}^G)^2>0\right\}>0. \tag{1.31}$$

On the other hand, the adaptive predictor $\hat{y}_{n+1}^{\mathrm{LS}}$ associated with the least squares estimate $(\sum_1^{n-1}\Phi_i\Phi_i')^{-1}\sum_1^{n-1}\Phi_i y_{i+1}$ of Θ satisfies

$$\limsup_{n\to\infty} \frac{\sum_{i=1}^n (\tilde{y}_{i+1}-\hat{y}_{i+1}^{\mathrm{LS}})^2}{\log n}<\infty \quad \text{a.s.}, \tag{1.32}$$

which implies that the convergence rate in (1.21) is $O(n^{-1}\log n)$ (cf. [18, p. 179]).

For the ARMAX system (1.1) with $C(q^{-1})\neq 1$, although the recursive estimator (1.13) has been called "approximate maximum likelihood" (AML), it does not arise from the maximization of the log-likelihood function, as in the off-line (nonrecursive) maximum likelihood estimator, when the ε_i are assumed to be normally distributed with mean 0 and variance σ^2. The recursive maximum likelihood estimator RML2, introduced by Åström and Söderström, replaces (1.13a) by

$$\Theta_n=\Theta_{n-1}+P_{n-1}\xi_{n-1}(y_n-\Theta_{n-1}'\Phi_{n-1}), \qquad P_n^{-1}=P_{n-1}^{-1}+\xi_n\xi_n', \tag{1.33a}$$

where letting $\Theta_n=(-\hat{a}_{n,1},\cdots,-\hat{a}_{n,p},\ \hat{b}_{n,1},\cdots,\hat{b}_{n,k},\ \hat{c}_{n,1},\cdots,\hat{c}_{n,h})'$, define ξ_n recursively by

$$\xi_n+\hat{c}_{n-1,1}\xi_{n-1}+\cdots+\hat{c}_{n-1,h}\xi_{n-h}=\Phi_n \tag{1.33b}$$

(cf. [2]). This algorithm is based on first replacing the derivative of the log-likelihood function by its linear approximation around the true parameter Θ and then replacing the unknown Θ by Θ_{n-1}, and would therefore lead to an asymptotically efficient estimator if Θ_{n-1} should converge to Θ. In § 5 we introduce an additional monitoring scheme to ensure that Θ_{n-1} is eventually close to Θ, and use the estended Lyapunov function (1.16) to analyze this modification of the RML2 algorithm, which we call the "monitored recursive maximum likelihood algorithm." We also extend in § 5 the RML2 algorithm (1.33) to the implicit system (1.9) and introduce an additional monitoring scheme to ensure that the recursive estimates θ_n generated by the algorithm are eventually close to the parameter vector θ of (1.9). By making use of extended stochastic Lyapunov functions, we are able to extend (1.32) to adaptive d-step ahead predictors based on θ_n.

In summary, the concept of extended stochastic Lyapunov functions provides a unified treatment of adpative predictors based on various recursive identification algorithms, using either the explicit or the implicit approach. In particular, we use this idea to improve in § 3 previous results on adaptive predictors based on extended least squares, to solve in § 4 an open problem in the literature concerning the global convergence of adaptive d-step ahead predictors based on the stochastic gradient algorithm without interlacing in the implicit approach, and to obtain in § 5 an analogue of (1.32) for the adaptive d-step ahead prediction problem by using the monitored recursive maximum likelihood algorithm that generalizes the least squares algorithm in (1.32). These results are of basic interest to adaptive control problems. In particular, while (1.21) leads to the self-optimizing property (1.22) of adaptive controllers based on the stochastic gradient algorithm, (1.33) and its extensions in § 5 lead to the much stronger property $\sum_{\Delta+1}^{n}(y_i-y_i^*-\eta_i)^2=O(\log n)$ almost surely for asymptotically efficient adaptive controllers.

2. Some preliminary lemmas. An important tool for the analysis of recursive identification and adaptive control algorithms is the following result from martingale theory.

LEMMA 1. *Let $\{\varepsilon_n\}$ be a martingale difference sequence with respect to an increasing sequence of σ-fields $\{\mathcal{F}_n\}$ such that* (1.3) *holds. Let z_n be an $\mathcal{F}_{n-1}$-measurable random variable for every n.*

(i) *$\sum_1^n z_i\varepsilon_i$ converges almost surely on $\{\sum_1^\infty z_i^2<\infty\}$, and for every $\eta>\frac{1}{2}$,*

$$\left(\sum_1^n z_i\varepsilon_i\right)\Big/\left(\sum_1^n z_i^2\right)^\eta\to 0\quad a.s.\ on\ \left\{\sum_1^\infty z_i^2=\infty\right\}.$$

Consequently,

$$\sum_1^n z_i\varepsilon_i=o\left(\sum_1^n z_i^2\right)+O(1)\quad a.s. \tag{2.1}$$

(ii) *$\sum_1^n|z_i|\varepsilon_i^2=O(\sum_1^n|z_i|)$ almost surely on $\{\sup_n|z_n|<\infty\}$. Moreover,*

$$\sum_1^n|z_i|\varepsilon_i^2=\sum_1^n|z_i|E(\varepsilon_i^2|\mathcal{F}_{i-1})+o\left(\sum_1^n|z_i|\right)\ on\ \left\{\sup_n|z_n|<\infty,\sum_1^\infty|z_n|=\infty\right\}. \tag{2.2}$$

(iii) *Let $T_1<T_2<\cdots$ be a sequence of stopping times (with respect to $\{\mathcal{F}_n\}$) such that $T_{j+1}-T_j\geqq d(\geqq 1)$. Let $\mathcal{G}_j=\mathcal{F}_{T_{j+1}}$ and let $w_j=|\sum_1^d\alpha_i\varepsilon_{T_j+i}|-E(|\sum_1^d\alpha_i\varepsilon_{T_j+i}||\mathcal{F}_{T_j})$, where $\alpha_1,\cdots,\alpha_d$ are constants. Then $\{w_j,\mathcal{G}_j,j\geqq 1\}$ is a martingale difference sequence with $\sup_j E(|w_j|^\alpha|\mathcal{G}_{j-1})<\infty$ almost surely.*

For the proof of parts (i) and (ii) of Lemma 1, see [19, p. 157], while part (iii) follows from that w_j is $\mathcal{G}_j$-measurable and that $E(w_j|\mathcal{F}_{T_j})=0$ and

$$E(|w_j|^\alpha|\mathcal{F}_{T_j})\leqq 2^\alpha\sum_{k=1}^\infty I_{\{T_j=k\}}E\left(\left|\sum_{i=1}^d\alpha_i\varepsilon_{k+i}\right|^\alpha\Big|\mathcal{F}_k\right).$$

While Lemma 1 is probabilistic in nature, Lemmas 2–5 below are algebraic. In particular, the algebraic identity (2.3) in Lemma 2 will be applied to analyze various recursive identification algorithms, in both the explicit and the implicit models. For a $\nu\times\nu$ matrix A, define $\|A\|=\sup_{\|x\|=1}\|Ax\|=\lambda_{\max}^{1/2}(A'A)$.

LEMMA 2. *Suppose that for $n\leqq t<m$, $\phi_t=(y_t,\cdots,y_{t-\nu+1},u_{t-\delta},\cdots u_{t-\delta-\kappa+1},\hat{y}_{t+d-1},\cdots,\hat{y}_{t+d-h})'$ and $C(q^{-1})(y_{t+d}-\eta_{t+d})=G(q^{-1})y_t+q^{-\delta}\Gamma(q^{-1})u_t$, where $\delta\geqq 0$, $d\geqq 1$, $\nu\geqq 1$, $\kappa\geqq 1$, and $C(q^{-1})=1+c_1q^{-1}+\cdots+c_hq^{-h}$, $G(q^{-1})=g_1+\cdots+g_\nu q^{-(\nu-1)}$ and $\Gamma(q^{-1})=\gamma_1+\cdots+\gamma_\kappa q^{-(\kappa-1)}$ are polynomials in the backward shift operator q^{-1}. Suppose that there exist $(\nu+\kappa+h)\times 1$ vectors θ_t such that $\hat{y}_{t+d}=\theta_t'\phi_t$ for $n\leqq t<m$. Then*

$$C(q^{-1})(y_s-\hat{y}_s-\eta_s)=-(\theta_{s-d}-\theta)'\phi_{s-d}\quad for\ m+d>s\geqq n+d, \tag{2.3}$$

where $\theta=(g_1,\cdots,g_\nu,\gamma_1,\cdots,\gamma_\kappa,-c_1,\cdots,-c_h)'$.

Proof. For $n\leqq t<m$,

$$\begin{aligned}C(q^{-1})&(y_{t+d}-\hat{y}_{t+d}-\eta_{t+d})\\&=C(q^{-1})(y_{t+d}-\eta_{t+d})-(C(q^{-1})-1)\hat{y}_{t+d}-\hat{y}_{t+d}\\&=(G(q^{-1})y_t+\Gamma(q^{-1})u_{t-\delta})-(c_1\hat{y}_{t+d-1}+\cdots+c_h\hat{y}_{t+d-h})-\theta_t'\phi_t\\&=\theta'\phi_t-\theta_t'\phi_t.\end{aligned}$$

□

LEMMA 3. *Let $\{D_n, n \geqq 0\}$ be a sequence of $L \times L$ real matrices such that $\sum_0^\infty \|D_n\| < \infty$ and let $D(z) = \sum_{n=0}^\infty D_n z^n$. Suppose that $D(e^{it}) + D'(e^{-it})$ is nonnegative definite for all $t \in [-\pi, \pi]$.*

(i) *Let $\{g_n, n \geqq 0\}$ be sequence of $L \times 1$ real vectors and let $f_n = \sum_{k=0}^n D_k g_{n-k}$. Then for any $N \geqq 0$, $\sum_{n=0}^N f_n' g_n \geqq 0$.*

(ii) *Suppose that $D_i = 0$ for all $i > h$. Let $M \geqq h$ and suppose that $f_n = \sum_{j=0}^h D_j g_{n-j}$ for $M \leqq n \leqq N$. Let $\{r_n, M \leqq n \leqq N\}$ be a nondecreasing sequence of positive numbers. Then*

$$\sum_{n=M}^{N} f_n' g_n / r_n \geqq \sum_{j=1}^{h} \sum_{t=0}^{h-j} g'_{M-1-t} D'_{j+t} g_{M-1+j} / r_{M-1+j}.$$

Proof. To prove (i), note that

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \left(\sum_{n=0}^{N} g_n e^{-\mathrm{int}} \right)' \left(\frac{D(e^{it}) + D'(e^{-it})}{2} \right) \left(\sum_{n=0}^{N} g_n e^{int} \right) dt$$

$$= \frac{1}{2\pi} \sum_{k=0}^{\infty} \sum_{n=0}^{N} \sum_{m=0}^{N} g_n' D_k g_m \int_{-\pi}^{\pi} e^{i(m-n)t} e^{ikt} \, dt$$

$$= \sum_{k=0}^{N} \sum_{\substack{0 \leqq m \leqq n \leqq N \\ m-n=-k}} g_n' D_k g_m = \sum_{n=0}^{N} g_n' \sum_{k=0}^{n} D_k g_{n-k} = \sum_{n=0}^{N} g_n' f_n.$$

Since $D(e^{it}) + D'(e^{-it})$ is nonnegative definite, (i) follows.

To prove (ii), let $g_n^* = g_n$ if $n \geqq M$ and let $g_n^* = 0$ otherwise. Let $f_n^* = \sum_{j=0}^h D_j g_{n-j}^*$. Then $f_n^* = f_n$ for $n \geqq M + h$ and $f_n - f_n^* = \sum_{m=n-h}^{M-1} D_{n-m} g_m$ for $M \leqq n < M + h$. Therefore

$$\sum_{n=M}^{N} g_n' f_n / r_n = \sum_{n=M}^{N} g_n^{*\prime} f_n^* / r_n + \sum_{j=1}^{h} g'_{M-1+j} \left(\sum_{k=j}^{h} D_k g_{M-1+j-k} \right) \Big/ r_{M-1+j}.$$

Let $S_n = \sum_{m=0}^n g_m^{*\prime} f_m^*$. By (i), $S_n \geqq 0$ for all $n \leqq N$. Since $g_n^* = 0$ for $n < M$, $S_{M-1} = 0$. Summation by parts gives

$$\sum_{n=M}^{N} g_n^{*\prime} f_n^* / r_n = r_N^{-1} S_N + \sum_{n=M}^{N-1} (r_n^{-1} - r_{n+1}^{-1}) S_n \geqq 0,$$

noting that $r_n^{-1} \geqq r_{n+1}^{-1} > 0$. Hence the desired conclusion follows. □

LEMMA 4. *Let $x_1, x_2, \cdots$ be $\nu \times 1$ vectors and let $A_n = A_{n-1} + x_n x_n' + \rho_n I$, where ρ_n are nonnegative scalars, I is the $\nu \times \nu$ identity matrix, and A_0 is a symmetric, positive-definite $\nu \times \nu$ matrix.*

(i) *If $\lim_{n\to\infty} \lambda_{\max}(A_n) < \infty$, then $\sum_{i=1}^\infty x_i' A_i^{-1} x_i < \infty$. If $\lim_{n\to\infty} \lambda_{\max}(A_n) = \infty$, then*

$$\sum_{i=1}^{n} x_i' A_i^{-1} x_i \leqq (1 + o(1)) \log \det A_n. \tag{2.4}$$

(ii) *Suppose that $\sup_n \rho_n < \infty$ and that $\lambda_{\min}(A_n) \to \infty$ and $x_n' A_n^{-1} x_n \to 0$ as $n \to \infty$. Then for every fixed $r = 0, \pm 1, \pm 2, \cdots$,*

$$x_n' A_{n+r}^{-1} x_n \sim x_n' A_n^{-1} x_n \quad \textit{as } n \to \infty. \tag{2.5}$$

Proof. By Lemma 2(i) of [19],

$$x_i' A_i^{-1} x_i = (|A_i| - |A_{i-1} + \rho_i I|) / |A_i|. \tag{2.6}$$

Since $|A_{i-1} + \rho_i I| \geqq |A_{i-1}|$, it follows from (2.6) that $x_i' A_i^{-1} x_i \leqq (|A_i| - |A_{i-1}|)/|A_i|$ and therefore (i) follows by the same argument as that used to prove Lemma 2(ii) of [19].

To prove (ii), we first show that

$$x_n' A_{n-1}^{-1} x_n \sim x_n' A_n^{-1} x_n \quad \text{as } n \to \infty. \tag{2.7}$$

By the matrix inversion lemma (cf. [3, p. 824]),

$$A_n^{-1} = (A_{n-1}+\rho_n I)^{-1} - \frac{(A_{n-1}+\rho_n I)^{-1} x_n x_n' (A_{n-1}+\rho_n I)^{-1}}{1 + x_n'(A_{n-1}+\rho_n I)^{-1} x_n},$$

and therefore

$$x_n' A_n^{-1} x_n = x_n'(A_{n-1}+\rho_n I)^{-1} x_n / \{1 + x_n'(A_{n-1}+\rho_n I)^{-1} x_n\}. \tag{2.8}$$

Since $(A_{n-1}+\rho_n I)^{-1} = A_{n-1}^{-1/2}(I+\rho_n A_{n-1}^{-1})^{-1} A_{n-1}^{-1/2} = A_{n-1}^{-1} + A_{n-1}^{-1/2} B_n A_{n-1}^{-1/2}$, where $B_n = \sum_{i=1}^{\infty} (-\rho_n A_{n-1}^{-1})^i$, and since $\rho_n \lambda_{\max}(A_{n-1}^{-1}) \to 0$ (implying that $\lambda_{\max}(B_n) \to 0$), it then follows that

$$x_n'(A_{n-1}+\rho_n I)^{-1} x_n = x_n' A_{n-1}^{-1} x_n + o(\|A_{n-1}^{-1/2} x_n\|^2) = (1+o(1)) x_n' A_{n-1}^{-1} x_n. \tag{2.9}$$

From (2.8) and (2.9), (2.7) follows.

We next show by induction that for $r = 1, 2, \cdots$,

$$x_n' A_{n-r}^{-1} x_n \sim x_n' A_n^{-1} x_n \quad \text{as } n \to \infty. \tag{2.10}$$

Note that (2.10) reduces to (2.7) when $r = 1$. Suppose that (2.10) holds for $1 \leqq r \leqq s-1$. Since $A_{n-1} = A_{n-s} + \sum_{j=1}^{s-1} (x_{n-j} x_{n-j}' + \rho_{n-j} I)$,

$$\begin{aligned} A_{n-1}^{-1} &= A_{n-s}^{-1/2} \left\{ I + \sum_{j=1}^{s-1} (A_{n-s}^{-1/2} x_{n-j} x_{n-j}' A_{n-s}^{-1/2} + \rho_{n-j} A_{n-s}^{-1}) \right\}^{-1} A_{n-s}^{-1/2} \\ &= A_{n-s}^{-1} + A_{n-s}^{-1/2} C_n A_{n-s}^{-1/2}, \end{aligned} \tag{2.11}$$

where

$$C_n = \sum_{i=1}^{\infty} \left\{ -\sum_{j=1}^{s-1} (A_{n-s}^{-1/2} x_{n-s+j} x_{n-s+j}' A_{n-s}^{-1/2} + \rho_{n-s+j} A_{n-s}^{-1}) \right\}^i. \tag{2.12}$$

Noting that $\|C\| = \lambda_{\max}(C) \leqq \operatorname{tr}(C)$ if C is symmetric and nonnegative definite, we have

$$\sum_{j=1}^{s-1} \|A_{n-s}^{-1/2} x_{n-s+j} x_{n-s+j}' A_{n-s}^{-1/2}\| \leqq \sum_{j=1}^{s-1} x_{n-s+j}' A_{n-s}^{-1} x_{n-s+j} \to 0, \tag{2.13}$$

since (2.10) holds for $1 \leqq r \leqq s-1$. From (2.13) and the fact that $\rho_{n-s+j} \lambda_{\max}(A_{n-s}^{-1}) = \rho_{n-s+j} / \lambda_{\min}(A_{n-s}) \to 0$, it follows that $\|C_n\| \to 0$, and therefore by (2.11),

$$x_n' A_{n-1}^{-1} x_n = x_n' A_{n-s}^{-1} x_n + o(x_n' A_{n-s}^{-1} x_n). \tag{2.14}$$

In view of (2.14) and (2.7), (2.10) holds for $r = s$.

For $r \geqq 1$, since $A_{n+r} = A_n + \sum_{j=1}^{r} (x_{n+j} x_{n+j}' + \rho_{n+j} I)$, we can make use of (2.10) and the same argument as in (2.11)-(2.14) to show that $x_n' A_{n+r}^{-1} x_n = x_n' A_n^{-1} x_n + o(x_n' A_n^{-1} x_n)$. □

LEMMA 5. *Suppose that the polynomial* $C(z) = 1 + c_1 z + \cdots + c_h z^h$ *is stable. For* $j = 1, \cdots, h$, *let* $\{c_{n,j}\}$ *be a sequence of numbers such that* $\lim_{n\to\infty} c_{n,j} = c_j$, *and let* $C_n(q^{-1}) = 1 + c_{n,1} q^{-1} + \cdots + c_{n,h} q^{-h}$.

(i) *Suppose that* ξ_n *and* ϕ_n *are* $L \times 1$ *vectors such that* $C_n(q^{-1})\xi_n = \phi_n$. *Then there exist* $K > 0$ *and* $0 < \rho < 1$ *such that for all* $t > m$

$$\|\xi_t\| \leqq K \left\{ \sum_{i=0}^{t-m-1} \rho^i \|\phi_{t-i}\| + \rho^{t-m} \sum_{r=0}^{h-1} \|\xi_{m-r}\| \right\}. \tag{2.15}$$

Consequently, there exists $K' > 0$ *such that for all* $n > m$,

$$\sum_{t=m+1}^{n} \|\xi_t\|^2 \leqq K' \left\{ \max_{0 \leqq r \leqq h-1} \|\xi_{m-r}\|^2 + \sum_{t=m+1}^{n} \|\phi_t\|^2 \right\}. \tag{2.16}$$

(ii) *Let* $G(q^{-1}) = g_1 + \cdots + g_p q^{-p+1}$, $\Gamma(q^{-1}) = \gamma_1 + \cdots + \gamma_k q^{-k+1}$, $G_n(q^{-1}) = g_{n,1} + \cdots + g_{n,p} q^{-p+1}$, $\Gamma_n(q^{-1}) = \gamma_{n,1} + \cdots + \gamma_{n,k} q^{-k+1}$, *where* $\lim_{n\to\infty} g_{n,j} = g_j$ *and* $\lim_{n\to\infty} \gamma_{n,j} = \gamma_j$ *for every j. Suppose that*

$$C(q^{-1})\tilde{y}_{n+d} = G(q^{-1})y_n + \Gamma(q^{-1})u_n, \qquad C_n(q^{-1})\hat{y}_{n+d} = G_n(q^{-1})y_n + \Gamma_n(q^{-1})u_n. \tag{2.17}$$

Then $\sum_{i=1}^n (\tilde{y}_{i+d} - \hat{y}_{i+d})^2 = o(\sum_{i=1}^n (y_i^2 + u_i^2))$.

Proof. For (i), see [19, pp. 161-162] and [9, p. 904]. To prove (ii), note that by (2.17),

$$\begin{aligned} C_n(q^{-1})(\hat{y}_{n+d} - \tilde{y}_{n+d}) &= C_n(q^{-1})\hat{y}_{n+d} - C(q^{-1})\tilde{y}_{n+d} - (C_n(q^{-1}) - C(q^{-1}))\tilde{y}_{n+d} \\ &= (G_n(q^{-1}) - G(q^{-1}))y_n + (\Gamma_n(q^{-1}) - \Gamma(q^{-1}))u_n \\ &\quad - (C_n(q^{-1}) - C(q^{-1}))\tilde{y}_{n+d}. \end{aligned} \tag{2.18}$$

Since $G_n - G \to 0$, $\Gamma_n - \Gamma \to 0$, and $C_n - C \to 0$, it follows from (2.18) and part (i) of the lemma that

$$\sum_{i=1}^n (\tilde{y}_{i+d} - \hat{y}_{i+d})^2 = o\left(\sum_{i=1}^n (y_i^2 + u_i^2 + \tilde{y}_{i+d}^2)\right). \tag{2.19}$$

Again by (2.17) and (i),

$$\sum_{i=1}^n \tilde{y}_{i+d}^2 = O\left(\sum_{i=1}^n (y_i^2 + u_i^2)\right). \tag{2.20}$$

From (2.19) and (2.20), the desired conclusion follows. □

3. Extended least squares and the associated adaptive predictors. To begin with, consider the model (1.1) with $C(q^{-1}) = 1$, i.e., the ARX model. In this case, the AML algorithm (1.13) reduces to the usual least squares estimator, for which (1.13b) becomes $\Phi_n = (y_n, \cdots, y_{n-p+1}, u_{n-\Delta+1}, \cdots, u_{n-\Delta-k+2})' = \Psi_n$. As shown in [18] and [19], the least squares one-step ahead predictors $\hat{y}_{n+1} = \Theta_n' \Phi_n$ satisfy

$$\sum_{n=1}^N (\tilde{y}_{n+1} - \hat{y}_{n+1})^2 I_{\{\Phi_n' P_n \Phi_n \leq \delta\}} = O(\log \det P_N^{-1}) \quad \text{for every } 0 < \delta < 1, \tag{3.1}$$

where $\tilde{y}_{n+1} = \Theta' \Psi_n$ is the optimal one-step ahead predictor of y_{n+1} assuming knowledge of the parameter vector $\Theta = (-a_1, \cdots, -a_p, b_1, \cdots, b_k)'$ and $P_n^{-1} = P_{n-1}^{-1} + \Phi_n \Phi_n'$ as in (1.13a). When the sample mean square boundedness assumption (1.20) holds for the input-output data, (3.1) implies that

$$\sum_{i=1}^N (\tilde{y}_{n+1} - \hat{y}_{n+1})^2 = O(\log N) \quad \text{a.s. on } \{\limsup_{n\to\infty} \Phi_n' P_n \Phi_n < 1\}. \tag{3.2}$$

For general $C(z)$ satisfying the positive real condition (1.15), Lai and Wei [9] showed that (3.1) still holds for the adaptive one-step ahead predictors $\hat{y}_{n+1} = \Theta_n' \Phi_n$ based on the AML algorithm Θ_n and the pseudoregression vector Φ_n defined in (1.13). It is also shown in [9] that

$$\sum_{n=1}^N \|\Phi_n - \Psi_n\|^2 = O\left(\log\left(2 + \sum_{n=1}^N \|\Phi_n\|^2\right)\right) \quad \text{a.s.} \tag{3.3}$$

If (1.20) holds, then since $\sum_{n=1}^N \varepsilon_n^2 = O(N)$ almost surely by Lemma 1(ii), $\sum_{n=1}^N \|\Psi_n\|^2 = O(N)$ almost surely and therefore $\sum_{n=1}^N \|\Phi_n\|^2 = O(N)$ almost surely by (3.3). Hence, under assumptions (1.15) and (1.20), (3.2) still holds for the adaptive predictor $\hat{y}_{n+1}$ based on the AML algorithm.

In [9], (3.1) was obtained from an analysis of the recursive inequalities for the extended stochastic Lyapunov function (1.16) that was also used to study the consistency of Θ_n. Earlier, Solo [8] used these recursive inequalities to transform (1.16) into a nonnegative almost supermartingale and thereby applies the martingale convergence theorem to establish the strong consistency of Θ_n under assumptions (1.14) and (1.15). There is, however, a gap in Solo's proof, as noted by Zhang [13]. Specifically, Solo's proof made use of claim (A6) in Appendix I of [8] that for $\nu \times 1$ vectors x_i, if $\sum_1^n \|x_i\|^2 = O(n)$ and $\sum_1^n x_i x_i'$ is nonsingular, then $x_n'(\sum_1^n x_i x_i')^{-1} x_n \to 0$. Zhang [13] found an error in the proof of (A6) and concluded that (A6) is "questionable." In fact, (A6) turns out to be false, as can be seen from the following example in the scalar case $\nu = 1$. Let $J = \{2, 2^2, 2^3, \cdots\}$ and let $x_n = 1$ if $n \notin J$ and $x_n = n^{1/2}$ if $n \in J$. Then $n \leqq \sum_1^n x_i^2 \leqq n + \sum_{i:2^i \leqq n} 2^i \leqq 3n$ for all n, and $x_n^2/\sum_1^n x_i^2 \geqq \frac{1}{3}$ for $n \in J$, violating (A6).

For d-step ahead prediction, Sin, Goodwin, and Bitmead [12] proposed an extension of the AML algorithm to construct adaptive predictors using the following implicit approach. Instead of working with (1.5), they introduced a further reparametrization to facilitate the analysis of the AML algorithm that directly estimates the parameters of this reparametrized model. Applying the division algorithm, they wrote

$$1 = \bar{F}(z)C(z) + z^d \bar{G}(z), \tag{3.4}$$

where $\bar{F}(z) = 1 + \bar{f}_1 z + \cdots + \bar{f}_{d-1} z^{d-1}$ and $\bar{G}(z) = \bar{g}_1 + \bar{g}_2 z + \cdots + \bar{g}_h z^{h-1}$. Let

$$\bar{C}(z) = 1 - z^d \bar{G}(z) = 1 - \bar{g}_1 z^d - \cdots - \bar{g}_h z^{d+h-1}. \tag{3.5}$$

From (3.4), $\bar{C}(z) = \bar{F}(z)C(z)$. Multiplying (1.5) by $\bar{F}(q^{-1})$ gives

$$\begin{aligned} &\bar{C}(q^{-1})\{y_{n+d} - F(q^{-1})\varepsilon_{n+d}\} \\ &\quad = \bar{F}(q^{-1})G(q^{-1})y_n + q^{-(\Delta-d)}\bar{F}(q^{-1})F(q^{-1})B(q^{-1})u_n. \end{aligned} \tag{3.6}$$

Therefore, analogous to (1.9), system (1.1) can be written in the prediction form

$$\begin{aligned} &y_{n+d} = \bar{\theta}'\bar{\psi}_n + \eta_{n+d} \quad \text{where } \eta_{n+d} = F(q^{-1})\varepsilon_{n+d} = y_{n+d} - \tilde{y}_{n+d}, \\ &\bar{\psi}_n = (y_n, \cdots, y_{n-p(d)-d+2}, u_{n-\Delta+d}, \cdots, u_{n-k-\Delta-d+3}, \tilde{y}_n, \cdots, \tilde{y}_{n-h+1})', \\ &\bar{\theta} = (g_1, g_1\bar{f}_1 + g_2, \cdots, \bar{f}_{d-1} f_{d-1} b_k, \bar{g}_1, \cdots, \bar{g}_h)'. \end{aligned} \tag{3.7}$$

In analogy with (1.13), Sin, Goodwin, and Bitmead [12] introduced the following extended least squares algorithm to estimate $\bar{\theta}$:

$$\bar{\theta}_n = \bar{\theta}_{n-d} + P_{n-d}\bar{\phi}_{n-d}(y_n - \bar{\theta}'_{n-d}\bar{\phi}_{n-d}), \tag{3.8a}$$

$$P_n^{-1} = P_{n-d}^{-1} + \bar{\phi}_n \bar{\phi}'_n, \tag{3.8b}$$

$$\begin{aligned} \bar{\phi}_n = (&y_n, \cdots, y_{n-p(d)-d+2}, u_{n-\Delta+d}, \cdots, u_{n-k-\Delta-d+3}, \\ &\bar{\theta}'_n\bar{\phi}_{n-d}, \cdots, \bar{\theta}'_{n-h+1}\bar{\phi}_{n-h+1-d})'. \end{aligned} \tag{3.8c}$$

Thus, (3.8) is an AML-type algorithm which replaces the $\tilde{y}_i$ in $\bar{\psi}_n$ by the "a posteriori" predictor $\bar{\theta}'_i\bar{\phi}_{i-d}$. Note also that (3.8) can be regarded as "interlacing" d unit-delay-type recursions for $\bar{\theta}_{j+dt}$ $(j = 0, \cdots, d-1)$.

The extended least squares d-step ahead predictor is

$$\hat{y}_{n+d} = \bar{\theta}'_n \bar{\phi}_n, \tag{3.9}$$

where $\bar{\theta}_n$ and $\bar{\phi}_n$ are given by (3.8). Assuming (1.20) and

$$\min_{|z|=1} \operatorname{Re}\left(\frac{1}{\bar{C}(z)} - \frac{1}{2}\right) > 0, \tag{3.10}$$

Sin, Goodwin, and Bitmead [12] modified Solo's [8] argument to prove that $n^{-1}\sum_1^n (\tilde{y}_{i+d}-\hat{y}_{i+d})^2 \to 0$ almost surely, i.e., the adaptive predictors (3.9) are globally convergent. As noted by Zhang [13], their proof uses Solo's [8] result (A6) to conclude that $\bar{\phi}'_n P_n \bar{\phi}_n \to 0$ almost surely. Since (A6) has been shown to be invalid, their proof only gives that under (1.20) and (3.10),

$$n^{-1}\sum_{i=1}^{n} (\tilde{y}_{i+d}-\hat{y}_{i+d})^2 \to 0 \quad \text{a.s.} \qquad \text{if } \lim_{n\to\infty} \bar{\phi}'_n P_n \bar{\phi}_n = 0 \quad \text{a.s.} \tag{3.11}$$

Modifying the proof of Theorem 1 of Lai and Wei [9] (instead of Solo's [8] arguments) and combining it with algebraic details similar to those provided by [12] leads to the following analogue of (3.2), which is considerably stronger than (3.11).

THEOREM 1. *Suppose that the random disturbances* ε_n *in the linear stochastic system* (1.1) *satisfy* (1.3) *and that the positive real assumption* (3.10) *holds. Consider the extended least squares algorithm* $\bar{\theta}_n$, *defined by* (3.8) *for the implicit model* (3.7), *and its associated adaptive d-step ahead predictor* (3.9). *Then for every* $0<\delta<1$,

$$\sum_{i=1}^{n} (\tilde{y}_{i+d}-\hat{y}_{i+d})^2 I_{\{\bar{\phi}'_i P_i \bar{\phi}_i \leqq \delta\}} = O(\log \det P_n^{-1}) \quad \textit{a.s.}, \tag{3.12}$$

$$\sum_{i=1}^{n} \|\bar{\phi}_i - \bar{\psi}_i\|^2 = O\left(\log\left(2+\sum_{i=1}^{n} \|\bar{\phi}_i\|^2\right)\right) \quad \textit{a.s.}, \tag{3.13}$$

where $\bar{\psi}_i$ *is defined in* (3.7). *Furthermore, if* (1.20) *also holds, then* $\sum_1^n \|\bar{\phi}_i\|^2 = O(n)$ *almost surely and*

$$\sum_{i=1}^{n} (\tilde{y}_{i+d}-\hat{y}_{i+d})^2 = O(\log n) \quad \textit{a.s. on } \{\limsup_{n\to\infty} \bar{\phi}'_n P_n \bar{\phi}_n < 1\}. \tag{3.14}$$

Proof. Let $f_n = (\bar{\theta}-\bar{\theta}_n)'\bar{\phi}_{n-d}$, $e_n = y_n - \bar{\theta}'_{n-d}\bar{\phi}_{n-d}$, $\hat{\eta}_n = y_n - \bar{\theta}'_n \bar{\phi}_{n-d}$, $w_n = \hat{\eta}_n - \eta_n$. By (3.16) of [12], $\bar{C}(q^{-1})w_n = f_n$. Define

$$Q_n = (\bar{\theta}_n - \bar{\theta})' P_{n-d}^{-1} (\bar{\theta}_n - \bar{\theta}). \tag{3.15}$$

Fix $j \in \{0, \cdots, d-1\}$ and let $a_{t,j} = a_{j+dt}$ for a sequence of vectors (matrices, scalars) a_n, so that $\bar{\theta}_{t,j} = \bar{\theta}_{j+dt}$, $P_{t,j} = P_{j+dt}$, etc. By (3.13) of [12],

$$\hat{\eta}_{t,j} = (1 - \bar{\phi}'_{t-1,j} P_{t-1,j} \bar{\phi}_{t-1,j}) e_{t,j}. \tag{3.16}$$

As shown in [12, p. 1163], it follows from (3.8), (3.15), and (3.16) that

$$Q_{t,j} = Q_{t-1,j} + f_{t,j}^2 - 2f_{t,j}\hat{\eta}_{t,j} - \bar{\phi}'_{t-1,j}P_{t-1,j}\bar{\phi}_{t-1,j}(1-\bar{\phi}'_{t-1,j}P_{t-1,j}\bar{\phi}_{t-1,j})e_{t,j}^2. \tag{3.17}$$

By (3.8a),

$$-f_{t,j} = (\bar{\theta}_{t-1,j}-\bar{\theta})'\bar{\phi}_{t-1,j} + \bar{\phi}'_{t-1,j}P_{t-1,j}\bar{\phi}_{t-1,j}(e_{t,j}-\eta_{t,j}) + \bar{\phi}'_{t-1,j}P_{t-1,j}\bar{\phi}_{t-1,j}\eta_{t,j}. \tag{3.18}$$

Since $\hat{\eta}_{t,j} = w_{t,j} + \eta_{t,j}$, it follows from (3.17) and (3.18) that

$$\begin{aligned} Q_{t,j} = {} & Q_{t-1,j} - f_{t,j}(2w_{t,j} - f_{t,j}) \\ & + 2\eta_{t,j}\{(\bar{\theta}_{t-1,j}-\bar{\theta})'\bar{\phi}_{t-1,j} + \bar{\phi}'_{t-1,j}P_{t-1,j}\bar{\phi}_{t-1,j}(e_{t,j}-\eta_{t,j})\} \\ & + 2\bar{\phi}'_{t-1,j}P_{t-1,j}\bar{\phi}_{t-1,j}\eta_{t,j}^2 - \bar{\phi}'_{t-1,j}P_{t-1,j}\bar{\phi}_{t-1,j}(1-\bar{\phi}'_{t-1,j}P_{t-1,j}\bar{\phi}_{t-1,j})e_{t,j}^2, \end{aligned} \tag{3.19}$$

which is of the same form as (24) in [9]. Let $g_i = w_i - f_i/2$. For $n = dT + \nu$ with $0 \leqq \nu < d$, we obtain by summing (3.19) that

$$Q_n + Q_{n-1} + \cdots + Q_{n-d+1} = Q_0 + \cdots + Q_{d-1} - 2 \sum_{i=d}^{n} f_i g_i$$

$$- \left(\sum_{j=0}^{\nu} \sum_{t=1}^{T} + \sum_{j=\nu+1}^{d-1} \sum_{t=1}^{T-1} \right) [2\eta_{t,j}\{(\bar{\theta}_{t-1,j} - \bar{\theta})' \bar{\phi}_{t-1,j} + \bar{\phi}'_{t-1,j} P_{t-1,j} \bar{\phi}_{t-1,j}(e_{t,j} - \eta_{t,j})\} \tag{3.20}$$

$$+ 2\bar{\phi}'_{t-1,j} P_{t-1,j} \bar{\phi}_{t-1,j} \eta^2_{t,j} - \bar{\phi}'_{t-1,j} P_{t-1,j} \bar{\phi}_{t-1,j} (1 - \bar{\phi}'_{t-1,j} P_{t-1,j} \bar{\phi}_{t-1,j}) e^2_{t,j}].$$

Since $w_i = (1/\bar{C}(q^{-1}))f_i$ by the stability of $\bar{C}(z)$, $g_i = (1/\bar{C}(q^{-1}) - \frac{1}{2})f_i$ and therefore by the positive real assumption (3.10) and Lemmas 3 and 5(i), there exist $\delta > 0$ (for which $1/\bar{C}(z) - \frac{1}{2} - \delta$ is positive real) and $K > 0$ such that

$$\sum_{i=d}^{n} f_i g_i + K \geqq \delta \sum_{i=d}^{n} f_i^2, \quad \sum_{i=d}^{n} f_i g_i + K \geqq \delta \sum_{i=d}^{n} f_i^2 \quad \text{for all } n \geqq d, \tag{3.21}$$

analogous to (25) in [9]. Note also that (3.16) and (3.18) are analogous to (26) of [9]. The rest of the proof of (3.12) and (3.13) is therefore the same as that of Theorem 1 of [9], where the only references to Solo [8] are related to (24) and (25) of [9], and (A6) of [8] is never used.

Suppose that (1.20) holds. Since $\sum_1^n \varepsilon_i^2 = O(n)$ almost surely by Lemma 1(ii), $\sum_1^n \eta_i^2 = O(n)$ almost surely. Hence $\sum_1^n \tilde{y}_i^2 = \sum_1^n (y_i - \eta_i)^2 \leqq 2(\sum_1^n y_i^2 + \sum_1^n \eta_i^2) = O(n)$ almost surely. Therefore $\sum_1^n \|\bar{\psi}_i\|^2 = O(n)$ almost surely, which together with (3.13) gives that

$$\sum_{i=1}^{n} \|\bar{\phi}_i\|^2 \leqq 2 \sum_{i=1}^{n} \|\bar{\psi}_i\|^2 + 2 \sum_{i=1}^{n} \|\bar{\phi}_i - \bar{\psi}_i\|^2 = O\left(n + \log \left(2 + \sum_{i=1}^{n} \|\bar{\phi}_i\|^2 \right) \right) \quad \text{a.s.,}$$

implying that $\sum_1^n \|\bar{\phi}_i\|^2 = O(n)$ almost surely. Hence

$$\log \det P_n^{-1} = O\left(\log \left(2 + \sum_1^n \|\bar{\phi}_i\|^2 \right) \right) = O(\log n)$$

almost surely, and therefore (3.14) follows from (3.12). □

Remark. Unlike the preceding arguments, the proof of Sin, Goodwin, and Bitmead [12] uses (3.17) to show that

$$\begin{aligned} &E[n^{-1}Q_n | \mathcal{F}_{n-d}] + E[n^{-1}S_n | \mathcal{F}_{n-d}] \\ &\quad \leqq (n-d)^{-1} Q_{n-d} + E[(n-1)^{-1} S_{n-1} | \mathcal{F}_{n-d}] \\ &\qquad - \rho n^{-1} E[f_n^2 | \mathcal{F}_{n-d}] + 2n^{-1} \bar{\phi}'_{n-d} P_{n-d} \bar{\phi}_{n-d} E[\eta_n^2 | \mathcal{F}_{n-d}], \end{aligned} \tag{3.22}$$

where $S_n = 2\sum_{i=d}^{n} f_i(g_i - \frac{1}{2}\rho f_i) + K$, and ρ and K are chosen by (3.10) so that $1/\bar{C}(z) - (1+\rho)/2$ is positive real and $S_n \geqq 0$ for all $n \geqq d$. Summing (3.22) from d to N and taking expectations, a crucial step in their argument is to prove that

$$E\left(\sum_{n=d}^{\infty} n^{-1} \bar{\phi}'_{n-d} P_{n-d} \bar{\phi}_{n-d} \right) < \infty, \tag{3.23}$$

which is then used to show that $E(\sum_{n=d}^{\infty} n^{-1} f_n^2) < \infty$, from which it follows that $\sum_d^{\infty} n^{-1} f_n^2 < \infty$ almost surely. Sin, Goodwin, and Bitmead [12] prove (3.23) by first showing that $\sum_d^{\infty} n^{-1} \bar{\phi}'_{n-d} P_{n-d} \bar{\phi}_{n-d} < \infty$ almost surely and then applying the monotone convergence theorem to conclude that (3.23) holds. However, this application of the monotone convergence theorem is invalid, and we cannot conclude from the almost sure finiteness of $Z \triangleq \sum_1^{\infty} n^{-1}(z_n / \sum_1^n z_i)$ that $EZ < \infty$ for nonnegative random variables z_n. In particular, letting $z_n = u_{n-\Delta}^2 = \bar{\phi}_{n-d}^2$ in the special case $d = \Delta = 1$ and $A(q^{-1}) = B(q^{-1}) = C(q^{-1}) = 1$, consider the following counterexample. Let $v_0, v_1, \cdots$ be independent exponential random variables with mean 1. Define $z_0 = v_0$, $z_n = nI_{\{\sum_1^{n-1} z_i < 2n\}} + v_n I_{\{\sum_1^{n-1} z_i \geqq 2n\}}$ for $n \geqq 1$. Then a standard argument shows that $\liminf_{n\to\infty} E(z_n/\sum_1^n z_i) > 0$ and that $P\{n/2 \leqq \sum_1^n z_i \leqq 3n$ for all large $n\} = 1$. Therefore, although $Z = \sum_1^\infty n^{-1}(z_n/\sum_1^n z_i) \leqq 3\sum_1^\infty z_n/(\sum_1^n z_i)^2 + O(1) < \infty$ almost surely, $EZ = \sum_1^\infty n^{-1}E(z_n/\sum_1^n z_i) = \infty$.

Theorem 1 suggests that if we use the extended least squares predictor $\hat{y}_{n+d} = \bar{\theta}'_n \bar{\phi}_n$ to predict y_{n+d} whenever $\bar{\phi}'_n P_n \bar{\phi}_n \leqq \delta$ (with $0 < \delta < 1$) and use some other predictor when this condition is violated, then we may be able to achieve a good overall performance. This idea will be further developed in Corollaries 2 and 3 of § 4 where we will use the stochastic gradient algorithm to give an adaptive predictor of y_{n+d} when $\bar{\phi}_n P'_n \bar{\phi}_n > \delta$.

4. The stochastic gradient algorithm and some extensions. To begin with, consider the stochastic gradient algorithm (1.29) that estimates the parameter vector (1.11) of the explicit system (1.1). As an application of Lemma 1 to the extended stochastic Lyapunov function $Q_n = \|\Theta_n - \Theta\|^2$, we prove the following corollary, part (ii) of which deals with a modification of (1.29) that constrains by projection the estimator to lie inside some convex region. Such constrained algorithms have been studied by Ljung [5], [6] and Kushner and Clark [20] by the ODE method.

COROLLARY 1. *Suppose that* $\min_{|z|=1} \operatorname{Re}\{C(z) - a/2\} > 0$ *and that the random disturbances* ε_n *in the linear stochastic system* (1.1) *satisfy* (1.3).

(i) *For the stochastic gradient algorithm* (1.29),

$$\limsup_{n\to\infty} \|\Theta_n\| < \infty \quad a.s., \tag{4.1}$$

$$\sum_{n=1}^{\infty} (e_n - \varepsilon_n)^2 / r_n < \infty \quad a.s., \tag{4.2}$$

$$\sum_{n=1}^{\infty} \|\Theta_n - \Theta_{n-1}\|^2 < \infty \quad a.s., \tag{4.3}$$

where e_n *and* r_n *are as defined in* (1.29b) *and* (1.29c).

(ii) *Let* $\{D_n\}$ *be a sequence of closed convex regions in* R^{p+k+h} *such that* $\Theta \in D_n$ *for all large n. Let* $\Pi_D(x)$ *denote the Euclidean projection of* x *into* D, *i.e.*, $\|x - \Pi_D(x)\| = \min\{\|x - y\|: y \in D\}$. *Suppose that we modify* (1.29a) *defining the stochastic gradient algorithm as*

$$\Theta_n = \Pi_{D_n}(\Theta_{n-1} + ar_{n-1}^{-1} e_n \Phi_{n-1}). \tag{4.4}$$

Then (4.1) *and* (4.2) *still hold. If, furthermore,* $D_n \supset D_{n-1}$ *for all large n, then* (4.3) *still holds.*

Proof. (i) Let $Q_i = \|\Theta_i - \Theta\|^2$. From (1.29a) it follows that

$$Q_i = Q_{i-1} + 2ar_{i-1}^{-1} e_i \Phi'_{i-1}(\Theta_{i-1} - \Theta) + a^2 r_{i-1}^{-2} e_i^2 \|\Phi_{i-1}\|^2. \tag{4.5}$$

Replacing e_i in (4.5) by $(e_i - \varepsilon_i) + \varepsilon_i$ and summing (4.5) over i give that for $n > h$,

$$\begin{aligned} Q_n = Q_h &+ 2a \sum_{i=h+1}^{n} \{r_{i-1}^{-1}(e_i - \varepsilon_i)\Phi'_{i-1}(\Theta_{i-1} - \Theta) + (a/2) r_{i-1}^{-2}(e_i - \varepsilon_i)^2 \|\Phi_{i-1}\|^2\} \\ &+ a^2 \sum_{i=h+1}^{n} r_{i-1}^{-2} \|\Phi_{i-1}\|^2 \varepsilon_i^2 + 2a \sum_{i=h+1}^{n} \varepsilon_i \\ &\times \{r_{i-1}^{-1}\Phi'_{i-1}(\Theta_{i-1} - \Theta) + ar_{i-1}^{-2}(e_i - \varepsilon_i)\|\Phi_{i-1}\|^2\}. \end{aligned} \tag{4.6}$$

Since $e_i-\varepsilon_i=(y_i-\varepsilon_i)-\Theta'_{i-1}\Phi_{i-1}$ is $\mathscr{F}_{i-1}$-measurable, it follows from (2.1) that

$$\begin{aligned}&\sum_{i=h+1}^{n}\varepsilon_i\{r_{i-1}^{-1}\Phi'_{i-1}(\Theta_{i-1}-\Theta)+ar_{i-1}^{-2}(e_i-\varepsilon_i)\|\Phi_{i-1}\|^2\}\\ &\qquad=o\left(\sum_{i=h+1}^{n}r_{i-1}^{-2}[\Phi'_{i-1}(\Theta_{i-1}-\Theta)]^2\right)+o\left(\sum_{i=h+1}^{n}r_{i-1}^{-2}(e_i-\varepsilon_i)^2\right)\\ &\qquad\quad+O(1)\quad\text{a.s.,}\end{aligned}\tag{4.7}$$

noting that $\|\Phi_t\|^2/r_t\leqq 1$. Moreover, $\sum_1^\infty r_t^{-2}\|\Phi_t\|^2<\infty$ since $r_t=r_0+\sum_1^t\|\Phi_i\|^2$. Hence

$$\sum_{i=h+1}^{n}r_{i-1}^{-2}\|\Phi_{i-1}\|^2\varepsilon_i^2=O\left(\sum_{i=h+1}^{n}r_{i-1}^{-2}\|\Phi_{i-1}\|^2\right)=O(1)\quad\text{a.s.,}\tag{4.8}$$

by Lemma 1(ii). By continuity and compactness, we can choose $\rho>0$ such that $\min_{|z|=1}\operatorname{Re}\{C(z)-(a+\rho)/2\}>0$. Moreover, by Lemma 2 (with $d=1$ and $\eta_t=\varepsilon_t$),

$$\Phi'_{i-1}(\Theta_{i-1}-\Theta)+(a+\rho)(e_i-\varepsilon_i)/2=-\{C(q^{-1})-\tfrac{1}{2}(a+\rho)\}(e_i-\varepsilon_i).\tag{4.9}$$

Since $\|\Phi_t\|^2/r_t\leqq 1$, it then follows from Lemma 3(ii) that

$$\begin{aligned}&\sum_{i=h+1}^{n}\{r_{i-1}^{-1}(e_i-\varepsilon_i)\Phi'_{i-1}(\Theta_{i-1}-\Theta)+(a/2)r_{i-1}^{-2}(e_i-\varepsilon_i)^2\|\Phi_{i-1}\|^2\}\\ &\qquad\leqq\sum_{i=h+1}^{n}r_{i-1}^{-1}(e_i-\varepsilon_i)\{\Phi'_{i-1}(\Theta_{i-1}-\Theta)+(a+\rho)(e_i-\varepsilon_i)/2\}\\ &\qquad\quad-(\rho/2)\sum_{i=h+1}^{n}r_{i-1}^{-1}(e_i-\varepsilon_i)^2\\ &\qquad\leqq-(\rho/2)\sum_{i=h+1}^{n}r_{i-1}^{-1}(e_i-\varepsilon_i)^2+O(1).\end{aligned}\tag{4.10}$$

Since $\Phi'_{i-1}(\Theta_{i-1}-\Theta)=-C(q^{-1})(e_i-\varepsilon_i)$,

$$\sum_{i=h+1}^{n}r_{i-1}^{-2}[\Phi'_{i-1}(\Theta_{i-1}-\Theta)]^2=O\left(\sum_{i=1}^{n}r_{i-1}^{-2}(e_i-\varepsilon_i)^2\right).\tag{4.11}$$

From (4.6)-(4.11), it follows that $Q_n\leqq\{-a\rho+o(1)\}\sum_{i=1}^n r_{i-1}^{-1}(e_i-\varepsilon_i)^2+O(1)$ almost surely, giving the desired conclusions (4.1) and (4.2). To prove (4.3), note that by (1.29a),

$$\begin{aligned}\sum_{i=1}^{n}\|\Theta_i-\Theta_{i-1}\|^2&=\sum_{i=1}^{n}a^2r_{i-1}^{-2}\|\Phi_{i-1}\|^2\{\varepsilon_i^2+2\varepsilon_i(e_i-\varepsilon_i)+(e_i-\varepsilon_i)^2\}\\ &\leqq(a^2+o(1))\sum_{i=1}^{n}r_{i-1}^{-1}(e_i-\varepsilon_i)^2+O(1)\quad\text{a.s.,}\end{aligned}$$

by (4.7) and (4.8), noting that $\|\Phi_t\|^2/r_t\leqq 1$. Hence (4.3) follows from (4.2).

(ii) Suppose that $\Theta\in D_i$ for all $i\geqq m(>h)$. For $i\geqq m$, since D_i is convex and $\Theta\in D_i$, it follows from (4.4) that

$$\begin{aligned}\|\Theta_i-\Theta_{i-1}\|^2&\leqq\|\Theta_{i-1}+ar_{i-1}^{-1}e_i\Phi_{i-1}-\Theta\|^2\\ &=\|\Theta_{i-1}-\Theta\|^2+2ar_{i-1}^{-1}e_i\Phi'_{i-1}(\Theta_{i-1}-\Theta)+a^2r_{i-1}^{-2}e_i^2\|\Phi_{i-1}\|^2,\end{aligned}$$

and therefore the same argument as before proves that (4.1) and (4.2) still hold. Suppose that $D_{i-1}\subset D_i$ for all $i\geqq m$. Then for $i\geqq m$, since $\Theta_{i-1}\in D_{i-1}\subset D_i$ and D_i is convex, it follows from (4.4) that $\|\Theta_i-\Theta_{i-1}\|^2\leqq\|(\Theta_{i-1}+ar_{i-1}^{-1}e_i\Phi_{i-1})-\Theta_i\|^2=a^2r_{i-1}^{-2}\|\Phi_{i-1}\|^2e_i^2$, and the same argument as before shows that (4.3) still holds. □

The ARMAX model (1.1) can be written as a linear regression model (1.12), and (1.29) represents the stochastic gradient algorithm to estimate the parameter vector Θ of this regression model. Making use of (4.1)-(4.3), Fuchs [16], [17] established the global convergence property (1.21) for the adaptive d-step ahead predictors defined by the explicit approach (1.18) in which the estimated polynomials are given by the stochastic gradient algorithm Θ_n, under assumptions (1.20), (1.25), and (1.26). An alternative approach for d-step ahead prediction is to express (1.1) as the regression model (1.9), in which $E(\eta_{n+d}|\mathscr{F}_n)=0$ while ψ_n is $\mathscr{F}_n$-measurable. The stochastic gradient algorithm estimating the parameter θ in the regression model $y_n=\theta'\psi_{n-d}+\eta_n$ (i.e., (1.9)) takes the form

$$\theta_n=\theta_{n-1}+(a/r_{n-d})\phi_{n-d}(y_n-\hat{y}_n), \tag{4.12a}$$

$$\phi_n=(y_n,\cdots,y_{n-p(d)+1},u_{n-\Delta+d},\cdots,u_{n-\Delta-k+2},\hat{y}_{n+d-1},\cdots,\hat{y}_{n+d-h})', \tag{4.12b}$$

$$r_n=r_{n-1}+\|\phi_n\|^2, \tag{4.12c}$$

$$\hat{y}_{n+d}=\theta_n'\phi_n, \tag{4.12d}$$

where $p(d)=p\vee(h-d+1)$. The extended stochastic Lyapunov function argument used in Corollary 1 can be modified to prove the global convergence of the adaptive predictors (4.12d) based on the stochastic gradient algorithm that does not involve interlacing in the implicit approach. This is the content of the following.

THEOREM 2. *Suppose that* $\min_{|z|=1}\operatorname{Re}\{C(z)-(d-1/2)a\}>0$ *and that the random disturbances* ε_n *in the linear stochastic system* (1.1) *satisfy* (1.3). *Consider the stochastic gradient algorithm* θ_n *defined by* (4.12) *for the implicit model* (1.9) *in which the* $\tilde{y}_i$ *and* η_i *are defined by* (1.6) *and* (1.7). *Then*

$$\limsup_{n\to\infty}\|\theta_n\|<\infty \quad a.s., \qquad \sum_{n=d+1}^{\infty}\|\theta_n-\theta_{n-1}\|^2<\infty \quad a.s., \tag{4.13}$$

$$\sum_{n=d+1}^{\infty}(\tilde{y}_n-\hat{y}_n)^2/r_{n-d}<\infty \quad a.s. \tag{4.14}$$

Consequently,

$$n^{-1}\sum_{t=d+1}^{n}(\tilde{y}_t-\hat{y}_t)^2\to 0 \quad a.s.\ on\ \left\{\limsup_{n\to\infty}n^{-1}\sum_{i=1}^{n}(y_i^2+u_i^2)<\infty\right\}. \tag{4.15}$$

If $B(z)\neq 0$ *and is stable, then on*

$$\{\limsup_{n\to\infty}n^{-1}\textstyle\sum_{t=1}^{n}y_t^2<\infty\}\cup\{\limsup_{n\to\infty}n^{-1}\textstyle\sum_{t=1}^{n}\hat{y}_t^2<\infty\},$$

$$n^{-1}\sum_{t=d+1}^{n}(\tilde{y}_t-\hat{y}_t)^2\to 0 \quad and \quad \sum_{t=1}^{n}(y_t^2+u_t^2+\hat{y}_t^2)=O(n) \quad a.s. \tag{4.16}$$

If $A(z)$ *is stable, then* (4.16) *holds on* $\{\limsup_{n\to\infty}n^{-1}\sum_{t=1}^{n}u_t^2<\infty\}$.

Proof. Let $Q_n=\|\theta_n-\theta\|^2$, $e_n=y_n-\hat{y}_n$. As in (4.6), it follows from (4.12a) that for $n>m$,

$$\begin{aligned}Q_n=Q_m&+2a\sum_{m+1}^{n}\{r_{i-d}^{-1}(e_i-\eta_i)\phi_{i-d}'(\theta_{i-1}-\theta)+(a/2)r_{i-d}^{-2}(e_i-\eta_i)^2\|\phi_{i-d}\|^2\}\\&+a^2\sum_{m+1}^{n}r_{i-d}^{-2}\|\phi_{i-d}\|^2\eta_i^2+2a\sum_{m+1}^{n}\eta_i\\&\times\{r_{i-d}^{-1}\phi_{i-d}'(\theta_{i-1}-\theta)+ar_{i-d}^{-2}(e_i-\eta_i)\|\phi_{i-d}\|^2\}.\end{aligned} \tag{4.17}$$

Note that r_{i-d}, ϕ_{i-d}, θ_{i-d}, and $e_i-\eta_i=\theta'\psi_{i-d}-\theta'_{i-d}\phi_{i-d}$ are $\mathscr{F}_{i-d}$-measurable. Since $\eta_i=\varepsilon_i+f_1\varepsilon_{i-1}+\cdots+f_{d-1}\varepsilon_{i-d+1}$, it follows from Lemma 1 that as $n\to\infty$,

$$\begin{aligned}&\sum_{m+1}^{n}\eta_i\{r_{i-d}^{-1}\phi'_{i-d}(\theta_{i-d}-\theta)+ar_{i-d}^{-2}(e_i-\eta_i)\|\phi_{i-d}\|^2\}\\&\qquad=o\left(\sum_{m+1}^{n}r_{i-d}^{-2}[\phi'_{i-d}(\theta_{i-d}-\theta)]^2\right)+o\left(\sum_{m+1}^{n}r_{i-d}^{-2}(e_i-\eta_i)^2\right)+O(1)\quad\text{a.s.,}\end{aligned}\tag{4.18}$$

$$\sum_{m+1}^{n}r_{i-d}^{-2}\|\phi_{i-d}\|^2\eta_i^2=O\left(\sum_{m+1}^{n}r_{i-d}^{-2}\|\phi_{i-d}\|^2\right)=O(1)\quad\text{a.s.,}\tag{4.19}$$

analogous to (4.7) and (4.8). Choosing $\rho>0$ such that $\operatorname{Re}\{C(z)-(d-\frac{1}{2})a-\rho\}>0$ for all $|z|=1$, we obtain by Lemma 2 that as in (4.9) and (4.10),

$$\begin{aligned}&\sum_{m+1}^{n}\{r_{i-d}^{-1}(e_i-\eta_i)\phi'_{i-d}(\theta_{i-d}-\theta)+(a/2)r_{i-d}^{-2}(e_i-\eta_i)^2\|\phi_{i-d}\|^2\}\\&\qquad\leqq-\sum_{m+1}^{n}r_{i-d}^{-1}(e_i-\eta_i)[\{C(q^{-1})-a/2-\rho\}(e_i-\eta_i)]-\rho\sum_{m+1}^{n}r_{i-d}^{-1}(e_i-\eta_i)^2.\end{aligned}\tag{4.20}$$

Noting that (4.17) involves $\theta_{i-1}-\theta$ instead of $\theta_{i-d}-\theta$, we write in the case $d>1$

$$\theta_{i-1}-\theta=(\theta_{i-d}-\theta)+\sum_{s=1}^{d-1}(\theta_{i-s}-\theta_{i-s-1}).\tag{4.21}$$

Fix $s=1,\cdots,d-1$. From (4.12a) and the inequality $|x'y|\leqq(\|x\|^2+\|y\|^2)/2$, it follows that

$$\begin{aligned}&\left|\sum_{m+1}^{n}r_{i-d}^{-1}(e_i-\eta_i)\phi'_{i-d}(\theta_{i-s}-\theta_{i-s-1})\right|\\&\qquad=\left|a\sum_{m+1}^{n}[r_{i-d}^{-1}(e_i-\eta_i)\phi_{i-d}]'[r_{i-s-d}^{-1}e_{i-s}\phi_{i-s-d}]\right|\\&\qquad\leqq(a/2)\left\{\sum_{m+1}^{n}r_{i-d}^{-2}(e_i-\eta_i)^2\|\phi_{i-d}\|^2+\sum_{m+1}^{n}r_{i-s-d}^{-2}e_{i-s}^2\|\phi_{i-s-d}\|^2\right\}\\&\qquad=(a+o(1))\sum_{m+1}^{n}r_{i-d}^{-2}(e_i-\eta_i)^2\|\phi_{i-d}\|^2+O(1)\quad\text{a.s.,}\end{aligned}\tag{4.22}$$

where the last relation above follows from an application of Lemma 1 to

$$\begin{aligned}\sum_{m+1}^{n}r_{i-s-d}^{-2}e_{i-s}^2\|\phi_{i-s-d}\|^2=&\sum_{m+1}^{n}r_{i-s-d}^{-2}(e_{i-s}-\eta_{i-s})^2\|\phi_{i-s-d}\|^2\\&+\sum_{m+1}^{n}r_{i-s-d}^{-2}\|\phi_{i-s-d}\|^2\eta_{i-s}^2\\&+2\sum_{m+1}^{n}r_{i-s-d}^{-2}\|\phi_{i-s-d}\|^2(e_{i-s}-\eta_{i-s})\eta_{i-s},\end{aligned}$$

noting that $e_{i-s}-\eta_{i-s}$ if $\mathscr{F}_{i-s-d}$-measurable and that $\|\phi_t\|^2/r_t\leqq 1$ and $\sum_1^\infty|\phi_t\|^2/r_t^2<\infty$.

Moreover, analogous to (4.22), we have

$$\begin{aligned}
&\left|\sum_{m+1}^{n} \eta_i r_{i-d}^{-1} \phi_{i-d}'(\theta_{i-s}-\theta_{i-s-1})\right| \\
&\qquad \leqq a\left|\sum_{m+1}^{n} \eta_i r_{i-d}^{-1} r_{i-s-d}^{-1} \phi_{i-d}' \phi_{i-s-d}(e_{i-s}-\eta_{i-s})\right| \\
&\qquad\quad + a\left|\sum_{m+1}^{n} [\eta_i r_{i-d}^{-1}\phi_{i-d}]'[\eta_{i-s} r_{i-s-d}^{-1}\phi_{i-s-d}]\right| \\
&\qquad = o\left(\sum_{m+1}^{n} r_{i-s-d}^{-1}(e_{i-s}-\eta_{i-s})^2\right) + O(1) + O\left(\sum_{m+1}^{n} r_{i-d}^{-2}\|\phi_{i-d}\|^2\eta_i^2\right) \\
&\qquad = o\left(\sum_{m+1}^{n} r_{i-d}^{-1}(e_i-\eta_i)^2\right) + O(1) \quad \text{a.s. by Lemma 1.}
\end{aligned} \tag{4.23}$$

Combining (4.21) with (4.20) and (4.22) gives

$$\begin{aligned}
&\sum_{m+1}^{n} \{r_{i-d}^{-1}(e_i-\eta_i)\phi_{i-d}'(\theta_{i-1}-\theta) + (a/2) r_{i-d}^{-2}(e_i-\eta_i)^2\|\phi_{i-d}\|^2\} \\
&\quad \leqq \{(d-1)a+o(1)\}\sum_{m+1}^{n} r_{i-d}^{-2}\|\phi_{i-d}\|^2(e_i-\eta_i)^2 + O(1) - \rho\sum_{m+1}^{n} r_{i-d}^{-1}(e_i-\eta_i)^2 \\
&\qquad - \sum_{m+1}^{n} r_{i-d}^{-1}(e_i-\eta_i)[\{C(q^{-1})-a/2-\rho\}(e_i-\eta_i)] \\
&\quad \leqq -(\rho+o(1))\sum_{m+1}^{n} r_{i-d}^{-1}(e_i-\eta_i)^2 + O(1) \\
&\qquad - \sum_{m+1}^{n} r_{i-d}^{-1}(e_i-\eta_i)[\{C(q^{-1})-(d-\tfrac{1}{2})a-\rho\}(e_i-\eta_i)] \\
&\quad \leqq -(\rho+o(1))\sum_{m+1}^{n} r_{i-d}^{-1}(e_i-\eta_i)^2 + O(1),
\end{aligned} \tag{4.24}$$

where the last inequality follows from Lemma 3(ii). As in (4.11), it follows from Lemma 2 that

$$\sum_{m+1}^{n} r_{i-d}^{-2}[\phi_{i-d}'(\theta_{i-d}-\theta)]^2 = O\left(\sum_{m+1}^{n} r_{i-d}^{-1}(e_i-\eta_i)^2\right). \tag{4.25}$$

From (4.17)-(4.19) together with (4.21) and (4.23)-(4.25), it follows that $Q_n + (2a\rho + o(1))\sum_{m+1}^{n} r_{i-d}^{-1}(e_i-\eta_i)^2 = O(1)$ almost surely, implying (4.13) and (4.14) as in the proof of Corollary 1. Note in this connection that $e_i - \eta_i = y_i - \hat{y}_i - \eta_i = \tilde{y}_i - \hat{y}_i$.

By (4.14) and the Kronecker lemma,

$$\begin{aligned}
\sum_{i=1}^{n} (y_i-\hat{y}_i-\eta_i)^2 &= O(1) \quad \text{on } \left\{\sup_n r_n < \infty\right\}, \\
&= o\left(\sum_{i=1}^{n-d} y_i^2 + \sum_{i=1}^{n-\Delta} u_i^2 + \sum_{i=1}^{n-1} \hat{y}_i^2\right) \quad \text{on } \left\{\sup_n r_n = \infty\right\}.
\end{aligned} \tag{4.26}$$

From Lemma 1(ii), (4.26), and the inequality

$$\sum_{i=1}^{n} \hat{y}_i^2 \leqq 2\sum_{i=1}^{n} (\hat{y}_i+\eta_i-y_i)^2 + 4\sum_{i=1}^{n} y_i^2 + 4\sum_{i=1}^{n} \eta_i^2, \tag{4.27}$$

it follows that

$$\sum_{i=1}^{n} \hat{y}_i^2 = O(n) \quad \text{a.s. on} \left\{ \limsup_{n\to\infty} n^{-1} \sum_{i=1}^{n} (y_i^2 + u_i^2) < \infty \right\}. \tag{4.28}$$

From (4.26) and (4.28), (4.15) follows.

Suppose that $B(z) \neq 0$ and is stable. by changing Δ if necessary, we can assume that $b_1 \neq 0$. Then by (1.1) and Lemma 5(i),

$$\sum_{i=1}^{n-\Delta} u_i^2 = O\left(\sum_{i=1}^{n} y_i^2 + \sum_{i=1}^{n} \varepsilon_i^2 \right) = O\left(\sum_{i=1}^{n} y_i^2 \right) + O(n) \quad \text{a.s.,} \tag{4.29}$$

and therefore

$$\sum_{i=1}^{n} u_i^2 = O(n) \quad \text{a.s. on} \left\{ \limsup_{n\to\infty} n^{-1} \sum_{i=1}^{n} y_i^2 < \infty \right\}. \tag{4.30}$$

From (4.26) and (4.29), it follows that

$$\begin{aligned} \sum_{i=1}^{n} y_i^2 &\leqq 2 \sum_{i=1}^{n} (y_i - \hat{y}_i - \eta_i)^2 + 4 \sum_{i=1}^{n} \hat{y}_i^2 + 4 \sum_{i=1}^{n} \eta_i^2 \\ &= o\left(\sum_{i=1}^{n-d} y_i^2 \right) + O\left(\sum_{i=1}^{n} \hat{y}_i^2 \right) + O(n) \quad \text{a.s.,} \end{aligned}$$

and therefore

$$\sum_{i=1}^{n} y_i^2 = O(n) \quad \text{a.s. on} \left\{ \limsup_{n\to\infty} n^{-1} \sum_{i=1}^{n} \hat{y}_i^2 < \infty \right\}. \tag{4.31}$$

On the event $\{\limsup_{n\to\infty} n^{-1} \sum_{i=1}^{n} y_i^2 < \infty\} \cup \{\limsup_{n\to\infty} n^{-1} \sum_{i=1}^{n} \hat{y}_i^2 < \infty\}$, it follows from (4.28), (4.30), and (4.31) that $\sum_{i=1}^{n} (y_i^2 + u_i^2 + \hat{y}_i^2) = O(n)$ almost surely, and therefore $\sum_{i=1}^{n} (y_i - \hat{y}_i - \eta_i)^2 = o(n)$ almost surely by (4.26).

Now assume that $A(z)$ is stable. Then by (1.1) and Lemma 5(i),

$$\sum_{i=1}^{n} y_i^2 = O\left(\sum_{i=1}^{n-\Delta} u_i^2 \right) + O\left(\sum_{i=1}^{n} \varepsilon_i^2 \right) = O\left(\sum_{i=1}^{n-\Delta} u_i^2 \right) + O(n) \quad \text{a.s.}$$

Hence on the event $\{\limsup_{n\to\infty} n^{-1} \sum_{i=1}^{n} u_i^2 < \infty\}$, $\sum_{i=1}^{n} y_i^2 = O(n)$ almost surely, and therefore $\sum_{i=1}^{n} \hat{y}_i^2 = O(n)$ almost surely by (4.28) and $\sum_{i=1}^{n} (y_i - \hat{y}_i - \eta_i)^2 = o(n)$ almost surely by (4.26). □

Noting that although the stochastic gradient algorithm leads to the adaptive controller (1.23)-(1.24) that is self-optimizing, its rate of convergence has been found in numerical studies to be much slower than that of the more commonly used "least squares iterations," Sin and Goodwin [21] suggest combining the ideas underlying both algorithms into what they call a "modified least squares" algorithm for the case $d = \Delta = 1$. Their algorithm has been modified and extended to general d by Zhang [13] who, defining $\bar{\phi}_n$ as in (3.8c), introduces the recursions

$$\bar{\theta}_n = \bar{\theta}_{n-d} + \alpha_{n-d} P_{n-d} \bar{\phi}_{n-d} (y_n - \bar{\theta}'_{n-d} \bar{\phi}_{n-d}), \tag{4.32a}$$

$$r_n = r_{n-1} + \|\bar{\phi}_n\|^2, \qquad R_n = (P_{n-d}^{-1} + \bar{\phi}_n \bar{\phi}'_n)^{-1}, \tag{4.32b}$$

$$\begin{aligned} &P_n = R_n \quad \text{and } \alpha_n = 1, \quad \text{if } r_n \operatorname{tr}(R_n) \leqq K_1 \quad \text{and } \bar{\phi}'_n P_{n-d} \bar{\phi}_n \leqq K_2, \\ &P_n = (r_{n-d}/r_n) P_{n-d} \quad \text{and } \alpha_n = 1/(1 + \bar{\phi}'_n P_n \bar{\phi}_n), \quad \text{otherwise,} \end{aligned} \tag{4.32c}$$

where K_1, K_2 are prescribed constants. Under assumptions (1.20) and (3.10), it is shown in [13] that the adaptive predictors $\hat{y}_{n+d} = \bar{\theta}'_n \bar{\phi}_n$ associated with (4.32) satisfy the global convergence property (1.21). The modified least squares algorithm of Sin and Goodwin [21] for the case $d = \Delta = 1$ is similar, but does not include the condition $\bar{\phi}'_n P_{n-1} \bar{\phi}_n \leqq K_2$ as in (4.32c) because Solo's [8] result (A6) has been used to conclude that $\bar{\phi}'_n P_{n-1} \bar{\phi}_n \to 0$. Zhang [13] finds (A6) questionable and further modifies the Sin-Goodwin algorithm to patch this gap and to extend to general d.

Instead of using matrix gain (3.8b) of the extended least squares algorithm, which we have studied in § 3, Zhang's modified least squares algorithm changes this gain by not including $\bar{\phi}_n \bar{\phi}'_n$ into the sum and deflating the matrix by a scalar multiple whenever certain conditions are not met. Note that the scalar gain $1/r_n = 1/(r_0 + \sum_1^n \|\bar{\phi}_i\|^2)$ of the stochastic gradient algorithm also appears in the condition $r_n \operatorname{tr}(R_n) \leq K_1$ and in the dampening factor r_{n-d}/r_n of (4.32c). Our results in Theorems 1 and 2 suggest a simpler and more direct way of combining the stochastic gradient algorithm with the extended least squares algorithm to produce a globally convergent adaptive predictor. This is the content of the following result.

COROLLARY 2. *Suppose that the random disturbances ε_n in the linear system* (1.1) *satisfy* (1.3) *and that the outputs y_n and inputs u_n satisfy* (1.20). *Assume that* (3.10) *holds and that* $\min_{|z|=1} \operatorname{Re}\{C(z) - (d - \frac{1}{2})a\} > 0$ *for some $a > 0$. Define the stochastic gradient algorithm θ_n by* (4.12) *and the extended least squares algorithm $\bar{\theta}_n$ by* (3.8). *Let $\hat{y}_{n+d}$ be the adaptive d-step ahead predictor associated with the stochastic gradient algorithm, as in* (4.12d). *Take $0 < \delta < 1$ and define*

$$\hat{y}^*_{n+d} = \bar{\theta}'_n \bar{\phi}_n \quad \text{if } \bar{\phi}'_n P_n \bar{\phi}_n \leqq \delta, \qquad = \hat{y}_{n+d} \quad \text{if } \bar{\phi}'_n P_n \bar{\phi}_n > \delta, \tag{4.33}$$

where P_n and $\bar{\phi}_n$ are given in (3.8b) *and* (3.8c). *Then*

$$n^{-1} \sum_{i=1}^n (\tilde{y}_{i+d} - \hat{y}^*_{i+d})^2 \to 0 \quad a.s., \tag{4.34}$$

$$\sum_{i=1}^n I_{\{\bar{\phi}'_i P_i \bar{\phi}_i > \delta\}} = O(\log n) \quad a.s. \tag{4.35}$$

Proof. By Theorem 1, $\sum_1^n \|\bar{\phi}_i\|^2 = O(n)$ almost surely since (1.20) holds, and

$$\sum_{i=1}^n (\tilde{y}_{i+d} - \bar{\theta}'_i \bar{\phi}_i)^2 I_{\{\bar{\phi}'_i P_i \bar{\phi}_i \leqq \delta\}} = O(\log \lambda_{\max}(P_n^{-1})) = O(\log n) \quad \text{a.s.} \tag{4.36}$$

By (4.15) and (1.20),

$$\sum_{i=1}^n (\tilde{y}_{i+d} - \hat{y}_{i+d})^2 = o(n) \quad \text{a.s.} \tag{4.37}$$

From (4.33), (4.36), and (4.37), (4.34) follows.

To prove (4.35), note that for $\nu = 0, \cdots, d-1$,

$$\sum_{i \leqq n, i \equiv \nu (\operatorname{mod} d)} \bar{\phi}'_i (P_i^{-1})^{-1} \bar{\phi}_i = O\left(\log\left(2 + \sum_{i=1}^n \|\bar{\phi}_i\|^2\right)\right) \quad \text{a.s.}, \tag{4.38}$$

by (3.8b) and Lemma 4(i). Since $\sum_1^n \|\bar{\phi}_i\|^2 = O(n)$ almost surely, (4.35) follows from (4.38). □

In view of (4.35), the stochastic gradient component of the adaptive predictor (4.33) is used very infrequently, only at a relative frequency of $O(n^{-1} \log n)$ within n

stages. At other times, the extended least squares component of (4.33) is used and the cumulative squared difference between the adaptive predictor and the optimal predictor at these times is of the order $O(\log n)$, as in (4.36). We can introduce at these times another modification to keep $\sum_{i=1}^{n} (\tilde{y}_{i+d} - \hat{y}_{i+d})^2$ within $O((\log n)^3)$ almost surely if the inputs and outputs eventually have finite moment generating functions, i.e., if $\limsup_{t\to\infty} E \exp(\lambda|u_t|) < \infty$ and $\limsup_{t\to\infty} E \exp(\lambda|y_t|) < \infty$ for some $\lambda > 0$. This is the content of the following corollary.

COROLLARY 3. *Suppose that the random disturbances* ε_n *in* (1.1) *satisfy* (1.3) *and that the outputs* y_n *and inputs* u_n *satisfy* (1.20) *and*

$$\limsup_{i\to\infty} \{E \exp(\lambda|y_i|^\alpha) + E \exp(\lambda|u_i|^\alpha)\} < \infty \quad \text{for some } \lambda > 0 \text{ and } \alpha > 0. \tag{4.39}$$

Assume that (3.10) *holds. Define the extended least squares algorithm* $\bar{\theta}_n$ *by* (3.8). *Take* $0 < \delta < 1$ *and define*

$$\begin{aligned} \hat{y}_{n+d} &= \bar{\theta}'_n \bar{\phi}_n \quad \text{if } \bar{\phi}'_n P_n \bar{\phi}_n \leqq \delta, \\ &= (\log n)^{1/\alpha} \quad \text{if } \bar{\phi}'_n P_n \bar{\phi}_n > \delta, \end{aligned} \tag{4.40}$$

where P_n *and* $\bar{\phi}_n$ *are given in* (3.8b) *and* (3.8c). *Then* (4.35) *holds and*

$$\sum_{i=1}^{n} (\tilde{y}_{i+d} - \hat{y}_{i+d})^2 = O((\log n))^{1+2/\alpha}) \quad \text{a.s.} \tag{4.41}$$

Proof. First note from the proof of Corollary 2 that (4.36), (4.38), and (4.35) still hold in the present case. By (3.10), $\bar{C}(z)(=\bar{F}(z)C(z))$ is stable and therefore $C(z)$ is stable. From (4.39) it follows that

$$\sum_{n=1}^{\infty} (P\{|u_n| > 2(\lambda^{-1}\log n)^{1/\alpha}\} + P\{|y_n| > 2(\lambda^{-1}\log n)^{1/\alpha}\}) = \sum_{n=1}^{\infty} O(\exp(-2\log n)) < \infty,$$

and therefore $\max(|u_n|, |y_n|) = O((\log n)^{1/\alpha})$ almost surely by the Borel-Cantelli lemma. Since $C(z)$ is stable, it then follows from (1.6) and Lemma 5(i) that $\tilde{y}_{n+d} = O((\log n)^{1/\alpha})$ almost surely. Hence by (4.40),

$$\sum_{i=1}^{n} (\tilde{y}_{i+d} - \hat{y}_{i+d})^2 I_{\{\bar{\phi}'_i P_i \bar{\phi}_i > \delta\}} = O\left((\log n)^{2/\alpha} \sum_{i=1}^{n} I_{\{\bar{\phi}'_i P_i \bar{\phi}_i > \delta\}}\right) \quad \text{a.s.} \tag{4.42}$$

From (4.35), (4.36), and (4.42), (4.41) follows. □

5. Consistent parameter estimation and monitored recursive maximum likelihood. In this section we will assume that $C(z)$ is stable. Suppose that we are able to find strongly consistent estimators Θ_n of the parameter vector Θ defined in (1.11). Then under assumption (1.20), the adaptive d-step ahead predictor $\hat{y}_{n+d}$ constructed from Θ_n by the explicit approach (1.18) satisfies the global convergence property (1.21). Here we will make use of the consistent estimators Θ_n in another way to provide adaptive predictors $\hat{y}_{n+d}$ that satisfy

$$\begin{aligned} &\limsup_{n\to\infty} \frac{\sum_{i=1}^{n} (\tilde{y}_{i+d} - \hat{y}_{i+d})^2}{\log n} \\ &\quad \leqq (2d-1)(p(d)+k+d-1+h) \limsup_{i\to\infty} E(\eta_i^2 | \mathcal{F}_{i-d}) \quad \text{a.s.,} \end{aligned} \tag{5.1}$$

where $p(d) = p \vee (h-d+1)$ and η_i is defined in (1.7). Such adaptive predictors are constructed by the implicit approach using the monitored recursive maximum likelihood algorithm defined below. Note that (5.1) is a stronger conclusion than (3.14) on adaptive predictors based on the extended least squares algorithm. Moreover, while the extended least squares algorithm needs the positive real assumption (3.10) for

(3.14) to hold, the monitored recursive maximum likelihood algorithm does not need such an assumption for (5.1).

The consistent estimators Θ_n will be used to provide "confidence sets" S_n for the parameter vector θ, defined in (1.8), of the implicit system such that S_n shrinks to θ as $n \to \infty$. For example, consider the AML algorithm Θ_n defined in (1.13) with pseudoregression vectors Φ_n. Under assumptions (1.15) and (1.17), it follows from Theorem 1 of [9] that $\{\log(\sum_1^n \|\Phi_i\|^2)\}/\lambda_{\min}(\sum_1^n \Phi_i\Phi_i') \to 0$ almost surely and that

$$\Theta_n - \Theta = O\left(\left\{\log\left(\sum_1^n \|\Phi_i\|^2\right)\right\}^{1/2} \Big/ \lambda_{\min}^{1/2}\left(\sum_1^n \Phi_i\Phi_i'\right)\right) \quad \text{a.s.} \tag{5.2}$$

Since the components of θ can be expressed as smooth functions of those of Θ, Θ_n induces a strongly consistent estimator θ_n^* of θ; in fact, (5.2) implies that

$$\theta_n^* - \theta = O\left(\left\{\log\left(\sum_{i=1}^n \|\Phi_i\|^2\right)\right\}^{1/2} \Big/ \lambda_{\min}^{1/2}\left(\sum_{i=1}^n \Phi_i\Phi_i'\right)\right) \quad \text{a.s.} \tag{5.3}$$

Hence we can define S_n to be a cube with center θ_n^* and width $\lambda_{\min}^{-1/3}(I + \sum_1^n \Phi_i\Phi_i')$. Then by (5.3),

$$P\{\theta \in S_n \text{ for all large } n\} = 1, \tag{5.4}$$

and as $n \to \infty$ the width of S_n converges to 0 almost surely.

The consistent estimators θ_n^* and the associated confidence sets S_n need only be updated occasionally at times $n(1) < n(2) < \cdots$ for monitoring the recursive maximum likelihood algorithm θ_n that we now introduce. The basic ideas underlying the algorithm θ_n are (i) to extend the RML2 algorithm (1.33) to the implicit system (1.9), and (ii) to constrain (monitor) the algorithm so that it lies inside $S_{n(j)}$ for $n(j) \leqq n < n(j+1)$. The projection which we use to constrain θ_n is taken with respect to the norm induced by the positive definite matrix P_{n-d}^{-1} defined in (5.6d) below, instead of the usual Euclidean norm. For $x \in R^{p(d)+k+d-1+h}$ and $n(j) \leqq n < n(j+1)$, let $\pi_n(x)$ denote the unique solution of the quadratic programming problem

$$(\pi_n(x) - x)' P_{n-d}^{-1}(\pi_n(x) - x) = \min_{y \in S_{n(j)}} \{(y-x)' P_{n-d}^{-1}(y-x)\}, \tag{5.5}$$

i.e.,$\pi_n(x)$ is the projection of x into $S_{n(j)}$ with respect to the norm induced by P_{n-d}^{-1}. It is convenient to choose $S_{n(j)}$ to be a cube so that we have linear constraints for the quadratic programming problem (5.5), which can be handled by simple computational methods (cf. [22]). Define $\theta_n = (\hat{g}_{n,1}, \cdots, \hat{g}_{n,p(d)}, \hat{b}_{n,1}, (\widehat{fb})_{n,2}, \cdots, (\widehat{fb})_{n,k+d-1}, -\hat{c}_{n,1}, \cdots, -\hat{c}_{n,h})'$ for $n > n(1)$ by the recursion

$$\theta_n = \pi_n(\theta_{n-1} + P_{n-d}\xi_{n-d}(y_n - \hat{y}_n)), \tag{5.6a}$$

$$\begin{aligned} &\xi_n + \hat{c}_{n,1}\xi_{n-1} + \cdots + \tilde{c}_{n,h}\xi_{n-h} = \phi_n, \quad \text{where} \\ &\phi_n = (y_n, \cdots, y_{n-p(d)+1}, u_{n-\Delta+d}, \cdots, u_{n-k-\Delta+2}, \hat{y}_{n+d-1}, \cdots, \hat{y}_{n+d-h})', \end{aligned} \tag{5.6b}$$

$$\hat{y}_{n+d} = \theta_n' \phi_n, \tag{5.6c}$$

$$P_n^{-1} = P_{n-1}^{-1} + \xi_n \xi_n' + \rho_n I, \tag{5.6d}$$

where

$$\rho_n \geqq 0 \quad \text{is } \mathscr{F}_n\text{-measurable with } \sup_n \rho_n < \infty \quad \text{a.s.} \tag{5.6e}$$

The following theorem, which is analogous to Theorem 1 on the extended least squares algorithm, gives asymptotic properties of the adaptive predictors (5.6c) associated with the monitored recursive maximum likelihood algorithm. These results are used to establish the conclusion (5.1) for the choice $\rho_n = 1/n$ in (5.6d) under certain conditions on the input-output data and the stopping times $n(j)$ in Corollary 4 below.

THEOREM 3. *Suppose that $C(z)$ is stable and that the random disturbances ε_n in the linear stochastic system* (1.1) *satisfy assumption* (1.3). *Let $n(1) < n(2) < \cdots$ be stopping times with respect to $\{\mathscr{F}_t\}$ and let $S_{n(j)}$ be an $\mathscr{F}_{n(j)}$-measurable, closed and convex set such that*

$$P\{\theta \in S_{n(j)} \textit{ for all large } j\} = 1 \quad \textit{and} \quad \lim_{j\to\infty} (\textit{diameter of } S_{n(j)}) = 0 \quad \textit{a.s.} \tag{5.7}$$

Define the monitored recursive maximum likelihood algorithm θ_n by (5.6), *where π_n is given by* (5.5) *for $n(j) \leqq n < n(j+1)$, and define $\tilde{y}_t$ and η_t by* (1.6) *and* (1.7).

(i) *Suppose that* $\sup_n |\varepsilon_n| < \infty$ *almost surely. Then on the event* $\{\lambda_{\max}(P_n^{-1}) \to \infty$ *and* $\xi'_n P_n \xi_n \to 0\}$,

$$\begin{aligned}\sum_{i\leqq n} (\tilde{y}_{i+d} - \hat{y}_{i+d})^2 \leqq (2d-1)&\left\{\limsup_{i\to\infty} E(\eta_i^2 \mid \mathscr{F}_{i-d}) + o(1)\right\} \log\det(P_n^{-1}) \\ &+ o\left(\sum_{i=1}^{n} \rho_i\right) \\ &+ o\left(\sum_{j:n(j)\leqq n+d} \sum_{s=1}^{h+d-1} [\|\xi_{n(j)-s}\|^2 + \|\xi_{n(j)-s}\|]\right) \quad \textit{a.s.}\end{aligned} \tag{5.8}$$

(ii) *Suppose that the $n(j)$ are stopping times with respect to $\{\mathscr{F}_{t-d+1}\}$ (i.e., $\{n(j)=t\} \in \mathscr{F}_{t-d+1}$) and such that $n(j+1) - n(j) \geqq d$. Then* (5.8) *still holds on* $\{\lambda_{\max}(P_n^{-1}) \to \infty$ *and* $\xi'_n P_n \xi_n \to 0\}$.

Proof. Let $Q_n = (\theta_n - \theta)' P_{n-d}^{-1} (\theta_n - \theta)$. For $n(j) \leqq n < n(j+1)$, since $\pi_n(x)$ is the projection of x into the closed convex set $S_{n(j)}$ with respect to the norm induced by P_{n-d}^{-1}, it follows from (5.6a) that if $\theta \in S_{n(j)}$,

$$\begin{aligned} Q_n &\leqq (\theta_{n-1} - \theta + P_{n-d}\xi_{n-d}(y_n - \hat{y}_n))' P_{n-d}^{-1} (\theta_{n-1} - \theta + P_{n-d}\xi_{n-d}(y_n - \hat{y}_n)) \\ &= (\theta_{n-1} - \theta)' P_{n-d}^{-1} (\theta_{n-1} - \theta) + 2\xi'_{n-d}(\theta_{n-1} - \theta)(y_n - \hat{y}_n) + \xi'_{n-d} P_{n-d} \xi_{n-d} (y_n - \hat{y}_n)^2 \\ &= Q_{n-1} + \rho_{n-d}(\theta_{n-1} - \theta)^2 + [\xi'_{n-d}(\theta_{n-1} - \theta)]^2 + 2\xi'_{n-d}(\theta_{n-1} - \theta)(y_n - \hat{y}_n) \\ &\quad + \xi'_{n-d} P_{n-d} \xi_{n-d} (y_n - \hat{y}_n)^2, \end{aligned} \tag{5.9}$$

noting that $P_t^{-1} = P_{t-1}^{-1} + \xi_t \xi'_t + \rho_t I$. Therefore on the event $E \triangleq \{\theta \notin S_{n(j)}$ for finitely many j's$\}$,

$$\begin{aligned} Q_n &\leqq \sum_{i=n(1)+1}^{n} [\xi'_{i-d}(\theta_{i-1} - \theta)]^2 + 2 \sum_{i=n(1)+1}^{n} \xi'_{i-d}(\theta_{i-1} - \theta)(y_i - \hat{y}_i) \\ &\quad + \sum_{i=n(1)+1}^{n} \xi'_{i-d} P_{i-d} \xi_{i-d} (y_i - \hat{y}_i)^2 + \sum_{i=n(1)+1}^{n} \rho_{i-d}(\theta_{i-1} - \theta)^2 + O(1) \\ &\leqq - \sum_{i=n(1)+1}^{n} [\xi'_{i-d}(\theta_{i-1} - \theta)]^2 + 2 \sum_{i=n(1)+1}^{n} \xi'_{i-d}(\theta_{i-1} - \theta) \\ &\quad \times [\xi'_{i-d}(\theta_{i-1} - \theta) + (y_i - \hat{y}_i - \eta_i)] \\ &\quad + 2 \sum_{i=n(1)+1}^{n} \xi'_{i-d}(\theta_{i-1} - \theta)\eta_i + \sum_{i=n(1)+1}^{n} \xi'_{i-d} P_{i-d} \xi_{i-d} (y_i - \hat{y}_i)^2 + o\left(\sum_{i=1}^{n-d} \rho_i\right) \\ &\quad + O(1) \quad \text{a.s.,} \end{aligned} \tag{5.10}$$

noting that $\theta_{i-1} - \theta \to 0$ almost surely by (5.7).

Let $C_t(q^{-1}) = 1 + \hat{c}_{t,1}q^{-1} + \cdots + \hat{c}_{t,h}q^{-h}$, $\hat{c}_{t,0} = 1$. From (2.3),

$$
\begin{aligned}
C(q^{-1})[\xi'_{i-d}(\theta_{i-1}-\theta)+(y_i-\hat{y}_i-\eta_i)] &= C(q^{-1})[\xi'_{i-d}(\theta_{i-1}-\theta)]-\phi'_{i-d}(\theta_{i-d}-\theta)\\
&= [C(q^{-1})-C_{i-d}(q^{-1})][\xi'_{i-d}(\theta_{i-1}-\theta)]\\
&\quad + \sum_{r=1}^{h} \hat{c}_{i-d,r}\xi'_{i-d-r}(\theta_{i-1-r}-\theta_{i-1})\\
&\quad + \phi'_{i-d}(\theta_{i-1}-\theta_{i-d}),
\end{aligned}
\tag{5.11}
$$

noting that $C_{i-d}(q^{-1})\xi'_{i-d}\theta = \phi'_{i-d}\theta$ and $(\sum_{r=0}^{h}\hat{c}_{i-d,r}\xi'_{i-d-r})\theta_{i-1} = \phi'_{i-d}\theta_{i-1}$ by (5.6b). Since $C(z)$ is stable and $\hat{c}_{i-d,r} \to c_r$ almost surely as $i \to \infty$ for $r = 1, \cdots, h$, and since $\theta_{i-1}-\theta_{i-s} = \sum_{j=i-s+1}^{i-1}(\theta_j-\theta_{j-1})$ for $s \geqq 1$, it follows from (5.11), (5.6b), and Lemma 5(i) that

$$
\begin{aligned}
&\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)+(y_i-\hat{y}_i-\eta_i)]^2\\
&\quad = o\left(\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)]^2\right)+O(1)\\
&\quad\quad + O\left(\sum_{i=1}^{n}\sum_{r=-d+1}^{h-1}[\xi'_{i-d-r}(\theta_i-\theta_{i-1})]^2\right) \quad \text{a.s.}
\end{aligned}
\tag{5.12}
$$

For $n(j) < i < n(j+1)$, $\theta_{i-1} \in S_{n(j)}$ and therefore $(\theta_i-\theta_{i-1})'P_{i-d}^{-1}(\theta_i-\theta_{i-1}) \leqslant \xi'_{i-d}P_{i-d}\xi_{i-d}(y_i-\hat{y}_i)^2$ by (5.6a). Hence by the Schwarz inequality, on $E_1 \triangleq E \cap \{\lim_{n\to\infty}\xi'_nP_n\xi_n = 0\}$,

$$
\begin{aligned}
&\sum_{i\notin\{n(1),n(2),\cdots\}}^{n}\ \sum_{r=-d+1}^{h-1}[\xi'_{i-d-r}P_{i-d}^{1/2}P_{i-d}^{-1/2}(\theta_i-\theta_{i-1})]^2\\
&\quad \leqq \sum_{i=n(1)+1}^{n}\left(\sum_{r=-d+1}^{h-1}\xi'_{i-d-r}P_{i-d}\xi_{i-d-r}\right)\xi'_{i-d}P_{i-d}\xi_{i-d}(y_i-\hat{y}_i)^2\\
&\quad = o\left(\sum_{i=n(1)+1}^{n}\xi'_{i-d}P_{i-d}\xi_{i-d}(y_i-\hat{y}_i)^2\right)+O(1)
\end{aligned}
\tag{5.13}
$$

by Lemma 4(ii). Hence by (5.12) and (5.13),

$$
\begin{aligned}
&\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)+(y_i-\hat{y}_i-\eta_i)]^2\\
&\quad = o\left(\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)]^2\right)+O(1)\\
&\quad\quad + o\left(\sum_{i=n(1)+1}^{n}\xi'_{i-d}P_{i-d}\xi_{i-d}(y_i-\hat{y}_i)^2\right)\\
&\quad\quad + o\left(\sum_{j:n(j)\leqq n}\ \sum_{r=-d+1}^{h-1}\|\xi_{n(j)-d-r}\|^2\right) \quad \text{a.s. on } E_1,
\end{aligned}
\tag{5.14}
$$

noting that $\theta_j-\theta_{j-1}\to 0$ almost surely in view of (5.7).

Since $(y_i-\hat{y}_i)^2=(y_i-\hat{y}_i-\eta_i)^2+2(y_i-\hat{y}_i-\eta_i)\eta_i+\eta_i^2$ and since $y_i-\hat{y}_i-\eta_i$ and $\xi'_{i-d}P_{i-d}\xi_{i-d}(\leqq 1)$ are $\mathscr{F}_{i-d}$-measurable, it follows from Lemma 1 that on E_1,

$$\begin{aligned}
&\sum_{i=n(1)+1}^{n} \xi'_{i-d}P_{i-d}\xi_{i-d}(y_i-\hat{y}_i)^2\\
&\quad\leqq \{\limsup_{i\to\infty} E(\eta_i^2\,|\,\mathscr{F}_{i-d})+o(1)\}\sum_{i=n(1)+1}^{n}\xi'_{i-d}P_{i-d}\xi_{i-d}\\
&\qquad+o\left(\sum_{i=n(1)+1}^{n}(y_i-\hat{y}_i-\eta_i)^2\right)+O(1) \qquad (5.15)\\
&\quad=\left\{\limsup_{t\to\infty} E(\eta_i^2\,|\,\mathscr{F}_{i-d})+o(1)\right\}\log\det P_{n-d}^{-1}\\
&\qquad+o\left(\sum_{i=n(1)+1}^{n}(y_i-\hat{y}_i-\eta_i)^2\right)+O(1)\quad\text{a.s.,}
\end{aligned}$$

by Lemma 4(i). Let $0<\lambda<\frac{1}{2}$. Using the inequality $A^2\leqq(1+\lambda^2)B^2+(1+\lambda^{-2})(A+B)^2$, we obtain from (5.14) and (5.15) that on E_1,

$$\begin{aligned}
&\sum_{i=n(1)+1}^{n}(y_i-\hat{y}_i-\eta_i)^2\\
&\quad\leqq(1+\lambda^2+o(1))\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)]^2 \qquad (5.16)\\
&\qquad+o(\log\det P_{n-d}^{-1})+o\left(\sum_{j:n(j)\leqq n}\sum_{s=1}^{h+d-1}\|\xi_{n(j)-s}\|^2\right)+O(1)\quad\text{a.s.}
\end{aligned}$$

Moreover, using the inequality $AB\leqq(\lambda^2A^2+\lambda^{-2}B^2)/2$, we obtain from (5.14) and (5.15) that on E_1

$$\begin{aligned}
&\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)][\xi'_{i-d}(\theta_{i-1}-\theta)+(y_i-\hat{y}_i-\eta_i)]\\
&\leqq(\lambda^2+o(1))\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)]^2 \qquad (5.17)\\
&\qquad+o(\log\det P_{n-d}^{-1})+o\left(\sum_{j:n(j)\leqq n}\sum_{s=1}^{h+d-1}\|\xi_{n(j)-s}\|^2\right)+o\left(\sum_{i=1}^{n-d}\rho_i\right)+O(1)\quad\text{a.s.}
\end{aligned}$$

Writing $\theta_{i-1}-\theta=\theta_{i-d}-\theta+\sum_{r=1}^{d-1}(\theta_{i-r}-\theta_{i-r-1})$, we now proceed to show that on E_1,

$$\begin{aligned}
&2\left|\sum_{i=n(1)+1}^{n}\xi'_{i-d}(\theta_{i-1}-\theta)\eta_i\right|\\
&\quad\leqq 2(d-1)\left\{\limsup_{i\to\infty}E(\eta_i^2\,|\,\mathscr{F}_{i-d})+o(1)\right\}\log\det P_{n-d}^{-1}\\
&\qquad+o\left(\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)]\right)+o\left(\sum_{j:n(j)\leqq n}\sum_{s=1}^{h+d-1}\|\xi_{n(j)-s}\|^2\right) \qquad (5.18)\\
&\qquad+o\left(\sum_{j:n(j)\leqq n}\sum_{r=1}^{d-1}\|\xi_{n(j)+r-d}\|\,|\eta_{n(j)+r}|\right)+O(1)\quad\text{a.s.}
\end{aligned}$$

Since $\xi'_{i-d}(\theta_{i-d}-\theta)$ is $\mathscr{F}_{i-d}$-measurable and since $\eta_i=\varepsilon_i+f_1\varepsilon_{i-1}+\cdots+f_{d-1}\varepsilon_{i-d+1}$, an application of Lemma 1(i) gives

$$\begin{aligned}\sum_{i=n(1)+1}^{n}\xi'_{i-d}(\theta_{i-d}-\theta)\eta_i&=o\left(\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-d}-\theta)]^2\right)+O(1)\\ &=o\left(\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-1}-\theta)]^2\right)\\ &\quad+o\left(\sum_{r=1}^{d-1}\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-r}-\theta_{i-r-1})]^2\right)\\ &\quad+O(1)\quad\text{a.s.}\end{aligned}\tag{5.19}$$

For fixed $r=1,\cdots,d-1$, we have analogous to (5.13) that on E_1

$$\begin{aligned}\sum_{i=n(1)+1}^{n}[\xi'_{i-d}(\theta_{i-r}-\theta_{i-r-1})]^2&=o\left(\sum_{i=n(1)+1}^{n-r}\xi'_{i-d}P_{i-d}\xi_{i-d}(y_i-\hat{y}_i)^2\right)\\ &\quad+o\left(\sum_{j:n(j)\leqq n-r}\|\xi_{n(j)+r-d}\|^2\right)+O(1).\end{aligned}\tag{5.20}$$

Moreover, since $\theta_{t-1}\in S_{n(j)}$ if $n(j)<t<n(j+1)$, we obtain by the Schwarz inequality and (5.6a) that

$$\begin{aligned}&\sum_{i\notin\{n(1)+r,n(2)+r,\cdots\}}^{n}|\xi'_{i-d}P^{1/2}_{i-r-d}P^{-1/2}_{i-r-d}(\theta_{i-r}-\theta_{i-r-1})\eta_i|\\ &\leqq\sum_{i\notin\{n(1)+r,n(2)+r,\cdots\}}^{n}(\xi'_{i-d}P_{i-r-d}\xi_{i-d})^{1/2}(\xi'_{i-r-d}P_{i-r-d}\xi_{i-r-d})^{1/2}|\eta_i||y_{i-r}-\hat{y}_{i-r}|\\ &\leqq\sum_{i\leqq n}\xi'_{i-d}P_{i-r-d}\xi_{i-d}\eta_i^2/2+\sum_{i\leqq n}\xi'_{i-r-d}P_{i-r-d}\xi_{i-r-d}(y_{i-r}-\hat{y}_{i-r})^2/2.\end{aligned}\tag{5.21}$$

Applying (5.15), Lemma 1(ii), and Lemma 4(ii) to (5.20), and combining the result with (5.19), (5.20), (5.15), and (5.16), we obtain (5.18).

Suppose that $\sup_n|\varepsilon_n|<\infty$ almost surely. Then $\sup_n|\eta_n|<\infty$ almost surely and therefore

$$\sum_{j:n(j)\leqq n}\sum_{r=1}^{d-1}\|\xi_{n(j)+r-d}\||\eta_{n(j)+r}|=O\left(\sum_{j:n(j)\leqq n}\sum_{s=1}^{d-1}\|\xi_{n(j)-s}\|\right)\quad\text{a.s.}\tag{5.22}$$

Now assume that the $n(j)$ are stopping times with respect to $\{\mathscr{F}_{t-d+1}\}$. Then for $r=1,\cdots,d-1$, $T_j\triangleq n(j)+r-d$ is a stopping time with respect to $\{\mathscr{F}_t\}$ and $\eta_{n(j)+r}=\sum_{i=1}^{d}f_{d-i}\varepsilon_{T_j+i}(f_0=0)$. Moreover, $\|\xi_{n(j)+r-d}\|$ is $\mathscr{F}_{T_j}$-measurable. Hence an application of Lemma 1(iii) and (i) gives

$$\begin{aligned}&\sum_{j:n(j)\leqq n}\sum_{r=1}^{d-1}\|\xi_{n(j)+r-d}\||\eta_{n(j)+r}|\\ &=\sum_{j:n(j)\leqq n}\sum_{r=1}^{d-1}\|\xi_{n(j)+r-d}\|E\left(\left|\sum_{i=1}^{d}f_{d-i}\varepsilon_{T_j+i}\right|\,|\,\mathscr{F}_{T_j}\right)\\ &\quad+o\left(\sum_{j:n(j)\leqq n}\sum_{r=1}^{d-1}\|\xi_{n(j)+r-d}\|^2\right)+O(1)\quad\text{a.s.}\end{aligned}\tag{5.22'}$$

Since $E(|\sum_{i=1}^{d} f_{d-i}\varepsilon_{T_j+i}| \,|\, \mathcal{F}_{T_j}) \leqq E^{1/\alpha}(|\sum_{i=1}^{d} f_{d-i}\varepsilon_{T_j+i}|^{\alpha} \,|\, \mathcal{F}_{T_j})$, either (5.22′) or (5.22) implies that

$$\begin{aligned}&\sum_{j:n(j)\leqq n}\sum_{r=1}^{d-1}\|\xi_{n(j)+r-d}\|\,|\eta_{n(j)+r}|\\ &\qquad = O\Bigg(\sum_{j:n(j)\leqq n}\sum_{s=1}^{d-1}[\|\xi_{n(j)-s}\|+\|\xi_{n(j)-s}\|^2]\Bigg)+O(1) \quad \text{a.s.}\end{aligned} \tag{5.23}$$

Applying (5.15)-(5.18) and (5.23) to (5.10), we obtain that on E_1,

$$\begin{aligned}&Q_n+(1-2\lambda^2+o(1))\sum_{i=n(1)+1}^{n}[\xi_{i-d}'(\theta_{i-1}-\theta)]^2\\ &\quad\leqq(2d-1)\Big\{\limsup_{i\to\infty}E(\eta_i^2\,|\,\mathcal{F}_{i-d})+o(1)\Big\}\log\det P_{n-d}^{-1}\\ &\qquad + o\Bigg(\sum_{j:n(j)\leqq n}\sum_{r=1}^{h+d-1}[\|\xi_{n(j)-r}\|+\|\xi_{n(j)-r}\|^2]\Bigg)+O(1) \quad \text{a.s.}\end{aligned} \tag{5.24}$$

Since $Q_n\geqq 0$, it follows from (5.24) and (5.16) that on E_1

$$\begin{aligned}\sum_{i=n(1)}^{n}(\tilde{y}_i-\hat{y}_i)^2 &= \sum_{i=n(1)}^{n}(y_i-\hat{y}_i-\eta_i)^2\\ &\leqq(1+\lambda^2+o(1))(1-2\lambda^2+o(1))^{-1}(2d-1)\\ &\quad\times\Big\{\limsup_{i\to\infty}E(\eta_i^2\,|\,\mathcal{F}_{i-d})+o(1)\Big\}\log\det P_{n-d}^{-1}\\ &\quad + o\Bigg(\sum_{j:n(j)\leqq n}\sum_{r=1}^{h+d-1}[\|\xi_{n(j)-r}\|+\|\xi_{n(j)-r}\|^2]\Bigg)+o\Bigg(\sum_{i=1}^{n-d}\rho_i\Bigg)\\ &\quad +O(1) \quad \text{a.s.}\end{aligned} \tag{5.25}$$

Since λ can be arbitrarily small, (5.25) implies that (5.8) holds on $E_1\cap\{\log\det P_n^{-1}\to\infty\}=E\cap\{\xi_n'P_n\xi_n\to 0$ and $\lambda_{\max}(P_n^{-1})\to\infty\}$. Since $P(E)=1$ by (5.7), the desired conclusion follows. □

COROLLARY 4. *With the same notation and assumptions as in Theorem* 3(i), *suppose that the input-output data satisfy*

$$\sum_{i=1}^{n}(y_i^2+u_i^2)=O(n) \quad \textit{and} \quad \max_{i\leqq n}(y_i^2+u_i^2)=o(\log n) \quad \textit{a.s.} \tag{5.26}$$

Then

$$\sum_{i=1}^{n}\|\xi_i\|^2=O(n) \quad \textit{and} \quad \|\xi_n\|^2=o(\log n) \quad \textit{a.s.} \tag{5.27}$$

Suppose furthermore that $\rho_n=1/n$ *and that the stopping times* $n(1)<n(2)<\cdots$ *are so chosen that*

$$\sum_{j:n(j)\leqq n}\max_{1\leqq r\leqq h+d-1}(\|\xi_{n(j)-r}\|+\|\xi_{n(j)-r}\|^2)=O(\log n) \quad \textit{a.s.} \tag{5.28}$$

(*which is possible in view of* (5.27)). *Then* (5.1) *holds.*

Proof. Since $\tilde{y}_i=y_i-\eta_i$ and since $\sup_i|\varepsilon_i|<\infty$ almost surely, it follows from (5.26) that

$$\sum_{i=1}^{n}\|\psi_i\|^2=O(n) \quad \text{and} \quad \max_{i\leqq n}\|\psi_i\|^2=o(\log n) \quad \text{a.s.,} \tag{5.29}$$

where ψ_i is defined in (1.9). By Lemma 2,

$$\begin{aligned} C(q^{-1})(y_n-\hat{y}_n-\eta_n) &= -(\theta_{n-d}-\theta)'(\phi_{n-d}-\psi_{n-d}) \\ &\quad -(\theta_{n-d}-\theta)'\psi_{n-d}, \quad \text{and therefore} \\ \hat{C}_{n-d}(q^{-1})(y_n-\hat{y}_n-\eta_n) &= -(\theta_{n-d}-\theta)'\psi_{n-d}, \end{aligned} \tag{5.30}$$

noting that

$$\phi_{n-d}-\psi_{n-d} = -(0,\cdots,0,y_{n-1}-\hat{y}_{n-1}-\eta_{n-1},\cdots,y_{n-h}-\hat{y}_{n-h}-\eta_{n-h})'. \tag{5.31}$$

Since $\theta_{n-d}\to\theta$ almost surely, it follows from (5.29), (5.30), and Lemma 5(i) that

$$\sum_{i=1}^{n}(y_i-\hat{y}_i-\eta_i)^2 = O\left(\sum_{i=1}^{n}\|\theta_{i-d}-\theta\|^2\|\psi_{i-d}\|^2\right) = o(n) \quad \text{a.s.}, \tag{5.32}$$

$$y_n-\hat{y}_n-\eta_n = O\left(\max_{i\leqq n}\|\theta_{i-d}-\theta\|\,\|\psi_{i-d}\|\right) = o((\log n)^{1/2}) \quad \text{a.s.} \tag{5.33}$$

In view of (5.31), it follows from (5.29), (5.32), and (5.33) that

$$\sum_{i=1}^{n}\|\phi_i\|^2 = O(n) \quad \text{and} \quad \max_{i\leqq n}\|\phi_i\|^2 = o(\log n) \quad \text{a.s.} \tag{5.34}$$

Since $\hat{C}_n(q^{-1})\xi_n=\phi_n$ by (5.6b), (5.27) follows from (5.34) and Lemma 5(ii).

Suppose that $\rho_n=1/n$ and that (5.28) holds. Since $P_n^{-1}=P_{n(1)}^{-1}+\sum_{j=n(1)+1}^{n}\xi_j\xi_j'+\sum_{j=n(1)+1}^{n}I/j$, $\lambda_{\min}(P_n^{-1})\geqq(1+o(1))\log n(\to\infty)$ and $\xi_n'P_n\xi_n\leqq\|\xi_n\|^2/\lambda_{\min}(P_n^{-1})\to 0$ almost surely by (5.27). Since $\log\det P_n^{-1}\leqq(p(d)+k+d-1+h)\log\lambda_{\max}(P_n^{-1})$, the desired conclusion (5.1) follows from (5.8), (5.27), and (5.28). □

Theorems 3 and 2 have recently enabled us to provide an asymptotically efficient adaptive control rule in the general delay case and without stability assumptions on $A(z)$, (cf. [23]). The rule involves parallel implementation of the stochastic gradient and monitored recursive maximum likelihood algorithms. The stochastic gradient component of the controller serves to stabilize the system even when $A(z)$ is not stable, as an application of Theorem 2. Together with an occasional dither signal to perturb the target values, it also leads to well-excited blocks of input-output data from which strongly consistent recursive estimates of the system parameters can be obtained by the method of moments to guide the recursive maximum likelihood algorithm, giving a control rule that can be shown by an application of Theorem 3 to satisfy

$$\begin{aligned} &\limsup_{n\to\infty}\frac{\sum_{i=\Delta+1}^{n}(y_i-y_i^*-\eta_i)^2}{\log n} \\ &\qquad \leqq(2d-1)(p(d)+k+d-1+h)\limsup_{i\to\infty}E(\eta_i^2\,|\,\mathscr{F}_{i-d}) \quad \text{a.s.} \end{aligned} \tag{5.35}$$

in the general delay case and without assuming $A(z)$ to be stable (cf. [23]).

Instead of the preceding implicit approach, it is natural to ask whether similar results can be obtained by the explicit approach, involving the monitored recursive maximum likelihood estimator Θ_n of the parameter vector $\Theta=(-a_1,\cdots,-a_p, b_1,\cdots,b_k,c_1,\cdots,c_h)'$ for system (1.1):

$$\Theta_n=\pi_n(\Theta_{n-1}+P_{n-1}\zeta_{n-1}e_n), \tag{5.36a}$$

$$\begin{aligned} &\zeta_n+\hat{c}_{n,1}\zeta_{n-1}+\cdots+\hat{c}_{n,h}\zeta_{n-h}=\Phi_n \quad \text{where} \\ &\Phi_n=(y_n,\cdots,y_{n-p+1},u_{n-\Delta+1},\cdots,u_{n-\Delta-k+2},e_n,\cdots,e_{n-h+1})', \end{aligned} \tag{5.36b}$$

$$e_n=y_n-\Theta_{n-1}'\Phi_{n-1}, \tag{5.36c}$$

$$P_n^{-1}=P_{n-1}^{-1}+\zeta_n\zeta_n'. \tag{5.36d}$$

The π_n in (5.36a) is the projection, with respect to the norm induced by $P_{n-1}^{-1}=P_0^{-1}+\sum_{i=1}^{n-1}\zeta_i\zeta_i'$, into a closed convex subset $S_{n(j)}$ which can be conveniently chosen to be a cube in R^{p+k+h}. An analogue of Theorem 3 for the adaptive one-step ahead predictors $\hat{y}_{n+1}=\Theta_n'\Phi_n$ can be proved by similar (and simpler) arguments and is given in the following.

THEOREM 4. *Suppose that $C(z)$ is stable and that the random disturbances ε_n in the linear stochastic system* (1.1) *satisfy assumption* (1.3). *Let $n(1)<n(2)<\cdots$ be stopping times with respect to $\{\mathscr{F}_t\}$ and let $S_{n(j)}$ be an $\mathscr{F}_{n(j)}$-measurable, closed, and convex subset of R^{p+k+h} such that $P\{\Theta\in S_{n(j)}$ for all large $j\}=1$, where we define Θ and Ψ_t by* (1.11) *and* (1.12). *Define the monitored recursive maximum likelihood estimator Θ_n by* (5.36), *where π_n is given by* (5.5) (*with $d=1$ and $S_{n(j)}\subset R^{p+k+h}$*) *for $n(j)\leqq n<n(j+1)$. Then on $\{\lambda_{\max}(P_n^{-1})\to\infty$ and $\zeta_n'P_n\zeta_n\to 0\}$,*

$$\sum_{i\leqq n}(\Theta'\Psi_i-\Theta_i'\Phi_i)^2\leqq\left\{\limsup_{i\to\infty}E(\varepsilon_i^2|\mathscr{F}_{i-1})+o(1)\right\}\log\det P_n^{-1} + o\left(\sum_{j:n(j)\leqq n+1}\ \sum_{r=1}^{h}\|\zeta_{n(j)-r}\|^2\right)\quad a.s. \tag{5.37}$$

For $d>1$, analysis of the adaptive d-step ahead predictors defined from Θ_n using the explicit approach (1.18) becomes prohibitively difficult because of the inherent nonlinearities in (1.18) and (1.4), and it is doubtful that they would provide sharp results of the kind given by the implicit approach in Corollary 4.

PARALLEL RECURSIVE ALGORITHMS IN ASYMPTOTICALLY EFFICIENT ADAPTIVE CONTROL OF LINEAR STOCHASTIC SYSTEMS*

TZE LEUNG LAI† AND ZHILIANG YING‡

Abstract. First, a review of some recent developments in stochastic adaptive control of linear stochastic systems is given. By integrating and refining several basic ideas in these developments, a relatively complete asymptotic solution to the adaptive control problem is then provided for such systems. The solution involves parallel implementation of a few basic recursive identification algorithms that serve to complement each other. It also involves occasional use of a dither signal to probe the system for information.

Key words. stochastic adaptive control, linear systems, self-optimizing, self-timing, asymptotic efficiency, stochastic approximation, recursive maximum likelihood, method of moments, occasional excitation, general delay, colored noise, martingale theory

AMS(MOS) subject classifications. primary 93E10, 93E20, 62L20; secondary 60G42

1. Introduction. A widely used stochastic model in the time series and stochastic control systems literature is the ARMAX system (autoregressive moving average system with exogenous inputs) defined by the linear difference equation

$$A(q^{-1})y_n = B(q^{-1})u_{n-d} + C(q^{-1})\varepsilon_n, \tag{1.1}$$

where $\{y_n\}$, $\{u_n\}$, and $\{\varepsilon_n\}$ denote the output, input, and disturbance sequences, respectively, $d \geqq 1$ represents the delay and

$$\begin{aligned} &A(q^{-1}) = 1 + a_1 q^{-1} + \cdots + a_p q^{-p}, \qquad B(q^{-1}) = b_1 + \cdots + b_k q^{-(k-1)}, \\ &C(q^{-1}) = 1 + c_1 q^{-1} + \cdots + c_h q^{-h} \end{aligned} \tag{1.2}$$

are scalar polynomials in the backward shift operator q^{-1}. Throughout the following we assume that $b_1 \neq 0$. Because of its theoretical interest and practical importance, the problem of determining the inputs u_n to keep the outputs y_{n+d} as close as possible to certain target values y^*_{n+d} when the system parameters are not known in advance but have to be estimated "on-line" (i.e., during the operation of the system) has been an important topic in the subject of stochastic adaptive control. Åström [1] and Kumar [2] have provided comprehensive surveys of the developments concerning this problem up to the early 1980s. In this paper, we first review several recent results and then integrate and refine some basic ideas in the literature to develop a relatively complete asymptotic solution to the adaptive control problem for ARMAX systems.

Throughout the following let $x_0 = (y_0, \cdots, y_{1-p}, u_0 \cdots u_{2-d-k}, \varepsilon_0, \cdots, \varepsilon_{1-h})'$ denote the "initial condition" of (1.1). Letting $\mathscr{G}_0$ be the σ-field generated by x_0 and letting $\mathscr{G}_n$ be the σ-field generated by $\{x_0, \varepsilon_1, \cdots, \varepsilon_n\}$, it will be assumed that

$$\begin{aligned} &\{\varepsilon_n, \mathscr{G}_n, n \geqq 1\} \text{ is a martingale difference sequence such that } E(\varepsilon_n^2 \mid \mathscr{G}_{n-1}) = \sigma^2 \\ &(\text{nonrandom}) > 0 \text{ and } \sup_n E(|\varepsilon_n|^\alpha \mid \mathscr{G}_{n-1}) < \infty \text{ almost surely for some } \alpha > 2. \end{aligned} \tag{1.3}$$

The input u_n is assumed to be "nonanticipating" in the sense that it involves only the current and past observations $y_n, y_{n-1}, u_{n-1}, \cdots$ and possibly also some extraneous

randomization ω_n. Specifically, for $n \geqq 1$, we assume that u_n is measurable with respect to the σ-field $\mathscr{F}_n$ generated by $\{x_0, y_1, \cdots, y_n, u_1, \cdots, u_{n-1}, \omega_1, \cdots, \omega_n\}$, where

(1.4) ω_n is independent of $\{x_0, \varepsilon_1, \varepsilon_2, \cdots\} \cup \{\omega_1, \cdots, \omega_{n-1}\}$.

In view of (1.1), (1.3), and (1.4), an induction argument shows that

(1.5) $\mathscr{G}_n \subset \mathscr{F}_n$ and $\{\varepsilon_n, \mathscr{F}_n, n \geqq 1\}$ is a martingale difference such that $E(\varepsilon_n^2 | \mathscr{F}_{n-1}) = \sigma^2$ and $\sup_n E(|\varepsilon_n|^\alpha | \mathscr{F}_{n-1}) < \infty$ almost surely.

We call the polynomial $B(z) = b_1 + \cdots + b_k z^{k-1}$ *stable* if all its zeros lie outside the unit circle. We will also call two or more polynomials *coprime* (or *relatively prime*) if their greatest common divisors have degree 0.

In principle, given a (joint) probability distribution of the random sequence $\{x_0, \varepsilon_1, \varepsilon_2, \cdots\}$ and a prior distribution π of the unknown parameter vector

$$\theta = (-a_1, \cdots, -a_p, b_1, \cdots, b_k, c_1, \cdots, c_h)', \tag{1.6}$$

the problem of adaptive control of system (1.1) with quadratic costs is simply a dynamic programming problem in which the "state" is the conditional distribution of the original system state and parameter vector given the past observations (cf. [2]). In particular, we can use backward induction to solve the dynamic programming equations for inputs $u_1, \cdots, u_{N-d}$ that minimize

$$\int E_\theta\left\{\sum_{i=d+1}^{N} (y_i - y_i^*)^2\right\} d\pi(\theta), \tag{1.7}$$

for every given horizon N, where the y_i^* are nonrandom target values for the outputs. However, the dynamic programming equations are prohibitively difficult to handle, both computationally and analytically. Moreover, the need to specify a realistic probability law for the initial condition x_0 and the unobservable random errors ε_n together with a reasonable prior distribution for the parameter vector θ in this Bayesian approach may also cause difficulties in practice.

Despite these difficulties in the implementation of the Bayesian approach, Bayesian analysis of some very simple examples has provided important insights into the structure of optimal control rules. In particular, Feldbaum [3] and subsequent authors have shown that Bayes rules have the "dual control" function of both probing the system for information about its parameters and trying to drive the outputs toward their target values (cf. the review and references in § 5 of [2]). Åström [1, p. 478] has provided an interesting numerical example, which took 180 CPU hours to compute on a VAX 11/780 computer, to illustrate this dual control effect in the adaptive control problem (1.7) for the simple ARX model

$$y_n - \alpha y_{n-1} = \beta u_{n-1} + \varepsilon_n, \tag{1.8}$$

with independently and identically distributed zero-mean normal ε_n, a normal prior distribution for β, known value $\alpha = 1$, and $N = 30$, $y_i^* \equiv 0$. The example shows that the Bayes rule takes relatively large and irregular control actions to probe the system when the Bayes estimate $\hat{\beta}_t$ of β has poor precision, but is well approximated when $\hat{\beta}_t$ has high precision by the "certainty-equivalence" rule

$$\hat{\beta}_t u_t = -y_t. \tag{1.9}$$

Suppose that in Åström's example concerning the ARX model (1.8), instead of assuming α to be known and β to have a normal prior distribution, we assume $\beta \neq 0$ to be known and α to have a normal prior distribution. This problem turns out to be more tractable and can be used to derive lower bounds on the cost of Bayes rules. First, note that for any nonanticipating input sequence $\{u_n\}$,

$$\begin{aligned}\int_{-\infty}^{\infty} E_\alpha\left\{\sum_{i=2}^{N}(y_i-\varepsilon_i)^2\right\}d\pi(\alpha) &= \sum_{i=1}^{N-1} E\{(\alpha y_i+\beta u_i)^2\}\\ &\geqq \sum_{i=1}^{N-1} E\{[\alpha - E(\alpha\,|\,y_1,u_1,\cdots,y_i,u_i)]^2 y_i^2\}.\end{aligned} \tag{1.10}$$

In particular, for a nonanticipating input sequence $\{u_n\}$ that satisfies the property

$$\lim_{N\to\infty} N^{-1}\sum_{i=2}^{N}(y_i-\varepsilon_i)^2=0 \quad \text{a.s. } [P_\alpha] \quad \text{for every } \alpha, \tag{1.11}$$

it can be shown that

$$\begin{aligned}&\sum_{i=1}^{n}\{\alpha-E(\alpha\,|\,y_1,u_1,\cdots,y_i,u_i)\}^2y_i^2\\ &\quad=(1+o(1))\sum_{i=1}^{n}\left\{\sum_{t=2}^{i}y_{t-1}\varepsilon_t\Big/\sum_{t=2}^{i}y_{t-1}^2\right\}^2y_i^2+O(1)\sim\sigma^2\log n \text{ a.s. } [P_\alpha]\end{aligned} \tag{1.12}$$

for every α. The first relation in (1.12) makes use of the representation of the Bayes estimate $E(\alpha\,|\,y_1,u_1,\cdots,y_i,u_i)$ in the Gaussian model as a convex combination of the prior mean of α and the least squares estimate of α based on the data $\{y_1,u_1,\cdots,y_i,u_i\}$ (cf. [4, p. 32]). Noting that (1.11) implies that $\sum_1^N y_i^2\sim\sigma^2N$ and $\sup_{i\leqq N}y_i^2=o(N)$ almost surely $[P_\alpha]$, the second asymptotic relation in (1.12) can be proved by a partial summation argument similar to that of [5, pp. 1206-1207]. From (1.10) and (1.12), it follows by an application of Fatou's lemma and Fubini's theorem that

$$\int_{-\infty}^{\infty}E_\alpha\left\{\sum_{i=2}^{N}(y_i-\varepsilon_i)^2\right\}d\pi(\alpha)\geqq(1+o(1))\sigma^2\log N \tag{1.13}$$

for all nonanticipating input sequences $\{u_n\}$ satisfying (1.11).

Lai [4] has extended the results (1.10), (1.12), and (1.13) above for the regulation problem (1.7) (with $y_i^*\equiv 0$) to general ARX models (1.1) (with $C(q^{-1})=1$) and unit delay $d=1$. Specifically, assuming $b_1(\neq 0)$ to be known and putting a truncated normal prior distribution π on $\lambda=b_1^{-1}(a_1,\cdots,a_p,-b_2,\cdots,-b_k)'$, it is shown in [4] that in analogy with (1.13),

$$\int E_\lambda\left\{\sum_{i=2}^{N}(y_i-\varepsilon_i)^2\right\}d\pi(\lambda)\geqq(1+o(1))\sigma^2(p+k-1)\log N \tag{1.14}$$

for all nonanticipating input sequences $\{u_n\}$ satisfying (1.11) and the additional growth condition that $u_n^2=O(n^\delta)$ almost surely for some $0<\delta<1$. The truncated normal prior distribution π in (1.14) is the restriction of a standard multivariate normal distribution to the λ-region defined by the following:

(1.15) $A(z)$ and $B(z)$ are stable, and the polynomials $a_1z^{p-1}+\cdots+a_p$ and $z^{k-1}B(z^{-1})$ are relatively prime.

In the case of unit delay $d=1$, if all the parameters of system (1.1) are known, then the optimal controller chooses the input u_t at stage t so that $E(y_{t+1}\,|\,\mathcal{F}_t)=y_{t+1}^*$, and its output at stage $t+1$ is $y_{t+1}^* + \varepsilon_{t+1}$. In view of this, Lai [4] defines the "regret" at stage N of an input sequence $\{u_n\}$ to be

$$R_N = \sum_{i=2}^{N} \{y_i - (y_i^* + \varepsilon_i)\}^2 = \sum_{i=2}^{N} \{E(y_i \mid \mathcal{F}_{i-1}) - y_i^*\}^2. \tag{1.16}$$

Note that (1.14) above represents a lower bound for the expected regret in the regulation problem $y_i^* \equiv 0$ within a Bayesian framework. For general delay d, definition (1.16) of "regret" can be extended to

$$\begin{aligned} R_N &= \sum_{i=d+1}^{N} \{E(y_i \mid \mathcal{F}_{i-d}) - y_i^*\} = \sum_{i=d+1}^{N} (y_i - y_i^* - \eta_i)^2, \text{ where} \\ \eta_i &= y_i - E(y_i \mid \mathcal{F}_{i-d}) = \varepsilon_i + f_1\varepsilon_{i-1} + \cdots + f_{d-1}\varepsilon_{i-d+1} \text{ for } i \geqq d, \end{aligned} \tag{1.17}$$

with $f_1, \cdots f_{d-1}$ depending only on $A(z)$ and $C(z)$, as will be shown in § 2. The regret R_N, which is 0 for the optimal controller assuming knowledge of all system parameters so that u_t is determined by $E(y_{t+d} \mid \mathcal{F}_t) = y_{t+d}^*$, can be regarded as the cumulative cost up to stage N due to lack of knowledge of the system parameters in an adaptive controller. Since

$$E\left\{ \sum_{i=d+1}^{N} (y_i - y_i^*)^2 \right\} = E(R_N) + E\left(\sum_{i=d+1}^{N} \eta_i^2 \right), \tag{1.18}$$

the problem of minimizing the total expected quadratic cost is equivalent to that of minimizing the expected value of the regret R_N.

An input sequence $\{u_n\}$ is said to be "self-optimizing" (or "globally convergent") if

$$R_n / n \to 0 \quad \text{a.s.} \tag{1.19}$$

Using martingale theory (cf. Lemma 1 of § 2) and the identity $\sum_{d+1}^{n} (y_i - y_i^*)^2 = \sum_{d+1}^{n} \eta_i^2 + \sum_{d+1}^{n} (y_i - y_i^* - \eta_i)^2 + 2\sum_{d+1}^{n} (y_i - y_i^* - \eta_i)\eta_i$, it can be shown that (1.19) is equivalent to

$$n^{-1} \sum_{d+1}^{n} (y_i - y_i^*)^2 \to \sigma_d^2 \triangleq \sigma^2(1 + f_1^2 + \cdots + f_{d-1}^2) = E\eta_d^2 \quad \text{a.s.} \tag{1.19$'$}$$

Since σ_d^2 is the long-run average cost of the optimal controller defined by $E(y_{t+d} \mid \mathcal{F}_t) = y_{t+d}^*$ that assumes knowledge of the system parameters, the equivalence between (1.19) and (1.19′) explains the term "self-optimizing" (cf. [2], [6]).

The idea of working with the "regret" instead of the original cost criterion in opimization problems with unknown parameters was introduced by Lai and Robbins [5] in the context of choosing the design levels to minimize $E(\sum_1^N y_i^2)$ in the two-parameter regression model

$$y_n = \beta(u_{n-1} - \mu) + \varepsilon_n, \tag{1.20}$$

with independently and identically distributed normal errors ε_n such that $E\varepsilon_1 = 0$ and $E\varepsilon_1^2 = \sigma^2$. If μ is known, then $u_t \equiv \mu$ is the optical choice of the design levels. However, this experimental design does not provide any information about the unknown slope β. To resolve the dilemma between the control objective of setting the inputs near μ and the need for information to estimate β and μ, Lai and Robbins [5] started by considering the situation in which $\beta \neq 0$ is known. In this case, the maximum likelihood estimate based on $u_0, y_1, \cdots, u_{n-1}, y_n$ is $\hat{\mu}_n = n^{-1} \sum_{i=1}^{n} (u_{i-1} - \beta^{-1} y_i)$, and therefore $\hat{\mu}_n - \mu = -n^{-1} \sum_{i=1}^{n} \varepsilon_i / \beta$ irrespective of how the design levels u_i are chosen. This suggests that there is no conflict between information (to estimate μ) and control (setting u_i at the current best guess of μ). In particular, the certainty-equivalence rule $u_t=\hat{\mu}_t$ has regret

$$R_n=\sum_{i=2}^{n}(y_i-\varepsilon_i)^2=\sum_{i=1}^{n-1}\left(i^{-1}\sum_{t=1}^{i}\varepsilon_t\right)^2\sim\sigma^2\log n\quad\text{a.s.}\tag{1.21}$$

(cf. [5]). Moreover, if we put a normal prior distribution π on μ then the separation principle shows that the Bayes rule minimizing $\int_{-\infty}^{\infty}E_\mu(R_n)\,d\pi(\mu)$ is simply given at every stage t by

$$u_t=E(\mu\,|\,u_0,y_1,\cdots,u_{n-1},y_n)=\hat{\mu}_t+O(t^{-1}),\tag{1.22}$$

and therefore as in (1.21), the regret of this Bayes rule also satisfies

$$R_n\sim\sigma^2\log n\quad\text{a.s.}\tag{1.23}$$

(cf. [4]). Without assuming $\beta(\neq 0)$ to be known in advance and without assuming the ε_i to be normal, Lai and Robbins [5] made use of the theory of adaptive stochastic approximation to find an input sequence $\{u_n\}$ whose regret R_n also has the same logarithmic order (1.23) as the Bayes rule that assumes β to be known and the ε_i to be normal.

Note that (1.23) clearly implies the self-optimizing property (1.19). For the regression model (1.20), it is in fact very easy to construct self-optimizing inputs by using schemes with "forced" learning (cf. [2, p. 348]). We need only make sure that there is enough information to estimate β and μ consistently by setting the design levels at K_1 during stages $n_1<n_2<\cdots$ and at $K_2(\neq K_1)$ during stages $n_1^*<n_2^*<\cdots$, where $\{n_i\}$ and $\{n_i^*\}$ are disjoint sequences of positive integers such that $n_i/i\to\infty$ and $n_i^*/i\to\infty$. Let $\hat{\beta}_t$ and $\hat{\alpha}_t$ be the least squares estimates of the slope β and the intercept $-\beta\mu$ based on all the observations at times $n_i\leqq t$ and $n_i^*\leqq t$. The inputs $u_t=-(\hat{\alpha}_t/\hat{\beta}_t)I_{\{\hat{\beta}_t\neq 0\}}$ are self-optimizing, noting that the times n_i and n_i^* at which "probing inputs" are introduced occur infrequently. However, the fact that $\hat{\alpha}_t$ and $\hat{\beta}_t$ are based only on observations at these infrequent times suggests that the self-optimizing rule may be quite inefficient since we are wasting the information from the other observations. Therefore, not only should an asymptotically efficient control rule have the self-optimizing property (1.19), but it should also be able to attain the logarithmic order (1.23) for the regret, emulating the Bayes rules that assume knowledge of β.

Because of the dynamical structure defined by the linear difference equation (1.1), the problem of adaptive control of system (1.1) is much more complex than that of the regression model (1.20). For example, if $A(z)$ is not stable, then using white-noise probing inputs may lead to exponentially divergent output trajectories. In fact, the important and challenging problem of finding self-optimizing control schemes for (1.1) that can be implemented in real time has been an active area of research since the seminal paper of Åström and Wittenmark [7] on "self-tuning regulators."

The "self-tuning" idea is to start by considering the case where the system parameters are known, for which the optimal controller can be represented in some convenient recursive form, and then to replace the parameters in the optimal controller by recursive estimates that converge. Åström and Wittenmark [7] showed that if the recursive estimates, which they chose to be of least squares type, should converge to some limit, then substituting the parameter vector in the optimal controller by this limit must necessarily give the optimal controller, justifying the use of the adjective "self-tuning." A central problem with this approach, which still remains unsettled, is whether the least-squares-type estimates are indeed convergent. Goodwin, Ramadge, and Caines [8] circumvented this problem by introducing another method, called the "stochastic gradient" (stochastic approximation) algorithm, to estimate a linear transformation θ^* of the parameter vector θ, and were able to establish the self-optimizing property (1.19′) for their scheme. In § 2 we give a brief review of several ideas in these and subsequent developments.

Sections 2 and 5 also review some recent results on d-step ahead adaptive predictors constructed by the so-called direct (or implicit) method. These results enable us to unify, integrate, and extend two different approaches of constructing self-tuning control rules. The first approach, to be considered in § 3, uses a scalar gain in the recursive identification algorithm, as in the Goodwin–Ramadge–Caines [8] method and subsequent modifications thereof. We will focus on one such modification, proposed by Caines and Lafortune [9], that adds a dither signal to the control action to persistently excite the input-output process for consistent estimation of the system parameters. In § 3, we give a short proof of the main results of [8] and [9] by using a different argument, which also enables us to substantially generalize the algorithms of [8] and [9]. In particular, we can modify the continually disturbed control scheme of Caines and Lafortune [9] by only adding the dither signal occasionally, giving an "ocasionally excited" input-output process. Using the input-output data only from those stages at which the system is excited by the inclusion of the dither signal, we show in § 4 that strongly consistent estimators of the system parameters can be obtained by the method of moments.

As noted by Sin and Goodwin [10], although the global convergence proofs in [8] only apply to the stochastic approximation scheme, "it seems that in practically all applications of stochastic adaptive control, a least squares iteration is used" since "it generally has much superior rates of convergence compared with stochastic approximation." Instead of a scalar gain as in [8], a matrix gain such as in the Åström–Wittenmark scheme is typically used. In § 5 we consider this alternative approach that involves a matrix gain to construct self-tuning controllers. In particular, by using a consistent but inefficient estimator such as that developed in § 4 to monitor a recursive maximum likelihood estimator of the parameters in a reparametrized model, d-step ahead adaptive predictors associated with the recursive identification scheme are shown not to differ very much from the minimum variance predictors that assume knowlege of the system parameters. This result also suggests the possibility of achieving a logarithmic order for the regret (see (1.24) below) by using the certainty-equivalence rule associated with the monitored recursive maximum likelihood algorithm to define the inputs when certain conditions are met.

In § 6 we show that by a parallel implementation of stochastic approximation (involving a scalar gain) and monitored recursive maximum likelihood (involving a matrix gain), a self-tuning controller that integrates both methods can be constructed. The stochastic approximation component of the controller serves to stabilize the system even when $A(z)$ is not stable. Together with an occasional dither signal to perturb the target values, it also leads to excited blocks of input-output data from which strongly consistent estimators of the system parameters can be obtained by the method of moments to guide the recursive maximum likelihood algorithm. The monitored recursive maximum likelihood component of the controller can be shown to satisfy the conditions of the main theorem of § 5. Not only is the resultant self-tuning controller self-optimizing in the sense of (1.19), but it also attains the following logarithmic order for the regret:

$$(1.24) \qquad R_n \leqq (1+o(1))\sigma_d^2\{(p \vee (h-d+1))+h+k+d-1\}(2d-1)\log n \quad \text{a.s.},$$

where σ_d^2 is defined in (1.19′). Here and in the sequel we use $\vee$ and $\wedge$ to denote maximum and minimum, respectively. Moreover, if $\log(1+\sum_{i=1}^{n} y_i^{*2}) = o(\log n)$, as in the regulation problem ($y_i^* \equiv 0$), we can further strengthen (1.24) into

$$(1.25)\qquad R_n \leqq (1+o(1))\sigma_d^2\{(p \vee (h-d+1))+d+k-2\}(2d-1)\log n \quad \text{a.s.}$$

Note that in the case where $d=1$ and $C(q^{-1})=1$ (so that $h=0$), (1.25) reduces to

$$(1.26)\qquad R_n \leqq (1+o(1))\sigma^2(p+k-1)\log n \quad \text{a.s.}$$

Comparing (1.26) with the lower bound (1.14) for the expected value of R_n within a Bayesian framework that assumes knowledge of b_1 in advance, we see that the *certainty-equivalence* rule thus constructed *closely emulates* the performance of the Bayes rule. Lai [4] calls such control rules "asymptotically efficient," in analogy with the minimal order of magnitude (1.23) for the regret R_n in adaptive control of the simple regression model (1.20). Extensions of these to multivariable systems will be considered in § 7, which also contains several other concluding remarks.

2. Adaptive prediction, recursive identification, and some basic lemmas. To begin with, consider the unit-delay, white noise case (i.e., $d=1=C(q^{-1})$), for which (1.1) can be written as a stochastic regression model

$$(2.1)\qquad y_{n+1} = \theta'\psi_n + \varepsilon_{n+1},$$

where $\theta = (-a_1, \cdots, -a_p, b_1, \cdots, b_k)'$ and $\psi_n = (y_n, \cdots, y_{n-p+1}, u_n, \cdots, u_{n-k+1})'$. When θ is known, the minimum variance 1-step ahead predictor of y_{t+1} is $E(y_{t+1}|\mathcal{F}_t) = \theta'\psi_t$, and the optimal controller chooses u_t so that $\theta'\psi_t = y_{t+1}^*$. An obvious modification of this control rule for the case of unknown θ is to "adapt" the optimal predictor $\theta'\psi_t$ by substituting the unknown θ by the least squares estimate θ_t, which has the recursive representation

$$(2.2a)\qquad \theta_t = \theta_{t-1} + P_{t-1}\psi_{t-1}(y_t - \theta'_{t-1}\psi_{t-1}),$$

$$(2.2b)\qquad P_t = P_{t-1} - P_{t-1}\psi_t\psi'_t P_{t-1}/(1+\psi'_t P_{t-1}\psi_t).$$

A first difficulty with this straightforward approach is that the controller $\theta'_t\psi_t = y_{t+1}^*$ need not be well defined since the coefficient $b_1^{(t)}$ of u_t in $\theta'_t\psi_t$ may be 0 unless some continuity assumptions are made on the distribution of $\{\varepsilon_t\}$. For the regulation problem $y_i^* \equiv 0$, Åström and Wittenmark [7] circumvented this difficulty by reparametrizing (2.1) as

$$(2.3)\qquad \begin{aligned} &y_{n+1} = b_1(u_n - \lambda' X_n) + \varepsilon_{n+1}, \quad \text{where} \\ &\lambda = (a_1/b_1, \cdots, a_p/b_1, -b_2/b_1, \cdots, -b_k/b_1)', \\ &X_n = (y_n, \cdots, y_{n-p+1}, u_{n-1}, \cdots, u_{n-k+1})', \end{aligned}$$

and replacing the unknown b_1 by $b \neq 0$ while using the least squares criterion to estimate λ. They also showed that if the estimates should converge then they must converge to λ. However, a difficult open problem is whether with positive probability these estimates may fail to converge in their certainty-equivalence regulator

$$(2.4)\qquad b(u_t - \lambda'_t X_t) = 0, \quad \text{where } \lambda_t = \arg\min_\lambda \sum_{i=1}^{t} (y_i - bu_{i-1} + b\lambda' X_{i-1})^2.$$

Instead of adhering to a prior guess b of b_1, an obvious modification of the Åström-Wittenmark approach is to update this guess with the current and past data. Lai and Wei [11] recently considered this modification under the assumption that $A(z)$

is stable. They also introduced occasional blocks of white-noise probing inputs and used only the data from these stages of forced learning to obtain a strongly consistent estimate $b(t)$ of b_1. Replacing b by $b(t)$ in (2.4) whenever $b(t) \neq 0$ and the number of probing inputs up to stage t does not fall below some threshold K_t (with $K_t \to \infty$ and $K_t = o(\log t)$) leads to a certainty-equivalence regulator, for system (1.1) with $d = 1$ and $C(q^{-1}) = 1$, whose regret has the logarithmic order (1.26), as shown by Lai and Wei [11]. A key step in their proof is the analysis of the cumulative squared difference $\sum_1^n (\tilde{y}_{t+1} - \hat{y}_{t+1})^2$ between the optimal predictor $\tilde{y}_{t+1} = \theta'\psi_t = b_1(u_t - \lambda' X_t)$ and the adaptive predictor $\hat{y}_{t+1} = b(t)(u_t - \lambda_t' X_t)$ in the stochastic regression model (2.3).

For the unit-delay colored-noise case, (1.1) can still be written in the form of a stochastic regression model (2.1) with θ given by (1.6) and

$$\psi_n = (y_n, \cdots, y_{n-p+1}, u_n, \cdots u_{n-k+1}, \varepsilon_n, \cdots, \varepsilon_{n-h+1})'. \tag{2.5}$$

However, the regressor ψ_n contains unobservable components $\varepsilon_n, \cdots, \varepsilon_{n-h+1}$. Replacing the unobservable ε_i by their estimates $\hat{\varepsilon}_i$ in the recursion (2.2) leads to the "extended least squares" algorithm of the form

$$\theta_t = \theta_{t-1} + P_{t-1}\phi_{t-1}(y_t - \theta_{t-1}'\phi_{t-1}), \qquad P_t^{-1} = P_{t-1}^{-1} + \phi_t\phi_t', \tag{2.6}$$

$$\phi_t = (y_t, \cdots, y_{t-p+1}, u_t, \cdots, u_{t-k+1}, \hat{\varepsilon}_t, \cdots, \hat{\varepsilon}_{t-h+1})'. \tag{2.7}$$

The estimates $\hat{\varepsilon}_i$ of ε_i in (2.7) are given either by the residuals $\hat{\varepsilon}_i = y_i - \theta_i'\phi_{i-1}$, in which case (2.6) is called the AML algorithm, or by the prediction errors $\hat{\varepsilon}_i = y_i - \theta_{i-1}'\phi_{i-1}$, in which case (2.6) is called the RML1 algorithm. Assuming that

$$\operatorname{Re}(1/C(e^{it}) - 1/2) > 0 \text{ for all } t \in [-\pi, \pi], \tag{2.8}$$

Lai and Wei [12] showed that for the AML algorithm θ_n and its associated adaptive 1-step ahead predictor $\hat{y}_{n+1} = \theta_n'\phi_n$,

$$\begin{gathered} \|\theta_n - \theta\| = O(\{\log \lambda_{\max}(P_n^{-1})\}^{1/2}/\lambda_{\min}^{1/2}(P_n^{-1})) \quad \text{a.s.}, \\ \sum_1^n \|\phi_i - \psi_i\|^2 = O(\log \lambda_{\max}(P_n^{-1})) \quad \text{a.s.}, \end{gathered} \tag{2.9}$$

$$\sum_{i=1}^n (\theta'\psi_i - \theta_i'\phi_i)^2 I_{\{\phi_i' P_i \phi_i \leqq \delta\}} = O(\log \lambda_{\max}(P_n^{-1})) \quad \text{a.s. for every } 0 < \delta < 1. \tag{2.10}$$

Making use of (2.9) and (2.10), they proved not only the self-optimizing property (1.19) but also the much stronger conclusion $R_n = O(\log n)$ almost surely for a modification of the certainty-equivalence rule based on the AML algorithm, under the assumptions of boundedness of the target values y_i^*, stability of the open-loop plant (i.e., $A(z)$ and $B(z)$ are stable), and assumption (2.8) for $C(z)$. A basic ingredient of this modification is a simple criterion to decide whether information is inadequate for approximating the unobservable $\theta'\psi_t$ by $\theta_t'\phi_t$. When the data show inadequate information for such approximation, instead of adhering to the certainty-equivalence formula $\theta_t'\phi_t = y_{t+1}^*$ to determine the output u_t, [12] proposes to introduce a block of white noise perturbations to improve the information content of the design, in such a way that the number of these perturbations up to stage n is kept within the order $O(\log n)$. This approach ensures that $\theta_t'\phi_t$ is eventually close to $\theta'\psi_t$ whenever certainty-equivalence inputs are used, although θ_t may not converge to θ. In fact, "self-tuning" holds in the sense that

$$\sum_{t \leqq n: \theta_t'\phi_t = y_{t+1}^*} (\theta'\psi_t - \theta_t'\phi_t)^2 = O(\log n) \quad \text{a.s.} \tag{2.11}$$

For this case of general delay d, it is convenient to reparametrize (1.1) in the following prediction form. By the division algorithm, there exist polynomials $F(z)=1+f_1z+\cdots+f_{d-1}z^{d-1}$ and $G(z)=g_1+\cdots+g_{p(d)}z^{p(d)-1}$with $p(d)=p\vee(h-d+1)$ such that

$$C(z)=A(z)F(z)+z^dG(z), \tag{2.12}$$

and therefore (1.1) can be rewritten in the form

$$C(q^{-1})\{y_{n+d}-F(q^{-1})\varepsilon_{n+d}\}=G(q^{-1})y_n+B(q^{-1})F(q^{-1})u_n \tag{2.13}$$

(cf. [2, p. 368], [13, p. 268], [14, p. 134]). Hence, in the case of known system parameters, the optimal d-step ahead predictor $\tilde{y}_{n+d}\triangleq E(y_{n+d}\,|\,\mathcal{F}_n)$ is given by

$$\tilde{y}_{n+d}+c_1\tilde{y}_{n+d-1}+\cdots+c_h\tilde{y}_{n+d-h}=G(q^{-1})y_n+(BF)(q^{-1})u_n, \tag{2.14}$$

where $(BF)(z)=B(z)F(z)=b_1+(bf)_2z+\cdots+(bf)_{k+d-1}z^{k+d-2}$, and its prediction error is

$$\eta_{n+d}\triangleq y_{n+d}-\tilde{y}_{n+d}=F(q^{-1})\varepsilon_{n+d}. \tag{2.15}$$

Let

$$\tilde{\theta}=(g_1,\cdots,g_{p(d)},b_1,(bf)_2,\cdots,(bf)_{k+d-1},-c_1,\cdots,-c_h)'. \tag{2.16}$$

Since $y_{n+d}=\tilde{y}_{n+d}+\eta_{n+d}$, we have by (2.14) the following prediction form of (1.1):

$$\begin{aligned} &y_{n+d}=\tilde{\theta}'\tilde{\psi}_n+\eta_{n+d}, \quad \text{where}\\ &\tilde{\psi}_n=(y_n,\cdots,y_{n-p(d)+1},u_n,\cdots,u_{n-k-d+2},\tilde{y}_{n+d-1},\cdots,\tilde{y}_{n+d-h})'. \end{aligned} \tag{2.17}$$

In the case of known system parameters, the optimal controller chooses u_n so that $\tilde{y}_{n+d}=y^*_{n+d}$. Without assuming knowledge of the parameters, it is natural to replace $\tilde{y}_{n+d}=\tilde{\theta}'\tilde{\psi}_n$ in the optimal controller by an adaptive predictor $\hat{y}_{n+d}$. In particular, Goodwin, Ramadge, and Caines [8] defined $\hat{y}_{n+d}$ by replacing the $\tilde{y}_i$ in $\tilde{\psi}_n$ by the target values y^*_i and the unknown parameters $\tilde{\theta}$ in (2.16) by a stochastic gradient (stochastic approximation) estimate of the form

$$\theta^*_n=\theta^*_{n-d}+(a/r^*_{n-d})\phi^*_{n-d}(y_n-\theta^{*\prime}_{n-d}\phi^*_{n-d}), \tag{2.18a}$$

$$r^*_n=r^*_{n-d}+\|\phi^*_n\|^2, \tag{2.18b}$$

where $\phi^*_n=(y_n,\cdots,y_{n-p(d)+1},u_n,\cdots,u_{n-k-d+2},y^*_{n+d-1},\cdots,y^*_{n+d-h})'$ and u_n is defined by

$$\theta^{*\prime}_n\phi^*_n=y^*_{n+d}. \tag{2.18c}$$

To ensure that the coefficient $b^*_{1,n}$ of u_n in (2.18c) is nonzero almost surely, Goodwin, Ramadge, and Caines assume that

(2.19) $(x_0,\varepsilon_1,\cdots,\varepsilon_n)$ is absolutely continuous with respect to Lebesgue measure for every $n\geqq 1$.

Their use of the scalar gain $1/r^*_{n-d}$ in (2.18) instead of the matrix gain $(P_0^{-1}+\sum_1^{n-d}\phi^*_i\phi^{*\prime}_i)^{-1}$ as in (2.2) or (2.6) considerably simplifies the analysis. Under certain additional stability and positive real assumptions on $B(z)$ and $C(z)$ and boundedness assumptions on $\{y^*_i\}$, they proved the self-optimizing property (1.19′) for the certainty-equivalence rule (2.18c) in the case $d=1$ and also in the case $C(q^{-1})=1$ and general d. For general delay and colored noise, Goodwin, Sin, and Saluja [15] suggested replacing (2.18b) by

$$r^*_n=r^*_{n-1}+\|\phi^*_n\|^2, \tag{2.20}$$

and showed how to extend the argument in [8] to prove the self-optimizing property of their scheme.

Clearly, other recursive identification algorithms can also be used to define adaptive predictors $\hat{y}_{n+d}$ and thereby to construct certainty-equivalence rules. The *direct* (or *implicit*) approach of adaptive prediction is to first obtain a recursive estimator θ_n of the parameter $\tilde{\theta}$ of the implicit system (2.17) and then to substitute the optimal predictor $\tilde{\theta}'\tilde{\psi}_n$ of y_{n+d} by $\theta'_n\phi_n$, where ϕ_n is a pseudoregression vector in which the undetermined components $\tilde{y}_i$ of $\tilde{\psi}_n$ are replaced by $\theta'_{i-d}\phi_{i-d}$, cf. [13, p. 181]. We have recently developed in [16] analogues of the bound (2.10) for the cumulative squared difference $\sum_1^n (\tilde{\theta}'\tilde{\psi}_i - \theta'_i\phi_i)^2$ between the optimal d-step ahead predictor $\tilde{\theta}'\tilde{\psi}_i$ and the adaptive predictor $\theta'_i\phi_i$ associated with a variety of recursive identification algorithms, including stochastic gradient, extended least squares, and monitored recursive maximum likelihood. In particular, for adaptive predictors associated with the stochastic gradient algorithm, the results of [16] are summarized in the following.

THEOREM 1. *Suppose that* $\operatorname{Re}\{C(e^{it})-(d-\frac{1}{2})a\}>0$ *for all* $|t|\leqq\pi$ *and some* $a>0$, *and that the random disturbances* ε_n *in the linear stochastic system* (1.1) *satisfy assumption* (1.3). *Let* $p(d)=p\vee(h-d+1)$. *Consider the stochastic gradient algorithm that estimates the parameter* $\tilde{\theta}$ *in the reparametrized model* (2.17) *by the recursion*

$$\theta_{n,G}=\theta_{n-1,G}+(a/r_{n-d})(y_n-\hat{y}_{n,G})\phi_{n-d,G}, \tag{2.21a}$$

$$\phi_{n,G}=(y_n,\cdots,y_{n-p(d)+1},u_n,\cdots,u_{n-k-d+2},\hat{y}_{n+d-1,G},\cdots,\hat{y}_{n+d-h,G})', \tag{2.21b}$$

$$r_n=r_{n-1}+\|\phi_{n,G}\|^2, \tag{2.21c}$$

$$\hat{y}_{n+d,G}=\theta'_{n,G}\phi_{n,G}. \tag{2.21d}$$

Then

$$\limsup_{n\to\infty}\|\theta_{n,G}\|<\infty \quad a.s., \tag{2.22}$$

$$\sum_{i=1}^{n}(\tilde{\theta}'\tilde{\psi}_i-\theta'_{i,G}\phi_{i,G})^2=o(r_n)+O(1) \quad a.s. \tag{2.23}$$

Moreover, if $B(z)$ *is stable, then*

$$\begin{gathered}\lim_{n\to\infty} n^{-1}\sum_{i=1}^{n}(\tilde{\theta}'\tilde{\psi}_i-\theta'_{i,G}\phi_{i,G})^2=0 \quad \textit{and}\\ \limsup_{n\to\infty} n^{-1}\sum_{i=1}^{n}(y_i^2+u_i^2)<\infty \quad \textit{a.s. on} \left\{\limsup_{n\to\infty} n^{-1}\sum_{i=1}^{n}(\theta'_{i,G}\phi_{i,G})^2<\infty\right\}.\end{gathered} \tag{2.24}$$

The proof of Theorem 1 and of analogous results for other recursive identification algorithms in [16] makes use of the idea of "extended stochastic Lyapunov functions." For an algorithm with a matrix gain P_{n-d} of the form $P_t^{-1}=P_{t-1}^{-1}+\phi_t\phi'_t$, [16] makes use of the extended stochastic Lyapunov function $(\theta_n-\tilde{\theta})'P_{n-d}^{-1}(\theta_n-\tilde{\theta})$, which typically does not converge. For the stochastic gradient algorithm with the scalar gain $1/r_{n-d}$, [16] uses $Q_n=\|\theta_{n,G}-\tilde{\theta}\|^2$ as the extended stochastic Lyapunov function and derives from the recursion (2.21a) recursive inequalities for Q_n. In the case of unit delay ($d=1$), Goodwin, Ramadge, and Caines [8] also derived similar recursive inequalities. However, in order to apply the martingale convergence theorem, they introduced a transformation of the form $Z_n=Q_n+S_n/r_{n-1}$ with $S_n\geqq 0$, and used the recursive inequalities to conclude that Z_n is a nonnegative almost supermartingale (or stochastic Lyapunov function; cf. [17], [18]). Instead of relying on the martingale convergence theorem, [16] works directly with the recursive inequalities for Q_n and applies certain martingale limit theorems, restated in Lemma 1 below for subsequent reference, to analyze these recursive inequalities, which turn out to involve not only Q_n but also $\sum_1^{n-d} (\tilde{\theta}'\tilde{\psi}_i - \theta_{i,G}\phi_{i,G})^2/r_i$. Thus Theorem 1 follows from such analysis of Q_n.

LEMMA 1. *Let $\{\varepsilon_n\}$ be a martingale difference sequence with respect to an increasing sequence of σ-fields $\{\mathscr{F}_n\}$ such that* $\sup_n E(|\varepsilon_n|^\alpha || \mathscr{F}_{n-1}) < \infty$ *almost surely for some $\alpha > 2$. Let z_n be an $\mathscr{F}_{n-1}$-measurable random variable for every n.*

(i) *$\sum_1^n z_i\varepsilon_i$ converges almost surely on $\{\sum_1^\infty z_i^2 < \infty\}$, and for every $\eta > \frac{1}{2}$,*

$$\left(\sum_1^n z_i\varepsilon_i\right) \Big/ \left(\sum_1^n z_i^2\right)^\eta \to 0 \quad a.s.\ on \left\{\sum_1^\infty z_i^2 = \infty\right\}.$$

Consequently,

$$\sum_1^n z_i\varepsilon_i = o\left(\sum_1^n z_i^2\right) + O(1) \quad a.s. \tag{2.25}$$

(ii) *$\sum_1^n |z_i|\varepsilon_i^2 = O(\sum_1^n |z_i|)$ almost surely on $\{\sup_n |z_n| < \infty\}$. Moreover,*

$$\sum_1^n |z_i|\varepsilon_i^2 = \sum_1^n |z_i|E(\varepsilon_i^2 | \mathscr{F}_{i-1}) + o\left(\sum_1^n |z_i|\right) \quad on \left\{\sup_n |z_n| < \infty, \sum_1^\infty |z_n| = \infty\right\}. \tag{2.26}$$

In §§ 3 and 6 we apply Theorem 1 and some extensions thereof to develop, for general delay and colored noise and without stability assumptions on $A(z)$, asymptotically efficient adaptive control schemes that satisfy (1.24) or (1.25) by using parallel implementation of $\theta_{n,G}$ and three other recursive identification algorithms. The remainder of this section states for subsequent reference some algebraic lemmas on the dynamics of (1.1) and on recursive estimation of its parameters.

LEMMA 2. *Suppose that for $n \leqq t < m$, $\phi_t = (y_t, \cdots, y_{t-\nu+1}, u_t, \cdots, u_{n-\kappa+1}, \hat{y}_{t+d-1}, \cdots, \hat{y}_{t+d-h})'$ and $C(q^{-1})(y_{t+d} - \eta_{t+d}) = G(q^{-1})y_t + \Gamma(q^{-1})u_t$, where $C(q^{-1}) = 1 + c_1q^{-1} + \cdots + c_hq^{-h}$, $G(q^{-1}) = g_1 + \cdots + g_\nu q^{-(\nu-1)}$ and $\Gamma(q^{-1}) = \gamma_1 + \cdots + \gamma_\kappa q^{-(\kappa-1)}$ are polynomials in the backward shift operator q^{-1}. Suppose that there exist $(\nu + \kappa + h) \times 1$ vectors θ_t such that $\hat{y}_{t+d} = \theta_t'\phi_t$ for $n \leqq t < m$. Then*

$$C(q^{-1})(y_s - \hat{y}_s - \eta_s) = -(\theta_{s-d} - \tilde{\theta})'\phi_{s-d} \quad for\ m + d > s \geqq n + d, \tag{2.27}$$

where $\tilde{\theta} = (g_1, \cdots, g_\nu, \gamma_1, \cdots, \gamma_\kappa, -c_1, \cdots, -c_h)'$.

LEMMA 3. *Let $\{D_n, n \geqq 0\}$ be a sequence of $L \times L$ real matrices such that $\sum_0^\infty \|D_n\| < \infty$ and let $D(z) = \sum_{n=0}^\infty D_nz^n$. Suppose that $D(e^{it}) + D'(e^{-it})$ is nonnegative definite for all $t \in [-\pi, \pi]$.*

(i) *Let $\{g_n, n \geqq 0\}$ be a sequence of $L \times 1$ real vectors and let $f_n = \sum_{k=0}^n D_kg_{n-k}$. Then for any $N \geqq 0$, $\sum_{n=0}^N f_n'g_n \geqq 0$.*

(ii) *Suppose that $D_i = 0$ for all $i > h$. Let $M \geqq h$ and suppose that $f_n = \sum_{j=0}^h D_jg_{n-j}$ for $M \leqq n \leqq N$. Let $\{r_n, M \leqq n \leq N\}$ be a nondecreasing sequence of positive numbers. Then*

$$\sum_{n=M}^N f_n'g_n/r_n \geqq \sum_{j=1}^h \sum_{t=0}^{h-j} g_{M-1-t}'D_{j+t}'g_{M-1+j}/r_{M-1+j}.$$

LEMMA 4. (i) *Consider the linear system $A(q^{-1})y_n = q^{-d}B(q^{-1})u_n + C(q^{-1})\varepsilon_n$, in which $A(q^{-1})$, $B(q^{-1})$, and $C(q^{-1})$ are the polynomials (1.2) in the unit delay operator q^{-1}. Suppose that $b_1 \neq 0$ and that $B(z)$ is stable. Then there exist $K > 0$, $0 < \rho < 1$, and $\alpha_0, \alpha_1, \cdots, \beta_0, \beta_1, \cdots$ such that* $\max(|\alpha_i|, |\beta_i|) \leqq K\rho^i$ *and for all $t \geqq n$,*

$$\left|u_t - \sum_{i=0}^{t-n} \alpha_iy_{t+d-i} - \sum_{i=0}^{t-n} \beta_i\varepsilon_{t+d-i}\right| \leqq K\rho^{t-n}\left\{\sum_{\nu=1}^{k-1} |u_{n-\nu}| + \sum_{\nu=1}^{p} |y_{n+d-\nu}| + \sum_{\nu=1}^{h} |\varepsilon_{n+d-\nu}|\right\}.$$

Consequently, there exists $K^*>0$ such that for all $t \geqq n+d$,

$$\sum_{i=n+d}^{t} u_{i-d}^2 \leqq K^* \left\{ \sum_{i=n-p+d}^{t} y_i^2 + \sum_{i=n-h+d}^{t} \varepsilon_i^2 + \sum_{\nu=1}^{k-1} u_{n-\nu}^2 \right\}.$$

(ii) *Suppose that the polynomial $C(z)=1+c_1z+\cdots+c_hz^h$ is stable. For $j=1,\cdots,h$, let $\{c_{n,j}\}$ be a sequence of numbers such that $\lim_{n\to\infty} c_{n,j}=c_j$, and let $C_n(q^{-1})=1+c_{n,1}q^{-1}+\cdots+c_{n,h}q^{-h}$. Suppose that ξ_n and ϕ_n are $L\times 1$ vectors such that $C_n(q^{-1})\xi_n=\phi_n$. Then there exist $K>0$ and $0<\rho<1$ such that for all $t>n$*

$$\|\xi_t\| \leqq K\left\{ \sum_{i=0}^{t-n-1} \rho^i \|\phi_{t-i}\| + \rho^{t-n} \sum_{r=0}^{h-1} \|\xi_{n-r}\| \right\}.$$

For the proofs of Lemmas 2 and 3, see [16]. The main ideas of the proof of Lemma 4(i) are given in [11, pp. 470-471], and the proof of Lemma 4(ii) uses similar arguments (cf. Step 1 in the Appendix of [12]).

LEMMA 5. *Let A_n be a symmetric, positive-definite $L\times L$ matrix. Suppose that*

$$\log \operatorname{tr}(A_n) \leqq (1+o(1)) \log n \text{ as } n\to\infty, \tag{2.28}$$

and that there exist $\tilde{L}(\leqq L)$ linearly independent $L\times 1$ vectors $v_1,\cdots,v_{\tilde{L}}$ satisfying the condition

$$\lim_{n\to\infty} \log(v_i'A_nv_i)/\log n = 0 \text{ for } i=1,\cdots,\tilde{L}. \tag{2.29}$$

Then $\limsup_{n\to\infty} (\log \det A_n)/\log n \leqq L-\tilde{L}$.

Proof. Let $\lambda_{n,1},\cdots,\lambda_{n,L}$ be the eigenvalues of the symmetric matrix A_n, and let $x_{n,1},\cdots,x_{n,L}$ be corresponding orthonormal eigenvectors. Let π_n be a permutation of $\{1,\cdots,L\}$ such that

$$\max_{1\leqq i\leqq \tilde{L}} |v_i'x_{n,\pi_n(1)}| \geqq \cdots \geqq \max_{1\leqq i\leqq \tilde{L}} |v_i'x_{n,\pi_n(L)}|. \tag{2.30}$$

We first show that

$$\rho \triangleq \liminf_{n\to\infty} \max_{1\leqq i\leqq \tilde{L}} |v_i'x_{n,\pi_n(\tilde{L})}| > 0. \tag{2.31}$$

Suppose that (2.31) is not true. Then in view of (2.30), there exist orthonormal vectors $X_{\tilde{L}},\cdots,X_L$ which are limit points of the sequences $\{x_{n,\pi_n(\tilde{L})}\},\cdots,\{x_{n,\pi_n(L)}\}$ such that $\max_{1\leqq i\leqq \tilde{L}} |v_i'X_j|=0$ for $\tilde{L}\leqq j\leqq L$. Hence the orthonormal vectors $X_{\tilde{L}},\cdots,X_L$ belong to the orthogonal complement of the linearly independent set $\{v_1,\cdots,v_{\tilde{L}}\}$, which is impossible since $(L-\tilde{L}+1)+\tilde{L}>L$.

Since $v_i'A_nv_i=\sum_{j=1}^{L}(v_i'x_{n,\tau_n(j)})^2\lambda_{n,\pi_n(j)} \geqq \sum_{j=1}^{\tilde{L}}(v_i'x_{n,\pi_n(j)})^2\lambda_{n,\pi_n(j)}$, it follows from (2.30) and (2.31) that for all large n,

$$\lambda_{n,\pi_n(j)} < 2\rho^{-2} \max_{1\leqq i\leq \tilde{L}} |v_i'A_nv_i|, \qquad j=1,\cdots,\tilde{L}. \tag{2.32}$$

From (2.32), it follows that for all large n,

$$\begin{aligned}\log\det A_n &= \sum_{j=1}^{L} \log \lambda_{n,\pi_n(j)} \leqq 2\rho^{-2}\tilde{L} \max_{1\leqq i\leqq \tilde{L}} \log(v_i'A_nv_i) + (L-\tilde{L}) \log \operatorname{tr} A_n \\ &\leqq (1+o(1))(L-\tilde{L}) \log n,\end{aligned}$$

by (2.28) and (2.29). □

LEMMA 6. *Consider the matrix polynomials (over the complex field)*

$$\begin{aligned} &A(z)=I+A_1z+\cdots+A_pz^p, \qquad B(z)=B_1+\cdots+B_kz^{k-1}, \\ &C(z)=I+C_1z+\cdots+C_hz^h, \end{aligned} \tag{2.33}$$

where I is the identity matrix and the A_i, B_i, and C_i are $\nu\times\nu$ matrices such that $\det B(z)\neq 0$ *for all* $|z|\leqq 1$. *Let* $\cdots, \varepsilon_{-1}, w_{-1}, \varepsilon_0, w_0, \varepsilon_1, w_1, \cdots$ *be independent, bounded* $\nu\times 1$ *random vectors such that the* ε_i *have a common distribution with mean* 0 *and positive-definite covariance matrix* $\sum$, *and the* w_i *have a common distribution with mean* 0 *and positive-definite covariance matrix V. Let* $d\geqq 1$ *and let* $\eta_i=\varepsilon_i+F_1\varepsilon_{i-1}+\cdots+F_{d-1}\varepsilon_{i-d+1}$, *where* $F_1,\cdots,F_{d-1}$ *are nonrandom* $\nu\times\nu$ *matrices. Let* $y_i=\eta_i+w_{i-d}$ *and define* u_i *by the linear difference equation*

$$A(q^{-1})y_n=B(q^{-1})u_{n-d}+C(q^{-1})\varepsilon_n, \tag{2.34}$$

where q^{-1} *denotes the backward shift operator. Suppose that the matrix polynomials* $z^pA(z^{-1})$, $z^{k-1}B(z^{-1})$, *and* $z^hC(z^{-1})$ *are left coprime, i.e., the determinants of their greatest common left divisors have degree* 0. *Then the* $\nu(p+k)\times\nu\{p+2(k-1)\nu+1\}$ *matrix H has full rank* $\nu(p+k)$, *where*

$$\begin{aligned}H=E\{&(y'_{-1},\cdots,y'_{-p},u'_{-d},\cdots,u'_{-d-k+1})'\\ &\times(y'_{-h-1},\cdots,y'_{-h-(k-1)\nu},w'_{-d},\cdots,w'_{-d-p-(k-1)\nu})\}.\end{aligned} \tag{2.35}$$

Proof. Let $b(z)=\det B(z)$ and let $\tilde{B}(z)$ denote the adjoint of $B(z)$. Then

$$\tilde{B}(z)B(z)=b(z)I,\quad \deg b(z)\leqq \nu(k-1),\quad \deg\tilde{B}(z)\leqq(\nu-1)(k-1). \tag{2.36}$$

Since $b(z)\neq 0$ for all $|z|\leqq 1$, we can invert (2.34) as

$$u_{n-d}=\{\tilde{B}(q^{-1})/b(q^{-1})\}\{A(q^{-1})y_n-C(q^{-1})\varepsilon_n\}. \tag{2.37}$$

Suppose that H is not of full rank. Then there exist $\nu\times 1$ vectors $\pi_1,\cdots,\pi_p$, $\gamma_0,\cdots\gamma_{k-1}$, not all 0, such that $(\pi'_1,\cdots,\pi'_p,\gamma'_0,\cdots,\gamma'_{k-1})H=0$, i.e.,

$$E\left\{\left(\sum_{i=1}^{p}\pi'_iy_{-i}+\sum_{i=0}^{k-1}\gamma'_iu_{-d-i}\right)y'_{-j}\right\}=0,\quad j=h+1,\cdots,h+(k-1)\nu, \tag{2.38}$$

$$E\left\{\left(\sum_{i=1}^{p}\pi'_iy_{-i}+\sum_{i=0}^{k-1}\gamma'_iu_{-d-i}\right)w'_{-j}\right\}=0,\quad j=d,\cdots,d+p+(k-1)\nu. \tag{2.39}$$

Let

$$L(z)=\sum_{i=1}^{p}\pi'_iz^i,\qquad \Gamma(z)=\sum_{i=0}^{k-1}\gamma'_iz^i. \tag{2.40}$$

Since $y_n=\eta_n+w_{n-d}$, it follows from (2.37) that

$$\begin{aligned}\sum_{i=1}^{p}\pi'_iy_{n-i}+\sum_{i=0}^{k-1}\gamma'_iu_{n-d-i}&=\{L(q^{-1})+\Gamma(q^{-1})\tilde{B}(q^{-1})A(q^{-1})/b(q^{-1})\}(\eta_n+w_{n-d})\\ &\quad-\{\Gamma(q^{-1})\tilde{B}(q^{-1})C(q^{-1})/b(q^{-1})\}\varepsilon_n.\end{aligned} \tag{2.41}$$

Recalling that $\{w_t\}$ and $\{\varepsilon_t\}$ are independent zero-mean random vectors with positive covariance matrices, (2.41) (with $n=0$) and (2.39) imply that

$$L(q^{-1})+\Gamma(q^{-1})\tilde{B}(q^{-1})A(q^{-1})/b(q^{-1})=q^{-(p+(k-1)\nu+1)}R(q^{-1})$$

for some power series $R(z)=\sum_{i=0}^{\infty}\rho_iz^i$, where the ρ_i are $1\times\nu$ vectors such that $\sum_0^\infty\|\rho_i\|<\infty$. Therefore

$$b(z)L(z)+\Gamma(z)\tilde{B}(z)A(z)=b(z)z^{p+(k-1)\nu+1}R(z). \tag{2.42}$$

In view of (2.36) and (2.40), the left-hand side of (2.42) is a matrix polynomial of degree less than or equal to $(k-1)\nu+p$, and therefore (2.42) implies that $R(z)=0$. Hence

$$b(q^{-1})L(q^{-1})=-\Gamma(q^{-1})\tilde{B}(q^{-1})A(q^{-1}). \tag{2.43}$$

From (2.41) and (2.43), it follows that

$$\sum_{i=1}^{p}\pi_i' y_{n-i}+\sum_{i=0}^{k-1}\gamma_i' u_{n-d-i}=-\{\Gamma(q^{-1})\tilde{B}(q^{-1})C(q^{-1})/b(q^{-1})\}\varepsilon_n=-\sum_{i=0}^{\infty}d_i'\varepsilon_{n-i}, \tag{2.44}$$

for some nonrandom $\nu\times 1$ vectors d_i such that $\sum_0^\infty \|d_i\|<\infty$. Recalling that $\operatorname{cov}(\varepsilon_n)$ is positive-definite and that $y_s=\varepsilon_s+F_1\varepsilon_{s-1}+\cdots+F_{d-1}\varepsilon_{s-d+1}+w_{s-d}$, it follows from (2.38) and (2.44) (with $n=0$) that

$$\Gamma(z)\tilde{B}(z)C(z)=b(z)\left\{\sum_{i=0}^{h}d_i'z^i+\sum_{i=h+(k-1)\nu+1}^{\infty}d_i'z^i\right\}. \tag{2.45}$$

In view of (2.36) and (2.40), the left-hand side of (2.45) is a polynomial of degree $\leqq k-1+(\nu-1)(k-1)+h<h+(k-1)\nu+1$, and therefore (2.45) implies that

$$\Gamma(z)\tilde{B}(z)C(z)=b(z)D(z)\quad\text{where } D(z)=\sum_{i=0}^{h}d_i'z^i. \tag{2.46}$$

From (2.40) and (2.43), $0=L(0)=-\Gamma(0)B_1^{-1}A(0)=-\gamma_0'B_1^{-1}$, noting that $\tilde{B}(0)/b(0)=(B(0))^{-1}=B_1^{-1}$ and that B_1 is invertible. Hence $\gamma_0=0$. Therefore $\Gamma(z)=\sum_{i=1}^{k-1}\gamma_i'z^i=z\sum_{j=0}^{k-2}\gamma_{j+1}'z^j$, $L(z)=z\sum_{j=0}^{p-1}\pi_{j+1}'z^j$. Setting $z=0$ in (2.46) then gives $(\det B(0))d_0'=0$, implying that $d_0=0$ and therefore $D(z)=z\sum_{j=0}^{h-1}d_{j+1}'z^j$. Hence (2.43) and (2.46) can be written as

$$\begin{gathered}\Gamma^*(z)\tilde{B}(z)A(z)/b(z)=-L^*(z),\ \Gamma^*(z)\tilde{B}(z)C(z)/b(z)=D^*(z),\text{ where}\\ L^*(z)=\sum_0^{p-1}\pi_{j+1}'z^j,\quad \Gamma^*(z)=\sum_0^{k-2}\gamma_{j+1}'z^j,\quad D^*(z)=\sum_0^{h-1}d_{j+1}'z^j.\end{gathered} \tag{2.47}$$

Let $\mathscr{B}(z)=z^{k-1}B(z^{-1})=B_1z^{k-1}+\cdots+B_k$, $\beta(z)=\det(\mathscr{B}(z))$ and let $\tilde{\mathscr{B}}(z)$ denote the adjoint of $\mathscr{B}(z)$. The $\beta(z)=z^{(k-1)\nu}\det(B(z^{-1}))$ and likewise $\tilde{\mathscr{B}}(z)=z^{(k-1)(\nu-1)}\tilde{B}(z^{-1})$, so

$$\tilde{B}(z^{-1})/b(z^{-1})=z^{k-1}\mathscr{B}(z)/\beta(z). \tag{2.48}$$

By (2.47) and (2.48),

$$\begin{gathered}\{z^{k-2}\Gamma^*(z^{-1})\}\{\tilde{\mathscr{B}}(z)/\beta(z)\}\{z^pA(z^{-1})\}=-z^{p-1}L^*(z^{-1}),\\ \{z^{k-2}\Gamma^*(z^{-1})\}\{\tilde{\mathscr{B}}(z)/\beta(z)\}\{z^hC(z^{-1})\}=z^{h-1}D^*(z^{-1}).\end{gathered}$$

Hence $\sum_1^{k-1}\gamma_{k-i}'z^{i-1}\{\tilde{\mathscr{B}}(z)/\beta(z)\}(z^pA(z^{-1}), z^hC(z^{-1}))$ is a matrix polynomial. This implies that $\gamma_1=\cdots=\gamma_{k-1}=0$ by Lemma 1(ii) of [19], since $\mathscr{B}(z)$, $z^pA(z^{-1})$, and $z^hC(z^{-1})$ are left coprime. Hence $\Gamma(z)=z\Gamma^*(z)=0$, and by (2.43), $L(z)=0$, contradicting that $\pi_1,\cdots,\pi_p,\gamma_0,\cdots,\gamma_{k-1}$ are not all zero. □

3. Stochastic gradient algorithms and occasionally disturbed control schemes. As an application of Theorem 1, we give a short proof of the self-optimizing property

(1.19) of the Goodwin–Ramadge–Caines scheme (2.18) in the unit-delay case ($d = 1, p(d) = p \vee h$), under their assumptions (2.19) and

$$B(z) \text{ is stable,} \tag{3.1a}$$

$$\operatorname{Re}\{C(e^{it}) - a/2\} > 0 \text{ for all } |t| \leqq \pi, \tag{3.1b}$$

$$\{y_t^*\} \text{ is a bounded nonrandom sequence.} \tag{3.1c}$$

In view of (2.18c),the vector ϕ_t^* in (2.18) is equivalent to (2.21b). Moreover, by (2.18c) and (3.1c), $\sup_n n^{-1} \sum_1^n (\theta_i^{*\prime}\phi_i^*)^2 < \infty$ almost surely. By (2.17) and (2.18c), $y_{n+1} - \varepsilon_{n+1} - y_{n+1}^* = \tilde{\theta}'\tilde{\psi}_n - \theta_n^{*\prime}\phi_n^*$, and therefore by Theorem 1, $n^{-1}\sum_1^n (y_i - y_i^* - \varepsilon_i)^2 \to 0$ almost surely, i.e., (1.19) holds for the Goodwin–Ramadge–Caines scheme (2.18).

To obtain strongly consistent estimates of the parameter vector (1.6) in the unit-delay case, Caines and Lafortune [9] replaced the definition of ϕ_i^* and (2.18c) in the Goodwin–Ramadge–Caines scheme by

$$\begin{aligned} &\theta_n^{*\prime}\phi_n^* = y_{n+1}^* + w_n, \\ &\phi_n^* = (y_n, \cdots, y_{n-p(1)+1}, u_n, \cdots u_{n-k+1}, y_n^* + w_{n-1}, \cdots, y_{n+1-h}^* + w_{n-h})', \end{aligned} \tag{3.2}$$

where w_t is independent of $\{x_0, \varepsilon_1, \varepsilon_2, \cdots, u_1, \cdots, u_{t-1}, w_1, \cdots, w_{t-1}\}$ and such that $Ew_t = 0$, $Ew_t^2 = v > 0$ and $\sup_t Ew_t^4 < \infty$. They proved that for this modified scheme

$$n^{-1}\sum_2^n (y_i - y_i^* - w_{i-1} - \varepsilon_i)^2 \to 0 \quad \text{a.s.} \tag{3.3}$$

Replacing y_i^* in the preceding paragraph by $y_i^* + w_{i-1}$, we can also obtain (3.3) as another corollary of Theorem 1. Making use of (3.3), Caines and Lafortune [9] showed that $n^{-1}\sum_{i=1}^n \psi_i\psi_i'$ converges almost surely to a positive-definite matrix. Using this "persistent excitation" property of the ψ_i and Solo's [20] consistency theorem for the AML algorithm, they obtained strongly consistent AML estimates of the system parameters. The control scheme (3.2), however, is not self-optimizing since (3.3) implies that $n^{-1}\sum_2^n (y_i - y_i^* - \varepsilon_i)^2 \to v > 0$ almost surely (cf. [9]). To preserve the self-optimizing property, the white-noise perturbations w_n should only be introduced in (3.2) infrequently, with relative frequency diminishing to 0, as will be done in Theorem 4 below.

The interlacing algorithm (2.18) is a composite of d recursions for $\theta_{j+nd}^*(n \geqq 1)$, $j = 0, 1, \cdots, d-1$. In contrast, the stochastic gradient algorithm of Theorem 1 does not involve such multiple recursions, and handles general delay d in exactly the same way as it handles the case $d = 1$. Thus, Theorem 1 leads to a stochastic gradient certainty-equivalence rule that differs from that of Goodwin et al. [8], [15] in the case where $d \geqq 2$ since interlacing is no longer needed.

The proof of Theorem 1 given in [16] can be readily extended to the situation in which the stochastic gradient scheme is applied only to broken blocks of successive observations and in which white-noise perturbations w_i are introduced only occasionally, an improvement over the Caines–Lafortune [9] continually disturbed control scheme. Moreover, our modification also works for general delay d without interlacing, and by choosing the perturbations w_i to have a continuous distribution, we can further dispense with the restrictive assumption (2.19) in the Caines–Lafortune scheme. This is the content of Theorem 2.

THEOREM 2. *Suppose that* $\operatorname{Re}\{C(e^{it}) - (d - \frac{1}{2})a\} > 0$ *for all* $|t| \leqq \pi$ *and some* $a > 0$, *and that the random disturbances* ε_n *in the linear stochastic system* (1.1) *satisfy assumption*

(1.3) with $\sup_n |\varepsilon_n| < \infty$ *almost surely. Let* $p(d) = p \vee (h - d + 1)$. *Let* $m_0 = 0$ *and let* $n_1 < m_1 < n_2 < m_2 < \cdots$ *be stopping times (with respect to* $\{\mathscr{F}_t\}$*) such that*

$$m_j - n_j \geqq d + h. \tag{3.4}$$

Let $\{w_n\}$ *be a sequence of random variables such that*

(3.5) w_n *is independent of* $\{x_0, \varepsilon_1, \varepsilon_2, \cdots, u_1, \cdots, u_{n-1}, w_1, \cdots, w_{n-1}\}$ *and the* w_n *are identically distributed with a common continuous distribution such that* $Ew_1 = 0$, $Ew_1^2 = v > 0$, *and* $|w_1| \leqq c$.

Define the modified stochastic gradient algorithm $\theta_{n,\tilde{G}}$ *recursively as follows: Choose* $\theta_{0,\tilde{G}}$ *such that its component* $b_{0,\tilde{G}}$ *estimating the component* b_1 *of the vector* $\tilde{\theta}$ *in (2.16) is nonzero. Let* $\theta_{t,\tilde{G}} = \theta_{0,\tilde{G}}$ *for* $t < n_1 + d$. *Let*

$$\phi_{n,\tilde{G}} = (y_n, \cdots, y_{n-p(d)+1}, u_n, \cdots, u_{n-k-d+2}, w_{n-1}, \cdots, w_{n-h})'. \tag{3.6}$$

For $m_{j-1} + d - 1 < n < n_j + d$, *define* $\theta_{n,\tilde{G}} = \theta_{m_{j-1}+d-1,\tilde{G}}$. *For* $n_j + d \leq n \leq m_j + d - 1$ *define*

$$\begin{aligned} \theta_{n,\tilde{G}} &= \theta_{n-1,\tilde{G}} + (a/\tilde{r}_{n-d})(y_n - w_{n-d})\phi_{n-d,\tilde{G}}, \\ \tilde{r}_{n-d} &= \tilde{r}_{n-d-1} + \|\phi_{n-d,\tilde{G}}\|^2, \end{aligned} \tag{3.7a}$$

$$\begin{aligned} \tilde{r}_{n_j-1} = {} & \sum_{i=1}^{j-1} \sum_{t=n_i+d}^{m_i+d-1} \|\phi_{t-d,\tilde{G}}\|^2 \\ & + \sum_{i=1}^{j} \left(1 \vee \sum_{\nu=0}^{p(d)-1} y_{n_i-\nu}^2 \vee \sum_{\nu=1}^{k+d-2} u_{n_i-\nu}^2\right) \\ & \times \log^2 \left\{ \sum_{i=1}^{j} \left(2 \vee \sum_{\nu=0}^{p(d)-1} y_{n_i-\nu}^2 \vee \sum_{\nu=1}^{k+d-2} u_{n_i-\nu}^2\right)\right\}. \end{aligned} \tag{3.7b}$$

Suppose that for $n_j \leqq n < m_j$ *the input* u_n *is chosen so that*

$$\theta'_{n,\tilde{G}}\phi_{n,\tilde{G}} = w_n \text{ if } b_{n,\tilde{G}} \neq 0, \quad \text{and } u_n = w_n \text{ otherwise,} \tag{3.8}$$

where $b_{n,\tilde{G}}$ *is the component of* $\theta_{n,\tilde{G}}$ *estimating* b_1. *Define* η_t *as in (2.15). Then* $P\{b_{n,\tilde{G}} = 0\} = 0$ *for every n and*

$$\limsup_{j\to\infty} \|u_{m_j+d-1,\tilde{G}}\| < \infty, \quad \lim_{j\to\infty} \sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} (y_t - \eta_t - w_{t-d})^2/\tilde{r}_{m_j-1} = 0 \quad a.s. \tag{3.9}$$

Proof. We first prove by induction that $P\{b_{n,\tilde{G}} = 0\} = 0$ for every n. By our choice of $\theta_{0,\tilde{G}}$, this is clearly true for $0(=m_0) \leqq n < n_1 + d$. Suppose that this is true for all $n \leqq t - 1$. If $n_j + d \leqq t \leqq m_j + d - 1$ for some j, then by (3.7a) and (3.8) together with (2.17),

$$\begin{aligned} b_{t,\tilde{G}} &= b_{t-1,\tilde{G}} + (a/\tilde{r}_{n-d})(\tilde{\theta}'\tilde{\psi}_{t-d} + \eta_t - w_{t-d})u_{t-d} \\ &= b_{t-1,\tilde{G}} + a(\tilde{r}_{t-d}b_{t-d,\tilde{G}})^{-1}(\tilde{\theta}'\tilde{\psi}_{t-d} + \eta_t - w_{t-d}) \\ &\quad \times \left\{ w_{t-d} - \sum_{i=0}^{p(d)-1} \lambda_i y_{t-d-i} - \sum_{i=1}^{k+d-2} \tilde{\lambda}_i u_{t-d-i} - \sum_{i=1}^{h} \lambda_i^* w_{t-d-i} \right\} \quad \text{a.s.,} \end{aligned} \tag{3.10}$$

where the λ_i, $\tilde{\lambda}_i$, λ_i^* represent the components of $\theta_{t-d,\tilde{G}}$. Since w_{t-d} is independent of $S_t \triangleq (\theta'_{0,\tilde{G}}, \cdots, \theta'_{t-1,\tilde{G}}, \tilde{\psi}'_{t-d}, x'_0, \tilde{r}_{t-d}, \eta_t, y_1, \cdots, y_{t-d}, u_1, \cdots, u_{t-d-1}, w_1, \cdots, w_{t-d-1})$ by (3.5) and (3.7), and since w_{t-d} has a continuous distribution, it then follows from (3.10) that $P\{b_{t,\tilde{G}} = 0 | S_t\} = 0$. If $m_{j-1} + d - 1 < t < n_j + d$ for some j, then $b_{t,\tilde{G}} = b_{m_{j-1},\tilde{G}}$, and by the induction assumption, $P\{b_{m_{j-1},\tilde{G}} = 0\} = 0$.

For simplicity, we will use θ_n and ϕ_n to denote $\theta_{n,\tilde G}$ and $\phi_{n,\tilde G}$. For $n_j \leqq n < m_j$, since $b_{n,\tilde G} \neq 0$ almost surely, (3.8) implies that $w_n = \theta'_n \phi_n$ almost surely. Therefore by Lemma 2, with probability 1,

$$C(q^{-1})(y_t - w_{t-d} - \eta_t) = -(\theta_{t-d} - \tilde\theta)'\phi_{t-d} \quad \text{for } n_j + d \leqq t \leqq m_j + d - 1. \tag{3.11}$$

Let $e_t = y_t - w_{t-d}$. From (3.7a) and (2.17), it follows by simple algebra (cf. the proof of Theorem 1 given in [16]) that

$$\begin{aligned} \|\theta_{n_{i+1}+d-1} - \tilde\theta\|^2 &= \|\theta_{m_i+d-1} - \tilde\theta\|^2 \\ &= \|\theta_{n_i+d-1} - \tilde\theta\|^2 + 2a \sum_{t=n_i+d}^{m_i+d-1} \{\tilde r_{t-d}^{-1}(e_t - \eta_t)\phi'_{t-d}(\theta_{t-1} - \tilde\theta) \\ &\quad + (a/2)\tilde r_{t-d}^{-2}(e_t - \eta_t)^2 \|\phi_{t-d}\|^2\} \\ &\quad + a^2 \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-2} \|\phi_{t-d}\|^2 \eta_t^2 + 2a \sum_{t=n_i+d}^{m_i+d-1} \eta_t \\ &\quad \cdot \{\tilde r_{t-d}^{-1}\phi'_{t-d}(\theta_{t-1} - \tilde\theta) + a\tilde r_{t-d}^{-2}(e_t - \eta_t)\|\phi_{t-d}\|^2\}. \end{aligned} \tag{3.12}$$

First note that $\{n_i + d \leqq t \leqq m_i + d - 1\} = \{n_i \leqq t - d\} \cap \{m_i > t - d\} \in \mathscr{F}_{t-d}$. Furthermore, ϕ_{t-d}, $\tilde r_{t-d}$ and $e_t - \eta_t = \tilde\theta' \tilde\psi_{t-d} - \theta'_{t-d}\phi_{t-d}$ are $\mathscr{F}_{t-d}$-measurable. Therefore an application of Lemma 1 (cf. the proof of Theorem 1 given in [16]) shows that with probability 1,

$$\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-2} \|\phi_{t-d}\|^2 \eta_t^2 = O\left(\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-2} \|\phi_{t-d}\|^2 \right) = O(1), \tag{3.13}$$

$$\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-2} \|\phi_{t-d}\|^2 (e_t - \eta_t)\eta_t = o\left(\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-2} (e_t - \eta_t)^2 \right) + O(1). \tag{3.14}$$

Writing $\theta_{t-1} - \tilde\theta = \sum_{s=1}^{d-1} (\theta_{t-s} - \theta_{t-s-1}) + (\theta_{t-d} - \tilde\theta)$ and noting that $\theta_{t-s} = \theta_{t-s-1}$ if $n_i \leqq t - s < n_i + d$, the same argument as that used in [16] for the proof of Theorem 1 can be used to show that with probability 1,

$$\begin{aligned} &\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-1} \phi'_{t-d}(\theta_{t-1} - \tilde\theta)\eta_t \\ &\quad = o\left(\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-2} [\phi'_{t-d}(\theta_{t-d} - \tilde\theta)]^2 \right) + o\left(\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-1} (e_t + \eta_t)^2 \right) \\ &+ O(1), \end{aligned} \tag{3.15}$$

$$\begin{aligned} &\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \{\tilde r_{t-d}^{-1}(e_t - \eta_t)\phi'_{t-d}(\theta_{t-1} - \tilde\theta) + (a/2)\tilde r_{t-d}^{-2}(e_t - \eta_t)^2 \|\phi_{t-d}\|^2\} \\ &\quad \leqq -(\rho + o(1)) \sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-1}(e_t - \eta_t)^2 + O(1) \\ &\qquad - \sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-1}(e_t - \eta_t)[\{C(q^{-1}) - (d - 1/2)a - \rho\}(e_t - \eta_t)], \end{aligned} \tag{3.16}$$

where $\rho > 0$ is so chosen that $\min_{|t| \leqq \pi} \operatorname{Re}\{C(e^{it}) - (d - 1/2)a - \rho\} > 0$.

From (3.11), it follows that

$$\begin{aligned} &\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-2} [\phi'_{t-d}(\theta_{t-d} - \tilde\theta)]^2 \\ &\quad = O\left(\sum_{i=1}^{j} \left\{ \sum_{t=n_i+d}^{m_i+d-1} \tilde r_{t-d}^{-2} (e_t - \eta_t)^2 + \tilde r_{n_i}^{-2} \max_{1 \leqq \nu \leqq h} (e_{n_i+d-\nu} - \eta_{n_i+d-\nu})^2 \right\} \right). \end{aligned} \tag{3.17}$$

Using the recursion $y_s = -\sum_{\nu=1}^{p} a_\nu y_{s-\nu} + \sum_{\nu=d}^{k+d-1} b_{\nu-d+1} u_{s-\nu} + \varepsilon_s + \sum_{\nu=1}^{h} c_\nu \varepsilon_{s-\nu}$, we can proceed inductively from $t=1$ to $t=(d-1)\vee 1$ to show that

$$\max_{1\leqq t\leqq d-1} y_{n_i+t}^2 = O\left(\sum_{\nu=0}^{p-1} y_{n_i-\nu}^2 \vee \sum_{\nu=1}^{k+d-2} u_{n_i-\nu}^2 \vee \sum_{\nu=1-d}^{h-1} \varepsilon_{n_i-\nu}^2\right),$$

in which the left-hand side is interpreted as 0 if $d-1=0$. Since $\sup_n |\varepsilon_n| < \infty$ almost surely, this implies that with probability 1,

$$\max_{1\wedge(d-h)\leqq t\leqq d-1} (y_{n_i+t}^2 + \eta_{n_i+t}^2) = O\left(1 \vee \nabla_{\nu=1}^{k+d-2} u_{n_i-\nu}^2 \vee \sum_{\nu=0}^{p(d)-1} y_{n_i-\nu}^2\right). \tag{3.18}$$

Recalling that $\sup_n |w_n| \leqq c$ and that $e_n = y_n - w_{n-d}$, we then obtain from (3.17) and (3.18) together with the definition of $\tilde{r}_{n_i-1}$ in (3.7b) that with probability 1,

$$\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde{r}_{t-d}^{-2} [\phi'_{t-d}(\theta_{t-d} - \tilde{\theta})]^2 = O\left(\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde{r}_{t-d}^{-1} (e_t - \eta_t)^2\right) + O(1). \tag{3.19}$$

Since $\operatorname{Re}\{C(e^{it}) - (d-1/2)a - \rho\} > 0$ for all $|t| \leqq \pi$, it follows from Lemma 3(ii) that

$$\begin{aligned} &-\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde{r}_{t-d}^{-1} (e_t - \eta_t) [\{C(q^{-1}) - (d-1/2)a - \rho\}(e_t - \eta_t)] \\ &\leqq -\sum_{i=1}^{j} \sum_{l=1}^{h} \sum_{\nu=0}^{h-1} c_{l+\nu} (e_{n_i+d-1-\nu} - \eta_{n_i+d-1-\nu})(e_{n_i+d-1+l} - \eta_{n_i+d-1+l}) / \tilde{r}_{n_i+l-1} \\ &\leqq \frac{1}{2} \sum_{i=1}^{j} \sum_{l=0}^{h-1} \sum_{\nu=1}^{h-1} \left\{ \frac{c_{l+\nu}^{1/2}}{\rho^{1/2} \tilde{r}_{n_i+l}^{1/2}} (e_{n_i+d-\nu} - \eta_{n_i+d-\nu}) \right\}^2 + \frac{\rho}{2} \sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i} \frac{(e_t - \eta_t)^2}{\tilde{r}_{t-d}}, \end{aligned} \tag{3.20}$$

using the inequality $|AB| \leqq (A^2 + B^2)/2$ and noting that $n_i + d + h \leqq m_i$. Moreover, since $e_n = y_n - w_{n-d}$ and $\sup_n (|w_n| + |\eta_n|) < \infty$ almost surely, it follows from (3.18) and (3.7b) that

$$\sum_{i=1}^{\infty} \sum_{\nu=1}^{h} (e_{n_i+d-\nu} - \eta_{n_i+d-\nu})^2 / \tilde{r}_{n_i} < \infty \quad \text{a.s.} \tag{3.21}$$

Combining (3.16) with (3.20) and (3.21) gives

$$\begin{aligned} &\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \{\tilde{r}_{t-d}^{-1} (e_t - \eta_t) \phi'_{t-d} (\theta_{t-1} - \tilde{\theta}) + (a/2) \tilde{r}_{t-d}^{-2} (e_t - \eta_t)^2 \|\phi_{t-d}\|^2\} \\ &\leqq -(\rho/2 + o(1)) \sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde{r}_{t-d}^{-1} (e_t - \eta_t)^2 + O(1) \quad \text{a.s.} \end{aligned} \tag{3.22}$$

From (3.12)-(3.15), (3.19), and (3.22), it follows that

$$\|\theta_{n_j+d-1} - \tilde{\theta}\|^2 \leqq -(\rho/2 + o(1)) \sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i+d-1} \tilde{r}_{t-d}^{-1} (e_t - \eta_t)^2 + O(1) \quad \text{a.s.}$$

Hence $\limsup_{j\to\infty} \|\theta_{m_{j-1}+d-1} - \tilde{\theta}\|^2 < \infty$ and $\sum_{i=1}^{\infty} \sum_{t=n_i+d}^{m_i+d-1} \tilde{r}_{t-d}^{-1} (e_t - \eta_t)^2 < \infty$ almost surely, implying the desired conclusion (3.9) by the Kronecker lemma. □

COROLLARY 1. *With the same notation and assumptions as in Theorem* 2, *let* $\#_j = \sum_{i=1}^{j} (m_i - n_i)$. *Assume furthermore that* $B(z)$ *is stable and that*

$$\begin{aligned} &\sum_{i=1}^{j} \left(1 \vee \sum_{\nu=0}^{p(d)-1} y_{n_i-\nu}^2 \vee \sum_{\nu=1}^{k+d-2} u_{n_i-\nu}^2\right) \log^2 \left\{\sum_{i=1}^{j} \left(2 \vee \sum_{\nu=0}^{p(d)-1} y_{n_i-\nu}^2 \vee \sum_{\nu=1}^{k+d-2} u_{n_i-\nu}^2\right)\right\} \\ &\qquad = O(\#_j) \quad \textit{a.s.} \end{aligned} \tag{3.23}$$

Then

$$\sum_{i=1}^{j}\left(\sum_{t=n_i}^{m_i+d-1} y_t^2+\sum_{t=n_i+d}^{m_i+d-1} u_{t-d}^2\right)=O(\#_j) \quad a.s., \tag{3.24}$$

$$\lim_{j\to\infty}\sum_{i=1}^{j}\sum_{t=n_i+d}^{m_i+d-1}(y_t-\eta_t-w_{t-d})^2/\#_j=0 \quad a.s. \tag{3.25}$$

Proof. From (3.6), (3.7b), and (3.23), it follows that

$$\tilde{r}_{m_j-1}=O\left(\#_j+\sum_{i=1}^{j}\sum_{t=n_i+d}^{m_i+d-1}(y_{t-d}^2+u_{t-d}^2)\right) \quad \text{a.s.} \tag{3.26}$$

Since $b_1\neq 0$ and $B(z)$ is stable, an application of Lemma 4(i) shows that

$$\sum_{t=n_i+d}^{m_i+d-1} u_{t-d}^2\leqq K\left\{\sum_{t=n_i-p+d}^{m_i+d-1} y_t^2+\sum_{t=n_i-h+d}^{m_i+d-1}\varepsilon_t^2+\sum_{\nu=1}^{k-1}u_{n_i-\nu}^2\right\} \tag{3.27}$$

for some $K>0$. In view of the assumption that $\sup_t|\varepsilon_t|<\infty$ almost surely, it follows from (3.26), (3.27), and (3.23) that

$$\tilde{r}_{m_j-1}=O\left(\#_j+\sum_{i=1}^{j}\sum_{t=n_i+1}^{m_i+d-1} y_t^2\right) \quad \text{a.s.} \tag{3.28}$$

Letting $e_t=y_t-w_{t-d}$, it follows from (3.9) and (3.28) that

$$\begin{aligned}\sum_{i=1}^{j}\sum_{t=n_i+d}^{m_i+d-1} e_t^2&\leqq 2\sum_{i=1}^{j}\sum_{t=n_i+d}^{m_i+d-1}\{\eta_t^2+(e_t-\eta_t)^2\}\\ &=O(\#_j)+o\left(\#_j+\sum_{i=1}^{j}\sum_{t=n_i+1}^{m_i+d-1} y_t^2\right) \quad \text{a.s.}\end{aligned} \tag{3.29}$$

Since $y_t^2\leqq 2e_t^2+2w_{t-d}^2$, the desired conclusion (3.24) follows from (3.29), (3.23), and (3.27). Moreover, from (3.9), (3.26), and (3.24), (3.25) follows. □

The proof of Theorem 1 given in [16] can also be readily extended to show that the same conclusions hold for the following modification of the stochastic gradient algorithm (2.21), noting that condition (3.32) below implies that ρ_n is $\mathcal{F}_{n-d}$-measurable and that $(\alpha+\rho_n w_n)^2\leqq \alpha a$, $(\rho_n\theta'_{n-d,G}\phi_{n-d,G})^2=O(r_{n-d})$. This modification can be used to define the input u_t by

$$\theta'_{t,G}\phi_{t,G}=y^*_{t+d}, \tag{3.30}$$

since $b_{t,G}\neq 0$ almost surely even without the continuity assumption (2.19) (cf. Theorem 2 and [21]).

THEOREM 3. *Suppose that in Theorem* 1 *we change* (2.21a) *to*

$$\theta_{n,G}=\theta_{n-1,G}+(\alpha+\rho_n w_n)r_{n-d}^{-1}(y_n-\hat{y}_{n,G})\phi_{n-d,G}, \tag{3.31}$$

where $\phi_{n,G}$, $\hat{y}_{n,G}$, and r_n are still given by (2.21b)-(2.21d), $0<\alpha<a$, *the w_n are random variables satisfying* (3.5) *for some* $c>0$, *and*

$$\rho_n=(a^{1/2}\alpha^{1/2}-\alpha)/\{r_{n-d}^{-1/2}|\theta'_{n-d,G}\phi_{n-d,G}|\vee c\}. \tag{3.32}$$

The initial value $\theta_{0,G}$ is so chosen that $b_{0,G}\neq 0$, where $b_{n,G}$ denotes the component of $\theta_{n,G}$ estimating b_1. Then (2.22) *and* (2.23) *still hold and*

$$P\{b_{n,G}=0\}=0 \quad \textit{for every } n. \tag{3.33}$$

Moreover, (2.24) *also holds if $B(z)$ is stable.*

4. Occasional excitation and strongly consistent parameter estimates using the method of moments. Throughout this section we will let $n_1 < m_1 < n_2 < m_2 < \cdots$ be stopping times such that (3.4) holds, and define the modified stochastic gradient algorithm $\theta_{n,\tilde{G}}$ and the associated pseudo-regression vector $\phi_{n,\tilde{G}}$ as in Theorem 2. Letting

$$J = \bigcup_{i=1}^{\infty} \{n_i, n_i+1, \cdots, m_i - 1\}, \tag{4.1}$$

we will assume that, as in Theorem 2, the inputs u_n are determined by (3.8) for $n \in J$. Making use of Corollary 1, we show in the following theorem that the input-output data at stages $t \in J$ have certain excitation properties, which we will use later for the construction of strongly consistent estimates of the parameter vector θ, defined by (1.6), of system (1.1).

THEOREM 4. *With the same notation and assumptions as in Theorem 2, assume that $B(z)$ is stable. Suppose that*

$$m_j - n_j \textit{ is } \mathscr{F}_{nj}\textit{-measurable}, \quad m_j - n_j \to \infty, \quad \textit{and}$$

$$\left(1 \vee \sum_{\nu=0}^{p(d)-1} y^2_{n_j-\nu} \vee \sum_{\nu=1}^{k+d-2} u^2_{n_j-\nu}\right) \log^2 \left\{ \sum_{i=1}^{j} \left(2 \vee \sum_{\nu=0}^{p(d)-1} y^2_{n_i-\nu} \vee \sum_{\nu=1}^{k+d-2} u^2_{n_i-\nu} \right)\right\} \tag{4.2}$$

$$= O(m_j - n_j) \quad \textit{a.s.}$$

Let $\#_j = \sum_{i=1}^{j} (m_i - n_i)$ *and define*

$$\begin{aligned} X_t &= (y_{t-1}, \cdots, y_{t-p}, u_{t-d}, \cdots, u_{t-d-k+1})', \\ Z_t &= (y_{t-h-1}, \cdots, y_{t-h-k+1}, w_{t-d}, \cdots, w_{t-d-p-k+1})'. \end{aligned} \tag{4.3}$$

Then (3.24), (3.25) *hold and there exists* $(p+2k-1)\times(p+k)$ *nonrandom matrix H such that*

$$\lim_{j\to\infty} \left(\sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} Z_t X_t' \right) \Big/ \#_j = H \quad \textit{a.s.} \tag{4.4}$$

If the polynomials $z^p A(z^{-1})$, $z^{k-1} B(z^{-1})$ and $z^h C(z^{-1})$ are coprime, then H has full rank $p+k$.

Proof. In view of (4.2), (3.23) holds and therefore by Corollary 1, (3.24) and (3.25) hold. By Lemma 4(i), there exist constants $C > 0$, $0 < \rho < 1$, and $\alpha_0, \alpha_1, \cdots, \beta_0, \beta_1, \cdots$ such that $|\alpha_t| \vee |\beta_t| \leqq C\rho^t$ and

$$\begin{aligned} &u_{t-d} = \alpha_0 y_t + \cdots + \alpha_{t-n} y_n + \beta_0 \varepsilon_t + \cdots + \beta_{t-n}\varepsilon_n + \Delta_{t,n} \quad \text{for } t \geqq n+d, \\ &\text{where } |\Delta_{t,n}| \leqq C\rho^{t-n} \left\{ \sum_{s=1}^{k-1} |u_{n-d-s}| + \sum_{s=1}^{p} |y_{n-s}| + \sum_{s=1}^{h} |\varepsilon_{n-s}| \right\}. \end{aligned} \tag{4.5}$$

From the definition of Δ_{t,n_i+d}, it follows that

$$\begin{aligned} \sum_{i=1}^{j} \sum_{t=n_1+1+d}^{m_i} \Delta^2_{t,n_i+d} &\leqq (k+p+h) \left(C^2 \sum_{s=1}^{\infty} \rho^{2s} \right) \sum_{i=1}^{j} \left(\sum_{\nu=1}^{k-1} u^2_{n_i-\nu} \right. \\ &\quad \left. + \sum_{\nu=1}^{p} y^2_{n_i+d-\nu} + h \sup_t \varepsilon_t^2 \right) = o(\#_j) \quad \text{a.s. by (4.2) and (3.18).} \end{aligned} \tag{4.6}$$

Let $\delta_t = y_t - \eta_t - w_{t-d}$. By (3.25), $\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i} \delta_t^2 = o(\#_j)$ almost surely and therefore

$$\begin{aligned} \sum_{i=1}^{j} \sum_{t=n_1+1+d}^{m_i} \left(\sum_{s=n_i+d}^{t} |\alpha_{t-s}\delta_s| \right)^2 &\leqq \sum_{i=1}^{j} \sum_{t=n_i+1+d}^{m_i} \left(\sum_{s=n_i+d}^{t} |\alpha_{t-s}| \right) \left(\sum_{s=n_i+d}^{t} |\alpha_{t-s}| \delta_s^2 \right) \\ &\leqq \sum_{i=1}^{j} \sum_{s=n_i+d}^{m_i} \delta_s^2 \left(\sum_{t=0}^{\infty} |\alpha_t| \right)^2 - o(\#_j) \quad \text{a.s.} \end{aligned} \tag{4.7}$$

For fixed $r \geqq 1$ and $s \geqq 1$, $s' \geqq 0$, since ε_{t-r} is $\mathcal{F}_{t-1}$-measurable and $\{n_i + s \leqq t \leqq m_i - s'\} \in \mathcal{F}_{t-s}$ by (4.2). We can apply Lemma 1(i) to conclude that for every $\delta > 0$,

$$\sum_{i=1}^{j} \sum_{t=n_i+s}^{m_i-s'} \varepsilon_{t-r}\varepsilon_t = o(\#_j^{1/2+\delta}) \quad \text{a.s.} \tag{4.8}$$

Moreover, by (2.26),

$$\sum_{i=1}^{j} \sum_{t=n_i+s}^{m_i-s'} \varepsilon_t^2 \sim \sigma^2 \#_j \quad \text{a.s.} \tag{4.9}$$

Likewise, in view of (3.5), we have

$$\sum_{i=1}^{i} \sum_{t=n_i+s}^{m_i-s'} w_t^2 \sim v \#_j \quad \text{a.s.} \tag{4.10}$$

$$\left| \sum_{i=1}^{j} \sum_{t=n_i+s}^{m_i-s'} \varepsilon_r w_t \right| + \left| \sum_{i=1}^{j} \sum_{t=n_i+s}^{m_i-s'} \varepsilon_t w_{t-r} \right| + \left| \sum_{i=1}^{j} \sum_{t=n_i+s}^{m_i-s'} \varepsilon_{t-r} w_t \right| = o(\#_j^{1/2+\delta}) \quad \text{a.s.} \tag{4.11}$$

Since $\eta_t = \varepsilon_t + f_1\varepsilon_{t-1} + \cdots + f_{d-1}\varepsilon_{t-d+1}$, it follows from (4.8)-(4.11) that for every fixed L,

$$\begin{aligned}
\lim_{j\to\infty} \Bigg\{ \sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} & (\eta_{t-h-1} + w_{t-h-1-d}, \cdots, \eta_{t-h-k+1} \\
& + w_{t-h-k+1-d}, w_{t-d}, \cdots, w_{t-p-k+1-d})' \\
\times \Bigg(& \eta_{t-1} + w_{t-1-d}, \cdots, \eta_{t-p} + w_{t-p-d}, \sum_{r=0}^{L} \alpha_r(\eta_{t-r} + w_{t-r-d}) + \beta_r\varepsilon_{t-r}, \cdots, \\
& \sum_{r=0}^{L} \alpha_r(\eta_{t-k+1-r} + w_{t-k+1-r-d}) + \beta_r\varepsilon_{t-k+1-r} \Bigg) \Bigg\} \Big/ \#_j = H_L \quad \text{a.s.,}
\end{aligned} \tag{4.12}$$

where $H_L = H_L(\alpha_0, \cdots, \alpha_L, \beta_0, \cdots, \beta_L, f_1, \cdots, f_{d-1}, \sigma^2, v)$ is a nonrandom matrix.

Since $\sup_t (|\varepsilon_t| + |w_t|) < \infty$ almost surely, and since $\sum_0^\infty (|\alpha_r| + |\beta_r|) < \infty$,

$$\lim_{L\to\infty} \sup_j \left\{ \sum_{i=1}^{j} \sum_{t=n_i}^{m_i} \sup_{0\leqq s<t} (\varepsilon_{t-s}^2 + w_{t-s}^2) \sum_{r=L+1}^{\infty} (|\alpha_r| + |\beta_r|) \right\} \Big/ \#_j = 0 \quad \text{a.s.} \tag{4.13}$$

Since $y_t = \eta_t + w_{t-d} + \delta_t$ with $\sum_{i=1}^{j} \sum_{t=n_i+d}^{m_i} \delta_t^2 = o(\#_j)$ almost surely, it follows from (4.5)-(4.7) together with (4.12) and (4.13) that (4.4) holds with $H (= \lim_{L\to\infty} H_L)$ equal to the common expected value of the stationary sequence of random matrices

$$\begin{aligned}
(\tilde\eta_{t-h-1} + \tilde w_{t-h-1-d}, \cdots, \tilde\eta_{t-h-k+1} + \tilde w_{t-h-k+1-d}, \tilde w_{t-d}, \cdots, \tilde w_{t-d-p-k+1})' \\
\times \Bigg(\tilde\eta_{t-1} + \tilde w_{t-1-d}, \cdots, \tilde\eta_{t-p} + \tilde w_{t-p-d}, \sum_{j=0}^{\infty} \{\alpha_j(\tilde\eta_{t-j} + \tilde w_{t-j-d}) + \beta_j\tilde\varepsilon_{t-j}\}, \cdots, \\
\sum_{j=0}^{\infty} \{\alpha_j(\tilde\eta_{t+1-k-j} + \tilde w_{t+1-k-j-d}) + \beta_j\tilde\varepsilon_{t+1-k-j}\} \Bigg),
\end{aligned}$$

where $\tilde\eta_t = \tilde\varepsilon_t + \cdots + f_{d-1}\tilde\varepsilon_{t-d+1}$ and $\cdots, \tilde\varepsilon_{-1}, \tilde w_{-1}, \tilde\varepsilon_0, \tilde w_0, \tilde\varepsilon_1, \tilde w_1, \cdots$ are independent, bounded random variables such that the $\tilde\varepsilon_i$ have the same distribution with mean 0 and variance σ^2, and the $\tilde w_i$ have a common distribution with mean 0 and variance v. Let $\tilde u_{t-d} = \sum_{j=0}^{\infty} \{\alpha_j(\tilde\eta_{t-j} + \tilde w_{t-j-d}) + \beta_j\tilde\varepsilon_{t-j}\}$. Then by the definitions of α_j and β_j,

$$A(q^{-1})(\tilde\eta_t + \tilde w_{t-d}) = B(q^{-1})\tilde u_{t-d} + C(q^{-1})\tilde\varepsilon_t.$$

Hence by Lemma 6, H has full rank $p+k$. □

In view of Theorem 4 on occasionally excited input-output systems, we can use the instrumental variables Z_t defined in (4.3) to construct strongly consistent estimates of $a_1, \cdots, a_p, b_1, \cdots, b_k$ based on the input-output data at stages $t \in J$. We can then estimate consistently the autocorrelation function of the colored-noise sequence $\{\varepsilon_n + c_1\varepsilon_{n-1} + \cdots + c_h\varepsilon_{n-h}\}$.

COROLLARY 2. *With the same notation and assumptions as in Theorem* 4, *suppose that the polynomials* $z^pA(z^{-1})$, $z^{k-1}B(z^{-1})$, *and* $z^hC(z^{-1})$ *are coprime. Let* $\lambda = (-a_1, \cdots, -a_p, b_1, \cdots, b_k)'$. *Define*

$$\lambda_{m_j} = (V_j'V_j)^{-1}V_j' \sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} Z_t y_t \quad \textit{where}$$
$$V_j = \sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} Z_t X_t', \tag{4.14}$$

and the inverse is the Moore–Penrose generalized inverse. Then

$$\lambda_{m_j} - \lambda = o(\#_j^{-1/2+\delta}) \quad a.s. \tag{4.15}$$

for every $\delta > 0$. *Let*

$$e_{j,t} = y_t - \lambda_{m_j}' X_t, \tag{4.16}$$

$$\rho_{m_j}(\nu) = \left(\sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} e_{j,t}e_{j,t-\nu} \right) \Big/ \left(\sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} \right), \quad \nu = 0, \cdots, h. \tag{4.17}$$

Then $\rho_{m_j}(\nu)$ *converges almost surely to the covariance* $\rho(\nu)$ *between* $C(q^{-1})\varepsilon_t$ *and* $C(q^{-1})\epsilon_{t-\nu}$ (*which is the same for all t since* $E(\varepsilon_t^2 | \mathscr{F}_{t-1}) = \sigma^2$); *in fact, for every* $\delta > 0$,

$$\rho_{m_j}(\nu) - \rho(\nu) = o(\#_j^{-1/2+\delta}) \quad \textit{a.s. for } \nu = 0, 1, \cdots, h. \tag{4.18}$$

Remark. In view of (4.16), the numerator of (4.17) can be expressed as

$$\begin{aligned}\sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} e_{j,t}e_{j,t-\nu} = {} & \sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} y_t y_{t-\nu} \\ & - \lambda_{m_j}' \sum_{i=1}^{j} \sum_{t=n_i+p+h+k+d}^{m_i} (X_{t+\nu}y_t + X_t y_{t-\nu}) \\ & + \lambda_{m_j}' \left(\sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} X_t X_{t-\nu}' \right) \lambda_{m_j},\end{aligned}$$

which can therefore be updated at stage m_j without calculating the residuals $e_{j,t}$.

Proof. Since $y_t = X_t'\lambda + \varepsilon_t + c_1\varepsilon_{t-1} + \cdots + c_h\varepsilon_{t-h}$, it follows from (4.14) and (4.3) that

$$\begin{aligned}\lambda_{m_j} = \lambda + (V_j'V_j)^{-1}V_j \sum_{i=1}^{j} \sum_{t=n_i+p+k+h+d}^{m_i} & \\ (\varepsilon_t + \cdots + c_h\varepsilon_{t-h})(y_{t-h-1}, \cdots, y_{t-h-k+1}, w_{t-d}, \cdots, w_{t-d-p-k+1})'.&\end{aligned} \tag{4.19}$$

In view of (3.5), (3.24), and Lemma 1(i), we have for every $\delta > 0$,

$$\begin{aligned}\sum_{i=1}^{j} \sum_{t=n_i+p+k+h}^{m_i} (\varepsilon_t + \cdots + c_h\varepsilon_{t-h})(y_{t-h-1}, \cdots, & \\ y_{t-h-k+1}, w_{t-d}, \cdots, w_{t-d-p-k+1})' = o(\#_j^{1/2+\delta}) \quad \text{a.s.}&\end{aligned} \tag{4.20}$$

Since $V_j / \#_j \to H$ almost surely and since $H'H$ is positive definite by Theorem 4, (4.15) follows from (4.19) and (4.20).

Noting that $e_{j,t}=C(q^{-1})\varepsilon_t+(\lambda-\lambda_{m_j})'X_t$ and that $\sum_{i=1}^{j}\sum_{t=n_i+p+k+h+d}^{m_i}(\|X_t\|+\|X_t\|^2)=O(\#_j)$ almost surely by an argument similar to the proof of Theorem 4, we obtain from (4.15) that for every $\delta>0$,

$$\sum_{i=1}^{j}\sum_{t=n_i+p+k+h+d}^{m_i}\{e_{m_j,t}\,e_{m_j,t-\nu}-[C(q^{-1})\varepsilon_t][C(q^{-1})\varepsilon_{t-\nu}]\}=o(\#_j^{1/2+\delta})\quad\text{a.s.}\tag{4.21}$$

for $\nu=0,1,\cdots,h$. Moreover, by (4.9) and (4.10),

$$\begin{aligned}\sum_{i=1}^{j}\sum_{t=n_i+p+k+h+d}^{m_i}\{(\varepsilon_t+c_1\varepsilon_{t-1}+\cdots+c_h\varepsilon_{t-h})(\varepsilon_{t-\nu}+\cdots+c_h\varepsilon_{t-\nu-h})-\rho(\nu)\}\\=o(\#_j^{1/2+\delta})\quad\text{a.s.}\end{aligned}\tag{4.22}$$

for every $\delta>0$. From (4.21) and (4.22), (4.18) follows. □

Suppose that m_j is so chosen that in addition to (4.2) we also have

$$m_j-n_j=O(\#_{j-1}),\ \ \#_{j-1}=O(m_j-n_j)\quad\text{a.s.}\tag{4.23}$$

Define an estimate $\mathbf{s}_j=(\sigma_0^{(j)},\cdots,\sigma_h^{(j)})'$ of $\mathbf{s}=(\sigma,c_1\sigma,\cdots,c_h\sigma)'$ by the following one-step modification of Wilson's [22] iterative algorithm

$$\mathbf{s}_{j+1}=\mathbf{T}_j^{-1}(f_j(0)+\rho_{m_j}(0),\cdots,f_j(h)+\rho_{m_j}(h))',\tag{4.24}$$

where $f_j(\nu)=\sum_{i=0}^{h-\nu}\sigma_i^{(j)}\sigma_{i+\nu}^{(j)}(\nu=0,\cdots,h)$ and $\mathbf{T}_j$ is a $(h+1)\times(h+1)$-matrix whose (μ,ν) element is $\sigma_{\mu+\nu}^{(j)}+\sigma_{\nu-\mu}^{(j)}$, setting $\sigma_i^{(j)}=0$ for $i>h$ or $i<0$. The basic idea behind (4.24) is essentially the same as Solo's [23] recursive implementation of Wilson's algorithm, and analogous to [23], we initialize (4.24) by setting $\sigma_0^{(0)}>0=\sigma_1^{(0)}=\cdots=\sigma_h^{(0)}$ and perform a stability test for the polynomial $\sum_{\nu=0}^{h}\sigma_\nu^{(j+1)}z^\nu$, redefining (4.24) by $\mathbf{s}_{j+1}=\mathbf{s}_j$ if the stability test fails.

From (4.23) it follows that $\limsup_{j\to\infty}\#_{j-1}/\#_j<1$ almost surely and therefore for every $\delta>0$, $\sum_{j=1}^{\infty}\#_j^{-1/2+\delta}<\infty$ almost surely, implying that

$$\prod_{j=1}^{n}(1+\#_j^{-1/2+\delta})\ \text{converges a.s. as}\ n\to\infty.\tag{4.25}$$

Furthermore, (4.23) implies that $\#_j=O(\#_{j-1})$ almost surely, and by (4.18), for every $\delta>0$,

$$\max_{0\le\nu\le h}|\rho_{m_j}(\nu)-\rho_{m_{j-1}}(\nu)|=O(\#_j^{-1/2+\delta})\quad\text{a.s.}\tag{4.26}$$

Hence a straightforward modification of Solo's argument in [23] can be used to show that $\mathbf{s}_j\to\mathbf{s}$ almost surely; moreover, further application of (4.26) gives the convergence rate $\mathbf{s}_j-\mathbf{s}=O(\#_j^{-1/2+\delta})$ almost surely for every $\delta>0$ (cf. [24]). Throughout the sequel we will let

$$\theta_{m_j}=(\lambda'_{m_j},\sigma_1^{(j)}/\sigma_0^{(j)},\cdots,\sigma_h^{(j)}/\sigma_0^{(j)})'.\tag{4.27}$$

Therefore under the assumptions of Corollary 2 and (4.23), θ_{m_j} provides a strongly consistent estimator of $(\lambda',c_1,\cdots,c_h)'(=\theta$, by (1.6)); in fact,

$$\theta_{m_j}=\theta+o(\#_j^{-1/2+\delta})\quad\text{a.s. for every}\ \delta>0.\tag{4.28}$$

5. Matrix gain and the monitored recursive maximum likelihood algorithm. By introducing occasional white-noise perturbations and applying the modified stochastic gradient algorithm $\theta_{n,\tilde{G}}$ in conjunction with these white-noise perturbations to define the inputs u_n for $n\in J$ as in (3.8), we showed in § 4 that the input-output data at stages

$t \in J$ have sufficient excitation properties to provide strongly consistent estimators θ_{m_j} of θ. These estimators are updated only occasionally at stages $n = m_j$ and therefore can afford more computational complexities than the stochastic gradient algorithms $\theta_{n,G}$, $\theta_{n,\tilde{G}}$, and the monitored recursive maximum likelihood algorithm $\theta_{n,M}$, to be introduced below, which must be updated at every stage n.

The strongly consistent estimate θ_{m_j} of the parameter vector θ in the explicit dynamical system (1.1) induces a strongly consistent estimate $\tilde{\theta}_{m_j}$ of the reparametrization $\tilde{\theta}$ in the implicit system (2.17), since the components of $\tilde{\theta}$ can be expressed as continuous functions of those of θ in view of (2.12). For example, in the case $d = 2$, it follows from (2.12) that $f_1 = c_1 - a_1$, $g_i = c_{i+1} - a_{i+1} - a_i f_1$ for $i = 1, \cdots, p \vee (h-1)$, where we set $c_i = 0$ for $i \geqq h$ and $a_j = 0$ for $j > p$; moreover, $(bf)_i = b_i + b_{i-1} f_1$ for $i = 2, \cdots, k$, and $(bf)_{k+1} = b_k f_1$. The convergence rate (4.28) for θ_{m_j} implies that in the reparametrized model (2.17) we again have

$$\tilde{\theta}_{m_j} = \tilde{\theta} + o(\#_j^{-1/2+\delta}) \quad \text{a.s. for every } \delta > 0. \tag{5.1}$$

Therefore, taking $0 < \delta < 1/2$ and $c > 0$ and letting $\mathbf{I}_j$ denote the cube in $R^{p(d)+k+d-1+h}$ with center at $\tilde{\theta}_{m_j}$ and width $c\#_j^{-1/2+\delta}$, we obtain from (5.1) that

$$P\{\tilde{\theta} \in \mathbf{I}_j \text{ for all large } j\} = 1; \tag{5.2}$$

moreover, $\mathbf{I}_j$ shrinks to $\tilde{\theta}$ as $j \to \infty$ with probability 1.

The basic ideas of the monitored recursive maximum likelihood algorithm $\theta_{n,M}$ for the estimation of $\tilde{\theta}$ are: (i) to extend the classical recursive maximum likelihood (RML2; cf. [25]) algorithm to the implicit system (2.17), and (ii) to constrain (monitor) the recursive algorithm so that it lies inside the "confidence interval" $\mathbf{I}_j$ for $\nu_j \leqq n < \nu_{j+1}$, where $(\nu_{j+1} >) \nu_j \geqq m_j$ is so chosen to accommodate the time for carrying out the more intensive computations required by $\tilde{\theta}_{m_j}$. The projection that we use to constrain $\theta_{n,M}$ is taken with respect to the norm induced by the positive-definite matrix P_{n-d}^{-1} defined in (5.4d) below, instead of the usual Euclidean norm. For $x \in R^{p(d)+k+d-1+h}$ and $\nu_j \leqq n < \nu_{j+1}$, let $\pi(x)$ denote the unique solution of the quadratic programming problem

$$(\pi_n(x) - x)' P_{n-d}^{-1} (\pi_n(x) - x) = \min_{y \in \mathbf{I}_j} \{(y-x)' P_{n-d}^{-1} (y-x)\}, \tag{5.3}$$

i.e., $\pi_n(x)$ is the projection of x into $\mathbf{I}_j$ with respect to the norm induced by P_{n-d}^{-1}. The choice of a cube for the confidence region $\mathbf{I}_j$ implies linear constraints for the quadratic programming problem (5.3), which can be handled by simple computational methods (cf. [26]). Define

$$\theta_{n,M} = (\hat{g}_{n,1}, \cdots, \hat{g}_{n,p(d)}, \hat{b}_{n,1}, (\widehat{bf})_{n,2}, \cdots, (\widehat{bf})_{n,k+d-1}, -\hat{c}_{n,1}, \cdots, -\hat{c}_{n,h})'$$

for $n > \nu_1$ by the recursion

$$\theta_{n,M} = \pi_n(\theta_{n-1,M} + P_{n-d} \xi_{n-d} (y_n - \hat{y}_{n,M})), \tag{5.4a}$$

$$\begin{gathered} \xi_n + \hat{c}_{n,1} \xi_{n-1} + \cdots + \hat{c}_{n,h} \xi_{n-h} = \phi_{n,M}, \quad \text{where} \\ \phi_{n,M} = (y_n, \cdots, y_{n-p(d)+1}, u_n, \cdots, u_{n-k-d+2}, \hat{y}_{n+d-1,M}, \cdots \hat{y}_{n+d-h,M})', \end{gathered} \tag{5.4b}$$

$$\hat{y}_{n+d,M} = \theta'_{n,M} \phi_{n,M}, \tag{5.4c}$$

$$P_n^{-1} = P_{n-1}^{-1} + \xi_n \xi'_n + I/n, \tag{5.4d}$$

where P_{ν_1} is a positive-definite matrix and $\theta_{\nu_1,M}$ represents an initial guess of $\tilde{\theta}$ (e.g., set $\theta_{\nu_1,M} = \tilde{\theta}_{m_1}$), and I denotes the identity matrix.

The recursive algorithm $\theta_{n,M}$ in (5.4) involves the $\mathcal{F}_{n-d}$-measurable matrix gain $P_{n-d}=\{P_{n-d-1}^{-1}+\xi_{n-d}\xi'_{n-d}+I/(n-d)\}^{-1}$. Since $\pi_n(x)$ is the projection of x into the closed convex set $\mathbf{I}_j$ with respect to the norm induced by P_{n-d}^{-1}, it follows from (5.4a) that the extended stochastic Lyapunov function $Q_n \triangleq (\theta_{n,M}-\tilde{\theta})'P_{n-d}^{-1}(\theta_{n,M}-\tilde{\theta})$ satisfies

$$\begin{aligned} Q_n &\leqq (\theta_{n-1,M}-\tilde{\theta}+P_{n-d}\xi_{n-d}(y_n-\hat{y}_{n,M}))'P_{n-d}^{-1}(\theta_{n-1,M}-\tilde{\theta}+P_{n-d}\xi_{n-d}(y_n-\hat{y}_{n,M})) \\ &= Q_{n-1}+(n-d)^{-1}\|\theta_{n-1,M}-\tilde{\theta}\|^2+[\xi'_{n-d}(\theta_{n-1,M}-\tilde{\theta})]^2 \\ &\qquad +2\xi'_{n-d}(\theta_{n-1,M}-\tilde{\theta})(y_n-\hat{y}_{n,M})+\xi'_{n-d}P_{n-d}\xi_{n-d}(y_n-\hat{y}_{n,M})^2, \end{aligned}$$

for $\nu_j \leqq n < \nu_{j+1}$. By making use of Lemmas 1, 2, and 4(ii) to analyze the above recursive inequalities, we have established in [16] the following basic property for the adaptive d-step ahead predictors $\hat{y}_{n+d,M}=\theta'_{n,M}\phi_{n,M}$, which will play a key role in the development in § 6 of asymptotically efficient certainty-equivalence-type rules whose regrets have the logarithmic order (1.24) or (1.25).

THEOREM 5. *Suppose that $C(z)$ is stable and that the random disturbances ε_n in the linear stochastic system* (1.1) *satisfy assumption* (1.3) *and the boundedness condition* $\sup_n |\varepsilon_n|<\infty$ *almost surely. Let $\nu_1<\nu_2<\cdots$ be stopping times with respect to $\{\mathcal{F}_t\}$ and let $\mathbf{I}_j$ be an $\mathcal{F}_{\nu_j}$-measurable, closed, and convex set such that* (5.2) *holds and*

$$\lim_{j\to\infty} (\textit{diameter of } \mathbf{I}_j)=0 \quad \textit{a.s.} \tag{5.5}$$

Define the monitored recursive maximum likelihood algorithm $\theta_{n,M}$ by (5.4), *where π_n is given by* (5.3) *for $\nu_j \leqq n<\nu_{j+1}$. Assume that*

$$\lambda_{\max}(P_n^{-1})\to\infty \textit{ and } \xi'_nP_n\xi_n\to 0 \quad \textit{a.s.} \tag{5.6}$$

Let $\sigma_d^2=E\eta_d^2$, where η_t is given in (2.15). *Then*

$$\begin{aligned} \sum_{i=1}^{n} \{E(y_{t+d}\,|\,\mathcal{F}_t)-\hat{y}_{t+d,M}\}^2 &\leqq (2d-1)(\sigma_d^2+o(1))(\log\det P_n^{-1}) \\ &\quad +o(\log n)+o\left(\sum_{j:\nu_j\leqq n+d}\ \sum_{r=1}^{h+d-1}[\|\xi_{\nu_j-r}\|^2+\|\xi_{\nu_j-r}\|]\right) \quad \text{a.s.} \end{aligned} \tag{5.7}$$

6. Adaptive control schemes based on parallel recursive identification algorithms. In this section we construct a class of certainty-equivalence-type rules that involve parallel implementation of the recursive identification algorithms $\theta_{n,G}$, $\theta_{n,\tilde{G}}$, and $\theta_{n,M}$ described in §§ 3 and 5 and whose control inputs are determined by one of the following three equations at every stage t: (i) $\theta'_{t,G}\phi_{t,G}=y^*_{t+d}$, (ii) $\theta'_{t,M}\phi_{t,M}=y^*_{t+d}$, (iii) $\theta'_{t,\tilde{G}}\phi_{t,\tilde{G}}=w_t$, where y^*_{t+d} represents the target value at stage $t+d$, and the w_t represent extraneous white-noise perturbations that satisfy condition (3.5). We will show that such adaptive control schemes have logarithmic order (1.24) for the regret $\sum_{d+1}^{n}(y_i-y_i^*-\eta_i)^2$ under the following assumptions on the linear stochastic system (1.1):

(6.1) $B(z)$ is stable.

(6.2) $\operatorname{Re}\{C(e^{it})-(d-1/2)a\}>0$ for all $|t|\leqq\pi$ and some $a>0$.

(6.3) The polynomials $z^pA(z^{-1})$, $z^{k-1}B(z^{-1})$ and $z^hC(z^{-1})$ are coprime.

(6.4) $\{\varepsilon_n\}$ satisfies (1.3) and $\sup_n|\varepsilon_n|<\infty$ almost surely.

(6.5) The target value y_n^* at stage n is $\mathcal{F}_{n-d}$-measurable and $\sum_1^n y_i^{*2}=O(n)$ almost surely, $y_n^{*2}=o((\log n)^\gamma)$ almost surely for some $0<\gamma<1$.

For the stochastic gradient algorithm $\phi_{n,G}$, we use the version defined by (3.31), (3.32), and (2.21b)-(2.21d). To define the sequence of stopping times $n_1 < m_1 < n_2 < \cdots$ associated with the modified stochastic gradient algorithm $\theta_{n,\tilde{G}}$ (cf. Theorem 2), take a nondecreasing sequence of constants $K_n \geqq d+h$ such that

$$K_n \to \infty,\ K_n = O((\log n)^{(1/2)\wedge(1-\gamma)}),\ K_{2n} = O(K_n), \tag{6.6}$$

where $\gamma(<1)$ is the same as in (6.5). Define inductively

$$\begin{aligned} n_j = \inf\Bigg\{ n > m_{j-1}\colon \sum_{i=1}^{j-1} (m_i - n_i) \leqq K_n \text{ and} \\ \left(\sum_{r=0}^{p(d)-1} y_{n-r}^2\right) \vee \left(\sum_{r=1}^{k+d-2} u_{n-r}^2\right) \leqq K_n/\log^2(K_n+2)\Bigg\}, \end{aligned} \tag{6.7}$$

$$\begin{aligned} m_j = n_j + \Bigg[K_{n_j} \vee \left(1 \vee \sum_{r=0}^{p(d)-1} y_{n_j-r}^2 \vee \sum_{r=1}^{k+d-2} u_{n_j-r}^2\right) \\ \times \log^2\left\{\sum_{i=1}^{j}\left(2 \vee \sum_{r=0}^{p(d)-1} y_{n_i-r}^2 \vee \sum_{r=1}^{k+d-2} u_{n_i-r}^2\right)\right\}\Bigg]. \end{aligned} \tag{6.8}$$

Note that the n_j and m_j defined by induction in this way are stopping times with respect to $\{\mathcal{F}_t\}$ and satisfy conditions (3.4) and (4.2).

Let $J = \bigcup_i \{n\colon n_i \leqq n \leqq m_i - 1\}$, as in (4.1), $J_n = \{t \in J\colon t \leqq n\}$, and use (3.8) to define the input u_n at stage n if $n \in J$. Using $\#(S)$ to denote the number of elements of a set S, define u_n for $n \notin J$ by

$$\theta'_{n,G}\phi_{n,G} = y^*_{n+d}, \text{ if } \#(J_n) \leqq K_n^{1/2} \quad \text{and } n \notin J. \tag{6.9}$$

By (3.33), (6.9) is well defined almost surely. Note that n_j is the first time n after m_{j-1} for which $\#(J_{n-1}) \leqq K_n$ (signalling too few white-noise excitations) and the subvectors $(y_n, \cdots, y_{n-p(d)+1})'$ and $(u_{n-1}, \cdots, u_{n-k-d+2})'$ of $\phi_{n,G}$ have squared lengths $\leqq K_n/\log^2(K_n+2)$, and that $m_j - n_j$ is a simple function of K_{n_j} and these components of $\phi_{n,G}$. By Lemma 7 below, the stopping times n_j and m_j defined by (6.7) and (6.8) are indeed finite almost surely. Moreover, they satisfy condition (4.23) in view of Lemma 9(i) below.

With n_j and m_j thus defined, define the recursive method-of-moments estimator θ_{m_j} as in § 4, which induces a strongly consistent estimate $\tilde{\theta}_{m_j}$ of the reparametrization $\tilde{\theta}$ in the implicit system (2.17). The cube $\mathbf{I}_j$ with center at $\tilde{\theta}_{m_j}$ and width $c\#_j^{-1/2+\delta}$ is used to define the monitored recursive maximum likelihood algorithm $\theta_{n,M} = (\hat{g}_{n,1}, \cdots, \hat{g}_{n,p(d)}, \hat{b}_{n,1}, \cdots, -\hat{c}_{n,h})'$ by (5.4), in which π_n is given by (5.3) for $\nu_j \leqq n \leqq \nu_{j+1}$, where $\nu_j(\geqq m_j)$ represents the time at which the auxiliary consistent estimate $\tilde{\theta}_{m_j}$ is available for monitoring the $\theta_{n,M}$. *In conjunction with* (3.8) *and* (6.9), we complete the specification of the input sequence $\{u_n\}$ by

$$\theta'_{n,M}\phi_{n,M} = y^*_{n+d} \quad \text{if } \#(J_n) > K_n^{1/2} \text{ and } n \notin J\ (n > \nu_1), \tag{6.10}$$

setting $u_n = w_n$ in the case where $\hat{b}_{n,1} = 0$ (for which u_n is not well defined by (6.10)), and applying (6.9) when $n \leqq \nu_1$. Since $\theta_{n,M} \to \tilde{\theta}$ almost surely and since $b_1 \neq 0$, it follows that with probability 1, $\hat{b}_{n,1} \neq 0$ and u_n is well defined by (6.10) for all large n.

THEOREM 6. *For the sequence of control inputs u_n defined above by* (3.8) *for $n \in J$ and by* (6.9) *and* (6.10) *for $n \notin J$,*

$$\limsup_{n\to\infty} \sum_{i=d+1}^{n} (y_i - y_i^* - \eta_i)^2/\log n \leqq (2d-1)(p(d)+k+d-1+h)E\eta_d^2 \quad \textit{a.s.}, \tag{6.11}$$

under assumptions (6.1)-(6.5), *where* η_i *is defined in* (2.15) *and* $p(d)=p\vee(h-d+1)$. *If furthermore*

$$\log\left(1+\sum_{i=1}^{n} y_i^{*2}\right)=o(\log n)\quad a.s., \tag{6.12}$$

then (6.11) *can be strengthened into*

$$\limsup_{n\to\infty}\sum_{i=d+1}^{n}(y_i-y_i^*-\eta_i)^2/\log n\leqq(2d-1)\{p(d)+k+d-2\}E\eta_d^2\quad a.s. \tag{6.13}$$

We preface the proof of Theorem 6 by the following five lemmas.

LEMMA 7. *Suppose that the inputs* u_n *are so chosen that* (6.9) *holds. Then* $\#(J)=\infty$ *almost surely.*

Proof. On the event $\{\#(J)<\infty\}$, it follows from (6.9) that $\theta'_{n,G}\phi_{n,G}=y^*_{n+d}$ for all large n, and therefore by (2.24) (cf. Theorem 3),

$$\sum_{n=1}^{N}\left\{\sum_{r=0}^{p(d)-1}y_{n-r}^2+\sum_{r=1}^{k+d-2}u_{n-r}^2\right\}=O(N)\quad \text{a.s. on } \{\#(J)<\infty\}, \tag{6.14}$$

noting that $\sum_1^N(y_i^*)^2=O(N)$ almost surely by (6.5). Since $K_n\to\infty$, (6.14) implies that

$$P\{\#(J)<\infty\}=P\left\{\#(J)<\infty \text{ and } \sum_{r=0}^{p(d)-1}y_{n-r}^2+\sum_{r=1}^{k+d-2}u_{n-r}^2\right.$$
$$\left.\leqq K_n/\log^2(K_n+2) \text{ for infinitely many } n\text{'s}\right\}=0,$$

where the last equality follows from (6.7). Hence $\#(J)=\infty$ almost surely. □

Define the following subsets of integers $\geqq d+1$:

$$\begin{aligned}\Lambda_N&=\{t\leqq N: t-d\notin J \text{ and } \#(J_{t-d})\leqq K_{t-d}^{1/2}\}=\{t\leqq N: (6.9) \text{ is used at } n=t-d\},\\ L_N&=\{t\leqq N: t-d\notin J \text{ and } \#(J_{t-d})>K_{t-d}^{1/2}\}=\{t\leqq N: (6.10) \text{ is used at } n=t-d\}.\end{aligned} \tag{6.15}$$

LEMMA 8. (i) $\#(J_n)=O(K_n)$ *almost surely.*

(ii) $\sum_{d+1}^n(y_i-y_i^*-\eta_i)^2=o(n)$ *and* $\sum_1^n(y_i^2+u_i^2)=O(n)$ *almost surely.*

Proof. (i) Let $\#_j=\sum_{i=1}^j(m_i-n_i)$. From (6.7) it follows that

$$\#_{j-1}\leqq K_{n_j},\quad\left(\sum_{r=0}^{p(d)-1}y_{n_j-r}^2\right)\vee\left(\sum_{r=1}^{k+d-2}u_{n_j-r}^2\right)\leqq K_{n_j}/\log^2(K_{n_j}+2). \tag{6.16}$$

Clearly (6.8) implies that

$$\sum_{i=1}^{j}\left(2\vee\sum_{r=0}^{p(d)-1}y_{n_i-r}^2\vee\sum_{r=1}^{k+d-2}u_{n_i-r}^2\right)=O\left(\sum_{i=1}^{j}(m_i-n_i)\right)=O(\#_j). \tag{6.17}$$

From (6.8), (6.16), and (6.17), it follows that with probability 1, for all large j,

$$\#_j\leqq(m_j-n_j)+K_{n_j}\leqq 2K_{n_j}+\{K_{n_j}/\log^2(K_{n_j}+2)\}\log^2\#_j. \tag{6.18}$$

Since (6.18) implies that $\log\#_j\leqq(1+o(1))\log K_{n_j}$ almost surely, we obtain from (6.18) that $\#_j\leqq(3+o(1))K_{n_j}$ almost surely, giving the desired conclusion in view of the monotonicity of K_n.

(ii) Since $y_t^* = \hat{y}_{t,G}$ for $t \in \Lambda_n$ and $y_t^* = \hat{y}_{t,M}$ for $t \in L_n$, it follows from Corollary 1, (6.18), (6.5), and (6.6) that

$$\sum_1^n (y_t - y_t^* - \eta_t)^2 = \sum_{t \in \Lambda_n} (y_t - \hat{y}_{t,G} - \eta_t)^2 + \sum_{t \in L_n} (y_t - \hat{y}_{t,M} - \eta_t)^2 + o(K_n (\log n)^\gamma) \quad \text{a.s.} \tag{6.19}$$

By Theorem 3, (2.23) holds and therefore by the Kronecker lemma,

$$\sum_1^n (y_t - \hat{y}_{t,G} - \eta_t)^2 = o\left(\sum_1^{n-d} (y_t^2 + u_t^2) + \sum_1^{n-1} \hat{y}_{t,G}^2 \right) + O(1) \quad \text{a.s.} \tag{6.20}$$

Since $C(q^{-1})(y_t - \hat{y}_{t,M} - \eta_t) = -(\theta_{t-d,M} - \tilde{\theta})'\phi_{t-d,M}$ by Lemma 2 and since $\theta_{t-d,M} - \tilde{\theta} \to 0$ almost surely, it follows from the stability of $C(z)$ and Lemma 4(ii) that

$$\begin{aligned} \sum_1^n (y_t - \hat{y}_{t,M} - \eta_t)^2 &= o\left(\sum_1^n \|\phi_{t-d,M}\|^2 \right) + O(1) \\ &= o\left(\sum_1^{n-d} (y_t^2 + u_t^2) + \sum_1^{n-1} \hat{y}_{t,M}^2 \right) + O(1) \quad \text{a.s.} \end{aligned} \tag{6.21}$$

By (6.19)-(6.21) together with (6.4) and (6.5),

$$\begin{aligned} \sum_1^n y_t^2 &\leqq 2 \sum_1^n (y_t^* + \eta_t)^2 + 2 \sum_1^n (y_t - y_t^* - \eta_t)^2 \\ &= O(n) + o\left(\sum_1^{n-d} y_t^2 + \sum_1^{n-d} u_t^2 + \sum_1^{n-1} (\hat{y}_{t,G}^2 + \hat{y}_{t,M}^2) \right) \quad \text{a.s.} \end{aligned} \tag{6.22}$$

Moreover, by (6.20)-(6.22) and (6.4),

$$\begin{aligned} \sum_1^n \hat{y}_{t,G}^2 + \sum_1^n \hat{y}_{t,M}^2 &\leqq 2 \sum_1^n (y_t - \hat{y}_{t,G} - \eta_t)^2 + 2 \sum_1^n (y_t - \hat{y}_{t,M} - \eta_t)^2 \\ &\quad + 4 \sum_1^n (y_t - \eta_t)^2 \\ &= O(n) + o\left(\sum_1^{n-d} y_t^2 + \sum_1^{n-d} u_t^2 + \sum_1^{n-1} (\hat{y}_{t,G}^2 + \hat{y}_{t,M}^2) \right) \quad \text{a.s.} \end{aligned} \tag{6.23}$$

Since $B(z)$ is stable, we can use Lemma 4(i) together with (6.4) to obtain that

$$\sum_1^{n-d} u_t^2 = O\left(\sum_1^n y_t^2 \right) + O(n) \quad \text{a.s.} \tag{6.24}$$

From (6.22)-(6.24), it follows that

$$\sum_1^n (y_t^2 + \hat{y}_{t,G}^2 + \hat{y}_{t,M}^2) = O(n) \quad \text{a.s.}, \qquad \sum_1^{n-d} u_t^2 = O(n) \quad \text{a.s.} \tag{6.25}$$

Combining (6.19)-(6.21) with (6.35), we obtain that $\sum_1^n (y_t - y_t^* - \eta_t)^2 = o(n)$ almost surely. □

LEMMA 9. (i) $\liminf_{n\to\infty} \#(J_n)/K_n > 0$ *almost surely.*

(ii) $\lim_{n\to\infty} \#(\Lambda_n) < \infty$ *almost surely, and therefore* $P\{(6.9)$ *is not used to determine the input* u_n *for all large* $n\} = 1$.

Proof. By Lemma 8(ii), $P(\Omega_0)=1$, where $\Omega_0=\{\limsup_{n\to\infty} n^{-1}\sum_1^n (y_i^2+u_i^2)<\infty\}$. On Ω_0, for all large n,

$$\min_{[n/4]\leqq t\leqq [n/2]}\left\{\sum_{r=0}^{p(d)-1} y_{t-r}^2+\sum_{r=1}^{k+d-2} u_{t-r}^2\right\}<\min_{t\geqq[n/4]} K_t/\log^2(K_t+2). \tag{6.26}$$

In view of the definition of n_j in (6.7), (6.26) implies that either $\#(J_{[n/4]})\geqq K_{[n/4]}$ or there exists $n_j\in\{[n/4],[n/4]+1,\cdots,[n/2]\}$. Since $m_j-n_j\geqq K_{n_j}$ and since K_n is nondecreasing, it then follows that on Ω_0, $\#(J_n)\geqq K_{[n/4]}$ for all large n, and therefore by (6.6), $K_n=O(K_{[n/4]})=O(\#(J_n))$, so there are only finitely many m's for which $\#(J_m)\leqq K_m^{1/2}$. □

LEMMA 10. *$\|\phi_{n,M}\|^2=o(K_n\vee(\log n)^\gamma)$, where γ is given in* (6.5).

Proof. From (3.25), it follows that

$$\max_{n_j+d\leqq t\leqq m_j-1+d}(y_t-w_{t-d}-\eta_t)^2=o(\#_j)\quad\text{a.s.} \tag{6.27}$$

Since $\#_j=O(K_{n_j})$ almost surely by Lemma 8(i) and since $|w_t|\leqq c$, it follows from (6.27) that

$$\lim_{j\to\infty}\left\{\max_{n_j+d\leqq t\leqq m_j-1+d}(y_t-\eta_t)^2/K_t\right\}=0\quad\text{a.s.} \tag{6.28}$$

Defining $\tilde\psi_n$ by (2.17), we obtain by (2.15) that

$$\begin{aligned}\phi_{n,M}-\tilde\psi_n=-(0,\cdots,0,y_{n+d-1}-\hat y_{n+d-1,M}-\eta_{n+d-1},\cdots,&\\ y_{n+d-h}-\hat y_{n+d-h,M}-\eta_{n+d-h})'.&\end{aligned} \tag{6.29}$$

Since by Lemma 2,

$$\begin{aligned}C(q^{-1})(y_n-\hat y_{n,M}-\eta_n)&=-\phi'_{n-d,M}(\theta_{n-d,M}-\tilde\theta)\\ &=-(\phi_{n-d,M}-\tilde\psi_{n-d})'(\theta_{n-d,M}-\tilde\theta)-\tilde\psi'_{n-d}(\theta_{n-d,M}-\tilde\theta),\end{aligned}$$

and since $\theta_{t,M}=(\hat g_{t,1},\cdots,-\hat c_{t,1},\cdots,-\hat c_{t,h})'$, it follows from (6.29) and (2.16) that

$$\hat C_{n-d}(q^{-1})(y_n-\hat y_{n,M}-\eta_n)=-\tilde\psi'_{n-d}(\theta_{n-d,M}-\tilde\theta), \tag{6.30}$$

where $\hat C_t(z^{-1})=1+\hat c_{t,1}z+\cdots+\hat c_{t,h}z^h\to C(z)$ almost surely (as $t\to\infty$). In view of (6.30) and Lemma 4(ii), there exist $D>0$ and $0<\rho_0<1$ such that with probability 1,

$$\begin{aligned}|y_t-\hat y_{t,M}-\eta_t|\leqq D\sup_{i\geqq\nu}\|\theta_{i-d,M}&\\ -\tilde\theta\|\left\{\sum_{i=\nu-d-(p(d)\vee h)}^{t-1}\rho_0^{t-i}(|y_i|+|\eta_i|)+\sum_{i=\nu-k-2d}^{t-d}\rho_0^{t-i}|u_i|\right\}&\\ +D\rho_0^{t-\nu}\sum_{r=0}^{h-1}|y_{\nu-r}-\hat y_{\nu-r,M}-\eta_{\nu-r}|\quad\text{for all } t>\nu.&\end{aligned} \tag{6.31}$$

Since $B(z)$ is stable, it follows from (6.31) and Lemma 4(i) that for some $A>0$ and $0<\rho<1$, we have with probability 1,

$$|y_t-\hat y_{t,M}-\eta_t|\leqq A\sup_{i\geqq\nu}\|\theta_{i-d,M}-\tilde\theta\|\sum_{i=\nu}^{t}\rho^{t-i}(|y_i|+|\varepsilon_i|)+A\rho^tU_\nu,\qquad t>\nu, \tag{6.32}$$

where U_ν is a nonnegative random variable.

Take any $0<\delta<1$. Since $\theta_t \to \tilde{\theta}$ almost surely, it follows from (6.32) that there exists a random variable τ_δ such that with probability 1,

$$|y_t - \hat{y}_{t,M} - \eta_t| \leqq \delta \max_{i \leqq t} (|y_i - \eta_i| + |\eta_i| + |\varepsilon_i|) + \delta \quad \text{for } t \geq \tau_\delta. \tag{6.33}$$

By choosing τ_δ large enough, we also have with probability 1 that

$$\hat{y}_{t,M} = y_t^* \quad \text{if } t \geqq \tau_\delta \quad \text{and } t-d \notin J, \tag{6.34}$$

in view of Lemma 9(ii) and (6.10), and that

$$|y_t - \eta_t| \leqq \delta K_t^{1/2} \quad \text{if } t \geqq \tau_\delta \quad \text{and } t-d \in J, \tag{6.35}$$

in view of (6.28). From (6.33)-(6.35), it follows that with probability 1,

$$|y_t - \eta_t| \leqq \delta K_t^{1/2} + |y_t^*| + \delta \max_{i \leqq t} |y_i - \eta_i| + \delta \max_{i \leqq t} (|\eta_i| + |\varepsilon_i| + 1), \quad t \geqq \tau_\delta,$$

and therefore

$$(1-\delta) \max_{\tau_\delta \leqq i \leqq t} |y_i - \eta_i| \leqq \max_{\tau_\delta \leqq i \leqq t} |y_i^*| + \delta K_t^{1/2} + O(1) \quad \text{as } t \to \infty. \tag{6.36}$$

Since δ can be arbitrarily small and since $\eta_t = O(1)$ almost surely, we obtain from (6.36) and (6.5) that

$$y_t^2 = o(K_t \vee (\log t)^\gamma) \quad \text{a.s.} \tag{6.37}$$

By (6.37) and Lemma 4(ii), $u_t^2 = o(K_{t+d} \vee (\log t)^\gamma)$ almost surely. Moreover, by (6.33) and (6.37), $\hat{y}_{t,M}^2 = o(K_t \vee (\log t)^\gamma)$ almost surely. □

LEMMA 11. (i) $\limsup_{n\to\infty} \sum_{i=1}^{n+d} (y_i - \hat{y}_{i,M} - \eta_i)^2 / \log n \leqq (2d-1)(p(d)+k+d-1+h) E\eta_d^2$ almost surely.

(ii) *Define the* $(p(d)+k+d-1+h) \times 1$ *vectors*

$$v_i = (0, \cdots, 0, 1, \overset{\longleftarrow h-i \longrightarrow}{0, \cdots, 0})', \; i = 1, \cdots, h, \quad v_{h+1} = \tilde{\theta}. \tag{6.38}$$

Then $v_1, \cdots, v_{h+1}$ *are linearly independent, and for* $i = 1, \cdots, h+1$,

$$\sum_{t=d+1}^{n} (v_i' \phi_{t-d,M})^2 = O\left(\log n + \sum_{t=1}^{n} (y_t^*)^2\right) \quad a.s.$$

Proof. (i) By (5.4b), $\hat{C}_n(q^{-1})\xi_n = \phi_{n,M}$, where $\hat{C}_t(z) = 1 + \hat{c}_{t,1} z + \cdots + \hat{c}_{t,h} z^h \to C(z)$ almost surely. Hence by Lemmas 4(ii) and 10,

$$\|\xi_n\|^2 = o(K_n \vee (\log n)^\gamma) \quad \text{a.s.} \tag{6.39}$$

Moreover, by (5.4d),

$$\lambda_{\min}(P_n^{-1}) \geqq \left(\sum_{i=\nu_1+1}^{n} i^{-1} \right) \sim \log n,$$

and therefore in view of (6.39) and (6.6),

$$\xi_n' P_n \xi_n \leqq \|\xi_n\|^2 / \lambda_{\min}(P_n^{-1}) = o(1) \quad \text{a.s.}$$

Hence we can apply Theorem 5 together with (6.40) and Lemma 8(i) to conclude that

$$\begin{aligned} \sum_{t=1}^{n+d} (y_t - \hat{y}_{t,M} - \eta_t)^2 \leqq{} & (2d-1)(E\eta_d^2 + o(1)) \log \det P_n^{-1} + o(\log n) \\ & + o(K_n^2 \vee K_n (\log n)^\gamma) \quad \text{a.s.} \end{aligned} \tag{6.40}$$

By (6.6) and (6.39), $\lambda_{\max}(P_{\nu_1}^{-1} + \sum_{t=\nu_1+1}^{n} \xi_t \xi_t') = o(n \log n)$ almost surely. Hence the desired conclusion follows.

(ii) Fix $i=1,\cdots,h$. From (6.38) and the definition of $\phi_{t,M}$ in (5.4b), it follows that $v_i'\phi_{t-d,M}=\hat{y}_{t-i,M}$. Combining this with (6.34) gives that with probability 1,

$$\sum_{t=d+1}^{n}(v_i'\phi_{t-d,M})^2\leqq\sum_{t=i+1}^{n}(y_{t-i}^*)^2+O(\#(J_{n+h})\sup_{t\leqq n-d}\|\phi_{t,M}\|^2)$$

$$\leqq\sum_{t=1}^{n}(y_t^*)^2+o(K_n^2\vee K_n(\log n)^\gamma),$$

by Lemmas 8(i) and 9. Moreover, by (6.34), with probability 1, for all large t,

$$v_{h+1}'\phi_{t-d,M}=\tilde{\theta}'\phi_{t-d,M}=(\tilde{\theta}-\theta_{t-d,M})'\phi_{t-d,M}+y_t^*\quad\text{if } t-d\notin J.$$

Since $(\tilde{\theta}-\theta_{t-d,M})'\phi_{t-d,M}=C(q^{-1})(y_t-\hat{y}_{t,M}-\eta_t)$ by Lemma 2, it then follows that

$$\sum_{t=d+1}^{n}(v_{h+1}'\phi_{t-d,M})^2=O\left(\sum_{t=1}^{n}(y_t-\hat{y}_{t,M}-\eta_t)^2+\sum_{t=1}^{n}(y_t^*)^2\right)+O(\#(J_n)\sup_{t\leqq n-d}\|\phi_{t,M}\|^2)$$

$$=O\left(\log n+\sum_{t=1}^{n}(y_t^*)^2\right)+o(K_n^2\vee K_n(\log n)^\gamma)\quad\text{a.s.}$$

by (i). Since $b_1\neq 0$, it is clear that $v_1,\cdots,v_{h+1}$ are linearly independent. □

Proof of Theorem 6. From (6.19), (6.6), and Lemmas 8(i) and 9(ii), it follows that

$$\sum_{i=1}^{n}(y_t-y_t^*-\eta_t)^2=\sum_{t\in L_n}(y_t-\hat{y}_{t,M}-\eta_t)^2+o(\log n)\quad\text{a.s.}\tag{6.41}$$

From (6.41) and Lemma 11(i), (6.11) follows.

Suppose furthermore that $\log(1+\sum_1^n(y_t^*)^2)=o(\log n)$ almost surely. Defining the linearly independent vectors $v_1,\cdots,v_{h+1}$ by (6.38), we obtain by Lemmas 4(ii) and 11(ii) that for $i=1,\cdots,h+1$,

$$\sum_{t\leqq n}(v_i'\xi_t)^2=O\left(\sum_{t\leqq n}(v_i'\phi_{t,M})^2\right)=O\left(\log n+\sum_{t=1}^{n+d}(y_t^*)^2\right)\quad\text{a.s.,}$$

noting that $\hat{C}_t(q^{-1})(v'\xi_t)=v'\phi_{t,M}$, where $\hat{C}_t(z)=1+\hat{c}_{t,1}z+\cdots+\hat{c}_{t,h}z^h\rightarrow C(z)$ almost surely. Since $P_n^{-1}=P_{\nu_1}^{-1}+\sum_{t=\nu_1+1}^n(\xi_t\xi_t'+t^{-1}I)$, it then follows that for $i=1,\cdots,h+1$,

$$\log(v_i'P_n^{-1}v_i)=\log\left\{v_i'P_{\nu_1}^{-1}v_i+\sum_{t=\nu_1+1}^{n}[(v_i'\xi_t)^2+t^{-1}\|v_i\|^2]\right\}=O(\log\log n)\quad\text{a.s.}\tag{6.42}$$

By (6.39), with probability 1, for all large n,

$$\log\operatorname{tr}(P_n^{-1})\leqq\log(n\log n)\sim\log n.\tag{6.43}$$

Combining (6.42) and (6.43), we can apply Lemma 5 to conclude that

$$\limsup_{n\to\infty}(\log\det P_n^{-1})/\log n\leqq(p(d)+k+d-1+h)-(h+1)=p(d)+k+d-2\quad\text{a.s.}$$

Therefore by (6.40),

$$\limsup_{n\to\infty}\sum_{t\leqq n}(y_t-\hat{y}_{t,M}-\eta_t)^2/\log n\leqq(2d-1)(p(d)+k+d-2)E\eta_d^2\quad\text{a.s.}$$

This and (6.41) give the desired conclusion (6.14). □

7. Extensions to multivariate systems and concluding remarks. Suppose that in (1.1), the y_n, ε_n, and u_{n-d} are $\nu\times 1$ vectors, and $A(q^{-1})$, $B(q^{-1})$, and $C(q^{-1})$ are matrix polynomials of the form (2.33) in the backward shift operator q^{-1}. As in (6.1), we will assume that $B(z)$ is a stable polynomial, i.e.,

(7.1) $$\det(B(z)) \neq 0 \quad \text{for all } |z| \leqq 1.$$

Moreover, analogous to (6.3)-(6.5), we will assume the following:

(7.2) The polynomials $z^p A(z^{-1})$, $z^{k-1}B(z^{-1})$ and $z^h C(z^{-1})$ are left coprime.

(7.3) $\{\varepsilon_n, \mathscr{G}_n, n \geqq 1\}$ is a martingale difference sequence such that $E(\varepsilon_n \varepsilon_n' \mid \mathscr{G}_{n-1}) = \Sigma$, a positive-definite nonrandom matrix, $\sup_n E(\|\varepsilon_n\|^\alpha \mid \mathscr{G}_{n-1}) < \infty$ almost surely for some $\alpha > 2$, and $\sup_n \|\varepsilon_n\| < \infty$ almost surely.

(7.4) y_n^* is an $\mathscr{F}_{n-d}$-measurable $\nu \times 1$ vector, $\sum_1^n \|y_i^*\|^2 = O(n)$ almost surely and $\|y_n^*\|^2 = o((\log n)^\gamma)$ for some $0 < \gamma < 1$.

In view of (7.1), $B_1 (= B(0))$ is nonsingular.

Let $\theta = (-A_1, \cdots, -A_p, B_1, \cdots, B_k, C_1, \cdots, C_h)'$, analogous to (1.6). In the unit-delay case $d = 1$, we can write (1.1) as a stochastic regression model (2.1) with $\psi_n = (y_n', \cdots, y_{n-p+1}', u_n', \cdots, u_{n-k+1}', \varepsilon_n', \cdots, \varepsilon_{n-h+1}')'$. The optimal controller assuming knowledge of θ and the initial condition x_0 determines the input u_n by the equation

(7.5) $$\theta' \psi_n = y_{n+1}^*.$$

In ignorance of θ and x_0, the so-called *explicit* (or *indirect*) approach of adaptive control is to replace θ in (7.5) by a recursive estimator θ_n and ψ_n by a pseudoregression vector ϕ_n that substitutes the unobservable ε_i in ψ_n either by the prediction error $y_i - \theta_{i-1}'\phi_{i-1}$ or by the residual $y_i - \theta_i'\phi_{i-1}$. In particular, Chen [27] used a modified least squares algorithm for θ_n, while Chen and Caines [28] used a stochastic gradient algorithm, and showed that the certainty-equivalence controller associated with either algorithm has the self-optimizing property (1.19) (with $R_n = \sum_2^N \|y_i - y_i^* - \varepsilon_i\|^2$) under certain assumptions.

In the unit-delay, single-input, single-output case (i.e., $d = 1 = \nu$), instead of the implicit approach as in § 6, we can use the explicit approach involving a parallel implementation of the stochastic gradient algorithms $\theta_{n,G}$, $\theta_{n,\tilde{G}}$ and the recursive maximum likelihood algorithm $\theta_{n,M}$ that are obvious modifications of (2.21), (3.7), and (5.4) for estimating the parameter vector (1.6) of the explicit model, instead of the parameter vector $\tilde{\theta}$ of the implicit model (2.17) considered in § 6. As shown in [16], there are exact analogues of Theorems 1 and 5 for the explicit case, and Theorems 2 and 3 can clearly be extended to the explicit case as well. The same argument also works for multivariable systems, for which we replace assumption (6.2) by

(7.6) $C(e^{it}) + C'(e^{-it}) - aI$ is positive definite for all $|t| \leqq \pi$ and some $a > 0$,

as has also been assumed by Chen and Caines [28]. Note that Lemma 3, which is a key tool in the proof of Theorem 2, has been stated for the multivariate positive real assumption (7.6). Moreover, Lemma 6, which is a key tool in the proof of Theorem 4, has also been stated under the multivariate coprime condition (7.2). Hence it is straightforward to generalize Theorem 4 to the multivariate case, and we can therefore obtain strongly consistent estimates of $(-A_1, \cdots, -A_p, B_1, \cdots, B_k)'$ by using the instrumental variables $Z_t = (y_{t-h-1}', \cdots, y_{t-h-k+1}', w_{t-1}', \cdots, w_{t-p-k}')'$, where the w_i satisfy the multivariate version of (3.5) and have a common positive-definite covariance matrix. A multivariate extension of the recursive implementation (4.24) of Wilson's [29] spectral factorization algorithm for multivariate time series can also be used to obtain strongly consistent estimates of $C_1, \cdots, C_h$, leading to the auxiliary estimator θ_{m_j} that satisfies (4.28).

Hence for unit-delay multivariate systems, under assumptions (7.1)-(7.4) and (7.6), we can modify the construction in § 6 (by using the explicit instead of the implicit approach) to obtain certainty-equivalence-type control rules that satisfy

$$\limsup_{n\to\infty} \sum_{i=2}^{n} \|y_i - y_i^* - \varepsilon_i\|^2/\log n \leqq \nu(p+k+h)\operatorname{tr}(\Sigma) \quad \text{a.s.} \tag{7.7}$$

Furthermore, if $\log(1+\sum_1^n \|y_i^*\|^2) = o(\log n)$ almost surely, then in analogy with (6.14), (7.7) can be strengthened as

$$\limsup_{n\to\infty} \sum_{i=2}^{n} \|y_i - y_i^* - \varepsilon_i\|^2/\log n \leqq \nu((p \vee h)+k-1)\operatorname{tr}(\Sigma) \quad \text{a.s.} \tag{7.8}$$

For the case of general delay, the construction in § 6 generalizes immediately to multivariable systems that satisfy either

$$A_j = a_j I \quad \text{for } j=1,\cdots,p, \tag{7.9}$$

so that $A(q^{-1})$ can be reduced to a scalar polynomial $1+a_1q^{-1}+\cdots+a_pq^{-p}$, or

$$C_j = c_j I \quad \text{for } j=1,\cdots,h, \tag{7.10}$$

so that $C(q^{-1})$ can be reduced to scalar polynomial $1+c_1q^{-1}+\cdots+c_hq^{-h}$. When (7.10) holds, $C(z)$ commutes with any $\nu\times\nu$ matrix polynomial and the minimum variance d-step ahead predictor $\tilde{y}_t \triangleq E(y_{t+d}\mid\mathcal{F}_t)$ can still be written in the form (2.14) with FB instead of BF, where $F(z)$, $G(z)$ are matrix polynomials uniquely determined by (2.12) (cf. [14, p. 135]). Hence a straightforward generalization of the construction in § 6 (using the implicit approach) leads to adaptive control rules that satisfy

$$\limsup_{n\to\infty} \sum_{i=1}^{n} \|y_i - y_i^* - \eta_i\|^2/\log n \leqq (2d-1)\{\nu(p(d)+k+d-1)+h\}E(\|\eta_d\|^2), \tag{7.11}$$

where $\eta_t = F(q^{-1})\varepsilon_t$, under assumptions (7.1)-(7.4) and (6.2), noting that $C(z)$ can be treated as a scalar polynomial in this case.

Case (7.9) has been studied by Goodwin, Ramadge, and Caines [8]. Let $\bar{c}(z) = \det(C(z))$ and $\tilde{C}(z)$ be the adjoint of $C(z)$. Let $F(z)$, $G(z)$ be the matrix polynomials uniquely determined by (2.12). Then (1.1) can be written in the following (d-step ahead) prediction form:

$$\bar{c}(q^{-1})[y_{n+d} - F(q^{-1})\varepsilon_{n+d}] = G(q^{-1})\tilde{C}(q^{-1})y_n + F(q^{-1})\tilde{C}(q^{-1})B(q^{-1})u_n \tag{7.12}$$

(cf. [8, pp. 852-853]). Hence, under assumptions (7.1)-(7.4) and

$$\operatorname{Re}\{\bar{c}(e^{it}) - (d-\tfrac{1}{2})a\} > 0 \quad \text{for all } |t| \leqq \pi \text{ and some } a>0, \tag{7.13}$$

a straightforward generalization of the construction in § 6 gives adaptive control rules whose regrets $\sum_{i=1}^n \|y_i - y_i^* - F(q^{-1})\varepsilon_i\|^2$ have logarithmic order. For $d=1$ (unit delay), assuming the positive real condition (7.13) together with some other conditions, Goodwin, Ramadge, and Caines [8] used the stochastic gradient algorithm to construct self-optimizing controllers in this case.

The logarithmic order for the regret of asymptotically efficient control rules also appears in the following classical problem of stochastic adaptive control. Consider k independent statistical populations specified respectively by univariate density functions $f(y;\theta_j)$ with finite means $\mu(\theta_j)$, $j=1,\cdots,k$, where the θ_j are unknown parameters belonging to some set Θ. How should we sample $y_1, y_2, \cdots$ sequentially from the k populations to maximize, in some sense, the expected value of the sum $S_n = y_1+\cdots+y_n$ as $n\to\infty$? This is the so-called "multi-armed bandit problem," whose name derives from an imagined slot machine with $k \geqq 2$ arms. When an arm is pulled, the player wins a random reward. For each arm j there is an unknown probability distribution Π_j of the reward. The player's problem is to choose a sequence of pulls on the k arms so as to maximize the long-run expected total reward (cf. [2], [30]).

Let $\theta = (\theta_1, \cdots, \theta_k)'$, $\mu^*(\theta) = \max_{j \leqq k} \mu(\theta_j)$. When θ is known, the optimal rule is to sample from the population whose mean attains $\mu^*(\theta)$. Without assuming θ to be known, an adaptive allocation rule u is a sequence of random variables $u_1, u_2, \cdots$, taking values in the set $\{1, \cdots, k\}$ and such that the event $\{u_n = j\}$ ("sample from Π_j at stage n") belongs to the σ-field $\mathscr{F}_{n-1}$ generated by the previous observations $u_1, y_1, \cdots, u_{n-1}, y_{n-1}$. Robbins [30] formulated a notion of "asymptotic optimality" for an adaptive allocation rule u as attaining

$$\lim_{n \to \infty} n^{-1} E_\theta S_n = \mu^*(\theta) \quad \text{for all } \theta \in \Theta. \tag{7.14}$$

This is analogous to the "self-optimizing" criterion (1.19′) for adaptive controllers in the ARMAX system (1.1). In the case $k = 2$, Robbins introduced the following class of certainty-equivalence rules with forced learning to achieve (7.14). Sample from Π_1 during stages $n_1 < n_2 < \cdots$ and from Π_2 during stages $n_1^* < n_2^* < \cdots$, where $\{n_i\}$ and $\{n_i^*\}$ are disjoint sequences of positive from Π_2 during stages $n_1^* < n_2^* < \cdots$, where $\{n_i\}$ and $\{n_i^*\}$ are disjoint sequences of positive integers such that $n_i / i \to \infty$ and $n_i^* / i \to \infty$. At stage $n \notin \{n_1, n_2, \cdots, n_1^*, n_2^*, \cdots\}$, sample from the population with the larger sample mean.

For an adaptive allocation rule, $E_\theta S_n = \sum_{j=1}^k \mu(\theta_j) E_\theta T_n(j)$, where $T_n(j)$ denotes the total number of observations from Π_j up to stage n (cf. [31]). Thus, maximizing $E_\theta S_n$ is equivalent to minimizing $E_\theta R_n$, where we define the regret R_n by

$$R_n = \sum_{j: \mu(\theta_j) < \mu^*(\theta)} (\mu^*(\theta) - \mu(\theta_j)) T_n(j), \tag{7.15}$$

which is a weighted sum of the sample sizes from the "inferior" populations. Note the analogy between (7.15) and (1.16). Lai and Robbins [31] recently showed that for any adaptive allocation rule satisfying $E_\theta R_n = o(n^a)$ for every $a > 0$ and every θ, we also have

$$\liminf_{n \to \infty} E_\theta R_n / \log n \geqq \sum_{j: \mu(\theta_j) < \mu^*(\theta)} (\mu^*(\theta) - \mu(\theta_j)) / I(\theta, \theta^*), \tag{7.16}$$

where $\mu(\theta^*) = \max_{j \leqq k} \mu(\theta_j)$ and $I(\theta, \lambda)$ denote the Kullback-Leibler information number. Moreover, adaptive allocation rules that attain the asymptotic lower bound in (7.16) at every θ are constructed in [31] for various parametric families of distributions. Such rules involve certain upper confidence bounds for $\mu(\theta_j)$ and are typically of the form: Sample at each stage from the population with the largest upper confidence bound. These upper confidence bounds are constructed by using generalized likelihood ratios, analogous to the maximum likelihood approach of § 5 that has been used in the construction of asymptotically efficient adaptive controllers for the ARMAX model in § 6.

As pointed out in [32], a common difficulty in the multi-armed bandit problem, the adaptive control problem in ARMAX systems studied herein, and the multiperiod control problem of choosing the design levels u_i in the regression model (1.20) to minimize $E(\sum_1^N y_i^2)$ is the dilemma between the object of efficient control and the need for information in estimating the system parameters. Although a Bayesian formulation (involving a suitable prior distribution on the unknown parameters) and the associated Bayes solution should, in principle, be able to resolve this dilemma, the Bayesian optimal control problem is prohibitively difficult to solve either numerically or analytically. A useful heuristic principle described in [32] to avoid these difficulties is to consider the fictitious situation that assumes knowledge of some crucial parameter(s) so that there is negligible conflict between estimation and control, leading to a more tractable Bayes problem. Analysis of this fictitious situation yields the asymptotic lower bound (7.16) for the expected regret in the multi-armed bandit problem, the logarithmic order (1.23) of the regret of the optimal rule in the multiperiod control problem for the regression model (1.20) with known β, and the asymptotic lower bound (1.14) for the Bayes regret in the regulation problem for the ARX model that assumes b_1 to be known (cf. [4], [5], [32]). The ensuing task, therefore, is to develop recursive control schemes whose regrets do not exceed asymptotically those in (7.16), (1.23), or (1.14), even when *all* parameters are unknown.

For the adaptive control problem of ARMAX systems, we have shown in § 6 that a modified version of the simple certainty-equivalence idea is powerful enough to accomplish this task. Since the goal is to emulate the performance of the Bayes rule, which is too complex even for off-line implementation, it is intuitively clear that a statistically efficient estimator should be used for the certainty-equivalent rule. This explains the use of the monitored recursive maximum likelihood algorithm introduced in § 5. Except in the white-noise case $C(z)=1$, the estimating equations defining the off-line maximum likelihood estimators (assuming independently and identically distributed Gaussian disturbances ε_i) are highly nonlinear. However, when monitored by an auxiliary *consistent* estimator, the recursive maximum likelihood estimator $\theta_{n,M}$ (which corresponds at every stage to a one-step Gauss–Newton iteration to solve the off-line estimating equation) is asymptotically as efficient as its off-line counterpart (cf. [33]). The need for an auxiliary consistent estimator (which we construct by the method of moments applied to blocks of well-excited input-output data) accounts for the modification (3.8) of the certainty-equivalence rule based on $\theta_{n,M}$. During the initial stages when the auxiliary consistent estimator may not be sufficiently reliable, it seems more prudent to use the stochastic gradient algorithm $\theta_{n,G}$ (which is known to have a stabilizing effect) instead of the (possibly not well monitored) $\theta_{n,M}$ in the certainty-equivalence rule. This is the rationale behind the additional modification (6.9) of the obvious certainty-equivalence rule based on $\theta_{n,M}$. Since the algorithms $\theta_{n,M}$, $\theta_{n,G}$, and $\theta_{n,\tilde{G}}$ used in the certainty-equivalence inputs of Theorem 6 are all recursive, running them in parallel does not cause difficulties for on-line implementation.

As shown in [33], the classical method of moments, which involves only a fixed number of auto/cross-covariances that can be easily updated, offers a reliable and versatile way to construct consistent recursive estimators in ARMAX systems but has not been fully explored in the recursive identification literature. Although the method of moments and its application only to certain segments of all available data are inefficient statistical procedures, they provide valuable initial parameter estimates around which we can linearize the complicated nonlinear estimating equations that define the statistically efficient but computationally intensive off-line maximum likelihood estimators. Such linearization leads to the monitored recursive maximum likelihood estimator of § 5, which is asymptotically as efficient as its off-line counterpart. Note in this connection that although the AML algorithm (2.6) has been called "approximate maximum likelihood," its statistical properties are actually unrelated to those of the off-line maximum likelihood estimator associated with Gaussian ε_i. Although it has some resemblance to the iterative EM algorithm that is sometimes used to compute the off-line maximum likelihood estimator, the AML algorithm is nothing more than a formal extension of the recursive least squares algorithm (2.2) and can run into serious difficulties when $C(z)$ differs so much from 1 (the white-noise case) that the positive real assumption (2.8) is violated (cf. [33]).

SENSITIVITY ANALYSIS OF OPTIMAL CONTROL PROBLEMS FOR WAVE EQUATIONS*

IRENA LASIECKA† AND JAN SOKOŁOWSKI‡

Abstract. Differential stability of the optimal solutions to an optimal control problem for hyperbolic partial differential equation is shown. The related results on the sensitivity analysis for hyperbolic equation with respect to perturbations of the coefficients of elliptic operator are provided.

Key words. wave equation, metric projection, sensitivity analysis, control constraints

AMS(MOS) subject classifications. 49B22, 49A29, 49A22, 93B30

1. Introduction. This paper is devoted to the sensitivity analysis of the boundary control constrained optimal control problems for the wave equation. We use the method proposed in [S6] combined with the recent results on the regularity of solutions to the wave equation [LLT], [LT1]. We consider for simplicity a quadratic problem; however, the same argument can be used in the convex case.

Since, in general, the model of the distributed parameter system described by the wave equation may not be known exactly, our results can be used to evaluate the increments of an optimal control corresponding to the given increments of the data, e.g., variable coefficients of the partial differential equation, or to the perturbation of the domain of integration.

For a specific convex optimal control problem any optimal control satisfies the necessary and sufficient optimality conditions in the form of an optimality system [L2]. By inspection of the optimality system it follows that in the case of control constraints, an optimal control is given by the unique fixed point of a metric projection onto the set of admissible constraints. This particular form of the optimal control allows us to obtain the right derivative of an optimal control with respect to the parameter. To this end the notion of Hadamard directional differentiability of the metric projection onto the polyhedric convex set in Hilbert space [H1], [M], is used. It seems that the same method of sensitivity analysis can be used for some nonconvex optimization problems such that the related results on the Hölder continuity of an optimal solution with respect to the parameter are known, such problems are the subject of a paper in preparation. There are several papers and monographs concerning the sensitivity analysis of finite-dimensional problems, in particular, in mathematical programming. On the other hand, the infinite-dimensional case requires the knowledge of the new results on the differential stability of metric projection onto the specific convex, closed subsets of Sobolev spaces. Such results are known in general only for a class of polyhedric sets [H1], [M], [RS2] defined by specific local constraints.

We provide here the results on sensitivity analysis for the wave equation which, we believe, is interesting on its own. We restrict ourselves in the present paper to a model problem. However, the method proposed here is general and can be used for a broad class of control problems including a class of state constrained optimal control problems, such as those considered in [RS1] in the elliptic case.

Consider the following optimal control problem depending on parameter $\varepsilon \in [0, \delta)$.

PROBLEM (P_ε). Find an element $u_\varepsilon \in K$ that minimizes the cost functional

$$I_\varepsilon(u) = \tfrac{1}{2}(Ry(T), y(T))_\Omega + \tfrac{1}{2}|u|_\Sigma^2 \tag{1.1}$$

over the convex set $K \subset L^2(\Sigma)$ of the form

$$K = \{u \in L^2(\Sigma) \,|\, 0 \leqq u(x, t) \leqq M \text{ for a.e. } (x, t) \in \Sigma\}. \tag{1.2}$$

Here by y we denote the solution of the state equation

$$y_{tt} = A_\varepsilon(x, \partial)y \quad \text{in } \Omega \times (0, T) \tag{1.3}$$

with the Neumann boundary condition

$$\frac{\partial y}{\partial n} = u \quad \text{on } \Sigma \tag{1.4}$$

subject to initial conditions

$$y(0) = y_0, \quad y_t(0) = y_1 \quad \text{in } \Omega, \tag{1.5}$$

where $u \in L^2(\Sigma)$ is control, and $y_0 \in L^2(\Omega)$ and $y_1 \in H^1(\Omega)$ are given elements. Here we have used the following notation:

$$A_\varepsilon(x, \partial)y = \operatorname{div}(a_\varepsilon \nabla y) \quad \forall y \in H^2(\Omega),$$

$$\varepsilon \in [0, \delta), \quad \delta > 0 \quad \text{is parameter},$$

$$\Omega \subset R^n, \quad Q = \Omega \times (0, T), \quad T > 0,$$

$$\Gamma = \partial\Omega, \qquad \Sigma = \partial\Omega \times (0, T),$$

$$\nabla y = \left(\frac{\partial y}{\partial x_1}, \cdots, \frac{\partial y}{\partial x_n}\right),$$

$$\mathbf{z} = (z_1, \cdots, z_n),$$

$$|\phi|_\Omega^2 = \int_\Omega [\phi(x)]^2\, dx,$$

$$|\phi|_\Gamma^2 = \int_\Gamma [\phi(x)]^2\, d\sigma,$$

$$|\phi|_\Sigma^2 = \int_0^T |\phi(x)|_\Gamma^2\, dt.$$

$H^2(\Omega)$ for $s \geqq 0$ denotes the usual Sobolev space of order s. $H^{-s}(\Omega) \equiv (H^s(\Omega))'$ where the duality is understood with respect to the pivot space $L^2(\Omega)$.

The following assumptions are imposed on the data of the problem: $\Omega \subset R^n$ is a bounded, open domain with the smooth boundary Γ. The coefficients $a_\varepsilon(x)$ are given by (for each $\varepsilon > 0$)

$$a_\varepsilon(x) = a_0(x) + \varepsilon a_1(x) + o(\varepsilon)(x) \quad \text{in } C^1(\Omega), \tag{1.6}$$

where $a_0(x) \geqq c > 0$ in Ω

$$R: L^2(\Omega) \to L^2(\Omega), \qquad R = R^* > 0$$

and either

(1.7) (i) $R \in \mathscr{L}(H^s(\Omega))$, $0 < s < \frac{1}{2}$ and $y_0 \in H^{1/2}(\Omega)$; $y_1 \in (H^{1/2}(\Omega))' = H^{-1/2}(\Omega)$, or

(1.7) (ii) $R \in \mathscr{L}(H^s(\Omega); H^{s-1}(\Omega))$, $1 \leqq s \leqq \frac{3}{2}$ and $y_0 \in H^{3/2}(\Omega)$, $y_1 \in H^{1/2}(\Omega)$.

It is standard to show that the optimal solution u_ε to the problem (P_ε) exists, is unique, and

$$|u_\varepsilon|_\Sigma \leqq C \quad \text{uniformly in } \varepsilon > 0.$$

The same holds true for unbounded set (1.2) of admissible controls, i.e., for $M = +\infty$.

Our main goal in this paper is to characterize the right-derivative q of the unique solution $u_\varepsilon \in K$ of Problem (P_ε) with respect to the parameter ε at $\varepsilon = 0$.

Several results on differential stability of solutions to control problems for elliptic and parabolic partial differential equations are given in [S1]-[S7] and [MS]. Problems with the state constraints are considered in [RS1]. The related results on sensitivity analysis of the variational inequalities can be found in [M], [H-S-Z], and [FP].

In the hyperbolic case, the main difficulty is related to the intrinsic "low" regularity of the solutions with the boundary inputs in $L^2(\Sigma)$. In fact, standard regularity theory for the wave equation with boundary nonhomogenous data (see [LM]) is inadequate to obtain the results on differential stability for Problem (P_ε). To cope with the problem, we shall use the recently obtained (in [LT1]) "sharp" regularity results for the Neumann problem, which will play a crucial role in our analysis.

Our main result is formulated in the theorem below.

THEOREM 1. *For each $\varepsilon > 0$, ε small enough*

$$u_\varepsilon = u_0 + \varepsilon q + o(\varepsilon) \quad \text{in } L^2(\Sigma), \tag{1.8}$$

where $|o(\varepsilon)|_\Sigma/\varepsilon \to 0$ with $\varepsilon \downarrow 0$.

The element $q \in L^2(\Sigma)$ is given by a unique solution of the following optimal control problem.

PROBLEM (Q). Find an element $q \in S \subset L^2(\Sigma)$ that minimizes the cost functional

$$J(u) = \tfrac{1}{2}(Rz(T), z(T))_\Omega + \tfrac{1}{2}|u|_\Sigma^2 \tag{1.9}$$

over cone

$$\begin{aligned} S = \{u \in L^2(\Sigma) \mid\, & u(x) \geqq 0 \text{ a.e. on } \{u_0(x) = 0\}, \\ & u(x) \leqq 0 \text{ a.e. on } \{u_0(x) = M\}, \\ & \textstyle\int_\Sigma (u_0(x,t) + a_0(x)p_0(x,t))u(x,t)\, d\Sigma = 0\}. \end{aligned} \tag{1.10}$$

Here we denote by $p_0 \in L^2(\Sigma)$ the trace on Σ of the adjoint state associated to the problem (P_0) (i.e., (P_ε) with $\varepsilon = 0$), i.e., $p \equiv p_0$ satisfies

$$p_{tt} = A(x, \partial)p, \qquad \frac{\partial}{\partial n} p = 0,$$

$$p(T) = 0, \qquad p_t(T) = Ry^0(T).$$

The state z for Problem (Q) is given for a given control $u \in L^2(\Sigma)$ by the unique solution of the following system:

$$z_{tt} = \operatorname{div}(a_0 \nabla z + a_1 \nabla y^0) \quad \text{in } Q, \tag{1.11}$$

$$\frac{\partial z}{\partial n} = u + \frac{a_1}{a_0} u_0 \quad \text{on } \Sigma, \tag{1.12}$$

$$z(0) = 0, \quad z_t(0) = 0 \quad \text{in } \Omega, \tag{1.13}$$

where y^0 is the solution of system (1.3)-(1.5) for $\varepsilon = 0$ and for $u = u_0$.

By standard argument it follows that an optimal control u_ε is uniquely determined by the optimality system [L2]. Let us recall that to derive the optimality system for Problem (P_ε) we define the Lagrangian

$$L_\varepsilon(u, y, p) \equiv -(y_t, p_t)_Q + (y_t(T), p(T))_\Omega - (y_1, p(0))_\Omega$$
$$+ (a_\varepsilon \nabla y, \nabla p)_Q - (u, a_\varepsilon p)_\Sigma + \tfrac{1}{2}|u|_\Sigma^2 + \tfrac{1}{2}(Ry(T), y(T))_\Omega, \qquad y(0) = y_0.$$

The first-order optimality conditions

$$\langle \mathscr{D}_y L_\varepsilon(u_\varepsilon, y_\varepsilon, p_\varepsilon); \delta y\rangle_Q = 0 \quad \forall \delta y,$$
$$\langle \mathscr{D}_p L_\varepsilon(u_\varepsilon, y_\varepsilon, p_\varepsilon); \delta p\rangle_Q = 0 \quad \forall \delta p,$$
$$u_\varepsilon \in K: \quad (\mathscr{D}_u L_\varepsilon(u_\varepsilon, y_\varepsilon, p_\varepsilon), v - u_\varepsilon)_\Sigma \geqq 0 \quad \forall v \in K,$$

where δy, $\delta p \in H^1(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega))$, $\delta y(0) = 0$, $\delta y_t(0) = 0$ lead to the following optimality system.

Find $(u_\varepsilon, y^\varepsilon, p^\varepsilon)$ such that the following system is satisfied:

State equation:

$$y^\varepsilon_{tt} = A_\varepsilon(x, \partial) y^\varepsilon \quad \text{in } Q, \tag{1.14}$$

$$\frac{\partial y^\varepsilon}{\partial n} = u_\varepsilon \quad \text{on } \Sigma, \tag{1.15}$$

$$y^\varepsilon(0) = y_0, \quad y^\varepsilon_t(0) = y_1 \quad \text{in } \Omega. \tag{1.16}$$

Adjoint state equation:

$$p^\varepsilon_{tt} = A_\varepsilon(x, \partial) p^\varepsilon \quad \text{in } Q, \tag{1.17}$$

$$\frac{\partial p^\varepsilon}{\partial n} = 0 \quad \text{on } \Sigma, \tag{1.18}$$

$$p^\varepsilon(T) = 0, \quad p^\varepsilon_t(T) = R y_\varepsilon(T) \quad \text{in } \Omega. \tag{1.19}$$

Optimality conditions:

$$u_\varepsilon \in K: \quad \int_\Sigma (u_\varepsilon + a_\varepsilon p_\varepsilon)(v - u_\varepsilon)\, d\Sigma \geqq 0 \quad \forall v \in K. \tag{1.20}$$

We see that an optimal control u_ε takes the form

$$u_\varepsilon = \Pi(-\gamma a_\varepsilon p_\varepsilon) = \Pi(-\{a_\varepsilon p_\varepsilon\}_{|\Sigma});$$

here $\gamma \in \mathscr{L}(H^s(\Omega); H^{s-1/2}(\Gamma))$, $s > \frac{1}{2}$ is the trace operator, Π denotes the metric projection in $L^2(\Sigma)$ onto the convex set (1.2); the explicit form of Π is given by (2.17).

The outline of the paper is as follows. In § 2 we recall the basic results for the wave equation that we need in the sequel. We also present a result on the directional differentiability of the metric projection onto the set of admissible controls.

In § 3 we formulate the results on the sensitivity analysis for the wave equation and prove the main result of the paper. In §§ 4 and 5 we provide the proofs of the results on the sensitivity analysis of the solutions of the state equation used for the Theorem 1.

2. Preliminaries.

2.1. Wave equation; regularity of the solutions. We will consider the optimal control problems for hyperbolic problems. First we recall the basic facts on hyperbolic initial boundary value problems that we use in the sequel.

Let us consider the wave equation

$$y_{tt} = \operatorname{div}(a_0 \nabla y) \quad \text{in } Q, \tag{2.1}$$

$$\frac{\partial y}{\partial n} = u \quad \text{on } \Sigma, \tag{2.2}$$

$$y(0) = y_0, \quad y_t(0) = y_1 \quad \text{in } \Omega, \tag{2.3}$$

where $a_0(\cdot) \in C^1(\bar{\Omega})$ is a given coefficient and $u(\cdot) \in L^2(\Sigma)$. We assume that $a_0(x) \geqq c > 0$, $x \in \bar{\Omega}$. The initial conditions $y_0 \in L^2(\Omega)$, $y_1 \in H^{-1}(\Omega)$. The solution $y(\cdot)$ of system (2.1)-(2.3) can be represented (see [LT2]) in the form

$$y(t) = (Lu)(t) + C(t)y_0 + S(t)y_1, \tag{2.4}$$

where the linear mapping

$$L: L^2(\Sigma) \rightarrow L^2(Q)$$

takes the form

$$(Lu)(t) = A \int_0^t S(t-\tau)(Nu)(\tau)\, d\tau - \int_0^t S(t-\tau)(Nu)(\tau)\, d\tau. \tag{2.5}$$

Here $A: L^2(\Omega \rightarrow L^2(\Omega))$ denotes the generator of the analytic semigroup associated with $A(x, \partial)$ and zero Neumann boundary conditions with

$$D(A) \equiv \{y \in H^2(\Omega);\ \partial y/\partial n|_\Gamma = 0\},$$

$C(t)$ and $S(t)$ are cosine and sine operators associated with A, and the Neumann operator is defined as follows:

$$N: L_2(\Gamma) \rightarrow L_2(\Omega),$$

$$-\operatorname{div}(a_0 \nabla(Nu)) + Nu = 0 \quad \text{in } \Omega, \tag{2.6}$$

$$\frac{\partial(Nu)}{\partial n} = u \quad \text{on } \Gamma. \tag{2.7}$$

By applying the regularity results of [LM] we obtain

$$L \in \mathscr{L}(L^2(\Sigma);\ C[0, T;\ H^{1/2}(\Omega)]). \tag{2.8}$$

Hence the adjoint (adjoint in the sense of L^2-topology) operator

$$L^* \in \mathscr{L}(L^1[0, T;\ (H^{1/2}(\Omega))'];\ L^2(\Sigma)), \tag{2.9}$$

where L^* is defined as follows:

$$(L^*f)(t) = \int_t^T N^*A^*S^*(\tau - t)f(\tau)\, d\tau = a_0\left(\int_t^T S^*(\tau - t)f(\tau)\, d\tau\right)\bigg|_\Gamma. \tag{2.10}$$

To obtain (2.10), we use

$$N^*A^*z = a_0 z|_\Gamma \quad \forall z \in D(A^*), \tag{2.11}$$

which can be obtained using Green's formula.

We will also need some properties of the linear mapping

$$L_T^*: L^2(\Sigma) \rightarrow (Lu)(T) \in D(A^{1/4}) = H^{1/2}(\Omega) \tag{2.12}$$

and of the adjoint mapping

$$L_T^*: D(A^{1/4})' \rightarrow L^2(\Sigma), \tag{2.13}$$

where

$$(L_T^*\psi)(t) = a_0(S^*(T-t)\psi)|_\Gamma \quad \forall \psi \in L^2(\Omega)$$

and X' stands for the dual space to X with respect to $L_2(\Omega)$ topology. To obtain (2.12), we have used the following identification:

$$\text{(2.14)} \qquad D(A^Q) = H^{2Q}(\Omega), \qquad 0 \leqq Q < \tfrac{3}{4}.$$

In the case where the coefficient a_0 in (2.1) is replaced by $a_\varepsilon \in C^1(\bar{\Omega})$ all the results remain valid with the estimates independent on $0 \leqq \varepsilon \leqq \delta$ in (2.8) and (2.12).

The partial differential equation interpretation of (2.10) is as follows:

$$(L^*f)(t) = a_0 w(t)_{|\Gamma},$$

where $w(t)$ satisfies

$$w_{tt} = A(x, \partial)w + f(t) \quad \text{in } Q,$$

$$\frac{\partial w}{\partial n} = 0 \quad \text{on } \Sigma,$$

$$w(T) = w_t(T) = 0 \quad \text{in } \Omega.$$

Similarly for (2.13),

$$(L_T^* y)(t) = a_0 z(t)_{|\Gamma}$$

where $z(t)$ satisfies

$$z_{tt} = A(x, \partial)z \quad \text{in } Q,$$

$$\frac{\partial z}{\partial n} = 0 \quad \text{on } \Sigma,$$

$$z(T) = 0, \quad z_t(T) = y \quad \text{in } \Omega.$$

In the sequel we will need stronger regularity results than those given in (2.8) and (2.12). In fact we will need "sharp" regularity results, which are collected in the lemma below.

LEMMA 1 [LT1]. *Let ρ be arbitrarily small.*

(i) $L_T \in \mathscr{L}(L^2(\Sigma); D(A^{1/4+\alpha})) \cap \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma); D(A^{3/4-\rho}))$;

(ii) $L_T^* \in \mathscr{L}((D(A^{1/4+\alpha}))'; L^2(\Sigma)) \cap \mathscr{L}(D(A^{1/4-\rho}); H^{1+2\alpha-2\rho}(\Sigma))$;

(iii) $L \in \mathscr{L}(L^2(\Sigma); C[0, T; D(A^{1/4+\alpha})]) \cap \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma); C[0, T; D(A^{3/4-\rho})])$;

(iv) $L \in \mathscr{L}(H^s(\Sigma); H^{s+1/2+2\alpha}(Q))$ *provided that for* $s + \frac{1}{2} + 2\alpha \geqq \frac{3}{2}$, $0 \leqq s \leqq 1$, *the compatibility condition* $u(0) = 0$ *on* Γ *is satisfied.*

Here $1/20 \leqq \alpha \leqq \alpha_0(\Omega)$ with $\alpha_0(\Omega)$ depending, in general, on the geometry of the domain Ω.

Remark 1. In [LT1] it was shown that for smooth domains Ω we have $\alpha_0(\Omega) \geqq 1/20$. However, in the special cases of the domain Ω, the value of $\alpha_0(\Omega)$ may be bigger. For example, if Ω is a sphere (respectively, parallelepiped) then $\alpha_0(\Omega) = 1/6$ (respectively, $\frac{1}{4}$). In any case, the results of Lemma 1 state that the regularity of the solutions to the wave equation with Neumann boundary data is "at least" "1/10" derivative higher than the regularity predicted by the standard theory. In our applications, however, the exact value of α_0 is not important. It is crucial, however, that $\alpha_0 > 0$.

2.2. Projection in $L^2(\Sigma)$. Let $K \subset L^2(\Sigma)$ be a set of the form

$$K = \{v \in L^2(\Sigma) \mid 0 \leqq v(x, t) \leqq M, (x, t) \in \Sigma\}. \tag{2.15}$$

Let us denote by $\Pi: L^2(\Sigma) \to L^2(\Sigma)$ the metric projection in $L^2(\Sigma)$ onto the set of admissible controls K, i.e.,

$$\forall f \in L^2(\Sigma): \quad |\Pi f - f|_\Sigma = \min_{v \in K} |v - f|_\Sigma. \tag{2.16}$$

It can be shown that

$$(\Pi f)(x, t) = \min \{M, \max \{f(x, t), 0\}\}; \tag{2.17}$$

therefore,

$$(\Pi f)(x, t) = F(f(x, t)), \tag{2.18}$$

where

$$F(r) = \begin{cases} M, & r > M, \\ r, & 0 \leqq r \leqq M, \\ 0, & r < 0. \end{cases} \tag{2.19}$$

Hence it follows that

$$\Pi: H^{s,s}(\Sigma) \to H^{s,s}(\Sigma) \tag{2.20}$$

is continuous for all $s \in [0, 1]$.

We also have the following result on the directional differentiability of the mapping:

$$\Pi: L^2(\Sigma) \to L^2(\Sigma).$$

LEMMA 2. *For $\tau > 0$, τ small enough*

$$\forall h \in L^2(\Sigma): \quad \Pi(f + \tau h) = \Pi(f) + \tau \Pi'_f h + o(\tau), \tag{2.21}$$

where $\|o(\tau)\|_{L^2(\Sigma)}/\tau \to 0$ with $\tau \downarrow 0$ and $\Pi'_f: L^2(\Sigma) \to L^2(\Sigma)$ is the metric projection in $L^2(\Sigma)$ onto cone

$$\begin{aligned} S_f = \{v \in L^2(\Sigma) \mid v(x, t) &\geqq 0 \text{ if } (\Pi f)(x, t) = f(x, t) = 0, \\ v(x, t) &\leqq 0 \text{ if } (\Pi f)(x, t) = f(x, t) = M, \\ v(x, t) &= 0 \text{ if } (\Pi f)(x, t) = 0 \text{ and} f(x, t) < 0 \\ &\text{or } (\Pi f)(x, t) = 0 \text{ and} f(x, t) > M\}. \end{aligned} \tag{2.22}$$

Proof of Lemma 2 is given in [S3].

3. Sensitivity analysis of optimal control problem. For any parameter $\varepsilon \in [0, \delta)$ the solution of state equation (1.3)-(1.5) takes the form (2.4) i.e.,

$$y(t) = (L_\varepsilon u)(t) + C_\varepsilon(t) y_0 + S_\varepsilon(t) y_1, \qquad t \in [0, T]; \tag{3.1}$$

therefore we denote

$$y(T) = L_{T,\varepsilon} u + C_\varepsilon(T) y_0 + S_\varepsilon(T) y_1. \tag{3.2}$$

Cost functional (1.1) can be rewritten as

$$\begin{aligned} I_\varepsilon(u) &= \tfrac{1}{2}(R L_{T,\varepsilon} u, L_{T,\varepsilon} u)_\Omega + (R L_{T,\varepsilon} u, C_\varepsilon(T) y_0 + S_\varepsilon(T) y_1)_\Omega \\ &\quad + \tfrac{1}{2}|u|_\Sigma^2 + \text{const}\,(y_0, y_1) = \tfrac{1}{2}(|u|_\Sigma^2 + (B_\varepsilon u, u)_\Sigma) - (f_\varepsilon, u)_\Sigma + \text{const}, \end{aligned} \tag{3.3}$$

where

$$B_\varepsilon = L^*_{T,\varepsilon} R L_{T,\varepsilon}, \tag{3.4}$$

$$f_\varepsilon = -L^*_{T,\varepsilon} R[C_\varepsilon(T)y_0 + S_\varepsilon(T)y_1]. \tag{3.5}$$

The unique optimal control $u_\varepsilon \in K$ that minimizes functional (3.3) over the set $K \subset L^2(\Sigma)$ can be characterized as the unique fixed point

$$u_\varepsilon = \Pi[-B_\varepsilon u_\varepsilon + f_\varepsilon] \tag{3.6}$$

where the metric projection Π in $L^2(\Sigma)$ onto K is defined by (2.17).

Below we formulate several lemmas that are fundamental for the proof of the main result. The proofs of the lemmas are relegated to § 4.

LEMMA 3 (regularity of optimal controls). *For* $\varepsilon \in [0, \delta)$

$$\|u_\varepsilon\|_{H^1(\Sigma)} \leqq C,$$

where the constant C *depends only on the data of the problem and not on* $\varepsilon > 0$.

From Lemma 1(iii) and Lemma 3 we obtain Corollary 1.

COROLLARY 1. *For* $\rho > 0$, ρ *arbitrary small*

$$Lu_\varepsilon \in C[0, T; H^{3/2-2\rho}(\Omega)]$$

uniformly in $\varepsilon > 0$.

LEMMA 4. *For any* $u \in H^1(\Sigma)$ *we have for* $\varepsilon > 0$, ε *small enough*

$$B_\varepsilon u = B_0 u + \varepsilon B' u + o(\varepsilon) u \quad \text{in } L^2(\Sigma),$$

where

$$B' \in \mathscr{L}(H^1(\Sigma); L^2(\Sigma))$$

is given by (4.18) *and*

$$\forall u \in H^1(\Sigma): \quad |o(\varepsilon)u|_\Sigma / \varepsilon \to 0 \quad \text{with } \varepsilon \downarrow 0.$$

LEMMA 5. *Assume that* $y_0 \in H^{1/2}(\Omega)$, $y_1 \in H^{-1/2}(\Omega)$. *For* $\varepsilon > 0$, ε *small enough*

$$f_\varepsilon = f_0 + \varepsilon f' + o(\varepsilon) \quad \text{in } L^2(\Sigma),$$

where f' *is given by* (4.27), *and* $|o(\varepsilon)|_\Sigma / \varepsilon \to 0$ *with* $\varepsilon \downarrow 0$.

Next we show that u_ε is Lipschitz continuous with respect to ε. Equation (3.6) is equivalent to the following variational inequality.

Find

$$u_\varepsilon \in K: \quad (u_\varepsilon + B_\varepsilon u_\varepsilon - f_\varepsilon, v - u_\varepsilon)_\Sigma \geqq 0 \quad \forall v \in K, \tag{3.7}$$

hence we have

$$(u_\varepsilon + B_\varepsilon u_\varepsilon - f_\varepsilon, u_0 - u_\varepsilon)_\Sigma \geqq 0, \tag{3.8}$$

$$(-u_0 + B_0 u_0 - f_0, u_0 - u_\varepsilon)_\Sigma \geqq 0, \tag{3.9}$$

and therefore

$$\begin{aligned} &|u_0 - u_\varepsilon|^2_\Sigma + (B_\varepsilon(u_0 - u_\varepsilon), u_0 - u_\varepsilon)_\Sigma \\ &\qquad \leqq (f_0 - f_\varepsilon, u_0 - u_\varepsilon)_\Sigma + ((B_0 - B_\varepsilon)u_0, u_0 - u_\varepsilon)_\Sigma. \end{aligned} \tag{3.10}$$

By Lemma 4, it follows that

$$(B_0 - B_\varepsilon)u_0 = \varepsilon B' u_0 + o(\varepsilon) \quad \text{in } L^2(\Sigma), \tag{3.11}$$

where $|o(\varepsilon)|_\Sigma / \varepsilon \to 0$ with $\varepsilon \downarrow 0$.

In view of (3.11) we have

$$|(B_0 - B_\varepsilon)u_0|_\Sigma \leqq C\varepsilon \tag{3.12}$$

for some constant C, which is independent of $\varepsilon \in [0, \delta)$.

Similarly, by Lemma 5

$$|f_0 - f_\varepsilon|_\Sigma \leqq C\varepsilon.$$

Finally from (3.10), in view of (3.12) and since

$$(B_\varepsilon u, u)_\Sigma = (RL_{T,\varepsilon}u, L_{T,\varepsilon}u)_\Sigma \geqq 0 \quad \forall u \in L^2(\Sigma),$$

it follows that

$$|u_\varepsilon - u_0|_\Sigma \leqq C\varepsilon. \tag{3.13}$$

Now we are in a position to prove the theorem.

Proof of Theorem 1. Let ε_n be a sequence such that $\varepsilon_n \downarrow 0$ with $n \to \infty$. In view of (3.13) it follows that

$$\left|\frac{1}{\varepsilon_n}(u_{\varepsilon_n} - u_0)\right|_\Sigma \leqq C,$$

hence there exists an element $q \in L^2(\Sigma)$ such that

$$u_{\varepsilon_n} = u_0 + \varepsilon_n q + r(\varepsilon_n) \quad \text{in } L^2(\Sigma), \tag{3.14}$$

where

$$r(\varepsilon_n)/\varepsilon_n \to 0 \quad \text{with } \varepsilon_n \downarrow 0 \quad \text{weakly in } L^2(\Sigma).$$

In the sequel we denote ε for ε_n.

We will prove that the element q is uniquely determined and characterized as the solution to Problem (Q) and that actually $r(\varepsilon)/\varepsilon \to 0$ strongly in $L^2(\Sigma)$. To this end we shall use the results of Lemmas 3–5.

By Lemmas 4 and 5 we have

$$B_\varepsilon = B_0 + \varepsilon B' + o(\varepsilon) \quad \text{in } \mathscr{L}(H^1(\Sigma); L^2(\Sigma)), \tag{3.15}$$

$$f_\varepsilon = f_0 + \varepsilon f' + o(\varepsilon) \quad \text{in } L^2(\Sigma), \tag{3.16}$$

where

$$\forall u \in H^1(\Sigma): \quad |o(\varepsilon)u|_\Sigma/\varepsilon \to 0 \quad \text{with } \varepsilon \downarrow 0 \tag{3.17}$$

and

$$B_\varepsilon, B_0 \in \mathscr{L}(L^2(\Sigma)) \quad \text{uniformly in } \varepsilon > 0, \tag{3.18}$$

$$B' \in \mathscr{L}(H^1(\Sigma); L^2(\Sigma)), \tag{3.19}$$

and therefore

$$B_\varepsilon u_\varepsilon - f_\varepsilon = B_0 u_0 - f_0 + \varepsilon[B'u_0 + B_0 q - f'] + o(\varepsilon) \quad \text{in } L^2(\Sigma). \tag{3.20}$$

The explicit forms of B', f' are given in (4.18) and (4.27), respectively. From the right-hand side of (3.6), in view of (2.21) and (3.20) it follows that

$$\begin{aligned} u_\varepsilon = \Pi[-B_\varepsilon u_\varepsilon - f_\varepsilon] &= \Pi[-B_0 u_0 + f_0] \\ &+ \varepsilon \Pi'_{\{-B_0 u_0 + f_0\}}[-B'u_0 - B_0 q + f'] + o(\varepsilon) \quad \text{in } L^2(\Sigma), \end{aligned} \tag{3.21}$$

and therefore in view of (3.14) we obtain

$$q = \Pi'_{\{-B_0 u_0 + f_0\}}[-B'u_0 - B_0 q + f'], \tag{3.22}$$

$$r(\varepsilon) = o(\varepsilon). \tag{3.23}$$

Hence by (3.22) we have

$$q \in S_{\{-B_0u_0+f_0\}},$$

since $\Pi': L^2(\Sigma) \to S_{\{-B_0u_0+f_0\}} \subset L^2(\Sigma)$ is the metric projection in $L^2(\Sigma)$ onto the cone $S_{\{-B_0u_0+f_0\}} \subset L^2(\Sigma)$.

Since the optimality conditions for the control problem under consideration read

$$u_0 \in K: \quad \int_\Sigma (u_0 + a_0p_0)(v-u_0)\,d\Sigma$$
$$= (u_0 + B_0u_0 - f_0, v-u_0)_\Sigma \leqq 0 \quad \forall v \in K,$$

it follows that we can identify

$$a_0p_{0|\Sigma} = B_0u_0 - f_0. \tag{3.24}$$

Thus in view of (3.7), it follows that the cone $S_{\{-B_0u_0+f_0\}} = S_{\{-a_0p_{0|\Sigma}\}}$ coincides with

$$\begin{aligned} S \equiv \{v \in L^2(\Sigma) \mid & v(x,t) \geqq 0 \text{ if } u_0(x,t) = -a_0(x)p_0(x,t) = 0, \\ & v(x,t) \leqq 0 \text{ if } u_0(x,t) = -a_0(x)p_0(x,t) = M, \\ & v(x,t) = 0 \text{ if } u_0(x,t) = 0 \text{ and } p_0(x,t) > 0 \\ & \text{or } u_0(x,t) = M \text{ and } a_0(x)p_0(x,t) < -M\}, \end{aligned} \tag{3.25}$$

which, in turn, by (3.7) is equivalent to the cone S defined by (1.10).

By standard arguments in optimization theory, we can show that in view of (1.14)-(1.20) Problem (Q) is equivalent to the following optimality system.

Find (q, z, w) such that the following system is satisfied:

State equation:

$$z_{tt} = A_0(x,\partial)z + \operatorname{div}(a_0\nabla y^0) \quad \text{in } Q, \tag{3.26}$$

$$\frac{\partial z}{\partial n} = q + \frac{a_1}{a_0}u_0 \quad \text{on } \Sigma, \tag{3.27}$$

$$z(0) = 0, \quad z_t(0) = 0 \quad \text{in } \Omega. \tag{3.28}$$

Adjoint state equation:

$$w_{tt} = A_\varepsilon(x,\partial)w + \operatorname{div}(a_0\nabla p^0) \quad \text{in } Q, \tag{3.29}$$

$$\frac{\partial w}{\partial n} = 0 \quad \text{on } \Sigma, \tag{3.30}$$

$$w(T) = 0, \quad w_t(T) = Rz(T) \quad \text{in } \Omega. \tag{3.31}$$

Optimality conditions:

$$q \in S: \quad \int_\Sigma (q + a_0w + a_1p_0)(v-q)\,d\Sigma \geqq 0 \quad \forall v \in S; \tag{3.32}$$

therefore the solution of Problem (Q) takes the following form:

$$q = \Pi'_{\{-a_0p_{0|\Sigma}\}}(-a_0w_{|\Sigma} - a_1p_{0|\Sigma}). \tag{3.33}$$

On the other hand, by using the definitions (3.4), (4.18), and (4.27) of B_0, B', and f', it is straightforward to verify that

$$-a_0w_{|\Sigma} - a_1p_{0|\Sigma} \equiv -B'u_0 + f' \quad \text{in } L^2(\Sigma); \tag{3.34}$$

therefore q given by (3.22) coincides with q defined by (3.33), and thus q defined by (3.22) is the unique solution of Problem (Q).

The proof of the theorem is thus completed. It remains to establish the validity of Lemmas 3-5.

4. Sensitivity analysis of the wave equation. We will prove that operators

$$B_\varepsilon \in \mathscr{L}(L^2(\Sigma); L^2(\Sigma))$$

and elements $f_\varepsilon \in L^2(\Sigma)$ are differentiable with respect to the parameter. We recall that

$$B_\varepsilon = L^*_{T,\varepsilon} R L_{T,\varepsilon} \tag{4.1}$$

where (1.7)(i) is satisfied, i.e.,

$$R \in \mathscr{L}(H^s(\Omega)), \qquad 0 \leqq s \leqq \tfrac{1}{2} \tag{4.2}$$

or (1.7)(ii) is satisfied and

$$f_\varepsilon = -L^*_{T,\varepsilon} R[C_\varepsilon(T)y_0 + S_\varepsilon(T)y_1]. \tag{4.3}$$

We start with the proof of Lemma 3.

Proof of Lemma 3.

Step 1.

$$f_\varepsilon \in H^1(\Sigma) \quad \text{with the norm uniform in } \varepsilon. \tag{4.4}$$

Note first that by (1.7)

$$R[C_\varepsilon(T)y_0 + S_\varepsilon(T)y_1] \in H^{1/2-2\rho}(\Omega) = D(A^{1/4-\rho}). \tag{4.5}$$

Here we have used the regularity of map R together with the well-known properties of sine $S(t)$ and cosine $C(t)$ operators (see [F1]):

$$\begin{aligned} &C(\cdot): D(A^s) \to C[0, T; D(A^s)], \\ &S(\cdot): D(A^s) \to C[0, T; D(A^{s+1/2})]. \end{aligned} \tag{4.6}$$

By Lemma 1(ii) applied to the representation (4.3) and by (4.5), we obtain

$$f_\varepsilon \in H^{1+2\alpha-2\rho}(\Sigma) \quad \text{uniformly in } \varepsilon > 0,$$

which in particular implies (4.4).

Step 2.

$$u_\varepsilon \in H^{4\alpha}(\Sigma) \quad \text{with the norm uniform in } \varepsilon > 0. \tag{4.7}$$

By Lemma 1(i) we have

$$L_{T,\varepsilon} \in \mathscr{L}(L^2(\Sigma); D(A^{1/4+\alpha}) = H^{1/2+2\alpha}(\Omega)).$$

Hence

$$RL_{T,\varepsilon} \in \mathscr{L}(L^2(\Sigma); H^{-1/2+2\alpha}(\Omega) = D(A^{1/4-\alpha})') \tag{4.8}$$

and by interpolating the regularity results given by Lemma 1(ii) we obtain

$$L^*_{T,\varepsilon} \in \mathscr{L}(D(A^{1/4-\alpha})'; H^{4\alpha}(\Sigma)). \tag{4.9}$$

Thus

$$L^*_{T,\varepsilon} R L_{T,\varepsilon} \in \mathscr{L}(L^2(\Sigma); H^{4\alpha}(\Sigma)) \tag{4.10}$$

and by the result of Step 1

$$B_\varepsilon u_\varepsilon + f_\varepsilon \in H^{4\alpha}(\Sigma) \tag{4.11}$$

with the norm uniform in $\varepsilon > 0$. The result in (4.7) follows now from (4.11), (3.6), and (2.20).

Step 3.

$$u_\varepsilon \in H^{8\alpha}(\Sigma). \tag{4.12}$$

By interpolating between the results in Lemma 1(i), we obtain

$$L_{T,\varepsilon} \in \mathscr{L}(H^{4\alpha}(\Sigma); D(A^{1/4+3\alpha}) = H^{1/2+6\alpha}(\Omega)). \tag{4.13}$$

Hence

$$RL_{T,\varepsilon} \in \mathscr{L}(H^{4\alpha}(\Sigma); H^{-1/2+6\alpha}(\Omega) = (D(A^{1/4-3\alpha}))'). \tag{4.14}$$

Interpolating between the results of Lemma 1(ii) gives

$$L^*_{T,\varepsilon} \in \mathscr{L}((D(A^{1/4-3\alpha}))'; H^{8\alpha}(\Sigma)). \tag{4.15}$$

By (4.14), (4.15), and (4.7)

$$L^*_{T,\varepsilon} RL_{T,\varepsilon} u_\varepsilon \in H^{8\alpha}(\Sigma),$$

which result combined with (4.4) gives

$$-B_\varepsilon u_\varepsilon + f_\varepsilon \in H^{8\alpha}(\Sigma).$$

The final conclusion in (4.7) is obtained, as before, by combining (4.15), (3.6), and (2.20).

Step 4.

$$u_\varepsilon \in H^1(\Sigma). \tag{4.16}$$

We apply the "bootstrap" argument by "boosting" successively the regularity of u_ε by the "4α" derivative. The procedure ends when the maximal regularity of the map $L_{T,\varepsilon}$ is achieved. Indeed, at the last step we have

$$L_T \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma); D(A^{3/4-\rho}))$$

and to obtain higher regularity of the map L_T, we need the compatibility condition $u_\varepsilon(t=0)=0$. Since such a condition does not hold, in general, we must stop our argument, obtaining

$$L_T u_\varepsilon \in D(A^{3/4-\rho}) = H^{3/2-2\rho}(\Omega).$$

Applying once more the regularity of $L^*_{T,\varepsilon} R$, we obtain

$$L^*_{T,\varepsilon} RL_T u_\varepsilon \in H^{1+2\alpha-2\rho}(\Sigma) \subset H^1(\Sigma)$$

for ρ arbitrarily small. Hence

$$-B_\varepsilon u_\varepsilon + f_\varepsilon \in H^1(\Sigma)$$

and the application of (2.20) yields the desired conclusion. □

Proof of Lemma 4 will follow through the sequence of propositions whose proofs are given in § 5.

PROPOSITION 1. *Let ρ be arbitrary small. For any $u \in H^{1-2\alpha-2\rho}(\Sigma)$*

$$(L_T - L_{T,\varepsilon})u = \varepsilon L'_T u + r_1(\varepsilon),$$

where

$$\frac{r_1(\varepsilon)}{\varepsilon} \to 0 \quad \textit{in } D(A^{1/4-\rho}) \quad \textit{with } \varepsilon \to 0$$

and

$$L'_T \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma);\ D(A^{1/4-\rho})).$$

PROPOSITION 2. *For any* $u \in H^{1-2\alpha-2\rho}(\Sigma)$

$$L_T^* R(L_T - L_{T,\varepsilon})u = \varepsilon L_T^* R L'_T u + r_2(\varepsilon)$$

where

$$\frac{r_2(\varepsilon)}{\varepsilon} \to 0 \quad \textit{in } L^2(\Sigma) \quad \textit{with } \varepsilon \to 0$$

and

$$L_T^* R L'_T \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma);\ L^2(\Sigma)).$$

PROPOSITION 3. *For any* $f \in D(A^{1/4-\rho})$

$$(L_T^* - L_{T,\varepsilon}^*)f = \varepsilon L_T^{*\prime} f + r_3(\varepsilon)$$

where

$$\frac{r_3(\varepsilon)}{\varepsilon} \to 0 \quad \textit{in } L^2(\Sigma) \quad \textit{with } \varepsilon \to 0$$

and

$$L_T^{*\prime} \in \mathscr{L}(D(A^{1/4-\rho});\ L^2(\Sigma)) \quad \textit{and} \quad L_T^{*\prime} \quad \textit{is given by } (5.23).$$

PROPOSITION 4. *For any* $u \in H^{1-2\alpha-\rho}(\Sigma)$

$$(L_T^* - L_{T,\varepsilon}^*) R L_T u = \varepsilon L_T^{*\prime} R L_T u + r_4(\varepsilon)$$

where

$$\frac{r_4(\varepsilon)}{\varepsilon} \to 0 \quad \textit{in } L^2(\Sigma) \quad \textit{with } \varepsilon \to 0$$

and

$$L_T^{*\prime} R L_T \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma);\ L^2(\Sigma)).$$

Proof of Lemma 4. We have

$$\begin{aligned}(B_0 - B_\varepsilon)u_0 &= (L_T^* - L_{T,\varepsilon}^*) R L_T u_0 + L_T^* R(L_T - L_{T,\varepsilon})u_0 + (L_{T,\varepsilon}^* - L_T^*) R(L_T - L_{T,\varepsilon})u_0 \\ &= \varepsilon[L_T^{*\prime} R L_T + L_T^* R L'_T]u_0 + o(\varepsilon) \\ &= \varepsilon B' u_0 + o(\varepsilon),\end{aligned}$$

where

(4.17) $$o(\varepsilon) = r_2(\varepsilon) + r_4(\varepsilon) - (L_{T,\varepsilon}^* - L_T)R(L_T - -L_{T,\varepsilon})u_0,$$

(4.18) $$B'u \equiv (L_T^{*\prime} R L_T + L_T^* R L'_T)u.$$

From Propositions 2 and 4 it follows that with L'_T and $L_T^{*\prime}$ given by (5.4) and (5.23)

$$B' \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma);\ L^2(\Sigma)),$$

hence in particular

$$B' \in \mathscr{L}(H^1(\Sigma);\ L^2(\Sigma))$$

and $r_2(\varepsilon)/\varepsilon \to 0$, $r_4(\varepsilon)/\varepsilon \to 0$ in $L^2(\Sigma)$ with $\varepsilon \to 0$. We also have

$$\frac{1}{\varepsilon}(L^*_{T,\varepsilon} - L^*_T)R(L_T - L_{T,\varepsilon})u_0 = (L^*_{T,\varepsilon} - L^*_T)R\frac{1}{\varepsilon}[\varepsilon L'_T u_0 + r(\varepsilon)].$$

By Proposition 1

(4.19) $R(L'_T u_0 + r_1(\varepsilon)/\varepsilon)$ is uniformly bounded in $H^{-1/2-2\rho}(\Omega) = D(A^{1/4+\rho})'$.

Moreover,

$$r_1(\varepsilon)/\varepsilon \to 0 \quad \text{in } D(A^{1/4+\rho})'. \tag{4.20}$$

On the other hand, for all $f \in D(A^{1/4+\rho})'$

$$\|(L^*_{T,\varepsilon} - L^*_T)f\|_{L^2(\Sigma)} \to 0. \tag{4.21}$$

Indeed from Lemma 1(ii) we obtain, in particular,

$$\|(L^*_{T,\varepsilon} - L^*_T)f\|_{L^2(\Sigma)} \leqq C_T \|f\|_{(D(A^{1/4+\rho}))'}. \tag{4.22}$$

On the other hand, it can be shown by standard methods that for $f \in D(A^{1/2})$

$$\|(L^*_{T,\varepsilon} - L^*_T)f\|_{L^2(\Sigma)} \to 0. \tag{4.23}$$

To see (4.23) it is enough to write

$$w(t) = (L^*_{T,\varepsilon} - L^*_T)f$$

with

$$\begin{aligned} &w(t) = a_0 \bar{w}(t)_{|\Gamma} + (a_0 - a_\varepsilon)z_{\varepsilon|\Gamma}, \\ &\bar{w}_{tt} - A\bar{w} = \varepsilon \operatorname{div}[(a_1 + r_0/\varepsilon)\nabla S_\varepsilon(T-t)f], \\ &\bar{w}(T) = \bar{w}_t(T) = 0, \qquad \bar{w}_{|\Gamma} = 0, \\ &z_\varepsilon(t) = S_\varepsilon(T-t)f. \end{aligned} \tag{4.24}$$

Since $S_\varepsilon(T-t)f \in C[0, T; D(A) \subset H^2(\Omega)]$ uniformly in ε

$$\|z_\varepsilon(t)_{|\Gamma}\| \leqq C \quad \text{in } C[0, T; H^{3/2}(\Gamma)] \tag{4.25}$$

and the right-hand side of (4.24) converges to zero strongly in $C[0, T; L^2(\Omega)]$. By standard results

$$\bar{w} \to 0 \quad \text{in } C[0, T; H^1(\Omega)],$$

hence, in particular by the trace theorem,

$$w \equiv \bar{w}_{|\Gamma} \to 0 \quad \text{in } L^2(\Sigma).$$

This together with (4.25) proves (4.23). Formulas (4.22), (4.23) and density of $D(A^{1/2})$ in $D(A^{1/4+\rho})'$ imply (4.21). To complete the proof it is enough to note that by (4.19), (4.20), and (4.22)

$$(L^*_{T,\varepsilon} - L^*_T)Rr_1(\varepsilon)/\varepsilon \to 0 \quad \text{in } L^2(\Sigma)$$

and by (4.19), (4.20), and (4.21)

$$(L^*_{T,\varepsilon} - L^*_T)RL'_T u_0 \to 0 \quad \text{in } L^2(\Sigma).$$

Hence

$$(L^*_{T,\varepsilon} - L^*_T)R(L'_T u_0 + r_1(\varepsilon)/\varepsilon) \to 0 \quad \text{in } L^2(\Sigma),$$

which completes the proof of Lemma 4. □

Proof of Lemma 5. We assume that

$$y_0 \in D(A^{1/4}), \qquad y_1 \in (D(A^{1/4}))'$$

and we denote

$$\begin{aligned} X(t) &\equiv S(t)y_1 + C(t)y_0, \\ X_\varepsilon(t) &\equiv S_\varepsilon(t)y_1 + C_\varepsilon(t)y_0, \\ w(t) &\equiv X(t) - X_\varepsilon(t). \end{aligned}$$

Then

$$\begin{aligned} &w_{tt} = Aw(t) + (A - A_\varepsilon)X_\varepsilon(t) \quad \text{in } Q, \\ &\frac{\partial w}{\partial n} = 0 \quad \text{on } \Sigma, \\ &w(0) = w_t(0) = 0 \quad \text{in } \Omega. \end{aligned}$$

Let $a_\varepsilon = a_0 + \varepsilon a_1 + r_0(\varepsilon)$.

Since

$$\begin{aligned} (A - A_\varepsilon)y &= -\varepsilon \operatorname{div}\left[\left(a_1 + \frac{r_0(\varepsilon)}{\varepsilon}\right)\nabla y\right], \\ (A - A_\varepsilon)X_\varepsilon &= -\varepsilon[g_\varepsilon \ddot{X}_\varepsilon + a_\varepsilon \nabla g_\varepsilon \cdot \nabla X_\varepsilon], \end{aligned}$$

where

$$g_\varepsilon \equiv \left(a_1 + \frac{r_0(\varepsilon)}{\varepsilon}\right)\frac{1}{a_\varepsilon} \to \frac{a_1}{a_0} \equiv g \quad \text{with } \varepsilon \downarrow 0.$$

Hence

$$\begin{aligned} w(t) &= \int_0^t S(t-\tau)(A - A_\varepsilon)X_\varepsilon(\tau)\,d\tau \\ &= -\varepsilon \int_0^t S(t-\tau)\left[g_\varepsilon \frac{d^2}{d\tau^2}X_\varepsilon(\tau) + a_\varepsilon \nabla g_\varepsilon \cdot \nabla X_\varepsilon(\tau)\right] d\tau. \end{aligned}$$

Therefore

$$\begin{aligned} w(t) &= -\varepsilon \int_0^t S(t-\tau)\left[g \frac{d^2}{d\tau^2}X(\tau) + a_0 \nabla g \cdot \nabla X(\tau)\right] d\tau + r(\varepsilon) \\ &= \varepsilon X'(y_0, y_1) + r(\varepsilon), \end{aligned}$$

where

$$\begin{aligned} \frac{1}{\varepsilon} r(\varepsilon) = \int_0^t S(t-\tau)\Bigg\{&\left[g_\varepsilon \frac{d^2}{d\tau^2}X_\varepsilon(\tau) - g\frac{d^2}{d\tau^2}X(\tau)\right] \\ &+ [a_0 \nabla g \cdot \nabla X(\tau) - a_\varepsilon \nabla g_\varepsilon \cdot \nabla X_\varepsilon(\tau)]\Bigg\}\,d\tau. \end{aligned}$$

Let us consider the case (1.7)(ii) (case (1.7)(i) is simpler, and hence is omitted). We shall show that

$$X'(y_0, y_1) \equiv -\int_0^t S(t-\tau)\left[g\frac{d^2}{d\tau^2}X(\tau) + a_0 \nabla\left(\frac{a_1}{a_0}\right) \cdot \nabla X(\tau)\right] d\tau \tag{4.26}$$

belongs to $C[0, T; D(A^{1/4-\rho})]$, and $(1/\varepsilon)r(\varepsilon) \to 0$ in $C[0, T; D(A^{1/4-\rho})]$.

In fact, since

$$\frac{d^2x}{dt^2}(\cdot)=AC(\cdot)y_0+AS(\cdot)y_1\in C[0, T; (D(A^{1/4+\rho}))']$$

and

$$\nabla X\in C[0, T; D(A^{1/4+\rho})'],$$

(4.6) implies that

$$X'(y_0, y_1)\in C[0, T; D(A^{1/4-\rho})].$$

Since

$$\|X_\varepsilon - X\|_{C[0,T;D(A^{3/4-\rho})]}\to 0,$$

using a similar argument as before, we can also show that

$$r(\varepsilon)/\varepsilon\to 0 \quad \text{in } C[0, T; D(A^{1/4-\rho})].$$

By (4.26), regularity of R, and Lemma 1(ii), we obtain

$$L_T^*RX'(y_0, y_1)\in L^2(\Sigma).$$

Since

$$R[C_\varepsilon(T)y_0+S_\varepsilon(T)y_1]\in D(A^{1/4-\rho}),$$

Proposition 3 yields

$$L_{T,\varepsilon}^{*\prime}R[C_\varepsilon(T)y_0+S_\varepsilon(T)y_1]\in L^2(\Sigma).$$

Writing

$$f_\varepsilon-f_0=(L_T^*-L_{T,\varepsilon}^*)R[C(T)y_0+S(T)y_1]+L_{T,\varepsilon}^*R[X-X_\varepsilon],$$

and using the result of Proposition 3, Lemma 1(ii), and (4.26), it follows that

$$f_\varepsilon-f_0=\varepsilon f'+r(\varepsilon),$$

where $r(\varepsilon)/\varepsilon\to 0$ in $L^2(\Sigma)$ and

$$f'=L_T^{*\prime}R[C(T)y_0+S(T)y_1]+L_T^*RX'\in L^2(\Sigma) \tag{4.27}$$

with X' given by (4.26) and $L_T^{*\prime}$ given by Proposition 3 (see also (5.23)). This completes the proof of Lemma 5.

5. Proofs of Propositions 1–4.

Proof of Proposition 1. Let

$$w\equiv(L-L_\varepsilon)u.$$

Then

$$\begin{aligned} &w_{tt}=Aw+(A(x,\partial)-A_\varepsilon(x,\partial))L_\varepsilon u \quad \text{in } Q,\\ &\frac{\partial w}{\partial n}=0 \quad \text{on } \Sigma,\\ &w(0)=w_t(0)=0 \quad \text{in } \Omega. \end{aligned} \tag{5.1}$$

With

$$a_\varepsilon=a_0+\varepsilon a_1+r_0(\varepsilon)$$

we have

$$|A(x, \partial) - A_\varepsilon(x, \partial)]y = -\varepsilon \operatorname{div}\left[\left(a_1 + \frac{r_0(\varepsilon)}{\varepsilon}\right)\nabla y\right],$$

hence

$$|A(x, \partial) - A_\varepsilon(x, \partial)]L_\varepsilon u = -\varepsilon\left[g_\varepsilon \frac{d^2}{dt^2} L_\varepsilon u + a_\varepsilon \nabla g_\varepsilon \cdot \nabla L_\varepsilon u\right],$$

where

$$g_\varepsilon \equiv \left[a_1 + \frac{r_0(\varepsilon)}{\varepsilon}\right]\frac{1}{a_\varepsilon} \to \frac{a_1}{a_0} \equiv g \quad \text{with } \varepsilon \downarrow 0. \tag{5.2}$$

The convergence takes place in $C^1(\bar{\Omega})$. Thus after denoting

$$\mathbf{h}_\varepsilon \equiv \nabla g_\varepsilon a_\varepsilon \to \nabla\left(\frac{a_1}{a_0}\right) a_0 \equiv \mathbf{h}, \tag{5.3}$$

$$(L_T - L_{T,\varepsilon})u = w(T) = -\varepsilon \int_0^T S(T-\tau)\left[g_\varepsilon \frac{d^2}{d\tau^2}(L_\varepsilon u)(\tau) + \mathbf{h}_\varepsilon \cdot \nabla(L_\varepsilon u)\, d\tau\right.$$

$$= \varepsilon \int_0^T S(T-\tau)\left[g \frac{d^2}{d\tau^2}(Lu)(\tau) + \mathbf{h} \cdot \nabla(Lu)(\tau)\right] d\tau - \varepsilon \int_0^T S(T-\tau)$$

$$\cdot \left[g_\varepsilon \frac{d^2}{d\tau^2}(Lu)(\tau) - g\frac{d^2}{d\tau^2}(Lu)(\tau)) + (\mathbf{h}_\varepsilon \cdot \nabla(L_\varepsilon u)(\tau) - \mathbf{h} \cdot \nabla(Lu)(\tau))\right] d\tau.$$

Let us denote

$$\begin{aligned} L'_T u &\equiv -\int_0^T S(T-\tau)\left[g\frac{d^2}{d\tau^2}(Lu)(\tau) + \mathbf{h}\cdot\nabla(Lu)(\tau)\right] d\tau \\ &= -\int_0^T S(T-\tau) \operatorname{div}(a_1 \nabla Lu(\tau))\, d\tau, \end{aligned} \tag{5.4}$$

$$\begin{aligned} -r_1(\varepsilon, u)/\varepsilon \equiv &\int_0^T S(T-\tau)\left[g_\varepsilon \frac{d^2}{d\tau^2}(L_\varepsilon u)(\tau) - g\frac{d^2}{d\tau^2}(Lu)(\tau)\right] d\tau \\ &+ \int_0^T S(T-\tau)[\mathbf{h}_\varepsilon \cdot \nabla(L_\varepsilon u(\tau)) - \mathbf{h}\cdot\nabla(Lu)(\tau)]\, d\tau. \end{aligned} \tag{5.5}$$

To prove Proposition 1 we need to show that

$$L'_T \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma); D(A^{1/4-\rho})), \tag{5.6}$$

$$r_1(\varepsilon, u)/\varepsilon \to 0 \quad \text{in } D(A^{1/4-\rho}), \quad u \in H^{1-2\alpha-2\rho}(\Sigma). \tag{5.7}$$

To accomplish this we first observe that

$$\frac{d^2}{dt^2} L_\varepsilon \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma); C[0, T; (D(A^{1/4+\rho}))']), \tag{5.8}$$

$$\nabla L_\varepsilon \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma); C[0, T; D(A^{1/4-\rho})]). \tag{5.9}$$

In fact from Lemma 1(i), we obtain

$$AL \in \mathscr{L}(H^{1-2\alpha-2\rho}(\Sigma); C[0, T; (D(A^{1/4+\rho}))']).$$

We also have that

$$ANLu = A^{1/4+\rho}A^{3/4-\rho}N, \qquad Lu \in (D(A^{1/4+\rho}))' \text{ bounded.}$$

Thus with $u \in H^{1-2\alpha-2\rho}(\Sigma)$

$$ALu - ANLu \in C[0, T; (D(A^{1/4+\rho}))']. \tag{5.10}$$

On the other hand, we have

$$\frac{d^2}{dt^2}(Lu) = [A - AN]Lu. \tag{5.11}$$

Therefore (5.8) follows from (5.10), and (5.11) and (5.9) follow from Lemma 1(ii) and from the derivative theorem in [LM]. To continue with the proof of (5.6) we recall that for any $\gamma > 0$

$$S(\cdot) \in \mathscr{L}(D(A^\gamma); C[0, T; D(A^{\gamma+1/2})]), \tag{5.12}$$

$$C(\cdot) \in \mathscr{L}(D(A^\gamma); C[0, T; D(A^\gamma)]). \tag{5.13}$$

Thus by the virtue of (5.8) the expression in the bracket in (5.4) is in $C[0, T; (D(A^{1/4-\rho}))']$ for $u \in H^{1-2\alpha-2\rho}(\Sigma)$, hence by (5.12), (5.13) $L'_T u \in D(A^{1/4-\rho})$ for $u \in H^{1-2\alpha-2\rho}(\Sigma)$ which a posteriori implies (5.6). As for (5.7), we note that by the same argument as before we have

$$\|r_1(\varepsilon, u)/\varepsilon\|_{D(A^{1/4-\rho})} \leqq C\|u\|_{H^{1-2\alpha-2\rho}(\Sigma)}. \tag{5.14}$$

Thus to prove (5.7), we first show that

$$\|L_\varepsilon u - Lu\|_{L^2[0,T;D(A^{3/4-\rho})]} \to 0 \quad \text{for } u \in H^{1-2\alpha-2\rho}(\Sigma). \tag{5.15}$$

Indeed, from (5.1)-(5.3)

$$(L_\varepsilon u - Lu)(t) = w(t) = -\varepsilon \int_0^t S(t-\tau)\left[g_\varepsilon \frac{d^2}{d\tau^2}(L_\varepsilon u)(\tau) + \mathbf{h}_\varepsilon \cdot \nabla(Lu)(\tau)\right] d\tau. \tag{5.16}$$

By (5.2), (5.3), (5.8), (5.9), and (5.12)

$$\|L_\varepsilon u - Lu\|_{C[0,T;D(A^{1/4-\rho})]} \to 0. \tag{5.17}$$

On the other hand, from Lemma 1(iv) we have

$$\|L_\varepsilon u - Lu\|_{H^{3/2-\rho}(Q)} \leqq C \quad \text{uniformly in } \varepsilon > 0. \tag{5.18}$$

By compactness of the imbedding

$$H^{3/2-\rho}(Q) \subset H^{3/2-2\rho}(Q)$$

and by (5.17), we obtain

$$\|L_\varepsilon u - Lu\|_{H^{3/2-2\rho}(Q)} \to 0, \tag{5.19}$$

which implies (5.15). The next step is to prove that for $u \in H^{1-2\alpha-2\rho}(\Sigma)$,

$$\frac{r_1(\varepsilon, u)}{\varepsilon} \to 0 \quad \text{in } D(A^{1/4-\rho}) \quad \text{with } \varepsilon \to 0.$$

Indeed, this follows from the representation (5.5), (5.12) and from the following convergence results which, in turn, are the consequences of (5.10), (5.11), (5.15):

$$\|\nabla(L_\varepsilon - L)u\|_{L^2[0,T;D(A^{1/4-\rho})]} \to 0, \tag{5.20}$$

$$\left\|\frac{d^2}{dt^2}(L_\varepsilon - L)u\right\|_{L^2[0,T;(D(A^{1/4+\rho}))']} \to 0. \tag{5.21}$$

□

Proof of Proposition 2. This follows from Proposition 1, from the assumption (1.7) which implies

$$R \in \mathscr{L}(H^{1/2-\rho}(\Omega); (H^{1/2+\rho}(\Omega))'),$$

and from smoothing property of L_T^*, i.e.,

$$L_T^* \in \mathscr{L}((D(A^{1/4+\alpha}))'; L^2(\Sigma))$$

(see Lemma 1(ii)). □

Proof of Proposition 3. Let

$$w(t) \equiv [S(T-t) - S_\varepsilon(T-t)]f.$$

Then

$$(L_T^* - L_{T,\varepsilon}^*)f = [a_0 S(T-t) - a_\varepsilon S_\varepsilon(T-t)]f_{|\Gamma} = a_0 w_{|\Gamma} + (a_0 - a_\varepsilon) z_{|\Gamma},$$

where $w(t)$ satisfies

$$\begin{aligned} &w_{tt} = Aw + (A - A_\varepsilon) S_\varepsilon(T-t) \quad \text{in } Q, \\ &\frac{\partial w}{\partial n} = 0 \quad \text{on } \Sigma, \qquad (5.22) \\ &w(T) = w_t(T) = 0 \quad \text{in } \Omega \end{aligned}$$

and $z(t) = S_\varepsilon(T-t)f$. Here (see (5.2), (5.3))

$$(A - A_\varepsilon) S_\varepsilon(T-t)f = -\varepsilon \left[g_\varepsilon \frac{d^2}{dt^2} S_\varepsilon(T-t)f + \mathbf{h}_\varepsilon \cdot \nabla S_\varepsilon(T-t)f \right].$$

Thus

$$\begin{aligned} w(t) &= \int_t^T S(\tau - t)(A - A_\varepsilon) S_\varepsilon(T-\tau) f\, dt \\ &= \varepsilon \int_t^T S(\tau - t)\left[g \frac{d^2}{d\tau^2}(S(T-\tau)f) + \mathbf{h} \cdot \nabla(S(T-\tau)f) \right] d\tau \\ &\quad + \varepsilon \int_t^T S(\tau - t) \left[g_\varepsilon \frac{d^2}{d\tau^2}(S_\varepsilon(T-\tau)f) \right. \\ &\quad \left. - g \frac{d^2}{d\tau^2}(S(T-\tau)f) + \mathbf{h}_\varepsilon \cdot \nabla(S_\varepsilon(T-\tau)f) - \mathbf{h} \cdot \nabla(S(T-\tau)f) \right] d\tau. \end{aligned}$$

Denote

$$\begin{aligned} L_T^{*\prime} f &\equiv -L^* \left[g \frac{d^2}{d\tau^2}(S(T-\tau)f) + \mathbf{h} \cdot \nabla(S(T-\tau)f) \right] \\ &= a_1 S(T-\cdot) f_{|\Gamma} \qquad (5.23) \\ &= -L^*[\operatorname{div}(a_1 \nabla(S(T-\cdot)f))] + \frac{a_1}{a_0} L_T^* f, \end{aligned}$$

$$\begin{aligned} r_3(\varepsilon,f)/\varepsilon \equiv L^*\Big[& g_\varepsilon \frac{d^2}{d\tau^2}(S_\varepsilon(T-\tau)f) - g\frac{d^2}{d\tau^2}(S(T-\tau)f) \\ & + \mathbf{h}_\varepsilon \cdot \nabla(S_\varepsilon(T-\tau)f) - \mathbf{h}\cdot\nabla(S(T-\tau)f)\Big] \\ & + \frac{r_1(\varepsilon)}{a_0} L_T^* f + (a_1 + r_1/\varepsilon) w_{|\Gamma}. \end{aligned} \tag{5.24}$$

Then

$$(L_T^* - L_{T,\varepsilon}^*)f = \varepsilon L_T^{*\prime} f + r_3(\varepsilon, f).$$

To prove Proposition 3 we need to show that

$$L_T^{*\prime} \in \mathscr{L}(D(A^{1/4-\rho});\, L^2(\Sigma)), \tag{5.25}$$

$$r_3(\varepsilon,f)/\varepsilon \to 0 \quad \text{in } L^2(\Sigma) \quad \text{for} f \in D(A^{1/4-\rho}). \tag{5.26}$$

Since

$$\frac{d^2}{d\tau^2}(S(T-\tau)f) = AS(T-\tau)f$$

By (5.12), (5.13)

$$\frac{d^2}{dt^2} S(T-\cdot) \in \mathscr{L}(D(A^{1/4-\rho});\, C[0,T;(D(A^{1/4+\rho}))']). \tag{5.27}$$

Also

$$\begin{aligned} \|\nabla(S(t-\cdot)f)\|_{c[0,T;(D(A^{1/4+\rho}))']} & \leqq C\|\nabla(S(T-\cdot)f)\|_{L^2(Q;R^n)} \\ & \leqq C\|A^{1/2}S(T-\cdot)f\|_{L^2(Q)} \leqq C\|f\|_{L^2(\Omega)} \\ & \leqq C\|f\|_{D(A^{1/4-\rho})}. \end{aligned} \tag{5.28}$$

Lemma 1(iii), after using duality, we obtain in particular

$$L^* \in \mathscr{L}(L_1(0,T;\, D(A^{1/4+\alpha})');\, L^2(\Sigma)). \tag{5.29}$$

(5.25) follows now from (5.27), (5.28), Lemma 1(ii), and (5.23).

As for (5.26), we write

$$\frac{r_3(\varepsilon,f)}{\varepsilon} = \frac{\hat{r}_3(\varepsilon,f)}{\varepsilon} + \frac{r_3^*(\varepsilon,f)}{\varepsilon}$$

where

$$\frac{r_3^*(\varepsilon,f)}{\varepsilon} = \frac{r_1(\varepsilon)}{a_0} L_T^* f + \left(a_0 + \frac{r_1}{\varepsilon}\right) w_{|\Gamma}.$$

By the result of Lemma 1(ii)

$$r_1(\varepsilon)\|L_T^* f\|_{L^2(\Sigma)} \to 0, \qquad f \in D(A^{1/4-\rho}).$$

Noting that

$$w_{|\Gamma}=\frac{\varepsilon}{a_0} L_T^*\left[g_\varepsilon \frac{d^2}{dt^2} S_\varepsilon(T-t)f+\mathbf{h}_\varepsilon \nabla(S_\varepsilon(T-t)f)\right]$$

and that

$$\frac{d^2}{dt^2} S_\varepsilon(T-\cdot)f=A_\varepsilon S_\varepsilon(T-\cdot)f\in(D(A^{3/4+\rho}))',$$

$$\nabla S_\varepsilon(T-\cdot)f\in D(A^{1/4-\rho}).$$

By (5.29) we also obtain that

$$\left(a_0+\frac{r_1}{\varepsilon}\right) w_{|\Gamma}\to 0 \quad \text{in } L^2(\Sigma).$$

Thus

$$\frac{r_3^*(\varepsilon,f)}{\varepsilon}\to 0 \quad \text{in } L^2(\Sigma).$$

As for $\hat{r}_3$, note

$$|\hat{r}_3(\varepsilon,f)/\varepsilon|_\Sigma \leqq C\|f\|_{D(A^{1/4-\rho})}.$$

To prove (5.26) it is enough to show that

$$|\hat{r}_3(\varepsilon,f)/\varepsilon|_\Sigma\to 0 \quad \text{for } f\in D \tag{5.30}$$

where D is a dense subset of $D(A^{1/4-\rho})$. In fact, let

$$D\equiv D(A).$$

Then it is straightforward to show that

$$\|[S_\varepsilon(T,\cdot)-S(T,\cdot)]f\|_{C[0,T;D(A)]}\to 0. \tag{5.31}$$

Consequently,

$$\left\|\frac{d^2}{dt^2}[S_\varepsilon(T,\cdot)-S(T,\cdot)]f\right\|_{C[0,T;L^2(\Omega)]}\to 0 \tag{5.32}$$

and

$$\|\nabla[S_\varepsilon(T,\cdot)-S(T,\cdot)]f\|_{C(0,T;L^2(\Omega)]}\to 0. \tag{5.33}$$

Formula (5.2), (5.3), (5.32), and (5.33) applied to the representation (5.24) together with regularity result (5.29) imply (5.26) as desired. □

Proof of Proposition 4. This follows from Proposition 3, after taking into account the regularity of mapping R, as well as the regularity of mapping L_T given in Lemma 1(i), i.e., $L_T u\in D(A^{3/4-\rho})$ (see Corollary 1). □

BOUNDARY CONTROLLABILITY OF THE COINCIDENCE SET IN THE OBSTACLE PROBLEM*

VIOREL BARBU† AND DAN TIBA‡

Abstract. Considered is a controlled obstacle problem on a domain Ω with the control $u \in U$ appearing in the boundary data. Given an open and smooth subset D of Ω, it is proved via optimization arguments that the problem $D \subset E_u$ is approximately solvable. Here E_u is the coincidence set corresponding to boundary control u.

Key words. obstacle problem, coincidence set, variational inequality, optimal control

1. Introduction. Let Ω and D be bounded domains of R^N, $N \geqq 2$, such that $D \subset \Omega$. We will assume that $\partial\Omega$ and ∂D are smooth manifolds of class C^m where m is a natural controlled number such that $m > N/2$.

Consider the controlled obstacle problem on

$$\begin{aligned} &\Delta y = 0 \quad \text{in } \{x \in \Omega;\ y(x) > \varphi(x)\},\\ &\Delta y \leqq 0 \quad \text{in } \Omega,\\ &y \geqq \varphi \quad \text{in } \Omega,\\ &y = u \quad \text{in } \partial\Omega, \end{aligned} \tag{1.1}$$

where $u \in H^{m-1/2}(\partial\Omega)$, and $\varphi \in C^m(\bar{\Omega})$.

For any u, we denote by $E_u = \{x \in \Omega;\ y(x) = \varphi(x)\}$ the coincidence set of the obstacle problem and introduce the notation $\Omega_0 = \Omega \backslash \bar{D}$.

In terms of variational inequality, problem (1.1) can be written as

$$y \in K_u;\ \int_\Omega \nabla y \cdot \nabla(y - z)\, dx \leqq 0, \quad \forall z \in K_u, \tag{1.2}$$

where $K_u = \{y \in H^1(\Omega);\ y \geqq \varphi \text{ in } \Omega,\ y = u \text{ in } \partial\Omega\}$.

We will study the following controllability problem:

(1.3) Find $u \in H^{m-1/2}(\partial\Omega)$ such that $D \subset E_u$.

This, in general, is not a well-posed problem. A common way to solve it is to transform it, via the least squares approach, into an optimal control problem governed by the variational inequality (1.2) (see [1], [4]). Here we will approach this problem by reformulating it as follows:

(P) Find $u \in H^{m-1/2}(\partial\Omega)$ such that $y^u = \varphi$ on ∂D and $y^u \geqq \varphi$ on Ω_0.

* Received by the editors May 8, 1989; accepted for publication (in revised form) November 30, 1990.

Here $y \in H^m(\Omega_0)$ is the solution to the elliptic boundary value problem

$$\Delta y = 0 \quad \text{in}\, \Omega_0, \tag{1.4}$$
$$\frac{\partial y}{\partial \nu} = \frac{\partial \varphi}{\partial \nu} \quad \text{in}\, \partial D, \quad y = u \quad \text{in}\, \partial \Omega,$$

where $\partial/\partial\nu$ is the inward normal derivative to ∂D.

We note that under our assumptions by standard existence results on elliptic boundary value problems, for every $u \in H^{m-1/2}(\partial\Omega)$, problem (1.4) has a unique solution $y^u \in H^m(\Omega_0) \subset C(\bar{\Omega}_0)$ (see [3]).

The relationship between problems (1.3) and (P) is clarified by Lemma 1.1 below.

LEMMA 1.1. *Assume that* $\Delta\varphi \leqq 0$ *in* D. *If* $y \in K_u$ *is the solution to problem* (1.4), *then the function* $\tilde{y}$ *defined by*

$$\tilde{y}(x) = y(x) \quad \text{if}\, x \in \Omega_0, \qquad y(x) = \varphi(x) \quad \text{if}\, x \in \bar{D}, \tag{1.5}$$

is the solution to the elliptic variational inequality (1.2).

Proof. Since ∂D is smooth we see by (1.5) that $\tilde{y} \in H^1(\Omega)$ and

$$\frac{\partial \tilde{y}}{\partial x_i} = \frac{\partial y}{\partial x_i} \quad \text{a.e. in}\, \Omega_0, \qquad \frac{\partial \tilde{y}}{\partial x_i} = \frac{\partial \varphi}{\partial x_i} \quad \text{a.e. in}\, D, \quad i = 1, 2, \cdots, n.$$

This yields, via Green's formula,

$$\begin{aligned}
\int_\Omega \nabla\tilde{y} \cdot \nabla(\tilde{y} - z)\, dx &= \int_{\Omega_0} \nabla y \cdot \nabla(y - z)\, dx + \int_D \nabla\varphi \cdot \nabla(\varphi - z)\, dx \\
&= -\int_{\Omega_0} \Delta y (y - z)\, dx - \int_{\partial D} \frac{\partial y}{\partial \nu}(y - z)\, d\sigma \\
&\quad - \int_D \Delta\varphi(\varphi - z)\, dx - \int_{\partial D} \frac{\partial \varphi}{\partial \nu}(\varphi - z)\, d\sigma \\
&= -\int_D (\varphi - z)\Delta\varphi\, dx \leqq 0 \quad \forall z \in K_u,
\end{aligned}$$

as claimed.

Lemma 1.1 shows that *problems* (1.3) and (P) *are equivalent.* However, problem (P) seems to be more convenient since it is governed by a linear elliptic equation, and so a least squares type approach will transform it into a convex control problem. Here we will use this approach to show that under suitable assumptions, problem (1.3) is approximately solvable in a sense to be explained later (see Theorems 2.1 and 2.2 below). This is quite an unexpected result if we take into account the complicated geometry of the coincidence set and it may be viewed as a controllability result for the coincidence set of the obstacle problem. In § 5 we will obtain similar results for the obstacle problem with Neumann boundary conditions.

We will use the usual notation for the spaces of continuously differentiable functions and for Sobolev spaces on Ω_0, Ω, and $\partial\Omega$.

2. The main results. Throughout this section we will assume that $\varphi \in C^m(\bar{\Omega})$ satisfies the conditions

$$\Delta\varphi(x) \leqq 0 \quad \forall x \in D, \tag{2.1}$$

$$\frac{\partial \varphi}{\partial \nu}(x) \geqq 0 \quad \forall x \in \partial D, \tag{2.2}$$

where $\partial/\partial\nu$ is the inward normal to ∂D. Assume further that ∂D is of class C^m; $m > N/2$.

THEOREM 2.1. *There is a sequence* $\{(u_n, y_n)\} \subset H^{m-1/2}(\partial\Omega) \times H^m(\Omega_0)$ *satisfying system* (1.4) *along with the constraints* $y_n \geqq \varphi$ *in* Ω_0 *and having the following property*:

(a) *For every smooth part* Γ *of* ∂D *there is no open domain* $\Pi \subset \Omega_0$ *such that* $\partial\Pi \cap \partial D = \Gamma$, $\partial\Pi \cap \partial\Omega \neq \emptyset$ *is a smooth submanifold of* $\partial\Omega$ *and*

$$y_{n_k}(x) > \varphi(x) \quad \forall x \in \Pi \tag{2.3}$$

for some subsequence $n_k \to \infty$.

Denote $\Omega_n = \{x \in \Omega_0;\ y_n(x) = \varphi(x)\}$. Theorem 2.1 shows that for every subsequence $\{n_k\} \to +\infty$ the set $\bigcap_{n_k} \Omega_{n_k}^c$ does not contain any open domain Π such that $\partial\Pi \cap \partial D$ and $\partial\Pi \cap \partial\Omega \neq \emptyset$ are smooth parts of ∂D and $\partial\Omega$, respectively (see Fig. 1).

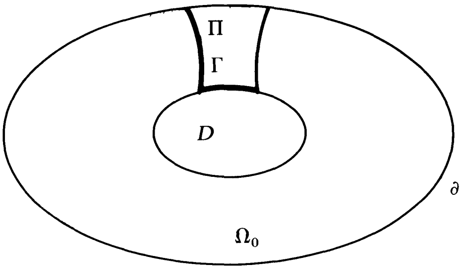

FIG. 1

Roughly speaking this means that Ω_n "asymptotically cover" the boundary ∂D. If $\Delta\varphi \leqq 0$ in D_0 then as an easy consequence of the Hopf maximum principle it follows that any open domain Ω_0' of Ω_0 having the property that $y_n = \varphi$ in $\partial\Omega_0' \backslash \partial D$, belongs to Ω_n. This fact allows us to precisely give in this case property (a), and so to give a more precise meaning to Theorem 2.1.

If $\Delta\varphi \geqq 0$ in Ω_0 then, again by the maximum principle, it follows by (1.4) that for every $u \in H^{m-1/2}(\partial\Omega)$ either $y^u \equiv \varphi$ or $y^u > \varphi$ in $\Omega_0 \cup \partial D$ and $\{x;\ y^u(x) = \varphi(x)\} \subset \partial\Omega$. Hence if $\Delta\varphi > 0$ then problem (P) has no solution.

THEOREM 2.2. *For every* $\varepsilon > 0$ *there is a connected open subset* Q_ε *of* Ω_0 *such that* $m(\Omega_0 \backslash Q_\varepsilon) \leqq \varepsilon$ *and a sequence* $\{(u_n, y_n)\} \subset H^{m-1/2}(\partial\Omega) \times H^m(\Omega_0)$ *satisfying system* (1.4) *and*

$$y_n \geqq \varphi \quad \text{a.e. in } Q_\varepsilon, \tag{2.4}$$

$$y_n \to \varphi \quad \text{weakly in } L^2(\partial D). \tag{2.5}$$

(Here m is the Lebesgue measure in R^N.)

3. Proof of Theorem 2.1. Consider the following family of optimal control problems: (P_n) Minimize $\{\int_{\partial D} y(x)\,dx + (1/2n)\|u\|^2_{H^{m-1/2}(\partial\Omega)}\}$ on all $(u, y) \in H^{m-1/2}(\partial\Omega) \times H^m(\Omega_0)$ subject to system (1.4) and to the state constraint $y(x) \geqq \varphi(x)$ for all $x \in \Omega_0$.

LEMMA 3.1. *Problem* (P_n) *has unique solution* (u_n, y_n). *Moreover, there are the functions* $p_n \in W^{1,q}(\Omega_0)$, $1 \leqq q < N/(N-1)$ *and the Borelian measures* $\mu_n \in M(\bar{\Omega}_0)$ *that satisfy the system*

$$\begin{gathered} \Delta y_n = 0 \quad \text{in } \Omega_0, \\ \frac{\partial y_n}{\partial\nu} = \frac{\partial\varphi}{\partial\nu} \quad \text{in } \partial D, \quad y_n = u_n \quad \text{in } \partial\Omega, \end{gathered} \tag{3.1}$$

$$-\Delta p_n = \mu_n \quad in\ \Omega_0,$$

$$\frac{\partial p_n}{\partial \nu} = 1 \quad in\ \partial D, \quad p_n = 0 \quad in\ \partial\Omega, \tag{3.2}$$

$$\frac{\partial p_n}{\partial \nu} = n^{-1} F u_n \quad in\ \partial\Omega, \tag{3.3}$$

$$\mu_n(y_n - z) \geqq 0 \quad \forall z \in C(\bar{\Omega}_0), \qquad z \geqq \varphi \quad on\ \bar{\Omega}_0. \tag{3.4}$$

Here $F: H^{m-1/2}(\partial\Omega) \to H^{-m+1/2}(\partial\Omega)$ is the canonical isomorphism of the space $H^{m-1/2}(\partial\Omega)$ onto its dual, and (3.2) is considered in the following weak sense:

$$\mu_n(\psi) - \int_{\Omega_0} \nabla p_n \cdot \nabla \psi \, dx + \int_{\partial D} \psi \, d\sigma + n^{-1}\langle F u_n, \psi \rangle = 0 \quad \forall \psi \in H^m(\Omega_0), \tag{3.5}$$

$$p_n = 0 \quad \text{in } \partial\Omega, \tag{3.6}$$

where $\langle \cdot, \cdot \rangle$ is the duality pairing between $H^{m-1/2}(\partial\Omega)$ and $H^{-m+1/2}(\partial\Omega)$. We note that since $p_n \in W^{1,q}(\Omega_0)$ the trace of p_n on ∂D belongs to $W^{1-1/q,q}(\partial D)$, and so (3.6) makes sense.

Proof of Lemma 3.1. We will show that there is at least one admissible pair (u, y). Then by standard division it follows that problem (P_n) has a unique solution (u_n, y_n). Moreover, we have for $\lambda \to 0$

$$u_\lambda \to u_n \quad \text{strongly in } H^{m-1/2}(\partial\Omega), \tag{3.7}$$

$$y_\lambda \to y_n \quad \text{strongly in } H^m(\Omega_0) \subset C(\bar{\Omega}_0), \tag{3.8}$$

where (u_λ, y_λ) is the solution to the following penalized problem:

(3.9) Minimize $\{\int_{\partial D} y \, d\sigma + (1/2n)\|u\|^2_{H^{m-1/2}(\partial\Omega)} + (1/2\lambda)\int_{\Omega_0} |(y-\varphi)^-|^2 \, dx\}$ subject to (1.4).

It is readily seen that there exists $p_\lambda \in H^2(\Omega_0)$ such that

$$-\Delta p_\lambda = \beta_\lambda(y_\lambda - \varphi) \quad \text{in } \Omega_0,$$

$$\frac{\partial p_\lambda}{\partial \nu} = 1 \quad \text{in } \partial D, \quad p_\lambda = 0 \quad \text{in } \partial\Omega, \tag{3.10}$$

$$\frac{\partial p_\lambda}{\partial \nu} = n^{-1} F u_\lambda \quad \text{on } \partial\Omega, \tag{3.11}$$

where $\beta_\lambda(r) = -\lambda^{-1} r^-$, for all $r \in R$.

Now let us remark for later use that there are $u_0 \in H^{m-1/2}(\partial\Omega)$ and $y_0 \in H^m(\Omega_0)$ such that $y_0(x) > \varphi(x)$, for all $x \in \bar{\Omega}_0$ and

$$\Delta y_0 = 0 \quad \text{in } \Omega_0,$$

$$\frac{\partial y_0}{\partial \nu} = \frac{\partial \varphi}{\partial \nu} \quad \text{in } \partial D, \quad y_0 = u_0 \quad \text{in } \partial\Omega. \tag{3.12}$$

Indeed, it suffices to take $u_0 \in H^{m-1/2}(\partial\Omega) \cap C^1(\partial\Omega)$ such that

$$\inf_{\partial\Omega} u_0 > \sup_{\bar{\Omega}_0} \varphi.$$

If y_0 is the corresponding solution to problem (3.12), then it follows by assumption (2.2) and the strong maximum principle that the infimum of y_0 on $\bar{\Omega}_0$ is attained on $\partial\Omega$ only. Hence $\underline{\inf}_{\Omega_0} y_0 > \underline{\sup}_{\Omega_0} \varphi$, as claimed.

Thus there is $\rho>0$ such that $y_0+\rho w \geqq \varphi$ on Ω_0 for all $w\in L^\infty(\Omega_0)$ with $\|w\|_{L^\infty(\Omega_0)}\leqq 1$. Multiplying (3.10) by $y-y_0-\rho w$ and integrating on Ω_0, we get, after some calculation involving Green's formula,

$$\begin{aligned}\rho\int_{\Omega_0}\Delta p_\lambda w\,dx &\leqq -\int_{\Omega_0}(y_\lambda-y_0)\Delta p_\lambda\,dx\\ &=-\int_{\partial D}(y_\lambda-y_0)\,d\sigma-\int_{\partial\Omega}(u_\lambda-u_0)\frac{\partial p_\lambda}{\partial\nu}\\ &=-\int_{\partial D}(y_\lambda-y_0)\,d\sigma-n^{-1}\langle Fu_\lambda,u_\lambda-u_0\rangle\end{aligned}$$

because

$$\beta_\lambda(y_\lambda-\varphi)(y_\lambda-y_0-\rho w)\geqq\frac{1}{2\lambda}(|(y_\lambda-\varphi)^-|^2-|(y_0+\rho w-\varphi)^-|^2).$$

Hence

$$\int_{\Omega_0}|\Delta p_\lambda|\,dx\leqq C\quad\forall\lambda>0,\tag{3.13}$$

where C is a positive constant independent of λ and n.

This implies that (see [3])

$$\|p_\lambda\|_{W^{1,q}(\Omega_0)}\leqq C\quad\forall\lambda>0,\tag{3.14}$$

where $1\leqq q<N/(N-1)$. Hence there is $p_n\in W^{1,q}(\Omega_0)$ and $\mu_n\in M(\bar\Omega_0)$ (the space of all Borel measures on $\bar\Omega_0$) such that on a subsequence $\lambda_k\to 0$

$$p_{\lambda_k}\to p_n\quad\text{weakly in } w^{1,q}(\Omega_0)$$

and on a subnet (generalized sequence) of $\{\beta_\lambda(y_\lambda-\varphi)\}$,

$$\beta_\lambda(y_\lambda-\varphi)\to\mu_n\quad\text{weak star in } M(\bar\Omega_0).$$

Then, letting λ tend to zero in (3.10) and (3.11), we see that y_n, u_n, p_n, and μ_n satisfy (3.1)-(3.4), thereby completing the proof of Lemma 3.1. Moreover, by estimates (3.13) and (3.14) we see that

$$\|\mu_n\|_{M(\bar\Omega_0)}+\|p_n\|_{W^{1,q}(\Omega_0)}\leqq C\quad\forall n.\tag{3.15}$$

Let us show that (u_n, y_n) satisfy the conditions of Theorem 2.1.

Let us assume that there is a domain $\Pi\subset\Omega_0$ satisfying condition (a) and argue from this to a contradiction. Since as readily seen by (3.4) support $\mu_n\subset\{x;\ y_n(x)=\varphi(x)\}$ we have

$$\begin{gathered}-\Delta p_{n_k}=0\quad\text{in }\Pi,\\ \frac{\partial p_{n_k}}{\partial\nu}=1\quad\text{in }\partial\Pi\cap\partial D,\quad p_{n_k}=0\quad\text{in }\partial\Pi\cap\partial\Omega,\end{gathered}\tag{3.16}$$

and

$$\frac{\partial p_{n_k}}{\partial\nu}=n_k^{-1}Fu_{n_k}\quad\text{in }\partial\Pi\cap\partial\Omega.\tag{3.17}$$

By estimate (3.15) we may assume without any loss of generality that

$$p_{n_k} \to p \quad \text{weakly in } W^{1,q}(\Omega_0). \tag{3.18}$$

Moreover, it is easily seen that $n_k^{-1} F u_{n_k} \to 0$ strongly in $H^{-m+1/2}(\partial\Omega)$. Thus letting n_k tend to $+\infty$ in (3.16) and (3.17), we see that p satisfies the equations

$$\begin{gathered} \Delta p = 0 \quad \text{in } \Pi, \\ \frac{\partial p}{\partial \nu} = 1 \quad \text{in } \partial\Pi \cap \partial D, \quad p = 0 \quad \text{in } \partial\Pi \cap \partial\Omega, \end{gathered} \tag{3.19}$$

$$\frac{\partial p}{\partial \nu} = 0 \quad \text{in } \partial\Pi \cap \partial\Omega. \tag{3.20}$$

Let $x_0 \in \partial\Pi \cap \partial\Omega$ be fixed, and let $r > 0$ be a sufficiently small number such that $B_{2r}(x_0) \cap \Omega \subset B_{2r}(x_0) \cap \Pi$.

Let $\alpha \in C_0^\infty(B_{2r}(x_0))$ be such that $\alpha = 1$ in $B_r(x_0)$. Then the function $\tilde{p} = \alpha p$ satisfies the equation

$$\Delta \tilde{p} = \nabla \alpha \cdot \nabla p + p \Delta \alpha \overset{\text{def}}{=} g \quad \text{in } B_{2r}(x_0) \cap \Omega = U$$

and

$$\tilde{p} = 0 \quad \text{in } \partial U.$$

Since $g \in L^q(U)$ we infer by the classical result of Agmon-Douglis-Nirenberg that $\tilde{p} \in W^{2,q}(U)$ and therefore $\nabla \tilde{p} \in L^{q^*}(U)$ where $1/q^* = 1/q - 1/N$. Repeating this argument several times and keeping in mind that $\tilde{p} = p$ on $B_r(x_0)$, it follows by standard interior and boundary regularity for elliptic equations (see, for instance, [3]) that $\tilde{p} \in C^2(\overline{B_\delta(x_0) \cap \Omega})$ where δ is suitable chosen. Since $\Delta p = 0$ in $B_\delta(x_0) \cap \Omega$ and by (3.20) $p = \partial p/\partial \nu = 0$ on $\partial\Omega \cap B_\delta(x_0)$ we conclude by the unique continuation theorem that $p = 0$ in $B_\delta(x_0) \cap \Omega$. Inasmuch as p is analytic in Π we infer that $p = 0$ in Π, and this contradicts the boundary condition $\partial p/\partial \nu = 1$ in $\partial\Pi \cap \partial D$. The contradiction we arrived at completes the proof.

Remark 3.1. To obtain an approximate solution to problem (P) we may use instead of (P_n) an optimal control of the following form:

(3.21) Minimize $\{\int_{\partial D} y(x)\, d\sigma + (1/2n)\|u\|^2_{L^2(\partial\Omega)}\}$ subject to (1.4) and state constraints $y \geqq \varphi$ in Ω_0.

Note that for every $u \in L^2(\partial\Omega)$ problem (1.4) has a unique solution $y \in L^2(\Omega_0)$ and $y \in H^2(\tilde{\Omega} \backslash \bar{D})$ for any domain $\tilde{\Omega}$, $D \subset \tilde{\Omega} \subset \Omega$ so that (3.21) makes sense. The solution (u_n, y_n) to problem (3.2) can be obtained as a limit for $\lambda \to 0$ of the solution (u_λ, y_λ) to the approximating optimality system (3.10) where $u_\lambda = n(\partial p_\lambda/\partial \nu)$.

4. Proof of Theorem 2.2. Let Q_ε be a connected open subset of Ω_0 such that $m((\Omega_0 \backslash Q_\varepsilon) \leqq \varepsilon$ and for a sufficiently small $\delta > 0$, $\{x \in \Omega_0;\ \text{dist}(x, \partial D) < \delta\} \cup \{x \in \Omega_0;\ \text{dist}(x, \partial\Omega) < \delta\} \subset Q_\varepsilon$.

Consider the following optimal control problem:

(4.1) Minimize $\{\frac{1}{2}\int_{\partial D} (y - \varphi)^2\, d\sigma + (1/2n)\|u\|^2_{H^{m-1/2}(\partial\Omega)}\}$ on all
$(u, y) \in H^{m-1/2}(d\Omega) \times H^m(\Omega_0)$ subject to system (1.4)
and to the state constraint $y \geqq \varphi$ in Q_ε.

Approximate problem (4.1) by the following family of penalized problems:

(4.2) Minimize $\{\frac{1}{2}\int_{\partial D} (y - \varphi)^2\, d\sigma + (1/2n)\|u\|^2_{H^{m-1/2}(\partial\Omega)} + (1/2\lambda)\int_{Q_\varepsilon} ((y - \varphi)^-)^2\, dx\}$ subject to (4.1).

If (u_λ, y_λ) is the optimal pair of problem (4.2), then we have as in the proof of Lemma 3.1 that

$$\begin{aligned} &u_\lambda \to u_n \quad \text{strongly in } H^{m-1/2}(\partial\Omega), \\ &y_\lambda \to y_n \quad \text{strongly in } H^m(\Omega_0), \end{aligned} \tag{4.3}$$

and

$$\begin{aligned} &-\Delta p_\lambda = \chi_\varepsilon \beta_\lambda(y_\lambda - \varphi) \quad \text{in } \Omega_0, \\ &\frac{\partial p_\lambda}{\partial \nu} = y_\lambda - \varphi \quad \text{in } \partial D, \quad p_\lambda = 0 \quad \text{in } \partial\Omega, \\ &\frac{\partial p_\lambda}{\partial \nu} = n^{-1} F u_\lambda \quad \text{in } \partial\Omega, \end{aligned} \tag{4.4}$$

where (u_n, y_n) is the solution to problem (4.1), $p_\lambda \in H^2(\Omega_0)$, and χ_ε is the characteristic function of the domain Q_ε.

Then, arguing as in the proof of Theorem 2.1, we conclude that $\{p_\lambda\}$ is bounded in $W^{1,q}(\Omega_0)$, $\{\Delta p_\lambda\}$ is bounded in $L^1(\Omega_0)$; therefore there are $p_n \in W^{1,q}(\Omega_0)$ and $\mu_n \in M(\bar{\Omega}_0)$ such that

$$\begin{aligned} &-\Delta p_n = \chi_\varepsilon \mu_n \quad \text{in } \Omega_0, \\ &\frac{\partial p_n}{\partial \nu} = y_n - \varphi \quad \text{in } \partial D, \quad y_n = 0 \quad \text{in } \partial\Omega, \\ &\frac{\partial p_n}{\partial \nu} = n^{-1} F u_n \quad \text{in } \partial\Omega. \end{aligned} \tag{4.5}$$

For $n \to \infty$, $\{y_n\}$ is bounded in $L^2(\partial D)$ and by estimate (3.15), $\{\mu_n\}$ is bounded in $M(\bar{\Omega}_0\}$, and $\{p_n\}$ is bounded in $W^{1,q}(\Omega_0)$. Thus there are $p \in W^{1,q}(\Omega_0)$ and $\mu \in M(\bar{\Omega}_0)$ such that

$$\begin{aligned} &-\Delta p = \chi_\varepsilon \mu \quad \text{in } \Omega_0, \\ &\frac{\partial p}{\partial \nu} = g \quad \text{in } \partial D, \quad p = 0 \quad \text{in } \partial\Omega, \\ &\frac{\partial p}{\partial \nu} = 0 \quad \text{in } \partial\Omega, \end{aligned} \tag{4.6}$$

where $g = w - \lim y_{n_k} - \varphi$ in $L^2(\partial D)$. In other words,

$$(\mu\chi_\varepsilon)(\psi) = \int_{\Omega_0} \nabla p \cdot \nabla \psi \, dx - \int_{\partial D} \psi g \, d\sigma \quad \forall \psi \in H^m(\Omega_0). \tag{4.7}$$

Hence

$$\begin{aligned} &-\Delta p = 0 \quad \text{in } \Omega_0 \backslash \bar{Q}\varepsilon, \\ &p = 0, \quad \frac{\partial p}{\partial \nu} = 0 \quad \text{in } \partial\Omega. \end{aligned}$$

Then, arguing as in the proof of Theorem 2.1, we deduce by the unique continuation theorem that $p = 0$ in $\Omega_0 \backslash \bar{Q}_\varepsilon$. Since p is analytic in $\Omega_0 \backslash \bar{Q}_\varepsilon$ and consequently in a neighborhood of ∂D we infer that $p \equiv 0$ in v. If in (4.7) we take supp $\psi \subset \Omega_0 \backslash \bar{Q}_\varepsilon$ we see that $g \equiv 0$, as claimed.

Clearly this argument implies that $y_n \to \varphi$ weakly in $L^2(\partial D)$, thereby completing the proof.

5. Neumann boundary conditions. Consider the controllability problem (1.3) for the variational inequality

$$\begin{aligned} &y-\Delta y=0 \quad \text{in } \{x\in\Omega;\, y(x)>\varphi(x)\},\\ &y-\Delta y\leqq 0 \quad \text{in } \Omega, \quad y\geqq\varphi \quad \text{in } \Omega, \\ &\frac{\partial}{\partial \nu}y=u \quad \text{in } \partial\Omega, \end{aligned} \tag{5.1}$$

where $u\in H^{m-3/2}(\partial\Omega)$, i.e.,

(5.2) Find $u\in H^{m-3/2}(\partial\Omega)$ such that $D\subset E_u$, where D is a given smooth subset of Ω and E_u is the coincidence set associated with problem (4.1).

We will assume as above that $\varphi\in C^m(\bar{\Omega})$, ∂D is of class C^m, and

$$\begin{aligned} &\varphi-\Delta\varphi\geqq 0 \quad \text{in } D,\\ &\frac{\partial\varphi}{\partial\nu}\geqq 0 \quad \text{in } \partial D. \end{aligned} \tag{5.3}$$

Then, arguing as in the proof of Lemma 1.1, which remains true in this case, we may reduce problem (4.2) to

(P_1) Find $u\in H^{m-3/2}(\partial\Omega)$ such that $y^u=\varphi$ on ∂D and $y^u\geqq\varphi$ on Ω, where y^u is the solution to boundary value problem

$$\begin{aligned} &y-\Delta y=0 \quad \text{in } \Omega_0,\\ &\frac{\partial y}{\partial\nu}=\frac{\partial\varphi}{\partial\nu} \quad \text{in } \partial D, \qquad \frac{\partial y}{\partial\nu}=u \quad \text{in } \partial\Omega. \end{aligned} \tag{5.4}$$

Also in this case we have a controllability result of the nature of Theorem 2.1.

THEOREM 5.1. *There is a sequence* $(u_n, y_n)\subset H^{m-3/2}(\partial\Omega)\times H^m(\Omega_0)$ *satisfying system* (5.4) *and the constraints* $y_n\geqq\varphi$ *in* Ω_0, *and having property* (a) *of Theorem* 2.1.

If it is assumed further that

$$\varphi-\Delta\varphi\geqq 0 \quad \text{in } \Omega_0, \tag{5.5}$$

then every subdomain Ω_0' of Ω_0 such that $y_n=\varphi$ on $\partial\Omega_0'\backslash\partial D$ belongs to Ω_n.

In other words, u_n is an approximating solution to controllability problem $\{u\in H^{m-3/2}(\partial\Omega);\, E_u\supset D\}$.

Since the proof of Theorem 5.1 is similar to that of Theorem 2.1, it will only be sketched.

Consider the following optimal control problem:

(P_n^1) Minimize $\{\int_{\partial D} y\, d\sigma+(1/2n)\|u\|^2_{H^{m-3/2}(\partial\Omega)}\}$ on all $(y,u)\in H^m(\Omega_0)\times H^{m-3/2}(\partial\Omega)$ subject to (5.4) and to state constraint $y\geqq\varphi$ on Ω_0.

We associate the following penalized problem:

(5.6) Minimize $\{\int_{\partial D} y\, d\sigma+(1/2n)\|u\|^2_{H^{m-3/2}(\partial\Omega)}+(1/2\lambda)\int_{\Omega_0}[(y-\varphi)]^2\,dx\}$ subject to (5.4)

and denote (u_n, y_n), (u_λ, y_λ) the corresponding solution to problem (P_n) and (5.6), respectively.

We have for $\lambda\to 0$

$$u_\lambda \to u_n \quad \text{strongly in } H^{m-3/2}(\partial\Omega), \tag{5.7}$$

$$y_\lambda \to y_n \quad \text{strongly in } H^{m}(\Omega_0) \tag{5.8}$$

and

$$\begin{gathered} p_\lambda - \Delta p_\lambda = \beta_\lambda(y_\lambda - \varphi) \quad \text{in } \Omega_0, \\ \frac{\partial p_\lambda}{\partial \nu} = 1 \quad \text{in } \partial D, \quad \frac{\partial p_\lambda}{\partial \nu} = 0 \quad \text{in } \partial\Omega, \end{gathered} \tag{5.9}$$

$$p_\lambda + n^{-1}\phi(u_\lambda) = 0 \quad \text{in } \partial\Omega, \tag{5.10}$$

where $\phi: H^{m-3/2}(\partial\Omega)\to H^{3/2-m}(\partial\Omega)$ is the canonical isomorphism of the space $H^{m-3/2}(\partial\Omega)$ onto its dual $H^{3/2-m}(\partial\Omega)$.

If (u_0, y_0) is the pair defined as in the proof of Theorem 2.1, then $\tilde{u}_0 = \partial y_0/\partial \nu$ is an admissible control for problem (P_n) and we find, as there, the estimate

$$\begin{aligned} \rho \int_{\Omega_0} |p_\lambda - \Delta p_\lambda|\, dx &\leqq -\int_{\partial D} (y_\lambda - y_0)\, d\sigma + \int_{\partial D} p_\lambda \frac{\partial}{\partial \nu}(y_\lambda - y_0)\, d\sigma \\ &= -\int_{\partial D} (y_\lambda - y_0)\, d\sigma - n^{-1} < \phi(u_\lambda), u_\lambda - u_0 > \leqq C, \end{aligned} \tag{5.11}$$

where C is independent of λ and n. (Here $\langle\cdot,\cdot\rangle$ is the duality pairing between $H^{m-3/2}(\partial\Omega)$ and $H^{3/2-m}(\partial\Omega)$.) Hence $\{p_\lambda - \Delta p_\lambda\}$ is bounded in $L^1(\Omega_0)$ and so by Lemma 2.3 of [3] it follows that $\{p_\lambda\}$ is bounded in $W^{1,q}(\Omega_0)$, where $1\leqq q< N(N-1)$. Thus we may pass to limit in (5.9) to get the optimality system associated with (P_n)

$$\begin{gathered} y_n - \Delta y_n = 0 \quad \text{in } \Omega_0, \\ \frac{\partial y_n}{\partial \nu} = \frac{\partial \varphi}{\partial \nu} \quad \text{in } \partial D, \quad \frac{\partial y_n}{\partial \nu} = u_n \quad \text{in } \partial\Omega, \end{gathered} \tag{5.12}$$

$$\begin{gathered} p_n - \Delta p_n = \mu_n \quad \text{in } \Omega_0, \\ \frac{\partial p_n}{\partial \nu} = 1 \quad \text{in } \partial D, \quad \frac{\partial p_n}{\partial \nu} = 0 \quad \text{in } \partial\Omega, \end{gathered} \tag{5.13}$$

$$p_n + n^{-1}\phi(u_n) = 0 \quad \text{in } \partial\Omega, \tag{5.14}$$

$$\mu_n \in M(\bar{\Omega}_0), \quad \mu_n(y_n - z) \geqq 0, \quad \forall z \in C(\bar{\Omega}_0), \quad z \geqq \varphi. \tag{5.15}$$

The solution $p_n \in W^{1,q}(\Omega_0)$ to system (5.13) should be understood, of course, in the weak sense (3.5), i.e.,

$$\mu_n(\psi) - \int_{\Omega_0} \nabla p_n \nabla \psi\, dx - \int_{\partial D} \psi\, d\sigma = 0, \quad \forall \psi \in H^m(\Omega_0).$$

Note also that the estimate (3.15) remains valid in this case. Arguing as in the proof of Theorem 2.1, it follows that (u_n, y_n) has the property required for Ω_n.

Now, if there is $\Pi \subset \Omega_0$ satisfying condition (a) of Theorem 2.1, we have

$$p_{n_k} - \Delta p_{n_k} = 0 \quad \text{in } \Pi,$$

$$\frac{\partial p_{n_k}}{\partial \nu} = 1 \quad \text{in } \partial\Pi \cap \partial D, \quad \frac{\partial p_{n_k}}{\partial \nu} = 0 \quad \text{in } \partial\Pi \cap \partial\Omega,$$

$$p_{n_k} = n_k^{-1}\phi(u_{n_k}) \quad \text{in } \partial\Pi \cap \partial\Omega,$$

and letting $n_k \to +\infty$ we see that there is $p \in W^{1,q}(\Omega_0)$ such that

$$p - \Delta p = 0 \quad \text{in } \Pi,$$

$$\frac{\partial p}{\partial \nu} = 1 \quad \text{in } \partial\Pi \cap \partial D, \quad \frac{\partial p}{\partial \nu} = 0 \quad \text{in } \partial\Pi \cap \partial\Omega,$$

$$p = 0 \quad \text{in } \partial\Pi \cap \partial\Omega.$$

As seen in the proof of Theorem 2.1 this implies, via regularity theory for elliptic boundary value problems and the unique continuation theorem, that $p = 0$ in Π, thereby completing the proof.

The theorem below follows by a similar argument.

THEOREM 5.2. *For every $\varepsilon > 0$, there is an open connected subset Q_ε of Ω_0 such that $m(\Omega_0 \backslash Q_\varepsilon) \leqq \varepsilon$ and a sequence $\{(u_n, y_n)\} \subset H^{m-3/2}(\partial\Omega) \times H^m(\Omega_0)$ satisfying system* (5.4) *and conditions* (2.4), (2.5) *in Theorem* 2.2.

A SUBSPACE DECOMPOSITION PRINCIPLE FOR SCALED GRADIENT PROJECTION METHODS: GLOBAL THEORY*

J. C. DUNN†

Abstract. Fast gradient projection methods for constrained minimization problems, $\min_\Omega J$, achieve their superior asymptotic convergence rates by scaling the objective function gradient $\nabla J(u)$ prior to the projection step. The scaling procedure investigated in this article decomposes $\nabla J(u)$ relative to specially constructed complementary orthogonal subspaces N and T, multiplies the N-component of $\nabla J(u)$ by a positive scalar $s_N(u)$, transforms the T-component of $\nabla J(u)$ with a bounded linear operator $S_T: T \to T$, and adds the resulting vectors to obtain the scaled gradient of J at u. A global convergence analysis is undertaken here for scaled gradient projection (SGP) methods that utilize this technique and a compatible steplength rule of the Bertsekas-Gafni type in closed convex Ω defined by m smooth inequality constraints. Extensive comparisons are drawn with a related SGP method based on the Gafni-Bertsekas dual cone decomposition technique. The two SGP schemes have similar global convergence properties, but the subspace decomposition procedure is generally easier to implement, and is better suited to convergence acceleration in nonpolyhedral Ω. A comprehensive local convergence theory has also been constructed for the new scheme and will be presented in a sequel to this article. In general, SGP algorithms are well suited to optimal control problems, network flow problems, and other cases where Ω is a Cartesian product of simple convex sets.

1. Introduction.

The gradient projection (GP) methods in [1]-[10] and the more recent scaled gradient projection (SGP) algorithms in [7] and [11]-[15] are useful for a variety of specially structured constrained minimization problems

$$\min_{u \in \Omega} J(u),$$

where J is a smooth real function on a real Hilbert space $\{\mathcal{U}, \langle \cdot, \cdot \rangle\}$ and Ω is a nonempty closed convex set in $\mathcal{U}$. These algorithms generate successive feasible approximations $u^i \in \Omega$ recursively with

$$u^{i+1} = P_\Omega(u^i + \sigma^i v^i), \tag{1a}$$

where at each $u \in \Omega$,

$$v = v_N + v_T, \tag{1b}$$

$$v_N = s_N P_N(-\nabla J(u)), \tag{1c}$$

$$v_T = P_T S_T P_{N^*}(-\nabla J(u)), \tag{1d}$$

$$N = \text{a closed convex cone containing } K(u), \tag{1e}$$

$$K(u) = \text{the normal cone at } u = \{w: \forall v \in \Omega, \langle w, v-u \rangle \leqq 0\}, \tag{1f}$$

$$\mathrm{N}^* = \text{the dual cone for } N = \{w^*: \forall w \in N, \langle w^*, w \rangle \leqq 0\}, \tag{1g}$$

$$T = \{v_N\}^\perp \cap N^*, \tag{1h}$$

$$[T] = \text{the closed linear hull of } T, \tag{1i}$$

(1j) $$\mu_3 \geqq s_N \geqq \mu_2 > 0,$$

$$S_T = \text{a bounded linear map from } [T] \text{ into } [T] \text{ such that}$$

(1k) $$\langle P_{N^*}(-\nabla J(u)), S_T P_{N^*}(-\nabla J(u))\rangle \geqq \mu_0 \|P_{N^*}(-\nabla J(u))\|^2$$

(1l) $$\|S_T\| \leqq \mu_1,$$

$$\sigma = \max s, \quad \text{subject to}$$

$$\frac{s}{\alpha} \in \{1, \beta, \beta^2, \cdots\},$$

and

(1m) $$J(u) - J(P_\Omega(u+sv)) \geqq \delta\{(s_N s)^{-1}\|u + sv_T - P_\Omega(u+sv)\|^2 + \langle P_{N^*}(-\nabla J(u)), v_T\rangle s\},$$

and where δ and β are fixed real numbers in (0, 1), α and $\mu_0, \cdots, \mu_3$ are fixed positive real numbers, and P_A denotes projection into the set A (relative to the fixed metric in $\mathcal{U}$). In practice, N^i, s_N^i, and S_T^i are further restricted at each iteration by auxiliary rules designed to control global and local convergence behavior.

When $N = \mathcal{U}$ and $s_N = 1$, the scheme (1) reduces to a simple Goldstein-Levitin-Polyak iteration [1], [2],

$$u^{i+1} = P_\Omega(u^i - \sigma^i \nabla J(u^i))$$

with a steplength rule of the Bertsekas type [3]. In this case, the corresponding iterate sequences $\{u^i\}$ behave globally and locally like their steepest descent counterparts for unconstrained minimization [16], [17]. More specifically, $\{J(u^i)\}$ is generally decreasing, limit points of $\{u^i\}$ are stationary, and u^i typically becomes "more stationary" with increasing i; however, the asymptotic rates of improvement may be quite poor, depending on the local structure of J and Ω [5], [6]. On the other hand, if $\Omega = \mathcal{U}$ and $N = \{0\} = K(u)$, then (1) reduces to an unconstrained variable metric gradient iteration,

$$u^{i+1} = u^i - \sigma^i S^i \nabla J(u^i)$$

with steplengths σ of the Armijo-Goldstein type [18]-[20]. Under these circumstances, it is possible to secure both the desired global convergence properties *and* fast asymptotic convergence rates by fixing δ in $(0, \frac{1}{2})$, setting $\alpha = 1$, and making sure that the scaling operators S^i approximate the Newtonian transformations $(\nabla^2 J(u^i))^{-1}$ on the span of $\{\nabla J(u^i)\}$ when u^i is near a nonsingular local minimizer of J [16], [17], [20]. Hence for general closed convex $\Omega \subset \mathcal{U}$, the question is this: Are there cones N large enough to preserve rudimentary descent and limit point stationarity properties for (1), yet small enough to ensure that the corresponding scaling subspaces $[T]$ will support Newton-like convergence-accelerating operators S_T? Bertsekas [11] and Gafni and Bertsekas [12] were the first to show that these two antagonistic requirements can indeed be satisfied in polyhedral convex sets Ω. The present article analyzes an alternative to the construction in [12] outlined previously in [15]; this alternative SGP scheme works in polyhedral Ω and also in nonpolyhedral Ω prescribed by finitely many smooth nonaffine inequality constraints.

The general cone construction in [12] proceeds from an affine inequality representation

(2a) $$\Omega = \{u : \forall j \in \mathcal{J}, \langle a^j, u\rangle - b^j \leqq 0\},$$

where $\mathcal{J}$ is an index set, $a^j \in \mathcal{U}$, and $b^j \in \mathbb{R}$; in a Hilbert space, every closed convex Ω has such a representation, with $\mathcal{J}$ finite only if Ω is polyhedral. Let ε_0 be an arbitrary but fixed positive real number, and at each $u \in \Omega$, put

(2b) $$d(u) = \|u - P_\Omega(u - \nabla J(u))\|,$$

(2c) $$\varepsilon(u) = \min\{\varepsilon_0, d(u)\},$$

$$\mathcal{J}(u)=\{j\in\mathcal{J}: \langle a^j, u\rangle - b^j \geqq -\|a^j\|\,\varepsilon(u)\}, \tag{2d}$$

$$C(u)=\{w: \forall j\in\mathcal{J}(u), \langle w, a^j\rangle \leqq 0\}. \tag{2e}$$

If $d(u)=0$, then u is *stationary*, i.e.,

$$\forall v\in\Omega, \quad \langle \nabla J(u), v-u\rangle \geqq 0,$$

or equivalently,

$$-\nabla J(u)\in K(u).$$

In this case, any closed convex cone $N\supset K(u)$ will serve for (1). If $d(u)\neq 0$, then u is not stationary and [12] employs cones N satisfying

$$N\supset C(u)^*=\{w^*: \forall w\in C(u), \langle w^*, w\rangle\leqq 0\} \tag{2f}$$

(actually, [12] imposes the somewhat stronger condition (13) in § 3).

The cone $C(u)^*$ is expressly designed to contain not only $K(u)$ but all neighboring normal cones $K(u')$ for $u'\in\Omega$ near u, and it is this feature that ultimately yields the robust global limit point stationarity theorem for (1)-(2) in arbitrary closed convex Ω [12]. Furthermore, if Ω is polyhedral and u is sufficiently close to a nonsingular local minimizer $\bar u$ (i.e., a $\bar u$ satisfying standard Kuhn-Tucker second-order sufficient conditions), then $C(u)^*=K(\bar u)$, and the cone T corresponding to the lower bound $N=C(u)^*$ in (2f) is just the tangent space $K(\bar u)^\perp$ for the unique polyhedral face $\mathcal{F}$ containing $\bar u$ in its relative interior ri $\mathcal{F}$. For $N^i\supset C(u^i)^*$, any sequence $\{u^i\}$ generated by (1)-(2) will converge to $\bar u$ from nearby starting points and eventually enter and remain within ri $\mathcal{F}$. In effect, these processes terminate in an "unconstrained" variable metric gradient iteration for J restricted to a translate of $K(\bar u)^\perp = T$. Hence in polyhedral Ω, (1)-(2) is locally linearly convergent to nonsingular minimizers $\bar u$, and can be *superlinearly* convergent if $N^i=C(u^i)^*$, $\delta\in(0,\frac12)$, $\alpha=1$, and the scaling operators S^i_T asymptotically approximate the inverse reduced Hessians

$$P_{T^i}\nabla^2 J(u^i)|_{T^i}^{-1}$$

in the one-dimensional subspaces generated by $P_{T^i}\nabla J(u^i)$. On the other hand, no comparable convergence acceleration claim is made in [12] for nonpolyhedral Ω, and it is unlikely that such a result can be proved. For example, suppose that $\mathcal{U}=\mathbb{R}^3$ and Ω is the unit ball $B(0,1)=\{u: \|u\|\leqq 1\}$ with affine inequality representation

$$B(0,1)=\{u: \forall j\in\mathcal{J}, \langle j, u\rangle - 1\leqq 0\},$$

where

$$\mathcal{J}=S(0,1)=\{j\in\mathcal{U}: \|j\|=1\}.$$

Near any nonsingular boundary point minimizer $\bar u\in S(0,1)$, it seems clear that Newton-like convergence acceleration is possible only if $[T]$ approximates the two-dimensional space tangent to the smooth manifold $S(0,1)$ at $\bar u$; however, for any u near but not equal to $\bar u$, the sets $C(u)$ and $C(u)^*$ in (2) are dual nondegenerate right circular cones, the cone T corresponding to $N=C(u)^*$ is typically a generator in $C(u)$, and $[T]$ is then a subspace of dimension one.

The alternative SGP formulation in [15] restricts the cone N to the family of closed *subspaces* containing $K(u)$; under these circumstances, $[T]=T=N^*=N^\perp$, and (1) reduces to the simpler subspace decomposition and scaling scheme

$$u\to P_\Omega(u+\sigma v) \tag{3a}$$

with

(3b) $$v = v_N + v_T,$$

(3c) $$v_N = -s_N P_N \nabla J(u),$$

(3d) $$v_T = -S_T P_T \nabla J(u),$$

(3e) $$N = \text{a closed subspace} \supset K(u),$$

(3f) $$K(u) = \{w\colon \forall v \in \Omega, \langle w, v-u\rangle \leqq 0\},$$

(3g) $$T = N^{\perp},$$

(3h) $$\mu_3 \geqq s_N \geqq \mu_2,$$

$$S_T = \text{a bounded linear map from } T \text{ into } T\text{, such that}$$

(3i) $$\langle P_T \nabla J(u), S_T P_T \nabla J(u)\rangle \geqq \mu_0 \|P_T \nabla J(u)\|^2$$

$$\|S_T\| \leqq \mu_1,$$

(3j) $$\sigma = \max s, \quad \text{subject to}$$

$$\frac{s}{\alpha} \in \{1, \beta, \beta^2, \cdots\}$$

and

(3k) $$J(u) - J(P_\Omega(u+sv)) \geqq \delta\{(s_N s)^{-1}\|u + sv_T - P_\Omega(u+sv)\|^2 - \langle P_T \nabla J(u), v_T\rangle s\}.$$

The subspaces N are further restricted as follows in closed convex sets with smooth inequality representations:

(4a) $$\Omega = \{u\colon g_i(u) \leqq 0, i = 1, \cdots, m\}.$$

Fix $\varepsilon_0 > 0$ and $\theta > 1$ (see Note 2 at the end of § 3) and at each $u \in \Omega$, put

(4b) $$d(u) = \|u - P_\Omega(u - \nabla J(u))\|,$$

(4c) $$\varepsilon(u) = \min\{\varepsilon_0, d(u)\},$$

(4d) $$\mathcal{J}_0(u) = \{j\colon g_j(u) = 0\},$$

(4e) $$\mathcal{J}(u) = \{j\colon g_j(u) \geqq -\theta\|\nabla g_j(u)\|\varepsilon(u)\} \supset \mathcal{J}_0(u),$$

(4f) $$\mathcal{G}_0(u) = \{\nabla g_j(u)\}_{j \in \mathcal{J}_0(u)},$$

(4g) $$\mathcal{G}(u) = \{\nabla g_j(u)\}_{j \in \mathcal{J}(u)} \supset \mathcal{G}_0(u),$$

(4h) $$N_0(u) = [\mathcal{G}_0(u) \cup \{0\}],$$

(4i) $$N(u) = [\mathcal{G}(u) \cup \{0\}] \supset N_0(u).$$

(Observe that the sets $\mathcal{J}_0(u)$, $\mathcal{J}(u)$, $\mathcal{G}_0(u)$, and $\mathcal{G}(u)$ may be empty at certain $u \in \Omega$.) Then [15] requires that

(4j) $$N \supset N(u).$$

This condition implies (3e) under the standard assumptions set forth in the following.

Constraint Qualification (Q). Either

(i) The functions g_j in (4a) are affine, i.e., $g_j(u) = \langle a^j, u\rangle - b^j$, with $a^j \in \mathcal{U}$ and $b^j \in \mathbb{R}$; or

(ii) Equation (4a) is a *normal representation* for Ω, i.e., for all $u \in \Omega$, $\mathcal{G}_0(u)$ is linearly independent.

Unless otherwise noted, it will be assumed that (4a) satisfies (Q).

When (Q) holds, the Hilbert space extension of the Farkas lemma [21] guarantees that $K(u)$ consists of zero and all nonnegative linear combinations of vectors in $\mathcal{G}_0(u)$, and hence that $N(u) \supset K(u)$. Moreover, the normality condition (Q)(ii) typically does hold when Ω is the kind of convex set for which the projections in (3) are readily implemented, e.g., Cartesian products of orthants, boxes, simplices, balls, cylinders, convex figures of revolution, and the like (feasible sets of this type are commonplace in optimal control and network flow applications [11]-[15]). On the other hand, in nonpolyhedral sets (4a), the subspace $N(u)$ is not large enough to contain neighboring normal cones $K(u')$, and hence the global convergence proof strategy developed in [12] for (1)-(2) cannot be applied to (3)-(4). A different approach based on special properties of the normal cone $K(u)$ in sets (4a) is fully developed in §§ 2-4 below. The resulting limit point stationarity theorem is somewhat narrower than its counterpart in [12] for arbitrary closed convex sets; however, the scheme (3)-(4) is generally easier to implement than (1)-(2), and its local convergence behavior appears equal or superior to the behavior of (1)-(2) in closed convex sets (4a) satisfying (Q). When Ω is polyhedral, and when $N = C(u)^*$ in (1)-(2) and $N = N(u)$ in (3)-(4), the corresponding SGP iterations turn out to be locally equivalent near nondegenerate stationary points, i.e., the two schemes generate identical iterates near $\bar{u}$ even though $N(u) \neq C(u)^*$ in general. With reference to [12], this means that (3)-(4) can be locally superlinearly convergent to nonsingular minimizers $\bar{u}$ in polyhedral sets (4a) if s_N and S_T are properly chosen. More generally, in any closed convex set (4a) satisfying (Q), the iteration (3)-(4) is at least locally linearly convergent to nonsingular local minimizers $\bar{u}$, and will converge superlinearly to such $\bar{u}$'s when S_T^i asymptotically approximates certain Newtonian scaling operators described in [14] on the span of $\{P_{T_i} \nabla J(u^i)\}$. Proofs for these claims are supplied in a sequel to the present article.

The cost of computing the various projections and Newtonian scaling operations is clearly an essential practical consideration that limits the application of SGP methods to problems with specially structured feasible sets and objective functions. Nevertheless, the class of likely problems is surprisingly large and includes the k-stage input-constrained discrete-time optimal control problems treated in [11] and later in [7] and [13]-[15]. For these problems, Ω is a Cartesian product of k simple convex sets defined by separable constraints, $N(u)$ and $T(u)$ are Cartesian products of k mutually orthogonal subspaces, and Newtonian scaling can be computed cheaply with dynamic programming methods or other techniques, typically in $O(k)$ flops. Under these circumstances, $\sigma(u)$ is also readily computed, and the cost per iteration for Newtonian SGP schemes is some fixed multiple of the unscaled GP cost, with a cost multiplier that depends on the complexity of the stagewise loss functions and dynamical transformations, but does *not* depend on k. For a more detailed discussion of these points, see [14], [15], [22]. For network flow applications of the SGP scheme, see [12].

2. The Bertsekas–Gafni steplength rule. Fix u in Ω and v in $\mathcal{U}$, and put

$$\phi(\sigma) = P_\Omega(u + \sigma v)$$

for $\sigma \geqq 0$. Our immediate objective is to show that near $\sigma = 0$, the quotients $\sigma^{-1}\langle \nabla J(u), u - \phi(\sigma)\rangle$ and $\sigma^{-1}(J(u) - J(\phi(\sigma)))$ are uniformly bounded below by a certain measure of nonstationarity for u when v satisfies (1). This bound points directly to the steplength rule (1m) and is crucial in the global convergence analysis for (1)-(2) in [12] and (3)-(4) in § 4.

Since P_Ω is nonexpansive,

$$\|\phi(\sigma) - u\| \leqq \|v\| \sigma \tag{5}$$

and therefore

$$J(u) - J(\phi(\sigma)) = \langle \nabla J(u), u - \phi(\sigma)\rangle + o(\sigma). \tag{6}$$

By the Hilbert space projection theorem [23],

$$u+\sigma v-\phi(\sigma)\in K(\phi(\sigma))$$

and thus

$$\sigma\langle v, \phi(\sigma)-u\rangle \geqq \|\phi(\sigma)-u\|^2.$$

Observe that by Lemma 2.2 of [24]

$$-\nabla J(u)=P_N(-\nabla J(u))+P_{N^*}(-\nabla J(u)) \tag{7a}$$

with

$$\langle P_N(-\nabla J(u)), P_{N^*}(-\nabla J(u))\rangle=0. \tag{7b}$$

Hence, if v satisfies (1), then

$$\sigma s_N\langle \nabla J(u), u-\phi(\sigma)\rangle \geqq \|u+\sigma v_T-\phi(\sigma)\|^2-\|v_T\|^2\sigma^2+\langle x, \phi(\sigma)-u\rangle\sigma \tag{8a}$$

with

$$x=(v_T+s_N P_{N^*}(-\nabla J(u)))\in T. \tag{8b}$$

This estimate is carried further in the next two lemmas.

LEMMA 1. *Let Ω be a closed convex set. Fix u in Ω and v in $\mathcal{U}$. Then for all x and σ,*

$$x\in K(u)^* \quad \textit{and} \quad \sigma\geqq 0 \Rightarrow \langle x, \phi(\sigma)-u\rangle \geqq \langle x, v\rangle\sigma+\|x\|\eta(\sigma),$$

where

$$\eta(\sigma)=o(\sigma)$$

as $\sigma\to 0_+$.

Proof. Observe that $v-P_{K(u)^*}v\in K(u)$ and therefore $\langle x, v-P_{K(u)^*}v\rangle\leqq 0$ for x in $K(u)^*$. Furthermore, by Lemmas 2.4 and 4.6 of [24],

$$\phi(\sigma)-u=(P_{K(u)^*}v)\sigma+o(\sigma)$$

and thus

$$\langle x, \phi(\sigma)-u\rangle \geqq \langle x, v\rangle\sigma+\|x\|\cdot o(\sigma). \qquad \square$$

LEMMA 2. *Assume that Ω is a closed convex set. Fix u in Ω, suppose that J is Fréchet differentiable at u, and let v satisfy* (1b)-(11). *Then for all $\sigma>0$,*

$$\langle \nabla J(u), u-\phi(\sigma)\rangle \geqq (s_N^{-1}\sigma^{-2}\|u+\sigma v_T-\phi(\sigma)\|^2+\langle P_{N^*}(-\nabla J(u)), v_T\rangle)\sigma+s_N^{-1}\|x\|\eta(\sigma),$$

where

$$x=[v_T+s_N P_{N^*}(-\nabla J(u))]\in T$$

and

$$\eta(\sigma)=o(\sigma)$$

as $\sigma\to 0_+$. In addition, for α fixed in $(0,\infty)$ *and all $\sigma\in(0,\alpha]$,*

$$s_N^{-1}\sigma^{-2}\|u+\sigma v_T-\phi(\sigma)\|^2+\langle P_{N^*}(-\nabla J(u)), v_T\rangle \geqq d_1(u)\geqq 0,$$

where

$$d_1(u)=\begin{cases}\langle P_{N_*}(-\nabla J(u)), v_T\rangle & \textit{if } P_{N^*}(-\nabla J(u))\neq 0,\\ s_N \min\{1, (s_N\alpha)^{-2}\}\, d(u)^2, & \textit{if } P_{N^*}(-\nabla J(u))=0,\end{cases}$$

$$d(u)=\|u-P_\Omega(u-\nabla J(u))\|$$

and

$$d_1(u)=0 \Leftrightarrow u \quad \textit{is stationary.}$$

Proof. By construction, $T\subset N^*\subset K(u)^*$, $x\in T$ and $\langle x, v_N\rangle=0$. Hence the first claim follows at once from (8) and Lemma 1. The remaining claims are consequences of the coercivity condition (1k) and the following key monotonicity conditions proved in [12], [9], and [8]. For all σ, τ,

$$\tau>\sigma>0 \Rightarrow \sigma^{-1}\|\delta(\sigma)-u\| \geqq \tau^{-1}\|\phi(\tau)-u\|, \tag{9a}$$

$$\tau>\sigma>0 \Rightarrow \|\phi(\tau)-u\| \geqq \|\phi(\sigma)-u\|. \tag{9b}$$

Thus if $P_{N^*}(-\nabla J(u))\neq 0$, note that $w-P_Tw\in T^*$ for all $w\in \mathcal{U}$, and therefore

$$\begin{aligned}\langle P_{N^*}(-\nabla J(u)),\, v_T\rangle &= \langle P_{N^*}(-\nabla J(u)),\, P_TS_TP_{N^*}(-\nabla J(u))\rangle\\ &\geqq \langle P_{N^*}(-\nabla J(u)),\, S_TP_{N^*}(-\nabla J(u))\rangle\\ &\geqq \mu_0\|P_{N^*}(-\nabla J(u))\|^2\\ &>0.\end{aligned} \tag{10}$$

On the other hand, if $P_{N^*}(-\nabla J(u))=0$, then $v_T=0$ and $P_N(-\nabla J(u))=-\nabla J(u)$, and conditions (9) therefore yield

$$\begin{aligned} s_N^{-1}\sigma^{-2}\|u+\sigma v_T-\phi(\sigma)\|^2 &= s_N[(s_N\sigma)^{-2}\|u-P_\Omega(u-s_N\sigma\nabla J(u))\|^2]\\ &\geqq s_N \min\{1, (s_N\alpha)^{-2}\}\, d(u)^2,\end{aligned}$$

where $d(u)=0$ if and only if u is stationary. To complete the proof, observe that if u is stationary, then $0=\|P_{K(u)^*}(-\nabla J(u))\|\geqq\|P_{N^*}(-\nabla J(u))\|$. □

The foregoing development parallels [12] with one notable departure: in [12], the cones N are required to satisfy a condition that implies (2f) (see (13) in § 3). Under these circumstances, Lemma 1 can be strengthened and the estimates in Lemma 2 are obtained with $\eta(\sigma)=0$ for $\sigma\|v\|<\varepsilon(u)$ (see (2c)). Improvements of this kind are needed later on in the global and local convergence analyses for (1)-(2) and (3)-(4); however, Lemma 2 is strong enough to establish the following basic strict descent property in the general setting of (1).

LEMMA 3. *Let the hypotheses of Lemma* 2 *hold and fix* δ *in* (0, 1). *Then for sufficiently small* σ *in* $(0, \alpha]$,

$$\begin{aligned} J(u)-J(\phi(\sigma)) &\geqq \delta[(s_N\sigma)^{-1}\|u+\sigma v_T-\phi(\sigma)\|^2+\langle P_{N^*}(-\nabla J(u)),\, v_T\rangle\sigma]\\ &\geqq \delta d_1(u)\sigma\end{aligned} \tag{11a}$$

with $d_1(u)\geqq 0$ *and*

$$d_1(u)=0 \Leftrightarrow u \quad \textit{is stationary.} \tag{11b}$$

Proof. If u is stationary, then $P_{N^*}(-\nabla J(u))=v_T=d(u)=d_1(u)=0$, and $\phi(\sigma)=u$ for all $\sigma\geqq 0$; in this case (11a) holds trivially for all $\sigma\geqq 0$. If u is not stationary, then (6) and Lemma 2 give

$$\begin{aligned} J(u)-J(\phi(\sigma)) &\geqq [s_N^{-1}\sigma^{-2}\|u+\sigma v_T-\phi(\sigma)\|^2+\langle P_{N^*}(-\nabla J(u)),\, v_T\rangle]\sigma+o(\sigma)\\ &\geqq d_1(u)\sigma+o(\sigma)\end{aligned}$$

as $\sigma\to 0_+$, with $d_1(u)>0$. Now observe that for some $\sigma_1\in(0,\alpha]$ and all $\sigma\in(0,\sigma_1]$, the foregoing estimate holds with

$$\left|\frac{o(\sigma)}{\sigma}\right| \leqq (1-\delta)d_1(u) \leqq (1-\delta)[s_N^{-1}\sigma^{-2}\|u+\sigma v_T-\phi(\sigma)\|^2+\langle P_{N^*}(-\nabla J(u)),\, v_T\rangle]. \qquad □$$

COROLLARY 1. *The fixed points of the* SGP *iteration* (1) *coincide with the stationary points of J in Ω.*

Proof. Suppose that v and σ are determined by (1). If u is stationary, then $\phi(\sigma)=u$ (see the proof of Lemma 3). Conversely, if u is not stationary, then $J(u)-J(\phi(\sigma))\geqq \delta d_1(u)\sigma>0$ and therefore $\phi(\sigma)\neq u$. □

Lemma 3 justifies the Bertsekas-Gafni steplength rule in the general setting of (1). No matter how the cones are constructed, the rule (1m) is well posed and strictly decreases J when u is nonstationary. Consequently, the sequences $\{J(u^i)\}$ produced by (1) are typically decreasing and must converge to $-\infty$ or some finite limit. In the latter case, it can be shown that the quantities $\sigma^i d(u^i)^2$ and $u^{i+1}-u^i$ must converge to zero. While these results alone do not ensure limit point stationarity or convergence of $\{u^i\}$ to any limit, they are important in the development of global and local convergence theories for (1)-(2) and (3)-(4).

LEMMA 4. *Assume that Ω is a closed convex set and that J is Fréchet differentiable in Ω. Let $\{u^i\}$ and $\{\sigma^i\}$ be generated by* (1). *Then $\{J(u^i)\}$ is nonincreasing and either*

$$\lim_{i\to\infty} J(u^i)=-\infty \tag{12a}$$

or

$$\lim_{i\to\infty} J(u^i)=\inf_i J(u^i)>-\infty \tag{12b}$$

and then

$$\lim_{i\to\infty} \sigma^i\|P_{N^{i*}}(-\nabla J(u^i))\|^2=0, \tag{12c}$$

$$\lim_{i\to\infty} (\sigma^i)^{-1}\|u^i-u^{i+1}\|^2=0, \tag{12d}$$

$$\lim_{i\to\infty} \|u^i-u^{i+1}\|^2=0, \tag{12e}$$

$$\lim_{i\to\infty} \sigma^i d(u^i)^2=0. \tag{12f}$$

Proof. Lemma 2 and (1m) imply that $\{J(u^i)\}$ is nonincreasing. If $\{J(u^i)\}$ is also bounded below, then (12b) holds and

$$\lim_{i\to\infty} (J(u^i)-J(u^{i+1}))=0.$$

The estimates (12c)-(12e) now follow easily from (1m), (10), and (11). To prove (12f), observe that (1j)-(1l), (7), and (9) yield

$$\begin{aligned} cd(u^i)&\leqq (s_N^i\sigma^i)^{-1}\|u^i-P_\Omega(u^i-s_N^i\sigma^i\nabla J(u^i))\|\\ &\leqq (\mu_2\sigma^i)^{-1}\|u^i-P_\Omega(u^i-s_N^i\sigma^i\nabla J(u^i))\|\\ &\leqq (\mu_2\sigma^i)^{-1}(\|u^i-u^{i+1}\|+(\mu_1+\mu_3)\sigma^i\|P_{N^{i*}}(-\nabla J(u^i))\|)\end{aligned}$$

with

$$c=\min\{1,(\alpha\mu_3)^{-1}\}>0.$$

Multiply both sides of this inequality by $\sqrt{\sigma^i}$, and (12f) will then follow from (12c)-(12d). □

3. Limit point stationarity. Lemma 4 falls short of establishing that every limit point of $\{u^i\}$ is stationary. This basic result will follow from (12f) if it can be shown that the steplengths σ^i associated with convergent subsequences of $\{u^i\}$ are bounded away from zero. Positive lower bounds for σ^i have indeed been demonstrated in [3] and [5] for unscaled GP algorithms (1) with $N=\mathcal{U}$; however, the proofs in question require locally Lipschitz continuous gradients ∇J, and do not extend readily to SGP iterations (1) with arbitrary closed convex cones $N \supset K(u)$. Reference [9] uses a different approach to establish limit point stationarity for unscaled GP processes (1) in polyhedral Ω when ∇J is merely continuous; with small modifications, the techniques in [9] will also prove the somewhat stronger result

$$\lim_{i\to\infty} d(u^i)=0$$

for unscaled GP when ∇J is uniformly continuous. Once again, however, the proof technique in [9] does not seem to work for (1) with arbitrary closed convex cones $N \supset K(u)$. It would appear that some further restrictions are needed on the cones N.

Proposition 2 of [12] establishes limit point stationarity for SGP sequences $\{u^i\}$ generated by (1)-(2) and the special class of closed convex cones

(13a) $$N^i = C^{i*} \supset C(u^i)^*,$$

where

(13b) $$C^i=\{w: \forall j\in \mathcal{J}^i, \langle w, a^j\rangle \leqq 0\}$$

and

(13c) $$\mathcal{J}^i \supset \mathcal{J}(u^i).$$

Nevertheless, with minor alterations the proof in [12] actually works for any closed convex cones N^i containing $C(u^i)^*$, and, in particular, for any closed *subspaces* $N^i \supset C(u^i)^*$. As explained below, this simple revision quickly yields a limit point stationarity theorem for the alternative SGP scheme (3)-(4) in polyhedral convex Ω; however, a more extensive proof modification is needed for (3)-(4) in nonpolyhedral sets (4a).

The following results sharpen the estimates in Lemmas 1 and 2 when the cones N satisfy (2).

LEMMA 5. *Let u belong to a closed convex set Ω with representation* (2a). *Fix $\varepsilon>0$ and put*

$$\mathcal{J}_\varepsilon(u)=\{j: \langle a^j, u\rangle - b^j \geqq -\|a^j\|\varepsilon\},$$
$$C_\varepsilon(u)=\{w: \langle a^j, w\rangle \leqq 0, \forall j\in\mathcal{J}_\varepsilon(u)\}.$$

Then for all $u'\in\Omega$, x and v in $\mathcal{U}$, and $\sigma\geqq 0$

$$\|u'-u\|<\varepsilon \Rightarrow K(u')\subset C_\varepsilon(u)^*$$

and

$$x\in C_\varepsilon(u) \quad \text{and} \quad \sigma\|v\|<\varepsilon \Rightarrow \langle x, \phi(\sigma)-u\rangle \geqq \langle x, v\rangle\sigma.$$

Proof. Suppose that $u'\in\Omega$ and $\|u'-u\|<\varepsilon$. Let w be a nonzero vector in the cone $C_\varepsilon(u)$, choose $h>0$ such that $0<h\|w\|\leqq \varepsilon-\|u'-u\|$, and put $v=u'+hw$. If $j\notin\mathcal{J}_\varepsilon(u)$, then

$$\begin{aligned}\langle a^j, v\rangle - b^j &= \langle a^j, u\rangle - b^j + \langle a^j, u'-u\rangle + \langle a^j, w\rangle h\\ &< \|a^j\|(-\varepsilon+\|u'-u\|+h\|w\|)\\ &\leqq 0.\end{aligned}$$

On the other hand, if $j \in \mathcal{J}_\varepsilon(u)$ then for any $h > 0$,

$$\langle a^j, v\rangle - b^j = \langle a^j, u'\rangle - b^j + \langle a^j, w\rangle h \leqq 0.$$

Consequently, $v \in \Omega$ and hence for all $w^* \in K(u')$,

$$\langle w^*, w\rangle = h^{-1}\langle w^*, v - u'\rangle \leqq 0.$$

Since this estimate holds for any vector w in $C_\varepsilon(u)$ it follows that $K(u') \subset C_\varepsilon(u)^*$. Therefore, in view of (5),

$$\begin{aligned} \varepsilon > \sigma\|v\| \geqq 0 &\Rightarrow K(\phi(\sigma)) \subset C_\varepsilon(u)^* \\ &\Rightarrow u + \sigma v - \phi(\sigma) \in C_\varepsilon(u)^* \\ &\Rightarrow \forall x \in C_\varepsilon(u), \quad \langle x, u + \sigma v - \phi(\sigma)\rangle \leqq 0. \qquad \square \end{aligned}$$

LEMMA 6. *Assume that Ω is a closed convex set with representation* (2a). *Fix u in Ω, suppose that J is Fréchet differentiable at u, and let v satisfy* (1b)–(1l) *and* (2). *Then for all $\sigma > 0$*

$$\varepsilon(u) > \sigma\|v\| \Rightarrow \langle \nabla J(u), u - \phi(\sigma)\rangle \geqq [s_N^{-1}\sigma^{-2}\|u + \sigma v_T - \phi(\sigma)\|^2 + \langle P_{N^*}(-\nabla J(u)), v_T\rangle]\sigma,$$

where the bracketed term on the right is bounded below by the quantity $d_1(u)$ in Lemma 2 when $\sigma \in (0, \alpha]$.

Proof. The lemma is proved by a repetition of the proof of Lemma 2, with Lemma 1 replaced by Lemma 5, and $\varepsilon = \varepsilon(u)$. □

Lemma 6 removes the restriction (13) imposed in Proposition 1 of [12] and produces a straightforward extension of the limit point stationarity result in Proposition 2 of [12].

THEOREM 1. *Assume that Ω is a closed convex set with representation* (2a). *Let J be continuously Fréchet differentiable in Ω and suppose that $\{u^i\}$ is generated by an* SGP *iteration* (1)–(2). *Then every subsequential limit of $\{u^i\}$ is stationary.*

Proof. Let Z_1 be an infinite set of positive integers and suppose that $u^i \to \bar{u}$ for $i \in Z_1$. Since Ω is closed and $d(\cdot)$ is continuous, $\bar{u}$ must lie in Ω and $d(u^i) \to d(\bar{u})$, $i \in Z_1$. As in the proof of Proposition 2 in [12], it will now be shown that $d(\bar{u}) > 0$ is impossible and that $\bar{u}$ must therefore be stationary.

Suppose that $d(\bar{u}) > 0$. Then by (12f)

$$\sigma^i \to 0, \qquad i \in Z_1.$$

In this case, the rule (1m) yields

$$J(u^i) - J(\phi^i) < \delta[(\beta^{-1}\sigma^i s_N^i)^{-1}\|u + \beta^{-1}\sigma^i v_T^i - \phi^i\|^2 + \langle P_{N^{i*}}(-\nabla J(u^i)), v_T^i\rangle \beta^{-1}\sigma^i] \tag{14a}$$

for $i \in Z_1$ and i sufficiently large, where

$$\phi^i = P_\Omega(u^i + \beta^{-1}\sigma^i v^i). \tag{14b}$$

Furthermore, since $\nabla J(\cdot)$ and $\varepsilon(\cdot)$ are continuous, (1j)–(1l) imply that for some $M > 0$,

$$\|v^i\| \leqq (\mu_1 + \mu_3)\|\nabla J(u^i)\| \leqq M, \qquad i \in Z_1, \tag{15}$$

$$\sigma^i\|v^i\| \to 0, \qquad i \in Z_1, \tag{16}$$

and

$$\beta^{-1}\sigma^i\|v\| < \varepsilon(u^i), \quad i \in Z_1, \quad i \text{ sufficiently large.}$$

In view of Lemma 6, inequality (5), and the mean value theorem, there are vectors $\xi^i \in \Omega$ on the line segment joining u^i and ϕ^i such that

$$\begin{aligned} J(u^i)-J(\phi^i) &\geqq \langle \nabla J(u^i), u^i-\phi^i\rangle - M\|\nabla J(\xi^i)-\nabla J(u^i)\|\beta^{-1}\sigma^i \\ &\geqq (\beta^{-1}\sigma^i s_N^i)^{-1}\|u^i+\beta^{-1}\sigma^i v_T^i-\phi^i\|^2 \\ &\qquad + \langle P_{N^{i*}}(-\nabla J(u^i)), v_T^i\rangle \beta^{-1}\sigma^i - M\|\nabla J(\xi^i)-\nabla J(u^i)\|\beta^{-1}\sigma^i, \end{aligned}$$

for $i \in Z_1$ and i sufficiently large, with

$$\|\xi^i-\phi^i\| \leqq \|u^i-\phi^i\| \leqq \sigma^i\|v^i\|.$$

Conditions (1j), (1k), inequality (10), and the foregoing estimates now yield

$$\begin{aligned} M\|\nabla J(\xi^i)-\nabla J(u^i)\| \geqq (1-\delta)[\mu_2(\beta^{-1}\sigma^i s_N^i)^{-2}\|u^i+\beta^{-1}\sigma^i v_T^i-\phi^i\|^2 \\ + \mu_0\|P_{N^{i*}}(-\nabla J(u^i))\|^2] \geqq 0 \end{aligned}$$

for $i \in Z_1$ and i sufficiently large, with

$$\|\nabla J(\xi^i)-\nabla J(u^i)\| \to 0, \qquad i \in Z_1.$$

Consequently,

$$(\beta^{-1}\sigma^i s_N^i)^{-1}\|u^i+\beta^{-1}\sigma^i v_T^i-\phi^i\| \to 0, \qquad i \in Z_1, \tag{17a}$$

$$P_{N^{i*}}(-\nabla J(u^i)) \to 0, \qquad i \in Z_1, \tag{17b}$$

and therefore

$$v_T^i \to 0, \qquad i \in Z_1,$$

because of (11). On the other hand, conditions (1j), (9), and the nonexpansive property for P_Ω give

$$\begin{aligned} d(u^i) &\leqq (\beta^{-1}\sigma^i s_N^i)^{-1}\|u^i - P_\Omega(u^i-\beta^{-1}\sigma^i s_N^i \nabla J(u^i))\| \\ &\leqq (\beta^{-1}\sigma^i s_N^i)^{-1}[\|u^i+\beta^{-1}\sigma^i v_T^i-\phi^i\| + \|\beta^{-1}\sigma^i v_T^i\| + \|\phi^i \\ &\qquad + \|\phi^i - P_\Omega(u^i-\beta^{-1}\sigma^i s_N^i\nabla J(u^i))\|] \\ &\leqq (\beta^{-1}\sigma^i s_N^i)^{-1}\|u^i+\beta^{-1}\sigma^i v_T^i-\phi^i\| + 2\mu_2^{-1}\|v_T^i\| + \|P_{N^{i*}}(-\nabla J(u^i))\| \end{aligned}$$

for $i \in Z_1$ and i sufficiently large, and so

$$\liminf_{\substack{i\to\infty \\ i\in Z_1}} (\beta^{-1}\sigma^i s_N^i)^{-1}\|u^i+\beta^{-1}\sigma^i v_T^i-\phi^i\| \geqq d(\bar{u}) > 0.$$

This contradiction proves that $d(\bar{u})>0$ is impossible. □

The following observation yields a corollary of Theorem 1 for SGP processes (3)-(4) in polyhedral convex sets.

Note 1. If Ω has a representation (4a) satisfying the constraint qualification (Q)(i), then the Farkas lemma implies that the cone $C(u)^*$ in (2) consists of zero and all nonnegative linear combinations of vectors in the set $\{a^j\}_{j\in\mathcal{J}(u)}$ with $\mathcal{J}(u)$ defined by (2d). Since the index set (2D) is no larger than its counterpart in (4e), it follows that $C(u)^*$ is contained in the closed subspace $N(u)$ in (4i). Hence for polyhedral convex Ω satisfying (Q)(i), the scheme (3)-(4) is subsumed by (1)-(2).

COROLLARY 1 OF THEOREM 1. *Assume that Ω is a polyhedral convex set with a representation* (4a) *that satisfies the constraint qualification* (Q)(i). *Let J be continuously Fréchet differentiable in Ω and suppose that $\{u^i\}$ is generated by an* SGP *iteration* (3)-(4). *Then every limit point of $\{u^i\}$ is stationary.*

Proof. The proof is immediate from Note 1 and Theorem 1. □

It has just been observed that (3)-(4) is a special case of (1)-(2) in polyhedral convex sets; moreover, it can be shown that if we choose $N = C(u)^*$ in (1)-(2), then the resulting SGP iteration is actually *equivalent* to some iteration (3)-(4) with $N = N(u)$ near nondegenerate stationary points $\bar{u}$ satisfying

$$-\nabla J(\bar{u}) \in \text{ri}\, K(\bar{u}); \tag{18}$$

i.e., the two constructions generate identical iterates near $\bar{u}$ even though $N(u) \neq C(u)^*$ in general. On the other hand, in nonpolyhedral convex sets (4a), $N(u)$ and $C(u)^*$ can be very different objects indeed, and (3)-(4) is neither a special case of (1)-(2), nor is it locally equivalent to (1)-(2). In particular, this means that limit point stationarity for (3)-(4) cannot be inferred from Theorem 1 in nonpolyhedral sets. Nevertheless, all limit points of (3)-(4) are stationary in closed convex sets (4a) satisfying (Q)(ii), and a proof can be based on the following alternatives to Lemmas 5 and 6.

The term $\phi(\sigma)$ appearing in Lemma 6 actually depends on u and v as well as σ, and for present purposes it is better to stress this dependence explicitly by writing $P_\Omega(u+\sigma v)$ in place of $\phi(\sigma)$.

LEMMA 7. *Let $\bar{u}$ be a nonstationary point for J in a closed convex set Ω with a representation* (4a) *that satisfies the constraint qualification* (Q)(ii). *Let $N(u)$ be defined by* (4) *at $u \in \Omega$, put $T(u) = N(u)^\perp$, and assume that the functions g_j in* (4a) *are continuously Fréchet differentiable at $\bar{u}$. Then for each $M > 0$ there are corresponding numbers $\Delta > 0$, $\rho > 0$, and $\kappa > 0$ such that for all $\sigma \in (0, \Delta]$, $u \in B(\bar{u}, \rho) \cap \Omega$, $x \in T(u)$, and $v \in B(0, M)$,*

$$\langle x, P_\Omega(u+\sigma v) - u\rangle \geqq \langle x, v\rangle \sigma + \|x\| \eta(\sigma, u, v)$$

with

$$\begin{aligned}\eta(\sigma, u, v) &= -\kappa \|\nabla g(P_\Omega(u+\sigma v)) - \nabla g(u)\|_2 \\ &\triangleq -\kappa \left(\sum_{j=1}^{m} \|\nabla g_j(P_\Omega(u+\sigma v)) - \nabla g_j(u)\|^2 \right)^{1/2}.\end{aligned}$$

Proof. (Q)(ii) and the Farkas lemma imply that each $u \in \Omega$, $K(u)$ consists of zero and all nonnegative linear combinations of vectors from the linearly independent set $\mathcal{G}_0(u)$. Furthermore, (5) implies that for all $\sigma \geqq 0$, $u \in \Omega$, and $v \in B(0, M)$

$$\|P_\Omega(u+\sigma v) - \bar{u}\| \leqq M\sigma + \|u - \bar{u}\|.$$

Since g_j and ∇g_j are continuous at $\bar{u}$, it follows that for some $\rho_1 > 0$, $\Delta_1 > 0$, $\gamma > 0$, and all $u \in B(\bar{u}, \rho_1) \cap \Omega$, $\sigma \in [0, \Delta_1]$, $v \in B(0, M)$, and $c \in \mathbb{R}^m$

$$\mathcal{J}_0(P_\Omega(u+\sigma v)) \subset \mathcal{J}_0(\bar{u}),$$

$$\{\nabla g_j(P_\Omega(u+\sigma v))\}_{j \in \mathcal{J}_0(\bar{u})} \quad \text{is linearly independent,}$$

and

$$\gamma \left\| \sum_{j \in \mathcal{J}_0(\bar{u})} c_j \nabla g_j(P_\Omega(u+\sigma v)) \right\| \geqq \left(\sum_{j \in \mathcal{J}_0(\bar{u})} c_j^2 \right)^{1/2}$$

Now write

$$\langle x, P_\Omega(u+\sigma v)-u\rangle = \langle x, v\rangle\sigma - \langle x, \psi(\sigma, u, v)\rangle$$

with

$$\psi(\sigma, u, v) = (u+\sigma v - P_\Omega(u+\sigma v)) \in K(P_\Omega(u+\sigma v))$$

and

$$\|\psi(\sigma, u, v)\| \leqq 2M\sigma.$$

For each $u \in B(\bar{u}, \rho_1)\cap\Omega$, $\sigma\in[0, \Delta_1]$, and $v \in B(0, M)$, there is a corresponding nonnegative $c \in \mathbb{R}^m$ such that

$$(j \notin \mathcal{J}_0(P_\Omega(u+\sigma v)) \Rightarrow c_j = 0), \qquad j = 1, \cdots, m,$$

$$\psi(\sigma, u, v) = \sum_{j=1}^{m} c_j \nabla g_j(P_\Omega(u+\sigma v)),$$

and

$$2\gamma M\sigma \geqq \left(\sum_{j=1}^{m} c_j^2\right)^{1/2},$$

and therefore

$$-\langle x, \psi(\sigma, u, v)\rangle \geqq \|x\|\eta(\sigma, u, v) - \left|\left\langle x, \sum_{j=1}^{m} c_j \nabla g_j(u)\right\rangle\right|$$

with

$$\eta(\sigma, u, v) = -2\gamma M\|\nabla g(P_\Omega(u+\sigma v)) - \nabla g(u)\|_2\sigma.$$

Now consider that for all $u \in \Omega$, $\sigma \geqq 0$, $v \in B(0, M)$, and $j \in \mathcal{J}_0(P_\Omega(u+\sigma v))$ there is a $\xi^j \in \Omega$ on the line segment between u and $P_\Omega(u+\sigma v)$ such that

$$g_j(u) \geqq -\|\nabla g_j(\xi^j)\|M\sigma$$

with

$$\|\xi^j - \bar{u}\| \leqq M\sigma + \|u-\bar{u}\|.$$

This follows at once from (5) and the mean value theorem. Since the functions $\varepsilon(\cdot)$ and $\|\nabla g_j(\cdot)\|$ are continuous and positive at $\bar{u}$ for $j \in \mathcal{J}_0(\bar{u})$, and since $\theta > 1$ in (4), it is now apparent that for some $\rho \in (0, \rho_1]$, $\Delta \in (0, \Delta_1]$, and all $u \in B(\bar{u}, \rho)\cap\Omega$, $\sigma \in [0, \Delta]$, $v \in B(0, M)$, and $j \in \mathcal{J}_0(P_\Omega(u+\sigma v))$,

$$\begin{aligned} g_j(u) &\geqq -\|\nabla g_j(u)\|\varepsilon(u) + (\tfrac{1}{2}\|\nabla g_j(u)\|\varepsilon(u) - \|\nabla g_j(\xi^j) - \nabla g_j(u)\|M\sigma) \\ &\geqq -\theta\|\nabla g_j(u)\|\varepsilon(u) \end{aligned}$$

and therefore

$$\mathcal{J}_0(P_\Omega(u+\sigma v)) \subset \mathcal{J}(u),$$

$$\sum_{j=1}^{m} c_j \nabla g_j(u) \in N(u),$$

and

$$\left\langle x, \sum_{j \in \mathcal{J}_0(P_\Omega(u+\sigma v))} c_j \nabla g_j(u)\right\rangle = 0$$

for all $x \in T(u)$. □

LEMMA 8. *Let $\bar{u}$ be a nonstationary point in a closed convex set Ω with a representation* (4a) *that satisfies the constraint qualification* (Q)(ii). *Assume that J and the functions g_j in* (4a) *are continuously Fréchet differentiable at $\bar{u}$ and suppose that v is determined by* (3b)-(3j) *and* (4) *at each $u \in \Omega$. Then for some $\rho > 0$, $\Delta > 0$, $\kappa > 0$, and all $u \in B(\bar{u}, \rho) \cap \Omega$ and $\sigma \in (0, \Delta]$,*

$$\langle \nabla J(u), u - P_\Omega(u + \sigma v) \rangle \geqq [s_N^{-1} \sigma^{-2} \| u + \sigma v_T - P_\Omega(u + \sigma v) \|^2 - \langle P_T \nabla J(u), v_T \rangle] \sigma \\ + s_N^{-1} \| x \| \eta(\sigma, u, v),$$

where

$$x = (v_T - s_N P_T \nabla J(u)) \in T,$$
$$\eta(\sigma, u, v) = -\kappa \| \nabla g(P_\Omega(u + \sigma v)) - \nabla g(u) \|_2 \sigma,$$

and the bracketed term on the right is bounded below by $d_1(u)$ in Lemma 2 *when $\sigma \in (0, \alpha]$ and $N^* = N^\perp = T$.*

Proof. Since $\nabla J(\cdot)$ is continuous at $\bar{u}$, and

$$\| v \| = \| -s_N P_N \nabla J(u) - S_T P_T \nabla J(u) \| \leqq (\mu_1 + \mu_3) \| \nabla J(u) \|,$$

it follows that $\| v \|$ is bounded above by some $M > 0$ when u is near $\bar{u}$ in Ω. Now repeat the proof of Lemma 2, with Lemma 1 replaced by Lemma 7. □

THEOREM 2. *Assume that Ω is a closed convex set with a representation* (4a) *that satisfies the constraint qualification* (Q)(ii). *Let J and the functions g_j in* (4a) *be continuously differentiable in Ω and suppose that $\{u^i\}$ is generated by an* SGP *iteration* (3)-(4). *Then every subsequential limit of $\{u^i\}$ is stationary.*

Proof. The proof scheme for Theorem 1 can be used here as well, with Lemma 8 taking the place of Lemma 6. Once again, if $u^i \to \bar{u}$, $i \in Z_1$, then $\bar{u}$ must lie in Ω. Moreover, if $d(\bar{u}) > 0$ then assertions (13)-(16) must hold as before, except that now $[T] = T = N^\perp = N^*$. Let M be the bound in (15). Then for all sufficiently large $i \in Z_1$, conditions (5), (13), Lemma 8, and the mean value theorem imply that for some $\xi^i \in \Omega$,

$$J(u^i) - J(\phi^i) \geqq \langle \nabla J(u^i), u^i - \phi^i \rangle - M \| \nabla J(\xi^i) - \nabla J(u^i) \| \beta^{-1} \sigma^i \\ - \kappa s_N^i \| x^i \| \, \| \nabla g(\phi^i) - \nabla g(u^i) \|_2 \beta^{-1} \sigma^i - M \| \nabla J(\xi^i) - \nabla J(u^i) \| \beta^{-1} \sigma^i$$

with

$$\phi^i = P_\Omega(u^i + \beta^{-1} \sigma^i v^i),$$
$$\| \xi^i - \phi^i \| \leqq \| u^i - \phi^i \| \leqq \sigma^i \| v^i \|,$$

and

$$\| x^i \| = \| v_T^i - s_N^i P_{T^i} \nabla J(u^i) \| \\ \leqq (\mu_1 + \mu_3) \| \nabla J(u^i) \| \\ \leqq M.$$

These estimates and (14) now produce

$$M \| \nabla J(\xi^i) - \nabla J(u^i) \| + \kappa \mu_3 \| \nabla g(\phi^i) - \nabla g(u^i) \|_2 \\ \geqq (1 - \delta) [\mu_2 (\beta^{-1} \sigma^i s_N^i)^{-2} \| u^i + \beta^{-1} \sigma^i v_T^i - \phi^i \|^2 + \mu_0 \| P_{T^i} \nabla J(u^i) \|^2] \geqq 0$$

for large $i \in Z_1$, with

$$\| \nabla J(\xi^i) - \nabla J(u^i) \| \to 0, \qquad i \in Z_1,$$

and

$$\|\nabla g(\phi^i)-\nabla g(u^i)\|_2 \to 0, \qquad i \in Z_1.$$

This leads to (17) as before, and from here on the proof is the same as the proof for Theorem 1. □

Note 2. Theorems 1 and 2 remain valid if the function $\varepsilon(\cdot)$ in (2) and (4) is replaced by any continuous measure of nonstationarity (i.e., any nonnegative continuous real function whose zeros coincide with the stationary points of J in Ω; in particular, this means that the parameter θ in (4) can be absorbed in $\varepsilon(\cdot)$ and is therefore superfluous in the present context. In fact, Theorem 1 continues to hold if $C(u)^*$ is replaced by any closed convex cone with the inclusion property expressed in Lemma 5 when $\varepsilon=\varepsilon(u)$, and $\varepsilon(\cdot)$ is a continuous measure of nonstationarity. However, local convergence proofs for (1)-(2) and (3)-(4) are more closely tied to the forms imposed on $\mathscr{I}(u)$, $C(u)^*$, and $N(u)$ in (2) and (4); this point is developed further in a sequel.

4. Global convergence in compact level sets. If all limit points of the sequence $\{u^i\}$ lie in a closed set $\mathscr{S}$, and if every subsequence of $\{u^i\}$ has a limit point, then it is easily seen that $\{u^i\}$ must converge to $\mathscr{S}$, i.e.,

$$\lim_{i\to\infty}\inf_{u\in\mathscr{S}}\|u^i-u\|=0.$$

Moreover, if $\mathscr{S}$ is a finite set and if

$$\lim_{i\to\infty}\|u^i-u^{i+1}\|=0,$$

then $\{u^i\}$ must converge to some vector in $\mathscr{S}$, i.e.,

$$\exists u\in\mathscr{S},\quad \lim_{i\to\infty}u^i=u.$$

These general observations and the results in §§ 2 and 3 produce a *global* convergence theorem for SGP iterations in compact sets, i.e., a convergence result that applies to all SGP sequences $\{u^i\}$ irrespective of their starting points u^1 in Ω.

THEOREM 3. *Let J be continuously Fréchet differentiable and assume that one of the following conditions holds*:

(i) Ω *is a closed convex set with representation* (2a), *and* $\{u^i\}$ *is generated by an* SGP *iteration* (1)-(2).

(ii) Ω *is a closed convex set with representation* (4a) *satisfying the constraint qualification* (Q), g_j *is continuously Fréchet differentiable for* $j=1,\cdots,m$, *and* $\{u^i\}$ *is generated by an* SGP *iteration* (3)-(4).

In addition, suppose that the level sets of J in Ω are compact. Then $\{u^i\}$ converges to the subset of stationary points

$$\mathscr{S}=\{u\colon d(u)=0 \textit{ and } J(u)\leqq J(u^1)\}$$

and

$$\lim_{i\to\infty}d(u^i)=0.$$

Furthermore, if $\mathscr{S}$ is a finite set, then $\{u^i\}$ converges to some vector in $\mathscr{S}$.

Proof. By a straightforward application of Lemma 4, Theorem 1 and its corollary, and Theorem 2, the theorem is proved. □

THE SENSITIVITY OF OPTIMAL CONTROL PROBLEMS TO TIME DELAY*

F. H. CLARKE† AND P. R. WOLENSKI‡

Abstract. A general class of time-delayed optimal control problems is studied. The goal is to characterize, in terms of the multipliers occurring in the necessary conditions, the rate of change of the value of the problem with respect to change in the delay. In particular, criteria for this dependence to be differentiable are given as well as a formula for the derivative. These appear to be the first results of this type.

Résumé. On étudie une classe générale de problèmes en contrôle optimal avec retard, le but étant de caractériser le taux de change de la valeur du problème par rapport au changement du retard, et ceci en terme des multiplicateurs figurant dans des conditions nécessaires d'optimalité. Comme cas particulier, on donne des critères impliquant que cette fonction soit différentiable, ainsi qu'une formule pour sa dérivée. Ces résultats semblent être les premiers de ce genre.

Key words. delayed systems, hereditary, retarded, nonsmooth analysis

1. Introduction.

Differential-difference equations and time delay (other terminology: lag, retarded, hereditary) optimal control problems have long been recognized as important models for real-life phenomena. However, explicit solutions to such problems are difficult to represent in even the simplest cases. If the time delay is very small, it may be preferable to ignore the delay and assume that the system is instantaneous. What error accrues from this simplification? The present paper addresses the issue of the sensitivity of the value function in time delay optimal control problems to small changes in the delay parameter. In the case of differential-difference equations, an explicit formula is derived for the derivative of the trajectory endpoint with respect to the delay.

Consider the following time delay optimal control problem:

$$\min J(x,u) \quad \text{over}$$

$x(\cdot)$ absolutely continuous on $[a,b]$, $u(\cdot)$ measurable on $[a,b]$ satisfying

$$\begin{aligned} &\dot{x}(t) = \phi(t, x(t), x(t-\Delta), u(t)) \quad \text{a.e. } t \in [a,b], \\ &u(t) \in U(t) \quad \text{a.e. } t \in [a,b], \qquad\qquad (1.1)\\ &x(t) = c(t) \quad \text{for} \quad t \in [a-\Delta, a]. \end{aligned}$$

Here J is a Bolza-type functional, and the data is given under appropriate assumptions (see §3). The delay Δ is constant but is a parameter of the problem. Let $V(\Delta)$ be the optimal value. The first main result (Theorem 3.1 below) contains bounds for certain

Dini derivatives of V. These estimates contain a term of the form

$$\int_a^b \langle -\dot{q}(t), \dot{x}(t-\Delta)\rangle \,\mathrm{dt}, \tag{1.2}$$

where $x(\cdot)$ is an optimal trajectory of (1.1), and $q(\cdot)$ is a "piece" of the adjoint variable associated with $x(\cdot)$ arising from the maximum principle. The integral (1.2) is of a type introduced here for the first time, for it couples the derivatives of primal and dual variables. It is not known whether (1.2) has geometrical significance.

It is more delicate to prove the opposite bounds on the Dini derivatives. Essentially, we need information on the limiting behavior of (1.2) under certain perturbations of the data, but this is difficult to obtain without introducing further assumptions. Two approaches are taken. The first hypothesizes "pointwise convergence of optimal controls" (see (H8) in §3) for which the conclusion (Theorem 3.2) is that one-sided derivatives of V in Δ actually exist and equal the respective bounds found in Theorem 3.1. The extra hypothesis (H8) is unsatisfactory due to its impractical nature, but on the other hand, we know of no example for which it fails. The second approach introduces a smoothness assumption on the Hamiltonian (see (H9) and (H10) in §6), and the derivatives of V are described (Theorem 6.1) in terms of Hamiltonian multipliers. The main results are reformulated in Theorem 7.1 for the case in which an endpoint constraint $x(b) \in C$ is added to the basic problem (1.1).

The basic theory of differential-difference equations is covered by Bellman and Cooke [BC2], Halanay [H1], and Driver [D2]. The major research trend is to treat time delay problems under the general framework of functional differential equations (see Hale [H2]). The state space in the latter is infinite-dimensional, which is appropriate in generalizing many topics from ordinary differential equation theory. Our approach is to revert back to a finite-dimensional viewpoint, which is natural under the circumstances. The problems under consideration here have constant delay, which could be zero. For simplicity, only one delay component is taken account of, but multiple delay components could be easily handled by the same methods.

A consequence of our results identifies the derivative of the trajectory endpoint of an ordinary differential equation (o.d.e.) whenever a time delay is introduced into the equation (see §8). Not much attention has been given to the behavior of systems under a change in the delay. Sugiyama [S] has shown that the trajectory depends continuously in the sup norm with respect to the delay parameter. Bellman and Cooke [BC1] obtained this result earlier with linear systems. The Sugiyama result follows directly from ours. Driver [D1] has derived conditions in which delay equations exhibit the same asymptotic properties as those without delay.

An introduction to time delay optimal control problems can be found in Oğuztöreli [O], Warga [W1], and Manitius [M1]. The time-delay version of the maximum principle was proven by Kharatishvili [K]. See [P, §27]. Clarke and Watkins [CW] derived a nonsmooth version of the maximum principle in the form of a Hamiltonian inclusion, a result crucial to the treatment of endpoint constraints in §7. Necessary conditions with nonsmooth data are also given by Warga [W2], [W3].

As already mentioned, our basic theory is applicable for only constant delay parameters. It would be of interest to extend our results to allow for delays dependent on time, state, and/or control. Maximum principles are available for such problems. See Banks [B] and Manitius [M2]. The impediment to generalizing our methods in this direction occurs in Lemma 4.1, where we must differentiate a function of the form $\Delta \longrightarrow \phi(x(t-\Delta))$, where ϕ is C^1 and $x(\cdot)$ is merely absolutely continuous. If Δ is a function of other parameters, such a (Banach space) differentiation is difficult to perform and utilize.

The methodology in the proof is that of nonsmooth analysis. We first bound the upper Dini derivative by a certain generalized directional derivative, which in turn is represented as the support function of the generalized gradient (Clarke [C1]). Since the generalized gradients are characterized as the closed convex hull of weak limits of proximal subgradients, the bound is seen to be a limit of more manageable quantities. The line of reasoning to this point has become standard [C1], [C2]. The novel approach in this paper is in the problem formulation and the consequent proximal subgradients that come under consideration. In brief, we will be led to consider proximal subgradients of an augmented value function $V(\Delta, \alpha)$, where $(\Delta, \alpha) \in \mathbb{R}^+ \times L^2[a,b]$. The variable Δ is the delay parameter, and α is a perturbation of the dynamic equation. The variable α does not appear in the original problem but is introduced to monitor the Δ-dependence. In general, proximal subgradients in a product space split into proximal subgradients of the components (not true of generalized gradients). This is of paramount interest to us, because the subgradient with respect to α can be calculated and represented as a dual variable (the nondelay case is in Clarke [C2]), whence the subgradient with respect to Δ procures a specific representation.

The outline of the paper is as follows. Section 2 contains preliminaries (problem formulation, maximum principle, proximal analysis); §3 contains the basic hypotheses and the statements of two main results; the proofs are given simultaneously in §4; §5 weakens the smoothness hypothesis on the endpoint cost function ℓ; §6 offers a Hamiltonian approach to a lower bound; the main results are formulated in §7 to include an endpoint constraint; and, in §8, the results are illustrated by three examples.

2. Preliminaries.

This section contains basic definitions and reviews some preliminary results. The analysis of estimating the Dini derivatives of the value function will require introducing certain modified and perturbed problems. We begin by describing the basic problem and these alterations of it.

Throughout the paper, $c(\cdot)$ is a fixed Lipschitz continuous function of order $||\dot{c}||_\infty$ on $[a-\overline{\Delta}, a]$, where $\overline{\Delta} > 0$. In all choices of Δ below, it is understood, if not explicitly stated, that $0 \leq \Delta < \overline{\Delta}$. Suppose we are given

$$
\begin{aligned}
\ell &: [0,\overline{\Delta}) \times \mathbb{R}^n \longrightarrow \mathbb{R}^1 \\
L &: [a,b] \times [0,\overline{\Delta}) \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^1 \\
\phi &: [a,b] \times [0,\overline{\Delta}) \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^n \\
U &: [a,b] \rightrightarrows \mathbb{R}^m.
\end{aligned}
$$

(The double arrow denotes that U is a set-valued map.) Precise assumptions on the data will be given in §3. The functional J is defined by

$$
\begin{aligned}
&J : [0,\overline{\Delta}) \times AC[a,b] \times \mathscr{M}[a,b] \longrightarrow \mathbb{R}^1 \cup \{\pm\infty\}, \\
&J(\Delta, x(\cdot), u(\cdot)) = \ell(\Delta, x(b)) + \int_a^b L(t, \Delta, x(t), x(t-\Delta), u(t))\, dt,
\end{aligned}
\tag{2.1}
$$

where $x(t-\Delta)$ is set equal to $c(t-\Delta)$ whenever $t - \Delta \leq a$. Here and elsewhere, $AC_n[a,b]$ denotes the absolutely continuous functions on $[a,b]$ into $\mathbb{R}^n$ (the subscript n will be dropped if the dimension is clear from the context), and $\mathscr{M}[a,b]$ is the set of measurable functions from $[a,b]$ into $\mathbb{R}^m$. If $u(\cdot) \in \mathscr{M}[a,b]$ satisfies $u(t) \in U(t)$ almost everywhere $t \in [a,b]$, then $u(\cdot)$ is called admissible.

The problem $P(\Delta)$ is defined as

$$\min J(\Delta, x, u) \text{ over } (x,u) \text{ satisfying}$$

$$\begin{aligned} &\dot{x}(t) = \phi(t, \Delta, x(t), x(t-\Delta), u(t)) \quad \text{a.e. } t \in [a,b], \\ &u(t) \in U(t) \quad \text{a.e. } t \in [a,b], \\ &x(t) = c(t) \quad \text{for} \quad t \in [a-\Delta, a]. \end{aligned} \tag{2.2}$$

Suppose that $v(\cdot) \in L^2_m[a,b]$ (:= the square integrable functions on $[a,b]$ with values in $\mathbb{R}^m$; again the subscript m will be dropped whenever the dimension is clear from the context). The problem $P_v(\Delta)$ is defined in the same manner as $P(\Delta)$ except that the term $||u-v||_2^2$ is added to the objective, where $|| \cdot ||_2$ denotes the $L^2[a,b]$ norm.

Suppose that $\alpha(\cdot) \in L^2_n[a,b]$. The problem $P(\Delta, \alpha)$ is the same as $P(\Delta)$ except that now the dynamic equation $\dot{x} = \phi$ is replaced by the perturbed equation

$$\dot{x}(t) = \phi(t, \Delta, x(t), x(t-\Delta), u(t)) + \alpha(t).$$

The problem $P_v(\Delta, \alpha)$ is defined by incorporating both alterations of the last two paragraphs.

The optimal value of $P(\Delta)$ is denoted by $V(\Delta)$. Similarly $V_v(\Delta)$, $V(\Delta, \alpha)$, $V_v(\Delta, \alpha)$ denote optimal values of $P_v(\Delta)$, $P(\Delta, \alpha)$, $P_v(\Delta, \alpha)$, respectively.

Given $u(\cdot) \in \mathscr{M}[a,b]$ admissible, $\alpha(\cdot) \in L^2_n[a,b]$, and $\Delta \in [0, \overline{\Delta})$, our assumptions on ϕ will imply that there exists a unique $x(\cdot) \in AC[a,b]$ satisfying $\dot{x}(t) = \phi(t, \Delta, x(t), x(t-\Delta), u(t)) + \alpha(t)$ almost everywhere $t \in [a,b]$, and $x(t-\Delta) = c(t-\Delta)$ whenever $t - \Delta \leq a$. This trajectory will be denoted by $x^{u,\Delta}_{\alpha}$. If $\alpha = 0$, we will simply write $x^{u,\Delta}$. The optimal solutions of $P(\Delta)$, that, is the *controls* that are minimizers, will be denoted by $\Sigma(\Delta)$. Similarly, we use the notation $\Sigma_v(\Delta)$, $\Sigma(\Delta, \alpha)$, and $\Sigma_v(\Delta, \alpha)$.

The (pseudo-) Hamiltonian $\mathscr{H}$ is defined by

$$\mathscr{H} : [a,b] \times [0, \overline{\Delta}) \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^n \longrightarrow \mathbb{R}^1$$

$$\mathscr{H}(t, \Delta, x, y, u, p) = \langle p, \phi(t, \Delta, x, y, u) \rangle - L(t, \Delta, x, y, u).$$

The preparation for and statements of the main results can be given more succinctly by utilizing $\mathscr{H}$. The classical maximum principle as it applies to the problem $P(\Delta)$ is due to Kharatishvili (see [K]) and says the following.

MAXIMUM PRINCIPLE. *Suppose that* $u(\cdot) \in \Sigma(\Delta)$ *and set* $x(\cdot) = x^{u,\Delta}(\cdot)$. *Then there exist absolutely continuous functions* $p(\cdot)$ *and* $q(\cdot)$ *from* $[a,b]$ *into* $\mathbb{R}^n$ *so that*

(i) $-p(b) = \nabla_x \ell(\Delta, x(b)), \quad q(b) = 0,$

(ii)

$$-\dot{p}(t) = \frac{\partial}{\partial x}\mathscr{H}^*(t, \Delta, x(t), x(t-\Delta), u(t), p(t) + q(t+\Delta)) \quad a.e. \;\; t \in [a,b],$$

$$-\dot{q}(t) = \frac{\partial}{\partial y}\mathscr{H}^*(t, \Delta, x(t), x(t-\Delta), u(t), p(t) + q(t+\Delta)) \quad a.e. \;\; t \in [a,b],$$

and

(iii) *for almost all* $t \in [a,b]$,
$\max \mathscr{H}(t, \Delta, x(t), x(t-\Delta), u, p(t) + q(t+\Delta))$ *over* $u \in U(t)$
occurs at $u = u(t)$.

In the above, the star (*) denotes transpose and, whenever $t+\Delta \geq b$, then $q(t+\Delta)$ is set equal to zero. Part (i) is the tranversality condition, (ii) contains the adjoint equations, and (iii) is the maximum condition.

Let P be a problem as described above, and Σ its set of optimal solutions. Fix $u(\cdot) \in \Sigma$. The maximum principle is applicable under the assumptions invoked in §3. Also, the pair (p, q) (referred to as a Pontryagin multiplier) is unique, and for notational convenience we set $M(u, P) = (p, q)$. Note that this notation and terminology is retained in the case when $P = P(0)$. In this special case, where $\Delta = 0$ and the problem is without delay, multipliers that arise from the usual maximum principle are broken into two pieces to become multipliers in our sense (this is illustrated in Example C of §8).

Techniques of proximal analysis play a prominent role in the analysis below. We give here a concise compilation of the material that will be used. The reader may consult [C1] or [C3] for a complete introduction to these ideas.

Suppose $X \subseteq \mathscr{X}$, where $\mathscr{X}$ is a real Hilbert space with inner product $\langle \cdot, \cdot \rangle$. Suppose $f : \mathscr{X} \to \mathbb{R}^1$ is locally Lipschitz near X and $x_0 \in X$. An element $\beta \in \mathscr{X}$ is a proximal subgradient of f at x_0 if there exists $\sigma > 0$ and a neighborhood Y of x_0 so that for each $x \in Y$, we have

$$f(x) \geq f(x_0) + \langle \beta, x - x_0 \rangle - \sigma ||x - x_0||^2. \tag{2.3}$$

The presubdifferential $\hat{\partial} f(x_0)$ and the generalized gradient $\partial f(x_0)$ of f at x_0 are defined as the weak limits of proximal subgradients and the closed convex hull of these, respectively:

$$\begin{aligned} \hat{\partial} f(x_0) = \{ \beta \in \mathscr{X} :\ & \text{there exist sequences } \{x_i\}_{i=1}^{\infty} \text{ and } \{\beta_i\}_{i=1}^{\infty} \text{ in } \mathscr{X} \\ & \text{so that } x_i \to x_0 \text{ strongly, } \beta_i \to \beta \text{ weakly , and } \beta_i \text{ is a proximal} \\ & \text{subgradient of } f \text{ at } x_i \}, \end{aligned} \tag{2.4}$$

and

$$\partial f(x_0) = \operatorname{cl} \operatorname{co} \hat{\partial} f(x_0). \tag{2.5}$$

In view of the extension to Hilbert spaces of Clarke's proximal normal formula (see Borwein and Strojwas [BS] or Loewen [L]), the definition of $\partial f(x_0)$ coincides with the usual definition that is given in [C1]. In particular, if x_0 is in X and $\omega \in \mathscr{X}$, the following holds:

$$\limsup_{\substack{x \to x_0 \\ h \downarrow 0}} \frac{f(x + h\omega) - f(x)}{h} = \sup \{ \langle \omega, \beta \rangle : \beta \in \partial f(x_0) \}. \tag{2.6}$$

The left side of (2.6) is denoted by $f^0(x_0; \omega)$. Note that $\partial f(x_0)$ on the right side of (2.6) can be replaced by $\hat{\partial} f(x_0)$. The set-valued map $x \to \partial f(x)$ is upper semicontinuous in the strong to weak topology, which means that if $x_i \to x_0$ strongly and $\beta_i \to \beta_0$ weakly with $\beta_i \in \partial f(x_i)$, then $\beta_0 \in \partial f(x_0)$. The same is true for $\hat{\partial} f(x)$.

The only Hilbert spaces of interest here will be $\mathbb{R}^n$ and $\mathbb{R}^1 \times L_n^2[a, b]$. The notation $\langle \cdot, \cdot \rangle$ will be used to denote the inner product on $\mathbb{R}^1 \times L_n^2[a, b]$ as well as the usual inner product on $\mathbb{R}^n$. This should cause no confusion. Hence for (Δ, α), $(\Delta', \alpha') \in \mathbb{R}^1 \times L_n^2[a, b]$, we write

$$\langle (\Delta, \alpha), (\Delta', \alpha') \rangle = \Delta \cdot \Delta' + \int_a^b \langle \alpha(t), \alpha'(t) \rangle \, \mathrm{dt}.$$

3. The main result. Recall the problem formulation $P(\Delta)$. The basic hypotheses on the data ℓ, L, ϕ, and U are the following. The notation L_Δ (respectively, L_1, L_2) is used to denote the derivative of $\Delta \to L(t, \Delta, x, y, u)$ (respectively, $x \to L(t, \Delta, x, y, u)$, $y \to L(t, \Delta, x, y, u)$), and similarly for ϕ_Δ, ϕ_1, ϕ_2.

(H1) $\ell : [0, \overline{\Delta}) \times \mathbb{R}^n \longrightarrow \mathbb{R}^1$ is C^1.

(H2) $L : [a, b] \times [0, \overline{\Delta}) \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^1$ is measurable in the first variable whenever the other variables are held fixed. For almost all $t \in [a, b]$, L is continuous in (Δ, x, y, u), and L_Δ, L_1, L_2 exist and are continuous in (Δ, x, y, u).

(H3) $\phi : [a, b] \times [0, \overline{\Delta}) \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^n$ is measurable in the first variable whenever the other variables are held fixed. For almost all $t \in [a, b]$, ϕ is continuous in (Δ, x, y, u), and ϕ_Δ, ϕ_1, ϕ_2 exist and are continuous in (Δ, x, y, u).

(H4) $U : [a, b] \rightrightarrows \mathbb{R}^m$ is measurable with nonempty compact values, and $\sup\{|u| : u \in U(t)\} \leq \gamma_1(t)$ almost everywhere $t \in [a, b]$ for some $\gamma_1 \in L^2[a, b]$.

(H5) ϕ and $[a, b]$ are such that for each $R > 0$, there exists $r_R > 0$ so that whenever $\alpha \in L^2[a, b]$ with $||\alpha||_2 \leq R$, $u(\cdot) \in \mathscr{M}[a, b]$ with $u(t) \in U(t)$ almost everywhere $t \in [a, b]$, and $\Delta \in [0, \overline{\Delta})$, the solution $x(\cdot)$ that satisfies $\dot{x}(t) = \phi(t, \Delta, x(t), x(t - \Delta), u(t)) + \alpha(t)$ almost everywhere $t \in [a, b]$ and $x(t) = c(t)$ on $[a - \Delta, a]$ also satisfies $||x|| \leq r_R$, where $|| \cdot ||$ denotes the sup norm on $[a - \Delta, b]$.

(H6) For each $r > 0$, there exist $\sigma_r(\cdot) \in L^2[a, b]$ and $\gamma_r(\cdot) \in L^1[a, b]$ so that $|\phi| + |\phi_\Delta| + |\phi_2| + |L_2| \leq \sigma_r(t)$, $|\phi_1| + |L| + |L_\Delta| + |L_1| \leq \gamma_r(t)$ almost everywhere $t \in [a, b]$ whenever the arguments (Δ, x, y, u) satisfy $\Delta \in [0, \overline{\Delta})$, $|x| \leq r$, $|y| \leq r$, $u \in U(t)$.

(H7) For each $\Delta \in [0, \overline{\Delta})$, $(x, y) \in \mathbb{R}^n \times \mathbb{R}^n$, and almost all $t \in [a, b]$, the set $\{(\phi(t, \Delta, x, y, u), L(t, \Delta, x, y, u) + \delta) : u \in U(t), \delta \geq 0\}$ is a closed convex subset of $\mathbb{R}^n \times \mathbb{R}^1$.

Remarks. (i) Assumption (H5) is satisfied, for example, if $\sup\{|\phi(t, \Delta, x, y, u)| : u \in U(t)\} \leq \gamma_2(t) + \gamma_3(t)(|x| + |y|)$ almost everywhere $t \in [a, b]$, where γ_2, $\gamma_3 \in L^1[a, b]$. The proof is an exercise in applying Gronwall's inequality and is left to the reader.

(ii) The growth conditions in (H6) and regularity conditions in (H3) on ϕ combine to guarantee that the dynamics in each problem $P(\Delta, \alpha)$ are satisfied by at least one $x(\cdot)$. The convexity assumption (H7) assures that the solution set Σ is nonempty for each problem P.

(iii) As mentioned in §2, techniques of nonsmooth analysis play a prominent role, and so it may be somewhat surprising that we hypothesize C^1 data rather than Lipschitz. The only difficulty in weakening the assumptions in this manner occurs in Lemma 4.1, where a chain rule is used with one of the functions absolutely continuous and not known to be Lipschitz. Hence if L or ϕ are Lipschitz but not C^1, nonsmooth chain rules (see, for example, [C1]) apparently do not apply. It is not clear how to overcome this obstacle. No difficulty arises, however, if the endpoint cost ℓ is assumed merely Lipschitz in the state variable, and we will do this in §5.

To facilitate the statements of the main results, we define the following functional E:

$$E\colon\ [0,\overline{\Delta}) \times AC_n[a,b] \times \mathscr{M}[a,b] \times AC_{2n}[a,b] \longrightarrow \mathbb{R}^1$$

$$\text{(3.1)}\quad E(\Delta,x,v,(p,q)) := \frac{\partial}{\partial\Delta}\ell(\Delta,x(b)) - \int_a^b \left[\frac{\partial}{\partial\Delta}\mathscr{H}(t,\Delta,x(t),x(t-\Delta),v(t),p(t)+q(t+\Delta)) + \langle\dot{q}(t),\dot{x}(t-\Delta)\rangle\right] \mathrm{dt}.$$

If $t-\Delta \le a$, then $x(t-\Delta) := c(t-\Delta)$, and if $t+\Delta \ge b$, then $q(t+\Delta) := 0$. The first main result follows.

THEOREM 3.1. *Assume that* (H1)-(H7) *hold, and let* $\Delta_0 \in [0,\overline{\Delta})$. *Then*

(a)

$$\limsup_{h\searrow 0} \frac{V(\Delta_0+h)-V(\Delta_0)}{h} \le \inf_{v\in\Sigma(\Delta_0)} E\Big(\Delta_0, x^{v,\Delta_0}, v, M(v,P(\Delta_0))\Big);$$

(b) *If* $\Delta_0 > 0$, *then*

$$\liminf_{h\nearrow 0} \frac{V(\Delta_0+h)-V(\Delta_0)}{h} \ge \sup_{v\in\Sigma(\Delta_0)} E\Big(\Delta_0, x^{v,\Delta_0}, v, M(v,P(\Delta_0))\Big).$$

The proof will be given in the next section. Note that we avoid negative arguments in discussing V, since the problem $P(\Delta)$ is not even defined for $\Delta < 0$.

Theorem 3.1 provides estimates on two Dini derivatives of $V(\Delta)$. Subtleties arise in attempting to apply the same proof technique to obtain similar estimates on the complementary Dini derivatives. As we will see, the complications surface in taking limits of terms that have the same form as the integral term in (3.1). We next address this issue in further detail, which will serve to motivate the added assumption in Theorem 3.2.

Let $\alpha \in L^2[a,b]$, $v_h \in \Sigma(\Delta+h,\alpha)$, $x_h(\cdot) = x_\alpha^{v_h,\Delta+h}(\cdot)$, $(p_h,q_h) = M(v_h,P(\Delta+h))$, and define $w_h(\cdot)$ by

$$w_h(t) = -\int_a^t \frac{\partial}{\partial\Delta}\mathscr{H}(s,\Delta+h,x_h(s),x_h(s-\Delta-h),v_h(s),p_h(s)+q_h(s+\Delta+h))\,\mathrm{ds}.$$

Then the integral term in (3.1) with this data is

$$\text{(3.2)}\qquad w_h(b) + \int_a^b \langle -\dot{q}_h(t), \dot{x}_h(t-\Delta-h)\rangle\,\mathrm{dt}.$$

We are interested in the behavior of (3.2) as $h \searrow 0$. The natural inclination is to apply the Dunford–Pettis criterion to $\{\dot{q}_h\}$ and $\{\dot{x}_h\}$ and obtain absolutely continuous functions $q(\cdot)$ and $x(\cdot)$, for which subsequences of $\{\dot{q}_h\}$ and $\{\dot{x}_h\}$ converge to $\dot{q}$ and $\dot{x}$ weakly. However, as the first and most serious objection, this is inadequate in determining the behavior of the integral in (3.2). Second, the $w_h(b)$ term depends on the optimal controls $v_h(\cdot)$, and it does not follow that $w_h(b)$ will converge as $h \to 0$ to an appropriate limit (an ad hoc and unsatisfactory convexity hypothesis could be introduced on the function $(\partial/\partial\Delta)\mathscr{H}(t,\Delta,x,y,\cdot,p)$ to mollify this objection). A third obstacle arises in determining the limiting function $q(\cdot)$. Is it a piece of the multiplier? The answer is "not necessarily," for the Pontryagin multipliers $M(v,P(\Delta))$ do not have sufficient closure properties under perturbations of the data to assure this.

One approach that overcomes the three above-mentioned pitfalls is to hypothesize "convergence of optimal controls." Another, more readily verifiable, approach will be given in §6. Consider

(H8) Fix $\Delta_0 \in (0, \overline{\Delta})$ (respectively, $\Delta_0 = 0$). For each pair of sequences $\{\alpha_i\}_{i=1}^{\infty} \subseteq L_n^2[a,b]$ and $\{h_i\}_{i=1}^{\infty}$ with $\alpha_i \to 0$ and $h_i \to 0$ (respectively, $h_i \searrow 0$) as $i \to \infty$, there exists $\{v_i(\cdot)\}_{i=1}^{\infty}$ with $v_i \in \Sigma(\Delta_0 + h_i, \alpha_i)$ so that a subsequence of $\{v_i(\cdot)\}$ converges almost everywhere on $[a,b]$ to some $v(\cdot) \in \mathscr{M}[a,b]$.

In a practical situation, (H8) may be very difficult to verify. On the other hand, it seems that producing an example for which it fails is not trivial. If $v(\cdot) \in \Sigma(\Delta)$, then we will show that (H8) holds under (Hl) - (H7) for the problem $P_v(\Delta)$. It is this fact that allows for the estimates in Theorem 3.1 to be obtained without further assumptions. Unfortunately, the penalization technique is inapplicable for estimating the opposite bounds.

The following asserts the existence of one-sided derivatives of V.

THEOREM 3.2. *Let* $\Delta_0 \in [0, \overline{\Delta})$, *and suppose* (Hl)–(H8) *hold. Then*

(a) $$\lim_{h \searrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} = \inf_{v \in \Sigma(\Delta_0)} E\Big(\Delta_0, x^{v,\Delta_0}, v, M(v, P(\Delta_0))\Big);$$

(b) *If* $\Delta_0 > 0$, *then*

$$\lim_{h \nearrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} = \sup_{v \in \Sigma(\Delta_0)} E\Big(\Delta_0, x^{v,\Delta_0}, v, M(v, P(\Delta_0))\Big).$$

The proof will be given in §4, simultaneously with that of Theorem 3.1. A criterion for two-sided differentiability can be immediately deduced from Theorem 3.2. We state this in the following corollary.

COROLLARY 3.3. *Let* $\Delta_0 \in (0, \overline{\Delta})$, *and suppose* (Hl)–(H8) *hold. Suppose further that* $\Sigma(\Delta_0)$ *consists of a single element* v. *Then* V *is differentiable at* Δ_0, *with derivative*

$$\frac{d}{d\Delta} V(\Delta_0) = E\Big(\Delta_0, x^{v,\Delta_0}, v, M(v, P(\Delta_0))\Big).$$

Note that, as a consequence of the expressions derived in Theorem 3.2 for the one-sided derivatives, we conclude that V will not be differentiable, in general, when the solution to the problem is not unique.

4. Proof Of Theorems 3.1 and 3.2. The proofs of Theorem 3.1 (a) and 3.2 (a) are broken into seven steps. The basic outline of the proof is this. It is shown first (Step 1) that the value function is locally Lipschitz in (Δ, α) on $[0, \overline{\Delta}) \times L_n^2[a,b]$. Next, estimates of the lim sup in Theorem 3.1 (a) and the analogous limit in Theorem 3.2 (a) are obtained (Step 2) by introducing a modified problem and applying the formula (2.4). This estimate further leads to introducing an auxiliary optimization problem arising from the definition of proximal subgradients. Since a solution of this auxiliary problem is known, necessary optimality conditions are applied (Step 3) to derive the main identity. The necessary conditions in the maximum principle then represent (Step 4) a proximal subgradient as a multiplier. The previous material is brought together (Step 5) into upper and lower estimates involving rather complicated limits. Finally, extensive limiting arguments (Steps 6 and 7) finish the proof of Theorem 3.1 (a). The proof of Theorem 3.2 (a) will be completed by altering slightly the final limiting arguments. The proofs of both (b) parts require only minor modifications in Step 2.

Step 1. It will be first shown that $V(\Delta, \alpha)$ is locally Lipschitz in (Δ, α) on $[0, \overline{\Delta}) \times L^2[a,b]$. Fix $\Delta \in [0, \overline{\Delta})$ and $R > 0$. Set $r := r_R$, where r_R is as in (H5). Suppose that $\alpha_1, \alpha_2 \in L^2[a,b]$ are so that $||\alpha_1||_2$, $||\alpha_2||_2 \leq R$. Let $u(\cdot) \in \Sigma(P(\Delta, \alpha_1))$, and let $x_1(\cdot) = x_{\alpha_1}^{u,\Delta}(\cdot)$ and $x_2(\cdot) = x_{\alpha_2}^{u,\Delta}$. Recall that this means

$$\dot{x}_1(t) = \phi(t, \Delta, x_1(t), x_1(t-\Delta), u(t)) + \alpha_1(t) \quad \text{a.e. } t \in [a,b],$$

$$x_1(t) = c(t) \quad \text{for} \quad t \in [a-\Delta, a],$$

and $x_2(\cdot)$ is a similar solution with α_1 replaced by α_2. We have for each $t \in [a,b]$,

$$\begin{aligned} |x_1(t) - x_2(t)| &\leq \int_a^t |\dot{x}_1(s) - \dot{x}_2(s)| \, \mathrm{ds} \\ &\leq \int_a^t |\alpha_1(s) - \alpha_2(s)| \, \mathrm{ds} + \int_a^t (\gamma_r(s) + \sigma_r(s)) |x_1(s) - x_2(s)| \, \mathrm{ds} \qquad (4.1) \\ &\leq (b-a)^{1/2} ||\alpha_1 - \alpha_2||_2 + \int_a^t (\gamma_r(s) + \sigma_r(s)) |x_1(s) - x_2(s)| \, \mathrm{ds}, \end{aligned}$$

where $\gamma_r(\cdot) \in L^1[a,b]$ and $\sigma_r(\cdot) \in L^2[a,b]$ are chosen as in (H6). From (4.1) and Gronwall's lemma, we deduce that

$$|x_1(t) - x_2(t)| \leq k_1 ||\alpha_1 - \alpha_2||_2 \tag{4.2}$$

for each $t \in [a,b]$, where $k_1 = (b-a)^{1/2}(1 + (||\gamma_r||_1 + ||\sigma_r||_1) \exp(||\gamma_r||_1 + ||\sigma_r||_1))$. Now (x_2, u) satisfies the dynamics of $P(\Delta, \alpha_2)$, so we have

$$\begin{aligned} V(\Delta, \alpha_2) &\leq J(\Delta, x_2, u) \\ &= \ell(\Delta, x_2(b)) + \int_a^b L(t, \Delta, x_2(t), x_2(t-\Delta), u(t)) \, \mathrm{dt} \\ &\leq \ell(\Delta, x_1(b)) + \int_a^b L(t, \Delta, x_1(t), x_1(t-\Delta), u(t)) \, \mathrm{dt} \qquad (4.3) \\ &\quad + k_2 \, |x_1(b) - x_2(b)| + \int_a^b (\gamma_r(t) + \sigma_r(t)) |x_1(t) - x_2(t)| \, \mathrm{dt}, \end{aligned}$$

where $k_2 = \sup\{\nabla_\xi \ell(\Delta, \xi) : ||\xi|| \leq r\}$. The last inequality is an immediate consequence of the mean value theorem, (H1) and (H6). Recall that $u \in \Sigma(P(\Delta, \alpha_1))$, so from (4.2) and (4.3) we have

$$V(\Delta, \alpha_2) \leq V(\Delta, \alpha_1) + k_3 ||\alpha_1 - \alpha_2||_2, \tag{4.4}$$

where $k_3 = k_1(k_2 + ||\gamma_r||_1 + ||\sigma_r||_1)$.

By retracing the above steps with α_1 and α_2 interchanged, we conclude from (4.4) that $V(\Delta, \cdot)$ is locally Lipschitz. Moreover, note that the Lipschitz constant does not depend on the choice of $\Delta \in [0, \overline{\Delta})$.

We now turn to the Lipschitz dependence with respect to Δ. Let $R > 0$, $0 < \Delta_1 < \Delta_2 < \overline{\Delta}$, and $\alpha \in L^2[a,b]$ with $||\alpha||_2 \leq R$. Set $r = r_R$. Let $u \in \Sigma(P(\Delta, \alpha))$, and let $x_1(\cdot) = x_\alpha^{u,\Delta_1}(\cdot)$ and $x_2(\cdot) = x_\alpha^{u,\Delta_2}(\cdot)$.

We have for each $t \in [a, b]$

$$\tag{4.5}\begin{aligned}|x_1(t) - x_2(t)| &\le \int_a^t |\dot{x}_1(s) - \dot{x}_2(s)|\,\mathrm{ds}\\ &= \int_a^t |\phi(s, \Delta_1, x_1(s), x_1(s - \Delta_1), u(s))\\ &\qquad\qquad - \phi(s, \Delta_2, x_2(s), x_2(s - \Delta_2), u(s))|\,\mathrm{ds}\\ &\le \int_a^t \{\sigma_r(s)(\Delta_2 - \Delta_1) + \sigma_r(s)|x_1(s - \Delta_1) - x_2(s - \Delta_2)|\\ &\qquad\qquad + \gamma_r(s)|x_1(s) - x_2(s)\}\ \mathrm{ds},\end{aligned}$$

where $\sigma_r(\cdot)$ and $\gamma_r(\cdot)$ are as in (H6).

Consider the second term in the integrand on the right side of (4.5). For each $s \in [a, t]$, we have

$$\tag{4.6}\begin{aligned}|x_1(s - \Delta_1) - x_2(s - \Delta_2)| &\le \int_{s-\Delta_2}^{s-\Delta_1} |\dot{x}_1(s')|\,\mathrm{ds}' + |x_1(s - \Delta_2) - x_2(s - \Delta_2)|\\ &\le \int_{s-\Delta_2}^{s-\Delta_1} (\sigma_r(s') + \alpha(s'))\,\mathrm{ds}' + |x_1(s - \Delta_2) - x_2(s - \Delta_2)|,\end{aligned}$$

where we set $\sigma_r(s) = \dot{c}(s)$ and $\alpha(s) = 0$ if $s < a$. Next, we use Hölder's inequality twice:

$$\tag{4.7}\begin{aligned}&\int_a^t \sigma_r(s) \int_{s-\Delta_2}^{s-\Delta_1} (\sigma_r(s') + \alpha(s'))\mathrm{ds}'\mathrm{ds}\\ &\le \|\sigma_r\|_2 \left\{ \int_a^t \left[\int_{s-\Delta_2}^{s-\Delta_1} (\sigma_r(s') + \alpha(s'))\mathrm{ds}' \right]^2 \mathrm{ds} \right\}^{1/2}\\ &\le \|\sigma_r\|_2(\Delta_2 - \Delta_1)^{1/2} \left\{ \int_a^t \int_{s-\Delta_2}^{s-\Delta_1} |\sigma_r(s') + \alpha(s')|^2\mathrm{ds}'\mathrm{ds} \right\}^{1/2}.\end{aligned}$$

Fubini's theorem applied to the double integral on the right-hand side of (4.7) gives

$$\begin{aligned}\int_a^t \int_{s-\Delta_2}^{s-\Delta_1} |\sigma_r(s') + \alpha(s')|^2\mathrm{ds}'\mathrm{ds} &\le \int_{a-\Delta_2}^{t-\Delta_1} \int_{s'-\Delta_1}^{s'-\Delta_2} |\sigma_r(s') + \alpha(s')|^2\mathrm{ds}\mathrm{ds}'\\ &\le (\Delta_2 - \Delta_1)\|\sigma_r + \alpha\|_2^2.\end{aligned}$$

Inserting this into (4.7) yields the estimate

$$\tag{4.8}\int_a^t \sigma_r(s) \int_{s-\Delta_2}^{s-\Delta_1} (\sigma_r(s') + \alpha(s'))\mathrm{ds}'\mathrm{ds} \le \|\sigma_r\|_2(\|\sigma_r\|_2 + \|\alpha\|_2)(\Delta_2 - \Delta_1).$$

Now we multiply (4.6) by $\sigma_r(s)$ and integrate from a to t. In light of (4.8), we obtain

$$\tag{4.9}\begin{aligned}&\int_a^t \sigma_r(s)|x_1(s - \Delta_1) - x_2(s - \Delta_2)|\mathrm{ds}\\ &\le \|\sigma_r\|_2(\|\sigma_r\|_2 + \|\alpha\|_2)(\Delta_2 - \Delta_2) + \int_a^t \sigma_r(s)|x_1(s - \Delta_2) - x_2(s - \Delta_2)|\mathrm{ds}.\end{aligned}$$

Plugging (4.9) into (4.5), we have

$$|x_1(t) - x_2(t)| \leq k_4(\Delta_2 - \Delta_1) + \int_a^t (\sigma_r(s + \Delta_2) + \gamma_r(s))|x_1(s) - x_2(s)|\mathrm{ds},$$

where $k_4 = \|\sigma_r\|_1 + \|\sigma_r\|_2(\|\sigma_r\|_2 + R)$, and $\sigma_r(s + \Delta_2)$ is set equal to zero if $s + \Delta_2$ exceeds b. Another application of Gronwall's lemma yields the inequality

$$|x_1(t) - x_2(t)| \leq k_5|\Delta_2 - \Delta_1|, \tag{4.10}$$

with $k_5 = k_4(1 + (\|\sigma_r\|_2 + \|\gamma_r\|_1) \exp\,(\|\sigma_r\|_1 + \|\gamma_r\|_1))$.

Analogously, similar reasoning shows that estimate (4.10) holds whenever $0 \leq \Delta_2 < \Delta_1 < \overline{\Delta}$.

The argument that derived (4.3) from (4.2) can be utilized here with only minor modifications, and the analogue to (4.4) is

$$|V(\Delta_2, \alpha) - V(\Delta_1, \alpha)| \leq k_6|\Delta_2 - \Delta_1| \tag{4.11}$$

for some constant k_6 that is independent of $\alpha \in L^2[a, b]$, provided $||\alpha||_2 \leq R$.

Finally, let $R > 0$ and set $k = \max\{k_3, k_6\}$ where k_3 and k_6 are as in (4.4) and (4.11). For each $\Delta_1, \Delta_2 \in [0, \overline{\Delta})$ and $\alpha_1, \alpha_2 \in L^2[a, b]$ with $||\alpha_1||_2$, $||\alpha_2||_2 \leq R$, we have

$$\begin{aligned}|V(\Delta_1, \alpha_1) - V(\Delta_2, \alpha_2)| &\leq |V(\Delta_1, \alpha_1) - V(\Delta_2, \alpha_1)| + |V(\Delta_2, \alpha_1) - V(\Delta_2, \alpha_2)| \\ &\leq k(|\Delta_1 - \Delta_2| + ||\alpha_1 - \alpha_2||_2).\end{aligned}$$

This is the statement that V is locally Lipschitz on $[0, \overline{\Delta}) \times L^2[a, b]$. □

Unless noted otherwise, $\Delta_0 \in (0, \overline{\Delta})$ is fixed. The case $\Delta_0 = 0$ will be handled separately at the end.

Step 2. Fix $v \in \Sigma(\Delta_0)$. Since $V_v(\Delta) \geq V(\Delta)$ for all $\Delta \in [0, \overline{\Delta})$ and $V_v(\Delta_0) = V(\Delta_0)$, we have

$$\begin{aligned}\limsup_{h\searrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} &\leq \limsup_{h\searrow 0} \frac{V_v(\Delta_0 + h) - V_v(\Delta_0)}{h} \\ &\leq \limsup_{\substack{h\searrow 0 \\ \Delta\to\Delta_0 \\ \alpha\to 0}} \frac{V_v(\Delta + h, \alpha) - V_v(\Delta, \alpha)}{h} \\ &= V_v^0((\Delta_0, 0); (1, 0)).\end{aligned}$$

Formula (2.6) is applicable because V_v is locally Lipschitz by Step 1. Hence the last above term equals

$$\sup\{\mu : (\mu, \beta) \in \partial V_v(\Delta_0, 0)\},$$

where the subgradient is taken with respect to both variables $(\Delta, \alpha) \in \mathbb{R}^+ \times L^2[a, b]$. This, in turn, can be expressed in terms of weak limits via (2.4) and (2.5), and since $v \in \Sigma(\Delta_0)$ is arbitrary, we obtain the following estimate:

$$\limsup_{h\searrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} \leq \inf_{v\in\Sigma(\Delta_0)} \sup \mu, \tag{4.12}$$

where the sup is taken over sequences $\{(\Delta_i, \alpha_i)\}_{i=1}^{\infty}$, $\{(\mu_i, \beta_i)\}_{i=1}^{\infty}$ of $\mathbb{R}^1 \times L^2[a, b]$ such that $(\Delta_i, \alpha_i) \to (\Delta_0, 0)$ strongly, $(\mu_i, \beta_i) \to (\mu, \beta)$ weakly (for some $\beta \in L^2[a, b]$), and (μ_i, β_i) is a proximal subgradient of V_v at (Δ_i, α_i).

A lower bound can also be obtained in a similar fashion. We have

$$\begin{aligned}\liminf_{h\searrow 0}\frac{V(\Delta_0+h)-V(\Delta_0)}{h} &\geq -\limsup_{\substack{h\searrow 0\\ \Delta\to\Delta_0\\ \alpha\to 0}}\frac{V(\Delta-h,\alpha)-V(\Delta,\alpha)}{h}\\ &= -V^0((\Delta_0,0);(-1,0))\\ &= \inf\{\mu:(\mu,\beta)\in\partial V(\Delta_0,0)\}.\end{aligned}$$

In a manner analogous to the above, we obtain the lower estimate

$$\liminf_{h\searrow 0}\frac{V(\Delta_0+h)-V(\Delta_0)}{h}\geq \inf\mu, \tag{4.13}$$

where the inf is taken over sequences $\{(\Delta_i,\alpha_i)\}_{i=1}^{\infty}$, $\{(\mu_i,\beta_i)\}_{i=1}^{\infty}$ of $\mathbb{R}^1\times L^2[a,b]$ such that $(\Delta_i,\alpha_i)\to(\Delta_0,0)$ strongly, $(\mu_i,\beta_i)\to(\mu,\beta)$ weakly (for some $\beta\in L^2[a,b]$), and (μ_i,β_i) is a proximal subgradient of V at (Δ_i,α_i).

Step 3. The bounds (4.12) and (4.13) introduce proximal subgradients and allow for the exploitation of the proximal subgradient inequality (2.3). The next lemma contains the fundamental identity. In this step and the next, we will take the lemmas with the object in mind to proving the estimates in Theorem 3.1. Similar statements are valid if the subscript "v" is dropped throughout, and these latter versions are required for the proof of Theorem 3.2.

LEMMA 4.1. *Suppose that* $(\Delta,\alpha)\in(0,\overline{\Delta})\times L^2[a,b]$, $v\in L^2[a,b]$, *and* $u\in\Sigma_v(\Delta,\alpha)$. *If* $(\mu,\beta)\in\mathbb{R}^1\times L^2[a,b]$ *is a proximal subgradient of* V_v *at* (Δ,α), *then*

$$\mu=\frac{\partial}{\partial\Delta}\ell(\Delta,x(b))+\int_a^b\{L_\Delta(\cdot)+\langle\beta(t),\phi_\Delta(\cdot)\rangle+\langle\phi_2^*(\cdot)(-\beta(t))-L_2^*(\cdot),\dot{x}(t-\Delta)\rangle\}\,dt,$$

where $x(\cdot)=x_\alpha^{u,\Delta}$, *and in the integrand, the functions with* $(\cdot)$ *are evaluated at* $(t,\Delta,x(t),x(t-\Delta),u(t))$.

Proof of Lemma 4.1. By the definition of proximal subgradients, there exists $\sigma>0$ so that for all $(\Delta',\alpha')\in(0,\overline{\Delta})\times L^2[a,b]$ near (Δ,α) in norm, we have

$$V_v(\Delta',\alpha')\geq V_v(\Delta,\alpha)+\langle(\mu,\beta),(\Delta'-\Delta,\alpha'-\alpha)\rangle-\sigma\|(\Delta'-\Delta,\alpha'-\alpha)\|^2. \tag{4.14}$$

If $y(\cdot)\in AC[a-\overline{\Delta},b]$ with $\dot{y}(\cdot)\in L^2[a,b]$ and $y(t)=c(t)$ on $[a-\Delta',a]$, and $\nu(\cdot)\in\mathscr{M}[a,b]$ with $\nu(t)\in U(t)$ almost everywhere $t\in[a,b]$, then $V_v(\Delta',\alpha')\leq J(\Delta',y,\nu)+\|\nu-v\|_2^2$, where $\alpha'(t):=\dot{y}(t)-\phi(t,\Delta,y(t),y(t-\Delta'),\nu(t))$. Substituting this choice of variables into (4.14), we can write

$$\begin{aligned}J(\Delta',y,\nu)+\|\nu-v\|_2^2-\mu\Delta'+\int_a^b\langle\beta(t),\phi(t,\Delta,y(t),y(t-\Delta'),\nu(t))-\dot{y}(t)\rangle\,dt\\ +\sigma\|(\Delta'-\Delta,\alpha'-\alpha)\|^2\geq V_v(\Delta,\alpha)-\langle(\mu,\beta),(\Delta,\alpha)\rangle.\end{aligned} \tag{4.15}$$

Now since $u\in\Sigma_v(\Delta,\alpha)$, the left-hand side of (4.15) has a local minimum in the variables (Δ',y,ν) at (Δ,x,u). Substitute (x,u) for (y,ν) in the left side of (4.15), and take the derivative with respect to Δ' at Δ. The result is zero, and the bounds on the integrands assumed on (H6) allow for differentiating under the integral. We obtain

$$\text{(4.16)}\quad \frac{\partial}{\partial\Delta}J(\Delta,x,u)-\mu+\int_a^b\langle\beta(t),\phi_\Delta(t,\Delta,x(t),x(t-\Delta),u(t)) \\ +\phi_2(t,\Delta,x(t),x(t-\Delta),u(t))(-\dot{x}(t-\Delta)\rangle\,\mathrm{dt}=0.$$

Recall that

$$J(\Delta,x,u)=\ell(\Delta,x(b))+\int_a^b L(t,\Delta,x(t),x(t-\Delta),u(t))\,\mathrm{dt},$$

and hence

(4.17)

$$\frac{\partial}{\partial\Delta}J(\Delta,x,u)=\frac{\partial}{\partial\Delta}\ell(\Delta,x(b))+\int_a^b L_\Delta(t,\Delta,x(t),x(t-\Delta),u(t))\,\mathrm{dt} \\ +\int_a^b\langle L_2^*(t,\Delta,x(t),x(t-\Delta),u(t)),-\dot{x}(t-\Delta)\rangle\,\mathrm{dt}.$$

Substituting (4.17) into (4.16) and rearranging terms gives

$$\mu=\frac{\partial}{\partial\Delta}\ell(\Delta,x(b)) \\ +\int_a^b\{L_\Delta(\cdot)+\langle\beta(t),\phi_\Delta(\cdot)\rangle+\langle\phi_2^*(\cdot)(-\beta(t))-L_2^*(\cdot),\dot{x}(t-\Delta)\rangle\}\,\mathrm{dt},$$

which is the assertion of the lemma. □

Step 4. The proximal subgradient inequality (4.15) can also be used to obtain information on the nature of $\beta(\cdot)$. The following lemma is an extension of Clarke [C2, Thm. 2.1] to problems with delay.

LEMMA 4.2. *In the notation of Lemma* 4.1, *we have* $-\beta(t)=p(t)+q(t+\Delta)$, *where* $(p,q)=M(u,P_v(\Delta,\alpha))$.

Proof. Replace Δ' by Δ in (4.15). Then it immediately follows from (4.15) that (x,u) is a local optimal solution to the optimal control problem

$$\min\ \ell(\Delta,y(b))+\int_a^b\Big\{L(t,\Delta,y(t),y(t-\Delta),\nu(t))+|\nu(t)-v(t)|^2 \\ +\langle\beta(t),\phi(t,\Delta,y(t),y(t-\Delta),\nu(t))-\dot{y}(t)\rangle \\ +\sigma|\dot{y}(t)-\phi(t,\Delta,y(t),y(t-\Delta),\nu(t))-\dot{x}(t) \\ +\phi(t,\Delta,x(t),x(t-\Delta),u(t))|^2\Big\}\,\mathrm{dt}$$

over possible (y,ν), and where $\dot{y}(t)$ is viewed as an additional control variable z without constraint. The maximum principle as given in §2 is applicable and asserts that there exist absolutely continuous functions $p(\cdot)$ and $q(\cdot)$ from $[a,b]$ to $\mathbb{R}^n$ such that

(i) $$-p(b) = \nabla_x \ell(\Delta, x(b)), \quad q(b) = 0,$$

(ii) $$-\dot{p}(t) = -L_1^*(t, \Delta, x(t), x(t-\Delta), u(t)) - \phi_1^*(t, \Delta, x(t), x(t-\Delta), u(t))\beta(t),$$ a.e. $t \in [a, b]$,

$$-\dot{q}(t) = -L_2^*(t, \Delta, x(t), x(t-\Delta), u(t)) - \phi_2^*(t, \Delta, x(t), x(t-\Delta), u(t))\beta(t),$$ a.e. $t \in [a, b]$,

and

(iii)
$$\begin{aligned}\max\{&\langle p(t) + q(t+\Delta), z\rangle - L(t, \Delta, x(t), x(t-\Delta), \nu) - |\nu - v(t)|^2\\ &-\langle \beta(t), \phi(t, \Delta, x(t), x(t-\Delta), \nu) - z\rangle\\ &-\sigma|z - \phi(t, \Delta, x(t), x(t-\Delta), \nu) - \dot{x}(t) + \phi(t, \Delta, x(t), x(t-\Delta), u(t))|^2\}\end{aligned}$$

over $\nu \in U(t)$, $z \in \mathbb{R}^n$ occurs at $\nu = u(t)$, $z = \dot{x}(t)$.

In the term maximized in (iii), substitute $u(t)$ for ν and differentiate with respect to z. Since this derivative is zero at $z = \dot{x}(t)$, it follows that $-\beta(t) = p(t) + q(t + \Delta)$. By substituting this into (ii), it becomes clear that the adjoint equations of the maximum principle applied to $(u, P_v(\Delta, \alpha))$ hold for (p, q). To conclude that $(p, q) = M(u, P_v(\Delta, \alpha))$ we must show that the maximum condition holds.

Again from (iii), we have that

$$\begin{aligned}(4.18)\quad \max\Bigg\{&\langle p(t) + q(t+\Delta), \phi(t, \Delta, x(t), x(t-\Delta), \nu)\rangle\\ &- L(t, \Delta, x(t), x(t-\Delta), \nu) - |\nu - v(t)|^2\\ &- \sigma|\phi(t, \Delta, x(t), x(t-\Delta), \nu) - \phi(t, \Delta, x(t), x(t-\Delta), u(t))|^2\Bigg\}\end{aligned}$$

over $\nu \in U(t)$ is achieved at $u(t) \in U(t)$. Let $S \subseteq \mathbb{R}^n \times \mathbb{R}^1$ be defined by

$$S := \{(-\phi(t, \Delta, x(t), x(t-\Delta), \nu), L(t, \Delta, x(t), x(t-\Delta), \nu) + |\nu - v(t)|^2 + \delta) : \delta \geq 0,\ \nu \in U(t)\},$$

and let $s_0 \in S$ be chosen as

$$s_0 = (-\phi(t, \Delta, x(t), x(t-\Delta), u(t)), L(t, \Delta, x(t), x(t-\Delta), u(t)) + |u(t) - v(t)|^2).$$

It follows from (4.18) that

$$\min\{\langle (p(t) + q(t+\Delta), 1), s\rangle + \sigma|s - s_0|^2\}$$

over $s \in S$ is attained at $s = s_0$. Now from the convexity hypothesis (H7), we have that S is convex. So from elementary convex analysis $\min\langle (p(t) + q(t+\Delta), 1), s\rangle$ over $s \in S$ is attained at $s = s_0$. Reverting back to the original notation, this means that the max of

$$\{\langle p(t) + q(t+\Delta), \phi(t, \Delta, x(t), x(t-\Delta), \nu)\rangle - L(t, \Delta, x(t), x(t-\Delta), \nu) - |\nu - v(t)|^2\}$$

over $\nu \in U(t)$ is achieved at $\nu = u(t)$. This is the maximum condition that finishes the demonstration that $(p, q) = M(u, P_v(\Delta, \alpha))$. □

Step 5. We now apply the results of Steps 3 and 4 to the proximal subgradients that arise in Step 2. The outcome of doing so is summarized in the following.

LEMMA 4.3. *We have*

(a)

$$\limsup_{h\searrow 0}\frac{V(\Delta_0+h)-V(\Delta_0)}{h}\le\inf_{v\in\Sigma(\Delta_0)}\ \limsup_{(\Delta,\alpha)}\ \inf_{u\in\Sigma_v(\Delta,\alpha)} E\Big(\Delta,x_\alpha^{u,\Delta},u,M(u,P_v(\Delta,\alpha))\Big);$$

(b)

$$\liminf_{h\searrow 0}\frac{V(\Delta_0+h)-V(\Delta_0)}{h}\ge\liminf_{(\Delta,\alpha)}\ \sup_{u\in\Sigma(\Delta,\alpha)} E\Big(\Delta,x_\alpha^{u,\Delta},u,M(u,P(\Delta,\alpha))\Big).$$

In (a), *the* lim sup *is taken over* $(\Delta,\alpha)\to(\Delta_0,0)$ *in* $\mathbb{R}^1\times L_n^2[a,b]$ *such that* V_v *has a proximal subgradient at* (Δ,α). *In* (b), *the* lim inf *is taken over* $(\Delta,\alpha)\to(\Delta_0,0)$ *in* $\mathbb{R}^1\times L_n^2[a,b]$ *such that* V *has a proximal subgradient at* (Δ,α).

Proof. (a) Recall estimate (4.12). Let $v\in\Sigma(\Delta_0)$ and $\{(\Delta_i,\alpha_i)\}_{i=1}^\infty$, $\{(\mu_i,\beta_i)\}_{i=1}^\infty$ be sequences of which the sup is taken over in (4.12). Pick any $u_i\in\Sigma_v(\Delta_i,\alpha_i)$ and set $x_i(\cdot)=x_{\alpha_i}^{u_i,\Delta_i}(\cdot)$. In light of Lemma 4.2, we may write $-\beta_i(t)=p_i(t)+q_i(t+\Delta_i)$ where $(p_i,q_i)=M(u_i,P_v(\Delta_i,\alpha_i))$. Observe that $q_i(\cdot)$ satisfies

$$-\dot q_i(t)=\frac{\partial}{\partial y}\mathscr{H}^*(t,\Delta_i,x_i(t),x_i(t-\Delta_i),u_i(t),p_i(t)+q_i(t+\Delta_i))\quad\text{a.e. } t\in[a,b],$$

and hence from Lemma 4.1 we conclude that

(4.19)

$$\begin{aligned}\mu_i=\frac{\partial}{\partial\Delta}\ell(\Delta_i,x_i(b))-\int_a^b\bigg[\frac{\partial}{\partial\Delta}\mathscr{H}\Big(t,\Delta_i,x_i(t),x_i(t-\Delta_i),u_i(t),p_i(t)+q_i(t+\Delta_i)\Big)\\ +\langle\dot q_i(t),\dot x_i(t-\Delta_i)\rangle\bigg]\,\mathrm{dt}\\ =E\Big(\Delta_i,x_i,u_i,M(u_i,P_v(\Delta_i,\alpha_i))\Big).\end{aligned}$$

Now (4.12) says that the right upper Dini derivative is bounded above by $\limsup_{i\to\infty}\mu_i$, and we have seen that each μ_i is represented as in (4.19). By then taking the inf over $v\in\Sigma(\Delta_0)$, it follows that (a) holds.

(b) The proof of (b) resembles that of (a). Estimate (4.13) gives a lower bound of the right lower Dini derivative of V at Δ_0 in the form $\liminf_{i\to\infty}\mu_i$, where μ_i has the representation (4.19) for some $u_i\in\Sigma(\Delta_i,\alpha_i)$. (Here we need to utilize the versions of Lemmas 4.1 and 4.2 that are without the subscript "v.") This is one of the choices the lim inf on the right side of (b) is taken over, hence estimate (b) is valid. □

The rest of the proofs of Theorems 3.1 (a) and 3.2 (a) now consists of calculating the lim sup and lim inf that occur in the right-hand sides of Lemma 4.3. Our proof will actually show that for fixed $v\in\Sigma(\Delta_0)$, the lim sup in the right-hand side of Lemma 4.3 (a) exists as a limit. Toward this end, we next show in effect that for $v\in\Sigma(\Delta_0)$, the problem $P_v(\Delta_0)$ satisfies (H8). In evaluating the lim inf in (b), we will not need this lemma, but rather will invoke (H8) directly.

LEMMA 4.4. *Let* $v\in\Sigma(\Delta_0)$, *and suppose* $\{h_i\}_{i=1}^\infty\subseteq\mathbb{R}^1$ *and* $\{\alpha_i\}_{i=1}^\infty\subseteq L^2[a,b]$ *are sequences such that* $h_i\to 0$ *and* $||\alpha_i||_2\to 0$ *as* $i\to\infty$. *Let* $u_i\in\Sigma_v(\Delta_i,\alpha_i)$. *Then a subsequence of* $\{u_i\}$ (that is not relabeled) *satisfies* $u_i(t)\to v(t)$ *almost everywhere* $t\in[a,b]$.

Proof. Note that $V_v(\Delta, \alpha)$ is continuous in (Δ, α) (Step 1). Hence

$$V(\Delta_0) = V_v(\Delta_0, 0) = \lim_{i\to\infty} V_v(\Delta_i, \alpha_i)$$

$$= \lim_{i\to\infty} \left\{ J(\Delta_i, x_i, u_i) + \|u_i - v\|_2^2 \right\}. \tag{4.20}$$

Suppose $\|u_i - v\|_2^2 \not\to 0$ as $i \to \infty$. Passing to a subsequence if necessary, assume $\|u_i - v\|_2^2 \geq \delta > 0$ for all i. Now $V(\Delta, \alpha)$ is also continuous in (Δ, α), and so

$$\begin{aligned} V(\Delta_0) = V(\Delta_0, 0) &= \lim_{i\to\infty} V(\Delta_i, \alpha_i) \\ &\leq \liminf_{i\to\infty} J(\Delta_i, x_i, u_i) \\ &\leq V(\Delta_0) - \delta. \end{aligned}$$

The last inequality follows from (4.20) and the assumption $\|u_i - v\|_2^2 \geq \delta$. This is a contradiction, so we must have $\|u_i - v\|_2^2 \to 0$, whence it follows that a subsequence satisfies $u_i(t) \to v(t)$ almost everywhere $t \in [a, b]$. □

Step 6. In this step, we show that the almost everywhere convergence of optimal controls induces nice convergence properties of the associated trajectories and multipliers.

We first focus attention on the lim sup in Lemma 4.3 (a). Fix $v(\cdot) \in \Sigma(\Delta_0)$. Let $\{\Delta_i\}_{i=1}^{\infty} \subseteq [0, \overline{\Delta})$, $\{\alpha_i\}_{i=1}^{\infty} \subseteq L^2[a, b]$ be such that $\Delta_i \to \Delta_0$, $\|\alpha_i\|_2 \to 0$, and $\alpha_i(t) \to 0$ almost everywhere $t \in [a, b]$ as $i \to \infty$. For each i, let $u_i \in \Sigma_v(\Delta_i, \alpha_i)$. Passing to a subsequence if necessary, and in view of Lemma 4.4, we may assume $u_i(t) \to v(t)$ almost everywhere $t \in [a, b]$. For the sake of brevity, let $x_i(\cdot) = x_{\alpha_i}^{u_i, \Delta_i}(\cdot), x(\cdot) = x^{v, \Delta_0}(\cdot)$, $(p_i(\cdot), q_i(\cdot)) = M(u_i, P_v(\Delta_i, \alpha_i))$, and $(p(\cdot), q(\cdot)) = M(v, P(\Delta_0))$.

LEMMA 4.5. *As $i \to \infty$, we have*

(a) $x_i(t) \to x(t)$ *uniformly over* $t \in [a, b]$,

(b) $\dot{x}_i(t) \to \dot{x}(t)$ *almost everywhere* $t \in [a, b]$.

Also, subsequences of $\{p_i\}$, $\{q_i\}$ (that are not relabeled) satisfy

(c) $q_i(t) \to q(t)$, $p_i(t) \to p(t)$ *uniformly over* $t \in [a, b]$,

(d) $\dot{q}_i(t) \to \dot{q}(t)$, $\dot{p}_i(t) \to \dot{p}(t)$ *almost everywhere* $t \in [a, b]$.

Proof. By (H5), there exists $r > 0$ so that $\|x_i\|_\infty \leq r$ for all i. Therefore from (H6) and $\dot{x}_i = \phi + \alpha_i$, we have $|\dot{x}_i(t)| \leq \sigma(t)$ for some $\sigma \in L^1[a, b]$. The Dunford–Pettis criterion implies that a subsequence (that is not relabeled) of $\{\dot{x}_i(\cdot)\}_{i=1}^{\infty}$ has a weak limit point $\dot{z}(\cdot)$, whence it immediately follows that $z(t) := c(a) + \int_a^t \dot{z}(s)\,\mathrm{ds}$ satisfies $x_i(t) \to z(t)$ for each $t \in [a, b]$. In fact, the convergence $x_i(t) \to z(t)$ is uniform over $t \in [a, b]$ since $|\dot{x}_i(t)|$ is bounded independent of i by an L^1 function. Then for almost all $t \in [a, b]$, we have $\dot{x}_i(t) = \phi(t, \Delta_i, x_i(t), x_i(t - \Delta_i), u_i(t)) + \alpha_i(t) \longrightarrow \phi(t, \Delta_0, z(t), z(t - \Delta_0), v(t))$ as $i \to \infty$, where we set $z(t) = c(t)$ if $t < a$. In particular, then, $\{\dot{x}_i(\cdot)\}$ converges weakly in $L^1[a, b]$ and almost everywhere on $[a, b]$, and by the uniqueness of weak limits, the limit functions must coincide. Thus $\dot{z}(t) = \phi(t, \Delta_0, z(t), z(t - \Delta_0), v(t))$ almost everywhere $t \in [a, b]$ with $z(t) = c(t)$ for $t \in [a - \Delta_0, a]$. However, $x(\cdot)$ is the unique function satisfying this equation, so we must have $z = x$. Therefore (a) and (b) hold.

Now consider the convergences in (c) and (d). Since $(p_i, q_i) = M(u_i, P_v(\Delta_i, \alpha_i))$, we have

(4.21)

$$\begin{aligned} -p_i(b) &= \nabla_x \ell(\Delta_i, x_i(b)), \quad q_i(b) = 0, \\ -\dot{p}_i(t) &= \phi_1^*(t, \Delta_i, x_i(t), x_i(t-\Delta_i), u_i(t))(p_i(t) + q_i(t+\Delta_i)) \\ &\qquad - L_1^*(t, \Delta_i, x_i(t), x_i(t-\Delta_i), u_i(t)) \quad \text{a.e. } t \in [a,b], \\ -\dot{q}_i(t) &= \phi_2^*(t, \Delta_i, x_i(t), x_i(t-\Delta_i), u_i(t))(p_i(t) + q_i(t+\Delta_i)) \\ &\qquad - L_2^*(t, \Delta_i, x_i(t), x_i(t-\Delta_i), u_i(t)) \quad \text{a.e. } t \in [a,b]. \end{aligned}$$

Similar arguments that were used to prove (a) and (b) can be used here. We merely sketch this : first obtain a priori bounds on $|p_i| + |q_i|$ from (H6), (4.21), and Gronwall's lemma. Second, it follows from (H6) and (4.21) that $|\dot{p}_i(t)| + |\dot{q}_i(t)| \leq \sigma(t)$ for some $\sigma(\cdot) \in L^1[a,b]$. Thus we can deduce the existence of a weak limit point $(\dot{p}(t), \dot{q}(t))$ of a subsequence of $\{(\dot{p}_i(t), \dot{q}_i(t))\}$ from the Dunford–Pettis criterion, and for which $(p_i(t), q_i(t)) \to (p(t), q(t))$ uniformly over $t \in [a,b]$ as $i \to \infty$. Third, we also have from (4.21) and Lemma 4.4 that $(\dot{p}_i(t), \dot{q}_i(t))$ converges almost everywhere $t \in [a,b]$. By the uniqueness of weak limits, the limiting function must be $(\dot{p}(t), \dot{q}(t))$. It is clear from (4.21) that (p, q) satisfies

$$\begin{aligned} -p(b) &= \nabla_x \ell(\Delta_0, x(b)), \quad q(b) = 0, \\ -\dot{p}(t) &= \phi_1^*(t, \Delta_0, x(t), x(t-\Delta_0), v(t))(p(t) + q(t+\Delta_0)) \\ &\qquad - L_1^*(t, \Delta_0, x(t), x(t-\Delta_0), v(t)) \quad \text{a.e. } t \in [a,b], \\ -\dot{q}(t) &= \phi_2^*(t, \Delta_0, x(t), x(t-\Delta_0), v(t))(p(t) + q(t+\Delta_0)) \\ &\qquad - L_2^*(t, \Delta_0, x(t), x(t-\Delta_0), v(t)) \quad \text{a.e. } t \in [a,b]. \end{aligned}$$

This says that (p, q) satisfies the transversality condition and the adjoint equations associated with $(v, P(\Delta_0))$. To finish the proof of (c) and (d), it is only left to show that the maximum condition also holds.

Recall that the pseudo-Hamiltonian is defined by

$$\mathscr{H}(t, \Delta, x, y, u, p) = \langle \phi(t, \Delta, x, y, u), p \rangle - L(t, \Delta, x, y, u).$$

We must show that for almost all $t \in [a,b]$,

$$\max \mathscr{H}(t, \Delta_0, x(t), x(t-\Delta_0), u, p(t) + q(t+\Delta_0)) \tag{4.22}$$

over $u \in U(t)$ is achieved at $u = v(t)$.

Let $t \in [a,b]$ so that the following four conditions hold:

(i) $\alpha_i(t) \to 0$ as $i \to \infty$,
(ii) $u_i(t) \to v(t)$ as $i \to \infty$,
(iii) ϕ and L are continuous in the other variables whenever t is fixed,
(iv) for each i, define $\Phi_i(u)$ by

$$\Phi_i(u) = \mathscr{H}(t, \Delta_i, x_i(t), x_i(t-\Delta_i), u, p_i(t) + q_i(t+\Delta_i)) - |u - v(t)|^2;$$

then max $\Phi_i(u)$ over $u \in U(t)$ is achieved at $u = u_i(t)$.

The t for which (i)–(iv) hold consists of a set of full measure in $[a,b]$. Define $\Phi(u)$ by

$$\Phi(u) = \mathscr{H}(t, \Delta_0, x(t), x(t-\Delta_0), u, p(t) + q(t+\Delta_0)) - |u - v(t)|^2.$$

A consequence of (i), (iii), and the convergences in parts (a) and (c) is that $\Phi_i(u) \to \Phi(u)$ uniformly over $u \in U(t)$. Obviously, from (iv), we have $\Phi_i(u_i(t)) \geq \Phi_i(u)$ for all $u \in U(t)$. Hence letting $i \to \infty$, we deduce from (ii) that

$$\max \Phi(u) \text{ over } u \in U(t) \text{ is achieved at } u = v(t). \tag{4.23}$$

The difference between (4.23) and (4.22) is that the term $|u - v(t)|^2$ appears in (4.23), but not in (4.22). Now a convexity argument similar to that used in the proof of Lemma 4.2 can be applied here to conclude that (4.22) follows from (4.23). (See (4.18) and the succeeding lines.) □

There is an obvious analogue of Lemma 4.5 that will be used in evaluating the lim inf on the right side of Lemma 4.3 (b). Unlike with (a), an element $v \in \Sigma(\Delta_0)$ is not fixed first, but rather will be obtained from (H8). Suppose that we are given $\{(\Delta_i, \alpha_i)\}$ as in (4.13) and $\{u_i\}$ satisfying $u_i \in \Sigma(\Delta_i, \alpha_i)$. We assume that (H8) holds, so there exists $v \in \mathscr{M}[a,b]$ such that an (unrelabeled) subsequence of $\{u_i\}$ satisfies $u_i(t) \to v(t)$ almost everywhere $t \in [a,b]$. We show that this $v(\cdot)$ is optimal for $P(\Delta_0)$.

LEMMA 4.6. *Let $v(\cdot)$ be as the previous paragraph. Then $v(\cdot) \in \Sigma(\Delta_0)$.*

Proof. Let $x_i(\cdot) = x_{\alpha_i}^{u_i,\Delta_i}(\cdot)$ and $x(\cdot) = x^{v,\Delta_0}(\cdot)$. We can show as in the proof of Lemma (4.5)(a) that $x_i(t) \to x(t)$ uniformly over $t \in [a,b]$. It then follows from the basic assumptions that $J(\Delta_i, x_i, u_i) \to J(\Delta_0, x, v)$ as $i \to \infty$. We have

$$\begin{aligned} V(\Delta_0) = V(\Delta_0, 0) &= \lim_{i\to\infty} V(\Delta_i, \alpha_i) \quad \text{(by Step 1)} \\ &= \lim_{i\to\infty} J(\Delta_i, x_i, u_i) \\ &= J(\Delta_0, x, v). \end{aligned}$$

It is now immediate that $v(\cdot) \in \Sigma(\Delta_0)$. □

The analogue of Lemma 4.5 for the small change in data just introduced can now be discerned. Assertions (a)-(d) hold for $u_i \in \Sigma(\Delta_i, \alpha_i)$, $x_i(\cdot) = x_{\alpha_i}^{u_i,\Delta_i}(\cdot)$, $x(\cdot) = x^{v,\Delta_0}(\cdot)$, $(p_i, q_i) = M(u_i, P(\Delta_i, \alpha_i))$, and $(p,q) = M(v, P(\Delta_0))$.

Step 7. We are ready to address the convergence of the integrals in Lemma 4.3. The next two lemmas are given abstract formulation so that they can also be used in §6. They concern weak convergence with deviating arguments.

LEMMA 4.7. *Suppose that $\psi(\cdot) \in L^2[a,b]$, $\{\psi_i(\cdot)\} \subseteq L^2[a,b]$ satisfy $|\psi_i(t)| \leq \gamma(t)$ for some $\gamma(\cdot) \in L^2[a,b]$, and $\psi_i(\cdot) \to \psi(\cdot)$ weakly in $L^2[a,b]$. Let $\{h_i\}_{i=1}^{\infty} \subseteq \mathbb{R}^1$ be such that $h_i \to 0$ as $i \to \infty$. Define $\Psi_i(t) = \psi_i(t - h_i)$ if $t - h_i \in [a,b]$, and let $\Psi_i(t)$ take on any values with absolute value less than $\gamma(t)$ if $t - h_i \notin [a,b]$ (and so that $\Psi_i(\cdot)$ remains measurable). Then $\Psi_i(\cdot) \to \psi(\cdot)$ weakly in $L^2[a,b]$.*

Proof. Let $\epsilon > 0$ and $g \in L^2[a,b]$. There exists continuous f on $[a,b]$ such that $||f - g||_2 < \epsilon$. We have

$$\begin{aligned} \left| \int_a^b \langle g(t), \Psi_i(t) - \psi(t) \rangle \, \mathrm{dt} \right| &\leq ||f - g||_2 \, ||\Psi_i(t) - \psi(t)||_2 + \left| \int_a^b \langle f(t), \Psi_i(t) - \psi(t) \rangle \, \mathrm{dt} \right| \\ &\leq \epsilon(||\gamma||_2 + ||\psi||_2) + \left| \int_a^b \langle f(t), \Psi_i(t) - \psi(t) \rangle \, \mathrm{dt} \right|. \end{aligned} \tag{4.24}$$

Let $a_i = a + |h_i|$ and $b_i = b - |h_i|$. Then for each i we have

$$\begin{aligned}\int_a^b \langle f(t), \Psi_i(t)\rangle \,\mathrm{dt} &= \int_{a_i}^{b_i} \langle f(t), \psi_i(t-h_i)\rangle \,\mathrm{dt} + \int_{[a,b]\setminus[a_i,b_i]} \langle f(t), \Psi_i(t)\rangle \,\mathrm{dt} \\ &= \int_{a_i-h_i}^{b_i-h_i} \langle f(t+h_i) - f(t), \psi_i(t)\rangle \,\mathrm{dt} - \int_{[a,b]\setminus[a_i-h_i, b_i-h_i]} \langle f(t), \psi_i(t)\rangle \,\mathrm{dt} \\ &\quad + \int_{[a,b]\setminus[a_i,b_i]} \langle f(t), \Psi_i(t)\rangle \,\mathrm{dt} + \int_a^b \langle f(t), \psi_i(t)\rangle \,\mathrm{dt}.\end{aligned}$$

The dominated convergence theorem implies that each of the first three integrals on the right-hand side goes to zero as $i \to \infty$. The fourth integral converges to $\int_a^b \langle f(t), \psi(t)\rangle \,\mathrm{dt}$ as $i \to \infty$, since $\psi_i \to \psi$ weakly. We conclude from (4.24) that $\Psi_i \to \psi$ weakly in $L^2[a, b]$. □

LEMMA 4.8. *Suppose that $\psi(\cdot)$, $\{\psi_i(\cdot)\}_{i=1}^{\infty}$, and $\{\Psi_i\}_{i=1}^{\infty}$ are as in Lemma 4.7. Suppose further that functions $g(\cdot)$ and $\{g_i(\cdot)\}_{i=1}^{\infty}$ are given so that $|g_i(t)| \le \sigma(t)$ for some $\sigma(\cdot) \in L^2[a, b]$, and that $g_i(t) \to g(t)$ almost everywhere $t \in [a, b]$ as $i \to \infty$. Then*

$$\int_a^b \langle g_i(t), \Psi_i(t)\rangle \,\mathrm{dt} \to \int_a^b \langle g(t), \psi(t)\rangle \,\mathrm{dt}$$

as $i \to \infty$.

Proof. By Lemma 4.7, we have

$$\int_a^b \langle g(t), \Psi_i(t)\rangle \,\mathrm{dt} \to \int_a^b \langle g(t), \psi(t)\rangle \,\mathrm{dt} \tag{4.25}$$

as $i \to \infty$. By assumption, $|\langle g_i(t) - g(t), \Psi_i(t)\rangle|$ is bounded almost everywhere $t \in [a, b]$ by an $L^1[a, b]$ function and goes to zero almost everywhere $t \in [a, b]$ as $i \to \infty$. Hence the dominated convergence theorem and (4.25) yield

$$\begin{aligned}\int_a^b \langle g_i(t), \Psi_i(t)\rangle \,\mathrm{dt} &= \int_a^b \langle g_i(t) - g(t), \Psi_i(t)\rangle \,\mathrm{dt} + \int_a^b \langle g(t), \Psi_i(t)\rangle \,\mathrm{dt} \\ &\to \int_a^b \langle g(t), \psi(t)\rangle \,\mathrm{dt}\end{aligned}$$

as $i \to \infty$. This proves the lemma. □

COROLLARY 4.9. *Let $\{x_i\}$, $\{q_i\}$, x, and q be as in Lemma 4.5. Then as $i \to \infty$, we have*

$$\int_a^b \langle \dot{q}_i(t), \dot{x}_i(t - \Delta_i)\rangle \,\mathrm{dt} \to \int_a^b \langle \dot{q}(t), \dot{x}(t - \Delta_0)\rangle \,\mathrm{dt}.$$

PROOF: Apply Lemma 4.8 to $\psi(t) = \dot{x}(t - \Delta_0)$, $\psi_i(t) = \dot{x}_i(t - \Delta_0)$, $h_i = \Delta_i - \Delta$, $g(t) = \dot{q}(t)$, and $g_i(t) = \dot{q}_i(t)$. It is routine to check hypotheses, and the conclusion follows directly. □

End of the proof of Theorem 3.1. Recall Lemma 4.3(a). Fix $v \in \Sigma(\Delta_0)$. Let $\{(\Delta_i, \alpha_i)\}_{i=1}^{\infty}$ be a sequence for which $(\Delta_i, \alpha_i) \to (\Delta_0, 0)$ in norm and V_v has a proximal subgradient at (Δ_i, α_i). Let $u_i \in \Sigma_v(\Delta_i, \alpha_i)$. We pass to a subsequence if necessary so that $\alpha_i(t) \to 0$, $u_i(t) \to v(t)$ almost everywhere $t \in [a,b]$, and so that the convergences in Lemma 4.5 are valid. It follows from (H1) that

$$\frac{\partial}{\partial\Delta}\ell(\Delta_i, x_i(b)) \to \frac{\partial}{\partial\Delta}\ell(\Delta_0, x(b)). \tag{4.26}$$

From (H2), (H3), and Lemmas 4.4 and 4.5 (a), (c), we conclude that

$$(\partial/\partial\Delta)\mathscr{H}(t, \Delta_i, x_i(t), x_i(t-\Delta_i), u_i(t), p_i(t) + q_i(t+\Delta_i))$$

converges for almost all $t \in [a,b]$ to

$$(\partial/\partial\Delta)\mathscr{H}(t, \Delta_0, x(t), x(t-\Delta_0), v(t), p(t) + q(t+\Delta_0))$$

as $i \to \infty$. Since each of these functions is bounded by an $L^1[a,b]$ function independent of i, the dominated convergence theorem implies

$$\begin{aligned}\int_a^b \frac{\partial}{\partial\Delta}&\mathscr{H}(t, \Delta_i, x_i(t), x_i(t-\Delta_i), u_i(t), p_i(t) + q_i(t+\Delta_i))\,\mathrm{dt}\\ &\to \int_a^b \frac{\partial}{\partial\Delta}\mathscr{H}(t, \Delta_0, x(t), x(t-\Delta_0), v(t), p(t) + q(t+\Delta_0))\,\mathrm{dt}\end{aligned} \tag{4.27}$$

as $i \to \infty$. Finally, from Corollary 4.9, we have

$$\int_a^b \langle \dot{q}_i(t), x_i(t-\Delta_i)\rangle\,\mathrm{dt} \to \int_a^b \langle \dot{q}(t), x(t-\Delta_0)\rangle\,\mathrm{dt} \tag{4.28}$$

as $i \to \infty$. Now the convergences (4.26), (4.27), and (4.28) hold for an arbitrary $v \in \Sigma(\Delta_0)$. Hence we conclude from Lemma 4.3(a) that

$$\begin{aligned}\limsup_{h\searrow 0} \frac{V(\Delta_0+h) - V(\Delta_0)}{h} \le \inf_{v\in\Sigma(\Delta_0)} \Bigg\{ &\frac{\partial}{\partial\Delta}\ell(\Delta_0, x(b))\\ &- \int_a^b \left[\frac{\partial}{\partial\Delta}\mathscr{H}\Big(t, \Delta_0, x(t), x(t-\Delta_0), v(t), p(t) + q(t+\Delta_0)\Big)\right.\\ &\left. + \ \langle \dot{q}(t), \dot{x}(t-\Delta_0)\rangle\right]\mathrm{dt}\Bigg\},\end{aligned} \tag{4.29}$$

where $x(\cdot) = x^{v,\Delta_0}(\cdot)$ and $(p(\cdot), q(\cdot)) = M(v, P(\Delta_0))$. This finishes the proof of Theorem 3.1 (a). □

The proof of (b) is analogous to that of (a). The only significant change is in Step 2, where we note that

$$\begin{aligned}\limsup_{h\searrow 0} \frac{V(\Delta_0-h) - V(\Delta_0)}{h} &\le \inf_{v\in\Sigma(\Delta_0)} -\frac{V_v(\Delta_0) - V_v(\Delta_0-h)}{h}\\ &\le - \sup_{v\in\Sigma(\Delta_0)} V_v^0((\Delta_0, 0); (1,0)).\end{aligned}$$

The rest of the proof proceeds as before; note that the statement of Theorem 3.1(b) ensues from replacing h above by $-h$. □

End of the proof of Theorem 3.2. To prove Theorem 3.2 (a), it suffices to show that under assumption (H8), the right-hand side of Lemma 4.3 (b) equals the right-hand side in (4.29), since, in view of Theorem 3.1(a), the limit exists and is equal to precisely that quantity.

Let $\{(\Delta_i,\alpha_i)\}_{i=1}^{\infty}$ be such that $(\Delta_i,\alpha_i)\to(\Delta_0,0)$ and V has a proximal subgradient at (Δ_i,α_i). Let $u_i\in\Sigma(\Delta_i,\alpha_i)$, and invoke (H8). We obtain a subsequence (not relabeled) and $v(\cdot)\in\mathscr{M}[a,b]$ so that $u_i(t)\to v(t)$ almost everywhere $t\in[a,b]$. By Lemma 4.6, we have $v(\cdot)\in\Sigma(\Delta_0)$. As pointed out at the end of Step 6, the assertions of Lemma 4.5 are valid with the data introduced here, and thus Corollary 4.9 is also valid. All of this leads directly to the convergences in (4.26), (4.27), and (4.28) for an appropriate subsequence. Therefore, from Lemma 4.3 (b), we conclude that

$$\begin{aligned}(4.30)\quad \liminf_{h\searrow 0}\frac{V(\Delta_0+h)-V(\Delta_0)}{h}\ge \inf_{v\in\Sigma(\Delta_0)}\Bigg\{&\frac{\partial}{\partial\Delta}\ell(\Delta_0,x(b))\\ &-\int_a^b\Bigg[\frac{\partial}{\partial\Delta}\mathscr{H}\Big(t,\Delta_0,x(t),x(t-\Delta_0),v(t),p(t)+q(t+\Delta_0)\Big)\\ &+\langle\dot q(t),\dot x(t-\Delta_0)\rangle\Bigg]\,\mathrm{dt}\Bigg\},\end{aligned}$$

where $x(\cdot)=x^{v,\Delta_0}(\cdot)$ and $(p(\cdot),q(\cdot))=M(v,P(\Delta_0))$. The conjunction of (4.30) with (4.29) finishes the proof of Theorem 3.2 (a).

The proof of (b) requires the same modification as the one made in the proof of Theorem 3.1 (b). □

Proof with $\Delta_0=0$. The only difficulty in letting $\Delta_0=0$ occurs in Step 2. It is not permissible there to have the delay parameter be less than zero. However, we can do the following (the notation is as in Step 2):

$$\begin{aligned}\limsup_{h\searrow 0}\frac{V(h)-V(0)}{h}&\le\limsup_{h\searrow 0}\frac{V_v(h)-V_v(0)}{h}\\ &\le\limsup_{\substack{h\searrow 0\\ \Delta\searrow 0\\ \alpha\to 0}}\frac{V_v(\Delta+h,\alpha)-V_v(\Delta,\alpha)}{h}\\ (4.31)\qquad&\le\limsup_{\Delta\searrow 0}\limsup_{\substack{h\searrow 0\\ \Delta'\to\Delta\\ \alpha\to 0}}\frac{V_v(\Delta'+h,\alpha)-V_v(\Delta',\alpha)}{h}\\ &\le\limsup_{\Delta\searrow 0}V_v^0((\Delta,0);(1,0))\\ &=\limsup_{\Delta\searrow 0}\ \sup\mu,\end{aligned}$$

where the last sup is taken over $(\mu,\beta)\in\mathbb{R}^1\times L^2[a,b]$, $\{(\mu_i,\beta_i)\}_{i=1}^{\infty}\subseteq\mathbb{R}^1\times L^2[a,b]$, $\{(\Delta_i,\alpha_i)\}_{i=1}^{\infty}\subseteq(0,\overline{\Delta})\times L^2[a,b]$ with $(\Delta_i,\alpha_i)\to(\Delta,0)$ in norm, $(\mu_i,\beta_i)\to(\mu,\beta)$ weakly, and (μ_i,β_i) is a proximal subgradient of $V_v(\cdot,\cdot)$ at (Δ_i,α_i) . A standard diagonalization argument can be used to absorb "$\limsup\limits_{\Delta\searrow 0}$" into the set at which the sup is taken over. That is, the right-hand side of (5.7) equals

$$\sup\Big\{\mu:(\mu,\beta),\{(\mu_i,\beta_i)\}_{i=1}^{\infty}\text{ with }(\Delta_i,\alpha_i)\to(0,0)\text{ in norm, }(\mu_i,\beta_i)\to(\mu,\beta)\text{ weakly, and }(\mu_i,\beta_i)\text{ is proximal subgradient of }V_v(\cdot,\cdot)\text{ at }(\Delta_i,\alpha_i)\Big\}.$$

From here, the proof of Theorem 3.1 proceeds, commencing with Step 3 precisely as before, with Δ_0 replaced by 0 throughout.

The proof of the opposite bounds with $\Delta_0 = 0$ contains no surprises. The slight modification in the limits introduced in (4.31) can be carried over to the situation in Theorem 3.2. Then as expected, the rest of the proof proceeds as before. □

5. Lipschitz terminal cost.

In this section, we consider problems in which the terminal cost function ℓ is assumed to be merely Lipschitz in the state variable. In addition to its intrinsic interest, the results here will be applied in §7, where endpoint constraints are introduced and a nondifferentiable penalization function will be needed to treat them. In place of (H1), we consider

(H1′) $\ell : [0, \overline{\Delta}) \times \mathbb{R}^n \longrightarrow \mathbb{R}^1$ is C^1 in the first and locally Lipschitz in the second variable. Furthermore, the set $\{(\Delta, x, \zeta) : \zeta \in \hat{\partial}_x \ell(\Delta, x)\}$ is closed in $[0, \overline{\Delta}) \times \mathbb{R}^n \times \mathbb{R}^n$.

Recall from (2.4) that $\hat{\partial}$ denotes the presubdifferential. The x subscript indicates that this is taken with respect to the x variable while Δ is held fixed. Obviously, (H1) implies (H1′). The closure statement is equivalent to saying the multifunction $(\Delta, x) \to \hat{\partial}_x \ell(\Delta, x)$ is upper semicontinuous on $[0, \overline{\Delta}) \times \mathbb{R}^n$. We point out that (H1′) is satisfied whenever ℓ is C^1 in Δ and convex in x.

The notation of the previous sections is maintained, except that the multiplier sets must incorporate new boundary conditions. For $u \in \Sigma(\Delta)$, $M(u, P(\Delta))$ is the *set* of pairs of absolutely continuous functions (p, q) that satisfy the transversality condition

$$-p(b) \in \hat{\partial}_x \ell(\Delta, x^{u,\Delta}(b)), \quad q(b) = 0, \tag{5.1}$$

and also satisfy the adjoint equations and the maximum condition of the maximum principle. In other words, the difference between what we now call $M(u, P(\Delta))$ and the function with the same designation in the previous sections is that $M(u, P(\Delta))$ includes all functions having the possible boundary conditions (5.1).

The maximum principle is still valid under (H1′). That is, $u \in \Sigma(\Delta)$ implies $M(u, P(\Delta)) \neq \emptyset$. The result of this section is a direct extension of the main results from §3.

THEOREM 5.1. *Assume that* (H1′), (H2)–(H7) *hold and* $\Delta_0 \in (0, \overline{\Delta})$. *We have*

(a)

$$\limsup_{h \searrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} \leq \inf_{v \in \Sigma(\Delta_0)} \sup_{(p,q) \in M(v, P(\Delta_0))} E\Big(\Delta_0, x^{v,\Delta_0}, v, (p, q)\Big),$$

and if $\Delta_0 > 0$, *then*

$$\liminf_{h \nearrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} \geq \sup_{v \in \Sigma(\Delta_0)} \inf_{(p,q) \in M(v, P(\Delta_0))} E\Big(\Delta_0, x^{v,\Delta_0}, v, (p, q)\Big);$$

(b) *In addition, assume that* (H8) *holds at* Δ_0. *Then*

$$\liminf_{h \searrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} \geq \inf_{v \in \Sigma(\Delta_0)} \inf_{(p,q) \in M(v, P(\Delta_0))} E\Big(\Delta_0, x^{v,\Delta_0}, v, (p, q)\Big),$$

and if $\Delta_0 > 0$, *then*

$$\limsup_{h \nearrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} \leq \sup_{v \in \Sigma(\Delta_0)} \sup_{(p,q) \in M(v, P(\Delta_0))} E\Big(\Delta_0, x^{v,\Delta_0}, v, (p, q)\Big).$$

(c) *In addition to the assumptions of* (b), *suppose that for each* $v \in \Sigma(\Delta_0)$, $M(v, P(\Delta_0))$ *consists of a single element. Then for all* $\Delta_0 \in [0, \overline{\Delta})$, $\lim_{h\searrow 0} (V(\Delta_0 + h) - V(\Delta_0)/h)$ *exists, and for all* $\Delta_0 \in (0, \overline{\Delta})$, $\lim_{h\nearrow 0}(V(\Delta_0 + h) - V(\Delta_0)/h)$ *exists, and are equal to the respective quantities as in Theorem* 3.2.

(d) *In addition to the assumptions of* (c), *suppose that* $\Sigma(\Delta_0)$ *consists of the single element* v. *Then, if* $\Delta_0 > 0$, *the two-sided derivative* $(d/d\Delta)V(\Delta_0)$ *exists and equals* $E(\Delta_0, x^{v,\Delta_0}, v, (p, q))$, *where* $M(v, P(\Delta_0)) = \{(p, q)\}$.

PROOF: This is nearly identical to the proof given in §4. First, note that (H1′) in place of (H1) does not affect the proof that V is locally Lipschitz in (Δ, α). The only significant modification needed in §4 occurs in the proof of Lemma 4.5, where we must now pass to another subsequence of $\{p_i\}$ if necessary to assure that $-p_i(b)$ converges to $-p(b)$. That the transversality condition (5.1) holds in the limit follows from (H1′). Since $M(v, P(\Delta))$ may contain more than one element, the lim sup on the right-hand side in Lemma 4.3(a) may no longer be an actual limit, and this is reflected in the theorem by taking the sup over $M(v, P(\Delta_0))$. □

6. The lower bound with Hamiltonian multipliers.

In this section, we use a Hamiltonian approach to obtain a lower bound for the right lower Dini derivative of $V(\Delta)$. The idea here, conceptually disjoint from assuming (H8), is to analyze the limiting behavior of trajectories and multipliers that satisfy a Hamiltonian inclusion. The optimal controls will play no major role, and for this reason we introduce the notation

$$\tilde{\Sigma}(\Delta) := \{x^{v,\Delta}(\cdot) : v \in \Sigma(\Delta)\},$$

$$\tilde{\Sigma}(\Delta, \alpha) := \{x^{v,\Delta}(\cdot) : v \in \Sigma(\Delta, \alpha)\}.$$

First, some preliminary definitions and remarks. Recall that the pseudo-Hamiltonian $\mathscr{H}$ is defined by

$$\mathscr{H}(t, \Delta, x, y, u, p) = \langle p, \phi(t, \Delta, x, y, u)\rangle - L(t, \Delta, x, y, u).$$

We now define the (true) Hamiltonian H by

$$H : [a, b] \times [0, \overline{\Delta}) \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \longrightarrow \mathbb{R}^1,$$

$$H(t, \Delta, x, y, p) = \max\{\mathscr{H}(t, \Delta, x, y, u, p) : u \in U(t)\}.$$

For $\alpha(\cdot) \in L^2[a, b]$, the Hamiltonian associated with $P(\Delta, \alpha)$ is denoted by H^α. Evidently, $H^\alpha = H + \langle p, \alpha(t)\rangle$. The generalized gradient of H with respect to (Δ, x, y, p) (always written as ∂H) can be calculated as follows (see [C1]):

$$(6.1)\quad \partial H(t, \Delta, x, y, p) = \operatorname{cl}\operatorname{co}\left\{\left(\frac{\partial}{\partial\Delta}\mathscr{H}(t, \Delta, x, y, u, p),\right.\right.$$
$$\left.\frac{\partial}{\partial x}\mathscr{H}^*(t, \Delta, x, y, u, p),\ \frac{\partial}{\partial y}\mathscr{H}^*(t, \Delta, x, y, u, p),\ \phi(t, \Delta, x, y, u)\right) :$$
$$\left. u \in U(t) \text{ such that } H(t, \Delta, x, y, p) = \mathscr{H}(t, \Delta, x, y, u, p)\right\}.$$

Throughout this section, we will assume (H1′) rather than (H1). In the definition of the (Hamiltonian) multipliers, we add an extra component w to what is usually done so as to manage the explicit Δ-dependence. Let $x(\cdot) \in \tilde{\Sigma}(\Delta)$. Then the set of Hamiltonian multipliers $\tilde{M}(x, P(\Delta))$ is defined by

$$\begin{aligned}\tilde{M}(x,P(\Delta)) = \Big\{ &(w,p,q) \in AC_{2n+1}[a,b] : \\ &w(a) = 0, \quad -p(b) \in \hat{\partial}_x \ell(\Delta, x(b)), q(b) = 0, \quad \text{and} \\ &(-\dot{w}(t), -\dot{p}(t), -\dot{q}(t), \dot{x}(t)) \in \partial H(t, \Delta, x(t), x(t-\Delta), p(t) + q(t+\Delta)) \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{a.e. } t \in [a,b] \Big\}.\end{aligned}$$

Whenever $t + \Delta \geq b$, $q(t+\Delta)$ is set equal to zero. For a problem $P(\Delta, \alpha)$, and with $x(\cdot) \in \tilde{\Sigma}(\Delta, \alpha)$, then $\tilde{M}(x, P(\Delta, \alpha))$ is defined similarly with H replaced by H^α.

Suppose that $v \in \Sigma(\Delta)$, and let $x(\cdot) = x^{v,\Delta}(\cdot)$ and $(p,q) \in M(v, P(\Delta))$. Define $w : [a,b] \to \mathbb{R}^1$ by

$$w(t) = -\int_a^t \frac{\partial}{\partial \Delta} \mathscr{H}(s, \Delta, x(s), x(s-\Delta), v(s), p(s) + q(s+\Delta))\, \mathrm{ds}. \tag{6.2}$$

It follows from the maximum principle and (6.1) that $(w,p,q) \in \tilde{M}(x, P(\Delta))$. In general, $\tilde{M}(x, P(\Delta))$ will contain other elements, which is true even for problems without delay; see Clarke [C2]. It can be shown, however, that if H is C^1 in (Δ, x, y), then $\tilde{M}(x, P(\Delta)) = \{(w,p,q) : (p,q) \in M(v, P(\Delta)),\ w(\cdot) \text{ as in (6.2)}\}$. Indeed, from [C1, Thm. 2.8.2] it follows that H is regular (see [C1, p. 39]), and consequently $\partial H \subseteq \partial_{(\Delta,x,y)} H \times \partial_p H$, where the subscripts on ∂ indicate a partial generalized gradient (see [C1, Prop. 2.3.15]). If H is C^1 in (Δ, x, y), then $\partial_{(\Delta,x,y)} H$ is the ordinary gradient. Thus, in light of (6.1), $(w,p,q) \in \tilde{M}(x, P(\Delta))$ implies that $(p,q) \in M(v, P(\Delta))$ and $w(\cdot)$ is defined by (6.2).

A necessary condition for $x(\cdot) \in \tilde{\Sigma}(\Delta)$ is that $\tilde{M}(x, P(\Delta)) \neq \emptyset$. This necessary optimality condition is applicable under weaker smoothness assumptions than we have hypothesized. In brief, the C^1 regularity in the state variables can be relaxed to mere Lipschitz with the Lipschitz constants satisfying an analogue of (H6). See Clarke and Watkins [CW].

The advantage Hamiltonian multipliers wield over Pontryagin multipliers is that $\tilde{M}(x, P(\Delta))$ has more robust closure properties (see Lemma 6.3 below). An alternative approach, that we do not develop, would be to deal with measure-relaxed problems in the sense of Warga [W1]. In any case, the convergence of the integral term in (3.2) remains problematic. We are only capable of overcoming this obstruction to our proof technique by invoking one of the following hypotheses:

(H9) For almost all $t \in [a,b]$, $(\partial/\partial y) H(t, \Delta, x, y, p)$ exists and is continuous in (Δ, x, y, p).

(H10) For almost all $t \in [a,b]$, $(\partial/\partial p) H(t, \Delta, x, y, p)$ exists and is continuous in (Δ, x, y, p).

Unlike (H8), (H9) or (H10) can often be verified directly and simply. For example, if the control is separated from y, then (H9) holds. That is, suppose that $\mathscr{H}$ has the form $\mathscr{H}(t, \Delta, x, y, u, p) = f_1(t, \Delta, x, y, p) + f_2(t, \Delta, x, u, p)$ where f_1, f_2 are measurable in t, smooth in (Δ, x, y, p), and f_2 is continuous in u. Then by using (6.1), we can easily verify (H9). Mayer problems with linear dynamics and the example considered in §8C exhibit this structure. An instance in which (H10) holds is when ϕ is linear in u and $L(t, \Delta, x, y, \cdot)$ is strictly convex.

The functional $\tilde{E}$, which is analogous to E of (3.1), is defined by

$$\tilde{E} : [0,\overline{\Delta}) \times AC_n[a,b] \times \mathbb{R}^1 \times AC_n[a,b] \longrightarrow \mathbb{R}^1,$$

$$\tilde{E}(\Delta, x(\cdot), w, q(\cdot)) = \frac{\partial}{\partial \Delta}\ell(\Delta, x(b)) + w + \int_a^b \langle -\dot{q}(t), \dot{x}(t-\Delta)\rangle \, \mathrm{dt}.$$

The main result of this section follows.

THEOREM 6.1. *Suppose that* (H1′), (H2)-(H7) *hold. Assume further that either* (H9) *or* (H10) *holds. Then for* $\Delta_0 \in [0,\overline{\Delta})$, *we have*

(a) $$\liminf_{h\searrow 0} \frac{V(\Delta_0+h)-V(\Delta_0)}{h} \geq \inf_{x\in\tilde{\Sigma}(\Delta_0)} \inf_{(w,p,q)\in\tilde{M}(x,P(\Delta_0))} \tilde{E}(\Delta_0, x, w(b), q);$$

(b) *If* $\Delta_0 > 0$, *then we have*

$$\limsup_{h\nearrow 0} \frac{V(\Delta_0+h)-V(\Delta_0)}{h} \leq \sup_{x\in\tilde{\Sigma}(\Delta_0)} \sup_{(w,p,q)\in\tilde{M}(x,P(\Delta_0))} \tilde{E}(\Delta_0, x, w(b), q).$$

Proof. We give the details for (a) and with $\Delta_0 \in (0,\overline{\Delta})$; part (b) and the case $\Delta_0 = 0$ are handled as they were in §4. We commence as in §4 through Lemma 4.3, where we now are only interested in the lower bound in Lemma 4.3 (b). Suppose that $\{(\Delta_i,\alpha_i)\}_{i=1}^{\infty} \subseteq [0,\overline{\Delta}) \times L^2[a,b]$ satisfies $(\Delta_i,\alpha_i) \to (\Delta_0, 0)$ as $i\to\infty$, and that V has a proximal subgradient at (Δ_i,α_i). Let $u_i \in \Sigma(\Delta_i,\alpha_i)$ and $(p_i,q_i) \in M(u_i, P(\Delta_i,\alpha_i))$, and set $x_i(\cdot) = x_{\alpha_i}^{u_i,\Delta_i}(\cdot)$. Define $w_i : [a,b] \to \mathbb{R}^1$ by

$$w_i(t) = -\int_a^t \frac{\partial}{\partial\Delta}\mathscr{H}(s,\Delta_i,x_i(s),x_i(s-\Delta_i),u_i(s),p_i(s)+q_i(s+\Delta_i))\,\mathrm{ds}.$$

Then we have $(w_i,p_i,q_i) \in \tilde{M}(x_i, P(\Delta_i,\alpha_i))$ for each i. As used in the proof of Lemma 4.5, we can obtain a priori bounds on $|x_i(t)|$, $|p_i(t)|$, and $|q_i(t)|$ independent of i and $t\in[a,b]$. Note from (H6) that $|(\dot{w}_i(t),\dot{p}_i(t),\dot{q}_i(t),\dot{x}_i(t))| \leq \gamma(t)$ for some $\gamma(\cdot) \in L^1[a,b]$. Then the Dunford–Pettis criterion provides a subsequence of $\{(w_i,p_i,q_i,x_i)\}$ (which is not relabeled) and absolutely continuous functions w,p,q, and x so that $(w_i(t),p_i(t),q_i(t),x_i(t)) \to (w(t),p(t),q(t),x(t))$ uniformly over $t\in[a,b]$, and $(\dot{w}_i,\dot{p}_i,\dot{q}_i,\dot{x}_i) \to (\dot{w},\dot{p},\dot{q},\dot{x})$ weakly in $L^1_{3n+1}[a,b]$ as $i\to\infty$.

LEMMA 6.2. *Let* $x(\cdot)$ *be as in the last paragraph. Then* $x(\cdot) \in \tilde{\Sigma}(\Delta_0)$.

Proof. The following is adapted from a standard existence theory argument. Let $F : [a,b]\times[0,\overline{\Delta})\times\mathbb{R}^n\times\mathbb{R}^n \rightrightarrows \mathbb{R}^n\times\mathbb{R}^1$ be the multifunction defined by $F(t,\Delta,x,y) = \{(\phi(t,\Delta,x,y,u), L(t,\Delta,x,y,u)+\delta) : u\in U(t),\ \delta\geq 0\}$. The values of F are closed and convex by (H7). Also, F is measurable in t and continuous in the other variables (see [C1, §3.1]). Define

$$z_i(t) = \int_a^t L(s,\Delta_i,x_i(s),x_i(s-\Delta_i),u_i(s))\,\mathrm{ds}.$$

Then

$$(\dot{x}_i(s)-\alpha_i(s), \dot{z}_i(s)) \in F(s,\Delta_i,x_i(s),x_i(s-\Delta_i)) \quad \text{a.e. } s\in[a,b].$$

Note that $\dot{x}_i(\cdot)-\alpha_i(\cdot) \to \dot{x}(\cdot)$ weakly in $L^1[a,b]$, and passing to another subsequence if necessary, there exists $z(\cdot)\in AC[a,b]$ so that $z_i(t)\to z(t)$ uniformly over $t\in[a,b]$, and $\dot{z}_i(\cdot)\to\dot{z}(\cdot)$ weakly in $L^1[a,b]$. Furthermore, the convex analysis argument used in the proof of [C1, Thm. 3.1.7] can be applied here with only minor modifications (to incorporate the delay Δ and delay component y), and this yields that

$$(\dot{x}(t),\dot{z}(t)) \in F(t,\Delta_0,x(t),x(t-\Delta_0)) \quad \text{a.e. } t\in[a,b].$$

Consequently, (x, z) can be represented from the Filippov lemma as the solution of

$$\dot{x}(t) = \phi(t, \Delta_0, x(t), x(t - \Delta_0), v(t)), \tag{6.3}$$

$$\dot{z}(t) = L(t, \Delta_0, x(t), x(t - \Delta_0), v(t)) + \delta(t), \tag{6.4}$$

where $v(\cdot) \in \mathscr{M}[a, b]$ satisfies $v(t) \in U(t)$ almost everywhere $t \in [a, b]$ and $\delta(\cdot)$ is measurable with $\delta(t) \geq 0$ almost everywhere $t \in [a, b]$. We have

$$\begin{aligned} V(\Delta_0) &= \lim_{i \to \infty} V(\Delta_i, \alpha_i) \\ &= \lim_{i \to \infty} \ell(\Delta_i, x_i(b)) + z_i(b) \qquad (\text{since } u_i \in \Sigma(\Delta_i, \alpha_i)) \\ &= \ell(\Delta_0, x(b)) + z(b) \end{aligned} \tag{6.5}$$

Moreover, it follows from (6.4) that

$$\begin{aligned} z(b) &\geq \int_a^b L(t, \Delta_0, x(t), x(t - \Delta_0), v(t))\, \mathrm{d}t \\ &\geq V(\Delta_0) - \ell(\Delta_0, x(b)) \qquad (\text{by (6.3) and definition of } V) \\ &= z(b). \qquad (\text{by (6.5)}). \end{aligned}$$

The conclusion is that $V(\Delta_0) = J(\Delta_0, x, v)$, and since $x(\cdot) = x^{v, \Delta_0}(\cdot)$ by (6.3), we deduce that $x(\cdot) \in \tilde{\Sigma}(\Delta_0)$. □

LEMMA 6.3. *Let (w, p, q, x) be as above. Then $(w, p, q) \in \tilde{M}(x, P(\Delta_0))$.*

Proof. For each i, the transversality condition

$$w_i(a) = 0, \quad -p_i(b) \in \hat{\partial}_x \ell(\Delta_i, x_i(b)), \quad q_i(b) = 0$$

is satisfied. Now $(w_i(a), p_i(b), q_i(b), x_i(b), \Delta_i) \to (w(a), p(b), q(b), x(b), \Delta_0)$ as $i \to \infty$. Hence by (H1′), we have

$$w(a) = 0, \quad -p(b) \in \hat{\partial}_x \ell(\Delta_0, x(b)), \quad q(b) = 0. \tag{6.6}$$

Also, for each i and almost all $t \in [a, b]$, the Hamiltonian inclusion

$$(-\dot{w}_i(t), -\dot{p}_i(t), -\dot{q}_i(t), \dot{x}_i(t)) \in \partial H^{\alpha_i}(t, \Delta_i, x_i(t), x_i(t - \Delta_i), p_i(t) + q_i(t + \Delta_i)) \tag{6.7}$$

holds. Recall that $H^\alpha = H + \langle p, \alpha(t) \rangle$. Using (6.1), we easily see that $\partial H^\alpha \subseteq \partial H = (0, 0, 0, \alpha(t))$, where $(0, 0, 0, \alpha(t)) \in \mathbb{R}^1 \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n$. Without loss of generality, $\alpha_i(t) \to 0$ as $i \to \infty$ almost everywhere $t \in [a, b]$. The modification in the proof of [C1, Thm. 3.1.7] to delay problems, which was also used in the proof of Lemma 6.2, implies that the Hamiltonian inclusion (6.7) is preserved in the limit as $i \to \infty$. That is, we have

$$(-\dot{w}(t), -\dot{p}(t), -\dot{q}(t), \dot{x}(t)) \in \partial H(t, \Delta_0, x(t), x(t - \Delta_0), p(t) + q(t + \Delta_0)) \quad \text{a.e. } t \in [a, b]. \tag{6.8}$$

By definition, (6.6) and (6.8) say that $(w, p, q) \in \tilde{M}(x, P(\Delta_0))$. □

We now come to the part of the proof where an extra hypothesis is required.

LEMMA 6.4. *Suppose that either* (H9) *or* (H10) *holds. Then*

$$\int_a^b \langle \dot{q}_i(t), \dot{x}_i(t-\Delta_i\rangle \, \mathrm{dt} \to \int_a^b \langle \dot{q}(t), \dot{x}(t-\Delta_0)\rangle \, \mathrm{dt} \tag{6.9}$$

as $i \to \infty$.

Proof. Recall that $(\dot{q}_i(\cdot), \dot{x}_i(\cdot)) \to (\dot{q}(\cdot), \dot{x}(\cdot))$ weakly in $L^2_{2n}[a,b]$ and $(p_i(t), q_i(t), x_i(t)) \to (p(t), q(t), x(t))$ uniformly over $t \in [a,b]$. It was mentioned in the preliminaries of this section that H and H^α are regular, and so

$$\partial H^\alpha \subseteq \partial_{(\Delta,x)} H \times \partial_y H \times (\alpha(t) + \partial_p H). \tag{6.10}$$

Suppose that (H9) holds, and thus $\partial_y H = \{\partial/\partial y H\}$ almost everywhere $t \in [a,b]$. Since $(w_i, p_i, q_i) \in \tilde{M}(x_i, P(\Delta_i, \alpha_i))$, we have by (6.10) that

$$-\dot{q}_i(t) = \partial/\partial y H(t, \Delta_i, x_i(t), x_i(t-\Delta_i), p_i(t) + q_i(t+\Delta_i)) \quad \text{a.e. } t \in [a,b]. \tag{6.11}$$

Since $(w,p,q) \in \tilde{M}(x, P(\Delta_0))$ (Lemma 6.3), we also have that

$$-\dot{q}(t) = \frac{\partial}{\partial y} H(t, \Delta_0, x(t), x(t-\Delta_0), p(t) + q(t+\Delta_0)) \quad \text{a.e. } t \in [a,b]. \tag{6.12}$$

By invoking (H9), we have that the right-hand side of (6.11) converges almost everywhere $t \in [a,b]$ to the right-hand side (6.12), wherefore $\dot{q}_i(t) \to \dot{q}(t)$ almost everywhere $t \in [a,b]$ as $i \to \infty$. Now the assumptions of Lemma 4.8 for the data $g_i = \dot{q}_i$, $g = \dot{q}$, $\psi_i(t) = \dot{x}_i(t-\Delta_0)$, $\psi(t) = \dot{x}(t-\Delta_0)$, $h_i = \Delta_i - \Delta_0$ can be easily verified. The conclusion of Lemma 4.8 with this data is (6.9).

Now suppose that (H10) holds, and thus $\partial_p H = \{\partial/\partial p H\}$ almost everywhere $t \in [a,b]$. Since $(w_i, p_i, q_i) \in M(x_i, P(\Delta_i, \alpha_i))$, we have by (6.10) that

$$\dot{x}_i(t) = \frac{\partial}{\partial p} H(t, \Delta_i, x_i(t), x_i(t-\Delta_i), p_i(t) + q_i(t+\Delta_i)) + \alpha_i(t) \quad \text{a.e. } t \in [a,b]. \tag{6.13}$$

From (6.10) (with $\alpha = 0$) and Lemma 6.3, it follows that

$$\dot{x}(t) = \frac{\partial}{\partial p} H(t, \Delta_0, x(t), x(t-\Delta_0), p(t) + q(t+\Delta_0)) \quad \text{a.e. } t \in [a,b]. \tag{6.14}$$

Since $\alpha_i(t) \to 0$ almost everywhere $t \in [a,b]$, (H10) implies that for almost all $t \in [a,b]$, the right-hand side of (6.13) approaches that in (6.14). Therefore $\dot{x}_i(t) \to \dot{x}(t)$ almost everywhere $t \in [a,b]$ as $i \to \infty$. Now we note that the assumptions of Lemma 4.8 are satisfied for the data $g_i = \dot{x}_i$, $g = \dot{x}$, $\psi_i(t) = \dot{q}_i(t+\Delta_0)$, $\psi(t) = \dot{q}(t+\Delta_0)$, $h_i = \Delta_i - \Delta_0$. The conclusion of Lemma 4.8 again implies that (6.9) holds. □

End of proof. Recall the lower bound in Lemma 4.3 (b). Let us set

$$\mu_i := \tilde{E}(\Delta_i, x_i, w_i(b), q_i).$$

We have shown that there exists $x(\cdot) \in \tilde{\Sigma}(\Delta_0)$ (see Lemma 6.2) and $(w,p,q) \in \tilde{M}(x, P(\Delta_0))$ (Lemma 6.3) such that $\mu_i \to \mu$ (Lemma 6.4), where

$$\mu := \tilde{E}(\Delta_0, x, w(b), q).$$

Now the sequence $\{(\Delta_i, \alpha_i)\}_{i=1}^\infty$ was chosen arbitrarily among those in which the lim inf is taken in Lemma 4.3 (b). Hence we conclude from Lemma 4.3 (b) that

$$\liminf_{h\to 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} \geq \inf_{x \in \tilde{\Sigma}(\Delta_0)} \; \inf_{(w,p,q) \in \tilde{M}(x, P(\Delta_0))} \tilde{E}(\Delta_0, x, w(b), q).$$

This was the assertion of the theorem. □

Remark. Assumptions (H9) and (H10) are stronger than what was required in the proof. The same conclusion of Theorem 6.1 can be drawn if we assume in place of (H9) that for fixed $\Delta_0 \in [0, \overline{\Delta})$, $(\partial/\partial y)H(t, \Delta_0, x, y, p)$ exists and is the only element in the set limit of $\partial_y H(t, \Delta_i, x_i, y_i, p_i)$ as $(\Delta_i, x_i, y_i, p_i) \to (\Delta_0, x, y, p)$. This must hold for almost all $t \in [a, b]$, and for $(x, y, p) \in \mathbb{R}^{3n}$. We can make a similar replacement for (H10).

In many situations, it may be known that the multiplier set associated with an optimal trajectory consists of only one element. This is true in two examples considered in §8. We give this property a precise statement. Consider the following.

(H11) Fix $\Delta_0 \in [0, \overline{\Delta})$. For each $x \in \tilde{\Sigma}(\Delta_0)$, $\tilde{M}(x, P(\Delta_0))$ contains only one element.

An immediate corollary to Theorems 3.1 and 6.1 is the following.

COROLLARY 6.5. *Let* $\Delta_0 \in [0, \overline{\Delta})$ *and suppose* (H1′), (H2)–(H7), (H11), *and either* (H9) *or* (H10) *holds. Then we have the following:*

(a) *The right derivative of* V *at* Δ_0 *exists, and*

$$\lim_{h \searrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} = \inf_{x \in \tilde{\Sigma}(\Delta_0)} \tilde{E}(\Delta_0, x, w(b), q),$$

where $\tilde{M}(x, P(\Delta_0)) = \{(w, p, q)\}$;

(b) *If* $\Delta_0 > 0$, *then the left derivative of* V *at* Δ_0 *exists, and*

$$\lim_{h \nearrow 0} \frac{V(\Delta_0 + h) - V(\Delta_0)}{h} = \sup_{x \in \tilde{\Sigma}(\Delta_0)} \tilde{E}(\Delta_0, x, w(b), q),$$

where $\tilde{M}(x, P(\Delta_0)) = \{(w, p, q)\}$;

(c) *In addition, suppose* $\tilde{\Sigma}(\Delta_0)$ *consists of a single element* x. *Let* $\{(w, p, q)\} = \tilde{M}(x, P(\Delta_0))$. *Then if* $\Delta_0 > 0$, *the derivative of* V *at* Δ_0 *exists and equals* $\tilde{E}(\Delta, x, w(b), q)$.

Remark. If (H11) is satisfied and $v \in \Sigma(\Delta_0)$, then $M(v, P(\Delta_0))$ also consists of only one element, say $M(v, P(\Delta_0)) = \{(p, q)\}$. Let $w(\cdot)$ be defined as in (6.2). We have that $\tilde{M}(x^{v, \Delta_0}, P(\Delta_0)) = \{(w, p, q)\}$. Note then that the conclusion of Corollary 6.5 is identical with that of Theorem 5.1 (c), (d), since in this case the values of E and $\tilde{E}$ coincide.

7. Endpoint constraints.

The previous theory is developed in this section to incorporate an endpoint constraint. The basic data is augmented by a closed, nonempty subset C of $\mathbb{R}^n$. It is convenient at this point to not allow ℓ to depend explicitly on Δ. In a concluding remark, it is noted under what assumptions Δ-dependence can be treated.

The basic problem we now consider is

$$\min J(\Delta, x, u) \quad \text{over} \quad x(\cdot) \in AC[a,b], \quad u(\cdot) \in \mathscr{M}[a,b],$$

satisfying

$$\begin{aligned} &\dot{x}(t) = \phi(t, \Delta, x(t), x(t-\Delta), u(t)) \quad \text{a.e. } t \in [a,b], \\ &u(t) \in U(t) \quad \text{a.e. } t \in [a,b], \\ &x(t) = c(t) \quad \text{for} \quad t \in [a-\Delta, a], \\ &x(b) \in C. \end{aligned} \tag{7.1}$$

The notation of this section will closely resemble that which was previously used. Problem (7.1) is denoted by $P_C(\Delta)$. The set of optimal solutions, the set of associated optimal trajectories, and the optimal value of $P_C(\Delta)$ are written as $\Sigma_C(\Delta)$, $\tilde{\Sigma}_C(\Delta)$, and $V_C(\Delta)$, respectively. Perturbations of the dynamics no longer require notation, but rather endpoint perturbations play a significant role. For $\xi \in \mathbb{R}^n$, $P_{C+\xi}(\Delta)$ (respectively, $P_{\{\xi\}}(\Delta)$) denotes problem (7.1) with C replaced by $C+\xi$ (respectively, $\{\xi\}$). Similar definitions are made for $\Sigma_{C+\xi}(\Delta)$, $\tilde{\Sigma}_{C+\xi}(\Delta)$, and $V_{C+\xi}(\Delta)$. If no feasible solution exists for $P_C(\Delta)$, then the convention $V_C(\Delta) = +\infty$ is adopted. If $V_C(\Delta) < +\infty$, then standard compactness arguments show that $\Sigma_C(\Delta) \neq \emptyset$.

Significant alterations occur in defining the multipliers. Recall that the distance function to a closed set $D \subseteq \mathbb{R}^n$ is defined by

$$d_D(\xi) = \inf\{|\xi - \xi'| : \xi' \in D\},$$

and is globally Lipschitz of order 1. For $\xi \in D$, the prenormal cone $\hat{N}_D(\xi)$ of D at ξ is given by

$$\hat{N}_D(\xi) := \text{cl} \bigcup_{k>0} k\, \hat{\partial} d_D(\xi).$$

Hamiltonians for $P_C(\Delta)$ are indexed by a nonnegative real parameter. For $\lambda \geq 0$, $H^\lambda : [a,b] \times [0, \overline{\Delta}) \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \longrightarrow \mathbb{R}^1$ is defined as

$$H^\lambda(t, \Delta, x, y, p) := \sup\left\{\langle p, \phi(t, \Delta, x, y, u)\rangle - \lambda L(t, \Delta, x, y, u) : u \in U(t)\right\}.$$

Suppose that $u(\cdot) \in \Sigma_C(\Delta)$ and $x(\cdot) = x^{u,\Delta}(\cdot) \in \tilde{\Sigma}_C(\Delta)$. The multiplier sets $M^\lambda(u, P_C(\Delta))$ and $\tilde{M}^\lambda(x, P_C(\Delta))$ of index $\lambda \geq 0$ associated with u and x are defined by

$$\begin{aligned} M^\lambda(u, P_C(\Delta)) := \Bigg\{ &(p,q) \in AC_{2n}[a,b] : \\ &-p(b) \in \lambda\, \hat{\partial}\ell(x(b)) + \hat{N}_C(x(b)), \quad q(b) = 0, \\ &-\dot{p}(t) = \phi_1^*(t, \Delta, x(t), x(t-\Delta), u(t))(p(t) + q(t+\Delta)) \end{aligned}$$

$$- \lambda L_1^*(t,\Delta,x(t),x(t-\Delta),u(t)) \quad \text{a.e. } t \in [a,b],$$

$$\begin{aligned} -\dot{q}(t) = \phi_2^*(t,\Delta,x(t),x(t-\Delta),u(t))(p(t)+q(t+\Delta)) \\ - \lambda L_2^*(t,\Delta,x(t),x(t-\Delta),u(t)) \quad \text{a.e. } t \in [a,b], \end{aligned}$$

$$\left.\begin{aligned} &\max \left\{\langle p(t)+q(t+\Delta), \phi(t,\Delta,x(t),x(t-\Delta),u)\rangle - \lambda L(t,\Delta,x(t),x(t-\Delta),u)\right\} \\ &\qquad \text{over } u \in U(t) \text{ occurs at } u = u(t) \quad \text{a.e. } t \in [a,b] \end{aligned}\right\},$$

$$\begin{aligned} \tilde{M}^\lambda(x, P_C(\Delta)) := \Big\{ &(w,p,q) \in AC_{2n+1}[a,b] : \\ &w(a) = 0, \quad -p(b) \in \lambda\,\hat{\partial}\ell(x(b)) + \hat{N}_C(x(b)), \quad q(b) = 0 \\ &(-\dot{w}(t), -\dot{p}(t), -\dot{q}(t), \dot{x}(t)) \in \partial H^\lambda(t,\Delta,x(t),x(t-\Delta),p(t)+q(t+\Delta)) \\ &\qquad \text{a.e. } t \in [a,b] \Big\}. \end{aligned}$$

In the latter definition, the subgradient ∂H^λ is taken with respect to the (Δ, x, y, p) variables.

Suppose that $x(\cdot) \in \tilde{\Sigma}_C(\Delta)$. It is always the case that $p \equiv 0$ (which implies $q \equiv 0$) is a component of an element of $\tilde{M}^0(x, P_C(\Delta))$. The trajectory $x(\cdot)$ is called normal if $\tilde{M}^0(x, P_C(\Delta))$ contains only elements in which the $p(\cdot)$ trajectory is identically equal to zero. The problem $P_C(\Delta)$ is called normal if each $x(\cdot) \in \tilde{\Sigma}_C(\Delta)$ is normal.

Note that since we are assuming ℓ is independent of Δ, assumption (H1$'$) of §5 reduces to

(H1$''$) $\ell : \mathbb{R}^n \to \mathbb{R}^1$ is local Lipschitz.

The main theorem of this section follows.

THEOREM 7.1. *Suppose* (H1$''$), (H2)–(H7) *hold, and let* $\Delta_0 \in [0, \overline{\Delta})$. *Assume that* $V_C(\Delta_0)$ *is finite and* $P_C(\Delta_0)$ *is normal. Then*

(a)

$$\limsup_{h \searrow 0} \frac{V_C(\Delta_0 + h) - V_C(\Delta_0)}{h} \le \inf_{v(\cdot) \in \Sigma_C(\Delta_0)} \; \sup_{(p,q) \in M^1(v, P_C(\Delta_0))} E(\Delta_0, x^{v,\Delta_0}, v, (p,q)),$$

and if $\Delta_0 > 0$, *then*

$$\liminf_{h \nearrow 0} \frac{V_C(\Delta_0 + h) - V_C(\Delta_0)}{h} \ge \sup_{v \in \Sigma_C(\Delta_0)} \; \inf_{(p,q) \in M^1(v, P_C(\Delta_0))} E(\Delta_0, x^{v,\Delta_0}, v, (p,q));$$

(b) *In addition to the basic hypotheses, assume that* (H8) *holds at* Δ_0 *with* Σ *replaced by* Σ_C. *Then*

$$\liminf_{h \searrow 0} \frac{V_C(\Delta_0 + h) - V_C(\Delta_0)}{h} \ge \inf_{v(\cdot) \in \Sigma_C(\Delta_0)} \; \inf_{(p,q) \in M^1(v, P_C(\Delta_0))} E(\Delta_0, x^{v,\Delta_0}, v, (p,q)),$$

and if $\Delta_0 > 0$, *then*

$$\limsup_{h \nearrow 0} \frac{V_C(\Delta_0 + h) - V_C(\Delta_0)}{h} \le \sup_{v(\cdot) \in \Sigma_C(\Delta_0)} \; \sup_{(p,q) \in M^1(v, P_C(\Delta_0))} E(\Delta_0, x^{v,\Delta_0}, v, (p,q));$$

(c) *In addition to the basic hypotheses of* (a), *assume that* (H9) *or* (H10) *holds. Then*

$$\liminf_{h\searrow 0} \frac{V_C(\Delta_0+h)-V_C(\Delta_0)}{h} \geq \inf_{x\in\tilde{\Sigma}_C(\Delta_0)} \inf_{(w,p,q)\in\tilde{M}^1(x,P_C(\Delta_0))} \tilde{E}(\Delta_0,x,w(b),q),$$

and if $\Delta_0 > 0$, *then*

$$\limsup_{h\nearrow 0} \frac{V_C(\Delta_0+h)-V_C(\Delta_0)}{h} \leq \sup_{x\in\tilde{\Sigma}_C(\Delta_0)} \sup_{(w,p,q)\in\tilde{M}^1(x,P_C(\Delta_0))} \tilde{E}(\Delta_0,x,w(b),q).$$

Proof. The basic idea is to replace $P_C(\Delta)$ by a free endpoint problem that satisfies the hypotheses of §5, and that has the same set of optimal solutions. The multipliers will also be related, and this will allow the conclusions of the theorem to be read off from the assertions of Theorems 5.1 and 6.1. We will only give the details for the right-hand limits and $0 < \Delta_0 < \overline{\Delta}$, the left-hand limits and the case $\Delta_0 = 0$ being similar.

It is convenient, then, to introduce further notation for the "penalized" problems. For $k > 0$, let $P_C^k(\Delta)$ denote the problem

$$\min \ell(x(b)) + kd_C(x(b)) + \int_a^b L(t,\Delta,x(t),x(t-\Delta),u(t))\,\mathrm{d}t$$

$$\text{over } u(\cdot)\in\mathscr{M}[a,b] \text{ satisfying } u(t)\in U(t) \quad \text{a.e. } t\in[a,b],$$

$$\text{where } x(\cdot)=x^{u,\Delta}(\cdot).$$

The rest of the notation is carried over to this context by adding a superscript k. That is, we have $\Sigma_C^k(\Delta), V_C^k(\Delta), P_{C+\xi}^k(\Delta)$, etc.

Step 1. As the first step, we use the normality hypothesis at Δ_0 to show that $P_{C+\xi}(\Delta)$ inherits feasibility and normality for all (Δ,ξ) near $(\Delta_0, 0)$. We begin with a controllability result of considerable independent interest.

PROPOSITION 7.2. *There exists* $\delta > 0$ *and* $0 \leq \Delta_1 < \Delta_0 < \Delta_2 < \overline{\Delta}$ *so that* $V_{C+\xi}(\Delta)$ *is finite for each* $|\xi| \leq \delta$ *and* $\Delta \in [\Delta_1, \Delta_2]$.

Proof. We argue by contradiction. Suppose that there exist sequences $\{\Delta_i\} \subseteq [0,\overline{\Delta})$, $\{\xi_i\} \subseteq \mathbb{R}^n$ so that $\Delta_i \to \Delta_0$, $\xi_i \to 0$ as $i \to \infty$, and $V_{C+\xi_i}(\Delta_i) = +\infty$ for all i. Define the reachable set $R(\Delta)$ by

$$R(\Delta) := \{x(b) : x(\cdot) = x^{u,\Delta}(\cdot), \quad u(\cdot) \text{ admissible}\}.$$

The assumptions $V_C(\Delta_0) < \infty$ and $V_{C+\xi_i}(\Delta_i) = +\infty$ are then equivalent to $R(\Delta_0) \cap C \neq \emptyset$ and $R(\Delta_i) \cap (C+\xi_i) = \emptyset$. Let $u_0(\cdot) \in \Sigma_C(\Delta_0)$, and so $x^{u_0,\Delta_0}(b) \in R(\Delta_0) \cap C$. As shown in §8A, the map $\Delta \to x^{u_0,\Delta}(b)$ is continuous at Δ_0, and therefore $d_{C+\xi_i}(x^{u_0,\Delta_i}(b)) \longrightarrow 0$ as $i \to \infty$. Let $\{k_i\}$ be a sequence such that $k_i \nearrow +\infty$ and $k_i d_{C+\xi_i}(x^{u_0,\Delta_i}(b)) \longrightarrow 0$.

Now let $u_i(\cdot) \in \sum_{C+\xi_i}^{k_i}(\Delta_i)$ and $x_i(\cdot) = x^{u_i,\Delta_i}(\cdot)$. We claim that $d_C(x_i(b)) \longrightarrow 0$ as $i \to \infty$. Indeed, if not, since (H5) and (H6) imply $J(\Delta,x,u)$ is bounded over all $\Delta \in [0,\overline{\Delta})$, admissible $u(\cdot)$, and $x(\cdot) = x^{u,\Delta}(\cdot)$, it would follow that $\limsup_{i\to\infty} V_{C+\xi_i}^{k_i}(\Delta_i) = +\infty$. On the other hand,

$$\begin{aligned}\limsup_{i\to\infty} V_{C+\xi_i}^{k_i}(\Delta_i) &\leq \limsup_{i\to\infty}\{J(\Delta_i,x^{u_0,\Delta_i}(\cdot),u_0) + k_i d_{C+\xi_i}(x^{u_0,\Delta_i}(b))\} \\ &= J(\Delta_0,x^{u_0,\Delta_0},u_0) = V_C(\Delta_0).\end{aligned} \tag{7.2}$$

This is a contradiction, which verifies the claim. We pass to a subsequence if necessary so that $x_i(b) \to \pi$ for some $\pi \in C$. Furthermore, we may assume that $x_i(\cdot)$ converges uniformly to some $x(\cdot)$, and $\dot{x}_i(\cdot)$ converges weakly in $L^2[a,b]$ to $\dot{x}(\cdot)$. We next claim that $x(\cdot) \in \tilde{\Sigma}_C(\Delta_0)$. To see this we can show, as in the proof of Lemma 6.2, that there exists admissible $v(\cdot)$ with $x(\cdot) = x^{v,\Delta_0}(\cdot)$, and such that

$$J(\Delta_0, x, v) \leq \liminf_{i\to\infty} J(\Delta_i, x_i, u_i).$$

Now $u_i \in \Sigma^{k_i}_{C+\xi_i}(\Delta_i)$, and so we conclude from (7.2) that

$$\limsup_{i\to\infty} J(\Delta_i, x_i, u_i) \leq \limsup_{i\to\infty} V^{k_i}_{C+\xi_i}(\Delta_i) \leq V_C(\Delta_0).$$

Hence $J(\Delta_0, x, v) \leq V_C(\Delta_0)$, and since $x(b) \in C$, it follows that $x(\cdot) \in \tilde{\Sigma}_C(\Delta_0)$, and the claim is proven. We will arrive at a contradiction by showing that $x(\cdot)$ is not normal.

Let $\pi_i \in C$ be chosen so that $d_{C+\xi_i}(x_i(b)) = |x_i(b) - \xi_i - \pi_i|$. Since $x_i(\cdot) \in \tilde{\Sigma}^{k_i}_{C+\xi_i}(\Delta_i)$, it follows readily that $x_i(\cdot)$ is also an optimal trajectory for the problem $P^{k_i}_{\{\xi_i+\pi_i\}}(\Delta_i)$. The necessary conditions guarantee the existence of arcs (w_i, p_i, q_i) contained in $\tilde{M}\left(x_i, P^{k_i}_{\{\xi_i+\pi_i\}}(\Delta_i)\right)$, which means that

$$(7.3) \qquad w_i(a) = 0, \quad -p_i(b) \in \hat{\partial}\ell(x_i(b)) + k_i\hat{\partial}d_{\{\xi_i+\pi_i\}}(x_i(b)), \quad q_i(b) = 0$$

and

$$(7.4) \quad (-\dot{w}_i(t), -\dot{p}_i(t), -\dot{q}_i(t), \dot{x}_i(t)) \in \partial H^1(t, \Delta_i, x_i(t), x_i(t-\Delta_i), p_i(t) + q_i(t+\Delta_i)) \quad \text{a.e. } t \in [a,b].$$

Since $x_i(b) - \xi_i \neq \pi_i$ for all i, $\zeta_i := (x_i(b) - \xi_i - \pi_i/|x_i(b) - \xi_i - \pi_i|)$ satisfies $|\zeta_i| = 1$ and $\{\zeta_i\} = \hat{\partial}d_{\{\xi_i+\pi_i\}}(x_i(b))$. Now elements of $\hat{\partial}\ell(x_i(b))$ are contained in a bounded set independent of i, and since $k_i \to \infty$, it follows from (7.3) that $|p_i(b)| \to +\infty$. Set $\lambda_i = |p_i(b)|^{-1}$ and define $(\overline{w}_i(t), \overline{p}_i(t), \overline{q}_i(t)) = \lambda_i(w_i(t), p_i(t), q_i(t))$. We have

$$(7.5) \qquad \overline{w}_i(a) = 0, \quad -\overline{p}_i(b) \in \lambda_i\hat{\partial}\ell(x_i(b)) + k_i\lambda_i\zeta_i, \quad \overline{q}_i(b) = 0.$$

Also by [C1, Prop. 3.2.4 (e)] and (7.4), we have

$$(7.6) \quad (-\dot{\overline{w}}_i(t), -\dot{\overline{p}}_i(t), -\dot{\overline{q}}_i(t), \dot{x}_i(t)) \in \partial H^{\lambda_i}(t, \Delta_i, x_i(t), x_i(t-\Delta_i), \overline{p}_i(t) + \overline{q}_i(t+\Delta_i)) \quad \text{a.e. } t \in [a,b].$$

Again we pass to a subsequence of $(\overline{w}_i, \overline{p}_i, \overline{q}_i)$, and obtain (w,p,q) so that $(\dot{\overline{w}}_i, \dot{\overline{p}}_i, \dot{\overline{q}}_i) \to (\dot{w}, \dot{p}, \dot{q})$ weakly in $L^1_{2n+1}[a,b]$ and $(\overline{w}_i, \overline{p}_i, \overline{q}_i) \to (w,p,q)$ uniformly on $[a,b]$. Obviously, $|p(b)| = 1$, and $-p(b) = \lim_{i\to\infty} \zeta_i$. Now $\zeta_i \in \hat{\partial}d_C(\pi_i)$ and $\pi_i \to \pi = x(b)$, hence $-p(b) \in \hat{\partial}d_C(x(b))$ by (H1$''$). Also (7.5) has $w(a) = 0$ and $q(b) = 0$. Furthermore, as we have used many times previously, (7.6) is preserved in the limit. That is,

$$(7.7) \quad (-\dot{w}(t), -\dot{p}(t), -\dot{q}(t), \dot{x}(t)) \in \partial H^0(t, \Delta_0, x(t), x(t-\Delta_0), p(t) + q(t+\Delta_0)) \quad \text{a.e. } t \in [a,b].$$

We conclude that $(w,p,q) \in \tilde{M}^0(x, P_C(\Delta_0))$ with $p \neq 0$, and this contradicts the normality of $x(\cdot)$. □

LEMMA 7.3. *There exists $\delta > 0$ and $0 \leq \Delta_1 < \Delta_0 < \Delta_2 < \overline{\Delta}$ so that $P_{C+\xi}(\Delta)$ is normal for each $|\xi| < \delta$ and $\Delta \in [\Delta_1, \Delta_2]$.*

Proof. For the proof, assume otherwise. There exist sequences $\{\Delta_i\}$, $\{\xi_i\}$ (with $\Delta_i \to \Delta_0, \xi_i \to 0$ as $i \to \infty$) such that for each i, there exist nonnormal arcs $x_i(\cdot) \in \tilde{\Sigma}_{C+\xi_i}(\Delta_i)$ and $(w_i, p_i, q_i) \in \tilde{M}^0(x_i, P_{C+\xi_i}(\Delta_i))$ with $p_i \not\equiv 0$. We may assume $|p_i(b)| = 1$. Once again, without relabeling, we pass to the convergence of subsequences, and obtain (w,p,q,x) for which $(\dot{w}_i, \dot{p}_i, \dot{q}_i, \dot{x}_i) \to (\dot{w}, \dot{p}, \dot{q}, \dot{x})$ weakly in $L^1_{3n+1}[a,b]$ and $(w_i, p_i, q_i, x_i) \to (w,p,q,x)$ uniformly on $[a,b]$. Previous arguments show that $x(\cdot) \in \tilde{\Sigma}_C(\Delta_0)$ and (w,p,q,x) satisfies the Hamiltonian inclusion (7.7). To obtain the contradiction $(w,p,q) \in \tilde{M}^0(x, P_C(\Delta_0))$, $p \neq 0$, it is only left to show that $-p(b) \in \hat{N}_C(x(b))$.

Since $-p_i(b) \in \operatorname{cl} \bigcup_{k>0} k\, \hat{\partial} d_{C+\xi_i}(x_i(b))$, there exists $k_i > 0$ and $\zeta_i \in \hat{\partial} d_{C+\xi_i}(x_i(b))$ so that $|-p_i(b) - k_i\zeta_i| \longrightarrow 0$ as $i \to \infty$. Without loss of generality, we may take $|\zeta_i| = 1$ for all i, which implies $k_i \to 1$. Note that $\hat{\partial} d_{C+\xi_i}(x_i(b)) = \hat{\partial} d_C(x_i(b) - \xi_i)$ and $x_i(b) - \xi_i \longrightarrow x(b)$. Therefore, the upper semicontinuity of $\hat{\partial} d_C$ gives that $-p(b) = \lim_{i\to\infty} \zeta_i \in \hat{\partial} d_C(x(b))$. This finishes the proof that $x(\cdot)$ is not normal, a contradiction at which the proof of Lemma 7.3 is complete. □

Henceforth, we fix $\delta > 0$ and $0 \leq \Delta_1 < \Delta_0 < \Delta_2 < \overline{\Delta}$ so that Proposition 7.2 and Lemma 7.3 are valid.

Step 2. In this step, we will obtain bounds on a Lipschitz constant that will be uniform in Δ. It is convenient to alter our notation *in this step only*, and write $V(\Delta, \xi)$ for $V_{C+\xi}(\Delta)$. We recall the following sensitivity estimate from [CW].

PROPOSITION 7.4 ([CW, Thm. 4]). *Suppose that $V(\Delta, \xi)$ is finite and $P_{C+\xi}(\Delta)$ is normal. Then $\xi' \longrightarrow V(\Delta, \xi')$ is Lipschitz near ξ with*

$$\partial_\xi V(\Delta, \xi) \subseteq \operatorname{cl}\ \operatorname{co} \Big\{ \zeta + p(b) : x(\cdot) \in \tilde{\Sigma}_{C+\xi}(\Delta), \zeta \in \hat{\partial}\ell(x(b)), \\ (w,p,q) \in \tilde{M}^1(x, P_{C+\xi}(\Delta)) \Big\}.$$

We next show that $\partial_\xi V(\Delta, \xi)$ is bounded independent of $\Delta \in [\Delta_1, \Delta_2]$ and $|\xi| \leq \delta$. Again, normality is the key ingredient.

LEMMA 7.5. *Define*

$$k_0 := \sup_{\substack{\Delta_1 \leq \Delta \leq \Delta_2 \\ |\xi| \leq \delta}} \{|z| : z \in \partial_\xi V(\Delta, \xi)\}.$$

Then $k_0 < +\infty$.

Proof. By Step 1 and Proposition 7.4, we have for each fixed $\Delta \in [\Delta_1, \Delta_2]$ and $|\xi| \leq \delta$ that $\sup\{|z| : z \in \partial_\xi V(\Delta, \xi)\} < \infty$. So if $k_0 = \infty$, then by Proposition 7.4 there exist $\Delta_i \in [\Delta_1, \Delta_2]$, $|\xi_i| \leq \delta$, $x_i(\cdot) \in \tilde{\Sigma}_{C+\xi_i}(\Delta_i)$, $\zeta_i \in \hat{\partial}\ell(x_i(b))$ and $(w_i, p_i, q_i) \in \tilde{M}^1(x_i, P_{C+\xi_i}(\Delta_i))$ such that $|\zeta_i + p_i(b)| \longrightarrow \infty$ as $i \to \infty$. It is immediate from (H5) that $\{x_i(b)\}$ is bounded, whence from (H1$''$) $\{\zeta_i\}$ is also bounded. It must therefore be the case that $\lambda_i := |p_i(b)|^{-1} \to 0$. The argument proceeds along now familiar lines: we may assume $\Delta_i \longrightarrow \Delta^* \in [\Delta_1, \Delta_2]$ and $\xi_i \to \xi^*$ with $|\xi^*| \leq \delta$. Set $(\overline{w}_i, \overline{p}_i, \overline{q}_i) = \lambda_i(w_i, p_i, q_i)$. Passing to an appropriate subsequence, we obtain (w,p,q,x) for which $(\dot{\overline{w}}_i, \dot{\overline{p}}_i, \dot{\overline{q}}_i, \dot{x}\cdot) \to (\dot{w}, \dot{p}, \dot{q}, \dot{x})$ weakly in $L^1_{3n+1}[a,b]$ and $(\overline{w}_i, \overline{p}_i, \overline{q}_i, x_i) \to (w,p,q,x)$ uniformly on $[a,b]$. We can argue as earlier (see the proof of Proposition 7.2) that $x(\cdot) \in \tilde{\Sigma}_{C+\xi^*}(\Delta^*)$ and $(w,p,q) \in \tilde{M}^0(x, P_{C+\xi^*}(\Delta^*))$ with $|p(b)| = 1$. This contradicts the normality of $P_{C+\xi^*}(\Delta^*)$ that was shown to hold in Lemma 7.3. □

Step 3. We are now ready to begin replacing $P_C(\Delta)$ by a free endpoint problem. The relevance of Steps 1 and 2 is that the penalization parameter can be chosen independently of $\Delta \in [\Delta_1, \Delta_2]$ and $|\xi| \leq \delta/2$.

LEMMA 7.6. *There exists $k_1 > 0$ so that for all $\Delta \in [\Delta_1, \Delta_2]$, $|\xi| \leq \delta/2$, and $u(\cdot) \in \Sigma^{k_1}_{C+\xi}(\Delta)$, we have $d_{C+\xi}(x^{u,\Delta}(b)) \leq \delta/2$.*

Proof. As noted earlier, (H5) and (H6) imply that there exists $\gamma > 0$ so that $|J(\Delta, x, u)| \leq \gamma$ for all $\Delta \in [0, \overline{\Delta})$, admissible $u(\cdot)$, and $x(\cdot) = x^{u,\Delta}(\cdot)$. Consequently, since $V_{C+\xi}(\Delta)$ is finite by Proposition 7.2, we have

$$\sup_{\substack{|\xi|\leq\delta/2 \\ \Delta\in[\Delta_1,\Delta_2]}} V_{C+\xi}(\Delta) \leq \gamma.$$

Let $k_1 > (4\gamma/\delta)$. Now suppose $|\xi| \leq \delta/2$, $\Delta \in [\Delta_1, \Delta_2]$, $u(\cdot) \in \Sigma^{k_1}_{C+\xi}(\Delta)$, and $x(\cdot) = x^{u,\Delta}(\cdot)$. If $d_{C+\xi}(x(b)) > \delta/2$, then

$$\begin{aligned} V^{k_1}_{C+\xi}(\Delta) &= J(\Delta, x, u) + k_1 d_{C+\xi}(x(b)) \\ &\geq -\gamma + k_1\,\delta/2 > \gamma \\ &\geq V_{C+\xi}(\Delta). \end{aligned} \tag{7.8}$$

For any $k > 0$, however, it is always the case that

$$V^{k}_{C+\xi}(\Delta) \leq V_{C+\xi}(\Delta). \tag{7.9}$$

Since (7.8) and (7.9) cannot both be valid, we conclude that $d_{C+\xi}(x(b)) \leq \delta/2$. □

LEMMA 7.7. *For $k > \max\{k_0, k_1\}$, we have $\Sigma^{k}_{C+\xi}(\Delta) = \Sigma_{C+\xi}(\Delta)$ for all $|\xi| \leq \delta/2$ and $\Delta \in [\Delta_1, \Delta_2]$.*

Proof. Fix $k > \max\{k_0, k_1\}$, $\Delta \in [\Delta_1, \Delta_2]$, and $|\xi| \leq \delta/2$. It suffices to show that if $u \in \Sigma^{k}_{C+\xi}(\Delta)$, then $x^{u,\Delta}(b) \in C + \xi$.

Let $u \in \Sigma^{k}_{C+\xi}(\Delta)$ and $x(\cdot) = x^{u,\Delta}(\cdot)$. We have

$$\begin{aligned} &V_{\{x(b)\}}(\Delta) + k\, d_{C+\xi}(x(b)) \\ &\quad\leq J(\Delta, x, u) + k\, d_{C+\xi}(x(b)) \\ &\quad= V^{k}_{C+\xi}(\Delta) \\ &\quad\leq V_{C+\xi}(\Delta) \qquad \text{(by (7.9))}. \end{aligned} \tag{7.10}$$

Let $\pi \in C + \xi$ such that $|\pi - x(b)| = d_{C+\xi}(x(b))$. By Lemma 7.6, we have $|\pi - x(b)| \leq \delta/2$. Also, a consequence of Lemma 7.5 is that $\xi' \to V_{C+\xi'}(\Delta)$ is Lipschitz of order k_0 on $|\xi'| \leq \delta$. Hence

$$\begin{aligned} V_{C+\xi}(\Delta) &\leq V_{C+\xi+x(b)-\pi}(\Delta) + k_0|x(b) - \pi| \\ &\leq V_{\{x(b)\}}(\Delta) + k_0 d_{C+\xi}(x(b)), \end{aligned} \tag{7.11}$$

the last inequality valid since $x(b) \in C + \xi + x(b) - \pi$. Combining (7.10) and (7.11) gives $k\, d_{C+\xi}(x(b)) \leq k_0 d_{C+\xi}(x(b))$, which can only be valid if $x(b) \in C + \xi$. □

Fix $k > 0$ so that Lemma 7.7 holds. The following corollary is immediate from Lemma 7.7 and the definitions.

COROLLARY 7.8. *For all $\Delta \in [\Delta_1, \Delta_2]$ and $|\xi| \leq \delta/2$, we have $V^{k}_{C+\xi}(\Delta) = V_{C+\xi}(\Delta)$ and $\tilde{\Sigma}^{k}_{C+\xi}(\Delta) = \tilde{\Sigma}_{C+\xi}(\Delta)$.*

Step 4. It remains only to compare multipliers and to apply previous results.

LEMMA 7.9. *Fix $\Delta \in [\Delta_1, \Delta_2]$ and $|\xi| < \delta/2$. Let $u(\cdot) \in \Sigma^k_{C+\xi}(\Delta)$ and $x(\cdot) = x^{u,\Delta}(\cdot)$. Then we have*

$$M(u, P^k_{C+\xi}(\Delta)) \subseteq M^1(u, P_{C+\xi}(\Delta)) \tag{7.12}$$

and

$$\tilde{M}(x, P^k_{C+\xi}(\Delta)) \subseteq \tilde{M}^1(x, P_{C+\xi}(\Delta)). \tag{7.13}$$

Proof. The only difference between the multipliers of the free endpoint problem $P^k_{C+\xi}(\Delta)$ and the constrained problem $P_{C+\xi}(\Delta)$ occurs in the transversality condition on $p(\cdot)$. The former has

$$-p(b) \in \hat{\partial}\ell(x(b)) + k\,\hat{\partial} d_{C+\xi}(x(b)).$$

However, since $\hat{\partial}\ell(x(b)) + k\,\hat{\partial} d_{C+\xi}(x(b)) \subseteq \hat{\partial}\ell(x(b)) + \hat{N}_{C+\xi}(x(b))$, it follows that the transversality condition defining $M^1(x, P_{C+\xi}(\Delta))$ is also satisfied. Hence (7.12) holds. The same reasoning shows that (7.13) is valid as well. □

End of proof. To verify the assertions of the theorem, we now need only to apply previous results to the problem $P^k_C(\Delta)$. Since the value functions and optimal solutions of $P^k_C(\Delta)$ and $P_C(\Delta)$ coincide for all Δ near Δ_0 (Lemma 7.7, Corollary 7.8), and the multiplier set of $P_C(\Delta_0)$ is larger than that of $P^k_C(\Delta_0)$ (Lemma 7.9), the bounds in Theorem 7.1(a) follow immediately from Theorem 5.1(a). Assumption (H8) on $P_C(\Delta_0)$ carries over to the same assumption on $P^k_C(\Delta_0)$ by Lemma 7.7, hence (b) follows from Theorem 5.1(b). Finally, (H9) and (H10) are only assumptions on the Hamiltonian and are not affected by the endpoint constraints. Thus (c) follows from Theorem 6.1. □

Remarks. (i) The proof of Theorem 7.1 shows that the multipliers for $P_C(\Delta)$ can be replaced by multiplier sets of the form (for k sufficiently large) :

$$M^\lambda_k(u, P_C(\Delta)) = \left\{ (p,q) : -p(b) \in \lambda\,\hat{\partial}\ell(x(b)) + k\,\hat{\partial} d_C(x(b)),\right.$$
$$q(b) = 0, \quad (p,q) \text{ satisfy the adjoint}$$
$$\left.\text{equations and the maximum condition}\right\}.$$

Similarly for $\tilde{M}^\lambda_k(x, P_C(\Delta))$. This gives potentially finer estimates.

(ii) The statement of Theorem 7.1 does not allow for ℓ to depend explicitly on Δ. The reason is that to apply Theorem 5.1, we must have the subgradient of the endpoint cost function with respect to the state variable to be upper semicontinuous. That is, $(\Delta,\xi) \rightrightarrows \hat{\partial}_\xi(\ell(\Delta,\xi) + d_C(\xi))$ must have a closed graph. This is not necessarily true if ℓ only satisfies (H1′). It is true, however, if ℓ satisfies (H1) (see [C1, p. 39]). Hence Theorem 7.1 could be given alternatively under (H1) rather than (H1″). In fact, (H1) could be weakened further to (H1′) plus "regularity" (see [C1]).

The relevant analogue of (H11) to endpoint constrained problems is that $M^1(x, P_C(\Delta_0))$ consists of a single element. We will encounter in §8C an example where this is so. The following corollary is the endpoint constrained version of Corollary 6.5.

COROLLARY 7.10. *Fix $\Delta_0 \in [0, \overline{\Delta})$. In addition to the basic hypotheses of Theorem 7.1, suppose that (H11) and either (H9) or (H10) hold. Then*

(a) $\lim_{h\searrow 0} \dfrac{V(\Delta_0+h)-V(\Delta_0)}{h} = \inf_{v\in\Sigma_C(\Delta_0)} E(\Delta_0, x^{v,\Delta_0}, v, (p,q)),$
where $M^1(v, P_C(\Delta_0)) = \{(p,q)\}$*;*

(b) *If* $\Delta_0 > 0$*, then*

$$\lim_{h\nearrow 0} \frac{V(\Delta_0+h)-V(\Delta_0)}{h} = \sup_{v\in\Sigma_C(\Delta_0)} E(\Delta_0, x^{v,\Delta_0}, v, (p,q)),$$

where $M^1(v, P_C(\Delta_0)) = \{(p,q)\}$*;*

(c) *Suppose, in addition, that* $\Sigma_C(\Delta_0)$ *consists of a single element* v*. Let* $M^1(v, P(\Delta_0)) = \{(p,q)\}$*. Then if* $\Delta_0 > 0$*, the derivative of* V *at* Δ_0 *exists and equals* $E(\Delta_0, x^{v,\Delta_0}, v, (p,q))$*.*

Proof. Note that (H11) implies that for $v \in \Sigma_C(\Delta_0), M^1(v, P_C(\Delta_0))$ also consists of a single element, and is the (p,q) coordinate of $\tilde{M}^1(x^{v,\Delta_0}, P_C(\Delta_0))$. (See the remark at the end of §6.) Moreover, in this case, the E and $\tilde{E}$ functionals give the same value, hence the corollary is an immediate consequence of Theorem 7.1(a) and (c). □

8. Three examples.

A. Endpoint dependence of a differential-difference equation. Consider the (uncontrolled) differential-difference equation

$$\text{(8.1)}\qquad \begin{aligned} \dot{x}(t) &= \phi(t, x(t), x(t-\Delta)) \text{ a.e. } t \in [a,b], \\ x(t) &= c(t) \text{ for } t \in [a-\Delta, a]. \end{aligned}$$

Assume that ϕ satisfies (H1)–(H6), except that now it is independent of $u \in \mathbb{R}^m$ and $\Delta \in [0, \bar{\Delta})$. The existence theory for (8.1) proclaims that a unique solution $x^\Delta(\cdot)$ exists, but as mentioned in the Introduction, little seems to be known concerning the dependence of $x^\Delta(\cdot)$ on the delay Δ. We show as an application of the results of §3 that $\Delta \to x^\Delta(b)$ is differentiable on $(0, \bar{\Delta})$, and present the precise formula for its right derivative at $\Delta = 0$. This result appears to be new.

PROPOSITION 8.1. *Define* $f : [0, \overline{\Delta}) \to \mathbb{R}^n$ *by* $f(\Delta) = x^\Delta(b)$*. Then for each* $\Delta \in (0, \overline{\Delta})$*,* $d/d\Delta f(\Delta)$ *exists. Moreover, the right derivative at* 0 *is given by*

$$\text{(8.2)}\qquad \frac{d^+}{d\Delta} f(0) = \int_a^b \phi_2(t, x^0(t), x^0(t))^*(Q(t))\dot{x}^0(t)\,dt,$$

where $Q(\cdot)$ *is the solution of the* $n \times n$ *matrix differential equation*

$$-\dot{Q}(t) = (\phi_1^*(t, x^0(t), x^0(t)) + \phi_2^*(t, x^0(t), x^0(t)))Q(t) \quad \text{a.e. } t \in [a,b],$$

$$-Q(b) = I \quad (= \text{identity matrix}).$$

Proof. Fix $j \in \{1, 2, \cdots, n\}$. Write $f^{(j)}(\Delta)$ for the jth component of $f(\Delta)$. We show $f^{(j)}(\Delta)$ is differentiable at each $\Delta \in (0, \Delta_0)$.

In the problem formulation $P(\Delta)$, define $\ell : [0, \overline{\Delta}) \times \mathbb{R}^n \longrightarrow \mathbb{R}^1$ by $\ell(\Delta, \xi) = \xi^{(j)}$, where $\xi^{(j)}$ denotes the jth component of ξ, and set $L \equiv 0$. Then $V(\Delta) = f^{(j)}(\Delta)$, and it is immediate from Corollary 3.3 that $V(\Delta)$ is differentiable for $\Delta \in (0, \overline{\Delta})$. (Equation (H8) is satisfied trivially.) Hence f is differentiable at each $\Delta \in (0, \overline{\Delta})$.

Of course, the above argument is also applicable when $\Delta = 0$. Now if (p,q) is the multiplier for $P(0)$ with this data, then $-p(b) = e_j$ (= the column vector with 1 in the jth coordinate and zeros elsewhere) and $q(b) = 0$, and $-(\dot{p}(t) + \dot{q}(t)) =$

$(\phi_1(t,x(t),x(t))+ \phi_2^*(t,x(t),x(t)))\,(p(t)+q(t))$ almost everywhere $t \in [a,b]$. Therefore $p(t)+q(t)$ is the jth column of $Q(t)$. Now by Theorem 3.2(a),

$$\frac{d^+}{d\Delta}V(0) = \int_a^b \langle -\dot q(t), \dot x^0(t)\rangle \,\mathrm{dt}.$$

Also, we have $-\dot q(t) = \phi_2^*(t,x^0(t),x^0(t))(p(t)+q(t))$. Hence $\lim_{\Delta\downarrow 0}(f^{(j)}(\Delta) - f^{(j)}(0)/\Delta)$ exists and equals the jth column of (8.2). This is true for each j, so the proof is complete. □

B. The linear problem of Mayer. We now study the case in which $\phi(t,\Delta,x,y,u)$ has the form $Ax+By+Cu$, where A and B are given $n\times n$ matrices and C a given $n\times m$ matrix. We suppose, in addition, that L is identically zero, U is a compact convex subset of $\mathbb{R}^m$, and ℓ satisfies (H1). Consider the (free endpoint) problem $P(\Delta_0)$ of §6. It is easy to confirm that (H1)–(H7) are satisfied, as well as (H11) (in the present setting, there is a one-to-one correspondence between Hamiltonian multipliers and Pontryagin multipliers).

The Hamiltonian H is given by

$$\begin{aligned} H(t,\Delta,x,y,p) &= \max_{u\in U}\langle p, Ax+By+Cu\rangle \\ &= \langle p, Ax+By\rangle + \max_{u\in U}\langle p, Cu\rangle. \end{aligned}$$

It is clear from this expression that (H9) is satisfied. With the preceding, we can derive from Corollary 6.5 a rather explicit formula for $(d^+/d\Delta)V(0)$.

PROPOSITION 8.2. *V is differentiable on $(0,\overline{\Delta})$. Moreover, the right derivative $(d^+/d\Delta)V(0)$ is given by*

$$\frac{d^+}{d\Delta}V(0) = \inf_{v\in\Sigma(0)} \frac{\partial}{\partial\Delta}\ell(\Delta,x(b)) + \int_a^b \langle -\dot q(t), \dot x(t)\rangle\,\mathrm{dt},$$

where

$$x(t) = e^{(A+B)(t-a)}c(a) + \int_a^t e^{(A+B)(t-s)}Cv(s)\,\mathrm{ds}$$

and

$$q(t) = B^* e^{(A^*+B^*)(b-t)}(-\nabla_x \ell(0,x(b))).$$

If $AB=BA$, the formula for $(d^+/d\Delta)V(0)$ further simplifies to

$$\inf_{v\in\Sigma(0)} \frac{\partial}{\partial\Delta}\ell(0,x(b)) + \langle \zeta, D(a)c(a) + \int_a^b D(s)Cv(s)\,\mathrm{ds}\rangle,$$

where $x(\cdot)$ is as above, $\zeta = -\nabla_x\ell(0,x(b))$, and D is the map from $[a,b]$ into the $n\times n$ matrices given by

$$D(s) = (b-s)e^{(A+B)(b-s)}B.$$

C. An example in renewable resource modeling. Our final example treats a more specific problem involving one of the better-known models in resource theory [C]. It involves a population biomass $x(t)$ evolving according to the dynamic equation

$$\dot x(t) = g(x(t)) - u(t)x(t), \qquad x(0) = x_0, \tag{8.3}$$

where g, the natural growth function, is C^1 and concave, x_0 is given, and the last term on the right in the dynamics reflects the effect on the population of applying a harvesting effort u (assumed to be constrained to a given interval $[0, u_{\max}]$). The discounted net revenue resulting from a choice of effort profile $u(t)$ is given by

$$\int_0^T e^{-\delta t}\{\pi x(t) - c\}u(t)dt, \tag{8.4}$$

where T is the planning horizon, δ the discount rate, π the resource price, and c the effort cost. We will impose the constraint $x(T) = x_T$ (given). The issue is to identify the control $u(\cdot)$ that maximizes revenue, subject to the constraints.

The nondelay problem described above is well understood. Under standard assumptions that we omit, the unique solution is of "turnpike" type; we briefly describe it now. A certain target population level x^* is identified by an algebraic equation involving all the data except the endpoint values. The optimal solution employs either no harvesting effort ($u = 0$) or maximal effort ($u = u_{\max}$) to guide $x(t)$ to x^* at the start (depending on whether x_0 is less than or greater than x^*). In the intermediate (singular or turnpike) stage, precisely the effort required to stay at x^* is applied. At the end, to honour the endpoint constraint, there is an interval in which u is constant: either 0 (if $x_T > x^*$) or $u_{\max}$ (if $x_T < x^*$). The two switching times will be denoted τ_1 and τ_2.

Determining x^*, τ_1, and τ_2 precisely is done by means of the (nondelay) maximum principle. The adjoint variable $r(t)$ is unique and positive throughout, and satisfies the adjoint equation

$$-\dot{r}(t) = [g'(x(t)) - u(t)]r(t) + e^{-\delta t}\pi u(t),$$

and the condition

$$u(t) \text{ maximizes } u \rightarrow \{e^{-\delta t}(\pi x(t) - c) - r(t)x(t)\}u \text{ over } u \in [0, u_{\max}].$$

Suppose now that we wish to consider the possible effect of a small delay in the natural growth law, a biologically realistic possibility. Then (8.3) might become, for example,

$$\dot{x}(t) = g(x(t - \Delta)) - u(t)x(t), \tag{8.5}$$

with $x(t)$ specified on $[-\Delta, 0]$.

The resulting time delay optimal control problem is no longer amenable to analytical solution; in fact, the solution is not known. We will apply the results of §7 to calculate the marginal effect of a small delay. (Hypotheses (H1)–(H7) are all satisfied under the usual assumptions.)

The Hamiltonian $\mathscr{H}$ for the new problem (8.5) is given by

$$\mathscr{H}(t, \Delta, x, y, u, p) = pg(y) - pux + e^{-\delta t}\{\pi x - c\}u,$$

so that (H9) holds. Now any element (w, p, q) of $\tilde{M}^1(x, P_C(0))$ is such that $w \equiv 0$ and (p, q) satisfies

$$-\dot{p}(t) = -(p(t) + q(t))u(t) + e^{-\delta t}\pi u(t),$$
$$-\dot{q}(t) = (p(t) + q(t))g'(x(t)), \quad q(T) = 0,$$

together with the maximum condition

$$u(t) \text{ maximizes } u \rightarrow \mathscr{H}(t, \Delta, x(t), x(t), u, p(t) + q(t)) \text{ over } u \in \ [0, u_{\max}].$$

We deduce from this that $p(t) + q(t)$ satisfies the (nondelay) maximum principle, whence $p + q$ and r coincide. Thus $p(T) = r(T)$ (known), and it follows that there is a single element $(0, p, q)$ in $\tilde{M}^1(x, P_C(0))$; i.e., (H11) is satisfied at $\Delta = 0$.

We are now in a position to apply Corollary 7.10, which gives a formula for $(d^+/d\Delta)V(0)$. Note that $\dot{x}$ is 0 along the intermediate stage of the solution, while $-\dot{q}(t) = r(t)g'(x(t))$ throughout. We may therefore summarize as follows.

PROPOSITION 8.3. *The following condition holds*:

$$\frac{d^+}{d\Delta}V(0) = \int_0^{\tau_1} r(t)g'(x(t))\dot{x}(t)dt + \int_{\tau_2}^{T} r(t)g'(x(t))\dot{x}(t)dt.$$

The two integrals figuring in this formula may be positive or negative in general. For example, in the typical situation in which we have $g'(x^*) > 0$, with $x_0 < x^*, x_T < x^*$, it is easy to see that the first integral is positive and the second negative.

In consequence, by setting either x_0 or x_T sufficiently near x^*, we can arrange to make $(d^+/d\Delta)V(0)$ either positive or negative, which shows that its sign cannot generally be determined by qualitative arguments.

A MONTE CARLO METHOD FOR SENSITIVITY ANALYSIS AND PARAMETRIC OPTIMIZATION OF NONLINEAR STOCHASTIC SYSTEMS*

JICHUAN YANG† AND HAROLD J. KUSHNER‡

Abstract. For high-dimensional or nonlinear problems there are serious limitations on the power of available computational methods for the optimization or parametric optimization of stochastic systems. The paper develops an effective Monte Carlo method for obtaining good estimators of systems sensitivities with respect to system parameters under quite general conditions on the systems and cost functions. The value of the method is borne out by numerical experiments, and the computational requirements are favorable with respect to competing methods when the dimension is high or the nonlinearities "severe." The method is a type of "derivative of likelihood ratio" method. Jump-diffusion, functional diffusion, and reflected diffusion models of broad types are covered by the basic technique (e.g., the type of limit model that arises in the analysis of queueing systems under heavy traffic, where the boundary reflection conditions are discontinuous). For a wide class of problems, the cost function or dynamics need not be smooth in the state variables; for example, where the cost is the probability of an event or "sign" functions appear in the dynamics. Under appropriate conditions, it is shown that the cost functions are differentiable with respect to the parameters. Since the basic diffusion (or other) model cannot be simulated exactly, two types of readily simulatable approximations are discussed in detail, and estimators of the derivatives of the cost functions for these approximations are obtained and analyzed. It is shown that these estimators and their expectations converge to those for the original problem. Thus, a robustness result for the sensitivity estimators, namely that the derivatives of the cost functions (and their estimators) for the simulatable approximations converge to those for the approximated process is proven. Such results are essential, in any case, if a simulation-based method is to be used with confidence.

Key words. Monte Carlo method for diffusions, parametric optimization of stochastic systems, sensitivity analysis, optimization of stochastic systems, nonlinear stochastic systems, high-dimensional stochastic systems, parametric optimization of jump-diffusion processes, likelihood ratio method for sensitivity analysis

1. Introduction.

The field of numerical optimization (or even the design of good controls) for stochastic systems is still in its infancy. For problems where the dimension of the state is greater than 3, the methods available for computing feedback controls are too time consuming to be of use, except for some very special cases. Also, for many applications, we do not want a feedback control (a control that depends on the current value of the full state), but rather a control that depends on the observed data (say, the position, or "error" over some time interval) and is easily constructable. For such reasons, it has been common to parametrize the control in some way, then to use some "rough" analysis to get an initial value for the parameter, and finally to use some type of Monte Carlo or stochastic approximation type method and either simulation or actual operating data to improve or optimize the parameters. In this paper, we will present a novel, very interesting, and successful method for doing this on a wide variety of problems. For a large class of problems, the method has significant advantages over currently available competing methods.

The basic results of the paper will be developed for systems that are fundamentally of the Itô equation type:

$$(1.1)\qquad dx = b(x,\alpha)dt + \sigma(x)dw, \quad x \in R^r, \quad \text{Euclidean r} - \text{space},$$

where α is the control parameter of concern. Jump-diffusion and various reflected diffusion models will also be dealt with. In practice, we must often work with a stochastic functional differential equation where the b and σ depend on the "past" values as well as the current value of the state. To see why this is so, consider the controlled problem modeled by the equation $dx = \tilde{b}(x,u)dt + \sigma(x)dw$, where u is the control. Commonly, we use controls that are functionals of the past observed data, say, the position $x^1(\cdot)$. Suppose that we choose the control form

$$(1.2)\qquad u(t) = \int_0^t \sum_{i=1}^{q} \beta_i e^{-\gamma_i(t-s)} x^1(s)\, ds = \sum_{i=1}^{q} u_i(t),$$

where the u_i are defined in the obvious way. Here $\alpha = \{\beta_i, \gamma_i, i \le q\}$, and the evolution equation for $x(\cdot)$ is actually a *stochastic functional differential equation.* Because of this need, most of the work in the paper uses the "functional" model. The computation is not usually as hard as it first appears. For example, for the case (1.2), $u(\cdot)$ is the solution to a linear differential equation driven by $x^1(\cdot)$. To better motivate the problem and to illustrate some points in the following sections, we describe some simple applications.

A typical application of concern is the case where the purpose of the control system is for the "position" $x^1(\cdot)$ to track a stochastic signal $z(\cdot)$, which does not depend on the control. Let E_α denote the expectation under parameter value α. For such an application, typical cost criteria of interest are

$$(1.3)\qquad V(\alpha) = E_\alpha C(x(\cdot),\alpha),$$

where, for example,

$$(1.4\text{a})\qquad C(x(\cdot),\alpha) = \int_0^T |x^1(s) - z(s)|\, ds,$$

or, alternatively,

$$(1.4\text{b})\qquad C(x(\cdot),\alpha) = I_{\{\sup_{s\le T} |x^1(s)-z(s)| \ge \Delta > 0\}}.$$

For such problems, the control is often chosen to be a linear functional of the "past" of the error $x^1(\cdot) - z(\cdot)$; e.g., for some parametrized kernel $g(\cdot)$, the control takes the form

$$(1.5)\qquad u(t) = \int_0^t g(t-s,\alpha)(x^1(s) - z(s))\, ds.$$

Another interesting example that is easily included in our framework comes from [1] and [2], which are concerned with the active control of a shock absorber of an automobile. The two-dimensional (one shock absorber) case in [1] and [2] is modeled by

$$(1.6)\qquad dx = \begin{pmatrix} x^2 \\ -ux^2 - \beta x^1 - \gamma \operatorname{sign}\ x^2 \end{pmatrix} dt + \begin{pmatrix} 0 \\ \sigma dw \end{pmatrix},$$

where $0 < \underline{u} < u \leq \overline{u} < \infty$ and

$$C(x(\cdot),\alpha) = \int_0^T |u(s)x^2(s) + \beta x^1(s) + \gamma \operatorname{sign} x^2(s)|^2 \, ds, \tag{1.7}$$

for positive constants β, γ. As a consequence of the analysis in [1], it was suggested there that suboptimal parametrized feedback controls of the "truncated" form

$$u(x,\alpha) = [\alpha_1 + \alpha_2 x^1 \text{ sign } x^2]\Big|_{\underline{u}}^{\overline{u}} \tag{1.8}$$

would work well.

The general Monte Carlo method for systems optimization involves getting a sequence of (hopefully improving) values $\{\alpha(n)\}$ of the parameter. Given the current parameter value $\alpha(n)$, we try to get a "reasonably" unbiased estimate of the gradient $V_\alpha(\alpha(n))$ and change $\alpha(n)$ according to some "stochastic gradient descent" method. One of the key questions in using Monte Carlo methods concerns how the gradient is to be estimated. Several methods are in current use, and we discuss them in §2. This paper is devoted to the development of a particularly useful and efficient "indirect" method that is based on a "derivative of a likelihood ratio," somewhat similar in spirit to [3]. The required computation scales linearly with the dimension of the state vector, plus a small additional computation that is linear in the dimension of the control. Numerical work suggests that the method is superior to the alternatives for many complex, nonlinear, or high-dimensional systems, in terms of both the variances of the estimates and the required computation time.

The general method will be defined in §3, where an unbiased estimator of $V_\alpha(\alpha)$ is given, assuming that the trajectory $x(\cdot)$ is available. In simulation work, we only have samples of *approximations of paths* of $x(\cdot)$, and not $x(\cdot)$ itself. Thus, it is important to analyze the quality of the estimates obtained by various approximations. A simple method, based on a discrete-time approximation, is given in §4. Sections 5–7 deal with a numerical method that uses a finite state Markov chain approximation. Each method has its own advantages.

In §8, we extend the result to a class of systems where the variance term also depends on the control. The general idea is applicable to any system whose "control terms" can be defined by a "Girsanov transformation." This is further illustrated in §9 by the reflected diffusion model and by a special form of the reflected diffusion which arises as a limit in the heavy-traffic modeling of a queueing system. The simulation of the physical model is usually quite hard and it is often advantageous to use the "simulatable" simple approximations to the simpler "heavy traffic" limit. In §10, we discuss the case where the noise vanishes. The basic calculations required to get the derivatives $V_\alpha(\alpha)$ for the purely deterministic problem are harder than those that our method requires for the stochastic problem. Because of this, it might be convenient to add small "artificial" noise and use the stochastic estimator. It is shown that, when a certain computable "zero mean" term is subtracted, the "vanishing noise" limit exists and is an unbiased estimator of the gradient for the deterministic problem.

The method of estimating the gradient $V_\alpha(\alpha)$ is a key component of a stochastic approximation method for optimizing the system. Such a stochastic approximation method and a detailed numerical study and comparison with alternatives will be given in a subsequent paper. Some numerical data appears in §11.

2. Some current methods for estimating $V_\alpha(\alpha)$. The discussion in this section will be somewhat loose, since we are only concerned with the relative advantages and limitations of different approaches, and it is supposed that the mathematical operations are justified. Unless otherwise mentioned, let α be real valued. The vector valued α case involves repeating the expressions for each component of α and will be commented on as necessary. Unless otherwise mentioned, we use the notation $x(\cdot,\alpha)$ for the solution of (1.1), under parameter α.

2.1. The mean square derivative method. Suppose that $C(\cdot)$ takes the form

$$C(x(\cdot,\alpha),\alpha) = \int_0^T k(x(s,\alpha),\alpha)\,ds + g(x(T,\alpha)), \tag{2.1}$$

and let $x_\alpha(\cdot,\alpha_0)$ denote the mean square derivative (assuming that it exists) of $x(\cdot,\alpha)$ with respect to α at α_0. This requires that $x(\cdot,\alpha)$ be defined with respect to the same Wiener process for α in a neighborhood of α_0. The process $x_\alpha(\cdot,\alpha_0)$ satisfies

$$\lim_{\delta\alpha\to 0} E\left|\frac{x(t,\alpha_0+\delta\alpha)-x(t,\alpha_0)}{\delta\alpha} - x_\alpha(t,\alpha_0)\right|^2 = 0,$$

for each t. For purposes of discussion, first let the model be the ordinary (not functional) Itô equation

$$dx(t,\alpha) = b(x(t,\alpha),\alpha)dt + \sigma(x(t,\alpha))dw. \tag{2.2}$$

Under differentiability conditions on the b and σ, $x_\alpha(\cdot,\alpha_0)$ satisfies [17, Chap. 8]

$$dx_\alpha(t,\alpha_0) = [b_\alpha(x(t,\alpha_0),\alpha_0) + b_x(x(t,\alpha_0),\alpha_0)\cdot x_\alpha(t,\alpha_0)]dt + dW(t), \tag{2.3}$$

where $W = (W_1,\cdots,W_r)$, and

$$dW_j = \sum_k \sigma'_{jk,x}(x(t,\alpha_0))x_\alpha(t,\alpha_0)dw_k(t),$$

and $b_x = (b_{1,x},\cdots,b_{r,x})$ is the Jacobian matrix. Then the quantity

$$\begin{aligned} Q(\alpha_0) = &\int_0^T [k_\alpha(x(s,\alpha_0),\alpha_0) + k'_x(x(s,\alpha_0),\alpha_0)x_\alpha(s,\alpha_0)]\,ds \\ &+ g'_x(x(T,\alpha_0))x_\alpha(T,\alpha_0) \end{aligned} \tag{2.4}$$

is an unbiased estimator of $V_\alpha(\alpha_0)$.

Where applicable, (2.4) is often used. For high-dimensional problems, the computational burden renders the method undesirable, since (2.2) and (2.3) must be solved. Typically, α is a vector. If α has K components, then K systems of the type (2.3) must be solved to estimate $V_\alpha(\alpha_0)$. Additionally, both the cost functional and $b(\cdot),\sigma(\cdot)$ must be x-differentiable, which eliminates cost functionals such as (1.4a), (1.4b), or systems such as (1.6). The requirement that system (2.2) must be defined with respect to the same Wiener process for α in a neighborhood of α_0 eliminates systems that are defined via the Girsanov transformation method. Also, it is difficult to extend the method to the reflected diffusion model.

If the control is of the form (1.2) or if system (2.2) is replaced by a stochastic functional differential equation, then (2.3) is replaced by a much more complicated equation, and the computational burden becomes even greater. These cited problems are not nearly as serious for the method defined in §3.

2.2. A finite difference method. Here, the estimator

$$[C(x(\cdot,\alpha_0+\delta\alpha),\alpha_0+\delta\alpha)-C(x(\cdot,\alpha_0),\alpha_0)]/\delta\alpha=\tilde{Q}(\alpha_0,\delta\alpha) \tag{2.5}$$

is used, for small $\delta\alpha$. If α is a vector with K components, then either $K+1$ (the "forward difference" method (2.5) used) or $2K$ (a "central difference" method used) simulations must be taken to get an estimator of the gradient $V_\alpha(\alpha_0)$. Thus the complexity of the computation is of the order of $r\cdot K$.

Unless special precautions are taken, the variance of the estimator goes to infinity as $\delta\alpha\to 0$. In certain cases, the variance can be kept bounded by reusing the same driving noises for all $K+1$ or $2K$ simulations, although the computational burden (for the vector-valued α case) can remain large. Suppose that for α in a neighborhood of α_0, the systems are all defined with respect to the same Wiener process. Sometimes, $x(\cdot,\alpha)$ and $C(x(\cdot,\alpha),\alpha)$ are almost everywhere continuous functions of the driving Wiener process path, and the *sample values* $C(x(\cdot,\alpha),\alpha)$ are actually differentiable functions of α at α_0. Then, we would use the same sample path of the Wiener process or an approximation to it in all the $(K+1)$ or $2K$ simulations. In practice, this approach can work quite well for small K. If the cost is of the "nonsmooth" form (1.4a), (1.4b) or if the system is highly nonlinear, then the properties deteriorate, and can be much worse than for the method developed in §3, from the points of view of the quality of the estimate and the computational requirements. This is borne out by numerical experiments.

The infinitesimal perturbation analysis (IPA) methods (of the type [4], [5]) do not seem to be applicable. In the next section, we develop the basic "likelihood ratio method," which has a reasonable computational requirement, yields estimators of "good quality" under broad conditions and avoids many of the difficulties cited above.

3. A likelihood ratio method. We will work with a class of systems for which the control terms can be defined in terms of a Girsanov measure transformation [6, Chap. IV.4]. Partition the state variable x as $x=(x_1,x_2)$, where $x_i\in R^{r_i}$, Euclidean r_i-space, and $r_1+r_2=r$. Let α_0 be interior to A_0, a compact parameter set, and let $x(\cdot)$ satisfy (3.1) under the conditions below:

$$dx=\begin{pmatrix} dx^1 \\ dx^2 \end{pmatrix}=\begin{pmatrix} b_1(x(\cdot),t) \\ b_2(x(\cdot),t,\alpha_0) \end{pmatrix}dt+\begin{pmatrix} \sigma_1(x(\cdot),t)dw_1 \\ \sigma_2(x(\cdot),t)dw_2 \end{pmatrix}. \tag{3.1}$$

α_0 will be the parameter value at which the derivative is taken. It is most convenient to do the basic work for real-valued α and then to state the trivial extensions to the vector case. Thus, unless mentioned otherwise, we suppose that α is real valued.

A remark on (3.1). Equation (3.1) looks complicated owing to the "functional" dependence of b_i and σ_i. Generally, unless the original system has a functional dependence due to, say, a delay, the dependence arises because the current value of the control might depend on past values of the state. Suppose, for example, that the model is

$$dx=b(x,u)dt+\sigma(x)dw, \tag{3.1$'$}$$

where the control u depends on α and on the "past"; e.g., for (1.2), we have

$$\dot{u}_i=\beta_i x^1-\gamma_i u_i, \tag{3.1$''$}$$

and the values of $b(\cdot)$ can be readily calculated or approximated by using (3.1″).

Let $T < \infty$ and let $C^r[0,T]$ denote the space of R^r-valued continuous functions on [0,T], with the sup norm topology. We will need the following assumptions.

(A3.1) For each $\alpha \in A_0$, $b_i(\cdot,\cdot,\alpha)$ and $\sigma_i(\cdot,\cdot)$ are measurable (vector- and matrix-valued) functions on $C^r[0,T] \times [0,T]$ and are nonanticipative in the sense that the values at time t depend only on $\{x(s), s \leq t\}$. Also, $\sigma_2^{-1}(x(\cdot),t)$ exists and is uniformly bounded. (We sometimes write $b = (b_1, b_2), \sigma = (\sigma_1, \sigma_2)$.)

(A3.2) The $w_i(\cdot), i = 1,2$, are standard vector-valued and mutually independent Wiener processes.

(A3.3) Equation (3.1) has a unique weak sense solution on $[0,T]$.

(A3.4) There is a bounded measurable function $b_{2,\alpha}(\cdot,\cdot,\alpha_0)$, which is the derivative of b_2 with respect to α at α_0 in the sense that

$$\left|\frac{b_2(x(\cdot),t,\alpha_0+\delta\alpha) - b_2(x(\cdot),t,\alpha_0)}{\delta\alpha} - b_{2,\alpha}(x(\cdot),t,\alpha_0)\right|$$

is bounded and converges to zero for almost all $(\omega,t), t \leq T$, as $\delta\alpha \to 0$.

(A3.5) For each $\alpha \in A_0, C(\cdot,\alpha)$ is a measurable function on $C^r[0,T]$. There is a measurable function $C_\alpha(\cdot,\alpha)$ such that

$$\lim_{\delta\alpha\to 0} E_{\alpha_0}\left|\frac{C(x(\cdot),\alpha_0+\delta\alpha) - C(x(\cdot),\alpha_0)}{\delta\alpha} - C_\alpha(x(\cdot),\alpha_0)\right|^2 = 0,$$

and for some constant K_1 and α in a neighborhood of α_0,

$$E_{\alpha_0}C^2(x(\cdot),\alpha) \leq K_1, \qquad E_{\alpha_0}C_\alpha^2(x(\cdot),\alpha) \leq K_1.$$

In cases such as (1.4a), (1.4b) where C does not depend explicitly on α, (A3.5) can be dropped.

Let $a_2 = \sigma_2\sigma_2'$. The solutions to the stochastic differential equation (3.1) for parameter values other than α_0 are defined via a Girsanov transformation [6, Chap. IV.4], as follows. For $\alpha_0 + \delta\alpha = \alpha \in A_0$, define

$$\delta b_2(t) = [b_2(x(\cdot),t,\alpha_0+\delta\alpha) - b_2(x(\cdot),t,\alpha_0)].$$

Let P_{α_0} denote the measure induced on $C^r[0,T]$ by $x(\cdot)$ under the parameter α_0 and define the measure $P_{\alpha_0+\delta\alpha}$ by the Radon–Nikodym derivative

$$dP_{\alpha_0+\delta\alpha}/dP_{\alpha_0} = \exp\left[\int_0^T [\sigma_2^{-1}(x(\cdot),t)\delta b_2(t)]'\,dw_2(t) - \frac{1}{2}\int_0^T |\sigma_2^{-1}(x(\cdot),t)\delta b_2(t)|^2\,dt\right].$$

Under $P_{\alpha_0+\delta\alpha}$, the processes $w_1(\cdot)$ and $w_2(t,\alpha_0+\delta\alpha) \equiv w_2(t) - \int_0^t \sigma_2^{-1}(x(\cdot),s)\delta b_2(s)\,ds$ are mutually independent Wiener processes. Also, rewriting (3.1) yields

$$dx = \begin{pmatrix} b_1(x(\cdot),t) \\ b_2(x(\cdot),t,\alpha_0+\delta\alpha) \end{pmatrix} dt + \begin{pmatrix} \sigma_1(x(\cdot),t)dw_1(t) \\ \sigma_2(x(\cdot),t)dw_2(t,\alpha_0+\delta\alpha) \end{pmatrix}. \tag{3.1a}$$

Thus $x(\cdot)$, under $P_{\alpha_0+\delta\alpha}$, is the solution process corresponding to parameter value $\alpha_0 + \delta\alpha$. Also, (3.1a) has a weak sense unique solution, since (3.1) does by (A3.3) [6, Chap. 4].

Define $Z(\cdot,\alpha_0)$ by

$$
\begin{aligned}
Z(t,\alpha_0) &= \int_0^t [\sigma_2^{-1}(x(\cdot),s)b_{2,\alpha}(x(\cdot),s,\alpha_0)]'dw_2(s) \\
&= \int_0^t [b'_{2,\alpha}(x(\cdot),s,\alpha_0)a_2^{-1}(x(\cdot),s)][dx_2(s) - b_2(x(\cdot),s,\alpha_0)ds].
\end{aligned} \tag{3.2}
$$

THEOREM 3.1. *Assume that the model* (3.1) *and* (A3.1)–(A3.5) *hold. Then* $V(\cdot)$ *is differentiable at* α_0 *and the quantity* $Q(\alpha_0)$ *defined by*

$$Q(\alpha_0) = Z(T,\alpha_0)C(x(\cdot),\alpha_0) + C_\alpha(x(\cdot),\alpha_0) \tag{3.3}$$

is an unbiased estimator of $V_\alpha(\alpha_0)$; *i.e.*, $E_{\alpha_0}Q(\alpha_0) = V_\alpha(\alpha_0)$.

Remark. Suppose that $C(x(\cdot),\alpha)$ takes the form

$$C(x(\cdot),\alpha) = \int_0^T k(x(\cdot,\alpha),s,\alpha)\,ds, \tag{3.4}$$

where k is nonanticipative and is bounded in the mean square sense. Then, since $E_{\alpha_0}k(x(\cdot),s,\alpha_0)[Z(T,\alpha_0) - Z(s,\alpha_0)] = 0$ for $s < T$, the quantity

$$\tilde{Q}(\alpha_0) = \int_0^T [k(x(\cdot),s,\alpha_0)Z(s,\alpha_0) + k_\alpha(x(\cdot),s,\alpha_0)]\,ds \tag{3.5}$$

is also an unbiased estimator of $V_\alpha(\alpha_0)$, and has a smaller variance than has $Q(\alpha_0)$. Numerical experiments indicate a variance reduction of a factor of $\frac{1}{2}$.

Suppose that an unbiased estimator $\overline{k}(s)$ of $k(x(\cdot),s,\alpha_0)$ with small variance is available. Then

$$\hat{Q}(\alpha_0) = \int_0^T \left[[k(x(\cdot),s,\alpha_0) - \overline{k}(s)]Z(s,\alpha_0) + k_\alpha(x(\cdot),s,\alpha_0)\right] ds \tag{3.5$'$}$$

will have smaller variance than $\tilde{Q}(\alpha_0)$. It is much easier to get excellent estimators for the $k(x(\cdot),\alpha,s)$ than for the derivatives and commonly the variances are negligible. The use of (3.5$'$) commonly reduces the variance by 20–50 percent.

Proof. Write

$$
\begin{aligned}
&[V(\alpha_0+\delta\alpha) - V(\alpha_0)]/\delta\alpha \\
&= [E_{\alpha_0+\delta\alpha}C(x(\cdot),\alpha_0+\delta\alpha) - E_{\alpha_0}C(x(\cdot),\alpha_0)]/\delta\alpha \\
&= E_{\alpha_0}[C(x(\cdot),\alpha_0+\delta\alpha)dP_{\alpha_0+\delta\alpha}/dP_{\alpha_0} - C(x(\cdot),\alpha_0)]/\delta\alpha \\
&= E_{\alpha_0}C(x(\cdot),\alpha_0)(dP_{\alpha_0+\delta\alpha}/dP_{\alpha_0} - 1)/\delta\alpha \\
&\quad + E_{\alpha_0}\left[\frac{C(x(\cdot),\alpha_0+\delta\alpha) - C(x(\cdot),\alpha_0)}{\delta\alpha}\right]\frac{dP_{\alpha_0+\delta\alpha}}{dP_{\alpha_0}}.
\end{aligned}
$$

Since $\lim_{\delta\alpha\to 0} E_{\alpha_0}|(dP_{\alpha_0+\delta\alpha})/dP_{\alpha_0} - 1|^2 = 0$, (A3.5) implies that the second right-hand term converges in mean to $E_{\alpha_0}C_\alpha(x(\cdot),\alpha_0)$. Also, it is readily shown that

$$\left(\frac{dP_{\alpha_0+\delta\alpha}}{dP_{\alpha_0}} - 1\right)/\delta\alpha \to Z(T,\alpha_0)$$

in mean square as $\delta\alpha \to 0$. The existence of $V_\alpha(\alpha_0)$ and representation (3.3) follow from these calculations. □

THE COMPUTATIONAL PROBLEM. Suppose that α is a vector with K components $(\alpha_1, \cdots, \alpha_K)$. Let $\alpha_0 = (\alpha_{0,1}, \cdots, \alpha_{0,K})$. To get an estimator of the gradient $V_\alpha(\alpha_0)$, we need to approximate the solution of (3.1) only once, and then compute the analogue of (3.2) for $b_{2,\alpha}$ replaced by b_{2,α_i} for each i. This computation is generally easier than getting a good approximation to either (3.1) or (2.3). The difference is particularly strong when (3.1) is a functional differential equation. Since $C(\cdot, \alpha)$ or $b(\cdot, \alpha)$ need not be x-differentiable here, cost functionals of the type (1.4b) and (1.7) can be included and so can systems of the type (1.6). Furthermore, we do not require that (3.1) have strong sense solutions, so that systems with discontinuous terms and that are defined by the Girsanov measure transformation method (such as (1.6)) can be used.

The idea of using stochastic methods for deterministic problems is sometimes attractive. To do this, we can simulate the deterministic system with a small amount of white noise added, and use (3.3). More will be said about this idea in §10. A similar procedure can be used if the stochastic system is not of the partitioned form (3.1). Simply add $\epsilon dw_3(\cdot)$ to the "dx_2 system," where $w_3(\cdot)$ is an R^{r_2}-valued Wiener process that is independent of $w_1(\cdot), w_2(\cdot)$, and ϵ is small, and use "corrections" analogous to that of §10.

Example (1.6)–(1.7). Here, $\alpha = (\alpha_1, \alpha_2)$, and $b_2(x, \alpha) = -u(x, \alpha)x^2 - \beta x^1 - \gamma \operatorname{sign} x^2$, where $u(\cdot)$ is defined by (1.8). For each $x, u(x, \alpha)$ is piecewise continuously differentiable in the components of α. For each α and $t > 0$, the probability is zero that $x^2(t) = 0$ and that the α-derivatives of $u(x(t), \alpha)$ and hence of $b_2(x(t), \alpha)$ do not exist. All the conditions of the theorem hold.

The jump-diffusion case. The method of Theorem 3.1 can be readily extended to the case where (3.1) is a jump-diffusion model. Let $D^r[0,T]$ denote the space of R^r-valued functions that are right continuous and have left-hand limits, and are continuous at T. The Skorokhod topology [7], [9] will be used on $D^r[0,T]$. Let $N(\cdot)$ be a Poisson measure [6, p. 42] with jump rate $\lambda < \infty$, and jump distribution $\Pi(\cdot)$ with compact support Λ. Let $q(\cdot)$ be a bounded measurable function on $D^r[0,T] \times [0,T] \times \Lambda$ with the property that $\lim_{s \uparrow t} \ q(\phi(\cdot), s, \gamma) = q(\phi(\cdot), t^-, \gamma)$ exists for all $\phi(\cdot) \in D^r[0,T]$. Let $q(\cdot)$ be nonanticipative in the sense used in (A3.1). Consider system (3.1) with the jump term $\int_\Lambda q(x(\cdot), t^-, \gamma) N(d\gamma dt)$ added [6; Chap. IV.9]:

$$dx = b(x(\cdot), t, \alpha)dt + \sigma(x(\cdot), t)dw + \int_\Lambda q(x(\cdot), t^-, \gamma)N(d\gamma dt). \tag{3.6}$$

Assume (A3.1)–(A3.5) with $C^r[0,T]$ replaced by $D^r[0,T]$. Then Theorems 3.1 and 3.2 continue to hold and the proof is unchanged.

The second derivative. The procedure of Theorem 3.1 can be repeated so that unbiased estimators of derivatives (or partial derivatives) of all orders can be obtained, if b_2 and C are smooth enough in α. For simplicity in the development, we let α be real valued. The general case should be clear.

THEOREM 3.2. *Assume* (A3.1)–(A3.5) *and the assumptions above on the jump terms. Let C and b_2 have second derivatives in the sense implied by* (A3.4) *and* (A3.5), *and let C be bounded. Define*

$$\begin{aligned} Q_2(\alpha_0) = &\left[Z^2(T, \alpha_0) - \int_0^T \left| \sigma_2^{-1}(x(\cdot), t) b_{2,\alpha}(x(\cdot), t, \alpha_0) \right|^2 dt \right] C(x(\cdot), \alpha_0) \\ &+ Z_\alpha(T, \alpha_0) C(x(\cdot), \alpha_0) + 2Z(T, \alpha_0) C_\alpha(x(\cdot), \alpha_0) + C_{\alpha\alpha}(x(\cdot), \alpha_0). \end{aligned} \tag{3.7}$$

Then

$$V_{\alpha\alpha}(\alpha_0) = E_{\alpha_0} Q_2(\alpha_0). \tag{3.8}$$

Proof. The proof is similar to that of Theorem 3.1, and only a few remarks will be made. For simplicity, suppose that C does not depend explicitly on α, and that we work with the diffusion case. For arbitrary $\alpha = \alpha_0 + \delta\alpha$, the process $Z(\cdot,\alpha)$ depends on $x(\cdot)$ and $w_2(\cdot,\alpha)$ and it is convenient to write this dependence explicitly by rewriting $Z(t,\alpha)$ in the form

$$\begin{aligned} &Z(t, \alpha_0 + \delta\alpha, w_2(\cdot, \alpha_0 + \delta\alpha), x(\cdot)) \\ &\quad = \int_0^t [\sigma_2^{-1}(x(\cdot), s) b_{2,\alpha}(x(\cdot), s, \alpha_0 + \delta\alpha)]'[dw_2(s) - \sigma_2^{-1}(x(\cdot), s)\delta b_2(s) ds], \end{aligned}$$

where $\delta b_2(s)$ is defined above Theorem 3.1.

Thus,

$$\begin{aligned} &(3.9) \\ &E_{\alpha_0+\delta\alpha} Z(T, \alpha_0 + \delta\alpha, w_2(\cdot, \alpha_0 + \delta\alpha), x(\cdot)) C(x(\cdot)) = E_{\alpha_0+\delta\alpha} Z(T, \alpha_0 + \delta\alpha, w_2(\cdot), x(\cdot)) \\ &\cdot C(x(\cdot)) - E_{\alpha_0+\delta\alpha} \int_0^T [\sigma_2^{-1}(x(\cdot), s) b_{2,\alpha}(x(\cdot), s, \alpha_0 + \delta\alpha)]' \sigma_2^{-1}(x(\cdot), s) \delta b_2(s)\, ds \cdot C(x(\cdot)). \end{aligned}$$

Dividing the second term on the right side of (3.9) by $\delta\alpha$ and taking $\delta\alpha \to 0$ yields

$$-E_{\alpha_0} \int_0^T |\sigma_2^{-1}(x(\cdot), s) b_{2,\alpha}(x(\cdot), s, \alpha_0)|^2\, ds \cdot C(x(\cdot)).$$

This is the second part of the first term of (3.7). The derivation of the other terms follows the lines of Theorem 3.1 and is omitted. □

4. A discrete-time approximation. Since we cannot obtain the paths $x(\cdot)$ or $w_2(\cdot)$ or the values of (3.3) exactly, some sort of approximation needs to be used. From a conceptual perspective, perhaps the simplest method is to use the following discrete-time form (with time-discretization parameter Δ):

$$x_{n+1}^\Delta = x_n^\Delta + b(x^\Delta(\cdot), n\Delta, \alpha_0)\Delta + \sigma(x^\Delta(\cdot), n\Delta)\delta w(n\Delta), \tag{4.1}$$

where $\delta w(n\Delta) = w(n\Delta + \Delta) - w(n\Delta)$. Let $x^\Delta(\cdot)$ be the piecewise constant interpolation of $\{x_n^\Delta\}$, defined by $x^\Delta(t) = x_n^\Delta$ on $[n\Delta, n\Delta + \Delta)$. Let $(x_{n,1}^\Delta, x_{n,2}^\Delta)$ denote the splitting of the components of x_n^Δ analogous to that in (3.1).

Define $Z^\Delta(\cdot, \alpha_0)$ to be the piecewise constant function with values

$$\begin{aligned} Z^\Delta(n\Delta, \alpha_0) &= \sum_{i=0}^{n-1} [\sigma_2^{-1}(x^\Delta(\cdot), i\Delta) b_{2,\alpha}(x^\Delta(\cdot), n\Delta, \alpha_0)]' \delta w_2(i\Delta) \\ (4.2) \qquad & \\ &= \sum_{i=0}^{n-1} [b_{2,\alpha}'(x^\Delta(\cdot), i\Delta, \alpha_0) a_2^{-1}(x^\Delta(\cdot), n\Delta)][\delta x_{i,2}^\Delta - b_2(x^\Delta(\cdot), i\Delta, \alpha)\Delta] \end{aligned}$$

on $[n\Delta, n\Delta + \Delta)$, where $\delta x_{i,2}^{\Delta} = x_{i+1,2}^{\Delta} - x_{i,2}^{\Delta}$. Let T be the integral multiple of Δ, and let the interpolations be left-continuous at T. By Theorem 4.1, the quantity

$$Q^{\Delta}(\alpha_0) = Z^{\Delta}(T, \alpha_0)C(x^{\Delta}(\cdot), \alpha_0) + C_{\alpha}(x^{\Delta}(\cdot), \alpha_0) \tag{4.3}$$

approximates (3.3). The analogue of (3.5) is

$$\sum_{i=0}^{T/\Delta-1} \Delta[k(x^{\Delta}(\cdot), i\Delta, \alpha_0)Z^{\Delta}(i\Delta, \alpha_0) + k_{\alpha}(x^{\Delta}(\cdot), i\Delta, \alpha_0)]. \tag{4.4}$$

To prove the convergence of $E_{\alpha_0}Q^{\Delta}(\alpha_0)$ to $V_{\alpha}(\alpha_0)$, we need to use the theory of weak convergence [7]–[9]. We will use the path space $D^p[0,T]$ with the Skorokhod topology, for appropriate p. The conditions used below are more restrictive than necessary, but they allow us to get to the main point easily. Assume the following.

(A4.1) $C(\cdot, \alpha_0), C_{\alpha}(\cdot, \alpha_0), \sigma_1(\cdot, \cdot), \sigma_2(\cdot, \cdot), b(\cdot, \cdot, \alpha)$, $b_{\alpha}(\cdot, \cdot, \alpha_0)$, and $\sigma_2^{-1}(\cdot, \cdot)$ are continuous functions on $D^r[0,T] \times [0,T]$, almost everywhere with respect to P_{α_0}, the measure induced by $x(\cdot, \alpha_0) = x(\cdot)$.

(A4.2) $C(\cdot, \alpha_0)$ and $C_{\alpha}(\cdot, \alpha_0)$ are bounded uniformly in A_0, $b(\cdot, \cdot, \alpha)$ and $\sigma(\cdot, \cdot)$ are bounded on bounded sets in $D^r[0,T]$ and uniformly in $\alpha \in A_0$.

(A4.3) Assumptions (A3.4) and (A3.5) hold with $x^{\Delta}(\cdot)$ replacing $x(\cdot)$, for each $\Delta > 0$.

Some preparatory calulations. The following representations are needed to state Theorem 4.1. Let P_{α}^{Δ} denote the measure induced by $x^{\Delta}(\cdot)$ on $D^r[0,T]$. Define $a = \sigma\sigma', a_2 = \sigma_2\sigma_2'$. Define

$$\begin{aligned} N(\alpha) = \exp -\frac{1}{2\Delta} \sum_{i=0}^{T/\Delta-1} & (\delta x_{i,2}^{\Delta} - b_2(x^{\Delta}(\cdot), i\Delta, \alpha)\Delta)' \\ & \cdot a_2^{-1}(x^{\Delta}(\cdot), i\Delta)(\delta x_{i,2}^{\Delta} - b_2(x^{\Delta}(\cdot), i\Delta, \alpha)\Delta), \\ \delta b_2^{\Delta}(i\Delta) = b_2(x^{\Delta}(\cdot), i\Delta, & \alpha_0 + \delta\alpha) - b_2(x^{\Delta}(\cdot), i\Delta, \alpha_0). \end{aligned}$$

Then

$$\begin{aligned} \frac{dP_{\alpha_0+\delta\alpha}^{\Delta}}{dP_{\alpha_0}^{\Delta}} &= \frac{N(\alpha_0 + \delta\alpha)}{N(\alpha_0)} \\ &= \exp\left[\sum_{i=0}^{T/\Delta-1} \delta b_2^{\Delta}(i\Delta)' a_2^{-1}(x^{\Delta}(\cdot), i\Delta)\delta x_{i,2}^{\Delta}\right. \\ &\quad - \Delta \sum_{i=0}^{T/\Delta-1} \delta b_2^{\Delta}(i\Delta)' a_2^{-1}(x^{\Delta}(\cdot), i\Delta) b_2(x^{\Delta}(\cdot), i\Delta, \alpha_0) \\ &\quad \left. - \frac{\Delta}{2} \sum_{i=0}^{T/\Delta-1} \delta b_2^{\Delta}(i\Delta)' a_2^{-1}(x^{\Delta}(\cdot), i\Delta)\delta b_2^{\Delta}(i\Delta)\right]. \end{aligned} \tag{4.5}$$

Thus under (A4.3),

$$\left(\frac{dP_{\alpha_0+\delta\alpha}^{\Delta}}{dP_{\alpha_0}^{\Delta}} - 1\right)\frac{1}{\delta\alpha} \to Z^{\Delta}(T, \alpha_0) \tag{4.6}$$

in mean square as $\delta\alpha \to 0$. Let E_{α}^{Δ} denote the expectation under parameter α and define $V^{\Delta}(\alpha) = E_{\alpha}^{\Delta}C(x^{\Delta}(\cdot), \alpha)$. By the next theorem, $E_{\alpha_0}^{\Delta}Q^{\Delta}(\alpha_0) = V_{\alpha}^{\Delta}(\alpha_0)$. Let $\Rightarrow$ denote weak convergence in the Skorokhod topology.

THEOREM 4.1. *Assume* (A3.1)–(A3.5) *and* (A4.1)–(A4.2). *Then*

$$\left(Z^{\Delta}(\cdot,\alpha_0), C(x^{\Delta}(\cdot),\alpha_0), C_{\alpha}(x^{\Delta}(\cdot),\alpha_0), x^{\Delta}(\cdot)\right)$$

$$\Rightarrow \left(Z(\cdot,\alpha_0), C(x(\cdot),\alpha_0), C_{\alpha}(x(\cdot),\alpha_0), x(\cdot)\right).$$

Also,

$$E^{\Delta}_{\alpha_0} Q^{\Delta}(\alpha_0) \to V_{\alpha}(\alpha_0). \tag{4.7}$$

Under the additional condition (A4.3),

$$E^{\Delta}_{\alpha_0} Q^{\Delta}(\alpha_0) = V^{\Delta}_{\alpha}(\alpha_0). \tag{4.8}$$

Remark on tightness. Let $\tau \le T$ denote a stopping time. Then a sufficient condition for tightness of $\{x^{\Delta}(\cdot), \Delta > 0\}$ is Theorem 2.7b of [9]:

$$\lim_{\delta\to 0} \overline{\lim_{\Delta}} \sup_{\tau} E|x^{\Delta}(\tau+\delta) - x^{\Delta}(\tau)|^2 = 0. \tag{4.9}$$

If $b(\cdot,\cdot,\alpha_0)$ and $\sigma(\cdot,\cdot)$ were bounded, then (4.9) holds. Otherwise, we exploit the uniqueness in (A3.3) and the almost everywhere continuity in (A4.1), and use a truncation procedure. The proof is standard and is omitted.

Extensions. Higher-order schemes. Methods for solving (3.1) of "higher order" than the simple "Euler" scheme (4.1), (4.2), can be used [16]. It is not necessarily advantageous to use such methods, however. In applications, many samples of the estimates are taken, and any extra time spent computing a single estimate will be at the expense of the number of samples taken. While higher-order methods might have smaller bias, it is the number of samples taken that determines the variance of the estimators, and both the bias and variance are important. Usually, in the early part of a Monte Carlo optimization method, smaller variance is more important than smaller bias.

5. A Markov chain approximation.

The form (4.1) is a "discrete time" approximation to (3.1). In this and the next two sections, we develop another computational approximation for (3.1), (3.2), which is a "discrete space" model. The method is based on an interpolated Markov chain approximation to $x(\cdot)$, and is a form of a method that has been very useful for solving the Bellman equation for optimal stochastic control problems [9], [10]. The idea can be used on a wide variety of problems. Experiments show that the numerical properties are roughly comparable to those of the method of §4, but are sometimes preferable in the sense of having smaller biases or variances. The method can also be extended to the controlled variance case (§8). When the underlying system (3.1) is unstable, it often yields better results than the method in §2.1 owing to the ease of controlling the "state increments." The method will be discussed first for the case of a "pure diffusion," and later for the jump diffusion. The basic technique will be defined in this section and a simple analogue of Theorem 4.1 proved. The next section concerns the convergence of the *derivative* of the cost for the chain to that for the diffusion, a fact that is not obvious. This result implies a "robustness" of the derivative estimates to the model. Section 7 concerns the convergence of the analogue of $Z(\cdot, \alpha_0)$ for the chain, and sheds some light on preferable constructions of the chain.

Definition of the approximating chain. We first describe the approximation when b and σ depend only on the current value of the state. We use h to denote the approximation parameter. For simplicity, we let it be scalar valued. For any parameter value α, let $\{\xi_n^h, n < \infty\}$ be a Markov chain that is locally consistent with $x(\cdot)$, under α, in the following sense. Let $E_{\alpha,n}^h$ denote expectation given $\{\xi_i^h, i \leq n\}$ and set $\delta\xi_n^h = \xi_{n+1}^h - \xi_n^h$. The parameter value α will be either stated, implied by $E_{\alpha,n}^h$ or else be α_0 by default. Suppose that there is a function $\Delta t^h(\cdot)$ (an interpolation interval) such that for $\xi_n^h = x$,

$$\begin{gathered}
E_{\alpha,n}^h \delta\xi_n^h = b(x,\alpha)\Delta t^h(x) + o(h^2), \\
E_{\alpha,n}^h \left[\delta\xi_n^h - E_{\alpha,n}^h \delta\xi_n^h\right]\left[\delta\xi_n^h - E_{\alpha,n}^h \delta\xi_n^h\right]' = a(x)\Delta t^h(x) + o(h^2), \\
|\delta\xi_n^h| = O(h), \\
c_0 h^2 \leq \Delta t^h(x) \leq c_1 h^2, \qquad c_i > 0.
\end{gathered} \tag{5.1}$$

We also suppose that the derivatives with respect to α of the $o(h^2)$ terms are $o(h^2)$. Define $\Delta t_n^h = \Delta t^h(\xi_n^h)$ and define $t_n^h = \sum_{i=0}^{n-1} \Delta t_i^h$. Define the continuous parameter interpolation $\xi^h(\cdot)$ by $\xi^h(t) = \xi_n^h$ on $[t_n^h, t_{n+1}^h)$. Under the uniqueness condition (A3.3) and the continuity of b and $\sigma, \xi^h(\cdot) \Rightarrow x(\cdot)$ for each α [9], [10]. The chain is easily simulated and provides a useful approximation to (3.1), (3.2). Let $p^h(y|x,\alpha)$ denote the one-step transition probabilities.

The stochastic functional differential equation case. In (3.1), the b and σ were allowed to depend on the "past" of the state process, and this can be readily carried over to the chain model, although we do lose the Markov property. Let $\Delta t^h(\cdot,\cdot)$ be a real-valued nonanticipative function (in the sense of (A3.1)) on $D^r[0,T] \times [0,T]$ satisfying

$$c_o h^2 \leq \Delta t^h(\phi(\cdot), t) \leq c_1 h^2,$$

where $\phi(\cdot)$ is the canonical point of $D^r[0,T]$. Define $\Delta t_n^h = \Delta t^h(\xi^h(\cdot), t_n^h)$, and replace the right-hand sides of the first two lines of (5.1) by

$$\begin{gathered}
b(\xi^h(\cdot,\alpha), t_n^h, \alpha)\Delta t_n^h + o(h^2), \\
a(\xi^h(\cdot,\alpha), t_n^h)\Delta t_n^h + o(h^2).
\end{gathered} \tag{5.2}$$

Here, we write the transition probability at time n as $p^h(y|\xi_i^h, i \leq n, \alpha)$.

Construction of the chain. A one-sided difference model. There are many methods for simulating chains with properties (5.1) or (5.2). Some general methods are in [9, Chap. 6] or [10, §5], where approximations based on both finite-difference and finite-element approximations to the differential operator of $x(\cdot)$ are given. The references deal with the pure Markov case, but the idea is trivially altered to suit the "functional" case, and we do that here. We next describe a basic scheme that is a functional form of a model in [9, Chap. 6], [10, §5], and then discuss variations and alternatives. The construction is only one suggestion but it illustrates the basic idea.

Let R_h^r be an h-grid on R^r (the set of points h units apart in each coordinate direction), and let e_i be the unit vector in the ith coordinate direction. Set $f^+ = \max(0, f), f^- = \max(0, -f)$. Define $\sigma\sigma' = a = \{a_{ij}\}$. Suppose that the current state

$\xi_n^h = x$. Then we let x communicate to $x \pm e_i h, x \pm e_i h \pm e_j h, x \pm e_i h \mp e_j h$, and construct the transition probability as follows.

For $\phi(\cdot) \in D^r[0,T]$, define

$$q_h(\phi(\cdot),t,\alpha) = \sum_i a_{ii}(\phi(\cdot),t) - \sum_{\substack{i \neq j \\ i,j}} |a_{ij}(\phi(\cdot),t)|/2 + h \sum_i |b_i(\phi(\cdot),t,\alpha)|, \tag{5.3}$$

and suppose that

$$a_{ii}(\phi(\cdot),t) - \sum_{j:j\neq i} |a_{ij}(\phi(\cdot),t)| \geq 0, \quad \text{for all} \quad t, \phi(\cdot), i. \tag{5.4}$$

Of course, $\phi(\cdot)$ represents the canonical path of $\xi^h(\cdot)$ for any α. Set

$$\Delta t^h(\phi(\cdot),t) = h^2/[\sum_i a_{ii}(\phi(\cdot),t) - \sum_{\substack{i \neq j \\ i,j}} |a_{ij}(\phi(\cdot),t)|/2]. \tag{5.5}$$

The Δt^h in [9] and [10] differs by $O(h^3)$ from that used here. Define

$$\begin{aligned} &p^h(x \pm e_i h | \xi_k^h, k < n, \xi_n^h = x, \alpha) \\ &\quad = [a_{ii}(\xi^h(\cdot),t_n^h)/2 - \sum_{j:j\neq i} |a_{ij}(\xi^h(\cdot),t_n^h)|/2 + h b_i^{\pm}(\xi^h(\cdot),t_n^h,\alpha)]/q_h(\xi^h(\cdot),t_n^h,\alpha), \end{aligned}$$

$$\begin{aligned} &p^h(x + e_i h + e_j h | \xi_k^h, k < n, \xi_n^h = x, \alpha) \\ &\quad = p^h(x - e_i h - e_j h | \xi_k^h, k < n, \xi_n^h = x, \alpha) \\ &\quad = a_{ij}^+(\xi^h(\cdot),t_n^h)/2q_h(\xi^h(\cdot),t_n^h,\alpha), \end{aligned} \tag{5.6}$$

$$\begin{aligned} p^h(x + e_i h - e_j h | \xi_i^h, i < n, \xi_n^h = x, \alpha) &= p^h(x - e_i h + e_j h | \xi_i^h, i < n, \xi_n^h = x, \alpha) \\ &= a_{ij}^-(\xi^h(\cdot),t_n^h)/2q_h(\xi^h(\cdot),t_n^h,\alpha). \end{aligned}$$

The process constructed from (5.6) satisfies (5.2) with Δt^h being given by (5.5) [9], [10]. Despite the formidable appearance of (5.6), it requires no more CPU time to simulate $\{\xi_n^h\}$ than the $\{x_n^\Delta\}$ defined in §4 does.

A central difference model. For $i = r_1 + 1, \cdots, r$ replace the $hb_i^{\pm}$ in the first equation of (5.6) by

$$\pm hb_i(\xi^h(\cdot),t_n^h,\alpha)/2, \tag{5.7}$$

and assume that h is small enough so that the numerators are nonnegative. Redefine q_h by dropping the $b_i, i > r_1$. (The $b_i, i \leq r_1$, do not depend on α.)

Discussion. State spaces such as R_h^r (or subsets of it) were used in [9], [10], since these references were concerned with a numerical solution to the Bellman equation for an optimal cost, and some "regularity" properties of the grid were essential for the programming. In the present problem, we are simply doing a simulation, and the scheme that is used can actually be changed at each step if we wish. There is considerably more flexibility, as long as (5.1) or (5.2) hold, as appropriate. For example, the stepsize can depend on the current value of x. To do this, we use c_i and an $h_o(\cdot)$ such that $c_3 h \le h_o(x) \le c_4 h$, and use $h_o(x)$ in lieu of h. In fact, it is often necessary to do such a "scaling" to get good numerical properties when the values of the dynamical terms vary considerably with x, particularly if the system is not stable. In addition, we need not use a grid that is aligned with the coordinate axes. The "local orientation" of the state transitions can depend on the current state. By aligning them with the "principle directions" of the matrix $\{a_{ij}\}$, the condition (5.4) can be eliminated.

The transition probabilities in (5.6) are no harder to calculate than are the coefficients in the discrete-time form (4.1), even for the functional dependence case. For a typical "functional" example, refer to the case discussed in §3, where the system is (3.1′), (3.1″). Then $\Delta t_n^h = \Delta t^h(\xi_n^h), a(\xi^h(\cdot), t_n^h) = a(\xi_n^h)$, and $b(\xi^h(\cdot), t_n^h, \alpha_0) = b(\xi_n^h, u_n^h)$ where $u_n^h = \sum_i^q u_{n,i}^h$ is the actual control action at step n. Let $\alpha_0 = (\beta_i, \gamma_i)$. Then letting $\xi^{h,1}$ denote the "position" component of ξ^h, we have

$$u_{n,i}^h = \sum_{k=0}^{n-1} e^{-\gamma_i (t_n^h - t_k^h)} \beta_i \xi_k^{h,1} \Delta t_k^h,$$

$$u_{n+1,i}^h = e^{-\gamma_i \Delta t_n^h} u_{n,i}^h + \beta_i \xi_n^{h,1} \Delta t^h(\xi_n^h).$$

Notation. Define

$$\delta W_n^{h,2} = \sigma_2^{-1}(\xi^h(\cdot), t_n^h)[\delta \xi_n^{h,2} - E_n^h \delta \xi_n^{h,2}],$$

and let $\tilde{Z}^h(\cdot, \alpha_0)$ be the piecewise constant process that takes the values on $[t_n^h, t_{n+1}^h)$:

$$\sum_{i=0}^{n-1} [\sigma_2^{-1}(\xi^h(\cdot), t_i^h) b_{2,\alpha}(\xi^h(\cdot), t_i^h, \alpha)]' \delta W_i^{h,2}. \tag{5.8}$$

For t in this interval, we can also write it in the form

$$\sum_{i:t_i^h \le t} b'_{2,\alpha}(\xi^h(\cdot), t_i^h, \alpha_0) a_2^{-1}(\xi^h(\cdot), t_i^h)[\delta \xi_i^{h,2} - b_2(\xi^h(\cdot), t_i^h \alpha_0) \Delta t_i^h] + \delta_h(t),$$

where $\delta_h(t) = O(ht)$. Note that $E_{\alpha_0,n}^h \delta W_n^{h,2} = 0$ and $E_{\alpha_0,n}^h \delta W_n^{h,2} (\delta W_n^{h,2})' = \Delta t_n^h I$. Hence $\delta W_n^{h,2}$ behaves "locally" like an increment to a Wiener process. Clearly, $\tilde{Z}^h(\cdot, \alpha_0)$ is an approximation to $Z(\cdot, \alpha_0)$, at least formally. Define

$$V^h(\alpha) = E_\alpha^h C(\xi^h(\cdot), \alpha),$$

$$\tilde{Q}^h(\alpha_0) = \tilde{Z}^h(T, \alpha_0) C(\xi^h(\cdot), \alpha_0) + C_\alpha(\xi^h(\cdot), \alpha_0).$$

The next theorem justifies the use of $\tilde{Q}^h(\alpha_0)$ as an asymptotically unbiased estimator of $V_\alpha(\alpha_0)$.

THEOREM 5.1. *Assume* (A3.1)–(A3.5), (A4.1)–(A4.2) *and let the chains satisfy the consistency conditions* (5.1) *or* (5.2). *Then, as* $h \to 0$,

$$\left(\tilde{Z}^h(\cdot, \alpha_0), C(\xi^h(\cdot), \alpha_0), C_\alpha(\xi^h(\cdot), \alpha_0), \xi^h(\cdot)\right)$$

$$\Rightarrow \Big(Z(\cdot,\alpha_0), C(x(\cdot),\alpha_0), C_\alpha(x(\cdot),\alpha_0), x(\cdot)\Big).$$

Also, as $h \to 0$

$$E^h_{\alpha_0}\tilde{Q}^h(\alpha_0) \to V_\alpha(\alpha_0).$$

For $\alpha \in A_0, \xi^h(\cdot) \Rightarrow x(\cdot)$ and the convergence is uniform in the sense that $V^h(\alpha) \to V(\alpha)$ uniformly in A_0.

Remark. The relationship between $E^h_{\alpha_0}\tilde{Q}^h(\alpha_0)$ and $V^h_\alpha(\alpha_0)$ will be made clear in the next section. The proof of the theorem is similar to that of Theorem 7.1, although Theorem 7.1 has some additional complications. In order not to duplicate the details, we omit the proof here, and refer the reader to §7. If the cost function has the form (3.4), then the obvious analogue of (3.5) is preferable.

6. Further properties of the chain approximation. In this section, we obtain an unbiased estimator of the derivative of the cost function for the chain $\{\xi^h_n\}$ at α_0 (Theorem 6.1) and show that its mean value converges to $V_\alpha(\alpha_0)$ as $h \to 0$ (Theorem 6.2). We will need the following assumptions. In fact, (A6.1) is a "typical" situation. In particular, it holds for the specific chains constructed in §5 if b_2 is α-differentiable.

(A6.1) There is $K_0 > 0$ such that for any $(n, y, \xi^h_i, i \le n)$ either $p^h(y|\xi^h_i, i \le n, \alpha)$ is zero for all $\alpha \in A_0$ or else it is $\ge K_0$ for all $\alpha \in A_0$. There is a bounded α-derivative p^h_α at α_0 in that

$$p^h(y|\xi^h_i, i \le n, \alpha_0 + \delta\alpha) = p^h(y|\xi^h_i, i \le n, \alpha_0) + \delta\alpha p^h_\alpha(y|\xi^h_i, i \le n, \alpha_0) + o(\delta\alpha),$$

where $o(\delta\alpha)$ is uniform in $y, \{\xi^h_i\}, n$.

(A6.2) Assumption (A3.5) holds for $\xi^h(\cdot)$ replacing $x(\cdot)$. The $C(\cdot,\cdot)$ and $C_\alpha(\cdot,\cdot)$ are bounded.

Define

$$v^h_i = p^h_\alpha(\xi^h_{i+1}|\xi^h_j, j \le i, \alpha_0)/p^h(\xi^h_{i+1}|\xi^h_j, j \le i, \alpha_0)$$

and define the piecewise constant process $Z^h(\cdot,\alpha_0)$ by $Z^h(t,\alpha_0) = \sum_{i=0}^{n-1} v^h_i$ on $[t^h_n, t^h_{n+1})$. Define

$$\begin{aligned} V^h(\alpha) &= E^h_\alpha C(\xi^h(\cdot),\alpha),\\ Q^h(\alpha_0) &= Z^h(T,\alpha_0)C(\xi^h(\cdot),\alpha_0) + C_\alpha(\xi^h(\cdot),\alpha_0),\\ N_h &= \min\{n : t^h_n \ge T\}. \end{aligned}$$

Note the N_h depends on the path, but not on the value of α directly. The asymptotic properties of $Z^h(\cdot,\alpha_0)$ will be developed in the next section.

THEOREM 6.1. *Assume* (A6.1) *and* (A6.2). *Then*

$$V^h_\alpha(\alpha_0) = E^h_{\alpha_0}Q^h(\alpha_0).$$

Proof. Let P^h_α denote the measure induced by the $\{\xi^h_i(\alpha), i \le N_h\}$. Then, by (A6.1), the P^h_α are mutually absolutely continuous and on any path $\{\xi^h_i, i \le N_h\}$,

$$\frac{dP^h_{\alpha_0+\delta\alpha}}{dP^h_{\alpha_0}} = \prod_{i=0}^{N_h-1} \frac{p^h(\xi^h_{i+1}|\xi^h_j, j \le i, \alpha_0 + \delta\alpha)}{p^h(\xi^h_{i+1}|\xi^h_j, j \le i, \alpha_0)}.$$

By (A6.1), we have

$$\frac{dP^h_{\alpha_0+\delta\alpha}}{dP^h_{\alpha_0}} = \prod_{i=0}^{N_h-1} (1 + v_i^h \delta\alpha + o(\delta\alpha)).$$

As in the proof of Theorem 3.1, we have

$$\begin{aligned}&\frac{V^h(\alpha_0+\delta\alpha) - V^h(\alpha_0)}{\delta\alpha}\\ &= E^h_{\alpha_0}\left[C(\xi^h(\cdot),\alpha_0)\left(\frac{dP^h_{\alpha_0+\delta\alpha}}{dP^h_{\alpha_0}} - 1\right)\Big/\delta\alpha + C_\alpha(\xi^h(\cdot),\alpha_0)\right] + \epsilon_1(\delta\alpha),\end{aligned}$$

where $\epsilon_1(\delta\alpha) \to 0$ as $\delta\alpha \to 0$. By the above calculations,

$$\left(\frac{dP^h_{\alpha_0+\delta\alpha}}{dP^h_{\alpha_0}} - 1\right)\Big/\delta\alpha \to Z^h(T,\alpha_0)$$

in the mean square sense as $\delta\alpha \to 0$, and the proof is concluded. □

In the next theorem we show that $Q^h(\alpha_0)$ is a good estimator for $V_\alpha(\alpha_0)$ for small enough h. We will require the following definition and condition. Define

$$v_i^h(\alpha_0,\delta\alpha) = \frac{p^h(\xi^h_{i+1}|\xi^h_j, j \le i, \alpha_0+\delta\alpha)}{p^h(\xi^h_{i+1}|\xi^h_j, j \le i, \alpha_0)} - 1.$$

(A6.3) $v_i^h(\alpha_0,\delta\alpha) = O(\delta\alpha h)$, where $O(\cdot)$ is uniform in all other variables.

Remark on A6.3. Condition (A6.3) seems to be a "typical" case in applications. See, for example, the model (5.6) or (5.7), where if $b(x(\cdot),t,\alpha)$ is Lipschitz continuous in α, uniformly in the other variables, then (A6.3) holds. It follows from (A6.3) and (A6.1) that $p^h_\alpha(y|\xi^h_i, i \le n, \alpha_0) = O(h)$ uniformly in all the variables. Note that (A6.3) implies that $v_i^h = O(h)$.

THEOREM 6.2. *Assume* (A3.1)–(A3.5), (A4.1)–(A4.2), *and* (A6.1), (A6.3). *Let* $\{\xi^h_n\}$ *satisfy the consistency condition* (5.1) *or* (5.2), *for each* α. *Then*

$$E^h_{\alpha_0} Q^h(\alpha_0) \to V_\alpha(\alpha_0).$$

Proof. For simplicity, we will suppose that $C(x(\cdot),\alpha)$ does not depend on α. We will first show that

$$(dP^h_{\alpha_0+\delta\alpha}/dP^h_{\alpha_0} - 1)/\delta\alpha$$

is approximated in an appropriate sense by $Z^h(T,\alpha_0)$, uniformly in h. Since $\sum_y p^h(y|\xi^h_i, i \le n, \alpha_0+\delta\alpha) \equiv 1$, we have

(6.1)

$$E^h_{\alpha_0,n} v_n^h(\alpha_0,\delta\alpha) + 1 = \sum_y \left\{\left[\frac{p^h(y|\xi^h_i, i \le n, \alpha_0+\delta\alpha)}{p^h(y|\xi^h_i, i \le n, \alpha_0)}\right] p^h(y|\xi^h_i, i \le n, \alpha_0)\right\} = 1.$$

Thus, $\sum_{i=0}^n v_i^h(\alpha_0,\delta\alpha)/\delta\alpha$ is a martingale sequence (under $P^h_{\alpha_0}$) and the variance is $nO(h^2)$, by (A6.3). By a similar calculation, we get that $E^h_{\alpha_0,n} v_n^h = 0$. Thus,

$\{\sum_{i=0}^{n} v_i^h\}$ is a martingale sequence with respect to the measure $P_{\alpha_0}^h$. By (A6.3), it has variance $O(h^2)n$. Since on the interval of interest, we have $n \leq N_h = O(T/h^2)$ by (5.1) or (5.2), the variances are bounded. Note also that $E_{\alpha_0,n}^h v_i^h(\alpha_0, \delta\alpha) v_j^h = 0$ for $i, j \geq n$ and $i \neq j$.

For an integer M, define the set $B(M, \delta\alpha) = \{|\sum_{i=0}^{N_h - 1} v_i^h(\alpha_0, \delta\alpha)| \geq M\delta\alpha\}$. Then, using the above estimates, we can show that

$$E_{\alpha_0}^h \left[\left[\prod_{i=0}^{N_h-1} (1 + v_i^h(\alpha_0, \delta\alpha)) - 1 \right] \Big/ \delta\alpha - \sum_{i=0}^{N_h-1} v_i^h \right] I_{B(M,\delta\alpha)} \to 0$$

as $M \to \infty$, uniformly in h and $\delta\alpha$. Thus

$$\frac{V^h(\alpha_0 + \delta\alpha) - V^h(\alpha_0)}{\delta\alpha}$$
$$= E_{\alpha_0}^h C(\xi^h(\cdot), \alpha_0) \left[\prod_{i=0}^{N_h-1} (1 + v_i^h(\alpha_0, \delta\alpha)) - 1 \right] (1 - I_{B(M,\delta\alpha)}) \Big/ \delta\alpha$$

modulo an error that goes to zero uniformly in h and $\delta\alpha$ as $M \to \infty$.

For the path not in $B(M, \delta\alpha)$, we can use the "exponential" approximation to the product and the bound $O(h)$ on v_i^h and $v_i^h(\alpha_0, \delta\alpha)/\delta\alpha$ to get

$$\begin{aligned} \prod_{i=0}^{N_h-1} (1 + v_i^h(\alpha_0, \delta\alpha)) &= \exp \sum_{i=0}^{N_h-1} [v_i^h(\alpha_0, \delta\alpha) + O^2(h\delta\alpha)] \\ &= 1 + \sum_{i=0}^{N_h-1} v_i^h \delta\alpha + o(\delta\alpha), \end{aligned}$$

where $o(\delta\alpha)$ depends on M, but is uniform in h and ω. Using the above estimates and letting $M \to \infty$ yields

$$\frac{V^h(\alpha_0 + \delta\alpha) - V^h(\alpha_0)}{\delta\alpha} = E_{\alpha_0}^h Q^h(\alpha_0) + \epsilon(\delta\alpha, h),$$

where $\epsilon(\delta\alpha, h) \to 0$ as $\delta\alpha \to 0$ and $h \to 0$.

By Theorem 5.1, $V^h(\alpha_0 + \delta\alpha) \to V(\alpha_0 + \delta\alpha)$ for any $\alpha_0 + \delta\alpha \in A_0$, and the rate of convergence is uniform in $\delta\alpha$. The sequence $\{Q^h(\alpha_0)\}$ is tight. Let h_n index a weakly convergent subsequence of $\{Q^h(\alpha_0)\}$ and of $\{\xi^h(\cdot)\}$ under both parameters $\alpha_0 + \delta\alpha$ and α_0, with the limit of $\{Q^{h_n}(\alpha_0)\}$ denoted by Q. By the weak convergence,

$$\frac{V(\alpha_0 + \delta\alpha) - V(\alpha_0)}{\delta\alpha} = EQ + \epsilon_1(\delta\alpha),$$

where $\epsilon_1(\delta\alpha) = \lim_{h \to 0} \epsilon(\delta\alpha, h) \to 0$ as $\delta\alpha \to 0$. By Theorem 3.1, $V_\alpha(\alpha_0)$ exists. Thus $EQ = V_\alpha(\alpha_0)$. Hence $E_{\alpha_0} Q$ does not depend on the chosen subsequence, and $E_{\alpha_0}^h Q^h(\alpha_0) \to V_\alpha(\alpha_0)$. □

7. The limits of $\mathbf{Z^h}$ for the chain approximation. Theorem 6.2 proved that $Z^h(T, \alpha_0)$ can be used to get an asymptoptically consistent estimator of $V_\alpha(\alpha_0)$. It is of interest to know whether $Z^h(T, \alpha_0) \Rightarrow Z(T, \alpha_0)$ as $h \to 0$. We will see in Theorem 7.1 that this is not always the case, and the proof will yield insight into the preferable numerical methods. Essentially, when the convergence is not the case, then the limit of $Z^h(T, \alpha_0)$ equals $Z(T, \alpha_0)$ plus an "error," where the error increases the variance of the estimator, but does not affect the mean. The "error" can be eliminated by an appropriate choice of the chain. Next, we present an example. Define $m_h(t) = \max\{i : t_i^h \le t\}$.

Example. Let σ and b depend only on the current state (i.e., no functional dependence) and suppose that $a_{ij}(x) = 0$ for $i \neq j$ and $a_{ii}(x) > 0$ all x and all i. The same result will hold if $a_{ii}(x) > 0$ for only some of the i and each x. We use the "central difference" method (5.7) on the grid R_h^r. The "one-sided difference" method of (5.6) yields the same results. Let $a_{ii}(x) - h|b_i(x, \alpha_0)| \ge 0$, all x and i. We have

$$p^h(x \pm e_i h | x, \alpha_0) = [a_{ii}(x) \pm hb_i(x, \alpha_0)] \Big/ \Big(2 \sum_j a_{jj}(x)\Big),$$

$$\Delta t^h(x) = h^2 / \sum_i a_{ii}(x).$$

We must have $\delta\xi_n^h = \pm he_i$, for some i. Given that value i, we have the following representation:

$$\begin{aligned} v_n^h &= \pm hb_{i,\alpha}(\xi_n^h, \alpha_0)/[a_{ii}(\xi_n^h) \pm hb_i(\xi_n^h, \alpha_0)] \\ &= \frac{\pm hb_{i,\alpha}(\xi_n^h, \alpha_0)}{a_{ii}(\xi_n^h)} \left[1 \mp \frac{hb_i(\xi_n^h, \alpha_0)}{a_{ii}(\xi_n^h)}\right] + o(h^2). \end{aligned}$$

We can rewrite the principal part of the above expression as

$$[b_\alpha'(\xi_n^h, \alpha_0) a^{-1}(\xi_n^h)][\delta\xi_n^h - \delta Y_n^h] + o(h^2), \tag{7.1}$$

where δY_n^h is a vector with jth component

$$h^2 b_j(\xi_n^h, \alpha_0) I_{\{\delta\xi_n^h = \pm e_j h\}} / a_{jj}(\xi_n^h).$$

From the transition probability above, we can calculate the probability, given the past, that $\delta\xi_n^h = \pm he_i$. Using this, the conditional expectation of the jth component, given the "past," is calculated to be

$$E_{\alpha_0,n}^h \delta Y_n^{h,j} = h^2 b_j(\xi_n^h, \alpha_0) \Big/ \sum_k a_{kk}(\xi_n^h) + o(h^2) = \Delta t^h(\xi_n^h) b_j(\xi_n^h, \alpha_0) + o(h^2) = O(h^2).$$

It can be readily shown that

$$E\left|\sum_{i=0}^{n-1} (\delta Y_i^h - E_{\alpha_0,i}^h \delta Y_i^h)\right|^2 = nO(h^4).$$

Thus, we can rewrite the sum of the terms (7.1) over $[0, m_h(t))$ as

$$\begin{aligned} &\sum_{n=0}^{m^h(t)} [b_\alpha'(\xi_n^h, \alpha_0) a^{-1}(\xi_n^h)](\delta\xi_n^h - b(\xi_n^h, \alpha_0)\Delta t_n^h) \\ &\qquad + (\text{term that goes to zero as } h \to 0). \end{aligned} \tag{7.2}$$

It can be shown that the sum in (7.2) converges weakly to $Z(\cdot, \alpha_0)$ as $h \to 0$, under the conditions of Theorem 6.2. Thus, for this case, the conclusions of Theorem 5.1 hold for $Z^h(\cdot, \alpha_0)$ replacing $\tilde{Z}^h(\cdot, \alpha_0)$. (That is, the two are asymptotically equivalent.)

If $a(\cdot)$ is not diagonal and a transition function such as (5.6) (or with the modification (5.7)) used, then it follows from the proof of Theorem 7.1 that $Z^h(\cdot,\alpha_0) \to Z(\cdot,\alpha_0)+\hat{Z}(\cdot)$, where $\hat{Z}(\cdot)$ is not necessarily identically zero and $EC(x(\cdot),\alpha_0)\hat{Z}(T) = 0$. Then $\hat{Z}(\cdot)$ contributes nothing to the mean value of the estimate, but causes an increase in the variance of the estimator. The problem can be readily avoided by "rotating" the local coordinates such that the local transitions are essentially along the principle directions of $a(\xi_n^h)$.

THEOREM 7.1. *Assume the conditions of Theorem* 6.2. *Then* $E[Z^h(T,\alpha_0)C(\xi^h(\cdot),\alpha_0) + C_\alpha(\xi^h(\cdot),\alpha_0)] \to V_\alpha(\alpha_0)$. *Let h index a weakly convergent subsequence of* $\{Z^h(\cdot,\alpha_0)\}$. *Then* $Z^h(\cdot,\alpha_0) \Rightarrow Z(\cdot,\alpha_0)+\hat{Z}(\cdot)$, *where* $Z(\cdot,\alpha_0)$ *and* $\hat{Z}(\cdot)$ *are orthogonal martingales and* $EC(x(\cdot),\alpha_0)\hat{Z}(T) = 0$.

Proof. As in Theorem 4.1, we need only work with the "truncated" b and σ. For this reason, as well as to simplify the development, we suppose that b and σ are bounded. Also, for simplicity, we drop the C_α term. To get the weak convergence, we use the martingale method (see, e.g., [8], [10, Thm. 4.5]), but the proof here will be self contained. First, tightness will be proved. Let $E^h_{\alpha_0,t}$ denote the expectation conditioned on the data up to interpolated time t or, equivalently, up to discrete time $m_h(t)$. For any real-valued $\delta > 0$ and τ being any stopping time (taking values $t_i^h, i \le N_h$), (5.1) or (5.2) imply that

(7.3)
$$\begin{aligned} E^h_{\alpha_0,\tau}|\xi^h(\tau+\delta)-\xi^h(\tau)|^2 &\le E^h_{\alpha_0\tau}\sum_{n=m_h(\tau)+1}^{m_h(\tau+\delta)}\{|\delta\xi_n^h - E^h_{\alpha_0,n}\delta\xi_n^h|^2 + |E^h_{\alpha_0,n}\delta\xi_n^h|^2\} + O(h) \\ &\le \text{ const } \cdot E^h_{\alpha_0,\tau}\left[\sum_{n=m_h(\tau)+1}^{m_h(\tau+\delta)}\Delta t^h(\xi^h(\cdot),t_n^h)\right] + O(h) \\ &= O(\delta)+O(h). \end{aligned}$$

Also,

$$(7.4)\quad E^h_{\alpha_0}|Z^h(\tau+\delta,\alpha_0)-Z^h(\tau,\alpha_0)|^2 = E^h_{\alpha_0}\left|\sum_{n=m_h(\tau)+1}^{m_h(\tau+\delta)} v_n^h\right|^2 = O(\delta)+O(h).$$

Then tightness of $\{Z^h(\cdot,\alpha_0),\xi^h(\cdot),h>0\}$ follows from (7.3), (7.4), and the criterion (4.9). Since the discontinuities in $\xi^h(\cdot)$ and $Z^h(\cdot,\alpha_0)$ are $O(h)$, the limit of any weakly convergent subsequence must have continuous paths with probability one.

We next obtain a local expansion of a test function that will be used to characterize the differential operator of the limits of the weakly convergent subsequences. Let $f(\cdot)$ be a smooth real-valued function on R^{r+1} with compact support and define $Z_n^h = \sum_{i=0}^{n-1} v_i^h$. Then, using the fact that $|\delta\xi_n^h| + |v_n^h| = O(h)$, we can write

(7.5)
$$\begin{aligned} E^h_{\alpha_0,n}f(\xi^h_{n+1},Z^h_{n+1}) - f(\xi_n^h,Z_n^h) &= E^h_{\alpha_0,n}[f_x'(\xi_n^h,Z_n^h)\delta\xi_n^h + f_z(\xi_n^h,Z_n^h)v_n^h] \\ &\quad + E^h_{\alpha_0,n}[\tfrac{1}{2}(\delta\xi_n^h)'f_{xx}(\xi_n^h,Z_n^h)\delta\xi_n^h \\ &\quad + \tfrac{1}{2}f_{zz}(\xi_n^h,Z_n^h)(v_n^h)^2 + (\delta\xi_n^h)'f_{zx}(\xi_n^h,Z_n^h)v_n^h] \\ &\quad + o(h^2). \end{aligned}$$

Note that by the consistency condition (5.1) or (5.2),

$$
\begin{aligned}
E^h_{\alpha_0,n} v^h_n \delta\xi^h_n &= \sum_y \left[\frac{(y-\xi^h_n)p^h_\alpha(y|\xi^h_i, i \le n, \alpha_0)}{p^h(y|\xi^h_i, i \le n, \alpha_0)} \right] p^h(y|\xi^h_i, i \le n, \alpha_0) \\
&= \sum_y (y-\xi^h_n)p^h_\alpha(y|\xi^h_i, i \le n, \alpha_0) = \frac{\partial}{\partial\alpha} E^h_{\alpha_0,n}\delta\xi^h_n \qquad (7.6)\\
&= \frac{\partial}{\partial\alpha} b(\xi^h(\cdot), t^h_n, \alpha_0)\Delta t^h(\xi^h(\cdot), t^h_n) + o(h^2).
\end{aligned}
$$

Define the bounded (uniformly in $h, n \le N_h$, since $\Delta t^h(t) \ge c_o h^2$ and $v^h_n = O(h)$) sequence $\overline{a}^h_n$ by

$$
\begin{aligned}
E^h_{\alpha_0,n}(v^h_n)^2 &= \sum_y \frac{p^h_\alpha(y|\xi^h_i, i \le n, \alpha_0)^2}{p^h(y|\xi^h_i, i \le n, \alpha_0)} \qquad (7.7)\\
&= \overline{a}^h_n \Delta t^h(\xi^h(\cdot), t^h_n).
\end{aligned}
$$

Define the piecewise constant function $\overline{A}^h(\cdot)$ by $\overline{A}^h(t) = \sum_{i=0}^{n-1} \overline{a}^h_i \cdot \Delta t^h(\xi^h(\cdot), t^h_n)$ on $[t^h_n, t^h_{n+1})$. The sequence $\{\overline{A}^h(\cdot), h > 0\}$ is easily shown to be tight and all the weak limits are continuous. In fact, the weak limits must be Lipschitz continuous, hence almost everywhere differentiable.

The martingale problem. For any integer q and any $t, s > 0$, let $t_i \le t \le t+s, i \le q$. Let $h(\cdot)$ be a real-valued bounded and continuous function of its arguments. For square matrices $F = \{F_{ij}\}$ and $G = \{G_{ij}\}$, recall the relationship $\sum_{i,j} F_{ij}G_{ji} =$ trace $F \cdot G$. By (7.5)–(7.7) and a truncated Taylor expansion, we can write

$$
\begin{aligned}
&E^h_{\alpha_0} h(\xi^h(t_i), Z^h(t_i, \alpha_0), \overline{A}^h(t_i), i \le q) \\
&\quad \times \Bigg[f(\xi^h(t+s), Z^h(t+s, \alpha_0)) - f(\xi^h(t), Z^h(t, \alpha_0)) \\
&\quad - \sum_{n=m_h(t)+1}^{m_h(t+s)} \bigg\{ f'_x(\xi^h_n, Z^h_n) b(\xi^h(\cdot), t^h_n, \alpha_0) + \frac{1}{2} \text{ trace } f_{xx}(\xi^h_n, Z^h_n) a(\xi^h(\cdot), t^h_n) \qquad (7.8)\\
&\qquad + \frac{1}{2} f_{zz}(\xi^h_n, Z^h_n)\overline{a}^h_n + b'_\alpha(\xi^h(\cdot), t^h_n, \alpha_0) f_{zx}(\xi^h_n, Z^h_n) \bigg\} \Delta t^h_n \Bigg] \\
&= E^h_{\alpha_0} \sum_{n=0}^{N_h-1} o(h^2) \to 0.
\end{aligned}
$$

Abusing notation, let h also index a weakly convergent subsequence of $\{\xi^h(\cdot), Z^h(\cdot, \alpha_0), \overline{A}^h(\cdot), h > 0\}$ with limit denoted by $\{(x(\cdot), Z(\cdot), \overline{A}(\cdot)\}$. Define $\overline{a}(\cdot)$ by $\overline{A}(t) = \int_0^t \overline{a}(s)ds$. Then using the weak convergence and the continuity conditions (A4.1), we have

$$
\begin{aligned}
(7.9) \quad Eh(x(t_i), Z(t_i), \overline{A}(t_i), i \le q) &\Bigg[f(x(t+s), Z(t+s)) - f(x(t), Z(t)) \\
&- \int_t^{t+s} du \bigg\{ f'_x(x(u), Z(u)) b(x(\cdot), u, \alpha_0)
\end{aligned}
$$

$$\left.\left.+\frac{1}{2}\text{trace } f_{xx}(x(u),Z(u))\cdot a(x(\cdot),u) +\frac{1}{2}f_{zz}(x(u),Z(u))\overline{a}(u)+b'_\alpha(x(\cdot),u,\alpha_0) \cdot f_{zx}(x(u),Z(u))\right\}\right] = 0.$$

The arbitariness of $q, h(\cdot), f(\cdot), t, s, \{t_i\}$ in (7.9) implies that $(x(\cdot), Z(\cdot))$ solves the martingale problem for the operator $A(\alpha_0)$ that is defined by the bracketed expression in (7.9), and with respect to the filtration $\mathcal{B}_t = \mathcal{B}(x(s), Z(s), \overline{A}(s), s \leq t)$. The form of the operator implies that the process $Z(\cdot)$ is a $\mathcal{B}_t$-martingale (since there is no first-order term f_z), and that $x(\cdot)$ satisfies (3.1) for some mutually independent $\mathcal{B}_t$-Wiener processes $w_1(\cdot), w_2(\cdot)$. (If $\sigma_1(\cdot)$ is degenerate, then we might have to augment the probability space by adding an "independent" Wiener process.)

We wish to show next that $Z(\cdot)$ can be represented as

$$Z(t) = Z(t,\alpha_0) + \hat{Z}(t) = \int_0^t [\sigma_2^{-1}(x(\cdot),u)b_{2,\alpha}(x(\cdot),u,\alpha_0)]'\,dw_2(u) + \hat{Z}(t), \tag{7.10}$$

where $\hat{Z}(\cdot)$ and $Z(\cdot,\alpha_0)$ are orthogonal stochastic integrals. Define $X(t) = \int_0^t \sigma_2(x(\cdot),u)\,dw_2(u)$, the martingale part of $x_2(\cdot)$. The mutual quadratic variation process (written as a row vector) is

$$\Big\langle X(\cdot), Z(\cdot)\Big\rangle(t) = \int_0^t b'_{2,\alpha}(x(\cdot),u,\alpha_0)\,du = \Big\langle X(\cdot), Z(\cdot,\alpha_0)\Big\rangle(t). \tag{7.11}$$

The first equality of (7.11) follows from the form of the operator $A(\alpha_0)$ or (equivalently) the representation (7.9), and the second follows from the definition of $Z(\cdot,\alpha_0)$. Also $< Z(\cdot) > (t) = \int_0^t \overline{a}(s)\,ds$. With the definition $\tilde{a}(t) = b'_{2,\alpha}(x(\cdot),t,\alpha_0)a_2^{-1}(x(\cdot),t)$ $b_{2,\alpha}$ $(x(\cdot),t,\alpha_0)$, we have

$$\Big\langle Z(\cdot,\alpha_0)\Big\rangle(t) = \int_0^t \tilde{a}(s)\,ds = \Big\langle Z(\cdot,\alpha_0), Z(\cdot)\Big\rangle(t). \tag{7.12}$$

The first equality follows from the definition of $Z(\cdot,\alpha_0)$, while the second follows from that definition and (7.11), if we note that $Z(\cdot,\alpha_0)$ can be defined as a stochastic integral with respect to the martingale $X(\cdot)$.

The equalities in (7.12) imply [12] the decomposition (7.10), where $< \hat{Z}(\cdot), Z(\cdot,\alpha_0) > (t) \equiv 0$. Finally, by Theorem 6.2,

$$EZ^h(T,\alpha_0)C(\xi^h(\cdot),\alpha_0) \to V_\alpha(\alpha_0) = E_{\alpha_0}Z(T,\alpha_0)C(x(\cdot),\alpha_0).$$

Hence $E_{\alpha_0}\hat{Z}(T)C(x(\cdot),\alpha_0) = 0$. □

Remark. Note that $< Z > (t) =< Z(\alpha_0) > (t)+ < \hat{Z} > (t)$. Hence, $\hat{Z}(t) = \int_0^t[\overline{a}(s) - \tilde{a}(s)]\,ds$. With the transition probabilities given, it is often possible to compute $\overline{a}$ and $\tilde{a}$, hence to evaluate the increase in variance of the estimator.

The jump-diffusion case. The discrete-time approximation of §4, and the Markov chain approximation of §5 can be readily extended to the jump-diffusion case (3.6) when neither the jump rate nor the jump distribution depend on α. We comment only on the Markov chain case. A Markov chain approximation to a jump diffusion was developed in [11]. The reference [11] was concerned with solving the Bellman or related equations for mean values of functionals of the process and this required that the state space for the Markov chain approximation be "nice," i.e., the jumps can take the state to only a finite set of points in the state space. Since we are not interested in solving for functionals of the chain explicitly, we have considerably more flexibility here than in [11].

Let γ denote the canonical "jump" of the Poisson measure $N(\cdot)$, and let the random variable γ_h be an approximation to γ with only a finite number of values and such that

$$\sup_{\phi(\cdot),t} |q(\phi(\cdot),t,\gamma_h) - q(\phi(\cdot),t,\gamma)| \xrightarrow{h} 0,$$

where $\phi(\cdot)$ is the canonical variable of $D^r[0,T]$. Let $\{\xi_n^h\}$ denote the approximating chain under the parameter value α. Let $\xi_n^h = x$ and $t_n^h = t$. To be consistent with (3.6), the probability of no jump at step n can be either $1-\lambda\Delta t^h(\xi^h(\cdot),t)$ (or $e^{-\lambda\Delta t^h(\xi^h(\cdot),t)}$, if we wish). In that case, let $\xi_{n+1}^h - x = O(h)$ and satisfy (5.1) or (5.2), according to the case. The probability of a jump is $\lambda\Delta t^h(\xi^h(\cdot),t)$ or $1-e^{-\lambda\Delta t^h(\xi^h(\cdot),t)}$. Then with this probability, we choose ξ_{n+1}^h to satisfy

$$\xi_{n+1}^h - x = q(\xi^h(\cdot),t,\tilde{\gamma}_h),$$

where $\tilde{\gamma}_h$ has the distribution of γ_h and is independent of $\xi_i^h, i \le n$.

All the previous theorems of §§5–7 continue to hold, and the proofs do not change. We note, in particular, that if there is a "jump" at stage n, then $p^h(\xi_{n+1}^h = y|\xi_i^h, i \le n/\alpha)$ does not depend on α. Hence $v_n^h = 0$ for those values of n at which there is a jump.

8. Variance depending on the control parameter. Up to this point, the variance was not allowed to depend on the control parameter α. The basic reason was that the measures P_α would not then be mutually absolutely continuous, so that the basic ideas of Theorem 3.1 could not be performed. For example, let P_α denote the measure induced on $D[0,T]$ by $\alpha w(\cdot), \alpha \ne 0$, where $w(\cdot)$ is a standard Wiener process. Then the P_α are not mutually absolutely continuous. Despite the lack of mutual absolute continuity, there is one interesting class for which the Markov chain method of §5 can be used to show that $V_\alpha(\alpha_0)$ exists and also to yield an estimator of it whose bias goes to zero as $h \to 0$. The direct discrete-time approximation of §4 does not work for this case.

The method is related to the time change argument that is used to construct a solution to a one-dimensional diffusion. It seems to work only when the state process is real valued. We will work with the process

$$dx = b(x,\alpha)dt + \sigma(x,\alpha)dw, \tag{8.1}$$

and cost

$$C(x(\cdot),\alpha) = \int_0^T k(x(s),\alpha)ds + g(x(T),\alpha).$$

The results of Theorem 8.1 below also hold if b, σ, and k are nonanticipative functionals of the state. However, in view of an already complicated notation, we let them be functions of only the present value of the state. We will need the following assumption.

(A8.1) $\sigma(x,\cdot)$ is continuously differentiable in α in A_0 in that there is a bounded continuous function $\sigma_\alpha(\cdot,\cdot)$ such that

$$\left|\frac{\sigma(x,\alpha+\delta\alpha)-\sigma(x,\alpha)}{\delta\alpha}-\sigma_\alpha(x,\alpha)\right|\to 0$$

as $\delta\alpha\to 0$, uniformly in $R\times A_0$, and similarly for $b(\cdot,\cdot), k(\cdot,\cdot)$, and $g(\cdot,\cdot)$. Also, $k(\cdot,\cdot), b(\cdot,\cdot), \sigma(\cdot,\cdot)$, $\sigma^{-1}(\cdot,\cdot)$, and $g(\cdot,\cdot)$ are bounded and continuous, and the first two derivatives of $g(\cdot,\alpha)$ are bounded and continuous.

The Markov chain approximation. Theorem 8.1 below uses either the "central difference" or the "one-sided difference" schemes discussed in §5. The details will be worked out for the first case only for simplicity. Before stating the theorem, we will do some preliminary calculations that will be needed below. We have $a=\sigma^2$ and the transition probabilities

$$\begin{aligned}p^h(x\pm h|x,\alpha_0)&=[a(x,\alpha_0)\pm hb(x,\alpha_0)]/2a(x,\alpha_0)\\&=\frac{1}{2}\pm hb(x,\alpha_0)/(2a(x,\alpha_0)),\end{aligned}\tag{8.2}$$

where we assume that $\inf_{x,\alpha}[a(x,\alpha)-h|b(x,\alpha)|]>0$. This can always be guaranteed if we let h depend on x. Also, $\Delta t^h(x,\alpha)=h^2/a(x,\alpha)$. Then to get the v_i^h, which are used to define $Z^h(\cdot,\alpha_0)$, we need to evaluate the expression

$$\begin{aligned}\frac{p_\alpha^h(x\pm h|x,\alpha_0)}{p^h(x\pm h|x,\alpha_0)}&=\frac{[\pm hb_\alpha(x,\alpha_0)/a(x,\alpha_0)\mp hb(x,\alpha_0)a_\alpha(x,\alpha_0)/a^2(x,\alpha_0)]}{[1\pm hb(x,\alpha_0)/a(x,\alpha_0)]}\\&=\pm hb_\alpha(x,\alpha_0)/a(x,\alpha_0)\mp hb(x,\alpha_0)a_\alpha(x,\alpha_0)/a^2(x,\alpha_0)\\&\quad-h^2b(x,\alpha_0)b_\alpha(x,\alpha_0)/a^2(x,\alpha_0)\\&\quad+h^2b^2(x,\alpha_0)a_\alpha(x,\alpha_0)/a^3(x,\alpha_0)+O(h^3).\end{aligned}\tag{8.3}$$

The first and third terms on the right side of (8.3) also occurred in the example given at the beginning of §7. The second and fourth terms are new here. In the sums below, N_h is the number of steps required for the interpolated time to reach (modulo $O(h^2)$) the value T, when the interpolation intervals are $\{\Delta t^h(\xi_i^h,\alpha_0)\}$. Thus, for any parameter value,

$$\sum_{i=0}^{N_h-1}\Delta t^h(\xi_i^h,\alpha_0)=T+O(h^2).$$

N_h depends on the path, but not otherwise on α. In the previous sections, Δt^h did not depend on α. Using (8.3), we can write

$$\begin{aligned}\sum_{i=0}^{N_h-1}v_i^h&=\sum_{i=0}^{N_h-1}\left[\frac{b_\alpha(\xi_i^h,\alpha_0)}{a(\xi_i^h,\alpha_0)}-\frac{b(\xi_i^h,\alpha_0)a_\alpha(\xi_i^h,\alpha_0)}{a^2(\xi_i^h,\alpha_0)}\right]\delta\xi_i^h\\&\quad-\sum_{i=0}^{N_h-1}\left[\frac{b_\alpha(\xi_i^h,\alpha_0)b(\xi_i^h,\alpha_0)}{a(\xi_i^h,\alpha_0)}-\frac{b^2(\xi_i^h,\alpha_0)a_\alpha(\xi_i^h,\alpha_0)}{a^2(\xi_i^h,\alpha_0)}\right]\\&\quad\cdot\Delta t^h(\xi_i^h,\alpha_0)+O(h).\end{aligned}\tag{8.4}$$

There is a similar expression for the "one-sided difference" case, where we use the transition probabilities

$$p^h(x\pm h|x,\alpha)=\frac{a(x,\alpha)/2+hb^\pm(x,\alpha)}{a(x,\alpha)+h|b(x,\alpha)|}.$$

DEFINITIONS. To state the next theorem, we need the following definitions. Let $A(\alpha)$ denote the differential operator of the $x(\cdot)$ defined by (8.1). Define

$$\overline{Z}^h(T,\alpha_0) = \sum_{i=0}^{N_h-1} v_i^h,$$

$$\begin{aligned}\overline{Z}(T,\alpha_0) = &\int_0^T \left[\frac{b_\alpha(x(s),\alpha_0)}{a(x(s),\alpha_0)} - \frac{b(x(s),\alpha_0)a_\alpha(x(s),\alpha_0)}{a^2(x(s),\alpha_0)}\right] dx(s)\\ &- \int_0^T \left[\frac{b_\alpha(x(s),\alpha_0)b(x(s),\alpha_0)}{a(x(s),\alpha_0)} - \frac{b^2(x(s),\alpha_0)a_\alpha(x(s),\alpha_0)}{a^2(x(s),\alpha_0)}\right] ds,\end{aligned} \tag{8.5}$$

$$\delta T^h(\alpha_0) = \sum_{i=0}^{N_h-1} \frac{a_\alpha(\xi_i^h,\alpha_0)}{a(\xi_i^h,\alpha_0)}\Delta t^h(\xi_i^h,\alpha_0),$$

$$\delta T(\alpha_0) = \int_0^T \frac{a_\alpha(x(s),\alpha_0)}{a(x(s),\alpha_0)}\, ds,$$

$$\begin{aligned}\overline{Q}^h(\alpha_0) = &\overline{Z}^h(T,\alpha_0)C(\xi^h(\cdot),\alpha_0) + C_\alpha(\xi^h(\cdot),\alpha_0)\\ &- \sum_{i=0}^{N_h-1} k(\xi_i^h,\alpha_0)\frac{a_\alpha(\xi_i^h,\alpha_0)}{a(\xi_i^h,\alpha_0)}\Delta t^h(\xi_i^h,\alpha_0)\\ &+ k(\xi_{N_h}^h,\alpha_0)\delta T^h(\alpha_0) + A(\alpha_0)g(\xi_{N_h}^h,\alpha_0)\delta T^h(\alpha_0),\end{aligned} \tag{8.6}$$

$$\begin{aligned}\overline{Q}(\alpha_0) = &\overline{Z}(T,\alpha_0)C(x(\cdot),\alpha_0) + C_\alpha(x(\cdot),\alpha_0) - \int_0^T k(x(s),\alpha_0)\frac{a_\alpha(x(s),\alpha_0)}{a(x(s),\alpha_0)}\, ds\\ &+ k(x(T),\alpha_0)\delta T(\alpha_0) + A(\alpha_0)g(x(T),\alpha_0)\delta T(\alpha_0).\end{aligned} \tag{8.7}$$

THEOREM 8.1. *Assume* (A8.1) *and that* (8.1) *has a* (*weak sense*) *unique solution for each* $\alpha \in A_0$. *Use the central difference formula* (8.2). *Then* $V(\cdot)$ *is differentiable and*

$$(\xi^h(\cdot),\overline{Q}^h(\alpha_0)) \Rightarrow (x(\cdot),\overline{Q}(\alpha_0)),$$

and $\overline{Q}(\alpha_0)$ *is an unbiased estimator of* $V_\alpha(\alpha_0), \alpha_0 \in A_0$. (*There is a similar result for the "one-sided difference" case.*)

Remark on the proof. The procedure of §§5 and 6 can be followed, except for two details. The first is that we do not have an a priori formula for an estimator of $V_\alpha(\alpha_0)$ analogous to (3.3). Second, the interpolation time interval $\Delta t^h(x,\alpha) = h^2/a(x,\alpha)$ depends on α here. Hence the number of discrete timesteps that are needed for the interpolated time to reach the value T depends on α. To see the point more clearly, consider the special case where σ does not depend on x, and write $\Delta t^h(x,\alpha) = \Delta t^h(\alpha), a(x,\alpha) = a(\alpha)$. Then

$$\begin{aligned}\Delta t^h(\alpha_0 + \delta\alpha) - \Delta t^h(\alpha_0) &= \Delta t_\alpha^h(\alpha_0)\delta\alpha + o(\delta\alpha)\\ &= -\,\Delta t^h(\alpha_0)[a_\alpha(\alpha_0)]\delta\alpha + o(\delta\alpha).\end{aligned}$$

Note that $N_h = T/\Delta t^h(\alpha_0)$ here. Let $a_\alpha(\alpha_0) > 0$. The interpolated time reached in N_h discrete steps is short of reaching T by the amount $T[a_\alpha(\alpha_0)/a(\alpha_0)]\delta\alpha + o(\delta\alpha)$. The terms in (8.6) and (8.7) that have not appeared in $Q^h(\alpha_0)$ and $Q(\alpha_0)$ are due to the "compensation" necessitated by this "shortfall."

Proof. By the weak convergence argument in Theorem 7.1, $V^h(\alpha_0) \to V(\alpha_0)$ and $\xi^h(\cdot) \Rightarrow x(\cdot)$, satisfying (8.1). (The weak convergence assertions below are all provided by arguments similar to that of Theorem 7.1.) Let $N_h(\delta\alpha)$ denote the number of discrete timesteps required for the interpolated time for the chain $\{\xi_i^h\}$ under parameter $\alpha_0 + \delta\alpha$ to reach time T; i.e., $\sum_{i=0}^{N_h(\delta\alpha)-1} \Delta t^h(\xi_i^h, \alpha_0 + \delta\alpha) = T$ (mod $O(h^2)$). To simplify the proof, we let k and g not depend on α. The additional details that would be required are minor. We can write

$$\begin{aligned} &E^h_{\alpha_0+\delta\alpha} C(\xi^h(\cdot)) - E^h_{\alpha_0} C(\xi^h(\cdot)) \\ &= E^h_{\alpha_0+\delta\alpha}\left[\sum_{i=0}^{N_h(\delta\alpha)-1} k(\xi_i^h)\Delta t^h(\xi_i^h, \alpha_0+\delta\alpha) + g(\xi^h_{N_h(\delta\alpha)})\right] \\ &\quad - E^h_{\alpha_0}\left[\sum_{i=0}^{N_h-1} k(\xi_i^h)\Delta t^h(\xi_i^h, \alpha_0) + g(\xi^h_{N_h})\right]. \end{aligned} \tag{8.8}$$

Let P^h_α denote the measure induced by the first N_h steps of $\{\xi_i^h\}$ under parameter α. The $P^h_\alpha, \alpha \in A_0$, are mutually absolutely continuous, and the right side of (8.8) can be rewritten as

$$E^h_{\alpha_0} S^h_1(\delta\alpha) + E^h_{\alpha_0+\delta\alpha} S^h_2(\delta\alpha) + E^h_{\alpha_0+\delta\alpha} S^h_3(\delta\alpha) + E^h_{\alpha_0+\delta\alpha} S^h_4(\delta\alpha), \tag{8.9}$$

where

$$S^h_1(\delta\alpha) = \left[\sum_0^{N_h-1} k(\xi_i^h)\Delta t^h(\xi_i^h, \alpha_0) + g(\xi^h_{N_h})\right]\left(\frac{dP^h_{\alpha_0+\delta\alpha}}{dP^h_{\alpha_0}} - 1\right),$$

$$S^h_2(\delta\alpha) = \sum_{i=0}^{N_h-1} k(\xi_i^h)\left[\Delta t^h(\xi_i^h, \alpha_0+\delta\alpha) - \Delta t^h(\xi_i^h, \alpha_0)\right],$$

$$S^h_3(\delta\alpha) = \sum_{i=N_h}^{N_h(\delta\alpha)-1} k(\xi_i^h)\Delta t^h(\xi_i^h, \alpha_0+\delta\alpha),$$

$$S^h_4(\delta\alpha) = \left[g(\xi^h_{N_h(\delta\alpha)}) - g(\xi^h_{N_h})\right].$$

(Of course, we omitted the terms that would occur if k and g depended on α.) We use the summation conventions $\sum_a^b = -\sum_b^a$ if $a > b-1$, and $\sum_a^{a-1} = 0$.

Using the convergence $[dP^h_{\alpha_0+\delta\alpha}/dP^h_{\alpha_0} - 1]/\delta\alpha$ to $\sum_{i=0}^{N_h-1} v_i^h$ as $\delta\alpha \to 0$, we see that $S^h_1(\delta\alpha)/\delta\alpha$ converges to the first term on the right of (8.6), as $\delta\alpha \to 0$. Note that (A6.1) holds here. Then letting $h \to 0$ and using representation (8.4) and the results of Theorem 6.1, a weak convergence proof similar to that of Theorem 7.1 yields (parameter α_0)

$$(\xi^h(\cdot), \overline{Z}^h(T, \alpha_0)C(\xi^h(\cdot), \alpha_0)) \Rightarrow (x(\cdot), \overline{Z}(T, \alpha_0)C(x(\cdot), \alpha_0)).$$

Note that

$$\begin{aligned}(8.10)\qquad \Delta t^h(x,\alpha_0+\delta\alpha)-\Delta t^h(x,\alpha_0) &= \Delta t^h_\alpha(x,\alpha_0)\delta\alpha+o(\delta\alpha)\\ &= -h^2\frac{a_\alpha(x,\alpha_0)}{a^2(x,\alpha_0)}\delta\alpha+o(\delta\alpha)\\ &= -\Delta t^h(x,\alpha_0)\frac{a_\alpha(x,\alpha_0)}{a(x,\alpha_0)}\delta\alpha+o(\delta\alpha).\end{aligned}$$

Using (8.10), we get that $S_2^h(\delta\alpha)/\delta\alpha$ converges to the third term of (8.6) as $\delta\alpha\to 0$. Then another weak convergence argument yields that the third term of (8.6) converges weakly to the third term of (8.7) as $h\to 0$. We can write (modulo $O(h^2)$)

$$S_3^h(\delta\alpha)=\int_{T^h(\delta\alpha)}^{T} k(\xi^h(s))\,ds,$$

where $T^h(\delta\alpha)$ is the amount of interpolated time that passes in the first N_h steps for $\{\xi_n^h\}$, under parameter $\alpha_0+\delta\alpha$: i.e., where the interpolation intervals are $\{\Delta t^h(\xi_n^h,\alpha_0+\delta\alpha)\}$. It equals

$$\begin{aligned}T^h(\delta\alpha) &= \sum_{i=0}^{N_h-1}\Delta t^h(\xi_i^h,\alpha_0+\delta\alpha)\\ &= \sum_{i=0}^{N_h-1}[\Delta t^h(\xi_i^h,\alpha_0)+\Delta t^h_\alpha(\xi_i^h,\alpha_0)\delta\alpha+O(h^2)o(\delta\alpha)]\\ (8.11)\qquad &= T+\sum_{i=0}^{N_h-1}\Delta t^h_\alpha(\xi_i^h,\alpha_0)\delta\alpha+O(h^2)+o(\delta\alpha)\\ &= T-\sum_{i=0}^{N_h-1}\frac{a_\alpha(\xi_i^h,\alpha_0)}{a(\xi_i^h,\alpha_0)}\Delta t^h(\xi_i^h,\alpha_0)\delta\alpha+O(h^2)+o(\delta\alpha).\end{aligned}$$

Using (8.11), we have that $S_3^h(\delta\alpha)/\delta\alpha$ converges to the fourth term of $\overline{Q}^h(\alpha_0)$ as $\delta\alpha\to 0$. Also, that fourth term converges weakly to the fourth term of $\overline{Q}(\alpha_0)$ as $h\to 0$. A similar analysis shows that the $S_4^h(\delta\alpha)/\delta\alpha$ converges (modulo $O(h)$) to the last term of $\overline{Q}^h(\alpha_0)$ as $\delta\alpha\to 0$, and that this limit converges weakly to the last term of $\overline{Q}(\alpha_0)$ as $h\to 0$.

By the limits obtained above when $\delta\alpha\to 0$ (but not $h\to 0$), we have proved that

$$(8.12)\qquad V_\alpha^h(\alpha_0)=E_{\alpha_0}^h\overline{Q}^h(\alpha_0)+O(h).$$

In the proof, α_0 was fixed, but (8.12) holds for any $\alpha_0\in A_0$. This implies that if $[\alpha_0,\alpha_1]\in A_0$, then

$$(8.13)\qquad V^h(\alpha_1)-V^h(\alpha_0)=\int_{\alpha_0}^{\alpha_1}E_\beta^h\overline{Q}^h(\beta)\,d\beta+O(h).$$

We also have

$$E_\beta^h\overline{Q}^h(\beta)\to E_\beta\overline{Q}(\beta)$$

uniformly on $[\alpha_0, \alpha_1]$, and the right-hand side is continuous in β. The convergence follows from the weak convergence and the assertions above. The proof of the uniformity and continuity assertion is by contradiction. Suppose, for example, that the uniform convergence is false. Then there are $\beta, h_n \to 0$, $\beta_n \to \beta$, and $\delta_0 > 0$ such that

$$|E^{h_n}_{\beta_n}\overline{Q}^{h_n}(\beta_n) - E_\beta \overline{Q}(\beta)| \geq \delta_0.$$

However $\overline{Q}^{h_n}(\beta_n) \Rightarrow \overline{Q}(\beta)$, a contradiction. A similar argument yields the asserted β-continuity. The facts above and (8.13) imply that

$$V(\alpha_1) - V(\alpha_0) = \int_{\alpha_0}^{\alpha_1} E_\beta \overline{Q}(\beta)\, d\beta.$$

This yields the differentiability of $V(\cdot)$ as well as the fact that $\overline{Q}^h(\alpha_0)$ is an asymptotically unbiased estimator of $V_\alpha(\alpha_0)$. □

9. Reflected diffusion and heavy-traffic problems. In this section we discribe, rather loosely, some of the wide variety of models to which the results of §§3–8 can be extended.

Controlled reflected diffusions. The basic idea of §3 readily extends to "reflected problems," since the Girsanov transformation idea does. In the interest of saving space, we present a somewhat loose discussion. Consider a reflected diffusion modeled as a solution to the Skorokhod problem [13] in a set G satisfying the condition.

(A9.1) G is the closure of a bounded open set with a continuously differentiable boundary. Let $n(x)$ denote the outward normal to the boundary ∂G at x, and let $\beta(x)$ denote the reflection direction. Let $-\beta'(x)n(x) \geq \beta_0 > 0$, for all $x \in \partial G$.

The system is defined by (write $x(t) = x(t, \alpha)$, var= variation)

$$\begin{aligned} x(t) &= x + \int_0^t b(x(s), \alpha)\, ds + \int_0^t \sigma(x(s))\, dw\,(s) + Y(t), \\ (\text{var}\ \ Y)(t) \equiv |Y|(t) &= \int_0^t I_{\{x(s)\in\partial G\}} d|Y|(s), \\ Y(t) &= \int_0^t \beta(x(s)) d|Y|(s). \end{aligned} \tag{9.1}$$

We let b and σ be functions of the present state only for notational simplicity. The general case of §3 can also be handled. Let $x(\cdot)$, under parameter α, induce the measure P_α. Suppose that $\sigma^{-1}(\cdot)$ is bounded and continuous. (The degenerate case can also be treated, as in §3.) The P_α are mutually absolutely continuous and $dP_{\alpha_0+\delta\alpha}/dP_{\alpha_0}$ is that given by Theorem 3.1, where σ_2, w_2, and b_2 are replaced by σ, w, and b. The entire proof of Theorem 3.1 can be carried over. The only restriction is that the $\beta(\cdot)$ not depend on α (for then we lose the mutual absolute continuity). The cost C can be a function of both $x(\cdot)$ and $Y(\cdot)$. The discrete-time and Markov chain approximations of §§4–7 also work. Some appropriate Markov chains are discussed in [10].

Heavy traffic models. We now describe a model that has been widely used in the analysis of queueing systems under heavy traffic in that the appropriately scaled and normalized queue length processes converge weakly to it, as the traffic intensity converges to unity (i.e., as the relative idle time converges to zero) [14], [15]. There are K connected processors, and p_{ij} is the probability that an output from processor i goes to processor j. The matrix $P = \{p_{ij}\}$ has a spectral radius less than unity. Thus, all customers eventually leave the system. The parameter α can correspond to "marginal" service or arrival rates, or to other control parameters. Let $B^i < \infty$ be the scaled buffer size and restrain $x^i(t)$, the ith component of the state, to be in $[0, B^i]$.

The system is

$$x(t) = x + \int_0^t b(x(s), \alpha)\, ds + \int_0^t \sigma(x(s))\, dw\,(s) + (I - P')Y(t) - U(t), \tag{9.2}$$

where $Y^i(\cdot)$(respectively, $U^i(\cdot)$) are nondecreasing and can increase only at the t at which $x^i(t) = 0$ (respectively, $x^i(t) = B^i$). All the comments in the above section on controlled reflected diffusions apply here. Also, the cost C can be a function of $x(\cdot), Y(\cdot)$ and $U(\cdot)$.

These examples illustrate the power and range of applicability of the basic idea. Note also that the "mean square derivative" method described in §2 cannot be used for either of the cases of this section.

Generally, it is nearly impossible to obtain unbiased estimators of the derivatives with respect to α for the original physical queueing system whose heavy traffic limit is (9.2). For this reason, we might want to approximate the physical queue process by (9.2), and then compute or estimate the "sensitivities" for (9.2).

10. The small noise problem. For deterministic systems, the "deterministic form" of the mean square derivative method of §2 is often used, and it is of interest to know whether the estimates (3.3) or (3.5) converge to the "deterministic" derivative, as $\sigma \to 0$. This will be shown to be the case under appropriate conditions. This result is of more than theoretical interest, since it is often useful to add "small noise" and do the stochastic computation if less computation time is required to get a good estimate. More will be said about this below.

The following assumption will be used.

(A10.1) $b_i(\cdot)$, $k(\cdot)$, and $g(\cdot)$ are bounded and continuous and have bounded and continuous (x, α)-derivatives of first order and x-derivatives of second order. The σ_i are constant matrices, σ_2^{-1} exists, and the $w_i(\cdot)$ are mutually independent Wiener processes.

The b_i, k, and g could be "nonanticipative" functionals as in §3. Then, however, the "variational" or "linearization" equation (10.2) would be much more complicated. The results to be presented hold under any conditions that allow a linearization analogous to (10.2), (10.7).

The deterministic calculation. The deterministic problem is (parameter α)

$$\dot{x}_1 = b_1(x), \quad \dot{x}_2 = b_2(x, \alpha), \quad x \in R^r, \tag{10.1}$$

$$V(\alpha) = \int_0^T k(x(s), \alpha)\, ds + g(x(T), \alpha).$$

Set $x_{\alpha_0}(t) = \partial x(t)/\partial\alpha$, with $\alpha = \alpha_0$. Then (parameter α_0)

$$\dot{x}_{\alpha_0} = b_\alpha(x, \alpha_0) + b_x(x, \alpha_0)x_{\alpha_0}, \tag{10.2}$$

$$V_\alpha(\alpha_0) = \int_0^T [k_\alpha(x(t),\alpha_0) + k'_x(x(t),\alpha_0)x_{\alpha_0}(t)]\,dt$$
$$+ [g_\alpha(x(T),\alpha_0) + g'_x(x(T),\alpha_0)x_{\alpha_0}(T)].$$

Let $\Phi(s,t), s \le t$, be the fundamental solution of the ODE $\dot{y} = b_x(x(t),\alpha_0)y$. Until the end, we drop the $g(\cdot)$ for simplicity. We have

$$V_\alpha(\alpha_0) = \int_0^T dt \left\{ k_\alpha(x(t),\alpha_0) + k'_x(x(t),\alpha_0)[\int_0^t \Phi(u,t)b_\alpha(x(u),\alpha_0)du] \right\}. \tag{10.3}$$

The evaluation of (10.3) can be quite cumbersome, particularly for high-dimensional systems, and where α is a vector. We will show that $V_\alpha(\alpha_0)$ can be approximated by a slight variation of the stochastic formula (3.5) for small ϵ.

The small noise stochastic system will be (parameter α)

$$dx^\epsilon = \begin{pmatrix} b_1(x^\epsilon) \\ b_2(x^\epsilon,\alpha) \end{pmatrix} dt + \epsilon \begin{pmatrix} \sigma_1 & dw_1 \\ \sigma_2 & dw_2 \end{pmatrix}, \tag{10.4}$$
$$V^\epsilon(\alpha) = E^\epsilon_\alpha C(x^\epsilon(\cdot),\alpha),$$
$$C(x^\epsilon(\cdot),\alpha) = \int_0^T k(x^\epsilon(t),\alpha)\,dt + g(x^\epsilon(T),\alpha).$$

A stochastic calculation. From Theorem 3.1, we have

$$V^\epsilon_\alpha(\alpha_0) = \int_0^T k(x^\epsilon(t),\alpha_0)Z^\epsilon(t,\alpha_0)\,dt + \int_0^T k_\alpha(x^\epsilon(t),\alpha_0)\,dt, \tag{10.5}$$

where $Z^\epsilon(\cdot,\alpha_0)$ is just the $Z(\cdot,\alpha_0)$ of Theorem 3.1, with variance scale parameter ϵ used. The second right-hand integral in (10.5) converges in the mean to the corresponding term of (10.3) and will be omitted henceforth. We next set up the problem so that the appropriate estimator can be defined, and then the theorem will be stated.

Write $x^\epsilon(t) = x(t)+\tilde{x}^\epsilon(t)$, where $x(\cdot)$ solves (10.1). Then $\sup_{t\le T} E|\tilde{x}^\epsilon(t)| = O(\epsilon^2)$. Using the definition of $Z^\epsilon(\cdot,\alpha_0)$, the first term on the right side of (10.5) can be written as

$$\frac{1}{\epsilon}\int_0^T dtk(x(t)+\tilde{x}^\epsilon(t),\alpha_0)\int_0^t [\sigma_2^{-1}b_{2,\alpha}(x(s)+\tilde{x}^\epsilon(s),\alpha_0)]'dw_2(s). \tag{10.6}$$

Expand $k(x(t)+\tilde{x}^\epsilon(t),\alpha_0) = k(x(t),\alpha_0)+k'_x(x(t),\alpha_0)\tilde{x}^\epsilon(t)+O(|\tilde{x}^\epsilon(t)|^2)$ and write (10.6) as

$$T^\epsilon_1 + T^\epsilon_2 + O(\epsilon^2),$$

where $E|O(\epsilon^2)| = O(\epsilon^2)$ and

$$T^\epsilon_1 = \frac{1}{\epsilon}\int_0^T dtk(x(t),\alpha_0)\int_0^t [\sigma_2^{-1}b_{2,\alpha}(x^\epsilon(s),\alpha_0)]'dw_2(s) = \int_0^T dt\; k(x(t),\alpha_0)Z^\epsilon(t,\alpha_0),$$

$$T^\epsilon_2 = \frac{1}{\epsilon}\int_0^T dtk'_x(x(t),\alpha_0)\tilde{x}^\epsilon(t)\int_0^t [\sigma_2^{-1}b_{2,\alpha}(x(s)+\tilde{x}^\epsilon(s),\alpha_0)]'dw_2(s).$$

Note that $ET_1^\epsilon = 0$, since $x(\cdot)$ is deterministic. Thus, we need not include T_1^ϵ in the estimator (also, its variance is $O(1/\epsilon^2)$, in general). We can write $\tilde{x}^\epsilon(\cdot)$ as

$$d\tilde{x}^\epsilon = b_x(x(t), \alpha_0) \cdot \tilde{x}^\epsilon dt + \epsilon\sigma dw + O(|\tilde{x}^\epsilon|^2)\, dt, \qquad \tilde{x}^\epsilon(0) = 0, \tag{10.7a}$$

or, equivalently,

$$\tilde{x}^\epsilon(t) = \epsilon \int_0^t \Phi(u,t)\sigma\, dw\,(u) + \delta_\epsilon(t), \tag{10.7b}$$

where $\sup_{t\leq T} E|\delta_\epsilon(t)| = O(\epsilon^2)$.

Next, expand the $b_{2,\alpha}$ in T_2^ϵ and substitute (10.7b) into it to yield

$$\begin{aligned} T_2^\epsilon = \int_0^T dt k_x'(x(t),\alpha_0) \int_0^t \Phi(u,t)\sigma\, dw\,(u) \\ \cdot \int_0^t [\sigma_2^{-1} b_{2,\alpha}(x(s),\alpha_0)]'\, dw_2\,(s) + O(\epsilon), \end{aligned} \tag{10.8}$$

where $E|O(\epsilon)| = O(\epsilon)$. The mean value of the primary term in (10.8) is

$$\int_0^T dt k_x'(x(t),\alpha_0) \int_0^t \Phi(u,t) b_\alpha(x(u),\alpha_0)\, du,$$

which is just (10.3) (with the k_α term dropped there).

Reintroducing the k_α term, and doing a similar expansion for the g component of the cost, the above discussion can be summarized by the following theorem.

THEOREM 10.1. *Assume* (A10.1). *Then* $V_\alpha^\epsilon(\alpha_0) \to V_\alpha(\alpha_0)$ *as* $\epsilon \to 0$. *Define*

$$\begin{aligned} \tilde{Q}^\epsilon(\alpha_0) = \left[\int_0^T k(x^\epsilon(t),\alpha_0) Z^\epsilon(t,\alpha_0)\, dt - \int_0^T k(x(t),\alpha_0) Z^\epsilon(t,\alpha_0) dt\right] \\ + \int_0^T k_\alpha(x(t),\alpha_0)\, dt + g_\alpha(x(T),\alpha_0) \\ + \left[g(x^\epsilon(T),\alpha_0) - g(x(T),\alpha_0)\right] Z^\epsilon(T,\alpha_0). \end{aligned} \tag{10.9}$$

Then $E\tilde{Q}^\epsilon(\alpha_0) \to V_\alpha(\alpha_0)$ *as* $\epsilon \to 0$. *The variance of each term is bounded uniformly in* ϵ.

The primary computational advantage in using (10.9) as a "surrogate" estimate of $V_\alpha(\alpha_0)$ is that we need not calculate $\Phi(\cdot,\cdot)$, an onerous task, nor evaluate the integrals in (10.3), separately for each component if α is a vector. The integrals in (10.9) are usually much easier to calculate than those in (10.3), and they require only a single simulation with no noise and one with small noise. If the variance of (10.9) is not too large, then it might be computationally advantageous to simulate the stochastic system several times and average the results, rather than work with (10.3). The preferable method depends on the case, however; see the next section.

11. Some numerical comparisons. Numerical comparisons of the methods of §§4 and 5 with the methods of §2 have been made on a number of problems, linear and nonlinear, and for both high and low dimension. Definitive comparisons are difficult, since each method allows different possibilities for variance reduction and realization.

Thus the results below are taken as only tentative. The runs for the finite-difference method were taken using common random numbers for all the runs needed to get a single finite-difference estimate of the gradient or derivative. This does provide some reduction in the variance of the estimators. For the methods of §§4 and 5, two approaches were used. The first used "independent" random variables for each sample run. The second (called AV for antithetic variable) took the sample runs in pairs, the random variables being "independent" from pair to pair, with those used in one member of the pair being the negative of those used in the other member of the pair. This did yield a substantial reduction in the variance of the estimators, as can be seen from the tabulated data below. For all cases 5,000 samples were taken.

Linear systems. If the system is linear and the cost function smooth, then the classical methods of §2 seem to have the advantage over the methods of §§4 and 5, at least for the systems simulated. The reasons are not clear (although, due to the linearity, we were able to simplify some of the calculations for the former methods), but all the methods should be treated as serious competitors until data indicates otherwise. The former methods used more computation time, as expected, but the variance of the estimates was sufficiently smaller, so as to give those methods the advantage (sometimes a clear advantage, other times only a slight advantage). The values of the finite-difference intervals were not too important (within reason), for the particular simulation method and problem class used. Also, the finite difference and the "mean square derivative" methods performed about the same, in terms of both CPU time and the quality of the estimates. The addition of noise to more than one state or using more complex dynamics shifts the preference.

Nonlinear systems. The numerical comparisons were more informative for nonlinear systems with "nonsmooth" cost functions. The data in Tables 1–5 was taken for the system

$$\ddot{x} - \dot{x}(1 - \alpha x^2) - x = .5 \quad \text{(white noise)} \tag{11.1}$$

with $x(0) = 1$, $\dot{x}(0) = 1$, $\alpha = 0.5$, and the cost function

$$P\{\sup_{2\geq t\geq 0} |x(t)| \geq 3.8\}. \tag{11.2}$$

Here the parameter is scalar valued and, for the finite-difference method, the difference interval is denoted by $\delta\alpha$, and the system is simulated by a discrete-time approximation of the type used in §4 with a time-difference interval of .01. Simulations indicate that the true value of the derivative is between -4.8 and -5.1 with a very high probability. We see from Table 1 that the value chosen for $\delta\alpha$ is important, and a substantial bias results if the value is too big. If the time interval is increased to .05, then the CPU time for the finite-difference case would be reduced to about 4 with essentially the same biases and variances. Comparing Tables 1 and 4, the advantage of the method of §4 over the finite difference method is apparent, particularly if bias is a concern. Note also the advantage provided by the antithetic variable (AV) method, by comparing Tables 2 and 3. We would expect that the differences would be more pronounced for higher-dimensional nonlinear problems. Similarly, comparing Tables 1 and 5 (with the cited adjustment for the time-difference interval to .05) shows the advantage of the method of §5 to the finite-difference method. The mean square derivative method is not applicable here, since the cost function $C(x(\cdot))$ used in (11.2) is not differentiable. Tables 3(a) and 5(a) use both antithetic variables and the centering (3.5′). The given CPU times are for 5,000 estimates of the derivatives.

These results should be used with caution, since all methods can undoubtably be improved. Much depends on the difficulty of approximating the differential equation, and we can find meaningful problems where any given method performs best.

In an application to stochastic approximation, we might be less concerned with the biases in the first few iterates than in the later iterates, and the particular method that is used might vary, according to need.

BALANCED PARAMETRIZATION OF CLASSES OF LINEAR SYSTEMS*

RAIMUND OBER†

Abstract. Canonical forms and parametrizations are presented for several sets of minimal systems of given dimension: asymptotically stable systems, allpass systems, bounded real systems, positive real systems, minimum-phase systems, and the class of all minimal systems. The approach is based on balancing techniques for these classes of systems. Applications of these results to Hankel operators and model reduction are discussed.

Key words. canonical form, parametrization, balanced realization, model reduction

AMS(MOS) subject classifications. 93B10, 93B20

1. Introduction and notation. Canonical forms for linear systems are of importance since they provide a unique state-space representation of linear systems. They therefore play a major role in system identification where a unique parametrization of the systems in the model set is essential. From a more theoretical point of view, canonical forms permit the study of topological and geometric properties of sets of linear systems [13], [15], [24]. For a survey of results and applications of canonical forms, see [15].

A definition of a canonical form is as follows.

DEFINITION 1.1. Let M be a set of minimal state-space systems. Then a map

$$\Gamma : M \mapsto M$$

is called a *canonical form* if

(1) $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D}) := \Gamma((A, B, C, D))$ is *system equivalent* to (A, B, C, D), i.e., there exists $T \in \Re^{n \times n}$, invertible such that

$$\tilde{A} = TAT^{-1}, \quad \tilde{B} = TB, \quad \tilde{C} = CT^{-1}, \quad \tilde{D} = D.$$

(2) If (A_1, B_1, C_1, D_1) and (A_2, B_2, C_2, D_2) are system equivalent, then

$$\Gamma((A_1, B_1, C_1, D_1)) = \Gamma((A_2, B_2, C_2, D_2)).$$

Various types of canonical forms for linear systems have been introduced and studied (see, e.g., [30], [12], [15]). Most of these canonical forms for multivariable systems are generalizations of the observer or controller canonical form for single-input single-output systems. The canonical forms presented here are based on balanced representations of linear systems. Balanced realizations for asymptotically stable systems were introduced in [19]. Other balancing techniques were then investigated in [7] for stochastic realizations, in [16] for the class of all minimal systems, and in [28] for bounded real systems. The motivation of those authors was to obtain a simple method for the approximation of a system by a lower-dimensional system in the same class.

It is shown in this paper that the balancing technique leads to canonical forms with desirable properties. In § 2 we consider balanced realizations as they were defined in [19] for asymptotically stable systems. The canonical form established for this class of systems is a modification of a similar canonical form presented in [22]. This canonical form has a structure that shows that allpass systems, which are considered in § 3, are

† Department of Engineering, Cambridge University, Trumpington Street, Cambridge CB1 1PZ, United Kingdom. Present address, Center for Engineering Mathematics, The University of Texas at Dallas, Richardson, Texas 75083.

in some sense building blocks of this canonical form. These results are the basis for the derivation of canonical forms of other classes of systems as presented in later sections of the paper. In [27] the canonical form in [22] was used to derive a canonical form for the class of minimal systems in terms of Riccati-balanced coordinates as introduced by [16]. This canonical form is rewritten in § 4 using the canonical form of § 2. Relating the class of bounded real systems to a subclass of multivariable asymptotically stable systems, it is possible to derive a canonical form for bounded real systems as presented in § 5. Via a Moebius-type transformation, the class of bounded real systems is mapped to the class of positive real systems. Since positive real systems are closely related to minimum-phase systems through spectral factorization, the canonical form derived for positive real systems in § 6 can be used in § 7 to derive a canonical form for minimum-phase systems. Section 8 deals with the relationship of the previous results to discrete-time systems. The question of model reduction of systems given in the canonical forms is considered in § 9. Examining the canonical forms, it appears that they have many common structural properties, which are discussed in § 10.

The objective of the paper is to show that for many classes of systems it is possible to derive canonical forms using the idea of balancing. The general principle of balancing is to associate with a particular class of systems a set of Riccati equations that are intrinsically related with the properties of the particular class of systems. The class of asymptotically stable systems is, for example, associated with a set of Lyapunov equations, whereas the set of positive real systems is associated with the positive real Riccati equations. It is then possible to define what a balanced realization means for such a class of systems. A system is called balanced if the solutions to the two associated equations are identical and diagonal. Having defined the notion of a balanced realization, it can be seen that such a realization of a particular system is not unique. One of the aims of this paper is to show that by imposing further constraints on the realization, it is indeed possible to obtain a unique realization, i.e., a canonical form.

The usefulness of canonical forms very much depends on their properties. One of the standard canonical forms, the controller canonical form, is of particular significance since the parameters of the canonical form have an immediate interpretation as the coefficients of the transfer function. There are, however, drawbacks of the controller canonical form especially concerning the resulting parametrization of linear systems. The set of parameters in the controller canonical form that lead to a minimal system is very complicated. This makes it difficult to use this canonical form in cases where it is necessary to have a geometrically well-behaved parameter space, e.g., in some optimization tasks. One of the main advantages of the canonical forms derived here is that it can be shown that the parameter spaces associated with a canonical form have—especially in the case of single-input single-output systems—desirable geometric properties. This is at the expense of having to partition the set of parametrized systems into suitable subsets. This means that even in the case of single-input single-output systems structural parameters must be introduced.

There would be several ways to derive the results presented here. One of them would be to treat each of the classes of systems separately and construct the canonical form from first principles. This approach would be very tedious, especially because of the complexity of the canonical forms in the case of multivariable systems. Instead, we are going to relate the various classes of systems to one another. This allows us to carry the canonical form over from one class of systems to another without having to repeat the basic construction.

Analyzing these canonical forms, it becomes apparent that all share certain structural properties. It is interesting to see that such widely differing classes of transfer functions, such as, for example, minimum-phase systems and bounded real systems, admit a parametrization that has very similar properties. Having a common structure has the advantage of allowing us to deal with the various classes of systems in a unified way. It was possible to exploit this common structure in the study of the connectivity properties of the various classes of systems [26].

For the presentation of our results we will use the common structure of the canonical forms. We will introduce the following notation, which allows us to simplify the statement of the canonical forms especially in the case of multivariable systems. Most of these definitions are, however, not important for the case of single-input single-output systems.

- A matrix $B=(b_{i,j})_{\substack{1\leqq i<k\\ 1\leqq j\leqq l}}$ is called *positive upper triangular* if there exist indices

$$1\leqq t_1<\cdots<t_j<\cdots<t_k\leqq l$$

such that

$$\begin{aligned} &b_{i,t_i}>0 && \text{for } 1\leqq i\leqq k,\\ &b_{i,j}=0 && \text{for } 1\leqq j<t_i \text{ and } 1\leqq i\leqq k,\\ &b_{i,j}\in\mathfrak{R} && \text{otherwise,}\end{aligned}$$

i.e.,

$$B=\begin{pmatrix} 0 & \cdots & 0 & b_{1,t_1} & b_{1,t_1+1} & \cdots & \cdot & \cdot & \cdot & \cdots & & & \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & b_{2,t_2} & b_{2,t_2+1} & \cdots & & & \\ \vdots & & \vdots & \vdots & \vdots & & \vdots & & & & & & \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & b_{k,t_k} & b_{k,t_k+1}\cdots \end{pmatrix}.$$

- A matrix A is said to be in *r-balanced form*, $1\leqq r\leqq n$, if for

$$A=\begin{pmatrix} A_{11} & A_{12}\\ A_{21} & A_{22}\end{pmatrix},\qquad A_{11}\in\mathfrak{R}^{r\times r},$$

we have
(1) A_{11} is skew symmetric.
(2) A_{12} and A_{22} are given by the set of indices

$$\begin{aligned} &1=h_1<\cdots<h_i<h_{i+1}<\cdots<h_q\leqq n-r,\\ &1\leqq g_q<\cdots<g_{i+1}<g_i<\cdots<g_1\leqq r\end{aligned}$$

in the following way:

(a) for $A_{12}=(a_{st})_{\substack{1\leqq s\leqq r\\ 1\leqq t\leqq n-r}}$ we have

$$\begin{aligned} &a_{g_i,h_i}>0 && \text{for } 1\leqq i\leqq q,\\ &a_{g_i,t}=0 && \text{for } t>h_i \quad \text{where } 1\leqq i\leqq q,\\ &a_{s,t}=0 && \text{for } t\geqq h_i \text{ and } s>g_i \quad \text{where } 1\leqq i\leqq q,\end{aligned}$$

i.e.,

$$A_{12}=\begin{pmatrix} \vdots & \vdots & & \vdots & \vdots & \vdots & \\ \cdot & \cdot & \cdots & a_{g_2-1,h_2-1} & a_{g_2-1,h_2} & a_{g_2-1,h_2+1} & \cdots \\ \cdot & \cdot & \cdots & a_{g_2,h_2-1} & a_{g_2,h_2} & 0 & \cdots \\ \cdot & \cdot & \cdots & a_{g_2+1,h_2-1} & 0 & 0 & \cdots \\ \vdots & \vdots & & \vdots & \vdots & \vdots & \\ a_{g_1-1,h_1} & a_{g_1-1,h_1+1} & \cdots & a_{g_1-1,h_2-1} & 0 & 0 & \cdots \\ a_{g_1,h_1} & 0 & \cdots & 0 & 0 & 0 & \cdots \\ 0 & 0 & \cdots & 0 & 0 & 0 & \cdots \\ \vdots & \vdots & & \vdots & \vdots & \vdots & \\ 0 & 0 & \cdots & 0 & 0 & 0 & \cdots \end{pmatrix}.$$

(b) A_{22} is given by

$$A_{22}=\begin{pmatrix} 0 & \alpha_2 & & & & \\ -\alpha_2 & 0 & \alpha_3 & & & \\ & -\alpha_3 & 0 & \cdot & & 0 \\ & & \ddots & \ddots & \ddots & \\ & 0 & & \cdot & 0 & \alpha_{n-r} \\ & & & & -\alpha_{n-r} & 0 \end{pmatrix},$$

where for $2\leqq i\leqq n-r$

$$\alpha_i\begin{cases} =0 & \text{if } i=h_s \text{ for some } 1\leqq s\leqq q, \\ >0 & \text{otherwise.} \end{cases}$$

(3) $A_{21}=-A_{12}^T$.

- Let $A=(a_{ij})_{\substack{1\leqq i\leqq n\\ 1\leqq j\leqq n}}$ then we denote by

(1) $[A]_l=(\bar{a}_{ij})_{\substack{1\leqq i\leqq n\\ 1\leqq j\leqq n}}$ the *lower triangular part* of A, i.e.,

$$\bar{a}_{ij}=\begin{cases} 0 & \text{for } j\geqq i, \\ a_{ij} & \text{for } j<i. \end{cases}$$

(2) $[A]_d=(\tilde{a}_{ij})_{\substack{1\leqq i\leqq n\\ 1\leqq j\leqq n}}$ the *diagonal part* of A, i.e.,

$$\tilde{a}_{ij}=\begin{cases} 0 & \text{for } j\neq i, \\ a_{ij} & \text{for } j=i. \end{cases}$$

- Let $(A, B, C, D)\in\mathfrak{R}^{n\times n}\times\mathfrak{R}^{n\times m}\times\mathfrak{R}^{p\times n}\times\mathfrak{R}^{p\times m}$ and $n_1,\cdots,n_j,\cdots,n_k$, $n_j\in\mathcal{N}$, $\sum_{j=1}^k n_j=n$. Then (A, B, C, D) is said to be *partitioned according to*

$n_1, \cdots, n_j, \cdots, n_k$ if

$$A = (A_{ij})_{1 \leq i,j \leq k}, \qquad A_{ij} \in \Re^{n_i \times n_j},$$

$$B = \begin{pmatrix} B_1 \\ \vdots \\ B_j \\ \vdots \\ B_k \end{pmatrix}, \qquad B_j \in \Re^{n_j \times m},$$

$$C = (C_1, \cdots, C_j, \cdots, C_k), \qquad C_j \in \Re^{p \times n_j}.$$

The following notation and abbreviations will be used throughout the paper.

- Classes of transfer functions:
  - —$TL_n^{p,m} = \{p \times m$ transfer functions of McMillan degree $n\}$.
  - —$TC_n^{p,m} = \{G(s) \in TL_n^{p,m} | G(s)$ has all its poles in the open left halfplane$\}$.
  - —$TA_n^m = \{G(s) \in TC_n^{m,m} | G(s)G(-s)^T = \sigma^2 I$, for some $\sigma > 0$, for all $s \in \mathscr{C}\}$.
  - —$TP_n^m = \{G(s) \in TC_n^{m,m} | G(\infty) + G(-\infty)^T > 0$, $G(iw) + G(-iw)^T > 0$ for all $w \in \Re\}$.
  - —$TB_n^{p,m} = \{G(s) \in TC_n^{p,m} | G(-\infty)^T G(\infty) < I$, $I - G(-iw)^T G(iw) > 0$ for all $w \in \Re\}$.
  - —$TM_n^m = \{G(s) \in TC_n^{m,m} | G(s)^{-1} \in TC_n^{m,m}\}$.

- Classes of state-space systems:
  - —The sets of minimal state-space realizations of the transfer functions in $TL_n^{p,m}$, $TC_n^{p,m}$, TA_n^m, TP_n^m, $TB_n^{p,m}$, and TM_n^m are denoted by $L_n^{p,m}$, $C_n^{p,m}$, A_n^m, P_n^m, $B_n^{p,m}$, and M_n^m.
  - —The corresponding sets of discrete time systems are defined in § 8.
- Symbols:
  - —diag $(A_1, \cdots, A_k)$ is a block diagonal matrix with $A_1, \cdots, A_k$ as its block diagonal entries.
  - —$\hat{I}_n :=$ diag $(+1, -1, +1, -1, \cdots, (-1)^{n+1}) \in \Re^{n \times n}$.
  - —$\mathscr{N}$ denotes the set of natural numbers, $\mathscr{C}$ denotes the set of complex numbers, and $\mathscr{R}$ the set of real numbers.

2. Asymptotically stable systems. In this section we will review some of the results on the balanced parametrization of asymptotically stable systems as given in [22]. The particular canonical form presented here for multivariable systems is, however, a simplified version of the one introduced in [22]. First, we will define a balanced realization of a minimal and asymptotically stable continuous-time system as introduced by Moore [19].

DEFINITION 2.1. The set of minimal and asymptotically stable systems $(A, B, C, D) \in \Re^{n \times n} \times \Re^{n \times m} \times \Re^{p \times n} \times \Re^{p \times m}$ is denoted by $C_n^{p,m}$. A system $(A, B, C, D) \in C_n^{p,m}$ is called *balanced* if there exists a diagonal matrix $\Sigma =$ diag $(\sigma_1, \cdots, \sigma_j, \cdots, \sigma_n)$ such that

$$(1) \qquad A\Sigma + \Sigma A^T = -BB^T, \qquad A^T\Sigma + \Sigma A = -C^T C.$$

The matrix Σ is called the gramian of the system (A, B, C, D) and its diagonal entries are said to be the *singular values* of the system.

Moore [19] has shown that each system in $C_n^{p,m}$ has an equivalent system that is balanced. Such a realization, however, is not unique. If $\Sigma =$ diag $(\sigma_1 I_{n(1)}, \cdots, \sigma_j I_{n(j)}, \cdots, \sigma_k I_{n(k)})$, $\sigma_1 > \cdots > \sigma_j > \cdots > \sigma_k > 0$, is the gramian of a balanced system (A, B, C, D), then all equivalent balanced systems with singular values ordered according to multiplicities are given by (QAQ^T, QB, CQ^T, D), where $Q = \operatorname{diag}(Q_1, \cdots, Q_j, \cdots, Q_k)$, $Q_j \in \Re^{n_j \times n_j}$, $Q_j^T Q_j = I_{n_j}$, for $1 \leqq j \leqq k$ (see, e.g., [19], [10]). Thus if Σ has distinct diagonal entries, (A, B, C, D) is unique up to a state-space transformation by a sign matrix, i.e., a diagonal matrix whose diagonal entries are ± 1. Hence for this case a canonical form can be obtained by constraining the first nonzero entry of each row of the B-matrix to be positive [17], [20], [22]. The following theorem gives a canonical form for all systems in $C_n^{p,m}$ in terms of balanced realizations. It thereby shows how to impose further constraints to obtain a unique balanced realization in the general case.

THEOREM 2.1. *The following two statements are equivalent*:

(1) $G(s) \in TC_n^{p,m}$.

(2) $G(s)$ *has a realization* $(A, B, C, D) \in \Re^{n \times n} \times \Re^{n \times m} \times \Re^{p \times n} \times \Re^{p \times m}$ *given by the parameters*:

$$\begin{array}{llll}
\sigma_1 > \cdots > \sigma_j > \cdots > \sigma_k > 0 & & & \\
n_1, \cdots, & n_j, \cdots, & n_k, & n_j \in \mathcal{N}, \sum_{j=1}^k n_j = n; \\
r_1, \cdots, & r_j, \cdots, & r_k, & r_j \in \mathcal{N}, \quad 1 \leqq r_j \leqq \min(n_j, m, p); \\
U_1, \cdots, & U_j, \cdots, & U_k, & U_j \in \Re^{p \times r_j}, \quad U_j^T U_j = I_{r_j}; \\
\tilde{B}_1, \cdots, & \tilde{B}_j, \cdots, & \tilde{B}_k, & \tilde{B}_j \in \Re^{r_j \times m} \textit{ positive upper triangular}; \\
\tilde{A}_1, \cdots, & \tilde{A}_j, \cdots, & \tilde{A}_k, & \tilde{A}_j \in \Re^{n_j \times n_j} \textit{ in } r_j\textit{-balanced form}; \\
D, & & & D \in \Re^{p \times m};
\end{array}$$

in the following way.

If (A, B, C, D) *is partitioned according to* $n_1, \cdots, n_j, \cdots, n_k$, *then*

(i) $B_j = \begin{pmatrix} \tilde{B}_j \\ 0 \end{pmatrix}, \qquad 1 \leqq j \leqq k,$

(ii) $C_j = (U_j \Delta_j, 0)$ *where* $\Delta_j = (\tilde{B}_j \tilde{B}_j^T)^{1/2}, \qquad 1 \leqq j \leqq k,$

(iii) $A_{jj} = \tilde{A}_j - \dfrac{1}{\sigma_j} [\operatorname{diag}(\Delta_j^2, 0)]_l - \dfrac{1}{2\sigma_j} [\operatorname{diag}(\Delta_j^2, 0)]_d, \qquad 1 \leqq j \leqq k,$

(iv) $A_{ij} = \dfrac{1}{\sigma_i^2 - \sigma_j^2} \operatorname{diag}((\sigma_j \tilde{B}_i \tilde{B}_j^T - \sigma_i \Delta_i U_i^T U_j \Delta_j), 0), \qquad 1 \leqq i, j \leqq k, \quad i \neq j,$

(v) $D \in \Re^{p \times m}$.

Moreover, (A, B, C, D) *as defined in* (2) *is balanced with gramian*

$$\Sigma = \operatorname{diag}(\sigma_1 I_{n_1}, \cdots, \sigma_j I_{n_j}, \cdots, \sigma_k I_{n_k}).$$

The map Γ, *which assigns to each system in* $C_n^{p,m}$ *the realization given in* (2), *is a canonical form.*

Proof. The derivation of the results is similar to the derivation of the canonical form for systems in $C_n^{p,m}$ as given in [22].

(1) $\Rightarrow$ (2) Let $(A, B, C, D) \in C_n^{p,m}$ be a balanced system with gramian $\Sigma = \sigma I_n$. Then it follows from the Lyapunov equations (1) that

$$A + A^T = -\frac{1}{\sigma} BB^T = -\frac{1}{\sigma} C^T C.$$

Since the realization (A, B, C, D) is unique up to a state-space transformation with a unitary matrix, we can assume without loss of generality that

$$B=\begin{pmatrix}\tilde{B}\\ 0\end{pmatrix},$$

where $\tilde{B}\in\Re^{r\times m}$, $r=\operatorname{rank}(B)$, is in positive upper triangular form. Note that this is a unique representation of B.

Since $BB^T=C^TC$ there exists a unique $U\in\Re^{p\times r}$, $U^TU=I_r$, such that

$$C=(U(\tilde{B}\tilde{B}^T)^{1/2},0).$$

If we write

$$A=\begin{pmatrix}A_{11} & A_{12}\\ A_{21} & A_{22}\end{pmatrix},\qquad A_{11}\in\Re^{r\times r},$$

we have

$$A_{11}+A_{11}^T=-\frac{1}{\sigma}\tilde{B}\tilde{B}^T.$$

Thus the diagonal elements of A_{11} are given by

$$[A_{11}]_d=-\frac{1}{2\sigma}[\tilde{B}\tilde{B}^T]_d.$$

Since

$$A_{11}=-\frac{1}{\sigma}\tilde{B}\tilde{B}^T-A_{11}^T,$$

A_{11} is completely parametrized by the entries of $\tilde{B}$ and those of the upper triangular part of A_{11}. The other blocks of A, i.e., A_{12}, A_{21}, and A_{22} are derived as in [22]. This completes the proof for the case of identical singular values. The general case follows as in [22].

(2) $\Rightarrow$ (1) This is a straightforward modification of Theorem 7.1 of [22]. □

The canonical form presented in the previous theorem is determined both by discrete and continuous parameters. Of the discrete parameters, $n_1,\cdots,n_k$ are of particular importance. They indicate the multiplicities of the singular values $\sigma_1,\cdots,\sigma_k$ and determine the partitioning of the state-space systems into blocks of sizes $n_1,\cdots,n_k$. To each such block corresponds the n_j-dimensional subsystem (A_{jj}, B_j, C_j, D), $1\leqq j\leqq k$. Such a subsystem is a system with identical singular values σ_j. An interesting aspect of the canonical form is that the off-diagonal blocks A_{ij}, $i\neq j$, of the A matrix, which interconnect the various subsystems, are completely determined by the parameters of the diagonal subsystems. It therefore becomes clear that each system is made up of building blocks that are systems with identical singular values. The derivation of a canonical form, therefore, essentially reduces to the derivation of a canonical form for systems with identical singular values. The complexity of the canonical form depends crucially on min (m,p), the minimum of the dimensions of the input and output spaces. As a consequence, the canonical form, if specialized to single-input single-output systems, is considerably simplified.

The following corollary states the canonical form for single-input single-output systems.

COROLLARY 2.1. *The following two statements are equivalent*:

(1) $g(s) \in TC_n^{1,1}$.

(2) $g(s)$ *has a realization* $(A, b, c, d) \in \Re^{n \times n} \times \Re^{n \times 1} \times \Re^{1 \times n} \times \Re^{1 \times 1}$ *given by the parameters*

$$
\begin{array}{ll}
\sigma_1 > \cdots > \sigma_j > \cdots > \sigma_k > 0, & \\
n_1, \cdots, n_j, \cdots, n_k, & n_j \in \mathcal{N}, \quad \sum_{j=1}^{k} n_j = n; \\
s_1, \cdots, s_j, \cdots, s_k, & s_j = \pm 1, \quad 1 \leqq j \leqq k; \\
b_1, \alpha(1)_1, \cdots, \alpha(1)_j, \cdots, \alpha(1)_{n_1-1}, & b_1 > 0, \quad \alpha(1)_j > 0, \quad 1 \leqq j \leqq n_1 - 1; \\
\vdots & \\
b_i, \alpha(i)_1, \cdots, \alpha(i)_j, \cdots, \alpha(i)_{n_i-1}, & b_i > 0, \quad \alpha(i)_j > 0, \quad 1 \leqq j \leqq n_i - 1; \\
\vdots & \\
b_k, \alpha(k)_1, \cdots, \alpha(k)_j, \cdots, \alpha(k)_{n_k-1}, & b_k > 0, \quad \alpha(k)_j > 0, \quad 1 \leqq j \leqq n_k - 1; \\
d, & d \in \Re;
\end{array}
$$

in the following way:

(i) $b = (\underbrace{b_1, 0, \cdots, 0}_{n_1}, \cdots, \underbrace{b_j, 0, \cdots, 0}_{n_j}, \cdots, \underbrace{b_k, 0, \cdots, 0}_{n_k})^T$,

(ii) $c = (\underbrace{s_1 b_1, 0, \cdots, 0}_{n_1}, \cdots, \underbrace{s_j b_j, 0, \cdots, 0}_{n_j}, \cdots, \underbrace{s_k b_k, 0, \cdots, 0}_{n_k})$,

(iii) *For* $A =: (A_{ij})_{1 \leqq i,j \leqq k}$, $A_{ij} \in \Re^{n_i \times n_j}$, $1 \leqq i, j \leqq k$, *we have*

(a) *block diagonal entries* A_{jj}, $1 \leqq j \leqq k$:

$$
A_{jj} = \begin{pmatrix}
a_{jj} & \alpha(j)_1 & & & & \\
-\alpha(j)_1 & 0 & \alpha(j)_2 & & & \\
 & -\alpha(j)_2 & 0 & \cdot & & 0 \\
 & & \ddots & \ddots & \ddots & \\
 & 0 & & \cdot & 0 & \alpha(j)_{n_j-1} \\
 & & & & -\alpha(j)_{n_j-1} & 0
\end{pmatrix}
$$

with $a_{jj} = -b_j^2 / 2\sigma_j$.

(b) *off-diagonal blocks* A_{ij}, $1 \leqq i, j \leqq k$, $i \neq j$:

$$
A_{ij} = \begin{pmatrix}
a_{ij} & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & 0
\end{pmatrix} \quad \text{with } a_{ij} = \frac{-b_i b_j}{s_i s_j \sigma_i + \sigma_j},
$$

(iv) $d \in \Re$.

Moreover, (A, b, c, d) *as defined in* (2) *is balanced with gramian*

$$\Sigma = \operatorname{diag}(\sigma_1 I_{n_1}, \cdots, \sigma_j I_{n_j}, \cdots, \sigma_k I_{n_k}).$$

The map Γ, *which assigns to each system in* $C_n^{1,1}$ *the realization given in* (2), *is a canonical form.*

Remark 2.1. The canonical form of Theorem 2.1 is closely related to the canonical form derived in [22]. The main difference between the two canonical forms is in the structure of the B-matrix. In [22] a subblock B_j corresponding to a set of repeated singular values is constrained to have orthogonal rows. The implication of this is that the corresponding subblock of A has a desirable symmetry property. Here we do not impose this symmetry on A and hence we can relax the constraints on B_j and obtain a much simplified parametrization of B. Another advantage of this canonical form is that the parameters enter freely and are not constrained by the orthogonality assumption on the rows of B_j. Note, however, that there are no differences between the two canonical forms for the case of SISO systems and for multivariable systems if the singular values are distinct.

As pointed out above, the canonical form is essentially determined by the diagonal subsystems that are determined by the block partitioning of the system corresponding to the multiplicities of the singular values. It is therefore not surprising that the canonical form reduces considerably in complexity, especially in the multivariable case, if the system has distinct singular values.

The significance of the previous theorem and corollary lies in the fact that not only is it shown that each asymptotically stable system has a unique representation and a canonical form having a certain structure, but possibly of greater importance, it is shown that the converse is also true. If we have given an arbitrary set of parameters that satisfy the stated constraints and if a system is formed from these parameters, then the theorem guarantees that this system is automatically minimal and asymptotically stable. We therefore have a parametrization of the set of asymptotically stable systems of fixed dimension. Equivalently, we can interpret the theorem as providing a parametrization of the set of transfer functions of fixed McMillan degree whose poles are in the left halfplane.

Note that especially in the single-input single-output case the parameter space has a nice geometric structure, since the continuous parameters are only determined by simple inequality constraints.

An important feature of a balanced realization of a linear system is its close relationship to the Hankel operator corresponding to the system. We define an *integral Hankel operator* with kernel $H(t) \in \mathfrak{R}^{p\times m}$, $t \geqq 0$, given by

$$\mathcal{H}: L^2_{\mathfrak{R}^m}([0,\infty[) \to L^2_{\mathfrak{R}^p}([0,\infty[),$$

$$u(t) \mapsto (\mathcal{H}(u))(s) = \int_0^\infty H(t+s)u(t)\,dt.$$

We assume that $\mathcal{H}$ is well defined and a finite rank operator. The singular values $(\sigma_j)_{1\leqq j \leqq n}$ of $\mathcal{H}$ are defined to be the nonzero eigenvalues of $(\mathcal{H}^*\mathcal{H})^{1/2}$ ordered with respect to their magnitude and taking into account their multiplicities. Under these conditions there exist families of orthonormal vectors (Schmidt vectors) $(v_j)_{1\leqq j\leqq n}$ and $(w_j)_{1\leqq j \leqq n}$ in $L^2_{\mathfrak{R}^m}([0,\infty[)$ and $L^2_{\mathfrak{R}^p}([0,\infty[)$, respectively, such that

$$\mathcal{H}v_j = \sigma_j w_j, \quad \mathcal{H}^* w_j = \sigma_j v_j, \quad 1 \leqq j \leqq n.$$

The significance of Hankel operators in a system-theoretic context is that for a system $(A, B, C, D) \in C_n^{p,m}$ the Hankel operator $\mathcal{H}$ with kernel $H(t) := Ce^{tA}B$ can be interpreted as an operator mapping past inputs to future outputs. If (A, B, C, D) is balanced, it can easily be verified that the singular values of the Hankel operator $\mathcal{H}$ equal the singular values of the system (A, B, C, D) [10]. Moreover, $v_j(t) = B^Te^{tA^T}e_j/\sqrt{\sigma_j}$ and $w_j(t) = Ce^{tA}e_j/\sqrt{\sigma_j}$, $1 \leqq j \leqq n$. Since $v_j(0) = B^Te_j/\sqrt{\sigma_j}$ and $w_j(0) = Ce_j/\sqrt{\sigma_j}$, $1 \leqq j \leqq n$, the starting points of the Schmidt vectors are fully determined by the B and C matrices and the singular values. This gives an interpretation of some of the parameters of a system in canonical form in terms of analytical properties of the corresponding Hankel operator.

By standard realization theory we know that there is a one-to-one correspondence between Hankel operators of rank n and asymptotically systems of McMillan degree n. The discussion in the previous paragraph implies that finding a canonical form for linear systems in terms of balanced realizations is equivalent to defining a unique basis for the eigenspaces of the nonzero eigenvalues of the operator $\mathscr{H}^*\mathscr{H}$. This observation gives another interpretation of the complexity of the canonical form in the case of repeated singular values.

If we now consider the Hankel operator $\mathscr{H}$ corresponding to a scalar transfer function in $TC_n^{1,1}$, the eigenvectors and Schmidt vectors of $\mathscr{H}$ coincide (up to a sign), since $\mathscr{H}$ is self-adjoint. If, moreover, (A, b, c, d) is in the canonical form of the previous corollary, the eigenvectors, respectively, Schmidt vectors, are given by $v_j(t) = b^T e^{tA^T} e_j/\sqrt{\sigma_j} = \tilde{s}_j w_j(t) = (\tilde{s}_j/\sqrt{\sigma_j}) c e^{tA} e_j$, $1 \leqq j \leqq n$, where we have used that $A = SA^TS$ and $c^T = Sb$ for $S = \operatorname{diag}(\tilde{s}_1, \cdots, \tilde{s}_j, \cdots, \tilde{s}_n) := \operatorname{diag}(s_1 \hat{I}_{n_1}, \cdots, s_j \hat{I}_n, \cdots, s_k \hat{I}_{n_k})$.

The eigenvalue corresponding to v_j is therefore calculated to be $\tilde{s}_j\sigma$, since

$$(\mathscr{H}v_j)(t) = \int_0^\infty H(t+s) v_j(s)\, ds = \frac{1}{\sqrt{\sigma_j}} \int_0^\infty c e^{(t+s)A} b b^T e^{sA^T} e_j\, ds$$

$$= \sigma_j \frac{1}{\sqrt{\sigma_j}} c e^{tA} e_j = \tilde{s}_j \sigma_j v_j(t).$$

This observation allows us to use the canonical form for scalar systems to investigate the dimensions of the eigenspaces of a finite rank Hankel operator.

THEOREM 2.2. *Let $h(t) \in \mathfrak{R}$, $t \geqq 0$, be the kernel of a finite rank Hankel operator $\mathscr{H}$ acting on $L^2_{\mathfrak{R}}([0, \infty[)$. If λ is a nonzero eigenvalue of $\mathscr{H}$, then*

$$|\dim(\ker(\lambda I - \mathscr{H})) - \dim(\ker(-\lambda I - \mathscr{H}))| \leqq 1.$$

Proof. By standard realization theory, $h(t)$, $t \geqq 0$, has a realization $(A, b, c, d) \in C_n^{1,1}$, where $n = \operatorname{rank}(\mathscr{H})$, i.e., $h(t) = c e^{tA} b$, $t \geqq 0$. We can assume that (A, b, c, d) is in the canonical form of Corollary 2.1. All nonzero eigenvalues of $\mathscr{H}$ are given by the diagonal entries of $S\Sigma = \operatorname{diag}(s_1\sigma_1 \hat{I}_{n_1}, \cdots, s_j\sigma_j \hat{I}_{n_j}, \cdots, s_k\sigma_k \hat{I}_{n_k})$. We know that $|\lambda| = |s_{i_0}\sigma_{i_0}|$ for some $1 \leqq i_0 \leqq k$, and therefore

$$|\dim(\ker(\lambda I - \mathscr{H})) - \dim(\ker(-\lambda I - \mathscr{H}))| = \operatorname{trace}|(s_{i_0} \hat{I}_{n_{i_0}})| \leqq 1. \qquad \square$$

As a simple corollary to this theorem we have that Hankel operators with positive eigenvalues cannot have repeated singular values.

COROLLARY 2.2. *If $\mathscr{H}$ as defined in the theorem has only nonnegative eigenvalues, then the multiplicity of each of the singular values is one.*

Note that single-input single-output systems whose corresponding Hankel operators have only positive nonzero eigenvalues can be characterized as relaxation systems [25].

Remark 2.2. Using a canonical form for symmetric multivariable systems, a similar result was obtained in [23] for self-adjoint Hankel operators acting on vector-valued spaces. More precisely, if $\mathscr{H}$ is a finite rank, self-adjoint Hankel operator acting on the space $L^2_{\mathfrak{R}^p}([0, \infty[)$, then

$$|\dim(\ker(\lambda I - \mathscr{H})) - \dim(\ker(-\lambda I - \mathscr{H}))| \leqq p,$$

where λ is a nonzero eigenvalue of $\mathscr{H}$.

The following remark gives further interpretations of the parameters of the canonical form and relates them to important analytical properties of the system.

Remark 2.3. If $(A, b, c, d) \in C_n^{1,1}$ is in balanced canonical form with $g(s) = c(sI - A)^{-1}b$ and $h(t) = ce^{tA}b$, $t \geqq 0$, then we have the following properties:

(i) $\|h(t)\|_2^2 := \int_0^\infty h(t)^2\,dt = \sum_{j=1}^k \sigma_j b_j^2$,

(ii) $\|g(s)\|_\infty := \sup_{w \in \Re} |g(iw)| \leqq 2\sum_{j=1}^k \sigma_j$,

(iii) $g(0) = \int_0^\infty h(t)\,dt = 2\sum_{j=1}^k s_j\sigma_j(\sum_{i=1}^{n(j)}(-1)^{i+1})$.

Note that if (A, b, c, d) has distinct singular values and $s_j = 1$ or $s_j = -1$, for all $1 \leqq j \leqq n$, then (ii) and (iii) imply that the bound in (ii) is attained, i.e.,

$$\|g(s)\|_\infty = 2\sum_{j=1}^n \sigma_j.$$

References to these results, which were slightly adapted here to our particular canonical form, can be found in [18] for (i) and (iii), [33] for (iii), and [10] for (ii).

3. Allpass systems. In the previous section we have seen that one of the main structural elements of the canonical form for asymptotically stable systems are systems with identical singular values. In this section we give an interpretation of such systems.

It was shown in [10] that each strictly proper system with identical singular values is the strictly proper part of an allpass system. Conversely, each allpass system has identical singular values. We can therefore say that the "building blocks" of the general canonical form are the strictly proper parts of allpass systems.

DEFINITION 3.1. A system $(A, B, C, D) \in C_n^{m,m}$ is called *allpass* if for $G(s) = C(sI - A)^{-1}B + D$ we have

$$G(s)G(-s)^T = \sigma^2 I, \qquad s \in \mathscr{C},$$

for some $\sigma > 0$. We denote by A_n^m the subset of $C_n^{m,m}$ containing all allpass systems. The set of transfer functions of systems in A_n^m is denoted by TA_n^m.

Remark 3.1. The usual definition of an allpass system is generalized here to the case where σ is not necessarily equal to one. Note that in the mathematical literature the transfer functions of allpass systems are referred to as inner functions in the case of $\sigma = 1$.

Allpass systems or inner functions play an important role in many aspects of control theory, circuit theory, and mathematics. It is therefore of interest to have a canonical form and a parametrization of these systems. To obtain such a canonical form and parametrization of allpass systems from the results for systems with identical singular values, it is necessary to impose a relation between the parameters U, $\tilde{B}$, D, and σ.

A canonical form for allpass systems is given in the following theorem.

THEOREM 3.1. *The following two statements are equivalent*:

(1) $G(s) \in TA_n^m$.

(2) $G(s)$ *has a realization* $(A, B, C, D) \in \Re^{n\times n} \times \Re^{n\times m} \times \Re^{m\times n} \times \Re^{m\times m}$ *given by the parameters*: $\sigma > 0$; $r \in \mathscr{N}$, $1 \leqq r \leqq n$; $\tilde{B} \in \Re^{r\times m}$ *is positive upper triangular*; $\tilde{A}$ *is in r-balanced form*; $D \in \Re^{m\times m}$ *is such that* $DD^T = \sigma^2 I$; $U = -D\tilde{B}^T\Delta^{-1}(\sqrt{\sigma})^{-1}$ *with* $\Delta = (\tilde{B}\tilde{B}^T)^{1/2}$; *in the following way*:

(i) $B = \begin{pmatrix} \tilde{B} \\ 0 \end{pmatrix}$;

(ii) $C = (U\Delta, 0)$ *where* $\Delta = (\tilde{B}\tilde{B}^T)^{1/2}$;

(iii) $A = \tilde{A} - \frac{1}{\sigma}[\operatorname{diag}(\Delta^2, 0)]_l - \frac{1}{2\sigma}[\operatorname{diag}(\Delta^2, 0)]_d$;

(iv) $D \in \Re^{m \times m}$ *is such that* $DD^T = \sigma^2 I$.

Moreover, (A, B, C, D) *as defined in* (2) *is balanced with gramian* $\Sigma = \sigma I_n$. *The map* Γ_a, *which assigns to each system in* A_n^m *the realization given in* (2), *is a canonical form.*

Proof. The proof is an application of Theorem 5.1 of [10] and Theorem 2.1. □

It follows from the previous theorem that a parametrization of systems with identical singular values immediately leads to a parametrization of allpass systems and vice versa. For SISO systems this canonical form has a particularly simple structure.

COROLLARY 3.1. *The following two statements are equivalent:*

(1) $g(s) \in TA_n^1$.

(2) $g(s)$ *has a realization* $(A, b, c, d) \in \Re^{n \times n} \times \Re^{n \times 1} \times \Re^{1 \times n} \times \Re^{1 \times 1}$ *given by the parameters*

$$\sigma > 0, \quad b > 0, \quad \alpha_j > 0, \quad 1 \leqq j \leqq n-1, \quad s_1 = \pm 1;$$

in the following way:

(i) $b = (b, 0, \cdots, 0)^T$;

(ii) $c = (s_1 b, 0, \cdots, 0)$;

(iii) $$A = \begin{pmatrix} a & \alpha_1 & & & & \\ -\alpha_1 & 0 & \alpha_2 & & & \\ & -\alpha_2 & 0 & \cdot & & 0 \\ & & \ddots & \ddots & \ddots & \\ & 0 & & \cdot & 0 & \alpha_{n-1} \\ & & & & -\alpha_{n-1} & 0 \end{pmatrix} \quad \textit{with } a = \frac{-b^2}{2\sigma};$$

(iv) $d = -s_1 \sigma$.

Moreover, (A, b, c, d) *as defined in* (2) *is balanced with gramian* $\Sigma = \sigma I_n$. *The map* Γ_a *which assigns to each system in* A_n^1 *the realization given in* (2), *is a canonical form.* □

Remark 3.2. The A-matrix in the canonical form for SISO allpass transfer functions is closely related to the so-called Schwarz form for matrices, which has been studied in connection with stability tests for matrices (see, e.g., [4]). The recursive structure of the tridiagonal matrix permits us to give explicit realization algorithms for allpass systems [21]. It also follows easily from this recursive structure that each allpass transfer function $g(s)$ can be written as a continued fraction as follows:

$$g(s) = -s_1\sigma + \cfrac{s_1 b^2}{s + \cfrac{b^2}{2\sigma} + \cfrac{\alpha_1^2}{s + \cfrac{\alpha_2^2}{\ddots \, s + \cfrac{\cdot}{s + \cfrac{\alpha_{n-1}^2}{s}}}}},$$

where $s_1, b, \sigma, \alpha_1, \cdots, \alpha_{n-1}$ are the same parameters as in the canonical form of the corollary.

4. Minimal systems. To apply the balancing technique in § 2, a system must be asymptotically stable. For minimal systems that are not necessarily asymptotically stable, Jonckheere and Silverman [16] have introduced a method that is not based on balancing solutions to Lyapunov equations but is instead based on balancing solutions to Riccati equations. Their definition of a Riccati-balanced system was extended in [27] to include a feed-through term.

DEFINITION 4.1. The class of systems $(A, B, C, D) \in \Re^{n\times n}\times\Re^{n\times m}\times\Re^{p\times n}\times\Re^{p\times m}$, which are minimal, is denoted by $L_n^{p,m}$. A system $(A, B, C, D)\in L_n^{p,m}$ is called *Riccati balanced* if there exists a positive diagonal matrix $\Sigma_l = \operatorname{diag}(q_1, \cdots, q_j, \cdots, q_n)$ such that

$$\begin{aligned}(A-BS_r^{-1}D^TC)^T\Sigma_l+\Sigma_l(A-BS_r^{-1}D^TC)-\Sigma_lBS_r^{-1}B^T\Sigma_l+C^TR_r^{-1}C=0,\\ (A-BS_r^{-1}D^TC)\Sigma_l+\Sigma_l(A-BS_r^{-1}D^TC)^T-\Sigma_lC^TR_r^{-1}C\Sigma_l+BS_r^{-1}B^T=0,\end{aligned}\tag{2}$$

where $S_r = I+D^TD$ and $R_r = I+DD^T$. Σ_l is called the *Riccati gramian* of the system.

The following canonical form for systems in $L_n^{p,m}$ is a modification of a canonical form derived in [27]. The canonical form presented here differs in two ways from the canonical form in [27]. The parametrization of the B-matrix has been changed analogously to the changes for the canonical form for asymptotically stable systems. Whereas in the present paper the B-matrix is chosen as a parameter of the system, in [27] the C-matrix serves as a parameter. As in the case of the present canonical form, such a change of parameter can be performed for all the canonical forms presented in this paper. The calculations involved are tedious but not difficult if it is noted that for $D\in\Re^{p\times m}$ we have that $D^T(I+DD^T)^{1/2}=(I+D^TD)^{1/2}D^T$.

THEOREM 4.1. *The following two statements are equivalent*:

(1) $G(s)\in TL_n^{p,m}$.

(2) *$G(s)$ has a realization $(A, B, C, D)\in\Re^{n\times n}\times\Re^{n\times m}\times\Re^{p\times n}\times\Re^{p\times m}$ given by the parameters*

$$\begin{array}{ll} q_1>\cdots>q_j>\cdots>q_k>0, & \\ n_1,\cdots,n_j,\cdots,n_k, & n_j\in\mathcal{N},\quad \sum_{j=1}^k n_j=n;\\ r_1,\cdots,r_j,\cdots,r_k, & r_j\in\mathcal{N},\quad 1\leqq r_j\leqq\min(n_j,m,p);\\ U_1,\cdots,U_j,\cdots,U_k, & U_j\in\Re^{p\times r_j},\quad U_j^TU_j=I_{r_j};\\ \tilde B_1,\cdots,\tilde B_j,\cdots,\tilde B_k, & \tilde B_j\in\Re^{r_j\times m}\ \textit{positive upper triangular};\\ \tilde A_1,\cdots,\tilde A_j,\cdots,\tilde A_k, & \tilde A_j\in\Re^{n_j\times n_j}\ \textit{in } r_j\textit{-balanced form};\\ D, & D\in\Re^{p\times m};\end{array}$$

in the following way:

If (A, B, C, D) is partitioned according to $n_1,\cdots,n_j,\cdots,n_k$, then

(i) $B_j=\begin{pmatrix}\tilde B_jS_r^{1/2}\\0\end{pmatrix}$ *where* $S_r=I+D^TD,\quad 1\leqq j\leqq k;$

(ii) $C_j=(R_r^{1/2}U_j\Delta_j,0)$ *where* $R_r=I+DD^T,\quad \Delta_j=(\tilde B_j\tilde B_j^T)^{1/2},\quad 1\leqq j\leqq k;$

(iii) $$A_{jj}=\tilde A_j-\frac{1-q_j^2}{q_j}[\operatorname{diag}(\Delta_j^2,0)]_l-\frac{1-q_j^2}{2q_j}[\operatorname{diag}(\Delta_j^2,0)]_d+\operatorname{diag}(\tilde B_jD^TU_j\Delta_j,0),\qquad 1\leqq j\leqq k;$$

(iv) $$A_{ij}=\frac{1}{q_i^2-q_j^2}\operatorname{diag}\left(\left(q_j(1+q_i^2)\tilde{B}_i\tilde{B}_j^T-q_i(1+q_j^2)\Delta_iU_i^TU_j\Delta_j\right),0\right)$$
$$+\operatorname{diag}(\tilde{B}_iD^TU_j\Delta_j,0),\qquad 1\leqq i,j\leqq k,\quad i\neq j;$$

(v) $D\in\Re^{p\times m}$.

Moreover, (A, B, C, D) as defined in (2), is Riccati balanced with gramian

$$\Sigma_l=\operatorname{diag}(q_1I_{n_1},\cdots,q_jI_{n_j},\cdots,q_kI_{n_k}).$$

The map Γ_l, which assigns to each system in $L_n^{p,m}$ the realization given in (2), is a canonical form. □

This canonical form reduces as follows to scalar systems.

COROLLARY 4.1. *The following two statements are equivalent*:

(1) $g(s)\in TL_n^{1,1}$.

(2) *$g(s)$ has a realization $(A, b, c, d)\in\Re^{n\times n}\times\Re^{n\times 1}\times\Re^{1\times n}\times\Re^{1\times 1}$ given by the parameters*

$$\begin{array}{rllll}
q_1>\cdots>q_j>\cdots>q_k>0, & & & & \\
n_1,\cdots,n_j,\cdots,n_k, & n_j\in\mathcal{N}, & \sum_{j=1}^k n_j=n; & & \\
s_1,\cdots,s_j,\cdots,s_k, & s_j=\pm1, & 1\leqq j\leqq k; & & \\
b_1,,\alpha(1)_1,\cdots,\alpha(1)_j,\cdots,\alpha(1)_{n_1-1}, & b_1>0, & \alpha(1)_j>0, & 1\leqq j\leqq n_1-1; \\
\vdots & & & \\
b_i,\alpha(i)_1,\cdots,\alpha(i)_j,\cdots,\alpha(i)_{n_i-1}, & b_i>0, & \alpha(i)_j>0, & 1\leqq j\leqq n_i-1; \\
\vdots & & & \\
b_k,\alpha(k)_1,\cdots,\alpha(k)_j,\cdots,\alpha(k)_{n_k-1}, & b_k>0, & \alpha(k)_j>0, & 1\leqq j\leqq n_k-1; \\
d, & d\in\Re; & &
\end{array}$$

in the following way:

(i) $$b=(\underbrace{b_1,0,\cdots,0}_{n_1},\cdots,\underbrace{b_j,0,\cdots,0}_{n_j},\cdots,\underbrace{b_k,0,\cdots,0}_{n_k})^T,$$

(ii) $$c=(\underbrace{s_1b_1,0,\cdots,0}_{n_1},\cdots,\underbrace{s_jb_j,0,\cdots,0}_{n_j},\cdots,\underbrace{s_kb_k,0,\cdots,0}_{n_k}),$$

(iii) *For $A=:(A_{ij})_{1\leqq i,j\leqq k}$ we have*

(a) *block diagonal entries A_{jj}, $1\leqq j\leqq k$*:

$$A_{jj}=\begin{pmatrix}
a_{jj} & \alpha(j)_1 & & & & \\
-\alpha(j)_1 & 0 & \alpha(j)_2 & & & \\
 & -\alpha(j)_2 & 0 & \cdot & & 0 \\
 & & \ddots & \ddots & \ddots & \\
 & 0 & & \cdot & 0 & \alpha(j)_{n_j-1} \\
 & & & & -\alpha(j)_{n_j-1} & 0
\end{pmatrix}$$

with $$a_{jj}=\frac{-b_j^2}{1+d^2}\left(\frac{1-q_j^2}{2q_j}-s_jd\right);$$

(b) *off-diagonal blocks* A_{ij}, $1 \leqq i, j \leqq k$, $i \neq j$:

$$A_{ij} = \begin{pmatrix} a_{ij} & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix} \quad \textit{with } a_{ij} = \frac{-b_i b_j}{1+d^2}\left(\frac{1 - s_i s_j q_i q_j}{s_i s_j q_i + q_j} - s_j d\right);$$

(iv) $d \in \mathfrak{R}$.

Moreover, (A, b, c, d) *as defined in* (2) *is Riccati balanced with Riccati gramian*

$$\Sigma_l = \operatorname{diag}(q_1 I_{n_1}, \cdots, q_j I_{n_j}, \cdots, q_k I_{n_k}).$$

The map Γ_l, *which assigns to each system in* $L_n^{1,1}$ *the realization given in* (2), *is a canonical form.*

Proof. The corollary follows immediately from the theorem and a straightforward reparametrization of the entries of the b-vector. □

It is instructive to note that this canonical form for minimal systems and the corresponding parametrization has essentially the same structure as the canonical form for asymptotically stable minimal systems. In fact, the only difference is the way in which the parameters enter those entries of the A-matrix that are functions of the other parameters. In later sections we will find that the same applies to all classes of systems considered in this paper. It should be noted, however, that in general it is not clear how the parameters of an asymptotically stable system that is parametrized using the above canonical form are related to those parameters with which the system is parametrized in the canonical form for asymptotically stable systems.

The way the canonical form for minimal systems was derived in [27] was by relating a minimal system to the state-space realization of its normalized left coprime factorization. If $G(s)$ is the transfer function of a linear system, then the normalized left coprime factorization $[N(s), M(s)]$ of $G(s)$ is defined such that $G(s) = M(s)^{-1}N(s)$, where $N(s)$, $M(s)$ are asymptotically stable with $M(s)$ proper and satisfy $NN^* + MM^* = I$. Such coprime factorizations play an important role in modern control theory [31]. If a state-space realization of $G(s)$ is available, a state-space realization of $[N(s), M(s)]$ can be calculated by solving the Riccati equations corresponding to the state-space realization of $G(s)$. The canonical form for minimal systems can then be derived by calculating the canonical form for asymptotically stable systems of the asymptotically stable coprime factors. Exploiting the state-space formulae that relate a state-space realization of a system to the state-space realization of its coprime factors, it was possible to derive the canonical form and the parametrization result for minimal systems.

In the following sections we will use the same approach to the derivation of canonical forms for other classes of systems. Rather than deriving a canonical form separately for each class of systems, explicit maps will be constructed to relate the state-space realizations of the class of systems to an appropriate subclass of the set of asymptotically stable systems. Thereby the canonical form for asymptotically stable systems can be exploited to derive a canonical form for other classes of systems.

5. Bounded real systems. An important subclass of asymptotically stable systems is that with transfer functions bounded by one on the imaginary axis. This class of so-called bounded real systems is used to parametrize all stabilizing controllers of a plant such that the closed-loop system satisfies an H^∞ constraint (see, e.g., [11]). In fact, transfer functions of bounded real systems are the real rational functions in the open unit ball of H^∞.

DEFINITION 5.1. Let $(A, B, C, D) \in C_n^{p,m}$ be such that $I - D^T D > 0$; then (A, B, C, D) is called *bounded real* if for $G(s) = C(sI - A)^{-1}B + D$ we have

$$I - G(-iw)^T G(iw) > 0, \qquad w \in \Re.$$

We denote by $B_n^{p,m}$ the subset of $C_n^{p,m}$ containing all bounded real systems. $TB_n^{p,m}$ denotes the set of transfer functions of systems in $B_n^{p,m}$.

Remark 5.1. Other authors call an asymptotically stable system bounded real if

$$I - G(-iw)^T G(iw) \geqq 0, \qquad w \in \Re.$$

In this section we will derive a canonical form for bounded real systems. To do this we first must define what we mean by balancing of bounded real systems. With the classes of systems that we considered in the previous sections, we associated certain Lyapunov and Riccati equations. A system was called balanced if the solutions to the corresponding equations were balanced, i.e., equal and diagonal. Bounded real systems can be shown to satisfy the so-called bounded real Riccati equation. We proceed analogously to define a balanced realization for bounded real systems. The following proposition states several well-known results relating bounded real systems to this Riccati equation (see, e.g., [5], [32]).

PROPOSITION 5.1. *Let $(A, B, C, D) \in C_n^{p,m}$ such that $S := I - D^T D > 0$ and $G(s) = C(sI - A)^{-1}B + D$; then*

(1) $I - G(-iw)^T G(iw) \geqq 0$, $w \in \Re$, *if and only if there exists $P = P^T > 0$ such that*

$$A^T P + PA + C^T C + (PB + C^T D)S^{-1}(PB + C^T D)^T = 0. \tag{3}$$

We call this Riccati equation the bounded real Riccati equation (BRRE).

(2) *If either of the conditions in* (1) *is satisfied, then $P = P^T > 0$ for any solution to* (3). *There exist solutions $P_{\min}$ and $P_{\max}$ to* (3) *such that for any solution $P = P^T$ we have*

$$0 < P_{\min} \leqq P \leqq P_{\max}.$$

(3) *If (A, B, C, D) is bounded real, i.e., $I - G(-iw)^T G(iw) > 0$, $w \in \Re$, then*

$$0 < P_{\min} < P_{\max}$$

and $P_{\min}$ is the unique solution to (3) *such that $A + BS^{-1}(B^T P + D^T C)$ is asymptotically stable.*

(4) *(A, B, C, D) is bounded real if there exists a solution $P = P^T > 0$ to* (3) *such that $A + BS^{-1}(B^T P + D^T C)$ is asymptotically stable. Moreover, $P_{\min}$ is the unique such solution.*

(5) *A system (A, B, C, D) is bounded real if and only if its dual system (A^T, C^T, B^T, D^T) is bounded real. If (A, B, C, D) is bounded real with $P_{\min}$ and $P_{\max}$ the minimal, respectively, maximal solution to* (3), *then $P_{\min}^{-1}$ is the maximal and $P_{\max}^{-1}$ the minimal solution to the BRRE corresponding to (A^T, C^T, B^T, D^T).*

A problem with the bounded real Riccati equation is that there is no unique positive-definite solution. Opdenacker and Jonckheere [28] introduced a balancing technique for bounded real systems by balancing the minimal solution with the inverse of the maximal solution to the BRRE. We will follow their definition since it is possible to derive the desired canonical form and realization result using this particular choice of solution. Note that balancing the minimal solution of the BRRE with the inverse of its maximal solution is the same as balancing the minimal solution with the minimal solution of the dual equation.

DEFINITION 5.2. A system $(A, B, C, D) \in B_n^{p,m}$ is called *bounded real balanced* if

$$P_{\min} = P_{\max}^{-1} = \operatorname{diag}(p_1, \cdots, p_j, \cdots, p_n) =: \Sigma_b,$$

where $P_{\min}$, $P_{\max}$ are the minimal, respectively, maximal solution to the BRRE. Σ_b is called the *bounded real gramian* of (A, B, C, D).

Remark 5.2. Note that since $P_{\max} > P_{\min}$ for systems in $B_n^{p,m}$ we have that $0 < \Sigma_b < I$.

Before we can derive a canonical form for bounded real systems we need several lemmas. The first of these states standard identities that we will frequently need.

LEMMA 5.1. *If $D \in \Re^{p\times m}$ is such that $S := I - D^TD > 0$ and $R := I - DD^T > 0$, then S and R have the following properties*:

(i) $D^TR^{-1} = S^{-1}D^T$,

(ii) $D^TR^{1/2} = S^{1/2}D^T$.

The canonical form for bounded real systems will be derived by mapping bounded real systems to a certain class of asymptotically stable systems. The significance of this map is that it maps bounded real balanced systems to asymptotically stable systems that are balanced with respect to the corresponding Lyapunov equations. A canonical form for bounded real systems can therefore be derived by bringing the associated asymptotically stable systems to the canonical form of Theorem 2.1. Reversing the map, we can obtain the desired canonical form for bounded real systems.

The following lemma establishes the map between bounded real systems and a subclass of asymptotically stable systems.

LEMMA 5.2. *Let $(A, B, C, D) \in B_n^{p,m}$. If $P_{\min}$ is the minimal and $P_{\max}$ the maximal solution to the* BRRE, *then with $S = I - D^TD$ and $R = I - DD^T$ we have that*

$$(A_c, B_c, C_c, D_c) := \left(A + BS^{-1}D^TC, [BS^{-1/2}, P_{\max}^{-1}C^TR^{-1/2}], \begin{bmatrix} R^{-1/2}C \\ S^{-1/2}B^TP_{\min} \end{bmatrix}, D\right)$$

$$\in C_n^{p+m,p+m}$$

and

$$A_cP_{\max}^{-1} + P_{\max}^{-1}A_c^T = -B_cB_c^T, \tag{4}$$

$$A_c^TP_{\min} + P_{\min}A_c = -C_c^TC_c. \tag{5}$$

Proof. First note that $\tilde{P} = \tilde{P}^T > 0$ solves the bounded real Riccati equation

$$A^TP + PA + C^TC + (PB + C^TD)S^{-1}(PB + C^TD)^T = 0$$

if and only if $\tilde{P}^{-1}$ solves the dual equation

$$AP + PA^T + BB^T + (PC^T + BD^T)R^{-1}(PC^T + BD^T)^T = 0.$$

It is now easy to verify that these two Riccati equations can be rewritten as the Lyapunov equations (4), (5) with $P_{\max}^{-1}$ and $P_{\min}$ as their solutions. Since $P_{\max}^{-1} > 0$ and $P_{\min} > 0$ we have that (A_c, B_c, C_c, D_c) is minimal if and only if A_c is asymptotically stable. Since (A_c, B_c, D_c, C_c) satisfies the Lyapunov equations (4), (5) we know that the eigenvalues of A_c are in the closed left halfplane. To show that they are in fact in the open left halfplane, assume there exists $w \in \Re$ and $x \in \mathscr{C}^n$ such that

$$A_cx = iwx.$$

By applying x to the right and x^* to the left of (5), i.e.,

$$x^*A_c^TP_{\min}x + x^*P_{\min}A_cx = 0 = -x^*C_c^TC_cx,$$

we obtain that $Cx=0$ and thus

$$A_c x = (A + BS^{-1}D^TC)x = Ax = iwx.$$

Hence by the PBH test we have that (A, B, C, D) is not observable, which is a contradiction to the assumption. This implies the asymptotic stability of A_c and the minimality of (A_c, B_c, C_c, D_c). □

In the following lemma the inverse of the map of the previous lemma will be investigated.

LEMMA 5.3. *Let* $(A, B, C, D) \in \Re^{n\times n} \times \Re^{n\times m} \times \Re^{p\times n} \times \Re^{p\times m}$ *be such that* $S := I - D^TD > 0$, $R := I - DD^T$, *and* $P = P^T > 0$, *such that* $P^{-1} > P$. *If*

$$(A_c, B_c, C_c, D_c) := \left(A + BS^{-1}D^TC, [BS^{-1/2}, PC^TR^{-1/2}], \begin{bmatrix} R^{-1/2}C \\ S^{-1/2}B^TP \end{bmatrix}, D \right) \in C_n^{p+m,p+m}$$

with

$$A_cP + PA_c^T = -B_cB_c^T, \tag{6}$$

$$A_c^TP + PA_c = -C_c^TC_c, \tag{7}$$

then $(A, B, C, D) \in C_n^{p,m}$. *Under the same conditions the eigenvalues of* $A + BS^{-1}(B^TP + D^TC)$ *are in the open left halfplane.*

Proof. First note that the Lyapunov equation (6) can be rewritten as

$$\begin{aligned} 0 = {} & (A + BS^{-1}D^TC + BS^{-1}B^TP)P + P(A + BS^{-1}D^TC + BS^{-1}B^TP)^T \\ & + (I - P^2)BS^{-1}B^T(I - P^2) - P^2BS^{-1}B^TP^2 + PC^TR^{-1}CP, \end{aligned} \tag{8}$$

which is equivalent to

$$\begin{aligned} 0 = {} & (A + BS^{-1}D^TC + BS^{-1}B^TP)^TP^{-1} + P^{-1}(A + BS^{-1}D^TC + BS^{-1}B^TP) \\ & + (P^{-1} - P)BS^{-1}B^T(P^{-1} - P) - PBS^{-1}B^TP + C^TR^{-1}C. \end{aligned} \tag{9}$$

Similarly, (7) can be rewritten as

$$\begin{aligned} 0 = {} & (A + BS^{-1}D^TC + BS^{-1}B^TP)^TP + P(A + BS^{-1}D^TC + BS^{-1}B^TP) \\ & - PBS^{-1}B^TP + C^TR^{-1}. \end{aligned} \tag{10}$$

Subtracting (10) from (9) we obtain

$$\begin{aligned} 0 = {} & (A + BS^{-1}D^TC + BS^{-1}B^TP)^T(P^{-1} - P) \\ & + (P^{-1} - P)(A + BS^{-1}D^TC + BS^{-1}B^TP) + (P^{-1} - P)BS^{-1}B^T(P^{-1} - P). \end{aligned} \tag{11}$$

Since $P^{-1} - P > 0$ we can pre- and post-multiply this equation by $(P^{-1} - P)^{-1}$, and hence

$$\begin{aligned} 0 = {} & (A + BS^{-1}D^TC + BS^{-1}B^TP)(P^{-1} - P)^{-1} \\ & + (P^{-1} - P)^{-1}(A + BS^{-1}D^TC + BS^{-1}B^TP)^T + BS^{-1}B^T. \end{aligned} \tag{12}$$

Since $(P^{-1} - P)^{-1} > 0$ this Lyapunov equation implies that $A + BS^{-1}D^TC + BS^{-1}B^TP$ is asymptotically stable if and only if $(A + BS^{-1}D^TC + BS^{-1}B^TP, BS^{-1/2})$ is controllable. If we assume that this is not the case, then there exist $\lambda \in \mathscr{C}$ and $x \in \mathscr{C}^n$ such that

$$x^*(A + BS^{-1}D^TC + BS^{-1}B^TP) = \lambda x^*, \qquad x^*BS^{-1/2} = 0.$$

Pre- and post-multiplying (12) by x^* and x, respectively, we obtain that $\operatorname{Re}(\lambda) \leqq 0$. Now assume that $\lambda = iw$, $w \in \Re$; then,

$$x^*(A + BS^{-1}D^TC) = iwx^*,$$

which is a contradiction to the asymptotic stability of $A + BS^{-1}D^TC$. Hence we have the controllability of

$$(A + BS^{-1}D^TC + BS^{-1}B^TP, BS^{-1/2})$$

and the asymptotic stability of $A + BS^{-1}D^TC + BS^{-1}B^TP$. An application of the PBH test now implies the controllability of (A, B).

We can show similarly that

$$(A + BS^{-1}D^TC + PC^TR^{-1}C, R^{-1/2}C)$$

is observable and hence that (A, C) is observable. Having shown the minimality of (A, B, C, D) it remains to show that A is asymptotically stable.

Note that the Lyapunov equation (7) can be rewritten as

$$A^TP + PA + C^TC + (B^TP + D^TC)^TS^{-1}(B^TP + D^TC) = 0.$$

Thus A is asymptotically stable if and only if

$$\left(A, \begin{bmatrix} C \\ S^{-1/2}(B^TP + D^TC) \end{bmatrix}\right)$$

is observable. But if this system is not observable we have that (A, C) is not observable, which is a contradiction to the minimality of (A, B, C, D).

We are now in a position to prove the main theorem of this section, which establishes a canonical form for bounded real systems. Note that the main problem in the proof of the theorem will be to show the "parametrization part" of the result, i.e., that a system with a particular structure is indeed bounded real. Due to the particular parametrization of the systems, a solution of the bounded real Riccati equation can be written immediately. To show that the system is bounded real, it is, however, necessary to show that this solution is the minimal solution. In the previous lemma we have already gone some way toward showing this.

THEOREM 5.1. *The following two statements are equivalent*:

(1) $B(s) \in TB_n^{p,m}$.

(2) $B(s)$ *has a realization* $(A, B, C, D) \in \Re^{n\times n} \times \Re^{n\times m} \times \Re^{p\times n} \times \Re^{p\times m}$ *given by the parameters*:

$$\begin{array}{ll}
1 > p_1 > \cdots > p_j > \cdots > p_k > 0, & \\
n_1, \cdots, n_j, \cdots, n_k, & n_j \in \mathcal{N}, \quad \sum_{j=1}^k n_j = n; \\
r_1, \cdots, r_j, \cdots, r_k, & r_j \in \mathcal{N}, \quad 1 \leqq r_j \leqq \min(n_j, m, p); \\
U_1, \cdots, U_j, \cdots, U_k, & U_j \in \Re^{p\times r_j}, \quad U_j^TU_j = I_{r_j}, \\
\tilde{B}_1, \cdots, \tilde{B}_j, \cdots, \tilde{B}_k, & \tilde{B}_j \in \Re^{r_j\times m} \textit{ positive upper triangular}; \\
\tilde{A}_1, \cdots, \tilde{A}_j, \cdots, \tilde{A}_k, & \tilde{A}_j \in \Re^{n_j\times n_j} \textit{ in } r_j\textit{-balanced form}; \\
D, & D \in \Re^{p\times m}, \quad I - D^TD > 0;
\end{array}$$

in the following way:

If (A, B, C, D) *is partitioned according to* $n_1, \cdots, n_j, \cdots, n_k$, *then*

(i) $B_j = \begin{pmatrix} \tilde{B}_jS^{1/2} \\ 0 \end{pmatrix}$ *where* $S = I - D^TD$, $1 \leqq j \leqq k$;

(ii) $C_j = (R^{1/2} U_j \Delta_j, 0)$ *where* $R = I - DD^T$, $\Delta_j = (\tilde{B}_j \tilde{B}_j^T)^{1/2}$, $1 \leqq j \leqq k$;

(iii) $$A_{jj} = \tilde{A}_j - \frac{1+p_j^2}{p_j}[\operatorname{diag}(\Delta_j^2, 0)]_l - \frac{1+p_j^2}{2p_j}[\operatorname{diag}(\Delta_j^2, 0)]_d - \operatorname{diag}(\tilde{B}_j D^T U_j \Delta_j, 0), \qquad 1 \leqq j \leqq k;$$

(iv) $$A_{ij} = \frac{1}{p_i^2 - p_j^2}(p_j(1-p_i^2)\operatorname{diag}(\tilde{B}_i \tilde{B}_j^T, 0) - p_i(1-p_j^2)\operatorname{diag}(\Delta_i U_i^T U_j \Delta_j, 0)) - \operatorname{diag}(B_i D^T U_j \Delta_j, 0), \qquad 1 \leqq i, j \leqq k, \quad i \neq j.$$

(v) $D \in \Re^{p \times m}$, $\quad I - D^T D > 0$.

Moreover, (A, B, C, D) *as defined in* (2) *is bounded real balanced with bounded real gramian*

$$\Sigma_b = \operatorname{diag}(p_1 I_{n_1}, \cdots, p_j I_{n_j}, \cdots, p_k I_{n_k}).$$

The map Γ_b, *which assigns to each system in* $B_n^{p,m}$ *the realization given in* (2), *is a canonical form.*

Proof. (1) ⇒ (2) Let $(A, B, C, D) \in B_n^{p,m}$ and let $(A_c, B_c, C_c, D_c) \in C_n^{p+m,p+m}$ be the uniquely defined system in Lemma 5.2. If $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ is another system in $B_n^{p,m}$ and $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c) \in C_n^{p+m,p+m}$ is given as in Lemma 5.2, then (A, B, C, D) and $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ are system equivalent if and only if (A_c, B_c, C_c, D_c) and $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ are system equivalent. Since (A_c, B_c, C_c, D_c) satisfies the Lyapunov equations (4) and (5) this shows that (A, B, C, D) is bounded real balanced with bounded real gramian Σ_b if and only if (A_c, B_c, C_c, D_c) is balanced with gramian $\Sigma = \Sigma_b = \operatorname{diag}(p_1 I_{n_1}, \cdots, p_j I_{n_j}, \cdots, p_k I_{n_k}) < 1$. We can therefore assume that (A_c, B_c, C_c, D_c) is in the canonical form of Theorem 2.1.

Partitioning the systems in the usual way and using the notation of Theorem 2.1, we obtain

$$B_{c,j} = (B_j S^{-1/2}, p_j C_j^T R^{-1/2}) = \begin{pmatrix} \tilde{B}_{c,j} \\ 0 \end{pmatrix}, \tag{13}$$

with $\tilde{B}_{c,j} \in \Re^{r_j \times (p+m)}$ positive upper triangular and

$$C_{c,j} = \begin{pmatrix} R^{-1/2} C_j \\ p_j S^{-1/2} B_j^T \end{pmatrix} = (U_{c,j} \Delta_{c,j}, 0), \tag{14}$$

where $U_{c,j} \in \Re^{(p+m) \times r_j}$, $U_{c,j}^T U_{c,j} = I_{r_j}$, and $\Delta_{c,j} = (\tilde{B}_{c,j} \tilde{B}_{c,j}^T)^{1/2}$. Since (A_c, B_c, C_c, D_c) is balanced, $B_{c,j} B_{c,j}^T = C_{c,j}^T C_{c,j}$ and therefore we have that

$$B_{c,j} B_{c,j}^T = B_j S^{-1} B_j^T + p_j^2 C_j^T R^{-1} C_j = C_j^T R^{-1} C_j + p_j^2 B_j S^{-1} B_j^T$$

and hence $B_j S^{-1} B_j^T = C_j^T R^{-1} C_j$, which implies that

$$B_{c,j} B_{c,j}^T = (1 + p_j^2) B_j S^{-1} B_j^T. \tag{15}$$

Therefore $r_j = \operatorname{rank}(B_{c,j}) = \operatorname{rank}(\tilde{B}_{c,j}) = \operatorname{rank}(B_j S^{-1/2})$, which implies together with (13) that

$$B_j S^{-1/2} = \begin{pmatrix} \tilde{B}_j \\ 0 \end{pmatrix}$$

with $\tilde{B}_j$ positive upper triangular. This shows (i).

The fact that

$$\operatorname{diag}(\tilde B_j\tilde B_j^T, 0) = B_jS^{-1}B_j^T = C_j^TR^{-1}C_j$$

immediately implies

$$R^{-1/2}C_j = (U_j\Delta_j, 0), \qquad \Delta_j = (\tilde B_j\tilde B_j^T)^{1/2},$$

for a unique $U_j \in \Re^{p\times r_j}$ such that $U_j^TU_j = I_{r_j}$ and hence (ii).

Since by Lemma 5.2

$$A_{c,jj} = \tilde A_{c,j} - \frac{1}{p_j}[B_{c,j}B_{c,j}^T]_l - \frac{1}{2p_j}[B_{c,j}B_{c,j}^T]_d = A_{jj} + B_jS^{-1}D^TC_j,$$

we have using (13), (14), (15)(i), and (15)(ii), and Lemma 5.1,

$$A_{jj} = \tilde A_{c,j} - \frac{1+p_j^2}{p_j}[\operatorname{diag}(\Delta_j^2, 0)]_l - \frac{1+p_j^2}{2p_j}[\operatorname{diag}(\Delta_j^2, 0)]_d - \operatorname{diag}(\tilde B_jD^TU_j\Delta_j, 0).$$

Hence we obtain (iii) by setting $\tilde A_j := \tilde A_{c,j}$.

The parametrization of A_{ij} in (iv) follows immediately from the parametrization of $A_{c,ij}$ in Theorem 2.1 as well as from the expressions for $A_{c,ij}$, $B_{c,j}$, and $C_{c,j}$ in Lemma 5.2.

(2) ⇒ (1) Let (A, B, C, D) be parametrized as in (2). To show $(A, B, C, D) \in C_n^{p,m}$ we construct

$$(A_c, B_c, C_c, D_c) := \left(A + BS^{-1}D^TC, [BS^{-1/2}, PC^TR^{-1/2}], \begin{bmatrix} R^{-1/2}C \\ S^{-1/2}B^TP \end{bmatrix}, D\right),$$

where $P = \operatorname{diag}(p_1I_{n_1}, \cdots, p_jI_{n_j}, \cdots, p_kI_{n_k})$, $S = I - D^TD$, and $R = I - DD^T$.

We must show that (A_c, B_c, C_c, D_c) is in balanced canonical form of Theorem 2.1. To do this we partition the systems in the standard way. Then

$$B_{c,j} = \begin{pmatrix} \tilde B_j & p_j\Delta_jU_j^T \\ 0 & 0 \end{pmatrix},$$

which is positive upper triangular. For $C_{c,j}$ we have

$$C_{c,j} = \begin{pmatrix} U_j\Delta_j & 0 \\ p_j\tilde B_j^T & 0 \end{pmatrix}.$$

Setting

$$\Delta_{c,j}^2 := \tilde B_{c,j}\tilde B_{c,j}^T = \operatorname{diag}((1+p_j^2)\Delta_j^2, 0)$$

and

$$U_{c,j} := \frac{1}{\sqrt{1+p_j^2}}\begin{pmatrix} U_j & 0 \\ p_j\tilde B_j^T\Delta_j^{-1} & 0 \end{pmatrix},$$

we have that

$$C_{c,j} = (U_{c,j}\Delta_{c,j}, 0)$$

with $U_{c,j}^TU_{c,j} = Ir_j$.

That $A_{c,jj}$ and $A_{c,ij}$ are of the required form follows similarly to the derivations in the first part of the proof. Thus (A_c, B_c, C_c, D_c) is parametrized in the balanced canonical form of Theorem 2.1 with gramian P and hence it is in $C_n^{p+m,p+m}$. Since $P^{-1} > P$ Lemma 5.3 implies that $(A, B, C, D) \in C_n^{p,m}$.

To show that (A, B, C, D) is bounded real balanced we must show that P is the minimal and that P^{-1} is the maximal solution to the BRRE. That (A, B, C, D) is bounded real and P is the minimal solution to the BRRE follows since, by construction, P solves the BRRE corresponding to (A, B, C, D) and because of Lemma 5.3 and Proposition 5.1. Repeating the above arguments for the dual system shows that P is also the minimal solution to the dual bounded real Riccati equation. Proposition 5.1 then implies that P^{-1} is the maximal solution to the BRRE. □

Specializing this theorem to the SISO case we obtain the following corollary.

COROLLARY 5.1. *The following two statements are equivalent*:

(1) $b(s) \in TB_n^{1,1}$.

(2) $b(s)$ *has a realization* $(A, b, c, d) \in \Re^{n\times n} \times \Re^{n\times 1} \times \Re^{1\times n} \times \Re^{1\times 1}$ *given by the parameters*:

$$\begin{array}{lll}
1 > p_1 > \cdots > p_j > \cdots > p_k > 0, & & \\
n_1, \cdots, n_j, \cdots, n_k, & n_j \in \mathcal{N}, \quad \sum_{j=1}^{k} n_j = n; & \\
s_1, \cdots, s_j, \cdots, s_k, & s_j = \pm 1, \quad 1 \leqq j \leqq k; & \\
b_1, \alpha(1)_1, \cdots, \alpha(1)_j, \cdots, \alpha(1)_{n_1-1}, & b_1 > 0, \quad \alpha(1)_j > 0, & 1 \leqq j \leqq n_1 - 1; \\
\vdots & & \\
b_i, \alpha(i)_1, \cdots, \alpha(i)_j, \cdots, \alpha(i)_{n_i-1}, & b_i > 0, \quad \alpha(i)_j > 0, & 1 \leqq j \leqq n_i - 1; \\
\vdots & & \\
b_k, \alpha(k)_1, \cdots, \alpha(k)_j, \cdots, \alpha(k)_{n_k-1}, & b_k > 0, \quad \alpha(k)_j > 0, & 1 \leqq j \leqq n_k - 1; \\
d, & d \in \Re, \quad |d| < 1; &
\end{array}$$

in the following way:

(i) $b = (\underbrace{b_1, 0, \cdots, 0}_{n_1}, \cdots, \underbrace{b_j, 0, \cdots, 0}_{n_j}, \cdots, \underbrace{b_k, 0, \cdots, 0}_{n_k})^T$,

(ii) $c = (\underbrace{s_1 b_1, 0, \cdots, 0}_{n_1}, \cdots, \underbrace{s_j b_j, 0, \cdots, 0}_{n_j}, \cdots, \underbrace{s_k b_k, 0, \cdots, 0}_{n_k})$,

(iii) *For* $A =: (A_{ij})_{1 \leqq i,j \leqq k}$ *we have*

(a) *block diagonal entries* A_{jj}, $1 \leqq j \leqq k$:

$$A_{jj} = \begin{pmatrix}
a_{jj} & \alpha(j)_1 & & & & \\
-\alpha(j)_1 & 0 & \alpha(j)_2 & & & \\
 & -\alpha(j)_2 & 0 & \cdot & & 0 \\
 & & \ddots & \ddots & \ddots & \\
 & 0 & & \cdot & 0 & \alpha(j)_{n_j-1} \\
 & & & & -\alpha(j)_{n_j-1} & 0
\end{pmatrix}$$

with $a_{jj} = \dfrac{-b_j^2}{1-d^2}\left(\dfrac{1+p_j^2}{2p_j} + s_j d\right)$;

(b) *off-diagonal blocks* A_{ij}, $1 \leqq i, j \leqq k$, $i \neq j$:

$$A_{ij} = \begin{pmatrix}
a_{ij} & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & 0
\end{pmatrix} \quad \textit{with } a_{ij} = \frac{-b_i b_j}{1-d^2}\left(\frac{1 + s_i s_j p_i p_j}{s_i s_j p_i + p_j} + s_j d\right);$$

(iv) $d \in \Re$, $|d| < 1$.

Moreover, (A, b, c, d) *as defined in* (2) *is bounded real balanced with bounded real gramian*

$$\Sigma_b = \operatorname{diag}(p_1 I_{n_1}, \cdots, p_j I_{n_j}, \cdots, p_k I_{n_k}).$$

The map Γ_b, *which assigns to each system in* $B_n^{1,1}$ *the realization given in* (2), *is a canonical form.*

Proof. The corollary follows immediately from the theorem and a straightforward reparametrization of the entries of the b-vector. □

If we analyze the canonical form we have just derived, we can see that it again has the same structure as the canonical forms of the previous sections. The only difference between this canonical form and the previous ones is in the way the parameters enter the A-matrix and that the parameters $p_1, \cdots, p_k$ are bounded by one.

6. Positive real systems. Positive real systems play an important role in many parts of deterministic and stochastic control and system theory. Balanced realizations of positive real systems were introduced in [7] because of their importance in stochastic systems theory (see, e.g., [8], [6]). In this section we will study the question of the parametrization of positive real systems. The approach we take is analogous to the one we have taken in previous sections. We associate a certain type of Riccati equation with positive real systems, the so-called positive real Riccati equations. Balanced realizations for positive real systems are then defined by balancing the minimal solutions of these equations. We could now derive a canonical form for positive real systems in an analogous way to the way the canonical form was derived for asymptotically stable systems in Theorem 2.1. Instead, we use a Moebius transformation to map positive real systems to bounded real systems. In this way we can easily carry to canonical form for bounded real systems over to provide a canonical form and parametrization for positive real systems.

DEFINITION 6.1. A system $(A, B, C, D) \in C_n^{m,m}$ such that $D + D^T > 0$ is called *positive real* if

$$G(iw) + G(-iw)^T > 0, \qquad w \in \Re.$$

We denote by P_n^m the subset of $C_n^{m,m}$ containing all positive real systems. TP_n^m denotes the set of transfer functions of systems in P_n^m.

The derivation of a canonical form for systems in P_n^m will be based on the relationship between positive real and bounded real systems obtained by applying a Moebius transformation to the set $TB_n^{m,m}$ which maps $TB_n^{m,m}$ to TP_n^m (see, e.g., [5]):

$$\begin{aligned} M\colon \quad & TB_n^{m,m} \to TP_n^m \\ & B(s) \;\mapsto P(s) := (I - B(s))^{-1}(I + B(s)). \end{aligned}$$

M is a bijection with inverse

$$\begin{aligned} M^{-1}\colon \quad & TP_n^m \to TB_n^{m,m} \\ & P(s) \mapsto B(s) := (P(s) - I)(P(s) + I)^{-1}. \end{aligned}$$

The corresponding state-space formulae are given in the following proposition.

PROPOSITION 6.1. *The map*

$$\begin{aligned} S_{BP}\colon \quad & B_n^{m,m} \to P_n^m \\ & (A, B, C, D) \mapsto (A + B(I-D)^{-1}C, \sqrt{2}\, B(I-D)^{-1}, \\ & \qquad\qquad \sqrt{2}(I-D)^{-1}C, (I-D)^{-1}(I+D)) \end{aligned}$$

is a bijection with inverse

$$
\begin{aligned}
S_{BP}^{-1}:\quad & P_n^m \to B_n^{m,m}\\
& (A, B, C, D) \mapsto (A - B(I+D)^{-1}C, \sqrt{2}\, B(I+D)^{-1},\\
&\qquad\qquad\qquad\qquad \sqrt{2}\,(I+D)^{-1}C, (D-I)(D+I)^{-1}),
\end{aligned}
$$

such that

- S_{BP} *preserves system equivalence.*
- $P = P^T > 0$ *is a solution to the* BRRE *for* $(A, B, C, D) \in B_n^{m,m}$ *if and only if* $P = P^T > 0$ *is a solution to the positive real Riccati equation* (PRRE)
$$\tilde{A}^T P + P\tilde{A} + (\tilde{C} - \tilde{B}^T P)^T (\tilde{D} + \tilde{D}^T)^{-1} (\tilde{C} - \tilde{B}^T P) = 0$$
for $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D}) := S_{BP}((A, B, C, D))$.

This proposition implies that we can define a balanced positive real system analogously to the bounded real case by balancing the minimal solution to the PRRE with the inverse of its maximal solution. Note that this amounts to balancing the minimal solution of the PRRE with the minimal solution of its dual equation.

DEFINITION 6.2. A system $(A, B, C, D) \in P_n^m$ is called *positive real balanced* if

$$P_{\min} = P_{\max}^{-1} = \operatorname{diag}(p_1, \cdots, p_j, \cdots, p_n) =: \Sigma_p,$$

where $P_{\min}$, $P_{\max}$ is the minimal, respectively, maximal solution to the PRRE. Σ_p is called the *positive real gramian* of (A, B, C, D).

As an immediate consequence of the previous proposition, we have that balancing is preserved by the map S_{BP}.

COROLLARY 6.1. *A system* $(A, B, C, D) \in B_n^{m,m}$ *is bounded real balanced with bounded real gramian* Σ_b *if and only if* $S_{BP}((A, B, C, D))$ *is positive real balanced with positive real gramian* $\Sigma_p = \Sigma_b$.

Proposition 6.1 together with the canonical form for bounded real systems in Theorem 5.1 allows us to immediately derive a canonical form for systems in P_n^m.

THEOREM 6.1. *The following two statements are equivalent*:

(1) $P(s) \in TP_n^m$.

(2) $P(s)$ *has a realization* $(A, B, C, D) \in \Re^{n\times n} \times \Re^{n\times m} \times \Re^{m\times n} \times \Re^{m\times m}$ *given by the following parameters*:

$$
\begin{array}{ll}
1 > p_1 > \cdots > p_j > \cdots > p_k > 0, & \\
n_1, \cdots, n_j, \cdots, n_k, & n_j \in \mathcal{N},\quad \sum_{j=1}^k n_j = n;\\
r_1, \cdots, r_j, \cdots, r_k, & r_j \in \mathcal{N},\quad 1 \leqq r_j \leqq \min(n_j, m);\\
U_1, \cdots, U_j, \cdots, U_k, & U_j \in \Re^{m\times r_j}, U_j^T U_j = I_{r_j};\\
\tilde{B}_1, \cdots, \tilde{B}_j, \cdots, \tilde{B}_k, & \tilde{B}_j \in \Re^{r_j\times m}\quad \textit{positive upper triangular};\\
\tilde{A}_1, \cdots, \tilde{A}_j, \cdots, \tilde{A}_k, & \tilde{A}_j \in \Re^{n_j\times n_j}\quad \textit{in } r_j\textit{-balanced form};\\
D_b, & D_b \in \Re^{m\times m},\quad I - D_b^T D_b > 0
\end{array}
$$

in the following way:

If (A, B, C, D) *is partitioned as* $n_1, \cdots, n_j, \cdots, n_k$, *then*,

(i) $B_j = \begin{pmatrix} \sqrt{2}\, \tilde{B}_j S^{1/2} (I - D_b)^{-1} \\ 0 \end{pmatrix}$ *where* $S = I - D_b^T D_b$, $1 \leqq j \leqq k$;

(ii) $C_j = (\sqrt{2}(I - D_b)^{-1} R^{1/2} U_j \Delta_j, 0)$ *where* $R = I - D_b D_b^T$, $\Delta_j = (\tilde{B}_j \tilde{B}_j^T)^{1/2}$, $1 \leqq j \leqq k$;

(iii) $$A_{jj}=\tilde{A}_j-\frac{1+p_j^2}{p_j}[\operatorname{diag}(\Delta_j^2,0)]_l-\frac{1+p_j^2}{2p_j}[\operatorname{diag}(\Delta_j^2,0)]_d$$
$$+\operatorname{diag}(\tilde{B}_jS^{-1/2}(I-D_b^T)(I-D_b)^{-1}R^{1/2}U_j\Delta_j,0)\,,\qquad 1\leqq j\leqq k;$$

(iv) $$A_{ij}=\frac{1}{p_i^2-p_j^2}(p_j(1-p_i^2)\operatorname{diag}(\tilde{B}_i\tilde{B}_j^T,0)-p_i(1-p_j^2)\operatorname{diag}(\Delta_iU_i^TU_j\Delta_j,0))$$
$$+\operatorname{diag}(\tilde{B}_iS^{-1/2}(I-D_b^T)(I-D_b)^{-1}R^{1/2}U_j\Delta_j,0),$$
$$1\leqq i,j\leqq k,\quad i\neq j.$$

(v) $D=(I-D_b)^{-1}(I+D_b)$.

Moreover, (A, B, C, D) as defined (2) is positive real balanced with positive real gramian

$$\Sigma_p=\operatorname{diag}(p_1I_{n_1},\cdots,p_jI_{n_j},\cdots,p_kI_{n_k}).$$

The map Γ_p, which assigns to each system in P_n^m the realization given in (2), is a canonical form.

COROLLARY 6.2. *The following two statements are equivalent:*

(1) $p(s)\in TP_n^1$.

(2) *$p(s)$ has a realization $(A,b,c,d)\in\mathfrak{R}^{n\times n}\times\mathfrak{R}^{n\times 1}\times\mathfrak{R}^{1\times n}\times\mathfrak{R}^{1\times 1}$ given by the parameters:*

$$\begin{array}{lll}
1>p_1>\cdots>p_j>\cdots>p_k>0 & & \\
n_1,\cdots,n_j,\cdots,n_k, & n_j\in\mathcal{N},\quad \sum_{j=1}^k n_j=n; & \\
s_1,\cdots,s_j,\cdots,s_k, & s_j=\pm1,\quad 1\leqq j\leqq k; & \\
b_1,\alpha(1)_1,\cdots,\alpha(1)_j,\cdots,\alpha(1)_{n_1-1}, & b_1>0,\quad \alpha(1)_j>0, & 1\leqq j\leqq n_1-1;\\
\vdots & & \\
b_i,\alpha(i)_1,\cdots,\alpha(i)_j,\cdots,\alpha(i)_{n_i-1}, & b_i>0,\quad \alpha(i)_j>0, & 1\leqq j\leqq n_i-1;\\
\vdots & & \\
b_k,\alpha(k)_1,\cdots,\alpha(k)_j,\cdots,\alpha(k)_{n_k-1}, & b_k>0,\quad \alpha(k)_j>0, & 1\leqq j\leqq n_k-1;\\
d, & d\in\mathfrak{R},\quad d>0; &
\end{array}$$

in the following way:

(i) $b=(\underbrace{b_1,0,\cdots,0}_{n_1},\cdots,\underbrace{b_j,0,\cdots,0}_{n_j},\cdots,\underbrace{b_k,0,\cdots,0}_{n_k})^T,$

(ii) $c=(\underbrace{s_1b_1,0,\cdots,0}_{n_1},\cdots,\underbrace{s_jb_j,0,\cdots,0}_{n_j},\cdots,\underbrace{s_kb_k,0,\cdots,0}_{n_k}),$

(iii) *For $A=:(A_{ij})_{1\leqq i,j\leqq k}$ we have*

(a) *block diagonal entries A_{jj}, $1\leqq j\leqq k$:*

$$A_{jj}=\begin{pmatrix}
a_{jj} & \alpha(j)_1 & & & & \\
-\alpha(j)_1 & 0 & \alpha(j)_2 & & & \\
 & -\alpha(j)_2 & 0 & \cdot & & 0\\
 & & \ddots & \ddots & \ddots & \\
 & 0 & & \cdot & 0 & \alpha(j)_{n_j-1}\\
 & & & & -\alpha(j)_{n_j-1} & 0
\end{pmatrix}$$

with $a_{jj}=\dfrac{-b_j^2}{4dp_j}(1-s_jp_j)^2;$

(b) *off-diagonal blocks* A_{ij}, $1 \leqq i, j \leqq k$, $i \neq j$:

$$A_{ij} = \begin{pmatrix} a_{ij} & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix} \quad \textit{with } a_{ij} = \frac{-b_i b_j}{2d(s_i s_j p_i + p_j)}(1 - s_i p_i)(1 - s_j p_j);$$

(iv) $d \in \Re$, $d > 0$.

Moreover, (A, b, c, d) *as defined in* (2) *is positive real balanced with positive real gramian*

$$\Sigma_p = \operatorname{diag}(p_1 I_{n_1}, \cdots, p_j I_{n_j}, \cdots, p_k I_{n_k}).$$

The map Γ_p, *which assigns to each system in* P_n^1 *the realization given in* (2), *is a canonical form.*

Note that in the derivation of the corollary from the theorem we have used an obvious reparametrization of the b-vector to obtain the usual statement of the result. The previous theorem and corollary show the by-now-expected structure of the canonical form.

7. Minimum-phase systems. The last class of systems for which we would like to derive a canonical form is the class of minimum-phase systems. A minimum-phase system is an asymptotically stable system whose inverse system is also asymptotically stable. Minimum-phase systems, therefore, are precisely those systems whose transfer functions are real rational functions in H^∞, which are units, i.e., invertible in H^∞. These systems are of importance in many different areas. In this section, however, we are mainly interested in results concerning minimum-phase systems that are motivated by problems in stochastic system theory, since those results allow us to use the canonical form derived for positive real systems to obtain a canonical form for minimum-phase systems.

DEFINITION 7.1. A system $(A, B, C, D) \in C_n^{m,m}$ such that D is invertible is called *minimum phase* if $A - BD^{-1}C$ has its eigenvalues in the open left halfplane. We denote by M_n^m the subset of $C_n^{m,m}$ containing all minimum-phase systems. TM_n^m denotes the set of transfer functions of systems in M_n^m.

The role minimum-phase systems play in the spectral factorization problem is indicated in the following proposition, which summarizes some standard results (see, e.g., [8], [32]).

PROPOSITION 7.1.

(1) *Let* $(A, B, C, D) \in C_n^{m,m}$ *such that* $D + D^T > 0$ *and assume that there exists a solution* $P = P^T > 0$ *to the corresponding* PRRE. *Then the following statements are equivalent*:

(i) $(A, B, C, D) \in P_n^m$.

(ii) *The minimal solution* $P_{\min}$ *and the maximal solution* $P_{\max}$ *to the* PRRE *are such that* $0 < P_{\min} < P_{\max}$.

(iii) *There exists a solution* P_0 *to the* PRRE *such that the eigenvalues of*

$$A - B(D + D^T)^{-1}(C - B^T P_0)$$

are in the open left halfplane.

If (iii) *is satisfied, then* $P_0 = P_{\min}$.

(2) *Let* $P(s) \in TP_n^m$ *with realization* $(A, B, C, D) \in P_n^m$. *Then*

$$P(iw) + P(-iw)^T = M(-iw)^T M(iw), \qquad w \in \Re,$$

for some $M(s) \in TM_n^m$. A minimal realization of $M(s)$ is given by

$$(A, B, C, D_m^{-T}(C - B^T P_{\min}), D_m),$$

where $P_{\min}$ is the minimal solution to the PRRE *corresponding to (A, B, C, D) and $D_m \in \mathfrak{R}^{m\times m}$ is such that $D_m^T D_m = D + D^T$.*

This proposition suggests how we can relate positive real systems to minimum-phase systems. The precise relationship is given in the following proposition where for a minimum-phase system with a given D-matrix we uniquely define an associated positive real system.

PROPOSITION 7.2. *For $D \in \mathfrak{R}^{m\times m}$, invertible, let*

$$M_{n,D}^m = \{(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D}) \in M_n^m \mid \tilde{D} = D\},$$
$$P_{n,D}^m = \{(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D}) \in P_n^m \mid \tilde{D} = \tfrac{1}{2} D^T D\},$$

with $TM_{n,D}^m$ and $TP_{n,D}^m$ the sets of corresponding transfer functions.

The map

$$S_{PM,D}\colon \quad P_{n,D}^m \to M_{n,D}^m$$
$$(A_p, B_p, C_p, D_p) \mapsto (A_m, B_m, C_m, D_m) := (A_p, B_p, D^{-T}(C_p - B_p^T P_{\min}), D),$$

where $P_{\min}$ is the minimal solution to the PRRE *corresponding to (A_p, B_p, C_p, D_p), is a bijection. Its inverse is given by*

$$S_{PM,D}^{-1}\colon \quad M_{n,D}^m \to P_{n,D}^m$$
$$(A_m, B_m, C_m, D_m) \mapsto (A_p, B_p, C_p, D_p) := (A_m, B_m, D^T C_m + B_m^T P, \tfrac{1}{2} D^T D),$$

where P is the solution to the Lyapunov equation

$$A_m^T P + P A_m = -C_m^T C_m. \tag{16}$$

Moreover, $S_{PM,D}$ preserves system equivalence.

Proof. By Proposition 7.1 the map $S_{PM,D}$ is well defined. To show that $S_{PM,D}^{-1}$ is well defined we first must show that for $(A_m, B_m, C_m, D_m) \in M_{n,D}^m$ the system $(A_p, B_p, C_p, D_p) = S_{PM,D}^{-1}((A_p, B_p, C_p, D_p))$ is in $C_n^{m,m}$.

First note that P solves the PRRE corresponding to (A_p, B_p, C_p, D_p). Let $P(s) = C_p(sI - A_p)^{-1}B_p + D_p$ and $M(s) = C_m(sI - A_m)^{-1}B_m + D_m$; then standard algebraic manipulations show that

$$P(iw) + P(-iw)^T = M(-iw)^T M(iw), \qquad w \in \mathfrak{R}.$$

Since by assumption $M(s)$ has McMillan degree n this implies that $P(s)$ also has McMillan degree n. This shows that $(A_p, B_p, C_p, D_p) \in C_n^{m,m}$.

$(A_p, B_p, C_p, D_p) \in P_n^m$ follows from Proposition 7.1 as

$$\tilde{A} := A_p - B_p(D_p + D_p^T)^{-1}(C_p - B_p^T P) = A_m - B_m D_m^{-1} C_m$$

has all its eigenvalues in the open left halfplane. It is now straightforward to verify that $S_{PM,D}$ is in fact a bijection and preserves system equivalence. □

We now define a minimum-phase system to be minimum-phase balanced if its corresponding positive real system is positive real balanced.

DEFINITION 7.2. A system $(A, B, C, D) \in M_n^m$ is called *minimum-phase balanced* if the system $S_{PM,D}^{-1}((A, B, C, D))$ is positive real balanced. The *minimum-phase gramian* Σ_m of (A, B, C, D) is defined to be the positive real gramian Σ_p of $S_{PM,D}^{-1}((A, B, C, D))$, i.e., $\Sigma_m = \Sigma_p$.

A canonical form for minimum-phase systems can now be derived using Proposition 7.2 to carry the canonical form for positive real systems over to the class of minimum-phase systems.

THEOREM 7.1. *The following two statements are equivalent*:

(1) $M(s) \in TM_n^m$.

(2) $M(s)$ *has a realization* $(A, B, C, D) \in \mathfrak{R}^{n\times n} \times \mathfrak{R}^{n\times m} \times \mathfrak{R}^{m\times n} \times \mathfrak{R}^{m\times m}$ *given by the parameters*:

$$\begin{array}{ll}
1 > p_1 > \cdots > p_j > \cdots > p_k > 0, & \\
n_1, \cdots, n_j, \cdots, n_k, & n_j \in \mathcal{N}, \quad \sum_{j=1}^k n_j = n; \\
r_1, \cdots, r_j, \cdots, r_k, & r_j \in \mathcal{N}, \quad 1 \leqq r_j \leqq \min(n_j, m); \\
U_1, \cdots, U_j, \cdots, U_k, & U_j \in \mathfrak{R}^{m\times r_j}, \quad U_j^T U_j = I_{r_j}; \\
\tilde{B}_1, \cdots, \tilde{B}_j, \cdots, \tilde{B}_k, & \tilde{B}_j \in \mathfrak{R}^{r_j \times m} \quad \textit{positive upper triangular}; \\
\tilde{A}_1, \cdots, \tilde{A}_j, \cdots, \tilde{A}_k, & \tilde{A}_j \in \mathfrak{R}^{n_j\times n_j} \quad \textit{in } r_j\textit{-balanced form}; \\
D, & D \in \mathfrak{R}^{m\times m}, \quad D \textit{ invertible}
\end{array}$$

in the following way:

If (A, B, C, D) *is partitioned according to* $n_1, \cdots, n_j, \cdots, n_k$, *then*,

(i) $B_j = \begin{pmatrix} \tilde{B}_j (D^T D)^{1/2} \\ 0 \end{pmatrix}, \quad 1 \leqq j \leqq k;$

(ii) $C_j = D^{-T}(D^T D)^{1/2}(U_j \Delta_j - p_j \tilde{B}_j^T, 0)$ *where* $\Delta_j = (\tilde{B}_j \tilde{B}_j^T)^{1/2}, \quad 1 \leqq j \leqq k;$

(iii) $$A_{jj} = \tilde{A}_j - \frac{1+p_j^2}{p_j}[\operatorname{diag}(\Delta_j^2, 0)]_l - \frac{1+p_j^2}{2p_j}[\operatorname{diag}(\Delta_j^2, 0)]_d + \operatorname{diag}(\tilde{B}_j U_j \Delta_j, 0), \quad 1 \leqq j \leqq k;$$

(iv) $$A_{ij} = \frac{1}{p_i^2 - p_j^2}(p_j(1-p_i^2)\operatorname{diag}(\tilde{B}_i \tilde{B}_j^T, 0) - p_i(1-p_j^2)\operatorname{diag}(\Delta_i U_i^T U_j \Delta_j, 0)) + \operatorname{diag}(\tilde{B}_i U_j \Delta_j, 0), \quad 1 \leqq i, j \leqq k, \quad i \neq j.$$

(v) $D \in \mathfrak{R}^{m\times m}$, *invertible.*

Moreover, (A, B, C, D) *as defined in* (2) *is minimum-phase balanced with minimum-phase gramian*

$$\Sigma_m = \operatorname{diag}(p_1 I_{n_1}, \cdots, p_j I_{n_j}, \cdots, p_k I_{n_k}).$$

The map Γ_m, *which assigns to each system in* M_n^m *the realization given in* (2), *is a canonical form.*

COROLLARY 7.1. *The following two statements are equivalent*:

(1) $m(s) \in TM_n^1$.

(2) $m(s)$ *has a realization* $(A, b, c, d) \in \mathfrak{R}^{n\times n} \times \mathfrak{R}^{n\times 1} \times \mathfrak{R}^{1\times n} \times \mathfrak{R}^{1\times 1}$ *given by the parameters*:

$$\begin{array}{ll}
1 > p_1 > \cdots > p_j > \cdots > p_k > 0, & \\
n_1, \cdots, n_j, \cdots, n_k, & n_j \in \mathcal{N}, \quad \sum_{j=1}^k n_j = n; \\
s_1, \cdots, s_j, \cdots, s_k, & s_j = \pm 1, \quad 1 \leqq j \leqq k; \\
b_1, \alpha(1)_1, \cdots, \alpha(1)_j, \cdots, \alpha(1)_{n_1-1}, & b_1 > 0, \quad \alpha(1)_j > 0, \quad 1 \leqq j \leqq n_1 - 1; \\
\vdots & \\
b_i, \alpha(i)_1, \cdots, \alpha(i)_j, \cdots, \alpha(i)_{n_i-1}, & b_i > 0, \quad \alpha(i)_j > 0, \quad 1 \leqq j \leqq n_i - 1; \\
\vdots & \\
b_k, \alpha(k)_1, \cdots, \alpha(k)_j, \cdots, \alpha(k)_{n_k-1}, & b_k > 0, \quad \alpha(k)_j > 0, \quad 1 \leqq j \leqq n_k - 1; \\
d, & d \in \mathfrak{R}, \quad d \neq 0
\end{array}$$

in the following way:

(i) $b=(\underbrace{b_1,0,\cdots,0}_{n_1},\cdots,\underbrace{b_j,0,\cdots,0}_{n_j},\cdots,\underbrace{b_k,0,\cdots,0}_{n_k})^T$,

(ii) $c=\frac{1}{d}((\underbrace{(s_1-p_1)b_1,0,\cdots,0}_{n_1},\cdots,\underbrace{(s_j-p_j)b_j,0,\cdots,0}_{n_j},\cdots,$

$\underbrace{(s_k-p_k)b_k,0,\cdots,0}_{n_k})$,

(iii) *For* $A=:(A_{ij})_{1\leqq i,j\leqq k}$ *we have*

(a) *block diagonal entries* A_{jj}, $1\leqq j\leqq k$:

$$A_{jj}=\begin{pmatrix} a_{jj} & \alpha(j)_1 & & & & \\ -\alpha(j)_1 & 0 & \alpha(j)_2 & & & \\ & -\alpha(j)_2 & 0 & \cdot & & 0 \\ & & \ddots & \ddots & \ddots & \\ & 0 & & \cdot & 0 & \alpha(j)_{n_j-1} \\ & & & & -\alpha(j)_{n_j-1} & 0 \end{pmatrix}$$

with $a_{jj}=\dfrac{-b_j^2}{2d^2p_j}(1-s_jp_j)^2$;

(b) *off-diagonal blocks* A_{ij}, $1\leqq i,j\leqq k$, $i\neq j$:

$$A_{ij}=\begin{pmatrix} a_{ij} & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix} \quad \textit{with } a_{ij}=\frac{-b_ib_j}{d^2(s_is_jp_i+p_j)}(1-s_ip_i)(1-s_jp_j);$$

(iv) $d\in\Re$, $d\neq 0$.

Moreover, (A, b, c, d) *as defined in* (2) *is minimum-phase balanced with minimum-phase gramian*

$$\Sigma_m=\operatorname{diag}(p_1I_{n_1},\cdots,p_jI_{n_j},\cdots,p_kI_{n_k}).$$

The map Γ_m, *which assigns to each system in* M_n^1 *the realization given in* (2), *is a canonical form.*

While the canonical form we have just derived has a structure that is very similar to the canonical forms derived for the other classes of systems, there is a certain loss of symmetry in this canonical form. This is most apparent in the case of single-input single-output systems. In the previously derived canonical forms, the entries of the b-vector and c-vector had the same modulus. Moreover, the canonical forms were sign-symmetric (see § 10 for a precise definition). The sign-symmetry is lost in the above canonical form for single-input single-output minimum-phase systems. By standard arguments it can be shown that all single-input single-output minimum-phase systems have a sign-symmetric realization; the canonical form for single-input single-output asymptotically stable systems of Corollary 2.1 restricted to minimum-phase systems is such an example. It is, however, not clear whether it is possible to find a "balancing scheme" for minimum-phase systems such that the corresponding canonical form is sign-symmetric for single-input single-output systems and at the same time leads to a parametrization whose parameter space has the desirable geometric structure of the canonical form presented here.

8. Discrete-time systems. The canonical forms derived in the previous sections dealt with continuous-time systems. In this section we will show that the standard technique of bilinearly transforming continuous-time systems to discrete-time systems can be applied to derive canonical forms for various classes of discrete-time systems. We first define the classes of systems that will be considered.

DEFINITION 8.1. Let $(A, B, C, D) \in \mathfrak{R}^{n\times n} \times \mathfrak{R}^{n\times m} \times \mathfrak{R}^{p\times n} \times \mathfrak{R}^{p\times m}$ and $G(z) = C(zI-A)^{-1}B+D$.

(1) If all eigenvalues of A are in the open unit disk, then (A, B, C, D) is called *discrete-time asymptotically stable.* The set of discrete-time asymptotically stable systems in $L_n^{p,m}$ is denoted by $D_n^{p,m}$ with $TD_n^{p,m}$ the corresponding set of transfer functions.

(2) A system $(A, B, C, D) \in D_n^{p,m}$ is called *discrete-time bounded real* if

$$I - G(e^{-i\theta})^T G(e^{i\theta}) > 0, \qquad \theta \in [0, 2\pi].$$

The set of discrete-time bounded real systems in $D_n^{m,m}$ is denoted by $DB_n^{p,m}$ with $TDB_n^{p,m}$ the corresponding set of transfer functions.

(3) A system $(A, B, C, D) \in D_n^{m,m}$ is called *discrete-time positive real* if

$$G(e^{-i\theta})^T + G(e^{i\theta}) > 0, \qquad \theta \in [0, 2\pi].$$

The set of discrete-time positive real systems in $D_n^{p,m}$ is denoted by DP_n^m with TDP_n^m the corresponding set of transfer functions.

(4) A system $(A, B, C, D) \in D_n^{m,m}$ is called *discrete-time minimum phase* if

$$\tilde{G}(z) := G(z)^{-1} \in TD_n^{m,m}.$$

The set of discrete-time minimum-phase systems in $D_n^{m,m}$ is denoted by DM_n^m with TDM_n^m the corresponding set of transfer functions.

(5) A system $(A, B, C, D) \in D_n^{m,m}$ is called *discrete-time allpass* if for some $\sigma > 0$,

$$G(e^{i\theta}) G(e^{-i\theta})^T = \sigma^2 I, \qquad \theta \in [0, 2\pi].$$

The set of discrete-time allpass systems in $D_n^{m,m}$ is denoted by DA_n^m with TDA_n^m the corresponding set of transfer functions.

The following proposition summarizes some basic results on the bilinear transformation.

PROPOSITION 8.1. *The transformation*

$$TU_n^{p,m}: TC_n^{p,m} \to TD_n^{p,m},$$

$$G_c(s) \mapsto G_d(z) := G_c\left(\frac{z-1}{z+1}\right)$$

is a bijection with inverse

$$(TU_n^{p,m})^{-1}: TD_n^{p,m} \to TC_n^{p,m},$$

$$G_d(z) \mapsto G_c(s) := G_d\left(\frac{1+s}{1-s}\right),$$

which induces a bijection between $TB_n^{p,m}$ and $TDB_n^{p,m}$. If $p = m$ then $TU_n^{m,m}$ induces a bijection between TA_n^m and TDA_n^m, TP_n^m and TDP_n^m, as well as TM_n^m and TDM_n^m.

This mapping also has a formulation in terms of state-space systems, which is given in the next proposition [3], [10], [22].

PROPOSITION 8.2. *The transformation*

$$SU_n^{p,m}: \quad C_n^{p,m} \to D_n^{p,m},$$
$$(A_c, B_c, C_c, D_c) \mapsto (A_d, B_d, C_d, D_d),$$
$$(A_d, B_d, C_d, D_d) := ((I-A_c)^{-1}(I+A_c), \sqrt{2}(I-A_c)^{-1}B_c, \sqrt{2}\, C_c(I-A_c)^{-1}, D_c + C_c(I-A_c)^{-1}B_c)$$

is a bijection with inverse

$$(SU_n^{p,m})^{-1}: \quad D_n^{p,m} \to C_n^{p,m},$$
$$(A_d, B_d, C_d, D_d) \mapsto (A_c, B_c, C_c, D_c),$$
$$(A_c, B_c, C_c, D_c) := ((I+A_d)^{-1}(A_d - I), \sqrt{2}(I+A_d)^{-1}B_d, \sqrt{2}\, C_d(I+A_d)^{-1}, D_d - C_d(I+A_d)^{-1}B_d),$$

which induces a bijection between $B_n^{p,m}$ and $DB_n^{p,m}$. If $p = m$, then $SU_n^{m,m}$ induces a bijection between A_n^m and DA_n^m, P_n^m and DP_n^m, as well as M_n^m and DM_n^m. The map $SU_n^{p,m}$ preserves system equivalence as well as sign-symmetry of state-space realizations if $p = m$; i.e., for $(A_c, B_c, C_c, D_c) = (SU_n^{m,m})^{-1}((A_d, B_d, C_d, D_d))$, $(A_d, B_d, C_d, D_d) \in D_n^{m,m}$ we have

$$A_c = SA_c^T S, \qquad B_c = SC_c^T$$

if and only if

$$A_d = SA_d^T S, \qquad B_d = SC_d^T,$$

for some $S = \operatorname{diag}(\pm 1, \cdots, \pm 1)$.

The previous proposition allows us to carry over the canonical forms for continuous-time asymptotically stable systems to the discrete-time case.

THEOREM 8.1. *If Γ, Γ_a, Γ_b, Γ_p, and Γ_m are the canonical forms for the sets $C_n^{p,m}$, A_n^m, $B_n^{p,m}$, P_n^m, and M_n^m as defined in the previous sections, then $D\Gamma := SU_n^{p,m}\Gamma(SU_n^{p,m})^{-1}$, $D\Gamma_a := SU_n^{m,m}\Gamma_a(SU_n^{m,m})^{-1}$, $D\Gamma_b := SU_n^{p,m}\Gamma_b(SU_n^{p,m})^{-1}$, $D\Gamma_p := SU_n^{m,m}\Gamma_p(SU_n^{m,m})^{-1}$, and $D\Gamma_m := SU_n^{m,m}\Gamma_m(SU_n^{m,m})^{-1}$ are canonical forms for the sets $D_n^{p,m}$, DA_n^m, $DB_n^{p,m}$, DP_n^m, and DM_n^m.*

Remark 8.1. Analogously to the continuous-time case we can introduce balancing techniques for the various classes of discrete-time systems by balancing solutions to the corresponding discrete-time Lyapunov and Riccati equations. Since the map $SU_n^{p,m}$ leaves such solutions invariant (see, e.g., [3], [10], [22]), $SU_n^{p,m}$, in fact, preserves balancing. Hence the canonical forms for discrete-time systems introduced in Theorem 8.1 are therefore in terms of balanced representations.

9. Model reduction. One of the main advantages of balanced representations is that they can be used for a very straightforward method of model reduction. Moore [19] has, in fact, introduced balanced realizations for stable linear systems to have an efficient way of performing model reduction. His scheme was based on the following state-space projection method. Consider an n-dimensional balanced system (A, B, C, D) and partition it conformally as

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}, \quad B = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix}, \quad C = (C_1, C_2),$$

such that for $1 \leqq N < n$, $A_{11} \in \mathfrak{R}^{N \times N}$, $B_1 \in \mathfrak{R}^{N \times m}$, and $C_1 \in \mathfrak{R}^{p \times N}$. The principal subsystem (A_{11}, B_1, C_1, D) is then considered to be an approximant of (A, B, C, D).

Pernebo and Silverman [29] were the first to show that the approximant of a balanced system in $C_n^{p,m}$ is again balanced, minimal, and asymptotically stable. Their result, however, assumes that truncation does not occur between states corresponding to repeated singular values. Otherwise the approximant may no longer be asymptotically stable and minimal. Analogous results with the same restriction were shown in [7] for positive real systems, in [16] for Riccati balanced systems, and in [28] for bounded real systems.

We now suggest a model reduction technique that is more suitable to our particular setup than the method discussed above. Rather than working with the state-space systems directly, we perform the model reduction by reducing the parameters corresponding to a certain system.

We have seen that associated with each system is a set of parameters as follows:

$$\begin{array}{ll}
\sigma_1 > \cdots > \sigma_j > \cdots > \sigma_k > 0, & \\
n_1, \cdots, n_j, \cdots, n_k, & n_j \in \mathcal{N}, \quad \sum_{j=1}^{k} n_j = n; \\
r_1, \cdots, r_j, \cdots, r_k, & r_j \in \mathcal{N}, \quad 1 \leqq r_j \leqq \min(n_j, m, p); \\
U_1, \cdots, U_j, \cdots, U_k, & U_j \in \mathfrak{R}^{p \times r_j}, \quad U_j^T U_j = I_{r_j}; \\
\tilde{B}_1, \cdots, \tilde{B}_j, \cdots, \tilde{B}_k, & \tilde{B}_j \in \mathfrak{R}^{r_j \times m} \quad \text{positive upper triangular}; \\
\tilde{A}_1, \cdots, \tilde{A}_j, \cdots, \tilde{A}_k, & \tilde{A}_j \in \mathfrak{R}^{n_j \times n_j} \quad \text{in } r_j\text{-balanced form}; \\
D, & D \in \mathfrak{R}^{p \times m}
\end{array}$$

A reduced-order system of degree N can now easily be defined by retaining of these parameters only those that correspond to the first N states; i.e., if j_N is such that $n_1 + \cdots + n_{j_N} < N \leqq n_1 + \cdots + n_{jn} + h_{j_N+1}$, then take the following parameters:

$$\begin{array}{ll}
\sigma_1, \cdots, \sigma_{j_N}, \sigma_{j_N+1}, & \\
n_1, \cdots, n_{j_N}, Pn_{j_N+1}, & Pn_{j_N+1} := N - (n_1 + \cdots + n_{j_N}); \\
U_1, \cdots, U_{j_N}, PU_{j_N+1}, PU_{j_N+1}, & \text{the first } \min(r_{j_N+1}, Pn_{j_N+1}) \\
 & \text{columns of } U_{j_N+1}. \\
\tilde{B}_1, \cdots, \tilde{B}_{j_N}, P\tilde{B}_{j_N+1}, & P\tilde{B}_{j_N+1} \text{ the first } \min(r_{j_N+1}, Pn_{j_N+1}) \\
 & \text{rows of } \tilde{B}_{j_N+1}; \\
\tilde{A}_1, \cdots, \tilde{A}_{j_N}, P\tilde{A}_{j_N+1}, P\tilde{A}_{j_N+1}, & \text{the principal submatrix of} \\
 & \tilde{A}_{j_N+1} \text{ of size } Pn_{j_N+1}.
\end{array}$$

By the parametrization results of the previous sections these parameters define a unique reduced-order system that is in the same class of the systems as the original system. We can call this scheme a *parameter projection method.*

We can summarize this method in the following theorem.

THEOREM 9.1. *If* (A, B, C, D) *is a continuous-time system in* $C_n^{p,m}(A_n^m, L_n^{p,m}, B_n^{p,m}, P_n^m, M_n^m)$ *given in the canonical form of Theorem* 2.1 (3.1, 4.1, 5.1, 6.1, 7.1) *with parameters*

$$\begin{array}{ll}
\sigma_1 > \cdots > \sigma_j > \cdots > \sigma_k > 0, & \\
n_1, \cdots, n_j, \cdots, n_k, & n_j \in \mathcal{N}, \quad \sum_{j=1}^{k} n_j = n; \\
r_1, \cdots, r_j, \cdots, r_k, & r_j \in \mathcal{N}, \quad 1 \leqq r_j \leqq \min(n_j, m, p); \\
U_1, \cdots, U_j, \cdots, U_k, & U_j \in \mathfrak{R}^{p \times r_j}, \quad U_j^T U_j = I_{r_j}; \\
\tilde{B}_1, \cdots, \tilde{B}_j, \cdots, \tilde{B}_k, & \tilde{B}_j \in \mathfrak{R}^{r_j \times m} \quad \textit{positive upper triangular}; \\
\tilde{A}_1, \cdots, \tilde{A}_j, \cdots, \tilde{A}_k, & \tilde{A}_j \in \mathfrak{R}^{n_j \times n_j} \quad \textit{in } r_j\textit{-balanced form}; \\
D, & D \in \mathfrak{R}^{p \times m};
\end{array}$$

then each N-dimensional system, $1 \leqq N < n$, *obtained by the balanced parameter space model reduction scheme, i.e., each system given by the parameters*

$$\begin{array}{ll}
\sigma_1, \cdots, \sigma_{j_N}, \sigma_{j_N+1}, & \\
n_1, \cdots, n_{j_N}, Pn_{j_N+1}, & Pn_{j_N+1} := N - (n_1 + \cdots + n_{j_N}); \\
U_1, \cdots, U_{j_N}, PU_{j_N+1}, & PU_{j_N+1} \textit{ the first } \min(r_{j_N+1}, Pn_{j_N+1}) \\
 & \textit{columns of } U_{j_N+1}; \\

and parametrized as in Theorem 2.1 (3.1, 4.1, 5.1, 6.1, 7.1) *is again in canonical form and therefore in the same class of systems, i.e., in* $C_N^{p,m}$ $(A_N^m, L_N^{p,m}, B_n^{p,m}, P_N^m, M_N^m)$.

From this result we can easily obtain a result concerning model reduction using the state-space projection method.

COROLLARY 9.1. *If* (A, B, C, D) *is a continuous-time system in* $C_n^{p,m}$ $(A_n^m, L_n^{p,m}, B_n^{p,m}, P_n^m, M_n^m)$ *given in the canonical form of Theorem* 2.1 (3.1, 4.1, 5.1, 6.1, 7.1) *then each N-dimensional principal subsystem of* (A, B, C, D) *is again in canonical form and therefore in the same class of systems, i.e., in* $C_N^{p,m}(A_N^m, L_N^{p,m}, B_n^{p,m}, P_N^m, M_N^m)$ *if for some* $0 \leqq j_N \leqq k-1$,

$$n_1 + \cdots + n_{j_N} + r_{j_N+1} \leqq N \leqq n_1 + \cdots + n_{j_N} + n_{j_N+1},$$

where we set $n_0 = 0$.

Proofs. The result follows by inspection since the reduced-order system is parametrized by a set of parameters as in Theorem 9.1. □

Because of the particular nature of the nonuniqueness of balanced realizations Corollary 9.1 is, in fact, more general than the results in [29], [7], [16], and [28], where it is assumed that truncation occurs at a point of nonrepeated singular values. We can recover these results immediately in the following corollary.

COROLLARY 9.2. *If* (A, B, C, D) *is a continuous-time system given in* $C_n^{p,m}(L_n^{p,m}, B_n^{p,m}, P_n^m, M_n^m)$ *that is Lyapunov balanced (Riccati balanced, bounded real balanced, positive real balanced, minimum-phase balanced) with gramian* $\Sigma = \operatorname{diag}(\sigma_1 I_{n_1}, \cdots, \sigma_k I_{n_k})$, *then the N-dimensional principal subsystem is in the same class of systems, i.e.,* $C_N^{p,m}(L_N^{p,m}, B_n^{p,m}, P_N^m, M_N^m)$, *if* $N = n_1 + n_2 + \cdots + n_{j_0}$, *for some* $j_0 = 1, \cdots, k$.

We obtain a very general model reduction result if either the input or the output dimension of the system is one. Then we have that the r_j parameters are also one, and hence the condition Corollary 9.1 is always satisfied.

COROLLARY 9.3. *Assume that* $\min(p, m) = 1$. *If* (A, B, C, D) *is a continuous-time system in* $C_n^{p,m}$ $(A_n^m, L_n^{p,m}, B_n^{p,m}, P_n^m, M_n^m)$ *given in the canonical form of Theorem* 2.1 (3.1, 4.1, 5.1, 6.1, 7.1), *then each N-dimensional principal subsystem of* (A, B, C, D) *is again in canonical form and therefore in the same class of systems, i.e., in* $C_N^{p,m}$ $(A_N^m, L_N^{p,m}, B_n^{p,m}, P_N^m, M_N^m)$.

Remark 9.1. Note that for the particular type of canonical forms presented in this paper we cannot, in general, expect to have a model reduction result based on the state-space projection method by which truncation can occur at an arbitrary place. This is due to the fact that we use $(\tilde{B}_j\tilde{B}_j^T)^{1/2}$ as a parameter in the C-matrix and that $(\tilde{B}_j\tilde{B}_j^T)^{1/2}$ has no specific structure. In the case of the canonical forms presented in [22] and [27], $(\tilde{B}_j\tilde{B}_j^T)^{1/2}$ was constrained to be diagonal and we have the general model reduction property.

In [1] and [22] a model reduction technique was suggested for balanced discrete-time systems in $D_n^{p,m}$ by carrying a discrete-time system over to a continuous-time system using the map $SU_n^{p,m}$. This corresponding continuous-time system is reduced to a lower-order system which is then mapped back to a discrete-time system using the inverse mapping. Thereby we obtain a lower-order approximant to the discrete-time system. The following corollary shows how it is possible to obtain in this way a discrete-time version of Corollary 9.1.

COROLLARY 9.4. *Let (A_d, B_d, C_d, D_d) be in one of the following classes of discrete-time asymptotically stable systems: $D_n^{p,m}$, DA_n^m, $DB_n^{p,m}$, DP_n^m, and DM_n^m. Assume that (A_d, B_d, C_d, D_d) is given in the corresponding canonical form. Let $(\hat{A}_c, \hat{B}_c, \hat{C}_c, \hat{D}_c)$ be the N-dimensional principal subsystem of $(A_c, B_c, C_c, D_c) = (SU_n^{p,m})^{-1}((A_d, B_d, C_d, D_d))$; then $(\hat{A}_d, \hat{B}_d, \hat{C}_d, \hat{D}_d) := SU_n^{p,m}((\hat{A}_c, \hat{B}_c, \hat{C}_c, \hat{D}_c))$ is in the corresponding subclass of N-dimensional systems, if*

$$n_1 + \cdots + n_{j_N} + r_{j_N+1} \leqq N \leqq n_1 + \cdots + n_{j_N} + n_{j_N+1}.$$

Clearly, all the other continuous-time results in this section can be carried over to discrete-time systems in the same way.

10. Final remarks. The paper dealt with canonical forms and parametrizations for the following classes of linear systems of fixed dimensions: asymptotically stable systems, allpass systems, the general class of minimal systems, positive real systems, bounded real systems, and minimum-phase systems. All the canonical forms are given in terms of balanced realizations for the particular class of systems. Several aspects of these parametrizations were discussed including model reduction.

It was pointed out that all the canonical forms have a similar structure. Only the way the parameters enter the entries of the system matrices determines whether or not a system belongs to a certain class of systems. We are going to make a few further remarks concerning common properties of the various canonical forms.

Sign-symmetry and Cauchy index. With the exception of minimum-phase systems all scalar systems that are given in one of the previously derived canonical forms have the so-called sign-symmetry property, i.e.,

$$A^T = SAS, \qquad b = Sc^T,$$

where S is a diagonal matrix whose diagonal terms are ±1. In particular, if

$$n_1, \cdots, n_j, \cdots, n_k, \qquad s_1, \cdots, s_j, \cdots, s_k$$

are the usual structural parameters of a scalar system given in one of the canonical forms of Corollaries 2.1, 3.1, 4.1, 5.1, 6.2, 7.1, then the sign-symmetry matrix S is

$$S = \operatorname{diag}(s_1\hat{I}_{n_1}, \cdots, s_j\hat{I}_{n_j}, \cdots, s_k\hat{I}_{n_k}),$$

where $\hat{I}_{n_j} = \operatorname{diag}(+1, -1, +1, \cdots, (-1)^{n_j+1}) \in \Re^{n_j \times n_j}$. Note that by Proposition 8.2 the canonical form of a discrete-time system is sign symmetric if its corresponding continuous-time system is sign symmetric. An important property of the sign-symmetry matrix of a system is that it can be related to the Cauchy index of its transfer function. The Cauchy index of a rational function is defined as follows.

DEFINITION 10.1. Let $p(x)$ and $q(x)$ be relatively prime polynomials with real coefficients. The Cauchy index $C_{\text{ind}}(g(x))$ of $g(x)=p(x)/q(x)$ is defined as the number of jumps from $-\infty$ to $+\infty$ minus the number of jumps from $+\infty$ to $-\infty$ of $g(x)$ as x varies from $-\infty$ to $+\infty$.

A consequence of a result in [2] is that if a system is sign symmetric with respect to a sign-symmetry matrix S, the Cauchy index of its transfer function $g(s)$ is given by

$$C_{\text{ind}}(g(s)) = \text{trace } (S).$$

In [25] it was shown that systems in $C_n^{1,1}$ with Cauchy index n characterize the so-called relaxation systems. These are systems whose impulse response is a completely monotonic function.

Geometric aspects of the parameter space. Another important aspect of the canonical forms presented in this paper is the comparatively simple structure of the parameter space. In many other canonical forms for minimal systems the parameter set at which the systems lose minimality is described by complicated sets of algebraic equations. Here minimality is preserved provided certain parameters are strictly positive. A disadvantage, however, is that even in the case of SISO systems several distinct structures are necessary to parametrize any of the classes of systems considered here.

Let S_n denote any of the following classes of single-input single-output systems: $C_n^{1,1}$, $L_n^{1,1}$, $B_n^{1,1}$, or P_n^1. We have shown that each system in S_n has associated with it a unique set of discrete parameters:

$$n_1, \cdots, n_j, \cdots, n_k, \qquad n_j \in \mathcal{N}, \ \textstyle\sum_{j=1}^k n_j = n,$$
$$s_1, \cdots, s_j, \cdots, s_k, \qquad s_j = \pm 1, \quad 1 \leqq j \leqq k.$$

If we denote by $S_n(n_1, n_2, \cdots, n_k; s_1, s_2, \cdots, s_k)$ the set of systems in S_n with the discrete parameters $(n_1, n_2, \cdots, n_k; s_1, s_2, \cdots, s_k)$, then we can clearly write the set S_n as the disjoint union of the sets $S_n(n_1, n_2, \cdots, n_k; s_1, s_2, \cdots, s_k)$, i.e.,

$$S_n = \bigcup_{\substack{1 \leqq k \leqq n \\ n_1+n_2+\cdots+n_k=n \\ s_1=\pm 1, s_2 \pm 1, \cdots, s_k=\pm 1}} S_n(n_1, n_2, \cdots, n_k; s_1, s_2, \cdots, s_k).$$

It follows easily from the structure of the continuous parameters that for each choice of discrete parameters $n_1, n_2, \cdots, n_k; s_1, s_2, \cdots, s_k$ the parameter set of $S_n(n_1, n_2, \cdots, n_k; s_1, s_2, \cdots, s_k)$ is, in fact, diffeomorphic to $\Re^{n+k} \times \Re$. Therefore we have a decomposition of the set S_n into disjoint "cells," each of which are diffeomorphic to a Euclidean space. The term "cell" is used here in a loose sense and not in its strict topological meaning. We will not go any further into a topological investigation of this decomposition. We refer to [9] and [14] where a different decomposition, which originates from a continued fraction expansion of scalar transfer functions, is introduced and investigated. It is, however, interesting to consider the number of cells in our decomposition. The total number of cells of S_n is easily seen by induction to be $2 \times 3^{n-1}$. The number of cells of dimension $n+k$ is equal to the number of different choices of k blocks of singular values times the possible choices of signs, which is 2^k and therefore gives

$$2^k \binom{n-1}{k-1}.$$

Note that we neglect the parameter that corresponds to the d-term, which is not relevant to the present discussion. Another number of interest is the number of cells of fixed dimension corresponding to a certain Cauchy index. These numbers are not so easily determined and we will just give a small table that contains these numbers for small dimensions.

Number of cells of given dimension and Cauchy index.

Order	dim	Cauchy index								
n	$n+k$	-4	-3	-2	-1	0	1	2	3	4
1	2				1		1			
2	3					2				
	4			1		2		1		
3	4				1		1			
	5				4		4			
	6		1		3		3		1	
4	5					2				
	6			2		8		2		
	7			6		12		6		
	8	1		4		6		4		1

It is surprising to see that the different numbers we have obtained coincide with the numbers found in [9] for the cell decomposition of $L_n^{1,1}$, which was derived from continued fractions of the transfer functions. Simple examples show, however, that this decomposition is not identical with the decomposition derived here. We have not considered minimum-phase systems here. Similar results, however, also hold for these systems.

The geometry of the parameter space was used in [26] to study connectivity properties of the various classes of systems. See [24] for the case of asymptotically stable systems.

STOCHASTIC REGULATOR THEORY FOR A CLASS OF ABSTRACT WAVE EQUATIONS*

A. V. BALAKRISHNAN†

Abstract. A class of steady-state stochastic regulator problems for abstract wave equations in a Hilbert space—of relevance to the problem of feedback control of large space structures using co-located controls/sensors—is studied. Both the control operator, as well as the observation operator, are finite-dimensional. As a result, the usual condition of exponential stabilizability invoked for existence of solutions to the steady-state Riccati equations is not valid. Fortunately, for the problems considered it turns out that strong stabilizability suffices. In particular, a closed form expression is obtained for the minimal (asymptotic) performance criterion as the control effort is allowed to grow without bound.

Key words. stochastic regulator, abstract wave equation, steady-state Riccati equation

1. Introduction. In this paper we consider a class of steady-state stochastic regulator problems arising in active stabilization of large space structures using co-located sensors and controllers [1]-[4]. We deal only with the abstract formulation of such problems as a wave equation in a Hilbert space (reference may be made to [2] to [3] for specific examples). In this formulation both the control operator and the observation operator are finite-dimensional. As a result, the theory is actually more difficult because the exponential stabilizability condition usually invoked for the existence of solutions of steady-state Riccati equations (e.g., in [4]) is not valid. The latter result—the lack of exponential stabilizability—follows from [7]. On the other hand, the noise model—the driving or "input" noise—is finite-dimensional—so that the complications of the infinite-dimensional Wiener process (see [5]) are avoided—even though, of course, it induces infinite-dimensional noise in the state variables. In particular, it turns out that steady-state covariance operators need not be nuclear, so that white noise theory [6] is more convenient (even if not essential, since the systems considered are linear!). Some background in this context is provided in [6]. Also we make extensive use of the notions and results of stochastic control theory developed in [6].

We begin in § 2 with the basic system description and problem formulation. The properties of the system essential in the sequel are outlined. In particular, the result of Benchimol [9] on strong stability plays a crucial role throughout. In fact, all "closed-loop" system semigroups are strongly stable and turn out to be adequate for asymptotic stationarity of the processes generated.

Section 3 presents the main results of proofs. A useful corollary provides an expression for the minimal attainable performance as control effort is increased without bound—in particular, in the application context it yields the minimal attainable mean square pointing error using co-located rate and attitude sensors.

2. System description and problem formulation. We begin with the state equation, which is a wave equation in a Hilbert space with random noise input:

$$M\ddot{x}(t)+Ax(t)+Bu(t)+BN_a(t)=0. \tag{2.1}$$

With $\mathscr{H}$ denoting the (separable) Hilbert space, M is a linear bounded self-adjoint operator on $\mathscr{H}$ into $\mathscr{H}$ which is nonnegative definite with a bounded inverse (zero is in the resolvent of M). In what follows we may, and will, assume M is the identity, without loss of generality in the theory. The operator A is unbounded, closed, with domain dense in $\mathscr{H}$ and is self-adjoint nonnegative definite, and has a compact resolvent with zero in the resolvent set. The operator B is finite-dimensional mapping $\mathscr{H}$ into R^n. The random noise is white Gaussian with spectral density matrix D_a. The control input $u(\cdot)$ is to be physically realizable so that $u(t)$ at time t is to be based only on observed data up to time t. The observations $v(\cdot)$ is given by

$$v(t) = \begin{vmatrix} v_p(t) \\ v_r(t) \end{vmatrix},$$

where

$$v_p(t) = B^*x(t) + N_p(t),$$
$$v_r(t) = B^*\dot{x}(t) + N_r(t), \tag{2.2}$$

where $N_p(\cdot)$, $N_r(\cdot)$ are independent white noises (independent also of the state noise $N_a(\cdot)$) with nonsingular spectral density matrices D_p and D_r, respectively. The optimization problem is a "stochastic regulator" problem: Minimize

$$\lim_{T\to\infty} \frac{1}{T}\left[\int_0^T \|B^*\dot{x}(t)\|^2\,dt + \lambda \int_0^T \|u(t)\|^2\,dt\right] \tag{2.3}$$

for fixed $\lambda > 0$. We are also interested in what happens as $\lambda \to 0$.

We begin by recasting (2.1) in the usual way with a slight difference in that a special inner product is introduced, which in fact is crucial in what follows.

Thus let $\mathscr{H}_E$ denote the energy-inner product space

$$\mathscr{H}_E = \mathscr{D}(\sqrt{A}) \times \mathscr{H}$$

with inner product defined by

$$[Y, Z]_E = [\sqrt{A}\,y_1, \sqrt{A}\,z_1] + [y_2, z_2],$$

where

$$Y = \begin{vmatrix} y_1 \\ y_2 \end{vmatrix}, \qquad Z = \begin{vmatrix} z_1 \\ z_2 \end{vmatrix}.$$

Defining, in the usual fashion (see [2], [6]),

$$\mathscr{A} = \begin{bmatrix} 0 & I \\ -A & 0 \end{bmatrix}, \qquad \mathscr{D}(\mathscr{A}) = \mathscr{D}(A) \times \mathscr{H},$$

$$\mathscr{B}u = \begin{bmatrix} 0 \\ -Bu \end{bmatrix}, \qquad \mathscr{B} \text{ mapping } R^n \text{ into } \mathscr{H}_E,$$

we being with (2.1) in the form

$$\dot{Y}(t) = \mathscr{A}Y(t) + \mathscr{B}u(t) + \mathscr{B}N_a(t), \tag{2.4}$$

where we note that (the adjoint $\mathscr{A}^*$ in $\mathscr{H}_E$ (in the energy-inner product!)):

$$\mathscr{A} + \mathscr{A}^* = 0, \qquad \mathscr{D}(\mathscr{A}) = \mathscr{D}(\mathscr{A}^*)$$

and $\mathscr{A}$ generates a strongly continuous isometric semigroup (actually a group). Also the observation $v(\cdot)$ goes over as

$$v(t) = CY(t) + N_0(t), \tag{2.5}$$

where

$$CY = \begin{vmatrix} B^*y_1 \\ B^*y_2 \end{vmatrix}, \qquad N_0(t) = \begin{vmatrix} N_p(t) \\ N_r(t) \end{vmatrix},$$

where C maps $\mathscr{H}_E$ into $R^n \times R^n$.

Next we make the crucial assumption that $\mathscr{A} \sim \mathscr{B}$ is controllable. A sufficient condition in terms of A and B is this: let ϕ be any eigenvector A:

$$A\phi = \omega^2\phi.$$

Then

$$B^*\phi = 0$$

only if $\phi = 0$. The proof exploits the fact that the eigenvectors of A are complete in $\mathscr{H}$. The controllability condition yields the Benchimol [9] result, which plays a central role in our theory that

$$\mathscr{A} - \mathscr{B}\mathscr{B}^*$$

is strongly stable. Furthermore, with $S_1(\cdot)$ denoting the semigroup generated by $(\mathscr{A} - \mathscr{B}\mathscr{B}^*)$ we have that for $Y \in \mathscr{D}(\mathscr{A})$,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|S_1(t)Y\|^2 &= \frac{1}{2}\{((\mathscr{A} - \mathscr{B}\mathscr{B}^*)S_1(t)Y, S_1(t)Y)_E + (S_1(t)Y, (\mathscr{A} - \mathscr{B}\mathscr{B}^*)S_1(t)Y)_E\} \\ &= -\|\mathscr{B}^*S_1(t)Y\|^2,\end{aligned}$$

and hence

$$\frac{1}{2}\|Y\|_E^2 - \frac{1}{2}\|S_1(t)Y\|_E^2 = \int_0^t \|\mathscr{B}^*S_1(\sigma)Y\|^2\,d\sigma.$$

The domain of $\mathscr{A}$ being dense in $\mathscr{H}_E$, this holds for every Y in $\mathscr{H}_E$. Hence taking limits as $t \to \infty$ we obtain

$$\frac{\|Y\|_e^2}{2} = \int_0^\infty \|\mathscr{B}^*S_1(\sigma)\|^2\,d\sigma. \tag{2.6}$$

Replacing $\mathscr{A}$ by $\mathscr{A}^*$ and equivalently $S_1(\cdot)$ by $S_1(\cdot)^*$, we also have that

$$\frac{\|Y\|_E^2}{2} = \int_0^\infty \|\mathscr{B}^*S_1(\sigma)^*Y\|^2\,d\sigma. \tag{2.6a}$$

Finally, (2.3) becomes: Minimize

$$\lim_{T\to\infty}\left\{\frac{1}{T}\int_0^T \|\mathscr{B}^*Y(t)\|^2\,dt + \frac{\lambda}{T}\int_0^T \|u(t)\|^2\,dt\right\} \tag{2.7}$$

(where $\mathcal{B}^*$ is the adjoint of $\mathcal{B}$ in the energy-inner product!) We note here, for future reference, that

$$\mathcal{L}^* v_p = \left|\begin{matrix} A^{-1}Bv_p \\ 0 \end{matrix}\right| \quad \text{if } \mathcal{L}Y = B^* y_1, \tag{2.8}$$

$$\mathcal{B}^* Y = -B^* y_2, \tag{2.9}$$

$$C^* v = \left|\begin{matrix} A^{-1}Bv_p \\ Bv_r \end{matrix}\right| \tag{2.10}$$

(where C^* is the adjoint of C in $\mathcal{H}_E$ (in the energy-inner products),

$$C^* D_0^{-1} C Y = \left|\begin{matrix} A^{-1}BD_p^{-1}B^* y_1 \\ BD_r^{-1}B^* y_2 \end{matrix}\right|, \tag{2.11}$$

where D_0 is the spectral density matrix of the process $N_0(\cdot)$).

The stochastic regulator problem is then embodied in (2.4), (2.5), and (2.7).

3. Main results.

THEOREM 3.1. *The stochastic regulator problem* (2.4), (2.5), (2.7) *has the optimal solution given by*

$$u_0(t) = \frac{-\mathcal{B}^* P_c \hat{Y}(t)}{\lambda}, \tag{3.1}$$

where P_c is the unique self-adjoint solution of

$$0 = [P_c Y, \mathcal{A} Y] + [\mathcal{A} Y, P_c Y] + [\mathcal{B}^* Y, \mathcal{B}^* Y] - \frac{[\mathcal{B}^* P_c Y, \mathcal{B}^* P_c Y]}{\lambda}, \qquad Y \in \mathcal{D}(\mathcal{A}), \tag{3.2}$$

and $\hat{Y}(\cdot)$ is defined by the "Kalman filter" equation

$$\dot{\hat{Y}}(t) = (\mathcal{A} - P_f C^* D_0^{-1} C)\hat{Y}(t) - \frac{\mathcal{B}\mathcal{B}^*}{\lambda} P_c \hat{Y}(t) + P_f C^* D_0^{-1} v(t), \tag{3.3}$$

where P_f is the unique self-adjoint solution of

$$\begin{aligned} 0 = {} & [P_f Y, \mathcal{A}^* Y] + [\mathcal{A}^* Y, P_f Y] + [\mathcal{B} D_a \mathcal{B}^* Y, Y] \\ & -[P_f C^* D_0^{-1} C P_f Y, Y], \qquad Y \in \mathcal{D}(\mathcal{A}^*). \end{aligned} \tag{3.4}$$

The corresponding (minimal) cost functional is

$$= \operatorname{Tr} \mathcal{B}^* P_f \mathcal{B}^* + \operatorname{Tr} \sqrt{D_0^{-1}}\, C P_f P_c P_f C^* \sqrt{D_0^{-1}}. \tag{3.5}$$

Also

$$\lim_{T \to \infty} \frac{1}{T} \int_0^T [\mathcal{B}^* Y(t), \mathcal{B}^* Y(t)]\, dt$$

goes (decreases) to

$$\operatorname{Tr} \mathcal{B}^* P_f \mathcal{B} \tag{3.6}$$

as $\lambda \to 0$.

We begin with some preliminary lemmas.

LEMMA 1. $\mathcal{A} - C^* D_0^{-1} C$ *generates a strongly stable semigroup $S_0(\cdot)$ such that for every Y in $\mathcal{H}_E$*

$$\int_0^\infty \|\sqrt{D_0^{-1}}\, C S_0(\sigma) Y\|^2 \, d\sigma < \infty. \tag{3.7}$$

Proof. Since $\mathscr{A}$ generates an isometric group it is enough to show that

$$\mathscr{A} \sim C^*\sqrt{D_0^{-1}}$$

is controllable. Let $S(\cdot)$ denote the semigroup generated by $\mathscr{A}$. Suppose

$$\sqrt{D_0^{-1}}\, CS(t)^* Y = 0, \qquad t \geqq 0. \tag{3.8}$$

We need to show that Y must then be zero. Now letting

$$S(t)^* Y = \begin{vmatrix} y_1(t) \\ y_2(t) \end{vmatrix}$$

we have that (since D_0 is nonsingular)

$$CS(t)^* Y = \begin{vmatrix} B^* y_1(t) \\ B^* y_2(t) \end{vmatrix} = 0, \qquad t \geqq 0. \tag{3.9}$$

However,

$$B^* y_2(t) = -\mathscr{B}^* S(t)^* Y$$

and, in particular, (3.9) implies that

$$\mathscr{B}^* S(t)^* Y = 0, \qquad 0 \leqq t,$$

which because of our assumption that

$$(\mathscr{A} \sim \mathscr{B})$$

is controllable, implies that

$$Y = 0.$$

Hence $(\mathscr{A} \sim C^*\sqrt{D_0^{-1}})$ is controllable and $(\mathscr{A} - C^* D_0^{-1} C)$ is strongly stable. Hence also (3.7) follows from (2.6) taking $\mathscr{B} = C^*\sqrt{D_0^{-1}}$ therein. Also using $\mathscr{A}^*$ in place of $\mathscr{A}$, we may replace $S_0(\sigma)$ by $S_0(\sigma)^*$.

As a consequence of this lemma we can state Lemma 2.

LEMMA 2. *Let the control $u(t) \equiv 0$, and define the process $\hat{Y}(\cdot)$ by*

$$\dot{\hat{Y}}(t) = (\mathscr{A} - \gamma C^* D_0^{-1} C)\hat{Y} + \gamma C^* D_0^{-1} v, \qquad \gamma > 0.$$

Then we have

$$\dot{Y}(t) = \mathscr{A} Y(t) + \mathscr{B} N_a(t),$$

$$\dot{\hat{Y}}(t) = \mathscr{A}\hat{Y}(t) + \gamma C^* D_0^{-1} C(Y(t) - \hat{Y}(t)) + \gamma C^* D_0^{-1} N_0,$$

and

$$Z(t) = Y(t) - \hat{Y}(t)$$

satisfies

$$\dot{Z}(t) = (\mathscr{A} - \gamma C^* D_0^{-1} C) Z(t) + \gamma C^* D_0^{-1} N_0 + \mathscr{B} N_a(t).$$

Let

$$\mathscr{R}(t) = E[Z(t) Z(t)^*].$$

Then $R(t)$ converges strongly to $R(\infty)$ and

$$[R(\infty) Y, Y] = \frac{\gamma \|Y\|_E^2}{2} + \int_0^\infty \|\sqrt{D_a}\, \mathscr{B}^* S_\gamma(s)^* Y\|^2 \, d\sigma, \tag{3.10}$$

where $S_\gamma(\cdot)$ is the semigroup generated by $\mathcal{A}-\gamma C^*D_0^{-1}C$, and the second term

$$\int_0^\infty \|\sqrt{D_a}\,\mathcal{B}^*S_\gamma(\sigma)Y\|^2\,d\sigma \leqq \frac{\|Y\|_E^2}{2\gamma}\|D_a\|\,\|D_0\|.$$

Proof. The proof is fairly immediate from

$$[R(t)Y, Y]=[\Lambda S_\gamma(t)^*Y, S_\gamma(t)^*Y] + \int_0^t [(\gamma^2C^*D_0^{-1}C+\mathcal{B}D_a\mathcal{B}^*)S_\gamma^*(\sigma)Y, S_\gamma^*(\sigma)Y]\,d\sigma,$$

where

$$\Lambda = E[(Y(0)-\hat{Y}(0))(Y(0)-\hat{Y}(0))^*].$$

See also [6] if necessary for a similar argument. Also

$$\int_0^\infty \|\mathcal{B}^*S_\gamma^*(\sigma)Y\|^2\,d\sigma<\infty$$

follows from

$$\int_0^\infty \|\mathcal{B}^*S_\gamma^*(\sigma)Y\|^2\,d\sigma \leqq \int_0^\infty \|CS_\gamma^*(\sigma)Y\|^2\,d\sigma \leqq \int_0^\infty \|D_0\|\,\|\sqrt{D_0^{-1}}\,CS_\gamma^*(\sigma)Y\|^2\,d\sigma = \frac{\|D_0\|\,\|Y\|_E^2}{2\gamma}.$$

THEOREM 3.2. *There exist admissible ("feedback") controls for which* (2.7) *is finite.*

Proof. We ignore $v_p(\cdot)$ and devise controls using only $v_r(\cdot)$ and the results in [7]. Note that

$$v_r(t)=-\mathcal{B}^*Y(t)+N_r(t).$$

If $D_a=d_aI$ and $D_0=d_0I$, we could use the results in [7] verbatim. For the more general case considered here we will now show that the choice

$$u(t)=-\mathcal{B}^*\hat{Y}(t), \tag{3.11}$$

where

$$\begin{aligned}\dot{\hat{Y}}(t)&=\mathcal{A}\hat{Y}(t)-\mathcal{B}(v_r(t)+\mathcal{B}^*\hat{Y}(t))-\mathcal{B}\mathcal{B}^*\hat{Y}(t),\\ \hat{Y}(0)&=0\end{aligned} \tag{3.12}$$

yields an admissible control which makes (2.7) finite. We may think of $\hat{Y}(\cdot)$ defined by (3.12) as a "suboptimal" estimate, and, of course, (3.11) is a suboptimal control—in other words, this is merely a technique to show that admissible controls exist for which (2.7) is finite.

LEMMA 3. *The operator*

$$\mathcal{A}_2=\begin{vmatrix}\mathcal{A}^*-\mathcal{B}\mathcal{B}^* & \mathcal{B}\mathcal{B}^*\\ \mathcal{B}\mathcal{B}^* & \mathcal{A}^*-2\mathcal{B}\mathcal{B}^*\end{vmatrix} \tag{3.13}$$

with domain $(\mathcal{D}(\mathcal{A})\times\mathcal{D}(\mathcal{A}))$ in $H_E\times H_E$ generates a strongly continuous semigroup

$S_Z(\cdot)$, which is strongly stable. Moreover, using the notation

$$S_Z(t)Z = \begin{vmatrix} Y(t) \\ \hat{Y}(t) \end{vmatrix}, \qquad Z = \begin{vmatrix} Y \\ \hat{Y} \end{vmatrix}$$

we have further that

$$\int_0^\infty \|\mathscr{B}^* Y(t)\|^2 \, dt + \int_0^\infty \|\mathscr{B}^* \hat{Y}(t)\|^2 \, dt < \infty \tag{3.14}$$

for each Z.

Proof. The semigroup generation property is immediate; only the strong stability property and (3.14) require additional proof.

Let $Z \in \mathscr{D}(\mathscr{A}_Z)$. Then if

$$S_Z(t)Z = \begin{vmatrix} Y(t) \\ \hat{Y}(t) \end{vmatrix},$$

we have

$$\dot{Y}(t) + \dot{\hat{Y}}(t) = (\mathscr{A}^* - \mathscr{B}\mathscr{B}^*)(Y(t) + \hat{Y}(t)).$$

Hence

$$Y(t) + \hat{Y}(t) = S_1(t)(Y + \hat{Y}), \qquad t \geqq 0, \tag{3.15}$$

where $S_1(\cdot)$ is the semigroup generated by $(\mathscr{A}^* - \mathscr{B}\mathscr{B}^*)$, and (3.15) continues to hold for all Z in $\mathscr{H}_E \times \mathscr{H}_E$. Similarly, from

$$\dot{\hat{Y}}(t) = \mathscr{A}^* Y(t) + \mathscr{B}\mathscr{B}^* \hat{Y}(t) = (\mathscr{A}^* - \mathscr{B}\mathscr{B}^*) Y(t) + \mathscr{B}\mathscr{B}^*(Y(t) + \hat{Y}(t)),$$

we have

$$Y(t) = S_1(t) Y + \int_0^t S_1(t-\sigma)\mathscr{B}\mathscr{B}^* S_1(\sigma)(Y + \hat{Y}) \, d\sigma \tag{3.16}$$

and also, similarly,

$$\hat{Y}(t) = S_1(t) \hat{Y} + \int_0^t S_1(t-\sigma)\mathscr{B}\mathscr{B}^* S_1(\sigma)(Y + \hat{Y}) \, d\sigma \tag{3.17}$$

for all Y, $\hat{Y}$ in $\mathscr{H}_E$. For any ψ in $\mathscr{H}_E$, let us show now that

$$[Y(t), \psi] \to 0 \quad \text{as } t \to \infty.$$

We have

$$[Y(t), \psi] = [S_1(t) Y, \psi] + \int_0^t [\mathscr{B}^* S_1(\sigma)(Y + \hat{Y}), \mathscr{B}^* S_1(t-\sigma)\psi] \, d\sigma. \tag{3.18}$$

Now $S_1(\cdot)$ being strongly stable and

$$\int_0^\infty \|\mathscr{B}^* S_1(\sigma) X\|^2 \, d\sigma < \infty \quad \text{for any } X \text{ in } \mathscr{H}_E$$

it follows readily that (3.18) goes to zero as $t \to \infty$. Similarly, so does $[\hat{Y}(t), \psi]$ using (3.17). Hence the semigroup $S_Z(\cdot)$ is weakly stable, and since it has a compact resolvent it follows that it is actually strongly stable (see [6] if necessary). Next

$$\mathscr{B}^* Y(t) = \mathscr{B}^* S_1(t) Y + \int_0^t \mathscr{B}^* S_1(t-\sigma)\mathscr{B}\mathscr{B}^* S_1(\sigma)(Y + \hat{Y}) \, d\sigma \tag{3.19}$$

since

$$\int_0^\infty \|\mathcal{B}^* S_1(t) Y\|^2 \, dt < \infty$$

and the second term is a convolution of functions in $L_2[0, \infty]$,

$$\int_0^\infty \|\mathcal{B}^* Y(t)\|^2 \, dt < \infty.$$

By a similar argument, using (3.17),

$$\int_0^\infty \|\mathcal{B}^* \hat{Y}(t)\|^2 \, dt < \infty$$

and hence we have proved (3.14).

We can now proceed to prove Theorem 3.2. We consider the coupled equations

$$\begin{aligned} \dot{Y}(t) &= \mathcal{A}Y(t) - \mathcal{B}\mathcal{B}^* \hat{Y}(t) + \mathcal{B}N_a(t), \\ \dot{\hat{Y}}(t) &= (\mathcal{A} - 2\mathcal{B}\mathcal{B}^*)\hat{Y}(t) + \mathcal{B}\mathcal{B}^* Y(t) - \mathcal{B}N_r(t). \end{aligned} \tag{3.20}$$

Writing

$$Z(t) = \left| \begin{matrix} Y(t) \\ \hat{Y}(t) \end{matrix} \right|, \qquad Z = \left| \begin{matrix} Y \\ \hat{Y} \end{matrix} \right|,$$

we obtain

$$\dot{Z}(t) = A_Z Z(t) + \left| \begin{matrix} \mathcal{B}N_a(t) \\ \mathcal{B}(-N_r(t)) \end{matrix} \right|.$$

Let

$$E[Z(t)Z(t)^*] = \mathcal{R}(t), \qquad \mathcal{R}(0) = \Lambda,$$

where, of course, $\mathcal{R}(t)$, $t \geqq 0$ is a linear bounded operator mapping $\mathcal{H}_E \times \mathcal{H}_E$ into itself, and Λ is self-adjoint, nonnegative definite and so is $\mathcal{R}(t)$ for each t. Then

$$[\mathcal{R}(t)Z, Z] = [\Lambda S_Z(t)Z, S_Z(t)Z] + \int_0^t \left[\left| \begin{matrix} \mathcal{B}D_a\mathcal{B}^* & 0 \\ 0 & \mathcal{B}D_r\mathcal{B}^* \end{matrix} \right| S_Z(\sigma)Z, S_Z(\sigma)Z \right] d\sigma,$$

where $S_Z(\cdot)$ is the adjoint of the semigroup generated by

$$\left| \begin{matrix} \mathcal{A} - \mathcal{B}\mathcal{B}^* & -\mathcal{B}\mathcal{B}^* \\ \mathcal{B}\mathcal{B}^* & \mathcal{A} - 2\mathcal{B}\mathcal{B}^* \end{matrix} \right|.$$

By Lemma 3, $S_Z(\cdot)$ is strongly stable and the second term in

$$\int_0^\infty [\mathcal{B}D_a\mathcal{B}^* Y(\sigma), Y(\sigma)] \, d\sigma + \int_0^\infty [\mathcal{B}D_r\mathcal{B}^* \hat{Y}(\sigma), \hat{Y}(\sigma)] \, d\sigma$$

(where we use the notation $S_Z(\sigma)Z = \left|{Y(\sigma) \atop \hat{Y}(\sigma)}\right|$)

$$\leqq \int_0^\infty \|D_a\| \, \|\mathcal{B}^* Y(\sigma)\|^2 \, d\sigma + \|D_a\| \int_0^\infty \|\mathcal{B}^* \hat{Y}(\sigma)\|^2 \, d\sigma$$

$$< \infty$$

by (3.14). Hence

$$\mathscr{R}(t) \text{ converges strongly to } \mathscr{R}(\infty),$$

$$[\mathscr{R}(\infty)Z, Z] < \infty \quad \text{for every } Z \text{ in } \mathscr{H}_E \times H_E,$$

and $\mathscr{R}(\infty)$ is linear bounded, self-adjoint, and nonnegative definite. Hence the process $Z(\cdot)$ defined (3.20) has a steady state, with steady-state covariance

$$\lim_{T\to\infty} E[Z(T)Z(T+t)^*] = S_Z(t)\mathscr{R}(\infty).$$

In particular, the finite-dimensional process

$$\mathscr{B}^* Y(t)$$

is Gaussian and asymptotically stationary. Therefore

$$(3.21) \qquad \lim_{T\to\infty} \frac{1}{T}\int_0^T \|\mathscr{B}^* Y(t)\|^2\, dt = \operatorname{Tr} \mathscr{B}^*\mathscr{R}_{11}\mathscr{B} < \infty$$

and, similarly,

$$(3.22) \quad \lim_{T\to\infty} \frac{1}{T}\int_0^T \|u(t)\|^2\, dt = \lim_{T\to\infty} \frac{1}{T}\int_0^T \|\mathscr{B}^* \hat{Y}(t)\|^2\, dt = \operatorname{Tr} \mathscr{B}^*\mathscr{R}_{22}B < \infty,$$

where we have used the representation for $\mathscr{R}(\infty)$:

$$\mathscr{R}(\infty) = \begin{vmatrix} \mathscr{R}_{11} & \mathscr{R}_{12} \\ \mathscr{R}_{21} & \mathscr{R}_{22} \end{vmatrix},$$

$\mathscr{R}_{ij}$ being linear bounded operators mapping $\mathscr{H}_E$ into $\mathscr{H}_E$, thus proving Theorem 3.2.

We are now ready to prove our main results in Theorem 3.1.

We follow in the main the arguments in [6, p. 351 et seq.], except that now we do not invoke exponential stability—replacing it, in fact, by the strong stability property. Thus let $P_f(t)$, $t \geqq 0$ be the solution of (the Riccati equation):

$$(3.23) \quad \frac{d}{dt}[P_f(t)Y, Y] = [\mathscr{A}^*Y, P_f(t)Y] + [P_f(t)Y, \mathscr{A}^*Y] + [\mathscr{B}D_a\mathscr{B}^*Y, Y]$$
$$-[P_fC^*D_0^{-1}CP_fY, Y]$$

for every Y in $\mathscr{D}(\mathscr{A}^*)(=\mathscr{D}(\mathscr{A}))$, with

$$P_f(0) = 0.$$

See [6] for the existence and uniqueness of solution. $P_f(t)$, $t \geqq 0$, is a self-adjoint, nonnegative definite mapping $\mathscr{H}_E$ into $\mathscr{H}_E$. Similarly, let $P_c(t)$ be the solution of

$$(3.24) \quad \frac{d}{dt}[P_c(t)Y, Y] = [P_c(t)Y, \mathscr{A}Y] + [\mathscr{A}Y, P_c(t)Y] + [\mathscr{B}^*Y, \mathscr{B}^*Y]$$
$$-\frac{[\mathscr{B}^*P_c(t)Y, \mathscr{B}^*P_c(t)Y]}{\lambda}$$

for Y in $\mathscr{D}(\mathscr{A})$, and

$$P_c(0) = 0.$$

Then both

$$[P_f(t)Y, Y] \quad \text{and} \quad [P_c(t)Y, Y]$$

are monotone nondecreasing, and our first step is to show that the limit is finite in each case. For this purpose let us use the control defined in Theorem 3.2. Then

$$\begin{aligned}(3.25)\qquad &\frac{1}{T}\int_0^T E[\mathscr{B}^*Y(t),\mathscr{B}^*Y(t)]\,dt+\frac{1}{T}\int_0^T E(\|u(t)\|^2)\,dt\\ &\geqq\frac{1}{T}\int_0^T \operatorname{Tr}\mathscr{B}^*P_f(t)\mathscr{B}^*\,dt\\ &+\frac{1}{T}\int_0^T \operatorname{Tr}\sqrt{D_0^{-1}}\,CP_f(t)P_c(T-t)P_f(t)C^*\sqrt{D_0^{-1}}\,dt.\end{aligned}$$

Now by Lemma 2, we see that

$$[P_f(t)Y,Y]<[R(\infty)Y,Y]<\infty$$

in the notation of (3.10). Hence $P_f(t)$ converges strongly to P_f, say. Then the right side of (3.23) converges to the right side of (3.4), while the left side of (3.23) since it converges must converge to zero. Hence P_f satisfies (3.4), and is, in fact, the unique self-adjoint linear bounded operator solution of (3.4). Next let us consider (3.24). Now we know that

$$[P_c(T)Y,Y]\leqq\int_0^T\|\mathscr{B}^*Y(t)\|^2\,dt+\lambda\int_0^T\|u(t)\|^2\,dt,$$

where

$$\dot Y(t)=\mathscr{A}Y+\mathscr{B}u,\qquad Y(0)=Y$$

for any $u(\cdot)$ in $L_2[0,T]$. Take now

$$u(t)=-\mathscr{B}^*Y(t).$$

Then

$$\begin{aligned}[P_c(T)Y,Y]&\leqq\int_0^T\|\mathscr{B}^*S(t)Y\|^2\,dt+\lambda\int_0^T\|\mathscr{B}^*S(t)Y\|^2\,dt\\ &\leqq\int_0^\infty\|\mathscr{B}^*S(t)Y\|^2\,dt+\lambda\int_0^\infty\|\mathscr{B}^*S(t)Y\|^2\,dt<\infty.\end{aligned}$$

Hence $[P_c(t)Y,Y]$ increases to a finite limit, or $P_c(\infty)$ (self-adjoint linear bounded) which then, of course, satisfies (3.2). In fact, it is immediate that

$$(3.26)\qquad P_c=P_c(\infty)=\sqrt{\lambda}\,I.$$

Hence the right side of (3.25) converges to

$$\operatorname{Tr}\mathscr{B}^*P_f\mathscr{B}+\operatorname{Tr}\sqrt{D_0^{-1}}\,CP_fP_cP_fC^*\sqrt{D_0^{-1}},$$

which is (3.5). Moreover, the choice (3.1) yields the cost functional (3.5). In fact, the system

$$(3.27)\qquad \dot{\hat Y}(t)=(\mathscr{A}-P_fC^*D_0^{-1}C)\hat Y(t)-\frac{\mathscr{B}\mathscr{B}^*}{\sqrt{\lambda}}\hat Y(t)+P_fC^*D_0^{-1}v(t),$$

$$(3.28)\qquad \dot Y(t)=\mathscr{A}Y(t)-\frac{\mathscr{B}\mathscr{B}^*}{\sqrt{\lambda}}\hat Y(t)+BN_a(t)$$

is asymptotically stationary, and

$$\lim_{t\to\infty} E[(Y(t) - \hat{Y}(t))Y(t)^*] = 0. \tag{3.29}$$

It is more convenient to replace (3.27), (3.28) by the system

$$\begin{matrix}\hat{Y}(t) = \\ Z(t) = \end{matrix}\begin{vmatrix} \mathscr{A} - \mathscr{B}\mathscr{B}^*/\lambda & P_f C^* D_0^{-1} C \\ 0 & \mathscr{A} - P_f C^* D_0^{-1} C \end{vmatrix}\begin{vmatrix} \hat{Y}(t) \\ Z(t) \end{vmatrix} + \begin{vmatrix} P_f C^* \sqrt{D_0^{-1}}\, N_0 \\ \mathscr{B} N_a(t) + P_f C^* \sqrt{D_0^{-1}}\, N_0(t) \end{vmatrix}, \tag{3.30}$$

where

$$Z(t) = Y(t) - \hat{Y}(t). \tag{3.31}$$

We can verify directly that the semigroup generated by

$$\begin{vmatrix} \mathscr{A} - \mathscr{B}\mathscr{B}^*/\lambda & P_f C^* D_0^{-1} C \\ 0 & \mathscr{A} - P_f C^* D_0^{-1} C \end{vmatrix}$$

is strongly stable and, furthermore, that system (3.30) is asymptotically stationary. Let

$$\mathscr{R} = \begin{vmatrix} \mathscr{R}_{11} & \mathscr{R}_{12} \\ \mathscr{R}_{21} & \mathscr{R}_{22} \end{vmatrix}$$

denote the steady-state covariance. Then we have, of course,

$$\mathscr{R}_{22} = P_f, \qquad \mathscr{R}_{12} = \mathscr{R}_{22} = 0$$

and $\mathscr{R}_{11}$is defined by

$$\left[\mathscr{R}_{11} Y, \left(\mathscr{A}^* - \frac{\mathscr{B}\mathscr{B}^*}{\lambda}\right) Y\right] + \left[\left(\mathscr{A}^* - \frac{\mathscr{B}\mathscr{B}^*}{\lambda}\right) Y, \mathscr{R}_{11} Y\right] + [P_f C^* D_0^{-1} C P_f Y, Y] = 0, \tag{3.32}$$

$$Y \in \mathscr{D}(\mathscr{A}^*).$$

An important property of $\mathscr{R}_{11}$ that follows from (3.32) is that $\mathscr{R}_{11}$ goes to zero strongly as $\lambda \to 0$. In particular, we have that

$$\lim_{\lambda\to 0}\left[\lim_{T\to\infty} \frac{1}{T}\int_0^T \|\mathscr{L}Y(t)\|^2\, dt\right] = \operatorname{Tr} \mathscr{L}P_f\mathscr{L}^*. \tag{3.33}$$

As a result we have the following useful corollary.

COROLLARY. *Consider the stochastic regulator problem for the system* (2.4), (2.5) *with the cost functional*

$$\lim_{T\to\infty} \left\langle \frac{1}{T}\int_0^T \|\mathscr{L}Y(t)\|^2\, dt + \frac{\lambda}{T}\int_0^T \|u(t)\|^2\, dt\right] \tag{3.34}$$

(*replacing* $\mathscr{B}^*$ *in* (2.7) *by* $\mathscr{L}$).

Let $q(\lambda)$ *denote the infimum of* (3.34). *Then*

$$\lim_{T\to 0} q(\lambda) = \operatorname{Tr} \mathscr{L}P_f\mathscr{L}^*. \tag{3.35}$$

In particular,

$$\lim_{\lambda\to 0}\left[\frac{1}{T}\int_0^T \|\mathscr{L}Y(t)\|^2\, dt\right] \geqq \operatorname{Tr} \mathscr{L}P_f\mathscr{L}^*. \tag{3.36}$$

Remark. The novelty in this result is that we do not need to exhibit the optimal control that minimizes (3.34) for each λ; and indeed we need not thus discuss whether an optimal control exists! Of course, $\mathscr{L}$ can be replaced by any finite-dimensional operator on $\mathscr{H}_E$.

Proof. For each $\lambda > 0$, the control $u(\cdot)$ defined by (3.1) which is optimal for (2.7), is certainly an admissible control since the corresponding value for (3.34) is

$$= \mathrm{Tr}\, \mathscr{L} P_f \mathscr{L}^* + \mathrm{Tr}\, \mathscr{L} \mathscr{R}_{11} \mathscr{L}^* + \mathrm{Tr}\, \mathscr{B}^* \mathscr{R}_{11} \mathscr{B}. \tag{3.37}$$

Hence

$$\lim_{\lambda \to 0} q(\lambda) \leqq \mathrm{Tr}\, \mathscr{L} P_f \mathscr{L}^*.$$

On the other hand, for any admissible control $u(\cdot)$

$$\lim_{t \to \infty} E[\mathscr{L} Y(t) Y(t)^* \mathscr{L}^*] = \mathrm{Tr}\, \mathscr{L} P_f \mathscr{L}^* + \mathrm{Tr}\, \mathscr{L} \hat{R} \mathscr{L}^*,$$

where

$$\hat{R} = \lim_{t \to \infty} E[\hat{Y}(t) \hat{Y}(t)^*],$$

where

$$\hat{Y}(t) = E[Y(t) \,|\, v(s), s \leqq t].$$

Hence

$$q(\lambda) \geqq \mathrm{Tr}\, \mathscr{L} P_f \mathscr{L}^*$$

and hence the result follows. Note, in particular, that

$$\mathscr{L} P_f \mathscr{L}^* = \mathrm{Tr}\, B^* P_{11} A^{-1} B,$$

where

$$P_f = \begin{vmatrix} P_{11} & P_{22} \\ P_{21} & P_{22} \end{vmatrix}.$$

FEEDBACK EQUIVALENCE FOR NONLINEAR SYSTEMS AND THE TIME OPTIMAL CONTROL PROBLEM*

B. BONNARD†

Abstract. This article relates the classification of affine control systems under the action of the feedback group, with a differential classification of a set of constrained Hamiltonian vector fields, arising from Pontryagin's Maximum Principle, for the time minimal control problem. They represent the singularities of the input-state mapping. This relation provides a method to compute feedback invariants.

Key words. nonlinear control systems, feedback classification, time optimal control, invariant theory

1. Introduction. Let X, $Y_1, \cdots, Y_m$ be analytic vector fields of $\mathfrak{R}^n$. We are dealing with control systems of the form

$$\frac{dx(t)}{dt} = X(x(t)) + Y(x(t))u(t), \tag{1}$$

where $x \in \mathfrak{R}^n$, $u \in \mathfrak{R}^m$, $Y = (Y_1, \cdots, Y_m)$. They are called *affine systems.*

Let (X, Y) and (X', Y') be two affine control systems. They are called *feedback equivalent* if there exists a C^ω diffeomorphism ψ of $\mathfrak{R}^n$ and a feedback $u = \alpha(x) + \beta(x)u'$, where $\alpha \in \mathscr{C}^\omega(\mathfrak{R}^n, \mathfrak{R}^m)$, $\beta \in \mathscr{C}^\omega(\mathfrak{R}^n, \mathrm{GL}(m, \mathfrak{R}))$ such that
(i) $X' = \psi * X + \psi * Y \cdot \alpha$,
(ii) $Y' = \psi * Y \cdot \beta$,
where $\psi*$ is defined by the following. Let Z be a vector field; then

$$\psi * Z = \frac{\partial \psi^{-1}}{\partial x} \quad (Z \circ \psi)$$

($\psi * Z$ is called the *image* of Z). This action defines a group structure on the set of triplets (ψ, α, β). This group is denoted by G_f.

The classification of linear controllable systems under the action of the Lie subgroup of G_f of triplets (ψ, α, β), where ψ, α are *linear* mappings and β is a *constant* mapping, is now well understood (see [8]). A complete set of (arithmetic) invariants is the set of controllability indices. Canonical forms, called Brunovsky's forms, have been exhibited.

The (local) feedback equivalence problem of system (1) with a linear system was solved around 1980. A chain of distributions is introduced and Brunovsky's canonical forms are recovered by integration of these distributions (see [19] and [18]).

In this article, we study the feedback classification for *generic* nonlinear systems. Our approach is coming from the philosophy of singularity theory and is justified by the following two remarks.

First, consider (ii). Let Δ_Y (respectively, $\Delta_{Y'}$) be the map $x \rightarrow$ the linear span of $\{Y_1(x), \cdots, Y_m(x)\}$ (respectively, $\{Y'_1(x), \cdots, Y'_m(x)\}$. Then, (ii) means that the two distributions Δ_Y and $\Delta_{Y'}$ are diffeomorphic. Therefore, a *first step* in the feedback classification of affine control systems is the *classification of distributions.* The classical results in this area are well known (see [15] for an exposition). They are Frobenius'

theorem for an involutive distribution and Darboux's classification for a generic distribution of codimension one. For recent developments in this theory see [12], but, in any case, all the results are *local* and mainly concern distributions with *constant rank.*

Now, when $Y=0$, (i) shows that the feedback classification is reduced to the analytic classification of vector fields. Near a point x_0 such that $X(x_0)\neq 0$, this problem is solved by the theorem of existence of solutions (X is equivalent to $\partial/\partial x_1$). Near a singular point x_0, i.e., $X(x_0)=0$, this classification is a difficult problem. It was first studied by Lyapunov, Poincaré, and Dulac (see [1]) and is still the object of investigations (see [24] and [26]). If we introduce the distribution $x\to\Re X(x)$, it can be interpreted as a classification problem for distributions of dimension one and with singularities.

The main contribution of this article is to show that with certain (reasonable) assumptions, the feedback classification of pairs (X, Y) is equivalent to the classification of the distribution Δ_Y and a vector field $Z_{\hat{H}}$, which will be defined later. These objects will be encoded in a *constrained vector field.*

Let us make this assertion precise. A system can be viewed as a map, called the *input-state mapping*, which assigns to an input $u(\cdot)$, the response of (1) denoted by $x(\cdot, x_0, u)$, where $x(0)=x_0$ is fixed. If we endow the set of inputs with the L^∞-norm, this map is differentiable and has *singularities*, which are called the *singular trajectories in the time optimal control problem* [5]. They can be parametrized by *Pontryagin's Maximum Principle* (PMP) (see [22]). If we introduce the Hamiltonian H, defined by

$$H(x, p, u)=\langle p, X(x)+Y(x)u\rangle,$$

where $p\in\Re^n\backslash\{0\}$ and $\langle\ ,\ \rangle$ denotes the standard inner product, the singular trajectories are the projections on the x-space of the *constrained Hamiltonian equation*

$$\dot{x}=\frac{\partial H}{\partial p},\qquad \dot{p}=-\frac{\partial H}{\partial x},\qquad (x, p)\in\Sigma,$$

where Σ is the surface $\{(x, p); \langle p, Y(x)\rangle=0\}$.

This equation defines two objects: *a surface* Σ and the solutions $(x(t), p(t))$ of the Hamiltonian equation *that stays in* Σ. We will show that they are the solutions of a vector field $Z_{\hat{H}}$ defined on Σ if m is even or on a proper subset of Σ if m is odd.

We prove that a singularity of the input-state mapping is feedback invariant. Therefore, we can define the action of the feedback group on this set of constrained Hamiltonian equation as follows: $(\psi, \alpha, \beta)\in G_f$ acts on $(\Sigma, Z_{\hat{H}})$ as a symplectic diffeomorphism of $\Re^{2n}$, $\boldsymbol{\psi}$ given by $x=\psi(y)$, $p=q(\partial\psi^{-1}/\partial y)$ (p, q must be written as row vectors). According to Klein, the pair $(\{\Sigma, Z_{\hat{H}}\}, G_f)$ defines a *geometry.*

Now we can formulate the main results of this article. *If two systems are feedback equivalent, then their associated Hamiltonian equations are G_f-equivalent. Moreover, if we restrict our classification to the set of pairs* (X, Y) *such that* (i) Δ_Y *is of constant rank, and* (ii) $m\leqslant n-1$ *when n is even or* $m\leqslant n-2$ *when n is odd, then, in general, the feedback classification problem is equivalent to the classification of our set of constrained Hamiltonian equations.*

"In general" means that our result is valid if we substract to the set of systems a *bad set.* This set is, roughly, the family of systems where the set of singular trajectories is too small to be a complete covariant, i.e., to separate all the orbits for the G_f-action on pairs (X, Y). It is worth pointing out that the *linear systems are in this bad set,* because the input-state mapping of a linear controllable system has no singularity.

The interest of our approach is the following. Understanding a geometry (E, G) consists mainly in describing the algebra of functions $I: E\to\Re$, which are constant on each orbit. They are called the *invariants.*, Now, the invariants of the geometry $(\{\Sigma, Z_{\hat{H}}\}, G_f)$ are feedback invariants. They can be more easily computed than the invariants of the geometry $(\{X, Y\}, G_f)$, because the feedback acts trivially.

Computing invariants is, in general, a dreadful problem. The second part of this article will indicate how to compute feedback invariants by using two nontrivial examples. The first example concerns the feedback invariants arising from the time optimality problem. Indeed, the singular trajectories are the solutions of PMP associated with the *time minimal or time maximal* control problem. Their *optimality status* is a feedback invariant. This problem will be studied when $n=2$ or 3. (When $n>3$, see [6].)

The second example concerns the classification of the vector field $Z_{\hat{H}}$ when we study the feedback classification of a class of homogeneous control systems. We connect this problem with the *linear classification of tensors* (vectors, forms, etc.). All the machinery of this theory can be used, in particular, to compute *polynomial* invariants (see [16] for a good description of this machinery). These computations are outlined for systems in $\mathfrak{R}^3$ and some feedback invariants are connected to the behaviours of the integral curves of $Z_{\hat{H}}$. This example is instructive. It shows that the vector field $Z_{\hat{H}}$ alone can be very rich and *encode informations concerning the optimality problem and the distribution* Δ_Y.

In the conclusion, we indicate how to deal with the feedback classification problem for *nonaffine* control systems. Again, the basic tool is *Pontryagin's Maximum Principle.*

2. Preliminaries.

2.1. Notation and definitions. Let M and N be two analytic manifolds. We denote by $\mathscr{V}^\omega(M)$ the set of analytic vector fields of M. If $M=\mathfrak{R}^n$, a vector field is identified with a map from $\mathfrak{R}^n$ into $\mathfrak{R}^n$. We denote by $\mathscr{C}^\omega(M, N)$ the set of analytic maps from M into N. Let G_d be the group of C^ω-diffeomorphisms of $\mathfrak{R}^n$. The coordinates of $\mathfrak{R}^{2n}=\mathfrak{R}^n\times\mathfrak{R}^n$ are denoted by (x, p). Let $x=(x_1, \cdots, x_n)$, $p=(p_1, \cdots, p_n)$ and endow $\mathfrak{R}^{2n}$ with its canonical symplectic structure defined by $\Omega=\sum_{i=1}^n dx_i\wedge dp_i$. Let Z be a vector field of $\mathfrak{R}^n$, and let g be the map from $\mathfrak{R}^{2n}$ into $\mathfrak{R}$ defined by $(x, p)\rightarrow\langle p, Z(x)\rangle$. The Hamiltonian vector field with Hamilton function g is denoted by $\mathbf{Z}$ and is called the *Hamiltonian lift* of Z.

2.2. Constrained differential equation.

Definition 2.2.1. Let $Z\in\mathscr{V}^\omega(\mathfrak{R}^n)$, $g\in\mathscr{C}^\omega(\mathfrak{R}^n, \mathfrak{R})$, $c\in\mathscr{C}^\omega(\mathfrak{R}^n, \mathfrak{R}^q)$ and set $\tilde{Z}=Z/g$. The pair $(\tilde{Z}, \{c=0\})$ is called a *constrained meromorphic differential equation.* The set $\{c=0\}$ is called the *constraints set.* Let W be the subset of $\mathfrak{R}^n$

$$\{c=0\}\cap\left\{\frac{\partial c}{\partial x}\cdot Z=0\right\},$$

and let us assume that g is not identically zero on W. Let $S=W\cap\{g=0\}$. On $W\backslash S$ there exists an analytic vector field whose solutions are the analytic curves $t\rightarrow x(t)$ that are almost everywhere solutions of $\tilde{Z}$, which stay in $\{c=0\}$.

Definition 2.2.2. Now, we define a *geometry* on the set of meromorphic constrained differential equation. Let G be a subgroup of G_d. With the notation of Definition 2.2.1., two constrained differential equations $(\tilde{Z}, \{c=0\})$ and $(\tilde{Z}', \{c'=0\})$ are said to be *G-equivalent* if there exists $\psi\in G$ such that

(i) $\{c=0\}=\psi(\{c'=0\})$,

(ii) $S=\psi(S')$,

(iii) $\psi*\tilde{Z}|_{W\backslash S}=\tilde{Z}'|_{W'\backslash S'}$.

Observe that since W is the union of S and integral curves of $\tilde{Z}|_{W\backslash S}$, then $W=\psi(W')$.

CONVENTION 2.2.3. The previous geometry will be denoted by $(\{\Sigma, \tilde{Z}|_{W\setminus S}\}, G)$. By solution of a constrained meromorphic differential equation $(\tilde{Z}, \{c=0\})$, we mean an integral curve of $\tilde{Z}|_{W\setminus S}$.

2.3. Definitions. Let E and F be two $\mathfrak{R}$-vector spaces, and let G be a group acting linearly on E and F. A homomorphism $\chi: G \to \mathfrak{R}\setminus\{0\}$ is called a *character*. Let χ be a character. A *semi-invariant* of weight χ is a map $\lambda: E \to \mathfrak{R}$ such that for all $g \in G$, for all $x \in E$, $\lambda(g\cdot x) = \chi(g)\lambda(x)$. It is an *invariant* if $\chi = 1$. A map $\lambda: E \to F$ is a *semi-covariant*, of weight χ, if for all $g \in G$, for all $x \in E$, $\lambda(g\cdot x) = \chi(g) g \cdot \lambda(x)$. It is called a *covariant* if $\chi = 1$.

2.4. Singular trajectories.

DEFINITION 2.4.1. Consider a system of $\mathfrak{R}^n$

$$\frac{dx(t)}{dt} = f(x(t), u(t)), \tag{2}$$

where $u(t)$ is a bounded measurable map from an interval $[0, T]$ into $\mathfrak{R}^m$ and f is a C^1 map from $\mathfrak{R}^n \times \mathfrak{R}^m$ into $\mathfrak{R}^n$.

Let u be a control defined on $[0, T]$ and take $x_0 \in \mathfrak{R}^n$. The response of system (2) to u, initiating from x_0, is an absolutely continuous map $t \to x(t, x_0, u)$ defined on a subinterval $[0, T']$ of $[0, T]$, solution of (2) for almost every $t \in [0, T']$ and such that $x(0) = x_0$. Consider a control u_0 defined on $[0, T]$ such that the response $t \to x(t, u_0, x_0)$ is defined on the whole interval $[0, T]$. Endow the set of controls defined on $[0, T]$ with the L^∞-norm, i.e., $\|u\| = \sup_{t\in[0,T]} |u(t)|$. Let x_0, T be fixed. We denote by $E^{x_0,T}$ the *input-state mapping*, which is given by $u \to x(T, x_0, u)$, and is defined in an open set denoted by $u_0 + V$, where V is a neighborhood of 0. The control u_0 is called *singular* on $[0, T]$ if the Fréchet derivative of $E^{x_0,T}$, denoted by $dE^{x_0,T}$, is not of full rank at u_0. The corresponding response $t \to x(t, x_0, u_0)$ is called a *singular trajectory* (on $[0, T]$).

LEMMA 2.4.2. *Let $v \in V$ and let $A(t) = (\partial f/\partial x)\ (x(t, x_0, u_0), u_0(t))$, $B(t) = (\partial f/\partial u)(x(t, x_0, u_0), u_0(t))$, then*

$$dE^{x_0,T}_{u_0}(v) = M(T) \int_0^T M^{-1}(t) B(t) v(t)\, dt,$$

where $M(t)$ is the $n \times n$ matrix solution of

$$\dot{M}(t) = A(t)M(t),\ M(0) = \text{identity}.$$

Proof. This result is well known (see, for instance, [14]).

PROPOSITION 2.4.3. *Consider, as before, a system of $\mathfrak{R}^n$:*

$$\dot{x}(t) = f(x(t), u(t)).$$

Then the pair u_0 and $x(t, x_0, u_0)$ is singular on $[0, T]$ if and only if there exists a (row) vector $p(t) \in \mathfrak{R}^n\setminus\{0\}$ solution for almost every $t \in [0, T]$ of the adjoint equation

$$\dot{p}(t) = -p(t)A(t), \tag{3}$$

and satisfying for almost every $t \in [0, T]$

$$\langle p(t), B(t)\rangle = 0. \tag{4}$$

Proof. By definition, u_0 is singular on $[0, T]$ if and only if the dimension of the linear span of

$$\left\{\int_0^T M(T)M^{-1}(t)B(t)v(t)\, dt;\quad v \in V\right\}$$

is less than n. Since V is a neighborhood of 0, there exists a (row) vector $\bar{p} \in \mathfrak{R}^n \backslash \{0\}$ such that

$$\bar{p}M(T)M^{-1}(t)B(t)=0 \quad \text{for almost every } t \in [0, T].$$

Let $p(t)=\bar{p}M(T)M^{-1}(t)$; then $p(t)$ is a solution of (3), satisfying (4) for almost every $t \in [0, T]$.

DEFINITION 2.4.4. A pair $(x(t), p(t))$ satisfying (2), (3), and (4) is called a *singular extremal* (corresponding to u_0). Let us denote by Σ the set

$$\left\{(x, p, u) \in \mathfrak{R}^n \times \mathfrak{R}^n \times \mathfrak{R}^m \text{ subject to } \left\langle p, \frac{\partial f}{\partial u}(x, u)\right\rangle = 0\right\}.$$

Let $\tilde{H}$ be the map from $\mathfrak{R}^n \times \mathfrak{R}^n \times \mathfrak{R}^m$ into $\mathfrak{R}$ defined by

$$\tilde{H}(x, p, u)=\langle p, f(x, u)\rangle.$$

The set of equations (2), (3), and (4) can be written as

$$\dot{x}=\frac{\partial \tilde{H}}{\partial p}, (2); \quad \dot{p}=-\frac{\partial \tilde{H}}{\partial x}, (3); \quad \frac{\partial \tilde{H}}{\partial u}=0, (4).$$

According to (2.1), (2) and (3) represent the Hamiltonian lift of system $x \to f(x, \cdot)$.

COROLLARY 2.4.5. *The set of singular extremals contains the solutions of* PMP *for the* time minimal and time maximal *control problem of system* (2).

3. Singular trajectories.

3.1. Computations of singular controls. From now on, we will consider C^ω affine control systems

$$\dot{x}(t)=X(x(t))+Y(x(t))u(t),$$

where $x \in \mathfrak{R}^n$, $u \in \mathfrak{R}^m$, and $Y=(Y_1, \cdots, Y_m)$. The surface Σ defined by $\{(x, p, u); \langle p, Y(x)\rangle=0\}$ is now interpreted as a subset of $\mathfrak{R}^n \times \mathfrak{R}^n$. Consider the constraints (4) written as

$$\text{(5)} \qquad \langle p(t), Y_i(x(t))\rangle=0 \quad \forall i=1, \cdots, m.$$

By Proposition 2.4.3, a singular extremal $(x(t), p(t))$ must satisfy relation (5) for almost every $t \in [0, T]$. Since $t \to (x(t), p(t))$ is continuous, (5) must be true for every $t \in [0, T]$.

For generic pairs (X, Y) (in Whitney's topology), the singular controls will be computed up to a negligible set of singularities as a (dynamic) feedback $(x, p) \to \hat{u}(x, p)$. Its role is to make a maximal subset of Σ invariant for the solutions of (2) and (3). Let us carry out the computations.

Differentiating, with respect to t, the relations

$$\langle p(t), Y_i(x(t))\rangle=0 \quad \forall i=1, \cdots, m$$

and since $x(t)$, $p(t)$ are solutions of (2) and (3), with $f=X+Yu$, we get the equation

$$\text{(6)} \qquad L(x(t), p(t))+O(x(t), p(t))u(t)=0,$$

where $O(x, p)$ is the $m \times m$ matrix (O_{ij}) with $O_{ij}=\langle p, [Y_j, Y_i](x)\rangle$, $L(x, p)$ is the $m \times 1$ matrix (L_i) with $L_i=\langle p, [X, Y_i](x)\rangle$ and where the Lie brackets are computed with the convention

$$[Z_1, Z_2](x)=\frac{\partial Z_2}{\partial x}(x)Z_1(x)-\frac{\partial Z_1}{\partial x}(x)Z_2(x).$$

Let s be the maximal rank of $O(x, p)$. By the antisymmetry property of the Lie bracket, O is an antisymmetric matrix. Let $\mathcal{S}_1$ be the set of pairs (X, Y) such that when m is even, $s = m$, or when m is odd, $s = m-1$. To compute the singular controls, we must distinguish two cases.

Case 1. *The number of inputs is even.* Let (X, Y) be in S_1 and let $\hat{u}$ be defined on an open dense subset of $\mathfrak{R}^n \times \mathfrak{R}^n$ by

$$\hat{u}(x, p) = -O^{-1}(x, p)L(x, p). \tag{7}$$

Now, choose (X, Y) such that det O is not identically zero on Σ. Define the singular control almost everywhere in Σ by $u(t) = \hat{u}(x(t), p(t))$.

Case 2. *The number of inputs is odd.* The computation is similar to the previous one, the only complication being the existence of a kernel for O. Let (X, Y) be in $\mathcal{S}_1$; then the dimension of ker $O(x, p)$ is one for almost every (x, p). Let $r_0 = (x_0, p_0)$ be such a point. Then (6) implies $L(r_0) = 0$ when $u \in \ker O(r_0)$.

This relation defines an additional constraint, which must be satisfied for a singular extremal. This is made precise by the following computation.

Near r_0 (all our computations are local), there exists a matrix $P(r) \in O(r)$, with $r = (x, p)$, such that

$$P^{-1}(r)O(r)P(r) = (\bar{O}_1, 0),$$

where $\bar{O}_1(r)$ is an antisymmetric $(m-1) \times (m-1)$ matrix. Moreover, $P(r)$ can be chosen analytic in the coefficients of $O(r)$, since the eigendirection corresponding to the zero eigenvalue of O depends analytically on the coefficients of O.

$P^{-1}L$ can be written as $(\bar{L}_1, \bar{L}_2)$ where $\bar{L}_1$ is an $(m-1)$ column vector, and $\bar{L}_2$ is a scalar. Let us write $\bar{u} = P^{-1}u$ as $\bar{u}_1 + \bar{u}_2$, where $\bar{u}_1 \in \mathfrak{R}^{m-1}$, $\bar{u}_2 \in \mathfrak{R}$. Then (6) is equivalent to

$$\bar{L}_1(r) + \bar{O}_1(r)\bar{u}_1 = 0, \tag{6a}$$

$$\bar{L}_2(r) = 0. \tag{6b}$$

Let $\hat{\bar{u}}_1$ be the map defined almost everywhere on $\mathfrak{R}^{2n}$ by

$$\hat{\bar{u}}_1(r) = -\bar{O}_1^{-1}(r)\bar{L}_1(r). \tag{7a}$$

To compute the component of the singular control in the kernel of O, we derive (6b) along a solution of (2) and (3). Observe that $\bar{L}_2(r)$ is near r_0, analytic in the coefficients of $O(r)$ and $L(r)$. They are of the form $\langle p, Z(x)\rangle$, where Z belongs to the Lie algebra generated by $\{X, Y_1, \cdots, Y_m\}$. Therefore, differentiating relation (6b) with respect to t along a solution $r(t)$ of (2), (3), we get a relation of the form

$$f_1(r(t)) + g_1(r(t))\bar{u}_1(t) + \bar{u}_2(t)g_2(r(t)) = 0. \tag{6c}$$

Let (X, Y) be chosen such that g_2 is not identically zero and let $\hat{\bar{u}}_2$ be the map defined almost everywhere on $\mathfrak{R}^{2n}$ by

$$\hat{\bar{u}}_2(r) = -(f_1(r) - g_1(r)\hat{\bar{u}}_1(r))g_2^{-1}(r). \tag{7b}$$

A control $u(t) = P\bar{u}(t)$ defined by the analytic restriction of $(\hat{\bar{u}}_1(r(t)), \hat{\bar{u}}_2(r(t))$ to $\Sigma \cap \{\bar{L}_2(r) = 0]$ is a singular control.

3.2. Notation. Let M be the variety defined by (i) when m is even, $\Sigma = M$, and (ii) when m is odd $M = \Sigma \cap \{\bar{L}_2 = 0\}$. Observe that in each case the number of equations defining M is *even.*

Let $\mathcal{S}_g$ (g means "good") be the set of pairs (X, Y) in $\mathcal{S}_1$ given by (i) when m is even, det O is not identically 0 on Σ, and (ii) when m is odd, O is almost everywhere on M of rank $m-1$ and g_2 is almost everywhere invertible on M.

Take $(X, Y) \in \mathcal{S}_g$. Let $\hat{u}$ be the map almost everywhere defined from $\mathfrak{R}^n \times \mathfrak{R}^n$ into $\mathfrak{R}^m$ (by (i) when m is even, $\hat{u}$ is given by (7), and (ii) when m is odd, $\hat{u} = P\hat{\bar{u}}$ is given by (7a) and (7b)). Let S be the of points of M such that $\hat{u}$ is not analytic.

From 3.1, on $M\backslash S$, the singular control is uniquely defined by the analytic map $\hat{u}$. In particular, in $M\backslash S$, every singular extremal corresponds to a unique singular control, whose role is to make $M\backslash S$ invariant for the solutions of (2) and (3). Such a singular extremal is said to be of *minimal order.* Let us denote by $\hat{H}$ the function defined almost everywhere on $\mathfrak{R}^{2n}$ by

$$\hat{H}(x, p) = \langle p, X(x) + Y(x)\hat{u}(x, p)\rangle$$

and let $\tilde{Z}_{\hat{H}}$ be the associated meromorphic Hamiltonian vector field. Let us denote $Z_{\hat{H}}$ its restriction to $M\backslash S$.

PROPOSITION 3.3. *Let (X, Y) be a system of $\mathcal{S}_g$. Then the singular extremals of* minimal order *are the solutions of the constrained Hamiltonian differential equation*

$$\dot{x} = \frac{\partial \hat{H}}{\partial p}, \qquad \dot{p} = -\frac{\partial \hat{H}}{\partial x}, \qquad (x, p) \in \Sigma. \tag{8}$$

Proof. By using the constraints $\langle p, Y(x)\rangle = 0$, we get

$$\frac{\partial \hat{H}}{\partial p} = X + Y\hat{u} + \left\langle p, Y\frac{\partial \hat{u}}{\partial p}\right\rangle = X + Y\hat{u} \quad \text{on } \Sigma$$

and

$$\frac{\partial \hat{H}}{\partial x} = \left\langle p, \frac{\partial X}{\partial x} + \frac{\partial Y}{\partial x}\hat{u}\right\rangle + \left\langle p, Y\frac{\partial \hat{u}}{\partial x}\right\rangle$$

$$= \left\langle p, \frac{\partial X}{\partial x} + \frac{\partial Y}{\partial x}\hat{u}\right\rangle \quad \text{on } \Sigma.$$

Remarks 3.4. On $M\backslash S$, a singular control can be interpreted as an unique *static* feedback such that Σ is made invariant for the solutions of the lifted system $\mathbf{X} + \mathbf{Y}u$.

The singular controls have been computed for a generic system. In the nongeneric case, the computation is similar. For instance, if the distribution Δ_Y is involutive, then O is identically zero on Σ, since, in this case, $\langle p, Y_i(x)\rangle = 0$ for all i implies $\langle p, [Y_j, Y_i]$-$(x)\rangle = 0$. Thus, the equation $L(x(t), p(t)) = 0$ must be satisfied and can be differentiated with respect to t to compute the singular controls (see § 6 for more details).

Only the singular extremals of minimal order have been computed. Computations outlined in [4] indicate that for generic pairs (X, Y), they are the only singular extremals. Moreover, if they exist they are contained in S, and [2] shows heuristically that they can be analyzed as solutions of the *meromorphic* differential equations associated to $\tilde{Z}_{\hat{H}}$ restricted to M.

4. Feedback classification and singular trajectories

DEFINITION 4.1. Let λ be the map that associates to a system (X, Y) of $\mathcal{S}_g$ the constrained differential equation (8); i.e., λ is the map $(X, Y) \to (\Sigma, Z_{\hat{H}})$.

Let $(\psi, \alpha, \beta) \in G_f$ and we lift ψ into a symplectic diffeomorphism $\boldsymbol{\psi}$ of $\mathfrak{R}^n \times \mathfrak{R}^n$ defined by

$$x = \psi(y), \qquad p = q\frac{\partial \psi^{-1}}{\partial y},$$

where p and q are row vectors. The action of (ψ, α, β) on $\lambda(X, Y)$ is by definition reduced to the action of $\boldsymbol{\psi}$ on $(\Sigma, Z_{\hat{H}})$ as given in Definition 2.2.2.

In other words, the feedback acts trivially and ψ acts as the symplectic change of coordinates $\boldsymbol{\psi}$ on $(\Sigma, Z_{\hat{H}})$. The corresponding geometry is denoted by $(\{\Sigma, Z_{\hat{H}}\}, G_f)$.

THEOREM 4.2. *The following diagram is commutative*:

$$\begin{tikzcd}
\mathcal{S}_g \arrow[r, "\lambda"] \arrow[d, "G_f"'] & \lambda(\mathcal{S}_g) \arrow[d, "G_f"] \\
\mathcal{S}_g \arrow[r, "\lambda"] & \lambda(\mathcal{S}_g)
\end{tikzcd}.$$

In other words, λ is a covariant.

Proof. Every $g \in G_f$ can be written as $g_2 \cdot g_1$ with $g_1 = (\psi, 0, \mathrm{id})$, $g_2 = (\mathrm{id}, \alpha, \beta)$. Take $(X, Y) \in \mathcal{S}_g$ and set $(X', Y') = g_1 \cdot (X, Y), (X'', Y'') = g_2 \cdot (X', Y')$. Let $\hat{H}$ (respectively, $\hat{H}'$, $\hat{H}''$), Σ (respectively, Σ', Σ''), M (respectively, M', M''), $\hat{u}$ (respectively, $\hat{u}'$, $\hat{u}''$), $Z_{\hat{H}}$ (respectively, $Z'_{H'}$, $Z''_{\hat{H}''}$), and S (respectively, S', S'') be the elements defined in § 3.2 and associated to system (X, Y) (respectively, $(\mathrm{X}', \mathrm{Y}')$, $(\mathrm{X}'', \mathrm{Y}'')$).

First, let us study the action of g_1, i.e., the action of the symplectic diffeomorphism $\boldsymbol{\psi}$ defined by

$$x = \psi(y), \qquad p = q\frac{\partial \psi^{-1}}{\partial y},$$

on those objects. Observe that the constraints $\langle p, Y(x)\rangle = 0$ are written in the (y, q) coordinates as $\langle q(\partial\psi^{-1}/\partial y),\ Y(\psi(y))\rangle = 0$. Since q is a row vector, this is equivalent to $\langle q, (\partial\psi^{-1}/\partial y)Y(\psi(y))\rangle = 0$, i.e., $\langle q, \psi * Y(y)\rangle = 0$. Hence $\boldsymbol{\psi}$ maps Σ' into Σ. Similarly, from § 3.1, we have that $\boldsymbol{\psi}$ maps M' onto M, S' onto S, and $\hat{u}' = \hat{u} \circ \boldsymbol{\psi}$ almost everywhere on $\mathfrak{R}^{2n}$. Thus we have

$$\begin{aligned}\hat{H}(x, p) &= \langle p, X(x) + Y(x)\hat{u}(x, p)\rangle = \left\langle q\frac{\partial\psi^{-1}}{\partial y}, X(\psi(y)) + Y(\psi(y))\hat{u}(\boldsymbol{\psi}(y, q))\right\rangle \\ &= \langle q, (\psi * X)(y) + (\psi * Y)(y)\hat{u}'(y, q)\rangle = \hat{H}'(y, q).\end{aligned}$$

Therefore the symplectic transformation $\boldsymbol{\psi}$ maps the solutions of the Hamiltonian equation of $\mathfrak{R}^{2n}$ defined by $\hat{H}$ onto those defined by $\hat{H}'$. In particular, $\psi * Z_{\hat{H}} = Z_{\hat{H}'}$.

Now let us study the action of the feedback $u' = \alpha(y) + \beta(y)u''$. Since $\beta(y)$ is invertible, this transformation induces a bijection on the set of inputs and maps biunivoquely the singular controls associated to (X', Y') onto those associated to (X'', Y''). Moreover, $(y(t), q(t))$ is a singular extremal associated to u' if and only if it is singular extremal associated to u''. This is geometrically obvious and can be proved as follows.

First, observe that $\Sigma' = \Sigma''$ because the constraints $\langle q, Y'(y)\rangle = 0$ and $\langle q, (Y'\beta)(y)\rangle = 0$ are equivalent, since $\beta(y) \in \mathrm{GL}(m, \mathfrak{R})$. Now, by using (2), (3), and (4), observe that if $(y(t), q(t))$ is a singular extremal corresponding to $u'(t)$ for (X', Y'), then it is a singular extremal corresponding to $u''(t)$ for (X'', Y'') and reciprocally.

In particular, $M' = M''$ almost everywhere since they are almost everywhere the union of singular extremals, and by continuity $M' = M''$. Moreover, by definition, $u'(t) = \alpha(y(t)) + \beta(y(t))u''(t)$, then $\hat{u}'(y, q) = \alpha(y) + \beta(y)\hat{u}''(y, q)$ on M'. Hence $S' = S''$. Therefore $\hat{H}'(y, q) = \langle q, X'(y) + Y'(y)\hat{u}'(y, q)\rangle = \langle q, X''(y) + Y''(y)\hat{u}''(y, q)\rangle = \hat{H}''(y, q)$, on $M' \backslash S'$. Then $Z_{\hat{H}'} = Z_{\hat{H}''}$. (The results can be obtained by direct computations.) □

For further studies, it is interesting to point out more geometry connected with the singular problem.

Remark 4.3. To generalize our theory to the C^∞ case, we remark that we may deal with a differential equation defined on the whole set M. This follows by taking into account the invariant meaning of the set S. For simplicitly, let us make this assertion more precise in the single input case. The variety M is then defined by $H_1=0$, $H_2=0$, where $H_1=\langle p, Y(x)\rangle$ and $H_2=\langle p, [X, Y](x)\rangle$. The set S is then defined by $H_1=H_2=\{H_1, H_2\}=0$, where $\{\ ,\ \}$ is the Poisson bracket. The singular control is given on $M\backslash S$ by

$$\hat{u}(x,p)=-\frac{\langle p,[X,[X, Y]](x)\rangle}{\langle p,[Y,[X, Y]](x)\rangle}.$$

Let us introduce the maps $f_1^{X,Y}:(x,p)\to\langle p,[X,[X, Y]](x)\rangle$ and $f_2^{X,Y}:(x,p)\to\langle p,[Y,[X, Y]](x)\rangle$. Now we analyze the action induced by G_f on the f_i's.

Let ψ be a C^ω-diffeomorphism: $x=\psi(y)$ and let $\boldsymbol{\psi}$ defined as usual by: $x=\psi(y)$, $p=q(\partial\psi^{-1}/\partial y)$. Set $X'=\psi * X$, $Y'=\psi * Y$.

Then we have

$$\begin{aligned}f_1^{X,Y}(x,p)&=\langle p,[X,[X, Y]](x)\rangle=\left\langle q\frac{\partial\psi^{-1}}{\partial y},[X,[X, Y]](\psi(y))\right\rangle\\&=\langle q,\psi*[X,[X, Y]](y)\rangle=<q,[\psi*X,[\psi*X,[\psi*Y]](y)\rangle\\&=f_1^{X',Y'}(\boldsymbol{\psi}^{-1}(x,p))\end{aligned}$$

and, similarly, $f_2^{X,Y}=f_2^{X',Y'}\circ\boldsymbol{\psi}^{-1}$.

Now let u be the feedback $\alpha(x)+\beta(x)u'$ and let $X'=(\mathrm{id},\alpha,\beta)\cdot X$, $Y'=(\mathrm{id},\alpha,\beta)\cdot Y$. Then, *on M* we have

$$f_1^{X',Y'}=\beta(f_1^{X,Y}+\alpha f_2^{X,Y}),\qquad f_2^{X',Y'}=\beta^2 f_2^{X,Y}.$$

Therefore, if we replace (8) by the *analytic* differential equation

$$(8')\qquad \frac{dx}{d\tau}=f_2\frac{\partial\hat{H}}{\partial p},\qquad\frac{dp}{d\tau}=-f_2\frac{\partial\hat{H}}{\partial x},\qquad(x,p)\in\Sigma,$$

and making G_f acting on f_2 and (8′) by *change of coordinates* $\boldsymbol{\psi}$ *only*, the previous results tell us that the maps

(i) $(X, Y)\to f_2^{X,Y}$ restricted to M,

(ii) $(X, Y)\in\mathcal{S}_g\to f_2\cdot\tilde{Z}_{\hat{H}}$ restricted to M ($\tilde{Z}_{\hat{H}}$ is defined in (3.2))

are *semicovariants.*

This has the following geometric interpretation. S is $\{f_2=0\}\cap M$, and the solutions $(x(\tau),p(\tau))$ of (8′) in $M\backslash S$ are the singular extremals $(x(t),p(t))$ of minimal order, reparametrized by the transformation $f_2\,dt=d\tau$. With this trick, we get an analytic vector field, defined on the whole M.

Remark 4.4. Now we will show that $Z_{\hat{H}}$ can be interpreted as an Hamiltonian vector field defined almost everywhere on M. for simplicity, let us investigate the single input case.

The variety M is then given by $\langle p, Y(x)\rangle=\langle p,[X, Y](x)\rangle=0$, and S is the set of points (x,p) of M defined by $\langle p,[Y,[X, Y]](x)\rangle=0$. Let K be the set of points of $\mathfrak{R}^n$ such that Y and $[X, Y]$ are colinear. Observe that K is feedback invariant and thus has an invariant meaning for the G_f action on pairs (X, Y). Assume that (X, Y) is chosen in $\mathcal{S}_g$ such that K is a proper subset of $\mathfrak{R}^n$, and let W be $M\cap(\mathfrak{R}^n\backslash K\times\mathfrak{R}^n)$.

Thus, W is a regular submanifold of $\mathfrak{R}^n \times \mathfrak{R}^n$, with even dimension. Let Ω' be the restriction of the symplectic form $\Omega = dx \wedge dp$ to $W \backslash S$.

Let us assume that $Y = \partial/(\partial x_1)$.

We claim that $(W\backslash S, \Omega')$ is a symplectic manifold. This can be (naively) proved as follows. Recall that x_i and p_i denote the coordinates of x and p, and let us write x and p as $(x_1, \bar{x})$ and $(p_1, \bar{p})$. X can be written as $X_1(\partial/(\partial x_1)) + \bar{X}(\partial/(\partial \bar{x}))$. Since $Y = \partial/(\partial x_1)$, $\langle p, Y(x)\rangle = 0$ is equivalent to $p_1 = 0$ and then $\langle p, [X, Y](x)\rangle = 0$ is equivalent to $\langle \bar{p}, \partial \bar{X}/(\partial x_1)\rangle = 0$. Moreover, if $\langle \bar{p}, (\partial^2 \bar{X})/(\partial x_1^2)\rangle \neq 0$, then by the implicit function theorem, the previous equation can be locally solved as $x_1 = f(\bar{x}, \bar{p})$. Now observe that on W, the condition $\langle \bar{p}, (\partial^2 \bar{X})/(\partial x_1^2)\rangle \neq 0$ is equivalent $\langle p, [Y, [X, Y]](x)\rangle \neq 0$. Moreover, $\Omega' = dx_1 \wedge dp_1 + d\bar{x} \wedge d\bar{p} = df(\bar{x}, \bar{p}) \wedge dp_1 + d\bar{x} \wedge d\bar{p} = d\bar{x} \wedge d\bar{p}$.

Since $Z_{\hat{H}}$ is tangent to $M\backslash S$, *the restriction of* $Z_{\hat{H}}$ *to* $W\backslash S$ *is a Hamiltonian vector field for* $(W\backslash S, \Omega')$ *whose Hamiltonian is the restriction of* $\hat{H}$ *to* $W\backslash S$. This vector field is analytic since $\langle p, [Y, [X, Y]](x)\rangle \neq 0$ on $W\backslash S$. □

Now we study when the feedback classification is equivalent to the G_f-classification of the constrained Hamiltonian equation (8). The first step is to reduce the feedback classification of pairs (X, Y) to the classification of distributions Δ_Y and the "orthogonal complement of X with respect to Δ_Y." This is a useful reduction to compute normal forms for the G_f-action on pairs (X, Y) (see [3] for such computations).

DEFINITION 4.5. We denote by G_d^Y the subgroup of analytic diffeomorphisms of $\mathfrak{R}^n$, leaving invariant the distribution Δ_Y, i.e.,

$$G_d^Y = \{\psi \text{ s.t. } \psi * Y_i \in \Delta_Y, \qquad \forall i = 1, \cdots, m\}.$$

Two vector fields X, X' are called *equivalent modulo* Δ_Y if there exists $\psi \in G_d^Y$ such that $\psi * X = X' \pmod{\Delta_Y}$, i.e., for all $x \in \mathfrak{R}^n$, $(\psi * X - X')(x) \in \Delta_Y(x)$.

LEMMA 4.6. *The following assertions are equivalent*:

(i) (X, Y) *and* (X', Y') *are feedback equivalent*;

(ii) (a) *There exists a* C^ω*-diffeomorphism* ψ_1 *such that* $\psi_1 * \Delta_Y = \Delta_{Y'}$,

(b) $\psi_1 * X$ *and* X' *are equivalent modulo* $\Delta_{Y'}$.

Proof. The proof is straightforward. Assume that (X, Y) and (X', Y') are feedback equivalent. Then there exists $(\psi_1, 0, \beta_1) \in G_f$ such that $(\psi_1, 0, \beta_1) \cdot (X, Y) = (\bar{X}, Y')$, where $\bar{X} = \psi_1 * X$. In other words, $\psi_1 * \Delta_Y = \Delta_{Y'}$.

Now the crucial fact is that we may restrict our analysis to the feedback classification problem, where $\Delta_{Y'}$ is fixed, i.e., for the subgroup action $\{(\psi, \alpha, \beta), \psi \in G_d^{Y'}\}$. Indeed, since $(\bar{X}, Y')$ is feedback equivalent to (X', Y'), then there exists $(\psi_2, \alpha_2, \beta_2) \in G_f$ such that

$$(\psi_2, \alpha_2, \beta_2) \cdot \bar{X} = X' \quad \text{and} \quad \psi_2 * \Delta_{Y'} = \Delta_{Y'}.$$

Hence $\psi_2 \in G_d^{Y'}$.

Now since $\psi_2 \in G_d^{Y'}$, $(\psi_2, \alpha_2, \beta_2) \cdot X$ can be written as $\psi_2 * \bar{X} (\bmod \Delta_{Y'}) + \theta$, where $\theta \in \Delta_{Y'}$. Hence (i)$\Rightarrow$(ii) and, similarly, (ii)$\Rightarrow$(i). □

Assumptions 4.7. Let $\mathcal{S}_r$ be the set of pairs (X, Y) such that

(i) $(X, Y) \in \mathcal{S}_g$,

(ii) The rank of the matrix $Y(x)$ is m, for all $x \in \mathfrak{R}^n$,

(iii) $\pi(M\backslash S)$ contains a (nonempty) open subset of $\mathfrak{R}^n$, where π is the projection $(x, p) \to x$.

THEOREM 4.8. *Let* (X, Y) *and* (X', Y') *be systems of* $\mathcal{S}_r$. *Then the following assertions are equivalent*:

(i) (X, Y) *and* (X', Y') *are feedback equivalent*,

(ii) *The constrained Hamiltonian vector fields $\lambda(X, Y)$ and $\lambda(X', Y')$ are G_f-equivalent.*

Proof. First, we need the following result.

LEMMA. *Let Σ and Σ' denote the constraints sets of (X, Y) and (X', Y'). Then Σ and Σ' are G_f-diffeomorphic if and only if Δ_Y and $\Delta_{Y'}$ are diffeomorphic.*

Proof. Let us assume the existence of a symplectic diffeomorphism ψ defined by $x=\psi(y)$, $p=q(\partial\psi^{-1}/\partial y)$, which maps Σ' onto Σ. Then we have

$$\begin{aligned}(y, q)\in\Sigma' &\Leftrightarrow\langle q, Y'(y)\rangle=0\Leftrightarrow(x, p)\in\Sigma\\ &\Leftrightarrow\langle p, Y(x)\rangle=0\Leftrightarrow\left\langle q\frac{\partial\psi^{-1}}{\partial y}, Y(\psi(y))\right\rangle=0\\ &\Leftrightarrow\langle q, \psi * Y(y)\rangle=0.\end{aligned}$$

Now fix $y\in\Re^n$ and observe that $\langle q, Y'(y)\rangle=0$ coincides with $\langle q, \psi * Y(y)\rangle=0$ if and only if there exists a unique $\beta(y)\in\mathrm{GL}\,(m, \Re)$ such that $Y'(y)\beta(y)=(\psi * Y)(y)$, since the rank of Y and Y' is m. Moreover, as $y\to Y(y)$, $Y'(y)$ are analytic, then $y\to\beta(y)$ is analytic.

We proved that ψ maps Σ' onto Σ if and only if $\Delta_{Y'}=\Delta_{\psi * Y}$, i.e., $\Delta_{Y'}$ and Δ_Y are ψ-diffeomorphic. □

Now we proceed to the proof of Theorem 4.8. From Theorem 4.2, (i)⟹(ii), and it remains to prove (ii)⟹(i).

Assume that the constrained vector field $\lambda(X, Y)$ and $\lambda(X', Y')$ are G_f-equivalent. Thus the varieties Σ and Σ' are G_f-diffeomorphic and then we may assume $\Sigma=\Sigma'$. By the previous lemma, it means $\Delta_Y=\Delta_{Y'}$.

Now since $\lambda(X, Y)$ and $\lambda(X', Y')$ are G_f-equivalent and $\Sigma=\Sigma'$, then there exists a diffeomorphism ψ of $\Re^n$ such that ψ preserves $\Sigma=\Sigma'$ and satisfies

$$\psi * Z_{\hat H}=Z_{\hat H'}\quad\text{on } M'\backslash S'.$$

Therefore $\psi\in G_d^Y$ and we have on $M'\backslash S'$ the following:

$$\begin{aligned}\psi * Z_{\hat H}&=\psi *\left(\frac{\partial\hat H}{\partial p}\frac{\partial}{\partial x}-\frac{\partial\hat H}{\partial x}\frac{\partial}{\partial p}\right)\\ &=\left(\psi * X+\psi * Y\cdot u\circ\psi\frac{\partial}{\partial y}+\cdots\frac{\partial}{\partial q}\right)\\ &=Z_{\hat H'}=\left(X'+Y'\hat u'\frac{\partial}{\partial y}+\cdots\frac{\partial}{\partial q}\right).\end{aligned}$$

In particular, on $M'\backslash S'$ we have

$$\psi * X+\psi * Y\cdot\hat u\circ\psi=X'+Y'\hat u.$$

Now since $\psi\in G_d^Y$, we have $\Delta_{\psi * Y}=\Delta_Y=\Delta_{Y'}$ and the previous equation implies that

$$\psi * X=X'(\mathrm{mod}\,\Delta_Y)\quad\text{on } \pi(M'\backslash S').$$

Now, by assumption, this equation holds on a nonempty open subset of $\Re^n$. By analycity, it is true everywhere. Thus, by Lemma 4.6, (ii)⟹(i) and Theorem 4.8 is proved.

COROLLARY 4.9. *Let us assume that n is even, $m\leq n-1$ or n is odd, $m\leq n-2$. Then for an open dense set of pairs (X, Y) (for Whitney's topology) the feedback classification is equivalent to the G_f-classification.*

Proof. M is defined by m equations in the even case or $m+1$ equations in the odd case. They are linear in p, and to eliminate p, we generically need at least $n-1$ equations. Hence, $\pi(M)$ is (generically) a proper subset of $\mathfrak{R}^n$ if n is even, $m > n-1$, or n is odd, $m > n-2$. This proves the result.

5. Optimality and feedback classification. By using two examples, we will show the connection between the feedback classification and the time optimality status of the singular trajectories.

5.1. Systems in $\mathfrak{R}^2$. Consider the following system of $\mathfrak{R}^2$:

$$\dot{v} = X(v) + uY(v), \tag{9}$$

where $v=(x,y)\in\mathfrak{R}^2$. Then, by using the equations $\langle p, Y(v)\rangle = \langle p, [X, Y](v)\rangle = 0$, where $p \in \mathfrak{R}^2\backslash\{0\}$, we see that the singular trajectories are contained in $L=\{v\in\mathfrak{R}^2$ subject to $\det(Y(v), [X, Y](v))\}=0$.

Hence, for an open dense set of systems, Assumption 4.7 (iii) is not satisfied and Theorem 4.8 cannot be applied to reduce the feedback classification of systems (X, Y) to the G_f-classification of pairs $(\Sigma, Z_{\hat{H}})$. This can be illustrated by the following example. Consider the two systems:

$$\text{(A)}\quad \dot{x}=x^2-y^2,\quad \dot{y}=u \qquad \text{(B)}\quad \dot{x}=x^2+y^2,\quad \dot{y}=u.$$

By a straightforward computation, we get that for *both systems*, L is the line $y=0$ on which the singular trajectories are the solutions of $\dot{x}=x^2$. Moreover, the constraints set Σ are the same. Nevertheless, (A) and (B) are not feedback equivalent since, clearly, the singular trajectory on $\{x>0\}$ is *time minimal* for (A) and *time maximal* for (B). Hence, Theorem 4.8, without Assumption 4.7(iii), is not valid. *Since the optimality status of a singular trajectory is not encoded in* $(\Sigma, Z_{\hat{H}})$, *an additional covariant has to be used to separate the orbits of* G_f *acting on systems* (X, Y). To construct this covariant we can proceed as follows.

Let γ be a singular trajectory defined on $[0, T]$ and let us assume that X and Y are never colinear on γ. Following [17], to evaluate the optimality status of γ, we introduce the form $\alpha = r\,dv$ defined in a neighborhood of γ by $\langle r, X\rangle = 1$, $\langle r, Y\rangle = 0$.

This form has the following nice properties:

(i) if γ_1 is a solution of (9) defined on $[0, t_1]$, then $\int_{\gamma_1}\alpha = \int_0^{t_1} dt = t_1$,

(ii) $d\alpha = 0$ on the singular trajectory γ.

Hence, let γ_1 be a solution of (9) starting at $t=0$ from $\gamma(0)$ and with endpoint $\gamma_1(t_1)=\gamma(T)$. Then we have

$$\begin{aligned}\int_\gamma \alpha - \int_{\gamma_1}\alpha &= \int_{\gamma\cup -\gamma_1} d\alpha \quad \text{(Stoke's theorem)}\\ &= T - t_1.\end{aligned}$$

Hence, the optimality status of γ can be characterized. For instance, for system (A), we have $d\alpha<0$ if $y>0$ and $d\alpha>0$ if $y<0$. This shows that the singular trajectory γ on $\{x>0\}$ is time minimal with respect to every solution of (A), in a C^0-neighborhood of γ.

5.2. Systems in $\mathfrak{R}^3$. Consider the following system:

$$\dot{v} = X(v) + uY(v), \tag{10}$$

where $v=(x,y,z)\in\mathfrak{R}^3$. Let

$$D_1^{X,Y} = \det(Y, [X, Y], [Y, [X, Y]]), \qquad D_2^{X,Y} = \det(Y, [X, Y], [X, [X, Y]]),$$

and $D_3^{X,Y} = \det(Y, [X, Y], X)$. (They will be denoted by D_i when no confusion is possible.)

Convention 5.2.1. For the remainder of this section, we consider only systems (X, Y) such that $D_1^{X,Y}$ is not identically zero. By singular trajectory of (X, Y), We mean a singular trajectory contained in $\mathfrak{R}^3 \backslash \{D_1^{X,Y} = 0\}$.

LEMMA 5.2.2. *The singular trajectories of* (X, Y) *are the solutions of*

$$\dot{v} = X(v) - \frac{D_2(v)}{D_1(v)} Y(v) \tag{11}$$

in $\mathfrak{R}^3 \backslash \{D_1 = 0\}$.

Proof. Since $p \neq 0$, the relations

$$\langle p, Y\rangle = \langle p, [X, Y]\rangle = \langle p, [X, [X, Y]]\rangle + u\langle p, [Y, [X, Y]]\rangle = 0$$

defining the singular control (see § 3.1) imply $D_2 + uD_1 = 0$. Thus, on $\mathfrak{R}^3 \backslash \{D_1 = 0\}$, the singular control is defined by a feedback $\hat{u}(v) = -D_2(v)/D_1(v)$.

DEFINITION 5.2.3. Let X_Y be the vector field on $\mathfrak{R}^3 \backslash \{D_1 = 0\}$ associated with (11), and let λ_π be the map $(X, Y) \to X_Y$. Observe that X_Y is the restriction of $\pi * Z_{\hat{H}}$ to $\mathfrak{R}^3 \backslash \{D_1 = 0\}$ and $\lambda_\pi = \pi \circ \lambda$, where π designs the map $(x, p) \to x$.

The action of G_f on $Z_{\hat{H}}$ induces the following action on X_Y:

$$(\psi, \alpha, \beta) \cdot X_Y = \psi * X_Y,$$

and from Theorems 4.2 and 4.8 we have the following proposition.

PROPOSITION 5.2.4. *The map* λ_π *is a covariant. Moreover, the feedback classification of pairs* (X, Y) *is equivalent to the* G_f*-classification of pairs* (Δ_Y, X_Y).

In particular, the time optimality status of singular trajectories is encoded in (Δ_Y, X_Y). We will briefly describe how this occurs.

LEMMA 5.2.5. *Let* $(\psi, \alpha, \beta) \in G_f$, *then*

(i) $D_i^{\psi * X, \psi * Y}(v) = \det(\partial\psi^{-1}/\partial v) D_i^{X,Y}(\psi(v))$, *for all* $i = 1, 2, 3$;

(ii) $D_1^{X + Y\alpha, Y\beta} = \beta^4 D_1^{X,Y}$;

(iii) $D_2^{X + Y\alpha, Y\beta} = \beta^3(D_2^{X,Y} + \alpha D_1^{X,Y})$;

(iv) $D_3^{X + Y\alpha, Y\beta} = \beta^2 D_3^{X,Y}$.

Proof. These relations can be obtained by straightforward computations. For instance,

$$\begin{aligned} D_1^{\psi * X, \psi * Y}(v) &= \det(\psi * Y(v), [\psi * X, \psi * Y](v), [\psi * Y, [\psi * X, [\psi * Y]]](v)) \\ &= \det(\psi * Y(v), \psi * [X, Y](v), \psi * [Y, [X, Y]](v)) \\ &= \det\left(\frac{\partial \psi^{-1}}{\partial v}\right) \det(Y, [X, Y], [Y, [X, Y]])(\psi(v)), \text{etc.} \end{aligned}$$

COROLLARY 5.2.6. *Let* $f: \mathfrak{R}^3 \to \mathfrak{R}$ *and define the action of* $(\psi, \alpha, \beta) \in G_f$ *on* f *as follows*: $(\psi, \alpha, \beta) \cdot f = f \circ \psi$. *then, we have the following* semicovariants:

(i) $\lambda_1: (X, Y) \to D_1^{X,Y}$,

(ii) $\lambda_3: (X, Y) \to D_3^{X,Y}$.

PROPOSITION 5.2.7. *The sets defined by* $D_3 = 0$, $D_1D_3 > 0$, *and* $D_1D_3 < 0$, *are invariant sets for the solutions of* $\dot{v} = X_Y(v)$.

Proof. On $\mathfrak{R}^3 \backslash \{D_1 = 0\}$, Y and $[X, Y]$ are independent and $D_3 = 0$ is the set of points where X belongs to the linear span of $\{X, [X, Y]\}$. Thus $\langle p, Y\rangle = \langle p, [X, Y]\rangle = 0$ implies $\langle p, X\rangle = 0$ on $D_3 = 0$. Moreover, if γ is a singular trajectory, with adjoint vector p, then the derivative of $t \to \langle p(t), X(\gamma(t))\rangle$ is $\langle p(t), [X, Y](\gamma(t))\rangle$ and is equal to 0.

Thus $X(\gamma(t))$ belongs to the linear span of $Y(\gamma(t))$ and $[X, Y](\gamma(t))$. (A shorter proof is to remark that $D_3=0$ corresponds to singular trajectories with Hamiltonian $H=0$.) Now $D_1D_3>0$ and $D_1D_3<0$ are invariant, since along a singular trajectory, the Lie bracket $[Y,[X, Y]]$ cannot cross the linear span of Y and $[X, Y]$ (by Convention 5.2.1, a singular trajectory is contained in $\mathfrak{R}^3\backslash\{D_1=0\}$).

DEFINITION 5.2.8. A singular trajectory γ is called

(i) exceptional if γ belongs to $D_3=0$,

(ii) hyperbolic if γ belongs to $D_1D_3>0$,

(iii) elliptic if γ belongs to $D_1D_3<0$.

PROPOSITION 5.2.9. *Let γ be a singular trajectory. Then there exists a C^0-neighborhood of γ such that γ is time minimal if γ is exceptional or hyperbolic and time maximal if γ is elliptic, with respect to all solutions of* (10) *contained in the neighborhood of γ if there exists no conjugate point along γ.*

The concept of conjugate point and the proof of this result are given in [6].

Remark 5.2.10. The optimality status of a singular trajectory is related to the two semicovariants λ_1 and λ_3. *This status is encoded in X_Y, since $D_3=0$, $D_1D_3>0$ are invariant sets for the solutions of $\dot{v}=X_Y(v)$.*

The proof of Proposition 5.2.9 of [6] is interesting because we compute a normal form in C^0-neighborhood of a singular trajectory γ for the action of G_f on pairs (X, Y).

6. Quadratic control systems. *Classical invariant theory* studies the actions of $\mathrm{GL}(n,\mathfrak{R})$ on the spaces of tensors: vectors, forms, etc. Computing the invariants for such actions is the main problem in analyzing the associated geometries. Thus, numerous algorithms have been described to achieve this task (see, for instance, [16]). We found it interesting to connect this theory with the feedback classification problem by using a specific class of polynomial systems.

DEFINITION 6.1. Consider the set $\mathcal{Q}$ of control systems of $\mathfrak{R}^n$, of the form

$$\dot{x}(t)=Q(x(t))+Bu(t), \tag{12}$$

where $Q=(Q_1,\cdots,Q_n)$, each Q_i being a quadratic form, and B is a constant $n\times m$ matrix whose columns are denoted by $b_1,\cdots,b_m$. They are called *quadratic control systems.*

Consider the subgroup $G_f'\subset G_f$ of triplets(P,α,β), where $P\in\mathrm{GL}(n,\mathfrak{R})$, $\alpha=(\alpha_1,\cdots,\alpha_m)$, each α_i being a quadratic form and β is constant. G_f' is a (Lie group) and acts on a system (Q, B) by the action induced by G_f. The family $\mathcal{Q}$ is *stable* for this action. Let G_d' be the subgroup of elements of the form $(P, 0, \mathrm{id})$ identified with $\mathrm{GL}(n, R)$, and let $G_d'^B$ be the subgroup of $\mathrm{GL}(n,\mathfrak{R})$, leaving invariant the flat distribution generated by $\{b_1,\cdots,b_m\}$, identified to span $\{b_1,\cdots,b_m\}$.

By using an algorithm similar to the one developed in § 3.1, we can compute (generically) the singular extremals.

6.2. Notation. (They are not compatible with § 3.2, but no confusion is possible.) Let Σ be the surface $\{(x,p)\in\mathfrak{R}^{2n}$ subject to $\langle p, B\rangle=0\}$, and let M be the set $\{(x,p)\in\mathfrak{R}^{2n}$ subject to $\langle p, B\rangle=\langle p,[Q,B](x)\rangle=0\}$. Denote by $L(x,p)$ the $m\times 1$ matrix (L_i), where $L_i=\langle p,[Q,[Q,b_i]](x)\rangle$ and let $O(p)$ be the $m\times m$ symmetric matrix (O_{ij}) where $O_{ij}=\langle p,[b_j,[Q,b_i]]\rangle$. Let S be the set $M\cap\mathfrak{R}^n\times\{p\in\mathfrak{R}^n, \det O(p)=0\}$. We denote by $\mathcal{Q}_g$ the set of pairs (Q, B) such that S is a proper subset of M. Take $(Q,B)\in\mathcal{Q}_g$ and let $\hat{u}(x,p)$ be the solution, almost everywhere defined on $\mathfrak{R}^{2n}$, of $L(x,p)+O(x,p)u=0$.

Let $\hat{H}$ be the function almost everywhere defined on $\mathfrak{R}^{2n}$ by $\langle p, Q(x)+B\hat{u}(x,p)\rangle$, and let $\tilde{Z}_{\hat{H}}$ the associated Hamiltonian vector field. The restriction of $\tilde{Z}_{\hat{H}}$ to $M\backslash S$ is denoted by $Z_{\hat{H}}$. A singular extremal of $M\backslash S$ is called of *order* $2m$ (since M is defined by $2m$ equations).

PROPOSITION 6.3. *Let* $(Q, B) \in \mathcal{Q}_g$; *then the singular extremals of order* $2m$ *are the solutions of the* homogeneous *equation*

$$\dot{x} = \frac{\partial \hat{H}}{\partial p}, \qquad \dot{p} = -\frac{\partial \hat{H}}{\partial x}, \qquad (x, p) \in \Sigma. \tag{13}$$

Proof. Compute as in § 3. Observe that the constraints Σ are homogeneous, and since L is quadratic in x and O is constant in x, $\hat{u}(x, p)$ is quadratic in x. Hence $Z_{\hat{H}}$ is homogeneous.

DEFINITION 6.4. Let $\mathcal{Q}_r$ be the set of pairs of $\mathcal{Q}_g$ such that the rank of B is m. Take $(Q, B) \in \mathcal{Q}_r$, then from § 6.2 and Proposition 6.3, the singular extremals in $M\backslash S$ are the solutions of an analytic vector field $Z_{\hat{H}}$. Let λ be the map that associates to $(Q, B) \in \mathcal{Q}_g$ (13). In other words, λ maps (Q, B) onto $(\Sigma, Z_{\hat{H}})$.

The group G'_f acts on pairs $(\Sigma, Z_{\hat{H}})$ by the action induces by G_f. Now observe that the number of equations defining M is $2m$. Hence, by arguments similar to those used in § 4, we have the following.

PROPOSITION 6.5. *The map* λ *is a covariant for the actions of* G'_f *on* $\mathcal{Q}_g$ *and* $\lambda(\mathcal{Q}_g)$.

PROPOSITION 6.6. *Let us assume that* $2m \leq n-1$. *Then for an open dense subset of* $\mathcal{Q}_r$ ($\mathcal{Q}$ *being identified with* $\mathfrak{R}^{((n^2(n+1))/2)+mn}$), *the* G'_f*-classification of pairs* (Q, B) *is equivalent to the* G'_f*-classification of pairs* $(\Sigma, Z_{\hat{H}})$.

Remark 6.7. The only invariant for the G_f-classification of the surfaces Σ is the rank of B, which is equal to m if $(Q, B) \in \mathcal{Q}_g$ and this classification problem is trivial.

7. Quadratic control systems in $\mathfrak{R}^3$.

7.1. Preliminaries. Consider a single input quadratic control system of $\mathfrak{R}^3$:

$$\dot{v}(t) = Q(v(t)) + u(t)b, \tag{14}$$

where $v = (x, y, z)$. As in § 5.2, we set $D_1 = \det(b, [Q, b], [b, [Q, b]])$, $D_2 = \det(b, [Q, b], [Q, [Q, b]])$, and $D_3 = \det(b, [Q, b], Q)$, and we adopt Convention 5.2.1. We consider only pairs (Q, b) such that D_1 is not identically zero on $\mathfrak{R}^3$, and by singular trajectory we mean a singular trajectory contained in $\mathfrak{R}^3\backslash\{D_1 = 0\}$.

From Lemma 5.2.2, the singular trajectories are the solutions of

$$\dot{v} = Q(v) - \frac{D_2(v)}{D_1(v)} b \tag{15}$$

in $\mathfrak{R}^3\backslash\{D_1 = 0\}$.

Let Z be a vector field of $\mathfrak{R}^3$ and let f be a map from $\mathfrak{R}^3$ into $\mathfrak{R}$. The action of G'_f on Z and f is defined by

$$\text{If } (P, \alpha, \beta) \in G'_f, \text{ then } (P, \alpha, \beta) \cdot Z = P * Z \text{ and } (P, \alpha, \beta) \cdot f = f \circ P.$$

By Proposition 5.2.4 and § 6, the G'_f-classification of pairs (Q, b) is equivalent to the G'_f-classification of pairs $(\mathfrak{R}b, Q_b)$, where Q_b designs the vector field on $\mathfrak{R}^3\backslash\{D_1 = 0\}$ defined by (15).

The aim of this section is to investigate the linear classification of vector fields $\{Q_b\}$, to solve the G'_f-classification of pairs (Q, b). *All the computations* (*which are lengthy*) *are omitted since they are detailed in* [2] *and* [5], *and we only present the geometric interpretations of the various semicovariants.*

7.2. Notation. The map $v \to -[Q, b](v)$ is linear and the associated matrix is denoted by A. Let ad A be the adjoint matrix corresponding to A (if A^{-1} exists, then ad $A = \det A \cdot A^{-1}$). Let $w = \operatorname{ad} A(b)$, and observe that $[Q, b](w)$ is colinear to b. Set $L_1 = \mathfrak{R} b$ and $L_2 = \mathfrak{R} w$, and let $\tilde{Q}_b$ be the analytic vector field of $\mathfrak{R}^3$ given by $\tilde{Q}_b = D_1 Q - D_2 b$.

From Lemma 5.2.5, we have the following results.

LEMMA 7.3. *For the G_f'-actions, we have the following* semicovariants:

(i) $\lambda_\pi : (Q, b) \to \tilde{Q}_b$,

(ii) $\lambda_1 : (Q, b) \to D_1$,

(iii) $\lambda_2 : (Q, b) \to D_2$ *restricted to* $D_1 = 0$,

(iv) $\lambda_3 : (Q, b) \to D_3$.

Remark 7.4. The maps λ_1, λ_2, and λ_3 are semicovariants, not covariants. Thus, only the sets $D_1 = 0$, $D_3 = 0$, and $D_1 = 0 \cap D_2 = 0$ have an invariant meaning. This is due to the following property. Since Q_b is homogeneous, with degree 2, then the map $v \to \varepsilon v$, $\varepsilon \in \mathfrak{R} \backslash \{0\}$, transforms Q_b into εQb. Thus, in our classification, we must identify Q_b with εQ_b, and we are dealing, in fact, with *projective geometry*, in which we have no nonconstant polynomial invariants. In particular, the λ_i's cannot be covariants.

7.5. Geometric interpretation of $\tilde{Q}_b$. $\tilde{Q}_b$ is a time reparametrization of the vector field Q_b, similar to the one performed in Remark 4.3. Thus, the solutions of $\dot{v} = \tilde{Q}_b(v)$ in $\mathfrak{R}^3 \backslash \{D_1 = 0\}$, are, up to a reparametrization, singular trajectories. Observe that $\tilde{Q}_b$ is a homogeneous cubic vector field in $\mathfrak{R}^3$.

7.6. Geometric interpretation of $D_1 = 0$. $D_1 = 0$ is the plane generated by $L_1 = \mathfrak{R} b$ and $L_2 = \mathfrak{R} w$ (computations). In particular, $\dot{v} = D_1 Q - D_2 b = -D_2 b$, in $D_1 = 0$. Since b is tangent to $D_1 = 0$, the plane $D_1 = 0$ is then an invariant set for the solutions of $\dot{v} = \tilde{Q}_b(v)$. This set is the union of two types of singularities. First, the set of points where b and $[Q, b]$ are collinear, which are the projections on $\mathfrak{R}^3$ of the singularities of the surface M, defined by $\langle p, b \rangle = \langle p, [Q, b] \rangle = 0$. Secondly, they are the projections onto $\mathfrak{R}^3$ of the set S given by $\langle p, [b, [Q, b]] \rangle = 0 \cap M$.

7.7. Geometric interpretation of $D_3 = 0$. From Definition 5.2.8, $D_3 = 0$ is formed with the exceptional trajectories and according to Proposition 5.2.9, is connected to the time optimality problem. In particular, $D_3 = 0$ is an invariant set for the solution of $\dot{v} = \tilde{Q}_b(v)$. Now observe that D_3 is a cubic form. Linear classification of cubic forms (on $\mathfrak{C}$) is well known. In particular, they have a nontrivial rational invariant, called the modulus. This invariant is very important in our classification problem (see Example 7.10).

7.8. Geometric interpretation of $D_1 = 0 \cap D_2 = 0$. First, observe that the map $v \to D_2(v)$ restricted to $D_1 = 0$ is a cubic form in two variables. By computing, we get that the solutions of $D_1 = 0 \cap D_2 = 0$ are the line $L_2 = \mathfrak{R} w$ and, if a discriminant δ is $\geqslant 0$ (δ is given in [5] and is a semi-invariant), two lines denoted by L_3 and L_4. We have the following nice properties.

Property 7.8.1. In control theory, the system (Q, b) is said to be *weakly controllable* if for all $v \in \mathfrak{R}^3$, $\{Q, b\}_{\text{A.L.}}(v)$ is of rank 3, where $\{Q, b\}_{\text{A.L.}}$ designs the Lie algebra generated by the two vector fields $\{Q, b\}$. This property is clearly feedback invariant and we have that $\{Q, b\}$ is weakly controllable if and only if D_2 is identically zero on $D_1 = 0$, i.e., *the semicovariant λ_2 maps the set on nonweakly controllable pair (Q, b) onto zero.*

Property 7.8.2. Here, we restricted our study to systems (Q, b) such that: span $\{b, [[Q, b], b], [[Q, b], [[Q, b], b]]\} = \mathfrak{R}^3$. By convention, a singular trajectory is a solution of (15), which is defined for $v \in \mathfrak{R}^3 \backslash \{(D_1 = 0\}$. We may ask the following question: when does a system (Q, b) admit singular trajectories $\neq\{0\}$ that are not contained in $\mathfrak{R}^3\backslash\{D_1=0\}$? An associated extremal has to satisfy the relation

$$\langle p, b\rangle = \langle p, [Q, b]\rangle = \langle p, [b, [Q, b]]\rangle = \langle p, [Q, [Q, b]]\rangle = 0,$$

and is then contained in $D_1=0 \cap D_2=0$. Further computations show the following. *There exists a nontrivial trajectory in* $D_1=0$ *if and only if* $L_3=L_4$ (L_3 and L_4 are the two lines previously defined), i.e., $\delta=0$. *Moreover, such a trajectory is supported by the line* $L_3=L_4$. This was predictable, since $D_1=0\cap D_2=0$ is then $L_2 \cup L_3$.

7.9. More semicovariants. Since the equation $\dot v = \tilde Q_b(v)$ is homogeneous, the distribution $v \to \mathfrak{R}\tilde Q_b(v)$ is invariant with respect to the transformations $v \to \varepsilon v$, $\varepsilon \neq 0$ and can be projected onto the sphere S^2. More precisely, if we set $r=(x^2+y^2+z^2)^{1/2}$, $\bar v = v/r$, and $r^2\,dt = d\sigma$, then the equation $dv/dt = \tilde Q_b(v)$ is equivalent to

$$\frac{dr}{d\sigma} = \langle \bar v, \tilde Q_b(\bar v)\rangle r, \tag{16}$$

$$\frac{d\bar v}{d\sigma} = \tilde Q_b(\bar v) - \langle \bar v, \tilde Q_b(\bar v) > \bar v. \tag{17}$$

Equation (17) is defined on S^2 and is called the *projected equation associated with* $\dot v = \tilde Q_b(v)$. *This equation encodes most of behaviors of singular trajectories and has to be carefully studied.*

An outline of this analysis is now given. Let $v_0 \in \mathfrak{R}^3\backslash\{0\}$. One line $\mathfrak{R}v_0$ such that $\tilde Q_b(v_0) = \varepsilon v_0$, $\varepsilon \in \mathfrak{R}$ is called a *ray*. If $\varepsilon = 0$, the ray is a set of singular points for $\dot v = \tilde Q_b(v)$ and if $\varepsilon \neq 0$, the ray is an asymptotic direction for solutions of this equation. Clearly, a ray corresponds bijectively to a singular point for the projected equation.

Now observe that $\tilde Q_b(v)$ can be written as $\tilde Q_b^c(v) + 1/5 \operatorname{div}(\tilde Q_b(v)) \cdot v$, where $\tilde Q_b^c$ is a cubic vector field preserving the standard volume form of $\mathfrak{R}^3$ (i.e., $\operatorname{div} \tilde Q_b^c = 0$). Both $\tilde Q_b$ and $\tilde Q_b^c$ have the same projected equation on S^2 and this decomposition of $\tilde Q_b$ corresponds to the splitting of $\dot v = \tilde Q_b(v)$ into (16) and (17). Moreover, we have the following lemma.

LEMMA. *The following maps are semicovariants*: $\lambda_4 : (Q, b) \to \operatorname{div} \tilde Q_b$, *and* $\lambda_5 : (Q, b) \to \tilde Q_b^c$.

Using the projected equation, the behavior of singular trajectories near $D_1 = 0$ has been classified in [5], in the generic and codimension-one cases. The generic classification is the following. The lines L_i correspond to the only singular points contained in $D_1 = 0$, for the projected equation. They are: *nodes* for $L_1 = \mathfrak{R}b$ and $L_2 = \mathfrak{R}w$, and *saddles* for L_3 and L_4.

Moreover, L_2, L_3, and L_4 are sets of singular points for $\dot v = \tilde Q_b(v)$, and L_1 is an asymptotic direction. Thus, we have the following important result.

PROPOSITION. *For generic pairs* (Q, b) *the distribution* $\mathfrak{R}b$ *is encoded in the vector field* Q_b *(as a ray of* $\tilde Q_b$*). In this case, the* G_f'*-classification of pairs* (Q, b) *is equivalent to the* G_f'*-classification of* Q_b, only.

Example 7.10. Consider the following system:

$$\dot x = a_1 yz + ub_1, \qquad \dot y = a_2 xz + ub_2, \qquad \dot z = a_3 xy + ub_3,$$

where a_1, $a_3 > 0$, $a_2 < 0$, $b = (b_1, b_2, b_3) \in \mathfrak{R}^3$. These equations describe the evolution of the angular velocity in the attitude control problem, when the rigid body is controlled by one torque, whose orientation is given by b, the parameters a_i describing the shape of the satellite. The vector b and in some extent the a_i's can be chosen by the system designer, and we may want to study the feedback classification problem, for this class of systems *when b and the parameters a_i vary.* We have the following results (see [5] for the details).

By computing, we get

$$\begin{aligned}
D_1(v) &= 2a_1b_2b_3(a_3b_2^2 - a_2b_3^2)x + 2a_2b_1b_3(a_1b_3^2 - a_3b_1^2)y \\
&\quad + 2a_3b_1b_2(a_2b_1^2 - a_1b_2^2)z, \\
D_2(v) &= a_3^2b_1b_2(b_1y + b_2x)(a_2x^2 - a_1y^2) \\
&\quad + a_1^2b_2b_3(b_2z + b_3y)(a_3y^2 - a_2z^2) \\
&\quad + a_2^2b_1b_3(b_1z + b_3x)(a_1z^2 - z_3x^2), \\
D_3(v) &= a_2a_3b_1x^2(b_2z - b_3y) + a_1a_3b_2y^2(b_3x - b_1z) \\
&\quad + a_1a_2b_3z^2(b_1y - b_2x).
\end{aligned}$$

The system is weakly controllable if and only if (i) $b_ib_j \neq 0$ for at least one pair (i, j), $i \neq j$, or (ii) $a_3b_1^2 - a_1b_3^2 \neq 0$. Conditions (i) and (ii) have the following interpretation . If (i) is not satisfied, then $D_1 = 0$ is equal to $\mathfrak{R}^3$ and (15) is not defined. If (i) is satisfied, but not (ii), then D_1 is a factor of D_2; this is conformed to Property 7.8.1.

From now on, we assume that (Q, b) is weakly controllable. We can suppose the following:

(1) $a_1 = a_3 = 1$, $a_2 = -1$ (change of coordinates),

(2) $b \in S^2$, i.e., $b_1^2 + b_2^2 + b_3^2 = 1$,

(3) b_1, b_2, $b_3 > 0$ and $b_1 - b_3 > 0$ (symmetries).

With these normalities, we have that

δ is given by $b_1^2b_3^2 - b_2^2b_3^2 - b_1^2b_2^2$ and the lines L_3 and L_4 exist and are distinct if and only if $\delta > 0$, and $L_3 = L_4$ if and only if $\delta = 0$.

The cubic form D_3 is reducible if and only if $b_2 = 0$ or $b_3 = 0$. More precisely, we have that

if $b_3 = 0$, then $D_3 = 0$ is the union of the plane $z = 0$ and the line $x = y = 0$,
if $b_2 = 0$, then D_3 is the union of $y = 0$ and the two planes $x = \pm z$.

We represent below four phase portraits for the projected equation, defined on S^2. They are obtained by direct computations ((i) and (iv)) and bifurcation analysis ((ii) and (iii)). The plane $D_1 = 0$, generated by L_1 and L_2, is identified with the equator, and we draw only the phase portrait in the northern hemisphere (the phase portrait in the southern hemisphere can be deduced by symmetry).

Cases (i) *and* (ii) (Fig. 1). Comments. Case (i) represents the situations $b = (b_1, 0, b_3)$, and case (ii) $b = (b_1, \varepsilon, b_3)$, $\varepsilon \neq 0$ and small. For both cases, L_3 and L_4 exist and are distinct. A separatrix cycle $O'L_3L_4$ in (i) is transformed in (ii) into a limit cycle corresponding to one loop of the cubic $D_3 = 0$ projected on S^2.

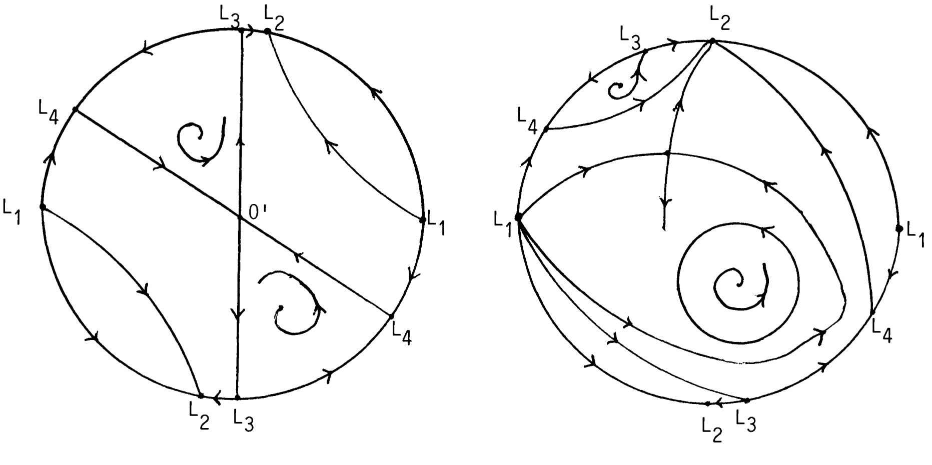
Cases (iii) *and* (iv) (Fig. 2). Comments. Case (iv) represents the situations $b = (b_1, b_2, 0)$, and (iii) $b = (b_1, b_2, \varepsilon)$, $\varepsilon \neq 0$ and small. In both cases, the two lines L_3 and L_4 do not exist. The transition (iii) → (iv) corresponds to the vanishing of a small limit cycle by Hopf bifurcation. This cycle is still a loop of $D_3 = 0$ projected on S^2.

The intermediary cases between (ii) and (iii) are described in [5].

Conclusion. Systems (Q, b) corresponding to cases (i)-(iv) are not feedback equivalent: *the phase portraits of $\tilde{Q}_b$ are not even C^0-equivalent.*

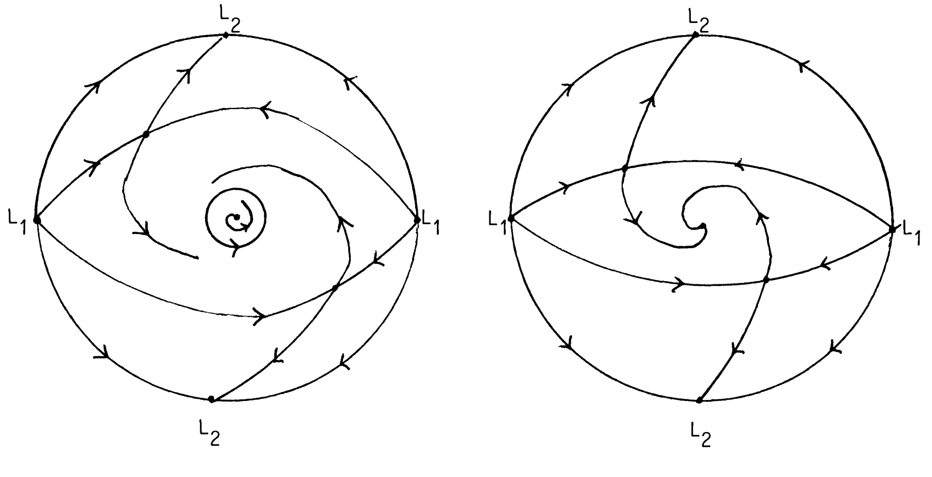
Now consider a quadratic system of $\mathfrak{R}^3$, with two inputs:

$$\dot{v}(t) = Q(v(t)) + Bu(t). \tag{18}$$



(i) (ii)

FIG. 1



(iii) (iv)

FIG. 2

Assume that rank $B = 2$, and let b_1 and b_2 be the columns of B. Let $L = \bigcap_{i=1,2}\{v \in \Re^3;\ \det(b_1, b_2, [Q, b_i](v)) = 0\}$. From § 6, the singular trajectories are contained in the vector space L, and we have the following canonical forms for the G_f'-classification.

PROPOSITION 7.11. *(Q, B) is G_f'-equivalent to*

$$Q_1(v)\frac{\partial}{\partial x} + u_1\frac{\partial}{\partial y} + u_2\frac{\partial}{\partial z},$$

where Q_1 has one of the following forms in Table 1.

The proof follows from straightforward computations. The remarkable property is the following. For orbits (a) and (b), the line L supporting the singular trajectories is precisely the one to choose to complete the linear span of $\{b_1, b_2\}$ to get the basis

TABLE 1

Normal forms	Geometric interpretation
(a) Generic orbits	dim $L=1$, $\Re^3=L+\text{Span } B$
(a_1) $Q_1=x^2+y^2+z^2$	Singular flow (on L): $\rightarrow\!-\!\overset{0}{\bullet}\!\rightarrow\!\rightarrow$
(a_2) $Q_1=x^2-y^2-z^2$	Optimality status of the singular trajectoires ($\neq 0$)
(a_3) $Q_3=x^2+y^2-z^2$	(a_1) = fast, (a_2) = slow, (a_3) = locally controllable
(b_1) $Q_1=y^2+z^2$	dim $L=1$, $\Re^3=L+\text{Span } B$
(b_2) $Q_1=y^2-z^2$	Singular flow: $\bullet\!-\!\bullet\!-\!\bullet\!-\!\bullet\!-\!\overset{0}{\bullet}\!-\!\bullet\!-\!\bullet\!-\!\bullet\!-\!\bullet\!\rightarrow$
	for (b_2) each singular trajectory is locally controllable, contrarily to (b_1)
(c) $Q_1=xz+y^2$	dim $L=1$, $L\subset \text{Span } B$
(d_1) $Q_1=x^2+y^2$	dim $L=2$, dim $(L\cap \text{Span } B)=1$
(d_2) $Q_1=x^2-y^2$	$\Re^3=L+\text{span } B$
	Singular flow: $\dot{x}=\varepsilon x^2$, $\dot{z}=u_2$
(d_3) $Q_1=y^2$	Orbits separated by nature of the singular flow and optimality status
(e) (Q, b) not weakly controllable	
(e_1) $Q_1=0$	$L=\Re^3$. Singular flow: $\dot{x}=0$, $\dot{y}=u_1$, $\dot{z}=u_2$
(e_2) $Q_1=x^2$	$L=\Re^3$. Singular flow: $\dot{x}=x^2$, $\dot{y}=u_1$, $\dot{z}=u_2$
(e_3) $Q_1=xy$	$L=\text{span } B$

for our canonical form. This classification for generic orbits, i.e., with maximal dimensions, is generalized to $\Re^n$, when $m=n-1$, in [3].

7.12. G_f-feedback equivalence with quadratic control systems. For simplicity, consider a single input system *in* $\Re^3$ denoted by (X, Y). We may ask the question, when is this system G_f-equivalent to a *quadratic* control system (Q, b)? (This problem can also be locally studied.) For such an equivalence, the distribution $\Re Y$ has to be equivalent to a flat distribution. Moreover, from Proposition 5.2.4, the vector field denoted by X_Y, whose solutions are the singular trajectories of (X, Y) contained in $\Re^3 \backslash \{D_1^{X,Y}=0\}$, must be, up to a change of time parameter, diffeomorphic to the homogeneous cubic vector field $\tilde{Q}_b$ introduced in § 7.2.

Thus, our problem is tightly connected with the C^ω-equivalence of a differential equation with a polynomial one. The local version of this problem is a standard question, extensively studied. Near a regular point, any vector field is diffeomorphic to $\partial/\partial x$. Near a singular point, this problem is very difficult. Relevant contributions were made by Lyapunov, Poincaré, and Dulac (see [1]), and this problem is still the object of contemporary studies (see [24] and [26], etc).

The G_f-equivalence of (X, Y) with a quadratic control system (Q, b) can also be solved using the G_f'-canonical forms computed in [3].

8. Conclusion. In this conclusion, we briefly indicate how to complete the results obtained in this article. First, note that our theory is global, in the sense that the singular flow is, up to a singular set, globally defined. On the other hand, with the trick introduced in Remark 4.3, we can delete this singular set. This is useful in studying the C^∞ case.

There is a gap in our aim to identify the feedback classification with the classification of pairs $(\Sigma, Z_{\hat{H}})$. We must assume that the singular trajectories are not contained in a proper subvariety of $\Re^n$. However, the analysis done in §§ 5.1 and 7.1 indicates how to avoid this assumption. The *position* of this subvariety with respect to the distribution Δ_Y and the *optimality status* of the singular trajectories allow us to carry out the classification. This position is encoded in pairs $(\Sigma, Z_{\hat{H}})$, but not the optimality status. The time optimality status is an invariant of the time minimal control problem. Therefore, we conjecture that for generic systems (X, Y) when the feedback classification is not trivial, i.e., when $m < n$, then the feedback classification is equivalent to the classification of the time minimal control problem. Under generic assumptions, the optimality status can be deduced from the so-called Legendre–Clebsch condition arising from the high-order maximal principle [21]. This can be applied to analyze the case $m = n - 1$, n odd.

Now a nontrivial extension of this article would be the analysis of the feedback equivalence problem, for general systems given by $\dot{x}(t) = f(x(t), u(t))$, where $x \in \Re^n$, $u \in \Re^m$, and f is smooth. The group action being extended to transformations of the form $x = \psi(y)$, $u' = \Phi(x, u)$, where the maps $y \to \psi(y)$ and $u \to \Phi(\cdot, u)$ are diffeomorphisms. Now observe that even in this case, the singularities of the input-state mapping are well defined. From § 2, it is clear that the maximum principle is still the key tool to investigate the feedback equivalence problem. Let us illustrate this assertion by an example.

Recall that the Hamiltonian $\tilde{H}$ is defined by $\tilde{H}(x, p, u) = \langle p, f(x, u)\rangle$.

Now observe that the surface Σ defined by $\partial\tilde{H}/\partial u = 0$ still has an invariant meaning for our classification problem. Consider the restriction of the Hessian matrix $(\partial^2\tilde{H})/(\partial u_i \partial u_j)$ to the surface Σ. This matrix is the intrinsic derivative and its rank is an invariant of the feedback classification problem. It has the following interpretation.

Let us assume the rank maximal, i.e., equal to m. Then the singular control can be (locally) computed as a map $\hat{u} : (x, p) \to \Re^m$, by using the implicit function theorem to solve the equation $\partial\tilde{H}/\partial u = 0$. Conversely, if the restriction of the Hessian matrix to Σ is identically zero, a straightforward analysis shows that, with regularity assumptions on the map $u \to f(x, u)$, then the system is feedback equivalent to an affine system. The vanishing of the Hessian matrix Σ being equivalent to say that the image of $\Re^m$ by the map $u \to f(x, u)$ is a flat submanifold of $\Re^m$. In other words, the only difference between the affine and nonaffine case is when solving the equation $\partial\tilde{H}/\partial u = 0$.

To summarize, the key to providing a general theory of the feedback classification is *Pontryagin's Maximum Principle.*

SOME CHARACTERIZATIONS OF OPTIMAL TRAJECTORIES IN CONTROL THEORY*

PIERMARCO CANNARSA† AND HALINA FRANKOWSKA‡

Abstract. Several characterizations of optimal trajectories for the classical Mayer problem in optimal control are provided. For this purpose the regularity of directional derivatives of the value function is studied: for instance, it is shown that for smooth control systems the value function V is continuously differentiable along an optimal trajectory $x:[t_0, 1]\to \mathbf{R}^n$ provided V is differentiable at the initial point $(t_0, x(t_0))$.

Then the upper semicontinuity of the optimal feedback map is deduced. The problem of optimal design is addressed, obtaining sufficient conditions for optimality. Finally, it is shown that the optimal control problem may be reduced to a viability one.

Key words. Hamilton-Jacobi equation, optimal synthesis, semiconcave function, viability theory, viscosity solutions, set-valued derivatives, sufficient conditions for optimality

AMS(MOS) subject classifications. 49K15, 49L05, 93B50, 93C15

1. Introduction.

Consider the optimal control problem

$$\text{minimize } g(x(1))$$

over all solutions of the control system

$$x'=f(t, x, u(t)), \qquad u(t)\in U \tag{1}$$

satisfying the initial condition

$$x(0)=\xi_0. \tag{2}$$

We recall that by a simple change of variables the classical Bolza problem in control theory

$$\text{minimize}\left\{\varphi(x(1))+\int_0^1 L(t, x(t), u(t))\,dt\right\}$$

over the trajectory control pairs (x, u) of (1), (2) may be reduced to the one under consideration.

The goal of the optimal control theory is to find necessary and sufficient conditions for optimality and to construct optimal trajectories. Several results establishing necessary conditions are available in the form of the maximum principle. In this paper, we show that additional information (including sufficient conditions for optimality, optimal design, and optimal synthesis) may be obtained from some properties of the value function, which is defined by

$$V(t_0, x_0)=\inf\{g(x(1))\,|\,x \text{ is a solution of (1) on } [t_0, 1], x(t_0)=x_0\}.$$

In general, even in very regular situations, the value function is not differentiable. Nevertheless, we prove in this paper that the differentiability of V is preserved along

optimal trajectories. More precisely, we show that if V is differentiable at some point (t_0, x_0) and $\bar{x}$ denotes any optimal solution starting from x_0 at time t_0, then V is differentiable at $(t, \bar{x}(t))$ for every $t \in [t_0, 1]$ (see Corollary 5.3). Actually, the derivative $-V'_x(t, \bar{x}(t))$ is equal to the co-state of the Pontriagin maximum principle, which we recall in § 4. In the same section, we also derive some inclusions connecting the co-state with the superdifferential of the value function. Among these results, Theorem 4.2 is related to [25] and Proposition 4.4 to [26, Prop. 3.1].

When the Hamiltonian H is smooth enough and the value function is differentiable at $(0, \xi_0)$, then the following necessary and sufficient condition for optimality holds true. Let $x(\cdot), p(\cdot)$ solve the Hamiltonian system

$$\begin{aligned} x'(t) &= \frac{\partial H}{\partial p}(t, x(t), p(t)), \\ p'(t) &= -\frac{\partial H}{\partial x}(t, x(t), p(t)), \qquad t \in [0, 1]. \end{aligned} \tag{3}$$

Then x is optimal if and only if $x(0) = \xi_0$, $p(0) = -V'_x(0, \xi_0)$ (see Theorem 4.6 for more general statements.)

Even when the Hamiltonian is not smooth, the value function may still be used to construct the optimal feedback map

$$G(t, x) = \left\{ v \in f(t, x, U) \,\middle|\, \frac{\partial V}{\partial(1, v)}(t, x) = 0 \right\}. \tag{4}$$

In fact, the following property holds true: a trajectory $\bar{x}$ of (1) is optimal for our optimization problem if and only if it is a solution of the differential inclusion

$$x' \in G(t, x), \qquad x(0) = \xi_0. \tag{5}$$

We refer to [17], [6] for some developments in this direction.

To investigate regularity properties of the set-valued map G, we prove the existence of the directional derivatives of V. For this aim we show that, under very general assumptions on the control system, the value function is semiconcave (see Theorem 5.1).

As a consequence of the semiconcavity of V, we obtain that the feedback map G is upper semicontinuous and has nonempty compact images (see Theorem 6.1).

In particular, whenever the feedback map G is single-valued, it is continuous. From the above it follows that in this special case, optimal trajectories are continuously differentiable.

Moreover, if the data are convex, then G has convex values and the inclusion (5) fits the well-investigated framework of upper semicontinuous convex-valued maps. When the map G does not have convex images, the above characterization of optimal trajectories is not easy to apply. To overcome this difficulty, we provide an alternative approach based on viability theory. More precisely, we observe that solving the optimal control problem is equivalent to solving a control system with state constraints:

(i) $t' = 1,$

(ii) $x' = f(t, x, u), \qquad u \in U,$

(iii) $z' = 0,$

(iv) $(t, x(t), z(t)) \in \text{Graph}(V),$

(v) $t(0) = 0, \quad x(0) = \xi_0, \quad z(0) = V(0, \xi_0).$

The last system is a viability problem and may be approached using many results of viability theory (see [20], [2], [1], and references contained therein). We underline that in this case dynamics (i)–(iii) remain regular, but we have to keep trajectories in the set Graph (V) according to the relation (iv) (see [18]).

Finally, we treat the case involving the endpoint constraints ($x(1)\in K_1$) via penalization techniques. We prove that the value function of such a problem may be approximated by the value function of problems with free endpoints (see Theorem 8.1). A similar result holds true for optimal trajectories.

Some of the results of the present paper were announced in [7]. Moreover, this approach may be extended to infinite-dimensional control problems, as we show in [8].

The plan of the paper is as follows. Section 2 contains basic material on the value function. In § 3 we recall some definitions of set-valued gradients and investigate properties of semiconcave functions. Necessary and sufficient conditions for optimality are described in § 4, while § 5 is devoted to the semiconcavity of the value function. The optimal feedback map is studied in § 6 and viability theory is applied to optimal trajectories in § 7. In § 8 we address the problem with endpoint constraints.

2. Value function in optimal control. Consider a complete separable metric space U and a continuous function

$$f:[0,1]\times\mathbf{R}^n\times U\to\mathbf{R}^n.$$

We associate with it the control system

$$x'(t)=f(t,x(t),u(t)),\qquad u(t)\in U\quad\text{a.e.}\tag{6}$$

An absolutely continuous function $x:[t_0,t_1]\to\mathbf{R}^n$ is called a trajectory of (6) if there exists a measurable function $u:[t_0,t_1]\to U$ such that $x'(t)=f(t,x(t),u(t))$ almost everywhere in $[t_0,t_1]$.

Let $g:\mathbf{R}^n\to\mathbf{R}$ and $\xi_0\in\mathbf{R}^n$ be given. We investigate the minimization problem

$$\text{minimize}\,\{g(x(1))\,|\,x\text{ is a solution of (6) on }[0,1],x(0)=\xi_0\}.\tag{7}$$

The dynamic programming approach associates with this problem the value function defined by

$$V(t_0,x_0)=\inf\{g(x(1))\,|\,x\text{ is a solution of (6) on }[t_0,1],x(t_0)=x_0\}.\tag{8}$$

Throughout the whole paper we impose the following assumptions:

$$\begin{array}{ll}\text{(i)} & f\text{ is continuous in }[0,1]\times\mathbf{R}^n\times U,\\ \text{(ii)} & \exists k\in L^1(0,1;\mathbf{R}_+),\ \forall(t,u)\in[0,1]\times U,\ f(t,\cdot,u)\text{ is }k(t)\text{-Lipschitz},\\ \text{(iii)} & \exists\gamma>0\text{ such that }\forall(t,u)\in[0,1]\times U,\ \|f(t,x,u)\|\leqq\gamma(\|x\|+1),\\ \text{(iv)} & g\text{ is locally Lipschitz.}\end{array}\tag{9}$$

Our assumptions allow us to apply the relaxation theorem from [2] to show that V is actually equal to the value function of the relaxed problem in which (6) is replaced by the differential inclusion

$$x'(t)\in\overline{\text{co}}\,f(t,x(t),U)\quad\text{a.e.}\tag{10}$$

We recall that an absolutely continuous function $x:[t_0,t_1]\mapsto\mathbf{R}^n$ is called a trajectory of (10) if for almost every $t\in[t_0,t_1]$, $x'(t)\in\overline{\text{co}}\,f(t,x(t),U)$. Hence we will study the following minimization problem:

$$\text{minimize}\,\{g(x(1))\,|\,x\text{ is a solution of (10) on }[0,1],x(0)=\xi_0\}.\tag{11}$$

The corresponding value function is given by

$$V^{\text{co}}(t_0,x_0)=\inf\{g(x(1))\,|\,x\text{ is a solution of (10) on }[t_0,1],x(t_0)=x_0\}.$$

THEOREM 2.1. *Assume* (9). *Then, for all* $(t_0,x_0)\in[0,1]\times\mathbf{R}^n$ *we have*

$$V(t_0,x_0)=V^{\text{co}}(t_0,x_0)=\min\{g(x(1))\,|\,x\textit{ is a solution of }(10)\textit{ on }[t_0,1],x(t_0)=x_0\}.$$

Proof. From the relaxation and the parametrization theorems (see [2]), we know that the closure in the metric of uniform convergence of trajectories of (6) defined on the time interval $[t_0, 1]$ and starting at x_0, which is compact in $\mathscr{C}([t_0, 1]; \mathbf{R}^n)$), is equal to the set of trajectories of (10) starting at x_0 and defined on $[t_0, 1]$. This ends the proof. □

It is well known that the value function is nondecreasing along trajectories of (6) and therefore a trajectory $x:[t_0, 1] \to \mathbf{R}^n$ satisfies $V(t_0, x(t_0)) = g(x(1))$ if and only if $V(t, x(t)) \equiv g(x(1))$. This leads to a verification technique in optimal control:

> A trajectory $x:[0, 1] \to \mathbf{R}^n$ of the control system (6) is optimal for the problem (7) if and only if $x(0) = \xi_0$ and $V(t, x(t)) \equiv \text{const}$ (in this case $V(t, x(t)) \equiv g(x(1))$).

Hence, instead of looking for an optimal trajectory for the problem (7), we can search for a trajectory of (6) satisfying the initial condition and such that the value function is constant along it.

We recall that the directional derivative of a function $\varphi: \mathbf{R}^n \to \mathbf{R}$ at $x_0 \in X$ in the direction $\Theta \in X$ (when it exists) is defined by

$$\frac{\partial \varphi}{\partial \Theta}(x_0) = \lim_{h \to 0+} \frac{\varphi(x_0 + h\Theta) - \varphi(x_0)}{h}.$$

PROPOSITION 2.2. *Assume* (9). *Then the value function V is locally Lipschitz. Furthermore, for every trajectory x of* (6) *on* $[0, 1]$ *and for almost every* $t \in [0, 1]$, *there exists the directional derivative*

$$\frac{\partial V}{\partial(1, x'(t))}(t, x(t)).$$

Proof. The local Lipschitz continuity of V is well known. It can be checked by arguments similar to [16, Thm. 4.2, p. 85] (see also [17]).

Fix a trajectory $x(\cdot)$. Then the function $t \to \varphi(t) := V(t, x(t))$ is absolutely continuous. Fix t such that φ and x are differentiable at t. Then

$$\lim_{h \to 0+} \frac{V(t+h, x(t) + hx'(t)) - V(t, x(t))}{h} = \lim_{h \to 0+} \frac{V(t+h, x(t+h)) - V(t, x(t))}{h}$$

and the proof follows. □

When the value function is directionally differentiable, it has many properties related to the dynamics of the system.

PROPOSITION 2.3. *Assume* (9). *If for some* $(t_0, x_0) \in [0, 1[\times \mathbf{R}^n$ *and* $v \in \overline{\text{co}}\, f(t_0, x_0, U)$, *V has the directional derivative at* (t_0, x_0) *in the direction* $(1, v)$, *then this directional derivative is nonnegative.*

Proof. Consider a solution $x(\cdot)$ of the differential inclusion (10) satisfying $x(t_0) = x_0$, $x'(t_0) = v$ (by [2] such solution does exist). Since V is locally Lipschitz at (t_0, x_0) and nondecreasing along trajectories of (10) (thanks to Theorem 2.1), we obtain

$$\lim_{h \to 0+} \frac{V(t_0 + h, x_0 + hv) - V(t_0, x_0)}{h} = \lim_{h \to 0+} \frac{V(t_0 + h, x(t_0 + h)) - V(t_0, x_0)}{h} \geqq 0. \quad \square$$

To characterize optimal trajectories, we introduce two following feedback maps $G: [0, 1] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ and $G^{\text{co}}: [0, 1] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ defined, respectively, by

$$G(t, x) = \left\{ v \in f(t, x, U) \,\middle|\, \frac{\partial V}{\partial(1, v)}(t, x) = 0 \right\}$$

and

$$G^{co}(t,x)=\left\{v\in\overline{\mathrm{co}}\,f(t,x,U)\;\middle|\;\frac{\partial V}{\partial(1,v)}(t,x)=0\right\}$$

(note that the sets $G(t,x)$ and $G^{co}(t,x)$ may be empty).

Then we have the following characterizations of optimal trajectories.

THEOREM 2.4. *Assume* (9). *Then the following two statements are equivalent*:

(i) *x is a trajectory of the differential inclusion*

$$x'\in G(t,x) \tag{12}$$

defined on the time interval $[t_0,1]$.

(ii) *x is a trajectory of the control system* (6) *defined on the time interval* $[t_0, 1]$ *and, for every* $t\in[t_0,1]$, $V(t,x(t))=g(x(1))$.

For the relaxed system (10) *the following two statements are equivalent*:

(iii) *x is a trajectory of the differential inclusion*

$$x'\in G^{co}(t,x) \tag{13}$$

defined on the time interval $[t_0,1]$.

(iv) *x is a trajectory of the differential inclusion* (10) *defined on the time interval* $[t_0,1]$ *and, for every* $t\in[t_0,1]$, $V(t,x(t))=g(x(1))$.

Proof. Fix a trajectory x of (12) defined on time interval $[t_0,1]$ and set $\varphi(t)=V(t,x(t))$ for every $t\in[t_0,1]$. Since V is locally Lipschitz (recall Proposition 2.2), φ is absolutely continuous. Thus, by Proposition 2.2, for almost all $t\in[t_0,1]$,

$$\varphi'(t)=\frac{\partial V}{\partial(1,x'(t))}(t,x(t)).$$

By Filippov's lemma $x(\cdot)$ is a solution to (6) (see [2]). Thus $\varphi'(t)=0$ almost everywhere in $[t_0,1]$. Consequently, φ is constant and is equal to $V(1,x(1))=g(x(1))$. Assume next that (ii) holds true. Then differentiating the map $t\to\varphi(t)$, we obtain that for every $t\in\,]t_0,1[$, $\varphi'(t)=0$. Thus

$$\frac{\partial V}{\partial(1,x'(t))}(t,x(t))=0$$

almost everywhere and therefore for almost all $t\in[t_0,1]$, $x'(t)\in G(t,x(t))$. The proof of the second statement is analogous and is omitted. □

COROLLARY 2.5. *Assume* (9). *Then a trajectory* $x:[0,1]\to\mathbf{R}^n$ *is an optimal solution of problem* (7) *if and only if it is a solution of the differential inclusion* (12) *and* $x(0)=\xi_0$. *An analogous statement holds true for the relaxed problem* (11) *and the differential inclusion* (13).

Proof. Since V is nondecreasing along trajectories of the control system (6), we deduce that $\bar{x}(\cdot)$ is optimal for the control problem (7) if and only if V is constant along $\bar{x}$. Theorem 2.4 ends the proof. □

THEOREM 2.6. *Assume* (9). *Then for every* $t_0\in[0,1]$, $x_0\in\mathbf{R}^n$, *inclusion* (13) *has at least one solution satisfying* $x(t_0)=x_0$.

Proof. Consider the optimal control problem

$$\text{minimize } g(x(1))$$

over the solutions of the differential inclusion

$$x'(t)\in\overline{\mathrm{co}}\,f(t,x(t),U)\quad\text{a.e. in }[t_0,1],\ x(t_0)=x_0.$$

By Theorem 2.1, it has at least one optimal solution $\bar{x}$. Furthermore, $V(t, \bar{x}(t)) \equiv g(\bar{x}(1))$. Theorem 2.4 ends the proof. □

3. Some preliminaries on nonsmooth functions. We denote by B the closed unit ball in $\mathbf{R}^n$ and by $B_r(x_0)$ the closed ball in $\mathbf{R}^n$ with radius r and center at x_0. Consider an open set $\Omega \subset \mathbf{R}^n$ and a function $\varphi : \Omega \to \mathbf{R}$. When φ is not differentiable, it is possible to define its gradient taking weaker limits of differential quotients.

DEFINITION 3.1. Let $x_0 \in \Omega$. The *superdifferential* of φ at x_0 is the closed convex set defined as follows:

$$D^+\varphi(x_0) = \left\{ p \in \mathbf{R}^n \;\middle|\; \limsup_{x \to x_0} \frac{\varphi(x) - \varphi(x_0) - \langle p, x - x_0 \rangle}{\|x - x_0\|} \leqq 0 \right\},$$

where $\langle \cdot, \cdot \rangle$ denotes the scalar product.

The *subdifferential* is defined in a similar way:

$$D^-\varphi(x_0) = \left\{ p \in \mathbf{R}^n \;\middle|\; \liminf_{x \to x_0} \frac{\varphi(x) - \varphi(x_0) - \langle p, x - x_0 \rangle}{\|x - x_0\|} \geqq 0 \right\}.$$

It is not difficult to show that φ is Fréchet differentiable at x_0 if and only if both the super- and the subdifferential of φ are not empty at x_0. In this case

$$D^+\varphi(x_0) = D^-\varphi(x_0) = \{\varphi'(x_0)\},$$

where $\varphi'(x_0)$ denotes the gradient of φ at x_0. We always have $D^+\varphi(x_0) = -D^-(-\varphi)(x_0)$.

The super- and subdifferential may also be characterized using the *Dini* directional derivatives, which are defined in the following definition.

DEFINITION 3.2. The *lower Dini derivative* of φ at x_0 in the direction Θ is given by

$$\partial^-\varphi(x_0)(\Theta) = \liminf_{h \to 0+, \Theta' \to \Theta} \frac{\varphi(x_0 + h\Theta') - \varphi(x_0)}{h}$$

and the *upper Dini derivative* of φ at x_0 in the direction Θ is defined by

$$\partial^+\varphi(x_0)(\Theta) = \limsup_{h \to 0+, \Theta' \to \Theta} \frac{\varphi(x_0 + h\Theta') - \varphi(x_0)}{h}. \tag{14}$$

Clearly,

$$\partial^-\varphi(x_0) = -\partial^+(-\varphi)(x_0). \tag{15}$$

When φ is Lipschitz at x_0, then the definition may be simplified as follows:

$$\partial^-\varphi(x_0)(\Theta) = \liminf_{h \to 0+} \frac{\varphi(x_0 + h\Theta) - \varphi(x_0)}{h}$$

and

$$\partial^+\varphi(x_0)(\Theta) = \limsup_{h \to 0+} \frac{\varphi(x_0 + h\Theta) - \varphi(x_0)}{h}.$$

From [17, Lemma 2.7] (see also [3, Chap. 6]) we know that

$$D^-\varphi(x_0) = \{ p \in \mathbf{R}^n \mid \forall \Theta \in \mathbf{R}^n, \partial^-\varphi(x_0)(\Theta) \geqq \langle p, \Theta \rangle \}$$

and

$$D^+\varphi(x_0) = \{ p \in \mathbf{R}^n \mid \forall \Theta \in \mathbf{R}^n, \partial^+\varphi(x_0)(\Theta) \leqq \langle p, \Theta \rangle \}. \tag{16}$$

DEFINITION 3.3. Assume that φ is Lipschitz at $x_0 \in \Omega$. The *regularized lower derivative* of φ at x_0 in the direction $\Theta \in \mathbf{R}^n$ is defined by

$$\varphi^o_-(x_0, \Theta) = \liminf_{h \to 0+, x \to x_0} \frac{\varphi(x+h\Theta) - \varphi(x)}{h}.$$

This notion is a "lower version" of Clarke's definition of directional derivative. Indeed, it can be easily checked that

$$(17) \qquad \varphi^o_-(x_0, \Theta) = -\varphi^o(x_0, -\Theta) = -(-\varphi)^o(x_0, \Theta),$$

where $\varphi^o(x_0, \Theta)$ denotes the directional derivative from [11].

PROPOSITION 3.4. *Let $\varphi : \mathbf{R}^n \to \mathbf{R}$ be Lipschitz at $x_0 \in \mathbf{R}^n$. Then the function $\Theta \to \varphi^o_-(x_0, \Theta)$ is concave.*

This result may be deduced from [11, Prop. 2.1.1].

We investigate next the closedness of the level sets of the regularized lower derivative.

PROPOSITION 3.5. *Let $\varphi : \mathbf{R}^n \to \mathbf{R}$ be a locally Lipschitz function and define the set-valued map $Q : \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ by*

$$Q(x) = \{\Theta \in \mathbf{R}^n \mid \varphi^o_-(x, \Theta) \leqq 0\}.$$

Then Q has nonempty closed images and the graph of the map Q is closed.

Proof. Clearly, for every x, $0 \in Q(x)$. It remains to show that for every sequence $(x_n, \Theta_n) \in \mathbf{R}^n \times \mathbf{R}^n$ converging to some (x, Θ) and satisfying $\Theta_n \in Q(x_n)$, we have $\Theta \in Q(x)$. Fix such a sequence and let $\varepsilon_n \to 0$. By the definition of $\varphi^o_-(x_n, \Theta_n)$, there exist $h_n \to 0+$, $x'_n \to x$ be such that for every n

$$\frac{\varphi(x'_n + h_n\Theta_n) - \varphi(x'_n)}{h_n} \leqq \varepsilon_n.$$

Consequently,

$$\varphi^o_-(x, \Theta) \leqq \liminf_{n \to \infty} \frac{\varphi(x'_n + h_n\Theta_n) - \varphi(x'_n)}{h_n} \leqq 0. \qquad \square$$

DEFINITION 3.6. Assume that φ is Lipschitz at $x_0 \in \Omega$. The *generalized gradient* of φ at x_0 is defined by

$$(18) \qquad \partial\varphi(x_0) = \{p \in \mathbf{R}^n \mid \forall \Theta \in \mathbf{R}^n, \ \varphi^o_-(x_0, \Theta) \leqq \langle p, \Theta \rangle\}.$$

We denote by $D^*\varphi(x_0)$ the set of all cluster points of gradients $\varphi'(x_n)$, when x_n converge to x_0 and φ is differentiable at x_n.

We note that

$$D^*\varphi(x_0) = \operatorname*{Lim\,sup}_{x \to x_0} \{\varphi'(x)\},$$

where $\mathrm{Lim\,sup}_{x \to x_0}$ denotes the upper limit when $x \to x_0$ (see [3, p. 41]).

In view of (17), the above definition of the generalized gradient is equivalent to the one given by Clarke. Comparing Definitions 3.1 and 3.6, we can easily realize that

$$(19) \qquad D^+\varphi(x_0) \subset \partial\varphi(x_0).$$

Moreover, it is clear that $D^*\varphi(x_0)$ is compact. From [11, Thm. 2.5.1], it follows that

$$(20) \qquad \partial\varphi(x_0) = \mathrm{co}\,(D^*\varphi(x_0)),$$

where co denotes the convex hull.

DEFINITION 3.7. Consider a convex subset K of $\mathbf{R}^n$. A function $\varphi : K \to \mathbf{R}$ is called semiconcave if there exists a function $\omega : \mathbf{R}_+ \times \mathbf{R}_+ \to \mathbf{R}_+$ such that

$$\begin{aligned} &\forall r \leqq R, \quad t \leqq T, \quad \omega(r, t) \leqq \omega(R, T), \quad \text{and} \\ &\forall R > 0, \quad \lim_{t \to 0+} \omega(R, t) = 0 \end{aligned} \tag{21}$$

and for every $R > 0$, $\lambda \in [0, 1]$ and any points $x, y \in K \cap RB$,

$$\lambda\varphi(x) + (1-\lambda)\varphi(y) \leqq \varphi(\lambda x + (1-\lambda)y) + \lambda(1-\lambda)\|x-y\|\omega(R, \|x-y\|).$$

We say that φ is semiconcave at x_0 if there exists a neighborhood of x_0 such that the restriction of φ to it is semiconcave. We call the above function ω a modulus of semiconcavity of φ.

Usually in the definition of semiconcavity $\omega(r, t) = ct$ for a nonnegative constant c (see [21], [22]), or $\omega(r, t) = ct^\alpha$ for $c \geqq 0$ and $\alpha \in]0, 1]$ [9]. We observe that every concave function $\varphi : K \to \mathbf{R}$ is semiconcave (with ω equal to zero). Furthermore, it is not difficult to check the following proposition.

PROPOSITION 3.8. *Let K be a convex subset of $\mathbf{R}^n$ and $\varphi : \mathbf{R}^n \to \mathbf{R}$ be continuously differentiable on a neighborhood of K. Then φ is semiconcave.*

Example 1. Consider a subset K of $\mathbf{R}^n$ and let $\operatorname{dist}(x, K)$ denote the distance from a point $x \in \mathbf{R}^n$ to K. Define the function $\varphi : \mathbf{R}^n \to \mathbf{R}_+$ by $\varphi(x) = \operatorname{dist}(x, K)^2$. Then, by a standard computation, φ is easily seen to be semiconcave.

In general, a Lipschitz function does not have directional derivatives. Our next aim is to show that for a semiconcave function, the directional derivatives exist and coincide with the regularized lower derivatives. This result was proved in [9], [10]. We provide a different proof of this fact for the sake of completeness.

THEOREM 3.9. *Let $x_0 \in \mathbf{R}^n$ and $\varphi : \mathbf{R}^n \to \mathbf{R}$ be Lipschitz and semiconcave at x_0. Then for every $\Theta \in \mathbf{R}^n$, the directional derivative $(\partial\varphi/\partial\Theta)(x_0)$ exists and is equal to the regularized lower derivative $\varphi^o_-(x_0, \Theta)$:*

$$\forall \Theta \in \mathbf{R}^n, \quad \frac{\partial\varphi}{\partial\Theta}(x_0) = \varphi^o_-(x_0, \Theta). \tag{22}$$

In particular, $D^+\varphi(x_0) \neq \emptyset$ and

$$D^+\varphi(x_0) = \partial\varphi(x_0) = \operatorname{co}(D^*\varphi(x_0)). \tag{23}$$

Consequently, the set-valued map $x \to D^+\varphi(x)$ is upper semicontinuous at x_0.

Proof. It is enough to consider the case $\|\Theta\| \leqq 1$. Let $\delta > 0$ be such that φ is semiconcave on $B_{2\delta}(x_0)$ with semiconcavity modulus $\omega(\cdot) := \omega(2\delta, \cdot)$. Fix $x \in B_\delta(x_0)$, $\Theta \in B$, and observe that for all $0 < h_1 \leqq h_2 \leqq \delta$ we have

$$\begin{aligned} \varphi(x + h_1\Theta) - \varphi(x) &= \varphi\left(\frac{h_1}{h_2}(x + h_2\Theta) + \left(1 - \frac{h_1}{h_2}\right)x\right) - \varphi(x) \\ &\geqq \frac{h_1}{h_2}\varphi(x + h_2\Theta) + \left(1 - \frac{h_1}{h_2}\right)\varphi(x) - \varphi(x) \\ &\quad - \frac{h_1}{h_2}\left(1 - \frac{h_1}{h_2}\right)h_2\|\Theta\|\omega(h_2\|\Theta\|) \\ &= \frac{h_1}{h_2}\varphi(x + h_2\Theta) - \frac{h_1}{h_2}\varphi(x) \\ &\quad - h_1\left(1 - \frac{h_1}{h_2}\right)\|\Theta\|\omega(h_2\|\Theta\|). \end{aligned}$$

Consequently, for all $0 < h_1 \leqq h_2 \leqq \delta$,

$$\frac{\varphi(x+h_1\Theta)-\varphi(x)}{h_1} \geqq \frac{\varphi(x+h_2\Theta)-\varphi(x)}{h_2} - \left(1-\frac{h_1}{h_2}\right)\omega(h_2\|\Theta\|)$$

and we proved that for every $x \in B_\delta(x_0)$

$$\forall 0 < h' \leqq h \leqq \delta,$$

$$\frac{\varphi(x+h'\Theta)-\varphi(x)}{h'} \geqq \frac{\varphi(x+h\Theta)-\varphi(x)}{h} - \omega(h\|\Theta\|). \tag{24}$$

Thus for every $0 < h \leqq \delta$,

$$\liminf_{h' \to 0+} \frac{\varphi(x_0+h'\Theta)-\varphi(x_0)}{h'} \geqq \frac{\varphi(x_0+h\Theta)-\varphi(x_0)}{h} - \omega(h\|\Theta\|).$$

Taking $\limsup_{h\to 0+}$ in the right-hand side of the above inequality yields that the directional derivative $(\partial\varphi/\partial\Theta)(x_0)$ does exist. Clearly, $(\partial\varphi/\partial\Theta)(x_0) \geqq \varphi_-^o(x_0,\Theta)$. To prove the opposite, fix $\varepsilon > 0$ and $0 < \lambda < \delta$. From the continuity of φ it follows that there exists $0 < \alpha < \delta$ such that for all $x \in B_\alpha(x_0)$,

$$\frac{\varphi(x_0+\lambda\Theta)-\varphi(x_0)}{\lambda} \leqq \frac{\varphi(x+\lambda\Theta)-\varphi(x)}{\lambda} + \varepsilon.$$

Thus, using (24), we obtain that

$$\frac{\varphi(x_0+\lambda\Theta)-\varphi(x_0)}{\lambda} \leqq \inf_{x\in B_\alpha(x_0), h\in]0,\lambda]} \frac{\varphi(x+h\Theta)-\varphi(x)}{h} + \omega(\lambda\|\Theta\|)+\varepsilon.$$

Letting ε, α, and λ converge to zero, we end the proof of the first statement. The second one results from (22) recalling (16), (18), and (20). □

PROPOSITION 3.10. *Let $\varphi : \mathbf{R}^n \to \mathbf{R}$ be Lipschitz and semiconcave at x_0. If $D^+\varphi(x_0)$ is a singleton, then φ is differentiable at x_0 and*

$$D^*\varphi(x_0) = \{\varphi'(x_0)\}.$$

In particular, if $D^+\varphi(x)$ is a singleton for all x near x_0, then φ is continuously differentiable at x_0.

The proof follows by exactly the same arguments as the ones in [9, Cor. 4.11 and 4.12].

DEFINITION 3.11. Let $K \subset \mathbf{R}^n$ be convex and $\varphi : K \to \mathbf{R}$ be given. Then φ is said to be semiconvex (respectively, semiconvex at x_0) whenever $-\varphi$ is semiconcave (respectively, semiconcave at x_0).

PROPOSITION 3.12. *Let $\varphi : \mathbf{R}^n \to \mathbf{R}$, $x_0 \in \mathbf{R}^n$. If φ is Lipschitz at x_0 and both semiconvex and semiconcave at x_0, then φ is continuously differentiable on a neighborhood of x_0.*

Proof. Since φ and $-\varphi$ are semiconcave at x_0 by Theorem 3.9, there exists a neighborhood $\mathcal{N}$ of x_0 such that for all $x \in \mathcal{N}$,

$$D^+\varphi(x) = \partial\varphi(x), \qquad D^+(-\varphi)(x) = \partial(-\varphi)(x).$$

Furthermore,

$$D^-\varphi(x) = -D^+(-\varphi)(x) = -\partial(-\varphi)(x) = \partial\varphi(x),$$

the last equality being a straightforward consequence of (20). Hence both $D^+\varphi(x)$ and $D^-\varphi(x)$ are nonempty and therefore φ is differentiable on $\mathcal{N}$. The conclusion follows from Proposition 3.10. □

4. Necessary and sufficient conditions for optimality. We begin this section with a sufficient condition for optimality which involves the superdifferential of the value function.

We associate with the control system (6) the Hamiltonian $H:[0,1]\times\mathbf{R}^n\times\mathbf{R}^n\to\mathbf{R}$ defined by

$$H(t,x,p)=\sup_{u\in U} < p, f(t,x,u)\rangle.$$

Under assumption (9), the function H is continuous, locally Lipschitz with respect to (x,p), and convex with respect to the third variable.

THEOREM 4.1. *Assume that* (9) *holds true and let* $\bar{x}:[0,1]\to\mathbf{R}^n$ *be a solution of the control system* (6), $\bar{x}(0)=\xi_0$ *and* $\bar{u}$ *be a corresponding control. If for almost every* $t\in[0,1]$, *there exists* $p(t)\in\mathbf{R}^n$ *such that*

$$(25)\qquad \begin{aligned}&\langle p(t),\bar{x}'(t)\rangle = H(t,\bar{x}(t),p(t)),\\ &(H(t,\bar{x}(t),p(t)),-p(t))\in D^+V(t,\bar{x}(t)),\end{aligned}$$

then $\bar{x}$ *is optimal for the problem* (7).

Proof. Consider the absolutely continuous function $\psi(t)=V(t,\bar{x}(t))$ and let $t\in[0,1]$ be such that the derivatives $\psi'(t)$ and $\bar{x}'(t)$ do exist and (25) holds true.

We first observe that (25) and (16) imply that

$$(26)\qquad \begin{aligned}0&=\langle((\langle p(t),\bar{x}'(t)\rangle,-p(t)),(1,\bar{x}'(t))\rangle\geqq\partial^+V(t,\bar{x}(t))(1,\bar{x}'(t))\\ &=\limsup_{h\to0+}\frac{V(t+h,\bar{x}(t)+h\bar{x}'(t))-V(t,\bar{x}(t))}{h}\\ &=\limsup_{h\to0+}\frac{V(t+h,\bar{x}(t+h))-V(t,\bar{x}(t))}{h}\\ &=\psi'(t).\end{aligned}$$

This yields that ψ is nonincreasing. Since the value function is also nondecreasing along trajectories of the control system (6), we deduce that the map $t\to V(t,\bar{x}(t))$ is constant. So $\bar{x}$ is optimal. □

The above map p may be constructed using the co-state variable of the maximum principle stated below.

THEOREM 4.2. *Assume that* (9) *holds true, that* f *is differentiable with respect to* x, *and* g *is differentiable. A trajectory control pair* $(\bar{x},\bar{u})$ *of the control system* (6) *with* $\bar{x}(0)=\xi_0$ *is optimal for the problem* (7) *if and only if the solution* $p:[0,1]\to\mathbf{R}^n$ *of the adjoint equation*

$$(27)\qquad -p'(t)=\left(\frac{\partial f}{\partial x}(t,\bar{x}(t),\bar{u}(t))\right)^*p(t),\, p(1)=-g'(\bar{x}(1))$$

satisfies the maximum principle

$$(28)\qquad \langle p(t),f(t,\bar{x}(t),\bar{u}(t))\rangle=\max_{u\in U}\langle p(t),f(t,\bar{x}(t),u)\rangle\quad \textit{a.e. in } [0,1]$$

and the generalized transversality conditions

$$(29)\qquad (H(t,\bar{x}(t),p(t)),-p(t))\in D^+V(t,\bar{x}(t))\quad \textit{a.e. in } [0,1],$$

$$(30)\qquad -p(t)\in D_x^+V(t,\bar{x}(t))\quad \forall t\in[0,1],$$

where $D_x^+V(t,\bar{x}(t))$ *denotes the superdifferential of* $V(t,\cdot)$ *at* $\bar{x}(t)$.

Furthermore, if V is semiconcave, then (29) *holds true everywhere in* $[0, 1]$.

We call such a function $p(\cdot)$ a co-state corresponding to the optimal trajectory $\bar{x}(\cdot)$.

Remark. The above theorem is a joint form of the maximum principle and the co-state inclusions (29), (30). In § 5 we provide a sufficient condition for V to be semiconcave.

Remark. The necessity of these conditions was proved in [17] under somewhat different assumptions. An inclusion on co-state p similar to (30) in the nonsmooth case was derived in [12]. An analogous statement is proved in [25] by a different method under stronger regularity assumptions. Necessary conditions in the form of generalized transversality conditions were proved in [26] as well. In this last paper, it is also shown that the subdifferentials of V and of $V(t, \cdot)$ along an optimal trajectory are at most singletons and are contained in the left-hand sides of (29) and (30), respectively. Another easy way to derive this fact is to use the remark following Definition 3.1.

Proof of Theorem 4.2. Sufficiency is a straightforward consequence of Theorem 4.1 and (28), (29). The fact that (27) and (28) are necessary is the well-known Pontryagin's maximum principle.

To prove the necessity of (29), fix $t \in [0, 1[$ such that $\bar{x}'(t) = f(t, \bar{x}(t), \bar{u}(t))$ and the equality (28) holds true, and let $\Theta \in \mathbf{R}^n$. Consider the solution $w(\cdot)$ of the linearized along $(\bar{x}, \bar{u})$ system

$$(31) \qquad \begin{aligned} &w'(s) = \frac{\partial f}{\partial x}(s, \bar{x}(s), \bar{u}(s))w(s), \quad s \in [t, 1], \\ &w(t) = \Theta. \end{aligned}$$

For every $h > 0$, let x_h be the solution to the differential equation

$$(32) \qquad \begin{aligned} &x'(s) = f(s, x(s), \bar{u}(s)), \quad s \in [t, 1], \\ &x(t) = \bar{x}(t) + h\Theta. \end{aligned}$$

From the variational equation we know that the quotients

$$\frac{x_h - \bar{x}}{h}$$

converge uniformly to w. Fix $\alpha \in \mathbf{R}$. Hence from (27) and (28), using that V is locally Lipschitz, nondecreasing along trajectories of (6), and constant along $\bar{x}$, we deduce that

$$\begin{aligned} &\partial^+ V(t, \bar{x}(t))(\alpha, \alpha\bar{x}'(t) + \Theta) \\ &\quad = \limsup_{h \to 0+} (V(t + \alpha h, \bar{x}(t) + h(\alpha\bar{x}'(t) + w(t))) - V(t, \bar{x}(t)))/h \\ &\quad = \limsup_{h \to 0+} (V(t + \alpha h, \bar{x}(t + \alpha h) + hw(t + \alpha h)) - V(t, \bar{x}(t)))/h \\ &\quad = \limsup_{h \to 0+} (V(t + \alpha h, x_h(t + \alpha h)) - V(t, \bar{x}(t)))/h \\ &\quad \leqq \limsup_{h \to 0+} (g(x_h(1)) - g(\bar{x}(1)))/h \\ &\quad = \langle g'(\bar{x}(1)), w(1)\rangle = \langle -p(t), w(t)\rangle \\ &\quad = \langle -p(t), -\alpha\bar{x}'(t)\rangle + \langle -p(t), \alpha\bar{x}'(t) + \Theta\rangle \\ &\quad = \alpha H(t, \bar{x}(t), p(t)) + \langle -p(t), \alpha\bar{x}'(t) + \Theta\rangle. \end{aligned}$$

Hence we deduce that for every $\alpha \in \mathbf{R}$ and $\Theta_1 \in \mathbf{R}^n$,

$$\partial^+ V(t, \bar{x}(t))(\alpha, \Theta_1) \leqq \alpha H(t, \bar{x}(t), p(t)) + \langle -p(t), \Theta_1 \rangle$$

and the proof of (29) follows from (16). To prove (30), observe that for every $t \in [0, 1]$, $\Theta \in \mathbf{R}^n$, and the solution w of (31),

$$\begin{aligned}\langle -p(t), \Theta \rangle &= \langle g'(\bar{x}(1)), w(1) \rangle \\ &\geqq \limsup_{h \to 0+} \left(V(t, \bar{x}(t) + h\Theta) - V(t, \bar{x}(t)) \right)/h = \partial_x^+ V(t, \bar{x}(t))(\Theta).\end{aligned}$$

This and (16) imply (30). When V is semiconcave, then the last statement follows from (29), (23), the continuity of $H(\cdot)$, $p(\cdot)$, $\bar{x}(\cdot)$, and Theorem 3.9. □

Remark. It can be shown that the conclusion of Theorem 4.2 remains true even when g is not differentiable, but $D^+g(\bar{x}(1) \neq \emptyset$. In this case we can take for $p(1)$ any element of $D^+g(\bar{x}(1))$. The same observation applies to Theorem 4.5 below.

Remark. For systems governed by an autonomous state equation—that is, with f independent of t—we can easily show that the Hamiltonian is constant along any optimal trajectory/co-state pair $(\bar{x}, p)$. Indeed, recalling (28), (27), for almost all $t, s \in [0, 1]$, we obtain

$$\begin{aligned}H(\bar{x}(t), p(t)) - H(\bar{x}(s), p(s)) &\geqq \langle p(t), f(\bar{x}(t), \bar{u}(s)) - f(\bar{x}(s), \bar{u}(s)) \rangle \\ &\quad + \langle p(t) - p(s), f(\bar{x}(s), \bar{u}(s)) \rangle = o(|t-s|).\end{aligned}$$

Since the above argument is symmetric,

$$|H(\bar{x}(t), p(t)) - H(\bar{x}(s), p(s))| \leqq o(|t-s|).$$

Since $t \to H(\bar{x}(t), p(t))$ is absolutely continuous, the above inequality implies that $H(\bar{x}(t), p(t))$ is constant.

When the Hamiltonian H is differentiable with respect to (x, p) at $(\bar{x}(t), p(t))$ for all $t \in [0, 1]$, then $\bar{x}$ and the co-state p satisfy the Hamiltonian system

$$\bar{x}'(t) = \frac{\partial H}{\partial p}(t, \bar{x}(t), p(t)),$$

$$p'(t) = -\frac{\partial H}{\partial x}(t, \bar{x}(t), p(t)).$$

More generally arguments similar to [19, Remark 4.10] imply the following proposition.

PROPOSITION 4.3. *Let $(t, \bar{x}, \bar{p}) \in [0, 1] \times \mathbf{R}^n \times \mathbf{R}^n$ and $\bar{u} \in U$ be such that*

$$\langle p, f(t, \bar{x}, \bar{u}) \rangle = H(t, \bar{x}, \bar{p}).$$

(i) *If $H(t, \cdot, \bar{p})$ is differentiable at $\bar{x}$, then*

$$\frac{\partial H}{\partial x}(t, \bar{x}, \bar{p}) = \left(\frac{\partial f}{\partial x}(t, \bar{x}, \bar{u}) \right)^* \bar{p}.$$

(ii) *If $H(t, \bar{x}, \cdot)$ is differentiable at $\bar{p}$, then*

$$\frac{\partial H}{\partial p}(t, \bar{x}, \bar{p}) = f(t, \bar{x}, \bar{u}).$$

It is well known that for every $(t, x) \in [0, 1] \times \mathbf{R}^n$ at which V is differentiable, we have

$$-\frac{\partial V}{\partial t}(t, x) + H\left(t, x, -\frac{\partial V}{\partial x}(t, x) \right) = 0. \tag{33}$$

When V is not differentiable at (t, x), the above equation has to be understood in the viscosity sense (see [13], [14]).

Since the Hamiltonian is continuous, we immediately deduce from (33) that

$$\text{(34)} \qquad \forall (t,x) \in [0,1]\times \mathbf{R}^n, \quad \forall (p_t, p_x) \in D^* V(t,x), \quad -p_t + H(t,x,-p_x) = 0.$$

Moreover, since $H(t, x, \cdot)$ is convex, (20) yields that

$$\text{(35)} \qquad \forall (t,x) \in]0,1[\times \mathbf{R}^n, \quad \forall (p_t, p_x) \in \partial V(t,x), \quad -p_t + H(t,x,-p_x) \leqq 0.$$

In particular, as $D^+ V(t,x) \subset \partial V(t,x)$, the inequality in (35) holds for all $(p_t, p_x) \in D^+ V(t,x)$ (in fact, by [14], [15], this inequality is the definition of viscosity subsolution).

The following is an adaptation of [26, Prop. 3.1].

PROPOSITION 4.4. *Assume* (9) *and let* $\bar{x}$ *be an optimal solution of problem* (8). *Then for every* $t \in]t_0, 1[$

$$\text{(36)} \qquad \forall (p_t, p_x) \in D^+ V(t, \bar{x}(t)), \quad -p_t + H(t, \bar{x}(t), -p_x) = 0.$$

Consequently, if for every $t \in]t_0, 1[$, $H(t, \bar{x}(t), \cdot)$ *is strictly convex, then* $D^+ V(t, \bar{x}(t))$ *is at most a singleton for every* $t \in]t_0, 1[$.

Proof. Let $\bar{u}$ be an optimal control corresponding to $\bar{x}$ and let $t \in]t_0, 1[$. Consider

$$\text{(37)} \qquad v \in \overline{\text{co}}\, f(t, \bar{x}(t), U)$$

such that for some $h_n \to 0+$, $\lim_{n\to\infty} (\bar{x}(t-h_n) - \bar{x}(t))/h_n = -v$. Then for all $(p_t, p_x) \in D^+ V(t, \bar{x}(t))$,

$$0 \geqq \limsup_{s \to t-} \frac{V(s, \bar{x}(s)) - V(t, \bar{x}(t)) - p_t(s-t) - \langle p_x, \bar{x}(s) - \bar{x}(t)\rangle}{|s-t| + \|\bar{x}(s) - \bar{x}(t)\|}.$$

Since $V(\cdot, \bar{x}(\cdot))$ is constant, the above estimate yields

$$0 \geqq \lim_{h \to \infty} \frac{-p_t(-h_n) - \langle p_x, \bar{x}(t-h_n) - \bar{x}(t)\rangle}{h_n} = p_t - \langle p_x, -v\rangle.$$

So we derived that

$$0 \leqq -p_t + \langle -p_x, v\rangle \leqq -p_t + H(t, x, -p_x)$$

From this last inequality and (35), we obtain (36). If $H(t, \bar{x}(t), \cdot)$ is strictly convex, then for all $(p_t^i, p_x^i) \in D^+ V(t, \bar{x}(t))$, $i = 1, 2$,

$$\begin{aligned} \tfrac{1}{2}(p_t^1 + p_t^2) &= \tfrac{1}{2}(H(t, \bar{x}(t), -p_x^1) + H(t, \bar{x}(t), -p_x^2)) \\ &\leqq H(t, \bar{x}(t), -\tfrac{1}{2}(p_x^1 + p_x^2)) = \tfrac{1}{2}(p_t^1 + p_t^2). \end{aligned}$$

If $(p_t^1, p_x^1) \neq (p_t^2, p_x^2)$, then in the above we will get a strict inequality, which would lead to a contradiction. Therefore $(p_t^1, p_x^1) = (p_t^2, p_x^2)$. □

We show next that, whenever $p(0) = -V_x'(0, \xi_0)$, we have the equality in the inclusion (30).

THEOREM 4.5. *Assume that* (9) *holds true, that* f *is differentiable with respect to* x *and* g *is differentiable. Suppose, furthermore, that the derivative* $V_x'(t_0, x_0)$ *exists and let* $\bar{x}$ *be an optimal solution for the problem* (8). *Consider the co-state* $p : [t_0, 1] \to \mathbf{R}^n$ *corresponding to* $\bar{x}$ *and given by Theorem* 4.2, *where the interval* $[0, 1]$ *is replaced by* $[t_0, 1]$ *and* ξ_0 *by* x_0. *Then*

$$\{-p(t)\} = D_x^+ V(t, \bar{x}(t)) \quad \forall t \in [t_0, 1].$$

In the next section, we show that under some additional regularity assumptions on f, $p(t)$ is equal to the derivative of the value function $V'_x(t, \bar{x}(t))$ for all t, provided $V'_x(t_0, x_0)$ exists.

Proof. We already know from Theorem 4.2 that

$$-p(t) \in D_x^+ V(t, \bar{x}(t)) \quad \forall t \in [t_0, 1].$$

Thus $p(t_0) = -V'_x(t_0, x_0)$.

Let $\bar{u}$ be an optimal control corresponding to $\bar{x}$. Fix Θ and let w, x_h have the same meaning as in the proof of Theorem 4.2 with t replaced by t_0. Then, since V is nondecreasing along trajectories of the control system (6) and constant along $\bar{x}$, for all $t \in [t_0, 1]$,

$$\begin{aligned}\langle p(t_0), \Theta\rangle = \langle -V'_x(t_0, x_0), \Theta\rangle &= -\lim_{h\to 0+} \frac{V(t_0, x_0 + h\Theta) - V(t_0, x_0)}{h} \\ &\geqq -\limsup_{h\to 0+} \frac{V(t, x_h(t)) - V(t, \bar{x}(t))}{h} \\ &= -\limsup_{h\to 0+} \frac{V(t, \bar{x}(t) + hw(t)) - V(t, \bar{x}(t))}{h} = -\partial_x^+ V(t, \bar{x}(t))(w(t)),\end{aligned}$$

where $\partial_x^+ V(t, \bar{x}(t))(w(t))$ denotes the upper Dini derivative of $V(t, \cdot)$ at $\bar{x}(t)$ in the direction $w(t)$.

Using (16) we deduce that for every $q \in D_x^+ V(t, \bar{x}(t))$, we have

$$\langle p(t_0), \Theta\rangle \geqq \langle -q, w(t)\rangle = \langle -q, X(t)\Theta\rangle = \langle -X(t)^* q, \Theta\rangle,$$

where X denotes the fundamental solution of

$$\begin{aligned}&X'(t) = \frac{\partial f}{\partial x}(t, \bar{x}(t), \bar{u}(t))X(t), \qquad t \in [t_0, 1],\\ &X(t_0) = Id.\end{aligned}$$

Since $\Theta \in \mathbf{R}^n$ is arbitrary, we have $p(t_0) = -X(t)^* q$. On the other hand, $p(\cdot)$ being a solution of (27), we know that $p(t_0) = X(t)^* p(t)$. Since for every $t \in [t_0, 1]$, the matrix $X(t)$ is nonsingular, we have proved that $-p(t) = q$. This yields that $D_x^+ V(t, \bar{x}(t))$ is single-valued and ends the proof. □

Whenever H happens to be more regular, we can prove the following theorem concerning optimal design. For every (t_0, x_0), define

$$D_x^* V(t_0, x_0) = D^* W(x_0), \tag{38}$$

where W is given by $W(x) = V(t_0, x)$.

THEOREM 4.6. *Assume that* (9) *holds true, that f is differentiable with respect to x, g is differentiable, and that $H(t, \cdot, \cdot)$ is differentiable on $\mathbf{R}^n \times (\mathbf{R}^n \backslash \{0\})$ for almost every $t \in [0, 1]$. Furthermore, assume that the sets $f(t, x, U)$ are convex and compact and for every $R > 1$ there exists a nonnegative integrable function $l_R \in L^1(0, 1; \mathbf{R}_+)$ such that for all $x, y \in RB$ and $p, q \in RB \backslash (1/R)B$*

$$\begin{aligned}&\left\|\frac{\partial H}{\partial x}(t, x, p) - \frac{\partial H}{\partial x}(t, y, q)\right\| + \left\|\frac{\partial H}{\partial p}(t, x, p) - \frac{\partial H}{\partial p}(t, y, q)\right\| \\ &\qquad \leqq l_R(t)(\|x - y\| + \|p - q\|).\end{aligned} \tag{39}$$

Let $(t_0, x_0) \in [0, 1] \times \mathbf{R}^n$ *and* $p_0 \neq 0$ *be such that*

$$-p_0 \in D_x^* V(t_0, x_0). \tag{40}$$

Then the Hamiltonian system

$$\begin{aligned} &x'(t) = \frac{\partial H}{\partial p}(t, x(t), p(t)), \qquad x(t_0) = x_0, \\ &p'(t) = -\frac{\partial H}{\partial x}(t, x(t), p(t)), \qquad p(t_0) = p_0, \\ &p(t) \neq 0, \qquad t \in [t_0, 1] \end{aligned} \tag{41}$$

has a unique solution $(\bar{x}(\cdot), \bar{p}(\cdot))$ *defined on* $[t_0, 1]$. *Moreover,* $\bar{x}(\cdot)$ *is an optimal solution of problem* (8).

Furthermore, if $g'(\cdot)$ *is continuous at* $\bar{x}(1)$, *then* $\bar{p}(\cdot)$ *is the co-state corresponding to* $\bar{x}(\cdot)$.

Remark. The above theorem extends a result of [10], which concerned a problem in calculus of variations. For such problems, condition (39) is natural. It is much more restrictive for nonlinear control systems. It is well known that $H(t, x, \cdot)$ is not differentiable at zero when $f(t, x, U)$ is not a singleton. This is why we eliminate $p = 0$ in our assumptions.

We observe that (39) is satisfied whenever the variables x and u are "separated":

$$f(t, x, u) = \varphi(t, x) + \psi(t, u),$$

where $\varphi(t, \cdot)$ has $k_R(t)$ Lipschitz gradient on RB for some $k_R \in L^1(0, 1; \mathbf{R}_+)$ and the boundary of $\psi(t, U)$ is sufficiently smooth.

Proof. By the very definition of $D_x^* V(t_0, x_0)$, it follows that there exists a sequence x_k converging to x_0 such that $V(t_0, \cdot)$ is differentiable at x_k and

$$-p_0 = \lim_{k \to \infty} \frac{\partial V}{\partial x}(t_0, x_k).$$

Let $(\bar{x}_k, u_k)$ be an optimal trajectory control pair for problem (8) with x_0 replaced by x_k. By Theorem 4.2 (applied with the interval $[0, 1]$ replaced by $[t_0, 1]$ and ξ_0 by x_k) there exists an absolutely continuous function $\bar{p}_k : [t_0, 1] \to \mathbf{R}^n$ such that

$$\begin{aligned} &-\bar{p}_k'(t) = \left(\frac{\partial f}{\partial x}(t, \bar{x}_k(t), \bar{u}_k(t))\right)^* \bar{p}_k(t) \quad \text{a.e. in } [t_0, 1], \\ &-\bar{p}_k(t_0) = \frac{\partial V}{\partial x}(t_0, x_k). \end{aligned} \tag{42}$$

Therefore, $p_k(t) \neq 0$ for all $t \in [t_0, 1]$ for sufficiently large k. By Proposition 4.3, for almost every $t \in [t_0, 1]$,

$$\begin{aligned} &\bar{x}_k'(t) = \frac{\partial H}{\partial p}(t, x_k(t), \bar{p}_k(t)), \qquad \bar{x}_k(t_0) = x_k, \\ &\bar{p}_k'(t) = -\frac{\partial H}{\partial x}(t, \bar{x}_k(t), \bar{p}_k(t)), \\ &\bar{p}_k(t_0) = -\frac{\partial V}{\partial x}(t_0, x_k). \end{aligned} \tag{43}$$

Recalling assumption (9) (iii), we conclude that $\bar{x}_k$, $k=1,\cdots$ are equicontinuous and equibounded. Furthermore, from (9)(ii) and (42) it follows that $\bar{p}_k$ are also equicontinuous and equibounded and the maps $t\to(\partial f/\partial x)(t,\bar{x}_k(t),u_k(t))$ are integrably bounded on $[t_0,1]$. So, taking a subsequence and keeping the same notation, we may assume that $(\bar{x}_k,\bar{p}_k)$ converge uniformly to some $(\bar{x},\bar{p})$ and $(\partial f/\partial x)(\cdot,\bar{x}_k(\cdot),u_k(\cdot))$ converge weakly in $L^1(t_0,1)$ to some $A(\cdot)$. In particular $\bar{p}(t_0)=p_0\neq 0$ and $\bar{p}$ solves the linear equation

$$-\bar{p}'(t)=A(t)^*\bar{p}(t)\quad \text{a.e. in } [t_0,1].$$

Thus $\bar{p}(t)\neq 0$ for all $t\in[t_0,1]$. Fix $R>1$ so that

$$\forall s\in[t_0,1],\quad \frac{2}{R}\leqq\|\bar{p}(s)\|\leqq\frac{R}{2}.$$

Then, for all sufficiently large k and all $s\in[t_0,1]$, we have $1/R\leqq\|p_k(s)\|\leqq R$. So, using (39) and taking the limit in (43), we deduce $(\bar{x},\bar{p})$ is a solution of the Hamiltonian system (41).

Since $\bar{p}$ never vanishes, the assumption (39) implies that $(\bar{x},\bar{p})$ is the only solution of (41). On the other hand,

$$V(t_0,x_0)=\lim_{k\to\infty}V(t_0,\bar{x}_k(t_0))=\lim_{k\to\infty}g(\bar{x}_k(1))=g(\bar{x}(1))$$

and therefore $\bar{x}$ is optimal for the problem (8).

Assume next that g' is continuous at $\bar{x}(1)$. Then $\bar{p}(1)=-g'(\bar{x}(1))\neq 0$. Let p_1 be a co-state corresponding to the optimal trajectory $\bar{x}$. Then $p_1(t)\neq 0$ for all $t\in[t_0,1]$ and, by Proposition 4.3, it solves the equation

$$(44)\qquad -p'(t)=\frac{\partial H}{\partial x}(t,\bar{x}(t),p(t))\quad \text{a.e. in } [t_0,1],\quad p(1)=-g'(\bar{x}(1)).$$

Since $\bar{p}$ is also a solution of (44), we deduce that $p_1=\bar{p}$ by uniqueness. The proof is complete. □

Remark. (i) By minor modifications of the above arguments it is easy to show that condition (40) may be replaced by the following one:

$$(45)\qquad (H(t_0,x_0,p_0),-p_0)\in D^*V(t_0,x_0).$$

In general, (40) and (45) are not comparable. If V is semiconcave, however, then (40) is more restrictive than (45). This can be shown using Proposition 5.2 below.

(ii) In calculus of variations, the necessity of (45) was proved in [10].

Other examples of problems for which (40) is necessary are given by optimal control problems having a unique optimal trajectory for the initial state (t_0,x_0).

THEOREM 4.7. *Assume* (9), *that g is continuously differentiable, that f is differentiable with respect to x, that* $f(t,x,U)$ *are convex and compact, and that H is continuously differentiable with respect to x. Further assume that, for every* $R>0$, *there exists a nonnegative integrable function* $l_R\in L^1(0,1;\mathbf{R}_+)$ *such that*

$$(46)\qquad \forall x,y,p\in RB,\quad \left\|\frac{\partial H}{\partial x}(t,x,p)-\frac{\partial H}{\partial x}(t,y,p)\right\|\leqq l_R(t)\|x-y\|.$$

If the problem (8) *has a unique optimal solution* $\bar{x}$, *then* $V(t,\cdot)$ *is differentiable at* $\bar{x}(t)$ *for all* $t\in[t_0,1]$.

Proof. Observe that for every $t\in[t_0,1]$, the problem (8) has a unique optimal solution for (t_0,x_0) replaced by $(t,\bar{x}(t))$. For this reason we only check that $V(t_0,\cdot)$ is differentiable at x_0.

By [11, pp. 33, 63] it suffices to show that $D_x^*V(t_0,x_0)$ is a singleton. Let $p_1,p_2\in D_x^*V(t_0,x_0)$ and consider sequences $\{x_k^1\}$ and $\{x_k^2\}$ converging to x_0, such that

$$\lim_{k\to+\infty}\frac{\partial V}{\partial x}(t_0,x_k^i)=p_i,\qquad i=1,2.$$

Let $\bar{x}_k^i$ be an optimal trajectory for problem (8) with x_0 replaced by x_k^i, $i=1,2$ and denote by p_k^i a corresponding co-state. Then, by Proposition 4.3,

$$\begin{aligned}(p_k^i)'(t)&=-\frac{\partial H}{\partial x}(t,\bar{x}_k^i(t),p_k^i(t)),\\ p_k^i(1)&=-g'(\bar{x}_k^i(1)),\\ p_k^i(t_0)&=-\frac{\partial V}{\partial x}(t_0,x_k^i).\end{aligned}$$

By assumption (9)(iii), $\bar{x}_k^i$ are bounded and equicontinuous. Since the solution of (8) is unique, we deduce that $\bar{x}_k^i$ converge uniformly to $\bar{x}$ for $i=2$. Taking subsequences and keeping the same notation, we may assume that p_k^i converge uniformly to the unique solution p of

$$p'(t)=-\frac{\partial H}{\partial x}(t,\bar{x}(t),p(t)),\qquad p(1)=-g'(\bar{x}(1)).$$

In particular, $p_1=p(t_0)=p_2$ and so $D_x^*V(t_0,x_0)$ is a singleton. □

THEOREM 4.8. *Under the assumptions of Theorem* 4.6, *assume that g is continuously differentiable. Then* $V(t_0,\cdot)$ *is differentiable at* x_0 *with derivative different from zero if and only if there is a unique optimal trajectory* $\bar{x}$ *for problem* (8) *and* $g'(\bar{x}(1))\neq 0$.

Proof. Assume that $(\partial V/\partial x)(t_0,x_0)\neq 0$. Let $\bar{x}$ be optimal for problem (8). By Theorem 4.2, $g'(\bar{x}(1))\neq 0$. By Proposition 4.3, every optimal trajectory/co-state pair solves the Hamiltonian system (41). This yields the uniqueness of optimal trajectory.

Conversely, assume that (8) has a unique optimal solution $\bar{x}$ and $g'(\bar{x}(1))\neq 0$. By Theorem 4.7, $V(t_0,\cdot)$ is differentiable at x_0. Theorem 4.2 implies that $(\partial V/\partial x)(t_0,x_0)\neq 0$. □

5. Semiconcavity properties of the value function.

We provide a sufficient condition for the semiconcavity of the value function $V:[0,1]\times\mathbf{R}^n\to\mathbf{R}$ introduced in the first section. Throughout the whole section we assume the following:

(47)
- (i) $f:[0,1]\times\mathbf{R}^n\times U\to\mathbf{R}^n$ is continuous,
- (ii) $\exists M>0$ such that $\forall(t,x,u)\in[0,1]\times\mathbf{R}^n\times U$, $\|f(t,x,u)\|\leqq M(\|x\|+1)$,
- (iii) $\exists L>0$ such that $\forall t_1,t_2\in[0,1],\forall x_1,x_2\in\mathbf{R}^n,\forall u\in U$, $\|f(t_1,x_1,u)-f(t_2,x_2,u)\|\leqq L(|t_1-t_2|+\|x_1-x_2\|)$,
- (iv) $\exists\omega:\mathbf{R}_+\times\mathbf{R}_+\to\mathbf{R}_+$ such that (21) holds true and $\forall\lambda\in[0,1],\forall u\in U,\forall R>0,\forall x_0,x_1\in RB,\forall t\in[0,1]$, $\|\lambda f(t,x_0,u)+(1-\lambda)f(t,x_1,u)-f(t,\lambda x_0+(1-\lambda)x_1,u)\|$ $\leqq\lambda(1-\lambda)\|x_1-x_0\|\omega(R,\|x_1-x_0\|)$,
- (v) $g:\mathbf{R}^n\to\mathbf{R}$ is locally Lipschitz and semiconcave.

Remark. (1) Assumption (47)(iv) holds true in particular when f is continuously differentiable with respect to x uniformly in (t,u). More precisely, (47)(iv) is satisfied if we assume that there exists a function $\omega: \mathbf{R}_+ \times \mathbf{R}_+ \to \mathbf{R}_+$ satisfying (21) such that

$$\left\| \frac{\partial f}{\partial x}(t, x_1, u) - \frac{\partial f}{\partial x}(t, x_2, u) \right\| \leqq \omega(R, \|x_1 - x_2\|)$$

for all $u \in U$, $t \in [0, 1]$, $x_1, x_2 \in RB$.

(2) Vice versa, Proposition 3.12 implies that, if f satisfies (47)(iv), then f is continuously differentiable with respect to x.

The main result of this section is the following theorem.

THEOREM 5.1. *If* (47) *holds true, then the value function is semiconcave on* $[0, 1] \times \mathbf{R}^n$.

Proof. For every $t \in [0, 1]$ and measurable function $u: [t, 1] \to U$, we denote by $y(\cdot\,; t, x, u)$ the solution of the system

$$y'(s) = f(s, y(s), u(s)), \qquad y(t) = x.$$

The Gronwall lemma implies that

$$\forall x \in RB, \quad \forall s \in [t, 1], \quad \|y(s)\| \leqq C_R := (R + M)\, e^M. \tag{48}$$

Moreover, for all $t \in [0, 1]$, $s \in [t, 1]$, $x_0, x_1 \in \mathbf{R}^n$ and all measurable functions $u: [t, 1] \to U$, we have

$$\|y(s; t, x_1, u) - y(s; t, x_0, u)\| \leqq e^{L(s-t)} \|x_1 - x_0\|. \tag{49}$$

Step 1. We claim that there exists $\omega_1: \mathbf{R}_+ \times \mathbf{R}_+ \to \mathbf{R}_+$ satisfying (21) such that for all $0 \leqq t \leqq s \leqq 1$, $R > 0$, $x_0, x_1 \in RB$, $\lambda \in [0, 1]$, and measurable functions $u: [t, 1] \to U$, we have

$$\begin{aligned} &\|\lambda y(s; t, x_1, u) + (1 - \lambda) y(s; t, x_0, u) - y(s; t, \lambda x_0 + (1 - \lambda) x_1, u)\| \\ &\quad \leqq \lambda(1 - \lambda) \|x_1 - x_0\| \omega_1(R, \|x_1 - x_0\|). \end{aligned}$$

Indeed, set $x_\lambda = \lambda x_0 + (1 - \lambda) x_1$ and define

$$y_\lambda(\tau) = \lambda y(\tau; t, x_1, u) + (1 - \lambda) y(\tau; t, x_0, u) - y(\tau; t, x_\lambda, u).$$

Then

$$\begin{aligned} y'_\lambda(\tau) &= \lambda f(\tau, y(\tau; t, x_1, u), u(\tau)) + (1 - \lambda) f(\tau, y(\tau; t, x_0, u), u(\tau)) \\ &\qquad - f(\tau, y(\tau; t, x_\lambda, u), u(\tau)), \\ y_\lambda(t) &= 0. \end{aligned}$$

Thus by assumptions (47)

$$\begin{aligned} \|y'_\lambda(\tau)\| \leqq \lambda(1 - \lambda) &\|y(\tau; t, x_1, u) - y(\tau; t, x_0, u)\| \\ &\cdot \omega(C_R, \|y(\tau; t, x_1, u) - y(\tau; t, x_0, u)\|) + L\|y_\lambda(\tau)\|, \end{aligned}$$

where C_R is defined in (48). Our claim follows from (49) and the Gronwall lemma.

Step 2. We claim that there exists $\omega_2: \mathbf{R}_+ \times \mathbf{R}_+ \to \mathbf{R}_+$ satisfying (21) such that for all $t \in [0, 1]$, $\lambda \in [0, 1]$, $R > 0$, and $x_0, x_1 \in RB$ the following inequality holds true:

$$\begin{aligned} &\lambda V(t, x_1) + (1 - \lambda) V(t, x_0) - V(t, \lambda x_1 + (1 - \lambda) x_0) \\ &\quad \leqq \lambda(1 - \lambda) \|x_1 - x_0\| \omega_2(R, \|x_1 - x_0\|). \end{aligned}$$

Indeed, define x_λ as in Step 1, fix $\varepsilon > 0$ and a control u_ε such that

$$V(t, x_\lambda) > g(y(1; t, x_\lambda, u_\varepsilon)) - \varepsilon.$$

Let ω_g denote a modulus of semiconcavity of g and L_R a Lipschitz constant of g on the ball of radius C_R. Then from (49) and Step 1, we get

$$\begin{aligned}\lambda V(t,x_1)&+(1-\lambda)V(t,x_0)-V(t,x_\lambda)\\&<\lambda g(y(1;t,x_1,u_\varepsilon))+(1-\lambda)g(y(1;t,x_0,u_\varepsilon))-g(y(1;t,x_\lambda,u_\varepsilon))+\varepsilon\\&\leqq \lambda(1-\lambda)\|y(1;t,x_1,u_\varepsilon)-y(1;t,x_0,u_\varepsilon)\|\\&\quad\cdot\omega_g(C_R,\|y(1;t,x_1,u_\varepsilon)-y(1;t,x_0,u_\varepsilon)\|)\\&\quad+L_R\|\lambda y(1;t,x_1,u_\varepsilon)+(1-\lambda)y(1;t,x_0,u_\varepsilon)-y(1;t,x_\lambda,u_\varepsilon)\|+\varepsilon\\&\leqq L'_R\lambda(1-\lambda)\|x_1-x_0\|\\&\quad\cdot(\omega_g(C_R,e^L\|x_1-x_0\|)+\omega_1(R,\|x_1-x_0\|))+\varepsilon\end{aligned}$$

for some L'_R depending only on L_R and L. Since $\varepsilon>0$ is arbitrary, our claim follows. Thus we proved the semiconcavity of $V(t,\cdot)$.

Step 3. Consider next $0\leqq t_1<t_0\leqq 1$, $R>0$, and let $x_0,x_1\in RB$, $\lambda\in[0,1]$. Define

$$x_\lambda=\lambda x_1+(1-\lambda)x_0,\qquad t_\lambda=\lambda t_1+(1-\lambda)t_0.$$

Pick any $\varepsilon>0$ and let u_ε be such that

$$V(t_0,y(t_0;t_\lambda,x_\lambda,u_\varepsilon))<V(t_\lambda,x_\lambda)+\varepsilon.$$

Define

$$\tau(s)=\begin{cases}\lambda s+(1-\lambda)t_0, & \text{if } t_1\leqq s\leqq t_0,\\ s & \text{otherwise.}\end{cases}\tag{50}$$

Since the value function is nondecreasing along trajectories of our control system, we have

$$\begin{aligned}\lambda V(t_1,x_1)&+(1-\lambda)V(t_0,x_0)-V(t_\lambda,x_\lambda)\\&\leqq\lambda V(t_0,y(t_0;t_1,x_1,u_\varepsilon\circ\tau))+(1-\lambda)V(t_0,x_0)\\&\quad-V(t_0,y(t_0;t_\lambda,x_\lambda,u_\varepsilon))+\varepsilon.\end{aligned}\tag{51}$$

Set $y_1(s)=y(s;t_1,x_1,u_\varepsilon\circ\tau)$, $y_\lambda(s)=y(s;t_\lambda,x_\lambda,u_\varepsilon)$, and let K_R denote the Lipschitz constant of V on $[0,1]\times C_RB$. By (51) and Step 2 we obtain

$$\begin{aligned}\lambda V(t_1,x_1)&+(1-\lambda)V(t_0,x_0)-V(t_\lambda,x_\lambda)\\&\leqq\lambda(1-\lambda)\|y_1(t_0)-x_0\|\omega_2(C_R,\|y_1(t_0)-x_0\|)\\&\quad+K_R\|\lambda y_1(t_0)+(1-\lambda)x_0-y_\lambda(t_0)\|.\end{aligned}\tag{52}$$

On the other hand, from assumption (47)(ii) it follows that

$$\forall s\in[t_1,t_0],\quad \|y_1(s)-x_0\|\leqq\|x_1-x_0\|+M_R(t_0-t_1),\tag{53}$$

where $M_R=M(1+C_R)$. Set

$$z(s)=\lambda y_1(\tau^{-1}(s))+(1-\lambda)x_0-y_\lambda(s)$$

and note that $z(t_\lambda)=0$, $z(t_0)=\lambda y_1(t_0)+(1-\lambda)x_0-y_\lambda(t_0)$. Furthermore, using (47)(iii), we obtain the following estimates:

$$\begin{aligned}\|z'(s)\|&=\|f(\tau^{-1}(s),y_1\circ\tau^{-1}(s),u_\varepsilon(s))-f(s,y_\lambda(s),u_\varepsilon(s))\|\\&\leqq L(|\tau^{-1}(s)-s|+\|y_1\circ\tau^{-1}(s)-y_\lambda(s)\|)\\&\leqq L\|z(s)\|+L(1-\lambda)\|y_1\circ\tau^{-1}(s)-x_0\|+L\frac{1-\lambda}{\lambda}(t_0-s).\end{aligned}$$

Therefore from the Gronwall inequality and (53) we deduce that

$$\begin{aligned}\|z(t_0)\| &\leqq L(1-\lambda)\int_{t_\lambda}^{t_0}\left(\|y_1\circ\tau^{-1}(s)-x_0\|+\frac{1}{\lambda}(t_0-s)\right)e^{L(t_0-s)}\,ds\\ &\leqq L\,e^L\lambda(1-\lambda)(t_0-t_1)\left(\|x_1-x_0\|+\left(\frac{1}{2}+M_R\right)(t_0-t_1)\right).\end{aligned}\tag{54}$$

Inequalities (52), (53), and (54) imply the conclusion. □

PROPOSITION 5.2. *Assume that the value function is semiconcave at a point* $(t_0, x_0)\in[0,1]\times\mathbf{R}^n$. *If* $D_x^+V(t_0,x_0)$ *is a singleton, then* V *is differentiable at* (t_0,x_0) *and* $D^*V(t_0,x_0)=\{V'(t_0,x_0)\}$.

Here at boundary points ($t_0\in\{0,1\}$), the above differentiability, of course, has to be understood in the one-sided sense.

Proof. Let $\pi_x:\mathbf{R}\times\mathbf{R}^n\to\mathbf{R}^n$ denote the projection on $\mathbf{R}^n$. Since

$$\pi_xD^+V(t_0,x_0)\subset D_x^+V(t_0,x_0)=:\{p_0\},$$

by (34) and (23) we conclude that

$$(p_t,p_x)\in D^*V(t_0,x_0)\Rightarrow p_x=p_0,\qquad p_t=H(t_0,x_0,-p_0).$$

Hence $D^+V(t_0,x_0)$ is a singleton. The conclusion follows from Proposition 3.10. □

COROLLARY 5.3. *Assume* (47) *that* g *is differentiable, and that the derivative* $V_x'(t_0,x_0)$ *does exist. Let* $\bar x$ *be an optimal solution of problem* (8).

Then for all $t\in[t_0,1]$, V *is differentiable at* $(t,\bar x(t))$ *and*

$$D^*V(t,\bar x(t))=\{V'(t,\bar x(t))\}.$$

Conversely, assume that $x:[t_0,1]\to\mathbf{R}^n$ *is a solution of* (6) *and that for every* $t\in[t_0,1]$, V *is differentiable at* $(t,x(t))$. *If the sets* $f(t,x,U)$ *are convex and compact, and*

$$-\left\langle\frac{\partial V}{\partial x}(t,x(t)),x'(t)\right\rangle=H\left(t,x(t),-\frac{\partial V}{\partial x}(t,x(t))\right)\quad \textit{a.e. in } [t_0,1],\tag{55}$$

then x *is optimal for problem* (8).

Proof. The first statement follows immediately from Proposition 5.2 and Theorem 4.5. To prove the second one, fix $\bar t\in[t_0,1]$ and let $\bar x:[\bar t,1]\to\mathbf{R}^n$ be an optimal solution of problem (8) with (t_0,x_0) replaced by $(\bar t,x(\bar t))$.

We already know that V is semiconcave. By Theorem 4.2, there exists $p(\bar t)\in\mathbf{R}^n$ such that

$$(H(\bar t,x(\bar t),p(\bar t)),-p(\bar t))=V'(\bar t,\bar x(\bar t)).$$

Since $\bar t\in[t_0,1]$ is arbitrary, assumption (55) and Theorem 4.1 end the proof. □

COROLLARY 5.4. *Under all assumptions of Theorem* 4.7 *assume* (47). *If problem* (8) *has a unique optimal solution* $\bar x$, *then* V *is differentiable at* $(t,\bar x(t))$ *for all* $t\in[t_0,1]$.

COROLLARY 5.5. *Under the hypotheses of Theorem* 4.6, *assume that* (47) *holds true and* g *is continuously differentiable. Then* $V(\cdot,\cdot)$ *is differentiable at* (t_0,x_0) *with the derivative* $(\partial V/\partial x)(t_0,x_0)$ *different from zero if and only if there is a unique optimal trajectory* $\bar x$ *for problem* (8) *satisfying* $g'(\bar x(1))\neq 0$.

Usually, the value function is not everywhere differentiable. However, that is always the case for "convex" problems, as we prove below (see also [4], [5], [9]).

PROPOSITION 5.6. *Assume that* (47) *holds true,* g *is convex, and for all* $t\in[0,1]$,

$$\text{Graph}\,(f(t,\cdot,U))\ \textit{is closed and convex.}\tag{56}$$

Then V is continuously differentiable on $[0,1]\times\mathbf{R}^n$ *and convex with respect to the second variable.*

Proof. By Theorem 2.1, assumption (56) yields that for every $(t_0, x_0)\in[0,1]\times\mathbf{R}^n$ there exists a solution $\bar{x}$ of the control system

$$x'=f(t,x(t),u(t)),\quad u(t)\in U,\quad x(t_0)=x_0,$$

satisfying $V(t_0,x_0)=g(\bar{x}(1))$.

Fix $t_0\in[0,1]$, $x_0, x_1\in\mathbf{R}^n$, $\lambda\in[0,1]$ and consider trajectories $x:[t_0,1]\to\mathbf{R}^n$ and $y:[t_0,1]\to\mathbf{R}^n$ such that $V(t_0,x_0)=g(x(1))$, $V(t_0,x_1)=g(y(1))$. Define the trajectory $z:[t_0,1]\to\mathbf{R}^n$ by $z(t)=\lambda x(t)+(1-\lambda)y(t)$. Then, using (56), we obtain that z is a solution of the control system (6) satisfying $z(t_0)=\lambda x_0+(1-\lambda)x_1$. Thus, by convexity of g,

$$V(t_0,\lambda x_0+(1-\lambda)x_1)\leqq g(z(1))\leqq\lambda V(t_0,x_0)+(1-\lambda)V(t_1,x_1)$$

and therefore $V(t_0,\cdot)$ is convex.

Next, as $V(t,\cdot)$ is both convex and semiconcave for all $t\in[0,1]$, Proposition 3.12 yields that $V(t,\cdot)$ is continuously differentiable on $\mathbf{R}^n$. The conclusion now follows from Proposition 5.2. □

6. Optimal feedback. One of the major issues of optimal control theory is to find an "equation" for optimal trajectories. Theorem 2.4 provides an inclusion formulation. However, in general, the set-valued map G is not regular enough to make us able to solve the inclusion (12). The situation is comparable to having an ordinary differential equation with a nonsmooth right-hand side: it may have solutions, but this solution cannot be obtained as, say, limits of Euler curves.

This is why we have to investigate regularity properties of G. In this section, we show that under the assumptions of Theorem 5.1, the feedback map G^{co} is upper semicontinuous and that so is G if we assume, in addition, that the sets $f(t,x,U)$ are closed.

The results of §§3 and 5 imply that under assumptions (47) the feedback maps $G:[0,1]\times\mathbf{R}^n\mapsto\mathbf{R}^n$ and $G^{\text{co}}:[0,1]\times\mathbf{R}^n\mapsto\mathbf{R}^n$ defined in § 2 are, respectively, equal to

$$G(t,x)=\{v\in f(t,x,U)\mid V_-^o(t,x)(1,v)=0\}$$

and

$$G^{\text{co}}(t,x)=\{v\in\overline{\text{co}}\,f(t,x,U)\mid V_-^o(t,x)(1,v)=0\}.$$

THEOREM 6.1. *Let us assume that* (47) *holds true. Then G^{co} has compact, nonempty images and is upper semicontinuous. The same holds true for the map G is we assume, in addition, that the sets $f(t,x,U)$ are closed.*

Proof. From Theorems 5.1 and 3.9 we know that for every $(t,x)\in[0,1[\times\mathbf{R}^n$ and every $\Theta\in\mathbf{R}^n$ the directional derivative $(\partial V/\partial(1,\Theta))(t,x)$ exists and is equal to the regularized lower derivative $V_-^o((t,x),(1,\Theta))$. Define the set-valued map

$$\hat{Q}:[0,1]\times\mathbf{R}^n\rightsquigarrow\mathbf{R}^n$$

by

$$\hat{Q}(t,x)=\{\Theta\in\mathbf{R}^n\mid V_-^o(t,x)(1,\Theta)\leqq 0\}.$$

From Proposition 3.5 we know that the set Graph $(\hat{Q})$ is closed. On the other hand, Proposition 2.3 implies that for every $v\in\overline{\text{co}}\,f(t,x,U)$, $(\partial V/\partial(1,v))(t,x)\geqq 0$. Thus

$$G(t,x)=\hat{Q}(t,x)\cap f(t,x,U),\qquad G^{\text{co}}(t,x)=\hat{Q}(t,x)\cap\overline{\text{co}}\,f(t,x,U).$$

This fact and the assumptions on f imply that the graphs of the set-valued maps G, G^{co} are closed. Furthermore, G^{co} takes its values in a compact set. From [2, p. 42] (see also [3, Chap. 1]) it follows that G and G^{co} are upper semicontinuous. □

COROLLARY 6.2. *Let us assume that* (47) *holds true and that the sets* $f(t, x, U)$ *are closed. If the map* G *is single-valued on a subset* $K \subset [0, 1] \times \mathbf{R}^n$, *then the function* $K \ni (t, x) \to G(t, x)$ *is continuous.*

A typical example of a nonlinear control system with closed convex images is the affine system

$$x' = f(x) + \sum_{i=1}^{k} u_i g_i(x), \qquad u_i \in [a, b],$$

where f and g_i are continuous functions from $\mathbf{R}^n$ to itself.

The feedback map G defined above, in general, does not have convex images because the map of directional derivatives is concave.

For this reason, in general, the feedback inclusion (12) is very difficult to investigate. When V happens to be differentiable and the sets $f(t, x, U)$ are closed and convex, then for obvious reasons the map G has convex compact images. Proposition 5.6 provides a sufficient condition for the continuous differentiability of V.

THEOREM 6.3. *Assume that* (47) *and* (56) *hold true and that* g *is convex. Then* G *has convex compact images and is upper semicontinuous. Furthermore, if for every* (t, x) *the set* $f(t, x, U)$ *is strictly convex, then* G *is single-valued and continuous.*

Proof. By Proposition 5.6, we know that V is continuously differentiable. This and the convexity of $f(t, x, U)$ yield that for all $(t, x) \in [0, 1[\times \mathbf{R}^n$,

$$G^{co}(t, x) = G(t, x) = f(t, x, U) \cap \{\Theta \in \mathbf{R}^n \mid V'(t, x)(1, \Theta) = 0\}$$

is convex. Theorem 6.1 ends the proof of the first statement. From Proposition 2.3 it follows that for all $(t, x) \in [0, 1[\times \mathbf{R}^n$,

$$v \in G(t, x) \Leftrightarrow v \in f(t, x, U) \text{ and}$$

$$\sup_{u \in U} \left\langle -\frac{\partial V}{\partial x}(t, x), f(t, x, u) \right\rangle = \left\langle -\frac{\partial V}{\partial x}(t, x), v \right\rangle.$$

This and strict convexity of $f(t, x, U)$ imply that G is single-valued. Corollary 6.2 completes the proof. □

7. Viability approach to optimal control. In this section, we provide an alternative approach to optimal trajectories based on viability techniques.

We first show the following characterization of optimal trajectories.

THEOREM 7.1. *Assume* (9). *Then a solution* $\bar{x}$ *of the control system* (6) *defined on the time interval* $[0, 1]$ *is optimal if and only if the function* $t \to (t, \bar{x}(t), V(0, \xi_0))$ *is a solution of the viability problem*

$$\begin{aligned} & t' = 1, \\ & x'(t) = f(t, x(t), u(t)), \qquad u(t) \in U \textit{ is measurable}, \\ (57) \qquad & z'(t) = 0, \\ & (t, x(t), z(t)) \in \text{Graph}(V) \quad \forall t \in [0, 1], \\ & t(0) = 0, \quad x(0) = \xi_0, \quad z(0) = V(0, \xi_0). \end{aligned}$$

Proof. We already observed that $\bar{x}(\cdot)$ is optimal if and only if the map $t \to V(t, \bar{x}(t))$ is constant on the time interval $[0, 1]$. On the other hand, $t \to (t, \bar{x}(t), z(t))$ is a solution of (57) if and only if $z(t)=V(t,\bar{x}(t))\equiv\text{const}$ and $\bar{x}(\cdot)$ is a solution of (6) satisfying $\bar{x}(0)=\xi_0$. □

Inclusion (57) is a viability problem which may be approached using many results of viability theory. Actually, the viability technique may be applied not only to the value function V but also to any continuous function W satisfying some inequalities from [17]. To state results in this direction, we need the following definition.

DEFINITION 7.2. Consider a continuous function $W:[0,1]\times\mathbf{R}^n\to\mathbf{R}$ and let $(t,x)\in[0,1]\times\mathbf{R}^n$. The contingent derivative of W at (t,x) in the direction $(w,v)\in\mathbf{R}\times\mathbf{R}^n$ is a subset of $\mathbf{R}$ defined by

$$\begin{aligned} &DW(t,x)(w,v)\\ (58)\qquad &:=\left\{u\in\mathbf{R}\;\middle|\;\liminf_{h\to0+,(w',v')\to(w,v)}\ \operatorname{dist}\left(u,\frac{W(t+hw',x+hv')-W(t,x)}{h}\right)=0\right\}.\end{aligned}$$

From [3, Chap. 6] it follows that the set $DW(t,x)(w,v)$ is closed and convex.

THEOREM 7.3. *Consider a continuous function* $W:[0,1]\times\mathbf{R}^n\to\mathbf{R}$ *and assume* (9). *If for every* $(t,x)\in[0,1]\times\mathbf{R}^n$,

$$0\in\{DW(t,x)(1,v)\,|\,v\in\overline{\text{co}}\,f(t,x,U)\},$$

then for all (t_0,x_0) *there exists a solution* $\bar{x}$ *of the differential inclusion*

$$x'(t)\in\overline{\text{co}}\,f(t,x(t),U)\quad\text{a.e. in }[t_0,1],\quad x(t_0)=x_0$$

such that $W(t,\bar{x}(t))\equiv W(1,\bar{x}(1))$.

Proof. It is not restrictive to assume that $t_0=0$. We extend W on $\mathbf{R}_+\times\mathbf{R}^n$ by setting for all $t>1$, $W(t,x)=W(1,x)$. Define the closed set $K=\text{graph}\,(W)$ and the map $F_1(t,x)=\{1\}\times\overline{\text{co}}\,f(t,x,U)\times\{0\}$. Set

$$\hat{F}(t,x)=\begin{cases}F_1(t,x) & \text{if } t\in[0,1[\\ \overline{\text{co}}\,(\{0\}\cup F_1(1,x)) & \text{if } t\geqq 1.\end{cases}$$

Then for every $(t,x)\in\mathbf{R}_+\times\mathbf{R}^n$, the contingent cone $T_K(t,x,W(t,x))$ to K at $(t,x,W(t,x))$ is equal to Graph $(DW(t,x))$ (see [3, Chap. 5]). Hence, by our assumption, for every $(t,x)\in[0,1[\times\mathbf{R}^n$ there exists $u\in F_1(t,x)$ such that $(1,u,0)\in T_K(t,x,W(t,x))$. Furthermore, for every $t\geqq1$ and $x\in\mathbf{R}^n$, we have $0\in\hat{F}(t,x)$. This proves that

$$\forall(t,x)\in\mathbf{R}_+\times\mathbf{R}^n,\quad \hat{F}(t,x)\cap T_K(t,x,W(t,x))\neq\emptyset.$$

By the assumptions, $\hat{F}$ is continuous and has closed convex images. Consequently, by the Haddad viability theorem[1] [20] (see also [1], [2]), the constrained system

$$\begin{aligned}&y'(t)\in\hat{F}(t,y(t))\quad\text{a.e.},\\ &y(t)\in K\quad\forall t\in[t_0,+\infty[,\\ &y(t_0)=(t_0,x_0,W(t_0,x_0))\end{aligned}$$

[1] This theorem states that, if an upper semicontinuous set-valued map F from a closed subset K of $\mathbf{R}^n$ into nonempty convex compact subsets of $\mathbf{R}^n$ has linear growth and satisfies the viability condition

$$\forall y\in K,\quad F(y)\cap T_K(y)\neq\emptyset,$$

then for every $y_0\in K$ there exists a solution of the differential inclusion

$$y'(t)\in F(y(t)),\quad y(0)=y_0,\quad y(t)\in K$$

defined on the whole half line $\mathbf{R}_+$.

has a solution $\bar{y}=(z_0, x, z):[t_0, +\infty[\to \mathbf{R}\times\mathbf{R}^n\times\mathbf{R}$. Then, from definition of K and $\hat{F}$, $z_0(t)=t$, $z(t)=W(t, x(t))$. On the other hand, $z'(t)=0$ almost everywhere in $[t_0, 1]$ and therefore $z\equiv\text{const}$. This ends the proof. □

THEOREM 7.4. *Consider a continuous function* $W:[0,1]\times\mathbf{R}^n\to\mathbf{R}$. *We assume that* f *does not depend on* t *and* (9) *holds true. If* $W(1,\cdot)=g(\cdot)$ *and*

$$\sup_{v\in\overline{\text{co}}\, f(x,U)} \inf D(-W)(t,x)(1,v)\leqq 0$$

(*where* $D(-W)(t,x)(1,v)\subset\mathbf{R}$ *is defined in* (58)), *then for every solution* $y(\cdot)=(t,x,z)(\cdot)$ *of*

$$(59)\qquad \begin{aligned} &t'=1,\\ &x'(t)=f(x(t),u(t)), \qquad u(t)\in U \textit{ is measurable},\\ &z'(t)=0,\\ &(t, x(t), z(t))\in \text{Graph}\,(W) \quad \forall t\in[0,1],\\ &t(0)=0, \quad x(0)=\xi_0, \quad z(0)=W(0,\xi_0), \end{aligned}$$

defined on the time interval $[0,1]$, *the trajectory* $x(\cdot)$ *is optimal for the problem* (7).

Proof. From [17] we deduce that W is nondecreasing along trajectories of (6). On the other hand, if $y(\cdot)=(t,x,z)(\cdot)$ is a solution of (59) defined on the time interval $[0,1]$, then $W(t,x(t))\equiv\text{const}$. □

8. Problem with endpoint constraints. In this section we investigate the case when the additional endpoint constraint is present:

$$x(1)\in K_1,$$

where K_1 is a given closed subset of $\mathbf{R}^n$. The corresponding value function is defined by

$$V(t_0, x_0)=\inf\{g(x(1))\,|\,x \text{ is a solution of (6) on } [t_0, 1], x(t_0)=x_0, x(1)\in K_1\}.$$

We observe that $V(t_0, x_0)=+\infty$ whenever no trajectory starting at x_0 at time t_0 hits K_1 at time one.

In this more general case, the value function may be discontinuous and we have either to develop a verification technique for a larger class of functions (some results in this direction were obtained in [17]) or to try to reduce the problem to a new one, where the data fits the Lipschitz framework. We will follow this second strategy and apply a penalization technique.

We provide only a convergence result showing that the problem with endpoint constraints may be approximated by free endpoint problems. Further developments are left to future work.

We impose assumptions (9) on the functions f and g, and we consider the family of penalized problems. With every $\varepsilon>0$, we associate the minimization problem

$$(\mathrm{P}_\varepsilon)\ \text{minimize}\left\{g(x(1))+\frac{1}{\varepsilon}\,\text{dist}\,(x(1), K_1)^2\,|\,x(\cdot) \text{ is a solution of (6)}, x(0)=\xi_0\right\}.$$

Define functions g_ε from $\mathbf{R}^n$ to $\mathbf{R}$ by

$$\forall x\in\mathbf{R}^n, \quad g_\varepsilon(x)=g(x)+\frac{1}{\varepsilon}\,\text{dist}\,(x, K_1)^2.$$

The value function V_ε corresponding to the problem (P_ε) is defined by (8) with g replaced by g_ε.

Since g_ε is locally Lipschitz, so does V_ε with the Lipschitz constant depending on ε. Hence the results obtained in the previous sections may be applied to V_ε.

Furthermore, if g is semiconcave, then, using Example 1 from § 3, we show that also the functions g_ε are semiconcave. This fact and Theorem 5.1 yield that, under assumptions (47), for every $\varepsilon > 0$ the value function V_ε is semiconcave on $[0, 1] \times \mathbf{R}^n$. Consequently, results concerning regularity of optimal feedback may be applied to penalized problems.

The aim of this section is to prove the convergence of V_ε to V.

THEOREM 8.1. *Assume* (9). *If the sets $f(t, x, U)$ are closed and convex, then for every $(t, x) \in [0, 1] \times \mathbf{R}^n$ the function $\mathbf{R}_+ \ni \varepsilon \to V_\varepsilon(t, x)$ is nonincreasing. Furthermore, for every $\varepsilon > 0$, $V_\varepsilon(t, x) \leqq V(t, x)$ and*

$$\lim_{\varepsilon \to 0+} V_\varepsilon(t, x) = V(t, x).$$

Proof. The first statement follows from the fact that the map $\varepsilon \to g_\varepsilon(x)$ is nonincreasing. The second one follows from the fact that $g(x(1)) = g_\varepsilon(x(1))$ whenever $x(1) \in K_1$.

Now fix $(t, x) \in [0, 1] \times \mathbf{R}^n$ and set $W(t, x) = \lim_{\varepsilon \to 0+} V_\varepsilon(t, x)$. Clearly, $W(t, x) \leqq V(t, x)$. To show the opposite, it is enough to consider the case $W(t, x) < +\infty$. Consider trajectory control pairs $(y^\varepsilon, u^\varepsilon)$ of control system (6) satisfying

$$V_\varepsilon(t, x) = g_\varepsilon(y^\varepsilon(1))$$

(they exist by Theorem 2.1). Then, by the relaxation and the parametrization theorems (see [2]), there exists a sequence $\varepsilon_n \to 0+$ and a trajectory $y(\cdot)$ of (6) defined on $[t, 1]$ such that $y^{\varepsilon_n} \to y$ uniformly on $[t, 1]$. On the other hand,

$$0 \leqq \operatorname{dist}(y^\varepsilon(1), K_1)^2 \leqq \varepsilon(W(t, x) - g(y^\varepsilon(1)))$$

and, therefore, taking the limit in the above inequality, we obtain $y(1) \in K_1$. Furthermore, from the inequality

$$V_\varepsilon(t, x) \geqq g(y^\varepsilon(1)),$$

we deduce that $W(t, x) \geqq g(y(1)) \geqq V(t, x)$. □

COROLLARY 8.2. *Under all assumptions of Theorem* 8.1, *consider a sequence $\varepsilon_n \to 0+$ and let $x^{\varepsilon_n}(\cdot)$ be an optimal solution to the problem* $(\mathrm{P}_{\varepsilon_n})$. *If problem* (P) *has at least one solution, then every cluster point $x(\cdot)$ of $\{x^{\varepsilon_n}(\cdot)\}$ in the metric of uniform convergence is an optimal solution of* (P).

Proof. Indeed, since (P) has a solution, by Theorem 8.1, for all $n > 0$,

$$g(x^{\varepsilon_n}(1)) \leqq g_{\varepsilon_n}(x^{\varepsilon_n}(1)) = V_{\varepsilon_n}(0, \xi_0) \leqq V(0, \xi_0) < +\infty$$

and, taking the limit, we deduce that $V(0, \xi_0) \geqq g(x(1)) \geqq V(0, \xi_0)$ and $x(1) \in K_1$. Thus x is optimal. □

NEW SIZE×CURVATURE CONDITIONS FOR STRICT QUASICONVEXITY OF SETS*

GUY CHAVENT†

Abstract. Given a closed, not necessarily convex set D of a Hilbert space, the problem of the existence of a neighborhood $\mathcal{V}$ on which the projection on D is uniquely defined and Lipschitz continuous is considered, and such that the corresponding minimization problem has no local minima. After having equipped the set D with a family $\mathcal{P}$ of paths playing for D the role the segments play for a convex set, the notion of strict quasiconvexity of $(D, \mathcal{P})$ is defined, which will ensure the existence of such a neighborhood $\mathcal{V}$. Two constructive sufficient conditions for the strict-quasiconvexity of D are given, the R_G-size × curvature condition and the Θ-size × curvature condition, which both amount to checking for the strict positivity of quantities defined by simple formulas in terms of arc length, tangent vectors, and radii of curvature along all paths of $\mathcal{P}$. An application to the study of wellposedness and local minima of a nonlinear least squares problem is given.

1. Introduction.

Let

$$F \text{ a Hilbert space,} \tag{1.1}$$

$$D \subset F \text{ a (not necessarily convex) subset} \tag{1.2}$$

be given. This paper is devoted to the study of the Hilbert projection on D. It is known (cf. [2]) that, when D is closed and bounded, the set of all $z \in F$ that admit a unique projection on D contains a dense countable intersection of open sets, called the Edelstein set, and defined by

$$\begin{aligned} ES = \{z \in F \mid \forall \varepsilon > 0, \exists \eta > 0 \text{ s.t. } X_j \in D, \|X_j - z\| \leqq d(z, D) + \eta, j = 0, 1 \\ \text{implies } \|X_0 - X_1\| \leqq \varepsilon\}. \end{aligned} \tag{1.3}$$

This result is not precise enough for the application to nonlinear least squares problems we have in mind, first because it gives only a generic result, and second because it does not give any insight into possible local minima on D of the "distance to z" function, whose presence or absence is critical when it comes to the actual numerical determination of the projection using an optimization algorithm.

Hence, it would be very useful to find conditions on D that ensure (i) that the Edelstein set contains some neighborhood $\mathcal{V}$ of D, and (ii) that ideally the $y \to d(y, z)$ function has no local minima on D whenever $z \in \mathcal{V}$. Necessary and sufficient conditions for point (i), involving the local curvature of D, have been extensively studied (cf., for example, [1] and [7]), but point (ii) has not received much attention.

The notion of the curvature of a set D is both delicate to define and difficult to apply to nonlinear least squares problems. That is why we will be looking only for *sufficient conditions for* (i) *and* (ii), which make it possible *to work only with the elementary notion of the curvature of a curve*, provided that the set D has been equipped with a collection $\mathcal{P}$ of paths P which will play for D the role of the segments for a convex set. This allows for an easy application to nonlinear least squares problems,

† Centre de la Recherche de Mathématique de la Décision, Université Paris Dauphine, 75775 Paris Cédex 16, France, and Institut National de Recherche en Informatique et en Automatique, BP 105, 78153 Le Chesnay Cédex, France.

where the paths $\mathcal{P}$ can be very naturally defined as the image of the segments of the admissible set by the mapping to be inverted. The notion of quasiconvex sets $(D, \mathcal{P})$ introduced in [6] following this line, together with a constructive sufficient condition (the γ-size × curvature condition) was a first answer to (i) and (ii): closed quasiconvex sets, which possess a neighborhood $\mathcal{V}$ on which the projection exists, is unique, and Lipschitz continuous, fully satisfy point (i), but not completely point (ii), as they do not eliminate local minima, which may exist provided their value is "large enough." Moreover, the γ-size × curvature condition introduced in [6] to recognize them does not seem to be very sharp, as, for example, it is far from recognizing all quasiconvex arcs of circles (cf. Figs. 3.2 and 3.3 below).

In this paper we remedy the above-mentioned weaknesses.

We first introduce the slightly stronger notion of a strictly quasiconvex set, which fully eliminates the possibility of local minima, as soon as the point to be projected is in the associated neighborhood $\mathcal{V}$.

Then we introduce the notion of a global radius of curvature R_G associated to the family of paths $\mathcal{P}$ and show that condition $R_G > 0$ (called the R_G-size × curvature condition) implies strict quasiconvexity of the set. This condition is shown to be sharp (see Figs. 3.2 and 3.3 below) as it recognizes exactly all strictly quasiconvex curves.

Third, we calculate a lower bound to R_G in terms of the usual radius of curvature R, the length Δ, and the deflection Θ associated to the family of paths $\mathcal{P}$; this, of course, leads to another sufficient condition for strict quasiconvexity of the set, called the Θ-size × curvature condition, which is also sharp because it recognizes exactly all strictly quasiconvex curves made up of one arc of a circle and one segment.

All geometrical quantities γ, R_G, R, Δ, and Θ are defined by infimum or supremum, over the collection of paths $\mathcal{P}$, of quantities easily computed on each path from the velocities and accelerations along the path.

Finally, we give an application to a nonlinear least squares problem in the case where the derivative of the nonlinear mapping to be inverted has a uniformly bounded pseudoinverse. A more detailed application to nonlinear least squares problems and their regularized versions can be found in [5].

2. Equipping the set with paths. The first step of our construction consists of choosing in the possibly nonconvex set D a collection $\mathcal{P}$ of paths P that will play for D the role the segments play for a convex set. We summarize here the corresponding definitions and notation, following paragraph 2.1 of [6].

DEFINITION 2.1 (Paths). A mapping $P:[0, L] \to D$ is a path if and only if

(2.1) $\nu \to P(\nu)$ is in $W^{2,\infty}([0, L])$;

(2.2) $\|P'(\nu)\|_F = 1$ for a.e. $\nu \in [0, L]$.

Note that this definition is slightly weaker than the one given in [6], where $\mathcal{C}^2$ regularity of the $\nu \to P(\nu)$ mapping was required. In fact, all results of [6] carry over when this new definition is used. We refer to [6] for a sufficient condition for a mapping to be reparametrizable in such a way that it is a path.

DEFINITION 2.2 (Attributes of a path). Let a path P be given. Then

(2.3) $\nu \in [0, L]$ is the arc-length along P;

(2.4) $\delta(P) \triangleq L$ is the length of P;

(2.5) $v(\nu) \triangleq P'(\nu)$ is the unit tangent vector to P at $P(\nu)$;

(2.6) $a(\nu) \triangleq P''(\nu)$ is the acceleration vector of P at $P(\nu)$;

(2.7) $\rho(\nu) \triangleq \|a(\nu)\|^{-1} \in IR^+ \cup \{+\infty\}$ is the radius of curvature of P at $P(\nu)$.

Because we will use only the parametrization by the arc length in this paper, we denote it simply by ν (note that in [6] the (reduced) arc length was denoted by $\bar{\nu}$, and all corresponding quantities wore bars, as quoted at the beginning of paragraph 3 of [6]; hence, $a(\nu)$ in this paper corresponds to $\bar{a}(\bar{\nu})$ in reference [6], etc.).

DEFINITION 2.3 (Collection of paths). A set of paths $\mathcal{P}$ is a *collection of paths* if and only if

(2.8) $\mathcal{P}$ *is made up of paths*;

(2.9) $\mathcal{P}$ *is complete*, i.e., $\forall X, Y \in D, X \neq Y, \exists P \in \mathcal{P}$, such that $P(0) = X$, $P(\delta(P)) = Y$;

(2.10) $\mathcal{P}$ is stable with respect to restriction, i.e., $\forall P \in \mathcal{P}, \forall \nu', \nu'' \in [0, \delta(P)], \nu' < \nu''$, the path $\tilde{P}: \nu \in [0, \nu'' - \nu'] \rightarrow P(\nu' + \nu)$ belongs to $\mathcal{P}$.

The set of paths $\mathcal{P}$ should contain the minimum number of paths that allow (2.9) to be satisfied (typically, one and only one path of $\mathcal{P}$ connects two given distinct points X and Y of D, but we do not put uniqueness in the requirements for a collection of paths because we do not exclude the possibility of choosing for $\mathcal{P}$ the minimum length paths between any two points of D, which may not be unique).

Note that hypothesis (2.1) implies that a path has a bounded curvature (by $\|a\|_\infty$), i.e., a strictly positive smallest radius of curvature. Hence we will be able to find paths $\mathcal{P}$ satisfying both Definitions 2.1 and 2.3 only if the set D itself is regular enough—intuitively if it also has a "bounded curvature."

DEFINITION 2.4 (Maximal paths). A subset $\mathcal{P}_M$ of $\mathcal{P}$ is said to be a collection of maximal paths for $\mathcal{P}$ if and only if

$$\mathcal{P} = \bigcup_{P \in \mathcal{P}_M} \{P' \mid P' \text{ is a subpath of } P\}. \tag{2.11}$$

Of course, such a $\mathcal{P}_M$ always exists because $\mathcal{P}_M = \mathcal{P}$ satisfies (2.11) by virtue of (2.10)! However, a more interesting case will be found when there exists a smallest collection of maximal paths: this will be the case in most of the applications to nonlinear least squares (see [6] and [5]), where $\mathcal{P}$ is the image, by a mapping φ, of the segments of a closed convex set C, so that $\mathcal{P}_M = \{\varphi([x, y]), x, y, \in \partial C\}$ obviously satisfies (2.11).

In the following, we will suppose that a collection of maximal paths $\mathcal{P}_M$ has been chosen.

3. Quasiconvex and strictly quasiconvex sets. Let the set D be equipped with a collection of paths $\mathcal{P}$. To a given point $z \in F$, a path $P \in \mathcal{P}$, and an arc length value $\nu \in [0, \delta(P)]$, we associate the number

$$k(z, P; \nu) = \langle z - P(\nu), a(\nu) \rangle_F \tag{3.1}$$

whose geometrical interpretation is given by (with the notation of Fig. 3.1)

$$k(z, P; \nu) = \frac{d(\nu)}{\rho(\nu)} \cos\theta = \frac{\overline{MH}}{\overline{MC}}. \tag{3.2}$$

We may then associate to z and P the number

$$k(z, P) = \operatorname*{sup\,ess}_{\nu \in [0, \delta(P)]} k(z, P; \nu) \tag{3.3}$$

and to z and $\eta > 0$ the number

$$k(z, \eta) = \sup_{P \in \mathcal{P}(z, \eta)} k(z, P), \tag{3.4}$$

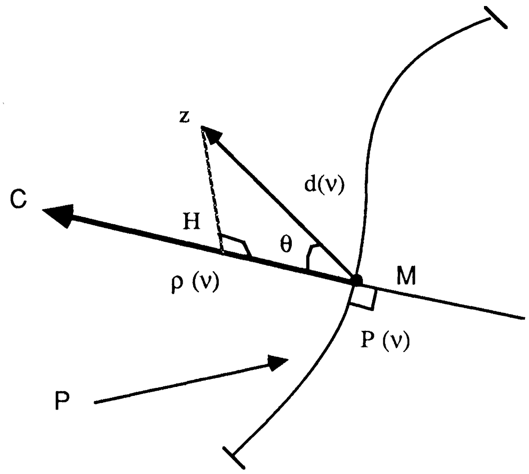

FIG. 3.1. *Notation for the geometrical interpretation of $k(z, P; \nu) = \langle z - P(\nu), a(\nu)\rangle_F$: C is the center of curvature of P at $P(\nu)$, and H is the orthogonal projection of z on the one-dimensional affine variety parallel to $a(\nu)$ and passing through $M = P(\nu)$.*

where the subcollection of paths $\mathcal{P}(z, \eta)$ is defined by

$$\mathcal{P}(z, \eta) = \{P \in \mathcal{P} \mid \|P(j) - z\|_F \leqq d(z, D) + \eta, j = 0, \delta(P)\}. \tag{3.5}$$

It will be convenient to define $k(z, 0)$ as the limit, when $\eta \to Ot$, of $k(z, 0)$.

We can now give the following definition.

DEFINITION 3.1 (Quasiconvexity of sets). A set $(D, \mathcal{P})$ is said to be *quasiconvex* if and only if

(i) $\mathcal{P}$ is a collection of paths;

(ii) There exists a neighborhood $\mathcal{V}$ of D in F, and a lower semicontinuous (l.s.c) function $\varepsilon : \mathcal{V} \to]0, +\infty]$ such that

$$\left.\begin{cases} z \in \mathcal{V} \\ 0 < \eta < \varepsilon(z) \end{cases}\right\} \Rightarrow k(z, \eta) < 1. \tag{3.6}$$

This is a slightly upgraded version of the definition of quasiconvexity given in [6] (where the $z \to \varepsilon(z)$ function was required to be continuous). All the results in [6] carry over when quasiconvexity is defined using Definition 3.1, and this upgraded definition allows us to prove the following proposition.

PROPOSITION 3.2. *Let $(D, \mathcal{P})$ be quasiconvex. Then there exists a largest open neighborhood $\mathcal{V}$ of D, and a largest l.s.c. function $\varepsilon : \mathcal{V} \to]0, +\infty[$ satisfying the definition of quasiconvexity.*

Proof. Let us denote by $\mathcal{V}_i$, ε_i, $i \in I$, all open neighborhoods and l.s.c. functions satisfying Definition 3.1. Then

$$\mathcal{V} = \bigcup_{i \in I} \mathcal{V}_i \tag{3.7}$$

is an open subset of F. If we denote by $\tilde{\varepsilon}_i$ the extension of ε_i to $\mathcal{V}$ by zero outside of $\mathcal{V}_i$, then $\tilde{\varepsilon}_i$ is l.s.c. as ε_i is l.s.c. on $\mathcal{V}_i$ and $\mathcal{V}_i$ is open. Define then

$$\varepsilon(z) = \sup_{i \in I} \tilde{\varepsilon}_i(z) \quad \forall z \in \forall, \tag{3.8}$$

which is l.s.c. as supremum of a family of l.s.c. functions. Hence $\mathcal{V}$, ε will satisfy the definition of quasiconvexity as soon as they satisfy (3.6), which we prove now. Let

$z \in \mathcal{V}$ and $0 < \eta < \varepsilon(z)$ be given, and set

$$\alpha = (\varepsilon(z) - \eta)/2 > 0.$$

From definition (3.8) of $\varepsilon(z)$, there exists $i_0 \in I$ such that

$$\tilde{\varepsilon}_{i0}(z) \geqq \varepsilon(z) - \alpha > \eta > 0.$$

This proves, as $\tilde{\varepsilon}_{i0}(z) > 0$, that $z \in \mathcal{V}_{i0}$. Hence $\mathcal{V}_{i0}$ and ε_{i0} satisfy the hypothesis of (3.6), so that

$$k(z, \eta) < 1,$$

which proves that $\mathcal{V}$ and $\varepsilon(z)$ satisfy (3.6). □

PROPOSITION 3.3. *Let $(D, \mathcal{P})$ be quasiconvex. Then the associated neighborhood $\mathcal{V}$ is included in the Edelstein set* (1.3), *and for any $z \in \mathcal{V}$, $0 < \eta < \varepsilon(z)$, and $P \in \mathcal{P}(z, \eta)$,*

(i) $\nu \to f(\nu) \triangleq \|P(\nu) - z\|_F^2$ *is strictly convex;*

(ii) $\nu \to d(\nu) \triangleq \|P(\nu) - z\|_F$ *is strictly quasiconvex.*

Proof. For $z \in \mathcal{V}$ and $P \in \mathcal{P}(z, \eta)$ we have

$$f''(\nu) \geqq 2(1 - k(z, \eta)) > 0 \quad \text{a.e.,}$$

which proves (i) and (ii), and also shows that the $\nu \to f(\nu) + \nu(\delta(P) - \nu)(1 - k(z, \eta))$ function is convex. Hence

$$f\left(\frac{\delta(P)}{2}\right) + \frac{\delta(P)^2}{4}(1 - k(z, \eta)) \leqq \frac{1}{2} f(0) + \frac{1}{2} f(\delta(P)).$$

However,

$$f\left(\frac{\delta(P)}{2}\right) \geqq d(z, D)^2, \qquad f(j) \leqq (d(z, D) + \eta)^2 \quad j = 0, \delta(P)$$

so that

$$\delta(P)^2 \leqq 4(1 - k(z, \eta))^{-1} \eta (2d(z, D) + \eta).$$

Let $X_j \in D$, $j = 0, 1$, be two η-projections of z on D:

$$\|X_j - z\| \leqq d(z, D) + \eta.$$

If we choose for P the path connecting X_1 and X_2, we see that $P \in \mathcal{P}(z, \eta)$; hence,

$$\|X_0 - X_1\|_F \leqq \delta(P) \leqq 2(1 - k(z, \eta))^{-1/2} \eta^{1/2} (2d(z, D) + \eta)^{1/2} \to 0 \text{ when } \eta \to 0,$$

which proves that z belongs to the Edelstein set. □

Proposition 3.3(ii) implies that the distance of any point z of $\mathcal{V}$ to any path of $\mathcal{P}$ having its extremities "not too far" from z is strictly quasiconvex.

Using the properties of the Edelstein set or the more precise results of [6], we can prove that, when $(D, \mathcal{P})$ is quasiconvex, the projection from $\mathcal{V}$ onto D is unique and Lipschitz continuous, and exists when D is closed. However, the "distance to z" function may still have, when $z \in \mathcal{V}$, parasitic local minima distinct from the global minimum. Of course, Proposition 3.3(ii) implies that these local minima are rejected at a distance of D larger than $d(z, D) + \varepsilon(z)$, but they may still exist and hence can be a source of trouble when we attempt to actually compute the projection using a gradient optimization algorithm.

We now introduce a new, stronger definition that will keep all the above-mentioned nice properties of quasiconvex sets with respect to projection, but will be much better behaved with respect to the problem of local minima.

DEFINITION 3.4 (Strict quasiconvexity of sets). A set $(D, \mathcal{P})$ is said to be *strictly quasiconvex* if and only if

(i) $(D, \mathcal{P})$ is quasiconvex for some neighborhood $\mathcal{V}$ and function $z \rightarrow \varepsilon(z)$;

(ii) $\mathcal{V}$ and ε satisfy, moreover,

$$\begin{array}{ll} z \in \mathcal{V} & \text{the "distance to } z\text{"} \\ P \in \mathcal{P} & \Rightarrow \text{function is strictly} \\ d(z, P) < d(z, D) + \varepsilon(z) & \text{quasiconvex along the path } P. \end{array} \tag{3.9}$$

The additional hypothesis (3.19) means (compare with Proposition 3.3(ii)) that the distance of any point z of $\mathcal{V}$ to any path of $\mathcal{P}$ that is "not too far" from z is strictly quasiconvex. We easily check that Proposition 3.2 extends to strictly quasiconvex sets.

PROPOSITION 3.5. *Let $(D, \mathcal{P})$ be strictly quasiconvex. Then there exists a largest open neighborhood $\mathcal{V}$ of D, and a largest l.s.c. function $\varepsilon : \mathcal{V} \rightarrow]0, +\infty]$ satisfying the definition of strict quasiconvexity.*

Of course, any neighborhood $\mathcal{V}$ associated by Definition 3.4 to a strictly quasiconvex set $(D, \mathcal{P})$ is included in the Edelstein set (1.3) by virtue of Proposition 3.3.

The following theorem summarizes the properties of strictly quasiconvex sets.

THEOREM 3.6 (Projection on strictly quasiconvex sets). *Suppose that*

$$(D, \mathcal{P}) \textit{ is strictly quasiconvex,} \tag{3.10}$$

and let $\mathcal{V}$, $\varepsilon(z)$ be the associated neighborhood and l.s.c. function.
Then

(i) *Uniqueness. For any $z \in \mathcal{V}$, there exists at most one projection $\hat{X}$ of z on D.*

(ii) *Local minima. If $z \in \mathcal{V}$ admits a (necessarily unique) projection $\hat{X}$ on D, the "distance to z" function has no parasitic local minimum on D distinct from $\hat{X}$.*

(iii) *Continuity. If $z_0, z_1 \in \mathcal{V}$ admit projections $\hat{X}_0, \hat{X}_1$ on D, and are close enough so that there exists $d \geqq 0$ satisfying*

$$\|z_0 - z_1\|_F + \max_{j=0,1} d(z_j, D) \leqq d < \min_{j=0,1} \{d(z_j, D) + \varepsilon(z_j)\}; \tag{3.11}$$

then, for any path P going from $\hat{X}_0$ to $\hat{X}_1$ we have

$$\|\hat{X}_0 - \hat{X}_1\| \leqq \delta(P) \leqq (1-k)^{-1} \|z_0 - z_1\|_F, \tag{3.12}$$

where $k < 1$ is defined by

$$\begin{aligned} &k = (k(z_0, \eta_0) + k(z_1, \eta_1))/2 \\ &0 < \eta_j = d - d(z_j, D) < \varepsilon(z_j), \qquad j = 0, 1. \end{aligned} \tag{3.13}$$

(iv) *Existence. If we suppose moreover that*

$$D \textit{ is closed in } F, \tag{3.14}$$

then any $z \in \mathcal{V}$ has a (unique) projection $\hat{X}$ on D, and any minimizing sequence X_n satisfies

$$\|X_n - \hat{X}\|_F \rightarrow 0 \tag{3.15}$$

and

$$\delta(P_n) \rightarrow 0 \textit{ where } P_n \textit{ is any path of } \mathcal{P} \textit{ going from } X_n \textit{ to } \hat{X}. \tag{3.16}$$

Proof. Properties (i), (iii), and (iv) result from the fact that strictly quasiconvex sets are quasiconvex sets, for which they have been proved to hold in [6]. Hence we are left with the proof of property (ii) on local minima. Let $X_0 \in D$ be one global minimum of the "distance to z" function, and suppose that this function admits a local minimum at $X_1 \neq X_0$. By definition of X_0 we have

$$\|z - X_0\| = d(z, D). \tag{3.17}$$

Then let $P \in \mathcal{P}$ connect X_0 to X_1. From (3.17) we obtain

$$d(z, P) = \|z - X_0\| = d(z, D) < d(z, D) + \varepsilon(z). \tag{3.18}$$

Then using property (3.9) of strictly quasiconvex sets we find that the "distance to z" function is strictly quasiconvex along the path P, which is impossible because this function has a global minimum at $\nu = 0$ and a local minimum at $\nu = \delta(P)$! □

We illustrate the notions of quasiconvex and strictly quasiconvex sets by considering the very simple case of a set D consisting in an arc of a circle of radius R and of length L. Simple geometric considerations show that

$$D \text{ is quasiconvex iff } \frac{L}{R} < 2\pi; \tag{3.19}$$

$$D \text{ is strictly quasiconvex iff } \frac{L}{R} < \pi. \tag{3.20}$$

We have illustrated in Fig. 3.2 for both cases the largest corresponding open neighborhood $\mathcal{V}$ whose existence is asserted by Propositions 3.2 and 3.5.

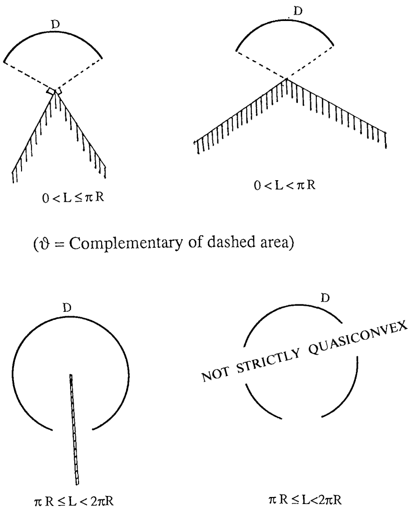

FIG. 3.2. *Largest open neighborhood $\mathcal{V}$ for quasiconvex ($L < 2\pi R$, left) and strictly quasiconvex ($L < \pi R$, right) arcs of circle.*

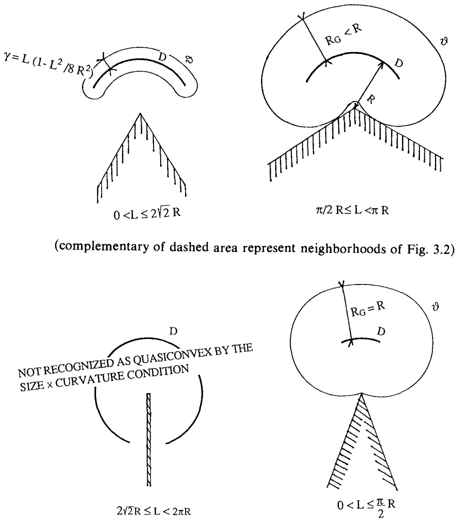
The first remark is that these neighborhoods are quite large; in particular, they are "infinite" on the "convex side" of the arc of the circle, and admit the center of the circle in their closure on the "concave side" of the arc of the circle.

However, if the quasiconvex neighborhood (Fig. 3.2, left) catches all points admitting a unique projection on D when $\pi R \leqq L < 2\pi R$, it misses many such points when $0 < L < \pi R$ (namely, all the points of the dashed area that are not on the axis of symmetry of the figure), whereas the strictly quasiconvex neighborhood (Fig. 3.2, right) does a much better job, as it catches in all cases exactly all points z admitting a unique projection on D with no local minima on D of the distance to z.

However, if it is simple to figure out the shape of these neighborhoods for sets D as simple as an arc of a circle, it becomes practically impossible for more complicated sets. Hence we need constructive sufficient conditions to recognize quasiconvexity and strict quasiconvexity, which will give us smaller cylindrical neighborhoods.

A first sufficient condition for quasiconvexity of sets was given in [6]: it associated, in a constructive way, a number γ to $(D, \mathscr{P})$, whose positiveness implied quasiconvexity of $(D, \mathscr{P})$ for a cylindrical neighborhood of D of size γ. This condition was not very precise: when applied to an arc of a circle, it read $L/R < 2\sqrt{2}$, and hence was far from recognizing all quasiconvex arcs of circles $(L/R < 2\pi)$, and the size γ of the corresponding cylindrical neighborhood was very small (see Fig. 3.3, left). We refer to this condition as the γ-size × curvature condition.



(complementary of dashed area represent neighborhoods of Fig. 3.2)

FIG. 3.3. *Cylindrical neighborhoods $\mathscr{V}$ given by the γ-size × curvature condition $(L < 2\sqrt{2}\, R$, left) and by the R_G-size × curvature condition $(L < \pi$, right).*

We turn now to the formulation of new sufficient conditions for strict quasiconvexity of sets, which will turn out to be much more precise that the γ-size × curvature condition: for arcs of circle they will give more (*strict* quasiconvexity) for less $(L/R < \pi$ instead of $L/R < 2\sqrt{2})$ together with a larger neighborhood! A preview of these results can be seen in Fig. 3.3, right.

4. The R_G-size × curvature condition: A new sufficient condition for strict quasiconvexity of sets.

We first introduce some new concepts associated with paths.

DEFINITION 4.1 (Affine normal subspace). Let a path P be given. Then, for any $\nu, \nu' \in [0, \delta(P)]$, $\nu \neq \nu'$, we define the *affine normal subspace* $N(\nu, \nu')$ to P at ν seen from ν' by

$$N(\nu, \nu') = \{z \in F \mid \langle z - P(\nu), \lambda v(\nu)\rangle_F \leqq 0 \quad \forall \lambda \in \mathbb{R}, \\ \nu + \lambda \in [\min(\nu, \nu'), \max(\nu, \nu')]\}. \tag{4.1}$$

This affine normal subspace is the dashed area passing through $P(\nu)$ on Fig. 4.1.

PROPOSITION 4.2. *Let a path P be given. Then, for any $\nu, \nu' \in [0, \delta(P)]$, $\nu \neq \nu'$, we have*

$$P(\nu) + a(\nu) \in N(\nu, \nu').$$

FIG. 4.1. *Examples of global radii of curvature for a path P.*

DEFINITION 4.3 (Global radius of curvature). Let a path P be given. Then, for any $\nu, \nu' \in [0, \delta(P)]$, $\nu \neq \nu'$, we define the global radius of curvature of P at ν seen from ν' by

$$\rho_G(\nu, \nu') = d(P(\nu), N(\nu, \nu') \cap N(\nu', \nu)) \in [0, +\infty] \tag{4.2}$$

with the natural convention that $\rho_G(\nu, \nu') = +\infty$ if $N(\nu, \nu') \cap N(\nu', \nu) = \emptyset$.

Note that $\rho_G(\nu, \nu') \neq \rho_G(\nu', \nu)$ in general. This global radius of curvature can be easily calculated.

PROPOSITION 4.4. *Let the path $P \in \mathcal{P}$ and $\nu, \nu' \in [0, \delta(P)]$, $\nu \neq \nu'$, be given, and denote*

$$\begin{aligned} X &= P(\nu), \qquad X' = P(\nu'), \\ v &= v(\nu), \qquad v' = v(\nu'), \\ N &= \operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle, \\ D &= \sqrt{1 - \langle v, v'\rangle^2}. \end{aligned} \tag{4.3}$$

Then $\rho_G(\nu, \nu')$ is given by

$$\rho_G(\nu, \nu') = \begin{cases} 0 & \text{if } N \leqq 0, \\ N & \text{if } N > 0 \quad \text{and} \quad \langle v, v'\rangle \leqq 0, \\ N/D & \text{if } N > 0 \quad \text{and} \quad \langle v, v'\rangle \geqq 0. \end{cases} \tag{4.4}$$

The proof of this formula is elementary, the basic ingredient being the projection of a point on a hyperplane. We have illustrated in Fig. 4.1 a few situations for the case of plane curves.

The relation with the usual (local) radius of curvature $\rho(\nu)$ is given by the following proposition.

PROPOSITION 4.5. *Let a path P be given. Then, for any $\nu \in [0, \delta(P)]$, there exists an open neighborhood $I(\nu)$ of ν in $[0, \delta(P)]$ such that, for any $\nu' \in I(\nu)$:*

$$\rho_G(\nu, \nu') = \frac{\operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle}{\sqrt{1 - \langle v, v'\rangle^2}}, \tag{4.5}$$

$$\rho_G(\nu', \nu) = \frac{\operatorname{sgn}(\nu' - \nu)\langle X' - X, v\rangle}{\sqrt{1 - \langle v, v'\rangle^2}} \tag{4.6}$$

and, for almost every $\nu \in [0, \delta(P)]$ *we have*

$$\rho_G(\nu, \nu') \to \rho(\nu), \tag{4.7}$$

$$\rho_G(\nu', \nu) \to \rho(\nu), \tag{4.8}$$

when $\nu' \to \nu$ *in* $I(\nu)$.

Proof. For any $v, \nu' \in [0, \delta(P)]$ we can always write

$$\operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle = |d\nu|\langle v_\theta, v'\rangle, \tag{4.9}$$

where

$$d\nu = \nu' - \nu, \qquad v_\theta = v(\nu + \theta d v) \quad 0 \leqq \theta \leqq 1.$$

Hence, given any $\nu \in [0, \delta(P)]$, we see that

$$\begin{matrix} \langle v, v'\rangle \to 1 \\ \langle v_\theta, v'\rangle \to 1 \end{matrix} \quad \text{when } d\nu \to 0, \tag{4.10}$$

which proves, in light of (4.4), that $\rho_G(\nu, \nu')$ is given by (4.5) when $d\nu$ is small enough. We could just as well have proved that $\rho_G(\nu', \nu)$ is given by (4.6) when $d\nu$ is small enough, which ends the proof of the existence of the interval $I(\nu)$ on which (4.5), (4.6) hold.

We now turn to the proof of (4.7). Let ν be a Lebesgue point for $a(\nu)$, $I(\nu)$ the corresponding interval, and $\nu' \in I(\nu)$, $\nu' \neq \nu$. Let us first transform the denominator of (4.5) then using the theorem of the median for v and v':

$$\langle v, v'\rangle = 1 - \frac{\delta^2}{2},$$

where

$$\delta = \|v' - v\|. \tag{4.11}$$

Hence the denominator of $\rho_G(\nu, \nu')$ may be rewritten as

$$\sqrt{1 - \langle v, v'\rangle^2} = \delta\left(1 - \frac{\delta^2}{4}\right)^{1/2} \tag{4.12}$$

and, using (4.9) for the numerator of ρ_G we obtain

$$\rho_G(\nu, \nu') = \frac{|d\nu|\langle v_\theta, v'\rangle}{\delta(1 - (\delta^2/4))^{1/2}}, \tag{4.13}$$

which, as $\langle v_\theta, v'\rangle \to 1$ and $\delta \to 0$, will prove (4.7) once we have found the limit of $\delta/|d\nu|$. But we have

$$\begin{aligned} \left|\frac{\delta}{|d\nu|} - \|a(\nu)\|\right| &= \left|\frac{1}{|d\nu|}\left\|\int_0^{d\nu} a(\nu + \varepsilon)\, d\varepsilon\right\| - \|a(\nu)\|\right| \\ &\leqq \frac{1}{|d\nu|}\left\|\int_0^{d\nu} [a(\nu + \varepsilon) - a(\nu)]\, d\varepsilon\right\| \\ &\leqq \frac{1}{|d\nu|}\int_0^{d\nu} \|a(\nu + \varepsilon) - a(\nu)\|\, d\varepsilon, \end{aligned}$$

which, by definition of the Lebesgue points, tends to zero when $d\nu \to 0$ (see, for example, Theorem 8.8 of [8]). Hence

$$\frac{\delta}{|d\nu|} \to \|a(\nu)\|, \quad \text{when } d\nu \to 0. \tag{4.14}$$

This shows that (4.7) holds at all Lebesgue points of $[0, \delta(P)]$. Because almost every point of $[0, \delta(P)]$ is a Lebesgue point, we have proved (4.7).

Then (4.8) follows immediately because

$$\rho_G(\nu, \nu') - \beta(d\nu) \leqq \rho_G(\nu', \nu) \leqq \rho_G(\nu, \nu') + \beta(d\nu), \tag{4.15}$$

with

$$\beta(d\nu) = \frac{|\langle X' - X, v - v' \rangle|}{\sqrt{1 - \langle v, v' \rangle^2}} = \frac{|d\nu| |\langle v_{\theta'}, v - v' \rangle|}{\sqrt{1 - \langle v, v' \rangle^2}},$$

where $0 < \theta' < 1$. Using (4.11) and (4.12) we obtain

$$\beta(d\nu) \leqq \frac{|d\nu|}{(1 + (\delta^2/4))^{1/2}} \to 0, \quad \text{when } d\nu \to 0. \tag{4.16}$$

This ends the proof of Proposition 4.5.

We are now naturally led to the following definition.

Definition 4.6 (Smallest global radii of curvature of a path). Let a path P be given. Then we define

$$\begin{aligned} R(P) &= \inf_{\nu \in [0, \delta(P)]} \rho(\nu) && \text{(smallest radius of curvature of } P\text{)}, \\ R_G(P) &= \inf_{\nu, \nu' \in [0, \delta(P)]} \rho_G(\nu, \nu') && \text{(smallest global radius of curvature of } P\text{)}. \end{aligned} \tag{4.17}$$

Of course, $R_G(P)$ is easily related to $R(P)$ using Proposition 4.5.

Proposition 4.7. *Let a path P be given. Then*

$$0 \leqq R_G(P) \leqq R(P) \leqq +\infty. \tag{4.18}$$

Remark 4.8. Unlike the number $\gamma(P)$ used in the size × curvature condition developed in [4] and [6] and recalled at the end of § 3, the number $R_G(P)$ depends only on the shape of the path P, and in no way on its parametrization (that is why in this paper we use only the parametrization by arc length, which is the most convenient for the formulas).

The significance of the smallest global radius of curvature comes from the following proposition.

Proposition 4.9. *Let a path $P \in \mathcal{P}$ and $z \in F$ be given. If*

$$R_G(P) > 0, \qquad d(z, P) < R_G(P),$$

then the $\nu \to d(\nu) = \|P(\nu) - z\|_F$ function is strictly quasiconvex.

Proof. Let $f(\nu) = d(\nu)^2$, and $\nu_0 \in [0, \delta(P)]$ be the value for which d and f attain their minimum on $[0, \delta(P)]$:

$$f(\nu_0) \leqq f(\nu), \quad \forall \nu \in [0, \delta(P)],$$

which implies

$$f'(\nu_0)\lambda \geqq 0, \quad \forall \lambda \in \mathbb{R}, \qquad \nu_0 + \lambda \in [0, \delta(P)];$$

i.e.,

$$\langle z-P(\nu_0), \lambda v(\nu_0)\rangle \leqq 0, \quad \forall \lambda \in \mathbb{R}, \qquad \nu_0+\lambda \in [0, \delta(P)],$$

which shows that

$$z \in N(\nu_0, \nu') \quad \text{for any } \nu' \in [0, \delta(P)], \nu' \neq \nu_0.$$

Suppose now that $\nu \to d(\nu)$ is not strictly quasiconvex. Then necessarily $d(\nu)$ has at least one local maximum for some value ν_1 in the *open interval* $]0, \delta(P)[$. Of course, $\nu \to f(\nu)$ also has a local maximum at the same $\nu_1 \in]0, \delta(P)[$, which implies that $f'(\nu_1)=0$; i.e.,

$$\langle z-P(\nu_1), v(\nu_1)\rangle = 0.$$

However, the preceding equation may be rewritten as

$$z \in N(\nu_1, \nu') \quad \text{for any } \nu' \in [0, \delta(P)], \nu' \neq \nu_1.$$

Hence we see that $z \in N(\nu_0, \nu_1) \cap N(\nu_1, \nu_0)$, which shows that

$$\rho_G(\nu_0, \nu_1) \leqq \|P(\nu_0)-z\|_F = d(z, P),$$

and, using definition (4.17):

$$R_G(P) \leqq \rho_G(\nu_0, \nu_1) \leqq d(z, P),$$

which contradicts the hypothesis $d(z, P) < R_G(P)$. This proves the strict quasiconvexity of d. □

DEFINITION 4.10 (Smallest radii of curvature of a set). We associate to a set $(D, \mathcal{P})$

$$\text{(4.19)} \qquad \begin{aligned} R(D) &= \inf_{P \in \mathcal{P}_M} R(P) && \text{(smallest radius of curvature in } D), \\ R_G(D) &= \inf_{P \in \mathcal{P}_M} R_G(P) && \text{(smallest global radius of curvature in } D), \end{aligned}$$

which, using (4.18), satisfy

$$\text{(4.20)} \qquad 0 \leqq R_G(D) \leqq R(D) \leqq +\infty.$$

This allows us to define a new "size × curvature" condition for the set D.

DEFINITION 4.11 (R_G-size × curvature condition). The set $(D, \mathcal{P})$ is said to satisfy a R_G-size × curvature condition if and only if

$$\text{(4.21)} \qquad R_G(D) > 0.$$

We give now our first main result.

THEOREM 4.12. *Let $(D, \mathcal{P})$ be given. If*

$$\text{(4.22)} \qquad R_G(D) > 0 \quad (R_G\textit{-size} \times \textit{curvature condition}),$$

then D is strictly quasiconvex, with a cylindrical neighborhood $\mathcal{V}$ given by

$$\text{(4.23)} \qquad \mathcal{V} = \{z \in F \mid d(z, D) < R_G(D)\},$$

and an $\varepsilon(z)$ function defined, for any $z \in \mathcal{V}$, by

$$\text{(4.24)} \qquad \varepsilon(z) = R_G(D) - d(z, D) > 0.$$

Hence Theorem 3.6 (on the properties of the projection) applies, the Lipschitz constant being given by (compare with (3.11)-(3.13))

$$\text{(4.25)} \qquad \|\hat{X}_0 - \hat{X}_1\|_F \leqq \delta(P) \leqq \left(1 - \frac{d}{R(D)}\right)^{-1} \|z_0 - z_1\|_F$$

as soon as z_0, z_1 are close enough so that there exists d satisfying

$$\|z_0 - z_1\|_F + \max_{j=0,1} d(z_j, D) \leqq d < R_G(D). \tag{4.26}$$

Proof. We check first that $\mathcal{V}$ and ε defined by (4.23) and (4.24) satisfy Definition 3.1 of quasiconvex sets. Let z, η, and P be given such that

$$d(z, D) < R_G(D) \quad (\text{i.e., } z \in \mathcal{V}), \tag{4.27}$$

$$0 < \eta < \varepsilon(z) = R_G(D) - d(z, D), \tag{4.28}$$

$$\|P(j) - z\| \leqq d(z, D) + \eta \qquad j = 0, \delta(P). \tag{4.29}$$

Hence $\|P(j) - z\| < R_G(D)$, $j = 0, \delta(P)$ which implies that $d(z, P) < R_G(D) \leqq R_G(P)$. Then by Proposition 4.9 we see that the $\nu \to d(\nu) = \|P(\nu) - z\|_F$ is strictly quasiconvex, and hence, using (4.29),

$$d(\nu) \leqq \max_{j=0,\delta(P)} \|P(j) - z\| \leqq d(z, D) + \eta, \quad \forall \nu \in [0, \delta(P)].$$

However, from definitions (4.6) and (4.10) we see that

$$\rho(\nu) \geqq R(P) \geqq R(D) \quad \text{for a.e. } \nu \text{ in } [0, \delta(P)].$$

Plugging the two last bounds into (3.2) yields

$$k(z, P; \nu) \leqq \frac{d(z, D) + \eta}{R(D)} \quad \text{for a.e. } \nu \text{ in } [0, \delta(P)],$$

which, as this bound is independent of the path P provided it belongs to $\mathcal{P}(z, \eta)$, proves that (cf. (3.4))

$$k(z, \eta) \leqq \frac{d(z, D) + \eta}{R(D)} < 1, \tag{4.30}$$

which shows that D is quasiconvex. The strict quasiconvexity of D results then directly from Proposition 4.9, and the formulas (4.25) and (4.26) follow immediately from (3.11)-(3.12) and (4.30). □

To illustrate this new sufficient condition, we check how well it recognizes strictly quasiconvex arcs of circles of radius R and length L. A simple calculation yields

$$R_G(D) = \begin{cases} R & 0 < \dfrac{L}{R} < \dfrac{\pi}{2}, \\ R \sin \dfrac{L}{R} & \dfrac{\pi}{2} \leqq \dfrac{L}{R} \leqq \pi, \\ 0 & \pi \leqq \dfrac{L}{R} < 2\pi, \end{cases} \tag{4.31}$$

which is strictly positive as long as

$$0 < \frac{L}{R} < \pi, \tag{4.32}$$

(compare with (3.20)).

Hence the *R_G-size × curvature condition recognizes exactly all strictly quasiconvex arcs of circles*! We have illustrated in Fig. 3.3, right, the neighborhoods $\mathcal{V}$ generated by (4.31), which turn out to be the *largest cylindrical neighborhoods* included in the *largest strictly quasiconvex neighborhood* (depicted as the complement of the dashed area). As mentioned at the end of § 3, comparison with the left part of Fig. 3.3 shows that the R_G-size×curvature condition is much more precise than the old γ-size× curvature condition.

In the general case, the R_G-size×curvature condition cannot be expected to be optimal (i.e., necessary for strict quasiconvexity), as nothing prevents equipping a convex set with paths $\mathcal{P}$ having small radii of curvature! However, it is reasonable to conjecture that the R_G-size×curvature condition becomes necessary in the case where the collection of paths $\mathcal{P}$ is made of minimum length paths of D. This matter will be discussed in a forthcoming paper.

5. Obtaining lower bounds on the global radius of curvature. Given a path $P \in \mathcal{P}$, we will try in this section to obtain lower bounds on its global radius of curvature $R_G(P)$.

In particular, we would like to substantiate the intuitive feeling that "arcs of circles are the worst paths," i.e., that for any path P we should have $R_G(P) = R(P)$ as soon as $\delta(P) \leqq (\pi/2)R(P)$ and $R_G(P) > 0$ as soon as $\delta(P) < \pi R(P)$, as suggested by Fig. 3.3 (right) for the case of an arc of a circle. To do that, we need to recall one (very natural) attribute of the paths.

DEFINITION 5.1 (Deflection). Given a path $P \in \mathcal{P}$, and $\nu, \nu' \in [0, \delta(P)]$, the *deflection of P between ν and ν' is*

$$\theta(\nu, \nu') = \operatorname{Arg}\cos\langle v(\nu), v(\nu')\rangle, \tag{5.1}$$

and the *largest deflection of P* is

$$\Theta(P) = \max \theta(\nu, \nu') \qquad \nu, \nu' \in [0, \delta(P)]. \tag{5.2}$$

Of course, $\theta(\nu, \nu')$ satisfies

$$\begin{aligned} &\theta(\nu, \nu') \in [0, \pi] && \forall \nu, \nu' \in [0, \delta(P)],\\ &\theta(\nu, \nu) = 0 && \forall \nu \in [0, \delta(P)],\\ &\theta(\nu, \nu') = \theta(\nu', \nu) && \forall \nu, \nu' \in [0, \delta(P)]. \end{aligned} \tag{5.3}$$

Given $\nu, \nu' \in [0, \delta(P)]$ and any function $g: [\nu, \nu'] \to \mathbb{R}$ we denote by $\operatorname{var} g$ the total variation (when it exists!) of g over the $[\nu, \nu']$ interval defined by

$$\operatorname{var} g = \sup_{\substack{N \in \mathbb{N} \\ \min(\nu,\nu') \leqq t_0 \leqq t_1 \cdots \leqq t_N = \max(\nu,\nu')}} \sum_{i=1}^{N} |g(t_i) - g(t_{i-1})|. \tag{5.4}$$

The regularity of the deflection function and its relation with the radius of curvature are given by the following lemma.

LEMMA 5.2. *Let $P \in \mathcal{P}$ be given. Then for any $\nu' \in [0, \delta(P)]$, the $\nu \to \theta(\nu, \nu')$ deflection function is absolutely continuous and has a bounded variation over* $[0, \delta(P)]$. *Hence $\partial\theta/\partial\nu(\nu, \nu')$ exists almost everywhere on* $[0, \delta(P)]$, $\partial\theta/\partial\nu(\cdot, \nu') \in L^1([0, \delta(P)])$, *and the usual formulas hold*

$$\theta(\nu, \nu') = \int_{\nu'}^{\nu} \frac{\partial\theta}{\partial\nu}(t, \nu')\, dt, \tag{5.5}$$

$$\operatorname{var} \theta(\cdot, \nu') = \int_{\nu}^{\nu'} \left|\frac{\partial\theta}{\partial\nu}(t, \nu')\right| dt. \tag{5.6}$$

Moreover,

$$(5.7)\qquad \left|\frac{\partial\theta}{\partial\nu}(\nu,\nu')\right| \leqq \|a(\nu)\| = \frac{1}{\rho(\nu)} \quad \text{for a.e. } \nu\in[0,\delta(P)],$$

which implies that in fact $\partial\theta/\partial\nu(\cdot,\nu')\in L^\infty([0,\delta(P)])$.

Proof. Let $P\in\mathcal{P}$ and $\nu'\in[0,\delta(P)]$ be given.

Step 1. There exists $\Delta\nu>0$ such that, for any $\nu_1,\nu_2\in[0,\delta(P)]$ and satisfying $|\nu_1-\nu_2|\leqq\Delta\nu$, we have

$$(5.8)\qquad \theta(\nu_1,\nu_2)\leqq\pi/3$$

and

$$(5.9)\qquad |\theta(\nu_1,\nu')-\theta(\nu_2,\nu')|\leqq\frac{\|v_1-v_2\|}{\sqrt{\cos\theta(\nu_1,\nu_2)}}\leqq\sqrt{2}\,\|v_1-v_2\|.$$

The existence of $\Delta\nu>0$ such that (5.8) holds results immediately from the uniform continuity of $\theta(\cdot,\cdot)$ over $[0,\delta(P)]\times[0,\delta(P)]$. To prove (5.9) we first use the triangular inequality for the curvilinear triangle on the unit sphere having $v(\nu_1)$, $v(\nu_2)$ and $v(\nu')$ as vertices:

$$(5.10)\qquad |\theta(\nu_1,\nu')-\theta(\nu_2,\nu')|\leqq\theta(\nu_1,\nu_2).$$

Using the theorem of the median we obtain, as in Proposition 4.5,

$$\cos\theta(\nu_1,\nu_2)=\langle v_1,v_2\rangle=1-\frac{\|v_1-v_2\|^2}{2}.$$

On the other hand, a Taylor-MacLaurin development of $\cos\theta$ to the order 2 yields

$$\cos\theta(\nu_1,\nu_2)=1-\frac{\theta(\nu_1,\nu_2)^2}{2}\cos(\alpha\theta(\nu_1,\nu_2))\qquad 0\leqq\alpha\leqq1.$$

However, from (5.8) we see that

$$\cos(\alpha\theta(\nu_1,\nu_2)\geqq\cos\theta(\nu_1,\nu_2)\geqq\tfrac{1}{2},$$

which finishes the proof of (5.9).

Step 2. We prove that $\theta(\cdot,\nu')$ is absolutely continuous and has a bounded variation, which automatically implies the existence of $\partial\theta/\partial\nu$ almost everywhere, and hence proves (5.5) and (5.6) (see, for example, Theorems 8.14 and 8.18 of [8]).

We begin by proving the absolute continuity. Let $\varepsilon>0$ be given, and let (α_i,β_i) $i=1,2,\cdots,N$ be disjoint segments of the interval $[0,\delta(P)]$ satisfying

$$\beta_i-\alpha_i\leqq\Delta\nu\quad\forall i=1,\cdots,N.$$

Then we see from (5.9) that

$$\sum_{i=1}^N|\theta(\beta_i,\nu')-\theta(\alpha_i,\nu')|\leqq\sqrt{2}\sum_{i=1}^N\|v(\beta_i)-v(\alpha_i)\|.$$

However, since $P\in W^{2,\infty}([0,\delta(P)]$ we have

$$\|v(\beta_i)-v(\alpha_i)\|\leqq\int_{\alpha_i}^{\beta_i}\|a(t)\|\,dt\leqq\|a\|_\infty(\beta_i-\alpha_i),$$

so that

$$\sum_{i=1}^N|\theta(\beta_i,\nu')-\theta(\alpha_i,\nu')|\leqq\sqrt{2}\,\|a\|_\infty\sum_{i=1}^N(\beta_i-\alpha_i)\leqq\varepsilon$$

as soon as the α_i, β_i satisfy

$$\sum_{i=1}^{N} (\beta_i - \alpha_i) \leqq \min\left\{\Delta\nu, \frac{\varepsilon}{\sqrt{2}\,\|a\|_\infty}\right\}.$$

We now prove that $\theta(\cdot, \nu')$ has a bounded variation over $[0, \delta(P)]$. Let $t_i\, i = 0, 1, \cdots, N$ be given such that

$$0 \leqq t_0 < t_1 < \cdots < t_N \leqq \delta(P).$$

We can always *add a finite number of points* to obtain a new subdivision

$$0 \leqq t'_0 < t'_1 < \cdots < t'_{N'} \leqq \delta(P)$$

(with $N' \geqq N$!) such that

$$|t'_i - t'_{i-1}| \leqq \Delta\nu, \qquad i = 1, 2, \cdots, N'.$$

Then, of course, the triangular inequality implies

$$\sum_{i=1}^{N} \|\theta(t_i, \nu') - \theta(t_{i-1}, \nu')| \leqq \sum_{i=1}^{N'} \|\theta(t'_i, \nu') - \theta(t'_{i-1}, \nu')|.$$

However, from (5.9) we find that for all $i = 1, \cdots, N'$ we have

$$|\theta(t'_i, \nu') - \theta(t'_{i-1}, \nu')| \leqq \sqrt{2}\, \|a\|_\infty (t'_1 - t'_{i-1}),$$

which shows that

$$\sum_{i=1}^{N} |\theta(t_i, \nu') - \theta(t_{i-1}, \nu')| \leqq \sqrt{2}\, \|a\|_\infty \delta(P)$$

independently of the positions of the points t_i, $i = 0, \cdots, N$, and of their number N.

Step 3. We prove (5.7). Let $\nu \in [0, \delta(P)]$ be a *Lebesgue point* for both $a(\cdot) \in L^\infty[0, \delta(P)]$ and $\partial\theta/\partial\nu(\cdot, \nu') \in L^1[0, \delta(P)]$ (almost every point of $[0, \delta(P)]$ has this property!). Hence we know (see (4.14) in the proof of Proposition 4.5) that

$$\|a(\nu)\| = \lim_{d\nu \to 0} \frac{\|v(\nu + d\nu) - v(\nu)\|}{|d\nu|}$$

and

$$\frac{\partial\theta}{\partial\nu}(\nu, \nu') = \lim_{d\nu \to 0} \frac{1}{d\nu} \int_{\nu}^{\nu + d\nu} \frac{\partial\theta}{\partial\nu}(t, \nu')\, dt,$$

which, using (5.5), may be rewritten as

$$\frac{\partial\theta}{\partial\nu}(\nu, \nu') = \lim_{d\nu \to 0} \frac{\theta(\nu + d\nu, \nu') - \theta(\nu, \nu')}{d\nu}.$$

If we choose $d\nu \leqq \Delta\nu$ of Step 1, we see from (5.9) that

$$\left|\frac{\theta(\nu + d\nu, \nu') - \theta(\nu, \nu')}{d\nu}\right| \leqq \frac{\|v(\nu + d\nu) - v(\nu)\|}{|d\nu|} \frac{1}{\sqrt{\cos\theta(\nu + d\nu, \nu)}},$$

which proves (5.7) when $d\nu \to 0$ as $\theta(\nu + d\nu, \nu) \to 0$. This ends the proof of Lemma 5.2. □

So much for the properties of the deflection function. We come now to our purpose, namely, obtaining a lower bound on $R_G(P)$, which reduces to finding a lower bound on $\rho_G(\nu, \nu')$ independent of ν and ν'. Looking at (4.4) giving $\rho_G(\nu, \nu')$, we see that the two pieces entering in this formula are

$$\text{sgn}\,(\nu'-\nu)\langle X'-X, v'\rangle \quad \text{and} \quad \sqrt{1-\langle v, v'\rangle 2}, \tag{5.11}$$

which are related to the deflection θ by

$$\text{sgn}\,(\nu'-\nu)\langle X'-X, v'\rangle = \int_{\min(\nu,\nu')}^{\max(\nu,\nu')} \cos\theta(t, \nu')\,dt \tag{5.12}$$

and

$$\sqrt{1-\langle v, v'\rangle 2} = \sin\theta(\nu, \nu'). \tag{5.13}$$

We now concentrate on obtaining a lower bound for $\text{sgn}\,(\nu', \nu)\langle X'-X, v'\rangle$. Our basic tool for that is the following lemma.

LEMMA 5.3. *Let $\nu, \nu' \in [0, \delta(P)]$ be given. Then the following inequalities hold*:

$$\text{var}\,\theta(\cdot, \nu') \leqq \int_{\min(\nu,\nu')}^{\max(\nu,\nu')} \frac{d\nu}{\rho(\nu)}, \tag{5.14}$$

$$\text{sgn}\,(\nu'-\nu)\langle X'-X, v'\rangle \geqq |\nu'-\nu| \cos\bar\theta + \bar R\,\text{var}\,\{\sin\theta(\cdot, \nu') - \theta(\cdot, \nu')\cos\bar\theta\}, \tag{5.15}$$

where

$$\bar R = \inf\text{ess}\,\rho(t) \qquad t\in[\nu, \nu'], \tag{5.16}$$

$$\bar\theta = \sup\theta(t, \nu') \qquad t\in[\nu, \nu']. \tag{5.17}$$

Proof. Let us consider the case where $\nu \leqq \nu'$ (the proof is similar if $\nu \geqq \nu'$). We remark first that (5.14) follows immediately from (5.6) and (5.7). Then from (5.12) and (5.17), we find that

$$\langle X'-X, v'\rangle = \int_\nu^{\nu'} (\cos\theta(t, v') - \cos\bar\theta)\,dt + (\nu'-\nu)\cos\bar\theta. \tag{5.18}$$

From Lemma 5.2 we know that

$$\rho(t)\left|\frac{d\theta}{d\nu}(t, \nu')\right| \leqq 1 \quad \text{for almost every } t \text{ of } [\nu, \nu']. \tag{5.19}$$

Plugging then (5.19) into (5.18) yields, as $\cos\theta(t, \nu') - \cos\bar\theta \geqq 0$ for all $t\in[\nu, \nu']$ and $\rho(t) \geqq \bar R$ for all $t\in[\nu, \nu']$:

$$\begin{aligned}\langle X'-X, v'\rangle &\geqq \bar R \int_\nu^{\nu'} (\cos\theta(t, \nu') - \cos\bar\theta)\left|\frac{\partial\theta}{\partial\nu}(t, \nu')\right| dt + (\nu'-\nu)\cos\bar\theta \\ &= \bar R \int_\nu^{\nu'} \left|\frac{\partial}{\partial\nu}(\sin\theta(t, \nu') - \theta(t, \nu')\cos\bar\theta)\right| dt + (\nu'-\nu)\cos\bar\theta,\end{aligned} \tag{5.20}$$

which, using (5.6) for the function $g(t) = \sin\theta(t, \nu') - \theta(t, \nu')\cos\bar\theta$, yields (5.15). □

The bounds (5.14) and (5.15) take advantage, through the total variation of the $\theta(\cdot, \nu')$ and $\sin\theta(\cdot, \nu') + \theta(\cdot, \nu')\cos\bar\theta$ functions, of much of the information contained in the shape of the deflection function $\theta(\cdot, \nu')$.

In particular, the lower bound (5.15) for the numerator of $\rho_G(\nu, \nu')$ increases when the variation of the deflection increases, which shows that "oscillating paths" have more chance to have positive global radii of curvature.

If we retain only from the shape of $\theta(\cdot, \nu')$ its maximum value $\bar{\theta}$ on $[\nu, \nu']$, we obtain the following corollary.

COROLLARY 5.4. *Let $\nu, \nu' \in [0, \delta(P)]$ be given. Then*

$$\bar{\theta} \leqq \int_{\min(\nu,\nu')}^{\max(\nu,\nu')} \frac{d\nu}{\rho(\nu)} \leqq \frac{|\nu' - \nu|}{\bar{R}}, \tag{5.22}$$

$$\operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle \geqq \bar{R} \sin \bar{\theta} + (|\nu' - \nu| - \bar{R} \cdot \bar{\theta}) \cos \bar{\theta}, \tag{5.23}$$

where $\bar{R}$, $\bar{\theta}$ are defined in (5.16) *and* (5.17).

Proof. Suppose $\nu \leqq \nu'$, for instance, and define $\bar{\nu} \in [\nu, \nu']$ by

$$\theta(\bar{\nu}, \nu') = \bar{\theta} = \sup \theta(t, \nu') \qquad t \in [\nu, \nu'].$$

Then (5.22) and (5.23) result immediately from (5.14), (5.15), and (5.4) with $N = 1$, $t_0 = \bar{\nu}$, $t_1 = \nu'$. □

We can put together formula (4.4) giving $\rho_G(\nu, \nu')$ and Corollary 5.4 to obtain the sought lower bound on $\rho_G(\nu, \nu')$.

PROPOSITION 5.5. *Let $P \in \mathcal{P}$, $\nu, \nu' \in [0, \delta(P)]$, $\nu \neq \nu'$, be given, and $\bar{R}$, $\bar{\theta}$ be defined by* (5.16) *and* (5.17).

(i) *If*

$$0 \leqq \bar{\theta} \leqq \pi/2, \tag{5.24}$$

then

$$\rho_G(\nu, \nu') \geqq \bar{R} + (|\nu' - \nu| - \bar{R} \cdot \bar{\theta}) \operatorname{cotan} \bar{\theta} \tag{5.25}$$

and the right-hand side of (5.25) *is strictly positive as soon as*

$$\bar{R} > 0 \qquad (\textit{independently of } |\nu' - \nu|!). \tag{5.26}$$

(ii) *If*

$$\frac{\pi}{2} \leqq \bar{\theta} \leqq \pi \tag{5.27}$$

then

$$\rho_G(\nu, \nu') \geqq \bar{R} \sin \bar{\theta} + (|\nu' - \nu| - \bar{R} \cdot \bar{\theta}) \cos \bar{\theta} \tag{5.28}$$

and the right hand side of (5.28) *is strictly positive as soon as the size × curvature condition*

$$|\nu' - \nu| / \bar{R} < \bar{\theta} - \tan \bar{\theta} \tag{5.29}$$

is satisfied (*note that, because of* (5.22), *condition* (5.29) *can be satisfied only of $\bar{\theta} < \pi$!*).

Proof. First we prove (i). As $\bar{\theta} \leqq \pi/2$ we have $\cos \bar{\theta} \geqq 0$, which shows by Corollary 5.4 that

$$\operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle \geqq 0, \tag{5.30}$$

and by definition of θ we have

$$\theta(\nu, \nu') \leqq \bar{\theta} \leqq \pi/2, \tag{5.31}$$

which shows that

$$\cos \theta(\nu, \nu') = \langle v, v'\rangle \geqq 0 \tag{5.32}$$

and

$$0 \leqq \sin \theta(\nu, \nu') \leqq \sin \bar{\theta}. \tag{5.33}$$

Using (5.30) and (5.32) in formula (4.4) for ρ_G then yields

$$\rho_G(\nu, \nu') = \frac{\operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle}{\sin \theta(\nu, \nu')}, \tag{5.34}$$

and, using (5.33),

$$\rho_G(\nu, \nu') \geqq \frac{\operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle}{\sin \bar{\theta}}, \tag{5.35}$$

which yields the sought result (5.25) using the lower bound (5.23) for the numerator.

Now we prove (ii). As $\pi/2 \leqq \theta < \pi$, we have no information on the sign of $\cos \theta(\nu, \nu') = \langle v, v'\rangle$. However, we see from (4.4) that, whatever the signs of $\operatorname{sgn}(\nu' - \nu) \times \langle X' - X, v'\rangle$ and $\langle v, v'\rangle$ may be, we always have

$$\rho_G(\nu, \nu') \geqq \operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle, \tag{5.36}$$

the equality holding when $\operatorname{sgn}(\nu' - \nu)\langle X' - X, v'\rangle \geqq 0$ and $\langle v, v'\rangle \leqq 0$. Then the sought lower bound (5.28) results immediately from (5.36) and formula (5.23) of Corollary 5.4, and the size × curvature condition (5.29) results immediately from (5.28) by noting that $\cos \bar{\theta} \leqq 0$. □

Formula (5.25) also gives us a more precise insight into the way $\rho_G(\nu, \nu')$ approaches $\rho(\nu)$ when $\nu' \to \nu$: if, for example, $t \to \rho(t)$ is an increasing function, then

$$\begin{aligned} &\rho_G(\nu, \nu') \geqq \rho(\nu) \quad \text{when } \nu' \geqq \nu, \\ &\rho_G(\nu, \nu') \geqq \rho(\nu') \quad \text{when } \nu' \leqq \nu \end{aligned} \tag{5.37}$$

as soon as ν' and ν are close enough so that the maximum deflection between v and v' is smaller than $\pi/2$.

We now deduce from Proposition 5.5 a lower bound for $R_G(P) = \inf_{\nu, \nu' \in [0, \delta(P)]} \rho_G(\nu, \nu')$, which is our second main result.

THEOREM 5.6. *Let a path $P \in \mathcal{P}$ be given. Then its maximum deflection $\Theta(P)$ (defined in (5.2)) is related to its length $\delta(P)$ and its smallest radius of curvature $R(P)$ by*

$$\Theta(P) \leqq \int_0^{\delta(P)} \frac{d\nu}{\rho(\nu)} \leqq \frac{\delta(P)}{R(P)}, \tag{5.38}$$

and the following lower bounds for $R_G(P)$ defined in (4.17) hold:

(i) *Low deflection paths. If*

$$0 \leqq \Theta(P) \leqq \pi/2 \tag{5.39}$$

then

$$R_G(P) = R(P) \tag{5.40}$$

independently of the length $\delta(P)$ of the path.

(ii) *Large deflection paths. If*

$$\pi/2 \leqq \Theta(P) \leqq \pi \tag{5.41}$$

then

$$R_G(P) \geqq R(P) \sin \Theta(P) + \{\delta(P) - R(P)\Theta(P)\} \cos \Theta(P), \tag{5.42}$$

which is strictly positive as soon as the length $\delta(P)$ of the path satisfies the size × curvature condition:

$$\delta(P)/R(P)<\Theta(P)-\tan\Theta(P), \tag{5.43}$$

(*once again, this condition can be satisfied only if* $\Theta(P)<\pi$!).

Proof. Note first that (5.38) is obtained immediately from (5.22) of Corollary 5.4 by taking $\nu=\nu_0$, $\nu'=\nu_1$, where $\nu_0, \nu_1\in[0, \delta(P)]$ are such that $\theta(\nu_0, \nu_1)=\Theta(P)$, and by noting that

$$\int_{\nu_0}^{\nu_1}\frac{d\nu}{\rho(\nu)}\leqq\int_0^{\delta(P)}\frac{d\nu}{\rho(\nu)}.$$

We now prove the results of (i). If $\Theta(P)\leqq\pi/2$, we obviously have for any $\nu, \nu'\in[0, \delta(P)]$,

$$0\leqq\bar\theta\leqq\Theta(P)\leqq\pi/2$$

so that part (i) of Proposition 5.5 applies. Hence

$$\rho_G(\nu, \nu')\geqq\bar R,$$

which implies, as $\bar R\geqq R(P)$, that

$$R_G(P)\geqq R(P).$$

But we know from Proposition 4.7 that

$$R_G(P)\leqq R(P),$$

which ends the proof of (5.40).

We now prove the results of (ii). As we now know only that $\pi/2\leqq\Theta(P)\leqq\pi$, two cases may happen for given $\nu, \nu'\in[0, \delta(P)]$: either $0\leqq\bar\theta\leqq\pi/2\leqq\Theta(P)$, and we find, as above,

$$\rho_G(\nu, \nu')\geqq R(P) \tag{5.44}$$

or $\pi/2\leqq\bar\theta\leqq\Theta(P)\leqq\pi$ and then we find from part (ii) of Proposition 5.5 that

$$\rho_G(\nu, \nu')\geqq\bar R\sin\bar\theta+(|\nu'-\nu|-\bar R\cdot\bar\theta)\cos\bar\theta.$$

However, since $\cos\bar\theta\leqq0$, this implies, as $|\nu'-\nu|\leqq\delta(P)$ and $\bar R\geqq R(P)$, that

$$\rho_G(\nu, \nu')\geqq R(P)\sin\bar\theta+(\delta(P)-R(P)\bar\theta)\cos\bar\theta.$$

However, the mapping $\alpha\to R(P)\sin\alpha+(\delta(P)-R(P)\alpha)\cos\alpha$ is decreasing over the $[0, \Theta(P)]$ interval, as its derivative is the $\alpha\to-\sin\alpha(\delta(P)-R(P)\alpha)$ function, which is negative over the $[0, \Theta(P)]$ interval because of (5.38). Hence we obtain, as $\bar\theta\leqq\Theta(P)$,

$$\rho_G(\nu, \nu')\geqq R(P)\sin\Theta(P)+(\delta(P)-R(P)\Theta(P))\cos\Theta(P). \tag{5.45}$$

When taking the minimum over all $\nu, \nu'\in[0, \delta(P)]$, we obtain (5.42) because the right-hand side of (5.45) is smaller than the right-hand side of (5.44).

Finally, (5.43) is obtained immediately by writing that the right-hand side of (5.42) is strictly positive. □

We have illustrated Theorem 5.6 in Figs. 5.1 and 5.2. For a path P with given smallest radius of curvature $R(P)$, Fig. 5.1 shows the *domain* of deflections $\Theta(P)$ and length $\delta(P)$, which are *recognized by Theorem* 5.6 *as associated to a strictly quasiconvex* path P. It is delimited by the following two curves:

$$\delta_{\max}(P)=\begin{cases}+\infty & \text{if } 0\leqq\Theta(P)\leqq\pi/2,\\ R(P)\{\Theta(P)-\tan\Theta(P)\} & \text{if } \pi/2<\Theta(P)\leqq\pi,\end{cases}$$

$$\delta_{\min}=R(P)\Theta(P).$$

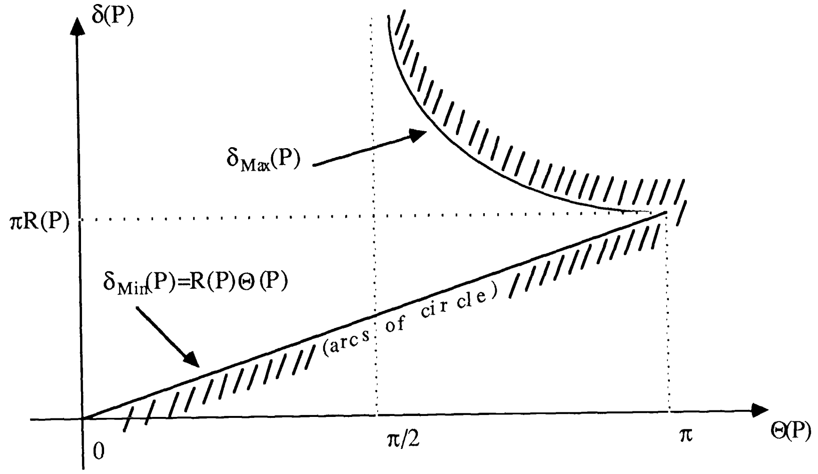

FIG. 5.1. *The domain of deflections* $\Theta(P)$ *and lengths* $\delta(P)$ *that are recognized as strictly quasiconvex by Theorem* 5.6 *for a path with a given* $R(P)$.

Note that (5.38) implies that the bottom boundary $\delta_{\min}(P)$ is a hard one, in the sense that there do not exist paths whose representative point is below that line. On the contrary, the upper boundary is soft, as there exist many paths having their representative points above that boundary, and that may or may not be strictly quasiconvex.

Figure 5.2 represents, for all paths recognized as strictly quasiconvex by Theorem 5.6, the domain of deflections $\Theta(P)$ and lower bounds R_G to $R_G(P)$ given by Theorem 5.6, namely,

$$R_G=\begin{cases} R(P) & \text{if } 0\leqq\Theta(P)\leqq\pi/2,\\ R(P)\sin\Theta(P)+\{\delta(P)-R(P)\Theta(P)\}\cos\Theta(P) & \text{if } \pi/2\leqq\Theta(P)\leqq\pi.\end{cases}$$

Note that here the upper boundary, which corresponds to paths that are arcs of circles, is not a hard boundary for the actual global radius of curvature $R_G(P)$: we may find paths with a deflection $\Theta(P)$ as close as desired from π but with a $R_G(P)=R(P)$ global radius of curvature!

We note also that the bounds given in Theorem 5.6 are sharp; when P is an arc of a circle, the inequalities in (5.38) and (5.42) become equalities, and the theorem recognizes exactly all strictly quasiconvex arcs of circles, as the equality in (5.38) implies that (5.43) is satisfied as soon as $\delta(P)/R(P)<\pi$. But the upper bound (5.43) for the admissible length $\delta(P)$ of a path with a maximum deflection larger than $\pi/2$ is also sharp, as may be seen from Fig. 5.3: given a maximum deflection $\pi/2\leqq\Theta(P)<\pi$, the worst thing to do (up to a change of scale, of course) is

—first go straight ahead with a length $|\tan\Theta(P)|$

—then turn an angle $\Theta(P)$ using an arc of a circle of radius one.

The resulting path has a length $\Theta(P)-\tan\Theta(P)$, and a zero $R_G(P)$ as obviously $\rho_G(0,\delta(P))=0$!

Of course, we may use Theorem 5.6 to construct various sufficient conditions for the strict quasiconvexity of a set, as we check easily from Theorem 4.12 that the only thing we must do is to find a lower bound for $R_G(P)$, $P\in\mathcal{P}_M$.

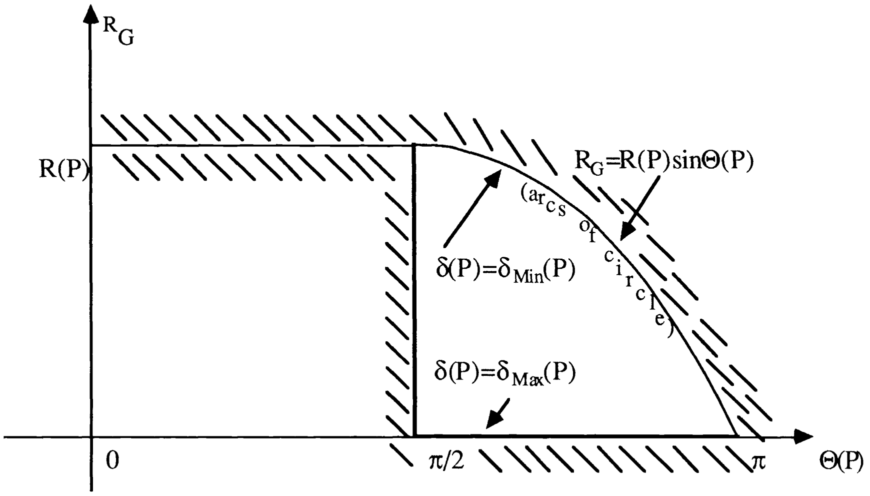

FIG. 5.2. *The domain of deflections* $\Theta(P)$ *and lower bounds* R_G *to* $R_G(P)$ *given by Theorem* 5.6 *for paths recognized by this theorem as in Fig.* 5.1.

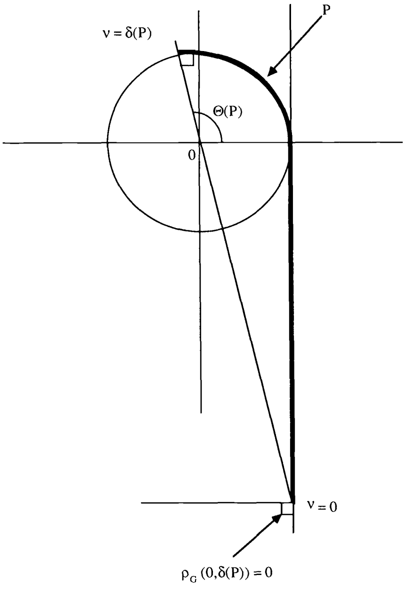

FIG. 5.3. *Illustration of the sharpness of the upper bound for the length of paths with a maximum deflection larger than* $\pi/2$.

We state here one such condition, which uses the following lower and upper bounds for the attributes of the set $(D, \mathcal{P})$:

Lower bound R to radii of curvature along paths:

$$R(P) \geqq R \quad \forall P \in \mathcal{P}_M, \tag{5.46}$$

Upper bound Δ *to path length*:

$$\delta(P) \leqq \Delta \quad \forall P \in \mathcal{P}_M, \tag{5.47}$$

Upper bound Θ to path maximal deflection:

$$\Theta(P) \leqq \Theta \quad \forall P \in \mathcal{P}_M. \tag{5.48}$$

Note that such an upper bound can be obtained by either formula

$$\Theta = \sup_{P \in \mathcal{P}_M} \int_0^{\delta(P)} \frac{d\nu}{\rho(\nu)} \quad \text{or} \quad \Theta = \sup_{P \in \mathcal{P}_M} \frac{\delta(P)}{R(P)}. \tag{5.49}$$

THEOREM 5.7. (Θ-size × curvature condition). *Let $(D, \mathcal{P})$ be given such that*

$$R > 0. \tag{5.50}$$

(i) *If*

$$0 \leqq \Theta \leqq \pi/2, \tag{5.51}$$

then

$$R_G(D) \geqq R > 0, \tag{5.52}$$

and $(D, \mathcal{P})$ is strictly quasiconvex for a cylindrical neighborhood of size at least R.

(ii) *If*

$$\pi/2 \leqq \Theta < \pi, \tag{5.53}$$

then

$$R_G(D) \geqq R \sin \Theta + (\Delta - R\Theta) \cos \Theta, \tag{5.54}$$

and $(D, \mathcal{P})$ is strictly quasiconvex, with a cylindrical neighborhood of the size of the right-hand side of (5.54) *at least, as soon as the maximum length of paths satisfy*

$$\Delta / R < \Theta - \tan \Theta. \tag{5.55}$$

6. One application to nonlinear least squares. We consider the problem

$$\text{find } x \in C \text{ such that } J(x) = \|\varphi(x) - z\|_F^2 = \min \text{ over } C, \tag{6.1}$$

where

$$\begin{aligned} &E \text{ is a Banach space, } F \text{ is a Hilbert space,} \\ &C \subset E \text{ is a closed convex set,} \\ &\varphi : C \to F \text{ is a } C^2\text{-mapping,} \\ &z \in F \text{ is a given point (data).} \end{aligned} \tag{6.2}$$

Because φ is of class C^2 there exists β such that

$$\|\varphi''(x)(y, y)\|_F \leqq \beta \|y\|^2 \quad \forall x \in C, \quad \forall y \in E, \tag{6.3}$$

and we suppose that the derivative $\varphi'(x)$ is uniformly invertible, i.e., that there exist α_m and α_M such that

$$\alpha_m \|y\|_E \leqq \|\varphi'(x) \cdot y\|_F \leqq \alpha_M \|y\|_E \quad \forall x \in C, \quad \forall y \in E. \tag{6.4}$$

We may then apply the results of § 5 to the set $D = \varphi(C)$ equipped with the paths

$$\mathcal{P} = \{\varphi([x, y]), x, y \in C\} \tag{6.5}$$

for which the subset

$$\mathcal{P}_M = \{\varphi([x, y]), x, y \in \partial C\} \tag{6.6}$$

is obviously a subfamily of maximal paths.

We easily check (cf. [6]) that, given a path $P=\varphi([x,y])$, x, $y\in C$, the arc length ν and radius of curvature ρ satisfy

$$\nu(t)=\int_0^t \|\varphi'(x_t)(y-x)\|_F\,dt \geqq \alpha_m t\|y-x\|_E, \tag{6.7}$$

$$\rho(\nu)\geqq \frac{\|\varphi'(x_t)(y-x)\|_F^2}{\|\varphi''(x_t)(y-x,y-x)\|_F}\geqq \frac{\alpha_m^2}{\beta}, \tag{6.8}$$

where

$$x_t=(1-t)x+ty \quad \forall t\in[0,1]. \tag{6.9}$$

From (6.7) and (6.8) we find that

$$\int_0^{\delta(P)} \frac{d\nu}{\rho(\nu)}\leqq \int_0^1 \frac{\|\varphi''(x_t)(y-x,y-x)\|_F}{\|\varphi'(x_t)(y-x)\|_F}\,dt \leqq \frac{\beta}{\alpha_m}\|y-x\|_E. \tag{6.10}$$

These formulas give us the following lower and upper bounds for the attributes of the paths of $D=\varphi(C)$:

$$\begin{aligned} &R=\alpha_m^2/\beta && \text{(lower bound to radii of curvature),}\\ &\Delta=\alpha_M \operatorname{diam} C && \text{(upper bound to path length),}\\ &\Theta=(\beta/\alpha_m)\operatorname{diam} C && \text{(upper bound to path deflection).}\end{aligned} \tag{6.11}$$

Using Theorem 5.7 we then obtain the following theorem.

THEOREM 6.1. *Let* (6.2)-(6.4) *hold, and let* R, Δ, Θ *be defined by* (6.11), *and define* R_G *by*

$$R_G=\begin{cases} R & \text{if } 0\leqq\Theta\leqq\pi/2,\\ R\sin\Theta+(\alpha_M-\alpha_m)\operatorname{diam} C\cos\theta & \text{if } \pi/2\leqq\Theta\leqq\pi.\end{cases} \tag{6.12}$$

If

$$\Theta=\frac{\beta}{\alpha_m}\operatorname{diam} C\leqq\frac{\pi}{2}, \tag{6.13}$$

or

$$\frac{\pi}{2}\leqq\Theta=\frac{\beta}{\alpha_m}\operatorname{diam} C<\pi \quad\text{and}\quad \left(\frac{\alpha_M}{\alpha_m}-1\right)\Theta<|\tan\Theta|, \tag{6.14}$$

then, for any z *such that*

$$d(z,\varphi(C))<R_G, \tag{6.15}$$

the nonlinear least squares problem (6.1) *has the following properties*:

(6.16) *existence of a unique global minimum* $\hat{x}$,

(6.17) *no local minimum,*

(6.18) *any minimizing sequence is a Cauchy sequence in* E *converging toward* $\hat{x}$,

(6.19) *Lipschitz-continuity of the* $z\to\hat{x}$ *mapping*:

$$\alpha_m\|\hat{X}_1-\hat{X}_2\|_E\leqq\left(1-\frac{d}{R}\right)^{-1}\|z_1-z_2\|_F \text{ as soon as}$$

$$\|z_1-z_2\|_F+\max_{j=1,2} d(z_j,\varphi(C))\leqq d<R_G. \tag{6.20}$$

Note that, under the same hypothesis, the γ-size curvature condition would read

$$\frac{\beta}{\alpha_m}\operatorname{diam} C < 2\sqrt{2} \tag{6.21}$$

and imply (6.16)-(6.19) but not (6.17), and (6.20) would hold only for $d < \gamma(D)$, which is usually much smaller than R_G.

H_∞ CONTROL WITH TRANSIENTS*

PRAMOD P. KHARGONEKAR[†], KRISHAN M. NAGPAL[‡], AND KAMESHWAR R. POOLLA[§]

Abstract. In H_∞ (or uniformly optimal) control problems, it is usually assumed that the system initial conditions are zero. In this paper, an H_∞-like control problem that incorporates uncertainty in initial conditions is formulated. This is done by defining a worst-case performance measure. Both finite and infinite horizon problems are considered. Necessary and sufficient conditions are derived for the existence of controllers that yield a closed-loop system for which the above-mentioned performance measure is less than a prespecified value. State-space formulae for the controllers are also presented.

Key words. H_∞ control theory, algebraic and differential Riccati equations, optimal control

1. Introduction.

Zames introduced the problem of H_∞ optimal control in his pioneering paper [18]. The essential idea was to design a controller to optimize the closed-loop system performance for the worst exogenous input. The expository book by Francis [6] presents a lucid account of the early developments in H_∞ control theory.

A significant new development in H_∞ control theory in the last two years has been the introduction of state-space methods. This has led to a rather transparent solution to the standard problem of H_∞ control theory. See Doyle et al. [5], Khargonekar [9], and the references cited there for the state-space approach to H_∞ control theory.

The H_∞ norm of a system can be defined in many different but equivalent ways. However, it is always (at least, implicitly) assumed that the initial condition of the system is zero. Thus, in most of the H_∞ control theory literature, it is assumed that the plant initial conditions are zero. There are a few exceptions. For example, Nagpal and Khargonekar [12] have considered an H_∞ type of estimation problem with nonzero initial conditions. In this paper, our principal aim is to extend the basic ideas and the recent results from the state-space approach to H_∞ control theory taking initial conditions into account explicitly. We consider this as the key conceptual contribution of the present paper. In recent independent parallel work, Didinsky and Basar [4] consider a minimax design problem for discrete-time systems with nonzero initial states. However, their problem formulation, as well as the results, bear little resemblance to our work.

In §2 we formulate an H_∞-type optimal control problem that incorporates initial conditions. This is done by introducing a new performance measure that is essentially the worst-case norm of the regulated outputs over all exogenous signals and initial conditions. We define this performance measure for both finite time and infinite time

horizons. For finite horizon problems we also allow for a penalty on the terminal state. This enables us to incorporate trade-offs between the norm of the controlled output and the size of the terminal state.

In §3 we state the main results of this paper. Here we present necessary and sufficient conditions for the existence of a linear controller such that the above-mentioned performance measure of the closed-loop system is less than a prespecified number. These necessary and sufficient conditions are given in terms of existence and properties of solutions to certain algebraic and differential Riccati equations. In the event that these necessary conditions are met, we provide explicit formulae for controllers that yield the prespecified performance. Our results in this paper may be regarded as the H_∞ analogue of the *nonstationary* linear quadratic Gaussian (LQG) control theory results. The results for infinite time horizon problems are natural generalizations of the results of Doyle et al. [5] for the situation of nonzero initial states, while those for finite time horizon problems are natural generalizations of the results of Tadmor [15] and Limebeer et al. [10]. In §4 we give proofs of the main results.

In this paper, we restrict our attention to finite-dimensional linear time-invariant plants. It should be noted that even though the plant is linear time-invariant, it is necessary to consider time-varying controllers since the natural (central) solutions even for linear time-invariant plants happen to be linear *time-varying.* This situation is analogous to the the finite horizon linear-quadratic regulator and Kalman filtering theory. Recall that for finite horizon linear-quadratic optimal control problems for linear time-invariant plants, the optimal controller turns out to be linear time-varying. Similarly, in the Kalman filtering problem, if the initial state covariance does not match the steady-state covariance, the Kalman filter is also linear time-varying. It is in this sense in which we regard our results in this paper as the H_∞ analogue of the nonstationary LQG control theory results. Results for finite horizon problems can be trivially extended to linear time-varying plants. Extensions to time-varying plants of the results for the infinite time horizon case are technically much more difficult but are possible along the lines of recent work by Tadmor [16] and Ravi, Nagpal, and Khargonekar [13]. These extensions are left for future research.

2. Worst-case H_∞-type performance measures with nonzero initial conditions.

Consider the finite-dimensional linear time-invariant system Σ:

$$\begin{aligned} \frac{dx}{dt} &= Ax + B_1w + B_2u, \\ z &= C_1x + D_{11}w + D_{12}u, \\ y &= C_2x + D_{21}w + D_{22}u. \end{aligned} \tag{1}$$

Here x, w, u, z, and y denote, respectively, the state, exogenous input, control input, regulated output, and measured output. It is assumed that the initial state $x(0)$ is possibly nonzero and *unknown.*

The control problem that we wish to address is that of designing a controller that internally stabilizes the closed-loop system and reduces z uniformly for all w and $x(0)$. More specifically, let K be a finite-dimensional linear (possibly time-varying) controller given by the system equations

$$\begin{aligned} \frac{d\xi}{dt} &= F(t)\xi(t) + G(t)y(t), \\ u(t) &= H(t)\xi(t) + J(t)y(t). \end{aligned} \tag{2}$$

Throughout this paper, we assume that the controllers are linear, finite-dimensional, and time-varying with continuous and bounded state-space realizations. (A time function $f(t)$ is called bounded if and only if there exists $M > 0$ such that for all $t \geq 0$ $\|f(t)\| < M$.) Let Σ_{cl} denote the resulting closed-loop system. The closed-loop system is called *well posed* if and only if $(I - JD_{22})^{-1}$ is bounded. The closed-loop system is called *internally stable* if and only if it is well posed and the unforced closed-loop system (i.e., $w = 0$,) with states x, ξ is exponentially stable. In finite horizon problems, a controller is called *admissible* if and only if it yields a well-posed feedback system. In infinite horizon problems, a controller is called *admissible* if and only if it yields an internally stable feedback system. For a fixed time $T > 0$, a symmetric positive-semidefinite matrix S, and a symmetric positive-definite matrix R, define the worst-case closed-loop performace measure as

$$J(\Sigma_{cl}, R, S, T) = \sup \left\{ \left[\frac{\|z\|_T^2 + x'(T)Sx(T)}{\|w\|_T^2 + x_0'Rx_0} \right]^{1/2} \right\}, \tag{3}$$

where $\xi(0) = 0$, and the supremum is taken over all $x(0) = x_0 \in \mathbf{R}^n$, $w \in L_2[0, T]$, $\|w\|_T^2 + x_0'Rx_0 \neq 0$. In this definition, T is allowed to be ∞ in which case $S := 0$ and the supremum on the right-hand side is taken over all $w \in L_2[0, \infty)$. Here $\|f\|_T = \left[\int_0^T \|f(t)\|^2 dt\right]^{1/2}$.

The performance measure $J(\Sigma_{cl}, R, S, T)$ can be regarded as the induced norm of the linear operator generated by the closed-loop system Σ_{cl}, which maps the pair $(x(0), w)$ to $(x(T), z)$. More explictly, consider the linear operator

$$\Gamma : \mathbf{R}^n \oplus L_2[0, T] \to \mathbf{R}^n \oplus L_2[0, T] : \ (x(0), w) \to (x(T), z).$$

Define the inner product on the domain of Γ to be

$$\langle (x_1, w_1), (x_2, w_2) \rangle := x_1'Rx_2 + \langle w_1, w_2 \rangle_{L_2[0,T]}$$

and the inner product on the co-domain as

$$\langle (x_1, z_1), (x_2, z_2) \rangle := x_1'Sx_2 + \langle z_1, z_2 \rangle_{L_2[0,T]},$$

where $<>_{L_2[0,T]}$ is the usual inner product in $L_2[0, T]$. These inner products induce corresponding (semi)norms in the domain and the range of Γ. Then the performance measure J is the induced operator norm of Γ. A similar interpretation can be given for the infinite horizon case.

We can now state the control problems considered in this paper. Given a real number $\gamma > 0$:

(i) Infinite Horizon Problem: Does there exist, and if so find, an internally stabilizing bounded linear time-varying controller such that

$$J(\Sigma_{cl}, R, 0, \infty) < \gamma?$$

(ii) Finite Horizon Problem: Does there exist, and if so find, a bounded linear time-varying controller such that

$$J(\Sigma_{cl}, R, S, T) < \gamma?$$

In the remainder of this section, we will present some results that serve in developing an understanding of the performance measure J. These results also elucidate the relationship between the cost functional J and the H_∞ norm of a system.

Consider the finite-dimensional linear (possibly time-varying) system Σ_a

$$\frac{dx}{dt} = Ax + Bw, \qquad z = Cx \tag{4}$$

and define $J(\Sigma_a, R, S, T)$ as above. We summarize some of the simpler properties of $J(\Sigma_a, R, S, T)$ in the following lemma.

LEMMA 1.1. *Let Σ_a be as above.*

(a) *If $R_1 \geq R_2$ then $J(\Sigma_a, R_1, S, T) \leq J(\Sigma_a, R_2, S, T)$.*

(b) *If $S_1 \geq S_2$, then $J(\Sigma_a, R, S_1, T) \geq J(\Sigma_a, R, S_2, T)$.*

(c) *If $T_1 \geq T_2$, then $J(\Sigma_a, R, 0, T_1) \geq J(\Sigma_a, R, 0, T_2)$.*

(d) *Suppose that Σ_a is time-invariant and asymptotically stable, then*

$$\lim_{\rho, T \to \infty} J(\Sigma_a, \rho I, 0, T) = \|T_{zw}\|_\infty := \sup\{\bar{\sigma}(T_{zw}(s)) : \operatorname{Re}(s) \geq 0\}, \tag{5}$$

where $T_{zw} := C(sI - A)^{-1}B$ denotes the system transfer function and, moreover,

$$J(\Sigma_a, R, 0, \infty) \geq \|T_{zw}\|_\infty. \tag{6}$$

Thus, $J(\Sigma_{cl}, R, S, T)$ is a generalization of the more familiar concept of the H_∞ norm of a system accommodating the possibility of nonzero initial conditions. The weighting matrix R is a measure of the relative importance of the uncertainty in initial conditions vis-à-vis the uncertainty in the exogenous signals w. A "smaller" choice of R reflects greater uncertainty in the initial condition. This connection is best illuminated by observing that as the smallest eigenvalue $\lambda_{\min}(R)$ of R approaches ∞, the unit ball in $\mathbf{R}^n \oplus L_2$ defined by

$$B_{\mathbf{R}^n \oplus L_2} := \left\{(x_0, w) \in \mathbf{R}^n \oplus L_2 : x_0' R x_0 + \|w\|^2 \leq 1\right\}$$

tends to $(0, B_{L_2})$, where $B_{L_2} := \{w \in L_2 : \|w\|^2 \leq 1\}$.

We now describe how the performance measure J can be computed for a given system. These results may be viewed as natural generalizations of existing work on the computation of the H_∞ norm of a linear time-invariant system (see, for example, Anderson [1], Willems [17], and Boyd, Balakrishnan, and Kabamba [2]).

THEOREM 1.2. *Consider the linear (possibly time-varying) system Σ_a as in (4) above. Let R, S be given symmetric matrices such that S is positive semidefinite and R is positive definite. Then the following are equivalent:*

(a) $J(\Sigma_a, R, S, T) < \gamma$.

(b) *There exists a symmetric matrix function $P(t), t \in [0, T]$ such that*

$$-\dot{P}(t) = A'(t)P(t) + P(t)A(t) + \frac{1}{\gamma^2}P(t)B(t)B'(t)P(t) + C'(t)C(t), P(T) = S \tag{7}$$

and $P(0) < \gamma^2 R$.

(c) *There exists a symmetric matrix function $Q(t) > 0, t \in [0, T]$ such that*

$$\dot{Q}(t) = A(t)Q(t) + Q(t)A'(t) + \frac{1}{\gamma^2}Q(t)C'(t)C(t)Q(t) + B(t)B'(t), Q(0) = R^{-1} \tag{8}$$

and $\gamma^2 Q^{-1}(T) > S$.

THEOREM 1.3. *Let* Σ_a *in* (4) *be a linear time-invariant, asymptotically stable system. Let* R *be a given symmetric positive-definite matrix. Then the following are equivalent:*

(a) $J(\Sigma_a, R, 0, \infty) < \gamma$.

(b) *There exists a symmetric matrix* P *such that*

$$0 = A'P + PA + (1/\gamma^2)PBB'P + C'C,$$

$(A + (1/\gamma^2)BB'P)$ *is asymptotically stable, and* $P < \gamma^2 R$.

(c) *There exists a symmetric* $Q(t)$ *that satisfies the Riccati differential eqution* (8) *for all* $t \geq 0$ *and is such that the autonomous system* $\dot{q}(t) = [A + (1/\gamma^2)Q(t)C'C]q(t)$ *is exponentially stable. Moreover,* $\lim_{t\to\infty} Q(t)$ *exists and equals* Q_∞*, where* Q_∞ *is the unique symmetric matrix with the following properties:*

$$AQ_\infty + Q_\infty A' + \frac{1}{\gamma^2}Q_\infty C'CQ_\infty + BB' = 0, \tag{9}$$

and $A + (1/\gamma^2)QC'C$ *is asymptotically stable.*

Proofs of Theorems 2.2 *and* 2.3. Equivalence of (a) and (b). We will first prove that (a) ⇒ (b) in Theorem 2.3. From Lemma 2.1, it follows that $J(\Sigma_a, R, 0, \infty) \geq \|C(sI - A)^{-1}B\|_\infty$. It follows from Anderson [1], Willems [17], and Boyd, Balakrishnan, and Kabamba [2] that $\|C(sI - A)^{-1}B\|_\infty < \gamma$, if and only if there exists a symmteric matrix P such that

$$0 = A'P + PA + \frac{1}{\gamma^2}PBB'P + C'C,$$

and $(A + (1/\gamma^2)BB'P)$ is asymptotically stable. To complete the necessity it remains to be shown that $P < \gamma^2 R$. Suppose that this is not the case. Then there exists a nonzero x_0 such that $x_0'(P - \gamma^2 R)x_0 \geq 0$. Straightforward algebra reveals that for system (4),

$$\frac{d(x'Px)}{dt} = \gamma^2 w'w - x'C'Cx - \left[\gamma w - \frac{1}{\gamma}B'Px\right]' \left[\gamma w - \frac{1}{\gamma}B'Px\right].$$

Now set $w = (1/\gamma^2)B'Px, x(0) = x_0$. Using stability of $(A + (1/\gamma^2)BB'P)$ and integrating the above equation from 0 to ∞ along the trajectory of Σ_a, we obtain

$$\gamma^2 x_0' R x_0 + \gamma^2\|w\|^2 - \|z\|^2 = \gamma^2 x_0' R x_0 - x_0' P x_0 \leq 0,$$

which contradicts $J(\Sigma_a, R, 0, \infty) < \gamma$. The proof of (b) ⇒ (a) of Theorem 2.3 can be readily completed by reversing the steps in the above argument to establish that the existence of P with the requisite properties is sufficient for $J(\Sigma_a, R, 0, \infty) < \gamma$.

Next we provide a brief sketch of the proof of equivalence of parts (a) and (b) of Theorem 2.2. Suppose $J(\Sigma_a, R, S, T) < \gamma$. It follows that the cost in the optimal control problem

$$\inf_{w \in L_2[0,t]} \left\{ \|w\|_T^2 - \frac{1}{\gamma^2}\left(\|Cx\|_T^2 + x'(T)Sx(T)\right) \right\}$$

subject to the system Σ_a with $x_0 = 0$ is nonnegative. The existence of $P(t)$ satisfying the Riccati differential equation of Theorem 2.2 now follows from standard arguments in classical linear-quadratic control theory (see, e.g., Brockett [3], Limebeer et al. [10]). The rest of the proof is analogous to that of Theorem 2.3.

Equivalence of (a) and (c). We next prove the existence of $Q(t)$ with the desired properties if $J(\Sigma_a, R, S, T) < \gamma$ (respectively, $J(\Sigma_a, R, 0, \infty) < \gamma$). Since H_∞ analysis Riccati equations are seldom written in this form, our proof of this part will be in much greater detail than the one involving $P(t)$ or P. The following arguments also appear implicitly in [12] and [13].

The following Hamiltonian system plays an important role in establishing the existence of $Q(t)$:

$$(10)\begin{pmatrix} \dot{p} \\ \dot{x} \end{pmatrix} = \begin{pmatrix} -A' & -\frac{1}{\gamma^2}C'C \\ BB' & A \end{pmatrix}\begin{pmatrix} p \\ x \end{pmatrix}, \quad \begin{pmatrix} p(0) \\ x(0) \end{pmatrix} = \begin{pmatrix} Rx_0 \\ x_0 \end{pmatrix}, \quad x_0 \in \mathbf{R}^n.$$

Let the transition matrix of this system be given by

$$(11) \qquad \begin{pmatrix} p(t) \\ x(t) \end{pmatrix} = \begin{pmatrix} \Phi_{11}(t,0) & \Phi_{12}(t,0) \\ \Phi_{21}(t,0) & \Phi_{22}(t,0) \end{pmatrix}\begin{pmatrix} p(0) \\ x(0) \end{pmatrix}.$$

In the following, for any $\tau \in [0,T]$ (for the infinite horizon case $\tau \in [0,\infty)$), we will use π_τ to denote the projection operator defined as $(\pi_\tau f)(t) = f(t)$ when $t \le \tau$ and $(\pi_\tau f)(t) = 0$ for $t > \tau$. Suboptimality of J implies that for some $\delta \neq 0$, $J^2(\Sigma_a, R, S, T) < \gamma^2(1-\delta^2)$ (respectively, $J^2(\Sigma_a, R, 0, \infty) < \gamma^2(1-\delta^2)$). Now for any $\tau \in (0,T]$ (respectively, $\tau \in (0,\infty)$), this implies that

$$(12) \qquad x_0'Rx_0 + \|\pi_\tau w\|^2 - \frac{1}{\gamma^2}\|\pi_\tau(Cx)\|^2 \ge \delta^2(x_0'Rx_0 + \|\pi_\tau w\|^2)$$

for all $x(0) \in \mathbf{R}^n$ and $w \in L_2[0,\tau]$ for system (4). From observation (12) we will now show that $[\Phi_{11}(t,0)R + \Phi_{12}(t,0)]$ and $[\Phi_{21}(t,0)R + \Phi_{22}(t,0)]$ are both nonsingular for all $t \in [0,T]$ (respectively, $t \in [0,\infty)$). First, suppose, contrary to what we want to prove, that for some $\tau \in (0,T]$ (respectively, $\tau \in (0,\infty)$), $[\Phi_{11}(\tau,0)R + \Phi_{12}(\tau,0)]$ is singular. Then there exists $x_0 \neq 0$ such that $[\Phi_{11}(\tau,0)R + \Phi_{12}(\tau,0)]x_0 = 0$. Thus for system (10) with $x(0) = x_0$ and $p(0) = Rx_0$, $p(\tau) = 0$. Choosing $w(t) = B'p(t)$ for $t \in [0,\tau]$, systems (4) and (10) have the same trajectory for x. Differentiating the product $x'(t)p(t)$ along the trajectory of (10), we obtain

$$(13) \qquad \frac{d(x'p)}{dt} = w'w - \frac{1}{\gamma^2}x'C'Cx.$$

Integrating (13) from 0 to τ and noting that $p(\tau) = 0$, we get

$$x_0'Rx_0 + \|\pi_\tau w\|^2 - \frac{1}{\gamma^2}\|\pi_\tau(Cx)\|^2 = 0,$$

which is a clear contradiction to (12) since $x(0) = x_0 \neq 0$. Nonsingularity of $[\Phi_{21}(t,0)R + \Phi_{22}(t,0)]$ is shown similarly. (If $[\Phi_{21}(\tau,0)R + \Phi_{22}(\tau,0)]$ is singular for some τ, then with an appropriately chosen $x(0) \neq 0$, $x(\tau)$ is zero and we arrive at a similar contradiction.)

Next, setting $Q(t) := [\Phi_{21}(t,0)R + \Phi_{22}(t,0)][\Phi_{11}(t,0)R + \Phi_{12}(t,0)]^{-1}$, straightforward differentiation shows that $Q(t)$ satisfies the desired Riccati differential equation. Note that $Q(t)$ is nonsingular for all $t > 0$ since $[\Phi_{21}(t,0)R + \Phi_{22}(t,0)]$ is also nonsingular. Since $Q(t)$ is nonsingular for all $t \ge 0$, $Q(0) > 0$, and $Q(t)$ is a continuous function of t, it now follows that $Q(t) > 0$ for all $t > 0$.

For the following proposition, we will need the Lyapunov differential equation

$$\dot{\mathcal{C}}(t) = A\mathcal{C} + \mathcal{C}A' + BB', \qquad \mathcal{C}(0) = R^{-1}. \tag{14}$$

Since A is a constant stable matrix, $\mathcal{C}(t)$ is bounded. Let $\rho \geq \sup_{t>0} \|\mathcal{C}(t)\|$, where the norm of a matrix is defined as the largest singular value.

Before proceeding with the remainder of the proof, we state a straightforward result from quadratic optimization theory which will prove very useful in some remaining parts of the proof. (The following result can be easily proven by standard completion of squares.)

PROPOSITION 1.4. *Consider the system Σ_a given by* (4) (*in the infinite horizon case A is also stable*), *and let $R > 0$ be a given positive-definite matrix. Then for any $\tau \in [0, T]$* (*respectively, $\tau \in [0, \infty)$ for the infinite horizon case*)

$$\inf_{x(0)\in\mathbf{R}^n, w\in\mathcal{L}_2[0,\tau]} \left(\|\pi_\tau w\|^2 + x'(0)Rx(0) - \frac{1}{\gamma^2}\|\pi_\tau z\|^2 \, : \, x(\tau) = x_\tau \right) = x_\tau' Q^{-1}(\tau) x_\tau, \tag{15}$$

$$\inf_{x(0)\in\mathbf{R}^n, w\in\mathcal{L}_2[0,\tau]} (\|\pi_\tau w\|^2 + x'(0)Rx(0) \, : \, x(\tau) = x_\tau) = x_\tau' \mathcal{C}^{-1}(\tau) x_\tau \geq \frac{1}{\rho}\|x_\tau\|^2, \tag{16}$$

where ρ is defined as above.

If $J(\Sigma_a, R, S, T) < \gamma$, then,

$$\inf_{x(0)\in\mathbf{R}^n, w\in\mathcal{L}_2[0,T]} \left(\|\pi_T w\|^2 + x'(0)Rx(0) - \frac{1}{\gamma^2}\|\pi_T z\|^2 \, : \, x(T) = x_T \right) - \frac{1}{\gamma^2} x_T' S x_T > 0$$

for all $x_T \in \mathbf{R}^n$. Invoking the above proposition, it now follows that $\gamma^2 Q^{-1}(T) > S$.

For part (c) of the infinite horizon case (Theorem 2.3), it still remains to be shown that $Q(t)$ is bounded, stabilizing, and asymptotically converges to the stabilizing solution of the corresponding algebraic Riccati equation. We first show that there exists a positive number $\nu < \infty$ such that $Q(t) \leq \nu I$ for all $t > 0$. Based on Proposition 2.1, now consider the following series of inequalities:

$$\begin{aligned} x_\tau' Q^{-1}(\tau) x_\tau &= \inf_{x(0)\in\mathbf{R}^n, w\in\mathcal{L}_2[0,\tau]} \left(\|\pi_\tau w\|^2 + x'(0)Rx(0) - \frac{1}{\gamma^2}\|\pi_\tau z\|^2 : x(\tau) = x_\tau \right) \\ &\geq \delta^2 \inf_{x(0)\in\mathbf{R}^n, w\in\mathcal{L}_2[0,\tau]} (\|\pi_\tau w\|^2 + x'(0)Rx(0) : x(\tau) = x_\tau) \quad \text{from (12)} \\ &= \delta^2 x_\tau' \mathcal{C}^{-1}(\tau) x_\tau \\ &\geq \frac{\delta^2}{\rho} x_\tau' x_\tau. \end{aligned} \tag{17}$$

The above bound, which is independent of τ and true for all $x_\tau \in \mathbf{R}^n$, shows that $Q^{-1}(\tau)$ is bounded below for all $\tau > 0$ or that $Q(\tau)$ is bounded.

Now we show that the time-varying system generated by $A + (1/\gamma^2)Q(t)C'C$ is exponentially stable. The Hamiltonian system associated with the optimization problem

$$\inf_{x(0)\in\mathbf{R}^n, w\in\mathcal{L}_2[0,\tau]} \left(\|\pi_\tau w\|^2 + x'(0)Rx(0) - \frac{1}{\gamma^2}\|\pi_\tau z\|^2 \, : \, x(\tau) = x_\tau \right),$$

which has a solution for all $\tau > 0$ and $x_\tau \in \mathbf{R}^n$ when $J(\Sigma_a, R, 0, \infty) < \gamma$, can be written as

$$\begin{pmatrix} \dot{p} \\ \dot{x} \end{pmatrix} = \begin{pmatrix} -A' & -\frac{1}{\gamma^2}C'C \\ BB' & A \end{pmatrix} \begin{pmatrix} p \\ x \end{pmatrix}, \qquad \begin{pmatrix} p(0) \\ x(\tau) \end{pmatrix} = \begin{pmatrix} Rx(0) \\ x_\tau \end{pmatrix}. \tag{18}$$

The optimal w then for the above optimization problem is $w(t) = B'p(t)$ and it can be easily verified that $x(t) = Q(t)p(t)$ for all $t \in [0, \tau]$. Integrating $d(x'p)/dt$ for the system (18), we get the optimal cost for the optimization problem and similar arguments as above yield

$$\begin{aligned} x'_\tau p(\tau) &= \inf_{x(0)\in\mathbf{R}^n, w\in\mathcal{L}_2[0,\tau]} \left(\|\pi_\tau w\|^2 + x'(0)Rx(0) - \frac{1}{\gamma^2}\|\pi_\tau z\|^2 : x(\tau) = x_\tau \right) \\ &\geq \delta^2(\|\pi_\tau B'p\|^2 + x'(0)Rx(0)) \quad \text{for system (18) (from (12))} \\ &> \delta^2 \frac{1}{\gamma^2}\|\pi_\tau Cx\|^2 \quad \text{for system (18), since } J(\Sigma_a, R, 0, \infty) < \gamma. \end{aligned} \tag{19}$$

Since $x(t) = Q(t)p(t)$, for system (18), the dynamics of p can also be written as

$$\dot{p}(t) = \left[-A' - \frac{1}{\gamma^2}C'(t)C(t)Q(t) \right] p(t). \tag{20}$$

Equations (19) and (20) imply that for all $\tau > 0$ and any $p(\tau) \in \mathbf{R}^n$,

$$x'_\tau p(\tau) = p'(\tau)Q(\tau)p(\tau) > \delta^2 \frac{1}{\gamma^2}\|\pi_\tau CQp\|^2$$

for system (20). Also note that system (20), with the output CQp is detectable (to be thought of here as a system moving backward in time) since A is assumed to be asymptotically stable. Thus the above equation implies that a detectable output for system (20) is *uniformly* bounded with respect to terminal time τ and the terminal condition $p(\tau)$. From Brockett [3] it follows that system (20) is exponentially stable moving backward. Note that the forward-moving system for which we want to establish exponential stability is nothing but the adjoint of system (20).

Next we show that $\lim_{t\to\infty} Q(t)$ exists and equals Q_∞, where Q_∞ is the solution of the algebraic Riccati equation with the properties described in part (c) of Theorem 2.3. Since the system is linear time-invariant, differentiating (8) we obtain

$$\ddot{Q}(t) = \left[A + \frac{1}{\gamma^2}Q(t)C'C \right] \dot{Q}(t) + \dot{Q}(t) \left[A + \frac{1}{\gamma^2}Q(t)C'C \right]'.$$

Since we have already established exponential stability of $A + (1/\gamma^2)Q(t)C'C$, it follows that $\dot{Q}(t)$ approaches 0 exponentially as t goes to ∞. Therefore, $\lim_{t\to\infty} Q(t)$ exists. Let $\lim_{t\to\infty} Q(t) = \bar{Q}$. Then $\bar{Q}$ satisfies the algebraic Riccati equation given in part (c) of Theorem 2.3. By using standard results on the stability of linear time-varying systems that are asymptotically time invariant, it follows that $A + (1/\gamma^2)\bar{Q}C'C$ is asymptotically stable. Since the stabilizing solution of the algebraic Riccati equation is unique, we conclude that $\bar{Q} = Q_\infty$.

It now remains to establish that (c) $\Rightarrow$ (a). We first consider Theorem 2.2. It is easily seen that

$$\frac{d(x'Q^{-1}x)}{dt} = w'w - \frac{1}{\gamma^2}x'C'Cx - [w - B'Q^{-1}x]'[w - B'Q^{-1}x]. \tag{21}$$

Integrating the above from 0 to T, we obtain

$$\begin{aligned} &x'(0)Rx(0) + \|w\|_T^2 - \frac{1}{\gamma^2}[\|z\|_T^2 + x'(T)Sx(T)] \\ (22) \qquad &= x'(T)\left[Q^{-1}(T) - \frac{1}{\gamma^2}S\right]x(T) + \|w - B'Q^{-1}x\|_T^2 \geq 0. \end{aligned}$$

To show that $J(\Sigma_a, R, S, T) < \gamma$, we still need to show that there exists a $\delta > 0$ such that the right-hand side of (22) is greater than or equal to $\delta^2(x_0'Rx_0 + \|w\|_T^2)$. Towards this goal, consider the mapping

$$\Gamma : \mathbf{R}^n \oplus L_2[0,T] \to \mathbf{R}^n \oplus L_2[0,T] : \ (x(0), w) \to (x(T), r),$$

where $r := w - B'Q^{-1}x$. On the domain of Γ, define the inner product:

$$\langle (x_1, w_1), (x_2, w_2) \rangle := x_1'Rx_2 + \langle w_1, w_2 \rangle_{L_2[0,T]},$$

where $\langle \cdot, \cdot \rangle_{L_2[0,T]}$ is the usual inner product in $L_2[0,T]$. On the co-domain of Γ, define the inner product:

$$\langle (x_1, r_1), (x_2, r_2) \rangle := x_1'\left[Q^{-1}(T) - \frac{1}{\gamma^2}S\right]x_2 + \langle w_1, w_2 \rangle_{L_2[0,T]}.$$

It can be easily verified that Γ is an invertible operator. Indeed, let $(x_T, r) \in \mathbf{R}^n \oplus L_2[0,T]$ be given. Then the following system

$$(23) \qquad \begin{aligned} &\dot{x} = (A + BB'Q^{-1})x + Br, \qquad x(T) = x_T, \\ &x(0) = x(0), \qquad w = r + B'Q^{-1}x, \end{aligned}$$

is the inverse of Γ. We will denote the inverse of Γ given by the above equations as Γ^{-1}. Since the problem is over finite horizon, Γ^{-1} has a bounded norm. From (22) we thus obtain

$$\begin{aligned} x'(0)Rx(0) + \|w\|_T^2 - \frac{1}{\gamma^2}[\|z\|_T^2 + x'(T)Sx(T)] &= x'(T)\left[Q^{-1}(T) - \frac{1}{\gamma^2}S\right]x(T) + \|r\|_T^2 \\ &\geq \frac{1}{\|\Gamma^{-1}\|^2}(x'(0)Rx(0) + \|w\|_T^2). \end{aligned}$$

It now follows that $J(\Sigma_a, R, S, T) < \gamma$.

Next we show that if part (c) of Theorem 2.3 is satisfied then $J(\Sigma_a, R, 0, \infty) < \gamma$. If the system Σ_a given in (4) is time invariant and stable, and the inner product on the domain of Σ_a ($\mathbf{R}^n \oplus L_2[0,\infty]$) is the same as in the domain of Γ defined above, then it is easily seen that Σ_a^*, the adjoint of Σ_a is given by

$$\Sigma_a^* : L_2[0,\infty) \to \mathbf{R}^n \oplus L_2[0,\infty),$$

$$(24) \qquad \begin{aligned} &\frac{dx_a}{dt} = -A'x_a - C'w_a, \qquad \lim_{t\to\infty} x_a(t) = 0, \\ &z_a = B'x_a, \\ &(\Sigma_a^* w_a)(t) = \begin{bmatrix} R^{-1}x_a(0) \\ z_a(t) \end{bmatrix}. \end{aligned}$$

(Since A is a Hurwitz matrix, it is not difficult to see that given any w_a in $L_2[0,\infty)$, there is a unique x_a in $L_2[0,\infty)$ that satisfies the state equation in (24).) To show $J(\Sigma_a, R, 0, \infty) < \gamma$ is equivalent to showing that $\|\Sigma_a\| = \|\Sigma_a^*\| < \gamma$. For showing $\|\Sigma_a^*\| < \gamma$, from (24) it follows that we must show

$$\sup_{0 \neq w_a \in \mathcal{L}_2[0,\infty)} \frac{x_a'(0)R^{-1}x_a(0) + \|z_a\|^2}{\|w_a\|^2} < \gamma^2.$$

We easily show that for the adjoint system given by (24),

$$\frac{d(x_a'Q(t)x_a)}{dt} = -\gamma^2 w_a'w_a + z_a'z_a + \left[\gamma w_a - \frac{1}{\gamma}CQ(t)x_a\right]' \left[\gamma w_a - \frac{1}{\gamma}CQ(t)x_a\right].$$

Integrating above from 0 to ∞, we obtain

$$(25) \quad \gamma^2\|w_a\|^2 = \|z_a\|^2 + x_a'(0)R^{-1}x_a(0) + \|v\|^2 \quad \text{where } v := \gamma w_a - \frac{1}{\gamma}CQx_a.$$

The adjoint system (24) can be written in terms of v as

$$\frac{dx_a}{dt} = -\left[A + \frac{1}{\gamma^2}Q(t)C'C\right]' x_a - \frac{1}{\gamma}C'v, \qquad \lim_{t\to\infty} x_a(t) = 0.$$

From the stabilizing property of $A + (1/\gamma^2)Q(t)C'C$, it follows that the above system is exponentially stable moving backward in time. Thus the map from v to w_a is continuous, and hence is bounded, and because of the boundary conditions, $v = 0 \Leftrightarrow w_a = 0$. Thus there exists an $\epsilon > 0$, such that $\|v\|^2 \geq \epsilon\|w_a\|^2$ for all v. This observation together with (25) shows that $\|\Sigma_a^*\| < \gamma$ or, equivalently, $J(\Sigma_a, R, 0, \infty) < \gamma$. □

To make our exposition more lucid, we will make certain simplifying assumptions in this paper. These assumptions are the same as in Doyle et al. [5]. We will assume the following:

(A1) $D_{11} = D_{22} = 0$.

(A2) $D_{12}'[\, C_1 \;\; D_{12}\,] = [\, 0 \;\; I\,]$.

(A3) $D_{21}[\, B_1' \;\; D_{21}'\,] = [\, 0 \;\; I\,]$.

For the infinite horizon case, we will also assume that

(A4) (A, B_1, C_1) is stabilizable and detectable.

(A5) (A, B_2, C_2) is stabilizable and detectable.

Assumption (A1) implies that there is no direct transmission from the exogenous input to regulated output and from the control input to the measured output. The latter assumption ensures that any proper controller leads to a well-posed feedback system. Assumption (A2) is quite common in the LQG literature and is tantamount to assuming that there is no *cross term* in the expression for $\|z\|^2$ and that the penalty on the control input u is normalized, i.e.,

$$\|z\|^2 = \|C_1x\|^2 + \|u\|^2.$$

Assumption (A3) is the dual of assumption (A2) and is analogous to the standard assumption in the Kalman filtering problem that the process noise and the measurement noise are uncorrelated and that the measurement noise is nonsingular and normalized. Assumption (A4) is a technical assumption and is a sufficient condition for certain systems to not have invariant zeros on the imaginary axis. Assumption (A5) is necessary and sufficient to guarantee the existence of an internally stabilizing controller for the system Σ. Assumption (A5) is not required in the finite horizon problems. The reader is referred to Glover and Doyle [7], [8], Safonov, Limebeer, and Chiang [14], and Zhou and Khargonekar [19] on techniques for removing assumptions (A1)–(A4).

2. Main results.

In this section, we state the principal contributions of this paper. Each result presents a necessary and sufficient condition for the solvability of a problem. These necessary and sufficient conditions are stated in terms of existence and properties of solutions to certain (algebraic and differential) Riccati equations. In the event the necessary conditons are met, a state-space formula for a particular (central) solution to the problem is given.

The first result treats the finite horizon state-feedback/full-information problem.

THEOREM 2.1. *Consider the system Σ as in* (1) *with $y = (x' \;\; w')'$. Let R, S be given symmetric matrices such that S is positive semidefinite and R is positive definite.*

(a) *There exists an admissible controller K such that*

$$J(\Sigma_{cl}, R, S, T) < \gamma$$

if and only if there exists a (*unique*) *symmetric matrix function $P(t), t \in [0, T]$ such that*

$$(26) \quad -\dot{P}(t) = A'P(t) + P(t)A + P(t)\left[\frac{1}{\gamma^2}B_1B_1' - B_2B_2'\right]P(t) + C_1'C_1, P(T) = S$$

and $P(0) < \gamma^2 R$.

(b) *In this case, the control law*

$$u(t) = -B_2'P(t)x(t) \tag{27}$$

achieves $J(\Sigma_{cl}, R, S, T) < \gamma$.

The next result addresses the state-feedback/full-information problem in the infinite horizon case.

THEOREM 2.2. *Consider the system Σ as in* (1) *with $y = (x' \;\; w')'$. Let R be a given positive-definite matrix.*

(a) *There exists an admissible controller K such that*

$$J(\Sigma_{cl}, R, 0, \infty) < \gamma$$

if and only if there exists a unique symmetric matrix P such that

$$(28) \quad \begin{array}{ll} \text{(i)} & A'P + PA + P\left(\frac{1}{\gamma^2}B_1B_1' - B_2B_2'\right)P + C_1'C_1 = 0, \\ \text{(ii)} & A + \left(1/\gamma^2)B_1B_1' - B_2B_2'\right)P \quad \textit{is asymptotically stable, and} \\ \text{(iii)} & 0 \leq P < \gamma^2 R. \end{array}$$

(b) *In this case, the control law*

$$u(t) = -B_2'Px(t) \tag{29}$$

achieves $J(\Sigma_{cl}, R, 0, \infty) < \gamma$.

In Theorems 2.1 and 2.2, the necessary conditions are established under the assumption that the controller has access to both x and w. Thus, the necessary conditons would still apply even if the controller has access only to the state x. On the other hand, if the necessary conditons for the existence of controllers are met, one control law that achieves specified performance bounds uses only the knowledge of the state x.

It is interesting to note that as γ approaches ∞, the solution given above approaches the standard solution to the finite and infinite horizon linear-quadratic regulator problem. For example, the Riccati differential equation in Theorem 2.1 approaches the corresponding Riccati equation of the linear-quadratic regulator problem with a terminal cost. Also, the necessary condition $P(0) < \gamma^2 R$ is trivially satisfied as γ approaches ∞. This is intuitively appealing since as γ approaches ∞, the performance requirement $J(\Sigma_{cl}, R, S, T) < \gamma$ becomes trivial, and the solution approaches the solution to the optimal linear-quadratic regulator problem. Analogous comments apply to the infinite-horizon case and also to the results to follow. Similar behavior has been noted previously in Doyle et al. [5] for central solutions to the standard H_∞ control problems.

Another interesting feature of Theorems 2.1 and 2.2 is the decoupling in the necessary conditions. The matrix R plays no role in the solutions of the (algebraic and differential) Riccati equations. In fact, if the required solutions exist, they are unique. Once these solutions have been found, we need to check whether $P(0) < \gamma^2 R$ (respectively, $0 \leq P < \gamma^2 R$) hold. It is interesting to note that the control law does not depend on R. As will be discussed below, the situation is quite different in output-feedback problems. There the control law depends on R explicitly. An intuitive explanation of this feature will be given following the statement of Theorem 3.4.

We next consider the output-feedback problem on a finite horizon.

THEOREM 2.3. *Consider the system Σ as in* (1). *Let R, S be given symmetric matrices such that S is positive semidefinite and R is positive definite.*

(a) *There exists an admissible output feedback controller K such that with the control law $u = Ky$,*

$$J(\Sigma_{cl}, R, S, T) < \gamma$$

if and only if the following three conditions hold:

(i) *There exists a symmetric matrix function $P(t)$ such that*

$$(30)\quad \begin{gathered} -\dot{P}(t) = A'P(t) + P(t)A + P(t)\left[\frac{1}{\gamma^2}B_1B_1' - B_2B_2'\right]P(t) + C_1'C_1, \\ P(T) = S \end{gathered}$$

and $P(0) < \gamma^2 R$.

(ii) *There exists a symmetric matrix function $Q(t) > 0$ for all $t \in [0, T]$ such that*

$$(31)\dot{Q}(t) = AQ(t) + Q(t)A' - Q(t)\left[C_2'C_2 - \frac{1}{\gamma^2}C_1C_1'\right]Q(t) + B_1B_1',$$

with $Q(0) = R^{-1}$.

(iii) *$\rho(1/\gamma^2 P(t)Q(t)) < 1$ for all $t \in [0, T]$.*

(b) *If the above conditions are met, then one controller that achieves*

$$J(\Sigma_{cl}, R, S, T) < \gamma$$

is given by

$$\begin{aligned} \frac{d\hat{x}(t)}{dt} &= \left[A + \frac{1}{\gamma^2} B_1 B_1' P\right] \hat{x}(t) + \left[I - \frac{1}{\gamma^2} Q(t) P\right]^{-1} \\ &\quad \cdot Q(t) C_2' [y(t) - C_2 \hat{x}(t)] + B_2 u(t), \\ \hat{x}(0) &= 0, \\ u(t) &= -B_2' P \hat{x}(t), \end{aligned} \tag{32}$$

(In the above theorem $\rho(\cdot)$ denotes the spectral radius.)

The next result gives a solution for the output-feedback problem in the infinite horizon case for linear time-invariant systems.

THEOREM 2.4. *Consider the system Σ as in* (1). *Let R be a given positive-definite matrix.*

(a) *There exists an admissible output-feedback controller K such that with the control law $u = Ky$,*

$$J(\Sigma_{cl}, R, 0, \infty) < \gamma$$

if and only if the following three conditions hold:

(i) *There exists a* (*unique*) *symmetric matrix P such that*

$$A'P + PA + P\left(\frac{1}{\gamma^2} B_1 B_1' - B_2 B_2'\right) P + C_1' C_1 = 0, \tag{33}$$

with $A + ((1/\gamma^2) B_1 B_1' - B_2 B_2') P$ being asymptotically stable and $\gamma^2 R > P \geq 0$.

(ii) *There exists a symmetric bounded matrix function $Q(t) > 0$ for all $t \geq 0$ such that*

$$\dot{Q}(t) = AQ(t) + Q(t)A' + [\frac{1}{\gamma^2} C_1 C_1' - Q(t)[C_2' C_2] Q(t) + B_1 B_1', Q(0) = R^{-1}. \tag{34}$$

and the unforced linear time-varying system

$$\dot{p}(t) = \left[A - Q(t)\left(C_2' C_2 - \frac{1}{\gamma^2} C_1' C_1\right)\right] p(t) \tag{35}$$

is exponentially stable.

(iii) *The function $(1 - \rho((1/\gamma^2) Q(t) P))^{-1} > 0$ for all $t \geq 0$ and is bounded.*

(b) *Moreover, if $Q(t)$ with above properties exists for all $t \geq 0$, then $\lim_{t \to \infty} Q(t)$ exists and equals Q_∞, where Q_∞ is the unique symmetric matrix with the following properties:*

$$A Q_\infty + Q_\infty A' - Q_\infty \left(C_2' C_2 - \frac{1}{\gamma^2} C_1' C_1\right) Q_\infty + B_1 B_1' = 0, \tag{36}$$

$A - Q_\infty \left[C_2' C_2 - (1/\gamma^2) C_1' C_1\right]$ is asymptotically stable, and $Q_\infty \geq 0$.

(c) *If the conditions above are met, then one controller that achieves $J(\Sigma_{cl}, R, 0, \infty) < \gamma$ is given by*

$$\begin{aligned} \frac{d\hat{x}(t)}{dt} &= \left[A + \frac{1}{\gamma^2}B_1B_1'P\right]\hat{x}(t) + \left[I - \frac{1}{\gamma^2}Q(t)P\right]^{-1} \\ &\quad \cdot Q(t)C_2'[y(t) - C_2\hat{x}(t)] + B_2u(t), \\ \hat{x}(0) &= 0 \\ u(t) &= -B_2'P\hat{x}(t), \end{aligned} \tag{37}$$

It should be noted that as in Doyle et al. [5], the necessary and sufficient conditions for the existence of controllers in the output-feedback problems are two decoupled Riccati equations and a "spectral radius" condition.

From the formulae for the controllers, we note that in contrast to the state-feedback problems, the initial condition weighting matrix R plays an important role in the controller formulae in the output-feedback problems. An intuitive explanation for this phenomenon is as follows. In the state-feedback problem, since the entire state is available for feedback, there is no uncertainty in the initial state as far as the controller is concerned. The only issue in the state-feedback case is whether the desired performance bound is achievable. This is verified by checking the inequalities $P(0) < \gamma^2 R$ in the finite-horizon case and $0 < P < \gamma^2 R$ in the infinite-horizon case. On the other hand, in the output-feedback case, the controller does not have complete knowledge of the initial state. Consequently, the controller gains depend on the relative weighting between the uncertainty in the initial state vis-à-vis that in the exogenous input w to satisfy the desired performance bound for all w and $x(0)$. Also, the controller gains change with time reflecting the relative importance of the information contained in measurements as compared to the prior information on the initial state. Finally, we would like to note that in the infinite time horizon case, as $t \to \infty$, the controller approaches the central controller for an associated standard H_∞ problem. This is intuitively appealing since assuming that the controller is internally stabilizing, as $t \to \infty$, the effect of nonzero initial states should disappear and the controller should be required only to attenuate the effect of exogenous signals w on z. This is exactly how the controller given in Theorem 2.4 behaves.

For sufficiently large R, the steady-state central controller itself has sufficient robustness to account for uncertainty due to unknown initial condition and we need not necessarily require a linear time-varying controller to achieve the desired performance. This is formally stated in the following result.

COROLLARY 2.5. *Let the conditions of Theorem* 3.4 *be satisfied and* R *be such that* $R^{-1} < Q_\infty$. *Then the linear time-invariant controller of the form given in Theorem* 3.4(c) *with* Q_∞ *replacing* $Q(t)$ *achieves* $J(\Sigma_{cl}, R, 0, \infty) < \gamma$.

3. Proofs.

Without loss of generality, we will assume that $\gamma = 1$.

Proof of Theorem 3.2. Suppose that both x, w are available as measurements to the controller and suppose that there exists a controller such that $J(\Sigma_{cl}, R, 0, \infty) < 1$. Then it follows from Lemma 2.1 that for the system Σ with $x_0 = 0$, we have

$$\sup_w \inf_u \frac{\|z\|}{\|w\|} < 1.$$

From Doyle et al. [5], it follows that there exists $P \geq 0$ such that P satisfies (28) and $(A + B_1B_1'P - B_2B_2'P)$ is asymptotically stable. It remains to be shown that $P < R$. We will prove this by contradicition.

Suppose that there exists $x_0 \neq 0$ such that $x_0'(P - R)x_0 \geq 0$. Now in the system Σ, set $x(0) = x_0$ and $w(t) = B_1'Pe^{(A+(B_1B_1'-B_2B_2')P)t}x_0$. Using the fact that

$A + (B_1B_1' - B_2B_2')P$ is asymptotically stable, it follows that w belongs to $L_2[0, \infty)$. For this particular w, we claim that

$$\sup_u \{ \ \|w(t)\|^2 - \|z(t)\|^2 \ \} = -x_0'Px_0.$$

Indeed, the (unique) optimal input u for the above optimal control problem and the corresponding state trajectory are

$$u(t) = \hat{u}(t) = -B_2'Pe^{(A+(B_1B_1'-B_2B_2')P)t}x_0,$$

$$\hat{x}(t) = e^{(A+(B_1B_1'-B_2B_2')P)(t-\tau)}x_0.$$

This can be shown, for example, by noting that for any $w \in L_2[0, \infty)$, the optimal u denoted by $\hat{u}$ is obtained from the following two-point boundary value problem

$$\begin{pmatrix} \dot{p} \\ \dot{x} \end{pmatrix} = \begin{pmatrix} -A' & C_1'C_1 \\ B_2B_2' & A \end{pmatrix} \begin{pmatrix} p \\ x \end{pmatrix} + \begin{pmatrix} 0 \\ B_1w \end{pmatrix}, \quad x(0) = x_0, \quad \lim_{t\to\infty} p(t) = 0,$$

$$\hat{u}(t) = B_2'p(t).$$

The above claim now follows by directly verifying that $p(t) = -Pe^{(A+(B_1B_1'-B_2B_2')P)t}x_0$. (Similar optimization plays an important role in Tadmor [15].)

Using this observation and the fact that $J(\Sigma_{cl}, R, 0, \infty) < 1$, it follows that

$$0 < x_0'Rx_0 + \|w\|^2 - \|z\|^2 \leq x_0'Rx_0 + \sup_u\{\|w\|^2 - \|z\|^2\} = x_0'(R-P)x_0 \leq 0,$$

which is a contradiction.

If there exists a $P \geq 0$ such that P satisfies (28) and $(A + B_1B_1'P - B_2B_2'P)$ is asymptotically stable, then using detectability of (A, C_1), standard Lyapunov techniques and a completion of squares argument together with $P < R$ can be employed to show that the control law (27) is internally stabilizing and achieves the desired performance bound. □

Proof of Theorem 3.1. Suppose that both x, w are available to the controller and suppose that there exists a controller such that $J(\Sigma_{cl}, R, S, T) < 1$. Now consider the system Σ with $x_0 = 0$. Then it follows that

$$\sup_w \inf_u \frac{\|z\|_T^2 + x(T)'Sx(T)}{\|w\|_T^2} < 1.$$

(The supremum and the infimum above are conducted over signals $w, u \in L_2[0, T]$.) Using the approach of Limebeer et al. [10] (which involves conjugate point analysis for a certain two-point boundary value problem associated with the quadratic game), it can be shown that there exists a $P(t)$ that satisfies (26). The details are omitted for the sake of brevity.

To complete the necessity it remains to be shown that $P(0) < R$. Suppose to the contrary that there exists $x_0 \neq 0$ such that $x_0'(R - P(0))x_0 \leq 0$. By differentiating $x'Px$ along the trajectories of Σ, and completing squares we obtain

$$(38) \quad \frac{d(x'Px)}{dt} = [u + B_2'Px]'[u + B_2'Px] - [w - B_1'Px]'[w - B_1'Px] + w'w - z'z.$$

With $x(0) = x_0$ and $w(t) = B_1'P(t)x(t)$, integrating the expression above from 0 to T yields

$$0 < x'(0)Rx(0) + \|w\|_T^2 - \|z\|_T^2 - x'(T)Sx(T) = x_0'(R-P)x_0 - \|u + B_2'Px\|_T^2 \leq 0,$$

which is a contradiction.

The proof of sufficiency in Theorem 3.1 follows readily by integrating (38) from 0 to T, and is omitted. □

Proofs of Theorems 3.3, 3.4, *and Corollary* 3.5.

Sufficiency proofs for Theorems 3.3 *and* 3.4. Here we show that if the solutions to the corresponding algebraic and differential Riccati equations of Theorems 3.3 and 3.4 exist and satisfy the required properties, then the controllers given by (32) and (37) achieve the desired performance bound. We consider the finite horizon and infinite horizon cases separately.

Finite horizon case. Integrating (38) from 0 to T, it is easily seen that

$$\begin{aligned} &x'(0)Rx(0) + \|w\|_T^2 - \|z\|_T^2 - x'(T)Sx(T) \\ &= x'(0)(R - P(0))x(0) + \|w - B_1'Px\|_T^2 - \|u + B_2'Px\|_T^2. \end{aligned} \tag{39}$$

We will show that if we use the controller (32) then there exists an $\epsilon > 0$ such that the right-hand side in the above equation is no less than $\epsilon(x'(0)Rx(0) + \|w\|_T^2)$. This will establish our claim that this controller achieves $J(\Sigma_{cl}, R, S, T) < 1$.

Let $Z(t) := [I - Q(t)P(t)]^{-1}Q(t)$. From conditions (a)-(i) and (a)-(ii) of Theorem 3.3, we obtain

$$\begin{aligned} \dot{Z}(t) &= [A + B_1B_1'P(t)]Z(t) + Z(t)[A + B_1B_1'P(t)]' \\ &\quad + Z(t)[P(t)B_2B_2'P(t) - C_2'C_2]Z(t) + B_1B_1' \end{aligned} \tag{40}$$

with

$$Z(0) = [R - P(0)]^{-1}.$$

Let $e := x - \hat{x}$, $r := w - B_1'Px$, $\nu := u + B_2'Px$ and $A_{tmp} := A + B_1B_1'P$. Consider the mapping

$$\Gamma_a : \mathbf{R}^n \oplus L_2[0,T] \to L_2[0,T] : \ (x(0), r) \to \nu.$$

In $\mathbf{R}^n \oplus L_2[0,T]$, (the domain of Γ_a), we define the following inner product:

$$\langle (x_1, r_1), (x_2, r_2) \rangle := x_1'(R - P(0))x_2 + \langle r_1, r_2 \rangle_{L_2[0,T]},$$

where $\langle \cdot, \cdot \rangle_{L_2[0,T]}$ is the usual inner product in $L_2[0,T]$. Fairly straightforward algebra reveals that if we use the controller (32), the system Γ_a can be realized as

$$\dot{e} = (A_{tmp} - ZC_2'C_2)e + (B_1 - ZC_2'D_{21})r, e(0) = x(0), \tag{41}$$

$$\nu = B_2'Pe.$$

It then follows from (40) and Theorem 2.2 that $J(\Gamma_a, R - P(0), 0, T) < 1$. This implies that if we use the controller (32) then there exists an $\epsilon > 0$ such that for all $(x(0), r) \in \mathbf{R}^n \oplus L_2[0,T]$,

$$x'(0)(R-P)x(0) + \|r\|_T^2 - \|\nu\|_T^2 \geq \epsilon(x'(0)(R-P)x(0) + \|r\|_T^2). \tag{42}$$

Next observe simply from the definition of r that the map $(x(0), w) \to (x(0), r)$ is an invertible finite-dimensional linear system and *since we are dealing with finite horizon problems,* this map and its inverse both are bounded. Thus there exists a $M > 0$ such that for all $(x(0), w) \in \mathbf{R}^n \oplus L_2[0, T]$,

$$x'(0)(R-P)x(0) + \|r\|_T^2 \geq M(x'(0)Rx(0) + \|w\|_T^2). \tag{43}$$

Combining the above two observations, we conclude that, using the controller (32),

$$x'(0)(R-P)x(0)+\|r\|_T^2-\|\nu\|_T^2 \geq \epsilon(x'(0)(R-P)x(0)+\|r\|_T^2) \geq \epsilon M(x'(0)Rx(0)+\|w\|_T^2) \tag{44}$$

for all $(x(0), w) \in \mathbf{R}^n \oplus L_2[0, T]$. From (39) It follows that that this controller achieves $J(\Sigma_{cl}, R, S, T) < 1$.

Infinite horizon case. Here we first need to show the internal stability of the closed-loop system. This is actually quite easy. Note that as t approaches ∞, the controller (37) approaches a linear time-invariant controller. Indeed, from condition (b) in the Theorem 3.4, it follows that the controller (37) approaches the so-called central solution in Doyle et al. [5]. It follows from Theorem 3 of Doyle et al. [5] that the asymptotic limit of the controller (37) internally stabilizes the system Σ. Now using standard results on the stability of linear time-varying systems, which are asymptotically time-invariant, it follows that (37) internally exponentially stabilizes Σ.

Showing that the controller (37) achieves $J(\Sigma_{cl}, R, 0, \infty) < 1$ follows the same lines as the finite horizon case. The only place where the finite horizon case arguments need further elaboration to be applicable here is in establishing (43). For establishing (43), it is sufficient to show that the operator from $(x(0), r) \to (x(0), w)$ is bounded. Toward that end we first show that the system Γ_a described by (41) is exponentially stable. Equation (40) can also be written as

$$\begin{aligned}\dot{Z}(t) = [A_{tmp} - ZC_2'C_2]Z(t) - Z(t)[A_{tmp} - ZC_2'C_2]' \\ +Z(t)[P(t)B_2B_2'P(t) + C_2'C_2]Z(t) + B_1B_1',\end{aligned}$$

where $A_{tmp} := A + B_1B_1'P(t)$. Since (A, B_1) is stabilizable, it follows that the pair $([A_{tmp} - ZC_2'C_2], [ZC_2' \;\; B_1])$ is also stabilizable. Existence of a bounded positive semidefinite Z with this stabilizability observation and an extension of the standard lemma of Lyapunov (see, Ravi, Nagpal, and Khargonekar [13]) implies that $A_{tmp} - ZC_2'C_2$ is exponentially stable.

With the controller (37) applied to the plant Σ, the closed-loop system equations can be written as (with $e := x - \hat{x}$)

$$\begin{aligned}\begin{pmatrix} \dot{x} \\ \dot{e} \end{pmatrix} = \begin{pmatrix} A + (B_1B_1' - B_2B_2')P & B_2'P \\ 0 & A_{tmp} - ZC_2'C_2 \end{pmatrix} \begin{pmatrix} x \\ e \end{pmatrix} \\ + \begin{pmatrix} B_1 \\ B_1 - ZC_2'D_{21} \end{pmatrix} r.\end{aligned} \tag{45}$$

Since $A + (B_1B_1' - B_2B_2')P$ and $A_{tmp} - ZC_2'C_2$ are both exponentially stable, the above system is exponentially stable. Thus the operator from $(x(0), r) \to (x(0), w)$ is bounded.

Proof of Corollary 3.5. The above arguments show that the linear time-invariant controller obtained by substituting Q_∞ in (37) for $Q(t)$ achieves $J(\Sigma_{cl}, Q_\infty^{-1}, 0, \infty) < 1$.

Since $R > Q_\infty^{-1}$, from Lemma 2.1 it follows that $J(\Sigma_{cl}, R, 0, \infty) \le J(\Sigma_{cl}, Q_\infty^{-1}, 0, \infty) < 1$.

Necessity of Theorems 3.3 *and* 3.4. Given a controller for which $J(\Sigma_{cl}, R, S, T) < \gamma$, (respectively, $J(\Sigma_{cl}, R, 0, \infty) < \gamma$,) condition (i) in Theorems 3.3 and 3.4 follows from the proof of Theorems 3.1 and 3.2.

As before, for any $\tau \in (0, T]$ (for the infinite horizon case $\tau \in (0, \infty)$), let π_τ denote the projection operator defined as $(\pi_\tau f)(t) = f(t)$ when $t \le \tau$ and $(\pi_\tau f)(t) = 0$ for $t > \tau$.

To show the existence of (31) and (34), we will use the results from Nagpal and Khargonekar [12]. We begin this with a simple but important observation. Suppose that $y(t) = 0$ for $t \in [0, \tau]$. Then since the controller is linear and causal, $u(t)$ must equal 0 for $t \in [0, \tau]$. (This property holds for internally stabilizing nonlinear time-varying causal controllers as well where internal stability is taken to mean finite gain L_2 stability.) A similar observation plays a central role in the work of Nagpal and Khargonekar [12] and this allows us to make use of some of their results in the present context.

Let $D_{21}^{\perp}$ be such that

$$\begin{bmatrix} D_{21} \\ D_{21}^{\perp} \end{bmatrix} \begin{bmatrix} D_{21} \\ D_{21}^{\perp} \end{bmatrix}' = I. \tag{46}$$

Such a $D_{21}^{\perp}$ exists due to assumption (A3). For any $\tau \in (0, T]$ (for the infinite horizon case $\tau \in (0, \infty)$), define

$$\text{(47)}\ W(\tau) := \{w \in L_2[0, T] : w(t) = -D_{21}' C_2 x(t) + D_{21}^{\perp\prime} v(t), t \in [0, \tau], v \in L_2[0, \tau]\}.$$

For any $w \in W(\tau)$, we easily observe that for all $t \in [0, \tau]$, $y(t) = 0$. Therefore, $u(t) = 0$, for all $t \in [0, \tau]$. Consequently, for $w \in W(\tau)$, the equations for (1) in the interval $t \in [0, \tau]$ become

$$\begin{aligned} \frac{dx}{dt} &= Ax + B_1 D_{21}^{\perp\prime} v, \qquad t \in [0, \tau], \\ z &= C_1 x, \\ y &= 0, \\ \|\pi_\tau w\|^2 &= \|\pi_\tau (C_2 x)\|^2 + \|\pi_\tau v\|^2. \end{aligned} \tag{48}$$

Since we are dealing with existence of suboptimal controllers, if there exists a controller such that $J^2(\Sigma_{cl}, R, 0, \infty) < 1$, then there also exists a controller such that $J^2(\Sigma_{cl}, R, 0, \infty) < 1 - \delta^2$ for some $\delta \neq 0$. Now for any $\tau \in (0, T]$ (for the infinite horizon case $\tau \in (0, \infty)$), let $w \in W(\tau)$. Then existence of a controller that achieves $J^2(\Sigma_{cl}, R, 0, \infty) < 1 - \delta^2$ implies that

$$\begin{aligned} & x_0' R x_0 + \|\pi_\tau v\|^2 + \|\pi_\tau (C_2 x)\|^2 - \|\pi_\tau (C_1 x)\|^2 \\ & \ge \delta^2 (x_0' R x_0 + \|\pi_\tau v\|^2 + \|\pi_\tau (C_2 x)\|^2) \end{aligned} \tag{49}$$

for all $x(0) \in \mathbf{R}^n$ and $v \in L_2[0, \tau)$ for system (48). From Nagpal and Khargonekar [12, Thms. 3, 4], the above inequality implies (a)-(ii) for Theorem 3.3 and (a)-(ii) and (b) for Theorem 3.4.

To obtain conditions (a)-(iii) of Theorems 3.3 and 3.4, we use the "separation" idea from Khargonekar [9]. This "separation" idea is roughly as follows : 1) We separate the time interval of the original problem into two subintervals; 2) during the first part, w is chosen so that $y \equiv 0$ (thus during this interval $u \equiv 0$); and 3) in the second interval, one chooses the "worst" w in an appropriate sense (which will soon become clear). Such a choice of w together with the inequality implied by the existence of a controller that achieves $J(\Sigma_{cl}, R, S, T) < 1$ (respectively, $J(\Sigma_{cl}, R, 0, \infty) < 1$ for the infinite horizon case), would lead us to conclude conditions (iii) of the two theorems.

Fix $\tau \in (0, T]$ (respectively, $\tau \in (0, \infty)$) and $x_\tau \in \mathbf{R}^n$. Let $w \in W(\tau)$ such that $v(t) = D_{21}^{\perp}B_1'Q^{-1}(t)x(t)$ for $t \in [0, \tau]$. With this choice of $x(\tau)$ and $v(t)$, it is easily seen by completion of squares that for system (48),

$$\begin{aligned} x_\tau'Q^{-1}(\tau)x_\tau &= x(0)'Rx(0) + \|\pi_\tau v\|^2 + \|\pi_\tau(C_2x)\|^2 - \|\pi_\tau(C_1'x)\|^2 \\ &= x(0)'Rx(0) + \|\pi_\tau w\|^2 - \|\pi_\tau z\|^2. \end{aligned} \tag{50}$$

We now consider the finite and the infinite horizon cases separately.

Finite horizon case. Fix $\tau \in (0, T]$ and $x_\tau \in \mathbf{R}^n$ and let $w \in W(\tau)$ be chosen as in the last paragraph. For $t \in (\tau, T]$, let $w(t) = B_1'P(t)x(t)$. Now integrating (38) from τ to T, we get

$$\begin{aligned} &\|(I - \pi_\tau)w\|^2 - \|(I - \pi_\tau)z\|^2 - x(T)'Sx(T) \\ &= -x_\tau'P(\tau)x_\tau - \|(I - \pi_\tau)(u + B_2'Px)\|^2. \end{aligned} \tag{51}$$

Combining (50) and (51) we obtain

$$\begin{aligned} 0 &\le x_0'Rx_0 + \|w\|_T^2 - \|z\|_T^2 - x(T)'Sx(T) \\ &= \{x(0)'Rx(0) + \|\pi_\tau w\|^2 - \|\pi_\tau z\|^2\} + \{\|(I - \pi_\tau)w\|^2 - \|(I - \pi_\tau)z\|^2 - x(T)'Sx(T)\} \\ &= x_\tau'[Q^{-1}(\tau) - P(\tau)]x_\tau - \|(I - \pi_\tau)(u + B_2'Px)\|^2. \end{aligned}$$

As the first inequality is *strict* for all $0 \ne x_\tau \in \mathbf{R}^n$, (since in this case either $w \ne 0$ or $x(0) \ne 0$), condition (iii) of Theorem 3.3 follows.

Infinite horizon case. Fix $\tau \in (0, \infty)$ and $x_\tau \in \mathbf{R}^n$ and let $w \in W(\tau)$ be chosen as in the finite horizon case. For $t \in (\tau, \infty)$, let $w(t) = B_1'Pe^{(A+(B_1B_1'-B_2B_2')P)(t-\tau)}x(\tau)$. Using the fact that $A + (B_1B_1' - B_2B_2')P$ is asymptotically stable, it follows that $(I - \pi_\tau)w$ belongs to $L_2[0, \infty)$. For this particular w as in the proof of Theorem 3.2, it can be shown that

$$\sup_u\{\|(I - \pi_\tau)w(t)\|^2 - \|(I - \pi_\tau)z(t)\|^2\} = -x'(\tau)P(\tau)x(\tau).$$

Using this observation and (50), we obtain

$$\begin{aligned} x_0'Rx_0 + \|w\|^2 - \|z\|^2 &= \{x(0)'Rx(0) + \|\pi_\tau w\|^2 - \|\pi_\tau z\|^2\} \\ &\quad+\{\|(I - \pi_\tau)w\|^2 - \|(I - \pi_\tau)z\|^2\} \\ &\le x_\tau'Q^{-1}(\tau)x_\tau - x_\tau'Px_\tau. \end{aligned}$$

Since the left-hand side is positive for all $0 \ne x_\tau \in \mathbf{R}^n$ (since that implies $w \ne 0$ or $x(0) \ne 0$), it follows that for all $\tau \in [0, \infty)$, $Q^{-1}(\tau) > P$. Hence $\rho(Q(\tau)P) < 1$ for all $\tau \in [0, \infty)$. Now $\lim_{t \to \infty} Q(\tau) = Q_\infty$. From Theorem 3 of Doyle et al. [5], $\rho(Q_\infty P) < 1$. Thus, $(1 - \rho(Q(\tau)P))^{-1}$ exists for all $\tau \in [0, \infty)$, is continuous, and has a limit as $\tau \to \infty$. Therefore it is bounded on $[0, \infty)$. Hence condition (iii) of the theorem follows. This completes the proof. □

4. Conclusions. In this paper we have formulated and solved an H_∞-like control problem, where, in addition to the exogenous signals in the state and measurement equations, we must also account for uncertainty in the initial condition. This was done by defining a suitable worst-case performance measure. It is hoped that these results may allow us to design control strategies that are robust to both exogenous signals and nonzero initial states.

It was shown by Mustafa and Glover [11] that the central solutions to H_∞ control problems have the additional property of maximizing the entropy of the closed-loop transfer matrix. It is clear that the controllers obtained in the present paper are analogous to the central solutions to the H_∞ control problem. The question arises then as to what is the analogue of entropy maximization property in the present context. This problem does not seem to have immediate answers since entropy is defined in terms of the closed-loop transfer function matrix evaluated along the imaginary axis. This definition has no obvious extension to our context where the controllers are time-varying. We leave a full investigation of this issue for future research.

Finally, we have formulated our problem in a purely deterministic context. A stochastic formulation of this problem should be an interesting undertaking.

H^∞ CONTROL OF LINEAR TIME-VARYING SYSTEMS: A STATE-SPACE APPROACH*

R. RAVI[†], K. M. NAGPAL[‡], AND P. P. KHARGONEKAR[§]

Abstract. In this paper the standard problem of H^∞ control theory for finite-dimensional linear time-varying continuous-time plants is considered. The problem is: given a real number $\gamma > 0$, find (if one exists) an internally stabilizing controller such that the closed-loop operator norm is less than γ. Under rather weak assumptions on the plant model, it is shown that a solution to this problem exists if and only if a pair of matrix Riccati differential equations admits positive semidefinite stabilizing solutions. State-space formulae for one solution to the problem are also given.

Key words. H_∞ control theory, linear time-varying systems, Riccati differential equations, optimal control

1. Introduction.

After the introduction of the H^∞ control problem by Zames [24], initial developments in H^∞ control theory were based on frequency domain and operator theoretic methods. The book by Francis [9] contains an excellent account of the results obtained using this approach. While most of the results were for linear time-invariant systems, several results on H^∞ or uniformly optimal control of linear time-varying discrete-time systems were obtained using these methods. See, for example, [6], [7], [8], [10], and the references cited there. Recently, some new and very interesting results on the H^∞ control of slowly varying systems using operator theoretic methods have also been obtained [23].

A major new development in H^∞ control theory during the last three years has been the introduction of state-space methods. (State-space representations were used even earlier in computing solutions to H_∞ control problems. By *state-space methods*, we are referring to the systematic use of state-space ideas, e.g., state-feedback, state-estimation, separation principle, etc., for deriving and computing solutions.) This state-space approach has proved to be quite successful in providing simple and intuitive solutions to the H^∞ control problem. The interested reader is referred to [5], [13] and the references contained there for these recent developments.

The state-space approach is particularly natural and appealing for the problem of H^∞ control of linear time-varying systems. Tadmor [21], [20] was the first to apply the state-space approach for linear time-varying systems. Recently, a simple game theoretic solution to the H^∞ control problem for the finite horizon case was given in [15]. In [21], Tadmor gave a solution to the H^∞ control problem for the finite horizon case, while [20] contained a solution for the infinite horizon case. It should be noted that the infinite horizon case is significantly more difficult since stability becomes an

important issue, whereas in the finite horizon case this is completely absent. Tadmor derived his results under the hypothesis that the input matrix for the exogenous signal and the output matrix for the controlled variables are nonsingular. The results in [15], for the finite horizon case, are derived under much less restrictive assumptions.

In the present paper, we give a solution to the infinite horizon case building on the previous work of [5], [15], [21], and [20]. We obtain necessary and sufficient conditions for the existence of solutions under the assumption that the plant is stabilizable from the exogenous inputs and detectable from the controlled outputs. These assumptions are significantly weaker than those in [20] — thus the main contribution of the paper is the generalization of existing results in [20] by relaxing assumptions to stabilizability and detectability. While it is trivial to conjecture our main results in view of the results in [5], the proofs of these results are not so easy to generalize. Indeed, even in the context of the linear quadratic Gaussian (LQG) problem, such generalizations involve significant technical difficulties. See (for the discrete-time case) [2] and [3] in this connection. For the H_∞ control problem, these generalizations are nontrivial as well. Indeed, our proof techniques are quite different, and in our opinion simpler, than those employed in [20]. Thus it is hoped that, in addition to generalizing existing results, these techniques will provide an alternative approach to proving some of the existing results even in the linear time-invariant case.

This paper is organized as follows. In §2, we set up the notation and the problem formulation. Here we present a few preliminary results and some of the machinery needed for proving the main result. Section 3 contains the statement and a proof of the main result.

2. Notation and preliminary results. Let $\mathcal{R}_+$ (respectively, $\mathcal{R}_-$) be the set of nonnegative (respectively, nonpositive) real numbers, and let $\mathcal{R} = \mathcal{R}_+ \cup \mathcal{R}_-$. Let $\mathcal{L}_2^m(\mathcal{R}_+)$ be the space of square integrable functions on $\mathcal{R}_+$ with values in $\mathcal{R}^m$. The extended space is defined as $\mathcal{L}_{2,e}^m(\mathcal{R}_+) := \{f : f$ is a measurable function on $\mathcal{R}_+$, $P_t f \in \mathcal{L}_2^m(\mathcal{R}_+)$, for all $t \in \mathcal{R}_+\}$ where $(P_t f)(\tau) = f(\tau)$ if $\tau \le t$, and 0 if $\tau > t$. In the sequel, the notation for these spaces will be abbreviated to $\mathcal{L}_2$ and $\mathcal{L}_{2,e}$, respectively, when the dimensions are unambiguous.

Consider the linear system

$$\Sigma_G := \left\{ \begin{array}{rcl} \dot{x}(t) & = & A(t)x(t) + B(t)u(t), \quad x(t_0) = x_0, \\ y(t) & = & C(t)x(t) + D(t)u(t). \end{array} \right. \tag{1}$$

Here $x(t)$, $u(t)$, and $y(t)$, when evaluated at time t, belong to $\mathcal{R}^n$, $\mathcal{R}^m$, and $\mathcal{R}^p$, respectively, and the matrices are all bounded functions of t. With $x(0) = 0$ it can be shown that Σ_G generates a causal, linear operator G mapping $\mathcal{L}_{2,e}^m(\mathcal{R}_+)$ to $\mathcal{L}_{2,e}^p(\mathcal{R}_+)$ given by

$$y(t) = \int_0^t C(t)\Phi_G(t,\tau)B(\tau)u(\tau)d\tau + D(t)u(t), \tag{2}$$

where $\Phi_G(t,\tau)$ is the state transition matrix of the homogeneous part of (1). In terms of Σ_G we have the following definitions.

DEFINITION. The system Σ_G is said to be *exponentially* (*or internally*) *stable* if there exist $c_1, c_2 > 0$ subject to $||\Phi_G(t,\tau)|| \le c_1 e^{-c_2(t-\tau)}$, for all $t \ge \tau$.

As this definition of stability deals with the homogeneous part of Σ_G alone, we will use the phrase, "A is stable," to mean that Σ_G is exponentially stable. By the same reasoning, we will also use the notation Σ_A interchangeably with Σ_G when referring to the state transition matrix.

If Σ_G is exponentially stable, then the input-output operator $G : \mathcal{L}_2^m(\mathcal{R}_+) \to \mathcal{L}_2^p(\mathcal{R}_+)$ is a bounded linear operator and its induced norm is defined as $\|G\| := \sup_{\|u\|\neq 0}(\|y\|/\|u\|)$. Note that an alternate notation for the input-output operator mapping u to y is T_{yu}.

DEFINITION. The system Σ_G is said to be *stabilizable* (respectively, *detectable*) if there exists a bounded function $K(t)$ (respectively, $L(t)$) such that the system $\dot{x}(t) = (A - BK)(t)x(t)$ (respectively, $\dot{x}(t) = (A - LC)(t)x(t)$) is exponentially stable. We also use the notation (A, B) stabilizable (respectively, (A, C) detectable) to denote this.

It is a fact that if Σ_G is stabilizable and detectable then it is exponentially stable if and only if G is a bounded operator (a proof for the discrete-time case is in [1]; the continuous-time case is also easily shown).

We briefly review the concept of a dual, which was first introduced by Kalman (see, e.g., [12]) as a means of relating regulation and estimation. We begin by considering the system Σ_G defined only over a finite time interval $[0, T]$. Let $t^* := -t$ and define $A(t^*) := A(t)$, $B(t^*) := B(t)$, $C(t^*) := C(t)$, and $D(t^*) := D(t)$. Then

$$(3) \qquad \Sigma_{G^*} := \begin{cases} \dot{x}^*(t^*) &= A'(t^*)x^*(t^*) + C'(t^*)u^*(t^*), \qquad x^*(-T) = x_0, \\ y^*(t^*) &= B'(t^*)x^*(t^*) + D'(t^*)u^*(t^*) \end{cases}$$

is called the *dual* of Σ_G. It can be shown that if $x^*(-T) = 0$ then Σ_{G^*} generates a causal, linear, and bounded system G^* mapping $\mathcal{L}_2^p([-T, 0])$ to $\mathcal{L}_2^m([-T, 0])$. Moreover, G^* can be identified with the *adjoint* of G. We are mainly interested in the case when $T = \infty$, and here we must make the additional assumption that the original system Σ_G is exponentially stable. Let $u^* \in \mathcal{L}_2^p(\mathcal{R}_+)$ and define

$$(4) \qquad x^*(t) := \int_t^\infty \Phi_G'(\tau, t)C'(\tau)u^*(\tau)d\tau.$$

By differentiating this we find that $x^*(t)$ satisfies

$$(5) \qquad -\dot{x}^*(t) = A'(t)x^*(t) + C'(t)u^*(t).$$

Because Σ_G is exponentially stable it can be shown, by applying Schwartz's inequality to (4), that $\lim_{t\to\infty} x^*(t) = 0$. If we define the output $y^*(t)$ as

$$(6) \qquad y^*(t) = B'(t)x^*(t) + D'(t)u^*(t),$$

then it is clear that $< u^*, y > = < y^*, u >$, for all $u \in \mathcal{L}_2^m(\mathcal{R}_+)$ and for all $u^* \in \mathcal{L}_2^p(\mathcal{R}_+)$, and $y = Gu$. It follows that (5) and (6) together define the adjoint of G. If in (5) and (6) we further make the change of variable $t^* = -t$, we obtain Σ_{G^*} exactly as in (3) but with the boundary condition replaced by $\lim_{t^*\to-\infty} x^*(t^*) = 0$. Note that Σ_{G^*} is defined only on $\mathcal{R}_-$ and is stable in the sense that there exist $c_1, c_2 > 0$ subject to $\|\Phi_{G^*}(t^*, \tau^*)\| \leq c_1 e^{-c_2(t^* - \tau^*)}$, and all $\tau^* \leq t^*$, for all $t^* \in \mathcal{R}_-$.

We are now ready to formulate the control problem considered in this paper. Consider the control system shown in Fig. 1. Let the finite-dimensional linear time-varying (FDLTV) plant G be described by

$$(7) \qquad \Sigma_G := \begin{cases} \dot{x}(t) &= A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), \\ z(t) &= C_1(t)x(t) + D_{12}(t)u(t), \\ y(t) &= C_2(t)x(t) + D_{21}(t)w(t), \end{cases}$$

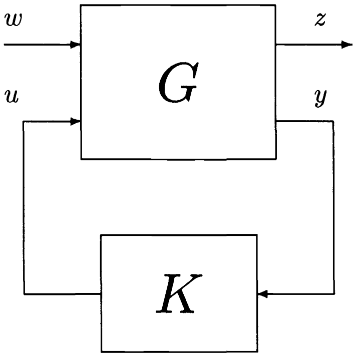

FIG. 1. *Standard feedback configuration.*

or in more compact packed matrix notation

$$\Sigma_G := \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & 0 & D_{12} \\ C_2 & D_{21} & 0 \end{array}\right].$$

Note that we have assumed that the direct feedthrough terms D_{11} and D_{22} are zero. This assumption, especially the first one, greatly reduces the length and complexity of the formulae to be derived in §3. The general forms can be obtained by constructions similar to those in [15], [17], and [25].

Let T_{zw} denote the closed-loop operator mapping w to z. Then the standard problem of H^∞ control theory for linear time-varying systems can be stated as follows. Given the FDLTV system G with a realization Σ_G, and a real number $\gamma > 0$, find (when one exists) an FDLTV controller K that exponentially (internally) stabilizes the closed-loop system and makes $||T_{zw}|| < \gamma$. Any controller that satisfies the above condition will be called an *admissible* controller.

Note that we are only seeking a controller that is *suboptimal* relative to the number γ. For most cases this is sufficient because we can come as close to the optimal value, $\inf_K ||T_{zw}||$, as we want by iterating on γ.

We make the following simplifying assumptions on Σ_G:

(A1) $D_{12}'(t)(C_1(t)\ \ D_{12}(t)) = (0\ \ I)$.

(A2) $\begin{pmatrix} B_1(t) \\ D_{21}(t) \end{pmatrix} D_{21}'(t) = \begin{pmatrix} 0 \\ I \end{pmatrix}$.

(A3) (A, B_1) is stabilizable.

(A4) (A, C_1) is detectable.

(A5) (A, B_2) is stabilizable.

(A6) (A, C_2) is detectable.

The full rank conditions on D_{12} and D_{21} are restrictive but essential for the theory to work. To remove this assumption we can use a reasoning similar to that in [14], where it is shown that if these conditions are not satisfied, we can perturb the matrices slightly so that they are satisfied, ensuring at the same time that the solution to the new problem is also a solution to the original one. The crucial fact that allows us to use this argument is that we are only dealing with a suboptimal problem. Dealing with these assumptions in a more direct manner is more difficult and has been done in the *time-invariant* case via the use of methods from singular control theory and almost invariant subspaces [19], [18]. It is unclear at this time if these methods can be

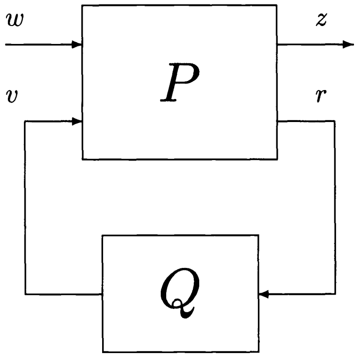

FIG. 2. *Feedback configuration for Lemma* 2.2.

extended to linear time-varying systems since very little is known about the singular cases even for the LQG problem for linear time-varying systems.

Assumptions (A5), (A6) are necessary for the existence of an exponentially stabilizing controller. For LTI systems, assumptions (A3), (A4) can be relaxed further to requiring that certain rank conditions be satisfied on the imaginary axis [11]. In the linear time-varying case, however, it is unclear what the corresponding assumptions should be since the role of the imaginary axis is very strongly related to time-invariance. This is also related to whether we consider linear time-varying systems on the half line or the entire real line for the time-axis. Techniques from operator theory suggest that this is related to the existence of certain inner-outer factorizations. We will restrict ourselves to assumptions (A3), (A4) in this paper, leaving further extensions for future work.

Before going on to the main result, we state three preliminary lemmas that we will need in the proof of Theorem 3.1. The first is a version of the Lyapunov stability theorem proved for discrete time systems in [2]. The following continuous-time version is proved in [16].

LEMMA 2.1. *Let Σ be defined as $\dot{x}(t) = A(t)x(t)$ and let C and B be such that (A, C) and (A, B) are detectable and stabilizable, respectively. Then either of the following statements is a sufficient condition for the system Σ to be exponentially stable.*

(1) *There exists a bounded nonnegative definite function $X(t)$, $t \in [0, \infty)$ such that*

$$\dot{X}(t) + A'(t)X(t) + X(t)A(t) = -C'(t)C(t).$$

(2) *There exists a bounded nonnegative definite function $Y(t)$, $t \in [0, \infty)$ such that*

$$\dot{Y}(t) - A(t)Y(t) - Y(t)A'(t) = B(t)B'(t).$$

The next result is the time-varying version of Lemma 15 in [5].

LEMMA 2.2. *Let P be a system partitioned as follows:*

$$P = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}$$

and let Q be another system connected to P as in Fig. 2. Suppose that P has an exponentially stable realization and that Q is given by a stabilizable and detectable *state-space realization. In addition, suppose that the resulting realization for the closed loop system is also stabilizable and detectable (from w and z, respectively). Let P be isometric, (i.e., $\|w\|^2+\|v\|^2 = \|z\|^2+\|r\|^2$, for all $v, w \in \mathcal{L}_2$), and let P_{21}^{-1} exist and be stable. Then the closed-loop system is exponentially stable and $||T_{zw}|| < 1$ if and only if Q is exponentially stable and $||Q|| < 1$, where T_{zw} is the closed-loop input-output operator mapping w to z.*

Proof. Sufficiency. As $||Q|| < 1$ and $||P_{22}|| \leq 1$ it follows that $(I-P_{22}Q)^{-1}$ exists as a stable operator. This, along with the fact that both P and Q are stable, implies closed-loop stability of the system in Fig. 2. Internal exponential stability then follows from the hypothesis that the closed-loop system is stabilizable and detectable. The norm bound is also easy to establish. From the isometric property of P it follows that

$$||z||^2 + ||r||^2 = ||w||^2 + ||v||^2. \tag{8}$$

As $||Q|| < 1$ we have

$$\begin{aligned} ||v||^2 - ||r||^2 &\leq -\varepsilon ||r||^2 \\ &\leq -\frac{\varepsilon}{||T_{wr}||^2} ||w||^2 \end{aligned} \tag{9}$$

for some $\varepsilon > 0$ and where $T_{wr} := P_{21}^{-1} - P_{21}^{-1}P_{22}Q$ is a bounded operator. From (8) and (9) it clearly follows that $||T_{zw}|| < 1$.

Necessity. From Fig. 2 we have

$$\begin{aligned} r &= P_{21}w + P_{22}v \\ &= P_{21}w + P_{22}Qr \\ \Rightarrow w &= P_{21}^{-1}r - P_{21}^{-1}P_{22}Qr. \end{aligned} \tag{10}$$

Let $\mathcal{M} := \{r \in \mathcal{L}_2 \text{ subject to } Qr \in \mathcal{L}_2\}$. From (10) it is easy to see that whenever $r \in \mathcal{M}$ we have $w \in \mathcal{L}_2$. This means that given any signal $r \in \mathcal{M}$ there exists a $w \in \mathcal{L}_2$ that generates it as an input to Q. From (8) and the fact that $||T_{zw}|| < 1$, it follows that whenever $r \in \mathcal{M}$,

$$||v||^2 - ||r||^2 = ||z||^2 - ||w||^2 \leq -\epsilon ||w||^2 \tag{11}$$

for some $\epsilon > 0$. Furthermore, as the closed loop is stable we must have that T_{rw}, the closed-loop operator mapping w to r, is bounded. Along with (11) this implies that

$$||v||^2 - ||r||^2 \leq -\frac{\epsilon}{||T_{rw}||} ||r||^2,$$

from which it follows that

$$\sup_{r \in \mathcal{M}, r \neq 0} \frac{||Qr||}{||r||} < 1. \tag{12}$$

To complete the proof we need to show that Q is stable. If we show this then (12), together with the definition of $\mathcal{M}$, implies that $||Q|| < 1$.

To establish the stability of Q we use a time-varying version of the proof of Theorem 1 in [22]. Assume Q is unstable. Because Q has finite gain on the set $\mathcal{M}$ (see (12)), it follows from Lemma 1 in [22] that $\mathcal{M}$ is a closed subspace of $\mathcal{L}_2$. If $M \neq \mathcal{L}_2$ then there is at least one nonzero d in $\mathcal{M}^\perp$, the orthogonal complement of

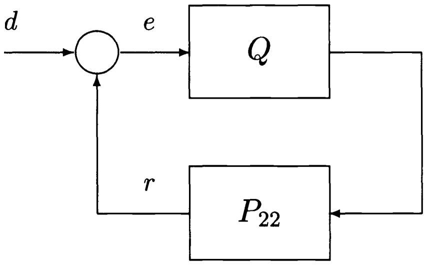

FIG. 3.

$\mathcal{M}$ in $\mathcal{L}_2$. As the closed loop is stable, it follows that the feedback system in Fig. 3 is also stable, and so for any $d \in \mathcal{L}_2$ both e and r are in $\mathcal{L}_2$, and, furthermore, we have $e \in \mathcal{M}$. Choose $d \in \mathcal{M}^\perp$. Then

$$\begin{aligned} & r = e - d \\ & \Rightarrow ||r||^2 = ||e||^2 + ||d||^2 \quad (\text{since } e \in \mathcal{M} \text{ and } d \in \mathcal{M}^\perp) \\ (13) \qquad & \Rightarrow ||e|| < ||r||. \end{aligned}$$

On the other hand, because $||P_{22}|| \leq 1$ and $||Q|| < 1$, it follows that $||e|| > ||r||$, which is a contradiction of (13). This proves our claim. □

Finally, we state a consequence of the definition of detectability that we will need in the following. Consider the system

$$(14) \qquad \Sigma := \begin{cases} \dot{x}(t) = A(t)x(t) + B(t)u(t), & x(0) = 0, \\ z(t) = C(t)x(t), \end{cases}$$

and assume that Σ is detectable.

LEMMA 2.3. *Let the system Σ be as in* (14). *If Σ is detectable then there exists a constant $\zeta > 0$ such that for any $T > 0$ and a reachable state x_T at time $t = T$,*

$$(15) \qquad \inf_{u \in \mathcal{L}_2([0,T])} (||P_T z||^2 + ||P_T u||^2 : \; x(0) = 0 \text{ and } x(T) = x_T) \geq \zeta ||x_T||^2.$$

Proof. As the system is detectable, there is a bounded function $L(t)$ subject to $(A - LC)(t)$ that is exponentially stable. System (14) can be equivalently written as

$$\begin{aligned} \dot{x}(t) &= (A - LC)(t)x(t) + B(t)u(t) + L(t)z(t), \qquad x(0) = 0, \\ z(t) &= C(t)x(t). \end{aligned}$$

As $(A - LC)(t)$ is exponentially stable, clearly there exists a number $\rho < \infty$ (independent of T) subject to

$$||x(T)||^2 < \rho(||P_T z||^2 + ||P_T u||^2).$$

The conclusion follows immediately by taking $\zeta = 1/\rho$. □

3. Main result.

THEOREM 3.1. *Let Σ_G satisfy assumptions* (A1)–(A6). *Then there exists a controller K that exponentially stabilizes the system Σ_G and makes $||T_{zw}|| < \gamma$ if and only if*

(1) *There is a bounded nonnegative definite solution to the Riccati equation*

$$\begin{aligned} -\dot{X}_\infty(t) &= A'(t)X_\infty(t) + X_\infty(t)A(t) \\ &\quad -X_\infty(t)(B_2(t)B_2'(t) - \tfrac{1}{\gamma^2}B_1(t)B_1'(t))X_\infty(t) + C_1'(t)C_1(t) \end{aligned} \tag{16}$$

subject to the system $\dot{x}(t) = (A-(B_2B_2'-\gamma^{-2}B_1B_1')X_\infty)(t)x(t)$ *is exponentially stable, and*

(2) *There is a bounded nonnegative definite solution to the Riccati equation*

$$\begin{aligned} \dot{Y}_{tmp}(t) &= A_{tmp}(t)Y_{tmp}(t) + Y_{tmp}(t)A_{tmp}'(t) \\ &\quad -Y_{tmp}(t)(C_2'(t)C_2(t) - \tfrac{1}{\gamma^2}X_\infty(t)B_2(t)B_2'(t)X_\infty(t))Y_{tmp}(t) \\ &\quad +B_1(t)B_1'(t), \quad Y_{tmp}(0) = 0 \end{aligned} \tag{17}$$

subject to the system $\dot{x}(t) = (A_{tmp} - Y_{tmp}(C_2'C_2 - \gamma^{-2}X_\infty B_2B_2'X_\infty))(t)x(t)$ *is exponentially stable, where*

$$A_{tmp} := \left(A + \tfrac{1}{\gamma^2}B_1B_1'X_\infty\right). \tag{18}$$

If these two conditions are met, then an admissible controller is given by

$$\Sigma_K := \begin{cases} \dot{q}(t) = (A - (B_2B_2' - \gamma^{-2}B_1B_1')X_\infty - Y_{tmp}C_2'C_2)(t)q(t) \\ \qquad\quad +Y_{tmp}(t)C_2'(t)y(t), \\ u(t) = -B_2'(t)X_\infty(t)q(t). \end{cases} \tag{19}$$

Note that in (16), as opposed to (17), no boundary condition is specified. This is similar to the corresponding results for the classical LQG problem in the infinite horizon case where the control Riccati equation does not have a boundary condition. It will be seen in the proof that X_∞ is obtained as the limit of the solutions of finite horizon Riccati differential equations as the terminal time approaches infinity.

We have given the necessary and sufficient conditions here in terms of two coupled Riccati differential equations. Since the coupling is only one way, i.e., the solution to the first enters the second but not vice versa, this presents no problems. It is possible to give an alternative set of necessary and sufficient conditions involving two uncoupled Riccati differential equations and a spectral radius condition. This is quite standard; see, for example, [15] and [20].

Proof. Note that there is no loss of generality in replacing γ by 1—hence in the proof we will work with this simplifying normalization.

Sufficiency. We will show that K, defined in (19), both stabilizes the system and makes $||T_{zw}|| < 1$. We start by making the change of variables $v := u + B_2'X_\infty x$ and $r := w - B_1'X_\infty x$. In terms of these variables we have a new system P defined by

$$\Sigma_P := \begin{cases} \dot{x} = (A - B_2B_2'X_\infty)x + B_1w + B_2v, \\ z = (C_1 - D_{12}B_2'X_\infty)x + D_{12}v, \\ r = -B_1'X_\infty x + w \end{cases} \tag{20}$$

and a corresponding controller C defined by

$$\Sigma_C := \begin{cases} \dot{e} = (A_{tmp} - Y_{tmp}C_2'C_2)e + (B_1 - Y_{tmp}C_2'D_{21})r, \\ v = B_2'X_\infty e, \end{cases} \tag{21}$$

where $e := x - q$.

We will now show that P is stable and norm preserving, i.e., $||(z' \ r')'|| = ||(w' \ v')'||$, for all $(w, v) \in \mathcal{L}_2 \times \mathcal{L}_2$. To establish this, let us rewrite (16) as

$$\begin{aligned}&\dot{X}_\infty(t) + (A - B_2B_2'X_\infty)'(t)X_\infty(t) + X_\infty(t)(A - B_2B_2'X_\infty)(t)\\&= -(X_\infty B_2B_2'X_\infty)(t) - (X_\infty B_1B_1'X_\infty)(t) - (C_1'C_1)(t).\end{aligned}$$

As (A, C_1) is detectable it follows that $((A - B_2B_2'X_\infty), (C_1' \mid X_\infty B_2 \mid X_\infty B_1)')$ is detectable; therefore, by Lemma 2.1, we have that $\dot{x}(t) = (A - B_2B_2'X_\infty)(t)x(t)$ is exponentially stable. To establish the norm condition, we differentiate $x'(t)X_\infty(t)x(t)$ along the trajectory of Σ_P to get

$$\begin{aligned}\frac{d(x'X_\infty x)}{dt} &= \dot{x}'(t)X_\infty(t)x(t) + x'(t)\dot{X}_\infty(t)x(t) + x'(t)X_\infty(t)\dot{x}(t)\\&= ((A - B_2B_2'X_\infty)(t)x(t) + B_1(t)w(t) + B_2(t)v(t))'X_\infty(t)x(t)\\&\quad -x'(t)(A'X_\infty + X_\infty A - X_\infty(B_2B_2' - B_1B_1')X_\infty + C_1'C_1)(t)x(t)\\&\quad +x'(t)X_\infty(t)((A - B_2B_2'X_\infty)(t)x(t) + B_1(t)w(t) + B_2(t)v(t)).\end{aligned}$$

Expanding this, substituting from (20) and (21), and cancelling a number of terms, gives

$$\frac{d(x'X_\infty x)}{dt} = w'w(t) - r'r(t) + v'v(t) - z'z(t). \tag{22}$$

By assumption, $x(0) = 0$. Furthermore, we have established that the system Σ_P is exponentially stable, which means that for every $(w, v) \in \mathcal{L}_2 \times \mathcal{L}_2$ we have that $\lim_{t\to\infty} x(t) = 0$. Consequently, we can integrate (22) between 0 and ∞ to get

$$0 = ||w||^2 - ||r||^2 + ||v||^2 - ||z||^2$$

or

$$||w||^2 + ||v||^2 = ||r||^2 + ||z||^2.$$

Let us now partition P as in Lemma 2.2. As $\dot{x}(t) = (A-(B_2B_2'-B_1B_1')X_\infty)(t)x(t)$ is exponentially stable, it follows that P_{21}^{-1} exists and is stable. Next we establish that Σ_C is stable and that $||C|| < 1$. We rewrite (17) as

$$\begin{aligned}&\dot{Y}_{tmp}(t) - (A_{tmp} - Y_{tmp}C_2'C_2)(t)Y_{tmp}(t) - Y_{tmp}(t)(A_{tmp} - Y_{tmp}C_2'C_2)'(t)\\&= (Y_{tmp}C_2'C_2Y_{tmp})(t) + (Y_{tmp}X_\infty B_2B_2'X_\infty Y_{tmp})(t) + (B_1B_1')(t).\end{aligned} \tag{23}$$

By assumption we have that $\dot{x}(t) = (A_{tmp} - Y_{tmp}C_2'C_2 + Y_{tmp}X_\infty B_2B_2'X_\infty)(t)x(t)$ is exponentially stable, which means $((A_{tmp} - Y_{tmp}C_2'C_2), (Y_{tmp}X_\infty B_2))$ and, consequently, $((A_{tmp} - Y_{tmp}C_2'C_2), (Y_{tmp}C_2' \mid Y_{tmp}X_\infty B_2 \mid B_1))$ is stabilizable. It follows from Lemma 2.1 that Σ_C is exponentially stable. Next we show that $||C|| < 1$. Let us define the dual Σ_{C^*} as

$$\begin{aligned}\dot{e}^*(t^*) &= (A_{tmp}' - C_2'C_2Y_{tmp})(t^*)e^*(t^*) + (X_\infty B_2)(t^*)r^*(t^*),\\ v^*(t^*) &= (B_1' - D_{21}'C_2Y_{tmp})(t^*)e^*(t^*),\end{aligned} \tag{24}$$

where $Y_{tmp}(t^*)$ is the solution to the time-reversed Riccati equation obtained from (17) as

$$\begin{aligned}-\dot{Y}_{tmp}(t^*) &= A_{tmp}(t^*)Y_{tmp}(t^*) + Y_{tmp}(t^*)A_{tmp}'(t^*) + B_1B_1'(t^*)\\&\quad -Y_{tmp}(t^*)(C_2'C_2 - X_\infty B_2B_2'X_\infty)(t^*)Y_{tmp}(t^*), \qquad Y_{tmp}(0) = 0.\end{aligned} \tag{25}$$

We consider the function $e^{*\prime} Y_{tmp} e^*(t^*)$ and calculate its derivative along the trajectory of (24). Substituting for $Y_{tmp}(t^*)$ from (25) gives us

(26)
$$\begin{aligned}\frac{d(e^{*\prime} Y_{tmp} e^*)}{dt^*} &= -v^{*\prime} v^*(t^*) + r^{*\prime} r^*(t^*) \\ &\quad -(r^* - B_2' X_\infty Y_{tmp} e^*)'(r^* - B_2' X_\infty Y_{tmp} e^*)(t^*).\end{aligned}$$

As we have established that Σ_{C^*} is exponentially stable, we have $\lim_{t^* \to -\infty} e^*(t^*) = 0$. This coupled with the fact that $Y_{tmp}(0) = 0$ allows us to integrate (26) from $-\infty$ to 0 to get

$$0 = ||r^*||^2 - ||v^*||^2 - ||r^* - B_2' X_\infty Y_{tmp} e^*||^2$$

or

$$||v^*||^2 - ||r^*||^2 = -||r^* - B_2' X_\infty Y_{tmp} e^*||^2. \qquad (27)$$

Clearly, $r^* - B_2' X_\infty Y_{tmp} e^*$ is the output of the following system with input r^*:

$$\left[\begin{array}{c|c} A_{tmp}' - C_2' C_2 Y_{tmp} & X_\infty B_2 \\ \hline -B_2' X_\infty Y_{tmp} & I \end{array}\right].$$

Note that the inverse of this system is given by

$$\left[\begin{array}{c|c} A_{tmp}' - C_2' C_2 Y_{tmp} + X_\infty B_2 B_2' X_\infty Y_{tmp} & X_\infty B_2 \\ \hline B_2' X_\infty Y_{tmp} & I \end{array}\right],$$

which maps $r^* - B_2' X_\infty Y_{tmp} e^*$ to r^*. As this is a stable system there exist δ with $0 < \delta < \infty$ such that $||r^*||^2 \leq \delta ||r^* - B_2' X_\infty Y_{tmp} e^*||^2$ or $-||r^* - B_2' X_\infty Y_{tmp} e^*||^2 \leq -1/\delta ||r^*||^2$. Coupling this with (27) gives

$$||v^*||^2 - ||r^*||^2 \leq -\frac{1}{\delta} ||r^*||^2, \qquad (28)$$

which means that $||C^*|| < 1$ or equivalently that $||C|| < 1$. A small amount of algebra shows that P and C satisfy all the assumptions of Lemma 2.2 (when C is substituted for Q). Therefore, as Σ_C is exponentially stable and $||C|| < 1$ it follows that the closed-loop system is stable and $||T_{zw}|| < 1$.

Necessity. In this part we assume that there exists an admissible controller; i.e., we have a controller K that stabilizes the closed loop and, in addition, makes $||T_{zw}|| < 1$, and show that the two Riccati differential equations have stabilizing solutions. For each case we will show that a nonnegative solution exists, that it is bounded, and, finally, that it is stabilizing.

Existence and boundedness of X_∞. Let us begin with a finite time horizon solution to the Riccati equation, which we will then extend to the infinite horizon. Let $T < \infty$ be the terminal time. As K is a *causal* admissible controller over $\mathcal{R}_+$ it is also admissible over $[0, T]$ for any T. In other words,

$$\begin{aligned} & ||T_{zw}|| < 1 \\ \Rightarrow & \sup_{w \neq 0} \frac{||z||}{||w||} < 1 \\ \Rightarrow & \sup_{P_T w \neq 0} \frac{||P_T z||}{||P_T w||} < 1 \quad \forall T \in \mathcal{R}_+. \end{aligned} \qquad (29)$$

From existing results on the finite horizon H_∞ control of linear time-varying systems in [21], [15], we conclude that this condition is sufficient for the existence of a bounded nonnegative definite solution to the finite horizon Riccati equation,

$$-\dot{X}_T(t) = A'(t)X_T(t) + X_T(t)A(t) - X_T(t)(B_2B_2' - B_1B_1')(t)X_T(t) + C_1'(t)C_1(t), \tag{30}$$
$$X_T(T) = 0.$$

The existence of a solution to (30) implies certain properties for the following differential game. Consider the system

$$\begin{array}{rcll} \dot{x}(t) & = & A(t)x(t) + B_1(t)w(t) + B_2(t)u(t), & x(0) = x_0, \\ z(t) & = & C_1(t)x(t) + D_{12}(t)u(t). & \end{array} \tag{31}$$

Set T to be the terminal time and define the cost function over $[0, T]$ as $J_T(w, u) := ||P_Tz||^2 - ||P_Tw||^2$. The two opposing players are the control input u and the exogenous signal w and we assume that these take values in $\mathcal{L}_2[0, T]$. The objective of the control input u is to minimize the cost while that of the exogenous signal w is to maximize it. Define $u_T^\star(x)(t) := -B_2'(t)X_T(t)x(t)$ and $w_T^\star(x)(t) := B_1'(t)X_T(t)x(t)$. Then a standard calculation involving completion of squares shows that for any u and w in $\mathcal{L}_2[0, T]$

$$J_T(w, u_T^\star(x)) \leq J_T(w_T^\star(x), u_T^\star(x)) = x_0'X_T(0)x_0 \leq J_T(w_T^\star(x), u). \tag{32}$$

It is important to note that the strategies $u_T^\star$ and $w_T^\star$ depend on x and are *not* open-loop saddle point strategies.

Now consider two different terminal times T_1 and T_2 with $T_1 \leq T_2$. We will next show that $X_{T_1}(t) \leq X_{T_2}(t)$, for all $t \in [0, T_1]$. Consider, first, the game over $[0, T_1]$. Suppose $w = w_{T_1}^\star(x)$. Then from (32) we have

$$x_0'X_{T_1}(0)x_0 \leq J_{T_1}(w_{T_1}^\star(x), u) \tag{33}$$

for any $u \in \mathcal{L}_2[0, T_1]$. Now let the terminal time be T_2 and let w_{T_2} be defined on $[0, T_2]$ as

$$w_{T_2}(t) := \begin{cases} w_{T_1}^\star(x)(t), & t \leq T_1, \\ 0, & T_1 < t \leq T_2. \end{cases}$$

Clearly,

$$\begin{aligned} J_{T_2}(w_{T_2}, u) &= \int_0^{T_1} (||z(t)||^2 - ||w_{T_2}(t)||^2)dt + \int_{T_1}^{T_2} (||z(t)||^2 - ||w_{T_2}(t)||^2)dt \\ &= J_{T_1}(w_{T_1}^\star(x), u) + \int_{T_1}^{T_2} ||z(t)||^2 dt \\ &\geq J_{T_1}(w_{T_1}^\star(x), u) \\ &\geq J_{T_1}(w_{T_1}^\star(x), u_{T_1}^\star(x)) = x_0'X_{T_1}(0)x_0. \end{aligned} \tag{34}$$

The above chain of inequalities holds for any $u \in \mathcal{L}_2[0, T_2]$, and, in particular, it holds for $u = u_{T_2}^\star(x)$. On the other hand, from (32) it follows that

$$x_0'X_{T_2}(0)x_0 = J_{T_2}(w_{T_2}^\star(x), u_{T_2}^\star(x)) \geq J_{T_2}(w_{T_2}, u_{T_2}^\star(x)). \tag{35}$$

Combining (34) and (35) we get that $x_0'X_{T_2}(0)x_0 \geq x_0'X_{T_1}(0)x_0$; and as this is true for any $x_0 \in \mathcal{R}^n$ it follows that $X_{T_2}(0) \geq X_{T_1}(0)$. But there is nothing sacred about choosing the starting time as $t = 0$. We could have played this game starting at any time $t \in [0, T_1]$ and hence it follows that $X_{T_2}(t) \geq X_{T_1}(t)$ for all $t \in [0, T_1]$.

Next we show that $X_T(t)$ remains a bounded function of time for every T. As K is admissible it follows, from (29), that (with $x_0 = 0$) there exist $\epsilon > 0$ subject to $||P_Tz||^2 - ||P_Tw||^2 \leq -\epsilon||P_Tw||^2$, for all $w \in \mathcal{L}_2([0,T])$ and all $T \in R_+$. Next, let $x_0 \neq 0$, let $u = Ky$, and set the initial states of the controller to be zero. As K is linear the output z of (31) to any input w can be written as

$$z(t) = z_1(t) + z_2(t), \tag{36}$$

where $z_1(t)$ is the homogeneous part of the solution (depending only on x_0) and $z_2(t)$ is the forced part (depending only on w). Clearly, we have, for any finite T,

$$||P_Tz||^2 \leq ||P_Tz_1||^2 + ||P_Tz_2||^2 + 2||P_Tz_1||\,||P_Tz_2||. \tag{37}$$

However, because K is an admissible controller the resulting closed-loop system is exponentially stable, which further implies that both z_1 and z_2 are in $\mathcal{L}_2(\mathcal{R}_+)$ for any $x_0 \in \mathcal{R}^n$ and $w \in \mathcal{L}_2(\mathcal{R}_+)$. This means that there are constants, $\alpha, \epsilon > 0$, that are independent of T subject to $||P_Tz_1|| < \alpha||x_0||$ and subject to $||P_Tz_2||^2 - ||P_Tw||^2 \leq -\epsilon||P_Tw||^2$. Combining this with (37), we get

$$\begin{aligned} \Rightarrow ||P_Tz||^2 - ||P_Tw||^2 &\leq \alpha^2||x_0||^2 + (||P_Tz_2||^2 - ||P_Tw||^2) + 2\alpha||P_Tw||\,||x_0|| \\ &\leq \alpha^2||x_0||^2 - ||P_Tw||(\epsilon||P_Tw|| - 2\alpha||x_0||) \qquad (38) \\ &\leq (1 + \frac{1}{\epsilon})\alpha^2||x_0||^2 =: \beta||x_0||^2. \qquad (39) \end{aligned}$$

Here we have used the fact that (38) is maximized by $||P_Tw|| = \alpha||x_0||/\epsilon$. It is important to note that the right side of (39) does not depend on T. Therefore pick any terminal time T and set $w(t) = w_T^\star(x)(t)$. Clearly, this w is in $\mathcal{L}_2[0,T]$. From (32) we have that

$$x_0'X_T(0)x_0 \leq J_T(w_T^\star(x), u) \tag{40}$$

for every $u \in \mathcal{L}_2[0,T]$. In particular, let $u = Ky$; from (39) and (40) it follows that

$$\begin{aligned} &x_0'X_T(0)x_0 \leq \beta||x_0||^2 \\ &\Rightarrow X_T(0) \leq \beta I. \end{aligned} \tag{41}$$

As argued before, the game can be played starting at any time t and nothing will change. Indeed β is independent of both starting times and terminal times. Consequently,

$$X_T(t) \leq \beta I \quad \forall\ T \in \mathcal{R}_+ \quad \forall t \leq T. \tag{42}$$

It follows that $\{X_T(\cdot)\}$, indexed by T, is a nondecreasing sequence of continuous functions that is bounded above. Hence there exists a unique, bounded function $X_\infty(\cdot)$ subject to $\lim_{T\to\infty} X_T(t) = X_\infty(t)$ for every $t \in \mathcal{R}_+$. Note, in addition, that for each T the function $X_T(\cdot)$ is the solution to the finite time Riccati equation (30) and is continuous with respect to initial conditions. It follows (using the same arguments as in [12]), that $X_\infty(\cdot)$ satisfies the infinite horizon Riccati equation (16).

Stability of $A - (B_2B_2' - B_1B_1')X_\infty$. We will now show that X_∞ is stabilizing; i.e., the system Σ defined as $\dot{x}(t) = (A - (B_2B_2' - B_1B_1')X_\infty)(t)x(t)$ is exponentially stable. We will show later that there exist $\xi < \infty$ such that given any initial time t_0 and initial condition $x(t_0) = x_0$ we have

$$||(I - P_{t_0})B_1'X_\infty x|| \leq \xi||x_0|| \quad \forall t_0 \in \mathcal{R}_+. \tag{43}$$

Assuming that this is done, the stability of Σ follows from the following argument. Note that Σ can be written as $\dot{x}(t) = (A - B_2B_2'X_\infty)(t)x(t) + B_1B_1'X_\infty(t)x(t)$ with initial condition $x(t_0) = x_0$. Let Σ_{aux} be an auxiliary system defined as

$$\dot{x} = (A - B_2B_2'X_\infty)x + u.$$

As Σ_{aux} is exponentially stable, the corresponding input-output system, assuming x to be the output, is input-output stable (see [1]). This implies that there exist $\zeta < \infty$ subject to

$$||(I - P_{t_0})x|| \leq \zeta||(I - P_{t_0})u|| \quad \forall t_0 \in \mathcal{R}_+. \tag{44}$$

Using the fact that $u = B_1'X_\infty x$ and taking into account (43) and (44), we get that for all initial states $x(t_0) = x_0$,

$$||(I - P_{t_0})x|| \leq \xi\zeta||x_0||,$$

where the bound is independent of the initial time or state. The exponential stability of Σ follows from Theorem 3 of [4, p. 190].

We will now demonstrate the existence of a uniform bound ξ satisfying (43). To this end, recall the definitions of α and ϵ from (38). Set $\eta \geq (\alpha/\epsilon)(1 + \sqrt{1+\epsilon})$, and consider the system Σ. Because $X_\infty(t) := \lim_{T\to\infty} X_T(t)$, it is clear that for T large enough, the state trajectory of the system Σ_T defined as $\dot{x}_T(t) = (A - (B_2B_2' - B_1B_1')X_T)(t)x_T(t)$ will approach x in the $\mathcal{L}_2$ sense on the interval $[t_0, t_1]$ for some $t_1 < T$. At this point we assume, in contradiction to what we want to show, that there does not exist any bound satisfying (43). Therefore, given any $\eta > 0$ (in particular, the one chosen above) there exist x_0, t_0, T, and an interval $[t_0, t_1]$ with $t_1 < T$ such that $||B_1'X_Tx_T||_{[t_0,t_1]} > \eta||x_0||$ where the subscript on the norm has the obvious meaning. As $T > t_1$, clearly $||B_1'X_Tx_T||_{[t_0,T]} > \eta||x_0||$ also.

Now consider, over the interval $[t_0, T]$, system (31). In (38) replace u by $u^\star := -B_2'X_Tx_T$ and the w by $w^\star := B_1'X_Tx_T$ and denote the resulting output by $z^\star$. We have

$$||z^\star||^2_{[t_0,T]} - ||w^\star||^2_{[t_0,T]} \leq \alpha^2||x_0||^2 - ||w^\star||_{[t_0,T]}(\epsilon||w^\star||_{[t_0,T]} - 2\alpha||x_0||). \tag{45}$$

Using (32) it follows that

$$x_0'X_T(t_0)x_0 \leq \alpha^2||x_0||^2 - ||w^\star||_{[t_0,T]}(\epsilon||w^\star||_{[t_0,T]} - 2\alpha||x_0||). \tag{46}$$

Because we have chosen T to force $||w^\star||_{[t_0,T]} = ||B_1'X_Tx_T||_{[t_0,T]} > \eta$ it follows that

$$x_0'X_T(t_0)x_0 \leq \left(\alpha^2 - \frac{\alpha^2}{\epsilon}(1 + \sqrt{1+\epsilon})(1 + \sqrt{1+\epsilon}) - 2)\right)||x_0||^2 \leq 0. \tag{47}$$

This violates the nonnegativity of X_T, however. Hence we have a contradiction, thereby proving the existence of ξ satisfying (43). It now follows that X_∞ is indeed a stabilizing solution to the first Riccati equation (16).

Existence of Y_{tmp}. As the admissible controller K is linear and causal, clearly $P_T y = 0 \Rightarrow P_T u = 0$, for all $T \in \mathcal{R}_+$. Let $D_\perp(t)$ be a matrix function defined subject to $\binom{D_{21}(t)}{D_\perp(t)}$, is square, and

$$\left(\begin{array}{c} D_{21}(t) \\ D_\perp(t) \end{array}\right)\left(\begin{array}{c} D_{21}(t) \\ D_\perp(t) \end{array}\right)' = I. \tag{48}$$

Now set

$$w(t) := -D_{21}'(t)C_2(t)x(t) + B_1'(t)X_\infty(t)x(t) + D_\perp'(t)v_1(t) \quad \forall t \in [0, T), \tag{49}$$

where $v_1 \in \mathcal{L}_2[0, T]$ is arbitrary. It can be checked (using assumption (A2)) that with w chosen as above, $y(t) = 0$, for all $t \in [0, T]$, and system (7) becomes

$$\begin{array}{rcl} \dot{x}(t) & = & A_{tmp}(t)x(t) + B_1(t)D_\perp'(t)v_1(t), \\ y(t) & = & 0 \quad \forall t \in [0, T), \end{array} \tag{50}$$

where A_{tmp} is defined in (18). Recall that $v = u + B_2'X_\infty x$ and $r = w - B_1'X_\infty x$ for $t \in [0, T)$. These become $v = B_2'X_\infty x$ and $r = -D_{21}'C_2 x + D_\perp' v_1$, respectively. Integrating both sides of (22) from 0 to T gives us

$$\begin{aligned} ||P_T z||^2 - ||P_T w||^2 &= ||P_T v||^2 - ||P_T r||^2 - x'(T)X_\infty x(T) \\ &= ||P_T B_2'X_\infty x||^2 - ||P_T v_1||^2 - ||P_T C_2 x||^2 - x'(T)X_\infty x(T) \end{aligned} \tag{51}$$

because $x(0) = 0$. Consider once again the system over $[T, \infty)$ and with initial state $x(T)$. Set $w(t) := B_1'(t)X_\infty(t)\Phi_{A-(B_2B_2'+B_1B_1')X_\infty}(t, T)x(T)$ for $t \in [T, \infty)$. Since the system $\dot{x}(t) = (A - (B_2B_2' - B_1B_1')X_\infty)(t)x(t)$ is exponentially stable, $(I - P_T)w \in \mathcal{L}_2$. With this choice of w, the unique input that minimizes the cost $J(u, w) = ||(I - P_T)z||^2 - ||(I - P_T)w||^2$ for this *linear quadratic optimal control problem* is given by $u(t) = -B_2'(t)X_\infty(t)\Phi_{A-(B_2B_2'+B_1B_1')X_\infty}(t, T)x(T)$ for $t \in [T, \infty)$. Moreover, the optimal cost is given by $x'(T)X_\infty(T)x(T)$. This can be shown by noting that for any $(I - P_T)w \in \mathcal{L}_2$, the optimal u is obtained from the following two-point boundary value problem:

$$\left(\begin{array}{c} \dot{p} \\ \dot{x} \end{array}\right) = \left(\begin{array}{cc} -A' & C_1'C_1 \\ B_2B_2' & A \end{array}\right)\left(\begin{array}{c} p \\ x \end{array}\right) + \left(\begin{array}{c} 0 \\ B_1 w \end{array}\right),$$

$$x(T) = x(T), \qquad \lim_{t\to\infty} p(t) = 0,$$

$$u(t) = B_2'p(t).$$

The above claim now follows by noting that $p(t) = -X_\infty(t)\Phi_{A-(B_2B_2'+B_1B_1')X_\infty}(t, T)x(T)$ solves the above two-point boundary value problem.

Thus for any admissible controller K, with $u = Ky$ and with w chosen as above, we have

$$||(I - P_T)z||^2 - ||(I - P_T)w||^2 \geq x'(T)X_\infty(T)x(T). \tag{52}$$

By adding together (51) and (52) and by defining w over $\mathcal{R}_+$ as

$$w(t) := \begin{cases} -D_{21}'(t)C_2(t)x(t) + B_1'(t)X_\infty(t)x(t) + D_\perp'(t)v_1(t), & t < T, \\ B_1'(t)X_\infty(t)\Phi_{A-(B_2B_2'+B_1B_1')X_\infty}(t, T)x(T), & t \geq T, \end{cases}$$

we get, for the system in (50),

$$||z||^2 - ||w||^2 \geq ||P_T B_2' X_\infty x||^2 - ||P_T v_1||^2 - ||P_T C_2 x||^2. \tag{53}$$

(We note that this idea of splitting the input has been used in a similar context in [13].) But with $u = Ky$ we have $||T_{zw}|| < 1$ or $||z||^2 - ||w||^2 < 0$, for all $w \neq 0$. Hence it follows from (53) that

$$||P_T B_2' X_\infty x||^2 - ||P_T v_1||^2 - ||P_T C_2 x||^2 < 0 \quad \text{whenever } P_T v_1 \neq 0 \tag{54}$$

for system (50). We will now show that (54) is a sufficient condition for the existence of a solution to the second Riccati equation (17), which we reproduce here for ease of reference as follows:

$$\begin{aligned} \dot{Y}_{tmp}(t) &= A_{tmp}(t)Y_{tmp}(t) + Y_{tmp}(t)A_{tmp}'(t) - Y_{tmp}(t)(C_2'(t)C_2(t) \\ &\quad -X_\infty(t)B_2(t)B_2'(t)X_\infty(t))Y_{tmp}(t) + B_1(t)B_1'(t), \quad Y_{tmp}(0) = 0. \end{aligned}$$

Define the co-state p as follows:

$$\dot{p}(t) = -A_{tmp}'(t)p(t) + (C_2'C_2 - X_\infty B_2 B_2' X_\infty)(t)x(t), \qquad p(0) = p_0. \tag{55}$$

If we set $v_1 := D_\perp B_1' p$ then from (50) and (55) we get

$$\begin{pmatrix} \dot{p} \\ \dot{x} \end{pmatrix} = \begin{pmatrix} -A_{tmp}' & C_2'C_2 - X_\infty B_2 B_2' X_\infty \\ B_1 B_1' & A_{tmp} \end{pmatrix} \begin{pmatrix} p \\ x \end{pmatrix}, \quad \begin{pmatrix} p(0) \\ x(0) \end{pmatrix} = \begin{pmatrix} p_0 \\ 0 \end{pmatrix}. \tag{56}$$

Let the transition matrix of this system be given by

$$\begin{pmatrix} p(t) \\ x(t) \end{pmatrix} = \begin{pmatrix} \Phi_{11}(t,\tau) & \Phi_{12}(t,\tau) \\ \Phi_{21}(t,\tau) & \Phi_{22}(t,\tau) \end{pmatrix} \begin{pmatrix} p(\tau) \\ x(\tau) \end{pmatrix}. \tag{57}$$

We will now show that $\Phi_{11}(t,0)$ is nonsingular for all $t \in \mathcal{R}_+$. Suppose, on the contrary, that there is a time T and a vector $p_0 \neq 0$ subject to $p(T) = \Phi_{11}(T,0)p_0 = 0$. Choosing $v_1 = D_\perp B_1' p$ as before, two cases arise: (1) $P_T v_1 = 0$ and (2) $P_T v_1 \neq 0$. The first case is taken care of easily because if $P_T v_1 = 0$ then $P_T x = 0$, which implies that $\dot{p}(t) = -A_{tmp}'(t)p(t)$ and $p(T) = 0$ (see (56)). This clearly is impossible in a homogeneous system with a nonzero initial condition; hence we are led to the required contradiction. On the other hand, if $P_T v_1 \neq 0$ then we can differentiate the product $x'(t)p(t)$ along the trajectory of (56) and rearrange the resulting equation to get

$$\frac{d(x'p)}{dt} = v_1'v_1 + x'C_2'C_2 x - x'X_\infty B_2 B_2' X_\infty x. \tag{58}$$

Note that $x(0) = 0$ and that $p(T) = 0$; therefore by integrating (58) from 0 to T, we get

$$0 = ||P_T B_2' X_\infty x||^2 - ||P_T v_1||^2 - ||P_T C_2 x||^2, \tag{59}$$

which is a clear contradiction to (54). This proves that $\Phi_{11}(t,0)$ is nonsingular for all $t \in \mathcal{R}_+$.

We set $Y_{tmp}(t) := \Phi_{21}(t,0)\Phi_{11}^{-1}(t,0)$ and a simple calculation shows us that Y_{tmp} satisfies the second Riccati equation (17). All that remains to be shown is that Y_{tmp} has the required properties; i.e., it is nonnegative definite, bounded, and stabilizing.

Nonnegativity is proved by relating Y_{tmp} to M, the solution to the following filter Riccati equation:

$$\dot{M}(t) = A_{tmp}(t)M(t) + M(t)A'_{tmp}(t) - M(t)C'_2(t)C_2(t)M(t) + B_1(t)B'_1(t), \quad M(0) = 0. \tag{60}$$

It can be shown that (A_{tmp}, C_2) is detectable.[1] This is sufficient to ensure that the Riccati equation above has a nonnegative, bounded solution. Clearly, $Y_{tmp}(t) \geq M(t)$, for all $t \in \mathcal{R}_+$ and because $M(t) \geq 0$ it follows that Y_{tmp} is nonnegative.

Boundedness of Y_{tmp}. Next we show that there is a number $\nu < \infty$ subject to $Y_{tmp}(t) \leq \nu I$, for all $t \in \mathcal{R}_+$. Note that for the entire discussion that follows we have assumed that $w(t)$ is chosen as in (49), i.e., to make $P_T y = 0$. Assume that $x(T)$ is a reachable state for system (50) at time $t = T$. Then, from Lemma 2.3, we have

$$\inf_{||P_T v_1|| < \infty} (||P_T C_2 x||^2 + ||P_T v_1||^2, \quad x(0) = 0, \quad x(T) = x(T)) \geq \zeta ||x(T)||^2, \tag{61}$$

where $\zeta > 0$ is independent of T. Let T be any terminal time subject to $Y_{tmp}(T) \neq 0$. Moreover, assume as before that the input to (50) is given by $v_1 = D_\perp B'_1 p$, where p satisfies the differential equation in (55). It is easy to see that the following hold up to $t = T$:

$$r(t) = B'_1(t)p(t) - D'_{21}(t)C_2(t)x(t), \tag{62}$$

$$x(t) = Y_{tmp}(t)p(t). \tag{63}$$

This means that $x(T)$ is reachable at $t = T$ using this choice of v_1 if and only if it is in the range space of $Y_{tmp}(T)$. Calculate the derivative of the quantity $x'(t)p(t)$ along the trajectory of (56), and integrate from 0 to T to get

$$x'(T)p(T) = ||P_T r||^2 - ||P_T v||^2. \tag{64}$$

From Lemma 2.2 it follows that with $u = Ky$, $||T_{zw}|| < 1$ implies $||T_{vr}|| < 1$.[2] This means that there exists $\varepsilon > 0$ subject to

$$||P_T v||^2 - ||P_T r||^2 \leq -\varepsilon ||P_T r||^2 \quad \forall ||P_T r|| \neq 0. \tag{65}$$

Clearly, (64) and (65) imply that $x'(T)p(T) \geq \varepsilon ||P_T r||^2$. Coupling this with (61), we get

$$x'(T)p(T) \geq \varepsilon \zeta x'(T)x(T). \tag{66}$$

Setting $x(T) := \lambda e$, where e is the eigenvector corresponding to the maximum eigenvalue of $Y_{tmp}(T)$ and λ is a scaling factor, we can make $x'(T)p(T) = (1/||Y_{tmp}(T)||)x'(T)x(T)$. Now by defining $\nu := 1/(\varepsilon\zeta)$ we have from the above equation

$$||Y_{tmp}(t)|| \leq \nu I \quad \forall t \in \mathcal{R}_+. \tag{67}$$

Stability of $A_{tmp} - Y_{tmp}(C'_2 C_2 - X_\infty B_2 B'_2 X_\infty)$. Finally, we prove that Y_{tmp} is stabilizing. From (56) and (63) with v_1 chosen as before ($v_1 = D_\perp B'_1 p$), we have

$$\dot{p}(t) = (-A'_{tmp} + (C'_2 C_2 - X_\infty B_2 B'_2 X_\infty)Y_{tmp})(t)p(t). \tag{68}$$

[1] See the Appendix.

[2] See the Appendix.

Let the boundary condition for (68) be $p(T) = p_T$. Clearly, given *any* $p_T \in \mathcal{R}^n$, there exists an initial condition p_0 in (56) subject to $p(T) = p_T$. Now existence of an admissible controller as in (65) implies

$$(69) \qquad ||P_T v||^2 - ||P_T r||^2 \leq -\varepsilon||P_T r||^2 \leq -\varepsilon||P_T v||^2 \quad \forall ||P_T r|| \neq 0.$$

Noting that $v(t) = B_2' X_\infty x(t) = B_2' X_\infty Y_{tmp} p(t)$ and r is given by (62), the above equation becomes

$$(70) \quad ||P_T B_2' X_\infty Y_{tmp} p||^2 \leq \frac{1}{\varepsilon}(||P_T B_1' p||^2 + ||P_T C_2 Y_{tmp} p||^2 - ||P_T B_2' X_\infty Y_{tmp} p||^2)$$

for system (68). Now, by setting $t^* = -t$, we get a time-reversed system for (68) defined as follows:

$$(71) \quad \begin{array}{rcl} \dot{p}(t^*) &=& (A_{tmp}' - (C_2'C_2 - X_\infty B_2 B_2' X_\infty)Y_{tmp})(t^*)p(t^*), \qquad p(-T) = p_T, \\ v(t^*) &=& B_2'(t^*)X_\infty(t^*)Y_{tmp}(t^*)p(t^*), \end{array}$$

where p_T is arbitrary. A repetition of the ideas in the sufficiency part, suitably dualized, shows that $\dot{x}(t^*) = (A_{tmp}' - C_2'C_2Y_{tmp})(t^*)x(t^*)$ is stable on $\mathcal{R}_-$. This means that the system defined in (71) is detectable. Observe that for the reversed time dual system given by (71), the equivalent of (69) and of (70) are

$$(72) \quad \begin{array}{rl} ||v||_{[-T,0]}^2 - ||r||_{[-T,0]}^2 &\leq -\varepsilon||r||_{[-T,0]}^2 \\ &\leq -\varepsilon||v||_{[-T,0]}^2 \end{array}$$

and

(73)

$$||B_2' X_\infty Y_{tmp} p||_{[-T,0]}^2 \leq \frac{1}{\varepsilon}(||B_1' p||_{[-T,0]}^2 + ||C_2 Y_{tmp} p||_{[-T,0]}^2 - ||B_2' X_\infty Y_{tmp} p||_{[-T,0]}^2),$$

respectively. Next consider the quantity $p'(t^*)Y_{tmp}(t^*)p(t^*)$ and calculate its derivative along the trajectory of (71). Substituting for $\dot{Y}_{tmp}(t^*)$ from (25) and integrating the resulting expression from $-T$ to 0, we get

$$(74) \quad ||B_1' p||_{[-T,0]}^2 + ||C_2 Y_{tmp} p||_{[-T,0]}^2 - ||B_2' X_\infty Y_{tmp}||_{[-T,0]}^2 = p_T' Y_{tmp}(-T) p_T.$$

Combining equations (67), (73), and (74) gives us

$$(75) \qquad ||B_2' X_\infty Y_{tmp} p||_{[-T,0]}^2 \leq \frac{\nu}{\varepsilon}||p_T||^2.$$

Note that ν/ε is independent of T. Equation (75) then simply states that the output of (71) is *uniformly* bounded with respect to starting times and initial conditions. As the system is detectable, this translates to uniform bound on the state of the system itself. In other words, using the fact that $(A_{tmp}' - C_2'C_2Y_{tmp})$ is exponentially stable and that system (71) can be equivalently written as

$$\begin{array}{rcl} \dot{p}(t^*) &=& (A_{tmp}' - (C_2'C_2 Y_{tmp})p(t^*) + X_\infty B_2 B_2' X_\infty)Y_{tmp})(t^*)p(t^*), \qquad p(-T) = p_T, \\ v(t^*) &=& B_2'(t^*)X_\infty(t^*)Y_{tmp}(t^*)p(t^*), \end{array}$$

we can easily derive a bound ζ, independent of T subject to

$$(76) \qquad ||p||_{[-T,0]}^2 \leq \zeta||p_T||^2.$$

By appropriately dualizing the arguments found in the proof of Theorem 3 of [4, p. 190], we can conclude from (76) that

$$\dot{p}(t^*) = (A'_{tmp} - (C'_2C_2 - X_\infty B_2B'_2X_\infty)Y_{tmp})(t^*)p(t^*)$$

is stable on $\mathcal{R}_-$ (the interested reader may also see [16]). Now we are done, as it follows that the dual of this system, defined, as usual, as

$$\dot{p}^*(t) = (A_{tmp} - Y_{tmp}(C'_2C_2 - X_\infty B_2B'_2X_\infty))(t)p^*(t),$$

is also exponentially stable. □

Appendix. In this Appendix we establish two important facts that we have used in the latter half of the necessity part of the proof but have not yet proved. Recall that in the first half of the necessity part we proved that the existence of an admissible controller implies that there is a bounded stabilizing solution X_∞ to the first Riccati equation. Given such an X_∞ we show, first, that the closed-loop operator T_{vr} is stable and $||T_{vr}|| < 1$, and second, that (A_{tmp}, C_2) is detectable. To begin with, note that

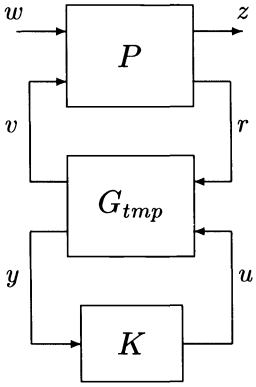

FIG. 4. *An equivalent representation.*

Fig. 1 can be redrawn as Fig. 4, where P is as defined in (20) and G_{tmp} is defined as follows:

$$\begin{aligned} \dot{x}_{tmp}(t) &= A_{tmp}(t)x_{tmp}(t) + B_1(t)r(t) + B_2(t)u(t), \\ v(t) &= B'_2(t)X_\infty(t)x_{tmp}(t) + u(t), \\ y(t) &= C_2(t)x_{tmp}(t) + D_{21}(t)r(t). \end{aligned} \tag{77}$$

Because K stabilizes the closed loop it can be shown that the modified system in Fig. 4 is also exponentially stable. The main idea is as follows. Let us denote by T_{vr} the closed-loop combination of G_{tmp} and K. Then, given any admissible linear controller K with a stabilizable and detectable realization, it is routine to verify that the realization for T_{vr} is also stabilizable and detectable. Similarly, the feedback connection of P and T_{vr} is verified to be stabilizable from w and detectable from z. Because T_{zw} is input-output stable and the corresponding realization is stabilizable and detectable, it follows that T_{zw} is (internally) exponentially stable as well.

Next, a direct calculation shows that P_{21} is stably invertible. Now it is clear that P and T_{vr} satisfy all the assumptions of Lemma 2.2 (with T_{vr} replacing Q). It follows that, as the closed loop is exponentially stable and $||T_{zw}|| < 1$, the system T_{vr} is stable and, furthermore, that $||T_{vr}|| < 1$. This establishes the first part.

For the second part note that because T_{vr} is internally exponentially stable, it follows that the system G_{tmp} is exponentially stabilized by K. It immediately follows that the realization given in (77) is stabilizable from u and detectable from y. In particular, (A_{tmp}, C_2) is detectable.

VELOCITY METHOD AND LAGRANGIAN FORMULATION FOR THE COMPUTATION OF THE SHAPE HESSIAN*

MICHEL C. DELFOUR† AND JEAN-PAUL ZOLÉSIO‡

Abstract. The object of this paper is to study the shape Hessian of a shape functional by the velocity (speed) method. It contains a review and an extension of the velocity method and its connections with methods using first- or second-order perturbations of the identity. The key point is that all these methods yield the same shape gradient but different and unequal shape Hessian since each method depends on a choice of "connection." However, for autonomous velocity fields the velocity method yields a canonical bilinear Hessian. Expressions obtained by other methods can be recovered by adding to that canonical term the shape gradient acting on the acceleration of the velocity field associated with the choice of perturbation of the identity. The second part of the paper is an application of the Lagrangian method with function space embedding to compute the shape gradient and Hessian of a simple cost function associated with the nonhomogeneous Dirichlet problem.

Key words. shape optimization, velocity method, Hessian, second-order derivatives

1. Introduction.

The object of this paper is to study the *shape Hessian* by the *velocity* (*speed*) *method* (cf. Céa [1]–[3] and Zolésio [1], [2]) and to apply the *Lagrangian method* with *function space embedding* to compute the shape gradient and Hessian of a simple cost function associated with the nonhomogeneous Dirichlet problem. To do this we introduce a general method that applies to *differentiable semiconvex* cost functionals with applications to more general problems than the simple illustrative example we have chosen to consider. We emphasize the use of the *function space embedding* method (cf. Delfour and Zolésio [1]–[4], [7]) combined with the implicit use of Lagrange multipliers. This paper complements our previous work, where we have used a variational formulation and *function space parametrization* for the Neumann problem (cf. Zolésio and Delfour [8]).

In shape sensitivity analysis the size of the computations can quickly become quite large. Therefore, it is extremely important to know and understand the fundamental structure of the shape gradient and the shape hessian to simplify the computations and obtain mathematically meaningful expressions. For this reason we systematically revise and update the velocity (speed) method and then present new results for the second-order shape derivative. In the process we show how to associate with methods of *perturbation of the identity* (first and second order) an appropriate nonautonomous family of velocity fields. For the shape gradient, the different methods yield expressions that may look different but are all equal. However, this is no longer true for the

shape Hessian. In fact, we will show in §2.4 that different perturbations of the identity can yield different final expressions that are not equal. The potentially confusing consequence of this fact is that we can introduce an infinity of definitions based on perturbations of the identity. However, we will show that they always contain a *canonical bilinear term* plus the shape gradient of the functional acting in the direction of an *acceleration* field, which is characteristic of the chosen perturbation. The canonical bilinear term exactly coincides with the second-order shape derivative obtained by the velocity (speed) method for autonomous velocity fields. Each expression arising from a perturbation of the identity can be strictly recovered by adding to the canonical term the shape gradient acting in the direction of an appropriate acceleration field. Therefore, we propose to refer to this canonical term as the *shape Hessian*.

The above considerations clarify the fundamental concepts and reduce their complexity, but they do not eliminate all the associated computations. We need methods that provide both quick formal computations and appropriate mathematical justifications. We use Lagrangian methods combined with the use of theorems on the derivative of a MinMax with respect to a parameter. Such methods are well known and extensively used in mechanical sciences, mathematical programming, and optimal control theory. Their application to shape sensitivity analysis is not completely straightforward since it leads to the *time-dependence* of the underlying function spaces appearing in the MinMax formulation. This phenomenon seems to be specific to that class of problems. Two techniques are available to get around this difficulty: the *function space parametrization* and the *function space embedding* methods. The first one has been used in Delfour and Zolésio [8], [9], the second one will be used here.

It is fair to say that the use of shape Hessians for discretized finite element models and finitely parametrized shapes have been used in many places in the engineering and mechanics literature. Some numerical expertise is available (cf., for instance, Bern [1], Bern, Chenot, Demay, and Zolésio [1]) and it is suspected that the really performing algorithms are not available in the open literature since they are marketable industrial products.

A few papers have dealt with the second variation of a shape cost function for linear partial differential equations models. To our knowledge, the first one by Fujii [1] used a second-order perturbation of the identity along the normal to the boundary for second-order linear elliptic problems. An extremely interesting paper by Arumugan and Pironneau [1], [2] used the shape second variation to solve the "ribblet problem." Finally, Simon [1] presented a computation of the second variation using a first-order perturbation of the identity. The first general approach to the computation of shape Hessians can be found in Delfour and Zolésio [8], [9]. It uses the velocity (speed) method and includes a simple illustrative example for the Neumann problem.

In conclusion, we would like to insist that the velocity method and methods using first- and second-order perturbations of the identity lead to three different second-order shape derivatives that are not equal. The velocity method with autonomous velocity fields provides the canonical bilinear shape Hessian and all the other derivatives can be recovered by special choices of nonautonomous velocity fields.

2. Shape derivative: definitions and properties.

In this section we recall and extend the definitions of a shape gradient and a shape Hessian based on the velocity method (cf. Zolésio [1], [2], Delfour and Zolésio [8], [9]) and discuss their relationship to various methods based on perturbations of the identity operator. The proof of each theorem is given in the Appendix.

2.1. Velocity (speed) method and perturbations of the identity operator. Let $V : [0,\tau] \times \mathbb{R}^N \to \mathbb{R}^N$ be a given velocity field for some fixed $\tau > 0$. The map V can be viewed as a family $\{V(t)\}$ of nonautonomous velocity fields on $\mathbb{R}^N$ defined by

$$x \mapsto V(t)(x) \overset{\text{def}}{=} V(t,x) : \mathbb{R}^N \mapsto \mathbb{R}^N. \tag{1}$$

Assume that

$$\text{(V)} \qquad \begin{cases} \forall x \in \mathbb{R}^N, & V(\cdot,x) \in C^0([0,\tau];\mathbb{R}^N), \\ \exists c > 0, \quad \forall x,y \in \mathbb{R}^N, & \|V(\cdot,y) - V(\cdot,x)\|_{C^0([0,\tau];\mathbb{R}^N)} \le c|y-x|, \end{cases}$$

where $V(\cdot,x)$ denotes the function $t \mapsto V(t,x)$. Associate with V the solution $x(t;X)$ of the ordinary differential equation

$$\frac{dx}{dt}(t) = V(t,x(t)), \quad t \in [0,\tau], \quad x(0) = X \in \mathbb{R}^N \tag{2}$$

and introduce the family of homeomorphisms

$$X \mapsto T_t(V)(X) \overset{\text{def}}{=} x(t,X) : \mathbb{R}^N \to \mathbb{R}^N \tag{3}$$

and the maps

$$(t,X) \mapsto T_V(t,X) \overset{\text{def}}{=} T_t(V)(X) : [0,\tau] \times \mathbb{R}^N \to \mathbb{R}^N, \tag{4}$$

$$(t,x) \mapsto T_V^{-1}(t,x) \overset{\text{def}}{=} T_t^{-1}(V)(x) : [0,\tau] \times \mathbb{R}^N \to \mathbb{R}^N. \tag{5}$$

By definition $T_0(X) = X$ and $T_0 = I$. Moreover, T_t is an evolution operator that verifies the usual semigroup property.

Note 2.1. In the sequel we will drop the V in $T_V(t,X)$ and $T_t(V)$ whenever no confusion is possible.

THEOREM 2.1. (i) *Under assumptions* (V) *on the map* V, *the maps* T *defined by* (3) *and* (4) *have the following properties*:

(T1)

$$\begin{aligned} &\forall X \in \mathbb{R}^N, \quad T(\cdot,X) \in C^1([0,\tau];\mathbb{R}^N), \\ &\exists c > 0, \quad \forall X,Y \in \mathbb{R}^N, \quad \|T(\cdot,Y) - T(\cdot,X)\|_{C^1([0,\tau];\mathbb{R}^N)} \le c|Y-X|, \end{aligned}$$

(T2)

$$\forall t \in [0,\tau], \quad X \mapsto T_t(X) = T(t,X) : \mathbb{R}^N \to \mathbb{R}^N \quad \textit{is bijective},$$

(T3)

$$\begin{aligned} &\forall x \in \mathbb{R}^N, \quad T^{-1}(\cdot,x) \in C^0([0,\tau];\mathbb{R}^N) \\ &\exists c > 0, \quad \forall x,y \in \mathbb{R}^N, \quad \|T^{-1}(\cdot,y) - T^{-1}(\cdot,x)\|_{C^0([0,\tau];\mathbb{R}^N)} \le c|y-x|. \end{aligned}$$

(ii) *If there exists a real number* $\tau > 0$ *and a map* $T : [0,\tau] \times \mathbb{R}^N \to \mathbb{R}^N$ *verifying assumptions* (T1), (T2), *and* (T3), *then the map*

$$(t,x) \mapsto V(t,x) = \frac{\partial T}{\partial t}(t, T_t^{-1}(x)) : [0,\tau] \times \mathbb{R}^N \to \mathbb{R}^N, \tag{6}$$

verifies assumptions (V), *where* T_t^{-1} *is the inverse of* $X \mapsto T_t(X)$.

This first theorem is an equivalence result. It says that we can either start from a family of velocity fields $\{V(t)\}$ on $\mathbb{R}^N$ or a family of transformations $\{T_t\}$ of $\mathbb{R}^N$ provided that the map $V, V(t,x) = V(t)(x)$, verifies (V) or the map $T, T(t,X) = T_t(X)$ verifies assumptions (T1), (T2), and (T3).

When we start from V, we obtain the velocity method. Given an initial domain Ω, the family of homeomorphisms $T_t(V)$ defines a family of transformed domains

$$\Omega_t = T_t(V)(\Omega) = \{T_t(V)(X) : X \in \Omega\}. \tag{7}$$

In examples where we start from T, it is usually possible to verify hypotheses (T1),(T2), and (T3) and construct the corresponding velocity field V defined in (6). For instance, perturbations of the identity to the first- or second-order fall in that category:

$$T(t,X) = X + tU(X) + \frac{t^2}{2}A(X) \quad (A = 0 \text{ for the first order}), \quad t \geq 0, \ X \in \mathbb{R}^N, \tag{8}$$

where U and A are given transformations of $\mathbb{R}^N$. It turns out that, for Lipschitz transformations U and A, we can construct a $\tau > 0$ for which hypotheses (T1), (T2), and (T3) are verified.

THEOREM 2.2. *Let U and A be two uniform Lipschitz transformations of* $\mathbb{R}^N$:

$$\exists c > 0, \quad \forall X,\ Y \in \mathbb{R}^N, \quad |U(Y) - U(X)| \leq c|Y - X|, \quad |A(Y) - A(X)| \leq c|Y - X|.$$

(i) *Let* $\tau = \min\{1, 1/4c\}$ *and T be given by* (8). *Then the velocity*

$$(t,x) \mapsto V(t,x) = U(T_t^{-1}(x)) + tA(T_t^{-1}(x)) : [0,\tau] \times \mathbb{R}^N \to \mathbb{R}^N, \tag{9}$$

on $[0,\tau]$ *verifies assumptions* (V).

Remark 2.1. This theorem only says that for Lipschitzian fields U and A there exists a $\tau > 0$, possibly very small, such that $\{T_t(X) :$ for all $t \in [0,\tau]\}$ is solution of the differential equation (2) for V given by (9). This is all we need to define a shape derivative and this is the general approach followed in the various papers using perturbations of the identity operator. So we do not need to restrict our hypotheses to autonomous linear and nilpotent U's and A's. Higher-order perturbations of the identity operator can be considered, and Theorem 2.2 will still apply for some sufficiently small $\tau > 0$. However, they are not necessary for first- and second-order derivatives.

Remark 2.2. Observe that from (8) and (9)

$$V(0) = U, \ \overset{\bullet}{V}(0)(x) \overset{\text{def}}{=} \frac{\partial V}{\partial t}(t,x)|_{t=0} = A - [DU]U, \tag{10}$$

where DU is the Jacobian matrix of U. The transformation $\overset{\bullet}{V}(0)$ of $\mathbb{R}^N$ is an *acceleration* field at $t = 0$, which will always be present even when $A = 0$.

2.2. Shape gradient. In general a, *shape functional* will be a map

$$\Omega \mapsto J(\Omega) : \mathcal{A} \subset \mathcal{P}(\mathbb{R}^N) \to \mathbb{R} \tag{11}$$

defined on a subset $\mathcal{A}$ of the set $\mathcal{P}(\mathbb{R}^N)$ of all subsets of $\mathbb{R}^N$. Under the action of a velocity V verifying assumptions (V), the domain Ω is transformed into a new domain $\Omega_t(V) = T_t(V)(\Omega)$.

DEFINITION 2.1. Given a velocity field V verifying assumptions (V), J is said to have an *Eulerian semiderivative* at Ω in the direction V if the following limit exists and is finite:

$$\lim_{t \searrow 0} [J(\Omega_t(V)) - J(\Omega)]/t. \tag{12}$$

Whenever it exists, it is denoted by $dJ(\Omega; V)$.

Remark 2.3. This is the original terminology introduced by Céa [1],[2] and Zolésio [1] in 1979. It is now widely recognized and used in all papers based on the velocity (speed) method.

This definition is quite general and covers situations where $dJ(\Omega; V)$ is a function of the whole family of velocity fields $\{V(t) : t \in [0, \tau]\}$. However, in most applications $dJ(\Omega; V)$ will only depend on $V(0)$, the velocity field at $t = 0$. This is a very important property since $dJ(\Omega; V)$ can then be obtained by using the autonomous vector field W,

$$W(t, x) = V(0, x) \quad \forall x \in \mathbb{R}^N \quad \forall t \geq 0,$$

instead of the nonautonomous field V. It is customary to use the notation $dJ(\Omega; V(0))$ for the Eulerian semiderivative computed for the autonomous field W and we make the identification $W \equiv V(0)$.

It turns out that the very important property $dJ(\Omega; V) = dJ(\Omega; V(0))$ can be obtained under a simple continuity hypothesis on the map $V \mapsto dJ(\Omega; V)$. This, of course, requires the introduction of a special topology on the space of velocity fields V. To be more precise, we introduce some notation. For any integers $k \geq 0$ and $m \geq 0$, and any compact subset K of $\mathbb{R}^N$

$$\mathcal{V}_K^{m,k} \;=\; C^m([0, \tau]; \mathcal{D}^k(K, \mathbb{R}^N)) \cap \mathcal{L}, \tag{13}$$

where $\mathcal{D}^k(K, \mathbb{R}^N)$ is the space of all k-times continuously differentiable maps from $\mathbb{R}^N$ to $\mathbb{R}^N$ with compact support in K and

$$\mathcal{L} = \{V : [0, \tau] \times \mathbb{R}^N \to \mathbb{R}^N : V \text{ verifies assumption (V)}\}. \tag{14}$$

When $k = \infty$ we drop the superscript ∞ and simply write $\mathcal{D}(K, \mathbb{R}^N)$ instead of $\mathcal{D}^\infty(K, \mathbb{R}^N)$. With the above definitions, we introduce the following new space:

$$\overset{\rightarrow}{\mathcal{V}}^{m,k} \overset{\text{def}}{=} \underset{K}{\underset{\rightarrow}{\lim}} \left\{\mathcal{V}_K^{m,k} : \forall K \;\text{ compact } \mathit{in}\ \mathbb{R}^N\right\}, \tag{15}$$

where $\underset{\rightarrow}{\lim}$ denotes the inductive limit endowed with its natural inductive limit topology. This is not a Fréchet space. For autonomous fields, the above constructions reduce to

$$\mathcal{V}^k = \mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N) \cap \text{ Lip}(\mathbb{R}^N, \mathbb{R}^N), \tag{16}$$

where Lip $(\mathbb{R}^N, \mathbb{R}^N)$ denotes the space of transformations of $\mathbb{R}^N$ that are uniformly Lipschitzian. Again, we will use the notation $\mathcal{D}(\mathbb{R}^N, \mathbb{R}^N)$ for $\mathcal{D}^\infty(\mathbb{R}^N, \mathbb{R}^N)$. In all cases, assumptions (V) will be verified.

THEOREM 2.3. *Let Ω be a domain in $\mathbb{R}^N$ and $m \geq 0$ and $k \geq 0$ be integers. Assume that for all V in $\overrightarrow{\mathcal{V}}^{m,k}$, $dJ(\Omega; V)$ exists and that the map*

$$V \mapsto dJ(\Omega; V) : \overset{\rightarrow}{\mathcal{V}}^{m,k} \to \mathbb{R} \tag{17}$$

is continuous. Then

$$\forall V \in \overset{\rightarrow}{\mathcal{V}}^{m,k}, \quad dJ(\Omega; V) = dJ(\Omega; V(0)). \tag{18}$$

In the above analysis we have chosen to follow the classical framework of the theory of distributions (cf. Schwartz [1]) and perturb the domain Ω by velocity fields V with compact support. This means that we simultaneously deal with bounded and unbounded domains Ω's. Theorem 2.3 is a generalization of the earlier result of Zolésio [1].

DEFINITION 2.2. Let Ω be a domain in $\mathbb{R}^N$.

(i) The shape functional J is said to be *shape differentiable* at Ω if the Eulerian semiderivative $dJ(\Omega; V)$ exists for all V in $\mathcal{D}(\mathbb{R}^N, \mathbb{R}^N)$ and the map

$$V \mapsto dJ(\Omega; V) : \mathcal{D}(\mathbb{R}^N, \mathbb{R}^N) \to \mathbb{R} \tag{19}$$

is linear and continuous.

(ii) The map (19) defines a vector distribution $G(\Omega)$, which will be called the *shape gradient* of J at Ω.

(iii) If there exists a finite $k \geq 0$ such that $G(\Omega)$ is continuous for the $\mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N)$-topology, we say that $G(\Omega)$ is of finite order qk.

The next theorem gives additional properties of shape differentiable functionals.

THEOREM 2.4 (Generalized Hadamard's structure theorem). *Let Ω be an open domain in $\mathbb{R}^N$ with boundary Γ and assume that J is shape differentiable.*

(i) *The support of $G(\Omega)$ is contained in Γ. Moreover, when the support of $G(\Omega)$ is compact the order of $G(\Omega)$ is finite.*

(ii) *If $G(\Omega)$ is of finite order $k \geq 0$ and Ω is an open domain in $\mathbb{R}^N$ with boundary Γ in C^{k+1}, then there exists a scalar distribution $g(\Omega)$ in $\mathcal{D}^k(\Gamma)'$ such that*

$$dJ(\Omega; V) = < g(\Omega),\ \gamma_\Gamma V \bullet n >_{\mathcal{D}^k(\Gamma)}, \tag{20}$$

where $\gamma_\Gamma V$ is the trace of V on Γ, n is the unit outward normal to Ω on Γ, and $V \bullet n$ denotes the scalar product of V and n in $\mathbb{R}^N$.

The name of the theorem comes from the famous prized paper by Hadamard [1], written in 1907, where he used velocity fields along the normal to the boundary Γ of a C^∞ domain to compute the derivative of the first eigenvalue of the plate. Theorem 2.4 was proved by Zolésio [1] in 1979. A new proof using Nagumo's [1] theorem is given in the Appendix.

Remark 2.4. When Γ is compact, $\mathcal{D}^k(\Gamma)$ coincides with $C^k(\Gamma)$.

2.3. Shape Hessian. We first study the second-order Eulerian semiderivative $d^2J(\Omega; V; W)$ of a functional $J(\Omega)$ for two nonautonomous vector fields V and W. A first theorem shows that under some natural continuity hypotheses, $d^2J(\Omega; V; W)$ is the sum of two terms: a "canonical term $d^2J(\Omega; V(0); W(0))$" plus the first-order Eulerian semiderivative $dJ(\Omega; \overset{\bullet}{V}(0))$ at Ω in the direction $\overset{\bullet}{V}(0)$ of the time-partial derivative $\partial_t V(t, x)$ at $t = 0$ of the velocity field $V(t)$.

As for first-order Eulerian semiderivatives, this first theorem reduces the study of second-order Eulerian semiderivatives to the autonomous case. So in §2.3.2 we will specialize to autonomous fields V and W in $\mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N)$ and give the equivalent of Hadamard's structure theorem for the canonical term.

2.3.1. Nonautonomous case. The basic framework introduced in §§2.1 and 2.2 has reduced the computation of the Eulerian semiderivative of $J(\Omega)$ to the computation of the derivative

$$j'(0) = dJ(\Omega; V(0)) \tag{21}$$

of the function

$$j(t) = J(\Omega_t(V)). \tag{22}$$

For $t \geq 0$, we naturally obtain

$$j'(t) = dJ(\Omega_t(V); V(t)). \tag{23}$$

This suggests the following definition.

DEFINITION 2.3. Let V and W belong to $\mathcal{L}$ and assume that for all $t \in [0, \tau]$, $dJ(\Omega_t(W); V(t))$ exists at $\Omega_t(W) = T_t(W)(\Omega)$ in the direction $V(t)$. The functional J is said to have a *second-order Eulerian semiderivative* at Ω in the directions (V, W) if the following limit exists:

$$\lim_{t \searrow 0} [dJ(\Omega_t(W); V(t)) - dJ(\Omega; V(0))]/t. \tag{24}$$

Whenever it exists, it is denoted by $d^2J(\Omega; V; W)$.

In this definition, the domain Ω is transformed into the domain $\Omega_t(W)$ under the action of the velocity field W. The vector function V appears in the expressions of $dJ(\Omega_t(W); V(t))$ and $dJ(\Omega; V(0))$, but does not contribute to the deformation of Ω.

Remark 2.5. This last definition is compatible with the second-order expansion of $j(t)$ with respect to t around $t = 0$:

$$j(t) \cong j(0) + tj'(0) + \frac{t^2}{2} j''(0), \tag{25}$$

where

$$j''(0) = d^2J(\Omega; V; V). \tag{26}$$

Remark 2.6. It is easy to construct simple examples with autonomous fields V and W showing that $d^2J(\Omega; V; W) \neq d^2J(\Omega; W; V)$ (cf. Delfour and Zolésio [8]).

The next theorem is the analogue of Theorem 2.3 and provides the canonical structure of the second-order Eulerian semiderivative.

THEOREM 2.5. *Let Ω be a domain in $\mathbb{R}^N$ and $m \geq 0$ and $\ell \geq 0$ be integers. Assume that*

(i) $\forall V \in \vec{\mathcal{V}}^{m+1,\ell}$, $\forall W \in \vec{\mathcal{V}}^{m,\ell}$, $d^2J(\Omega; V; W)$ *exists*;

(ii) $\forall W \in \vec{\mathcal{V}}^{m,\ell}$, $\forall t \in [0, \tau]$, *J has a shape gradient at $\Omega_t(W)$ of order ℓ*;

(iii) $\forall U \in \mathcal{V}^{\ell}$, *the map*

$$W \mapsto d^2J(\Omega; U; W) : \vec{\mathcal{V}}^{m,\ell} \to \mathbb{R} \tag{27}$$

is continuous. Then for all V in $\vec{\mathcal{V}}^{m+1,\ell}$ and all Win $\vec{\mathcal{V}}^{m,\ell}$

$$d^2J(\Omega; V; W) = d^2J(\Omega; V(0); W(0)) + dJ(\Omega; \dot{V}(0)), \tag{28}$$

where

$$\dot{V}(0)(x) = \lim_{t \searrow 0} [V(t, x) - V(0, x)]/t. \tag{29}$$

2.3.2. Autonomous case.

DEFINITION 2.4. Let Ω be a domain in $\mathbb{R}^N$.

(i) The functional $J(\Omega)$ is said to be *shape differentiable* at Ω if

$$\forall V, \quad \forall W \text{ in } \mathcal{D}(\mathbb{R}^N, \mathbb{R}^N), \quad d^2J(\Omega; V; W) \tag{30}$$

exist and the map

$$(V, W) \mapsto d^2J(\Omega; V; W) : \mathcal{D}(\mathbb{R}^N, \mathbb{R}^N) \times \mathcal{D}(\mathbb{R}^N, \mathbb{R}^N) \to \mathbb{R} \tag{31}$$

is bilinear and continuous. We denote by h the bilinear and continuous map (31).

(ii) Denote by $H(\Omega)$ the continuous linear map on the tensor product $\mathcal{D}(\mathbb{R}^N, \mathbb{R}^N) \otimes \mathcal{D}(\mathbb{R}^N, \mathbb{R}^N)$, associated with h:

$$(32) \qquad d^2J(\Omega; V; W) = \langle H(\Omega), V \otimes W\rangle = h(V, W),$$

where $V \otimes W$ is the tensor product of V and W defined as

$$(33) \qquad (V \otimes W)_{ij}(x, y) = V_i(x)W_j(y), \quad 1 \leq i, \quad j \leq N,$$

and $V_i(x)$ (respectively, $W_j(y)$) is the ith (respectively jth) component of the vector V(respectively W) (cf. Schwartz's [2] kernel theorem and Gelfand and Vilenkin [1]). $H(\Omega)$ will be called the *shape Hessian* of J at Ω.

(iii) When there exists a finite integer $\ell \geq 0$ such that $H(\Omega)$ is continuous on $\mathcal{D}^\ell(\mathbb{R}^N, \mathbb{R}^N) \otimes \mathcal{D}^\ell(\mathbb{R}^N, \mathbb{R}^N)$, we say that $H(\Omega)$ is of finite order ℓ.

THEOREM 2.6. *Let Ω be an open domain in $\mathbb{R}^N$ with boundary Γ and assume that J is twice shape differentiable at Ω.*

(i) *$H(\Omega)$ (that is, h) has support in $\Gamma \times \Gamma$. Moreover, when the support of $H(\Omega)$ is compact the order of $H(\Omega)$ is finite.*

(ii) *If $H(\Omega)$ is of finite order ℓ, $\ell \geq 0$, and Ω is an open domain with boundary Γ in $C^{\ell+1}$, then there exists a continuous linear map $h(\Omega)$ on the tensor product $\mathcal{D}^\ell(\Gamma, \mathbb{R}^N) \otimes \mathcal{D}^\ell(\Gamma)$ such that*

$$(34) \qquad d^2J(\Omega); V; W) = \langle h(\Omega), (\gamma_\Gamma V) \otimes ((\gamma_\Gamma W) \bullet n)\rangle,$$

where $\gamma_\Gamma V$ is the trace of V on Γ; $(\gamma_\Gamma V) \otimes ((\gamma_\Gamma W) \bullet n)$ is defined as the tensor product

$$(35) \quad ((\gamma_\Gamma V) \otimes (\gamma_\Gamma W) \bullet n))_i(x, y) = (\gamma_\Gamma V_i)(x)((\gamma_\Gamma W) \bullet n)(y), \quad x, y \in \Gamma, \quad 1 \leq i \leq N;$$

$V_i(x)$ is the ith component of $V(x)$; and

$$(36) \qquad ((\gamma_\Gamma W) \bullet n)(y) = (\gamma_\Gamma W)(y) \bullet n(y), \qquad y \in \Gamma.$$

Remark 2.7. Finally, under the assumptions of Theorems 2.5 and 2.6,

$$(37) \quad d^2J(\Omega; V; W) = \langle h(\Omega), (\gamma_\Gamma V(0)) \otimes ((\gamma_\Gamma W(0)) \bullet n)\rangle + \langle g(\Omega), (\gamma_\Gamma \dot{V}(0)) \bullet n\rangle$$

for all V in $\vec{\mathcal{V}}^{m+1,\ell}$ and W in $\vec{\mathcal{V}}^{m,\ell}$.

2.4. Comparison with methods of perturbation of the identity. At this juncture it is instructive to compare first- and second-order Eulerian semiderivatives obtained by the velocity (speed) method with those obtained by first- and second-order perturbations of the identity, that is, when the transformations T_t are specified a priori by

$$(38) \qquad T_t(X) = X + tU(X) + \frac{t^2}{2}A(X), \qquad X \in \mathbb{R}^N,$$

where U and A are transformations of $\mathbb{R}^N$ verifying the hypotheses of Theorem 2.2. The transformation T_t in (38) is a *second-order* perturbation when $A \neq 0$ and a *first-order* perturbation when $A = 0$.

According to Theorem 2.2, first- and second-order Eulerian semiderivatives associated with (38) can be equivalently obtained by applying the velocity (speed) method to the nonautonomous velocity fields V_{UA} given by (9). So when J verifies the hypotheses of Theorem 2.4,

$$(39) \qquad dJ(\Omega; V_{UA}) = dJ(\Omega; V_{UA}(0)) = dJ(\Omega; U),$$

where we have used the first part of Remark 2.2, which says that

$$V_{UA}(0) = U \text{ and } \overset{\bullet}{V}_{UA}(0) = A - [DU]U. \tag{40}$$

Similarly, if V_{WB} is another velocity field corresponding to

$$T_t(X) = X + tW(X) + \frac{t^2}{2}B(X),\ X \in \mathbb{R}^N, \tag{41}$$

where W and B verify the condition of Theorem 2.2, then when J verifies the assumptions of Theorem 2.6,

$$d^2J(\Omega; V_{UA}; V_{WB}) = d^2J(\Omega; V_{UA}(0); V_{WB}(0)) + dJ(\Omega; \overset{\bullet}{V}_{UA}(0)) \tag{42}$$

and

$$d^2J(\Omega; V_{UA}; V_{WB}) = d^2J(\Omega; U; W) + dJ(\Omega; A - [DU]U). \tag{43}$$

Expressions (39) and (43) are to be compared with the following expressions obtained by the velocity (speed) method for the two autonomous vector fields U and W:

$$dJ(\Omega; U) \quad \text{and} \quad d^2J(\Omega; U; W). \tag{44}$$

For the shape gradient the two expressions coincide; for the shape hessian we recognize the bilinear term in (43) and (44) but the two expressions differ by the term

$$dJ(\Omega; A - [DU]U). \tag{45}$$

Even for a first-order perturbation ($A = 0$), we have a quadratic term in U.

This situation is analogous to the classical problem of defining second-order derivatives on a manifold. The term (45) would correspond to the connection while the bilinear term $d^2J(\Omega; V; W)$ would be the candidate for the *canonical* second-order shape derivative. In this context, we will refer to the corresponding distribution $H(\Omega)$ as the *canonical shape Hessian*. All other second-order shape derivatives are obtained from $H(\Omega)$ by adding the gradient term $g(\Omega)$ acting as the appropriate acceleration field (connection).

Remark 2.8. The method of perturbation of the identity can be made *more canonical* by using the following family of transformations:

$$T_t(X) = X + tU(X) + \frac{t^2}{2}(A + [DU]U), \tag{46}$$

which yields

$$dJ(\Omega; U) \tag{47}$$

for the gradient and

$$d^2J(\Omega; U; W) + dJ(\Omega; A) \tag{48}$$

for the Hessian, where for a first-order perturbation ($A = 0$), the second term disappears.

Remark 2.9. Denote by $\mathcal{A}^{\ell+1}$ the set of all open domains Ω in $\mathbb{R}^N$ with a boundary Γ that is $C^{\ell+1}$, $\ell \geq 0$. Assume that there exists a domain Ω^* in $\mathcal{A}^{\ell+1}$ that minimizes a given domain functional $J(\Omega)$ over all Ω in $\mathcal{A}^{\ell+1}$. Then if J is twice shape differentiable for all Ω in $\mathcal{A}^{\ell+1}$, Ω^* verifies the following necessary conditions:

$$dJ(\Omega^*; V) = 0 \quad \forall V \in \mathcal{D}(\mathbb{R}^N, \mathbb{R}^N), \tag{49}$$

$$d^2J(\Omega^*; W; W) \geq 0 \quad \forall W \in \mathcal{D}(\mathbb{R}^N, \mathbb{R}^N). \tag{50}$$

Obviously, necessary conditions are not, in general, sufficient conditions. This fact is well known in optimization problems over vector spaces. For shapes the situation is even more delicate since a space of domains is not a vector space, and traditional concepts such as convexity are more difficult to formalize and use. We also know that, always in general, optimal domains are not necessarily smooth. Microstructures or domains with fractal boundaries naturally occur as in the optimization of the thickness of a plate (cf. Cheng and Olhoff [1]). This type of phenomenon is similar to the one encountered in chattering control.

3. A saddle point formulation of the Dirichlet problem. Let Ω be a bounded open domain in $\mathbb{R}^N$ with a sufficiently smooth boundary Γ. Let f and g be two fixed functions in $H^{1/2+\epsilon}(\mathbb{R}^N)$ and $H^{2+\epsilon}(\mathbb{R}^N)$, respectively, for some arbitrary small $\epsilon > 0$. Consider the solution y in $H^2(\Omega)$ to the nonhomogeneous Dirichlet boundary value problem:

$$-\Delta y = f \quad \text{in } \Omega, \qquad y = g \quad \text{on } \Gamma. \tag{1}$$

Our objective is to transform this problem into finding the saddle point of a volume Lagrangian functional. This technique can be applied to other boundary value problems with Dirichlet conditions.

Note that y is also the solution of the weak equation

$$\int_\Omega (\Delta y + f)\psi \, dx + \int_\Gamma (y - g)\mu \, d\Gamma = 0 \tag{2}$$

for all ψ in $H^2(\Omega)$ and μ in $H^{1/2}(\Gamma)$, since the corresponding continuous convex-concave functional

$$L(\phi,\ \psi,\ \mu) = \int_\Omega (\Delta\phi + f)\psi \, dx + \int_\Gamma (\phi - g)\mu \, d\Gamma \tag{3}$$

has a unique saddle point $(\hat{\phi}, \hat{\psi}, \hat{\mu})$, which is completely characterized by the equations

$$\Delta\hat{\phi} + f = 0 \quad \text{in } \Omega, \tag{4}$$

$$\hat{\phi} - g = 0 \quad \text{in } \Gamma, \tag{5}$$

$$\int_\Omega \Delta\phi \ \hat{\psi} \, dx + \int_\Gamma \phi\hat{\mu} \, d\Gamma = 0 \quad \forall\phi \in H^2(\Omega), \tag{6}$$

where the last equation yields

$$\Delta\hat{\psi} = 0 \quad \text{in } \Omega, \qquad \hat{\psi} = 0 \quad \text{on } \Gamma, \quad \text{and} \quad \hat{\mu} = \frac{\partial\hat{\psi}}{\partial n} \quad \text{on } \Gamma. \tag{7}$$

The proof of this can be found in Ekeland and Temam [1, Prop. 1.6]. Of course, this implies that the saddle point is unique and given by

$$(\hat{\phi}, \hat{\psi}, \hat{\mu}) = (y, 0, 0). \tag{8}$$

The purpose of the above computation was to characterize the multiplier $\hat{\mu}$

$$\hat{\mu} = \frac{\partial\hat{\psi}}{\partial n} \quad \text{on } \Gamma, \tag{9}$$

to rewrite the previous functional as a function of two variables instead of three:

$$L(\phi,\psi)=\int_\Omega(\Delta\phi+f)\psi\,dx+\int_\Gamma(\phi-g)\frac{\partial\psi}{\partial n}\,d\Gamma, \tag{10}$$

for (ϕ,ψ) in $H^2(\Omega)\times H^2(\Omega)$. It is also advantageous for shape problems to get rid of boundary integrals whenever it is possible. So noting that

$$\int_\Gamma(\phi-g)\frac{\partial\psi}{\partial n}\,d\Gamma=\int_\Omega \operatorname{div}[(\phi-g)\nabla\psi]\,dx, \tag{11}$$

we finally use the functional

$$L(\phi,\psi)=\int_\Omega\{(\Delta\phi+f)\psi+(\phi-g)\Delta\psi+\nabla(\phi-g)\bullet\nabla\psi\}\,dx \tag{12}$$

on $H^2(\Omega)\times H^2(\Omega)$. It is readily seen that it has a unique saddle point $(\hat\phi,\hat\psi)$ in $H^2(\Omega)\times H^2(\Omega)$, which is completely characterized by the following saddle point equations:

$$\Delta\hat\phi+f=0\quad\text{in }\Omega,\qquad \hat\psi=g\quad\text{on }\Gamma,\quad \Delta\hat\psi=0\quad\text{in }\Omega,\quad \hat\psi=0\quad\text{on }\Gamma. \tag{13}$$

4. Shape gradient for the Dirichlet problem.

4.1. Formulation and formal computations. Consider the cost function

$$J(\Omega)=\frac{1}{2}\int_\Omega|y(\Omega)-y_d|^2\,dx \tag{1}$$

associated with the solution $y=y(\Omega)$ of the Dirichlet problem (3.1) and the given function y_d in $H^{1/2+\epsilon}(\mathbb{R}^N)$ for some arbitrary fixed $\epsilon>0$.

As in §3, we reformulate this problem as the saddle point of a functional by introducing the Lagrangian

$$G(\Omega,\phi,\psi)=\frac{1}{2}\int_\Omega|\phi-y_d|^2\,dx+\int_\Omega\{(\Delta\phi+f)\psi+(\phi-g)\Delta\psi+\nabla(\phi-g)\bullet\nabla\psi\}\,dx \tag{2}$$

on $H^2(\Omega)\times H^2(\Omega)$. It is readily seen that $G(\Omega,\cdot,\cdot)$ has a unique saddle point $(\hat\phi,\hat\psi)$, which is completely characterized by the following saddle point equations:

$$\Delta\hat\phi+f=0\quad\text{in }\Omega,\quad \hat\phi=g\quad\text{on }\Gamma, \tag{3}$$

$$\int_\Omega\{(\hat\phi-y_d)\phi+\Delta\phi\hat\psi+\phi\Delta\hat\psi+\nabla\phi\bullet\nabla\hat\psi\}\,dx=0\quad\forall\ \phi\in H^2(\Omega). \tag{4}$$

The last equation is equivalent to

$$\int_\Omega[(\hat\phi-y_d)+\Delta\hat\psi]\phi\,dx+\int_\Gamma\frac{\partial\phi}{\partial n}\hat\psi\,d\Gamma=0\quad\forall\phi\in H^2(\Omega) \tag{5}$$

or

$$\Delta\hat\psi+(\hat\phi-y_d)=0\text{ in }\Omega,\quad\hat\psi=0\text{ on }\Gamma, \tag{6}$$

by using the theorem on the surjectivity of the trace. In the folllowing, we will use the notation (y,p) for the saddle point $(\hat\phi,\hat\psi)$. As a result, we have

$$J(\Omega)=\operatorname*{Min}_{\phi\in H^2(\Omega)}\ \operatorname*{Max}_{\psi\in H^2(\Omega)}\ G(\Omega,\phi,\psi). \tag{7}$$

We will now use the above Lagrangian formulation combined with the velocity method (cf. Céa [1]–[3]; Zolésio [1], [2], Delfour and Zolésio [1]–[4], [7]–[9]) to compute the shape gradient of $J(\Omega)$. Recall that the domain Ω is perturbed by a velocity vector field V that induces a family of homeomorphisms (cf. §2.1)

$$T_t : \mathbb{R}^N \to \mathbb{R}^N, \qquad T_t(X) = x(t), \tag{8}$$

which transforms the domain Ω into the new domains

$$\Omega_t = T_t(\Omega), \quad t \in [0,\tau]. \tag{9}$$

The Shape semiderivative is defined as (cf. §2.2)

$$dJ(\Omega; V) = \lim_{t\searrow 0}[J(\Omega_t) - J(\Omega)]/t \tag{10}$$

whenever the limit exists. For t in $[0,\tau]$

$$J(\Omega_t) = \operatorname*{Min}_{\phi\in H^2(\Omega_t)} \ \operatorname*{Max}_{\psi\in H^2(\Omega_t)} \ G(\Omega_t, \phi, \psi) \tag{11}$$

and the technical difficulty arises from the time dependence of the underlying function spaces. There are two methods to get around the time dependence in the underlying function spaces (cf. Delfour and Zolésio [1], [2]):

– the *function space parametrization* and

– the *function space embedding.*

In the first case, we parametrize the functions in $H^2(\Omega_t)$ by elements of $H^2(\Omega)$ through the transformation

$$\phi \mapsto \phi \circ T_t^{-1} \ : \ H^2(\Omega) \to H^2(\Omega_t), \tag{12}$$

where "$\circ$" denotes the composition of the two maps and we introduce the *parametrized Lagrangian*,

$$\tilde{G}(t,\phi,\psi) = G(T_t(\Omega), \phi \circ T_t^{-1}, \psi \circ T_t^{-1}) \tag{13}$$

on $H^2(\Omega) \times H^2(\Omega)$. In the function space embedding method, we introduce a large enough fixed domain, D which contains all the transformations $\{\Omega_t : 0 \le t \le \tau\}$ of Ω.

In this paper, we will use the function space embedding method with $D = \mathbb{R}^N$

$$J(\Omega_t) = \operatorname*{Min}_{\Phi\in H^2(\mathbb{R}^N)} \ \operatorname*{Max}_{\Psi\in H^2(\mathbb{R}^N)} \ G(\Omega_t, \Phi, \Psi). \tag{14}$$

Capital letters will be used for the functions on $\mathbb{R}^N$ and lowercase letters for the functions on Ω or Ω_t. As could be expected, the price to pay for the use of this method is that the set of saddle points

$$S(t) = X(t) \times Y(t) \ \subset H^2(\mathbb{R}^N) \times H^2(\mathbb{R}^N) \tag{15}$$

is not a singleton anymore since

$$X(t) = \{\Phi \in H^2(\mathbb{R}^N) : \Phi|_{\Omega_t} = y_t\}, \tag{16}$$

$$Y(t) = \{\Psi \in H^2(\mathbb{R}^N) : \Psi|_{\Omega_t} = p_t\}, \tag{17}$$

where (y_t, p_t) is the unique solution in $H^2(\Omega_t) \times H^2(\Omega_t)$ to the previous saddle point equations on Ω_t

$$\Delta y_t + f = 0 \quad \text{in} \quad \Omega_t, \qquad y_t = g \quad \text{on } \Gamma_t, \tag{18}$$

$$\Delta p_t + (y_t - y_d) = 0 \ \text{ in } \ \Omega_t, \qquad p_t = 0 \quad \text{on } \ \Gamma_t. \tag{19}$$

We are now ready to apply the theorem of Correa and Seeger [1], which says that under appropriate hypotheses (to be checked in the next section)

$$dJ(\Omega; V) = \operatorname*{Min}_{\Phi \in X(0)} \operatorname*{Max}_{\Psi \in Y(0)} \partial_t G(\Omega_t, \Phi, \Psi). \tag{20}$$

Since we have already characterized $X(0)$ and $Y(0)$, we only need to compute the partial derivative of

(21)

$$G(\Omega_t, \Phi, \Psi) = \int_{\Omega_t} \left\{ \frac{1}{2} |\Phi - y_d|^2 + (\Delta\Phi + f)\Psi + (\Phi - g)\Delta\Psi + \nabla(\Phi - g) \bullet \nabla\Psi \right\} dx.$$

If we assume that Ω_t is sufficiently smooth, then

$$f, y_d \in H^{1/2+\epsilon}(\mathbb{R}^N), \quad g \in H^{2+\epsilon}(\mathbb{R}^N) \Rightarrow y, \quad p \in H^{\frac{5/2+\epsilon}{(}}\Omega) \tag{22}$$

and we can choose to consider our saddle points $S(t)$ in $H^{5/2+\epsilon}(\mathbb{R}^N) \times H^{5/2+\epsilon}(\mathbb{R}^N)$ rather than $H^2(\mathbb{R}^N) \times H^2(\mathbb{R}^N)$. If Φ and Ψ belong to $H^{5/2+\epsilon}(\mathbb{R}^N)$, then

$$\begin{aligned} &\partial_t G(\Omega_t, \Phi, \Psi) \\ &= \int_{\Gamma_t} \{\frac{1}{2}(\Phi - y_d)^2 + (\Delta\Phi + f)\Psi + (\Phi - g)\Delta\Psi + \nabla(\Phi - g) \bullet \nabla\Psi\} V \bullet n_t \, d\Gamma_t. \end{aligned} \tag{23}$$

This expression is an integral over the boundary Γ, which will not depend on Φ and Ψ outside of $\bar{\Omega}$. As a result the Min and the Max can be dropped in expression (20), which reduces to

(24)

$$dJ(\Omega; V) = \int_{\Gamma} \left\{ \frac{1}{2}(y - y_d)^2 + (\Delta y + f)p + (y - g)\Delta p + \nabla(y - g) \bullet \nabla p \right\} V \bullet n \, d\Gamma.$$

But

$$p = 0 \quad \text{and} \quad y - g = 0 \quad \Rightarrow \quad \nabla p = \frac{\partial p}{\partial n} n, \quad \nabla(y - g) = \frac{\partial}{\partial n}(y - g)\, n \quad \text{on } \Gamma \tag{25}$$

and finally

$$dJ(\Omega; V) = \int_{\Gamma} \left\{ \frac{1}{2}(g - y_d)^2 + \frac{\partial}{\partial n}(y - g)\frac{\partial p}{\partial n} \right\} V \bullet n \, d\Gamma. \tag{26}$$

4.2. Verification of the hypotheses. As we have seen, the computation of the shape gradient is both quick and easy. We now turn to the step-by-step verification of the hypotheses of the underlying theorem. Many of the constructions given below are "canonical" and can be repeated for different problems in different contexts.

THEOREM 4.1 (Correa and Seeger [1]). *Let $\tau > 0$, the sets X and Y, and the functional $L : [0, \tau] \times X \times Y \to \mathbb{R}$ be given. Denote by*

$$S(t) = X(t) \times Y(t) \subset X \times Y \tag{27}$$

the set of saddle points of the functional $L(t, \cdot\, , \cdot)$ on $X \times Y$. Assume that

$$\forall t \in [0, \tau], \quad S(t) \neq \varnothing \tag{H1}$$

and that

(H2) $$\forall(x,y) \in \left[X(0) \times \bigcup_{0\le t\le\tau} Y(t)\right] \cup \left[\bigcup_{0\le t\le\tau} X(t) \times Y(0)\right],$$
$$\partial_t L(t,x,y) \textit{ exists on } [0,\tau].$$

Moreover, assume that there exist topologies $\mathcal{T}_X$ on X and $\mathcal{T}_Y$ on Y such that for all sequences $t_n \to 0$ as $n \to \infty$, $0 \le t_n \le \tau$, there exist $(x_0, y_0) \in S(0)$ and a subsequence of $\{t_n\}$, still denoted $\{t_n\}$, such that

(H3) $\forall n, \quad \exists (x_n, y_n) \in S(t_n) \quad$ *and* $\quad (x_n, y_n) \to (x_0, y_0) \quad$ *in* $\mathcal{T}_X \times \mathcal{T}_Y \quad$ *as* $n \to \infty$,

(H4) $$\forall y \quad \textit{in } Y(0)_2 \quad \liminf_{\substack{t\searrow 0\\ n\to\infty}} \partial_t L(t, x_n, y) \ge \partial_t L(0, x_0, y)$$
$$(\textit{resp.}\, \forall x \in X(0),\ \limsup_{\substack{t\searrow 0\\ n\to\infty}} \partial_t L(t, x, y_n) \le \partial_t L(0, x, y_0)).$$

Then the function
$$g(t) = \underset{x\in X}{\text{Min}}\ \underset{y\in Y}{\text{Max}}\ L(t,x,y)$$
on $[0,\tau]$ has a semiderivative at $t = 0$ given by
$$dg(0) = \lim_{t\searrow 0}[g(t) - g(0)]/t$$
$$= \underset{x\in X(0)}{\text{Inf}}\ \underset{y\in Y(0)}{\text{Sup}}\ \partial_t L(0,x,y) = \underset{y\in Y(0)}{\text{Sup}}\ \underset{x\in X(0)}{\text{Inf}}\ \partial_t L(0,x,y).$$

Let y_d and $f \in H^1(\mathbb{R}^N)$ and $g \in H^{5/2}(\mathbb{R}^N)$ so that

(28) $$X = Y = H^3(\mathbb{R}^N).$$

The saddle points $S(t) = X(t) \times Y(t)$ are given by

(29) $$X(t) = \{\Phi \in X : \Phi|_{\Omega_t} = y_t\},$$

(30) $$Y(t) = \{\Psi \in Y : \Psi|_{\Omega_t} = p_t\}.$$

The sets $X(t)$ and $Y(t)$ are not empty since it is always possible to construct a continuous linear extension

(31) $$\Pi^m : H^m(\Omega) \to H^m(\mathbb{R}^N)$$

for each $m \ge 1$. For instance, with $m = 1$ and a boundary Γ, which is $W^{1,\infty}$, see Agmon, Douglis, and Nirenberg [1], [2] and, for $m > 1$, see Babić [1] (cf. also Nečas [1]). Using this Π^m, we then define the following extension:

(32) $$\Pi_t^m : H^m(\Omega_t) \to H^m(\mathbb{R}^N),$$

(33) $$\Pi_t^m(\phi) = [\Pi^m(\phi \circ T_t)] \circ T_t^{-1}.$$

In the following, m is fixed and equal to 3, so we will drop the superscript m and define the extensions

(34) $$Y_t = \Pi_t y_t, \qquad P_t = \Pi_t p_t$$

of y_t and p_t, respectively. Hence,

$$Y_t \in X(t) \quad \text{and} \quad P_t \in Y(t) \Rightarrow S(t) \neq \emptyset. \tag{35}$$

So condition (H1) is verified. Condition (H2) follows from the hypotheses on f, y_d, and g. To check conditions (H3) and (H4), we need two general theorems that can be used in various contexts and problems.

THEOREM 4.2. *For $V \in \mathcal{D}^1(\mathbb{R}^N, \mathbb{R}^N)$ and $\Phi \in L^2(\mathbb{R}^N)$,*

$$\lim_{t \searrow 0} \Phi \circ T_t = \Phi \quad \textit{and} \quad \lim_{t \searrow 0} \Phi \circ T_t^{-1} = \Phi \quad \textit{in} L^2(\mathbb{R}^N). \tag{36}$$

Proof. (i) The space $\mathcal{D}(\mathbb{R}^N)$ of infinitely continuously differentiable functions with compact support in $\mathbb{R}^N$ is dense in $L^2(\mathbb{R}^N)$. So given $\epsilon > 0$, there exists Φ_ϵ in $\mathcal{D}(\mathbb{R}^N)$such that

$$||\Phi - \Phi_\epsilon||_{L^2}^2 < \epsilon^2 / \max \{J_t^{-1} : 0 \leq t \leq \tau\}.$$

Hence,

$$||\Phi \circ T_t - \Phi|| \leq ||\Phi_\epsilon \circ T_t - \Phi_\epsilon|| + ||\Phi \circ T_t - \Phi_\epsilon \circ T_t|| + ||\Phi - \Phi_\epsilon||. \tag{37}$$

But

$$\forall t \in [0, \tau], \quad \int_{\mathbb{R}^N} |\Phi \circ T_t - \Phi_\epsilon \circ T_t|^2 \, dx = \int_{\mathbb{R}^N} |\Phi - \Phi_\epsilon|^2 J_t^{-1} \, dx \leq \epsilon^2.$$

So the last two terms in (37) are less than 2ϵ. It remains to evaluate the first term for a fixed function Φ_ϵ with compact support K in $\mathbb{R}^N$. Recall that, since $\Phi_\epsilon = 0$ on the boundary ∂K of K, $T_t(K) = K$ for all t in $[0, \tau]$ (use Nagumo's [1] theorem twice as in the proof of Theorem 2.4(i)). Moreover, by compactness of K, Φ_ϵ is uniformly continuous on $\mathbb{R}^N$ and

$$\exists \delta > 0, \quad \forall x, y \in \mathbb{R}^N, \quad |x - y| < \delta \Rightarrow |\Phi_\epsilon(y) - \Phi_\epsilon(x)| < \epsilon / m(K)^{1/2}.$$

T_t is also uniformly continuous on K and

$$\exists \eta > 0, \quad \forall t, \ 0 \leq t < \eta, \quad \forall x \in K, \quad |T_t x - x| < \delta.$$

By construction

$$\text{supp } (\Phi_\epsilon \circ T_t) = T_t \text{ (supp } \Phi_\epsilon) \subset K$$

and

$$\Phi_\epsilon = 0 \text{ and } \Phi_\epsilon \circ T_t = 0 \text{ outside of } K.$$

Finally,

$$\int_{\mathbb{R}^N} |\Phi_\epsilon(T_t x) - \Phi_\epsilon(x)|^2 \, dx = \int_K |\Phi_\epsilon(T_t x) - \Phi_\epsilon(x)|^2 \, dx \leq \epsilon^2$$

and this implies that

$$\forall \epsilon > 0, \quad \exists \eta > 0, \quad \forall t, \ 0 \leq t \leq \eta, \quad ||\Phi \circ T_t - \Phi||_{L^2(\mathbb{R}^N)} \leq 3\epsilon.$$

(ii) For the second part of (36) we make a change of variable and use the result of part (i)

$$\int_{\mathbb{R}^N} |\Phi \circ T_t^{-1} - \Phi|^2 \, dx = \int_{\mathbb{R}^N} |\Phi - \Phi \circ T_t|^2 J_t \, dx \leq \epsilon^2.$$

This completes the proof of Theorem 4.2. □

COROLLARY. *Under the assumptions of Theorem* 4.2 *for* $m \geq 1$, V *in* $\mathcal{D}^m(\mathbb{R}^N, \mathbb{R}^N)$, *and* $\Phi \in H^m(\mathbb{R}^N)$,

$$(38) \qquad \lim_{t \searrow 0} \Phi \circ T_t = \Phi \quad \textit{and} \quad \lim_{t \searrow 0} \Phi \circ T_t^{-1} = \Phi \quad \textit{in} \quad H^m(\mathbb{R}^N).$$

Remark 4.1. In fact, for $m \geq 1$ and $V \in \mathcal{D}^m(\mathbb{R}^N, \mathbb{R}^N)$ the transformation

$$(39) \qquad S(t)\Phi = \Phi \circ T_t, \quad \forall \Phi \in H^m(\mathbb{R}^N), \quad \forall t, \quad 0 \leq t \leq \tau,$$

defines a strongly continuous semigroup of class C_0 on $H^m(\mathbb{R}^N)$ with infinitesimal generator

$$\mathcal{A}\Phi = \nabla\Phi \bullet V, \qquad \mathcal{D}(\mathcal{A}) = \{\Phi \in H^m(\mathbb{R}^N) : \nabla\Phi \bullet V \in H^m(\mathbb{R}^N)\}.$$

THEOREM 4.3. *Under the assumptions of Theorem* 4.2,

$$(40) \qquad y^t \longrightarrow y^0 \quad \textit{in} \quad H^m(\Omega) - \textit{strong (respectively, weak)}$$

implies that

$$Y_t \longrightarrow Y_0 \quad \textit{in} \quad H^m(\mathbb{R}^N) - \textit{strong (respectively, weak)}.$$

Proof. The strong case is obvious. We prove the weak case for $m = 0$. By definition,

$$Y_t = (\Pi y^t) \circ T_t^{-1}$$

and for all Φ in $L^2(\mathbb{R}^N)$, we consider

$$\int_{\mathbb{R}^N} Y_t \ \Phi \, dx = \int_{\mathbb{R}^N} (\Pi y^t) \circ T_t^{-1} \ \Phi \, dx = \int_{\mathbb{R}^N} \Pi y^t \ \Phi \circ T_t \ J_t \, dx.$$

We have shown in Theorem 4.2 that

$$\Phi \circ T_t \longrightarrow \Phi \quad \text{in} \quad L^2(\mathbb{R}^N)\text{-} - \textit{strong} \ .$$

In addition, $J_t \longrightarrow 1$ and by linearity and continuity of Π

$$\Pi y^t \longrightarrow \Pi y \quad \text{in} \quad L^2(\mathbb{R}^N) - \text{weak}.$$

Hence,

$$\forall \Phi \in L^2(\mathbb{R}^N), \qquad \int_{\mathbb{R}^N} Y_t \ \Phi \, dx \longrightarrow \int_{\mathbb{R}^N} \Pi y \ \Phi \, dx = \int_{\mathbb{R}^N} Y_0 \ \Phi \, dx.$$

This proves the weak convergence. □

To verify condition (H3), we transform (y_t, p_t) on Ω_t to $(y^t, p^t) = (y_t \circ T_t, p_t \circ T_t)$ on Ω. The pair (y^t, p^t) is the transported pair of solutions from Ω_t to Ω. It is the unique solution in $H^1(\Omega) \times H^1(\Omega)$ of the system

$$(41) \qquad -\text{div}[A(t)\nabla y^t] = J_t \ f \circ T_t \quad \text{in} \quad \Omega, \qquad y^t = g \circ T_t \quad \text{on} \quad \Gamma,$$

$$(42) \qquad -\text{div}[A(t)\nabla p^t] = J_t(y^t - y_d \circ T_t) \ \text{ in } \ \Omega, \qquad p^t = 0 \ \text{ on } \ \Gamma,$$

where

$$(43) \qquad A(t) = J_t(DT_t)^{-1*}(DT_t)^{-1}, \qquad J_t = |\text{det} DT_t|,$$

DT_t is the Jacobian matrix of T_t and $(DT_t)^{-1*}$ is the transposed form of $(DT_t)^{-1}$.

For sufficiently smooth domains Ω and vector fields V, the pair $\{y^t, p^t\}$ is bounded in $H^1(\Omega) \times H^1(\Omega)$ as t goes to zero . Since $H^1(\Omega)$ is a Hilbert space, we can extract weakly convergent subsequences to some $(\bar{y}, \bar{p})$ in $H^1(\Omega) \times H^1(\Omega)$. However, by linearity of the equation with respect to (y^t, p^t) and continuity of the coefficients with respect to t, the limit point $(\bar{y}, \bar{p})$ will coincide with (y^0, p^0), since the system has a unique solution at $t = 0$. Then we go back to the equation for y^t and y and show that the convergence is strong in $H^1(\Omega)$. Finally, by using the regularity of the data and the classical regularity theorems we show that $(y^t, p^t) \to (y, p)$ in $H^3(\Omega) \times H^3(\Omega)$.

For the verification of condition (H4), we go back to expression (3.23), which can be rewritten as a volume integral

$$\begin{aligned} &\partial_t G(\Omega_t, \Phi, \Psi) \\ (44) \quad &= \int_{\Omega_t} \operatorname{div}\left\{ \left[\frac{1}{2}(\Phi - y_d)^2 + (\Delta\Phi + f)\Psi + (\Phi - g)\Delta\Psi + \nabla(\Phi - g) \bullet \nabla\Psi \right] V \right\} dx \end{aligned}$$

for $(\Phi, \Psi) \in H^3(\mathbb{R}^N) \times H^3(\mathbb{R}^N)$. Now introduce the map

$$\begin{aligned} (\Phi, \Psi) \mapsto F(\Phi, \Psi) &= \left[\frac{1}{2}(\Phi - y_d)^2 + (\Delta\Phi + f)\Psi + (\Phi - g)\Delta\Psi + \nabla(\Phi - g) \bullet \nabla\Psi \right] V \\ &: H^3(\mathbb{R}^N) \times H^3(\mathbb{R}^N) \to (H^1(\mathbb{R}^N))^N. \end{aligned}$$

It is bilinear and continuous. Finally, the map

$$\begin{aligned} (45) \quad & (t, F) \mapsto \int_{\Gamma_t} F \circ n_t \, d\Gamma = \int_{\Omega_t} F \, dx = \int_{\Omega} (\operatorname{div} F) \circ T_t \; J_t^{-1} \, dx \\ & : [0, \tau] \times H^1(\mathbb{R}^N) \to \mathbb{R} \end{aligned}$$

is continuous. Then

$$(46) \qquad (t, \Phi, \Psi) \mapsto \partial_t G(\Omega_t, \Phi, \Psi) = \int_{\Gamma_t} F(\Phi, \Psi) \bullet n_t \, d\Gamma_t$$

is continuous and condition (H4) is verified. This completes the verification of the four conditions of Theorem 4.1. □

5. Shape Hessian for the Dirichlet problem.

5.1. Formulation and formal computations. We proceed as in §§3 and 4 and provide the mathematical justification in §5.2. For the second derivative, we need two autonomous vector fields V and W on $\mathbb{R}^N$ and the expression of the first derivative $dJ(\Omega_t(W); V)$, where $\Omega_t(W)$ is the perturbation of the domain Ω by the vector field W:

$$(1) \qquad dJ(\Omega_t(W); V) = \int_{\Omega_t(W)} \operatorname{div}\left\{ \left[\frac{1}{2}(g - y_d)^2 + \nabla(y_t - g) \bullet \nabla p_t \right] V \right\} dx,$$

where (y_t, p_t) are the unique solutions in $H^3(\Omega_t(W)) \times H^3(\Omega_t(W))$ to the equations

$$(2) \qquad \Delta y_t + f = 0 \quad \text{in } \Omega_t(W), \qquad y_t = g \quad \text{on } \Gamma_t(W),$$

$$(3) \qquad \Delta p_t + (y_t - y_d) = 0 \quad \text{in } \Omega_t(W), \qquad p_t = 0 \text{ on } \Gamma_t(W).$$

Then, we express (1) as a MinMax over a new Lagrangian:

$$(4) \qquad dJ(\Omega_t(W); V) = \underset{\Phi, \Psi \in H^3(\mathbb{R}^N)}{\operatorname{Min}} \; \underset{P, \Sigma \in H^2(\mathbb{R}^N)}{\operatorname{Max}} G(\Omega_t, \Phi, \Psi, P, \Sigma),$$

where $G = G(\Omega_t, \Phi, \Psi, P, \Sigma)$ is given by

$$G = \int_{\Omega_t} \left\{ \operatorname{div} \left[\frac{1}{2}(g - y_d)^2 + \nabla(\Phi - g) \bullet \nabla\Psi \right] V \right\} + [\Delta\Phi + f]P + (\Phi - g)\Delta P + \nabla(\Phi - g) \bullet \nabla P + [\Delta\Psi + \Phi - y_d]\Sigma + \Psi\Delta\Sigma + \nabla\Psi \bullet \nabla\Sigma \Big\} \, dx. \tag{5}$$

This new Lagrangian is affine in (P, Σ), but is not necessarily convex in (Φ, Ψ). However, it is semiconvex in (Φ, Ψ) and we will see that Correa and Seeger [1] will still apply to our special Lagrangian where the sets $X(t) \times Y(t)$,

$$X(t) \subset H^3(\mathbb{R}^N) \times H^3(\mathbb{R}^N), \tag{6}$$

$$Y(t) \subset H^2(\mathbb{R}^N) \times H^2(\mathbb{R}^N) \tag{7}$$

will be given by the usual "saddle point equations":

$$\int_{\Omega_t} [\Delta\hat{\Phi} + f]P + (\hat{\Phi} - g)\Delta P + \nabla(\hat{\Phi} - g) \bullet \nabla P \, dx = 0 \quad \forall P, \tag{8}$$

$$\int_{\Omega_t} [\Delta\hat{\Psi} + \hat{\Phi} - y_d]\Sigma + \hat{\Psi}\Delta\Sigma + \nabla\hat{\Psi} \bullet \nabla\Sigma \, dx = 0 \quad \forall\Sigma, \tag{9}$$

$$\int_{\Omega_t} \left[\operatorname{div}\{[\nabla(\hat{\Phi} - g) \bullet \nabla\Psi]V\} + \Delta\Psi\hat{\Sigma} + \Psi\Delta\hat{\Sigma} + \nabla\Psi \bullet \nabla\hat{\Sigma} \right] dx = 0 \quad \forall\Psi, \tag{10}$$

$$\int_{\Omega_t} \left[\operatorname{div}\{[\nabla\Phi \bullet \nabla\hat{\Psi}]V\} + \Delta\Phi\hat{P} + \Phi\Delta\hat{P} + \nabla\Phi \bullet \nabla\hat{P} + \Phi\hat{\Sigma} \right] dx = 0 \quad \forall\Phi. \tag{11}$$

It is obvious that (8) and (9) yield

$$\hat{\Phi}|_{\Omega_t} = y_t \quad \text{and} \quad \hat{\Psi}|_{\Omega_t} = p_t. \tag{12}$$

Similarly, (10) and (11) have solutions $(\hat{\Sigma}, \hat{P})$ in $H^2(\mathbb{R}^N) \times H^2(\mathbb{R}^N)$ such that

$$Y_t' = \hat{\Sigma}|_{\Omega_t}, \qquad P_t' = \hat{P}|_{\Omega_t} \tag{13}$$

are unique in $H^2(\Omega_t) \times H^2(\Omega_t)$ and solutions of

$$\Delta Y_t' = 0 \text{ in } \Omega_t(W), \qquad Y_t' = -\frac{\partial}{\partial n_t}(y_t - g)V \bullet n_t \quad \text{on } \Gamma_t(W), \tag{14}$$

$$\Delta P_t' = 0 \quad \text{in } \Omega_t(W), \qquad P_t' = -\frac{\partial p_t}{\partial n_t} V \bullet n_t \quad \text{on } \Gamma_t(W). \tag{15}$$

It can be shown that Y_t' and P_t' coincide with the "partial derivative" with respect to t of appropriate extensions of y_t and p_t from $\Omega_t(W)$ to $\mathbb{R}^N$.

Finally, the partial derivative of the Lagrangian G with respect to t is given by

$$\partial_t G = \int_{\Gamma_t} \left\{ \operatorname{div} \left\{ \left[\frac{1}{2}(g - y_d)^2 + \nabla(\Phi - g) \bullet \nabla\Psi \right] V \right\} + [\Delta\Phi + f]P + (\Phi - g)\Delta P + \nabla(\Phi - g) \bullet \nabla P + [\Delta\Psi + \Phi - y_d]\Sigma + \Psi\Delta\Sigma + \nabla\Psi \bullet \nabla\Sigma \right\} W \bullet n_t \, d\Gamma_t \tag{16}$$

for Φ, Ψ, P, Σ in $H^3(\mathbb{R}^N)$, y_d and f in $H^2(\mathbb{R}^N)$, and g in $H^{7/2}(\mathbb{R}^N)$. The immediate consequence of this computation is that y_t, p_t, Y_t', P_t' all belong to $H^3(\Omega_t)$. But Y_t', P_t' in $H^3(\Omega_t)$ require that y_t and p_t belong to $H^4(\Omega_t)$. This is precisely why we chose the above smoothness for y_d, f, and g.

Therefore, we must consider our saddle points $X(t) \times Y(t)$ in $(H^4(\mathbb{R}^N) \times H^4(\mathbb{R}^N)) \times (H^3(\mathbb{R}^N) \times H^3(\mathbb{R}^N))$,

$$X(t) = \{(\Phi, \Psi) \in H^4(\mathbb{R}^N) \times H^4(\mathbb{R}^N) : \Phi|_{\Omega_t} = y_t, \Psi|_{\Omega_t} = p_t\}, \tag{17}$$

$$Y(t) = \{(P, \Sigma) \in H^3(\mathbb{R}^N) \times H^3(\mathbb{R}^N) : P|_{\Omega_t} = P_t', \Sigma|_{\Omega_t} = Y_t'\}. \tag{18}$$

Finally, since $\partial_t G$ is a functional on Ω_t, it will only use the restriction to Ω_t of the various functions in $X(t) \times Y(t)$. Therefore, the Min and the Max can be removed and

$$\begin{aligned} d^2J(\Omega; V; W) = \int_\Gamma \Bigg\{ &\operatorname{div}\left\{\left[\frac{1}{2}(y - y_d)^2 + \frac{\partial}{\partial n}(y - g)\frac{\partial p}{\partial n}\right] V\right\} \\ &+ [\Delta y + f]P_V' + (y - g)\Delta P_V' + \nabla(y - g) \bullet \nabla P_V' \\ &+ [\Delta p + y - y_d]Y_V' + p\Delta Y_V' + \nabla p \bullet \nabla Y_V' \Bigg\} W \bullet n \, d\Gamma. \end{aligned} \tag{19}$$

But

$$\Delta y + f = 0, \quad y = g, \quad \Delta p + y - y_d = 0, \quad \text{and} \quad p = 0 \quad \text{on } \Gamma, \tag{20}$$

and

$$\begin{aligned} d^2J(\Omega; V; W) = \int_\Gamma \Bigg\{ &\operatorname{div}\left\{\left[\frac{1}{2}(g - y_d)^2 + \frac{\partial}{\partial n}(y - g)\frac{\partial p}{\partial n}\right] V\right\} \\ &+ \frac{\partial}{\partial n}(y - g)\frac{\partial P_V'}{\partial n} + \frac{\partial p}{\partial n}\frac{\partial Y_V'}{\partial n} \Bigg\} W \bullet n \, d\Gamma, \end{aligned} \tag{21}$$

where we have added the subscript V to P' and Y' to emphasize that they both depend on V. The last step consists in the elimination of P_V', which will introduce Y_W'. To do that, we set $\psi = \hat{\Psi}_V|_{\Omega_t} = P_V'$ in (10) with $V = W$and $t = 0$

$$\begin{aligned} &\int_\Omega \left[\operatorname{div}\{[\nabla(y - g) \bullet \nabla\psi]W\} + \Delta\psi Y_W' + \psi\Delta Y_W' + \nabla\psi \bullet \nabla Y_W'\right] dx = 0 \\ &\Rightarrow \int_\Omega \nabla(y - g) \bullet \nabla P_V' W \bullet n \, d\Gamma + \int_\Omega \Delta P_V' Y_W' + P_V' \Delta Y_W' + \nabla P_V' \bullet \nabla Y_W' \, dx = 0 \end{aligned} \tag{22}$$

and $\phi = \hat{\Phi}_W|_{\Omega_t} = Y_W'$ in (11) with $t = 0$,

$$\begin{aligned} &\int_\Omega \left[\operatorname{div}\{[\nabla\Phi \bullet \nabla p]V\} + \Delta\Phi P_V' + \Phi\Delta P_V' + \nabla\Phi \bullet \nabla P_V' + \Phi Y_V'\right] dx = 0 \\ &\Rightarrow \int_\Gamma \nabla Y_W' \bullet \nabla p \; V \bullet n \, d\Gamma + \int_\Gamma \Delta Y_W' P_V' + Y_W' \Delta P_V' + \nabla Y_W' \bullet \nabla P_V' + Y_W' Y_V' \, dx = 0. \end{aligned} \tag{23}$$

This yields the following identity:

$$\int_\Gamma \nabla(y - g) \bullet \nabla P_V' \; W \bullet n \, d\Gamma = \int_\Gamma \nabla Y_W' \bullet \nabla p \; V \bullet n \, d\Gamma + \int_\Gamma Y_W' Y_V' \, dx \tag{24}$$

or

$$\int_{\Gamma} \frac{\partial}{\partial n}(y-g)\frac{\partial P'_V}{\partial n} W \bullet n \, d\Gamma = \int_{\Gamma} \frac{\partial Y'_W}{\partial n}\frac{\partial p}{\partial n} V \bullet n \, d\Gamma + \int_{\Gamma} Y'_W Y'_V \, dx. \tag{25}$$

As a result

$$\begin{aligned} d^2 J(\Omega; V; W) = \int_{\Gamma} & \operatorname{div}\left\{\left[\frac{1}{2}(g-y_d)^2 + \frac{\partial}{\partial n}(y-g)\frac{\partial p}{\partial n}\right] V\right\} W \bullet n \, d\Gamma \\ & + \int_{\Gamma} \frac{\partial p}{\partial n}\left[\frac{\partial Y'_W}{\partial n} V \bullet n + \frac{\partial Y'_V}{\partial n} W \bullet n\right] d\Gamma + \int_{\Gamma} Y'_W Y'_V \, dx, \end{aligned} \tag{26}$$

where Y'_V is the unique solution of

$$\Delta Y'_V = 0 \quad \text{in } \Omega, \qquad Y'_V = -\frac{\partial}{\partial n}(y-g) V \bullet n \quad \text{on } \Gamma. \tag{27}$$

5.2. Verification of the hypotheses. In §5.1, we have boldly applied the conclusion of the theorem of Correa and Seeger to a Lagrangian that contains a cost functional that is not necessarily convex. This means that the corresponding Lagrangian functional does not necessarily have saddle points. Yet, the conclusions of the theorem extend to *semiconvex* cost functionals (§5.2.1). The verification of the hypotheses will essentially be the same as for the gradient in §4.2 (§5.2.2).

5.2.1. Semiconvex cost functionals. Consider a Lagrangian functional of the form

$$G(t,x,y) = F(t,x) + b(t,x,y) \tag{28}$$

for a family of continuous bilinear forms $b(t,x,y)$ on $X \times Y$ and continuous cost functionals $F(t,x)$ on X. Formally, the saddle point equations are given by

$$x^t \in X, \quad b(t,x^t,y) = 0 \quad \forall y \in Y \tag{29}$$

$$y^t \in Y, \quad dF(t,x^t;x) + b(t,x,y^t) = 0 \quad \forall x \in X. \tag{30}$$

When $G(t,x,y)$ is convex in x and concave in y, (29)–(30) characterize the saddle points $X(t) \times Y(t) \subset X \times Y$ of $G(t,\cdot,\cdot)$. So, when $F(t,x)$ is not convex in x, (29)–(30) need not characterize saddle points of $G(t,\cdot,\cdot)$.

We say that the functional $F(t,x)$ is *semiconvex* in x if there exists a family of continuous convex functionals $C(t,x)$ on X such that $F(t,x) + C(t,x)$ is convex in x. This means that $F(t,\cdot) + C(t,\cdot)$ and $C(t,\cdot)$ both have directional derivatives and hence $F(t,\cdot)$ also has a directional derivative: the following limit exists

$$dF(t,x;x') = \lim_{\theta \searrow 0} \frac{F(t,x+\theta x') - F(t,x)}{\theta}. \tag{31}$$

Denote by $X(t)$ the set of all solutions

$$x^t \in X, \quad b(t,x^t,y) = 0 \quad \forall y \in Y \tag{32}$$

and assume that

$$\forall x^t \in X(t), \quad F(t,x^t) = J(t); \tag{33}$$

that is, $F(t,x^t)$ is only a function of t. We use $J(t)$ as the definition of our cost function.

Now, assume that $F(t,\cdot)$ is semiconvex and that

$$\forall x^t \in X(t), \quad C(t,x^t) = J_0(t); \tag{34}$$

that is $C(t,x^t)$ is only a function of t. Again, use $J_0(t)$ as the definition of the cost function associated with C. Finally, let

$$J_C(t) = F(t,x^t) + C(t,x^t), \tag{35}$$

which is also only a function of t. Then it is obvious that

$$J(t) = J_C(t) - J_0(t) \tag{36}$$

and that (if $dJ_C(0)$ and $dJ_0(0)$ exist)

$$dJ(0) = dJ_C(0) - dJ_0(0). \tag{37}$$

So, we are back to the use of the theorem of Correa and Seeger [1] for both J_C and J_0. Construct the Lagrangians

$$G_C(t,x,y){=}F(t,x) + C(t,x) + b(t,x,y), \tag{38}$$

$$G_0(t,x,y) {=}C(t,x) + b(t,x,y) \tag{39}$$

and assume that if all the hypotheses are verified both for G_0 and G_C,

$$J_0(t) = \operatorname*{Min}_{x\in X} \ \operatorname*{Max}_{y\in Y} \ G_0(t,x,y), \tag{40}$$

$$dJ_0(0) = \operatorname*{Min}_{x\in X(0)} \ \operatorname*{Max}_{y\in Y_0(0)} \ \partial_t G_0(0,x,y), \tag{41}$$

$$J_C(t) = \operatorname*{Min}_{x\in X} \ \operatorname*{Max}_{y\in Y} \ G_C(t,x,y), \tag{42}$$

$$dJ_C(0) = \operatorname*{Min}_{x\in X(0)} \ \operatorname*{Max}_{y\in Y_C(0)} \ \partial_t G_C(0,x,y), \tag{43}$$

where the saddle point equations for J_0 are given by

$$x^t \in X, \quad B(t,x^t,y) = 0 \quad \forall y, \tag{44}$$

$$y_0^t \in Y, \quad dC(t,x^t;x) + b(t,x,y_0^t) = 0 \quad \forall x, \tag{45}$$

and the saddle point equations for $J_C(t)$

$$x^t \in X, \quad B(t,x^t,y) = 0 \quad \forall y, \tag{46}$$

$$y_C^t \in Y, \quad dC(t,x^t;x) + dF(t,x^t;x) + b(t,x,y_C^t) = 0 \quad \forall x. \tag{47}$$

Assume that

$$dJ_0(0) = \partial_t C(0,x^0) + \partial_t b(0,x^0,y_0^0), \ \forall x^0 \in X(0), \ \forall y_0^0 \in Y_0(0), \tag{48}$$

and that $dC(0,x^0;x)$ and $dF(0,x^0;x)$ are independent of the point x^0 chosen in $X(0)$. By subtracting (45) from (47), construct the new variable $y^0 = y_C^0 - y_0^0$, which is a solution of

$$y^0 \in Y, \ dF(0,x^0;x) + b(0,x,y^0) = 0, \ \forall x, \tag{49}$$

and the set

$$Y(0) = \{y_C^0 - y_0^0 : y_C^0 \in Y_C(0), \ y_0^0 \in Y_0(0)\}.$$

Now,

$$\begin{aligned} dJ_C(0) &= \operatorname*{Min}_{x\in X(0)} \operatorname*{Max}_{y\in Y_C(0)} \partial_t F(0,x) + \partial_t C(0,x) + \partial_t b(0,x,y) \\ &= \operatorname*{Min}_{x\in X(0)} \operatorname*{Max}_{\substack{y_0^0\in B_0(0)\\ y_0\in Y(0)}} \{\partial_t F(0,x) + \partial_t b(0,x,y^0) + \partial_t C(0,x) + \partial_t b(0,x,y_0^0)\}. \end{aligned}$$

However, for all $(x^0, y_0^0) \in X(0) \times Y_0(0)$,

$$\partial_t C(0,x^0) + \partial_t b(0,x^0,y_0^0) = dJ_0(0),$$

and finally,

$$dJ(0) = dJ_C(0) - dJ_0(0) = \operatorname*{Min}_{x\in X(0)} \operatorname*{Max}_{y\in Y(0)} [\partial_t F(0,x) + \partial_t b(0,x,y)], \tag{50}$$

where the saddle point $(x^0, y^0) \in X(0) \times Y(0)$ is the solution of the "formal saddle point equations" (29)–(30) for $t = 0$.

In §4.2, the cost functional is semiconvex since there exists a constant $C > 0$ large enough so that

$$dJ(\Omega_t(W); V) + C\ [||y_t||^2_{H^4(\Omega_t)} + ||p_t||^2_{H^4(\Omega_t)}\ ] \tag{51}$$

is convex and continuous on $H^4(\Omega_t) \times H^4(\Omega_t)$. The functional

$$C(t,\phi,\psi) = c||\phi||^2_{H^4(\Omega_t)} + ||\psi||^2_{H^4(\Omega_t)} \tag{52}$$

is clearly convex and continuous on $H^4(\Omega_t) \times H^4(\Omega_t)$. This provides a complete justification for the use of the conclusions of Correa and Seeger.

5.2.2. Verification of the hypotheses. We have chosen to work in $H^4(\mathbb{R}^N) \times H^4(\mathbb{R}^N) \times H^3(\mathbb{R}^N) \times H^3(\mathbb{R}^N)$ and introduced appropriate hypotheses on f, y_d, and g in §5.1. From this point on, the technique is the same as the one used in §4.2 for the gradient. Therefore, we will not repeat it here.

6. Appendix. Proofs of the theorems of §2.

Proof of Theorem 2.1. (i) Properties (T1) follow by standard arguments.

Condition (T2). Associate with X in $\mathbb{R}^N$ the function

$$y(s) = T_{t-s}(X), \qquad 0 \le s \le t. \tag{1}$$

Then

$$\frac{dy}{ds}(s) = -V(t-s, y(s)), \quad 0 \le s \le t, \quad y(0) = T_t(X). \tag{2}$$

For each $x \in \mathbb{R}^N$, the differential equation

$$\frac{dy}{ds}(s) = -V(t-s, y(s)), \quad 0 \le s \le t, \quad y(0) = x \in \mathbb{R}^N \tag{3}$$

has a unique solution in $C^1([0,t]; \mathbb{R}^N)$. The solutions of (3) define a Lipschitzian mapping

$$x \mapsto S_t(x) = y(t) : \mathbb{R}^N \to \mathbb{R}^N \tag{4}$$

such that

$$\exists c > 0, \quad \forall t \in [0,\tau], \quad \forall x, y \in \mathbb{R}^N, \quad |S_t(y) - S_t(x)| \le c|y - x|. \tag{5}$$

Now in view of (2) and (3)

$$S_t(T_t(X)) = y(t) = T_{t-t}(X) = X \Rightarrow S_t \circ T_t = I \quad \text{on } \mathbb{R}^N.$$

To obtain the other identity, consider the function

$$z(r) = y(t-r;x),$$

where $y(\cdot, x)$ is the solution of (3) for some arbitrary x in $\mathbb{R}^N$. By definition

$$\frac{dz}{dr}(r) = V(r, z(r)), \quad z(0) = y(t,x)$$

and necessarily

$$\begin{aligned} x = y(0;x) = z(t) = T_t(y(t;x)) = T_t(S_t(x)) \\ \Rightarrow T_t \circ S_t = I \quad \text{on } \mathbb{R}^N \Rightarrow S_t = T_t^{-1} : \mathbb{R}^N \to \mathbb{R}^N. \end{aligned}$$

Condition (T3). The uniform Lipschitz continuity in (T3) follows from (5) and we only need to show that

$$\forall x \in \mathbb{R}^N, \quad T^{-1}(\cdot, x) \in C^0([0,\tau]; \mathbb{R}^N).$$

Given t in $[0,\tau]$, pick an arbitrary sequence $\{t_n\}, t_n \to t$. Then for each $x \in \mathbb{R}^N$ there exists $X \in \mathbb{R}^N$ such that

$$T_t(X) = x \quad \text{and} \quad T_{t_n}(X) \to T_t(X) = x.$$

But

$$T_{t_n}^{-1}(x) - T_t^{-1}(x) = T_{t_n}^{-1}(T_t(X)) - T_t^{-1}(T_t(X)) = T_{t_n}^{-1}(T_t(X)) - T_{t_n}^{-1}(T_{t_n}(X)).$$

By the uniform Lipschitz continuity of T_t^{-1},

$$|T_{t_n}^{-1}(x) - T_t^{-1}(x)| = |T_{t_n}^{-1}(T_t(X)) - T_{t_n}^{-1}(T_{t_n}(X))| \le c|T_t(X) - T_{t_n}(X)|$$

and the last term converges to zero as t_n goes to t.

(ii) The first part of condition (V) is verified since for each $x \in \mathbb{R}^n$ and t, s in $[0,\tau]$,

$$\begin{aligned} &|V(t,x) - V(s,x)| \\ &\le \left|\frac{\partial T}{\partial t}(t, T_t^{-1}(x)) - \frac{\partial T}{\partial t}(t, T_s^{-1}(x))\right| + \left|\frac{\partial T}{\partial t}(t, T_s^{-1}(x)) - \frac{\partial T}{\partial t}(s, T_s^{-1}(x))\right| \\ &\le c|T_t^{-1}(x) - T_s^{-1}(x)| + \left|\frac{\partial T}{\partial t}(t, T_s^{-1}(x)) - \frac{\partial T}{\partial t}(s, T_s^{-1}(x))\right|. \end{aligned}$$

So from (T3) and (T1) $s \mapsto V(s,x)$ is continuous at $s = t$ and hence for all x in $\mathbb{R}^N$, $V(\cdot, x) \in C^0([0,\tau]; \mathbb{R}^N)$. The Lipschitzian property follows directly from the Lipschitzian properties (T1) and (T3): for all x and y in $\mathbb{R}^N$,

$$\begin{aligned} |V(t,y) - V(t,x)| &= \left|\frac{\partial T}{\partial t}(t, T_t^{-1}(y)) - \frac{\partial T}{\partial t}(t, T_t^{-1}(x))\right| \\ &\le c\left|T_t^{-1}(y) - T_t^{-1}(x)\right| \le cc'|y-x|. \end{aligned}$$

This proves that V verifies condition (V). □

Proof of Theorem 2.2. (i) By definition of T in (2.8), $t \mapsto T(t,X)$ and $t \mapsto (\partial T/\partial t)(t,X) = U(X) + tA(X)$ are continuous on $[0,\infty[$. Moreover, for all X and Y,

$$|T(t,Y) - T(t,X)| \le \left[1 + tc + \frac{t^2}{2}c\right] |Y - X|$$

and

$$\left|\frac{\partial T}{\partial t}(t,Y)-\frac{\partial T}{\partial t}(t,X)\right| \leq \ [c+tc]\ |Y-X|.$$

Thus condition (T1) is verified for any finite $\tau > 0$. To check condition (T2) we need to prove that $X \mapsto T_t(X) = T(t,X) : \mathbb{R}^N \mapsto \mathbb{R}^N$ is bijective. For all Y and X,

$$T_t(Y)-T_t(X) = Y - X + t[U(Y)-U(X)] + \frac{t^2}{2}[A(Y)-A(X)]$$

and

$$|T_t(Y)-T_t(X)| \geq |Y-X| - ct|Y-X| - c\frac{t^2}{2}|Y-X|.$$

So for $\tau = \min\{1, 1/4c\}$ and for all t in $[0,\tau]$

$$(6) \qquad |T_t(Y)-T_t(X)| \geq \frac{1}{2}|Y-X|.$$

Hence T_t is injective and, a fortiori, bijective since $\mathbb{R}^N$ is finite-dimensional.

The last part of the proof is the uniform Lipschitzian property of T_t^{-1}. In view of (6) for all x and y

$$(7) \qquad \frac{1}{2}|T_t^{-1}(y)-T_t^{-1}(x)| \ \leq \ |T_t(T_t^{-1}(y))-T_t(T_t^{-1}(x))| \ = \ |y-x|.$$

To complete our argument, we prove the continuity with respect to t for each x. Let $X = T_t^{-1}(x)$. For any s in $[0,\tau]$

$$T_s^{-1}(x)-T_t^{-1}(x) \ = \ T_s^{-1}(T_t(X))-T_t^{-1}(T_t(X)) \ = \ T_s^{-1}(T_t(X))-T_s^{-1}(T_s(X))$$

and in view of (7)

$$|T_s^{-1}(x)-T_t^{-1}(x)| \ \leq \ 2|T_t(X)-T_s(X)|.$$

The continuity of $T_s^{-1}(x)$ at $s=t$ now follows from the continuity of $T_s(X)$ at $s=t$. Thus condition (T3) is verified. □

Proof of Theorem 2.3. By definition of the inductive limit topology on $\overrightarrow{\mathcal{V}}^{m,k}$, it is sufficient to prove the continuity for any compact subset K of $\mathbb{R}^N$. So given V in $\mathcal{V}_K^{m,k}$ construct the sequence

$$V_n(t) = V(t/n), \quad 0 \leq t \leq \tau, \quad \text{for integers } n \geq 1.$$

By continuity of V, $\{V_n\}$ converges in $V_K^{m,k}$ to the autonomous field $\tilde{V}$, $\tilde{V}(t,x) = V(0,x)$ for all $t \in [0,\tau]$. Hence by continuity of (2.17)

$$dJ(\Omega;V_n) \rightarrow dJ(\Omega;V(0))$$

and by uniqueness of the limit we obtain (2.18). □

Proof of Theorem 2.4. (i) For any V in $\mathcal{D}^k(\mathbb{R}^N,\mathbb{R}^N)$ such that $V=0$ on Γ, we have by Nagumo's [1] theorem (cf. also Aubin and Cellina [1] for an English version)

$$\forall t \in [0,\tau], \quad T_t(\bar{\Omega}) \subset \bar{\Omega}.$$

Now always by Nagumo's [1] theorem applied to (3) in the proof of Theorem 2.1

$$\forall t \in [0,\tau], \quad T_t^{-1}(\bar{\Omega}) = S_t(\bar{\Omega}) \subset \bar{\Omega}.$$

Necessarily, $T_t(\bar{\Omega}) = \bar{\Omega}$ and since T_t is a homeomorphism and Ω is open

$$\forall t \in [0,\tau], \quad T_t(\Omega) = \Omega \quad \Rightarrow \quad \forall t \in [0,\tau], \quad J(\Omega_t) = J(\Omega) \quad \Rightarrow \quad dJ(\Omega;V) = 0.$$

(ii) Since the open domain Ω has a boundary Γ that is C^{k+1}, there exists a unique outward normal $n(x)$ that belongs to $C^k(\Gamma, \mathbb{R}^N)$. Define the subspace

$$L^k_\Omega \ = \ \{V \in \mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N) \ : \ (\gamma_\Gamma V) \bullet n \ = \ 0 \text{ on } \Gamma\}$$

of $\mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N)$. It is closed and linear. Moreover, by using Nagumo's [1] theorem twice for all V in L^k_Ω, the corresponding transformation T_t has the property

$$T_t(\Omega) = \Omega, \quad \forall t \in [0, \tau]$$

and necessarily

$$dJ(\Omega; V) \ = \ 0 \quad \Rightarrow \quad V \in \ker(G(\Omega)).$$

This induces a continuous linear map

$$[G(\Omega)] \ : \ \mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N)/L^k_\Omega \ \to \ \mathbb{R} \tag{8}$$

such that

$$\langle [G(\Omega)], q_L(V)\rangle_{\mathcal{D}^k/L^k} \ = \ dJ(\Omega; V) \ = \ \langle G(\Omega), V\rangle_{\mathcal{D}^k},$$

where

$$q_L \ : \mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N) \ \to \ \mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N)/L^k_\Omega \tag{9}$$

is the canonical surjection. For a boundary Γ that is C^{k+1}, there exists a unique outward normal $n(x)$ that belongs to $C^k(\Gamma, \mathbb{R}^N)$. As a result, the kernel of the map

$$V \ \mapsto \ \gamma_\Gamma V \bullet n \ : \ \mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N) \ \to \ \mathcal{D}^k(\Gamma) \tag{10}$$

coincides with L^k_Ω, where γ_Γ is the trace operator from $\mathbb{R}^N$ to Γ. Moreover, the map (10) is surjective since it is always possible for a C^{k+1} boundary ($k \geq 0$) to construct a C^k-extension N on $\mathbb{R}^N$ of the unit normal n on Γ (cf. Agmon, Douglis, and Nirenberg [1], [2]). Similarly, for any v in $\mathcal{D}^k(\Gamma)$, there exists an extension $\tilde{v}$ in $\mathcal{D}^k(\mathbb{R}^N)$ and the vector $V = \tilde{v}N$ belongs to $\mathcal{D}^k(\mathbb{R}^N, \mathbb{R}^N)$ and coincides with vn on Γ. As a result, the map

$$q_L(V) \ \mapsto \ p_L(q_L(V)) \ : \ \mathcal{D}(\mathbb{R}^N, \mathbb{R}^N)/L^k_\Omega \ \to \ \mathcal{D}(\Gamma) \tag{11}$$

is a well-defined isomorphism. In particular, there exists a scalar distribution $g(\Omega)$ in $\mathcal{D}(\Gamma)'$ such that (2.20) is verified. □

Proof of Theorem 2.5. The differential quotient (2.24) can be split into the sum of two terms

$$[dJ(\Omega_t(W); V(0)) - dJ(\Omega; V(0))]/t + [dJ(\Omega_t(W); V(t)) - dJ(\Omega_t(W); V(0))]/t. \tag{12}$$

In view of Theorem 2.5 (i) and (iii), for all U in $\mathcal{V}^\ell$

$$d^2J(\Omega; U; W) = d^2J(\Omega; U; W(0))$$

by the same argument as in the proof of Theorem 2.4 for the gradient. Hence the first term converges to

$$d^2J(\Omega; V(0); W) = d^2J(\Omega; V(0); W(0)).$$

For the second term recall that V belongs to $\overset{\to m+1,\ell}{\mathcal{V}}$ and observe that the vector field

$$\tilde{V}(t) = [V(t) - V(0)]/t$$

belongs to $\overset{\to m,\ell}{\mathcal{V}}$ and that $\tilde{V}(0) = \overset{\bullet}{V}(0)$. Thus by linearity of $dJ(\Omega; V)$ the second term in (12) can be written as

$$dJ(\Omega_t(W); [V(t) - V(0)]/t) = dJ(\Omega_t(W); \tilde{V}(t)).$$

For any V in $\overset{\to m+2,\ell}{\mathcal{V}}$, $\tilde{V}$ belongs to $\overset{\to m+1,\ell}{\mathcal{V}}$. Then by assumption (i)

$$\lim_{t\searrow 0}[dJ(\Omega_t(W);\tilde{V}(t)) - dJ(\Omega;\tilde{V}(0))]/t = d^2J(\Omega;\tilde{V};W),$$

which implies that

$$\lim_{t\searrow 0} dJ(\Omega_t(W);\tilde{V}(t)) = dJ(\Omega;\tilde{V}(0)) = dJ(\Omega;\overset{\bullet}{V}(0)).$$

Now by hypothesis (ii), $U \mapsto dJ(\Omega;U)$ is linear and continuous on $\mathcal{D}^{\ell}(\mathbb{R}^N,\mathbb{R}^N)$ and the map

$$V \mapsto \overset{\bullet}{V}(0) \mapsto dJ(\Omega;\overset{\bullet}{V}(0)) : \overset{\to m+2,\ell}{\mathcal{V}} \to \mathcal{V}^{\ell} \to \mathbb{R}$$

is linear and continuous (hence uniformly continuous) for the topology $\overset{\to m+1,\ell}{\mathcal{V}}$ for all V in the dense subspace $\overset{\to m+2,\ell}{\mathcal{V}}$. Hence it uniquely and continuously extends to all elements of $\overset{\to m+1,\ell}{\mathcal{V}}$. This completes the proof of the theorem. □

Proof of Theorem 2.6. (i) It is sufficient to prove that

(a) for all $V, W \in \mathcal{D}(\mathbb{R}^N,\mathbb{R}^N)$ such that $W = 0$ in a neighbourhood of Γ, $d^2J(\Omega;V;W) = 0$ and

(b) for all $V, W \in \mathcal{D}(\mathbb{R}^N,\mathbb{R}^N)$ such that $V = 0$ in a neighbourhood of Γ, $d^2J(\Omega;V;W) = 0$.

In case (a) the proof is similar to the one in Theorem 2.4 for the gradient, and we even have the stronger result that for W such that $W = 0$ on Γ

$$\Omega_t(W) = \Omega, \quad \forall t \in [0,\tau] \quad \Rightarrow \quad dJ(\Omega_t(W);V) = dJ(\Omega;V) \quad \Rightarrow \quad d^2J(\Omega;V;W) = 0.$$

In case (b) $V = 0$ in a neighbourhood N of Γ and in $\mathbb{R}^N\backslash K$, the complement of the compact supports K of V. So $U = (\mathbb{R}^N\backslash K)$ is a neighbourhood of Γ where $V = 0$. By construction $U \cap K = \emptyset$ and there exists a bounded neighbourhood $\mathcal{U}$ of K such that $\bar{\mathcal{U}} \cap \Gamma = \emptyset$. Since $\bar{\mathcal{U}}$ is compact and Γ is closed, the minimum distance d from $\bar{\mathcal{U}}$ to Γ is finite and nonzero. Let

$$N(\Gamma) = \{y \in \mathbb{R}^N : d_\Gamma(y) < d/2\},$$

where

$$d_\Gamma(y) = \inf\{|y-x| : x \in \Gamma\}.$$

For all X in Γ

$$T_t(X) - X = \int_0^t W(T_s(X))\,ds = tW(X) + \int_0^t [W(T_s(X)) - W(X)]\,ds$$

and since W is uniformly Lipschitzian by assumption (V) on W

$$|T_t(X) - X| \le t|W(X)| + ct \max_{[0,t]} |T_s(X) - X|.$$

It can easily be shown that for $t < 1/c$

$$\max_{[0,t]} |T_s(X) - X| < \frac{t}{1-ct}|W(X)|.$$

Thus

$$\sup_{X\in\Gamma} \max_{[0,t]} |T_s(X) - X| \le \frac{t}{1-ct} \sup_{X\in\Gamma} |W(X)|.$$

However, W is continuous with compact support. Therefore,

$$\sup_{X\in\Gamma}|W(X)| \le \sup_{X\in \operatorname{supp} W}|W(X)| = \|W\|_{C^0(\mathbb{R}^N;\mathbb{R}^N)} < \infty$$

and there exists $\tau > 0$ such that

$$\forall s \in [0,\tau], \quad \frac{s}{1-cs}\|W\|_{C^0} < \frac{d}{2}.$$

By definition and the previous inequalities

$$d_\Gamma(T_s(X)) = \inf_{Y\in\Gamma}|T_s(X)-Y| \le |T_s(X)-X| < \frac{d}{2}$$

for all s in $[0,\tau]$ and all $X\in\Gamma$. This implies that

$$\forall s\in[0,\tau], \forall X\in\Gamma, \quad \Gamma_s(W) = T_s(W)(\Gamma) \subset N(\Gamma).$$

By construction $V = 0$ in $N(\Gamma)$ since the distance from K to Γ is greater than or equal to d. Therefore,

$$\forall s\in[0,\tau], \quad V \in L^\infty_{\Omega_s(W)}$$

and as in the proof of Theorem 2.4(ii), for all $s > 0$ $dJ(\Omega_s(W);V) = 0$ and necessarily $d^2J(\Omega;V;W) = 0$.

(ii) We have already established in (i) that the bilinear form

$$(V,W) \mapsto h(V,W) : \mathcal{D}(\mathbb{R}^N,\mathbb{R}^N)\times\mathcal{D}(\mathbb{R}^N,\mathbb{R}^N) \to \mathbb{R}$$

is zero for all $V\in\mathcal{D}(\mathbb{R}^N,\mathbb{R}^N)$ and $W\in\mathcal{D}(\mathbb{R}^N,\mathbb{R}^N)$ such that $W=0$ on Γ and also zero for all $W\in\mathcal{D}(\mathbb{R}^N,\mathbb{R}^N)$ and $V\in\mathcal{D}(\mathbb{R}^N,\mathbb{R}^N)$ for which $V=0$ in a neighbourhood of Γ. By density all this is still true in $\mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N)$ and now by the same argument as in the proof of Theorem 2.4 for all V in $\mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N)$

$$[W] \mapsto h(V,W) : \mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N)/L^\ell_\Omega \to \mathbb{R}$$

is well defined, linear, and continuous. For the first component it is necessary to show that for all W in

$$D^\ell_\Gamma = \{V\in\mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N) : \partial^\alpha V = 0 \text{ on } \Gamma,\ \forall|\alpha|\le\ell\},$$

the bilinear form $h(V,W)=0$. We first prove the result for the subspace

$$A = \mathcal{D}(\Omega;\mathbb{R}^N)\oplus\mathcal{D}(\mathbb{R}^N\backslash\bar\Omega;\mathbb{R}^N).$$

Then we prove that $\bar A = D^\ell_\Gamma$. Finally, by density and continuity, the result holds for the $\mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N)$-closure $\bar A$ of A.

For any V in A, there exist $V_1\in\mathcal{D}(\Omega;\mathbb{R}^N)$ and $V_2\in\mathcal{D}(\mathbb{R}^N\backslash\bar\Omega;\mathbb{R}^N)$ such that $V = V_1+V_2$. Moreover,

$$K_1 = \operatorname{supp} V_1 \subset \Omega \quad\text{and}\quad K_2 = \operatorname{supp} V_2 \subset \mathbb{R}^N\backslash\bar\Omega$$

are compact subsets of the open sets Ω and $\mathbb{R}^N\backslash\bar\Omega$, respectively. Hence $V_1 = 0$ (respectively, $V_2=0$) in the open neighbourhood $\mathbb{R}^N\backslash K_1$ (respectively, $\mathbb{R}^N\backslash K_2$) of Γ and necessarily $V = V_1+V_2 = 0$ in the neighbourhood $U = \mathbb{R}^N\backslash(K_1\cup K_2)$ of Γ. Hence from part (i) $h(V,W)=0$.

By definition of D^ℓ_Γ,

$$D^\ell_\Gamma \subset \mathcal{D}^\ell(\bar\Omega;\mathbb{R}^N)\oplus\mathcal{D}^\ell(\mathbb{R}^N\backslash\Omega;\mathbb{R}^N).$$

Now

$$A \subset D^\ell_\Gamma \text{ and } \bar{A} = \overline{\mathcal{D}(\Omega;\mathbb{R}^N)} \oplus \overline{\mathcal{D}(\mathbb{R}^N\backslash\bar{\Omega};\mathbb{R}^N)} \subset D^\ell_\Gamma$$

and

$$\overline{\mathcal{D}(\Omega;\mathbb{R}^N)} = \mathcal{D}^\ell(\bar{\Omega};\mathbb{R}^N) \quad \text{and} \quad \overline{\mathcal{D}(\mathbb{R}^N\backslash\bar{\Omega};\mathbb{R}^N)} = \mathcal{D}^\ell(\mathbb{R}^N\backslash\Omega;\mathbb{R}^N).$$

This proves that $\bar{A} = D^\ell_\Gamma$. To complete the proof, note, that by continuity of $V \mapsto h(V,W)$, for all W in $\mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N)$ the map

$$[V] \mapsto h(V,W) : \mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N)/D^\ell_\Gamma \to \mathbb{R}$$

is well defined, linear, and continuous. Finally, the map

$$([V],[W]) \mapsto h(V,W) : (\mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N)/L^\ell_\Omega) \times (\mathcal{D}^\ell(\mathbb{R}^N,\mathbb{R}^N)/D^\ell_\Gamma) \to \mathbb{R}$$

is well defined, bilinear, and continuous. □

NUMERICAL METHODS FOR STOCHASTIC SINGULAR CONTROL PROBLEMS*

HAROLD J. KUSHNER† AND LUIZ FELIPE MARTINS‡

Abstract. The paper develops a powerful class of numerical methods for stochastic singular control problems. The basic models used are diffusion or reflected diffusions, but the method is of general applicability. The central idea is that of the Markov chain approximation method, where an approximation to the control problem is found for which an optimal solution is computable, and which is an arbitrarily good approximation to the original problem and its optimal value function. The methods are convenient to program and use (and they have been used with success), and they cover a wide variety of problems. In fact, for the singular problem, they seem to be the only ones currently available. Owing to problems in proving tightness of certain processes that occur in the convergence proofs, the methods of proof used for the nonsingular problems need modifications. Examples of useful approximations, the algorithms, and the convergence proofs are given. To illustrate the power of the methods, two classes of problems are dealt with: the first is a class of discounted problems, and the second is an average-cost-per-unit time problem subject to some constraints, which arises in the study of multicustomer class queueing networks under conditions of heavy traffic. The method is applicable to the more standard singular control and ergodic problems with greater ease.

Key words. numerical methods for stochastic control, singular stochastic control, ergodic stochastic control, Markov chain approximations, weak convergence methods, constrained ergodic problems, optimal stochastic control

AMS(MOS) subject classifications. 93E25, 93E20

1. Introduction. Singular stochastic control problems occur in many forms. They have been the subjects of general studies and have arisen in models of financial economics, minimum-fuel-type problems [1]–[6], the modelling of controlled queuing, and production systems under conditions of heavy traffic [7]–[9], among other places. To date, there are few analytical solutions and (to the authors' knowledge) there is no work on the systematic design and convergence proofs for algorithms for numerical methods for the calculation or approximation of the optimal value function, although numerical calculations (using Markov chain approximations) have been carried out in [13]. In this paper, we develop a class of convergent numerical methods for this computation, which works under quite broad conditions. The methods are extensions of the so-called Markov chain approximation approach of [10], [11]. They are convenient to program and use in applications, and have been used with success by the authors. At this time, they seem to be the only available methods for these problems. Reference [11] is an updated version of [10]. Rather than take a very general approach, the versatility and power of our methods will be illustrated by treating two different classes of problems. The methods used are the same as would be used for other singularly controlled problems. The first problem is a reflected singularly controlled diffusion of the type that arises in the modelling of queues and production systems under heavy traffic conditions [7]. We start with a two-dimensional version, just for notational simplicity. This particular problem has a rich enough structure so

that it can be used to illustrate the numerical method for the general singular control problem, as will be seen. Of course, as with any numerical method for solving partial differential equations (PDEs) or related systems, there is a "curse of dimensionality." The algorithms have been successfully used on numerous two- and three-dimensional problems. Our problem differs from those in [1]–[6], mainly in the nature of the boundary. For any numerical method, the state space needs to be bounded, and some condition (reflecting or otherwise) put on the boundary.

The second type of situation with which we work is an ergodic and constrained singular control problem, which has also arisen in heavy traffic analysis [9], [13]. Owing to the constraint, it is more complex than the standard ergodic problem, but the approximation methods and results can be readily adapted to other types of singular control ergodic problems.

Let $D[0,\infty)$ denote the space of functions that are right continuous and have left-hand limits, and with the Skorokhod topology [14], [15]. We use the arrow $\Rightarrow$ to denote weak convergence. All the weak convergence analysis will be on this space or its k-fold products $D^k[0,\infty)$ for appropriate k.

In §2 we define the first class of singular control problems. Section 3 deals with the numerical approximation, states the numerical algorithm, and makes a plausability argument concerning the convergence. The general technique of approximation and numerical solution introduced there is of general use for singular control problems. Section 4 concerns a rescaling that is necessary to deal with the tightness problems in the convergence proof. The actual convergence theorem is proved in §5. To illustrate the applicability of the method to a wide class of singular control problems, a somewhat harder case is discussed in §6, and the trivial adaptations required of the method are given. Section 7 formulates the second class of problems, a singular control problem with an average-cost-per-unit time criterion and with some additional constraints. We chose this class due to the complications and challenges that it presents. However, as will be seen, the numerical method works well and is widely applicable. In §8 the numerical approximation is presented together with several simplifications. The actual algorithm is given in §9. Due to the constraints, a linear programming rather than a dynamic programming method needs to be used. However, if the constraints were not present, any of the dynamic programming-based numerical methods that are usable for ergodic problems for Markov chains can be used. The proof of convergence is in §10. Some numerical data is also presented.

2. A reflected singularly controlled diffusion.

2.1. Definition of the problem. Let $G^i > 0$ and define the two-dimensional box $G = [0, G^1] \times [0, G^2]$. Let P be a degenerate Markov transition matrix, whose spectral radius is less than unity. For any two-dimensional vector X, we write its components as (X^1, X^2). Models of the type (2.1) (with or without controls) arise as heavy traffic limits of certain controlled queueing systems [7], [8], [16]:

$$\begin{aligned} X(t) = X(0) &+ \int_0^t b(X(s))ds + \int_0^t \sigma(X(s))dW(s) \\ &+ J(t) + (I - P')Y(t) - U(t), \quad X(t) \in G \quad \text{for all } t \geq 0. \end{aligned} \tag{2.1}$$

X is two-dimensional, $W(\cdot)$ is a standard R^2-valued Wiener process, the components of $J(\cdot)$, $Y(\cdot)$, and $U(\cdot)$ are in $D[0,\infty)$, and $J(0) = Y(0) = U(0) = 0$. The reflection terms $Y^i(\cdot)$ and $U^i(\cdot)$ are nondecreasing and can increase only when $X^i(t) = 0$ (respectively, $X^i(t) = G^i$).

The term $J(\cdot) = (J^1(\cdot), J^2(\cdot))$ is a "singular" control and is represented as follows: There is $K(\cdot) = (K^{12}(\cdot), K^{21}(\cdot))$ right continuous with $K^{ij}(0) = 0$ and $K^{ij}(\cdot)$ nondecreasing such that

$$J^1 = -K^{12} + c_2K^{21}, \qquad J^2 = c_1K^{12} - K^{21}, \tag{2.2}$$

where $1 \geq c_i > 0$. Define the vectors $v_1 = (-1, c_1)$ and $v_2 = (c_2, -1)$. $K(\cdot)$ is called the control. Since we are concerned only with the numerical method in this paper, the reader is referred to the references for the motivation for the model. We mention only that in [7] the $X(t)$ are the (weak) limits of a scaled queueing system with two processors. The p_{ij} are the probabilities that a completed service at processor i is sent to processor j $(i, j = 1, 2)$, and the K^{ij} represent the weak limit of the suitably scaled number of customers who were intended for processor i but who were actually rerouted to processor j. Without loss of generality, we let $p_{ii} = 0$. Familiarity with [7] is not needed here. As mentioned in the Introduction, the model is canonical in the sense that it has a rich enough structure so that (as will be seen below) the methods are applicable to typical singularly controlled systems of any dimension, and it is chosen for illustrative purposes and to simplify the development only.

It is possible that there will be an impulsive control action at $t = 0$. Then $X(\cdot)$, $J(\cdot)$ will be discontinuous there and will not be right continuous at that point.

2.2. Admissible controls. We say that a control $K(\cdot)$ is *admissible* or that $(K(\cdot), W(\cdot))$ is an *admissible pair* if $K(\cdot)$ is nonanticipative with respect to $W(\cdot)$.

In the absence of control, $Y(\cdot)$ and $U(\cdot)$ are continuous [16], [7]. In the presence of control, they might be discontinuous. For example, and loosely speaking, it is possible that on some time interval, $X(\cdot)$ will be on the boundary of G and the increments of $J(\cdot)$ will "point out of G." Of course, $X(\cdot)$ cannot leave G due to the reflection terms $Y(\cdot)$ and $U(\cdot)$, but such $J(\cdot)$ might cause $Y(\cdot)$ and $U(\cdot)$ to be discontinuous. For the type of problem that motivated the particular example, if G is chosen appropriately, then we would expect the control to "push away" from the boundary of G, and if this did not occur, then an enlargement of G might be called for.

2.3. The cost function. For $\alpha_i > 0$, $\beta_i > 0$, and $\beta > 0$, define the cost function

$$\begin{aligned} V(X(0), K, W) &= E\int_0^\infty e^{-\beta t}k(X(t))dt, \\ &+ E\int_0^\infty e^{-\beta t}[\alpha_1 dK^{12}(t) + \alpha_2 dK^{21}(t) + \beta_1 dU^1(t) + \beta_2 dU^2(t)], \qquad (2.3) \\ V(x) &= \inf V(x, K, W), \end{aligned}$$

where the infimum is over all admissible pairs. Assume the following.

Assumption 2.1. $b(\cdot)$, $\sigma(\cdot)$, and $k(\cdot)$ are continuous on G.

We write the cost as $V(X(0), K, W)$, since it is determined by the joint distribution of $X(0)$, $K(\cdot)$, and $W(\cdot)$. Since we do not require the control to be of the "feedback" form, we cannot write the cost as a function of $K(\cdot)$ only. In the "physical problem" leading to (2.1)–(2.3), the $U^i(\cdot)$ in (2.3) "penalizes" customers lost due to full buffers.

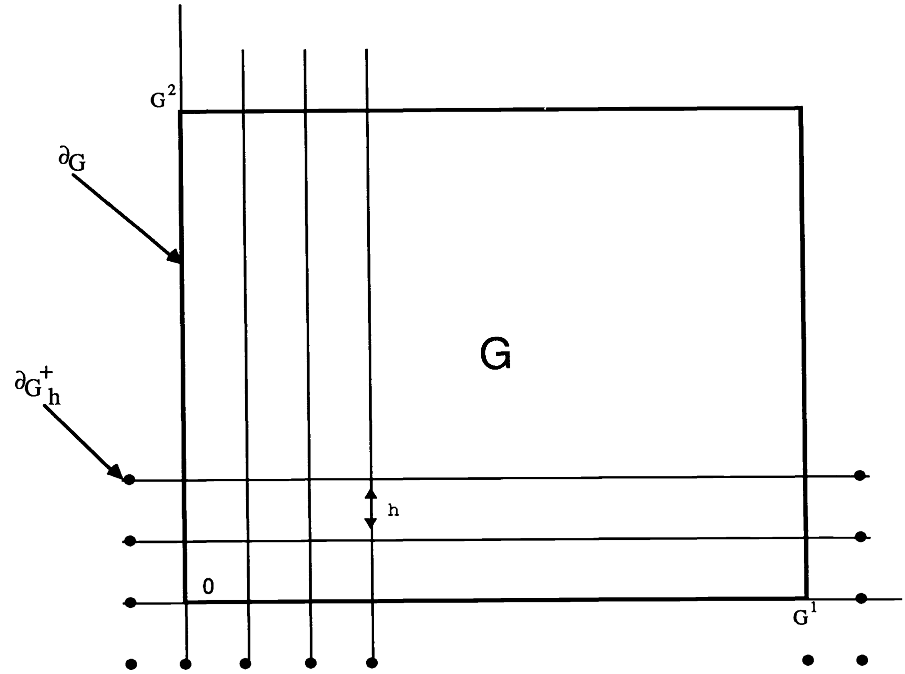

FIG. 1. *The numerical grid.*

3. A Markov chain approximation. The basic idea behind the numerical method is to find a discrete parameter Markov chain and associated control problem that is readily solvable and that approximates system (2.1)–(2.3) under the optimal control, in a sense to be described. The method is like that of [10], [11], but due to the presence of the singular control, some modifications of the technique of these references are required. Let h be an approximation parameter (h is a scalar here, but it could be vector valued; for example, in Fig. 1, the grid spacing could depend on the direction). Below, we will define a controlled Markov chain $\{\xi_n^h,\ n < \infty\}$, an admissible class of controls, and an associated control problem that provides an approximation to (2.1)–(2.3) in the following sense: An appropriate continuous parameter interpolation of the sequence of controlled chains $\{\xi_n^h,\ n < \infty\}$ converges weakly to a process satisfying (2.1) with an admissible pair $(K(\cdot), W(\cdot))$, as $h \to 0$. Let $V^h(x)$ denote the optimal value function for the control problem for the chain when $\xi_0^h = x$. Also, the continuous parameter interpolation of the *optimally controlled chain* converges weakly to the *optimally controlled* $X(\cdot)$ process and $V^h(x) \to V(x)$, for $x = X(0) \in G$. The numerical method thus consists in solving the optimal control problem for the chain. The particular chain that is used is chosen for convenience in solving the associated optimal control problem. The general approach has been used frequently. For the more classical stochastic control problems of [10], [11], there are standard and easily programmable methods for choosing the transition functions for the chain and for solving the control problem. Some modifications are required for the singular control problem and these will be discussed next.

To facilitate the development, we use a simple form for the state space, the G_h^+ defined below. Other forms will be discussed later, but the guiding ideas remain the same.

Define the h-grid G_h on G by $G_h = \{(kh, \ell h): 0 \le k \le G^1/h,\ 0 \le \ell \le G^2/h\}$, where we assume without loss of generality that the G^i are integral multiples of h. Define the "extended h-grid" $G_h^+ = \{(kh, \ell h): -1 \le k \le G^1/h{+}1,\ -1 \le \ell \le G^2/h{+}1\}$. Define $\partial G_h = G_h \cap \partial G$, the grid points on the boundary of G, and the "reflecting boundary" $\partial G_h^+ = G_h^+ - G_h$. See Fig. 1. The extended grid G_h^+ and ∂G_h^+ are not necessary but are introduced to allow us to deal with the reflection terms in a computationally efficient way. For states in the set G_h, the transition function for the Markov chain will be chosen such that the chain "behaves like" a controlled diffusion. When the state of the chain reaches ∂G_h^+ (i.e., has left G), it will be reflected back to G in a way that is consistent with the properties of the reflection terms $(I - P')Y - U$ in (2.1) (see Case 3 below). If we did not introduce ∂G_h^+, then the transition function would be more complex for states on ∂G. Define $\delta\xi_n^h = \xi_{n+1}^h - \xi_n^h$ and let E_n^h denote the expectation given all the data up to step n.

3.1. A heuristic discussion of the properties of the chain. Loosely speaking, the terms $J(\cdot)$, $Y(\cdot)$, and $U(\cdot)$ act either "instantaneously" or "impulsively." Intuitively, at the "instants" when $J(\cdot)$ changes there is no change in the $\int b\,dt + \int \sigma\,dW$ term. Since the behavior of the chain is supposed to "mimic" that of (2.1), we suppose that, for $\xi_n^h = x \in G_h$, we can choose to apply or not to apply a control. If we do not apply a control, then (loosely speaking) the increment $\delta\xi_n^h$ is to "behave like" an increment of $\int b\,dt + \int \sigma\,dW$ over a small time interval. We call this a "diffusion step." If we do apply a control at step n then, for consistency with the behavior of (2.1) at a "control instant," we will have

$$\delta\xi_n^h = (v_1 \delta K_n^{h,12} + v_2 \delta K_n^{h,21}) + (\text{small error}) \tag{3.1}$$

for some nonnegative control increments $\delta K_n^{h,ij}$ (only one of which will be nonzero). For programming simplicity and without loss of generality, we will restrict the $\delta K_n^{h,ij}$ to certain convenient values. See Case 2 below.

We can now write

$$\begin{aligned}\delta\xi_n^h = \delta\xi_n^h I_{\{\text{diffusion step at } n\}} &+ \delta\xi_n^h I_{\{\text{control step at } n\}} \\ &+ \delta\xi_n^h I_{\{\text{reflection step at } n\}}.\end{aligned} \tag{3.2}$$

The chain and the control will be chosen so that only one of the terms in (3.2) is positive. The transition function will be chosen so that the second term on the right will be (3.1). The third term on the right will have the form (see Case 3 below)

$$(I - P')\delta Y_n^h - \delta U_n^h + \text{"small error"} \tag{3.3}$$

for appropriate δY_n^h and δU_n^h, and the first term on the right will be formally similar to an increment in $\int b\,dt + \int \sigma\,dW$ over a small time interval.

The transition function $p^h(x, y \mid \text{control})$ for the chain is sometimes written as $p^h(x, y)$ if no control is used. We now define appropriate transition functions.

3.2. The transition functions.

Case 1. Let $\xi_n^h = x \in G_h$ and suppose that no control is exerted. Then (following the method in [10], [11]) the transition function is chosen such that the first two moments of $\delta\xi_n^h$ are "close" to those of $\int b\,dt + \int \sigma\,dW$ over a small time interval. In particular, define $a(x) = \sigma(x)\sigma'(x)$. Then for some $c_0 > 0$ and some "interpolation

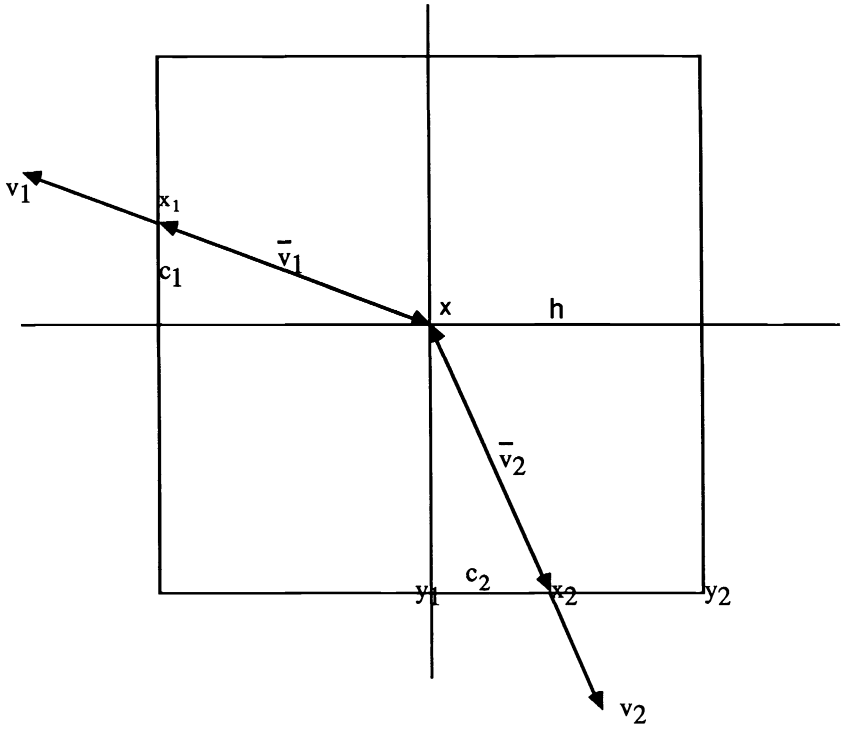

FIG. 2. *The control directions.*

interval" $\Delta t^h(x)$ satisfying $0 < c_0 h^2 \le \Delta t^h(x) \to 0$, we suppose that

$$
\begin{aligned}
&E_n^h \delta\xi_n^h = b(x)\Delta t^h(x) + O(h^\rho \Delta t^h(x)), \quad \rho > 0,\\
&\delta M_n^h = \delta\xi_n^h - E_n^h \delta\xi_n^h,\\
&E_n^h \delta M_n^h (\delta M_n^h)' = a(x)\Delta t^h(x) + O(h^\rho \Delta t^h(x)),\\
&|\xi_{n+1}^h - \xi_n^h| = O(h).
\end{aligned} \tag{3.4}
$$

The required p^h can be readily constructed. Some among the many possibilities are in [10], [11].

Case 2. *The control step.* Suppose that $x = \xi_n^h \in G_h$ and we decide to exert control, thus $\Delta t^h(x) = 0$. Define $\delta K_n^h = (\delta K_n^{h,12}, \delta K_n^{h,21})$ and $\delta J_n^h = v_1 \delta K_n^{h,12} + v_2 \delta K_n^{h,21}$. The transition probability $p^h(x, y \mid \text{control})$ will be chosen to satisfy (3.1). The "impulsive" control action is determined by a choice of the direction (either v_1 or v_2) together with the "impulse size" in that direction. For programming simplicity, we limit the choice of the nonnegative increments $\delta K_n^{h,ij}$ in the following way. Refer to Fig. 2 where $x = (x^1, x^2)$. Let x_i denote the intersection of the direction vectors v_i with the grid lines. Set $\bar{v}_i = x_i - x$. We restrict the δK so that the δJ take values either $\bar{v}_1$ or $\bar{v}_2$. Thus $\delta K_n^{h,ij}$ equals either 0 or h.

We restrict the values of $\delta K_n^{h,ij}$ since the method is easier to program if the choices are fewer and "local." Allowing arbitrary values for $\delta K_n^{h,ij}$ would yield the same limit results as in §5.

The points $x + \bar{v}_i = x_i$ are not usually in the grid G_h, unless the c_i equal unity. The actual transition function is chosen by a randomization so that the mean increment

$E_n^h \delta\xi_n^h$ is either $\bar{v}_1$ or $\bar{v}_2$, according to the choice of control action. In particular, if $\bar{v}_2$ is the chosen mean increment, then $\delta K_n^h = (0, h)$ and we use the transition function

$$p^h(x, y_1 \mid (0,h) = \delta K) = 1 - c_2 = 1 - p^h(x, y_2 \mid (0,h) = \delta K), \tag{3.5}$$

$$y_1 = (x^1, x^2 - h), \qquad y_2 = (x^1 + h, x^2 - h).$$

An analogous choice is used under $\bar{v}_1$. In the next section, we interpolate the $\{\xi_n^h\}$ into a continuous parameter process $\xi^h(\cdot)$. If at some n there is a control action, then the interpolation time is zero. In this sense, the original control problem is approximated by one in which the control acts impulsively.

Remark. The randomization is a perfectly natural numerical procedure. In fact, it is equivalent to a finite element approximation of $V(\cdot)$, i.e., a piecewise linear approximation. See the discussion in [11, §6] or the remark in Case 3 below.

By definition,

$$E_n^h \delta\xi_n^h = \delta J_n^h. \tag{3.6}$$

Let us define $\delta \tilde{J}_n^h = O(h)$ by

$$\delta\xi_n^h = \delta J_n^h + \delta \tilde{J}_n^h. \tag{3.7}$$

Then

$$E \sup_{n \le N} \left| \sum_{j=0}^{n-1} \delta \tilde{J}_j^h \right|^2 = NO(h^2) = O(h) E \sum_{j=0}^{N-1} |\delta J_j^h|. \tag{3.8}$$

In Theorem 5.3, (3.8) will be used to show that the $\{\delta \tilde{J}_n^h\}$ are asymptotically negligible, which implies that only the mean directions contribute to the limit, thus justifying the randomizations. The $\delta \tilde{J}_n^h$ are the "small errors" in (3.1). In analogy to (2.3), if $\delta K_n^{h,ij} \neq 0$ at step n, then the cost realized in this control step is $\alpha_i h = \alpha_i \delta K_n^{h,ij}$.

Case 3. *The reflection step.* For programming purposes, it seems simpler to separate the "diffusion" and "reflection" components of the chain approximation to (2.1) for $x \in \partial G$. This is the reason for the introduction of the separate "reflecting boundary" ∂G_h^+. We now discuss the reflection step for $x = \xi_n^h \in \partial G_h^+$. A useful method is described in [11, end of §9] and in [17] and we apply it to our problem here. The idea is similar to that of Case 2, namely, choose a mean reflection direction and state increment "consistent" with (2.1), and then "randomize" so that the actual new state is on the set of grid points ∂G_h. Let $x = (x^1, x^2) = \xi_n^h \in \partial G_h^+$. Refer to Fig. 3.

3.3. The transition function for the reflection step: the formal definition. We now fill in the details of the above heuristic discussion and obtain analogues of the U and Y terms needed for the convergence analysis in §5. There are three cases to be distinguished, depending on whether the components of $\xi_n^h = x = (x^1, x^2) \in \partial G_h^+$ are "too large," "too small," or a combination of these two: Case 3(i), all $x^i \ge 0$, some $x^i > G^i$ (the set of points between (a, b, c) in Fig. 3); Case 3(ii), all $x^i \le G^i$, some $x^i < 0$ (the set of points between (e, g, j)); Case 3(iii), some $x^i < 0$, some $x^j > G^j$ (the points d and k).

Case 3(i). Take $x = \xi_n^h \in \partial G_h^+$ to the nearest point on G_h, and define $\delta U_n^h = (\delta U_n^{h,1}, \delta U_n^{h,2}) = -\delta \xi_n^h$.

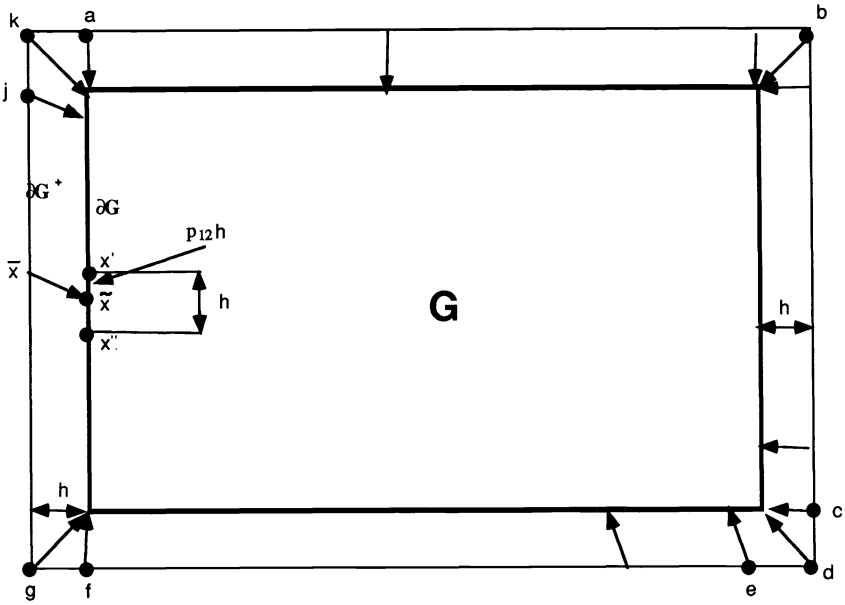

FIG. 3. *The reflection directions* ∂G.

Case 3(ii). To be consistent with the properties of the reflection term $(I - P')Y$ in (2.1), we first find a vector $\delta Y_n^h = (\delta Y_n^{h,1}, \delta Y_n^{h,2})$ with nonnegative components and the following properties: $\delta Y_n^{h,i} = 0$; if $x^i \geq 0$, the point $x + (I - P')\delta Y_n^h = \tilde{x}$ is on ∂G_h; if $x^i < 0$, then $\tilde{x}^i = 0$. This procedure yields a "consistent" reflection direction. However, $\tilde{x}$ will not generally be on ∂G_h. Refer to Fig. 3, and consider the point $\bar{x}$. Let x' and x'' denote the "neighboring" grid points to $\tilde{x}$, i.e., $\tilde{x} \in [x', x'']$. (In higher dimensions, we use a minimal set of points in ∂G_h such that $\tilde{x}$ is in its convex hull.) Define the transition function $p^h(\bar{x}, x') = |\tilde{x} - x''|/h = 1 - p^h(\bar{x}, x'')$. Thus, we randomize among x' and x'' keeping the mean value $\tilde{x}$. For the example in Fig. 3 where $x = \bar{x}$, we have $\delta Y_n^{h,2} = 0$, since $x^2 > 0$, and also

$$\tilde{x} - \bar{x} = (I - P') \begin{pmatrix} \delta Y_n^{h,1} \\ 0 \end{pmatrix} = \begin{pmatrix} h \\ 0 \end{pmatrix},$$

$$h = \delta Y_n^{h,1}, \qquad p^h(\bar{x}, x'') = p_{12}.$$

Case 3(iii). This is a combination of Cases 3(i) and 3(ii), since one component of x is "too big" and one is "too small." First, δY_n^h is defined, as in Case 3(ii), and then a δU_n^h is defined. To see the simple procedure, let $\xi_n^h = x =$ point d in Fig. 3, where $x^1 > G^1$ and $x^2 < 0$. Choose $\delta Y_n^{h,1} = 0$, $\delta Y_n^{h,2} \geq 0$ such that the second component of $\tilde{x} = x + (I - P')\delta Y_n^h$ is 0. The first component of $\tilde{x}$ will be greater than G^1 unless $p_{21} = 1$. Now, choose $\delta U_n^{h,1} = \tilde{x}^1 - G^1$, $\delta U_n^{h,2} = 0$. For reference in the dynamic programming equation (3.13) below, note that $\delta U_n^{h,1} = (1 - p_{21})h$ in this example. If $\xi_n^h =$ point k in the figure, then $\delta U_n^{h,1} = 0$ and $\delta U_n^{h,2} = (1 - p_{12})h$.

The method just described is indeed the "general method" for arbitrary state spaces. We calculate the intersection on ∂G of the line from $x \in \partial G_h^+$ in the reflection direction, and then randomize such that the mean point of intersection is preserved.

3.4. Representation of $\delta\xi_n^h$ in the reflection step. The following representation will be needed in §5.

In general, by the randomization used in Case 3, there is $\delta\tilde{Y}_n^h$ such that for $\xi_n^h \in \partial G_h^+$,

$$\begin{aligned} &\delta\xi_n^h = (I - P')\delta Y_n^h + \delta\tilde{Y}_n^h - \delta U_n^h, \\ &E_n^h \delta\tilde{Y}_n^h = 0, \qquad \delta\tilde{Y}_n^h = O(h), \end{aligned} \tag{3.9}$$

and the components of δY_n^h and $\delta\tilde{Y}_n^h$ (respectively, δU_n^h) can be nonzero only if $\xi_n^{h,i} < 0$ ($> G^i$, respectively). Define

$$U_n^h = \sum_{i=0}^{n-1} \delta U_i^h, \quad Y_n^h = \sum_{i=0}^{n-1} \delta Y_i^h, \quad \tilde{Y}_n^h = \sum_{i=0}^{n-1} \delta\tilde{Y}_i^h, \quad K_n^h = \sum_{i=0}^{n-1} \delta K_i^h.$$

We use K^h to denote the control policy. By the centering about conditional expectations, we have

$$\begin{aligned} E_n^h \left| \sum_{i=n}^{n+m-1} \delta\tilde{Y}_i^h \right|^2 &= O(h^2) E_n^h \quad (\#\text{ of reflection steps in } [n, n+m)) \\ &= O(h) E_n^h |Y_{n+m}^h - Y_n^h| \leq O(h^2) m. \end{aligned} \tag{3.10}$$

It will be shown in Theorem 5.3 that $E|Y_n^h|$ is bounded uniformly in h over the time interval of interest. Hence, formula (3.10) implies that the contributions of the $\{\delta\tilde{Y}_n^h\}$ terms vanish as $h \to 0$. Thus, the "randomization" in the reflection step has no effect in the limit.

3.5. The control problem for the chain. We say that a control policy K^h is *admissible* for the chain if it preserves the Markov property

$$P\{\xi_{n+1}^h = y \mid \xi_i^h, \ \delta K_i^h, \ i \leq n, \ \xi_n^h = x\} = p^h(x, y \mid \delta K_n^h).$$

Define $\Delta t_n^h = \Delta t^h(\xi_n^h)$ if n is a diffusion step, and set $\Delta t_n^h = 0$ otherwise. Define $t_n^h = \sum_{i=0}^{n-1} \Delta t_i^h$. With initial condition $\xi_0^h = x$ and control policy K^h, the cost function for the chain is defined to be

$$\begin{aligned} V^h(x, K^h) &= E \textstyle\sum_{n=0}^{\infty} e^{-\beta t_n^h} k(\xi_n^h) \Delta t_n^h \\ &+ E \textstyle\sum_{n=0}^{\infty} e^{-\beta t_n^h} [\alpha_1 \delta K_n^{h,12} + \ \alpha_2 \delta K_n^{h,21} + \beta_1 \delta U_n^{h,1} + \beta_2 \delta U_n^{h,2}]. \end{aligned} \tag{3.11}$$

This cost function is analogous to (2.3), in the sense that the sums in (3.11) "look like" integrals, due to the definition of the interpolation intervals. For $\xi_0^h = x$, define

$$V^h(x) = \inf_{K^h} V^h(x, K^h),$$

where the infimum is over all admissible policies.

3.5.1. The dynamic programming equation for the chain. The programming equation for (3.11) is the following. Write $p^h(x, y \mid \bar{v}_i)$ for the transition probability if the control is an increment in the direction v_i. For $x \in G_h$,

$$\begin{aligned} V^h(x) = \min \Big\{ & e^{-\beta \Delta t^h(x)} \textstyle\sum_y p^h(x, y) V^h(y) + k(x) \Delta t^h(x), \\ & \min_i \Big[\textstyle\sum_y p^h(x, y \mid \bar{v}_i) V^h(y) + \alpha_i h \Big] \Big\}. \end{aligned} \tag{3.12}$$

For $x \in \partial G_h^+$

$$V^h(x) = \textstyle\sum_y p^h(x,y)V^h(y) + \beta_1 h I_{\{x^1>G^1,x^2\geq 0\}} \tag{3.13}$$
$$+\ \beta_1 h(1-p_{21})I_{\{x^1>G^1,x^2<0\}} + \beta_2 h I_{\{x^2>G^2,x^1\geq 0\}}$$
$$+\ \beta_2 h(1-p_{12})I_{\{x^2>G^2,x^1<0\}}.$$

The reason for the $(1-p_{ij})$ terms is given in the discussion of Case 3(iii) above.

Particularly efficient methods for solving (3.12), (3.13) will be discussed in a forthcoming report. However, they can be solved by any of the usual iteration in policy or value space methods. In (3.12), there is a choice between no control and control, and a choice of the two alternatives for the control. There is no discount factor in the "control" term of (3.12), since $\Delta t_n^h = 0$ at any step at which there is a control action. A similar consideration holds for the reflection term (3.13).

3.5.2. A note on computation. In computing via the approximation in value space method, it has been observed that the rate of convergence of the iterates to $V^h(x)$ is much slower for $x \in \partial G_h^+$ than for $x \in G_h$. While we do not understand the reasons for this phenomenon, it should be kept in mind in setting the stopping criterion for the iterations.

3.5.3. Extensions. The method for the higher-dimensional problem $(r > 2)$ should be clear from the foregoing. The basic technique for dealing with the control and boundary terms is the same.

3.6. A formal dynamic programming (Bellman) equation for (2.1), (2.3). We now make some *purely formal* comments concerning the relationship between the numerical algorithm and a finite difference approximation to the Bellman equation for (2.1), (2.3). The comparison will provide a better intuitive feeling for the control step calculations. Write the *formal* Bellman equation, ignoring the boundary terms: Let $\mathcal{L}$ be the differential operator of the "diffusion" part of (2.1). Then (see [2] for a related problem)

$$0 = \min\left\{\mathcal{L}V(x) + k(x) - \beta V(x),\ \min_i (V_x'(x)v_i + \alpha_i)\right\}. \tag{3.14}$$

Note that the form of (3.14) implies a choice of "diffusion" or "control." A formal derivation of (3.14) can be obtained by writing $K^{ij}(\cdot)$ in the form $K^{ij}(t) = \int_0^t u^{ij}(s)ds$, with $0 \leq u^{ij}(s) \leq \infty$, and deriving the Bellman equation for the nonsingular problem. It will turn out that $u^{ij}(s)$ is either zero or infinity.

3.6.1. A finite difference interpretation of (3.12), (3.13). With appropriate choices of $p^h(x,y)$ for the diffusion step (particularly those based on the "finite difference model" in [10], [11]), the "diffusion part" of (3.11) can be rewritten in terms of a formal finite difference approximation to $\mathcal{L}V(x) + k(x)$ in (3.14). We now do the analogue for the control term in (3.14). Let e_i denote the unit vector in the ith coordinate direction and note that

$$1 - c_1 = p^h(x, x - e_1 h \mid \delta K = (h,0)),$$
$$1 - c_2 = p^h(x, x - e_2 h \mid \delta K = (0,h)).$$

Subtract $V^h(x)$ from both sides of (3.12). Then the inner minimum in (3.12), divided by h, equals $(i \neq j)$

$$\min_i \left[\frac{(V^h(x-e_ih) - V^h(x))}{h}(1-c_i) + \frac{(V^h(x-e_ih+e_jh) - V^h(x))}{h}c_i + \alpha_i\right]$$

$$\approx \min_i [V^h_{x_i}(x) - c_i V^h_{x_j}(x) + \alpha_i] = \min_i [V^h_x(x)' v_i + \alpha_i],$$

which is just the corresponding term in (3.14) with the superscript h dropped.

4. Interpolation and rescaling.

4.1. Preliminary results. The methods that have been used to show $V^h(x) \to V(x)$ for the more classical problems in [10], [11] need modification before they can be applied to the singular control problem. We first define some standard interpolations. Then we show why we might not have tightness and weak convergence in the Skorokhod topology and, finally, we define the rescaling that is used to obtain the desired limit results. The problem will also be put into a form that will be used in the convergence proofs of §5. Define $\xi^h(\cdot)$ by $\xi^h(t) = \xi^h_n$ on $[t^h_n, t^h_{n+1})$ for all n in which a diffusion step is used. Since $t^h_{n+1} = t^h_n$ if n is a control or reflection step, this defines $\xi^h(t)$ for all t. Define the process

$$K^{h,ij}(t) = \sum_{n:t^h_{n+1} \le t} \delta K^{h,ij}_n. \tag{4.1}$$

Define $B^h(\cdot)$, $M^h(\cdot)$, $Y^h(\cdot)$, $U^h(\cdot)$, $\tilde{Y}^h(\cdot)$, and $\tilde{J}^h(\cdot)$ by (4.1), but using (respectively) the sequences $\{b(\xi^h_n)\Delta t^h_n\}$, $\{\delta M^h_n\}$, $\{\delta Y^h_n\}$, $\{\delta U^h_n\}$, $\{\delta \tilde{Y}^h_n\}$, and $\{\delta \tilde{J}^h_n\}$. Define $J^h(t) = v_1 K^{h,12}(t) + v_2 K^{h,21}(t)$.

Now write

$$\begin{aligned} \xi^h_n &= x + \sum_{i=0}^{n-1} \delta\xi^h_i I_{\{\text{diffusion step at } i\}} \\ &\quad + \sum_{i=0}^{n-1} \delta\xi^h_i I_{\{\text{control step at } i\}} + \sum_{i=0}^{n-1} \delta\xi^h_i I_{\{\text{reflection step at } i\}}. \end{aligned}$$

Using representations (3.4), (3.7), (3.9), and the definitions of the above interpolations, the above formula yields (for $\xi^h(0) = x$)

$$\begin{aligned} \xi^h(t) &= x + B^h(t) + M^h(t) + J^h(t) + (I - P')Y^h(t) \\ &\quad - U^h(t) + \tilde{Y}^h(t) + \tilde{J}^h(t) + \textstyle\sum_{i:t^h_i \le t} O(h^\rho \Delta t^h_i), \end{aligned} \tag{4.2}$$

where

$$B^h(t) = \int_0^t B(\xi^h(s))ds + O(h).$$

Also, $\{\sum_{i=0}^{n-1} \delta M^h_i\}$ is a martingale and

$$E^h_t[M^h(t+s) - M^h(t)][M^h(t+s) - M^h(t)]' = E^h_t \int_t^{t+s} a(\xi^h(s))ds + O(h^\rho),$$

where E^h_t denotes the expectation given the data up to interpolated time t.

Approximating $e^{-\beta t^h_n}$ by $e^{-\beta t}$ on $[t^h_n, t^h_{n+1})$, for an admissible policy K^h, we have the representation for the cost

(4.3)

$$\begin{aligned} V^h(x, K^h) &= E \textstyle\int_0^\infty e^{-\beta s} k(\xi^h(s))ds \\ &\quad + E \textstyle\int_0^\infty e^{-\beta s}[\alpha_1 dK^{h,12}(s) + \alpha_2 dK^{h,21}(s) + \beta_1 dU^{h,1}(s) + \beta_2 dU^{h,2}(s)]. \end{aligned}$$

The similarity of (4.2), (4.3) with (2.1), (2.3) suggests that our continuous parameter interpolations are appropriate.

4.2. A difficulty with the weak convergence. To prove that $V^h(x) \to V(x)$, we would like to use the weak convergence technique of [10] or [11]. By that method, we first prove tightness of the set of processes in (4.2). We then extract a weakly convergent subsequence and show that the limit satisfies (2.1) for some admissible pair $(K(\cdot), W(\cdot))$, where $K(\cdot) = \lim_h K^h(\cdot)$, and that either $V^h(x) \to V(x, K, W)$ or $\underline{\lim}_h V^h(x) \geq V(x, K, W)$. This implies that $\underline{\lim}_h V^h(x) \geq V(x)$. The reverse inequality $\overline{\lim}_h V^h(x) \leq V(x)$ is then proved by a separate argument.

This method does not work here, since we do not know whether $\{K^h(\cdot)\}$ is tight. Owing to the time scaling, it is possible to alternate diffusion and control steps in such a way that the "limit" has a "jump," and there is no convergence in the Skorokhod topology.

There are several ways to handle this "singular" problem. The pseudopath topology that was used in [18] for a weak convergence study of a singular control problem could be used. We prefer to use a time change argument of the type used in [7] since it is more direct. The idea is to rescale time so that tightness is assured, take weak limits, and then use an inverse transformation to obtain the desired result. The method is quite useful for the study of limits of sequences of singularly controlled processes. In preparation for this work in the next section, we introduce the following rescaling.

4.3. The rescaled processes. Define $\Delta\hat{t}_n^h$ by $\Delta\hat{t}_n^h = \Delta t_n^h$ if step n is a "diffusion" step, $\Delta\hat{t}_n^h = 0$ if we reflect on step n, and $\Delta\hat{t}_n^h = h$ if we control at step n. Set $\hat{t}_n^h = \sum_{i=0}^{n-1} \Delta\hat{t}_i^h$. Define $\hat{T}^h(\cdot)$ by $\hat{T}^h(0^-) = 0$, and $\hat{T}^h(t) = \sum_{i=0}^{n} \Delta t_i^h = t_{n+1}^h$ on the interval $[\hat{t}_n^h, \hat{t}_{n+1}^h]$. Thus $\hat{T}^h(\cdot)$ does not increase at these t at which a control step occurs.

Define the rescaled and interpolated processes $\hat{\xi}^h(\cdot)$ and $\hat{M}^h(\cdot)$ by $\hat{\xi}^h(t) = \xi_n^h$ on $[\hat{t}_n^h, \hat{t}_{n+1}^h)$ and $\hat{M}^h(t) = \sum_{i=0}^{n-1} \delta M_i^h$ on $[\hat{t}_n^h, \hat{t}_{n+1}^h)$, and define $\hat{K}^h(\cdot)$, $\hat{J}^h(\cdot)$, $\hat{Y}^h(\cdot), \cdots$, analogously to $\hat{M}^h(\cdot)$. We can write

$$\begin{aligned}\hat{\xi}^h(t) = x + \hat{B}^h(t) + \hat{M}^h(t) + \hat{J}^h(t) + (I - P')\hat{Y}^h(t) - \hat{U}^h(t) \\ + \hat{\hat{Y}}^h(t) + \hat{\tilde{J}}^h(t) + (\text{negligible error}),\end{aligned} \tag{4.4}$$

$$\begin{aligned}V^h(x, K^h) = E \textstyle\int_0^\infty e^{-\beta\hat{T}^h(s^-)} k(\hat{\xi}^h(s)) d\hat{T}^h(s) \\ + E \textstyle\int_0^\infty e^{-\beta\hat{T}^h(s^-)} [\alpha_1 d\hat{K}^{h,12}(s) \\ + \alpha_2 d\hat{K}^{h,21}(s) + \beta_1 d\hat{U}^{h,1}(s) + \beta_2 d\hat{U}^{h,2}(s)].\end{aligned} \tag{4.5}$$

Comment. The rescaling "stretches out" the control and state processes, so that they are smoother and tightness can be proved. In fact, the $\hat{K}^{h,ij}(\cdot)$ are Lipschitz continuous with constant unity for all ω. In the next section, the weak convergence analysis is done for the rescaled process. Then, via an inverse time transformation of the limit process, $V^h(x) \to V(x)$ is obtained. The time rescaling arguments parallel those in [7] as closely as possible, but the notation and many details are different, since in [7], we worked with a "physical" heavy traffic process with a different structure.

5. The convergence theorem. Theorem 5.3 proves the weak convergence of the rescaled processes and gives a representation of the limit in terms of a rescaled form of (2.1). It also shows that by a natural inverse scaling, we recover a process of the form (2.1). Theorem 5.4 proves that $V^h(x)$ converges to the cost for some process of the type (2.1). Theorem 5.6 completes the proof that $V^h(x) \to V(x)$.

We next quote two results that will be needed in the proof of Theorems 5.3 and 5.5.

THEOREM 5.1 (The reflection mapping). *Let P be a degenerate Markov transition matrix, with spectral radius less than unity. Let $z(\cdot) \in D^k[0,\infty)$ and consider the equation*

$$x(t) = z(t) + (I - P')y(t) - u(t), \quad x^i(t) \in [0, G^i] \text{ for all } t. \tag{5.1}$$

There is a unique continuous function (in the topology of uniform convergence on bounded time intervals) $F(\cdot)$ such that $(y(\cdot), u(\cdot)) = F(z(\cdot))$ has the following properties: $F(\cdot)$ maps $C^k[0,\infty)$ into $C^k[0,\infty)$ and $D^k[0,\infty)$ into $D^k[0,\infty)$; the $y^i(\cdot)$ (respectively, $u^i(\cdot)$) are nondecreasing and nonnegative and can increase only when $x^i(t) = 0$ (respectively, $x^i(t) = G^i$), and $y(0) = u(0) = 0$. Also, (5.1) *holds.*

The proof is in [7, §8] and is an extension of a similar theorem in [16].

THEOREM 5.2. *Assume that Assumption* 2.1 *holds true. Let $V^h(x,0)$ denote the cost with no control used. Then $\sup_{x,h} V^h(x,0) < \infty$. Let $\{K^{h,ij}(n+1) - K^{h,ij}(n), h, n\}$ be uniformly integrable. Then so is $\{U^h(n+1) - U^h(n),\ h, n\}$.*

The proof is the same as that of [7, Thms. 7, 9]; just replace the $(M^\epsilon, B^\epsilon, B_i)$ there by our (M^h, B^h, G^i).

Define the process $\hat{H}^h(\cdot)$ by

$$\hat{H}^h(\cdot) = (\hat{\xi}^h(\cdot), \hat{M}^h(\cdot), \hat{B}^h(\cdot), \hat{K}^h(\cdot), \hat{\tilde{J}}^h(\cdot), \hat{Y}^h(\cdot), \hat{\tilde{Y}}^h(\cdot), \hat{U}^h(\cdot), \hat{T}^h(\cdot)).$$

The statement of Theorem 5.3 is a little long, but it seems preferable to have the results in one place.

THEOREM 5.3. *Assume that Assumption* 2.1 *holds true, and let $K^h(\cdot)$ be admissible control policies. Then $\{\hat{H}^h(\cdot)\}$ is tight and the limit of any weakly convergent subsequence is continuous with probability one (w.p.*1.*) Let $\hat{H}(\cdot)$ denote the limit of such a subsequence. Then $\hat{\tilde{Y}}(\cdot)$ and $\hat{\tilde{J}}(\cdot)$ are identically zero w.p.*1 *and ($z(0) = x$ here)*

$$\hat{\xi}(t) = x + \hat{M}(t) + \hat{B}(t) + \hat{J}(t) + (I - P')\hat{Y}(t) - \hat{U}(t), \tag{5.2}$$

where $\hat{J}(t) = v_1\hat{K}^{12}(t) + v_2\hat{K}^{21}(t)$, $\hat{B}(t) = \int_0^t b(\hat{\xi}(s))d\hat{T}(s)$, and $\hat{M}(\cdot)$ is a $\mathcal{B}(\hat{H}(s), s \leq t)$-martingale with quadratic variation process $\int_0^t a(\hat{\xi}(s))d\hat{T}(s)$.

*Assume, further, that $\sup_h E|K^h(t)| < \infty$ for each t. Then, $\hat{T}(t) \to \infty$ w.p.*1. *For $t < \infty$, define the inverse $T(\cdot)$ by $T(t) = \inf\{s: \hat{T}(s) > t\}$. Then $T(t) \to \infty$ w.p.*1 *as $t \to \infty$. For any process $\hat{\phi}(\cdot)$, define the rescaled process $\phi(\cdot)$ by $\phi(t) = \hat{\phi}(T(t))$. Then*

$$\xi(t) = x + M(t) + B(t) + J(t) + (I - P')Y(t) - U(t), \tag{5.3}$$

where $J(t) = v_1K^{12}(t) + v_2K^{21}(t)$ and $B(t) = \int_0^t b(\xi(s))ds$. Also, $M(\cdot)$ is a $\mathcal{B}_t = \mathcal{B}(H(s), s \leq t)$-martingale with quadratic variation $\int_0^t a(\xi(s))ds$. Finally, there is a $\mathcal{B}_t$-Wiener process $W(\cdot)$ such that $M(t) = \int_0^t \sigma(\xi(s))dW(s)$ and $(K(\cdot) - K(0), W(\cdot))$ is an admissible pair.

Remark. By the definition of $T(\cdot)$ and the continuity of $\hat{H}(\cdot)$, the components of $H(\cdot)$ have paths in $D[0,\infty)$. However, $T(\cdot)$, $\xi(\cdot)$, $K(\cdot)$, $U(\cdot)$, or $Y(\cdot)$ might be discontinuous due to an "accumulation" of control actions at some time point. Consider one case, where $\hat{T}(t) = 0$ on an interval $[0,\delta)$, $\delta > 0$. This can happen if control and diffusion steps alternate for the chain, with a reflection step taken where necessary. For this case, $K(0) \neq 0$. Consider another case, where there is an "accumulation" of control actions "pushing out of G" when $\xi_n^h \in \partial G_h$. Then $Y(\cdot)$ or $U(\cdot)$ would be discontinuous. If such "accumulations" occurred at $t = 0$, then there would be an impulsive change in the state at $t = 0$ of magnitude $K(0) + (I - P')Y(0) - U(0)$.

Proof. Part 1. *Tightness.* Let τ denote a finite stopping time. By the boundedness of $b(\cdot)$ and the martingale property of $\{M_n^h,\ n < \infty\}$, we have (the $O(\cdot)$ terms do not depend on τ)

$$E_\tau^h |B^h(\tau + s) - B^h(\tau)| \leq O(s) + O(h),$$
$$E_\tau^h |M^h(\tau + s) - M^h(\tau)|^2 \leq O(s) + O(h).$$

By [15, Thm. 2.7b], a sufficient condition for tightness of a sequence of processes $\{\phi_n(\cdot)\}$ with paths in $D[0, \infty)$ is that for each $T < \infty$

$$\lim_{s \to 0} \overline{\lim_{n}} \sup_{\tau \leq T} E|\phi_n(\tau + s) - \phi_n(\tau)| = 0, \tag{5.4}$$

where the supremum is over all stopping times less than T. Thus $\{B^h(\cdot),\ M^h(\cdot)\}$ is tight. Hence so is $\{\hat{B}^h(\cdot), \hat{M}^h(\cdot)\}$ due to the "stretching out" of the timescale. By the definition of the "stretched out" timescale, $|\hat{K}^h(t + s) - \hat{K}^h(t)| \leq |s| + O(h)$. Thus $\{\hat{K}(\cdot)\}$ is tight. Consequently, by (3.8), $\{\hat{\tilde{J}}^h(\cdot)\}$ converges weakly to the zero process.

Note that a reflection step can occur only after a diffusion or control step. Then (3.10) and the fact that $\Delta \hat{t}_n^h \geq c_0 h^2$ (see (3.4) above) for the control or diffusion step imply that for $s > 0$ and any bounded stopping time τ

$$\begin{aligned} E_\tau^h |\hat{\tilde{Y}}^h(\tau + s) - \hat{\tilde{Y}}^h(\tau)|^2 &= O(h^2) E_\tau^h \text{ (number of reflection steps of } \hat{\xi}^h(\cdot) \text{ in} \\ &\qquad \text{interpolated interval } [\tau, \tau + s)) \\ &= O(h^2) E_\tau^h \text{ (number of diffusion or control steps of } \hat{\xi}^h(\cdot) \\ &\qquad \text{in interpolated interval } [\tau, \tau + s)) \\ &= O(h^2)(s/h^2 + 1) = O(s) + O(h^2), \end{aligned}$$

which together with (5.4) yields the tightness of $\{\hat{\tilde{Y}}^h(\cdot)\}$. All the limits of weakly convergent subsequences of these processes are continuous w.p.1, since the jumps are all of order $O(h)$. We also have

$$E_\tau^h |\hat{\tilde{Y}}^h(\tau + s) - \hat{\tilde{Y}}^h(\tau)|^2 = O(h) E_\tau^h |\hat{Y}^h(\tau + s) - \hat{Y}^h(\tau)|.$$

Write (4.4) as

$$\hat{\xi}^h(t) = \hat{Z}^h(t) + (I - P')\hat{Y}^h(t) - \hat{U}^h(t),$$

where $\hat{Z}^h(\cdot)$ is defined in the obvious way from (4.4). We have proved that $\{\hat{Z}^h(\cdot)\}$ is tight and all the limits are continuous processes. By Theorem 5.1, there is a unique continuous function $F(\cdot)$ (not depending on h) that is continuous and is such that $(\hat{Y}^h(\cdot), \hat{U}^h(\cdot)) = F(\hat{Z}^h(\cdot))$ is the unique process for which $\hat{\xi}^h(t) \in G$ and where the components of $(\hat{Y}^h(\cdot),\ \hat{U}^h(\cdot))$ can increase only when $\hat{\xi}^h(\cdot)$ is on the appropriate part of the boundary. Now by the continuity of $F(\cdot)$, $\{\hat{Y}^h(\cdot), \hat{U}^h(\cdot)\}$ is tight and all weak limits are continuous. This and the above estimate on $\hat{\hat{Y}}^h(\cdot)$ imply that $\hat{\hat{Y}}^h(\cdot)$ converges weakly to the zero process. (Note that we defined $\hat{Y}^h(\cdot)$ and $\hat{U}^h(\cdot)$ a priori. The representation of Theorem 5.1 tells us that they can also be obtained as a function of $\hat{Z}^h(\cdot)$. This latter representation is useful to prove the tightness and continuity properties of $\hat{U}^h(\cdot)$ and $\hat{Y}^h(\cdot)$, as in [16], [17], [7].)

Part 2. *Weak convergence.* Abusing terminology, let h index a weakly convergent subsequence, with limit denoted by $\hat{H}(\cdot)$. The paths of $\hat{H}(\cdot)$ are continuous w.p.1, and $\hat{\hat{J}}(t) = \hat{\hat{Y}}(t) \equiv 0$. The limit satisfies (5.2). Since

$$\hat{B}^h(t) = \int_0^t b(\hat{\xi}(s))d\hat{T}^h(s) + O(h), \tag{5.5}$$

we have the representation $\hat{B}(t) = \int_0^t b(\hat{\xi}(s))d\hat{T}(s)$.

Recall that $\{M_n^h\}$ is a martingale and that

$$E_n^h[M_{n+m}^h - M_n^h][M_{n+m}^h - M_n^h]' = E_n^h \sum_{i=n}^{n+m-1} [a(\xi_i^h)\Delta t_i^h + O(h^\rho)\Delta t_i^h].$$

Let $\hat{E}_t^h$ denote the expectation conditioned on $\hat{\mathcal{B}}_t^h \equiv \mathcal{B}(\hat{H}^h(s),\ s \le t)$. For any bounded $\hat{\mathcal{B}}_t^h$-stopping time τ, we can write

$$\hat{E}_\tau^h[\hat{M}^h(\tau + s) - \hat{M}^h(\tau)] = 0,$$

$$\begin{aligned}\hat{E}_\tau^h&[\hat{M}^h(\tau + s) - \hat{M}^h(\tau)][\hat{M}^h(\tau + s) - \hat{M}^h(\tau)]' \\ &= \hat{E}_\tau^h \int_\tau^{\tau+s} a(\hat{\xi}^h(s))d\hat{T}^h(s) + O(h).\end{aligned} \tag{5.6}$$

Let q be an arbitrary integer, let $t_i \le t < s$, $i \le q$, and let $h(\cdot)$ be a bounded and continuous real-valued function of its arguments. Then (5.6) implies that

$$Eh(\hat{H}^h(t_i), i \le q)[\hat{M}^h(t + s) - \hat{M}^h(t)] = 0,$$

$$\begin{aligned}Eh(\hat{H}^h(t_i), i \le q)\Big(&[\hat{M}^h(t + s) - \hat{M}^h(t)][\hat{M}^h(t + s) - \hat{M}^h(t)]' \\ &- \int_t^{t+s} a(\hat{\xi}^h(s))d\hat{T}^h(s)\Big) = O(h^\rho).\end{aligned} \tag{5.7}$$

By taking limits in (5.7), we see that (5.7) holds with the h superscript dropped. The arbitrariness of $h(\cdot)$, q, t_i, t, and s imply that $\hat{M}(\cdot)$ is a $\hat{\mathcal{B}}_t$-martingale with the quadratic variation given in the theorem statement.

Part 3. *The construction of* $\xi(\cdot)$. Since $\sup_h E|K^h(t)| < \infty$ for each t by hypothesis, we have $\hat{T} \to \infty$ w.p.1 as $t \to \infty$. This is because, *loosely speaking,* $\hat{T}^h(t + |K^h(t)|) \approx t$. Thus the inverse function $T(s)$ defined in the theorem statement exists for each s. Note that for $u \ge 0$, we have $\{T(s) \le u\} = \{\hat{T}(u) \ge s\} \in \hat{\mathcal{B}}_u$. Thus

$T(s)$ is a $\hat{\mathcal{B}}_t$-stopping time for each s. Consequently, $M(\cdot)$ is a $\mathcal{B}_t \equiv \mathcal{B}(H(s),\ s \le t)$-martingale. The quadratic variation of $M(\cdot)$ is easily calculated to be $\int_0^t a(\xi(s))ds$. (This fact follows simply by rescaling the limit of (5.7).) Hence, there is a $\mathcal{B}_t$-Wiener process $W(\cdot)$ such that $M(t) = \int_0^t \sigma(\xi(s))dW(s)$. Clearly, $(K(\cdot), W(\cdot))$ is an admissible pair, since $\mathcal{B}_t$ measures $\{K(s),\ s \le t\}$ for each t. If $a(\cdot)$ is degenerate at some point, then we might have to augment the probability space by adding an "independent" Wiener process. It is also easily shown that $B(t) = \int_0^t b(\xi(s))ds$. Thus representation (5.3) follows from (5.2). □

The next theorem characterizes the limit of the costs $V^h(x, K^h)$ and gives "one half" of the desired convergence theorem for $\{V^h(x)\}$.

THEOREM 5.4. *Assume that Assumption* 2.1 *holds true and use the notation of Theorem* 5.3. *If* $\{K^h(n+1) - K^h(n),\ h, n\}$ *is uniformly integrable, then for the weakly convergent subsequence in Theorem* 5.3 (*indexed by* h),

$$V^h(x, K^h) \to V(x, K, W).$$

If the uniform integrability hypothesis is not satisfied, then

$$\underline{\lim}_h V^h(x, K^h) \ge V(x, K, W) \ge V(x).$$

Proof. By the weak convergence and the continuity of the limit $\hat{H}(\cdot)$,

$$V^h(x) = E\sum_{n=0}^{\infty} e^{-\beta t_n^h} k(\xi_n^h)\Delta t_n^h = E\int_0^{\infty} e^{-\hat{T}^h(s^-)} k(\hat{\xi}^h(s))d\hat{T}^h(s), \tag{5.8}$$

$$E\int_0^{\infty} e^{-\hat{T}^h(s^-)} k(\hat{\xi}^h(s))d\hat{T}^h(s) \to E\int_0^{\infty} e^{-\beta\hat{T}(s)} k(\hat{\xi}(s))d\hat{T}(s).$$

On inversion of the timescale, the right side of (5.8) can be written as $E\int_0^\infty e^{-\beta t} k(\xi(t))dt$. By the uniform integrability of $\{K^h(n+1) - K^h(n),\ h, n\}$ and Theorem 5.2, $\{U^h(n+1) - U^h(n),\ h, n\}$ is uniformly integrable. The right-hand sum in (3.11) can be written as

$$E\int_0^{\infty} e^{-\beta\hat{T}^h(s^-)}[\alpha_1 d\hat{K}^{h,12}(s) + \alpha_2 d\hat{K}^{h,21}(s) + \beta_1 d\hat{U}^{h,1}(s) + \beta_2 d\hat{U}^{h,2}(s)]. \tag{5.9}$$

By the weak convergence, continuity of the limit process, and uniform integrability, (5.9) converges to

$$E\int_0^{\infty} e^{-\beta\hat{T}(s)}[\alpha_1 d\hat{K}^{12}(s) + \alpha_2 d\hat{K}^{21}(s) + \beta_1 d\hat{U}^{1}(s) + \beta_2 d\hat{U}^{2}(s)].$$

On inversion of the timescale, the above expression can be written as

$$E\int_0^{\infty} e^{-\beta t}[\alpha_1 dK^{12}(t) + \alpha_2 dK^{21}(t) + \beta_1 dU^{1}(t) + \beta_2 dU^{2}(t)]. \tag{5.10}$$

The right-hand sides of (5.8) and (5.10) add up to $V(x, K, W)$. In the absence of the uniform integrability, we use Fatous' lemma to get $\underline{\lim}_h V^h(x, K^h) \ge V(x, K, W)$. □

THEOREM 5.5. *Assume that Assumption* 2.1 *holds true. Then*

$$\varliminf_{h} V^h(x) \geq V(x). \tag{5.11}$$

Proof. Let K_0^h denote an optimal admissible policy for $\{\xi_n^h, n < \infty\}$. By Theorem 5.2 and the discounted nature of the cost function, we have the following: For any $\delta > 0$, there is a $T > 0$ (independent of h) such that for each h there is a δ-optimal policy $K^h(\cdot)$ for which no control is exercised after T, i.e., for n such that $t_n^h \geq T$. Since $\sup_h V^h(x) < \infty$ by Theorem 5.2, we have $\sup_h |K^h(t)| < \infty$ for each t. Then the theorem follows from Theorem 5.4 and the fact that for any weakly convergent subsequence of $\{\hat{H}^h(\cdot)\}$ with limit $\hat{H}(\cdot)$ and with the rescaled process defined by $H(\cdot) = \hat{H}(T(\cdot))$, we have $V(x, K, W) \geq V(x)$, where $(K(\cdot), W(\cdot))$ is the admissible pair in $H(\cdot)$. □

To complete the proof that $V^h(x) \to V(x)$, we need to show that $\overline{\lim}_h V^h(x) \leq V(x)$. To do this, we need to exploit the optimality of $V^h(x)$. This is done in the next theorem.

DEFINITION. The solution to (2.1) is said to be *unique in the weak sense* if the probability law of $(K(\cdot), W(\cdot))$ determines that of $(X(\cdot), K(\cdot), W(\cdot))$. We will need the following assumption.

Assumption 5.1. For each $\delta > 0$, there is some δ-optimal control for (2.1), (2.3) for which the solution to (2.1) is unique in the weak sense. The uncontrolled system (2.1) (i.e., with $K(t) \equiv 0$) has a weak sense unique solution for each initial condition.

THEOREM 5.6. *Assume that Assumptions* 2.1 *and* 5.1 *hold true. Then* $V^h(x) \to V(x)$.

Proof. To exploit the fact that $V^h(x)$ is an optimal cost for the chain $\{\xi_n^h, n < \infty\}$, we choose a particular δ-optimal control for (2.1), (2.3), such that the approximation can be applied to the chain and the associated cost compared with $V^h(x)$. The theorem will follow from a comparison of the costs associated with appropriate weakly convergent subsequences. The chosen δ-optimal control is not a "practical" control, but it does give the desired inequalities. The proof is an adaptation of a method used for a "heavy traffic" problem in [7]. The proof of the existence of a δ-optimal control with the following properties is in [7, §6]. There are analogous proofs for other singular control problems. Let $\delta > 0$. Then under Assumptions 2.1 and 5.1 there is a δ-optimal admissible (with respect to the Wiener process $W(\cdot)$) control $K(\cdot)$ for (2.1), (2.2) with the following properties: (i) There are $T_\delta < \infty$, $\Delta > 0$, $\gamma > 0$, and $\rho > 0$ such that the $K^{ij}(\cdot)$ are constant on the intervals $[n\Delta, n\Delta + \Delta)$, only one of its components can jump at a time, and the jumps take values in the discrete set $k\rho$, $k = 1, 2, \cdots$; also, $K(\cdot)$ is bounded and is constant on $[T_\delta, \infty)$; (ii) the values are determined by the conditional probability laws (which defines the functions $q_{nki}(\cdot)$)

$$\begin{aligned} &P\{dK^{ij}(n\Delta) = k\rho \mid K(m\Delta), m < n, W(s), s \leq n\Delta\} \\ &\quad = P\{dK^{ij}(n\Delta) = k\rho \mid K(m\Delta), m < n, W(p\gamma), p\gamma \leq n\Delta\} \\ &\quad \equiv q_{nki}(K(m\Delta), m < n, W(p\gamma), p\gamma \leq n\Delta), \end{aligned} \tag{5.12}$$

and the $q_{nki}(\cdot)$ can be supposed to be continuous in the W-variables for each value of the control variables. Equation (5.12) says essentially that the conditional distribution of $dK(n\Delta)$, given the "past," equals the conditional distribution given only certain sampled values of the "past," and that it is a continuous function of these values.

We next adapt this control policy (5.12) to the chain $\{\xi_n^h\}$. To do this with minimal effort, assume that $\sigma^{-1}(x)$ exists for $x \in G$. The general case is handled by an "approximation" procedure. If step n is a "diffusion" step, then define

$$\delta W_n^h = \sigma^{-1}(\xi_n^h)[\delta \xi_n^h - E_n^h \delta \xi_n^h].$$

Define $W_n^h = \sum_{i=0}^{n-1} \delta W_i^h$ and $W^h(\cdot)$ by $W^h(t) = W_n^h$ on $[t_n^h, t_{n+1}^h)$. Note that

$$E_n^h[W_{n+m}^h - W_n^h] = 0,$$

$$E_n^h[W_{n+m}^h - W_n^h][W_{n+m}^h - W_n^h]' = E_n^h \sum_{i=n}^{n+m-1} \Delta t_i^h(1 + O(h^\rho))I,$$

where I is the identity matrix.

By a proof analogous to the weak convergence part of Theorem 5.3, it is easily shown that $\{W^h(\cdot)\}$ converges weakly to a standard vector-valued Wiener process $W(\cdot)$; in fact, this Wiener process can be used in the representation of the $M(\cdot)$ given at the end of Theorem 5.3.

The δ-optimal control $K(\cdot)$ defined by (5.12) is "impulsive," and we will adapt it for use on the chain. As preparation for the proof, we first note the following. Suppose that we wish to apply a control of "impulsive" magnitude δK^{ij} to the chain at some interpolated time t_0. Define $n_h = \min\{k: t_k^h \geq t_0\}$. Then starting at step n_h, apply $[\delta K^{ij}/h]$ successive control steps, each of the randomized type of Case 2 in §3 (with reflection steps intervening if a control step takes the chain out of G_h). As shown in Theorem 5.3, the effects of the randomization disappear as $h \to 0$. Let $K_0^h(\cdot)$ denote the continuous parameter interpolation (analogous to (4.1)) of the control just defined. We note further that $\{K_0^h(\cdot)\}$ is tight in the Skorohod topology, and the weak limit is just a step function of jump δK^{ij} at time t_0. When using such controls, there is no need to rescale time in the convergence proof, as was done in Theorem 5.3. The tightness holds because the values of the times t_n^h do not increase during the sequence of successive control steps just described, since $\Delta t_k^h = 0$ if k is a control or reflection step. Hence the interpolation $K^{h,ij}(\cdot)$ is just a step function with jump $h[\delta K^{ij}/h]$ at time $t_{n_h}^h$. Analogous arguments can be used if there are a finite number of such jumps at discrete times $\{t_k\}$.

With the observations in the last paragraph, we are ready to define the "adapted" form of $K(\cdot)$ for use on $\{\xi_n^h,\ n < \infty\}$. Let $K^h(\cdot)$ denote the interpolated form of the "adaptation." We will define $K^h(\cdot)$ such that it has the same number of impulsive changes as does $K(\cdot)$ (at most T_δ/Δ), each being uniformly bounded. Each of the impulses is to be realized for the chain via the method used in the example above. The impulses are to occur as soon after the "interpolated times" $k\Delta$ as possible. Let δK_n^h denote the value of the impulse that we would like to apply to the chain at interpolated time $n\Delta$. Define $\bar{t}_n^h = \min\{t_k^h: t_k^h \geq n\Delta\}$. Then the δK_n^h are chosen by the conditional probability rule

$$\begin{aligned} P\{\delta K_n^{h,ij} &= \rho k \mid \xi^h(s), s \leq \bar{t}_n^h, \delta K_m^h, m < n\} \\ &= q_{nki}(\delta K_m^h, m < n, W^h(p\gamma), p\gamma \leq n\Delta). \end{aligned}$$

The sequence $\{K^h(\cdot), W^h(\cdot)\}$ is tight. By construction, the weak limit has the distribution of the $(K(\cdot), W(\cdot))$ of (5.12). Thus we can denote the limit by $(K(\cdot), W(\cdot))$ without confusion.

By a weak convergence argument analogous to that of Theorem 5.3, but *without the time rescaling,* we get $\{\xi^h(\cdot),\ K^h(\cdot),\ W^h(\cdot),\ Y^h(\cdot),\ U^h(\cdot)\}$ converges weakly to a set $(\xi(\cdot),\ K(\cdot),\ W(\cdot),\ Y(\cdot),\ U(\cdot))$, solving (2.1).

By the weak sense uniqueness to the uncontrolled form of (2.1) for each initial condition, and the impulsive nature of the control, the solution to (2.1) under the "impulsive" δ-optimal control $K(\cdot)$ used here is also unique in the weak sense. Thus $\xi(\cdot)$ is the unique solution to (2.1) driven by the chosen δ-optimal control. Since $\{K^h(\cdot)\}$ is bounded, Theorem 5.4 implies that $V^h(x, K^h) \to V(x, K, W)$. By the optimality of $V^h(x)$ and the δ-optimality of $K(\cdot)$, $V(x, K, W) \le V(x) + \delta$ and $V^h(x, K^h) \ge V^h(x)$. Thus $\overline{\lim}_h V^h(x) \le V(x)$. This together with Theorem 5.5 yields the theorem. □

6. A minimum-fuel-type problem. In the previous sections, only two directions (v_1 and v_2) were allowed for the control actions (in addition to the possibility of no control) at each step. This limitation was due only to the structure of the original class of physical problems. To illustrate other possibilities, in this section we discuss a problem where the number of possible control directions is infinite. Again, a special case will be used to make the main point. The chosen case has an interesting additional feature due to the possibility of a rapidly varying control. Again, the problem is canonical in that it is representative of a large class.

We consider a form of a problem dealt with by Soner and Shreve [2], where

$$\begin{aligned} &dX = b(X)dt + \sigma(X)dW + dJ, \\ &J(t) = \int_0^t v(s)dK(s), \end{aligned} \tag{6.1}$$

where $|v(s)| \equiv 1$, and $K(\cdot)$ is a real-valued, right continuous, and nondecreasing singular control with $K(0) = 0$. Thus the control consists of the direction vectors $v(s)$ and the integral of the "force." For $\beta > 0$, the cost is

$$V(X(0), J, W) = E\int_0^\infty e^{-\beta t} k(X(t))dt + E\int_0^\infty e^{-\beta t} dK(t), \tag{6.2}$$

for a bounded and continuous $k(\cdot)$. For ease of development, a two-dimensional case will be used. It should be clear, however, that the method works in any dimension.

For computational reasons, $X(\cdot)$ must be confined to a bounded set G. For concreteness, we use the box $G = [-g^1, g^1] \times [-g^2, g^2]$ where $g^i > 0$, and we reflect orthogonally to the boundary when on the boundary. Thus the *computational model* is

$$X(t) = X(0) + \int_0^t b(X(s))ds + \int_0^t \sigma(X(s))dW(s) + J(t) + Y(t) - U(t), \tag{6.3}$$

where $Y(\cdot)$ and $U(\cdot)$ are the reflection terms; the $Y^i(\cdot)$ (respectively, $U^i(\cdot)$) can increase only when $X^i(t) = -g^i$ (g^i, respectively). Again, we use a rectangular grid G_h in G and define the extended grid G_h^+ and boundaries ∂G_h^+ and ∂G_h analogously to the definitions in §3.

For the choice of transition probabilities for the chain, we have the same three cases as in §3. The diffusion step is handled exactly as was Case 1 (§3). When $x = \xi_n^h \in \partial G_h^+$, we reflect to the closest point on ∂G_h, so the reflection step is simpler here, and no randomization is needed.

The control step (Case 2 of §3) is somewhat different. Refer to Fig. 4, where $\xi_n^h = x$, and the next step is to be a control step. The form of the original model (6.1) implies that the state increment in the control step can be in any direction and with any magnitude. For programming simplicity for the Markov chain model, we limit the

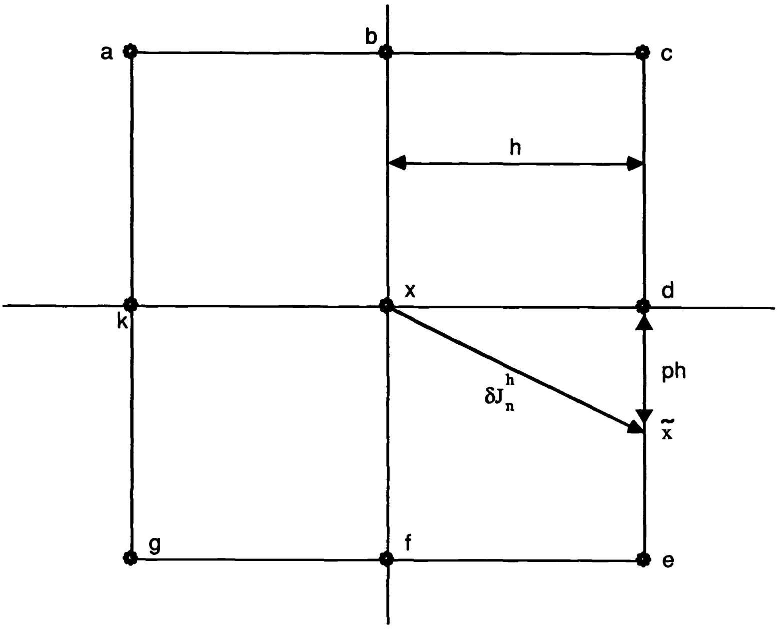

FIG. 4. *The control directions.*

magnitude of the control increments so that the state transitions are local. To realize an arbitrary direction, randomizations are used as in §3. In particular, we suppose for the Markov chain model that the control actions are the vectors connecting x to points on the boundary of the square in the figure. Each point on the boundary defines a direction and a magnitude of the control action. This "size" restriction on the magnitude can be removed. From the theoretical point of view, it is not needed. Let the δJ_n^h in the figure be the actual desired control action. This action takes x to a point $\tilde{x}$ on the boundary of the square. As in §3, $\tilde{x}$ is not usually a grid point, and we define the transition probability by taking δJ_n^h to be the *conditional mean value* $(E_n^h \delta\xi_n^h)$ of the increment in the state. Analogously to the situation in §3, for this example the control step transition probabilities are obtained by the randomization

$$p^h(x, d|\delta J_n^h) = (1 - p) = 1 - p^h(x, e|\delta J_n^h), \tag{6.4}$$

where p is defined in the figure. For consistency with (6.2), the cost associated with this increment δJ_n^h is the "magnitude" $\delta K_n^h \equiv |\delta J_n^h| = h(1 + p^2)^{1/2}$. Define the direction v_n^h by $\delta J_n^h = v_n^h \delta K_n^h$.

Let $p^h(x, y|\delta J)$ denote the transition probabilities under control action δJ. If no control is used at a step, we write the transition probability simply as $p^h(x, y)$. Then the dynamic programming equation analogous to (3.12), (3.13) is: For $x \in \partial G_h^+$,

$$V^h(x) = V^h(\text{nearest point to } x \text{ on } \partial G_h); \tag{6.5}$$

for $x \in G_h$,

$$\begin{aligned} V^h(x) = \min \Big\{ & e^{-\beta \Delta t^h(x)} \textstyle\sum_y p^h(x, y) V^h(y) + k(x) \Delta t^h(x), \\ & \min_{\delta J} \Big[\textstyle\sum_y p^h(x, y|\delta J) V^h(y) + |\delta J| \Big] \Big\}. \end{aligned} \tag{6.6}$$

The inner minimum concerns the minimum cost over all possible control actions, given that we use some control. The outer minimum chooses the better of (no control, the best control).

6.1. The inner minimum in (6.6). The computation of the inner minimum in (6.6) is not as formidable as it might seem. There are eight segments to consider, depending on where δJ points, namely, $(a,b),\cdots,(g,k)$, (k,a). We take the minimum over each segment separately. Consider segment (d,e). Then the minimum over the segment is (where p is defined in Fig. 4)

$$\min_{0\leq p\leq 1}[(1-p)V^h(x+e_1h)+pV^h(x+e_1h-e_2h)+h(1+p^2)^{1/2}]. \tag{6.7}$$

If $V^h(x+e_1h-e_2h)\geq V^h(x+e_1h+e_2h)$, then segment (d,e) will never be preferred to segment (c,d). In this way, we reduce the number of segments that need to be considered to four.

To evaluate the minimum in (6.7), note that if $V^h(x+e_1h)\leq V^h(x+e_1h-e_2h)$, then zero is the best value of p. If $[V^h(x+e_1h-e_2h)-V^h(x+e_1h)]/h\leq -1/\sqrt{2}$, then the best value of p is unity. Otherwise, the best value is obtained by differentiating and satisfies

$$\frac{-p}{\sqrt{1+p^2}}=\frac{[V^h(x+e_1h-e_2h)-V^h(x+e_1h)]}{h}.$$

The above procedure could be simplified by using only a finite number of possible values for the δJ. With appropriate choices, the optimal cost functions can be approximated as well as desired.

6.2. The convergence $\mathbf{V^h(x)\to V(x)}$. Define

$$J_n^h=\sum_{i=0}^{n-1}\delta J_n^h, K_n^h=\sum_{i=0}^{n-1}\delta K_i^h.$$

Define $\xi^h(\cdot)$, $J^h(\cdot)$, $K^h(\cdot)$, and the scaled processes $\hat{\xi}^h(\cdot),\cdots$, analogously to what was done in §4. Then Theorems 5.3–5.6 continue to hold with the following modifications. For Theorem 5.3, $\hat{J}^h(\cdot)\Rightarrow\hat{J}(\cdot)$, $\hat{K}^h(\cdot)\Rightarrow\hat{K}(\cdot)$, but $\hat{J}(\cdot)$ has the representation $\hat{J}(t)=\int_0^t\hat{v}(s)d\hat{K}_0(s)$, for a $\hat{v}(\cdot)$ and $\hat{K}_0(\cdot)$ satisfying $|\hat{v}(s)|\equiv 1$ and $\hat{K}_0(t)\leq\hat{K}(t)$ for all t. Also, for $\xi_0^h=x$,

$$\begin{aligned}\xi(t)=x&+\textstyle\int_0^t B(\xi(s))ds+\int_0^t\sigma(\xi(s))dW(s)\\&+\textstyle\int_0^t v(s)dK_0(s)+Y(t)-U(t).\end{aligned} \tag{6.8}$$

The fact that $\hat{K}_0(t)$ might be less than $\hat{K}(t)$ (or, equivalently, $K_0(t)\leq K(t)$) for some t is due to the fact that rapid time variations in the directions $\hat{v}^h(s)$ (the continuous parameter interpolation of the $\{v_n^h\}$ in the "stretched out" timescale) can cause a "cancellation" or "reduction" in the effects of the control. For example, consider the case where $\delta J_{n+1}^h=-\delta J_n^h$, for a consecutive sequence of values of n. Then the effects of this sequence would not appear in the limits $\hat{J}(\cdot)$ or $J(\cdot)$ since these limits are "averages" of the directions (loosely speaking), but they would appear in $\hat{K}(\cdot)$ and $K(\cdot)$.

The analogue of Theorem 5.4 holds, but with

$$\underline{\lim}_{h} V^h(x, J^h) \geq V(x, J, W).$$

Theorem 5.5 holds and so does Theorem 5.6. The proof of the analogue of Theorem 5.6 involves first showing that for any $\delta > 0$ there is a simple form of a δ-optimal control that has only finitely many impulses, each being bounded and taking a discrete number of values. Then the argument of Theorem 5.6 can be carried over.

7. A constrained and ergodic singular control problem. Ergodic singular control problems require some variations of the methods of the previous sections. To illustrate the general ideas, we will work with a particular but important problem class of the type developed by Harrison [8], Wein [9], [13], and Harrison and Wein [12] to model the input control for a queueing network with several customer classes with priorities and "throughput" constraints. The details of the development and analysis of the models are in the references and will only be briefly discussed, so that we can concentrate on the numerics. A numerical study of the model was carried out in [13] using the Markov chain approximation method, but no convergence proof was available. Our notation will be different from that in the references. Because of the constraint and the absence of a cost on the use of singular control, the model has some additional interest. The technique readily specializes to the more standard "ergodic" situations.

The basic system model is

$$X(t) = X(0) + bt + \sigma W(t) + J(t), \quad X(t) \in R^r, \tag{7.1}$$

where $J(\cdot)$ is a control that takes the special form

$$J^i(t) = K^i(t) - K^{r+1}(t), \quad i \leq r, \tag{7.2}$$

where the $K^i(\cdot)$ are the singular controls, i.e., they are right continuous, nondecreasing, and satisfy $K^i(0) = 0$. The $K(\cdot) = (K^1(\cdot), \cdots, K^{r+1}(\cdot))$ is said to be *admissible* or $(K(\cdot), W(\cdot))$ is said to be an *admissible pair* if $K(\cdot)$ is nonanticipative with respect to $W(\cdot)$. The results can readily be extended to include state-dependent drift and covariance, but for simplicity we concentrate on the cited problem. The system is subject to the constraints

$$\overline{\lim_{T}} \frac{1}{T} EK^i(t) \leq \lambda_i, \quad i = 1, \cdots, r+1, \quad \lambda_i > 0, \tag{7.3}$$

and the cost is

$$\gamma(K) = \overline{\lim_{T}} \frac{1}{T} E \int_0^T k(X(t))dt,$$

for a continuous $k(\cdot)$. Write $\lambda = (\lambda_1, \cdots, \lambda_{r+1})$ and define $\bar{\gamma}(\lambda) = \inf \gamma(K)$, where the inf is over all admissible controls such that (7.3) holds and $X(\cdot)$ is stationary. The λ-dependence of $\bar{\gamma}(\cdot)$ will be needed in §10.

The physical model leading to (7.1)–(7.3) contains $r+1$ servers, and $K^i(\cdot)$ is the heavy traffic limit of the suitably scaled, idle time of server i. The $X^i(\cdot)$ is called a workload imbalance in [8], [9], [13]. Roughly speaking, the workload of server i at time t is the (suitably scaled) amount of work that exists for server i from all the customers in the system at time t. The workload imbalance is a weighted difference of the workload of servers $i \leq r$ and $r+1$. This formulation is a very clever way of simplifying the problem when there are many classes of customers with priorities. The constraint (7.3) guarantees a maximum throughput for the system. Although the problem has a special structure, "ergodic" forms of the problems in the previous sections can be dealt with by the same techniques.

7.1. The "numerical" state space. For simplicity in the development, we work with $r = 2$. The method will obviously work for any r. The procedures and results of the previous sections will be used where possible. For numerical purposes, we need to bound the state space and use a setup somewhat similar to that in §3. Define g^i and the "box" G as in §6. The process $X(\cdot)$ will be confined to G for numerical purposes. Normally in such problems, we need to experiment with the "numerical boundary" to find one that is a suitable compromise between computational efficiency and minimal interference with the essential features of the optimal value function and control. For numerical purposes, we let $X(\cdot)$ reflect instantaneously on ∂G, with the reflection directions being orthogonal to the boundary except at the corners, where they point "diagonally" in.

With this modification (7.1) becomes

$$X(t) = X(0) + bt + \sigma W(t) + J(t) + Y(t) - U(t). \tag{7.4}$$

$Y(\cdot)$ and $U(\cdot)$ are the usual reflection terms. They are nondecreasing, take value zero at $t = 0$, and $Y^i(\cdot)$ (respectively, $U^i(\cdot)$) can increase only at points t for which $X^i(t) = -g^i$ (respectively, g^i). Those properties uniquely characterize $Y(\cdot)$ and $U(\cdot)$ (Theorem 5.1). For the problem in [9], [13], $Y(t) = U(t) = 0$, for all t, if G is large enough, since the optimal $J(\cdot)$ confines the $X(\cdot)$ to a bounded set.

The computational problem for even noncontrolled ergodic problems is still in its infancy, also. One promising approach to the computation of invariant measures is in [19].

8. The Markov chain approximation. The procedure of §3 will be followed to construct an approximating chain and control problem. Again, the numerical procedure consists in solving the optimal control problem for the Markov chain model. The convergence proofs in §10 show that the optimal value functions for the chain converge to $\bar{\gamma}(\beta)$.

For the approximation parameter h, let the g^i be integral multiples of h. Let G_h and G_h^+ denote the h-grid and extended h-grid, respectively, on G, as in §3. We also use the other notation of §3, where applicable. The types of state transitions are divided into the same three cases as in §3. The reflection case (Case 3) (for $\xi_n^h \in \partial G_h^+$) is trivial here, since we simply reflect back to the nearest point on ∂G_h. The diffusion step is also as for Case 1, and any transition function $p^h(x,y)$ can be used provided that (3.1) holds. Indeed, due to the lack of state dependence here, it is easier to construct transition functions with the required properties. Also $\Delta t^h(x) = \Delta t^h$, not depending on x. In general (3.4) implies that $\Delta t^h = h^2/Q$ for some real $Q > 0$.

8.1. The control step. The transition function for the control step in §§3 or 6 was obtained by first choosing the mean direction and then randomizing. Due to the particular structure of $J(\cdot)$ here, the randomization is not necessary, although it might be in problems where $J(\cdot)$ has a different structure.

If step n is a control step for the chain, then set $\delta\xi_n^h = \delta J_n^h = (\delta J_n^{h,1}, \cdots, \delta J_n^{h,r})$, and write $\delta J_n^{h,i} = \delta K_n^{h,i} - \delta K_n^{h,r+1}$. Write $\delta K_n^h = (\delta K_n^{h,1}, \cdots, \delta K_n^{h,r+1})$. We use $r = 2$

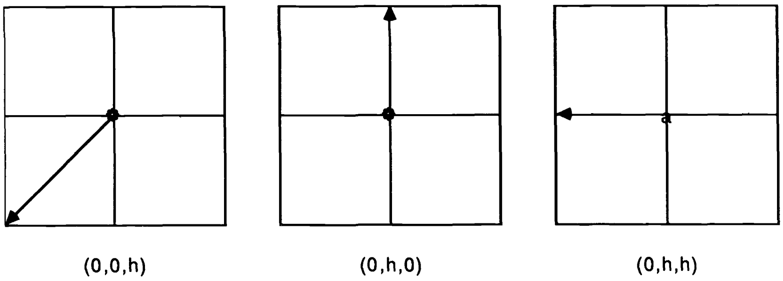

FIG. 5. *Examples of control directions for the ergodic problem.*

until further notice. If n is not a control step, then define $\delta J_n^h = \delta K_n^h = 0$. Suppose that $\xi_n^h = x \in G_h$, and we elect to exercise control. Then, as in §3, the transition function $p^h(x, y|\text{control})$ must be "locally" consistent with (7.4). We let the values of the $\delta K_n^{h,i}$ be either 0 or h. We could allow the increments to take values in any bounded interval $[0, k_0]$ or in the set of points $[\ell h,\ \ell = 0, \cdots, \ell_0,\ \ell_0 < \infty]$ and still get the same convergence results. It is usually simpler, however, for the programming to work with "local transitions." For our case $r = 2$, there are seven possibilities for the control actions (we eliminate the cases $\delta K = (0,0,0)$ and (h,h,h), since they keep us at the same state). Write $x = (x^1, x^2)$. Then the possible control actions are (refer to Fig. 5) $\delta K = (0,0,h)$, yielding $\xi_{n+1}^h = (x^1 - h, x^2 - h)$; $\delta K = (0,h,0)$, yielding $\xi_{n+1}^h = (x^1, x^2 + h)$; $\delta K = (h,0,0)$, yielding $\xi_{n+1}^h = (x^1 + h, x^2)$; $\delta K = (0,h,h)$, yielding $\xi_{n+1}^h = (x^1 - h, x^2)$; $\delta K = (h,0,h)$, yielding $\xi_{n+1}^h = (x^1, x^2 - h)$; and $\delta K = (h,h,0)$, yielding $\xi_{n+1}^h = (x^1 + h, x^2 + h)$. The transition function for the case of general r should be obvious.

8.2. The control problem for the Markov chain. In [11, §11] a convergence theory for the discretization of ergodic control problems is given. Owing to both the constraint (7.3) and the "tightness problems" stemming from the nature of the singular control problem as discussed in §4, that development cannot be used directly here. We will develop the appropriate adaptation of the technique of §§3–6. Set $\Delta t_n^h = 0$ if step n is either a control or reflection step, and set $\Delta t_n^h = \Delta t^h$ otherwise. (In [13], $\Delta t_n^h = \Delta t^h$ was used for all n. The limit results are the same for both cases, since it can be shown that the "fraction of the number of steps" spent either on the boundary or controlling goes to zero as $h \to 0$.) Define the interpolation $\xi^h(\cdot)$ as in §4. For the Markov chain model, we will work with feedback policies and stationary chains. Since the state space is finite, for each feedback policy, there is some stationary chain. $\{\xi_n^h,\ n < \infty\}$ will refer to such a stationary chain. If the stationary chain under the chosen feedback policy is not unique, then pick any one. The choice will be irrelevant. Let $\{\delta K_n^h\}$ denote the sequence of control actions for the chain. We use K^h to denote the control policy. Define the interpolation $K^h(\cdot)$ (intervals $\{\Delta t_n^h\}$) from $\{\delta K_n^h\}$ analogously to (4.1).

Let $N^h(T) = \min\{n : t_n^h \geq T\}$. A literal translation of the continuous parameter problem into the stationary chain yields the cost

$$\lim_T \frac{E \sum_{n=0}^{N^h(T)-1} k(\xi_n^h) \Delta t_n^h}{T} \tag{8.1}$$

and the constraint

$$\lim_T \frac{E\sum_{n=0}^{N^h(T)-1} \delta K_n^{h,i}}{T} \le \lambda_i. \tag{8.2}$$

It is implied by the proof of Theorem 10.1 and the comments below (9.1) that if (8.2) holds, then the fraction of steps that are either control or reflection steps is $O(h)$. By using this, (8.1) and (8.2) can be approximated by (with errors of the order $O(h)$ in (8.4))

$$\lim_N \frac{1}{N} E \sum_{n=0}^{N-1} k(\xi_n^h) \equiv \gamma^h(K^h), \tag{8.3}$$

$$\lim_N \frac{1}{N} E \sum_{n=0}^{N-1} \delta K_n^{h,i} \le \lambda_i \Delta t^h. \tag{8.4}$$

For the same reasons, the left sides of (8.1) and (8.2) equal (modulo $O(h)$), respectively,

$$\lim_T \frac{1}{T} \int_0^T Ek(\xi^h(s))ds, \qquad \lim_T \frac{1}{T} EK^{h,i}(T).$$

Define $\bar{\gamma}^h(\lambda) = \inf_{K^h}(K^h)$, subject to (8.3) and the stationarity of $\{\xi_n^h,\ n < \infty\}$.

Due to the constraint (8.2), a dynamic programming formulation such as (3.12) and (3.13) cannot be used, and the optimization problem must be phrased in terms of a linear programming (LP) formulation [20], [21].

9. The LP formulation.

A control policy for $\{\xi_n^h,\ n < \infty\}$ is said to be *pure Markov* if for each state a unique control action is assigned. A control policy is said to be *randomized Markov* if for each state a distribution (depending only on the present state) of control actions is assigned. Due to the constraint, there might not be an optimal control in the class of pure Markov policies, but one always exists in the class of randomized Markov policies.

The LP formulation uses stationary chains $\{\xi_n^h,\ n < \infty\}$ and randomized Markov policies. Let $p^h(x, y \mid \delta K)$ denote the transition function, given a control action δK. We use $\delta K = 0 \equiv (0,0,0)$ to denote that no control is used. We use π^h to denote the stationary probabilities for the chain, i.e., $\pi^h(x) = P\{\xi_n^h = x\}$, $\pi^h(x, \delta K) = P\{\xi_n^h = x,\ \delta K_n^h = \delta K\}$, $\pi^h(\delta K^i = 0) = P\{\delta K_n^i = 0\}$, $\pi^h(G_h) = \sum_{x \in G_h} \pi^h(x)$, etc. The control to be used at any state is determined by the conditional distribution $P\{\delta K_n^h = \delta K \mid \xi_n^h = x\} = \pi^h(x, \delta K)/\pi^h(x)$.

Thus $\pi^h(x) = \sum_{\delta K} \pi^h(x, \delta K)$ and $\pi^h(\delta K) = \sum_x \pi^h(x, \delta K)$. The fact that the probabilities sum to unity yields the constraints

$$\pi^h(x) = \sum_{y,\delta K} p^h(y, x \mid \delta K)\pi^h(y, \delta K), \quad \sum_x \pi^h(x) = 1, \quad \pi^h(x, \delta K) \ge 0. \tag{9.1}$$

Following the development in [13], and using the fact that $\Delta t_n^h = 0$ if $\xi_n^h \in \partial G_h^+$ or if n is a control step, the constraint (8.2) can be written as

$$\frac{E\delta K_n^i}{E\Delta t_n^h} = \frac{h\pi^h(\delta K^i \ne 0)}{(h^2/Q)\pi^h(G_h, \delta K = 0)} \le \lambda_i$$

or

$$\pi^h(\delta K^i = h) \le \frac{\lambda_i h}{Q}\pi^h(G_h, \delta K = 0) = O(h). \tag{9.2}$$

Note that (9.2) implies the probability that any step n is a control step is $O(h)$. Using this and the fact that a reflection step must be followed by either a control or a diffusion step yields than the mean value of the total variation of the $U^h(\cdot)$ and $Y^h(\cdot)$ terms on the interpolated time interval $[0,T]$ is (modulo $O(h)$ times the value of (9.3))

$$\pi^h(\partial G_h^+) \cdot h(T/\Delta t^h) = O(1/h)\pi^h(\partial G_h^+). \tag{9.3}$$

The proof of Theorem 10.1 below implies that the mean variation of the reflection terms for a stationary process satisfying the constraints is bounded uniformly in h on any fixed interpolated time interval. Thus by (9.3), $\pi^h(\partial G_h^+) = O(h)$. Using this and (9.2) yields that $\pi^h(G_h, \delta K = 0) = 1 - O(h)$, and (modulo $O(h^2)$) we can rewrite (9.2) as

$$\pi^h(\delta K^i = h) \le \lambda_i h/Q, \qquad i \le r+1. \tag{9.4}$$

An analogous argument applied to (8.1) yields the cost function

$$\frac{\sum_{x\in G_h} k(x)\pi^h(x, \delta K = 0)}{\pi(G_h, \delta K = 0)} = \sum_{x\in G_h} k(x)\pi^h(x) \equiv \gamma^h(K^h), \tag{9.5}$$

where the equalities are all modulo $O(h)$. Define $\gamma^h = \inf_{K^h}\gamma^h(K^h)$, where the infimum is over the randomized Markov policies satisfying (9.4).

9.1. The LP problem. For the numerical procedure, the LP formulation of the Markov chain control problem is the minimization of the right-hand side of (9.5) subject to the constraints (9.1) and (9.4). The "activity" variables of the LP formulation are the $\pi^h(x, \delta K)$. The number of constraints totals $\bar{N}^h =$ (number of points in the state space G_h^+ plus 1) plus $(r+1)$, the first set of (9.1) yielding the first group and the second group coming from the $r+1$ constraints (9.4). $\bar{N}^h$ is the maximum number of nonzero variables in any basic solution to the LP. Thus there are at most $(r+2)$ states x that $\pi^h(x, \delta K)$ might be positive for more than one value of δK. Thus, there are at most $(r+2)$ states at which the control is actually "randomized," for any h. The effects of these states disappears as $h \to 0$.

Since the state space G_h^+ is finite, for each h and each randomized or pure Markov control policy, there is at least one stationary chain for each transition function. The LP solution gives a least cost stationary chain, whether or not the least cost chain is unique.

10. The convergence theorem.

10.1. Preliminary calculations. The following facts and definitions will be useful in Theorem 10.2. Let $\pi^h(\cdot)$ denote the optimal steady-state probabilities, via the LP (9.1), (9.4), (9.5). Let $\{\xi_n^h,\ \delta K_n^h,\ n < \infty\}$ denote the associated stationary chain and control policy. Let γ^h denote the associated ergodic cost. We have that $\delta\xi_n^h$ equals δY_n^h or δU_n^h if n is a reflection step and $\delta\xi_n^h = \delta K_n^h$ if n is a control step. If n is a "diffusion" step, then (see (3.4))

$$\delta\xi_n^h = b\Delta t^h + \beta_n + O(h^\rho \Delta t^h),$$

where

$$E_n^h \beta_n^h \beta_n^{h'} = \sigma\sigma' \Delta t^h + O(h^p \Delta t^h), \qquad E_n^h \beta_n^h = 0.$$

Thus

$$\xi_{n+1}^h = \xi_0^h + bn\Delta t^h + \sum_{i=0}^{n} \beta_i^h + J_{n+1}^h + Y_{n+1}^h - U_{n+1}^h + (\text{negligible terms}).$$

The negligible terms are

$$\sum_{i=0}^{n-1} O(h^p \Delta t_i^h) - b\Delta t^h (\text{number of reflection or control steps in } [0, n]).$$

The continuous parameter interpolation is (see §4 for the definitions)

$$\xi^h(t) = \xi^h(0) + bt + M^h(t) + J^h(t) + Y^h(t) - U^h(t) + (\text{negligible terms}). \tag{10.1}$$

Let $0 < t_1 < \cdots < t_q$, where $|t_{i+1} - t_i| > \Delta t^h$ for small h. Then due to the stationarity of $\{\xi_n^h,\ n < \infty\}$ and the independence of Δt^h of x, the distribution of $\{\xi^h(t_0 + t_i),\ K^h(t_0 + t_i) - K^h(t_0),\ i \le q\}$ does not depend on t_0 for small h. Also, by the stationarity and the constraint (9.4),

$$E[K^{h,i}(t_0 + t) - K^{h,i}(t_0)] \le \lambda_i t + O(h) \quad \text{for all } t, t_0. \tag{10.2}$$

The problem of proving tightness for $\{K^h(\cdot)\}$ is the same here as that in §4, and we cannot necessarily find a weakly convergent subsequence of $\{\xi^h(\cdot),\ K^h(\cdot), \cdots\}$ in the Skorokhod topology. However, a variant of the rescaling method used in Theorem 5.3 will work. Define the processes $\hat{T}^h(\cdot)$, $\hat{\xi}^h(\cdot)$, $\hat{K}^h(\cdot), \cdots$, as in §4 and Theorem 5.3.

The "tightness" situation is better here than in the problem of §§2–6, since the probability that any n is a control step is $O(h)$. It will be seen that this implies that $\hat{T}(\cdot)$ and $\xi(\cdot)$ are continuous w.p.1 at each t. In the convergence proof we will need to show that $\xi^h(t)$ converges to $\xi(t)$ in distribution for each t. A basic tool is formally stated in the following "continuous mapping" lemma, whose proof is easy and is omitted. Let R denote the real line.

LEMMA 10.1. *Let $\hat{\tau}(\cdot)$ be a nonnegative, nondecreasing function with $\hat{\tau}(0) = 0$, which is right continuous and let $\hat{\tau}(t) \to \infty$ as $t \to \infty$. Define $\tau(\cdot)$ by $\tau(t) = \inf\{s : \hat{\tau}(s) > t\}$. Then $\tau(\cdot) \in D[0, \infty)$. Define the map $\Phi : D[0, \infty) \to R$ by $\Phi(\hat{\tau}(\cdot)) = \tau(t_0)$. Suppose that $\tau(\cdot)$ is continuous at t_0. Then $\Phi(\cdot)$ is continuous at $\hat{\tau}(\cdot)$.*

10.2. The convergence theorem: Part 1.

THEOREM 10.2. *The sequence $\{\hat{\xi}^h(\cdot), \cdots, \hat{T}^h(\cdot)\}$ is tight. Abusing notation, let h index a weakly convergent subsequence with limit denoted by $(\hat{\xi}(\cdot),\ \hat{K}(\cdot), \cdots, \hat{T}(\cdot))$. Define $T(\cdot)$, $\xi(\cdot)$, $K(\cdot), \cdots$ as in Theorem 5.3. Then there is a standard vector-valued Wiener process $W(\cdot)$ such that*

$$\xi(t) = \xi(0) + bt + \sigma W(t) + J(t) + Y(t) - U(t), \tag{10.3}$$

where $J^i = K^i - K^{r+1}$ and $K(\cdot)$ is nonanticipative with respect to $W(\cdot)$. The $Y(\cdot)$ and $U(\cdot)$ are the appropriate reflection terms. The distribution of $(\xi(t_0 + \cdot),\ K(t_0 + \cdot) - K(t_0))$ does not depend on t_0. Also,

$$\begin{gathered} \gamma^h = \gamma^h(K^h) \to \gamma(K) = E\int_0^T k(\xi(s))ds/T, \quad \text{for each } T > 0, \\ EK^i(t) \le \lambda_i t, \quad \text{for all } t. \end{gathered} \tag{10.4}$$

Proof. The tightness of $\{\hat{\xi}^h(\cdot), \cdots, \hat{T}^h(\cdot)\}$ is proved as in Theorem 5.3, as is representation (10.3) and the nonanticipativness of $K(\cdot)$. For any $t, s \geq 0$, (10.2) implies that

$$E|K^i(t+s) - K^i(t)| \leq \overline{\lim_h} E|K^{h,i}(t+s) - K^{h,i}(t)| \leq \beta_i s. \tag{10.5}$$

The bound on $\{K^{h,i}(\cdot)\}$ in (10.2) implies that $\hat{T}(t) \to \infty$ w.p.1 as $t \to \infty$. Let $\mathcal{T}$ denote the set $\mathcal{T} = \{t: P\{T(\cdot)$ is discontinuous at $t\} > 0\}$. We claim that $\mathcal{T}$ is empty. The proof is as follows: Let $T(0^-) = 0$. Given $t_0 \geq 0$, suppose that there are $\delta_i > 0$ such that

$$P\{T(t_0^+) - T(t_0^-) \geq \delta_1\} \geq \delta_0.$$

This can only happen if for any $\delta_2 > 0$,

$$\overline{\lim_h} P\{|K^h(t_0 + \delta_2) - K^h(t_0 - \delta_2)| \geq \delta_1/2\} \geq \delta_0/2.$$

But due to the arbitrariness of δ_2, this latter inequality is impossible by (10.5). This implies that the probability is zero that $T(\cdot)$ will jump more than δ_1 at t_0, which proves the claim, since δ_1 is arbitrary. Thus $T(\cdot)$ is continuous w.p.1 at each $t \geq 0$, and so is $K(\cdot)$. Now by representation (10.3) and Theorem 5.1, $Y(\cdot)$, $U(\cdot)$, and $\xi(\cdot)$ are also continuous w.p.1 at each $t \geq 0$.

Now define the inverse function $T^h(t) = \inf\{s: \hat{T}^h(s) > t\}$. We can write

$$\xi^h(t) = \hat{\xi}^h(T^h(t)), \qquad K^h(t) = \hat{K}^h(T^h(t)). \tag{10.6}$$

Let q be an integer and let $0 \leq t_1 < \cdots < t_q$. Since $T(\cdot)$ is continuous w.p.1 at each t, we have that $\{T^h(t_i), i \leq q\}$ converges weakly to $\{T(t_i), i \leq q\}$. Now Lemma 10.1, the definitions of $T^h(\cdot)$ and $T(\cdot)$, the weak convergence of $\{\hat{\xi}^h(\cdot), \cdots, \hat{T}^h(\cdot)\}$ to $(\hat{\xi}(\cdot), \cdots, \hat{T}(\cdot))$, the w.p.1 continuity of $\hat{\xi}(\cdot)$ and $\hat{K}(\cdot)$ at each t, and (10.6) yield (in the sense of weak convergence)

$$\xi^h(t_i) \to \hat{\xi}(T(t_i)) = \xi(t_i), \qquad i \leq q, \tag{10.7}$$

$$K^h(t_{i+1}) - K^h(t_i) \to \hat{K}(T(t_{i+1})) - \hat{K}(T(t_i)) = K(t_{i+1}) - K(t_i), \qquad i \leq q.$$

By (10.7) and the fact that the distribution of $(\xi^h(t_0 + \cdot), K^h(t_0 + \cdot) - K^h(t_0))$ does not depend on t_0 (in the sense used above (10.2)), we have that $\xi(\cdot)$ is stationary and the distribution of $(\xi(t_0 + \cdot), K(t_0 + \cdot) - K(t_0))$ does not depend on t_0. By the stationarity properties, the cost can be represented as follows:

$$\begin{aligned} t\gamma^h &= E\int_0^t k(\xi^h(s))ds + O(h) \\ &= E\int_0^{T^h(t)} k(\hat{\xi}^h(s))d\hat{T}^h(s) + O(h) \\ &\to E\int_0^{T(t)} k(\hat{\xi}(s))d\hat{T}(s) = E\int_0^t k(\xi(s))ds \\ &= tEk(\xi(0)) = t\gamma(K), \end{aligned}$$

and the theorem is proved. □

Theorem 5.2 implies that

$$\underline{\lim_h} \bar{\gamma}^h(\lambda) \geq \bar{\gamma}(\lambda).$$

10.3. The convergence theorem, completed. For the problem of §2, it was not hard to find a convenient δ-optimal comparison control so that the "reverse inequality," $\overline{\lim}_h V^h(x) \le V(x)$ could be obtained in Theorem 5.6. It is more difficult to choose a "comparison control" for the ergodic problem. We need to find a "nice" δ-optimal control for the ergodic problem for (7.4) with constraint (7.3), which can be adapted to $\{\xi_n^h, n < \infty\}$ so that a result such as in Theorem 5.6 can be proved. Little is known concerning optimal or δ-optimal controls for singular control problems for either the ergodic or nonergodic case. To proceed, we need to make an assumption on the existence of a δ-optimal control of a particular form.

Numerical experience and the literature concerning problems where an optimal control has been characterized (for ergodic or not ergodic problems) [2], [9], suggest that Assumption 10.2, below, is quite reasonable. Assumption 10.1 is needed, since the constraint (9.4) is not necessarily satisfied when the control of Assumption 10.2 is applied to the chain, and it is necessary to perturb the constraint slightly. Assumption 10.1 also does not seem to be restrictive, although we have not been able to prove that it holds in general. A typical control boundary from [13] is shown in Fig. 6.

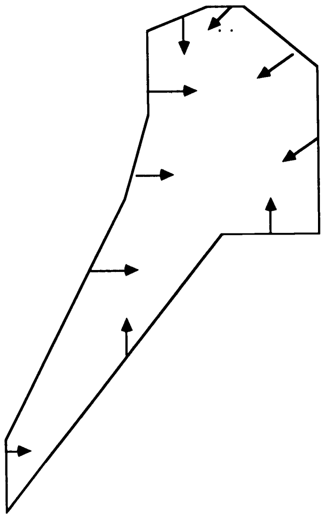

FIG. 6. *A numerical solution: Piecewise linear approximation to the boundary.*

Assumption 10.1. $\bar{\gamma}(\cdot)$ is continuous at λ if all $\lambda_i > 0$.

For $\delta_0 > 0$ and $\lambda_i - \lambda_0 > 0$, define $\lambda - \delta_0 = (\lambda_1 - \delta_0, \cdots, \lambda_{r+1} - \delta_0)$.

Assumption 10.2. For any small $\delta_0 > 0$ and constraint vector $\lambda - \delta_0$, there is a δ-optimal control $K_\delta(\cdot)$ (define $J_\delta(\cdot) = \{K_\delta^i(\cdot) - K_\delta^3(\cdot), i = 1,2\}$) satisfying the following conditions. There is a set $\hat{G}$ that is the closure of an open set in G and is such that the boundary $\partial\hat{G}$ is composed of a finite number of segments $\partial\hat{G}_1, \cdots$, each being continuously differentiable. The segments are nontangent at the corners where they meet. $J_\delta(\cdot)$ reflects to the "interior" of $\hat{G}$, and the directions of reflection on $\partial\hat{G}$, are constant on each $\partial\hat{G}_i$. The reflection directions $\{\bar{v}_i\}$ are taken from the set of seven directions defined in §7. The reflectings are not in opposite directions on adjacent boundary segments. There is a weak sense unique stationary process $X_\delta(\cdot)$

satisfying

$$X_\delta(t) = X_\delta(0) + bt + \sigma W(t) + J_\delta(t) \tag{10.8}$$

and

$$P\{X_\delta(t) \text{ is an } \varepsilon\text{-neighborhood of any “corner” of } \partial\hat{G}\} \xrightarrow{\varepsilon} 0. \tag{10.9}$$

Remark. By “reflecting to the interior,” we mean that the angles between $\bar{v}_i$ and the outward normals to $\partial\hat{G}_i$ are strictly greater than $\pi/2$.

Remark. The condition seems broad as it stands, since the boundary segments can be made aritrarily small. But we note that the condition can be weakened to allow continuous (rather than constant) reflection directions on each segment, subject to the “interior pointing” and “corner” conditions in Assumption 10.2.

THEOREM 10.3. *Assume that Assumptions* 10.1 *and* 10.2 *hold true. Then*

$$\bar{\gamma}^h(\lambda) \to \bar{\gamma}(\lambda).$$

Proof. We need only prove that

$$\overline{\lim_h} \bar{\gamma}^h(\lambda) \leq \bar{\gamma}(\lambda). \tag{10.10}$$

Let $\delta > 0$. By Assumption 10.1, choose small $\delta_0 > 0$ such that

$$\bar{\gamma}(\lambda - \delta_0) \leq \bar{\gamma}(\lambda) + \delta. \tag{10.11}$$

Following the general approach in Theorem 5.6, we “adapt” $J_\delta(\cdot)$ to $\{\xi_n^h,\ n < \infty\}$ as follows. The state space is just $\hat{G} \cap G_h$. For any step n where distance $(\xi_n^h, \partial\hat{G}) > h$, use the diffusion step transition probabilities. Otherwise, the step will be a control step with the increment $\delta\xi_n^h \equiv \delta J_n^h$ being in the reflection direction of the nearest boundary segment. If two boundary segments are equally close, use any one of the two directions. By (10.9), the choice will not matter in the limit. As in §8, we can write $\delta J_n^h = \delta K_n^i - \delta K_n^3$ for some $i = 1, 2$, where one or more of the components of $\{\delta K_n^i,\ i \leq 3\}$ are positive. Analogously to the notation in §8, let $K_\delta^h(\cdot)$ denote the “adapted” control policy and accordingly define $J_\delta^h(\cdot)$.

For each h, there is at least one stationary process under the given control policy. Let $\{\xi_n^h,\ n < \infty\}$ be such a stationary process and define $\xi^h(\cdot)$, $\hat{\xi}^h(\cdot)$, $\hat{T}^h(\cdot), \cdots$, in the usual way. Suppose for the moment that (it will be shown to hold below)

$$\sup_h E|K^h(t)|^2 < \infty, \quad \text{for each } t < \infty. \tag{10.12}$$

Then we have

$$P\{\text{control used at step } n\} = O(h). \tag{10.13}$$

(See (9.2) for a related calculation.) Using (10.13) and a proof similar to that of Theorem 10.2, it can be shown that $\gamma^h(K_\delta^h) \to \gamma(K_\delta)$ and that the limit process $\xi(\cdot)$ satisfies (10.8) with control $K_\delta(\cdot)$, and that the distributions of $(\xi(t_0 + \cdot),\ K_\delta(t_0 + \cdot) - K_\delta(t_0))$ do not depend on t_0.

As in Theorem 10.2, (10.13) implies that the set $\mathcal{T}$ (defined in Theorem 10.2) is empty. Thus, $K_\delta^h(t) \to K_\delta(t)$ in distribution for each $t \geq 0$. Hence, (10.12) implies

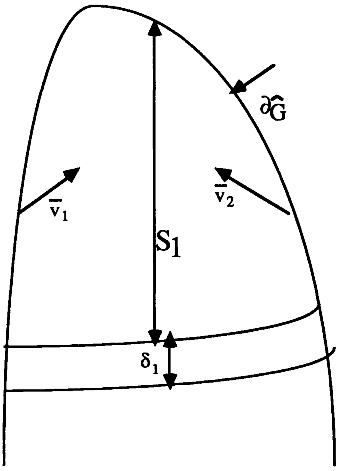

FIG. 7. *A boundary sector.*

that $EK^h_\delta(t) \to EK_\delta(t)$. Since $EK_\delta(t) \le (\lambda_i - \delta_0)t$, we have $EK^h_\delta(t) \le \lambda_i t$ for small h. Since $\bar{\gamma}^h(\lambda)$ is the optimal ergodic value for the stationary chain under constraint value β, we have that $\bar{\gamma}^h(\lambda) \le \gamma^h(K^h_\delta)$ for small h. Since, by Assumption 10.2, $K_\delta(\cdot)$ is δ-optimal under constraint vector $\lambda - \delta_0$, we have $\gamma(K_\delta) \le \bar{\gamma}(\lambda - \delta_0) + \delta$. The above facts imply that for small h, $\bar{\gamma}^h(\lambda) \le \gamma^h(K^h_\delta) \to \gamma(K_\delta) \le \bar{\gamma}(\lambda - \delta_0) + \delta$. Now (10.10) follows from this, (10.11), and the arbitrariness of δ and δ_0. Thus only (10.12) remains to be proved.

To prove (10.12), we adapt the proof of [7, Thm. 7]. Recall that $Y^h_n = U^h_n \equiv 0$ here, and write $\xi^h(t)$ in the form

$$\xi^h(t) = \xi^h(0) + D^h(t) + J^h_\delta(t), \tag{10.14}$$

where (10.14) defines $D^h(t)$. Let S_1 denote the intersection of a closed disc with $\hat{G}$ such that at most half of two adjacent segments of $\partial\hat{G}$ are included. For ease of description, refer to Fig. 7, where a "typical" S_1 is defined. Let $N_h(S)$ denote the h neighborhood of a set S. For small $\delta_1 > 0$, define the stopping times $\{\tau^h_n\}$ recursively by

$$\tau^h_1 = \min\{t \colon \xi^h(t) \in N_h(\partial\hat{G} \cap S_1)\} \wedge 1,$$

$$\tau^h_{2m} = \min\{t > \tau_{2m-1} \colon \text{distance}(\xi^h(t), S_1) \ge \delta_1\} \wedge 1,$$

$$\tau^h_{2m+1} = \min\{t > \tau_{2m} \colon \xi^h(t) \in N_h(\partial\hat{G} \cap S_1)\} \wedge 1.$$

Define $N^h = \min\{m \colon \tau^h_{2m} = 1\}$.

By (10.14), we can write

$$J^h_\delta(1) = \left(\sum_{m=1}^{N^h+1} [\xi^h(\tau^h_{2m}) - \xi^h(\tau^h_{2m-1})] - \sum_{m=1}^{N^h+1} [D^h(\tau^h_{2m}) - D^h(\tau^h_{2m-1})] \right). \tag{10.15}$$

By (10.15) and the properties of $D^h(\cdot)$, we see that there are $c_i > 0$ such that

$$E|J^h(1)|^2 \le c_1 + c_2 E|N^h|^2.$$

So we need only bound $E|N^h|^2$. Refer again to Fig. 7. There is $\delta_2 > 0$ such that (for small h) for $\xi^h(t)$ to go from the exterior of $N_{\delta_1}(S_1) \cap \hat{G}$ at some time t to $N_h(S_1 \cap \partial\hat{G})$ at some time $t+s$, we need $|D^h(t+s) - D^h(t)| \geq \delta_2$. Recall that $D^h(\cdot)$ is the interpolation of a sum of terms that are either proportional to Δt^h or else are martingale differences whose variances are $O(\Delta t^h)$. Thus given $\delta_3 > 0$, there is $\delta_4 > 0$ such that for all finite stopping times τ and small h,

$$(10.16) \qquad P\{\sup_{\tau+\delta_4 \geq s \geq \tau} |\, D^h(s) - D^h(\tau)| \geq \delta_2 |\text{ data up to time } \tau\} \leq 1 - \delta_3.$$

Inequality (10.16) implies that (for $m \geq 1$)

$$(10.17) \qquad P\{\tau^h_{2m+1} - \tau^h_{2m} \geq \delta_4 \mid \text{data up to time } \tau^h_{2m}\} \geq \delta_3.$$

But (10.17) implies that all moments of N^h are bounded uniformly in h. Thus $\sup_h E|J^h(1)|^2 < \infty$. Inequality (10.12) follows from that by the stationarity and the fact that the $\bar{v}_i$ on adjacent boundary segments do not point in opposite directions. □

A FRAMEWORK FOR TWO-DIMENSIONAL HYPERSTABILITY THEORY BASED PROVABLY CONVERGENT ADAPTIVE TWO-DIMENSIONAL IIR FILTERING*

SANKAR BASU†

Abstract. A set of results for two-dimensional quarter plane causal systems reminiscent of one-dimensional hyperstability theory have been reported. The key to this development is a little known result of Landau [*Math. Ann.*, 62 (1906), p. 272], which asserts that a positive polynomial in two variables can be expressed as the sum of squares of polynomials in one variable whose coefficients are real rational functions of the other variable. The tools used are largely based on notions of passivity and the results obtained can be interpreted as a two-dimensional quarter plane causal generalization of the fact that if the total flow of energy into a dissipative system is upper bounded then both input and output asymptotically die out to zero. An adaptive two-dimensional recursive filtering scheme potentially useful in propagating wave type two-dimensional problems is considered next. It is then shown via our two-dimensional hyperstability results that the adaptive scheme converges in an appropriate sense.

Key words. two-dimensional system, passive scattering systems, adaptive filtering, circuit synthesis

1. Introduction. The purpose of this paper is two-fold. The first is to develop two-dimensional (2-D) counterparts of some central aspects of the well-known hyperstability theory [1], [4], and the second is to show its applications in 2-D adaptive signal processing schemes mostly paralleling the one-dimensional developments reported in [28], [32], [36]. While our developments are largely motivated by potential applications in adaptive filtering, in view of the important role of hyperstability theory in various areas of system theory such as in control system systhesis [1], stochastic realization [2], digital filter stability [3], etc., we believe that 2-D extension of such a theory is of independent interest. In relating these apparantly disparate notions, the one-dimensional Kalman–Popov–Yakubovitch (KPY) lemma (otherwise known as the positive real lemma [5]), which provides a characterization of the property of dissipativeness of arbitrary (minimal) realization of systems, proves to be pivotal. While the KPY lemma can be derived via techniques akin to those known in linear quadratic optimal control theory [6], it can alternatively be viewed [5] as a consequence of synthesizability of positive (real) transfer functions or spectral factorability of parahermitian positive definite transfer matrices [2], or as a combination of both. Note that in the case of scalar transfer functions this last result is a reformulation of the fact that positive polynomials can be expressed as the sum of squares of two real polynomials. It is, however, well known [15] that this latter fact does not extend to 2-D dimensions in general. Our starting point in this work is a little known theorem of Landau [7] as a follow up of earlier work on the theory of curves by Hilbert [8] that positive polynomials in two variables can, in fact, be expressed as a sum of squares of polynomials in one variable whose coefficients are real rational functions of the other

Part of this work was carried out when the author had a visiting appointment at the Laboratory for Information and Decision Sciences at the Massachusetts Institute of Technology, Cambridge, Massachusetts 02139.

variable.[1] When interpreted as a spectral factorability type result, it allows us to embed an arbitrary positive or bounded (real) vector valued transfer function into a lossless positive or bounded (real) matrix. This is reminiscent of unitary dilation of contractive operators [14] and is well known in 1-D (infinite-dimensional) system theory. This key observation, along with synthesizability of lossless 2-D transfer function matrices [24]–[26], then demonstrate the synthesizability of arbitrary positive or bounded (real) transfer functions—a fact that has remained unavailable in the literature thus far. Since a passive synthesis automatically provides a dissipative realization, it in turn leads the way to a weak form of the 2-D KPY lemma and to our 2-D hyperstability results.

We wish to make a further observation on the 2-D aspect of our problem. It is well known that the local states such as those in 2-D Roesser's state space model [15] or in any other 2-D state model do not contain the full information regarding the complete history of the system. On the other hand, the global states are known to be infinite-dimensional. Although the details of our 2-D theory differ considerably from the theory of infinite-dimensional systems (which, in fact, are at least partially motivated by the study of partial differential/difference equations) analogous results, namely, those on linear quadratic optimal control [11], the KPY lemma [12], [13], including lossless embedding, i.e., unitary dilation of contractive operators [14], exist in this context. At a broad conceptual level these can, therefore, be taken to be supportive of the line of development reported in the present paper.

We now turn to applications in adaptive filtering. While recent literature has witnessed a profusion of activity in 1-D adaptive filtering both in the deterministic and stochastic context, in spite of its potential practical applicability, very little has been reported for higher dimensional problems. We refer to the books [34]–[38] and the recent review [33] for a survey of 1-D adaptive signal processing, whereas works of more control theoretic flavor are available, e.g., in [39], [41], [42]. Among these, the only deterministic recursive filtering scheme for which convergence of the adaptation algorithm can be theoretically demonstrated is known as the HARF (hyperstable adaptive recursive filter) and was first reported in [28]. Subsequently, the theory has been elaborated and further variations and simplifications are reported in [29]–[32], [36]. In this paper we show that the 2-D hyperstability theory developed in the first part of the paper can be crucially exploited in extending HARF, including its proof of convergence, to 2-D. Since we consider quarter plane causal filters, 2-D problems of the propagating wave type (specifically, those admitting hyperbolic differential/difference equation formulation), i.e., those arising in beamforming and/or target tracking, are expected to be particularly suitable problem areas where this theoretical study can find use. It may be mentioned that the need for adaptive filtering in image processing type 2-D problems has also been recently recognized (see, e.g., [44]–[46]) and the potential relevance of our work in this area, at least at a conceptual level, cannot be excluded by any means.

In §2 notation and terminologies are introduced first. In §3 a specific type of weak convergence of 2-D quarter plane signals relevant to our ensuing discussions on 2-D adaptive filtering is discussed. In §4 the hyperstability results are developed, while §5 introduces its applications to 2-D HARF type algorithms. In §6 discussions are presented and conclusions are drawn. An appendix is included to elaborate on Landau's theorem and its relevance to 2-D lossless embedding on which this entire

[1] The result also follows from combined use of Corollary 1.10 and the Cassel–Phister Theorem 1.3 in [9].

work is based.

2. Notation and terminology. Two-dimensional discrete signals are denoted by symbols such as $u(m,n)$ or $y(m,n)$ etc., where (m,n) are points in 2-D lattice space. All signals, unless otherwise specified or obvious from the context, are of quarter plane support. In the 2-D lattice space the following set of points will be of interest: the triangular set $T_N = \{(m,n);\ 0 \leq m+n \leq N\}$; the line set $C_N = \{(m,n);\ m+n = N\}$ and the trapezoidal set $R_{n_0 N} = \{(m,n);\ n_0 \leq m+n \leq N\} = T_N \setminus T_{n_0-1}$.

Z-transforms of 2-D signals, e.g., $u(m,n)$, $y(m,n)$ etc., will be denoted by $U(z_1, z_2)$, $Y(z_1, Z_2)$ etc., where z_1, z_2 are the transform variables. Similarly, p_1, p_2 will be used to denote the (Laplace) transform variables for continuous signals, which we will also feature in the present work. The (closed) unit bidisc of the complex biplane will be denoted by $(\bar{D})$ D, i.e., $\bar{D} = \{(z_1, z_2);\ |z_i| \leq 1, i = 1,2\}$ or $D = \{(z_1, z_2);\ |z_i| < 1, i = 1,2\}$ and its distinguished boundary $|z_1| = |z_2| = 1$ will be denoted by T. Also, the notation "Re" will denote the real part of a complex number. A real polynomial is one which has real valued coefficients, and a real rational function is the ratio of two real polynomials. The superscript $*$ denotes complex conjugation. If $g = g(z_1, z_2)$ is a rational function then its paraconjugate is $g_* = g^*(-p_1^*, -p_2^*)$ and if $a = a(z_1, z_2)$ is a rational function then its discrete paraconjugate is $\tilde{a} = a^*(z_1^{*^{-1}}, z_2^{*^{-1}})$. The partial degree of a two-variable polynomial g in the variable z_i is denoted by $\deg_i g$.

The notation $\|\cdot\|$ denotes a Eucledian norm of a row or a column vector. The norm $|H|$ of a matrix H denotes the spectral norm $|H| = \sup_{\|x\|} \|Hx\|$. A rational matrix (i.e., one with rational function entries) is real rational if its entries are so. The superscript T denotes Hermitian transpose, whereas superscript t denotes simply transpose of a matrix; $\tilde{}$ as a superscript or $*$ as a subscript to a rational matrix denotes the matrix with the corresponding operations performed on its entries and subsequently transposed (sometimes known as the parahermitian transpose). The notation $\oplus$ denotes the direct sum of matrices.

A rational function $g = g(p_1, p_2)$ is said to be *positive* if $\mathrm{Re} g \geq 0$, whenever $\mathrm{Re} p_i > 0$, $i = 1,2$. Similarly, $a = a(z_1, z_2)$ is *discrete positive* if $\mathrm{Re} a \geq 0$ in D. Also, $g = g(p_1, p_2)$ is *bounded* if $\|g\| \leq 1$, whenever $\mathrm{Re} p_i > 0$, i=1,2, and a is *discrete bounded* if $\|a\| \leq 1$ in D. If, in addition, the rational function concerned is a real rational function then it is included in the terminology by saying g is positive real, a is discrete positive real etc., as the case may be. Furthermore, a is said to *strictly discrete positive* (real) if it is discrete positive (real) and, in its irreducible form, neither its numerator nor its denominator has any zero in $\bar{D}$. Correspondingly, a is said to *strictly discrete bounded* (real) if it is discrete bounded (real) and $\|a\| < 1$ in $\bar{D}$.

3. Almost everywhere convergence of 2-D quarter plane double sequences. Our applications in adaptive 2-D IIR filtering of hyperstability theory require consideration of convergence of double sequences $x(m,n)$ in the quarter plane. We need to make precise a notion of convergence which does not demand that $x(m,n)$'s individually become small far away from the origin of the 2-D lattice space, but at "most" points they do in an areawise sense. We proceed as follows.

Let $\nu_\epsilon(C_N)$ be the number of points on C_N such that the 2-D signal $x(m,n)$ satisfies $|x(m,n)| > \epsilon$. Then $x(m,n)$ is said to be *almost everywhere convergent to zero* if for any n_0 and *arbitrary* ϵ we have

$$(1) \qquad \lim_{N\to\infty} \frac{\sum_{k=n_0}^{n_0+N} \nu_\epsilon(C_k)}{\ln(N+n_0+1)! - \ln n!} \le C < \infty,$$

where C is a constant independent of N.

The intuitive content of this definition is as follows. Consider the trapezoidal set R_{n_0N} in the 2-D lattice space, which, in fact, is of width $(N+1)$ with parallel sides of the trapezoid being the lines C_{n_0} and C_N. Note that the total number of points in R_{n_0N} is

$$(2) \qquad |R_{n_0N}| = \frac{1}{2}(N+1)(N+2n_0+2).$$

Before proceeding further we need to recall Stirling's formula [47] which estimates $n!$ for large n as follows:

$$\ln n! \approx (n-1)\ln n - n + \frac{1}{2}\ln n + \frac{1}{2}\ln 2\pi.$$

The essential point for us is that as $n \to \infty$, $\ln n!$ grows as $(n-1)\ln n$ which is faster than n but slower than n^2.

Thus as $N \to \infty$, the ratio

$$\begin{aligned} &\frac{1}{R_{n_0N}}\{\text{Number of points in } R_{n_0N} \text{ where } |x(m,n)| > \epsilon\} \\ = \quad & \frac{1}{R_{n_0N}} \sum_{k=n}^{N} \nu_\epsilon(C_k) \\ \le \quad & \frac{C}{R_{n_0N}}\{\ln(N+n_0+1)! - \ln n_0!\} \\ = \quad & C\frac{\ln(N+n_0+1)! - \ln n_0!}{\frac{1}{2}(N+1)(N+2n_0+2)} \\ \longrightarrow \quad & 0, \end{aligned}$$

where the first inequality follows from (1), the last equality follows from (2), and the last limit follows from the fact that, due to Stirling's formula, the numerator grows with N as $(N+n_0+1)\{\ln(N+n_0+1)-1\}$, whereas the denominator grows as N^2.

Thus, almost everywhere convergence to zero of $x(m,n)$ implies that the relative number of points in R_{n_0N}, where $|x(m,n)| > \epsilon$ with ϵ arbitrary, is small in the asymptotic limit $N \to \infty$.

Now let us define

$$(3) \qquad S_N = \sum\sum_{T_N} |x(m,n)|.$$

We then have the following result.

THEOREM 3.1. *If* (4) *holds for all integers* $N \ge 0$, *where* α, β *are constants independent of* N

$$S_N \leq N \cdot \alpha + \beta \tag{4}$$

then $x(m,n)$ is almost everywhere convergent to zero.

Proof. Fix $\epsilon > 0$ arbitrarily. Suppose for contradiction that $x(m,n)$ is not almost everywhere convergent to zero. Then for some fixed n_0 it is possible to find an integer N, arbitrarily large, such that

$$\sum_{k=n_0}^{n_0+N} \nu_\epsilon(C_k) > C\{\ln(N+n_0+1)! - \ln n_0!\} \tag{5}$$

for every fixed constant C. However, we also have from (3) and the definition of $\nu_\epsilon(C_k)$ that

$$S_{n_0+N} - S_{n_0-1} \geq \sum_{k=n_0}^{n_0+N} \epsilon\nu_\epsilon(C_k). \tag{6}$$

Combining (5) and (6) we have that for some fixed n_0 there exists arbitrarily large N such that the following inequality set holds true:

$$S_{n_0+N} - S_{n_0-1} > \epsilon C\{\ln(N+n_0+1)! - \ln n_0!\}, \tag{7}$$

i.e.,

$$S_{n_0+N} > S_{n_0-1} + \epsilon C \ln(N+n_0+1)! - \epsilon C \ln n_0!. \tag{8}$$

The second term in (8), by Stirling's formula, grows with N as $(N+n_0+1)\{\ln(N+n_0+1) - 1\}$, which is faster than the linear growth condition imposed on S_N by (4). Thus, (8) contradicts (4). Since $\epsilon > 0$ is arbitrarily small we have completed the proof of our result.

We next explore some useful properties of almost everywhere convergent sequences.

PROPOSITION 3.2. *Let $x(m,n)$ and $y(m,n)$ be both double sequences with quarter plane support each convergent to zero in the almost everywhere sense. Then $z(m,n) = x(m,n) + y(m,n)$ has the same property.*

Proof. Let $\nu_\epsilon(C_k)$ and $\mu_\epsilon(C_k)$ be the number of points on C_k where $|x(m,n)| > \epsilon$ and $|y(m,n)| > \epsilon$, respectively. Then if $\lambda_{2\epsilon}(C_k)$ denote the number of points on C_k, where $|z(m,n)| > 2\epsilon$ then we have

$$\lambda_{2\epsilon}(C_k) \leq \nu_\epsilon(C_k) + \mu_\epsilon(C_k).$$

Thus, we have

$$\begin{aligned}
&\lim_{N\to\infty} \frac{\sum_{k=n_0}^{n_0+N} \lambda_{2\epsilon}(C_k)}{\ln(N+n_0+1)! - \ln n_0!} \\
\leq\ & \lim_{N\to\infty} \frac{\sum_{k=n_0}^{n_0+N} \nu_\epsilon(C_k)}{\ln(N+n_0+1)! - \ln n_0!} + \lim_{N\to\infty} \frac{\sum_{k=n_0}^{n_0+N} \mu_\epsilon(C_k)}{\ln(N+n_0+1)! - \ln n_0!} \\
\leq\ & C_x + C_y < \infty,
\end{aligned}$$

where C_x and C_y are constants in (1) corresponding to almost everywhere convergence of $x(m,n)$ and $y(m,n)$, respectively. Since ϵ is arbitrary the almost everywhere convergence of $z(m,n)$ is demonstrated.

We will say that a double sequence is *asymptotically bounded almost everywhere* if for any finite n_0, (1) holds for *some* number ϵ. Clearly, a double sequence is asymptotically bounded almost everywhere if it converges to zero almost everywhere as $N \to \infty$.

We then have the following proposition.

PROPOSITION 3.3. *If $x(m,n)$ and $y(m,n)$ are two double sequences with quarter plane support such that $x(m,n)$ is almost everywhere convergent to zero and $y(m,n)$ is asymptotically bounded almost everywhere, then $z(m,n) = x(m,n)y(m,n)$ is almost everywhere convergent to zero.*

Proof. Let $\nu_\epsilon(C_k)$ be the number of points on C_k where $|x(m,n)| > \epsilon$ and $\mu_\kappa(C_k)$ denote the number of points C_k where $|y(m,n)| > \kappa$. Then we have

$$\lim_{N\to\infty} \frac{\sum_{k=n_0}^{n_0+N} \nu_\epsilon(C_k)}{\ln(N+n_0+1)! - \ln n_0!} \le C_x < \infty \tag{9}$$

$$\lim_{N\to\infty} \frac{\sum_{k=n_0}^{n_0+N} \mu_\kappa(C_k)}{\ln(N+n_0+1)! - \ln n_0!} \le C_y < \infty, \tag{10}$$

where (9) holds for arbitrary ϵ and (10) holds only for a *fixed* κ.

Now, let $\lambda_{\epsilon\kappa}(C_k)$ be the number of points on C_k where $|z(m,n)| > \epsilon\kappa$. Then $\lambda_{\epsilon\kappa}(C_k) \le \nu_\epsilon(C_k) + \mu_\kappa(C_k)$ and due to (9) and (10) we have

$$\lim_{N\to\infty} \frac{\sum_{k=n_0}^{n_0+N} \lambda_{\epsilon\kappa}(C_k)}{\ln(N+n_0+1)! - \ln n_0!} \le C_x + C_y < \infty. \tag{11}$$

Since ϵ is arbitrary and κ is fixed, the last equality proves that $z(m,n)$ is convergent to zero almost everywhere.

The following proposition follows almost immediately from the definition of almost everywhere boundedness.

PROPOSITION 3.4. *Let $x(m,n)$ and $y(m,n)$ be two double sequences with quarter plane support.*

1. *If $|x(m,n)| < K < \infty$, K =constant and $y(m,n)$ is asymptotically bounded almost everywhere then $z(m,n) = x(m,n) + y(m,n)$ is also asymptotically bounded almost everywhere.*
2. *If $x(m,n)$ and $y(m,n)$ are both asymptotically bounded almost everywhere then so is $z(m,n) = x(m,n)y(m,n)$.*

4. 2-D hyperstability type results. In this section we develop the main results on 2-D extensions of hyperstability theory. Although many other variations of the results could be presented and further generalizations of them are possible, our main goal is to arrive at statements of certain facts that would allow us to prove the convergence of the adaptive algoritm to be discussed in §5.

Before proceeding further it is important to emphasize an important distinction between 1-D and 2-D systems. Among the many possible ways in which the "successive" states of a 2-D quarter plane system can be updated from "previous" states, we focus on the one in which all states on C_N are simultaneously computed from those on C_{N-1}. For computation of C_N from C_{N-1}, boundary values of the state variables, namely those at $(0, N)$ and at $(N, 0)$, need to be specified. Note that these do not influence the evolution of the system until states on C_N have been computed. Thus, unlike in 1-D, *new* boundary values of states can keep adding information to the system not previously used and can thus influence the output as computation progresses. Consequently, notions related to stability, e.g., boundedness, etc., of output and/or state may, in general, require qualifications as to the specified boundary values of the states. However, in most of what follows we validly assume, unless otherwise specified, that the boundary values of states are zero and thus, the evolution of the system is completely governed by its zero state response, i.e., by its transfer function only.

The main results of this section are the 2-D hyperstability theorems stated in Theorems 4.1 and 4.2.

THEOREM 4.1 (Bounded version). *Let $H = H(z_1, z_2)$ be the scalar transfer function of a 2-D quarter plane causal system. Let H be strictly discrete bounded (real) (i.e., $|H| < 1$ in $\bar{D}$), $u(m,n)$ be an input, $y(m,n)$ be the corresponding output from the system while the boundary conditions are assumed zero. Also, let*

$$S_N = \sum_{T_N}\sum |u(m,n)|^2 - |y(m,n)|^2. \tag{12}$$

Then we have the following:

(i) *If $S_N \le K_1 N + K_2$, where K_1 and K_2 are constants independent of N then for some β with $K_1' = |\beta|^2 K_1$ and $K_2' = |\beta|^2 K_2$ we have*

$$\sum_{T_N}\sum |u(m,n)|^2 \le K_1' N + K_2'; \ \sum_{T_N}\sum |y(m,n)|^2 \le K_1' N + K_2'. \tag{13}$$

Consequently, both $y(m,n)$ and $u(m,n)$ converge to zero almost everywhere.

(ii) *If $S_N \le K < \infty$ for every nonnegative integer N then we have that $y(m,n) \to 0$ and $u(m,n) \to 0$ as $(m+n) \to \infty$ in the usual sense.*

Before undertaking a detailed proof of Theorem 4.1 we will make several comments on its intuitive contents and on our strategy for its proof. First, note that a realization of a (strictly) discrete bounded transfer function can be viewed as a (strictly) dissipative system, whereas the expression for S_N clearly indicates that it stands for the total flow of energy into the system minus the total flow of energy out of the system over the triangular region T_N. Thus the boundedness condition $S_N \le K < \infty$ implies that the net flow of energy into the system from outside is at most K. Now, since the system is strictly dissipative, if there is no energy input from the boundary values of the state variables (i.e., if they are assumed to be zero), in order for the energy conservation law to hold, the energy stored in the state variables must die out to zero; consequently, the output must also die out to zero. This last arguement, in fact, requires minimality of the realization so that self-sustaining oscillatory modes, which are neither uncontrollable from the input nor unobservable from the output, are excluded. However, the conclusion of the theorem remains true even if the realization is nonminimal. This latter point is vital in our proof of Theorem 4.1 because of the fact that in 2-D, minimal realization, its characterization, and its properties are not yet clearly understood [19].

Second, if $S_N \leq K_1 N + K_2$, i.e., if the net flow of energy into the system is not bounded but can only grow at most linearly with (the propagation of the "computational wavefront") N, the asymptotic decay of the output cannot be argued as above, and in fact, is not even true. However, we do have convergence of $y(m,n)$ to zero in the almost everywhere sense as discussed in §3. Here we may only roughly mention that since the "area" of the triangle T_N increases as N^2 with N, a linear rate of inflow of energy cannot keep up with the increase in area so that it is, in an average sense, thinly distributed over the 2-D lattice space for large N.

Third, although we have assumed that the boundary values of the states, i.e., those at points $(m,0)$ and $(0,n)$ for nonnegative m and n are zero, it is not exactly necessary for the validity of Theorem 4.1 (the same holds for Theorem 4.2 to follow). It should be plausible for the above discussions and would be more transparent in the proof that both conclusions (i) and (ii) of Theorem 4.1 remain valid if we assume that the boundary values of the states are square summable, i.e., only a finite amount of energy is fed into the system from boundary values of states, while (i) only remains valid if we allow this energy to grow at most linearly with N.

A proof of the above theorem will be given essentially via circuit theoretic arguments. In particular, we draw from existing results on structurally passive synthesis of 2-D lossless trnasfer functions [24]–[26] and a little known 2-D spectral factorizability type result by Landau [7]. Landua's result allows us to embed an arbitrary 2-D bounded (real) or positive (real) transfer function into a 2-D lossless scattering or immittance matrix. The embedding, in physical terms, can be viewed as the operation of resistor extraction [5], thus leaving a lossless multiport to be synthesized via procedures estabilished in [24]–[26]. This then yields a structurally passive synthesis of arbitrary 2-D bounded (real) transfer functions. Note that in 1-D, a minimal passive synthesis along with the state space isomorphism result [2] directly yields the positive real (KPY) lemma, or the bounded real lemma, which in turn can be crucially exploited to provide proofs of the 1-D hyperstability theorems as elaborated in [2] and [4]. Although in our 2-D context we do not necessarily have a minimal passive synthesis via the procedure outlined above, and a state space isomorphism result is not known, a weak 2-D version of the hyperstability theorem useful in the present context of adaptive 2-D signal processing, namely that stated in Theorems 4.1 and 4.2, can indeed be proved. Theorem 4.1 and its counterpart in [28] are weak in the sense that we only require the input $u(m,n)$ and the output $y(m,n)$, but not necessarily the states in a realization of H to be asymptotically zero, while the original formulation of the hyperstability theorem in [1], [2], and [4] requires, in addition, that the state variables in a minimal realization of H necessarily converge to zero.

To proceed we first establish the following result.

LEMMA 4.2. *Let $H = H(z_1, z_2)$ be a rational matrix of size $(1 \times \ell)$, which, in addition, is discrete bounded. Then there exist integers p, q and matrices A, B, C, and D of appropriate sizes such that*

$$H(z_1, z_2) = A + B(z_1^{-1} I_p \oplus z_2^{-1} I_q - D)^{-1} C \tag{14}$$

along with

$$I - T^* T \geq 0, \tag{15}$$

where

$$T = \begin{bmatrix} A & B \\ C & D \end{bmatrix}. \tag{16}$$

Furthermore, if H is real rational then T is real.

Remark 4.1. Note that Lemma 4.2 essentially states that a *passive* 2-D Roesser's state space realization for the transfer function $H(z_1, z_2)$ can be obtained. If B, C, D are partitioned as

$$D = \begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix}; B = \begin{bmatrix} B_1 & B_2 \end{bmatrix}; C = \begin{bmatrix} C_1 \\ C_2 \end{bmatrix}, \tag{17}$$

where D_{11}, D_{12} are of respective sizes $(p \times p)$; B_1, B_2 has, respectively, p and q columns; C_1, C_2 has, respectively, p and q rows, then $H(z_1, z_2)$ can be viewed as the transfer function between the input vector $u(m,n)$ and the output $y(m,n)$ in the Roesser's state space model:

$$\begin{bmatrix} x_h(m+1,n) \\ x_v(m,n+1) \end{bmatrix} = \begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix} \begin{bmatrix} x_h(m,n) \\ x_v(m,n) \end{bmatrix} + \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} u(m,n), \tag{18}$$

$$y(m,n) = \begin{bmatrix} B_1 & B_2 \end{bmatrix} \begin{bmatrix} x_h(m,n) \\ x_v(m,n) \end{bmatrix} + Au(m,n). \tag{19}$$

A realization satisfying (15) to (19) will henceforth be called a "*passive realization*" of a discrete bounded H.

Remark 4.2. The matrix inequality in (15) is equivalent to the existence of two further matrices L and W such that

$$1 - T^*T = \begin{bmatrix} L^* \\ W^* \end{bmatrix} \begin{bmatrix} L & W \end{bmatrix}, \tag{20}$$

where L is of size $(r \times \ell)$ and W is of size $(r \times (p+q))$ for some $r \leq p+q+1$. Equations (15) and (16) together can be viewed as a weak form of a 2-D bounded real lemma for the transfer function H. It is weak in that it applies only to the specific realization obtained in Lemma 4.2. The lack of a 2-D state space isomorphism result prevents further generalization to arbitrary "minimal" realizations in 2-D. Note further that (15) and (16) combined together can be written in a more familiar form:

$$I_p - A^*A - C^*C = L^*L, \tag{21}$$

$$-A^*B - C^*D = L^*W, \tag{22}$$

$$I_q - B^*B - D^*D = W^*W. \tag{23}$$

COROLLARY 4.3. *Let $H = H(z_1, z_2)$ be a (real) rational matrix of size $(1 \times \ell)$, which, in addition, is discrete bounded. Let A, B, C, D as in (16) be a passive* *realization of H. Let L and W be defined as in* (20) *or, equivalently, in* (21)–(23). *Then we have*

$$1 - \tilde{H}(z_1, z_2)H(z_1, z_2) = \tilde{P}(z_1, z_2)P(z_1, z_2), \tag{24}$$

where $P(z_1, z_2)$ *is the transfer function of the Roesser's state space model given by*

$$\begin{bmatrix} x_h(m+1, n) \\ x_v(m, n+1) \end{bmatrix} = \begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix} \begin{bmatrix} x_h(m, n) \\ x_v(m, n) \end{bmatrix} + \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} u(m, n), \tag{25}$$

$$\eta(m, n) = \begin{bmatrix} W_1 & W_2 \end{bmatrix} \begin{bmatrix} x_h(m, n) \\ x_v(m, n) \end{bmatrix} + Lu(m, n) \tag{26}$$

with $W = \begin{bmatrix} W_1 & W_2 \end{bmatrix}$. *In other words,* $P(z_1, z_2)$ *is given by*

$$P(z_1, z_2) = L + W[z_1^{-1} I_p \oplus z_2^{-1} I_q - D]^{-1} C. \tag{27}$$

Proof. The proof is routine algebraic manipulation for which we adopt the compact notation $\zeta I = z_1 I_p \oplus z_2 I_q$. By substituting for H from (14) and expanding the product, then from (21),(22),(23) by making the replacements $I_p - A^*A = C^*C + L^*L$, $A^*B = -(C^*D + L^*W)$, $B^*B = I_q - D^*D - W^*W$ and subsequently rearranging terms we can write

$$1 - \tilde{H}(z_1, z_2)H(z_1, z_2) = \tilde{P}(z_1, z_2)P(z_1, z_2) + C^*(t_1 + t_2 + t_3)C, \tag{28}$$

where

$$t_1 = I - (\zeta I - D^*)^{-1}(\zeta^{-1} I - D)^{-1},$$

$$t_2 = D(\zeta^{-1} I - D)^{-1} + (\zeta I - D^*)^{-1} D^*,$$

and

$$t_3 = (\zeta I - D^*)^{-1} D^* D (\zeta^{-1} I - D)^{-1}.$$

Since we obviously have

$$\begin{aligned} t_1 &= (\zeta I - D^*)^{-1}\{(\zeta I - D^*)(\zeta^{-1} I - D) - I\}(\zeta^{-1} I - D)^{-1} \\ &= (\zeta I - D^*)^{-1}\{D^* D - D^* \zeta^{-1} - D\zeta\}(\zeta^{-1} I - D)^{-1} \end{aligned}$$

and

$$\begin{aligned} t_2 &= (\zeta I - D^*)^{-1}\{D^*(\zeta^{-1} I - D) + (\zeta I - D^*)D\}(\zeta^{-1} I - D)^{-1} \\ &= (\zeta I - D^*)^{-1}\{D^* \zeta^{-1} + D\zeta - 2D^* D\}(\zeta^{-1} I - D)^{-1} \end{aligned}$$

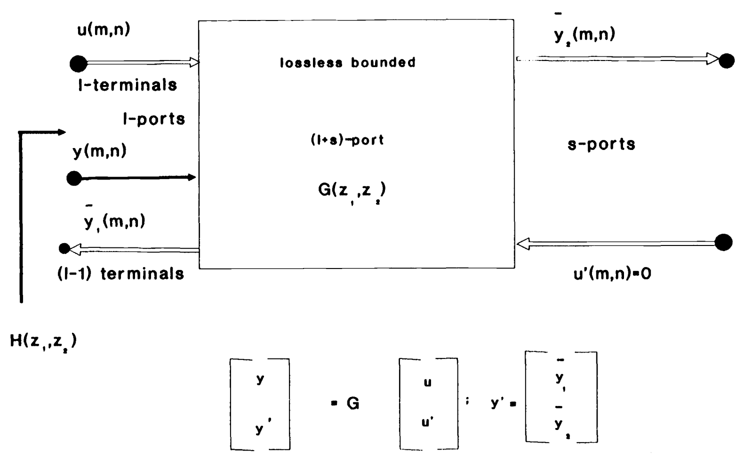
it follows after further expansion that $t_1 + t_2 + t_3 = 0$, thus proving the corollary.

Proof of Lemma 4.2. It follows from the 2-D discrete embedding Theorem (cf. Theorem A.4) that there exists a 2-D discrete lossless bounded (real) matrix $G(z_1, z_2)$ of size $(s+\ell) \times (s+\ell)$ such that the top left $(1 \times \ell)$ block of G is $H(z_1, z_2)$. We thus have the situation depicted in Fig. 1, in which

$$\begin{bmatrix} Y(z_1,z_2) \\ Y'(z_1,z_2) \end{bmatrix} = G(z_1,z_2) \begin{bmatrix} U(z_1,z_2) \\ U'(z_1,z_2) \end{bmatrix} \tag{29}$$

$$G = G(z_1,z_2) = \begin{bmatrix} H & G_{12} \\ G_{21} & G_{22} \end{bmatrix}, \tag{30}$$

where G_{22} is of size $(\ell + s - 1) \times s$ and capital letters are used to denote transform domain variables corresponding to small english letters.



u(m,n)
l-terminals
l-ports
y(m,n)
$\bar{y}_1(m,n)$
(l-1) terminals
H(z₁,z₂)
lossless bounded
(l+s)-port
G(z₁,z₂)
$\bar{y}_2(m,n)$
s-ports
u'(m,n)=0
$\begin{bmatrix} y \\ y' \end{bmatrix} = G \begin{bmatrix} u \\ u' \end{bmatrix}$; $y' = \begin{bmatrix} \bar{y}_1 \\ \bar{y}_2 \end{bmatrix}$

FIG. 1

Now, it is known that [24]–[26] it is possible to obtain a passive (in fact, minimal) synthesis for any 2-D discrete lossless bounded matrix, and thus of $G(z_1, z_2)$ in particular. More specifically, one way of viewing the synthesis procedure is to extract p of z_1-type delays and q of z_2 delays in such a way that we are left with a constant lossless bounded multiport with as many as $(p+q+s+\ell)$ ports. Let the transfer function of the constant lossless bounded $(p+q+s+\ell)$-port be given by (cf. Fig. 2) $\bar{T}$ as

$$\begin{bmatrix} y(m,n) \\ x_h(m+1,n) \\ x_v(m,n+1) \\ y'(m,n) \end{bmatrix} = \bar{T} \begin{bmatrix} u(m,n) \\ x_h(m+1,n) \\ x_v(m,n+1) \\ u'(m,n) \end{bmatrix} \tag{31}$$

and partition $\bar{T}$ as

$$\bar{T} = \begin{bmatrix} A & B & T_{13} \\ C & D & T_{23} \\ T_{31} & T_{32} & T_{33} \end{bmatrix}, \tag{32}$$

where A is $(1 \times \ell)$, D is $(p+q)$ square, T_{33} is $(\ell + s - 1) \times s$. Since $\bar{T}$ is lossless bounded we have $\bar{T}^*\bar{T} = I$, which in view of (32) yields (33) in which T is as in (16)

$$I - T^*T \geq 0. \tag{33}$$

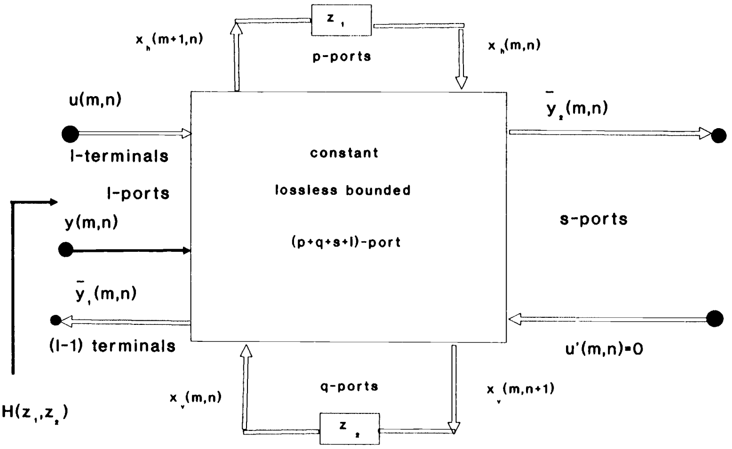


FIG. 2

Clearly, since in Fig. 2 $x_h(m,n)$ and $x_v(m,n)$ are outputs of z_1 and z_2 type delays, respectively, they are valid state variables. Furthermore, by setting $u'(m,n) = 0$ it can be verified from (32) that T obtained as above then indeed corresponds to Roesser's state space model (18) and (19). It then is well known that the transfer function H between $u(m,n)$ and $y(m,n)$ is indeed given by the formula (14), thus completing the proof of the present lemma.

We will need the following notions for the developments to follow.

Remark 4.3. Let $H = H(z_1, z_2)$ be a (real) rational matrix of size $(1 \times \ell)$, holomorphic in $\bar{D}$. If $\alpha = sup_{\bar{D}}|H(z_1, z_2)|$ then clearly α is a well-defined finite real number. We then consider $H_\alpha = H_\alpha(z_1, z_2) = \alpha^{-1}H(z_1, z_2)$. Obviously, then $\|H_\alpha\| \leq 1$ in $\bar{D}$. Thus, H_α is a discrete bounded (real) matrix for which there exists a passive realization as in Remark 4.1. This, in fact, also gives us a realization of H, if the A-matrix and the C-matrix in (18) and (19) are replaced by αA and αC, respectively. Such a realization of a transfer function H, holomorphic in $\bar{D}$, will also be referred to as a "*passive realization.*"

We can then state the following result.

LEMMA 4.4. *Let $H = H(z_1, z_2)$ be a rational discrete bounded (real) transfer function of a passive realization having ℓ-inputs and 1-output operating under zero boundary conditions. Let $u(m,n)$ be the input vector and $y(m,n)$ be the corresponding output, whereas let $\eta(m,n)$ be given by*

$$\eta(m,n) = W\phi(m,n) + Lu(m,n), \tag{34}$$

where

$$\phi(m,n) = \begin{bmatrix} x_h(m,n) \\ x_v(m,n) \end{bmatrix}$$

is the state vector in the passive realization of H. We then have the following:

(i) *If for all nonnegative integer N*

$$\sum_{T_N}\sum \|u(m,n)\|^2 \leq K_1N + K_2 \tag{35}$$

then for all nonnegative integer N

$$\sum_{T_N}\sum |y(m,n)|^2 \leq K_1N + K_2, \tag{36}$$

where K_1 and K_2 are constants independent of N.

(ii) *If we have that for all nonegative integer N*

$$S_N = \sum_{T_N}\sum [\|u(m,n)\|^2 - |y(m,n)|^2] \leq K_1N + K_2 \tag{37}$$

then necessarily for all nonnegative integer N we have

$$\sum_{T_N}\sum \|\eta(m,n)\|^2 \leq K_1N + K_2. \tag{38}$$

Proof. Consider a passive realization of H as in (18),(19). If in this realization we denote by $\hat{\phi}(m,n)$ the vector

$$\hat{\phi}(m,n) = \begin{bmatrix} x_h(m+1,n) \\ x_v(m,n+1) \end{bmatrix}, \tag{39}$$

then we have from (18)

$$\begin{aligned} \|\hat{\phi}(m,n)\|^2 &= [D\phi(m,n) + Cu(m,n)]^*[D\phi(m,n) + Cu(m,n)] \\ &= \|\phi(m,n)\|^2 - \|\eta(m,n)\|^2 + \|u(m,n)\|^2 - |y(m,n)|^2, \end{aligned} \tag{40}$$

where the last step follows via the use of (22),(23),(19), and (26). Next, by summing (40) over the set of all (m,n) in T_N we have

$$
\begin{aligned}
\sum_{T_N}\sum \|\hat{\phi}(m,n)\|^2 &= \sum_{T_N}\sum \|\phi(m,n)\|^2 - \sum_{T_N}\sum \|\eta(m,n)\|^2 \\
&+ \sum_{T_N}\sum [\|u(m,n)\|^2 - |y(m,n)|^2]. \qquad (41)
\end{aligned}
$$

Recalling the definition of $\hat{\phi}(m,n)$ and $\phi(m,n)$ in terms of $x_h(m,n)$, $x_v(m,n)$ and then cancelling the identical terms in the left- and right-hand sides of (41) and then finally by adding the terms $x_v(0,N)$ and $x_h(N,0)$ to both sides, we can write

$$
\begin{aligned}
\sum\sum\nolimits_{C_N} \|\phi(m,n)\|^2 &= \sum_{m=0}^{N} \|x_h(m,0)\|^2 + \sum_{n=0}^{N} \|x_v(0,n)\|^2 \\
&- \sum_{T_N}\sum \|\eta(m,n)\|^2 \\
&+ \sum_{T_N}\sum [\|u(m,n)\|^2 - |y(m,n)|^2]. \qquad (42)
\end{aligned}
$$

Note that the above is a manifestation of energy conservation law. The first term in the left-hand side is a measure of energy stored in the realization at the Nth stage of computation, the first two terms in the right-hand side are measures of energy coming from boundary conditions, whereas the second and the third terms, respectively, represent the total dissipation out of and the net flow of energy into the system over the entire region T_N of the 2-D lattice space.

Since the boundary conditions are assumed zero, i.e., $x_h(m,0) = x_v(0,n) = 0$ for all m, n we have the following obvious inequality set:

$$
\sum_{T_N}\sum |y(m,n)|^2 \le \sum_{T_N}\sum \|u(m,n)\|^2 \qquad (43)
$$

and

$$
\sum_{T_N}\sum \|\eta(m,n)\|^2 \le \sum_{T_N}\sum [\|u(m,n)\|^2 - |y(m,n)|^2]. \qquad (44)
$$

Conclusion (i) of the present lemma then follows from (43), whereas conclusion (ii) follows from (37) and (44).

Remark 4.4. If, instead of $x_h(m,0) = x_v(0,n) = 0$ as in the above theorem, we have

$$
\sum_{m=0}^{\infty} \|x_h(m,0)\|^2 \le C_h < \infty; \ \sum_{n=0}^{\infty} \|x_v(0,n)\|^2 \le C_v < \infty, \qquad (45)
$$

then it is clear from (42) that inequalities (43) and (44) still remain valid with an additional finite term $(C_h + C_v)$ in their right-hand sides. The conclusion of Lemma 4.4 thus still holds under this less restrictive situation. The physical implication of this is that if the total energy fed by the boundary values to the system is finite then the hyperstability theorem remains true.

For a complete proof of Theorem 4.1 we will need the following sequence of results of somewhat technical nature.

LEMMA 4.5. *Let $H = H(z_1, z_2)$ be a rational matrix of size $(\ell \times 1)$ which is holomorphic as well as nonzero in $\bar{D}$. Then there exists a rational matrix $G = G(z_1, z_2)$ of size $(1 \times \ell)$ such that $GH = 1$ and each entry of G is holomorphic in $\bar{D}$, i.e., H has a "stable" left inverse G. Furthermore, if H is real rational then so is G.*

Proof. We can write $H = [\phi_{i1}]/d$, where ϕ_{i1}, for $i = 1$ to ℓ and d are polynomials. Clearly, then $d \neq 0$ and the ϕ_{i1}'s are not simultaneously zero in $\bar{D}$.

Next, let (ζ_i, ω_i); $i = 1$ to m (we assume $m < \infty$; otherwise, due to Bezout's theorem in algebraic geometry, the ϕ_{i1}'s must have a common factor, after the extraction of which the essential problem can once again be reduced to the case $m < \infty$) be the common zeros of the set of polynomials ϕ_{i1}; $i = 1$ to ℓ. Let us order these zeros such that $|\zeta_i| > 1$ for $i = 1$ to ν and $|\omega_i| > 1$ for $i = \nu + 1$ to m and then consider the real polynomial

$$\pi = \pi(z_1, z_2) = \prod_{i=1}^{\nu}(z_1 - \zeta_i)(z_1 - \zeta_i^*) \prod_{i=\nu+1}^{m} (z_2 - \omega_i)(z_2 - \omega_i^*).$$

Clearly, π is zero whenever the ϕ_i's simultaneously vanish. Thus, by invoking Hilbert's Nullstellensatz [10, p. 5] it follows that there exists a nonnegative integer μ such that π^μ belongs to the ideal generated by ϕ_{i1}; $i = 1$ to ℓ. That is, there exist polynomials ψ_{1i}; $i = 1$ to ℓ such that $\sum_{i=1}^{\ell} \phi_{i1}\psi_{1i} = \pi^\mu$. Since π is clearly nonzero in $\bar{D}$ the desired result immediately follows by defining $G = [G_{1i}]$ with $G_{1i} = \psi_{1i}/\pi^\mu$ for $i = 1$ to ℓ. Furthermore, if H is real rational then it also follows from Nullstellensatz that ψ_{1i}'s are real polynomials and then G_{1i}'s are real rational functions.

LEMMA 4.6. *If $G = G(z_1, z_2)$ is the (real) rational transfer function of a one-input ℓ-output system and G is holomorphic in $\bar{D}$ then there exists a constant α such that $G_1 = \frac{1}{\alpha}G$ is discrete bounded (real), and thus, G admits a passive realization.*

Proof. Since G is holomorphic in $\bar{D}$, $\alpha = \sup_{\bar{D}} |G| < \infty$. Define then $G_1 = \frac{1}{\alpha}G$, which obviously satisfies $\sup_{\bar{D}} |G_1| = 1$. In particular, $\sup_T |G_1| \leq 1$ i.e., $(I_\ell - \tilde{G}_1 G_1) \geq 0$ on T. This, along with holomorphy of G_1 in $\bar{D}$ imply (cf. Theorem 28 in [23]) that G_1 is a discrete bounded (real) matrix. Thus, in view of Remark 4.1, G_1 admits a passive realization, which, due to $G = \alpha G_1$ and Remark 4.3, implies that G also admits a passive realization.

COROLLARY 4.7. *If H is a (real) rational matrix of size $(1 \times \ell)$ such that it is holomorphic as well as nonzero in $\bar{D}$ then there is a (real) rational left inverse G of H that admits a passive realization.*

Proof. Choose G to be the left inverse of H as prescribed in Lemma 4.5. Since such a G is neccesarily holomorphic in $\bar{D}$, due to Lemma 4.6, it admits a passive realization.

LEMMA 4.8. *Let $G = G(z_1, z_2)$ be a $(1 \times \ell)$ (real) rational matrix which is holomorphic in $\bar{D}$, $u(m, n)$ be the input vector, $y(m, n)$ be the corresponding output from a passive realization of $G(z_1, z_2)$ operating under zero boundary conditions. Then a linear bound on the input energy*

$$\sum_{T_N}\sum \|u(m,n)\|^2 \leq K_1 N + K_2 \quad \text{for all } N \tag{46}$$

implies the following linear bound on the output energy:

(47) $$\sum_{T_N}\sum |y(m,n)|^2 \le (K_1N + K_2)|\alpha|^2 \quad \textit{for all } N,$$

where $\alpha = sup_{\bar{D}}|G(z_1, z_2)| < \infty$ *and* K_1 *and* K_2 *are constants independent of* N.

Proof. Note that in view of Remark 4.3 under the conditions stated $G_\alpha(z_1, z_2) = \frac{1}{\alpha}G(z_1, z_2)$ is a discrete bounded (real) transfer function and a passive realization of G_α is obtained by replacing the A-matrix and the C-matrix in that for G by $A' = \alpha A$ and $C' = \alpha C$, respectively. Equivalently, the two realizations can be viewed as identical with the input for G_α being replaced by $u_\alpha(m,n) = \alpha u(m,n)$. We thus have from (46) that

(48) $$\sum_{T_N}\sum \|u_\alpha(m,n)\|^2 \le (K_1N + K_2)|\alpha|^2.$$

Since G is discrete bounded (real) it follows by invoking Lemma 4.4(ii) that the output $y(m,n)$ from G due to the input $u(m,n)$, which is the same as the output from G_α due to the input $u_\alpha(m,n)$ satisfies the inequality (47).

LEMMA 4.9. *Let* $H = H(z_1, z_2)$ *be a* $(\ell\times 1)$ *rational discrete bounded (real) matrix holomorphic as well as nonzero in* $\bar{D}$. *If the output vector* $y(m,n)$ *from a one-input* ℓ*-output system with transfer function* H *operating under zero boundary conditions corresponding to an input* $u(m,n)$ *is linearly bounded as*

(49) $$\sum_{T_N}\sum \|y(m,n)\|^2 \le K_1N + K_2,$$

then the input $u(m,n)$ *must also be linearly bounded as*

(50) $$\sum_{T_N}\sum |u(m,n)|^2 \le K_1'N + K_2',$$

where $K_1' = |\beta|^2K_1$, $K_2' = |\beta|^2K_2$ *and* K_1, K_2, β *are constants independent of* N.

Proof. Consider a left inverse G of H such that G admits a passive realization. Such a G exists due to Corollary 4.7. Since G is left inverse of H, $u(m,n)$ can be viewed as the output from this passive realization of G, when driven with input $y(m,n)$ under zero boundary conditions. In fact, as in the proof of Lemma 4.8 we have $G_1 = \frac{1}{\beta}G$, where $\beta = \sup_{\bar{D}}|G| < \infty$, G_1 is discrete bounded (real), and realization of G is obtained by multiplying the A-matrix and the C-matrix in that of G_1 by β. Thus, from Lemma 4.4(i) it follows that the output $u(m,n)$ obeys the linear bound (50) with $K_1' = |\beta|^2K_1$, $K_2' = |\beta|^2K_2$.

We now turn to the proof of Theorem 4.1.

Proof of Theorem 4.1. Consider a passive realization of $H(z_1, z_2)$ as in (18) and (19) with associated $\eta(m,n)$ as in (26), where L and W are defined via (20) or (21)–(23). We then have from part (ii) of Lemma 4.4 that if $S_N \le K_1N + K_2$ then

(51) $$\sum_{T_N}\sum \|\eta(m,n)\|^2 \le K_1N + K_2.$$

Next, note that $\eta(m,n)$ can be viewed, as in Corollary 4.3, as the output from a Roesser's state space model described by (25) and (26), which has the transfer function $P(z_1,z_2)$ as in (27). Since $H(z_1,z_2)$ is assumed to be strictly bounded, i.e., $|H| < 1$ in $\bar{D}$, we conclude from (24) that $\tilde{P}P \neq 0$ in $\bar{D}$. In particular, $P \neq 0$ in $\bar{D}$. Also, since H is strictly bounded (real), P along with H is holomorphic in $\bar{D}$. Thus, by likening P with H, and $\eta(m,n)$ with $y(m,n)$ it follows, in view of (51), from Lemma 4.9 that the input $u(m,n)$ to $P(z_1,z_2)$ is linearly bounded as

$$\sum_{T_N}\sum |u(m,n)|^2 \leq K_1'N + K_2', \tag{52}$$

where $K_1'/K_1 = K_2'/K_2 = |\beta|^2$ is a constant as in Lemma 4.9.

Furthermore, since $u(m,n)$ is the input and $y(m,n)$ is the output from the realization (18) and (19) (operating under zero initial conditions), whose transfer function $H = H(z_1,z_2)$ is strictly discrete bounded (real) it follows by again applying Lemma 4.4 (i) that

$$\sum_{T_N}\sum |y(m,n)|^2 \leq K_1'N + K_2'. \tag{53}$$

Part (ii) of Theorem 4.1 corresponds to assuming $K_1 = 0$, $K_2 = K$. Thus, in this case it follows from (53) that $y(m,n) \to 0$ as $(m+n) \to \infty$ in the usual sense. Furthermore, if $K_1 \neq 0$ then the result of part (i) follows by invoking Theorem 3.1 on almost everywhere convergence along with (53).

Alternative strategy of proof of Theorem 4.1. Consider $H(z_1,z_2) = \sum_{r=0}^{\infty} h_r(z_1,z_2)$, where h_r is a homogeneous polynomial of degree r. If H is strictly bounded real rational then $s(\lambda) = H(\lambda z_1, \lambda z_2)$ is a bounded function of λ for fixed z_1, z_2 in the closed unit bidisc.

If $Y(z_1,z_2) = \sum_{m,n}^{\infty} y(m,n)z_1^m z_2^n = \sum_{r=0}^{\infty} y_r(z_1,z_2)$ is the output corresponding to the input $U(z_1,z_2) = \sum_{m,n}^{\infty} u(m,n)z_1^m z_2^n = \sum_{r=0}^{\infty} u_r(z_1,z_2)$, where y_r and u_r are homogeneous polynomials of degree r, then clearly $y_0+\lambda y_1+\cdots = (h_0+\lambda h_1+\cdots)(u_0+\lambda u_1+\cdots)$. By equating coefficients of similar powers of λ we obtain $\tilde{y}_N = \Delta_N \cdot \tilde{u}_N$, where $\tilde{u}_N = [u_0, u_1, \cdots u_N]^t$, $\tilde{y}_N$ is defined analogously, and Δ_N is the lower triangular Toeplitz matrix with its first column equal to $[h_0, h_1, \cdots h_N]^t$. Thus, for any N,

$$||\tilde{u}_N||^2 - ||\tilde{y}_N||^2 = \tilde{u}_N^*(I_{N+1} - \Delta_N^*\Delta_N)\tilde{u}_N \geq (1-\mu_N)||\tilde{u}_N||^2 > 0, \tag{54}$$

where the norm $||\cdot||$ is computed for $z_1 = z_2 = \exp(j\omega)$; ω =real, and μ_N is the largest eigenvalue of $\Delta_N^*\Delta_N$. The last inequality in (54) is a consequence of boundedness of $s(\lambda)$ [16], from which it also follows that there exists an α such that $\mu_N < \alpha^2 < \infty$ for all real ω. Thus,

$$||\tilde{u}_N||^2 \leq \frac{||\tilde{u}_N||^2 - ||\tilde{y}_N||^2}{1-\alpha^2}. \tag{55}$$

But since

$$\left(\frac{1}{2\pi}\right)^2 \int_0^{2\pi}\int_0^{2\pi} ||\tilde{u}_N(e^{j\omega_1}, e^{j\omega_2})||^2 d\omega_1 d\omega_2 = \sum_{T_N}\sum |u(m,n)|^2, \tag{56}$$

it follows that boundedness of S_N as in (12) by $K_1N + K_2$ implies the first equation (13) with $K_i' = K_i/(1 - \alpha^2)$ for $i = 1, 2$, whereas the second equation (13) follows from (54).

For the purpose of application of the 2-D hyperstability theorem to adaptive signal processing in the next section a version different from that in Theorem 4.1 proves to be more appropriate.

THEOREM 4.10 (Positive version). *Let $F = F(z_1, z_2)$ be the scalar rational transfer function of a 2-D quarter plane causal system. Let F be strictly discrete positive (real) (i.e., $\mathrm{Re}F > 0$ in D), $p(m,n)$ be an input , $q(m,n)$ be the corresponding output from the system while the boundary conditions are assumed to be zero . Also let*

$$E_N = \mathrm{Re}\left\{\sum_{T_N}\sum p^*(m,n)q(m,n)\right\}. \tag{57}$$

Then we have the following:

(i) *If $E_N \leq K - 1N + K_2$, where K_1 and K_2 are constants independent of N then*

$$\sum_{T_N}\sum |p(m,n)|^2 \leq K_1'N + K_2',$$

$$\sum_{T_N}\sum |q(m,n)|^2 \leq K_1'N + K_2',$$

where $K_1' = |\beta|^2K_1, K_2' = |\beta|^2K_2$, and β are finite constants independent of N. Consequently, $p(m,n)$ and $q(m,n)$ converge to zero almost everywhere in the sense decribed earlier.

(ii) *If $E_N \leq K < \infty$ for every nonnegative integer N then we have that $p(m,n) \to 0$ and $q(m,n) \to 0$ as $(m+n) \to \infty$ in the usual sense.*

Proof. Consider signals $u(m,n) = p(m,n) + q(m,n)$ and $y(m,n) = P(m,n) - q(m,n)$, which can be viewed, respectively, as the input and the corresponding output from a system with transfer function $H = (1 - F)/(1 + F)$ operating under zero initial conditions. Since F is strictly discrete postive (real), it follows that H is strictly discrete bounded (real). Furthermore, since $4\Re\{p^*(m,n)q(m,n)\} = |u(m,n)|^2 - |y(m,n)|^2$ we have if $E_N \leq K_1N + K_2$ then

$$S_N = \sum_{T_N}\sum |u(m,n)|^2 - y|(m,n)|^2 \leq 4(K_1'N + K_2'). \tag{58}$$

It then follows from Theorem 4.1(i) that both $u|(m,n)|^2$ and $y|(m,n)|^2$ satisfy (13) for some constants $K_1', K_2', |\beta|$ independent of N such that $K_1' = |\beta|^2, K_2' = |\beta|^2K_2$:

$$\sum_{T_N}\sum |u(m,n)|^2 \leq K_1'N + K_2',$$

$$\sum_{T_N}\sum |y(m,n)|^2 \leq K_1'N + K_2'.$$

Thus, since $|p(m,n)|^2 + |q(m,n)|^2 = \frac{1}{2}(|u(m,n)|^2 = |y(m,n)|^2)$ it follows that

$$\sum_{T_N}\sum |p(m,n)|^2 \leq K_1'N + K_2',$$

$$\sum_{T_N}\sum |q(m,n)|^2 \le K_1'N + K_2'.$$

The rest of the arguement then follows as in the proof of Theorem 4.1.

5. A 2-D hyperstability based adaptive filtering scheme. In this section we demonstrate an application of 2-D hyperstability type results to problems of adaptive 2-D signal processing. The framework for this study is a direct 2-D generalization of that known as the HARF (hyperstable adaptive recursive filtering) algorithm in 1-D signal processing literature (see [28]–[32], [38]), which in turn is a modification of certain system identication techniques documented in [40].

The signal to tracked is assumed to be generated by a quarter plane causal linear shift invariant (LSI) ARMA process whose transfer function is assumed holomorphic in $\bar{D}$ and is thus stable in a strict sense [23]. Consequently,

$$y(m,n) = \sum_{\substack{k=0 \\ k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1} a_{k\ell}\,y(m-k,n-\ell) + \sum_{k=0}^{M_2}\sum_{\ell=0}^{N_2} b_{k\ell}\,u(m-k,n-\ell) \tag{59}$$

The estimated signal $\hat{y}(m,n)$ is obtained as

$$\hat{y}(m,n) = \sum_{\substack{k=0 \\ k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1} \hat{a}_{k\ell}(m,n)f(m-k,n-\ell) + \sum_{k=0}^{M_2}\sum_{\ell=0}^{N_2} \hat{b}_{k\ell}(m,n)u(m-k,n-\ell), \tag{60}$$

where $f(m-k,n-\ell)$, as described via (61), is the output from an auxiliary quarter plane shift varying recursive process driven by the same input $u(\cdot,\cdot)$ as in (59),(60):

$$\begin{aligned} f(m,n) &= \sum_{\substack{k=0 \\ k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1} \hat{a}_{k\ell}(m+1,n+1)f(m-k,n-\ell) \\ &+ \sum_{k=0}^{M_2}\sum_{\ell=0}^{N_2} \hat{b}_{k\ell}(m+1,n+1)u(m-k,n-\ell) \end{aligned} \tag{61}$$

Finally, the coefficients $\hat{a}_{k\ell}(m,n)$ and $\hat{b}_{k\ell}(m,n)$ are adapted according to the following adaptation rules:

$$\hat{a}_{k\ell}(m+1,n+1) = \hat{a}_{k\ell}(m,n) + \mu_{k\ell}\hat{y}(m-k,n-\ell)\frac{\bar{v}(m,n)}{t(m,n)} \tag{62}$$

$$\hat{b}_{k\ell}(m+1,n+1) = \hat{b}_{k\ell}(m,n) + \rho_{k\ell}u(m-k,n-\ell)\frac{\bar{v}(m,n)}{t(m,n)}, \tag{63}$$

where

$$(64)\ \bar{v}(m,n) = y(m,n) - \hat{y}(m,n) + \sum_{\substack{k=0 \\ k+\ell\neq 0}}^{L_1} \sum_{\ell=0}^{L_2} c_{k\ell}[y(m-k,n-\ell) - f(m-k,n-\ell)]$$

and

$$(65)\quad t(m,n) = 1 + \sum_{\substack{k=0 \\ k+\ell\neq 0}}^{M_1} \sum_{\ell=0}^{N_1} \mu_{k\ell} f^2(m-k,n-\ell) + \sum_{k=0}^{M_2} \sum_{\ell=0}^{N_2} \rho_{k\ell} u^2(m-k,n-\ell),$$

where $\mu_{k\ell} \geq 0$, $\rho_{k\ell} \geq 0$, are some constants and with $c_{k\ell}$'s to be specified appropriately so that the algorithm converges, i.e., $y(m,n) \to \hat{y}(m,n)$ in some sense.

In fact, the adaptation scheme (60)–(65) can be more transparently viewed by considering the difference signal

$$(66)\qquad e(m,n) = y(m,n) - f(m,n),$$

which drives the moving average process with transfer function:

$$(67)\qquad \sum_{k=0}^{L_1} \sum_{\ell=0}^{L_2} c_{k\ell} z_1^k z_2^\ell;\ c_{00} = 1$$

to yield the averaged output $v(m,n)$. The estimation error signal $(y(m,n) - \hat{y}(m,n))$ is then added to it to yield $v(m,n) + (y(m,n) - \hat{y}(m,n))$, which in turn drives the adaptation algorithm. The scheme can be represented via signal flow diagram as in Fig. 3.

It is not necessary for the sizes of the masks $\{\hat{a}_{k\ell}(\cdot,\cdot)\}$ and $\{\hat{b}_{k\ell}(\cdot,\cdot)\}$ to be the same as those for $\{a_{k\ell}\}$ and $\{b_{k\ell}\}$. The only restriction is that the supports of the masks $\{\hat{a}_{k\ell}(\cdot,\cdot)\}$ and $\{\hat{b}_{k\ell}(\cdot,\cdot)\}$, respectively contain those of $\{a_{k\ell}\}$ and $\{b_{k\ell}\}$. However, to keep notational complications down we have assumed the masks to have same support.

We next demonstrate that (59)–(65) combined with adequate boundary conditions in fact determine a valid quarter plane causal recursive scheme. For this, we first assume that all of the boundary values needed for computation, namely $f(m,n)$, where m and/or n is negative and $\hat{a}_{k\ell}(m,0)$, $\hat{b}_{k\ell}(0,n)$ for $m \geq 0$, $n \geq 0$ are all zero. We further assume that $\hat{a}_{k\ell}(m,n)$, $\hat{b}_{k\ell}(m,n)$ are known for $(m,n) \in C_N$ and $(m,n) \in C_{N+1}$. Also, we assume that $f(m,n)$'s are known in $R_{P,N-1}$, where $P = 2\max(M_1,N_1)$ and the input $u(m,n)$'s are known in $R_{Q,N}$, where $Q = 2\max(M_2,N_2)$.

We then first use (60) to compute $\hat{y}(m,n)$ on C_N. Next we compute $\hat{a}_{k\ell}(m,n)$, $\hat{b}_{k\ell}(m,n)$ on C_{N+2} by using (62)–(65). Finally, $f(m,n)$ on C_N can be computed using (61). We then obviously have $f(m,n)$ in $R_{P,N}$, while $u(m,n)$ in $R_{Q,N+1}$ is obtained from the input data. The recursive scheme described above can then be repeated for larger values of N.

Our next task is to show the convergence of the estimated signal $\hat{y}(m,n)$ to the desired signal $y(m,n)$. For this, let us define

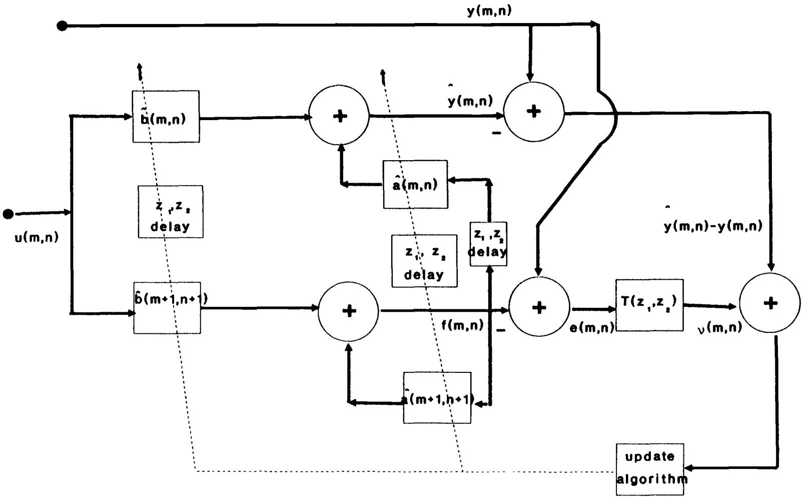

FIG. 3

$$
\begin{aligned}
&(68) \qquad w(m,n) = \sum_{\substack{k=0\\k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1}[a_{k\ell} - \hat{a}_{k\ell}(m+1,n+1)]f(m-k,n-\ell)\\
&(69) \qquad\qquad\quad + \sum_{k=0}^{M_2}\sum_{\ell=0}^{N_2}[b_{k\ell} - \hat{b}_{k\ell}(m+1,n+1)]u(m-k,n-\ell).
\end{aligned}
$$

We obviously have (see Fig. 3) that

$$
v(m,n) = \sum_{k=0}^{L_1}\sum_{\ell=0}^{L_2} c_{k\ell}e(m-k,n-\ell). \tag{70}
$$

Furthermore, via some algebraic manipulations we can write

$$
e(m,n) = \sum_{\substack{k=0\\k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1} a_{k\ell}e(m-k,n-\ell) + w(m,n). \tag{71}
$$

Consequently, the transfer function between $v(m,n)$ and $w(m,n)$ is given by

$$
T = \frac{\sum_{k=0}^{L_1}\sum_{\ell=0}^{L_2} c_{k\ell}z_1^k z_2^\ell}{1 - \sum_{k=0}^{M_1}\sum_{\ell=0}^{N_1} a_{k\ell}z_1^k z_2^\ell}. \tag{72}
$$

The entire feedback system of (62)–(65) can then be combined into the closed-loop configuration in Fig. 4., where the upper block is a linear shift invariant 2-D system with transfer function $T = T(z_1, z_2)$.

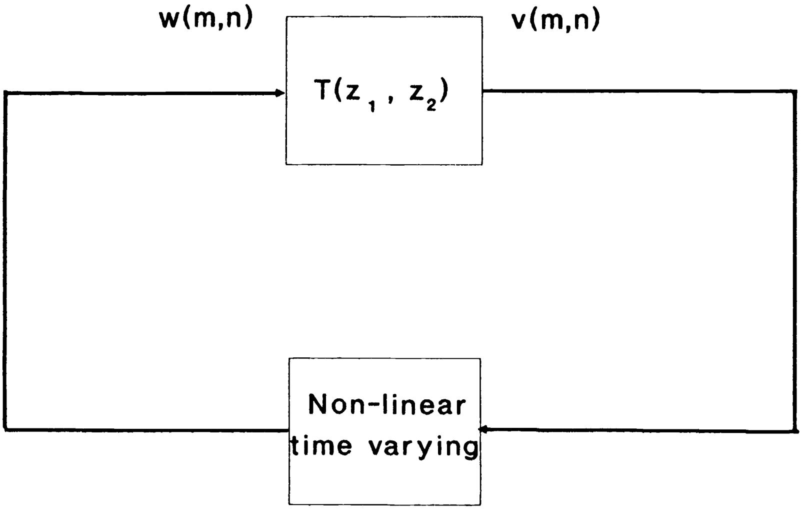

FIG. 4

Note that the denominator polynomial in T is the denominator of the transfer function of the unknown process given in (59), and is assumed to be devoid of zeros in $\bar{D}$, or in the terminology of [23] is a strictly Schur, thus, in particular, an immittance Schur polynomial. As shown in Theorem 27 of [23], given (real) $a_{k\ell}$'s it is then possible to find $c_{k\ell}$'s in (72) such that T is a discrete positive (real) function. It then follows that one can also find $c_{k\ell}$'s such that T is strictly discrete positive (real) (for example, if H is a (real) rational discrete positive, holomorphic in $\bar{D}$ then $1+H$ is (real) rational strictly discrete positive (real) and has the same denominator as in H).

Remark 5.1. We further wish to remark that the above considerations demand that the $a_{k\ell}$'s be known, which in reality are not. However, some knowledge of the values of the parameters $a_{k\ell}$'s, namely, a range of allowable values may be available. It has recently been shown [21] that via an extension of Kharitonov-theory for robustness of stability (see [43] for 1-D results) that in such a case it is possible to specify admissible intervals for the $c_{k\ell}$'s so that T in (72) remains strictly positive (real).

Before a complete proof of convergence of the adaptation algorithm can be given it would be necessary to focus on a 2-D state space realization of $T(z_1, z_2)$. The entire purpose of this discussion in the present context is to demonstrate that there is a realization of T for which it is reasonable to assume that the boundary conditions are zero.

For this, define the following variables for the state-variables of the Roesser's state space model:

$$(73) \qquad \bar{e}(m,n) \overset{\text{def}}{=} y(m,n) - f(m,n)$$

$$e_v(m,n) \overset{\text{def}}{=} \begin{bmatrix} \bar{e}(m,n-1) \\ \bar{e}(m,n-2) \\ \vdots \\ \bar{e}(m,n-N_1) \end{bmatrix} \tag{74}$$

$$e_h(m,n) \overset{\text{def}}{=} \begin{bmatrix} \bar{e}_{m-1,n} \\ \bar{e}_{m-2,n} \\ \vdots \\ \bar{e}_{m-1,N_1} \end{bmatrix}, \tag{75}$$

where

$$\bar{e}_{\mu,\nu} \overset{\text{def}}{=} \begin{bmatrix} \bar{e}(\mu,\nu) \\ \bar{e}(\mu,\nu-1) \\ \vdots \\ \bar{e}(\mu,\nu-N_1) \end{bmatrix}. \tag{76}$$

The feedback matrix $\mathcal{A}$ in the Roesser state space model is then defined as the matrix $\bar{A}$ from which the N_1-the row and the first column has been deleted and

$$\bar{A} \overset{\text{def}}{=} \begin{bmatrix} A_0 & A_1 & \cdots & \cdots & A_{M_1} \\ A_0 & A_1 & \cdots & \cdots & A_{M_1} \\ \bigcirc & I & \cdots & \cdots & \bigcirc \\ \vdots & \vdots & & & \vdots \\ \bigcirc & \bigcirc & \cdots & \cdots & I \end{bmatrix}, \tag{77}$$

where

$$A_i \overset{\text{def}}{=} \left.\begin{bmatrix} a_{i0} & a_{i1} & \cdots & a_{iN_1} \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix}\right\} (n_2+1); \text{ for } i = 1 \text{ to } M_1 \tag{78}$$

and A_0 is the top companion matrix whose first row is $[\ a_{00} \quad a_{01} \quad \cdots \quad a_{1N_1}\ ]$.

The input matrix is $\mathcal{B} = [1\ 0 \cdots 0]^T$ and the output matrix $\mathcal{C}$ is the matrix $\bar{C}$ from which the first entry has been deleted and where

$$\bar{C}^T \overset{\text{def}}{=} [\ \bar{C}_0^T \quad \bar{C}_1^T \quad \cdots \quad \bar{C}_{M_1}^T\ ] \tag{79}$$

with

$$\bar{C}_i^T \overset{\text{def}}{=} [c_{i0}\ c_{i1} \cdots c_{iN_1}] \text{ for } i = 0 \text{ to } M_1. \tag{80}$$

We then have equations (81) and (82) for a 2-D Roesser state space model in standard form.

$$\begin{bmatrix} e_v(m,n+1) \\ e_h(m+1,n) \end{bmatrix} = \mathcal{A} \begin{bmatrix} e_v(m,n) \\ e_h(m,n) \end{bmatrix} + \mathcal{B}w(m,n) \tag{81}$$

$$v(m,n) = \mathcal{C} \begin{bmatrix} e_v(m,n) \\ e_h(m,n) \end{bmatrix} + w(m,n) \tag{82}$$

realizing the transfer function $T = T(z_1, z_2)$. The details of algebraic manipulations verifying this fact is routine and runs parallel to the 1-D case [29]. The essential point for us is that since it is reasonable to assume that $y(k,0) = y(0,\ell) = 0$ for $k < 0$, $\ell < 0$, by imposing

$$f(k,0) = f(0,\ell) = 0 \text{ for } k < 0, \ell < 0 \tag{83}$$

it can be seen in view of (73) to (76) that $e_v(0,n) = 0$, $e_h(m,0) = 0$ for all nonnegative values of m and n.

We are now ready to derive the promised convergence result.

THEOREM 5.1. *Assume the following regarding the above recursive scheme*:

1. *T in* (72) *is strictly discrete positive (real).*
2. *Boundary conditions in the auxiliary process f(m,n) are set to zero as in* (83).
3. *The input signal is bounded, i.e.,* $|u(m,n)| < K < \infty$ *for all* m, n; K *=constant.*
4. *Each of the estimated parameter values* $\hat{a}_{k\ell}(m,n)$, $\hat{b}_{k\ell}(m,n)$ *are zero along the boundary, i.e., if* $m = 0$ *and/or* $n = 0$.

Then the estimated signal $\hat{y}(m,n)$ *converges to the desired signal* $y(m,n)$ *in the sense that* $(\hat{y}(m,n) - y(m,n))$ *converges to zero in the almost everywhere sense.*

Proof. We first define the parameter estimation errors:

$$\bar{a}_{k\ell}(m,n) = a_{k\ell} - \hat{a}_{k\ell}(m,n) \tag{84}$$

$$\bar{b}_{k\ell}(m,n) = b_{k\ell} - \hat{b}_{k\ell}(m,n). \tag{85}$$

Also, routine algebraic manipulation with (62)–(66) and (70) yields

$$\bar{v}(m,n) = v(m,n)t(m,n). \tag{86}$$

Further manipulations as elaborated in [28] in the 1-D case can be performed with (86) to produce the following expression for $w(m,n)v(m,n)$:

$$\begin{aligned} 2w(m,n)v(m,n) &= s(m,n) - s(m+1,n+1) \\ &- \{\sum_{\substack{k=0 \\ k+\ell\neq 0}}^{M_1} \sum_{\ell=0}^{N_1} \mu_{k\ell} f^2(m-k,n-\ell)v^2(m,n) \\ &+ \sum_{k=0}^{M_2} \sum_{\ell=0}^{N_2} \rho_{k\ell} u^2(m-k,n-\ell)v^2(m,n)\}, \end{aligned} \tag{87}$$

where

$$s(m,n) = \sum_{\substack{k=0\\ k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1} \bar{a}_{k\ell}^2(m,n)/\mu_{k\ell} + \sum_{k=0}^{M_2}\sum_{\ell=0}^{N_2} \bar{b}_{k\ell}^2(m,n)/\rho_{k\ell}. \tag{88}$$

Since $\mu_{k\ell} \geq 0$, $\rho_{k\ell} \geq 0$ by choice of these parameters, we have from (87) that for all (m,n):

$$2w(m,n)v(m,n) \leq s(m,n) - s(m+1,n+1). \tag{89}$$

Considering (89) for each $(m,n) \in T_N$, adding the resulting set of inequalities, and finally cancelling the common terms with opposite sign we then obtain (90)

$$2\sum\sum_{T_N} w(m,n)v(m,n) \leq \{s(0,0) + \sum_{m=1}^{N} s(m,0) + \sum_{n=1}^{N} s(0,n)\} - \sum_{D_N} s(m,n), \tag{90}$$

where $D_N = C'_{N+1} \cup C'_{N+2}$ and $C'_N = C_N \setminus \{(N,0)\} \cup \{(0,N)\}$.

Since as is obvious from (88) the last term in (90) can be dropped without affecting the inequality. Inequality (91) is then obtained by substituting for $s(m,n)$ from (88) in the resulting inequality:

$$\begin{aligned} &\sum\sum_{T_N} w(m,n)v(m,n) \\ &\leq \frac{1}{2}[\sum_{\substack{k=0\\ k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1}\{\sum_{n=1}^{N} \bar{a}_{k\ell}^2(0,n) + \sum_{m=1}^{N} \bar{a}_{k\ell}^2(m,0) + \bar{a}_{k\ell}^2(0,0)\} \\ &\quad + \sum_{k=0}^{M_2}\sum_{\ell=0}^{N_2}\{\sum_{n=1}^{N} \bar{b}_{k\ell}^2(0,n) + \sum_{m=1}^{N} \bar{b}_{k\ell}^2(m,0) + \bar{b}_{k\ell}^2(0,0)\}]. \end{aligned} \tag{91}$$

Also, since the parameter estimates along the boundary $(m,0)$ and $(0,n)$ are set to zero, we have $\bar{a}_{k\ell}(0,n) = \bar{a}_{k\ell}(m,0) = a_{k\ell}$, $\bar{b}_{k\ell}(0,n) = \bar{b}_{k\ell}(m,0) = b_{k\ell}$. Thus, (91) above yields

$$\sum\sum_{T_N} w(m,n)v(m,n) \leq K_1 N + K_2, \tag{92}$$

where

$$K_1 = 2K_2 = \sum_{\substack{k=0\\ k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1} a_{k\ell}^2 + \sum_{k=0}^{M_2}\sum_{\ell=0}^{N_2} b_{k\ell}^2. \tag{93}$$

Next, observe that $w(m,n)$ and $v(m,n)$ are, respectively, the input and output from the transfer function T, which is strictly discrete positive (real). Furthermore, since the system realizing T can be assumed to be operating under zero boundary conditions the total response due to the system (including the transient response) is equal to its zero state response and is solely determined by the transfer function T. Thus, the realization given by (81) and (82) can be replaced by a passive realization of T operating under zero boundary conditions without altering $w(m,n)$ and $v(m,n)$. Theorem 4.10 thus applies to the present situation, which in turn yields that

$$\sum_{T_N}\sum |v(m,n)|^2 \leq K_1'N + K_2' \tag{94}$$

for some constants K_1' and K_2'.

Next, observe that the moving average transfer function $\sum_{k=0}^{L_1}\sum_{\ell=0}^{L_2} c_{k\ell} z_1^k z_2^\ell$ is nonzero in $\bar{D}$, has $e(m,n)$ at its input and $v(m,n)$ satisfying (94) as its output when implemented with zero boundary conditions. Thus by invoking Lemma 4.9 it follows that

$$\sum_{T_N}\sum |e(m,n)|^2 \leq K_1''N + K_2'', \tag{95}$$

where K_1'' and K_2'' are some constants independent of N. We, therefore, have from Theorem 3.1 that $e(m,n) = y(m,n) - f(m,n)$ converges to zero almost everywhere. In particular, $e(m,n)$ is asymptotically bounded almost everywhere. But since $y(m,n)$ is the output from a quarter plane causal strictly discrete positive real, thus bounded input bounded output stable [15] transfer function with bounded input $|u(m,n)| < K$, $y(m,n)$ must be bounded for all $m, n \geq 0$. Consequently, it follows from Proposition 3.4(i) that $f(m,n) = y(m,n) - e(m,n)$ must be asymptotically bounded almost everywhere.

Next, recall that (86) can, by using (65), be explicitly written as

$$\begin{aligned}\bar{v}(m,n) &= v(m,n)\\ &\cdot\left\{1 + \sum_{\substack{k=0\\ k+\ell\neq 0}}^{M_1}\sum_{\ell=0}^{N_1}\mu_{k\ell} f^2(m-k,n-\ell) + \sum_{k=0}^{M_2}\sum_{\ell=0}^{N_2}\rho_{k\ell}u^2(m-k,n-\ell)\right\}.\end{aligned} \tag{96}$$

Invoking almost everywhere asymptotic boundedness property of $f(m,n)$, the boundedness $|u(m,n)| < K$, and Proposition 3.4 it follows that the term inside the brackets in (96) is asymptotically bounded almost everywhere. Since $v(m,n)$ converges to zero almost everywhere, by Proposition 3.3 so does $\bar{v}(m,n)$. Finally, by recalling from (64) that

$$\begin{aligned}&\hat{y}(m,n) - y(m,n)\\ &\quad = \bar{v}(m,n) - \sum_{\substack{k=0\\ k+\ell\neq 0}}^{L_1}\sum_{\ell=0}^{L_2} c_{k\ell}\{y(m-k,n-\ell) - f(m-k,n-\ell)\}\end{aligned} \tag{97}$$

and using the facts that both $\bar{v}(m,n)$ and $\{y(m,n)-f(m,n)\}$ converges to zero almost everywhere along with Proposition 3.2 we conclude that $\hat{y}(m,n)-y(m,n)$ converges to zero almost everywhere, thus completing the proof of Theorem 5.1.

We also have the following more restrictive result.

THEOREM 5.2. *Assuming* (1) *through* (3) *in Theorem* 5.1 *to hold and that the parameter estimates are such that for each k, ℓ*

$$\sum_{m=0}^{N} \bar{a}_{k\ell}^2(m,0) < \infty; \sum_{n=0}^{N} \bar{a}_{k\ell}^2(0,n) < \infty \tag{98}$$

and

$$\sum_{m=0}^{N} \bar{b}_{k\ell}^2(m,0) < \infty; \sum_{n=0}^{N} \bar{b}_{k\ell}^2(0,n) < \infty \tag{99}$$

hold true in the recursive scheme described via (59)–(65), *we have that $\hat{y}(m,n)$ converges to $y(m,n)$ in the usual sense as $(m+n) \to \infty$.*

Proof. It follows from (91),(98), and (99) that under the conditions stated

$$\sum\sum_{T_N} w(m,n)v(m,n) < \infty \tag{100}$$

for every N, i.e., (92) is satisfied with $K_1 = 0$ and some K_2, not necessarily given by (94). Following a similar chain of arguments we then conclude:

$$\sum\sum_{T_N} |e(m,n)|^2 < \infty$$

as a counterpart of (95). Thus, we have $e(m,n) \to 0$ as $(m+n) \to \infty$. The rest of the proof follows by mimicking arguments in the proof of Theorem 5.1, but now using convergence and boundedness in the usual sense.

Satisfaction of conditions (98) and (99), in view of (84) and (85), require that the chosen boundary values of the parameter estimates along the boundary $(m,0)$ and $(0,n)$ are asypmtotically (i.e., as $m \to \infty$, $n \to \infty$) the correct (unbiased) estimates. Although there is no way to guarantee this, some intelligent choice of these may, in practice, yield better results than the most conservative strategy of setting them to zero as in Theorem 5.1. A suggestion is to set $\hat{a}_{k\ell}(m,0) = \hat{a}_{k\ell}(m-1,1)$ and $\hat{a}_{k\ell}(0,n) = \hat{a}_{k\ell}(1,n-1)$, the latter quantities having been computed via the parameter update scheme (62) to (65). Similarly for the $\hat{b}_{k\ell}(m,n)$'s when m and/or n is zero. However, such a scheme, although reasonable from an intuitive viewpoint, defies our convergence analysis presented above.

6. Discussions and Conclusions. A continuous domain analogue of the 2-D hyperstability theory can be developed and the results applied to a continuous version of the adaptive filtering problem. Note that a continuous version of hyperstable adaptive identifier exists in 1-D literature [40].

A straightforward n-D ($n > 2$) extension of the theory developed here does not seem to be possible because of the following two reasons. First, a higher dimensional analogue of Landau's theorem does not exist, and second, perhaps more serious, is the infeasibility of synthesis of lossless n-D ($n > 2$) paraunitary matrices holomorphic in $\bar{D}$ [26]. Although a passive realizability theory based approach to higher dimensional problems is not possible due to the above reasons, since the essential contents of Theorems 4.1 and 4.10 do not state anything regarding the realization of $H(z_1, z_2)$ or $F(z_1, z_2)$, but only have to do with its input-output properties, namely, strict positivity or boundedness, an approach using exclusively transform domain methods may be fruitful.

A matricial generalization of the hyperstability Theorems 4.1 and 4.10 for multi-input–multi-output 2-D systems may be conjectured, but a proof would require a matrix version of Landau's theorem, or equivalently, an appropriate 2-D generalization of Youla's spectral factorability result [27] in our context.

The vital importance of the spectral factorability [27] result mentioned above in diverse areas of 1-D system theory is well known. Since Landau's theorem can, in some sense, be viewed as a 2-D scalar analogue of this result, we believe that many other ramifications of it would be possible in the context of 2-D systems. In the present paper we have demonstrated its use in 2-D hyperstability theory and in 2-D adaptive filtering only.

In all of the 2-D recursions considered in the present paper, the set of points C_N of the 2-D lattice space for a fixed N, has been viewed as a "computational wavefront," i.e., all points on C_N can be simultaneously computed from C_{N-1}, C_{N-2}, $\cdots$, etc. While this is attractive and may have some advantages in parallel implementation, the role of C_N as a computational wavefront can be replaced by L-shaped sets: $L_N = \{(m, N); m = 0 \text{ to } N\} \cup \{(N, n); n = 0 \text{ to } N\}$ in the 2-D lattice space. In fact, all results of §§3 and 4 can be modified accordingly. It should then be possible to derive an appropriate version of the HARF algorithm for this recursive scheme. Apart from other possibilities of recursion, the 2-D HARF can be simplified as in 1-D [30], [31] and it is likely that its properties can be studied via 2-D Lyapunov theory [20].

A. Some results on 2-D passive synthesis. THEOREM A.1 (E. LANDAU [7]). *Let $f(x_1, x_2)$ be a polynomial in x_1, x_2 with real coefficients, which is such that $f(x_1, x_2) \geq 0$ for all real x_1, x_2. Then $f(x_1, x_2)$ can be written as*

$$f(x_1, x_2) = \frac{1}{d(x_1)} \sum_{i=1}^{\nu} N_i^2(x_1, x_2) \tag{101}$$

where $d(x_1)$, $N_i(x_1, x_2)$; $i = 1$ to ν are polynomials with real coefficients and the integer ν is at most equal to 4.

LEMMA A.2. *Let $S = N/g$ be a bounded (real) matrix of size $(1 \times n)$ in two variables p_1, p_2 i.e., $SS_* \leq 1$ in* Re $p_1 > 0$, Re $p_2 > 0$, *where N is a polynomial row vector and g is the least common denominator of S. Then $(gg_* - NN_*)$ can be decomposed as:*

$$gg_* - NN_* = \frac{1}{dd_*} \sum_{i=1}^{m} P_{i*} P_i \tag{102}$$

where each P_i is a polynomial in two variables p_1 and p_2, and d is a one variable polynomial in p_1 (or p_2) devoid of zeros in the open right half plane and $m \leq 2$.

Proof. Since S is a bounded (real) function we have that $(gg_* - NN_*) \geq 0$ for all $p_1 = j\omega_1$ and $p_2 = j\omega_2$. Furthermore, for $p_1 = j\omega_1$ and $p_2 = j\omega_2$ $(gg_* - NN_*)$ can be viewed as a polynomial in ω_1 and ω_2, with real coefficients. Thus, by Landau's theorem we can write for $p_1 = j\omega_1$ and $p_2 = j\omega_2$ that

$$gg_* - NN_* = \frac{1}{D(\omega_1)} \sum_{i=1}^{\nu} P_i^2(\omega_1, \omega_2) \tag{103}$$

where D and each P_i are polynomials with real coefficients and $\nu \leq 4$.

Assume without loss of generality that ν =even, and let $m = \nu/2$. By using the identity $P^2 + Q^2 = (P + jQ)(P - jQ)$ in (103) we can then write

$$\sum_{i=1}^{\nu} P_i^2(\omega_1, \omega_2) = \sum_{i=1}^{m} M_i(\omega_1, \omega_2) M_i^*(\omega_1, \omega_2) \tag{104}$$

where M_i's in (104) are polynomials in ω_1, ω_2 with coefficients complex conjugates of those in M_i^*'s.

Note further that since $(gg_* - NN_*) \geq 0$ for all $p_1 = j\omega_1$, $p_2 = j\omega_2$ and real ω_1, ω_2 it follows from (103) that $D(\omega_1) \geq 0$ for all ω_1. Thus, by a standard result, $D(\omega_1)$ can be written as $D(\omega_1) = M_D(\omega_1) M_D^*(\omega_1)$, where $M_D(\omega_1)$ is a polynomial with coefficients complex conjugates of those in $M_D^*(\omega_1)$. To summarize, the polynomial identity

$$M_D(\omega_1) M_D^*(\omega_1)(gg_* - NN_*) = \sum_{i=1}^{m} M_i(\omega_1, \omega_2) M_i^*(\omega_1, \omega_2) \tag{105}$$

holds for all real valued ω_1, ω_2.

Now consider the polynomials $P_i = P_i(p_1, p_2)$, of which the coefficients are such that $P_i(j\omega_1, j\omega_2) = M_i(\omega_1, \omega_2)$. Then $P_{i*}(j\omega_1, j\omega_2) = M_i^*(\omega_1, \omega_2)$. Thus, we have $P_i(p_1, p_2) P_{i*}(p_1, p_2) = M_i(\omega_1, \omega_2) M_i^*(\omega_1, \omega_2)$ for $p_1 = j\omega_1$, $p_2 = j\omega_2$, where ω_1, ω_2 are arbitrary real. Via the same argument we can then write: $d_1(p_1) d_{1*}(p_1) = M_D(\omega_1) M_D^*(\omega_1)$, where $d_1(p_1)$ is a real polynomial in p_1 and $d_{1*}(p_1)$ is its paraconjugate. Thus, from (105) we can write that

$$d_1 d_{1*}(gg_* - NN_*) = \sum_{i=1}^{m} P_i P_{i*} \tag{106}$$

holds for $p_1 = j\omega_1$ and $p_2 = j\omega_2$, with ω_1, ω_2 arbitrary real, where the criptic notation $d_1 = d_1(p_1)$, $P_i = P_i(p_1, p_2)$ have been used. Since (106) is a polynomial equation we can conclude from an analytic continuation argument that (106), in fact, holds for all p_1 and p_2.

Finally, we can write $d_1 d_{1*} = dd_*$ via a regrouping of the factors of $d_1 d_{1*}$ such that the polynomial $d = d(p_1)$ does not have any zero in open right half plane. The validity of (102) is thus established from (106). The form (102) with $d = d(p_2)$ is obtained in exactly similar manner by choosing D to be a polynomial in ω_2 in the Landau decomposition.

THEOREM A.3 (Continuous embedding). [2] *Let N/g be a 2-D (real) rational matrix of size $(1 \times n)$, where $N = N(p_1, p_2)$ is a polynomial row vector of size $(1 \times n)$ and $g = g(p_1, p_2)$ the least common denominator polynomial of N/g. If N/g is, in addition, a bounded (real) matrix then there exists a 2-D lossless bounded (real) rational $(m \times m)$ matrix $(m > n)$ (i.e., H is holomorphic in* Re $p_1 > 0$, Re$p_2 > 0$ *with $HH_* = I_m$) such that H can be partitioned as*

$$H = \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}; \text{ where } H_{11} = \frac{N}{g}. \tag{107}$$

Remark A.1. An analogous result, if N/g is an $(n \times 1)$ vector, can be proven in a similar manner, but we do not require this in the context of this paper. However, if N/g is an $(m \times n)$ matrix $(m, n > 1)$ then a similar result can be conjectured, but is presently not available.

Proof of Theorem A.3. Define an $(n \times n)$ polynomial matrix S_{11} such that the first row of S_{11} is N/g and the rest of the elements are zero. Also, since N/g is discrete bounded (real) it follows from Lemma A.2 that there exists a polynomial row vector $V = V(p_1, p_2)$, say, of size $(1 \times m)$ such that

$$1 - \frac{NN_*}{gg_*} = \frac{VV_*}{(gd)(gd)_*}, \tag{108}$$

where d is a polynomial in p_1 only, devoid of zeros in the open right half plane. Next, define a rational matrix S_{12} of size $n \times (m + n - 1)$ as

$$S_{12} = \begin{bmatrix} \frac{V}{gd} & 0 \\ 0 & I_{n-1} \end{bmatrix} \tag{109}$$

and two further matrices S_{21} and S_{22} as

$$S_{21} = S'_{21}\frac{\alpha}{\alpha_*}; \; S'_{21} = -S_{12*}(I + S_{11*})^{-1}(I + S_{11}) \tag{110}$$

$$S_{22} = S'_{22}\frac{\alpha}{\alpha_*}; \; S'_{22} = I - S_{12*}(I + S_{11*})^{-1}S_{12}, \tag{111}$$

where α is a polynomial to be specified later in course of the proof, and I's are identity matrices of appropriate sizes. It can then be routinely verified that the square matrix S of size $(m + 2n - 1)$ as in

$$S = \begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix} \tag{112}$$

satisfies $SS_* = I$.

[2] Subsequent to the preparation of the paper, this result has been derived from Landau's theorem for matrix (not necessarily vector) valued N/g in [17] and its consequences in passive synthesis is discussed in [18].

We next claim that by proper choice of α it is possible to make S holomorphic in Re $p_1 > 0$, Re $p_2 > 0$. For this, first note that S_{11} and S_{12} are clearly holomorphic in Re$p_1 > 0$, Re $p_2 > 0$, and choose α to be product of those irreducible factors in the least common denominator of $S_{12*}(I + S_{11*})^{-1}$ having a zero in Re $p_1 > 0$, Re $p_2 > 0$. Since S_{11} is a discrete bounded matrix, $(I - S_{11})(I + S_{11})^{-1}$ is a positive matrix. Thus, it follows from the identity

$$(I + S_{11})^{-1} = \frac{1}{2}\{I + (I - S_{11})(I + S_{11})^{-1}\} \tag{113}$$

that $(I + S_{11})^{-1}$ is a positive matrix. Consequently [22], $(I + S_{11})^{-1}$ and thus, $(I + S_{11})^{-1}S_{12}$ is holomorphic in Re $p_1 > 0$, Re$p_2 > 0$, which in turn imply that the least common denominator of $S_{12*}(I + S_{11*})^{-1}$ does not have a zero in Re$p_1 < 0$, Re$p_2 < 0$. Since the chosen α is a factor of this last mentioned denominator, α does not have any zero in Re$p_1 < 0$, Re$p_2 < 0$ either. Thus, the factor α/α_* is holomorphic in Re$p_1 > 0$, Re$p_2 > 0$, which additionally cancels all factors having zeros in Re$p_1 > 0$, Re$p_2 > 0$ in the denominators of S'_{21}, S'_{22}. We have thus constructed a lossless bounded (real) S of which S_{11} and, thus, $H_{11} = N/g$ is a submatrix at its top left corner. Finally, H as in (107) is obtained by appropriately repartitioning S.

Remark A.2. Note that the above result does not imply that gH = polynomial matrix, nor does it imply that the H obtained via the procedure outlined above has the smallest possible size for a given N/g. Thus, if the discrete lossless bounded H is synthesized as in [24,25,26] to yield a synthesis of N/g, the minimality of neither the dynamic elements, i.e., the number of p_1 and p_2 type elements (in fact, this number is at most $\deg_1(dg)+\deg_2(dg)$ in the present case) nor the number of "fully absorbing" ports (in continous domain these correspond to resistors) created in the synthesis procedure is ensured.

THEOREM A.4 (Discrete embedding). *Let B/a be a discrete bounded (real) rational matrix function in two variable z_1, z_2, where B is a polynomial row vector of size $(1 \times n)$ and a is the least common denominator polynomial of the entries of B/a. Then there exists a discrete lossless bounded (real) rational matrix G (i.e., G is holomorphic in $\bar{D}$ and $\tilde{G}G = I$) such that G can be partitioned as*

$$G = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix}; \textit{ where } G_{11} = \frac{B}{a}. \tag{114}$$

Proof. Consider the action of the double bilinear transformation

$$z_i = \frac{1 - p_i}{1 + p_i}; \ i = 1, 2 \tag{115}$$

on $G_{11} = B/a$, which produces the bounded (real) rational matrix N/g of the variables p_1, p_2, in which N is a polynomial vector of size $(1 \times n)$ and g is the least common denominator polynomial of the entries of N/g, i.e., we have

$$\frac{N}{g} = \left[\frac{B}{a}\right]_{z_i = \frac{1-p_i}{1+p_i}}; \ \frac{B}{a} = \left[\frac{N}{g}\right]_{p_i = \frac{1-z_i}{1+z_i}}; \ i = 1, 2. \tag{116}$$

Invoking Theorem A.3 we obtain the lossless bounded (real) rational matrix H as in (107) with $H_{11} = N/g$. Now consider the action of the inverse transform to yield

$$G = [H]_{p_i = \frac{1-z_i}{1+z_i}}\ ;\ i = 1, 2. \tag{117}$$

We then correspondingly also have

$$\frac{B}{a} = G_{11} = [H_{11}]_{p_i = \frac{1-z_i}{1+z_i}}\ ;\ i = 1, 2$$

Since it can be trivially shown from the corresponding property of H that G is a discrete lossless bounded (real) rational matrix, the proof of the present theorem is complete.

Acknowledgments. The author expresses deepest gratitude to Professor A. Fettweis for continued discussions on passive system theory over the last several years, to Dr. A. Kummert of his group for pointing out reference [7] and its potential relevance in scalar continuous embedding in the summer of 1988, and to Dr. A. Tan (a former graduate student) for checking many of the calculations reported in this paper. He also thanks Professor Christian Berg for pointing out [9], and an anonymous reviewer for constructive suggestions.
