APPROXIMATION THEORY FOR LINEAR-QUADRATIC-GAUSSIAN OPTIMAL CONTROL OF FLEXIBLE STRUCTURES*

J. S. GIBSON† AND A. ADAMIAN†

Abstract. This paper presents approximation theory for the linear-quadratic-Gaussian optimal control problem for flexible structures whose distributed models have bounded input and output operators. The main purpose of the theory is to guide the design of finite-dimensional compensators that approximate closely the optimal compensator, which is infinite-dimensional. Design of the optimal compensator separates into an optimal linear-quadratic control problem and a dual optimal state estimation problem; the solution to each problem lies in the solution to an infinite-dimensional Riccati operator equation. The approximation scheme in the paper approximates the infinite-dimensional LQG problem with a sequence of finite-dimensional LQG problems defined for a sequence of finite-dimensional, usually finite-element or modal, approximations of the distributed model of the structure. Two Riccati matrix equations determine the solution to each approximating problem.

The finite-dimensional equations for numerical approximation are developed, including formulas for converting matrix control and estimator gains to their functional representation to allow comparison of gains based on different orders of approximation. Convergence of the approximating control and estimator gains and of the corresponding finite-dimensional compensators is studied. Also, convergence and stability of the closed-loop systems produced with the finite-dimensional compensators are discussed. The convergence theory is based on the convergence of the solutions of the finite-dimensional Riccati equations to the solutions of the infinite-dimensional Riccati equations. A numerical example with a flexible beam, a rotating rigid body, and a lumped mass is given.

Key words. linear-quadratic-Gaussian optimal control, approximation theory, flexible structures, distributed systems

1. Introduction.

The first question that must be answered when designing a controller for a flexible structure is whether a finite-dimensional model is sufficient as a basis for a controller that will produce the required performance, or is a distributed model necessary? While some structures can be modeled well by a fixed number of dominant modes, there are structures whose flexible character can be captured sufficiently for precise control only by a distributed model. Still others—perhaps most of the aerospace structures of the future—can be modeled sufficiently for control purposes by some finite-dimensional approximation, but an adequate approximation may be impossible to determine before design of the controller, or compensator. This paper deals with structures that are flexible enough to require a distributed model in the design of an optimal LQG compensator.

The linear-quadratic-Gaussian optimal control problem for distributed, or infinite-dimensional, systems is a generalization to Hilbert space of the LQG problem for finite-dimensional systems. The solution to the infinite-dimensional problem yields an infinite-dimensional state-estimator-based compensator, which is optimal in the context of this paper. By a separation principle [B1], [C4], the problem reduces to a deterministic linear-quadratic optimal control problem an an optimal estimation, or filtering, problem with Gaussian white noise. The solutions to both the control and filtering problems involve Riccati operator equations, which are generalizations of the Riccati matrix equations in the finite-dimensional case. Current results on the infinite-dimensional LQG problem are most complete for problems where the input and measurement operators are bounded, as this paper requires throughout. This bounded-

ness also permits the strongest approximation results here. For related control problems with unbounded input and measurement, see [C3], [C5], [C6], [D2], [I2], [I3], [L1]-[L4].

Our primary objective in this paper is to approximate the optimal infinite-dimensional LQG compensator for a distributed model of a flexible structure with finite-dimensional compensators based on approximations to the structure, and to have these finite-dimensional compensators produce near optimal performance of the closed-loop system. We discuss how the gains that determine the finite-dimensional compensators converge to the gains that determine the infinite-dimensional compensator, and we examine the sense in which the finite-dimensional compensators converge to the infinite-dimensional compensator. With this analysis, we can predict the performance of the closed-loop system consisting of the distributed plant and a finite-dimensional compensator that approximates the infinite-dimensional compensator.

Our design philosophy is to let the convergence of the finite-dimensional compensators indicate the order of the compensator that is required to produce the desired performance of the structure. The two main factors that govern rate of convergence are the desired performance (e.g., fast response) and the structural damping. We should note that any one of our compensators whose order is not sufficient to approximate the infinite-dimensional compensator closely will not, in general, be the optimal compensator of that fixed order, i.e., the optimal fixed-order compensator that would be constructed with the design philosophy in [B7], [B8]. But as we increase the order of approximation to obtain convergence, our finite-dimensional compensators become essentially identical to the compensator that is optimal over compensators of all orders.

An important question, of course, is how large a finite-dimensional compensator we must use to approximate the infinite-dimensional compensator. In [G6]-[G8], and [M1], we have found that our complete design strategy yields compensators of reasonable size for distributed models of complex space structures. This strategy in general requires two steps to obtain an implementable compensator that is essentially identical to the optimal infinite-dimensional compensator: the first step determines the optimal compensator by letting the finite-dimensional compensators converge to it, the second step reduces the order of a large (converged) approximation to the optimal compensator. The first step, which involves control theory and approximation theory for distributed systems, is the subject of this paper. For the second step, a simple modal truncation of the large compensator sometimes is sufficient, but there are more sophisticated methods in finite-dimensional control theory for order reduction. For example [G9], [M1], we have found that balanced realizations [M2] work well for reducing large compensators.

The approximation theory in this paper follows from the application of approximation results in [B6], [G3], [G4] to a sequence of finite-dimensional optimal LQG problems based on a Ritz–Galerkin approximation of the flexible structure. For the optimal linear-quadratic control problem, the approximation theory here is a substantial improvement over that in [G1] because here we allow rigid-body modes, more general structural damping (including damping in the boundary), and much more general finite-element approximations. These generalizations are necessary to accommodate common features of complex space structures and the most useful finite-element schemes. For example, we write the equations for constructing the approximating control and estimator gains and finite-dimensional compensators in terms of matrices that are built directly from typical mass, stiffness and damping matrices for flexible structures, along with actuator influence matrices and measurement matrices.

For the estimator problem, this paper presents some of the first rigorous approximation theory. (We have used less complete versions of the results in previous research [G7]-[G9], [M1].) We note also [I1] that as in the finite-dimensional case, the infinite-dimensional optimal estimation problem is the dual of the infinite-dimensional optimal control problem, and the solutions to both problems have the same structure. Because we exploit this duality to obtain the approximation theory for the estimation problem from the approximation theory for the optimal control problem, the analysis in this paper is almost entirely deterministic. We discuss the stochastic interpretation of the estimation problem and the approximating state estimators briefly, but we are concerned mainly with deterministic questions about the structure and convergence of approximations to an infinite-dimensional compensator and the performance—especially stability—of the closed-loop systems produced by the approximating compensators.

The paper has two main parts, which correspond roughly to the separation of the optimal LQG problem into an optimal linear-quadratic regulator problem and an optimal state estimation problem. The first half, §§ 2-6, deal with the control system and the optimal regulator problem. Sections 7-10 treat the state estimator and the compensator that is formed by applying the control law of the first half of the paper to the output of the estimator.

While this paper is primarily theoretical, we present a detailed numerical example in §§ 6 and 10. The structure in this example consists of an Euler-Bernoulli beam attached to a rotating rigid hub on one end and to a lumped mass on the other end. We emphasize the fact that we do not solve, or even write down, the coupled partial and ordinary differential equations of motion. For both the definition and numerical solution of the problem, only the kinetic and strain energy functionals and a dissipation functional for the damping are required. In § 6, we show the approximating functional control gains obtained by using a standard finite-element approximation of the beam, and we discuss the effect on convergence of structural damping and of the ratio of state weighting to control weighting in the performance index. As suggested by a theorem in § 5, the functional gains do not converge when no structural damping is modeled.

In § 10, we complete the compensator design for the example. Assuming that white noise corrupts the single measurement and that distributed white noise disturbs the structure, we compute the gains for the finite-dimensional estimators and show the functional estimator gains. As in the control problem, the functional gains do not converge when no damping is modeled. We apply the control laws computed in § 6 to the output of the estimators in § 10 to construct the finite-dimensional compensators, and we show the frequency response of these compensators. As predicted by § 9.3, the frequency response of the nth compensator converges to the frequency response of the optimal infinite-dimensional compensator as n increases. In § 10.3, we discuss the structure and dimension of the finite-dimensional compensator that should be implemented.

2. The control system.

We consider the system

$$\ddot{x}(t)+D_0\dot{x}(t)+A_0x(t)=B_0u(t), \qquad t>0 \tag{2.1}$$

where $x(t)$ is in a real Hilbert space H and $u(t)$ is in R^m for some finite m. The linear stiffness operator A_0 is densely defined and self-adjoint with compact resolvent and has at most a finite number of negative eigenvalues. We will postpone discussion of the damping operator D_0 momentarily, except to say that it is symmetric and nonnegative. The input operator B_0 is a linear operator from R^m to H, and hence is bounded.

By natural modes, we will mean the eigenvectors ϕ_j of the eigenvalue problem

$$\lambda_j\phi_j = A_0\phi_j. \tag{2.2}$$

From our hypotheses on A_0, we know that these eigenvalues form an infinitely increasing sequence of real numbers of which all but a finite number are positive. Also, the corresponding eigenvectors are complete in H and satisfy

$$\langle\phi_i, \phi_j\rangle_H = \langle A_0\phi_i, \phi_j\rangle_H = 0, \qquad i \neq j. \tag{2.3}$$

For $\lambda_j > 0$, $\omega_j = \sqrt{\lambda_j}$ is a *natural frequency*.

Remark 2.1. Our analysis includes the system

$$M_0\ddot{x}(t) + D_0\dot{x}(t) + A_0x(t) = B_0u(t), \qquad t > 0 \tag{2.1'}$$

where the mass operator M_0 is a self-adjoint, bounded, and coercive linear operator on a real Hilbert space H_0. The operators A_0, B_0, and D_0 in (2.1') have the same properties with respect to H_0 that the corresponding operators in (2.1) have with respect to H. To include (2.1') in our analysis, we need only take H to be H_0 with the norm-equivalent inner product $\langle\cdot,\cdot\rangle_H = \langle M_0\cdot,\cdot\rangle_{H_0}$, and multiply (2.1') on the left by M_0^{-1}. In H, the operator $M_0^{-1}A_0$ is self-adjoint with compact resolvent, and $M_0^{-1}D_0$ is symmetric and nonnegative. With no loss of generality then, we will refer henceforth only to (2.1) and assume that the H-inner product accounts for the mass distribution.

2.1. The energy spaces and the first-order form of the system.

2.1.1. The elastic-strain-energy space V and total-energy space E. We choose a bounded, self-adjoint linear operator A_1 on H such that $\tilde{A}_0 = A_0 + A_1$ is coercive; i.e., there exists $\rho > 0$ for which

$$\langle\tilde{A}_0x, x\rangle_H \geqq \rho\|x\|_H^2, \qquad x \in D(\tilde{A}_0) = D(A_0). \tag{2.4}$$

In applications such as our example in § 6, it is natural to select for A_1 an operator whose null space is the orthogonal complement (in H) of the eigenspace of A_0 corresponding to nonpositive eigenvalues. Obviously, any A_1 that makes $\tilde{A}_0$ coercive must be positive definite on the nonpositive eigenspace of A_0.

With A_1 chosen, we define the Hilbert space V to be the completion of $D(A_0)$ with respect to the inner product $\langle v_1, v_2\rangle_V = \langle\tilde{A}_0v_1, v_2\rangle_H$, v_1 and $v_2 \in D(A_0)$. Note that $V = D(\tilde{A}_0^{1/2})$ and $\langle v_1, v_2\rangle_V = \langle\tilde{A}_0^{1/2}v_1, \tilde{A}_0^{1/2}v_2\rangle_H$. (Since A_1 is a bounded operator on H, different choices of A_1 yield V's with equivalent norms, thus containing the same elements.)

In the usual way, we will use the imbedding

$$V \subset H = H' \subset V'$$

where the injections from V into H and from H into V' are continuous with dense ranges. We denote by Λ_V the Riesz map from V onto its dual V'. Then $\tilde{A}_0$ is the restriction of Λ_V to $D(A_0)$ in the sense that

$$(\Lambda_Vv_1)v = \langle v, \tilde{A}_0v_1\rangle_H, \qquad v_1 \in D(A_0), \quad v \in V. \tag{2.5}$$

Now we define the *total energy space* $E = V \times H$, noting that when A_0 is coercive and $x(t)$ is the solution to (2.1), then $\|(x(t), \dot{x}(t))\|_E^2$ is twice the total energy (kinetic plus potential) in the system. We want to write (2.1) as a first-order evolution equation on E. To do this, we must determine the semigroup generator for the open-loop system. We will derive this generator by constructing its inverse explicitly. This approach seems mathematically efficient, and we will need the inverse of the generator for the approximation scheme. First, we must state our precise hypotheses on damping and discuss its representation.

2.1.2. The damping functional and operator. Actually, we do *not* require an operator D_0 defined from some subset of H into H. Rather, we assume only that there exists a damping functional

$$d_0(v_1, v_2): V \times V \to R \tag{2.6}$$

such that d_0 is bilinear, symmetric, continuous (on $V \times V$), and nonnegative. Under these hypotheses, there is a unique bounded linear operator Λ_D from V into V' such that

$$d_0(v, v_1) = (\Lambda_D v_1)v, \qquad v_1, v \in V. \tag{2.7}$$

The operator $D_V = (\Lambda_V^{-1}\Lambda_D)$ is then a bounded linear operator from V to V, and D_V is self-adjoint (on V) because d_0 is symmetric. Also

$$d_0(v, v_1) = \langle v, D_V v_1 \rangle_V = \langle D_V v, v_1 \rangle_V, \qquad v_1, v \in V. \tag{2.8}$$

Remark 2.2. We chose to begin our description of the control system model with (2.1) because its form is familiar in the context of flexible structures. In applications such as the example in § 6, however, it is easier to begin with a strain-energy functional from which the correct strain-energy inner product for V is obvious. The stiffness operator is then defined in terms of the Riesz map for V (see [S3] for this approach). Either way, the only thing that needs to be computed in applications is the V-inner product; an explicit A_0 need not be written down.

2.1.3. The semigroup generator. We define $\tilde{A}^{-1} \in L(E, E)$ by

$$\tilde{A}^{-1} = \begin{bmatrix} -D_V & -\tilde{A}_0^{-1} \\ I & 0 \end{bmatrix}. \tag{2.9}$$

This operator is clearly one-to-one, and its range is dense, since V is dense in H and $D(A_0)$ is dense in V. Now, we take

$$\tilde{A} = (\tilde{A}^{-1})^{-1}. \tag{2.10}$$

Direct calculation of the inner product shows

$$\left\langle \tilde{A}^{-1}\begin{bmatrix} v \\ h \end{bmatrix}, \begin{bmatrix} v \\ h \end{bmatrix} \right\rangle_E = -d_0(h, h), \tag{2.11}$$

so that $\tilde{A}$ is dissipative with dense domain. Also, since $D(\tilde{A}^{-1}) = E$, $\tilde{A}$ is maximal dissipative by [G1, Thm. 2.1]. Therefore, $\tilde{A}$ generates a C_0-contraction semigroup on E.

Finally, the open-loop semigroup generator is

$$A = \tilde{A} + \begin{bmatrix} 0 & 0 \\ A_1 & 0 \end{bmatrix}, \qquad D(A) = D(\tilde{A}) \tag{2.12}$$

where A_1 is the bounded linear operator chosen to make $\tilde{A}_0$ coercive. With

$$B = \begin{bmatrix} 0 \\ B_0 \end{bmatrix} \in L(R^m, E), \tag{2.13}$$

the first-order form of (2.1) is

$$\dot{z}(t) = Az(t) + Bu(t), \qquad t > 0 \tag{2.14}$$

where $z = (x, \dot{x}) \in E$.

We should note that Showalter [S3, Chap. VI] elegantly derives a semigroup generator for a class of second-order systems that includes the flexible-structure model here. The presentation here is most useful for our approximation theory because of the explicit construction of the inverse of the semigroup generator.

In many structural applications, the open-loop semigroup is analytic. Showalter obtains an analytic semigroup when the damping functional is V-coercive, for example, when there exists a damping operator D_0 that is both A_0-bounded and as strong as A_0. Such a damping operator results from the Kelvin–Voigt viscoelastic material model. Chen and Russell [C1] have shown that the semigroup is analytic for a class of damping operators involving $A_0^{1/2}$, and recently Chang and Lasiecka [C6] have shown that the semigroup is analytic if $c_0 A_0^{\mu} \leqq D_0 \leqq c_1 A_0^{\mu}$ for some μ such that $\frac{1}{2} \leqq \mu \leqq 1$ and c_0 and c_1 positive and finite. If the damping operator is bounded relative to A_0^{μ} for $\mu < 1$, then A has compact resolvent.

Finally, we can guarantee that the open-loop semigroup generator is a spectral operator (i.e., its eigenvectors are complete in E) only for a damping operator that is a linear combination of an H-bounded operator and a fractional power of A_0. However, nowhere do we use or assume anything about the eigenvectors of either the open-loop or the closed-loop semigroup generator. The natural modes—of undamped free vibration—in (2.2) are always complete in both H and V.

2.2. The adjoint of $\tilde{A}$. Since D_V is self-adjoint on V, direct calculation shows that $\tilde{A}^{-*}$ (i.e., the adjoint of $\tilde{A}^{-1}$ with respect to the E-inner product) is

$$\tilde{A}^{-*} = \begin{bmatrix} -D_V & \tilde{A}_0^{-1} \\ -I & 0 \end{bmatrix}. \tag{2.15}$$

Then $\tilde{A}^* = (\tilde{A}^{-*})^{-1}$. Having $\tilde{A}^{-*}$ explicitly facilitates proving strong convergence for approximating adjoint semigroups.

2.3. Exponential stability. The following theorem states that, if there are no rigid-body modes and if the damping is coercive (basically, all structural components have positive damping), then the open-loop system is uniformly exponentially stable. That the decay rate given depends only on the lower bound for the stiffness operator and the upper and lower bounds for the damping functional is essential for convergence results for the approximating optimal control problems of subsequent sections. The theorem is a generalization of Theorem 6.1 of [G1] to allow more general damping, but the proof is entirely different and much nicer. The current proof uses an explicit Lyapunov functional for the homogeneous part of the system in (2.14). Recall that $T(\cdot)$ is the open-loop semigroup, with generator A, and E is the total energy space $V \times H$.

THEOREM 2.3. *Suppose that A_0 and d_0 are H-coercive. Let ρ be the positive constant in* (2.4), *and let δ_0 and δ_1 be positive constants such that*

$$\delta_0 \|v\|_H^2 \leqq d_0(v, v) \leqq \delta_1 \|v\|_V^2, \qquad v \in V. \tag{2.16}$$

Then

$$\|T(t)\| \leqq \left(1 + \frac{\delta_0}{\sqrt{\rho}} + \frac{\delta_1 \delta_0}{2}\right)^{1/2} \exp\left[-t \Big/ \left(\frac{2}{\delta_0} + \frac{2}{\sqrt{\rho}} + \delta_1\right)\right], \qquad t \geqq 0. \tag{2.17}$$

Proof. For $\gamma > \max\{1/\sqrt{\rho}, 2/\delta_0\}$, define $Q \in L(E)$ as

$$Q = \begin{bmatrix} (\gamma I + \Lambda_V^{-1} \Lambda_D) & A_0^{-1} \\ I & \gamma I \end{bmatrix}. \tag{2.18}$$

Since D_V is self-adjoint and nonnegative on V, Q is self-adjoint and coercive on E. It is shown in [G6] that $\langle QAz, z \rangle_E \leqq -\|z\|_E^2$ and that (2.17) holds. □

3. The optimal control problem. Section 3.1 presents some preliminary definitions and results for the optimal linear-quadratic regulator problem on an arbitrary real Hilbert space. These results are generic in the sense that the Hilbert space E is not necessarily the energy space of § 2, and the operators A, B, etc., do not necessarily represent an abstract flexible structure as in § 2. In the second half of the paper, having such generic results will allow us to obtain the approximation theory for the infinite-dimensional state estimator from the analogous results for the control problem. Section 3.2 gives some important implications of the general results for the case where the control system is that defined in § 2. The proofs of the new results in this section (those after Theorem 3.3) are technical and sometimes tedious. They are given in [G6].

3.1. The generic optimal regulator problem. Let a linear operator A generate a C_0-semigroup $T(t)$ on a real Hilbert space E, and suppose $B\in L(R^m, E)$, $Q\in L(E, E)$, and $R\in L(R^m)$, with Q nonnegative and self-adjoint and R positive definite and symmetric. The *optimal control problem on* E is to choose the control $u\in L_2(0,\infty; R^m)$ to minimize the cost functional

$$J(z(0), u)=\int_0^\infty (\langle Qz(t), z(t)\rangle_E+\langle Ru(t), u(t)\rangle_{R^m})\,dt \tag{3.1}$$

where the state $z(t)$ is given by

$$z(t)=T(t)z(0)+\int_0^t T(t-\eta)Bu(\eta)\,d\eta, \qquad t\geqq 0. \tag{3.2}$$

DEFINITION 3.1. A function $u\in L_2(0,\infty; U)$ is an *admissible control for the initial state* z, or simply an *admissible control for* z, if $J(z, u)$ is finite; i.e., if the state $z(t)$ corresponding to the control $u(t)$ and the initial condition $z(0)=z$ is in $L_2(0,\infty; E)$.

DEFINITION 3.2. Let the operators A, B, Q, and R be as defined above. An operator Π in $L(E)$ is a solution of the Riccati algebraic equation if Π maps the domain of A into the domain of A^* and satisfies the Riccati algebraic equation

$$A^*\Pi+\Pi A-\Pi BR^{-1}B^*\Pi+Q=0. \tag{3.3}$$

THEOREM 3.3 (Theorems 4.6 and 4.11 of [G4]). *There exists a nonnegative self-adjoint solution of the Riccati algebraic equation if and only if, for each* $z\in E$, *there is an admissible control for the initial state* z. *If* Π *is the minimal nonnegative self-adjoint solution of* (3.3), *then the unique control* $u(\cdot)$ *that minimizes* $J(z, u)$ *and the corresponding optimal trajectory* $z(\cdot)$ *are given by*

$$u(t)=-R^{-1}B^*\Pi z(t) \tag{3.4}$$

and

$$z(t)=S(t)z \tag{3.5}$$

where $S(t)$ *is the semigroup generated by* $A-BR^{-1}B^*\Pi$. *Also,*

$$J(z, u)=\min_v J(z, v)=\langle \Pi z, z\rangle_E. \tag{3.6}$$

If, for each initial state and admissible control,

$$\lim_{t\to\infty}\|z(t)\|=0, \tag{3.7}$$

then there exists at most one nonnegative self-adjoint solution of (3.3). *If* Q *is coercive, then* (3.7) *holds for each initial state and admissible control and* $S(t)$ *is uniformly exponentially stable.*

We will refer to $T(t)$ as the *open-loop semigroup* and to $S(t)$ as the *optimal closed-loop semigroup.*

To prepare for the convergence analysis in §§ 5 and 9, we now present some estimates for the decay rate of the closed-loop system in the optimal control problem.

THEOREM 3.4. *Suppose that the open-loop semigroup* $T(\cdot)$ *satisfies*

$$\|T(t)\| \leqq M_1 e^{\alpha_1 t}, \qquad t \geqq 0, \tag{3.8}$$

for positive constants M_1 *and* α_1, *that* Π *is the minimal nonnegative self-adjoint solution to* (3.3), *and that* $S(t)$ *is the optimal closed-loop semigroup in Theorem* 3.3. *If there exists a constant* M_0 *such that, for each* $z \in E$,

$$\int_0^\infty \|S(t)z\|^2 \, dt \leqq M_0(\langle \Pi z, z\rangle_E + \|z\|^2) \tag{3.9}$$

and a constant M_0' *such that*

$$\|\Pi\| \leqq M_0', \tag{3.10}$$

then there exist positive constants M_2 *and* α_2, *which are functions of* M_0, M_0', M_1, *and* α_1 *only, such that*

$$\|S(t)\| \leqq M_2 e^{-\alpha_2 t}, \qquad t \geqq 0. \tag{3.11}$$

LEMMA 3.5. *Suppose there exist positive constants* M *and* α *such that*

$$\|T(t)\| \leqq M e^{-\alpha t}, \qquad t \geqq 0. \tag{3.12}$$

If $z(0) \in E$, $h \in L_2(0, \infty; E)$, *and* $z(t) = T(t)z(0) + \int_0^t T(t-s)h(s)\, ds$, *then*

$$\int_0^\infty \|z(t)\|^2 \, dt \leqq \left[\frac{M}{\sqrt{2a}} \|z(0)\| + \frac{M}{\alpha} \|h\|_{L_2} \right]^2. \tag{3.13}$$

LEMMA 3.6. *Suppose that* E *is finite-dimensional and that the pair* (Q, A) *is observable* (*in the usual finite-dimensional sense*). *Then there exists a constant* M, *which is a function of* A, B, *and* Q *only, such that*

$$\int_0^\infty \|z(t)\|^2 \, dt \leqq M \left(\int_0^\infty (\langle Qz(t), z(t)\rangle_E + \|u(t)\|^2) \, dt \right) \tag{3.14}$$

where $z(t)$ *is given by* (3.2).

The next theorem says, among other things, that if the open-loop control system decouples into a finite-dimensional part that is stabilizable (in the usual finite-dimensional sense) and an infinite-dimensional part that is uniformly exponentially stable, then the entire system is uniformly exponentially stabilizable, so that (3.3) has a nonnegative self-adjoint solution.

THEOREM 3.7. *Suppose that there exists a finite-dimensional subspace* $E_0 \subset D(A)$ *such that* E_0 *and* $E_0^\perp$ *reduce* A (*and* $T(t)$), *and write*

$$A = \begin{bmatrix} A_{11} & 0 \\ 0 & A_{22} \end{bmatrix}, \quad B = \begin{bmatrix} B_{11} \\ B_{21} \end{bmatrix}, \quad Q = \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}^* & Q_{22} \end{bmatrix} \tag{3.15}$$

where A_{11} *and* A_{22} *are the restrictions of* A *to* E_0 *and* $D(A) \subset E_0^\perp$, *respectively. Similarly,*

$$T(t) = \begin{bmatrix} T_{11}(t) & 0 \\ 0 & T_{22}(t) \end{bmatrix}. \tag{3.16}$$

Also, suppose that the pair (A_{11}, B_{11}) *is stabilizable and that there exist positive constants* M_1', α_1', *and* β *such that*

$$\|T_{22}(t)\| \leqq M_1' e^{-\alpha_1' t}, \qquad t \geqq 0 \tag{3.17}$$

and

$$\max\{\|B\|, \|Q\|\} \leqq \beta. \tag{3.18}$$

(i) *Then there exists* $F \in L(E, R^m)$ *such that* $A - BF$ *generates a uniformly exponentially stable semigroup on E. Also,* (3.3) *has a nonnegative self-adjoint solution, and the minimal such solution satisfies* (3.10) *with* M_0' *a function of* $A_{11}, B_{11}, R, M_1', \alpha_1'$, *and* β *only.*

(ii) *If* $Q_{12} = 0$ *and the pair* (Q_{11}, A_{11}) *is observable, then there exists a unique nonnegative self-adjoint solution* Π *to* (3.3), *and there exist positive constants* M_2 *and* α_2*—which depend on* $A_{11}, B_{11}, Q_{11}, R, M_1', \alpha_1'$, *and* β *only—such that the optimal closed-loop semigroup satisfies*

$$\|S(t)\| \leqq M_2 e^{-\alpha_2 t}, \qquad t \geqq 0. \tag{3.19}$$

Remark 3.8. When we say in Theorem 3.4 that M_2 and α_2 are functions of M_0, M_0', M_1, α_1 only, we mean, for example, that for two optimal control problems on different spaces E, with different operators A, B, etc., if the same constants M_0, M_0', M_1, and α_1 work in (3.8)-(3.10) for both problems, then the same constants M_2 and α_2 will work in (3.11) for both problems. Similarly, in Theorem 3.7(ii), as long as $E_0, A_{11}, B_{11}, Q_{11}, R, M_1', \alpha_1'$, and β remain the same, the same M_2 and α_2 will work in (3.19) even if $E_0^\perp, A_{22}, B_{21}$, and Q_{22} change.

3.2. Application to optimal control of flexible structures. For the rest of this section, $A_0, A_1, A, T(t), B_0$, and B are the operators defined in § 2.1, and $E = V \times H$ is the energy space defined there.

Remark 3.9. Theorem 3.7 is useful mainly when all but a finite number of modes have coercive damping in the open-loop system and the damped and undamped parts of the open-loop system remain orthogonal. This is the case, for example, with modal damping. The next theorem does not require orthogonality of the damped and undamped parts of the system, but it does require an independent actuator for each undamped mode. The situation of Theorem 3.10 is typical in aerospace structures: any elastic component should have some structural damping, but rigid-body modes are common; for a structure to be controllable, an actuator is required for each rigid-body mode.

THEOREM 3.10. (i) *Suppose that* $A_1 = B_0 B_0^*$ *and that* $\tilde{A}_0 = A_0 + A_1$ *and* $\tilde{d}_0 = d_0 + A_1$ *are H-coercive, so that there exist positive constants* ρ, γ, *and* β *such that, for all* $v \in V$,

$$\|v\|_V^2 \geqq \rho \|v\|_H^2, \tag{3.20}$$

$$\rho \|v\|_H^2 \leqq \tilde{d}_0(v, v) \leqq \gamma \|v\|_V^2, \tag{3.21}$$

and

$$\max\{\|B_0\|, \|Q\|, \|R\|\} \leqq \beta. \tag{3.22}$$

(*The V-continuity of* d_0 *implies the second inequality in* (3.21).) *Then* (3.3) *has a minimal nonnegative self-adjoint solution* Π, *which satisfies* (3.10) *with* M_0' *a function of* ρ, γ, *and* β *only.*

(ii) *Suppose also that*

$$\langle Qz, z\rangle_E \geqq \rho \|z\|_E^2, \qquad z \in E. \tag{3.23}$$

Then the optimal closed-loop semigroup satisfies

$$\|S(t)\| \leqq M_2 e^{-\alpha_2 t}, \qquad t \geqq 0 \tag{3.24}$$

where M_2 and α_2 are positive constants depending on ρ, γ, and β only.

Now we will consider the structure of the optimal control law in more detail. Since $\Pi \in L(E, E)$ and $E = V \times H$, we can write

$$\Pi = \begin{bmatrix} \Pi_0 & \Pi_1 \\ \Pi_1^* & \Pi_2 \end{bmatrix} \tag{3.25}$$

where $\Pi_0 \in L(V, V)$, $\Pi_1 \in L(H, V)$, $\Pi_2 \in L(H, H)$, and Π_0 and Π_2 are nonnegative and self-adjoint. With $z = (x, \dot{x})$, as in § 2, (3.4) becomes

$$u(t) = -R^{-1} B_0^* [\Pi_1^* x(t) + \Pi_2 \dot{x}(t)]. \tag{3.26}$$

Since $B_0 \in L(R^m, H)$, we must have vectors $b_i \in H$, $1 \leqq i \leqq m$, such that

$$B_0 u = \sum_{i=i}^{m} b_i u_i \quad \text{for } u = [u_1 u_2 \cdots u_m]^T \in R^m. \tag{3.27}$$

Also, for $h \in H$,

$$B_0^* h = [\langle b_1, h\rangle_H \langle b_2, h\rangle_H \cdots \langle b_m, h\rangle_H]^T. \tag{3.28}$$

Since $\Pi_1^* x(t)$ and $\Pi_2 \dot{x}(t)$ are elements of H, we see from (3.26) and (3.28) that the components of the optimal control have the feedback form

$$u_i(t) = -\langle f_i, x(t)\rangle_V - \langle g_i, x(t)\rangle_H, \qquad i = 1, \cdots, m \tag{3.29}$$

where $f_i \in V$ and $g_i \in H$ are given by

$$f_i = \sum_{j=1}^{m} (R^{-1})_{ij} \Pi_1 b_j, \quad g_i = \sum_{j=1}^{m} (R^{-1})_{ij} \Pi_2 b_j, \quad i = 1, \cdots, m. \tag{3.30}$$

We call f_i and g_i *functional gains.*

4. The approximation scheme.

4.1. Approximation of the open-loop system.

Hypothesis 4.1. There exists a sequence of finite-dimensional subspaces V_n of V such that the sequence of orthogonal projections P_{Vn} converges V-strongly to the identity where P_{Vn} is the V-projection onto V_n. Also, each V_n is the span of n linearly independent vectors e_j.

Since it should cause no confusion, we will omit the subscript n and write just e_j, keeping in mind that the basis vectors may change from one V_n to another, as in most finite-element schemes. Also, we will refer to the Hilbert space $E_n = V_n \times V_n$, which has the same inner product as $E = V \times H$.

For $n \geqq 1$, we approximate $x(t)$ by

$$x_n(t) = \sum_{j=1}^{n} \xi_j(t) e_j \tag{4.1}$$

where $\xi(t) = (\xi_1(t), \xi_2(t), \cdots, \xi_n(t))^T$ satisfies

$$M^n \ddot{\xi}(t) + D^n \dot{\xi}(t) + K^n \xi(t) = B_0^n u(t), \tag{4.2}$$

and the mass matrix M^n, damping matrix D^n, stiffness matrix K^n, and actuator influence matrix B_0^n are given by

$$\begin{aligned} &M^n=[\langle e_i, e_j\rangle_H], \qquad D^n=[d_0(e_i, e_j)], \\ &K^n=[\langle A_0^{1/2}e_i, A_0^{1/2}e_j\rangle_H]=[\langle e_i, e_j\rangle_V]-[\langle A_1 e_i, e_j\rangle_H], \\ &B_0^n=[\langle e_i, b_j\rangle_H]. \end{aligned} \tag{4.3}$$

Of course, (4.2) can be written as

$$\dot{\eta}=A^n\eta+B^n u \tag{4.2'}$$

where

$$\eta=[\xi^T, \dot{\xi}^T]^T \tag{4.4}$$

and

$$A^n=\begin{bmatrix} 0 & I \\ -M^{-n}K^n & -M^{-n}D^n \end{bmatrix}, \qquad B^n=\begin{bmatrix} 0 \\ M^{-n}B_0^n \end{bmatrix}. \tag{4.5}$$

(*Note.* Throughout this paper, we use the superscript n in the designation of matrices in the nth approximating system and control problem such as A^n, B^n, M^n, etc. Hence the superscript n indicates the order of approximation—it *never* indicates a power of the matrix. By M^{-n}, we denote the inverse of the mass matrix M^n.

In the designation of a linear operator in the nth approximation, we use the subscript n. For example, A_n and B_n are the operators whose matrix representations are A^n and B^n, respectively.)

For convergence analysis, it is useful to note that (4.1) and (4.2) or (4.2′) are equivalent to

$$\dot{z}_n(t)=A_n z_n(t)+B_n u(t) \tag{4.6}$$

where $z_n=(x_n, \dot{x}_n)\in E_n$, and $A_n\in L(E_n)$ and $B_n\in L(R^m, E_n)$ are the operators whose matrix representations are given in (4.5). Also, for any real λ,

$$\lambda-A_n\begin{bmatrix} v_n^1 \\ v_n^2 \end{bmatrix}=\begin{bmatrix} h_n^1 \\ h_n^2 \end{bmatrix} \tag{4.7}$$

is equivalent to

$$(\lambda^2M^n+\lambda D^n+K^n)\alpha^1=(\lambda M^n+D^n)\beta^1+M^n\beta^2 \tag{4.8}$$

and

$$\alpha^2=\lambda\alpha^1-\beta^1 \tag{4.9}$$

if

$$v_n^j=\sum_{i=1}^n \alpha_i^j e_i \quad \text{and} \quad h_n^j=\sum_{i=1}^n \beta_i^j e_i, \quad j=1,2. \tag{4.10}$$

Next, we will prepare to invoke the Trotter-Kato semigroup approximation theorem to show how (4.2), (4.2′), and (4.6) approximate (2.1) and (2.14). First, we will treat the case in which A_0 is coercive (no rigid-body modes), so that $A_1=0$ and $\tilde{A}_0=A_0$; the general case is a straightforward extension. For A_0 coercive, the open-loop semigroup generator A is maximal dissipative. Also, for each n, A_n is dissipative on E_n. The main idea here is to project $(\lambda-A)^{-1}$ onto V_n in a certain inner product and observe that the result is exactly $(\lambda - A_n)^{-1}$, where A_n is the operator on E_n in (4.6) and (4.7). Of course, we need only do this for real $\lambda > 0$.

For real $\lambda > 0$ then, define an inner product on V by

$$\langle \cdot, \cdot \rangle_\lambda = \lambda^2 \langle \cdot, \cdot \rangle_H + \lambda d_0(\cdot, \cdot) + \langle \cdot, \cdot \rangle_V. \tag{4.11}$$

Under the hypotheses in § 2 on d_0, $\langle \cdot, \cdot \rangle_\lambda$ is norm-equivalent to $\langle \cdot, \cdot \rangle_V$. For $n \geqq 1$, let $P_n(\lambda)$ be the projection of V onto V_n in the inner product $\langle \cdot, \cdot \rangle_\lambda$. Now let $h_1, h_2 \in H$ and note that

$$(\lambda - A)\begin{bmatrix} v^1 \\ v^2 \end{bmatrix} = \begin{bmatrix} h^1 \\ h^2 \end{bmatrix} \tag{4.12}$$

is equivalent to

$$\begin{bmatrix} v^1 \\ v^2 \end{bmatrix} = A^{-1}\left[\lambda \begin{bmatrix} v^1 \\ v^2 \end{bmatrix} - \begin{bmatrix} h^1 \\ h^2 \end{bmatrix}\right]. \tag{4.13}$$

With A^{-1} from (2.10), (4.13) is equivalent to

$$(I + \lambda D_V + \lambda^2 A_0^{-1})v^1 = (\lambda A_0^{-1} + D_V)h^1 + A_0^{-1}h^2 \tag{4.14}$$

and

$$v_2 = \lambda v^1 - h^1. \tag{4.15}$$

If

$$v_n^1 = P_n(\lambda)v^1 \quad \text{and} \quad v_n^2 = P_n(\lambda)v^2, \tag{4.16}$$

it follows from (4.11) and (4.14) that

$$\begin{aligned} \langle e_i, v_n^1 \rangle_\lambda &= \lambda^2 \langle e_i, A_0 A_0^{-1} v^1 \rangle_H + \lambda \langle e_i, D_V v^1 \rangle_V + \langle e_i, v^1 \rangle_V \\ &= \langle e_i, (\lambda A_0^{-1} + D_V)h^1 + A_0^{-1}h^2 \rangle_V, \end{aligned} \tag{4.17}$$

and from (4.15) that

$$\langle e_i, v_n^2 \rangle_\lambda = \langle e_i, v^2 \rangle_\lambda = \lambda \langle e_i, v^1 \rangle_\lambda - \langle e_i, h^1 \rangle_\lambda. \tag{4.18}$$

Now, for $h^1 = h_n^1 \in V_n$, $h^2 = h_n^2 \in V_n$, and v_n^1, v_n^2, h_n^1 and h_n^2 written as in (4.10), (4.17) and (4.18) yield (4.8) and (4.9) again.

This shows that

$$\begin{bmatrix} P_n(\lambda) & 0 \\ 0 & P_n(\lambda) \end{bmatrix} (\lambda - A)^{-1}|_{E_n} = (\lambda - A_n)^{-1}, \tag{4.19}$$

which yields

$$\begin{bmatrix} P_n(\lambda) & 0 \\ 0 & P_n(\lambda) \end{bmatrix} (\lambda - A)^{-1} P_{En} = (\lambda - A_n)^{-1} P_{En} \tag{4.20}$$

where P_{En} *is the E-projection of E onto* E_n. The projection P_{En} can be written

$$P_{En} = \begin{bmatrix} P_{Vn} & 0 \\ 0 & P_{Hn} \end{bmatrix} \tag{4.21}$$

where P_{Vn} is the V-projection onto V_n, as before, and P_{Hn} is the H-projection onto V_n. Since the V-norm is stronger than the H-norm and the norm induced by the λ-inner product is equivalent to the V-norm, it follows from Hypothesis 4.1 that $(\lambda - A_n)^{-1} P_{En}$ converges E-strongly to $(\lambda - A)^{-1}$ as $n \to \infty$. Now, with A_n extended to $E_n^\perp$ as, say $n(P_{En} - I)$, the Trotter–Kato Theorem [K1, Thm. 2.16, p. 504] yields the following.

THEOREM 4.2. *For A_0 coercive, let $T_n(\cdot)$ be the (contraction) semigroup generated on E_n by A_n. Then, for each $t \geqq 0$, $T_n(t)P_{En}$ converges strongly to $T(t)$, uniformly in t for t in bounded intervals.*

In the general case, when A_0 is not coercive, the open-loop generator A is obtained from the dissipative $\tilde{A}$ by the bounded perturbation in (2.12) so that [G3, Thm. 6.6] yields the following generalization of Theorem 4.2.

COROLLARY 4.3. *Let $T_n(\cdot)$ be the semigroup generated on E_n by A_n. Then, for each $t \geqq 0$, $T_n(t)P_{En}$ converges strongly to $T(t)$, uniformly in t for t in bounded intervals.*

THEOREM 4.4. *When A has compact resolvent, $(\lambda - A_n)^{-1}P_{En}$ converges in $L(E)$ to $(\lambda - A)^{-1}$.*

Proof. This follows from (4.20) and a standard result that the projections of a compact linear operator onto a sequence of subspaces converge in norm if the projections converge strongly to the identity, as do P_{En} and $P_n(\lambda)$. □

That the adjoint semigroups also converge strongly follows from an argument entirely analogous to the proof of Theorem 4.2. In particular, equations such as (4.11)-(4.17) are used to show that

$$\begin{bmatrix} P_n(\lambda) & 0 \\ 0 & P_n(\lambda) \end{bmatrix} (\lambda - A^*)^{-1}P_{En} = (\lambda - A_n^*)^{-1}P_{En}. \tag{4.22}$$

In showing this, A^{-*} is used as A^{-1} was used previously. Also, care must be taken to calculate A_n^* with respect to the E-inner product. The results is Theorem 4.5.

THEOREM 4.5. *Let $T_n(\cdot)$ be the sequence of semigroups in Corollary 4.3. Then, for each $t \geqq 0$, $T_n^*(t)P_{En}$ converges strongly to $T^*(t)$, uniformly in t for t in bounded intervals.*

Finally, for the approximation to the actuator influence operator $B \in L(R^m, E)$, recall $B_n \in L(R^m, E_n)$, the operator whose matrix representation is the matrix B^n in (4.5). From (4.3), it follows that

$$B_n = P_{En}B. \tag{4.23}$$

Since B has finite rank m, B_n and B_n^* converge in norm to B and B^*, respectively.

4.2. The approximating optimal control problems. The *nth optimal control problem* is as follows. Given $z_n(0) = (x_n(0), \dot{x}_n(0)) \in E_n$, choose $u \in L_2(0, \infty; R^m)$ to minimize

$$J_n(z_n(0), u) = \int_0^\infty (\langle Q_n z_n(t), z_n(t)\rangle_E + \langle Ru(t), u(t)\rangle_{R^m})\, dt, \tag{4.24}$$

where $Q_n = P_{En}Q|_{En}$. We assume the following hypothesis.

Hypothesis 4.6. For each $n \geqq 1$ and $z_n(0) \in E_n$, there exists an admissible control (Definition 3.1) for (4.6) and (4.24).

A sufficient condition for Hypothesis 4.6 is that, for each n, the system (A_n, B_n) be stabilizable.

By Theorem 3.3, the optimal control $u_n(t)$ has the feedback form

$$u_n(t) = -R^{-1}B_n^*\Pi_n z_n(t) \tag{4.25}$$

where Π_n is a linear operator on E_n, Π_n is nonnegative and self-adjoint, and Π_n satisfies the Riccati equation

$$A_n^*\Pi_n + \Pi_n A_n - \Pi_n B_n R^{-1}B_n^*\Pi_n + Q_n = 0. \tag{4.26}$$

As a result of Hypothesis 4.6, (4.26) has at least one nonnegative, self-adjoint solution. The minimal such solution is the correct Π_n here. If the system (A_n, Q_n) is observable, then Π_n is the unique nonnegative, self-adjoint solution to (4.26) and is positive definite. If we write Π_n as

$$\Pi_n = \begin{bmatrix} \Pi_{0n} & \Pi_{1n} \\ \Pi_{1n}^* & \Pi_{2n} \end{bmatrix}, \tag{4.27}$$

then (4.25) becomes

$$u_n(t) = -R^{-1}B_0^*[\Pi_{1n}^* x_n(t) + \Pi_{2n}\dot{x}_n(t)]. \tag{4.28}$$

The feedback law (4.28) can be written in functional-feedback form, just as in § 3. We have

$$u_n(t) = [u_{1n}(t)u_{2n}(t) \cdots u_{mn}(t)]^T \tag{4.29}$$

where

$$u_{in}(t) = -\langle f_{in}, x_n(t)\rangle_V - \langle g_{in}, \dot{x}_n(t)\rangle_H, \qquad 1 \leqq i \leqq m, \tag{4.30}$$

and

$$f_{in} = \sum_{j=1}^{m} (R^{-1})_{ij}\Pi_{1n}P_{Hn}b_j, \qquad 1 \leqq i \leqq m, \tag{4.31a}$$

$$g_{in} = \sum_{j=1}^{m} (R^{-1})_{ij}\Pi_{2n}P_{Hn}b_j, \qquad 1 \leqq i \leqq m. \tag{4.31b}$$

Of course, f_{in} and g_{in} are the nth approximations to the functional gains f_i and g_i in (3.30).

For numerical solution of the nth problem, we need the matrix representations of these equations. We begin with the following Grammian matrices:

$$\tilde{K}^n = [\langle e_i, e_j\rangle_V] = K^n + [\langle A_1 e_i, e_j\rangle_H] \tag{4.32}$$

and

$$W^n = \begin{bmatrix} \tilde{K}^n & 0 \\ 0 & M^n \end{bmatrix}. \tag{4.33}$$

(*Note.* The matrix W^{-n} will be the inverse of W^n.)

Now recall $Q_n = P_{En}Q|_{En}$. Since $Q = Q^* \in L(E)$ and $E = V \times H$, we can write

$$Q = \begin{bmatrix} Q_0 & Q_1 \\ Q_1^* & Q_2 \end{bmatrix} \tag{4.34}$$

where $Q_0 = Q_0^* \in L(V)$, $Q_1 \in L(H, V)$, and $Q_2 = Q_2^* \in L(H)$. Straightforward calculation shows that

$$Q^n = W^{-n}\tilde{Q}^n \tag{4.35}$$

where Q^n is the matrix representation of Q_n and $\tilde{Q}^n$ is the nonnegative, symmetric matrix

$$\tilde{Q}^n = \begin{bmatrix} \tilde{Q}_0^n & \tilde{Q}_1^n \\ \tilde{Q}_1^{nT} & \tilde{Q}_2^n \end{bmatrix} \tag{4.36}$$

with

$$\tilde{Q}_0^n = [\langle e_i, Q_0 e_j\rangle_V], \quad \tilde{Q}_1^n = [\langle e_i, Q_1 e_j\rangle_V], \quad \tilde{Q}_2^n = [\langle e_i, Q_2 e_j\rangle_H]. \tag{4.37}$$

Also, recall that A_n and B_n are the operators whose matrix representations are given by (4.5), and note that the matrix representations of A_n^* and B_n^* are $W^{-n}(A^n)^T W^n$ and $(B^n)^T W^n$, respectively.

With the matrix representation of Π_n denoted by Π^n, the Riccati operator equation (4.26) is equivalent to the Riccati matrix equation

$$W^{-n}(A^n)^T W^n \Pi^n + \Pi^n A^n - \Pi^n B^n R^{-1}(B^n)^T W^n \Pi^n + Q^n = 0. \tag{4.38}$$

While Π_n is self-adjoint, Π^n in general is not symmetric, but the matrix

$$\tilde{\Pi}^n = W^n \Pi^n \tag{4.39}$$

is symmetric and nonnegative, and positive definite if Π_n is. Premultiplying (4.38) by W^n, we obtain

$$(A^n)^T \tilde{\Pi}^n + \tilde{\Pi}^n A^n - \tilde{\Pi}^n B^n R^{-1}(B^n)^T \tilde{\Pi}^n + \tilde{Q}^n = 0, \tag{4.40}$$

which is the Riccati matrix equation to be solved numerically.

Now we need one more set of matrix equations for the numerical solution of the nth optimal control problem. Since the functional gains f_{in} and g_{in} are elements of V_n, they can be written as

$$f_{in} = \sum_{j=1}^{n} \beta_j^{f_i} e_j \quad \text{and} \quad g_{in} = \sum_{j=1}^{n} \beta_j^{g_i} e_j, \quad i = 1, \cdots, m \tag{4.41}$$

where $\beta^{f_i}, \beta^{g_i} \in R^n$. Partitioning Π^n as in (4.27) and working out the matrix representation of (4.31), we obtain

$$\begin{bmatrix} \beta^{f_1} & \beta^{f_2} & \cdots & \beta^{f_m} \\ \beta^{g_1} & \beta^{g_2} & \cdots & \beta^{g_m} \end{bmatrix} = W^{-n} \tilde{\Pi}^n B^n R^{-1}. \tag{4.42}$$

See [G6] for a derivation of (4.42) that is more natural in terms of finite-dimensional control theory.

5. Convergence. As in § 3, § 5.1 will state some results for the optimal linear regulator problem involving generic linear operators A, B, Q, etc., on an arbitrary real Hilbert space E, and § 5.2 will expand on these results for the particular class of control problems treated in this paper. The proofs of the results in this section are given in [G6].

5.1. Generic approximation results. Let the Hilbert space E and the linear operators A, $T(\cdot)$, B, Q, and R be as in § 3. Suppose that there is a sequence of finite-dimensional subspaces E_n, with the projection of E onto E_n denoted by P_{En}, such that P_{En} converges strongly to the identity as $n \to \infty$, and suppose that there exist sequences of operators $A_n \in L(E_n)$, $B_n \in L(R^m, E_n)$, $Q_n = Q_n^* \in L(E_n)$, $Q_n \geqq 0$, such that we have the following strong convergence. For all $z \in E$ and $t \geqq 0$,

$$\exp(A_n t) P_{En} z \to T(t) z \quad \text{and} \quad \exp(A_n^* t) P_{En} z \to T^*(t) z \tag{5.1}$$

as $n \to \infty$, uniformly in t for t in bounded intervals; for each $u \in R^m$,

$$B_n u \to Bu; \tag{5.2}$$

for each $z \in E$,

$$Q_n P_{En} z \to Qz. \tag{5.3}$$

THEOREM 5.1. *Suppose that for each n there is a nonnegative, self-adjoint linear operator* Π_n *on* E_n *that satisfies the Riccati algebraic equation*

$$A_n^* \Pi_n + \Pi_n A_n - \Pi_n B_n R^{-1} B_n^* \Pi_n + Q_n = 0. \tag{5.4}$$

If there exist positive constants M and β, *independent of n, such that*

$$\|\exp([A_n - B_n R^{-1} B_n^* \Pi_n] t)\| \leqq M e^{-\beta t}, \qquad t \geqq 0, \tag{5.5}$$

and if $\|\Pi_n\|$ *is bounded uniformly in n, then the Riccati algebraic equation* (3.3) *has a nonnegative self-adjoint solution* Π, *and, for each* $z \in E$,

$$\Pi_n P_{En} z \to \Pi z \tag{5.6}$$

and

$$\exp([A_n - B_n R^{-1} B_n^* \Pi_n]t) P_{En} z \to S(t)z \tag{5.7}$$

uniformly in $t \geqq 0$, *where* $S(\cdot)$ *is the semigroup generated by* $A - BR^{-1}B^*\Pi$. *If there exists a positive constant* δ, *independent of n, such that*

$$Q_n \geqq \delta, \tag{5.8}$$

then $\|\Pi_n\|$ *being bounded uniformly in n guarantees the existence of positive constants M and* β *for which* (5.5) *holds for all n.*

THEOREM 5.2. *The strong convergence in* (5.6) *implies uniform norm convergence of the optimal feedback laws*:

$$\|B_n^* \Pi_n P_{En} - B^* \Pi\| \to 0 \quad as\ n \to \infty. \tag{5.9}$$

THEOREM 5.3. *Assume the hypotheses of Theorem* 5.1 *but do not assume* (5.5) *or* (5.8). *If* $\|\Pi_n\|$ *is bounded uniformly in n, then the Riccati algebraic equation* (3.3) *has a nonnegative self-adjoint solution* Π *and, for each* $z \in E$, $\Pi_n P_{En} z$ *converges weakly to* Πz.

5.2. Convergence of the approximating optimal control problems of § 4.2. For the rest of this section, A_0, A_1, A, $T(t)$, B_0, and B are the operators defined in § 2. The operators A_n, B_n, Q_n, and Π_n are the operators in the approximation scheme of § 4. Also, $\Pi \in L(E_n, E_n)$ is the minimal nonnegative, self-adjoint solution of the Riccati operator equation (4.26). According to Corollary 4.3 and Theorem 4.5, the Ritz-Galerkin approximation scheme presented in § 4.1 converges as required in (5.1); (5.2) and (5.3) follow from (4.23) and the definition $Q_n = P_{En} Q|_{En}$ in § 4.2. Also, Hypothesis 4.6 guarantees for each n the existence of the required solution of the Riccati equation (5.4) in Theorem 5.1.

Since Π_n is nonnegative and self-adjoint, its eigenvalues, which are also the eigenvalues of its matrix representation, are real and nonnegative, and its norm is equal to its maximum eigenvalue.

THEOREM 5.4. *If Q is E-coercive and* $d_0 = 0$ (*i.e., there is no open-loop damping*), *then there is no nonnegative self-adjoint solution of the Riccati operator equation* (3.3), *and*

$$\|\Pi_n\| \to \infty \quad as\ n \to \infty. \tag{5.10}$$

THEOREM 5.5. *Suppose that* A_0 *and* $d_0(\cdot, \cdot)$ *are both H-coercive. Then there exist positive constants* M_1 *and* α_1, *independent of n, such that*

$$\|\exp[A_n t]\| \leqq M_1 e^{-\alpha_1 t}, \qquad t \geqq 0. \tag{5.11}$$

THEOREM 5.6. *Suppose that* A_0 *has an invariant subspace* V_0 *that is also invariant under the damping map* D_V, *that* $E_0 = V_0 \times V_0$ *is a stabilizable subspace for the control system, and that the restrictions of* A_0 *and* $d_0(\cdot, \cdot)$ *to* $V_0^\perp$ *are both H-coercive. Also, suppose that* V_0 *has finite dimension* n_0 *and that, for each* $n \geqq n_0$ *in the approximation scheme, the first* n_0 e_i*'s span* V_0 *and the rest are orthogonal to* V_0 *in both V and H.*

(i) *Then* (3.3) *has a nonnegative self-adjoint solution* Π, *and for each* $n \geqq n_0$, (5.4) *has a nonnegative self-adjoint solution* Π_n. *Also*, Π_n *is bounded uniformly in n, so that* Π_n *converges to* Π *weakly, as in Theorem* 5.3.

(ii) *If E_0 and $E_0^\perp$ (the E-orthogonal complement of E_0) are invariant under Q, and if the part of the open-loop system on E_0 is observable with the measurement Qz, then* (5.5)–(5.7) *hold as in Theorem* 5.1.

Remark 5.7. In applications, the subspace V_0 in Theorem 5.6 usually contains rigid-body modes. The theorem includes the case where both A_0 and d_0 are H-coercive on all of V (no rigid-body modes and all modes damped). In this case, V_0 is the trivial subspace.

Remark 5.8. Otherwise, for applications to flexible structures, Theorem 5.6 usually requires two things: first, modal damping must be modeled for the structure, so that the natural modes remain uncoupled in the open-loop system; second, the natural mode shapes must be used for the basis functions in the approximating optimal control problems. Although these requirements may seem restrictive from a mathematical standpoint, such modeling and approximation predominate in engineering practice. Also, we get our strongest convergence results under these conditions. For applications where the basis vectors are not the natural mode shapes, the following theorem is useful.

THEOREM 5.9. *Suppose that $A_0+B_0B_0^*$ and $d_0+B_0B_0^*$ are H-coercive. Then* (3.3) *has a nonnegative solution* Π, *for each n* (5.4) *has a nonnegative self-adjoint solution* Π_n, *and* $\|\Pi_n\|$ *is bounded uniformly in n. Hence, Theorem* 5.3 *applies. Furthermore, if Q is E-coercive, then* (5.5)–(5.8) *hold in Theorem* 5.1.

THEOREM 5.10. *If* (5.6) *holds for each $z \in E$, then*

$$\|f_{in}-f_i\|_V \to 0, \quad \|g_{in}-g_i\|_H \to 0 \quad \text{as } n \to \infty \tag{5.12}$$

where f_i and g_i are the functional gains in (3.32), *and f_{in} and g_{in} are the approximating functional gains in* (4.31) *and* (4.41).

Note that (5.9) and (5.12) are equivalent.

6. Example.

6.1. The control system. One end of the uniform Euler–Bernoulli beam in Fig. 6.1 and Table 6.1 is attached rigidly (cantilevered) to a rigid hub (disc), which is free to rotate about its center, point 0, which is fixed. Also, a point mass m_1 is attached to the other end of the beam. The control is a torque u applied to the disc, and all motion is in the plane.

The angle θ represents the rotation of the disc (the rigid-body mode), $w(t, s)$ is the elastic deflection of the beam from the rigid-body position, and $w_1(t)$ is the displacement of m_1 from the rigid-body position. For technical reasons, we do not yet impose the condition $w_1(t) = w(t, l)$; more will be said on this later.

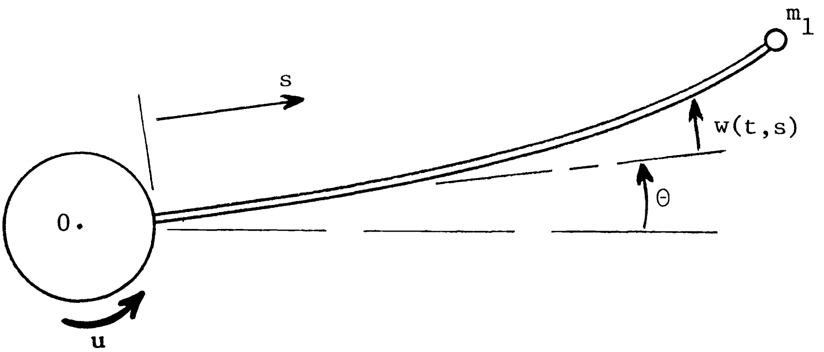

FIG. 6.1. *Control system.*

TABLE 6.1
Structural data.

r = hub radius	10 in
l = beam length	100 in
I_0 = hub moment of inertia about axis perpendicular to page through 0	100 slug in^2
m_b = beam mass per unit length	.01 slug/in
m_1 = tip mass	1 slug
EI = product of elastic modulus and second moment of cross section for beam	13,333 slug in^3/sec^2
fundamental frequency of undamped structure	.9672 rad/sec

The control problem is to stabilize rigid-body motions and linear (small) transverse elastic vibrations about the state $\theta = 0$ and $w = 0$. Our linear model assumes not only that the elastic deflection of the beam is linear but also that the axial inertial force produced by the rigid-body angular velocity has negligible effect on the bending stiffness of the beam. The rigid-body angle need not be small.

For this example, it is a straightforward exercise to derive the three coupled differential equations of motion in θ, w, and w_1, and they do have the form (2.1′). However, to emphasize the fact that we do not use the explicit partial differential equations, we will not write these equations here. Rather, we will write only what is normally needed in applications: the kinetic and strain-energy functionals, the damping functional, and the actuator influence operator.

Remark 2.1 applies to this example, and to most examples with complex structures. The generalized displacement vector is

$$x = (\theta, w, w_1) \in H_0 = R \times L_2(0, l) \times R. \tag{6.1}$$

The kinetic energy in the system is

$$\text{Kinetic Energy} = \tfrac{1}{2}\langle \dot{x}, \dot{x} \rangle_H \tag{6.2}$$

where H is H_0 with the inner product

$$\begin{aligned}\langle x, \hat{x} \rangle_H = m_b \int_0^l [w + (r+s)\theta][\hat{w} + (r+s)\hat{\theta}]\, ds + I_0\theta\hat{\theta} + m_1[w_1 + (r+l)\theta]\\ \cdot [\hat{w}_1 + (r+l)\hat{\theta}].\end{aligned} \tag{6.3}$$

As in most applications, we need not write the mass operator explicitly, but there exists a unique self-adjoint linear operator M_0 on H_0 such that

$$\langle x, \hat{x} \rangle_H = \langle M_0 x, \hat{x} \rangle_{H_0}. \tag{6.4}$$

It is easy to see that M_0 is bounded and coercive. Hence H_0 and H have equivalent norms. The input operator for (2.1′) (which maps R to H_0) is

$$B_0 = (1, 0, 0). \tag{6.5}$$

Remark 2.2 also applies here. The only strain energy is in the beam and is given by

$$\text{Strain Energy} = \tfrac{1}{2}a(x, x) \tag{6.6}$$

with

$$a(x, \hat{x}) = EI \int_0^l w''\hat{w}''\, ds \tag{6.7}$$

where $(\cdot)''=\partial^2(\cdot)/\partial s^2(\cdot)$. To make $a(\cdot,\cdot)$ into an inner product, we must account for rigid-body rotation. Thus we set

$$\langle x,\hat{x}\rangle_V=a(x,\hat{x})+\theta\hat{\theta} \tag{6.8}$$

and define

$$V=\{x=(\theta,\phi,\phi(1)):\ \phi\in H^2(0,l),\ \phi(0)=\phi'(0)=0\}. \tag{6.9}$$

Also, we have

$$\langle x,\hat{x}\rangle_V=a(x,\hat{x})+\langle B_0B_0^*x,\hat{x}\rangle_{H_0} \tag{6.10}$$

so that $A_1=B_0B_0^*$. *But we need neither A_1 nor A_0 explicitly. We need only* (6.7) *and* (6.8), *along with* (6.3), *to compute the required inner products.*

We assume that the beam has Voigt–Kelvin viscoelastic damping [C2], so that the damping operator in (2.1) is

$$D_0=c_0A_0 \tag{6.11}$$

where c_0 is a constant. This means that the damping functional is

$$d_0(x,\hat{x})=c_0a(x,\hat{x}),\qquad x,\hat{x}\in V. \tag{6.12}$$

6.2. The optimal control problem. We take $Q=I$ in the performance index in (3.1). This means that the state weighting term $\langle Qz,z\rangle_E$ is twice the total energy in the structure plus the square of the rigid-body rotation. Since there is one input, the control weighting R is a scalar.

According to (3.31), the optimal control has the feedback form

$$u(t)=-\langle f,x(t)\rangle_V-\langle g,\dot{x}(t)\rangle_H \tag{6.13}$$

where $x(t)$ has the form (6.1), and

$$f=(\alpha_f,\phi_f,\beta_f)=R^{-1}\Pi_1B_0\in V,\qquad g=(\alpha_g,\phi_g,\beta_g)=R^{-1}\Pi_2B_0\in H. \tag{6.14}$$

Note that $\beta_f=\phi_f(l)$ is not used in the control law—recall (6.7) and (6.8).

6.3. Approximation. Our approximation of the distributed model of the structure is based on a finite-element approximation of the beam that uses Hermite cubic splines as basis functions [S1], [S4]. Because the basis vectors e_j in the approximation scheme in § 4 must be in the space V defined in (6.9), we write them as

$$e_1=(1,0,0),\quad e_j=(0,\phi_j,\phi_j(1)),\quad j=2,3,\cdots \tag{6.15}$$

where the ϕ_j's are the cubic splines. When we use n_e elements to approximate the beam, there are $2n_e$ linearly independent splines. Thus, with the rigid-body mode, the order of approximation is $n=2n_e+1$.

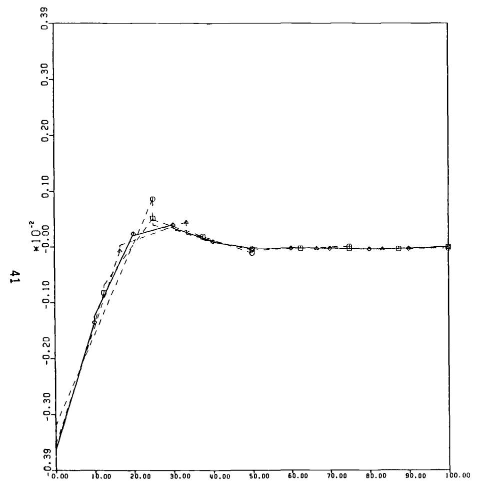
For the numerical solution to the optimal control problem, we have only to plug into the formulas of § 4. The matrices in (4.3) are calculated according to (6.3), (6.7), and (6.8), with B_0 given by (6.5). The matrices A^n and B^n are given by (4.5) and, since $Q=I$, the matrix $\tilde{Q}^n$ is the W^n in (4.33). With these matrices, we solve the Riccati equation (4.40) and use (4.41) and (4.45) to compute the approximations to the functional gains, which are

$$f_n=(\alpha_{fn},\phi_{fn},\beta_{fn}),\qquad g_n=(\alpha_{gn},\phi_{gn},\beta_{gn}). \tag{6.16}$$

For convergence, we satisfy all the hypotheses of Theorem 5.9. In particular, since Q is the identity on E, it is coercive. Theorem 5.9 implies that the solutions to the finite-dimensional Riccati equations converge as in Theorem 5.1 and that the functional control gains converge as in Theorem 5.10.

6.4. Numerical results. Figures 6.2(a) and 6.2(b) show the computed functional gain kernels ϕ''_{fn} and ϕ_{gn} for the damping coefficient $c_0 = 10^{-4}$, the control weighting $R = .05$, and $n_e = 4, 6, 8$, and 10 beam elements. Table 6.2 lists the corresponding scalar components of the gains. We have plotted ϕ''_{fn} because the second derivative appears in the strain-energy inner product in (6.7) and (6.8) and ϕ_{fn} converges in $H^2(0, l)$. Note that, since the Hermite cubic splines have discontinuous second derivatives at the nodes, the approximations to ϕ''_f are discontinuous at the nodes. Although H^2-convergence guarantees only L_2-convergence for ϕ''_{fn}, it can be shown that ϕ''_{fn} converges uniformly on $[0, l]$ for this problem.

Tables 6.2 and 6.3 omit β_{fn} to emphasize the fact that it does not appear in the feedback law and the fact that the convergence of β_{fn} is not an independent piece of information about the convergence of the control gains; since $\phi_{fn}(0) = \phi'_{fn}(0) = 0$, the convergence of ϕ''_{fn} implies the convergence of $\beta_{fn} = \phi_{fn}(l)$. On the other hand, although $\beta_{gn} = \phi_{gn}(l)$ for each n, the H-norm convergence of g_n does not enforce this condition in the limit, as the V-norm convergence of f_n enforces $\beta_f = \phi_f(l)$. Hence, as far as we can tell from our results in §§ 3 and 5, β_{fn} is an independent indicator of the convergence of the control gains, as well as being used in the control law in (6.13). However, the behavior of ϕ_{gn} in Fig. 6.2(b) suggests that g_n converges in V. Stronger results on the continuity of ϕ_g and the convergence of $\phi_{gn}(l)$ should follow from a theorem stating that, because the open-loop semigroup generator A is analytic, the solution to the



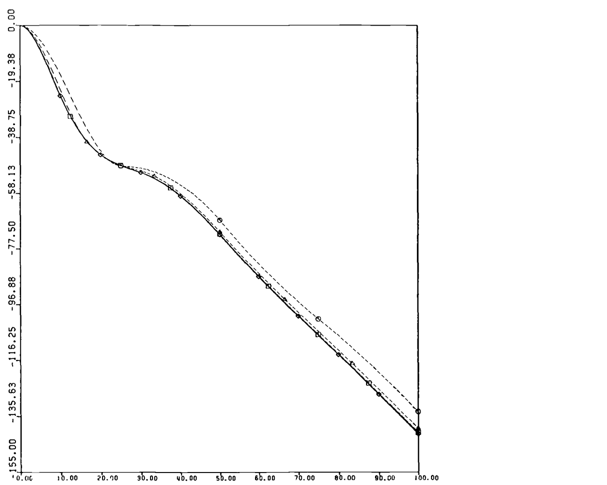


FIG. 6.2(a). *Functional control gain component* ϕ''_{fn}. *Damping coefficient* $c_0 = 10^{-4}$; *control weighting* $R = .05$; *number of elements* $n_e = 4, 6, 8, 10$.

FIG. 6.2(b). *Functional control gain component* ϕ_{gn}. *Damping coefficient* $c_0 = 10^{-4}$; *control weighting* $R = .05$; *number of elements* $n_e = 4, 6, 8, 10$.

TABLE 6.2

n_e	α_{fn}	α_{gn}	β_{gn}
4	4.4721	1.2440	−133.87
6	4.4721	1.2973	−139.69
8	4.4721	1.3106	−141.15
10	4.4721	1.3141	−141.54

infinite-dimensional Riccati equation maps all of E into $D(A^*)$. The fact that $\phi''_{fn}(l)$ converges to zero in Fig. 6.2(a) also suggests such a theorem, but we have not proved it.

With the state weighting Q fixed, the two factors that determine the rate of convergence are c_0 and R. Although we have used splines to approximate the beam, the relation between the convergence rate and c_0 and R probably can be interpreted best in terms of the number of natural modes of the structure that the optimal infinite-dimensional controller really controls. Strictly speaking, the controller controls all modes, but the functional gains lie essentially in the span of some finite number of modes. This would be the number of modes required for convergence of the gains if we used the natural modes as the basis vectors in the approximation. The rest of the modes are practically (but not exactly) orthogonal to the functional gains, so that the optimal feedback law essentially ignores them. In general, the lighter the damping, the more modes that will be controlled for given Q and R; the cheaper the control, the more modes that will be controlled for given Q and c_0. The question of the convergence of the finite-element approximation to the functional gains then becomes a question of how many modes the optimal control really wants and how many elements it takes to approximate those modes.

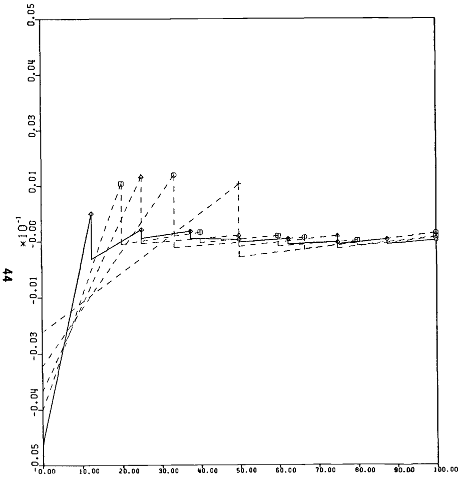
Numerical experience with optimal control of flexible structures has shown this modal interpretation of the convergence of the approximating control laws to be very useful, and that it is difficult to improve on the natural modes as basis vectors for the approximation scheme (see [G5]). However, whether the natural modes are always or almost always the best basis vectors is an open question. We use the cubic splines here to demonstrate that a standard finite-element approximation works quite well. Also, to use the natural modes as basis vectors here, we first would have to compute them using a finite-element approximation—as in most real problems—and we do not know in advance which or how many modes are needed. On the other hand, if the most important natural modes are determined from experiment, then modal approximation should be best.

Figures 6.3(a) and 6.3(b) and Table 6.3 represent attempts to compute an optimal control law for the structure when $R=.05$ but $c_0=0$. Since Q is the identity operator in E and hence coercive, Theorem 5.4 says that no optimal control law exists and that the norm of the solution to the finite-dimensional Riccati equation grows without bound as the number of elements increases. This is reflected in the nonconvergence of α_{gn}, ϕ_{gn}, and β_{gn}, although α_{fn} converges and the convergence of ϕ''_{fn} is unclear.

TABLE 6.3
Scalar components of functional control gains. Zero damping; control weighting $R=.05$.

n_e	α_{fn}	α_{gn}	β_{gn}
2	4.4721	1.0516	−112.23
3	4.4721	1.3061	−140.18
4	4.4721	1.4758	−159.11
5	4.4721	1.5996	−172.64
8	4.4721	1.8407	−199.39

In applications where the structural damping is not known, except that it is very light, it is tempting and not uncommon engineering practice to assume zero damping in the design of a control law for the first few modes, while trusting whatever damping is in the higher modes to take care of them. However, if high performance requirements



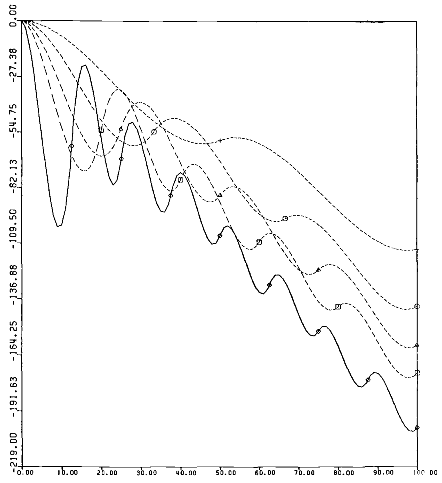


FIG. 6.3(a). *Functional control gain component* ϕ''_{fn}. *Zero damping*; *control weighting* $R = .05$; *number of elements* $n_e = 2, 3, 4, 5, 8$.

(large Q) or coupling between modes in the closed-loop system necessitate a control law based on a more accurate approximation of the structure, Theorem 5.4 and the current example warn that the higher-order control laws are likely to be meaningless and rather strange if no damping is modeled.

We should note that we have seen similar problems [G10] where Π_n remains bounded and the gains converge for zero damping but finite-rank Q. In such cases, Theorem 5.3 says that an optimal control law exists for the distributed model of the structure and that the finite-dimensional control laws converge to an optimal infinite-dimensional control law. Also, Balakrishnan [B2] has shown that an infinite-dimensional optimal control law exists for no damping when $Q = BB^*$.

7. The optimal infinite-dimensional estimator, compensator, and closed-loop system.

7.1. The generic problem. Let A, $T(t)$, and B be as in § 3.1, with E an arbitrary real Hilbert space. The differential equation corresponding to (3.2) is, of course,

$$\dot{z}(t) = Az(t) + Bu(t), \qquad t > 0. \tag{7.1}$$

We assume that we have a p-dimensional measurement vector $y(t)$ given by

$$y(t) = C_0 u(t) + Cz(t) \tag{7.2}$$

where $C_0 \in L(R^m, R^p)$ and $C \in L(E, R^p)$ for some positive integer p.

DEFINITION 7.1. For any $\hat{F} \in L(R^p, E)$, the system

$$\dot{\hat{z}}(t) = A\hat{z}(t) + Bu(t) + \hat{F}[y(t) - C_0 u(t) - C\hat{z}(t)], \qquad t > 0, \tag{7.3}$$

will be called an *observer, or estimator* (we use the terms interchangeably) for the system (7.1)-(7.2). Let $\hat{S}(t)$ be the semigroup generated by $A - \hat{F}C$. The observer in (7.3) is strongly (uniformly exponentially) stable if $\hat{S}(t)$ is strongly (uniformly exponentially) stable.

To justify this definition, we write

$$e(t) = z(t) - \hat{z}(t) \tag{7.4}$$

and, with (7.1)-(7.3), obtain

$$e(t)=\hat{S}(t)e(0), \qquad t \geqq 0. \tag{7.5}$$

Of course, an observer, or estimator, is necessary because the full state $z(t)$ will not be available for direct feedback, and the feedback control must be based on an estimate of $z(t)$. When, as in this paper, the desired control law has the form

$$u(t)=-Fz(t) \tag{7.6}$$

for some $F \in L(E, R^m)$, the observer in (7.3) can be used to construct $\hat{z}(t)$ from the measurement in (7.2) and then the control law in (7.6) can be applied to $\hat{z}(t)$. The control applied to the system is then

$$u(t)=-F\hat{z}(t), \tag{7.7}$$

and the resulting closed-loop system is

$$\begin{bmatrix} z(t) \\ \hat{z}(t) \end{bmatrix} = S_{\infty\infty}(t) \begin{bmatrix} z(0) \\ \hat{z}(0) \end{bmatrix}, \qquad t \geqq 0 \tag{7.8}$$

where $S_{\infty\infty}(t)$ is the semigroup generated on $E \times E$ by the operator

$$A_{\infty\infty}=\begin{bmatrix} A & -BF \\ \hat{F}C & [A-BF-\hat{F}C] \end{bmatrix}, \qquad D(A_{\infty\infty})=D(A)\times D(A). \tag{7.9}$$

With the estimator error $e(t)$ defined by (7.4), it is easy to show that (7.8) is equivalent to (7.5) and

$$\dot{z}(t)=(A-BF)z(t)+BFe(t), \qquad t>0 \tag{7.10}$$

where $(A-BF)$ generates a semigroup $S(t)$ on E. Also, it is easy to prove the following.

THEOREM 7.2. *Suppose that there exist positive constants M_1, M_2, α_1, and α_2 such that*

$$\|S(t)\| \leqq M_1 e^{-\alpha_1 t}, \quad \|\hat{S}(t)\| \leqq M_2 e^{-\alpha_2 t}, \quad t \geqq 0. \tag{7.11}$$

Then, for each real $\alpha_3 < \min\{\alpha_1, \alpha_2\}$, there exists a constant M_3 such that

$$\|S_{\infty\infty}(t)\| \leqq M_3 e^{-\alpha_3 t}, \qquad t \geqq 0. \tag{7.12}$$

Also,

$$\sigma(A_{\infty\infty})=\sigma(A-BF)\cup\sigma(A-F\hat{C}) \tag{7.13}$$

where $\sigma(A_{\infty\infty})$ is the spectrum of $A_{\infty\infty}$.

The observer in (7.3) and the control law in (7.7) constitute a compensator for the control system in (7.1) and (7.2). The transfer function of this compensator is

$$\Phi(s)=-F(sI-[A-BF+\hat{F}(C_0F-C)])^{-1}\hat{F}, \tag{7.14}$$

which is an $m \times p$ matrix function of the complex variable s. When E has infinite dimension, the compensator transfer function is irrational, except in degenerate, usually unimportant cases.

The foregoing definitions of this section and Theorem 7.2 are straightforward generalizations to infinite dimensions of observer-controller results in finite dimensions. Balas [B3] and Schumacher [S2] have used similar extensions.

Now suppose that $\hat{F}$ is chosen as

$$\hat{F}=\hat{\Pi}C^*\hat{R}^{-1} \tag{7.15}$$

where $\hat{\Pi} \in L(E, E)$ is the minimal nonnegative self-adjoint solution to the Riccati equation

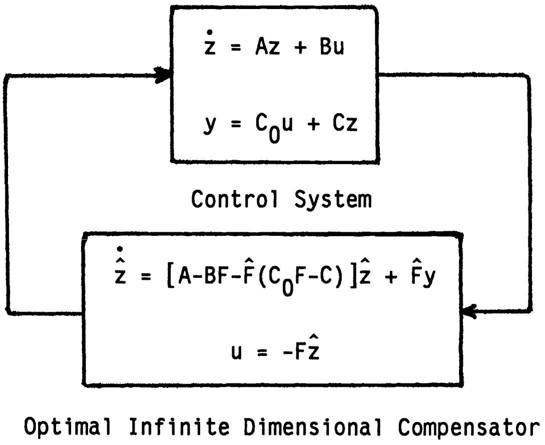
$$A\hat{\Pi} + \hat{\Pi}A^* - \hat{\Pi}C^*\hat{R}^{-1}C\hat{\Pi} + \hat{Q} = 0, \tag{7.16}$$

with $\hat{Q} \in L(E, E)$ nonnegative and self-adjoint and $\hat{R} \in L(R^p, R^p)$ symmetric and positive definite. Theorem 3.3 (with A, B, Q, R, Π, and $S(t)$ replaced by A^*, C^*, $\hat{Q}$, $\hat{R}$, $\hat{\Pi}$, and $\hat{S}^*(t)$) gives sufficient conditions for $\hat{\Pi}$ to exist and for the semigroup $\hat{S}^*(t)$—and equivalently its adjoint, the $\hat{S}(t)$ generated by $A - \hat{\Pi}C^*\hat{R}^{-1}C$—to be uniformly exponentially stable.

DEFINITION 7.3. When the control gain operator is

$$F = R^{-1}B^*\Pi, \tag{7.17}$$

with Π the solution to the Riccati equation (3.3) and the observer gain operator is given by (7.15) and (7.16), we will call the compensator consisting of the observer in (7.3) and the control law in (7.7) the *optimal infinite-dimensional compensator*, and (7.8) *the optimal closed-loop system.* (See Fig. 7.1.)



$\dot{z} = Az + Bu$
$y = C_0u + Cz$
Control System
$\dot{\hat{z}} = [A-BF-\hat{F}(C_0F-C)]\hat{z} + \hat{F}y$
$u = -F\hat{z}$
Optimal Infinite Dimensional Compensator

FIG. 7.1. *Optimal closed-loop system.*

Remark 7.4. The infinite-dimensional observer defined by (7.3), (7.15), and (7.16) is the optimal estimator for the stochastic version of (7.1) and (7.2) when (7.1) is disturbed by a stationary Gaussian white noise process with zero mean and covariance operator $\hat{Q}$ and the measurement in (7.2) is contaminated by similar noise with covariance $\hat{R}$. For infinite-dimensional stochastic estimation and control, see [B1], [C4]. When the state weighting operator Q in (3.1) is trace class, the optimal infinite-dimensional compensator minimizes the time-average of the expected steady-state value of the integrand in (3.1). Existing theory for stochastic control of infinite-dimensional systems requires trace-class Q, but we have a well-defined compensator for any bounded nonnegative self-adjoint Q and $\hat{Q}$, as long as the solutions to the Riccati equations exist. As the next two sections show (without assuming trace-class $\hat{Q}$), the infinite-dimensional compensator is the limit of a sequence of finite-dimensional compensators, each of which can be interpreted as an optimal LQG compensator for a finite-dimensional model of the structure. Therefore, we do not require trace-class Q in our definition of the optimal compensator, even though this compensator solves a precise optimization problem only when Q is trace class.

This paper is concerned primarily with how the finite-dimensional compensators converge to the infinite-dimensional compensator, and the analysis of this convergence requires only the theory of infinite-dimensional Riccati equations for deterministic optimal control problems and the corresponding approximation theory. While the stochastic interpretation of the infinite-dimensional compensator and, in § 8.2, of the finite-dimensional estimators should be motivational, nothing in the rest of the paper depends on a stochastic formulation. We assume that the operators Q, R, $\hat{Q}$, and $\hat{R}$ are determined by some design criteria. In many engineering applications, deterministic criteria such as the stability margin and robustness of the closed-loop system, rather than a stochastic performance index and an assumed noise model, govern the choice of Q, R, $\hat{Q}$, and $\hat{R}$.

7.2. Application to structures. For the rest of the paper, $E = V \times H$ as in § 2, and A and B are the operators defined there.

The measurement operator C in (7.2) now must have the form

$$C = [C_1 \quad C_2] \tag{7.18}$$

where $C_1 \in L(V, R^p)$ and $C_2 \in L(H, R^p)$. Hence, if we denote by $(C(x, \dot{x}))_i$ the ith component to the p-vector $C(x, \dot{x})$, for $(x, \dot{x}) \in E$, then there must exist $c_{1i} \in V$ and $c_{2i} \in H$ such that

$$(C(x, \dot{x}))_i = \langle C_{1i}, x \rangle_V + \langle C_{2i}, \dot{x} \rangle_H, \qquad i = 1, \cdots, p. \tag{7.19}$$

Also, the estimator gain operator F is given by

$$\hat{F}y = \sum_{i=1}^{p} (\hat{f}_i, \hat{g}_i) y_i \tag{7.20}$$

for $y = [y_1 y_2 \cdots y_p]^T \in R^p$, where the *functional estimator gains* $\hat{f}_i$ and $\hat{g}_i$ are elements of V and H, respectively.

For the optimal estimator gains, we can partition $\hat{\Pi}$ as

$$\hat{\Pi} = \begin{bmatrix} \hat{\Pi}_0 & \hat{\Pi}_1 \\ \hat{\Pi}_1^* & \hat{\Pi}_2 \end{bmatrix} \tag{7.21}$$

and use (7.15) and (7.19) to get

$$\hat{f}_i = \sum_{j=1}^{p} (\hat{R})_{ij} (\hat{\Pi}_0 c_{1j} + \hat{\Pi}_1 c_{2j}), \tag{7.22a}$$

$$\hat{g}_i = \sum_{j=1}^{p} (\hat{R}^{-1})_{ij} (\hat{\Pi}_1^* c_{1j} + \hat{\Pi}_2 c_{2j}), \qquad i = 1, 2, \cdots, p. \tag{7.22b}$$

Now let us partition $\hat{Q}$ as in (4.34):

$$\hat{Q} = \begin{bmatrix} \hat{Q}_0 & \hat{Q}_1 \\ \hat{Q}_1^* & \hat{Q}_2 \end{bmatrix}. \tag{7.23}$$

In the optimal control problem, we almost always have a nonzero Q_0 because this operator penalizes the generalized displacement. For the results in this paper, $\hat{Q}_0$ can be nonzero in the observer problem, and, as in the control problem, some of the strongest convergence results for finite-dimensional approximations can be proved only for coercive $\hat{Q}$. However, if the observer is to be thought of as an optimal filter, then $\hat{Q}$ should be the covariance operator of the noise that disturbs (2.1). In this case, $\hat{Q}_0 = 0$ and $\hat{Q}_1 = 0$.

8. Approximation of the infinite-dimensional estimator.

8.1. The approximating finite-dimensional estimators. Here, the scheme for the approximation of the flexible structure is that in § 4.

Hypothesis 8.1. There exists a sequence $C_n \in L(E_n, R^p)$ such that

$$\|C_n P_{En} - C\| \to 0 \quad \text{as } n \to \infty \tag{8.1}$$

and a sequence $\hat{Q}_n \in L(E_n)$, $\hat{Q}_n^* = \hat{Q}_n \geqq 0$, such that

$$\hat{Q}_n P_{En} \to \hat{Q} \quad \text{strongly as } n \to \infty. \tag{8.2}$$

Hypothesis 8.2. For each n, the system (A_n^*, C_n^*) is stabilizable. In particular, any unstable modes of the system (C_n, A_n) are observable.

The nth *observer*, or nth *estimator*, is

$$\dot{\hat{z}}_n = A_n \hat{z}_n + B_n u + \hat{F}_n(y - C_0 u - C_n \hat{z}_n) \tag{8.3}$$

where the estimator gain $\hat{F}_n$ is

$$\hat{F}_n = \hat{\Pi}_n C_n^* \hat{R}^{-1}, \tag{8.4}$$

and $\hat{\Pi}_n$ is the nonnegative self-adjoint solution to the Riccati operator equation

$$A_n \hat{\Pi}_n + \hat{\Pi}_n A_n^* - \hat{\Pi}_n C_n^* \hat{R}^{-1} C_n \hat{\Pi}_n + \hat{Q}_n = 0. \tag{8.5}$$

Hypothesis 8.2 implies that such a solution exists and is unique.

On-line computations will be based on the equivalent differential equation

$$\dot{\hat{\eta}} = A^n \hat{\eta} + B^n u + \hat{F}^n(y - C_0 u - C^n \hat{\eta}) \tag{8.6}$$

where $\hat{\eta}(t) \in R^{2n}$, A^n and B^n are the matrix representations of the operators A_n and B_n, as in § 4, and C^n is the matrix representation of C_n. The $2n \times p$ gain matrix $\hat{F}^n$ is

$$\hat{F}^n = \hat{\Pi}^n W^{-n} (C^n)^T \hat{R}^{-1} \tag{8.7}$$

where W^n is the $2n \times 2n$ Grammian matrix in (4.33) and $\hat{\Pi}^n$ satisfies

$$A^n \hat{\Pi}^n + \hat{\Pi}^n W^{-n} (A^n)^T W^n + \hat{\Pi}^n W^{-n} (C^n)^T \hat{R}^{-1} C^n \hat{\Pi}^n + Q^n = 0, \tag{8.8}$$

with $\hat{Q}^n$ the matrix representation of $\hat{Q}_n$. The relationship between $\hat{z}_n = (\hat{x}_n, \dot{\hat{x}}_n)$ and $\hat{\eta}$ is, of course,

$$\hat{x}_n(t) = \sum_{i=1}^{n} \hat{\xi}_i(t) e_i \tag{8.9}$$

and

$$\hat{\eta} = [\hat{\xi}^T \dot{\hat{\xi}}^T]^T. \tag{8.10}$$

It is straightforward to show that (8.7) is the matrix representation of (8.4) and that the $2n \times 2n$ Riccati matrix equation (8.8) is the matrix representation of (8.5), with $\hat{\Pi}^n$ the matrix representation of $\hat{\Pi}_n$.

In (4.39), we defined the symmetric matrix $\tilde{\Pi}^n = W^n \Pi^n$ and then obtained the Riccati equation (4.40) to solve for $\tilde{\Pi}^n$. We proceed in a similar fashion here, but with an interesting difference. Since $\hat{\Pi}_n$ and $\hat{Q}_n$ are nonnegative self-adjoint operators on E_n and $\hat{\Pi}^n$ and Q^n are their matrix representations, the matrices $W^n \hat{\Pi}^n$ and $W^n \hat{Q}^n$ are nonnegative and symmetric. Hence, the matrices

$$\tilde{\hat{\Pi}}^n = \hat{\Pi}^n W^{-n} \tag{8.11}$$

and

$$\tilde{\hat{Q}}^n = \hat{Q}^n W^{-n} \tag{8.12}$$

are nonnegative and symmetric. Substitution of (8.11) and (8.12) into (8.7) and (8.8) yields

$$\hat{F}^n = \tilde{\hat{\Pi}}^n (C^n)^T \hat{R}^{-1} \tag{8.13}$$

and

$$A^n \tilde{\hat{\Pi}}^n + \tilde{\hat{\Pi}}^n (A^n)^T - \tilde{\hat{\Pi}}^n (C^n)^T \hat{R}^{-1} C^n \tilde{\hat{\Pi}}^n + \tilde{\hat{Q}}^n = 0, \tag{8.14}$$

the Riccati matrix equation to be solved numerically in the nth approximation to the infinite-dimensional estimator. In view of the relationship between (8.5) and (8.8) and the relationship between (8.8) and (8.14), we see that Hypothesis 8.1 guarantees the existence of a unique nonnegative symmetric solution to (8.14).

To see the relationship between the matrices in (8.14) and the operators in (8.5) more clearly—and the difference between the current approximation scheme and that used in § 4.2 for the control problem—suppose that we take $\hat{Q}_n = P_{En} \hat{Q}|_{En}$. Let $\tilde{\tilde{Q}}^n$ be defined as in (4.36) and (4.37) with Q_0, Q_1, and Q_2 replaced by $\hat{Q}_0$, $\hat{Q}_1$, and $\hat{Q}_2$. Then

$$\tilde{\hat{Q}}^n = W^{-n} \tilde{\tilde{Q}}^n W^{-n}. \tag{8.15}$$

For example, if Q in the control problem and $\hat{Q}$ in the estimator problem are both equal to the identity, then the $\tilde{Q}^n$ in (4.35)-(4.42) is W^n and $\tilde{\hat{Q}}^n = W^{-n}$. This may seem suspicious, but § 8.2 should demonstrate that we are solving the appropriate estimator problem here.

The only thing missing now for numerical implementation of the nth estimator is to give C^n, the matrix representation of C_n, explicitly. We write

$$C^n = [C_1^n \quad C_2^n] \tag{8.16}$$

where the $p \times n$ matrices C_1^n and C_2^n are, respectively, the matrix representations of the approximations to the operators C_1 and C_2 in (7.18). We can cover virtually all applications by assuming $C_n = C|_{En}$, in which case the ith column of C_1^n is the p-vector equal to $C_1 e_i$, and the ith column of C_2^n is the p-vector equal to $C_2 e_i$.

8.2. Stochastic interpretation of the approximating estimators. Using only the deterministic setting above, we will proceed subsequently to analyze the finite-dimensional estimators and the compensators based on them. Nonetheless, we should consider momentarily the sequence of finite-dimensional stochastic estimation problems whose solutions are given by the equations of the preceding section.

First, recall how the covariance operator of a Hilbert space-valued random variable is defined. The covariance operator of an E-valued random variable ω is the operator Q for which

$$\text{expected value } \{\langle z, \omega \rangle_E \langle \hat{z}, \omega \rangle_E\} = \langle Qz, \hat{z} \rangle_E, \quad z, \hat{z} \in E. \tag{8.17}$$

(See [B1], [C4].)

With $\hat{F}_n$ given by (8.4) and (8.5), (8.3) is the Kalman-Bucy filter for the system

$$\dot{z}_n = A_n z_n + B_n u + \omega_n, \tag{8.18}$$

$$y = C_0 u + C_n z_n + \omega_0 \tag{8.19}$$

where $\omega_n(t)$ is an E_n-valued white noise process with covariance operator $\hat{Q}_n$ and $\omega_0(t)$ is an R^p-valued white noise process with covariance operator (matrix) $\hat{R}$. Next, careful inspection will show that the filter defined by (8.6), (8.13), and (8.14) is the matrix representation of the filter defined by (8.3), (8.4), and (8.5).

With z_n and η related as in (4.1) and (4.4), (8.18) and (8.19) are equivalent to the system

$$\dot{\eta} = A^n \eta + B^n u + \nu, \tag{8.20}$$

$$y = C_0 u + C^n \eta + \omega_0 \tag{8.21}$$

where $\nu(t)$ is the R^{2n}-valued noise process related to $\omega_n(t)$ by

$$\omega_n(t) = \sum_{i=1}^{n} (\nu_i(t) e_i,\ \nu_{i+n}(t) e_i). \tag{8.22}$$

Certainly, a Kalman–Bucy filter for (8.20) and (8.21) has the form (8.6) with the filter gain given by (8.13) and (8.14). This particular filter is the matrix representation of the filter defined by (8.3), (8.4), and (8.5) if and only if the matrix $\tilde{\hat{Q}}^n$ defined by (8.12) is the covariance of the process $\nu(t)$. Since $\hat{Q}^n$ is the matrix representation of $\hat{Q}_n$, straightforward calculation using (8.12) and (8.17) shows that the $\tilde{\hat{Q}}^n$ in (8.12) is indeed the correct covariance matrix.

The finite-dimensional observers can be interpreted now as a sequence of filters designed for the sequence of finite-dimensional approximations to the flexible structure, with the nth approximate system disturbed by the noise process $\omega_n(t)$, whose covariance operator is $\hat{Q}_n$. By Hypothesis 8.1, these covariance operators converge to the operator $\hat{Q}$ of § 7. If we have a reliable model of a stationary, zero-mean Gaussian disturbance for the structure, then we can take the covariance operator for this disturbance to be $\hat{Q}$ and think of the infinite-dimensional observer as the optimal estimator. But this interpretation is not necessary for the rest of our analysis.

8.3. The approximating functional estimator gains. The nth estimator gain operator in (8.4) has the same form as the infinite-dimensional estimator gain in (7.15) and (7.20). We have

$$\hat{F}_n y = \sum_{i=1}^{p} (\hat{f}_{in}, \hat{g}_{in}) y_i \tag{8.23}$$

for $y = [y_1 y_2 \cdots y_p]^T \in R^p$, where the functional estimator gains $\hat{f}_{in}$ and $\hat{g}_{in}$ are elements of $V_n = H_n$. The matrix $\hat{F}^n$ in (8.7) and (8.13) is the matrix representation of $\hat{F}_n$. Therefore, if we write

$$\hat{F}^n = \begin{bmatrix} \beta^{f_1} & \beta^{f_2} & \cdots & \beta^{f_m} \\ \beta^{g_1} & \beta^{g_2} & \cdots & \beta^{g_m} \end{bmatrix} \tag{8.24}$$

where the columns $\beta^{f_i}, \beta^{g_i} \in R^n$, then

$$\hat{f}_{in} = \sum_{j=1}^{n} \beta_j^{f_i} e_j, \quad i = 1, \cdots, p, \qquad \hat{g}_{in} = \sum_{j=1}^{n} \beta_j^{g_i} e_j, \quad i = 1, \cdots, p. \tag{8.25}$$

For convergence analysis, it is useful to note from $\hat{f}_{in}$ and $\hat{g}_{in}$ are also given by equations corresponding to (7.22). With the measurement operator C written as in (7.19) and $C_n = C|_E$, we have

$$\hat{f}_{in} = \sum_{j=1}^{p} (\hat{R}^{-1})_{ij} (\hat{\Pi}_{0n} P_{Vn} c_{ij} + \hat{\Pi}_{1n} P_{Hn} c_{2j}), \tag{8.26a}$$

$$\hat{g}_{in} = \sum_{j=1}^{p} (\hat{R}^{-1})_{ij} (\hat{\Pi}_{1n}^{*} P_{Vn} c_{ij} + \hat{\Pi}_{2n} P_{Hn} c_{2j}) \tag{8.26b}$$

where the $\hat{\Pi}_{in}$'s are the blocks of $\hat{\Pi}_n$, as in (7.21).

8.4. Convergence. Now we will indicate the sense in which the finite-dimensional estimators/observers approximate the infinite-dimensional estimator in § 7. The proofs of the convergence results in this section are given in [G6].

THEOREM 8.3. (i) *If $\|\hat{\Pi}_n\|$ is bounded uniformly in n, then the Riccati algebraic equation* (7.16) *has a nonnegative self-adjoint solution $\hat{\Pi}$ and $\hat{\Pi}_n P_{En}$ converges weakly to $\hat{\Pi}$.*

(ii) *If there exist positive constants M and β, independent of n, such that*

$$\|\exp([A_n - \hat{\Pi}_n C_n^* \hat{R}^{-1} C_n]t)\| \leqq M e^{-\beta t}, \qquad t \geqq 0, \tag{8.27}$$

then $\|\hat{\Pi}_n\|$ is bounded uniformly in n, $\hat{\Pi}_n P_{En}$ converges strongly to $\hat{\Pi}$, and $\exp([A_n - \hat{\Pi}_n C_n^* R^{-1} C_n]t) P_{En}$ *converges strongly to $\hat{S}(t)$, the semigroup generated by $A - \hat{\Pi} C^* R^{-1} C$, the convergence uniform in $t \geqq 0$.*

(iii) *If $\hat{Q}_n$ is bounded away from zero uniformly in n, then $\|\hat{\Pi}_n\|$ being bounded uniformly in n guarantees the existence of positive constants M and β for which* (8.27) *holds for all n.*

THEOREM 8.4. *If $\hat{Q}$ is E-coercive and $d_0 = 0$, then there is no nonnegative self-adjoint solution of the Riccati operator equation* (7.16), *and*

$$\|\hat{\Pi}_n\| \to \infty \quad \text{as } n \to \infty. \tag{8.28}$$

Our purpose for bothering to state this dual result to Theorem 5.4 is to point out the following question. Can Theorem 8.4 be modified to include the case where $\hat{Q}$ has the form (7.23) with $\hat{Q}_0 = 0$, $\hat{Q}_1 = 0$, and $\hat{Q}_2$ coercive on H?

Next, we have the dual result to Theorem 5.6.

THEOREM 8.5. *Suppose that A_0 has an invariant subspace V_0 that is also invariant under the damping map D_V, that $E_0 = V_0 \times V_0$ is an observable subspace, and that the restrictions of A_0 and $d_0(\cdot, \cdot)$ to $V_0^\perp$ are both H-coercive. Also, suppose that V_0 has finite dimension n_0 and that, for each $n \geqslant n_0$ in the approximation scheme, the first n_0 e_i's span V_0 and the rest are orthogonal to V_0 in both V and H.*

(i) *Then* (7.16) *has nonnegative solution $\hat{\Pi}$, and $\|\hat{\Pi}_n\|$ is bounded uniformly in n, so that $\hat{\Pi}_n P_{En}$ converges to $\hat{\Pi}$ weakly.*

(ii) *If E_0 and $E_0^\perp$ (the E-orthogonal complement of E_0) are invariant under $\hat{Q}$, and if the E_0-part of the system $(A, \hat{Q})$ is controllable, then the hypothesis of Theorem* 8.3(ii) *holds.*

THEOREM 8.6. *If $\hat{\Pi}_n P_{En}$ converges strongly to $\hat{\Pi}$, then*

$$\|\hat{f}_{in} - \hat{f}_i\|_V \to 0 \quad \text{and} \quad \|\hat{g}_{in} - \hat{g}_i\|_H \to 0, \quad \text{as } n \to \infty \tag{8.29}$$

where $\hat{f}_i$ and $\hat{g}_i$ are the functional estimator gains in (7.20) *and $\hat{f}_{in}$ and $\hat{g}_{in}$ are the approximating functional gains in* (8.25).

9. The finite-dimensional compensators and realizable closed-loop systems.

9.1. Closing the loop. The nth compensator consists of the nth approximation to the optimal control law in § 4, applied to the output of the nth estimator/observer in § 8, i.e., the feedback control

$$u_n = -F_n \hat{z}_n \tag{9.1}$$

where

$$F_n = R^{-1} B_n^* \Pi_n \tag{9.2}$$

(recall (4.25)) and $\hat{z}_n(t)$ is the solution to (8.3). Equivalently, this compensator can be written as

$$u_n = -F^n \hat{\eta} \tag{9.3}$$

where

$$F^n = R^{-1} B^{nT} \tilde{\Pi}^n \tag{9.4}$$

and the $2n$-vector $\hat{\eta}(t)$ is the solution to (8.6). On-line computations will be based on the latter representation, and the block diagram in Fig. 9.1 shows the realizable closed-loop system that results from the nth compensator. We will refer to this system as the nth *closed-loop system.*

This closed-loop system is equivalent to

$$\begin{bmatrix} z(t) \\ \hat{z}_n(t) \end{bmatrix} = S_{\infty n}(t) \begin{bmatrix} z(0) \\ \hat{z}_n(0) \end{bmatrix} \tag{9.5}$$

where $S_{\infty,n}(t)$ is the semigroup on $E \times E_n$ generated by

$$A_{\infty n} = \begin{bmatrix} A & -BF_n \\ \hat{F}_n C & [A_n - B_n F_n - \hat{F}_n C_n] \end{bmatrix}, \qquad D(A_{\infty n}) = D(A) \times E_n. \tag{9.6}$$

Note that $A_{\infty n}$ has compact resolvent if and only if A does.

9.2. Convergence of the closed-loop systems. Now we will consider the sense in which the nth closed-loop system approximates the optimal closed-loop system in § 7 (Definition 7.3). Recall from §§ 4.1 and 8.1 how the approximating open-loop semigroups $T_n(\cdot)$ and their adjoints converge strongly and how the input operators B_n, the measurement operators C_n, and their respective adjoints converge in norm. See [G6] for the proofs of the results in this section.

Hypothesis 9.1. As $n \to \infty$,

$$\|F_n P_{En} - F\| \to 0, \tag{9.7}$$

$$\|\hat{F}_n - \hat{F}\| \to 0. \tag{9.8}$$

Remark 9.2. Of course, we are interested primarily in the case where the gains F and $\hat{F}$ are the optimal LQG gains in (7.15) and (7.17) and F_n and $\hat{F}_n$ are the corresponding approximations in §§ 4 and 8 (i.e., (9.2) and (8.4)). However, for the analysis of this section, we need only Hypothesis 9.1 for some $F \in L(E, R^m)$, $\hat{F} \in L(R^p, E)$ and approximating sequences F_n and $\hat{F}_n$. Any such gain operators will yield closed-loop semigroup generators $A_{\infty\infty}$ in (7.9) and $A_{\infty n}$ in (9.6).

We denote the projection of $E \times E$ onto $E \times E_n$ by P_{EEn}. From the strong convergence of the open-loop semigroups and the uniform norm convergence of the control and estimator gains, we have Theorem 9.3.

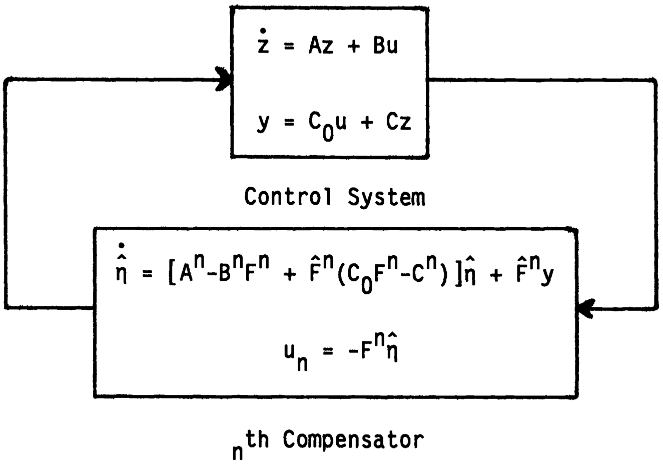


FIG. 9.1. *nth closed-loop system.*

THEOREM 9.3. *For $t \geqq 0$, $S_{\infty n}(t) P_{EEn}$ converges strongly to $S_{\infty\infty}(t)$, and the convergence is uniform in t for t in bounded intervals.*

We should expect at least Theorem 9.3, but we need more. We should require, for example, that if $S_{\infty\infty}(t)$ is uniformly exponentially stable, then $S_{\infty n}(t)$ must be also for n sufficiently large. Although numerical results for numerous examples with various kinds of damping and approximations suggest that this is usually true, we have been unable to prove it in general. We do have the following important case.

THEOREM 9.4. (i) *Suppose that the basis vectors of the approximation scheme are the natural modes of undamped free vibration and that the structural damping does not couple the modes. Then $\| S_{\infty n}(t) - S_{\infty\infty}(t)|_{ExE_n} \|$ converges to zero uniformly in bounded t-intervals.*

(ii) *If, additionally, $S_{\infty\infty}(t)$ is uniformly exponentially stable, then $S_{\infty n}(t)$ is uniformly exponentially stable for n sufficiently large.*

9.3. Convergence of the compensator transfer functions. The transfer function of the nth compensator (shown in the bottom block of Fig. 9.1) is

$$\Phi_n(s) = -F_n(sI - [A_n - B_n F_n + \hat{F}_n(C_0 F_n - C_n)])^{-1} \hat{F}_n, \tag{9.9}$$

which is an $m \times p$ matrix function of the complex variable s for each n, as is the similar transfer function $\Phi(s)$ in (7.14) for the infinite-dimensional compensator. We continue to assume Hypothesis 9.1. The proofs of the following results are given in [G6]. We will denote the resolvent set of $[A - BF + \hat{F}(C_0 F - C)]$ by $\rho([A - BF + \hat{F}(C_0 F - C)])$.

THEOREM 9.5. *There exists a real number a_1 such that, if $\operatorname{Re}(s) > a_1$, then $s \in \rho([A_n - B_n F_n + \hat{F}_n(C_0 F_n - C_n)])$ for all n, and $\Phi_n(s)$ converges to $\Phi(s)$, uniformly in compact subsets of such s.*

This result leaves much to be desired. For example, it does not guarantee that any subset of the imaginary axis will lie in $\rho([A_n - B_n F_n + \hat{F}_n(C_0 F_n - C_n)])$ for sufficiently large n, even if all of the imaginary axis lies in $\rho([A - BF + \hat{F}(C_0 F - C)])$. As with the convergence of the closed-loop systems, we can get more for certain important cases.

Remark 9.6. If the open-loop semigroup $T(\cdot)$ (whose generator is A) is an analytic semigroup, then there exist real numbers a, θ and M, with θ and M positive, such that $\rho([A - BF + \hat{F}(C_0 F - C)])$ contains the sector $\{s\colon |\arg(s - a)| < \pi/2 + \theta\}$, and for each s in this sector,

$$\|(sI - [A - BF + \hat{F}(C_0 F - C)])^{-1}\| \leqq M/|s - a|. \tag{9.10}$$

THEOREM 9.7. (i) *If the basis vectors of the approximation scheme are the natural modes of undamped free vibration and the structural damping does not couple the modes, then each s in $\rho([A - BF + \hat{F}(C_0 F - C)])$ is in $\rho([A_n - B_n F_n + \hat{F}_n(C_0 F_n - C_n)])$ for n sufficiently large and $\Phi_n(s)$ converges to $\Phi(s)$ as $n \to \infty$, uniformly in compact subsets $\rho([A - BF + \hat{F}(C_0 F - C)])$.*

(ii) *If, additionally, $T(\cdot)$ is an analytic semigroup, then $\Phi_n(s)$ converges to $\Phi(s)$ uniformly in the sector described in Remark* 9.6.

THEOREM 9.8. *If A has compact resolvent, then $\Phi_n(s)$ converges to $\Phi(s)$ for each $s \in \rho([A - BF + F(C_0 \hat{F} - C)])$, uniformly in compact subsets.*

10. Closing the loop in the example. As in Definition 7.3, the optimal closed-loop system is formed with the optimal infinite-dimensional compensator, which consists of the optimal control law for the distributed model of the structure applied to the output of an optimal infinite-dimensional state estimator. This optimal control law is the limit of the approximating finite-dimensional control laws in § 6. In this section, we first approximate the infinite-dimensional estimator, as in § 8, and then apply the approximating control laws in § 6 to the approximating finite-dimensional estimators to produce a sequence of finite-dimensional compensators that approximate the optimal compensator.

10.1. The estimator problem. We assume that the only measurement is the rigid-body angle θ and that this measurement has zero-mean Gaussian white noise with variance $\hat{R} = 10^{-4}$. We model the process noise as a zero-mean Gaussian white disturbance that has a component distributed uniformly over the beam, as well as two concentrated components that exert a force on the tip mass and a moment on the hub. For this disturbance, the covariance operator $\hat{Q}$ has the form (7.23) with $\hat{Q}_0 = 0$, $\hat{Q}_1 = 0$, and $\hat{Q}_2 = I$.

We construct the approximating estimators as in § 8.1. The gain for the nth estimator is given by (8.13) with the solution to the Riccati matrix equation (8.14). For the rigid-body measurement, the matrix C^n is

$$C^n = [1 \quad 0 \quad 0 \quad 0 \quad \cdots]. \tag{10.1}$$

According to (8.15), the matrix $\tilde{\hat{Q}}^n$ is

$$\tilde{\hat{Q}}^n = \begin{bmatrix} 0 & 0 \\ 0 & M^{-n} \end{bmatrix}, \tag{10.2}$$

since W^n is the matrix in (4.33). (As always, M^{-n} is the inverse of the mass matrix.) Recall from § 6.3 that $n = 2n_e + 1$ where n_e is the number of elements.

Our only use for the functional estimator gains is to measure the convergence of the finite-dimensional estimators to the optimal infinite-dimensional estimator. To see the convergence of the approximating estimator gains, we compute the approximating functional estimator gains as in § 8.3. As do the functional control gains, the functional estimator gains have the form

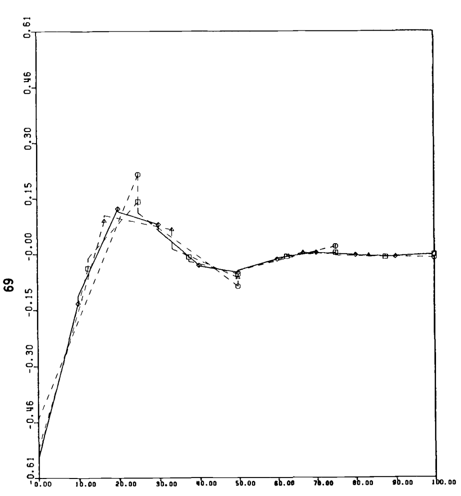
$$\hat{f} = (\alpha_f, \phi_f, \beta_f), \qquad \hat{g} = (\alpha_g, \phi_g, \beta_g), \tag{10.3}$$

and the corresponding approximations have the form

$$\hat{f}_n = (\alpha_{fn}, \phi_{gn}, \beta_{gn}), \qquad \hat{g}_n = (\alpha_{gn}, \phi_{gn}, \beta_{gn}). \tag{10.4}$$

Remark 10.1. We cannot guarantee as much about convergence for the approximating estimators as we could for the approximating control problems in § 6. Since the damping in this example does not couple the natural modes, and the rigid-body mode is observable, we would have part (i) of Theorem 8.5 if we were using the natural mode shapes as basis vectors. Therefore, we know at least that a solution to the infinite-dimensional Riccati equation (7.16) exists and that the infinite-dimensional estimator that we want to approximate exists. The numerical results indicate that the solutions to the finite-dimensional Riccati equations are bounded in n and that the functional estimator gains converge in norm. The rigid-body mode prevents our guaranteeing a priori all the convergence that we want. If a torsional spring and damper were attached to the hub in the current example, we would have coercive stiffness and damping, and Theorem 8.5(ii) would guarantee that the solutions to the finite-dimensional Riccati equations converge strongly and that the functional estimator gains converge in norm for the basis vectors used here.

For damping coefficient $c_0 = 10^{-4}$, Figs. 10.1(a) and 10.1(b) show ϕ''_{fn} and ϕ_{gn}, and Table 10.1 lists the scalars α_{fn}, α_{gn}, and β_{gn}. Since $\phi_{fn}(0) = \phi'_{fn}(0) = 0$, the convergence of ϕ''_{fn} implies the convergence of $\beta_{fn} = \phi_{fn}(l)$; as in the control problem, β_{fn} is



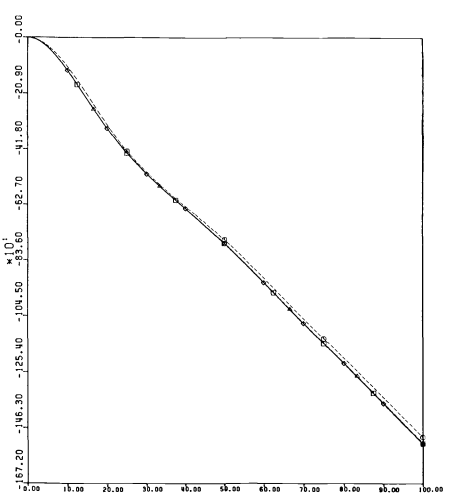


FIG. 10.1(a). *Functional estimator gain component* ϕ''_{fn}. *Damping* $c_0 = 10^{-4}$; *estimator* $R = 10^{-4}$; *number of elements* $n_e = 4, 6, 8, 10$.

FIG. 10.1(b). *Functional estimator gain component* ϕ_{gn}. *Damping* $C_0 = 10^{-4}$; *estimator* $R = 10^{-4}$; *number of elements* $n_e = 4, 6, 8, 10$.

n_e	α_{fn}	α_{gn}	β_{gn}
4	5.3195	14.149	−1495.7
6	5.3567	14.347	−1517.5
8	5.3611	14.371	−1520.1
10	5.3623	14.377	−1520.8

not an independent piece of information about the estimator gains while, as far as our results go, β_{gn} is. We maintain analogy with the control problem and list only β_{gn} in Table 10.1.

10.2. Approximation of the optimal compensator. Finally, for the damping $c_0 = 10^{-4}$, $R = .05$ in the control problem and $\hat{R} = 10^{-4}$ in the estimator problem, we construct the finite-dimensional compensator in Fig. 9.1; i.e., for each $n = 2n_e + 1$, we apply the n_eth control law represented by the functional gains in Fig. 6.2 and Table 6.2 to the output of the n_eth estimator represented by the functional gains in Fig. 10.1 and Table 10.1. As the number of elements increases, the transfer function in (9.9) of the finite-dimensional compensator converges to the transfer function in (7.14) of the optimal infinite-dimensional compensator, as described in § 9.3. Theorem 9.5 and Remark 9.6 apply. Figure 10.2 shows the frequency response (bode plots) of the finite-dimensional compensators for 4, 6, 8, and 10 elements. The phase plot is for 10 elements only. These plots indicate that the finite-dimensional compensator for eight or more elements is virtually identical to the optimal infinite-dimensional compensator, as predicted by the functional gain convergence in Figs. 6.2 and 10.1

10.3. Comments on the structure and dimension of the implementable compensators. Although this paper does not address the problem of obtaining the lowest-order compensator that closely approximates the infinite-dimensional compensator,

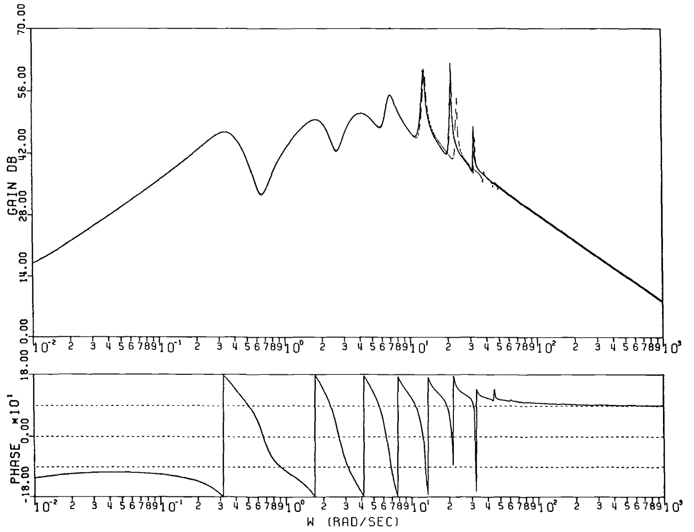

FIG. 10.2. *Frequency response* (*bode plot*) *of compensators. Damping* $c_0 = 10^{-4}$; *control* $R = .05$, *estimator* $R = 10^{-4}$; *number of elements* $n_e = 4$, 6, 8, 10.

we should note that the compensators based on eight and ten elements here are unnecessarily large because the finite-element scheme that we chose is not nearly the most efficient in terms of the dimension required for convergence. (The dimension of the first-order differential equation in the compensator is $2(2n_e + 1)$.) We used cubic Hermite splines here to demonstrate that the finite-element scheme most often used to approximate beams in other engineering applications can be used in approximating the optimal compensator. In [G5], we compare the present scheme with one using cubic B-splines and one using the natural mode shapes as basis vectors. The natural mode shapes yield the fastest converging compensators, but the B-splines are almost as good. The only advantages of the Hermite splines result from the fact that the coding to build the basic matrices (mass, stiffness, etc.) is simpler than for B-splines and the fact that, before the Riccati equations based on, say, 10 natural modes are solved, a much larger finite-element approximation of the structure must be used to get the 10 modes accurately.

To understand the redundancy in the large finite-dimensional compensators here, it helps to consider the structure of the optimal compensator. It is based on an infinite-dimensional state estimator that has a representation of each of the structure's modes. In the present example, the optimal compensator estimates and controls the first six modes significantly, the next three modes slightly, and virtually ignores the rest. This observation is based on the projections of the functional gains onto the natural modes and on comparison of the open-loop and closed-loop eigenvalues. (See [G5] for more detail, including the spectrum of the closed-loop system—which is stable—obtained with the ten-element compensator here.) The infinite-dimensional compensator then has an infinite number of modes that contribute nothing to the input-output map of the compensator. These inactive modes are just copies of all the open-loop modes past the first nine. They can be truncated from the compensator without affecting the closed-loop system response significantly. The number of active modes in the compensator—i.e., the modes that contribute to the input-output map—depends on the structural damping and the Q's and R's in the LQG problem statement.

(See the discussion in § 6.4 about the effect of damping and control weighting on performance.)

The compensator computed here based on 10 elements has 21 modes (although we did not do the computations in modal coordinates). Nine of these compensator modes are virtually identical to the nine active modes in the infinite-dimensional compensator, and the 12 inactive modes are approximations to the tenth through twenty-first open-loop modes of the structure. The inactive modes result from the large number of elements needed to approximate the active compensator modes accurately. Now that we essentially have the optimal compensator in the ten-element compensator, we could truncate the 12 inactive modes and implement a compensator with nine modes. And we probably could reduce the compensator even further using an order reduction method such as balanced realizations.

11. Conclusions. For the deterministic linear-quadratic optimal regulator problem for a flexible structure with bounded input operator (the B_0 in (2.1)), the approximation theory in §§ 4 and 5 is reasonably complete. The most important extensions should be to the corresponding (very difficult) problem with unbounded input operator, for which there exists little approximation theory. Because of the different kinds of boundary input operators, stiffness operators and structural damping, all of which must be considered in detail when B_0 is unbounded, it seems unlikely that the approximation theory for the unbounded-input case can be made as complete as the theory here.

The convergence results in § 8 for the estimation problem are less complete than those for the control problem because rigid-body modes present more technical difficulties for the proofs in the estimator case. However, our analysis and numerical experience suggest that the difficulties only make the proofs harder and that the convergence in the estimation problem is identical to the convergence in the control problem, and that controllable and observable rigid-body modes make no qualitative difference in either problem.

Where we would most like to have substantial improvement over the results of this paper is in § 9.2, which considers how the approximating closed-loop systems obtained by controlling the distributed model of the structure with the finite-dimensional compensators converge to the optimal closed-loop system, obtained with the infinite-dimensional compensator. Theorem 9.4 gives us what we want for problems where the damping does not couple the natural modes of free vibration, and where the natural mode shapes are the basis vectors for the approximation scheme. In particular, this theorem says that, if the optimal closed-loop system is uniformly exponentially stable, then so are the approximating closed-loop systems for sufficiently large order of approximation. We have verified numerically the stability of the approximating closed-loop systems for the example in §§ 6 and 10 where the basis vectors are not the modes. This example and others have made us suspect that Theorem 9.4 is true when the basis vectors satisfy Hypothesis 4.1 only and when the damping couples the modes. The methods in [I1] should be useful in completing the analysis.

Another possible approach to analyzing the convergence of the approximating closed-loop systems to the optimal closed-loop system is to use the input–output description in frequency domain. Results such as those in § 9.3 are useful for this, although for the closed-loop stability we want, we probably need the transfer functions of the finite-dimensional compensators to converge more uniformly on the compensator resolvent set than we have proved here. In our example, Fig. 10.2 indicates that these transfer functions converge uniformly on the imaginary axis, but we have no theorem that guarantees this.

Appendix. Errata for [G1]. In the first paragraph of the proof of Theorem 2.1 on page 689 of [G1], the first sentence should be:

> If a dissipative operator is invertible, its inverse is dissipative.

At the beginning of the fifth line of the same paragraph, the expression $(\alpha x + y)$ should be deleted the first time it occurs. The next-to-last sentence of the paragraph should be:

> Hence, if a densely defined maximal dissipative operator has dense range, its inverse is maximal dissipative.

The theorem is correct as stated.

In the current paper, we use Theorem 2.1 of [G1] to conclude that the operator $\tilde{A}$ defined in § 2 is maximal dissipative (see (2.10)-(2.12)).

SUFFICIENT CONDITIONS FOR DYNAMIC STATE FEEDBACK LINEARIZATION*

B. CHARLET†, J. LÉVINE†, AND R. MARINO‡

Abstract. Sufficient conditions are given for the existence of a dynamic state feedback compensator for a multi-input nonlinear system such that the closed loop system is transformable into a linear controllable one by an extended state space change of coordinates. An example shows that the conditions are not necessary. Necessary conditions are also given which are shown to be sufficient when the number of states minus the number of controls is equal to one. Several examples illustrate how the sufficient conditions obtained lead to the design of the dynamic compensator.

Key words. nonlinear systems, feedback linearization, dynamic compensator

AMS(MOS) subject classifications. 93B10, 93C10, 53A55

1. Introduction. We address the problem of transforming a nonlinear control system

$$\dot{z} = f(z) + \sum_{i=1}^{m} g_i(z)u_i(t) = f(z) + G(z)u \qquad z \in \mathbb{R}^n, \quad u \in \mathbb{R}^m \tag{1}$$

with $f(0) = 0$ and rank $G(0) = m$ into a linear controllable system

$$\dot{x} = Ax + Bv \qquad x \in \mathbb{R}^{n'}, \quad v \in \mathbb{R}^{m'} \tag{2}$$

with $n' \geqq n$, $m' \geqq m$.

Since 1973 [16] this problem has been studied using increasingly more general transformations. State space diffeomorphisms

$$x = \varphi(z), \quad \varphi(0) = 0, \quad x \in \mathbb{R}^n, \quad z \in \mathbb{R}^n \tag{3}$$

were the first transformations to be studied in [16]. State feedback transformations

$$u = \alpha(z) + \beta v \qquad v \in \mathbb{R}^m \tag{4}$$

with $\alpha(0) = 0$ and β a nonsingular $m \times m$ constant matrix were then introduced by Brockett [3] and later generalized in [15] and [11] by

$$u = \alpha(z) + \beta(z)v \qquad v \in \mathbb{R}^m \tag{5}$$

where the nonsingular matrix β was allowed to depend on the state as well. The study of the above transformations led to complete characterizations of those systems (1) transformable into (2) by (3) ([16], [24]), which are called state linearizable, and of those systems transformable into (2) by (3) and (5) ([15], [11]), which are called static feedback linearizable. Adaptive feedback linearization and its robustness versus unmodeled dynamics are studied in [25]. For those systems that are not static feedback

‡ Dipartimento di Ingegneria Elettronica, Seconda Università di Roma "Tor Vergata," Via O. Raimondo, 00173 Rome, Italy. The research of this author was partially supported by Ministero Pubblica Istruzione (Fondi 40%).

linearizable, the problem of partial feedback linearization was posed in [17], namely, the transformation of (1) by (3) and (5) into a partially linear and controllable system

$$\begin{aligned} \dot{x}^{(1)} &= Ax^{(1)} + Bv && x^{(1)} \in \mathbb{R}^{p} \\ \dot{x}^{(2)} &= \gamma(x^{(1)}, x^{(2)}) + \delta(x^{(1)}, x^{(2)})v && x^{(2)} \in \mathbb{R}^{n-p} \end{aligned} \tag{6}$$

where (A, B) is a controllable pair. This problem was solved in [17], [18] where the dimension and the construction of the largest feedback linearizable subsystem are given for any system (1).

Partial feedback linearization is related to input-output decoupling. Given m outputs

$$y_j = h_j(z) \qquad 1 \leqq j \leqq m \tag{7}$$

the input-output decoupling problem is to determine a transformation (3), (5) that takes the system (1), (7) into

$$\begin{aligned} \dot{x}^{(1)} &= Ax^{(1)} + Bv && x^{(1)} \in \mathbb{R}^{p} \\ \dot{x}^{(2)} &= \gamma(x^{(1)}, x^{(2)}) + \delta(x^{(1)}, x^{(2)})v && x^{(2)} \in \mathbb{R}^{n-p} \\ y &= Cx^{(1)} && \end{aligned} \tag{8}$$

with (A, B, C) in prime canonical form [19], namely, $A = \text{block diag}\,[A_1, \cdots, A_p]$, $B = \text{block diag}\,[B_1, \cdots, B_p]$, $C = \text{block diag}\,[C_1, \cdots, C_p]$, with, for every $i = 1, \cdots, p$,

$$A_i = \begin{pmatrix} 0 & 1 & & \\ & \ddots & \ddots & 0 \\ 0 & & \ddots & \ddots \\ & & \ddots & 1 \\ & & & 0 \end{pmatrix}, \quad B_i = \begin{pmatrix} 0 \\ \vdots \\ \vdots \\ 0 \\ 1 \end{pmatrix}, \quad C_i = (0 \quad \cdots \quad \cdots \quad 0 \quad 1).$$

Necessary and sufficient conditions are available for this problem (see [13]). For linear systems it is known that those conditions can be weakened if one allows for a dynamic compensator [20]. This motivated the introduction of a nonlinear dynamic state feedback transformation [23]

$$\begin{aligned} \dot{w} &= a(z, w) + B(z, w)v && w \in \mathbb{R}^{q} \\ u &= \alpha(z, w) + \beta(z, w)v && v \in \mathbb{R}^{m} \end{aligned} \tag{9}$$

with $\alpha(0, 0) = 0$, $a(0, 0) = 0$. The dynamic state feedback (9) is a generalization of the static state feedback (5).

Necessary and sufficient conditions for input-output decoupling via transformations (9) and extended state space diffeomorphism

$$x = \varphi(z, w) \qquad x \in \mathbb{R}^{n+q} \tag{10}$$

were obtained in [7], [8], and [21]. In [12] and [14] sufficient conditions are given to achieve both input-output decoupling and full linearization, that is, $x^{(2)} = 0$ in (6), via transformations (9), (10).

In [4] and [5] the problem of transforming the system (1) into (2) via transformations (9) and (10), which will be called the dynamic feedback linearization problem, is studied: it is shown that single input systems (1) that are dynamically feedback linearizable are also statically feedback linearizable; two very special classes of dynamically feedback linearizable multi-input systems are given in [4]. A different approach is taken by [9]: transformations (9) are considered, but the closed-loop system is no longer required to be linear and controllable in some new coordinates of the extended space (z, w): the only requirement is the existence of a w-dependent state space change of coordinates

$$x=\varphi(z, w), \qquad \varphi(0,0)=0, \qquad z\in\mathbb{R}^n, \quad x\in\mathbb{R}^n \tag{11}$$

in which the system is linear and controllable from v. While this is a less restrictive notion of dynamic feedback linearization, the stability properties of the dynamic compensator (9) remain to be analyzed. This analysis, which could be quite difficult, is not needed with our notion of dynamic feedback linearization.

In this paper we present fairly general sufficient conditions for a system (1) to be dynamic feedback linearizable by a special class of dynamic compensators (prolongations) and extended space diffeomorphism (10). Compensators are restricted to be of the following form ($u^{(\mu)}=(d^\mu u/dt^\mu)$, $w=(u_1,\cdots,u_1^{(\mu_1)},\cdots,u_m,\cdots,u_m^{(\mu_m)})$):

$$\begin{pmatrix} u_1^{(\mu_1)} \\ \vdots \\ u_m^{(\mu_m)} \end{pmatrix} = \alpha(z,w)+\beta(z,w)\begin{pmatrix} v_1 \\ \vdots \\ v_{m'} \end{pmatrix} \tag{12}$$

with $\mu_i\geqq 0$, $1\leqq i\leqq m$, $\mu=\sum_{i=1}^m \mu_i$, $\alpha(0,0)=0$, $\beta(z,w)$ of full rank m ($m'\geqq m$) in V_0, a neighborhood of the origin in $\mathbb{R}^{n+\mu}$, which can be realized as

$$\begin{aligned}
&\dot w_i^j = w_{i+1}^j \qquad 1\leqq i\leqq \mu_j-1, \quad 1\leqq j\leqq m, \quad \mu_j>1\\
&\dot w_{\mu_j}^j=\alpha_j(z,w)+\sum_{l=1}^{m'}\beta_{j,l}(z,w)v_l(t)=v_j'(t) \qquad 1\leqq j\leqq m, \quad \mu_j>0\\
&u_j=w_1^j \qquad 1\leqq j\leqq m, \quad \mu_j>0\\
&u_j=\alpha_j(z,w)+\sum_{l=1}^{m'}\beta_{j,l}(z,w)v_l(t)=v_j'(t) \qquad 1\leqq j\leqq m, \quad \mu_j=0.
\end{aligned} \tag{13}$$

In § 4 sufficient conditions are obtained that require the involutivity of certain distributions defined on the original state space. The distributions are computed on the basis of the given vector fields $f, g_1, \cdots, g_m$ and on a set of integers $\mu_1, \cdots, \mu_m$ that characterize the linearizing dynamic compensator (13). The sufficient conditions are helpful in determining the structure of the dynamic compensator on the basis of the Lie algebraic structure of the system. When $\mu_1=\cdots=\mu_m=0$ and $m'=m$, the conditions coincide with the necessary and sufficient conditions for static feedback linearization. We show by examples that the conditions are not necessary. However, they are general enough to apply for a detailed nonlinear model of rigid body dynamics that is not static feedback linearizable but is shown to be dynamically feedback linearizable.

In § 3 we show that the controllability of the linear approximation of system (1) at the origin is a necessary condition for dynamic feedback linearization; as a corollary of the main result of § 4, it turns out that it is also sufficient when $m=n-1$ in (1).

2. Basic results and definitions. In this section, we consider a general dynamic compensator of the form

$$\begin{aligned}
\dot w &= a(z,w)+B(z,w)v \qquad w\in\mathbb{R}^q\\
u &= \alpha(z,w)+\beta(z,w)v \qquad v\in\mathbb{R}^{m'}, \quad m'\geqq m.
\end{aligned} \tag{14}$$

System (1) controlled by (14), which is called the extended system, becomes

$$\begin{aligned}
\dot z &= f(z)+G(z)\alpha(z,w)+G(z)\beta(z,w)v\\
\dot w &= a(z,w)+B(z,w)v
\end{aligned} \tag{15}$$

and is written as

$$\dot{\tilde{z}} = \tilde{f}(\tilde{z}) + \tilde{G}(\tilde{z})v = \tilde{f}(\tilde{z}) + \sum_{i=1}^{m'} \tilde{g}_i(\tilde{z})v_i \tag{16}$$

where $\tilde{z} = (z, w)$ is the extended state and

$$\tilde{f} = \begin{pmatrix} f(z) + G(z)\alpha(z, w) \\ a(z, w) \end{pmatrix}, \qquad \tilde{G} = \begin{pmatrix} G(z)\beta(z, w) \\ B(z, w) \end{pmatrix}. \tag{17}$$

If $u_j = \alpha_j(\tilde{z}) + \sum_{i=1}^{m'} \beta_{j,i}(\tilde{z})v_i$, $1 \leqq j \leqq m$, are viewed as m outputs for system (16), we can define the corresponding differential output rank (see [1], [10]). Denoting by $u^{(k)}$ the kth time derivative of u considered as an output for system (16), we define the sequence of subspaces $E_0 \subset E_1 \subset \cdots \subset E_{n+q}$ by:

$$E_k = sp\{\mathrm{d}\tilde{z}, \mathrm{d}\dot{u}, \cdots, \mathrm{d}u^{(k)}\}.$$

The differential output rank $d^o(u)$ is defined by:

$$d^o(u) = \dim E_{n+q} - \dim E_{n+q-1}.$$

In the single input case ($m = 1$), it is proved in [1] that the computation of the differential output rank reduces to the computation of the classical rank of the decoupling matrix (see, for example, [13]).

In this case, the characteristic index ν is defined by:

$$\begin{aligned} &\nu = 0 \quad \text{if } \beta_i(\tilde{z}) \neq 0 \qquad \text{for some } i, \quad 1 \leqq i \leqq m' \\ &\nu = \min\{r \mid L_{\tilde{g}_i} L_{\tilde{f}}^{r-1}\alpha(\tilde{z}) \neq 0 \quad \text{for some } i, \quad 1 \leqq i \leqq m'\}.^{(1)} \end{aligned} \tag{18}$$

Let

$$\delta_i(\tilde{z}) = \begin{cases} \beta_i(\tilde{z}) & \text{if } \nu = 0 \\ L_{\tilde{g}_i} L_{\tilde{f}}^{\nu-1} a(\tilde{z}) & \text{if } \nu > 0. \end{cases} \tag{19}$$

When ν is finite, the $1 \times m'$ matrix

$$D(\tilde{z}) = (\delta_1(\tilde{z}), \cdots, \delta_{m'}(\tilde{z})) \tag{20}$$

is called the decoupling matrix of the compensator (14) for system (1) with $m = 1$. In this case, $d^o(u) = \operatorname{rank} D$.

DEFINITION 2.1. A dynamic compensator (14) is said to be regular for system (1) if the corresponding differential output rank $d^o(u)$ is equal to m in V_0, a neighborhood of the origin in $\mathbb{R}^{n+q}$.

Note that the static state feedback (5), with $\beta(z)$ nonsingular, or the dynamic compensator (13) with $\beta(\tilde{z})$ nonsingular, are nonsingular compensators according to the above definition.

DEFINITION 2.2. A system (1) is said to be locally static feedback linearizable if there exists a feedback transformation (5), (3), in a neighborhood of $z = 0$, which transforms system (1) into system (2) with $n' = n$, $m' = m$.

DEFINITION 2.3. A system (1) is said to be locally dynamic feedback linearizable if there exists a regular dynamic compensator (14) and an extended space diffeomorphism (10) defined in a neighborhood of $(z, w) = (0, 0)$ which transform system (1) into system (2) with $n' = n + q$, and such that $\varphi(0, 0) = (0, 0)$.

[1] If f is a smooth vector field and α a smooth function, the *Lie derivative of* α *with respect to* f is defined, in local coordinates, by $L_f\alpha = \sum_{n=1}^{n} f_i(\partial\alpha/\partial x_i)$. We also not $L_f^0\alpha = \alpha$ and $L_f^k\alpha = L_f(L_f^{k-1}\alpha)$ for all $k \geqq 1$.

We now recall from [15] and [11] basic definitions and results. Define the distributions

$$\mathcal{G}_0 = sp\{g_j, 1 \leqq j \leqq m\} \tag{21}$$
$$\mathcal{G}_i = sp\{\mathrm{ad}_f^l g_j, 0 \leqq l \leqq i, 1 \leqq j \leqq m\},^{(2)} \qquad i > 0,$$

which enjoy the recursion properties

$$\mathcal{G}_{i+1} = \mathcal{G}_i + \mathrm{ad}_f^{i+1}\mathcal{G}_0 = \mathcal{G}_i + \mathrm{ad}_f\mathcal{G}_i \tag{22}$$

where $\mathrm{ad}_f\mathcal{G} = sp\{\mathrm{ad}_f\, Y, Y \in \mathcal{G}\}$. By definition $\mathcal{G}_0 \subset \mathcal{G}_1 \subset \cdots \subset \mathcal{G}_i \subset \cdots$.

We recall that a distribution $\mathcal{G}$ is involutive if and only if, given any pair of vector fields g_1 and g_2 in $\mathcal{G}$, their Lie bracket $[g_1, g_2]$ belongs to $\mathcal{G}$.

THEOREM 2.1. *System* (1) *is locally static feedback linearizable if and only if, in* U_0, *a neighborhood of the origin in* $\mathbb{R}^n$:

(i) $\mathcal{G}_i$ *is an involutive distribution of constant rank for every* $i \geqq 0$;

(ii) rank $\mathcal{G}_{n-1} = n$.

The distributions $\mathcal{G}_i$ are invariant under change of coordinates (3), and under the assumption (i), they are invariant under state feedback transformations (5).

Let $m_0 = \mathrm{rank}\, \mathcal{G}_0$, $m_i = \mathrm{rank}\, \mathcal{G}_i - \mathrm{rank}\, \mathcal{G}_{i-1}$, $i > 1$, in U_0. The m indices (since $m_0 = m$),

$$k_j = \mathrm{card}\,\{i \mid m_i \geqq j\}, \qquad 1 \leqq j \leqq m,$$

are uniquely associated with a system (1) satisfying (i) and (ii): they are invariant under a state-space change of coordinates (3) and state feedback transformations (5). They are called controllability indices.

It has been shown in [5] that dynamic feedback linearizability implies static feedback linearizability when $m' = m = 1$. We now generalize this result for arbitrary $m' \geqq m = 1$.

THEOREM 2.2. *The following statements are equivalent*:

(i) *System* (1) *with* $m = 1$ *is locally static feedback linearizable.*

(ii) *System* (1) *with* $m = 1$ *is locally dynamic feedback linearizable.*

Proof. The proof is an easy generalization of the main result in [5]; (i)⇒(ii) is obvious.

(ii)⇒(i). By assumption (ii) there exists a linearizing compensator (9) for system (1) with $m = 1$ and characteristic index ν. We first establish a relationship between the distributions $\mathcal{G}_i$ defined by (21) for system (1) and the distributions $\tilde{\mathcal{G}}_i$ defined for system (16) with $m = 1$ obtained by using the linearizing compensator:

$$\tilde{\mathcal{G}}_0 = sp\{\tilde{g}_k, 1 \leqq k \leqq m'\} \tag{23}$$
$$\tilde{\mathcal{G}}_i = \tilde{\mathcal{G}}_{i-1} + sp\{\mathrm{ad}_{\tilde{f}}^i\, \tilde{g}_k, 1 \leqq k \leqq m'\}$$

CLAIM.

$$\mathrm{ad}_{\tilde{f}}^i\, \tilde{g}_j = \begin{pmatrix} 0 \\ * \end{pmatrix} \qquad \text{if } i < \nu \tag{24}$$
$$\mathrm{ad}_{\tilde{f}}^i\, \tilde{g}_j = \begin{pmatrix} \gamma_j \mathrm{ad}_f^{i-\nu}\, g + X_{j,i} \\ * \end{pmatrix} \qquad \text{if } i \geqq \nu,$$

where $X_{j,i} \in \overline{\mathcal{G}_{i-\nu-1}}$ *and* $\gamma_j = (-1)^\nu \delta_j$, δ_j *being defined by* (19).

[2] We denote by $\mathrm{ad}_f\, g = [f, g]$ the *Lie bracket of the smooth vector fields f and g.* In local coordinates, $[f, g] = \sum_{n=1}^n \sum_{j=1}^n f_j(\partial g_i/\partial x_j) - g_j(\partial f_i/\partial x_j))(\partial/\partial x_i)$. We also note $\mathrm{ad}_f^0\, g = g$ and $\mathrm{ad}_f^k\, g = [f, \mathrm{ad}_f^{k-1}\, g]$ for all $k \geqq 1$.

Proof of the claim. The proof is by induction on i. For $i=0$ we have

$$\tilde{g}_j=\begin{pmatrix}\beta_j g\\ b\end{pmatrix}$$

with $\beta_j=\gamma_j$ and $X_{j,0}=0$ if $\nu=0$ and $\beta_j=0$ if $\nu\geqq 1$.

We assume that the claim holds true for an integer i: we shall prove it for $i+1$. We consider two cases: $i\geqq\nu$; $i<\nu$. If $i\geqq\nu$,

$$\begin{aligned}\mathrm{ad}_f^{i+1}\tilde{g}_j&=\left[\begin{pmatrix}f(z)+\alpha(z,w)g(z)\\ a(z,w)\end{pmatrix},\begin{pmatrix}\gamma_j(z,w)\,\mathrm{ad}_f^{i-\nu}g+X_{j,i}\\ *\end{pmatrix}\right]\\ &=\begin{pmatrix}\gamma_j\,\mathrm{ad}_f^{i+1-\nu}g+X_{j,i+1}\\ *\end{pmatrix},\end{aligned}$$

where

$$X_{j,i+1}=[f,X_{j,i}]+\alpha[g,X_{j,i}]+(L_{\tilde f}\gamma_j)\,\mathrm{ad}_f^{i-\nu}g-(L_{\mathrm{ad}_f^i}\tilde{g}\alpha)g+\alpha\gamma_j\,\mathrm{ad}_g\,\mathrm{ad}_f^{i-\nu}g+\frac{\partial X_{j,i}}{\partial w}a.$$

Since $X_{j,i}\in\overline{\mathscr{G}_{i-\nu-1}}$ and $\gamma_j=(-1)^\nu\delta_j$, $X_{j,i}$ can be written as

$$X_{j,i}(z,w)=\sum_k\sigma_k(z,w)\Gamma_{k,j,i}(z),$$

with $\Gamma_{k,j,i}\in\overline{\mathscr{G}_{i-\nu-1}}$, thus

$$\frac{\partial X_{j,i}}{\partial w}a=\sum_k(L_a\sigma_k)\Gamma_{k,j,i}\in\overline{\mathscr{G}_{i-\nu-1}}$$

and $X_{j,i+1}$ belongs to $\overline{\mathscr{G}_{i-\nu}}$.

If $i<\nu$, by assumption

$$\mathrm{ad}_{\tilde f}^i\tilde{g}_j=\begin{pmatrix}0\\ *\end{pmatrix}$$

so

$$\mathrm{ad}_{\tilde f}^{i+1}\tilde{g}_j=\begin{pmatrix}-(L_{\mathrm{ad}_f^i}\tilde{g}_j\alpha)g\\ *\end{pmatrix}.$$

Since

$$L_{\mathrm{ad}_f^i}\tilde{g}_j\alpha=\begin{cases}0 & \text{if } i<\nu-1\\ (-1)^iL_{\tilde{g}_j}L_{\tilde f}^i\alpha & \text{if } i=\nu-1\end{cases}$$

then

$$\mathrm{ad}_{\tilde f}^{i+1}\tilde{g}_j=\begin{cases}\begin{pmatrix}0\\ *\end{pmatrix} & \text{if } i\leqq\nu-2\\ \begin{pmatrix}\gamma_j g\\ *\end{pmatrix} & \text{if } i=\nu-1.\end{cases}$$

The claim is proved.

We now show, by contradiction, that the distributions $\mathscr{G}_i$ must be involutive. Suppose that the distributions $\mathscr{G}_i$ are not all involutive i, $0\leqq i\leqq n-1$. Let $k<n$ be the smallest integer such that $\mathscr{G}_k$ is not involutive; then for some j, $0\leqq j\leqq k-1$,

$$[\mathrm{ad}_f^j g,\mathrm{ad}_f^k g]\notin\mathscr{G}_k. \tag{25}$$

Let l be such that $\gamma_l \neq 0$; according to the claim

$$(26) \qquad [\mathrm{ad}_{\tilde{f}}^{j+\nu}\, \tilde{g}_l, \mathrm{ad}_{\tilde{f}}^{k+\nu}\, \tilde{g}_l] = \left[\begin{pmatrix} \gamma_l \,\mathrm{ad}_f^j\, g + X_{l,j+\nu} \\ * \end{pmatrix}, \begin{pmatrix} \gamma_l \,\mathrm{ad}_f^k\, g + X_{l,k+\nu} \\ * \end{pmatrix}\right],$$

where $X_{l,j+\nu} \in \overline{\mathscr{G}_{j-1}} = \mathscr{G}_{j-1}$ and $X_{l,k+\nu} \in \overline{\mathscr{G}_{k-1}} = \mathscr{G}_{k-1}$: it follows from (25) and (26) that $\tilde{\mathscr{G}}_{k+\nu}$ is not involutive and this contradicts the assumption (ii). We established that $\mathscr{G}_i$ is involutive for every $i, 0 \leqq i \leqq n-1$. We remark that the claim implies that $\mathscr{G}_i = T\pi(\tilde{\mathscr{G}}_{i+\nu})$ where π is the projection $(x, w) \overset{\pi}{\mapsto} x$. To eliminate the input redundancies we can make a suitable choice of basis and decompose $\tilde{\mathscr{G}}_{\nu+i}$ in the following way:

$$\tilde{\mathscr{G}}_{\nu+i} = E_i \oplus F_i,$$

where $T\pi$ induces a bijection from E_i to $\mathscr{G}_i$ and $F_i = \tilde{\mathscr{G}}_{\nu+i} \cap \ker T\pi$. Thus we have

$$\operatorname{rank} \tilde{\mathscr{G}}_{\nu+i} = \operatorname{rank} \mathscr{G}_i + \operatorname{rank} F_i.$$

Since the functions $\tilde{x} \mapsto \operatorname{rank} \mathscr{G}_i(\pi(\tilde{x}))$ and $\tilde{x} \mapsto \operatorname{rank} F_i(\tilde{x})$ are lower semicontinuous and since $\tilde{\mathscr{G}}_i$ has constant rank, F_i and $\mathscr{G}_i$ also have constant rank.

Let $\mathscr{G}_* = \bigcup_{i=0}^{\infty} \mathscr{G}_i$ and $\tilde{\mathscr{G}}_* = \bigcup_{i=0}^{\infty} \tilde{\mathscr{G}}_i$ we have $T\pi(\tilde{\mathscr{G}}_*) = \mathscr{G}_*$. Assumption (ii) implies that $\tilde{\mathscr{G}}_* = T\mathbb{R}^{n+q}$, so we have $\mathscr{G}_* = T\mathbb{R}^n$, but since $\mathscr{G}_* = \mathscr{G}_{n-1}$, $(z \in \mathbb{R}^n)$, we have $\operatorname{rank} \mathscr{G}_{n-1} = n$. □

3. A necessary condition. We give an easy necessary condition for nonlinear system dynamic linearization.

THEOREM 3.1. *If system* (1) *is locally dynamic feedback linearizable, then its linear approximation at the origin* $\dot{z} = \nabla_z f(0) z + G(0) u \triangleq Fz + Gu$ *is controllable, i.e.,* $\operatorname{rank}(G, FG, \cdots, F^{n-1}G) = n$.

Proof. According to the assumptions, there exists a dynamic compensator (9) and an extended state diffeomorphism $x = \varphi(z, w)$ that transform the extended system into a linear controllable one (2). Consider the extended system:

$$(27) \qquad \begin{aligned} \dot{z} &= f(z) + G(z)\alpha(z, w) + G(z)\beta(z, w)v \\ \dot{w} &= a(z, w) + B(z, w)v. \end{aligned}$$

It follows that the linear approximation of (27)

$$(28) \qquad \begin{aligned} \dot{z} &= (\nabla_z f)(0)z + G(0)(\nabla_z \alpha)(0,0)z + G(0)(\nabla_w \alpha)(0,0)w + G(0)\beta(0,0)v \\ \dot{w} &= (\nabla_z a)(0,0)z + (\nabla_w a)(0,0)w + B(0,0)v \end{aligned}$$

is equivalent, up to a linear change of coordinates to a linear controllable system and thus is controllable. A straightforward computation then shows that the controllability of (28) implies that the linear approximation of (1) is controllable, i.e., it satisfies the Kalman criterion. □

This condition is obviously not sufficient, as is shown by the following example:

$$(29) \qquad \begin{aligned} \dot{x}_1 &= x_2 + x_3^2, \\ \dot{x}_2 &= x_3, \\ \dot{x}_3 &= u. \end{aligned}$$

The linear approximation at the origin of this system is

$$\dot{x} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} x + \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} u,$$

which is controllable. However, according to Theorem 2.1, the single input system (29) is not static feedback linearizable and, according to Theorem 2.2, it is not dynamic feedback linearizable.

4. Sufficient conditions. In this section we investigate the structure of the distribution $\tilde{\mathcal{G}}_i$ for the following extended system, given by system (1) along with a dynamic compensator (12) or (13)

$$
\begin{aligned}
&\dot{z}=f(z)+\sum_{j,\mu_j\geqq 1} w_1^j g_j(z)+\sum_{j,\mu_j=0} v_j'(t)g_j(z)\\
(30)\qquad &\dot{w}_i^j=w_{i+1}^j \qquad 1\leqq j\leqq m,\quad \mu_j>1,\quad 1\leqq i\leqq \mu_j-1\\
&\dot{w}_{\mu_j}^j=v_j' \qquad 1\leqq j\leqq m,\quad \mu_j\geqq 1,
\end{aligned}
$$

which can be written as

$$
(31)\qquad \dot{\tilde{z}}=\tilde{f}(\tilde{z})+\sum_{j=1}^{m}\tilde{g}_j(\tilde{z})v_j'(t),
$$

where

$$
\begin{aligned}
&\tilde{z}=(z, w_1^j,\cdots,w_{\mu_j}^j;\ 1\leqq j\leqq m,\ \mu_j\geqq 1)=(z,w)\\
&\tilde{f}=f+\sum_{j,\mu_j\geqq 1} w_1^j g_j+\sum_{j,\mu_j\geqq 2}\ \sum_{i=1}^{\mu_j-1} w_{i+1}^j\frac{\partial}{\partial w_i^j}\\
(32)\qquad &\\
&\tilde{g}_j=\begin{cases} g_j & \text{if } \mu_j=0\\ \dfrac{\partial}{\partial w_{\mu_j}^j} & \text{if } \mu_j\geqq 1.\end{cases}
\end{aligned}
$$

The distributions $\tilde{\mathcal{G}}_i$ for system (31) are defined in the extended space (z, w) as

$$
(33)\qquad \tilde{\mathcal{G}}_i=sp\{\mathrm{ad}_{\tilde{f}}^l\,\tilde{g}_j,\ 0\leqq l\leqq i,\ 1\leqq j\leqq m\}.
$$

We now define on the original state space a set of distributions that depend on the indices $\{\mu_1,\cdots,\mu_m\}$ and that play a crucial role in this paper:

$$
\begin{aligned}
&\Delta_0=sp\{g_k,\ 1\leqq k\leqq m,\ \mu_k=0\}\\
(34)\qquad &\\
&\Delta_{i+1}=\Delta_i+\mathrm{ad}_f\Delta_i+sp\{g_k,\ 1\leqq k\leqq m,\ \mu_k=i+1\}.
\end{aligned}
$$

By definition, $\Delta_0\subset\Delta_1\subset\cdots\subset\Delta_i\subset\cdots$. The following lemma gives conditions under which the set of distributions $\tilde{\mathcal{G}}_i$ in the extended state space is clearly related to the set of distributions Δ_i in the original state space.

LEMMA 4.1. *If for all i, $i\geqq 0$ and for all j, $1\leqq j\leqq m$, such that $\mu_j\geqq 1$*

$$
[g_j,\Delta_i]\subset\Delta_{i+1}
$$

then, for $i\geqq 0$

$$
(35)\qquad \tilde{\mathcal{G}}_i=\Delta_i+sp\left\{\frac{\partial}{\partial w_{\mu_j}^j}\,\middle|\,\mu_j\geqq 1\right\}+\cdots+sp\left\{\frac{\partial}{\partial w_{\mu_j-i}^j}\,\middle|\,\mu_j\geqq i+1\right\}.
$$

Proof. Let us compute $\tilde{\mathcal{G}}_0$

$$
\begin{aligned}
\tilde{\mathcal{G}}_0&=sp\{\tilde{g}_1,\cdots,\tilde{g}_m\}\\
&=sp\{g_k\,|\,\mu_k=0\}+sp\left\{\frac{\partial}{\partial w_{\mu_j}^j}\,\middle|\,\mu_j\geqq 1\right\}.
\end{aligned}
$$

By definition of Δ_0 we have:

$$\tilde{\mathscr{G}}_0 = \Delta_0 + sp\left\{\frac{\partial}{\partial w^j_{\mu_j}} \,\middle|\, \mu_j \geqq 1\right\}.$$

We now proceed by induction in the computation of the distributions $\tilde{\mathscr{G}}_i$ by showing that if

$$\tilde{\mathscr{G}}_i = \Delta_i + sp\left\{\frac{\partial}{\partial w^j_{\mu_j}} \,\middle|\, \mu_j \geqq 1\right\} + \cdots + sp\left\{\frac{\partial}{\partial w^j_{\mu_j - i}} \,\middle|\, \mu_j \geqq i+1\right\}$$

then, under the assumption of Lemma 4.1 we have

$$\tilde{\mathscr{G}}_{i+1} = \Delta_{i+1} + sp\left\{\frac{\partial}{\partial w^j_{\mu_j}} \,\middle|\, \mu_j \geqq 1\right\} + \cdots + sp\left\{\frac{\partial}{\partial w^j_{\mu_j - i - 1}} \,\middle|\, \mu_j \geqq i+2\right\},$$

which can be shown by computing

$$\tilde{\mathscr{G}}_{i+1} = \tilde{\mathscr{G}}_i + \mathrm{ad}_{\tilde{f}}\, \tilde{\mathscr{G}}_i.$$

We have

$$\begin{aligned} \mathrm{ad}_{\tilde{f}}\, \tilde{\mathscr{G}}_i &= sp\{\mathrm{ad}_{\tilde{f}}\, X;\ X \in \tilde{\mathscr{G}}_i\} \\ &= sp\left\{\mathrm{ad}_f\, Y + \sum_{j, \mu_j \geqq 1} w^j_1\, \mathrm{ad}_{g_j}\, Y;\ Y \in \Delta_i\right\} + sp\{g_j \mid \mu_j = i+1\} \\ &\quad + sp\left\{\frac{\partial}{\partial w^j_{\mu_j}};\ \mu_j \geqq 1\right\} + \cdots + sp\left\{\frac{\partial}{\partial w^j_{\mu_j - i - 1}};\ \mu_j \geqq i+2\right\}. \end{aligned}$$

Consider $[g_j, \Delta_i]$ for those j such that $\mu_j \geqq 1$; by the assumptions of the lemma we have $[g_j, \Delta_i] \subset \Delta_{i+1}$ for all j such that $\mu_j \geqq 1$. According to the definition of Δ_{i+1}, we have proved that the lemma holds true for $i+1$. Since the induction has been proved for $i = 0$, the lemma holds true for every $i \geqq 0$. □

THEOREM 4.2. *If for a set of integers* $\{\mu_1, \cdots, \mu_m\}$, $0 \leqq \mu_1 \leqq \cdots \leqq \mu_m$, $\mu = \sum_{i=1}^m \mu_i$, *the distributions, up to input reordering,*

$$\Delta_0 = sp\{g_k;\ \mu_k = 0\}$$

$$\Delta_{i+1} = \Delta_i + \mathrm{ad}_f \Delta_i + sp\{g_k;\ \mu_k = i+1\}, \qquad i \geqq 0$$

are such that in U_0, *a neighborhood of the origin*

(i) Δ_i *is involutive and of constant rank for* $0 \leqq i \leqq n + \mu_m - 1$;

(ii) rank $\Delta_{n+\mu_m-1} = n$;

(iii) $[g_j, \Delta_i] \subset \Delta_{i+1}$ *for all* j, $1 \leqq j \leqq m$, *such that* $\mu_j \geqq 1$ *and all* i, $0 \leq i \leq n + \mu_m - 1$; *then the system* (1) *is locally dynamic feedback linearizable by a dynamic compensator* (12) *with indices* $\mu_1, \ldots, \mu_m$ *and a local diffeomorphism in* V_0, *a neighborhood of the origin in the extended state space* $\mathbb{R}^{n+\mu}$.

Proof. According to Lemma 4.1, assumption (iii) guarantees that (35) holds for every $i \geqq 0$. Since Δ_i only depends on z, being defined on the original state space, it follows from (35) and assumption (i) that the distributions $\tilde{\mathscr{G}}_i$ are involutive and of constant rank for every $i \geqq 0$.

By assumption (ii), equality (35) for $i = n + \mu_m - 1$ implies that rank $\tilde{\mathscr{G}}_{n+\mu_m-1} = n + \mu$ and thus rank $\tilde{\mathscr{G}}_{n+\mu-1} = n + \mu$. We can then apply Theorem 2.1 to the extended system (30), which guarantees the existence of an extended state feedback

$$v' = \alpha(z, w) + \beta(z, w) v$$

with $\alpha(0,0)=0, \beta(z,w)$ nonsingular $m\times m$ matrix, and of an extended space diffeomorphism

$$x=\varphi(z,w), \qquad \varphi(0,0)=0 \qquad z\in\mathbb{R}^{n+\mu}$$

transforming the system (30) into a linear controllable one in x-coordinates. In conclusion we have proved that there exist a dynamic state feedback compensator (12) with indices $\mu_1, \cdots \mu_m$ and an extended space diffeomorphism (10) transforming the system (1) into a linear and controllable one of dimension $n+\mu$. □

COROLLARY 4.3. *Consider system* (1) *with* $m=n-1$. *The following statements are equivalent*:

(i) *System* (1) *is locally dynamic feedback linearizable.*

(ii) *The linear approximation of system* (1) *at the origin is controllable.*

Proof. (i)⇒(ii) follows from Theorem 3.1.

(ii)⇒(i). Since the linear approximation of system (1) is controllable, there exists a vector field g_i such that $\mathrm{ad}_f g_i$ does not belong to $\mathscr{G}_0$; furthermore $\mathscr{G}_1=T\mathbb{R}^n$. There are two cases. Either $\mathscr{G}_0$ is involutive and therefore, since $\mathscr{G}_1=T\mathbb{R}^n$, according to Theorem 2.1, system (1) is static feedback linearizable. In the opposite case, we set $\mu_k=1$ if $k\neq i$ and $\mu_i=0$, we have

- $\Delta_0=sp\{g_i\}$ which is of rank 1 and involutive.
- $\Delta_1=\mathscr{G}_0+sp\{\mathrm{ad}_f g_i\}=T\mathbb{R}^n$ since $n=m+1$.

The assumptions of Theorem 4.2 are met and system (1) is dynamic feedback linearizable. □

Remark 1. Corollary 4.3 agrees with the sufficient conditions obtained in [5]. Corollary 4.3 is false if $m<n-1$ in system (1), as shown by (29) (single-input system). A multi-input counterexample is given by the following system

$$\dot{x}_1=x_2+x_3^2$$

$$\dot{x}_2=x_3$$

$$\dot{x}_3=u_1$$

$$\dot{x}_4=u_2$$

Its linear approximation at the origin is controllable; nevertheless, it can be easily seen that the system is a dynamic extension of (29) by setting $m'=2$, $w_1=x_4$, $\dot{w}_1=u_2$, and $u=u_1$ with the notations of (14). Since (29) is not dynamic feedback linearizable by virtue of Theorem 2.2, it is also true for any dynamic extension of (29) (by contradiction), which proves that our multi-input system is not dynamic feedback linearizable.

Remark 2. Conditions (i) and (iii) of Theorem 4.2 have some redundancy. In fact the involutivity of Δ_{i+1} and the inclusion $\Delta_i\subset\Delta_{i+1}$ imply

$$[g_j, \Delta_{i+1}]\subset\Delta_{i+1}$$

and therefore

$$[g_j, \Delta_i]\subset\Delta_{i+1}$$

for all j, $1\leqq j\leqq m$, such that $\mu_j\leqq i+1$. Hence only the conditions

$$[g_j, \Delta_i]\subset\Delta_{i+1}$$

for all $i\geqq 0$ and for all j, $1\leqq j\leqq m$, such that $\mu_j>i+1$ are not contained in assumption (i).

Remark 3. The conditions of Theorem 4.2 are invariant under state space diffeomorphism (3), but they are not invariant under feedback transformations (5).

Remark 4. If $\mu_i = 0, 1 \leqq i \leqq m$, then $\Delta_j = \mathscr{G}_j$ for every $j \geqq 0$. Since condition (i) of Theorem 4.2 requires that the distributions $\Delta_j = \mathscr{G}_j$ be involutive, condition (iii) of Theorem 4.2 is always satisfied (in fact $[g_j, \Delta_i] \subset \Delta_i$, $1 \leqq j \leqq m$, in this case). Conditions (i) and (ii) of Theorem 4.2 coincide then with the necessary and sufficient conditions of Theorem 2.1. Theorem 4.2 can be viewed as a generalization of Theorem 2.1.

Remark 5. For those systems for which Theorem 4.2 applies, we can compute the controllability indices of system (30) from (35) on the basis of the distributions Δ_i. Let

$$\begin{aligned} \tilde{m}_0 &= \text{rank } \tilde{\mathscr{G}}_0 = m \\ \tilde{m}_i &= \text{rank } \tilde{\mathscr{G}}_i - \text{rank } \tilde{\mathscr{G}}_{i-1} \\ &= \text{rank } \Delta_i - \text{rank } \Delta_{i-1} + \text{card } \{j \mid \mu_j \geqq i+1;\ 1 \leqq j \leqq m\}, \end{aligned}$$

then

$$\tilde{k}_j = \text{card}\,\{i \mid \tilde{m}_i \geqq j\}, \qquad 1 \leqq j \leqq m,$$

is such that $\sum_{j=1}^{m} \tilde{k}_j = n + \mu$. Up to an input renumbering, we can then associate to any vector field g_j an index $\tilde{k}_j - \mu_j$ so that

$$\text{rank}\,\{g_j, \cdots, \text{ad}_f^{\tilde{k}_j - \mu_j - 1} g_j;\ 1 \leqq j \leqq m\} = n.$$

System (30) can be transformed into a linear controllable system with controllability indices $(\tilde{k}_1, \cdots, \tilde{k}_m)$ as follows:

1. Determine m functions $\varphi_1(z), \cdots, \varphi_m(z)$ such that:

   (i) The $m \times m$ matrix

   $$D(x) = (\langle \text{d}\varphi_i, \text{ad}_f^{\tilde{k}_i - \mu_j - 1} g_j \rangle)$$

   is nonsingular;

   (ii) $\langle \text{d}\varphi_i, \text{ad}_f^{\lambda} g_j \rangle = 0$, for every j, $1 \leqq j \leqq m$, and every λ, $0 \leqq \lambda < \tilde{k}_i - \mu_j - 1$.

2. The extended state space diffeomorphism is given by

   $$\varphi(z, w) = (\varphi_1, \cdots, L_{\tilde{f}}^{\tilde{k}_1 - 1} \varphi_1, \cdots, \varphi_m, \cdots, L_{\tilde{f}}^{\tilde{k}_m - 1} \varphi_m)$$

   with $\tilde{f}$ and $\tilde{g}_i$ being given by (30) and (32).

3. The extended state feedback transformation is (up to the former input renumbering)

   $$v'(t) = \alpha(z, w) + \beta(z, w) v(t) = \tilde{D}^{-1} \left[\begin{pmatrix} L_{\tilde{f}}^{\tilde{k}_1} \varphi_1(z, w) \\ \vdots \\ L_{\tilde{f}}^{\tilde{k}_m} \varphi_m(z, w) \end{pmatrix} + v(t) \right]$$

   with

   $$\tilde{D}_j^i(z, w) = L_{\tilde{g}_i} L_{\tilde{f}}^{\tilde{k}_j - 1} \varphi_j(z, w).$$

Remark 6. The sufficient conditions of Theorem 4.2 may be helpful in finding the structure of a dynamic compensator if it exists. We sketch the analysis in a particular case.

Assume that $\Lambda_0 = sp\{g_1, \cdots, g_{m-1}\}$ is an involutive subdistribution of $\mathscr{G}_0$. We assume that for each $i \geqq 0$, we have

$$\overline{\mathscr{G}_i} = \mathscr{G}_i + I(\{\text{ad}_f^k g_m, 0 \leqq k \leqq i\})$$

where $I(\{\text{ad}_f^k g_m, 0 \leqq k \leqq i\})$ is the Lie ideal of the Lie algebra $\overline{\mathscr{G}_i}$ generated by $\{\text{ad}_f^k g_m, 0 \leqq k \leqq i\}$. These conditions mean that the noninvolutivity of the distributions $\mathscr{G}_i$ is due to brackets involving g_m.

This specific Lie algebra structure of the distributions $\mathcal{G}_i$ and $\overline{\mathcal{G}_i}$ leads to the construction of a dynamic compensator of type (12) with $\mu_1=\cdots=\mu_{m-1}=0$ and $\mu_m\neq 0$. It remains to choose the value of μ_m. The following procedure gives bounds on the length of the chain of integrators.

We define the following distributions and indices

$$\Lambda_{i+1}=\Lambda_i+\mathrm{ad}_f\,\Lambda_i$$

$$i_0=\inf\{i\,|\,\mathcal{G}_i\neq\overline{\mathcal{G}_i}\}$$

$$\mu=\sup\{0,\{i_0-k\,|\,[\mathrm{ad}_f^k\,g_m,\mathrm{ad}_f^{i_0}\,\Lambda_0]\not\subset\mathcal{G}_{i_0},0\leqq k\leqq i_0\}\}$$

$$r=\sup\{i\,|\,\Lambda_i \text{ involutive and } \mathrm{ad}_{g_m}\,\Lambda_{i-1}\subset\Lambda_i\}.$$

Let $\mu_1=\cdots=\mu_{m-1}=0$. Assume that $\mu\leqq r$. Then let us choose μ_m and the distributions Δ_i as follows:

$$(36)\qquad\begin{aligned}&\mu+1\leqq\mu_m\leqq r+1\\&\Delta_i=\Lambda_i && \forall i\leqq\mu_m-1\\&\Delta_{\mu_m}=\Lambda_{\mu_m}+sp\{g_m\}\\&\Delta_{i+1}=\Delta_i+\mathrm{ad}_f\Delta_i && \forall i\geq\mu_m.\end{aligned}$$

According to the definition of the distributions Λ_i and of the index r, to Theorem 4.2 and to Remark 2, if Δ_i is involutive for all $i\geqq\mu_m$ then system (1) is dynamic feedback linearizable by the dynamic compensator (12) defined with $\mu_1=\cdots=\mu_{m-1}=0$ and μ_m given by (36).

If μ_m is chosen less than or equal to μ, Δ_{i_0} cannot be involutive:

$$\Delta_{i_0}=\sum_{k=0}^{i_0}\mathrm{ad}_f^k\,\Lambda_0+sp\{\mathrm{ad}_f^k\,g_m,0\leqq k\leqq i_0-\mu_m\},$$

$\mathrm{ad}_f^{i_0-\mu}\,g_m\subset\Delta_{i_0}$ which implies, according to the definition of μ, that $\Delta_{i_0}\subset\mathcal{G}_{i_0}$ is not involutive.

On the contrary, if the index μ_m is chosen strictly greater than $r+1$, then

$$\Delta_{r+1}=\Lambda_{r+1}$$

and according to the definition of r, Δ_{r+1} is not involutive. Therefore, the only possible choice is $\mu+1\leqq\mu_m\leqq r+1$.

5. Examples.

Example 1. This example illustrates how the sufficient conditions of Theorem 4.2 can lead to the construction of a linearizing dynamic compensator. Consider the system

$$\begin{aligned}\dot x_1&=x_2,\\\dot x_2&=u_1,\\\dot x_3&=u_2,\\\dot x_4&=x_3-x_3u_1;\end{aligned}$$

that is,

$$\dot x=f(x)+u_1g_1(x)+u_2g_2(x)$$

with

$$f = x_2 \frac{\partial}{\partial x_1} + x_3 \frac{\partial}{\partial x_4},$$

$$g_1 = \frac{\partial}{\partial x_2} - x_3 \frac{\partial}{\partial x_4},$$

$$g_2 = \frac{\partial}{\partial x_3}.$$

Easy computations give

$$\mathrm{ad}_{g_1} g_2 = \frac{\partial}{\partial x_4},$$

$$\mathrm{ad}_f g_2 = -\frac{\partial}{\partial x_4},$$

$$\mathrm{ad}_f g_1 = -\frac{\partial}{\partial x_1}.$$

The system is not feedback linearizable since $\mathscr{G}_0$ is not involutive and, therefore, condition (i) of Theorem 2.1 fails, whereas condition (ii) is satisfied, i.e., rank $\mathscr{G}_1 = 4$. Analyzing the Lie algebraic structure of the system we have that $sp\{g_1, g_2, \mathrm{ad}_f g_2\}$ is involutive and of constant rank 3 whereas $sp\{g_1, g_2, \mathrm{ad}_f g_1\}$ is not involutive. According to Remark 6, this leads us to choose $\mu_1 = 1$ and $\mu_2 = 0$, so that we have

$$\Delta_0 = sp\{g_2\},$$

$$\Delta_1 = sp\{g_2, \mathrm{ad}_f g_2, g_1\},$$

$$\Delta_2 = sp\{g_2, g_1, \mathrm{ad}_f g_1, g_2\}.$$

The conditions of Theorem 4.2 are satisfied. The controllability indices are $(3, 2)$ and

$$\mathrm{rank}\,\{g_1, \mathrm{ad}_f g_1, g_2, \mathrm{ad}_f g_2\} = 4.$$

The dynamic compensator is then

$$\frac{\mathrm{d}u_1}{\mathrm{d}t} = v_1', \qquad u_2 = v_2'.$$

Following the procedure outlined in Remark 5, the extended space change of coordinates is obtained solving

$$\mathrm{d}\varphi_1 \in (\Delta_1)^\perp, \qquad \mathrm{d}\varphi_2 \in (\Delta_0)^\perp$$

with

$$\begin{pmatrix} \langle \mathrm{d}\varphi_1, \mathrm{ad}_f g_1 \rangle & \langle \mathrm{d}\varphi_1, \mathrm{ad}_f^2 g_2 \rangle \\ \langle \mathrm{d}\varphi_2, g_1 \rangle & \langle \mathrm{d}\varphi_1, \mathrm{ad}_f g_2 \rangle \end{pmatrix}$$

nonsingular; a solution is $\varphi_1 = x_1$, $\varphi_2 = x_4$. The diffeomorphism is then

$$\varphi = (\varphi_1, L_{\tilde f}\varphi_1, L_{\tilde f}^2\varphi_1, \varphi_2, L_{\tilde f}\varphi_2) = (x_1, x_2, u_1, x_4, x_3 - x_3 u_1)$$

and the extended state feedback transformation is

$$\begin{pmatrix} v_1' \\ v_2' \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ -x_3 & 1 - u_1 \end{pmatrix}^{-1} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}.$$

The dynamic compensation has a singularity at $u_1 = 1$ where there is a loss of controllability.

Example 2. This example shows that condition (iii) of Theorem 4.2 is not necessary. Consider the system

$$\begin{aligned} \dot{x}_1 &= x_2 + x_3 u_2, \\ \dot{x}_2 &= x_3 + x_1 u_2, \\ \dot{x}_3 &= u_1 + x_2 u_2, \\ \dot{x}_4 &= u_2; \end{aligned}$$

i.e.,

$$\dot{x} = f(x) + u_1 g_1(x) + u_2 g_2(x)$$

with

$$f = x_2 \frac{\partial}{\partial x_1} + x_3 \frac{\partial}{\partial x_2}, \quad g_1 = \frac{\partial}{\partial x_3}, \quad g_2 = x_3 \frac{\partial}{\partial x_1} + x_1 \frac{\partial}{\partial x_2} + x_2 \frac{\partial}{\partial x_3} + \frac{\partial}{\partial x_4}.$$

We can compute

$$\mathrm{ad}_{g_2} g_1 = -\frac{\partial}{\partial x_1}, \quad \mathrm{ad}_{g_2}^2 g_1 = \frac{\partial}{\partial x_2}, \quad \mathrm{ad}_{g_2}^3 g_1 = -\frac{\partial}{\partial x_3};$$

that is, rank $\overline{\mathscr{G}_0} = 4$, and

$$\mathrm{ad}_f g_1 = -\frac{\partial}{\partial x_2}, \quad \mathrm{ad}_f^2 g_1 = \frac{\partial}{\partial x_1}, \quad \mathrm{ad}_f g_2 = -x_1 \frac{\partial}{\partial x_1} + x_3 \frac{\partial}{\partial x_3}.$$

Since $\mathscr{G}_0$ is not involutive, the system is not static feedback linearizable; however, rank $\mathscr{G}_2 = 4$ and the linear approximation at the origin is controllable. If we set $\mu_1 = 0$ and $\mu_2 = 3$, the extended system

$$\begin{aligned} \dot{x}_1 &= x_2 + x_3 w_1, \\ \dot{x}_2 &= x_3 + x_1 w_1, \\ \dot{x}_3 &= v_1' + x_2 w_1, \\ \dot{x}_4 &= w_1, \\ \dot{w}_1 &= w_2, \\ \dot{w}_2 &= w_3, \\ \dot{w}_3 &= v_2' \end{aligned}$$

turns out to be static feedback linearizable; in fact,

$$\tilde{\mathscr{G}}_0 = sp\left\{\frac{\partial}{\partial w_3}, \frac{\partial}{\partial x_3}\right\}$$

$$\tilde{\mathscr{G}}_1 = \tilde{\mathscr{G}}_0 + sp\left\{\frac{\partial}{\partial w_2}, \frac{\partial}{\partial x_2} + w_1 \frac{\partial}{\partial x_1}\right\}$$

$$\tilde{\mathscr{G}}_2 = \tilde{\mathscr{G}}_1 + sp\left\{\frac{\partial}{\partial w_1}, (1 - w_2)\frac{\partial}{\partial x_1} + w_1^2 \frac{\partial}{\partial x_2} + w_1 \frac{\partial}{\partial x_3}\right\}.$$

When $w_1^3+w_2-1\neq 0$ (i.e., when u_1 satisfies $\dot{u}_1\neq 1-u_1^3$) we have

$$\tilde{G}_2=\tilde{G}_1+sp\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}\right\}.$$

Thus rank $\tilde{\mathscr{G}}_2=6$ and, again when $w_1^3+w_2-1\neq 0$, we have $\tilde{\mathscr{G}}_3=T\mathbb{R}^7$. Hence the distributions $\tilde{\mathscr{G}}_i$ satisfy the conditions of Theorem 2.1 as long as $w_1^3+w_2-1\neq 0$. On the other hand, $\Delta_0=sp\{\partial/\partial x_3\}$, $\Delta_1=sp\{(\partial/\partial x_3), (\partial/\partial x_2)\}$ and condition (iii) of Theorem 4.2 fails since $\mathrm{ad}_{g_2} g_1$ is not contained in Δ_1; note that formula (35) does not hold for $i=1$.

This example illustrates the role of condition (iii): although not necessary, it allows us to check the involutivities and constant rank condition for the distributions $\tilde{\mathscr{G}}_i$ on the basis of the distributions Δ_i defined on the original state space.

Example 3. Theorem 6.5 of [12, p. 136] was the first general result where dynamic feedback linearization was achieved. The present example shows that the sufficient conditions obtained in Theorem 4.2 and Corollary 4.3 are different than those given in [12], which we now recall. The notations are those of [12]. Define the codistributions Ω_k, $k\geqq 0$:

$$\Omega_0=sp\{\mathrm{d}h\}=sp\{\mathrm{d}h_1,\cdots,\mathrm{d}h_p\},$$

$$\Omega_{k+1}=\Omega_k+L_f(\Omega_k\cap\mathscr{G}_0^\perp)+\sum_i L_{g_i}(\Omega_k\cap\mathscr{G}_0^\perp),$$

$$\Omega^*=\bigcap_{k=0}^{\infty}\Omega_k.$$

Recall that if $\omega=\sum_i \omega_i\,dx_i$ is a smooth 1-form and $\gamma=\sum_i \gamma_i(\partial/\partial x_i)$ is a smooth vector field, we have

$$L_\gamma\omega=\left(\frac{\partial\omega^T}{\partial x}\gamma\right)^T+\omega\frac{\partial\gamma}{\partial x}.$$

Recall also that $\Delta^*=(\Omega^*)^\perp$ is the largest (f,g)-invariant distribution contained in $\mathrm{Ker}\,\mathrm{d}h=\Omega_0^\perp$.

In [12] the following result is proved.

Assume that:

(A1) $$\Delta^*=\{0\},$$

(A2) $$\sum_i L_{g_i}(\Omega_k\cap\mathscr{G}_0^\perp)\subset\Omega_k \textit{ for every } k\geqq 0.$$

Then the system is locally dynamic feedback linearizable.

Consider the system, which was suggested to us by Respondek:

$$\begin{aligned}\dot{x}_1&=u_1,\\ \dot{x}_2&=x_3+\varphi(x)u_1,\\ \dot{x}_3&=u_2,\\ y_1&=h_1(x),\\ y_2&=h_2(x),\end{aligned}\tag{37}$$

with $\varphi(0)=0$, $(\partial\varphi/\partial x_3)(x)\neq 0$, for all $x\in\mathbb{R}^3$, and h_1, h_2 two generic output functions. The linear approximation at the origin is controllable and Corollary 4.3 applies. Thus, h_1, h_2 can be constructed according to Remark 5.

Let us prove that there cannot exist two analytic output functions h_1, h_2 for the system (37) such that the sufficient conditions of [12] are satisfied.

We have

$$f = x_3 \frac{\partial}{\partial x_2}$$

and

$$g_1 = \frac{\partial}{\partial x_1} + \varphi \frac{\partial}{\partial x_2}, \qquad g_2 = \frac{\partial}{\partial x_3}.$$

Thus $\mathscr{G}_0^{\perp} = sp\{(\varphi, -1, 0)\}$. Since $\mathscr{G}_0^{\perp}$ is one-dimensional, two cases can arise:

- $\mathscr{G}_0^{\perp} \cap \Omega_0 = 0$, which implies that $\Omega^* = \Omega_0$ and thus Δ^* is one-dimensional, $\Delta^* \neq 0$. Thus (A1) is violated.
- $\mathscr{G}_0^{\perp} \cap \Omega_0 = \mathscr{G}_0^{\perp}$ and we have $L_{g_1}(\varphi, -1, 0) = (\varphi(\partial\varphi/\partial x_2), -(\partial\varphi/\partial x_2), -(\partial\varphi/\partial x_3))$, $L_{g_2}(\varphi, -1, 0) = ((\partial\varphi/\partial x_3), 0, 0)$. It results that, if $(\partial\varphi/\partial x_3) \neq 0$, $\Omega_0 + \sum_i L_{g_i}(\Omega_0 \cap \mathscr{G}_0^{\perp}) = T^*\mathbb{R}^3 \neq \Omega_0$, which proves that (A2) is violated.

The claim is proved.

Example 4 (rigid body dynamics). We consider a general model of rigid body dynamics that includes the case of aircraft dynamics [5]. Our general purpose here is to show that Theorem 4.2 applies to important classes of mechanical systems rather than deal with specific applications of aircraft control.

Let (x, y, z) be the coordinates of the center of mass in an absolute frame with the vertical z-axis oriented downward, (u, v, w) the velocity components in a relative frame linked to the rigid body, (p, q, r) the components of the kinetic moment in the relative frame, (Φ, Θ, Ψ) the roll, pitch, and yaw angles, respectively. Let $\xi = (x, y, z, u, v, w, \Phi, \Theta, \Psi)^T$ be the state vector.

We consider p, q, r, and ρ (ρ is the thrust) as control variables. The equations of motion are

$$\begin{aligned}
\dot{x} &= u \cos\Psi \cos\Theta + v(\cos\Psi \sin\Theta \sin\Phi - \sin\Psi \cos\Phi) \\
&\quad + w(\cos\Psi \sin\Theta \cos\Phi + \sin\Psi \sin\Phi), \\
\dot{y} &= u \sin\Psi \cos\Theta + v(\sin\Psi \sin\Theta \sin\Phi + \cos\Psi \cos\Phi) \\
&\quad + w(\sin\Psi \sin\Theta \cos\Phi - \cos\Psi \sin\Phi), \\
\dot{z} &= -u \sin\Theta + v \cos\Theta \sin\Phi + w \cos\Theta \cos\Phi, \\
\dot{u} &= -g \sin\Theta + rv - qw + \frac{X_0(\xi)}{m} + \frac{J\rho}{m}, \qquad (38) \\
\dot{v} &= g \cos\Theta \sin\Phi - ru + pw + \frac{Y(\xi)}{m}, \\
\dot{w} &= g \cos\Theta \cos\Phi + qu - pv + \frac{Z(\xi)}{m}, \\
\dot{\Phi} &= p + \mathrm{tg}\Theta(q \sin\Phi + r \cos\Phi), \\
\dot{\Theta} &= q \cos\Phi - r \sin\Phi, \\
\dot{\Psi} &= \frac{q \sin\Phi + r \cos\Phi}{\cos\Theta},
\end{aligned}$$

where $(X_0(\xi)+J\rho,\ Y(\xi),\ Z(\xi))$ are the components of the force vector excepting gravity. The model is of the type

$$\dot{\xi}=f(\xi)+pg_1(\xi)+qg_2(\xi)+rg_3(\xi)+\rho g_4(\xi) \tag{39}$$

with f, g_1, g_2, g_3, and g_4 obtained from (38).

The reader can compute the Lie brackets $\mathrm{ad}_{g_i} g_j$ with $1\leqq i,j\leqq 4$ and check that, independently of the type of functions that $X_0(\xi)$, $Y(\xi)$, and $Z(\xi)$ may be in specific cases,

- $sp\{g_1, g_2, g_3\}$ is involutive;
- $\mathscr{G}_0=sp\{g_1, g_2, g_3, g_4\}$ is not involutive, rank $\mathscr{G}_0=4$;
- $\overline{\mathscr{G}_0}=\mathscr{G}_0+sp\{\mathrm{ad}_{g_4} g_2, \mathrm{ad}_{g_4} g_3\}$ $=sp\{(\partial/\partial u), (\partial/\partial v), (\partial/\partial w), (\partial/\partial\Phi), (\partial/\partial\Theta), (\partial/\partial\Psi)\}$, rank $\overline{\mathscr{G}_0}=6$;
- $\mathscr{G}_1=\mathscr{G}_0+\mathrm{ad}_f\mathscr{G}_0\neq\overline{\mathscr{G}_1}=T\mathbb{R}^9$, rank $\mathscr{G}_1=7$ and rank $\overline{\mathscr{G}_1}=9$.

Since $\mathscr{G}_0$ is not involutive, the system is not feedback linearizable. However, it is clear from the Lie bracket configuration that all the noninvolutivities are caused by g_4 and, according to Remark 6, if we choose $\mu_1=\mu_2=\mu_3=0$ and $\mu_4=1$, we have

$$\Delta_0=sp\{g_1, g_2, g_3\}$$
$$\Delta_1=\Delta_0+\mathrm{ad}_f\,\Delta_0+sp\{g_4\}=\overline{\mathscr{G}_0}$$
$$\Delta_2=\Delta_1+\mathrm{ad}_f\,\Delta_1=T\mathbb{R}^9.$$

Therefore, the sufficient conditions of Theorem 4.2 are satisfied, which leads to the compensator

$$\begin{aligned}\dot{\rho}&=v_4,\\ p&=v_1,\\ q&=v_2,\\ r&=v_3.\end{aligned} \tag{40}$$

Define the functions

$$\begin{aligned}y_1&=x,\\ y_2&=y,\\ y_3&=z,\\ y_4&=\rho,\end{aligned}$$

and the extended space diffeomorphism

$$(\xi,\rho)\mapsto\tilde{\xi},$$

where

$$\tilde{\xi}=(y_1, L_{\tilde{f}}y_1, L_{\tilde{f}}^2y_1, y_2, L_{\tilde{f}}y_2, L_{\tilde{f}}^2y_2, y_3, L_{\tilde{f}}y_3, L_{\tilde{f}}^2y_3, y_4)^T.$$

The dynamic compensator (40) together with extended state feedback

$$v=D^{-1}(v'-D_0),$$

where

$$D_0^1 = \frac{L_f X_0}{m} \cos \Psi \cos \Theta + \frac{L_f Y}{m} (\cos \Psi \sin \Theta \sin \Phi - \sin \Psi \cos \Phi)$$
$$+ \frac{L_f Z}{m} (\cos \Psi \sin \Theta \cos \Phi + \sin \Psi \sin \Phi),$$

$$D_0^2 = \frac{L_f X_0}{m} \sin \Psi \cos \Theta + \frac{L_f Y}{m} (\sin \Psi \sin \Theta \sin \Phi + \cos \Psi \cos \Phi)$$
$$+ \frac{L_f Z}{m} (\sin \Psi \sin \Theta \cos \Phi - \cos \Psi \sin \Phi),$$

$$D_0^3 = \frac{L_f X_0}{m} \sin \Theta + \frac{L_f Y}{m} \cos \Theta \sin \Phi + \frac{L_f Z}{m} \cos \Theta \cos \Phi,$$

$$D_0^4 = 0,$$

and

$$D_1^1 = \frac{Y}{m} (\cos \Psi \sin \Theta \cos \Phi) - \frac{Z}{m} (\cos \Psi \sin \Theta \sin \Phi) + \varepsilon_1^1,$$

$$D_1^2 = -\frac{X_0 + J\rho}{m} (\cos \Psi \sin \Theta \cos \Phi + \sin \Psi \sin \Phi) + \frac{Z}{m} \cos \Psi \cos \Theta + \varepsilon_1^2,$$

$$D_1^3 = \frac{X_0 + J\rho}{m} (\cos \Psi \sin \Theta \sin \Phi - \sin \Psi \cos \Phi) - \frac{Y}{m} \cos \Psi \cos \Theta + \varepsilon_1^3,$$

$$D_1^4 = \frac{J}{m} \cos \Psi \cos \Theta,$$

$$D_2^1 = \frac{Y}{m} (\sin \Psi \sin \Theta \cos \Phi - \cos \Psi \sin \Phi) - \frac{Z}{m} (\sin \Psi \sin \Theta \sin \Phi + \cos \Psi \cos \Phi) + \varepsilon_2^1,$$

$$D_2^2 = -\frac{X_0 + J\rho}{m} (\sin \Psi \sin \Theta \cos \Phi - \cos \Psi \sin \Phi) + \frac{Z}{m} \sin \Psi \cos \Theta + \varepsilon_2^2,$$

$$D_2^3 = \frac{X_0 + J\rho}{m} (\sin \Psi \sin \Theta \sin \Phi + \cos \Psi \cos \Phi) - \frac{Y}{m} \sin \Psi \cos \Theta + \varepsilon_2^3,$$

$$D_2^4 = \frac{J}{m} \sin \Psi \cos \Theta,$$

$$D_3^1 = \frac{\cos \Theta}{m} (-Y \cos \Phi + Z \sin \Phi) + \varepsilon_3^1,$$

$$D_3^2 = \frac{X_0 + J\rho}{m} \cos \Theta \cos \Phi + \frac{Z}{m} \sin \Theta + \varepsilon_3^2,$$

$$D_3^3 = -\left(\frac{X_0 + J\rho}{m} \cos \Theta \sin \Phi + \frac{Y}{m} \sin \Theta \right) + \varepsilon_3^3,$$

$$D_3^4 = \frac{J}{m} \sin \Theta,$$

and $D_4^1 = D_4^2 = D_4^3 = 0$ and $D_4^4 = 1$, with

$$\varepsilon_1^i = \cos\Psi\cos\Theta\,\frac{L_{g_i}X_0}{m} + (\cos\Psi\sin\Theta\sin\Phi - \sin\Psi\cos\Phi)\frac{L_{g_i}Y}{m}$$

$$+ (\cos\Psi\sin\Theta\cos\Phi + \sin\Psi\sin\Phi)\frac{L_{g_i}Z}{m} \qquad 1 \leqq i \leqq 3,$$

$$\varepsilon_2^i = \sin\Psi\cos\Theta\,\frac{L_{g_i}X_0}{m} + (\sin\Psi\sin\Theta\sin\Phi + \cos\Psi\cos\Phi)\,\frac{L_{g_i}Y}{m}$$

$$+ (\sin\Psi\sin\Theta\cos\Phi - \cos\Psi\sin\Phi)\frac{L_{g_i}Z}{m} \qquad 1 \leqq i \leqq 3,$$

$$\varepsilon_3^i = \sin\Theta\,\frac{L_{g_i}X_0}{m} + \cos\Theta\sin\Phi\,\frac{L_{g_i}Y}{m} + \cos\Theta\cos\Phi\,\frac{L_{g_i}Z}{m} \qquad 1 \leqq i \leqq 3$$

makes the closed loop system linear and controllable:

$$\frac{d^3 y_i}{dt^3} = v_i', \qquad 1 \leqq i \leqq 3$$

$$\dot{y}_4 = v_4'.$$

6. Conclusions. We have studied the problem of dynamic feedback linearization (Definition 2.1 and Definition 2.3) for nonlinear systems (1). Theorem 2.2 shows that for single input systems the set of dynamic feedback linearizable systems coincides with the set of static feedback linearizable systems. Theorem 3.1 shows that the controllability of the linear approximation at the origin is a necessary condition for dynamic feedback linearization, which is also sufficient when $m = n - 1$ in (1); this means that mild conditions identify dynamic feedback linearizable systems when the number of states minus the number of controls is equal to one. This is no longer true if $m < n - 1$.

Theorem 4.2 gives sufficient conditions for dynamic feedback linearization via special types of dynamic compensators (prolongations). The conditions are not necessary (Example 2) but are more general than existing sufficient conditions (Example 3) and include the known necessary and sufficient conditions for static feedback linearization. A contrived example (Example 1) and a model of complex dynamical system, namely the dynamics of a rigid body (Example 4), show how the sufficient conditions of Theorem 4.2 lead to the explicit determination of the linearizing dynamic compensator.

The challenging problem of finding necessary and sufficient conditions for dynamic feedback linearization remains open however. We have solved the problem only when $m = n - 1$ and we have established that it is a multi-input phenomenon; in the general case we have obtained constructive sufficient (but not necessary) conditions and necessary conditions.

QUADRATIC APPROXIMATIONS IN CONVEX NONDIFFERENTIABLE OPTIMIZATION*

MANLIO GAUDIOSO† AND MARIA FLAVIA MONACO†

Abstract. An implementable descent method for the unconstrained minimization of convex nonsmooth functions of several variables is described. The algorithm is characterized by the use of a set of quadratic approximations of the objective function in order to compute the search direction. The resulting direction finding subproblem is shown to be equivalent to a structured parametric quadratic programming problem. The convergence of the algorithm to the minimum is proved, and numerical experience is reported.

Key words. nondifferentiable optimization, bundle methods

AMS(MOS) subject classifications. 90C25, 65K05

1. Introduction. The research in the area of the numerical methods for nondifferentiable optimization is presently stimulated both by the relevant results that are being obtained in the field of nonsmooth analysis as well as by the practical need of algorithms performing better than those currently available.

The above motivations concurrently stimulate the research for numerical methods no longer exclusively based on piecewise linear approximations of the functions to be minimized.

In particular, the results presented in [7], [24] provide an extension to the convex nondifferentiable functions of the concept of second order derivative, through the definition of second subdifferential; on the other hand, parallel to the historical development of the numerical methods for the unconstrained minimization of smooth functions, "Newton type" methods are expected to replace "gradient type" methods [17].

This paper describes an implementable descent method for the unconstrained minimization of convex (not necessarily smooth) functions of several variables which takes advantage of the information available on the curvature of the objective function along certain directions. The algorithm is related to the family of bundle methods [12], [16], [5], the substantial difference being in the direction-finding step.

In fact, generalizing the approach presented in [6], the search direction is obtained by minimizing the directional derivative on a compact set which approximates the level set of the objective function. The approximation consists of a set of quadratic constraints generated on the basis of the "bundle" of information available.

The paper is organized as follows. In § 2 the approach is described with emphasis on the definition of the auxiliary problem to be solved at each step of the algorithm in order to find a search direction. Section 3 is devoted to the analysis of the auxiliary problem and to its reduction to a parametric quadratic program. The overall algorithm is stated in § 4. Finally the results of numerical experiments are reported in § 5.

The basic background of the paper is convex analysis, for which the fundamental reference is Rockafellar's book [20]. General references for the numerical methods are [1], [9], and [26]; in particular the bundle methods, which are strictly related to our approach, are surveyed in [14].

Standard notations are adopted throughout the paper. The symbol $\|\cdot\|$ denotes the euclidean norm. In the sequel, given a set A of the n-dimensional euclidean space,

* Received by the editors June 13, 1988; accepted for publication (in revised form) April 11, 1990.

† Dipartimento di Sistemi, Universita della Calabria 87036 Rende (CS), Italy.

we denote the convex hull of A as conv (A) and the vector of minimum norm in A (i.e., the nearest point to the origin) as Nr (A).

2. Preliminaries. Let f be a proper convex function defined on the n-dimensional euclidean space R^n. Our aim is to devise a descent method for the unconstrained minimization of f. Since the core of our approach is the determination of a search direction (possibly a descent one), we focus on this problem.

We assume that, in some iterative procedure, at a given current point $x \in R^n$, the following information is available: a subgradient vector of f at x, $g \in \partial f(x)$; a set of previously generated points x_i, $i \in F$ such that $f(x_i) > f(x)$, and the corresponding subgradients $g_i \in \partial f(x_i)$, $i \in F$.

We look for a search direction d^* obtained as a solution of a problem of the type

$$\min_d f'(x, d) \qquad h(d) \leqq 0,$$

where $f'(x, d)$ is the directional derivative of f at x along d and $h(d)$ is some reasonable model of $f(x+d)-f(x)$. In other words, the feasible region is an approximation of the level set of f at the point x, i.e., of the set

$$S(x) = \{d \mid f(x+d) \leqq f(x)\}.$$

The approach is motivated by a simple interpretation of Newton's direction in the convex quadratic case. In fact, if this is the case, a scalar multiple of Newton's direction is obtainable as a solution of

$$\min_{d \in S(x)} f'(x, d).$$

The approach has been utilized in [6] in connection with piecewise linear approximations of f, giving rise to a variant of the bundle type methods.

In this paper we will define the function $h(d)$ through explicit consideration of the curvature of f. To this aim some basic concepts are in order. Let α_i and α_i', $i \in F$ be defined as follows:

$$\alpha_i = f(x) - f(x_i) - g_i^T(x - x_i) \qquad i \in F$$

$$\alpha_i' = f(x_i) - f(x) - g^T(x_i - x) \qquad i \in F.$$

The value α_i represents the difference between $f(x)$ and the value at x of the linearization obtained starting from x_i, $i \in F$. Symmetrically, α_i' is the difference between the actual value of f and the linearization based on x, both evaluated at x_i. By convexity both α_i and α_i', $i \in F$ are nonnegative.

From the definitions, letting $d_i = x - x_i$, $i \in F$, it follows that

$$\alpha_i + \alpha_i' = (g - g_i)^T d_i \qquad i \in F$$

and, if in addition f is quadratic, say $f(x) = \frac{1}{2}x^TQx + b^Tx$, we have that $\alpha_i = \alpha_i' = \frac{1}{2}d_i^TQd_i$.

The meaning of α_i and α_i' is pictorially described in Fig. 1.

Letting $d = y - x$, $y \in R^n$, we define a set of convex quadratic functions $h_i(d)$, $i \in F$ in the following way:

$$h_i(d) = \tfrac{1}{2}\beta_i d^T d + (g_i + \beta_i d_i)^T d - \vartheta_i \qquad i \in F$$

where

$$\beta_i = (g - g_i)^T d_i / \|d_i\|^2 \quad \text{and} \quad \vartheta_i = \tfrac{1}{2}|\alpha_i - \alpha_i'|.$$

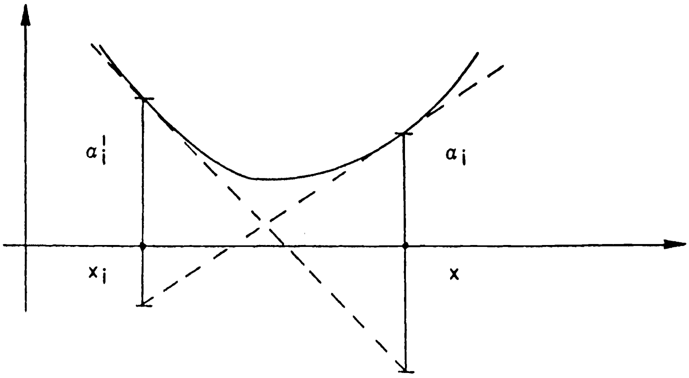

FIG. 1

The functions $h_i(d)$ are the basic elements for constructing the desired approximation of the level set. We note that the gradient of $h_i(d)$ evaluated at $d=-d_i$ is g_i and the directional derivative of $h_i(d)$, evaluated at $d=0$, along the direction d_i is equal to g^Td_i.

This means that $h_i(d)$ interpolates the first order properties of the function f at the points x_i and x, in the latter case solely along the direction d_i.

As far as the values of the functions are concerned, it is easy to verify that

$$h_i(0)=-\vartheta_i$$

$$h_i(-d_i)=\begin{cases} f(x_i)-f(x) & \text{if } \vartheta_i=\frac{1}{2}(\alpha_i-\alpha_i') \\ f(x_i)-f(x)-(\alpha_i'-\alpha_i) & \text{if } \vartheta_i=\frac{1}{2}(\alpha_i'-\alpha_i). \end{cases}$$

Note that $h_i(d)$ is a convex quadratic function whose curvature is completely defined by the value β_i obtained from information on f along d_i; its gradient at the point $d=0$, $g_i+\beta_i d_i$, can be considered as the gradient of the original function f at x_i, "transferred in a quadratic fashion" to the point x.

We define the sets S_i, $i\in F$ as

$$S_i=\{d|h_i(d)\leqq 0\}.$$

Each set S_i is consistent with the level set $S(x)$ in the sense that $S_i\cap S(x)\neq\emptyset$ (in fact at least $d=0$ is in the intersection).

We define the function $h(d)$ as follows:

$$h(d)=\max_{i\in F} h_i(d)$$

and, therefore, the approximation adopted for the level set is

$$S'=\bigcap_{i\in F} S_i=\{d|h_i(d)\leqq 0, \quad i\in F\}.$$

In conclusion, in order to find a search direction from the current point x, we solve

$$\min_d f'(x,d) \qquad h_i(d)=\tfrac{1}{2}\beta_i d^Td+(g_i+\beta_i d_i)^Td-\vartheta_i\leqq 0, \quad i\in F.$$

If the information available on the subdifferential at x is solely g, the objective function is the inner product g^Td. More in general, if a set of ε-subgradients g_i,

$g_i \in \partial_\varepsilon f(x)$, $i \in C$ of f at x are available, the directional derivative is replaced by the ε-directional derivative, i.e., the objective function becomes

$$\min_d \max_{g \in \operatorname{conv}(\Gamma_C)} g^T d$$

where Γ_C is defined as

$$\Gamma_C = \{g_i | i \in C\}.$$

Consequently the problem may be rewritten as

$$\text{(P)} \qquad \min_{d,v} v \qquad v \geqq g_i^T d \quad i \in C \qquad h_i(d) \leqq 0 \quad i \in F.$$

Before discussing the properties of (P) we just note that its feasible region is nonempty and convex.

3. The search direction finding subproblem. In this section we discuss some properties of problem (P). In the sequel we assume $\beta_i > 0$, $i \in F$ and, for simplicity of notation, we define $g_i' = g_i + \beta_i d_i$, $i \in F$.

The following proposition summarizes the properties of (P).

PROPOSITION 1. *Let S' be the set of directions d feasible for* (P) *and let* (d^*, v^*) *be the optimal solution. Then*

(a) *S' has nonempty interior unless it reduces to* $\{0\}$;

(b) $v^* \leqq 0$;

(c) *if $\vartheta_i > 0$ for all $i \in F$ then $v^* = 0$ if and only if* $0 \in \operatorname{conv}(\Gamma_C)$;

(d) *if the set $I = \{i \in F | \vartheta_i = 0\}$ is nonempty, then $v^* = 0$ is equivalent to* $0 \in \operatorname{conv}(\Gamma_C \cup \Gamma_I)$ *where* $\Gamma_I = \{g_i' | i \in I\}$.

Proof. (a) S' is the intersection of the closed balls S_i, $i \in F$

$$S_i = \{d | \, \|d + g_i'/\beta_i\|^2 \leqq r_i^2\}, \quad \text{where } r_i^2 = \|g_i'/\beta_i\|^2 + 2\vartheta_i/\beta_i.$$

S' is nonempty since each S_i contains the origin. The property follows from convexity of S' and from strict convexity of the euclidean space;

(b) consequence of feasibility of $(d, v) = (0, 0)$;

(c) the condition $\vartheta_i > 0$ for all $i \in F$ implies that S' has nonempty interior (in fact $0 \in \operatorname{int} S'$). Since $\Omega(\mathrm{P})$, the feasible region of (P), is the epigraph of the convex function $\max_{i \in C} g_i^T d$, $d \in S'$, it follows from Lemma 7.3 in [20, p. 54] that $\Omega(\mathrm{P})$ has nonempty interior, and consequently, that Slater's constraint qualification holds for (P); thus, (P) being a convex program, Kuhn-Tucker conditions are both necessary and sufficient for optimality.

The Kuhn-Tucker conditions for (P) are:

$$(1) \qquad \sum_{i \in C} \mu_i g_i + \sum_{i \in F} \pi_i g_i' + \left(\sum_{i \in F} \pi_i \beta_i \right) d = 0$$

$$(2) \qquad \mu_i \geqq 0 \qquad i \in C$$

$$(3) \qquad \pi_i \geqq 0 \qquad i \in F$$

$$(4) \qquad \sum_{i \in C} \mu_i = 1$$

$$(5) \qquad \pi_i(h_i(d)) = 0 \qquad i \in F$$

$$(6) \qquad \mu_i(v - g_i^T d) = 0 \qquad i \in C.$$

If $v^* = 0$, the direction $d = 0$ attains the optimal value. Since $0 \in \operatorname{int} S'$, from (5) the multipliers π_i must be identically zero, hence the "only if" part follows from (1).

The "if" part follows by noting that $0 \in \operatorname{conv}(\Gamma_C)$ implies that the Kuhn-Tucker conditions are satisfied by letting $d=0$, $v=0$, $\pi_i=0$, for all $i \in F$.

(d) We note first that $v^*=0$ if and only if the following system of linear inequalities has no feasible solution d:

$$\begin{aligned} &g_i^T d < 0 \qquad i \in C \\ &g_i'^T d < 0 \qquad i \in I. \end{aligned}$$

From Gordan's theorem of the alternatives [18] we have that infeasibility of the above system of linear inequalities is equivalent to feasibility of the system

$$(7) \qquad \begin{aligned} &\sum_{i \in C} \mu_i g_i + \sum_{i \in I} \pi_i g_i' = 0 \\ &\mu_i \geqq 0,\ \pi_i \geqq 0 \text{ and not all the } \mu_i \text{ and the } \pi_i \text{ equal to } 0 \end{aligned}$$

which in turn is equivalent to $0 \in \operatorname{conv}(\Gamma_C \cup \Gamma_I)$. □

The meaning of $v^*=0$ is different in (c) and (d). In particular, under the hypothesis of (c), $v^*=0$ indicates that an approximate optimality condition is verified at the current point x. Under the hypothesis of (d), $v^*=0$ may either indicate that the approximate optimality condition is verified or that the model of the level set is inadequate. More precisely, the approximation of the level set may be inherently contradictory ($S'=\{0\}$) or it may not fit with the local descent properties of f (empty intersection of S' and the set of the descent directions at x).

Our approach to the solution of (P) is based on the solution of its dual:

$$(\mathrm{D}) \qquad \begin{aligned} &\max_{\mu,\pi,d} \left(\sum_{i \in C} \mu_i g_i \right)^T d + \sum_{i \in F} \pi_i h_i(d) \\ &\sum_{i \in C} \mu_i g_i + \sum_{i \in F} \pi_i g_i' + \left(\sum_{i \in F} \pi_i \beta_i \right) d = 0 \\ &\sum_{i \in C} \mu_i = 1 \\ &\mu_i \geqq 0 \quad i \in C, \qquad \pi_i \geqq 0 \quad i \in F. \end{aligned}$$

It is easy to verify that problem (D) is always feasible. Moreover, corresponding to the feasible triplets (μ, π, d) for which $\pi \neq 0$, it is possible to express d as function of μ and π. (We note in passing that feasible triplets $(\mu, 0, d)$ exist if and only if $0 \in \operatorname{conv}(\Gamma_C)$).

Thus we eliminate d by putting

$$d = -\frac{\sum_{i \in C} \mu_i g_i + \sum_{i \in F} \pi_i g_i'}{\sum_{i \in F} \pi_i \beta_i}.$$

Consequently (D) becomes

$$\begin{aligned} &\min \frac{1}{2} \frac{\|\sum_{i \in C} \mu_i g_i + \sum_{i \in F} \pi_i g_i'\|^2}{\sum_{i \in F} \pi_i \beta_i} + \sum_{i \in F} \pi_i \vartheta_i \\ &\mu_i \geqq 0 \qquad i \in C \\ &\pi_i \geqq 0 \qquad i \in F \\ &\sum_{i \in C} \mu_i = 1. \end{aligned}$$

Defining the matrices G and G' whose columns are, respectively, the vectors g_i, $i \in C$, and g'_i, $i \in F$ and, also, the vectors μ, π, β, ϑ, $e^T = (1, 1, 1, \cdots, 1)$ of appropriate dimension, the above problem may be rewritten in compact form as follows:

$$\text{(FD)} \qquad \begin{aligned} &\min \frac{1}{2} \frac{\|G\mu + G'\pi\|^2 + \pi^T(\vartheta\beta^T + \beta\vartheta^T)\pi}{\beta^T\pi} \\ &e^T\mu = 1 \\ &\mu \geqq 0, \qquad \pi \geqq 0. \end{aligned}$$

Hence (FD) is a fractional programming problem, the numerator being a quadratic function and the denominator linear. Moreover, numerator and denominator are, respectively, convex and nonnegative on the feasible region.

In order to approach problem (FD), we define the following parametric quadratic programming problem in the nonnegative scalar parameter p

$$\text{(QP(p))} \qquad \begin{aligned} &\min \tfrac{1}{2}(\|G\mu + G'\pi\|^2 + \pi^T(\vartheta\beta^T + \beta\vartheta^T)\pi) - p\beta^T\pi \\ &e^T\mu = 1 \qquad \mu \geqq 0 \qquad \pi \geqq 0. \end{aligned}$$

PROPOSITION 2. *For positive values of the parameter p, the following statements are equivalent*:

(a) (QP(p)) *is unbounded from below*:

(b) *there exists a solution $\pi \geqq 0$, $\pi \neq 0$ to the system of linear equations*

$$G'\pi = 0, \qquad \vartheta^T\pi = 0.$$

Proof. The implication (b) implies (a) follows immediately by noting that, by hypothesis, $\beta > 0$ and that conv (Γ_C) is bounded.

To prove (a) implies (b) we note first that, because the norm of $G\mu$ is bounded on the feasible region, for all feasible μ the following holds:

$$\begin{aligned} &\tfrac{1}{2}(\|G\mu + G'\pi\|^2 + \pi^T(\vartheta\beta^T + \beta\vartheta^T)\pi) - p\beta^T\pi \\ &\qquad \geqq \tfrac{1}{2}(\|G'\pi\|^2 + \pi^T(\vartheta\beta^T + \beta\vartheta^T)\pi) + \min_{g_i \in \Gamma_C} g_i^T(G'\pi) + \tfrac{1}{2}\|u\|^2 - p\beta^T\pi \end{aligned}$$

where $u = \text{Nr}(\Gamma_C)$.

Defining $q(\pi)$ as the function on the right-hand side of the above inequality, we have that

$$q(\pi) = \min_{i \in C} q_i(\pi)$$

where, for all $i \in C$, $q_i(\pi)$ is the quadratic function

$$q_i(\pi) = \tfrac{1}{2}(\|G'\pi\|^2 + \pi^T(\vartheta\beta^T + \beta\vartheta^T)\pi) + g_i^T(G'\pi) + \tfrac{1}{2}\|u\|^2 - p\beta^T\pi.$$

From the unboundedness assumption, it follows that $q(\pi)$ must be necessarily unbounded on the feasible region. Moreover, since the cardinality of Γ_C is finite, at least one of the functions $q_i(\pi)$ must be unbounded from below. On the other hand, if (b) is not verified, all the quadratics $q_i(\pi)$ have finite minimum since the hessian matrix is strictly copositive [19]. Hence the proof follows. □

Proposition 2 indicates how to proceed to solve (FD). In fact, by solving (QP(p)) for any choice of the parameter $p > 0$, two possible outcomes may result:

(a) unbounded solution;

(b) finite minimum.

Case (a) may occur if and only if $S' = \{0\}$, which in general indicates inconsistency of the level set approximation. Whenever case (b) occur we may infer that problem

(QP(p)) has finite minimum for all the values of the nonnegative parameter p and, hence, that the function

$$\text{(QP(p))} \qquad \begin{aligned} &F(p)=\min \tfrac{1}{2}(\|G\mu+G'\pi\|^2+\pi^T(\vartheta\beta^T+\beta\vartheta^T)\pi)-p\beta^T\pi \\ &e^T\mu=1 \qquad \mu\geqq 0, \quad \pi\geqq 0 \end{aligned}$$

is well defined for $p\geqq 0$.

Further insight may be gained by determining $F(0)$. In fact different conclusions about (P) may be drawn according to $F(0)=0$ or $F(0)>0$. We observe first that $F(0)=0$ with the corresponding $\pi=0$ imply $0\in\operatorname{conv}(\Gamma_C)$; otherwise $F(0)=0$ and $\pi\neq 0$ imply the existence of a feasible solution to (7).

The implications of the case $F(0)>0$ are analyzed in the following proposition.

PROPOSITION 3. *If* $F(0)>0$ *then*:

(a) $0\notin\operatorname{conv}(\Gamma_C)$;

(b) *the system* (7) *has no solution.*

Moreover there exists a positive p^* *such that* $F(p^*)=0$ *and the corresponding* $\pi(p^*)\neq 0$.

Proof. (a) and (b) follow immediately from the definition of $F(0)$. Recalling the Kuhn-Tucker conditions for (QP(p)):

$$(8) \qquad \begin{aligned} &G^TG\mu+G^TG'\pi-\sigma e\geqq 0 \\ &G'^TG\mu+(G'^TG'+\vartheta\beta^T+\beta\vartheta^T)\pi-p\beta\geqq 0 \\ &\mu^T(G^TG\mu+G^TG'\pi-\sigma e)=0 \\ &\pi^T[G'^TG\mu+(G'^TG'+\vartheta\beta^T+\beta\vartheta^T)\pi-p\beta]=0 \\ &e^T\mu=1 \qquad \mu\geqq 0, \quad \pi\geqq 0 \end{aligned}$$

where σ is the multiplier (unconstrained in sign) of the constraint $e^T\mu=1$, we have, from (8) and from boundedness of conv (Γ_C), that, for sufficiently large values of p, the optimal pair (μ, π) cannot be of the type $(\mu, 0)$. Moreover, it is easy to show that $F(p)$ is continuous and $\lim_{p\to\infty} F(p)=-\infty$. Hence, since $F(0)>0$, we conclude that a solution p^* to the equation $F(p)=0$ exists. Finally we note that, corresponding to the optimal pair $(\mu(p^*), \pi(p^*))$, it is $\pi(p^*)\neq 0$ (otherwise the same pair should have been optimal for $p=0$, determining $F(0)=0$, which contradicts the hypothesis). □

As it will be explained in detail in the next section, the case $F(0)=0$ suggests either stopping or resetting in a possible descent procedure. On the other hand, assuming $F(0)>0$, we have the equivalence of solving the nonlinear equation $F(p)=0$ and solving the fractional programming problem (FD) (see [8], [21] for a complete treatment of the parametric approach to fractional programming).

In fact, taking into account that $\pi(p^*)\neq 0$, it is easy to show that the couple $(\mu(p^*), \pi(p^*))$ is optimal for (FD). Moreover since $F(p)$ is a concave, strictly decreasing function, the solution p^* is unique and the standard numerical methods for fractional programming apply to our case.

4. The algorithm. In this section we introduce a model descent algorithm characterized by the use of a search direction obtained through solution of problem (P). In the sequel, for the sake of simplicity of notation, we describe one iteration of the method that we define as the "main step." We assume that at x, the current estimate of the minimum, the following information is available:

— An approximation of the ε-subdifferential of f at x, for a given $\varepsilon>0$, i.e., a bundle Γ_C of subgradients of f evaluated at points "sufficiently close" to x. The bundle is assumed to contain at least g, a subgradient of f at x; in fact it reduces to the singleton after a successful line search (see step 3 below).

— The points x_i, $i \in F$ (considered "far" from x), the scalar parameters β_i, ϑ_i $i \in F$ and the related bundle of subgradients $\Gamma_F = \{g_i | i \in F\}$.

The meaning of points "close" and "far" deserves explanation. We consider close to x any point y such that, for the given $\varepsilon > 0$, each subgradient at y belongs to the ε-subdifferential of f at x. This is certainly true for all y satisfying

$$\|y - x\| \leqq t'$$

where $t' \leqq \varepsilon / 2K$ and K is any upper bound on the norm of the subgradient (see [6]). In our approach we consider "far from x" all points previously obtained in the descent procedure. Whenever $F = \emptyset$, as is the case either at the beginning of the algorithm or after a reset (see Step 1 and Step 2 below), the search direction is obtained by letting

$$d^* = -\mathrm{Nr}\,(\mathrm{conv}\,(\Gamma_C)).$$

Moreover, in this case, v^* is set to the value $-\|d^*\|^2$.

Main step. The positive parameters t', $r_{\max}$, η, m_1, m_2, $0 < m_2 < m_1 < 1$ are given.

STEP 1. Define the current parametric quadratic programming (QP(p)) and solve for $p = 0$.

Case (a) $F(0) = 0$ and $\pi^* = 0$: Stop (Optimality).

Case (b) $F(0) = 0$ and $\pi^* \neq 0$: Exit from main step (Reset F).

Case (c) $F(0) > 0$: Go to Step 2 (Finding a search direction).

STEP 2. Select a positive p and solve (QP(p)).

Case (a) Solution unbounded: Exit from main step (Reset F).

Case (b) Solve the nonlinear equation $F(p) = 0$ to obtain p^* and the corresponding optimal pair (μ^*, π^*); set

$$d^* = -\frac{G\mu^* + G'\pi^*}{\beta^T \pi^*}.$$

If $\|d^*\| > r_{\max}$, then scale d^* by putting $d^* = r_{\max}(d^* / \|d^*\|)$; set

$$v^* = -\tfrac{1}{2}\beta^T \pi^* \|d^*\|^2 - \vartheta^T \pi^*.$$

If $|v^*| < \eta$ then exit from main step (Reset F) else go to Step 3.

STEP 3. Perform a line search along d^* finding $t > 0$ and $g^+ \in \partial f(x + td^*)$ such that

(9) $$g^{+T} d^* \geqq m_1 v^*$$

and either

(10) *Case* (a) $f(x + td^*) - f(x) \leqq m_2 t v^*$

or

(11) *Case* (b) $t\|d^*\| \leqq t'$.

In Case (a) update the estimate of the minimum putting $x^+ = x + td^*$, set $\Gamma_F = \Gamma_F \cup \Gamma_C$ and calculate the new vectors β and ϑ. Moreover set $\Gamma_C = \{g^+\}$ and iterate the main step. In Case (b) set $\Gamma_C = \Gamma_C \cup \{g^+\}$ and return to Step 1.

Before stating the convergence properties of the algorithm, we briefly comment on the various steps.

We note first that, whenever Case (a) at Step 1 occurs, $0 \in \mathrm{conv}\,(\Gamma_C)$; hence the calculations are stopped because the current x is ε-optimal.

Case (b) at Step 1 indicates that no feasible descent direction exists, i.e., that possibly the local model (represented by Γ_C) and the global one (represented by Γ_F) are incongruent. Thus we cancel the information provided by the points x_i, $i \in F$, and exit from the main step. Possible satisfaction of the ε-optimality condition at the current point will be detected at the restart.

Coming to Step 2 we note that, according to Proposition 2, occurrence of Case (a) implies that Γ_F does not provide useful information in order to determine a search direction and that, on the other hand, the ε-optimality condition $0 \in \operatorname{conv}(\Gamma_C)$ is not satisfied. Hence we reset F by letting $F = \varnothing$. The scaling of d^* is to prevent the search direction from becoming arbitrarily large in norm: it has the same effect of introducing a safeguarding ball constraint in problem (P). On the other hand, the reset based on the value of $|v^*|$ is aimed to avoid shrinking phenomena of the feasible region of (P) that may occur even at points far from the minimum.

As for the line search (Step 3), the algorithm does not differ significantly from the usual line searches procedures in bundle methods [26]. Here we remark that success or failure of the line search (Case (a) and Case (b), respectively), apart from the actual modification of the current estimate of the minimum, results in different strategies for updating the bundle of information. In particular in Case (a), since a "serious step" is performed, all the information related to x is kept and the set F is updated, whereas, in Case (b) (null step), the ε-subdifferential at x is enriched by the gradient g^+.

The convergence of the algorithm is based on the following two propositions.

PROPOSITION 4. *If at any point x the algorithm generates a sequence $\{d_k^*\}$ of nondescent directions, then the corresponding sequence $\{v_k^*\}$ converges to zero.*

Proof. Suppose that a sequence of search directions has been generated and no significant descent steps have been obtained along any of them (Case (b) of the line search). Since at most only one reset may occur, it is sufficient to consider only the sequences $\{v_k^*\}$, $\{d_k^*\}$ generated after the reset. As a consequence of (9) and being $m_1 < 1$, the sequence $\{v_k^*\}$ is monotonically increasing. Moreover it is bounded from above by zero and hence it is convergent, say to v'. To prove that $v' = 0$, we note first that $\{\|d_k^*\|\}$ is bounded. Thus consider two convergent subsequences $\{d_h^*\}$, $\{v_h^*\}$, $h \in H$ and let s be the successor of h in the subsequences. Assuming that g^+ is the subgradient evaluated along d_h^*, the following hold:

$$g^{+T} d_h^* \geqq m_1 v_h^*, \qquad g^{+T} d_s^* \leqq v_s^*,$$

hence

$$g^{+T}(d_s^* - d_h^*) \leqq v_s^* - m_1 v_h^*.$$

Passing to the limit, we have $(1-m_1)v' \geqq 0$ and, since $v' \leqq 0$, we conclude that $v' = 0$, □

Proposition 4 ensures that the procedure may not remain blocked for infinitely many iterations at a point not satisfying the ε-optimality criterion. On the other hand, the following proposition guarantees that after a finite number of successful line searches the ε-optimality condition is satisfied if the objective function is bounded from below.

PROPOSITION 5. *If the function f is bounded from below and has finite minimum, for any choice of the starting point x_0 the algorithm terminates in a finite number of steps at a point satisfying the ε-optimality criterion.*

Proof. Assume that the algorithm generates an infinite subsequence $\{d_k^*\}$, $k \in K$ of directions corresponding to successful line searches. Thus we may write

$$f(x_k + t_k d_k^*) - f(x_k) \leqq m_2 t_k v_k^* \qquad k \in K$$

with

$$t_k \| d_k^* \| > t'.$$

Since f is bounded from below, we have that $\{t_k v_k^*\}$, $k \in K$ must converge to zero, which contradicts $|v_k^*| > \eta$ and $t_k > t'/r_{\max}$. Hence after a finite number of descent steps the algorithm cannot generate further descent directions and, as a consequence of Proposition 4, the current point satisfies the ε-optimality condition. □

5. Numerical experiments. We report briefly on some numerical experiments performed coding our algorithm in FORTRAN 77 (double precision) on an IBM PC.

Before discussing the results we wish to emphasize that the algorithm previously described may in fact be considered as a model algorithm, for a number of decisions may be made differently at various steps, giving rise possibly to quite distinct implementations of the basic idea. In particular, the proximity threshold t' has to be properly decided; it is necessary to specify the resetting strategy (partial resetting could be taken into consideration as well), to define appropriate maximum sizes for both Γ_C and Γ_F, to set the tolerance parameters for $F(0) = 0$ and $F(p) = 0$ etc.

The equation $F(p) = 0$ has been solved via Newton's method and the quadratic programming problem solved by the Harwell Subroutine Library code VE02AD.

The line search has been implemented by adopting a slightly modified version of Lemarechal's subroutine MLIS4.

We have considered the following standard test functions; their complete definitions may be found in the quoted references.

1. MAXQUAD [15].

$$f(x) = \max_{1 \leqq i \leqq 5} \{x^T A_i x - b_i^T x\}$$

$$n = 10, \quad f(x^*) = -0.841408, \quad x_0^T = (1, 1, \cdots, 1), \quad f(x_0) = 5337.$$

2. SHOR [25].

$$f(x) = \max_{1 \leqq i \leqq 10} \left\{ b_i \sum_{j=1}^{5} (x_j - a_{ij})^2 \right\}.$$

$$n = 5, \quad f(x^*) = 22.60016, \quad x_0^T = (0, 0, 0, 0, 1), \quad f(x_0) = 80.$$

3. ROSEN-SUZUKI [2].

$$f(x) = \max_{1 \leqq i \leqq 4} \{f_i(x)\}, \quad f_i(x) \text{ quadratic}$$

$$n = 4, \quad f(x^*) = -44, \quad x_0^T = (0, 0, 0, 0), \quad f(x_0) = 0.$$

4. CHARALAMBOUS-CONN [2].

$$f(x) = \max \{x_1^2 + x_2^4, (2 - x_1)^2 + (2 - x_2)^2, 2e^{-x_1 + x_2}\}$$

$$n = 2, \quad f(x^*) = 1.95222, \quad x_0^T = (1.0, -0.1), \quad f(x_0) = 5.41.$$

5. CHARALAMBOUS-CONN [2].

$$f(x) = \max \{x_1^4 + x_2^2, (2 - x_1)^2 + (2 - x_2)^2, 2e^{-x_1 + x_2}\}$$

$$n = 2, \quad f(x^*) = 2.0, \quad x_0^T = (2, 2), \quad f(x_0) = 20.$$

6. DEMYANOV-MALOZEMOV [3].

$$f(x) = \max\{5x_1 + x_2, -5x_1 + x_2, x_1^2 + x_2^2 + 4x_2\}$$

$$n = 2, \quad f(x^*) = -3, \quad x_0^T = (1, 1), \quad f(x_0) = 6.$$

7. MAXQ [22].

$$f(x) = \max_{1 \leqq i \leqq 20} x_i^2$$

$$n = 20, \quad f(x^*) = 0, \quad x_0^T = (1, 2, \cdots, 10, -11, -12, \cdots, -20), \quad f(x_0) = 400.$$

8. EQUILIBRIUM [15]. It is a set of three problems ($n = 5$, 8, 10) of the form:

$$f(x) = \max_{1 \leqq i \leqq n} f_i(x) \quad \text{subject to } \sum_{i=1}^{n} x_i = 1 \quad x_i \geqq 0, \qquad i = 1, \cdots, n$$

$$f(x^*) = 0, \qquad x_0^T = (1/n, 1/n, \cdots, 1/n)$$

$$n = 5, \quad f(x_0) = 20.22; \qquad n = 8, \quad f(x_0) = 9.78; \qquad n = 10, \quad f(x_0) = 26.97.$$

The above test problems are widely adopted in the literature and numerical results may be found, for example, in [2], [4], [9], [10], [11], [13], [22], [23], [25], [27].

In our experiments we have noted some degree of insensitivity to the choice of the tolerance parameter in the solution of $F(p) = 0$, (which has been set to 10^{-8}), whereas the tolerance parameter on the condition $F(0) = 0$ seems to have a stronger impact on the performance of the algorithm; in fact it not only dictates the accuracy of the solution but also influences the frequency of the resets (Cases (a) and (b) at Step 1 of the algorithm). We have adopted values ranging between 10^{-4} and 10^{-6}.

Since the test problems are all of finite minimax type, we have set the maximum size of the bundle Γ_C to the number of functions to be maximized. We have noted that a too large size of Γ_F increases the computational overhead with no apparent improvement in the overall performance (in general very few of the quadratic constraints are active at the solution of the auxiliary problem). Thus we have set the maximum size of Γ_F equal to that of Γ_C.

Our results are summarized in Table 1 where we report, for each test problem, the total number of iterations (both descent and nondescent ones), the number of function and gradient evaluations, and the function value at the stop.

On the limited number of problems tackled, the results seem comparable with those available in the literature. They demonstrate that the use of nonuniform ball constraints in the auxiliary problem is viable. On the other hand, substantial improvement in the performance would be expected by devising more sophisticated answers

TABLE 1

Test problem	Iterations	f/g eval.	$f(x_k)$	$f(x^*)$
1	40	65	−0.84140	−0.841408
2	29	59	22.60016	22.600162
3	24	53	−43.99999	−44
4	11	21	1.95222	1.952224
5	8	19	2.00000	2
6	20	41	−3.00000	−3
7	86	135	0.00000	0
8 ($n = 5$)	23	79	0.00001	0
8 ($n = 8$)	36	106	0.00006	0
8 ($n = 10$)	38	120	0.00040	0

to a number of open questions (e.g., more judicious management of the exchange of information between the bundles Γ_C and Γ_F).

6. Conclusions. We have described a model algorithm for minimizing a convex function based on the construction of suitable quadratic constraints. It may be interpreted as a bundle method embedding an automatic technique for bounding the norm of the stepsize.

The numerical experience on some standard test problems, which shows feasibility of the basic ideas underlying the approach, suggests that further research efforts should be made in order to make the proposal more competitive.

Acknowledgment. We are indebted to K. Kiwiel for suggesting some corrections to a preliminary version of the paper.

AN INVERSE CONVOLUTION METHOD FOR REGULAR PARABOLIC EQUATIONS*

D. S. GILLIAM†, B. A. MAIR‡, AND C. F. MARTIN§

Abstract. In this paper, the problem of determining an unknown boundary control of a parabolic distributed parameter system, evolving over finite or infinite time, from incomplete, approximate interior temperature measurements is investigated.

First, an exact solution is obtained for square integrable boundary controls associated with a general class of parabolic equations on a finite spatial interval under the assumption that the interior temperature is known for all times.

Then, it is shown that this exact solution can be used to develop a stable algorithm for the numerical solution of this problem, without the introduction of standard regularization techniques. This algorithm assumes only knowledge of a finite, discrete set of approximate temperature readings.

One advantage of this inversion process is the availability of a priori error bounds based on the measurement errors and frequency of sampling that are obtained in this paper. Another useful feature is that it encompasses boundary controls which are arbitrary linear combinations of surface temperature and flux.

Numerical results are presented.

1. Introduction.

There has been considerable interest in the control, observation, and stabilization of parabolic distributed parameter systems via point sensors and actuators [8], [9]. The present work is concerned with the related question of whether or not point observation uniquely determines the boundary control for a class of parabolic boundary value problems. More precisely, the problem can be stated as follows: *From incomplete data obtained by observing the system at a given point in the spatial domain over a finite time interval, uniquely reconstruct the boundary control for this time interval within a specified class.* Varying forms of this type of problem can be found in the literature under the general heading of inverse heat conduction problems [1], [4], [6], [7], [18], [20]. The problem is often recovering the temperature and/or heat flux at the boundary from data sampled in the interior of the domain. Numerous applications of physical importance can be cast in this general setting but as is well known, such problems are ill-posed.

The technique considered here for recovering unknown surface data is based on an extension of the method developed in [12] for a very special class of problems.

§ Department of Mathematics, Texas Tech University, Lubbock, Texas 79409. This research was supported in part by National Science Foundation grant DMS 8905-344 and National Security Agency grant MDA 904-85-H0009.

The present method is to first compute the transfer function between the observation and control and then use a product representation for the transfer function to obtain a sequence of approximates to the control using a convolution method. It is shown that the iterates $\{f_n\}$ converge in the sense of $L^2(0, \infty)$ assuming that the sampled data derives from an L^2 control. The analysis is carried out for parabolic equations in one spatial dimension for general, regular, self-adjoint Sturm–Liouville spatial operators acting in the Hilbert state space of functions square integrable in a finite interval $[a, b]$; however, this technique can be extended to higher-dimensional rectangular bodies by using results in [13].

In addition to investigating theoretical aspects of this inverse heat conduction problem, this paper shows that the exact solution obtained in Theorem 2.1 can be used to develop a numerical solution to this problem. An important consideration here is the behavior of the inversion process in the presence of finite, noisy data. Due to the ill-posedness of this problem, the iterates obtained by using approximate data, instead of the true temperature readings, may not converge to the unknown boundary control.

Despite this unpredictable behavior of these approximations for large iterations, this paper shows how to obtain a suitable iteration level depending on the noise measurement error and frequency of measurements. Error bounds are also given for this iteration level. This problem of choosing an appropriate iteration level is similar to optimal selection problems that occur in standard regularization techniques (cf. [7], [17], [18], [20], [22]).

In § 2 we describe the basic model and state the main result. Section 3 contains a discussion of the solution of the direct problem and a useful representation for the solution of this problem as a convolution integral with kernel $K(x, t)$. In § 4 we obtain an infinite product representation for the Fourier transform of $K(x, t)$ (i.e., the system transfer function). This is in part carried out by introducing an associated Sturm–Liouville system whose spectrum corresponds to the transmission zeros of the transfer function as described in [5]. In what follows, considerable use is made of a knowledge of the properties of these transmission zeros and their relation to the eigenvalues of the original system. Also in § 4, we prove the main result stated in § 2 under the restriction that the eigenvalues and transmission zeros lie in the left half-plane, and in § 5 we remove these restrictions using a state feedback argument to shift the spectrum into the left half-plane.

We now briefly describe the inversion scheme developed in § 6. Assume that finitely many temperature readings $\{v_k\}$ are taken at the interior spatial point x_0 and at equispaced time points $\{t_k\}$ in the finite interval $[0, T]$, with error bounded above by ε and time step size h. Let v be an approximation to the true temperature u at x_0 formed by interpolating the points $\{(t_k, v_k)\}$ (e.g., by a polynomial spline). Now, by inserting v for u in the exact solution $\{f_n\}$ obtained in Theorem 2.1, we obtain a sequence of iterates $\{g_n\}$. As mentioned above, $\{g_n\}$ may be badly behaved for large n. However, we show that there is an integer $N(h, \varepsilon)$ such that $\{g_{N(h,\varepsilon)}\}$ converges to the true boundary control in $L^2[0, T]$ as h and $\varepsilon \to 0+$. In addition, a method of obtaining the value of $N(h, \varepsilon)$ is given, with the corresponding error estimates.

Finally, § 7 contains results of numerical experiments that demonstrate the appropriateness of the choice of $N(h, \varepsilon)$ and the numerical feasibility of this inversion process.

2. Notation and statement of the main result. In what follows we consider spatial and boundary operators L, B_1, B_2 given by:

$$(Lv)(x)=\frac{1}{\omega(x)}[(p(x)v'(x))'-q(x)v(x)], \qquad a<x<b$$
$$B_1(v)=h_1v(a)-k_1v'(a) \tag{2.1}$$
$$B_2(v)=h_2v(b)+k_2v'(b)$$

where prime denotes differentiation with respect to x, $p\in C^1[a,b]$; q, $\omega\in C[a,b]$, p and ω are strictly positive on $[a,b]$; h_1, k_1, h_2, and k_2 are nonnegative constants such that $h_1+k_1\neq 0$ and $h_2+k_2\neq 0$.

The present paper is concerned with the problem of determining $f(t)$, assuming:

$$\begin{aligned} &Lu=u_t, \qquad a<x<b, \qquad t>0\\ &B_1u(\cdot,t)=f(t), \qquad t>0\\ &B_2u(\cdot,t)=0, \qquad t>0\\ &u(x,0)=0, \qquad a<x<b, \end{aligned} \tag{2.2}$$

and we are able to observe the temperature values

$$\{u(x_0,t): t>0\}$$

for a fixed $x_0\in(a,b)$. Furthermore, we assume that $f\in L^2(0,\infty)$. In general, additional conditions on f are necessary to guarantee the existence of a unique solution to the direct problem of finding $u(x,t)$ given $f(t)$ in (2.2). However, here we are interested in the inverse problem of determining f assuming that $u(x,t)$ exists and that we know some of its values. One very important feature of the present method is that it can be used to recover data which is only square-integrable on finite subintervals. The reason for this is that the method only requires knowledge of the solution over a time interval $(0,T)$ to recover the unknown data for the interval $(0,T)$. Therefore, even though the results below are stated for square-integrable boundary data on $(0,\infty)$, much more general data can be considered on any finite subinterval.

Throughout this paper a central role is played by the following Sturm-Liouville systems:

$$(L-\mu_n)\psi_n=0, \quad x\in[x_0,b], \qquad \psi_n(x_0)=0, \qquad B_2\psi_n=0, \tag{2.3}$$

$$(L-\lambda_n)\varphi_n=0, \quad x\in[a,b], \qquad B_1\varphi_n=0, \qquad B_2\varphi_n=0, \tag{2.4}$$

and the function $w:[a,b]\times\mathbb{C}\to\mathbb{C}$ which satisfies

$$\begin{aligned} &(L-\lambda)w(x,\lambda)=0, \qquad a<x<b\\ &w(b,\lambda)=k_2, \qquad w'(b,\lambda)=-h_2. \end{aligned} \tag{2.5}$$

For notational convenience, we define

$$\Delta=\frac{b-a}{b-x_0}. \tag{2.6}$$

Then from standard estimates for eigenvalues of regular Sturm-Liouville systems (cf. [3]),

$$\lim_{n\to\infty}\frac{\mu_n}{\lambda_n}=\Delta^2>1. \tag{2.7}$$

Hence, there exist $\alpha\geqq 1$ and integer $m\geqq 1$ such that

$$1<\frac{\mu_n}{\lambda_n}\leqq\alpha\Delta^2, \quad \text{for all } n\geqq m. \tag{2.8}$$

Throughout this paper, α and m are considered fixed constants.

In the particular case when the spatial operator L is of the form $k(d^2/dx^2)$ for some constant k, and $k_1=k_2=0$, then $(\mu_n/\lambda_n)=\Delta^2$ for all n, so we can take $\alpha=m=1$.

With the notation from (2.1)-(2.8), we can state the main result of the paper.

THEOREM 2.1. *Assume u and f satisfy system* (2.2), $x_0\in(a,b)$ *is chosen so that* $w(x_0,0)\neq 0$, *and the values* $\{u(x_0,t)\colon t>0\}$ *are known. Also, assume that the eigenvalues* $\{\mu_n\}_{n=1}^{\infty}$, $\{\lambda_n\}_{n=1}^{\infty}$ *of the systems are strictly negative. Then the sequence f_n given by*

$$f_0(t)=\frac{h_1w(a,0)-k_1w'(a,0)}{w(x_0,0)}u(x_0,t)$$

$$f_n(t)=\frac{\mu_n}{\lambda_n}f_{n-1}(t)-\mu_n\left(1-\frac{\mu_n}{\lambda_n}\right)\int_0^t \exp\left(\mu_n(t-s)\right)f_{n-1}(s)\,ds$$

converges to f in $L^2(0,\infty)$. If in addition $f'\in L^2(0,\infty)$, then $\|f_n-f\|_2\leqq(C/n)\|f'\|_2$, for all $n\geqq m$, where C is a constant (*independent of n, f*).

In § 5, we use the result of Theorem 2.1 combined with state feedback to analyze the more general case of nonnegative eigenvalues. Also, conditions are given that ensure that $w(x_0,0)\neq 0$ holds for all $x_0\in(a,b)$. In general, the set of points for which $w(x_0,0)=0$ is a finite set.

The numerical implementation of this scheme involves the calculation of certain parameters (such as eigenvalues) of the system, which might not be known exactly. Even if $u(x_0,t)$ is known exactly, the inherent ill-posedness of the problem may lead to magnification of any errors due to approximating these parameters. However, it is shown in [14] that this inversion scheme is stable under the approximation of eigenvalues.

In § 6 we show how to compensate for its instability under noisy data by the choice of an appropriate level of iteration. Furthermore, if $w(\cdot,0)$ is not known in closed form, the values $w(a,0)$, $w'(a,0)$ and $w(x_0,0)$ may be obtained either by a series solution of the initial value problem (2.5) or by the numerical solution of the two-dimensional linear system of ordinary differential equations,

$$W'=\begin{pmatrix}0 & 1/p\\ q & 0\end{pmatrix}W,\qquad W(b)=\begin{pmatrix}k_2\\ -p(b)h_2\end{pmatrix}$$

where

$$W(x)=\begin{pmatrix}w(x)\\ p(x)w'(x)\end{pmatrix}.$$

3. The direct problem. We now describe the well-known solution of the direct problem in terms of a convolution of the control f with the inverse transform of the system transfer function, denoted by $K(x,t)$. Although many of the following results appear in a variety of sources, they are briefly repeated here for completeness and notational convenience.

From the classical theory of ordinary differential equations, we can find a function $v\colon[a,b]\times\mathbb{C}\to\mathbb{C}$ such that

$$(3.1)\qquad \begin{aligned}&(L-\lambda)v(x,\lambda)=0, && a<x<b\\ &v(a,\lambda)=k_1, && v'(a,\lambda)=h_1\end{aligned}$$

and the functions

$$\lambda\mapsto v(x,\lambda),\qquad \lambda\mapsto w(x,\lambda)$$

are entire functions of λ of order $\leqq\frac{1}{2}$ (cf. [15]).

Let

$$W(v, w)(x, \lambda) = v(x, \lambda)w'(x, \lambda) - v'(x, \lambda)w(x, \lambda)$$

be the Wronskian of v, w. Then, by a result of Abel (cf. [15]), $p(x)W(v, w)(x, \lambda)$ is independent of $x \in [a, b]$; hence, we define

$$W(\lambda) = p(x)W(v, w)(x, \lambda). \tag{3.2}$$

Therefore, W is an entire function of λ of order $\leqq \frac{1}{2}$.

Now, consider the regular Sturm-Liouville eigenvalue problem in (2.4). This system has countably many distinct eigenvalues $\{\lambda_n : n = 1, 2, \cdots\}$ such that

$$\cdots \lambda_3 < \lambda_2 < \lambda_1$$

and $\lim_{n\to\infty} \lambda_n = -\infty$ with corresponding eigenfunctions $\{\varphi_n\}$ which form a complete orthonormal basis for $L^2_\omega[a, b]$.

In this section (and the succeeding one) we assume that $\lambda_1 < 0$. In this case, the Green's function for the above system,

$$g(x, y; \lambda) = \begin{cases} \dfrac{v(x, \lambda)w(y, \lambda)}{W(\lambda)}, & a \leqq x < y \\ \dfrac{v(y, \lambda)w(x, \lambda)}{W(\lambda)}, & y \leqq x \leqq b \end{cases}$$

satisfies the following conditions.

1. The map

$$(x, y) \in [a, b] \times [a, b] \to g(x, y, \lambda)$$

is continuous for each $\lambda \in \mathbb{C}$.

2. For each $y \in [a, b]$, $\lambda \in \mathbb{C}$,
$$(L - \lambda)g(\cdot, y, \lambda) = \delta(\cdot - y), \qquad B_1 g(\cdot, y, \lambda) = B_2 g(\cdot, y, \lambda) = 0.$$

3. For each x, y, the function,

$$\lambda \mapsto g(x, y, \lambda)$$

is analytic on $\mathbb{C}$ except for simple poles at each eigenvalue λ_n.

4. The function g is represented by

$$g(x, y, \lambda) = -\sum_{n=0}^{\infty} \frac{\varphi_n(x)\varphi_n(y)}{\lambda - \lambda_n},$$

if $\lambda \neq \lambda_n$.

Now, for each x, $y \in [a, b]$, define,

$$G(x, y; t) = \begin{cases} -\sum\limits_{n=0}^{\infty} \varphi_n(x)\varphi_n(y)\, e^{\lambda_n t}, & t > 0 \\ 0, & t \leqq 0. \end{cases}$$

Then it is easily seen that for each x, y, the following conditions hold.

5. The function

$$t \mapsto G(x, y, t) \in L^1(\mathbb{R}).$$

6. The Fourier transform of $G(x, y, \cdot)$ is given by

$$\hat{G}(x, y, \xi) = g(x, y; i\xi), \qquad \xi \in \mathbb{R}. \tag{3.3}$$

7. For each y,

$$(L-i\xi)\hat{G}(\cdot, y, \xi) = \delta(\cdot - y).$$

8. For each y,

$$\left(L-\frac{\partial}{\partial t}\right)G(\cdot, y, t) = \delta(\cdot - y)\delta(t)$$

$$B_1 G(\cdot, y, t) = 0 = B_2 G(\cdot, y, t).$$

9. $G(x, y, t)$ is the fundamental solution for the parabolic equation

$$Lu = \frac{\partial u}{\partial t} \quad \text{on } [a, b] \times (0, \infty)$$

(cf. [11], [15]) satisfying

$$|G(x, y, t)| \leqq Ct^{-1/2} \exp\left(-\frac{\alpha(x-y)^2}{t}\right), \qquad t > 0 \tag{3.4}$$

and

$$\left|\frac{\partial G}{\partial x}(x, y, t)\right| \leqq Ct^{-3/2} \exp\left(-\alpha\frac{(x-y)^2}{t}\right), \qquad t > 0 \tag{3.5}$$

for strictly positive constants C, α.

From [22], the solution of the direct problem defined by the system (2.2) is given by:

$$u(x, t) = \frac{-p(a)}{h_1}\int_0^t \frac{\partial}{\partial y} G(x, y, t-s)|_{y=a} f(s)\, ds, \quad \text{if } h_1 \neq 0$$

$$u(x, t) = \frac{-p(a)}{k_1}\int_0^t G(x, a, t-s) f(s)\, ds, \quad \text{if } k_1 \neq 0.$$

Hence, if we define, for each $x \in [a, b]$, $t > 0$,

$$K(x, t) = \begin{cases} \dfrac{-p(a)}{h_1}\dfrac{\partial}{\partial y} G(x, y, t)|_{y=a}, & \text{if } h_1 \neq 0 \\ \dfrac{-p(a)}{k_1} G(x, a, t), & \text{if } k_1 \neq 0, \end{cases}$$

we have the following result.

THEOREM 3.1. *If $f \in L^2(0, \infty)$, the function $u(x, t) = K(x, \cdot) * f(t)$, is a solution of the direct problem defined by* (2.2) *and this u is the unique solution of* (2.2) *if f is continuous on* $(0, \infty)$ *with limit* 0 *at* $t = 0$.

4. Proof of the main result. In this section, we use the above representation for the solution of the direct problem to solve the inverse problem of determining f in (2.2).

Before turning to the proof of the main result, it is necessary to obtain an infinite product expansion for the Fourier transform of the function $t \to K(x_0, t)$ for any $x_0 \in (a, b)$ for which $w(x_0, 0) \neq 0$ in terms of the eigenvalues for two regular Sturm-Liouville problems.

Throughout this section, x_0 denotes a fixed point in (a, b), and $\lambda_1 < 0$.

THEOREM 4.1. *The Fourier transform,*

$$\hat{K}(x_0, \xi) = -p(a)\frac{w(x_0, i\xi)}{W(i\xi)}$$

$$= -w(x_0, i\xi)/W(v, w)(a, i\xi), \qquad \xi \in \mathbb{R}.$$

Proof. First, consider $h_1 \neq 0$. For all $t > 0$,

$$K(x_0, t) = \frac{-p(a)}{h_1} \frac{\partial}{\partial y} G(x_0, y, t)|_{y=a}.$$

By (3.5),

$$|K(x_0, t)| \leqq Ct^{-3/2} \exp\left(\frac{-\alpha(x_0 - a)^2}{t}\right), \qquad t > 0.$$

Hence, $t \mapsto K(x_0, t)$ is in $L^p(0, \infty)$, for all $p \geqq 1$. For any $\xi \in \mathbb{R}$ and $a \leqq y \leqq a + \varepsilon < x_0$, where $\varepsilon > 0$,

$$\begin{aligned}\left|\frac{\partial G}{\partial y}(x_0, y, t)\, e^{-i\xi t}\right| &\leqq \frac{C}{t^{3/2}} \frac{t^{1/4}}{(x_0 - y)^{1/2}} = Ct^{-5/4}(x_0 - y)^{-1/2} \\ &\leqq Ct^{-5/4}(x_0 - a - \varepsilon)^{-1/2}\end{aligned}$$

and

$$\int_1^\infty t^{-5/4}\, dt < \infty.$$

Hence,

$$\int_1^\infty \frac{\partial G}{\partial y}(x_0, y, t)\, e^{-i\xi t}\, dt$$

is uniformly convergent for $y \in [a, a + \varepsilon]$. This implies that,

$$\int_1^\infty K(x_0, t)\, e^{-i\xi t}\, dt = \frac{-p(a)}{h_1}\left(\frac{\partial}{\partial y} \int_1^\infty G(x_0, y, t)\, e^{-i\xi t}\, dt\right)\bigg|_{y=a}.$$

Now,

$$\int_0^1 K(x_0, t)\, e^{-i\xi t}\, dt = \frac{-p(a)}{h_1}\left(\frac{\partial}{\partial y} \int_0^1 G(x_0, y, t)\, e^{-i\xi t}\, dt\right)\bigg|_{y=a}.$$

That is,

$$\begin{aligned}\hat{K}(x_0, \xi) &= \frac{-p(a)}{h_1} \frac{\partial}{\partial y} \hat{G}(x_0, y, \xi)|_{y=a} \\ &= \frac{-p(a)}{h_1} \frac{\partial}{\partial y} g(x_0, y, i\xi)|_{y=a}, \quad \text{by (3.3)} \\ &= \frac{-p(a)}{h_1} \frac{v'(a, i\xi) w(x_0, i\xi)}{W(i\xi)} \\ &= -p(a) \frac{w(x_0, i\xi)}{W(i\xi)}, \quad \text{by (3.1)}.\end{aligned}$$

For $k_1 \neq 0$, $K(x_0, t) = -p(a)G(x_0, a, t)/k_1$. By (3.4), $t \mapsto K(x_0, t)$ is in $L^p(0, \infty)$, for all $p \geqq 1$. Hence

$$\begin{aligned}\hat{K}(x_0, \xi) &= \frac{-p(a)}{k_1} \hat{G}(x_0, a, \xi) \\ &= \frac{-p(a)}{k_1} g(x_0, a, i\xi), \quad \text{by (3.3)} \\ &= \frac{-p(a)}{k_1} \frac{v(a, i\xi) w(x_0, i\xi)}{W(i\xi)} \\ &= -p(a) \frac{w(x_0, i\xi)}{W(i\xi)}, \quad \text{by (3.1)}.\end{aligned}$$

THEOREM 4.2. *If* $w(x_0, 0) \neq 0$, *then*,

$$\hat{K}(x_0, \xi) = \frac{w(x_0, 0)}{h_1 w(a, 0) - k_1 w'(a, 0)} \frac{\prod_{n=1}^{\infty}(1 - (i\xi/\mu_n))}{\prod_{n=1}^{\infty}(1 - (i\xi/\lambda_n))}.$$

Proof. $w(x_0, z) = 0$ if and only if

$$(L - z)w(x, z) = 0, \qquad x \in [x_0, b]$$
$$w(x_0, z) = 0$$
$$h_2 w(b, z) + k_2 w'(b, z) = 0,$$

which holds if and only if there exists $n = 1, 2, 3, \cdots$ such that $z = \mu_n$. Notice that

$$-W(v, w)(a, z) = -v(a, z)w'(a, z) + v'(a, z)w(a, z)$$
$$= h_1 w(a, z) - k_1 w'(a, z).$$

Thus, $-W(v, w)(a, z) = 0$ if and only if

$$(L - z)w(x, z) = 0, \qquad x \in [a, b]$$
$$h_1 w(a, z) - k_1 w'(a, z) = 0$$
$$h_2 w(b, z) + k_2 w'(b, z) = 0$$

which is true if and only if there exists $n = 1, 2, \cdots$ such that $z = \lambda_n$.

The result follows from Hille [15], since

$$z \mapsto w(x_0, z)$$

and

$$z \mapsto W(v, w)(a, z)$$

are entire functions of order $\leqq \frac{1}{2}$, $w(x_0, 0) \neq 0$ and $\lambda_n < 0$ for all n. In fact, for all $z \in \mathbb{C}$,

$$w(x_0, z) = w(x_0, 0) \prod_{n=1}^{\infty} \left(1 - \frac{z}{\mu_n}\right)$$

$$h_1 w(a, z) - k_1 w'(a, z) = (h_1 w(a, 0) - k_1 w'(a, 0)) \prod_{n=1}^{\infty} \left(1 - \frac{z}{\lambda_n}\right).$$

Proof of Theorem 2.1 By Theorems 3.1 and 4.2,

$$\hat{f}(\xi) = \frac{h_1 w(a, 0) - k_1 w'(a, 0)}{w(x_0, 0)} \frac{\prod_{n=1}^{\infty}(1 + ia_n\xi)}{\prod_{n=1}^{\infty}(1 + ib_n\xi)} \hat{u}(x_0, \xi),$$

where $a_n = -1/\lambda_n > 0$ and $b_n = -1/\mu_n > 0$. By (2.8), $a_n > b_n$ for all $n \geqq m$. Standard estimates (cf. [3]) give $a_n = 0(n^2)$, hence $\sum_1^{\infty} a_n < \infty$ and $\sum_{n=N+1}^{\infty} a_n \leqq C/N$ for all $N \geqq m$ where C is a constant.

The result follows from an easy modification of Theorem 3.1 in [12].

5. The general case. In this section, it is shown that it can be assumed that the eigenvalues of the operator L on the interval $[a, b]$, with respect to the classical homogeneous radiation boundary conditions (2.1), all lie in the left half-plane. As has been the case thus far, we assume that the system parameters are all known so that, in particular, all the eigenvalues are known. If finitely many of these happen to be nonnegative, we show that by using state feedback, it is possible to reconstruct the original unknown boundary input f by a modification of our main result.

If the eigenvalues for the systems (2.3), (2.4) are all strictly negative, define $\eta = 0$. If not, choose $\eta > 0$ such that for every μ, λ satisfying (2.3), (2.4), respectively, we have

$$\mu < \eta \quad \text{and} \quad \lambda < \eta.$$

Then the systems:

$$(5.1)\qquad \begin{aligned} &Lu = u_t, \qquad a<x<b, \qquad t>0\\ &B_1 u(\cdot, t) = f(t), \qquad t>0\\ &B_2 u(\cdot, t) = 0, \qquad t>0\\ &u(x,0) = 0, \qquad a<x<b \end{aligned}$$

and

$$(5.2)\qquad \begin{aligned} &(L-\eta)U = U_t, \qquad a<x<b, \qquad t>0\\ &B_1 U(\cdot, t) = e^{-\eta t} f(t), \qquad t>0\\ &B_2 U(\cdot, t) = 0, \qquad t>0\\ &U(x,0) = 0, \qquad a<x<b \end{aligned}$$

are equivalent if $U(x, t) = e^{-\eta t} u(x, t)$.

Also note that if w_η satisfies

$$(5.3)\qquad \begin{aligned} &((L-\eta)-\lambda) w_\eta(x,\lambda) = 0, \qquad a<x<b\\ &w_\eta(b,\lambda) = k_2, \qquad w_\eta'(b,\lambda) = -h_2 \end{aligned}$$

then $w_\eta(x, \lambda) = w(x, \eta + \lambda)$.

Let $\{\mu_n\}_{n=1}^\infty$ and $\{\lambda_n\}_{n=1}^\infty$ be as defined earlier in (2.3), (2.4).

Now, for $\eta > \lambda_1$ and $w(x_0, \eta) \neq 0$, define for $t>0$ the sequence $f_n^\eta(t)$ by:

$$f_0^{(\eta)}(t) = \frac{h_1 w(a,\eta) - k_1 w'(a,\eta)}{w(x_0,\eta)}\, U(x_0, t)$$

$$f_n^{(\eta)}(t) = \frac{\mu_n - \eta}{\lambda_n - \eta} f_{n-1}^{(\eta)}(t) - (\mu_n - \eta)\left(1 - \frac{(\mu_n-\eta)}{(\lambda_n - \eta)}\right) \exp\left((\mu_n - \eta)t\right) * f_{n-1}^{(\eta)}(t).$$

Then, $\{f_n^{(\eta)}\}$ converges to $f^{(\eta)} = e^{-\eta t} f(t)$ in $L^2(0,\infty)$ and if $(f^{(\eta)'}) \in L^2(0, \infty)$, then

$$\|f_n^{(\eta)} - f^{(\eta)}\|_2 = O\left(\frac{1}{n}\right) \quad \text{as } n \to \infty.$$

In order to apply the inversion process it is required that

$$w(x_0, \eta) = w_\eta(x_0, 0) \neq 0.$$

It is therefore of interest to know exactly what restriction this places on the choice of x_0. The following remark indicates that under a variety of conditions, there is no restriction on the choice of x_0, or, at most one point must be omitted. In general, the set of x_0 that must be excluded is a finite set. We note the following special cases.

1. If q in (2.1) is identically zero, then $w(x_0, \eta) \neq 0$ for all $x_0 \in (a, b)$.
2. If q is strictly positive, then

$$w(x_0, \eta) \frac{\partial w}{\partial x}(x_0, \eta) = 0$$

for at most one $x_0 \in [a, b]$ (cf. [15, p. 437]). Hence, in this case if h_1 or k_1, or h_2 or k_2 is zero, then $w(x_0, \eta) \neq 0$, for all $x_0 \in (a, b)$. Also, if q is strictly postive and h_2 and k_2 are not zero (or h_1 and k_1 are not zero), then $w(x_0, \eta) = 0$ for at most one $x_0 \in (a, b)$.

6. The inversion scheme. Here we describe and analyze a technique for the numerical implementation of the inversion scheme obtained in § 4. Numerical evidence of the success of this method in dealing with both surface temperature and heat flux is presented in the next section. An interesting and very useful feature of this technique, which is obtained here, is the availability of an estimate on an appropriate iteration level which depends on the accuracy of the available temperature readings. The method described here assumes only the knowledge of a finite, discrete set of approximate values of the temperature at an interior point x_0.

Throughout this section we assume that the system (2.2) is being observed for a finite time T, so the boundary control f is defined only on $[0, T]$. We extend f to all of $\mathbb{R}$ by defining it to be zero off $[0, T]$. Let x_0 be fixed in (a, b) such that $w(x_0, 0) \neq 0$, and $\mu_1, \lambda_1 < 0$. Denote the true temperature $u(x_0, t)$ by $u(t)$.

Now assume that the temperature is observed at a discrete set of times $\{t_1, t_2, \cdots, t_M\}$, where $t_k = kh$, $h > 0$ is fixed, and $t_M = T$.

Let v_k be the approximate temperature reading at time t_k, $k = 1, 2, \cdots, M$, with measurement error given by

$$|v_k - u(t_k)| \leqq \varepsilon, \quad \text{for } k = 1, 2, \cdots, M. \tag{6.1}$$

For notational convenience, let $t_0 = 0$, $v_0 = 0$.

Due to the accumulation of round-off errors, it is more efficient to replace the iterative generation of the sequence $\{f_n\}$ of approximations to the boundary control f by the following formula:

$$f_N(t) = A\left(\prod_{n=1}^{N} \frac{\mu_n}{\lambda_n}\right)\left\{u(t) + \sum_{n=1}^{N} \gamma_{N,n} \exp(\mu_n t) * u(t)\right\} \tag{6.2}$$

where

$$A = \frac{h_1 w(a, 0) - k_1 w'(a, 0)}{w(x_0, 0)},$$

$$\gamma_{N,n} = \prod_{k=1}^{N} (\mu_n - \lambda_k) \Big/ \prod_{\substack{k=1 \\ k \neq n}}^{N} (\mu_n - \mu_k), \qquad n = 1, \cdots, N.$$

This result is easily obtained by a partial fraction decomposition of the Fourier or Laplace transform of f_N.

Now the first step in this numerical procedure is to generate an approximation, v, to the true temperature u, such that

$$v(t_k) = v_k, \qquad k = 0, 1, 2, \cdots, M. \tag{6.3}$$

In the numerical examples presented here, v was chosen to be the cubic spline with the "not-a-knot" condition (cf. [10]). However, higher degree polynomial splines may also be used. Since v_k is only approximately equal to $u(t_k)$, to analyze the error between u and v, we introduce an intermediate function σ.

LEMMA 6.1. *For each* δ, $0 < \delta < h$, *there exists* $\sigma \in \mathscr{C}^{\infty}(\mathbb{R})$ *such that*:

(a) $\sigma(t_k) = v_k$, *for* $k = 0, 1, \cdots, M$.

(b) $\sigma(t) = 0$ *for* $t \leqq 0$ *and* $\sigma(t) = u(t)$ *for* $t \geqq T + \delta/2$.

(c) $\|\sigma - u\|_2 < T^{1/2}\varepsilon$.

(d) $\|\sigma^{(n)}\|_\infty \leqq C_n(\varepsilon/\delta^n + \|f\|_2)$, *for all* $n = 1, 2, \cdots$, *where* C_n *is a constant* (*independent of* δ, h, ε).

Proof. Choose $\Psi \in \mathscr{C}^\infty(\mathbb{R})$ such that

(i) $0 \leqq \Psi(t) \leqq 1$, for all $t \in \mathbb{R}$,

(ii) $\Psi^{(n)}(t) = 0$, for all $|t| \geqq 1$ and $n = 0, 1, 2, \cdots$,

(iii) $\|\Psi\|_\infty = \Psi(0) = 1$.

For each $k = 1, 2, \cdots, M$, define,

$$J_k = (t_k - \delta/2, t_k + \delta/2),$$

and

$$\Psi_k(t) = \Psi\left(\frac{2}{\delta}(t - t_k)\right), \quad \text{for } t \in J_k.$$

Let $\sigma = \sum_{k=1}^M (v_k - u(t_k))\Psi_k + u$.

Then, by the disjointness of $\{J_k : k = 1, 2, \cdots, M\}$,

$$\sigma(t) = \begin{cases} (v_k - u(t_k))\Psi_k(t) + u(t), & \text{if } t \in J_k \\ u(t), \quad \text{if } t \notin \bigcup\limits_{k=1}^{M} J_k. \end{cases}$$

From Theorem 3.1 and [14], we have that,

$$u = K(x_0, \cdot) * f,$$

where

$$|\hat{K}(x_0, \xi)| \leqq C \exp\left\{-\left(\frac{x_0 - a}{2}\right)\sqrt{\frac{|\xi|}{2}}\right\},$$

for all $\xi \in \mathbb{R}$, for some constant C.

Hence the Sobolev embedding theorem implies $u \in \mathscr{C}^\infty(\mathbb{R})$ and Young's inequality gives

$$\|u^{(n)}\|_\infty \leqq \|K^{(n)}(x_0, \cdot)\|_2 \|f\|_2.$$

It then follows that $\sigma \in \mathscr{C}^\infty(\mathbb{R})$ and $\|u^{(n)}\|_\infty \leqq C_n \|f\|_2$.

(a) and (b) of Lemma 6.1 are easily verified.

$$\begin{aligned} \|\sigma - u\|_2^2 &= \sum_{k=1}^M \int_{J_k} (v_k - u(t_k))^2 \Psi_k^2(t)\, dt \\ &\leqq \varepsilon^2 M \frac{\delta}{2} \|\Psi\|_2^2 < \varepsilon^2 T. \end{aligned}$$

If $t \in J_k$, then

$$\begin{aligned} |\sigma^{(n)}(t)| &\leqq |v_k - u(t_k)|\,|\Psi_k^{(n)}(t)| + |u^{(n)}(t)| \\ &\leqq \varepsilon\left(\frac{2}{\delta}\right)^n |\Psi^{(n)}(t)| + C_n \|f\|_2 \\ &\leqq C_n\left(\frac{\varepsilon}{\delta^n} + \|f\|_2\right). \end{aligned}$$

If $t \notin \bigcup_{k=1}^M J_k$, $|w^{(n)}(t)| = |u^{(n)}(t)| \leqq C_n \|f\|_2$.

This completes the proof.

Consequently, v is an interpolant of the points $(t_k, \sigma(t_k))$ on the graph of the $\mathscr{C}^\infty$ function σ, hence, depending on the other imposed conditions on v, we may have an estimate of the form:

$$\|v-\sigma\|_2 \leqq C_p \|w^{(p)}\|_\infty h^p \tag{6.4}$$

for some integer p and constant $C_p > 0$.

Throughout the remainder of this paper, C denotes a constant which is not necessarily the same at each occurrence, and p is a fixed constant.

THEOREM 6.1. *If v satisfies* (6.4) *then*

$$\|v-u\|_2 \leqq C(\varepsilon + h^p \|f\|_2).$$

Proof. By choosing $n = p$ and $\delta = h/2$ in Lemma 6.1(d) and using (6.4), we obtain

$$\|v-\sigma\|_2 \leqq C(\varepsilon + h^p \|f\|_2).$$

The result follows from the triangle inequality and Lemma 6.1(c).

The strategy for the numerical implementation of Theorem 2.1 is to compute approximations to f by using the formula (6.2) where v is inserted for the unknown function u. These approximations will be denoted g_N. So,

$$g_N(t) = A\left(\prod_{n=1}^{N} \frac{\mu_n}{\lambda_n}\right)\left\{v(t) + \sum_{n=1}^{N} \gamma_{N,n} \exp(\mu_n t) * v(t)\right\}. \tag{6.5}$$

Since v is "close" to u, g_N is "close" to f_N for each N, however, due to the ill-posed nature of the problem, $\{g_N\}$ usually will not converge to f. It will now be shown how to overcome this difficulty by choosing an appropriate level of iteration.

LEMMA 6.2. *Let $r > 0$, $s > 0$. If*

$$h \leqq \exp(-(2\alpha\Delta^2 - 1)^{(m+1)/r})$$

and

$$\varepsilon \leqq \exp(-(2\alpha\Delta^2 - 1)^{(m+1)/s}),$$

then there exist positive integers $N_r(h)$, $M_s(\varepsilon)$, and $N_{r,s}(h, \varepsilon)$ such that

$$\frac{r \log\log(1/h)}{\log(2\alpha\Delta^2 - 1)} - 1 \leqq N_r(h) \leqq \frac{r \log\log(1/h)}{\log(2\alpha\Delta^2 - 1)},$$

and, if $\varepsilon > 0$,

$$\frac{s \log\log(1/\varepsilon)}{\log(2\alpha\Delta^2 - 1)} - 1 \leqq M_s(\varepsilon) \leqq \frac{s \log\log(1/\varepsilon)}{\log(2\alpha\Delta^2 - 1)},$$

$$N_{r,s}(h, \varepsilon) = \min(N_r(h), M_s(\varepsilon)),$$

and, $N_{r,s}(h, 0) = N_r(h)$, and

$$\|g_{N_{r,s}(h,\varepsilon)} - f\|_2 \leqq C\left(\frac{2\alpha\Delta^2 + 1}{2\alpha\Delta^2 - 1}\right)^{m-1} \{h^p(\log 1/h)^r \|f\|_2 + \varepsilon(\log 1/\varepsilon)^2\}$$
$$+ \|f_{N_{r,s}(h,\varepsilon)} - f\|_2.$$

Proof. By using the recurrence relations satisfied by $\{f_n\}$ and $\{g_n\}$, Young's inequality, and (2.7), it can be shown that

$$\|g_n - f_n\|_2 \leqq C\left(\frac{2\alpha\Delta^2 + 1}{2\alpha\Delta^2 - 1}\right)^{m-1} (2\alpha\Delta^2 - 1)^n \|v - u\|_2, \quad \text{for } n \geqq m,$$

(cf. [16]). Hence, by Theorem 6.1,

$$\|g_n - f\|_2 \leqq C\left(\frac{2\alpha\Delta^2+1}{2\alpha\Delta^2-1}\right)^{m-1}(2\alpha\Delta^2-1)^n(\varepsilon + h^p\|f\|_2) + \|f_n - f\|_2.$$

Now, by the assumptions on h and ε,

$$m \leqq \frac{r \log\log(1/h)}{\log(2\alpha\Delta^2-1)} - 1$$

and

$$m \leqq \frac{s \log\log(1/\varepsilon)}{\log(2\alpha\Delta^2-1)} - 1.$$

So we can choose $N_r(h)$, $M_s(\varepsilon)$ and $N_{r,s}(h, \varepsilon)$ as in the statement of the lemma, and $N(h, \varepsilon) \geqq m$. The result follows by noting that

$$(2\alpha\Delta^2-1)^{N_{r,s}(h,\varepsilon)} \leqq \min\{(\log 1/h)^r, (\log 1/\varepsilon)^s\}.$$

Now, as ε, h approach zero, there must exist r, s such that h, ε, r, s satisfy the conditions in Lemma 6.2. In the following, we assume such r, s are fixed and let h, ε tend to zero.

Let H^1 denote the Sobolev space $\{f \in L^2 : f' \in L^2\}$ and $\|\cdot\|_{H^1}$ the norm on H^1.

THEOREM 6.2. *Let h, ε and $N_{r,s}(h, \varepsilon)$ be as in Lemma 6.2. Then,*

$$\lim_{h,\varepsilon \to 0+} g_{N_{r,s}(h,\varepsilon)} = f, \quad \text{in } L^2.$$

Furthermore, for all f in any given ball, $\{f \in H^1 : \|f\|_{H^1} \leqq D\}$,

$$\begin{aligned}\|g_{N_{r,s}(h,\varepsilon)} - f\|_2 &= O(h^p(\log 1/h)^r + \varepsilon(\log 1/\varepsilon)^s) \\ &\quad + O\left(\frac{1}{\log\log 1/h} + \frac{1}{\log\log 1/\varepsilon}\right) \\ &= O\left(\frac{1}{\log\log 1/h} + \frac{1}{\log\log 1/\varepsilon}\right).\end{aligned}$$

Proof. The first assertion follows from Lemma 6.2 and from the first assertion in Theorem 2.1.

For the second assertion, note that,

$$\frac{1}{N_{r,s}(h, \varepsilon)} \leqq \frac{1}{N_r(h)} + \frac{1}{M_s(\varepsilon)} = O\left(\frac{1}{\log\log 1/h} + \frac{1}{\log\log 1/\varepsilon}\right).$$

The proof then follows from Lemma 6.2 and Theorem 2.1.

Now, the conditions on on ε, h, r, s in Lemma 6.2 only require r and s to be bounded below. Hence, for given ε and h, $N_{r,s}(h, \varepsilon)$ may be chosen arbitrarily large. However, Theorem 6.2 indicates that the error between $g_{N_{r,s}(h,\varepsilon)}$ and f may become unbounded as r, $s \to \infty$. To make an appropriate choice for r, s it seems reasonable to require that the error be minimized.

From the proof of Lemma 6.2 and Theorem 6.2, this leads to the problem of minimizing

$$H(r)=C_m(\Delta)h^p(\log 1/h)^r+\frac{\log(2\alpha\Delta^2-1)}{r\log\log 1/h},\quad \text{subject to}$$

$$r\geqq r_0=(m+1)\frac{\log(2\alpha\Delta^2-1)}{\log\log 1/h};\quad \text{and}$$

$$E(s)=C_m(\Delta)\varepsilon(\log 1/\varepsilon)^s+\frac{\log(2\alpha\Delta^2-1)}{s\log\log 1/\varepsilon},\quad \text{subject to}$$

$$s\geqq s_0=(m+1)\frac{\log(2\alpha\Delta^2-1)}{\log\log 1/\varepsilon},\quad \text{where}$$

$$C_m(\Delta)=A\left(\frac{2\alpha\Delta^2+1}{2\alpha\Delta^2-1}\right)^{m-1}.$$

By elementary calculations, the minimum of H occurs either at r_0 or at r_1 for which $H'(r_1)=0$ and $r_0\leqq r_1$. By using the equation $H'(r_1)=0$ and the inequality $r_1\geqq r_0$, it can be seen that the minimum of H occurs at a point in the interval

$$[r_0,\{h^pC_m(\Delta)(m+1)^2\log(2\alpha\Delta^2-1)\log\log 1/h\}^{-1}]. \tag{6.6}$$

A similar analysis for $E(r)$ shows that the minimum of E occurs at a point in the interval

$$[s_0,\{\varepsilon C_m(\Delta)(m+1)^2\log(2\alpha\Delta^2-1)\log\log 1/\varepsilon\}^{-1}]. \tag{6.7}$$

The determination of the exact location of these minima requires the solution of a highly nonlinear equation which cannot be solved exactly. However, by using the bounds in (6.6), (6.7) and the convexity of the functions H and E, it is readily shown that the Newton-Raphson technique (applied to the location of the zeros of H' and E') enables us to numerically determine the location of these minima to any desired degree of accuracy.

Using these approximate values of r and s in Lemma 6.2, we obtain an approximate level of iteration which guarantees the stability of the inversion process. In the numerical results presented later, these iteration levels are referred to as *recommended iterates.*

This demonstrates the feasibility of the proposed inversion process given only finite, discrete, noisy temperature readings.

We conclude this section by examining the problem of the computation of the convolutions appearing in the inversion scheme. To overcome this, it is suggested that the approximation v be chosen to be a polynomial spline of some degree q. Then the convolutions can be calculated exactly as follows.

$$v(t)=\sum_{j=1}^{q}C_{ij}(t-t_i)^j,\quad \text{for } t\in[t_i,t_{i+1}],$$

$i=0,1,2,\cdots,M-1$, where C_{ij} are known.

$$\begin{aligned}\exp(\mu_nt)*v(t)|_{t=t_k}&=\sum_{i=0}^{k-1}\int_{t_i}^{t_{i+1}}\exp(\mu_n(t_k-s))v(s)\,ds\\&=\sum_{i=0}^{k-1}\exp(\mu_nh(k-i))\sum_{j=1}^{p}C_{ij}I_{nj},\end{aligned}$$

where

$$I_{n1}=\frac{1-\exp(-\mu_n h)}{\mu_n}$$

$$I_{n(j+1)}=-\frac{h^j}{\mu_n}\exp(-\mu_n h)+\frac{j}{\mu_n}I_{nj}.$$

Finally, this inversion scheme can be extended to deal with higher-dimensional rectangular bodies. For example, consider the following system on a two-dimensional rectangle.

$$\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}=\frac{\partial u}{\partial t},\qquad 0<x<a,\qquad 0<y<b,\qquad t>0$$

$$u(x,y,0)=0,\qquad 0\leqq x\leqq a,\qquad 0\leqq y\leqq b$$

$$u(x,0,t)=u(x,b,t)=0,\qquad 0\leqq x\leqq a,\qquad t\geqq 0$$

$$u(a,y,t)=0,\qquad 0\leqq y\leqq b,\qquad t\geqq 0$$

$$u(0,y,t)=f(y,t),\qquad 0\leqq y\leqq b,\qquad t\geqq 0.$$

Then, the following integral representation theorem is well known (cf. [13]):

$$u(x,y,t)=\int_0^t \varphi_a(x,t-s)\int_0^b G_b(y,t,\xi,s)f(\xi,s)\,d\xi\,ds,$$

where φ_a and G_b are Green's functions for corresponding one-dimensional problems.

In [13], it was shown that for each fixed $x_0\in(0,a)$, the values of $u(x_0,y,t)$ for $y\in(0,b)$, $t>0$, uniquely determine the boundary function f. Due to the form of the kernel appearing in the above integral representation, Theorem 2.1 extends naturally to a technique for recovering the Fourier coefficients

$$\tilde{f}_m(t)=\int_0^b \psi_m(y)f(y,t)\,dy,$$

thus determining f by $f(y,t)=\sum\tilde{f}_m(t)\psi_m(y)$.

7. Numerical results. In this section, we present the results of numerical tests of the inversion scheme described in § 6 for surface temperature and flux, boundary conditions in the cases when the boundary function is the characteristic function of [0.25, 0.5] and $\sin(2\pi t)$. The system is observed at discrete, equispaced points over the interval $[0,T]$, $T=1$ or $T=2$. Our results demonstrate the appropriateness of the choice of the so-called *recommended iterates*, for an oscillatory boundary control which lies in the Sobolev space H^1. The effectiveness of this method is also demonstrated for the characteristic function boundary control, although our mathematical analysis does not seem to cover this case.

In all the results presented here, the following values are fixed.

$$a=0,\qquad b=\pi,\qquad x_0=0.1,\qquad h_2=1,\qquad k_2=0,$$

and

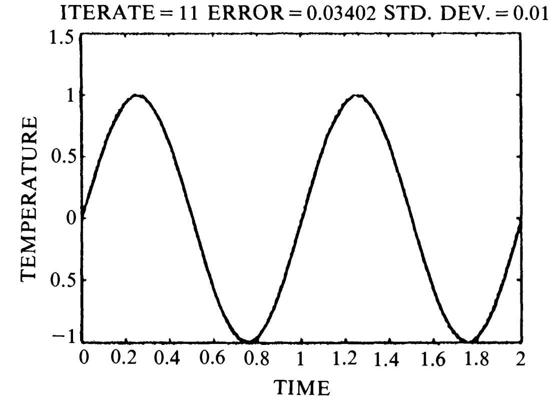
$$L\equiv\frac{d^2}{dx^2}.$$

As it is not possible to obtain exact solutions to these direct problems for the finite rod, the data was generated by using a series solution and taking enough terms to guarantee an accuracy of 10^{-4} at each sampling point

$$(x_0, t_k).$$

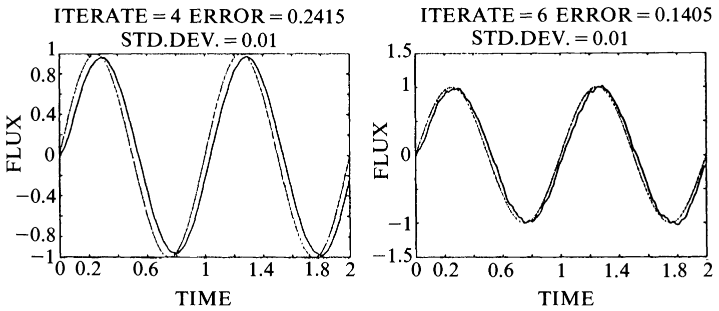
Then random noise was added to these approximate values with standard deviation the magnitude of *std. dev.* as indicated in each figure below. The quantity *error* indicated in each diagram is the $L^2(0, T)$ error between the indicated *iterate* and the true boundary function.

In all the figures below, the approximation produced by the inversion scheme is in solid line and the true boundary function appears as a dotted graph.



ITERATE = 11 ERROR = 0.03402 STD. DEV. = 0.01

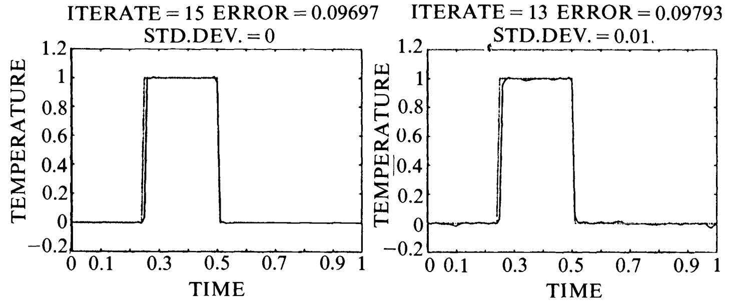
FIG. 1. *Sine surface temperature,* 11 *iterates.*



ITERATE = 4 ERROR = 0.2415 STD.DEV. = 0.01

ITERATE = 6 ERROR = 0.1405 STD.DEV. = 0.01

FIG. 2. *Sine heat flux with time step size* 0.01.



ITERATE = 15 ERROR = 0.09697 STD.DEV. = 0

ITERATE = 13 ERROR = 0.09793 STD.DEV. = 0.01

FIG. 3. *Discontinuous surface temperature.*

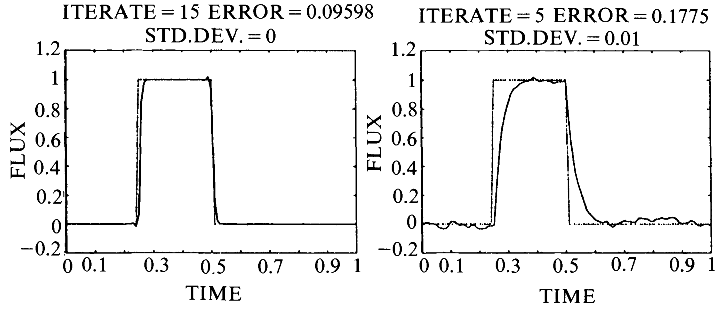


FIG. 4. *Discontinuous surface heat flux.*

Example 7.1. In this case, $h_1 = 1$, $k_1 = 0$, $f(t) = \sin(2\pi t)$ on $[0, 2]$ and time step size, $h = 0.04$. The inversion scheme produced Table 1 and Fig. 1.

We now present a result for the recovery of flux (Table 2, Fig. 2).

Example 7.2. Here, $h_1 = 0$, $k_1 = 1$, $f(t)$ as in Example 7.1 and time step size, $h = 0.01$.

The next two examples (see Figs. 3, 4) present data on the recovery of f in the case when

$$f(t) = \begin{cases} 1, & \frac{1}{4} \leqq t \leqq \frac{1}{2} \\ 0, & \text{otherwise.} \end{cases}$$

Although the analysis in the paper does not provide explicit error bounds for this case, the numerical results are surprisingly good. In both examples the time step size is 0.01.

These numerical results compare favorably with those in [7], [18]. In this regard, it is important to note that the problem was analyzed in [7], [18], for a semi-infinite rod, whereas our results are valid for a rod of finite length.

INITIAL BOUNDARY VALUE PROBLEMS AND OPTIMAL CONTROL FOR NONAUTONOMOUS PARABOLIC SYSTEMS*

P. ACQUISTAPACE,† F. FLANDOLI,‡ AND B. TERRENI§

Abstract. A large class of linear nonautonomous parabolic systems in bounded domains is considered, with control acting on the boundary through Dirichlet or Neumann conditions, from the point of view of semigroup theory. The results from [*Rend. Sem. Mat. Univ. Padova*, 78 (1987), pp. 47-107], [*On fundamental solutions for abstract parabolic equations*, Lecture Notes in Math., Vol. 1223, Springer-Verlag, Berlin, Heidelberg, 1986, pp. 1-11] on abstract homogeneous parabolic Cauchy problems allow operators with varying domains and Hölder continuous coefficients to be handled. A representation formula for solutions corresponding to square integrable control functions is derived and used to solve a linear-quadratic regulator problem over finite time horizon, by a direct study of the associated integral Riccati equation.

Key words. optimal control, parabolic systems, boundary control, Riccati equation

1. Introduction. During the last two decades relevant progress has been made in the theory of boundary control of partial differential equations. In the case of equations of parabolic type, both variational and semigroup methods have been successfully applied (see, for instance, [L2], [DS], [S1], [S2], [Fa], [B1], [La], [LT1], [LT2], [F1], [F2]). Most of these (and other) papers deal with autonomous parabolic equations. Only [L2] and [DS] present results on the boundary control in the nonautonomous case, by variational techniques.

This paper concerns nonautonomous systems of parabolic type, from the point of view of semigroup theory. Our first purpose is to develop a suitable approach to nonhomogeneous initial boundary value problems based on the theory of evolution operators, in view of its application to boundary control problems.

Section 2 is devoted to this basic question. As in the autonomous case we are able to deal with control functions which are only square integrable in time and space. In particular our main goal is to derive a representation formula for solutions, similar to the classical one (see [B2], [La], [LT1]), which will prove to be very useful in the treatment of control problems.

Section 2 is organized as follows. Section 2.1 contains a detailed analysis of two concrete systems of equations of parabolic type with nonhomogeneous Dirichlet or Neumann boundary conditions, which motivate the abstract model to be introduced afterwards. In §§ 2.2 and 2.3 we study an abstract homogeneous nonautonomous parabolic Cauchy problem by the methods of [AT1], [AT2], which allow us to handle operators with variable domains and whose coefficients are just Hölder continuous in time. In § 2.4, by using the properties of the Dirichlet and Neumann maps, we obtain an abstract formulation of the concrete nonhomogeneous problems analyzed in § 2.1. Finally, in § 2.5 we derive the representation formula for solutions of the abstract version of nonhomogeneous initial boundary value problems; this formula is meaningful for nonregular boundary data and will be considered as the state equation for the control problems of § 3.

The second part of the paper, namely § 3, deals with the linear-quadratic regulator (L-Q-R) problem, over finite time horizon, for an abstract evolution equation which includes the concrete models discussed in § 2. Here we follow the approach of [F2], based on a direct solution of the Riccati equation arising in the L-Q-R problem. However our assumptions on the final state cost operator P_T (see (3.13) below) are weaker than those imposed in [F2], and suggested by the more general results of [DI1]. We are able to solve directly the basic integral Riccati equation under general assumptions, much weaker and more natural for the applications than those imposed in [DS], where the Riccati equation was deduced from the optimality system (see Remark 2.3(iii) below). It turns out that our approach in the more general setting of nonautonomous problems still allows us to employ standard techniques of control theory. This fact lets us hope that many other results on boundary control problems, such as, e.g., infinite horizon optimal control [F2], [LT3], [DI2], [D], and the control of stochastic systems [F2], [I], can also be extended to the nonautonomous framework.

We conclude this section by listing some notation.

If X is a Banach space and $a<b$ we set:

$L^p(a,b;X):=$ space of strongly measurable functions $f:]a,b[\to X$ such that $\int_a^b \|f(t)\|_X^p\,dt<\infty$ ($1\leqq p<\infty$; obvious modifications for $p=\infty$); $C^k([a,b],X):=$ space of functions $f:[a,b]\to X$ which are k times continuously differentiable ($k\in\mathbb{N}$);

$C^{k+\vartheta}([a,b],X):=$ space of functions $f\in C^k([a,b],X)$ such that $f^{(k)}$ is ϑ-Hölder continuous ($k\in\mathbb{N}$, $\theta\in]0,1[$).

If X, Y are Banach spaces, we set:

$\mathscr{L}(X,Y):=$ space of bounded linear operators $T:X\to Y$;

$\mathscr{L}(X):=\mathscr{L}(X,X)$;

$C_s([a,b],\mathscr{L}(X,Y)):=$ space of operator-valued functions $T(\cdot):[a,b]\to\mathscr{L}(X,Y)$ which are strongly continuous, i.e., $T(\cdot)x\in C^0([a,b],Y)$ for each $x\in X$.

If H is a Hilbert space, we set:

$\Sigma(H):=$ space of self-adjoint operators $T\in\mathscr{L}(H)$;

$\Sigma^+(H):=$ space of self-adjoint operators $T\in\mathscr{L}(H)$ which are positive, i.e., $(Tx|x)_H\geqq 0$ for each $x\in H$.

If H is a Hilbert space and T is a linear operator in H, we set:

$D_T:=$ domain of T;

$\sigma(T):=$ spectrum of T;

$\rho(T):=$ resolvent set of T;

$T^*:=$ adjoint operator of T (whenever it exists).

Finally, if $m\in\mathbb{N}^*$ and Ω is a bounded open set of $\mathbb{R}^n$, we shall use the following spaces of $\mathbb{C}^m$-valued functions:

$$[C^k(\bar{\Omega})]^m,[C^{k+\vartheta}(\bar{\Omega})]^m,[L^p(\Omega)]^m(k\in\mathbb{N},\vartheta\in]0,1[,p\in[1,\infty]),$$

whose definitions are clear, and the usual Sobolev spaces

$[W^{\vartheta,p}(\Omega)]^m$, $[W^{\vartheta,p}(\partial\Omega)]^m(p\in[1,\infty[,\vartheta\in\mathbb{R})$,

$[W_0^{\vartheta,p}(\Omega)]^m(p\in[1,\infty[,\vartheta\in]1/p,\infty[)$.

2. Nonautonomous parabolic systems.

2.1. Two classical examples. We consider in this section two particular types of parabolic initial boundary value problems, namely, two parabolic systems with Dirichlet and Neumann conditions, respectively. We think of them as prototypes of the class of problems which are covered by the general theory of this section.

Let Ω be a bounded open set of $\mathbb{R}^n$, with boundary $\partial\Omega$ of class C^2. Fix $T>0$ and let $\{A_{sj}(t,x)\}_{s,j=1,\cdots,n}$ a set of $N\times N$ complex-valued matrices defined in $[0,T]\times\bar{\Omega}$, fulfilling the following hypotheses:

(2.1) (regularity)

$$A_{sj}\in C^{\alpha+1/2}([0,T],[C^0(\bar\Omega)]^{N^2})\cap C^{\alpha}([0,T],[C^1(\bar\Omega)]^{N^2}),$$

(2.2) (strong ellipticity)

$$\operatorname{Re}\sum_{sj=1}^{n}(A_{sj}(t,x)\cdot\eta_j\,|\,\eta_s)_{\mathbb{C}^N}$$

$$\geqq \nu\sum_{s=1}^{n}|\eta_s|^2\quad \forall\eta_1,\cdots,\eta_n\in\mathbb{C}^N,\quad \forall(t,x)\in[0,T]\times\bar\Omega\quad(\nu>0).$$

Under the above assumptions we consider the following problems:

$$(2.3)\quad \begin{aligned}&D_ty(t,x)-\sum_{sj=1}^{n}D_s[A_{sj}(t,x)\cdot D_jy(t,x)]+y(t,x)=0\quad\text{in }[0,T]\times\bar\Omega,\\&y(t,x)=u(t,x)\quad\text{in }[0,T]\times\partial\Omega,\\&y(0,x)=y_0(x)\quad\text{in }\bar\Omega;\end{aligned}$$

$$(2.4)\quad \begin{aligned}&D_ty(t,x)-\sum_{sj=1}^{n}D_s[A_{sj}(t,x)\cdot D_jy(t,x)]+y(t,x)=0\quad\text{in }[0,T]\times\bar\Omega,\\&\sum_{sj=1}^{n}A_{sj}(t,x)\cdot D_jy(t,x)\nu_s(x)=u(t,x)\quad\text{in }[0,T]\times\partial\Omega,\\&y(0,x)=y_0(x)\quad\text{in }\bar\Omega,\end{aligned}$$

where y_0, u are prescribed data on the parabolic boundary of $[0,T]\times\bar\Omega$. Here $\nu(x)$ is the unit outward normal vector at $x\in\partial\Omega$. It is well known that if u, y_0 are sufficiently smooth and fulfill suitable compatibility conditions at $\partial\Omega$ at $t=0$, then problems (2.3), (2.4) possess a unique solution; in addition we want to prove a representation formula for such solutions which will allow us to generalize the concept of solution to the case of less regular data u, y_0.

Concerning existence and uniqueness, we will invoke the results of Theorem 4.7 of [AT3]; to this purpose we just need that problems (2.3), (2.4) obey the requirements given there, namely, we need that the operator $\{\sum_{sj=1}^{n}D_s(A_{sj}(t,x)\cdot D_j)\}$, with boundary conditions of Dirichlet or of conormal derivative type, satisfies the ellipticity assumptions of [ADN] and [GG]. This is in fact true, as pointed out in Remark 2.3(i) below. Hence we can state the following propositions.

PROPOSITION 2.1. *Under assumptions* (2.1), (2.2), *let* $y_0\in[W^{2,2}(\Omega)]^N$, *and let u be the trace on* $[0,T]\times\partial\Omega$ *of a function* $U\in C^{\alpha}([0,T],[W^{1,2}(\Omega)]^N)\cap C^{\alpha+1/2}([0,T],[L^2(\Omega)]^N)$; *assume moreover that*

$$(2.5)\qquad \sum_{sj=1}^{n}A_{sj}(0,x)\cdot D_jy_0(x)\nu_s(x)=u(0,x)\quad \textit{a.e. on }\partial\Omega.$$

Then problem (2.4) *has a unique solution y such that*

$$(2.6)\qquad y\in C^1([0,T],[L^2(\Omega)]^N)\cap C([0,T],[W^{2,2}(\Omega)]^N).$$

PROPOSITION 2.2. *Under assumptions* (2.1), (2.2) *let* $y_0\in[W^{2,2}(\Omega)]^N$, *and let u be the trace on* $[0,T]\times\partial\Omega$ *of a function* $U\in C^{\alpha}([0,T],[W^{2,2}(\Omega)]^N)\cap C^{\alpha+1}([0,T],[L^2(\Omega)]^N)$; *assume moreover that*

$$(2.7)\qquad y_0(x)=u(0,x)\quad\textit{a.e. on }\partial\Omega.$$

Then problem (2.3) *has a unique solution y such that* (2.6) *holds.*

Proof. The proofs of Propositions 2.1, 2.2 follow by Theorem 4.7 of [AT3] with minor modifications (since the operators considered there are not in divergence form). □

Remark 2.3. (i) If we confine ourselves to problem (2.3), we may replace hypothesis (2.2) by the weaker one

$$\text{(2.8)}\quad \operatorname{Re}\sum_{sj=1}^{n}(A_{sj}(t,x)\xi_s\xi_j\cdot\eta\,|\,\eta)_{\mathbb{C}^N}\geqq\nu|\xi|^2|\eta|^2\quad\forall\xi\in\mathbb{R}^n,\quad\forall\eta\in\mathbb{C}^N,\ \forall(t,x)\in[0,T]\times\bar{\Omega};$$

then the operator $\{\sum_{sj=1}^{n}D_s(A_{sj}(t,x)\cdot D_j)\}$, with Dirichlet boundary conditions, still satisfies the ellipticity assumptions of [ADN] and [GG], as pointed out in [Am, pp. 659-660]. On the other hand, we are not able to prove the same assertion in the case of problem (2.4); that is, in order that the above operator, endowed with boundary conditions of conormal derivative type, satisfies the ellipticity assumptions of [ADN] and [GG], we need the stronger hypothesis (2.2) (this can be seen by adapting the argument of [ADN, p. 44]).

(ii) Adding lower order terms in problem (2.3), or (2.4), does not alter the situation: indeed, the change of unknown $v:=e^{\omega t}y$ (for a suitable $\omega\in\mathbb{R}$) leads to a new problem where the new differential operators still enjoy the properties stated in Proposition 2.4 below; in particular, the abstract hypothesis (2.29) is preserved.

(iii) In (2.1) it is assumed that the coefficients of the differential operators satisfy suitable Hölder conditions with respect to time. Such a requirement is necessary in order to fulfill the abstract assumption (2.29)(ii) below, which in turn allows us to construct the evolution operator for the abstract problem (2.28), with its regularity properties (3.4). If the coefficients are just bounded and measurable in t, then we can get some results for the concrete problems (2.3), (2.4) (see [LM1]), i.e., for the state equation; however the subsequent step, namely the study of the Riccati equation, seems very difficult and needs stronger hypotheses (see [DS]).

Existence and uniqueness of the solution of problems (2.3) and (2.4) is now guaranteed, at least for smooth data y_0, u. Our next goal is to establish a representation formula for the solution, which should possess the following features:

(i) It reduces to known representation formulas whenever they hold: see, e.g., [Te] for the autonomous versions of (2.3)-(2.4), [AT1] and [AT2] in the case of homogeneous boundary conditions, [B2] and [La] within the context of control theory;

(ii) It yields "weak" solutions, in some sense, when the data are less smooth;

(iii) It is handy from the point of view of control theory.

In order to construct such a formula, we need to reformulate problems (2.3), (2.4) in an abstract form, and to establish some properties of the evolution operators of the new problem. This will be the object of the next section.

2.2. The abstract formulation of initial boundary value problems. Consider again the situation of § 2.1, under assumptions (2.1), (2.2). If we define, for each $t\in[0,T]$, the differential operators

$$\text{(2.9)}\qquad \mathscr{A}(t,x,D)v:=\sum_{sj=1}^{n}D_s[A_{sj}(t,x)\cdot D_jv]-v,\qquad x\in\bar{\Omega},$$

$$\text{(2.10)}\qquad \mathscr{B}_0v:=v_{|\partial\Omega},$$

$$\text{(2.11)}\qquad \mathscr{B}_1(t,x,D):=\sum_{sj=1}^{n}A_{sj}(t,x)\nu_s(x)\cdot D_jv,\qquad x\in\partial\Omega,$$

then we can introduce the following linear operators:

$$\begin{aligned} &D_{A_0(t)} := \{v \in [W^{2,2}(\Omega)]^N : \mathscr{B}_0 v = 0\} = [W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega)]^N, \\ &A_0(t)v := \mathscr{A}(t, \cdot, D)v, \end{aligned} \tag{2.12}$$

$$\begin{aligned} &D_{A_1(t)} := \{v \in [W^{2,2}(\Omega)]^N : \mathscr{B}_1(t, \cdot, D)v = 0\}, \\ &A_1(t)v := \mathscr{A}(t, \cdot, D)v, \end{aligned} \tag{2.13}$$

where $t \in [0, T]$.

The main properties of the operators $A_0(t)$, $A_1(t)$ are listed in the following proposition.

PROPOSITION 2.4. *Under assumptions* (2.1), (2.2) *we have for* $r = 0, 1$:

(i) *For each* $t \in [0, T]$, $A_r(t)$ *is the infinitesimal generator of an analytic semigroup in* $[L^2(\Omega)]^N$;

(ii) *for each* $t \in [0, T]$, $D_{A_r(t)}$ *is dense in* $[L^2(\Omega)]^N$;

(iii) *the family* $\{A_r(t)\}_{t \in [0,T]}$ *satisfies Hypothesis* II *of* [AT1], *i.e., there exists* $\vartheta_0 \in]\pi/2, \pi]$ *such that*

$$\begin{aligned} &\|A_r(t)[\lambda - A_r(t)]^{-1}[A_r(t)^{-1} - A_r(\tau)^{-1}]\|_{\mathscr{L}([L^2(\Omega)]^N)} \\ &\leqq c\frac{|t-\tau|^{\alpha+1/2}}{|\lambda|^{1/2}} \quad \forall t, \tau \in [0, T], \end{aligned} \tag{2.14}$$

provided λ *belongs to the sector* $S_{\vartheta_0} := \{z \in \mathbb{C} : |\arg z| < \vartheta_0\}$.

Proof. (i) It is well known (see [Am], [GG]) that the resolvent set of the operators $A_r(t)$ contains the sector

$$S_{\vartheta_0} + \omega = \{z \in \mathbb{C} : |\arg (z - \omega)| < \vartheta_0\}$$

for suitable $\vartheta_0 \in]\pi/2, \pi]$ and $\omega \in \mathbb{R}$; we want to show here that we can choose $\omega = 0$ and that

$$\|[\lambda - A_r(t)]^{-1}\|_{\mathscr{L}([L^2(\Omega)]^N)} \leqq \frac{c}{1+|\lambda|} \quad \forall \lambda \in \overline{S_{\vartheta_0}}. \tag{2.15}$$

Suppose first $r = 0$. Fix $t \in [0, T]$ and let $\lambda \in \mathbb{C}$ be such that either $\operatorname{Re} \lambda > 0$ or $(M/\nu)|\operatorname{Re} \lambda| \leqq \frac{1}{2}|\operatorname{Im} \lambda|$. For $v \in [W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega)]^N$ set

$$f(x) := \lambda v(x) - \mathscr{A}(t, x, D)v, \qquad x \in \Omega.$$

Multiplying by v (with respect to the inner product of $[L^2(\Omega)]^N$) and integrating by parts, we get

$$\begin{aligned} &(1+\lambda)\int_\Omega |v|^2\,dx + \int_\Omega \sum_{sj=1}^{n} (A_{sj}(t, x) \cdot D_j v(x) \,|\, D_s v(x))_{\mathbb{C}^N}\,dx \\ &= \int_\Omega (f(x)\,|\,g(x))_{\mathbb{C}^N}\,dx. \end{aligned} \tag{2.16}$$

By taking the real part, we obtain by (2.2)

$$(1+\operatorname{Re}\lambda)\int_\Omega |v|^2\,dx + \nu\int_\Omega |Dv|^2\,dx \leqq \|f\|_{[L^2(\Omega)]^N} \cdot \|v\|_{[L^2(\Omega)]^N}; \tag{2.17}$$

on the other hand, by taking the imaginary part in (2.16),

$$|\mathrm{Im}\,\lambda|\int_\Omega |v|^2\,dx \leqq \|f\|_{[L^2(\Omega)]^N}\cdot\|v\|_{[L^2(\Omega)]^N}+M\int_\Omega |Dv|^2\,dx,$$

where

$$M:=\sum_{sj=1}^{n}\sup_{[0,T]\times\bar\Omega}|A_{sj}(t,x)|. \tag{2.18}$$

Hence by (2.17)

$$|\mathrm{Im}\,\lambda|\int_\Omega |v|^2\,dx \leqq \left(1+\frac{M}{\nu}\right)\|f\|_{[L^2(\Omega)]^N}\cdot\|v\|_{[L^2(\Omega)]^N}+\frac{M}{\nu}|\mathrm{Re}\,\lambda|\int_\Omega |Dv|^2\,dx.$$

Consequently, if $(M/\nu)|\mathrm{Re}\,\lambda|\leqq\frac{1}{2}|\mathrm{Im}\,\lambda|$ we deduce that

$$|\mathrm{Im}\,\lambda|\int_\Omega |v|^2\,dx \leqq 2\left(1+\frac{M}{\nu}\right)\|f\|_{[L^2(\Omega)]^N}\cdot\|v\|_{[L^2(\Omega)]^N}, \tag{2.19}$$

whereas if $(M/\nu)\,\mathrm{Re}\,\lambda>\frac{1}{2}|\mathrm{Im}\,\lambda|$ (2.17) yields

$$(1+\mathrm{Re}\,\lambda)\int_\Omega |v|^2\,dx \leqq \|f\|_{[L^2(\Omega)]^N}\cdot\|v\|_{[L^2(\Omega)]^N}. \tag{2.20}$$

Combining (2.19) and (2.20) we get the estimate

$$\|v\|_{[L^2(\Omega)]^N}\leqq\frac{c}{1+|\lambda|}\|\lambda v-\mathscr{A}(t,\cdot,D)v\|_{[L^2(\Omega)]^N}\quad\forall\lambda\in\overline{S_{\vartheta_0}},$$

where

$$\vartheta_0=\pi-\mathrm{arctg}\frac{2M}{\nu},\qquad c=2\left(1+\frac{M}{\nu}\right)\sqrt{1+(\nu/2M)^2}+1;$$

since we already know that $\rho(A_0(t))$ is not empty, the desired estimate (2.15) for $r=0$ follows from the above inequality by standard arguments.

The case $r=1$ is completely analogous and we find the same constants ϑ_0 and c.

The proof of part (ii) is obvious in both cases $r=0$, 1.

(iii) Consider the case $r=0$. Fix $f\in[L^2(\Omega)]^N$, and set $v:=[A_0(\tau)]^{-1}f$, $w:=[\lambda-A_0(t)]^{-1}[\lambda-A_0(\tau)]v$; then we must estimate

$$v-w=A_0(t)[\lambda-A_0(t)]^{-1}[A_0(t)^{-1}-A_0(\tau)^{-1}]f.$$

The function $v-w$ solves the problem

$$\lambda(v-w)-\mathscr{A}(t,\cdot,D)(v-w)=\sum_{sj=1}^{n}D_s([A_{sj}(t,\cdot)-A_{sj}(\tau,\cdot)]\cdot D_jv)\quad\text{in }\Omega,$$
$$v-w\in[W^{2,2}(\Omega)\cap W_0^{1,2}(\Omega)]^N.$$

Multiplying by $v-w$ (in $[L^2(\Omega)]^N$), an integration by parts yields

$$(1+\lambda)\int_\Omega |v-w|^2\,dx+\int_\Omega\sum_{sj=1}^{n}(A_{sj}(t,x)\cdot D_j(v-w)\,|\,D_s(v-w))_{\mathbb{C}^N}\,dx$$
$$=-\int_\Omega\sum_{sj=1}^{n}([A_{sj}(t,x)-A_{sj}(\tau,x)]\cdot D_jv\,|\,D_s(v-w))_{\mathbb{C}^N}\,dx,$$

which implies

$$\begin{aligned}(2.21)\qquad &(1+\operatorname{Re}\lambda)\int_\Omega |v-w|^2\,dx+\frac{\nu}{2}\int_\Omega |D(v-w)|^2\,dx\\ &\leqq\frac{1}{2\nu}\int_\Omega\sum_{sj=1}^n |A_{sj}(t,\cdot)-A_{sj}(\tau,\cdot)|^2|Dv|^2\,dx,\end{aligned}$$

$$\begin{aligned}(2.22)\qquad &|\operatorname{Im}\lambda|\int_\Omega |v-w|^2\,dx\leqq\frac{1}{2}\int_\Omega\sum_{sj=1}^n |A_{sj}(t,\cdot)-A_{sj}(\tau,\cdot)|^2|Dv|^2\,dx\\ &+\left(M+\frac{1}{2}\right)\int_\Omega |D(v-w)|^2\,dx.\end{aligned}$$

If we set

$$(2.23)\qquad N:=\sum_{sj=1}^n\ \sup_{0\leqq\tau<t\leqq T}\ \sup_{x\in\Omega}\frac{|A_{sj}(t,x)-A_{sj}(\tau,x)|}{|t-\tau|^{\alpha+1/2}},$$

then by (2.22) and (2.21) we easily get

$$\begin{aligned}|\operatorname{Im}\lambda|\int_\Omega |v-w|^2\,dx\leqq N^2\left[\frac{1}{2}+\left(M+\frac{1}{2}\right)\nu^{-2}\right]|t-\tau|^{2\alpha+1}\int_\Omega |Dv|^2\,dx\\ +\frac{2}{\nu}\left(M+\frac{1}{2}\right)|\operatorname{Re}\lambda|\int_\Omega |v-w|^2\,dx.\end{aligned}$$

Hence if $(2/\nu)(M+\frac{1}{2})|\operatorname{Re}\lambda|\leqq\frac{1}{2}|\operatorname{Im}\lambda|$

$$(2.24)\qquad |\operatorname{Im}\lambda|\int_\Omega |v-w|^2\,dx\leqq N^2\left[1+\frac{2M+1}{\nu^2}\right]|t-\tau|^{2\alpha+1}\int_\Omega |Dv|^2\,dx,$$

whereas if $(2/\nu)(M+\frac{1}{2})\operatorname{Re}\lambda>\frac{1}{2}|\operatorname{Im}\lambda|$

$$(2.25)\qquad \operatorname{Re}\lambda\int_\Omega |v-w|^2\,dx\leqq\frac{N^2}{2\nu}|t-\tau|^{2\alpha+1}\int_\Omega |Dv|^2\,dx.$$

Recalling that, by (2.17),

$$\int_\Omega |Dv|^2\,dx\leqq\frac{1}{\nu}\int_\Omega |f|^2\,dx,$$

we conclude that

$$|\lambda|\int_\Omega |v-w|^2\,dx\leqq\frac{N^2}{\nu}\left(1+\frac{2M+1}{\nu^2}\right)\sqrt{1+[\nu/(4M+2)]^2}\,|t-\tau|^{2\alpha+1}\int_\Omega |f|^2\,dx,$$

and (2.14) follows for $r=0$, with

$$\vartheta_0=\pi-\operatorname{arctg}\frac{4M+2}{\nu},\qquad c=N\nu^{-1/2}\left(1+\frac{2M+1}{\nu^2}\right)^{1/2}\left[1+\left(\frac{\nu}{4M+2}\right)^2\right]^{1/4}.$$

Concerning the case $r=1$, we proceed similarly and we find that $v-w$ now solves the problem

$$\lambda(v-w)-\mathscr{A}(t,\cdot,D)(v-w)=\sum_{sj=1}^n D_s([A_{sj}(t,\cdot)-A_{sj}(\tau,\cdot)]\cdot D_jv)\quad\text{in }\Omega,$$

$$\sum_{sj=1}^n A_{sj}(t,\cdot)\nu_s\cdot D_j(v-w)=\sum_{sj=1}^n [A_{sj}(\tau,\cdot)-A_{sj}(t,\cdot)]\nu_s\cdot D_jv\quad\text{on }\partial\Omega;$$

arguing as above, and taking into account the boundary conditions, we obtain the result with the same constants ϑ_0 and c. The proof of Proposition 2.4 is complete. □

Remark 2.5. The estimates (2.15) and (2.14) do not need that A_{sj} belongs to $C^\alpha([0, T], [C^1(\bar{\Omega})]^N)$.

Consider now the operators $A_r(t)^*$, i.e., the adjoint operators of $A_r(t)(t \in [0, T], r = 0, 1)$. It is easy to verify that they are defined by

$$\begin{aligned} &D_{A_0(t)^*} := [W^{1,2}(\Omega) \cap W_0^{1,2}(\Omega)]^N, \\ (2.26)\qquad &A_0(t)^* y := \overline{\mathscr{A}(t, \cdot, D)} y = \sum_{sj=1}^{n} D_j[\overline{{}^tA_{sj}(t, \cdot)} \cdot D_s y] - y, \end{aligned}$$

$$\begin{aligned} &D_{A_1(t)^*} := \left\{ y \in [W^{2,2}(\Omega)]^N : \overline{\mathscr{B}_1(t, \cdot, D)} y = \sum_{sj=1}^{n} \overline{{}^tA_{sj}(t, \cdot)} \nu_s \cdot D_j y = 0 \right\}, \\ (2.27)\qquad &A_1(t)^* y := \overline{\mathscr{A}(t, \cdot, D)} y, \end{aligned}$$

where $\overline{{}^tA_{sj}}$ is the matrix whose elements are the conjugates of the elements of the transposed ${}^tA_{sj}$ of A_{sj}. Consequently, it is clear that the following result holds.

PROPOSITION 2.6. *All statements of Proposition* 2.4 *are true if* $A_r(t)$ *is replaced by* $A_r(t)^*$.

The results of Propositions 2.4 and 2.6 allow us to apply to the operators $\{A_r(t)\}_{t \in [0,T]}$, $\{A_r(t)^*\}_{t \in [0, T]}$ the abstract theory of [AT1], [AT2], and [Ac] concerning linear nonautonomous parabolic Cauchy problems of the following kind:

$$(2.28)\qquad \begin{aligned} &u'(t) - A(t)u(t) = f(t), \qquad t \in [0, T], \\ &u(0) = x, \end{aligned}$$

where $f \in C([0, T], E)$, $x \in E$ (E being a general Banach space) and $\{A(t)\}_{t \in [0,T]}$ fulfills (2.15) and (2.14). In the next section we will recall some facts concerning a problem such as (2.28).

2.3. The study of the abstract problem. We now consider problem (2.28), but we restrict our considerations to the case of a Hilbert space H, which is enough for our successive applications. We assume that:

(2.29) $\{A(t)\}_{t \in [0,T]}$ is a family of closed linear operators in H, such that:

$$\text{(i)}\quad \|[\lambda - A(t)]^{-1}\|_{\mathscr{L}(H)} \leqq \frac{M}{1 + |\lambda|} \quad \forall \lambda \in \overline{S_{\vartheta_0}}, \quad \forall t \in [0, T],$$

$$\text{(ii)}\quad \|A(t)[\lambda - A(t)]^{-1}[A(t)^{-1} - A(s)^{-1}]\|_{\mathscr{L}(H)} \leqq B \frac{|t - s|^{\alpha + 1/2}}{|\lambda|^{1/2}}$$

$$\forall \lambda \in S_{\vartheta_0}, \quad \forall t, s \in [0, T],$$

where $\vartheta_0 \in]\pi/2, \pi]$ and α, M, $B > 0$.

In particular, $A(t)$ generates an analytic semigroup $e^{\xi A(t)}$ which can be represented as a Dunford integral:

$$(2.30)\qquad e^{\xi A(t)} = (2\pi i)^{-1} \int_\Gamma e^{\xi \lambda} [\lambda - A(t)]^{-1} \, d\lambda,$$

Γ being a smooth path contained in S_{ϑ_0} and joining $+\infty\, e^{-i\vartheta}$ to $+\infty\, e^{i\vartheta}$, $\vartheta \in]\pi/2, \vartheta_0[$. Moreover, the fractional powers $[-A(t)]^{\gamma}$ are well defined and we have the representations

$$(2.31) \qquad [-A(t)]^{-\gamma} = (2\pi i)^{-1} \int_{\Gamma'} (-\lambda)^{-\gamma} [\lambda - A(t)]^{-1}\, d\lambda, \qquad \gamma > 0,$$

$$(2.32) \qquad [-A(t)]^{-\gamma}\, e^{\xi A(t)} = (2\pi i)^{-1} \int_{\Gamma'} (-\lambda)^{-\gamma}\, e^{\xi\lambda} [\lambda - A(t)]^{-1}\, d\lambda$$

where $\Gamma' \subset S_{\theta_0}$ joins $+\infty\, \mathrm{e}^{-i\theta}$ to $+\infty\, \mathrm{e}^{i\theta}$ leaving 0 on its right-hand side. We also recall the well-known continuous inclusions

$$(2.33) \qquad \begin{gathered} D_{A(t)}(\gamma + \varepsilon, \infty) \subset D_{[-A(t)]^{\gamma}} \subset D_{A(t)}(\gamma, \infty) \\ \forall \gamma \in]0, 1[, \quad \forall \varepsilon \in]0, 1-\gamma[, \quad \forall t \in [0, T]; \end{gathered}$$

here $D_{A(t)}(\gamma, p)$, $1 \leqq p \leqq \infty$, is the real interpolation space $(D_{A(t)}, H)_{1-\gamma,\infty}$ introduced in [LP], which can be characterized in the following way:

$$(2.34) \qquad D_{A(t)}(\gamma, p) = \{x \in H\colon \xi \to \xi^{-\gamma} \| [e^{\xi A(t)} - 1]x \|_H \in L^p(0, \infty; d\xi/\xi)\}.$$

We need the following lemma.

LEMMA 2.7. *Under assumption* (2.29) *we have for each* t, $s \in [0, T]$:

(i) $$\| [-A(t)]^{-\vartheta} - [-A(s)]^{-\vartheta} \|_{\mathscr{L}(H)} \leqq \begin{cases} c(\vartheta, \alpha) |t-s|^{\alpha+1/2} & \textit{if } \vartheta > \tfrac{1}{2}, \\ c(\vartheta, \alpha, \sigma) |t-s|^{\sigma(\alpha+1/2)} \quad \forall \sigma \in]0, 2\vartheta[& \textit{if } \vartheta \in]0, \tfrac{1}{2}]; \end{cases}$$

(ii) $$\| [-A(t)]^{\vartheta}\, e^{\xi A(t)} \|_{\mathscr{L}(H)} \leqq c(\vartheta) \xi^{-\vartheta} \quad \forall \xi > 0;$$

(iii) $$\| [-A(t)]^{\vartheta}\, e^{\xi A(t)} - [-A(s)]^{\vartheta}\, e^{\xi A(s)} \|_{\mathscr{L}(H)} \leqq c(\vartheta, \alpha) |t-s|^{\alpha+1/2} \xi^{-\vartheta-1/2} \quad \forall \xi > 0.$$

Proof. (i) An easy check shows that

$$[\lambda - A(t)]^{-1} - [\lambda - A(s)]^{-1} = -A(t)[\lambda - A(t)]^{-1} [A(t)^{-1} - A(s)^{-1}] A(s) [\lambda - A(s)]^{-1};$$

hence by (2.31) and (2.29) we get

$$\| [-A(t)]^{-\vartheta} - [-A(s)]^{-\vartheta} \|_{\mathscr{L}(H)} \leqq c \int_{\Gamma'} |\lambda|^{-\vartheta} \left[\frac{M}{1 + |\lambda|} \right]^{1-\sigma} \left[\frac{B|t-s|^{\alpha+1/2}}{|\lambda|^{1/2}} \right]^{\sigma} |d\lambda| \qquad \forall \sigma \in [0, 1],$$

which easily leads to the result.

Parts (ii) and (iii) follow similarly by (2.32) and (2.29). □

We are ready to state the main result concerning problem (2.28).

PROPOSITION 2.8. *Under assumption* (2.29), *the evolution operator* $U(t, s) \in \mathscr{L}(H, D_{A(t)})$, *associated to problem* (2.28), *exists and possesses the following properties*:

(i) $(t, s) \to U(t, s) \in C(\Delta, \mathscr{L}(H)) \cap C_s(\bar{\Delta}, \mathscr{L}(H))$, *where* $\Delta := \{(t, s) \in [0, T]\colon s < t\}$, *and*

$$U(t, t) = 1, \quad U(t, \tau) U(\tau, s) = U(t, s) \quad \forall \tau \in [s, t];$$

(ii) $(t, s) \to A(t) U(t, s) \in C(\Delta, \mathscr{L}(H))$ *and*

$$A(t) U(t, s) = \frac{\partial}{\partial t} U(t, s), \quad \| A(t) U(t, s) \|_{\mathscr{L}(H)} \leqq M_1 (t-s)^{-1} \quad \forall 0 \leqq s \leqq t \leqq T;$$

(iii) *If* $s \in [0, t[$ *and* $x \in D_{A(s)}$, *then* $\partial/\partial s U(t, s)x = -U(t, s)A(s)x$ *in the following sense*:

$$h^{-1}[U(t, s+h) - U(t, s)]x \to -U(t, s)A(s)x \quad \text{in } H \quad \text{as } h \to 0_+,$$

$$h^{-1}[U(t, s+h) - U(t, s)]A(s+h)^{-1}A(s)x \to -U(t, s)A(s)x \quad \text{in } H \quad \text{as } h \to 0_-;$$

(iv) *If* γ, $\beta \in [0, 1]$, *then* $(t, s) \to [-A(t)]^{\gamma} U(t, s)[-A(s)]^{-\beta} \in C(\Delta, \mathscr{L}(H))$ *and*

$$\|[-A(t)]^{\gamma} U(t, s)[-A(s)]^{-\beta}\|_{\mathscr{L}(H)} \leqq M_{\gamma\beta}[(t-s)^{\beta-\gamma} + 1] \quad \forall 0 \leqq s \leqq t \leqq T;$$

(v) *If* $0 \leqq \gamma \leqq \beta \leqq 1$, *then* $(t, s) \to [-A(t)]^{\gamma} U(t, s)[-A(s)]^{-\beta} \in C(\bar{\Delta}, \mathscr{L}(H))$.

Proof. Parts (i)-(iii) are proved in Theorem 3.2 of [Ac] (recall that the domains $D_{A(t)}$ are dense in H here), with the exception of the assertion $(t, s) \to U(t, s) \in C_s(\bar{\Delta}, \mathscr{L}(H))$. In order to show this property, we first recall that by the density of domains and by Lemma 1.9(i) of [AT1] we have

$$\lim_{n\to\infty} \|x - n[n - A(\tau)]^{-1}x\|_H = 0 \quad \forall x \in H, \quad \forall \tau \in [0, T], \tag{2.35}$$

$$\begin{aligned} &\|A(s)[n - A(s)]^{-1} - A(\tau)[n - A(\tau)]^{-1}\|_{\mathscr{L}(H)} \leqq Bn^{1/2}|\tau - s|^{\alpha+1/2} \\ &\qquad\qquad \forall n \in \mathbb{N}^+, \quad \forall \tau, s \in [0, T]. \end{aligned} \tag{2.36}$$

Now let $(\tau, \tau) \in \partial\Delta$, $x \in H$; then we have (see [Ac, formula (2.6)]):

$$\begin{aligned} U(t, s)x - x &= [e^{(t-s)A(s)}x - x] + \int_s^t Z(r, s)x\, dr \\ &= [e^{(t-s)A(s)} - 1]\{[x - n[n - A(\tau)]^{-1}x] \\ &\quad + [n[n - A(\tau)]^{-1} - n[n - A(s)]^{-1}]x\} \\ &\quad + \int_0^{t-s} e^{\sigma A(s)}[nA(s)[n - A(s)]^{-1} - nA(\tau)[n - A(\tau)]^{-1}]x\, d\sigma \\ &\quad + \int_0^{t-s} e^{\sigma A(s)} nA(\tau)[n - A(\tau)]^{-1}x\, d\sigma + \int_s^t Z(r, s)x\, dr; \end{aligned}$$

hence by (2.36) and Lemma 2.2(i) of [Ac] we easily obtain

$$\begin{aligned} \|U(t, s)x - x\|_H \leqq c(M, \beta, \alpha)\{&(1 + n(t-s))\|x - n[n - A(\tau)]^{-1}x\|_H \\ &+ \|x\|_H[(1 + n(t-s))n^{1/2}|\tau - s|^{\alpha+1/2} + (t-s)^{\alpha}]\}. \end{aligned}$$

By (2.35) there exists $\nu_\varepsilon \in \mathbb{N}^*$ such that

$$\|x - \nu_\varepsilon[\nu_\varepsilon - A(\tau)]^{-1}x\|_H < \tfrac{1}{2}\varepsilon^2[c(M, \beta, \alpha)]^{-1};$$

choosing $n = \nu_\varepsilon$ and $\delta_\varepsilon > 0$ such that

$$c(M, \beta, \alpha)[(1 + \nu_\varepsilon\delta_\varepsilon)\tfrac{1}{2}\varepsilon^2[c(M, \beta, \alpha)]^{-1} + \|x\|_H(1 + \nu_\varepsilon\delta_\varepsilon)\nu_\varepsilon^{1/2}\delta_\varepsilon^{\alpha+1/2} + \|x\|_H\delta_\varepsilon^{\alpha}] < \varepsilon,$$

we immediately get

$$\|U(t, s)x - x\|_H \leqq \varepsilon \quad \text{if } |t - \tau| + |\tau - s| < \delta_\varepsilon.$$

Note that, in particular, the above proof shows that

$$(t, s) \to e^{(t-s)A(s)} \in C_s(\bar{\Delta}, \mathscr{L}(H)). \tag{2.37}$$

Let us prove (iv). We write

$$[-A(t)]^{\gamma} U(t, s)[-A(s)]^{-\beta} = -[-A(t)]^{\gamma-1}[A(t)U(t, s)][-A(s)]^{-\beta};$$

since each operator in the right-hand side is in $C(\Delta, \mathscr{L}(H))$, we get that the left-hand side also belongs to $C(\Delta, \mathscr{L}(H))$. In order to prove the estimate, we remark that if $x \in H$, then $t \to U(t, s)[-A(s)]^{-\beta}x$ is the classical solution [AT1, Def. 1.6] of the problem

$$(2.38) \qquad \begin{aligned} &u'(t)-A(t)u(t)=0, \qquad t \in]s, T], \\ &u(0)=[-A(s)]^{-\beta}x, \end{aligned}$$

and consequently [AT1, Thm. 6.3(i)] $t \to [A(t)U(t, s)][-A(s)]^{-\beta}x$ solves the integral equation

$$(2.39) \qquad v(t)-[Q_s v](t)=A(t)\, e^{(t-s)A(t)}[-A(s)]^{-\beta}x, \qquad t \in [s, T],$$

where the integral operator Q_s is defined [Ac, (2.1)-(2.2)] by

$$(2.40) \qquad [Q_s v](t) := \int_s^t A(t)^2\, e^{(t-\tau)A(t)}[A(t)^{-1}-A(\tau)^{-1}]v(\tau)\, d\tau, \qquad t \in [s, T].$$

Hence we can write

$$\begin{aligned} &[-A(t)]^{\gamma}U(t, s)[-A(s)]^{-\beta}x \\ &\quad = -[-A(t)]^{\gamma-1}[Q_s([A(t)U(t, s)][-A(s)]^{-\beta}x)](t) \\ &\qquad -[-A(t)]^{\gamma}\, e^{(t-s)A(t)}[-A(s)]^{-\beta}x \\ (2.41) \quad &\quad = -\int_s^t [-A(t)]^{\gamma+1}\, e^{(t-\tau)A(t)}[A(t)^{-1}-A(\tau)^{-1}]A(\tau)U(\tau, s)[-A(s)]^{-\beta}x\, d\tau \\ &\qquad -[[-A(t)]^{\gamma}\, e^{(t-s)A(t)}-[-A(s)]^{\gamma}\, e^{(t-s)A(s)}][-A(s)]^{-\beta}x \\ &\qquad -[-A(s)]^{\gamma-\beta}\, e^{(t-s)A(s)}x, \end{aligned}$$

and by Lemma 2.7 we readily obtain the result.

Finally, we prove (v). By (2.41) it is enough to show that if $(t, s) \to (\tau, \tau)$ in Δ and $x \in H$, then

$$\|([-A(s)]^{\gamma-\beta}\, e^{(t-s)A(s)}-[-A(\tau)]^{\gamma-\beta})x\|_H \to 0.$$

If $\beta=\gamma$ this follows by (2.37); otherwise we can write

$$\begin{aligned} &([-A(s)]^{\gamma-\beta}\, e^{(t-s)A(s)}-[-A(t)]^{\gamma-\beta})x \\ &\quad = \int_0^{t-s} [-A(s)]^{\gamma-\beta+1}\, e^{\xi A(s)}x\, d\xi + [[-A(s)]^{\gamma-\beta}-[-A(\tau)]^{\gamma-\beta}]x, \end{aligned}$$

which by Lemma 2.7 implies the result. □

Assume now that the adjoint operator $A(t)^*$ of $A(t)$ also satisfies (2.29), i.e.,

$$(2.42) \qquad \begin{aligned} &\text{(i)} \quad \|[\lambda - A(t)^*]^{-1}\|_{\mathscr{L}(H)} \leqq \frac{M}{1+|\lambda|} \quad \forall \lambda \in \overline{S_{\vartheta_0}}, \quad \forall t \in [0, T], \\ &\text{(ii)} \quad \|A(t)^*[\lambda - A(t)^*]^{-1}[[A(t)^*]^{-1}-[A(s)^*]^{-1}]\|_{\mathscr{L}(H)} \\ &\qquad \leqq B\frac{|t-s|^{\alpha+1/2}}{|\lambda|^{1/2}} \quad \forall \lambda \in S_{\vartheta_0}, \quad \forall t, s \in [0, T]. \end{aligned}$$

Then Proposition 2.8 also holds for $A(t)^*$.

The next result concerns the adjoint operator $U(t, s)^*$ of the evolution operator $U(t, s)$ relative to $A(t)$.

PROPOSITION 2.9. *Under assumptions* (2.29), (2.42) *let* $U(t, s)$ *be the evolution operator of problem* (2.28). *Then*:

(i) $U(t, s)^* \in \mathscr{L}(H, D_{A(s)^*})$, *for all* $s \in [0, t[$;

(ii) *For each* $\varphi \in H$, $s \to U(t, s)^*\varphi$ *solves the problem*

$$\begin{aligned} &\frac{d}{ds} U(t, s)^*\varphi = -A(s)^* U(t, s)^*\varphi, \qquad s \in [0, t[, \\ &U(t, t)^*\varphi = \varphi. \end{aligned} \tag{2.43}$$

Proof. First of all, we show that the solution of (2.43) exists. Fix $t_0 \in]0, T]$ and set

$$V(t_0; t, s) := \text{the evolution operator relative to } B(t) := A(t_0 - t)^*, \quad t \in [0, t_0]. \tag{2.44}$$

This means that

$$\begin{aligned} &\frac{d}{dt} V(t_0; t, s)\varphi = A(t_0 - t)^* V(t_0; t, s)\varphi, \qquad t \in]s, t_0], \\ &V(t_0; s, s)\varphi = \varphi. \end{aligned} \tag{2.45}$$

Set $W(t, s) := V(t; t - s, 0)$, $s \in [0, t]$. Then, applying Proposition 2.8 to problem (2.45), we get $W(t, s) \in \mathscr{L}(H, D_{A(s)^*})$ and

$$\begin{aligned} \frac{d}{ds} W(t, s)\varphi = -\left[\frac{d}{d\tau} V(t; \tau, 0)\varphi\right]_{\tau = t-s} &= -[A(t-\tau)^* V(t; \tau, 0)\varphi]_{\tau = t-s} \\ &= -A(s)^* W(t, s)\varphi, \qquad s \in [0, t[, \end{aligned}$$

$$W(t, t)\varphi = V(t; 0, 0)\varphi = \varphi,$$

i.e., $W(t, s)$ solves (2.43). The proof will be complete by showing that

$$V(t; t - s, 0) = W(t, s) = U(t, s)^*. \tag{2.46}$$

Indeed for $r \in]s, t[$ we have

$$\begin{aligned} &\frac{d}{dr} (W(t, r)\varphi \mid U(r, s)x)_H \\ &\qquad = -(A(r)^* W(t, r)\varphi \mid U(r, s)\varphi)_H + (W(t, r)\varphi \mid A(r) U(r, s)\varphi)_H = 0, \end{aligned}$$

so that $(W(t, r)\varphi \mid U(r, s)x)_H = \text{const.}$ for all $r \in [s, t]$. As $r \to t^-$ and $r \to s^+$ we get

$$(\varphi \mid U(r, s)x)_H = (W(t, r)\varphi \mid x)_H \quad \forall \varphi, x \in H,$$

i.e., $W(t, s) = U(t, s)^*$. □

COROLLARY 2.10. *Under assumptions* (2.29), (2.42) *we have for* $\gamma, \beta \in [0, 1]$:

$$\|[-A(s)^*]^\gamma U(t, s)^* [-A(t)^*]^{-\beta}\|_{\mathscr{L}(H)} \leqq M_{\gamma\beta}[(t-s)^{\beta-\gamma} + 1] \quad \forall 0 \leqq s < t \leqq T.$$

Proof. We have by (2.44) and (2.46)

$$[-A(s)^*]^\gamma U(t, s)^* [-A(t)^*]^{-\beta} = [[-B(\tau)]^\gamma V(t; \tau, 0)[-B(0)]^{-\beta}]_{\tau = t-s};$$

hence the result follows by applying Proposition 2.8 to problem (2.45). □

COROLLARY 2.11. *Under assumptions* (2.29), (2.42) *let* $\beta, \gamma \in [0, 1]$. *Then for* $0 \leqq s < t \leqq T$ *the closed linear operator*

$$[-A(t)]^{-\beta} U(t, s)[-A(s)]^\gamma$$

possesses an extension $\overline{[-A(t)]^{-\beta}U(t,s)[-A(s)]^{\gamma}} \in \mathscr{L}(H)$, *which satisfies*

$$\|\overline{[-A(t)]^{-\beta}U(t,s)[-A(s)]^{\gamma}}\|_{\mathscr{L}(H)} \leqq M_{\gamma\beta}[(t-s)^{\beta-\gamma}+1] \quad \forall 0 \leqq s < t \leqq T.$$

Proof. As

$$[[-A(s)]^{\gamma}]^* = [[-A(s)]^*]^{\gamma} \quad \forall \gamma \in [0,1],$$

if $x \in D_{[-A(s)]^{\gamma}}$ and $\varphi \in H$ we have

$$([-A(t)]^{-\beta}U(t,s)[-A(s)]^{\gamma}x\,|\,\varphi)_H = (x\,|\,[-A(s)^*]^{\gamma}U(t,s)^*[-A(t)^*]^{-\beta}\varphi)_H,$$

and by Corollary 2.10

$$|([-A(t)]^{-\beta}U(t,s)[-A(s)]^{\gamma}x\,|\,\varphi)_H| \leqq M_{\gamma\beta}[(t-s)^{\beta-\gamma}+1]\|x\|_H\,\|\varphi\|_H;$$

choosing $y := [-A(t)]^{-\beta}U(t,s)[-A(s)]^{\gamma}x$ and $\varphi := y/\|y\|_H$, by the density of $D_{[-A(s)]^{\gamma}}$ in H we get the result. □

The study of the abstract problem (2.28) (which concerns homogeneous boundary conditions) is complete. In the next section we will introduce nonhomogeneous boundary data in the abstract framework.

2.4. The Dirichlet and Neumann maps. Let us go back to problems (2.3), (2.4): we will examine the regularity properties of the Dirichlet and Neumann maps $G_0(t)$, $G_1(t)$ which are defined by (see (2.9)-(2.11)):

$$u := G_0(t)g \Leftrightarrow \begin{cases} \mathscr{A}(t,\cdot,D)u = 0 & \text{in } \Omega, \\ \mathscr{B}_0 u = g & \text{on } \partial\Omega, \end{cases} \tag{2.47}$$

$$u := G_1(t)g \Leftrightarrow \begin{cases} \mathscr{A}(t,\cdot,D)u = 0 & \text{in } \Omega, \\ \mathscr{B}_1(t,\cdot,D)u = g & \text{on } \partial\Omega. \end{cases} \tag{2.48}$$

PROPOSITION 2.12. *Let* $A_0(t)$, $A_1(t)$ *be defined by* (2.12), (2.13), *respectively. If* $r = 0, 1$ *the operator* $G_r(t)$ *is well defined from* $[L^2(\partial\Omega)]^N$ *into* $D_{[-A_r(t)]^{\vartheta}}$, *for each* $\vartheta \in]0, \alpha_r[$, *where* $\alpha_0 := \frac{1}{4}$ *and* $\alpha_1 := \frac{3}{4}$. *Moreover,*

$$t \to [-A_r(t)]^{\vartheta}G_r(t) \in L^{\infty}(0,T;\mathscr{L}([L^2(\partial\Omega)]^N,[L^2(\Omega)]^N)) \quad \forall \vartheta \in]0,\alpha_r[.$$

Proof. This result was pointed out in [La] assuming $\partial\Omega \in C^{\infty}$; here we give an independent proof.

Let us start with the case $r = 0$. Fix $t \in [0,T]$, let $g \in [W^{1/2,2}(\partial\Omega)]^N$, and consider the variational problem corresponding to (2.9), (2.10):

$$\begin{aligned} &\mathscr{A}(t,\cdot,D)u_0 = 0 && \text{in } \Omega, \\ &u_0 = g && \text{on } \partial\Omega, \end{aligned} \tag{2.49}$$

which means

$$\begin{aligned} &\sum_{sj=1}^{n}\int_{\Omega}[(A_{sj}(t,x)\cdot D_j u_0\,|\,D_s\varphi)_{\mathbb{C}^N} + (u_0\,|\,\varphi)_{\mathbb{C}^N}]\,dx = 0 \quad \forall \varphi \in [C_0^{\infty}(\Omega)]^N, \\ &u_0 - G \in [W_0^{1,2}(\Omega)]^N, \end{aligned} \tag{2.50}$$

where G is an element of $[W^{1,2}(\Omega)]^N$ whose trace on $\partial\Omega$ is g, and such that

$$\|g\|_{[W^{1/2,2}(\partial\Omega)]^N} \leqq c_0\|G\|_{[W^{1,2}(\Omega)]^N} \leqq c_1\|g\|_{[W^{1/2,2}(\partial\Omega)]^N}. \tag{2.51}$$

By Poincaré inequality and Lax-Milgram theorem, problem (2.50) is uniquely solvable: we denote its solution u_0 by $S_0(t)g$, and we easily get the estimate

$$\|S_0(t)g\|_{[W^{1,2}(\Omega)]^N} \leqq c(M, \nu, c_0, c_1)\|g\|_{[W^{1/2,2}(\partial\Omega)]^N} \quad \forall g \in [W^{1/2,2}(\partial\Omega)]^N, \tag{2.52}$$

where $M := \sum_{sj=1}^n \|A_{sj}\|_{C([0,T],[C^1(\bar{\Omega})]^{N^2})}$.

Note that if $g \in [W^{3/2,2}(\partial\Omega)]^N$, then by (2.1) and the classical results of [ADN] we have $S_0(t) \in [W^{2,2}(\Omega)]^N$ and

$$\|S_0(t)g\|_{[W^{2,2}(\Omega)]^N} \leqq c\|g\|_{[W^{3/2,2}(\partial\Omega)]^N} \quad \forall g \in [W^{3/2,2}(\partial\Omega)]^N. \tag{2.53}$$

We want now to estimate $S_0(t)$ in a lower norm. For $g \in [W^{1/2,2}(\partial\Omega)]^N$ set $u_0 := S_0(t)g$ and let ψ be the variational solution of

$$\begin{aligned} &\sum_{sj=1}^n \int_\Omega [(\overline{{}^tA_{sj}(t,x)} \cdot D_s\psi | D_j\varphi)_{\mathbb{C}^N} + (\psi|\varphi)_{\mathbb{C}^N}]\, dx = \int_\Omega (u_0|\varphi)_{\mathbb{C}^N}\, dx \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \forall \varphi \in [C_0^\infty(\Omega)]^N, \\ &\psi = 0 \quad \text{on } \partial\Omega; \end{aligned} \tag{2.54}$$

as $u_0 \in [W^{1,2}(\Omega)]^N \subset [L^2(\Omega)]^N$, we have $\psi \in [W^{2,2}(\Omega)]^N \cap [W_0^{1,2}(\Omega)]^N$, and

$$-\sum_{sj=1}^n D_j(\overline{{}^tA_{sj}(t,\cdot)} \cdot D_s\psi) + \psi = u_0 \quad \text{a.e. in } \Omega; \tag{2.55}$$

in addition

$$\|\psi\|_{[W^{3/2,2}(\partial\Omega)]^N} \leqq c\|\psi\|_{[W^{2,2}(\Omega)]^N} \leqq c\|u_0\|_{[L^2(\Omega)]^N}. \tag{2.56}$$

By density we may choose $\varphi = \psi$ in (2.50); an integration by parts yields

$$\int_\Omega \left(u_0 \middle| \psi - \sum_{sj=1}^n D_j[\overline{{}^tA_{sj}(t,x)} \cdot D_s\psi]\right)_{\mathbb{C}^N} dx = -\int_{\partial\Omega} \left(u_0 \middle| \sum_{sj=1}^n \overline{{}^tA_{sj}(t,x)} \cdot D_s\psi\nu_j\right)_{\mathbb{C}^N} d\sigma,$$

and by (2.55) (since $u_0 = g$ on $\partial\Omega$)

$$\int_\Omega |u_0|^2\, dx = -\int_{\partial\Omega} \left(g \middle| \sum_{sj=1}^n \overline{{}^tA_{sj}(t,x)} \cdot D_s\psi\nu_j\right)_{\mathbb{C}^N} d\sigma. \tag{2.57}$$

Now, as $\partial\Omega \in C^2$, the function $d(x)$, i.e., the distance of $x \in \Omega$ from $\partial\Omega$, is of class C^2 in a neighbourhood of $\partial\Omega$ and $Dd(x) = -\nu(x)$ on $\partial\Omega$ (see [GT, Appendix]); moreover we can clearly modify $d(x)$ inside Ω in order to get $d \in C^2(\bar{\Omega})$. Hence by (2.57) and (2.56) it follows that

$$\begin{aligned} \|u_0\|^2_{[L^2(\Omega)]^N} &= |\langle g, \overline{{}^tA_{sj}(t,x)} \cdot D_s\psi\nu_j\rangle_{[W^{-1/2,2}(\partial\Omega)]^N,[W^{1/2,2}(\partial\Omega)]^N}| \\ &\leqq \|g\|_{[W^{-1/2,2}(\partial\Omega)]^N} \|\overline{{}^tA_{sj}} \cdot D_s\psi\nu_j\|_{[W^{1/2,2}(\partial\Omega)]^N} \\ &\leqq c\|g\|_{[W^{-1/2,2}(\partial\Omega)]^N} \|\overline{{}^tA_{sj}} \cdot D_s\psi D_jd\|_{[W^{1,2}(\Omega)]^N} \\ &\leqq c(M,\Omega)\|g\|_{[W^{-1/2,2}(\partial\Omega)]^N} \|\psi\|_{[W^{2,2}(\Omega)]^N} \\ &\leqq c\|g\|_{[W^{-1/2,2}(\partial\Omega)]^N} \|u_0\|_{[L^2(\Omega)]^N}, \end{aligned}$$

that is,

$$\|S_0(t)g\|_{[L^2(\Omega)]^N} \leqq c\|g\|_{[W^{-1/2,2}(\partial\Omega)]^N} \quad \forall g \in [W^{1/2,2}(\partial\Omega)]^N. \tag{2.58}$$

We now interpolate between (2.58) and (2.52), using Theorems 7.7 and 9.4 of [LM]: the proof of such theorems requires $\partial\Omega \in C^\infty$, but it can be readily adapted to our case. The result of interpolation is the estimate

$$\|S_0(t)g\|_{[W^{1/2,2}(\partial\Omega)]^N} \leqq c\|g\|_{[L^2(\partial\Omega)]^N} \quad \forall g \in [W^{1/2,2}(\partial\Omega)]^N, \tag{2.59}$$

which shows that the linear operator $S_0(t)$ may be boundedly extended to an operator $G_0(t) \in \mathscr{L}([L^2(\partial\Omega)]^N, [W^{1/2,2}(\Omega)]^N)$ defined by (compare with (2.47))

$$(2.60)\qquad \begin{aligned} &G_0(t): [L^2(\partial\Omega)]^N \to [W^{1/2,2}(\Omega)]^N,\\ &G_0(t)g := S_0(t)g \quad \forall g \in [W^{1/2,2}(\partial\Omega)]^N. \end{aligned}$$

We now turn to the case $r=1$. Fix $t \in [0, T]$, let $g \in [W^{1/2,2}(\partial\Omega)]^N$, and consider the problem corresponding to (2.9), (2.11):

$$(2.61)\qquad \begin{aligned} &\mathscr{A}(t, x, D)u_1 = 0 \quad \text{in } \Omega,\\ &\mathscr{B}_1(t, x, D)u_1 = g \quad \text{on } \partial\Omega, \end{aligned}$$

which, by [ADN], has a unique solution $u_1 := S_1(t)g \in [W^{2,2}(\Omega)]^N$, such that

$$(2.62)\qquad \|S_1(t)g\|_{[W^{2,2}(\Omega)]^N} \leqq c\|g\|_{[W^{1/2,2}(\partial\Omega)]^N} \quad \forall g \in [W^{1/2,2}(\partial\Omega)]^N.$$

Multiply by u_1 in $[L^2(\Omega)]^N$ in (2.61) and integrate by parts: the result is

$$\begin{aligned} \nu \int_\Omega |Du_1|^2\, dx + \int_\Omega |u_1|^2\, dx &\leqq \int_\Omega [(A_{sj}(t, x) \cdot D_j u_1 | D_s u_1)_{\mathbb{C}^N} + (u_1 | u_1)_{\mathbb{C}^N}]\, dx\\ &= \int_{\partial\Omega} (g | u_1)_{\mathbb{C}^N}\, d\sigma = |\langle g, u_1\rangle_{[W^{-1/2,2}(\partial\Omega)]^N, [W^{1/2,2}(\partial\Omega)]^N}|\\ &\leqq c\|g\|_{[W^{-1/2,2}(\partial\Omega)]^N} \|u_1\|_{[W^{1,2}(\Omega)]^N}, \end{aligned}$$

which implies

$$(2.63)\qquad \|S_1(t)g\|_{[W^{1,2}(\Omega)]^N} \leqq c\|g\|_{[W^{-1/2,2}(\partial\Omega)]^N} \quad \forall g \in [W^{1/2,2}(\partial\Omega)]^N.$$

Interpolation between (2.63) and (2.62) (see the remark after (2.58)) yields

$$(2.64)\qquad \|S_1(t)g\|_{[W^{3/2,2}(\Omega)]^N} \leqq c\|g\|_{[L^2(\partial\Omega)]^N} \quad \forall g \in [W^{1/2,2}(\partial\Omega)]^N,$$

i.e., S_1 may be boundedly extended to an operator $G_1(t) \in \mathscr{L}([L^2(\partial\Omega)]^N, [W^{3/2,2}(\Omega)]^N)$ defined by (compare with (2.48)):

$$(2.65)\qquad \begin{aligned} &G_1(t): [L^2(\partial\Omega)]^N \to [W^{3/2,2}(\Omega)]^N,\\ &G_1(t)g := S_1(t)g \quad \forall g \in [W^{1/2,2}(\partial\Omega)]^N. \end{aligned}$$

Now we recall that by Theorem 3.1 of [L1] we have for $r=0, 1$ (see (2.34)):

$$(2.66)\qquad D_{[-A_r(t)]^\vartheta} = D_{A_r(t)}(\vartheta, 2) \quad \forall \vartheta \in]0, 1[,$$

$$(2.67)\qquad D_{[-A_r(t)^*]^\vartheta} = D_{A_r(t)^*}(\vartheta, 2) \quad \forall \vartheta \in]0, 1[.$$

On the other hand, the real interpolation spaces $D_{A_r(t)}(\vartheta, 2)$ and $D_{A_r(t)^*}(\vartheta, 2)$ can be characterized in the following way:

$$(2.68)\qquad \begin{aligned} &D_{A_0(t)}(\vartheta, 2) = D_{A_0(t)^*}(\vartheta, 2)\\ &= \begin{cases} [W^{2\vartheta,2}(\Omega)]^N & \text{if } \vartheta \in]0, \tfrac14[,\\ \left\{u \in [W^{1/2,2}(\Omega)]^N : \displaystyle\int_\Omega d(x)^{-1}|u(x)|^2\, dx < \infty\right\} & \text{if } \vartheta = \tfrac14,\\ [W_0^{2\vartheta,2}(\Omega)]^N & \text{if } \vartheta \in]\tfrac14, 1[\setminus\{\tfrac12\},\\ [B_0^{1,2}(\Omega)]^N & \text{if } \vartheta = \tfrac12; \end{cases} \end{aligned}$$

(2.69)

$$D_{A_1(t)}(\vartheta, 2) = \begin{cases} [W^{2\vartheta,2}(\Omega)]^N & \text{if } \vartheta \in \left]0, \tfrac{3}{4}\right[\setminus\{\tfrac{1}{2}\}, \\ [B^{1,2}(\Omega)]^N & \text{if } \vartheta = \tfrac{1}{2}, \\ \left\{u \in [W^{3/2,2}(\Omega)]^N : \int_\Omega d(x)^{-1} \left| \sum_{sj=1}^n A_{sj}(t, x) \cdot D_j u(x) D_s d(x) \right|^2 dx < \infty \right\} & \\ & \text{if } \vartheta = \tfrac{3}{4}, \\ \{u \in [W^{2\vartheta,2}(\Omega)]^N : \mathscr{B}_1(t, \cdot, D)u = 0 \text{ on } \partial\Omega\} & \text{if } \vartheta \in \left]\tfrac{3}{4}, 1\right[; \end{cases}$$

(2.70)

$$D_{A_1(t)^*}(\vartheta, 2) = \begin{cases} [W^{2\vartheta,2}(\Omega)]^N & \text{if } \vartheta \in \left]0, \tfrac{3}{4}\right[\setminus\{\tfrac{1}{2}\}, \\ [B^{1,2}(\Omega)]^N & \text{if } \vartheta = \tfrac{1}{2}, \\ \left\{u \in [W^{3/2,2}(\Omega)]^N : \int_\Omega d(x)^{-1} \left| \sum_{sj=1}^n \overline{{}^t A_{sj}(t, x)} \cdot D_s u(x) D_j d(x) \right|^2 dx < \infty \right\} & \\ & \text{if } \vartheta = \tfrac{3}{4}, \\ \{u \in [W^{2\vartheta,2}(\Omega)]^N : \overline{\mathscr{B}_1(t, \cdot, D)}u = 0 \text{ on } \partial\Omega\} & \text{if } \vartheta \in \left]\tfrac{3}{4}, 1\right[. \end{cases}$$

Here $[B^{1,2}(\Omega)]^N$ is the Besov–Nikol'skij space. A proof of the results (2.68)–(2.70) is in Theorem 7.5 of [Gr] (see also [Tr, Thm. 4.3.3]) in the case $N = 1$ and $\partial\Omega \in C^\infty$, but the same argument works in our situation.

The above results (namely, (2.66)–(2.69) together with (2.60), (2.65)) show that

$$(2.71) \qquad \begin{aligned} G_0(t) &\in \mathscr{L}([L^2(\partial\Omega)]^N, D_{[-A_0(t)]^\vartheta}) \quad \forall \vartheta \in \left]0, \tfrac{1}{4}\right[, \\ G_1(t) &\in \mathscr{L}([L^2(\partial\Omega)]^N, D_{[-A_1(t)]^\vartheta}) \quad \forall \vartheta \in \left]0, \tfrac{3}{4}\right[; \end{aligned}$$

the norms of $G_0(t)$, $G_1(t)$ are bounded independently of $t \in [0, T]$ in view of (2.59), (2.64).

On the other hand, if we set

$$F_n(t) := [-A_r(t)]^\vartheta \exp\left(\frac{1}{n} A_r(t)\right) G_r(t),$$

we have $F_n \in C([0, T], \mathscr{L}([L^2(\partial\Omega)]^N, [L^2(\Omega)]^N))$ by Lemma 2.7(ii); in addition, choosing $\rho \in \left]0, \alpha_r - \vartheta\right[$ (with $\alpha_0 = \frac{1}{4}$, $\alpha_1 = \frac{3}{4}$) we see that

$$\begin{aligned} &\|F_n(t) - [-A_r(t)]^\vartheta G_r(t)\|_{\mathscr{L}([L^2(\partial\Omega)]^N, [L^2(\Omega)]^N)} \\ &\quad \leqq \left\| \int_0^{1/n} [-A_r(t)]^{1-\rho} \exp(\xi A_r(t))\, d\xi \right\|_{\mathscr{L}([L^2(\Omega)])^N} \\ &\quad\quad \cdot \|[-A_r(t)]^{\vartheta+\rho} G_r(t)\|_{\mathscr{L}([L^2(\partial\Omega)]^N, [L^2(\Omega)]^N)} \leqq \frac{c}{n^\rho}, \end{aligned}$$

so that $F_n(t) \to [-A_r(t)]^\vartheta G_r(t)$ in $\mathscr{L}([L^2(\partial\Omega)]^N, [L^2(\Omega)]^N)$ as $n \to \infty$, uniformly with respect to t; thus $[-A_r(\cdot)]^\vartheta G_r(\cdot)$ is a continuous function. This shows that

$$(2.72) \qquad [-A_0(\cdot)]^\vartheta G_0(\cdot) \in C([0, T], \mathscr{L}([L^2(\partial\Omega)]^N, [L^2(\Omega)]^N)) \quad \forall \vartheta \in \left]0, \tfrac{1}{4}\right[,$$

$$(2.73) \qquad [-A_1(\cdot)]^\vartheta G_1(\cdot) \in C([0, T], \mathscr{L}([L^2(\partial\Omega)]^N, [L^2(\Omega)]^N)) \quad \forall \vartheta \in \left]0, \tfrac{3}{4}\right[,$$

and, in particular, the proof is complete. □

We are ready to write a representation formula for (regular) solutions of problems (2.3), (2.4), which depends just on low-order norms, and hence can be extended to the case of less smooth data. This construction will be performed in the next section.

2.5. The representation formula. Consider again problems (2.3), (2.4) with smooth data: our representation formula for their solution is provided by the following proposition.

PROPOSITION 2.13. *Assume* (2.1), (2.2), *let* $y_0 \in [W^{2-r,2}(\Omega)]^N$ *and* $u \in C^{\alpha}([0, T], [W^{2-r,2}(\Omega)]^N) \cap C^{\alpha+1-r/2}([0, T], [L^2(\Omega)]^N)$ $(r=0$ *or* $r=1)$, *and suppose moreover that the compatibility conditions* (2.7) *or* (2.5) *hold. Then the solution of problem* (2.3), *or* (2.4), *is given by*

$$y(t, \cdot) = U_r(t, 0)y_0 + \int_0^t [[-A_r(s)^*]^{1-\vartheta} U_r(t, s)^*]^*[-A_r(s)]^{\vartheta} G_r(s)u(s, \cdot)\, ds, \tag{2.74}$$

$$t \in [0, T] \quad (\vartheta \in]0, \alpha_r[).$$

Proof. By Proposition 2.2 or 2.1 we know that problems (2.3) or (2.4) have a unique solution

$$y \in C^0([0, T], [W^{2,2}(\Omega)]^N) \cap C^1([0, T], [L^2(\Omega)]^N).$$

Consider the function $y - G_r(t)u$: by (2.47), (2.48), (2.53), and (2.62) we get (see (2.9))

$$\begin{aligned} &y(t, \cdot) - G_r(t)u(t, \cdot) \in D_{A_r(t)}, \\ &A_r(t)[y(t, \cdot) - G_r(t)u(t, \cdot)] = \mathscr{A}(t, \cdot, D)y(t, \cdot). \end{aligned} \tag{2.75}$$

Next, denoting by $U_r(t, s)$ the evolution operator associated to $\{A_r(t)\}_{t\in[0,T]}$, we have by Corollary 2.10

$$\|[-A_r(s)^*]^{\gamma} U_r(t, s)^*\|_{\mathscr{L}([L^2(\Omega)]^N)} \leqq M_{\gamma}(t-s)^{-\gamma} \quad \forall \gamma \in]0, 1[, \quad \forall 0 \leqq s < t \leqq T,$$

and consequently

$$\|[[-A_r(s)^*]^{\gamma} U_r(t, s)^*]^*\|_{\mathscr{L}([L^2(\Omega)]^N)} \leqq M_{\gamma}(t-s)^{-\gamma} \quad \forall \gamma \in]0, 1[, \quad \forall 0 \leqq s < t \leqq T. \tag{2.76}$$

Now fix $t \in [0, T]$, let $z \in D_{A_r(t)^*}$, and define

$$h(s) := (y(s, \cdot) \,|\, U_r(t, s)^* z)_{[L^2(\Omega)]^N}, \qquad s \in [0, t[. \tag{2.77}$$

By Proposition 2.9 and (2.75) we may compute

$$\begin{aligned} h'(s) &= (D_s y(s, \cdot) \,|\, U_r(t, s)^* z) - (y(s, \cdot) - G_r(s)u(s, \cdot) \,|\, A_r(s)^* U_r(t, s)^* z) \\ &\quad - (G_r(s)u(s, \cdot) \,|\, A_r(s)^* U_r(t, s)^* z) \\ &= (A(s, \cdot, D)y(s, \cdot) \,|\, U_r(t, s)^* z) \\ &\quad - (A_r(s)[y(s, \cdot) - G_r(s)u(s, \cdot)] \,|\, U_r(t, s)^* z) - (G_r(s)u(s, \cdot) \,|\, A_r(s)^* U_r(t, s)^* z) \\ &= -(G_r(s)u(s, \cdot) \,|\, A_r(s)^* U_r(t, s)^* z). \end{aligned}$$

On the other hand, by (2.72), (2.73) we may write for $\vartheta \in]0, \alpha_r[$ (with $\alpha_0 = \frac{1}{4}$, $\alpha_1 = \frac{3}{4}$)

$$\begin{aligned} h'(s) &= ([-A_r(s)]^{\vartheta} G_r(s)u(s, \cdot) \,|\, [-A_r(s)^*]^{1-\vartheta} U_r(t, s)^* z) \\ &= ([[-A_r(s)^*]^{1-\vartheta} U_r(t, s)^*]^*[-A_r(s)]^{\vartheta} G_r(s)u(s, \cdot) \,|\, z), \qquad s \in]0, t[, \end{aligned}$$

and $h' \in L^2(0, t)$. Hence by integrating in $]0, t[$ we get

$$\begin{aligned} &(y(t, \cdot) \,|\, z)_{[L^2(\Omega)]^N} - (U_r(t, 0)y_0(\cdot) \,|\, z)_{[L^2(\Omega)]^N} \\ &\quad = \left(\int_0^t [[-A_r(s)^*]^{1-\vartheta} U_r(t, s)^*]^*[-A_r(s)]^{\vartheta} G_r(s)u(s, \cdot)\, ds \,\Big|\, z \right)_{[L^2(\Omega)]^N}, \end{aligned}$$

and finally by density we deduce (2.74). □

Remark 2.14. (i) The representation formula (2.74) makes sense for any $y_0 \in [L^2(\Omega)]^N$ and $u \in [L^2(]0, T[\times \partial\Omega)]^N$, since by Proposition 2.2(i), (2.76), and (2.72), (2.73) we have

$$(2.78) \qquad \|y(t,\cdot)\|_{[L^2(\Omega)]^N} \leqq c\left\{\|y_0\|_{[L^2(\Omega)]^N} + \int_0^t (t-s)^{\vartheta-1}\|u(s,\cdot)\|_{[L^2(\partial\Omega)]^N}\,ds\right\},$$

which implies

$$(2.79) \qquad \|y\|^2_{[L^2(]0,T[\times\Omega)]^N} \leqq c\left\{T\|y_0\|^2_{[L^2(\Omega)]^N} + \frac{T^{2\vartheta}}{\vartheta^2}\|u\|^2_{[L^2(]0,T[\times\partial\Omega)]^N}\right\}.$$

(ii) We may rewrite formula (2.74) in a shorter, although improper, form, namely

$$(2.80) \qquad y(t) = U_r(t,0)y_0 - \int_0^t U_r(t,s)A_r(s)G_r(s)u(s)\,ds, \qquad t \in [0, T],$$

where the integrand is to be understood as in (2.74). In the foregoing section we will study an abstract version of (2.80) (see (3.1) below) within the context of control theory.

3. The L-Q-R problem over finite-time horizon.

3.1. State problem and cost functional. This section concerns the classical linear-quadratic regulator (L-Q-R) problem, over finite horizon $[0, T]$, for a class of abstract evolution equations corresponding to nonautonomous parabolic systems with boundary control. As we have shown in § 2, an equation of the form

$$(3.1) \qquad y(t) = U(t,0)y_0 - \int_0^t U(t,s)A(s)G(s)u(s)\,ds, \qquad t \in [0, T],$$

is appropriate to cover a wide class of concrete problems. In § 2 we derived in two concrete examples equation (2.80), which is an equation of the form (3.1), under hypotheses (2.1) and (2.2) (or, from the abstract point of view, (2.29) and (2.42)). Such assumptions will not be directly needed in most part of the next results on control problems; thus, in order to identify those properties which are really relevant from the control point of view, and to point out both analogies and novelties of the nonautonomous case with respect to the autonomous one (treated, e.g., in [B1], [La], [LT1], [LT2], [F1], [F2]), we will hereafter impose explicitly only assumptions (3.2)-(3.5) listed below.

Let H, U two separable (for simplicity) complex Hilbert spaces. In (3.1) we shall take $y_0 \in H$ and $u \in L^2(0, T; U)$. Here is our list of hypotheses:

(3.2) $\{A(t)\}_{t\in[0,T]}$ is a family of closed linear operators in H with (dense) domains $D_{A(t)}$, such that $A(t)$ generates an analytic semigroup in H and $0 \in \rho(A(t))$.

(3.3) $\{U(t,s)\}_{0\leqq s\leqq t\leqq T}$ is the (strongly continuous) evolution operator in H associated to $\{A(t)\}_{t\in[0,T]}$; in particular,

$$\|U(t,s)\|_{\mathscr{L}(H)} \leqq M_0, \text{ for all } (t,s) \in \bar{\Delta}, \text{ where } \Delta := \{(t,s) \in [0,T]^2 \colon s < t\}.$$

(3.4) The operator-valued function $(t,s) \to U(t,s)^*$ belongs to $C_s([0,T], \mathscr{L}(H))$; moreover, for each $\eta \in [0,1]$ and $(t,s) \in \Delta$, $U(t,s)^* \in \mathscr{L}(H, D_{[-A(s)^*]^\eta})$, the map $(t,s) \to [-A(s)^*]^\eta U(t,s)^*$ is strongly measurable and satisfies

$$\|[-A(s)^*]^\eta U(t,s)^*[-A(t)^*]^{-\mu}\|_{\mathscr{L}(H)} \leqq M_{\eta\mu}[(t-s)^{\mu-\eta}+1]$$

$$\forall (t,s) \in \Delta, \quad \forall \eta, \mu \in [0,1].$$

(3.5) $\{G(t)\}_{t\in[0,T]}$ is a family of operators in $\mathscr{L}(U, H)$ such that there exists $\alpha \in]0, 1]$ with the following properties: $G(t) \in \mathscr{L}(U, D_{[-A(t)^*]^\alpha})$ for each $t \in [0, T]$ and the map $t \to [-A(t)]^\alpha G(t)$ belongs to $L^\infty(0, T; \mathscr{L}(U, H))$.

Remark 3.1. (i) The above assumptions can be relaxed in various directions, with minor consequences on the subsequent results. So, for instance, (3.4) is needed only for $\eta = 1-\alpha$: in this case we would obtain slightly weaker regularity results for the Riccati equation. However, the applications discussed in § 2 do not motivate a further level of generality.

(ii) Condition (3.4) with $\mu > 0$ is not necessary to give sense to equation (3.1): just a much weaker version of it is needed in order to define the L-Q-R problem (3.10) below. However it will be used in (more or less) this generality as a technical tool in the study of the Riccati equation. Except for (3.4) with $\mu > 0$, all the other assumptions are the natural (and minimal, in a sense) ones in order to give a meaning to equation (3.1) and problem (3.10).

(iii) In the examples of § 2, we have under assumptions (2.1), (2.2):

$H = [L^2(\Omega)]^N$, $U = [L^2(\partial\Omega)]^N$;

$\{A(t)\}$, defined by (2.12) or (2.13), fulfills (3.2) by Proposition 2.4;

The existence of $\{U(t, s)\}$ with the properties (3.3) is guaranteed by Proposition 2.8(i);

Conditions (3.4) for $\{U(t, s)^*\}$ are proved in Corollary 2.10;

$\{G(t)\}$, defined by (2.47) or (2.48), satisfies (3.5) in view of Proposition 2.12.

As at the end of § 2, we agree that the formal notation $U(t, s)A(s)G(s)$ stands for $[[-A(s)^*]^{1-\alpha}U(t, s)^*]^*[-A(s)]^\alpha G(s)$, which is well defined as an element of $\mathscr{L}(U, H)$ for each $(t, s) \in \Delta$, by (3.4)-(3.5). More precisely we have Lemma 3.2.

LEMMA 3.2. *The operator-valued function*

$$U(t, s)A(s)G(s) := [[-A(s)^*]^{1-\alpha}U(t, s)^*]^*[-A(s)]^\alpha G(s), \qquad 0 \leqq s < t \leqq T, \tag{3.6}$$

is strongly measurable with respect to $s \in [0, t[$ *for each fixed* $t \in]0, T]$, *and strongly continuous with respect to* $t \in]s, T]$ *for each fixed* $s \in [0, T[$. *Moreover,*

$$\|U(t, s)A(s)G(s)\|_{\mathscr{L}(U,H)} \leqq c(t-s)^{\alpha-1} \quad \forall (t, s) \in \Delta. \tag{3.7}$$

Proof. The first assertion follows directly by (3.4), (3.5). Concerning the second one, let $s \in [0, T[$ and $t_0 \in]s, T]$ be fixed: it is easy to verify that if $t \in](s+t_0)/2, T]$ we have

$$U(t, s)A(s)G(s) = U(t, (s+t_0)/2)[U((s+t_0)/2, s)A(s)G(s)];$$

but $t \to U(t, (s+t_0)/2)$ is strongly continuous, whereas the bounded operator $U((s+t_0)/2, s)A(s)G(s)$ does not depend on t, so that $U(t, s)A(s)G(s)$ is strongly continuous at $t = t_0$. Finally, the estimate (3.7) follows by (3.4) and (3.5). □

The next lemma gives a precise interpretation of the function (3.1).

LEMMA 3.3. (i) *If* $u \in L^2(0, T; U)$, *then* (3.1) *defines a function* $y \in L^2(0, T; H)$ *and*

$$\|y\|_{L^2(0,T;H)} \leqq c\{\|y_0\|_H + \|u\|_{L^2(0,T;U)}\}. \tag{3.8}$$

(ii) *If* $u \in L^p(0, T; U)$ *for some* $p > 1/\alpha$, *then* $y \in C([0, T], H)$ *and*

$$\|y\|_{C([0,T],H)} \leqq c\{\|y_0\|_H + \|u\|_{L^p(0,T;U)}\}. \tag{3.9}$$

Proof. Part (i) is an easy consequence of (3.3), (3.7) and Young's inequality.

(ii) If $p>1/\alpha$, by (3.7) we have for $0\leqq r<t\leqq T$

$$\left\|\int_r^t U(t,s)A(s)G(s)u(s)\,ds\right\|_H \leqq \left[\int_r^t c(t-s)^{-(1-\alpha)p/(p-1)}\,ds\right]^{(p-1)/p}\|u\|_{L^p(r,T;U)}$$
$$\leqq c\frac{p-1}{\alpha p-1}(t-r)^{\alpha-1/p}\|u\|_{L^p(0,T;U)},$$

which, together with (3.30), implies in particular (3.9). Moreover, if $t_0\in\,]0,T]$ and $\varepsilon>0$, we have for small $\delta>0$

$$\left\|\int_{t_0-\delta}^t U(t,s)A(s)G(s)u(s)\,ds\right\|_H \leqq \varepsilon \quad \forall t\in[t_0-\delta, t_0+\delta].$$

Therefore by (3.3) we get for $|t-t_0|\leqq\delta$:

$$\begin{aligned}
&\|y(t)-y(t_0)\|_H\\
&\quad\leqq \|U(t,0)y_0-U(t_0,0)y_0\|_H\\
&\qquad+\left\|[U(t,t_0-\delta)-U(t_0,t_0-\delta)]\int_0^{t_0-\delta}U(t_0-\delta,s)A(s)G(s)u(s)\,ds\right\|_H\\
&\qquad+\left\|\int_{t_0-\delta}^t U(t,s)A(s)G(s)u(s)\,ds\right\|_H+\left\|\int_{t_0-\delta}^{t_0} U(t_0,s)A(s)G(s)u(s)\,ds\right\|_H\\
&\quad\leqq \|U(t,0)y_0-U(t_0,0)y_0\|_H+(2M_0+2)\varepsilon,
\end{aligned}$$

and the result follows by the strong continuity of $t\to U(t,0)$. The case $t_0=0$ is even simpler. □

We can now define the optimal control problem which is the object of our study in this section. We shall consider the following L-Q-R problem:

(3.10) Minimize

$$J(u):=\int_0^T[(M(t)y(t)|y(t))_H+(N(t)u(t)|u(t))_U]\,dt+(P_Ty(T)|y(T))_H$$

over all controls $u\in L^2(0,T;U)$ subject to the state equation (3.1).

Here we assume:

(3.11) $M(t)\in\Sigma^+(H)$, for all $t\in[0,T]$ and $M\in L^\infty(0,T;\mathscr{L}(H))$;

(3.12) $N(t)\in\Sigma^+(U)$ with $N(t)\geqq\nu>0$, for all $t\in[0,T]$ and $N\in C_s([0,T],\mathscr{L}(U))$;

(3.13) $P_T\in\Sigma^+(H)$, and there exists $\beta\in\,](\frac{1}{2}-\alpha),\frac{1}{2}]\cap[0,\frac{1}{2}]$ such that $P_T\in\mathscr{L}(H,D_{[-A(T)^*]^{2\beta}})$.

Remark 3.4. Due to Lemma 3.3 of [F1], assumption (3.13) implies that the operator $[-A(T)^*]^{\beta-\varepsilon}P_T[-A(T)]^{\beta-\varepsilon}(\varepsilon\in\,]0,\beta])$ can be extended to an operator $L_\varepsilon\in\mathscr{L}(H)$.

Note that y, given by (3.1), is not continuous in general, but only in $L^2(0,T;H)$: hence the term $(P_Ty(T)|y(T))_H$ is not well defined a priori for all controls $u\in L^2(0,T;U)$, but only for controls in a dense subspace of $L^2(0,T;U)$, by Lemma 3.3(ii). However, the regularity property (3.13), along with (3.4), yields Lemma 3.5.

LEMMA 3.5. *The mapping $u\to(P_Ty(T)|y(T))_H$, defined (for instance) from $C([0,T],U)$ into $\mathbb{R}$, is locally uniformly continuous with respect to the topology of $L^2(0,T;U)$, and hence it can be extended to $L^2(0,T;U)$.*

Proof. Let L_ε be the bounded extension to H of the operator $[-A(T)^*]^{\beta-\varepsilon}P_T[-A(T)]^{\beta-\varepsilon}$ (see Remark 3.4). If $u\in C([0,T],U)$, choosing $\varepsilon\in\,]0,\beta-(\frac{1}{2}-\alpha)[$ we have by (3.1), (3.3), (3.4), and (3.5)

$$\begin{aligned}
&(P_Ty(T)\,|\,y(T))_H\\
&\quad=\|L_\varepsilon^{1/2}[-A(T)]^{-\beta+\varepsilon}y(T)\|_H^2\\
&\quad\leqq\|L_\varepsilon^{1/2}\|^2_{\mathscr{L}(H)}\Bigg\{\|[-A(T)]^{-\beta+\varepsilon}U(T,0)y_0\|_H\\
&\qquad\qquad+\int_0^T\|[[-A(s)^*]^{1-\alpha}U(T,s)^*[-A(T)^*]^{-\beta+\varepsilon}]^*[-A(s)]^\alpha G(s)u(s)\|_H\,ds\Bigg\}^2\\
&\quad\leqq c\left\{\|y_0\|_H^2+\left[\int_0^T[1+(T-s)^{\beta+\alpha-\varepsilon-1}]\|u(s)\|_U\,ds\right]^2\right\}\\
&\quad\leqq c\{\|y_0\|_H^2+(T+T^{2\beta+2\alpha-2\varepsilon-1})\|u\|^2_{L^2(0,T;U)}\}.
\end{aligned}$$

Hence if u_1, $u_2\in C([0,T],U)$ and y_1, y_2 are the corresponding functions (3.1) with initial state y_0 we have

$$\begin{aligned}
&|(P_Ty_1(T)\,|\,y_1(T))_H-(P_Ty_2(T)\,|\,y_2(T))_H|\\
&\quad\leqq[\|L_\varepsilon^{1/2}[-A(T)]^{-\beta+\varepsilon}y_1(T)\|_H+\|L_\varepsilon^{1/2}[-A(T)]^{-\beta+\varepsilon}y_2(T)\|_H]\\
&\qquad\cdot\|L_\varepsilon^{1/2}[-A(T)]^{-\beta+\varepsilon}[y_1(T)-y_2(T)]\|_H\\
&\quad\leqq c\{\|y_0\|_H+\|u_1\|_{L^2(0,T;U)}+\|u_2\|_{L^2(0,T;U)}\}\|u_1-u_2\|^2_{L^2(0,T;U)}.\qquad\square
\end{aligned}$$

Remark 3.6. The initial state y_0 can be taken in a space larger than H without changing the main results of this and subsequent sections. More precisely, we need to fulfill two essential requirements, namely (1°) $y\in L^2(0,T;H)$, and (2°) $[-A(T)]^{-\beta}y(T)$ is well defined; in order to get them, it is sufficient that $[-A(0)]^{-\delta}y_0\in H$ for some $\delta\in\,]0,\frac{1}{2}[$, i.e., that y_0 belongs to the dual of $D_{[-A(0)^*]^\delta}$ with respect to H (indeed $[-A(0)]^{-\delta}$ can be extended to an isomorphism between the dual of $D_{[-A(0)^*]^\delta}$ and H). In this case the condition $y\in L^2(0,T;H)$ is satisfied because of (3.4) (with $\mu=0$), since we have

$$\begin{aligned}
(U(t,0)y_0\,|\,x)_H&=([-A(0)]^{-\delta}y_0\,|\,[-A(0)^*]^\delta U(t,0)^*x)_H\\
&\leqq\|[-A(0)]^{-\delta}y_0\|_H M_{\delta 0}t^{-\delta}\|x\|_H\quad\forall x\in H,
\end{aligned}$$

i.e., $\|U(t,0)y_0\|_H\leqq ct^{-\delta}$, $\delta\in\,]0,\frac{1}{2}[$; on the other hand, $[-A(T)]^{-\beta}y(T)$ is well defined (even if $\delta\in[\frac{1}{2},1[$) by (3.4), since

$$[-A(T)]^{-\beta}U(T,0)y_0=[[-A(0)^*]^\delta U(T,0)^*[-A(T)^*]^{-\beta}]^*[-A(0)]^{-\delta}y_0.$$

3.2. The Riccati equation. The main step in the solution of problem (3.10) is the direct study of the associated Riccati equation, which takes the form

$$\begin{aligned}
P(t)=U(T,t)^*P_TU(T,t)+\int_t^T U(s,t)^*&\\
\cdot[M(s)-P(s)A(s)G(s)N(s)^{-1}G(s)^*A(s)^*P(s)]U(s,t)\,ds.&
\end{aligned}\tag{3.14}$$

The nonlinear term in (3.14) is not well defined in the present form. For this reason we consider the following version of (3.14):

$$P(t) = U(T, t)^* P_T U(T, t) + \int_t^T U(s, t)^* \cdot [M(s) - [[-A(s)^*]^{1-\alpha} P(s)]^* K(s) [-A(s)^*]^{1-\alpha} P(s)] U(s, t)\, ds, \tag{3.15}$$

where

$$K(s) := [-A(s)]^{\alpha} G(s) N(s)^{-1} [[-A(s)]^{\alpha} G(s)]^*. \tag{3.16}$$

By (3.5) and (3.12) we have

$$K(\cdot) \in L^{\infty}(0, T; \Sigma^+(H)). \tag{3.17}$$

Note that the integration in (3.15) is performed in the strong sense.

PROPOSITION 3.7 (local solution). *There exist an interval $[T_0, T]$ and a unique function $P \in C_s([T_0, T], \Sigma(H))$ such that*:

(i) $[-A(\cdot)^*]^{1-\alpha} P(\cdot)$ *is well defined and strongly measurable from* $[T_0, T]$ *into* $\mathscr{L}(H)$,

(ii) $\|[-A(t)^*]^{1-\alpha} P(t)\|_{\mathscr{L}(H)} \leqq c(T-t)^{-(1-\alpha-2\beta)\vee 0}$, *for all* $t \in [T_0, T[$,

(iii) $P(\cdot)$ *solves* (3.15) *in* $[T_0, T]$.

Proof. For any $T_0 \in [0, T[$ denote by $B_\gamma(T_0, T)$ the Banach space of all strongly measurable functions $Q: [T_0, T[\to \mathscr{L}(H)$ such that

$$\|Q\|_{B_\gamma(T_0,T)} := \sup_{T_0 \leqq t \leqq T} (T-t)^{\gamma} \|Q(t)\|_{\mathscr{L}(H)} < \infty,$$

where $\gamma := (1-\alpha-2\beta) \vee 0$. For $Q \in B_\gamma(T_0, T)$, define

$$\Gamma_{T_0}(Q)(t) := [-A(t)^*]^{1-\alpha} U(T, t)^* P_T U(T, t) + \int_t^T [-A(t)^*]^{1-\alpha} U(s, t)^* [M(s) - Q(s)^* K(s) Q(s)] U(s, t)\, ds, \qquad t \in [T_0, T].$$

Let us show that Γ_{T_0} maps $B_\gamma(T_0, T)$ into itself. By (3.4), (3.13), (3.3), (3.11), and (3.17) we get

$$\begin{aligned} &\|\Gamma_{T_0}(Q)(t)\|_{\mathscr{L}(H)} \\ &\quad \leqq M_{1-\alpha,2\beta}[1 + (T-t)^{2\beta+\alpha-1}] \|[-A(T)^*]^{2\beta} P_T\|_{\mathscr{L}(H)} \|U(T, t)\|_{\mathscr{L}(H)} \\ &\qquad + M_{1-\alpha,0} \int_t^T (s-t)^{\alpha-1} [\|M(s)\|_{\mathscr{L}(H)} \\ &\qquad + \|K(s)\|_{\mathscr{L}(H)} (T-s)^{-2\gamma} \|Q\|^2_{B_\gamma(T_0,T)}] \|U(s, t)\|_{\mathscr{L}(H)}\, ds \\ &\quad \leqq c[(T-t)^{-\gamma} + (T-t)^{\alpha} + (T-t)^{\alpha-2\gamma} \|Q\|^2_{B_\gamma(T_0,T)}] \quad \forall t \in [T_0, T[; \end{aligned}$$

this shows that $\Gamma_{T_0}(Q) \in B_\gamma(T_0, T)$ and

$$\|\Gamma_{T_0}(Q)\|_{B_\gamma(T_0,T)} \leqq c_1 + c_2 (T - T_0)^{\alpha-\gamma} \|Q\|^2_{B_\gamma(T_0,T)}. \tag{3.18}$$

Next, we show that Γ_{T_0} is a contradiction in the ball

$$B_\gamma(T_0, T; \rho) := \{Q \in B_\gamma(T_0, T) : \|Q\|_{B_\gamma(T_0,T)} \leqq \rho\}$$

for a suitable $\rho > 0$. Indeed if $Q_1, Q_2 \in B_\gamma(T_0, T; \rho)$ we have as before:

$$\begin{aligned}\|\Gamma_{T_0}(Q_1)(t) - \Gamma_{T_0}(Q_2)(t)\|_{\mathscr{L}(H)} &\\ \leqq c \int_t^T (s-t)^{\alpha-1}[\|Q_1(s)\|_{\mathscr{L}(H)} + \|Q_2(s)\|_{\mathscr{L}(H)}]\|Q_1(s) - Q_2(s)\|_{\mathscr{L}(H)}\, ds &\\ \leqq c(T-t)^{\alpha-2\gamma}\rho\|Q_1 - Q_2\|_{B_\gamma(T_0,T)}, \quad \forall t \in [T_0, T[, &\end{aligned}$$

which implies

$$\|\Gamma_{T_0}(Q_1) - \Gamma_{T_0}(Q_2)\|_{B_\gamma(T_0,T)} \leqq c\rho(T-t)^{\alpha-\gamma}\|Q_1 - Q_2\|_{B_\gamma(T_0,T)}. \tag{3.19}$$

By (3.18) and (3.19) we see that it is possible to choose a (large) $\rho > 0$ and a $T_0 \in [0, T[$ (close to T), such that Γ_{T_0} maps $B_\gamma(T_0, T; \rho)$ into itself and is a contraction in $B_\gamma(T_0, T; \rho)$. Thus we get a unique solution of the equation

$$Q = \Gamma_{T_0}(Q) \quad \text{in } [T_0, T[.$$

Hence $P := [-A(\cdot)^*]^{\alpha-1}Q(\cdot)$ is the unique operator-valued function that satisfies (i)-(iii). The property $P \in C_s([T_0, T], \mathscr{L}(H))$ follows by (3.15), whereas the property $P(t) \in \Sigma(H)$ is a consequence of the fact that $P(\cdot)^*$ is also in $C_s([T_0, T], \mathscr{L}(H))$ and satisfies (i)-(iii), so that $P(t)^* \equiv P(t)$ in $[T_0, T]$. □

Remark 3.8. Since $[-A(T_0)]^{1-\alpha}P(T_0) \in \mathscr{L}(H)$, for each $\beta \in]\frac{1}{2} - \alpha, (1-\alpha)/2[\cap [0, (1-\alpha)/2[$ the operator $[-A(T_0)^*]^\beta P(T_0)[-A(T_0)]^\beta$ is continuous with respect to the topology of H (see [F1, Lemma 3.3]).

The result of Proposition 3.7 justifies the following definition:

DEFINITION 3.9. Let J be an interval in $[0, T]$ such that $T \in J$. We say that P is a solution of (3.15) in J if:

(i) $P \in C_s(J, \Sigma(H))$, $[-A(\cdot)^*]^{1-\alpha}P(\cdot)$ is well defined and strongly measurable from J into $\mathscr{L}(H)$,

(ii) For each $\tau \in J \backslash \{T\}$ there exists a constant $c(\tau)$ such that

$$\|[-A(t)^*]^{1-\alpha}P(t)\|_{\mathscr{L}(H)} \leqq c(\tau)(T-t)^{-\gamma} \quad \forall t \in [\tau, T[,$$

where $\gamma = (1 - \alpha - 2\beta) \vee 0$,

(iii) $P(\cdot)$ satisfies (3.15) in J.

We must prove the existence and uniqueness of a global solution, i.e., a solution in $[0, T]$, of (3.15). The proof will be based on an a priori bound; to this purpose we introduce an evolution operator which will be related to the optimal trajectories of problem (3.10).

LEMMA 3.10. *Let P be a solution of* (3.15) *in J. Consider the integral equation*

$$\begin{aligned}\Phi(t,s)x = U(t,s)x + \int_s^t & [[-A(r)^*]^{1-\alpha}U(t,r)^*]^*K(r)\\ &\cdot [[-A(r)^*]^{1-\alpha}P(r)]^*\Phi(r,s)x\, dr, \qquad t \in J,\end{aligned} \tag{3.20}$$

where $x \in H$. Then there exists a unique operator-valued function $\Phi : \overline{\Delta_J} \to \mathscr{L}(H)$, with $\Delta_J := \{(t,s) \in J^2 : t > s\}$, such that $\Phi(t,s)x$ is a solution in $C([s,T],H)$ of (3.20) *for each $x \in H$ and $s \in J$. Moreover, Φ is a strongly continuous evolution operator.*

Proof. Fix $s \in J$. If $\Phi(\cdot, s)x \in C([s, T], H)$, then

$$[-A(\cdot)^*]^{1-\alpha}P(\cdot)\Phi(\cdot, s)x \in L^p(s, T; H)$$

for some $p > 1/\alpha$ (by Definition 3.9(ii)); thus (3.16), (3.5), (3.12), and Lemma 3.3(i) imply that the right-hand side of (3.20) is in $C([s, T], H)$. Therefore it is standard to apply the contraction principle to (3.20), in order to get existence of a unique solution of (3.20) in $C([s, T], H)$, denoted by $\Phi(\cdot, s)x$. The proof that Φ is a strongly continuous evolution operator is classical. □

Using the evolution operator Φ it is possible to rewrite the Riccati equation (3.15) in two alternative integral forms as follows.

LEMMA 3.11. *If P is a solution of* (3.15) *in J and $\bar{T} \in J$, then for each $t \in J \cap [0, \bar{T}]$*

$$P(t) = \Phi(\bar{T}, t)^* P(\bar{T}) \Phi(\bar{T}, t) + \int_t^{\bar{T}} \Phi(s, t)^* \cdot [M(s) + [[-A(s)^*]^{1-\alpha} P(s)]^* K(s) [-A(s)^*]^{1-\alpha} P(s)] \Phi(s, t)\, ds, \tag{3.21}$$

$$P(t) = U(\bar{T}, t)^* P(\bar{T}) \Phi(\bar{T}, t) + \int_t^{\bar{T}} U(\sigma, t)^* M(\sigma) \Phi(\sigma, t)\, d\sigma. \tag{3.22}$$

Proof. The proof is classical (see, e.g., [Gi], [LT1]). □

We are now able to prove the following a priori bound, which is the key point in showing global existence.

LEMMA 3.12. *There exists $c > 0$ with the following property: if P is a solution of* (3.15) *in some interval J, then*

$$\|[-A(t)^*]^{1-\alpha} P(t)\|_{\mathscr{L}(H)} \leqq c(T-t)^{-\gamma} \quad \forall t \in J \backslash \{T\}, \tag{3.23}$$

where $\gamma = (1 - \alpha - 2\beta) \vee 0$.

Proof. Of course (3.23) is obvious if $t \in J \cap [T_0, T[$, with T_0 given by Proposition 3.7. Thus we may confine ourselves to consider the interval $J \cap [0, T_0]$.

Our first step consists in showing that there exists $c > 0$, independent of P and J, such that

$$\|P(t)\|_{\mathscr{L}(H)} \leqq c \quad \forall t \in J. \tag{3.24}$$

Indeed, choose $\bar{T} = T$ in Lemma 3.11: by (3.21) we have

$$P(t) \geqq 0 \quad \forall t \in J; \tag{3.25}$$

moreover, by (3.15) we get

$$\begin{aligned}(P(t)x \mid x)_H &\leqq \|P_T^{1/2} U(T, t)x\|_H^2 + \int_t^T \|M(s)^{1/2} U(s, t)x\|_H^2\, ds \\ &\leqq c\|x\|_H^2 \quad \forall x \in H, \quad \forall t \in J,\end{aligned}$$

with c independent of P and J. Thus (3.24) follows by (3.25). Next, by (3.22) we deduce for $s, t \in J \cap [0, T_0]$, $s \leqq t$:

$$\begin{aligned}[-A(t)^*]^{1-\alpha} P(t) \Phi(t, s) &= [-A(t)^*]^{1-\alpha} U(T_0, t)^* P(T_0) \Phi(T_0, s) \\ &\quad + \int_t^{T_0} [-A(t)^*]^{1-\alpha} U(\sigma, t)^* M(\sigma) \Phi(\sigma, s)\, d\sigma \\ &=: I_1(t, s) + I_2(t, s),\end{aligned} \tag{3.26}$$

where T_0 is taken as in Proposition 3.7. By (3.21) and (3.24) we obtain a first estimate:

$$\int_s^{T_0} \|K(t)^{1/2} [-A(t)^*]^{1-\alpha} P(t) \Phi(t, s)x\|_H^2\, dt \leqq c\|x\|_H^2 \quad \forall x \in H, \quad \forall s \in J \cap [0, T_0], \tag{3.27}$$

with c independent of $s \in J \cap [0, T_0]$ and $x \in H$.

The proof now proceeds in the following manner. Starting from (3.27), we will apply a bootstrap process in order to get more and more summability for the function $[-A(\cdot)^*]^{1-\alpha}P(\cdot)\Phi(\cdot, s)x$ in the interval $J \cap [s, T_0]$, where $s \in J \cap [0, T_0]$. Our final goal is the estimate

$$(3.28)\quad \|[-A(t)^*]^{1-\alpha}P(t)\Phi(t, s)x\|_H \leqq c\|x\|_H \quad \forall x \in H, \quad \forall s, t \in J \cap [0, T_0], \quad s \leqq t,$$

with c independent of x, P, s, t, and J: choosing in (3.28) $s = t$, (3.23) will follow, thus completing the proof of Lemma 3.12.

The bootstrap procedure works as follows. Let $p \in [2, \infty[$ be given, and set

$$p_0 := \begin{cases} \dfrac{p}{1-\alpha p} & \text{if } p \in \left[2, \dfrac{1}{\alpha}\right], \\ +\infty & \text{if } p \geqq \dfrac{1}{\alpha}. \end{cases}$$

Clearly, if $\alpha \in [\frac{1}{2}, 1]$ we have $1/\alpha \leqq 2$ so that $p_0 = +\infty$ whatever be p. If otherwise $\alpha \in]0, \frac{1}{2}[$, then

$$(3.29)\qquad p_0 - p = \frac{\alpha p^2}{1-\alpha p} \geqq \frac{4\alpha}{1-2\alpha} > 0 \quad \forall p \in \left[2, \frac{1}{\alpha}\right].$$

Assuming the truth of the estimate (c independent of x, P, s, J)

$$(3.30)\quad \|[-A(\cdot)^*]^{1-\alpha}P(\cdot)\Phi(\cdot, s)x\|_{L^p(s,T_0;H)} \leqq c\|x\|_H \quad \forall x \in H, \quad \forall s \in J \cap [0, T_0],$$

we will prove the same estimate with p replaced by p_0. This argument starts with $p = 2$, in which case we assume (3.27) instead of (3.30), and stops after a finite number of iterations (by virtue of (3.29)), the final estimate being (3.28). Suppose that (3.30) holds for a certain $p \geqq 2$: by (3.26) it is enough to show that

$$(3.31)\qquad \|I_1(\cdot, s)\|_{L^{p_0}(s,T_0;H)} \leqq c\|x\|_H,$$

$$(3.32)\qquad \|I_2(\cdot, s)\|_{L^{p_0}(s,T_0;H)} \leqq c\|x\|_H.$$

Concerning (3.31), by (3.27), using (3.3), (3.4), and (3.17) we get

$$\int_s^{T_0} \|\Phi(t, s)x\|_H^{p_0}\, dt$$

$$\leqq c\left\{\|x\|_H^{p_0} + \int_s^{T_0}\left[\int_s^t (t-r)^{\alpha-1}\|[-A(r)^*]^{1-\alpha}P(r)\Phi(r, s)x\|_H\, dr\right]^{p_0} dt\right\}$$

and a Young-type estimate [HLP, Thm. 383], along with our assumption (3.30), yields

$$\int_s^{T_0} \|\Phi(t, s)x\|_H^{p_0}\, dt \leqq c\|x\|_H^{p_0},$$

with c independent of P and J (with obvious modifications if $p_0 = \infty$). The bound (3.31) now follows by (3.4) and (3.11), applying the simplest version of Young's inequality.

Let us verify (3.32). First we observe that for any $\eta \in [0, 1[$ and $\varepsilon \in]0, 1-\eta[$ the operator $[-A(T_0)^*]^{1-\eta-\varepsilon}P(T_0)[-A(T_0)]^\eta$ can be uniquely extended to a bounded linear operator in H. Indeed, by (3.15) and (3.13) we have for each $x \in D_{[-A(T_0)]^\eta}$

$$\begin{aligned}
&[-A(T_0)^*]^{1-\eta-\varepsilon} P(T_0)[-A(T_0)]^\eta x \\
&\quad = [[-A(T_0)^*]^{1-\eta-\varepsilon} U(T, T_0)^*[-A(T)^*]^{-2\beta}][[-A(T)^*]^{2\beta} P_T] \\
&\qquad \cdot [[-A(T_0)^*]^\eta U(T, T_0)^*]^* x + \int_{T_0}^{T} [-A(T_0)^*]^{1-\eta-\varepsilon} U(s, T_0)^* \\
&\qquad \cdot [M(s) - [[-A(s)^*]^{1-\alpha} P(s)]^* K(s)[-A(s)^*]^{1-\alpha} P(s)] \\
&\qquad \cdot [[-A(T_0)^*]^\eta U(s, T_0)^*]^* x \, ds,
\end{aligned}$$

and hence by (3.4), (3.13), (3.11), and Proposition 3.7

$$\begin{aligned}
&\|[-A(T_0)^*]^{1-\eta-\varepsilon} P(T_0)[-A(T_0)]^\eta x\|_H \\
&\quad \leqq c\left\{[1+(T-T_0)^{2\beta-1+\eta+\varepsilon}][1+(T-T_0)^{-\eta}] + \int_{T_0}^{T} (s-T_0)^{\varepsilon-1}(T-s)^{-2\gamma}\, ds\right\} \|x\|_H \\
&\quad \leqq c\|x\|_H
\end{aligned}$$

(with c independent of x, P, J). Moreover, if $\eta > 1/p - \alpha$ we have by (3.20), (3.3), (3.4), (3.17), and (3.30)

$$\begin{aligned}
\|[-A(T_0)]^{-\eta}\Phi(T_0, s)x\|_H &\leqq c\|x\|_H + c\left[\int_s^{T_0} (T_0 - r)^{(\alpha-1+\eta)p/(p-1)}\, dr\right]^{(p-1)/p} \\
&\qquad \cdot \|[-A(\cdot)]^{1-\alpha} P(\cdot)\Phi(\cdot, s)x\|_{L^p(0,T_0;H)} \leqq c\|x\|_H
\end{aligned}$$

(c independent of x, P, s, J). Therefore we can rewrite $I_1(t, s)$ as

$$\begin{aligned}
I_1(t, s) &= [[-A(t)^*]^{1-\alpha} U(T_0, t)^*[-A(T_0)^*]^{\eta+\varepsilon-1}] \\
&\qquad \cdot [[-A(T_0)^*]^{1-\eta-\varepsilon} P(T_0)[-A(T_0)]^\eta][[-A(T_0)]^{-\eta}\Phi(T_0, s)];
\end{aligned}$$

hence if we take $\eta \in]1/p - \alpha, 1/p[$ and $\varepsilon \in]0, 1/p[$ we see using (3.4) that

$$\begin{aligned}
&\int_s^{T_0} \|[-A(t)^*]^{1-\alpha} U(T_0, t)^*[-A(T_0)^*]^{\eta+\varepsilon-1} x\|_H^{p_0}\, dt \\
&\qquad \leqq c \int_s^{T_0} (T_0 - t)^{(\alpha-\eta-\varepsilon)p_0}\, dt \|x\|_H^{p_0} \leqq c\|x\|_H^{p_0},
\end{aligned}$$

since $(\eta + \varepsilon - \alpha)p_0 < 1$. Thus we immediately obtain (3.32). Hence we get (3.30) with p replaced by p_0; consequently (3.28) follows, and the proof of Lemma 3.12 is complete. □

We can now prove the main result of this section.

THEOREM 3.13 (global solution). *There exists a unique solution P of equation* (3.15) *in* $[0, T]$. *Moreover, it has the following properties*:

(i) $P(t) \geqq 0$ *for each* $t \in [0, T]$;

(ii) *P satisfies the integral Riccati equations* (3.21) *and* (3.22);

(iii) *P satisfies the bounds* (3.24) *in* $[0, T]$ *and* (3.23) *in* $[0, T[$;

(iv) *For each $\eta \in [0, 1[$, the linear operator $[-A(t)^*]^\eta P(t)$, $t \in [0, T[$, is well defined, strongly measurable in t, and equibounded on compact subsets of* $[0, T[$.

Proof. Let T_0 be given by Proposition 3.7. For each $T_1 \in [0, T_0[$, consider the Banach space $L^\infty(T_1, T_0; \mathscr{L}(H))$ and the balls

$$B(T_1, T_0; \rho) := \{Q \in L^\infty(T_1, T_0; \mathscr{L}(H)) : \|Q\|_{L^\infty(T_1, T_0; \mathscr{L}(H))} \leqq \rho\}, \qquad \rho > 0.$$

Define the mapping Γ_{T_1,T_0} on $L^\infty(T_1, T_0; \mathscr{L}(H))$ by

$$\begin{aligned}\Gamma_{T_1,T_0}(Q)(t) := {} & [[-A(t)^*]^{1-\alpha}U(T_0, t)^*[-A(T_0)^*]^{\alpha-1}][[-A(T_0)^*]^{1-\alpha}P(T_0)U(T_0, t)] \\ & + \int_t^{T_0} [-A(t)^*]^{1-\alpha}U(s, t)^*[M(s) - Q(s)^*K(s)Q(s)]U(s, t)\, ds, \\ & \qquad t \in [T_1, T_0[,\end{aligned}$$

$$\Gamma_{T_1,T_0}(Q)(T_0) := [-A(T_0)^*]^{1-\alpha}P(T_0).$$

As in the proof of Proposition 3.7, we have

$$\begin{aligned}\|\Gamma_{T_1,T_0}(Q)\|_{L^\infty(T_1,T_0;\mathscr{L}(H))} \leqq {} & c_1\|[-A(T_0)^*]^{1-\alpha}P(T_0)\|_{\mathscr{L}(H)} + c_2 \\ & + c_3(T_0 - T_1)^\alpha \|Q\|^2_{L^\infty(T_1,T_0;\mathscr{L}(H))}, \\ & \forall Q \in L^\infty(T_1, T_0; \mathscr{L}(H)),\end{aligned} \tag{3.33}$$

$$\begin{aligned}&\|\Gamma_{T_1,T_0}(Q_1) - \Gamma_{T_1,T_0}(Q_2)\|_{L^\infty(T_1,T_0;\mathscr{L}(H))} \\ &\leqq c_4\rho(T_0 - T_1)^\alpha \|Q_1 - Q_2\|_{L^\infty(T_1,T_0;\mathscr{L}(H))} \quad \forall Q_1, Q_2 \in L^\infty(T_1, T_0; \mathscr{L}(H));\end{aligned} \tag{3.34}$$

here $c_1, \cdots, c_4$ are constants independent of T_1, T_0. Using the a priori bound (3.23), by (3.33) and (3.34) we see that we can select $\rho > 0$ and $T_1 \in]0, T_0[$ such that:

(a) $T_0 - T_1$ and ρ are independent of T_0;

(b) Γ_{T_1,T_0} is a contraction which maps $B(T_1, T_0; \rho)$ into itself. Thus there exists a unique solution Q of the equation

$$Q = \Gamma_{T_1,T_0}(Q)$$

in the space $L^\infty(T_1, T_0; \mathscr{L}(H))$, and this procedure can be repeated in the interval $[T_1 - (T_0 - T_1), T_1]$, and so on, with constant step. As in the proof of Proposition 3.7, we conclude that there exists a unique solution P of (3.15) in $[0, T]$.

Finally, property (i) follows by (3.25), and similarly properties (ii) and (iii) are proved in Lemmas 3.11 and 3.12. As to (iv), it is sufficient to use (3.4), (3.11) and the last assertion of Lemma 3.10 in equation (3.22) with $\bar{T} = T$. □

3.3. Synthesis. The results of the preceding section lead to the following theorem.

THEOREM 3.14. *Let $y_0 \in H$ be given. Then*:

(i) *There exists a unique optimal control $\hat{u}_0 \in L^2(0, T; U)$ for problem* (3.10);

(ii) *Denoting by $P(\cdot)$ the solution of the Riccati equation* (3.15), *we have*

$$J(\hat{u}_0) = (P(0)y_0|y_0)_H; \tag{3.35}$$

(iii) *If $\hat{y}_0 \in L^2(0, T; H)$ is the optimal trajectory, i.e., the solution of the state equation* (3.1) *corresponding to $\hat{u}_0(\cdot)$, we have the feedback formula for $\hat{u}_0(\cdot)$*:

$$\hat{U}_0(t) = N(t)^{-1}G(t)^*A(t)^*P(t)\hat{Y}_0(t), \qquad t \in [0, T[; \tag{3.36}$$

(iv) *The optimal trajectory $\hat{y}_0(\cdot)$ is expressed by*

$$\hat{y}_0(t) = \Phi(t, 0)y_0, \tag{3.37}$$

where $\Phi(t, s)$ is defined by the integral equation (3.20) *with $J = [0, T]$*;

(v) *The optimal pair $(\hat{u}_0, \hat{y}_0)$ is characterized by the following optimality system*:

$$\begin{aligned}&\hat{Y}_0(t) = U(t, 0)Y_0 - \int_0^t U(t, s)A(s)G(s)\hat{U}_0(s)\, ds, \\ &\hat{u}_0(t) = N(t)^{-1}G(t)^*A(t)^*p(t), \qquad t \in [0, T[, \\ &p(t) = U(T, t)^*P_T\hat{y}_0(T) + \int_t^T U(s, t)^*M(s)\hat{y}_0(s)\, ds.\end{aligned} \tag{3.38}$$

In (3.36) and (3.38) we have set

$$G(t)^*A(t)^* := -[[-A(t)]^\alpha G(t)]^*[-A(t)^*]^{1-\alpha}; \tag{3.39}$$

as both operators $P(t)$, $U(r, t)^*$ (with $r > t$) have their range contained in $D_{[-A(t)^*]^\eta}$ for each $\eta \in [0, 1[$, both (3.36) and (3.38) are meaningful.

Proof. Recalling (3.39), set

$$\hat{u}_0(t) := N(t)^{-1}G(t)^*A(t)^*P(t)\Phi(t, 0)Y_0; \tag{3.40}$$

note that $\hat{u}_0 \in L^2(0, T; U)$ because of (3.23) (since $2(1-\alpha-2\beta) < 1$) and Lemma 3.10 (with $J = [0, T]$). Now let $\hat{y}_0(\cdot)$ be the function (3.1) corresponding to $\hat{u}_0(\cdot)$. Then $\hat{y}_0 \in L^2(0, T; H)$ by Lemma 3.3(i). Moreover, comparing (3.1) with (3.20), and taking into account (3.16), we see that (3.37) holds. Consequently (3.40) implies (3.36). In addition, evaluating $P(0)Y_0$ by means of (3.21) with $\bar{T} = T$, we easily check that (3.35) also holds. Next, setting $p(t) := P(t)\hat{Y}_0(t)$, (3.40) and (3.37) immediately yield

$$\hat{U}_0(t) = N(t)^{-1}G(t)^*A(t)^*p(t);$$

on the other hand, by (3.37) and (3.22) with $\bar{T} = T$ we obtain the last equation in (3.38), so that the pair $(\hat{u}_0, \hat{y}_0)$ satisfies (3.38).

In order to conclude the proof of the theorem, it is sufficient to show that:

(a) If $(\hat{u}_0, \hat{y}_0)$ is a solution of the system (3.38) in $L^2(0, T; U) \times L^2(0, T; H)$, then $\hat{U}_0$ is an optimal control;

(b) The optimal control is unique.

From the equality

$$(z_1 \mid z_1) - (z_2 \mid z_2) = (z_1 - z_2 \mid z_1 - z_2) + 2\operatorname{Re}(z_2 \mid z_1 - z_2),$$

which holds true for any inner product, we derive for each $u \in L^2(0, T; U)$, denoting by $y(\cdot)$ the corresponding function (3.1)

$$J(u) - J(\hat{u}_0) = I_1(u, \hat{u}_0) + I_2(u, \hat{u}_0), \tag{3.41}$$

where $J(\cdot)$ is the cost functional appearing in (3.10) and

$$\begin{aligned} I_1(u, \hat{u}_0) := \int_0^T &\{(M(t)[y(t) - \hat{Y}_0(t)] \mid y(t) - \hat{Y}_0(t))_H \\ &+ (N(t)[u(t) - \hat{u}_0(t)] \mid u(t) - \hat{u}_0(t))_U\}\, dt \\ &+ (P_T[y(T) - \hat{Y}_0(T)] \mid y(T) - \hat{Y}_0(T))_H, \\ I_2(u, \hat{u}_0) := 2\operatorname{Re} \int_0^T &\{(M(t)\hat{Y}_0(t) \mid y(t) - \hat{Y}_0(t))_H + (N(t)\hat{u}_0(t) \mid u(t) - \hat{u}_0(t))_U\}\, dt \\ &+ 2\operatorname{Re}(P_T\hat{Y}_0(T) \mid y(T) - \hat{Y}_0(T))_H. \end{aligned}$$

Now, using (3.1) and integrating by parts,

$$\begin{aligned} I_2(u, \hat{u}_0) = 2\operatorname{Re} \int_0^T \Big\{ -\int_s^T &(M(t)\hat{Y}_0(t) \mid U(t, s)A(s)G(s)[u(s) - \hat{u}_0(s)])_H\, dt \\ &+ (N(s)\hat{u}_0(s) \mid u(s) - \hat{u}_0(s))_U \\ &- (P_T\hat{Y}_0(T) \mid U(T, s)A(s)G(s)[u(s) - \hat{u}_0(s)])_H \Big\}\, ds, \end{aligned}$$

and by the last two identities in (3.38) we easily get

$$I_2(u, \hat{u}_0) = 2 \operatorname{Re} \int_0^T (-G(s)^*A(s)^*p(s) + N(s)\hat{u}_0(s) \,|\, u(s) - \hat{u}_0(s))_U \, ds = 0.$$

On the other hand, clearly, $I_1(u, \hat{u}_0) \geqq 0$, so that (3.41) yields

$$J(u) \geqq J(\hat{u}_0) \quad \forall u \in L^2(0, T; U),$$

i.e., $\hat{u}_0$ is an optimal control. This proves (a).

Finally, if $\bar{u}$ is another optimal control, the equality $J(\hat{u}_0) = J(\bar{u})$ implies

$$I_1(\bar{u}, \hat{u}_0) = 0,$$

and by the uniform coerciveness of $N(t)$ (see (3.12)) we obtain $\bar{u} = \hat{u}_0$. This proves (b). The proof of Theorem 3.14 is complete. □

APPLICATIONS OF A SPLITTING ALGORITHM TO DECOMPOSITION IN CONVEX PROGRAMMING AND VARIATIONAL INEQUALITIES*

PAUL TSENG†

Abstract. Recently Han and Lou proposed a highly parallelizable decomposition algorithm for minimizing a strongly convex cost over the intersection of closed convex sets. It is shown that their algorithm is in fact a special case of a splitting algorithm analyzed by Gabay for finding a zero of the sum of two maximal monotone operators. Gabay's convergence analysis for the splitting algorithm is sharpened, and new applications of this algorithm to variational inequalities, convex programming, and the solution of linear complementarity problems are proposed. For convex programs with a certain separable structure, a multiplier method that is closely related to the alternating direction method of multipliers of Gabay-Mercier and of Glowinski-Marrocco, but which uses both ordinary and augmented Lagrangians, is obtained.

Key words. maximal monotone operator, augmented Lagrangian, alternating minimization

AMS(MOS) subject classifications. 49, 90

1. Introduction. One of the most important applications of convex duality theory is in decomposition algorithms for solving problems with special structure. A canonical example is the following separable convex programming problem

$$\begin{array}{ll} \text{minimize} & f(x)+g(z) \\ \text{subject to} & Ax+Bz=b, \end{array} \tag{1.1}$$

where $f:\mathcal{R}^n\to(-\infty,\infty]$ and $g:\mathcal{R}^m\to(-\infty,\infty]$ are given convex functions, A is a given $r\times n$ matrix, B is a given $r\times m$ matrix, and b is a given vector in $\mathcal{R}^r$. In our notation, all vectors are column vectors and $\mathcal{R}^k$ denotes the k-dimensional Euclidean space.

By attaching a Lagrange multiplier vector $p\in\mathcal{R}^r$ to the constraints in (1.1), the problem (1.1) can be decomposed into two independent problems involving, respectively, x and z. One algorithm based on this dual approach, proposed by Uzawa [61] and others, operates by successively minimizing the Lagrangian function

$$L(x,z,p)=f(x)+g(z)+\langle p, b-Ax-Bz\rangle,$$

with respect to x and z (with p fixed) and then updating the multipliers by the iteration

$$p:=p+c(b-Ax-Bz),$$

where c is a positive stepsize and $\langle\cdot,\cdot\rangle$ denotes the usual Euclidean inner product. (We assume for the sake of discussion that the minimum above is attained.) It can be shown that this algorithm is convergent if both f and g are strongly convex and c is chosen to be sufficiently small. (In this case the dual functional defined by $q(p)=\min_{x,z}L(x,z,p)$ is differentiable and this algorithm can be viewed as a gradient method for maximizing q.)

Unfortunately, for many problems of interest, the function f may be strongly convex but not g. This is particularly the case when a problem is transformed in a way to bring about a structure that is favorable for decomposition (see § 4 for an example).

A solution to this difficulty is suggested by a recent work of Han and Lou. In [28] they proposed a decomposition algorithm for minimizing a strongly convex function over the intersection of a finite collection of closed convex sets. It can be shown, by introducing auxiliary variables, that this convex program is a special case of (1.1) (see § 4). Moreover, it can be shown that their algorithm is similar to the dual gradient method above, except for the key difference that the Lagrangian function is replaced by an augmented Lagrangian function when the minimization is taken with respect to z.

The above discussion suggests the following generalization of the Han and Lou algorithm for solving the general problem (1.1). (The main interest here is in problems where f is strongly convex and separable but g is not strongly convex.) At each iteration of this algorithm, the ordinary Lagrangian $L(x, z, p)$ is first minimized with respect to x (with z and p held fixed), and then the augmented Lagrangian

$$L_c(x, z, p) = L(x, z, p) + c\|Ax + Bz - b\|^2/2$$

is minimized with respect to z (with x and p held fixed), where $\|\cdot\|$ denotes the norm induced by $\langle \cdot, \cdot \rangle$, i.e., $\|x\| = \sqrt{\langle x, x\rangle}$. Finally, the multipliers are updated according to the usual augmented Lagrangian iteration

$$p := p + c(b - Ax - Bz),$$

and the process is repeated. This algorithm, which for ease of reference will be called the *alternating minimization algorithm*, has the nice feature that, if B has full column rank, then both minimizations involve strongly convex objective functions. Moreover, if f is separable (in addition to being strongly convex), then the first minimization is also separable—a feature that makes this algorithm particularly suitable for problems where f is separable and g is such that the minimization of the augmented Lagrangian with respect to z is easily carried out.

The above approach of introducing a form of regularization to induce positive curvature in the objective functions is not new. It was first employed in the *alternating direction method of multipliers*, proposed by Gabay and Mercier [20], Glowinski and Marrocco [25] and extended by Gabay [17] (also see [4], [13], [14], [16], [18], [22], [23], [58] for related works), which is another multiplier method that alternates between minimization with respect to x and minimization with respect to z. The only difference between this algorithm and the one above (i.e., the alternating minimization algorithm) is that, at each iteration, x is updated by minimizing the augmented Lagrangian rather than the ordinary Lagrangian as in the above algorithm. The quadratic term of the augmented Lagrangian adversely affects the decomposition of the minimization with respect to x based on separability properties of f, and this is an advantage for the above algorithm. On the other hand, in contrast with the alternating direction method of multipliers, the penalty parameter c in the above algorithm must be chosen from a restricted range (as will be seen later), usually through trial and error.

It turns out that the alternating minimization algorithm is itself a dual application of an algorithm, suggested by Lions and Mercier and Passty and studied extensively by Gabay, for finding a zero of the sum of two maximal monotone operators. (Such operators have been studied extensively owing to their role in convex analysis and in solving certain partial differential equations. Finding a zero of the sum of these operators is a fundamental problem (see for example [5], [11], [12], [34], [50], [57]).) Let $\mathcal{H}$ be a real Hilbert space and let $\Pi : \mathcal{H} \to \mathcal{H}$ and $\Psi : \mathcal{H} \to \mathcal{H}$ be two maximal monotone operators such that Π^{-1} is in addition strongly monotone. We associate with Π and Ψ

the following problem:

$$\text{(1.2)} \qquad \text{Find } p^* \in \mathcal{H} \text{ satisfying } 0 \in \Pi(p^*) + \Psi(p^*).$$

Lions and Mercier [34] and, independently, Passty [51] suggested the following *splitting* iteration for solving (1.2), whereby a *forward Euler* step for Π is alternated with a *backward Euler* step for Ψ, i.e.,

$$\text{(1.3)} \qquad p := [I + c\Psi]^{-1}[I - c\Pi]p,$$

with c being some positive stepsize. Passty showed that, under certain assumptions, the *weighted average* of the iterates generated by (1.3), weighted by the respective stepsizes, converges to a solution of (1.2). (Interestingly, Passty's result does not require Π^{-1} to be strongly monotone.) The first "practical" convergence result was given by Gabay [19] (also see [17, Chap. 6]), who showed that the iterates converge weakly to a solution of (1.2) if c is fixed and is strictly less than twice the modulus of Π^{-1}. Gabay also gave sufficient conditions for the strong convergence of the iterates and discussed applications of the splitting iteration to decomposition in convex programming and variational inequalities. However, Gabay's applications were to the original problem (giving rise to methods such as that of Bruck [6] and of Goldstein [26]) rather than to the dual. Finally, we remark that Lemaire [32] recently gave a detailed convergence analysis for (1.3) when Ψ is the subdifferential of a closed convex function and Π is in addition strongly monotone.

The purpose of this paper is twofold: (1) to show that the alternating minimization algorithm (and hence the algorithm of Han and Lou) is an application of the iteration (1.3) to the dual of (1.1) and, (2) to give additional dual applications of (1.3) to decomposition in convex programming and variational inequalities. We begin by giving in § 2 a proof of convergence for the iteration (1.3)—different from one given by Gabay—that does not require the stepsize c to be fixed and shows that, if either Π or Ψ is strongly monotone, then the convergence is at least linear. In § 3 we apply (1.3) to variational inequalities possessing a certain separable structure to obtain a new decomposition algorithm for this problem. The latter algorithm in turn is applied, in § 4, to (1.1) to obtain the alternating minimization algorithm and, in § 5, to linear complementarity problems with positive semi-definite matrices to obtain a new matrix splitting algorithm for these problems.

We briefly describe the notation used throughout this paper. For any real matrix E, we denote by E^T the transpose of E and by $\|E\|$ the L_2-norm of E, i.e., $\|E\|$ is the square root of the largest eigenvalue of E^TE. For any set Ω, we denote by $\delta_\Omega(\cdot)$ the *indicator* function for Ω, i.e., $\delta_\Omega(x)$ is zero if $x \in \Omega$ and is ∞ otherwise. For any real Hilbert space $\mathcal{H}$ endowed with an inner product $\langle \cdot, \cdot \rangle$, we say that a multifunction $T: \mathcal{H} \to \mathcal{H}$ is a *monotone operator* if

$$\langle y - y', x - x' \rangle \geqq 0 \quad \text{whenever } y \in T(x),\ y' \in T(x').$$

It is said to be *maximal monotone* if, in addition, the graph

$$\{(x, y) \in \mathcal{H} \times \mathcal{H} \mid y \in T(x)\}$$

is not properly contained in the graph of any other monotone operator $T': \mathcal{H} \to \mathcal{H}$. We denote by $\mathcal{D}(T)$ the *effective domain* of T, i.e.,

$$\mathcal{D}(T) = \{x \in \mathcal{H} \mid T(x) \neq \emptyset\},$$

and by T^{-1} the *inverse* of T, i.e.,

$$(T^{-1})(y) = \{x \in \mathcal{H} \mid y \in T(x)\}, \qquad \forall y \in \mathcal{H}.$$

It is easily seen from symmetry that the inverse of a maximal monotone operator is also a maximal monotone operator. For any monotone operator $T: \mathcal{H} \to \mathcal{H}$, the *modulus* of T will denote the largest nonnegative scalar σ such that

$$(1.4) \qquad \langle y-y', x-x'\rangle \geq \sigma\|x-x'\|^2 \quad \text{whenever } y \in T(x), y' \in T(x'),$$

where $\|\cdot\|$ is the norm induced by $\langle \cdot, \cdot \rangle$, i.e., $\|x\| = \sqrt{\langle x, x\rangle}$. We will say that T is *strongly monotone* (or *coercive*) if its modulus is positive. For any closed convex function $h: \mathcal{H} \to (-\infty, \infty]$ and any $x \in \mathcal{H}$, we denote by dom (h) the effective domain of h, i.e.,

$$\text{dom}\,(h) = \{x \in \mathcal{H} \mid h(x) < \infty\},$$

and by $\partial h(x)$ the *subdifferential* of h at x, i.e.,

$$\partial h(x) = \{y \in \mathcal{H} \mid h(x') - h(x) \geqq \langle y, x'-x\rangle \text{ for all } x' \in \mathcal{H}\}.$$

For any other real Hilbert space $\mathcal{V}$ endowed with an inner product $\langle \cdot, \cdot \rangle$ and any continuous linear operator $A: \mathcal{V} \to \mathcal{H}$ (see [62]), we will denote by $A': \mathcal{H} \to \mathcal{V}$ the *adjoint* of A, i.e.,

$$\langle Ax, y\rangle = \langle x, A'y\rangle, \quad \forall x \in \mathcal{V}, y \in \mathcal{H},$$

and by $\|A\|$ the *operator norm* of A, i.e,

$$\|A\| = \sup_{\|x\| \leqq 1} \|Ax\|.$$

2. A splitting algorithm for the sum of two maximal monotone operators. Let $\mathcal{H}$, $\mathcal{V}$, and $\mathcal{W}$ be three real Hilbert spaces each equipped with an inner product. For convenience, we will denote each of these inner products generically as $\langle \cdot, \cdot \rangle$ and the norm induced by it as $\|\cdot\|$, with the choice of the inner product being implied by the context. Let $\Phi: \mathcal{V} \to \mathcal{V}$ and $\Gamma: \mathcal{W} \to \mathcal{W}$ be two maximal monotone operators, let $A: \mathcal{V} \to \mathcal{H}$ and $B: \mathcal{W} \to \mathcal{H}$ be two continuous linear operators, and let b be an element of $\mathcal{H}$. Consider the following problem [cf. (1.2)]:

$$(2.1) \qquad \text{Find } p^* \in \mathcal{H} \text{ satisfying } b \in A\Phi(A'p^*) + B\Gamma(B'p^*).$$

We make the following standing assumptions regarding (2.1):

Assumption A.

(a) (2.1) has a solution.

(b) Φ^{-1} is strongly monotone with modulus σ.

(c) $B\Gamma B'$ is a maximal monotone operator.

Notice that Assumption A(b) implies that Φ^{-1} is surjective (see [5, Corollary 2.4]), so that for every $p \in \mathcal{H}$ there exists an $x \in \mathcal{V}$ satisfying $x \in \Phi(A'p)$. Moreover, there exists an $x^* \in \mathcal{V}$ satisfying

$$(2.2) \qquad x^* \in \Phi(A'p^*), \quad \forall \text{ solutions } p^* \text{ of } (2.1).$$

To see the latter, note that if p_1 and p_2 are two solutions of (2.1), then there exist $x_1 \in \Phi(A'p_1)$, $z_1 \in \Gamma(B'p_1)$ such that $b = Ax_1 + Bz_1$ and there exist $x_2 \in \Phi(A'p_2)$, $z_2 \in \Gamma(B'p_2)$ such that $b = Ax_2 + Bz_2$. Hence,

$$0 = \langle x_2 - x_1, A'p_2 - A'p_1\rangle + \langle z_2 - z_1, B'p_2 - B'p_1\rangle \geqq \sigma\|x_2 - x_1\|^2,$$

where the inequality follows from the facts that Γ is monotone and that Φ^{-1} is monotone with modulus σ. Since $\sigma > 0$, this shows $x_1 = x_2$.

Consider the following algorithm for solving (2.1): Begin with any $p(0)\in\mathcal{H}$. At the tth iteration, we are given a $p(t)\in\mathcal{H}$; we generate the next iterate $p(t+1)\in\mathcal{H}$ by first computing an

$$x(t)\in\Phi(A'p(t)), \tag{2.3a}$$

then a $z(t)\in\mathcal{W}$ satisfying

$$z(t)\in\Gamma(B'[p(t)-c(t)(Ax(t)+Bz(t)-b)]), \tag{2.3b}$$

and finally setting

$$p(t+1)=p(t)+c(t)(b-Ax(t)-Bz(t)), \tag{2.3c}$$

where $c(t)$ is some positive stepsize to be specified. We will show later that $z(t)$ is well defined [i.e., there exists a $z(t)$ satisfying (2.3b)].

To see the connection between the above iteration (2.3a)-(2.3c) and the splitting iteration (1.3), let us apply B to both sides of (2.3b). By using (2.3c), we then obtain

$$[p(t)-p(t+1)]/c(t)+b-Ax(t)\in B\Gamma(B'p(t+1)),$$

which, when combined with (2.3a), yields

$$p(t+1)=[I+c(t)B\Gamma B']^{-1}(c(t)b+[I-c(t)A\Phi A']p(t)), \tag{2.4}$$

or, equivalently,

$$p(t+1)=[I+c(t)\Psi]^{-1}[I-c(t)\Pi]p(t), \tag{2.5}$$

where we let $\Pi(p)=A\Phi(A'p)-b$ and $\Psi(p)=B\Gamma(B'p)$. The iteration (2.5) is clearly of the form (1.3). In addition, Ψ is maximal monotone [cf. Assumption A(c)] and Π^{-1} is maximal strongly monotone (cf. [19, Prop. 4.1] and the maximal strongly monotone property of Φ^{-1}). A simple calculation shows that the modulus of Π^{-1} is equal to $\sigma/\|A\|^2$.

Now we show that $z(t)$ is well defined. Since $B\Gamma B'$ is by assumption a maximal monotone operator, then by a result of Minty [41], the proximal mapping $[I+c(t)B\Gamma B']^{-1}$ is single valued and defined on all of $\mathcal{H}$, so that by (2.4), $p(t+1)$ is well defined. This in turn shows that $\Gamma(B'p(t+1))$ is nonempty so that, by (2.3b) and (2.3c), there exists $z(t)\in\mathcal{W}$ satisfying (2.3b).

By using the relation (2.5), we can conclude from a result of Gabay [19, Thm. 6.1] (also see [17, Chap. 6]) that $\{p(t)\}$ converges weakly to a solution of (2.1), provided that $c(t)$ is fixed at some value between 0 and $2\sigma/\|A\|^2$ (twice the modulus of Π^{-1}) for all t. Below we sharpen this result of Gabay by showing that $\{p(t)\}$ converges weakly even if $c(t)$ is changing with t. Moreover, we show that both $\{x(t)\}$ and $\{Bz(t)\}$ converge strongly, and if either $A\Phi A'$ or $B\Gamma B'$ is strongly monotone, then the convergence is at least linear.

PROPOSITION 1. *The sequences* $\{x(t)\}$, $\{z(t)\}$, $\{p(t)\}$ *generated by* (2.3a)-(2.3c) *are well defined. If in addition* $\{c(t)\}$ *satisfies*

$$\varepsilon\leqq c(t)\leqq 2\sigma/\|A\|^2-\varepsilon,\quad \forall t, \tag{2.6}$$

for some $\varepsilon\in(0,\sigma/\|A\|^2]$, *then the following hold*:

(a) $\{x(t)\}\to x^*$ *in the strong topology.*

(b) $\{Bz(t)\}\to b-Ax^*$ *in the strong topology.*

(c) $\{p(t)\}\to$ *a solution of* (2.1) *in the weak topology.*

(d) *If either* $A\Phi A'$ *or* $B\Gamma B'$ *is strongly monotone, then* $\{x(t)\}$, $\{Bz(t)\}$, $\{p(t)\}$ *converge at least linearly with a convergence ratio of* $\sqrt{(1-\delta^2\varepsilon^2)/(1+\eta^2\varepsilon^2)}$, *where* δ *and* η *denote the modulus of, respectively,* $A\Phi A'$ *and* $B\Gamma B'$.

The proof of Proposition 1, which is based on an argument used by Glowinski and Le Tallec [23] (also see [4, § 3.4.4]) for the alternating direction method of multipliers, is given in Appendix A. It is unclear if the proof given by Gabay can be extended to show Proposition 1 since it uses a lemma of Opial [46] which requires the algorithmic mapping to be *stationary.*

Note that Proposition 1(b) implies that if $B'B$ is an isomorphism of $\mathscr{H}$, then $\{z(t)\}$ converges. Also, it can be shown that Proposition 1 holds even if the solutions of (2.3a) and (2.3b) are computed inexactly. Unfortunately, the amount of inexactness allowable cannot be easily estimated. Also, notice that, by letting $\Pi(p)=A\Phi(A'p)-b$ and $\Psi(p)=B\Gamma(B'p)$, we can restrict our attention to iterations of the simpler form (2.5). However, by doing so, we will only be able to infer the convergence of $\{Ax(t)\}$, not the convergence of $\{x(t)\}$.

We have thus far assumed $B\Gamma B'$ to be maximal (it is automatically monotone since Γ is monotone), but for practical uses we must translate this assumption into conditions on Γ and B that are more easily verified. For this purpose, the following equivalent set of conditions given by Gabay [19, proof of Prop. 4.1] (also see [17, Chap. 6]) will be useful to us.

LEMMA 1. *$B\Gamma B'$ is maximal monotone if and only if, for each $c>0$, the effective domain of the multifunction $p\to(\Gamma^{-1}+cB'B)^{-1}B'p$ is all of $\mathscr{H}$.*

By Lemma 1, $B\Gamma B'$ is maximal monotone if, for each $c>0$, $\Gamma^{-1}+cB'B$ is strongly monotone (since $\Gamma^{-1}+cB'B$ is then surjective by [5, Corollary 2.4]), and the latter holds if either $B'B$ is an isomorphism of $\mathscr{H}$ or if Γ^{-1} is strongly monotone (cf. (4.7) and (4.8) in [19]). These requirements can, in certain special cases, be relaxed further. For example, if Γ^{-1} is the subdifferential mapping of a closed proper convex function g, then it suffices to require that the function $z\to g(z)+\|Bz\|^2$ attains its minimum at some point (see § 4).

3. Application to variational inequalities. Let $\mathscr{X}$ and $\mathscr{Z}$ be two polyhedral sets in, respectively, $\mathscr{R}^n$ and $\mathscr{R}^m$. Let $R:\mathscr{R}^n\to\mathscr{R}^n$ and $S:\mathscr{R}^m\to\mathscr{R}^m$ be two single valued continuous functions and let $f:\mathscr{R}^n\to(-\infty,\infty]$ and $g:\mathscr{R}^m\to(-\infty,\infty]$ be two closed convex functions. Also, let A be an $r\times n$ matrix, B be an $r\times m$ matrix, and b be an element of $\mathscr{R}^r$. Consider the following problem:

$$\text{Find } x^*\in\mathscr{X} \text{ and } z^*\in\mathscr{Z} \text{ satisfying } Ax^*+Bz^*=b \text{ and}$$

$$\langle x-x^*, R(x^*)\rangle+\langle z-z^*, S(z^*)\rangle+f(x)-f(x^*)+g(z)-g(z^*)\geqq 0, \tag{3.1}$$

$$\forall x\in\mathscr{X},\ z\in\mathscr{Z} \text{ satisfying } Ax+Bz=b.$$

This problem, called the *variational inequality* problem, has numerous applications to numerical computation—including the solution of a system of equations, constrained and unconstrained optimization, traffic assignment problems, game theory, and saddle point problems (see [1], [4, § 3.5], [9], [16], [22], [30]). For example, the convex program (1.1) is a special case of (3.1) with R and S taken to be the zero functions. In this section we will derive a decomposition algorithm for (3.1) by applying the splitting iteration (2.3a)-(2.3c).

We make the following assumptions regarding (3.1).

Assumption B.

(a) (3.1) has a solution.

(b) $R+\partial f$ is strongly monotone (with modulus σ).

(c) For each $c>0$, the effective domain of the multifunction $p\to(S+\partial g+\partial\delta_{\mathscr{Z}}+cB^TB)^{-1}B^Tp$ is all of $\mathscr{R}^r$.

(d) There exist $x \in \mathrm{ri}\,(\mathrm{dom}\,(f)) \cap \mathscr{X}$ and $z \in \mathrm{ri}\,(\mathrm{dom}\,(g)) \cap \mathscr{Z}$ satisfying $Ax + Bz = b$.

Part (c) of Assumption B seems a bit complicated, but notice that it holds automatically if either $S + \partial g$ is strongly monotone or if B has full column rank (cf. Lemma 1). Part (d) of Assumption B combines the usual feasibility assumption for (3.1) with a constraint qualification. The latter is required in order to assert the existence of an optimal Lagrange multiplier vector associated with the constraints $Ax + Bz = b$. Note that we could have embedded the constraints $x \in \mathscr{X}$ and $z \in \mathscr{Z}$ in, respectively, f and g by the use of the indicator functions $\delta_{\mathscr{X}}$ and $\delta_{\mathscr{Z}}$. But had we done so, we would not have been able to infer (from the available duality results) the existence of an optimal Lagrange multiplier vector without making additional assumptions.

Since $R + \partial f$ is strongly monotone, it is easily seen that the first n coordinates of a solution of (3.1) are uniquely determined; i.e., there exists an $x^* \in \mathscr{X}$ such that every solution of (3.1) is of the form (x^*, z^*), where z^* is some element of $\mathscr{Z}$.

We claim that (3.1) is a special case of the problem (2.1). To see this, let (x^*, z^*) be a solution of the variational inequality (3.1). Then, it is easily seen that (x^*, z^*) solves the following convex program:

$$\text{(3.2)} \qquad \begin{array}{ll} \text{minimize} & \langle R(x^*), x\rangle + \langle S(z^*), z\rangle + f(x) + g(z) \\ \text{subject to} & x \in \mathscr{X},\ z \in \mathscr{Z},\ Ax + Bz = b, \end{array}$$

so that, by [54, Thm. 28.2] (also using Assumption B(d)), there exists an optimal Lagrange multiplier vector $p^* \in \mathscr{R}^r$ associated with the constraints $Ax + Bz = b$. From the Kuhn-Tucker conditions for (3.2) we then have

$$\text{(3.3a)} \qquad A^T p^* \in R(x^*) + \partial f(x^*) + \partial \delta_{\mathscr{X}}(x^*),$$

$$\text{(3.3b)} \qquad B^T p^* \in S(z^*) + \partial g(z^*) + \partial \delta_{\mathscr{Z}}(z^*),$$

$$\text{(3.3c)} \qquad Ax^* + Bz^* = b.$$

Let $F: \mathscr{R}^n \to \mathscr{R}^n$ and $G: \mathscr{R}^m \to \mathscr{R}^m$ be the multifunctions given by, respectively,

$$\text{(3.4a)} \qquad F(x) = R(x) + \partial f(x) + \partial \delta_{\mathscr{X}}(x),$$

$$\text{(3.4b)} \qquad G(z) = S(z) + \partial g(z) + \partial \delta_{\mathscr{Z}}(z).$$

Then, we can write (3.3a)-(3.3c) equivalently as

$$\text{(3.5)} \qquad b \in AF^{-1}(A^T p^*) + BG^{-1}(B^T p^*).$$

Since both $\partial f + \partial \delta_{\mathscr{X}}$ and $\partial g + \partial \delta_{\mathscr{Z}}$ are maximal monotone (see Rockafellar [55]) and both R and S are monotone and continuous, it is easily seen that both F and G are maximal monotone. (In general, the sum of two maximal monotone operators need not be maximal monotone.) Since F is, in addition, strongly monotone with modulus σ [cf. Assumption B(b)], it then follows that the problem of finding a p^* satisfying (3.5) is a special case of (2.1), and moreover, parts (a) and (b) of Assumption A hold. By Assumption B(d), for each $c > 0$, the effective domain of the multifunction $p \to (G + cB^T B)^{-1} B^T p$ is all of $\mathscr{R}^r$, so that, by Lemma 1, $BG^{-1}B^T$ is maximal monotone. This shows that part (c) of Assumption A also holds.

Let us apply the splitting iteration (2.3a)-(2.3c) to the problem of finding a p^* satisfying (3.5). This generates a sequence of iterates $\{p(t)\}$, $\{x(t)\}$ and $\{z(t)\}$ according to the following iteration: Given $p(t)$, first compute an $x(t) \in \mathscr{X}$ satisfying

$$\text{(3.6a)} \qquad \langle x - x(t), R(x(t)) - A^T p(t)\rangle + f(x) - f(x(t)) \geqq 0, \quad \forall x \in \mathscr{X},$$

then compute a $z(t) \in \mathscr{Z}$ satisfying

$$\langle z - z(t), S(z(t)) - B^T(p(t) - c(t)(Ax(t) + Bz(t) - b))\rangle + g(z) - g(z(t)) \geqq 0, \quad \forall z \in \mathscr{Z}, \tag{3.6b}$$

and finally update the multiplier vector by

$$p(t+1) = p(t) + c(t)(b - Ax(t) - Bz(t)), \tag{3.6c}$$

where $c(t)$ is some positive stepsize. We leave the issue of computing $x(t)$ and $z(t)$ open. (Methods for computing $x(t)$ and $z(t)$ are discussed in [4], [10], [16], [22], [30], [49].)

Since Assumption A holds for (3.5), we immediately obtain from Proposition 1 the following proposition.

PROPOSITION 2. *The sequence of iterates* $\{x(t)\}$, $\{z(t)\}$, $\{p(t)\}$ *generated by* (3.6a)–(3.6c) *are well defined. If in addition* $\{c(t)\}$ *satisfies*

$$\varepsilon \leqq c(t) \leqq 2\sigma/\|A\|^2 - \varepsilon, \quad \forall t,$$

for some $\varepsilon \in (0, \sigma/\|A\|^2]$, *then the following hold*:

(a) $\{x(t)\} \to x^*$.

(b) $\{Bz(t)\} \to b - Ax^*$.

(c) $\{p(t)\} \to$ *a solution of* (3.5).

(d) *If either* $AF^{-1}A^T$ *or* $BG^{-1}B^T$ *is strongly monotone, where F and G are given by* (3.4a) *and* (3.4b), *respectively, then* $\{x(t)\}$, $\{Bz(t)\}$, $\{p(t)\}$ *converge at least linearly with a convergence ratio of* $\sqrt{(1-\delta^2\varepsilon^2)/(1+\eta^2\varepsilon^2)}$, *where* δ *and* η *denote the modulus of, respectively,* $AF^{-1}A^T$ *and* $BG^{-1}B^T$.

It was pointed out to us by the referee that the relationship between (3.1) and (3.5) also follows from a general duality framework studied by Gabay [19, § 3]. In particular, let $\mathscr{H}$ and $\mathscr{V}$ be two real Hilbert spaces, let Λ be a maximal monotone operator on $\mathscr{H}$, let $h: \mathscr{V} \to (-\infty, \infty]$ be a closed convex function, and let E be a continuous linear operator from $\mathscr{H}$ to $\mathscr{V}$. For each variational inequality of the form:

$$\text{Find } u \text{ such that } 0 \in \Lambda(u) + E'\partial h(Eu), \tag{3.7}$$

let us associate a dual variational inequality of the following form:

$$\text{Find } \lambda \text{ such that } 0 \in \Lambda_E^T(\lambda) + (\partial h)^{-1}(\lambda), \tag{3.8}$$

where $\Lambda_E^T(\lambda) = \{-Ev \mid -E'\lambda \in \Lambda(v)\} = -E\Lambda^{-1}(-E'\lambda)$. Gabay showed that, under the qualification condition

$$\text{there exists } u \in \text{int}\,(\mathscr{D}(\Lambda)) \text{ such that } Eu \in \text{dom}\,(h), \tag{3.9}$$

a vector u is a solution of (3.7) if and only if there exists a solution λ of (3.8) such that $-E'\lambda \in \Lambda(u)$ [19, Thm. 3.1]. Now, it is easily seen that (3.1) is a special case of (3.7) where h is the indicator function of $\{-b\}$, $\Lambda(x, z) = F(x) + G(z)$ with F and G given by (3.4a), (3.4b), respectively, and $E = [-A \;\; -B]$. Hence, we obtain from (3.8) that the corresponding dual variational inequality (in the sense of Gabay) is

$$\text{Find } \lambda \text{ such that } 0 \in AF^{-1}(A^T\lambda) + BG^{-1}(B^T\lambda) - b,$$

which is exactly (3.5). An important advantage of Gabay's duality result is that it applies to general maximal monotone operators. However, the qualification condition (3.9), when applied to (3.1), yields the condition: there exist $x \in \text{int}\,(\text{dom}\,(f) \cap \mathscr{X})$ and $z \in \text{int}\,(\text{dom}\,(g) \cap \mathscr{Z})$ satisfying $Ax + Bz = b$, which is stronger than our qualification condition, namely Assumption B(d).

4. Application to separable convex programming: the alternating minimization algorithm. Let us return to the separable convex program (1.1):

$$\text{(4.1)}\qquad \begin{aligned}&\text{minimize} && f(x)+g(z)\\ &\text{subject to} && Ax+Bz=b,\ x\in\mathscr{X},\ z\in\mathscr{Z},\end{aligned}$$

where $f:\mathscr{R}^n\to(-\infty,\infty]$, $g:\mathscr{R}^m\to(-\infty,\infty]$ are closed convex functions, A is an $r\times n$ matrix, B is an $r\times m$ matrix, and b is a vector in $\mathscr{R}^r$. In this section we will derive the alternating minimization algorithm for solving (4.1) by applying the iteration (3.6a)-(3.6c).

We make the following assumptions regarding (4.1).

Assumption C.

(a) f is strongly convex with modulus $\alpha>0$, i.e., for any $\lambda\in(0,1)$, there holds

$$\text{(4.2)}\quad \lambda f(x)+(1-\lambda)f(y)-f(\lambda x+(1-\lambda)y)\geqq\alpha\lambda(1-\lambda)\|x-y\|^2,\quad \forall x\in\mathscr{R}^n,\quad \forall y\in\mathscr{R}^n.$$

(b) The function $g(z)+\|Bz\|^2$ attains its minimum at some point in $\mathscr{Z}$.

(c) There exist $x\in\operatorname{ri}(\operatorname{dom}(f))\cap\mathscr{X}$ and $z\in\operatorname{ri}(\operatorname{dom}(g))\cap\mathscr{Z}$ satisfying $Ax+Bz=b$.

Assumption C(c) implies that the problem (4.1) is feasible. We claim that (4.1) in fact has an optimal solution. To see this, note that because f and g are closed and f is strongly convex, if (4.1) does not have an optimal solution, then there must exist z and w such that $Bw=0$ and $g(z+\lambda w)$ is strictly decreasing with $\lambda\geqq 0$—contradicting Assumption C(b). Moreover, the strict convexity of f implies that the x component of an optimal solution of (4.1) is *unique*, which we denote by x^*.

Notice that Assumption C(b) holds if either g has a minimizer or B has full column rank. If Assumption C(b) does not hold, but (4.1) has an optimal solution, then we can define the perturbation function $h(w)=\inf\{g(z)\,|\,w=Bz,\ z\in\mathscr{Z}\}$, which is proper convex. If in addition h is closed, we can instead solve the reduced problem $\min_{x,w}\{f(x)+h(w)\,|\,Ax+w=b\}$, which can be seen to satisfy parts (a) and (b) of Assumption C.

(4.1) is clearly a special case of the variational inequality problem (3.1). Furthermore, the strong convexity condition (4.2) implies that ∂f is strongly monotone with modulus 2α. Hence parts (a), (b), and (d) of Assumption B hold (with $\sigma=2\alpha$). Finally, by Assumption C(b), for any $p\in\mathscr{R}^r$ and $c>0$, the function $z\to g(z)-\langle p, Bz\rangle+c\|Bz\|^2/2$ attains its minimum at some point z. Then, z satisfies $B^Tp\in\partial g(z)+cB^TBz$, so part (b) of Assumption B holds.

By applying the iteration (3.6a)-(3.6c) to (4.1), we obtain the following algorithm, earlier named the alternating minimization algorithm, that generates a sequence of iterates $\{x(t)\}$, $\{z(t)\}$, $\{p(t)\}$ according to:

$$\text{(4.3a)}\qquad x(t)=\operatorname*{argmin}_{x\in\mathscr{X}}\{f(x)-\langle p(t), Ax\rangle\},$$

$$\text{(4.3b)}\qquad z(t)=\operatorname*{argmin}_{z\in\mathscr{Z}}\{g(z)-\langle p(t), Bz\rangle+c(t)\|Ax(t)+Bz-b\|^2/2\},$$

$$\text{(4.3c)}\qquad p(t+1)=p(t)+c(t)(b-Ax(t)-Bz(t)),$$

where each $c(t)$ is some positive stepsize. ($p(0)$ is arbitrarily chosen.)

Since Assumption B holds for this special case of (3.1), convergence of the above algorithm follows from Proposition 2.

PROPOSITION 3. *The sequences* $\{x(t)\}$, $\{z(t)\}$, $\{p(t)\}$ *generated by* (4.3a)-(4.3c) *are well defined. If in addition* $\{c(t)\}$ *satisfies*

$$\varepsilon \leqq c(t) \leqq 4\alpha/\|A\|^2 - \varepsilon, \quad \forall t,$$

for some $\varepsilon \in (0, 2\alpha/\|A\|^2]$, *then the following hold*:

(a) $\{x(t)\} \to x^*$.

(b) $\{Bz(t)\} \to b - Ax^*$.

(c) $\{p(t)\} \to$ *an optimal Lagrange multiplier vector associated with the constraints* $Ax + Bz = b$.

(d) *If either* $A(\partial f)^{-1}A^T$ *or* $B(\partial g)^{-1}B^T$ *is strongly monotone, then the rate of convergence of* $\{x(t)\}$, $\{Bz(t)\}$, $\{p(t)\}$ *is at least linear.*

(e) *If the convex function* $g(z) + \|Bz\|^2$ *has bounded level sets, then* $\{z(t)\}$ *is bounded and, for any of its limit points* z^∞, (x^*, z^∞) *is an optimal solution of* (4.1).

Proof. Parts (a)-(d) follow directly from Proposition 2. To prove part (e), let z^* be an element of $\mathscr{Z}$ which, together with x^*, forms an optimal solution of (4.1). Since $z(t) = \operatorname{argmin}_{z \in \mathscr{Z}} \{g(z) - \langle p(t+1), Bz\rangle\}$ for all t [cf. (4.3b)-(4.3c)], we then have that

$$g(z(t)) - \langle p(t+1), Bz(t)\rangle \leqq g(z^*) - \langle p(t+1), Bz^*\rangle, \quad \forall t.$$

Since $\{Bz(t)\} \to b - Ax^* = Bz^*$ and $\{p(t)\}$ is bounded [cf. parts (b) and (c)], this yields

$$\limsup_{t \to \infty} \{g(z(t))\} \leqq g(z^*). \tag{4.4}$$

Hence $g(z(t)) + \|Bz(t)\|^2$ is bounded and, by hypothesis, $\{z(t)\}$ is bounded. Since g is closed, (4.4) implies that each limit point of $\{z(t)\}$, say z^∞, satisfies $g(z^\infty) \leqq g(z^*)$. Since $Bz^\infty = b - Ax^*$ (cf. part (b)), then (x^*, z^∞) is feasible for (4.1) and its cost $f(x^*) + g(z^\infty)$ does not exceed $f(x^*) + g(z^*)$. This shows that (x^*, z^∞) is an optimal solution of (4.1). □

In practice, the threshold $4\alpha/\|A\|^2$ is typically unknown, and some trial and error may be required to select the sequence $c(t)$. This is a drawback of the alternating minimization algorithm.

Remark 1. Note that the hypothesis in Proposition 3(e) holds if B has full column rank or if g has bounded level sets. In practice, the latter can always be enforced by constraining z to be inside the ball $\{z \in \mathscr{R}^m \mid \|z\| \leqq \mu\}$ with μ taken to be a very large number. An example for which Proposition 3(d) applies is when $f(x) = \|x - d\|^2/2$ for some $d \in \mathscr{R}^n$ and A has full row rank. Straightforward calculation finds that $A(\partial f)^{-1}(A^T p) = AA^T p + Ad$ and hence $A(\partial f)^{-1}A^T$ is strongly monotone with a modulus equal to the smallest eigenvalue of AA^T.

Remark 2. In the special case where $A = -I$ and f is the indicator function for $\{0\}$, it can be seen that the alternating minimization algorithm reduces to the *method of multipliers* [27], [29], [53] (also see [3], [4], [36], [52], [56]) for minimizing $g(z)$ subject to $Bz = b$, i.e.,

$$z(t) = \operatorname{argmin}_z \{g(z) - \langle p(t), Bz\rangle + c(t)\|b - Bz\|^2/2\}, \quad p(t+1) = p(t) + c(t)(b - Bz(t)).$$

By Proposition 3 (and using the observation that the modulus of ∂f is "infinite"), if $\{c(t)\}$ is bounded away from zero, then both $\{Bz(t)\}$ and $\{p(t)\}$ converge.

Remark 3. In the special case where $B = -I$ and g is the indicator function for $\{0\}$, the alternating minimization algorithm can be seen to reduce to the dual gradient method discussed in § 1 for minimizing $f(x)$ subject to $Ax = b$, i.e.,

$$x(t) = \operatorname*{argmin}_x \{f(x) - \langle p(t), Ax\rangle\}, \qquad p(t+1) = p(t) + c(t)(b - Ax(t)).$$

By Proposition 3, if $\{c(t)\}$ is bounded strictly between zero and $4\alpha/\|A\|^2$, then both $\{x(t)\}$ and $\{p(t)\}$ converge. This method was first proposed by Uzawa [61] for the more general case where f is strictly convex, but no explicit bound on the stepsizes was given. Other discussions of this algorithm can be found in [3, § 2.6] and in [15], [31], [36], [52].

4.1 Minimization of a strongly convex function over the intersection of a finite collection of closed convex sets. Consider the following problem.

$$\text{(4.5)} \qquad \begin{aligned} &\text{minimize} && f(x) \\ &\text{subject to} && x \in \mathscr{X}_1 \cap \cdots \cap \mathscr{X}_k, \end{aligned}$$

where $f: \mathscr{R}^n \to \mathscr{R}$ is a strongly convex differentiable function (with modulus, say, α) and each $\mathscr{X}_i$ is a closed convex set in $\mathscr{R}^n$. This is a well studied problem in optimization. In particular, there has been proposed a number of algorithms for solving this problem based on the splitting idea (see Lions and Temam [35] and Temam [59]). In this section we show that the recent algorithm of Han and Lou [28] for solving this problem is a special case of the alternating minimization algorithm; hence, it also uses the splitting idea. Moreover, we will use Proposition 3 to improve the convergence results given by Han and Lou.

We make the following assumption regarding (4.5).

Assumption D. Either (a) ri $(\mathscr{X}_1) \cap \cdots \cap$ ri $(\mathscr{X}_k) \neq \varnothing$ or (b) $\mathscr{X}_1 \cap \cdots \cap \mathscr{X}_k \neq \varnothing$ and all $\mathscr{X}_i$'s are polyhedral sets.

Since $\mathscr{X}_1 \cap \cdots \cap \mathscr{X}_k \neq \varnothing$ by Assumption D and f has bounded level sets (since f is strongly convex), it follows that (4.5) has an optimal solution which, by the strict convexity of f, is unique. We will denote this optimal solution by x^*.

By introducing the auxiliary variables $z_1, z_2, \ldots, z_k$, we can transform (4.5) into the following form:

$$\text{(4.6)} \qquad \begin{aligned} &\text{minimize} && f(x) + g(z_1, \ldots, z_k) \\ &\text{subject to} && x = z_i, \qquad i = 1, \cdots, k, \end{aligned}$$

where $g: \mathscr{R}^{nk} \to (-\infty, \infty]$ is the indicator function for $\mathscr{X}_1 \times \cdots \times \mathscr{X}_k$, i.e.,

$$g(z_1, \cdots, z_k) = \sum_i \delta_{\mathscr{X}_i}(z_i).$$

The problem (4.6) is clearly a special case of (4.5) where f and g are as above, b is the zero vector in $\mathscr{R}^{nk}$, B is the negative of the $kn \times kn$ identity matrix, and A is the $kn \times n$ matrix composed of $kn \times n$ identity matrices stacked one on top of the next. Moreover, since f is strongly convex, part (a) of Assumption C holds. Since the function $(z_1, \cdots, z_k) \to g(z_1, \cdots, z_k) + \sum_i \|z_i\|^2$ has bounded level sets so that it attains its minimum at some point, part (b) of Assumption C also holds. Finally, since dom $(f) = \mathscr{R}^n$ and dom $(g) = \mathscr{X}_1 \times \cdots \times \mathscr{X}_k$, Assumption D implies that part (c) of Assumption C holds.

Motivated by the above observation, let us apply the alternating minimization algorithm to the problem (4.6). This produces the following iteration:

$$\text{(4.7a)} \qquad x(t) = \operatorname*{argmin}_x \left\{ f(x) - \sum_i \langle p_i(t), x \rangle \right\},$$

$$\text{(4.7b)} \qquad z_i(t) = \operatorname*{argmin}_{z_i \in \mathscr{X}_i} \{ \langle p_i(t), z_i \rangle + c(t) \|x(t) - z_i\|^2/2 \}, \qquad i = 1, \cdots, k,$$

$$\text{(4.7c)} \qquad p_i(t+1) = p_i(t) + c(t)(z_i(t) - x(t)), \qquad i = 1, \cdots, k,$$

where p_i ($i=1,\cdots,k$) is a Lagrange multiplier vector associated with the constraints $x=z_i$ and $c(t)$ is some positive stepsize. (The initial multipliers $p_i(0)$ are chosen arbitrarily.) Note that the iterations (4.7b)-(4.7c) are highly parallelizable, and the same is true for iteration (4.7a) if f is separable.

Since Assumption C holds for this special case of (4.1), convergence of the iterates generated by (4.7a)-(4.7c) follows from Proposition 3.

COROLLARY 1. *The sequences* $\{x(t)\}$, $\{z(t)\}$, $\{p(t)\}$ *generated by* (4.7a)-(4.7c) *are well defined. If in addition* $\{c(t)\}$ *satisfies*

$$\varepsilon \leqq c(t) \leqq 4\alpha/k-\varepsilon, \quad \forall t,$$

for some $\varepsilon \in (0, 2\alpha/k]$, *then the following hold*:

(a) $\{x(t)\} \to x^*$.

(b) $\{z_i(t)\} \to x^*$, for all i.

(c) $\{p_i(t)\} \to$ *an optimal Lagrange multiplier vector associated with the constraints* $x=z_i$ *in* (4.6), *for all i.*

To see the connection between the above algorithm and that of Han and Lou, let f^* denote the conjugate function of f [54], i.e., $f^*(y)=\sup_x \{\langle y, x\rangle - f(x)\}$ for all $y \in \mathcal{R}^n$. Since f is strongly convex, then f^* is differentiable everywhere, so that (4.7a) is equivalent to

$$x(t)=\nabla f^*\left(\sum_i p_i(t)\right). \tag{4.8a}$$

Also (4.7b) can be written equivalently as

$$z_i(t)=P_{\mathcal{X}_i}(x(t)-p_i(t)/c(t)), \qquad i=1,\cdots,k, \tag{4.8b}$$

where $P_{\mathcal{X}_i}(\cdot)$ denotes the orthogonal projection onto $\mathcal{X}_i$ in the norm $\|\cdot\|$. The iteration (4.8a)-(4.8b), (4.7c) can be seen to be *identical* to that in the Han and Lou algorithm. On the other hand, our results improve upon those obtained by Han and Lou since their algorithm further restricts $p_i(0)$ to be zero for all i and $c(t)$ to take on a fixed value inside $(0, 2\alpha/k]$ for all t. In addition, Corollary 3 asserts convergence of the iterates $\{x(t)\}$, $\{z_1(t)\}, \cdots, \{z_k(t)\}$, $\{p(t)\}$ without requiring $\mathcal{X}_1 \cap \cdots \cap \mathcal{X}_k$ to have a nonempty interior (compare with [28, Thm. 4.9]). We remark that a different extension of the Han and Lou algorithm which allows inexact minimization in (4.7a), (4.7b) was recently proposed by Mouallif, Nguyen, and Strodiot [44].

5. Application to linear complementarity problems. Let M be an $r \times r$ positive semidefinite (not necessarily symmetric) matrix, i.e., $\langle p, Mp\rangle \geqq 0$ for all p. Let w be a vector in $\mathcal{R}^r$. Consider the following problem associated with M and w:

$$\text{Find } p^* \in \mathcal{R}^r \text{ satisfying } Mp^*+w \geqq 0, p^* \geqq 0, \langle Mp^*+w, p^*\rangle = 0. \tag{5.1}$$

We assume that (5.1) has a solution. This problem, called the *linear complementarity problem* (LCP for short), is a fundamental problem in optimization (see [2], [9], [37], [45]).

One method for solving (5.1) is based on the notion of *matrix splitting*. In this method, we fix a *splitting* (J, K) of M [47], i.e.,

$$M=J+K. \tag{5.2}$$

At the tth iteration, we are given an iterate $p(t) \geqq 0$ ($p(0)$ is chosen arbitrarily); we choose a *relaxation* parameter $\omega(t)>0$ and then compute the next iterate $p(t+1)$

satisfying the following linear complementarity condition

$$(5.3\text{a})\qquad (\omega(t)I+K)p(t+1)-(\omega(t)I-J)p(t)+w\geqq 0, \qquad p(t+1)\geqq 0,$$

$$(5.3\text{b})\qquad \langle(\omega(t)I+K)p(t+1)-(\omega(t)I-J)p(t)+w, p(t+1)\rangle = 0.$$

(Note that, in the absence of the nonnegativity constraints, the iteration (3.5a)-(3.5b) reduces to the iteration $(\omega(t)I+K)p(t+1)=(\omega(t)I-J)p(t)-w$, which is well known in numerical analysis (see [47]).)

Convergence of the iterates $p(t)$ generated by the matrix splitting iteration (5.3a)-(5.3b) has been well studied (see [33], [37], [48]). However, convergence typically requires that the solution is unique (in addition to other assumptions on the problem and on the matrix splitting), which does not necessarily hold for the problem (5.1). Below we apply the iteration (3.6a)-(3.6c) to the problem (5.1) to obtain a (new) splitting (J, K) of M for which the iterates generated by (5.3a)-(5.3b) *converge to a solution of* (5.1). To the best of our knowledge, this is the first matrix splitting algorithm that is provably convergent on problems having possibly multiple solutions.

PROPOSITION 4. *Let J and K be matrices satisfying* (5.2) *and suppose that*

$$(5.4\text{a})\qquad J=APA^T,$$

for some $n\times n$ $(n\leqq r)$ *positive definite* matrix P and some $r\times n$ matrix A, and

$$(5.4\text{b})\qquad K=CQC^T,$$

for some $m\times m$ $(m\leqq r)$ *positive definite* matrix Q and some $r\times m$ matrix C. If $1/\omega(t)$ is bounded strictly between zero and $2\sigma/\|A\|^2$ for all t, where σ is the smallest eigenvalue of $((P^{-1})^T+P^{-1})/2$, then $\{p(t)\}$ generated by (5.3a)-(5.3b) is well defined and converges to a solution of (5.1). If, in addition, J is positive definite, then the rate of convergence is at least linear.

Proof. The basic idea of the proof is to use (5.4a)-(5.4b) to convert (5.1) into a special case of (3.1). Then, we show that (3.6a)-(3.6c) applied to this special case is identical to (5.3a)-(5.3b).

First, we introduce a slack variable $s=Mp+w$ so that (5.1) can be written equivalently as

$$\text{Find } p^* \text{ and } s^* \text{ such that } Mp^*-s^*=-w,\ s^*\geqq 0,\ p^*\geqq 0,\ \langle s^*, p^*\rangle = 0.$$

By using the observation that the set of conditions $s\geqq 0$, $p\geqq 0$, $\langle s, p\rangle=0$ is equivalent to $-p\in\partial\delta(s)$, where δ is the indicator function for the nonnegative orthant in $\mathcal{R}^r$, we obtain, upon using (5.4a)-(5.4b), that the above problem is equivalent to

$$\text{Find } p^* \text{ and } s^* \text{ such that } APA^Tp^*+CQC^Tp^*-s^*=-w, \qquad 0\in\partial\delta(s^*)+p^*.$$

By introducing the auxiliary variables $x=PA^Tp$ and $u=QC^Tp$, we can write the above problem as

$$(5.5)\qquad \begin{aligned}&\text{Find } p^*,\ s^*,\ x^* \text{ and } u^* \text{ such that } Ax^*+Cu^*-s^*=-w,\\ &-p^*\in\partial\delta(s^*),\quad A^Tp^*=P^{-1}x^*,\quad C^Tp^*=Q^{-1}u^*,\end{aligned}$$

which in turn is equivalent to the following variational inequality problem:

$$(5.6)\qquad \begin{aligned}&\text{Find } (x^*, u^*, s^*) \text{ such that } Ax^*+Cu^*-s^*=-w,\ s^*\geqq 0, \text{ and}\\ &\langle x-x^*, P^{-1}x^*\rangle+\langle u-u^*, Q^{-1}z^*\rangle\geqq 0,\\ &\text{for all } (x, u, s) \text{ satisfying } Ax+Cu-s=-w,\ s\geqq 0.\end{aligned}$$

Hence, (5.6) has a solution, and any solution of (5.1) is an optimal Lagrange multiplier vector associated with the constraints $Ax+Cu-s=-w$.

By comparing (5.6) with (3.1), we see that (5.6) is a special case of (3.1) with A as above and with $B=[C\ -I]$, $b=-w$, $R(x)=P^{-1}x$, $S(u,s)=Q^{-1}u$, $f(x)=0$, $g(u,s)=0$, $\mathscr{X}=\mathscr{R}^n$, and $\mathscr{Z}=\mathscr{R}^m\times[0,\infty)^r$. Moreover, since (5.6) has a solution and its constraint set is polyhedral, parts (a) and (d) of Assumption B hold. Since P is positive definite, then the operator $x\to P^{-1}x$ is maximal strongly monotone (with modulus equal to the smallest eigenvalue of $((P^{-1})^T+P^{-1})/2$) and part (b) of Assumption B holds. Finally, for each $c>0$, we have from the positive definite property of Q that $\langle u, Q^{-1}u\rangle + c\|Cu-s\|^2>0$ for all $(u,s)\neq 0$. This implies that, for each $c>0$, the operator $(u,s)\to(Q^{-1}u, \partial\delta(s))+c(C^TCu-C^Ts, -Cu+s)$ is maximal strongly monotone, so that it is surjective (cf. [5, Corollary 2.4]) and part (c) of Assumption B holds.

Let us apply the iteration (3.6a)-(3.6c), with $c(t)=1/\omega(t)$, to this special case of (3.1). This generates a sequence of iterates $\{x(t)\}$, $\{u(t)\}$, $\{s(t)\}$, $\{p(t)\}$ satisfying $p(t)\geqq 0$, $s(t)\geqq 0$, and

$$\langle x-x(t), P^{-1}x(t)-A^Tp(t)\rangle\geqq 0, \quad \forall x\in\mathscr{R}^n,$$

$$\langle u-u(t), Q^{-1}u(t)-C^T(p(t)-(Ax(t)+Cu(t)-s(t)-b)/\omega(t))\rangle$$
$$+\langle s-s(t), p(t)-(Ax(t)+Cu(t)-s(t)-b)/\omega(t)\rangle\geqq 0, \quad \forall u\in\mathscr{R}^m, \quad \forall s\in[0,\infty)^r,$$

$$p(t+1)=p(t)+(b-Ax(t)-Cu(t)+s(t))/\omega(t),$$

which can be seen as equivalent to

$$0=P^{-1}x(t)-A^Tp(t), \tag{5.7a}$$

$$0=Q^{-1}u(t)-C^Tp(t+1), \tag{5.7b}$$

$$p(t+1)\geqq 0, s(t)\geqq 0, \langle p(t+1), s(t)\rangle=0, \tag{5.7c}$$

$$p(t+1)=p(t)+(b-Ax(t)-Cu(t)+s(t))/\omega(t). \tag{5.7d}$$

Now the conditions (5.7a), (5.7b) are equivalent to, respectively,

$$x(t)=PA^Tp(t), \qquad u(t)=QC^Tp(t+1),$$

which, when combined with (5.7c) and (5.7d), yield

$$(I+CQC^T/\omega(t))p(t+1)-(I-APA^T/\omega(t))p(t)-b/\omega(t)=s(t)/\omega(t)\geqq 0,$$
$$p(t+1)\geqq 0, \langle p(t+1), s(t)\rangle=0.$$

By (5.4a)-(5.4b), the above iteration is exactly (5.3a)-(5.3b). Moreover, Proposition 2(c) shows that $\{p(t)\}$ is well defined and converges to a solution of (5.1). If in addition $J=APA^T$ is positive definite, then Proposition 2(d) shows that $\{p(t)\}$ converges at least linearly. □

Notice that if J is *symmetric* positive semidefinite, then J can always be factored as $J=APA^T$ for some positive definite diagonal matrix P and some matrix A with orthonormal columns (see [21], [47]), so that (5.4a) holds automatically and, in addition, it can be seen that $\sigma=1/\|J\|$ and $\|A\|=1$. If K is *symmetric* positive semidefinite, then by the same argument (5.4b) holds automatically. In this case, the iteration (5.3a)-(5.3b) can be carried out by minimizing a convex quadratic function over the nonnegative orthant. If K is not symmetric but is, say, tridiagonal, then a direct method such as that described in [8] may be used.

To illustrate some of the advantages of the above matrix splitting, suppose that M is of the form

$$M=DPD^T+EQE^T,$$

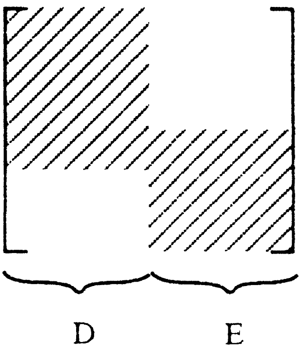

FIG. 1(a). *The matrix* $[D\ \ E]$ *has a staircase structure.*

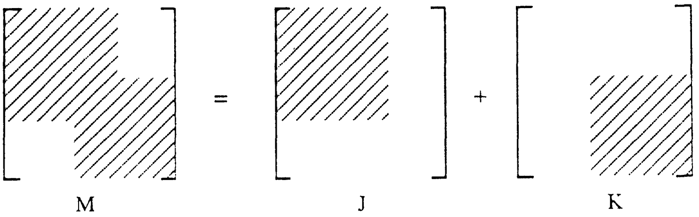

FIG. 1(b). *The matrix M decomposes into the sum of an upper block diagonal matrix J and a lower block diagonal matrix K.*

where P and Q are positive definite diagonal matrices and D and E are matrices of appropriate dimension (such form arises in, for example, quadratic programs with strictly convex separable costs and linear inequality constraints). Suppose that we choose $J=DPD^T$ and $K=EQE^T$. Then, if the matrix $[D\ \ E]$ has the staircase structure shown in Fig. 1(a), the matrices J and K would have, respectively, the upper and lower block diagonal form shown in Fig. 1(b). In this case the problem (5.3a)-(5.3b) is significantly smaller in dimension than the original problem (5.1).

Appendix A. In this appendix we prove Proposition 1. Let p^* be any solution of (2.1). Then, by (2.2),

(A.1a) $$x^*\in\Phi(A'p^*),$$

and there exists some $z^*\in\mathcal{W}$ satisfying

(A.1b) $$z^*\in\Gamma(B'p^*),$$

(A.1c) $$Ax^*+Bz^*=b.$$

From (2.3a)-(2.3c) we also have that, for all t, there holds

(A.2a) $$x(t)\in\Phi(A'p(t)),$$

(A.2b) $$z(t)\in\Gamma(B'p(t+1)).$$

Fix any integer $t\geqq 0$ and, for convenience, let $c=c(t)$. Since $A'p^*\in\Phi^{-1}(x^*)$ and $A'p(t)\in\Phi^{-1}(x(t))$ [cf. (A.1a) and (A.2a)], we have (also using Assumption A(b)) that

$$\begin{aligned}0&=\langle A'p(t)-A'p^*, x(t)-x^*\rangle-\langle A'p(t)-A'p^*, x(t)-x^*\rangle\\&\geqq\sigma\|x(t)-x^*\|^2-\langle p(t)-p^*, Ax(t)-Ax^*\rangle\\&=c\langle Ax(t)-Ax^*, Ax(t)-Ax^*\rangle-\langle p(t)-p^*, Ax(t)-Ax^*\rangle\\&\quad-c\|Ax(t)-Ax^*\|^2+\sigma\|x(t)-x^*\|^2.\end{aligned}$$

Let $\theta=-c\|Ax(t)-Ax^*\|^2+\sigma\|x(t)-x^*\|^2$. The above relation then implies

$$\begin{aligned}0&\geqq\langle -p(t)+c(Ax(t)+Bz(t)-b)+p^*, Ax(t)-Ax^*\rangle\\ &\quad -c\langle Bz(t)-Bz^*, Ax(t)-Ax^*\rangle+\theta\\ &=\langle -\hat{p}(t+1), Ax(t)-Ax^*\rangle-c\langle B\hat{z}(t), A\hat{x}(t)\rangle+\theta,\end{aligned}\tag{A.3}$$

where we let $\hat{x}(t)=x(t)-x^*$, $\hat{z}(t)=z(t)-z^*$, $\hat{p}(t+1)=p(t+1)-p^*$, and the equality follows from (2.3c). Similarly, since $z^*\in\Gamma(B'p^*)$ and $z(t)\in\Gamma(B'p(t+1))$ [cf. (A.1b) and (A.2b)], we have from the monotone property of Γ that

$$\begin{aligned}0&=\langle B'p(t+1)-B'p^*, z(t)-z^*\rangle-\langle B'p(t+1)-B'p^*, z(t)-z^*\rangle\\ &\geqq-\langle p(t+1)-p^*, Bz(t)-Bz^*\rangle\\ &=\langle -\hat{p}(t+1), Bz(t)-Bz^*\rangle.\end{aligned}\tag{A.4}$$

Summing (A.3)-(A.4) and using the fact $Ax^*+Bz^*=b$ (cf. (A.1c)), we obtain

$$\begin{aligned}0&\geqq\langle -\hat{p}(t+1), Ax(t)+Bz(t)-b\rangle-c\langle B\hat{z}(t), A\hat{x}(t)\rangle+\theta\\ &=\langle \hat{p}(t+1), \hat{p}(t+1)-\hat{p}(t)\rangle/c-c\langle B\hat{z}(t), A\hat{x}(t)\rangle+\theta,\end{aligned}$$

where $\hat{p}(t)=p(t)-p^*$ and the equality follows from (2.3c). This, together with the identities (cf. (2.3c))

$$\begin{aligned}2\langle \hat{p}(t+1), \hat{p}(t+1)-\hat{p}(t)\rangle&=\|\hat{p}(t+1)-\hat{p}(t)\|^2+\|\hat{p}(t+1)\|^2-\|\hat{p}(t)\|^2,\\ \|\hat{p}(t+1)-\hat{p}(t)\|^2/c^2&=\|A\hat{x}(t)\|^2+\|B\hat{z}(t)\|^2+2\langle B\hat{z}(t), A\hat{x}(t)\rangle,\end{aligned}$$

implies that

$$0\geqq\|\hat{p}(t+1)\|^2-\|\hat{p}(t)\|^2+c^2\|A\hat{x}(t)\|^2+c^2\|B\hat{z}(t)\|^2+2c\theta,$$

so that, by the definition of c and θ, there holds

$$\begin{aligned}\|\hat{p}(t)\|^2&\geqq\|\hat{p}(t+1)\|^2-c(t)^2\|A\hat{x}(t)\|^2+2c(t)\sigma\|\hat{x}(t)\|^2+c(t)^2\|B\hat{z}(t)\|^2\\ &\geqq\|\hat{p}(t+1)\|^2+c(t)(2\sigma-c(t)\|A\|^2)\|\hat{x}(t)\|^2+c(t)^2\|B\hat{z}(t)\|^2.\end{aligned}$$

Since the choice of t and p^* was arbitrary and, by (2.6), both $2\sigma/\|A\|^2-c(t)$ and $c(t)$ are bounded away from ε, we obtain that, for any solution p^* of (2.1), there holds

$$\|p(t)-p^*\|^2\geqq\|p(t+1)-p^*\|^2+\varepsilon^2\|A\|^2\|x(t)-x^*\|^2+\varepsilon^2\|Bz(t)+Ax^*-b\|^2,\quad\forall t.\tag{A.5}$$

Equation (A.5) shows that $\{p(t)\}$ is bounded and $\sum_{t=0}^{\infty}\|x(t)-x^*\|^2<\infty$, $\sum_{t=0}^{\infty}\|Bz(t)+Ax^*-b\|^2<\infty$, so that

$$\{x(t)\}\to x^*\text{ strongly},\qquad \{Bz(t)\}\to b-Ax^*\text{ strongly}.\tag{A.6}$$

This proves parts (a) and (b).

To prove part (c), note that since (cf. (A.2b))

$$Bz(t)\in B\Gamma(B'p(t+1)),\quad\forall t,$$

and $B\Gamma B'$ is maximal monotone, we have from (A.6) and the limit property for maximal monotone operators (e.g., [5, Prop. 2.5]) that, if p^∞ is any weak limit point of $\{p(t)\}$, then

$$b-Ax^*\in B\Gamma(B'p^\infty).$$

Similarly, we have from (A.2a), (A.6) and the maximal monotone property of $A\Phi A'$ (cf. [19, Prop. 4.1] and the maximal strong monotone property of Φ^{-1}) that

$$Ax^*\in A\Phi(A'p^\infty).$$

Hence, $b \in A\Phi(A'p^\infty)+B\Gamma(B'p^\infty)$ and p^∞ solves (2.1). Then, by using an argument given in [57, proof of Thm. 1] (attributed to Martinet [39]), we obtain that this weak limit point p^∞ is unique. For completeness we give the argument here. Suppose that $\{p(t)\}$ has two weak limit points, say p_1^∞ and p_2^∞. Then, both p_1^∞ and p_2^∞ are solutions of (2.1), so that each can play the role of p^* in (A.5), and we obtain the existence of the limits.

$$\lim_{t\to\infty} \|p(t)-p_k^\infty\| = \mu_k < \infty, \qquad k=1,2.$$

By writing

$$\|p(t)-p_2^\infty\|^2 = \|p(t)-p_2^\infty\|^2 + 2\langle p(t)-p_1^\infty, p_1^\infty - p_2^\infty\rangle + \|p_1^\infty - p_2^\infty\|^2,$$

we see that the limit of $\{\langle p(t)-p_1^\infty, p_1^\infty-p_2^\infty\rangle\}$ must also exist and

$$2\lim_{t\to\infty}\langle p(t)-p_1^\infty, p_1^\infty-p_2^\infty\rangle = (\mu_2)^2-(\mu_1)^2-\|p_1^\infty-p_2^\infty\|^2.$$

Since p_1^∞ is a weak limit point of $\{p(t)\}$, this limit cannot be different from 0. Hence

$$(\mu_2)^2-(\mu_1)^2 = \|p_1^\infty-p_2^\infty\|^2 > 0.$$

By an analogous argument with p_1^∞ and p_2^∞ reversed in role, we also obtain $(\mu_1)^2-(u_2)^2 > 0$. This is a contradiction and hence p^∞ is unique.

Finally we prove part (d). Let p^* be a solution of (2.1). (p^* is unique since $A\Phi A' + B\Gamma B'$ is strongly monotone.) From (A.1a)-(A.1b) and (A.2a)-(A.2b) we have that

$$Ax^* \in A\Phi(A'p^*), \qquad b - Ax^* \in B\Gamma(B'p^*),$$

$$Ax(t) \in A\Phi(A'p(t)), \qquad Bz(t) \in B\Gamma(B'p(t+1)), \quad \forall t.$$

Fix any integer $t \geqq 0$. Since δ and η are the moduli of $A\Phi A'$ and $B\Gamma B'$, respectively, the above relation implies that

$$\langle Ax(t)-Ax^*, p(t)-p^*\rangle \geqq \delta\|p(t)-p^*\|^2,$$

$$\langle Bz(t)+Ax^*-b, p(t+1)-p^*\rangle \geqq \eta\|p(t+1)-p^*\|^2,$$

and hence, by the Cauchy-Schwarz inequality,

$$\|Ax(t)-Ax^*\| \geqq \delta\|p(t)-p^*\|,$$

$$\|Bz(t)+Ax^*-b\| \geqq \eta\|p(t+1)-p^*\|.$$

This together with (A.5) yields

$$\|p(t)-p^*\|^2 \geqq \|p(t+1)-p^*\|^2 + \varepsilon^2\delta^2\|p(t)-p^*\|^2 + \varepsilon^2\eta^2\|p(t+1)-p^*\|^2,$$

so that (since either δ or η is positive) $\|p(t)-p^*\|^2$ converges to zero at least linearly with a convergence ratio of $(1-\varepsilon^2\delta^2)/(1+\varepsilon^2\eta^2)$. Since we also have from (A.5) that

$$\|p(t)-p^*\|^2 \geqq \varepsilon^2\|A\|^2\|x(t)-x^*\|^2 + \varepsilon^2\|Bz(t)+Ax^*-b\|^2,$$

so that both $\|x(t)-x^*\|$ and $\|Bz(t)+Ax^*-b\|$ are upper bounded by some constant times $\|p(t)-p^*\|$, then part (d) follows. (Note that, in this case, $\{p(t)\}$ converges in the strong topology.) □

Acknowledgments. Thanks are due to D. P. Bertsekas and J. Eckstein for their many insightful comments. I am particularly indebted to the former for introducing me to this general area. Thanks are also due to an anonymous referee whose comments led to many improvements in the paper.

ON THE LINEAR QUADRATIC GAUSSIAN PROBLEM WITH CORRELATED NOISE AND ITS RELATION TO MINIMUM VARIANCE CONTROL*

R. H. KWONG†

Abstract. The linear quadratic Gaussian (LQG) stochastic control problem with correlated dynamic and observation noise and no information delay is studied. An explicit feedback solution is given for finite as well as infinite time problems. These results are then applied to minimum variance control of single-input single-output ARMAX systems. The LQG controller and the minimum variance controller obtained using input–output methods are shown to be identical for any system delay, extending a result of [5].

Key words. LQG stochastic control, correlated noise, minimum variance control, ARMAX systems, certainty equivalence

AMS(MOS) subject classifications. 93E11, 93E20

1. Introduction. The linear quadratic Gaussian (LQG) problem has been extensively discussed in the literature [2], [4], [6], [7], [14]. The standard formulation of the problem assumes either that the dynamic and the observation noise processes are uncorrelated, or that the control at time k is a function of the observations up to time $k-1$. There does not seem to be an explicit solution published for the problem in which the dynamic and observation noise processes were correlated, and that the control at time k is allowed to depend on observations up to time k. This problem we shall henceforth refer to as the general LQG problem. The only result previously published known to this author is given in [4]. However, this reference treats the special case in which the quadratic cost does not have any terms involving the state, except for the terminal penalty. Furthermore, the system matrix is assumed to be invertible, and the solution given is not explicitly in feedback form. The method of introducing output feedback and a new dynamic noise process uncorrelated with the observation noise is mentioned in [14]. However, no explicit solution is given.

The presence of this gap in the LQG theory is rather surprising in that one of the standard problems in stochastic control, minimum variance control for ARMAX systems, when the ARMAX system is described in the innovations form [6], [7], is a problem of this type. There exists a large body of literature on minimum variance control of ARMAX systems [2], [8], [9], [13], [17]. Many results for multivariable systems, minimum and nonminimum phase systems, as well as systems with general cost weightings have been developed. These results have been further extended to treat self-tuning control problems [3], [10]. Many successful applications of this control scheme have also been documented [2], [11]. However, most of these treatments use an input–output polynomial matrix approach. The connection between the LQG problem formulated in state space form and that formulated in input–output form does not seem to have been a topic of specific concern in these papers, and has not been explicitly considered. In fact, there appears to have been some doubt expressed in the literature [19] as to whether or not linear regulator design based on the innovations state space model for ARMAX systems will lead to the same optimal control law as that obtained using an input–output polynomial approach. In [5], such an explicit

connection between polynomial and state space formulations of minimum variance control was explored. However, that result was not obtained using a control gain derived from the solution of a Riccati equation, so that strictly speaking, it did not fully map the connections between state space LQG theory and polynomial minimum variance control. Moreover, the treatment is restricted to only the unit delay case.

In this paper, we solve the general LQG problem and explore extensions and applications of these results. In § 2, we formulate the stochastic control problem and point out the complications introduced by the correlation between the dynamic and observation noise. In § 3, we solve the stochastic control problem over a finite time interval, giving the optimal control law in feedback form. The result is given a certainty equivalence interpretation using an augmented state. The structure of the optimal control allows for easy extension to infinite time problems. In particular, the steady state version of the finite time control law is shown to be optimal for the average cost per unit time problem. These results are then applied to the minimum variance control problem for scalar ARMAX systems in § 4. We prove the "folk theorem" that the state space LQG theory gives the identical control law as the usual polynomial approach, for any delay $d \geqq 1$. As far as we know, this is the first complete proof of this folk theorem in the general delay case, extending the results of [5]. Section 5 contains the concluding remarks.

2. The general LQG problem. We begin by stating some well-known results from LQG theory, [6], [7], mainly to establish notation.

Consider the linear stochastic system

$$x_{k+1} = A_k x_k + B_k u_k + C_k w_k, \qquad x_{k_0} = x_0 \tag{2.1a}$$

$$y_k = H_k x_k + e_k; \tag{2.1b}$$

w_k is assumed to be zero mean normalized Gaussian white noise, i.e., $E w_k w_j^T = I\delta_{kj}$, where δ_{kj} is the Kronecker delta function: $\delta_{kj} = 1$ if $k = j$, 0 otherwise. e_k is assumed to be zero mean Gaussian white noise with $E e_k e_j^T = R_k \delta_{kj}$. w_k and e_k are allowed to be correlated with $E e_k w_j^T = G_k \delta_{kj}$. The initial state x_0 is a Gaussian random variable independent of w_k and e_k, with mean m_0 and covariance Σ_0. R_k is assumed to satisfy $R_k \geqq \delta I$, some $\delta > 0$. The control u_k is allowed to take the form $u_k = \phi_k(y^k)$ where $y^k = \{y_{k_0}, y_{k_0+1}, \cdots, y_k\}$. The objective of control is to find, in the class of admissible control laws, the one that minimizes

$$J = E\left\{ x_N^T Q x_N + \sum_{k=k_0}^{N-1} \|D_k x_k + F_k u_k\|^2 \right\} \tag{2.2}$$

where $Q \geqq 0$ and $\|x\|$ denotes the Euclidean vector norm $(x^T x)^{1/2}$. It is well-known [6], [7], that the conditional means $\hat{x}_{k/k-1} = E(x_k/y^{k-1})$ and $\hat{x}_{k/k} = E(x_k/y^k)$ are generated by the following Kalman filtering equations

$$\hat{x}_{k/k} = \hat{x}_{k/k-1} + P_k H_k^T (H_k P_k H_k^T + R_k)^{-1} \nu_k \tag{2.3a}$$

$$\hat{x}_{k+1/k} = A_k \hat{x}_{k/k} + B_k u_k + C_k G_k^T (H_k P_k H_k^T + R_k)^{-1} \nu_k \tag{2.3b}$$

$$\hat{x}_{k_0/k_0-1} = m_0 \tag{2.3c}$$

$$\nu_k = y_k - H_k \hat{x}_{k/k-1}. \tag{2.3d}$$

The innovations process ν_k is known to be a white noise process [6], [7]. For notational convenience, we write

$$\Lambda_k = H_k P_k H_k^T + R_k \tag{2.4}$$

and

$$K_k=(A_kP_kH_k^T+C_kG_k^T)\Lambda_k^{-1}. \tag{2.5}$$

The error covariance $P_k=E[(x_k-\hat{x}_{k/k-1})(x_k-\hat{x}_{k/k-1})^T]$ satisfies the filtering Riccati difference equation

$$P_{k+1}=A_kP_kA_k^T+C_kC_k^T-K_k\Lambda_kK_k^T \tag{2.6a}$$

$$P_{k_0}=\Sigma_0. \tag{2.6b}$$

It is also well known [6], [7] that if admissible control laws are restricted to be of the form $u_k=\phi_k(y^{k-1})$, so that there is a one-step information delay, the optimal control law is given by

$$u_k=-(B_k^TS_{k+1}B_k+F_k^TF_k)^{-1}(B_k^TS_{k+1}A_k+F_k^TD_k)\hat{x}_{k/k-1} \tag{2.7}$$

where S_k satisfies the control Riccati difference equation

$$S_k=A_k^TS_{k+1}A_k+D_k^TD_k-L_k^T\Gamma_kL_k \tag{2.8a}$$

$$S_N=Q \tag{2.8b}$$

with

$$\Gamma_k=B_k^TS_{k+1}B_k+F_k^TF_k \tag{2.9}$$

assumed to be invertible for all k (guaranteed, for example, if $F_k^TF_k\geqq\delta I$ for some $\delta>0$) and

$$L_k=\Gamma_k^{-1}(B_k^TS_{k+1}A_k+F_k^TD_k). \tag{2.10}$$

The above result does not require any conditions on the product $C_kG_k^T$ and is one standard formulation of the certainty equivalence principle. On the other hand, if u_k is allowed to be of the form $\phi_k(y^k)$ but with $C_kG_k^T=0$, then the optimal control law is given by

$$u_k=-L_k\hat{x}_{k/k}. \tag{2.11}$$

This is the standard formulation of the certainty equivalence principle for the case of no information delay [4], [14].

If the system matrices are constant, and the criterion is

$$J_{av}=\lim_{N\to\infty}\frac{1}{N}E\sum_{k=0}^{N-1}\|Dx_k+Fu_k\|^2 \tag{2.12}$$

under the appropriate structural assumptions of stabilizability and detectability, the steady-state versions of (2.7) and (2.11) are again optimal for the one-step observation delay and no delay cases, respectively, [6], [7], [14].

However, in the general case, where $C_kG_k^T\neq 0$ and $u_k=\phi_k(y^k)$, the control law (2.11) will not be optimal. This is illustrated by the following simple example, using the criterion J_{av}.

$$x_{k+1}=u_k+cw_k \qquad |c|<1$$

$$y_k=x_k+w_k.$$

The criterion is

$$J_{av}=\lim_{N\to\infty}\frac{1}{N}E\sum_{k=0}^{N-1}x_k^2.$$

For the standard form of certainty equivalence control (2.11), the steady-state version yields $u_k = 0$, resulting in $J_{av} = c^2$. However, the optimal control law is in fact $u_k = -cy_k$, resulting in $x_{k+1} = -cx_k$ and $J_{av} = 0$.

Let us look at the standard approach [6], [7], [14] to derive the optimal control law in the partial observations case. It involves reformulating the partial observations problem into a perfect observations problem using the optimal estimate as the new state. Since there is no information delay, we expect that $\hat{x}_{k/k}$ should be involved. If we write a state equation for $\hat{x}_{k/k}$, from (2.3a, (2.3b) we get

$$\hat{x}_{k+1/k+1} = A_k\hat{x}_{k/k} + B_k u_k + C_k G_k^T \Lambda_k^{-1} \nu_k + P_{k+1} H_{k+1}^T \Lambda_{k+1}^{-1} \nu_{k+1}. \tag{2.13}$$

The noise process on the right-hand side of (2.13) is, however, not white. This is why the standard equivalence control law is not directly applicable here.

3. Explicit feedback solution of the general LQG problem. Even though in (2.13) we do not get a standard state space model with white noise input for the process $\hat{x}_{k/k}$, it does suggest the approach to solving the problem. Consider the augmented state $\xi_k = [\hat{x}_{k/k}^T \quad \nu_k^T]^T$. The process ξ_k satisfies the equation

$$\xi_{k+1} = \begin{bmatrix} A_k & C_k G_k^T \Lambda_k^{-1} \\ 0 & 0 \end{bmatrix} \xi_k + \begin{bmatrix} B_k \\ 0 \end{bmatrix} u_k + \begin{bmatrix} P_{k+1} H_{k+1}^T \Lambda_{k+1}^{-1} \\ I \end{bmatrix} \nu_{k+1}. \tag{3.1}$$

If we now define the matrices

$$\bar{A}_k = \begin{bmatrix} A_k & C_k G_k^T \Lambda_k^{-1} \\ 0 & 0 \end{bmatrix}$$

$$\bar{B}_k = \begin{bmatrix} B_k \\ 0 \end{bmatrix}$$

$$\bar{C}_k = \begin{bmatrix} P_{k+1} H_{k+1}^T \Lambda_{k+1}^{-1} \\ I \end{bmatrix}$$

then ξ_k satisfies the standard state equation with white noise input ν_{k+1}

$$\xi_{k+1} = \bar{A}_k \xi_k + \bar{B}_k u_k + \bar{C}_k \nu_{k+1}. \tag{3.2}$$

Observe that ξ_k is known given y^k.

We can now follow [6], [7], [14] to transform the quadratic cost criterion in terms of the observed state process ξ_k and u_k as follows:

$$J = E\left[\hat{x}_{N/N}^T Q \hat{x}_{N/N} + \sum_{k=k_0}^{N-1} \|D_k \hat{x}_{k/k} + F_k u_k\|^2\right] + \operatorname{tr}\left(Q P_{N/N} + \sum_{k=k_0}^{N-1} D_k P_{k/k} D_k^T\right) \tag{3.3}$$

where $P_{k/k} = E(x_k - \hat{x}_{k/k})(x_k - \hat{x}_{k/k})^T$ is related to P_k by

$$P_{k/k} = P_k - P_k H_k^T \Lambda_k^{-1} H_k P_k. \tag{3.4}$$

Note that the last two terms of (3.3) are independent of u_k. Hence by defining $\bar{D}_k = [D_k \quad 0]$, $\bar{Q} = \left[\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}\right]$, we see that minimizing J is equivalent to minimizing $\bar{J}$

$$\bar{J} = E\left[\xi_N^T \bar{Q} \xi_N + \sum_{k=k_0}^{N-1} \|\bar{D}_k \xi_k + F_k u_k\|^2\right]. \tag{3.5}$$

The following result, solving the general LQG problem over a finite time interval, may now be stated.

THEOREM 1. *The optimal control law for the general* LQG *problem in the class of control laws of the form* $u_k = \phi_k(y^k)$ *is given by*

$$u_k = -(B_k^T S_{k+1} B_k + F_k^T F_k)^{-1}[(B_k^T S_{k+1} A_k + F_k^T D_k)\hat{x}_{k/k} + B_k^T S_{k+1} C_k G_k^T (H_k P_k H_k^T + R_k)^{-1} \nu_k]. \tag{3.6}$$

Equivalently, the optimal control law can also be written as

$$u_k = -L_k \hat{x}_{k/k-1} - (L_k P_k H_k^T + \Gamma_k^{-1} B_k^T S_{k+1} C_k G_k^T)\Lambda_k^{-1} \nu_k \tag{3.7a}$$

or

$$u_k = -L_k \hat{x}_{k/k} - \Gamma_k^{-1} B_k^T S_{k+1} C_k G_k^T R_k^{-1}(y_k - H\hat{x}_{k/k}) \tag{3.7b}$$

where Γ_k *and* L_k *are defined in* (2.9) *and* (2.10), *respectively.*

Proof. It follows from (3.2) and (3.5) and the standard LQG theory for perfect state observations [6], [7], [14] that the optimal control law is given by

$$u_k = -(\bar{B}_k^T \bar{S}_{k+1} \bar{B}_k + F_k^T F_k)^{-1}[\bar{B}_k^T \bar{S}_{k+1} \bar{A}_k + F_k^T \bar{D}_k]\xi_k \tag{3.8}$$

where $\bar{S}_k$ satisfies the Riccati difference equation analogous to (2.8) with $\bar{A}_k$, $\bar{B}_k$, $\bar{D}_k$, $\bar{Q}$ replacing A_k, B_k, D_k, and Q, respectively. Partitioning $\bar{S}_k$ into

$$\bar{S}_k = \begin{bmatrix} S_1(k) & S_2(k) \\ S_2^T(k) & S_3(k) \end{bmatrix}$$

it is readily seen, by a straightforward calculation, that $S_1(k)$ is in fact just S_k of (2.8). Since $\bar{B}_k^T \bar{S}_{k+1} \bar{A}_k = [B_k^T S_1(k+1) A_k \quad B_k^T S_1(k+1) C_k G_k^T \Lambda_k^{-1}]$ and $\bar{B}_k^T \bar{S}_{k+1} \bar{B}_k + F_k^T F_k = \Gamma_k$, substitution into (3.8) gives (3.6). Using (2.3a) and the definitions of L_k, P_k, and K_k, (3.6) can immediately be rewritten as (3.7a). To show (3.7b), we note the easily verified relation

$$(H_k P_k H_k^T + R_k)^{-1} \nu_k = R_k^{-1}(y_k - H_k \hat{x}_{k/k}).$$

On substituting this equation into (3.6), (3.7b) follows.

Observe that (3.6) reduces to the standard certainty equivalence control law (2.11) if $C_k G_k^T = 0$. Although (2.11) is not optimal for the general LQG problem, we will now give an interpretation of (3.7b) as a certainty equivalence control law for an augmented system.

Since we know [6], [7], [14] that the standard certainty equivalence principle applies when there is no correlation between dynamic and observation noise, we first transform dynamic noise so that it becomes uncorrelated with the observation noise.

Let $\varepsilon_k = w_k - G_k^T R_k^{-1} e_k$. Then the system equation (2.1) can be written in the form

$$x_{k+1} = A_k x_k + B_k u_k + C_k G_k^T R_k^{-1}(y_k - H_k x_k) + C_k \varepsilon_k. \tag{3.9}$$

The process ε_k is uncorrelated with e_k. We now ask the following question. The results of Theorem 1 give the optimal control as a feedback law on a state estimate. Can we find an appropriate state and its corresponding perfectly observed linear quadratic optimal control problem, whose solution gives the *same* feedback law as Theorem 1, but now on the perfectly observed state? The choice is suggested by the optimal feedback law of (3.7b). Define the augmented state

$$p_k = [x_k^T \quad y_k^T]^T.$$

The right-hand side of (3.7b) can be interpreted as a feedback law on the optimal estimate of p_k since $E(p_k/y^k) = [\hat{x}_{k/k}^T \quad y_k^T]^T$. This suggests that p_k may be the appropriate state process.

We can write the following equation for p_k.

$$\begin{bmatrix} I & 0 \\ -H_{k+1} & I \end{bmatrix}\begin{bmatrix} x_{k+1} \\ y_{k+1} \end{bmatrix} = \begin{bmatrix} A_k - C_kG_k^TR_k^{-1}H_k & C_kG_k^TR_k^{-1} \\ 0 & 0 \end{bmatrix}\begin{bmatrix} x_k \\ y_k \end{bmatrix} + \begin{bmatrix} B_k \\ 0 \end{bmatrix} w_k + \begin{bmatrix} C_k\varepsilon_k \\ e_{k+1} \end{bmatrix}. \tag{3.10}$$

This is in the form

$$E_{k+1}p_{k+1} = \tilde{A}_kp_k + \tilde{B}_ku_k + \theta_k \tag{3.11}$$

with obvious definitions for E_{k+1}, $\tilde{A}_k$, $\tilde{B}_k$, and θ_k. Since E_k^{-1} exists for all k, we can also write (3.11) in state form as follows:

$$p_{k+1} = E_{k+1}^{-1}\tilde{A}_kp_k + E_{k+1}^{-1}\tilde{B}_ku_k + E_{k+1}^{-1}\theta_k. \tag{3.12}$$

The above discussion suggests that we solve the optimal control problem, assuming that p_k is perfectly observed, and connect the resulting feedback law to that given in (3.7b). Define $\tilde{D}_k = [D_k \quad 0]$ and $\tilde{Q} = [\begin{smallmatrix} Q & 0 \\ 0 & 0 \end{smallmatrix}]$. The cost criterion for the perfectly observed problem becomes

$$J_p = E\left\{\sum_{k=0}^{N-1} \|\tilde{D}_kp_k + F_ku_k\|^2 + p_N^T\tilde{Q}p_N\right\}.$$

The associated control Riccati equation is given by

$$\begin{aligned} \tilde{S}_k = {} & \tilde{A}_k^TE_{k+1}^{-T}\tilde{S}_{k+1}E_{k+1}^{-1}\tilde{A}_k - (\tilde{A}_k^TE_{k+1}^{-T}\tilde{S}_{k+1}E_{k+1}^{-1}\tilde{B}_k + \tilde{D}_k^TF_k) \\ & \cdot (\tilde{B}_k^TE_{k+1}^{-T}\tilde{S}_{k+1}E_{k+1}^{-1}\tilde{B}_k + F_k^TF_k)^{-1} \\ & \cdot (\tilde{B}_k^TE_{k+1}^{-T}\tilde{S}_{k+1}E_{k+1}^{-1}\tilde{A}_k + F_k^T\tilde{D}_k) + \tilde{D}_k^T\tilde{D}_k \end{aligned} \tag{3.13}$$

where $E_{k+1}^{-T} = (E_{k+1}^{-1})^T$.

Let

$$\hat{S}_k = E_k^{-T}\tilde{S}_kE_k^{-1}.$$

We will need the following lemma.

LEMMA 1. *Partition*

$$\hat{S}_k = \begin{bmatrix} \hat{S}_k^{11} & \hat{S}_k^{12} \\ \hat{S}_k^{21} & \hat{S}_k^{22} \end{bmatrix}.$$

Then $\hat{S}_k^{11} = S_k$ *where* S_k *is the solution to the original Riccati equation* (2.8).

Proof. First we observe that

$$E_k^{-1} = \begin{bmatrix} I & 0 \\ H_k & I \end{bmatrix}.$$

Hence

$$\tilde{A}_kE_k^{-1} = \begin{bmatrix} A_k & C_kG_k^TR_k^{-1} \\ 0 & 0 \end{bmatrix} = \hat{A}_k, \qquad \tilde{D}_kE_k^{-1} = \tilde{D}_k.$$

On premultiplying by E_k^{-T} and post-multiplying by E_k^{-1} in (3.13), we have

$$\begin{aligned} \hat{S}_k = {} & \hat{A}_k^T\hat{S}_{k+1}\hat{A}_k - (\hat{A}_k^T\hat{S}_{k+1}\tilde{B}_k + \tilde{D}_k^TF_k)(\tilde{B}_k^T\hat{S}_{k+1}\tilde{B}_k + F_k^TF_k)^{-1} \\ & \cdot (\tilde{B}_k^T\hat{S}_{k+1}\hat{A}_k + F_k^T\tilde{D}_k) + \tilde{D}_k^T\tilde{D}_k^T. \end{aligned} \tag{3.14}$$

Using the structure of $\hat{A}_k$, $\tilde{B}_k$, and $\tilde{D}_k$, we find that

$$\tilde{B}_k^T \hat{S}_{k+1} \tilde{B}_k + F_k^T F_k = B_k^T \hat{S}_{k+1}^{11} B_k + F_k^T F_k \tag{3.15}$$

$$\tilde{B}_k^T \hat{S}_{k+1} \hat{A}_k + F_k^T \tilde{D}_k = A_k^T \hat{S}_{k+1}^{11} B_k + F_k^T D_k. \tag{3.16}$$

On substitution into (3.14), we find $\hat{S}_k^{11}$ satisfies exactly the same equation as S_k. The lemma is proved.

We can now establish the precise connection between the solution of the perfectly observed problem with state p_k and cost criterion J_p, and the optimal control law (3.7b) of Theorem 1. The optimal control law for the system (3.12) with cost criterion J_p is given by

$$\begin{aligned} u_k &= -(\tilde{B}_k^T E_{k+1}^{-T} \bar{S}_{k+1} E_{k+1}^{-1} \tilde{B}_k + F_k^T F_k)^{-1} (\tilde{B}_k^T E_{k+1}^{-T} \bar{S}_{k+1} E_{k+1}^{-1} \tilde{A}_k + F_k^T \tilde{D}_k) p_k \\ &= -(\tilde{B}_k^T \hat{S}_{k+1} \tilde{B}_k + F_k^T F_k)^{-1} (\tilde{B}_k^T \hat{S}_{k+1} \tilde{A}_k + F_k^T \tilde{D}_k) p_k. \end{aligned} \tag{3.17}$$

Using Lemma 1 in (3.17), we find that

$$\begin{aligned} u_k &= -\Gamma_k^{-1} \{ B_k^T S_{k+1} [(A_k - C_k G_k^T R_k^{-1} H_k) x_k + C_k G_k^T R_k^{-1} y_k] + F_k^T D_k x_k \} \\ &= -L_k x_k - \Gamma_k^{-1} B_k^T S_{k+1} C_k G_k^T R_k^{-1} (y_k - H x_k). \end{aligned} \tag{3.18}$$

On comparing (3.18) with (3.7b), we see that two feedback laws are identical. Thus the optimal control law (3.7b) for the general LQG problem can be interpreted as a certainty equivalence control law with the augmented state $p_k = [x_k^T \quad y_k^T]^T$ in (3.17) replaced by $\hat{p}_{k/k} = [\hat{x}_{k/k}^T \quad y_k^T]^T$.

Next we turn to infinite time problems. The one we will be primarily interested in is the average cost per unit time problem, although results for the discounted cost problem can be obtained as well using similar techniques. We assume the system to be time-invariant so that it is described by

$$x_{k+1} = A x_k + B u_k + C w_k \tag{3.19a}$$

$$y_k = H x_k + e_k \tag{3.19b}$$

with the cost criterion J_{av} given by (2.12). Admissible control laws u_k are of the form $\phi_k(y^k)$ such that J_{av} exists and that $\lim_{N\to\infty} (1/N) E\|x_N\|^2 = 0$. For the rest of this section, we assume $F^T F > 0$.

Define

$$\begin{aligned} \hat{A} &= A - B(F^T F)^{-1} F^T D \\ \hat{D} &= D - F(F^T F)^{-1} F^T D \\ \check{A} &= A - C G^T R^{-1} H \\ \check{C} &= C[I - G^T R^{-1} G]^{1/2}. \end{aligned}$$

It is known [7] that if (A, B) is stabilizable and $(\hat{D}, \hat{A})$ detectable, there exists a unique positive semidefinite solution to the control algebraic Riccati equation (CARE)

$$S = A^T S A + D^T D - L^T \Gamma L \tag{3.20}$$

where

$$\begin{aligned} \Gamma &= B^T S B + F^T F \\ L &= \Gamma^{-1} (B^T S A + F^T D). \end{aligned}$$

Similarly, if $(\check{A}, \check{C})$ is stabilizable and (H, A) detectable, there exists a unique positive semidefinite solution to the filter algebraic Riccati equation (FARE)

$$P = APA^T + CC^T - K\Lambda K^T \tag{3.21}$$

where

$$\Lambda = HPH^T + R$$

and

$$K = (APH^T + CG^T)\Lambda^{-1}.$$

Let $M_k = (LP_kH^T + \Gamma^{-1}B^TSCG^T)\Lambda_k^{-1}$ and $M = (LPH^T + \Gamma^{-1}B^TSCG^T)\Lambda^{-1}$. Then it is also true that $\lim_{k\to\infty} K_k = K$ and $\lim_{k\to\infty} M_k = M$.

As one may expect, the solution to the average cost per unit time problem is given by the steady-state version of (3.6) or (3.7).

THEOREM 2. *Assume that (A, B) and $(\check{A}, \check{C})$ are stabilizable, and that (H, A) and $(\hat{D}, \hat{A})$ are detectable. Then the optimal control law for the average cost per unit time problem is given by*

$$\begin{aligned} u_k &= -(L\hat{x}^s_{k/k-1} + M\bar{\nu}_k) \\ &= -(L\hat{x}^s_{k/k} + \Gamma^{-1}B^TSCG^T\Lambda^{-1}\bar{\nu}_k) \\ &= -[L\hat{x}^s_{k/k} + \Gamma^{-1}B^TSCG^TR^{-1}(y_k - H\hat{x}^s_{k/k})] \end{aligned} \tag{3.22}$$

where $\hat{x}^s_{k/k-1}$, $\hat{x}^s_{k/k}$, and $\bar{\nu}_k$ are generated by the steady-state Kalman filter

$$\hat{x}^s_{k+1/k} = A\hat{x}^s_{k/k-1} + Bu_k + K\bar{\nu}_k \tag{3.23a}$$

$$\bar{\nu}_k = y_k - H\hat{x}^s_{k/k-1} \tag{3.23b}$$

$$\hat{x}^s_{k/k} = \hat{x}^s_{k/k-1} + PH^T\Lambda^{-1}\bar{\nu}_k. \tag{3.23c}$$

Proof. The proof is similar to that in [7] for the one-step information delay case. Owing to the similarity of the calculations, some details will be omitted.

First we show that the control law

$$u_k = -L\hat{x}_{k/k-1} - M_k\nu_k \tag{3.24}$$

is admissible and optimizes J_{av}. Then we will show that the control law (3.22) is also admissible and yields the same optimal cost. Let $\tilde{x}_{k/k-1} = x_k - \hat{x}_{k/k-1}$. Under the control law (3.24), we obtain the closed-loop system

$$\hat{x}_{k+1/k} = (A - BL)\hat{x}_{k/k-1} + (K_k - BM_k)H\tilde{x}_{k/k-1} + (K_k - BM_k)e_k \tag{3.25}$$

$$\tilde{x}_{k+1/k} = (A - K_kH)\tilde{x}_{k/k-1} + (Cw_k - K_ke_k). \tag{3.26}$$

Define the matrices

$$A_k^c = \begin{bmatrix} A - BL & (K_k - BM_k)H \\ 0 & A - K_kH \end{bmatrix}$$

$$A^c = \begin{bmatrix} A - BL & (K - BM)H \\ 0 & A - KH \end{bmatrix}$$

$$N_k = \begin{bmatrix} 0 & K_k - BM_k \\ C & -K_k \end{bmatrix}$$

$$N = \begin{bmatrix} 0 & K - BM \\ C & -K \end{bmatrix}$$

$$W = \begin{bmatrix} I & G^T \\ G & R \end{bmatrix}.$$

W is the covariance of the process $\psi_k = [w_k^T \quad e_k^T]^T$. Using the fact that $\lim_{k\to\infty} \|A_k^c - A^c\| = 0$, $\lim_{k\to\infty} \|N_k - N\| = 0$, and A^c is asymptotically stable [7], we see that A_k^c is exponentially stable. Hence the process $\eta_k = [\hat{x}_{k/k-1}^T \quad \tilde{x}_{k/k-1}^T]^T$ has a correlation matrix $\Sigma_\eta(k) = E\eta_k\eta_k^T$ that satisfies

$$\Sigma_\eta(k+1) = A_k^c\Sigma_\eta(k)A_k^{c^T} + N_kWN_k^T. \tag{3.27}$$

By the time-varying Lyapunov lemma [1], $\lim_{k\to\infty}\Sigma_\eta(k) = \Sigma_\eta$ exists and is bounded. This implies that $E\|x_k\|^2$ is bounded for all k. Thus (3.24) is an admissible control law. Denote this control law by u'. Let

$$J_N(u) = E\left\{x_N^TSx_N + \sum_{k=0}^{N-1} \|Dx_k + Fu_k\|^2\right\}$$

where S is the unique positive semidefinite solution of CARE (3.20). Theorem 1 yields that $J_N(u) \geqq J_N(u')$. Furthermore, since for any admissible control law u,

$$\lim_{N\to\infty} \frac{1}{N} J_N(u) = J_{av}(u) \geqq J_{av}(u')$$

we see that u' is indeed optimal.

We now examine the closed-loop system under the time-invariant control law (3.22), denoted by u^*. Let $\beta_k = [\hat{x}_{k/k-1}^{s^T} \quad x_k^T - \hat{x}_{k/k-1}^{s^T}]^T$. Then

$$\beta_{k+1} = A^c\beta_k + N\psi_k. \tag{3.28}$$

Putting $\Sigma_\beta(k) = E\beta_k\beta_k^T$, we have immediately that $\lim_{k\to\infty}\Sigma_\beta(k) = \Sigma_\beta$ exists, and that

$$\Sigma_\beta = A^c\Sigma_\beta A^{c^T} + NWN^T. \tag{3.29}$$

Hence u^* is also admissible. Taking limit on both sides of (3.27), we see that $\Sigma_\eta = \Sigma_\beta$. A straightforward calculation similar to that in [7] now gives

$$J_{av}(u^*) = J_{av}(u').$$

Hence the control law u^*, given by (3.22), is also optimal, completing the proof.

The form of the optimal control is of course entirely expected given the results of Theorem 1 and standard LQG theory. In the next section, we shall use Theorem 2 to prove the explicit connection between LQG theory and minimum variance control for ARMAX systems with general delay.

4. Minimum variance control for SISO ARMAX systems. Consider the single-input single-output (SISO) ARMAX system

$$A(z^{-1})y_k = z^{-d}B(z^{-1})u_k + C(z^{-1})w_k \tag{4.1}$$

where

$$A(z^{-1}) = 1 + a_1z^{-1} + \cdots + a_nz^{-n}$$
$$B(z^{-1}) = b_d + b_{d+1}z^{-1} + \cdots + b_nz^{-n+d}$$
$$C(z^{-1}) = 1 + c_1z^{-1} + \cdots + c_nz^{-n}$$

and w_k is an independent and identically distributed zero-mean Gaussian sequence with $Ew_k^2 = \sigma^2$, z^{-1} is the backward shift, and $d \geqq 1$ is the system delay. Assume that the polynomials $B(q)$ and $C(q)$ have no roots in $|q| \leqq 1$. Then it is well known [14] that the optimal control law in the class of control laws of the form $u_k = \phi_k(y^k)$ which minimizes $\lim_{N\to\infty}(1/N)\sum_{k=0}^{N-1} Ey_k^2$ is given by

$$u_k = -\frac{G(z^{-1})}{B(z^{-1})F(z^{-1})} y_k \tag{4.2}$$

where the polynomials $F(z^{-1})$ and $G(z^{-1})$, of degrees $d-1$ and $n-1$, respectively, are determined by the equation

$$C(q)=A(q)F(q)+q^dG(q). \tag{4.3}$$

Furthermore, the closed-loop system is stable.

Let us reformulate the minimum variance control problem in the LQG framework. It is well known [6], [7] that the ARMAX description can be represented in innovation state space form as follows:

$$x_{k+1}=\begin{bmatrix} 0 & \cdots & 0 & -a_n \\ 1 & & \vdots & \\ 0 & & \vdots & \vdots \\ \vdots & & 0 & \\ 0 & \cdots & 1 & -a_1 \end{bmatrix} x_k+\begin{bmatrix} b_n \\ \vdots \\ b_d \\ 0 \\ \vdots \\ 0 \end{bmatrix} u_k+\begin{bmatrix} c_n-a_n \\ \vdots \\ c_1-a_1 \end{bmatrix} w_k = Ax_k+bu_k+cw_k \tag{4.4a}$$

$$y_k=[0 \quad \cdots \quad 0 \quad 1]x_k+w_k=hx_k+w_k. \tag{4.4b}$$

Observe that

$$hA^{j-1}b=0, \qquad j<d \tag{4.5a}$$

$$hA^{d-1}b=b_d. \tag{4.5b}$$

The cost criterion

$$J_{av}=\lim_{N\to\infty}\frac{1}{N}E\sum_{j=0}^{N-1}y_j^2=\lim_{N\to\infty}\frac{1}{N}E\sum_{j=0}^{N-1}(hx_j)^2+\sigma^2$$

so that J_{av} is minimized if and only if $\bar{J}_{av}=\lim_{N\to\infty}(1/N)\sum_{k=0}^{N-1}E(hx_k)^2$ is minimized.

The minimum variance control problem becomes that of LQG control with average cost per unit time criterion for the system described by (4.4a), (4.4b). Although the two approaches have been widely referred to as giving the same control law, an explicit proof cannot be found in the literature for the general delay case. In this section, we will prove this "folk theorem" using the general results of the previous section.

First, we observe that the minimum variance control problem is a singular control problem in LQG terminology since there is no control weighting. This singular problem can be converted to a nonsingular one as shown in [12], [18]. The control algebraic Riccati equation is given by

$$S=A^TSA-A^TSb(b^TSb)^{-1}b^TSA+h^Th \tag{4.6}$$

and it has been shown by Silverman [18] that the unique positive semidefinite solution in the minimum phase case is given by

$$S=\sum_{j=0}^{d-1}A^{j^T}h^ThA^j. \tag{4.7}$$

Furthermore the closed-loop system matrix $A-BL$ is stable. It is also well known [7], [15] that with $C(q)$ stable, the unique positive semidefinite solution to the filter algebraic Riccati equation

$$P=APA^T+\sigma^2cc^T-(APh^T+\sigma^2c)(hPh^T+\sigma^2)^{-1}(hPA^T+\sigma^2c^T)$$

is $P=0$. According to Theorem 2, the optimal control law is given by

$$u_k=-\Gamma^{-1}b^TS(A\hat{x}^s_{k/k-1}+K\bar{\nu}_k) \tag{4.8}$$

where $\hat{x}^s_{k/k-1}$ satisfies

(4.9a) $$\hat{x}^s_{k+1/k} = (A - ch)\hat{x}^s_{k/k-1} + bu_k + cy_k$$

(4.9b) $$\bar{\nu}_k = y_k - h\hat{x}^s_{k/k-1}.$$

Using (4.5) and (4.7) in (4.8) and (4.9), we can solve for the optimal controller transfer function from y to u to give

(4.10) $$u_k = -\frac{1}{b_d}\left\{hA^{d-1}(A-ch)\left[zI - \left(I - \frac{1}{b_d}bhA^{d-1}\right)(A-ch)\right]^{-1} \cdot \left[I - \frac{1}{b_d}bhA^{d-1}\right]c + hA^{d-1}c\right\}y_k.$$

To show that the state space LQG theory gives the same controller as the ARMAX minimum variance controller amounts to showing that (4.2) and (4.10) represents the same transfer function. Although (4.10) looks formidable, it in fact has a great deal of structure. This structure enables us to prove the following theorem.

THEOREM 3. *Assume that $d \geqq 1$ and that the polynomials $B(q)$ and $C(q)$ have no roots in $|q| \leqq 1$. Then the control law given in* (4.10) *minimizes J_{av} and is identical to the minimum variance control law* (4.2). *Furthermore, the closed-loop system is stable.*

Proof. Theorem 2 and the preceding calculations show that the control law (4.10) minimizes J_{av}, and that the closed-loop system is stable. It remains to show the equivalence of (4.2) and (4.10). Let

$$\bar{A} = A - ch$$
$$\bar{B} = \left(I - \frac{1}{b_d}bhA^{d-1}\right).$$

Then the controller of (4.10) is

(4.11) $$u_k = -\frac{1}{b_d}hA^{d-1}\{\bar{A}(zI - \bar{B}\bar{A})^{-1}\bar{B} + I\}cy_k.$$

By the matrix inversion lemma, the term inside the curly brackets can be simplified to give

(4.12) $$u_k = -\frac{1}{b_d}hA^{d-1}(I - z^{-1}\bar{A}\bar{B})^{-1}cy_k.$$

Let

(4.13) $$H(z^{-1}) = \frac{1}{b_d}hA^{d-1}(I - z^{-1}\bar{A}\bar{B})^{-1}c,$$

i.e., $H(z^{-1})$ is the controller transfer function. For the unit delay case $(d=1)$, the reader is referred to [5] or [16]. Here we concentrate on the case $d > 1$.

We make repeated use of the matrix inversion lemma in the following form: For any invertible matrix Z and vectors α, β, whenever the indicated inverse exists,

(4.14) $$(Z + \alpha\beta^T)^{-1} = Z^{-1} - \frac{Z^{-1}\alpha\beta^T Z^{-1}}{1 + \beta^T Z^{-1}\alpha}.$$

We also make use of the following result, proved in [15]:

(4.15) $$\frac{G(z^{-1})}{A(z^{-1})} = zh(zI - A)^{-1}A^{d-1}c.$$

We begin by noting that since $d > 1$, $hb = 0$. Hence

$$(4.16)\qquad (I - z^{-1}\bar{A}\bar{B})^{-1} = z\left[zI - A + ch + \frac{1}{b_d}AbhA^{d-1}\right]^{-1}.$$

Applying (4.14), with $zI - A + ch$ identified as Z, α as $(1/b_d)Ab$, and β^T as hA^{d-1}, we readily verify that

$$(4.17)\qquad \begin{aligned} b_dH(z^{-1}) &= hA^{d-1}z\left(zI - A + ch + \frac{1}{b_d}AbhA^{d-1}\right)^{-1}c \\ &= \frac{zhA^{d-1}(zI - A + ch)^{-1}c}{1 + hA^{d-1}(zI - A + ch)^{-1}(Ab/b_d)}. \end{aligned}$$

In the Appendix, the following two equations are proved:

$$(4.18)\qquad hA^{d-1}(zI - A + ch)^{-1}c = \frac{G(z^{-1})}{zC(z^{-1})}$$

$$(4.19)\qquad 1 + hA^{d-1}(zI - A + ch)^{-1}\frac{Ab}{b_d} = \frac{1}{b_d}\frac{B(z^{-1})}{A(z^{-1})}\frac{C(z^{-1}) - z^{-d}G(z^{-1})}{C(z^{-1})}.$$

On using (4.3), we see that (4.19) becomes

$$1 + hA^{d-1}(zI - A + ch)^{-1}\frac{Ab}{b_d} = \frac{1}{b_d}\frac{B(z^{-1})F(z^{-1})}{C(z^{-1})}.$$

Substituting (4.18) and (4.20) into (4.17), we find

$$b_dH(z^{-1}) = \frac{b_dG(z^{-1})}{B(z^{-1})F(z^{-1})}$$

which is the desired result.

Remark. The control law (4.10) is identical to (4.2) whether or not $B(q)$ is stable. However, if $B(q)$ is not stable, closed-loop stability no longer holds. The case where $B(q)$ is not stable but where the closed-loop system is required to be stable requires a somewhat different treatment using the stabilizing rather than optimizing solution of the Riccati equation. These results and extensions to the multivariable case will be reported elsewhere.

5. Conclusions. We have given an explicit solution in feedback form to the LQG problem with correlated dynamic and observation noise and no information delay. Certainty equivalence in its standard form is shown not to hold, but is shown to hold for an augmented system. The general results are applied to the minimum variance control problem for SISO ARMAX systems and the equivalence of the two approaches explicitly demonstrated. It is believed that these results fill an apparent gap in the LQG theory. Using these results, further connections between state space and ARMAX formulations for multivariable stochastic control problems, examined, for example, in [17], can be explored. Such investigations will be reported in forthcoming papers.

Appendix. The following equations will be proved:

$$(\text{A.1})\ (\text{i})\qquad hA^{d-1}(zI - A + ch)^{-1}c = \frac{G(z^{-1})}{zC(z^{-1})}$$

$$(\text{A.2})\ (\text{ii})\qquad 1 + hA^{d-1}(zI - A + ch)^{-1}\frac{Ab}{b_d} = \frac{1}{b_d}\frac{B(z^{-1})}{A(z^{-1})}\frac{[C(z^{-1}) - z^{-d}G(z^{-1})]}{C(z^{-1})}.$$

Proof of (i). Applying matrix inversion as in (4.14) to $(zI-A+ch)^{-1}$, we have

$$\begin{aligned} hA^{d-1}(zI-A+ch)^{-1}c &= h(zI-A)^{-1}A^{d-1}c - \frac{h(zI-A)^{-1}A^{d-1}ch(zI-A)^{-1}}{1+h(zI-A)^{-1}c}c \\ &= \frac{h(zI-A)^{-1}A^{d-1}c}{1+h(zI-A)^{-1}c}. \end{aligned}\tag{A.3}$$

It is easily verified that

$$1+h(zI-A)^{-1}c = \frac{C(z^{-1})}{A(z^{-1})}.\tag{A.4}$$

We finally obtain, on using (4.15), that

$$hA^{d-1}(zI-A+ch)^{-1}c = \frac{z^{-1}G(z^{-1})}{A(z^{-1})}\,\frac{A(z^{-1})}{C(z^{-1})} = z^{-1}\frac{G(z^{-1})}{C(z^{-1})}.$$

Proof of (ii). Applying matrix inversion as before, we have that

$$\begin{aligned} &hA^{d-1}(zI-A+ch)\frac{Ab}{b_d} \\ &\quad = h(zI-A)^{-1}A^{d-1}\frac{Ab}{b_d} - \frac{h(zI-A)^{-1}A^{d-1}ch(zI-A)^{-1}(Ab/b_d)}{1+h(zI-A)^{-1}c} \\ &\quad = \frac{[1 \quad z \quad \cdots \quad z^{n-1}]A(A^{d-1}b/b_d)}{z^nA(z^{-1})} \\ &\qquad - \frac{z^{-1}G(z^{-1})}{z^nA(z^{-1})C(z^{-1})}[1 \quad z \quad \cdots \quad z^{n-1}]\frac{Ab}{b_d} \end{aligned}\tag{A.5}$$

on using the structure of $h(zI-A)^{-1}$ and (4.15). Now observe that

$$\frac{1}{b_d}A^{d-1}b = \begin{bmatrix} 0 & \cdots & 0 & \frac{b_n}{b_d} & \frac{b_{n-1}}{b_d} & \cdots & \frac{b_{d+1}}{b_d} & 1 \end{bmatrix}^T\tag{A.6}$$

$$\frac{1}{b_d}Ab = \begin{bmatrix} 0 & \frac{b_n}{b_d} & \cdots & \frac{b_{d+1}}{b_d} & 1 & 0 & \cdots & 0 \end{bmatrix}^T\tag{A.7}$$

and

$$[1 \quad z \quad \cdots \quad z^{n-1}]A = [z \quad \cdots \quad z^{n-1} \quad -(a_1z^{n-1}+\cdots+a_n)].\tag{A.8}$$

Substituting (A.6)-(A.8) into (A.5), we obtain

$$\begin{aligned} hA^{d-1}(zI-A+ch)\frac{Ab}{b_d} &= \frac{-\sum_{i=1}^n a_iz^{n-1}+(1/b_d)\sum_{j=d+1}^n b_jz^{n+d-j}}{z^nA(z^{-1})} \\ &\quad - \frac{z^{-1}G(z^{-1})}{z^nA(z^{-1})C(z^{-1})}\,\frac{1}{b_d}\sum_{j=d}^n b_jz^{n-j+1}. \end{aligned}\tag{A.9}$$

Hence

$$\begin{aligned} 1+hA^{d-1}(zI-A+ch)\frac{Ab}{b_d} &= \frac{z^n+(1/b_d)\sum_{j=d+1}^n b_jz^{n+d-j}}{z^nA(z^{-1})} \\ &\quad - \frac{z^{-1}G(z^{-1})}{z^nA(z^{-1})C(z^{-1})}\,\frac{1}{b_d}\sum_{j=d}^n b_jz^{n-j+1} \\ &= \frac{1}{b_d}\,\frac{B(z^{-1})}{A(z^{-1})} - \frac{1}{b_d}z^{-d}\frac{G(z^{-1})B(z^{-1})}{C(z^{-1})A(z^{-1})} \\ &= \frac{1}{b_d}\,\frac{B(z^{-1})}{A(z^{-1})}\left[\frac{C(z^{-1})-z^{-d}G(z^{-1})}{C(z^{-1})}\right]. \end{aligned}$$

NOTE ON THE CONVERGENCE OF SIMULATED ANNEALING ALGORITHMS*

U. FAIGLE† AND W. KERN†

Abstract. Generalizing the results of Faigle and Schrader [*Inform. Process. Lett.*, 27 (1988), pp. 189-194] a short inductive proof is given that shows that the stationary distributions of a simulated annealing algorithm converge to a distribution, where nonoptimal elements are generated with probability zero, provided that the "weak reversibility condition" of Hajek [*Math. Oper. Res.*, 13 (1988), pp. 311-329] holds.

Key words. simulated annealing, Markov process, combinatorial optimization, convergence

AMS(MOS) subject classifications. 90C40, 68J05

1. Introduction.

Simulated annealing was proposed by Metropolis et al. [Met53] as a Monte Carlo method for the evaluation of state equations in statistical mechanics. Its potential as a promising tool for approximately solving large-scale combinatorial optimization problems was later pointed out in [Kir83] and [Cer85].

Essentially, the method proceeds as follows. In order to generate an element of minimal weight in a set with some neighborhood structure, we iteratively choose a random neighbor of the current element. Whether this new element is accepted as the new current element depends on the outcome of a second probabilistic experiment, where the discriminating probability usually is based on the weights of the two elements under consideration and on a temperature parameter $t > 0$. Guided by thermodynamical analogies, we hope to generate an element of "lowest energy," i.e., of minimal weight, as $t \rightarrow 0$ (see, e.g., [Bur84], [Ros85], or [Gol86]).

We should make the scope of our investigation very clear. Any practical implementation of simulated annealing will, of course, try to include a feature that permits us to always keep track of the best solution discovered during the search procedure so far. From a theoretical point of view, it is obvious that such a feature guarantees that we encounter a globally best solution with probability eventually approaching one even in a pure random search (without any simulated annealing mechanism) (see also [Ani87]). Simulated annealing is a good deal more subtle in that it tries to steer the search procedure in the "right direction," i.e., it tries to eventually only generate solutions that are close to optimal with high probability.

However little is presently known about how to implement a simulated annealing algorithm so that the best results are achieved. Thus reports about practical success with simulated annealing are also skeptical (see, e.g., [Joh84]).

From a theoretical point of view, a simulated annealing algorithm can be modeled as an inhomogeneous Markov process, whose transition probabilities depend on the parameter t. In this framework, however, a rigorous analysis of the convergence behavior appears to be quite involved (see, e.g., [Haj88], [Chi88], [Tsi89]).

On the other hand, it is not too hard to show that for a large class of accepting probability functions, the stationary distributions of the homogeneous Markov processes associated with each fixed t converge with $t \rightarrow 0$ to a (generally unknown) limiting distribution, which, in fact, is also the limiting distribution of the inhomogeneous process if the temperature is lowered "slowly enough," where "slowly enough" roughly means so slowly that during the search procedure an optimal solution is encountered

* Received by the editors March 22, 1989; accepted for publication (in revised form) April 15, 1990.

† Faculty of Applied Mathematics, University of Twente, P.O. Box 217, 7500 AE Enschede, the Netherlands.

at all with probability one (see Theorem 2 of [Ani87]). Somewhat surprisingly, this result is independent of the particular neighborhood structure.

With respect to the goal of simulated annealing, therefore, the question arises of whether the limiting distribution has the desirable property that nonoptimal elements only occur with probability zero. As it turns out, the affirmative answer to this question very much depends on the neighborhood structure. Roughly speaking, it seems that this structure should be in a sense "symmetric." Thus an affirmative answer is given in [Lun86] for numerically symmetric neighborhods, while in [Fai88] and [Con88] this condition is relaxed to combinatorially symmetric neighborhoods.

The purpose of this paper is to provide a short argument for an even more general model of symmetry, namely, the "weak reversibility" of Hajek [Haj88] (see also [Con89]), which stipulates only that an element i be reachable from an element j without exceeding weight c whenever j is reachable from i without exceeding weight c.

An incidental remark may be in order. Experimental results indicate that an appropriate neighborhood structure might be even more important for a practically successful simulated annealing algorithm than the choice of the temperature levels (see, e.g., [Fai88a], [Gol88]). To make this more precise, however, is beyond the current theoretical understanding of simulated annealing.

We discuss simulated annealing algorithms in terms of Markov processes in § 2. The proof of our main result is given in § 3.

2. Simulated annealing and Markov processes. In this section, we give a short description of simulated annealing algorithms in terms of Markov processes.

Let $S=\{1,2,\cdots,n\}$ be a finite set whose elements are weighted with real numbers c_i $(i\in S)$. Furthermore, let $A=(a_{ij})$ be a *stochastic* $(n\times n)$-matrix, i.e., $a_{ij}\geqq 0$ and

$$\sum_{j=1}^{n} a_{ij}=1 \qquad (i=1,\cdots,n).$$

With A we associate the (directed) *neighborhood graph* $G=G(A)$, whose vertices are the elements of S and whose edges are those pairs (i,j) of vertices satisfying

$$i=j \quad \text{or} \quad a_{ij}>0.$$

We will assume that G is strongly connected or, equivalently, that the homogeneous Markov process with transition matrix A is *irreducible.* In particular, there is a unique *stationary distribution* of A, i.e., a probability distribution $\pi=(\pi_1,\cdots,\pi_n)\in\mathbb{R}^n$ on S such that

$$\pi A=\pi.$$

Note that the rows of the matrix

$$\Pi=\lim_{k\to\infty} A^k$$

are identical to π (provided the limit exists).

Consider a family of *accepting probability functions*, i.e., functions $f_t:\mathbb{R}\times\mathbb{R}\to\mathbb{R}$ such that for every choice of $c_1', c_2',\cdots,c_n'\in\mathbb{R}$, there exists some t_0 with the properties

(i) $0<f_t(c_i',c_j')\leqq 1$ if $c_j'\geqq c_i'$ and $t\leqq t_0$

(ii) $f_t(c_i',c_j')f_t(c_j',c_k')=f_t(c_i',c_k')$ if $c_k'\geqq c_j'\geqq c_i'$ and $t\leqq t_0$,

where the index $t>0$ is a *temperature* parameter.

Examples are provided by the standard exponential accepting probabilities

$$f_t(c_i',c_j')=\exp\{-(c_j'-c_i')/t\},$$

or by the functions

$$f_t(c_i',c_j')=\frac{c_i'}{c_j'}\cdot t^{(c_j'-c_i')}.$$

Relative to A and f_t, we define the stochastic matrix $P(t)=(p_{ij}(t))$ via

$$p_{ij}(t)=\begin{cases} a_{ij} & \text{if } c_i \geqq c_j, \\ a_{ij}f_t(c_i, c_j) & \text{if } c_i < c_j, \\ 1-\sum_{m\neq i} p_{im}(t) & \text{if } i=j. \end{cases}$$

Note that the matrices A and $P(t)$ possess the same neighborhood graph G!

A *simulated annealing algorithm* relative to (A, f_t) is a random walk on G according to a chosen *annealing schedule* $t_1 \geqq t_2 \geqq \cdots \geqq t_l \geqq \cdots$ with

$$\lim_{l\to\infty} t_l = 0,$$

that is, a discrete inhomogeneous Markov process whose transition probabilities in the lth step are given by the matrix $P(t_l)$.

It follows from Theorem 2 of [Ani87] that

$$\pi^* = \lim_{t\to 0} \pi(t)$$

exists, where $\pi(t)$ is the stationary distribution of $P(t)$, for a large class of accepting probability functions, including the standard

$$f_t(x, y) = \exp\{-(y-x)/t\}.$$

Moreover, π^* is the limiting distribution for the simulated annealing algorithm if the temperature is lowered "slowly enough" (see also [Haj88]).

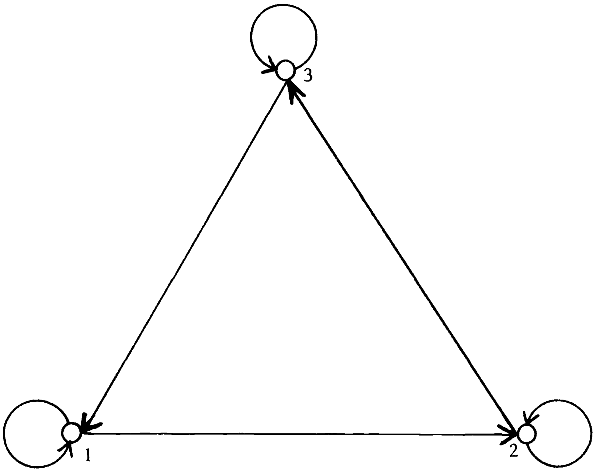
In this note, we are not interested in the choice of annealing schedules, but concentrate on the problem of whether

$$\lim_{t\to 0} \pi_s(t) = 0$$

if $s \in S$ is not *optimal*, i.e., if $s \notin S^0 = \{s \in S\colon c_r \geqq c_s \text{ for all } r \in S\}$.

Our next example shows that such a strong convergence property cannot be expected if we do not impose further conditions on the neighborhood structure A.

Example. Let $S=\{1, 2, 3\}$ and let the neighborhood matrix $A=(a_{ij})$ be defined by $a_{12}=a_{23}=a_{31}=1$. This yields $G(A)$ as follows:



Relative to the cost function $c_i = i$ $(i=1, 2, 3)$, we have $2 \notin S^0$. Yet, it is easy to see that the standard exponential accepting function yields the stationary probability:

$$\pi_2(t) = \frac{1}{2+e^{-1/t}}$$

and hence $\lim_{t\to 0} \pi_2(t) = \frac{1}{2} \neq 0$.

We will, therefore, assume that our neighborhood structure satisfies the "weak reversibility condition" relative to the weights c_i, which was introduced by Hajek in [Haj88]. To be more precise, we will assume that the neighborhood graph G satisfies the following condition relative to $c_1, \cdots, c_n$:

(WR) Each connected component of $G(c_i)$ is strongly connected.

Here $G(c_i)$ is the graph induced by G on the vertex set $S(c_i) = \{j \in S: c_j \leqq c_i\}$. Also recall that a directed graph is said to be *strongly connected* if every pair (u, v) of vertices is connected by a directed path from u to v.

We can now state our main result.

THEOREM 1. *If* (WR) *holds for* G, *then there exists a constant* K *and some* $t_0 > 0$ *such that*

$$\pi_r(t) \leqq K f_t(c_s, c_r) \pi_s(t)$$

whenever $t \leqq t_0$, $c_r > c_s$.

COROLLARY 2. *Assume that* (WR) *holds for* G *and that* $\lim_{t\to 0} f_t(c_s, c_r) = 0$ *for all* $c_r > c_s$. *Then*

$$\lim_{t\to 0} \pi_s(t) = 0$$

for all $s \in S \backslash S^0$.

To get an idea for the proof of Theorem 1, let us consider the case of the exponential accepting function

$$f_t(x, y) = \exp\{-(y-x)/t\}.$$

Suppose we knew that the associated stationary distributions $\pi(t)$ were, in a sense, "generalized Maxwell-Boltzmann," i.e., of the form

$$\pi_s(t) = Z(t) \cdot k_s \cdot e^{-c_s/t},$$

where $Z(t) = (\sum k_s e^{-c_s/t})^{-1}$ is a normalizing factor and the k_s's are constants depending only on s. Then, of course, Theorem 1 would follow immediately.

While we suspect that, under (WR), the stationary distributions are indeed "generalized Maxwell-Boltzmann," it turns out that Theorem 1 can be derived without first establishing a special form of $\pi(t)$. It suffices to show that the probabilities in question can be bounded from above by probabilities of the Maxwell-Boltzmann type. We will prove this in the next section.

3. Proof of the main result. For the proof of the main result, we replace the matrix A by a family $\{A(t)\}$ of stochastic matrices satisfying the ε-condition:

(EC) There exists an $\varepsilon > 0$ such that for each t and matrix $A(t) = (a_{ij}(t))$,

$$a_{ij}(t) \neq 0 \quad \text{implies } a_{ij}(t) \geqq \varepsilon$$

whenever $i \neq j$, and all $A(t)$'s have the same neighborhood graph.

For example, $A(t) := A$, for all t, gives rise to such a family.

With the notation as in the previous section, we can now formulate our main results as follows.

THEOREM 3. *Let* $\{A(t)\}$ *be a family of irreducible stochastic matrices satisfying the conditions* (EC) *and* (WR). *Then there exists a constant* K *and some* $t_0 > 0$ *such that*

$$\pi_r(t) \leqq K f_t(c_s, c_r) \pi_s(t)$$

whenever $t \leqq t_0$, $c_r > c_s$.

Proof. The proof is by induction on

$$m = |S| + |\{c_i : i \in S\}|,$$

i.e., the size of the ground set plus the number of distinct objective function values. For $m = 2$, there is nothing to prove. Thus assume $m \geqq 3$ and the theorem holds for values smaller than m. Now, either there exist two optimal solutions i and $j \in S^0$ with $a_{ij}(t) > 0$ (Case i below) or not (Case ii below). In the first case we modify the chain by "glueing" i and j into a single new optimal solution. This reduces the size of the ground set and hence our inductive assumption applies to the modified problem. In the second case, we "shift" all optimal solutions to the "second-to-best" level of the objective function value. (Note that such a "second-to-best" level must exist, since otherwise, in view of Case ii, the neighborhood graph would be disconnected.) This reduces the number of "level sets," i.e., the number of distinct weight function values, and hence, again, the inductive assumption applies to the modified problem. In both cases we show that the inductive assumption for the (smaller) modified problem implies that the claim also holds for the original problem. We now describe the above arguments in more detail.

Case i. There exist two distinct optimal elements $i, j \in S^0$ such that $a_{ij}(t) \geqq \varepsilon > 0$.

Because G is strongly connected, we have $\pi_i(t) > 0$ and $\pi_j(t) > 0$ for all $t > 0$. Thus

$$\lambda(t) = \frac{\pi_j(t)}{\pi_i(t) + \pi_j(t)}$$

is well defined.

This allows us to identify i and j as follows. For each matrix $A(t)$, we carry out the following construction:

(a) multiply the ith row by $\lambda(t)$
(b) multiply the jth row by $1 - \lambda(t)$
(c) add the new jth row to the new ith row
(d) delete the jth row
(e) add the new jth column to the new ith column
(f) delete the jth column.

It is clear that the resulting $(n-1) \times (n-1)$-matrices $\hat{A}(t)$ are stochastic and the underlying neighborhood graph $\hat{G}$ arises by contracting the edge (i, j) in G. Hence condition (WR) obviously holds for $\hat{A}(t)$.

Next let us verify that the family $\hat{A}(t)$ satisfies an ε-condition (EC). This amounts to showing that the multipliers $\lambda(t)$ and $1 - \lambda(t)$ can be bounded from below by some term which is independent of t. First note that

$$\pi_j(t) \geqq p_{ij}(t)\pi_i(t) = a_{ij}(t)\pi_i(t) \geqq \varepsilon\pi_i(t) \qquad (t > 0).$$

Thus

$$1 - \lambda(t) = \frac{\pi_j(t)}{\pi_i(t) + \pi_j(t)} \geqq \frac{\varepsilon}{1 + \varepsilon} \geqq \frac{\varepsilon}{2}.$$

Furthermore, since G satisfies (WR), we conclude that there exists a path from j to i in G, all of whose vertices are optimal. By multiplying the transition probabilities along this path, we get

$$\pi_i(t) \geqq \varepsilon^{n-1}\pi_j(t) \qquad (t > 0).$$

Thus

$$\lambda(t) = \frac{\pi_i(t)}{\pi_i(t) + \pi_j(t)} \geqq \frac{\varepsilon^{n-1}}{1 + \varepsilon^{n-1}} \geqq \frac{\varepsilon^{n-1}}{2}.$$

Hence both $\lambda(t)$ and $1-\lambda(t)$ can be bounded from below by $\varepsilon^{n-1}/2$. From this it is obvious that the family $\hat{A}(t)$ satisfies an ε-condition (EC) with $\hat{\varepsilon} := \varepsilon^n/2$.

Summarizing, we have shown that $\hat{A}(t)$ satisfies all conditions of Theorem 1. Hence, by induction, we conclude that the claim holds for $\hat{A}(t)$, i.e., there exist a constant $\hat{K}$ and some $\hat{t}_0 > 0$ such that

$$\hat{\pi}_r(t) \leqq \hat{K} f_t(c_s, c_r)\hat{\pi}_s(t)$$

holds for the stationary distribution $\hat{\pi}$ of the modified chain, whenever $t < t_0$ and $c_r > c_s$.

On the other hand, however, it is obvious that the stationary distribution $\hat{\pi}$ of the modified chain $\hat{P}(t)$ must be related to $\pi(t)$ via

$$\hat{\pi}_i(t) = \pi_i(t) + \pi_j(t),$$
$$\hat{\pi}_k(t) = \pi_k(t) \quad \text{for } k \neq i, j.$$

But this further implies that Theorem 1 also holds for the original chain with $\hat{K} = K \cdot 2 \cdot \varepsilon^{-(n-1)}$.

Case ii. For every two distinct $i, j \in S^0$, $a_{ij}(t) = 0$.

The idea for settling this case consists in reducing the number of different values assumed by the weights c_i. Thus we define

$$\delta := \min\{c_i : i \in S \backslash S^0\} - \min\{c_j : j \in S^0\}$$

and consider the weights $\hat{c}_i$ given by

$$\hat{c}_i = \begin{cases} c_i + \delta & \text{if } i \in S^0, \\ c_i & \text{if } i \in S\backslash S^0. \end{cases}$$

By induction, we know that the stationary distribution $\hat{\pi}(t)$ of the associated matrix $\hat{P}(t)$ satisfies

$$\hat{\pi}_r(t) \leqq \hat{K} f_t(\hat{c}_s, \hat{c}_r)\hat{\pi}_s(t) \quad \text{whenever } \hat{c}_r > \hat{c}_s,$$

for a suitable constant $\hat{K}$.

Now consider the vector $\bar{\pi}(t)$ with components

$$\bar{\pi}_i(t) = \begin{cases} \pi_i(t) & \text{if } i \in S\backslash S^0, \\ f_t(c_i, c_i + \delta)\pi_i(t) & \text{if } i \in S^0. \end{cases}$$

We claim that $\bar{\pi}(t)\hat{P}(t) = \bar{\pi}(t)$, i.e., up to normalizing, $\bar{\pi}(t)$ is the stationary distribution of $\hat{P}(t)$.

To verify the claim, first recall that

$$\sum_{i \in S} p_{ij}(t)\pi_i(t) = \pi_j(t).$$

Using the fact that

$$\hat{p}_{ij}(t) = 0 = p_{ij}(t) \quad \text{if } i, j \in S^0, i \neq j$$

and the multiplicative property

$$f_t(c_i, c_i + \delta) f_t(\hat{c}_i, \hat{c}_m) = f_t(c_i, c_m) \quad \text{if } i \in S^0, m \in S\backslash S^0,$$

we get the following:

For $i \in S^0$,

$$\begin{aligned} \hat{p}_{ii}(t)\bar{\pi}_i(t) &= \left[1 - \sum_{m \notin S^0} \hat{p}_{im}(t)\right] f_t(c_i, c_i + \delta)\pi_i(t) \\ &= \left[f_t(c_i, c_i + \delta) - \sum_{m \notin S^0} p_{im}(t)\right]\pi_i(t) \\ &= \left[\bar{\pi}_i(t) - \sum_{m \notin S^0} p_{im}(t)\right]\pi_i(t). \end{aligned}$$

For $i \notin S^0$, j arbitrary,

$$\hat{p}_{ij}(t)\bar{\pi}_j(t) = p_{ij}(t)\pi_j(t).$$

Thus

$$\sum_{i \in S} \hat{p}_{ij}(t)\bar{\pi}_i(t) = \bar{\pi}_j(t).$$

Writing $z(t) = \sum_{i \in S} \bar{\pi}_j(t)$, we therefore conclude that

$$\hat{\pi}(t) = z^{-1}(t)\bar{\pi}(t)$$

is the (unique) stationary distribution of $\hat{P}(t)$.

But this implies that the theorem holds for $P(t)$. Indeed, if $c_r > c_s$, then we have

$$\pi_r(t) \leqq \hat{K}f_t(c_r, c_s)\pi_s(t)$$

for $s \notin S^0$ and

$$\pi_r(t) \leqq \hat{K}f_t(\hat{c}_s, c_r)\bar{\pi}_s(t) = \hat{K}f_t(c_r, c_s)\pi_s(t)$$

for $s \in S^0$. □

THE SINGULAR H_∞ CONTROL PROBLEM WITH DYNAMIC MEASUREMENT FEEDBACK*

A. A. STOORVOGEL†

Abstract. This paper is concerned with the H_∞ problem with measurement feedback. The problem is to find a dynamic feedback from the measured output to the control input such that the closed-loop system has an H_∞ norm strictly less than some a priori given bound γ and such that the closed-loop system is internally stable. Necessary and sufficient conditions are given under which such a feedback exists. The only assumption that must be made is that there are no invariant zeros on the imaginary axis for two subsystems. Contrary to recent publications no assumptions are made on the direct feedthrough matrices of the plant. It turns out that this problem can be reduced to an almost disturbance decoupling problem with measurement feedback and internal stability, i.e., the problem in which we can make the H_∞ norm *arbitrarily small.*

Key words. quadratic matrix inequality, Riccati equation, almost disturbance decoupling, measurement feedback, internal stability

1. Introduction.

After the original formulation of the H_∞ problem in [22] much work has been done on the solution of this problem. Initially almost all the work was done in a mixture of time-domain and frequency-domain techniques (see [1], [4], [5]). In the last few years two new methods have evolved: the polynomial approach (see [9]) and a time-domain approach (see [2], [8], [12], [13], [20]).

This paper handles the problem in the time domain. This has the advantage that we directly obtain an upper bound on the necessary dynamic order of the controller, namely, the dynamic order of the original plant. A similar result was obtained in [10] and [11] using frequency domain techniques. Moreover, in our opinion, the results are more intuitive.

In the above-mentioned literature it was assumed that there are no invariant zeros on the imaginary axis and that the direct feedthrough matrices of the plant are nonsingular. In literature two methods have been proposed to tackle the H_∞ problem without these assumptions:

- Apply a small perturbation on the output matrices such that these assumptions are satisfied for the perturbed system. Then solve the H_∞ problem for the perturbed system. If the perturbation satisfies some prerequisites then a controller works for the original system if it works for the perturbed system. However, we do not know a priori how large the perturbations are allowed to be. Hence if for a certain perturbation no suitable controller exists, then we are not sure whether or not a suitable controller exists for a smaller perturbation (see [19]).
- Apply a transformation in the frequency domain:
$$G(s) \to \tilde{G}(s) := G\left(\frac{s+\varepsilon}{1+\varepsilon s}\right) \qquad (\varepsilon > 0).$$
If we can find a suitable controller for the original system, then we can find a controller for the transformed plant for ε small enough. Vice versa, if for some ε there exists a suitable controller for the transformed system then the same

controller is a suitable controller for the original system. This approach has the same disadvantage as the previous one since it is not clear how small we should choose ε. Another problem is that we still must make the assumption that the transfer matrix from control input to output is left invertible as a rational matrix (see [15]).

Recently, in the case of state feedback, a method of handling the singularity of the direct feedthrough matrix (see [18]) without the above-mentioned disadvantages was proposed. In the present paper we shall develop a method of handling these singularities in the case of measurement feedback. Our results reduce to the known results in [2] and [20] in case these singularities do not occur.

The necessary and sufficient conditions under which there exists an internally stabilizing dynamic compensator which makes the H_∞ norm strictly less than some a priori given bound γ are formulated in a way that differs from those found in recent publications [2], [20]. In these papers the results are formulated in terms of two Riccati equations. However in the case where there are singularities of the direct feedthrough matrices, these Riccati equations do not exist. We have two quadratic matrix inequalities that replace the role of these Riccati equations. The solution of each of these quadratic matrix inequalities must satisfy rank conditions. Moreover, we have a condition which couples these two matrix inequalities. The spectral radius of the product of the two solutions of these matrix inequalities should be smaller than a certain a priori given upper bound. In the regular case the first rank condition together with the quadratic matrix inequality reduces to a Riccati equation and the second rank condition guarantees that it is a stabilizing solution of the Riccati equation.

The proof of our main result only uses the result for the state feedback H_∞ control problem. Our proof will use ideas used in [2] to solve the regular H_∞ problem with measurement feedback but is independent of the results in [2] and is entirely self-contained.

The outline of the paper is as follows. In § 2 we formulate the problem and present the main result. Moreover, we show that in the regular case and the state feedback case this result reduces to the known results in [2] and [18], respectively. In § 3 it is shown that the conditions for the existence of a suitable compensator as given in our main theorem are necessary. It is also shown that the problem of finding such a compensator is equivalent to finding such a compensator for another system, i.e., it is shown that any compensator which internally stabilizes this new system and makes the closed-loop H_∞ norm less than γ has the same properties when applied to the original system and vice versa. This new system has some desirable properties and using these properties in § 4, it is shown that for this new system we can even make the H_∞ norm arbitrarily small. In § 5 a method for finding the desired compensator is discussed. We finish in § 6 with some concluding remarks. The proofs of § 3 are given in Appendix B since they are rather technical. Appendix A introduces a number of suitably chosen bases and some of the properties the system matrices have in these new bases. These will be needed in Appendix B.

2. Problem formulation and main results. We consider the linear, time-invariant, finite-dimensional system:

$$\Sigma: \begin{cases} \dot{x} = Ax + Bu + Ew, \\ y = C_1x + D_1w, \\ z = C_2x + D_2u, \end{cases} \tag{2.1}$$

where $x \in \mathcal{R}^n$ is the state, $u \in \mathcal{R}^m$ the control input, $w \in \mathcal{R}^l$ the unknown disturbance,

$y \in \mathcal{R}^p$ the measured output, and $z \in \mathcal{R}^q$ the unknown output to be controlled. A, B, E, C_1, C_2, D_1, and D_2 are matrices of appropriate dimensions. We would like to minimize the effect of the disturbance w on the output z, using the measured output y, by finding an appropriate control input u. More precisely, we seek a *dynamic* compensator F described by the following equations:

$$\Sigma_F : \begin{cases} \dot{p} = Kp + Ly, \\ u = Mp + Ny, \end{cases} \tag{2.2}$$

such that after applying the feedback $u = Fy$ in the system (2.1), the resulting closed-loop system, whose transfer matrix is denoted by G_F, is internally stable and has minimal H_∞ norm, i.e., such that

$$\|G_F\|_\infty := \sup_{\omega \in \mathcal{R}} \sigma[G_F(i\omega)] \tag{2.3}$$

is minimized over all possible dynamic feedback laws F that make the closed-loop system internally stable. Here $\sigma[M]$ denotes the largest singular value of the matrix M. Internally stable means that when $w \equiv 0$ then for every initial state of the system and controller the state of the system and controller in the interconnection both converge to zero as $t \to \infty$. If the controller is given by (2.2) and the system is given by (2.1) this is equivalent to requiring that the following matrix is asymptotically stable:

$$\begin{pmatrix} A + BNC_1 & BM \\ LC_1 & K \end{pmatrix}. \tag{2.4}$$

Although this is our ultimate goal, in this paper we shall derive necessary and sufficient conditions under which we can find a dynamic feedback law which makes the resulting H_∞ norm of the closed-loop system strictly less than some a priori given bound γ and such that the resulting closed-loop system is internally stable.

A central role in our study of the problem above will be played by the *quadratic matrix inequality*. For any $\gamma > 0$ and matrix $P \in \mathcal{R}^{n \times n}$ we define the following matrix:

$$F_\gamma(P) := \begin{pmatrix} A^TP + PA + C_2^TC_2 + \gamma^{-2}PEE^TP & PB + C_2^TD_2 \\ B^TP + D_2^TC_2 & D_2^TD_2 \end{pmatrix}. \tag{2.5}$$

If $F_\gamma(P) \geqq 0$, we say P is a solution of the quadratic matrix inequality at γ. We also define a dual version of this quadratic matrix inequality. For any $\gamma > 0$ and matrix $Q \in \mathcal{R}^{n \times n}$ we define the following matrix:

$$G_\gamma(Q) := \begin{pmatrix} AQ + QA^T + EE^T + \gamma^{-2}QC_2^TC_2Q & QC_1^T + ED_1^T \\ C_1Q + D_1E^T & D_1D_1^T \end{pmatrix}. \tag{2.6}$$

If $G_\gamma(Q) \geqq 0$, we say that Q is a solution of the dual quadratic matrix inequality at γ. In addition to these two matrices we define two polynomial matrices, whose role is again completely dual:

$$L_\gamma(P, s) := [sI - A - \gamma^2EE^TP \quad -B], \tag{2.7}$$

$$M_\gamma(Q, s) := \begin{bmatrix} sI - A - \gamma^{-2}QC_2^TC_2 \\ -C_1 \end{bmatrix}. \tag{2.8}$$

We note that $L_\gamma(P, s)$ is the controllability pencil associated with the system:

$$\dot{x} = (A + \gamma^{-2}EE^TP)x + Bu, \tag{2.9}$$

while $M_\gamma(Q, s)$ is the observability pencil associated with the system:

$$\dot{x} = (A + \gamma^{-2} Q C_2^T C_2)x, \qquad y = -C_1 x. \tag{2.10}$$

We define the following two transfer matrices which again play a dual role:

$$G(s) := C_2(sI - A)^{-1}B + D_2, \tag{2.11}$$

$$H(s) := C_1(sI - A)^{-1}E + D_1. \tag{2.12}$$

In the formulation of our main result we also require the concept of *invariant zero* of the system $\Sigma = (A, B, C, D)$. These are all $s \in \mathscr{C}$ such that

$$\operatorname{rank} \begin{pmatrix} sI - A & -B \\ C & D \end{pmatrix} < \operatorname{normrank} \begin{pmatrix} sI - A & -B \\ C & D \end{pmatrix}. \tag{2.13}$$

Here "normrank" denotes the rank of a matrix as a matrix with entries in the field of rational functions. Moreover let $\mathscr{C}^+ (\mathscr{C}^0, \mathscr{C}^-)$ denote all $s \in \mathscr{C}$ such that Re $s > 0$ (Re $s = 0$, Re $s < 0$). Finally, let $\rho(M)$ denote the spectral radius of the matrix M. We are now in the position to formulate our main result.

THEOREM 2.1. *Consider the system* (2.1). *Assume that the systems* (A, B, C_2, D_2) *and* (A, E, C_1, D_1) *have no invariant zeros in* $\mathscr{C}^0$. *Then the following two statements are equivalent*:

(i) *There exists a linear, time-invariant, finite-dimensional dynamic compensator* F *of the form* (2.2) *such that by applying* $u = Fy$ *in* (2.1) *the resulting closed-loop system, with transfer matrix* G_F, *is internally stable and has* H_∞ *norm less than* γ, *i.e.,* $\|G_F\|_\infty < \gamma$.

(ii) *There exist positive semidefinite solutions* P, Q *of the quadratic matrix inequalities* $F_\gamma(P) \geqq 0$ *and* $G_\gamma(Q) \geqq 0$ *satisfying* $\rho(PQ) < \gamma^2$, *such that the following rank conditions are satisfied*:

(1) rank $F_\gamma(P) = $ normrank G,

(2) rank $G_\gamma(Q) = $ normrank H,

(3) $\operatorname{rank} \begin{pmatrix} L_\gamma(P, s) \\ F_\gamma(P) \end{pmatrix} = n + \operatorname{normrank} G \quad \forall s \in \mathscr{C}^0 \cup \mathscr{C}^+$,

(4) $\operatorname{rank} (M_\gamma(Q, s) \; G_\gamma(Q)) = n + \operatorname{normrank} H \, \forall s \in \mathscr{C}^0 \cup \mathscr{C}^+$.

Remarks.

(i) Note that since $P \geqq 0$ and $Q \geqq 0$ the matrix PQ has only real and nonnegative eigenvalues.

(ii) The construction of a dynamic compensator satisfying (i) can be done according to the method as described in § 5. It turns out that it is always possible to find a compensator of the same dynamic order as the original plant.

(iii) By Corollary A5 we know that a solution P of the quadratic matrix inequality $F_\gamma(P) \geqq 0$ satisfying (1) and (3) is unique. By dualizing Corollary A5 it can also be shown that a solution Q of the dual quadratic matrix inequality $G_\gamma(Q) \geqq 0$ satisfying (2) and (4) is unique. The existence of P and Q can be checked via a state-space transformation and investigating a reduced order Riccati equation.

(iv) We shall prove this theorem only for the case $\gamma = 1$. The general result can then be easily obtained by scaling.

Before we prove this result we look more closely at the result for two special cases.

State feedback: $C_1 = I$, $D_1 = 0$. In this case we have $y = x$, i.e., we know the state of the system. The first matrix inequality $F_\gamma(P) \geqq 0$ together with rank conditions (1) and (3) does not depend on C_1 or D_1 so we cannot expect a simplification there. However $G_\gamma(Q)$ does get a special form:

$$G_\gamma(Q)=\begin{pmatrix} AQ+QA^T+EE^T+\gamma^{-2}QC_2^TC_2Q & Q \\ Q & 0 \end{pmatrix}. \tag{2.14}$$

Using this special form it can be easily seen that $G_\gamma(Q)\geqq 0$ if and only if $Q=0$. For the rank conditions it is interesting to investigate the normrank of H. We have

$$\text{normrank } H=\text{normrank }(sI-A)^{-1}E=\text{rank } E. \tag{2.15}$$

It can be easily checked, by using (2.15), that $Q=0$ satisfies rank conditions (2) and (4). The condition $\rho(PQ)<\gamma^2$ is trivially satisfied when $Q=0$. We find that in this case condition (ii) of Theorem 2.1 becomes:

There exists a positive semidefinite solution P of the matrix inequality $F_\gamma(P)\geqq 0$ such that the following two rank conditions are satisfied:

(1) rank $F_\gamma(P)=$ normrank G,

(2) rank $\begin{pmatrix} L_\gamma(P,s) \\ F_\gamma(P) \end{pmatrix}=n+\text{normrank } G \quad \forall s\in \mathscr{C}^0\cup\mathscr{C}^+$,

which is exactly the result obtained in [18].

Regular case: *D_1 surjective and D_2 injective.* In this case it can be shown, in the same way as in [18], that $F_\gamma(P)\geqq 0$ together with rank condition (1) is equivalent to the condition

$$A^TP+PA+C_2^TC_2+\gamma^{-2}PEE^TP-(PB+C_2^TD_2)(D_2^TD_2)^{-1}(B^TP+D_2^TC_2)=0.$$

The dual version of this proof can be applied to the dual matrix inequality $G_\gamma(Q)\geqq 0$ together with rank condition (2). These conditions turn out to be equivalent to the condition:

$$AQ+QA^T+EE^T+\gamma^{-2}QC_2^TC_2Q-(QC_1^T+ED_1^T)(D_1D_1^T)^{-1}(C_1Q+D_1E^T)=0.$$

The two remaining rank conditions (3) and (4) turn out to be equivalent with the requirement that the following two matrices are asymptotically stable:

$$A+\gamma^{-2}EE^TP-B(D_2^TD_2)^{-1}(B^TP+D_2^TC_2),$$
$$A+\gamma^{-2}QC_2^TC_2-(QC_1^T+ED_1^T)(D_1D_1^T)^{-1}C_1.$$

Together with the remaining condition $\rho(PQ)<\gamma^2$, we thus re-obtain exactly the conditions derived in [2] and [6].

3. Reduction of the original problem to an almost disturbance decoupling problem. In this section the implication (i)⇒(ii) in Theorem 2.1 will be proven. Moreover, in case the conditions (ii) of Theorem 2.1 are satisfied, we shall show that the problem of finding a suitable compensator F for the system (2.1) is equivalent to finding a suitable compensator F for a *new system* which has some very nice structural properties. In the next section the H_∞ problem for this new system will be tackled. *In the remainder of this paper we assume* $\gamma=1$. The general result can be easily obtained by scaling. Define $F(P)$, $G(Q)$, $L(P,s)$, and $M(Q,s)$ to be equal to $F_1(P)$, $G_1(Q)$, $L_1(P,s)$, and $M_1(Q,s)$, respectively.

LEMMA 3.1. *Assume that (A, B, C_2, D_2) and (A, E, C_1, D_1) have no invariant zeros on $\mathscr{C}^0$. If there exists a linear, time-invariant, finite-dimensional dynamic compensator F such that the resulting closed-loop system is internally stable and has H_∞ norm less than one, then the following two conditions are satisfied*:

(i) *There exists a solution* $P \geqq 0$ *of the quadratic matrix inequality* $F(P) \geqq 0$ *satisfying the following two rank conditions*:

(1) rank $F(P) =$ normrank G,

(2) $\operatorname{rank}\begin{pmatrix} L(P, s) \\ F(P) \end{pmatrix} = n + \operatorname{normrank} G \quad \forall s \in \mathscr{C}^0 \cup \mathscr{C}^+.$

(ii) *There exists a solution* $Q \geqq 0$ *of the dual quadratic matrix inequality* $G(Q) \geqq 0$ *satisfying the following two rank conditions*:

(1) rank $G(Q) =$ normrank H,

(2) $\operatorname{rank}(M(Q, s)\ G(Q)) = n + \operatorname{normrank} H \quad \forall s \in \mathscr{C}^0 \cup \mathscr{C}^+.$

Proof. Since there exists an internally stabilizing feedback which makes the H_∞ norm less than one for the problem with measurement feedback there certainly also exists an internally stabilizing feedback which makes the H_∞ norm less than one in the full information case, i.e., the case where both x and w are known. This implies, according to [18], that there exists a matrix P satisfying the conditions in (i). By dualization it can be easily shown that there also exists a matrix Q satisfying the conditions in (ii). □

Assume there exist P and Q satisfying the conditions in parts (i) and (ii) of Lemma 3.1. We make the following factorization of $F(P)$:

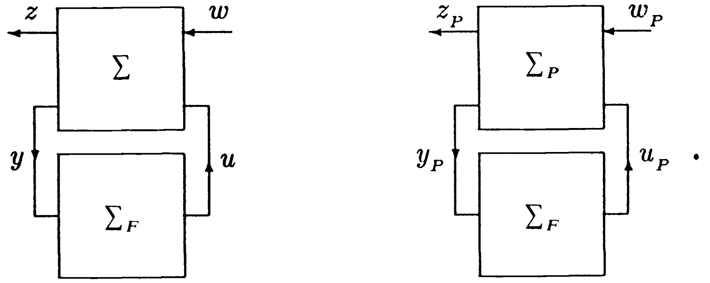
$$F(P) = \begin{pmatrix} C_{2,P}^T \\ D_P^T \end{pmatrix} (C_{2,P} \quad D_P) \tag{3.1}$$

where $C_{2,P}$ and D_P are matrices of suitable dimensions. This can be done since $F(P) \geqq 0$. We define the following system:

$$\Sigma_P : \begin{cases} \dot{x}_P = (A + EE^T P)x_P + Bu_P + Ew_P, \\ y_P = (C_1 + D_1 E^T P)x_P + D_1 w_P, \\ z_P = C_{2,P} x_P + D_P u_P. \end{cases} \tag{3.2}$$

LEMMA 3.2. *Let P satisfy Lemma* 3.1(i). *Moreover let an arbitrary linear time-invariant finite-dimensional compensator F be given, described by* (2.2). *Consider the following two systems, where the system on the left is the interconnection of* (2.1) *and* (2.2) *and the system on the right is the interconnection of* (3.2) *and* (2.2):

(3.3)



Then the following statements are equivalent:

(i) *The system on the left is internally stable and its transfer matrix from w to z has H_∞ norm less than one.*

(ii) *The system on the right is internally stable and its transfer matrix from w_P to z_P has H_∞ norm less than one.*

Proof. See appendix B for the proof. □

If for the original system (2.1) there exists an internally stabilizing, linear, time-invariant, finite-dimensional compensator such that the resulting closed-loop matrix has H_∞ norm less than one then, by applying Lemma 3.2, we know that the *same* compensator is internally stabilizing for the new system (3.2) and yields a closed-loop transfer matrix with H_∞ norm less than one. Hence if we consider for this new system the two quadratic matrix inequalities we know from Lemma 3.1 that there exist positive semidefinite solutions to these inequalities satisfying a number of rank conditions. We shall now formalize this in the following lemma. Define $A_P := (A + EE^TP)$ and $C_{1,P} := (C_1 + D_1E^TP)$. Then for arbitrary X and Y in $\mathscr{R}^{n\times n}$ we define the following matrices:

$$\bar{F}(X) := \begin{pmatrix} A_P^TX + XA_P + C_{2,P}^TC_{2,P} + XEE^TX & XB + C_{2,P}^TD_P \\ B^TX + D_P^TC_{2,P} & D_P^TD_P \end{pmatrix}, \tag{3.4}$$

$$\bar{G}(Y) := \begin{pmatrix} A_PY + YA_P^T + EE^T + YC_{2,P}^TC_{2,P}Y & YC_{1,P}^T + ED_1^T \\ C_{1,P}Y + D_1E^T & D_1D_1^T \end{pmatrix}, \tag{3.5}$$

$$\bar{L}(X, s) := [sI - A_P - EE^TX \quad -B], \tag{3.6}$$

$$\bar{M}(Y, s) := \begin{bmatrix} sI - A_P - YC_{2,P}^TC_{2,P} \\ -C_{1,P} \end{bmatrix}. \tag{3.7}$$

Moreover, we define two new transfer matrices:

$$\bar{G}(s) := C_{2,P}(sI - A_P)^{-1}B + D_P, \tag{3.8}$$

$$\bar{H}(s) := C_{1,P}(sI - A_P)^{-1}E + D_1. \tag{3.9}$$

LEMMA 3.3. *Let P and Q satisfy part* (i) *and part* (ii) *in Lemma* 3.1, *respectively. Assume* (A, B, C_2, D_2) *and* (A, E, C_1, D_1) *have no invariant zeros on* $\mathscr{C}^0$. *Then we have the following two results*:

(i) $X := 0$ *is a solution of the quadratic matrix inequality* $\bar{F}(X) \geqq 0$ *and satisfies the following two rank conditions*:

(1) rank $\bar{F}(X) =$ normrank $\bar{G}$,

(2) rank $\begin{pmatrix} \bar{L}(X, s) \\ \bar{F}(X) \end{pmatrix} = n +$ normrank $\bar{G} \quad \forall s \in \mathscr{C}^0 \cup \mathscr{C}^+$.

(ii) *There exist a matrix Y satisfying the quadratic matrix inequality* $\bar{G}(Y) \geqq 0$ *together with the following two rank conditions*:

(1) rank $\bar{G}(Y) =$ normrank $\bar{H}$,

(2) rank $(\bar{M}(Y, s) \quad \bar{G}(Y)) = n +$ normrank $\bar{H} \quad \forall s \in \mathscr{C}^0 \cup \mathscr{C}^+$,

if and only if $I - QP$ is invertible. Moreover, in that case $Y := (I - QP)^{-1}Q$ is the unique solution. This matrix Y is positive semidefinite if and only if

$$\rho(PQ) < 1. \tag{3.10}$$

Proof. See Appendix B for the proof. □

Proof of (i)⇒(ii) *in Theorem* 2.1. The first part can be obtained directly from Lemma 3.1. By Lemma 3.2 we know that also for the transformed system Σ_P there exists a dynamic compensator which internally stabilizes the system and makes the H_∞ norm less than one. By applying Lemma 3.1 to this new system, this implies that there exists a matrix $Y \geqq 0$ satisfying Lemma 3.3(ii). Hence by Lemma 3.3 we have (3.10) and therefore all the conditions in Theorem 2.1(ii) are satisfied. □

In the remainder of this section we assume that the conditions of Theorem 2.1(ii) are satisfied.

In order to prove the implication (ii)⇒(i) in Theorem 2.1 we transform the system (3.2) once again. This time, however, we use the dualized version of the original transformation. By Lemma 3.3 we know $Y = (I - QP)^{-1}Q \geqq 0$ satisfies $\bar{G}(Y) \geqq 0$. We factorize $\bar{G}(Y)$:

$$\bar{G}(Y) = \begin{pmatrix} E_{P,Q} \\ D_{P,Q} \end{pmatrix} (E_{P,Q}^T \quad D_{P,Q}^T) \tag{3.11}$$

where $E_{P,Q}$ and $D_{P,Q}$ are matrices of suitable dimensions. We define the following system:

$$\text{(3.12)}\qquad \Sigma_{P,Q}:\begin{cases} \dot{x}_{P,Q}=A_{P,Q}x_{P,Q}+B_{P,Q}u_{P,Q}+E_{P,Q}w,\\ y_{P,Q}=C_{1,P}x_{P,Q}\qquad\qquad\quad +D_{P,Q}w,\\ z_{P,Q}=C_{2,P}x_{P,Q}+D_Pu_{P,Q},\end{cases}$$

where

$$\text{(3.13)}\qquad A_{P,Q}:=A_P+YC_{2,P}^TC_{2,P},$$

$$\text{(3.14)}\qquad B_{P,Q}:=B+YC_{2,P}^TD_P.$$

By applying Lemma 3.3 to the system $\Sigma_{P,Q}$ with the corresponding matrix inequalities we note that $X_{P,Q}:=0$ and $Y_{P,Q}:=0$ satisfy the matrix inequalities and the corresponding rank conditions for this new system. It can be shown that this implies that

$$\text{(3.15)}\qquad \operatorname{rank}\begin{pmatrix} sI-A_{P,Q} & -B_{P,Q}\\ C_{2,P} & D_P\end{pmatrix}=n+\operatorname{rank}\,(C_{2,P}\quad D_P)\quad \forall s\in\mathscr{C}^0\cup\mathscr{C}^+$$

and

$$\text{(3.16)}\qquad \operatorname{rank}\begin{pmatrix} sI-A_{P,Q} & -E_{P,Q}\\ C_{1,P} & D_{P,Q}\end{pmatrix}=n+\operatorname{rank}\begin{pmatrix} E_{P,Q}\\ D_{P,Q}\end{pmatrix}\quad \forall s\in\mathscr{C}^0\cup\mathscr{C}^+.$$

By applying Lemma 3.2 and its dualized version the following corollary can be derived.

COROLLARY 3.4. *Let an arbitrary compensator F of the form* (2.2) *be given. The following two statements are equivalent*:

(i) *The compensator F when applied to the system Σ, described by* (2.1), *is internally stabilizing and the resulting closed-loop transfer matrix has H_∞ norm less than one.*

(ii) *The compensator F when applied to the system $\Sigma_{P,Q}$, described by* (3.12), *is internally stabilizing and the resulting closed-loop transfer matrix has H_∞ norm less than one.*

In the next section we shall show how to solve the H_∞ problem for a system satisfying the extra conditions (3.15) and (3.16). It turns out that for this new system we can even make the H_∞ norm arbitrarily small.

4. The solution of the almost disturbance decoupling problem. Assume that the following system is given:

$$\text{(4.1)}\qquad \Sigma:\begin{cases} \dot{x}=Ax+Bu+Ew\\ y=C_1x+\qquad\; D_1w,\\ z=C_2x+D_2u,\end{cases}$$

such that the following two conditions are satisfied:

$$\text{(4.2)}\qquad \begin{pmatrix} sI-A & -B\\ C_2 & D_2\end{pmatrix}=n+\operatorname{rank}\,(C_2\quad D_2)\quad \forall s\in\mathscr{C}^0\cup\mathscr{C}^+$$

and

$$\text{(4.3)}\qquad \begin{pmatrix} sI-A & -E\\ C_1 & D_1\end{pmatrix}=n+\operatorname{rank}\begin{pmatrix} E\\ D_1\end{pmatrix}\quad \forall s\in\mathscr{C}^0\cup\mathscr{C}^+.$$

From the previous section we know that if the conditions in part (ii) of Theorem 2.1 are satisfied then it is always possible to transform our system into a new system that satisfies the conditions (4.2) and (4.3). Moreover, if a compensator F given by (2.2) internally stabilizes this new system and makes the H_∞ norm of the resulting closed-loop transfer matrix smaller than one, then it does the same with the closed-loop system associated with the original system. In fact, we shall prove a stronger result.

THEOREM 4.1. *Assume system* (4.1) *is given satisfying* (4.2) *and* (4.3). *Then for all $\varepsilon > 0$ there exists a linear, time-invariant, finite-dimensional dynamic compensator F such that the closed-loop system is internally stable and has H_∞ norm less than ε.*

Remark. We note that even if for this new system we can make the H_∞ norm arbitrarily small, for the original system we are only sure that the H_∞ norm will be less than one. It is very well possible that a compensator for the new system yields an H_∞ norm of say 0.0001 while the same compensator makes the H_∞ norm of the original plant only 0.9999.

Before we can prove this result we have to do some preparatory work. We first have to introduce a number of subspaces from geometric control theory as follows.

DEFINITION 4.2. Assume we have a system

$$\Sigma_{ci}: \begin{cases} \dot{x} = Ax + Bu, \\ y = C_2x + D_2u. \end{cases} \tag{4.4}$$

We define *the strongly controllable subspace* $\mathcal{T}(\Sigma_{ci})$ as the smallest subspace $\mathcal{T}$ of $\mathcal{R}^n$ for which there exists a mapping G such that

$$(A + GC_2)\mathcal{T} \subset \mathcal{T}, \tag{4.5}$$

$$\operatorname{Im}(B + GD_2) \subset \mathcal{T}. \tag{4.6}$$

We also define the subspace $\mathcal{T}_g(\Sigma_{ci})$ as the smallest subspace $\mathcal{T}$ of $\mathcal{R}^n$ for which there exists a matrix G such that (4.5) and (4.6) are satisfied and, moreover, $A + GC_2 | \mathcal{R}^n / \mathcal{T}$ is asymptotically stable. It is well known that these subspaces are well defined in this way. A system is called *strongly controllable* if its strongly controllable subspace is equal to the whole state space.

We also define the dual versions of these subspaces as follows.

DEFINITION 4.3. Assume we have a system

$$\Sigma_{di}: \begin{cases} \dot{x} = Ax + Ew, \\ y = C_1x + D_1u. \end{cases} \tag{4.7}$$

We define *the weakly unobservable subspace* $\mathcal{V}(\Sigma_{di})$ as the largest subspace $\mathcal{V}$ of $\mathcal{R}^n$ for which there exists a mapping F such that

$$(A + EF)\mathcal{V} \subset \mathcal{V}, \tag{4.8}$$

$$(C_1 + D_1F)\mathcal{V} = \{0\}. \tag{4.9}$$

We also define the subspace $\mathcal{V}_g(\Sigma_{di})$ as the largest subspace $\mathcal{V}$ for which there exists a mapping F such that (4.8) and (4.9) are satisfied and, moreover, $A + EF | \mathcal{V}$ is asymptotically stable. It is well known that these subspaces are well defined in this way. A system is called *strongly observable* if its weakly unobservable subspace is equal to $\{0\}$.

In order to calculate these subspaces the following lemma will come in handy.

LEMMA 4.4. *$\mathcal{T}(\Sigma_{ci})$ equals the limit of the following sequence of subspaces*:

$$\begin{aligned} &\mathcal{T}_0(\Sigma_{ci}) := 0, \quad \mathcal{T}_{i+1}(\Sigma_{ci}) := \{x \in \mathcal{R}^n \mid \exists \tilde{x} \in \mathcal{T}_i(\Sigma_{ci}),\ u \in \mathcal{R}^m \textit{ such that} \\ &\qquad\qquad x = A\tilde{x} + Bu \textit{ and } C_2\tilde{x} + D_2u = 0\}. \end{aligned} \tag{4.10}$$

It is well known (see [16]) *that* $\mathcal{T}_i(\Sigma_{ci})$ $(i=1, 2, \cdots)$ *is a nondecreasing sequence of subspaces that attains its limit in a finite number of steps. In the same way* $\mathcal{V}(\Sigma_{di})$ *equals the limit of the following sequence of subspaces*:

$$\mathcal{V}_0(\Sigma_{di}) := \mathcal{R}^n, \quad \mathcal{V}_{i+1}(\Sigma_{di}) := \{x \in \mathcal{R}^n \mid \exists \tilde{u} \in \mathcal{R}^m, \text{ such that } Ax + E\tilde{u} \in \mathcal{V}_i(\Sigma_{di}) \text{ and } C_1 x + D_1 \tilde{u} = 0\}. \tag{4.11}$$

Moreover, if G is a mapping such that (4.5) *and* (4.6) *are satisfied for* $\mathcal{T} = \mathcal{T}(\Sigma_{ci})$ *and if F is a mapping such that* (4.8) *and* (4.9) *are satisfied for* $\mathcal{V} = \mathcal{V}(\Sigma_{di})$, *then we have the following two equalities*:

$$\mathcal{T}_g(\Sigma_{ci}) = [\mathcal{T}(\Sigma_{ci}) + \mathcal{X}_b(A+GC_2)] \cap \langle \mathcal{T}(\Sigma_{ci}) + C_2^{-1} \operatorname{im} D_2 \mid A + GC_2 \rangle, \tag{4.12}$$

$$\mathcal{V}_g(\Sigma_{di}) = \mathcal{V}(\Sigma_{di}) \cap \mathcal{X}_g(A+EF) + < A+EF \mid \mathcal{V}(\Sigma_{di}) \cap E \ker D_1 \rangle. \tag{4.13}$$

Here $\mathcal{X}_b(A+GC_2)$ *denotes the modal subspace of the matrix* $A+GC_2$ *with respect to the closed right halfplane and* $\mathcal{X}_g(A+EF)$ *denotes the modal subspace of the matrix* $A+EF$ *with respect to the open left halfplane. Finally,* $\langle A+EF \mid \mathcal{V}(\Sigma_{di}) \cap E \ker D_1 \rangle$ *denotes the smallest* $A+EF$ *invariant subspace containing* $\mathcal{V}(\Sigma_{di}) \cap E \ker D_1$ *and* $\langle \mathcal{T}(\Sigma_{ci}) + C_2^{-1} \operatorname{im} D_2 \mid A + GC_2 \rangle$ *denotes the largest* $A+GC_2$ *invariant subspace contained in* $\mathcal{T}(\Sigma_{ci}) + C_2^{-1} \operatorname{im} D_2$.

Proof. The proof is almost entirely well known except possibly (4.12) and (4.13) in case the D-matrices are unequal to zero. This can be proven by first showing that there exists a G satisfying (4.5) and (4.6) for which (4.12) holds and after that, showing that the equality is independent of our particular choice of G satisfying (4.5) and (4.6). The same can be done for (4.13). Details are left to the reader. □

We can express the rank conditions (4.2) and (4.3) in terms of these subspaces (see [3], [17]) as follows.

LEMMA 4.5. *Let system* (4.1) *be given. The rank condition* (4.2) *is satisfied if and only if*

$$\mathcal{V}_g(\Sigma_{ci}) + \mathcal{T}(\Sigma_{ci}) = \mathcal{R}^n. \tag{4.14}$$

The rank condition (4.3) *is satisfied if and only if*

$$\mathcal{V}(\Sigma_{di}) \cap \mathcal{T}_g(\Sigma_{di}) = \{0\}. \tag{4.15}$$

Here Σ_{ci} *is given by* (4.4) *and* Σ_{di} *is given by* (4.7).

Using this we can derive the following lemma.

LEMMA 4.6. *Let system* (4.1) *be given satisfying* (4.2) *and* (4.3). *For all* $\varepsilon > 0$ *there exist mappings F and G such that* $A+BF$ *and* $A+GC_1$ *are asymptotically stable and, moreover,*

$$\|(C_2 + D_2 F)(sI - A - BF)^{-1}\|_\infty < \varepsilon \tag{4.16}$$

and

$$\|(sI - A - GC_1)(E + GD_1)\|_\infty < \varepsilon. \tag{4.17}$$

Proof. By Definition 4.3 we know there exists a mapping $\tilde{F}$ such that

$$(A + B\tilde{F})\mathcal{V}_g(\Sigma_{ci}) \subset \mathcal{V}_g(\Sigma_{ci}), \tag{4.18}$$

$$(C_2 + D_2\tilde{F})\mathcal{V}_g(\Sigma_{ci}) = \{0\}, \tag{4.19}$$

and moreover, $A + B\tilde{F} \mid \mathcal{V}_g(\Sigma_{ci})$ is asymptotically stable. Define the canonical projection $\Pi : \mathcal{R}^n \to \mathcal{R}^n / \mathcal{V}_g(\Sigma)$. By (4.19) there exists a mapping $\bar{C}$ such that $C_2 + D_2\tilde{F} = \bar{C}\Pi$.

Moreover, by (4.18) there exists a mapping $\bar{A}$ such that $\Pi(A+B\tilde{F})=\bar{A}\Pi$. Finally, define $\bar{B}:=\Pi B$ and the system:

$$(4.20) \qquad \Sigma_{fs}:\begin{cases} \dot{p}=\bar{A}p+\bar{B}u, \\ z=\bar{C}p+D_2u. \end{cases}$$

It can be easily shown by induction using the algorithm (4.10) that $\mathcal{T}_i(\Sigma_{fs})=\Pi\mathcal{T}_i(\Sigma_{ci})$ for $i=0, 1, \cdots$. Hence we have

$$\mathcal{T}(\Sigma_{fs})=\Pi\mathcal{T}(\Sigma_{ci})=\Pi\{\mathcal{T}(\Sigma_{ci})+\mathcal{V}_g(\Sigma_{ci})\}=\Pi\mathcal{R}^n=\mathcal{R}^n/\mathcal{V}_g(\Sigma_{ci}).$$

This implies that the system (4.20) is strongly controllable.

Define F_0 such that $(\bar{C}+D_2F_0)^TD_2=0$ and define M such that $\ker D_2=\operatorname{im} M$. It can be easily checked that $\mathcal{T}(\Sigma_{fs})=\mathcal{T}(\bar{A}+\bar{B}F_0, \bar{B}M, \bar{C}+D_2F_0, 0)$. Hence by Theorem 3.36 of [21] we know there exist an $\bar{F}$ such that

$$(4.21) \qquad \|(\bar{C}+D_2F_0)\, e^{((\bar{A}+\bar{B}F_0)+\bar{B}M\bar{F})t}\|_1<\varepsilon$$

and such that $\bar{A}+\bar{B}F_0+\bar{B}M\bar{F}$ is asymptotically stable.

Define $F:=\tilde{F}+(F_0+M\bar{F})\Pi$; then

$$(4.22) \qquad A+BF\,|\,\mathcal{V}_g(\Sigma_{ci})=A+B\tilde{F}\,|\,\mathcal{V}_g(\Sigma_{ci}),$$

$$(4.23) \qquad \Pi(A+BF)=(\bar{A}+\bar{B}F_0+\bar{B}M\bar{F})\Pi.$$

It can be easily shown that this implies that $A+BF$ is asymptotically stable. Moreover, we have

$$(4.24) \qquad (C_2+D_2F)\, e^{(A+BF)t}=(\bar{C}+D_2F_0)\, e^{((\bar{A}+\bar{B}F_0)+\bar{B}M\bar{F})t}$$

for all $t>0$. Using (4.24), we find for all $s\in i\mathcal{R}$ (use that $|e^{st}|=1$):

$$\begin{aligned}\|(C_2+D_2F)(sI-(A+BF))^{-1}\| &= \left\|\int_0^\infty (C_2+D_2F)\, e^{((A+BF)-sI)t}\,dt\right\| \\ &\leqq \int_0^\infty \|(C_2+D_2F)\, e^{((A+BF)-sI)t}\|\,dt \\ &= \|(C_2+D_2F)\, e^{(A+BF)t}\|_1 \\ &= \|(\bar{C}+D_2F_0)\, e^{((\bar{A}+\bar{B}F_0)+\bar{B}M\bar{F})t}\|_1 \\ &\leqq \varepsilon.\end{aligned}$$

This implies (4.16). Therefore F satisfies all the requirements of the lemma. The existence of a G such that $A+GC$ is asymptotically stable and such that (4.17) is satisfied can be obtained by dualization. □

We can now prove Theorem 4.1.

Proof of Theorem 4.1. Let $\varepsilon>0$. We first choose a mapping F such that

$$(4.25) \qquad \|(C_2+D_2F)(sI-A-BF)^{-1}\|_\infty<\varepsilon/3\|E\|^{-1}$$

and such that $A+BF$ is asymptotically stable. This can be done according to Lemma 4.6. Next choose a mapping G such that

$$(4.26) \qquad \|(sI-A-GC_1)^{-1}(E+GD_1)\|_\infty<\min\{\varepsilon/3\|D_2F\|^{-1}, \|E\|\,\|BF\|^{-1}\}$$

and such that $A+GC_1$ is asymptotically stable. Again Lemma 4.6 guarantees the existence of such a G. We apply the following dynamic feedback compensator to the system (4.1):

$$\Sigma_{F,G}:\begin{cases}\dot{p}=Ap+Bu+G(C_1p-y),\\ u=Fp.\end{cases} \tag{4.27}$$

The closed-loop system is given by (where $e:=x-p$):

$$\Sigma_{\mathrm{cl}}:\begin{cases}\begin{pmatrix}\dot{x}\\ \dot{e}\end{pmatrix}=\begin{pmatrix}A+BF & -BF\\ 0 & A+GC_1\end{pmatrix}\begin{pmatrix}x\\ e\end{pmatrix}+\begin{pmatrix}E\\ E+GD_1\end{pmatrix}w,\\ z=(C_2+D_2F\quad -D_2F)\begin{pmatrix}x\\ e\end{pmatrix}.\end{cases} \tag{4.28}$$

It is clear that this is an internally stabilizing feedback. We now calculate the transfer matrix from w to z of this system:

$$\begin{aligned}&(C_2+D_2F)(sI-A-BF)^{-1}E\\ &\quad-(C_2+D_2F)(sI-A-BF)^{-1}BF(sI-A-GC_1)^{-1}(E+GD_1)\\ &\quad-D_2F(sI-A-GC_1)^{-1}(E+GD_1).\end{aligned}$$

Using (4.25) and (4.26) it can easily be shown that this closed-loop transfer matrix has H_∞ norm less than ε. □

We are now able to complete the proof of Theorem 2.1.

Proof of the implication (ii)⇒(i) *of Theorem* 2.1. Since we can transform the original system into a system satisfying (4.2) and (4.3) we know by Lemma 4.1 that we can find an internally stabilizing dynamic compensator for this new system which is such that the closed-loop transfer matrix has H_∞ norm less than one. By applying Corollary 3.4 we know that this compensator F satisfies the requirements in Theorem 2.1(i). □

5. The design of an admissible compensator. In this section we shall give a method to calculate a dynamic compensator F such that the closed-loop system is internally stable and, moreover, the closed-loop transfer matrix has H_∞ norm less than one. We shall derive this F step by step, using the following conceptual algorithm.

(i) Calculate P and Q satisfying part (ii) of Theorem 2.1. This can, for instance, be done using Lemma A4. If they do not exist or if $\rho(PQ)\geqq 1$, then there does not exist a dynamic feedback satisfying part (i) of Theorem 2.1 and we stop.

(ii) Perform the factorizations (3.1) and (3.11). We can now construct the system $\Sigma_{P,Q}$ as given by (3.12).

We now start solving the almost disturbance decoupling problem for the system (3.12) we obtained in step (ii). As in § 4 we shall rename our variables and assume that we have a system in the form (4.1). We set $\varepsilon=1$. We have to construct matrices F and G such that (4.25) and (4.26) are satisfied and, moreover, such that $A+BF$ and $A+GC_1$ are asymptotically stable. We shall only discuss the construction of F. The construction of G can be obtained by dualization.

(iii) Construct $\mathcal{V}_g(\Sigma_{ci})$ by using Lemma 4.4.

(iv) Construct an $\tilde{F}$ such that (4.18) and (4.19) are satisfied and, moreover, such that $A+B\tilde{F}\,|\,\mathcal{V}_g(\Sigma_{ci})$ is asymptotically stable.

(v) Define the canonical projection $\Pi:\mathscr{R}^n \to \mathscr{R}^n/\mathscr{V}_g(\Sigma)$ and the mappings $\bar{A}$, $\bar{B}$, and $\bar{C}$ satisfying:
   (1) $\Pi(A+B\tilde{F})=\bar{A}\Pi$,
   (2) $\bar{B}:=\Pi B$,
   (3) $C_2+D_2\tilde{F}=\bar{C}\Pi$.
   Construct the system Σ_{fs} as given by (4.20).

(vi) Construct F_0 such that $(\bar{C}+D_2F_0)^T D_2=0$ and M such that $\operatorname{im}\bar{B}M=\bar{B}\ker D_2$. Define the following matrices:
   (1) $\tilde{A}:=\bar{A}+\bar{B}F_0$,
   (2) $\tilde{B}:=\bar{B}M$,
   (3) $\tilde{C}:=\bar{C}+D_2F_0$,
   and the system

$$\Sigma_{ht}:\begin{cases}\dot{x}=\tilde{A}x+\tilde{B}u,\\ z=\tilde{C}x.\end{cases} \tag{5.1}$$

In this way we obtained a strongly controllable system (5.1), for which we have to find a static feedback $\bar{F}$ such that the closed-loop system is internally stable and such that the closed-loop impulse response satisfies the $\mathscr{L}_1$ norm bound $\varepsilon/3\|E\|^{-1}$. We shall use a method for this which was given in [21].

(vii) We construct a new basis for the state space. We shall construct it by induction. Choose $x_1\in\ker\tilde{C}\cap\operatorname{im}\tilde{B}$ and v_1 such that $x_1=\tilde{B}v_1$. If x_1 does not exist go to item (viii). Assume $\{x_1,\cdots,x_i\}$ and $\{v_1,\cdots,v_i\}$ are given. Denote by $\mathscr{S}_i$ the linear span of $\{x_1,\cdots,x_i\}$. If $\{\tilde{A}x_i+\operatorname{im}\tilde{B})\cap\ker\tilde{C}\subset\mathscr{S}_i$ and $\operatorname{im}\tilde{B}\cap\ker\tilde{C}\subset\mathscr{S}_i$, then goto step (viii). Otherwise, if $(\tilde{A}x_i+\operatorname{im}\tilde{B})\cap\ker\tilde{C}\not\subset\mathscr{S}_i$, then choose v such that $\tilde{A}x_i+\tilde{B}v\in\ker\tilde{C}$ and $\tilde{A}x_i+\tilde{B}v\notin\mathscr{S}_i$. Set $x_{i+1}=\tilde{A}x_i+\tilde{B}v$ and $v_{i+1}=v$. (If $(\tilde{A}x_i+\operatorname{im}\tilde{B})\cap\ker\tilde{C}\subset\mathscr{S}_i$, then choose v such that $\tilde{B}v\in\ker\tilde{C}$ and $\tilde{B}v\notin\mathscr{S}_i$. Set $x_{i+1}=\tilde{B}v$ and $v_{i+1}=v$. Set $i:=i+1$ and repeat this paragraph again.

(viii) Define $\mathscr{R}_a^*(\ker\tilde{C})=\mathscr{S}_i$. Define a linear mapping F such that $Fx_j=v_j$, $j=1,\cdots,i$ and extend it to the whole state space. In [21] it has been shown that $A\mathscr{R}_a^*(\ker\tilde{C})+\operatorname{im}\tilde{B}=\mathscr{T}(\Sigma_{ht})=\mathscr{R}^n$. Therefore it is easily seen that we can extend $\{x_1,\cdots,x_i\}$ to a basis of $\mathscr{R}^n$ which can be written as

$$\begin{matrix}\tilde{B}v_1, & A_F\tilde{B}v_1, & \cdots, & A_F^{r_1}\tilde{B}v_1,\\ \tilde{B}v_2, & A_F\tilde{B}v_2, & \cdots, & A_F^{r_2}\tilde{B}v_2,\\ \vdots & \vdots & & \vdots\\ \tilde{B}v_j, & A_F\tilde{B}v_j, & \cdots, & A_F^{r_j}\tilde{B}v_j,\end{matrix}$$

where $A_F=\tilde{A}+\tilde{B}F$ and for those $k=1,\cdots,j$ for which $r_k\geqq 1$ we have $\tilde{B}v_k$, $A_F\tilde{B}v_k,\cdots,A_F^{r_k-1}\tilde{B}v_k\in\ker\tilde{C}$.

(ix) We define the following sequence of vectors. For $i=1,\cdots,j$ we define:

$$\begin{aligned} x_{i,1}(n) &:= \left(I+\frac{1}{n}A_F\right)^{-1}\tilde{B}v_i\\ x_{i,2}(n) &:= \left(I+\frac{1}{n}A_F\right)^{-1}A_F x_{i,1}(n)\\ \vdots\quad & \quad\vdots\\ x_{i,r_i+1}(n) &:= \left(I+\frac{1}{n}A_F\right)^{-1}A_F x_{i,r_i}(n). \end{aligned}$$

Since $x_{i,k}(n) \to A_F^{k-1}\tilde{B}v_i$ as $n \to \infty$ for $i = 1, \cdots, j$ and $k = 1, \cdots, r_i + 1$ it can be easily seen that for n sufficiently large the vectors $\{x_{i,k}(n),\ i = 1, \cdots, j;\ k = 1, \cdots, r_i + 1\}$ are linearly independent and hence form a basis of $\mathcal{R}^n$ again. Let N be such that for all $n > N$ these vectors indeed form a basis.

(x) For all $n > N$ define a linear mapping $\bar{F}_n$ by

$$\begin{aligned} \bar{F}_n x_{i,1}(n) \quad &:= -nv_i \\ \bar{F}_n x_{i,2}(n) \quad &:= -n^2 v_i \\ \vdots \qquad & \qquad \vdots \\ \bar{F}_n x_{i,r_i+1}(n) \quad &:= -n^{r_i+1} v_i. \end{aligned}$$

This determines $\bar{F}_n$ uniquely. Define $F_n := F + \bar{F}_n$. It is shown in [21] that the spectrum of $\tilde{A} + \tilde{B}F_n$ is the set $\{-n\}$. Moreover, we have

$$\lim_{n\to\infty} \|\tilde{C}\, e^{(A+BF_n)t}\|_1 = 0.$$

Choose n such that the impulse response satisfies the required $\mathcal{L}_1$ bound $\varepsilon/3\|E\|^{-1}$. This F_n is internally stabilizing and satisfies the $\mathcal{L}_1$ bound. Now we can construct the F we were looking for:

(xi) Define $F = \tilde{F} + (F_0 + MF_n)\Pi$. This F is internally stabilizing and is such that (4.25) is satisfied.

We construct G by dualizing the construction of F and the required dynamic compensator is finally given by (4.27).

6. Conclusion. In this paper we have given a complete treatment of the H_∞ problem with measurement feedback without restrictions on the direct feedthrough matrices. It remains however an open problem how we can treat invariant zeros on the imaginary axis. Other open problems are the minimally required dynamic order of the controller and the behaviour of the feedbacks and closed-loop system if we make the bound γ tighter. The latter problem has been investigated previously. It is possible that the infimum can only be attained by a nonproper controller (see [4]). But using the ideas of this paper it is perhaps possible to characterize whether or not this problem arises.

Finally, it would be interesting to characterize all solutions. In our opinion it is, however, in general not possible to obtain a characterization similar to the one obtained in [2]. This is due to the fact that the so-called central controller can be nonproper.

In our opinion this paper gives support to our claim that the approach to solve the H_∞ problem in the time-domain is a much more intuitive and appealing approach than the other methods used in recent papers.

Appendix A. A preliminary system transformation. In this section we shall choose bases in input, output, and state space that will give us much more insight into the structure of our problem. Although these decompositions are not necessary in the formulation of the main steps of the proof of Theorem 2.1, the details of the proof are very much concerned with these decompositions. It will be shown that the matrices defining our systems in these bases have a very particular structure. For details we refer to [18]. We shall display this structure by writing down the matrices with respect to these suitably chosen bases for the input, state, and output spaces.

Our basic tool is the strongly controllable subspace. This subspace has already been defined in Definition 4.2.

We shall give one property of the strongly controllable subspace at this point which will come in handy in the sequel (see [7], [16]).

LEMMA A1. *Consider the system* (4.4). *The system is strongly controllable if and only if*

$$\text{(A1)} \qquad \begin{pmatrix} sI-A & -B \\ C_2 & D_2 \end{pmatrix}$$

has rank $n+\operatorname{rank}(C_2 \quad D_2)$ *for all* $s \in \mathscr{C}$.

We can now define the bases for the system (2.1) which will be used in the sequel. It is also possible to define a dual version of this decomposition but we will only need this one. First choose a basis of the control input space $\mathscr{R}^m$. Decompose $\mathscr{R}^m = \mathscr{U}_1 \oplus \mathscr{U}_2$ such that $\mathscr{U}_2 = \ker D_2$ and $\mathscr{U}_1$ arbitrary. Choose a basis $u_1, u_2, \cdots, u_m$ of $\mathscr{R}^m$ such that $u_1, u_2, \cdots, u_i$ is a basis of $\mathscr{U}_1$ and $u_{i+1}, \cdots, u_m$ is a basis of $\mathscr{U}_2$.

Next choose *an orthonormal basis* $z_1, z_2, \cdots, z_p$ of the output space $\mathscr{R}^p$ such that $z_1, \cdots, z_j$ is a basis of im D_2 and $z_{j+1}, \cdots, z_p$ is a basis of $(\text{im } D_2)^\perp$. Because this is an orthonormal basis this basis transformation does not change the norm $\|z\|$.

Finally, we choose a decomposition of the state space $\mathscr{R}^n = \mathscr{X}_1 \oplus \mathscr{X}_2 \oplus \mathscr{X}_3$ such that $\mathscr{X}_2 = \mathscr{T}(\Sigma_{ci}) \cap C_2^{-1} \text{ im } D_2$, $\mathscr{X}_2 \oplus \mathscr{X}_3 = \mathscr{T}(\Sigma_{ci})$ and $\mathscr{X}_1$ arbitrary. We choose a corresponding basis $x_1, x_2, \cdots, x_n$ such that $x_1, \cdots, x_r$ is a basis of $\mathscr{X}_1$, $x_{r+1}, \cdots, x_s$ is a basis of $\mathscr{X}_2$ and $x_{s+1}, \cdots, x_n$ is a basis of $\mathscr{X}_3$.

With respect to these bases the maps B, C_2, and D_2 have the following form:

$$\text{(A2)} \qquad B = (B_1 \quad B_2), \quad C_2 = \begin{pmatrix} \hat{C}_1 \\ \hat{C}_2 \end{pmatrix}, \quad D_2 = \begin{pmatrix} \hat{D}_2 & 0 \\ 0 & 0 \end{pmatrix},$$

where $\hat{D}_2$ is invertible. Next, we define a linear mapping $F_0 : \mathscr{R}^n \to \mathscr{R}^m$ by

$$\text{(A3)} \qquad F_0 := \begin{pmatrix} -\hat{D}_2^{-1}\hat{C}_1 \\ 0 \end{pmatrix} \quad \text{and hence } C_2 + D_2F_0 = \begin{pmatrix} 0 \\ \hat{C}_2 \end{pmatrix}.$$

We have the following properties of this decomposition which are proven in [18].

LEMMA A2. *Let* F_0 *be given by* (A3). *Then we have*

(i) $(A+BF_0)(\mathscr{T}(\Sigma) \cap C_2^{-1} \text{ im } D_2) \subseteq \mathscr{T}(\Sigma)$,

(ii) im $B_2 \subseteq \mathscr{T}(\Sigma)$,

(iii) $\mathscr{T}(\Sigma) \cap C_2^{-1} \text{ im } D_2 \subseteq \ker \hat{C}_2$.

By applying this lemma we find that the matrices $A+BF_0$, B, $C_2+D_2F_0$ and D_2 with respect to these bases have the following form:

$$\text{(A4)} \qquad \begin{aligned} A+BF_0 &= \begin{pmatrix} A_{11} & 0 & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{pmatrix}, & B &= \begin{pmatrix} B_{11} & 0 \\ B_{21} & B_{22} \\ B_{31} & B_{32} \end{pmatrix}, \\ C_2+D_2F_0 &= \begin{pmatrix} 0 & 0 & 0 \\ C_{21} & 0 & C_{23} \end{pmatrix}, & D_2 &= \begin{pmatrix} \hat{D}_2 & 0 \\ 0 & 0 \end{pmatrix}. \end{aligned}$$

We decompose the matrices $\hat{C}_1$ and E correspondingly:

$$\text{(A5)} \qquad \hat{C}_1 = (C_{11} \quad C_{12} \quad C_{13}), \qquad E = \begin{pmatrix} E_1 \\ E_2 \\ E_3 \end{pmatrix}.$$

These matrices turn out to have some nice structural properties, which have been shown in [18].

LEMMA A3. *We have the following properties*:

(i) C_{23} *is injective,*

(ii) *the system*

$$\Sigma_1 := \left[\begin{pmatrix} A_{22} & A_{23} \\ A_{32} & A_{33} \end{pmatrix}, \begin{pmatrix} B_{22} \\ B_{32} \end{pmatrix}, (0 \quad I), 0\right] \tag{A6}$$

is strongly controllable,

(iii) *we have*

$$\text{normrank } G = \text{rank} \begin{pmatrix} C_{23} & 0 \\ 0 & \hat{D}_2 \end{pmatrix}, \tag{A7}$$

where G is the transfer matrix defined by $G(s) := C_2(sI-A)^{-1}B + D_2$.

We need the following results from [18] which connects the conditions of Theorem 2.1 to the matrices as defined in [A4].

LEMMA A4. *Assume* $P \in \mathcal{R}^{n\times n}$ *is symmetric and* $F(P) \geqq 0$. *Then we have the following*:

(i) $P\mathcal{T}(\Sigma) = 0$, *i.e., in our decomposition P can be written as*

$$P = \begin{pmatrix} P_1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \tag{A8}$$

(ii) *If P has the form* (A8), *then*

$$\begin{aligned} R(P_1) &:= P_1A_{11} + A_{11}^TP_1 + C_{21}^TC_{21} + P_1(E_1E_1^T - B_{11}(\hat{D}_2^T\hat{D}_2)^{-1}B_{11}^T)P_1 \\ &\quad -(P_1A_{13} + C_{21}^TC_{23})(C_{23}^TC_{23})^{-1}(A_{13}^TP_1 + C_{23}^TC_{21}) \geqq 0. \end{aligned} \tag{A9}$$

Moreover, $R(P_1) = 0$ *if and only if* rank $F(P) =$ normrank G.

(iii) *If* $R(P_1) = 0$, *then we have*

$$\text{rank} \begin{pmatrix} L(P,s) \\ F(P) \end{pmatrix} = n + \text{normrank } G \quad \forall s \in \mathcal{C}^0 \cup \mathcal{C}^+$$

if and only if

$$Z(P_1) := A_{11} + E_1E_1^TP_1 - B_{11}(\hat{D}_2^T\hat{D}_2)^{-1}B_{11}^TP_1 - A_{13}(C_{23}^TC_{23})^{-1}(A_{13}^TP_1 + C_{23}^TC_{21})$$

is an asymptotically stable matrix. Moreover, in that case also the matrix

$$A_{11} - B_{11}(\hat{D}_2^T\hat{D}_2)^{-1}B_{11}^TP_1 - A_{13}(C_{23}^TC_{23})^{-1}(A_{13}^TP_1 + C_{23}^TC_{21})$$

is an asymptotically stable matrix.

COROLLARY A5. *If there exists a matrix* $P \geqq 0$ *such that* $F(P) \geqq 0$ *and moreover*:

(i) rank $F(P) =$ normrank G,

(ii) $\text{rank} \begin{pmatrix} L(P,s) \\ F(P) \end{pmatrix} = n + \text{normrank } G \quad \forall s \in \mathcal{C}^0 \cup \mathcal{C}^+$,

then this matrix is uniquely defined by the above inequality and the corresponding two rank conditions.

Proof. By Lemma A4 a solution P must be of the form (A8) where P_1 is a solution of the algebraic Riccati equation $R(P_1) = 0$ such that $Z(P_1)$ is asymptotically stable. Denote the Hamiltonian matrix corresponding to this algebraic Riccati equation by

H; then we have

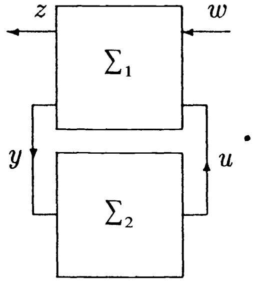
$$H\begin{pmatrix} I \\ P_1 \end{pmatrix} = \begin{pmatrix} I \\ P_1 \end{pmatrix} Z(P_1). \tag{A10}$$

Since a Hamiltonian matrix has the property that λ is an eigenvalue if and only if $-\lambda$ is an eigenvalue of H, we know that an n-dimensional invariant subspace $\mathcal{W}$ of H such that $H \mid \mathcal{W}$ is asymptotically stable must be unique. This implies that P_1 is unique and hence also P is unique. □

Appendix B. Proofs concerning the system transformations. In order to prove Lemma 3.2 we must first do some preparatory work. We first recall the following lemma from [2] which we shall use in the sequel.

LEMMA B1. *Suppose we have the following interconnection of two systems Σ_1 and Σ_2, both described by some state-space representation*:

(B1)



Assume Σ_1 is internally stable and its transfer matrix L from $\binom{w}{u}$ to $\binom{z}{y}$ satisfies $L^{\sim}L = I$ where $L^{\sim}(s) := L^T(-s)$. Moreover, assume that if we decompose L:

$$L =: \begin{pmatrix} L_{11} & L_{12} \\ L_{21} & L_{22} \end{pmatrix} \tag{B2}$$

compatible with the sizes of w, u, z, and y, we have $L_{21}^{-1} \in H_\infty$ and $\lim_{s\to\infty} L_{22}(s) = 0$. Then the following two statements are equivalent:

(i) *The closed-loop system* (B1) *is internally stable and its closed-loop transfer matrix has H_∞ norm less than one.*

(ii) *The system Σ_2 is internally stable and its transfer matrix has H_∞ norm less than one.*

Proof. This is a well-known result although written down here in a different way. Note that if the closed-loop system (B1) is internally stable, then Σ_2 is stabilizable and detectable. This can be shown either by writing down the closed-loop differential equation or by noting that an unstable uncontrollable mode in Σ_2 cannot be controlled by y and hence is still unstable and uncontrollable in the closed-loop system and the same for an unstable unobservable mode. The result in this form can then be obtained by using the work in [14]. □

We shall now assume that we have chosen the bases described in Appendix A. Let P satisfy the conditions of Lemma 3.1(i). Hence we know P has the form (A8). It is easily shown that it is sufficient to prove the lemma for one specific choice of $C_{2,P}$ and D_P. We define the following matrices:

$$C_{2,P} := \begin{pmatrix} \hat{D}_2(\hat{D}_2^T\hat{D}_2)^{-1}B_{11}^TP_1 + C_{11} & C_{12} & C_{13} \\ C_{23}(C_{23}^TC_{23})^{-1}(A_{13}^TP_1 + C_{23}^TC_{21}) & 0 & C_{23} \end{pmatrix}, \tag{B3}$$

(B4) $$D_P := \begin{pmatrix} \hat{D}_2 & 0 \\ 0 & 0 \end{pmatrix} (= D_2).$$

By writing down $F(P)$ in terms of the chosen bases and by using the fact that P_1 satisfies the algebraic Riccati equation $R(P_1) = 0$ where $R(P_1)$ is defined by (A9), it can be checked after some effort that these matrices indeed satisfy (3.1). We define the following matrices:

(B5) $$\tilde{A} := A_{11} - A_{13}(C_{23}^T C_{23})^{-1}(A_{13}^T P_1 + C_{23}^T C_{21}) - B_{11}(\hat{D}_2^T \hat{D}_2)^{-1} B_{11}^T P_1,$$

(B6) $$\tilde{C}_1 := -(\hat{D}_2^T)^{-1} B_{11}^T P_1,$$

(B7) $$\tilde{C}_2 := C_{21} - C_{23}(C_{23}^T C_{23})^{-1}(A_{13}^T P_1 + C_{23}^T C_{21}),$$

(B8) $$\tilde{B}_{11} := B_{11} \hat{D}_2^{-1},$$

(B9) $$\tilde{B}_{12} := A_{13}(C_{23}^T C_{23})^{-1} C_{23}^T - P_1^{\dagger} C_{21}^T (I - C_{23}(C_{23}^T C_{23})^{-1} C_{23}^T),$$

where † denotes the Moore–Penrose inverse. We now define the following system:

(B10) $$\Sigma_U : \begin{cases} \dot{x}_U = \tilde{A} x_U + (\tilde{B}_{11} \quad \tilde{B}_{12}) u + E_1 w, \\ y_U = -E_1^T P_1 x_U + w, \\ z_U = \begin{pmatrix} \tilde{C}_1 \\ \tilde{C}_2 \end{pmatrix} x_U + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} u. \end{cases}$$

We have the following properties of the system Σ_U.

LEMMA B2. *The system Σ_U is internally stable. Let U denote the transfer matrix of Σ_U from $\binom{u}{w}$ to $\binom{y_u}{z_u}$. We have $U^{\sim} U = I$ where $U^{\sim}(s) := U^T(-s)$. If we decompose U:*

(B11) $$U := \begin{pmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{pmatrix}$$

compatible with the sizes of u, w, y_U, and z_U then we have $U_{21}^{-1} \in H_\infty$ and $\lim_{s \to \infty} U_{22}(s) = 0$.

Proof. The fact that Σ_U is internally stable and that $U_{21}^{-1} \in H_\infty$ follows directly from the fact that $\tilde{A}$ and $\tilde{A} + E_1 E_1^T P_1$ are asymptotically stable by Lemma A4(iii). The fact that $\lim_{s \to \infty} U_{22}(s) = 0$ can be checked trivially. It can be easily checked using Lemma A4(ii) that P_1 is the controllability gramian of Σ_U. Moreover, we have

(B12) $$\begin{pmatrix} \begin{pmatrix} 0 \\ 0 \end{pmatrix} & \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \\ I & (0 \quad 0) \end{pmatrix} \begin{pmatrix} -E_1^T P_1 \\ \begin{pmatrix} \tilde{C}_1 \\ \tilde{C}_2 \end{pmatrix} \end{pmatrix} + \begin{pmatrix} \begin{pmatrix} \tilde{B}_{11}^T \\ \tilde{B}_{12}^T \end{pmatrix} \\ E_1^T \end{pmatrix} P_1 = 0.$$

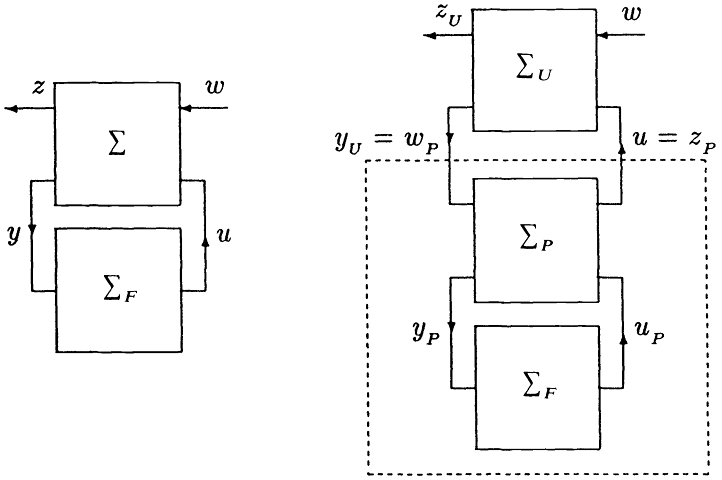
This can be checked by simply writing out and using the fact that

$$\ker P_1 \subset \ker (I - C_{23}(C_{23}^T C_{23})^{-1} C_{23}^T) C_{21}.$$

The result that $U \sim U = I$ then follows by applying Theorem 5.1 of [5]. □

Proof of Lemma 3.2. We have our special choice of $C_{2,P}$ and D_P given by (B3) and (B4). As we have already noted, taking this special choice for C_P and D_P is not essential. We shall first compare the following two systems:

(B13)



The system on the left is the same as the system on the left in (3.3), and the system on the right is described by the system (B10) interconnected with the system on the right in (3.3). We decompose the state of Σ, x into x_1, x_2, and x_3 according to the choice of bases described in Appendix A and decompose the state of Σ_P into $x_{1,P}$, $x_{2,P}$, $x_{3,P}$ of corresponding sizes. (Note that Σ and Σ_P have the same state space $\mathscr{R}^n$.) Writing out all the differential equations using the decompositions of the matrices given in (A3)-(A5) we find

$$\left\{\begin{array}{l} \begin{pmatrix} \dot{x}_U - \dot{x}_{1,P} \\ \dot{x}_P \\ \dot{p} \end{pmatrix} = \begin{pmatrix} \tilde{A} + E_1 E_1^T P_1 & 0 & 0 \\ * & A + BNC_1 & BM \\ * & LC_1 & K \end{pmatrix} \begin{pmatrix} x_U - x_{1,P} \\ x_P \\ p \end{pmatrix} + \begin{pmatrix} 0 \\ E + BND_1 \\ LD_1 \end{pmatrix} w, \\ \qquad z = (* \quad C_2 + D_2NC_1 \quad D_2M) \begin{pmatrix} x_U - x_{1,P} \\ x_P \\ p \end{pmatrix} + D_2ND_1\omega. \end{array}\right.$$

The $*$ denotes matrices which are unimportant for this argument. The system on the right is internally stable if and only if the system described by the above set of equations is internally stable. If we also derive the system equations for the system on the left in (B13) we immediately see that, since $\tilde{A} + E_1 E_1^T P_1$ is asymptotically stable, the system on the left is internally stable if and only if the system on the right is internally stable. Moreover, if we take zero initial conditions and both systems have the same input w, then we have $z = z_U$, i.e., the input-output behaviour of both systems are equivalent. Hence the system on the left has H_∞ norm less than one if and only if the system on the right has H_∞ norm less than one.

By Lemma B2 we may apply Lemma B1 to the system on the right in (B13) and hence we find that the closed-loop system is internally stable and has H_∞ norm less than one if and only if the dashed system is internally stable and has H_∞ norm less than one.

Since the dashed system is exactly the system on the right in (3.3) and the system on the left in (B13) is exactly equal to the system on the left in (3.3), we have completed the proof. □

We will now prove Lemma 3.3. In fact, we will prove the dual version of this lemma since this is much more convenient to us. We first factorize $G(Q)$:

$$G(Q) := \begin{pmatrix} E_Q \\ D_Q \end{pmatrix} (E_Q^T \quad D_Q^T). \tag{B14}$$

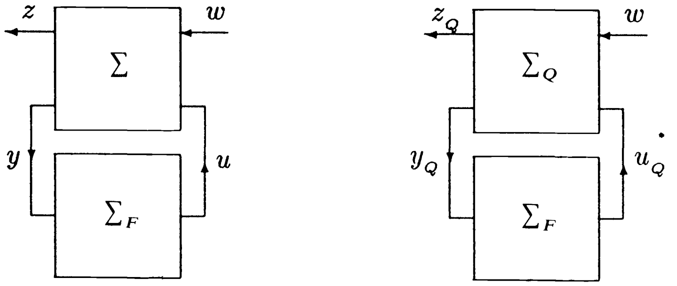
Define $A_Q := A + QC_2^TC_2$ and $B_Q := B + QC_2^TD_2$ and the system:

$$\Sigma_Q : \begin{cases} \dot{x}_Q = A_Qx_Q + B_Qu_Q + E_Qw, \\ y_Q = C_1x_Q \qquad\qquad + D_Qw \\ z_Q = C_2x_Q + D_2u_Q. \end{cases} \tag{B15}$$

By using the well-known facts that F stabilizes Σ if and only if F^T stabilizes Σ^T and $\|G\|_\infty = \|G^T\|_\infty$, we can derive the following dualized version of Lemma 3.2 for this dual system as follows.

LEMMA B3. *Let Q satisfy Lemma* 3.1(ii). *Moreover, let an arbitrary linear time-invariant finite-dimensional compensator F be given, described by* (2.2). *Let the following two systems be given where the system on the left is the interconnection of* (2.1) *and* (2.2) *and the system on the right is the interconnection of* (B15) *and* (2.2).

(B16)



Then the following statements are equivalent:

(i) *The system on the left is internally stable and its transfer matrix has H_∞ norm less than one.*

(ii) *The system on the right is internally stable and its transfer matrix has H_∞ norm less than one.*

We now investigate how the matrices appearing in the matrix inequality and the rank conditions look like for this new system Σ_Q:

$$\tilde{F}(X) := \begin{pmatrix} A_Q^TX + XA_Q + C_2^TC_2 + XE_QE_Q^TX & XB_Q + C_2^TD_2 \\ B_Q^TX + D_2^TC_2 & D_2^TD_2 \end{pmatrix}, \tag{B17}$$

$$\tilde{G}(Y) := \begin{pmatrix} A_QY + YA_Q^T + E_QE_Q^T + YC_2^TC_2Y & YC_1^T + E_QD_Q^T \\ C_1Y + D_QE_Q^T & D_QD_Q^T \end{pmatrix}, \tag{B18}$$

$$\tilde{L}(X, s) := (sI - A_Q - E_QE_Q^TX \quad -B_Q), \tag{B19}$$

$$\tilde{M}(Y, s) := \begin{pmatrix} sI - A_Q - YC_2^TC_2 \\ -C_1 \end{pmatrix}. \tag{B20}$$

Moreover, we define two new transfer matrices:

$$\tilde{G}(s) := C_2(sI - A_Q)^{-1}B_Q + D_2, \tag{B21}$$

$$\tilde{H}(s) := C_1(sI - A_Q)^{-1}E_Q + D_Q. \tag{B22}$$

Using these definitions we have the following result.

LEMMA B4. *Let Q satisfy Lemma* 3.1(ii). *Then $Y=0$ is the unique solution of the quadratic matrix inequality $G(Y)\geqq 0$ satisfying the following rank conditions*:

(1) $\operatorname{rank}\tilde{G}(Y)=\operatorname{normrank}\tilde{H}$,

(2) $\operatorname{rank}(\tilde{M}(Y,s)\quad \tilde{G}(Y))=n+\operatorname{normrank}\tilde{H}\quad \forall s\in\mathscr{C}^0\cup\mathscr{C}^+$.

Proof. It is trivial to check that $\tilde{G}(0)\geqq 0$. Moreover, since $\tilde{G}(0)=G(Q)$ and $\tilde{M}(0,s)=M(Q,s)$ it remains to show that normrank $\tilde{H}=$ normrank H. We have

$$\begin{aligned}\operatorname{normrank}\tilde{H}&=\operatorname{normrank}\begin{pmatrix} sI-A_Q & E_Q\\ -C_1 & D_Q\end{pmatrix}-n\\ &=\operatorname{normrank}\begin{pmatrix} sI-A_Q & E_QE_Q^T & D_QE_Q^T\\ -C_1 & D_QE_Q^T & D_QD_Q^T\end{pmatrix}-n\\ &=\operatorname{normrank}(M(Q,s)\quad G(Q))-n\\ &=\operatorname{normrank}H.\end{aligned}$$

Y is unique by Corollary A5. This is exactly what we had to prove. □

LEMMA B5. *There exists a solution X of the matrix inequality $\tilde{F}(X)\geqq 0$ satisfying the following two rank conditions*:

(1) $\operatorname{rank}\tilde{F}(X)=\operatorname{normrank}\tilde{G}$,

(2) $\operatorname{rank}\begin{pmatrix} r\tilde{L}(X,s)\\ \tilde{F}(X)\end{pmatrix}=n+\operatorname{normrank}\tilde{G}\quad \forall s\in\mathscr{C}^0\cup\mathscr{C}^+$,

if and only if $I-PQ$ is invertible. Moreover, in that case the solution is unique and is given by $X=(I-PQ)^{-1}P$. We have $X\geqq 0$ if and only if

$$\rho(PQ)<1. \tag{B23}$$

Proof. We first make a transformation on $\tilde{F}(X)$:

$$F_{tr}(X):=\begin{pmatrix} I & (I+XQ)F_0^T\\ 0 & I\end{pmatrix}\tilde{F}(X)\begin{pmatrix} I & 0\\ F_0(I+QX) & I\end{pmatrix} \tag{B24}$$

$$=\begin{pmatrix} \bar{A}^TX+X\bar{A}+\bar{C}_2^T\bar{C}_2+XMX & XB\\ B^TX & D_2^TD_2\end{pmatrix}, \tag{B25}$$

where

$$\bar{A}:=A+BF_0+Q(C_2+D_2F_0)^T(C_2+D_2F_0), \tag{B26}$$

$$\bar{C}_2:=C_2+D_2F_0, \tag{B27}$$

$$M:=(A+BF_0)Q+Q(A^T+F_0^TB^T)+EE^T+Q\bar{C}_2^T\bar{C}_2Q, \tag{B28}$$

and F_0 as defined in (A3). We also transform the second matrix appearing in the rank conditions:

$$\begin{aligned}W(X,s)&:=\begin{pmatrix} I & 0 & -QF_0^T\\ 0 & I & (I+XQ)F_0^T\\ 0 & 0 & I\end{pmatrix}\begin{pmatrix}\tilde{L}(X,s)\\ \tilde{F}(X)\end{pmatrix}\begin{pmatrix} I & 0\\ F_0(I+QX) & I\end{pmatrix}\\ &=\begin{pmatrix} sI-\bar{A}-MX & -B\\ \bar{A}^TX+X\bar{A}+\bar{C}_2^T\bar{C}_2+XMX & XB\\ B^TX & D_2^TD_2\end{pmatrix}.\end{aligned}$$

We have the following equality:

$$\text{(B29)} \qquad \operatorname{normrank} \tilde{G} = \operatorname{normrank} \begin{pmatrix} sI - A_Q & -B_Q \\ C_2 & D_2 \end{pmatrix} - n$$

$$\text{(B30)} \qquad = \operatorname{normrank} \begin{pmatrix} I & QC_2^T \\ 0 & I \end{pmatrix} \begin{pmatrix} sI - A_Q & -B_Q \\ C_2 & D_2 \end{pmatrix} - n$$

$$\text{(B31)} \qquad = \operatorname{normrank} \begin{pmatrix} sI - A & -B \\ C_2 & D_2 \end{pmatrix} - n = \operatorname{normrank} G.$$

Therefore the conditions that $X \geqq 0$ has to satisfy can be reformulated as:

(i) $F_{tr}(X) \geqq 0$,

(ii) rank $F_{tr}(X) = \operatorname{normrank} G$,

(iii) rank $W(X, s) = \operatorname{normrank} G + n \quad \forall s \in \mathscr{C}^0 \cup \mathscr{C}^+$.

Moreover, we note that $T(A, B, C_2, D_2) = T(\bar{A}, B, \bar{C}_2, D_2)$. This can be shown by using the fact that the new system is obtained by a state feedback and an output injection (note that $B = B + Q(C_2 + D_2F_0)^T D_2$) and it is well known that the strongly controllable subspace is invariant under feedback and output injection. This can easily be shown using the algorithm (4.10). We now choose the bases from Appendix A. By Lemma A4(i) we know that if X exists then it will have the form

$$\text{(B32)} \qquad X = \begin{pmatrix} X_1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

for some positive semidefinite matrix X_1. Note that there is small difference since M is not necessarily positive semidefinite, but it can be easily seen from the proof in [18] that this difference is not important. We use this decomposition for X and the corresponding decompositions for P and Q:

$$\text{(B33)} \qquad P = \begin{pmatrix} P_1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \qquad Q = \begin{pmatrix} Q_{11} & Q_{12} & Q_{13} \\ Q_{21} & Q_{22} & Q_{23} \\ Q_{31} & Q_{32} & Q_{33} \end{pmatrix}.$$

Together with the decompositions for the other matrices as given in (A4)-(A5) we can decompose $F_{tr}(X)$ correspondingly:

$$\begin{pmatrix} X_1\tilde{A}_{11} + \tilde{A}_{11}^T X_1 + C_{21}^T C_{21} + X_1 M_{11} X_1 & 0 & X_1 \tilde{A}_{13} + C_{21}^T C_{23} & X_1 B_{11} & 0 \\ 0 & 0 & 0 & 0 & 0 \\ \tilde{A}_{13}^T X_1 + C_{23}^T C_{21} & 0 & C_{23}^T C_{23} & 0 & 0 \\ B_{11}^T X_1 & 0 & 0 & \hat{D}_2^T \hat{D}_2 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

where

$$\text{(B34)} \qquad \tilde{A}_{11} := A_{11} + Q_{11} C_{21}^T C_{21} + Q_{13} C_{23}^T C_{21},$$

$$\text{(B35)} \qquad \tilde{A}_{13} := A_{13} + Q_{11} C_{21}^T C_{23} + Q_{13} C_{23}^T C_{23},$$

$$\text{(B36)} \qquad M_{11} := A_{11} Q_{11} + A_{13} Q_{13}^T + Q_{11} A_{11}^T + Q_{13} A_{13}^T + E_1 E_1^T$$
$$+ Q_{11} C_{21}^T (C_{21} Q_{11} + C_{23} Q_{13}) + Q_{13} C_{23}^T (C_{21} Q_{11} + C_{23} Q_{13}).$$

The rank condition $\operatorname{rank} F_{tr}(X) = \operatorname{normrank} G$ is, according to Lemma A3(iii), equivalent with the condition that the rank of the above matrix is equal to the rank of the submatrix

$$\text{(B37)} \qquad \begin{pmatrix} C_{23}^T C_{23} & 0 \\ 0 & \hat{D}_2^T \hat{D}_2 \end{pmatrix}.$$

Therefore the Schur complement with respect to this submatrix should be zero. This implies that if we define

$$\begin{aligned} \tilde{R}(X_1) := {} & X_1 \tilde{A}_{11} + \tilde{A}_{11}^T X_1 + C_{21}^T C_{21} + X_1 (M_{11} - B_{11} (\hat{D}_2^T \hat{D}_2)^{-1} B_{11}^T) X_1 \\ & - (X_1 \tilde{A}_{13} + C_{21}^T C_{23})(C_{23}^T C_{23})^{-1} (\tilde{A}_{13}^T X_1 + C_{23}^T C_{21}), \end{aligned}$$

then X_1 should satisfy $\tilde{R}(X_1) = 0$. Moreover, if we decompose $W(X, s)$ correspondingly, then we can show by using elementary row and column operations that for any matrix X in the form (B32), where X_1 satisfies $\tilde{R}(X_1) = 0$, that for all $s \in \mathscr{C}$, $W(X, s)$ has the same rank as the following matrix:

$$\text{(B38)} \qquad \begin{pmatrix} sI - \tilde{Z}(X_1) & 0 & 0 & 0 & 0 \\ * & sI - A_{22} & -A_{23} & 0 & -B_{22} \\ * & -A_{32} & sI - A_{33} & 0 & -B_{32} \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

where

$$\text{(B39)} \quad \tilde{Z}(X_1) := \tilde{A}_{11} + M_{11} X_1 - B_{11} (\hat{D}_2^T \hat{D}_2)^{-1} B_{11}^T X_1 - \tilde{A}_{13} (C_{23}^T C_{23})^{-1} (\tilde{A}_{13}^T X_1 + C_{23}^T C_{21}).$$

The matrix

$$\text{(B40)} \qquad \begin{pmatrix} sI - A_{22} & -A_{23} & -B_{22} \\ -A_{32} & sI - A_{33} & -B_{32} \\ 0 & I & 0 \end{pmatrix}$$

has full row rank for all $s \in \mathscr{C}$ by Lemma A3(ii) and Lemma A1. Hence the rank of the matrix (B38) is $n + \operatorname{normrank} G$ for all $s \in \mathscr{C}^+ \cup \mathscr{C}^0$ if and only if the matrix $\tilde{Z}(X_1)$ is asymptotically stable. Using this we can now reformulate the conditions that $X_1 \geqq 0$ must satisfy:

(i) $\tilde{R}(X_1) = 0$,

(ii) $\tilde{Z}(X_1)$ is asymptotically stable.

That is, X_1 should be the positive semidefinite stabilizing solution of the algebraic Riccati equation $\tilde{R}(X_1) = 0$. Denote the Hamiltonian corresponding to this ARE by H_{new}. We know that P_1 is the stabilizing solution of the algebraic Riccati equation $R(P_1) = 0$ as given by (A9). Denote the Hamiltonian corresponding to this algebraic Riccati equation by H_{old}. Then it can be checked that

$$\text{(B41)} \qquad H_{\text{old}} = \begin{pmatrix} I & Q_{11} \\ 0 & I \end{pmatrix} H_{\text{new}} \begin{pmatrix} I & -Q_{11} \\ 0 & I \end{pmatrix}.$$

Since P_1 is the stabilizing solution of the Riccati equation corresponding to the Hamiltonian H_{old} we know that the modal subspace of H_{old} corresponding to the open left halfplane is given by

$$\text{(B42)} \qquad \mathscr{X}_g(H_{\text{old}}) = \operatorname{Im}\begin{pmatrix} I \\ P_1 \end{pmatrix}.$$

Combining (B41) and (B42), we find

$$\text{(B43)} \qquad \mathscr{X}_g(H_{\text{new}}) = \operatorname{Im}\begin{pmatrix} I & -Q_{11} \\ 0 & I \end{pmatrix}\begin{pmatrix} I \\ P_1 \end{pmatrix} = \operatorname{Im}\begin{pmatrix} I - Q_{11}P_1 \\ P_1 \end{pmatrix}.$$

Therefore we know that there exists a stabilizing solution to the algebraic Riccati equation $\tilde{R}(X_1) = 0$ if and only if $I - Q_{11}P_1$ is invertible and in that case the solution is given by $X_1 = P_1(I - Q_{11}P_1)^{-1}$. This implies that $X = P(I - QP)^{-1} = (I - PQ)^{-1}P$. The requirement $X \geqq 0$ is satisfied if and only if $\rho(PQ) < 1$, which can be checked straightforwardly. This completes the proof. □

Acknowledgment. I thank Harry Trentelman for reading the preliminary draft of this paper and for suggesting many improvements. Moreover, I thank him for his help on the section about the construction of the required compensator.

ASYMPTOTICALLY STABILIZING FEEDBACK CONTROLS AND THE NONLINEAR REGULATOR PROBLEM*

HENRY HERMES†

Abstract. Continuous asymptotically stabilizing feedback controls are constructed for two-dimensional, and certain three-dimensional, small time locally controllable affine systems. The Lie products which determine controllability induce a dilation; it suffices to work with the approximating homogeneous system associated with this dilation. A cost functional is then constructed which is such that the associated Hamilton-Jacobi-Bellman equation is homogeneous, forcing the solution (which is a Lyapunov function for the optimally controlled system) to be homogeneous and thereby determining its basic form. The process may be viewed as a generalization of the linear regulator construction.

Key words. stabilization, controllability, nonlinear control, nonlinear regulator, Hölder continuous feedback

AMS(MOS) subject classification. 93D15

Introduction. Our goal is to develop a method to establish the existence, and exhibit the construction, of continuous asymptotically stabilizing feedback controls for n-dimensional, real analytic, affine control systems of the form

$$\dot{x} = X(x) + uY(x), \qquad X(0) = 0. \tag{1}$$

Our methods use high-order homogeneous approximations and the nonlinear analogue of the classical linear regulator problem.

Brockett [1] gave the following three necessary conditions for the existence of a C^1 feedback control $x \to u(x)$ which makes the solution $x(t) = 0$ of (1) locally asymptotically stable.

(B1) The linearized system should have no uncontrollable modes associated with eigenvalues whose real part is positive.

(B2) For each y in a nbd of zero there exists an open-loop control $t \to u_y(t)$ such that the corresponding solution of (1) initiating from y tends to zero as $t \to \infty$.

(B3) The map $\gamma: \mathbb{R}^n \times \mathbb{R}^1 \to \mathbb{R}^n$ defined by $\gamma(x, u) = X(x) + uY(x)$ must be onto a nbd of zero.

Prior to Brockett's paper, Sontag and Sussmann [2] showed that certain nonlinear systems could have rest solutions made asymptotically stable by continuous, but not C^1, feedback control.

Kawski [3] showed that condition (B1) is not necessary for the existence of a C^0 asymptotically stabilizing feedback control for a two-dimensional system of the form (1). Indeed, he showed that the zero solution of the system $\dot{x}_1 = u$, $\dot{x}_2 = x_2 - x_1^3$ could be made locally asymptotically stable via feedback of the form $u(x) = (4E/3)x_2^{1/3} - x_1 - K(x_1^3 - x_2)$.

System (1) is said to be small time locally controllable (at zero), denoted STLC, if for any $t_1 > 0$ the set of points attainable at time t_1 by solutions initiating from zero, corresponding to all admissible open-loop controls $t \to u(t)$, contains a full nbd of zero. By reversing time, clearly if (1) is STLC, then the system $\dot{x} = -X(x) + u(Y)(x)$

is such that all points in some nbd of zero can be steered to zero in arbitrarily small time. Sufficient conditions for STLC (see [4]-[6]), when satisfied for system (1), also imply STLC of the reversed time system. Indeed, in the real analytic case, Sussmann has shown STLC of system (1) and the reversed time system are equivalent. Hence STLC of system (1) is sufficient for property (B2). We shall assume STLC throughout, although it is by no means necessary for (B2).

An outline of a proof of the necessity of condition (B3) via fixed point theory is given in [1]; a proof in the continuous category, based on index theory, is given in [7]. It follows that (B3) is therefore a necessary condition for the existence of a continuous, i.e., C^0, asymptotically stabilizing feedback control. For dimension $n=2$, STLC implies (B3).

Kawski's main result in [3] is the following theorem.

THEOREM 1 (Kawski [3]). *If the two-dimensional, real analytic system* (1) *is* STLC, *then there exists a continuous feedback control which makes the zero solution locally asymptotically stable.*

His method is via the construction of a Lyapunov function V having trajectory derivative $\dot{V}$ negative semidefinite along solutions of the controlled system and such that (essentially) LaSalle's theorem applies on the set where $\dot{V}=0$. The methods are limited to dimension $n=2$. Our first task here is to illustrate the ideas involved in the nonlinear regulator method by using these to prove Theorem 1. The resulting construction of a feedback control and Lyapunov function V (see Lemma 2) is such that when applied to the example $\dot{x}_1=u$, $\dot{x}_2=x_2-x_1^3$ gives the trajectory derivative $\dot{V}(x)$ negative definite. The proof of Lemma 2 contains the main ideas of the nonlinear regulator approach and of this paper.

Many examples and results for two-dimensional systems, some related to the above and others for systems which are not STLC, can be found in [8]. The use of center manifold theory for establishing smooth asymptotically stabilizing feedback controls for two-dimensional systems can be found in [9].

In dimension $n \geqq 3$ much less is known. The system $\dot{x}_1=u$, $\dot{x}_2=x_1$, $\dot{x}_3=-x_1^3$ is STLC but clearly does not satisfy condition (B3). Specifically, the point $(0,0,\varepsilon)$, $\varepsilon \neq 0$, is not in the range of the map γ, hence this system does not admit a continuous asymptotically stabilizing feedback control. In § 2 we utilize the nonlinear regulator method to show the (surprising) result that the seemingly more difficult to control system $\dot{x}_1=u$, $\dot{x}_2=x_1$, $\dot{x}_3=x_3-x_1^3$ does admit a continuous, asymptotically stabilizing, feedback control.

1. Homogeneity and the nonlinear regulator.

The constructions that make the linear regular problem tractable, e.g., the Riccati equation, etc., result from homogeneity properties of the linear system and quadratic cost functional involved. We will elaborate on this comment shortly, but first introduce the more general notions of homogeneity. A *dilation* $\delta_\varepsilon^r : \mathbb{R}^n \to \mathbb{R}^n$ will be a map of the form $\delta_\varepsilon^r x = (\varepsilon^{r_1}x_1, \cdots, \varepsilon^{r_n}x_n)$ where $x=(x_1,\cdots,x_n)$ are given local coordinates, $1=r_1 \leqq \cdots \leqq r_n$ are integers, and $\varepsilon > 0$. If all $r_i=1$ we write δ_ε^1 and refer to this as the *standard dilation.* A function $h:\mathbb{R}^n \to \mathbb{R}^1$ is homogeneous of degree s with respect to δ_ε^r if $h(\delta_\varepsilon^r x)=\varepsilon^s h(x)$. Functions homogeneous of degree s will be denoted by H_s with H_0 denoting constant functions and $H_s=\{0\}$ if $s<0$. If $h \in H_s$, $g \in H_q$, it follows that $\partial h/\partial x_j \in H_{s-r_j}$ while the product $hg \in H_{s+q}$. A vector field X on $\mathbb{R}^n$ is homogeneous of degree s with respect to δ_ε^r if $Xh \in H_{q-s}$ whenever $h \in H_q$. Thus if in local coordinates $X(x)=\sum_{j=1}^n a_j(x)\partial/\partial x_j$, X is homogeneous of degree s means $a_j \in H_{r_j-s}$. This has (sadly) become standard usage but the reader should be warned that a vector field $X(x)=\sum_{j=1}^n a_j(x)\partial/\partial x_j$, which is homogeneous of degree m with respect to δ_ε^1 in the classical sense (i.e., $a_i(\varepsilon x) = \varepsilon^m a_i(x)$), now becomes homogeneous of degree $(1-m)$ in the present sense.

1.1. The linear regulator. The well-known "pole placement" theorems show that a controllable linear system on $\mathbb{R}^n$

$$\dot{x} = Ax + Bu, \qquad u \in \mathbb{R}^k \tag{2}$$

can have its zero solution made globally asymptotically stable via linear feedback $u^*(x) = Kx$. This was first established by Kalman [10] in his study of the linear regulator problem. Specifically, consider the controllable system (2) with cost functional (to be minimized)

$$C(u) = \int_0^\infty (u'Ru + x'Wx)\,dt, \qquad R, W \text{ positive, definite, symmetric.}$$

Then for any $x(0) = x^0 \in \mathbb{R}^n$ there is a solution $\varphi(t, x^0)$ with $\varphi(t, x^0) \to 0$ as $t \to \infty$ and the "cost, or value, from x^0" denoted $V(x^0)$ is defined and continuous on $\mathbb{R}^n$ (see [11, p. 198]). Following Kalman [10] for $p \in \mathbb{R}^n$ form

$$H(x, p, u) = p'Ax + p'Bu + u'Ru + x'Wx. \tag{3}$$

Minimize $H(x, p, u)$ with respect to u. Since there are no bounds on the control values, this requires $H_u(x, p, u) = 2Ru + B'p = 0$ or

$$u^*(x, p) = (\tfrac{1}{2})R^{-1}B'p.$$

Next, let $H^*(x, p) = H(x, p, u^*(x, p))$ and the value function V must satisfy the Hamilton-Jacobi-Bellman (HJB) equation

$$H^*(x, V_x(x)) = 0, \quad V(0) = 0, \quad V(x) > 0 \quad \text{if } x \neq 0. \tag{4}$$

Now the homogeneity of the problem comes into play. Consider $(x_1, \cdots, x_n, V, p_1, \cdots, p_n)$ as local coordinates for the first jet bundle $J^1(\mathbb{R}^n, \mathbb{R}^1)$. With any dilation $\delta_\varepsilon^r x = (\varepsilon^{r_1}x_1, \cdots, \varepsilon^{r_n}x_n)$ and integer $m > r_n$ associate the dual dilation $\delta_\varepsilon^{r*}p = (\varepsilon^{m-r_1}p_1, \cdots, \varepsilon^{m-r_n}p_n)$ and dilation γ_ε^r on $J^1(\mathbb{R}^n, \mathbb{R}^1)$ defined by $\gamma_\varepsilon^r(x, V, p) = (\delta_\varepsilon^r x, \varepsilon V, \delta_\varepsilon^{r*}p)$. If $H^*(x, p)$ is homogeneous of degree m with respect to γ_ε^r, i.e., $H^*(\delta_\varepsilon^r x, \delta_\varepsilon^{r*}p) = \varepsilon^m H^*(x, p)$, we expect a solution V of the HJB equation which is homogeneous of degree m.

In the linear problem, letting δ_ε^r be the standard dilation δ_ε^1 and $m = 2$ (so δ_ε^{r*} is also the standard dilation) it follows that $H^*(x, p)$ is homogeneous of degree two and we should seek a solution of (4) of the form

$$V(x) = x'Ex, \tag{5}$$

where, without loss of generality, E may be assumed to be symmetric. Substitution of this V into (4) yields $2x'EAx - x'EBR^{-1}B'Ex + x'Wx = 0$ or that E should satisfy the "stationary Riccati equation"

$$A'E + EA - EBR^{-1}B'E = -W. \tag{6}$$

Given positive-definite matrices R, W, (6) determines a unique positive-definite symmetric matrix E. The solution of (4) is $V(x) = x'Ex$ and the optimal feedback control (which provides global asymptotic stability of (2)) is

$$u^*(x) = -\tfrac{1}{2}R^{-1}B'V_x(x) = -R^{-1}B'Ex. \tag{7}$$

The well-known results above were repeated since they form an example and a guide for the nonlinear regulator problem which follows.

1.2. The nonlinear regulator. For the linear regulator, a positive-definite homogeneous (of degree two) form with respect to the standard dilation δ_ε^1 was known to have the representation $V(x)=x'Ex$ with E a positive-definite matrix. The next lemma gives elementary conditions which tell when forms $V(x)$, which are homogeneous of even degree with respect to an arbitrary dilation, are positive definite. We denote by $\alpha=(\alpha_1,\cdots,\alpha_n)$ a multi-index with all α_i nonnegative rationals and let $|x|^\alpha=|x_1|^{\alpha_1}\cdots|x_n|^{\alpha_n}$. Then $|x|^\alpha$ is homogeneous of degree m with respect to $\delta_\varepsilon^r x=(\varepsilon^{r_1}x_1,\cdots,\varepsilon^{r_n}x_n)$ if and only if $\sum_{i=1}^n \alpha_i r_i=m$.

LEMMA 1. *Let $\delta_\varepsilon^r x=(\varepsilon^{r_1}x_1,\cdots,\varepsilon^{r_n}x_n)$ be a given dilation and $V(x)=\sum C_\alpha|x|^\alpha$ with the sum taken over a finite set of multi-indices $\alpha=(\alpha_1,\cdots,\alpha_n)$ which satisfy $\sum_{i=1}^n \alpha_i r_i=m$, m an even integer. Thus V is homogeneous of degree m with respect to δ_ε^r. Call a multi-index α mixed if more than one α_i is nonzero and assume the nonmixed multi-indices $\alpha^1=(m/r_1,0,\cdots,0),\cdots,\alpha^n=(0,\cdots,m/r_n)$ all appear in the sum defining V and have corresponding coefficients $C_{\alpha_i}=E_i>0$, $i=1,\cdots,n$. If*

$$\sum|C_\alpha|\left(\frac{1}{E_1}\right)^{\alpha_1 r_1/m}\cdots\left(\frac{1}{E_n}\right)^{\alpha_n r_n/m}<1 \tag{8}$$

with the sum taken over all mixed α in the sum defining V, then V is positive definite on $\mathbb{R}^n$.

Proof. Let E denote $(E_1,\cdots,E_n)$ and define

$$\Gamma_E=\{x\in\mathbb{R}^n\colon E_1|x_1|^{m/r_1}+E_2|x_2|^{m/r_2}+\cdots+E_n|x_n|^{m/r_n}=1\}.$$

Then Γ_E is a closed hypersurface which "encloses" the origin. For $x\in\Gamma_E$, $|x_1|\leqq(1/E_1)^{r_1/m},\cdots,|x_n|\leqq(1/E_n)^{r_n/m}$ and hence $|x_i|\to 0$ as E_i increases. We write $V(x)=\sum_{i=1}^n E_i|x_i|^{m/r_i}+\sum C_\alpha|x|^\alpha$ with the latter sum taken over mixed α occurring in the original sum defining V. Thus if

$$\sum|C_\alpha||x|^\alpha\leqq\sum|C_\alpha|\left(\left(\frac{1}{E_1}\right)^{\alpha_1 r_1/m}\cdots\left(\frac{1}{E_n}\right)^{\alpha_n r_n/m}\right)<1$$

we see $V(x)>0$ on Γ_E. Since $V\in H_m$, i.e., $V(\delta_\varepsilon^r x)=\varepsilon^m V(x)$, this implies V is positive definite on $\mathbb{R}^n$. □

Example 1.1. Let $n=2$, $\delta_\varepsilon^r x=(\varepsilon x_1,\varepsilon^3 x_2)$, $m=4$, and $V(x)=16x_1^4+Cx_1x_2+x_2^{4/3}$. Then $V\in H_4$, $E_1=16$, $E_2=1$, and the only mixed $\alpha=(1,1)$. Thus if $|C|(1/16)^{1/4}(1/1)^{3/4}<1$, or $|C|<2$, V is positive definite.

Example 1.2 (the lemma is not sharp). Take $n=2$, $\delta_\varepsilon^r x=(\varepsilon x_1,\varepsilon x_2)$, $m=2$, and $V(x)=x_1^2+Cx_1x_2+x_2^2$. Then $E_1=E_2=1$; the only mixed $\alpha=(1,1)$, and the lemma gives V positive definite if $|C|(1/1)^{1/2}(1/1)^{1/2}<1$ or $|C|<1$. Clearly, $|C|<2$ suffices.

Proof of Theorem 1. Since the two-dimensional system (1) was assumed STLC, $Y(0)\neq 0$ and we can choose local coordinates so that $Y(0)=\partial/\partial x_1$. If, in these coordinates $X(x)=a_1(x)\partial/\partial x_1+a_2(x)\partial/\partial x_2$, choose feedback $u(x)=-a_1(x)+\mu(x)$ so (renaming μ as u) with no loss of generality we may assume system (1) has the form

$$\dot{x}_1=u,\quad \dot{x}_2=a_2(x),\quad a_2(0)=0;$$

i.e., $X(x)=a_2(x)\partial/\partial x_2$, $Y=\partial/\partial x_1$. From [12], STLC at zero implies there is an integer k such that the Lie product $(ad^kY,X)(0)=(0,\partial^k a_2(0)/\partial x_1^k)\neq 0$ and that the smallest such k must be odd. This means that $a_2(x)=x_1^k q(x)+p(x)$ where $q(0)=C_0\neq 0$ and $\partial^j p(0)/\partial x_1^j=0, j=0,\cdots,k$. Thus a canonical form for a two-dimensional STLC system of the form (1) may be taken as

$$\dot{x}_1=u,\qquad \dot{x}_2=x_1^k q(x)+p(x) \tag{9}$$

with k odd and p, q, as above.

With system (9) associate the dilation $\delta_\varepsilon^r x(\varepsilon x_1, \varepsilon^k x_2)$ and expand q, p in homogeneous polynomials relative to this dilation, i.e., from the form of p, q

$$q(x) = C_0 + \sum_{j=1}^{\infty} q_j(x), \qquad q_j \in H_j,$$

$$p(x) = C_1 x_2 + \sum_{j=k+1}^{\infty} p_j(x), \qquad p_j \in H_j.$$

We write (9) as

$$\dot{x}_1 = u, \qquad \dot{x}_2 = C_0 x_1^k + C_1 x_2 + R(x), \tag{10}$$

where

$$R(x) = \sum_{j=1}^{\infty} x_1^k q_j(x) + \sum_{j=k+1}^{\infty} p_j(x)$$

and thus the vector field $R(x)\partial/\partial x_2$ is a sum of vector fields homogeneous of degree $\leqq -1$ with respect to δ_ε^r. We shall call

$$\dot{x}_1 = u, \qquad \dot{x}_2 = C_0 x_1^k + C_1 x_2, \qquad C_0 \neq 0, \tag{11}$$

the approximating system.

The proof will proceed by showing the following lemma.

LEMMA 2. *There exists a continuous feedback control $u^* \in H_1$ for the approximating system* (11) *such that*

(a) *Solutions to* (11) *with $u = u^*(x)$ are unique.*

(b) *The zero solution of* (11) *with $u = u^*(x)$ is globally asymptotically stable.*

(c) *There is a positive-definite Lyapunov function $V \in H_{k+1}$ such that its trajectory derivative $\dot{V}(x)$ along solutions of* (11), *with $u = u^*(x)$, is negative definite.*

The vector field $u^*(x)\partial/\partial x_1 + (C_0 x_1^k + C_1 x_2)\partial/\partial x_2$ is then homogeneous of degree zero with respect to δ_ε^r while the "remainder" vector field $R(x)\partial/\partial x_2$ is a sum of vector fields homogeneous of degrees less than or equal to -1. The conclusion of the proof of Theorem 1 then follows from Theorem 2.

THEOREM 2 [13, Thm. 1]. *Let W be a continuous vector field on $\mathbb{R}^n$ with $W(0) = 0$ which is homogeneous of degree m with respect to a dilation $\delta_\varepsilon^r x = (\varepsilon^{r_1} x_1, \cdots, \varepsilon^{r_n} x_n)$ and such that solutions to initial value problems for $\dot{x} = W(x)$ are unique. Let Z be a continuous sum of vector fields homogeneous of degree less than or equal to $(m-1)$. If the zero solution of $\dot{x} = W(x)$ is locally asymptotically stable, then the same is true for the zero solution of $\dot{x} = W(x) + Z(x)$.*

Proof of Lemma 2. Throughout, the dilation is $\delta_\varepsilon^r x = (\varepsilon x_1, \varepsilon^k x_2)$, k odd and determined by the Lie products which showed STLC. With system (11) consider the optimization problem of reaching the origin while minimizing the cost functional

$$C(u) = \int_0^\infty [e u^{k+1}(s) + h_{k+1}^+(x(s))\, ds], \qquad e > 0$$

with $h_{k+1}^+ \in H_{k+1}$ positive definite and free to be chosen later. Following the linear regulator approach, define

$$H(x, p, u) = p_1 u + C_0 p_2 x_1^k + C_1 x_2 + e u^{k+1} + h_{k+1}^+(x).$$

Since the values of u are unconstrained, minimizing H with respect to u yields

$$u^*(x, p) = -\left(\frac{p_1}{e(k+1)}\right)^{1/k}. \tag{12}$$

Define

$$H^*(x,p)=H(x,p,u^*(x,p))=-\gamma p_1^{(k+1)/k}+C_0p_2x_1^k+C_1p_2x_2+h_{k+1}^+(x), \tag{13}$$

where

$$\gamma=\left(\frac{k}{k+1}\right)\left(\frac{1}{e(k+1)}\right)^{1/k}>0. \tag{14}$$

Note that if we define the dual dilation to δ_ε^r as $\delta_\varepsilon^{r*}p=(\varepsilon^{k+1-r_1}p_1,\varepsilon^{k+1-r_2}p_2)=(\varepsilon^kp_1,\varepsilon p_2)$, then with $\gamma_\varepsilon^r(x,V,\dot{p})=(\delta_\varepsilon^r x,\varepsilon V,\delta_\varepsilon^{r*}p)$ as a dilation on $J^1(\mathbb{R}^2,\mathbb{R}^1)$ we have $H^*(x,p)$ homogeneous of degree $(k+1)$ with respect to γ_ε^r.

The HJB equation is

$$0=H^*(x,V_x(x))=-\gamma V_{x_1}^{(k+1)/k}+C_0x_1^kV_{x_2}+C_1x_2V_{x_2}+h_{k+1}^+(x). \tag{15}$$

The interpretation of this equation is that a solution V is such that $V(x)$ is the optimal cost to reach the origin starting from x. Since the integrand in the cost functional is positive definite, we seek a positive-definite solution V of (15). Since (11) is STLC we know (e.g., [14]) that (15) has a continuous positive-definite viscosity solution. The homogeneity of $H^*(x,p)$ with respect to γ_ε^r implies we should seek a solution $V\in H_{k+1}$ with respect to δ_ε^r. For this two-dimensional case the Brockett necessary condition (B3) is automatically satisfied and we shall show that (11) has a C^1, positive-definite solution $V\in H_{k+1}$. Specifically, since $h_{k+1}^+\in H_{k+1}$ has been left free, we actually show that there exists a C^1, positive-definite $V\in H_{k+1}$ such that

$$-\gamma V_{x_1}^{(k+1)/k}(x)+C_0x_1^kV_{x_2}(x)+C_1x_2V_{x_2}(x) \tag{16}$$

is negative definite. From (12), this will yield

$$u^*(x)=-\left(\frac{V_{x_1}(x)}{e(k+1)}\right)^{1/k} \tag{17}$$

as the desired continuous feedback control.

Since we expect $V\in H_{k+1}$ and $V\in C^1$, choose the form of V as

$$V(x)=\beta_1x_1^{k+1}+\beta_2x_1x_2+2\beta_3x_2^{(k+1)/k},\ \beta_1,\beta_2>0. \tag{18}$$

Note that terms such as $x_1^kx_2^{1/k}$, $x_1^{k-1}x_2^{2/k}$ are in H_{k+1} but were omitted since they would not yield a C^1 function V. From Lemma 1, V is positive definite if

$$|\beta_2|<(\beta_1)^{1/(k+1)}(\beta_3)^{k/(k+1)}. \tag{19}$$

Substituting V, as given in (18), into (16) and calling $g(x)$ the result yields

$$\begin{aligned}g(x)={}&-\gamma[(k+1)\beta_1x_1^k+\beta_2x_2]^{(k+1)/k}+C_0\beta_2x_1^{k+1}\\&+C_0\left(\frac{k+1}{k}\right)\beta_3x_1^kx_2^{1/k}+C_1\beta_1x_1x_2+C_1\left(\frac{k+1}{k}\right)\beta_3x_2^{(k+1)/k}.\end{aligned} \tag{20}$$

Our goal is to choose β_1, β_2, β_3, and $e>0$; hence $\gamma>0$, so that (19) is satisfied and $g\in H_{k+1}$ is negative definite.

Make the local coordinate change (which preserves homogeneity)

$$y_1=x_1,\qquad y_2=2(k+1)\beta_1x_1^k+\beta_2x_2$$

and inverts as

$$x_1=y_1,\qquad x_2=\left(\frac{1}{\beta_2}\right)(y_2-(k+1)\beta_1y_1^k),\quad \beta_2\neq 0.$$

With a slight abuse of notation by again using g for the resulting function, and adding and subtracting y_1^{k+1}, we obtain

$$\begin{aligned} g(y) = & -y_1^{k+1} - \gamma y_2^{(k+1)/k} + (1 + C_0\beta_2 - C_1(k+1)\beta_1)y_1^{k+1} + C_1 y_1 y_2 \\ & + C_0\left(\frac{k+1}{k}\right)\beta_3\left[\left(\frac{1}{\beta_2}\right)(y_2 - (k+1)\beta_1 y_1^k)\right]^{1/k} y_1^k \\ & + C_1\frac{(k+1)}{k}\beta_3\left[\left(\frac{1}{\beta_2}\right)(y_2 - (k+1)\beta_1 y_1^k)\right]^{(k+1)/k}. \end{aligned}$$

Again, $g(\delta_\lambda^r y) = \lambda^{k+1} g(y)$. Define

$$\Gamma = \{y \colon y_1^{k+1} + \gamma y_2^{(k+1)/k} = 1\}.$$

Then Γ is a closed curve which encircles the origin. Since $g \in H_{k+1}$ if we can choose $\beta_1, \beta_2, \beta_3$, and $\gamma > 0$ to make g negative on Γ, it follows that g will be negative definite. But on Γ, $|y_1| \leqq 1$ and $|y_2| \leqq 1/\gamma$; hence $y_2 \to 0$ as $\gamma \to \infty$ or equivalently as $e \to 0$. (Intuitively, $e \to 0$ means we weight the cost of control less.) Thus for $y \in \Gamma$ and $e > 0$ sufficiently small, terms in $g(y)$ having a factor y_2 are insignificant and we omit these. For this case

$$g(y) \cong -1 + f(\beta) y_1^{k+1}, \qquad |y_1| \leqq 1.$$

It suffices to show that we can choose β_1, β_2, β_3 to satisfy (19) and so that $f(\beta) < 1$ or $F(\beta) = f(\beta) - 1 < 0$ where

$$\begin{aligned} F(\beta) = & C_0\beta_2 - C_1(k+1)\beta_1 - C_0\left(\frac{k+1}{k}\right)\beta_3\left[\left(\frac{\beta_1}{\beta_2}\right)(k+1)\right]^{1/k} \\ & \cdot \left[1 - \left(\frac{C_1}{C_0}\right)\frac{(k+1)\beta_1}{\beta_2}\right]. \end{aligned} \tag{21}$$

To see that this can always be done, first choose $\beta_1 = 1$; next choose β_2 so that $\beta_2 C_0 > 0$ (recall $C_0 \neq 0$ in (11)) and $|\beta_2|$ sufficiently large so that $C_1(k+1)/(C_0\beta_2) < 1$. From (21) it is then clear that for $\beta_3 > 0$ and sufficiently large, $F(\beta) < 0$. Finally, by increasing β_3 if necessary (i.e., assure $\beta_3^{3/4} > |\beta_2|$) we can satisfy (19).

With the choices as above, $V(x)$ as given by (18) is positive definite while with $u = u^*(x)$ as given by (17), the trajectory derivative of V along solutions of (11) is $\dot{V}(x) = g(x)$ which is negative definite.

Finally, we show that we have uniqueness of solutions of (11) even though $u^*(x)$ is only continuous. With $u = u^*(x)$ (11) becomes $\dot{x}_1 = -(V_{x_1}(x)/(k+1)e)^{1/k}$, $\dot{x}_2 = C_0 x_1^k + C_1 x_2$ and the only difficulties can occur on the curve $\Lambda = \{x \colon V_{x_1}(x) = 0\}$. But on Λ, the vector field is

$$C_0\left(\left(1 - \frac{(k+1)\beta_1 C_1}{C_0\beta_2}\right)x_1^k\right)\frac{\partial}{\partial x_2}$$

and our choice of β_1, β_2 was such that $(1 - ((k+1)\beta_1 C_1/C_0\beta_2)) \neq 0$ while also $C_0 \neq 0$. Since a normal to Λ is $\eta = (k(k+1)\beta_1 x_1^k, \beta_2)$, it follows that for $x \neq 0$ the vector field defined by the right side of (11) is transverse to Λ. By Theorem 14.1 of [15], this means that solutions of (11) are unique. □

The control u^* constructed in Lemma 2 provides *global* asymptotic stability for the zero solution of the approximating system (11) and, by Theorem 2, local asymptotic stability for the zero solution of the original system having (11) as its approximation.

Example 1.3. For the Kawski example $\dot{x}_1 = u$, $\dot{x}_2 = x_2 - x_1^3$ we have $k = 3$, $C_0 = -1$, $C_1 = 1$. To construct V, first choose $\beta_1 = 1$; next, since $C_0 < 0$, we want $B_2 < 0$ and such that $-4/\beta_2 < 1$. Choose $\beta_2 = -32$ in which case (with β_3 still free), from (21), $F(\beta) = 28 - (7/12)\beta_3$. Thus $\beta_3 > 36$ suffices to make $F(\beta) < 0$ while use of Lemma 2.1, or (19), requires $\beta_3^{3/4} > |\beta_2| = 32$, or $\beta_3 > 101.6$. Thus, for example,

$$V(x) = x_1^2 - 32x_1x_2 + 200x_2^{4/3}$$

is positive definite and for $e > 0$ sufficiently small,

$$u^*(x) = -\left(\frac{1}{2e^{1/3}}\right)(2x_1 - 32x_2)^{1/3}$$

is an asymptotically stabilizing feedback control for which the trajectory derivative $\dot{V}(x)$ is negative definite.

Example 1.4 (linear regulator or $k = 1$). With $k = 1$, $C_0 = C_1 = 1$ in (11) we have the linear system $\dot{x}_1 = u$, $\dot{x}_2 = x_1 + x_2$, or $\dot{x} = Ax + bu$, $A = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 1 \end{smallmatrix}\right)$, $b = \left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right)$. To construct an asymptotically stabilizing feedback control choose $\beta_1 = 1$; then in (21) we want $\beta_2 > 0$ and such that $2/\beta_2 < 1$ or $\beta_2 > 2$. Choose $\beta_2 = 4$ which gives $F(\beta) = 2 - \beta_3/2$ or $\beta_3 > 4$ makes $F(\beta) < 0$. From (19) we need $2 < \beta_1^{1/2}\beta_3^{1/2}$ or $\beta_3 > 4$. Choose $\beta_3 = 8$, hence $V(x) = x_1^2 + 4x_1x_2 + 8x_2^2$ is positive definite and $u^*(x) = -(1/2e)(2x_1 + 4x_2)$ is an asymptotically stabilizing feedback control for $e > 0$ sufficiently small. Here (referring to the cost functionals for the linear regulator) $R = e$ while $V(x) = x'Ex$ with $E = \left(\begin{smallmatrix} 1 & 2 \\ 2 & 8 \end{smallmatrix}\right)$. We are assured that for $e > 0$ sufficiently small

$$(A'E + EA) - \left(\frac{1}{e}\right)(Ebb'E) = -W, \quad W \text{ positive definite} \tag{22}$$

since the trajectory derivative now is $\dot{V}(x) = g(x) = -x'Wx$. Computing in (22) yields

$$\begin{pmatrix} 4 & 10 \\ 10 & 16 \end{pmatrix} - \left(\frac{1}{e}\right)\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix} = -W$$

and for, say, $e = \frac{1}{5}$, we do obtain that $W = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 4 \end{smallmatrix}\right)$ is positive definite.

2. A three-dimensional example. Theorem 1, and the construction of an asymptotically stabilizing feedback control for a two-dimensional system of the form (1) which is STLC, is a consequence of the ability to characterize canonical (nilpotent) approximating systems, i.e., (11), for such systems. For $n \geqq 3$, such canonical approximations have not yet been classified; hence, we deal with the specific following example.

Example 2.1. For $n = 3$ consider the system of the form (1) having

$$X(x) = x_1\frac{\partial}{\partial x_2} + (cx_3 - x_1^3)\frac{\partial}{\partial x_3}, \qquad Y = \frac{\partial}{\partial x_1}. \tag{23}$$

As remarked in the Introduction, if $c = 0$, this system does not satisfy condition (B3) and hence does not admit a continuous asymptotically stabilizing feedback control. However, if $c \neq 0$ (we shall assume $c > 0$ which is the interesting case), condition (B3) is satisfied and we shall construct a continuous asymptotically stabilizing control.

Let $\mathcal{S}^1 = \{(ad^\nu X, Y) : \nu = 0, 1, \cdots\}$, $\mathcal{S}^j$ denote the set of all Lie products if i-tuples of elements of $\mathcal{S}^1$ with $i \leqq j$, and $\mathcal{S}^j(0)$ denote the elements of $\mathcal{S}^j$ evaluated at zero. Then $\dim \operatorname{span} \mathcal{S}^1(0) = 2 = \dim \operatorname{span}\{Y(0), [X, Y](0)\}$; $\dim \operatorname{span} \mathcal{S}^2(0) = 2$ while $(ad^3 Y, X)(0) \in \mathcal{S}^3(0)$ is independent of span $\mathcal{S}^2(0)$; i.e., dim span $\mathcal{S}^3(0) = 3$. The system (23) is, in the terminology of [4] and [5], an odd system since dimension span $\mathcal{S}^j(0)$ increases only for odd integers $j$and is STLC for any value of c. The dilation associated with a three-dimensional system of the form (1) having $\dim \operatorname{span} \mathcal{S}^1(0)=2$, $\dim \operatorname{span} \mathcal{S}^2(0)=2$, $\dim \operatorname{span} \mathcal{S}^3(0)=3$ is $\delta_\varepsilon^r x=(\varepsilon x_1, \varepsilon x_2, \varepsilon^3 x_3)$. Our construction will show, by Theorem 2, local asymptotic stability of the zero solution of any system of the form (1) having system (23), with $c \neq 0$, as its (nilpotent) approximating system relative to δ_ε^r.

With system (23), consider the optimization problem of minimizing $C(u)=\int_0^\infty [eu^4(s)+h_4^+(x(s))]\,ds$, $e>0$, $h_4^+ \in H_4$ and positive definite. Then, with the terminology as in the proof of lemma 2,

$$H(x,p,u)=p_1u+p_2x_1+cp_3x_3-p_3x_1^3+eu^4+h_4^+(x),$$

$$u^*(x,p)=-\left(\frac{p_1}{4e}\right)^{1/3},$$

$$H^*(x,p)=-\gamma p_1^{4/3}+p_2x_1+cp_3x_3-p_3x_1^3+h_4^+(x)$$

with

$$\gamma=\left(\frac{3}{4}\right)\left(\frac{1}{e}\right)^{1/3}>0.$$

The HJB equation is $H^*(x, V_x(x))=0$, with data $V(0)=0$, V positive definite. We expect $V \in H_4$. Thus we try

$$V(x)=E_1x_1^4+\beta_1x_1x_2^3+\beta_2x_1x_3+E_2x_2^4+\beta_3x_2x_3+E_3x_3^{4/3} \tag{24}$$

and require E_1, E_2, $E_3>0$. Lemma 1 shows that V is positive definite if

$$|\beta_1|\left(\frac{1}{E_1}\right)^{1/4}\left(\frac{1}{E_2}\right)^{3/4}+|\beta_2|\left(\frac{1}{E_1}\right)^{1/4}\left(\frac{1}{E_3}\right)^{3/4}+|\beta_3|\left(\frac{1}{E_2}\right)^{1/4}\left(\frac{1}{E_3}\right)^{3/4}<1. \tag{25}$$

The HJB "inequality," i.e., the analogue of (16), which we wish to have negative definite is

$$-\gamma V_{x_1}^{4/3}(x)+x_1V_{x_2}(x)+cx_3V_{x_3}(x)-x_1^3V_{x_3}(x). \tag{26}$$

Substituting from (24) into (26) gives

$$\begin{aligned}g(x)=&-\gamma(4E_1x_1^3+\beta_1x_2^3+\beta_2x_3)^{4/3}+3\beta_1x_1^2x_2^2+4E_2x_1x_2^3+(\beta_3+c\beta_2)x_1x_3\\&+c\beta_3x_2x_3+(\tfrac{4}{3})cE_3x_3^{4/3}-\beta_2x_1^4-\beta_3x_1^3x_2-(\tfrac{4}{3})E_3x_1^3x_3^{1/3}.\end{aligned}$$

Change coordinates to

$$y_1=x_1,\quad y_2=x_2,\quad y_3=4E_1x_1^3+\beta_1x_2^3+\beta_2x_3,$$

which inverts as

$$x_1=y_1,\quad x_2=y_2,\quad x_3=\left(\frac{1}{\beta_2}\right)(y_3-4E_1y_1^3-\beta_1y_2^3),$$

where we assume $\beta_2 \neq 0$. Again, abusing notation by retaining the symbol g after the variable change, and from symmetry considerations choosing $\beta_3=\beta_2\neq 0$, we obtain

$$\begin{aligned}g(y)=&-\gamma y_3^{4/3}-(4cE_1+\beta_2+4E_1)y_1^4-c\beta_1y_2^4+(4E_2-\beta_1-c\beta_1)y_1y_2^3\\&+3\beta_1y_1^2y_2^2-(\beta_2+4c)y_1^3y_2+2(c+1)y_1y_3+cy_2y_3\\&+\left(\frac{4}{3}\right)E_3\left(\frac{1}{\beta_2}\right)^{1/3}(y_3-4E_1y_1^3-\beta_1y_2^3)^{1/3}\left[\left(\frac{c}{\beta_2}\right)(y_3-4E_1y_1^3-\beta_1y_2^3)-y_1^3\right].\end{aligned}$$

Our goal is to show that β_1, β_2, E_1, E_2, E_3 can be chosen so that V is positive definite and the homogeneous function $g \in H_4$ is negative definite. Let

(i) $E_2 = 16$, $\beta_1 > 0$, $4cE_1 + \beta_2 + 4E_1 > 0$ and define

$$\Gamma = \{y\colon (4cE_1 + \beta_2 + 4E_1)y_1^4 + c\beta_1 y_2^4 + \gamma y_3^{4/3} = 1\}.$$

It is here that $c \neq 0$ plays a basic role! The choice (i) ensures Γ is an ellipsoid enclosing the origin. From the homogeneity of g, if we can show g is negative on Γ, then g will be negative definite. For $y \in \Gamma$, $|y_3| \leqq (1/\gamma)^{3/4}$, $|y_2| \leqq (1/\beta_1 c)^{1/4}$, $|y_1| \leqq 1/(4cE_1 + \beta_2 + 4E_1)^{1/4}$.

For $e > 0$ sufficiently small, $\gamma > 0$ can be made sufficiently large so that terms in $g(y)$ having a factor y_3 become negligible. Thus we have $g < 0$ on Γ if we can choose β_1, β_2, E_1, E_3 such that for $y \in \Gamma$,

$$\begin{aligned} f(y) = {} & (4E_2 - \beta_1 - c\beta_1)y_1 y_2^3 + 3\beta_1 y_1^2 y_2^2 - (\beta_2 + 4c)y_1^3 y_2 \\ & + \left(\frac{4}{3}\right) E_3 \left(\frac{1}{\beta_2}\right)^{1/3} (4E_1 y_1^3 + \beta_1 y_2^3)^{1/3} \left[\left(\frac{c}{\beta_2}\right)(4E_1 y_1^3 + \beta_1 y_2^3) + y_1^3\right] < 1. \end{aligned} \tag{27}$$

We do this by showing that the constants can be chosen so that the inequality holds where any line $y_2 = \alpha y_1$, α real, intersects Γ. Such a line intersects Γ in two points; however, from the homogeneity of f, the values of f at these points are the same. Abusing notation, let $f(\alpha)$ denote the value of f at the points where the line $y_2 = \alpha y_1$ intersects Γ, and $y_1(\alpha)$ denote the y_1 coordinate of such an intersection. Then $y_1(\alpha) \to 0$ as $\alpha \to \infty$ and the line $x_1 = 0$, or $\alpha = \infty$, must be handled separately. Here $|y_2| = (1/c\beta_1)^{1/4}$, $y_1 = 0$ and (27) requires

$$\left(\frac{4}{3}\right) cE_3 \left(\frac{1}{\beta_2}\right)^{4/3} (\beta_1)^{4/3} \left(\frac{1}{c\beta_1}\right) = \left(\frac{4}{3}\right) E_3 \left(\frac{1}{\beta_2}\right)^{4/3} \beta_1^{1/3} < 1.$$

Choose

(ii) $\beta_1^{1/3} = (\frac{3}{8})(\beta_2^{4/3}/E_3) > 0$. This choice ensures $\beta_1 > 0$ and that $\lim_{\alpha \to \infty} f(\alpha) = \frac{1}{2} < 1$ independently of future choices of β_2, E_3. Furthermore, by continuity of f, there exists an $M > 0$ such that $f(\alpha) < 1$ for $|\alpha| > M$; hence, we need only concern ourselves with $|\alpha| \leqq M$. From (27),

$$\begin{aligned} f(\alpha) = \Big\{ & (4E_2 - \beta_1 - c\beta_1)\alpha^3 + 3\beta_1 \alpha^2 - (\beta_2 + 4c)\alpha \\ & + \left(\frac{4}{3}\right) E_3 \left(\frac{1}{\beta_2}\right)^{1/3} (4E_1 + \alpha^3 \beta_1)^{1/3} \left[\left(\frac{c}{\beta_2}\right)(4E_1 + \alpha^3 \beta_1) + 1\right]\Big\} y_1^4(\alpha). \end{aligned} \tag{28}$$

Choose $E_1 = 1$ and $\beta_2 = -(4c + 3) < 0$ which satisfies (i). Next, noting (ii), choose $E_3 > 0$ large enough to make $\beta_1 < \min\{3/cM^3, 4/M^3, 1\}$. Then for $|\alpha| \leqq M$, $(4E_1 + \alpha^3\beta_1)^{1/3} > 0$, $[(c/\beta_2)(4E_1 + \alpha^3\beta_1) + 1] > 0$ and hence by increasing E_3 further, if necessary, we can assure the coefficient of $y_1^4(\alpha)$ is negative in (28), i.e., $f(\alpha) \leqq 0$ if $|\alpha| \leqq M$, and also that (25) holds, i.e., V is positive definite. Then if $u^*(x) = -(V_{x_1}(x)/4e)^{1/3}$ is the control used in system (23), the trajectory derivative of V along solutions of (23) is $\dot{V}(x) = g(x)$ which is negative definite and $x = 0$ is a globally asymptotically stable solution.

3. Concluding remarks. Our eventual goal is to show that if system (1) is STLC and satisfies additional necessary conditions, it does admit a continuous locally asymptotically stabilizing feedback control. We would also like to construct such a control. The basic approach here, shown feasible for $n = 2$, and for special cases when

$n=3$, is based on the following ideas. For the general system (1), let $\mathcal{S}^1=\{(ad^\nu X, Y)\colon \nu=0,\cdots\}$ and $\mathcal{S}^j$ denote the set of all Lie products of i-tuples of elements from $\mathcal{S}^1$ having $i\leqq j$. Let $L(\mathcal{S}^1)$ denote the Lie algebra of vector fields generated by $\mathcal{S}^1$; $L(\mathcal{S}^1)(0)$ the elements of $L(\mathcal{S}^1)$ evaluated at zero and assume $\dim L(\mathcal{S}^1)(0)=n$ which is a necessary condition for STLC. For ease of discussion, also assume the system is "odd," i.e., $\dim \operatorname{span} \mathcal{S}^{j+1}(0)=\dim \operatorname{span} \mathcal{S}^j(0)$ for odd j. This is a sufficient condition for STLC [4] and determines a dilation $\delta^r_\varepsilon x=(\varepsilon^{r_1}x_1,\cdots,\varepsilon^{r_n}x_n)$ where $r_i=1$ for $1\leqq i\leqq n_1=\dim \operatorname{span} \mathcal{S}^1(0)$, $r_i=2$ for $n_1+1\leqq i\leqq n_2=\dim \operatorname{span} \mathcal{S}^2(0)$, etc. Note that "odd" implies that all r_i are odd. Let $k=r_n$; i.e., k is the smallest integer such that $\dim \operatorname{span} \mathcal{S}^k(0)=n$. We can choose local coordinates $x=(x_1,\cdots,x_n)$, (see [6]) so that $Y=\partial/\partial x_1$ and $X(x)=X^0(x)+X^{-1}(x)+\cdots$, where X^j is homogeneous of degree j with respect to δ^r_ε. The approximating system then is $\dot{x}=X^0(x)+uY$. First use some feedback (as in the proof of Theorem 1) to eliminate the first component of X^0; i.e., we may assume $X^0(x)=\sum_{i=2}^n a_i(x)\partial/\partial x_i$, $a_i(0)=0$, $i=2,\cdots,n$. The choice of cost functional of the form

$$C(u)=\int_0^\infty [eu^{k+1}(s)+h^+_{k+1}(x(s))]\,ds, \qquad e>0,$$

with h^+_{k+1} positive definite and homogeneous of degree $(k+1)$, forces the optimal control $u^*(x,p)$ to be such that $H^*(x,p)=H(x,p,u^*(x,p))$ is homogeneous of degree $(k+1)$ with respect to the dilation $\gamma^r_\varepsilon(x,V,p)=(\delta^r_\varepsilon x, \varepsilon V, \delta^{r*}_\varepsilon p)$. Then STLC implies that the associated HJB "inequality," e.g., see (16), $-\gamma(V_{x_1}(x))^{(k+1)/k}+\sum_{j=2}^n a_j(x)V_{x_j}\leqq 0$, with equality only for $x=0$, does have a continuous viscosity solution V which is positive definite and homogeneous of degree $(k+1)$ with respect to δ^r_ε. The problem is to find additional necessary conditions for system (1), which, if satisfied, are sufficient to ensure that this solution is C^1. The homogeneity of V is such that the vector field $W(x)=X^0(x)+u^*(x, V_x(x))Y$ is homogeneous to degree zero. This means the approximating system is "good" in the sense that asymptotic stability of its zero solution implies, by Theorem 2, local asymptotic stability of the zero solution of the original system with control $u(x)=u^*(x, V_x(x))$.

Initially, the hope was that STLC and the necessary condition (B3) would be sufficient for the existence of a continuous asymptotically stabilizing feedback control for system (1). In a recent paper Coron [16] has given a necessary condition which is stronger than (B3) (i.e., it implies (B3) but the converse is not true); however, STLC and the Coron condition are not sufficient for the existence of a continuous asymptotically stabilizing feedback control even in the case when X is homogeneous of degree zero with respect to an "odd" dilation (see [17]).

RAPID BOUNDARY STABILIZATION OF THE WAVE EQUATION*

VILMOS KOMORNIK†

Abstract. The boundary stabilization of the wave equation in bounded domains is studied. It is shown that a particular choice of the feedback leads to fast energy decay. Explicit decay rate estimates are obtained.

Key words. wave equation, boundary feedback

AMS(MOS) subject classifications. primary 35L05; secondary 93D15

1. Introduction. The decay of the local energy of solutions of the wave equation in exterior domains has been thoroughly investigated since the early 1960's; cf. Lax et al. [18], Lax and Phillips [19], Morawetz et al. [22] and their bibliography. The study of the analogous problem in bounded domains with an "energy absorbing" boundary began in the mid-1970s; cf. Quinn and Russell [23], Rauch and Taylor [24], Slemrod [27]. For the latter problem exponential energy decay was first proved by Chen [3] by adapting the multiplier techniques developed earlier for the exterior problem.

The research has been continued along two, somewhat opposite, lines:

- Finding large classes of feedbacks giving exponential decay;
- Finding special feedbacks giving fast energy decay.

In the first direction the most general results up to now have been proved by Bardos et al., [1]. In a large, natural class of feedbacks the authors have characterized those giving exponential decay. We remark that their method does not provide explicit decay rate estimates.

In the present paper we are interested in the second problem. We are going to show that a suitable special choice of the feedback leads to rapid, in some sense optimal energy decay. Moreover, strong explicit decay rate estimates will be obtained.

We turn to the formulation of our results. Let Ω be a bounded domain in $\mathbb{R}^n$ $(n \geqq 1)$ with a boundary Γ of class C^2; let us denote by ν the outward unit normal to Γ. Fix a point $x^0 \in \mathbb{R}^n$ arbitrarily and set

$$m(x) = x - x^0 \quad (x \in \mathbb{R}^n) \quad \text{and} \quad R = \sup\{|m(x)| : x \in \Omega\}. \tag{1.1}$$

Let Γ_+ and Γ_- be two disjoint open subsets of Γ such that

$$m \cdot \nu \geqq 0 \quad \text{on } \Gamma_+, \quad m \cdot \nu \leqq 0 \quad \text{on } \Gamma_-, \quad \text{and} \quad \bar{\Gamma}_+ \cup \bar{\Gamma}_- = \Gamma \tag{1.2}$$

($\cdot$ denotes the scalar product of $\mathbb{R}^n$).

Fix two nonnegative functions K, $L \in L^\infty(\Gamma_+)$ and consider the following system:

$$u'' - \Delta u = 0 \quad \text{in } \Omega \times (0, \infty), \tag{1.3}$$

$$u = 0 \quad \text{on } \Gamma_- \times (0, \infty), \tag{1.4}$$

$$\partial_\nu u + Ku' + Lu = 0 \quad \text{on } \Gamma_+ \times (0, \infty), \tag{1.5}$$

$$u(0) = u^0 \quad \text{and} \quad u'(0) = u^1 \quad \text{on } \Omega. \tag{1.6}$$

(Here and in the following ∂_ν denotes the normal derivative and $'$ the time derivative; the Laplacian Δ is taken in the space variables.) This system is well posed in the

following sense: if we put

$$V=\{v\in H^1(\Omega)\,|\,v=0 \text{ on } \Gamma_-\}, \tag{1.7}$$

for every initial data $(u^0, u^1)\in V\times L^2(\Omega)$ the system (1.3)-(1.6) has a unique solution satisfying

$$u\in C([0,\infty);\, V)\cap C^1([0,\infty);\, L^2(\Omega)). \tag{1.8}$$

Furthermore, the system is dissipative: the energy of the solutions, defined by

$$\begin{aligned} E &= E(t)=E(u,u',t)\\ &:=\frac{1}{2}\int_\Omega u'(t)^2+|\nabla u(t)|^2\,dx+\frac{1}{2}\int_{\Gamma_+} Lu(t)^2\,d\Gamma, \end{aligned} \tag{1.9}$$

is decreasing in $t\in[0,\infty)$.

The purpose of this paper is to show that much stronger results hold if we choose the functions K and L appropriately. The main result concerns the case $n>1$.

THEOREM 1. *Fix a positive function $k\in L^\infty(\Gamma_+)$ such that*

$$k\geqq 1/R \quad \textit{and} \quad k|m|\leqq 1 \quad \textit{on } \Gamma_+ \tag{1.10}$$

and put

$$K=(m\cdot\nu)k \quad \textit{and} \quad L=\frac{n-1}{2}(m\cdot\nu)k^2. \tag{1.11}$$

(a) *For $n=2,3$ the solutions of* (1.3)-(1.6) *satisfy the following estimates*:

$$E(t)\leqq e^{1-(t/4R)}E(0) \quad \forall t\geqq 4R \quad \textit{if } n=2, \tag{1.12}$$

$$E(t)\leqq e^{1-(t/2R)}E(0) \quad \forall t\geqq 2R \quad \textit{if } n=3. \tag{1.13}$$

(b) *Let $n>3$ and assume that*

$$\bar\Gamma_+\cap\bar\Gamma_-=\varnothing. \tag{1.14}$$

Then the solutions of (1.3)-(1.6) *satisfy estimates* (1.13).

The simplest choice of a function k satisfying (1.10) is the constant function $1/R$.

In the (much simpler) case $n=1$ stronger results hold.

THEOREM 2. *Assume that $n=1$ and choose*

$$K=1 \quad \textit{and} \quad L=0. \tag{1.15}$$

Let us denote by $|\Omega|$ the length of the interval Ω. Then the solutions of (1.3)-(1.6) *have the following properties*:

$$E(t)=0 \quad \forall t\geqq|\Omega| \quad \text{if } \Gamma_-=\varnothing, \tag{1.16}$$

$$E(t)=0 \quad \forall t\geqq 2|\Omega| \quad \text{if } \Gamma_-\neq\varnothing. \tag{1.17}$$

Theorem 1 improves various earlier results proved by Chen [3], [4], Lagnese [14], [15], Quinn and Russell [23], Rauch and Taylor [24], Russell [26], Slemrod [27], Triggiani [28], Zuazua [29], [30] and Komornik and Zuazua [12], [13]; cf. also Lions [20]. Our proof will refine a method introduced in [12] and [13]; we will also use several ideas of Grisvard [5], Haraux [6], Lagnese [15], Zuazua [30], and Komornik [7]. Our results were announced in [11].

Several remarks are in order.

Remark 1.1. The geometrical hypothesis (1.14) is satisfied if Ω is star-shaped with respect to x^0 or more generally, if $\Omega=\Omega_1\backslash\bar\Omega_2$, where Ω_1,Ω_2 are star-shaped domains with respect to x^0 and $\bar{\Omega}_2 \subset \Omega_1$. It seems reasonable (but it has not yet been proved) that estimates (1.13) remain valid for $n > 3$ without hypothesis (1.14) (see Lemmas 2.2 and 4.1 below).

Remark 1.2. Theorem 1 remains valid for every bounded convex domain Ω, even if its boundary is not of class C^2, provided that $\Gamma_- = \varnothing$ (i.e., $x^0 \in \bar{\Omega}$).

Remark 1.3. If $n = 2$ and $\Gamma_- \neq \varnothing$, then the proof given below shows that, in fact, estimates (1.12) remain valid by replacing $4R$ by $4R(c+1)/(c+2)$, where c is the least positive constant satisfying

$$\int_{\Gamma_+} Lv^2 \, d\Gamma \leqq c \int_\Omega |\nabla v|^2 \, dx \quad \forall v \in V. \tag{1.18}$$

Remark 1.4. The role of the factor $(m \cdot \nu)$ in the feedback was first observed in [12] and [13], where feedbacks of the form $\partial_\nu u + k(m \cdot \nu)u' = 0$ were applied. The more general form (1.5) with $L \neq 0$ was introduced by Zuazua [29], [30] to make the feedback more robust. In Theorem 1 the special choice (1.10), (1.11) of the coefficients is essential.

Remark 1.5. According to a general principle due to Russell [26], for a system invariant with respect to time reversal, uniform exponential stabilizability implies exact controllability. In particular, estimates (1.13) yield the following exact controllability result:

Let $T > 2R$. Then for every initial data $(u^0, u^1) \in V \times L^2(\Omega)$ there exists a function $v \in L^2(0, \infty; L^2(\Gamma_+))$ such that $v(t) = 0$ for all $t > T$ and such that the solution of (1.3), (1.4), (1.6), and

$$\partial_\nu u = v \quad \text{on } \Gamma_+ \times (0, \infty) \tag{1.19}$$

satisfies $u(t) = 0$ for all $t > T$.

In other words, the "control" v drives the system to rest in time T.

At the same time, estimates (1.13) yield another exact controllability result (under the same condition $T > 2R$ but with different function spaces) concerning the system (1.3), (1.4), (1.6), and

$$u = v \quad \text{on } \Gamma_+ \times (0, \infty). \tag{1.20}$$

These results were first obtained (for every $n \geqq 1$) by Lions [20], [21], applying a direct approach, the Hilbert Uniqueness Method (HUM). (Two different, constructive versions of his proofs were later given in [7]-[10].)

If Ω is an n-dimensional ball or cube of centre x^0 (or, more generally, if Ω is contained in a ball of centre x^0 and contains at least one diameter of this ball), then in the above exact controllability theorems the number $2R$ cannot be replaced by any smaller constant. In this sense estimates (1.13) are optimal.

On the other hand, in general the constant $2R$ is not optimal; let us denote by T_0 the least constant such that the above systems are exactly controllable whenever $T > T_0$. The constant T_0 is the same for both systems; cf. [1], where T_0 was determined geometrically. It is an open question whether estimates (1.13) remain valid if we replace $2R$ by T_0.

Remark 1.6. The proof of Theorem 1, given below, may easily be generalized [17] for more general partitions (Γ_+, Γ_-) of the boundary by using, as in [14], [15], more general vector fields instead of $m(x)$. The results are, however, less explicit.

The method may also be adapted, following [13] or [16], respectively, for some nonlinear systems and for other, not necessarily hyperbolic systems.

The plan of this paper is the following. In the next section we discuss briefly the interpretation and the well-posedness of the system (1.3)-(1.6) and establish two related basic identities. Using these identities, in §3 we prove Theorem 1 in the case $n>3$ and obtain some weaker results if $n\leqq 3$. Finally, the proofs of Theorems 1 and 2 are completed for $n\leqq 3$ in §4.

2. Well-posedness and some identities. The results of this section hold for any nonnegative functions K, $L\in L^\infty(\Gamma_+)$ in (1.5); the special choice (1.10), (1.11) will not be needed here.

Assume first that system (1.3)-(1.6) has a sufficiently smooth solution. Then for every $t\in[0,\infty)$ we have $u(t)$, $u'(t)\in V$, and, multiplying (1.5) by an arbitrary function $v\in V$, integrating on Γ_+, and applying Green's formula, we find

$$\int_\Omega (\Delta u)v+\nabla u\cdot\nabla v\,dx+\int_{\Gamma_+}(Ku'+Lu)v\,d\Gamma=0. \tag{2.1}$$

This leads to the interpretation of (1.3)-(1.6) in the operational form

$$(u,u')'+A(u,u')=0 \quad \text{in} \quad (0,\infty), \tag{2.2}$$

$$(u,u')(0)=(u^0,u^1), \tag{2.3}$$

where A is a linear operator in $V\times L^2(\Omega)$ defined by

$$D(A)=\Big\{(u,z)\in V\times V\,|\,\Delta u\in L^2(\Omega),$$
$$\int_\Omega(\Delta u)v+\nabla u\cdot\nabla v\,dx+\int_{\Gamma_+}(Kz+Lu)v\,d\Gamma=0, \forall v\in V\Big\}, \tag{2.4}$$

and

$$A(u,z)=(-z,-\Delta u). \tag{2.5}$$

(We refer to, e.g., Lagnese [16] for the explanation of this interpretation in similar problems.)

The form (1.9) of the energy suggests to consider in V the euclidean norm defined by

$$\|v\|_V^2=\int_\Omega|\nabla v|^2+v^2\,dx+\int_{\Gamma_+}Lv^2\,d\Gamma,\quad v\in V; \tag{2.6}$$

it is equivalent to the norm induced by $H^1(\Omega)$.

We claim that $A+I$ is a maximal monotone operator in the Hilbert space $V\times L^2(\Omega)$. The monotonicity follows easily from (2.5), (2.6), (2.1), and from $K, L\geqq 0$: given $(u,z)\in D(A)$ arbitrarily, we have

$$\begin{aligned}
&((A+I)(u,z),(u,z))_{V\times L^2(\Omega)}\\
&=(u-z,u)_V+(z-\Delta u,z)_{L^2(\Omega)}\\
&=\int_\Omega\nabla(u-z)\cdot\nabla u+(u-z)u+(z-\Delta u)z\,dx+\int_{\Gamma_+}L(u-z)u\,d\Gamma\\
&=\int_\Omega|\nabla u|^2+u^2+z^2-uz\,dx+\int_{\Gamma_+}Kz^2+Lu^2\,d\Gamma\\
&\geqq 0.
\end{aligned}$$

For the maximal monotonicity of $A+I$ it is sufficient to show that $A+2I$ is surjective (cf., e.g., Brézis [2]). Given $(v, f) \in V \times L^2(\Omega)$ arbitrarily, consider the equation

$$\begin{aligned} &\int_\Omega \nabla u \cdot \nabla w + 4uw\,dx + \int_{\Gamma_+} (2K+L)uw\,d\Gamma \\ &\qquad = \int_\Omega (2v+f)w\,dx + \int_{\Gamma_+} Kvw\,d\Gamma \quad \forall w \in V. \end{aligned} \tag{2.7}$$

Applying the Lax-Milgram theorem, we find that (2.7) has a unique solution $u \in V$. Applying (2.7) with $w \in \mathscr{D}(\Omega)$, we obtain also that $\Delta u = 4u - 2v - f \in L^2(\Omega)$. Therefore, (2.7) may also be written in the form

$$\int_\Omega \nabla u \cdot \nabla w + (\Delta u)w\,dx + \int_{\Gamma_+} (K(2u-v) + Lu)w\,d\Gamma = 0.$$

Putting $z = 2u - v$, we obtain $(u, z) \in D(A)$. Finally, we have

$$(A+2I)(u, z) = (-z+2u, -\Delta u + 2z) = (v, f).$$

Now we apply the Hille-Yosida theory in the form given in, e.g., Brézis [2]. It follows that, for every initial data $(u^0, u^1) \in V \times L^2(\Omega)$, system (1.3)-(1.6) has a unique solution such that

$$(u, u') \in C([0,\infty); V \times L^2(\Omega)). \tag{2.8}$$

Furthermore, $e^{-t}\|(u, u')(t)\|_{V\times L^2(\Omega)}$ decreases as $t \to \infty$; in particular, from (1.9) and (2.6), it follows that

$$2E(t) \leqq e^{2t}\|(u^0, u^1)\|^2_{V\times L^2(\Omega)} \quad \forall t \geqq 0. \tag{2.9}$$

Moreover,

$$D(A) \text{ is dense in } V \times L^2(\Omega) \tag{2.10}$$

and for every initial data $(u^0, u^1) \in D(A)$ the solution of (1.3)-(1.6) has the following stronger regularity properties:

$$(u, u') \in C([0,\infty); D(A)) \cap C^1([0,\infty); V \times L^2(\Omega)). \tag{2.11}$$

Let us note that (1.3) and (2.11) imply that

$$\Delta u \in C([0,\infty); L^2(\Omega)); \tag{2.12}$$

however, we do not have

$$u \in C([0,\infty); H^2(\Omega)) \tag{2.13}$$

in general.

Let us now assume that the geometrical condition (1.14) is satisfied. Then we have $D(A) \subset H^2(\Omega) \times V$ with continuous imbedding: this may be proved in the same way as an analogous result in Lagnese [16, Chap. 3, §4.2.1.]. In this case we deduce from (2.11) that

$$u \in C([0,\infty); H^2(\Omega)) \cap C^1([0,\infty); V) \cap C^2([0,\infty); L^2(\Omega)). \tag{2.14}$$

It is well known (cf., e.g., [21]) that the relation $D(A) \subset H^2(\Omega) \times V$ also holds if Ω is convex and $\Gamma_- = \varnothing$, without any regularity assumption on its boundary. Therefore, the regularity properties (2.14) hold in this case, too.

In the rest of this section we will consider only solutions of (1.3)-(1.6) satisfying (2.14). All the calculations below will be justified by this regularity.

Remark 2.1. More precisely, the proof of Lemma 2.2 below will use (2.14). For the other calculations the regularity properties (2.11), (2.12) will be sufficient.

LEMMA 2.1. *Let u be a solution of* (1.3)-(1.6) *satisfying* (2.14). *Then*

$$E(S)-E(T)=\int_S^T\int_{\Gamma_+}K(u')^2\,d\Gamma\,dt \tag{2.15}$$

whenever $0\leqq S<T<\infty$.

Proof. Multiplying (1.3) by u', integrating by parts on $\Omega\times(S,T)$, and applying (1.4) and (1.5), we obtain

$$\begin{aligned}0&=\int_S^T\int_\Omega u'(u''-\Delta u)\,dx\,dt\\&=-\int_S^T\int_\Gamma u'\partial_\nu u\,d\Gamma\,dt+\left[\frac{1}{2}\int_\Omega (u')^2+|\nabla u|^2\,dx\right]_S^T\\&=\int_S^T\int_{\Gamma_+}K(u')^2\,d\Gamma\,dt+\left[\frac{1}{2}\int_\Omega (u')^2+|\nabla u|^2\,dx+\frac{1}{2}\int_{\Gamma_+}Lu^2\,d\Gamma\right]_S^T\end{aligned}$$

and the lemma follows from (1.9). □

Let us recall the following identity, essentially due to F. Rellich [25].

LEMMA 2.2. *If $v\in H^2(\Omega)$, then*

$$\int_\Omega 2(\Delta v)m\cdot\nabla v+(2-n)|\nabla v|^2\,dx=\int_\Gamma 2(\partial_\nu v)m\cdot\nabla v-(m\cdot\nu)|\nabla v|^2\,d\Gamma. \tag{2.16}$$

Proof. We apply Green's formula as follows:

$$\begin{aligned}&2\int_\Omega(\Delta v)m\cdot\nabla v\,dx\\&\quad=2\int_\Gamma(\partial_\nu v)m\cdot\nabla v\,d\Gamma-2\int_\Omega\nabla v\cdot\nabla(m\cdot\nabla v)\,dx\\&\quad=2\int_\Gamma(\partial_\nu v)m\cdot\nabla v\,d\Gamma-\int_\Omega 2|\nabla v|^2+m\cdot\nabla|\nabla v|^2\,dx\\&\quad=\int_\Gamma 2(\partial_\nu v)m\cdot\nabla v-(m\cdot\nu)|\nabla v|^2\,d\Gamma+\int_\Omega(n-2)|\nabla v|^2\,dx.\end{aligned}$$ □

Using Lemma 2.2 we finally establish our basic identity.

LEMMA 2.3. *Let u be a solution of* (1.3)-(1.6) *satisfying* (2.14). *Then*

$$\begin{aligned}&2\int_S^T E(t)\,dt-\int_S^T\int_{\Gamma_-}(m\cdot\nu)(\partial_\nu u)^2\,d\Gamma\,dt\\&\qquad+\left[\int_\Omega u'(2m\cdot\nabla u+(n-1)u)\,dx\right]_S^T\\&\quad=\int_S^T\int_{\Gamma_+}(m\cdot\nu)\{(u')^2-|\nabla u|^2\}\\&\qquad+\{Lu^2-(Ku'+Lu)(2m\cdot\nabla u+(n-1)u)\}\,d\Gamma\,dt\end{aligned}\tag{2.17}$$

whenever $0\leqq S<T<\infty$.

Proof. Following [12], [19], or [20], we multiply (1.3) by $2m\cdot\nabla u+(n-1)u$ and integrate by parts:

$$\begin{aligned}0&=\int_S^T\int_\Omega (2m\cdot\nabla u+(n-1)u)(u''-\Delta u)\,dx\,dt\\&=(1-n)\int_S^T\int_\Gamma u\partial_\nu u\,d\Gamma\,dt+\left[\int_\Omega u'(2m\cdot\nabla u+(n-1)u\,dx\right]_S^T\\&\quad+\int_S^T\int_\Omega -2(m\cdot\nabla u)\Delta u-m\cdot\nabla(u')^2\\&\quad+(n-1)(|\nabla u|^2-(u')^2)\,dx\,dt\\&=\int_S^T\int_\Gamma (1-n)u\partial_\nu u-(m\cdot\nu)(u')^2\,d\Gamma\,dt\\&\quad+\left[\int_\Omega u'(2m\cdot\nabla u+(n-1)u)\,dx\right]_S^T\\&\quad+\int_S^T\int_\Omega -2(m\cdot\nabla u)\Delta u+(u')^2+(n-1)|\nabla u|^2\,dx\,dt.\end{aligned}$$

Applying Lemma 2.2 shows that

$$\begin{aligned}&\int_S^T\int_\Omega (u')^2+|\nabla u|^2\,dx\,dt+\left[\int_\Omega u'(2m\cdot\nabla u+(n-1)u)\,dx\right]_S^T\\&=\int_S^T\int_\Gamma (m\cdot\nu)((u')^2-|\nabla u|^2)+\partial_\nu u(2m\cdot\nabla u+(n-1)u)\,d\Gamma\,dt.\end{aligned}$$

If we use (1.4), (1.5) and (1.9) then (2.17) follows. □

3. Proof of Theorem 1 if condition (1.14) is satisfied. Our proof is based on (2.17). (We recall that this identity was proved under hypothesis (1.14).) We begin by estimating its different terms. The special choice (1.10), (1.11) of the functions K, L will play a crucial role. In Lemmas 3.1–3.3 below we consider an arbitrary solution of (1.3)–(1.6), where $(u^0,u^1)\in D(A)$. We remark that these lemmas are valid for all $n\geqq 1$.

LEMMA 3.1. *We have*

$$\left|\int_\Omega u'(2m\cdot\nabla u+(n-1)u)\,dx\right|\leqq 2RE\quad\forall t\geqq 0 \tag{3.1}$$

where E is the expression in (1.9).

Proof. We proceed as in [7]. First we apply the divergence theorem as follows:

$$\begin{aligned}&\int_\Omega (2m\cdot\nabla u+(n-1)u)^2\,dx\\&\quad=\int_\Omega ((2m\cdot\nabla u)^2+(n-1)^2u^2+(2n-2)m\cdot\nabla(u^2)\,dx\\&\quad=\int_\Omega (2m\cdot\nabla u)^2+(1-n^2)u^2\,dx+(2n-2)\int_\Gamma (m\cdot\nu)u^2\,d\Gamma.\end{aligned}$$

Using (1.1) and (1.2), the last expression is majorized by

$$4R^2\int_\Omega |\nabla u|^2\,dx+(2n-2)\int_{\Gamma_+}(m\cdot\nu)u^2\,d\Gamma.$$

By this estimate, (3.1) now follows from the Cauchy-Schwarz inequality and (1.9)-(1.11):

$$\begin{aligned}&\left|\int_\Omega u'(2m\cdot\nabla u+(n-1)u)\,dx\right|\\&\leqq R\|u'\|^2_{L^2(\Omega)}+\frac{1}{4R}\|2m\cdot\nabla u+(n-1)u\|^2_{L^2(\Omega)}\\&\leqq R\left\{\int_\Omega (u')^2+|\nabla u|^2\,dx+\int_{\Gamma_+} Lu^2\,d\Gamma\right\}\\&=2RE.\end{aligned}$$

□

To estimate the right-hand side of (2.17) we generalize a method used in [13] for the case $L=0$.

LEMMA 3.2. *The integral on the right-hand side of* (2.17) *is majorized by*

$$\int_{\Gamma_+} 2RK(u')^2+\frac{3-n}{2}Lu^2\,d\Gamma.$$

Proof. Using (1.11) the function under the integral sign takes the following form:

$$(3.2)\qquad \begin{aligned}(m\cdot\nu)\Big\{&(u')^2-|\nabla u|^2+\frac{n-1}{2}k^2u^2\\&-\left(ku'+\frac{n-1}{2}k^2u\right)(2m\cdot\nabla u+(n-1)u)\Big\}.\end{aligned}$$

Applying the Cauchy-Schwarz inequality and using (1.10) we have

$$\begin{aligned}&\left|\left(ku'+\frac{n-1}{2}k^2u\right)2m\cdot\nabla u\right|\\&\leqq|m|^2\left(ku'+\frac{n-1}{2}k^2u\right)^2+|\nabla u|^2\\&\leqq(u')^2+\frac{(n-1)^2}{4}k^2u^2+(n-1)kuu'+|\nabla u|^2.\end{aligned}$$

Since $m\cdot\nu\geqq 0$ on Γ_+ by (1.2); hence (3.2) is majorized by

$$\begin{aligned}&(m\cdot\nu)\left\{2(u')^2+\left(\frac{n-1}{2}+\frac{(n-1)^2}{4}-\frac{(n-1)^2}{2}\right)k^2u^2\right\}\\&=(m\cdot\nu)\left\{2(u')^2+\frac{3-n}{2}\frac{n-1}{2}k^2u^2\right\}.\end{aligned}$$

Using (1.10) and (1.11) again, (3.2) is majorized by

$$2RK(u')^2+\frac{3-n}{2}Lu^2.$$

□

LEMMA 3.3. *We have*

$$(3.3)\qquad 2\int_S^T E(t)\,dt+\frac{n-3}{2}\int_S^T\int_{\Gamma_+} Lu^2\,d\Gamma\,dt\leqq 4RE(S)$$

whenever $0\leqq S<T<\infty$.

Proof. Estimating the last two integrals of (2.17) by Lemmas 3.1 and 3.2 we find that

$$2\int_S^T E(t)\,dt-\int_S^T\int_{\Gamma_-}(m\cdot\nu)(\partial_\nu u)^2\,d\Gamma\,dt$$
$$\leqq 2R(E(S)+E(T))+\int_S^T\int_{\Gamma_+} 2RK(u')^2+\frac{3-n}{2}Lu^2\,d\Gamma\,dt.$$

Applying Lemma 2.1 we conclude that

$$\begin{aligned}&2\int_S^T E(t)\,dt-\int_S^T\int_{\Gamma_-}(m\cdot\nu)(\partial_\nu u)^2\,d\Gamma\,dt\\ &\leqq 4RE(S)+\frac{3-n}{2}\int_S^T\int_{\Gamma_+}Lu^2\,d\Gamma\,dt.\end{aligned}\tag{3.4}$$

Since $m\cdot\nu\leqq 0$ on Γ_- by (1.2), the lemma follows. □

Now assume that $n\neq 2$. Then the second term in (3.3) is nonnegative because $L\geqq 0$ on Γ_+, and $L=0$ if $n=1$ (cf. (1.11)). Hence,

$$\int_S^T E(t)\,dt\leqq 2RE(S),\quad 0\leqq S<T<\infty.$$

Letting $T\to\infty$ we conclude that

$$\int_S^\infty E(t)\,dt\leqq 2RE(S)\quad\forall S\in[0,\infty)\quad\text{if } n\neq 2.\tag{3.5}$$

Now we apply a usual Gronwall-type argument as in, for example, [6] or [15]. Writing (3.5) in the form

$$\frac{d}{ds}\left(e^{s/2R}\int_s^\infty E(t)\,dt\right)\leqq 0\quad\forall s\geqq 0,$$

we conclude that

$$e^{s/2R}\int_s^\infty E(t)\,dt\leqq\int_0^\infty E(t)\,dt\quad\forall s\geqq 0.$$

Since $E(t)$ is decreasing and nonnegative (cf. Lemma 2.1 and (1.9)), the integral on the left-hand side is minorized by $2RE(s+2R)$. On the other hand, the integral on the right-hand side is majorized by $2RE(0)$ (cf. 3.5)). Hence

$$2RE^{(s/2R)}E(s+2R)\leqq 2RE(0)\quad\forall s\geqq 0,$$

which is equivalent to (1.13).

Now assume that $n=2$. Then the second term in (3.3) is not necessarily greater than or equal to zero, but it is always minorized by $-\int_S^T E(t)\,dt$ (cf. (1.9)). This leads to the estimate

$$\int_S^\infty E(t)\,dt\leqq 4RE(S)\quad\forall S\in[0,\infty)\tag{3.6}$$

instead of (3.5) and, replacing $2R$ by $4R$ everywhere in the above reasoning, we obtain estimates (3.12).

If $\Gamma_-\neq\varnothing$, then by (1.18) the second term of (3.3) is minorized also by $-(c/(c+1))\int_S^T E(t)$. This leads to the stronger estimates mentioned in Remark 1.3.

We have thus shown that if the geometrical condition (1.14) is satisfied and if $(u^0, u^1) \in D(A)$, then the solution of (1.3)-(1.6) satisfies (1.12) if $n=2$, and (1.13) if $n \neq 2$. In fact these estimates remain valid under the weaker condition $(u^0, u^1) \in V \times L^2(\Omega)$ on the initial data: this result follows easily by a standard density argument, based on (2.9) and (2.10).

In particular, Theorem 1 is completely proved for $n > 3$. □

4. Proof of the theorems for $n \leqq 3$. Let us first consider the cases $n = 2, 3$. We are going to show that in these cases the estimates (3.12), respectively, (3.13), remain valid even if (1.14) is not satisfied. Again, it is sufficient to consider initial data (u^0, u^1) belonging to $D(A)$. The difficulty is that now the solutions do not satisfy (2.17) in general.

On the other hand, let us observe that in the proof of estimates (3.12) and (3.13) in §3 we used only the inequality part "$\leqq$" of (2.17). (See also [12] and [13] on the same issue.) Hence for the proof of Theorem 1 it is sufficient to establish the following inequality, replacing (2.16).

LEMMA 4.1. *Assume that $n \leqq 3$ and let $(u, z) \in D(A)$. Then*

$$\begin{aligned} &\int_\Omega 2(\Delta u) m \cdot \nabla u + (2-n)|\nabla u|^2 \, dx \\ &\qquad \leqq \int_\Gamma 2(\partial_\nu u) m \cdot \nabla u - (m \cdot \nu)|\nabla u|^2 \, d\Gamma. \end{aligned} \tag{4.1}$$

Inequality (4.1) has been proved by Grisvard [5] in the special case $K = L = 0$. It is shown in [13] that his proof may be easily adapted for the more general case $K \geqq 0$, $L = 0$. In fact the same arguments may be used for the proof in the present case $K \geqq 0$, $L \geqq 0$. We omit the details.

Finally we turn to the proof of Theorem 2. Now Ω is a bounded open interval; let us denote it by (a, b).

Consider first the case $\Gamma_- = \varnothing$. The solution of (1.3)-(1.6) may be computed by the method of D'Alembert. Putting

$$U^1(s) = \int_\alpha^s u^1(r) \, dr, \quad s \in [a, b] \tag{4.2}$$

and then extending u^0, U^1 to $\mathbb{R}$ by

$$u^0(x) = u^0(b) \quad \text{and} \quad U^1(x) = U^1(b) \quad \text{if } x > b, \tag{4.3}$$

$$u^0(x) = u^0(a) \quad \text{and} \quad U^1(x) = U^1(a) \quad \text{if } x < a, \tag{4.4}$$

we obtain

$$2u(x, t) = u^0(x+t) + u^0(x-t) + U^1(x+t) - U^1(x-t). \tag{4.5}$$

If $t > b - a$, then from (4.2)-(4.5) we conclude that

$$2u(x, t) = u^0(b) + u^0(a) + U^1(b) - U^1(a),$$

independently of t and x. Hence (1.16) follows.

Now consider the case $\Gamma_- \neq \varnothing$. Since $\Gamma_+ \neq \varnothing$, there are two possibilities: either $\Gamma_- = \{a\}$ or $\Gamma_- = \{b\}$. We may assume by symmetry that $\Gamma_- = \{a\}$. If we define u^0 and U^1 on $\mathbb{R}$ by (4.2), (4.3), and

$$u^0(x) = -u^0(2a - x) \quad \text{and} \quad U^1(x) = U^1(2a - x) \quad \text{if } x < a, \tag{4.6}$$

the solution of (1.3)-(1.6) is given again by (4.5). In particular, for $t > 2(b-a)$ we conclude from (4.2), (4.3), (4.5), and (4.6) that

$$u(x, t) = 0 \quad \forall x \in [a, b], \quad \forall t > 2(b-a).$$

Hence (1.17) follows. □

ON MINIMUM ENERGY PROBLEMS*

G. DA PRATO†, A. J. PRITCHARD‡, AND J. ZABCZYK

Abstract. A stochastic system described by a semilinear equation with a small noise is considered. Under suitable hypotheses, the rate functionals for the family of distributions associated to the solution and the exit time and exit place of the solution are computed.

Key words. stochastic systems, optimization, semilinear equations, exit time

AMS(MOS) subject classifications. 93B05, 93C20, 93E20

1. Introduction. The paper is concerned with several deterministic optimization questions which arise in the theory of small noise distributed systems.

Let us assume that a stochastic system is described by a semilinear equation

$$dX^\varepsilon = (AX^\varepsilon + F(X^\varepsilon))dt + \sqrt{\varepsilon}\, dW, \quad X^\varepsilon(0) = a \in H, \qquad \varepsilon > 0, \tag{1.1}$$

where A and F are, respectively, linear and nonlinear parts of the drift term and W is a Wiener process with incremental covariance Q on a Hilbert space H.

The optimization problems considered in this paper are motivated by the problem of finding the rate functionals for the family of distributions $\mathscr{L}(X^\varepsilon(\cdot))$, $\varepsilon > 0$. They are also related to the problem of calculating (for a given domain) the exit time and exit place of the processes $X^\varepsilon(\cdot)$, $\varepsilon > 0$, (see [4], [5], [11], [12], [14], [15]). Here and in the sequel the distribution of a random variable ξ is denoted as $\mathscr{L}(\xi)$.

If $E_T(a, \cdot)$ is the rate functional for the family of measures $\mu_\varepsilon = \mathscr{L}(X^{x,\varepsilon}(T))$, $\varepsilon > 0$, then also of importance is the functional $E_\infty(a, b) = \inf_{T>0} E_T(a, b)$, $a, b \in H$, which is sometimes called the *quasipotential* ([4], [5]). For an appropriate choice of the initial condition, E_∞ is the rate functional for the invariant distributions (ν_ε) of the process X^ε.

Assume that a is a stable equilibrium point for the deterministic system $\dot{z} = Az + F(z)$, and let $\mathscr{D}$ be a set contained in H which is open with respect to the strong topology and contains the point a. Define

$$\tau^\varepsilon = \inf\{t \geqq 0;\ X^\varepsilon(t) \in \partial\mathscr{D}\}$$

then $\lim_{\varepsilon\downarrow 0} \ln \varepsilon\mathscr{E}(\tau^\varepsilon)$ is called the *exit rate.*

Now let $y^{a,\phi}(\cdot)$ be a solution to the following controlled equation:

$$\dot{y} = Ay + F(y) + Q^{1/2}\phi, \qquad y(0) = a$$

in which ϕ stands for a square integrable function from $[0, +\infty[$ into H.

Under fairly general conditions, (see [14]), we have

$$E_T(a, b) = \frac{1}{2}\inf\left\{\int_0^T \|\phi(s)\|^2\, ds;\ y^{a,\phi}(T) = b\right\}$$

and see [5], [12], and [14],

$$\lim_{\varepsilon\downarrow 0} \ln \varepsilon\mathscr{E}(\tau^\varepsilon) = \inf_{b\in\partial\mathscr{D}} E_\infty(a, b). \tag{1.2}$$

The set of all those points where the infimum in (1.2) is attained is the *exit set*, and this also has an important probabilistic interpretation (see [4], [5], [13]).

The present paper is concerned with the problem of finding or estimating E_T and E_∞ and is also concerned with the problem of minimizing E_∞ over the boundary of a given set D. We will refer to them as the minimum energy problem and the exit problem, respectively. We show that in certain important cases explicit solutions are possible.

The paper is divided into three parts. The first part is devoted to the minimum energy problem for linear systems. Here we gather partially known results. Basic formulae and estimates are given in Theorem 2.2. The next section starts from an upper estimate for the energy E_∞ which, however, is only valid locally. The main result of the paper is formulated in Theorem 3.7 which gives explicit formulae for E_∞ for the so called *gradient systems*. The first part of the theorem is an extension of a result by Friedlin [5] which also allows for a much larger class of drift terms. The second part is concerned with systems of second order in time, which are not discussed in [5]. All the basic steps of the proof are the same as those for the related results in finite dimensional spaces (see [4]); they require more sophisticated control theoretic and analytical developments. The final part presents a complete solution of the exit problem when the dynamics are linear.

This paper is a shortened version of the report [3], to which we will refer for additional details.

2. Minimum energy problem for linear systems. Consider a linear control system

$$\dot{y} = Ay + Bu, \qquad y(0) = a \in H \tag{2.1}$$

on a Hilbert space H. The operator A generates a C_0-semigroup of linear operators $S(t)$, $t \geqq 0$ and B is a bounded linear operator from a Hilbert space U into H. We will always assume $u(\cdot) \in L^2[0, T; U]$ for arbitrary $T > 0$.

The mild solution of (2.1) is given by

$$y(t) = S(t)a + \int_0^t S(t-s)Bu(s)\, ds, \qquad t \geqq 0. \tag{2.2}$$

Let us fix $T > 0$ and consider the following linear operator L_T acting from $L^2[0, T; U]$ into H:

$$L_T u = \int_0^T S(T-s)Bu(s)\, ds. \tag{2.3}$$

Thus

$$y(T) = S(T)a + L_T u.$$

Recall that if L is a bounded linear operator between Hilbert spaces H_1, H_2, then the value of its pseudoinverse operator L^{-1} at a point $y \in \operatorname{Im} L \subset H_2$ is characterized as the unique vector $x \in H_1$ such that

$$Lx = y, \qquad \langle x - z, x \rangle = 0 \quad \text{for all } z \in H_1, \qquad Lz = y.$$

Equivalently $x = L^{-1}y$ is the element with the smallest norm satisfying $Lx = y$.

It is clear that there exists a control $u(\cdot) \in L^2[0, T; U]$ transferring a to b in time T if and only if $b - S(T)a \in \operatorname{Im} L_T$, and it is clear that the control which achieves this and minimizes the functional $u \to \int_0^T \|u(s)\|^2\, ds$—called the *energy* functional—is

$$u = L_T^{-1}(b - S(T)a). \tag{2.4}$$

Let us recall that the system (2.1) is null controllable in time $T>0$ if an arbitrary state $b\in H$ can be transferred to 0 in time T. Moreover, the set $\mathcal{R}_T$ of all states which can be reached from 0 in time $T>0$ with controls $u(\cdot)\in L^2[0, T; H]$ is called the reachable space in time T. If $\mathcal{R}_T$ is the whole space then the system is said to be exactly controllable in time T. Finally a semigroup $S(t)$ is said to be stable if, for some positive constants M and ω we have $\|S(t)\|\leqq Me^{-\omega t}$ (see [1], [2]).

Define the linear operator

$$R_t=\int_0^t S(r)BB^*S^*(r)\,dr, \qquad t\geqq 0.$$

We have the following proposition (see [1], [2]).

Proposition 2.1. (i) *The function R_t, $t\geqq 0$, is the unique solution of the equation*

$$\text{(2.5)}\qquad \frac{d}{dt}\langle R_tx, x\rangle=2\langle R_tA^*x, x\rangle+\|B^*x\|^2, \qquad x\in D(A^*), \qquad t\geq 0; \qquad R_0=I.$$

(ii) *If A generates a stable semigroup then* $\lim_{t\to+\infty} R_t=R$ *exists and is the unique solution of the equation*

$$\text{(2.6)}\qquad 2\langle RA^*x, x\rangle+\|B^*x\|^2=0, \qquad x\in D(A^*).$$

The following theorem gives general results for the functionals $E_T(a, b)$, the minimal energy of transferring a to b in time T, and $E_\infty(a, b)$, $a, b\in H$, $T>0$. In its formulation we will use the convection that if an element x is not in the domain of an unbounded operator C we set $\|Cx\|=+\infty$.

Theorem 2.2. (i) *For arbitrary $T>0$ and $a, b\in H$:*

$$E_T(a, b)=\|R_T^{1/2})^{-1}(S(T)a-b)\|^2.$$

(ii) *If $S(t)$ is stable and the system* (2.1) *is null controllable in time $T_0>0$, then*

$$E_\infty(0, b)=\|(R^{1/2})^{-1}b\|^2 \qquad b\in H.$$

Moreover, there exists $C>0$, such that

$$\text{(2.7)}\qquad \|(R^{1/2})^{-1}b\|^2\leqq E_T(0, b)\leqq C\|(R^{1/2})^{-1}b\|^2, \qquad b\in H, \qquad T\geqq T_0.$$

Proof. The proof of (i) can be found, for instance, in [1]. To prove (ii) let us remark that the null controllability in time T_0 is equivalent to the fact that for a constant $C_1>0$ and all $x\in H$,

$$\int_0^{T_0}\|B^*S^*(r)x\|^2\,dr=\|R_{T_0}^{1/2}x\|^2\geqq C_1\|S^*(T_0)x\|^2.$$

But

$$\|R^{1/2}x\|^2=\sum_{k=0}^{\infty}\int_{kT_0}^{(k+1)T_0}\|B^*S^*(r)x\|^2\,dr$$

and for a constant $C_2>0$,

$$\int_0^{T_0}\|B^*S^*(r)x\|^2\,dr\leqq C_2\|x\|^2, \qquad x\in H.$$

Consequently, for some constants $M>0$, $\omega>0$, $C_3>0$,

$$\begin{aligned}\|R^{1/2}x\|^2 &= \int_0^{T_0} \|B^*S^*(r)x\|^2\,dr + C_2\sum_{k=1}^{\infty}\|S^*(kT_0)x\|^2\\ &\leqq \int_0^{T_0}\|B^*S^*(r)x\|^2\,dr + C_2M^2\sum_{k=0}^{\infty} e^{-\omega kT_0}\|S^*(T_0)x\|^2\\ &\leqq \left\{1+\frac{C_2}{C_1}M^2(1-e^{-\omega T_0})^{-1}\right\}\int_0^{T_0}\|B^*S^*(r)x\|^2\,dr\\ &\leqq C_3\|R_{T_0}^{1/2}x\|^2, \qquad x\in H.\end{aligned}$$

Hence $\operatorname{Im} R^{1/2}\subset \operatorname{Im} R_{T_0}^{1/2}$. Since the operator $(R_{T_0}^{1/2})^{-1}R^{1/2}$ is closed and thus bounded it follows that (2.14) holds. Now $\lim_{T\uparrow\infty}R_T=R$ so (2.13) must hold as well.

We now consider two special cases. Assume that $A: D(A)\subset H\rightarrow H$ is a negative definite operator on a Hilbert space H and that $C: H\rightarrow H$ is a bounded operator. The operators A and $\mathcal{A}$,

$$\mathcal{A}=\begin{bmatrix}0 & I\\ A & C\end{bmatrix},\ D(\mathcal{A})=D(A)\times D(-A)^{1/2}$$

define C_0-semigroups on H and $\mathcal{H}=D(-A)^{1/2}\times H$. The semigroups define mild solutions of the following Cauchy problems

(2.8) $\qquad \dot{x}=Ax, \qquad x(0)\in H$

(2.9) $\qquad \ddot{x}=Ax+C\dot{x}, \qquad x(0)\in D(-A)^{1/2}, \quad \dot{x}(0)\in H.$

The controlled version of (2.8)-(2.9) are

(2.10) $\qquad \dot{y}=Ay+u, \qquad y(0)=x\in H$

(2.11) $\qquad \ddot{y}=Ay+C\dot{y}+u, \qquad y(0)\in D(-A)^{1/2}), \qquad \dot{y}(0)=v\in H.$

We have the following theorem.

THEOREM 2.3. (i) *Assume that the operator A is negative definite, then the reachable set $\mathcal{R}_T$ for the system* (2.10) *is, for all $T>0$, exactly $D((-A)^{1/2})$ and*

$$E_\infty(0,b)=2\|(-A)^{1/2}b\|^2, \qquad b\in H.$$

(ii) *If in addition the operator C is negative definite, bounded and $(-C)^{1/2}$ commutes with $(-A)^{1/2}$ then the system* (2.11) *is exactly controllable and*

$$E_\infty\left(\begin{bmatrix}0\\0\end{bmatrix},\begin{bmatrix}a\\b\end{bmatrix}\right)=2\|(-C)^{1/2}(-A)^{1/2}a\|^2+2\|(-C)^{1/2}b\|^2, \qquad \begin{bmatrix}a\\b\end{bmatrix}\in\mathcal{H}.$$

Proof. For the details of the proof see [3]. The proof that (2.11) is exactly controllable is similar to the one given for the one dimensional wave equation in [2], although, of course, a more general spectral decomposition is required.

This result does not generalize to arbitrary semigroups; however for analytic semigroups the first part of (i) can be generalized. To do this we must introduce the real interpolation space $D_A(1/2,2)$. We recall that $D_A(1/2,2)$ is the set of all x in H such that there exists a function $y(\cdot)\in W^{1,2}(0,\infty;H)\cap L^2(0,\infty;D(A))$ such that $y(0)=x$ (see [7]).

THEOREM 2.4. *Suppose that A generates an analytic semigroup on H, then the reachable set for system* (2.10) *does not depend on time and is equal to $D_A(1/2,2)$. Moreover the energy norm $(E_\infty(0,\cdot))^{1/2}$ is equivalent to the norm of $D_A(1/2,2)$.*

Proof. Let $T>0$, $u(\cdot)\in L^2[0,T;H]$; then the solution of (2.10) is given by

$$y(t)=\int_0^t S(t-s)u(s)\,ds$$

and we have (see [8]) that $y(\cdot)\in W^{1,2}(0,\infty;H)\cap L^2(0,\infty;D(A))$. Hence $y(T)\in D_A(1/2,2)$.

Conversely let $x\in D_A(1/2,2)$; then we want to show that there exists a control $u(\cdot)\in L^2[0,T;H]$ such that $y(T)=x$. Now since $x\in D_A(1/2,2)$ there exists $z(\cdot)\in W^{1/2}(0,\infty;H)\cap L^2(0,\infty;D(A))$ such that $z(0)=x$. Choose a C^∞ real function $\phi(\cdot)$ such that $\phi(0)=0$, $\phi(T)=1$ and set

$$\xi(t)=\phi(t)z(T-t),\qquad u(t)=\dot\xi(t)-A\xi(t);\qquad t\in[0,T]$$

Then $u(\cdot)L^2[0,T;H]$, $\xi(t)=y(t)$ and $\xi(T)=y(T)=x$ as required.

We now consider

$$y(t)=S(t)x+\int_0^t S(t-s)u(s)\,ds$$

and first suppose that $x\in D_A(1/2,2)$. Then there exists $z(\cdot)\in W^{1,2}(0,\infty;H)\cap L^2(,\infty;D(A))$ such that $z(0)=x$. Let h be a real valued C^∞ function such that $h(0)=1$, $h(T)=0$ and set $y(t)=h(t)z(t)$, then $y(0)=x$, $y(T)=0$ and $\dot y(\cdot)-Ay(\cdot)\in L^2[0,T;H]$. Thus it suffices to choose $u(t)=\dot y(t)-Ay(t)$. For $x\in H$ we first choose $u(t)=0$ in $[0,T/2]$; thus $y(T/2)\in D_A(\frac12,2)$. Now by the previous argument we can find a control $u(\cdot)\in L^2[T/2,T;H]$ such that $y(T)=0$.

3. Minimum energy problems for nonlinear systems. Results like Theorems 2.2, 2.4 for linear systems do not have immediate generalizations to nonlinear ones. However local results can be obtained via linearization as we shall show in Theorem 3.1. This theorem will also play a role in proving Theorem 3.7, which is an extension of Theorem 2.3 and is the most important result of the paper.

Denote by V_T the space Im $L_T=$ Im $R_T^{1/2}$ associated with the control system (2.1), equipped with the norm $\|.\|_T$:

$$\|x\|_T=\|(R_T^{1/2})^{-1}x\|=\|L_T^{-1}x\|.$$

It follows immediately from the control theoretic interpretation that if $t\leqq s$,

$$V_t\subset V_s\quad\text{and}\quad \|x\|_s\leqq\|x\|_t\qquad x\in V_t.$$

Let us assume that for all $T>0$ sufficiently small, $F: V_T\to U$ and for all $r>0$, there exists $N_{r,T}>0$ such that

$$\|F(a)-F(b)\|_U\leqq N_{r,T}\|a-b\|_T\qquad\text{provided } \|a\|_T\leqq r,\quad \|b\|_T\leqq r. \tag{3.1}$$

Consider the following equation:

$$\dot y=(Ay+BF(y))+Bu,\qquad y(0)=0, \tag{3.2}$$

which has the following mild form:

$$y(t)=\int_0^t S(t-r)BF(y(r))\,dr+\int_0^t S(t-r)Bu(r)\,dr. \tag{3.3}$$

THEOREM 3.1. *If* $2N_{r,T}\sqrt{T}<1$ *and* $\|b\|_T\leqq r((1-2N_{r,T}\sqrt{T})/2N_{r,T}\sqrt{T})$ *then*

$$E_T(0,b)\leqq(\|b\|_T+rN_{r,T}\sqrt{T})^2.$$

We will need the following result, also of independent interest.

PROPOSITION 3.2. *A mild solution* $y(\cdot)$ *of* (2.1) *with initial condition* 0 *is* V_T*-continuous on* $[0,T]$.

Proof. Fix $0 \leqq t \leqq s \leqq T$, then

$$y(s)-y(t)=\int_0^s S(s-r)Bu(r)\,dr-\int_0^t S(t-r)Bu(r)\,dr$$
$$=\int_0^s S(s-r)B\{u(r)-u(r-(s-t))I_{[s-t,s]}(r)\}\,dr.$$

Thus, from the definition of the norms in V_s and V_T,

$$(3.4)\qquad \|y(s)-y(t)\|_T^2 \leqq \|y(s)-y(t)\|_s^2 \leqq \int_0^s \|u(r)-u(r-(s-t))I_{[s-t,s]}(r)\|^2\,dr$$
$$=\int_{s-t}^s \|u(r)-u(r-(s-t))\|^2\,dr+\int_{s-t}^s \|u(r)\|^2\,dr.$$

But the right-hand side of (3.4) tends to 0 as $s-t \to 0$ and so the result follows.

Proof. The equation (3.2) can be written as

$$y(t)=L_tF(y)+L_tu$$

where $F(y)$ denotes the function $F(y(s))$ $s \in [0, T]$. If there exists a control $u(\cdot)$ that transfer zero to b in time T, then

$$(3.4)\qquad x=L_TF(y)+L_Tu.$$

Set

$$(3.5)\qquad u=L_T^{-1}(b-L_TF(y)).$$

We will now show that the following equation

$$(3.6)\qquad y(t)=L_tF(y)+L_tL_T^{-1}(b-L_TF(y)) \qquad t \in [0, T]$$

has a V_T-continuous solution. Note that then necessarily

$$y(T)=L_TF(y)+x-L_TF(y)=x$$

and the transferring control is given by (4.6).

For $z \in Z=C[0, T; V_T]$ define $\phi(z)$ by

$$\phi(z)(t)=L_tF(z)+L_tL_T^{-1}(x-L_TF(z)).$$

It follows from Theorem 4.1 that ϕ: $Z \to Z$. Note

$$\phi(0)(t)=L_tL_T^{-1}x \quad t \in [0, T]$$

and hence

$$\sup_{t \leqq T} \|L_tL_T^{-1}b\|_T^2 \leqq \int_0^T \|L_T^{-1}b(s)\|_U^2\,ds=\|b\|_T^2.$$

So $\|\phi(0)\|_Z \leqq \|b\|_T$. Let $w, z \in Z$, then

$$\phi(w)(t)-\phi(z)(t)=L_t[F(w)-F(z)]+L_tL_T^{-1}(L_T[F(z)-F(w)])$$

and hence

$$\|\phi(w)-\phi(z)\|_Z \leqq \|L.(F(w)-F(z))\|_Z-\|L.L_T^{-1}(L_T[F(z)-F(w)])\|_Z$$
$$\leqq 2\left\{\int_0^T \|F(w(s))-F(z(s))\|_U^2\,ds\right\}^{1/2}.$$

If $\|w\|_Z \leqq r$, $\|z\|_Z \leqq r$, then

$$\|\phi(w)-\phi(z)\|_Z \leqq 2N_{r,T}\left\{\int_0^T \|w(s)-z(s)\|_T^2\, ds\right\}^{1/2} \leqq 2N_{r,T}\sqrt{T}\|w-z\|_Z.$$

To show that the iterates $z_n = \phi^n(0)$, $n = 1, 2, \cdots$, are convergent it is enough to prove that $\|z_n\|_Z \leqq r$, for $n = 1, 2, \cdots$. Set $k = 2N_{r,T}\sqrt{T}$, then

$$\|\phi^n(0)\|_Z \leqq \|\phi^n(0)-\phi^{n-1}(0)\|_Z + \|\phi^{n-1}(0)-\phi^{n-2}(0)\|_Z + \cdots + \|\phi^2(0)-\phi^1(0)\|_Z$$

$$\leqq (k^{n-1}+\cdots+k)\|\phi(0)\|_Z \leqq \frac{k}{1-k}\|b\|_T.$$

So by the induction argument if

$$\frac{2N_{r,T}\sqrt{T}}{(1-2N_{r,T}\sqrt{T})}\|xb\|_T \leqq r,$$

then $\|\phi^n(0)\|_Z \leqq r$ for all $n = 1, 2, \cdots$. The sequence $\{z_n\}$ is thus convergent in Z to a solution $y(\cdot)$ of the equation (3.6). Now

$$\left\{\int_0^T \|u(s)\|^2\, ds\right\}^{1/2} = \|b - L_T F(u)\|_T \leqq \|b\|_T + \left\{\int_0^T \|F(y(s))\|_U^2\, ds\right\}^{1/2}$$

$$\leqq \|b\|_T + N_{r,T}\left\{\int_0^T \|y(s)\|_T^2\, ds\right\}^{1/2} \leqq \|b\|_T + rN_{r,T}\sqrt{T}.$$

This complete the proof.

Remark 3.3. With a similar proof to the one above we can show that there exists a unique solution of equation (3.2) on the interval $[0, T]$ for any control satisfying

$$2N_{r,T}\sqrt{T} < 1 \quad \text{and} \quad \sup_{t\leqq T}\|L_t u\|_T < r\frac{1-2N_{r,T}\sqrt{T}}{2N_{r,T}\sqrt{T}}.$$

Also, nonzero initial states can be taken into account.

COROLLARY 3.4. *Assume that for a given $T>0$ the transformation F satisfies* (3.1) *with $N_{r,T}\downarrow 0$ as $r\downarrow 0$. Then for arbitrary $\varepsilon>0$ there exists $\delta>0$ such that if $\|b\|_T<\delta$, then $E_T(0,b)\leqq\varepsilon$.*

Proof. The result follows immediately from Theorem 3.1.

We will show that Theorem 2.3 can be extended to nonlinear systems of the form

$$\dot{y} = Ay - U'(y) + u, \qquad y(0) = a_0 \in H \tag{3.7}$$

$$\ddot{y} = Ay - U'(y) - \beta\dot{y} + u, \qquad y(0) = a_0 \in D(-A)^{1/2}, \qquad \dot{y}(0) = b_0 \in H. \tag{3.8}$$

We will make the following assumptions

(i) *A is a negative definite operator on the Hilbert space H.*

(ii) *U is a functional from $V = D((-A)^{1/2})$ into R_+ of class C^1, $U(0)=0$, $DU(0)=0$.*

(iii) *There exists a mapping $U'\colon V\to H$, Lipschitz on bounded sets such that*

$$DU(x;h) = \langle U'(x), h\rangle, \quad \text{for all } x, h\in V,$$

where $DU(x; h)$ denotes the value of the Fréchet derivatives at x in the direction h.

(iv) *β is a positive constant.*

Example 3.5. Let $A = (d^2/dx^2)$, $D(A) = W_0^1(0, L)\cap W^2(0, L)$. For any positive integer k, we shall denote by $W^k(0, L)$ the Sobolev space consisting of all the real functions on $[0, T]$ which have square integrable derivatives of any order less or equal to k. Moreover, we set $W_0^1(0, L) = \{u \in W^1(0, L);\ u(0) = u(L) = 0\}$. Then $V = D(-A)^{1/2} = W_0^1(0, L)$. Define

$$U(x) = \int_0^L \phi(x(s))\,ds, \qquad x \in V,$$

where ϕ is a real valued function of class C^1. It is easy to see that

$$U'(x)(s) = \phi'(x(s)), \qquad s \in [0, L], \qquad x \in V.$$

The assumptions (ii) and (iii) are satisfied in this case.

Example 3.6. The functional $U(x) = \|(-A)^{1/2}x\|^2, x \in V$ obviously satisfies the condition (ii) and $DU(x; h) = 2\langle(-A)^{1/2}x, (-A)^{1/2}h\rangle$, $x, h \in V$. But $U'(x)$ is defined only for $x \in D(A)$, so (iii) does not hold.

The minimal energy required to transfer a_0 to a_1 for the system (3.7) and from $\left[\begin{smallmatrix} a_0 \\ b_0 \end{smallmatrix}\right]$ to $\left[\begin{smallmatrix} a_1 \\ b_1 \end{smallmatrix}\right]$ for the system (3.8) will be denoted by $E_T(a_0, a_1)$ and $E_T(\left[\begin{smallmatrix} a_0 \\ b_0 \end{smallmatrix}\right], \left[\begin{smallmatrix} a_1 \\ b_1 \end{smallmatrix}\right])$, respectively. Also $E_\infty(\cdot, \cdot) = \inf_{T>0} E_T(\cdot, \cdot)$.

We denote by $z^a(\cdot)$, $z\left[\begin{smallmatrix} a \\ b \end{smallmatrix}\right](\cdot)$ the solutions of the uncontrolled systems

$$\dot{z} = Az - U'(z), \qquad z(0) = a \in H \tag{3.9}$$

$$\ddot{z} = Az - U'(z) - \beta\dot{z}, \qquad z(0) = a \in D(-A)^{1/2}, \qquad \dot{z}(0) = b \in H. \tag{3.10}$$

THEOREM 3.7. *Assume that the assumptions* (i)-(iv) *hold.*

(1) *If* $a \notin D(-A)^{1/2}$ *then* $E(0, a) = +\infty$.

(2) *If* $a \in D(-A)^{1/2}$ *and* $(-A)^{1/2}z^a(t) \to 0$ *as* $t \to \infty$ *in* H, *then*

$$E_\infty(0, a) = \|(-A)^{1/2}a\|^2 + 2U(a). \tag{3.11}$$

(3) *If* $\left[\begin{smallmatrix} a_0 \\ b_0 \end{smallmatrix}\right] \in \mathscr{H}$ *and* $z^{\left[\begin{smallmatrix} a \\ b \end{smallmatrix}\right]}(t) \to 0$ *as* $t \to \infty$ *in* $\mathscr{H}$, *then*

$$E_\infty\left(\begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} a \\ b \end{bmatrix}\right) = \beta[\|(-A)^{1/2}a\|^2 + 2U(a) + \|b\|^2]. \tag{3.12}$$

Proof. The proof is based on the following identities. For the system (3.7), with $y(0) \in D(-A)^{1/2}$

$$\begin{aligned} \frac{1}{2}\int_0^T \|u(s)\|^2\,ds = \frac{1}{2}\int_0^T &\|u(s) + 2Ay(s) - 2U'(y(s))\|^2\,ds \\ &+ [\|(-A)^{1/2}y(T)\|^2 + 2U(y(T)) - \|(-A)^{1/2}y(0)\|^2 \\ &- 2U(y(0))]. \end{aligned} \tag{3.13}$$

For the system (3.8), with $y(0) \in D(-A)^{1/2}$, $\dot{y}(0) \in H$,

$$\begin{aligned} \frac{1}{2}\int_0^T \|u(s)\|^2\,ds = \frac{1}{2}\int_0^T &\|u(s) - 2\beta\dot{y}(s)\|^2\,ds \\ &+ \beta[\|(-A)^{1/2}y(T)\|^2 + 2U(y(T)) + \|\dot{y}(T)\|^2 \\ &- \|(-A)^{1/2}y(0)\|^2 - 2U(y(0)) - \|\dot{y}(0)\|^2]. \end{aligned} \tag{3.14}$$

To show that (3.13) holds let us use the fact that the mild solution of (3.7) is in fact a strong solution. Elementary calculations give

$$\begin{aligned} \backslash f(1, 2)\backslash i(0, T, \|u(s)\|^2\,ds) = \frac{1}{2}\int_0^T &\|u(s) + 2Ay(s) - 2U'(y(s))\|^2\,ds) \\ &- 2\int_0^T \langle\dot{y}(s), Ay(s) - U'(y(s))\rangle\,ds \end{aligned} \tag{3.15}$$

It remains to show that

$$\int_0^T \langle \dot{y}(s), U'(y(s))\rangle \, ds = U(y(T)) - U(y(0)) \tag{3.16}$$

and

$$-2\int_0^T \langle \dot{y}(s), Ay(s)\rangle \, ds = \|(-A)^{1/2}y(T)\|^2 - \|(-A)^{1/2}y(0)\|^2. \tag{3.17}$$

In fact the identities (3.16) and (3.17) are true for arbitrary functions $y(\cdot)$ from $W^{1,2}(0, T; H) \cap L^2(0, T; D(A))$. To see this consider a sequence $\{y_n(\cdot)\}$ of functions from $C^1(0, T; D(A))$ converging to y both in $W^{1,2}(0, T; H)$ and in $L^2(0, T; D(A))$ topologies. Such a sequence exists since the domain $D(A)$ is dense in H. For each n and all $t \in [0, T]$

$$\frac{d}{dt} U(y_n(t)) = DU(y_n(t); \dot{y}_n(t)) = \langle U'(y_n(t)), \dot{y}_n(t)\rangle$$

and

$$\frac{d}{dt}\|(-A)^{1/2}y_n(t)\|^2 = \frac{d}{dt}\langle Ay_n(t), y_n(t)\rangle = 2\langle Ay_n(t), \dot{y}_n(t)\rangle.$$

So the identities (3.16) and (3.17) hold for each y_n, $n = 1, 2, \cdots$. However, we can pass to the limit in the above identities and therefore (3.16) and (3.17) hold for general

To prove (3.14) note that the functional U is defined on all state space and is of class C^1. Thus if the control $u(\cdot)$ is smooth and initial condition is in the domain of the generator then

$$\begin{aligned}\frac{1}{2}\int_0^T \|u(s)\|^2 \, ds &= \frac{1}{2}\int_0^T \|u(s) - 2\beta\dot{y}(s) + 2\beta\dot{y}(s)\|^2 \, ds \\ &= \frac{1}{2}\int_0^T \|u(s) - 2\beta\dot{y}(s)\|^2 \, ds + 2\int_0^T \langle \dot{y}(s) - Ay(s) + U'(y(s)), \dot{y}\rangle \, ds\end{aligned}$$

and consequently (3.14) holds in this case. The general case is obtained by a standard approximation argument.

Note that if $\dot{z}(t) = Az(t) - U'(z(t))$, $t \in [0, T]$, then for $y(t) = z(T-t)$ we have

$$\dot{y}(t) + Ay(t) - U'(y(t)) = 0, \qquad y(0) = z(T), y(T) = z(0), \qquad t \in (0, T).$$

Moreover, the function $y(\cdot)$ is a solution of (3.7) when $u(t) = -2Ay(t) + 2U'(y(t))$, $t \in [0, T]$, and for this control the first term on the right-hand side of (3.13) vanishes. Hence $u(\cdot) \in L^2[0, T; H]$ and

$$\begin{aligned}&E_T(0, a) \geqq \|(-A)^{1/2}a\|^2 + 2U(a)\\ &E_T(z^a(T), a) = \|(-A)^{1/2}a\|^2 + 2U(a) - \|(-A)^{1/2}z^a(T)\|^2 - 2U(z^a(T)).\end{aligned} \tag{3.18}$$

But

$$E_{T+1}(0, a) \leqq E_1(0, z^a(T)) + E_T(z^a(T), a).$$

Since $\|(-A)^{1/2}z^a(T)\| \to 0$ as $T \to \infty$ it follows from Theorem 3.1 but $E_1(0, z^a(T)) \to 0$ as $T \to \infty$. Thus

$$\lim_{T\to\infty} E_T(z^a(T), a) = \|(-A)^{1/2}a\|^2 + 2U(a)$$

and

$$\inf_{T>0} E_T(0, a) \leqq \|(-A)^{1/2}a\|^2 + 2U(a)$$

and so formula (3.11) holds. Formula (3.12) can be proved in a similar way.

Remark 3.8. Assume that Q is a linear positive definite operator that commutes with A (more precisely with the spectral measure associated with A) and consider the following system:

$$\ddot{y} = Q^{-1}Ay - \tfrac{1}{2}Q^{-1}U'(y) - \tfrac{1}{2}Q\dot{y} + u$$

$$y(0) = x \in D(-A)^{1/2}, \dot{y}(0) = v \in H.$$

Then the formula (3.12) can be generalized to the following

$$E\left(\begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} a \\ b \end{bmatrix}\right) = \|(-A)^{1/2}a\|^2 + U(a) + \langle Qb, b\rangle \tag{3.19}$$

with basically the same proof.

Remark 3.9. Let $\mathscr{E}$ be a separable Banach space containing H such that the inclusion operator i: $\mathscr{H} \to \mathscr{E}$ is radonifying. This means that if $\mathscr{E}$ is a Hilbert space then i is Hilbert–Schmidt. Then there exists an invariant measure on $\mathscr{E}$ for the process

$$dX = Ydt \qquad dY = (Q^{-1}AX + \tfrac{1}{2}Q^{-1}U'(X) - \tfrac{1}{2}QY)\,dt + dW$$

and up to a multiplicative constant is of the form

$$e^{-(1/2)U(x)}\mu\begin{bmatrix} dx \\ dy \end{bmatrix}$$

where μ is a Gaussian invariant measure for the linear system

$$dX = Y\,dt \qquad dY = (Q^{-1}AX - \tfrac{1}{2}\,QY)\,dt + dW.$$

The measure μ is cylindrical on $\mathscr{H}$ with mean vector o and covariance operator

$$R = \begin{bmatrix} Q^{-1} & 0 \\ 0 & Q^{-1} \end{bmatrix}. \tag{3.20}$$

The representation (3.20) is valid provided we introduce a new but equivalent inner product $\langle \cdot, \cdot \rangle_1$ on $\mathscr{H}$

$$\left\langle \begin{bmatrix} a_1 \\ b_1 \end{bmatrix}, \begin{bmatrix} a_2 \\ b_2 \end{bmatrix} \right\rangle_1 = \langle (-Q^{-1}A)^{1/2}a_1, (-Q^{-1}A)^{1/2}\rangle + \langle b_1, b_2\rangle.$$

The proof of this result follows from [15].

4. The exit problem. For details of the stochastic exit problem see [5], [12]. Here we discuss its deterministic analogue. To fix ideas we concentrate on the system (3.7) and assume that the conditions of Theorem 3.7 are satisfied. In addition let $\mathscr{E}$ be a Banach space containing $D(-A)^{1/2}$ and such that the inclusion operator i: $\mathscr{H} \to \mathscr{E}$ is randonifying, which means that the image $i(\gamma)$ of the cylindrical Gaussian measure $N(0, I)$ has an extension to a σ-additive measure on Borel subsets of $\mathscr{E}$.

Example 4.1 (Compare [5]). Let

$$A = \frac{d^2}{dx^2}, \qquad D(A) = W_0^1(0, L) \cap W^2(0, L).$$

Then

$$D(-A)^{1/2}=W_0^1(0,L).$$

If $E=C[0,L]$, then the inclusion $i: W_0^1(0,L)\to\mathscr{E}$ is radonifying (see [6]).

Let $\mathscr{D}$ be a bounded open set in $\mathscr{E}$ containing 0. For arbitrary $\varepsilon>0$ define

$$(\partial\mathscr{D})_\varepsilon=\{x\in\mathscr{E}, \text{distance}_{\mathscr{E}}\,(x,\partial\mathscr{D})<\varepsilon\} \tag{4.1}$$

and let

$$r_\varepsilon^-=\inf\{E_\infty(0,b);\ b\in(\partial\mathscr{D})_\varepsilon\cap\bar{\mathscr{D}}\},$$
$$r_\varepsilon^+=\inf\{E_\infty(0,b);\ b\in(\partial\mathscr{D})_\varepsilon\cap\mathscr{D}^c\},$$

where $\bar{\mathscr{D}}$ and $\mathscr{D}^c$ denote, respectively, the closure and the complement of $\mathscr{D}$.

$$\hat{r}=\inf\{E_\infty(0,b);\ b\in\partial\mathscr{D}\}.$$

If

$$r^-=\lim_{\varepsilon\downarrow 0} r_\varepsilon^-,\ r^+=\lim_{\varepsilon\downarrow 0} r_\varepsilon^+$$

then $r^-\leqq\hat{r}$, $r^+\leqq\hat{r}$ and we expect that in fact $r^-=r^+=\hat{r}$. The numbers r^-, r^+, and $\hat{r}$ will be called, respectively, the lower, the upper exit rates, and the exit rate.

The following problems are of interest for both deterministic and stochastic systems.

PROBLEM 4.2. Under what conditions $r^-=r^+=\hat{r}$?

PROBLEM 4.3. Assume that $r^-=r^+=\hat{r}$. Calculate $\hat{r}$ and describe as explicitly as possible the set

$$\hat{\mathscr{E}}=\{b\in\partial\mathscr{D});\ E_\infty(0,b)=\hat{r}\} \tag{4.2}$$

which will be called the *exit set.*

For linear systems some answers to the above questions are available assuming that $\mathscr{E}=H$(see [12]); here we consider a different situation and give rather specific answers to both the problems. Namely we consider the problem

$$\inf_{u\in\mathscr{D}^c}\|Au\|_H^2,$$

where A is a closed operator on $H=L^2(\Gamma)$ with the domain $D(A)\subset C(\bar{\Gamma})=E$, $C(\bar{\Gamma})$ being the space of continuous functions on $\bar{\Gamma}\subset R^n$ and $\mathscr{D}$ is a bounded neighborhood of 0 in E. If $u\notin D(A)$, we set $\|Au\|=+\infty$. We will assume also that:

(i) The operator $G=A^{-1}$ is an integral operator with a continuous kernel $g(\cdot,\cdot)$:

$$Gv(x)=\int_\Gamma g(x,y)v(y)\,dy,\qquad x\in\Gamma,\quad v\in H.$$

(ii) The set $\mathscr{D}$ is of the following form:

$$\mathscr{D}=\{u\in E;\ -b(x)<u(x)<a(x),x\in\Gamma\}$$

where $a(\cdot)$ and $b(\cdot)$ are positive functions on $\bar{\Gamma}$.

The following result holds.

THEOREM 4.4. *Assume* (i) *and* (ii) *hold. Then* $r^-=r^+=\hat{r}$ *and*

$$\hat{r}=\inf_{x\in\Gamma}\left\{(a(x)\wedge b(x)\left(\int_\Gamma g^2(x,y)\,dy\right)^{-1}\right\}. \tag{4.3}$$

Let Γ_0 be the set of all $x \in \Gamma$ for which the infimum in (4.3) *is attained. If Γ_0 is nonempty then*

$$\hat{\mathscr{E}} = \left\{ (Gv^x)(\cdot);\ v^x(\cdot) = \frac{\hat{r}}{a(x) \wedge b(x)} g(x, \cdot), x \in \Gamma_0 \right\}.$$

Proof. Let us fix $x \in \Gamma$ and a positive number c; first we will solve the problem: $\inf\{\|Au\|^2;\ u(x) \geqq c, u \in E\}$ (if $u \notin D(A)$, $\|Au\| = +\infty$), which is equivalent to

$$\inf_{Gv(x) \geqq c} \|v\|^2 = \inf_{Gv(x) = c} \|v\|^2 \tag{4.4}$$

where $Gv(x) = \langle g(x, \cdot). v\rangle_H$. The proof of the following lemma is straightforward.

LEMMA 4.5. *Let H be a Hilbert space, $v \in H$ and $c > 0$, then for the problem $\inf\{\|u\|_H;\ \langle u, v\rangle = c\}$ the infimum is attained at $u = cv\|v\|^{-2}$ and is equal to $c\|v\|^{-1}$.*

Therefore the problem (4.4) has a unique solution $v^x(\cdot) = cg(x, \cdot)(\int_\Gamma g^2(x, y)\, dy)^{-1}$ and the minimum value is $c^2\|v^x(\cdot)\|^{-2}$. The statement of the theorem now follows easily.

Example 4.6. Let $A_1 = (d^2/dx^2)$, $D(A_1) = W_0^1(0, 1) \cap W^2(0, 1)$, $\mathscr{E} = C_0(0, 1)$ the space of continuous functions vanishing at 0 and 1, $U' = 0$ and

$$\mathscr{D} = \{z \in \mathscr{E};\ |z(x)| < a, x \in [0, 1]\}.$$

PROPOSITION 4.7. *For the above example $r^- = r^+ = \hat{r} = 4a^2$ and the exit set consists of exactly two functions $\pm\hat{z}$*

$$\hat{z}(t) = \begin{cases} (a/2)t & \text{if } t \in [0, \frac{1}{2}] \\ (a/2)(1-t) & \text{if } t \in [\frac{1}{2}, 1]. \end{cases}$$

Proof. The proof follows from Theorem 4.4 and elementary calculations.

Example 4.8. Here we take $A_2 = -A_1^2$ where A_1 is the same as in Example 4.6. Note that then $D(-A_2)^{1/2} = D(A_1)$ and

$$\|(-A_2)^{1/2}z\| = \int_0^1 \left[\frac{d^2z}{dx^2}(x)\right]^2 dx.$$

The set $\mathscr{D}$ is the same as that in Example 4.6.

PROPOSITION 4.9. *For the above example $r^- = r^+ = \hat{r} = 48a^2$ and the exit set consists of exactly two functions $\pm\hat{z}$*

$$\hat{z}(t) = \begin{cases} at(3-4t^2) & \text{if } t \in [0, \frac{1}{2}] \\ a(1-t)(3-4(1-t)^2) & \text{if } t \in [\frac{1}{2}, 1]. \end{cases}$$

Remark 4.10. It is clear that a similar result is true for the operator $A_n = (-1)^{n+1}A_1^n$. We could also start from the operator $A_1 = (d^2/dx^2)$ on $L^2(0, 1; \mathbf{R}^d)$ of square integrable vector functions. $\mathscr{E} = C(0, 1; \mathbf{R}^d)$ and the set $\mathscr{D}$ could be of more general character

$$\mathscr{D} = \{z;\ z(s) \in T(s), s \in [0, 1]\}$$

where T is a multifunction with values in $\mathbf{R}^d$. Some additional subtleties arise here.

Remark 4.11. It would be interesting to consider in detail the case $A_1 = \Delta$ on $L^2(\Gamma)$, Γ bounded in $\mathbf{R}^n$, $D(A_1) = W_0^1(\Gamma) \cap W^2(\Gamma)$ and $A_m = (-1)^{m+1}A_1^m$. Under well-known conditions, $D(A_m) \subset c(\bar{\Gamma})$ and the exit problem, as formulated in Problems 1 and 2 can be posed correctly. Some related comments can be found in [5].

PSEUDODIFFERENTIAL PERTURBATIONS AND STABILIZATION OF DISTRIBUTED PARAMETER SYSTEMS: DIRICHLET FEEDBACK CONTROL PROBLEMS*

MICHAEL PEDERSEN†

Abstract. The stabilization problems for parabolic and hyperbolic partial differential equations with Dirichlet boundary condition are considered. The systems are stabilized by a boundary feedback in

(1) The operator equation,

(2) The boundary condition,

(3) Both the operator equation and the boundary condition;

the existence of feedback semigroups in these cases is also proved. The main tool in the investigation is a pseudodifferential transformation that transforms the domains of the feedback semigroup generators into classical operator domains, where a direct resolvent analysis can be employed. The transformation turns out to be a shortcut to some of the stabilization results of Lasiecka and Triggiani in [*J. Differential Equations*, 47 (1983), pp. 245-272], [*SIAM J. Control Optim.*, 21(1983), pp. 766-802], and [*Appl. Math. Optim.*, 8(1981), pp. 1-37], and it illuminates to some extent how a change of boundary condition influences the systems.

Key words. partial differential equations, stabilization, pseudodifferential operators, boundary feedback control

AMS(MOS) subject classifications. 35J05, 93D25

Orientation. This paper is concerned with boundary feedback stabilization problems for parabolic and hyperbolic evolution equations associated with elliptic differential operators. Boundary feedback systems have been studied intensively during the last 10 years by Lasiecka and Triggiani and others; we refer here only to [7]-[9]. Lasiecka and Triggiani employ a semigroup-based method, related to work of Washburn [15] and Balakrishnan [1]. This semigroup-integral representation method is based on the theory of fractional power spaces and second-order operators are considered. Lasiecka and Triggiani prove the existence of a feedback semigroup on negative order fractional power spaces strictly larger than $L^2(\Omega)$, and then the semigroup is restricted to $L^2(\Omega)$.

We describe here a pseudodifferential operator approach that allows us to work directly in $L^2(\Omega)$, and we construct in a direct way the resolvent of the 2m-order operator of the evolution equation we consider. The explicit resolvent construction is then used to derive stabilization results for the boundary feedback semigroup of the problem, and to improve some of the estimates given in [7]-[9].

Another advantage is the application of the pseudodifferential point of view to *characterize* various types of feedback systems appearing in the literature. Some of the first results on the stabilization of feedback systems are due to Nambu [11] and Triggiani [13], where the systems are stabilized by a suitable manipulation (control) in the operator equation. Such manipulations are included in what we denote *perturbations of the first kind.* Another possibility, usually considered more complicated than manipulating with the operator equation, is the manipulation with the boundary condition. Stabilization of a system by the changes of the boundary condition is treated in [7]-[9]. It is this kind of manipulation of the boundary condition that is usually understood

* Received by the editors January 15, 1989; accepted for publication (in revised form) January 29, 1990. This work was partially supported by the Carlsberg Foundation.

as a boundary control, or as a boundary feedback for systems where the control is a feedback of the state. We denote this kind of control *a perturbation of the second kind.* For both types of perturbations it is most realistic to assume that the feedback controls are of finite rank.

One of the main results of this paper is that we can, in general, *transform* a perturbation of the second kind into the more simple and well-understood perturbation of the first kind, where a "classical" approach can be taken for obtaining stabilization results. It turns out that the transformation can be regarded as a generalized change of coordinates in the space $H^m(\Omega)$, a feature that is also of interest in the case of optimal control of systems. But the optimal problem is not elaborated on in this paper.

For the sake of generality, we also introduce a combination of the perturbations. Here we manipulate *both* the operator equation *and* the boundary condition and call this a *perturbation of the third kind.* For such systems it is possible to construct a system operator that is *variational* (i.e., associated with a suitable semibounded sesquilinear form), and calculations on this operator demonstrate the linking of "interior terms" and "boundary terms." The stabilization procedure suggested for such systems with mixed feedbacks is perhaps not optimal with respect to dimensionality, but it is simple, and the theory elucidates the nature of the boundary feedback systems.

The pseudodifferential approach thus allows us to obtain stabilization results in a unified setting for all three kinds of perturbations. Moreover, we treat parabolic as well as hyperbolic problems. In all cases we conclude that it is possible to construct finite rank feedback mechanisms that give exponential decrease of the L^2-norm of the state. For perturbations of the first and second kind this is achieved by the pole-assignment theorem, while for perturbations of the third kind positivity arguments are used.

The results on perturbations of the first and second kind are contained in § 5 of this paper, while § 6 deals with the perturbations of the third kind. Section 1 is an introduction to the notation used throughout the paper; § 2 introduces the specific form of the perturbations considered. Section 3 and 4 deal with some results of pseudodifferential calculus, most importantly the transformation techniques employed.

1. Introduction and notation. We consider stabilization of parabolic and hyperbolic differential equations of the form

$$\begin{aligned} &\partial_t u + Au = 0 && \text{in } \Omega && \text{for } t > 0,\\ &\gamma u = 0 && \text{on } \Gamma && \text{for } t > 0,\\ &u = u_0 && \text{in } \Omega && \text{for } t = 0, \end{aligned} \tag{1.1}$$

and

$$\begin{aligned} &\partial_t^2 u + Au = 0 && \text{in } \Omega && \text{for } t \in \mathbb{R},\\ &\gamma u = 0 && \text{on } \Gamma && \text{for } t \in \mathbb{R},\\ &u = u_0 && \text{in } \Omega && \text{at } t = 0,\\ &\partial_t u = u_1 && \text{in } \Omega && \text{at } t = 0. \end{aligned} \tag{1.2}$$

Here A is a formally self-adjoint, uniformly strongly elliptic differential operator of order $2m$, of the form

$$A = \sum_{|\alpha|,|\beta| \leqq m} D^\beta a_{\alpha\beta}(x) D^\alpha, \tag{1.3}$$

with $C^\infty(\bar{\Omega})$-coefficients $a_{\alpha\beta}$ on a bounded, open domain $\Omega \subset \mathbb{R}^n$, $n \geqq 2$, with smooth boundary $\partial\Omega = \Gamma$. γ is the *Dirichlet trace operator*

$$\gamma = \{\gamma_j\}_{0 \leqq j < m} \tag{1.4}$$

where

$$\gamma_j u = \left(\frac{1}{i}\frac{\partial}{\partial n}\right)^j u|_\Gamma. \tag{1.5}$$

(n is the normal, directed inward.)

We denote similarly

$$\nu = \{\gamma_j\}_{m \leqq j < 2m} \tag{1.6}$$

the *Neumann trace operator*, and we define the *Cauchy-data* ρu as

$$\rho u = \{\gamma u, \nu u\}. \tag{1.7}$$

Moreover, we use the multi-index notation

$$D^\alpha = D_1^{\alpha_1}, \cdots, D_n^{\alpha_n}, \qquad D_j^{\alpha_j} = \left(\frac{1}{i}\frac{\partial}{\partial x_j}\right)^{\alpha_j}. \tag{1.8}$$

The *Dirichlet realization* A_γ of A is the operator that acts as does A in $L^2(\Omega)$, and with domain

$$D(A_\gamma) = \{u \in H^{2m}(\Omega) \mid \gamma u = 0\} = H^{2m}(\Omega) \cap H_0^m(\Omega), \tag{1.9}$$

where $H^s(\Omega)$ is the Sobolev space of $L^2(\Omega)$-functions with $L^2(\Omega)$-derivatives up to order s. It is well known that A_γ is an unbounded, self-adjoint operator in $L^2(\Omega)$, and since the embedding $H^s(\Omega) \to H^t(\Omega)$ is compact for $s > t$, the resolvent $R(\lambda, A_\gamma)$ of A_γ is a compact operator in $L^2(\Omega)$ for all λ outside the spectrum of A_γ, $\mathrm{sp}(A_\gamma)$. Hence A_γ has a sequence of real eigenvalues $\lambda_1 \leqq \lambda_2 \leqq \cdots$ converging to infinity. We see that (1.1) and (1.2) are the time-dependent evolution problems associated with A_γ, generalizing the heat equation, respectively, the wave equation. When $\lambda_1 > 0$, all solutions $u(t, x)$ of (1.1) are exponentially decreasing for $t \to \infty$, and all solutions of (1.2) are bounded; we will call this the *stable* case. However, if some eigenvalues are negative, there are solutions both of (1.1) and (1.2) that grow in an exponential manner as $t \to \infty$. It is therefore of interest to investigate how we can change the systems to obtain the stable case, and that is the aim of this paper.

2. Perturbations of the boundary value problems. By a *perturbation of the first kind* of the system (1.1) we will understand a system of the form

$$\begin{aligned} &\partial_t u + Au + Gu = 0 && \text{in } \Omega && \text{for } t > 0, \\ &\gamma u = 0 && \text{on } \Gamma && \text{for } t > 0, \\ &u = u_0 && \text{in } \Omega && \text{at } t = 0. \end{aligned} \tag{2.1}$$

Here the interior operator A is replaced by $A + G$ where G has finite rank and is of the special form $G = KT$, where

(i) T is a *trace operator* that maps functions on Ω into functions on Γ, in the form of a column vector.

(ii) K is a *Poisson operator* that maps functions on Γ into functions on Ω, of the form of a row vector.

An operator G of this special form is denoted as a *singular Green operator.* This kind of operator is carefully explained, as well as the trace and Poisson operators, in Grubb [5]. They are all operators entering in the "Boutet de Monvel-calculus" (cf. Boutet de Monvel [2]).

Stabilization of the *a priori* unstable system (1.1) by a perturbation of the first kind has been studied, e.g., in Nambu [11] and Triggiani [14], and it is shown there that it is possible to choose G of finite rank, such that (2.1) is stable.

By a *perturbation of the second kind* of the system (1.1) we will understand a system of the form

$$\begin{aligned} &\partial_t u + Au = 0 && \text{in } \Omega && \text{for } t>0, \\ &\gamma u = T'u && \text{on } \Gamma && \text{for } t>0, \\ &u = u_0 && \text{in } \Omega && \text{at } t=0, \end{aligned} \tag{2.2}$$

where the boundary operator γ is replaced by $\gamma - T'$, T' being a trace operator of finite rank.

Both (2.1) and (2.2) are so-called *boundary feedback systems,* and we will especially be interested in the case where T' is of the special form

$$T'u = \sum_{j=1}^{N} (u \mid w_j) g_j \tag{2.3}$$

(here $(\cdot\mid\cdot)$ is the usual $L^2(\Omega)$ inner product, $w_j \in C^\infty(\bar{\Omega})$, $g_j \in C^\infty(\Gamma)^m$, $j = 1, 2, \cdots, N$).

For applications, the w_j can be thought of as sensor functions and the g_j as boundary actuators.

T' defined in (2.3) is called a *finite-dimensional feedback operator,* and in contrast to γ it is of a nonlocal nature. (One of the major differences between the perturbations (2.1) and (2.2) is that in (2.1) the boundary condition is *local,* whereas in (2.2) it is nonlocal.)

Boundary feedback systems have been studied in a number of papers by Lasiecka and Triggiani (see, e.g., Lasiecka and Triggiani [7]-[9]). One of the main results is that, under suitable hypotheses, it is possible to choose the functions w_j and g_j appearing in (2.3), such that the system is stable. Lasiecka and Triggiani took a semigroup approach to investigate the system (2.2), using developments of the semigroup approach presented in Washburn [15] and Balakrishnan [1]. (The basic idea of a semigroup model is presented in Fattorini [4], where ordinary differential equations are considered.)

By a *perturbation of the third kind* of the system (1.1) we will understand a system of the form

$$\begin{aligned} &\partial_t u + Au + Gu = 0 && \text{in } \Omega && \text{for } t>0, \\ &\gamma u = T'u && \text{on } \Gamma && \text{for } t>0, \\ &u = u_0 && \text{in } \Omega && \text{at } t=0, \end{aligned} \tag{2.4}$$

where the operators G and T' are of the types considered above.

We define perturbations of the system (1.2) in an analogous way.

In the following we present a pseudodifferential operator method to investigate the systems above. This gives us in an easy way many of the results of Lasiecka and Triggiani [7]-[9], as well as similar results for the hyperbolic problem

$$\begin{aligned} &\partial_t^2 u + Au = 0 && \text{in } \Omega && \text{for } t \in \mathbb{R}, \\ &\gamma u = T'u && \text{on } \Gamma && \text{for } t \in \mathbb{R}, \\ &u = u_0 && \text{in } \Omega && \text{at } t=0, \\ &\partial_t u = u_1 && \text{in } \Omega && \text{at } t=0 \end{aligned} \tag{2.5}$$

(a perturbation of the second kind of (1.2)).

Here we would like to point out that there now exists a quite general theory that includes all the above perturbations when they have "smooth coefficients," namely, the theory of *pseudodifferential boundary problems*. For these, the solvability of parabolic problems such as (2.2) (and far more general cases) has been discussed in great detail in Grubb [5]. However, in the work that follows, we use only some basic results of the pseudodifferential point of view. But the techniques were crucial to obtain the simplicity of the proofs, and the theory was very helpful for the understanding of the underlying problems.

One of our main results is that we can, in general, *transform* a perturbation of the second kind into a perturbation of the first kind, whenever the boundary condition is *normal*, in the sense described in Grubb [5]. This includes all "classical" normal boundary conditions, as well as the feedback boundary condition $\gamma u - T'u = 0$, with T' given by (2.3). In this case, however, a special transformation of the systems (2.2) and (2.5) proves to be very useful. It turns out that the transformation can be regarded as a generalized change of coordinates, and the resulting transformed system operator $A+G$ is merely a finite-dimensional, A-bounded perturbation of A. In this case, stabilization theory for perturbations of the first kind is straightforward, as we can apply the well-known "pole assignment theorem" due to Wonham (see Wonham [16]).

3. Normal operator realizations. Assume that $Tu = 0$ is a *normal boundary condition* in the sense of Grubb [5], i.e., the highest order normal derivatives enter with a surjective coefficient matrix. We will then define a *normal realization* of the operator A in (1.3) the following way. Let A_T be the operator that acts as does A in $L^2(\Omega)$, with domain

$$D(A_T) = \{u \in H^{2m}(\Omega) \mid Tu = 0\}. \tag{3.1}$$

Then the realization A_T of A is called a normal realization.

It is shown in Grubb [5, Lemma 1.6.8], that normal realizations have dense domains in $L^2(\Omega)$. According to Grubb, there exists an operator Λ, (see (4.4)) that is a homeomorphism in $H^s(\Omega)$ for any $s \geqq 0$, such that Λ defines a bijection

$$\Lambda\colon \quad D(A_T) \tilde{\to} D(A_\gamma) = H^{2m}(\Omega) \cap H_0^m(\Omega), \tag{3.2}$$

where A_γ is the Dirichlet realization from § 1.

Moreover, we have Lemma 3.1.

LEMMA 3.1. *Let T' be given by* (2.3) *and define*

$$T = \gamma - T'. \tag{3.3}$$

Then $Tu = 0$ is a normal boundary condition, and the operator realization A_T of A is a closed, densely defined operator in $L^2(\Omega)$.

Proof. We only have to show that A_T is closed. Let (u_n) be a sequence in $D(A_T)$ converging to $u \in L^2(\Omega)$, and assume that (Au_n) converges to $v \in L^2(\Omega)$. We must show that $u \in D(A_T)$ with $Au = v$. Since $u_n \to u$ in $L^2(\Omega)$, we have that $Au_n \to Au$ in $\mathcal{D}'(\Omega)$ (space of distributions on Ω), so that $v = Au \in L^2(\Omega)$ and $u_n \to u$ in the space $\{v \in L^2(\Omega) \mid Av \in L^2(\Omega)\}$. Now $\gamma u_n \to \gamma u$ in $\prod_{0 \leqq k < m} H^{-1/2-k}(\Gamma)$ (see Lions and Magenes [10]) and since

$$\gamma u_n = \sum_{j=1}^{N} (u_n \mid w_j) g_j \quad \text{where } (u_n \mid w_j) \to (u \mid w_j), \quad j = 1, 2, \cdots, N,$$

we see that $\gamma u_n \to \sum_{j=1}^N (u|w_j)g_j$, so γu equals $\sum_{j=1}^N (u|w_j)g_j$ as an element of $\prod_{0\leqq k<m} H^{1/2-k}(\Gamma)$. Now, since $g_j \in C^\infty(\Gamma)^m \subseteq \prod_{0\leqq k<m} H^{2m-k-1/2}(\Gamma)$, $j=1,2,\cdots,N$, we have that $\gamma u \in \prod_{0\leqq k<m} H^{2m-k-1/2}(\Gamma)$. But then by the regularity of the Dirichlet problem for A, $Au \in L^2(\Omega)$ and $\gamma u \in \prod_{0\leqq k<m} H^{2m-k-1/2}(\Gamma)$ imply that $u \in H^{2m}(\Omega)$. Altogether, $u \in H^{2m}(\Omega)$ with $\gamma u - \sum_{j=1}^N (u|w_j)g_j = 0$, so $u \in D(A_T)$. □

4. The pseudodifferential transformations. Consider for $l=1,2$ the parabolic, respectively, hyperbolic perturbation of the second kind

$$\partial_t^l u + A_T u = 0, \qquad u \in D(A_T), \tag{4.1}$$

with $T=\gamma-T'$, T' given by (2.3).

Using (3.2) this can be transformed into

$$\partial_t^l \Lambda^{-1} v + A_T \Lambda^{-1} v = 0, \qquad v \in D(A_\gamma), \tag{4.2}$$

where $v=\Lambda u$. Acting with Λ from the left in (4.2) we find

$$\partial_t^l v + \Lambda A_T \Lambda^{-1} v = 0, \qquad v \in D(A_\gamma). \tag{4.3}$$

It is shown in Lemma 1.6.8 of Grubb [5] that Λ and Λ^{-1} can be chosen in the following form:

$$\Lambda = 1 - K_0 T', \qquad \Lambda^{-1} = 1 - K_0 Q_0 T', \tag{4.4}$$

where K_0 is a certain standard type of Poisson operator, chosen such that K_0T' has small norm, a Q_0 is a certain pseudodifferential operator, that is bijective and elliptic in $\prod_{0\leqq k<2m} H^{s-k}(\Omega)$, $s\geqq 0$. Then

$$\Lambda A_T \Lambda^{-1} = (1-K_0T')A_T(1-K_0Q_0T') = A_T + G, \tag{4.5}$$

where

$$G = K_0 T' A_T K_0 Q_0 T' - A_T K_0 Q_0 T' - K_0 T' A_T, \tag{4.6}$$

is a singular Green operator of finite rank.

Hence (4.3) is a perturbation of the first kind.

We have thus obtained Proposition 4.1.

PROPOSITION 4.1. *For any trace operator T' of the form* (2.3) *there exist operators Λ and Λ^{-1} of the form* (4.4) *such that* (4.1) *can be replaced by* (4.3), *with $v=\Lambda u$, the operators described by* (4.5)-(4.6). □

However there is also a special variant adapted particularly to the Dirichlet problem that is more convenient for the stabilization problem.

Assume, for the moment, that 0 is not an eigenvalue of A_γ. (In the case where 0 is an eigenvalue, we replace A by $A+\delta$ for a small constant δ, carry out the constructions for this, and remove δ afterwards; see the explanation after Remark 5.3.) Let K_γ be the Poisson operator that solves the Dirichlet problem for A, i.e., K_γ maps φ into the solution u of

$$Au = 0 \quad \text{in } \Omega, \qquad \gamma u = \varphi \quad \text{on } \Gamma. \tag{4.7}$$

Since $K_\gamma T'$ has finite rank, the bounded operator $1-K_\gamma T'$ is a Fredholm operator with index 0 in $L^2(\Omega)$, and it maps $H^{2m}(\Omega)$ into $H^{2m}(\Omega)$.

Since

$$\gamma(1-K_\gamma T')u = \gamma u - T'u = Tu, \tag{4.8}$$

we have that

$$(1-K_\gamma T')D(A_T) \subseteq D(A_\gamma), \tag{4.9}$$

and moreover, if $u \in D(A_T)$ and $v = (1 - K_\gamma T')u$, then

$$Av = A(1 - K_\gamma T')u = Au. \tag{4.10}$$

Now we assume that T' can be chosen such that $1 - K_\gamma T'$ is a bijection in $H^{2m}(\Omega)$ (this will be done later; see § 5). Then $1 - K_\gamma T'$ maps $D(A_T)$ bijectively onto $D(A_\gamma)$, and hence defines a homeomorphism:

$$1 - K_\gamma T'\colon \quad D(A_T) \tilde{\to} D(A_\gamma) \qquad (= H^{2m}(\Omega) \cap H^m(\Omega)). \tag{4.11}$$

We have then established the useful factorization

$$A_T = A_\gamma(1 - K_\gamma T'), \tag{4.12}$$

in a precise sense. (See also Remark 1.1 in [8].)

Now proceeding as above, the problems

$$\partial_t^l u + A_T u = 0, \qquad u \in D(A_T), \quad l = 1, 2 \tag{4.13}$$

transform into

$$\partial_t^l v + (1 - K_\gamma T')A_\gamma v = 0, \qquad v \in D(A_\gamma), \quad l = 1, 2, \tag{4.14}$$

where $v = (1 - K_\gamma T')u$.

Thus we have transformed the perturbation of the second kind (4.13) into a perturbation of the first kind (4.14), and we are able to calculate the system operator in an easy way.

We have thus obtained Theorem 4.2.

THEOREM 4.2. *Assume that* $0 \notin \mathrm{sp}(A_\gamma)$. *The boundary feedback systems*

$$\begin{aligned} &\partial_t u + Au = 0 && \text{in } \Omega && \text{for } t > 0, \\ &\gamma u = T'u && \text{on } \Gamma && \text{for } t > 0, \\ &u = u_0 && \text{in } \Omega && \text{at } t = 0, \end{aligned} \tag{4.15}$$

and

$$\begin{aligned} &\partial_t^2 u + Au = 0 && \text{in } \Omega && \text{for } t \in \mathbb{R}, \\ &\gamma u = T'u && \text{on } \Gamma && \text{for } t \in \mathbb{R}, \\ &u = u_0 && \text{in } \Omega && \text{at } t = 0, \\ &\partial_t u = u_1 && \text{in } \Omega && \text{at } t = 0, \end{aligned} \tag{4.16}$$

with T' *given by* (2.3), *transform into the systems*

$$\begin{aligned} &\partial_t v + Av - K_\gamma T'Av = 0 && \text{in } \Omega && \text{for } t > 0, \\ &\gamma v = 0 && \text{on } \Gamma && \text{for } t > 0, \\ &v = v_0 && \text{in } \Omega && \text{for } t = 0, \end{aligned} \tag{4.15$'$}$$

and

$$\begin{aligned} &\partial_t^2 v + Av - K_\gamma T'Av = 0 && \text{in } \Omega && \text{for } t \in \mathbb{R}, \\ &\gamma v = 0 && \text{on } \Gamma && \text{for } t \in \mathbb{R}, \\ &v = v_0 && \text{in } \Omega && \text{for } t = 0, \\ &\partial_t v = v_1 && \text{in } \Omega && \text{for } t = 0. \end{aligned} \tag{4.16$'$}$$

Since

$$K_\gamma T'Av = \sum_{j=1}^{N} (Av \mid w_j) K_\gamma g_j, \tag{4.17}$$

for $v \in H^{2m}(\Omega)$, $K_\gamma T'A$ has finite rank, and we see that

$$\tilde{A} = A - K_\gamma T'A, \tag{4.18}$$

can be regarded as a finite-dimensional perturbation of A.

We obviously have ($\|\cdot\|_s$ is the $H^s(\Omega)$-norm):

$$\|K_\gamma T'Av\|_0 \leqq c\|Av\|_0 \leqq c\|Av\|_0 + \|v\|_0 \tag{4.19}$$

for $v \in D(A_\gamma)$, so $K_\gamma T'A$ is A-bounded. Since A_γ is the infinitesimal generator of an analytic semigroup on $L^2(\Omega)$, so is $\tilde{A}_\gamma$, from the perturbation result in Proposition 1 of Zabczyk [17].

We have thus obtained Theorem 4.3.

THEOREM 4.3. *The realization $\tilde{A}_\gamma$ of the operator*

$$\tilde{A} = A - K_\gamma T'A, \tag{4.20}$$

with domain

$$D(\tilde{A}_\gamma) = H^{2m}(\Omega) \cap H_0^m(\Omega) \quad (= D(A_\gamma)), \tag{4.21}$$

is the infinitesimal generator of an analytic semigroup $e^{-\tilde{A}_\gamma t}$, $t \geqq 0$ on $L^2(\Omega)$, giving the solution to (4.15′) *as*

$$v(t, x) = e^{-\tilde{A}_\gamma t} v_0(x), \qquad x \in \Omega, \quad t \geqq 0, \tag{4.22}$$

when $v_0 \in L^2(\Omega)$. The solution to the original system (4.15) *is then*

$$u(t, x) = (1 - K_\gamma T')^{-1} e^{-\tilde{A}_\gamma t}(1 - K_\gamma T')u_0(x), \qquad x \in \Omega, \quad t \geqq 0 \tag{4.23}$$

when $u_0 \in L^2(\Omega)$. A similar result holds of course for the realization $(A+G)_\gamma$ of the operator discussed in (4.3)–(4.6).

Remark 4.4. Both problems $(\partial_t + A_T)u = 0$ and $(\partial_t + \tilde{A}_\gamma)u = 0$ are special cases of the general parabolic pseudodifferential boundary value problems treated in [5]. It is shown in Theorem 4.1.1 of [5] that the solution operator is an analytic semigroup.

5. An application of the pseudodifferential transformation to stabilization. We will now show how the transformation from § 4 can be used as a shortcut to some of the results of Lasiecka and Triggiani [7]–[9], which have been a great motivation to us.

The assumed instability of the systems (1.1) and (1.2) is caused by the negative eigenvalues in the pure point spectrum $\operatorname{sp}(A_\gamma)$ of A_γ, and we will show that we can choose a finite-dimensional feedback boundary condition

$$\gamma u = T'u, \tag{5.1}$$

where T' is defined by

$$T'u = \sum_{j=1}^{N} (u \mid w_j) g_j \tag{5.2}$$

(see (2.4)), such that the systems

$$\begin{aligned} &\partial_t u + Au = 0 && \text{in } \Omega && \text{for } t > 0,\\ &\gamma u = T'u && \text{in } \Gamma && \text{for } t > 0,\\ &u = u_0 && \text{in } \Omega && \text{for } t = 0, \end{aligned} \tag{5.3}$$

and

$$(5.4)\quad \begin{aligned} &\partial_t^2 u + Au = 0 && \text{in } \Omega && \text{for } t \in \mathbb{R}, \\ &\gamma u = T'u && \text{on } \Gamma && \text{for } t \in \mathbb{R}, \\ &u = u_0 && \text{in } \Omega && \text{at } t = 0, \\ &\partial_t u = u_1 && \text{in } \Omega && \text{at } t = 0, \end{aligned}$$

are *stable* systems (in the sense described in § 1). We will apply the pseudodifferential transformation to the perturbations of the second kind (5.3) and (5.4) and then apply Wonham's "pole assignment theorem" (Wonham [16]) on the resulting perturbations of the first kind. This, combined with a resolvent analysis, gives us the desired results.

Let the eigenvalues of A_γ be arranged in a nondecreasing sequence

$$(5.5)\qquad \lambda_1 \leqq \lambda_2 \leqq \cdots \leqq \lambda_{K-1} \leqq 0 < \lambda_K \leqq \cdots,$$

each eigenvalue repeated according to multiplicity, and let $\{\varphi_j\}_{j\geqq 1}$ be a corresponding set of orthonormalized eigenfunctions of A_γ. Now define P_u and P_s as the orthogonal projections of $L^2(\Omega)$ on the orthogonal subspaces X_u, respectively X_s, defined by

$$(5.6)\qquad X_u = \operatorname{span}\{\varphi_j\}_{1\leqq j<K}, \qquad X_s = \overline{\operatorname{span}}\{\varphi_j\}_{j\geqq K}.$$

Remark 5.1. The results in Lasiecka and Triggiani [7]-[9] are formulated as if nonself-adjoint realizations are treated as well, but on the other hand, the treatment is based heavily on the orthogonal projections on the eigenspaces X_u and X_s. Orthogonality of eigenspaces in general requires at least that A_γ is normal, i.e., $A_\gamma A_\gamma^* = A_\gamma^* A_\gamma$, but we know of no Dirichlet realization A_γ satisfying this without being self-adjoint. □

Since X_u and $X_s \cap D(A_\gamma)$ are invariant subspaces for A_γ, we can define the restrictions

$$(5.7)\qquad A_u = A_\gamma|_{X_u}, \qquad A_s = A_\gamma|_{X_s \cap D(A_\gamma)}.$$

Then A_u is a bounded operator on X_u and A_s is an unbounded operator with domain $D(A_s) = X_s \cap D(A_\gamma)$. Note that P_u and P_s commute with A_γ on $D(A_\gamma)$. Now writing $f_u = P_u f$, $f_s = P_s f$ for $f \in L^2(\Omega)$, we have that when $u \in D(A_T)$ ((see 3.1) and (4.11)), then $v = (1 - K_\gamma T')u \in D(A_\gamma)$ satisfies

$$(5.8)\qquad Av = Au, \quad v_u \in X_u, \quad v_s \in D(A_s).$$

(Note that $v_s \in D(A_s)$ despite the fact that u_s does not necessarily belong to $D(A_s)$.)

Instead of working with the integral representation of the solution operator for the unperturbed problem as in Lasiecka and Triggiani [8], we attack the resolvents directly and in this way avoid negative fractional power domains.

We use the factorization

$$(5.9)\qquad A_T = A_\gamma(1 - K_\gamma T')$$

in the discussion of the resolvent equation

$$(5.10)\qquad (A_T - \lambda)u = f, \qquad f \in L^2(\Omega).$$

First we consider the case where we are allowed to *decouple* the feedback by assuming that

$$(5.11)\qquad P_s w_j = 0, \qquad j = 1, 2, \cdots, N$$

(i.e., the w_j are in X_u; the "unstable" eigenspace).

Then we write (5.10) in projected and factorized form

$$\begin{pmatrix} P_u \\ P_s \end{pmatrix}(A_\gamma(1-K_\gamma T')(u_u+u_s)-\lambda(u_u+u_s))=\begin{pmatrix} f_u \\ f_s \end{pmatrix} \tag{5.12}$$

and we compute, for $u \in D(A_T)$:

$$\begin{aligned} P_uA_\gamma(1-K_\gamma T')(u_u+u_s)-P_u\lambda(u_u+u_s) &= A_\gamma P_u(1-K_\gamma T')(u_u+u_s)-\lambda u_u \\ &= A_u u_u - A_u P_u K_\gamma T' u_u - \lambda_{u_u}, \\ P_sA_\gamma(1-K_\gamma T')(u_u+u_s)-P_s\lambda(u_u+u_s) &= A_\gamma P_s(1-K_\gamma T')(u_u+u_s)-\lambda u_s \\ &= A_s(u_s - P_s K_\gamma T' u_u) - \lambda u_s. \end{aligned}$$

Since $u_s - P_s K_\gamma T' u_u = v_s$ belongs to $D(A_s)$, the factorization (5.12) is legimate, and (5.12) reduces to

$$A_u u_u - A_u P_u K_\gamma T' u_u - \lambda u_u = f_u, \tag{5.13}$$

$$A_s(u_s - P_s K_\gamma T' u_u) - \lambda u_s = f_s \tag{5.14}$$

(see also (5.42)), where we observe that (5.13) is a finite-dimensional resolvent equation for the matrix operator

$$\bar{A}_u = A_u - A_u P_u K_\gamma T'. \tag{5.15}$$

At this point we can use the same arguments as Lasiecka and Triggiani [8] to get a good choice of T'. We give the full details in the most straightforward case, and refer to Lasiecka and Triggiani for partial information on other cases.

PROPOSITION 5.2. *Assume that the Neumann traces* $\{\nu\varphi_j\}_{1\leqq j<K}$ *are linearly independent, so that*

$$\dim(\nu X_u) = \dim(X_u) \quad (=K-1), \tag{5.16}$$

and let $\{c_j\}_{1\leqq j<K}$ *be an arbitrarily given set of* $K-1$ *distinct, real numbers.*

Then there exists a number N *and a set*

$$\{w_j, g_j\}_{1\leqq j \leqq N}, \tag{5.17}$$

where $w_j \in X_u$ *and* $g_j \in C^\infty(\Gamma)^m$, *such that with*

$$T'u = \sum_{j=1}^{N} (u \mid w_j) g_j, \tag{5.18}$$

the eigenvalues of the matrix operator $\bar{A}_u$, *defined by*

$$\bar{A}_u v = (A_u - A_u P_u K_\gamma T')v \quad \textit{for } v \in X_u, \tag{5.19}$$

are precisely the set $\{c_j\}_{1\leqq j<K}$.

The number N *can be taken as the largest multiplicity of the unstable eigenvalues* $\{\lambda_j\}_{1\leqq j<K}$. *In particular,* $N=1$ *when the eigenvalues are simple.*

Proof. Assume first that *all* of the eigenvalues $\{\lambda_j\}_{1\leqq j<K}$ are simple and take $N=1$. Consider T' of the form

$$T'u = (u \mid w) g. \tag{5.20}$$

In the basis $\{\varphi_j\}_{1\leqq j<K}$ of X_u, the matrix $\bar{A}_u$ has the form

$$\begin{pmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & & \vdots \\ \vdots & & \ddots & \vdots \\ 0 & & \cdots & \lambda_{K-1} \end{pmatrix} - P(g)W^t, \tag{5.21}$$

where $P(g)$ is the column vector

$$(5.22)\qquad P(g)=\begin{pmatrix} \lambda_1(K_\gamma g\,|\,\varphi_1) \\ \lambda_2(K_\gamma g\,|\,\varphi_2) \\ \vdots \\ \lambda_{K-1}(K_\gamma g\,|\,\varphi_{K-1}) \end{pmatrix}$$

and W^t is the transpose of the column vector W given by

$$(5.23)\qquad W=\begin{pmatrix} (\varphi_1\,|\,w) \\ (\varphi_2\,|\,w) \\ \vdots \\ (\varphi_{K-1}\,|\,w) \end{pmatrix}.$$

Consider now the control matrix of the pair (A_u, W):

$$[W \quad A_u W \quad \cdots \quad A_u^{K-2}W]$$

$$(5.24)\qquad =\begin{pmatrix} (\varphi_1\,|\,w) & \lambda_1(\varphi_1\,|\,w) & \cdots & \lambda_1^{K-2}(\varphi_1\,|\,w) \\ (\varphi_2\,|\,w) & \lambda_2(\varphi_2\,|\,w) & \cdots & \lambda_2^{K-2}(\varphi_2\,|\,w) \\ \vdots & \vdots & & \vdots \\ (\varphi_{K-1}\,|\,w) & \lambda_{K-1}(\varphi_{K-1}\,|\,w) & \cdots & \lambda_{K-1}^{K-2}(\varphi_{K-1}\,|\,w) \end{pmatrix}.$$

The determinant of the control matrix is calculated to be

$$(5.25)\qquad \prod_{1\leqq j<K}(\varphi_j\,|\,w)\prod_{1\leqq l<k<K}(\lambda_k-\lambda_l),$$

by reduction to a Vandermonde determinant. Since the eigenvalues are assumed to be simple, we can choose $w\in X_u$, satisfying $(\varphi_j\,|\,w)\neq 0$ for $j=1,2,\cdots,K-1$, such that the determinant is different from 0. This implies that the pair (A_u, W) is controllable, so by the pole assignment theorem (Wonham [16]) there exists a matrix

$$(5.26)\qquad \tilde{P}=\begin{pmatrix} p_1 \\ p_2 \\ \vdots \\ p_{K-1} \end{pmatrix}, \qquad p_j\in\mathbb{C}, \quad j=1,2,\cdots,K-1,$$

for which the matrix $A_u-\tilde{P}W^t$ has the set $\{c_j\}_{1\leqq j<K}$ as eigenvalues. Now we will choose $g\in C^\infty(\Gamma)^m$ such that $\tilde{P}=P(g)$, i.e., such that

$$(5.27)\qquad \lambda_j(K_\gamma g\,|\,\varphi_j)=p_j,$$

for $j=1,2,\cdots,K-1$.

From the formula (A10) in the Appendix we have that

$$(5.28)\qquad (K_\gamma g\,|\,\varphi_j)=\frac{-1}{\lambda_j}(g\,|\,\mathscr{A}^{10*}\nu\varphi_j)_\Gamma.$$

Here $\mathscr{A}^{10}$ is (since A is elliptic) an invertible $m\times m$ matrix of differential operators over Γ, that maps $\prod_{m\leqq k<2m}H^{2m-k-1/2}(\Gamma)$ onto $\prod_{0\leqq k<m}H^{m+k+1/2}(\Gamma)$, and $(\cdot\,|\,\cdot)_\Gamma$ is the $L^2(\Gamma)^m$ inner product.

Since the set

$$(5.29)\qquad \{\nu\varphi_1, \nu\varphi_2, \cdots, \nu\varphi_{K-1}\},$$

is linearly independent, so also is the set

$$\{\mathscr{A}^{10^*}\nu\varphi_1, \mathscr{A}^{10^*}\nu\varphi_2, \cdots, \mathscr{A}^{10^*}\nu\varphi_{K-1}\}. \tag{5.30}$$

Hence it is possible to choose $g \in C^\infty(\Gamma)^m$, satisfying

$$(g \mid \mathscr{A}^{10*}\nu\varphi_j) = -p_j, \qquad j = 1, 2, \cdots, K-1, \tag{5.31}$$

and this choice of g gives us the components of the desired $P(g)$, in view of (5.28). This ends the proof in the case of simple eigenvalues.

Now assume that one or more of the eigenvalues $\{\lambda_j\}_{1\leqq j<K}$ have multiplicity larger than 1, and let us take σ to be the largest occurring multiplicity. Take $N=\sigma$ and consider T' of the form

$$T'u = \sum_{j=1}^{\sigma} (u \mid w_j) g_j. \tag{5.32}$$

In this case $A_u - A_u P_u K_\gamma T'$ can be written

$$\begin{pmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & & \vdots \\ \vdots & & \ddots & \vdots \\ 0 & & \cdots & \lambda_{K-1} \end{pmatrix} - P(\{g_i\}_{1\leqq i\leqq\sigma})\, W_\sigma^t, \tag{5.33}$$

where $P(\{g_i\}_{1\leqq i\leqq\sigma})$ is the $(K-1)\times\sigma$ matrix

$$P(\{g_i\}_{1\leqq i\leqq\sigma}) = \begin{pmatrix} \lambda_1(K_\gamma g_1 \mid \varphi_1) & \lambda_1(K_\gamma g_2 \mid \varphi_2) & \cdots & \lambda_1(K_\gamma g_\sigma \mid \varphi_1) \\ \lambda_2(K_\gamma g_1 \mid \varphi_2) & \lambda_2(K_\gamma g_2 \mid \varphi_2) & \cdots & \lambda_2(K_\gamma g_\sigma \mid \varphi_2) \\ \vdots & \vdots & & \vdots \\ \lambda_{K-1}(K_\gamma g_1 \mid \varphi_{K-1}) & \lambda_{K-1}(K_\gamma g_2 \mid \varphi_{K-1}) & \cdots & \lambda_{K-1}(K_\gamma g_\sigma \mid \varphi_{K-1}) \end{pmatrix} \tag{5.34}$$

and W_σ is the $(K-1)\times\sigma$ matrix

$$W_\sigma = \begin{pmatrix} (\varphi_1 \mid w_1) & (\varphi_1 \mid w_2) & \cdots & (\varphi_1 \mid w_\sigma) \\ (\varphi_2 \mid w_1) & (\varphi_2 \mid w_2) & \cdots & (\varphi_2 \mid w_\sigma) \\ \vdots & & & \\ (\varphi_{K-1} \mid w_1) & (\varphi_{K-1} \mid w_2) & \cdots & (\varphi_{K-1} \mid w_\sigma) \end{pmatrix}. \tag{5.35}$$

Considering the form of the control matrix

$$[W_\sigma \quad A_u W_\sigma \quad \cdots \quad A_u^{K-2} W_\sigma], \tag{5.36}$$

we see that if $w_1, w_2, \cdots, w_\sigma$ are chosen in X_u such that

$$\operatorname{rank} W_\sigma = \sigma, \tag{5.37}$$

then the rank of the control matrix (5.36) is $K-1$ (because a regular $(K-1)\times(K-1)$ submatrix can be extracted, after suitable row-column operations). Then according to Wonham's theorem, there exists a complex matrix

$$\tilde{P}_\sigma = \begin{pmatrix} p_{11} & p_{12} & \cdots & p_{1\sigma} \\ p_{21} & p_{22} & \cdots & p_{2\sigma} \\ \vdots & \vdots & & \vdots \\ p_{K-1,1} & p_{K-1,2} & \cdots & p_{K-1,\sigma} \end{pmatrix} \tag{5.38}$$

such that the eigenvalues of the matrix $A_u - \tilde{P}_\sigma W_\sigma^t$ are $\{c_j\}_{1\leqq j<K}$.

To obtain $\tilde{P}_\sigma = P(\{g_i\}_{1 \leqq i \leqq \sigma})$ we use that, as in (5.28),

$$(K_\gamma g_i \mid \varphi_j) = \frac{-1}{\lambda_j}(g_i \mid \mathscr{A}^{10^*}\nu\varphi_j)_\Gamma. \tag{5.39}$$

In view of (5.16) we can choose $g_i \in C^\infty(\Gamma)^m$, $i = 1, 2, \cdots, \sigma$, satisfying

$$(g_i \mid \mathscr{A}^{10*}\nu\varphi_j)_\Gamma = -p_{ji}, \qquad j = 1, 2, \cdots, K-1, \quad i = 1, 2, \cdots, \sigma, \tag{5.40}$$

and this choice of $\{g_i\}_{1 \leqq i \leqq \sigma}$ provides us with the desired $P(\{g_i\}_{1 \leqq i \leqq \sigma})$. □

Remark 5.3. For the application of the Wonham theorem here, it is important that the range of $P_u K_\gamma$ fills out all of X_u; this is reformulated as the question of whether the Neumann traces of the Dirichlet eigenfunctions in X_u are linearly independent. In that case the results are easy to formulate and allow N to be very low; otherwise, the results become increasingly complicated and require (in general) higher N, the more linear dependence there is. Lasiecka and Triggiani have in [8] an upper and lower bound on the number N of feedback terms necessary in (5.18), once the number of linearly independent Neumann traces are given, but the discussion of the size of $\dim(\nu X_u)$ for differential operators on general domains in $\mathbb{R}^n$ in the literature is far from complete, as far as we know.

Let us now dispose of the temporary assumption $0 \notin \operatorname{sp}(A_\gamma)$ from § 4. Everything done thus far can be done without changes with the translated operator $A_\gamma - \delta$, $\delta > 0$, so that if $0 \in \operatorname{sp}(A_\gamma)$, we take a $\delta > 0$ such that $0 \notin \operatorname{sp}(A_\gamma - \delta)$. Then after determining the new realization $A_T - \delta$ that moves the eigenvalues $\lambda_1 - \delta, \lambda_2 - \delta, \cdots, \lambda_{K-1} - \delta$, and leaves $\lambda_j - \delta, j \geqq K$ unaffected, we just add δ to $A_T - \delta$. Then the moved eigenvalues will be increased with δ, and so will the unaffected eigenvalues; i.e., they will return to be the eigenvalues of A_s.

Let us now choose the set $\{c_j\}_{1 \leqq j < K}$ occurring in Proposition 5.2 such that $c_j \geqq \lambda_K (>0), j = 1, 2, \cdots, K-1$. With T' chosen according to the theorem, the operator $P_u(1 - K_\gamma T')$ is injective, hence bijective, on X_u, and since $w_j \in X_u$, $1 - K_\gamma T'$ is the identity on X_s. Then, as promised in § 4, $1 - K_\gamma T'$ is bijective from $H^{2m}(\Omega)$ to $H^{2m}(\Omega)$ ($K_\gamma T'$ has C^∞-range) and maps $D(A_T)$ onto $D(A_\gamma)$. This justifies the factorization (4.12). Define $R(\lambda, \bar{A}_u)$ as the resolvent of $\bar{A}_u$ in X_u, for all $\lambda \notin \{c_j\}_{1 \leqq j < K}$ and let $R(\lambda, A_s)$ be the resolvent of A_s in X_s, defined for all $\lambda \notin \{\lambda_j\}_{j \geqq K}$.

We can then write the solution to (5.13) as

$$u_u = R(\lambda, \bar{A}_u) f_u, \qquad \lambda \notin \{c_j\}_{1 \leqq j < K}. \tag{5.41}$$

We see that if $u \in D(A_T)$, then $v = (1 - K_\gamma T')u$ belongs to $D(A_\gamma)$, hence $v_s \in D(A_s)$. Since

$$\begin{aligned} v_s &= P_s(1 - K_\gamma T')u = P_s(1 - K_\gamma T')(u_u + u_s) \\ &= u_s - P_s K_\gamma T' u_u, \end{aligned} \tag{5.42}$$

we see that $u_s - P_s K_\gamma T' u_u \in D(A_s)$, so (5.14) is justified and can be written as

$$(A_s - \lambda)(u_s - P_s K_\gamma T' u_u) = f_s + \lambda P_s K_\gamma T' u_u. \tag{5.43}$$

For all $\lambda \notin \{\lambda_j\}_{j \geqq K}$ we have

$$u_s - P_s K_\gamma T' u_u = R(\lambda, A_s)(f_s + \lambda P_s K_\gamma T' u_u). \tag{5.44}$$

Inserting (5.41), we find for all $\lambda \notin (\{c_j\}_{1 \leqq j < K} \cup \{\lambda_j\}_{j \geqq K})$:

$$u_s = P_s K_\gamma T' R(\lambda, \bar{A}_u) f_u + R(\lambda, A_s)(f_s + \lambda P_s K_\gamma T' R(\lambda, \bar{A}_u) f_u), \tag{5.45}$$

so that

$$
\begin{aligned}
u &= u_u + u_s \\
&= R(\lambda, \bar{A}_u)f_u + P_sK_\gamma T'R(\lambda, \bar{A}_u)f_u + R(\lambda, A_s)f_s \\
&\quad + \lambda R(\lambda, A_s)P_sK_\gamma T'R(\lambda, \bar{A}_u)f_u \\
&= (1 + P_sK_\gamma T' + \lambda R(\lambda, A_s)P_sK_\gamma T')R(\lambda, \bar{A}_u)f_u + R(\lambda, A_s)f_s.
\end{aligned}
\tag{5.46}
$$

We have now obtained Proposition 5.4.

PROPOSITION 5.4. *The resolvent* $R(\lambda, A_T)$ *solving* (5.13)-(5.14) *can be written in the form*

$$R(\lambda, A_T)f = (R_{11} \quad R_{12})\begin{pmatrix} f_u \\ f_s \end{pmatrix}. \tag{5.47}$$

where

$$
\begin{aligned}
R_{11} &= (1 + P_sK_\gamma T' + \lambda R(\lambda, A_s)P_sK_\gamma T')R(\lambda, \bar{A}_u), \\
R_{12} &= R(\lambda, A_s),
\end{aligned}
\tag{5.48}
$$

so $R(\lambda, A_T)$ *is well defined for all* λ *outside the spectrum of* A_T, *and maps* $L^2(\Omega)$ *into* $H^{2m}(\Omega)$.

Let us then prove Proposition 5.5.

PROPOSITION 5.5. *Assume that the prescribed eigenvalues* $\{c_j\}_{1 \leqq j < K}$ *of* $\bar{A}_u$ *are chosen such that* $c_j \geqq \lambda_K$, $j = 1, \cdots, K-1$. *There is then a constant* $M_T > 0$, *independent of* λ, *such that the resolvent* $R(\lambda, A_T)$ *satisfies the inequality*

$$\|R(\lambda, A_T)\|_{L^2, L^2} \leqq \frac{M_T}{\operatorname{dist}(\lambda, I_K)} \tag{5.49}$$

as an operator in $L^2(\Omega)$. *Here* $I_K = [\lambda_K, \infty[$, *which in this case equals the closed convex hull of the spectrum of* A_T.

Proof. A_s is a self-adjoint, positive operator on $X_s \cap D(A_\gamma)$, satisfying

$$
\begin{aligned}
\|(A_s - \lambda)u\|_0\|u\|_0 &\geqq |((A_s - \lambda)u \,|\, u)| \\
&= |((A_s - \operatorname{Re}\lambda)u \,|\, u) - i \operatorname{Im}\lambda \|u\|_0^2| \\
&= (((A_s - \operatorname{Re}\lambda)u \,|\, u)^2 + (\operatorname{Im}\lambda \|u\|_0)^2)^{1/2} \\
&\geqq \begin{cases} |\operatorname{Im}\lambda| \|u\|_0^2 & \text{if } \operatorname{Re}\lambda \geqq \lambda_K \\ ((\lambda_K - \operatorname{Re}\lambda)^2 + (\operatorname{Im}\lambda)^2)^{1/2}\|u\|_0^2 & \text{if } \operatorname{Re}\lambda \leqq \lambda_K \end{cases} \\
&\geqq \operatorname{dist}(\lambda, I_K)\|u\|_0^2;
\end{aligned}
$$

hence,

$$\|R(\lambda, A_s)\|_{L^2, L^2} \leqq \operatorname{dist}(\lambda, I_K)^{-1}. \tag{5.50}$$

$R(\lambda, \bar{A}_u)$ is a $(K-1) \times (K-1)$ matrix of the form

$$R(\lambda, \bar{A}_u) = \det(\bar{A}_u - \lambda)^{-1} p(\lambda, \bar{A}_u), \tag{5.51}$$

where $p(\lambda, \bar{A}_u)$ is a polynomial in λ (this follows easily from the inversion formula for matrices), and

$$\det(\bar{A}_u - \lambda) = \text{const.} \cdot \prod_{1 \leqq j < K} (\lambda - c_j). \tag{5.52}$$

Therefore $\|R(\lambda, \bar{A}_u)\|_{L^2,L^2}$ is $O(|\lambda - c_k|^{-1})$ in a neighbourhood of each $c_k \in \{c_j\}_{1\leqq j<K}$. For $|\lambda\gamma \to \infty$ we write

$$\bar{A}_u - \lambda = -\lambda(1 - \lambda^{-1}\bar{A}_u) \tag{5.53}$$

and we see that $R(\lambda, \bar{A}_u)$ is $O(|\lambda|^{-1})$ for $|\lambda| \to \infty$, since $(1-\lambda^{-1}\bar{A}_u)^{-1}$ can be expressed by a Neumann series in $\lambda^{-1}\bar{A}_u$ for $|\lambda| > \|\bar{A}_u\|_{L^2,L^2}$. We can then conclude that

$$\|R(\lambda, \bar{A}_u)\|_{L^2,L^2} \leqq M(\text{dist}\,(\lambda, \text{sp}\,(\bar{A}_u)))^{-1}, \tag{5.54}$$

where M is a constant independent of λ.

Obviously, $\text{sp}\,(\bar{A}_u) \subset I_K$, and since $\text{sp}\,(\bar{A}_u)$ is bounded, $\|\lambda R(\lambda \bar{A}_u)\|_{L^2,L^2}$ is $O(1)$ for $|\lambda| \to \infty$; moreover, $P_s K_\gamma T'$ is a bounded operator, and the decomposition $f \to f_u + f_s$ is bounded and λ-independent. Then, from the form of $R(\lambda, A_T)$ (5.47)-(5.48), we find that

$$\begin{aligned} \|R(\lambda, A_T)\|^2_{L^2,L^2} &\leqq \frac{M'^2}{\text{dist}\,(\lambda, \text{sp}\,(\bar{A}_u))^2} + \frac{1}{\text{dist}\,(\lambda, I_K)^2} \\ &\leqq \frac{M_T^2}{\text{dist}\,(\lambda, I_K)^2}, \end{aligned} \tag{5.55}$$

where M' and M_T are positive constants. □

Using Lemma 3.1, Proposition 5.2, and Proposition 5.5 we find Theorem 5.6.

THEOREM 5.6. *Assume that*

(1) *The Neumann traces* $\{\nu\varphi_j\}_{1\leqq j<K}$ *of the Dirichlet eigenfunctions* φ_j *are linearly independent* (*but see also Remark* 5.3);

(2) *The largest occurring multiplicity of the Dirichlet eigenvalues* $\{\lambda_j\}_{1\leqq j<K}$ *of* A *is* N. *Then there exists a finite-dimensional boundary condition*

$$\gamma u = T'u \quad on\ \Gamma \tag{5.56}$$

where

$$T'u = \sum_{j=1}^{N} (u \,|\, w_j) g_j. \tag{5.57}$$

$w_j \in X_u$, $g_j \in C^\infty(\Gamma)^m$, $j = 1, 2, \cdots, N$, *such that the realization* A_T *of* A, *with domain*

$$D(A_T) = \{u \in H^{2m}(\Omega) \,|\, Tu = \gamma u - T'u = 0\}, \tag{5.58}$$

is the infinitesimal generator of an analytic semigroup $e^{-A_T t}$, $t \geqq 0$ *on* $L^2(\Omega)$, *giving the solution to the Dirichlet boundary feedback parabolic system* (5.3) *as*

$$u(t, x) = e^{-A_T T} u_0(x), \qquad x \in \Omega, \quad t \geqq 0, \tag{5.59}$$

when $u_0 \in L^2(\Omega)$, *and such that the solution* (5.59) *satisfies the damping estimate*

$$\|u(t, \cdot)\|_0 \leqq M e^{-\lambda_K t} \|u_0\|_0, \qquad t \geqq 0, \quad M > 0, \tag{5.60}$$

where λ_K *is the first positive Dirichlet eigenvalue of* A. *Moreover, the operators*

$$\cos\,(A_T^{1/2} t) \quad and \quad \sin\,(A_T^{1/2} t), \tag{5.61}$$

are well defined, and we can write the solution to the hyperbolic problem (5.4) *as*

$$u(t, x) = \cos\,(A_T^{1/2} t) u_0 + A_T^{-1/2} \sin\,(A_T^{1/2} t) u_1(x), \tag{5.62}$$

$x \in \Omega$, $t \in \mathbb{R}$, *when* $u_0, u_1 \in L^2(\Omega)$.

Remark 7. We see that in the "decoupled" case where $w_j \in X_u$, $j = 1, \cdots, K-1$, the estimate (5.60) holds. When $P_s w_j \neq 0$, the damping coefficient λ_K must be substituted by $\lambda_K - \varepsilon$, as we shall see later. Lasiecka and Triggiani did not mention the sharper estimate (5.60) for the decoupled case. Moreover, one of the slightly mysterious facts about the perturbation of the second kind is that the operator A_T can never be self-adjoint. This is a consequence of Proposition 1.7.11 in Grubb [5]. What is shown there is, more precisely, that A_T cannot even be weakly semibounded, i.e., cannot even satisfy

$$\text{(5.63)} \qquad \operatorname{Re} e^{i\theta}(A_T u \mid u) \geqq -c\|u\|_m^2 \quad \text{for } u \in D(A_T),$$

some c and θ, when $T' \neq 0$. It may be of interest to observe that Neumann problems behave differently as follows.

If A_T is the realization defined by a Neumann feedback boundary condition $\nu u + S\gamma u = T'u$, then (5.63) holds for general S and T' (for the conditions in Theorem 1.7.13 of [5] are void in the Neumann case). Let us also recall from [5, § 1.7] that weak semiboundedness (5.63) assures m-boundedness

$$\text{(5.64)} \qquad |(A_T u \mid v)| \leqq C\|u\|_m \|v\|_m \quad \text{for } u \in D(A_T),$$

for normal pseudodifferential boundary problems.

Since in the Dirichlet case, the realization A_T is never semibounded, the semigroup $e^{-A_T t}$, $t \geqq 0$ is never a *contraction* semigroup, hence the constant M in (5.60) is always greater than 1. This has also been noted by Lasiecka and Triggiani, who considered the translated Laplacian in [8].

Remark 5.8. Comparison of (5.59) and (4.23) show that for the semigroups we have

$$\text{(5.65)} \qquad e^{-A_T t} = (1 - K_\gamma T')^{-1} e^{-\tilde{A}_\gamma t}(1 - K_\gamma T').$$

This justifies the term "generalized change of coordinates" from § 2.

Now it is straightforward to extend the theory to include more general cases where $P_s w_j \neq 0$. The operator T' considered above can be written

$$\text{(5.66)} \qquad T'u = \sum_{j=1}^{N} (u \mid P_u w_j) g_j,$$

so if we let the w_j be arbitrary and define the operator T'' as

$$\text{(5.67)} \qquad T''u = \sum_{j=1}^{N} (u \mid P_s w_j) g_j,$$

we see that the decoupled case considered above corresponds to the case where $T'' = 0$.

The operator T_1, defined by

$$\text{(5.68)} \qquad T_1 u = \gamma u - T'u - T''u,$$

defines a normal boundary condition $T_1 u = 0$ (in the sense of Grubb [5]), just as T did, hence the operator realization A_{T_1} of A, with domain

$$\text{(5.69)} \qquad D(A_{T_1}) = \{u \in H^{2m}(\Omega) \mid T_1 u = 0\},$$

is a densely defined, closed operator in $L^2(\Omega)$. Here T_1 can be regarded as a perturbation of the trace operator $T = \gamma - T'$.

Let K_T be the Poisson solution operator defined by $u = K_T \varphi$, where u is the solution of

$$\text{(5.70)} \qquad Au = 0 \quad \text{in } \Omega, \qquad Tu = \varphi \quad \text{on } \Gamma.$$

We assume in the following that T (i.e., the sets $\{P_u w_j\}_{1 \leqq j < K}$ and $\{g_j\}_{1 \leqq j < K}$) is chosen such that the conclusions of Theorem 5.6 are valid, and then we study A_{T_1}.

Here we use that A_T is chosen to be bijective from $D(A_T)$ to $L^2(\Omega)$, which implies that K_T is well defined. Observe also the estimate

$$\begin{aligned}\|K_TT''u\|_0 &= \left\| \sum_{j=1}^{N} (u\,|\,P_sw_j)K_Tg_j \right\|_0 \\ &\leqq \|u\|_0 \sum_{j=1}^{N} \|P_sw_j\|_0\|K_Tg_j\|_0,\end{aligned} \tag{5.71}$$

where $\|K_Tg_j\|_0$ depends only on the sets $\{P_uw_j\}_{1\leqq j<K}$ and $\{g_j\}_{1\leqq j<J}$.

LEMMA 5.9. *Assume that the sets* $\{P_uw_j\}_{1\leqq j<K}$ *and* $\{g_j\}_{1\leqq j<K}$ *are chosen such that the conclusions of Theorem* 5.6 *are valid. Then there exists a constant* $r_1>0$, *such that for* $\|P_sw_j\|_0<r_1$, $j=1, 2, \cdots, N$ *the operator*

$$1-K_TT'' \tag{5.72}$$

is a homeomorphism in $L^2(\Omega)$ *and in* $H^{2m}(\Omega)$, *and, in particular, defines a bijection*

$$1-K_TT''\colon \quad D(A_{T_1}) \overset{\sim}{\to} D(A_T). \tag{5.73}$$

Moreover, when $u\in D(A_{T_1})$ *and* $v=(1-K_TT'')u$, *then* $Au=Av$, *in fact we have the factorization*

$$A_{T_1}=A_T(1-K_TT''). \tag{5.74}$$

Proof. Let $r_1>0$ be chosen such that for $\|P_sw_j\|_0<r_1$, $j=1, 2, \cdots, N$, we have $\|K_TT''\|_{L^2,L^2}\leqq\frac{1}{2}$. This is possible by (5.71). Now $1-K_TT''$ is a bounded operator in $L^2(\Omega)$ and is inverted by a Neumann series

$$(1-K_TT'')^{-1}=\sum_{m=0}^{\infty} (K_TT'')^m, \tag{5.75}$$

converging in the operator norm in $L^2(\Omega)$. Thus $1-K_TT''$ is a homeomorphism of $L^2(\Omega)$ onto itself.

Since K_T has range in $H^{2m}(\Omega)$, we see that $1-K_TT''$ is likewise a homeomorphism of $H^{2m}(\Omega)$, onto itself, and, since

$$T(1-K_TT'')u=Tu-T''u=T_1u, \tag{5.76}$$

$u\in D(A_{T_1})$ if and only if $v=(1-K_TT'')u\in D(A_T)$, so $1-K_TT''$ defines a bijection of $D(A_{T_1})$ onto $D(A_T)$. The last observation follows from the fact that $AK_T=0$. □

We will now study the resolvent $R(\lambda, A_{T_1})$ of A_{T_1}, and we start out with the equation

$$\begin{aligned}&(A-\lambda)u=f \quad \text{in } \Omega,\\ &T_1u=0 \quad \text{on } \Gamma.\end{aligned} \tag{5.77}$$

Using (5.73) with $v=(1-K_TT'')u$ we get

$$\begin{aligned}&(A-\lambda)(v+K_TT''u)=f \quad \text{in } \Omega,\\ &Tv=0 \quad \text{on } \Gamma,\end{aligned} \tag{5.78}$$

so that

$$\begin{aligned}&(A-\lambda)v=f+\lambda K_TT''u \quad \text{in } \Omega,\\ &Tv=0 \quad \text{on } \Gamma,\end{aligned} \tag{5.79}$$

i.e., if λ is in the resolvent set of A_T,

$$\begin{aligned} v &= R(\lambda, A_T)(f+\lambda K_T T''u) \quad \text{in } \Omega, \\ Tv &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{5.80}$$

For u this gives

$$u - K_T T''u = v = R(\lambda, A_T)(f+\lambda K_T T''u), \tag{5.81}$$

so that

$$(1-(1+\lambda R(\lambda, A_T))K_T T'')u = R(\lambda, A_T)f. \tag{5.82}$$

Let us denote, for $\varepsilon > 0$, $0 < \theta < \pi/2$ the obtuse sector (disjoint from I_K)

$$W_{\lambda_K,\varepsilon,\theta} = \left\{ z \in \mathbb{C} \,\middle|\, z = (\lambda_K - \varepsilon) + r\, e^{i\omega},\ r \geqq 0, \frac{\pi}{2} - \theta < \omega < \frac{3\pi}{2} + \theta \right\}.$$

From the estimate (5.49) we see that $\lambda R(\lambda, A_T)$ is bounded on $W_{\lambda_K,\varepsilon,\theta}$, and hence for any $\varepsilon > 0$, any $\theta \in]0, \pi/2[$, there exists by (5.71) a constant $r > 0$ such that for $w_j \in L^2(\Omega)$, satisfying $\|P_s w_j\|_0 < r \leqq r_1$, $j = 1, 2, \cdots, N$, we have

$$\|(1+\lambda R(\lambda, A_T))K_T T''\|_{L^2,L^2} \leqq \tfrac{1}{2} \tag{5.83}$$

for all $\lambda \in W_{\lambda_K,\varepsilon,\theta}$.

With the w_j, $j = 1, 2, \cdots, N$, chosen in this way, the resolvent $R(\lambda, A_{T_1})$ of A_{T_1} is a well-defined, bounded operator in $L^2(\Omega)$ for $\lambda \in W_{\lambda_K,\varepsilon,\theta}$, given by (see (5.73))

$$\begin{aligned} R(\lambda, A_{T_1}) &= (1-(1+\lambda R(\lambda, A_T))K_T T'')^{-1} R(\lambda, A_T) \\ &= \sum_{m=0}^{\infty} ((1+\lambda R(\lambda, A_T))K_T T'')^m R(\lambda, A_T), \end{aligned} \tag{5.84}$$

and satisfying the estimate

$$\|R(\lambda, A_{T_1})\|_{L^2,L^2} \leqq \frac{c_1}{|\lambda - \lambda_K|}. \tag{5.85}$$

Here $c_1 > 0$ is a constant, independent of λ.

Altogether, we have obtained Theorem 5.10.

THEOREM 5.10. *Let $\varepsilon > 0$ be given, and assume that the sets $\{P_u w_j\}_{1 \leqq j < K}$ and $\{g_j\}_{1 \leqq j < K}$ are chosen such that the conclusions of Theorem 5.6 are valid. The finite-dimensional Dirichlet boundary feedback*

$$\gamma u = T'u + T''u = \sum_{j=1}^{N} (u \mid w_j) g_j \tag{5.86}$$

defines a realization A_{T_1} of A, with domain

$$D(A_{T_1}) = \{u \in H^{2m}(\Omega) \mid T_1 u = 0\}, \tag{5.87}$$

where T_1 is the trace operator defined by

$$T_1 = \gamma - T' - T'', \tag{5.88}$$

and there exists a constant $r>0$, *such that for arbitrary choices of* $P_s w_j$, *with* $\|P_s w_j\|_0 < r$, A_{T_1} *is the infinitesimal generator of an analytic semigroup* $e^{-A_{T_1}t}$, $t \geqq 0$, *on* $L^2(\Omega)$, *giving the solution to the Dirichlet boundary feedback control system*

$$(5.89)\qquad \begin{aligned} &\partial_t u + Au = 0 && \textit{in } \Omega \quad \textit{for } t>0, \\ &\gamma u = \sum_{j=1}^{N} (u\,|\,w_j) g_j && \textit{on } \Gamma \quad \textit{for } t>0, \\ &u = u_0 && \textit{in } \Omega \quad \textit{at } t=0, \end{aligned}$$

as

$$(5.90)\qquad u(t,x) = e^{-A_{T_1}t} u_0(x), \qquad t \geqq 0, \quad x \in \Omega, \quad u_0 \in L^2(\Omega),$$

where the solution (5.90) *satisfies*

$$(5.91)\qquad \|u(t,\cdot)\|_0 \leqq M' e^{-(\lambda_K - \varepsilon)t} \|u_0\|_0, \qquad t \geqq 0.$$

Here λ_K *is the first positive Dirichlet eigenvalue of* A, *and* M' *is a constant greater than zero.*

We will now use the factorization (5.74) in the investigation of the hyperbolic problem for A_{T_1}.

The boundary value problem

$$(5.92)\qquad \partial_t^2 u + A_{T_1} u = 0, \qquad u \in D(A_{T_1})$$

transforms by (5.74) into

$$(5.93)\qquad (1 - K_T T'')^{-1} \partial_t^2 v + A_T v = 0, \qquad v \in D(A_T)$$

where $v = (1 - K_T T'')u$.

Acting with $(1 - K_T T'')$ from the left in (5.93) we find

$$(5.94)\qquad \partial_t^2 v + (1 - K_T T'') A_T v = 0, \qquad v \in D(A_T).$$

Moreover, if we now impose on the w_j to satisfy $P_s w_j \in D(A_T^*)$, $j = 1, 2, \cdots, N$, then for $v \in D(A_T)$:

$$\begin{aligned} \|K_T T'' A_T v\|_0 &= \left\| \sum_{j=1}^{N} (A_T v\,|\,P_s w_j) K_T g_j \right\|_0 \\ &= \left\| \sum_{j=1}^{N} (v\,|\,A_T^* P_s w_j) K_T g_j \right\|_0 \\ &\leqq \|v\|_0 \sum_{j=1}^{N} \|A_T^* P_s w_j\|_0 \|K_T g_j\|_0. \end{aligned}$$

This shows that $K_T T'' A_T$ acts as an L^2-bounded operator on $D(A_T)$, when $P_s w_j \in D(A_T^*)$, $j = 1, 2, \cdots, N$.

Therefore, (5.94) (and with it (5.92) in a related sense) is simply a *bounded* perturbation of

$$(5.95)\qquad \begin{aligned} &\partial_t^2 v + Av = 0 && \text{in } \Omega \quad \text{for } t \in \mathbb{R}, \\ &Tv = 0 && \text{on } \Gamma \quad \text{for } t \in \mathbb{R}, \\ &v = v_0 && \text{in } \Omega \quad \text{at } t = 0, \\ &\partial_t v = v_1 && \text{in } \Omega \quad \text{at } t = 0, \end{aligned}$$

treated in Theorem 5.6. Since the spectrum of A_T is assumed to be contained in $\mathbb{R}_+$, we find from standard bounded perturbation theory (see, e.g., Sova [12] and Fattorini [3]) that the operators

$$\cos((A_T - K_T T'' A_T)t), \tag{5.96}$$

$$\sin((A_T - K_T T'' A_T)t) \tag{5.97}$$

are well-defined, bounded, bounded operators in $L^2(\Omega)$ for $P_s w_j \in D(A_T^*)$, $j = 1, 2, \cdots, N$, and $t \in \mathbb{R}$. From Theorem 1.6.11 of Grubb [5] we find that

$$D(A_T^*) = \{u \in H^{2m}(\Omega) \,|\, \dot{I}^x \mathscr{A}^{01*} \gamma u = 0\} \tag{5.98}$$

where $\dot{I}^x$ is the "reflection" of the index set, replacing $\{k\}_{0 \leqq k < m}$ by $\{2m-k-1\}_{0 \leqq k < m}$, and $\mathscr{A}^{01}$ is the $m \times m$ matrix differential operator, appearing in Green's formula ((A4) in the Appendix) for A, it is invertible since A is elliptic. We see from Example 1.6.12. of Grubb [5] that the action of the realization A_T^* is of the form $A + G$, for a certain singular Green operator G of finite rank, whereas the domain $D(A_T^*)$ is simply characterized as

$$D(A_T^*) = D(A_\gamma) = H^{2m}(\Omega) \cap H_0^m(\Omega). \tag{5.99}$$

We have thus obtained Theorem 5.11.

THEOREM 5.11. *Let the set* $\{w_j, g_j\}_{1 \leqq j \leqq N}$ *be chosen according to Theorem* 5.10, *and assume furthermore that* $P_s w_j$, $j = 1, 2, \cdots, N$, *are chosen in* $D(A_\gamma) = H^{2m}(\Omega) \cap H_0^m(\Omega)$. *Then the operators*

$$C(t) = \cos((A_T - K_T T'' A_T)t) \tag{5.100}$$

and

$$S(t) = (A_T - K_T T'' A_T)^{-1/2} \sin((A_T - K_T T'' A_T)^{1/2} t) \tag{5.101}$$

on $L^2(\Omega)$, *are well defined for* $t \in \mathbb{R}$, *giving the solution to the system*

$$\begin{aligned} &\partial_t^2 v + (1 - K_T T'')Av = 0 && \textit{in } \Omega \quad \textit{for } t \in \mathbb{R}, \\ &\gamma v = \sum_{j=1}^{N} (v \,|\, P_u w_j) g_j && \textit{on } \Gamma \quad \textit{for } t \in \mathbb{R}, \\ &v = v_0 && \textit{in } \Omega \quad \textit{at } t = 0, \\ &\partial_t v = v_1 && \textit{in } \Omega \quad \textit{at } t = 0, \end{aligned} \tag{5.102}$$

as

$$v(t, x) = C(t)v_0(x) + S(t)v_1(x), \qquad x \in \Omega, \quad t \in \mathbb{R}, \quad v_0, v_1 \in L^2(\Omega). \tag{5.103}$$

The solution to the original system

$$\begin{aligned} &\partial_t^2 u + Au = 0 && \textit{in } \Omega \quad \textit{for } t \in \mathbb{R}, \\ &\gamma u = \sum_{j=1}^{N} (u \,|\, w_j) g_j && \textit{on } \Gamma \quad \textit{for } t \in \mathbb{R}, \\ &u = u_0 && \textit{in } \Omega \quad \textit{at } t = 0, \\ &\partial_t u = u_1 && \textit{in } \Omega \quad \textit{at } t = 0, \end{aligned} \tag{5.104}$$

is then by (5.74)

$$\begin{aligned} u(t, x) = {} & (1 - K_T T'')^{-1} C(t)(1 - K_T T'')u_0(x) \\ & + (1 - K_T T'')^{-1} S(t)(1 - K_T T'')u_1(x), \ x \in \Omega, \quad t \in \mathbb{R}, \quad u_0, u_1 \in L^2(\Omega). \end{aligned} \tag{5.105}$$

6. Stabilization by perturbations of the third kind. To get a complete picture, we shall now also discuss briefly how we can stabilize the systems (1.1) and (1.2) by changing *both* the boundary condition and the system operator. The stabilized systems will then take the form

$$\begin{aligned} &\partial_t u + Au + Gu = 0 && \text{in } \Omega && \text{for } t \geqq 0, \\ &\gamma u = T'u && \text{on } \Gamma && \text{for } t \geqq 0, \\ &u = u_0 && \text{in } \Omega && \text{at } t = 0, \end{aligned} \tag{6.1}$$

respectively,

$$\begin{aligned} &\partial_t^2 u + Au + Gu = 0 && \text{in } \Omega && \text{for } t \in \mathbb{R}, \\ &\gamma u = T'u && \text{on } \Gamma && \text{for } t \in \mathbb{R}, \\ &u = u_0 && \text{in } \Omega && \text{at } t = 0, \\ &\partial_t u = u_1 && \text{in } \Omega && \text{at } t = 0, \end{aligned} \tag{6.2}$$

and we say that the systems (6.1) and (6.2) are associated with the realization $B = (A+G)_T$, where

$$Bu = (A+G)u, \tag{6.3}$$

defined on

$$D(B) = \{u \in H^{2m}(\Omega) \mid Tu = 0\}, \tag{6.4}$$

with

$$T = \gamma - T'. \tag{6.5}$$

We will now determine operators G and T', such that (6.1) and (6.2) are stable systems of feedback type. Here, we can, in fact, make B a self-adjoint generator of an analytic *contraction* semigroup. Here we will point out that the following construction is not very "economical," as we typically use a large number of feedback terms, but the construction clarifies to a great extent the interaction between the system operator equation and the boundary equation.

As in the preceding paragraph, let $\{\varphi_j\}_{j \geqq 1}$ be an orthonormalized set of eigenfunctions for A_γ, enumerated according to the ordering of the eigenvalues (5.5), but now define the boundary feedback operator T' as

$$T'u = \sum_{j=1}^{K-1} (u \mid \varphi_j) h_j, \tag{6.6}$$

where $K-1$ is the number of negative eigenvalues of A_γ, repeated according to multiplicity, and

$$h_j \in C^\infty(\Gamma)^m, \qquad j = 1, 2, \cdots, K-1, \tag{6.7}$$

are chosen linearly independent, with no other conditions on them. Moreover, define the operator G as

$$G = K'\nu + G', \tag{6.8}$$

where ν is the Neumann trace operator (1.6) and

$$K' = -T'^* \mathscr{A}^{01}, \qquad G' = -T'^*(\mathscr{S} - c)\gamma. \tag{6.9}$$

Here c is a positive constant to be determined later, $\mathscr{A}^{01}$ is the upper right corner in the coefficient matrix (A3) in Green's formula (see the Appendix), whereas $\mathscr{S}$ is the coefficient matrix appearing in the boundary term in the "halfways" Green formula for a convenient sesquilinear form $a(u, v)$ associated with A (see (A6)).

Let $a(u, v)$ be a symmetric sesquilinear form on $H^m(\Omega)$ associated with A, of the form (A5), and recall that, by the Gårding inequality, $a(u, v)$ is $H_0^m(\Omega)$-coercive. It is well known how A_γ is the *variational operator* associated with the triple $(a, H_0^m(\Omega), L^2(\Omega))$ (see, e.g., Grubb [5, § 1.7]). Let us define the sesquilinear form $a_1(u, v)$ on $H^m(\Omega)$ by

$$a_1(u, v) = a(u, v) + c(T'u \mid \gamma v)_\Gamma. \tag{6.10}$$

Let U be the closed subspace of $H^m(\Omega)$:

$$U = \{u \in H^m(\Omega) \mid \gamma u = T'u\}, \tag{6.11}$$

and observe that U is dense in $L^2(\Omega)$, since $T = \gamma - T'$ defines a normal boundary condition $Tu = 0$ (so that already $D(A_T)$ is dense in $L^2(\Omega)$; cf. Lemma 3.1). Let B_1 be the operator associated with the triple $(a_1, U, L^2(\Omega))$, defined as follows:

$$\begin{aligned} &D(B_1) = \{u \in U \mid \exists f \in L^2(\Omega) \text{ so that } a_1(u, v) = (f \mid v) \text{ for all } v \in U\}, \\ &B_1 u = f. \end{aligned} \tag{6.12}$$

We will show that $B = B_1$, where B is the realization defined in (6.3)-(6.5).

LEMMA 6.1.

$$B \subseteq B_1. \tag{6.13}$$

Proof. For $u \in D(B)$, $v \in U$ we have in view of (6.4), (6.9), (6.11), and formula (A6) of the Appendix:

$$\begin{aligned} a_1(u, v) &= a(u, v) + c(T'u \mid \gamma v)_\Gamma \\ &= (Au \mid v) - (\mathscr{A}^{01}\nu u + \mathscr{S}\gamma u \mid \gamma v)_\Gamma + c(T'u \mid \gamma v)_\Gamma \\ &= (Au \mid v) - (\mathscr{A}^{01}\nu u + \mathscr{S}\gamma u \mid T'v)_\Gamma + c(\gamma u \mid T'v)_\Gamma \\ &= (Au - T'^*(\mathscr{S} - c)\gamma u - T'^*\mathscr{A}^{01}\nu u \mid v) \\ &= ((A + G)u \mid v). \end{aligned}$$

This shows that $u \in D(B_1)$ with $B_1 u = (A + G)u$, so it follows that $D(B) \subset D(B_1)$ with $B_1 u = Bu$ there. □

For $l \in \mathbb{N}$ we define the subspace W_l of $H_0^m(\Omega)$ by

$$W_l = \overline{\operatorname{span}}^m \{\varphi_j\}_{j \leqq l} \qquad (H^m(\Omega) - \text{closure}). \tag{6.14}$$

Note that for $u \in W_K$, γu and $T'u$ are zero, so $W_K \subseteq U$.

LEMMA 6.2. *There exists a linearly independent set of functions $\{v_j\}_{1 \leqq j < K}$ in $U \setminus W_K$, such that*

$$U = \operatorname{span}\{v_j\}_{1 \leqq j < K} \dotplus W_K. \tag{6.15}$$

Proof. According to Lemma 1.6.8 of Grubb [5] (see our § 3) we can write U of the form

$$U = \Lambda^{-1} H_0^m(\Omega) \tag{6.16}$$

where Λ and Λ^{-1} are bounded operators in $H^s(\Omega)$, for all $s \geqq 0$.

Choose a linearly independent set $\{z_j\}_{1\leqq j<K}$ in $H_0^m(\Omega)$ such that the matrix

$$C=((z_i\,|\,(\Lambda^{-1})^*\varphi_j)_{i,j})_{1\leqq i,j<K} \tag{6.17}$$

is regular, and define

$$v_j=\Lambda^{-1}z_j, \qquad j=1,2,\cdots,K-1; \tag{6.18}$$

this is clearly a linearly independent set in U.

Moreover, for $1\leqq j<K$

$$\begin{aligned}\gamma v_j=\gamma\Lambda^{-1}z_j&=\sum_{k=1}^{K-1}(\Lambda^{-1}z_j\,|\,\varphi_k)h_k\\&=\sum_{k=1}^{K-1}(z_j\,|\,(\Lambda^{-1})^*\varphi_k)h_k\neq 0\end{aligned} \tag{6.19}$$

since C is regular, so none of the v_j lie in $H_0^m(\Omega)$.

Since

$$\gamma\begin{pmatrix}v_1\\v_2\\\vdots\\v_{K-1}\end{pmatrix}=C\begin{pmatrix}h_1\\h_2\\\vdots\\h_{K-1}\end{pmatrix} \tag{6.20}$$

the set $\{\gamma v_j\}_{1\leqq j<K}$ is linearly independent, so $\gamma(\sum_{j=1}^{K-1}\alpha_jv_j)=0$ implies that $\alpha_j=0$, $j=1,2,\cdots,K-1$. Then also

$$\operatorname{span}\{v_j\}_{1\leqq j<K}\cap W_K=\{0\}.$$

Since $W_K\subseteq U$ and $\operatorname{span}\{v_j\}_{1\leqq j<K}\subseteq U$, the inclusion

$$\operatorname{span}\{v_j\}_{1\leqq j<K}\dotplus W_K\subseteq U \tag{6.21}$$

is evident.

To show the inclusion the other way, let $u\in U$ and invert (6.20) to get

$$\gamma u=\sum_{j=1}^{K-1}(u\,|\,\varphi_j)h_j=\sum_{j=1}^{K-1}\left((u\,|\,\varphi_j)\sum_{k=1}^{K-1}\alpha_{jk}\gamma v_k\right), \qquad \alpha_{jk}\in\mathbb{C}. \tag{6.22}$$

The last term equals $\sum_{k=1}^{K-1}\beta_k\gamma v_k$, where

$$\beta_k=\sum_{j=1}^{K-1}(u\,|\,\varphi_j)\alpha_{jk}, \qquad k=1,2,\cdots,K-1. \tag{6.23}$$

If we define

$$w=u-\sum_{j=1}^{K-1}\beta_jv_j \tag{6.24}$$

then by (6.22),

$$\gamma w=\gamma u-\sum_{j=1}^{K-1}\beta_j\gamma v_j=0, \tag{6.25}$$

hence (since u and the v_j lie in U)

$$0=\gamma w=\sum_{j=1}^{K-1}(w\,|\,\varphi_j)h_j. \tag{6.26}$$

But the set $\{h_j\}_{1\leqq j<K}$ is linearly independent, so (6.26) implies that

$$(w\,|\,\varphi_j)=0, \qquad j=1,2,\cdots,K-1. \tag{6.27}$$

Then, from (6.24)

$$u=\sum_{j=1}^{K-1}\beta_j v_j+w\in \operatorname{span}\{v_j\}_{1\leqq j<K}\dotplus W_K. \qquad \square \tag{6.28}$$

Since $\bar{W}_K^0$ (i.e., the $L^2(\Omega)$-closure) has a L^2-complement $(\bar{W}_K^0)^\perp$ of dimension $K-1$, we can obtain (by a small perturbation, if necessary) that the v_j are chosen outside $\bar{W}_K^0$. More precisely, the following construction can be used:

Let $v_j=\varphi_j+a_j$, where the a_j are chosen such that

(1) $v_j\notin \bar{W}^0$. This is achieved if $\|a_j\|_0\leqq\frac{1}{2}$, since $\|\varphi_j\|_0=1$ and $\varphi_j\perp W_K$.

(2) $C=((z_i\,|\,(\Lambda^{-1})^*\varphi_j)_{i,j})_{1\leqq i,j<K}$ is regular, when $z_i=\Lambda v_i$. Since $(z_i\,|\,(\Lambda^{-1})^*\varphi_j)=(\varphi_i+a_i\,|\,\varphi_j)=\delta_{ij}+(a_i\,|\,\varphi_j)$, this is achieved by choosing $\max_j\|a_j\|_0$ so small that the norm of the matrix $((a_i\,|\,\varphi_j)_{i,j})_{1\leqq i,j<K}$ is $\leqq\frac{1}{2}$.

(3) $z_j\in H_0^m(\Omega)$. Since $C_0^\infty(\Omega)$ is dense in $L^2(\Omega)$ we can, for a given $\varepsilon>0$ choose $z_j\in C_0^\infty(\Omega)$ such that $\|z_j-\Lambda\varphi_j\|_0\leqq\varepsilon$. Then $a_j=\Lambda^{-1}(z_j-\Lambda\varphi_j)$, with norm $\|a_j\|_0\leqq \varepsilon\|\Lambda^{-1}\|_{L^2,L^2}$. If ε is then adjusted so that (1) and (2) hold, we have a solution $\{v_j\}_{1\leqq j<K}$ with the required property. Then we have a decomposition of $u\in U$ as

$$u=v+w \tag{6.29}$$

where $v\in\operatorname{span}\{v_j\}_{1\leqq j<K}$, $v_j\notin\bar{W}_K^0 j=1,2,\cdots,K-1$, and $w\in W_K$, and the projections

$$u\to v, \qquad u\to w \tag{6.30}$$

are then continuous in $L^2(\Omega)$ so we have an inequality

$$\|v\|_0+\|w\|_0\leqq C\|u\|_0 \tag{6.31}$$

with a constant $C>0$.

LEMMA 6.3. *$a(u,v)$ is m-coercive on U, i.e., (since a is symmetric on $H^m(\Omega)$),*

$$\operatorname{Re} a(u,u)=a(u,u)\geqq C_0\|u\|_m^2-k\|u\|_0^2 \tag{6.32}$$

for $u\in U$, with constants $C_0>0$ and $k\in\mathbb{R}$.

Proof. Recall that the L^2-norm and the H^m-norm are equivalent on a finite-dimensional space, so that we have positive constants C' and C'', such that

$$C'\|v\|_0\leqq\|v\|_m\leqq C''\|v\|_0. \tag{6.33}$$

Let $u\in U$ and write $u=v+w$ as in (6.29). Then

$$\operatorname{Re} a(u,u)=a(u,u)=a(w,w)+2\operatorname{Re} a(v,w)+a(v,v).$$

For any $\varepsilon>0$ we can find constants C_1, $C_2>0$, such that

$$\begin{aligned}2|a(v,w)|&\leqq 2C_1\|w\|_m\|v\|_m\\ &\leqq\varepsilon^2\|w\|_m^2+\frac{C_1^2}{\varepsilon^2}\|v\|_m^2\\ &\leqq\varepsilon^2\|w\|_m^2+\frac{C_2}{\varepsilon^2}\|u\|_0^2.\end{aligned} \tag{6.34}$$

Here we have used (6.31) for v, together with (6.33).

Since $a(u, v)$ is $H_0^m(\Omega)$-coercive, we find, using (6.31) for w,

$$
\begin{aligned}
a(w, w) &\geqq C_3\|w\|_m^2 - C_4\|w\|_0^2 \\
&\geqq C_3\|w\|_m^2 - C_5\|u\|_0^2,
\end{aligned}
\tag{6.35}
$$

with constants $C_3, C_4, C_5 > 0$.

Moreover, since

$$
a(v, v) \leqq C_6\|v\|_m^2 \leqq C_7\|v\|_0^2 \leqq C_8\|u\|_0^2,
\tag{6.36}
$$

with $C_6, C_7, C_8 > 0$, we have that

$$
a(u, u) \geqq (C_3 - \varepsilon^2)\|w\|_m^2 - \left(\frac{C_2}{\varepsilon^2} + C_5 + C_8\right)\|u\|_0^2.
\tag{6.37}
$$

Then, for all $\varepsilon' > 0$:

$$
\begin{aligned}
\|w\|_m^2 = \|u - v\|_m^2 &\geqq \|u\|_m^2 - 2\|v\|_m\|u\|_m + \|v\|_m^2 \\
&\geqq \|u\|_m^2 + C'^2\|v\|_0^2 - \left(\frac{1}{\varepsilon'^2}\|v\|_m^2 + \varepsilon'^2\|u\|_m^2\right) \\
&\geqq (1 - \varepsilon'^2)\|u\|_m^2 + \left(C'^2 - \frac{1}{\varepsilon'^2}C''^2\right)\|v\|_0^2 \\
&\geqq (1 - \varepsilon'^2)\|u\|_m^2 - \left|C'^2 - \frac{1}{\varepsilon'^2}C''^2\right| C\|u\|_0^2.
\end{aligned}
\tag{6.38}
$$

Choosing $0 < \varepsilon^2 < C_3$ and $0 < \varepsilon' < 1$ and inserting the result of (6.38) in (6.37), we finally obtain (6.32). □

LEMMA 6.4. $B_1 = B_1^*$.

Proof. Since for $u \in U$

$$
a_1(u, u) = a(u, u) + c(T'u \mid \gamma u)_\Gamma = a(u, u) + c(T'u \mid T'u)_\Gamma \geqq a(u, u),
\tag{6.39}
$$

a_1 is m-coercive on U. Then B_1 is the *variational* operator associated with the triple $(a_1, U, L^2(\Omega))$, and since $a_1(u, v)$ is symmetric on U, $B_1 = B_1^*$. (see, e.g., Grubb [5], § 1.7.) □

Now we note that the boundary value problem

$$
\begin{aligned}
&Au + Gu = f, \qquad f \in L^2(\Omega), \\
&Tu = 0
\end{aligned}
\tag{6.40}
$$

is elliptic, since the Dirichlet problem for A

$$
\begin{aligned}
&Au = f, \qquad f \in L^2(\Omega), \\
&\gamma u = 0
\end{aligned}
\tag{6.41}
$$

is elliptic and G has the form (6.8)-(6.9) where T'^* and T' obviously are integral operators with C^∞-kernels, hence of order $-\infty$. (Problem (6.40) and (6.41) have the same principal symbols.) We can then use Theorem 1.6.11 and Example 1.6.12 of Grubb [5] to show that $B = B^*$. It is shown there that when

$$
B = (A + G)_T
\tag{6.42}
$$

is an elliptic realization of a formally self-adjoint operator A, with

$$
G = K'\nu + G', \qquad T = \gamma - T'
\tag{6.43}
$$

then $B=B^*$ if

$$T'=-(\mathscr{A}^{01^*})^{-1}K^{1^*},\qquad G'=G'^*+T'^*\mathscr{A}^{00^*}\gamma. \tag{6.44}$$

Using that $K'=-T'^*\mathscr{A}^{01}$ (see (6.9)) and that $\mathscr{A}^{00}=\mathscr{S}-\mathscr{S}^*$ (see Lemma A1 of the appendix), we compute

$$-(\mathscr{A}^{01*})^{-1}K'^*=(\mathscr{A}^{01*})^{-1}\mathscr{A}^{01*}T'=T' \tag{6.45}$$

and

$$\begin{aligned} G'^*+T'^*\mathscr{A}^{00}\gamma &= -T'^*(\mathscr{S}^*-c)\gamma+T'^*(\mathscr{S}^*-\mathscr{S})\gamma \\ &= -T'^*(\mathscr{S}-c)\gamma \\ &= G', \end{aligned} \tag{6.46}$$

hence $B=B^*$, according to (6.44).

We now have Theorem 6.5.

THEOREM 6.5.

$$B=B_1. \tag{6.47}$$

Proof. $B\subseteq B_1$ implies that $B_1^*\subseteq B^*$. But $B=B^*$ and $B_1=B_1^*$. □

We have hereby shown that the realization

$$B=(A+G)_T \tag{6.48}$$

is the *variational* operator associated with the triple $(a_1, U, L^2(\Omega))$.

THEOREM 6.6. *Assume that the operators G and T are chosen such that the operator $B=(A+G)_T$ is the variational operator associated with the triple $(a_1, U, L^2(\Omega))$, and let $\zeta<1$ be given. There exists a constant $c>0$ such that the sesquilinear form*

$$a_1(u,v)=a(u,v)+c(T'u\,|\,\gamma v)_\Gamma \tag{6.49}$$

satisfies, for all $u\in U$

$$a_1(u,u)\geqq \zeta\lambda_K\|u\|_0^2. \tag{6.50}$$

Proof. We write $u\in U$ as $u=v+w$ as in (6.29). Then

$$\begin{aligned} \frac{a_1(u,u)}{\|u\|_0^2} &= \frac{a(v+w,v+w)+c(T'(v+w)\,|\,\gamma(v+w))_\Gamma}{(v+w\,|\,v+w)} \\ &= \frac{a(v+w,v+w)+c(T'(v+w)\,|\,T'(v+w))_\Gamma}{(v+w\,|\,v+w)} \\ &= \frac{a(w,w)+2\,\mathrm{Re}\,a(v,w)+a(v,v)+c\|T'v\|_0^2}{\|w\|_0^2+2\,\mathrm{Re}\,(v\,|\,w)+\|v\|_0^2}. \end{aligned}$$

Now since

$$\begin{aligned} &a(w,w)\geqq C_1\|w\|_m^2-C_2\|w\|_0^2, \qquad C_1, C_2>0, \\ &a(w,w)\geqq \lambda_K\|w\|_0^2 \end{aligned} \tag{6.51}$$

we have, for all $\varepsilon > 0$

$$(6.52)\quad \begin{aligned} 2|a(v, w)| &\leqq \varepsilon^2\|w\|_m^2 + \frac{C_3}{\varepsilon^2}\|v\|_m^2 \\ &\leqq \varepsilon^2\|w\|_m^2 + \frac{C_4}{\varepsilon^2}\|v\|_0^2 \\ &\leqq \varepsilon^2\left(\frac{1}{C_1}a(w, w) + \frac{C_2}{C_1}\|w\|_0^2\right) + \frac{C_4}{\varepsilon^2}\|v\|_0^2 \\ &\leqq \varepsilon^2\left(\frac{1}{C_1} + \frac{1}{\lambda_K}\cdot\frac{C_2}{C_1}\right)a(w, w) + \frac{C_4}{\varepsilon^2}\|v\|_0^2 \end{aligned}$$

with constants $C_3, C_4 > 0$.

Moreover, for all $\varepsilon' > 0$

$$(6.53)\quad 2|(v\,|\,w)| \leqq 2\|v\|_0\|w\|_0 \leqq \varepsilon'^2\|w\|_0^2 + \frac{1}{\varepsilon'^2}\|v\|_0^2,$$

so we find that

$$(6.54)\quad \frac{a_1(u, u)}{\|u\|_0^2} \geqq \frac{\left(1 - \varepsilon^2\left(\frac{1}{C_1} + \frac{1}{\lambda_K}\cdot\frac{C_2}{C_1}\right)\right)a(w, w) - \left(\frac{C_4}{\varepsilon^2} + C_6\right)\|v\|_0^2 + c\|T'v\|_0^2}{(1 + \varepsilon'^2)\|w\|_0^2 + \left(1 + \frac{1}{\varepsilon'^2}\right)\|v\|_0^2},$$

where we also used that $|a(v, v)| \leqq C_5\|v\|_m^2 \leqq C_6\|v\|_0^2$, $C_5, C_6 > 0$ (cf. (6.33)).

Then, in particular,

$$(6.55)\quad \frac{a_1(u, u)}{\|u\|_0^2} \geqq \frac{\left(1 - \varepsilon^2\left(\frac{1}{C_1} + \frac{1}{\lambda_K}\cdot\frac{C_2}{C_1}\right)\right)\lambda_K\|w\|_0^2 - \left(\frac{C_4}{\varepsilon^2} + C_6\right)\|v\|_0^2 + c\|T'v\|_0^2}{(1 + \varepsilon'^2)\|w\|_0^2 + \left(1 + \frac{1}{\varepsilon'^2}\right)\|v\|_0^2}.$$

T' is injective from span $\{v_j\}_{1\leqq j<K}$ to span $\{h_j\}_{1\leqq j<K}$, so we have that

$$(6.56)\quad \|T'v\|_0^2 \geqq C_7\|v\|_0^2,$$

with a positive constant C_7.

Hence

$$(6.57)\quad \frac{a_1(u, u)}{\|u\|_0^2} \geqq \frac{\alpha\lambda_K\|w\|_0^2 + \beta\|v\|_0^2}{\mu\|w\|_0^2 + \theta\|v\|_0^2},$$

where

$$\alpha = 1 - \varepsilon^2\left(\frac{1}{C_1} + \frac{1}{\lambda_K}\cdot\frac{C_2}{C_1}\right), \qquad \beta = cC_7 - \frac{C_4}{\varepsilon^2} - C_6,$$

$$\mu = 1 + \varepsilon'^2, \qquad \theta = 1 + \frac{1}{\varepsilon'^2}.$$

Considering the function

$$(6.58)\quad f(s) = \frac{\alpha\lambda_K s + \beta}{\mu s + \theta}, \qquad s \geqq 0,$$

which is nonincreasing for $s\to\infty$ when $\lambda_K\alpha\theta-\mu\beta\leqq 0$, we see that

$$\frac{a_1(u,u)}{\|u\|_0^2}\geqq\frac{\alpha}{\mu}\lambda_K, \tag{6.59}$$

if

$$\beta\geqq\frac{\alpha\theta}{\mu}\lambda_K. \tag{6.60}$$

Then if we choose c in the definition of a_1 such that

$$c\geqq\frac{\left(1-\varepsilon^2\left(\frac{1}{C_1}+\frac{1}{\lambda_K}\cdot\frac{C_2}{C_1}\right)\right)\lambda_K\left(1+\frac{1}{\varepsilon'^2}\right)}{C_7(1+\varepsilon'^2)}+\frac{C_4}{C_7\varepsilon^2}+\frac{C_6}{C_7}, \tag{6.61}$$

then

$$a_1(u,u)\geqq\frac{1-\varepsilon^2\left(\frac{1}{C_1}+\frac{1}{\lambda_K}\cdot\frac{C_2}{C_1}\right)}{1+\varepsilon'^2}\lambda_K\|u\|_0^2. \tag{6.62}$$

With ε and ε' chosen such that

$$\frac{1-\varepsilon^2\left(\frac{1}{C_1}+\frac{1}{\lambda_K}\cdot\frac{C_2}{C_1}\right)}{1+\varepsilon'^2}=\zeta$$

and c chosen such that (6.61) holds, we see that

$$a_1(u,u)\geqq\zeta\lambda_K\|u\|_0^2 \tag{6.63}$$

as claimed. □

We now have Theorem 6.7.

THEOREM 6.7. *With the hypotheses of Theorem* 6.6 *we have that, given any* $\zeta<1$, *there exists a constant* $c>0$ *such that the self-adjoint operator realization*

$$B=(A+G)_T\quad (\textit{see } (6.3)\text{-}(6.5)) \tag{6.64}$$

has its spectrum in the halfline $[\zeta\lambda_K,\infty[$, *and is the infinitesimal generator of an analytic semigroup* e^{-Bt}, $t\geqq 0$, *on* $L^2(\Omega)$, *giving the solutions to the parabolic system*

$$\begin{aligned} &\partial_t u+Au+Gu=0 && \textit{in } \Omega && \textit{for } t>0,\\ &\gamma u=T'u && \textit{on } \Gamma && \textit{for } t>0,\\ &u=u_0 && \textit{in } \Omega && \textit{at } t=0, \end{aligned} \tag{6.65}$$

as

$$u(t,x)=e^{-Bt}u_0(x),\qquad x\in\Omega,\quad t\geqq 0,\quad u_0\in L^2(\Omega). \tag{6.66}$$

The solution satisfies

$$\|u(t,\cdot)\|_0\leqq e^{-\zeta\lambda_K t}\|u_0\|_0,\qquad t\geqq 0. \tag{6.67}$$

Moreover, the operators

$$\begin{aligned} C(t)&=\cos(B^{1/2}t),\\ S(t)&=B^{-1/2}\sin(B^{1/2}t) \end{aligned} \tag{6.68}$$

are well defined for $t \in \mathbb{R}$, giving the solution to the hyperbolic problem

$$(6.69)\qquad \begin{array}{lll} \partial_t^2 u + Au + Gu = 0 & \text{in } \Omega & \text{for } t \in \mathbb{R}, \\ \gamma u = T'u & \text{on } \Gamma & \text{for } t \in \mathbb{R}, \\ u = u_0 & \text{in } \Omega & \text{at } t = 0, \\ \partial_t u = u_1 & \text{in } \Omega & \text{at } t = 0, \end{array}$$

as

$$(6.70)\qquad u(t,x) = C(t)u_0(x) + S(t)u_1(x), \qquad x \in \Omega, \quad t \in \mathbb{R},$$

when $u_0, u_1 \in L^2(\Omega)$.

Remark 6.8. In the light of Proposition 1.7.11 of Grubb [5], it is of interest to note that the realization constructed above is weakly semibounded and m-bounded (cf. Remark 5.7) because we have compensated for the nonlocalness in the boundary condition by nonlocal terms in the system operator equation, satisfying

$$(6.71)\qquad K'^* = -\mathscr{A}^{01*}T'.$$

Example 6.9. Let us calculate the operator G in the case where $A = -\Delta$. Since

$$(6.72)\qquad T'u = \sum_{j=1}^{K-1} (u \mid \varphi_j)h_j,$$

we have that

$$(6.73)\qquad T'^*\psi = \sum_{j=1}^{K-1} (\psi \mid h_j)_\Gamma \varphi_j,$$

hence

$$(6.74)\qquad \begin{aligned} Gu &= -T'^*\mathscr{A}^{01}\nu u - T'^*(\mathscr{S} - c)\gamma u \\ &= -\sum_{j=1}^{K-1} (\mathscr{A}^{01}\nu u - (\mathscr{S} - c)\gamma u \mid h_j)_\Gamma \varphi_j. \end{aligned}$$

Now the terms in the Green formula (see (A4) of the appendix) are particularly simple since

$$(6.75)\qquad \mathscr{A} = i\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

$$(6.76)\qquad (-\Delta u \mid v) - (u \mid -\Delta v) = i(\nu u \mid \gamma v)_\Gamma + i(\gamma u \mid \nu v)_\Gamma.$$

Then (6.74) reduces to

$$(6.77)\qquad Gu = -\sum_{j=1}^{K-1} (i\nu u + c\gamma u \mid h_j)_\Gamma \varphi_j.$$

Appendix. Green's formulas. Using the notation given in (1.5)-(1.8) we have, for the formally self-adjoint operator A (1.3)

$$(\mathrm{A1})\qquad (Au \mid v) - (u \mid Av) = (\mathscr{A}\rho u \mid \rho v)_\Gamma,$$

where $\mathscr{A}$ is a skew-triangular $2m\times 2m$ matrix of differential operators over the boundary Γ, of the form

$$\text{(A2)}\qquad \mathscr{A}=\begin{pmatrix} S_1^0 & \cdots & S_{2m-1}^0 & S_{2m}^0\\ S_2^0 & \cdots & S_{2m}^0 & 0\\ \vdots & & & \\ S_{2m}^0 & \cdots & 0 & 0\end{pmatrix}+\begin{pmatrix}\text{lower order} & & 0\\ & \cdot^{\cdot^{\cdot}} & \vdots\\ 0 & \cdots & 0\end{pmatrix},$$

the S_k^0 being differential operators on Γ of order $2m-k$ (see, e.g., Grubb [5], § 1.3).

We usually write $\mathscr{A}$ in $m\times m$ blocks as

$$\text{(A3)}\qquad \mathscr{A}=\begin{pmatrix}\mathscr{A}^{00} & \mathscr{A}^{01}\\ \mathscr{A}^{10} & 0\end{pmatrix}$$

and we have the following version of the Green formula:

$$\text{(A4)}\qquad (Au\,|\,v)-(u\,|\,Av)=(\mathscr{A}^{01}\nu u+\mathscr{A}^{00}\gamma u\,|\,\gamma v)_\Gamma+(\mathscr{A}^{10}\gamma u\,|\,\nu v)_\Gamma$$

for $u, v\in H^{2m}(\Omega)$. The coefficient matrices $\mathscr{A}^{ij}$ here are uniquely determined from A.

Now consider a *symmetric* sesquilinear form with $a_{\alpha\beta}\in C^\infty(\bar\Omega)$, $\bar a_{\alpha\beta}=a_{\beta\alpha}$ for all α, β,

$$\text{(A5)}\qquad a(u,v)=\sum_{|\alpha|,|\beta|\leqq m}(a_{\alpha\beta}D^\beta u\,|\,D^\alpha v)$$

associated with A. For such a form we have a "halfways" Green formula, for $u\in H^{2m}(\Omega)$ and $v\in H^m(\Omega)$:

$$\text{(A6)}\qquad (Au\,|\,v)-a(u,v)=(\mathscr{A}^{01}\nu u+\mathscr{S}\gamma u\,|\,\gamma v)_\Gamma$$

where the operator $\mathscr{S}$ is of the same type as $\mathscr{A}^{00}$ in (A3). Since $\mathscr{A}^{01^*}=-\mathscr{A}^{10}$ when A is formally self-adjoint, we have Lemma A1.

LEMMA A1.

$$\text{(A7)}\qquad \mathscr{A}^{00}=\mathscr{S}-\mathscr{S}^*.$$

Proof. For $u, v\in H^{2m}(\Omega)$ we have

$$\begin{aligned}(Au\,|\,v)&=a(u,v)+(\mathscr{A}^{01}\nu u+\mathscr{S}\nu u\,|\,\gamma v)_\Gamma,\\ (u\,|\,Av)=\overline{(Av\,|\,u)}&=\overline{a(u,v)+(\mathscr{A}^{01}\nu v+\mathscr{S}\gamma v\,|\,\gamma u)_\Gamma}\\ &=a(u,v)+(\mathscr{A}^{01*}\gamma u\,|\,\nu v)_\Gamma+(\mathscr{S}^*\gamma u\,|\,\gamma v)_\Gamma\end{aligned}$$

so that

$$\text{(A8)}\qquad (Au\,|\,v)-(u\,|\,Av)=(\mathscr{A}^{01}\nu u+(\mathscr{S}-\mathscr{S}^*)\gamma u\,|\,\gamma v)_\Gamma+(\mathscr{A}^{10}\gamma u\,|\,\nu v)_\Gamma.$$

Comparing (A8) with (A4) gives us (A7). □

Now let K_γ be the Poisson solution operator to the Dirichlet problem for A, i.e., K_γ maps ψ into u, where

$$\text{(A9)}\qquad Au=0\quad\text{in }\Omega,\qquad \gamma u=\psi\quad\text{on }\Gamma.$$

We can then specify the action of K_γ the following way.

PROPOSITION A2. *The Poisson solution operator K_γ to the Dirichlet problem for A satisfies*

$$\text{(A10)}\qquad (K_\gamma\psi\,|\,\varphi_j)=\frac{-1}{\lambda_j}(\psi\,|\,\mathscr{A}^{10^*}\nu\varphi_j)_\Gamma,\qquad j\geqq 1.$$

Proof. Just insert $u = K_\gamma \psi$ and $v = \varphi_j$ (the eigenfunctions of A_γ) in (A4), and use that $\gamma v = 0$. Moreover, $\lambda = \bar{\lambda}$ since A is self-adjoint. □

Acknowledgments. The author is deeply grateful to Gerd Grubb, University of Copenhagen, for her patience in teaching us the pseudodifferential theory, and to Martin Bendsøe, Technical University of Denmark, for many fruitful discussions and much advice.

VIABILITY PROBLEMS FOR NONAUTONOMOUS DIFFERENTIAL INCLUSIONS*

PETER TALLOS†

Abstract. In this paper the existence of viable solutions to nonautonomous differential inclusions is proved. The set-valued map on the right-hand side is assumed to be integrably bounded, measurable in t, and upper semicontinuous in x with nonempty convex, compact values. The cases of convex and nonconvex viability domains and also the time-dependent case are considered. An example for control systems is also given.

Key words. nonautonomous differential inclusions, measurable right-hand side, tangent cones, viable trajectories

AMS(MOS) subject classifications. 49A50, 34A60

1. Introduction. In this paper we investigate the existence of viable solutions to nonautonomous differential inclusions. More precisely, consider a finite-dimensional space X and let K be a nonempty closed subset of X. Let F be a set-valued map defined on $\mathbf{R}\times K$ with nonempty convex compact values in X. If x_0 is given in K, we look for a solution to the differential inclusion

$$x'(t)\in F(t, x(t)), \qquad x(0)=x_0, \tag{1}$$

which is *viable*, i.e.,

$$x(t)\in K \quad \text{for every } t\geqq 0. \tag{2}$$

Existence theorems for viable solutions to autonomous differential inclusions were proven by Haddad [10] (see also the book of Aubin and Cellina [2]). Moreover, the time-dependent viability theorem states that if for some $T>0$ the map F is bounded and upper semicontinuous on $[0, T]\times K$ and the tangential condition

$$F(t, x)\cap T_K(x)\neq\varnothing$$

holds true for every $(t, x)\in[0, T]\times K$, then for every x_0 in K there exists a viable solution defined on $[0, T]$ (see [2, Thm. 4.41]). Here $T_K(x)$ denotes the Bouligand contingent cone to K at x.

However, most of the classical existence theorems for differential inclusions (see, for instance, Filippov [7], Zaremba [16]) have been extended to the case of nonautonomous inclusions, when the set-valued map on the right-hand side is only measurable with respect to t (Himmelberg and Van Vleck [11], Olech [12], Plis [13]). Such differential inclusions are provided, for example, by "linearization" of an autonomous inclusion along a trajectory (see Frankowska [8], [9] for variational inclusions). It is a natural question to ask whether the time-dependent viability theorem remains true when only measurability in t is assumed for F and the boundedness assumption is replaced by integrably boundedness.

* Received by the editors December 7, 1987; accepted for publication (in revised form) May 29, 1990. This research was carried out in part while the author was visiting the International Institute for Applied Systems Analysis at Laxenburg, Austria.

In § 2 we give some preliminary facts, and in § 3 we provide an affirmative answer for convex viability domains. The proof is constructive and it appears as a refined version of Haddad's proof [10] (see also [2, Thm. 4.2.3]). The construction is based on the systematic use of the measurable selection theorem (see [2], [5]). A similar result was obtained by Deimling [6] by using a Scorza-Dragoni-type theorem of Rzeżuchowski [14] and reducing the problem to the autonomous case. In § 4 we deal with the nonconvex case and prove the existence of viable solutions under a stronger tangential condition. In particular, we use the Clarke tangent cone, since this cone is always convex, even if K is not. We define a sequence of upper semicontinuous approximations of F and use the time-dependent viability theorem. By passing to the limit, we get a viable solution of the original problem. Finally, in § 5 we consider time-dependent viability domains and an example for control systems is given.

2. Preliminaries. First we formulate the definition of integrably boundedness. The set-valued map F is said to be *integrably bounded*, if there exists a locally L^1 function l, i.e., a measurable function with $l \in L^1[0, T]$ for every $T > 0$ such that for almost every t in $\mathbf{R}$ and for every x in K

$$F(t, x) \subset l(t)(1+|x|)B$$

is valid, where B is the closed unit ball in X.

As is well known, if F is integrably bounded, by a change of t and a retraction in x, we may assume without loss of generality that for a $T > 0$

$$|v| \leqq 1 \tag{3}$$

for every $v \in F(t, x)$ and $(t, x) \in [0, T] \times K$.

The following two propositions will be used for proving the convergence of the sequence of approximate solutions. For the proofs we refer, for instance, to Olech [12].

LEMMA 1. *Suppose that F is integrably bounded and we are given two sequences $y_n \in L^1[0, T]$ and $x_n \in C[0, T]$ with*

$$\lim_{n\to\infty} d(y_n(t), F(t, x_n(t))) = 0 \quad a.e.,$$

where $y_n \to y$ weakly in L^1, $x_n \to x$ uniformly on $[0, T]$ and d denotes the distance function. Then

$$y(t) \in \bigcap_{m=1}^{\infty} \operatorname{cl} \operatorname{co} \bigcup_{n=m}^{\infty} F(t, x_n(t))$$

almost everywhere in $[0, T]$.

LEMMA 2. *Consider the set-valued map F and the sequence x_n in Lemma 1 and assume in addition that F is upper semicontinuous in x with convex compact values. Then*

$$\bigcap_{m=1}^{\infty} \operatorname{cl} \operatorname{co} \bigcup_{n=m}^{\infty} F(t, x_n(t)) = F(t, x(t))$$

for each t in $[0, T]$.

In the next sections we will use the concepts of the Bouligand contingent cone, the intermediate cone and the Clarke tangent cone. Recall that the *Bouligand contingent cone* to K at x is defined by

$$T_K(x) = \left\{ v \in X : \liminf_{h\to 0+} \frac{1}{h} d_K(x+hv) = 0 \right\},$$

where d_K denotes the distance function from the set K.

The *intermediate cone*, introduced by Ursescu [15], is defined by

$$I_K(x)=\left\{v\in X:\ \lim_{h\to 0+}\frac{1}{h}\,d_K(x+hv)=0\right\}.$$

The same concept was used by Frankowska in [8] for solving optimization problems for differential inclusions.

The *Clarke tangent cone* is defined by

$$C_K(x)=\left\{v\in X:\ \lim_{y\to x, h\to 0+}\frac{1}{h}\,d_K(y+hv)=0\right\}.$$

This cone is always convex.

Obviously, $C_K(x)\subset I_K(x)\subset T_K(x)$, and moreover, they coincide if K is convex. For details concerning various concepts of tangent cones and their properties we refer to Aubin and Ekeland [3] and Frankowska [8].

We will need the following simple proposition.

LEMMA 3. *Let $y\in K$ be fixed and define*

$$\Delta_h(y)=\sup_{v\in I_K(y)\cap B}\frac{1}{h}\,d_K(y+hv),$$

where B is the closed unit ball in X. Then

$$\lim_{h\to 0+}\Delta_h(y)=0.$$

Proof. Let $\varepsilon>0$ be given. Since $I_K(y)\cap B$ is compact we can find points $v_1,\cdots,v_m$ in $I_K(y)\cap B$ such that

$$I_K(y)\cap B\subset\bigcup_{i=1}^{m}\left(v_i+\frac{\varepsilon}{2}B\right).$$

On the other hand, for every $i=1,\cdots,m$ there exists a $\delta_i>0$ such that

$$\frac{1}{h}\,d_K(y+hv_i)<\frac{\varepsilon}{2}$$

if $h<\delta_i$. Put $\delta=\min\{\delta_1,\cdots,\delta_m\}$. Now take any v in $I_K\cap B$. Then there exists a j with $v\in v_j+(\varepsilon/2)B$. If $h<\delta$, by the Lipschitz continuity of d_K, we get

$$\frac{1}{h}\,d_K(y+hv)\leqq\frac{1}{h}\,d_K(y+hv_j)+|v-v_j|<\varepsilon,$$

consequently $\Delta_h(y)<\varepsilon$. □

3. Convex viability domains. In this section we prove the existence of viable solutions in the case of convex viability domains. For the construction we need the measurable selection theorem (see, for instance, Aubin and Cellina [2, p. 90]) and the convexity of K allows us to make use of the mean value theorem (see [2, p. 21]).

THEOREM 1. *Let K be closed, convex and suppose that F is integrably bounded, measurable in t, and upper semicontinuous in x with nonempty convex compact values. Assume that the tangential condition*

$$F(t,x)\cap T_K(x)\neq\varnothing \tag{4}$$

holds true for almost every t in $\mathbf{R}$ and for every x in K. Then for every $x_0\in K$ and for every $T>0$ there exists a viable solution to (1) *defined on* $[0, T]$.

Proof. Let $x_0 \in K$ be given and choose a $T > 0$ arbitrarily. Then, in view of (3), every trajectory for F through x_0 on $[0, T]$, if any exist, obviously lies in $x_0 + TB$, where B denotes the closed unit ball in X. On the other hand, $K \cap (x_0 + TB)$ is a compact subset of X and, since the contingent cone depends only on the local shape of K around x, for each $0 < \rho < T$ and $x \in K \cap (x_0 + \rho B)$, we clearly have that $T_K(x) = T_{K \cap (x_0 + TB)}(x)$. Hence, without loss of generality we may assume that K is compact.

Since K is convex, we have that $T_K(y) = I_K(y)$ for each $y \in K$. Fix an integer n; then, in view of Lemma 3, for every y in K there exists $0 < h_y < 1/n$ such that

$$\Delta_{h_y}(y) < \frac{1}{3nT}. \tag{5}$$

Since $T_K(y)$ is closed, we can find a measurable selection $f_y(t) \in F(t, y) \cap T_K(y)$ on $[0, T]$. Consider the sets

$$U(y) = \left\{ x \in X \colon d_K(x + h_y f_y(t)) < d_K(y + h_y f_y(t)) + \frac{h_y}{3nT} \text{ a.e.} \right\}.$$

By the Lipschitz continuity of d_K, $U(y)$ is open and $y \in U(y)$ for every $y \in K$, hence, there is a $0 < \delta_y < 1/n$ with $y + \delta_y B \subset U(y)$. Since K is compact, we can select finitely many points $y_1, \cdots, y_m$ in K such that

$$K \subset \bigcup_{i=1}^{m} (y_i + \delta_i B), \tag{6}$$

where $\delta_i = \delta_{y_i}$. Introduce the notation $h_i = h_{y_i}$, $f_i = f_{y_i}$ for $i = 1, \cdots, m$. Put $h_0(n) = \min\{h_1, \cdots, h_m\}$, then $0 < h_0(n) < 1/n$.

Now we construct the approximate solution x_n on the interval $[0, T]$. Set $t_0 = 0$ and $x_n(t_0) = x_0$. In view of (6), we can find an index $1 \leqq i \leqq m$ with $x_0 \in y_i + \delta_i B$. Thus, we get

$$d_K(x_0 + h_i f_i(t)) < d_K(y_i + h_i f_i(t)) + \frac{h_i}{3nT}.$$

Consider the following set-valued map on $[0, T]$:

$$Z_i(t) = K \cap \left\{ z \in X \colon z - x_0 - h_i f_i(t)| \leqq d_K(x_0 + h_i f_i(t)) + \frac{h_i}{3nT} \right\}.$$

Then Z_i is obviously measurable and admits nonempty closed values. Thus, by the measurable selection theorem, we can take a measurable selection z_i of Z_i with $z_i(t) \in K$ for almost every t in $[0, T]$.

Set $t_1 = h_i$, $v_0(t) = 1/h_i(z_i(t) - x_0)$ and define x_n on the interval $[t_0, t_1]$ by

$$x_n(t) = x_0 + \int_{t_0}^{t_1} v_0(s)\, ds.$$

Since K is convex, we obtain

$$x_n(t_1) = \frac{1}{h_i} \int_0^{h_i} z_i(t)\, dt \in K$$

by the mean value theorem.

The construction can be proceeded by induction. Suppose we have constructed x_n on the subinterval $[0, t_k]$ and $x_n(t_k) \in K$. In view of (6), we can find an index $1 \leqq j \leqq m$ such that $x_n(t_k) \in y_j + \delta_j B$, thus

$$d_K(x_n(t_k) + h_j f_j(t)) < d_K(y_j + h_j f_j(t)) + \frac{h_j}{3nT} \tag{7}$$

for almost every t. Introduce the following set-valued map on $[0, T]$:

$$Z_j(t) = K \cap \left\{ z \in X \colon |z - x_n(t_k) - h_j f_j(t)| \leqq d_K(x_n(t_k) + h_j f_j(t)) + \frac{h_j}{3nT} \right\}.$$

Then Z_j is clearly measurable with nonempty closed values. Take a measurable selection z_j of Z_j; then $z_j(t) \in K$ for almost every t in $[0, T]$.

Set $t_{k+1} = t_k + h_j$, $v_k(t) = 1/h_j(z_j(t) - x_n(t_k))$ and define x_n on the interval $[t_k, t_{k+1}]$ by

$$x_n(t) = x_n(t_k) + \int_{t_k}^{t} v_k(s)\, ds.$$

The convexity of K implies that

$$(8) \qquad x_n(t_{k+1}) = \frac{1}{h_j} \int_{t_k}^{t_k + h_j} z_j(t)\, dt \in K$$

by the mean value theorem. Therefore the construction can be continued.

Since $t_{k+1} - t_k \geqq h_0(n) > 0$ for each k, we reach the point T within finitely many steps. Hence, the approximate solution x_n can be defined on the whole interval $[0, T]$ and we obtain a partition $0 = t_0 < \cdots < t_p = T$ of $[0, T]$ for every n.

Now we prove the convergence of approximate solutions. We deduce from the above construction that each x_n is absolutely continuous and for almost every $t \in [t_k, t_{k+1}]$ we have

$$|x_n'(t) - f_j(t)| = \left| \frac{1}{h_j}(z_j(t) - x_n(t_k) - f_j(t)))\right|$$

$$\leqq \frac{1}{h_j} d_K(x_n(t_k) + h_j f_j(t)) + \frac{1}{3nT}$$

for a suitable index $1 \leqq j \leqq m$. In view of the definition of f_j, we get

$$(9) \qquad x_n'(t) \in F(t, y_j) + \left[\frac{1}{h_j} d_K(x_n(t_k) + h_j f_j(t)) + \frac{1}{3nT} \right] B.$$

For every $0 \leqq k \leqq p-1$ denote by i_k the corresponding index for which $x_n(t_k) \in y_{i_k} + \delta_{i_k} B$. Let us introduce the following functions on $[0, T]$:

$$e_k(t) = \begin{cases} 1 & \text{if } t \in [t_k, t_{k+1}], \\ 0 & \text{otherwise.} \end{cases}$$

Then (9) can be written in the following form:

$$(10) \qquad x_n'(t) \in F(t, x_n(t) + a_n(t)) + q_n(t) B$$

almost everywhere in $[0, T]$, where

$$a_n(t) = \sum_{k=0}^{p-1} y_{i_k} e_k(t) - x_n(t)$$

and

$$q_n(t) = \sum_{k=0}^{p-1} e_k(t) \frac{1}{h_{i_k}} d_K(x_n(t_k) + h_{i_k} f_{i_k}(t)) + \frac{1}{3nT}.$$

Making use of (5) and (7), we get

$$\|q_n\|_{L^1} = \sum_{k=0}^{p-1} \int_{t_k}^{t_{k+1}} \frac{1}{h_{i_k}} d_K(x_n(t_k) + h_{i_k} f_{i_k}(t))\, dt + \frac{1}{3n}$$

$$\leqq \sum_{k=0}^{p-1} \left[\Delta_{h_{i_k}}(y_{i_k}) + \frac{1}{3nT} \right] (t_{k+1} - t_k) + \frac{1}{3n} \leqq \frac{1}{n}.$$

Therefore, taking a subsequence, we may assume that $q_n \to 0$ almost everywhere in $[0, T]$.

On the other hand, for every n, x_n is absolutely continuous, $x_n(0) = x_0$, and for almost every $t \in [0, T]$

$$|x_n'(t)| \leqq 1 + \frac{2}{3nT} \tag{11}$$

by (9). Thus, by the Dunford-Pettis criterion we can select a subsequence, again denoted by x_n, which converges uniformly on $[0, T]$ to an absolutely continuous function x, moreover $x_n' \to x'$ weakly in $L^1[0, T]$. Furthermore, $a_n \to 0$ uniformly on $[0, T]$. Indeed, since $\delta_i < 1/n$ for each i, by (11) we have

$$|a_n(t)| = \left| \sum_{k=0}^{p-1} y_{i_k} e_k(t) - x_n(t) \right|$$

$$\leqq \sum_{k=0}^{p-1} |y_{i_k} - x_n(t_k)|\, e_k(t) + \left| \sum_{k=0}^{p-1} x_n(t_k)\, e_k(t) - x_n(t) \right|$$

$$\leqq \frac{1}{n} + \frac{1}{n}\left(1 + \frac{2}{3nT}\right).$$

Using Lemmas 1 and 2, we deduce from (10) that

$$x'(t) \in \bigcap_{m=1}^{\infty} \operatorname{cl\,co} \bigcup_{n=m}^{\infty} F(t, x_n(t) + a_n(t)) = F(t, x(t))$$

almost everywhere in $[0, T]$. Hence, in view of (8), we get that x is a viable solution to (1) on $[0, T]$. □

Remark. A similar result was proven by Deimling in [6]. The proof is based on the reduction of the problem to the autonomous case by using a Scorza-Dragoni type theorem of Rzeżuchowski [14].

4. Nonconvex viability domains. In this section we prove the existence of viable trajectories when K is closed, but not necessarily convex. The following method will be used. For every $h > 0$ we define an approximation F_h of the set-valued map F, which enjoys more regularity than F, then we apply Haddad's theorem for F_h. Passing to the limit $h \to 0$ we get a viable solution of the original inclusion. However, we need a stronger tangential condition in this case, namely, we use the Clarke tangent cone.

THEOREM 2. *Let K be nonempty closed and suppose that F is integrably bounded, measurable in t, and upper semicontinuous in x with nonempty convex compact values. We posit the tangential condition*

$$F(t, x) \cap C_K(x) \neq \varnothing \tag{12}$$

for almost every t in **R** *and every x in K. Then for every $x_0 \in K$ and $T > 0$ there exists a viable solution to* (1) *defined on* $[0, T]$.

Proof. Let $x_0 \in K$ and $T > 0$ be given. For every $h > 0$ define F_h by the Aumann-integral

$$F_h(t, x) = \frac{1}{h} \int_t^{t+h} F(s, x)\, ds,$$

where $(t, x) \in [0, T] \times K$. Then for all $h > 0$, for almost every $t \in [0, T]$ and for all $x \in K$ we have

$$F_h(t, x) \cap C_K(x) \neq \emptyset. \tag{13}$$

Indeed, take a measurable selection f of the measurable closed-valued map $s \to F(s, x) \cap C_K(x)$. Since $C_K(x)$ is convex, we get

$$\frac{1}{h} \int_t^{t+h} f(s)\, ds \in F_h(t, x) \cap C_K(x)$$

by the mean value theorem.

We show that F_h is upper semicontinuous on $[0, T] \times K$ for each fixed $h > 0$. Let $(t, x) \in [0, T] \times K$ and $\varepsilon > 0$ be given. Take an arbitrary $\gamma > 0$ and define

$$\eta(s, x, \gamma) = \sup \left\{ \sup_{u \in F(s,y)} d(u, F(s, x)) \colon |x - y| \leqq \gamma \right\}.$$

Then η is measurable in s (see [5, Thm. III.9, Lemma III.39]) and by (3), $\eta(s, x, \gamma) \leqq 2$ for almost every $s \in [0, T]$ and for every $x \in K$ and $\gamma > 0$. Moreover, $\eta(s, x, \gamma) \to 0$ if $\gamma \to 0$, by the upper semicontinuity of F. Hence, by Lebesgue's dominated convergence theorem

$$\lim_{\gamma \to 0} \frac{1}{h} \int_t^{t+h} \eta(s, x, \gamma)\, ds = 0.$$

Choose a $0 < \delta < \varepsilon h/4$ such that

$$\frac{1}{h} \int_t^{t+h} \eta(s, x, \delta)\, ds < \frac{\varepsilon}{2} \tag{14}$$

is valid.

Now take an $(r, y) \in [0, T] \times K$ such that $|t - r| < \delta$, $|x - y| < \delta$ and pick $w \in F_h(r, y)$. In view of the definition of F_h, we can find a measurable selection $g(s) \in F(s, y)$ with

$$w = \frac{1}{h} \int_r^{r+h} g(s)\, ds.$$

Consider the following set-valued map:

$$\Phi(s) = F(s, x) \cap \{u \in X \colon |u - g(s)| \leqq \eta(s, x, \delta)\}.$$

Then Φ is obviously measurable with nonempty closed values. Let f be a measurable selection of Φ and set

$$v = \frac{1}{h} \int_t^{t+h} f(s)\, ds.$$

Then $v \in F_h(t, x)$, and by (14) we have

$$\begin{aligned}|v-w| &= \frac{1}{h}\left|\int_t^{t+h} f(s)\,ds - \int_r^{r+h} g(s)\,ds\right| \\ &\leqq \frac{1}{h}\left|\int_t^r |g(s)|\,ds\right| + \frac{1}{h}\int_t^{t+h} |f(s)-g(s)|\,ds + \frac{1}{h}\left|\int_{t+h}^{r+h} |g(s)|\,ds\right| \\ &\leqq \frac{\varepsilon}{4} + \frac{1}{h}\int_t^{t+h} \eta(s, x, \delta)\,ds + \frac{\varepsilon}{4}.\end{aligned}$$

Thus, F_h is upper semicontinuous on $[0, T] \times K$.

Since for every $h > 0$, F_h is a bounded map with nonempty convex compact values, furthermore the tangential condition (13) is valid, we can apply the time-dependent viability theorem (see [1, Thm. 4.4.1]). Hence, for every $x_0 \in K$ and $T > 0$ there exists a viable trajectory x_h for F_h through x_0 defined on $[0, T]$. This means that

$$\begin{aligned}&x_h'(t) \in F_h(t, x_h(t)) \quad \text{a.e. in } [0, T], \\ &x_h(0) = x_0, \\ &x_h(t) \in K \quad \text{for every } t \text{ in } [0, T].\end{aligned}$$

By the boundedness assumption (3), there exists a subsequence denoted by $x_n = x_{h_n}$ that converges uniformly on $[0, T]$ to an absolutely continuous function x with $h_n \to 0$ and $x_n' \to x'$ weakly in $L^1[0, T]$.

Since the set-valued map $t \to F(t, x(t))$ can be assumed to be measurable (see [14]), it follows that the map $t \to \eta(t, x(t), \gamma)$ is also measurable for every $\gamma > 0$ (see [5, Chap. 3]). On the other hand, $\eta(t, x(t), \gamma) \to 0$ almost everywhere, if $\gamma \to 0+$.

Let δ_n be any sequence converging decreasingly to zero. We show that

$$\lim \frac{1}{h_n}\int_t^{t+h_n} \eta(s, x(s), \delta_n)\,ds = 0 \tag{15}$$

almost everywhere in $[0, T]$. Indeed, it is clear that there is a set $H \subset [0, T]$ of measure T such that for every $t \in H$

$$\lim_{h\to 0+} \frac{1}{h}\int_t^{t+h} \eta(s, x(s), \delta_n)\,ds = \eta(t, x(t), \delta_n)$$

for each n. In fact, H is a countable intersection of sets of measure T. Take a point $t \in H$ and let $\varepsilon > 0$ be given. Then we can find an n_0 with $\eta(t, x(t), \delta_{n_0}) < \varepsilon/2$, and an n_1 such that

$$\frac{1}{h_n}\int_t^{t+h_n} \eta(s, x(s), \delta_{n_0})\,ds < \eta(t, x(t), \delta_{n_0}) + \frac{\varepsilon}{2}$$

for $n \geqq n_1$. Hence, if $n \geqq \max\{n_0, n_1\}$ we have

$$\begin{aligned}\frac{1}{h_n}\int_t^{t+h_n} \eta(s, x(s), \delta_n)\,ds &\leqq \frac{1}{h_n}\int_t^{t+h_n} \eta(s, x(s), \delta_{n_0})\,ds \\ &< \eta(t, x(t), \delta_{n_0}) + \frac{\varepsilon}{2} < \varepsilon,\end{aligned}$$

because η is increasing with respect to δ.

Pick a point $s \in [t, t+h_n]$ and introduce the notation

$$|x_n(t) - x(s)| \leqq |x_n(t) - x(t)| + h_n = \delta_n.$$

We may assume (by taking a subsequence if necessary) that δ_n converges decreasingly to zero. Moreover, we have

$$(16)\qquad \begin{aligned} x_n'(t) &\in \frac{1}{h_n}\int_t^{t+h_n} F(s, x_n(t))\,ds \\ &\subset \frac{1}{h_n}\int_t^{t+h_n} F(s, x(s))\,ds + \frac{1}{h_n}\int_t^{t+h_n} \eta(s, x(s), \delta_n)\,ds\,B. \end{aligned}$$

Making use of (15), (16) and the Lebesgue-point equality

$$(17)\qquad \lim_{n\to\infty} \frac{1}{h_n}\int_t^{t+h_n} F(s, x(s))\,ds = F(t, x(t))$$

(see [4]), we get

$$(18)\qquad d(x_n'(t), F(t, x(t))) \to 0$$

almost everywhere in $[0, T]$. Thus, by Lemmas 1 and 2, relation (18) and the obvious $x(t) \in K$ show that x is a viable solution to (1) defined on $[0, T]$. □

5. The time-dependent case. If the viability domain K depends on t we can prove the existence of viable trajectories by standard arguments. We express the tangential condition in terms of the graphical derivative of the set-valued map K (see Aubin and Ekeland [3]).

Let K be a set-valued map defined on the interval $[0, T]$ with nonempty values in X. Recall that the *graphical derivative* of K at $(t, x) \in \operatorname{graph} K$ is defined as the set-valued map $DK(t, x)$, whose graph is $C_{\operatorname{graph} K}(t, x)$. More precisely $v \in DK(t, x)(u)$ if and only if $(u, v) \in C_{\operatorname{graph} K}(t, x)$. Several properties of this derivative, including chain rule and inverse function theorem, can be found in [3] and [1].

Now consider a set-valued map F defined on graph K with nonempty convex compact values in X, and let x_0 be a given point in $K(0)$. A solution to the differential inclusion problem

$$(19)\qquad x'(t) \in F(t, x(t)), \qquad x(0) = x_0$$

is said to be *viable* if

$$(20)\qquad x(t) \in K(t)$$

for every $t \in [0, T]$.

THEOREM 3. *Let the graph of K be closed and suppose that F is integrably bounded, measurable in t, and upper semicontinuous in x with nonempty convex compact values. Assume that the tangential condition*

$$(21)\qquad F(t, x) \cap DK(t, x)(1) \neq \emptyset$$

holds true for almost every $t \in [0, T]$ *and every* x *in* $K(t)$. *Then for every* x_0 *in* $K(0)$ *there exists a viable solution to* (19) *defined on* $[0, T]$.

Proof. By using the usual transformation of the state space with a trivial modification, it can easily be seen that all assumptions of Theorem 2 are satisfied. Moreover, the tangential condition (21) reduces to (12), hence, the statement of the theorem follows from Theorem 2. □

Remark. The concept of the graphical derivative of a set-valued map clearly depends on what tangent cone is chosen. Therefore, if the graph of K is convex and closed, the above theorem can be reformulated in terms of the *contingent derivative* of K, i.e., by replacing the Clarke tangent cone with the Bouligand contingent cone.

As an illustration of the above theorem consider the following example. Let X and Y be finite-dimensional spaces. Let K be a set-valued map defined on the interval $[0, T]$ with nonempty values in X, and let $x_0 \in K(0)$ be given. Consider the control differential equation

$$x'(t) = f(t, x(t), u(t)), \qquad x(0) = x_0, \tag{22}$$

where the control set $U \subset Y$ is compact, the controls are the measurable functions u with $u(t) \in U$ almost everywhere in $[0, T]$, and f: graph $K \times U \to X$ is integrably bounded, measurable in t, and continuous in (x, u).

The problem can be expressed in the following way. Does there exist a control u such that the control system (22) has a viable trajectory, i.e., a solution x such that $x(t) \in K(t)$ for every $t \in [0, T]$? We solve this problem by rewriting the differential equation (22) as a differential inclusion and applying Theorem 3. As is well known, by Filippov's implicit function lemma (see [5, p. 85]), the differential equation (22) and the corresponding differential inclusion have the same set of trajectories.

We will use the following assumption:

$$f(t, x, U) \subset X \text{ is convex} \tag{23}$$

for almost every $t \in [0, T]$ and every $x \in K(t)$. This condition is satisfied, for instance, if f is affine with respect to u and U is convex.

Let us introduce the feedback map C defined by

$$C(t, x) = \{u \in U : f(t, x, u) \in DK(t, x)(1)\}$$

for every $(t, x) \in$ graph K.

THEOREM 4. *Let the graph of K be closed and suppose that the feedback map*

$$C(t, x) \neq \emptyset \tag{24}$$

for every $(t, x) \in$ graph K. Then, under the above assumptions, for every $x_0 \in K(0)$ there exist a control u and a viable trajectory x of (22) *that are related by*

$$u(t) \in C(t, x(t)) \tag{25}$$

almost everywhere in $[0, T]$.

Proof. Introduce the following set-valued map on graph K:

$$F(t, x) = \{f(t, x, u) : u \in U\}.$$

Then F clearly satisfies all assumptions of Theorem 3. Moreover, by (24), the tangential condition (21) is also fulfilled. Thus, there exists a viable trajectory x for F through x_0. By Filippov's implicit function lemma, we can find a control u such that

$$x'(t) = f(t, x(t), u(t))$$

almost everywhere in $[0, T]$. This means that x is a solution to (22). Since obviously $x'(t) \in DK(t, x(t))(1)$, we have that (25) is also satisfied. □

A detailed discussion of the above problem for autonomous equations and time-independent viability domains can be found in [1] and [2].

Acknowledgments. The author is greatly indebted to J.-P. Aubin and H. Frankowska for helpful discussions. The author also thanks the referees for critical comments to the earlier versions of the paper.

CONTINUOUS-TIME STOCHASTIC ADAPTIVE CONTROL*

M. GEVERS†, G. C. GOODWIN‡, AND V. WERTZ†

Abstract. This paper establishes global boundedness for a continuous-time stochastic adaptive control algorithm. It is shown that, with probability one, the system inputs and outputs satisfy a sample mean square boundedness property. The algorithm and method of analysis are not directly analogous to the discrete-time case, since special features are necessary to handle the continuous-time problem.

Key words. global boundedness, stochastic adaptive control

1. Introduction. It is now well known that global boundedness can be established for discrete-time stochastic adaptive control algorithms—see, for example, [1]-[3].

However, to date there has been no corresponding result for continuous-time systems. Preliminary work in this direction appears in [4]-[8]. However, the available adaptive control results rely upon unproven and data dependent conjectures, e.g., the normalized regression vector, $(\varphi^T\varphi/r)$, is assumed to be uniformly bounded. Inspection of the details of the algorithms indicates that this is most likely not true. A further restriction in the work reported in [5] and [6] is that the relative degree of the system is taken to be zero, i.e., there is a direct feedthrough term between input and output. This leads to questions about the validity of the resulting control law as the closed-loop system contains an algebraic loop.

This paper presents a new algorithm for continuous-time stochastic adaptive control in the ideal case (no unmodelled dynamics) together with a proof of global boundedness. The main feature of the algorithm is a new normalization technique that guarantees that the normalized regression vector $(\varphi^T\varphi/r)$ is bounded. Also, the proof of boundedness of the system states has several novel features including a special technique for handling strictly proper systems.

The paper was inspired by an earlier paper [9] which explored the link between discrete- and continuous-time *deterministic* adaptive control theory. The current paper does this for the stochastic case.

Novel aspects of our analysis are the following: We first establish existence and uniqueness for the solutions of the nonlinear stochastic differential equation for the parameter estimation algorithm. We then establish properties of the parameter estimator that hold irrespective of the control law. Finally, we establish a continuous-time key technical lemma that is analogous to that given for continuous-time deterministic systems in [9].

These preliminary results can be combined with a wide class of certainty equivalence control laws to establish global boundedness of all internal variables of the resultant algorithm. We illustrate by using an adaptive pole assignment algorithm as in [10] and [11] for deterministic continuous time systems.

The results are believed to be of importance, in their own right, insofar as they formally establish the boundedness of all system states and parameters for a continuous-time stochastic adaptive control algorithm. However, they also give further insight into

the discrete-time theory, since they show what happens in the case of rapid sampling as shown in [18]. We have also recently [22] built on the results established here to establish global boundedness for a stochastic model reference adaptive control algorithm which is the continuous-time counterpart of the discrete-time stochastic adaptive minimum variance control results given in [1].

2. The model. In previous papers dealing with continuous-time stochastic adaptive control, an integral operator model has been used (see for example, [4]-[8]). Here, however, we adopt the more conventional continuous-time state space innovations representation, i.e.,

$$dx_t = Ax_t\,dt + Bu_t\,dt + K\,d\omega_t \tag{2.1}$$

$$dy_t = Cx_t\,dt + d\omega_t \tag{2.2}$$

where ω_t is a Wiener process with incremental covariance $\sigma^2\,dt$, x_t is a state vector of dimension n, u_t is a scalar control input, and dy_t is the scalar output of the system. The matrices A, B, K, C contain unknown but fixed parameters. We will denote by $\mathcal{F}_t$ the increasing σ-fields generated by $\{\omega_s, 0 \leqq s \leqq t\}$ and the unknown initial conditions x_0, and we will assume that $\|x_0\|^2$ is bounded. This model is the basis of stochastic control in the nonadaptive literature [12], [15]. It has also been proposed for the adaptive case [7]. Notice that y_t is the integral of the output.

Without loss of generality, we assume that the above model is in observer form where

$$A = \begin{bmatrix} -a_{n-1} & 1 & & \\ -a_{n-2} & & \ddots & \\ \vdots & & & 1 \\ -a_0 & & & 0 \end{bmatrix}; \quad B = \begin{bmatrix} b_{n-1} \\ \vdots \\ b_0 \end{bmatrix}; \quad K = \begin{bmatrix} k_{n-1} \\ \vdots \\ k_0 \end{bmatrix} \tag{2.3}$$

$$C = [1 \quad 0 \quad 0]. \tag{2.4}$$

For the purpose of adaptive control it is convenient to reexpress this model in fractional form [9]. We therefore reparametrize the system as follows. Let

$$E(\rho) = \rho^n + e_{n-1}\rho^{n-1} + \cdots + e_0 \tag{2.5}$$

$$G^T = [g_{n-1}, \cdots, g_0] \quad \text{with } g_i = e_i - a_i; \qquad i = 0, \cdots, n-1 \tag{2.6}$$

and

$$E = \begin{bmatrix} -e_{n-1} & 1 & & \\ \vdots & & \ddots & \\ \vdots & & & 1 \\ -e_0 & & 0 & 0 \end{bmatrix} \tag{2.7}$$

where the coefficients are arbitrary subject to $E(\rho)$ having all its zeros in the open left half plane and $K \neq G$.

Then, (2.1), (2.2) can be rewritten as

$$dx_t = Ex_t\,dt + Bu_t\,dt + (K - G)\,d\omega_t + G\,dy_t \tag{2.8}$$

$$dy_t = Cx_t\,dt + d\omega_t. \tag{2.9}$$

Using superposition, (2.8), (2.9) can also be expressed as

$$d\phi_t^1 = E\phi_t^1\,dt + G\,dt_t \tag{2.10}$$

$$d\phi_t^2 = E\phi_t^2\,dt + Bu_t\,dt \tag{2.11}$$

$$d\phi_t^3 = E\phi_t^3\,dt + (K-G)\,d\omega_t \tag{2.12}$$

$$dy_t = C[\phi_t^1\,dt + \phi_t^2\,dt + \phi_t^3\,dt] + d\omega_t. \tag{2.13}$$

Since y_t is a scalar, we have that $C(sI-E)^{-1}B = B^T(sI-E^T)^{-1}C^T$, etc. Hence (2.10) to (2.13) can be rewritten as

$$d\phi_t^y = E^T\phi_t^y\,dt + C^T\,dy_t \tag{2.14}$$

$$d\phi_t^u = E^T\phi_t^u\,dt + C^Tu_t\,dt \tag{2.15}$$

$$d\phi_t^\omega = E^T\phi_t^\omega\,dt + C^T\,d\omega_t \tag{2.16}$$

$$dy_t = [G^T\phi_t^y + B^T\phi_t^u + (K-G)^T\phi_t^\omega]\,dt + d\omega_t. \tag{2.17}$$

In (2.14)-(2.16) we choose $\phi_0^y = 0$, $\phi_0^u = 0$, and ϕ_0^ω such that

$$(K-G)^T\phi_0^\omega = Cx_0. \tag{2.18}$$

Equation (2.17) is in the form of a linear regression, i.e.,

$$dy_t = \phi_t^T\theta\,dt + d\omega_t \tag{2.19}$$

where

$$\phi_t^T = [(\phi_t^y)^T, (\phi_t^u)^T, (\phi_t^\omega)^T] \tag{2.20}$$

$$\theta^T = [G^T, B^T, (K-G)^T] = [G^T, B^T, F^T]. \tag{2.21}$$

Note that ϕ_t does not depend on the unknown system parameters since E is known. Thus, (2.14)-(2.16) simply represent a state space form of the usual regression vector as in [2] and [9]. To make the comparison with the regression vector formulations more complete, we might note that with $\rho \triangleq (d/dt)$ we have, with some abuse of notation and ignoring initial conditions,

$$(\phi_t^u)^T = \left[\frac{\rho^{n-1}}{E(\rho)}u, \cdots, \frac{1}{E(\rho)}u\right] \tag{2.22}$$

and similarly for ϕ_t^y, ϕ_t^ω. In the following, however, we will use the rigorous state space formulation as outlined earlier.

3. Pseudolinear regression estimation algorithm. The model (2.14)-(2.17) is not quite in a form that is suitable for parameter estimation. This is because the component ϕ_t^ω depends on the unmeasured noise source ω_t. Thus, as in the discrete case [1]-[3], [13], we define the predicted output by a pseudoregression in which $d\omega_t$ is replaced by the prediction error. Thus we define

$$d\hat{y}_t = \psi_t^T\hat{\theta}_t\,dt \tag{3.1}$$

where $\hat{\theta}_t$ is some bounded $\mathcal{F}_t$-measurable function. Later in this section we will define $\hat{\theta}_t$ as an estimate of θ using a stochastic differential equation driven by the data y_t, u_t. Also, in (3.1) we have

$$\psi_t^T = [(\psi_t^y)^T, (\psi_t^u)^T, (\psi_t^e)^T] \tag{3.2}$$

$$d\psi_t^y = E^T\psi_t^y\,dt + C^T\,dy_t \tag{3.3}$$

$$d\psi_t^u = E^T\psi_t^u\,dt + C^Tu_t\,dt \tag{3.4}$$

$$d\psi_t^e = E^T\psi_t^e\,dt + C^T\,de_t \tag{3.5}$$

$$de_t = dy_t - d\hat{y}_t = dy_t - \psi_t^T\hat{\theta}_t\,dt. \tag{3.6}$$

It is assumed that $\psi_0 = 0$ and that $\hat{\theta}_0$ is $\mathscr{F}_0$-measurable. With this choice of initial conditions, $\psi_t^y = \phi_t^y$ and $\psi_t^u = \phi_t^u$ for $t \geqq 0$.

The effect of using pseudoregressions can be further clarified as follows. We define

$$\eta_t = \phi_t^T \theta - \psi_t^T \hat{\theta}_t. \tag{3.7}$$

We then obtain

$$de_t - d\omega_t = \eta_t \, dt. \tag{3.8}$$

Note that η_t is the "deterministic part" of the prediction error. Now let

$$\gamma_t \triangleq \psi_t^e - \phi_t^\omega. \tag{3.9}$$

Then from (3.5), (3.7), (2.16) we have

$$d\gamma_t = E^T \gamma_t \, dt + C^T \eta_t \, dt, \quad \text{with } \gamma_0 = -\phi_0^\omega. \tag{3.10}$$

Noting that

$$\psi_0^y = \phi_0^y = 0 \quad \text{and} \quad \psi_0^u = \phi_0^u = 0, \tag{3.11}$$

then

$$(K - G)^T \gamma_t = -(\phi_t - \psi_t)^T \theta. \tag{3.12}$$

In particular,

$$(K - G)^T \gamma_0 = -Cx_0. \tag{3.13}$$

Note that γ_0 cannot be made zero if x_0 is unknown, but we will assume that $\|\gamma_0\|^2$ is bounded; this is consistent with our assumption on x_0 and (3.13).

Denoting

$$\tilde{\theta}_t \triangleq \hat{\theta}_t - \theta \tag{3.14}$$

we then have from (3.12), (3.10) that

$$\eta_t = -(K - G)^T \gamma_t - \psi_t^T \tilde{\theta}_t \tag{3.15a}$$

where

$$d\gamma_t = (A - KC)^T \gamma \, dt + C^T(-\psi_t^T \tilde{\theta}_t) \, dt. \tag{3.15b}$$

We thus see that η_t is related to $-\psi_t^T \tilde{\theta}_t$ by the following transfer function equation

$$D(\rho)\eta_t = E(\rho)[-\psi_t^T \tilde{\theta}_t] \tag{3.16}$$

where $D(\rho)$ is the characteristic polynomial of the optimal Kalman filter for the system, i.e.,

$$D(\rho) = \rho^n + (k_{n-1} + a_{n-1})\rho^{n-1} + \cdots (k_0 + a_0) = \det(\rho I - A + KC) \tag{3.17}$$

and where $E(\rho)$ is as in (2.5).

As is standard in pseudoregression algorithms [3], we require that sufficient prior knowledge is available to choose the observer polynomial $E(\rho)$ so as to satisfy the following assumption.

Assumption 1. $D(\rho)$ is strictly Hurwitz and the filter $E(\rho)$ is chosen such that

(1) $\operatorname{Re} \sigma_i(E(\rho)) \leqq -\alpha < 0$, $i = 1, \cdots, n$ where $\sigma_i(E)$ are the roots of E.

(2) D/E is input strictly passive, i.e., there exists $\varepsilon > 0$ and $K > 0$ such that

$$\forall T > 0, \int_0^T y_\tau u_\tau \, d\tau \geqq \varepsilon \int_0^T u_\tau^2 \, d\tau - K\|\gamma_0\|^2 \tag{3.18}$$

where y_t is the output of the filter D/E driven by u_t.

We will later need the following technical result on input strictly passive systems.

LEMMA 3.1. *Let $H(s)$ be input strictly passive with impulse response h, and let $y=h_* u$. Let $r_t>0$ be monotonically nondecreasing. Then there exists $\varepsilon>0$ such that for all $T>0$ and all u_t:*

$$\int_0^T \frac{y_t u_t}{r_t}\,dt \geqq \varepsilon \int_0^T \frac{u_t^2}{r_t}\,dt - \frac{K\|\gamma_0\|^2}{r_0}. \tag{3.19}$$

Proof. The proof follows immediately from (3.18) on using the result in Appendix A. □

Motivated by the discrete-time algorithm given in [1], we next define the estimation algorithm as

$$d\hat{\theta}_t = \frac{\psi_t}{r_t}(dy_t - \psi_t^T\hat{\theta}_t\,dt) \tag{3.20}$$

where

$$r_t \triangleq \sup_{0\leqq\tau\leqq t} \psi_\tau^T\psi_\tau + \int_0^t \psi_\tau^T\psi_\tau\,d\tau + c_0; \qquad c_0>0 \tag{3.21}$$

and c_0 is any positive deterministic number. Note that $\hat{\theta}_t$ is obtained by an Ito integral which makes sense locally since (ψ_t/r_t) is $\mathcal{F}_t$-measurable and continuous.

The definition of r_t given above is not quite the analogue of that used in discrete time. We will discuss the reason for the difference later.

Noting that $d\theta=0$ and using the definition of e_t and η_t given in (3.6), (3.8), we observe from (3.14) and (3.20) that $\tilde{\theta}_t$ is the solution of the following stochastic differential equation

$$d\tilde{\theta}_t = \frac{\psi_t}{r_t}\eta_t\,dt + \frac{\psi_t}{r_t}\,d\omega_t. \tag{3.22}$$

In the following we will require that $\tilde{\theta}_t$ be bounded. We guarantee this by introducing a projection scheme as described below. We first introduce the following assumption.

Assumption 2. There exists a known parameter value θ_c and a positive number R_1 such that the true value θ lies inside $\mathcal{C}_1$ where

$$\mathcal{C}_1 = \{\theta: \|\theta-\theta_c\| \leqq R_1\}.$$

Let R_2 be another positive number larger than R_1. We then modify the parameter estimator to ensure that $\|\hat{\theta}_t-\theta_c\|<R_2$ for all t. We do this by using the following projection scheme.

Parameter estimator with projection. Let τ be a time for which the solution of (3.20) is such that $\|\hat{\theta}_\tau-\theta_c\|=R_2$. Denote the corresponding value of $\hat{\theta}_\tau$ by $\hat{\theta}_{\tau_-}$. At time τ, the estimate $\hat{\theta}_\tau$ is then defined as

$$\hat{\theta}_\tau \triangleq \theta_c + \frac{R_1}{R_2}(\dot{\hat{\theta}}_{\tau_-} - \theta_c). \tag{3.23}$$

For $t\geqq\tau$, (3.20) is then integrated with initial condition $\hat{\theta}_\tau$ defined by (3.23). This makes $\hat{\theta}_t$ right continuous at the projection times.

4. A general class of feedback control laws. We consider a general class of control laws in state feedback form:

$$u_t = -[l_{n-1},\cdots,l_0]\psi_t^u - [p_{n-1},\cdots,p_0]\psi_t^y + y^*. \tag{4.1}$$

This is equivalent to the feedback law

$$Q(\rho)u_t = -P(\rho)y_t + E(\rho)y_t^* \tag{4.2}$$

where

$$Q(\rho) = E(\rho) + L(\rho);\ L(\rho) = l_{n-1}\rho^{n-1} + \cdots + l_0;\ P(\rho) = p_{n-1}\rho^{n-1} + \cdots + p_0. \tag{4.3}$$

Note that the control law transfer function is $-P/Q$, which is strictly proper. Also, y_t^* denotes a bounded reference signal. For the moment, we make no assumptions about L, P stabilizing the system or whether the control law depends on the estimated parameters $\hat{\theta}$. To allow for the latter possibility, we express the control law as:

$$u_t = -[\hat{l}_{n-1}, \cdots, \hat{l}_0]\psi_t^u - [\hat{p}_{n-1}, \cdots, \hat{p}_0]\psi_t^y + y_t^*. \tag{4.4}$$

For the moment, the only restriction we place on the above general control law is that $\hat{l}_{n-1}, \cdots, \hat{l}_0, \hat{p}_{n-1}, \cdots, \hat{p}_0$ by Lipschitz functions of $\hat{\theta}$.

From the model (2.1), (2.2), the general controller (4.4), the definition of ψ_t ((3.2)-(3.5)), and the definition of the errors ((3.6)-(3.8)), we can write:

$$d\psi_t = A_t\psi_t\,dt + B_1(\eta_t\,dt + d\omega_t) + B_2 y_t^*\,dt \tag{4.5}$$

where

$$A_t = \left[\begin{array}{ccc|ccc|ccc}
-\hat{a}_{n-1} & \cdots & -\hat{a}_0 & \hat{b}_{n-1} & \cdots & \hat{b}_0 & \hat{f}_{n-1} & \cdots & \hat{f}_0 \\
 & & 0 & & & & & & \\
 & I_{n-1} & \vdots & & & & & & \\
\cdots & & 0 & \cdots & & \cdots & \cdots & & \cdots \\
\hline
-\hat{p}_{n-1} & \cdots & -\hat{p}_0 & -\hat{q}_{n-1} & \cdots & -\hat{q}_0 & 0 & \cdots & 0 \\
 & & & & & 0 & & & \\
 & & & & I_{n-1} & \vdots & & & \\
\cdots & & \cdots & \cdots & & 0 & \cdots & & \cdots \\
\hline
0 & \cdots & 0 & 0 & \cdots & 0 & -e_{n-1} & \cdots & -e_0 \\
 & & & & & & & & 0 \\
 & & & & & & & I_{n-1} & \vdots \\
\cdots & & \cdots & \cdots & & \cdots & \cdots & & 0
\end{array}\right] \tag{4.6a}$$

$$B_1^T = [10 \cdots 010 \cdots 0] \tag{4.6b}$$

$$B_2^T = [0 \cdots 010 \cdots 0] \tag{4.6c}$$

where B_1^T has 1's in the first and $(2n+1)$st positions and B_2^T has 1 in the $(n+1)$st position.

A key point about (4.5) is that A_t is a Lipschitz function of $\tilde{\theta}_t$ provided the general control law (4.2) is chosen in which $\hat{l}_{n-1}, \cdots, \hat{l}_0, \hat{p}_{n-1}, \cdots, \hat{p}_0$ are Lipschitz in $\tilde{\theta}$.

5. General properties of the estimation algorithm with feedback. We first address the question of existence and uniqueness [14] of the solution of the full set of equations describing the system and estimation algorithm. Combining (3.14), (3.22), and (4.5), the full set of equations is

$$d\psi_t = \left[A_t(\tilde{\theta}_t)\psi_t - B_1\psi_t^T\tilde{\theta}_t - B_1\int_0^t h_{t-\tau}\psi_\tau^T\tilde{\theta}_\tau\,d\tau\right]dt + B_1\,d\omega_t + B_2 y_t^*\,dt \tag{5.1a}$$

$$d\tilde{\theta}_t = \left[-\frac{\psi_t\psi_t^T}{r_t(\psi.)}\tilde{\theta}_t - \int_0^t h_{t-\tau}\frac{\psi_t\psi_\tau^T}{r_t(\psi.)}\tilde{\theta}_\tau\,d\tau\right]dt + \frac{\psi_t}{r_t(\psi.)}\,d\omega_t \tag{5.1b}$$

where $A_t(\tilde{\theta}_t) \equiv A_t(\hat{\theta}_t)$ and h_t is the impulse response of the strictly proper part of the transfer function E/D in (3.16).

We then have the following result.

LEMMA 5.1. *The composite set of* (5.1) *has a unique solution with continuous sample paths almost surely up to the random time T of the first explosion.* (*That is, T is the first time that either a component of ψ or $\tilde{\theta}$ becomes infinite or $T=\infty$.*)

Proof. We first note from (4.6a) that $A_t(\tilde{\theta}_t)$ is Lipschitz in $\tilde{\theta}_t$ due to the assumed form of the dependence of $\hat{l}_{n-1}, \cdots, \hat{l}_0, \hat{p}_{n-1}, \cdots, \hat{p}_0$ on $\hat{\theta}$. This implies that the coefficient vectors multiplying dt and $d\omega_t$ in (5.1) are locally Lipschitz with respect to the supremum norm on sample paths—see Appendix B (that is, given a compact set in the space of ψ_t, $\tilde{\theta}_t$, the functions are Lipschitz with constant depending on the choice of the set).

The result then follows from Theorems (14.18) and (14.20) of [20]. □

Note that Lemma 5.1 does not use the projection of the parameter estimates as described at the end of § 3. When this additional facet of the algorithm is included, we can strengthen Lemma 5.1 as follows.

LEMMA 5.2. *With the addition of the projection scheme* (3.23) *to* (5.1b), *then $\hat{\theta}_t$ remains in $\mathscr{C}_2$ for all t and the composite set of equations* (5.1) *has a unique solution almost surely with sample paths* (ψ_t, $\tilde{\theta}_t$) *which are continuous except at the projection times.*

Proof. Up to the time of the first projection, θ_t is bounded and thus (5.1a) is a linear time varying equation with bounded coefficients and hence ψ_t cannot become unbounded in a finite time. Hence the first projection occurs strictly before the explosion time T of Lemma 5.1 (unless both T and the first projection time are infinite).

After projection, we can apply Lemma 5.1 again and repeat the same argument. Hence due to the linearity of (5.1b) for given $\psi.$, $\tilde{\theta}_t$ exists, is unique and is bounded by the projection. Then (5.1a) is a linear equation with bounded coefficients, and hence ψ_t exists almost surely for all t. □

Lemma 5.2 provides the basic existence and uniqueness result necessary to establish the following result giving properties of the parameter estimator. This result does not depend on a priori boundedness of the system states. Note, however, that we have already established that $\tilde{\theta}_t$ and ψ_t/r_t are bounded.

THEOREM 5.1. *For the general class of feedback control laws described in* § 4 *and under Assumptions* 1 *and* 2, *the following properties hold for the model* ((2.1), (2.2)) *and the estimator* (3.20)-(3.21) *with the projection scheme* (3.23):

$$\text{(i)}\quad \limsup_{t\to\infty}\int_0^t \frac{\eta_\tau^2}{r_\tau}\,d\tau \leqq K_1 < \infty \qquad \textit{a.s.} \tag{5.2}$$

where K_1 is a random variable (*realisation dependent*).

(5.3) (ii) *For all finite* Δ, $\lim_{t\to\infty}\sup_{0\leqq T\leqq\Delta}\|\hat{\theta}_{t+T}-\hat{\theta}_t\| = 0$ *a.s.*

(iii) *There exists a finite random time t_R beyond which no further parameter projections occur.*

Proof. (a) Starting from (3.22) and using Ito's rule (see, e.g., [15]), we have that, between projections:

$$
\begin{aligned}
d(\tilde{\theta}_t^T\tilde{\theta}_t) &= 2\tilde{\theta}_t^T\frac{\psi_t}{r_t}(\eta_t\,dt+d\omega_t)+\sigma^2\frac{\|\psi_t\|^2}{r_t^2}\,dt \\
&= -\frac{2}{r_t}(-\tilde{\theta}_t^T\psi_t\eta_t-\varepsilon\eta_t^2)\,dt-2\varepsilon\frac{\eta_t^2}{r_t}\,dt+2\tilde{\theta}_t^T\frac{\psi_t}{r_t}\,d\omega_t+\sigma^2\frac{\|\psi_t\|^2}{r_t^2}\,dt
\end{aligned}
\tag{5.4}
$$

for some $\varepsilon>0$.

Note that from (3.23) and using Assumption 2, at the times of projection we have $\|\tilde{\theta}_t\|^2 \leqq \|\tilde{\theta}_{t_-}\|^2-(R_2-R_1)^2$.

Defining $\xi_t \triangleq -\tilde{\theta}_t^T\psi_t\eta_t-\varepsilon\eta_t^2$ where ε is as in Assumption 1, integrating (5.4) and accounting for projections yields

$$
\begin{aligned}
\tilde{\theta}_t^T\tilde{\theta}_t \leqq \tilde{\theta}_s^T\tilde{\theta}_s &-2\int_s^t\frac{\xi_\lambda}{r_\lambda}\,d\lambda-2\varepsilon\int_s^t\frac{\eta_\lambda^2}{r_\lambda}\,d\lambda+2\int_s^t\tilde{\theta}_\lambda^T\frac{\psi_\lambda}{r_\lambda}\,d\omega_\lambda \\
&+\int_s^t\sigma^2\frac{\|\psi_\lambda\|^2}{r_\lambda^2}\,d\lambda - N_{t,s}(R_2-R_1)^2
\end{aligned}
\tag{5.5}
$$

where $N_{t,s}$ is the number of times that projections occur between times s and t. Consider now the integral

$$\int_0^t\frac{\|\psi_\lambda\|^2}{r_\lambda^2}\,d\lambda.$$

We have, using (3.21),

$$\int_0^t\frac{\|\psi_\lambda\|^2}{r_\lambda^2}\,d\lambda \leqq \int_0^t\frac{dr_\lambda}{r_\lambda^2}=\frac{1}{r_0}-\frac{1}{r_t}\leqq\frac{1}{r_0}=\frac{1}{c_0}. \tag{5.6}$$

(This operation makes makes sense due to Bonnet's and Du Bois-Reymond's formulae [21] which allow the integral to be considered as a Riemann integral.) We now define $\mathscr{X}_t$ as the solution of the Ito integral

$$d\mathscr{X}_t=\frac{2\tilde{\theta}_t^T\psi_t}{r_t}\,d\omega_t,\qquad \mathscr{X}_0=\frac{\sigma^2}{c_0}+\frac{2K\|\gamma_0\|^2}{r_0}+\tilde{\theta}_0^T\tilde{\theta}_0. \tag{5.7}$$

This integral makes sense thanks to (5.6) and Lemma 5.2. Since c_0, r_0, γ_0, and $\tilde{\theta}_0$ are $\mathscr{F}_0$-measurable, $(\mathscr{X}_t, \mathscr{F}_t)$ is a martingale. Moreover it follows from (5.5) and (5.6) that $\mathscr{X}_t$ satisfies

$$
\begin{aligned}
\mathscr{X}_t \geqq \tilde{\theta}_t^T\tilde{\theta}_t &+2\int_0^t\frac{\xi_\lambda}{r_\lambda}\,d\lambda+2\varepsilon\int_0^t\frac{\eta_\lambda^2}{r_\lambda}\,d\lambda+\frac{\sigma^2}{c_0}-\int_0^t\sigma^2\frac{\|\psi_\lambda\|^2}{r_\lambda^2}\,d\lambda+\frac{2K\|\gamma_0\|^2}{r_0} \\
&+N_{t,0}[R_2-R_1]^2
\end{aligned}
\tag{5.8}
$$

and is positive in view of Lemma 3.1 and (5.6). Thus $(\mathscr{X}_t, \mathscr{F}_t)$ is a positive martingale and hence

$$\lim_{t\to\infty}\mathscr{X}_t=\mathscr{X}<\infty \qquad \text{a.s.} \tag{5.9}$$

Using (5.9) and noting (5.6) and Lemma 3.1, we conclude that (5.2) holds for some finite random variable K_1.

This establishes (i). Also, since $R_2 > R_1$, then from (5.8), (5.9) $N_{t,0}$ is bounded almost surely. Hence (iii) follows.

(b) Now let $t \geqq t_R$. Then from (3.22) we can write, using $\|x+y\|^2 \leqq 2\|x\|^2 + 2\|y\|^2$,

$$\begin{aligned}\|\tilde{\theta}_{t+T}-\tilde{\theta}_t\|^2 &\leqq 2\left\{\left\|\int_t^{t+T}\frac{\psi_\tau\eta_\tau}{r_\tau}\,d\tau\right\|^2+\left\|\int_t^{t+T}\frac{\psi_\tau}{r_\tau}\,d\omega_\tau\right\|^2\right\}\\ &\leqq 2T\int_t^{t+T}\frac{\|\psi_\tau\|^2}{r_\tau^2}\eta_\tau^2\,d\tau+2\left\|\int_t^{t+T}\frac{\psi_\tau}{r_\tau}\,d\omega_\tau\right\|^2.\end{aligned} \tag{5.10}$$

The last inequality is obtained by applying the Schwartz inequality. We consider the two terms of the right-hand side of (5.10) separately.

Consider a realization for which (i) holds. Thus, given $\varepsilon > 0$, $\Delta > 0$ there exists a $t_0(\Delta, \varepsilon)$ such that for all $t \geqq t_0$

$$\int_t^{t+T}\frac{\eta_\tau^2}{r_\tau}\,d\tau \leqq \frac{1}{4}\frac{\varepsilon^2}{\Delta} \quad \forall t \geqq t_0 \quad \text{and} \quad 0 \leqq T \leqq \Delta. \tag{5.11}$$

Since $(\|\psi_\tau\|^2/r_\tau) \leqq 1$ by our definition (3.21) of r_τ, it follows that

$$2T\int_t^{t+T}\frac{\|\psi_\tau\|^2}{r_\tau^2}\eta_\tau^2\,d\tau \leqq \frac{1}{2}\varepsilon^2 \quad \forall t \geqq t_0 \quad \text{and} \quad \forall\, T \in [0, \Delta] \tag{5.12}$$

and hence

$$\limsup_{t\to\infty}\ \sup_{0\leqq T\leqq\Delta} 2T\int_t^{t+T}\frac{\|\psi_\tau\|^2}{r_\tau^2}\eta_\tau^2\,d\tau = 0. \tag{5.13}$$

Since (i) holds almost surely, so does (5.13). The result then follows using part (a) of Lemma C.1 (Appendix C) for the second term on the right-hand side of (5.10). □

To make use of the result in Theorem 5.1, we will need the following continuous-time Kronecker lemma. Since we have been unable to find a proof in the literature for this continuous-time version, we supply one in Appendix D. It parallels the discrete-time proof given in [2].

LEMMA 5.3 (Continuous-time Kronecker Lemma). *Assume that*

(A.1) $S_t = \int_0^t x_\tau\,d\tau$ *converges to* $S < \infty$ *as* $t \to \infty$.

(A.2) $b_t > 0$ *is monotone nondecreasing and* $\lim_{t\to\infty} b_t = \infty$.

Then

$$\lim_{t\to\infty}\frac{1}{b_t}\int_0^t b_\tau x_\tau\,d\tau = 0.$$

Proof. For the proof see Appendix D.

We now prove a continuous time equivalent of the discrete-time key technical lemma given in [1], [2].

LEMMA 5.4. *Consider a realisation produced by the model* (2.1)–(2.2). *Suppose the estimator is such that*

$$\limsup_{t\to\infty}\int_0^t\frac{\eta_\tau^2}{r_\tau}\,d\tau \leqq K_1 < \infty \tag{5.14}$$

and the controller is such that the following growth condition is satisfied:

$$\frac{r_t}{t} \leqq C + \frac{K_2}{t}\int_0^t \eta_\tau^2\,d\tau \tag{5.15}$$

where r_t, η_t are as defined before and C, K_2 are finite positive constants. Then

$$(5.16) \qquad \text{(i)} \ \limsup_{t\to\infty} \frac{r_t}{t} \leqq K_3 < \infty$$

$$(5.17) \qquad \text{(ii)} \ \lim_{t\to\infty} \frac{1}{t} \int_0^t \eta_\tau^2 \, d\tau = 0.$$

Proof. (i) From (5.15) and the nonnegativity of η_τ^2 and r_τ it follows that

$$\frac{r_t}{t} \leqq C + K_2 \int_0^t \frac{\eta_\tau^2}{r_\tau} \frac{r_\tau}{\tau} \, d\tau.$$

The result then follows from the Bellman-Gronwall lemma (see e.g., [17]) using (5.14):

(ii) Suppose first that $\lim_{t\to\infty} r_t = \infty$. Then, by the Kronecker Lemma 5.3:

$$(5.18) \qquad \lim_{t\to\infty} \frac{1}{r_t} \int_0^t \eta_\tau^2 \, d\tau = 0.$$

Hence, using (5.16) and (5.18)

$$(5.19) \qquad \lim_{t\to\infty} \frac{1}{t} \int_0^t \eta_\tau^2 \, d\tau = \lim_{t\to\infty} \frac{r_t}{t} \frac{1}{r_t} \int_0^t \eta_\tau^2 \, d\tau = 0.$$

Alternatively, if $\lim_{t\to\infty} r_t \leqq K_4 < \infty$ for some K_4, then

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t \eta_\tau^2 \, d\tau \leqq \lim_{t\to\infty} \frac{1}{t} \frac{K_4}{r_t} \int_0^t \eta_\tau^2 \, d\tau$$

$$\leqq \lim_{t\to\infty} \frac{K_4}{t} \int_0^t \frac{\eta_\tau^2}{r_\tau} \, d\tau = 0$$

using (5.2). The last inequality follows from the monotonicity of r_τ. □

Comment 5.1. A key feature of our estimator is our choice of r_t (see (3.21)). It guarantees that $(\|\psi_t\|^2/r_t) \leqq 1$ for all t, and this is crucial in establishing (5.2). In [5], [6] the equivalent term to r_t is defined as $r_t = \int_0^t \psi_\tau^T \psi_\tau \, d\tau$ and, as a consequence, all the convergence proofs require the assumption that $(\|\psi_t\|^2/r_t)$ is almost surely bounded. This assumption is rather unrealistic given that ψ_t contains signals driven by white noise.

Comment 5.2. Comparing the properties of our estimator with those proved for the continuous-time deterministic algorithms in [9], we observe that we have not proved the uniform boundedness of $(\eta_t/r_t^{1/2})$ or of something like $\dot{\hat{\theta}}$; neither have we proved $\dot{\hat{\theta}} \in L_2$. The uniform boundedness of $(\eta_t/r_t^{1/2})$ is not needed in the subsequent analysis $((\eta_t/r_t^{1/2}) \in L_2$ suffices). As for $\dot{\tilde{\theta}}$, it does not exist in our stochastic framework, but the conditions on $\dot{\tilde{\theta}}$ in [9] are replaced by the weaker condition of (5.3).

Comment 5.3. The remaining step in the development is to verify the growth condition (5.15). This will require us to impose additional constraints on the general feedback law described in § 4. In particular, we will choose the feedback so as to stabilize the (frozen) estimated model.

6. Boundedness of the system states. Finally we show that, provided the feedback control law is appropriately chosen as a function of $\hat{\theta}$, then the adaptive law stabilizes the system in the sense that all system states and the input are mean square bounded almost surely.

The proofs given below depend upon the fact that the certainty equivalence control law stabilize the frozen *estimated* model. This is true of a wide class of algorithms. However, to be specific, we will illustrate the analysis procedure by considering adaptive pole assignment. In this algorithm the polynomials $\hat{L}$ and $\hat{P}$ defining the control law are computed from the estimated $\hat{A}(\hat{\theta}_t)$ and $\hat{B}(\hat{\theta}_t)$ as follows.

Let

$$\hat{\theta} = [\hat{g}_{n-1}, \cdots, \hat{g}_0, \hat{b}_{n-1}, \cdots, \hat{b}_0, \hat{f}_{n-1}, \cdots, \hat{f}_0]$$

and define (cf. (2.6), (2.21))

$$\begin{aligned} &\hat{a}_i = e_i - \hat{g}_i; \qquad i = 0, \cdots, n-1 \\ &\hat{A}(\rho) = \rho^n + \hat{a}_{n-1}\rho^{n-1} + \cdots + \hat{a}_0 \\ &\hat{B}(\rho) = \hat{b}_{n-1}\rho^{n-1} + \cdots + \hat{b}_0 \\ &\hat{F}(\rho) = \hat{f}_{n-1}\rho^{n-1} + \cdots + \hat{f}_0. \end{aligned}$$

Then, for a given possibly time varying A^* of degree $2n$, solve the following equation for $\hat{Q}$ and $\hat{P}$:

$$\hat{Q}\hat{A} + \hat{P}\hat{B} = A^* \quad \text{with} \quad \operatorname{Re} \lambda_i(A^*) \leqq -\beta < 0, \qquad i = 1, \cdots, 2n \tag{6.1}$$

where $\lambda_i(A^*)$ are the eigenvalues of the polynomial A^*. Finally compute

$$\hat{L}(\rho) = \hat{Q}(\rho) - E(\rho).$$

Equation (6.1) can also be written

$$M(\hat{\theta}) \begin{bmatrix} \hat{q}_0 \\ \vdots \\ \hat{q}_{n-1} \\ \hat{p}_0 \\ \vdots \\ \hat{p}_{n-1} \end{bmatrix} = \begin{bmatrix} a_0^* \\ \vdots \\ \vdots \\ \vdots \\ a_{2n-1}^* \end{bmatrix}. \tag{6.2}$$

The polynomial A^* is a design polynomial available to the user. The only restriction we require on the polynomial $A^*(t)$ is seen in the following assumption.

Assumption 3. For all t, the polynomial $A^*(t)$ is continuous and bounded, has a uniform stability margin (i.e., $\operatorname{Re} \lambda_i(A^*(t)) \leqq -\beta < 0$, $i = 1, \cdots, 2n$), and $\lim_{t\to\infty} \sup_{0 \leqq T \leqq \Delta} \|a^*(t+T) - a^*(t)\| = 0$ for some $\Delta > 0$, where a^* is the vector of coefficients of A^*.

As in § 4, we also require that $\hat{L}$, $\hat{P}$ be Lipschitz functions of $\hat{\theta}$ for all time. We note that the projection facility (3.23) ensures that $\hat{\theta} \in \mathscr{C}_2$ for all time. Then, the Lipschitz condition is guaranteed provided all models corresponding to $\hat{\theta} \in \mathscr{C}_2$ are uniformly stabilizably. This assumption appears in all contemporary treatments of indirect adaptive control (see, for example, [2], [10], [19]). We remark that this assumption can be eliminated in the case of direct adaptive control of stably invertible systems. However, this is only achieved at the expense of a much more complex stability proof (see [9], [22]) which necessarily builds on the result presented here. For the case of indirect adaptive pole assignment we introduce the following additional assumption.

Assumption 4. Assumption 2 is satisfied and there exists a known positive constant ε such that for all θ_t in $\mathscr{C}_2$,

$$\det M(\theta_t) \geqq \varepsilon.$$

Subject to Assumption 4, the projection scheme ensures that $\det M(\hat{\theta}_t) \geqq \varepsilon$ for all t. In view of (6.2) this will ensure that $\hat{L}$, $\hat{P}$ are Lipschitz functions of $\hat{\theta}$ as required.

We next establish that, for the above adaptive control law, the homogeneous part of (4.5) is exponentially stable.

LEMMA 6.1. *Consider the differential equation*

$$\frac{d}{dt}\psi_t = A_t\psi_t$$

with A_t given by (4.6a). *Assume that the $\hat{a}_i$, $\hat{b}_i$, $\hat{f}_i$ are estimated using the parameter estimator of* § 3 *including the projection scheme* (3.23) *and that Assumptions* 1–4 *hold. Then* (6.1) *is exponentially stable almost surely.*

Proof. We have shown in Theorem 5.1 that there exists a random time t_R beyond which no further projections occur. Thus, for $t > t_R$ $\hat{\theta}_t$ is sample continuous from Lemma 5.2. Therefore $\hat{A}$, $\hat{B}$, $\hat{F}$ are sample continuous and, by Assumption 4, $\hat{Q}$ and $\hat{P}$ are sample continuous given that $\hat{q}_i$ and $\hat{p}_i$ can be written as the solution of the linear system (6.2) or $M(\hat{\theta})\hat{c} = a^*$, where the elements of M are either zero or $\hat{a}_i$, $\hat{b}_j$. For the same reason, A_t is uniformly bounded. The eigenvalues of A_t are the roots of $E(s)$ and the $2n$ roots of $\hat{A}^*$; therefore, by Assumptions 1 and 3 $\operatorname{Re} \lambda_i(A_t) \leqq -\delta < 0$, $i = 1, \cdots, 3n$, for all t, where $\delta \triangleq \min(\alpha, \beta)$. Finally,

$$M(\hat{\theta}_t)[\hat{c}_{t+T} - \hat{c}_t] + [M(\hat{\theta}_{t+T}) - M(\hat{\theta}_t)]\hat{c}_{t+T} = a^*_{t+T} - a^*_t.$$

Therefore, by the triangle inequality,

$$\|\hat{c}_{t+T} - \hat{c}_t\| \leqq \|M^{-1}(\hat{\theta}_t)\| \{\|M(\hat{\theta}_{t+T}) - M(\hat{\theta}_t)\| \cdot \|\hat{c}_{t+T}\| + \|a^*_{t+T} - a^*_t\|\}.$$

Hence, using (5.3) and Assumption 3 it follows that

$$\lim_{t\to\infty} \sup_{0 \leqq T \leqq \Delta} \|A_{t+T} - A_t\| = 0 \quad \text{a.s. for some } \Delta > 0. \tag{6.3}$$

The result then follows from Lemma 3 of [10]. □

We now establish the main result of this paper.

THEOREM 6.1. *Consider the system* ((2.1), (2.2)), *with the parameter vector θ satisfying Assumption* 2, *the parameter estimator of* § 3 *with projection, an observer polynomial E satisfying Assumption* 1, *and an adaptive pole assignment control law of the form* (4.2), (6.1) *satisfying Assumptions* 3 *and* 4. *Then, for arbitrary finite initial conditions and an arbitrary, piecewise continuous, uniformly bounded reference input y^*_t, the following results hold*:

(i) $\displaystyle \limsup_{t\to\infty} \frac{1}{t}\int_0^t \|\psi_\tau\|^2 \, d\tau < \infty$ *a.s.*

(ii) $\displaystyle \limsup_{t\to\infty} \frac{1}{t}\int_0^t u_\tau^2 \, d\tau < \infty$ *a.s.*

(iii) $\displaystyle \limsup_{t\to\infty} \frac{1}{t}\int_0^t |Cx_\tau|^2 \, d\tau < \infty$ *a.s.*

Proof. (i) We first establish (5.15), i.e., that there exist finite random variables C and K such that:

$$\frac{r_t}{t} \leqq C + \frac{K}{t}\int_0^t \eta_\tau^2 \quad \text{a.s.}$$

Now by definition

$$r_t \triangleq \sup_{0 \leqq \tau \leqq t} \|\psi_\tau\|^2 + \int_0^t \|\psi_\tau\|^2 \, d\tau + c_0. \tag{6.4}$$

From (4.5)

$$\psi_t = \phi(t,0)\psi_0 + \int_0^t \phi(t,\tau)B_1\eta_\tau\,d\tau + \int_0^t \phi(t,\tau)B_2 y_\tau^*\,d\tau + \int_0^t \phi(t,\tau)B_1\,d\omega_\tau$$

$$= \psi_t^{(1)} + \psi_t^{(2)} \tag{6.5}$$

where $\psi_t^{(1)}$ is the sum of the first three terms, $\psi_t^{(2)}$ is the last term and $\phi(t,\tau)$ denotes the state transition matrix for (4.5). Because ϕ is exponentially stable by Lemma 6.1 and y_τ^* is uniformly bounded, it follows using the Cauchy-Schwartz inequality that there exist finite constants K_1 and K_2 such that

$$\|\psi_t^{(1)}\|^2 \leqq K_1 + K_2 \int_0^t \eta_\tau^2\,d\tau \tag{6.6}$$

for all t. Also, by Lemma C.2

$$\frac{1}{t}\|\psi_t^{(2)}\|^2 \to 0 \quad \text{a.s.} \tag{6.7}$$

as $t \to \infty$.

Similarly, using a continuous-time version of the proof of Lemma B.3.3 in [2], it follows that there exist finite constants K_3 and K_4 such that

$$\int_0^t \|\psi_\tau^{(1)}\|^2\,d\tau \leqq K_3 + K_4 \int_0^t \eta_\tau^2\,d\tau \tag{6.8}$$

for all t. Finally, by Lemma C.2,

$$\limsup_{t\to\infty} \frac{1}{t}\int_0^t \|\psi_\tau^{(2)}\|^2\,d\tau \leqq K_5 < \infty \quad \text{a.s.} \tag{6.9}$$

Combining (6.6) to (6.9) we obtain

$$\begin{aligned}\frac{r_t}{t} &= \frac{1}{t}\sup_{0\leqq\tau\leqq t}\|\psi_\tau\|^2 + \frac{1}{t}\int_0^t \|\psi_\tau\|^2\,d\tau + \frac{c_0}{t}\\ &\leqq \frac{1}{t}\max\left[\sup_{0\leqq\tau\leqq 1}\|\psi_\tau\|^2,\ \sup_{1\leqq\tau\leqq t}\|\psi_\tau\|^2\right] + \frac{1}{t}\int_0^t \|\psi_\tau\|^2\,d\tau + \frac{c_0}{t}\\ &\leqq K_6 + \frac{K_7}{t}\int_0^t \eta_\tau^2\,d\tau \quad \text{a.s.}\end{aligned} \tag{6.10}$$

Thus, we have established (5.15) so that, by Lemma 5.4, there exists a finite K_8 such that

$$\frac{r_t}{t} \leqq K_8 \quad \text{a.s.} \tag{6.11}$$

It follows from the definition of r_t that

$$\limsup_{t\to\infty} \frac{1}{t}\int_0^t \|\psi_\tau\|^2\,dt < \infty \quad \text{a.s.,} \tag{6.12}$$

which establishes part (i) of the theorem.

(ii) Since $u_t = \hat{\xi}_t\psi_t + y_t^*$, where $\hat{\xi}_t$ is a vector whose components are $\{\hat{p}_i\}$ and $\{\hat{l}_i\}$ (see (4.4) and the definition of ψ_t) it follows from (6.10) and the boundedness of $\{\hat{p}_i\}$ and $\{\hat{l}_i\}$ that

$$\limsup_{t\to\infty} \frac{1}{t}\int_0^t u_\tau^2\,d\tau < \infty \quad \text{a.s.} \tag{6.13}$$

which establishes part (ii) of the theorem.

(iii) From (2.9), (2.19), (3.7), and (3.8) we have

$$Cx_t = \psi_t^T \hat{\theta}_t + \eta_t. \tag{6.14}$$

Therefore, since $\hat{\theta}_t$ is bounded, $\lim_{t\to\infty} \sup (1/t) \int_0^t \eta_t^2 \, d\tau = 0$, (Lemma 5.4) and $\lim_{t\to\infty} \sup (1/t) \int_0^t \|\psi_\tau\|^2 \, d\tau < \infty$ almost surely (see (6.12)), it follows that

$$\limsup_{t\to\infty} \frac{1}{t} \int_0^t [Cx_t]^2 \, dt < \infty \quad \text{a.s.} \tag{6.15}$$

which establishes part (iii) of the theorem. □

Comment 6.1. Note that Cx_t is the "deterministic part" of the output. Thus, (6.15) establishes that this part of the output is sample mean square bounded. This is all that can be said about the output since it contains a Wiener process.

Comment 6.2. The proof of Theorem 6.1 relies on the now standard argument on robustness of bounded solutions of exponentially stable linear time varying systems.

7. Conclusions. This paper has analyzed a class of continuous-time stochastic adaptive control algorithms and has shown that, under suitable conditions, they will almost surely ensure global boundedness of all the internal variables, in a sample mean square sense. Previous results in the same direction relied upon an assumption on the normalized regression vector which, in fact, meant that the noise driving the system was wide band but bounded. Moreover, the systems described in previous works were of relative degree zero.

The results described in this paper are thus believed to constitute the first complete and rigorous analysis of a realistic continuous time stochastic adaptive control algorithm.

The main result is a boundedness result that states that the deterministic part of the output remains almost surely bounded in the sample mean square sense. No tracking property is achieved, but the analysis described here has recently been extended to a model reference control algorithm yielding a result on the asymptotic tracking error [22], which is analogous to the discrete-time tracking error result established in [1].

Appendix A.

LEMMA A.1. *Let r_τ be a nondecreasing function with $r_0 > 0$. Then*

$$\int_0^T f_\tau \, d\tau \geqq -K; \qquad K > 0, \quad \forall T \geqq 0 \tag{A.1}$$

implies

$$\int_0^T \frac{f_\tau}{r_\tau} \, d\tau \geqq -\frac{K}{r_0}; \quad \forall T \geqq 0. \tag{A.2}$$

Proof. Let $\rho_\tau = (1/r_\tau)$, $\tau \geqq 0$, and denote $F_t = \int_0^t f_\tau \, d\tau + K$. Then, by integration by parts:

$$\int_0^T f_\tau \rho_\tau \, d\tau = \rho_T F_T + \left\{ -\int_0^T F_\tau \, d\rho_\tau \right\} - \rho_0 K.$$

The first term is nonnegative because $\rho_T > 0$ and $F_T \geqq 0$. The second term is also nonnegative because $F_\tau \geqq 0$, for all $\tau \geqq 0$ by (A.1), and $d\rho_\tau \leqq 0$ since ρ_τ is nonincreasing. □

Appendix B.

LEMMA B.1. *The coefficient vectors in* (5.1) *are locally Lipschitz with respect to the supremum norm on the sample paths ψ_t, $\tilde{\theta}_t$.*

Proof. We consider (5.1a), (5.1b) separately. Equation (5.1a) has the form:

$$d\psi_t = f_1(t, \tilde{\theta}_\cdot, \psi_\cdot)\,dt + B_1\,d\omega_t + B_2 y_t^*\,dt \tag{B.1}$$

where

$$f_1(t, \tilde{\theta}_\cdot, \psi_\cdot) = \left[A_t(\tilde{\theta}_t)\psi_t - B_1\psi_t^T\tilde{\theta}_t - B_1\int_0^t h_{t-\tau}\psi_\tau^T\tilde{\theta}_\tau\,d\tau\right]. \tag{B.2}$$

We then have, by the triangle inequality,

$$\begin{aligned}
&\|f_1(t, \tilde{\theta}_\cdot^1, \psi_\cdot^1) - f_1(t, \tilde{\theta}_\cdot^2, \psi_\cdot^2)\| \\
&\leqq \|A_t(\tilde{\theta}_t^1)\psi_t^1 - A_t(\tilde{\theta}_t^2)\psi_t^2\| + \|-B_1(\psi_t^1)^T\tilde{\theta}_t^1 + B_1(\psi_t^2)^T\tilde{\theta}_t^2\| \\
&\quad + \left\|-B_1\int_0^t h_{t-\tau}\left[(\psi_\tau^1)^T\tilde{\theta}_\tau^1 - (\tilde{\psi}_\tau^2)^T\tilde{\theta}_\tau^2\right]d\tau\right\| \\
&\leqq \|A_t(\tilde{\theta}_t^1) - A_t(\tilde{\theta}_t^2)\|\ \mathrm{Max}\,(\|\psi_t^1\|, \|\psi_t^2\|) \\
&\quad + \mathrm{Max}\,(\|A_t(\tilde{\theta}_t^1)\|, \|A_t(\tilde{\theta}_t^2)\|)\|\psi_t^1 - \psi_t^2\| + \|B_1\|\,\|\psi_t^1 - \psi_t^2\|\ \mathrm{Max}\,(\|\tilde{\theta}_t^1\|, \|\tilde{\theta}_t^2\|) \\
&\quad + \|B_1\|\ \mathrm{Max}\,(\|\psi_t^1\|, \|\psi_t^2\|)\|\tilde{\theta}_t^1 - \tilde{\theta}_t^2\| + \|B_1\|\left(\int_0^t |h_{t-\tau}|\,d\tau\right)
\end{aligned} \tag{B.3}$$

$$\begin{aligned}
&\left\{\sup_{0\leqq\tau\leqq t}\|\psi_\tau^1 - \psi_\tau^2\|\ \sup_{0\leqq\tau\leqq t}\mathrm{Max}\,(\|\tilde{\theta}_\tau^1\|\cdot\tilde{\theta}_\tau^2\|)\right. \\
&\left.\quad + \sup_{0\leqq\tau\leqq t}\mathrm{Max}\,(\|\psi_\tau^1\|, \|\psi_\tau^2\|)\ \sup_{0\leqq\tau\leqq t}\|\tilde{\theta}_\tau^1 - \tilde{\theta}_\tau^2\right\} \\
&\leqq K_n\left\{\sup_{0\leqq\tau\leqq t}\|\psi_\tau^1 - \psi_\tau^2\| + \sup_{0\leqq\tau\leqq t}\|\tilde{\theta}_\tau^1 - \tilde{\theta}_\tau^2\|\right\}
\end{aligned} \tag{B.4}$$

where the last line follows since $A_t(\tilde{\theta}_t)$ is Lipschitz in $\tilde{\theta}_t$ and since $\int |h_{t-\tau}|\,d\tau < \infty$ by the exponential stability of $(E-D)/D$. In (B.4), the notation K_n indicates that the Lipschitz constant depends on the maximum values of ψ, $\tilde{\theta}$ in the compact set defining the local conditions.

For (5.1b) the proof is similar on noting that, by the Cauchy-Schwartz inequality,

$$\frac{|\psi_t^T\psi_{t-\tau}|}{r_t} \leqq \frac{|\psi_t^T\psi_t|^{1/2}|\psi_{t-\tau}^T\psi_{t-\tau}|^{1/2}}{r_t} \tag{B.5}$$

and that

$$\frac{|\psi_t^T\psi_t|}{r_t} \leqq 1 \quad\text{and}\quad \frac{|\psi_{t-\tau}^T\psi_{t-\tau}|}{r_t} \leqq 1 \quad \text{by definition of } r_t. \qquad \square$$

Appendix C.

LEMMA C.1 ("In-flight Lemma"). *Let* $S_t = \int_0^t h(\tau)\,d\omega_\tau$. *Assume that*

(C.1)
(i) $h(\tau)$ *is* $\mathcal{F}_s$ *measurable for* $\tau \leqq s$, *and*
(ii) $\int_0^\infty \|h(\tau)\|^2\,d\tau \leqq K < \infty$ a.s.
where K *is* $\mathcal{F}_0$*-measurable.*

Then

(C.2)
(a) *given* $\Delta > 0$,
$\lim_{t\to\infty}\sup_{0\leqq\tau\leqq\Delta}\|S_{t+\tau} - S_t\|^2 = 0$ a.s.
(b) $\|S_t\|^2$ *converges to a finite limit* a.s.

Proof. (a) Take any $t_0 \in [0, \Delta)$ and partition the positive real line in intervals of length Δ: $0, t_0, t_0+\Delta, t_0+2\Delta, \cdots$. Define

$$L_j(t_0) = \sup_{T \in [0,\Delta]} \|S_{t_0+(j-1)\Delta+T} - S_{t_0+(j-1)\Delta}\|^2; \qquad j = 1, 2, \cdots \tag{C.3}$$

and let

$$T_j(t_0) = \arg\left\{ \sup_{T \in [0,\Delta]} \|S_{t_0+(j+1)\Delta+T} - S_{t_0+(j-1)\Delta}\|^2 \right\}. \tag{C.4}$$

Also define

$$J_n(t_0) = \sum_1^n L_j + K - \sum_{j=1}^n \int_{t_0+(j-1)\Delta}^{t_0+(j-1)\Delta+T_j} \|h(\tau)\|^2 \, d\tau; \qquad n = 1, 2, \cdots. \tag{C.5}$$

Then, by assumption (i), we have

$$\begin{aligned} E\{J_{n+1}(t_0) \mid \mathscr{F}_n\} &= J_n(t_0) + E\{L_{n+1}(t_0) \mid \mathscr{F}_n\} - E\left\{ \int_{t_0+n\Delta}^{t_0+n\Delta+T_n} \|h(\tau)\|^2 \, d\tau \mid \mathscr{F}_n \right\} \\ &= J_n(t_0) \quad \text{a.s.} \end{aligned}$$

Therefore, using assumption (ii), $J_n(t_0)$ is a nonnegative martingale, and hence converges almost surely to a finite limit [16]. Hence, since the sum of the last two terms in (C.5) decreases monotonically, $L_j(t_0)$ converges to zero almost surely. Now recalling (C.3), since $L_j(t_0)$ goes to zero (almost surely) for any t_0, we conclude that (a) holds.

(b) By the Ito rule [13]

$$\|S_t\|^2 = \|S_s\|^2 + 2S_s \int_s^t h(\tau) \, d\omega_\tau + \sigma^2 \int_s^t |h(\tau)\|^2 \, d\tau. \tag{C.6}$$

Now define

$$X_t = \|S_t\|^2 + K\sigma^2 - \sigma^2 \int_0^t \|h(\tau)\|^2 \, d\tau. \tag{C.7}$$

We note that X_t is positive and $\mathscr{F}_s$-measurable for $t \leqq s$. Substituting (C.6) into (C.7)

$$\begin{aligned} X_t &= \|S_s\|^2 + 2S_s \int_s^t h(\tau) \, d\omega_\tau + \sigma^2 \int_s^t \|h(\tau)\|^2 \, d\tau + K\sigma^2 - \sigma^2 \int_0^t \|h(\tau)\|^2 \, d\tau \\ &= X_s + 2S_s \int_s^t h(\tau) \, d\omega_\tau. \end{aligned} \tag{C.8}$$

Taking conditional expectations yields

$$E[X_t \mid \mathscr{F}_s] = X_s. \tag{C.9}$$

Therefore, using (C.1) in (C.7), X_t is a nonnegative martingale and hence converges [16] to a finite limit almost surely. This limit is a random variable. The last term in (C.7) is monotone nondecreasing and bounded, thus it converges also. Thus $\|S_t\|^2$ converges also to a finite random variable. □

LEMMA C.2. *Let $S_t \triangleq \int_0^t \phi(t, \tau)a_\tau \, d\omega_\tau$ where $\phi(t, \tau)$ is the state transition matrix of an exponentially stable system and a_τ is uniformly bounded. Then, there exist finite random variables K_1 and K_2, such that*

(C.10) (i) $\limsup_{t\to\infty} \|S_t\|^2 < K_1$ a.s.

(C.11) (ii) $\limsup_{t\to\infty} \frac{1}{t}\int_0^t \|S_t\|^2 \, d\tau < K_2$ a.s.

Proof. (i) $S_t = S_s + \int_s^t \phi(t, \tau)a_\tau \, d\omega_\tau$. Hence using the Ito rule we have

$$S_t^2 = S_s^2 + 2S_s \int_s^t \phi(t, \tau)a_\tau \, d\omega_\tau + \int_s^t \sigma^2\phi(t, \tau)^2 a_\tau^2 \, d\tau.$$

Let $\mathcal{F}_t$ denote the increasing σ-fields generated by $\{\omega_s, 0 \leqq s \leqq t\}$. Then

$$E\{S_t^2 | \mathcal{F}_s\} = S_s^2 + \sigma^2 \int_s^t \phi(t, \tau)^2 a_\tau^2 \, d\tau.$$

We note that, by the assumption on ϕ and a, there exists a constant $K < \infty$ such that

$$\int_0^T \phi(T, \tau)^2 a_\tau^2 \, d\tau < K \text{ for all } T.$$

Let X_t be defined by

$$X_t \triangleq S_t^2 + \sigma^2 K - \sigma^2 \int_0^t \phi(t, \tau)^2 a_\tau^2 \, d\tau.$$

Clearly $X_t \geqq 0$ for all t and

$$E[X_t | \mathcal{F}_s] = S_s^2 + \sigma^2 K - \sigma^2 \int_0^s \phi(s, \tau)^2 a_\tau^2 \, d\tau$$
$$= X_s.$$

It follows that $(X_t, \mathcal{F}_t)$ is a positive martingale so that there exists a finite random variable X_∞ such that

$$X_t \to X_\infty \quad \text{a.s.}$$

as $t \to \infty$. Hence

$$\limsup_{t\to\infty} S_t^2 \leqq X_\infty \quad \text{a.s.}$$

(ii) This part follows as in part (i). □

Appendix D.

CONTINUOUS TIME KRONECKER LEMMA. *Assume that*

(D.1) $S_t = \int_0^t x_\tau \, d\tau$ *converges to* $S < \infty$ *as* $t \to \infty$

(D.2) $b_t \geqq 0$ *is monotone nondecreasing and* $\lim_{t\to\infty} b_t = \infty$.

Then

$$\lim_{t\to\infty} \frac{1}{b_t} \int_0^t b_\tau x_\tau \, d\tau = 0.$$

Proof. (1) We first establish that, under the same assumptions:

$$\lim_{t\to\infty} y_t = 0, \text{ where } y_t \triangleq \frac{1}{b_t}\int_0^t (S_\tau - S)\, db_\tau.$$

By (D.1), for any $\varepsilon > 0$, $\exists t(\varepsilon)$ s.t. $\forall \tau \geqq t(\varepsilon)$, $|S_\tau - S| < \varepsilon$. Therefore

$$|y_t| \leqq \frac{1}{b_t}\left|\int_0^{t(\varepsilon)} (S_\tau - S)\, db_\tau\right| + \frac{1}{b_t}\int_{t(\varepsilon)}^t |S_\tau - S|\, db_\tau$$
$$\leqq \frac{1}{b_t}\cdot C(t(\varepsilon)) + \varepsilon\left[1 - \frac{b(t(\varepsilon))}{b_t}\right]$$

where

$$\frac{b(t(\varepsilon))}{b_t} < 1, \lim_{t\to\infty}\frac{b(t(\varepsilon))}{b_t} = 0$$

and $C(t(\varepsilon))$ is a constant. Therefore by (D.2), $\lim_{t\to\infty}|y_t| \leqq \varepsilon$ with ε arbitrarily small, and hence $\lim_{t\to\infty} y_t = 0$.

(2) Integrating by parts,

$$\frac{1}{b_t}\int_0^t b_\tau x_\tau\, d\tau = \frac{1}{b_t}[b_\tau S_\tau]_0^t - \frac{1}{b_t}\int_0^t S_\tau\, db_\tau$$
$$= S_t - \frac{1}{b_t}\int_0^t S_\tau\, db_\tau \quad (\text{using } S_0 = 0)$$
$$= S_t - S - \frac{1}{b_t}\int_0^t (S_\tau - S)\, db_\tau.$$

Using (D.1) and part (1) of the proof establishes the result. □

Acknowledgments. The authors gratefully acknowledge technical help during the writing of this paper from Bob Bitmead, David Mayne, Sean Meyn, and Peter Moylan. In addition, the authors are particularly grateful to Rene Boel and Mark Davies for their assistance with the proof of existence and uniqueness of the equations describing the system and algorithm.

A CHARACTERIZATION OF ALL SOLUTIONS TO THE FOUR BLOCK GENERAL DISTANCE PROBLEM*

K. GLOVER†, D. J. N. LIMEBEER‡, J. C. DOYLE§, E. M. KASENALLY‡, AND M. G. SAFONOV¶

Abstract. All solutions to the four block general distance problem which arises in H^∞ optimal control are characterized. The procedure is to embed the original problem in an all-pass matrix which is constructed. It is then shown that part of this all-pass matrix acts as a generator of all solutions. Special attention is given to the characterization of all optimal solutions by invoking a new descriptor characterization of all-pass transfer functions. As an application, necessary and sufficient conditions are found for the existence of an H^∞ optimal controller. Following that, a descriptor representation of all solutions is derived.

Key words. H^∞-optimal control, four block problem, Parrott's theorem, general distance problems, indefinite Riccati equations, indefinite factorization, linear quadratic differential games, Nehari's theorem

AMS(MOS) subject classifications.

1. Introduction. The four block general distance problem has its genesis in certain recent work on H^∞ optimal control [7], [10], [14], [15], [43]. In typical H^∞ design situations, a nominal plant model is known, and the design engineer has the task of selecting various frequency-dependent weights. The plant model and weights are then combined into a single matrix

$$P(s)=\begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}(s) \tag{1.1}$$

and we seek to characterize all internally stabilizing controllers which satisfy $\|F_l(P, K)\|_\infty \leqq \gamma$. Rather than tackling this (nonlinear) problem directly, it can be converted into another problem which is linear in a *free parameter*. That is, find all those $Q \in H_\infty^+$ such that

$$\|(T_{11}+T_{12}QT_{21})(s)\|_\infty \leqq \gamma \tag{1.2}$$

in which $T_{11}(s)$, $T_{12}(s)$, and $T_{21}(s)$ may always be chosen stable with $T_{12}(s)$ and $T_{21}(s)$ parts of inner matrices [10], [14], [15], [43], [46]. We change nothing by rewriting (1.2) as

$$\left\| \left(T_{11}+[T_\perp T_{12}]\begin{bmatrix} 0 & 0 \\ 0 & Q \end{bmatrix}\begin{bmatrix} \tilde{T}_\perp \\ T_{21} \end{bmatrix}\right)(s) \right\|_\infty \leqq \gamma, \qquad Q \in \mathscr{H}_\infty^+ \tag{1.3}$$

in which $T_\perp(s)$ and $\tilde{T}_\perp(s)$ are chosen to make $[T_\perp T_{12}](s)$ and $[\tilde{T}_\perp^\sim T_{21}^\sim]^\sim(s)$ inner. This, too, is always possible [2], [10], [16], [43]. Finally, by invoking the norm preserving property of inner matrices, we see that (1.3) is equivalent to the characterization of all $Q \in \mathscr{H}_\infty^{+,p\times m}$ such that

$$\left\| \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22}+Q \end{bmatrix}(s) \right\|_\infty \leqq \gamma \tag{1.4}$$

where

$$\begin{bmatrix} \dot{R}_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix}(s) = \begin{bmatrix} T_{\perp}^{\sim} \\ T_{12} \end{bmatrix} T_{11}[\tilde{T}_{\perp}^{\sim} T_{21}^{\sim}](s) \in RH_{-}^{\infty}. \tag{1.5}$$

In this paper we will study the four block general distance problem given in (1.4) because of its intrinsic interest, and also due to its applicability to H^{∞} control.

Historical accounts of the development of solutions to this problem are contained in [11], [14] and [43]. Briefly, Doyle et al. [10], originally suggested a solution to the four block problem (1.4) based on the work of Davis et al. [9]. Other approaches included work on Hankel plus Toplitz operators in Jonckheere and Juang, [26] and on band extension problems in Dym and Gohberg [12]. These approaches certainly provide a theoretical solution, but when implemented on a computer, suffer from serious degree inflation problems. In an attempt to understand these inflation phenomena in the context of H^{∞} control, detailed cancellation analyses were carried out in [30], [31], [32], and [23] for cases of increasing complexity, and a controller with degree no greater than that of $P(s)$ in (1.1) was shown to exist. The outcome of this work also showed that solutions with $\deg(Q) \leqq \deg(R)$ exist to (1.4). These observations lead to the expectation that the original algorithm could be greatly improved and progress was made in [3] where just three Riccati equations of modest degree were required. The purpose of this paper is to present a new solution to the four block general distance problem requiring just two Riccati equations and also treating the optimal cases.

As indicated above, the solutions to the four block general distance problem can give representation formulae for all solutions to the H^{∞} control problem (1.2). One such formula is given in § 5 where the optimal cases are treated in detail. This solution requires two Riccati equations to be solved or, more precisely, (for certain optimal cases) for the appropriate stable invariant subspaces of two Hamiltonian matrices to be calculated. Solution formulae based on two Riccati equations were presented without proof in [20] for the suboptimal case and subsequently derivations for a limited class of plants were given in [11] using techniques similar to the state feedback results of Khargonekar, Petersen, and Rotea [28]. Formulae for certain optimal cases were given in [33], [35], and [45] using a descriptor representation and giving relations to interpolation. Many alternative and, in several cases, totally independent derivations of these results are now available using a variety of techniques. A solution based on J-spectral factorization theory is given in [22], while the related approach based on the notion of conjugation is employed in [29]. Hung has derived a formula in terms of two Riccati equations which deals with certain optimal situations [24], while Verma and Romig have a closed formula for one block problems [48]. An interesting by-product of this activity has been the discovery of a number of new interconnections. In [28], Khargonekar et al. note a connection between $\mathscr{H}^{\infty}$ control and game theory. The interplay between indefinite factorization and game theory, probably first noticed by Banker [4], has been rediscovered in the more general setting of $\mathscr{H}^{\infty}$ control [20], [22], [40]. The connection between risk sensitive optimal control [49] and game theory, originally discovered by Jacobson in the perfect information case [25], has also received renewed interest in the wider setting of $\mathscr{H}^{\infty}$ control [5], [20] and entropy minimization [21], [38]. Results on the finite horizon, time-varying case are given in [34] and [47], and finally, a solution applicable to distributed systems may be found in [13] and is due to Foias and Tannenbaum.

Section 2 contains a summary of the notation we will use. In § 3 we derive necessary and sufficient conditions for the existence of a suboptimal solution to the four block problem, and give a representation formula for all solutions. We treat the optimal case in detail in § 4. Section 5 deals with the application to $\mathcal{H}^\infty$ control theory. We derive necessary and sufficient conditions for the existence of a solution, and then give a formula for all solutions. By setting up the analysis in a descriptor framework, we are able to give a simple and complete treatment of all the optimal cases. In the event that $P_{11}(\infty)\neq 0$ and $P_{22}(\infty)\neq 0$, the controller formulae become cumbersome to write down. To obviate this difficulty, we employ the loop shifting transformations introduced in [45] to reduce the general case to a problem in which $P_{11}(\infty)=0$ and $P_{22}(\infty)=0$. We summarize the key findings of this work in the conclusions (§ 6).

2. Notation and Preliminaries.

The aim of this short section is to summarize the notation we intend to use; most of it is standard.

2.1. Notation.

$\mathbb{R}, \mathbb{R}_+, \mathbb{C}$	real, nonnegative, and complex numbers,
$\mathbb{R}(s)$	field of rational functions in s with real coefficients,
$\mathbb{C}_+, \mathbb{C}_-$	open right (respectively, left) half plane,
$\mathbb{F}^{p\times m}$	set of $p\times m$ matrices with elements in $\mathbb{F}(=\mathbb{R}, \mathbb{C}, \mathbb{R}(s)$ etc.),
$\lambda(A)$	spectrum of a square matrix A,
$\lambda_{\max}(A)$	eigenvalue of A with largest modulus,
A'	complex conjugate transpose of $A\in\mathbb{C}^{p\times m}$ (transpose if $A\in\mathbb{R}^{p\times m}$),
$A^{\#}$	generalized inverse,
$A^{\dagger}$	Moore-Penrose inverse,
$A\geqq 0, A>0$	A is positive semidefinite (respectively, positive definite),
$A\leqq 0, A<0$	A is negative semidefinite (respectively, negative definite),
$\mathcal{L}_\infty^{(p\times m)}$	space of $p\times m$ matrices with entries that are bounded on the $j\omega$-axis (including the point at ∞),
$\|\cdot\|_\infty$	$\mathcal{L}^\infty$-norm of matrices in $\mathcal{L}^\infty$,
$\mathcal{H}_\infty^{+,p\times m}$	subspace of $\mathcal{L}^\infty$; $p\times m$ matrices which are analytic and bounded in $\mathbb{C}_+$,
$\mathcal{H}_\infty^{-,p\times m}$	subspace of $\mathcal{L}^\infty$; $p\times m$ matrices which are analytic and bounded in $\mathbb{C}_-$,
$\|\cdot\|_H$	Hankel norm,
$\mathcal{RL}_\infty^{p\times m}$	same as $\mathcal{L}^{\infty(p\times m)}$ except elements are taken from $\mathbb{R}^{(p\times m)}(s)$,
$\mathcal{RH}_\infty^{+,p\times m}$	same as $\mathcal{H}_\infty^{+,(p\times m)}$ except elements are taken from $\mathbb{R}^{(p\times m)}(s)$,
$\mathcal{RH}_\infty^{-,p\times m}$	same as $\mathcal{H}_\infty^{-,(p\times m)}$ except elements are taken from $\mathbb{R}^{(p\times m)}(s)$,
$G^\sim(s)$	$G(-\bar{s})'$, the para-Hermitian conjugate of $G(s)$,
$\bar{\sigma}(A)=\|A\|_2$	the spectral norm of A,
Re s	real part of s,
$\mathcal{RH}_2(\mathcal{RH}_2^\perp)$	sets of functions $f(s)$ which are analytic in $\mathbb{C}_+(\mathbb{C}_-)$ such that $\sup_{\xi>0}\int_{-\infty}^{\infty}\|f(\xi+j\omega)\|_2^2\,d\omega<\infty(\sup_{\xi<0}\int_{-\infty}^{\infty}\|f(\xi+j\omega)\|_2^2\,d\omega<\infty)$,
$\rho(A)$	spectral radius.

Associated with a transfer function matrix $G(s)\in\mathbb{R}(s)^{p\times m}$ of McMillan degree $\leqq n$ is a state-space realization

$$G(s)=D+C(sI-A)^{-1}B \tag{2.1}$$

where $A\in\mathbb{C}^{n\times n}$, $B\in\mathbb{C}^{n\times m}$, $C\in\mathbb{C}^{p\times n}$, and $D\in\mathbb{C}^{p\times m}$. We will use the alternative notation $G(s)\overset{s}{=}(A, B, C, D)$ or

$$G(s)\overset{s}{=}\left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right] \tag{2.2}$$

for realizations of $G(s)$. Generalized state-space models or descriptor system models [37] give rise to transfer functions via $G(s) = D + C(sE - A)^{-1}B \overset{s}{=} (A, B, C, D, E)$.

In the above notation, we have $G^{\sim}(s) \overset{s}{=} (-A', C', -B', D')$ and in the case that D is nonsingular, we have $G^{-1}(s) \overset{s}{=} (A - BD^{-1}C, BD^{-1}, -D^{-1}C, D^{-1})$. The system zeros of $G(s)$ are given by $\{\lambda(A - BD^{-1}C)\} \supseteq \{\text{McMillan zeros of } G(s)\}$; these sets are equal if the realization is minimal. If $G^{-1}(s) = G^{\sim}(s)$, then $G(s)$ is all-pass. $G(s)$ is called stable if all its poles are in $\mathbb{C}_-$.

We will talk about basis changes T in the state-space of $G(s)$; we will take this to mean $G(s) \overset{s}{=} (A, B, C, D) \xrightarrow{T} G(s) \overset{s}{=} (TAT^{-1}, TB, CT^{-1}, D)$. For descriptor system models, basis changes are given by

$$G(s) \overset{s}{=} (A, B, C, D, E) \xrightarrow{U,V} G(s) \overset{s}{=} (UAV, UB, CV, D, UEV).$$

We shall also make use of linear fractional transformations which are defined by

$$F_l\left\{\begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}, U\right\} = H_{11} + H_{12}U(I - H_{22}U)^{-1}H_{21} \tag{2.3}$$

where U is of dimension $l \times m$ if H_{22} has dimension $m \times l$.

3. Construction of an all-pass embedding. In this section we derive necessary and sufficient conditions for the existence of a $Q_{22}(s) \in \mathcal{RH}_\infty^+$ such that

$$\left\|\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} + Q_{22} \end{bmatrix}\right\|_\infty < 1 \tag{3.1}$$

for given $R_{ij}(s) \in \mathcal{RH}_\infty^{-,p_i \times m_j}$, and necessary conditions for the existence of $Q_{22}(s) \in \mathcal{RH}_\infty^+$ such that

$$\left\|\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} + Q_{22} \end{bmatrix}\right\|_\infty \leqq 1. \tag{3.2}$$

For simplicity, we will assume that

$$\bar{\sigma}([R_{11}(\infty), R_{12}(\infty)]) < 1 \tag{3.3}$$

and

$$\bar{\sigma}\left(\begin{bmatrix} R_{11}(\infty) \\ R_{21}(\infty) \end{bmatrix}\right) < 1. \tag{3.4}$$

If $\bar{\sigma}([R_{11}(j\omega), R_{12}(j\omega)]) < 1$ and $\bar{\sigma}([R_{11}^{\sim}(j\omega), R_{21}^{\sim}(j\omega)]) < 1$ for some ω, but not at $\omega = \infty$, then a bilinear transformation of the half plane into the half plane can give an equivalent problem satisfying (3.3) and (3.4). If however $\bar{\sigma}([R_{11}(j\omega), R_{12}(j\omega)]) = 1$ for all ω or $\bar{\sigma}([R_{11}^{\sim}(j\omega), R_{21}^{\sim}(j\omega)]) = 1$ for all ω, then significant modifications in detail need to be performed and so this case is not treated here in the interests of brevity and clarity.

Necessity of the conditions will be derived by assuming such a $Q_{22}(s)$ exists and finding an all-pass dilation of (3.2) to the following special structure, which is used to preserve the integrity of the first row and column of (3.1) and (3.2):

$$E_{aa}(s) = \begin{array}{c} \\ p_1 \\ p_2 \\ p_3 \\ p_4 \end{array} \begin{array}{c} \begin{array}{cccc} m_1 & m_2 & m_3 & m_4 \end{array} \\ \begin{bmatrix} R_{11} & R_{12} & R_{13} & 0 \\ R_{21} & E_{22} & E_{23} & E_{24} \\ R_{31} & E_{32} & E_{33} & E_{34} \\ 0 & E_{42} & E_{43} & E_{44} \end{bmatrix} \end{array} \tag{3.5}$$

where $E_{ij} = R_{ij} + Q_{ij}$, $i, j = 2, 3, 4$, $Q_{ij}(s) \in \mathcal{RH}_\infty^{+,p_i \times m_j}$, $R_{ij}(s) \in \mathcal{RH}_\infty^{-,p_i \times m_j}$. With the all-pass dilation constructed in a particular way (Lemma 3.1), so that R_{13}, R_{31}, $E_{24}^{\sim}$, $E_{42}^{\sim}$

being full rank in $\mathbb{C}_-$ (i.e., R_{13} and R_{31} are minimum phase), it turns out that (3.2) implies that (Proposition 3.2)

$$\|R_a^{\sim}\|_H \leqq 1 \tag{3.6}$$

where

$$R_a := \begin{bmatrix} R_{11} & R_{12} & R_{13} \\ R_{21} & R_{22} & R_{23} \\ R_{31} & R_{32} & R_{33} \end{bmatrix} \tag{3.7}$$

and R_a does not depend on Q_{22}. Similarly, it will be shown in Proposition 3.3 that (3.1) implies that

$$\|R_a^{\sim}\|_H < 1. \tag{3.8}$$

The sufficiency of (3.8) is derived in § 3.2 via a state-space construction along the lines of Glover [17], [18]. Finally, all solutions are derived from this particular solution of (3.1).

3.1. Necessary conditions. We now construct the all-pass dilation of (3.2).

LEMMA 3.1. *Suppose there exists* $Q_{22}(s) \in \mathcal{RH}_\infty^+$ *such that* (3.2) *holds with* R_{ij} *satisfying* (3.3) *and* (3.4). *Then there exists an all-pass dilation in the form* (3.5) *where*

$$E_{aa}E_{aa}^{\sim} = E_{aa}^{\sim}E_{aa} = I, \tag{3.9}$$

$$m_3 = p_1, \quad m_4 \leqq p_2, \quad p_3 = m_1, \quad p_4 \leqq m_2, \tag{3.10}$$

$$R_{13} \in \mathcal{RH}_\infty^-, \quad \text{rank } R_{13} = p_1 \quad \forall \text{ Re } s < 0, \tag{3.11}$$

$$R_{31} \in \mathcal{RH}_\infty^-, \quad \text{rank } R_{31} = m_1 \quad \forall \text{ Re } s < 0, \tag{3.12}$$

$$E_{23} := -[R_{21} \quad E_{22}][R_{11} \quad R_{12}]^{\sim}(R_{13}^{-1})^{\sim}, \tag{3.13}$$

$$E_{32} := -(R_{31}^{-1})^{\sim}[R_{11}^{\sim} \quad R_{21}^{\sim}]\begin{bmatrix} R_{12} \\ E_{22} \end{bmatrix}, \tag{3.14}$$

$$\text{rank } E_{24} = m_4 \quad \forall \text{ Re } s > 0, \tag{3.15}$$

$$\text{rank } E_{42} = p_4 \quad \forall \text{ Re } s > 0, \tag{3.16}$$

$$\begin{bmatrix} E_{33} & E_{34} \\ E_{43} & E_{44} \end{bmatrix} := -\begin{bmatrix} R_{31} & E_{32} \\ 0 & E_{42} \end{bmatrix}\begin{bmatrix} R_{11}^{\sim} & R_{21}^{\sim} \\ R_{12}^{\sim} & E_{22}^{\sim} \end{bmatrix}\begin{bmatrix} (R_{13}^{-1})^{\sim} & -(R_{13}^{-1})^{\sim}E_{23}^{\sim}(E_{24}^{l})^{\sim} \\ 0 & (E_{24}^{l})^{\sim} \end{bmatrix} \tag{3.17}$$

where $E_{24}^{l}E_{24} = I$, *with* E_{24}^{l} *analytic in* Re $s > 0$.

Proof. First let $R_{13}^{\sim}$ and $R_{31}^{\sim}$ be stable minimum phase spectral factors satisfying

$$R_{13}R_{13}^{\sim} = I - R_{11}R_{11}^{\sim} - R_{12}R_{12}^{\sim} \geqq 0 \quad \forall s = j\omega, \tag{3.18}$$

$$R_{31}^{\sim}R_{31} = I - R_{11}^{\sim}R_{11} - R_{21}^{\sim}R_{21} \geqq 0 \quad \forall s = j\omega \tag{3.19}$$

where the nonnegativity follows from (3.2). Furthermore, (3.3) implies rank $R_{13}(\infty) = p_1$ and (3.4) implies rank $R_{31}(\infty) = m_1$, hence R_{13} and R_{31} are square with R_{13}^{-1} and R_{31}^{-1} analytic in Re $s < 0$. Relations (3.2) and (3.9) also imply that

$$0 \leqq I - \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & E_{22} \end{bmatrix}\begin{bmatrix} R_{11}^{\sim} & R_{21}^{\sim} \\ R_{12}^{\sim} & E_{22}^{\sim} \end{bmatrix} = \begin{bmatrix} R_{13}R_{13}^{\sim} & R_{13}E_{23}^{\sim} \\ E_{23}R_{13}^{\sim} & I - R_{21}R_{21}^{\sim} - E_{22}E_{22}^{\sim} \end{bmatrix}$$

yielding

$$E_{23} = -(R_{21}R_{11}^{\sim} + E_{22}R_{12}^{\sim})(R_{13}^{\sim})^{-1}. \tag{3.20}$$

The second row of (3.5) may now be completed as follows:

(3.21)
$$E_{24}E_{24}^{\sim} := I - R_{21}R_{21}^{\sim} - E_{22}E_{22}^{\sim} - E_{23}E_{23}^{\sim} \geqq 0.$$

Similarly,

(3.22)
$$\begin{aligned} E_{32} &= -(R_{31}^{\sim})^{-1}(R_{11}^{\sim}R_{12} + R_{21}^{\sim}E_{22}), \\ E_{42}^{\sim}E_{42} &:= I - R_{12}^{\sim}R_{12} - E_{22}^{\sim}E_{22} - E_{23}^{\sim}E_{23} \geqq 0. \end{aligned}$$

It is then simply verified that (3.17) completes the dilation. □

Now let us examine the partially agumented system

(3.23)
$$E_a := \begin{bmatrix} R_{11} & R_{12} & R_{13} \\ R_{21} & E_{22} & E_{23} \\ R_{31} & E_{32} & E_{33} \end{bmatrix}$$

in more detail. First, note that since E_{aa} is all-pass by Lemma 3.1, that

(3.24)
$$\|E_a\|_\infty \leqq 1.$$

Also by (3.17) and (3.9)

$$\begin{aligned} E_{33} &= -[R_{31} \quad E_{32}][R_{11} \quad R_{12}]^{\sim}(R_{13}^{-1})^{\sim} \\ &= -(R_{31}^{-1})^{\sim}[I - R_{11}^{\sim}R_{11} - R_{21}^{\sim}R_{21} \quad -R_{11}^{\sim}R_{12} - R_{21}^{\sim}E_{22}][R_{11} \quad R_{12}]^{\sim}(R_{13}^{-1})^{\sim} \end{aligned}$$

(3.25)
$$= -(R_{31}^{-1})^{\sim}R_{11}^{\sim}(R_{13}^{-1})^{\sim} + (R_{31}^{-1})^{\sim}[R_{11}^{\sim} \quad R_{21}^{\sim}]\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & E_{22} \end{bmatrix}\begin{bmatrix} R_{11}^{\sim} \\ R_{12}^{\sim} \end{bmatrix}(R_{13}^{-1})^{\sim}.$$

Hence,

(3.26)
$$E_a = T_1\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & E_{22} \end{bmatrix}T_2 + T_3$$

where

(3.27)
$$T_1 = \begin{bmatrix} I & 0 \\ 0 & I \\ -(R_{31}^{-1})^{\sim}R_{11}^{\sim} & -(R_{31}^{-1})^{\sim}R_{21}^{\sim} \end{bmatrix},$$

(3.28)
$$T_2 = \begin{bmatrix} I & 0 & -R_{11}^{\sim}(R_{13}^{-1})^{\sim} \\ 0 & I & -R_{12}^{\sim}(R_{13}^{-1})^{\sim} \end{bmatrix},$$

(3.29)
$$T_3 = \begin{bmatrix} 0 & 0 & (R_{13}^{-1})^{\sim} \\ 0 & 0 & 0 \\ (R_{31}^{-1})^{\sim} & 0 & -(R_{31}^{-1})^{\sim}R_{11}^{\sim}(R_{13}^{-1})^{\sim} \end{bmatrix}.$$

(3.30) Note that T_1, T_2, and T_3 are analytic in Re $s > 0$.

Relation (3.26) implies that

(3.31)
$$E_a = T_1\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix}T_2 + T_1\begin{bmatrix} 0 & 0 \\ 0 & Q_{22} \end{bmatrix}T_2 + T_3.$$

Now define R_{23}, R_{32}, and R_{33} such

(3.32)
$$\begin{aligned} R_a &:= \begin{bmatrix} R_{11} & R_{12} & R_{13} \\ R_{21} & R_{22} & R_{23} \\ R_{31} & R_{32} & R_{33} \end{bmatrix} \\ &= (\text{constant}) + \left\{T_1\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix}T_2\right\}_{\text{anticausal}}. \end{aligned}$$

That is,

$$E_a = R_a + T_4Q_{22}T_5 + T_6 \tag{3.33}$$

where $T_4 = T_1[0 \quad I]'$; $T_5 = [0 \quad I]T_2$; $(T_4Q_{22}T_5 + T_6) \in \mathcal{RH}_\infty^+$ since T_4, T_5, T_6, Q_{22} are analytic in $\operatorname{Re}(s) > 0$ and $\|E_a\|_\infty \leqq 1$ implies that $(T_4Q_{22}T_5 + T_6)$ has no poles on the imaginary axis. Hence (3.24), (3.33) and Nehari's theorem give that $\|R_a^{\sim}\|_H \leqq 1$.

The important observation here is that R_a can be constructed without explicit knowledge of Q_{22}. Moreover, R_{11}, R_{12}, R_{13}, R_{21}, R_{22}, R_{31} uniquely determine R_a. The following proposition has thus been established.

PROPOSITION 3.2. *If there exists* $Q_{22} \in \mathcal{RH}_\infty^+$ *such that* (3.2) *holds with* R_{ij} *satisfying* (3.3) *and* (3.8), *then*

$$\|R_{11} \quad R_{12}\|_\infty \leqq 1, \tag{3.34}$$

$$\left\| \begin{matrix} R_{11} \\ R_{21} \end{matrix} \right\|_\infty \leqq 1, \tag{3.35}$$

and

$$\|R_a^{\sim}\|_H \leqq 1 \tag{3.36}$$

where R_a *is given in* (3.32). □

For the case of strict inequality in (3.1), all the above inequalities can be made strict and this is now proven.

PROPOSITION 3.3. *If there exists* $Q_{22} \in \mathcal{RH}_\infty^+$ *such that* (3.1) *holds with* R_{ij} *satisfying* (3.3) *and* (3.4), *then*

$$\|R_{11} \quad R_{12}\|_\infty < 1, \tag{3.37}$$

$$\left\| \begin{matrix} R_{11} \\ R_{21} \end{matrix} \right\|_\infty < 1, \tag{3.38}$$

and

$$\|R_a^{\sim}\|_H < 1 \tag{3.39}$$

where R_a *is given in* (3.32). □

Proof. Formulae (3.37) and (3.38) are immediate consequences of (3.1) and also imply that R_{13}, R_{31} may be chosen with inverses in $\mathcal{RH}_\infty^-$. Note that in the expression for E_a given in (3.33), R_a, T_4, T_5, and T_3 are all independent of Q_{22}. Furthermore, for $\Delta \in \mathcal{RH}_\infty^+$, define

$$E_\alpha(\Delta) := R_a + T_4(Q_{22} + \Delta)T_5 + T_6. \tag{3.40}$$

Then $\|E_a(\Delta)\|_\infty \leqq 1$ for all Δ such that

$$\|\Delta\|_\infty < 1 - \left\| \begin{matrix} R_{11} & R_{12} \\ R_{21} & E_{22} \end{matrix} \right\|_\infty. \tag{3.41}$$

Since the construction of Lemma 3.1 will still work, we will now suppose that $\|R_a^{\sim}\|_H = 1$ and construct a contradiction. For all Δ satisfying (3.41), we have

$$E_a(\Delta)V(s) = U(-s) \tag{3.42}$$

where V and U are the Laplace transforms of the corresponding Schmidt vectors for the Hankel operator corresponding to $R_a^{\sim}$ [14], [36]. Note that $U, V \in \mathcal{RH}_2$. Hence $(E_a(\Delta) - E_a(0))V(s) = 0 \Rightarrow T_4\Delta T_5V(s) = 0$ for all Δ satisfying (3.41). Thus

$$T_5V(s) = 0. \tag{3.43}$$

Now consider the last block row of (3.42)

$$[R_{31} \quad E_{32} \quad E_{33}]V(s) = [0 \quad 0 \quad I]U(-s)$$

and substitute for E_{33} as

$$E_{33} = -(R_{31}R_{11}^{\sim} + E_{32}R_{12}^{\sim})(R_{13}^{-1})^{\sim}$$

yielding

$$R_{31}[I \quad 0 \quad -R_{12}^{\sim}(R_{13}^{-1})^{\sim}]V(s) + E_{32}[0 \quad I \quad -R_{12}^{\sim}(R_{13}^{-1})]V(s) = [0 \quad 0 \quad I]U(-s).$$

The second term is $E_{32}T_5V(s) = 0$ by (3.43). Hence

$$[I \quad 0 \quad -R_{11}^{\sim}(R_{13}^{-1})^{\sim}]V(s) = R_{31}^{-1}[0 \quad 0 \quad I]U(-s). \tag{3.44}$$

The left-hand side of (3.44) is in $\mathscr{RH}_2$ where the right-hand side is in $\mathscr{RH}_2^{\perp}$ and hence both must be zero. This together with (3.28) and (3.43) gives that $T_2V(s) = 0$ which, when substituted into (3.42) using (3.26), gives

$$U(-s) = T_3V(s)$$

but $U(-s) \in \mathscr{RH}_2^{\perp}$ and $T_3V(s) \in \mathscr{RH}_2$ so that both must be zero contradicting U being the Laplace transform of a Schmidt vector. □

3.2. State-space construction and sufficient conditions. We will first construct a state-space description of $\mathrm{R_a}$ given in (3.32). The terms R_{13} and R_{31} come from standard spectral factorization problems and it is a routine exercise to find out the realization of R_a.

LEMMA 3.4. *Let*

$$\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} \in \mathscr{RH}_{\infty}^{-}$$

be such that (3.2) *holds for some* $Q_{22} \in \mathscr{RL}_{\infty}$ *and have the state-space realization*

$$\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} \overset{s}{=} \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & 0 \end{array}\right] \tag{3.45}$$

where $\operatorname{Re} \lambda_i(A) > 0$ *for all i. Then* R_a *given by* (3.32) *has a state-space realization of the form*

$$R_a \overset{s}{=} \left[\begin{array}{c|ccc} A & B_1 & B_2 & B_3 \\ \hline C_1 & D_{11} & D_{12} & D_{13} \\ C_2 & D_{21} & * & * \\ C_3 & D_{31} & * & * \end{array}\right] \tag{3.46}$$

where

$$D_{13}D_{13}' = I - D_{11}D_{11}' - D_{12}D_{12}' > 0, \tag{3.47}$$

$$D_{31}'D_{31} = I - D_{11}'D_{11} - D_{21}'D_{21} > 0, \tag{3.48}$$

$$B_3 = (XC_1' - [B_1 \quad B_2][D_{11} \quad D_{12}]')(D_{13}^{-1})', \tag{3.49}$$

$$C_3 = (D_{31}^{-1})'(B_1'Y - [D_{11}' \quad D_{21}'][C_1' \quad C_2']'). \tag{3.50}$$

$X = X' \geqq 0$ *is the unique solution to the algebraic Riccati equation*

$$-XA' - AX + [B_1 \quad B_2][B_1 \quad B_2]' + B_3B_3' = 0 \tag{3.51}$$

such that $\operatorname{Re}\lambda_i(A-B_3D_{13}^{-1}C_1)\geqq 0$ *for all i.* $Y=Y'\geqq 0$ *is the unique solution to the algebraic Riccati equation*

$$-YA-A'Y+[C_1' \quad C_2'][C_1' \quad C_2']'+C_3'C_3=0 \tag{3.52}$$

such that $\operatorname{Re}\lambda_i(A-B_1D_{31}^{-1}C_3)\geqq 0$ *for all i.*

Proof. The construction of B_3 and D_{13} to form R_{13}, and C_3 and D_{31} to form R_{31} uses standard techniques for calculating spectral factors using Riccati equations [1], [50].

The realization of R_a clearly matches R_{11}, R_{12}, R_{13}, R_{21}, R_{22}, and R_{31}. It remains to verify that R_{23}, R_{32}, and R_{33} given in (3.32) match the given realization. This is a routine state-space manipulation and uses the following realizations:

$$(R_{31}^{-1})^{\sim}[R_{11}^{\sim} \quad R_{21}^{\sim}] \overset{s}{=} \left[\begin{array}{c|c} -A'+C_3'(D_{31}^{-1})'B_1' & C_3'(D_{31}^{-1})'[D_{11}' \quad D_{21}']-[C_1' \quad C_2'] \\ \hline (D_{31}^{-1})'B_1' & (D_{31}^{-1})'[D_{11}' \quad D_{21}'] \end{array}\right]$$

and the dual

$$\begin{bmatrix} R_{11}^{\sim} \\ R_{12}^{\sim} \end{bmatrix}(R_{13}^{-1})^{\sim} \overset{s}{=} \left[\begin{array}{c|c} -A'+C_1'(D_{13}^{-1})'B_3' & C_1'(D_{13}^{-1})' \\ \hline \begin{bmatrix} D_{11}' \\ D_{12}' \end{bmatrix}(D_{13}^{-1})'B_3'-\begin{bmatrix} B_1' \\ B_2' \end{bmatrix} & \begin{bmatrix} D_{11}' \\ D_{12}' \end{bmatrix}(D_{13}^{-1})' \end{array}\right].$$

Equations (3.50) and (3.52) then give that

(3.53)

$$(R_{31}^{-1})^{\sim}[R_{11}^{\sim} \quad R_{21}^{\sim}]\begin{bmatrix} C_1 \\ C_2 \end{bmatrix}(sI-A)^{-1}=-C_3(sI-A)^{-1}+\{\text{terms in analytic in } \operatorname{Re}(s)>0\}$$

and (3.49) and (3.51) imply that

(3.54)

$$(sI-A)^{-1}[B_1 \quad B_2]\begin{bmatrix} R_{11}^{\sim} \\ R_{21}^{\sim} \end{bmatrix}(R_{13}^{-1})^{\sim}=-(sI-A)^{-1}B_3+\{\text{terms in analytic in } \operatorname{Re}(s)>0\}.$$

The definition of R_a in (3.32) together with (3.53) and (3.54) then give the result. □

We now immediately have the following corollaries of Propositions 3.2 and 3.3, on noting that X and Y are the Gramians for R_a and hence $\|R_a\|_H^2=\rho(XY)$ [14], [6].

COROLLARY 3.5. *Let*

$$\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix}\in \mathcal{RH}_\infty^-$$

satisfy (3.3) *and* (3.4) *with the state-space realization of* (3.45). *Then*

(i) *If there exists* $Q_{22}\in\mathcal{RH}_\infty^+$ *satisfying* (3.2), *then* $\rho(XY)\leqq 1$.

(ii) *If there exists* $Q_{22}\in\mathcal{RH}_\infty^+$ *satisfying* (3.1), *then* $\rho(XY)<1$. □

Now that we have an explicit state-space realization of R_a and a condition on the Gramians we can attempt a state-space constrution of an all-pass embedding along the lines of (3.3) (without assuming knowledge of a candidate Q_{22}). This construction can be carried out along the lines of Glover [17], [18] and will then give a sufficiency proof. We will consider the case $\|R_a\|_H<1$ in this section with the $\|R_a\|_H=1$ considered in § 4.

First, consider the unitary dilation of the D-matrix. Such a dilation can be constructed in the form

$$(3.55)\qquad D_e = \begin{array}{c} \\ p_1 \\ p_2 \\ p_3 = m_1 \\ m_2 \geqq p_4 \end{array} \begin{array}{c} \begin{array}{cccc} m_1 & m_2 & m_3 = p_1 & m_4 \leqq p_2 \end{array} \\ \left[\begin{array}{cccc} D_{11} & D_{12} & D_{13} & 0 \\ D_{21} & D_{22} & D_{23} & D_{24} \\ D_{31} & D_{32} & D_{33} & D_{34} \\ 0 & D_{42} & D_{43} & 0 \end{array}\right] \end{array}.$$

In (3.55) $\left[\begin{smallmatrix} D_{24} \\ D_{34} \end{smallmatrix}\right]$ is chosen to be an orthonormal basis for the nullspace of $[D_{21}' \quad D_{31}']$ (which has dimension p_2 since rank $D_{31} = m_1$, and also implies that D_{24}^{-1} exists). Similarly, $[D_{42} \quad D_{43}]'$ is an orthonormal basis for the nullspace of $[D_{12} \quad D_{13}]$, and D_{42}^{-1} exists. The remaining terms are then uniquely given by

$$(3.56)\qquad \begin{bmatrix} D_{22} & D_{23} \\ D_{32} & D_{33} \end{bmatrix} = -\begin{bmatrix} D_{21}' & D_{31}' \\ D_{24}' & D_{34}' \end{bmatrix}^{-1} \begin{bmatrix} D_{11}' & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} D_{12} & D_{13} \\ D_{42} & D_{43} \end{bmatrix}.$$

Now suppose that we can find a realization of $E_{aa} = R_{aa} + Q_{aa}$ in the form

$$(3.57)\qquad R_{aa} \overset{s}{=} \left[\begin{array}{c|c} A & B_e \\ \hline C_e & * \end{array}\right] \overset{s}{=} \begin{bmatrix} R_a & 0 \\ 0 & 0 \end{bmatrix},$$

$$(3.58)\qquad Q_{aa} \overset{s}{=} \left[\begin{array}{c|c} \hat{A} & \hat{B}_e \\ \hline \hat{C}_e & 0 \end{array}\right], \quad \operatorname{Re} \lambda_i(\hat{A}) < 0 \quad \forall i$$

where

$$(3.59)\qquad B_e = [B_1 \quad B_2 \quad B_3 \quad 0],$$

$$(3.60)\qquad C_e' = [C_1' \quad C_2' \quad C_3' \quad 0],$$

$$(3.61)\qquad \hat{B}_e = [0 \quad \hat{B}_2 \quad \hat{B}_3 \quad \hat{B}_4],$$

$$(3.62)\qquad \hat{C}_e' = [0 \quad \hat{C}_2' \quad \hat{C}_3' \quad \hat{C}_4'],$$

and

$$(3.63)\qquad E_{aa} \overset{s}{=} \left[\begin{array}{cc|c} A & 0 & B_e \\ 0 & \hat{A} & \hat{B}_e \\ \hline C_e & \hat{C}_e & D_e \end{array}\right].$$

In order to construct $\hat{A}$, $\hat{B}_e$, and $\hat{C}_e$ such that E_{aa} is all-pass, we will write the all-pass lemma equations of Glover [16, Thm. 5.1] with postulated solutions to the Lyapunov equations as follows:

$$(3.64)\qquad X_e = \begin{bmatrix} -X & I \\ I & YZ^{-1} \end{bmatrix}$$

where

$$(3.65)\qquad Z = I - XY,$$

$$(3.66)\qquad Y_e = X_e^{-1} = \begin{bmatrix} -Y & Z' \\ Z & ZX \end{bmatrix}.$$

(The form of X_e and Y_e essentially comes from Glover [16, Lemma 8.2] but this need not concern us.) With this value for X_e, $\hat{A}$, $\hat{B}_e$, $\hat{C}_e$ can be constructed to satisfy the conditions of [16, Thm. 5.1], viz. D_e unitary and

$$\begin{bmatrix} A & 0 \\ 0 & \hat{A} \end{bmatrix} X_e + X_e \begin{bmatrix} A' & 0 \\ 0 & \hat{A}' \end{bmatrix} + \begin{bmatrix} B_e \\ \hat{B}_e \end{bmatrix} [B_e' \quad \hat{B}_e'] = 0, \tag{3.67}$$

$$D_e[B_e' \quad \hat{B}_e'] + [C_e \quad \hat{C}_e] X_e = 0. \tag{3.68}$$

Postmutiplying (3.68) by the invertible matrix $\left[\begin{smallmatrix} I & -Y \\ 0 & Z \end{smallmatrix}\right]$ yields the equivalent expressions

$$\hat{C}_e = C_e X - D_e B_e' \tag{3.69}$$

and

$$-D_e B_e' Y + D_e \hat{B}_e' Z + C_e = 0.$$

Since Z is nonsingular

$$\hat{B}_e = (Z^{-1})'(Y B_e - C_e' D_e) \tag{3.70}$$

and (3.68) holds.

Now let E be the left-hand side of (3.67); then $[I \quad 0]E[I \quad 0]' = 0$ by (3.51) and $[I \quad 0]Y_e E Y_e [I \quad 0]' = 0$ by (3.52). $\hat{A}$ will be chosen to make $[I \quad 0]E[0 \quad I]' = 0$ as

$$\hat{A} = -A' - \hat{B}_e B_e' \tag{3.71}$$

$$= (Z^{-1})'\{-(I - YX)A' - (YB_e - C_e' D_e) B_e'\}$$

$$= (Z^{-1})'\{-A' - YAX + C_e' D_e B_e'\}. \tag{3.72}$$

With this value of $\hat{A}$ we obtain $[I \quad 0]E = 0$ and hence

$$\begin{bmatrix} I & 0 \\ -Y & Z' \end{bmatrix} E \begin{bmatrix} I & -Y \\ 0 & Z \end{bmatrix} = 0$$

and thus $E = 0$. Therefore, with these values of $\hat{A}$, $\hat{B}_e$, and $\hat{C}_e$, E_a satisfies (3.67) and (3.68) and is hence all-pass. Furthermore, $YZ^{-1} \geqq 0$ since $\rho(XY) < 1$ by Corollary 3.5 and hence $\operatorname{Re} \lambda_i(\hat{A}) < 0$ (by Wonham [52, Lemma 12.2, p. 227]) since $\hat{A} Y Z^{-1} + Z'^{-1} Y \hat{A}' + \hat{B}_e \hat{B}_e' = 0$ and $(\hat{A}, \hat{B}_e)$ is clearly stabilizable. Therefore $Q_{aa} \in \mathcal{RH}_\infty^+$ and it remains to show that $\hat{B}_e$ and $\hat{C}_e$ have the zero terms given in (3.61) and (3.62). From (3.70) and (3.50)

$$Z' \hat{B}_e [I \quad 0 \quad 0 \quad 0]' = Y B_1 - [C_1' \quad C_2' \quad C_3'] \begin{bmatrix} D_{11} \\ D_{21} \\ D_{31} \end{bmatrix} = 0.$$

Similarly, (3.69) and (3.49) give that

$$[I \quad 0 \quad 0 \quad 0] \hat{C}_e = C_1 X - [D_{11} \quad D_{12} \quad D_{13}] \begin{bmatrix} B_1' \\ B_2' \\ B_3' \end{bmatrix} = 0.$$

Therefore we have verified that Q_{aa} given by (3.58), (3.72), (3.69), and (3.70) satisfy (3.61) and (3.62) and, for all unitary D_e, gives an all-pass E_{aa} with $Q_{aa} \in \mathcal{RH}_\infty^+$. Note that once the form of D_e and X_e have been specified, all the other terms are uniquely determined and the required zero structure on Q_{aa} has been ensured by fixing the form of the first row and column of R_{aa} to be as in (3.5). All solutions can also be generated from this Q_{aa} as will now be stated in the main result of this section.

THEOREM 3.6. *Let $R_{ij} \in \mathcal{RH}_\infty^{-,p_i \times m_j}$ for $i, j = 1, 2$ have the realization*

$$\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} \overset{s}{=} \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & * \end{array}\right]$$

with $\operatorname{Re} \lambda_i(A) > 0$ *for all i, and*

$$\bar{\sigma}[D_{11} \quad D_{12}] < 1, \qquad \bar{\sigma}[D'_{11} \quad D'_{21}] < 1.$$

(a) *Then there exists $Q \in \mathcal{RH}_\infty^+$ such that*

$$\left\| \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} + Q \end{bmatrix} \right\|_\infty < 1 \tag{3.73}$$

if and only if (3.37), (3.38) *and* $\|R_a\|_H < 1$, *or equivalently if and only if* (3.37), (3.38) *and* $\rho(XY) < 1$ *where* $X, Y \geqq 0$ *are as defined in Lemma* 3.4.

(b) *If the conditions of part* (a) *are satisfied, then each* $Q \in \mathcal{RH}_\infty^+$ *satisfying* (3.73) *is given by*

$$Q = F_l \left\{ \begin{bmatrix} Q_{22} & Q_{24} \\ Q_{42} & Q_{44} \end{bmatrix}; \Phi \right\} \tag{3.74}$$

for some $\Phi \in \mathcal{RH}_\infty^+$ *and* $\|\Phi\|_\infty < 1$, *where*

$$\begin{bmatrix} Q_{22} & Q_{24} \\ Q_{42} & Q_{44} \end{bmatrix} \overset{s}{=} \left[\begin{array}{c|cc} \hat{A} & \hat{B}_2 & \hat{B}_4 \\ \hline \hat{C}_2 & D_{22} & D_{24} \\ \hat{C}_4 & D_{42} & 0 \end{array}\right] \tag{3.75}$$

with D_{ij}, D_e *given by* (3.55). *The remaining matrices are given by*

$$\begin{bmatrix} \hat{C}_2 \\ \hat{C}_4 \end{bmatrix} = \begin{bmatrix} C_2 X \\ 0 \end{bmatrix} - \begin{bmatrix} D_{21} & D_{22} & D_{23} \\ 0 & D_{42} & D_{43} \end{bmatrix} \begin{bmatrix} B'_1 \\ B'_2 \\ B'_3 \end{bmatrix}, \tag{3.76}$$

$$[\hat{B}_2 \quad \hat{B}_4] = (Z^{-1})' \{ Y[B_2 \quad 0] - [C'_1 \quad C'_2 \quad C'_3] \} \begin{bmatrix} D_{12} & 0 \\ D_{22} & D_{24} \\ D_{32} & D_{34} \end{bmatrix}, \tag{3.77}$$

$$Z = I - XY, \qquad \hat{A} = (Z^{-1})' \{ -A' - YAX + C'_e D_e B'_e \}. \tag{3.78}$$

(c) *If R_{ij} satisfies* (3.34) *and* (3.35) *and* $\rho(XY) < 1$, *then every solution* $Q \in \mathcal{RH}_\infty^+$ *such that*

$$\left\| \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} + Q \end{bmatrix} \right\|_\infty \leqq 1$$

is given by (3.74) *for some* $\Phi \in \mathcal{RH}_\infty^+$ *with* $\|\Phi\|_\infty \leqq 1$.

Proof. Part (a) follows from Propositions 3.2 and 3.3, Corollary 3.5, and the construction preceding the theorem statement. Part (b) follows in a similar way to that given in Glover [17], [18] as follows. First, recall that E_{aa} is all-pass where

$$E_{aa}(s) = \begin{bmatrix} R_{11} & R_{12} & R_{13} & 0 \\ R_{21} & E_{22} & E_{23} & Q_{24} \\ R_{31} & E_{32} & E_{33} & Q_{34} \\ 0 & Q_{42} & Q_{43} & Q_{44} \end{bmatrix}$$

and hence,

$$F_l\left\{E_{aa}, \begin{bmatrix} 0 & 0 \\ 0 & \Phi \end{bmatrix}\right\} = \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22}+Q \end{bmatrix} \quad \text{satisfies} \quad \left\| \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22}+Q \end{bmatrix} \right\|_\infty < 1$$

if $\|\Phi\|_\infty < 1$ [19], [42] where

$$Q = F_l\left\{\begin{bmatrix} Q_{22} & Q_{24} \\ Q_{42} & Q_{44} \end{bmatrix}; \Phi\right\} \in \mathcal{RH}_\infty^+.$$

That Q is in $\mathcal{RH}_\infty^+$ follows from a small gain argument since $Q_{ij} \in \mathcal{RH}_\infty^+$ and $\Phi \in \mathcal{RH}_\infty^+$ with $\|Q_{44}\Phi\|_\infty < 1$. Hence all such Q satisfy (3.73).

To show that all such Q can be expressed as in (3.74) we first show that Q_{24}^{-1}, $Q_{42}^{-1} \in \mathcal{RH}_\infty^+$. The A-matrix of Q_{24}^{-1} is given by

$$\begin{aligned} \hat{A} - \hat{B}_2 D_{42}^{-1} \hat{C}_4 &= -A' - \hat{B}_e B_e' - \hat{B}_2(-B_2' - D_{42}^{-1} D_{43} B_3') \\ &= -A' - (\hat{B}_3 - \hat{B}_2 D_{42}^{-1} D_{43}) B_3' \end{aligned}$$

since D_e is unitary, $D_{42}^{-1} D_{43} = -D_{12}'(D_{13}^{-1})'$; hence,

$$\begin{aligned} \hat{B}_3 - \hat{B}_2 D_{42}^{-1} D_{43} &= [\hat{B}_2 \quad \hat{B}_3] \begin{bmatrix} D_{12}' \\ D_{13} \end{bmatrix} (D_{13}^{-1})' \\ &= \hat{B}_e D_e' \begin{bmatrix} I \\ 0 \\ 0 \\ 0 \end{bmatrix} (D_{13}^{-1})' \quad \text{by (3.70)} \\ &= (Z^{-1})'\left(Y B_e D_e' \begin{bmatrix} I \\ 0 \\ 0 \\ 0 \end{bmatrix} - C_1' \right)(D_{13}^{-1})' \\ &= (Z^{-1})'(YX - I)C_1'(D_{13}^{-1})' \quad \text{by (3.49)} \\ &= -C_1'(D_{13}^{-1})'. \end{aligned}$$

Hence $\hat{A} - \hat{B}_2 D_{42}^{-1} \hat{C}_4 = -(A' - C_1'(D_{13}^{-1})' B_3')$ and $Q_{42}^{-1} \in \mathcal{RH}_\infty^+$ since $\operatorname{Re} \lambda_i(A - B_3 D_{13}^{-1} C_1) < 0$ are the zeros of R_{13} which, by construction, has no zeros in $\operatorname{Re} s > 0$. See (3.51).

A similar argument gives that $\hat{A} - \hat{B}_4 D_{24}^{-1} \hat{C}_2 = -(Z^{-1})'(A - B_1 D_{31}^{-1} C_3)' Z'$ and hence $Q_{24}^{-1} \in \mathcal{RH}_\infty^+$. Suppose that Q satisfies (3.73) and define Φ such that (3.74) holds, that is,

$$\Psi := Q_{24}^{-1}(Q - Q_{22}) Q_{42}^{-1} = \Phi(I - Q_{44}\Phi)^{-1}$$

and

$$\Phi = -(I + \Psi Q_{44})^{-1} \Psi$$

and Φ clearly exists as a proper rational function in $\mathcal{L}_\infty$. Furthermore $\|\Phi\|_\infty < 1$ since

$$\left\| F_l\left(E_{aa}, \begin{pmatrix} 0 & 0 \\ 0 & \Phi \end{pmatrix}\right) \right\|_\infty < 1, \qquad Q_{44}(\infty) = 0$$

(see [30]). Suppose that Φ has a coprime factorization over $\mathcal{RH}_\infty^+$ as $\Phi = UV^{-1}$ with $U, V \in \mathcal{RH}_\infty^+$. Since U, V is coprime and Q_{44} is stable, U, $(V - Q_{44}U)$ is also coprime, and a coprime factorization of $\Psi = U(V - Q_{44}U)^{-1}$. Since $\Psi \in \mathcal{RH}_\infty^+$ the winding number of $\det(V - Q_{44}U)(j\omega)$ around the origin must be zero. However, $\det(V - Q_{44}U)(j\omega) = \det V(j\omega) \det(I - Q_{44}\Phi)(j\omega)$ and hence the winding number of $\det V(j\omega)$ is zero, since that of $\det(I - Q_{44}\Phi)(j\omega)$ is zero (because $\|Q_{44}\Phi\|_\infty < 1$) hence $\Phi \in \mathcal{RH}_\infty^+$.

(c) The major difference between this case and part (b) is that R_{13}^{-1}, R_{31}^{-1} need not be in $\mathcal{RH}_\infty^-$ and Q_{24}^{-1}, Q_{42}^{-1} need not be in $\mathcal{RH}_\infty^+$; however, R_{13}, R_{31}, Q_{24}, and Q_{42} will still be full rank in the appropriate halfplanes and only rank deficient at a finite number of points on $s = j\omega$. The proof that (3.74) with $\|\Phi\|_\infty \leqq 1$ gives a class of solutions for Q is the same as in part (b) except that we now need to prove that $\|Q_{44}\|_\infty < 1$. Suppose $\|Q_{44}\|_\infty = 1$. Since E_{aa} is all-pass if $\bar{\sigma}(Q_{44}(j\omega_0)) = 1$ for some ω_0 then $\operatorname{rank}[Q_{42}(j\omega_0) \quad Q_{43}(j\omega_0)] < p_4 = m_3 = p_1$, i.e., $[Q_{42} \quad Q_{43}]$ has an imaginary axis zero. Now

$$[Q_{42} \quad Q_{43}] \overset{s}{=} \left[\begin{array}{c|cc} \hat{A} & \hat{B}_2 & \hat{B}_3 \\ \hline \hat{C}_4 & D_{42} & D_{43} \end{array}\right]$$

$$= [D_{42} \quad D_{43}] \left[\begin{array}{c|cc} \hat{A} & \hat{B}_2 & \hat{B}_3 \\ \hline -B_2' & I & 0 \\ -B_3' & 0 & I \end{array}\right] \quad \text{from (3.76)}$$

and

$$\hat{A} + [\hat{B}_2 \quad \hat{B}_3][B_2 \quad B_3]' = -A' \quad \text{by (3.71)}$$

and hence the zeros of $[Q_{42} \quad Q_{43}]$ can only appear at $\lambda_i(-A')$. But $\operatorname{Re} \lambda_i(-A') < 0$. Thus $\operatorname{rank}[Q_{42}(j\omega) Q_{43}(j\omega)] = p_4 = m_3 = p_1$ for all ω, giving $\|Q_{44}\|_\infty < 1$.

To prove that (3.74) with $\|\Phi\|_\infty \leqq 1$ gives all solutions we first need that

$$\left\| F_l\left(E_{aa}, \begin{pmatrix} 0 & 0 \\ 0 & \Phi \end{pmatrix}\right) \right\|_\infty \leqq 1$$

implies $\|\Phi\|_\infty \leqq 1$, when R_{13}, R_{31}, Q_{24}, Q_{42} are only full rank for almost all $s = j\omega$. This is simply proved by noting that if $\bar{\sigma}(\Phi(j\omega_0)) > 1$ then $\bar{\sigma}(\Phi(s)) > 1$ for all s in some neighbourhood of $j\omega_0$, and hence we can find ω_1 such that $\bar{\sigma}(\Phi(j\omega_1)) > 1$ and R_{13}, R_{31}, E_{24}, and E_{42} all have full rank at $j\omega_1$; a contradiction is then easily established.

Finally, defining Ψ and Φ as in (b) with $\Phi = UV^{-1}$ we obtain that $\det V(j\omega) \neq 0$ for all ω since $\|\Phi\|_\infty \leqq 1$, $\det(I - Q_{44}\Phi)(j\omega) \neq 0$ for all ω since $\|Q_{44}\Phi\|_\infty < 1$, and hence $\Psi = U(V - Q_{44}U)^{-1}$ and $\det(V - Q_{44}U) = \det(V) \det(I - Q_{44}\Phi) \neq 0$ for all ω implies that $\Psi \in \mathcal{RH}_\infty$ and the result follows as in (b). □

Remark. Theorem 3.6 gives a complete solution to the problem when $\rho(XY) < 1$, the case when $\rho(XY) = 1$ is substantially more involved and is given in § 4. The solution of

$$\left\| \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} + Q \end{bmatrix} \right\|_\infty \leqq \gamma$$

for the minimum possible γ will require an iterative search on γ with the problem scaled to γ at each step (e.g., scale $D_{ij} \to \gamma^{-1} D_{ij}$, $B_i \to \gamma^{-1/2} B_i$, $C_i \to \gamma^{-1/2} C_i$). A value of γ will be achievable if the algebraic Riccati equations for $X(\gamma)$ and $Y(\gamma)$ have solutions with $\rho(X(\gamma)Y(\gamma)) \leqq 1$. The optimal value of γ can occur when $\rho(X(\gamma)Y(\gamma)) = 1$ or when γ is the largest value such that the Hamiltonians for $X(\gamma)$ or $Y(\gamma)$ have imaginary axis eigenvalues. In this way the optimal value of γ can be calculated to any desired accuracy and a problem with $\rho(XY) = 1$ normally results.

4. Descriptor all-pass systems and the sufficient conditions. In this section we propose to lift the assumption that $\|R_a^{\sim}\|_H < 1$ and treat the case when $\|R_a^{\sim}\|_H = 1$. Before starting the general analysis, we consider a simple example which illustrates an important feature of the four block problem at optimality. Consider

$$\inf_{q \in \mathscr{H}_\infty^+} \left\| \begin{bmatrix} r_{11} & 0 \\ 0 & r_{22}+q \end{bmatrix} \right\|_\infty \tag{4.1}$$

in which $r_{11}, r_{22} \in \mathscr{H}_\infty^-$. It is immediate that there are two cases which require separate consideration. These are

$$(1) \quad \|r_{22}\|_H < \|r_{11}\|_\infty, \tag{4.2a}$$

$$(2) \quad \|r_{22}\|_H \geqq \|r_{11}\|_\infty. \tag{4.2b}$$

In the first case, any $q(s) \in \mathscr{H}_\infty^+$ for which $\|r_{22}+q\|_\infty \leqq \|r_{11}\|_\infty$ will be an optimal solution; a continuum of such solutions exist. In the second case, however, the (unique) optimal Nehari extension of $r_{22}(s)$ is the only solution. This example shows that there may or may not be a reduction in the size of the solution set at optimality. In the one block case, the size of the solution set always decreases at optimality [16].

In the general case there are also two forms of optimality. To see this we temporarily suppose that $Q(s)$ in (3.2) is allowed to range over $\mathscr{L}_\infty$. Under these conditions we have

$$\inf_{Q \in \mathscr{L}_\infty} \left\| \begin{matrix} R_{11} & R_{12} \\ R_{21} & R_{22}+Q \end{matrix} \right\|_\infty = \max\left\{ \left\| \begin{bmatrix} R_{11} \\ R_{21} \end{bmatrix} \right\|_\infty, \|[R_{11} \quad R_{12}]\|_\infty \right\} \tag{4.3}$$

by Parrott's theorem [39], [41, Thm. 1.2]; a particularly nice treatment of Parrott's theorem is given in Young [53]. The point is that in certain cases

$$\inf_{Q \in \mathscr{L}_\infty} \left\| \begin{matrix} R_{11} & R_{12} \\ R_{21} & R_{22}+Q \end{matrix} \right\|_\infty = \inf_{Q \in \mathscr{H}_\infty^+} \left\| \begin{matrix} R_{11} & R_{12} \\ R_{21} & R_{22}+Q \end{matrix} \right\|_\infty \tag{4.4}$$

and the requirement that Q be an element of $\mathscr{H}_\infty^+$ rather than just $\mathscr{L}_\infty$ makes no difference to the achievable norm. This Parrott type of optimality has already been covered by Theorem 3.6. The alternative form of optimality is treated below.

4.1. All optimal solutions: the general case. The purpose of this section is to treat sufficiency in the case that $\|R_a^{\sim}\|_H = 1$. We will take Lemma 3.4 as our starting point and then show that an all-pass embedding may still be constructed along the lines of Theorem 3.6. The key difficulty in the case of $\|R_a^{\sim}\|_H = 1$ is that Z in (3.65) is singular. Our approach to this problem will be to construct the all-pass embedding in a descriptor framework. We begin with an all-pass lemma for descriptor systems of the form (4.5) and (4.6) below. Apart from dealing with the standard case of a possibly singular E, we need to cater to the case of $\det(sE-A) \equiv 0$; $(sE-A)$ singular for all values of s.

THEOREM 4.1. *Consider the descriptor system of equations*

$$sEx(s) = Ax(s) + Bu(s), \tag{4.5}$$

$$y = Cx(s) + Du(s), \tag{4.6}$$

and suppose that there exists a matrix T such that

$$AT + T'A' + BB' = 0, \tag{4.7}$$

$$ET = T'E'. \tag{4.8}$$

Then

(a) *If T is nonsingular and*

$$CT = LB' \tag{4.9}$$

for some L, (4.5) *and* (4.6) *define a unique tranfer function given by*

$$G(s) = D + C(sE - A)^{\#}B \tag{4.10}$$

in which $(\cdot)^{\#}$ denotes a generalized inverse (which is defined in (4.16) *below).*

(b) *If T is nonsingular and*

$$\text{(i)}\quad DD' = I, \tag{4.11}$$

$$\text{(ii)}\quad CT + DB' = 0, \tag{4.12}$$

then

$$GG^{\sim} = I. \tag{4.13}$$

(c) *If $ET \geqq 0$ and $(sE - A, B)$ is stabilizable (i.e., $x'(sE - A) = 0, x'E \neq 0, x'B = 0 \Rightarrow (s + \bar{s}) < 0$), then all the finite eigenvalues of $sE - A$ satisfy $(s + \bar{s}) < 0$.*

Proof. In the proof of part (a), we use (4.7) and (4.8) to establish that $\mathcal{R}(B) \subset \mathcal{R}(sE - A)$. This allows (4.5) to be solved for $x(s)$ given any $u(s)$. Following that, (4.9) is used to prove that $\mathcal{N}(sE - A) \subset \mathcal{N}(C)$ which establishes the existence of the unique transfer function (4.10).

Suppose $sE - A$ has Smith diagonalization

$$sE - A = N(s)F(s)M(s) \tag{4.14}$$

in which $N(s)$ and $M(s)$ are unimodular polynomial matrices and

$$F(s) = \begin{bmatrix} F_1(s) & 0 \\ 0 & 0 \end{bmatrix}. \tag{4.15}$$

We define

$$(sE - A)^{\#} := M^{-1}(s)\begin{bmatrix} F_1^{-1}(s) & 0 \\ 0 & 0 \end{bmatrix} N^{-1}(s). \tag{4.16}$$

To show that (4.5) has a solution for $x(s)$ given any $u(s)$, we note that (4.7) and (4.8) give

$$(sE - A)T + T'(-sE' - A') = BB' \tag{4.17}$$

and hence from (4.14)

$$\begin{aligned} &FMT(N^{\sim})^{-1} + N^{-1}T'M^{\sim}F^{\sim} = N^{-1}BB'(N^{\sim})^{-1} \\ &\Rightarrow [0 \quad I]N^{-1}B = 0. \end{aligned} \tag{4.18}$$

It is clear from (4.18) that $\mathcal{R}(B) \subset \mathcal{R}(sE - A)$ and thus that (4.5) has a solution for all $u(s)$. A simple verification shows that $x(s)$ solves (4.5) if and only if

$$\begin{aligned} x(s) &= M^{-1}(s)\left\{\begin{bmatrix} F_1^{-1} & 0 \\ 0 & 0 \end{bmatrix} N^{-1}(s)Bu(s) + \begin{bmatrix} 0 \\ I \end{bmatrix} w(s)\right\} \\ &= (sE - A)^{\#}Bu(s) + M^{-1}(s)\begin{bmatrix} 0 \\ I \end{bmatrix} w(s) \end{aligned} \tag{4.19}$$

for some $w(s)$. Next, we note that (4.17) gives

$$\begin{aligned}
&(T')^{-1}(sE-A)+(-sE'-A)T^{-1}=(T')^{-1}BB'T^{-1}\\
&\Rightarrow (M^{\sim})^{-1}(T')^{-1}NF+F^{\sim}N^{\sim}T^{-1}M^{-1}=(M^{\sim})^{-1}(T')^{-1}BB'T^{-1}M^{-1}\\
&\Rightarrow B'T^{-1}M^{-1}\begin{bmatrix}0\\ I\end{bmatrix}=0.
\end{aligned}\tag{4.20}$$

Thus

$$\begin{aligned}
y(s)&=Cx(s)+Du(s)\\
&=Du(s)+C(sE-A)^{\#}Bu(s)+CM^{-1}\begin{bmatrix}0\\ I\end{bmatrix}w(s)\\
&=\{D+C(sE-A)^{\#}B\}u(s)+LB'T^{-1}M^{-1}\begin{bmatrix}0\\ I\end{bmatrix}w(s)\\
&=G(s)u(s)
\end{aligned}$$

by (4.9) and (4.20).

(b) Equations (4.12), (4.14), and (4.16) imply that

$$\begin{aligned}
C(sE-A)^{\#}(sE-A)&=-DB'T^{-1}M^{-1}\begin{bmatrix}I & 0\\ 0 & 0\end{bmatrix}M\\
&=-DB'T^{-1}\quad\text{by (4.20)}\\
&=C\quad\text{by (4.12).}
\end{aligned}\tag{4.21}$$

Thus

$$\begin{aligned}
I-GG^{\sim}=I-DD'-C(sE-A)^{\#}BD'-DB'(-sE-A')^{\#}C'&\\
-C(sE-A)^{\#}((sE-A)T+T'(-sE'-A'))&\\
\times(-sE-A')^{\#}C'\quad\text{by (4.10) and (4.17)}&\\
=0\quad\text{by (4.11), (4.12), and (4.21).}&
\end{aligned}\tag{4.22}$$

(c) Let λ be a finite eigenvalue of $(sE-A)$. Then there exists a corresponding eigenvector x such that (i) $x'E\neq 0$ and $x'(\lambda E-A)=0$. $x'(4.7)x\Rightarrow(\lambda+\bar{\lambda})x'ETx=-x'BB'x\leqq 0$. If $x'B\neq 0$, then $\lambda+\bar{\lambda}<0$ since $ET\geqq 0$. If $x'B=0$, then $\lambda+\bar{\lambda}<0$ by the stabilizability assumption. □

Proceeding as before, we postulate matrices T and E which are associated with equations (4.7) and (4.8), and which satisfy (4.12)

$$T=\begin{bmatrix}-X & Z\\ I & Y\end{bmatrix},\qquad E=\begin{bmatrix}I & 0\\ 0 & Z'\end{bmatrix}\tag{4.23}$$

where X, Y, and Z are defined in (3.51), (3.52), and (3.65). Equations (3.67) and (3.68) become

$$\begin{bmatrix}A & 0\\ 0 & \hat{A}_0\end{bmatrix}\begin{bmatrix}-X & Z\\ I & Y\end{bmatrix}+\begin{bmatrix}-X & I\\ Z' & Y\end{bmatrix}\begin{bmatrix}A' & 0\\ 0 & \hat{A}_0'\end{bmatrix}+\begin{bmatrix}B_e\\ \hat{B}_{e0}\end{bmatrix}[B_e'\quad \hat{B}_{e0}']=0\tag{4.24}$$

and

$$D_e[B_e'\quad \hat{B}_{e0}']+[C_e\quad \hat{C}_{e0}]\begin{bmatrix}-X & Z\\ I & Y\end{bmatrix}=0,\tag{4.25}$$

respectively. Evaluating the first column of (4.25) and comparing with (3.69) gives

$$\hat{C}_{e0} = \hat{C}_e = C_eX - D_eB'_e. \tag{4.26}$$

In the same way, the second column of (4.25) together with (3.70) yields

$$\hat{B}_{e0} = YB_e - C'_eD_e = Z'\hat{B}_e \tag{4.27}$$

for any unitary D_e. $\hat{B}_{e0}$ therefore retains the critical zero (1, 1) entry. The (1, 1) partition of (4.24) is zero by (3.51). From the (2, 1) partition of (4.24) we obtain

$$\hat{A}_0 = -Z'A' - \hat{B}_{e0}B'_e = -A' - YAX + C'_eD_eB'_e = Z'\hat{A}. \tag{4.28}$$

It is now easy to check that the remaining equations in (4.24) are also satisfied.

We also note that $(Z', \hat{A}_0, \hat{B}_{e0})$ is stabilizable since if $x'Z' \neq 0$, $x'[sZ' - \hat{A}_0, \hat{B}_{e0}] = 0 \Rightarrow x'[sZ' + Z'A'] = 0 \Rightarrow s + \bar{s} < 0$ since Re $(\lambda_i(A)) > 0$. We can now prove the sufficiency of the condition in Corollary 3.5(i).

THEOREM 4.2. *Given that the conditions of Corollary* 3.5(i) *are satisfied, then*

(a) $Q_{aa}(s) := D_e + \hat{C}_{e0}(sZ' - \hat{A}_0)^{\#}\hat{B}_{e0} \in \mathcal{RH}_\infty$,
(b) $R_{aa} + Q_{aa}$ *is all-pass.*
Hence the conditions are both necessary and sufficient.

Proof. Equations (4.24) and (4.25) give that Theorem 4.1 can be applied to show that $R_{aa} + Q_{aa}$ is well defined and all-pass. Since $R_{aa}^{\sim} \in \mathcal{RH}_\infty$, Q_{aa} has no poles on $s = j\omega$ or at infinity. All the finite poles will be at eigenvalues of $(sZ' - \hat{A}_0)$ which are in the open left halfplane by Theorem 4.1(c) since $(Z', \hat{A}_0, \hat{B}_{e0})$ is stabilizable and from the (2, 2)-block of (4.24) and $Z'Y = Y - YXY \geqq 0$ since $\rho(XY) \leqq 1$. The sufficiency of the condition follows from (a) and (b) by using the (2, 2) entry of $Q_{aa}(s)$. □

4.2. Characterization of all solutions. Theorem 4.2 gives a solution in the case $\|R_a\|_H = 1$ in descriptor form. All solutions can be generated from $Q_{aa}(s)$ but the more detailed structure is required. To keep the notation simple the simplifying assumption

$$\begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

will be made for this section. Model matching problems arising from H^∞ control can in fact always be reduced to this case (see [45]). The main difference in the approach in § 3 is that all solutions to the problem with R_a rather than R are determined. We wish to write any solution

$$\begin{bmatrix} \bar{Q}_{22} & \bar{Q}_{23} \\ \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix}$$

as

$$\begin{bmatrix} \bar{Q}_{22} & \bar{Q}_{23} \\ \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix} = \begin{bmatrix} Q_{22} & Q_{23} \\ Q_{32} & Q_{33} \end{bmatrix} + \begin{bmatrix} \tilde{Q}_{24} \\ \tilde{Q}_{34} \end{bmatrix} \Phi(I - \tilde{Q}_{44}\Phi)^{-1}[\tilde{Q}_{42} \quad \tilde{Q}_{43}]$$

for $\|\Phi\|_\infty \leqq 1$, $\Phi \in H_\infty^+$. We need to show that such a Φ exists for all suitable $\bar{Q}_{ij}$, and this is not immediately clear since

$$\begin{bmatrix} \tilde{Q}_{24} \\ \tilde{Q}_{34} \end{bmatrix} \quad \text{and} \quad [\tilde{Q}_{42} \quad \tilde{Q}_{43}]$$

are not invertible. The following technical lemma will be used to check the existence of a Φ given any

$$\begin{bmatrix} \bar{Q}_{22} & \bar{Q}_{23} \\ \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix}.$$

LEMMA 4.3. *Suppose that*

$$P(s) = \begin{array}{c c} & \begin{array}{cc} m_1 & m_2 \end{array} \\ \begin{array}{c} p_1 \\ p_2 \end{array} & \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} \end{array} (s) \in R\mathcal{L}_\infty,\ X \in R\mathcal{L}_\infty^{p_1 \times m_1}$$

in which $p_1 \geqq m_2$, $m_1 \geqq p_2$ *and* $P_{22}(\infty) = 0$. *Suppose also that* P_{12} *has a left inverse* $P_{12}^l \in \mathcal{L}_\infty$ *and* P_{21} *has a right inverse* $P_{21}^r \in \mathcal{L}_\infty$. *Then if there exists a rational matrix* $R \in \mathcal{L}_\infty$ *with* rank $(R) \geqq p_1 - m_2$ *for almost all s such that*

$$\text{(4.29)} \qquad \text{(i)} \quad R[X - P_{11} \quad P_{12}] = 0,$$

and if there exists a rational matrix $S \in \mathcal{L}_\infty$ *with* rank $(S) \geqq m_1 - p_2$ *for almost all s such that*

$$\text{(4.30)} \qquad \text{(ii)} \quad \begin{bmatrix} X - P_{11} \\ P_{21} \end{bmatrix} S = 0,$$

then there exists a rational matrix Φ *such that* $F_l(P, \Phi) = X$. *More particularly,*

$$\text{(4.31)} \qquad \Phi = (I + \Psi P_{22})^{-1} \Psi$$

where

$$\text{(4.32)} \qquad \Psi = P_{12}^l (X - P_{11}) P_{21}^r.$$

Proof. The idea of the proof is to establish that (i) and (ii) guarantee the existence of a solution Ψ to the equation $X - P_{11} = P_{12} \Psi P_{21}$. We then set $\Psi = \Phi(I - P_{22}\Phi)^{-1}$ and solve for Φ.

It follows from (i) that $(X - P_{11}) \in \mathcal{N}(R)$. Since $\dim \mathcal{R}(P_{12}) = m_2 \geqq \dim \mathcal{N}(R)$, it follows from (i) that $(X - P_{11}) \in \mathcal{N}(R) \equiv \mathcal{R}(P_{12})$ and therefore that the equation $P_{12} Z = (X - P_{11})$ has a solution $Z = P_{12}^l (X - P_{11})$. In the same way we have $(X - P_{11})^\sim \in \mathcal{R}(P_{21}^\sim)$. Since $Z^\sim \in \mathcal{R}(X - P_{11})^\sim$, we have $Z^\sim \in \mathcal{R}(P_{21}^\sim)$ and consequently $\Psi P_{21} = Z$ has a solution $\Psi = P_{12}^l (X - P_{11}) P_{21}^r \in \mathcal{L}_\infty$. It follows from $P_{22}(\infty) = 0$ and $\Psi = \Phi(I - P_{22}\Phi)^{-1}$ that $\Phi = (I + \Psi P_{22})^{-1} \Psi$ is a proper rational matrix. □

The detailed structure of $Q_{aa}(s)$ will now be examined when

$$\begin{bmatrix} D_{11} & D_{12} \\ D_{21} & D_{22} \end{bmatrix} = 0.$$

In this case we may choose

$$\text{(4.33)} \qquad D_e = \begin{bmatrix} 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \\ I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \end{bmatrix}$$

and substituting (4.33) into (4.26)-(4.28) yields

$$\text{(4.34)} \qquad \hat{C}'_{e0} = [0 \quad XC'_2 \quad XC'_3 - B_1 \quad -B_2],$$

$$\hat{B}_{e0} = [0 \quad YB_2 \quad YB_3 - C_1' \quad -C_2'], \tag{4.35}$$

$$\hat{A}_0 = -A' - YAX + C_3'B_1' + C_1'B_3'. \tag{4.36}$$

Since (3.51) and (3.52) have an appropriate dual relationship to each other, their solutions may be transformed to the balanced form

$$X = \begin{bmatrix} \bar{X} & 0 \\ 0 & I_k \end{bmatrix}, \quad Y = \begin{bmatrix} \bar{Y} & 0 \\ 0 & I_k \end{bmatrix}, \quad \bar{Z} = I - \bar{X}\bar{Y} \tag{4.37}$$

by an appropriate change of basis in the state space of $R(s)$; k is the multiplicity of the unit singular value of $\Gamma_{R_a^\sim}$. This balancing induces the following partitioning on B_e and C_e in (3.59) and (3.60).

$$\begin{bmatrix} B_{e1} \\ B_{e2} \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} & B_{13} & 0 \\ B_{21} & B_{22} & B_{23} & 0 \end{bmatrix}, \tag{4.38}$$

$$\begin{bmatrix} C_{e1}' \\ C_{e2}' \end{bmatrix} = \begin{bmatrix} C_{11}' & C_{12}' & C_{13}' & 0 \\ C_{21}' & C_{22}' & C_{23}' & 0 \end{bmatrix}. \tag{4.39}$$

Furthermore if rank $B_{22} = l < k$, then an additional unitary change of basis on the k states can give $B_{22} = \left[\begin{smallmatrix} B_{221} \\ 0 \end{smallmatrix}\right]$, with B_{221} full rank.

Substitution into (3.49) and (3.50) gives

$$\begin{bmatrix} B_{13} \\ B_{23} \end{bmatrix} = \begin{bmatrix} \bar{X}C_{11}' \\ C_{21}' \end{bmatrix}, \tag{4.40}$$

$$\begin{bmatrix} C_{13}' \\ C_{23}' \end{bmatrix} = \begin{bmatrix} \bar{Y}B_{11} \\ B_{21} \end{bmatrix}. \tag{4.41}$$

Finally, (3.51) and (3.52) become

(4.42)

$$-\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}\begin{bmatrix} \bar{X} & 0 \\ 0 & I_k \end{bmatrix} - \begin{bmatrix} \bar{X} & 0 \\ 0 & I_k \end{bmatrix}\begin{bmatrix} A_{11}' & A_{21}' \\ A_{12}' & A_{22}' \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & \bar{X}C_{11}' \\ B_{21} & B_{22} & C_{21}' \end{bmatrix} \begin{bmatrix} B_{11} & B_{12} & \bar{X}C_{11}' \\ B_{21} & B_{22} & C_{21}' \end{bmatrix}' = 0,$$

(4.43)

$$-\begin{bmatrix} A_{11}' & A_{21}' \\ A_{12}' & A_{22}' \end{bmatrix}\begin{bmatrix} \bar{Y} & 0 \\ 0 & I_k \end{bmatrix} - \begin{bmatrix} \bar{Y} & 0 \\ 0 & I_k \end{bmatrix}\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} + \begin{bmatrix} C_{11}' & C_{12}' & \bar{Y}B_{11} \\ C_{21}' & C_{22}' & B_{21} \end{bmatrix} \begin{bmatrix} C_{11}' & C_{12}' & \bar{Y}B_{11} \\ C_{21}' & C_{22}' & B_{21} \end{bmatrix}' = 0.$$

The (2, 2) blocks of (4.42) and (4.43) establish the following equation:

$$B_{22}B_{22}' = C_{22}'C_{22} \tag{4.44}$$

and consequently that there exists a matrix U such that

$$UB_{22}' = C_{22}, \qquad U := C_{22}(B_{22}')^{\dagger} = (C_{22}')^{\dagger}B_{22}. \tag{4.45}$$

It now follows that a descriptor representation for $Q_{aa}(s)$ is given by

$$\begin{bmatrix} \bar{Z}' & 0 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} -A'_{11} - \bar{Y}A_{11}\bar{X} + C'_{13}B'_{11} + C'_{11}B'_{13} & -C'_{12}UB'_{22} \\ -B_{22}B'_{12} & -B_{22}B'_{22} \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 & \bar{Y}B_{12} & -\bar{Z}'C'_{11} & -C'_{12} \\ 0 & B_{22} & 0 & -B_{22}U' \end{bmatrix}\begin{bmatrix} u_1 \\ u_2 \\ u_3 \\ u_4 \end{bmatrix}, \tag{4.46}$$

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ C_{12}\bar{X} & UB'_{22} \\ -B'_{11}\bar{Z}' & 0 \\ -B'_{12} & -B'_{22} \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \\ I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \end{bmatrix}\begin{bmatrix} u_1 \\ u_2 \\ u_3 \\ u_4 \end{bmatrix} \tag{4.47}$$

on substituting (4.37) to (4.41) into (4.34)-(4.36). The (2, 1) block of (4.46) gives

$$\begin{aligned} 0 &= -B_{22}B'_{12}x_1 - B_{22}B'_{22}x_2 + B_{22}u_2 - B_{22}U'u_4 \\ &\Rightarrow B'_{22}x_2 = (B_{22})^{\dagger}(-B_{22}B'_{12}x_1 + B_{22}u_2 - C'_{22}u_4). \end{aligned} \tag{4.48}$$

Substituting (4.48) into (4.46) and (4.47) gives the state-space realization,

$$\begin{bmatrix} Q_{22} & Q_{23} & Q_{24} \\ Q_{32} & Q_{33} & Q_{34} \\ Q_{42} & Q_{43} & Q_{44} \end{bmatrix}(s) \overset{s}{=} \left[\begin{array}{c|ccc} \tilde{A} & (\bar{Z}')^{-1}(\bar{Y}B_{12} - C'_{12}U) & -C'_{11} & -(\bar{Z}')^{-1}C'_{12}(I - C_{22}C^{\dagger}_{22}) \\ \hline C_{12}\bar{X} - UB'_{12} & U & 0 & (I - C_{22}C^{\dagger}_{22}) \\ -B'_{11}\bar{Z}' & 0 & 0 & 0 \\ -(I - B^{\dagger}_{22}B_{22})B'_{12} & I - B^{\dagger}_{22}B_{22} & 0 & -B^{\dagger}_{22}C'_{22} \end{array}\right] \tag{4.49}$$

where

$$\tilde{A} = (\bar{Z}')^{-1}(-A'_{11} - \bar{Y}A_{11}\bar{X} + C'_{13}B'_{11} + C'_{11}B'_{13} + C'_{12}C_{22}(B'_{22})^{\dagger}B'_{12}).$$

Suppose that Θ_1 and Θ_3 are orthogonal bases for $\mathscr{R}(B'_{22})$ and $\mathscr{R}(C_{22})$, respectively, and that Θ_2 and Θ_4 are chosen to make $[\Theta_2 \quad \Theta_1]$ and $[\Theta_4 \quad \Theta_3]$ orthogonal.[1] If we multiply the last row of (4.49) by $[\begin{smallmatrix}\Theta'_2 \\ \Theta'_1\end{smallmatrix}]$ and the last column by $[\Theta_4 \quad \Theta_3]$, we obtain

$$\begin{bmatrix} Q_{22} & Q_{23} & \tilde{Q}_{24} & 0 \\ Q_{32} & Q_{33} & \tilde{Q}_{34} & 0 \\ \tilde{Q}_{42} & \tilde{Q}_{43} & \tilde{Q}_{44} & 0 \\ 0 & 0 & 0 & -I_l \end{bmatrix}(s) \tag{4.50}$$

[1] If B'_{22} has a singular value decomposition

$$B'_{22} = [Y_1 \quad Y_2]\begin{bmatrix} 0 & 0 \\ 0 & \Gamma \end{bmatrix}\begin{bmatrix} U'_1 \\ U'_2 \end{bmatrix},$$

then $[\Theta_2 \quad \Theta_1] = [Y_1 \quad Y_2]$ and $(B'_{22})^{\dagger} = U_2\Gamma^{-1}Y'_2$.

$$\overset{s}{=}\left[\begin{array}{c|cccc} \tilde{A} & (\bar{Z}')^{-1}(\bar{Y}B_{12}-C_{12}'U) & -C_{11}' & -(\bar{Z}')^{-1}C_{12}'\Theta_4 & 0 \\ \hline C_{12}\bar{X}-UB_{12}' & U & 0 & \Theta_4 & 0 \\ -B_{11}'\bar{Z}' & 0 & 0 & 0 & 0 \\ -\Theta_2'B_{12}' & \Theta_2' & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -I_l \end{array}\right]$$

in which

$$l = \operatorname{rank}(B_{22}) = \operatorname{rank}(C_{22}) \leqq k. \tag{4.51}$$

Equation (4.50) has an interesting structure in that it shows how the effective dimension of the free parameter is reduced by l. We will examine this point a little further and obtain a constraining equation on the free parameter Φ which is reminicent of [16, eq. (8.69)]. Following that, we will prove that

(4.52)

$$\begin{bmatrix} Q_{22} & \tilde{Q}_{24} \\ \tilde{Q}_{42} & \tilde{Q}_{44} \end{bmatrix}(s) \overset{s}{=} \left[\begin{array}{c|cc} \tilde{A} & (\bar{Z}')^{-1}(\bar{Y}B_{12}-C_{12}'U) & -(\bar{Z}')^{-1}C_{12}'\Theta_4 \\ \hline C_{12}\bar{X}-UB_{12}' & U & \Theta_4 \\ -\Theta_2'B_{12}' & \Theta_2' & 0 \end{array}\right]$$

captures all solutions in the optimal case corresponding to $\|\Gamma_{R_a^\sim}\| = 1$.

Let us write the left-hand side of (4.50) as

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} Q_{22} & \tilde{Q}_{24} & 0 \\ \tilde{Q}_{42} & \tilde{Q}_{44} & 0 \\ 0 & 0 & I_l \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} \tag{4.53}$$

and allow this to induce the following partitioning on the free contraction $\Phi(s)$

$$\begin{bmatrix} u_2 \\ u_3 \end{bmatrix} = \begin{bmatrix} \Phi_{11} & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{bmatrix} \begin{bmatrix} y_2 \\ y_3 \end{bmatrix}. \tag{4.54}$$

Since $u_3 = y_3$ we may eliminate this variable in (4.54) to obtain

$$\begin{aligned} u_2 &= (\Phi_{11} + \Phi_{12}(I-\Phi_{22})^{-1}\Phi_{21})y_2 \quad \text{if } \det(I-\Phi_{22}(\infty)) \neq 0 \text{ is assumed} \\ &= \left(F_l\left\{\begin{bmatrix} \Phi_{11} & \Phi_{12} \\ \Phi_{21} & \Phi_{22} \end{bmatrix}, I_l\right\}\right) y_2 = \tilde{\Phi} y_2 \end{aligned} \tag{4.55}$$

in which $\|\tilde{\Phi}\| \leqq 1$ by Redheffer's theorem [42]. A class of solutions is therefore given by

$$Q = F_l\left\{\begin{bmatrix} Q_{22} & \tilde{Q}_{24}' \\ \tilde{Q}_{42} & \tilde{Q}_{44} \end{bmatrix}, \tilde{\Phi}\right\}. \tag{4.56}$$

Transforming back to the coordinates in (4.53) gives

$$\Phi = U[\Theta_2 \quad \Theta_1] \begin{bmatrix} \tilde{\Phi} & 0 \\ 0 & I_l \end{bmatrix} \begin{bmatrix} \Theta_2' \\ \Theta_1 \end{bmatrix} \tag{4.57}$$

and $(4.57)B_{22}'$

$$\Rightarrow \Phi B_{22}' = C_{22}, \tag{4.58}$$

which is a linear constraint on Φ and similar to that obtained in [16].

We are now in a position to state and prove the main result of this section.

THEOREM 4.4. *Let $R_{ij} \in \mathcal{RH}_\infty^{-,p_i,m_j}$ for $i, j = 1, 2$ have the realization*

$$\begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} \overset{s}{=} \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & 0 & 0 \\ C_2 & 0 & 0 \end{array}\right]$$

with $\operatorname{Re} \lambda_i(A) > 0$.

If the conditions of Corollary 3.5(i) *are met, then every* $Q \in \mathcal{RH}_\infty^+$ *satisfying*

$$\left\| \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} + Q \end{bmatrix} \right\|_\infty \leqq 1$$

is given by

$$Q = F_l\left(\begin{bmatrix} Q_{22} & \tilde{Q}_{24} \\ \tilde{Q}_{42} & \tilde{Q}_{44} \end{bmatrix}, \Phi \right) \quad \textit{for some } \Phi \in \mathcal{RH}_\infty^+ \textit{ with } \|\Phi\|_\infty \leqq 1 \tag{4.59}$$

in which

$$\begin{bmatrix} Q_{22} & \tilde{Q}_{24} \\ \tilde{Q}_{42} & \tilde{Q}_{44} \end{bmatrix}$$

has a state-space realization given by (4.52). □

Proof. The proof can be deduced using arguments similar to those given in the proof of Theorem 3.6. We begin by making two preliminary observations. First, it is an immediate consequence of Redheffers theorem that (4.59) captures a class of solutions. Second,

$$\begin{bmatrix} R_{11} & R_{12} & R_{13} \\ R_{21} & R_{22} + \bar{Q}_{22} & R_{23} + \bar{Q}_{23} \\ R_{31} & R_{32} + \bar{Q}_{32} & R_{33} + \bar{Q}_{33} \end{bmatrix} \begin{bmatrix} R_{11}^\sim & V_{11} \\ R_{12}^\sim & V_{21} \\ R_{13}^\sim & V_{31} \end{bmatrix} = \begin{bmatrix} I & U_{11}(-s) \\ 0 & U_{21}(-s) \\ 0 & U_{31}(-s) \end{bmatrix} \tag{4.60}$$

for any

$$Q = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \bar{Q}_{22} & \bar{Q}_{23} \\ 0 & \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix}$$

such that $\|R_a + Q\|_\infty = \|R_a^\sim\|_H = 1$ where $V(s)$ and $U(-s)$ are the maximal Schmidt vectors of the Hankel operator $\Gamma_{R_a^\sim}$ [14], [18]. Since

$$\begin{bmatrix} R_{11} & R_{12} & R_{13} \\ V_{11}^\sim & V_{21}^\sim & V_{31}^\sim \end{bmatrix}(\infty) = \begin{bmatrix} 0 & 0 & I \\ C_{21} & C_{22} & C_{23} \end{bmatrix},$$

it is immediate that

$$p_1 + k \geqq \operatorname{rank} \begin{bmatrix} R_{12}^\sim & V_{21} \\ R_{13}^\sim & V_{31} \end{bmatrix} \geqq p_1 + \operatorname{rank}(C_{22}) \tag{4.61}$$

for almost all s; k is the multiplicity of the unit Hankel singular value of $\Gamma_{R_a^\sim}$. Similarly, since $\|R_{aa} + Q_{aa}\|_\infty = \|R_{aa}^\sim\|_H = 1$

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & \bar{Q}_{22} - Q_{22} & \bar{Q}_{23} - Q_{23} \\ 0 & \bar{Q}_{32} - Q_{32} & \bar{Q}_{33} - Q_{33} \\ 0 & \tilde{Q}_{42} & \tilde{Q}_{43} \end{bmatrix} \begin{bmatrix} R_{11}^\sim & V_{11} \\ R_{12}^\sim & V_{21} \\ R_{13}^\sim & V_{31} \end{bmatrix} = 0. \tag{4.62}$$

In the same way we have that

$$(4.63)\qquad \begin{bmatrix} R_{11}^{\sim} & R_{21}^{\sim} & R_{31}^{\sim} \\ U_{11}^{\sim} & U_{21}^{\sim} & U_{31}^{\sim} \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & \bar{Q}_{22}-Q_{22} & \bar{Q}_{23}-Q_{23} & \tilde{Q}_{24} \\ 0 & \bar{Q}_{32}-Q_{32} & \bar{Q}_{33}-Q_{33} & \tilde{Q}_{34} \end{bmatrix} = 0$$

and

$$(4.64)\qquad \operatorname{rank} \begin{bmatrix} R_{11}^{\sim} & R_{21}^{\sim} & R_{31}^{\sim} \\ U_{11}^{\sim} & U_{21}^{\sim} & U_{31}^{\sim} \end{bmatrix} \geqq m_1 + \operatorname{rank}(B_{22}).$$

We now show that $[\begin{smallmatrix}\tilde{Q}_{24}\\ \tilde{Q}_{34}\end{smallmatrix}]$ has an asymptotically stable left inverse while $[\tilde{Q}_{42} \quad \tilde{Q}_{43}]$ has an asymptotically stable right inverse. Substituting from (4.50) gives

$$(4.65)\qquad \begin{bmatrix} \tilde{Q}_{24} \\ \tilde{Q}_{34} \end{bmatrix} \overset{s}{=} \left[\begin{array}{c|c} \tilde{A} & -(\bar{Z}')^{-1}C_{12}'\Theta_4 \\ \hline C_{12}\bar{X}-UB_{12}' & \Theta_4 \\ -B_{11}'\bar{Z}' & 0 \end{array}\right]$$

and a simple calculation yields[2]

$$(4.66)\qquad \begin{bmatrix} \tilde{Q}_{24} \\ \tilde{Q}_{34} \end{bmatrix}^{l} \overset{s}{=} \left[\begin{array}{c|c} -(\bar{Z}')^{-1}A_{11}\bar{Z} & (\bar{Z}')^{-1}[C_{12}' \quad C_{13}'] \\ \hline \Theta_4'[C_{12}\bar{X}-UB_{12}'] & \Theta_4' \quad 0 \end{array}\right].$$

$$(4.67)\qquad [\tilde{Q}_{42} \quad \tilde{Q}_{43}] \overset{s}{=} \left[\begin{array}{c|cc} \tilde{A} & (\bar{Z}')^{-1}[\bar{Y}B_{12}-C_{12}'U]-C_{11}' & \\ \hline -[\Theta_2' \quad 0]\begin{bmatrix} B_{12}' \\ B_{13}' \end{bmatrix} & \Theta_2' & 0 \end{array}\right]$$

has a right inverse

$$(4.68)\qquad [\tilde{Q}_{42} \quad \tilde{Q}_{43}]^{r} \overset{s}{=} \left[\begin{array}{c|c} -A_{11}' & -(\bar{Z}')^{-1}[\bar{Y}B_{12}-C_{12}'U]\Theta_2 \\ \hline B_{12}' & \Theta_2 \\ B_{13}' & 0 \end{array}\right].$$

Since $\lambda_i(A_{11})>0$, the left and right inverses in (4.66) and (4.68) are asymptotically stable. Furthermore,

$$(4.69)\qquad \operatorname{rank} \begin{bmatrix} \tilde{Q}_{24} \\ \tilde{Q}_{34} \end{bmatrix} = p_2 - \operatorname{rank}(B_{22}) \quad \text{for all } \operatorname{Re}(s) \geqq 0,$$

$$(4.70)\qquad \operatorname{rank}[\tilde{Q}_{42} \quad \tilde{Q}_{43}] = m_2 - \operatorname{rank}(B_{22}) \quad \text{for all } \operatorname{Re}(s) \geqq 0.$$

Hence, we may invoke Lemma 4.3 and the all-pass character of E_{aa} to establish the existence of a $\|\Phi\|_\infty \leqq 1$ such that

$$(4.71)\qquad \begin{bmatrix} \bar{Q}_{22} & \bar{Q}_{23} \\ \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix} = F_l\left(\begin{bmatrix} Q_{22} & Q_{23} & \tilde{Q}_{24} \\ Q_{32} & Q_{33} & \tilde{Q}_{34} \\ \tilde{Q}_{42} & \tilde{Q}_{43} & \tilde{Q}_{44} \end{bmatrix} ; \Phi \right).$$

It remains for us to show that any such $\Phi \in \mathscr{BH}_\infty^+$. It follows immediately that

$$(4.72)\qquad \Psi = \begin{bmatrix} \tilde{Q}_{24} \\ \tilde{Q}_{34} \end{bmatrix}^{l} \begin{bmatrix} \bar{Q}_{22}-Q_{22} & \bar{Q}_{23}-Q_{23} \\ \bar{Q}_{32}-Q_{32} & \bar{Q}_{33}-Q_{33} \end{bmatrix} [\tilde{Q}_{42} \quad \tilde{Q}_{43}]^{r}$$

[2] $$G(s) \overset{s}{=} \begin{bmatrix} A & BD \\ C & D \end{bmatrix} \Rightarrow G^{l}(s) \overset{s}{=} \begin{bmatrix} A-BC & -B \\ D^{l}C & D^{l} \end{bmatrix}$$

and a dual result is clearly true in the case of a right inverse.

is stable. Now suppose that Φ has a coprime factorization $\Phi = ND^{-1}$ with $N, D \in \mathcal{RH}_\infty^+$. Since $\Psi = \Phi(I - Q_{44}\Phi)^{-1}$ is stable, and $\Psi = N(D - Q_{44}N)^{-1}$ is a coprime factorization, it follows that $(D - Q_{44}N)$ is outer. We may now deduce from

$$\det(D - \tilde{Q}_{44}N)(j\omega) = \det D(j\omega) \cdot \det(I - \tilde{Q}_{44}\Phi)(j\omega) \tag{4.73}$$

and $\|\tilde{Q}_{44}\Phi\|_\infty < 1$ that the winding number of $\det D(j\omega)$ around the origin is zero. This means that D is outer and therefore that $\Phi = ND^{-1} \in \mathcal{RH}_\infty^+$ as required. □

5. A representation formula for all internally stabilizing controllers that satisfy a closed-loop H^∞ norm constraint. In this section we will show how the solution to the four block problem given in §§ 3 and 4 may be used to solve a rational $\mathcal{H}^\infty$ control problem. Suppose we are given

$$P = \begin{array}{cc} \begin{array}{cc} l & m \end{array} & \\ \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} & \begin{array}{c} p \\ q \end{array} \end{array} \overset{s}{=} \begin{array}{cc} \begin{array}{ccc} n & l & m \end{array} & \\ \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{22} \end{array}\right] & \begin{array}{c} n \\ p \\ q \end{array} \end{array} \tag{5.1}$$

in which $p \geqq m$ and $l \geqq q$, and that we seek all controllers that stabilize $F_l(P, K)$ and that satisfy the norm constraint

$$\|F_l(P, K)\|_\infty \leqq \gamma. \tag{5.2}$$

We will make a number of assumptions regarding (5.1), the last of which is temporary and is removed in our later development.

(i) (A, B_2, C_2) is stabilizable and detectable.

(ii) $\operatorname{rank}(D_{12}) = m$ and $\operatorname{rank}(D_{21}) = q$.

(iii) $\operatorname{rank}\left(\begin{bmatrix} j\omega I - A & -B_2 \\ C_1 & D_{12} \end{bmatrix}\right) = n + m$ for all real ω.

(iv) $\operatorname{rank}\left(\begin{bmatrix} j\omega I - A & -B_1 \\ C_2 & D_{21} \end{bmatrix}\right) = n + q$ for all real ω.

(v) *Temporary assumption.* $D_{11} = 0$ and $D_{22} = 0$.

Additionally, the results that follow presume that the problem has been scaled so that the columns of D_{12} and D'_{21} are orthogonal. This is always possible by assumption (ii) (see [43]). We will introduce $D_\perp$ and $\tilde{D}_\perp$ which make $[D_\perp D_{12}]$ and $[\tilde{D}'_\perp D'_{21}]$ unitary.

The main results of this section will now be stated, and their proofs will be given in the following three sections. Theorem 5.1 gives necessary and sufficient conditions for the existence of a solution, while Theorem 5.2 characterizes all the solutions. Assumption (v) will be removed in § 5.3.

THEOREM 5.1. *Suppose that $P(s)$ is given by* (5.1) *and that assumptions* (i)–(v) *are satisfied. Then for any $\gamma > 0$ there exists an internally stabilizing controller $K(s)$ such that $\|F_l(P, K)\|_\infty \leqq \gamma$, if and only if*:

(i) *There exists*

$$\begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix} \in \mathcal{R}^{2n \times n} \text{ of } \operatorname{rank}(n)$$

such that

$$H_\infty \begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix} = \begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix} T_x, \quad \operatorname{Re} \lambda_i(T_x) \leqq 0 \quad \forall i, \tag{5.3}$$

$$X'_{\infty 1} X_{\infty 2} = X'_{\infty 2} X_{\infty 1} \tag{5.4}$$

where

(5.5) $$H_\infty = \begin{bmatrix} A - B_2 D'_{12} C_1 & \gamma^{-2} B_1 B'_1 - B_2 B'_2 \\ -C'_1 D_\perp D'_\perp C_1 & -(A - B_2 D'_{12} C_1)' \end{bmatrix}.$$

(ii) *There exists*

$\begin{bmatrix} Y_{\infty 1} \\ Y_{\infty 2} \end{bmatrix} \in \mathcal{R}^{2n \times n}$ *of* rank (n) *such that*

(5.6) $$J_\infty \begin{bmatrix} Y_{\infty 1} \\ Y_{\infty 2} \end{bmatrix} = \begin{bmatrix} Y_{\infty 1} \\ Y_{\infty 2} \end{bmatrix} T_Y, \quad \operatorname{Re} \lambda_i(T_Y) \leqq 0 \quad \forall i,$$

(5.7) $$Y'_{\infty 1} Y_{\infty 2} = Y'_{\infty 2} Y_{\infty 1}$$

where

(5.8) $$J_\infty = \begin{bmatrix} (A - B_1 D'_{21} C_2)' & \gamma^{-2} C'_1 C_1 - C'_2 C_2 \\ -B_1 \tilde{D}'_\perp \tilde{D}_\perp B'_1 & -(A - B_1 D'_{21} C_2) \end{bmatrix},$$

and

(iii)

(5.9) $$\begin{bmatrix} X'_{\infty 2} X_{\infty 1} & \gamma^{-1} X'_{\infty 2} Y'_{\infty 2} \\ \gamma^{-1} Y'_{\infty 2} X_{\infty 2} & Y'_{\infty 2} Y_{\infty 1} \end{bmatrix} \geqq 0.$$

Remark 5.1 (connections with previous results). In the case where $X_{\infty 1}$ and $Y_{\infty 1}$ are invertible we have $(5.9) \geqq 0$ if and only if

$$\begin{bmatrix} (X'_{\infty 1})^{-1} & 0 \\ 0 & (Y'_{\infty 1})^{-1} \end{bmatrix} (5.9) \begin{bmatrix} X_{\infty 1}^{-1} & 0 \\ 0 & Y_{\infty 1}^{-1} \end{bmatrix} = \begin{bmatrix} X_\infty & \gamma^{-1} X_\infty Y_\infty \\ \gamma^{-1} Y_\infty X_\infty & Y_\infty \end{bmatrix} \geqq 0$$

$$\Rightarrow \begin{bmatrix} I & 0 \\ \gamma^{-1} Y_\infty & I \end{bmatrix} \begin{bmatrix} X_\infty & 0 \\ 0 & Y_\infty(I - \gamma^{-2} X_\infty Y_\infty) \end{bmatrix} \begin{bmatrix} I & \gamma^{-1} Y_\infty \\ 0 & I \end{bmatrix} \geqq 0.$$

Thus (5.9) is equivalent to the three conditions (1) $X_\infty \geqq 0$, (2) $Y_\infty \geqq 0$, and (3) $\rho(X_\infty Y_\infty) \leqq \gamma^2$. These last three conditions are given in [11] and [20] in the suboptimal case. The optimal cases in which X_∞ and Y_∞ exist were considered in [33] where a connection with vector interpolation is given.

The conditions of Theorem 5.1 treat the cases in which $X_{\infty 1}$ and/or $Y_{\infty 1}$ are singular. Examples of this type of optimality are given in [27].

THEOREM 5.2. *If the conditions of Theorem* 5.1 *are satisfied, then all internally stabilizing controllers K that satisfy* $\|F_l(P, K)\|_\infty \leqq \gamma$ *are given by*

(5.10) $K = F_l(\mathcal{K}, U)$ *with* $U \in \mathcal{RH}_+^\infty$, $\|U\|_\infty \leqq \gamma$, $\det(I - \mathcal{K}_{22}(\infty) U(\infty)) \neq 0$

where

(5.11) $$\mathcal{K}(s) = \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} + \begin{bmatrix} C_{k1} \\ C_{k2} \end{bmatrix} (sE_k - A_k)^{\#} [B_{k1} \quad B_{k2}],$$

(5.12) $$E_k = Y'_{\infty 1} X_{\infty 1} - \gamma^{-2} Y'_{\infty 2} X_{\infty 2},$$

(5.13) $$B_{k1} = Y'_{\infty 1} B_1 D'_{21} + Y'_{\infty 2} C'_2,$$

(5.14) $$B_{k2} = Y'_{\infty 1} B_2 + \gamma^{-2} Y'_{\infty 2} C'_1 D_{12},$$

(5.15) $$C_{k1} = -D'_{12} C_1 X_{\infty 1} - B'_2 X_{\infty 2},$$

(5.16) $$C_{k2} = -C_2 X_{\infty 1} - \gamma^{-2} D_{21} B'_1 X_{\infty 2},$$

(5.17) $$A_k = E_k T_x + B_{k1} C_{k2}$$

(5.18) $$= T'_Y E_k + B_{k2} C_{k1}.$$ □

Remark 5.2 (computations, degree reduction, and the effective dimension of the free parameter). There are two possible consequences of E_k being singular. First, sE_k-A_k may have eigenvalues at infinity which do not appear as poles of $\mathscr{H}(s)$, and second, sE_k-A_k may be singular for all values of s. The same remarks applied to the realization of $Q_{aa}(s)$ given in § 4, and this was shown to be reducible to a standard state-space realization. The reason was twofold: First, $E_{aa}=R_{aa}+Q_{aa}$ satisfies the descriptor all-pass equations of Theorem 4.1, and second the realization of Q_{aa} has a particular structure as shown in § 4.3. It is easy to use the linear fractional relationship between $\mathscr{H}(s)$ and $Q_{aa}(s)$ to verify that the calculations, which were previously applied to $Q_{aa}(s)$ in § 4, are applicable to the realization of $\mathscr{H}(s)$, and these are now outlined. Suppose orthogonal changes of basis U and V are chosen so that $UE_kV=[\begin{smallmatrix}\hat{E}_k & 0\\ 0 & 0\end{smallmatrix}]$ in which $\hat{E}_k$ is nonsingular. Then (5.13) to (5.17) become

$$\hat{A}_k=UA_kV=\begin{bmatrix}\hat{A}_{k11} & \hat{A}_{k12}\\ \hat{A}_{k21} & \hat{A}_{k22}\end{bmatrix}, \tag{5.19}$$

$$\hat{B}_k=U[B_{k1}\quad B_{k2}]=\begin{bmatrix}\hat{B}_{k11} & \hat{B}_{k12}\\ \hat{B}_{k21} & \hat{B}_{k22}\end{bmatrix}, \tag{5.20}$$

$$\hat{C}_k=\begin{bmatrix}C_{k1}\\ C_{k2}\end{bmatrix}V=\begin{bmatrix}\hat{C}_{k11} & \hat{C}_{k12}\\ \hat{C}_{k21} & \hat{C}_{k22}\end{bmatrix} \tag{5.21}$$

in which the partitioning is compatible with that of $\hat{E}_k$. As explained in § 4, the state dimension of $\mathscr{H}(s)$ may be reduced by the rank defect of E_k by a singular perturbation type procedure. Direct calculation shows that a state-space model that is free of infinite eigenvalues is given by

$$A_{kr}=\hat{E}_k^{-1}[I\quad -\hat{A}_{k12}\hat{A}_{k22}^{\dagger}]\hat{A}_k\begin{bmatrix}I\\ 0\end{bmatrix}, \tag{5.22}$$

$$[B_{kr1}\quad B_{kr2}]=\hat{E}_k^{-1}[I\quad -\hat{A}_{k12}\hat{A}_{k22}^{\dagger}]\hat{B}_k, \tag{5.23}$$

$$\begin{bmatrix}C_{kr1}\\ C_{kr2}\end{bmatrix}=\hat{C}_k\begin{bmatrix}I\\ -\hat{A}_{k22}^{\dagger}\hat{A}_{k21}\end{bmatrix}, \tag{5.24}$$

$$\begin{bmatrix}D_{kr11} & D_{kr12}\\ D_{kr21} & D_{kr22}\end{bmatrix}=\begin{bmatrix}0 & I\\ I & 0\end{bmatrix}-\begin{bmatrix}\hat{C}_{k12}\\ \hat{C}_{k22}\end{bmatrix}\hat{A}_{k22}^{\dagger}[\hat{B}_{k21}\quad \hat{B}_{k22}]. \tag{5.25}$$

To explicitly show the reduction in dimension of the free parameter $U(s)$, we select orthogonal matrices Y and Z (which always exist) such that

$$Y[C_{kr2}\quad D_{kr21}]=\begin{bmatrix}\bar{C}_{kr2} & \bar{D}_{kr21}\\ 0 & 0\end{bmatrix}, \tag{5.26}$$

$$\begin{bmatrix}B_{kr2}\\ D_{kr12}\end{bmatrix}Z=\begin{bmatrix}\bar{B}_{kr2} & 0\\ \bar{D}_{kr12} & 0\end{bmatrix}, \tag{5.27}$$

$$YD_{kr22}Z=\begin{bmatrix}\bar{D}_{kr22} & 0\\ 0 & \gamma^{-1}I\end{bmatrix}. \tag{5.28}$$

Thus

$$\mathscr{H}(s)=\begin{bmatrix}D_{kr11} & \bar{D}_{kr12}\\ \bar{D}_{kr21} & \bar{D}_{kr22}\end{bmatrix}+\begin{bmatrix}C_{kr1}\\ \bar{C}_{kr2}\end{bmatrix}(sI-A_{kr})^{-1}[B_{kr1}\quad \bar{B}_{kr2}]. \qquad \square \tag{5.29}$$

5.1. A review of controller parameterization theory. The purpose of this section is to show how the original H^∞ control problem may be recast as a four block general distance problem. Our treatment of parameterization theory will be brief, as this material is standard and the details already appear in several places [10], [14], [15], [43]. Since P_{11}, P_{12}, P_{21}, and P_{22} share the same state-space it is clear the K stabilizes $F_l(P, K)$ if and only if it stabilizes P_{22}. Since (A, B_2, C_2) is assumed stabilizable and detectable, such controllers always exist. Let

$$P_{22} = N_r D_r^{-1} = D_l^{-1} N_l \tag{5.30}$$

be left and right coprime stable rational matrix fraction descriptions of P_{22} and

$$\begin{bmatrix} V_r & U_r \\ -N_l & D_l \end{bmatrix} \begin{bmatrix} D_r & -U_l \\ N_r & V_l \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix} \tag{5.31}$$

the corresponding Bezout identities. All the matrices in (5.31) belong to $\mathcal{H}_+^\infty$, and the set of all compensators which stabilize P_{22} and thus also P are given by [43]

$$K = F_l(K_0, Q), \qquad Q \in \mathcal{H}_+^\infty \tag{5.32}$$

where

$$K_0(s) = \begin{bmatrix} -V_r^{-1} U_r & -V_r^{-1} \\ V_l^{-1} & V_l^{-1} N_r \end{bmatrix}. \tag{5.33}$$

Since

$$K(I - P_{22}K)^{-1} = (-D_r Q - U_l) D_l$$

we obtain

$$\begin{aligned} \mathcal{R}(s) &= P_{11} + P_{12}K(I - P_{22}K)^{-1}P_{21} \\ &= (P_{11} - P_{12}U_l D_l P_{21}) - (P_{12}D_r)Q(D_l P_{21}) \\ &= T_{11} + T_{12}QT_{21}, \end{aligned} \tag{5.34}$$

which is an affine parameterization of all internally stable closed loops.

Since (A, B_2) is stabilizable there exists a state feedback matrix F such that $A - B_2F$ is stable. Similarly, since (C_2, A) is detectable there exists an output injection matrix H such that $A - HC_2$ is stable. Given any such pair of stabilizing matrices F and H, the right and left coprime factorizations of P_{22} together with the solutions of the Bezout identities are given by [10], [14], [15], and [43]

$$\begin{bmatrix} D_r & -U_l \\ N_r & V_l \end{bmatrix} \overset{s}{=} \left[\begin{array}{c|cc} A - B_2F & B_2 & H \\ \hline -F & I & 0 \\ C_2 & 0 & I \end{array}\right] \tag{5.35}$$

and

$$\begin{bmatrix} V_r & U_r \\ -N_l & D_l \end{bmatrix} \overset{s}{=} \left[\begin{array}{c|cc} A - HC_2 & B_2 & H \\ \hline F & I & 0 \\ -C_2 & 0 & I \end{array}\right]. \tag{5.36}$$

Substituting (5.35) and (5.36) into (5.33) yields

$$K_0(s) \overset{s}{=} \left[\begin{array}{c|cc} A - B_2F - HC_2 & H & B_2 \\ \hline -F & 0 & I \\ -C_2 & I & 0 \end{array}\right] \tag{5.37}$$

after simplification. We will now make the following specific choices of the stabilizing matrices F and H which will lead to all-pass properties in T_{12} and T_{21} in (5.34). Specifically, we define F and H by

$$F = D_{12}'C_1 + B_2'X, \tag{5.38}$$

$$H = B_1D_{21}' + YC_2' \tag{5.39}$$

where X and Y are the unique stabilizing solutions to

$$X(A - B_2D_{12}'C_1) + (A - B_2D_{12}'C_1)'X - XB_2B_2'X + C_1'D_\perp D_\perp' C_1 = 0 \tag{5.40}$$

and

$$Y(A - B_1D_{21}'C_2)' + (A - B_1D_{21}'C_2)Y - YC_2'C_2Y + B_1\tilde{D}_\perp'\tilde{D}_\perp B_1' = 0. \tag{5.41}$$

Direct substitution into (5.34) leads to

$$\begin{bmatrix} T_{11} & T_\perp & T_{12} \\ \tilde{T}_\perp & 0 & 0 \\ T_{21} & 0 & 0 \end{bmatrix}(s) \overset{s}{=} \left[\begin{array}{cc|ccc} A - B_2F & B_2F & B_1 & -X^\dagger C_1'D_\perp & B_2 \\ 0 & A - HC_2 & B_1 - HD_{21} & 0 & 0 \\ \hline C_1 - D_{12}F & D_{12}F & 0 & D_\perp & D_{12} \\ 0 & -\tilde{D}_\perp B_1'Y^\dagger & \tilde{D}_\perp & 0 & 0 \\ 0 & C_2 & D_{21} & 0 & 0 \end{array}\right]. \tag{5.42}$$

With this particular choice of F and H, $[T_\perp \mid T_{12}]$ and $[\tilde{T}_\perp^\sim \mid T_{21}^\sim]$ are all-pass [10], [14], [15], [43]. We call $T_\perp(s)$ and $\tilde{T}_\perp(s)$ all-pass extensions of T_{12} and T_{21}, respectively, and this all-pass property allows us to write

$$\left\| T_{11} - [T_\perp \ \ T_{12}] \begin{bmatrix} 0 & 0 \\ 0 & Q \end{bmatrix} \begin{bmatrix} \tilde{T}_\perp \\ T_{21} \end{bmatrix} \right\|_\infty = \left\| \begin{matrix} R_{11} & R_{12} \\ R_{21} & R_{22} - Q \end{matrix} \right\|_\infty \tag{5.43}$$

where

$$R(s) = \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} = \begin{bmatrix} T_\perp^\sim \\ T_{12}^\sim \end{bmatrix} T_{11}[\tilde{T}_\perp^\sim \ \ T_{21}^\sim]. \tag{5.44}$$

Substituting (5.42) into (5.44) gives

$$R(s) \overset{s}{=} \left[\begin{array}{cc|cc} -(A - B_2F)' & XB_1(B_1 - HD_{21})' & XB_1\tilde{D}_\perp' & XB_1D_{21}' \\ 0 & -(A - HC_2)' & Y^\dagger B_1\tilde{D}_\perp' & -C_2' \\ \hline D_\perp' C_1X^\dagger & 0 & 0 & 0 \\ -B_2' & FY & 0 & 0 \end{array}\right], \tag{5.45}$$

which describes the four block problem to be solved.

In the case where X and/or Y are singular, this realization will not be minimal and it will be convenient to delete the nonminimal states as follows [31], [32]. Let

$$X = U\begin{bmatrix} X_1 & 0 \\ 0 & 0 \end{bmatrix}U', \quad X_1 > 0 \quad \text{where } U = [U_1 \ \ U_2] \text{ is unitary;}$$

$$Y = V\begin{bmatrix} Y_1 & 0 \\ 0 & 0 \end{bmatrix}V', \quad Y_1 > 0 \quad \text{where } V = [V_1 \ \ V_2] \text{ is unitary.}$$

The Riccati equations for X and Y then give that

$$U_1'(A - B_2D_{12}'C_1)U_2 = U_1'(A - B_2F)U_2 = 0, \qquad D_\perp' C_1U_2 = 0$$

$$V_2'(A - B_1D_{21}'C_2)V_1 = V_2'(A - HC_2)V_1 = 0, \qquad V_2'B_1\tilde{D}_\perp' = 0$$

$$B_1 - HD_{21} = B_1\tilde{D}_\perp'\tilde{D}_\perp - YC_2'D_{21} \Rightarrow V_2'(B_1 - HD_{21}) = 0$$

$$C_1 - D_{12}F = D_\perp D_\perp' C_1 - D_{12}B_2'X \Rightarrow (C_1 - D_{12}F)U_2 = 0$$

The state transformation $[\begin{smallmatrix} U' & 0 \\ 0 & V' \end{smallmatrix}]$ applied to $R(s)$ then exhibits the nonminimal modes which may be removed, and this followed by the state transformation $[\begin{smallmatrix} X_1^{-1} & 0 \\ 0 & Y_1 \end{smallmatrix}]$ gives

$$(5.46)\quad R(s)=\left[\begin{array}{c|cc} A_R & B_{R1} & B_{R2} \\ \hline C_{R1} & 0 & 0 \\ C_{R2} & 0 & 0 \end{array}\right] \overset{s}{=} \left[\begin{array}{cc|cc} -A_F' & U_1'B_1B_{1H}' & U_1'B_1\tilde{D}_\perp' & U_1'B_1D_{21}' \\ 0 & -A_H' & V_1'B_1\tilde{D}_\perp' & -Y_1V_1'C_2' \\ \hline D_\perp'C_1U_1 & 0 & 0 & 0 \\ -B_2'U_1X_1 & FV_1 & 0 & 0 \end{array}\right].$$

An alternative realization for $R(s)$ can be obtained via a state-space transformation

$$T_R=\begin{bmatrix} I & -U_1'V_1 \\ 0 & I \end{bmatrix}.$$

That is,

$$(5.47)\qquad R(s)\overset{s}{=}\left[\begin{array}{cc|cc} -A_F' & C_{1F}'C_1V_1 & 0 & U_1'H \\ 0 & -A_H' & V_1'B_1\tilde{D}_\perp' & -Y_1V_1'C_2' \\ \hline D_\perp'C_1U_1 & D_\perp'C_1V_1 & 0 & 0 \\ -B_2'U_1X_1 & D_{12}'C_1V_1 & 0 & 0 \end{array}\right]$$

where

$$\begin{aligned} A_F &= X_1U_1'(A-B_2F)U_1X_1^{-1} \\ A_H &= Y_1^{-1}V_1'(A-HC_2)V_1Y_1 \\ B_{1H} &= Y_1^{-1}V_1'(B_1-HD_{21}) = Y_1^{-1}V_1'B_1\tilde{D}_\perp'\tilde{D}_\perp - V_1'C_2'D_{21} \\ C_{1F} &= (C_1-D_{12}F)U_1X_1^{-1} = D_\perp D_\perp'C_1U_1X_1^{-1} - D_{12}B_2'U_1 \end{aligned}$$

and the Riccati equations for X and Y can be rewritten as

$$(5.48)\qquad A_F'X_1^{-1}+X_1^{-1}A_F+C_{1F}'C_{1F}=0,$$

$$(5.49)\qquad A_HY_1^{-1}+Y_1^{-1}A_H'+B_{1H}B_{1H}'=0.$$

5.2. Necessary and sufficient conditions. A necessary condition for $\left\|R+\begin{bmatrix} 0 & 0 \\ 0 & Q \end{bmatrix}\right\|_\infty \leqq \gamma$ is $\|R_{11} \quad R_{12}\|_\infty \leqq \gamma \Leftrightarrow \|T_\perp^\sim T_{11}[\tilde{T}_\perp^\sim \quad T_{21}^\sim]\|_\infty \leqq \gamma \Leftrightarrow \|T_\perp^\sim T_{11}\|_\infty \leqq \gamma$.

However,

$$\begin{aligned} T_\perp^\sim T_{11} &\overset{s}{=} \left[\begin{array}{c|c} -(A-B_2F)' & XB_1 \\ \hline D_\perp'C_1X^\dagger & 0 \end{array}\right] \\ &\overset{s}{=} \left[\begin{array}{c|c} -A_F' & U_1'B_1 \\ \hline D_\perp'C_1U_1 & 0 \end{array}\right] \end{aligned}$$

so that the corresponding spectral factorization Riccati equation to find R_{13} (note that $R_{13}R_{13}^\sim=\gamma^2I-[R_{11} \quad R_{12}][R_{11}^\sim \quad R_{12}^\sim]^\sim=\gamma^2I-T_\perp^\sim T_{11}T_{11}^\sim T_\perp$) has a solution $\hat{X}\geqq 0$ satisfying

$$H_{\hat{X}}\begin{bmatrix} I \\ \hat{X} \end{bmatrix}=\begin{bmatrix} I \\ \hat{X} \end{bmatrix}T_{\hat{X}}, \qquad \operatorname{Re}\lambda_i(T_{\hat{X}})\leqq 0 \quad \forall i$$

where

$$(5.50)\qquad H_{\hat{X}}=\begin{bmatrix} A_F & \gamma^{-2}U_1'C_1'D_\perp D_\perp'C_1U_1 \\ -U_1'B_1B_1'U_1 & -A_F' \end{bmatrix}.$$

Similarly, the condition $\|R_{\widetilde{11}} \quad R_{\widetilde{21}}\|_\infty \leqq \gamma$ implies that there exists $\hat{Y} \geqq 0$ such that

$$H_{\hat{Y}} \begin{bmatrix} I \\ \hat{Y} \end{bmatrix} = \begin{bmatrix} I \\ \hat{Y} \end{bmatrix} T_{\hat{Y}}, \qquad \operatorname{Re} \lambda_i(T_{\hat{Y}}) \leqq 0 \quad \forall i,$$

where

$$H_{\hat{Y}} = \begin{bmatrix} A_H' & \gamma^{-2} V_1' B_1 \tilde{D}_\perp' \tilde{D}_\perp B_1' V_1 \\ -V_1' C_1' C_1 V_1 & -A_H \end{bmatrix}. \tag{5.51}$$

In order to apply the necessary and sufficient conditions of Theorem 4.2, the solutions to the Riccati equations (3.51) and (3.52) (which determine R_{13} and R_{31}) in $R(s)$ are required, and they are now given.

LEMMA 5.3. *For the realization of $R(s)$ defined in* (5.46) *the Riccati equations*:

$$-P_1 A_R' - A_R P_1 + B_{R1} B_{R1}' + B_{R2} B_{R2}' + \gamma^{-2} P_1 C_{R1}' C_{R1} P_1 = 0 \tag{5.52a}$$

$$-Q_1 A_R - A_R' Q_1 + C_{R1}' C_{R1} + C_{R2}' C_{R2} + \gamma^{-2} Q_1 B_{R1}' B_{R1} Q_1 = 0 \tag{5.52b}$$

are satisfied for

$$P_1 = \begin{bmatrix} \hat{X} & 0 \\ 0 & Y_1 \end{bmatrix}, \qquad Q_1 = T_R' Q_0 T_R$$

$$T_R = \begin{bmatrix} I & -U_1' V_1 \\ 0 & I \end{bmatrix}, \qquad Q_0 = \begin{bmatrix} X_1 & 0 \\ 0 & \hat{Y} \end{bmatrix},$$

and

$$\operatorname{Re} \lambda_i(A_R - \gamma^{-2} P_1 C_{R1}' C_{R1}) \geqq 0 \quad \forall i,$$

$$\operatorname{Re} \lambda_i(A_R - \gamma^{-2} B_{R1} B_{R1}' Q_1) \geqq 0 \quad \forall i.$$

Proof. P_1 is simply shown to satisfy (5.52) by (5.49) and (5.50) with antistability given by the stability of $T_{\hat{X}}$ and A_H. An analogous derivation applies to Q_0 for the alternative realization of R in (5.47) and then $T_R'^{-1}$ relates Q_1 to Q_0. □

Proof of Theorem 5.1. Theorem 4.2 and the above calculations give the necessary and sufficient conditions for controllers to exist to be that $\hat{X} \geqq 0$ and $\hat{Y} \geqq 0$ exist, and

$$\lambda_{\max}(P_1 Q_1) \leqq \gamma^2.$$

To write this condition as that stated in the theorem, we write

$$\begin{aligned} \gamma^2 I - P_1 Q_1 &= (\gamma^2 T_R^{-1} - P_1 T_R' Q_0) T_R \\ &= \begin{bmatrix} \gamma I & 0 \\ 0 & Y_1 \end{bmatrix} \Pi(\gamma) \begin{bmatrix} X_1 & 0 \\ 0 & \gamma I \end{bmatrix} T_R \end{aligned} \tag{5.53}$$

in which

$$\Pi(\gamma) = \begin{bmatrix} \gamma X_1^{-1} - \gamma^{-1} \hat{X} & U_1' V_1 \\ V_1' U_1 & \gamma Y_1^{-1} - \gamma^{-1} \hat{Y} \end{bmatrix}.$$

Since P_1 and Q_1 are both monotonically decreasing functions of γ [51], $\lambda_{\max}(P_1 Q_1)$ is also a monotonically decreasing function of γ, and so $\lambda_{\max}(P_1 Q_1) \leqq \gamma^2$ if and only if $\Pi(\gamma) \geqq 0$.

This condition now needs to be written in terms of $X_{\infty 1}$, $X_{\infty 2}$, $Y_{\infty 1}$, and $Y_{\infty 2}$. The Riccati equations for X_1 (5.48) give, as in [11, § VII.C], that

$$\begin{bmatrix} X_1^{-1} & -\gamma^{-2}I \\ I & 0 \end{bmatrix} H_{\hat{X}} \begin{bmatrix} 0 & I \\ -\gamma^{-2}I & \gamma^2 X_1^{-1} \end{bmatrix} = \begin{bmatrix} U_1' & 0 \\ 0 & U_1' \end{bmatrix} H_\infty \begin{bmatrix} U_1 & 0 \\ 0 & U_1 \end{bmatrix}.$$

Hence

$$\begin{bmatrix} U_1' & 0 \\ O & U_1' \end{bmatrix} H_\infty \begin{bmatrix} U_1 & 0 \\ 0 & U_1 \end{bmatrix} \begin{bmatrix} X_1^{-1} & -\gamma^{-2}I \\ I & 0 \end{bmatrix} \begin{bmatrix} I \\ \hat{X} \end{bmatrix} = \begin{bmatrix} X_1^{-1} & -\gamma^{-2}I \\ I & 0 \end{bmatrix} \begin{bmatrix} I \\ \hat{X} \end{bmatrix} T_{\hat{X}}$$

$$= \begin{bmatrix} X_1^{-1} - \gamma^{-2}\hat{X} \\ I \end{bmatrix} T_{\hat{X}}$$

and exploiting the structure of $U'(A - B_2 D_{12}' C_1)U$ and $U' C_1' D_\perp$ give

$$H_\infty \begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix} = \begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix} T_x$$

where

$$X_{\infty 1} = U_1(X_1^{-1} - \gamma^{-2}\hat{X})U_1' + U_2 U_2',$$
$$X_{\infty 2} = U_1 U_1'$$

satisfy

$$X_{\infty 1}' X_{\infty 2} = X_{\infty 2}' X_{\infty 1}$$

and all such matrices are given by $\left[\begin{smallmatrix} X_{\infty 1} \\ X_{\infty 2} \end{smallmatrix}\right] S$ for a nonsingular S. (This comes from the strict stability of $U_2'(A - B_2 D_{12}' C_1)U_2$ and the uniqueness of $\hat{X}$.) Furthermore, exploiting the structure of $\left[\begin{smallmatrix} U' & 0 \\ 0 & U' \end{smallmatrix}\right] H_\infty \left[\begin{smallmatrix} U & 0 \\ 0 & U \end{smallmatrix}\right]$ shows that if $X_{\infty 1}' X_{\infty 2} = X_{\infty 2}' X_{\infty 1}$ then $\hat{X} = \hat{X}'$ exists. An analogous argument applies to $Y_{\infty 1}$, $Y_{\infty 2}$, and $\hat{Y}$. The final condition $\Pi(\gamma) \geqq 0$ is equivalent to

$$0 \leqq \begin{bmatrix} U_1 & 0 \\ 0 & V_1 \end{bmatrix} \Pi(\gamma) \begin{bmatrix} U_1' & 0 \\ 0 & V_1' \end{bmatrix}$$
$$= \gamma \begin{bmatrix} X_{\infty 2}' X_{\infty 1} & \gamma^{-1} X_{\infty 2}' Y_{\infty 2} \\ \gamma^{-1} Y_{\infty 2}' X_{\infty 2} & Y_{\infty 2}' Y_{\infty 1} \end{bmatrix}. \qquad \square$$

5.3. Characterization of all solutions. Theorem 4.4 characterizes all optimal solutions to the model matching problem and Theorem 5.2 claims to do the same for the feedback control problem. A derivation of the formula in Theorem 5.2 can be obtained by applying Theorem 4.4 to generate all $Q(s)$'s, and then substituting into $K_0(s)$ to generate all $K(s)$'s. Finally, all the nonminimal modes are removed from this parameterization. In the rest of this section we assume, without loss of generality, that $\gamma = 1$ for simplicity.

Applying Theorem 4.2 to the realization of R given in (5.46) gives

$$\begin{bmatrix} Q_{22} & Q_{24} \\ Q_{42} & Q_{44} \end{bmatrix} = \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} + \begin{bmatrix} C_{R2} P_1 \\ -B_{R2}' \end{bmatrix}$$
$$\cdot ((I - Q_1 P_1)s - (-A_R' - Q_1 A_R P_1 + Q_1 B_{R1} B_{R1}' + C_{R1}' C_{R1} P_1))^{-1}$$
$$\cdot [Q_1 B_{R2} \quad -C_{R2}'].$$

Recall from (5.53) that

$$(I - Q_1 P_1) = T_R' \begin{bmatrix} X_1 & 0 \\ 0 & I \end{bmatrix} \Pi \begin{bmatrix} I & 0 \\ 0 & Y_1 \end{bmatrix}$$

in which $\Pi = \Pi(1)$. Changing coordinates gives

$$\begin{bmatrix} Q_{22} & Q_{24} \\ Q_{42} & Q_{44} \end{bmatrix} = \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} + \begin{bmatrix} \hat{C}_{01} \\ \hat{C}_{02} \end{bmatrix} (s\Pi - \hat{A}_0)^{-1} [\hat{B}_{01} \quad \hat{B}_{02}]$$

$$\text{(5.54a)} \quad \hat{A}_0 = \begin{bmatrix} X_1^{-1} & 0 \\ 0 & I \end{bmatrix} (-T_R'^{-1} A_R' - Q_0 T_R A_R P_1 + Q_0 T_R B_{R1} B'_{R1} + T_R'^{-1} C'_{R1} C_{R1} P_1) \begin{bmatrix} I & 0 \\ 0 & Y_1^{-1} \end{bmatrix},$$

$$\text{(5.55)} \quad \begin{bmatrix} \hat{C}_{01} \\ \hat{C}_{02} \end{bmatrix} = \begin{bmatrix} C_{R2} P_1 \\ -B'_{R2} \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & Y_1^{-1} \end{bmatrix} = \begin{bmatrix} -B_2' U_1 X_1 \hat{X} & F V_1 \\ -D_{21} B_1' U_1 & C_2 V_1 \end{bmatrix},$$

$$\text{(5.56)} \quad \begin{aligned} [\hat{B}_{01} \quad \hat{B}_{02}] &= \begin{bmatrix} X_1^{-1} & 0 \\ 0 & I \end{bmatrix} [Q_0 T_R B_{R2} \quad -T_R'^{-1} C'_{R2}] \\ &= \begin{bmatrix} U_1' H & U_1' B_2 \\ -\hat{Y} Y_1 V_1' C_2' & -V_1' C_1' D_{12} \end{bmatrix}, \end{aligned}$$

$$\text{(5.54b)} \quad \begin{aligned} \hat{A}_{011} &= X_1^{-1} A_F + A_F' \hat{X} + X_1^{-1} U_1' C_1' D_\perp D_\perp' C_1 U_1 \hat{X} \\ &= X_1^{-1} A_F - X_1^{-1} A_F X_1 \hat{X} - U_1' B_2 B_2' U_1 X_1 \hat{X} \end{aligned}$$

$$\text{(5.54c)} \quad \begin{aligned} \hat{A}_{012} &= -(U_1' B_1 B'_{1H} + U_1' V_1 A_H') = -U_1'(B_1(B_1 - HD_{21})' + Y(A - HC_2)') V_1 Y_1^{-1} \\ &= U_1' A Y V_1 Y_1^{-1} = U_1' A V_1, \end{aligned}$$

$$\text{(5.54d)} \quad \begin{aligned} \hat{A}_{021} &= -(B_{1H} B_1' U_1 - V_1' U_1 A_F) + \hat{Y} V_1' B_1 \tilde{D}_\perp' \tilde{D}_\perp B_1' U_1 + V_1' C_1' D_\perp D_\perp' C_1 U_1 \hat{X} \\ &= (\hat{Y} - Y_1^{-1}) V_1' B_1 \tilde{D}_\perp' \tilde{D}_\perp B_1' U_1 + V_1' C_1' D_\perp D_\perp' C_1 U_1 (\hat{X} - X_1^{-1}) \\ &\quad - V_1'(A - B_2 D_{12}' C_1 - B_1 D_{21}' C_2)' U_1, \end{aligned}$$

$$\text{(5.54e)} \quad \begin{aligned} \hat{A}_{022} &= A_H Y_1^{-1} + \hat{Y} A_H' + \hat{Y} V_1' B_1 \tilde{D}_\perp' \tilde{D}_\perp B_1' V_1 Y_1^{-1} \\ &= A_H Y_1^{-1} + \hat{Y} Y_1 (-A_H Y_1^{-1} - V_1' C_2' C_2 V_1) \\ &= (I - \hat{Y} Y_1) A_H Y_1^{-1} - \hat{Y} Y_1 V_1' C_2' C_2 V_1. \end{aligned}$$

The characterization of all $K(s)$ is given by

$$\begin{aligned} K(s) &= F_l\left(K_0, F_l\left(\begin{bmatrix} Q_{22} & Q_{24} \\ Q_{42} & Q_{44} \end{bmatrix}, U\right)\right) \\ &= F_l(\mathcal{K}, U) \end{aligned}$$

where

$$\mathcal{K} = F_l \left\{ \begin{bmatrix} K_{011} & 0 & K_{012} & 0 \\ 0 & 0 & 0 & I \\ K_{021} & 0 & K_{022} & 0 \\ 0 & I & 0 & 0 \end{bmatrix}, \begin{bmatrix} Q_{22} & Q_{24} \\ Q_{42} & Q_{44} \end{bmatrix} \right\}.$$

Substituting for the realization gives that

$$\text{(5.57)} \quad \mathcal{K}(s) = \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} + \hat{C}_1 (s\hat{E}_1 - \hat{A}_1)^{-1} \hat{B}_1$$

where

$$\hat{E}_1 = \begin{bmatrix} I & 0 \\ 0 & \Pi \end{bmatrix}, \tag{5.58}$$

$$\hat{A}_1 = \begin{bmatrix} A - B_2F - HC_2 & B_2\hat{C}_{01} \\ -\hat{B}_{01}C_2 & \hat{A}_0 \end{bmatrix}, \tag{5.59}$$

$$\hat{B}_1 = \begin{bmatrix} H & B_2 \\ \hat{B}_{01} & \hat{B}_{02} \end{bmatrix}, \tag{5.60}$$

$$\hat{C}_1 = \begin{bmatrix} -F & \hat{C}_{01} \\ -C_2 & \hat{C}_{02} \end{bmatrix}. \tag{5.61}$$

This realization contains rank (X) uncontrollable modes and rank (Y) unobservable modes and these are exhibited by the following transformation. First, define

$$X_{\infty 11} = X_1^{-1} - \hat{X}, \qquad Y_{\infty 11} = Y_1^{-1} - \hat{Y}$$

$$T_l = \begin{bmatrix} V' & 0 & 0 \\ -U_1' & I & 0 \\ -Y_{\infty 11}'V_1' & 0 & I \end{bmatrix}, \qquad T_r = \begin{bmatrix} U & U_1X_{\infty 11} & V_1 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix}, \tag{5.62}$$

$$\hat{E}_2 = T_l\hat{E}_1T_r = \begin{bmatrix} V'U & V'U_1X_{\infty 11} & \begin{bmatrix} I \\ 0 \end{bmatrix} \\ [-I \quad 0] & 0 & 0 \\ -Y_{\infty 11}V_1'U & V_1'U_1 - Y_{\infty 11}V_1'U_1X_{\infty 11} & 0 \end{bmatrix}, \tag{5.63}$$

$$\hat{A}_2 = T_l\hat{A}_1T_r = \begin{bmatrix} \hat{A}_{211} & \hat{A}_{212} & \hat{A}_{213} \\ \hat{A}_{221} & \hat{A}_{222} & \hat{A}_{223} \\ \hat{A}_{231} & \hat{A}_{232} & \hat{A}_{233} \end{bmatrix}, \tag{5.64}$$

$$\hat{B}_2 = T_l\hat{B}_1 = \begin{bmatrix} \hat{B}_{21} \\ \hat{B}_{22} \\ \hat{B}_{23} \end{bmatrix}, \qquad \hat{C}_2 = \hat{C}_1T_r = [\hat{C}_{21} \quad \hat{C}_{22} \quad \hat{C}_{23}], \tag{5.65}$$

$$\hat{B}_{22} = 0 \quad \text{by (5.56)},$$

$$\hat{C}_{23} = 0 \quad \text{by (5.57)},$$

$$\begin{aligned} [\hat{A}_{221} \quad \hat{A}_{222} \quad \hat{A}_{223}] &= -U_1'[A - B_2F - HC_2 \quad -B_2B_2'U_1X_1\hat{X} \quad B_2FV_1]T_r \\ &\quad + [-U_1'HC_2 \quad \hat{A}_{011} \quad \hat{A}_{012}]T_r \\ &= [-U_1'(A - B_2F) \quad X_1^{-1}A_FX_1X_{\infty 11} \quad \hat{A}_{012} - U_1'B_2FV_1]T_r \\ \Rightarrow \hat{A}_{221} &= [-U_1'(A - B_2F)U_1 \quad 0], \qquad \hat{A}_{222} = 0, \qquad \hat{A}_{223} = 0 \end{aligned}$$

Hence the first rank (X) states are uncontrollable. Furthermore,

$$\hat{A}_{213} = V'(A - B_2F - HC_2)V_1 + V'B_2FV_1 = \begin{bmatrix} V_1'(A - HC_2)V_1 \\ 0 \end{bmatrix},$$

$$\begin{aligned} [\hat{A}_{231} \quad \hat{A}_{232} \quad \hat{A}_{233}] &= -Y_{\infty 11}V_1'[A - B_2F - HC_2 \quad -B_2B_2'U_1X_1\hat{X} \quad B_2FV_1]T_r \\ &\quad + [\hat{Y}Y_1V_1'C_2'C_2 \quad \hat{A}_{021} \quad \hat{A}_{022}]T_r \end{aligned}$$

$\Rightarrow \hat{A}_{233} = 0$ and the last rank (Y) states are unobservable. A reduced state model can hence be obtained and its realization transformed as follows:

$$\hat{E}_3 = [V_2 \quad -V_1]\begin{bmatrix} V_2'U_2 & V_2'U_1X_{\infty 11} \\ -Y_{\infty 11}V_1'U_2 & V_1'U_1 - Y_{\infty 11}V_1'U_1X_{\infty 11}\end{bmatrix}\begin{bmatrix} U_2' \\ U_1' \end{bmatrix} \tag{5.66}$$

without loss of generality (see proof of Theorem 5.1) we can assume

$$X_{\infty 1} = U\begin{bmatrix} X_{\infty 11} & 0 \\ 0 & I \end{bmatrix}U', \qquad X_{\infty 2} = U_1U_1',$$

$$Y_{\infty 1} = V\begin{bmatrix} Y_{\infty 11} & 0 \\ 0 & I \end{bmatrix}V', \qquad Y_{\infty 2} = V_1V_1'$$

and hence

$$\hat{E}_3 = Y_{\infty 1}'X_{\infty 1} - Y_{\infty 2}'X_{\infty 2} = E_k,$$

$$\begin{aligned}
\hat{B}_3 = [B_{k1} \quad B_{k2}] &= [V_2 \quad -V_1]\begin{bmatrix} V_2' & 0 \\ -Y_{\infty 11}'V_1' & I \end{bmatrix}\begin{bmatrix} H & B_2 \\ -\hat{Y}Y_1V_1'C_2' & -V_1'C_1'D_{12}\end{bmatrix} \\
&= [Y_{\infty 1}' \quad -V_1]\begin{bmatrix} H & B_2 \\ -\hat{Y}Y_1V_1'C_2' & -V_1'C_1'D_{12}\end{bmatrix} \\
&= [Y_{\infty 1}'(YC_2' + B_1D_{21}') + V_1(I - Y_{\infty 11}Y_1)V_1'C_2', \\
&\qquad Y_{\infty 1}'B_2 + V_1V_1'C_1'D_{12}] \\
&= [Y_{\infty 2}'C_2' + Y_{\infty 1}'B_1D_{21}' \quad Y_{\infty 1}'B_2 + Y_{\infty 2}'C_1'D_{12}],
\end{aligned} \tag{5.67}$$

$$\begin{aligned}
\hat{C}_3 = \begin{bmatrix} C_{k1} \\ C_{k2} \end{bmatrix} &= \begin{bmatrix} -F & -B_2'U_1X_1\hat{X} \\ -C_2 & -D_{21}B_1'U_1 \end{bmatrix}\begin{bmatrix} U_2 & U_1X_{\infty 11} \\ 0 & I \end{bmatrix}\begin{bmatrix} U_2' \\ U_1' \end{bmatrix} \\
&= -\begin{bmatrix} F & B_2'U_1X_1\hat{X} \\ C_2 & D_{21}B_1'U_1 \end{bmatrix}\begin{bmatrix} X_{\infty 1} \\ U_1' \end{bmatrix} \\
&= -\begin{bmatrix} D_{12}'C_1X_{\infty 1} + B_2'X_{\infty 2} \\ C_2X_{\infty 1} + D_{21}B_1'X_{\infty 2} \end{bmatrix},
\end{aligned} \tag{5.68}$$

$$\begin{aligned}
\hat{A}_3 &= [Y_{\infty 1}' \quad -V_1]\begin{bmatrix} A - B_2F - HC_2 & -B_2B_2'U_1X_1\hat{X} \\ \hat{Y}Y_1V_1'C_2'C_2 & \hat{A}_{021} \end{bmatrix}\begin{bmatrix} X_{\infty 1} \\ U_1' \end{bmatrix} \\
&= [Y_{\infty 1}' \quad -Y_{\infty 2}']\left\{H_\infty + \begin{bmatrix} -B_1D_{21}' \\ C_2' \end{bmatrix}[C_2 \quad D_{21}B_1'] + \begin{bmatrix} L_{11} & L_{12} \\ L_{21} & L_{22} \end{bmatrix}\right\}\begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix}
\end{aligned} \tag{5.69}$$

where

$$L_{11} = -B_2B_2'X - YC_2'C_2,$$

$$L_{12} = B_2B_2'(I - U_1X_1\hat{X}U_1') - B_1\tilde{D}_\perp'\tilde{D}_\perp B_1',$$

$$L_{21} = -(I - V_1\hat{Y}Y_1V_1')C_2'C_2 + C_1'D_\perp D_\perp'C_1,$$

$$L_{22} = (A - B_2D_{12}'C_1 - B_1D_{21}'C_2)' + V_1\hat{A}_{021}U_1',$$

$$V_1'L_{22}U_1 = (\hat{Y} - Y_1^{-1})V_1'B_1\tilde{D}_\perp'\tilde{D}_\perp B_1'U_1 + V_1'C_1'D_\perp D_\perp'C_1U_1(\hat{X} - X_1^{-1}).$$

The equations $XX_{\infty 1}+U_1X_1\hat{X}U_1'=U_1U_1'$ and $Y_{\infty 1}Y+V_1\hat{Y}Y_1V_1'=V_1V_1'$ and direct substitution gives

$$[Y_{\infty 1} \quad -Y_{\infty 2}]\begin{bmatrix} L_{11} & L_{12} \\ L_{21} & L_{22} \end{bmatrix}\begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix}=0$$

and finally $\hat{A}_3=A_k$ since

$$H_\infty\begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix}=\begin{bmatrix} X_{\infty 1} \\ X_{\infty 2} \end{bmatrix}T_x. \qquad \square$$

5.4. Removing assumption (v). In this section we show how we might tackle problems in which $D_{11}\neq 0$ and/or $D_{22}\neq 0$. The idea is to show that assumption (v) results in no loss of generality, and that the original problem with $D_{11}\neq 0$ and $D_{22}\neq 0$ may be replaced with an equivalent problem in which $\hat{D}_{11}=0$ and $\hat{D}_{22}=0$. This observation is particularly useful in theoretical work requiring state-space calculations, since, as we will soon show, the case $D_{11}\neq 0$ leads to controllers with an unwieldy number of terms.

Step 1. The purpose of this step is to solve the four block problem at infinity. Suppose F_∞ is a constant feedback to be defined, and suppose also that $P(s)$ is as given in (5.1). Then for any such F_∞

(5.70)

$$\bar{P}(s)=F_l\left(\left[\begin{array}{cc|c} P_{11} & P_{12} & P_{12} \\ P_{21} & P_{22} & P_{22} \\ \hline P_{21} & P_{22} & P_{22} \end{array}\right], F_\infty\right)$$

$$=\left[\begin{array}{c|cc} \bar{A} & \bar{B}_1 & \bar{B}_2 \\ \hline \bar{C}_1 & \bar{D}_{11} & \bar{D}_{12} \\ \bar{C}_2 & \bar{D}_{21} & \bar{D}_{22} \end{array}\right]$$

$$=\left[\begin{array}{c|cc} A+B_2F_\infty(I-D_{22}F_\infty)^{-1}C_2 & B_1+B_2F_\infty(I-D_{22}F_\infty)^{-1}D_{21} & B_2(I-F_\infty D_{22})^{-1} \\ \hline C_1+D_{12}F_\infty(I-D_{22}F_\infty)^{-1}C_2 & D_{11}+D_{12}F_\infty(I-D_{22}F_\infty)^{-1}D_{21} & D_{12}(I-F_\infty D_{22})^{-1} \\ (I-D_{22}F_\infty)^{-1}C_2 & (I-D_{22}F_\infty)^{-1}D_{21} & (I-D_{22}F_\infty)^{-1}D_{22} \end{array}\right].$$

To find an F_∞ that solves the problem at infinity, we define $Q_\infty=F_\infty(I-D_{22}F_\infty)^{-1}$ and apply Parrott's result [39], which states that

$$Q_\infty=-D_{12}'(D_{11}+D_{11}\tilde{D}_\perp'(\gamma^2I-(D_\perp'D_{11}\tilde{D}_\perp')'(D_\perp'D_{11}\tilde{D}_\perp'))^{-1}(D_\perp'D_{11}\tilde{D}_\perp')'D_\perp'D_{11})D_{21}'$$

solves the problem

$$\left\|\begin{bmatrix} D_\perp'D_{11}\tilde{D}_\perp' & D_\perp'D_{11}D_{21}' \\ D_{12}'D_{11}\tilde{D}_\perp' & D_{12}'D_{11}D_{21}'+Q_\infty \end{bmatrix}\right\|_2<\gamma.$$

(A solution exists if and only if $\gamma>\gamma_p=\max\{\|D_\perp'D_{11}\|, \|D_{11}\tilde{D}_\perp'\|\}$). Back substitution gives

$$F_\infty=(I+Q_\infty D_{22})^{-1}Q_\infty$$

in which the existence of the inverse is assumed. There are two points to note:

(1) $\|\bar{D}_{11}\|_2<\gamma$.

(2) $I-D_{22}F_\infty=(I+D_{22}Q_\infty)^{-1}$ which shows that the existence of $(I+D_{22}Q_\infty)^{-1}\Rightarrow$ the existence of $(I-D_{22}F_\infty)^{-1}$.

Step 2. Here we select an orthogonal Θ-matrix in Fig. 1 such that $(F_l(\Theta, \bar{P}_{11}(s))(\infty))_{11}=0$. Note that

$$\bar{D}_{11} := D_{11} + D_{12}Q_\infty D_{21}$$

and define

$$\begin{bmatrix} \Theta_{11} & \Theta_{12} \\ \Theta_{21} & \Theta_{22} \end{bmatrix} = \gamma^{-1}\begin{bmatrix} \gamma^{-1}\bar{D}_{11} & (I-\gamma^{-2}\bar{D}_{11}\bar{D}'_{11})^{1/2} \\ -(I-\gamma^{-2}\bar{D}'_{11}\bar{D}_{11})^{1/2} & \gamma^{-1}\bar{D}'_{11} \end{bmatrix},$$

which satisfies $\Theta\Theta' = \gamma^{-2}I$ for all $\gamma \geqq \gamma_p$. By direct computation

(5.71)

$$\hat{P}(s) = F_l\left(\left[\begin{array}{cc|cc} \Theta_{11} & 0 & \Theta_{12} & 0 \\ 0 & 0 & 0 & I \\ \hline \Theta_{21} & 0 & \Theta_{22} & 0 \\ 0 & I & 0 & 0 \end{array}\right], \bar{P}(s)\right) \overset{s}{=} \left[\begin{array}{c|cc} \hat{A} & \hat{B}_1 & \hat{B}_2 \\ \hline \hat{C}_1 & 0 & \hat{D}_{12} \\ \hat{C}_2 & \hat{D}_{21} & \hat{D}_{22} \end{array}\right]$$

$$\overset{s}{=} \left[\begin{array}{c|cc} \bar{A}+\bar{B}_1\Theta_{22}(I-\bar{D}_{11}\Theta_{22})^{-1}\bar{C}_1 & \bar{B}_1(I-\Theta_{22}\bar{D}_{11})^{-1}\Theta_{21} & \bar{B}_2+\bar{B}_1\Theta_{22}(I-\bar{D}_{11}\Theta_{22})^{-1}\bar{D}_{12} \\ \hline \Theta_{12}(I-\bar{D}_{11}\Theta_{22})^{-1}\bar{C}_1 & 0 & \Theta_{12}(I-\bar{D}_{11}\Theta_{22})^{-1}\bar{D}_{12} \\ \bar{C}_2+\bar{D}_{21}\Theta_{22}(I-\bar{D}_{11}\Theta_{22})^{-1}\bar{C}_1 & \bar{D}_{21}(I-\Theta_{22}\bar{D}_{11})^{-1}\Theta_{21} & \bar{D}_{22}+\bar{D}_{21}\Theta_{22}(I-\bar{D}_{11}\Theta_{22})^{-1}\bar{D}_{12} \end{array}\right],$$

which has the required property that $\hat{D}_{11}=0$. It is an immediate consequence of a specialization of Redheffer's theorem that $\|F_l(\bar{P}, K)\|_\infty \leqq \gamma$ if and only if $\|F_l(\bar{P}, K)\|_\infty \leqq \gamma^{-1}$ [30]. A small gain argument shows that the internal stability property is preserved for all $\gamma > \gamma_p$.

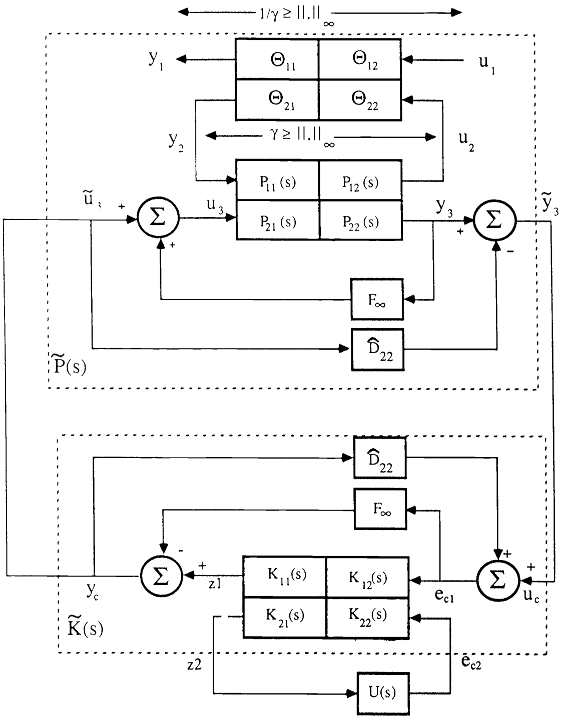

FIG. 1. *Loop transformations.*

Step 3. Here we eliminate $\hat{D}_{22}$ by connecting $(\hat{D}_{22}-\hat{D}_{22})$ in parallel with $\hat{P}_{22}(s)$ which is illustrated in Fig. 1. See also [20].

Step 4. Compute $\tilde{K}(s)$ using equations (5.11)-(5.18). (Note that $\hat{D}'_{12}\hat{D}_{12}\neq I$ and $\hat{D}_{21}\hat{D}'_{21}\neq I$ so another scaling is required.)

Step 5. Reverse the effects of $\hat{D}_{22}$ and F_∞ to obtain a representation formula for all controllers. Yet another calculation verifies that

$$\begin{bmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{bmatrix} = F_l\left\{\left[\begin{array}{cc|c} F_\infty & \tilde{K}_{12} & -I \\ \tilde{K}_{21} & \tilde{K}_{22}-\tilde{K}_{21}\hat{D}_{22}\tilde{K}_{12} & \tilde{K}_{21}\hat{D}_{22} \\ \hline -I & \hat{D}_{22}\tilde{K}_{12} & -\hat{D}_{22} \end{array}\right], \tilde{K}_{11}\right\}.$$

Note that the effects of the scale introduced in Step 4 must now be reversed.

It remains to show that provided γ is big enough, the realization for $P(s)$ in (5.1) satisfies (i)-(iv) if and only if the realization for $\hat{P}(s)$ given in (5.70) satisfies these same assumptions. In our analysis below, we treat the transformation between $P(s)$ and $\bar{P}(s)$ first, and the transformation between $\bar{P}(s)$ and $\hat{P}(s)$ second.

LEMMA 5.4. *Assumptions* (i)-(iv) *apply to the realization in* (5.1) *if and only if they apply to the realization in* (5.70).

Proof. (i) Stabilizibility and detectability are invariant under output feedback. Assumption (ii) is immediate from (5.70). Assumption (iii) and (iv) follow from

$$\begin{bmatrix} sI-\bar{A} & -\bar{B}_2 \\ \bar{C}_1 & \bar{D}_{12} \end{bmatrix} = \begin{bmatrix} sI-A & -B_2 \\ C_1 & D_{12} \end{bmatrix}\begin{bmatrix} I & 0 \\ F_\infty(I-D_{22}F_\infty)^{-1}C_2 & (I-F_\infty D_{22})^{-1} \end{bmatrix}$$

$$\begin{bmatrix} sI-\bar{A} & \bar{B}_1 \\ -\bar{C}_2 & \bar{D}_{21} \end{bmatrix} = \begin{bmatrix} I & B_2F_\infty(I-D_{22}F_\infty)^{-1} \\ 0 & (I-D_{22}F_\infty)^{-1} \end{bmatrix}\begin{bmatrix} sI-A & B_1 \\ -C_2 & D_{21} \end{bmatrix}.$$

LEMMA 5.5. *Suppose that an internally stabilizing controller exists such that* $\|F_l(P,K)\|_\infty \leqq \gamma$. *Then*

(1) $(\hat{A}, \hat{B}_2, \hat{C}_2)$ *is stabilizable and detectable.*

(2) rank $(D_{12})=m \Leftrightarrow$ rank $(\hat{D}_{12})=m$, *and* rank $(D_{21}) \Leftrightarrow$ rank $(\hat{D}_{21})=q$.

(3) rank $\left(\left[\begin{smallmatrix} j\omega I-A & B_2 \\ -C_1 & D_{12} \end{smallmatrix}\right]\right)=n+m$ *for all real* ω *if and only if* rank $\left(\left[\begin{smallmatrix} j\omega I-\hat{A} & \hat{B}_2 \\ -\hat{C}_1 & \hat{D}_{12} \end{smallmatrix}\right]\right)=n+m$ *for all real* ω.

(4) rank $\left(\left[\begin{smallmatrix} j\omega I-A & -B_1 \\ C_2 & D_{21} \end{smallmatrix}\right]\right)=n+q$ *for all real* ω *if and only if* rank $\left(\left[\begin{smallmatrix} j\omega I-\hat{A} & -\hat{B}_1 \\ \hat{C}_2 & \hat{D}_{21} \end{smallmatrix}\right]\right)=n+q$ *for all real* ω.

Proof. (1) Since $\|\Theta_{22}\|_2<\gamma^{-1}$, it follows from a small gain argument that $F_l(\hat{P},K)$ is internally stable. As K is an internally stabilizing controller for $\hat{P}(s)$, it follows that $(\hat{A}, \hat{B}_2, \hat{C}_2)$ is stabilizable and detectable.

(2) This follows from the invertibility of Θ_{12} and Θ_{21}, (5.70) and (5.71).

Parts (3) and (4) follow from Lemma 5.3 and the identities

$$\begin{bmatrix} sI-\hat{A} & \hat{B}_2 \\ -\hat{C}_1 & \hat{D}_{12} \end{bmatrix} = \begin{bmatrix} I & \bar{B}_1\Theta_{22}(I-\bar{D}_{11}\Theta_{22})^{-1} \\ 0 & \Theta_{12}(I-\bar{D}_{11}\Theta_{22})^{-1} \end{bmatrix}\begin{bmatrix} sI-\bar{A} & \bar{B}_2 \\ -\bar{C}_1 & \bar{D}_{12} \end{bmatrix},$$

$$\begin{bmatrix} sI-\hat{A} & -\hat{B}_1 \\ \hat{C}_2 & \hat{D}_{21} \end{bmatrix} = \begin{bmatrix} sI-\bar{A} & -\bar{B}_1 \\ \bar{C}_2 & \bar{D}_{21} \end{bmatrix}\begin{bmatrix} I & 0 \\ \Theta_{22}(I-\bar{D}_{11}\Theta_{22})^{-1}\bar{C}_1 & (I-D_{22}\Theta_{22})^{-1}\Theta_{21} \end{bmatrix}. \quad \square$$

If we need to calculate a controller generator in terms of the original plant description, it is possible to repeat calculations of the type given in the previous two sections (these have only been checked in detail by the present authors in the case where X_∞ and Y_∞ exist). In this event Step 2 is left out and we proceed as follows: Execute Step 1 as before; note that this step can be carried out if and only if max $(\|D'_\perp D_{11}\|_2, \|D_{11}\tilde{D}'_\perp\|_2)<\gamma$. After this step there holds $\|D_{11}\|_2<\gamma$. Execute Step 3 as before to remove $\bar{D}_{22}$. Execute Step 4 using the results of Theorem 5.1′ and Theorem 5.2′ given below. End with Step 5 as before.

THEOREM 5.1′. *Suppose that $P(s)$ is given by* (5.1), *and that the assumptions* (i)–(iv) *are satisfied with $D_{22}=0$ and $\|D_{11}\|_2<\gamma$. Then internally stabilizing controllers exist for $\gamma>0$ with $\|F_l(P,K)\|_\infty \leqq \gamma$ if and only if*

(i) *Condition* (i) *of Theorem* 5.1 *is satisfied with* (5.5) *replaced by*

$$H_\infty=\begin{bmatrix} H_{\infty 11} & H_{\infty 12} \\ H_{\infty 21} & -H'_{\infty 11}\end{bmatrix}$$

in which

$$H_{\infty 11}=A+(B_1D'_{11}D_\perp D'_\perp-\gamma^2B_2D'_{12})(\gamma^2I-D_{11}D'_{11}D_\perp D'_\perp)^{-1}C_1$$
$$H_{\infty 21}=-C'_1D_\perp(I-\gamma^{-2}D'_\perp D_{11}D'_{11}D_\perp)^{-1}D'_\perp C_1$$
$$H_{\infty 12}=(B_1-B_2D'_{12}D_{11})(\gamma^2I-D'_{11}D_\perp D'_\perp D_{11})^{-1}(B_1-B_2D'_{12}D_{11})'-B_2B'_2$$

(ii) *Condition* (ii) *of Theorem* 5.1 *is satisfied with* (5.8) *replaced by*

$$J_\infty=\begin{bmatrix} J_{\infty 11} & J_{\infty 12} \\ J_{\infty 21} & -J'_{\infty 11}\end{bmatrix}$$

where

$$J_{\infty 11}=A+B_1(\gamma^2I-\tilde D'_\perp\tilde D_\perp D'_{11}D_{11})^{-1}(\tilde D'_\perp\tilde D_\perp D'_{11}C_1-\gamma^2D'_{21}C_2),$$
$$J_{\infty 21}=-B_1\tilde D'_\perp(I-\gamma^{-2}\tilde D_\perp D'_{11}D_{11}\tilde D'_\perp)^{-1}\tilde D_\perp B'_1,$$
$$J_{\infty 12}=(C_1-D_{11}D'_{21}C_2)'(\gamma^2I-D_{11}\tilde D'_\perp\tilde D_\perp D'_{11})^{-1}(C_1-D_{11}D'_{21}C_2)-C'_2C_2.$$

(iii) $$\begin{bmatrix} X'_{\infty 2}X_{\infty 1} & \gamma^{-1}X'_{\infty 2}Y_{\infty 2} \\ \gamma^{-1}Y'_{\infty 2}X_{\infty 2} & Y'_{\infty 2}Y_{\infty 1}\end{bmatrix}\geqq 0.$$ □

All the solutions may be characterized by Theorem 5.2′.

THEOREM 5.2′. *If the conditions of Theorem* 5.1′ *are satisfied, then all internally stabilizing controllers satisfying $\|F_l(P,K)\|_\infty\leqq\gamma$ are given by*

$$K=F_l(\mathscr{K},U)\quad \textit{with } U\in RH^\infty_+,\quad \|U\|_\infty\leqq\gamma$$

where

$$\mathscr{K}(s)=\begin{bmatrix} 0 & D_{k12} \\ D_{k21} & D_{k22}\end{bmatrix}+\begin{bmatrix} C_{k1} \\ C_{k2}\end{bmatrix}(sE_k-A_k)^{\#}[B_{k1}\quad B_{k2}],$$

$$E_k=Y'_{\infty 1}X_{\infty 1}-\gamma^{-2}Y'_{\infty 2}X_{\infty 2},$$
$$B_{k1}=(\gamma^2Y'_{\infty 1}B_1+Y'_{\infty 2}C'_1D_{11}+Y'_{\infty 2}C'_2D_{21}(\gamma^2I-D'_{11}D_{11}))(\gamma^2I-\tilde D'_\perp\tilde D_\perp D'_{11}D_{11})^{-1}D'_{21},$$
$$C_{k1}=-D'_{12}(\gamma^2I-D_{11}D'_{11}D_\perp D'_\perp)^{-1}(\gamma^2C_1X_{\infty 1}+D_{11}B'_1X_{\infty 2}$$
$$+(\gamma^2I-D_{11}D'_{11})D_{12}B'_2X_{\infty 2}),$$
$$D_{k12}=\{I-D'_{12}D_{11}(\gamma^2I-D'_{11}D_\perp D'_\perp D_{11})^{-1}D'_{11}D_{12}\}^{1/2},$$
$$D_{k21}=\{I-D_{21}D'_{11}(\gamma^2I-D_{11}\tilde D'_\perp\tilde D_\perp D'_{11})^{-1}D_{11}D'_{21}\}^{1/2},$$
$$D_{k22}=-(D^{-1}_{k21})'D_{21}D'_{11}(\gamma^2I-D_{11}\tilde D'_\perp\tilde D_\perp D'_{11})^{-1}D_{12}D_{k12},$$
$$A_k=E_kT_x+B_{k1}D^{-1}_{k21}C_{k2}$$
$$=T'_YE_k+B_{k2}D^{-1}_{k12}C_{k1},$$
$$B_{k2}=\{Y'_{\infty 1}B_2+(Y'_{\infty 1}B_1\tilde D'_\perp\tilde D_\perp D'_{11}+Y'_{\infty 2}(C'_1-C'_2D_{21}D'_{11}))$$
$$\cdot(\gamma^2I-D_{11}\tilde D'_\perp\tilde D_\perp D'_{11})^{-1}D_{12}\}D_{k12},$$
$$C_{k2}=-D_{k21}\{C_2X_{\infty 1}+D_{21}(\gamma^2I-D'_{11}D_\perp D'_\perp D_{11})^{-1}(D'_{11}D_\perp D'_\perp C_1X_{\infty 1}+B'_1X_{\infty 2}$$
$$-D'_{11}D_{12}B'_2X_{\infty 2})\}.$$ □

6. Conclusions. The purpose of this paper was to derive a representation formula for all H_∞^+ solutions to the four block general distance problem in which particular attention was paid to the optimal cases. The suboptimal case was treated in § 3, and was derived by an all-pass embedding procedure which is reminiscent of that introduced by Parrott [39]. The optimal case was treated in § 4 and the formula for all solutions appears as (4.52) and (4.59). Section 5 dealt with the application to H^∞ optimal control. In addition, we note the following:

(1) In contrast to the one block problem, there are two types of optimality. The first is essentially the same as that addressed in Parrott's theorem [39], and has nothing to do with the requirement that the approximation Q be an element of H_∞^+. The second is associated with a Hankel norm condition on R_a in (3.46). In the first type of optimality, special algorithms may be required to take care of axis phenomena in the spectral factorization problems (3.18) and (3.19). These issues are addressed in detail in [8].

(2) The analysis in § 3 breaks down when $\|R_a\|_H = 1$ since Z in (3.65) becomes singular. This difficulty is addressed in § 4 where we introduce an alternative construction based on descriptor representations of all-pass transfer functions; see also [35] and [44] in this connection. In the case of this Hankel norm type of optimality, the effective dimension of the free parameter drops by rank $(B_{22}) \leqq k$. B_{22} is defined in (4.38) and k is the multiplicity of the largest Hankel singular value of R_a. This loss of effective dimension may be characterized by the linear constraining equation (4.45) which is similar to that given in [16, eq. (6.23)].

(3) An important application of this work is the derivation of a closed form representation formula for all controllers that satisfy an L^∞ norm constraint. One such formula is given in § 5 and appears in equations (5.10)-(5.18) in the case that $D_{11} = 0$ and $D_{22} = 0$ in the realization of $P(s)$ given in (5.1). All the optimal cases are covered.

(4) The case in which $D_{11} \neq 0$ has been treated by direct calculation and the results are given in Theorem 5.2′. Since these formulae are awkward to write down, an alternative approach based on loop shifting is also presented [45]. The idea here is to replace the original problem which has $D_{11} \neq 0$ with an equivalent problem in which $\hat{D}_{11} = 0$.

DUALITY RELATIONSHIPS FOR ENTROPY-LIKE MINIMIZATION PROBLEMS*

J. M. BORWEIN† AND A. S. LEWIS‡

Abstract. This paper considers the minimization of a convex integral functional over the positive cone of an L_p space, subject to a finite number of linear equality constraints. Such problems arise in spectral estimation, where the objective function is often entropy-like, and in constrained approximation. The Lagrangian dual problem is finite-dimensional and unconstrained. Under a quasi-interior constraint qualification, the primal and dual values are equal, with dual attainment. Examples show the primal value may not be attained. Conditions are given that ensure that the primal optimal solution can be calculated directly from a dual optimum. These conditions are satisfied in many examples.

Key words. convex programming, duality, spectral estimation, entropy, moment problem

AMS(MOS) subject classifications. primary 90C25, 49A27; secondary 41A46, 42A70

1. Introduction. A number of authors have recently considered dual approaches to the solution of optimization problems of the form

$$\text{(EP)}\qquad \begin{array}{ll} \inf & \displaystyle\int_T \phi(x(t))\,dt \\ \text{subject to} & Ax=b, \\ & x\geqq 0, \qquad x\in L_p(T). \end{array}$$

Here, (T, dt) is a σ-finite measure space, $1\leqq p\leqq\infty$, $\phi:\mathbb{R}\to(-\infty,\infty]$ is convex, and $A: L_p\to\mathbb{R}^n$ is continuous. Such problems arise in a number of areas. When (for $p<\infty$), $\phi(x)=(1/p)x^p$ we obtain the constrained L_p approximation problem (see [Micchelli, Smith, Swetits, and Ward, 1985]). These problems appear in the theory of constrained interpolation [Irvine, Marin, and Smith, 1986], and also as a result of using the L_p norm as the objective function in spectral estimation problems (see, for example, [Goodrich and Steinhardt, 1986] and [Ben-Tal, Borwein, and Teboulle, 1988a]). A number of different objective functions can be used. Typically, they are "entropic" in form, for instance $\phi(x)=-\log x$ [Burg, 1975] and $\phi(x)=x\log x$ [Johnson and Shore, 1984]. A survey of common objective functions may be found in [Ben-Tal, Borwein, and Teboulle, 1988b]. For simplicity of exposition we will only consider the autonomous case, where the function ϕ does not depend explicitly on the variable t. The non-autonomous case is a simple extension.

Let us denote the function $\phi+\delta(\cdot|\mathbb{R}_+)$ by ϕ_+ (where δ denotes an indicator function [Rockafellar, 1970]). Assuming ϕ_+ is a *normal convex integrand* in the sense of [Rockafellar, 1968], we can write the Lagrangian dual problem as

$$\text{(DEP)}\qquad \begin{array}{ll} \sup & \displaystyle b^T\lambda-\int_T (\phi_+)^*((A^T\lambda)(t))\,dt \\ \text{subject to} & \lambda\in\mathbb{R}^n, \end{array}$$

* Received by the editors May 31, 1988; accepted for publication (in revised form) January 22, 1990. This research was supported by the Natural Sciences and Engineering Research Council of Canada.

† Department of Mathematics, Statistics, and Computing Science, Dalhousie University, Halifax, Nova Scotia, Canada B3H 3J5.

‡ Department of Combinatorics and Optimization, Faculty of Mathematics, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1.

where * denotes convex conjugation and $A^T:\mathbb{R}^n \to L_q(T)$ $((1/p)+(1/q)=1)$ is the adjoint map. It is known (see, for example, [Ben-Tal, Borwein, and Teboulle, 1988b]) that under a suitable constraint qualification the values of (EP) and (DEP) are equal, with dual attainment.

Suppose now that ϕ_+ is closed and essentially strictly convex, so, by [Rockafellar, Thm. 26.3, 1970], $(\phi_+)^*$ is essentially smooth. (We defer precise definitions to a later section.) Suppose that $\bar{\lambda}$ is optimal for (DEP). *Assuming that* $(A^T\bar{\lambda})(t) \in \operatorname{int}(\operatorname{dom}(\phi_+)^*)$, *and that we can differentiate through the integral*, we then obtain

$$b - A(((\phi_+)^*)'((A^T\bar{\lambda})(\cdot))) = 0. \tag{1.1}$$

If we now set $\bar{x}(t) = ((\phi_+)^*)'((A^T\bar{\lambda})(t))$, $t \in T$, then by [Rockafellar, Thm. 23.5, 1970],

$$(A^T\bar{\lambda})(t) \in \partial\phi_+(\bar{x}(t)), \quad \text{a.e.},$$

so $\phi_+(\bar{x}(t)) + (\phi_+)^*((A^T\bar{\lambda})(t)) = \bar{x}(t)(A^T\bar{\lambda})(t)$, almost everywhere and, since $(\phi_+)^*$ is increasing, $\bar{x} \geqq 0$. Thus, by (1.1) $\bar{x}(t)$ is feasible for (EP) and, integrating over T, has the same objective value as the dual and hence is optimal (by weak duality).

The question of when the above assumptions are justified has, to the authors' knowledge, never been addressed in the published literature on the subject. Since the derivation of primal solutions is of paramount importance, this question is clearly extremely significant. The aim of this paper is therefore to give these matters a rigorous treatment. We begin by deriving the basic duality result from the theory developed in [Borwein and Lewis, 1988]. We then give some examples to show how the above assumptions can fail. This will motivate our rigorous treatment of the derivation of primal solutions.

2. Duality.

We will begin by deriving the fundamental duality result.

DEFINITION 2.1 [Borwein and Lewis, 1988]. Let (X, τ) be a topological vector space, with convex $C \subset X$. The *quasi-relative interior* of C $(\tau - \operatorname{qri} C)$ is the set of those $x \in C$ for which $\operatorname{cl} \mathbb{P}(C - x)$ is a subspace.

(Here, $\operatorname{cl} \mathbb{P}B$ denotes the closed cone generated by B.) Note that if X is normed, the weak and norm quasi-relative interiors coincide.

Example 2.2 [Borwein and Lewis, 1988]. Let T be a σ-finite measure space, $1 \leqq p \leqq \infty$, $(1/p)+(1/q)=1$ and let $X = L_p(T)$, $Y = L_q(T)$. Then

$$\sigma(X, Y) - \operatorname{qri} X_+ = \{x \mid x(t) > 0 \text{ a.e.}\}.$$

LEMMA 2.3. *Let X be a topological vector space with convex C_1, $C_2 \subset X$ satisfying $\operatorname{cl} C_1 = \operatorname{cl} C_2$. For any $x \in C_1 \cap C_2$, $x \in \operatorname{qri} C_1$ if and only if $x \in \operatorname{qri} C_2$.*

Proof. The result follows immediately from the fact that $\operatorname{cl} \mathbb{P}(C_1 - x) = \operatorname{cl} \mathbb{P}(C_2 - x)$. □

The following duality result may be found in [Borwein and Lewis, Cor. 4.10, 1988].

THEOREM 2.4. *Let X be locally convex, $f: X \to (-\infty, \infty]$ convex, $A: X \to \mathbb{R}^n$ continuous and linear, $b \in \mathbb{R}^n$, and $P \subset \mathbb{R}^n$ a polyhedral cone. Consider the following dual pair of problems*:

$$\text{(CM)} \qquad \begin{array}{ll} \inf & f(x) \\ \textit{subject to} & Ax \in b + P, \\ & x \in C, \end{array}$$

$$\text{(DCM)} \qquad \begin{array}{ll} \max & b^T\lambda - (f + \delta(\cdot \mid C))^*(A^T\lambda) \\ \textit{subject to} & \lambda \in P^+. \end{array}$$

If there exists a feasible $\hat{x} \in \operatorname{qri}((\operatorname{dom} f) \cap C)$ *for* (CM), *then the values of* (CM) *and* (DCM) *are equal* (*with attainment in* (DCM)).

To use the above result in our case we need to compute the conjugate of certain integral functionals. We will need the following result concerning normal convex integrands.

THEOREM 2.5. *Let T be a finite measure space, $1 \leqq p \leqq \infty$, and suppose $\psi : \mathbb{R} \to (-\infty, \infty]$ is closed, convex, and proper. Define $I_\psi : L_p(T) \to (-\infty, \infty]$ by $I_\psi(x) = \int_T \psi(x(t))\, dt$. Then $(I_\psi)^* : L_q(T) \to (-\infty, \infty]$ is given by $(I_\psi)^* = \int_T \psi^*(y(t))\, dt$.*

Proof. For the proof see the corollary to Theorem 2 in [Rockafellar, 1968]. □

We can now derive the required duality result.

COROLLARY 2.6. *Suppose T is a finite measure space, $1 \leqq p \leqq \infty$, $\phi : \mathbb{R} \to (-\infty, \infty]$ with ϕ_+ closed and convex, $a_i \in L_q(T)$ for $i = 1, \cdots, n$, and $b \in \mathbb{R}^n$. Consider the following dual pair of problems*:

$$(\mathrm{EP}_p) \qquad \begin{aligned} &\inf && \int_T \phi(x(t))\, dt \\ &\textit{subject to} && \int_T x(t) a_i(t)\, dt = b_i, \qquad i = 1, \cdots, n, \\ & && x \geqq 0, \qquad x \in L_p(T), \end{aligned}$$

$$(\mathrm{DEP}_p) \qquad \begin{aligned} &\max && b^T\lambda - \int_T (\phi_+)^* \left[\sum_{i=1}^n \lambda_i a_i(t) \right] dt \\ &\textit{subject to} && \lambda \in \mathbb{R}^n. \end{aligned}$$

Suppose further that the following constraint qualification holds:

(CQ) *There exists a feasible $\hat{x}$ for* (EP_p) *with $\hat{x} \in \sigma(L_p, L_q) - \operatorname{qri}(\operatorname{dom} I_\phi \cap (L_p)_+)$.*

Then the values of (EP_p) *and* (DEP_p) *are equal* (*with dual attainment*).

Suppose furthermore that $(0, \infty) \subset \operatorname{dom} \phi$. Then (CQ) *is equivalent to requiring the existence of a feasible $\hat{x} \in \operatorname{dom} I_\phi$ with $\hat{x}(t) > 0$ almost everywhere. In particular, if* $\operatorname{ess\,sup} x < +\infty$ *and* $\operatorname{ess\,inf} x > 0$ *then* $x \in \operatorname{dom} I_\phi$.

Proof. In Theorem 2.4, set $X = L_p(T)$ with the $\sigma(L_p, L_q)$ topology, $f = I_\phi$, $C = (L_p)_+$, A defined by $(Ax)_i = \langle x, a_i \rangle = \int_T x(t) a_i(t)\, dt$ for $i = 1, \cdots, n$, and $P = \{0\}$. Then $f + \delta(\cdot \mid C) = I_{\phi_+}$, so by Theorem 2.5, $(f + \delta(\cdot \mid C))^* = I_{\phi_+^*}$. Also, $P^+ = \mathbb{R}^n$, and $A^T\lambda = \sum_{i=1}^n \lambda_i a_i$, so the duality result follows.

If $(0, \infty) \subset \operatorname{dom} \phi$ then the set $K := \{x \in L_\infty \mid \operatorname{ess\,inf} x > 0\}$ is contained in $\operatorname{dom} I_\phi \cap (L_p)_+$. To see this, observe that if $x \in L_\infty$ with $\operatorname{ess\,inf} x > 0$, then there exist $M, \varepsilon > 0$ with $\varepsilon \leqq x(t) \leqq M$, almost everywhere. Since $(0, \infty) \subset \operatorname{dom} \phi$, ϕ is continuous on $(0, \infty)$, by [Rockafellar, Thm. 10.1, 1970], and so the set $\phi[\varepsilon, M] \subset \mathbb{R}$ is compact. Thus, $\phi(x(\cdot))$ is bounded on T, and so $x \in \operatorname{dom} I_\phi$.

Now K is dense in $(L_p)_+$ (the proof essentially follows [Rudin, Thm. 3.13, 1966]). Thus, we have

$$\begin{aligned} \operatorname{cl} K &\subset \operatorname{cl}(\operatorname{dom} I_\phi \cap (L_p)_+) \\ &\subset \operatorname{cl}((L_p)_+) \\ &= (L_p)_+ \\ &= \operatorname{cl} K, \end{aligned}$$

so $\operatorname{cl}(\operatorname{dom} I_\phi \cap (L_p)_+) = (L_p)_+$. Applying Lemma 2.3 it follows that if $\hat{x} \in (\operatorname{dom} I_\phi) \cap \operatorname{qri}(L_p)_+$ then $\hat{x} \in \operatorname{qri}((\operatorname{dom} I_\phi) \cap (L_p)_+)$, and the result follows by Example 2.2. □

In the case where the measure space is nonatomic and totally finite, we can handle nonconvex objectives (as observed by the referee). Suppose that ϕ_+ is lower semicontinuous (not necessarily convex), but that ϕ_+^* and ϕ_+^{**} are proper. Then, with A as before, if we define

$$h(b) := \inf\left\{\int_T \phi_+(x(t))\,dt \,|\, Ax=b,\ x\in L_1\right\},$$

the domain of h is convex, and h is a convex function. This is a consequence of the Liapunov convexity theorem [Holmes, p. 108, 1975]. In fact if we define the value function of the regularized problem,

$$\bar{h}(b) := \inf\left\{\int_T \phi_+^{**}(x(t))\,dt \,|\, Ax=b,\ x\in L_1\right\},$$

then whenever the constraint qualification is satisfied at b, in other words $b\in A(\mathrm{qri}\,(\mathrm{dom}\, I_{\phi_+}))$, we have $h(b)=\bar{h}(b)$. This follows from [Rockafellar, Thm. 3H, 1976], and the fact that the constraint qualification forces h to be lower semicontinuous at b. In conclusion, our results apply equally well to ϕ as to ϕ^{**}. See also [Ioffe and Tihomorov, 1968] for similar ideas.

In some common cases the constraint qualification is particularly easy to check. The next result gives conditions under which the constraint qualification is no more arduous than primal consistency. Note that in most applications the a_i's are actually continuous (at least piecewise).

DEFINITION 2.7 [Borwein and Lewis, 1988]. A set of measurable functions $a_i: T\to\mathbb{R}$, $i=1,\cdots,n$, on a measure space T are called *pseudo-Haar* if they are linearly independent on every nonnull subset of T.

PROPOSITION 2.8. *Consider the measure space* $[\alpha,\beta]\subset\mathbb{R}$, *with Lebesgue measure, and suppose* $a_i:[\alpha,\beta]\to\mathbb{R}$ *are analytic and linearly independent. Then they are pseudo-Haar on* $[\alpha,\beta]$.

(A real function f defined on an open interval in $\mathbb{R}$ is called *analytic* if it is represented locally by an absolutely convergent power series at any point in the interval, cf. [Bochner and Martin, 1964].)

Proof. We will show that if a real function f is analytic on an open interval $T\supset[\alpha,\beta]$, and is not identically zero on $[\alpha,\beta]$, then it has at most finitely many zeros on $[\alpha,\beta]$. The result then follows immediately.

Suppose f has infinitely many zeros on $[\alpha,\beta]$. By compactness, there exists a sequence $x_i\to x_0\in[\alpha,\beta]$ as $i\to\infty$, with $f(x_i)=0$, $x_i\neq x_0$, for $i=1,2,\cdots$. Since f is analytic, for some $\delta>0$ there is an absolutely convergent power series $f(x)=\sum_{n=0}^{\infty} c_n(x-x_0)^n$, for $x\in N_\delta(x_0)$. Suppose the c_n's are not all 0, and let c_m be the first nonzero coefficient. Then

$$f(x)=(x-x_0)^m\left\{c_m+(x-x_0)\sum_{n=m+1}^{\infty} c_n(x-x_0)^{n-m-1}\right\},$$

for $x\in N_\delta(x_0)$. Since the series $\sum_{n=m+1}^{\infty} c_n(x-x_0)^{n-m-1}$ converges absolutely on $N_\delta(x_0)$, by a standard power series result it converges uniformly on $N_{\delta/2}(x_0)$, so in particular it is continuous at x_0. We then have

$$\begin{aligned}0&=(x_i-x_0)^{-m}f(x_i)\\ &=c_m+(x_i-x_0)\sum_{n=m+1}^{\infty} c_n(x_i-x_0)^{n-m-1},\end{aligned}$$

and letting $i\to\infty$ implies $c_m=0$, which is a contradiction.

Thus, $c_n = 0$ for all n, so $f(x) = 0$ on $N_\delta(x_0)$. But 0 is an analytic function on the domain T which agrees with f on $N_\delta(x_0)$, so by [Bochner and Martin, Thm. 4, Chap. II, 1964], $f \equiv 0$ on T. This is a contradiction. □

The following result shows essentially that if the constraint functions a_i are pseudo-Haar and (EP_p) is consistent for any $1 \leqq p \leqq \infty$ then there is in fact a feasible $\hat{x}$ in the norm interior of $(L_\infty)_+$. In the case when $(0, \infty) \subset \operatorname{dom} \phi$, $\hat{x}$ clearly satisfies the constraint qualification, so the result shows that the constraint qualification is always satisfied for a consistent primal (providing 0 is not the only primal feasible solution).

THEOREM 2.9. *Suppose (T, μ) is a finite measure space and $0 \leqq x \in L_p(T)$ is nonzero $(1 \leqq p \leqq \infty)$. Suppose further that $a_i \in L_q(T)$, $i = 1, \cdots, n$, are pseudo-Haar. Then there exists a $y \in L_\infty(T)$ and $\varepsilon > 0$ with $y(t) \geqq \varepsilon$ almost everywhere and $\langle x, a_i\rangle = \langle y, a_i\rangle$, each i.*

Proof. Since $0 \neq x \geqq 0$, there exists $T_1 \subset T$ with $\mu(T_1) > 0$ and a $\delta > 0$ such that $x(t) \geqq \delta$ almost everywhere on T_1. We claim that

$$\left\{\left(\int_{T_1} u a_i \, d\mu\right)_{i=1}^n \,\middle|\, u \in L_\infty(T_1)\right\} = \mathbb{R}^n. \tag{2.10}$$

Suppose not. Since the left-hand side is clearly a subspace, there exists $\lambda \neq 0$ such that $\sum_{i=1}^n \lambda_i \int_{T_1} u a_i \, d\mu = 0$, for all $u \in L_\infty(T_1)$. This implies $\sum_{i=1}^n \lambda_i a_i(t) = 0$ almost everywhere on T_1, which contradicts the fact that the a_i's are pseudo-Haar. Thus, (2.10) holds.

Now define

$$C = \left\{\left(\int_{T_1} u a_i \, d\mu\right)_{i=1}^n \,\middle|\, u \in L_\infty(T_1),\ \|u\|_\infty < \delta/2\right\}.$$

Since, by (2.10), $\mathbb{P}C = \mathbb{R}^n$, it follows that $0 \in \operatorname{int} C$ [Rockafellar, Cor. 6.4.1, 1970].

Let us now define a sequence of functions $(x_m) \subset L_\infty(T)$ by

$$x_m(t) = \begin{cases} m, & \text{if } x(t) > m, \\ x(t), & \text{if } \dfrac{1}{m} \leqq x(t) \leqq m, \\ \dfrac{1}{m}, & \text{if } x(t) < \dfrac{1}{m}. \end{cases}$$

For $p < \infty$ we have

$$\|x_m - x\|_p^p \leqq \int_{\{t \mid x(t) > m\}} x(t)^p \, d\mu + \int_{\{t \mid x(t) < 1/m\}} \left(\frac{1}{m}\right)^p d\mu \to 0, \quad \text{as } m \to \infty,$$

and in the case $p = \infty$, clearly $\|x_m - x\|_\infty \leqq 1/m$, for m large. Thus, $((\langle x_m - x, a_i\rangle))_{i=1}^n \to 0$ as $m \to \infty$, and so, since $0 \in \operatorname{int} C$, for $m > 1/\delta$ sufficiently large, $((x_m - x, a_i\rangle)_{i=1}^n \in C$. It then follows that $\langle x_m - x, a_i\rangle = \langle v, a_i\rangle$, each $i = 1, \cdots, n$, for some $v \in L_\infty(T)$ with $\|v\|_\infty < \delta/2$ and $v(t) = 0$ almost everywhere on T_1^c.

Finally, set $y = x_m - v$. Then $y \in L_\infty(T)$, and almost everywhere on T_1^c, $y(t) = x_m(t) \geqq 1/m$. On T_1 we know $x(t) \geqq \delta > 1/m$ almost everywhere, so $x_m(t) \geqq \min\{x(t), m\} \geqq \delta$, almost everywhere. Since $v(t) \leqq \delta/2$ almost everywhere it follows that $y(t) \geqq \delta/2$ almost everywhere on T_1. The result now follows. □

For a given set of constraint functions a_i, $i = 1, \cdots, n$, the question of for what b's the problem (EP_p) is consistent is known as the *extendibility problem.* Simple conditions are known, for example, when $T = [0, 1]$ with Lebesgue measure and $a_i(t) = t^{i-1}$ (one of the "classical" moment problems), and for the case when $T = [-\pi, \pi]$ with Lebesgue measure and $\{a_1(\theta), \cdots, a_{2k+1}(\theta)\} = \{1, \cos\theta, \sin\theta, \cdots, \cos k\theta, \sin k\theta\}$ (the trigonometric moment problem). See, for example, [Karlin and Studden, 1966] and [Ben-Tal, Borwein, and Teboulle, 1988b] for more information.

PROPOSITION 2.11. *If ϕ_+ is strictly convex on* dom ϕ_+, *then any optimal solution to* (EP$_p$) *is unique.*

Proof. If ϕ_+ is strictly convex on dom ϕ_+ then so is I_{ϕ_+} on dom I_{ϕ_+}. To see this, suppose $x_1, x_2 \in \operatorname{dom} I_{\phi_+}$, with $x_1 \neq x_2$, and $0<\gamma<1$. By strict convexity of ϕ_+, $\gamma\phi_+(x_1(t))+(1-\gamma)\phi_+(x_2(t)) \leqq \phi_+(\gamma x_1(t)+(1-\gamma)x_2(t))$, with strict inequality on a nonnull set. It follows that $\gamma I_{\phi_+}(x_1)+(1-\gamma)I_{\phi_+}(x_2)<I_{\phi_+}(\gamma x_1+(1-\gamma)x_2)$. The result now follows. □

3. Examples. In the course of the derivation of a primal solution described in § 1, the crucial step was differentiating through the integral in the dual objective function to obtain (1.1). The following example shows clearly the sort of difficulties that can occur.

For $1 \leqq p<2$, consider the convex integral functional $I: L_p[0,1] \to (-\infty, \infty]$ defined by

$$I(x)=\begin{cases} -\int_0^1 \log x(t)\, dt, & x(t)>0 \text{ a.e.}, \\ +\infty, & \text{otherwise}. \end{cases}$$

By [Rockafellar, Thm. 22, 1974], $y \in \partial I(x)$ if and only if $y(t) \in \partial(-\log)(x(t))=\{-1/x(t)\}$, almost everywhere, for $x(t)>0$ almost everywhere. With a slight abuse of notation, let us denote the function that is identically equal to one by 1. Then $\partial I(1)=\{-1\}$, so I has a unique subgradient at 1.

Now define $h \in L_p[0,1]$ by $h(t)=1/\sqrt{t}$. For any $\varepsilon>0$, $1-\varepsilon/\sqrt{t} \leqq 0$ on a set of nonzero measure, so $I(1-(\varepsilon/\sqrt{t}))=+\infty$. Thus, the directional derivative $I'(1;-h)=+\infty$.

On the other hand, we have

$$I'(1;h)=\lim_{\varepsilon \downarrow 0} \frac{1}{\varepsilon}\left\{-\int_0^1 \log\left(1+\frac{\varepsilon}{\sqrt{t}}\right) dt\right\}.$$

It is straightforward to check that as $\varepsilon \downarrow 0$, $(1/\varepsilon)\log(1+(\varepsilon/\sqrt{t})) \uparrow (1/\sqrt{t})$, so by the monotone convergence theorem, $I'(1;h)=-\int_0^1 (1/\sqrt{t})\, dt=-2$.

Thus, I has no Gateaux derivative at 1 although it has a unique subgradient there. The choice of space is clearly important here. In the case $p=\infty$, we have $1 \in \|\cdot\|_\infty-\operatorname{int}(\operatorname{dom} I)$, and it is easy to see that I is $\|\cdot\|_\infty$-continuous at 1. Thus, in this case the Gateaux derivative does exist: $\nabla I(1)=-1$ (see, for example, [Holmes, 1975]).

Simple examples show that even when the constraint qualification is satisfied we cannot necessarily expect primal attainment in (EP$_p$).

Example 3.1. Consider the following semi-infinite linear program:

$$\begin{array}{ll} \inf & \int_0^1 x(t)\, dt \\ \text{subject to} & \int_0^1 t x(t)\, dt=1, \qquad x \geqq 0, \quad x \in L_p[0,1]. \end{array}$$

In this problem $\phi(x)=x$, so $(\phi_+)^*(y)=\sup_{x \geqq 0}\{xy-x\}=\delta(y \mid (-\infty,1])$. Thus, the dual problem is

$$\begin{array}{ll} \max & \lambda-\int_0^1 \delta(\lambda t \mid (-\infty,1])\, dt \\ \text{subject to} & \lambda \in \mathbb{R}. \end{array}$$

The optimal dual solution is clearly $\bar{\lambda}=1$, giving value 1. The constraint qualification is clearly satisfied by $\hat{x}(t)=2$, so the primal value is also 1, by Corollary 2.6. However, since $x(t) > tx(t)$ almost everywhere, $\int_0^1 x(t)\,dt > \int_0^1 tx(t)\,dt = 1$ for any feasible x, so the optimal value is not attained (for any $1 \leqq p \leqq \infty$).

The above behavior can be observed even when the function ϕ is essentially strictly convex.

Example 3.2. Consider the following problem:

$$\begin{aligned} &\inf && \int_0^{2\pi} \left(\frac{1}{x(t)}\right) dt \\ &\text{subject to} && \int_0^{2\pi} x(t)\sin t\,dt = 1, \qquad x \geqq 0, \quad x \in L_p[0, 2\pi]. \end{aligned}$$

In this case $\phi(x) = 1/x$, $x > 0$, and ∞ otherwise. Thus, $(\phi_+)^*(y) = \sup_{x>0}\{xy - (1/x)\}$, so by differentiation,

$$(\phi_+)^*(y) = \begin{cases} -2\sqrt{-y}, & y \leqq 0, \\ \infty, & \text{otherwise.} \end{cases}$$

The dual problem therefore becomes

$$\begin{aligned} &\max && \lambda - \int_0^{2\pi} (-2\sqrt{-\lambda \sin t})\,dt \\ &\text{subject to} && -\lambda \sin t \geqq 0 \text{ a.e. on } [0, 2\pi], \qquad \lambda \in \mathbb{R}. \end{aligned}$$

The only dual feasible solution is $\bar{\lambda} = 0$, so the dual value is 0. The constraint qualification is satisfied by

$$\hat{x}(t) = \begin{cases} 1, & 0 \leqq t < \pi \\ \frac{1}{2}, & \pi \leqq t \leqq 2\pi, \end{cases}$$

since

$$\int_0^{2\pi} \hat{x}(t)\sin t\,dt = [-\cos\theta]_0^{\pi} + \frac{1}{2}[-\cos\theta]_{\pi}^{2\pi} = 1.$$

Thus, the primal value is also 0, by Corollary 2.6, or direct computation. However, this value clearly is not attained.

In both of the above examples the function $(\phi_+)^*$ is differentiable on the interior of its domain, but the manipulation described in the introduction is manifestly invalid since there exists no primal optimal solution. Our last example shows how attainment in the primal problem can depend on the choice of space for the primal variables.

Example 3.3. Consider the following problem:

$$\begin{aligned} &\inf && \int_0^1 \left(\frac{1}{x(t)}\right) dt \\ &\text{subject to} && \int_0^1 tx(t)\,dt = 1, \qquad x \geqq 0, \quad x \in L_p[0, 1]. \end{aligned}$$

In a similar fashion to Example 3.2, the dual problem is

$$\begin{aligned} &\max && \lambda - \int_0^1 (-2\sqrt{-\lambda t})\,dt \\ &\text{subject to} && -\lambda t \geqq 0, \text{ a.e. on } [0, 1], \qquad \lambda \in \mathbb{R}. \end{aligned}$$

This is equivalent to $\max\{\lambda+\frac{4}{3}\sqrt{-\lambda}\,|\,\lambda\leqq 0\}$. By differentiation, the optimum occurs at $\bar{\lambda}=-\frac{4}{9}$, giving a dual value of $\frac{4}{9}$.

The constraint qualification is again satisfied by, for instance, $\hat{x}(t)=2$, almost everywhere on $[0,1]$. The primal value is therefore also $\frac{4}{9}$. The manipulation described in the introduction (differentiating the dual objective function) may now be performed, at least formally, to obtain $\bar{x}(t)=3/2\sqrt{t}$. It may be checked that $\bar{x}$ satisfies the primal constraint and has value $\frac{4}{9}$. Thus, it is optimal, at least for $1\leqq p<2$, and by Proposition 2.11 it is the unique primal optimal solution. However, $\bar{x}\notin L_p[0,1]$ for $2\leqq p\leqq\infty$, so for these values of p there exists no primal optimal solution (otherwise we would obtain a contradiction to Proposition 2.11). Note finally that the question of primal attainment for this problem is not affected by the addition of the extra constraint $\int_0^1 x(t)\,dt=3$, since $\bar{x}$ remains feasible. This provides a counterexample whose constraints are in the form of a standard moment problem.

4. Primal solutions. We shall now give a rigorous treatment of conditions ensuring the existence of a primal optimal solution. We begin with some simple results aimed at identifying the domain of the functional $I_{\phi_+^*}$.

PROPOSITION 4.1. *The function* $(\phi_+)^*:\mathbb{R}\to(-\infty,\infty]$ *is monotone increasing.*

Proof. The result follows immediately from the definition:

$$(\phi_+)^*(y)=\sup_{x\geqq 0}\{yx-\phi(x)\}. \qquad \square$$

LEMMA 4.2. *Suppose* $\phi:\mathbb{R}\to(-\infty,\infty]$ *with* ϕ_+ *closed, convex, and proper. Define* $d:=\lim_{x\to\infty}(\phi(x)/x)$ (*this limit exists*). *Then* $\operatorname{cl}(\operatorname{dom}(\phi_+)^*)=(-\infty,d]$.

Proof. Define $\psi(x)=\phi_+(x)-y(x)$. Then by [Rockafellar, Cor. 13.3.4, 1970], $y\in\operatorname{cl}(\operatorname{dom}(\phi_+)^*)$ if and only if $(\psi 0^+)(z)\geqq 0$, for all z. By [Rockafellar, Thm. 8.5, 1970],

$$\begin{aligned}(\psi 0^+)(z)&=\lim_{\lambda\to\infty}\frac{\psi(v+\lambda z)-\psi(v)}{\lambda}\\&=\lim_{\lambda\to\infty}\frac{\phi_+(v+\lambda z)-\phi_+(v)-y\lambda z}{\lambda}\\&=\lim_{\lambda\to\infty}\left(\frac{\phi_+(v+\lambda z)}{v+\lambda z}\,\frac{v+\lambda z}{\lambda}\right)-yz\\&=(d-y)z,\end{aligned}$$

for any $v\in\operatorname{dom}\phi_+$ and for $z>0$. For $z<0$, $(\psi 0^+)(z)=+\infty$, and $(\psi 0^+)(0)=0$. Thus, $(\psi 0^+)(z)\geqq 0$, for all z, if and only if $y\leqq d$. The result now follows by Proposition 4.1. $\square$

LEMMA 4.3. *Suppose* ϕ *is as in Lemma* 4.2. *The functional* $I_{(\phi_+)^*}:L_\infty(T)\to(-\infty,\infty]$ *is* $\|\cdot\|_\infty$*-continuous at any* $y\in L_\infty(T)$ *for which* $\operatorname{ess\,sup} y<d$.

Proof. There exist $M>0$ and $\varepsilon>0$ such that $-M\leqq y(t)\leqq d-\varepsilon$, almost everywhere on T. By Lemma 4.2, $\operatorname{int}(\operatorname{dom}(\phi_+)^*)=(-\infty,d)$, so $(\phi_+)^*$ is continuous on this set, by [Rockafellar, Thm. 10.1, 1970]. It follows that $(\phi_+)^*$ is uniformly continuous on $[-2M,d-(\varepsilon/2)]$. Thus, if $y_n\to y$ uniformly on T, $(\phi_+)^*(y_n(t))\to(\phi_+)^*y(t)$ uniformly, and so $I_{\phi_+^*}(y_n)\to I_{\phi_+^*}(y)$, as required. Alternatively, it is sufficient to observe that $I_{\phi_+^*}$ is bounded above on some neighborhood of y [Holmes, 1975]. $\square$

We will use the following ideas from [Rockafellar, 1970].

DEFINITION 4.4. A proper convex function $f:\mathbb{R}^n\to(-\infty,\infty]$ is *essentially strictly convex* if f is strictly convex on every convex subset of $\{x\,|\,\partial f(x)\neq\phi\}$.

Note that if $n=1$, f is essentially strictly convex if and only if f is strictly convex on dom f. This follows from the fact that if $f:\mathbb{R}^n\to(-\infty,\infty]$ is convex, the only way in which it can fail to be strictly convex on dom f is if it is actually affine on some line segment. To see this, suppose f is not strictly convex on dom f. Without loss of generality suppose $f(0)=f(x_0)=0$ for some $x_0\neq 0$, and that for some $0<\lambda_0<1$, $f(\lambda_0x_0)=0$. Convexity implies $f(\lambda x_0)\leqq 0$ for all $0\leqq\lambda\leqq 1$, so suppose we have strict inequality for some λ, and without loss of generality suppose $0<\lambda<\lambda_0$. We then have

$$\begin{aligned}0&=f(\lambda_0x_0)\\&=f\left(\left(\frac{1-\lambda_0}{1-\lambda}\right)(\lambda x_0)+\left(\frac{\lambda_0-\lambda}{1-\lambda}\right)(x_0)\right)\\&\leqq\left(\frac{1-\lambda_0}{1-\lambda}\right)f(\lambda x_0)+\left(\frac{\lambda_0-\lambda}{1-\lambda}\right)f(x_0)\\&<0,\end{aligned}$$

which is a contradiction. Thus, $f(x)=0$ on $[0,x_0]$.

However, if f is essentially strictly convex then it is certainly strictly convex on ri (dom f) $\subset\{x\,|\,\partial f(x)\neq\phi\}$, and the above argument then shows it must be strictly convex on dom f (provided $n=1$).

DEFINITION 4.5. A proper convex function $f:\mathbb{R}^n\to(-\infty,\infty]$ is *essentially smooth* if f is differentiable on int (dom f) $\neq\phi$, and $\|\nabla f(x_i)\|\to\infty$ whenever $(x_i)\subset$ int (dom f) with $x_i\to$ some x in the boundary of dom f.

THEOREM 4.6. *If $f:\mathbb{R}^n\to(-\infty,\infty]$ is closed, proper, and convex, then f is essentially strictly convex if and only if f^* is essentially smooth.*

Proof. For the proof see [Rockafellar, Thm. 26.3, 1970]. □

The following result gives conditions for dual solutions to be unique.

THEOREM 4.7. *Consider the problem* (DEP$_p$) *of Corollary* 2.6. *Suppose* $\{a_1,\cdots,a_n\}$ *is linearly independent and ϕ_+ is essentially smooth. Then any optimal solution is unique.*

Proof. Suppose $\lambda^1\neq\lambda^2$ are both optimal solutions of (DEP$_p$). The two functions $\sum_{i=1}^n\lambda_i^ja_i(t)\in$ dom $(\phi_+)^*$ almost everywhere, $j=1,2$. Since the a_i's are linearly independent, they differ on a nonnull subset of T, T_1 say. By Theorem 4.5, $(\phi_+)^*$ is strictly convex on dom $(\phi_+)^*$, so if we set $\lambda^3=\frac{1}{2}\lambda^1+\frac{1}{2}\lambda^2$, then

$$(\phi_+)^*\left(\sum_{i=1}^n\lambda_i^3a_i(t)\right)\leqq\frac{1}{2}(\phi_+)^*\left(\sum_{i=1}^n\lambda_i^1a_i(t)\right)+\frac{1}{2}(\phi_+)^*\left(\sum_{i=1}^n\lambda_i^2a_i(t)\right),$$

almost everywhere, with strict inequality on T_1. It follows that λ^3 is an improvement on λ^1 and λ^2, which is a contradiction. □

We are now ready to prove our main result. We shall be concerned specifically with the dual pair (EP$_1$) and (DEP$_1$), so the primal variable will lie in $L_1(T)$. In this result we shall give conditions allowing us to obtain the primal optimal solution by differentiating the dual objective function at the optimum, as described in the introduction. This function involves the convex functional $I_{\phi_+^*}:L_\infty(T)\to(-\infty,\infty]$, whose subgradients lie in $L_\infty^*(T)$. We shall use the results in [Rockafellar, 1971] to decompose such subgradients into their singular and continuous (lying in $L_1(T)$) parts. Finally, we shall find a condition ensuring the singular part vanishes, which will lead to the desired conclusion. The result could alternatively be proved by a direct differentiation argument (see [Ben-Tal, Borwein, and Teboulle, 1988b]), but we shall use the ideas from our proof again in the last section.

THEOREM 4.8. *Consider the dual pair of problems* (EP_1) *and* (DEP_1). *Suppose that all the assumptions of Corollary 2.6 are met, and that* ϕ_+ *is strictly convex on* dom ϕ_+. *Let* $\bar{\lambda}$ *be dual optimal. Suppose finally that the following assumption is satisfied*:

$$d := \lim_{x\to\infty} \frac{\phi(x)}{x} > \operatorname{ess\,sup} \sum_{i=1}^{n} \bar{\lambda}_i a_i. \tag{4.9}$$

Then the unique primal optimal solution is given by

$$\bar{x}(t) = ((\phi_+)^*)'\left(\sum_{i=1}^{n} \bar{\lambda}_i a_i(t)\right).$$

Proof. By Corollary 2.6 we know that the primal and dual values are equal, with dual attainment. Let us denote the constraint map by $A: L_1(T) \to \mathbb{R}^n$, so $(Ax)_i = \langle x, a_i\rangle$, each i. The adjoint map $A^T: \mathbb{R}^n \to L_\infty(T)$ is therefore defined by $A^T\lambda = \sum_{i=1}^n \lambda_i a_i$. It is thus $\mathbb{R}^n - \|\cdot\|_\infty$ continuous, so we can define $A^{TT}: L_\infty^*(T) \to \mathbb{R}^n$, and we will have $A^{TT}|_{L_1(T)} = A$.

The dual objective function is $-g(\lambda)$, where $g: \mathbb{R}^n \to (-\infty, \infty]$ is defined by $g(\lambda) = -b^T\lambda + I_{\phi_+^*}(A^T\lambda)$, and since $\bar{\lambda}$ is dual optimal, $0 \in \partial g(\bar{\lambda})$. However, $\sum_{i=1}^n \bar{\lambda}_i a_i \in$ range (A^T) and $I_{\phi_+^*}$ is continuous at this point, by (4.9) and Lemma 4.3. It follows by [Borwein, Thm. 4.1, 1981] or [Rockafellar, Thm. 19, 1974] that $\partial g(\bar{\lambda}) = -b + A^{TT}\,\partial I_{\phi_+^*}(A^T\bar{\lambda})$, and so there exists $\bar{\mu} \in \partial I_{\phi_+^*}(A^T\bar{\lambda}) \subset L_\infty^*(T)$ with $A^{TT}\bar{\mu} = b$.

By definition of the subgradient, for all $y \in L_\infty(T)$, $\bar{\mu}(y - A^T\bar{\lambda}) \leqq I_{\phi_+^*}(y) - I_{\phi_+^*}(A^T\bar{\lambda})$. Thus, $\bar{\mu} \geqq 0$, since if not, we could find a $y \leqq A^T\bar{\lambda}$ with $\bar{\mu}(y - A^T\bar{\lambda}) > 0$, implying $I_{\phi_+^*}(A^T\bar{\lambda}) < I_{\phi_+^*}(y)$, which contradicts the fact that $(\phi_+)^*$ is monotone increasing by Proposition 4.1.

We can now apply [Rockafellar, Cor. 1B, 1971] to deduce the existence of a $z \in L_1(T)$ and a singular component $\nu \in L_\infty^*(T)$ such that $\bar{\mu} = z + \nu$, where $z(t) \in \partial(\phi_+)^*((A^T\bar{\lambda})(t))$, almost everywhere and ν attains its maximum over dom $I_{\phi_+^*}$ at $A^T\bar{\lambda}$. However, we know $A^T\bar{\lambda} \in$ int (dom $I_{\phi_+^*}$), from which it follows that $\nu = 0$ (alternatively, see [Rockafellar, Cor. 2C, 1971]). Furthermore, we know $(A^T\bar{\lambda})(t) \in$ int (dom $(\phi_+)^*$), almost everywhere, and from Theorem 4.6 we know $(\phi_+)^*$ is essentially smooth. Thus, $z \in L_1(T)$, $z \geqq 0$, $Az = b$, and $z(t) = ((\phi_+)^*)'((A^T\bar{\lambda})(t))$, almost everywhere. In particular, z is primal feasible.

Finally, since ϕ_+ is closed,

$$\phi_+(z(t)) + (\phi_+)^*((A^T\bar{\lambda})(t)) = z(t)(A^T\bar{\lambda})(t), \quad \text{a.e.,}$$

by [Rockafellar, Thm. 23.5, 1970]. Integrating over T gives

$$\begin{aligned} I_{\phi_+}(z) + I_{\phi_+^*}(A^T\bar{\lambda}) &= \langle z, A^T\bar{\lambda}\rangle \\ &= (Az)^T\bar{\lambda} \\ &= b^T\bar{\lambda}, \end{aligned}$$

so z has the same objective value as the dual value, so it is optimal by weak duality. Uniqueness follows by Proposition 2.11. □

5. Special cases. The last result of the previous section (Theorem 4.8) showed that under suitable conditions, if the dual optimal solution $\bar{\lambda}$ satisfied the condition that ess sup $\sum_{i=1}^n \bar{\lambda}_i a_i < d$, where d was defined to be $\lim_{x\to\infty}(\phi(x)/x)$, we could obtain the unique primal solution by differentiating the dual objective function. If $d = \infty$ then this condition is clearly no restriction. However, if $d < \infty$ then condition (4.9) may fail; this is the case, for instance, in Example 3.2. In this final section we shall consider conditions on ϕ that ensure a priori that condition (4.9) will hold.

We begin by defining another constant associated with ϕ. Assuming ϕ_+ is essentially strictly convex, we know by Lemma 4.2 that $\mathrm{cl}\,(\mathrm{dom}\,(\phi_+)^*)=(-\infty, d]$, and that $(\phi_+)^*$ is essentially smooth by Theorem 4.6. Let us define (assuming $d<\infty$)

$$c:=\underline{\lim}_{y\uparrow d}\,(d-y)((\phi_+)^*)'(y). \tag{5.1}$$

Lemma 5.2. *Suppose ϕ_+ is essentially strictly convex and essentially smooth. Then*

$$c=\underline{\lim}_{x\to\infty}\,(d-\phi'_+(x))x. \tag{5.3}$$

Proof. By [Rockafellar, Thm. 26.5, 1970], ϕ'_+ is one-to-one from $\mathrm{int}\,(\mathrm{dom}\,\phi_+)$ to $\mathrm{int}\,(\mathrm{dom}\,(\phi_+)^*)=(-\infty, d)$, continuous in both directions, and $((\phi_+)^*)'=(\phi'_+)^{-1}$. Note that since $d<\infty$, $(k,\infty)\subset \mathrm{dom}\,\phi_+$, for k sufficiently large, so expression (5.3) is well defined. Furthermore, $\phi'_+(x)$ increases to d as x increases to ∞, continuously, using l'Hôpital's rule and the convexity of ϕ_+. Thus, we have

$$\begin{aligned} c&=\underline{\lim}_{y\uparrow d}\,(d-y)((\phi_+)^*)'(y)\\ &=\underline{\lim}_{x\uparrow\infty}\,(d-\phi'_+(x))((\phi_+)^*)'(\phi'_+(x))\\ &=\underline{\lim}_{x\to\infty}\,(d-\phi'_+(x))x, \end{aligned}$$

as required. □

We will now restrict our attention to the case where the underlying measure space T is a compact real interval with Lebesgue measure. We will need the following lemma.

Lemma 5.4. *Suppose $h\in C[\alpha,\beta]$, $h(t_0)=0$ for some $\alpha\leqq t_0\leqq\beta$, and h is Lipschitz (or in particular, continuously differentiable) at t_0. Then $1/h\notin L_1[\alpha,\beta]$.*

Proof. Suppose first that h is continuously differentiable at t_0. Define a function $g:[\alpha,\beta]\to\mathbb{R}$ by

$$g(t)=\begin{cases} h(t)/(t-t_0), & t\neq t_0,\\ h'(t_0), & t=t_0.\end{cases}$$

By L'Hôpital's rule, g is continuous, so by compactness, $|g(t)|\leqq M$ for all $t\in[\alpha,\beta]$, for some M. Since $h(t)=(t-t_0)g(t)$ for all $t\in[\alpha,\beta]$, $|h(t)|\leqq M|t-t_0|$, so h is Lipschitz at t_0.

Now assume h is Lipschitz at t_0, so $|h(t)|\leqq M|t-t_0|$, for all $t\in[\alpha,\beta]$. Thus,

$$\frac{1}{|h(t)|}\geqq\frac{1}{M|t-t_0|}\quad \forall t\in[\alpha,\beta],\quad t\neq t_0.$$

Since clearly $1/|t-t_0|\notin L_1[\alpha,\beta]$, the result follows. □

For the last step in the above argument, it is critical that the underlying measure is Lebesgue measure (or at least is greater than some positive multiple of Lebesgue measure). The underlying space is important, too. Consider, for example, $T=[-1,1]\times[-1,1]\subset\mathbb{R}^2$, with Lebesgue measure. Then $1/\|t\|\in L_1(T)$.

Theorem 5.5. *Let $T=[\alpha,\beta]$, with Lebesgue measure, and each a_i be locally Lipschitz (or in particular, continuously differentiable), $i=1,\cdots,n$. Consider the dual pair of problems* (EP$_1$) *and* (DEP$_1$). *Suppose that all of the assumptions of Corollary* 2.6 *are met, and that ϕ_+ is strictly convex on* dom ϕ_+. *Suppose that*

$$\textit{there exists } \mu\in\mathbb{R}^n \textit{ with } \sum_{i=1}^{n}\mu_i a_i(s)<d\quad \forall s\in[\alpha,\beta], \tag{5.6}$$

where $d := \lim_{x\to\infty} (\phi(x)/x)$, and if $d<\infty$ define $c := \lim_{y\uparrow d} (d-y)((\phi_+)^*)'(y)$. Suppose that either $d=\infty$ or $d<\infty$ and $c>0$. Then the unique primal optimal solution is given by $\bar{x}(t) = ((\phi_+)^*)'(\sum_{i=1}^n \bar{\lambda}_i a_i(t))$, where $\bar{\lambda}$ is a dual optimal solution.

Proof. Just as in the proof of Theorem 4.8, we know that $0 \in \partial g(\bar{\lambda})$, where $g(\lambda) = -b^T\lambda + I_{\phi_+^*}(A^T\lambda)$. We can write (5.6) as

$$\text{range}\,(A^T) \cap \text{cont}\,(I_{\phi_+^*}) \neq \phi,$$

by Lemma 4.3, so it follows by [Rockafellar, Thm. 19, 1974] or [Borwein, Thm. 4.1, 1981] that $\partial g(\lambda) = -b + A^{TT}\,\partial I_{\phi_+^*}(A^T\lambda)$. Thus, there exists $\bar{\mu} \in \partial I_{\phi_+^*}(A^T\bar{\lambda})$. Applying [Rockafellar, Cor. 1B, 1971] just as in the proof of Theorem 4.8, it follows that there exists $z \in L_1(T)$ with $z(t) \in \partial(\phi_+)^*((A^T\bar{\lambda})(t))$, almost everywhere.

The next step is to observe that since $(\phi_+)^*$ is essentially smooth (by Theorem 4.6), $\partial(\phi_+)^*(d) = \phi$. To see this, recall that as $y \uparrow d$, $((\phi_+)^*)'(y) \uparrow \infty$, by the definition of essentially smooth, and the fact that, by Lemma 4.2, $\text{cl}\,(\text{dom}\,(\phi_+)^*) = (-\infty, d]$. If $u \in \partial(\phi_+)^*(d)$ then $u(y-d) \leqq (\phi_+)^*(y) - (\phi_+)^*(d)$, for all y. By the mean value theorem, given any $M>0$ there exists $y<d$ with $(\phi_+)^*(d) - (\phi_+)^*(y) = ((\phi_+)^*)'(z)(d-y) \geqq M(d-y)$, for some $y<z<d$. It follows that $u \geqq M$, which is a contradiction as M was arbitrary.

Since $z(t) \in \partial(\phi_+)^*((A^T\bar{\lambda})(t))$ almost everywhere, it follows that $(A^T\bar{\lambda})(t) < d$, almost everywhere, and so $z(t) = ((\phi_+)^*)'((A^T\bar{\lambda})(t))$, almost everywhere. We know from Theorem 4.8 that if $\text{ess sup}\, A^T\bar{\lambda} < d$ then $\bar{x} = z$ is the unique primal optimal solution, as required. Since the a_i's are continuous on $[\alpha, \beta]$, the only alternative is $(A^T\bar{\lambda})(t_0) = d$, for some $\alpha \leqq t_0 \leqq \beta$. We will show that, in this case, z cannot possibly lie in $L_1[\alpha, \beta]$, giving a contradiction. This will complete the proof.

Assume therefore that for some $\alpha \leqq t_0 \leqq \beta$, $\sum_{i=1}^n \bar{\lambda}_i a_i(t_0) = d < \infty$. By the definition of c, there exists $\varepsilon > 0$ such that $(d-y)((\phi_+)^*)'(y) \geqq c/2 > 0$, for all $d > y \geqq d - \varepsilon$. By the continuity of the a_i's, there exists $\delta > 0$ such that $\sum_{i=1}^n \bar{\lambda}_i a_i(t) \geqq d - \varepsilon$, for all $|t - t_0| \leqq \delta$. Thus,

$$\begin{aligned} z(t) &= ((\phi_+)^*)'\left(\sum_{i=1}^n \bar{\lambda}_i a_i(t)\right) \\ &\geqq \frac{c}{2(d - \sum_{i=1}^n \bar{\lambda}_i a_i(t))}, \end{aligned}$$

for all $|t - t_0| \leqq \delta$. But by Lemma 5.4, the right-hand side is not integrable (on either $[t_0 - \delta, t_0]$ or $[t_0, t_0 + \delta]$), so $z \notin L_1[\alpha, \beta]$. This completes the proof. □

Note in particular that condition (5.6) will always hold if one of the a_i's is a nonzero constant function.

We will conclude with a number of examples of typical objective functions ϕ, taken from [Ben-Tal, Borwein, and Teboulle, 1988b]. Some of these objectives are taken from the literature, others are new. For each function we give the numbers d and c of Theorem 5.5. It is easy to check that ϕ_+ is closed and essentially strictly convex in each case.

Examples 5.6.

(i) $$\phi_+(x) = \begin{cases} -\log x, & x>0, \\ \infty, & x \leqq 0, \end{cases}$$

$$(\phi_+)^*(y) = \begin{cases} -1-\log(-y), & y<0, \\ \infty, & y \geqq 0, \end{cases} \qquad d=0, \quad c=1.$$

(ii) $$\phi_+(x)=\begin{cases} x\log x - x, & x>0,\\ 0, & x=0,\\ \infty, & x<0,\end{cases}$$

$$(\phi_+)^*(y)=e^y, \qquad d=\infty.$$

(iii) $$\phi_+ + (x)=\begin{cases} \dfrac{1}{p}x^p, & x\geqq 0, \quad (\text{with } 1<p<\infty),\\ \infty, & x<0,\end{cases}$$

$$(\phi_+)^*(y)=\frac{1}{q}(y^+)^q, \qquad d=\infty.$$

(iv) $$\phi_+(x)=\begin{cases} e^x-1, & x\geqq 0,\\ \infty, & x<0,\end{cases}$$

$$(\phi_+)^*(y)=\begin{cases} y\log y - y+1, & y\geqq 1,\\ 0, & y<1,\end{cases} \qquad d=\infty.$$

(v) $$\phi_+(x)=\begin{cases} \dfrac{\gamma x - x^\gamma}{1-\gamma}, & x\geqq 0,\\ \infty, & x<0,\end{cases} \quad \left(\text{with } 0<\gamma<1,\ \frac{1}{\gamma}-\frac{1}{\psi}=1\right),$$

$$(\phi_+)^*(y)=\begin{cases} \left(1-\dfrac{1}{\psi}y\right)^{-\psi}, & y\leq \psi,\\ \infty, & \text{otherwise},\end{cases} \qquad d=\psi, \quad c=\infty.$$

(vi) $$\phi_+(x)=\begin{cases} k-\sqrt{k^2-x^2}, & 0\leqq x\leqq k,\\ \infty, & \text{otherwise},\end{cases}$$

$$(\phi_+)^*(y)=\begin{cases} k(\sqrt{1+y^2}-1), & y\geqq 0,\\ 0, & y<0,\end{cases} \qquad d=\infty.$$

(vii) $$\phi_+(x)=\begin{cases} x\log x-(1+x)\log(1+x), & x>0,\\ 0, & x=0,\\ \infty, & x<0,\end{cases}$$

$$(\phi_+)^*(y)=\begin{cases} -\log(1-e^y), & y<0,\\ \infty, & y\geqq 0,\end{cases} \qquad d=0, \quad c=\infty.$$

(viii) $$\phi_+(x)=\begin{cases} \dfrac{1}{x}, & x>0,\\ \infty, & x\leqq 0,\end{cases}$$

$$(\phi_+)^*(y)=\begin{cases} -2\sqrt{-y}, & y\leqq 0,\\ \infty, & y>0,\end{cases} \qquad d=0, \quad c=0.$$

In all of the above examples, ϕ_+ is strictly convex on its domain, and except in cases (iii), (iv), and (vi) it is also essentially smooth. With the exception of case (vi), $(0,\infty)\subset \operatorname{dom}\phi_+$, so the constraint qualification will simply require the existence of a feasible $\hat{x}\in\operatorname{dom} I_{\phi_+}$ with $\hat{x}(t)>0$, almost everywhere. In the case of (vi) it can be checked using the results of [Borwein and Lewis, 1988] that the constraint qualification requires the existence of a feasible $\hat{x}$ with $0<\hat{x}(t)<k$, almost everywhere. Example (viii) shows, as we would expect, that the assumptions of Theorem 5.5 fail for Example 3.2.

Suppose finally that $(\phi_+)^*$ is actually continuously differentiable on (∞, d), as is the case in all of the above examples. With the assumptions of Theorem 5.5 it then follows that the unique optimal solution of (EP_1), $\bar{x}$, is actually continuous on T, so it certainly lies in L_p for any $1 \leqq p \leqq \infty$. Thus, $\bar{x}$ will in fact be the unique optimal solution for (EP_p), for any $1 \leqq p \leqq \infty$, and also for the analogous problem posed in $C[\alpha, \beta]$.

1-DETERMINACY OF FEASIBLE SETS*

TOSHIHIRO MATSUMOTO†, SUSUMU SHINDOH‡, AND RYUICHI HIRABAYASHI§

Abstract. Germs of feasible sets, 1-determinacy of feasible sets, (strongly) restricted A-equivalence of map germs, and (strongly) restricted 1-determinacy of map germs are defined. Then each concept of 1-determinacy is characterized by a necessary and sufficient condition. Finally, it is demonstrated that all of these concepts are equivalent in some sense.

Key words. feasible sets, 1-determinacy, (strongly) restricted A-equivalence, singularity

1. Introduction.

There are many articles on the study of nonlinear programs from the topological point of view (see, for example, Kojima [9], Jongen, Jonker, and Twilt [7], [8], Guddat and Jongen [4], Fujiwara [1], etc.). In 1986, Guddat, Jongen, and Rueckmann [5] proved that a feasible set of a nonlinear program becomes a topological manifold under the assumption that Mangasarian–Fromovitz constraint qualification (MF-condition) holds at every point of the feasible set. Guddat, Jongen, and Rueckmann [5], Jongen, Jonker, and Twilt [8], and Guddat and Jongen [4] developed a structural stability theory of nonlinear programs. Especially, in [5], Guddat, Jongen, and Rueckmann proved that it is necessary and sufficient to assume the condition mentioned above for a feasible set to be structurally stable. Hence, for the topological study of nonlinear programs, it is natural to assume that the condition above holds.

In [11], under the assumption above, we obtained a necessary condition and a sufficient condition that a feasible set of a nonlinear program has a standard differential structure. In this paper we investigate a situation that the sufficient condition obtained in [11] becomes necessary and sufficient. For this purpose we study a singularity theory of feasible sets. The first and important papers on the singularity theory related to nonlinear programs are Jongen, Jonker, and Twilt [6] and Siersma [12] (1982). In [6], under a generic situation, Jongen, Jonker, and Twilt studied one-parameter families of feasible sets and developed a surgery theory of feasible sets related to the Morse theory. On the other hand, in [12], Siersma developed a singularity theory on finite determinacy, unfolding and classification for manifolds with corners, assuming that gradient vectors of active constraints are linearly independent.

We are also interested in constructing a singularity theory for nonlinear programs under the MF-condition. This construction, however, is not so easy. Hence, we have to go step by step. Therefore, in this paper we only study 1-determinacy of feasible sets and prove that this is equivalent to studying the 1-determinacy of mappings (Gibson [3]) in a restricted sense.

1.1. Notation and symbols.

R^n	n-dimensional Euclidean space,
C^∞	the class of any times continuously differentiable mappings,
$f\|U$	the restriction of a mapping f to the set U,

$\sim_x$	the equivalent relation on the set of all C^∞-maps $\{f: R^n \to R^p\}$ at x defined by $f_1 \sim_x f_2$ if and only if there exists an open neighborhood U satisfying $f_1 \mid U = f_2 \mid U$,
D_x	differential operator with respect to x,
I_n	the identity matrix of order n,
$E_{n,p}$	the set of all C^∞ map germs of $(R^n, 0) \to R^p$,
$E^0_{n,p}$	the set of all C^∞ map germs of $(R^n, 0) \to (R^p, 0)$,
Diff_n	the set of all C^∞-diffeomorphic germs of $(R^n, 0) \to (R^n, 0)$,
Diff^1_n	the subset of $\phi \in \mathrm{Diff}_n$ with $D_x\phi(0) = I_n$,
K_n	$= \{\Psi_{\sigma,u} \in \mathrm{Diff}_n \mid$there exist a germ $u \in E_{n,n}$ such that $u_i(0) \neq 0$ $(i = 1, \cdots, n)$ and a permutation σ on $\{1, \cdots, n\}$ satisfying $\Psi_{\sigma,u}(x) = (u_1(x)x_{\sigma(1)}, \cdots, u_n(x)x_{\sigma(n)})^T\}$ where u_i is the ith component of u,
K^1_n	$= K_n \cap \mathrm{Diff}^1_n$,
$G_{n,p}$	$= \mathrm{Diff}_p \times \mathrm{Diff}_n$,
$H_{n,p}$	$= K_p \times \mathrm{Diff}_n$,
$H^1_{n,p}$	$= K^1_p \times \mathrm{Diff}^1_n$,
$f \approx_G g$	if and only if $G_{n,p} \cdot f = G_{n,p} \cdot g$ (A-equivalence),
$f \approx_H g$	if and only if $H_{n,p} \cdot f = H_{n,p} \cdot g$ (restricted A-equivalence),
$f \approx_{H^1} g$	if and only if $H^1_{n,p} \cdot f = H^1_{n,p} \cdot g$ (strongly A-equivalence),
$j^1 f$	the Taylor expansion of order one of f at $x = 0$ for $f \in E^0_{n,p}$ (the 1-jet of f),
$J^1 f$	$= \{g \in E^0_{n,p} : j^1 g = j^1 f\}$,
f	is 1-determined if and only if $J^1 f \subset G_{n,p} \cdot f$,
f	is restricted 1-determined if and only if $J^1 f \subset H_{n,p} \cdot f$,
f	is strongly restricted 1-determined if and only if $J^1 f \subset H^1_{n,p} \cdot f$,
$M[g]$	$= \{x \in R^n$: $g(x) \geqq 0$ for a C^∞ mapping g: $(R^n, 0) \to (R^p, 0)\}$,
$M[g]_0$	is the feasible set germ,
$M[\ ]_0$	is the set of all feasible set germs at $0 \in R^n$,
δ^i_j	is Kronecker's delta,
$M(p, n : R)$	is the set of real $p \times n$ matrices,
R_+	the set of nonnegative numbers,
$C_g(0)$	the cotangent cone of $M[g]_0$,
B	$= \{\xi_k\}^p_{k=1}$: a basis for $C_g(0)$,
B_k	$= \{j$: $Dg_j(0) \in R_+\xi_k\}$,
$G_k(x)$	$= \min\{g_j(x) : j \in B_k\}$,
class C	$= \{g \in E^0_{n,p}$: $M[g]_0 = M[G]_0\}$,
$C_g(0)^d$	the dual cone (the tangent cone) of $M[g]_0$.

2. Restricted 1-determinacy of C^∞-map germs. Let R^n be the n-dimensional Euclidean space. For a given point $\bar{x} \in R^n$, define an equivalence relation $\sim_{\bar{x}}$ on the set of all any times continuous differentiable (C^∞) maps $\{f: R^n \to R^p\}$ by $f_1 \sim_{\bar{x}} f_2$ if there exists an open neighborhood U of $\bar{x}$ that satisfies $f_1 | U = f_2 | U$. Here $f | U$ denotes the restriction of a mapping f to U. A C^∞-map germ from R^n to R^p at $\bar{x}$ is defined as an equivalence class with respect to $\sim_{\bar{x}}$. If f_1 and f_2 are two representatives of a germ f at $\bar{x}$, then obviously $f_1(\bar{x}) = f_2(\bar{x}) (= \bar{y})$. This same value $\bar{y}$ is called the value of the germ f at $\bar{x}$ and denoted by $f(\bar{x})$. To show this explicitly, we write $f: (R^n, \bar{x}) \to (R^p, \bar{y})$.

Let $E_{n,p}$ be the set of all C^∞-map germs at zero of $R^n \to R^p$, $E^0_{n,p}$ be the subset of $f \in E_{n,p}$ with $f(0) = 0$, Diff_n be the set of all C^∞-diffeomorphic germ ϕ's of $(R^n, 0) \to (R^n, 0)$, and Diff^1_n be the subset of Diff_n such that $D_x\phi(0) = I_n$, where D_x denotes the partial differential operator with respect to x and I_n is the unit matrix of order n.

Define a subset of Diff_n by $K_n := \{\Psi_{\sigma,u} \in \mathrm{Diff}_n \mid$ there exist a germ $u \in E_{n,n}$ such that $u_i(0) \neq 0$ $(i=1,\cdots,n)$ and a permutation σ on $\{1,\cdots,n\}$ satisfying $\Psi_{\sigma,u}(x) = (u_1(x)x_{\sigma(1)},\cdots,u_n(x)x_{\sigma(n)})^T\}$, where u_i is the ith component of u and T denotes the transpose of vectors. Moreover, define a subset of Diff_n by $K_n^1 := K_n \cap \mathrm{Diff}_n^1 = \{\Psi_{\sigma,u} \in \mathrm{Diff}_n^1 \mid u_i(0) = 1$ $(i=1,\cdots,n)$ and $\sigma = \mathrm{id}\}$ where id is the identical permutation. Let $G_{n,p} := \mathrm{Diff}_p \times \mathrm{Diff}_n$, $H_{n,p} := K_p \times \mathrm{Diff}_n$ and $H_{n,p}^1 := K_p^1 \times \mathrm{Diff}_n^1$. Then it is clear that $H_{n,p}^1 \subseteq H_{n,p} \subseteq G_{n,p}$ as subgroups. $G_{n,p}$ acts on $E_{n,p}^0$ from left and right as follows. For any $\alpha = (\beta,\gamma) \in G_{n,p}$ and $f \in E_{n,p}^0$, $\alpha \cdot f := \beta \circ f \circ \gamma^{-1}$, i.e., the diagram below is commutative:

$$\begin{tikzcd}
R^n \arrow[r, "f"] \arrow[d, "\gamma"'] & R^p \arrow[d, "\beta"] \\
R^n \arrow[r, "\alpha \cdot f"'] & R^p.
\end{tikzcd}$$

Since $H_{n,p}$ and $H_{n,p}^1$ are subgroups of $G_{n,p}$, they also act on $E_{n,p}^0$ from left and right. Suppose f and $g(\in E_{n,p}^0)$ are in the same orbit by $G_{n,p}$ (respectively, $H_{n,p}$, $H_{n,p}^1$), i.e., $G_{n,p} \cdot g = G_{n,p} \cdot f$ (respectively, $H_{n,p} \cdot g = H_{n,p} \cdot f$, $H_{n,p}^1 \cdot g = H_{n,p}^1 \cdot f$); then we write $f \approx_G g$ (respectively, $f \approx_H g$, $f \approx_{H^1} g$). Since it is obvious that these relations are equivalence relations, we call these equivalence relations A-equivalence (see, for instance, Gibson [3]), restricted A-equivalence, and strongly restricted A-equivalence, respectively. We will mainly investigate the (strongly) restricted A-equivalence in the following because it takes an important role in studying the singularities of feasible sets in nonlinear programs.

Denote the 1-jet of $f \in E_{n,p}^0$ at $0 \in R^n$ by $j^1 f := (D_x f_1(0)x,\cdots,D_x f_p(0)x)$ and put $J_f^1 := \{g \in E_{n,p}^0 \mid j^1 g = j^1 f\}$. If $J_f^1 \subseteq G_{n,p} \cdot f$ (respectively, $H_{n,p} \cdot f$, $H_{n,p}^1 \cdot f$) holds, then f is called 1-determined (respectively, restricted 1-determined, strongly restricted 1-determined).

For a $g \in E_{n,p}^0$, denote $\{x \in R^n \mid g_i(x) \geqq 0,\ i=1,2,\cdots,p\}$ by $M[g]$. $M[g]$ is called the feasible set defined by g. For $0 \in R^n$, define an equivalence relation on the set $\{M[g] \mid g \in E_{n,p}^0\}$ by $M[g_1] \sim M[g_2]$ if there exists a neighborhood U of $0 \in R^n$ such that $M[g_1] \cap U = M[g_2] \cap U$. A feasible set germ on R^n at $0 \in R^n$ is defined as an equivalence class with respect to $\sim$ and denoted by $M[g]_0$. Denote the set of all feasible set germs at $0 \in R^n$ by $M[\ ]_0$. It is clear that for a germ $g \in E_{n,p}^0$ and any representatives g_1 and g_2 of g, $M[g_1] \sim M[g_2]$. Hence we may define a feasible set germ $M[g]_0$ by $M[g_1]_0$ for any C^∞-map germ $g \in E_{n,p}^0$ and its representative g_1. Let ρ be a map assigning $g \in E_{n,p}^0$ to $M[g]_0$. It is also clear that ρ is onto from $E_{n,p}^0$ to $M[\ ]_0$. We say that $M[g]_0$ is 1-determined if $M[g]_0$ is diffeomorphic to $M[h]_0$ by the action of Diff_n (denoted by $M[g]_0 \cong M[h]_0$) whenever $M[j^1 g]_0 = M[j^1 h]_0$.

Remark 2.1. Note that ρ is not one to one. For example, let $g, h \in E_{n,p}^0$ be given by $g_i = \delta_i^1 x_1$ and $h_i = \delta_i^1 x_1^3$ for $i = 1,2,\cdots,p$, where $\delta_i^j = 1$ $(i=j)$, or 0 (otherwise). Then $g \not\approx h$ but $M[g]_0 = M[h]_0$.

With respect to 1-determinancy of C^∞-map germs, the lemma below holds.

LEMMA 2.2. *Let $f \in E_{n,p}^0$. Then f is restricted* 1*-determined if and only if f is strongly restricted* 1*-determined.*

Proof. It is sufficient to show the only if part, since the if part is clear. Suppose $J_f^1 \subset H_{n,p} \cdot f$. Let $g \in J_f^1$. Note that $D_x g(0)x = D_x f(0)x \in J_f^1$. Then, by the assumption, there exist $\alpha_i = (\beta_i, \phi_i) \in H_{n,p}$ $(i=1,2)$ such that

$$\beta_1 \circ f \circ \phi_1^{-1}(x) = D_x f(0)x = D_x g(0)x = \beta_2 \circ g \circ \phi_2^{-1}(x),$$

i.e.,

$$\beta_1 \circ f(x) = \langle D_x f(0), \phi_1(x) \rangle$$

and

$$\beta_2 \circ g(x) = \langle D_x g(0), \phi_2(x) \rangle.$$

Let $\beta_1(y) = (u_1(y) y_{\sigma(1)}, \cdots, u_p(y) y_{\sigma(p)})$, where $u_i(0) \neq 0$ $(1 \leqq i \leqq p)$ and σ is a permutation on $\{1, \cdots, p\}$. By differentiating $u_i(f(x)) f_{\sigma(i)}(x) = \langle D_x f_i(0), \phi_1(x) \rangle$, we have $u_i(0) D_x f_{\sigma(i)}(0) = D_x f_i(0) D_x \phi_1(0)$. Hence $D_x f_i(0) = u_i(0) D_x f_{\sigma(i)}(0)(D_x \phi_1(0))^{-1}$. This leads to

$$(u_i(f(x))/u_i(0)) f_{\sigma(i)}(x) = \langle D_x f_{\sigma(i)}(0), (D_x \phi_1(0))^{-1} \phi_1(x) \rangle.$$

Set $\tau = \sigma^{-1}$, $\tilde{u}_i(x) = u_{\tau(i)}(x)/u_{\tau(i)}(0)$ and $\tilde{\phi}(x) = (D_x \phi_1(0))^{-1} \phi_1(x)$; then we get $\tilde{u}_i(f(x)) f_i(x) = \langle D_x f_i(0), \tilde{\phi}(x) \rangle$. Obviously, $\tilde{u}_i(0) = 1$ and $D_x \tilde{\phi}(0) = I_n$. By repeating the same argument for $D_x g(0) x = \beta_2 \circ g \circ \phi_2^{-1}(x)$, we see that there exist $\tilde{\alpha}_i = (\tilde{\beta}_i, \tilde{\phi}_i) \in H^1_{n,p}$ $(i = 1, 2)$ satisfying

$$\tilde{\beta}_1 \circ f \circ \tilde{\phi}_1^{-1}(x) = D_x f(0) x = D_x g(0) x = \tilde{\beta}_2 \circ g \circ \tilde{\phi}_2^{-1}(x).$$

Define $\bar{\beta}(y) = \tilde{\beta}_2^{-1} \circ \tilde{\beta}_1(y)$ and $\bar{\phi}(x) = \tilde{\phi}_2^{-1} \circ \tilde{\phi}_1(x)$. Then $g(x) = \bar{\beta} \circ f \circ \bar{\phi}^{-1}(x)$. It is easily shown that $(\bar{\beta}, \bar{\phi}) \in H^1_{n,p}$. □

The following four definitions are fundamental in what follows. Let $M(p, n : R)$ be the set of real $p \times n$ matrices.

DEFINITION 2.3. Let $A \in M(p, n : R)$. We say that A is of type 1 if

(1) rank $A = \min(p, n)$,

(2) $p \leqq n + 2$,

(3) All the minors of degree n of A are nonzero.

DEFINITION 2.4. Let $A \in M(p, n : R)$. We say A is of type (*) if for any $g \in E^0_{n,p}$ with $D_x g(0) = A$; then there exist $z \in E_{n,p}$ such that $z_i(0) \neq 0$ $(1 \leqq i \leqq p)$ and $\phi \in \mathrm{Diff}_n$ satisfying $z_i(x) g_i(x) = \langle D_x g_i(0), \phi(x) \rangle$ $(1 \leqq i \leqq p)$.

DEFINITION 2.5. Let $g \in E^0_{n,p}$. We say that g is irredundant if $D_x g_i(0)$ and $D_x g_j(0)$ are linearly independent to each other for $i \neq j$.

Remark 2.6. The definition of "irredundant" is related to that of "smoothness condition" in [11].

DEFINITION 2.7. Let $g \in E^0_{n,p}$. We say that g is a minimal representative if $M[g]_0 \neq M[g^{\langle i \rangle}]_0$ for all i where $g^{\langle i \rangle}$ is defined by $g_j^{\langle i \rangle} = (1 - \delta^i_j) g_j$.

Remark 2.8. The definition of "a minimal representative" is related to that of "a conical basis" in [11].

When we study topological properties of $M[g]$, it is essential to assume that the well-known MF-condition holds (see, for example, Guddat and Jongen [4], Guddat, Jongen, and Rueckmann [5]):

Condition 2.9. Let $A \in M(p, n : R)$. Then there exists a $w \in R^n$ such that $Aw > 0$ holds.

Condition 2.10 (Mangasarian and Fromovitz [10]). Let $g \in E^0_{n,p}$. Then $D_x g(0)$ satisfies Condition 2.9.

Remark 2.11. Since we do not treat equality constraints, the MF-condition coincides with the Cottle constraints qualification (Gauvin [2]).

According to [11], we restrict the problem to the class below. Let $g \in E^0_{n,p}$. Define the cotangent cone $C_g(0)$ by

$$C_g(0) = \left\{ \sum_{1 \leqq i \leqq p} r_i D_x g_i(0) : r_i \geqq 0 \ (1 \leqq i \leqq p) \right\}.$$

Since $C_g(0)$ is finitely generated, there is a nonnegative integer q such that a basis of $C_g(0)$ is $B := \{\xi_k\}_{k=1}^q$. It is easily shown that q is independent of the choice of a basis. Define the index subset by $B_k := \{j: D_x g_j(0) \in R_+ \xi_k\}$ and the minimal constraint function by $G_k(x) := \min\{g_j(x): j \in B_k\}$, where $R_+ = \{r \in R: r \geqq 0\}$. $M[g]_0 = M[G]_0$ does not necessarily hold. So, in the remainder of the paper, we assume that $g \in E_{n,p}^0$ is always in the class $C = \{g \in E_{n,p}^0: g$ satisfies $M[g]_0 = M[G]_0\}$.

We will introduce two main results of the paper [11] in the following theorem.

THEOREM 2.12 [11]. *Let $n \geqq 2$ and $A \in M(p, n: R)$. Suppose the matrix A satisfies Condition* 2.9; *then A is of type* 1 *if and only if A is of type* (*).

Proof. Only if. Let A be of type 1. If $p \leqq n$, then rank $D_x g(0) = p$, where $g \in E_{n,p}^0$ with $D_x g(0) = A$. Hence it is easy to show the existence of $z \in E_{n,p}$ with $z_i(0) \neq 0$ $(1 \leqq i \leqq p)$ and $\phi \in \mathrm{Diff}_n$ such that $z_i(x) g_i(x) = \langle D_x g_i(0), \phi(x)\rangle$ $(1 \leqq i \leqq p)$. (See, for example, Jongen, Jonker, and Twilt [7].) If $p > n$, i.e., $p = n+1$ or $n+2$, the proof is constructive. In fact, we can construct $z(x)$ and $\phi(x)$ for any $g \in E_{n,p}^0$ with $D_x g(0) = A$ in the category of C^∞ map germs. For more details, see Theorem 4.2 of [11].

If. Suppose that A is of type (*). It is easily shown that rank $A = \min(p, n)$. If $p \leqq n$, it is clear that A is of type 1. If $p > n$, we must treat this carefully. In this case, without loss of generality, we may assume that A is of the form $[I_n, B^T]^T$, where B is a matrix of an appropriate size. By constructing $g \in E_{n,p}^0$ such that $D_x g(0) = A$ and each g_i $(1 \leqq i \leqq p)$ is a linear or a quadratic map germ, we can verify that each entry of B is nonzero, rank $B \leqq 2$ and all the minors of B with order two are not equal to zero. If $p \geqq n+3$, then it is easy to construct a g with $D_x g(0) = A$, leading to a contradiction. For more details, see Lemma 3.4 and Theorem 3.2 of [11]. □

THEOREM 2.13 (characterization of 1-determinacy of feasible sets). *Let $n \geqq 2$ and $g \in E_{n,p}^0$ be irredundant, a minimal representative, and satisfy Condition* 2.10. *Then $M[g]_0$ is* 1*-determined if and only if $D_x g(0)$ is of type* 1.

Proof. Only if. Suppose that $M[g]_0$ is 1-determined. Then $M[g]_0 \cong M[j^1 g]_0$. By Theorem 3.1 of [11], it follows that there exist $z_i(x)$ $(1 \leqq i \leqq p)$ satisfying

$$g_i(x) z_i(x) = \langle D_x g_i(0), y(x)\rangle \qquad (1 \leqq i \leqq p)$$

where $y(x)$ is a local diffeomorphism from $M[g]_0$ to $M[j^1 g]_0$ and $y(0) = 0$. This implies that $D_x g(0)$ is of type (*). By Theorem 2.12, we see that $D_x g(0)$ is of type 1.

If. Suppose that $D_x g(0)$ is of type 1. Define the cotangent cone $C_g(0)$ and its dual cone (the tangent cone) $C_g(0)^d$ of $M[g]_0$ by

$$C_g(0) = \left\{ \sum_{1 \leqq i \leqq p} r_i D_x g_i(0) : r_i \geqq 0 \ (1 \leqq i \leqq p) \right\}$$

and

$$C_g(0)^d = \{v \in R^n : \langle v, u\rangle \geqq 0 \text{ for every } u \in C_g(0)\}.$$

Note that $M[j^1 g]_0 = M[j^1 h]_0$ means $C_g(0)^d = C_h(0)^d$). (See Appendix D in [11].)

Let $p \leqq n$. Then rank $D_x g(0) = p$. In this case, there exists a local diffeomorphism y_g with $y_g(0) = 0$ from $M[g]_0$ to $C_g(0)^d$. (See, for example, Jongen, Jonker, and Twilt [7].) From the fact that $g(0) = h(0) = 0 \in R^p$ and rank $D_x g(0) = p$, we see that rank $D_x h(0) = p$. Hence there exists a local diffeomorphism y_h from $M[h]_0$ to $C_h(0)^d$. Since $C_g(0)^d = C_h(0)^d$, it follows that $y_h^{-1} \circ y_g$ is a local diffeomorphism from $M[g]_0$ to $M[h]_0$, i.e., $M[g]_0$ is 1-determined.

Next, suppose $p \geqq n$. By Theorem 4.2 of [11], we can construct a local diffeomorphism y_g from $M[g]_0$ to $C_g(0)^d$ since $D_x g(0)$ is of type 1. The assumptions with respect to g and $M[j^1 g]_0 = M[j^1 h]_0$ imply rank $D_x h(0) = n$. It is easily shown that $D_x h(0)$ is also of type 1. Repeating the same argument above, we obtain a local diffeomorphism y_h of $M[h]_0$ to $C_h(0)^d$. Thus $y_h^{-1} \circ y_g$ is a local diffeomorphism from $M[g]_0$ to $M[h]_0$ since $C_g(0)^d = C_h(0)^d$. Therefore $M[g]_0$ is 1-determined. □

In order to get an understanding of Theorem 2.13, we give two examples with $g:(R^3, 0) \to (R^5, 0)$ below.

Example 2.14. Let $g_i(x) = x_i$ $(1 \leqq i \leqq 3)$, $g_4(x) = 2x_1 + x_2 - x_3$, and $g_5(x) = x_1 + x_1^2 + 2x_2 - x_3$. Then $M[g]_0$ is 1-determined. (Note that $D_xg(0)$ is of type 1.) To show this, we must construct a $\phi \in \mathrm{Diff}_3$ and $z_i(x)$ $(1 \leqq i \leqq 5)$ with $z_i(0) \neq 0$ satisfying

$$z_i(x)g_i(x) = \langle D_xg_i(0), \phi(x)\rangle \qquad (1 \leqq i \leqq 5).$$

Assuming $z_3(x) = 1$ with no loss of generality, a tedious calculation (see Appendix B in [11]) shows that

$$z_1(x) = (3 + 3x_1 + 2x_2 - 3x_3)/3(1 - x_1),$$
$$z_2(x) = (3 - x_1)/3(1 - x_1), \qquad z_3(x) = 1,$$
$$z_4(x) = (1 + x_1)/(1 - x_1), \qquad z_5(x) = 1/(1 - x_1)$$

and $\phi = (\phi_1, \phi_2, \phi_3)$ is given by

$$\phi_1(x) = x_1z_1(x), \quad \phi_2(x) = x_2z_2(x), \quad \phi_3(x) = x_3z_3(x).$$

Example 2.15. Let $g_i(x) = x_i$ $(1 \leqq i \leqq 3)$, $g_4(x) = 2x_1 + x_2 - x_3$, and $g_5(x) = x_1 + x_2 - x_3 - x_3^2$. Then $M[g]_0$ is not 1-determined. (Note that $D_xg(0)$ is not of type 1.) Suppose there exists a $\phi \in \mathrm{Diff}_3$ and $z_i(x)$ $(1 \leqq i \leqq 5)$ such that

$$z_i(x)g_i(x) = \langle D_xg_i(0), \phi(x)\rangle \qquad (1 \leqq i \leqq 5).$$

Then

$$\phi_1(x) = x_1z_1(x), \quad \phi_2(x) = x_2z_2(x), \quad \phi_3(x) = x_3z_3(x),$$
$$2\phi_1(x) + \phi_2(x) - \phi_3(x) = (2x_1 + x_2 - x_3)z_4(x),$$
$$\phi_1(x) + \phi_2(x) - \phi_3(x) = (x_1 + x_2 - x_3 - x_3^2)z_5(x).$$

Without loss of generality, we may assume $z_3(x) = 1$. From equations above, we obtain

$$(*) \qquad 2x_1z_1(x) + x_2z_2(x) - x_3 = (2x_1 + x_2 - x_3)z_4(x)$$

and

$$(**) \qquad x_1z_1(x) + x_2z_2(x) - x_3 = (x_1 + x_2 - x_3 - x_3^2)z_5(x).$$

Consider the Taylor expansion at 0 of each $z_i(x)$. Put

$$z_1(x) = a_1 + s_1x_1 + s_2x_2 + s_3x_3 + \cdots,$$
$$z_2(x) = a_2 + t_1x_1 + t_2x_2 + t_3x_3 + \cdots,$$
$$z_4(x) = a_4 + u_1x_1 + u_2x_2 + u_3x_3 + \cdots,$$
$$z_5(x) = a_5 + v_1x_1 + v_2x_2 + v_3x_3 + \cdots.$$

Substitute these Taylor expansions into (*) and (**). Then it is easily shown that $a_1 = a_2 = a_4 = a_5 = 1$. Furthermore, we have $t_2 + t_3 = 0$ from (*) and $t_2 + t_3 + 1 = 0$ from (**). This is a contradiction.

Now we are in a position to characterize the restricted 1-determinacy of C^∞-map germs.

LEMMA 2.16. *Let $f \in E^0_{n,p}$. Suppose f is strongly restricted* 1*-determined*; *then $D_xf(0)$ is of type* (*).

Proof. We must prove that $A = D_xf(0)$ has the property (*) of Definition 2.3. Suppose that $g \in E_{n,p}^0$ satisfies $D_xg(0) = A(= D_xf(0))$. Since f is strongly restricted 1-determined and $D_xg(0) = D_xf(0)$, g is also strongly restricted 1-determined. This implies $g(x) \approx_{H^1} D_xg(0)x$. Hence there exist $\phi \in \mathrm{Diff}_n^1$ and $u \in E_{n,p}$ such that $u_i(0) = 1$ and $g_i(x)u_i(g(x)) = \langle D_xg_i(0), \phi(x)\rangle$ for $i = 1, 2, \cdots, p$. Set $z_i(x) := u_i(g(x))$ for $1 \leqq i \leqq p$ and the lemma holds. □

THEOREM 2.17. *Let $n \geqq 2$ and $f \in E_{n,p}^0$. Suppose f satisfies Condition* 2.10; *then the following two conditions are equivalent*:

(1) *f is restricted* 1*-determined,*

(2) *$D_xf(0)$ is of type* 1.

Proof. From Theorem 2.12 and Lemmas 2.4 and 2.16, (1) clearly implies (2). Conversely, we will consider the case that condition (2) holds. Suppose that $g \in E_{n,p}^0$ satisfies $D_xg(0) = D_xf(0)$. If $p < n$, then $\operatorname{rank} D_xg(0) = \operatorname{rank} D_xf(0) = \min(p, n) = p$. Hence there exist $\tilde{f}, \tilde{g} \in \mathrm{Diff}_n$ such that $f = \nu \circ \tilde{f}$ and $g = \nu \circ \tilde{g}$, where ν is the natural projection from R^n to R^p. Define $\phi \in \mathrm{Diff}_n$ by $\tilde{g}^{-1} \circ \tilde{f}$. Then $\tilde{f} = \tilde{g} \circ \phi$. Hence $f = \nu \circ \tilde{f} = \nu \circ \tilde{g} \circ \phi = g \circ \phi$. This shows that $f \approx_H g$. When $p \geqq n$, from Theorem 2.12, there exist $z \in E_{n,p}$ such that $z_i(0) \neq 0$ and $\phi \in \mathrm{Diff}_n$ such that $g_i(x)z_i(x) = \langle D_xg_i(0), \phi(x)\rangle$ for $1 \leqq i \leqq p$. Since $p \geqq n$, $\operatorname{rank} D_xg(0) = n$. Hence the equation $y = g(x)$ can be solved with respect to x, i.e., there exists $h \in E_{p,n}^0$ such that locally $h \circ g = \mathrm{Id}_{R^n}$. Therefore $g_i(x)z_i(h(g(x))) = \langle D_xg_i(0), \phi(x)\rangle$ for $1 \leqq i \leqq p$. This means $g \approx_H j^1g(0) = D_xg(0)x$. Similarly, we have $f \approx_H j^1f(0) = D_xf(0)x$. Since $D_xg(0) = D_xf(0)$, we obtain $g \approx_H j^1g(0) = j^1f(0) \approx_H f$. □

COROLLARY 2.18. *Let $n \geqq 2$ and $g \in E_{n,p}^0$ be irredundant, a minimal representative, and satisfy Condition* 2.10. *Then the next three statements are equivalent*:

(1) *g is restricted* 1*-determined,*

(2) *g is strongly restricted* 1*-determined,*

(3) *$M[g]_0$ is* 1*-determined.*

Proof. The proof is clear from Lemma 2.4, and Theorems 2.13 and 2.17. □

ASYMPTOTIC LOCATIONS OF EIGENFREQUENCIES OF EULER–BERNOULLI BEAM WITH NONHOMOGENEOUS STRUCTURAL AND VISCOUS DAMPING COEFFICIENTS*

HANKUN WANG† AND GOONG CHEN‡

Abstract. A slender beam has two spatially nonhomogeneous damping terms. The first one acts opposite to the bending moment time derivative and is sometimes called *structural damping*, while the second acts opposite to the velocity and is called *viscous damping*. When these damping coefficients are constant, it is known that structural damping causes a strong attenuation rate that is frequency-proportional, whereas viscous damping causes a constant attenuation rate for all frequencies. In this paper, using the method of Birkhoff [*Trans. Amer. Math. Soc.*, 9 (1908), pp. 219-231], [*Trans. Amer. Math. Soc.*, 9 (1908), pp. 373-395], and Birkhoff and Langer [*Proc. Amer. Acad. Arts Sci.*, (2) 58 (1923), pp. 51-128] explicit asymptotic expressions for the eigenfrequencies of the nonhomogeneous damping problem are derived. It is shown that the asymptotic patterns of the eigenspectrum remain similar to the constant coefficients case. The viscous damping effect is also shown to cause a constant shift to both the attenuation rates and the frequencies; thus it is overwhelmed by the structural damping effect.

Because experimentally it has been observed that all eigenfrequencies of light beams essentially lie within the asymptotic regime, the asymptotic formulas derived herein should be useful in determining the pole assignment for feedback stabilization.

1. Introduction.

The analysis of damping is important in the understanding of mechanical behavior and control of vibrating systems. For lightweight flexible vibrating structures in contemporary large space technology, the EB (Euler-Bernoulli) beam equation is the most commonly used mathematical model. Several papers [4], [5], [10], [11], [12] have addressed questions in the modeling and analysis of distributed damping on an EB beam, for which it has been noted that the rate of attenuation of eigenmodes is roughly proportional to the frequency. Consequently, a "square root" operator was incorporated in the EB equation to model the distributed damping effect. The simplest such modeling equation is

$$(1.1)\quad m\frac{\partial^2}{\partial t^2}y(x,t)-2m\gamma_1\frac{\partial^2}{\partial t\partial x^2}y(x,t)+EI\frac{\partial^4}{\partial x^4}y(x,t)=0,\qquad 0<x<\pi,\quad t>0,$$

where m, EI, and γ_1 are positive constants signifying, respectively, the mass density, flexural rigidity, and damping coefficient. The beam length has been chosen to be π just for the sake of some notational convenience later. Associated with (1.1) the hinged boundary conditions are used at both ends:

$$(1.2)\qquad y(0,t)=y_{xx}(0,t)=y(\pi,t)=y_{xx}(\pi,t)=0.$$

Two initial conditions $y(x,0)$, $y_t(x,0)$ will also need to be prescribed, but they will not be used here.

Let λ be an eigenfrequency and $\phi(x)$ be an eigenmode. Then

$$(1.3)\qquad y(x,t)=e^{\lambda t}\phi(x),\qquad 0\leqq x\leqq\pi,$$

leads to the following eigenvalue problem:

$$\begin{aligned}(1.4)\qquad & a^4\phi^{(4)}(x)-2\gamma_1\lambda\phi''(x)+\lambda^2\phi(x)=0, \qquad 0<x<\pi,\ a\equiv\left(\frac{EI}{m}\right)^{1/4},\\ & \phi(0)=\phi''(0)=\phi(\pi)=\phi''(\pi)=0.\end{aligned}$$

We easily derive that

$$\begin{aligned}(1.5)\qquad & \lambda=-\gamma_1k^2\pm ik^2\sqrt{a^4-\gamma_1^2}, \\ & \phi(x)=\sin kx, \qquad k=1,2,3,\cdots,\end{aligned}$$

where $k^2(a^4-\gamma_1^2)^{1/2}$ is the frequency. The spectral pattern is shown in Fig. 1. All eigenfrequencies lie on the rays which form angles

$$(1.6)\qquad \theta=\pm\tan^{-1}\frac{\gamma_1}{\sqrt{a^4-\gamma_1^2}}$$

with respect to the imaginary axis. Note that generally the value of γ is not large, thus we can assume

$$(1.7)\qquad a^4-\gamma_1^2>0.$$

More recently, Russell has proposed a more elaborate damping model with governing integrodifferential equation

$$\begin{aligned}(1.8)\qquad & m\frac{\partial^2}{\partial t^2}y(x,t)-2\frac{\partial}{\partial x}\int_0^\pi h(x,\xi)\left[\frac{\partial^2}{\partial t\partial x}y(x,t)-\frac{\partial^2}{\partial t\partial \xi}y(\xi,t)\right]d\xi \\ & \qquad +EI\frac{\partial^4}{\partial x^4}y(x,t)=0, \qquad 0<x<\pi, \quad t>0,\end{aligned}$$

to model frequency-proportional damping. The kernel h herein satisfies

$$h(x,\xi)=h(\xi,x) \quad \text{and} \quad \int_0^\pi\int_0^\pi h(x,\xi)[f(x)-f(\xi)]^2\,dx\,d\xi\geqq 0$$

for any function $f\in L^2(0,\pi)$. This model takes into account the presence of reinforced fibers and seems particularly suitable to model modern matrix materials. As of this writing, only small progress has been made in analyzing the asymptotic location of

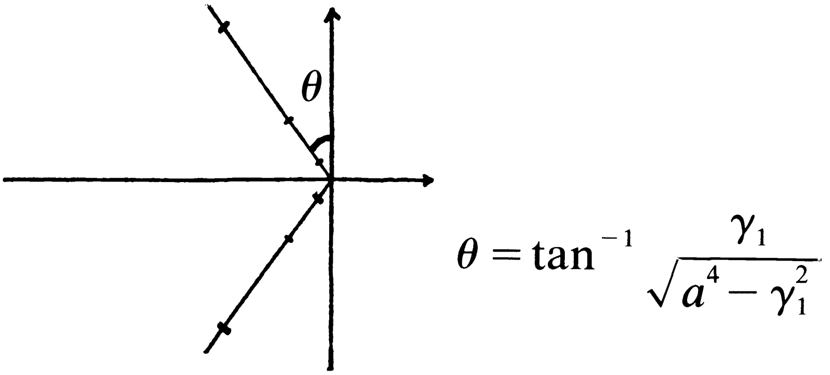

FIG. 1. *Spectral pattern of frequency proportional damping.*

the eigenspectrum, or the holomorphic semigroup property for the general equation (1.6).

We can regard (1.8) as an EB equation *with essentially a variable damping coefficient* for the term $(\partial^3/\partial t\partial x^2)y(x, t)$, with the understanding that such a coefficient is now a convoluted integrodifferential operator. Therefore to analyze the eigenspectrum pattern of (1.8) it is fundamental that we understand the corresponding problems for a simpler damped EB equation

$$m\frac{\partial^2}{\partial t^2}y(x, t)-2m\gamma_1(x)\frac{\partial^3}{\partial t\partial x^2}y(x, t)+EI\frac{\partial^4}{\partial x^4}y(x, t)=0, \tag{1.9}$$

where $\gamma_1(x)\geqq 0$ is now a *nonhomogeneous damping coefficient.* As a matter of fact, using the basic asymptotic analysis developed herein and by using this idea of viewing the convoluted integrodifferential term in Russell's equation (1.8) as something like a spatial varying damping coefficient in equation (1.9), in a recent conference proceedings [13] Wang has been able to derive an *identical* asymptotic formula (cf. (3.23)) for Russell's model (1.8) subject to the hinged boundary conditions (1.2). From the purely mathematical point of view, the eigenspectrum pattern of this equation is worth investigation in its own right as (1.9) is now much more general than (1.1).

From the control theoretic point of view, in the feedback stabilization of a vibrating structure, it is often necessary to study closed-loop systems with variable coefficients. For example, consider a controlled beam

$$m\frac{\partial^2}{\partial t^2}y(x, t)+EI\frac{\partial^4}{\partial x^4}y(x, t)=\gamma_1(x)u(x, t), \tag{1.10}$$

where $\gamma_1(x)\geqq 0$ is a locally supported function (i.e., the support of γ_1 is a proper subset of $(0, \pi)$), signifying the span on the beam interval $(0, \pi)$ where the controller is distributed (cf. Fig. 2).

If we feedback the rate of bending moment

$$u(x, t)=2m\frac{\partial^3}{\partial t\partial x^2}y(x, t)$$

in (1.10), then the closed-loop system will be just (1.9). The classical separation of variables approach will not give us the *precise* locations of the spectrum because equation (1.9) contains variable coefficients and does not have closed form solutions in general. Therefore the best hope lies in asymptotic solutions. Although the expressions we have derived herein are *asymptotic formulas,* there is both theoretical and experimental evidence from our work elsewhere [6], [7], [9] on beam theory that the eigenspectrum will be *in the asymptotic regime even for very low frequencies.* Therefore the analysis of locations of eigenfrequencies and their damping rates carried out in this paper may provide vital information for the *pole assignment* of the closed-loop

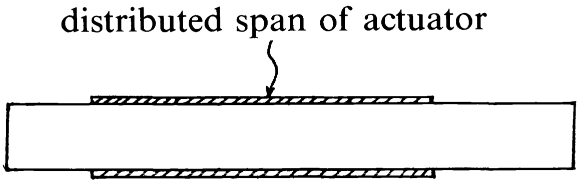

FIG. 2. *A beam with controller distributed on only part of the span.*

system. In this paper, we will actually move one step further by studying the model

$$\text{(1.11)}\qquad m\frac{\partial^2}{\partial t^2}y(x,t)-2m\gamma_1(x)\frac{\partial^3}{\partial t\partial x^2}y(x,t)+2m\gamma_2(x)\frac{\partial}{\partial t}y(x,t)+EI\frac{\partial^4}{\partial x^4}y(x,t)=0,$$

$$\gamma_1(x)\geqq 0,\quad \gamma_2(x)\geqq 0,\quad 0\leqq x\leqq \pi,\ t>0,$$

which takes into account two types of variable coefficient damping forces, the first one, $-2m\gamma_1(x)\partial^3 y/\partial t\partial x^2$, is proportional to the time derivative of bending and is sometimes termed *structural damping* (cf. [5], [11]), while the second one, $2m\gamma_2(x)\partial y/\partial t$, is proportional to velocity and is commonly referred to as *viscous damping*. As $\gamma_1(x)$ is not large, let us further assume

$$\text{(1.12)}\qquad a^4-\gamma_1^2(x)\geqq\delta>0\quad\text{on } [0,\pi],\quad \text{for some } \delta>0.$$

Our treatment and results here are also good for the equation

(1.11)′

$$m\frac{\partial^2}{\partial t^2}y(x,t)-2m\frac{\partial}{\partial x}\left[\gamma_1(x)\frac{\partial^2}{\partial t\,\partial x}y(x,t)\right]+2m\gamma_2(x)\frac{\partial}{\partial t}y(x,t)+EI\frac{\partial^4}{\partial x^4}y(x,t)=0,$$

which is perhaps an even more natural analogue of (1.8). See Remark 3.5.

If in (1.11), we let $\gamma_1(x)\equiv 0$ and $\gamma_2(x)\equiv\gamma_2>0$ on $[0,\pi]$:

$$\text{(1.13)}\qquad m\frac{\partial^2}{\partial t^2}y(x,t)+2m\gamma_2\frac{\partial}{\partial t}y(x,t)+EI\frac{\partial^4}{\partial x^4}y(x,t)=0$$

subject to the same boundary conditions (1.2), then a simple separation of variables argument shows that all eigenfrequencies λ satisfy

$$\text{(1.14)}\qquad \lambda=-\gamma_2\pm i\sqrt{a^4k^4-\gamma_2^2},\qquad k\in\mathbb{Z}.$$

Thus all sufficiently high eigenfrequencies have a uniform stability margin $-\gamma_2$.

Our paper is also motivated by an earlier study in Chen et al. [8], which states that for the second-order wave equation with a nonhomogeneous viscous damping coefficient:

$$\text{(1.15)}\qquad \frac{\partial^2 w(x,t)}{\partial t^2}+2\gamma(x)\frac{\partial w(x,t)}{\partial t}-c^2\frac{\partial^2 w(x,t)}{\partial x^2}=0,\qquad 0<x<\pi,\ t>0,$$

subject to various conservative boundary conditions at 0 and π,

the rate of damping will be the average at high frequencies

$$\text{(1.16)}\qquad -\frac{1}{\pi}\int_0^\pi \gamma(x)\,dx,$$

thus asymptotically the rate of damping caused by the variable coefficient $\gamma(x)$ in (1.15) is "homogenized" to become its average. For our system (1.11), (1.2) under study, we wonder what kind of "homogenization" result will hold for its eigenspectrum. To be precise, we pose the following questions:

(Q1) Consider equation (1.9) subject to (1.2). For large eigenfrequencies $\lambda=\mu+i\nu$, $\mu,\nu\in\mathbb{R}$, will the slope asymptotically satisfy (a homogenization property like (1.6))

$$\lim_{|\lambda|\to\infty}\frac{\mu}{\nu}=\pm\tan^{-1}\frac{\gamma_{1,av}}{\sqrt{a^4-\gamma_{1,av}^2}},$$

where

$$\gamma_{1,av} \equiv \frac{1}{\pi}\int_0^\pi \gamma_1(x)\,dx?$$

(Q2) Consider the equation

$$m\frac{\partial^2}{\partial t^2}y(x,t)+2m\gamma_2(x)\frac{\partial}{\partial t}y(x,t)+EI\frac{\partial^4}{\partial x^4}y(x,t)=0 \tag{1.17}$$

subject to boundary conditions (1.2). For large eigenfrequencies $\lambda = \mu+i\nu$, μ, $\nu \in \mathbb{R}$, will the stability margin satisfy (a homogenization property like (1.16))

$$\lim_{|\lambda|\to\infty} \mu = -\gamma_{2,av},$$

where

$$\gamma_{2,av} \equiv \frac{1}{\pi}\int_0^\pi \gamma_2(x)\,dx?$$

An answer to (Q2) was also briefly mentioned in [8] without any rigorous treatment.

The main objective of this paper is to determine the asymptotic locations of the eigenfrequencies of (1.11), and to answer (Q1) and (Q2) in order to apply to various modeling, stabilization and control problems mentioned earlier. Our contributions are the following:

(i) We have shown that at large frequencies a spectral pattern like Fig. 1 will emerge. Asymptotically, all large eigenvalues will fall in a close vicinity of two rays on the left halfplane whose angle (i.e., θ, cf. Fig. 1) is determinable by $\gamma_1(x)$.

(ii) We are able to compare the magnitudes of contributions by $\gamma_1(x)$ and $\gamma_2(x)$ in the asymptotic estimates of eigenfrequencies λ.

The idea for our paper came from the work [8] cited earlier based on an asymptotic expansion procedure of Birkhoff [1], [2] and Birkhoff and Langer [3]. The eigenvalue problem treated here constitutes a fourth-order problem, but its complexity and difficulty seem to have quadrupled (instead of being merely doubled). The form of the asymptotic solution also looks rather different from the one in [8] because equation (1.1) is not homogeneous of the same degree in x and t. An additional transformation (cf. (2.4) in § 2) is required and an adjustment of the Birkhoff–Langer procedure ensues, yielding a successful asymptotic treatment.

In § 2, we transform the eigenvalue problem into a first-order ordinary differential equation containing a large parameter.

In § 3, we derive asymptotic estimates of eigenvalues and state the main results.

In § 4, a higher order asymptotic estimation is carried out to help compare the structural and viscous damping effects.

Finally in § 5, we furnish proofs which rigorize the formal asymptotic expansions.

2. Transforming the eigenvalue problem into a first-order system with a large parameter. We consider the eigenvalue problem corresponding to equation (1.11). Let us again assume that the energy-conserving *hinged* boundary conditions (1.2) are in effect. They are imposed here for the sole purpose of simplifying presentations. (Other types of boundary conditions such as the clamped, roller-supported, free, and dissipative conditions can be treated along similar lines of estimation as given here and in [4] and [9], but the calculations usually are much lengthier and more tedious; cf. Remark

2.1.) Using (1.3) and dividing by m, we obtain

$$(2.1)\quad \begin{aligned} &a^4\phi^{(4)}(x)-2\lambda\gamma_1(x)\phi''(x)+2\lambda\gamma_2(x)\phi(x)+\lambda^2\phi(x)=0, \qquad 0\leqq x\leqq \pi,\\ &\phi(0)=\phi''(0)=\phi(\pi)=\phi''(\pi)=0, \end{aligned}$$

where as before $a\equiv(EI/m)^{1/4}$.

Let

$$(2.2)\qquad \Phi(x)=\begin{bmatrix} \phi(x)+\lambda^{-1}a^2\phi''(x)\\ -\phi(x)+\lambda^{-1}a^2\phi''(x)\end{bmatrix}.$$

Then (2.1) is equivalent to

$$(2.3)\quad \begin{aligned} &\Phi''(x)=[\lambda(A+B(x))+C(x)]\Phi(x),\\ &M\Phi(0)=0, \qquad M\Phi(\pi)=0, \end{aligned}$$

where

$$(2.4)\quad \begin{aligned} &A=a^{-2}\begin{bmatrix} 0 & 1\\ -1 & 0\end{bmatrix}, \qquad B(x)=a^{-4}\cdot\gamma_1(x)\begin{bmatrix} 1 & 1\\ 1 & 1\end{bmatrix},\\ &C(x)=a^{-2}\cdot\gamma_2(x)\begin{bmatrix} -1 & 1\\ -1 & 1\end{bmatrix}, \qquad M=\begin{bmatrix} 1 & -1\\ 1 & 1\end{bmatrix}. \end{aligned}$$

To further reduce (2.3) to a first-order system, we let

$$(2.5)\qquad \rho^2=\lambda, \qquad Y(x)=\begin{bmatrix} \Phi(x)\\ \rho^{-1}\Phi'(x)\end{bmatrix},$$

resulting in

$$(2.6)\quad \begin{aligned} &Y'(x)=[\rho(\mathscr{A}+\mathscr{B}(x))+\rho^{-1}\mathscr{C}(x)]Y(x), \qquad 0\leqq x\leqq\pi,\\ &\begin{bmatrix} M & 0\\ 0 & 0\end{bmatrix}Y(0)=0, \qquad \begin{bmatrix} M & 0\\ 0 & 0\end{bmatrix}Y(\pi)=0, \end{aligned}$$

where

$$(2.7)\qquad \mathscr{A}=\begin{bmatrix} 0 & I_2\\ A & 0\end{bmatrix}, \quad \mathscr{B}(x)=\begin{bmatrix} 0 & 0\\ B(x) & 0\end{bmatrix}, \quad \mathscr{C}(x)=\begin{bmatrix} 0 & 0\\ C(x) & 0\end{bmatrix}.$$

Remark 2.1. From the very definitions of $\Phi(x)$ in (2.2) and $Y(x)$ in (2.5), it is easy to see that any set of boundary conditions involving $\phi^{(j)}(0)$, $\phi^{(j)}(\pi)$, $0\leqq j\leqq 3$, two at each end, can be expressed as

$$\mathscr{M}_0Y(0)=0, \qquad \mathscr{M}_\pi Y(\pi)=0,$$

where $\mathscr{M}_0$ and $\mathscr{M}_\pi$ are 4×2 constant matrices. The case of hinged boundary conditions (1.2) results in perhaps the simplest such matrices

$$\mathscr{M}_0=\mathscr{M}_\pi=\begin{bmatrix} M & 0_2\\ 0_2 & 0_2\end{bmatrix} \qquad 0_2 \text{ is the zero } 2\times 2 \text{ matrix.}$$

This is naturally so because the hinged boundary conditions correspond to the "square root" model [5], and it is also observed in (2.2) that only $\phi(x)$ and $\phi''(x)$ (the "square root") appear in $\Phi(x)$. Actually in (2.3) we can just write the boundary conditions as

$$\Phi(0)=0, \qquad \Phi(\pi)=0.$$

To give a presentation in the *general* context, we keep the matrix M here.

We now diagonalize the dominant coefficient matrix $\mathcal{A}+\mathcal{B}(x)$. Let

$$b(x)\equiv i\frac{\sqrt{a^4-\gamma_1^2(x)}}{a^2+\gamma_1(x)},\qquad \xi_1(x)\equiv\frac{[\gamma_1(x)+i\sqrt{a^4-\gamma_1^2(x)}]^{1/2}}{a^2},$$

$$\xi_2(x)\equiv\frac{[\gamma_1(x)-i\sqrt{a^4-\gamma_1^2(x)}]^{1/2}}{a^2},$$

$$\text{(2.8)}\qquad Q(x)=\left[\begin{array}{cc:cc} 1 & 1 & 1 & 1 \\ b(x) & -b(x) & -b(x) & b(x) \\ \hdashline \xi_1(x) & -\xi_2(x) & \xi_2(x) & -\xi_1(x) \\ b(x)\xi_1(x) & b(x)\xi_2(x) & -b(x)\xi_2(x) & -b(x)\xi_1(x) \end{array}\right]$$

$$\equiv\begin{bmatrix} Q_{11}(x) & Q_{12}(x) \\ Q_{21}(x) & Q_{22}(x)\end{bmatrix},$$

where $Q_{ij}(x)$, $1\leqq i,j\leqq 2$, are all 2×2 matrices. Then

$$Q^{-1}(x)=\begin{bmatrix} \frac{1}{4} & \frac{1}{4b(x)} & \frac{1}{4\xi_1(x)} & \frac{1}{4b(x)\xi_1(x)} \\ \frac{1}{4} & -\frac{1}{4b(x)} & -\frac{1}{4\xi_2(x)} & \frac{1}{4b(x)\xi_2(x)} \\ \frac{1}{4} & -\frac{1}{4b(x)} & \frac{1}{4\xi_2(x)} & -\frac{1}{4b(x)\xi_2(x)} \\ \frac{1}{4} & \frac{1}{4b(x)} & -\frac{1}{4\xi_1(x)} & -\frac{1}{4b(x)\xi_1(x)} \end{bmatrix},$$

so

$$\text{(2.9)}\quad Q^{-1}(x)[\mathcal{A}+\mathcal{B}(x)]Q(x)=\begin{bmatrix} \xi_1(x) & & 0 & \\ & -\xi_2(x) & & \\ & & \xi_2(x) & \\ & 0 & & -\xi_1(x) \end{bmatrix}\equiv R(x)$$

is now diagonalized. Let

$$\text{(2.10)}\qquad Y(x)=Q(x)Z(x).$$

Then the differential equation in (2.6) becomes

$$\text{(2.11)}\qquad \begin{aligned} Z'(x)&=\rho Q^{-1}(x)[\mathcal{A}+\mathcal{B}(x)]Q(x)Z(x)-Q^{-1}(x)Q'(x)Z(x)\\ &\quad+\rho^{-1}Q^{-1}(x)\mathcal{C}(x)Q(x)Z(x)\\ &=[\rho R(x)+S(x)+\rho^{-1}T(x)]Z(x), \end{aligned}$$

where

$$\text{(2.12)}\qquad S(x)\equiv -Q^{-1}(x)Q'(x),\qquad T(x)\equiv Q^{-1}(x)\mathcal{C}(x)Q(x),$$

subject to boundary conditions

$$\text{(2.13)}\quad \begin{bmatrix} MQ_{11}(0) & MQ_{12}(0) \\ 0 & 0 \end{bmatrix}Z(0)=0,\qquad \begin{bmatrix} MQ_{11}(\pi) & MQ_{12}(\pi) \\ 0 & 0 \end{bmatrix}Z(\pi)=0.$$

Let us assume that the damping coefficient functions satisfy

$$\text{(2.14)}\qquad \gamma_1,\gamma_2\in C^1([0,\pi]).$$

Consequently from (2.12), we have

$$S \in C^0_{n\times n}([0,\pi]), \qquad T \in C^1_{n\times n}([0,\pi]). \tag{2.15}$$

Following [1]-(3), we now seek a *matrix solution* Z of (2.11) which has a formal asymptotic expansion

$$Z(x) = [P_0(x) + \rho^{-1}P_1(x) + \rho^{-2}P_2(x) + \cdots]\, e^{\rho\Gamma(x)}, \tag{2.16}$$

where

$$\Gamma(x) = \int_0^x R(u)\, du, \tag{2.17}$$

and $P_0(x), P_1(x), \cdots$, are $n\times n$ matrix functions satisfying

$$\begin{aligned}
&\rho^1\colon && P_0R = RP_0\\
&\rho^0\colon && P_0' + P_1R = RP_1 + SP_0\\
&\rho^{-1}\colon && P_1' + P_2R = RP_2 + TP_0 + SP_1\\
& && \vdots\\
&\rho^{-j}\colon && P_j' + P_{j+1}R = RP_{j+1} + TP_{j-1} + SP_j\\
& && \vdots
\end{aligned} \tag{2.18}$$

Remark 2.2. Although (2.11) appears slightly more general than does (19) in [3, p. 71] (due to the presence of the extra term $\rho^{-1}T(x)$ in (2.11)), the asymptotic expansion will go through because the matrix $\mathcal{A} + \mathcal{B}(x)$ has four *distinct* eigenvalues $\pm\xi_1(x)$ and $\pm\xi_2(x)$ on $[0,\pi]$, cf. (2.9). The distinctness of eigenvalues of the matrix $R(x)$ (or equivalently, $\mathcal{A} + \mathcal{B}(x)$) is essential to the applicability of the ansatz (2.16).

Let us denote

$p_{ij}^{(k)}$: the (i,j)-entry of the matrix P_k,

σ_{ij}, τ_{ij}: the (i,j)-entry of matrices S and T, respectively.

$$\zeta_1(x) = \xi_1(x), \quad \zeta_2(x) = -\xi_2(x), \quad \zeta_3(x) = \xi_2(x), \quad \zeta_4(x) = -\xi_1(x). \tag{2.19}$$

Using the arguments as in [3, p. 75], we get

$$\begin{aligned}
&p_{ij}^{(0)}(x) = 0 \quad \text{if } i\neq j, \quad 1\leqq i, \quad j\leqq 4,\\
&p_{jj}^{(0)}(x) = f_j^{(0)} \exp\left[\int_0^x \sigma_{jj}(u)\, du\right], \qquad j=1,2,3,4, \quad f_j \text{ are constants;}
\end{aligned} \tag{2.20}$$

$$\begin{aligned}
&p_{ij}^{(1)}(x) = \frac{\sigma_{ij}(x)p_{jj}^{(0)}(x)}{\zeta_j(x)-\zeta_i(x)} \quad \text{if } i\neq j, \quad 1\leqq i, \quad j\leqq 4,\\
&p_{jj}^{(1)'}(x) - \sum_{k=1}^4 \sigma_{jk}(x)p_{kj}^{(1)}(x) - \sum_{k=1}^4 \tau_{jk}p_{kj}^{(0)}(x) = 0, \qquad k=1,2,3,4
\end{aligned} \tag{2.21}$$

and for $l\geqq 2$,

$$\begin{aligned}
&p_{ij}^{(l)}(x) = \frac{-p_{ij}^{(l-1)'}(x) + \sum_{k=1}^4 [\sigma_{ik}(x)p_{kj}^{(l-1)}(x) + \tau_{ik}(x)p_{kj}^{(l-2)}(x)]}{\zeta_j(x)-\zeta_i(x)},\\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad i\neq j, \quad 1\leqq i, \quad j\leqq 4,\\
&p_{jj}^{(l)'}(x) - \sum_{k=1}^4 \sigma_{jk}(x)p_{kj}^{(l)} - \sum_{k=1}^4 \tau_{jk}(x)p_{kj}^{(l-1)}(x) = 0, \qquad i\neq j, \quad 1\leqq i, \quad j\leqq 4.
\end{aligned} \tag{2.22}$$

Note that the second equation in (2.20) and (2.21) can be solved by a quadrature. Thus all the matrices $P_i(x)$, $i=0,1,2,\cdots$, can be formally determined in a recursive way.

3. Asymptotic estimation of eigenfrequencies. We first determine the leading term $P_0(x)$ by (2.20), wherein the diagonal entries $\sigma_{jj}(x)$ of S are easily found to be

$$\sigma_{11}(x)=-\frac{1}{4}\left(\frac{b'(x)}{b(x)}+\frac{\xi_1'(x)}{\xi_1(x)}+\frac{b'(x)\xi_1(x)+b(x)\xi_1'(x)}{b(x)\xi_1(x)}\right)=-\frac{1}{2}\frac{[b(x)\xi_1(x)]'}{b(x)\xi_1(x)},$$

$$\sigma_{22}(x)=-\frac{1}{4}\left(\frac{b'(x)}{b(x)}+\frac{\xi_2'(x)}{\xi_2(x)}+\frac{b'(x)\xi_2(x)+b(x)\xi_2'(x)}{b(x)\xi_2(x)}\right)=-\frac{1}{2}\frac{[b(x)\xi_2(x)]'}{b(x)\xi_2(x)},$$

$$\sigma_{33}(x)=\sigma_{22}(x),\qquad \sigma_{44}(x)=\sigma_{11}(x).$$

Therefore

$$\begin{aligned}
p_{11}^{(0)}(x)&=f_1^{(0)}\cdot\exp\left\{-\frac{1}{2}\int_0^x\frac{[b(u)\xi_1(u)]'}{b(u)\xi_1(u)}\,du\right\}=f_1^{(0)}\cdot\sqrt{\frac{b(0)\xi_1(0)}{b(x)\xi_1(x)}},\\
p_{22}^{(0)}(x)&=f_2^{(0)}\cdot\exp\left\{-\frac{1}{2}\int_0^x\frac{[b(u)\xi_2(u)]'}{b(u)\xi_2(u)}\,du\right\}=f_2^{(0)}\cdot\sqrt{\frac{b(0)\xi_2(0)}{b(x)\xi_2(x)}},\\
p_{33}^{(0)}(x)&=f_3^{(0)}\cdot\sqrt{\frac{b(0)\xi_2(0)}{b(x)\xi_2(x)}},\\
p_{44}^{(0)}(x)&=f_4^{(0)}\sqrt{\frac{b(0)\xi_1(0)}{b(x)\xi_1(x)}}.
\end{aligned}\tag{3.1}$$

The constants $\tilde{f}_j^{(0)}$, $j=1,2,3,4$, can be chosen freely as long as they are nonzero. We simply choose them equal to one so that

(3.2)

$$P_0(x)=\operatorname{diag}\left[\left(\frac{b(0)\xi_1(0)}{b(x)\xi_1(x)}\right)^{1/2},\left(\frac{b(0)\xi_2(0)}{b(x)\xi_2(x)}\right)^{1/2},\left(\frac{b(0)\xi_2(0)}{b(x)\xi_2(x)}\right)^{1/2},\left(\frac{b(0)\xi_1(0)^{1/2}}{b(x)\xi_1(x)}\right)^{1/2}\right].$$

We now formally write (2.16) as

$$\begin{aligned}
Z(x)&=\left[P_0(x)+\frac{P_1(x)}{\rho}+\frac{P_2(x)}{\rho^2}+\cdots\right]e^{\rho\Gamma(x)}\\
&\equiv\left[P_0(x)+\frac{\Psi(x,\rho)}{\rho}\right]e^{\rho\Gamma(x)},
\end{aligned}\tag{3.3}$$

where

$$\begin{aligned}
\Psi(x,\rho)&=P_1(x)+\rho^{-1}P_2(x)+\cdots\\
&\equiv[\psi_{ij}(x,\rho)]_{4\times4},\qquad 1\leqq i,\quad j\leqq 4.
\end{aligned}\tag{3.4}$$

Since $Y(x)$ as defined in (2.4), (2.5) is a *vector solution*, and since $Z(x)$ is the *fundamental matrix solution* of (2.11), the transformation (2.10) will actually give us

$$Y(x)=Q(x)Z(x)\vec{c},\tag{3.5}$$

where $\vec{c}$ is a 4×1 constant vector with entries c_1, c_2, c_3, and c_4 in $\mathbb{C}$. Thus (2.13) becomes

$$\begin{bmatrix}MQ_{11}(0)&MQ_{12}(0)\\0&0\end{bmatrix}Z(0)\vec{c}=0,\qquad\begin{bmatrix}MQ_{11}(\pi)&MQ_{12}(\pi)\\0&0\end{bmatrix}Z(\pi)\vec{c}=0.\tag{3.6}$$

From (2.8), (3.2), (3.3), we obtain from the boundary conditions in (2.13) that

$$
(3.7)\quad
\begin{bmatrix} M & 0_2 \\ 0_2 & M \end{bmatrix}
\cdot
\begin{bmatrix}
1+\frac{\tilde{\psi}_{11}(\rho)}{\rho} & 1+\frac{\tilde{\psi}_{12}(\rho)}{\rho} & 1+\frac{\tilde{\psi}_{13}(\rho)}{\rho} & 1+\frac{\tilde{\psi}_{14}(\rho)}{\rho} \\
b(0)+\frac{\tilde{\psi}_{21}(\rho)}{\rho} & -b(0)+\frac{\tilde{\psi}_{22}(\rho)}{\rho} & -b(0)+\frac{\tilde{\psi}_{23}(\rho)}{\rho} & b(0)+\frac{\tilde{\psi}_{24}(\rho)}{\rho} \\
K_1E_1(\rho) & K_2E_2(\rho) & K_2E_3(\rho) & K_1E_4(\rho) \\
\quad +\frac{E_1(\rho)\tilde{\psi}_{31}(\rho)}{\rho} & \quad +\frac{E_2(\rho)\tilde{\psi}_{32}(\rho)}{\rho} & \quad +\frac{E_3(\rho)\tilde{\psi}_{33}(\rho)}{\rho} & \quad +\frac{E_4(\rho)\tilde{\psi}_{34}(\rho)}{\rho} \\
b(\pi)K_1E_1(\rho) & -b(\pi)K_2E_2(\rho) & -b(\pi)K_2E_3(\rho) & b(\pi)K_1E_4(\rho) \\
\quad +\frac{E_1(\rho)\tilde{\psi}_{41}(\rho)}{\rho} & \quad +\frac{E_2(\rho)\tilde{\psi}_{42}(\rho)}{\rho} & \quad +\frac{E_3(\rho)\tilde{\psi}_{43}(\rho)}{\rho} & \quad +\frac{E_4(\rho)\tilde{\psi}_{44}(\rho)}{\rho}
\end{bmatrix}
\cdot \vec{c}
\equiv \mathbb{M}\Lambda(\rho)\vec{c} = 0,
$$

where

$$
(3.8)\quad
\begin{aligned}
&K_1 \equiv [b(0)\xi_1(0)/b(0)\xi_1(\pi)]^{1/2}, \qquad K_2 = [b(0)\xi_2(0)/b(\pi)\xi_2(\pi)]^{1/2}, \\
&\Gamma_1(\pi) = \int_0^\pi \xi_1(x)\,dx, \qquad \Gamma_2(\pi) = \int_0^\pi \xi_2(x)\,dx, \\
&E_1(\rho) = e^{\rho\Gamma_1(\pi)}, \quad E_2(\rho) = e^{-\rho\Gamma_2(\pi)}, \quad E_3(\rho) = e^{\rho\Gamma_2(\pi)}, \quad E_4(\rho) = e^{-\rho\Gamma_1(\pi)}, \\
&\tilde{\psi}_{1k}(\rho) = \sum_{i=1}^4 \psi_{ik}(0,\rho), \quad \tilde{\psi}_{2k}(\rho) = b(0)\sum_{i=1}^4 (-1)^{[i/2]}\psi_{ik}(0,\rho), \\
&\tilde{\psi}_{3k}(\rho) = \sum_{i=1}^4 \psi_{ik}(\pi,\rho), \quad \tilde{\psi}_{4k}(\rho) = b(\pi)\sum_{i=1}^4 (-1)^{[i/2]}\psi_{ik}(\pi,\rho), \qquad k = 1,2,3,4.
\end{aligned}
$$

It is easy to see that K_1, K_2, $\Gamma_1(\pi)$, and $\Gamma_2(\pi)$ are bounded. From [3], we know that $\tilde{\psi}_{jk}(\rho)$, $1 \leqq j, k \leqq 4$, are uniformly bounded for $|\rho|$ large. ρ is an eigenvalue of (2.11) and (2.13) if and only if the determinant of the product matrix in (3.7) is zero. But the matrix $\mathbb{M}$ in (3.7) is invertible, and the constant vector $\vec{c}$ is nontrivial, therefore

$$
(3.9)\qquad \det \Lambda(\rho) = 0.
$$

First let us determine the roots of the simpler equation

$$
(3.10)\quad \det \begin{bmatrix}
1 & 1 & 1 & 1 \\
b(0) & -b(0) & -b(0) & b(0) \\
K_1E_1 & K_2E_2 & K_2E_3 & K_1E_4 \\
b(\pi)K_1E_1 & -b(\pi)K_2E_2 & -b(\pi)K_2E_3 & b(\pi)K_1E_4
\end{bmatrix} \equiv \det \Lambda_0 = 0,
$$

obtained by neglecting $\mathcal{O}(\rho^{-1})$ terms in $\Lambda(\rho)$. This determinant is easy to expand, giving

$$
(3.11)\qquad \det \Lambda_0 = 4b(0)b(\pi)K_1K_2(E_1 - E_4)(E_3 - E_2) = 0.
$$

By (1.12), $b(0)$, $b(\pi)$, K_1, and K_2 are all nonzero. Therefore

$$
(3.12)\qquad E_1 - E_4 = e^{\rho\Gamma_1(\pi)} - e^{-\rho\Gamma_1(\pi)} = 0,
$$

or

$$E_3 - E_2 = e^{\rho\Gamma_2(\pi)} - e^{-\rho\Gamma_2(\pi)} = 0. \tag{3.13}$$

The roots ρ of (3.12) are determined by

$$e^{2\rho\Gamma_1(\pi)} = 1,$$

$$\begin{aligned}\rho &= \frac{1}{2\Gamma_1(\pi)} \cdot i2k\pi, \qquad k \in \mathbb{Z} \\ &= i \cdot \frac{a^2 k\pi}{\int_0^\pi [\gamma_1(x) + i\sqrt{a^4 - \gamma_1^2(x)}]\, dx}.\end{aligned} \tag{3.14}$$

Noting that

$$[\gamma_1(x) + i\sqrt{a^4 - \gamma_1^2(x)}]^{1/2} = \frac{1}{\sqrt{2}}[\sqrt{a^2 + \gamma_1(x)} + i\sqrt{a^2 - \gamma_1(x)}],$$

we obtain from (3.14) that

$$\begin{aligned}\rho_1(k) &\equiv i \frac{\sqrt{2}\, ka^2\pi}{\int_0^\pi \sqrt{a^2 + \gamma_1(x)}\, dx + i\int_0^\pi \sqrt{a^2 - \gamma_1(x)}\, dx} \\ &= \frac{\beta + i\alpha}{\alpha^2 + \beta^2}(\sqrt{2}\, a^2\pi) \cdot k, \qquad k \in \mathbb{Z},\end{aligned} \tag{3.15}$$

where

$$\alpha \equiv \int_0^\pi \sqrt{a^2 + \gamma_1(x)}\, dx, \qquad \beta \equiv \int_0^\pi \sqrt{a^2 - \gamma_1(x)}\, dx. \tag{3.16}$$

Similarly, from (3.13) we obtain

$$\rho_2(k) = \frac{-\beta + i\alpha}{\alpha^2 + \beta^2}(\sqrt{2}\, a^2\pi) \cdot k, \qquad k \in \mathbb{Z}. \tag{3.17}$$

Let

$$G_{ik} = \{\rho \in \mathbb{C} \mid {}^{-1 \leqq \operatorname{Re}(\rho - \rho_i(k)) \leqq 1}_{-1 \leqq \operatorname{Im}(\rho - \rho_i(k)) \leqq 1}\}, \qquad i = 1, 2, \quad |k| \geqq k_0,$$

$$G_i^+ = \bigcup_{k=k_0}^{+\infty} G_{ik}, \quad G_i^- = \bigcup_{k=-k_0}^{-\infty} G_{ik}, \quad i = 1, 2,$$

$$G_i = G_i^+ \cup G_i^-,$$

where k_0 is a large positive integer. Then we have the following lemma.

LEMMA 3.1.

$$\det \Lambda(\rho) = \det \Lambda_0 + \rho^{-1}(g_1(\rho)E_3(\rho) + g_2(\rho)), \qquad \rho \in G_1^+, \tag{3.18}$$

$$\det \Lambda(\rho) = \det \Lambda_0 + \rho^{-1}(g_3(\rho)E_2(\rho) + g_4(\rho)), \qquad \rho \in G_1^-, \tag{3.18$'$}$$

and

$$\det \Lambda(\rho) = \det \Lambda_0 + \rho^{-1}(g_5(\rho)E_1(\rho) + g_6(\rho)), \qquad \rho \in G_2^+, \tag{3.19}$$

$$\det \Lambda(\rho) = \det \Lambda_0 + \rho^{-1}(g_7(\rho)E_4(\rho) + g_8(\rho)), \qquad \rho \in G_2^-, \tag{3.19$'$}$$

where $g_i(\rho)$, $i = 1, 2, \cdots, 8$ *is uniformly bounded.*

The proofs of Lemmas 3.1 and 3.2 will be given in § 5.

As in [8], we compare the roots of (3.9) with those of (3.10). The results show that the two sequences of roots $\rho_1(k)$, $\rho_2(k)$ constitute a first-order asymptotic approximation of roots of (3.9) in the following sense.

LEMMA 3.2. *Let $\rho_1(k)$, $\rho_2(k)$, $k \in \mathbb{Z}$, be the roots of* (3.10) *and let $\tilde{\rho}$ be a root of* (3.9). *Then there exists a bound $B > 0$ such that for any $\tilde{\rho}$: $|\tilde{\rho}| \geqq B$, there exists some $\tilde{k} \in \mathbb{Z}$ such that*

$$|\tilde{\rho} - \rho_j(\tilde{k})| \leqq 1, \qquad j = 1 \text{ or } 2, \tag{3.20}$$

where $\tilde{k}$ is dependent only on $\tilde{\rho}$.

Consequently, any solution $\tilde{\rho}$ of (3.9) satisfies

$$\tilde{\rho} = \rho_j(k) + \mathcal{O}(1), \qquad j = 1, 2, \quad |k| \text{ large.} \tag{3.21}$$

From (3.21), we can now determine the asymptotic distribution pattern of the eigenfrequencies λ of (1.11) and (1.2). From (2.5), (3.15), (3.17),

$$\begin{aligned}\lambda = \rho^2 &= [\rho_j(k) + \mathcal{O}(1)]^2 \qquad k = 1 \text{ or } 2, |k| \text{ large},\\ &= \frac{(-\alpha^2 + \beta^2) \pm 2i\alpha\beta}{(\alpha^2 + \beta^2)^2}(2a^4\pi^2k^2) + \mathcal{O}(k), \quad \text{“+” for } j = 1, \text{ “−” for } j = 2.\end{aligned}$$

Therefore we see that asymptotically eigenfrequencies λ are located at the vicinity of two rays on the left half plane whose angles with respect to the imaginary axis are

$$\begin{aligned}\theta_j &\equiv \lim_{k\to\infty} \tan^{-1} \frac{(\alpha^2 + \beta^2)^{-2}[(-\alpha^2 + \beta^2)(2a^4\pi^2k^2) + \mathcal{O}(k)]}{(\alpha^2 + \beta^2)^{-2}[(\pm 2\alpha\beta)(2a^4\pi^2k^2) + \mathcal{O}(k)]},\\ &\qquad\qquad \text{“+” for } j = 1, \text{ “−” for } j = 2,\\ &= \pm\tan^{-1}\frac{\beta^2 - \alpha^2}{2\alpha\beta}.\end{aligned} \tag{3.22}$$

We conclude

THEOREM 3.3. *Let $\lambda = \mu + i\nu$, $\mu, \nu \in \mathbb{R}$, be a large eigenfrequency of* (1.11) *and* (1.2). *Then*

$$\lim_{|\lambda|\to\infty} \frac{\mu}{\nu} = \pm\frac{1}{2}\frac{[\int_0^\pi \sqrt{a^2 + \gamma_1(x)}\,dx]^2 - [\int_0^\pi \sqrt{a^2 - \gamma_1(x)}\,dx]^2}{[\int_0^\pi \sqrt{a^2 + \gamma_1(x)}\,dx] \cdot [\int_0^\pi \sqrt{a^2 - \gamma_1(x)}\,dx]}. \tag{3.23}$$

Hence the damping rate μ is asymptotically proportional to the frequency ν, with the constants of proportionality (3.23) *depending only on the function $\gamma_1(x)$ satisfying* (1.12), (2.14).

Remark 3.4. (i) Theorem 3.3 points out that the answer to (Q1) in § 1 is *negative.* The “homogenization” formula (3.23) is much more complex than the one in (Q1).

(ii) Note that when

$$\gamma_1(x) \equiv \gamma_1 \quad \text{a positive constant,} \tag{3.24}$$

then the slopes in (3.23) become

$$\pm\frac{1}{2}\frac{[\pi\sqrt{a^2 + \gamma_1}]^2 - [\pi\sqrt{a^2 - \gamma_1}]^2}{[\pi\sqrt{a^2 + \gamma_1}][\pi\sqrt{a^2 - \gamma_1}]} = \pm\frac{\gamma_1}{\sqrt{a^4 - \gamma_1^2}},$$

consistent with (1.6).

Remark 3.5. If instead of (1.11), we treat (1.11)′, then the eigenvalue problem (2.1) becomes

(2.1)′

$$a^4\phi^{(4)}(x) - 2\lambda\gamma_1(x)\phi''(x) - 2\lambda\gamma_1'(x)\phi'(x) + 2\lambda\gamma_2(x)\phi(x) + \lambda^2\phi(x) = 0, \qquad 0 \leqq x \leqq \pi,$$

$$\phi(0) = \phi''(0) = \phi(\pi) = \phi''(\pi) = 0.$$

Following the same transformation and diagonalization procedures as in (2.1)-(2.11), we will obtain, in lieu of (2.11), an equivalent first-order system

$$Z'(x)=[\rho R(x)+S(x)+\rho^{-1}T(x)]Z(x), \tag{2.11$'$}$$

where

$$S(x)=Q^{-1}(x)\cdot\mathscr{D}(x)Q(x)-Q^{-1}(x)Q'(x),$$

$$\mathscr{D}(x)\equiv\begin{bmatrix}0 & 0\\ 0 & D(x)\end{bmatrix},\qquad D(x)\equiv a^{-2}\gamma_1'(x)\begin{bmatrix}1 & -1\\ 1 & -1\end{bmatrix},$$

and everything else remains unchanged. Since (3.23) in Theorem 3.3 is independent of $S(x)$ or $S(x)$ in (2.11) or (2.11)$'$, we see that the very same structural damping property holds good for (1.11)$'$.

4. A high-order approximation under the assumption of uniform structural damping in order to examine the effects of viscous damping. So far in our analysis of damping, we see that in (1.11) the effect of the term $-2m\gamma_1(x)\partial^3y(x,t)/\partial t\partial x^2$ completely overwhelms that of the viscous $2m\gamma_2(x)\partial y(x,t)/\partial t$. Nevertheless, we are still curious to determine what is the order of magnitude of the (asymptotic) effect of the viscous damping term.

We make a quick observation at (2.11): in

$$Z'(x)=[\rho R(x)+S(x)+\rho^{-1}T(x)]Z(x),$$

only the matrix $\rho^{-1}T(x)$ depends on the viscous coefficient $\gamma_2(x)$, with magnitude $\mathscr{O}(\rho^{-1})$, whereas the matrix $S(x)$, depending on $\gamma_1(x)$ and $\gamma_1'(x)$, still has a larger order of magnitude $\mathscr{O}(1)$. Therefore even if we go to the second-order approximation of $Z(x)$, i.e., to obtain $P_1(x)$ in (2.16), the asymptotic effect contributed by viscosity $\gamma_2(x)$ still would be overshadowed by $S(x)$. In order to satisfy our probing curiosity and to avoid lengthy calculations, we assume

$$S(x)\equiv 0,$$

resulting in a simpler equation

$$Z'(x)=[\rho R(x)+\rho^{-1}T(x)]Z(x). \tag{4.1}$$

This is equivalent to assuming (3.24) for model (1.11) or (1.11)$'$. (The reader can also see from (2.22) that if $S(x)\not\equiv 0$, the solution of $P_1(x)$ is a great deal more complicated in general because it may not be in diagonal form and lack closed form solutions, causing a severe obstacle in obtaining higher order approximations.)

Under the uniform structural damping assumption (3.24), now we can obtain $P_1(x)$ explicitly as a diagonal matrix:

$$\begin{aligned}P_1(x)&=\operatorname{diag}\left[\int_0^x\tau_{11}(u)\,du,\int_0^x\tau_{22}(u)\,du,\int_0^x\tau_{33}(u)\,du,\int_0^x\tau_{44}(u)\,du\right]\\&=\frac{b^2-1}{4a^2b}\operatorname{diag}\left[\frac{1}{\xi_1}\eta(x),-\frac{1}{\xi_2}\eta(x),\frac{1}{\xi_2}\eta(x),-\frac{1}{\xi_1}\eta(x)\right],\end{aligned}$$

where

$$b=i\frac{\sqrt{a^4-\gamma_1^2}}{a^2+\gamma_1}\quad\text{(from (2.8))},$$

ξ_1, ξ_2 as in (2.8) formerly, now are constant through (3.24),

$$\eta(x)\equiv\int_0^x\gamma_2(u)\,du.$$

The very fact that $P_1(x)$ is a diagonal matrix crucially facilitates the tractability of our problem. Also, from (3.2) and (2.9), (2.17),

$$(4.2)\qquad P_0(x)=I_4,\qquad \Gamma(x)=\operatorname{diag}[\xi_1x,-\xi_2x,\xi_2x,-\xi_1x].$$

From the ansatz (2.16), using (4.2), we can rewrite

$$Z(x)=[I+\rho^{-2}\hat{\Psi}(x,\rho)]E(x,\rho),$$

where

$$\begin{aligned}E(x,\rho)&\equiv[I+\rho^{-1}P_1(x)]\,e^{\rho\Gamma(x)}\\ &=\operatorname{diag}\left(\left(1+\frac{b^2-1}{4a^2b\xi_1\rho}\,\eta(x)\right)\exp(\rho\xi_1x),\left(1+\frac{b^2-1}{4a^2b\xi_2\rho}\,\eta(x)\right)\exp(-\rho\xi_2x),\right.\\ &\qquad\left.\cdot\left(1-\frac{b^2-1}{4a^2b\xi_2\rho}\,\eta(x)\right)\exp(\rho\xi_2x),\left(1-\frac{b^2-1}{4a^2b\xi_1\rho}\,\eta(x)\right)\exp(-\rho\xi_1x)\right),\end{aligned}\tag{4.3}$$

$$\hat{\Psi}(x,\rho)\equiv[P_2(x)+\rho^{-1}P_3(x)+\cdots+\rho^{-n}P_{n+2}(x)+\cdots][I+\rho^{-1}P_1(x)]^{-1}.$$

The boundedness and holomorphic properties of this function $\hat{\Psi}(x,\rho)$ are similar to those of $\Psi(x,\rho)$ in (3.4) so we will not repeat the discussions here. The boundary conditions in (3.6) require that ρ satisfies

$$(4.4)\qquad \det\{\tilde{\Lambda}(\rho)+\rho^{-2}\tilde{\hat{\Psi}}(\rho)\}=0,$$

where

$$\tilde{\Lambda}(\rho)=\begin{bmatrix}1&1&1&1\\ b&-b&-b&b\\ \left[1+\frac{b^2-1}{4a^2b\xi_1\rho}\eta(\pi)\right]&\left[1+\frac{b^2-1}{4a^2b\xi_2\rho}\eta(\pi)\right]&\left[1-\frac{b^2-1}{4a^2b\xi_2\rho}\eta(\pi)\right]&\left[1-\frac{b^2-1}{4a^2b\xi_1\rho}\eta(\pi)\right]\\ \cdot\exp(\rho\xi_1\pi)&\cdot\exp(-\rho\xi_2\pi)&\cdot\exp(\rho\xi_2\pi)&\cdot\exp(-\rho\xi_1\pi)\\ b\left[1+\frac{b^2-1}{4a^2b\xi_1\rho}\eta(\pi)\right]&-b\left[1+\frac{b^2-1}{4a^2b\xi_2\rho}\eta(\pi)\right]&-b\left[1-\frac{b^2-1}{4a^2b\xi_2\rho}\eta(\pi)\right]&b\left[1-\frac{b^2-1}{4a^2b\xi_1\rho}\eta(\pi)\right]\\ \cdot\exp(\rho\xi_1\pi)&\cdot\exp(-\rho\xi_2\pi)&\cdot\exp(\rho\xi_2\pi)&\cdot\exp(-\rho\xi_1\pi)\end{bmatrix}$$

and

$$\tilde{\hat{\Psi}}(\rho)=\begin{bmatrix}\tilde{\hat{\psi}}_{11}(\rho)&\tilde{\hat{\psi}}_{12}(\rho)&\tilde{\hat{\psi}}_{13}(\rho)&\tilde{\hat{\psi}}_{14}(\rho)\\ \tilde{\hat{\psi}}_{21}(\rho)&\tilde{\hat{\psi}}_{22}(\rho)&\tilde{\hat{\psi}}_{23}(\rho)&\tilde{\hat{\psi}}_{24}(\rho)\\ \tilde{\hat{\psi}}_{31}(\rho)\exp(\rho\xi_1\pi)&\tilde{\hat{\psi}}_{32}(\rho)\exp(-\rho\xi_2\pi)&\tilde{\hat{\psi}}_{33}(\rho)\exp(\rho\xi_2\pi)&\tilde{\hat{\psi}}_{34}(\rho)\exp(-\rho\xi_1\pi)\\ \tilde{\hat{\psi}}_{41}(\rho)\exp(\rho\xi_1\pi)&\tilde{\hat{\psi}}_{42}(\rho)\exp(-\rho\xi_2\pi)&\tilde{\hat{\psi}}_{43}(\rho)\exp(\rho\xi_2\pi)&\tilde{\hat{\psi}}_{44}(\rho)\exp(-\rho\xi_1\pi)\end{bmatrix}\tag{4.5}$$

with

$$\tilde{\hat{\psi}}_{1k}(\rho)=\sum_{i=1}^{4}\hat{\psi}_{ik}(0,\rho),$$

$$\tilde{\hat{\psi}}(\rho)=b\sum_{i=1}^{4}(-1)^{[i/2]}\hat{\psi}_{ik}(0,\rho),$$

$$\tilde{\hat{\psi}}_{3k}(\rho)=\sum_{i=1}^{4}\hat{\psi}_{ik}(\pi,\rho),$$

$$\tilde{\hat{\psi}}_{4k}(\rho)=b\sum_{i=1}^{4}(-1)^{[i/2]}\hat{\psi}_{ik}(\pi,\rho)$$

for $k=1,2,3,4$.

The approximation of ρ is done by dropping the $\mathcal{O}(\rho^{-2})$ terms in (4.4):

$$\begin{aligned} 0 &= \det \tilde{\Lambda}(\rho) \\ &= 4b^2\left[\left(1+\frac{b^2-1}{4a^2b\xi_1\rho}\,\eta(\pi)\right)e^{\rho\xi_1\pi}-\left(1-\frac{b^2-1}{4a^2b\xi_1\rho}\,\eta(\pi)\right)e^{-\rho\xi_1\pi}\right] \\ &\quad\cdot\left[\left(1-\frac{b^2-1}{4a^2b\xi_2\rho}\,\eta(\pi)\right)e^{\rho\xi_2\pi}-\left(1+\frac{b^2-1}{4a^2b\xi_2\rho}\,\eta(\pi)\right)e^{-\rho\xi_2\pi}\right]. \end{aligned} \tag{4.6}$$

This is of a higher order approximation to ρ than that given in § 3. Therefore ρ satisfies either

$$\left[1+\frac{b^2-1}{4a^2b\xi_1\rho}\,\eta(\pi)\right]e^{\rho\xi_1\pi}-\left[1-\frac{b^2-1}{4a^2b\xi_1\rho}\,\eta(\pi)\right]e^{-\rho\xi_1\pi}=0 \tag{4.7}$$

or

$$\left[1-\frac{b^2-1}{4a^2b\xi_2\rho}\,\eta(\pi)\right]e^{\rho\xi_2\pi}-\left[1+\frac{b^2-1}{4a^2b\xi_2\rho}\right]e^{\rho\xi_2\pi}=0. \tag{4.8}$$

Note that (4.7) is obtainable from (4.8) by the formal change of variable

$$\xi_2=-\xi_1, \tag{4.9}$$

therefore we need only solve (4.7), where from

$$\begin{aligned} e^{2\pi\xi_1\rho} &= \left(1-\frac{(b^2-1)\eta(\pi)}{4a^2b\xi_1\rho}\right)\Big/\left(1+\frac{(b^2-1)\eta(\pi)}{4a^2b\xi_1\rho}\right)\equiv\omega(\rho), \\ \rho &= \frac{1}{2\pi\xi_1}\ln\omega(\rho)+i\frac{k}{\xi_1}, \qquad k\in\mathbb{Z}. \end{aligned} \tag{4.10}$$

Since

(4.11)

$$\ln\omega(\rho)=-\frac{(b^2-1)\eta(\pi)}{2a^2b\xi_1}\frac{1}{\rho}+2\cdot\left[\frac{(b^2-1)\eta(\pi)}{4a^2b\xi_1}\right]^2\frac{1}{\rho^2}+\cdots=\mathcal{O}(\rho^{-1}), \qquad |\rho| \text{ large},$$

so

$$\frac{k}{\rho}=-i\xi_1+\mathcal{O}(\rho^{-2}), \tag{4.12}$$

we have

$$\begin{aligned} \rho^2 &= -\frac{k^2}{\xi_1^2}+\frac{k}{\pi\xi_1^2}\ln\omega(\rho)+\frac{1}{4\pi^2\xi_1^2}\ln^2(\omega(\rho)) \\ &\equiv \mathcal{F}_1+\mathcal{F}_2+\mathcal{F}_3, \end{aligned} \tag{4.13}$$

where

$$\mathcal{F}_1=-\frac{k^2}{\xi_1^2}=-\frac{a^4k^2}{\gamma_1+i\sqrt{a^4-\gamma_1^2}}=-k^2\gamma_1+ik^2\sqrt{a^4-\gamma_1^2},$$

$$
\begin{aligned}
\mathscr{F}_2 &= i\frac{k}{\pi\xi_1^2}\ln \omega(\rho)\\
&= i\frac{k}{\pi\xi_1^2}\left[-\frac{(b^2-1)\eta(\pi)}{2a^2b\xi_1}\frac{1}{\rho}+\mathscr{O}(\rho^{-2})\right] \quad \text{(by (4.11))}\\
&= -i\frac{(b^2-1)\eta(\pi)}{2a^2b\pi\xi_1^3}\frac{k}{\rho}+\mathscr{O}(\rho^{-1})\\
&= -\frac{(b^2-1)\eta(\pi)}{2a^2b\pi\xi_1^2}+\mathscr{O}(\rho^{-1}) \quad \text{(by (4.12))}\\
&= -\frac{\left[-\dfrac{(a^4-\gamma_1^2)}{(a^2+\gamma_1)^2}-1\right]\eta(\pi)}{2a^2\pi\cdot i\cdot\dfrac{(a^4-\gamma_1^2)^{1/2}}{a^2+\gamma_1}\cdot\left[\dfrac{\gamma_1+i(a^4-\gamma_1^2)^{1/2}}{a^4}\right]}+\mathscr{O}(\rho^{-2})\\
&= -\frac{\eta(\pi)}{\pi}-i\frac{\gamma_1}{\sqrt{a^4-\gamma_1^2}}\frac{\eta(\pi)}{\pi}+\mathscr{O}(\rho^{-2})\\
\mathscr{F}_3 &= \mathscr{O}(\rho^{-2}).
\end{aligned}
$$

Combining the above in (4.13), we therefore have

$$
\rho^2=-\left(k^2\gamma_1+\frac{\eta(\pi)}{\pi}\right)+i\left(k^2\sqrt{a^4-\gamma_1^2}-\frac{\gamma_1}{\sqrt{a^4-\gamma_1^2}}\frac{\eta(\pi)}{\pi}\right)+\mathscr{O}\left(\frac{1}{k}\right), \tag{4.14}
$$

$k\in\mathbb{Z}$ is large.

Similarly, (4.8) will lead to

$$
\rho^2=-\left(k^2\gamma_1+\frac{\eta(\pi)}{\pi}\right)-i\left(k^2\sqrt{a^4-\gamma_1^2}-\frac{\gamma_1}{\sqrt{a^4-\gamma_1^2}}\frac{\eta(\pi)}{\pi}\right)+\mathscr{O}\left(\frac{1}{k}\right). \tag{4.15}
$$

Now we return to solve

$$
\det[\tilde{\Lambda}(\sqrt{\lambda})+\lambda^{-1}\tilde{\Psi}(\sqrt{\lambda})]=0, \tag{4.16}
$$

namely, (4.4). By a careful perturbation argument, we can again show that the eigenfrequencies λ of (1.11), (1.2) have the asymptotic expansion

$$
\lambda=-\left(k^2\gamma_1+\frac{\eta(\pi)}{\pi}\right)\pm i\left(k^2\sqrt{a^4-\gamma_1^2}-\frac{\gamma_1}{\sqrt{a^4-\gamma_1^2}}\frac{\eta(\pi)}{\pi}\right)+\mathscr{O}\left(\frac{1}{k}\right), \quad |\lambda| \text{ large.} \tag{4.17}
$$

Therefore we conclude

THEOREM 3.6. *Consider* (1.11) *and* (1.2). *Assume that* $\gamma_1(x)\equiv\gamma_1$ *is constant satisfying* (1.7). *Let* λ *be an eigenfrequency of the system*; *then for* $|\lambda|$ *large,*

$$
\lambda=-\left(k^2\gamma_1+\frac{\eta(\pi)}{\pi}\right)\pm i\left(k^2\sqrt{a^4-\gamma_1^2}-\frac{\gamma_1}{\sqrt{a^4-\gamma_1^2}}\frac{\eta(\pi)}{\pi}\right)+\mathscr{O}\left(\frac{1}{k}\right), \tag{4.18}
$$

$k\in\mathbb{Z}$ *is large.*

Therefore we see that, asymptotically, the contribution of the viscous damping term $2m\gamma_2(x)\partial y/\partial t$ to the total rate of decay

$$
-\left[k^2\gamma_1+\frac{\eta(\pi)}{\pi}\right] \tag{4.19}
$$

is rather insignificant because the contribution $\eta(\pi)/\pi=\int_0^\pi \gamma_2(x)\,dx/\pi$ is fixed, whereas $k^2\gamma_1$ can grow large very fast. If $\gamma_1(x)$ is not constant, then the asymptotic decay rate (4.19) would contain a $\mathcal{O}(k)$ term, which is still of larger order of magnitude than $\eta(\pi)/\pi$. Also, it contributes a constant phase shift

$$-\frac{\gamma_1}{\sqrt{a^4-\gamma_1^2}}\,\frac{\eta(\pi)}{\pi}$$

to the overall (temporal) phase

$$k^2\sqrt{a^4-\gamma_1^2}-\frac{\gamma_1}{\sqrt{a^4-\gamma_1^2}}\,\frac{\eta(\pi)}{\pi}.$$

A special case of (4.18) is when

$$\gamma_1(x)\equiv\gamma_1=0.$$

Then we have

$$\begin{aligned}\lambda&=-\frac{\eta(\pi)}{\pi}\pm i\cdot k^2a^2+\mathcal{O}\left(\frac{1}{k}\right)\\ &=-\frac{1}{\pi}\int_0^\pi \gamma_2(x)\,dx\pm i\cdot k^2a^2+\mathcal{O}\left(\frac{1}{k}\right).\end{aligned}\tag{4.20}$$

This says that the rate of decay is the average of the viscous damping coefficient function $\gamma_2(x)$ on $[0,\pi]$. This is consistent with (1.14) and has also answered (Q2) *affirmatively* which was posed earlier in § 1.

5. Proofs of two technical lemmas.

Proof of Lemma 3.1. We pointed out earlier in § 3 that in $\Lambda(\rho)$ of (3.7), K_1, K_2, $\Gamma_1(\pi)$, and $\Gamma_2(\pi)$ are finite, $\psi_{jk}(\rho)$, $1\leqq j,\ k\leqq 4$, are uniformly bounded for $|\rho|$ large. Let k_0 be a sufficiently large positive integer, and $k\in\mathbb{Z}$, $|k|\geqq k_0$. Let $\rho\in G_{1k}$. Then

$$\begin{aligned}\rho&=\frac{\beta}{\alpha^2+\beta^2}(\sqrt{2}\,a^2\pi)k+\varepsilon_1+i\left[\frac{\alpha}{\alpha^2+\beta^2}(\sqrt{2}\,a^2\pi)k+\varepsilon_2\right]\\ &=\rho_1(k)+(\varepsilon_i+i\varepsilon_2)\qquad\text{(cf. (3.16))},\end{aligned}$$

where $|\varepsilon_1|\leqq 1$, $|\varepsilon_2|\leqq 1$. We have

$$\begin{aligned}|E_1(\rho)|&=|e^{[\rho_1(k)+\varepsilon_1+i\varepsilon_2]\Gamma_1(\pi)}|=|e^{\rho_1(k)\Gamma_1(\pi)}\cdot e^{(\varepsilon_1+i\varepsilon_2)\Gamma-1(\pi)}|\\ &=|e^{(\varepsilon_1+i\varepsilon_2)\Gamma_1(\pi)}|,\qquad(\because\rho_1(k)\Gamma_1(\pi)=ik\pi),\\ |E_4(\rho)|&=|e^{-[\rho_1(k)+\varepsilon_1+i\varepsilon_2]\Gamma_1(\pi)}|=|e^{-(\varepsilon_1+i\varepsilon_2)\Gamma_1(\pi)}|,\\ |E_2(\rho)|&=|e^{-[\rho_1(k)+\varepsilon_1+i\varepsilon_2]\Gamma_2(\pi)}|=|e^{-(\varepsilon_1+i\varepsilon_2)\Gamma_2(\pi)}|\left|\exp\left(-\frac{\beta+i\alpha}{\alpha^2+\beta^2}(\sqrt{2}\,a^2k\pi)(\alpha-i\beta)\right)\right|\\ &=|e^{-(\varepsilon_1+i\varepsilon_2)\Gamma_2(\pi)}|\cdot\left|\exp\left(-\left(\frac{2\alpha\beta}{\alpha^2+\beta^2}+i\frac{\alpha^2-\beta^2}{\alpha^2+\beta^2}\right)\cdot\sqrt{2}\,a^2k\pi\right)\right|,\end{aligned}$$

so

$$|E_2(\rho)|\to+\infty\quad\text{as }k\to+\infty,$$

$$|E_3(\rho)|\to+0\quad\text{as }k\to-\infty.$$

Similarly, we can show that

$$|E_3(\rho)| \to +\infty \quad \text{as } k \to +\infty,$$
$$|E_3(\rho)| \to 0 \quad \text{as } k \to -\infty.$$

Let us look at the case $\rho \in G_{1k}^+$, $k \geqq k_0$. From the above, we see that $E_1(\rho)$, $E_2(\rho)$, and $E_4(\rho)$ are bounded uniformly in k in ρ, while $|E_3(\rho)| \to +\infty$ as $k \to +\infty$. Applying the fact that

$$\det \begin{bmatrix} a_{11}+b_{11} & a_{12} & a_{13} & a_{14} \\ a_{21}+b_{21} & a_{22} & a_{23} & a_{24} \\ a_{31}+b_{31} & b_{32} & a_{33} & a_{34} \\ a_{41}+b_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix}$$
$$= \det \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix} + \det \begin{bmatrix} b_{11} & a_{12} & a_{13} & a_{14} \\ b_{21} & a_{22} & a_{23} & a_{24} \\ b_{31} & a_{32} & a_{33} & a_{34} \\ b_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix},$$

four times, we can expand $\det \Lambda(\rho)$ into four determinants, such that

$$\det \Lambda(\rho) = \det \Lambda_0(\rho) + \sum_{j=1}^{3} \det \Lambda_j(\rho).$$

In each $\Lambda_j(\rho)$, $j = 1, 2, 3$, there is at least one column having $1/\rho$ as a common factor. Hence we get (3.18).

The other cases (3.18)′, (3.19), and (3.19)′ can all be treated in the same manner. So the proof is complete. □

Proof of Lemma 3.2. We proceed in two steps.

(1) There exists $k_1 \in \mathbb{Z}^+$ such that for $k \in \mathbb{Z}$, $|k| \geqq k_1$, there exists one and only one solution $\tilde{\rho}$ of (3.9) in G_{ik}, for $i = 1, 2$.

We need only consider the case $i = 1$, $k \geqq k_1$. From Lemma 3.1, equation (3.9) can be written as

$$4b(0)b(\pi)K_1K_2[E_1(\rho) - E_4(\rho)][E_3(\rho) - E_2(\rho)] + \rho^{-1}[g_1(\rho)E_3(\rho) + g_2(\rho)] = 0,$$

$$E_1(\rho) - E_4(\rho) + \frac{1}{\rho} \cdot \frac{g_1(\rho)E_3(\rho) + g_2(\rho)}{4b(0)b(\pi)K_1K_2[E_3(\rho) - E_2(\rho)]} = 0, \tag{5.1}$$

or

$$E_1(\rho) - E_4(\rho) + \frac{1}{\rho} g(\rho) = 0, \tag{5.2}$$

where $g(\rho)$ is uniformly bounded for $\rho \in G_{1k}^+$, $k \geqq k_1$. Define $F(\rho) = E_1(\rho) - E_4(\rho)$. For $\rho \in \partial G_{1k}^+$,

$$\begin{aligned} |F(\rho)| &= |e^{[\rho_1(k)+\varepsilon_1+i\varepsilon_2](\alpha+i\beta)} - e^{-[\rho_1(k)+\varepsilon_1+i\varepsilon_2](\alpha+i\beta)}| \\ &= |e^{(\varepsilon_1+i\varepsilon_2)(\alpha+i\beta)} - e^{-(\varepsilon_1+i\varepsilon_2)(\alpha+i\beta)}| \quad \text{(by (3.12))} \\ &= |e^{-(\varepsilon_1\alpha-\varepsilon_2\beta)} \cdot e^{-i(\varepsilon_1\beta+\varepsilon_2\alpha)}| \cdot |e^{2(\varepsilon_1\alpha-\varepsilon_2\beta)}\, e^{2i(\varepsilon_1\beta+\varepsilon_2\alpha)} - 1|. \end{aligned}$$

Refer to Fig. 3. On l_1: $\varepsilon_1 = 1$, $-1 \leqq \varepsilon_2 \leqq 1$, we have

$$\begin{aligned} |F(\rho)| &= |e^{-(\alpha-\varepsilon_2\beta)}| \cdot |e^{2(\alpha-\varepsilon_2\beta)}\, e^{2i(\beta+\varepsilon_2\alpha)} - 1| \\ &\geqq e^{-(\alpha-\beta)}[e^{2(\alpha-\beta)} - 1] \equiv M_1 > 0 \qquad (\because \alpha > \beta). \end{aligned}$$

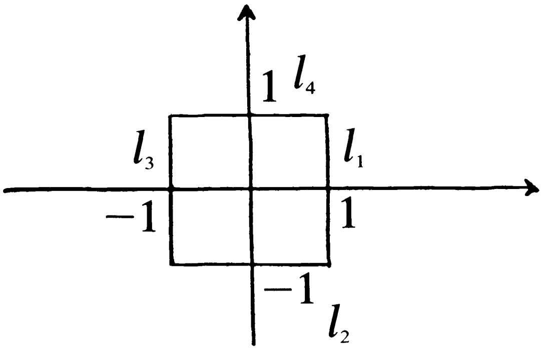

FIG. 3. *A small neighborhood.*

On l_3: $\varepsilon_1=-1, -1\leqq\varepsilon_2\leqq 1$,

$$\begin{aligned}|F(\rho)|&=|e^{-(-\alpha-\varepsilon_2\beta)}|\cdot|e^{2(-\alpha-\varepsilon_2\beta)}\,e^{2i(-\beta+\varepsilon_2\alpha)}-1|\\&\geqq e^{(\alpha-\beta)}[1-e^{-2(\alpha-\beta)}]\equiv M_2>0.\end{aligned}$$

On l_2: $-1\leqq\varepsilon_1\leqq 1$, $\varepsilon_2=-1$,

$$\begin{aligned}|F(\rho)|&=|e^{-(\varepsilon_1\alpha+\beta)}|\cdot|e^{2(\varepsilon_1\alpha+\beta)}\cdot e^{2i(\varepsilon_1\beta-\alpha)}-1|\\&\geqq e^{-(\alpha+\beta)}\cdot|e^{2(\varepsilon_1\alpha+\beta)}\,e^{2i(\varepsilon_1\beta-\alpha)}-1|.\end{aligned}$$

We claim that

$$\min_{-1\leqq\varepsilon_1\leqq 1}|e^{2(\varepsilon_1\alpha+\beta)}\,e^{2i(\varepsilon_1\beta-\alpha)}-1|>0.$$

Otherwise, there exists $\varepsilon_1^0\in[-1,1]$ such that

$$e^{2(\varepsilon_1^0\alpha+\beta)}\cdot e^{2i(\varepsilon_1^0\beta-\alpha)}-1=0,$$

implying

$$\begin{matrix}2(\varepsilon_1^0\alpha+\beta)=0\\2(\varepsilon_1^0\beta-\alpha)=0\end{matrix},\quad\text{i.e.,}\quad-\frac{\beta}{\alpha}=\varepsilon_1^0=\frac{\alpha}{\beta}.$$

So $\alpha^2+\beta^2=0$, $\alpha=\beta=0$. This is a contradiction. Therefore on l_2,

$$|F(\rho)|\geqq M_3>0\quad\text{for some } M_3.$$

Finally, on l_4: $-1\leqq\varepsilon_1\leqq 1$, $\varepsilon_2=1$,

$$\begin{aligned}|F(\rho)|&=|e^{-(\varepsilon_1\alpha-\beta)}|\cdot|e^{2(\varepsilon_1\alpha-\beta)}\cdot e^{2i(\varepsilon_b\beta+\alpha)}-1|\\&\geqq e^{-(\alpha-\beta)}\cdot|e^{2(\varepsilon_1\alpha-\beta)}\,e^{2i(\varepsilon_i\beta+\alpha)}-1|\geqq M_4>0,\end{aligned}$$

for some $M_4>0$, for the same reason as on l_3.

Let $M_5\equiv\min(M_1, M_2, M_3, M_4)$.

The uniform boundedness of g means that there exists $M_6>0$ such that

$$|g(p)|\leqq M_6\quad\text{for all } \rho\in G_{1k}^+,\ k\geqq k_0.$$

Choose $k_1\geqq k_0$ such that for $\rho\in G_{1k}^+$,

$$|\rho|>\frac{2M_6}{M_5}.$$

Then for $\rho \in \partial G^{1k}$, $k \geqq k_1$, we have

$$|E_1(\rho) - E_4(\rho)| \geqq M_5 > \frac{M_5}{2} \geqq \left| \frac{1}{\rho} g(\rho) \right|.$$

Since $E_1(\rho)$, $E_4(\rho)$, and $\rho^{-1}g(\rho)$ are all analytic in ρ, by Rouché's theorem there exists one and only one solution $\tilde{\rho}$ of (3.7) in G^+_{1k}. The other cases can be treated similarly.

(2) For $|\rho|$ large, there are no solutions $\tilde{\rho}$ of (3.9) outside $G_1 \cup G_2$.

From (5.1) and (5.2), we can write

$$e^{2\tilde{\rho}\Gamma_1(\pi)} - 1 + \frac{1}{\tilde{\rho}} \frac{g(\tilde{\rho})}{e^{-\tilde{\rho}\Gamma_1(\pi)}} = 0$$

or

$$e^{2\tilde{\rho}\Gamma_1(\pi)} - 1 + \frac{1}{\rho} \hat{g}(\tilde{\rho}) = 0. \tag{5.3}$$

Assume that as $|\tilde{\rho}| \to \infty$, $\exp[2\tilde{\rho}\Gamma_1(\pi)]$ becomes unbounded. Then from our foregoing discussions, we have

$$|\hat{g}(\tilde{\rho})| \text{ bounded as } |\tilde{\rho}| \to \infty, \qquad |\exp[2\tilde{\rho}\Gamma_1(\pi)]| \to \infty.$$

Therefore from (5.3)

$$\begin{aligned} \tilde{\rho} &= \frac{1}{2\Gamma_1(\pi)} \ln\left(1 - \frac{\hat{g}(\rho)}{\rho}\right) + i\frac{k\pi}{\Gamma_1(\pi)} \\ &= \rho_1(k) + \frac{1}{2\Gamma_1(\pi)} \ln\left(1 - \frac{\hat{g}(\rho)}{\rho}\right), \end{aligned}$$

showing that $\tilde{\rho} \in G_1$ for $|\tilde{\rho}|$ large.

If instead we use equations derived from (3.19), (3.19)′, then $\tilde{\rho} \in G_2$ for $|\rho|$ large. □

EXPONENTIAL DECAY OF THE ENERGY OF A ONE-DIMENSIONAL NONHOMOGENEOUS MEDIUM*

JONG UHN KIM†

Abstract. The energy method based on wave propagation is used to show that locally distributed damping can stabilize the motion of a composite bar exponentially fast.

Key words. exponential decay, nonhomogeneous bar, energy method

AMS(MOS) subject classifications. 35R05, 73K05, 93D20

Introduction. In this paper we prove that locally distributed damping can stabilize the motion of a one-dimensional nonhomogeneous medium exponentially fast. Specifically, we consider either longitudinal or torsional vibration of a nonhomogeneous bar. The bar is composed of two different segments, only one of which is damped.

The model equations are

$$m_1(x)\frac{\partial^2 u}{\partial t^2}-\frac{\partial}{\partial x}\left(a_1(x)\frac{\partial u}{\partial x}\right)=0 \quad \text{in } (0,\infty)\times(L_1, L_2), \tag{0.1}$$

$$m_2(x)\frac{\partial^2 u}{\partial t^2}-\frac{\partial}{\partial x}\left(a_2(x)\frac{\partial u}{\partial x}\right)+b(x)\frac{\partial u}{\partial t}=0 \quad \text{in } (0,\infty)\times(L_2, L_3), \tag{0.2}$$

where $L_1 < L_2 < L_3$.

The bar is represented by the interval (L_1, L_3) and consists of two different parts, represented by (L_1, L_2) and (L_2, L_3), respectively. Here, $m_i(x)$, $a_i(x)$, $i = 1, 2$, and $b(x)$ are appropriate physical coefficients accociated with each segment. At the interface $x = L_2$, we impose the transmission condition:

$$\lim_{x\to L_2-} u(t,x) = \lim_{x\to L_2+} u(t,x), \tag{0.3}$$

$$\lim_{x\to L_2-} a_1(x)\frac{\partial u}{\partial x}(t,x) = \lim_{x\to L_2+} a_2(x)\frac{\partial u}{\partial x}(t,x). \tag{0.4}$$

At the boundary $x = L_1, L_3$, we assume

$$u(t, L_1) = u(t, L_3) = 0. \tag{0.5}$$

It is known that the energy of a single bar with damping distributed over the whole interval decays exponentially fast with the homogeneous Dirichlet boundary condition (see [1]). Here we join two different bars, only one of which has damping. An obvious question is whether or not the energy of the combined system decays exponentially fast. Similar problems have been discussed in [2], [3], and [7]. Chen gave a talk on [3] at VPI and his talk motivated the present work. Reference [3] presents a general theorem on an abstract evolution equation with partially distributed damping. The result of [3] can cover various types of evolution equations. The conditions in [3] for

† Department of Mathematics, Virginia Polytechnic Institute and State University, Blacksburg, VA 24061. This research was supported by Air Force Office of Scientific Research grants AFOSR-86-0085 and AFOSR-89-0268.

the exponential decay of energy involve eigenvalues and eigenfunctions of the associated stationary system. Chen et al. also discussed some specific examples for which these conditions can be easily verified. In fact, if $m_1 = m_2 = \text{const.}$, $a_1 = a_2 = \text{const.}$, and $b(x) > 0$ on a certain subinterval, the above problem reduces to one of the examples treated in [3]. However, when m_i and a_i, $i = 1, 2$, are variable, it is not obvious whether we can verify all the conditions needed for their theorem. The well-established properties of eigenvalues and eigenfunctions of the Sturm-Liouville problem are not sufficient. In this paper, we employ the energy method in the same spirit as in [7]. Rauch and Taylor [7] treated problems on compact manifolds of any dimension without boundary and also the case of a one-dimensional bounded domain with boundary. Their discussion of the latter case gives a clue for our problem. But more involved energy estimates are necessary since the operator (after our problem is put in the framework of [7]) is not strictly dissipative (according to [7]) at any point of the interval. We also need a quantitative analysis of the energy transmission across the interface. The main tool we shall use is a multiplier technique due to Lasiecka, Lions, and Triggiani [5]. Our argument depends heavily on the phenomenon of wave propagation and does not extend to nonhyperbolic evolution equations such as Euler's beam equation.

In § 1, we present some technical preliminaries, and in § 2, we state the main result and give the proof.

Notation. $(\ )_x$ or $[\ ]_x$ denotes an interval for the x variable. Similarly, $(\ )_t$ or $[\ ]_t$ is an interval for the t variable. For the derivatives of a function, we use the following notation:

$$\partial_t f = f_t = \frac{\partial f}{\partial t}, \quad \partial_x f = f_x = \frac{\partial f}{\partial x}, \quad \partial_{xx} f = f_{xx} = \frac{\partial^2 f}{\partial x^2}, \text{ etc.}$$

When Ω is an open subset of R^n, $n \geqq 1$, then $\mathscr{D}'(\Omega)$ is the space of distributions, and $H^m(\Omega)$ and $H_0^m(\Omega)$ are the standard notation for the Sobolev spaces.

When E is a Banach space and I is an open interval, we use the following notation:

(0.6) $L^p(I; E) =$ the set of all E-valued strongly measurable L^p functions on I.

(0.7) $C_0^m(I; E) = \{f \in C^m(I; E)\colon \operatorname{supp} f \text{ is a compact subset of } I\}$.

(0.8) $\rho_\varepsilon(t) = \rho(t/\varepsilon)/\varepsilon$, where $\rho(t) =$ a nonnegative even C^∞ function with support in $(-1, 1)$ and integral one.

1. Preliminaries.

We shall present some properties of one-dimensional hyperbolic equations, which will be used later.

LEMMA 1.1. *Let $A(x) \in C^1([J_1, J_2])$ and $B(x) \in C([J_1, J_2])$ be 2×2 matrices. Suppose that $A(x)$ has real eigenvalues $\lambda_1(x)$ and $\lambda_2(x)$ such that $0 < \alpha \leqq \lambda_1(x) \leqq \beta$ and $-\beta \leqq \lambda_2(x) \leqq -\alpha$, for all $x \in [J_1, J_2]$, for some positive constants $\alpha < \beta$. Then, for given $h(t) \in L^2(T_1, T_2)$, there is a function $v \in C([J_1, J_2]_x : L^2(T_1, T_2)_t)$ satisfying the hyperbolic system*

$$\partial_t v - A(x)\,\partial_x v + B(x) v = 0 \quad \text{in } (T_1, T_2) \times (J_1, J_2), \tag{1.1}$$

$$v(t, J_2) = h(t) \quad \text{for almost all } t \in (T_1, T_2). \tag{1.2}$$

Furthermore, for $0 < c < \min(J_2 - J_1, \alpha(T_2 - T_1)/2)$, v is uniquely determined in a trapezoidal region $\sum = \{(t, x)\colon J_2 - c \leqq x \leqq J_2,\ T_1 + (J_2 - x)/\alpha \leqq t \leqq T_2 - (J_2 - x)/\alpha\}$, and

$$\int_{T_1 + c/\alpha}^{T_2 - c/\alpha} |v(t, x)|^2\, dt \leqq M \int_{T_1}^{T_2} |h(t)|^2\, dt \tag{1.3}$$

holds for each $J_2 - c \leqq x \leqq J_2$, where M is a positive constant independent of x, v, and h.

Proof. The proof seems to be known, hence we shall only sketch it. First, extend $h(t)$ such that $\tilde{h}(t)=h(t)$, for $T_1 \leqq t \leqq T_2$ and $\tilde{h}(t)=0$, otherwise. Next, choose a sequence $\{h_n(t)\} \subset C_0^\infty((-\infty,\infty))$ which approximates $\tilde{h}(t)$ in $L^2(-\infty,\infty)$. For each $h_n(t)$, we use the method of characteristics to find $v_n \in C^1((-\infty,\infty)_t \times [J_1, J_2]_x)$ satisfying (1.1) and $v_n(t, J_2)=h_n(t)$, for all $t \in (-\infty,\infty)$. We then obtain a standard energy estimate for v_n in terms of the L^2 norm of $h_n(t)$. By means of this estimate, we can easily establish the existence of $v \in C([J_1, J_2]_x; L^2(T_1, T_2))$ satisfying (1.1)-(1.3). The uniqueness of v in $\sum$ is well known and the proof will be omitted.

LEMMA 1.2. *Let $\Omega=(T_1, T_2)_t \times (J_1, J_2)_x$ and assume that $b(x) \in C([J_1, J_2])$, $m(x)$ and $a(x) \in C^1([J_1, J_2])$ with $m(x), a(x) \geqq c > 0$, for all $x \in [J_1, J_2]$, for some constant c. If $u \in H^1(\Omega)$ satisfies*

$$(1.4) \qquad m(x)\,\partial_{tt}u - \partial_x(a(x)\,\partial_x u) + b(x)\,\partial_t u = 0 \quad \text{in } \mathscr{D}'(\Omega),$$

then for any small $\delta > 0$, we have

$$(1.5) \qquad \partial_t u, \partial_x u \in C([J_1, J_2]_x; L^2(T_1+\delta, T_2-\delta)_t),$$

$$(1.6) \qquad \partial_t u, \partial_x u \in C([T_1, T_2]_t; L^2(J_1+\delta, J_2-\delta)_x)$$

and

$$(1.7) \qquad \begin{aligned} &\|\partial_t u(x)\|_{L^2(T_1+\delta, T_2-\delta)_t} + \|\partial_x u(x)\|_{L^2(T_1+\delta, T_2-\delta)_t} \\ &\quad \leqq M_\delta(\|\partial_t u\|_{L^2(\Omega)} + \|\partial_x u\|_{L^2(\Omega)}) \quad \text{for each } x \in [J_1, J_2], \end{aligned}$$

$$(1.8) \qquad \begin{aligned} &\|\partial_t u(t)\|_{L^2(J_1+\delta, J_2-\delta)_x} + \|\partial_x u(t)\|_{L^2(J_1+\delta, J_2-\delta)_x} \\ &\quad \leqq M_\delta(\|\partial_t u\|_{L^2(\Omega)} + \|\partial_x u\|_{L^2(\Omega)}) \quad \text{for each } t \in [T_1, T_2], \end{aligned}$$

where M_δ stands for positive constants depending only on δ.

Proof. Fix any small $\delta > 0$ and $\xi > 0$. Choose $\varphi_1(t) \in C_0^\infty((T_1, T_2))$ and $\varphi_2(x) \in C_0^\infty((J_1, J_2))$ such that $\varphi_1(t)=1$, for $t \in [T_1+\delta, T_2-\delta]$ and $\varphi_2(x)=1$, for $x \in [J_1+\xi, J_2-\xi]$.

Next we set $\varphi(t,x)=\varphi_1(t)\varphi_2(x)$ and $v=\varphi u$. Then v satisfies

$$(1.9) \qquad m(x)\,\partial_{tt}v - \partial_x(a(x)\,\partial_x v) = g \quad \text{in } \mathscr{D}'(\Omega),$$

where

$$g = -b(x)\varphi u_t + 2m\varphi_t u_t + m\varphi_{tt}u - 2a\varphi_x u_x - a_x\varphi_x u - au\varphi_{xx}.$$

We let

$$(1.10) \qquad v_\varepsilon = v * \rho_\varepsilon, \quad g_\varepsilon = g * \rho_\varepsilon \quad \text{for small } \varepsilon > 0,$$

where $\rho_\varepsilon(t)$ is the regularizer defined by (0.8) and the convolution is taken in the t variable. Then, for every small $\varepsilon > 0$,

$$v_\varepsilon \in C_0^\infty((T_1, T_2)_t; H_0^1(J_1, J_2)_x)$$

and

$$(1.11) \qquad m(x)\,\partial_{tt}v_\varepsilon - \partial_x(a(x)\,\partial_x v_\varepsilon) = g_\varepsilon$$

holds. Hence, $\partial_x v_\varepsilon \in C_0^\infty((T_1, T_2)_t; H_0^1(J_1, J_2)_x)$. We shall show that $\{\partial_t v_\varepsilon(x)\}$ and $\{\partial_x v_\varepsilon(x)\}$ converge in $L^2(T_1, T_2)_t$ as $\varepsilon \to 0$ uniformly in $x \in [J_1, J_2]$. Let $w = v_\varepsilon - v_{\varepsilon'}$. Then

$$(1.12) \qquad m(x)\,\partial_{tt}w - \partial_x(a(x)\,\partial_x w) = g_\varepsilon - g_{\varepsilon'}.$$

Let us multiply (1.12) by w_x, choose any $x_0 \in [J_1, J_2]$, and integrate over $[T_1, T_2] \times [x_0, J_2]$:

$$\begin{aligned}(1.13)\qquad &\int_{T_1}^{T_2} m(x_0) w_t(t, x_0)^2\, dt + \int_{T_1}^{T_2} a(x_0) w_x(t, x_0)^2\, dt \\ &\leqq M \int_{T_1}^{T_2} \int_{J_1}^{J_2} (w_t^2 + w_x^2)\, dx\, dt + \int_{T_1}^{T_2} \int_{J_1}^{J_2} (g_\varepsilon - g_{\varepsilon'})^2\, dx\, dt,\end{aligned}$$

where M is a positive constant independent of x_0, ε, and ε'. We next choose any $t_0 \in [T_1, T_2]$, multiply (1.12) by w_t, and integrate over $[T_1, t_0] \times [J_1, J_2]$:

$$(1.14)\quad \int_{J_1}^{J_2} m(x) w_t(t_0, x)^2\, dx + \int_{J_1}^{J_2} a(x) w_x(t_0, x)^2\, dx = 2 \int_{T_1}^{t_0} \int_{J_1}^{J_2} (g_\varepsilon - g_{\varepsilon'}) w_t\, dx\, dt.$$

By virtue of Gronwall's inequality, it follows that

$$\begin{aligned}(1.15)\qquad &\int_{J_1}^{J_2} m(x) w_t(t, x)^2\, dx + \int_{J_1}^{J_2} a(x) w_x(t, x)^2\, dx \\ &\leqq M \int_{T_1}^{T_2} \int_{J_1}^{J_2} (g_\varepsilon - g_{\varepsilon'})^2\, dx\, dt \quad \text{for all } t \in [T_1, T_2],\end{aligned}$$

where M is a positive constant independent of ε and ε'. Combining (1.13) and (1.15), we obtain

$$(1.16)\qquad \int_{T_1}^{T_2} w_t(t, x_0)^2\, dt + \int_{T_1}^{T_2} w_x(t, x_0)^2\, dt \leqq M \int_{T_1}^{T_2} \int_{J_1}^{J_2} (g_\varepsilon - g_{\varepsilon'})^2\, dx\, dt,$$

where M is a positive constant independent of x_0, ε, and ε'. It follows from (1.16) that $\{\partial_t v_\varepsilon(x)\}$ and $\{\partial_x v_\varepsilon(x)\}$ converge in $L^2(T_1, T_2)_t$ uniformly in $x \in [J_1, J_2]$. Therefore, $\partial_t u, \partial_x u \in C([J_1 + \xi, J_2 - \xi]_x; L^2(T_1 + \delta, T_2 - \delta)_t)$. Since ξ is arbitrary, we conclude that

$$(1.17)\qquad \partial_t u, \partial_x u \in C((J_1, J_2)_x; L^2(T_1 + \delta, T_2 - \delta)_t),$$

for each $0 < \delta < (T_2 - T_1)/2$. Next we extend $m(x)$, $a(x)$, and $b(x)$ such that $\tilde{b}(x) \in C([J_1 - 1, J_2 + 1])$, $\tilde{m}(x)$ and $\tilde{a}(x) \in C^1([J_1 - 1, J_2 + 1])$ with $\tilde{m}(x), \tilde{a}(x) \geqq c/2 > 0$ for all $x \in [J_1 - 1, J_2 + 1]$. Then, we consider the hyperbolic system

$$(1.18)\quad \partial_t U - \begin{pmatrix} 0, & 1 \\ \tilde{a}(x)/\tilde{m}(x), & 0 \end{pmatrix} \partial_x U + \begin{pmatrix} 0, & 0 \\ -\tilde{a}_x(x)/\tilde{m}(x), & \tilde{b}(x)/\tilde{m}(x) \end{pmatrix} U = 0.$$

Let α be a positive constant such that

$$(1.19)\qquad \tilde{a}(x)/\tilde{m}(x) \geqq \alpha^2 \quad \text{for all } x \in [J_1 - 1, J_2 + 1].$$

Fix any small $\eta > 0$. We apply Lemma 1.1 by choosing $\binom{\partial_x u}{\partial_t u}$ at $x = J_1 + \eta$ as the initial datum to find a function

$$U \in C([J_1 - 1, J_1 + \eta]_x; L^2(T_1 + \delta, T_2 - \delta)_t),$$

which is equal to $\binom{\partial_x u}{\partial_t u}$ in $(J_1, J_1 + \eta) \times (T_1 + \delta + \eta/\alpha, T_2 - \delta - \eta/\alpha)$. Since δ and η are arbitrary, we derive that $\partial_t u, \partial_x u \in C([J_1, J_2)_x; L^2(T_1 + \delta, T_2 - \delta)_t)$ for each small $\delta > 0$. Similarly, we can apply Lemma 1.1 near $x = J_2$ and obtain the continuity at $x = J_2$. Now the proof of (1.5) is complete.

To obtain the estimate (1.7), we first derive an analogue of (1.13) for v_ε defined by (1.10):

$$(1.20)\quad \int_{T_1}^{T_2} v_{\varepsilon t}(t,x)^2\,dt + \int_{T_1}^{T_2} v_{\varepsilon x}(t,x)^2\,dt \leqq M(\delta,\xi)\|u\|^2_{H^1(\Omega)} \quad \text{for all } x\in[J_1,J_2],$$

where $M(\delta,\xi)$ is a positive constant depending only on δ and ξ. It follows from (1.20) that

$$(1.21)\qquad \int_{T_1+\delta}^{T_2-\delta} (u_t(t,x)^2+u_x(t,x)^2)\,dt \leqq M(\delta,\xi)\|u\|^2_{H^1(\Omega)},$$

for each $x\in[J_1+\xi, J_2-\xi]$.

Again we apply Lemma 1.1 with the initial datum $\binom{\partial_x u}{\partial_t u}$ at $x=J_1+\xi$ and at $x=J_2-\xi$, respectively. Formulas (1.3) and (1.21) imply

$$(1.22)\qquad \begin{aligned}&\int_{T_1+\delta+\xi/\alpha}^{T_2-\delta-\xi/\alpha} (u_t(t,x)^2+u_x(t,x)^2)\,dt\\ &\leqq M(\delta,\xi)\|u\|^2_{H^1(\Omega)} \quad \text{for all } x\in[J_1,J_1+\xi]\cup[J_2-\xi,J_2],\end{aligned}$$

where $M(\delta,\xi)$ is a positive constant depending only on δ and ξ. Since δ and ξ are arbitrary, it follows from (1.21) and (1.22) that for each $\delta>0$,

$$(1.23)\qquad \int_{T_1+\delta}^{T_2-\delta} (u_t(t,x)^2+u_x(t,x)^2)\,dt \leqq M_\delta\|u\|^2_{H^1(\Omega)},$$

for all $x\in[J_1,J_2]$. Next we let

$$(1.24)\qquad \tilde u = u - \frac{1}{\operatorname{meas}(\Omega)}\int_\Omega u(t,x)\,dt\,dx.$$

Then, $\tilde u\in H^1(\Omega)$ and satisfies (1.4). Therefore, $\tilde u$ satisfies (1.23)

$$(1.25)\qquad \int_{T_1+\delta}^{T_2-\delta} (\tilde u_t(t,x)^2+\tilde u_x(t,x)^2)\,dt \leqq M_\delta\|\tilde u\|^2_{H^1(\Omega)},$$

for all $x\in[J_1,J_2]$. But, $\partial_t u=\partial_t\tilde u$, $\partial_x u=\partial_x\tilde u$, and, by Poincare's inequality,

$$(1.26)\qquad \|\tilde u\|_{H^1(\Omega)} \leqq C(\|\partial_t\tilde u\|_{L^2(\Omega)}+\|\partial_x\tilde u\|_{L^2(\Omega)})$$

holds. Now (1.7) is obvious. The proof of (1.6) and (1.8) can be carried out in a similar manner, and we omit the details.

LEMMA 1.3. *Let $\Omega=(T_1,T_2)\times(J_1,J_2)$, $b(x)\in C([J_1,J_2])$, and $m(x), a(x)\in C^1([J_1,J_2])$ with $m(x), a(x)\geqq c>0$, for all $x\in[J_1,J_2]$. Suppose that u satisfies*

$$(1.27)\qquad u\in H^1(\Omega),$$

$$(1.28)\qquad m(x)\,\partial_{tt}u-\partial_x(a(x)\,\partial_x u)+b(x)\,\partial_t u=0 \quad \text{in } \mathscr{D}'(\Omega).$$

Then, it holds that

$$(1.29)\qquad \|\partial_x u\|_{L^2(\Omega_\delta)} \leqq M_\delta(\|\partial_t u\|_{L^2(\Omega)}+\|u\|_{L^2(\Omega)}),$$

for each small $\delta>0$, where

$$\Omega_\delta=(T_1+\delta, T_2-\delta)\times(J_1+\delta, J_2-\delta),$$

and M_δ is a positive constant independent of u and dependent only on δ.

Proof. It follows from (1.9)

$$(1.30)\quad -\int_\Omega m(x)v_t(t,x)^2\,dt\,dx+\int_\Omega a(x)v_x(t,x)^2\,dt\,dx=\int_\Omega g(t,x)v(t,x)\,dt\,dx.$$

Using $\varphi_x u_x=\partial_x(\varphi_x u)-\varphi_{xx}u$ and integration by parts, we can easily derive (1.29) from (1.30).

2. Main result. Throughout this section, we assume the following:

(i) $m_1(x), a_1(x)\in C^1([L_1,L_2])$ and

$$(2.1)\qquad m_1(x), a_1(x)\geqq\beta_1>0\quad\text{for all } x\in[L_1,L_2].$$

(ii) $m_2(x), a_2(x)\in C^1([L_2,L_3])$ and

$$(2.2)\qquad m_2(x), a_2(x)\geqq\beta_2>0\quad\text{for all } x\in[L_2,L_3].$$

(iii) $b(x)\in C([L_2,L_3])$ and

$$(2.3)\qquad b(x)\geqq\beta_3>0\quad\text{for all } x\in[L_2,L_3].$$

Here β_i's are positive constants, and we do not assume that $a_1(L_2)=a_2(L_2)$ or $m_1(L_2)=m_2(L_2)$.

We define

$$(2.4)\qquad \zeta=4(L_3-L_1)\left\{\max_{x\in[L_1,L_2]}(m_1(x)/a_1(x))^{1/2}+\max_{x\in[L_2,L_3]}(m_2(x)/a_2(x))^{1/2}\right\}.$$

Before we present the main result on the uniform stabilization, the existence and uniqueness of solutions should be made precise.

LEMMA 2.1. *If $u_0(x)\in H_0^1(L_1,L_3)$ and $u_1(x)\in L^2(L_1,L_3)$, then there is a unique function u such that*

$$(2.5)\qquad u\in C([0,\infty)_t;H_0^1(L_1,L_3)_x),\qquad \partial_t u\in C([0,\infty)_t;L^2(L_1,L_3)_x),$$

$$(2.6)\qquad u(0,x)=u_0(x),\quad \partial_t u(0,x)=u_1(x)\quad \textit{for almost all } x\in(L_1,L_3),$$

$$(2.7)\qquad \begin{aligned}&-\int_0^\infty\int_{L_1}^{L_2} m_1(x)u_t\phi_t\,dx\,dt-\int_0^\infty\int_{L_2}^{L_3} m_2(x)u_t\phi_t\,dx\,dt\\&+\int_0^\infty\int_{L_1}^{L_2} a_1(x)u_x\phi_x\,dx\,dt+\int_0^\infty\int_{L_2}^{L_3} a_2(x)u_x\phi_x\,dx\,dt\\&+\int_0^\infty\int_{L_2}^{L_3} b(x)u_t\phi\,dx\,dt=0\end{aligned}$$

holds for every $\phi\in C_0^\infty((0,\infty)\times(L_1,L_3))$.

Proof. This lemma seems to be known. We can prove this by following the procedure in the proof of Theorem 8.1 of [6, p. 265] and Theorem 8.2 of [6, p. 275]. The argument is due to [8]. We omit the details.

Next we show that the above solution satisfies the transmission condition at $x=L_2$.

LEMMA 2.2. *For any $T>0$, the above solution u satisfies:*

$$(2.8)\qquad \partial_t u, \partial_x u\in C([L_1,L_2]_x;L^2(0,T)_t),$$

$$(2.9)\qquad \partial_t u, \partial_x u\in C([L_2,L_3]_x;L^2(0,T)_t),$$

$$(2.10)\qquad \lim_{x\to L_2-}u(t,x)=\lim_{x\to L_2+}u(t,x)\quad \textit{in } C([0,T]_t),$$

$$(2.11)\qquad \lim_{x\to L_2-}a_1(x)\,\partial_x u(t,x)=\lim_{x\to L_2+}a_2(x)\,\partial_x u(t,x)\quad \textit{in } L^2(0,T)_t.$$

Proof. It is easy to see that the solution can be uniquely extended to $(-\infty, \infty)_t$ so that

$$u \in C((-\infty, \infty)_t; H_0^1(L_1, L_3)_x), \tag{2.12}$$

$$\partial_t u \in C((-\infty, \infty)_t; L^2(L_1, L_3)_x). \tag{2.13}$$

Now (2.8) and (2.9) follow from Lemma 1.2. Condition (2.12) implies (2.10).

To show (2.11), we fix any $T > 0$ and $\psi \in C_0^\infty((0, T))$.

Let us denote by $[,]$ the L^2 inner product in $L^2(0, T)_t$. Then, according to (2.7),

$$\begin{aligned} &-\int_{L_1}^{L_2} m_1(x)[u_t, \psi_t](x)\phi(x)\,dx - \int_{L_2}^{L_3} m_2(x)[u_t, \psi_t](x)\phi(x)\,dx \\ &+\int_{L_1}^{L_2} a_1(x)[u_x, \psi](x)\phi_x(x)\,dx + \int_{L_2}^{L_3} a_2(x)[u_x, \psi](x)\phi_x(x)\,dx \\ &+\int_{L_2}^{L_3} b(x)[u_t, \psi](x)\phi(x)\,dx = 0, \end{aligned} \tag{2.14}$$

holds for each $\phi \in C_0^\infty((L_1, L_3))$.

This implies, by choosing $\phi \in C_0^\infty((L_1, L_2))$ and $\phi \in C_0^\infty((L_2, L_3))$,

$$-m_1(x)[u_t, \psi_t](x) - \partial_x(a_1(x)[u_x, \psi](x)) = 0 \quad \text{in } \mathscr{D}'((L_1, L_2)_x), \tag{2.15}$$

and

$$-m_2(x)[u_t, \psi_t](x) - \partial_x(a_2(x)[u_x, \psi](x)) + b(x)[u_t, \psi](x) = 0 \quad \text{in } \mathscr{D}'((L_2, L_3)_x). \tag{2.16}$$

Since $[u_t, \psi_t](x) \in L^2(L_1, L_3)$, we infer from (2.15) and (2.16) that $\partial_x(a_1(x)[u_x, \psi](x)) \in L^2(L_1, L_2)$ and $\partial_x(a_2(x)[u_x, \psi](x)) \in L^2(L_2, L_3)$, and that (2.15) and (2.16) hold in $L^2(L_1, L_2)$ and $L^2(L_2, L_3)$, respectively. Hence, for each $\phi \in C_0^\infty((L_1, L_3))$,

$$\begin{aligned} &-\int_{L_1}^{L_2} m_1(x)[u_t, \psi_t](x)\phi(x)\,dx - \int_{L_2}^{L_3} m_2(x)[u_t, \psi_t](x)\phi(x)\,dx \\ &-\int_{L_1}^{L_2} \phi(x)\,\partial_x(a_1(x)[u_x, \psi](x))\,dx - \int_{L_2}^{L_3} \phi(x)\,\partial_x(a_2(x)[u_x, \psi](x))\,dx \\ &+\int_{L_2}^{L_3} b(x)[u_t, \psi](x)\phi(x)\,dx = 0. \end{aligned} \tag{2.17}$$

After integration by parts using (2.8) and (2.9), we compare (2.14) and (2.17) so that

$$\lim_{x \to L_2-} \phi(x)a_1(x)[u_x, \psi](x) = \lim_{x \to L_2+} \phi(x)a_2(x)[u_x, \psi](x). \tag{2.18}$$

Since (2.18) holds for all $\phi \in C_0^\infty((L_1, L_3))$ and $\psi \in C_0^\infty((0, T))$, (2.8) and (2.9) imply (2.11). This completes the proof of Lemma 2.2.

We are now ready to present the main result. Let u be the above solution and we set

$$E(t) = \langle u_t, u_t\rangle_1 + \langle u, u\rangle_2, \tag{2.19}$$

where $\langle,\rangle_1$ and $\langle,\rangle_2$ are defined by

$$\langle \varphi_1, \varphi_2\rangle_1 = \int_{L_1}^{L_2} m_1(x)\varphi_1(x)\varphi_2(x)\,dx + \int_{L_2}^{L_3} m_2(x)\varphi_1(x)\varphi_2(x)\,dx, \tag{2.20}$$

$$\langle \varphi_1, \varphi_2\rangle_2 = \int_{L_1}^{L_2} a_1(x)(\partial_x\varphi_1)(\partial_x\varphi_2)\,dx + \int_{L_2}^{L_3} a_2(x)(\partial_x\varphi_1)(\partial_x\varphi_2)\,dx. \tag{2.21}$$

The main result is Theorem 2.3.

THEOREM 2.3. *There are constants $C>0$ and $\alpha>0$ independent of u such that*

$$E(t)\leqq Ce^{-\alpha t}E(0) \quad \textit{for all } t\geqq 0. \tag{2.22}$$

The remainder of this section will be expended on the proof of (2.22).

The basic idea is to establish

$$E(T)\leqq k(T)E(0) \tag{2.23}$$

for some $T>0$, where $0<k(T)<1$ is a constant independent of u. Formula (2.23) implies (2.22). For (2.23), we need Lemma 2.4.

LEMMA 2.4. *Let $T>3\zeta$ (defined by (2.4)) and define a function space*

$$X=\{v\in H^1((0,T)\times(L_1,L_3)):\ v(t,L_1)=v(t,L_3)=0$$

$$\textit{for almost all } t\in(0,T), \textit{ and } v \textit{ satisfies}$$

$$(2.7)\ \textit{for every } \phi\in H_0^1((0,T)\times(L_1,L_3))\}.$$

Then for each $\varepsilon>0$, there is a positive constant $C(T,\varepsilon)$ such that

$$\int_\zeta^{T-\zeta}(\langle v_t,v_t\rangle_1+\langle v,v\rangle_2)\,dt\leqq C(T,\varepsilon)\int_0^T\int_{L_2}^{L_3}v_t^2\,dx\,dt+\varepsilon\int_0^T\int_{L_2}^{L_3}v^2\,dx\,dt, \tag{2.24}$$

for all $v\in X$.

We shall show that (2.24) implies (2.23).

First, $E(t)$ satisfies

$$E(t_2)=E(t_1)-2\int_{t_1}^{t_2}\int_{L_2}^{L_3}b(x)u_t^2\,dx\,dt \quad \text{for all } t_2\geqq t_1\geqq 0. \tag{2.25}$$

Since $u\in C([0,T]_t;H_0^1(L_1,L_3)_x)$ and $E(t)$ is nonincreasing in t by (2.25), it is easy to see that

$$\int_0^T\int_{L_2}^{L_3}u^2\,dx\,dt\leqq MTE(0), \tag{2.26}$$

where M is a positive constant independent of u and T. By choosing $\varepsilon=1/T$, it follows from (2.3), (2.24), (2.25), and (2.26) that

$$\int_\zeta^{T-\zeta}E(t)\,dt\leqq\frac{1}{2\beta_3}(E(0)-E(T))C\left(T,\frac{1}{T}\right)+ME(0). \tag{2.27}$$

Since $E(t)$ is nonincreasing in t, we have

$$TE(T)\leqq\int_\zeta^{T-\zeta}E(t)\,dt+2\zeta E(0), \tag{2.28}$$

which, combined with (2.27), yields

$$\left\{T+\frac{1}{2\beta_3}C\left(T,\frac{1}{T}\right)\right\}E(T)\leqq\left\{M+2\zeta+\frac{1}{2\beta_3}C\left(T,\frac{1}{T}\right)\right\}E(0). \tag{2.29}$$

Hence, by taking $T>M+2\zeta$, we get (2.23).

Before proceeding to prove Lemma 2.4, we need to show Lemma 2.5.

LEMMA 2.5. *Let $v\in X$. Then v satisfies*

$$\lim_{x\to L_2-}\partial_t v(t,x)=\lim_{x\to L_2+}\partial_t v(t,x) \quad \textit{in } L^2(\delta,T-\delta) \textit{ for any } \delta>0, \tag{2.30}$$

$$\lim_{x\to L_2-}a_1(x)\,\partial_x v(t,x)=\lim_{x\to L_2+}a_2(x)\,\partial_x v(t,x) \quad \textit{in } L^2(\delta,T-\delta) \textit{ for any } \delta>0. \tag{2.31}$$

Proof. Since $\partial_x v \in L^2((0, T) \times (L_1, L_3))$, we find that $v \in C([L_1, L_3]_x; L^2(0, T)_t)$ possibly after a modification on a set of measure zero. Thus, we have

$$\lim_{x \to L_2-} v(t, x) = \lim_{x \to L_2+} v(t, x) \quad \text{in } L^2(0, T)_t. \tag{2.32}$$

In the meantime, it follows from Lemma 1.2 that

$$\partial_t v, \partial_x v \in C([L_1, L_2]_x; L^2(\delta, T-\delta)_t), \tag{2.33}$$

$$\partial_t v, \partial_x v \in C([L_2, L_3]_x; L^2(\delta, T-\delta)_t), \tag{2.34}$$

for any $\delta > 0$, which, together with (2.32), yield (2.30). Equation (2.31) can be derived by the same argument as for (2.11), and we omit the details.

Proof of Lemma 2.4. Suppose that (2.24) is false. Then there is some $\varepsilon_0 > 0$ and sequences $\{C_n\}_{n=1}^{\infty}, \{v_n\}_{n=1}^{\infty} \subset X$ such that $C_n \to \infty$ and

$$\int_{\zeta}^{T-\zeta} (\langle \partial_t v_n, \partial_t v_n \rangle_1 + \langle v_n, v_n \rangle_2)\, dt > C_n \int_0^T \int_{L_2}^{L_3} (\partial_t v_n)^2\, dx\, dt + \varepsilon_0 \int_0^T \int_{L_2}^{L_3} v_n^2\, dx\, dt. \tag{2.35}$$

Meanwhile, it follows from Lemma 1.2 that for all $x \in [L_2, L_3]$,

$$\int_{3\zeta/4}^{T-3\zeta/4} \{(\partial_t v_n(t, x))^2 + (\partial_x v_n(t, x))^2\}\, dt \leqq C \int_{\zeta/2}^{T-\zeta/2} \int_{L_2}^{L_3} \{(\partial_t v_n)^2 + (\partial_x v_n)^2\}\, dx\, dt, \tag{2.36}$$

where C is a positive constant independent of v_n.

Noting that $U = \binom{\partial_x v_n}{\partial_t v_n}$ satisfies

$$\partial_t U - \begin{pmatrix} 0, & 1 \\ a_1(x)/m_1(x), & 0 \end{pmatrix} \partial_x U + \begin{pmatrix} 0, & 0 \\ -\partial_x a_1(x)/m_1(x), & 0 \end{pmatrix} U = 0, \tag{2.37}$$

in $(0, T) \times (L_1, L_2)$ and recalling (2.4), we can use (1.3) of Lemma 1.1 to derive for all $x \in [L_1, L_2]$,

$$\begin{aligned} &\int_{\zeta}^{T-\zeta} \{(\partial_t v_n(t, x))^2 + (\partial_x v_n(t, x))^2\}\, dt \\ &\qquad \leqq C \int_{3\zeta/4}^{T-3\zeta/4} \{(\partial_t v_n(t, L_2))^2 + (\partial_x v_n(t, L_2))^2\}\, dt, \end{aligned} \tag{2.38}$$

where C denotes a positive constant independent of v_n.

Now, we combine Lemma 2.5, (2.36), and (2.38) to find

$$\begin{aligned} &\int_{\zeta}^{T-\zeta} \int_{L_1}^{L_2} \{m_1(x)(\partial_t v_n)^2 + a_1(x)(\partial_x v_n)^2\}\, dx\, dt \\ &\qquad \leqq C \int_{\zeta/2}^{T-\zeta/2} \int_{L_2}^{L_3} \{m_2(x)(\partial_t v_n)^2 + a_2(x)(\partial_x v_n)^2\}\, dx\, dt, \end{aligned} \tag{2.39}$$

where C is a positive constant independent of v_n. Hence, it follows that

$$\begin{aligned} &\int_{\zeta/2}^{T-\zeta/2} \int_{L_2}^{L_3} \{m_2(x)(\partial_t v_n)^2 + a_2(x)(\partial_x v_n)^2\}\, dx\, dt \\ &\qquad > \frac{C_n}{C+1} \int_0^T \int_{L_2}^{L_3} (\partial_t v_n)^2\, dx\, dt + \frac{\varepsilon_0}{C+1} \int_0^T \int_{L_2}^{L_3} v_n^2\, dx\, dt. \end{aligned} \tag{2.40}$$

Now we set

$$w_n = v_n \Bigg/ \left(\int_{\zeta/2}^{T-\zeta/2} \int_{L_2}^{L_3} \{m_2(x)(\partial_t v_n)^2 + a_2(x)(\partial_x v_n)^2\}\, dx\, dt \right)^{1/2}. \tag{2.41}$$

Then $w_n \in X$ and

$$\int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3}\{m_2(x)(\partial_t w_n)^2 + a_2(x)(\partial_x w_n)^2\}\,dx\,dt = 1, \tag{2.42}$$

$$1 > \frac{C_n}{C+1}\int_0^T\int_{L_2}^{L_3}(\partial_t w_n)^2\,dx\,dt + \frac{\varepsilon_0}{C+1}\int_0^T\int_{L_2}^{L_3} w_n^2\,dx\,dt, \tag{2.43}$$

hold for every n.

According to Lemma 1.3, we derive from (2.43)

$$\int_{\zeta/8}^{T-\zeta/8}\int_{L_2+\eta}^{L_3-\eta}(\partial_x w_n)^2\,dx\,dt \leqq M \quad \text{for all } n, \tag{2.44}$$

where $\eta = \frac{1}{4}(L_3 - L_2)$ and M is a positive constant. By means of (2.43), (2.44), we can apply Lemmas 1.1 and 1.2 in the same manner as for (2.39) to obtain

$$\int_{\zeta/4}^{T-\zeta/4}\left(\int_{L_2}^{L_2+\eta} + \int_{L_3-\eta}^{L_3}\right)(\partial_x w_n)^2\,dx\,dt \leqq M \quad \text{for all } n, \tag{2.45}$$

so that

$$\int_{\zeta/4}^{T-\zeta/4}\int_{L_2}^{L_3}\{(\partial_x w_n)^2 + (\partial_t w_n)^2\}\,dx\,dt \leqq M \quad \text{for all } n. \tag{2.46}$$

Again by the same argument as for (2.39), we obtain from (2.46)

$$\int_{\zeta/2}^{T-\zeta/2}\int_{L_1}^{L_2}\{(\partial_x w_n)^2 + (\partial_t w_n)^2\}\,dx\,dt \leqq M \quad \text{for all } n. \tag{2.47}$$

By (2.46) and (2.47), we can extract a subsequence still denoted by $\{w_n\}$ such that

$$\partial_x w_n \to \partial_x w_\infty \text{ weakly in } L^2((\zeta/2, T-\zeta/2)\times(L_1, L_3)) \cap L^2((\zeta/4, T-\zeta/4)\times(L_2, L_3)), \tag{2.48}$$

$$\partial_t w_n \to \partial_t w_\infty \text{ weakly in } L^2((\zeta/2, T-\zeta/2)\times(L_1, L_3)) \cap L^2((\zeta/4, T-\zeta/4)\times(L_2, L_3)), \tag{2.49}$$

for some $w_\infty \in L^2(\zeta/2, T-\zeta/2; H_0^1(L_1, L_3)_x) \cap H^1((\zeta/4, T-\zeta/4)\times(L_2, L_3))$ with $\partial_t w_\infty \in L^2((\zeta/2, T-\zeta/2)\times(L_1, L_3)) \cap L^2((\zeta/4, T-\zeta/4)\times(L_2, L_3))$. This w_∞ also satisfies

$$\int_{\zeta/2}^{T-\zeta/2}(-\langle\partial_t w_\infty, \partial_t\phi\rangle_1 + \langle w_\infty, \phi\rangle_2)\,dt + \int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3} b(x)(\partial_t w_\infty)\phi\,dx\,dt = 0, \tag{2.50}$$

for every $\phi \in H_0^1((\zeta/2, T-\zeta/2)\times(L_1, L_3))$, and a similar equation for every $\phi \in H_0^1((\zeta/4, T-\zeta/4)\times(L_2, L_3))$. Next we shall investigate the implication of (2.42) and (2.43) on w_∞. The following version of the div-curl lemma is useful.

LEMMA 2.6. *Let $\{p_n\}_{n=1}^\infty$, $\{q_n\}_{n=1}^\infty$, $\{r_n\}_{n=1}^\infty$, and $\{s_n\}_{n=1}^\infty$ be bounded sequences in $L^2(\Omega)$, where Ω is a bounded open subset of R^2. Suppose that $\partial_x p_n = \partial_t q_n$, for each n and that $\{\partial_t r_n + \partial_x s_n\}_{n=1}^\infty$ is bounded in $L^2(\Omega)$. If $p_n \to p$, $q_n \to q$, $r_n \to r$ and $s_n \to s$ weakly in $L^2(\Omega)$, then*

$$p_n r_n + q_n s_n \to pr + qs \quad \text{in } \mathscr{D}'(\Omega).$$

Proof. See [4] for the proof.

By setting $p_n=\partial_t w_n$, $q_n=\partial_x w_n$, $r_n=m_2(x)\,\partial_t w_n$, $s_n=-a_2(x)\,\partial_x w_n$, we use (2.46), (2.48), (2.49), and

$$m_2(x)\,\partial_{tt}w_n-\partial_x(a_2(x)\,\partial_x w_n)+b(x)\,\partial_t w_n=0 \quad \text{in } \mathscr{D}'((0,T)\times(L_2,L_3)) \tag{2.51}$$

to conclude

$$\begin{aligned} &m_2(x)(\partial_t w_n)^2-a_2(x)(\partial_x w_n)^2\\ &\quad\to m_2(x)(\partial_t w_\infty)^2-a_2(x)(\partial_x w_\infty)^2 \quad \text{in } \mathscr{D}'((\zeta/4,T-\zeta/4)\times(L_2,L_3)).\end{aligned} \tag{2.52}$$

By virtue of (1.7), (1.8), and (2.46), we find

$$\begin{aligned}&\int_{\zeta/2}^{T-\zeta/2}\left(\int_{L_2}^{L_2+\varepsilon_1}+\int_{L_3-\varepsilon_1}^{L_3}\right)\{(\partial_x w_n)^2+(\partial_t w_n)^2\}\,dx\,dt\le M\varepsilon_1\\ &\qquad\qquad\text{for all } n \text{ and all small } \varepsilon_1>0,\end{aligned} \tag{2.53}$$

$$\begin{aligned}&\int_{L_2+\varepsilon_1}^{L_3-\varepsilon_1}\left(\int_{\zeta/2}^{\zeta/2+\varepsilon_2}+\int_{T-\zeta/2-\varepsilon_2}^{T-\zeta/2}\right)\{(\partial_x w_n)^2+(\partial_t w_n)^2\}\,dt\,dx\leqq C(\varepsilon_1)\varepsilon_2\\ &\qquad\qquad\text{for all } n \text{ and all small } \varepsilon_2>0.\end{aligned} \tag{2.54}$$

Here, M and $C(\varepsilon_1)$ are positive constants.

Fix any small $\varepsilon>0$, and choose ε_1 so that

$$M\varepsilon_1<\varepsilon \qquad (M \text{ is the same as in (2.53)}) \tag{2.55}$$

and then, choose ε_2 so that

$$C(\varepsilon_1)\varepsilon_2<\varepsilon \qquad (C(\varepsilon_1) \text{ is the same as in (2.54)}). \tag{2.56}$$

There is a function $\Psi\in C_0^\infty((\zeta/2,T-\zeta/2)\times(L_2,L_3))$ such that $0\leqq\Psi\leqq1$ and $\Psi(t,x)=1$, for $(t,x)\in[\zeta/2+\varepsilon_2,T-\zeta/2-\varepsilon_2]\times[L_2+\varepsilon_1,L_3-\varepsilon_1]$.

By (2.52), it is clear that

$$\begin{aligned}&\lim_{n\to\infty}\int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3}\Psi\{m_2(x)(\partial_t w_n)^2-a_2(x)(\partial_x w_n)^2\}\,dx\,dt\\ &\quad=\int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3}\Psi\{m_2(x)(\partial_t w_\infty)^2-a_2(x)(\partial_x w_\infty)^2\}\,dx\,dt.\end{aligned} \tag{2.57}$$

Combining (2.53)-(2.57), we obtain

$$\begin{aligned}&\overline{\lim_{n\to\infty}}\left|\int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3}\{m_2(x)(\partial_t w_n)^2-a_2(x)(\partial_x w_n)^2\}\,dx\,dt\right.\\ &\qquad\left.-\int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3}\{m_2(x)(\partial_t w_\infty)^2-a_2(x)(\partial_x w_\infty)^2\}\,dx\,dt\right|\\ &\qquad<C\varepsilon \quad \text{where } C \text{ is a positive constant independent of } \varepsilon.\end{aligned} \tag{2.58}$$

Note that w_∞ also satisfies (2.53) and (2.54). Since ε is arbitrary, we have

$$\begin{aligned}&\lim_{n\to\infty}\int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3}\{m_2(x)(\partial_t w_n)^2-a_2(x)(\partial_x w_n)^2\}\,dx\,dt\\ &\quad=\int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3}\{m_2(x)(\partial_t w_\infty)^2-a_2(x)(\partial_x w_\infty)^2\}\,dx\,dt.\end{aligned} \tag{2.59}$$

In the meantime, it follows from (2.43) that

$$\lim_{n\to\infty}\int_0^T\int_{L_2}^{L_3}(\partial_t w_n)^2\,dx\,dt=0 \tag{2.60}$$

and thus

$$\int_{\zeta/4}^{T-\zeta/4}\int_{L_2}^{L_3}(\partial_t w_\infty)^2\,dx\,dt=0. \tag{2.61}$$

Now we see from (2.42), (2.59), (2.60), and (2.61) that

$$\int_{\zeta/2}^{T-\zeta/2}\int_{L_2}^{L_3}a_2(x)(\partial_x w_\infty)^2\,dx\,dt=1. \tag{2.62}$$

Since $\partial_t w_\infty\equiv 0$ in $(\zeta/4, T-\zeta/4)\times(L_2, L_3)$, it follows from Lemma 1.2 that

$$\lim_{x\to L_2+}a_2(x)\partial_x w_\infty(t,x)=\beta \quad \text{in } L^2(\zeta/2, T-\zeta/2), \tag{2.63}$$

for some constant β. By the same argument as for (2.30) and (2.31), we see that

$$\lim_{x\to L_2-}\partial_t w_\infty(t,x)=0 \quad \text{in } L^2(3\zeta/4, T-3\zeta/4), \tag{2.64}$$

$$\lim_{x\to L_2-}a_1(x)\,\partial_x w_\infty(t,x)=\beta \quad \text{in } L^2(3\zeta/4, T-3\zeta/4). \tag{2.65}$$

Let us consider the initial value problem:

$$-\begin{pmatrix}0, & 1\\ a_1(x)/m_1(x), & 0\end{pmatrix}\partial_x Y-\begin{pmatrix}0, & 0\\ \partial_x a_1(x)/m_1(x), & 0\end{pmatrix}Y=0, \tag{2.66}$$

$$Y(L_2)=\begin{pmatrix}\beta/a_1(L_2)\\ 0\end{pmatrix}. \tag{2.67}$$

Then, by Lemma 1.1, we conclude that

$$Y(x)=\begin{pmatrix}\partial_x w_\infty(t,x)\\ \partial_t w_\infty(t,x)\end{pmatrix} \quad \text{in } (\zeta, T-\zeta)\times(L_1, L_2). \tag{2.68}$$

Consequently, $\partial_t w_\infty\equiv 0$ in $(\zeta, T-\zeta)\times(L_1, L_3)$, and w_∞ satisfies, according to (2.50),

$$\langle w_\infty, \phi\rangle_2=0 \quad \text{for all } \phi\in H_0^1((L_1, L_3)), \tag{2.69}$$

which yields $w_\infty\equiv 0$ in $(\zeta, T-\zeta)\times(L_1, L_3)$. This contradicts (2.62), for $\partial_t w_\infty\equiv 0$ in $(\zeta/2, T-\zeta/2)\times(L_2, L_3)$. This completes the proof.

3. Final remarks. We have considered only a special combination of different bars. But it is obvious that the same method can be applied to any combination of several different bars at least one of which is damped.

In (2.3), we assumed that $b(x)\geqq\beta_3>0$, for all $x\in[L_2, L_3]$. If $b(x)\geqq\beta_3>0$, only for $x\in I\subset[L_2, L_3]$, then we can regard the bar as a combination of different bars: $[L_2, L_3]=I\cup$(one or two segments). Then, the same method can be still applied.

It is also easy to see that the boundary condition at one end can be replaced by the homogeneous Neumann boundary condition.

Note added in proof. After this paper was submitted, the author found the works of Ho [9] and Lagnese [10] which are closely related to our problem. They considered the case of smooth coefficients without discontinuity by different methods.

ON A CONVEX PARAMETER SPACE METHOD FOR LINEAR CONTROL DESIGN OF UNCERTAIN SYSTEMS*

J. C. GEROMEL†, P. L. D. PERES†, AND J. BERNUSSOU‡

Abstract. This paper presents a new procedure for continuous and discrete-time linear control systems design. It consists of the definition of a *convex* programming problem in the parameter space that, when solved, provides the feedback gain. One of the most important features of the procedure is that additional design constraints are easily incorporated in the original formulation, yielding solutions to problems that have raised a great deal of interest within the last few years. This is precisely the case of the decentralized control problem and the quadratic stabilizability problem of uncertain systems with both dynamic and input uncertain matrices. In this last case, necessary and sufficient conditions for the existence of a linear stabilizing gain are provided and, to the authors' knowledge, this is one of the first numerical procedures able to handle and solve this interesting design problem for high-order, continuous-time or discrete-time linear models. The theory is illustrated by examples.

Key words. linear system control, linear programming, cutting-plane techniques, robust control

1. Introduction. The Linear-Quadratic Problem (LQP) has been extensively studied in the last decades. As a natural consequence of an enormous deal of work and interest, many properties of its solution came to light (see, for instance, [1] and the references therein). One of the most important properties states that the optimal solution of the LQP can be expressed as a linear feedback law which stabilizes the closed-loop system. It can be numerically determined by finding the positive-definite solution of a Riccati-type equation which also provides a quadratic Lyapunov function associated with the closed-loop system [1]. This important fact has served as a basis for the analysis of the dynamic behaviour of the closed-loop system when subjected to several classes of perturbations yielding many known robustness conditions [9], [21], [22].

However, almost all properties of the LQP, including those mentioned above, disappear when any additional design constraints are added. Among the problems raised, either the linearity of the optimal control law is lost or the associated problem to be solved in the parameter space (the elements of the matrix gain) does not present any property like convexity which obviously is an interesting one for optimization purposes [8], [15]. Furthermore, generally an initial feasible gain which stabilizes the system is asked for and this can be a difficult task depending on the strucure of the design constraints. In the case of the decentralized control problem, a tentative can be made from the solutions of the LQP associated to the isolated subsystems. Unfortunately, this procedure works only if the plant is weakly coupled [23] or if certain matching conditions are fulfilled [10].

More recently, the LQP has been used to determine stabilizing feedback gains for uncertain systems (see [24] and the references therein). When some matching conditions are fulfilled, the stabilizing gain is determined from a Riccati-type equation, provided

it admits a positive-definite solution [17]. However, it is important to keep in mind that in all cases we must handle a nonlinear equation that probably must be solved many times until it is decided whether or not there is a positive-definite solution [12], [17]. This can be a serious drawback mainly if high-order systems are under consideration.

In this paper we propose a convex parameter space method for linear system control design. It is based on the fact that the stabilizability property is related to the existence of a nonempty convex cone defined on the parameter space in the elements of a positive-definite matrix. Consequently, the feedback control synthesis derives from the global solution of a *convex* problem defined over the above-mentioned convex cone.[1]

The paper contributes in several directions. First, the convexity of the design problem opens the possibility of solving it, directly in the parameter space, by means of the most powerful tools available to date in the mathematical programming literature. Furthermore, additional convex design constraints are easily incorporated into the original problem. This fact allows us to solve the decentralized control problem for a wide class (called strongly decentralized) of linear dynamic systems. Necessary and sufficient conditions for its solvability are provided. Another contribution is related to the concept of quadratic stabilizability of uncertain systems [3]. Assuming the set of uncertainties is bounded and convex (an hyper-rectangle, for instance), the uncertain system is shown to be quadratically stabilizable if and only if the intersection of a finite number of convex cones is nonempty. This simplifies the results of [3] and enables us once again to find the Lyapunov function by means of a convex problem. The feedback gain is found directly from its solution which is numerically determined by constraints generation or by its dual the Dantzig–Wolfe decomposition principle (column generation) [13]. Finally, all the results above are generalized to discrete-time systems. In this case, the quadratic stabilizability problem is solved for the first time without assuming any special system structure or matching conditions.

The paper is organized as follows. The first sections are devoted to the analysis of continuous-time systems. In § 2 some definitions are introduced and the basic design problem is stated. Extensions for dealing with decentralized control and quadratic stabilization of uncertain systems are considered in § 3. Since one of the main control objectives is to get a small feedback gain, the index of the basic design problem is chosen for this purpose.[2] It will be defined in terms of an extended system model introduced in § 4. In the next section, several numerical aspects are considered. In particular, the iterative procedure for control design is stated and its convergence analysed.

In § 6 the same results for discrete-time systems are stated. Although there exist many different theoretical aspects when compared with the theory developed for continuous-time systems, it will be shown that the same numerical procedure can still be used. Finally in § 7 some examples are solved and simulation results are included and compared with others available in the literature. In § 8 we summarize the most important conclusions.

2. Definitions and problem statement. In this section we introduce the basic design problem written directly in the parameter space. Its relationship with the classical LQP

[1] For alternative approaches leading to convex programming problems, see [6] and [20]. Unfortunately, the parametrization introduced results in high-order compensators.

[2] In principle, other important performance functions can be considered, making use of the concept of majorization [19].

is investigated as well. Consider a continuous-time linear system

(1) (S): $\dot{x} = Ax(t) + Bu(t)$,

where $x(t) \in \Re^n$ is the state vector and $u(t) \in \Re^m$ is the control vector. The real matrices A and B are of appropriate dimensions. Let us define the following set of matrices:

$$\begin{aligned} \Sigma_0 &\triangleq \{-xx' \in \Re^{n\times n}: \|x\| = 1\}, \\ \Sigma_S &\triangleq \{2A'xx' \in \Re^{n\times n}: B'x = 0, \|x\| = 1\}, \end{aligned} \tag{2}$$

where $\|x\|$ denotes the Euclidean norm of $x \in \Re^n$. Denoting the inner product of matrices in the $\Re^{n\times n}$ as $\langle W, X\rangle \triangleq \text{Trace}\,(W'X)$, the set $\mathscr{C}$ will be important in further developments:

$$\mathscr{C} \triangleq \{W \in \Re^{n\times n}: \langle W, X\rangle < 0, X \in \Sigma\}, \tag{3}$$

where $\Sigma \triangleq \Sigma_0 \cup \Sigma_S$ and W is assumed to be real and symmetric . This set is strongly related to the stabilizability of system (S). This property can be easily verified by noting that:[3]

$$\langle W, X\rangle < 0: X \in \Sigma_0 \Leftrightarrow x'Wx > 0 \quad \forall x \in \Re^n \tag{4}$$

and a similar relation holds for $X \in \Sigma_S$, that is,

$$\langle W, X\rangle < 0: X \in \Sigma_S \Leftrightarrow x'(AW + WA')x < 0 \quad \forall x: B'x = 0. \tag{5}$$

Consequently, for $W \in \mathscr{C}$, both inequalities (4) and (5) hold simultaneously. In view of the above, the interpretation of $\mathscr{C}$ is quite simple. Indeed, (4) states that $W = W' > 0$ (positive definiteness) and (5) implies that all modes of (1) belonging to the nullspace of B' are asymptotically stable. Using a definition given in [25], we conclude that this is possible only if the pair (A, B) is stabilizable. More precisely, we have the following result.

THEOREM 1. *The set $\mathscr{C}$ defined in* (3) *is such that*

(a) *$\mathscr{C} \neq \emptyset$ if and only if (A, B) is stabilizable.*

(b) *$\mathscr{C}$ is a convex cone.*

(c) *If $W_* \notin \mathscr{C}$, there exists $X_* \in \Sigma$ such that the set*

$$\mathscr{C}_* \triangleq \{W \in \Re^{n\times n}: \langle W, X_*\rangle < 0\}$$

satisfies $W_* \notin \mathscr{C}_* \supset \mathscr{C}$.

Proof. The proof of part (a) is simple and is left to the reader. The proof that $\mathscr{C}$ is a convex set follows from its definition (3). Indeed, $\mathscr{C}$ is the intersection of an infinite number of open halfspaces defined by linear (and hence convex) inequalities. On the other hand, for any $W \in \mathscr{C}$, $\lambda W \in \mathscr{C}$, for all $\lambda > 0$, consequently $\mathscr{C}$ is a cone. To prove the last part, we define X_* as follows:

$$X_* \triangleq \arg\max \{\langle W_*, X\rangle: X \in \Sigma\}. \tag{6}$$

Since by assumption $W_* \notin \mathscr{C}$, then $\langle W_*, X\rangle \geqq 0$, which implies that $W_* \notin \mathscr{C}_*$. In addition, X_* being an element of Σ, it is obvious that $\mathscr{C}$ is a subset of $\mathscr{C}_*$. This proves the theorem.

Theorem 1 deserves some remarks. From the proof we verify that in fact $\mathscr{C}$ is an open convex set. However, being a cone, it can be rewritten as

$$\mathscr{C} = \{W \in \Re^{n\times n}: \langle W, X\rangle \leqq -\beta, X \in \Sigma\} \tag{7}$$

[3] For arbitrary matrices with appropriate dimension, Trace (AB) = Trace (BA).

with $\beta > 0$. Now, $\mathscr{C}$ is closed and no loss of generality is introduced by a particular choice of $\beta > 0$. Indeed, as will be seen in the sequel, the parameter β has no influence on the determination of a stabilizing feedback gain. However, it is important to note that in this case the set $\mathscr{C}_*$ must be changed into

$$\mathscr{C}_* = \{W \in \Re^{n\times n} : \langle W, X_* \rangle \leqq -\beta\}. \tag{8}$$

Based on the above discussion, we adopt throughout the text the normalized value $\beta = 1$.

Part (c) of Theorem 1 states that for each $W_* \notin \mathscr{C}$ there exists a separating hyperplane which separates W_* from $\mathscr{C}$. It is calculated from the optimal solution of problem (6). At first glance it appears difficult to solve. However, from the definition of Σ we readily see that

$$\max\{\langle W_*, X \rangle : X \in \Sigma\} = \max\{\rho_0, \rho_S\}, \tag{9}$$

where ρ_0 and ρ_S are the optimal values of the left-hand side of (9) with Σ replaced by Σ_0 and Σ_S, respectively. Using (2), we get

$$\rho_0 = -\lambda_m[W_*], \qquad \rho_S = \lambda_M[T'\Theta(W_*)T], \tag{10}$$

where $\Theta(W) \triangleq AW + WA'$, $T \in \Re^{n\times n-m}$ is an orthonormal matrix spanning the null-space of B' and $\lambda_m[\cdot]$, $\lambda_M[\cdot]$ denote the minimum and the maximum eigenvalues of $[\cdot]$, respectively. Obviously, the optimal solution $X_* \in \Sigma$ is determined from the normalized eigenvectors associated with ρ_0 or ρ_S.

Now, assume that the pair (A, B) is stabilizable and pick up from $\mathscr{C}$ a generic element W. From (4), we have $W = W' > 0$ and, using Finsler's lemma (see, for example, [17]) to (5), there exists a symmetric positive-definite matrix $R \in \Re^{m\times m}$ such that $\Theta(W) < BR^{-1}B'$ (see [4] for a particular choice of R). Consequently, the symmetric positive definite matrix $Q \in \Re^{n\times n}$

$$Q = W^{-1}[BR^{-1}B' - \Theta(W)]W^{-1} \tag{11}$$

is such that $P = W^{-1} > 0$ solves the following Riccati equation:

$$A'P + PA - PBR^{-1}B'P + Q = 0. \tag{12}$$

This shows that the linear time-invariant feedback gain $K = R^{-1}B'W^{-1}$ is such that the control law $u(t) = -Kx(t)$ stabilizes (1) asymptotically and is optimal with respect to the quadratic index

$$\min_u \int_0^\infty \{x(t)'Qx(t) + u(t)'Ru(t)\}\,dt \tag{13}$$

with $V(x) = x'Px$ being a Lyapunov function for the closed-loop system. From the results above, we conclude that there is a one-to-one correspondence between each element of $\mathscr{C}$ and a pair of positive-definite matrices (Q, R) which defines a standard LQP. That is, the condition $\mathscr{C} \neq \varnothing$ and the existence of a positive-definite solution for (12) are equivalent.

However, from a numerical point of view, the above equivalence no longer takes place. In the classical LQ design, matrices Q and R are chosen and (12) is solved for $P > 0$, giving rise to the optimal feedback gain. As discussed in the Introduction, the nonlinear nature of (12) imposes serious difficulties for the inclusion in the LQP of additional design constraints.

Theorem 1 allows us to work directly in the parameter space $\Re^{n\times n}$. A particular stabilizing gain (and optimal in a certain sense) can be determined from

$$\min\{f(W) : W \in \mathscr{C}\}, \tag{14}$$

where $f(\cdot)$: $\Re^{n\times n}\to\Re$ is a convex matrix-valued function. Again, in view of Theorem 1, (14) is a feasible *convex* problem whenever the pair (A, B) is stabilizable. As will be seen in the sequel, all machinery available to date in the mathematical programming literature can be used to solve it. Furthermore, additional design constraints like decentralization or parameter uncertainties are relatively easily incorporated in the basic structure.

Keeping this fact in mind, the final choice of the index $f(W)$ follows from a simple design strategy: Define convex constraints which reflect the designer objectives (a degree of stability $\alpha>0$ may also be included by simple substitution of A by $A+\alpha\mathbf{I}$ in Σ_S) and choose $f(W)$ such as the feedback gain determined from the optimal solution of (14) be "small." This procedure will be deeply analysed in § 4.

3. Decentralized and uncertain systems. First, we analyse the decentralized control problem [5], [24]. To this end, we assume that in (1), B is a block-diagonal matrix, that is,

$$B=B_D=\text{block-diagonal}\{B_1,\cdots,B_N\},\tag{15}$$

where $B_i\in\Re^{n_i\times m_i}$, $i=1\cdots N$. For convenience we introduce the following notation. A subscript "D" in a matrix indicates that it is block-diagonal, each block with appropriate dimensions. The set $\mathscr{C}$ is now replaced by

$$\mathscr{C}_D\triangleq\{W_D\in\Re^{n\times n}:\langle W_D,X\rangle<0,X\in\Sigma\}\tag{16}$$

and we define a class of decentralized dynamic systems.

DEFINITION 1. The system (S) is called *strongly decentralized* if there exist $W_D=W'_D>0$ and K_D such that $(A-BK_D)'W_D^{-1}+W_D^{-1}(A-BK_D)<0$.

Note that for this class not only the system must be stabilized by a decentralized gain but, in addition, the Lyapunov equation associated with the closed-loop matrix must have a block-diagonal solution. It is important to note that almost all the results available in the decentralized control literature deal with this class of systems.

THEOREM 2. *The system* (S) *is strongly decentralized if and only if* $\mathscr{C}_D\neq\emptyset$.

Proof. The "only if" part is proved assuming that there exist W_D and K_D satisfying Definition 1. In this case $(A-BK_D)W_D+W_D(A-BK_D)'<0$. Multiplying this inequality by x' on the left and x on the right, for $x\in\Re^n$ arbitrary, we get $\langle W_D,X\rangle<0$: $X\in\Sigma_S$. Since W_D is positive definite and block-diagonal, we conclude that $W_D\in\mathscr{C}_D$.

The "if" part is proved by construction. Take any $W_D\in\mathscr{C}_D$ and determine R_D such that $\Theta(W_D)<BR_D^{-1}B'$ (this is always possible by Finsler's lemma). Define $K_D=R_D^{-1}B'_DW_D^{-1}$ and observe that

$$\begin{aligned}(A-BK_D)'W_D^{-1}&+W_D^{-1}(A-BK_D)\\&=A'W_D^{-1}+W_D^{-1}A-2W_D^{-1}BR_D^{-1}B'W_D^{-1}\\&\leqq W_D^{-1}\{\Theta(W_D)-BR_D^{-1}B'\}W_D^{-1}<0.\end{aligned}\tag{17}$$

Note that by assumption $B=B_D$, and the theorem follows from Definition 1.

As a final comment, we note that Theorem 1, as well as all remarks after it, remains valid if we replace the matrices by their decentralized representation. Obviously, the difference between both theorems stems from the decentralized nature of the matrices involved. In fact, $\mathscr{C}_D$ could be defined from $\mathscr{C}$ by adding a number of linear constraints which reduce to zero all off-diagonal elements of $W\in\Re^{n\times n}$. As a conclusion, we note that the optimal solution of (14) for decentralized control synthesis is easier to calculate than the former one since fewer variables are involved.

Now we turn our attention to uncertain systems control. First, we consider the case in which only the A matrix is uncertain. The general case will be analysed in the next section. Suppose the linear system (1) is such that $A \in D_A$, where

$$D_A \triangleq \left\{ A \in \Re^{n \times n} \colon A = \sum_{i=1}^{N} \lambda_i A_i,\ \lambda_i \geqq 0,\ \sum_{i=1}^{N} \lambda_i = 1 \right\}. \tag{18}$$

Obviously, D_A is a convex and bounded domain. It is defined by a convex combination of the "extreme" matrices A_i, $i = 1 \cdots N$. We claim that this representation of D_A is quite general. A particular and important case corresponds to linear systems where the coefficients are known up to a certain precision defined by bounding them from below and above (interval matrices).

DEFINITION 2. A collection of linear systems defined by $(A_1, \cdots, A_N, B)$ is quadratically stabilizable via linear feedback control if there exist $W = W' > 0$ and K such that $(A_i - BK)'W^{-1} + W^{-1}(A_i - BK) < 0$ for all $i = 1 \cdots N$.

Defining the convex cone (see equation (3)):

$$\mathscr{C}_U \triangleq \{ W \in \Re^{n \times n} \colon \langle W, X \rangle < 0, X \in \Sigma_U \}, \tag{19}$$

where $\Sigma_U \triangleq \Sigma_0 \cup \Sigma_1 \cup \cdots \cup \Sigma_N$. The sets Σ_i, $i = 1, \cdots N$ are given by (2) with A replaced by A_i, $i = 1 \cdots N$. We have the following result.

THEOREM 3. *The collection* $(A_i, \cdots, A_N, B)$ *is quadratically stabilizable via linear control if and only if* $\mathscr{C}_U \neq \varnothing$.

Proof. The "only if" part is obvious and thus omitted (see the proof of Theorem 2). For the "if" part take an arbitrary $W \in \mathscr{C}_U$, define $\Theta_i(W) \triangleq A_i W + WA_i'$, and determine positive definite matrices R_i such that $\Theta_i(W) < BR_i^{-1}B'$, $i = 1 \cdots N$.

It is clear that any matrix $R = R' > 0$ such that $R^{-1} \geqq R_i^{-1}$ for all $i = 1 \cdots N$ satisfies $\Theta_i(W) < BR^{-1}B'$. Setting $K = R^{-1}B'W^{-1}$, we get

$$\begin{aligned} &(A_i - BK)'W^{-1} + W^{-1}(A_i - BK) \\ &= A_i'W^{-1} + W^{-1}A_i - 2W^{-1}BR^{-1}B'W^{-1} \\ &\leqq W^{-1}\{\Theta_i(W) - BR^{-1}B'\}W^{-1} < 0, \qquad i = 1 \cdots N \end{aligned} \tag{20}$$

and the theorem is proved by Definition 2.

It is interesting to observe that with the positive-definite matrices

$$Q_i = W^{-1}[BR^{-1}B' - \Theta_i(W)]W^{-1}, \qquad i = 1 \cdots N \tag{21}$$

all Riccati equations

$$A_i'P_i + P_iA_i - P_iBR^{-1}B'P_i + Q_i = 0 \tag{22}$$

have the same positive-definite solution, namely, $P_i = W^{-1}$, $i = 1 \cdots N$. Consequently, to each pair (A_i, B) it is possible to define a LQP which provides a linear feedback gain independent of the index $i = 1 \cdots N$.

On the other hand, we can verify that the set Σ_U does not introduce any fundamental additional difficulty for the determination of the separating hyperplane (see Theorem 1). Suppose that $W_* \notin \mathscr{C}_U$; then

$$\max \{ \langle W_*, X \rangle \colon X \in \Sigma_U \} = \max \{ \rho_0, \rho_1, \cdots, \rho_N \}, \tag{23}$$

where ρ_0 is given in (10) and

$$\rho_i = \lambda_M[T'\Theta_i(W_*)T], \qquad i = 1 \cdots N. \tag{24}$$

The optimal solution $X_* \in \Sigma_U$ is determined from the normalized eigenvectors associated to ρ_0 and $\rho_1 \cdots \rho_N$.

THEOREM 4. *Assume $A \in D_A$. The system* (S) *is quadratically stabilizable via linear control if and only if the same holds for the collection* $(A_i, \cdots, A_N, B)$.

Proof. The necessity is obvious since $A_i \in D_A$. The sufficiency is proved by taking $K = R^{-1}B'W^{-1}$ where $W \in \mathscr{C}_U$ and R is the matrix defined in the proof of Theorem 3. For all $A \in D_A$, we have (remember that $\lambda_i \geqq 0$ and $\sum_{i=1}^N \lambda_i = 1$)

$$\begin{aligned}(25)\qquad &(A-BK)'W^{-1}+W^{-1}(A-BK)\\ &=\left(\sum_{i=1}^N \lambda_i A_i - BK\right)' W^{-1} + W^{-1}\left(\sum_{i=1}^N \lambda_i A_i - BK\right)\\ &=\sum_{i=1}^N \lambda_i\{(A_i-BK)'W^{-1}+W^{-1}(A_i-BK)\}\\ &\leqq -\sum_{i=1}^N \lambda_i Q_i < 0,\end{aligned}$$

where the last inequality follows from (20) and (21). This proves the theorem proposed.

In view of both Theorems 3 and 4, we conclude that the uncertain system (S) is quadratically stabilizable via linear control if and only if all extreme matrices which define the uncertain domain D_A are quadratically stabilizable via linear control. This improves the results of [16] (mainly because it can be generalized to cope with uncertainties in the input matrix too) since only a finite (N) number of matrices have to be handled.

We want to stress that $\mathscr{C}_U$ is a convex cone for which separating hyperplanes are easy to determine (23). Based on this property, we propose in § 5 a simple and efficient algorithm which verifies whether or not $\mathscr{C}_U \neq \emptyset$ and an affirmative answer provides the stabilizing feedback again.

4. The extended system. In this section we introduce the extended system model associated to system (S). The idea was first proposed in [2] and, as is seen below, it allows us to solve the problems stated previously in a much more general framework. For convenience, through this section we note $p = n + m$.

The extended system associated to (S) is defined by

$$(26)\qquad (\mathrm{E}):\quad \dot z = Fz(t) + Gv(t),$$

where $z(t) \in \mathfrak{R}^p$ is the extended state vector and $v(t) \in \mathfrak{R}^m$ is the control vector. Matrices $F \in \mathfrak{R}^{p\times p}$ and $G \in \mathfrak{R}^{p\times m}$ are given by

$$(27)\qquad F = \begin{bmatrix} A & -B \\ 0 & 0 \end{bmatrix}, \qquad G = \begin{bmatrix} 0 \\ I \end{bmatrix}.$$

As in § 2 we define the sets of matrices

$$(28)\qquad \begin{aligned}\Sigma_0 &\triangleq \{-zz' \in \mathfrak{R}^{p\times p}:\ G'z = 0,\ \|z\| = 1\},\\ \Sigma_E &\triangleq \{2F'zz' \in \mathfrak{R}^{p\times p}:\ G'z = 0,\ \|z\| = 1\}.\end{aligned}$$

Note that Σ_0 in (28) is slightly different from the set defined in (2). As a consequence, the elements of the cone

$$(29)\qquad \mathscr{C} \triangleq \{\mathscr{W} \in \mathfrak{R}^{p\times p}:\ \langle \mathscr{W}, Z\rangle < 0,\ Z \in \Sigma\}$$

with $\Sigma \triangleq \Sigma_0 \cup \Sigma_E$ are not necessarily positive-definite matrices.

COROLLARY 5. *The set $\mathscr{C}$ defined in* (29) *has the properties stated in Theorem* 1.

Proof. Only part (a) is proved. For the proof of parts (b) and (c) see Theorem 1. Assuming (A, B) is stabilizable, there exist matrices $W = W' > 0$ and K with appropriate dimensions such that

$$(A - BK)'W^{-1} + W^{-1}(A - BK) < 0. \tag{30}$$

Forming the matrix $\mathscr{W} \in \Re^{p \times p}$ as

$$\mathscr{W} = \begin{bmatrix} W & W'K' \\ KW & ? \end{bmatrix} \tag{31}$$

and, using the definition of $\mathscr{C}$, we conclude that $\mathscr{W} \in \mathscr{C}$. Conversely, assume that $\mathscr{W} \in \mathscr{C}$. Partitioning it as

$$\mathscr{W} = \begin{bmatrix} W_1 & W_2 \\ W_2' & W_3 \end{bmatrix}, \tag{32}$$

we immediately note that with $W = W_1$ and $K = W_2' W_1^{-1}$, (30) holds. This proves the first part of the corollary.

From the above we conclude that no condition is required for the matrix $W_3 \in \Re^{m \times m}$ and, more importantly, for any $\mathscr{W} \in \mathscr{C}$ it is always possible to choose W_3 such that $\mathscr{W} \in \mathscr{C}$ and $\mathscr{W} = \mathscr{W}' \geqq 0$.

Consequently, there is no loss of generality if we redefine $\mathscr{C}$ as being (see the discussion concerning the closure of $\mathscr{C}$ just after Theorem 1)

$$\mathscr{C} \triangleq \{\mathscr{W} = \mathscr{W}' \geqq 0 \colon \langle \mathscr{W}, Z \rangle \leqq -1, Z \in \Sigma\}. \tag{33}$$

Now, assume that $\mathscr{W} \in \mathscr{C}$ is partitioned according to (32). Two facts are of great importance. First, $W_1 \geqq \mathbf{I}$ and, second, the positive definiteness of $\mathscr{W}$ implies that $W_3 \geqq W_2' W_1^{-1} W_2$. For all $\mathscr{W} \in \mathscr{C}$ the corresponding stabilizing gains satisfy

$$KK' \leqq KW_1K' = W_2' W_1^{-1} W_2 \leqq W_3 = G'\mathscr{W}G, \tag{34}$$

which implies that $\|K\|^2 \leqq \lambda_M[G'\mathscr{W}G]$. We can select a small stabilizing gain from the solution of the basic design problem (14) with

$$f(\mathscr{W}) \triangleq \lambda_M[G'\mathscr{W}G]. \tag{35}$$

It is important to note that $f(\mathscr{W})$ is a convex (but not everywhere differentiable) function. Indeed, its epigraph [13] can be written as

$$\operatorname{epi} f \triangleq \{(\rho, \mathscr{W}) \colon \rho \geqq \langle \mathscr{W}, Z \rangle, Z \in \Sigma_0^{\perp}\}, \tag{36}$$

where $\Sigma_0^{\perp}$ is orthogonal to Σ_0 defined in (28).[4] At this point, it is obvious that the basic design problem can be rewritten as

$$\min \{\rho \colon (\rho, \mathscr{W}) \in \operatorname{epi} f, \mathscr{W} \in \mathscr{C}\}. \tag{37}$$

In the next section we propose an algorithm based on the dual-simplex procedure able to detect whether $\mathscr{C} \neq \varnothing$ and in the affirmative determine a stabilizing feedback gain with small norm (in the sense discussed above).

Some remarks are now in order. A decentralized optimal gain can be obtained from (37) by simply imposing on $\mathscr{W}$ the structure

$$\mathscr{W} = \begin{bmatrix} W_{1D} & W_{2D} \\ W_{2D}' & ? \end{bmatrix}. \tag{38}$$

[4] $\Sigma_0^{\perp}$ is given by $\Sigma_0^{\perp} \triangleq \{zz' \in \Re^{p \times p} \colon z \in \text{Range}(G), \|z\| = 1\}$. Note that for all $X \in \Sigma_0$ and $Y \in \Sigma_0^{\perp} \Rightarrow \langle X, Y \rangle = 0$.

In this case the decentralized control problem can be solved in a more general framework since we do not need to assume a special structure for the input matrix, that is, $B = B_D$.

Another important remark concerns the function $f(\mathcal{W})$ defined in (35). Indeed, problem (37) can be significantly simplified by imposing on $\mathcal{W}$ the particular structure

$$\mathcal{W} = \begin{bmatrix} W_1 & W_2 \\ W_2' & \rho \mathbf{I} \end{bmatrix}. \tag{39}$$

In this case, $f(\mathcal{W}) = \rho$, and (37) simplifies to

$$\min \{\rho \colon \mathcal{W} \in \mathcal{C}\}. \tag{40}$$

We are now in position to generalize our previous results to uncertain systems with both A and B uncertain matrices. To this end, we assume that A and B belong to polyhedral convex domain with $n_E(A)$ and $n_E(B)$ extreme matrices, respectively. In the same way, we assume that the extended system (E) is such that $F \in D_F$ where

$$D_F \triangleq \left\{ F \in \Re^{p \times p} \colon F = \sum_{i=1}^{M} \lambda_i F_i, \lambda_i \geqq 0, \sum_{i=1}^{M} \lambda_i = 1 \right\} \tag{41}$$

and $M = n_E(A) \times n_E(B)$. Following Definition 2, we say that the collection of linear systems $\{(A_i, B_i), i = 1 \cdots M\}$ is quadratically stabilizable via linear feedback control if there exist $W = W' > 0$ and K such that $(A_i - B_i K)' W^{-1} + W^{-1}(A_i - B_i K) < 0$ for all $i = 1 \cdots M$. As before we define the convex cone

$$\mathcal{C}_U \triangleq \{\mathcal{W} \in \Re^{p \times p} \colon \langle \mathcal{W}, Z \rangle < 0, Z \in \Sigma_U\}, \tag{42}$$

where $\Sigma_U \triangleq \Sigma_0 \cup \Sigma_1 \cup \cdots \cup \Sigma_M$. The sets Σ_i $i = 1 \cdots M$ are given by (28) with F replaced by F_i $i = 1 \cdots M$.

COROLLARY 6. *The collection* $\{(A_i, B_i), i = 1 \cdots M\}$ *is quadratically stabilizable via linear control if and only if* $\mathcal{C}_U \neq \emptyset$.

Proof. The "if" part closely follows the proof of Corollary 5. For the proof of the "only if" part, take any $\mathcal{W} \in \mathcal{C}_U$. Partitioning it as (32), we have

$$A_i W_1 + W_1 A_i' < W_2 B_i' + B_i W_2', \qquad i = 1 \cdots M. \tag{43}$$

On the other hand, with $W = W_1$ and $K = W_2' W_1^{-1}$, simple calculations yield

$$(A_i - B_i K)' W^{-1} + W^{-1}(A_i - B_i K) = W^{-1}[A_i W_1 + W_1 A_i' - W_2 B_i' - B_i W_2'] W^{-1} < 0. \tag{44}$$

Since the above inequality holds for all $i = 1 \cdots M$, the corollary is proved.

COROLLARY 7. *Assume that* $F \in D_F$. *The system* (S) *is quadratically stabilizable via linear control if and only if the same holds for the collection* $\{(A_i, B_i), i = 1 \cdots M\}$.

Proof. Once again the necessity is obvious. For the sufficiency, suppose the collection $\{(A_i, B_i), i = 1 \cdots M\}$ satisfies Corollary 6. In this case $\mathcal{C}_U \neq \emptyset$. After partitioning $\mathcal{W} \in \mathcal{C}_U$, setting $W = W_1$, $K = W_2' W_1^{-1}$, and noting that for each $F \in D_F$ there exist $\lambda_i \geqq 0$, $\sum_{i=1}^{M} \lambda_i = 1$ such that

$$(A, B) = \sum_{i=1}^{M} \lambda_i (A_i, B_i), \tag{45}$$

we immediately obtain for all $F \in D_F$

$$(A - BK)' W^{-1} + W^{-1}(A - BK) = \sum_{i=1}^{M} \lambda_i \{(A_i - B_i K)' W^{-1} + W^{-1}(A_i - B_i K)\} < 0, \tag{46}$$

where the last inequality follows from (44). This concludes the proof of the corollary.

We close this section with some remarks. From the definition of the extended system (E), it has been possible to determine an objective function for the basic design problem in such a way that a small feedback gain is provided by its optimal solution. This is an important practical aspect mainly because many other design requirements can be imposed by a proper choice of additional convex constraints.

The analysis of uncertain systems stability has been possible in the general case corresponding to A and B uncertain matrices. The results reported here generalize those available in the literature in several directions. First, in contrast with what is done in [16], we provided necessary and sufficient conditions for stabilizability of a collection of multivariable systems by means of linear feedback. Numerically speaking, the result of Corollary 7 is important. Indeed, the "abstract condition" given in [3] can be effectively solved with an important reduction of the computational burden since only a finite number of "extreme" models have to be considered.

5. Numerical procedure. In this section we present an algorithm for solving the convex programming problem[5]

$$\min\{f(\mathcal{W}): \mathcal{W}\in\mathcal{C}\}, \tag{47}$$

where $f(\cdot)$ is convex and $\mathcal{C}$ is a convex cone. From the results presented before, a particular design problem can be considered by a particular choice of the cone $\mathcal{C}$ and the structure of $\mathcal{W}\in\Re^{p\times p}$. The algorithm must be able to detect whether $\mathcal{C}\neq\emptyset$ and in the affirmative case provide $\mathcal{W}^*\in\mathcal{C}$ such that $f(\mathcal{W}^*)\leqq f(\mathcal{W})$, for all $\mathcal{W}\in\mathcal{C}$.

In our context, the more general problem to be solved can be stated as

$$\begin{aligned}&\min \rho\\ &\langle\mathcal{W}, Z\rangle\leqq\rho \quad \text{for all } Z\in\Sigma_0^{\perp},\\ &\langle\mathcal{W}, Z\rangle\leqq-\beta_i \quad \text{for all } Z\in\Sigma_i, \quad i=0\cdots M+1,\end{aligned} \tag{48}$$

where $\beta_i=1$, $i=0\cdots M$. The constraint corresponding to $i=M+1$ imposes $\mathcal{W}\geqq 0$. Consequently, we set $\beta_{M+1}=0$ and

$$\Sigma_{M+1}\triangleq\{-zz'\in\Re^{p\times p}: \|z\|=1\}. \tag{49}$$

For convenience, matrices $\mathcal{W}\in\Re^{p\times p}$ and $\Theta_i(\mathcal{W})=F_i\mathcal{W}+\mathcal{W}F_i'\in\Re^{p\times p}$ are partitioned according to (32), that is,

$$\mathcal{W}=\begin{bmatrix}W_1 & W_2\\ W_2' & W_3\end{bmatrix}, \quad \Theta_i(\mathcal{W})=\begin{bmatrix}\Theta_{1i}(\mathcal{W}) & ?\\ ? & ?\end{bmatrix}, \quad i=1\cdots M, \tag{50}$$

where $W_1\in\Re^{n\times n}$ and $\Theta_{1i}(\mathcal{W})\in\Re^{n\times n}$. Note that for each $\mathcal{W}\notin\mathcal{C}$ a separating hyperplane between $\mathcal{W}$ and $\mathcal{C}$ is readily calculated (see Theorem 1).

- *Step* 1. Set the iteration index $l=0$ and

$$\mathcal{W}^l=\begin{bmatrix}\mathbf{I} & 0\\ 0 & 0\end{bmatrix}.$$

- *Step* 2. Define the constants ρ_i, $i=0,\cdots,M+1$ as being

$$\begin{aligned}\rho_0&=-\lambda_m[W_1^l],\\ \rho_i&=\lambda_M[\Theta_{1i}(\mathcal{W}^l)], \qquad i=1\cdots M,\\ \rho_{M+1}&=-\lambda_m[\mathcal{W}^l]\end{aligned}$$

[5] See also [18]. The difficulty is that $\mathcal{C}$ is not known explicitly.

and determine $\omega^* = \max\{\rho_i + \beta_i : i = 0, \cdots, M+1\}$. If $\omega^* \leqq 0$ go to Step 6. Otherwise set $i^* = i$ such that $\rho_i + \beta_i = \omega^*$ and go to next step.

- *Step* 3. Set $\gamma^l = -\beta_{i^*}$ and determine $Z^l \in \Sigma_{i^*}$ from the normalized eigenvector associated to ρ_{i^*}. Clearly, z^l has the form $z^l = [(x^l)' \, 0]'$ if $0 \leqq i^* \leqq M$.
- *Step* 4. Determine the normalized eigenvector $y^l \in \Re^m$ associated to $\lambda_M[W_3^l]$. Set $z^l = [0 \, (y^l)']'$, $Y^l = (z^l)(z^l)'$ and solve by any applicable method the linear programming problem

$$\begin{aligned} &\min \rho \\ &\langle \mathcal{W}, Y^j \rangle \leqq \rho, \\ &\langle \mathcal{W}, Z^j \rangle \leqq \gamma^j, \end{aligned} \qquad j = 0, \cdots, l. \tag{51}$$

- *Step* 5. If (51) is unfeasible then $\mathcal{C} = \varnothing$, **stop**. Otherwise, let $\mathcal{W}^{l+1}$ be its optimal solution. Make $l \leftarrow l+1$ and go back to Step 2.
- *Step* 6. $\mathcal{W}^l \in \mathcal{C}$. Determine the feedback gain $K = (W_2^l)'(W_1^l)^{-1}$.

The algorithm above works with the relaxed version of problem (48). Thanks to its convexity, at each iteration two linear constraints are added to the relaxed master problem (51) which approximates better both the epi f and the cone $\mathcal{C}$. Each linear constraint is defined in terms of Z^l, which satisfies

$$Z^l = \arg\max\{\langle \mathcal{W}^l, Z\rangle : Z \in \Sigma\}. \tag{52}$$

This fact contributes to reducing the number of iterations since the rate of convergence of this class of algorithms depends mainly on the deepness of the cut associated to each separating hyperplane.

On the other hand, calling ρ^{l+1} the minimum value of the index in (51), the dual representation of its first l constraints gives for some $\mu_j \geqq 0$, $\sum_{j=1}^{l} \mu_j = 1$:

$$\begin{aligned} \rho^{l+1} &= \sum_{j=0}^{l} \mu_j \langle \mathcal{W}^{l+1}, Y^j \rangle \\ &= \left\langle \mathcal{W}^{l+1}, \sum_{j=0}^{l} \mu_j Y^j \right\rangle. \end{aligned} \tag{53}$$

Consequently, the relaxed master problem approximates $f(\mathcal{W}) \cong \langle \mathcal{W}, Y\rangle$ where Y is iteratively determined. Note that in the previous version of the algorithm, it stops when some feasible $\mathcal{W} \in \mathcal{C}$ is reached.

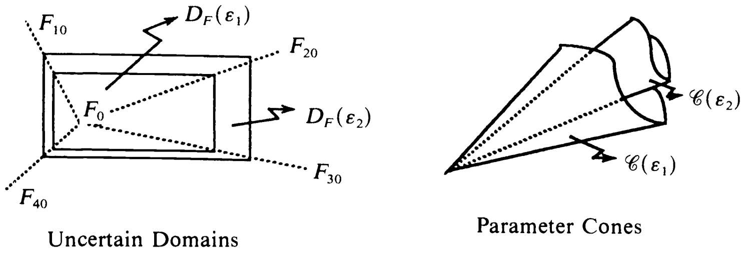
It is obvious that both structures (38) and (39) can be imposed to solve problems with decentralized constraints and simpler objective function. In the last case, (51) simplifies considerably to

$$\min\{\rho : \langle \mathcal{W}, Z^j \rangle \leqq \gamma^j, j = 1, \cdots, l\}. \tag{54}$$

The algorithm is sufficiently general to cope with other important problems. Indeed, the generalization to handle D_F convex but not necessarily polyhedral is immediate. The same occurs to the problem of synthesizing a linear feedback control so as to maximize the uncertainty parameter region [11]. Consider $D_F(\varepsilon)$, $\varepsilon \geqq 0$, the uncertainty domain defined in (41) for $F_i = F_0 + \varepsilon F_{1i}$, $i = 1 \cdots M$ (see Fig. 1) and assume that $\mathcal{C}(\varepsilon) \neq \varnothing$ for $\varepsilon = 0$.

In this case, the object function of (48) depends on $\varepsilon \in \Re$ and for each $\varepsilon \geqq 0$ it can be calculated by our procedure. The problem is to find ε for which $\mathcal{C}(\varepsilon) = \varnothing$ or $\rho(\varepsilon) = +\infty$. Since $\rho(\varepsilon)$ measures the magnitude of the feedback gain, from a practical point of view we have to solve

$$\max\{\varepsilon : \rho(\varepsilon) \leqq \rho_{\max}\}, \tag{55}$$



Uncertain Domains

Parameter Cones

FIG. 1. *Geometric interpretation of* $D_F(\varepsilon)$ *and* $\mathscr{C}(\varepsilon)$ *for* $\varepsilon_2 > \varepsilon_1$.

which needs in addition only a one-dimensional search. We claim that this approach appears to be more efficient than the one proposed in [11] since it avoids the calculation of the control gain itself which is determined only at the end of the iterative process.

THEOREM 8. *Suppose the algorithm generates the sequence of matrices* $\mathscr{W}^l$, $l = 0, 1, \cdots$. *Then, the following hold*:

(a) *If* $\mathscr{C} \neq \emptyset$, *any limit matrix of this sequence solves* (47).

(b) *If* $\mathscr{C} = \emptyset$, *an iteration index l will exist for which the linear problem* (51) *at Step* 4 *is unfeasible.*[6]

Proof. The proof is based on the convexity of problem (47). It follows the same pattern as that presented in [7] (see also [14]).

With regard to the convergence, Step 4 is of great importance. Since only two (or even one if (54) is under consideration) constraints are added to the linear programming problem (51), one of the best ways to solve it is using the DUAL-SIMPLEX procedure. Indeed, at any further iteration, the basis matrix is readily determined from the one of the previous iteration [13].

On the other hand, the global convergence stated in Theorem 8 is not destroyed if the algorithm is arranged by discarding the nonbinding constraints at the end of each iteration. Using the fact that $\mathscr{W}$ is symmetric, at most $p(p+1)/2$ linearly indepedent constraints have to be retained [14].

Of course this is not essential since the sequence ρ^l, $l = 0, 1, \cdots$ will still be monotonically nondecreasing (and bounded in the case $\mathscr{C} \neq \emptyset$) but certainly contributes for the global efficiency of the algorithm proposed.

6. Discrete-time systems design. We now focus our attention on discrete-time system given by

$$(56) \qquad (\mathrm{S}): \quad x(t+1) = Ax(t) + Bu(t),$$

where $x(t) \in \mathfrak{R}^n$ and $u(t) \in \mathfrak{R}^m$ are the state and control vectors. An important observation is that due to some nonlinear relationships introduced by the discrete-time Lyapunov equation, the feedback control design cannot be accomplished in the original space ($\mathfrak{R}^n$). For this reason, we immediately define the extended system associated to (S):

$$(57) \qquad (\mathrm{E}): \quad z(t+1) = Fz(t) + Gv(t),$$

where $z(t) \in \mathfrak{R}^p$, $v(t) \in \mathfrak{R}^m$ and F and G are given by (27). For convenience, throughout this section we use the same notation introduced in § 4.

[6] In practice, problem (51) is also declared unfeasible if, for some index l, $\rho^l > \rho_{\max}$, where $\rho_{\max}$ is a sufficiently large positive parameter.

The set Σ_E defined in (28) is now redefined as

$$\Sigma_E \triangleq \{F'zz'F - zz' \in \Re^{p\times p}\colon G'z = 0, \|z\| = 1\} \tag{58}$$

while the cone $\mathscr{C}$ defined in (29) moves to

$$\mathscr{C} \triangleq \{\mathscr{W} = \mathscr{W}' \geqq 0 \in \Re^{p\times p}\colon \langle \mathscr{W}, Z\rangle < 0, Z \in \Sigma\}, \tag{59}$$

where, as before, $\Sigma \triangleq \Sigma_0 \cup \Sigma_E$. From (59) we note the main difference between discrete-time and continuous-time linear system control design. Indeed, in the continuous-time case, the nonnegativeness constraint $\mathscr{W} \geqq 0$ has been introduced without loss of generality. On the contrary, in the discrete-time case, it is crucial to get the next results.

THEOREM 9. *The set $\mathscr{C}$ defined in* (59) *has the properties stated in Theorem* 1.

Proof. Once again only part (a) will be proved. The remaining ones are simple (for details see the proof of Theorem 1). Suppose first that (A, B) is stabilizable; then there exist matrices $W = W' > 0$ and K with appropriated dimensions such as

$$(A - BK)W(A - BK)' - W < 0. \tag{60}$$

Defining the matrix $\mathscr{W} \in \Re^{p\times p}$ as

$$\mathscr{W} = \begin{bmatrix} W & WK' \\ KW & KWK' \end{bmatrix} \tag{61}$$

and using the definition of $\mathscr{C}$, we conclude that indeed, $\mathscr{W} \in \mathscr{C}$. Conversely, assume that $\mathscr{W} \in \mathscr{C}$ is partitioned according to (32) and define $W = W_1$ and $K = W_2'W_1^{-1}$. Since any $z \in \Re^p$ such that $G'z = 0$ can be written as $z' = [x' \ \ 0]$ with $x \in \Re^n$ we have

$$x'[(A - BK)W(A - BK)' - W]x = z'[F\mathscr{W}F' - \mathscr{W}]z - x'B(W_3 - W_2'W_1^{-1}W_2)B'x. \tag{62}$$

The first term on the right-hand side of (62) is strictly negative because $\mathscr{W} \in \mathscr{C}$ and the second one is nonnegative because all feasible $\mathscr{W}$ are nonnegative definite matrices. Consequently, (60) holds and the theorem is proved.

For optimization purposes, the theorem above states that $\mathscr{C}$ is a convex cone which can be replaced by (33). The feedback gain is bounded below by $f(\mathscr{W})$ defined in (35) in which case the basic design problem (37) can be still used. Furthermore, a decentralized gain can be calculated (if any) by simply setting to $\mathscr{W}$ the structure (38).

Note, however, that in the discrete-time case, if we use the simplified version (40) of the basic design problem then only the sufficient part of Theorem 9 is achieved.

We now generalize the results of Theorem 9 to uncertain discrete-time systems. To this end we assume that (E) is such that $F \in D_F$ where D_F is the convex domain given in (41).

We say that the collection of linear systems $\{(A_i, B_i), i = 1 \cdots M\}$ is quadratically stabilizable via linear control if there exist $W = W' > 0$ and K such that $(A_i - B_iK)W(A_i - B_iK)' - W < 0$ for all $i = 1 \cdots M$. Defining the convex cone

$$\mathscr{C}_U \triangleq \{\mathscr{W} = \mathscr{W}' \geqq 0 \in \Re^{p\times p}\colon \langle \mathscr{W}, Z\rangle < 0, Z \in \Sigma_U\}, \tag{63}$$

where $\Sigma_U \triangleq \Sigma_0 \cup \Sigma_1 \cup \cdots \cup \Sigma_M$ and Σ_i $i = 1 \cdots M$ are given by (58) with F replaced by F_i $i = 1 \cdots M$, we can prove that the collection $\{(A_i, B_i), i = 1 \cdots M\}$ is quadratically stabilizable via linear feedback control if and only if $\mathscr{C}_U \neq \varnothing$.

The proof of the main result of this section (Theorem 11) is based on the following property.

LEMMA 10. *Assume that $\mathscr{W} = \mathscr{W}' \geqq 0 \in \Re^{p\times p}$; then*

$$F\mathscr{W}F' \leqq \sum_{i=1}^{M} \lambda_i F_i \mathscr{W} F_i' \quad \forall F \in D_F. \tag{64}$$

Proof. For arbitrary but fixed $z \in \Re^p$ define the function $g(\cdot): \Re^{p\times p} \to \Re$

$$g(F) \triangleq z'F\mathscr{W}F'z. \tag{65}$$

This function is convex. Indeed, for all $F, \Gamma \in \Re^{p\times p}$ we have

$$\frac{d^2}{d\alpha^2} g(F+\alpha\Gamma) = 2z'\Gamma\mathscr{W}\Gamma'z \geqq 0, \tag{66}$$

where the inequality follows from the nonnegativeness of $\mathscr{W}$. Using this fact together with the definition of D_F, we get

$$\begin{aligned} z'F\mathscr{W}F'z &= g\left(\sum_{i=1}^{M} \lambda_i F_i\right) \\ &\leqq \sum_{i=1}^{M} \lambda_i g(F_i) \\ &= z'\left\{\sum_{i=1}^{M} \lambda_i F_i \mathscr{W} F_i'\right\} z. \end{aligned} \tag{67}$$

Since $z \in \Re^p$ is arbitrary, (67) implies (64) and the lemma is proved.

THEOREM 11. *Assume that $F \in D_F$. The system* (S) *is quadratically stabilizable via linear control if and only if the same holds for the collection* $\{(A_i, B_i), i = 1 \cdots M\}$.

Proof. The necessity is obvious. For the sufficiency, suppose the $\mathscr{C}_U \neq \emptyset$. Partitioning $\mathscr{W} \in \mathscr{C}_U$ according to (32), setting $W = W_1$, $K = W_2' W_1^{-1}$, and recalling that $\mathscr{W} \geqq 0$, we get for all $F \in D_F$ and $z' = [x' \;\; 0]$, $x \in \Re^n$ (see (62)):

$$x'[(A-BK)W(A-BK)' - W]x \leqq z'[F\mathscr{W}F' - \mathscr{W}]z. \tag{68}$$

Now, using (64) it follows that

$$\begin{aligned} z'[F\mathscr{W}F' - \mathscr{W}]z &\leqq z'\left[\sum_{i=1}^{M} \lambda_i F_i \mathscr{W} F_i' - \mathscr{W}\right] z \\ &\leqq \sum_{i=1}^{M} \lambda_i z'[F_i \mathscr{W} F_i' - \mathscr{W}]z \\ &< 0 \quad \forall F \in D_F. \end{aligned} \tag{69}$$

Finally, (69) together with (68) proves the theorem proposed.

This theorem implies that the algorithm proposed in § 5 can be still used to determine a small feedback gain just sufficient to stabilize a given uncertain discrete-time system. To this end it is sufficient to define $\Theta_i(\mathscr{W}) \triangleq F_i\mathscr{W}F_i' - \mathscr{W}$, $i = 1 \cdots M$. As before, this is a linear function of $\mathscr{W} \in \Re^{p\times p}$ and the relaxation procedure will determine the feedback gain whenever $\mathscr{C} \neq \emptyset$.

7. Examples. In this section, some examples covering the main problems discussed are given to illustrate the usefulness of the approach.

The first example is borrowed from [16], where it is shown how to stabilize a denumerable set of operating points (a set of linear systems) by means of a nonlinear control. The proposed approach has been run (results below) under the same data, resulting in a linear feedback gain stabilizing simultaneously each of the four systems.

The systems are of third order with the following structure:

$$\dot{x} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ 0 & 0 & -30 \end{bmatrix} x + \begin{bmatrix} b_1 \\ 0 \\ 30 \end{bmatrix} u$$

and the numerical data (in Table 1):

For the W_1 and W_2 matrices the final results are

$$W_1 = \begin{bmatrix} 171.5583 & -15.9527 & -5.1070 \\ -15.9527 & 2.5890 & 0.6497 \\ -5.1070 & 0.6497 & 1.5261 \end{bmatrix}, \qquad W_2 = \begin{bmatrix} 1.4005 \\ -0.7400 \\ 0.0444 \end{bmatrix}$$

resulting in a K such as

$$K = [-0.0411 \quad -0.5729 \quad 0.1355].$$

With the given approach, not only the four operating points are stabilized, but also all the systems given by a linear convex combination of the former. This is partly verified on Fig. 2 where the root loci of the following systems are plotted:

$$A = \mu(A_i - B_iK) + (1-\mu)(A_j - B_jK),$$
$$i \neq j, \quad i, j = 1, 2, 3, 4, \quad 0 \leqq \mu \leqq 1$$

in the open-loop ($K = 0$) and the closed-loop (K given above) cases. In open loop, some systems are unstable, with a part of the root locus inside the right half complex plane. It is verified that the closed-loop root loci all lie in the stable part of the complex plane.

Some experiments have also been performed for discrete-time systems. The one given below is derived from the preceding example in the following way:

$$x(t+1) = \tilde{A}_i x(t) + \tilde{B}_i u(t), \qquad i = 1, 2, 3, 4,$$

where

$$\tilde{A}_i = \exp[A_i \Delta t],$$
$$\tilde{B}_i = \int_0^{\Delta t} \exp(A_i \tau) B_i \, d\tau.$$

The sample period Δt has been chosen equal to 0.1, which gives the data (Table 2).

The same processing as for the continuous case was repeated, leading to the following results and the same conclusion as for the stability (see Fig. 3):

$$W_1 = \begin{bmatrix} 3620.22 & -335.211 & -122.406 \\ -335.211 & 50.9528 & 16.8288 \\ -122.406 & 16.8288 & 23.772 \end{bmatrix}, \qquad W_2 = \begin{bmatrix} 4.6330 \\ -6.0835 \\ 2.7064 \end{bmatrix}$$

resulting in a K such as

$$K = [-0.0230 \quad -0.3513 \quad 0.2441].$$

TABLE 1

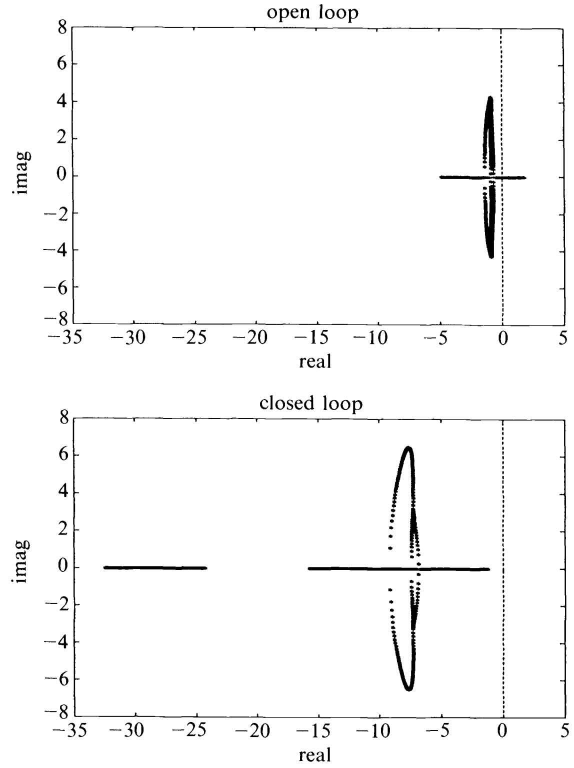

FIG. 2. *Open-loop and closed-loop continuous root loci.*

The last example concerns the problem of decentralization. It has been borrowed from [26], where it is presented as a mechanical manipulator control example. The difference here is twofold: First the decentralization constraint is imposed, then the uncertainty intervals on the parameters are enlarged.

The system is written as

$$\frac{d}{dt}\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \end{bmatrix} = \begin{bmatrix} -1/\tau_1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ k_{11} & -k_{11} & (c_1 - k_{12}) & 0 & 0 & c_2 \\ 0 & 0 & 0 & -1/\tau_2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & c_3 & k_{21} & -k_{21} & -k_{22} \end{bmatrix}$$

$$\cdot \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \end{bmatrix} + \begin{bmatrix} 1/\tau_1 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 1/\tau_2 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}.$$

The decentralized constraints restricts u_1 to involve (x_1, x_2, x_3) and u_2 to involve (x_4, x_5, x_6). The nominal system is defined by the following data:

$$k_{11} = k_{21} = 10, \qquad k_{12} = k_{22} = 2,$$

TABLE 2

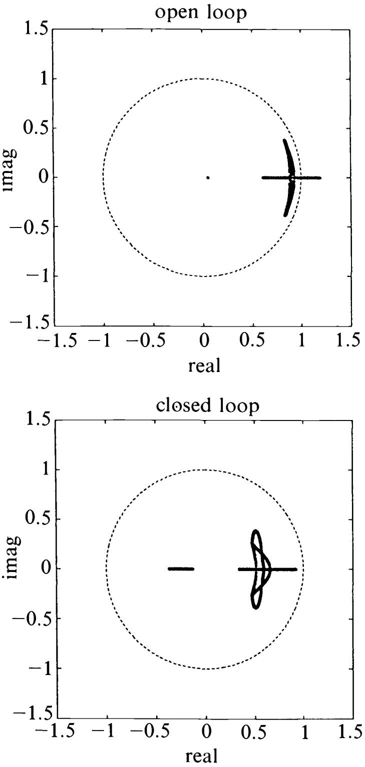

FIG. 3. *Open-loop and closed-loop discrete root loci.*

$$\tau_1 = \tau_2 = 0.1,$$

$$c_1 = 0.2, \qquad c_2 = c_3 = 0.1.$$

The first simulation (Fig. 4) is performed from the results in [26] on the nominal system, and the associated feedback K:

$$K = \begin{bmatrix} 5.67 & 114.0 & 14.4 & 0.017 & 0.321 & 0.094 \\ 0.017 & 0.321 & 0.094 & 5.63 & 113.0 & 14.2 \end{bmatrix}.$$

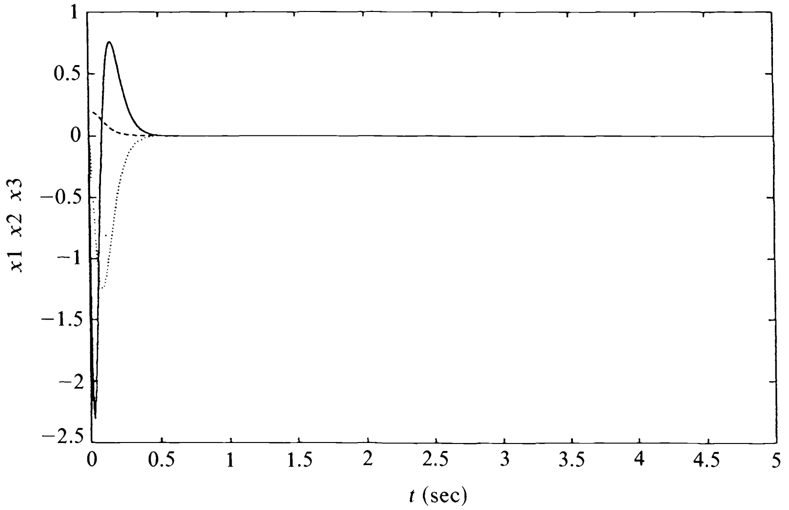

FIG. 4. *Nominal parameter values—centralized gain.*

Throughout the figures only the three first-state variables are plotted, from the initial conditions

$$x_0 = [0.3 \quad 0.2 \quad 0 \quad 0.7 \quad 0.2 \quad 0]'.$$

For the nominal system the proposed approach provided the W_1 and W_2 matrices

$$W_1 = \begin{bmatrix} 3.2437 & 0.8842 & -1.0682 & 0 & 0 & 0 \\ 0.8842 & 1.4231 & -0.7962 & 0 & 0 & 0 \\ -1.0682 & -0.7962 & 3.2437 & 0 & 0 & 0 \\ 0 & 0 & 0 & 3.2437 & 0.8854 & -1.2115 \\ 0 & 0 & 0 & 0.8854 & 1.4657 & -0.9280 \\ 0 & 0 & 0 & -1.2115 & -0.9280 & 3.2437 \end{bmatrix},$$

$$W_2 = \begin{bmatrix} -0.8240 & 0 \\ -0.5724 & 0 \\ 1.5125 & 0 \\ 0 & -0.7607 \\ 0 & -0.6179 \\ 0 & 1.5161 \end{bmatrix}$$

from which follows the decentralized gain

$$K = \begin{bmatrix} -0.0869 & -0.1198 & 0.4083 & 0 & 0 & 0 \\ 0 & 0 & 0 & -0.0439 & -0.1337 & 0.4127 \end{bmatrix}.$$

Figure 5 shows the responses for the decentralized gain.

Finally, the case of both uncertainty and decentralized constraints has been run. The uncertainty affects the parameters τ_1, τ_2, c_1, c_2, and c_3 in the following way:

$$0.02 \leqq \tau_1 = \tau_2 \leqq 0.18,$$

$$-14.8 \leqq c_1 \leqq 15.2,$$

$$-7.9 \leqq c_2 = c_3 \leqq 8.1.$$

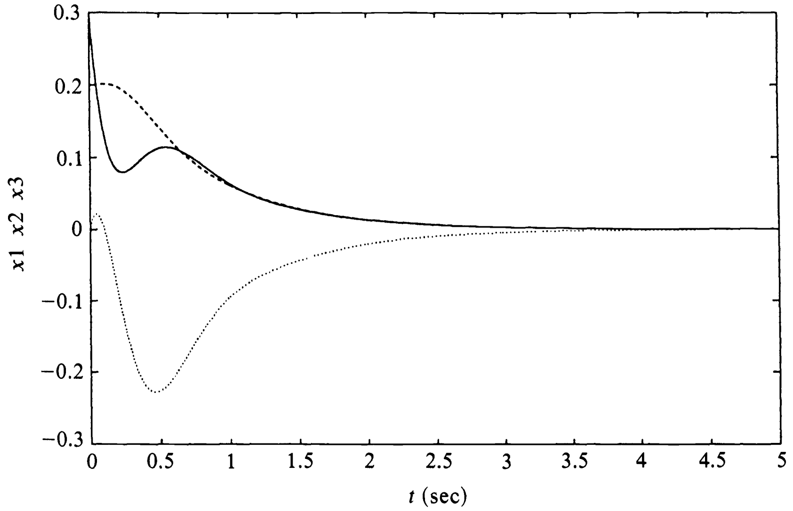

FIG. 5. *Nominal parameter values—decentralized gain.*

The numerical results are

$$W_1 = \begin{bmatrix} 38.4122 & 2.5394 & -14.175 & 0 & 0 & 0 \\ 2.5394 & 2.7764 & -0.2563 & 0 & 0 & 0 \\ -14.175 & -0.2563 & 7.7523 & 0 & 0 & 0 \\ 0 & 0 & 0 & 38.4122 & 1.9798 & -11.0742 \\ 0 & 0 & 0 & 1.9798 & 2.1106 & -0.1876 \\ 0 & 0 & 0 & -11.0742 & -0.1876 & 6.0045 \end{bmatrix},$$

$$W_2 = \begin{bmatrix} 21.2088 & 0 \\ -3.1099 & 0 \\ 19.6773 & 0 \\ 0 & 50.6388 \\ 0 & -1.7759 \\ 0 & 14.5368 \end{bmatrix},$$

which give the following robust gain:

$$K = \begin{bmatrix} 5.3936 & -4.9236 & 12.2377 & 0 & 0 & 0 \\ 0 & 0 & 0 & 4.6937 & -4.2712 & 10.9442 \end{bmatrix}.$$

In Figs. 6 and 7 are plotted the results of a numerical simulation where the coefficients are time-varying according to

$$\tau_1 = 0.1 + 0.08 \cos(0.1t),$$

$$\tau_2 = 0.1 + 0.08 \sin(0.5t),$$

$$c_1 = 0.2 + 15.0 \cos(0.1t),$$

$$c_2 = 0.1 - 8.0 \cos(0.2t),$$

$$c_3 = 0.1 - 8.0 \cos(0.1t).$$

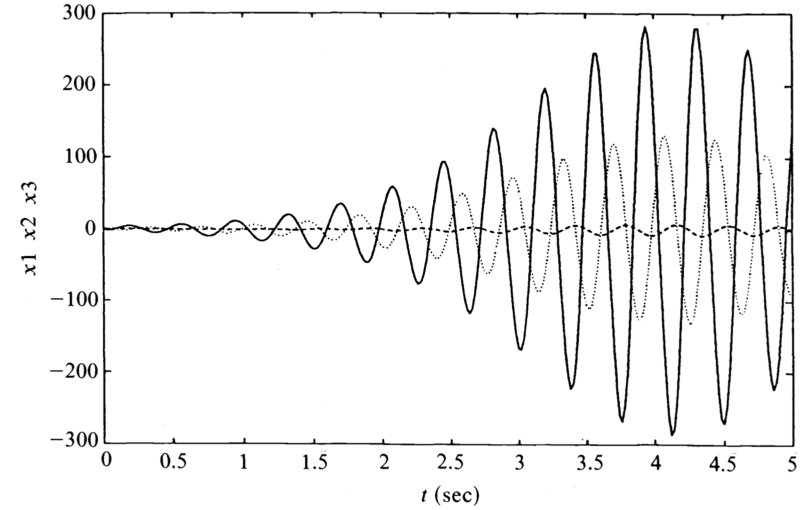

FIG. 6. *Uncertain parameters—centralized nominal gain.*

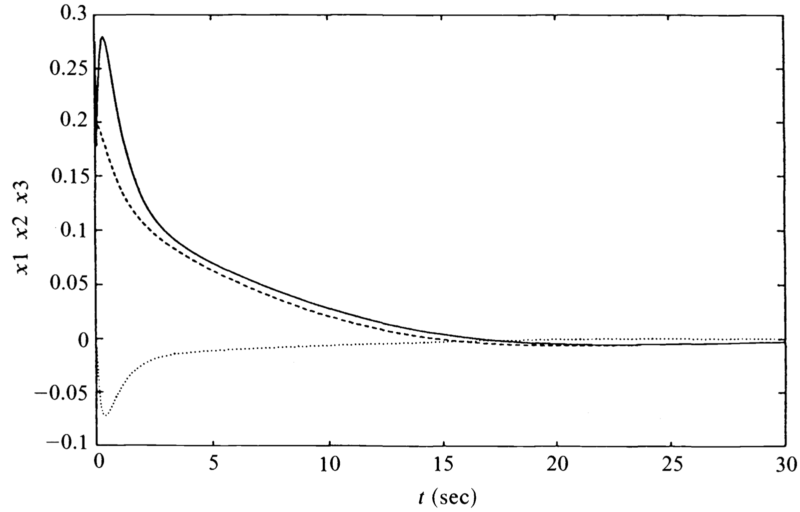

FIG. 7. *Uncertain parameters—decentralized robust gain.*

Figure 6 corresponds to the centralized gain given in [26], and Fig. 7 shows the one obtained by the robust decentralized gain given above. Note that the perturbations correspond to rather big variation around the nominal values. That almost causes divergence of the response plotted in Fig. 6 within a five-second interval time, while the plot of Fig. 7 drawn over a 20-second interval time shows a good damping of the response.

8. Conclusions. In this paper we introduced a new parameter space method for linear system control design. One of its most important features is that the feedback gain is determined from the solution of a *convex* problem. This is a key result because it opens the possibility of applying the most powerful techniques available to date in the mathematical programming literature for the solution of the above-mentioned problem. Furthermore, large-scale systems can be handled more efficiently by means of decomposition procedures (this important aspect has not been analysed in this paper).

The procedure is sufficiently general to solve several important design problems including the decentralized control problem and optimal control of uncertain systems by means of linear feedback. For them, necessary and sufficient conditions for solvability have been provided in terms of existence of some convex cones.

It is important to stress that the same algorithm can be used for both discrete-time and continuous-time systems control design. Indeed, the necessary and sufficient condition for the solvability of the quadratically stabilization problem of uncertain systems can be written as

$$\begin{gathered} T'\mathcal{W}T > 0, \\ T'\Theta_i(\mathcal{W})T < 0, \qquad i = 1 \cdots M, \\ \mathcal{W} \geqq 0, \end{gathered}$$

where $T \in \Re^{p\times n}$ is a matrix spanning the nullspace of G' and $\Theta_i(\cdot)$, $i = 1 \cdots M$ are linear functions of $\mathcal{W} \in \Re^{p\times p}$. At each iteration only the linear cut to be added to the master linear programming problem depends on the dynamic (continuous-time or discrete-time) representation of the system.

The present approach proposes a bridge between optimal control problems formulated on the parameter space and one of the most important and basic properties of mathematical programming programs—the convexity. As a natural consequence, it allows to solve several control problems in a unique and well-posed (numerically speaking) way, a fact which does not hold even for the LQ design.

Acknowledgment. The authors wish to thank Reviewer 2 for several helpful comments.

ON THE CONVERGENCE OF THE PROXIMAL POINT ALGORITHM FOR CONVEX MINIMIZATION*

OSMAN GÜLER†

Abstract. The proximal point algorithm (PPA) for the convex minimization problem $\min_{x\in H} f(x)$, where $f: H \to R \cup \{\infty\}$ is a proper, lower semicontinuous (lsc) function in a Hilbert space H is considered. Under this minimal assumption on f, it is proved that the PPA, with positive parameters $\{\lambda_k\}_{k=1}^{\infty}$, converges in general if and only if $\sigma_n = \sum_{k=1}^{n} \lambda_k \to \infty$. Global convergence rate estimates for the residual $f(x_n) - f(u)$, where x_n is the nth iterate of the PPA and $u \in H$ is arbitrary are given. An open question of Rockafellar is settled by giving an example of a PPA for which x_n converges weakly but not strongly to a minimizer of f.

Key words. proximal point algorithm, convex programming, strong convergence

1. Introduction.

Let H be a real Hilbert space. We consider the minimization problem

$$\min_{x\in H} f(x), \tag{1.1}$$

where $f: H \to \mathbf{R} \cup \{\infty\}$ is a proper, lower semicontinuous (lsc) convex function, where we follow the terminology established in Aubin and Ekeland [1] or Rockafellar [16]. Many convex programming problems with or without constraints can be reduced to (1.1).

One method for solving (1.1) is the *proximal point algorithm* (PPA) first introduced by Martinet [10]. The PPA is based on the notion of *proximal mapping* J_λ,

$$J_\lambda(x) = x_\lambda = \arg\min_{x\in H} \left\{ f(z) + \frac{1}{2\lambda} \|z - x\|^2 \right\}, \tag{1.2}$$

introduced by Moreau [12]. The PPA is an iterative procedure, which starts at a point $x_0 \in H$, and generates recursively a sequence of points $x_{k+1} = J_{\lambda_{k+1}(x_k)}$, where $\{\lambda_k\}_{k=1}^{\infty}$ is a sequence of positive numbers.

It turns out that a proximal mapping can be defined for an arbitrary *maximal monotone operator* $A: H \to H$. Recall that a multivalued mapping $A: H \to H$ is said to be a *monotone operator* if $w' \in A(x')$ and $w \in A(x)$ imply $\langle w' - w, x' - x \rangle \geqq 0$. Clearly, if A is a monotone operator, then

$$\begin{aligned} w \in A(x),\ w' \in A(x') \Rightarrow & \|(x' + w') - (x + w)\|^2 \\ & \geqq \|x' - x\|^2 + \|w' - w\|^2; \end{aligned} \tag{1.3}$$

in particular

$$x' \neq x \Rightarrow (I + A)(x) \cap (I + A)(x') = \varnothing. \tag{1.4}$$

A monotone operator A is said to be *maximal monotone* if the graph $G(A) = \{(w, x) \in H \times H \mid w \in A(x)\}$ is not properly contained in the graph of any other monotone operator $A': H \to H$. A *solution* to A is a point $x^* \in H$ such that $0 \in A(x^*)$.

Many problems that involve convexity can be formulated as finding the solution of a maximal monotone operator. For example, convex minimization, concave-convex

saddle-point problems, and solutions of games can be formulated in this way. In particular, the subdifferential $A=\partial f$ is a maximal monotone operator, and a point $x^*\in H$ minimizes f if and only if $0\in\partial f(x^*)$. The classical result of Minty [11] states that a monotone operator A is maximal if and only if $I+A$ is surjective. If A is a maximal monotone operator and $\lambda>0$, the operator J_λ, defined by $J_\lambda(x)=(I+\lambda A)^{-1}(x)$, is called the *resolvent* of A. It follows from (1.4) that the resolvent J_λ is a single-valued operator on H. Moreover, (1.3) implies that J_λ is nonexpansive: that is, if $x, y\in H$, $\|J_\lambda(y)-J_\lambda(x)\|\leqq\|y-x\|$. Also, the *Yosida approximation* A_λ, $A_\lambda(x)=(x-J_\lambda(x))/\lambda$, is Lipschitz continuous with constant $1/\lambda$. That is, for $x, y\in H$, $\|A_\lambda(y)-A_\lambda(x)\|\leqq\|y-x\|/\lambda$.

The PPA for a maximal monotone operator is an iterative procedure that starts at a point $x_0\in H$, and generates recursively a sequence of points $x_{k+1}=J_{\lambda_{k+1}}(x_k)$, where $\{\lambda_k\}_{k=1}^\infty$ is a sequence of positive numbers. It is treated in the papers [4], [7], [10], [17], and [18]. The important paper of Brézis and Lions [4] contains many interesting results. Rockafellar [18] shows how the PPA can be applied in convex programming. We stress that when $A=\partial f$, the PPA described here reduces to the iteration described above in the context of (1.1).

Notation. We use the following notation in the paper. If f is a proper, lsc convex function on H, the *effective domain* of f is the set $\{x\in H: f(x)<\infty\}$, which we denote by $D(f)$. We will sometimes refer to lsc convex functions as *closed* functions. The infimum of f is denoted by $f^*=\inf_{x\in H}f(x)$, and the set of minimizers of f (possibly empty) is denoted by $X^*=\{x\in H: f(x)=f^*\}$. If $A: H\to H$ is a multivalued operator, the *domain* of A is the set $D(A)=\{x\in H: A(x)\neq\emptyset\}$, and the *range* of A is the set $R(A)=\bigcup\{A(x): x\in D(A)\}$. If the sequence $\{\lambda_k\}_{k=1}^\infty$ of positive numbers lists the proximal parameters, we define $\sigma_n=\sum_{k=1}^n\lambda_k$. By convention $\sigma_0=0$. If the sequence $\{x_k\}_{k=0}^\infty$ is the trajectory of a PPA, we will write $y_k\equiv A_{\lambda_k}(x_{k-1})=(x_{k-1}-x_k)/\lambda_k$. We use $J_\lambda(x)$ and x_λ interchangeably. If A is maximal monotone then $A(x)$ is closed and convex (see Aubin and Ekeland [1, Prop. 3, §6.7]. In this case, if $A(x)\neq\emptyset$, we denote the least norm element of $A(x)$ by A^0x. For any set $S\subseteq H$, we define the *distance function* $\rho(x, S)=\inf\{\|x-s\|: s\in S\}$.

Every maximal monotone operator engenders a *nonlinear contractive semigroup* $\{S(t): t\geqq 0\}$ of maps $S(t):\overline{D(A)}\to\overline{D(A)}$, satisfying the following properties for $t, s\geqq 0$ and $x, y\in\overline{D(A)}$:

(i) $S(0)x=x$,

(ii) $S(t+s)x=S(t)S(s)x$ (semigroup property), and

(iii) $\|S(t)x-S(t)y\|\leqq\|x-y\|$.

Indeed, $S(t)x=u(t)$, where $u(t)$ is the unique solution to the *differential inclusion*

$$\frac{du}{dt}\in -Au(t),\qquad u(0)=x. \tag{1.5}$$

For an excellent treatment of nonlinear contractive semigroups in a Hilbert space, the reader is referred to Brézis [3].

There is an intimate relationship between nonlinear (contractive) semigroups and the proximal point algorithm. If we discretize the differential inclusion (1.5) by the backward Euler differencing, we obtain

$$\frac{x_k-x_{k-1}}{\lambda_k}\in -A(x_k), \tag{1.6}$$

and we obtain $x_k=(I+\lambda_kA)^{-1}x_{k-1}\equiv J_{\lambda_k}(x_{k-1})$. Therefore, PPA is just the backward Euler discretization of the differential inclusion (1.5). It is important to keep this connection in mind, since PPA inherits many of the nice properties of the contractive semigroup $S(t)$ and vice versa. See §5 for details.

In this paper, we restrict our attention to the case $A = \partial f$ for two reasons. The first reason is subdifferentials of convex functions form an important subclass of maximal monotone operators. The second, and perhaps the more important reason, is that the operator ∂f has special properties (for example, demipositivity; see Bruck [5]) not shared by other maximal monotone operators. We exploit the special properties of ∂f to obtain sharper results.

In the literature, the convergence properties of the PPA are studied only in the case where f has a minimizer, and the convergence rate of the algorithm is given only in the case where f is strongly convex. Moreover, the convergence rate is given in terms of the closeness of x_k to a minimizer of f. We depart from this tradition. We give convergence of the PPA under the weakest conditions, even in cases where f has no minimizer, or is unbounded from below. Our convergence rate results are in terms of the residual $f(x_k) - f(u)$ where u is an arbitrary point in H.

The organization of the rest of the paper is as follows. In §2, we establish the convergence properties of the PPA under the weakest possible assumptions. We establish global convergence rate results along with some interesting results which we use in later sections. In §3, we sharpen the convergence rate result for the residual $f(x_n) - f^*$ in the case where the PPA trajectory converges strongly to a minimizer of f. In §4, we present a fundamental estimate due to Kobayashi. In §5, we answer an open question posed by Rockafellar [17]: Does the PPA always converge strongly? We give a proper, closed function in an infinite-dimensional Hilbert space for which the PPA converges weakly but not strongly.

2. The convergence of the proximal point algorithm. Let H be a Hilbert space and $f: H \to \mathbf{R} \cup \{\infty\}$ be a proper, closed convex function. We are concerned with the convergence properties of the PPA applied to the minimization of f. In the literature, convergence results for the PPA are given only in the case where f has a minimizer, and convergence rate results are given in the case in which f enjoys strong convexity properties. Moreover, the convergence rate results are only asymptotic.

In this section, we prove the convergence of the PPA under the weakest possible conditions and provide global convergence rate estimates for the residual $f(x_n) - f(u)$, where x_n is the nth iterate of the PPA and u is any point in H. The behavior of x_n and $y_n = (x_{n-1} - x_n)/\lambda_n$ is also studied.

The following result is well known. Since the proof is short, we include it.

LEMMA 2.1. *$\{\|y_n\|\}_{n=1}^{\infty}$ is a decreasing sequence.*

Proof. Since $y_n \in \partial f(x_n)$, $y_{n+1} \in \partial f(x_{n+1})$, and ∂f is a monotone operator, we have $\langle y_{n+1} - y_n, x_{n+1} - x_n \rangle \geqq 0$. Since $y_{n+1} = (x_n - x_{n+1})/\lambda_{n+1}$, we obtain $\langle y_{n+1} - y_n, y_{n+1} \rangle \leqq 0$, which implies $\|y_{n+1}\|^2 \leqq \langle y_n, y_{n+1} \rangle \leqq \|y_n\| \cdot \|y_{n+1}\|$. The lemma is proved. □

The following result contains the *fundamental estimate* from which we derive most of the convergence results of this section.

LEMMA 2.2. *Let $\{\lambda_j\}_{j=1}^{\infty}$ be an arbitrary sequence of positive numbers. Suppose the* PPA *starts at x_0 and generates the sequence $\{x_n\}_{n=0}^{\infty}$, where $x_n = J_{\lambda_n}(x_{n-1})$. Then for any $u \in H$,*

$$f(x_n) - f(u) \leqq \frac{\|u - x_0\|^2}{2\sigma_n} - \frac{\|u - x_n\|^2}{2\sigma_n} - \frac{\sigma_n}{2} \|y_n\|^2. \tag{2.1}$$

Proof. Recall that $y_k = (x_{k-1} - x_k)/\lambda_k \in \partial f(x_k)$. By the convexity of f we have

$$f(u) - f(x_k) \geqq \langle y_k, u - x_k \rangle = \lambda_k^{-1} \langle x_{k-1} - x_k, u - x_k \rangle. \tag{2.2}$$

Therefore,

$$\begin{aligned}2\lambda_k(f(u)-f(x_k)) &\geqq 2\langle x_{k-1}-x_k, u-x_k\rangle \\ &= \|x_{k-1}-x_k\|^2+\|u-x_k\|^2-\|u-x_{k-1}\|^2 \\ &= \lambda_k^2\|y_k\|^2+\|u-x_k\|^2-\|u-x_{k-1}\|^2.\end{aligned} \tag{2.3}$$

Summing (2.3) for $k=1,\cdots,n$, we obtain

$$2\sigma_n f(u)-2\sum_{k=1}^n \lambda_k f(x_k) \geqq \sum_{k=1}^n \lambda_k^2\|y_k\|^2+\|u-x_n\|^2-\|u-x_0\|^2. \tag{2.4}$$

Setting x_{k-1} for u in (2.2) yields

$$f(x_{k-1})-f(x_k) \geqq \lambda_k^{-1}\|x_{k-1}-x_k\|^2=\lambda_k\|y_k\|^2. \tag{2.5}$$

Recall that $\sigma_k=\sum_{j=1}^k \lambda_j$, for $k\geqq 1$. Multiplying (2.5) by σ_{k-1}, we obtain

$$\sigma_{k-1}f(x_{k-1})-\sigma_k f(x_k)+\lambda_k f(x_k) \geqq \sigma_{k-1}\lambda_k\|y_k\|^2.$$

Summing the last inequality for $k=1,\cdots,n$ and noting $\sigma_0=0$, we obtain

$$-\sigma_n f(x_n)+\sum_{k=1}^n \lambda_k f(x_k) \geqq \sum_{k=2}^n \sigma_{k-1}\lambda_k\|y_k\|^2. \tag{2.6}$$

Adding twice (2.6) to (2.4) yields

$$\begin{aligned}2\sigma_n(f(u)-f(x_n)) &\geqq 2\sum_{k=2}^n \sigma_{k-1}\lambda_k\|y_k\|^2+\sum_{k=1}^n \lambda_k^2\|y_k\|^2+\|u-x_n\|^2-\|u-x_0\|^2 \\ &\geqq \left(\sum_{k=1}^n \lambda_k^2+2\sum_{k=2}^n \sigma_{k-1}\lambda_k\right)\|y_n\|^2+\|u-x_n\|^2-\|u-x_0\|^2 \\ &= \sigma_n^2\|y_n\|^2+\|u-x_n\|^2-\|u-x_0\|^2,\end{aligned}$$

where the second inequality follows from Lemma 2.1. Rearranging the terms of the inequality above gives (2.1). □

The next theorem contains the convergence properties of the PPA under the weakest possible assumptions. It is the main result of this section.

THEOREM 2.1. *Let the sequence $\{x_n\}_{n=0}^\infty$ be the trajectory of a* PPA. *For any $u\in H$ the following global convergence estimate holds*:

$$f(x_n)-f(u) \leqq \frac{\|u-x_0\|^2}{2\sigma_n}. \tag{2.7}$$

Consequently, if $\sigma_n\to\infty$, then $f(x_n)\downarrow f^*=\inf_{x\in H}f(z)$. If $X^*\neq\emptyset$, then x_n converges weakly to a minimizer of f. Moreover,

$$f(x_n)-f^* \leqq \frac{\rho(x_0,X^*)^2}{2\sigma_n}. \tag{2.8}$$

Proof. The estimate (2.7) follows immediately from (2.1). In order to prove that $f(x_n)$ converges to f^*, we first consider the case $f^*>-\infty$. Let $\varepsilon>0$ be arbitrary, and choose a point x^ε such that $f(x^\varepsilon)\leqq f^*+\varepsilon$. From (2.7) we obtain $f(x_n)\leqq f^*+\varepsilon+\|x^\varepsilon-x\|^2/(2\sigma_n)$. Since $\sigma_n\to\infty$ as $n\to\infty$, we have $f(x_n)\leqq f^*+2\varepsilon$ for large enough n. Line (2.5) shows that $f(x_n)$ is nonincreasing. Since ε is arbitrary, $f(x_n)\downarrow f^*$. The proof of the convergence in the case $f^*=-\infty$ is similar.

It remains to prove the assertions about the case $X^* \neq \emptyset$. In this case, the weak convergence of x_n to a minimizer of f is proved in Brézis and Lions [4, Thm. 9]. Formula (2.8) follows by substituting x^* for u in (2.7), where x^* is the point in X^* closest to x. □

Remark 2.1. The condition $\sigma_n \to \infty$ is the *weakest* condition in order to ensure that $f(x_n) \downarrow f^*$. If $\sigma_n \to \sigma < \infty$, then x_n always *converges strongly*:

$$(2.9) \qquad \|x_{n+p} - x_n\| \leqq \sum_{j=n+1}^{n+p} \|x_{j-1} - x_j\| = \sum_{j=n+1}^{n+p} \lambda_j \|y_j\| \leqq \left(\sum_{j=n+1}^{n+p} \lambda_j \right) \|y_{n+1}\|.$$

Since $\sigma_n \to \sigma$, (2.9) shows that x_n is a Cauchy sequence, and therefore converges strongly to some point x^∞, even if f does not have a minimizer! Even if $X^* \neq \emptyset$, we have

$$\|x - x^\infty\| \leqq \sum_{j=1}^{\infty} \|x_{j-1} - x_j\| = \sum_{j=1}^{\infty} \lambda_j \|y_j\| \leqq \sigma \|y_1\|,$$

so that $\rho(x^\infty, X^*) \geqq \rho(x, X^*) - \|x - x^\infty\| \geqq \rho(x, X^*) - \sigma\|y_1\|$. If σ is small, then $\rho(x^\infty, X^*) > 0$, and $x^\infty \notin X^*$.

Remark 2.2. In [7], Güler introduced new proximal point algorithms for minimizing f. The first of these algorithms converges under the condition $\sum_{k=1}^{\infty} \lambda_k^{1/2} = \infty$. Note that under this condition, which is weaker than $\sigma_n \to \infty$, the standard PPA need not converge.

By setting x_0 for u in (2.1), we obtain the following result.

COROLLARY 2.1. *In a proximal point algorithm the following estimate holds*:

$$(2.10) \qquad f(x_n) \leqq f(x_0) - \frac{\|x_0 - x_n\|^2}{2\sigma_n}.$$

The next result will be useful in this section as well as in §5.

THEOREM 2.2. *Let* $A = \partial f$ *and* $u \in D(A)$. *In a proximal point algorithm the following estimates hold*:

$$(2.11) \qquad \|y_n\| \leqq \frac{\|x_n - x_0\|}{\sigma_n},$$

$$(2.12) \qquad \|y_n\| \leqq \|A^0 u\| + \frac{\|u - x_0\|}{\sigma_n}.$$

Proof. Formula (2.11) follows by substituting x_n for u in (2.1). From the convexity of f we obtain $f(x_n) \geqq f(u) + \langle A^0 u, x_n - u \rangle$, which implies $f(u) - f(x_n) \leqq \|A^0 u\| \cdot \|x_n - u\|$. Using this inequality in (2.1), we obtain

$$\begin{aligned} \sigma_n^2 \|y_n\|^2 &\leqq \|u - x_0\|^2 - \|u - x_n\|^2 + 2\sigma_n \|A^0 u\| \cdot \|x_n - u\| \\ &\leqq \|u - x_0\|^2 - \|u - x_n\|^2 + (\sigma_n^2 \|A^0 u\|^2 + \|x_n - u\|^2) \\ &= \|u - x_0\|^2 + \sigma_0^2 \|A^0 u\|^2 \\ &\leqq (\|u - x_0\| + \sigma_n \|A^0 u\|)^2. \end{aligned}$$

The theorem is proved. □

Remark 2.3. In Theorem 9 of [4] Brézis and Lions prove a weaker version of (2.12), in a special case. In particular, they prove that if $X^* \neq \emptyset$, then $\|y_n\| \leqq \sqrt{2}\, \rho(x, X^*)/\sigma_n$. However, their proof can be modified along the lines of the proof of our Lemma 2.2 so as to eliminate the factor $\sqrt{2}$. Our stronger estimate (2.12) is essential to prove (i) of Theorem 2.3 below.

The following continuous version of Theorem 2.2 can be obtained from it by passing to the limit. It will be needed in §5.

COROLLARY 2.2. *Let $A = \partial f$. For any $x \in \overline{D(A)}$ and $u \in D(A)$, we have*

$$\|A^0 S(t)x\| \leqq \frac{\|S(t)x - x\|}{t}, \tag{2.13}$$

$$\|A^0 S(t)x\| \leqq \|A^0 u\| + \frac{\|u - x\|}{t}. \tag{2.14}$$

Remark 2.4. A different proof of Corollary 2.2 is given in Brézis [3, Thm. 2.3.2].

The following result gives information about the behavior of x_n and y_n in a PPA.

THEOREM 2.3. *Let $A = \partial f$ and let v be the least norm element of $\overline{R(\partial f)}$. If $\sigma_n \to \infty$, then*:

(i) *y_n converges strongly to v,*

(ii) *x_n/σ_n converges strongly to $-v$.*

(iii) *$\{x_n\}_{n=0}^{\infty}$ is bounded if and only if f has a minimizer, that is, $X^* \neq \varnothing$. We have $\|x_n\| \to \infty$ if and only if $X^* = \varnothing$.*

Proof. $\overline{R(\partial f)}$ is a closed convex set. See, for example, Brézis [3, Thm. 2.2.2]. Therefore, the least norm element, $v \in \overline{R(\partial f)}$ exists and is the projection of zero onto $\overline{R(\partial f)}$. Let $\varepsilon > 0$ be arbitrary, and choose $x^\varepsilon \in D(\partial f)$ such that $\|A^0 x^\varepsilon\| \leqq v\| + \varepsilon$. Substituting x^ε for u in (2.12), and letting $n \to \infty$, we obtain

$$\lim_{n\to\infty} \|y_n\| = \inf_{n \geqq 1} \|y_n\| \leqq \|A^0 x^\varepsilon\| \leqq \|v\| + \varepsilon,$$

where we use the fact that $\sigma_n \to \infty$ in the first inequality above. Since ε is arbitrary, $\lim_{n\to\infty} \|y_n\| = \|v\|$. By the parallelogram identity, $\|y_n - v\|^2 + \|y_n + v\|^2 = 2\|y_n\|^2 + 2\|v\|^2$, which implies

$$\|y_n - v\|^2 = 2\|y_n\|^2 + 2\|v\|^2 - 4\|(y_n + v)/2\|^2. \tag{2.15}$$

Now, since $\overline{R(\partial f)}$ is convex, $(y_n + v)/2 \in \overline{R(\partial f)}$, and thus we have $\|(y_n + v)/2\| \geqq \|v\|$. By triangular inequality we also have $\|(y_n + v)/2\| \leqq \|y_n\|/2 + \|v\|/2 \to \|v\|$ as $n \to \infty$. Therefore $\|(y_n + v)/2\| \to \|v\|$. Letting $n \to \infty$ in (2.15), we conclude that y_n converges strongly to v and (i) is proved.

To prove (ii), we note that $(x - x_n)/\sigma_n = \sigma_n^{-1} \sum_{i=1}^n (x_{i-1} - x_i) = \sigma_n^{-1} \sum_{i=1}^n \lambda_i y_i$. Since $y_n \to v$ strongly, by an application of the Silverman-Toeplitz theorem (see, for example, Dunford and Schwartz [6]), we obtain that $(x - x_n)/\sigma_n$ converges strongly to v. Since $\sigma_n \to \infty$, x_n/σ_n converges strongly to $-v$. This proves (ii). Part (iii) is known in the literature, See, for example, Reich [15] for a proof. □

Remark 2.5. Reich [15] actually proves (ii) for an arbitrary maximal monotone operator by a different method.

COROLLARY 2.3. *Let $A = \partial f$. Suppose a* PPA *generates the sequence $\{x_n\}_{n=0}^{\infty}$, where $\sigma_n = \sum_{k=1}^n \lambda_k \to \infty$. Then, if $f^* > -\infty$, y_n converges strongly to zero. Consequently, if $f^* > -\infty$, then $0 \in \overline{R(\partial f)}$.*

Proof. Summing (2.5) for $k = 1, \cdots, n$, we obtain

$$\infty > f(x) - f^* \geqq f(x) - f(x_n) \geqq \sigma_n \|y_n\|^2.$$

Since $\sigma_n \to \infty$, we have $y_n \to 0 = v$, where v is the least norm element of $\overline{R(\partial f)}$. □

Remark 2.6. Ekeland's ε-variational principle (see Aubin and Ekeland [1, Chap. 5]) can be used to prove the fact that if $f^* > -\infty$, then there exists x_n, y_n with $y_n \in \partial f(x_n)$, $f(x_n) \downarrow f^*$, and $y_n \to 0$. Corollary 2.3 shows that such x_n and y_n can be generated by a PPA.

Remark 2.7. It is tempting to conjecture the converse of Corollary 2.3, namely, if $0 \in \overline{R(\partial f)}$, then $f^* > -\infty$. However, this conjecture is false. In the first draft of the paper we had a counterexample. One of the referees suggested the following simple counterexample:

$$f(x) = \begin{cases} -\sqrt{x} & \text{if } x \geqq 0, \\ +\infty & \text{otherwise.} \end{cases}$$

Observe that $f(x) \to -\infty$ as $x \to \infty$, while $\partial f(x) \to 0$. The other referee suggested another simple counterexample:

$$f(x) = \begin{cases} 1 - x & \text{if } x \leqq 1, \\ -\log(x) & \text{if } x \geqq 1. \end{cases}$$

Again $f(x) \to -\infty$ as $x \to \infty$, while $\partial f(x) \to 0$.

3. The convergence rate of the proximal point algorithm. Let $f: H \to \mathbf{R} \cup \{\infty\}$ be a proper, closed convex function. Assume that $X^* \neq \emptyset$, that is, f has minimizers. Let $\{\lambda_j\}_{j=1}^{\infty}$ be a sequence of positive numbers with $\sigma_n \to \infty$. Consider the proximal point algorithm for minimizing f, with parameters $\{\lambda_k\}$, starting at an initial point $x_0 \in H$. We saw in §2 that the points x_k generated by the PPA converge weakly to a minimizer of f. Using Theorem 2.1, we have $f(x_n) - f^* \leqq \rho(x, X^*)^2/(2\sigma_n)$, which implies $f(x_n) - f^* = O(\sigma_n^{-1})$. We shall see in §5 that x_n need not converge strongly to any minimizer of f. However, if x_n *does* converge strongly to a minimizer of f, we can improve the converge rate $O(\sigma_n^{-1})$ above to $o(\sigma_n^{-1})$.

THEOREM 3.1. *Let $\{\lambda_n\}_{n=1}^{\infty}$ be a sequence of positive numbers and $\sigma_n \to \infty$. Let $f: H \to \mathbf{R} \cup \{\infty\}$ be a proper, closed convex function which has a minimizer. Consider the* PPA *starting at $x = x_0$ and generating the points $x_n = (x_{n-1})_{\lambda_n}$. If x_n converges strongly to a minimizer of f, then the convergence rate estimate*

$$f(x_n) - f^* = o\left(\frac{1}{\sigma_n}\right),$$

holds, that is, $\sigma_n(f(x_n) - f^*) \to 0$.

Proof. Suppose x_n converges strongly to $x^* \in X^*$. For brevity, we denote that $W_k = f(x_k) - f(x^*) = f(x_k) - f^*$. We can rewrite (2.5) as

$$W_{k-1} - W_k \geqq \lambda_k^{-1} \|x_{k-1} - x_k\|^2. \tag{3.1}$$

Substituting x^* for u in (2.2), we obtain

$$\begin{aligned} f(x^*) &\geqq f(x_k) + \lambda_k^{-1}\langle x_{k-1} - x_k, x^* - x_k\rangle \\ &= f(x_k) + \lambda_k^{-1}\langle x_{k-1} - x_k, x^* - x_{k-1}\rangle + \lambda_k^{-1}\|x_{k-1} - x_k\|^2 \\ &\geqq f(x_k) - \lambda_k^{-1}\|x_{k-1} - x_k\| \cdot \|x_{k-1} - x^*\|. \end{aligned}$$

Therefore, $\|x_{k-1} - x_k\| \geqq \lambda_k W_k \|x_{k-1} - x^*\|^{-1}$. Using this inequality in (3.1), we obtain

$$\begin{aligned} W_{k-1} &\geqq W_k + \frac{1}{\lambda_k}(\lambda_k W_k \|x_{k-1} - x^*\|^{-1})^2 \\ &= W_k + \frac{\lambda_k}{\|x_{k-1} - x^*\|^2} W_k^2 = W_k\left(1 + \frac{\lambda_k}{\|x_{k-1} - x^*\|^2} W_k\right). \end{aligned}$$

Inverting this inequality, we obtain

$$W_{k-1}^{-1} \leqq W_k^{-1}\left(1 + \frac{\lambda_k}{\|x_{k-1} - x^*\|^2} W_k\right)^{-1}. \tag{3.2}$$

We want to obtain a recursive inequality from (3.2). We have from (1.2),

$$f(x_k) \leqq f(x_k) + \frac{1}{2\lambda_k}\|x_k - x_{k-1}\|^2 \leqq f(x^*) + \frac{1}{2\lambda_k}\|x^* - x_{k-1}\|^2,$$

so that $0 \leqq W_k\lambda_k\|x^* - x_{k-1}\|^{-2} \leqq \frac{1}{2}$. The function $(1+t)^{-1}$ is convex for $t > -1$, hence $(1+t)^{-1} \leqq 1 - 2t/3$, for $t \in [0, \frac{1}{2}]$. Using this fact, we obtain from (3.2) that

$$W_{k-1}^{-1} \leqq W_k^{-1}\left(1 - \frac{2\lambda_k}{3\|x_{k-1} - x^*\|^2} W_k\right) = W_k^{-1} - \frac{2\lambda_k}{3\|x_{k-1} - x^*\|^2},$$

or equivalently,

$$W_k^{-1} - W_{k-1}^{-1} \geqq \frac{2\lambda_k}{3\|x_{k-1} - x^*\|^2}. \tag{3.3}$$

This is the desired recursive inequality. Summing (3.3) for $k = 1, \cdots, n$, we obtain

$$W_n^{-1} \geqq W_n^{-1} - W_0^{-1} \geqq \frac{2}{3}\sum_{k=1}^{n} \frac{\lambda_k}{\|x_{k-1} - x^*\|^2},$$

which implies

$$f(x_n) - f(x^*) \equiv W_n \leqq \frac{3}{2}\frac{1}{\sum_{k=1}^{n} \lambda_k\|x_{k-1} - x^*\|^{-2}}. \tag{3.4}$$

Multiplying (3.4) by σ_n gives

$$\sigma_n(f(x_n) - f(x^*)) \leqq \frac{3}{2}\frac{1}{\sigma_n^{-1}\sum_{k=1}^{n} \lambda_k\|x_{k-1} - x^*\|^{-2}}.$$

Since $\|x_n - x^*\| \to 0$, $\|x_n - x^*\|^{-1} \to \infty$. Therefore, using the Silverman-Toeplitz theorem (see Dunford and Schwartz [6]), $\sigma_n^{-1}\sum_{k=1}^{n} \lambda_k\|x_{k-1} - x^*\|^{-2} \to \infty$ also. Consequently, $f(x_n) - f(x^*) = o(\sigma_n^{-1})$. □

4. A fundamental estimate. Let $A: H \to H$ be a maximal monotone operator. Consider two proximal trajectories $\{x_k\}_{k=0}^{\infty}$, and $\{\hat{x}_k\}_{k=0}^{\infty}$. A remarkable estimate due to Kobayasi, Kobayashi, and Oharu [8], [9] (see also Pavel [14]) gives an estimate for the distance $\|x_k - \hat{x}_l\|$ between an arbitrary point x_k in the first trajectory and the point $\hat{x}_l$ on the second trajectory. This estimate can be used as the basis for the theory of nonlinear contractive semigroups and nonlinear evolution equations in Banach spaces. We shall use it in §5 to help settle a question posed by Rockafellar [17] on the strong convergence of the PPA. Since Kobayashi's estimate does not seem to be known in the optimization literature, but is likely to have further applications in optimization, we develop a special version of it here which will be enough for our purposes. The interested reader should consult Kobayasi, Kobayashi, and Oharu [9], or Pavel [14] for the general version of the estimate.

We will use two simple lemmas, valid for any monotone operator (not necessarily maximal).

LEMMA 4.1. *If $A: H \to H$ is a monotone operator, then for any $\lambda > 0$, and $y_i \in A(x_i)$, $i = 1,2$,*

$$\|x_1 - x_2\| \leqq \|x_1 - x_2 + \lambda(y_1 - y_2)\|.$$

Lemma 4.1 follows from the application of (1.3) to the operator λA.

LEMMA 4.2. *If A is a monotone operator, then for any $\lambda, \mu \geqq 0$, and $y_i \in A(x_i)$, $i=1,2$, the following inequality holds*:

$$(\lambda+\mu)\|x_1-x_2\| \leqq \lambda\|x_2+\mu y_2-x_1\|+\mu\|x_1+\lambda y_1-x_2\|.$$

Proof. We have

$$\mu(x_1+\lambda y_1-x_2)-\lambda(x_2+\mu y_2-x_1)=(\lambda+\mu)(x_1-x_2)+\lambda\mu(y_1-y_2). \tag{4.1}$$

By Lemma 4.1,

$$\|x_1-x_2\| \leqq \left\|(x_1-x_2)+\frac{\lambda\mu}{\lambda+\mu}(y_1-y_2)\right\|,$$

so that

$$\begin{aligned}(\lambda+\mu)\|x_1-x_2\| &\leqq \|(\lambda+\mu)(x_1-x_2)+\lambda\mu(y_1-y_2)\|\\ &=\|\mu(x_1+\lambda y_1-x_2)-\lambda(x_2+\mu y_2-x_1)\|\\ &\leqq \lambda\|x_2+\mu y_2-x_1\|+\mu\|x_1+\lambda y_1-x_2\|,\end{aligned}$$

where the equality follows from (4.1). The proof is complete. □

We now return to the PPA. In the remainder of this section we assume that a maximal monotone operator $A: H \to H$ is given, and that it generates the proximal trajectory $\{x_k\}_{k=0}^{\infty}$, with $x_0=x$ and parameters $\{\lambda_k\}_{k=1}^{\infty}$.

LEMMA 4.3. *For any $u \in D(A)$, and $k \geqq 0$,*

$$\|x_k-u\| \leqq \|x_0-u\|+\sigma_k\|A^0 u\|. \tag{4.2}$$

Proof. Let v be an arbitrary element of $A(u)$. Since $y_j=(x_{j-1}-x_j)/\lambda_j \in A(x_j)$, we have $x_{j-1}=x_j+\lambda_j y_j$. From Lemma 4.1,

$$\begin{aligned}\|x_j-u\| &\leqq \|x_j-u+\lambda_j(y_j-v)\|=\|x_{j-1}-u-\lambda_j v\|\\ &\leqq \|x_{j-1}-u\|+\lambda_j\|v\|.\end{aligned} \tag{4.3}$$

The lemma follows by summing (4.3) for $j=1,\cdots,k$ and noting that $v \in A(u)$ is arbitrary. □

Consider two proximal trajectories $\{x_k\}_{k=0}^{\infty}$, and $\{\hat{x}_l\}_{l=0}^{\infty}$. We will derive an estimate for the distance $\|x_k-\hat{x}_l\|$ for arbitrary k and l. This estimate will be obtained recursively.

We first prove some preliminary results. Denote the mesh of the first proximal trajectory by $d=\max_{1\leqq k\leqq N}\lambda_k$. Similarly, the mesh of the second proximal trajectory is defined by $\hat{d}=\max_{1\leqq l\leqq \hat{N}}\hat{\lambda}_l$. Also, we define $\alpha_{k,l}=\hat{\lambda}_l/(\lambda_k+\hat{\lambda}_l)$ and $\beta_{k,l}=1-\alpha_{k,l}=\lambda_k/(\lambda_k+\hat{\lambda}_l)$. Finally, we define

$$c_{k,l}=\sqrt{(\sigma_k-\hat{\sigma}_l)^2+d\sigma_k+\hat{d}\hat{\sigma}_l}.$$

LEMMA 4.4. $\alpha_{k,l}c_{k-1,l}+\beta_{k,l}c_{k,l-1} \leqq c_{k,l}$.

Proof. We have

$$\begin{aligned}\alpha_{k,l}c_{k-1,l}+\beta_{k,l}c_{k,l-1} &= \alpha_{k,l}^{1/2}(\alpha_{k,l}^{1/2}c_{k-1,l})+\beta_{k,l}^{1/2}(\beta_{k,l}^{1/2}c_{k,l-1})\\ &\leqq \sqrt{\alpha_{k,l}c_{k-1,l}^2+\beta_{k,l}c_{k,l-1}^2},\end{aligned}$$

where the inequality follows from the Cauchy-Schwarz inequality and the fact that

$\alpha_{k,l}+\beta_{k,l}=1$. Therefore,

$$\begin{aligned}(\alpha_{k,l}c_{k-1,l}+\beta_{k,l}c_{k,l-1})^2 &\leqq \alpha_{k,l}c_{k-1,l}^2+\beta_{k,l}c_{k,l-1}^2\\ &= \alpha_{k,l}((\sigma_{k-1}-\hat{\sigma}_l)^2+d\sigma_{k-1}+\hat{d}\hat{\sigma}_l)\\ &\qquad +\beta_{k,l}((\sigma_k-\hat{\sigma}_{l-1})^2+d\sigma_k+\hat{d}\hat{\sigma}_{l-1})\\ &= \alpha_{k,l}((\sigma_k-\hat{\sigma}_l-\lambda_k)^2+d(\sigma_k-\lambda_k)+\hat{d}\hat{\sigma}_l)\\ &\qquad +\beta_{k,l}((\sigma_k-\hat{\sigma}_l+\hat{\lambda}_l)^2+d\sigma_k+\hat{d}(\hat{\sigma}_l-\hat{\lambda}_l))\\ &= \frac{\hat{\lambda}_l}{\lambda_k+\hat{\lambda}_l}(c_{k,l}^2+\lambda_k^2-2\lambda_k(\sigma_k-\hat{\sigma}_l)-d\lambda_k)\\ &\qquad +\frac{\lambda_k}{\lambda_k+\hat{\lambda}_l}(c_{k,l}^2+\hat{\lambda}_l^2+2\hat{\lambda}_l(\sigma_k-\hat{\sigma}_l)-\hat{d}\hat{\lambda}_l)\\ &= c_{k,l}^2+\frac{\lambda_k\hat{\lambda}_l}{\lambda_k+\hat{\lambda}_l}((\lambda_k-d)+(\hat{\lambda}_l-\hat{d}))\leqq c_{k,l}^2.\end{aligned}$$

The lemma is proved. □

THEOREM (Kobayashi) 4.1. *Let $u\in D(A)$ be an arbitrary point. Then, for any $k=0,\cdots,N$ and $l=0,\cdots,\hat{N}$,*

$$\|x_k-\hat{x}_l\|\leqq\|x_0-u\|+\|\hat{x}_0-u\|+\sqrt{(\sigma_k-\hat{\sigma}_l)^2+d\sigma_k+\hat{d}\hat{\sigma}_l}\cdot\|A^0u\|.$$

Proof. Observe that the coefficient of $\|A^0u\|$ in the desired estimate is simply $c_{k,l}$. The proof will be by induction. We start by proving the theorem for the pairs $(k,0)$ and $(0,l)$. We have

$$\begin{aligned}\|x_k-\hat{x}_0\| &\leqq \|x_k-u\|+\|\hat{x}_0-u\|\\ &\leqq \|x_0-u\|+\|\hat{x}_0-u\|+\sigma_k\|A^0u\|\\ &\leqq \|x_0-u\|+\|\hat{x}_0-u\|+c_{k,0}\|A^0u\|,\end{aligned}$$

where the second inequality follows from Lemma 4.3, and the last inequality follows from the fact that $\sigma_k\leqq c_{k,0}$, which is easy to see. This proves the theorem for $(k,0)$. By symmetry, the theorem is also true for the pair $(0,l)$.

Suppose we have proved the theorem for the pairs $(k-1,l)$ and $(k,l-1)$. From Lemma 4.2, we obtain

$$(\lambda_k+\hat{\lambda}_l)\|x_k-\hat{x}_l\|\leqq\lambda_k\|\hat{x}_l+\hat{\lambda}_l\hat{y}_l-x_k\|+\hat{\lambda}_l\|x_k+\lambda_k y_k-\hat{x}_l\|.$$

Noting that $\hat{x}_{l-1}=\hat{x}_l+\hat{\lambda}_l\hat{y}_l$ and $x_{k-1}=x_k+\lambda_k y_k$, we have

$$\begin{aligned}\|x_k-\hat{x}_t\| &\leqq \frac{\hat{\lambda}_l}{\lambda_k+\hat{\lambda}_l}\|x_{k-1}-\hat{x}_l\|+\frac{\lambda_k}{\lambda_k+\hat{\lambda}_l}\|x_k-\hat{x}_{l-1}\|\\ &= \alpha_{k,l}\|x_{k-1}-\hat{x}_l\|+\beta_{k,l}\|x_k-\hat{x}_{l-1}\|\\ &\leqq \alpha_{k,l}(\|x_0-u\|+\|\hat{x}_0-u\|+c_{k-1,l}\|A^0u\|)\\ &\qquad +\beta_{k,l}(\|x_0-u\|+\|\hat{x}_0-u\|+c_{k,l-1}\|A^0u\|)\\ &\leqq \|x_0-u\|+\|\hat{x}_0-u\|+(\alpha_{k,l}c_{k-1,l}+\beta_{k,l}c_{k,l-1})\|A^0u\|\\ &\leqq \|x_0-u\|+\|\hat{x}_0-u\|+c_{k,l}\|A^0u\|,\end{aligned}$$

where the second inequality follows from the induction hypothesis, and the last inequality follows from Lemma 4.4. The theorem is proved. □

Theorem 4.1 can be used to prove that as the mesh of the backward discretization $\max_{k\geqq 1} \lambda_k \to 0$ in (1.6), the proximal trajectory converges to a (unique) *discrete scheme* solution to the differential inclusion (1.5). It turns out that this solution coincides with the usual solution $u(t)=S(t)x$ (also called the strong solution) discussed in §1. See Kobayashi [8], or Pavel [14, Chap. 1, §3] for more details.

COROLLARY 4.1. *The following estimates hold*:

$$\|x_k - S(t)x\| \leqq \sqrt{(\sigma_k - t)^2 + d\sigma_k} \cdot \|A^0x\|, \tag{4.4}$$

$$\|S(t)x - S(s)x\| \leqq |t-s| \cdot \|A^0x\|. \tag{4.5}$$

Proof. Choose $\hat{x}_0 = x$ and apply Theorem 4.1. As $\hat{d}\to 0$, the second proximal trajectory converges to the continuous path $S(t)x$, and (4.4) follows. Estimate (4.5) is proved similarly. □

5. On the strong convergence of the proximal point algorithm. We noted in §2 that the trajectory of the PPA converges weakly to a minimizer of a proper, closed convex function, provided that $X^* \neq \varnothing$ and $\sigma_k \to \infty$. In [17], Rockafellar posed the question of whether weak convergence can be strengthened to strong convergence. This question is also important for us since strong convergence has a bearing on the rate of convergence of the PPA. By Theorem 2.1, $f(x_n) - f^* = O(\sigma_n^{-1})$ in the case of weak convergence; however, by Theorem 3.1 $f(x_n) - f^* = o(\sigma_n^{-1})$ in the case of strong convergence. Of course, in finite dimensions, weak and strong convergence are equivalent. There are also cases (see, for example, [4], [5]) where we can show strong convergence.

In this section, we answer Rockafellar's open question in the negative. In particular, we prove that in l^2 there is a function f such that given any positive bounded sequence $\{\lambda_j\}_{j=1}^\infty$, there is a starting point $x \in D(f)$, and the PPA starting from x with $x_{k+1} = (x_k)_{\lambda_{k+1}}$ converges weakly, but not strongly.

We proceed in the following way. A well-known result of Bruck [5] states that $S(t)x$ converges weakly to a minimizer of f. Baillon [2], following a suggestion of Komura, constructed a proper, closed convex function in l^2 and a point $x \in \overline{D(f)}$ such that $S(t)x$ converges weakly, but not strongly, to a minimizer of f. In [13], Passty showed that the strong (respectively, weak) convergence of $S(t)x$ is equivalent to the strong (respectively, weak) convergence of a PPA trajectory under very restrictive conditions. By using the special properties of the monotone operator ∂f outlined in §2, and the fundamental estimate of Kobayashi described in §4, we show the asymptotic equivalence of the trajectory of a PPA and $S(t)$ under the condition that the sequence $\{\lambda_k\}_{k=1}^\infty$ is bounded.

DEFINITION 5.1. Let C be convex subset of H. A contractive evolution system on C is a two-parameter family of maps $\{U(t,s)\colon 0 \leqq s \leqq t\}$ from C into C satisfying:

(i) $U(t,t)x = x$ for all $x \in C$ and $t \geqq 0$,

(ii) $U(t,s)U(s,r)x = U(t,r)x$ for all $x \in C$ and $0 \leqq r \leqq s \leqq t$, and

(iii) $\|U(t,s)x - U(t,s)y\| \leqq \|x-y\|$ for all $x, y \in C$ and $0 \leqq s \leqq t$.

DEFINITION 5.2. A contractive evolution system $U(t,s)$ is asymptotically equal to a contractive semigroup $S(t)$ if, for all $x \in C$, we have

(i) $\lim_{t\to\infty} \|U(t+h,s)x - S(h)U(t,s)x\| = 0$ for all $t \geqq 0$, uniformly in $h \geqq 0$, and

(ii) $\lim_{t\to\infty} \|U(t+h,t)S(t)x - S(t+h)x\| = 0$ uniformly in $h \geqq 0$. The system U is called an asymptotic semigroup if there is a semigroup to which it is asymptotically equal.

Intuitively, that U and S are asymptotically equal means the following: if we follow one of the trajectories, say S, for a sufficiently long time t and arrive at the point $S(t)x$, then it matters little whether we follow S or U for any length of time h in the future, because the two trajectories will be close to each other.

The concept of asymptotic equality is important because of the following result proved in Passty [13].

LEMMA 5.1. *Let A be a maximal monotone operator on H, and let $S(t)$ be the contractive semigroup generated by A on $\bar{C}$. Let $U(t, s)$ be a contractive evolution system which is asymptotically equal to $S(t)$ on $D(A)$. Then the following are equivalent*:

(i) *$S(t)x$ converges strongly* (*respectively weakly*) *as $t\to\infty$ for all $x\in D(A)$*,

(ii) *$U(t, s)x$ converges strongly* (*respectively weakly*) *as $t\to\infty$ for all $x\in D(A)$, and $s\geqq 0$.*

Remark 5.1. From the proof given in Passty [13], it can be seen that in proving (i) implies (ii) in the lemma, only condition (i) of Definition 5.2 is needed. Similarly, only condition (ii) of Definition 5.2 is needed for proving that (ii) implies (i).

LEMMA 5.2. *Let $\{k(n)\}_{n=0}^{\infty}$ be a sequence of strictly increasing positive integers, where $k(0)=0$. Define $\sigma_m^n=\sum_{j=k(m)+1}^{k(n)}\lambda_j$, and $\prod_m^n=\prod_{j=k(m)+1}^{k(n)}J_{\lambda_j}$.* (*If $n\leqq m$, we define $\sigma_m^n=0$ and $\prod_m^n x=x$.*) *Then, for any $n, p\geqq 1$,*

$$(5.1)\qquad \left\|S(\sigma_n^{n+p})x-\prod_n^{n+p}x\right\|\leqq\sum_{m=n+1}^{n+p}\left\|S(\sigma_{m-1}^m)\left(\prod_n^{m-1}x\right)-\prod_{m-1}^m\left(\prod_n^{m-1}x\right)\right\|,$$

$$(5.2)\qquad \left\|S(\sigma_n^{n+p})x-\prod_n^{n+p}x\right\|\leqq\sum_{m=n+1}^{n+p}\left\|S(\sigma_{m-1}^m)S(\sigma_n^{m-1})x-\prod_{m-1}^m S(\sigma_n^{m-1})x\right\|.$$

Proof. We prove the lemma by induction on p. We first prove (5.1). It is evidently true for $p=1$. Assuming it is true for p, we prove it for $p+1$. We have

$$\begin{aligned}
\left\|S(\sigma_n^{n+p+1})x-\prod_n^{n+p+1}x\right\| &= \left\|S(\sigma_{n+p}^{n+p+1})S(\sigma_n^{n+p})x-\prod_{n+p}^{n+p+1}\left(\prod_n^{n+p}x\right)\right\| \\
&\leqq \left\|S(\sigma_{n+p}^{n+p+1})S(\sigma_n^{n+p})x-S(\sigma_{n+p}^{n+p+1})\left(\prod_n^{n+p}x\right)\right\| \\
&\quad+\left\|S(\sigma_{n+p}^{n+p+1})\left(\prod_n^{n+p}x\right)-\prod_{n+p}^{n+p+1}\left(\prod_n^{n+p}x\right)\right\| \\
&\leqq \left\|S(\sigma_n^{n+p})x-\prod_n^{n+p}x\right\|+\left\|S(\sigma_{n+p}^{n+p+1})\left(\prod_n^{n+p}x\right)-\prod_{n+p}^{n+p+1}\left(\prod_n^{n+p}x\right)\right\| \\
&\leqq \sum_{m=n+1}^{n+p}\left\|S(\sigma_{m-1}^m)\left(\prod_n^{m-1}x\right)-\prod_{m-1}^m\left(\prod_n^{m-1}x\right)\right\| \\
&\quad+\left\|S(\sigma_{n+p}^{n+p+1})\left(\prod_n^{n+p}x\right)-\prod_{n+p}^{n+p+1}\left(\prod_n^{n+p}x\right)\right\| \\
&= \sum_{m=n+1}^{n+p+1}\left\|S(\sigma_{m-1}^m)\left(\prod_n^{m-1}x\right)-\prod_{m-1}^m\left(\prod_n^{m-1}x\right)\right\|,
\end{aligned}$$

where the second inequality follows since $S(t)$ is contractive, and the last inequality follows from the induction hypothesis. This proves (5.1).

We now prove (5.2). The proof is again by induction on p. Equation (5.2) is clearly true for $p=1$. Assuming it is true for p, we prove it for $p+1$. We have

$$\begin{aligned}
\left\| S(\sigma_n^{n+p+1})x-\prod_n^{n+p+1} x\right\| &= \left\| \prod_{n+p}^{n+p+1}\prod_n^{n+p} x-S(\sigma_{n+p}^{n+p+1})S(\sigma_n^{n+p})x\right\| \\
&\leqq \left\| \prod_{n+p}^{n+p+1}\left(\prod_n^{n+p} x\right)-\prod_{n+p}^{n+p+1} S(\sigma_n^{n+p})x\right\| \\
&\quad + \left\| \prod_{n+p}^{n+p+1} S(\sigma_n^{n+p})x-S(\sigma_{n+p}^{n+p+1})S(\sigma_n^{n+p})x\right\| \\
&\leqq \left\| \prod_n^{n+p} x-S(\sigma_n^{n+p})x\right\| + \left\| \prod_{n+p}^{n+p+1} S(\sigma_n^{n+p})x \right. \\
&\qquad\qquad \left. -S(\sigma_{n+p}^{n+p+1})S(\sigma_n^{n+p})x\right\| \\
&\leqq \sum_{m=n+1}^{n+p} \left\| S(\sigma_{m-1}^m)S(\sigma_n^{m-1})x-\prod_{m-1}^m S(\sigma_n^{m-1})x\right\| \\
&\quad + \left\| \prod_{n+p}^{n+p+1} S(\sigma_n^{n+p})x-S(\sigma_{n+p}^{n+p+1})S(\sigma_n^{n+p})x\right\| \\
&= \sum_{m=n+1}^{n+p+1} \left\| S(\sigma_{m-1}^m)S(\sigma_n^{m-1})x-\prod_{m-1}^m S(\sigma_n^{m-1})x\right\|,
\end{aligned}$$

where the second inequality follows since $\prod_{n+p}^{n+p+1}$ is contractive, and the last inequality follows from the induction hypothesis. This proves (5.2). □

Let the sequence $\{\lambda_j\}_{j=1}^{\infty}$ of positive numbers be the parameters of a PPA such that $\sigma_n\to\infty$. We *define* an integer-valued function $n(t)$ for $t\geqq 0$ as follows: $n(0)=0$, and for $t>0$, $n(t)$ is the integer satisfying

$$\sigma_{n(t)-1}<t\leqq\sigma_{n(t)}.$$

We are interested in the contractive evolution system $U(t,s)$, defined for $0\leqq s\leqq t$ by the formula $U(t,s)x=(\prod_{i=n(s)+1}^{n(t)} J_{\lambda_i})x$, where we let $(\prod_{i=1}^{0} J_{\lambda_i})x=x$. It is easy to show that $U(t,s)$ is a contractive evolution system using the fact that J_λ is a contractive mapping.

The following theorem is the main result of this section. This sharpens Theorem 1 in Passty [13] in the case where $A=\partial f$ in that our conditions on the parameters $\{\lambda_k\}_{k=1}^{\infty}$ are much more relaxed than Passty's. Our relaxed conditions are possible because of the special properties of the operator $A=\partial f$ given in §2. However, Passty's Theorem 1 applies to an arbitrary maximal monotone operator.

THEOREM 5.1. *Suppose* $f: H\to\mathbf{R}\cup\{\infty\}$ *is a closed convex function and assume that* f *has a minimizer. Let* $\{\lambda_j\}_{j=1}^{\infty}$ *be a bounded sequence of positive numbers such that* $\sigma_n\to\infty$. *Then the contractive evolution system* $U(t,s)$ *defined above is asymptotically equal to the contractive semigroup* $S(t)$ *generated by* ∂f.

Proof. By Lemma 5.1, we need to verify the conditions (i) and (ii) in Definition 5.2.

For the sake of simple notation, we define $\sigma_s^t = \sum_{j=n(s)+1}^{n(t)} \lambda_j$, and $\prod_s^t = \prod_{j=n(s)+1}^{n(t)} J_{\lambda_j}$. If $t \leqq s$, we let $\sigma_s^t = 0$, and $\prod_s^t x = x$. Note that we also define σ_m^n in Lemma 5.2. However, no confusion should arise, since it will be clear from the context which definition is intended.

Let us first verify condition (i) in Definition 5.2. Without loss of generality, we may assume that $s = 0$. Fix $t > 0$. For an arbitrary $h > 0$, we have

$$\begin{aligned}
\left\| U(t+h,0)x - S(h)U(t,0)x \right\| &= \left\| \prod_0^{t+h} x - S(h)\prod_0^t x \right\| \\
&= \left\| \prod_t^{t+h}\left(\prod_0^t x\right) - S(h)\left(\prod_0^t x\right) \right\| \\
&\leqq \left\| \prod_t^{t+h}\left(\prod_0^t x\right) - S(\sigma_t^{t+h})\left(\prod_0^t x\right) \right\| \\
&\quad + \left\| S(\sigma_t^{t+h})\left(\prod_0^t x\right) - S(h)\prod_0^t x \right\|.
\end{aligned}$$

We first estimate the second term in the last expression above:

$$\begin{aligned}
\left\| S(\sigma_t^{t+h})\prod_0^t x - S(h)\prod_0^t x \right\| &\leqq |\sigma_t^{t+h} - h| \cdot \left\| A^0 \prod_0^t x \right\| \\
&\leqq \frac{|\sigma_t^{t+h} - h|}{\sigma_{n(t)}} \rho(x, X^*) \\
&\leqq \frac{\max\{\lambda_{n(t)}, \lambda_{n(t+h)}\}}{\sigma_{n(t)}} \rho(x, X^*) \qquad (5.3)\\
&\leqq \frac{\Lambda}{\sigma_{n(t)}} \rho(x, X^*),
\end{aligned}$$

where $\Lambda = \max_{j \leqq 1} \lambda_j$. Here the first inequality follows from (4.5), and the second inequality follows from (2.12) with x^* replacing u, where x^* is the element of X^* closest to x. The third inequality follows easily from the definition of σ_t^{t+h}. Since $\sigma_{n(t)} \to \infty$ as $t \to \infty$, the last term in (5.3) can be made as small as desired by choosing t large enough.

It remains to estimate the first term:

$$\left\| S(\sigma_t^{t+h})\left(\prod_0^t x\right) - \prod_t^{t+h}\left(\prod_0^t x\right) \right\|.$$

The idea is to *partition* the interval $[0, \sigma_{n(t+h)}]$ into subintervals and use Lemma 5.2 on each subinterval. The subintervals will be of the form $[\sigma_{k(i)}, \sigma_{k(i+1)}]$, for $i = 0, \cdots, n+p$, such that $k(i) = n(t)$ for some t, where we assume $n(t) = k(n)$ (note the two meanings of n here) and $n(t+h) = k(n+p)$. We will impose more conditions on the sequence $k(i)$ later. We have

$$
\begin{aligned}
\left\| S(\sigma_t^{t+h})\left(\prod_0^t x\right) - \prod_t^{t+h}\left(\prod_0^t x\right)\right\| &= \left\| S(\sigma_n^{n+p})\left(\prod_0^n x\right) - \prod_n^{n+p}\left(\prod_0^n x\right)\right\| \\
&\leqq \sum_{m=n+1}^{n+p} \left\| S(\sigma_{m-1}^m) \prod_n^{m-1}\left(\prod_0^n x\right) - \prod_{m-1}^{m}\prod_n^{m-1}\left(\prod_0^n x\right)\right\| \\
&= \sum_{m=n+1}^{n+p} \left\| S(\sigma_{m-1}^m)\left(\prod_0^{m-1} x\right) - \prod_{m-1}^{m}\left(\prod_0^{m-1} x\right)\right\| \\
&\leqq \sum_{m=n+1}^{n+p} \sqrt{d_m \sigma_{m-1}^m}\left\| A^0\left(\prod_0^{m-1} x\right)\right\| \\
&\leqq \sum_{m=n+1}^{n+p} \sqrt{d_m \sigma_{m-1}^m}\,\frac{\rho(x, X^*)}{\sigma_0^{m-1}} \\
&\leqq \sqrt{\Lambda}\rho(x, X^*) \sum_{m=n+1}^{n+p} \frac{\sqrt{\sigma_{m-1}^m}}{\sigma_0^{m-1}},
\end{aligned}
$$

where the first inequality follows from (5.1), and the second inequality from (4.4). The third inequality follows from (2.12), with x^* replacing u, where x^* is the element of X^* closest to x. Here $d_m = \max_{j=k(m-1)+1}^{k(m)} \lambda_j$. We are interested in making the term

$$
\sum_{m=n+1}^{n+p} \frac{\sqrt{\sigma_{m-1}^m}}{\sigma_0^{m-1}}
$$

small. Clearly, if $t \to \infty$, then $n(t) \to \infty$ also. Therefore, if we can ensure that

$$
\sum_{m=1}^{\infty} \frac{\sqrt{\sigma_{m-1}^m}}{\sigma_0^{m-1}} < \infty,
$$

we are done. There are many choices for $k(i)$ which can accomplish this. For example, if we choose $k(i)$ such that

$$
\sigma_{k(i)-1} < i^2 \leqq \sigma_{k(i)} \tag{5.4}
$$

we can easily check that

$$
\sqrt{\sigma_{m-1}^m}/\sigma_0^{m-1} \leqq \sqrt{2m-1+\Lambda}/(m-1)^2
$$

and therefore the infinite series above converges. This proves (i) of Definition 5.2.

Next, we need to verify condition (ii) in Definition 5.2. We have

$$
\begin{aligned}
\|U(t+h, t)S(t)x - S(t+h)x\| &= \left\| \prod_t^{t+h} S(t)x - S(t+h)x \right\| \\
&\leqq \left\| \prod_t^{t+h} S(t)x - S(\sigma_t^{t+h})S(t)x \right\| \\
&\quad + \|S(\sigma_t^{t+h})S(t)x - S(h)S(t)x\|.
\end{aligned}
$$

The second term above can be estimated as follows:

$$
\begin{aligned}
\|S(\sigma_t^{t+h})x - S(h)S(t)x\| &\leqq |\sigma_t^{t+h} - h| \cdot \|A^0 S(t)x\| \\
&\leqq \frac{|\sigma_t^{t+h} - h|}{t}\,\rho(x, X^*) \qquad (5.5) \\
&\leqq \frac{\Lambda}{t}\,\rho(x, X^*),
\end{aligned}
$$

where the first inequality follows from (4.5), and the second one from (2.14). Therefore, the last term in (5.5) can be made as small as desired by choosing t large enough.

Finally, we estimate the remaining term:

$$\begin{aligned}\left\| \prod_{t}^{t+h} S(t)x - S(\sigma_t^{t+h})S(t)x \right\| &= \left\| \prod_{n}^{n+p} S(t)x - S(\sigma_n^{n+p})S(t)x \right\| \\ &\leqq \sum_{m=n+1}^{n+p} \left\| S(\sigma_{m-1}^m)S(\sigma_n^{m-1})S(t)x - \prod_{m-1}^{m} S(\sigma_n^{m-1})S(t)x \right\| \\ &= \sum_{m=n+1}^{n+p} \left\| S(\sigma_{m-1}^m)S(\sigma_n^{m-1}+t)x - \prod_{m-1}^{m} S(\sigma_n^{m-1}+t)x \right\| \\ &\leqq \sum_{m=n+1}^{n+p} \sqrt{d_m\sigma_{m-1}^m}\|A^0S(\sigma_n^{m-1}+t)x\| \\ &\leqq \sum_{m=n+1}^{n+p} \sqrt{d_m\sigma_{m-1}^m}\frac{\rho(x, X^*)}{\sigma_n^{m-1}+t} \\ &\leqq \sqrt{\Lambda}\rho(x, X^*) \sum_{m=n+1}^{n+p} \frac{\sqrt{\sigma_{m-1}^m}}{\sigma_0^{m-1}-\lambda_{k(n)}} \\ &\leqq \sqrt{\Lambda}\rho(x, X^*) \sum_{m=n+1}^{n+p} \frac{\sqrt{\sigma_{m-1}^m}}{\sigma_0^{m-1}-\Lambda},\end{aligned}$$

where the first inequality follows from (5.2), the second inequality from (4.4), and the third one from (2.14). If $k(i)$ is chosen as in (5.4), it is easy to check, as above, that

$$\sum_{m=n+1}^{n+p} \frac{\sqrt{\sigma_{m-1}^m}}{\sigma_0^{m-1}-\Lambda} \leqq \sum_{m=n+1}^{n+p} \frac{\sqrt{2m-1+\Lambda}}{(m-1)^2-\Lambda} \to 0$$

as $n \to \infty$. This proves (ii) of Definition 5.2. □

COROLLARY 5.1. *There exists a proper, closed convex function f in l^2 such that given any bounded positive sequence $\{\lambda_j\}_{j=1}^{\infty}$, there exists a point $x \in D(f)$ for which* PPA *starting at x, $x_{k+1} = (x_k)_{\lambda_{k+1}}$ converges weakly, but not strongly to a minimizing point of f.*

Proof. By Baillon's theorem [2], there exists a function f in $H = l^2$ and a starting point x such that $S(t)x$ converges weakly but not strongly to a minimizer of f. By Theorem 5.1, $U(t, s)$, defined above, is asymptotically equivalent to $S(t)$. Therefore, by Lemma 5.1, there exists a point $\bar{x}$ such that $U(t, s)\bar{x}$ also converges weakly but not strongly to a minimizer of f. □

Acknowledgments. The author thanks the two anonymous referees for their helpful comments.

REALIZATION OF ACAUSAL WEIGHTING PATTERNS WITH BOUNDARY-VALUE DESCRIPTOR SYSTEMS*

RAMINE NIKOUKHAH†, BERNARD C. LEVY‡, AND ALAN S. WILLSKY§

Abstract. This paper examines the realization of acausal weighting patterns with two-point boundary-value descriptor systems (TPBVDSs). Attention is restricted to the subclass of TPBVDSs that are *stationary*, so that their input-output weighting pattern is shift-invariant, and *extendible*, i.e., their weighting pattern can be extended outwards indefinitely. Then, given an infinite acausal shift-invariant weighting pattern, the realization problem consists of constructing a minimal TPBVDS over a fixed interval, whose extended weighting pattern matches the given pattern. The realization method that is proposed relies on a new transform, the (s, t)-transform, which is better adapted to the analysis of descriptor dynamics than the standard z-transform, since it handles zero and infinite frequencies in a symmetric way. This new transform is used to determine the dimension of a minimal realization, and then to construct a minimal realization by obtaining state-space representations for two homogeneous rational matrices in s and t obtained from the causal and anticausal components of the weighting pattern.

1. Introduction.

There exists an extensive literature [1]-[4] on the state-space realization problem for linear time-invariant causal systems, i.e., for systems which admit an input-output description of the form

$$y(k)=\sum_{l=-\infty}^{\infty} W(k-l)u(l), \tag{1.1}$$

where the impulse response (weighting pattern) $W(.)$ satisfies

$$W(k)=0 \quad \text{for } k\leqq 0. \tag{1.2}$$

However, for many physical systems, in particular when the independent variable is space rather than time, the causality condition (1.2) does not hold. For example, if we consider the temperature of a heated rod, there is no reason to assume that the temperature at any point of the rod depends exclusively on the applied heat on one side of that point. Weighting patterns that do not satisfy (1.2) are called acausal. The objective of this paper is to develop a realization theory for acausal weighting patterns in terms of *two-point boundary-value descriptor systems* (TPBVDSs) of the form

$$Ex(k+1)=Ax(k)+Bu(k), \qquad 0\leqq k\leqq N-1, \tag{1.3}$$

with boundary condition

$$V_i x(0)+V_f x(N)=v, \tag{1.4}$$

and output

$$y(k) = Cx(k), \qquad 0 \leqq k \leqq N. \tag{1.5}$$

The motivation for considering this class of systems is that the discrete-time descriptor dynamics (1.3) are noncausal, in the sense that they contain components which propagate in both time directions [5]. The boundary conditions (1.4) are another source of noncausality, since they are expressed symmetrically in terms of the system variables at both ends of the interval $[0, N]$. Thus, TPBVDSs have a totally acausal structure which is ideally suited to model noncausal systems [6]-[8]. Motivated by the earlier work of Krener [9]-[10], and Gohberg, Kaashoek, and Lerer [11]-[13] for boundary-value systems with standard nondescriptor dynamics, a complete system theory of TPBVDSs has been developed in [14]-[18], including concepts such as reachability, observability, and minimality. In this paper, we restrict our attention to stationary and extendible TPBVDSs, namely TPBVDSs whose weighting pattern is shift-invariant, and where the interval of definition $[0, N]$ of the TPBVDS can be extended outwards indefinitely, without changing the weighting pattern. This extension process yields an extended weighting pattern $W(k)$ defined for all $k \in \mathbf{Z}$, where the weighting pattern of the original TPBVDS and of all its extensions are restrictions of $W(k)$.

The realization problem that we consider can be stated as follows. Given a weighting pattern $W(k)$, construct a minimal TPBVDS over a sufficiently large interval $[0, N]$, which has $W(k)$ as its extended weighting pattern. As for causal time-invariant systems, where the z-transform plays a useful role in transforming the realization problem into a state-space representation problem for proper rational matrix transfer functions, it is shown that the TPBVDS realization problem can be formulated in the frequency domain as a state-space representation problem for rational transfer functions. However, instead of using the z-transform, we introduce a new transform, the (s, t)-transform, which handles zero and infinite frequencies symmetrically, and is therefore well adapted to the analysis of descriptor systems. Specifically, the (s, t)-transform of a matrix sequence $H(k)$ is defined as

$$H(s, t) = \sum_{k=-\infty}^{\infty} H(k) t^{k-1}/s^k. \tag{1.6}$$

Because of its special structure, $H(s, t)$ is strictly proper when viewed as a function of both s and t, but not necessarily strictly proper in s and t separately. When $H(s, t)$ is rational, this last observation leads us to construct minimal state-space representations of the form

$$H(s, t) = K(sD - tF)^{-1}G, \tag{1.7}$$

where the descriptor dynamics appearing in (1.7) generalize the causal dynamics that are usually employed for strictly proper rational matrices in z.

The (s, t) transform is used here to characterize the dimension of TPBVDS realizations in terms of the McMillan degree of rational matrices in s and t, and to formulate the TPBVDS realization problem as a state-space realization in the (s, t)-domain. More precisely, if $W_f(s, t)$ and $W_b(s, t)$ denote the (s, t)-transforms of the causal and anticausal parts of the weighting pattern $W(k)$, and if

$$W(s, t) = W_f(s, t) + W_b(s, t), \tag{1.8a}$$

$$H_r(s, t) = [\, W_f(s, t)\, W_b(s, t)], \qquad H_o(s, t) = \begin{bmatrix} W_f(s, t) \\ W_b(s, t) \end{bmatrix}, \tag{1.8b}$$

it is shown that minimal TPBVDS realizations of the extended weighting pattern $W(k)$ have dimension

$$n=\omega+\rho-\tau, \tag{1.9}$$

where ω, ρ, and τ denote the McMillan degrees of $H_r(s,t)$, $H_o(s,t)$, and $W(s,t)$, respectively. We also develop a minimal realization procedure, which relies on constructing minimal state-space representations of the form (1.7) for *both* $H_r(s,t)$ and $H_o(s,t)$. The reason why it is necessary to construct state-space representations for two rational matrices, instead of one for the causal case, is that the TPBVDS realization problem requires finding descriptor dynamics (1.3) and boundary conditions (1.4), which together realize $W(k)$. It is the search for boundary conditions that makes the TPBVDS realization problem significantly harder than the causal problem.

This paper is organized as follows. In § 2, we review several results concerning the stationarity, minimality, and extendibility of TPBVDSs that will be used later. It is shown in § 3 that the effect of the boundary conditions on the extended weighting pattern of the system can be characterized completely by a single matrix, called the decomposition matrix, which appears as a parameter of both the causal and anticausal parts of $W(k)$. This matrix simplifies significantly the presentation of our realization results. In § 4, we examine a direct but naive TPBVDS realization procedure consisting in constructing separate minimal realizations of the causal and anticausal components of $W(k)$. Although the resulting realization is generally nonminimal, it is minimal when the weighting pattern $W(k)$ is summable. Furthermore, it yields necessary and sufficient conditions for the realizability of acausal weighting patterns. The (s,t)-transform is introduced in § 5 and is used to formulate the TPBVDS realization problem in the frequency domain. A method for constructing minimal state-space representations of the form (1.7) for rational matrices in s and t is also presented. Finally, § 6 contains the two main results of our paper, namely the characterization (1.9) for the dimension of a minimal realization, and a minimal TPBVDS realization procedure in the frequency domain.

2. Two-point boundary-value descriptor systems. In this section, we review several properties of TPBVDSs, such as stationarity, minimality, and extendibility, that will be needed in the development of our TPBVDS realization procedure.

2.1. Model description. Consider a linear time-invariant TPBVDS of the form (1.3)-(1.5), where x and v are n-dimensional, u is m-dimensional, y is p-dimensional, and E, A, B, and C are constant matrices. We assume that the length N of the interval of definition satisfies $N\geqq 2n$, so that all modes can be excited and observed. In [14] it was shown that if the system (1.3)-(1.4) is well posed, by left multiplication of (1.3) and (1.4) with invertible matrices, we can bring this system to the following *normalized form*, where there exists scalars α and β such that

$$\alpha E+\beta A=I \tag{2.1}$$

(this is referred to as the *standard form* for the pencil $\{E, A\}$), and

$$V_iE^N+V_fA^N=I. \tag{2.2}$$

Note that (2.1) implies that E and A commute, that E, A, and the system have a common set of eigenvectors,[1] and that $\{E^k, A^k\}$ is a regular pencil for all $k\geqq 0$. Another

[1] v is an eigenvector of the system if $v\neq 0$ and for some σ, $(\sigma E-A)v=0$. σ is called an eigenmode of the system; for descriptor systems σ can be ∞.

consequence of (2.1) is that the space of matrices $\{A^K E^L;\ K, L \geqq 0\}$ is spanned by the n matrices $\{A^k E^{n-1-k};\ 0 \leqq k \leqq n-1\}$. This last result, which was derived in [14], is a generalization of the Cayley-Hamilton theorem to matrix pencils in the standard form (2.1). We assume throughout this paper that (2.1) and (2.2) hold.

As derived in [14], the map from $\{\mathbf{u}, v\}$ to $\mathbf{x}$ has the form:

$$x(k) = A^k E^{N-k} v + \sum_{l=0}^{N-1} G(k, l) B u(l), \tag{2.3}$$

where the Green function $G(k, l)$ is given by

$$G(k, l) = \begin{cases} A^k[A - E^{N-k}(V_i A + \omega V_f E) E^k] E^{l-k} A^{N-l-1} \Gamma^{-1}, & l \geqq k, \\ E^{N-k}[\omega E - A^k(V_i A + \omega V_f E) A^{N-k}] E^l A^{k-l-1} \Gamma^{-1}, & l < k, \end{cases} \tag{2.4}$$

and where ω is any number such that

$$\Gamma = \omega E^{N+1} - A^{N+1} \tag{2.5}$$

is invertible.

The map from inputs $\mathbf{u}$ to outputs $\mathbf{y}$ specifies the weighting pattern W of the system. Setting $v = 0$ in (2.3), we obtain

$$y(k) = \sum_{l=0}^{N-1} W(k, l) u(l), \tag{2.6}$$

with

$$W(k, l) = C G(k, l) B. \tag{2.7}$$

2.2. Stationarity. In contrast with the causal case, where time-invariant state-space models have a time-invariant impulse response, the weighting pattern $W(k, l)$ given by (2.7) is not, in general, a function of the difference $k - l$. TPBVDSs that have this property are called *stationary*.

THEOREM 2.1 [15]. *The* TPBVDS (1.3)-(1.5) *is stationary if and only if*

$$O_s[V_i, E] R_s = O_s[V_i, A] R_s = 0, \tag{2.8a}$$

$$O_s[V_f, E] R_s = O_s[V_f, A] R_s = 0, \tag{2.8b}$$

where $[X, Y]$ *denotes the commutator product of* X *and* Y

$$[X, Y] = XY - YX \tag{2.9}$$

and

$$R_s = [E^{n-1} B A E^{n-2} B \cdots A^{n-1} B], \tag{2.10a}$$

$$O_s^T = [(E^{n-1})^T C^T (A E^{n-2})^T C^T \cdots (A^{n-1})^T C^T]. \tag{2.10b}$$

The matrices R_s and O_s in (2.10) are the *strong reachability* and *strong observability* matrices of the TPBVDS. If they have full rank, the triplets (E, A, B) and (C, E, A) are said, respectively, to be strongly reachable, and strongly observable (see [14]-[15] for a detailed study of the properties of strong and weak reachability and observability). The stationarity conditions (2.8a) and (2.8b) state that V_i and V_f must commute with E and A, except for parts that are either in the left nullspace of R_s or the right nullspace of O_s. Consequently, if R_s and O_s have full rank, i.e., if the TPBVDS is strongly reachable and strongly observable, V_i and V_f must commute with E and A.

It is easily verified that the weighting pattern of a stationary TPBVDS defined over $[0, N]$ is given by

$$W(k)=\begin{cases} CV_iA^{k-1}E^{N-k}B, & 1\leqq k\leqq N, \\ -CV_fE^{-k}A^{N+k-1}B, & 1-N\leqq k\leqq 0. \end{cases} \tag{2.11}$$

2.3. Minimality. Since our goal is to realize shift-invariant acausal weighting patterns with stationary TPBVDSs, we need to be able to determine whether or not a system in this class is minimal. This issue was examined in [15] and [18], leading to the following definition and characterization of minimality.

DEFINITION 2.1. A TPBVDS is *minimal* if its state x has the lowest dimension among all TPBVDSs having the same weighting pattern.

THEOREM 2.2. *The stationary* TPBVDS (1.3)-(1.5) *is minimal if and only if*

(2.12a) $[V_iR_s \quad V_fR_s]$ *has full row rank,*

(2.12b) $\begin{bmatrix} O_sV_i \\ O_sV_f \end{bmatrix}$ *has full column rank,*

(2.12c) $\ker(O_s)\subset \operatorname{im}(R_s)$.

It was also shown in Corollary 5.1 of [15] that Theorem 2.2 implies the following corollary.

COROLLARY. *Let $(C_j, V_i^j, V_f^j, E_j, A_j, N)$ with $j=1, 2$ be two minimal and stationary realizations of the same weighting pattern, where $\{E_j, A_j\}$, $j=1, 2$ are in standard form for the same α and β. Then, there exists an invertible matrix T such that*

$$B_2=TB_1, \qquad C_2=C_1T^{-1}, \tag{2.13a}$$

$$O_s^1(V_i^1-T^{-1}V_i^2T)R_s^1=O_s^1(V_f^1-T^{-1}V_f^2T)R_s^1=0, \tag{2.13b}$$

and

$$(A_1-T^{-1}A_2T)R_s^1=(E_1-T^{-1}E_2T)R_s^1=0, \tag{2.13c}$$

$$O_s^1(A_1-T^{-1}A_2T)=O_s^1(E_1-T^{-1}E_2T)=0, \tag{2.13d}$$

where R_s^1 and O_s^1 are the strong reachability and observability matrices for system 1.

2.4. Extendibility. The concept of extendibility was introduced in [15] for stationary TPBVDSs. It was later extended to nonstationary TPBVDSs in [18]. In this paper, we shall consider only the stationary case.

DEFINITION 2.2. The stationary TPBVDS (1.3)-(1.5) is *extendible* (or input-output extendible) if given any interval $[K, L]$ containing $[0, N]$, there exists a stationary TPBVDS over this larger interval with the same dynamics as in (1.3), but with new boundary matrices $V_i(K, L)$ and $V_f(K, L)$ such that the weighting pattern $W_N(k)$ of the original system is the restriction of the weighting pattern $W_{L-K}(k)$ of the new extended system, i.e.,

$$W_N(k)=W_{K-L}(k) \quad \text{for } 1-N\leqq k\leqq N. \tag{2.14}$$

Our characterization of the property of extendibility for stationary TPBVDSs relies on the notion of Drazin inverse of a matrix [19, p. 8].

DEFINITION 2.3. Let F be an arbitrary square matrix, and let T be an invertible real transformation such that

$$F=T\begin{bmatrix} M & 0 \\ 0 & N \end{bmatrix}T^{-1}, \tag{2.15a}$$

where M is invertible and N is nilpotent. For example, the real Jordan form of F has the above structure. The *Drazin inverse* of F is defined as

$$F^D = T\begin{bmatrix} M^{-1} & 0 \\ 0 & 0 \end{bmatrix} T^{-1}. \tag{2.15b}$$

It can be shown that the Drazin inverse is unique and possesses the following properties:

(i) F^D can be expressed as a polynomial of F, so that it commutes with F. Thus, if a subspace is F-invariant, it is also F^D-invariant.

(ii) When F is invertible, $F^D = F^{-1}$.

(iii) If μ is the degree of nilpotency of N, i.e., if $N^{\mu-1} \neq 0$ and $N^\mu = 0$, then for $k \geqq \mu$

$$F^{k+1}F^D = F^k. \tag{2.16}$$

(iv) Let G be any matrix. Then, the condition

$$\ker(F^\mu) \subset \ker(G) \tag{2.17a}$$

is equivalent to

$$GFF^D = G. \tag{2.17b}$$

(v) If $\{E, A\}$ is a regular pencil in standard form, we have [18, pp. 33-34]

$$EE^D + AA^D - EE^DAA^D = I. \tag{2.18}$$

The extendibility property can then be characterized as follows.

THEOREM 2.3 [15]. *A stationary* TPBVDS *is extendible if and only if*

$$O_s(V_i - V_iE^DE)R_s = 0, \tag{2.19a}$$

$$O_s(V_f - V_fA^DA)R_s = 0. \tag{2.19b}$$

From conditions (2.19), by using the E-, A-, E^D-, and A^D-invariance of im (R_s) [15] and the generalized Cayley-Hamilton theorem, it is easy to check that for an extendible stationary TPBVDS, the weighting pattern (2.11) can be rewritten as

$$W(k) = \begin{cases} CV_iE^NE^D(AE^D)^{k-1}B, & 1 \leqq k \leqq N, \\ -CV_fA^NA^D(EA^D)^{-k}B, & 1-N \leqq k \leqq 0. \end{cases} \tag{2.20}$$

Given an extendible stationary TPBVDS over $[0, N]$ with weighting pattern $W_N(k)$, it is of interest to ask whether it is possible to extend this TPBVDS in a consistent way over intervals of increasing lengths, i.e., so that this progressive extension process gives rise to a unique extended weighting pattern $W(k)$ defined for all k. A procedure to achieve this objective is given by Theorem 2.4.

THEOREM 2.4. *An extendible stationary* TPBVDS *admits extendible extensions over any interval. Furthermore, the weighting pattern of these extendible extensions is unique.*

Proof. Given an extendible stationary TPBVDS $(C, V_i, V_f, E, A, B, N)$, consider the TPBVDS $(C, \tilde{V}_i, \tilde{V}_f, E, A, B, M)$ defined over an interval of length $M > N$, with

$$\tilde{V}_i = V_iE^N(E^D)^M, \qquad \tilde{V}_f = V_fA^N(A^D)^M. \tag{2.21}$$

It is easy to check that this new TPBVDS is in normalized form, and by using the E-, A-, E^D-, and A^D-invariance of im (R_s), that it is stationary and extendible. According to (2.20), its weighting pattern can be expressed as

$$\tilde{W}_M(k) = \begin{cases} C\tilde{V}_iE^ME^D(AE^D)^{k-1}B, & 1 \leqq k \leqq M, \\ -C\tilde{V}_fA^MA^D(EA^D)^{-k}B, & 1-M \leqq k \leqq 0. \end{cases} \tag{2.22}$$

Substituting (2.21) inside (2.22), and noting from $N > n$ that we have $E^{M+N}(E^D)^M = E^N$ and $A^{M+N}(A^D)^M = A^N$, we find

$$\tilde{W}_M(k) = \begin{cases} CV_iE^NE^D(AE^D)^{k-1}B, & 1 \leqq k \leqq M, \\ -CV_fA^NA^D(EA^D)^{-k}B, & 1-M \leqq k \leqq 0. \end{cases} \tag{2.23}$$

This implies

$$\tilde{W}_M(k) = W_N(k) \quad \text{for } 1-N \leqq k \leqq N, \tag{2.24}$$

so that the TPBVDS $(C, \tilde{V}_i, \tilde{V}_f, E, A, B, M)$ specified by (2.21) is an extension of $(C, V_i, V_f, E, A, B, N)$.

To prove the uniqueness of the extended weighting pattern $\tilde{W}_M(k)$, observe that if $\tilde{W}_M(k)$ is the weighting pattern of an arbitrary extendible extension of TPBVDS (1.3)-(1.5) to an interval of length $M > N$, it can be expressed as (2.22), and satisfies (2.24), so that it is uniquely specified on $[1-N, N]$. Since $N > n$, by applying the standard Cayley-Hamilton theorem to matrices AE^D and EA^D in (2.22), we see that $\tilde{W}_M(k)$ is also uniquely specified on $[N+1, M]$ and $[1-M, -N]$. □

Thus, we can associate to an extendible system a sequence of extendible systems over progressively larger intervals, and with consistent weighting patterns. In this way, we can construct an infinite weighting pattern, called the *extended weighting pattern* of the system, which is such that the weighting pattern of the system and of all its extensions are restrictions of this extended weighting pattern.

From (2.23), the extended weighting pattern of an extendible stationary TPBVDS (1.3)-(1.5) is given by

$$W(k) = \begin{cases} C(V_iE^N)E^D(AE^D)^{k-1}B, & k > 0, \\ -C[I-(V_iE^N)]A^D(EA^D)^{-k}B, & k \leqq 0, \end{cases} \tag{2.25}$$

where we have taken into account the normalization (2.2).

3. Internal description of a weighting pattern. The matrix V_iE^N specifies entirely the effect of the boundary conditions on the extended weighting pattern $W(k)$ given by (2.25). This motivates the introduction of the following concept.

DEFINITION 3.1. Let $(C, V_i, V_f, E, A, B, N)$ be a stationary and extendible TPBVDS. Then P is a *decomposition matrix* of this system if

$$O_sPR_s = O_s(E^NV_i)R_s. \tag{3.1}$$

The motivation for calling P a decomposition matrix is that the extended weighting pattern (2.25) can be expressed as

$$W(k) = \begin{cases} CPE^D(AE^D)^{k-1}B, & k > 0, \\ -C(I-P)A^D(EA^D)^{-k}B, & k \leqq 0. \end{cases} \tag{3.2}$$

Thus, if the identity matrix is decomposed into P and $I-P$, the matrices P and $I-P$ appear as parameters of the causal and anticausal parts of $W(k)$. Also, by using (2.8), (2.19), (3.1), and the fact that im (R_s) and ker (O_s) are E- and A-invariant, it is easy to check that a decomposition matrix P satisfies

$$O_s(PA-AP)R_s = O_s(PE-EP)R_s = 0, \tag{3.3a}$$

$$O_s(P-PEE^D)R_s = 0, \tag{3.3b}$$

$$O_s[(I-P)-(I-P)AA^D]R_s = 0. \tag{3.3c}$$

As is clear from Definition 3.1, one particular choice of decomposition matrix is

$$P = V_iE^N. \tag{3.4}$$

This choice is not unique in general. If P is a decomposition matrix, so is $P+Q$, where Q is any matrix such that O_sQR_s equals zero.

The expression (3.2) for the extended weighting pattern $W(k)$ motivates the introduction of the following concept.

DEFINITION 3.2. A five-tuple (C, P, E, A, B) is said to be an *internal description* of the acausal weighting pattern $W(k)$ if it satisfies (3.2) and (3.3), and if $\{E, A\}$ is in standard form. Furthermore, (C, P, E, A, B) is *minimal* if it has the smallest dimension among all internal descriptions of $W(k)$.

Given an acausal weighting pattern $W(k)$, a possible procedure for constructing a minimal, extendible, stationary TPBVDS $(C, V_i, V_f, E, A, B, N)$ that admits $W(k)$ as extended weighting pattern consists therefore in dividing the realization problem into two steps. First, find a minimal internal description (C, P, E, A, B) of $W(k)$. Next, given a finite interval $[0, N]$, find some appropriate boundary matrices V_i and V_f such that the corresponding TPBVDS is extendible and stationary, and such that P is a decomposition matrix associated to these matrices. The following result guarantees the validity of this two-step realization approach.

THEOREM 3.1. *Consider a weighting pattern $W(k)$ with internal description (C, P, E, A, B). Then, for any interval length N, there exists matrices V_i and V_f such that the* TPBVDS $(C, V_i, V_f, E, A, B, N)$ *is normalized, extendible, stationary, and has $W(k)$ as its extended weighting pattern. P is a decomposition matrix of the* TPBVDS $(C, V_i, V_f, E, A, B, N)$. *Furthermore, this* TPBVDS *is minimal if and only if the internal description (C, P, E, A, B) of $W(k)$ is minimal.*

Proof. Let

$$V_i = P(E^D)^N + \sigma X(\sigma E^N + A^N)^{-1}, \tag{3.5a}$$

$$V_f = (I-P)(A^D)^N + X(\sigma E^N + A^N)^{-1}, \tag{3.5b}$$

where

$$X = I - PEE^D - (I-P)AA^D = (I-P)EE^D + PAA^D - EE^DAA^D, \tag{3.6}$$

and where σ is any scalar such that $\sigma E^N + A^N$ is invertible. The second equality in (3.6) is a consequence of identity (2.18). Relations (3.5)-(3.6) specify a TPBVDS $(C, V_i, V_f, E, A, B, N)$. By direct calculation, it is easy to check that V_i and V_f satisfy the normalization (2.2), and that the stationarity and extendibility conditions (2.8) and (2.19) for $(C, V_i, V_f, E, A, B, N)$ are implied, respectively, by the relations (3.3a) and (3.3b)-(3.3c) for (C, P, E, A, B). Noting that

$$O_sXR_s = 0, \tag{3.7}$$

we can also verify that the extended weighting pattern (2.28) associated to $(C, V_i, V_f, E, A, B, N)$ is equal to the weighting pattern $W(k)$ given by (3.2). Finally, taking (3.7) and (3.3b) into account, the matrix V_i given by (3.5a) satisfies

$$O_sV_iE^NR_s = O_sPE^DER_s = O_sPR_s, \tag{3.8}$$

so that P is a decomposition matrix of $(C, V_i, V_f, E, A, B, N)$.

If the internal description (C, P, E, A, B) is not minimal, there exists an internal description (C', P', E', A', B') of smaller dimension, and the above construction yields an extendible stationary TPBVDS realizing $W(k)$, of smaller dimension than $(C, V_i, V_f, E, A, B, N)$, thus showing that this last TPBVDS is not minimal. Conversely, if the TPBVDS $(C, V_i, V_f, E, A, B, N)$ given by (3.5)-(3.6) is not minimal, we can find a lower-dimensional stationary TPBVDS $(C', V_i', V_f', E', A', B', N)$ that is a minimal realization of $W(k)$ over $[0, N]$. According to Corollary 5.2 of [15], this TPBVDS must be extendible and has $W(k)$ for extended weighting pattern. Then $P' = V_i' E'^N$ is a decomposition matrix for this lower-dimensional realization, thus showing that the internal description (C, P, E, A, B) is not minimal. □

Given an internal description (C, P, E, A, B) of the weighting pattern $W(k)$, the following result shows that it is possible to characterize the minimality of this internal description directly, without invoking minimality conditions for an associated TPBVDS.

THEOREM 3.2. *The internal description* (C, P, E, A, B) *of* $W(k)$ *is minimal if and only if*

(3.9a) $R_w = [R_s \quad PR_s]$ *has full row rank,*

(3.9b) $O_w = \begin{bmatrix} O_s \\ O_s P \end{bmatrix}$ *has full column rank,*

(3.9c) $\ker(O_s) \subset \operatorname{im}(R_s)$.

Proof. According to Theorem 3.1, we can associate to (C, P, E, A, B) an extendible stationary TPBVDS $(C, V_i, V_f, E, A, B, N)$, which is minimal if and only if (C, P, E, A, B) is minimal. This TPBVDS is minimal if and only if conditions (2.12) are satisfied. Thus, we need only to show that conditions (2.12) and (3.9) are equivalent. Suppose that conditions (2.12) are satisfied, but (3.9a) is not. Then, there exists $v \neq 0$ such that

$$v^T R_s = 0, \tag{3.10a}$$

$$v^T P R_s = 0. \tag{3.10b}$$

But from (3.10a) and (2.12c) we can conclude that v^T must belong to the row space of O_s. From (3.10b), we find

$$v^T P R_s = v^T V_i E^N R_s = 0. \tag{3.11}$$

Combining (3.10a) and (3.11) yields

$$v^T V_f A^N R_s = 0. \tag{3.12}$$

Since the system is extendible, we have

$$v^T V_i E E^D R_s = v^T V_i R_s, \tag{3.13a}$$

$$v^T V_f A A^D R_s = v^T V_f R_s. \tag{3.13b}$$

But, since R_s is E- and A-invariant, the range spaces of $E^N R_s$ and $A^N R_s$ coincide, respectively, with the ranges of $EE^D R_s$ and $AA^D R_s$. Combining (3.11)-(3.13), we obtain

$$v^T V_i R_s = v^T V_f R_s = 0, \tag{3.14}$$

which contradicts the assumption that (2.12a) is satisfied. Thus, (3.9a) is implied by (2.12). A similar argument can be used to show that (3.9b) is implied by (2.12).

To prove the converse, assume that (3.9) is satisfied and (2.12a) is not. Then, there exists $v \neq 0$ such that

$$v^T V_i R_s = v^T V_f R_s = 0, \tag{3.15}$$

which because of the E- and A-invariance of R_s implies

$$v^T V_i E^N R_s = v^T V_f A^N R_s = 0. \tag{3.16}$$

This in turn implies

$$v^T R_s = 0, \tag{3.17}$$

so that according to (3.9c) v^T belongs to the row space of O_s. Thus,

$$v^T V_i E^N R_s = v^T P R_s = 0. \tag{3.18}$$

But (3.17) and (3.18) contradict (3.9a). Consequently, (2.12a) is implied by (3.9). A similar argument shows that (3.9) implies (2.12b), thus proving the theorem. □

In the following, by analogy with the weak reachability and observability matrices that were introduced in [14] and [15], to characterize the concepts of weak reachability and observability for a TPBVDS $(C, V_i, V_f, E, A, B, N)$, the matrices R_w and O_w appearing in (3.9a) and (3.9b) will be called the *weak reachability* and *weak observability* matrices of the internal description (C, P, E, A, B). As will be shown below, these two matrices play a key role in the construction of a minimal internal description of the weighting pattern $W(k)$.

Theorem 3.2 implies that two minimal internal descriptions of a weighting pattern $W(k)$ can be related as follows.

COROLLARY. *Consider two minimal internal descriptions $(C_j, P_j, E_j, A_j, B_j)$, with $j=1, 2$, of the same weighting pattern $W(k)$, which are in standard form for the same α and β. Then, there exists an invertible matrix T such that relations* (2.13a), (2.13c)-(2.13d), *and*

$$O_s^1(P_1 - T^{-1}P_2T)R_s^1 = 0 \tag{3.19}$$

are satisfied.

Proof. According to Theorem 3.1, we can construct two minimal TPBVDSs $(C, V_i^j, V_f^j, E, A, B, N)$ associated to the two given internal descriptions of $W(k)$. Then, there exists an invertible matrix T such that relations (2.13) are satisfied. Consequently, the strong reachability and observability matrices of systems 1 and 2 are related through

$$R_s^2 = TR_s^1, \qquad O_s^2 = O_s^1 T^{-1}. \tag{3.20}$$

From (2.13b) and (3.19), we can deduce that

$$O_s^1 V_i^1 R_s^1 = O_s^2 V_i^2 R_s^2, \tag{3.21}$$

which implies

$$O_s^1 V_i^1 E_1^N R_s^1 = O_s^2 V_i^2 E_2^N R_s^2, \tag{3.22}$$

or equivalently,

$$O_s^1 P_1 R_s^1 = O_s^2 P_2 R_s^2, \tag{3.23}$$

which proves (3.19). □

4. Realizability conditions and separable realization. In § 3, we have reduced the minimal TPBVDS realization problem to the following problem. Given an infinite weighting pattern $W(k)$, find a minimal internal description (C, P, E, A, B) of $W(k)$.

4.1. Realizability conditions. As a first step, we characterize the weighting patterns that admit a finite-dimensional internal description.

THEOREM 4.1. *A sequence $W(k)$ admits a finite-dimensional internal description if and only if there exists scalars a_i, $1 \leqq i \leqq n_f$ and b_i, $1 \leqq i \leqq n_b$ such that*

$$W(n_f + l) = \sum_{i=1}^{n_f} a_i W(n_f + l - i) \quad \textit{for all } l > 0, \tag{4.1a}$$

$$W(-n_b + l) = \sum_{i=1}^{n_b} b_i W(-n_b + l + i) \quad \textit{for all } l \leqq 0. \tag{4.1b}$$

Proof. Necessity is shown by applying the standard Cayley–Hamilton theorem to matrices AE^D and EA^D in (3.2). To prove sufficiency, consider the decomposition

$$W(k)=W_f(k)+W_b(k), \tag{4.2a}$$

$$W_f(k)=W(k)1(k-1), \qquad W_b(k)=W(k)1(-k), \tag{4.2b}$$

of $W(k)$ into its causal and anticausal parts, where $1(k)$ denotes the unit step function, i.e.,

$$1(k)=\begin{cases}1 & \text{for } k\geqq 0,\\ 0 & \text{for } k<0.\end{cases}$$

Conditions (4.1a) and (4.1b) imply that $W_f(k)$ and $W_b(k)$ can be realized by finite-dimensional causal and anticausal systems, respectively. Let (C_f, A_f, B_f) and (C_b, A_b, B_b) be such realizations, so that

$$W_f(k)=C_fA_f^{k-1}B_f \quad \text{for } k>0, \tag{4.3a}$$

$$W_b(k)=C_bA_b^{-k}B_b \quad \text{for } k\leqq 0. \tag{4.3b}$$

Then, it is clear that

$$C=[C_f - C_b], \qquad P=\begin{bmatrix} I & 0\\ 0 & 0\end{bmatrix}, \tag{4.4a}$$

$$E=\begin{bmatrix} I & 0\\ 0 & A_b\end{bmatrix}, \quad A=\begin{bmatrix} A_f & 0\\ 0 & I\end{bmatrix}, \quad B=\begin{bmatrix} B_f\\ B_b\end{bmatrix} \tag{4.4b}$$

is an internal description of $W(k)$, so that the theorem is proved. □

4.2. Separable realization. Let us continue to analyze the realization obtained by decomposing the weighting pattern $W(k)$ into causal and anticausal components, and then constructing minimal realizations for each of these components separately. Given a finite interval $[0, N]$, the internal description (4.4) yields the following extendible stationary TPBVDS realization of $W(k)$:

$$\begin{bmatrix} I & 0\\ 0 & A_b\end{bmatrix}x(k+1)=\begin{bmatrix} A_f & 0\\ 0 & I\end{bmatrix}x(k)+\begin{bmatrix} B_f\\ B_b\end{bmatrix}u(k), \tag{4.5a}$$

$$\begin{bmatrix} I & 0\\ 0 & 0\end{bmatrix}x(0)+\begin{bmatrix} 0 & 0\\ 0 & I\end{bmatrix}x(N)=\begin{bmatrix} v_f\\ v_b\end{bmatrix}, \tag{4.5b}$$

$$y(k)=[C_f - C_b]x(k). \tag{4.5c}$$

An interesting feature of this realization is that it consists of two decoupled subsystems, which propagate, respectively, in the forward and backward directions. An extendible stationary TPBVDS with this structure is called *separable.* Also, observe that in (4.5b) the boundary matrices satisfy $V_i=P$ and $V_f=I-P$, regardless of the interval length. Thus, in the separable case, there is no real distinction between internal descriptions and minimal TPBVDS realizations.

Unfortunately, the separable realization (4.5) is not always minimal, as can be seen from the following example, which is an adaptation of an example presented in [20] for boundary-value systems with standard nondescriptor dynamics.

Example 4.1. Consider the weighting pattern

$$W(k)=\begin{cases}1, & k\geqq 1,\\ \frac{1}{2}, & k\leqq 0.\end{cases} \tag{4.6}$$

Its separable realization takes the form

$$x_f(k+1)=x_f(k)+u(k), \qquad x_f(0)=v_f, \tag{4.7a}$$

$$x_b(k)=x_b(k+1)+\tfrac{1}{2}u(k), \qquad x_b(N)=v_b, \tag{4.7b}$$

$$y(k)=y_f(k)+y_b(k). \tag{4.7c}$$

However, this realization is not minimal, since W admits also the following one-dimensional realization:

$$x(k+1)=x(k)+u(k), \tag{4.8a}$$

$$y(k)=\tfrac{1}{2}x(k), \tag{4.8b}$$

$$2x(0)-x(N)=v. \tag{4.8c}$$

In this case, the reason we can realize both the causal and anticausal parts of W with a single one-dimensional system is that they have both the same mode, $\sigma=1$. □

In general, when the causal and anticausal parts of W share a common mode, the realization approach consisting in constructing separately minimal realizations of the causal and anticausal parts of W does not yield a minimal realization.

4.3. Summable weighting patterns. Nevertheless, the separable realization (4.5) turns out to be minimal for the class of weighting patterns $W(k)$ that are *summable*, i.e., such that

$$\sum_{k=-\infty}^{\infty} \|W(k)\| < \infty, \tag{4.9}$$

where $\|\cdot\|$ denotes an arbitrary matrix norm. This class of weighting patterns is important, since it corresponds to BIBO stable systems.

THEOREM 4.2. *When the extended weighting pattern $W(k)$ is summable, the separable* TPBVDS *realization* (4.4)-(4.5) *is strongly reachable and observable, and is therefore minimal.*

Proof. Since $W(k)$ is summable, its causal and anticausal parts $W_f(k)$ and $W_b(k)$ are also summable. This implies that the matrices A_f and A_b appearing in the minimal realizations of W_f and W_b are stable, i.e., their eigenvalues are located inside the unit circle. Consider now the matrix

$$[sE-tA\,|\,B]=\begin{bmatrix} sI-tA_f & 0 & B_f \\ 0 & sA_b-tI & B_b \end{bmatrix}. \tag{4.10}$$

It is shown in Theorem 4.1 of [14] that if this matrix has full rank for $(s,t)\neq(0,0)$, the system is strongly reachable. But since A_f and A_b are stable, the eigenmodes of $sI-tA_f$ and sA_b-tI are such that $s/t<1$ and $s/t>1$, respectively, so that these two matrix pencils do not have any common eigenmode. Furthermore, since the state-space realizations (C_f, A_f, B_f) and (C_b, A_b, B_b) are minimal, the submatrices

$$[sI-tA_f\,|\,B_f] \quad \text{and} \quad [sA_b-tI\,|\,B_b]$$

have full rank. This implies that the matrix (4.10) has full rank, so that TPBVDS (4.5) is strongly reachable. By a similar argument, we can show that

$$\begin{bmatrix} sE-tA \\ C \end{bmatrix}=\begin{bmatrix} sI-tA_f & 0 \\ 0 & sA_b-tI \\ C_f & C_b \end{bmatrix} \tag{4.11}$$

has full rank and that the TPBVDS (4.5) is strongly observable. According to Theorem 3.2, the TPBVDS (4.5) is therefore minimal. □

In the remainder of the paper, we will focus our attention on the general case where $W(k)$ is not summable. In this case, minimal realizations are usually not separable. To obtain a minimal realization, two approaches are possible. One method consists in starting from a nonminimal TPBVDS realization, say the separable realization (4.5), and then using the procedure described in [15] for removing the components of this TPBVDS that are not weakly reachable, not weakly observable, or simultaneously not strongly reachable and observable. An alternative realization approach, that we shall follow here, relies on the introduction of a new transform, the (s, t)-transform, and on formulating the realization problem as a state-space representation problem in the (s, t) domain.

5. The (s, t)-transform and state-space representation of rational matrices. One difficulty associated with the use of the z-transform for analyzing discrete-time descriptor systems is that since the dynamics of such systems are singular, infinite frequencies cannot be handled in the same way as other frequencies [21]. This motivates the introduction of the transform

$$H(s,t)=\sum_{k=-\infty}^{\infty} H(k)t^{k-1}/s^{k}. \tag{5.1}$$

It can be expressed in terms of the standard z-transform $H(z)$ as

$$H(s,t)=H(s/t)/t. \tag{5.2}$$

Relation (5.2) shows that the z-transform can be obtained from the (s, t)-transform simply by replacing (s, t) by $(z, 1)$, and conversely, the (s, t)-transform is obtained from the z-transform by replacing z with s/t, and dividing the result by t. From (5.2), we see also that when $H(s, t)$ exists, it has a particular type of homogeneity and is strictly proper in (s, t) in the sense that

$$\lim_{c\to\infty} H(cs,ct)=\lim_{c\to\infty} H(s,t)/c=0. \tag{5.3}$$

Note, however, that it is not necessarily strictly proper in s and t separately, so that the corresponding z-transform may not be proper.

In the following, we shall restrict our attention to the case when $H(z)$ and $H(s, t)$ are *rational*. Then, from (5.2), we see that the numerator and denominator polynomials of all entries of $H(s, t)$ are *homogeneous*, i.e., each such polynomial has the form

$$p(s,t)=\sum_{i=0}^{d} p_i s^{d-i}t^{i},$$

where d is the degree of p. Furthermore, from (5.3), we see also that the relative degree in s and t of all entries of $H(s, t)$, i.e., the difference between the denominator and numerator degrees is exactly one. Thus, the transformation (5.2) has the effect of transforming rational matrices $H(z)$, proper or not, into strictly proper homogeneous rational matrices in the two variables s and t with relative degree one. The analysis of this paper will focus exclusively on this specific class of rational matrices. Note that the idea of studying the structure at infinity of rational matrices in z through the introduction of a homogenizing transform is not totally new. It has been considered, for example, in [22, pp. 158-162, 182-187] and [23].

5.1. Formulation of the realization problem. In the causal case, the z-transform plays an important role in the solution of the minimal realization problem. Specifically, given a causal weighting pattern $W(k)$, the minimal realization problem is equivalent to finding matrices (C, A, B) of minimal dimension such that the z-transform $W(z)$ admits the *state-space representation*

$$W(z) = C(zI - A)^{-1}B. \tag{5.4}$$

For the case of acausal weighting patterns, the situation is more complex. If (C, P, E, A, B) is an internal description of the weighting pattern $W(k)$, and if $W_f(k)$ and $W_b(k)$ are the causal and anticausal parts of $W(k)$, the (s, t)-transforms of $W_f(k)$ and $W_b(k)$ can be expressed as

$$W_f(s,t) = \sum_{k=1}^{\infty} CPE^D(AE^D)^{k-1}Bt^{k-1}/s^k = CPE^D(sI - tAE^D)^{-1}B, \tag{5.5a}$$

$$\begin{aligned} W_b(s,t) &= \sum_{k=-\infty}^{0} -C(I-P)A^D(EA^D)^kBt^{k-1}/s^k \\ &= C(I-P)A^D(sEA^D - tI)^{-1}B. \end{aligned} \tag{5.5b}$$

Then, we use the matrix identities [19, p. 80]

$$(sE - tA)^{-1} = E^D(sI - tAE^D)^{-1} - A^D(I - EE^D)\sum_{k=0}^{\mu_E - 1}(sEA^D)^k/t^{k+1}, \tag{5.6a}$$

$$(sE - tA)^{-1} = A^D(sEA^D - tI)^{-1} + E^D(I - AA^D)\sum_{k=0}^{\mu_A - 1}(tAE^D)^k/s^{k+1}, \tag{5.6b}$$

where μ_E and μ_A denote the indices of the nilpotent parts of E and A, respectively. Taking into account the properties (3.3a)-(3.3c) of the decomposition matrix P, we obtain

$$W_f(s,t) = CP(sE - tA)^{-1}B = C(sE - tA)^{-1}PB, \tag{5.7a}$$

$$W_b(s,t) = C(I-P)(sE - tA)^{-1}B = C(sE - tA)^{-1}(I-P)B. \tag{5.7b}$$

Note that $W_f(s, t)$ and $W_b(s, t)$ do not have, in general, the same regions of convergence. However, by analytic continuation, it is possible to extend their domains of definition to the whole plane while using the same notation. This yields the three representations:

$$W(s,t) = W_f(s,t) + W_b(s,t) = C(sE - tA)^{-1}B, \tag{5.8}$$

$$H_r(s,t) = [\,W_f(s,t)\; W_b(s,t)] = C(sE - tA)^{-1}[PB\;(I-P)B], \tag{5.9}$$

$$H_o(s,t) = \begin{bmatrix} W_f(s,t) \\ W_b(s,t) \end{bmatrix} = \begin{bmatrix} CP \\ C(I-P) \end{bmatrix}(sE - tA)^{-1}B. \tag{5.10}$$

Since the specification of an acausal weighting pattern $W(k)$ is equivalent to the specification of $W_f(s, t)$ and $W_b(s, t)$, we see from (5.8)-(5.10) that the construction of an internal description (C, P, E, A, B) of $W(k)$ can be expressed as a state-space realization problem for rational matrices in s and t. However, in contrast to the causal case, the need to specify P and to achieve minimality implies that we must, in general, obtain state-space representations for the *three* rational matrices $W(s, t)$, $H_r(s, t)$, and $H_b(s, t)$, instead of a single rational matrix for causal systems. Furthermore, since we are considering acausal systems, the computation of any of these state-space representations requires an extension of known state-space realization techniques. We consider this problem first in the next section.

5.2. State-space representations of homogeneous rational matrices in s and t. The above discussion motivates the following *minimal state-space representation problem.* Given an homogeneous rational matrix function $H(s, t)$ of relative degree one, find matrices (K, D, F, G) of lowest possible dimension such that

$$H(s, t) = K(sD - tF)^{-1}G. \tag{5.11}$$

This problem is the counterpart of the minimal state-space representation problem for a strictly proper rational matrix $H(z)$, where we seek to find matrices (K, F, G) of smallest size such that

$$H(z) = K(zI - F)^{-1}G. \tag{5.12}$$

The difference between (5.11) and (5.12) is that, as was noted earlier, the one-dimensional rational transfer function $H(z) = H(z, 1)$ associated to (5.11) is not necessarily proper, so that the representation (5.12) is not applicable to this case.

An important feature of the minimal representation (5.12) is that it is unique up to a similarity transform. For the minimal representation (5.11), even if we impose the additional requirement that $\{D, F\}$ should be in standard form, i.e., that there exists α and β such that

$$\alpha D + \beta F = I, \tag{5.13}$$

the matrices (K, D, F, G) are not unique. To ensure uniqueness, α and β must be chosen a priori. In the causal case, i.e., when $H(z)$ is strictly proper, this was done implicitly in (5.12) by forcing D to be equal to I, which corresponds to selecting $\alpha = 1$ and $\beta = 0$. For the more general case that we consider here, any pair (α, β) is acceptable as long as

$$H(\alpha, -\beta) < \infty. \tag{5.14}$$

This last condition can be viewed as an extension of the condition $H(\infty) < \infty$ for proper transfer functions.

THEOREM 5.1. *A matrix function $H(s, t)$ admits a state-space representation* (5.11) *if and only if it is rational, homogeneous in s and t, and with relative degree one. Under these conditions, if (α, β) is a pair of scalars such that $H(\alpha, -\beta)$ exists, $H(s, t)$ admits a unique minimal representation, up to a similarity transform, satisfying* (5.11) *and* (5.13). *The dimension r of this minimal realization, i.e., the size of D and F, is given by*

$$r = d(H(\alpha z, 1 - \beta z)), \tag{5.15}$$

where $d(\cdot)$ denotes the usual McMillan degree, and where $H(\alpha z, 1 - \beta z)$ is a strictly proper rational matrix in z.

Proof. If $H(s, t)$ admits a representation of the form (5.11), it is clear that it must be rational, homogeneous in s and t, and of relative degree one. To prove sufficiency, we need to construct such a representation. Let α and β be such that $H(\alpha, -\beta)$ exists. Then, consider the rational matrix $H(\alpha z, 1 - \beta z)$. This matrix is strictly proper in z because

$$\lim_{z \to \infty} H(\alpha z, 1 - \beta z) = \lim_{z \to \infty} H(\alpha, -\beta)/z = 0. \tag{5.16}$$

It can therefore be realized as

$$H(\alpha z, 1 - \beta z) = K(zI - F)^{-1}G. \tag{5.17}$$

Now, assume that $\alpha \neq 0$ (otherwise, reverse the roles of D and F), and let

$$w = \frac{\alpha}{\alpha t + \beta s}, \qquad z = \frac{s}{\alpha t + \beta s}. \tag{5.18}$$

In this case

$$s = \frac{\alpha z}{w}, \qquad t = \frac{1 - \beta z}{w}, \tag{5.19}$$

which implies that

$$H(s, t) = wH(\alpha z, 1 - \beta z) = wK(zI - F)^{-1}G = K(sD - tF)^{-1}G, \tag{5.20}$$

with

$$D = \frac{I - \beta F}{\alpha}. \tag{5.21}$$

Since there is a one-to-one correspondence between the representation (5.17) of $H(\alpha z, 1 - \beta z)$ and the representation (5.20) of $H(s, t)$ with D given by (5.21), the dimension and uniqueness properties of these two representations are the same. This implies that minimal state-space representations of $H(s, t)$ satisfying (5.20) and (5.21) are related by a similarity transform, and have a dimension r equal to the McMillan degree of $H(\alpha z, 1 - \beta z)$. □

COROLLARY. *The state-space representation* (5.11), (5.13) *is minimal if and only if* (D, F, G) *is strongly reachable and* (K, D, F) *is strongly observable. Furthermore, the dimension of a minimal state-space representation is equal to the rank of the Hankel matrix* O_sR_s, *where* O_s *and* R_s *are the strong observability and reachability matrices associated, respectively, to* (K, D, F) *and* (D, F, G).

Proof. It can be assumed without loss of generality that $\alpha \neq 0$ in (5.13). Then, the representation (5.11), (5.13) of $H(s, t)$ is minimal if and only if the representation (5.17) of $H(\alpha z, 1 - \beta z)$ is minimal, or equivalently if and only if (K, F) is observable and (F, G) is reachable, where observability and reachability are defined here in the sense of causal systems. Since $\alpha \neq 0$, this is equivalent to requiring that (K, D, F) and (D, F, G) are strongly observable, and strongly reachable, respectively (see [14, Thm. 4.1]).

It was also shown in Theorem 5.1 that the dimension r of a minimal state-space representation is equal to the McMillan degree of $H(\alpha z, 1 - \beta z)$. But according to the realization theory of causal systems, this McMillan degree is equal to the rank of the Hankel matrix

$$\bar{H} = \overline{OR}, \tag{5.22}$$

where $\bar{O}$ and $\bar{R}$ are the observability and reachability matrices associated to the pairs (K, F) and (F, G), respectively. But with $\alpha \neq 0$, the nullspace of $\bar{O}$ coincides with that of O_s, and the range of $\bar{R}$ with that of R_s. This implies that the rank of $\bar{H}$ is equal to that of O_sR_s, thus proving the corollary. □

One relatively unsatisfactory aspect of Theorem 5.1 is that the dimension r of a minimal state-space representation of $H(s, t)$ is characterized in terms of the McMillan degree of the one-dimensional rational matrix $H(\alpha z, 1 - \beta z)$, and not directly in terms of $H(s, t)$. It turns out that it is possible to characterize r directly from $H(s, t)$ by extending the concept of McMillan degree as follows.

DEFINITION 5.1. Given a homogeneous and strictly proper rational matrix $H(s, t)$ in s and t, the *McMillan degree* of $H(s, t)$ is defined as the degree of the least common multiple of the denominators of all minors of $H(s, t)$.

Then, we have Theorem 5.2.

THEOREM 5.2. *If $H(s, t)$ is realizable, i.e., if it is homogeneous of relative degree one, the dimension of a minimal state-space representation of $H(s, t)$ is equal to its McMillan degree.*

Proof. Consider the minimal representation

$$H(s, t) = K(sD - tF)^{-1}G. \tag{5.23}$$

Without loss of generality, it can be assumed that the pencil $sD - tF$ is in Weierstrass canonical form (see [24, p. 28]), so that

$$K = [K_1 \quad K_2], \quad D = \begin{bmatrix} D_1 & 0 \\ 0 & N \end{bmatrix}, \quad F = \begin{bmatrix} F_1 & 0 \\ 0 & F_2 \end{bmatrix}, \quad G = \begin{bmatrix} G_1 \\ G_2 \end{bmatrix}, \tag{5.24}$$

where N is nilpotent and D_1 and F_2 are invertible. The rational matrix

$$H_1(s, t) = K_1(sD_1 - tF_1)^{-1}G_1 \tag{5.25}$$

can then be expressed as

$$H_1(s, t) = K_1(zD_1 - F_1)^{-1}G_1/t = \bar{H}_1(z)/t, \tag{5.26}$$

where $z = s/t$. Since there is a one-to-one correspondence between $H_1(s, t)$ and $\bar{H}_1(z)$, the dimensions of minimal representations of these two rational matrices must be equal. But, $\bar{H}_1(z)$ is a strictly proper rational matrix in z, so that the dimension of its minimal representation is equal to its McMillan degree, i.e., to the degree of the least common multiple $a_1(z)$ of the denominators of all minors of $\bar{H}_1(z)$. Also, since D_1 is invertible, t is not a factor of the denominator of any of the entries, and thus of any of the minors of $H_1(t, s)$. Let $p_1(s, t)$ denote the least common multiple of the denominators of the minors of $H_1(s, t)$. Since t is not a factor of $p_1(s, t)$, the degree of $p_1(s, t)$ is just the degree in z of $p_1(z, 1) = a_1(z)$. This shows that the degree of $p_1(s, t)$ equals the McMillan degree of $\bar{H}_1(z)$, which is in turn equal to the dimension of D_1 and F_1.

For the second block of the representation (5.24), we proceed similarly. Let

$$H_2(s, t) = K_2(sN - tF_2)^{-1}G_2, \tag{5.27}$$

and denote by $p_2(s, t)$ the least common multiple of the denominators of the minors of $H_2(s, t)$. Since F_2 is invertible, s is not a factor of $p_2(s, t)$. This implies that the degree of $p_2(s, t)$ is just the degree in t of $p_2(1, t)$, which, by analogy with the previous case, is just the dimension of N and F_2. Also, since N is nilpotent and (N, F_2) is in standard form, we have

$$p_2(s, t) = \det(sN - tF_2) = at^{n_2}, \tag{5.28}$$

where a is a constant, and n_2 the dimension of N and F_2.

Noting that

$$H(s, t) = H_1(s, t) + H_2(s, t) \tag{5.29}$$

and the fact that $p_1(s, t)$ and $p_2(s, t)$ have no common factors, we can easily deduce that the least common multiple $p(s, t)$ of the denominators of the minors of H satisfies

$$p(s, t) = p_1(s, t)p_2(s, t). \tag{5.30}$$

The degree of $p(s, t)$ is therefore equal to the sum of the dimensions of the blocks of (5.24), which is the dimension of D and F. □

Example 5.1. Consider the sequence

$$H(k)=\begin{cases}-1, & k=0,\\ 1, & k=1,\\ 0 & \text{otherwise.}\end{cases} \tag{5.31}$$

Its (s, t)- and z-transforms are, respectively,

$$H(s, t)=\frac{1}{s}-\frac{1}{t}, \tag{5.32a}$$

$$H(z)=-1+\frac{1}{z}. \tag{5.32b}$$

Already we can see the advantage of using the (s, t)-transform: $H(s, t)$ has one mode at zero and one at infinity, where $H(z)$ has only a pole at $z=0$.

From Theorem 5.2, we see that the dimension of a minimal representation, simply select $\alpha=\beta=1$, and perform the realization

$$H(z, 1-z)=\frac{1}{z}-\frac{1}{1-z}=[1 \quad 1]\left(zI-\begin{bmatrix}0 & 0\\ 0 & 1\end{bmatrix}\right)^{-1}\begin{bmatrix}1\\ 1\end{bmatrix}, \tag{5.33}$$

which implies that

$$K=[1 \quad], \quad D=\begin{bmatrix}1 & 0\\ 0 & 0\end{bmatrix}, \quad F=\begin{bmatrix}0 & 0\\ 0 & 1\end{bmatrix}, \quad G=\begin{bmatrix}1\\ 1\end{bmatrix}. \tag{5.34}$$

6. Minimal realization.

In § 5, it was shown that the specification of an internal description (C, P, E, A, B) of a weighting pattern $W(k)$ yields the three state-space representations (5.8)-(5.10) for the rational matrices $W(s, t)$, $H_r(s, t)$, and $H_o(s, t)$. This suggests that the construction of a minimal internal description of $W(k)$ can be formulted as a state-space representation problem in the (s, t)-domain. It turns out that the link existing between minimal state-space representations of rational matrices and minimal internal descriptions is less direct than for causal systems, since an internal description (C, P, E, A, B) can be minimal, even though *none* of the state-space representations (5.8)-(5.10) is minimal.

6.1. Dimension of a minimal realization.

THEOREM 6.1. *The dimension n of a minimal internal description of $W(k)$ is given by*

$$n=\omega+\rho-\tau, \tag{6.1}$$

where if $d(\cdot)$ denotes the generalized McMillan degree introduced in Definition 5.1,

$$\omega=d(H_r(s, t)), \quad \rho=d(H_o(s, t)), \quad \tau=d(W(s, t)). \tag{6.2}$$

Proof. Let (C, P, E, A, B) be a minimal internal description of $W(k)$. Then, $W(s, t)$, $H_r(s, t)$, and $H_o(s, t)$ admit state-space representations of the form (5.8)-(5.10), and from the corollary of Theorem 5.1, ω, ρ, and τ are the ranks of the Hankel matrices O_sR_w, O_wR_s, and O_sR_s, respectively. But, according to the minimality conditions (3.9a)-(3.9b), R_w and O_w have full rank, which implies that ω and ρ are the ranks of the strong observability and reachability matrices O_s and R_s, respectively. From condition (3.9c), we can also deduce that the rank of O_sR_s equals the rank of O_s plus that of R_s minus n, so that

$$\tau=\rho+\omega-n, \tag{6.3}$$

which implies (6.1). □

Example 6.1. Consider the weighting pattern

$$W(k)=\begin{cases} a^k & k\geqq 1, \\ ba^k, & k<1, \end{cases} \tag{6.4}$$

where a and b are scalar parameters with $a<1$. Using Theorem 4.1, it is straightforward to check that $W(k)$ is realizable. From Theorem 6.1, we find that the dimension of a minimal internal description of $W(k)$ is given by

$$\begin{aligned} n&=d\Bigg(\Bigg[\frac{a}{s-at}\ \frac{ab}{s-at}\Bigg)\Bigg]+d\left(\begin{bmatrix}\dfrac{a}{s-at}\\ \dfrac{-ab}{s-at}\end{bmatrix}\right)-d\left(\frac{(1-b)a}{s-at}\right)\\ &=\begin{cases}1+1-1=1 & \text{for } b\neq 1,\\ 1+1-0=2 & \text{for } b=1.\end{cases}\end{aligned} \tag{6.5}$$

When $b\neq 1$, a minimal internal description of $W(k)$ is

$$C=\frac{a}{1-b},\quad P=\frac{1}{1-b},\quad E=1,\quad A=a,\quad B=1. \tag{6.6}$$

The causal and anticausal parts $W_f(s, t)$ and $W_b(s, t)$ of W have the same pole, namely $s/t=a$, which explains why they can be realized with a single eigenmode. The resulting TPBVDS realization is strongly reachable, strongly observable, and nonseparable.

When $b=1$, a minimal internal description of $W(k)$ is

$$C=[a\quad a],\quad P=\begin{bmatrix}1&0\\0&0\end{bmatrix},\quad E=I,\quad A=aI,\quad B=\begin{bmatrix}1\\1\end{bmatrix}. \tag{6.7}$$

This separable realization is not strongly reachable, and is not strongly observable. Note that in the realization (6.6), the system matrices tend to ∞ as $b\to 1$. Thus, $b=1$ can be viewed as a singularity in the sense that the dimension of a minimal internal description of W is two only when b is exactly equal to one. □

6.2. Minimal realization procedure. One interesting aspect of Theorem 6.1 is that as an intermediate step in the evaluation of the dimension n of a minimal internal description of $W(k)$, we obtain ω and ρ, which are, respectively, the ranks of the strong observability and reachability matrices of a minimal internal description. This observation leads to the following procedure for constructing a minimal internal description of W.

Step 1. Construct the minimal state-space representations

$$H_r(s, t)=[W_f(s, t)\,W_b(s, t)]=\bar{C}(s\bar{E}-t\bar{A})^{-1}[\bar{B}_f\quad \bar{B}_b], \tag{6.8}$$

$$H_o(s, t)=\begin{bmatrix}W_f(s, t)\\ W_b(s, t)\end{bmatrix}=\begin{bmatrix}\tilde{C}_f\\ \tilde{C}_b\end{bmatrix}(s\tilde{E}-t\tilde{A})^{-1}\tilde{B}, \tag{6.9}$$

where if α and β are such that $W_f(\alpha, -\beta)$ and $W_b(\alpha, -\beta)$ are defined, the pairs $\{\bar{E}, \bar{A}\}$ and $\{\tilde{E}, \tilde{A}\}$ satisfy the normalization condition (2.1) for the same α and β. Since the representations (6.8) and (6.9) are both minimal, the sizes of the matrices $\{\bar{E}, \bar{A}\}$ and $\{\tilde{E}, \tilde{A}\}$ are equal, respectively, to ω and ρ.

Step 2. Let

$$\bar{B} = \bar{B}_f + \bar{B}_b, \qquad \tilde{C} = \tilde{C}_f + \tilde{C}_b. \tag{6.10}$$

From (6.8)-(6.9), we find

$$\begin{aligned} W(s, t) &= W_f(s, t) + W_b(s, t) \\ &= \bar{C}(s\bar{E} - t\bar{A})^{-1}\bar{B} = \tilde{C}(s\tilde{E} - t\tilde{A})^{-1}\tilde{B}, \end{aligned} \tag{6.11}$$

so that $(\bar{C}, \bar{E}, \bar{A}, \bar{B})$ and $(\tilde{C}, \tilde{E}, \tilde{A}, \tilde{B})$ are two state-space representations, in general nonminimal, of $W(s, t)$. The minimality of representations (6.8) and (6.9) implies that $(\bar{C}, \bar{E}, \bar{A}, \bar{B})$ and $(\tilde{C}, \tilde{E}, \tilde{A}, \tilde{B})$ are, respectively, strongly observable and strongly reachable. By decomposing these two representations into strongly reachable/unreachable, and strongly observable/unobservable components, respectively, we obtain

$$\bar{C} = [\bar{C}_1 \quad \bar{C}_2], \quad \bar{E} = \begin{bmatrix} \bar{E}_1 & \bar{E}_2 \\ 0 & \bar{E}_4 \end{bmatrix}, \quad \bar{A} = \begin{bmatrix} \bar{A}_1 & \bar{A}_2 \\ 0 & \bar{A}_4 \end{bmatrix}, \quad \bar{B} = \begin{bmatrix} \bar{B}_1 \\ 0 \end{bmatrix}, \tag{6.12}$$

and

$$\tilde{C} = [0 \quad \tilde{C}_2], \quad \tilde{E} = \begin{bmatrix} \tilde{E}_1 & \tilde{E}_2 \\ 0 & \tilde{E}_4 \end{bmatrix}, \quad \tilde{A} = \begin{bmatrix} \tilde{A}_1 & \tilde{A}_2 \\ 0 & \tilde{A}_4 \end{bmatrix}, \quad \tilde{B} = \begin{bmatrix} \tilde{B}_1 \\ \tilde{B}_2 \end{bmatrix}. \tag{6.13}$$

In the following, it will be assumed that the representations (6.8) and (6.9) are in the coordinate systems corresponding to (6.12) and (6.13), respectively.

Step 3. From (6.11), we find that

$$W(s, t) = \bar{C}_1(s\bar{E}_1 - t\bar{A}_1)^{-1}\bar{B}_1 = \tilde{C}_2(s\tilde{E}_4 - t\tilde{A}_4)^{-1}\tilde{B}_2, \tag{6.14}$$

where the representations $(\bar{C}_1, \bar{E}_1, \bar{A}_1, \bar{B}_1)$ and $(\tilde{C}_2, \tilde{E}_4, \tilde{A}_4, \tilde{B}_2)$ are both strongly reachable and observable. This implies that they must be related by a similarity transformation, i.e., there exists a matrix T such that

$$\bar{C}_1 = \tilde{C}_2 T^{-1}, \quad \bar{E}_1 = T\tilde{E}_4 T^{-1}, \quad \bar{A}_1 = T\tilde{A}_4 T^{-1}, \quad \bar{B}_1 = T\tilde{B}_2. \tag{6.15}$$

The matrix T is given by

$$T = \bar{M}_s \tilde{M}_s^T (\tilde{M}_s \tilde{M}_s^T)^{-1}, \tag{6.16}$$

where $\bar{M}_s$ and $\tilde{M}_s$ denote, respectively, the strong reachability matrices of $(\bar{E}_1, \bar{A}_1, \bar{B}_1)$ and $(\tilde{E}_4, \tilde{A}_4, \tilde{B}_2)$. Furthermore, since the representations (6.14) are minimal, the matrices $\bar{E}_1$, $\bar{A}_1$, $\tilde{E}_4$ and $\tilde{A}_4$ have dimension τ, where τ is given by (6.2), and consequently, the blocks $\{\bar{E}_4, \bar{A}_4\}$, and $\{\tilde{E}_1, \tilde{A}_1\}$ in the decompositions (6.12) and (6.13) have respective dimensions $\omega - \tau$ and $\rho - \tau$.

Step 4. The matrices C, E, A, and B of a minimal internal description are now selected as

$$E = \begin{bmatrix} \tilde{E}_1 & \tilde{E}_2 T^{-1} & * \\ 0 & \bar{E}_1 & \bar{E}_2 \\ 0 & 0 & \bar{E}_4 \end{bmatrix}, \qquad A = \begin{bmatrix} \tilde{A}_1 & \tilde{A}_2 T^{-1} & * \\ 0 & \bar{A}_1 & \bar{A}_2 \\ 0 & 0 & \bar{A}_4 \end{bmatrix}, \tag{6.17a}$$

$$C = [0 \quad \bar{C}_1 \quad \bar{C}_2], \qquad B = \begin{bmatrix} \tilde{B}_1 \\ \bar{B}_1 \\ 0 \end{bmatrix}, \tag{6.17b}$$

where * indicates an arbitrary block entry. The role of the similarity transformation T is to guarantee that the component which is common to state-space representations (6.8) and (6.9) is expressed in the same coordinate system. Note that (5.17) corresponds to a four part Kalman decomposition of (C, E, A, B) into strongly reachable/unreachable and observable/unobservable parts, where according to (3.9c), there is no strongly unreachable and unobservable component, since the internal description that we are constructing must be minimal.

By using this last observation, we can immediately conclude from (6.11) that

$$W(s,t)=C(sE-tA)^{-1}B. \tag{6.18}$$

If we denote

$$B_f=\begin{bmatrix} * \\ \bar{B}_f \end{bmatrix}, \qquad C_f=[\tilde{C}_f \quad *]\begin{bmatrix} I & 0 & 0 \\ 0 & T^{-1} & 0 \\ 0 & 0 & I \end{bmatrix}, \tag{6.19}$$

from (6.8) and (6.9), it is also easy to check that

$$W_f(s,t)=C(sE-tA)^{-1}B_f=C_f(sE-tA)^{-1}B. \tag{6.20}$$

Expanding $W_f(s,t)$ in power series of $s-\alpha$ and $t+\beta$ in the vicinity of $(s,t)=(\alpha,-\beta)$, noting that $\alpha E+\beta A=I$, and matching the coefficients of $(s-\alpha)^i(t+\beta)^j$ for all i, j in (6.20) yields

$$O_sR_s^f=O_s^fR_s, \tag{6.21}$$

where R_s^f and O_s^f denote the strong reachability and observability matrices associated respectively to (E, A, B_f) and (C_f, E, A).

Step 5. The matrix P is then obtained by solving the equation

$$O_sPR_s=O_sR_s^f. \tag{6.22}$$

The existence of a solution is guaranteed by identity (6.21), which shows that the row and column spaces of the matrix on the right side of (6.22) are spanned by O_s and R_s, respectively. The solution of (6.22) is generally not unique, since we can add to any solution P a matrix Q such that $O_sQR_s=0$, i.e., a matrix of the form

$$Q=\begin{bmatrix} * & * & * \\ 0 & 0 & * \\ 0 & 0 & * \end{bmatrix}. \tag{6.23}$$

We must now prove that the matrices (C, P, E, A, B) given by (6.17) and (6.22) specify an internal description of $W(k)$. This requires showing that the state-space representation identities (5.9)-(5.10) are satisfied, as well as properties (3.3). The relation

$$O_sPR_s=O_sR_s^f=O_s^fR_s, \tag{6.24}$$

implies

$$CPR_s=CR_s^f, \qquad O_sPB=O_s^fB, \tag{6.25}$$

so that from the Cayley-Hamilton theorem and (6.20), we have

$$CP(sE-tA)^{-1}B=C(sE-tA)^{-1}PB=W_f(s,t). \tag{6.26}$$

When combined with (6.18), this yields the representations (5.9)-(5.10). To prove relations (3.3a), we use (6.24) and the fact that the reachability matrices R_s and R^f_s, and observability matrices O_s and O^f_s are constructed from the same matrices E and A. Then, from the Cayley-Hamilton theorem, there exist matrices K_E and K_A which satisfy

$$ER_s = R_s K_E, \qquad AR_s = R_s K_A, \tag{6.27a}$$

$$ER^f_s = R^f_s K_E, \qquad AR_s = R^f_s K_A, \tag{6.27b}$$

i.e., the same matrices K_E and K_A can be used to characterize the E- and A-invariance of the range spaces of both R_s and R^f_s. Similarly, the E- and A-invariance of the nullspaces of O_s and O^f_s can be characterized by a single pair of matrices. Taking this feature into account in (6.24), it can be checked easily that the constraints (3.3a) are satisfied. To prove relations (3.3b) and (3.3c), we use identities (5.6a)-(5.6b). Substituting (5.6a) inside (6.26), and noting that the weighting pattern $W_f(k)$ is causal, we find

$$CPA^D(I-EE^D)(EA^D)^k B = 0 \tag{6.28}$$

for $0 \leqq k \leqq \mu_E - 1$. Expressing the pencil $\{E, A\}$ in Weierstrass canonical form, it is then easy to check that (6.28) is equivalent to (3.3b). Similarly, to derive (3.3c), we substitute (5.6b) inside the state-space representation

$$W_b(s,t) = C(I-P)(sE - tA)^{-1}B \tag{6.29}$$

and use the fact that $W_b(k)$ is an anticausal weighting pattern. Thus, (C, P, E, A, B) is an internal description of $W(k)$. Since its dimension n obeys (6.1), it is *minimal.*

Example 6.2. Let

$$W(k) = \begin{cases} 0, & k = 1, \\ -1, & k \neq 1. \end{cases} \tag{6.30}$$

Then

$$W_f(s,t) = \frac{-t}{s(s-t)}, \qquad W_b(s,t) = \frac{1}{s-t}, \tag{6.31}$$

and according to Theorem 6.1, the dimension of a minimal internal description of $W(k)$ is

$$n = 2 + 2 - 1 = 3. \tag{6.32}$$

Since $\omega = \rho = 2$, we can also conclude that the minimal internal description is neither strongly reachable nor strongly observable. To obtain a minimal description, the first step is to construct the minimal state-space representations

$$[W_f \quad W_b] = \begin{bmatrix} \dfrac{-t}{s(s-t)} & \dfrac{1}{s-t} \end{bmatrix} = [1 \quad 1]\left(sI - t\begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}\right)^{-1} \begin{bmatrix} 1 & 0 \\ -1 & 1 \end{bmatrix}, \tag{6.33a}$$

$$\begin{bmatrix} W_f \\ W_b \end{bmatrix} = \begin{bmatrix} \dfrac{-t}{s(s-t)} \\ \dfrac{1}{s-t} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix}\left(sI - t\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}\right)^{-1} \begin{bmatrix} -1 \\ 1 \end{bmatrix}, \tag{6.33b}$$

which satisfy the normalization condition (2.1) with $\alpha = 1$, $\beta = 0$. This yields

$$\bar{B} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \qquad \tilde{C} = [1 \quad 0]. \tag{6.34}$$

In this case, we can select $T=1$, and

$$C=[0 \quad 1 \quad 1], \quad E=I, \quad A=\begin{bmatrix} 1 & 0 & * \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad B=\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}, \tag{6.35}$$

where * denotes an arbitrary entry. Finally, by solving (6.22) we find

$$P=\begin{bmatrix} * & * & * \\ 0 & 1 & * \\ 1 & 0 & * \end{bmatrix}. \tag{6.36}$$

The above realization procedure can be simplified significantly if the minimal internal description is either strongly observable or strongly reachable, i.e., if the integers ω and ρ in (6.2) satisfy either $\omega = n$ or $\rho = n$.

Strongly observable case $(\omega = n)$. In this case, only the state-space representation (6.8) is needed, and we can select $(C, E, A, B) = (\bar{C}, \bar{E}, \bar{A}, \bar{B})$. Also, since O_s has full rank, (6.24) for P reduces to

$$PR_s = R_s^f. \tag{6.37}$$

Strongly reachable case $(\rho = n)$. Then, only the representation (6.9) is needed, and we can select $(C, E, A, B) = (\tilde{C}, \tilde{E}, \tilde{A}, \tilde{B})$. Furthermore, (6.24) for P becomes

$$O_s P = O_s^f. \tag{6.38}$$

The previous realization procedure, or its simplification for the strongly observable and reachable cases, is of interest only when it yields a minimal internal description which is not separable, since in the separable case, the realization of § 4 is minimal. the following result provides a test for determining whether a weighting pattern admits a separable minimal description.

THEOREM 6.2. *$W(k)$ has a separable minimal realization if and only if the minimal dimension n given by* (6.1) *satisfies*

$$n = d(W_f(s, t)) + d(W_b(s, t)). \tag{6.39}$$

Proof. If we construct two minimal realizations of W_f and W_b, and combine them to realize $W(k)$ as shown in (4.4)-(4.5), we obtain a description of dimension $d(W_f(s, t)) + d(W_b(s, t))$. This description will therefore be minimal if and only if (6.39) is satisfied, where n is given by (6.1). □

7. Conclusions. In this paper, the minimal TPBVDS realization problem for acausal shift-invariant weighting patterns has been examined. By restricting our attention to extendible stationary TPBVDSs, it was shown that the minimal TPBVDS realization problem is equivalent to the problem of finding a minimal internal description for the weighting pattern $W(k)$ of interest. Introducing the (s, t) transform and characterizing minimal state-space representations of homogeneous rational matrices in (s, t), a frequency-domain approach was developed for finding the dimension of a minimal internal description, and for constructing such a description.

Since the assumption that the weighting pattern $W(k)$ is shift-invariant is restrictive, particularly for acausal systems, it would be of interest to extend the above theory to the nonstationary case. Also, we have limited our attention here to deterministic systems. Since there exists a complete and elegant stochastic realization theory for causal systems [25]-[27], it is natural to ask whether a similar theory can be developed for acausal stochastic systems. For the Gaussian case, some preliminary stochastic realization results have been presented in [28] for boundary value systems with standard nondescriptor dynamics, and in [18] for TPBVDSs.

THE DYNAMIC PROGRAMMING EQUATION FOR THE TIME-OPTIMAL CONTROL PROBLEM IN INFINITE DIMENSIONS*

VIOREL BARBU†

Abstract. The existence and uniqueness of a viscosity solution for the Bellman equation associated with the time-optimal control problem for a semilinear evolution equation in Hilbert space is provided. Applications to time-optimal control problems governed by parabolic equations are given.

Key words. time-optimal control problem, minimal time function, Hamilton-Jacobi equation, viscosity solution

AMS(MOS) subject classifications. 35F20, 35F25, 49B10, 49C05

1. Introduction. In this paper, we study the time-optimal control problem

$$\inf\{T;\ \exists u\in \mathcal{U},\ y'+Ay+Fy=Bu \text{ in } (0;T);\ y(0)=y_0,\ y(T)=0\} \tag{1.1}$$

in a real Hilbert space H, where A is a linear self-adjoint positive-definite operator in H, F is a nonlinear maximal monotone (single-valued) operator, and

$$\mathcal{U}=\{u\in L^2_{\text{loc}}(R^+;\ U);\ u(t)\in K \text{ a.e. } t>0\}. \tag{1.2}$$

Here U is a real Hilbert space and K is a closed convex and bounded subset of U; $0\in K$. B is a linear continuous operator from U to H and B^* is its adjoint.

Throughout in the sequel we shall denote by $|\cdot|$ and $(\cdot,\cdot)$ the norm and the scalar product of H, respectively. The norm of U will be denoted $|\cdot|_U$ and the scalar product $\langle\cdot,\cdot\rangle$. Further assume that the operator $A+F$ is maximal monotone. Then it is well known (see, for instance, [1], [5]) that for every $y_0\in\overline{D(A+F)}$ (the closure of the domain $D(A+F)$ of the operator $A+F$) the Cauchy problem

$$\begin{aligned} &y'+Ay+Fy=Bu \quad \text{in } (0,T),\\ &y(0)=y_0 \end{aligned} \tag{1.3}$$

has a unique weak solution $y=y(t,y_0,u)\in C([0,T];H)$. (We have denoted by $C([0,T];H)$ the space of all H-valued continuous functions on $[0,T]$.)

For every $y_0\in\overline{D(A+F)}$ let us denote by $\phi(y_0)$ the value of problem (1.1), i.e.,

$$\phi(y_0)=\inf\{T;\ \exists u\in\mathcal{U},\ y(T,y_0,u)=0\}. \tag{1.4}$$

The function $\phi:\overline{D(A+F)}\to[0,\infty]$ is called *the minimal time function* associated to problem (1.1) and formally it is a solution to the stationary Hamilton-Jacobi equation (the Bellman equation)

$$h(-B^*D\phi(y))+(Ay+Fy,D\phi(y))=1 \quad \forall y\in D(A+F)\backslash\{0\}, \tag{1.5}$$

$$\phi(0)=0,\quad \phi\geqq 0 \quad \text{in } \overline{D(A+F)}. \tag{1.6}$$

Here $h:H\to R$ is the support function of K, i.e.,

$$h(p)=\sup\{\langle p,u\rangle;\ u\in K\} \quad \forall p\in H. \tag{1.7}$$

We will prove here under appropriate assumptions on the evolution system (1.3) that the minimal time function ϕ is the unique weakly continuous viscosity solution

* Received by the editors September 20, 1989; accepted for publication (in revised form) March 29, 1990.

to (1.5), which satisfies conditions (1.6). This result has been established in the framework of the theory of viscosity solutions in infinite dimensions developed by Crandall and Lions [8]-[11] (see also [12]) and could be viewed as an illustration of this theory on time-optimal control problems. The verification of the general assumptions on distributed control processes governed by semilinear parabolic equations contains much of the substance of this paper. For some related finite-dimensional results we refer to [4]. We might expect to find significant applications of the theory of viscosity solutions to other classes of optimal control problems.

Recently, Tătaru [17] has introduced a general notion of viscosity solution for infinite-dimensional Hamilton–Jacobi equations with nonlinear unbounded terms which cover equations of the form (1.5).

2. Existence and uniqueness of viscosity solutions. We begin by formulating the main assumptions under which (1.5) will be studied.

(i) A is a linear maximal monotone self-adjoint operator in H with compact resolvent. Denote by $D(A)$ the domain of A and by V the space $D(A^{1/2})$ endowed with the norm $\|x\| = (|x|^2 + |A^{1/2}x|^2)^{1/2}$.

(ii) F is a maximal monotone single-valued operator of the form $F = \partial j$ where $j : H \to]-\infty, +\infty]$ is a lower semicontinuous convex function. Moreover, $F0 = 0$, $\overline{D(F)} = H$ and

$$(2.1) \qquad (Ay, Fy) \geqq 0 \quad \forall y \in D(A) \cap D(F) \neq \emptyset.$$

By ∂j we have denoted the subdifferential of function j.

(iii) The operator $(I + A)^{-1}F$ is locally Lipschitz from H to V, i.e., for every $r > 0$ there is $L(r) > 0$ such that

$$(2.2) \qquad \|(I + A)^{-1}(Fy - Fz)\| \leqq L(r)|y - z| \quad \text{for } |y|, |z| \leqq r.$$

(iv) The minimal time function ϕ is finite and weakly continuous on $\overline{D(A+F)} = H$.

It follows by assumptions (2.1) that $A + F$ is maximal monotone in $H \times H$ and $\overline{D(A+F)} = \overline{D(A) \cap D(F)} = H$ (see, e.g., [3, p. 129]). Moreover, $A + F = \partial\tilde{j}$, where $\tilde{j}(y) = \frac{1}{2}|A^{1/2}y|^2 + j(y)$. Recall (see, e.g., [1], [5]) that $-(A+F)$ generates a nonlinear semigroup of contractions $e^{-(A+F)t}$ on $\overline{D(A+F)} = H$.

In particular, assumption (iv) holds if $U = H$, $B = I$ (the unity operator in H) and $K = \{u \in H; |u| \leqq \rho\}$. Indeed in this case we have (see [6])

$$\phi(y_0) - \phi(z_0) \leqq \rho|y_0 - z_0| \quad \forall y_0, z_0 \in \overline{D(A+F)} = H.$$

If $\{y_0^n\}$ is weakly convergent to y_0, then since by assumptions (i) and (ii) the operator $S(t) = e^{-(A+F)t}$ is compact for $t > 0$, we have on a subsequence, again denoted y_0^n, $S(\varepsilon)y_0^n \to S(\varepsilon)y_0$, and therefore

$$\lim_{n\to\infty} \phi(S(\varepsilon)y_0^n) = \phi(S(\varepsilon)y_0).$$

Inasmuch as $\phi(y_0^n) \leqq \phi(S(\varepsilon)y_0^n) + \varepsilon$, for all $\varepsilon > 0$, this yields

$$\limsup_{n\to\infty} \phi(y_0^n) \leqq \varepsilon + \rho|S(\varepsilon)y_0 - y_0| + \phi(y_0).$$

Since ε can be chosen arbitrarily small we may conclude that

$$\limsup_{n\to\infty} \phi(y_0^n) \leqq \phi(y_0).$$

On the other hand, it is readily seen that the function ϕ is weakly lower semicontinuous. Hence $\lim_{n\to\infty} \phi(y_0^n)=\phi(y_0)$ as claimed.

We shall discuss in the next section other situations where these assumptions hold.

Consider the Hamilton-Jacobi equation

$$E(y, \phi, D\phi)+(Ay+Fy, D\phi)=0 \quad \text{in } \Omega \tag{2.3}$$

where Ω is an open subset of H and $E\colon \Omega\times R\times H\to R$ is a continuous function.

DEFINITION 1. A *strong viscosity* solution to (2.3) in Ω is a continuous function $\phi\in C(\Omega)$ provided for all $\psi\in C^1(\Omega)$:

(a) If $\phi-\psi$ attains a local maximum at $y_0\in\Omega$ and $\nabla\psi(y)=\alpha(y)(\nabla\psi_1(y)+\psi_2'(|y|)\operatorname{sgn} y)$ for all $y\in\Omega$, where $\psi_1\in C^1(\Omega)$, $\psi_2\in C^1(R^+)$ and $\alpha\in C(\Omega)$ are such that $A\nabla\psi_1\in C(\Omega)$, $\alpha\geqq 0$ in Ω, $\psi_2'(0)=0$, $\psi_2'(r)>0$ for $r>0$, then

$$E(y_0, \phi(y_0), \nabla\psi(y_0))+\alpha(y_0)(y_0, A\nabla\psi_1(y_0))+\alpha(y_0)((I+A)^{-1}Fy_0, (I+A)\nabla\psi_1(y_0))\leqq 0 \tag{2.4}$$

(b) If $\phi-\psi$ attains a local minimum at $y_0\in\Omega$ and $\nabla\psi(y)=\alpha(y)(\nabla\psi_1(y)-\psi_2'(|y|)\operatorname{sgn} y)$ for all $y\in\Omega$, where ψ_1, ψ_2 and α satisfy the above conditions, then

$$\begin{aligned}E(y_0, \phi(y_0), \nabla\psi(y_0))&+\alpha(y_0)((I+A)^{-1}Fy_0, (I+A)\nabla\psi_1(y_0))\\&+\alpha(y_0)(y_0, A\nabla\psi_1(y_0))\geqq 0.\end{aligned} \tag{2.5}$$

This notion of solution is slightly stronger than that introduced by Crandall and Lions [10], [11] for Hamilton-Jacobi equations in Hilbert spaces. In accordance with this general concept of viscosity solution we say that $\phi\in C(\Omega)$ is a *viscosity solution* to (2.3) provided for all $\psi\in C^1(\Omega)$:

(j) If $\phi-\psi$ attains a local maximum at $y_0\in\Omega$ and $\psi(y)=\psi_1(y)+\psi_2(|y|)$, where $\psi_1\in C^1(\Omega)$ and $\psi_2\in C^1(R^+)$ are such that $A\nabla\psi_1\in C(\Omega)$, $\psi_2(0)=0$, $\psi_2'(r)>0$ for $r>0$, then

$$E(y_0, \phi(y_0), \nabla\psi(y_0))+(y_0, A\nabla\psi_1(y_0))+((I+A)^{-1}Fy_0, (I+A)\nabla\psi_1(y_0))\leqq 0.$$

(jj) If $\phi-\psi$ attains a local minimum at y_0 and $\psi(y)=\psi_1(y)-\psi_2(|y|)$, where ψ_1, ψ_2 are as above, then

$$E(y_0, \phi(y_0), \nabla\psi(y_0))+(y_0, A\nabla\psi_1(y_0))+((I+A)^{-1}Fy_0, (I+A)\nabla\psi_1(y_0))\geqq 0.$$

THEOREM 1. *Let* (i)–(iv) *hold. Then there is a unique weakly continuous strong viscosity solution to* (1.5) *on* $H\backslash\{0\}$ *which satisfies condition* (1.6), *namely, the minimal time function* ϕ.

If F is locally Lipschitz on H, Theorem 1 is implied by the general existence and uniqueness results proved in [11].

Proof. (1) Existence. By the dynamic programming principle we have for all $t>0$

$$\phi(y_0)=\inf\{t+\phi(y(t, y_0, u));\ u\in\mathcal{U}\}. \tag{2.6}$$

Note that for every $y_0\in\overline{D(A+F)}=H, u\in\mathcal{U}$ and $T>0$, $t^{1/2}y(t, y_0, u)\in W^{1,2}([0, T]; H)=\{z\in L^2(0, T; H);\ dz/dt\in L^2(0, T; H)\}$ and

$$\frac{d}{dt}y(t, y_0, u)+Ay(t, y_0, u)+Fy(t, y_0, u)=Bu(t) \quad \text{a.e. } t\in(0, T). \tag{2.7}$$

Moreover, if $u\in W^{1,2}([0, T]; H)$, then $t(dy/dt)\in L^\infty(0, T; H)$ and

$$\frac{d^+}{dt}y(t)+Ay(t)+Fy(t)=Bu(t) \quad \forall t\in(0, T). \tag{2.8}$$

Let $y_0 \in H\backslash\{0\}$ be a local maximum for $\phi - \psi$ where ψ is as in Definition 1. Then, for any $u \in \mathcal{U}$ and $t > 0$,

$$\phi(y_0) - \psi(y_0) \geqq \phi(y(t, y_0, u)) - \psi(y(t, y_0, u))$$

and for $u(t) \equiv u_0 \in K$ it follows by (2.6) and (2.8) that

$$-1 \leqq \lim_{t \to 0} t^{-1} \int_0^t (\nabla\psi(y(s, y_0, u_0)), Bu_0 - Ay(s, y_0, u_0) - Fy(s, y_0, u_0))\, ds$$
$$\leqq (u_0, B^*\nabla\psi(y_0)) - (y_0, A\nabla\psi_1(y_0))\alpha(y_0) - \alpha(y_0)((I+A)^{-1}Fy_0, (I+A)\nabla\psi_1(y_0)),$$

and inasmuch as u_0 is arbitrary in K the conclusion is now

$$h(-B^*\nabla\psi(y_0)) + (y_0, A\nabla\psi_1(y_0))\alpha(y_0) + ((I+A)^{-1}Fy_0, (I+A)\nabla\psi_1(y_0))\alpha(y_0) \leqq 1,$$

as desired.

Assume now that $y_0 \neq 0$ is a local minimum point for $\phi - \psi$ where $\nabla\psi(y) = (\nabla\psi_1(y) - \psi_2'(y)\operatorname{sgn} y)\alpha(y)$. We have

$$\phi(y_0) - \phi(y(t, y_0, u)) \leqq \psi(y_0) - \psi(y(t, y_0, u)) \quad \forall u \in \mathcal{U}, \quad t \in [0, \delta]. \tag{2.9}$$

Let (y^*, u^*) be an optimal pair in problem (1.3), i.e., $y^*(t) = y(t, y_0, u^*)$ and $y^*(\phi(y_0)) = 0$. (The existence of a such a pair is an immediate consequence of the compacity of the level sets $\{y \in H; \frac{1}{2}(Ay, y) + j(y) + |y|^2 \leqq \lambda\}$ and follows by standard arguments.)

Let $y_0^\varepsilon \in D(A) \cap D(F)$ be such that $y_0^\varepsilon \to y_0$ for $\varepsilon \to 0$ and let $y_\varepsilon(t) = y(t, y_0^\varepsilon, u^*)$. Then, we have

$$y_\varepsilon(t) \to y^*(t) \quad \text{uniformly on } [0, T] \text{ in } H$$

and

$$\psi(y_\varepsilon(t)) - \psi(y_0^\varepsilon) = \int_0^t (\nabla\psi(y_\varepsilon(s)), Bu^*(s) - Ay_\varepsilon(s) - Fy_\varepsilon(s))\, ds$$
$$\geqq \int_0^t (\nabla\psi(y_\varepsilon(s)), Bu^*(s))\, ds - \int_0^t (A\nabla\psi_1(y_\varepsilon(s)), y_\varepsilon(s))\, ds$$
$$- \int_0^t ((I+A)\nabla\psi_1(y_\varepsilon(s)), (I+A)^{-1}Fy_\varepsilon(s))\, ds.$$

Letting ε tend to zero, we get

$$\psi(y^*(t)) - \psi(y_0) \geqq \int_0^t (\nabla\psi(y^*(s)), Bu^*(s))\, ds$$
$$- \int_0^t \alpha(y^*(s))(A\nabla\psi_1(y^*(s)), y^*(s))$$
$$- \int_0^t \alpha(y^*(s))((I+A)\nabla\psi_1(y^*(s)), (I+A)^{-1}Fy^*(s))\, ds.$$

Then by (2.6) and (2.7) we infer that

$$1 + \lim_{t \downarrow 0} t^{-1}\left(\int_0^t (B^*\nabla\psi(y^*(s)), u^*(s)\right) ds$$
$$- \int_0^t \alpha(y^*(s))(y^*(s), A\nabla\psi_1(y^*(s)))\, ds$$
$$- \int_0^t \alpha(y^*(s))((I+A)^{-1}Fy^*(s), (I+A)\nabla\psi_1(y^*(s)))\, ds\Big) \leqq 0$$

and therefore

$$\alpha(y_0)(A\nabla\psi_1(y_0), y_0)+\alpha(y_0)((I+A)\nabla\psi_1(y_0), (I+A)^{-1}Fy_0)+h(-B^*\nabla\psi(y_0))\geqq 1$$

as claimed.

(2) Uniqueness. Using a device due to Kružkov [14] (see also [15]), we show first that (1.5) can be reduced via the transformation $\tilde{\phi}=1-e^{-\phi}$ to the equation

$$\tilde{\phi}+h(-B^*D\tilde{\phi})+(Ay+Fy, D\tilde{\phi})=1 \quad \text{in } H\backslash\{0\}. \tag{2.10}$$

Namely, we have the following lemma.

LEMMA 1. *If ϕ is a strong viscosity solution to* (1.5) *in $H\backslash\{0\}$, then the function $\tilde{\phi}=1-e^{-\phi}$ is a viscosity solution to* (2.10).

Proof. Let $\psi\in C^1(H\backslash\{0\})$ be as in condition (j) and let y_0 be a local maximum point for $\tilde{\phi}-\psi$. This yields

$$\phi(y)+\ln(1-e^{\phi(y_0)}(\psi(y)-\psi(y_0)))\leqq\phi(y_0) \quad \forall y\in B(y_0) \tag{2.11}$$

where $B(y_0)=\{y\in H; |y-y_0|\leqq r_0\}$ is a sufficiently small neighborhood of y_0 such that

$$2e^{\phi(y_0)}|\psi(y)-\psi(y_0)|\leqq 1 \quad \forall y\in B(y_0).$$

Consider a function $\tilde{\psi}\in C^1(H\backslash 0)$ such that

$$\tilde{\psi}(y)=\psi(y) \quad \text{for } y\in B(y_0), \qquad |\tilde{\psi}(y)-\psi(y_0)|\leqq\tfrac{2}{3}e^{-\phi(y_0)} \quad \forall y\in H.$$

Denote by χ the function

$$\chi(y)=-\ln(1-e^{\phi(y_0)}(\tilde{\psi}(y)-\tilde{\psi}(y_0)))$$

and since ϕ is a viscosity solution to (1.5) we have by Definition 1

$$e^{\phi(y_0)}h(-B^*\nabla\psi(y_0))+(y_0, A\nabla\psi_1(y_0))\,e^{\phi(y_0)}$$
$$+((I+A)^{-1}Fy_0, (I+A)\nabla\psi_1(y_0))\,e^{\phi(y_0)}\leqq 1$$

i.e.,

$$\tilde{\phi}(y_0)+h(-B^*\nabla\psi(y_0))+((I+A)^{-1}Fy_0, (I+A)\nabla\psi_1(y_0))+(y_0, A\nabla\psi_1(y_0))\leqq 1$$

as claimed.

The case when y_0 is a local minimum point for $\tilde{\phi}-\psi$ and $\psi=\psi_1-\psi_2(|y|)$ can be treated similarly.

According to Lemma 1 to complete the proof of Theorem 1 it suffices to prove that (2.10) has a unique viscosity solution which is weakly continuous and satisfies the conditions

$$\tilde{\phi}(0)=0, \quad 0\leqq\tilde{\phi}\leqq 1 \quad \text{in } H\backslash\{0\}. \tag{2.12}$$

To this end, following a general method to prove uniqueness of the viscosity solution developed in [9] and [10], consider the Hamiltonian

$$H(z, p, q)=h(-B^*p)-h(B^*q)+(Ax+Fx, p)+(Ay+Fy, q), \qquad z=(x, y).$$

Let ϕ_1, ϕ_2 be two viscosity solutions to (2.10) which are weakly continuous on H and satisfy (2.12) and let w be the function

$$w(z)=\phi_1(x)-\phi_2(y), \qquad z=(x, y)\in H\times H.$$

For every $\varepsilon>0$ consider the function $\Phi_\varepsilon: H\times H\to R$ defined by

$$\Phi_\varepsilon(x, y)=\rho(|x|^2+|y|^2)+\varepsilon^{-1}(\varepsilon^{4\omega}+\|x-y\|_*^2)^{1/2\omega} \tag{2.13}$$

where $\rho>0$, $\omega=L^2(1/\sqrt{\rho})+1$, and $\|x\|_*^2=((I+A)^{-1}x, x)$.

Inasmuch as the function $w-\Phi_\varepsilon$ is weakly lower semicontinuous on $H\times H$ there is $z_\varepsilon=(x_\varepsilon, y_\varepsilon)$ such that

$$w(z_\varepsilon)-\Phi_\varepsilon(x_\varepsilon, y_\varepsilon)\geqq w(z)-\Phi_\varepsilon(x, y)\quad \forall(x, y)\in H\times H. \tag{2.14}$$

We have $\Phi_\varepsilon=\rho(|x|^2+|y|^2)+\psi_\varepsilon(x, y)$ where

$$\nabla_x\psi_\varepsilon(x, y)=(\varepsilon\omega)^{-1}(I+A)^{-1}(x-y)(\varepsilon^4+\|x-y\|_*^2)^{1/2\omega-1},$$
$$\nabla_y\psi_\varepsilon(x, y)=-\nabla_x\psi_\varepsilon(x, y).$$

It is readily seen that

$$w+H(z, Dw)=0\quad \text{in } (H\backslash\{0\})\times(H\backslash\{0\})$$

in the viscosity sense. Hence if $x_\varepsilon\neq 0$ and $y_\varepsilon\neq 0$, we have

$$\begin{aligned}w(z_\varepsilon)&+h(-B^*(2\rho x_\varepsilon+\nabla_x\psi_\varepsilon(x_\varepsilon, y_\varepsilon)))-h(B^*(2\rho y_\varepsilon-\nabla_x\psi_\varepsilon(x_\varepsilon, y_\varepsilon)))\\ &+(\varepsilon\omega)^{-1}|x_\varepsilon-y_\varepsilon|^2(\varepsilon^{4\omega}+\|x_\varepsilon-y_\varepsilon\|_*^2)^{1/2\omega-1}\\ &+(\varepsilon\omega)^{-1}((I+A)^{-1}(Fx_\varepsilon-Fy_\varepsilon), x_\varepsilon-y_\varepsilon)(\varepsilon^{4\omega}+\|x_\varepsilon-y_\varepsilon\|_*^2)^{1/2\omega-1}\\ &\leqq(\varepsilon\omega)^{-1}\|x_\varepsilon-y_\varepsilon\|_*^2(\varepsilon^{4\omega}+\|x_\varepsilon-y_\varepsilon\|_*^2)^{1/2\omega-1}.\end{aligned}$$

By assumptions (iii) this yields

$$\begin{aligned}w(z_\varepsilon)-\Phi_\varepsilon(z_\varepsilon)&\leqq C\rho^{1/2}-\varepsilon^{-1}(\varepsilon^{4\omega}+\|x_\varepsilon-y_\varepsilon\|_*^2)^{1/2\omega}\\ &+(\varepsilon\omega)^{-1}\left(L\left(\frac{1}{\sqrt{\rho}}\right)|x_\varepsilon-y_\varepsilon|\|x_\varepsilon-y_\varepsilon\|_*-|x_\varepsilon-y_\varepsilon|^2\right)\\ &\cdot(\varepsilon^{4\omega}+\|x_\varepsilon-y_\varepsilon\|_*^2)^{1/2\omega-1}+(\varepsilon\omega)^{-1}(\varepsilon^{4\omega}+\|x_\varepsilon-y_\varepsilon\|_*^2)^{1/2\omega}\end{aligned} \tag{2.15}$$

because $h(p)-h(q)\leqq C|p-q|$ for all $p, q\in H$.

On the other hand, we see by (2.14) that

$$\rho(|x_\varepsilon|^2+|y_\varepsilon|^2)\leqq\phi_1(x_\varepsilon)\leqq 1. \tag{2.16}$$

Then after some calculation involving (2.15) we get the estimate

$$w(z_\varepsilon)-\Phi_\varepsilon(z_\varepsilon)\leqq C\rho^{1/2}$$

where C is a positive constant independent of ρ and ε. Then by (2.14) we see that

$$\phi_1(x)-\phi_2(x)\leqq C\rho^{1/2}+2\rho|x|^2+\varepsilon\quad \forall x\in H. \tag{2.17}$$

Since ρ and ε can be chosen arbitrarily small, it follows by (2.17) that $\phi_1=\phi_2$ in H.

If $x_\varepsilon=0$, $y_\varepsilon=0$, then again by (2.14) we have

$$\phi_1(x)-\phi_2(x)\leqq 2\rho|x|^2\quad \forall x\in H,$$

and so $\phi_1=\phi_2$. Similarly, if $x_\varepsilon=0$ and $y_\varepsilon\neq 0$ once again using inequality (2.14), we get

$$\rho|y_\varepsilon|^2+\varepsilon^{-1}(\varepsilon^{4\omega}+\|y_\varepsilon\|_*^2)^{1/2\omega}\leqq\varepsilon$$

and therefore $y_\varepsilon=0$.

Let us now assume that $x_\varepsilon\neq 0$ and $y_\varepsilon=0$. Then we have

$$\rho|x_\varepsilon|^2+\varepsilon^{-1}(\varepsilon^{4\omega}+\|x_\varepsilon\|_*^2)^{1/2\omega-1}\leqq\varepsilon+\phi_1(x_\varepsilon)\leqq 1+\varepsilon \tag{2.18}$$

and therefore

$$\|x_\varepsilon\|_*\leqq(\varepsilon(1+\varepsilon))^\omega.$$

Thus if $x_{\varepsilon_n}\neq 0$ and $y_{\varepsilon_n}=0$, for a sequence $\varepsilon_n\to 0$ we have

$$x_{\varepsilon_n}\to 0\quad \text{strongly in } V^* \text{ and weakly in } H$$

and therefore $\phi_1(x_{\varepsilon_n}) \to 0$ (because ϕ_1 is weakly continuous). (We have denoted here by V^* the dual of the space V endowed with the norm $\|\cdot\|_*$.)

Then again by (2.14) we have

$$\phi_1(x) - \phi_2(x) \leqq \phi_1(x_{\varepsilon_n}) + 2\rho|x|^2 + \varepsilon_n \quad \forall x \in H\backslash\{0\}.$$

Hence $\phi_1 = \phi_2$, thereby completing the proof.

3. The time-optimal problem for a semilinear parabolic equation. Consider the distributed control system

$$\begin{aligned} &\frac{\partial y}{\partial t} - \Delta y + \beta(y) = u \quad \text{in } \Omega \times (0, \infty), \\ &y(x, 0) = y_0(x), \quad x \in \Omega, \qquad y = 0 \quad \text{in } \partial\Omega \times (0, \infty) \end{aligned} \tag{3.1}$$

where Ω is a bounded and open subset of R^N with a sufficiently smooth boundary $\partial\Omega$ (for instance, of class C^2), and β is a continuous monotonically increasing function on r such that $\beta(0) = 0$ and

$$|\beta(y) - \beta(z)| \leqq C(1 + |y|^\rho + |z|^\rho)|y - z| \quad \forall y, z \in R \tag{3.2}$$

where $0 \leqq \rho \leqq 2/N$ if $N \geqq 3$, $0 \leqq \rho < 1$ if $N = 2$, and $\rho = 1$ if $N = 1$.

Let $K = \{u \in L^2(\Omega);\ |u(x)| \leqq \alpha \text{ a.e. } x \in \Omega\}$ and let $\phi : L^2(\Omega) \to R^+$ be the minimal time function associated with system (3.1),

$$\phi(y_0) = \inf\{T;\ \exists u \in L^2(0, T; L^2(\Omega)),\ u(t) \in K, \text{a.e. } t \in (0, T);\ y(T, y_0, u) = 0\}. \tag{3.3}$$

Here $y(\cdot, y_0, u) \in C([0, T]; L^2(\Omega))$ is the solution to problem (3.1).

Let us check assumptions (i)-(iv) of § 2 where $H = L^2(\Omega)$, $A = -\Delta$, $D(A) = H_0^1(\Omega) \cap H^2(\Omega)$, $V = H_0^1(\Omega)$, $V^* = H^{-1}(\Omega)$, and $(Fy)(x) = \beta(y(x))$ for almost every $x \in \Omega$, $y \in D(F)$ where

$$D(F) = \{y \in L^2(\Omega);\ \beta(y) \in L^2(\Omega)\}.$$

$H_0^1(\Omega)$, $H^2(\Omega)$, and $H^{-1}(\Omega)$ are Sobolev spaces on Ω.

Since assumptions (i), (ii), are obviously satisfied, we confine ourselves to checking (iii) and (iv).

By the Sobolev imbedding theorem,

$$\|A^{-1}(Fy - Fz)\|_{H_0^1(\Omega)} = \|Fy - Fz\|_{H^{-1}(\Omega)} \leqq C\|\beta(y) - \beta(z)\|_{L^p(\Omega)} \quad \forall y, z \in L^2(\Omega)$$

where $p = 2N/(N+2)$ if $N \geqq 3$, $1 < p \leqq 2$ if $N = 2$, and $p = 1$ if $N = 1$.

Then by (3.2) we see that

$$\|A^{-1}(Fy - Fz)\|_{H_0^1(\Omega)} \leqq C(1 + \|y\|_{L^2(\Omega)}^{2/N} + \|z\|_{L^2(\Omega)}^{2/N})\|y - z\|_{L^2(\Omega)},$$

respectively,

$$\|A^{-1}(Fy - Fz)\|_{H_0^1(\Omega)} \leqq C(1 + \|y\|_{L^2(\Omega)}^{\rho} + \|z\|_{L^2(\Omega)}^{\rho})\|y - z\|_{L^2(\Omega)}$$

for $N = 2$

$$\|A^{-1}(Fy - Fz)\|_{H_0^1(\Omega)} \leqq C(1 + \|y\|_{L^2(\Omega)} + \|z\|_{L^2(\Omega)})\|y - z\|_{L^2(\Omega)}$$

for $N = 1$.

Let us now prove that assumption (iv) holds in the present situation. We shall first prove that any $y_0 \in L^\infty(\Omega)$ can be steered to origin in finite time. To this aim arguing as in [2], consider the feedback system

$$(3.4)\qquad \begin{aligned} &\frac{\partial y}{\partial t} - \Delta y + \beta(y) + \alpha \operatorname{sgn} y = 0 && \text{in } \Omega \times R^+,\\ &y(x,0) = y_0(x) && \text{in } \Omega,\\ &y = 0 && \text{in } \partial\Omega \times R^+ \end{aligned}$$

where $\operatorname{sgn} y = y|y|^{-1}$ if $y \neq 0$ and $\operatorname{sgn} 0 = [-1, 1]$. Recall that problem (3.4) has a unique solution $y \in C([0, T]; L^2(\Omega))$ such that

$$t^{1/2} y \in L^2(0, T; H^2(\Omega) \cap H_0^1(\Omega)), \quad t^{1/2} \frac{\partial y}{\partial t} \in L^2(0, T; L^2(\Omega)) \quad \forall t > 0.$$

Consider the function $z = \|y_0\|_{L^\infty(\Omega)} - \alpha t$ and note that

$$(3.5)\qquad \begin{aligned} &\frac{\partial z}{\partial t} - \Delta z + \alpha \operatorname{sgn} z \ni 0 && \text{in } \Omega \times (0, \alpha^{-1}\|y_0\|_{L^\infty(\Omega)}),\\ &z(x,0) = \|y_0\|_{L^\infty(\Omega)} && \text{in } \Omega,\\ &z \geqq 0 && \text{in } \partial\Omega \times (0, \alpha^{-1}\|y_0\|_{L^\infty(\Omega)}). \end{aligned}$$

Subtracting (3.4) and (3.5) and multiplying by $(y-z)^+$, we get after some calculation that

$$\frac{d}{dt}\|(y-z)^+\|^2_{L^2(\Omega)} \leqq 0 \quad \text{a.e. } t \in (0, \alpha^{-1}\|y_0\|_{L^\infty(\Omega)}).$$

Hence

$$y(x,t) \leqq \|y_0\|_{L^\infty(\Omega)} - \alpha t \quad \forall x \in \Omega, \quad t \in (0, \alpha^{-1}\|y_0\|_{L^\infty(\Omega)})$$

and therefore

$$|y(x,t)| \leqq \|y_0\|_{L^\infty(\Omega)} - \alpha t \quad \forall (x,t) \in \Omega \times [0, \alpha^{-1}\|y_0\|_{L^\infty(\Omega)}].$$

Hence

$$(3.6)\qquad \phi(y_0) \leqq \alpha^{-1}\|y_0\|_{L^\infty(\Omega)} \quad \forall y_0 \in L^\infty(\Omega).$$

Let $S(t)$ be the semigroup generated on $L^2(\Omega)$ by the operator $-(A+F)$, i.e., $S(t)y_0 = y(t)$ where y is the solution to boundary value problem

$$\begin{aligned} &\frac{\partial y}{\partial t} - \Delta y + \beta(y) = 0 \quad \text{in } \Omega \times R^+,\\ &y(0) = y_0 \quad \text{in } \Omega \qquad y = 0 \quad \text{in } \partial\Omega \times R^+. \end{aligned}$$

If z is the solution to the linear parabolic equation

$$\begin{aligned} &\frac{\partial z}{\partial t} - \Delta z = 0 \quad \text{in } \Omega \times R^+,\\ &z(0) = |y_0| \quad \text{in } \Omega \qquad z = 0 \quad \text{in } \partial\Omega \times R^+, \end{aligned}$$

it follows by the maximum principle that

$$|y(x,t)|\leqq z(x,t) \quad \forall (x,t)\in \Omega\times R^+,$$

i.e.,

$$\|S(t)y_0\|_{L^\infty(\Omega)}\leqq Ct^{-N/2}\|y_0\|_{L^2(\Omega)} \quad \forall t>0 \tag{3.7}$$

because, as is well known,

$$\|S_0(t)y_0\|_{L^\infty(\Omega)}\leqq Ct^{-N/2}\|y_0\|_{L^2(\Omega)} \quad \forall t>0 \tag{3.8}$$

where C is a positive constant independent of y_0. (Here $S_0(t)$ is the C_0-semigroup generated by $-A$ on $L^2(\Omega)$.) Then taking into account the obvious inequality

$$\phi(y_0)\leqq \phi(S(t)y_0)+t \quad \forall t>0, \quad y_0\in L^2(\Omega), \tag{3.9}$$

we infer that $\phi(y_0)<\infty$ for all $y_0\in L^2(\Omega)$. (As a matter of fact we may extend ϕ on all of $L^1(\Omega)$.)

Now let $y_0\in L^2(\Omega)$ be arbitrary but fixed and let $\{y_0^n\}\subset L^2(\Omega)$ be such that $y_0^n\rightarrow y_0$ weakly in $L^2(\Omega)$ for $n\rightarrow\infty$. Since the function ϕ is obviously weakly lower semicontinuous on $L^2(\Omega)$ (this is an immediate consequence of the fact that a time-optimal controller exists and follows by standard arguments) it remains to show that

$$\limsup \phi(y_0^n)\leqq \phi(y_0). \tag{3.10}$$

Keeping in mind inequality (3.9) and the fact that for each $t>0$ the operator $S(t)$ is weakly-strongly continuous on $L^2(\Omega)$, without any loss of generality we may assume that

$$y_0^n\rightarrow y_0 \quad \text{strongly in } L^2(\Omega). \tag{3.11}$$

Let $u_0\in \mathcal{U}$ be such that $y(t_0,u_0)=0$ where $t_0=\phi(y_0)$ and let y_n be the corresponding solution to problem (1.3), i.e.,

$$\frac{\partial y_n}{\partial t}-\Delta y_n+\beta(y_n)=u_0 \quad \text{in } \Omega\times R^+,$$

$$y_n(0)=y_0^n \quad \text{in } \Omega, \qquad y_n=0 \quad \text{in } \partial\Omega\times R^+.$$

By (3.6), (3.7), and (3.9) we have

$$\begin{aligned}\phi(y_0^n)&\leqq \phi(y_0)+\phi(y_n(t_0))\\ &\leqq \phi(y_0)+\phi(S(\varepsilon)y_n(t_0))+\varepsilon\\ &\leqq \phi(y_0)+\varepsilon+C\varepsilon^{-N/2}\alpha^{-1}\|y_n(t_0)\|_{L^2(\Omega)}.\end{aligned} \tag{3.12}$$

On the other hand, it follows by (3.11) that $y^n(t)\rightarrow y(t)$ uniformly on $[0,t_0]$ in the strong topology of $L^2(\Omega)$ where $y(t)=y(t,y_0,u_0)$. Hence $\|y_n(t_0)\|_{L^2(\Omega)}\rightarrow 0$ as $n\rightarrow\infty$. If in (3.12) we take $\varepsilon=\varepsilon_n$ such that

$$\varepsilon_n\rightarrow 0, \quad \varepsilon_n^{-N/2}\|y_n(t_0)\|_{L^2(\Omega)}\rightarrow 0 \quad \text{for } n\rightarrow\infty$$

we get (3.10) as desired.

We note parenthetically that we have proved that the minimal time function ϕ for system (1.3) is weakly continuous on $L^2(\Omega)$ under the weaker assumption that β is a maximal monotone graph in $R\times R$ such that $0\in\beta(0)$.

Thus Theorem 1 is applicable in the present situation.

COROLLARY 1. *Under assumption* (3.2) *the dynamic programming equation of the time-optimal control problem for system* (3.1)

$$\alpha\|D\phi(y)\|_{L^1(\Omega)}+(Ay+Fy,D\phi(y))=1 \quad \textit{in } L^2(\Omega)\backslash\{0\} \tag{3.13}$$

has a unique strong viscosity solution satisfying conditions

$$\phi(0)=0, \quad \phi(y)\geqq 0 \quad \forall y\in L^2(\Omega), \tag{3.14}$$

namely, the minimal time function (3.3).

4. The time-optimal problem for boundary control of the heat equation. Consider the boundary control system

$$\begin{aligned} &\frac{\partial y}{\partial t}-\Delta y=0 \quad \text{in } \Omega\times(0,\infty),\\ &y(x,0)=y_0(x), \qquad x\in\Omega,\\ &y(x,t)=u(x,t) \quad \forall(x,t)\in\partial\Omega\times(0,\infty) \end{aligned} \tag{4.1}$$

where Ω is a bounded, open, connected set of R^n with C^∞-boundary, and $u\in L^\infty(\partial\Omega\times(0,\infty))$ are subject to constraints

$$|u(x,t)|\leqq\alpha \quad \text{a.e. } (x,t)\in\partial\Omega\times(0,\infty). \tag{4.2}$$

The maximum principle for the time-optimal problem associated with boundary control system (4.1), (4.2) has been obtained by Fattorini [13].

If we denote by $A: L^2(\Omega)\to L^2(\Omega)$ the operator $-\Delta$ with homogeneous Dirichlet conditions, i.e., $D(A)=H_0^1(\Omega)\cap H^2(\Omega)$ and for $u\in L^2(\Omega)$ we set $\theta=Bu$, where $\theta\in L^2(\Omega)$ is the weak solution to Dirichlet problem

$$\Delta\theta=0 \quad \text{in } \Omega, \qquad \theta=u \quad \text{in } \partial\Omega,$$

we may write system (4.1) as

$$\begin{aligned} &y'(t)+A(y(t)-Bu(t))=0 \quad \text{in } R^+,\\ &y(0)=y_0. \end{aligned}$$

Equivalently,

$$\begin{aligned} &z'(t)+Az(t)=Bu(t) \quad \text{in } R^+,\\ &z(0)=A^{-1}y_0=z_0 \end{aligned} \tag{4.3}$$

where $z=A^{-1}y$.

Let $\phi: L^2(\Omega)\to R^+$ be the minimal time function corresponding to system (4.3), i.e.,

$$\begin{aligned} \phi(z_0)=\inf\{T;\ \exists u\in L^\infty(\partial\Omega\times(0,\infty)), &|u|\leqq\alpha\\ &\text{a.e. in } \partial\Omega\times(0,\infty),\ z(T)=0\}. \end{aligned} \tag{4.4}$$

Let us first show that ϕ is everywhere finite and weakly continuous on $L^2(\Omega)$. Indeed by the results of Russell [16], $\phi(z_0)<\infty$ for all $z_0\in D(A)$.

Then, by the obvious inequality

$$\phi(z_0)\leqq\phi(e^{-A\varepsilon}z_0)+\varepsilon \quad \forall z_0\in L^2(\Omega), \tag{4.5}$$

we infer that $\phi<\infty$ on $L^2(\Omega)$, as claimed. Applying Theorem 1 in [7], it follows that the minimal time function ϕ is continuous on $L^2(\Omega)$, and since the semigroup e^{-At} is compact for $t>0$ we conclude that ϕ is weakly continuous on $L^2(\Omega)$.

Recalling that B^* (the adjoint operator of B) is given by $B^*p=-(\partial/\partial\nu)A^{-1}p$ in $\partial\Omega$ for $p\in L^2(\Omega)$, we may write the Bellman equation associated with system (4.3)

$$\alpha\left\|\frac{\partial}{\partial\nu}A^{-1}D\phi(y)\right\|_{L^1(\partial\Omega)}+(Ay, D\phi(y))=1 \quad \text{for } y\neq 0. \tag{4.6}$$

Applying Theorem 1, we find Corollary 2.

COROLLARY 2. *The minimal time function ϕ is the unique weakly continuous strong viscosity solution to* (4.6) *in $L^2(\Omega)\backslash\{0\}$ satisfying the conditions*

$$\phi(0)=0,\quad \phi\geqq 0 \quad \textit{in } L^2(\Omega). \tag{4.7}$$

Now if $\psi(y)=\phi(A^{-1}y)$ is the minimal time function associated with system (4.1) we see by (4.6) that, formally, it satisfies the equation

$$\alpha\left\|\frac{\partial}{\partial\nu}D\psi(y)\right\|_{L^1(\Omega)}+(Ay, D\psi(y))=1. \tag{4.8}$$

Then Corollary 2 implies the existence and uniqueness of a viscosity solution $\psi:(D(A))^*\to(0,\infty)$ for (4.8) in $(D(A))^*\backslash\{0\}$. (We have denoted by $(D(A))^*$ the dual space of $D(A)$.)

Acknowledgment. I am indebted to Professor P. L. Lions for some useful remarks on an earlier version of this paper.

EXISTENCE OF CONTROL LYAPUNOV FUNCTIONS AND APPLICATIONS TO STATE FEEDBACK STABILIZABILITY OF NONLINEAR SYSTEMS*

J. TSINIAS†

Abstract. The asymptotic and practical stabilization for the affine in the control nonlinear systems, which extends the results of Artstein, Sontag, and Tsinias is explored. Sufficient conditions for the existence of control Lyapunov functions are presented guaranteeing stabilization. The corresponding feedback laws are smooth, except possibly at the equilibrium of the system.

Key words. control Lyapunov functions, state feedback, stabilizability.

AMS(MOS) subject classification. 93D15

1. Introduction.

Feedback stabilization of nonlinear systems is a problem of great importance in control theory. Geometric, decomposition, and linearization methods, Lyapunov and center manifold theorems, as well as sliding mode techniques have been used by many authors to derive necessary and sufficient conditions for stabilization of systems at a specified equilibrium. Regularity assumptions of the stabilizing feedback near the equilibrium play an important role in the theory that has been developed (see, for instance, [1]-[14], [16]-[19], [22], [23], [27]-[42]). Linear, smooth, almost smooth, sliding mode, and piecewise-analytic controllers have been used in the previously mentioned works where the various types of regularity requirements lead to many different notions of stabilization. In particular, in [3], [29], [31], [32], [37]-[39] the corresponding necessary and sufficient conditions for stabilization are of Lyapunov type, the proposed stabilizers are smooth except possibly at the equilibrium, and their construction is based on the existence of an appropriate control Lyapunov function.

Our main purpose is to explore further the asymptotic and practical stabilization problem for a wide class of affine in the control nonlinear systems. This class can be characterized in terms of computable control Lyapunov functions, which in certain cases depend directly on the dynamics of the system. The main techniques used to do this are Lyapunov's direct methods [15], [21], [26], [45] and the converse stability theorems of Massera [24], Kurzweil [20], and Wilson [43], [44]. It will be useful to recall here the precise definitions of the notions of stabilization, control Lyapunov functions, and the most important results provided in [3], [31], [37], and [38], as well as some further generalizations.

Consider the system

$$\dot{x}=f(x)+\sum_{i=1}^{l} u_i g_i(x)=f(x)+g(x)u, \tag{1.1}$$

where the state space is R^n and the control $u=(u_1,\cdots,u_l)'$ takes values on R^l. We assume that $0\in R^n$ is an equilibrium for f. The vector fields $f, g_1,\cdots,g_l$ are supposed to be smooth (C^∞).

We say that (1.1) is *asymptotically stabilizable* (at zero) by means of the feedback law $u=k(x)$, if $0\in R^n$ is an asymptotically stable equilibrium for the resulting closed-loop system

$$\dot{x}=f(x)+g(x)k(x). \tag{1.2}$$

* Received by the editors November 20, 1989; accepted for publication (in revised form) May 9, 1990.

† Department of Mathematics, National Technical University, Zografou Campus, 15773 Athens, Greece.

System (1.1) is said to be *practically stabilizable* (at zero) by means of the family of feedback laws $\{k_r, r>0\}$, if for any sufficiently small r and for any x_0 near the open sphere $S(0, r)$ of radius r around zero, the corresponding trajectory $x_r(t, x_0)$ of the closed-loop system

$$\dot{x} = f(x) + g(x)k_r(x) \tag{1.3}$$

enters $S(0, r)$ after some time $t = T < +\infty$ and it stays in this region thereafter. We note that the notion of practical stability is discussed by La Salle and Lefschetz [21].

DEFINITION 1.1. The system (1.1) satisfies the *Lyapunov condition* at zero (L.C.), if there exist a neighborhood N of $0 \in R^n$ and a real function $\Phi: N \to R$, which is at least continuously differentiable on N, is positive definite, i.e., $\Phi(0) = 0$ and $\Phi(x) > 0$ for $x \in N - \{0\}$, and such that for any $x \in N - \{0\}$ the following condition holds:

$$g_i(\Phi)(x) \overset{\text{def}}{=} D\Phi g_i(x) = 0, \qquad i = 1, \cdots, l \Rightarrow f(\Phi)(x) < 0, \tag{1.4}$$

where $D\Phi$ denotes the derivative of Φ. A continuously differentiable real function Φ is called a *control Lyapunov function*, if it is positive definite and satisfies condition (1.4).

We say that the control Lyapunov function Φ above satisfies the *bounded* control property, if there exists a positive real function $d: N \to R$ such that d is bounded on N and for every $x \in N - \{0\}$ there exists a vector $u \in R^l$ satisfying the following inequalities:

$$\|u\| < d(x), \tag{1.5}$$

$$f(\Phi)(x) + g(\Phi)(x)u < 0, \tag{1.6}$$

where $g(\Phi) \overset{\text{def}}{=} (g_1(\Phi), \cdots, g_l(\Phi))$ and $\| \ \|$ is the usual Euclidean norm. If, in addition, $d(x) \to 0$ as $x \to 0$, then we say that Φ satisfies the *small* control property.

The next theorem was originally established in [3]. Versions and generalizations of this theorem can also be found in [31], [37]-[39].

THEOREM 1.2. (i) *The system* (1.1) *satisfies the* L.C., *if and only if it is asymptotically stabilizable at zero by means of a feedback law $u = k(x)$, which is smooth for $x \neq 0$ near zero.*

(ii) *The corresponding control Lyapunov function Φ satisfies the bounded control property, if and only if there exists a stabilizer $u = k(x)$, which is smooth for $x \neq 0$ near zero and satisfies $\|k(x)\| < d(x)$, where d is defined in* (1.5). *It turns out that k is bounded in a neighborhood of zero and if, in addition, Φ satisfies the small control property then $k(x) \to 0$ as $x \to 0$.*

We note that the smoothness property of the stabilizing feedback laws constructed in [31] and [37] requires the smoothness of the Lyapunov function Φ, since they depend directly on the Lie derivatives $f(\Phi)$ and $g(\Phi)$. In [3] the regularity properties of the proposed feedback laws require only the differentiability of Φ.

DEFINITION 1.3. The system (1.1) satisfies the *practical Lyapunov condition* (P.L.C.), if there exist a family of continuously differentiable mappings

$$\Phi_r: R^n \to R, \quad \Phi_r(0) = 0, \quad r > 0,$$

and compact neighborhoods N and N_r of $0 \in R^n$ such that $N_r \subset S(0, r) \subset N_r$, Φ_r is strictly positive for x outside N_r and for any sufficiently small r condition (1.4) holds with $\Phi = \Phi_r$ and $x \in N_r - N_r$ and further

$$\min\{\Phi_r(x), x \in \partial N_r\} > \max\{\Phi_r(x), x \in S[0, r]\}, \tag{1.7a}$$

where ∂N is the boundary of N. Moreover, for any sequences $\{r_i\} \subset R^+$ and $\{x_{r_i}\} \subset N$ with $\lim r_i = 0$ and $\lim x_{r_i} = a$ as $i \to +\infty$, we have

$$\overline{\lim}\, \Phi_{r_i}(x_{r_i}) = 0 \quad \text{for } a = 0, \quad \text{and} \quad \underline{\lim}\, \Phi_{r_i}(x_{r_i}) > 0 \quad \text{for } a > 0. \tag{1.7b}$$

The corresponding family $\{\Phi_r\}$ of the mappings above is called *control Lyapunov family.*

We say that the control Lyapunov family $\{\Phi_r\}$ satisfies the *bounded* control property, if there exist a positive real function $d(x)$, which is bounded on a neighborhood N of zero, and a family of positive real numbers $\{c_r, r>0\}$ such that $c_r \to 0$ as $r \to 0$ and for any sufficiently small r conditions (1.6) and (1.7) hold with $\Phi = \Phi_r$, $x \in N_{2r} - N_{1r}$ and for some vector $u \in R^l$ with

$$\|u\| < d(x) + c_r.$$

If, in addition, $d(x) \to 0$ as $x \to 0$, then we say that $\{\Phi_r\}$ satisfies the *small* control property.

The following theorem presents sufficient conditions for practical stabilization. Its proof follows by using arguments similar for those of the proof of Theorem 1.2.

THEOREM 1.4. (i) *If the system* (1.1) *satisfies the* P.L.C., *then it is practically stabilizable at zero by means of a family of smooth feedback laws* $\{k_r(x)\}$.

(ii) *Moreover, if the control Lyapunov family* $\{\Phi_r\}$ *satisfies the bounded* (*small*) *control property, then for any r the corresponding stabilizer* k_r *satisfies the inequality*

$$\|k_r(x)\| < d(x) + c_r, \tag{1.8}$$

for x near zero, where d and c_r *are as given in Definition* 1.3.

Obviously, if (1.1) satisfies the L.C., it also satisfies the P.L.C. Furthermore, as a consequence of Proposition 4 of [38] and the corollary in paragraph 7 of Sontag [32] we obtain the following result.

PROPOSITION 1.5. *If the system* (1.1) *is asymptotically stabilizable by means of the feedback* $u = k(x)$, *which is continuous in a neighborhood of zero, then it is practically stabilizable by means of a family of smooth feedback laws.*

In § 2 we consider systems (1.1) of the form

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} f_1(x_1, x_2) \\ f_2(x_1, x_2) \end{pmatrix} + \begin{pmatrix} 0 \\ g_2(x_1, x_2) \end{pmatrix} u, \tag{1.9}$$
$$x = (x_1', x_2')' \in R^{n_1} \times R^{n_2}, \quad n_1 + n_2 = n, \quad u \in R^l$$

and we derive sufficient conditions for the existence of control Lyapunov functions guaranteeing stabilization. We note that similar decompositions have been considered by Vidyasagar and other authors [41], [42], [36], [10] but their methodology is quite different. Let us explain briefly the main idea of § 2 by the following interesting case. Consider a single input system (1.9) with $n_2 = 1$, namely, g_2 is a real function. Let us assume that there is a continuously differentiable map $v = \phi(x_1)$ with $\phi(0) = 0$, which is the unique solution of the equation $g_2(x_1, v) = 0$ and simultaneously asymptotically stabilizes the system $\dot{x}_1 = f_1(x_1, v)$, $v \in R^{n_2}$ at zero (see Example 4.3 of this paper). Then the system (1.9) satisfies the L.C. and so by Theorem 1.2 it is asymptotically stabilizable at $0 \in R^n$. Indeed, consider a smooth Lyapunov function $V(x_1)$ for the closed-loop system $\dot{x}_1 = f_1(x_1, \phi(x_1))$ and define

$$\Phi(x) = V(x_1) + \tfrac{1}{2}(x_2 - \phi(x_1))^2.$$

Obviously, Φ is continuously differentiable and positive definite. Moreover, Φ is a control Lyapunov function for (1.9). Indeed, for any $x \neq 0$ with

$$g_2(\Phi)(x) = (x_2 - \phi(x_1)) g_2(x_1, x_2) = 0$$

it follows that $x_2 = \phi(x_1)$; therefore,

$$\begin{aligned} f(\Phi)(x) &= f_1(V)(x_1, x_2) + (x_2 - \phi(x_1)) f_2(x_1, x_2)(x_2 - \phi(x_1)) D\phi(x_1) f_1(x_1, x_2)|_{x_2 = \phi(x_1)} \\ &= f_1(V)(x_1, \phi(x_1)) < 0. \end{aligned}$$

It turns out that (1.9) satisfies the L.C. and so by Theorem 1.2 it is stabilizable at zero by meaŋs of a feedback law which is smooth for $x \neq 0$ near zero. The previous discussion is applicable to systems of the form

$$\overset{(n)}{x} = f_2(x, \overset{(1)}{x}, \cdots, \overset{(n-1)}{x}) + ug_2(x, \overset{(1)}{x}, \cdots, \overset{(n-1)}{x}), \quad x \in R \quad \text{where } \overset{(i)}{x} = \frac{d^i x}{dt^i},$$

or equivalently

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \vdots \\ \dot{x}_n \end{pmatrix} = \begin{pmatrix} x_2 \\ x_3 \\ \vdots \\ f_2(x) \end{pmatrix} + u \begin{pmatrix} 0 \\ 0 \\ \vdots \\ g_2(x) \end{pmatrix}, \qquad f_2(0) = g_2(0) = 0.$$

The above system satisfies the L.C. provided that $x_n = \phi(x_1, x_2, \cdots, x_{n-1})$, $\phi(0) = 0$ is the unique solution of $g_2(x) = 0$ and $0 \in R^{n-1}$ is an asymptotically stable equilibrium for the lower-dimensional system

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \vdots \\ \dot{x}_{n-1} \end{pmatrix} = \begin{pmatrix} x_2 \\ x_3 \\ \vdots \\ \phi(x_1, x_2, \cdots, x_{n-1}) \end{pmatrix}.$$

In § 2 we extend the above analysis to more general cases. In particular, in Theorems 2.1 and 2.2 we provide sufficient conditions for the existence of a control Lyapunov function depending only on the stability behavior of the mappings f_1 and g_2.

Special emphasis is given to asymptotic and practical stabilization for systems (1.9), whose control term g_2 is constant and have the form

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} f_1(x_1, x_2) \\ f_2(x_1, x_2) \end{pmatrix} + \begin{pmatrix} 0 \\ u \end{pmatrix}, \qquad (x_1, x_2) \in R^{n_1} \times R^{n_2}, \quad u \in R^{n_2}. \tag{1.10}$$

Proposition 2.3 and Theorems 2.4 and 2.6 of this paper generalize some well-known results of [23], [34], and [37] concerning the case (1.10).

Section 3 deals with the relationship between the Lyapunov conditions and the position on the complex plane of the uncontrollable eigenvalues of the linearization of (1.1) at zero. Finally, in § 4 we illustrate the theory we develop by four numerical examples.

2. Main results.

To begin with, we state and prove a theorem, where the L.C. is characterized in terms of suitable positive functions concerning the lower-dimensional subsystems of (1.9):

$$\dot{x}_1 = f_1(x_1, v), \qquad v \in R^{n_2}, \tag{2.1}$$

$$\dot{x}_2 = g_2(x_1, x_2)u, \qquad u \in R^l. \tag{2.2}$$

THEOREM 2.1. (i) *Suppose that there exist neighborhoods N and N_1 of $0 \in R^n$ and $0 \in R^{n_1}$, respectively, and mappings $r: N \to R^l$, $\phi: N_1 \to R^{n_2}$, and $W: N \to R$ such that $\phi(0) = 0$, ϕ is continuous, and W is continuously differentiable, and let us denote*

$$M = \{x \in N\colon x_2 = \phi(x_1)\}, \qquad S_1 = \{x \in N\colon W(x) = 0\}, \quad \textit{and}$$

$$S_2 = \left\{x \in N\colon \left(\frac{\partial W}{\partial x_2} g_2 r\right)(x) = 0\right\}.$$

Assume that

(a) *For any* $x=(x_1', x_2')'$ *near zero it follows that*

$$W(x) \geqq 0 \quad \text{and} \quad S_2 \subset S_1 = M.$$

(b) *The system* (2.1) *is asymptotically stabilizable at* $0 \in R^{n_1}$ *by means of the feedback law* $v=\phi(x_1)$.

Under the previous assumptions (a) *and* (b) *the system* (1.9) *satisfies the* L.C. *Let* Φ *be the corresponding control Lyapunov function.*

(ii) *Let us further assume that r is bounded,* ϕ *and* $\partial W/\partial x_2$ *continuously differentiable, and*

(c) *There exist positive constants c and* $a \leqq 2$ *such that*

$$\left(\frac{\partial W}{\partial x_2} g_2 r\right)(x) \leqq -c\|x_2-\phi(x_1)\|^a, \tag{2.3}$$

for x near $0 \in R^n$.

Then, if $a \leqq 1$ *the function* Φ *satisfies the small control property, and if* $1 < a \leqq 2$ *and in addition* $0 \in R^{n_1}$ *is an exponentially stable equilibrium for the closed-loop system* $\dot{x}_1 = f_1(x_1, \phi(x_1))$, *then the control Lyapunov function* Φ *satisfies the bounded control property.*

Proof. (i) Since $0 \in R^{n_1}$ is an asymptotically stable equilibrium for the system

$$\dot{x}_1 = f_1(x_1, \phi(x_1)) \tag{2.4}$$

then the converse Lyapunov theorem of Kurzweil [20] asserts that there exists a smooth Lyapunov function $V: R^{n_1} \to R$ such that $V(0)=0$, $V(x_1)>0$ and

$$DVf_1(x_1, \phi(x_1)) < 0$$

for $x_1 \neq 0$ near zero. Obviously, by assumption (a) the function

$$\Phi = V + W$$

is positive definite. Let $f=(f_1', f_2')'$ and $g=(0', g_2')'$. Then

$$f(\Phi)=f_1(V)+f(W) \quad \text{and} \quad g(\Phi)=\frac{\partial W}{\partial x_2} g_2.$$

For any $x \neq 0$ such that $g(\Phi)(x)=((\partial W/\partial x_2)g_2)(x)=0$ it follows by assumption (a) that $x_2=\phi(x_1)$; hence,

$$DW(x_1, \phi(x_1))=0$$

and so

$$f(\Phi)(x)=DVf_1(x_1, \phi(x_1))<0.$$

Therefore (1.9) satisfies the L.C. and $\Phi = V+W$ is a control Lyapunov function.

(ii) Let us assume that (2.3) holds and let $a \leqq 1$. Define

$$q(x) = -DVf_1(x_1, \phi(x_1)) + \|x_2-\phi(x_1)\|^2.$$

Clearly, q is positive definite. Since f and $\partial W/\partial x_2$ are continuously differentiable and $DW(x_1, \phi(x_1))=0$, there are positive contants c_1 and c_2 such that

$$\|DW(x)\| \leqq c_1\|x_2-\phi(x_1)\|, \tag{2.5}$$

$$\|Df(x)\| \leqq c_2 \quad \text{for } x \text{ near zero.} \tag{2.6}$$

Let $b(x) = c_2\|DV(x_1)\| + c_1\|f(x)\| + \|x_2 - \phi(x_1)\|$. Then by (2.3), (2.5), and (2.6) it follows that

$$\begin{aligned}|(f(\Phi)+q)(x)| &\leqq c_2\|DV(x_1)\|\,\|x_2-\phi(x_1)\| + c_1\|f(x)\|\,\|x_2-\phi(x_1)\| + \|x_2-\phi(x_1)\|^2\\ &\leqq b(x)\|x_2-\phi(x_1)\| \leqq b(x)\|x_2-\phi(x_1)\|^a \leqq -\frac{b(x)}{c}(D\Phi gr)(x)\end{aligned}$$

and, therefore,

$$\left\{f(\Phi)+g(\Phi)\left(\frac{rb}{c}\right)\right\}(x) \leqq -q(x) < 0 \quad \text{for } x \neq 0 \text{ near } \textit{zero}.$$

Since r is bounded and b is continuous with $b(0)=0$, it follows that Φ satisfies the small control property.

Let us finally assume that (2.3) holds with $1 < a \leqq 2$, ϕ is continuously differentiable, and $0 \in R^{n_1}$ is exponentially stable for (2.4). Since $\phi(0)=0$, there is a constant $c_3 > 0$ such that

$$\|\phi(x_1)\| < c_3\|x_1\|, \quad x_1 \text{ near } 0 \in R^{n_1} \tag{2.7}$$

and since $f(0)=0$ it follows by (2.6) and (2.7) that

$$\begin{aligned}\|f(x)\| &\leqq c_2(\|x_1\|+\|x_2\|) \leqq c_2(\|x_1\|+\|\phi(x_1)\|+\|x_2-\phi(x_1)\|)\\ &\leqq c_2((c_3+1)\|x_1\|+\|x_2-\phi(x_1)\|),\end{aligned} \tag{2.8}$$

for all x in a neighborhood of $0 \in R^n$. Exponential stability of $0 \in R^{n_1}$ with respect to (2.4) implies the existence of a continuously differentiable function V and a positive constant $c_4 > 0$ such that

$$DVf_1(x_1, \phi(x_1)) \leqq -c_4\|x_1\|^2, \quad \text{and} \tag{2.9}$$

$$\|DV(x_1)\| \leqq \|x_1\| \tag{2.10}$$

for x_1 near zero [15], [45]. Let

$$\begin{aligned}q(x) = -f_1(V)(x_1, \phi(x_1)) - DV\frac{\partial f_1}{\partial x_2}(x_1, \phi(x_1))(x_2-\phi(x_1))\\ -f(W)(x) + k\|x_2-\phi(x_1)\|^2, \qquad k > 0.\end{aligned}$$

Then (2.5)-(2.10) imply that there are constants M_1, $M_2 > 0$ such that

$$q(x) \geqq c_4\|x_1\|^2 - M_1\|x_1\|\,\|x_2-\phi(x_1)\| + (k-M_2)\|x_2-\phi(x_1)\|^2$$

and so q is positive definite, provided that k is a suitably large positive constant. Finally, let $L > 0$ such that

$$\left\|f(x)-f(x_1,\phi(x_1)) - \frac{\partial f_1}{\partial x_2}(x_1,\phi(x_1))(x_2-\phi(x_1))\right\| < L\|x_2-\phi(x_1)\|^2 \tag{2.11}$$

locally around $0 \in R^n$. From (2.11) and assumption (c), there is a positive constant $s > 0$ satisfying

$$\begin{aligned}|(f(\Phi)+q)(x)| = |f_1(V)(x) + f(W)(x) - f_1(V)(x_1, \phi(x_1))\\ -DV\frac{\partial f_1}{\partial x_2}(x_1,\phi(x_1))(x_2-\phi(x_1)) - f(W)(x) + k\|x_2-\phi(x_1)\|^2|\\ \leqq s\|x_2-\phi(x_1)\|^a \leqq -\frac{s}{c}(g(\Phi)r)(x)\end{aligned}$$

and so

$$\left\{f(\Phi)+g(\Phi)\left(\frac{rs}{c}\right)\right\}(x) \leqq -q(x)<0$$

for $x \neq 0$ locally around zero. Since rs/c is bounded, Φ satisfies the bounded control property. □

The next theorem is one of our main results and is a consequence of Theorem 2.1(i). It provides a control Lyapunov function that depends directly on the dynamics of the systems (2.1) and (2.2) and its proof is based on the converse Lyapunov theorem established by Wilson [43], [44].

THEOREM 2.2. *Suppose that there exist neighborhoods N_1 and N of $0 \in R^{n_1}$ and $0 \in R^n$, respectively, and mappings $r: N \to R^l$ and $\phi: N_1 \to R^{n_2}$ such that r is Lipschitz continuous, ϕ is continuous with $\phi(0)=0$, the origin $0 \in R^{n_1}$ is an asymptotically stable equilibrium for* (2.4) *and the set*

$$M=\{x \in N: x_2=\phi(x_1), x_1 \in N_1\}$$

is asymptotically stable with respect to

$$\dot{x}=(\hat{g})(x) \overset{\text{def}}{=} \begin{pmatrix} 0 \\ (g_2 r)(x) \end{pmatrix}, \qquad x=(x_1', x_2') \in R^{n_1} \times R^{n_2}. \tag{2.12}$$

Then (1.9) *satisfies the* L.C.

Proof. Consider the system (2.12) evolving on $X \overset{\text{def}}{=} \{x \in R^n: x_1 \in N_1\}$. Note that the restriction of (2.12) to the space R^{n_1} gives $\dot{x}_1=0$ and so the region X is positively invariant. According to [43] and [44], since $M \subset X$ is asymptotically stable with respect to (2.12), there exists a smooth Lyapunov function $W: X \to R$ of M, namely, $W(x)>0$ and $(DW\hat{g})(x)<0$ for $x \notin M$, whereas $W(x)=0$ for $x \in M$. It turns out that $((\partial W/\partial x_2) g_2 r)(x)<0$ for $x_2 \neq \phi(x_1)$ near zero and $((\partial W/\partial x_2) g_2 r)(x)=0$ if and only if $x_2=\phi(x_1)$. Therefore, the assumptions (a) and (b) of Theorem 2.1 are fulfilled and the system (1.9) satisfies the L.C. □

Next we specialize Theorem 2.1 to the particular case of systems (1.10). In this case without loss of generality we assume that $f_2 \equiv 0$. Indeed, otherwise we apply the smooth law $u \to -f_2+u$ and the system (1.10) becomes

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix}=\begin{pmatrix} f_1(x_1, x_2) \\ 0 \end{pmatrix}+\begin{pmatrix} 0 \\ I \end{pmatrix} u. \tag{2.13}$$

It is well known (see, for instance, [23], [34], [37]) that if (2.1) is asymptotically stabilizable by means of the smooth feedback

$$v=\phi(x_1), \qquad \phi(0)=0,$$

then (2.13) is also smoothly asymptotic stabilizable (hence there exists a control Lyapunov function satisfying the small control property). If the smoothness requirements for the map ϕ are relaxed, further generalizations are possible. For instance, let us assume that ϕ is continuously differentiable. Then, as in Theorems 3 and 4 of [37], it can be shown that (2.13) admits a control Lyapunov function satisfying the small control property. The following proposition asserts that the last statement is also an immediate consequence of Theorem 2.1(ii).

PROPOSITION 2.3. *Consider the system* (2.13) *and suppose that* (2.1) *is asymptotically stabilizable by means of the feedback law $v=\phi(x_1)$, $\phi(0)=0$, which is continuously differentiable in a neighborhood of $0 \in R^{n_1}$. Then* (2.13) *satisfies the* L.C. *and the corresponding control Lyapunov function satisfies the small control property.*

Proof. Let V be a smooth Lyapunov function for (2.4) and let

$$W(x)=\tfrac{1}{2}\|x_2-\phi(x_1)\|^2.$$

Obviously, W is nonnegative definite and $\partial W/\partial x_2$ continuously differentiable near zero. Define $r=(r_1,\cdots,r_{n_2})'$ with $r_i(x)=-\mathrm{sgn}\,(x_2-\phi(x_1))_i$. Then

$$\left(\frac{\partial W}{\partial x_2}g_2 r\right)(x)=\left(\frac{\partial W}{\partial x_2}r\right)(x)\leqq -\|x_2-\phi(x_1)\|,$$

r is uniformly bounded on R^n and so W satisfies the properties (a) and (b) of Theorem 2.1. In particular, (2.3) holds with $a=1$; therefore, the function $\Phi=V+W$ satisfies the small control property. □

In the rest part of the paper we deal with the practical stabilization problem for the system (2.13). We shall establish that under the only assumption that the stabilization law $v=\phi$ for (2.1) is *Lipschitz continuous*, then there exists a control Lyapunov family, which satisfies the small control property of Definition 1.3. Therefore, in that case practical stabilization is possible by means of a family of feedback laws $\{k_r\}$ satisfying (1.8).

THEOREM 2.4. *Let us assume that* (2.1) *is asymptotically stabilizable by means of the feedback law* $v=\phi(x_1)$ *with* $\phi(0)=0$. *Then*

(i) *If* ϕ *is continuous near zero, then* (2.13) *satisfies the* P.L.C.

(ii) *If* ϕ *is Lipschitz continuous, then* (2.13) *satisfies the* P.L.C. *and, further, the corresponding control Lyapunov family satisfies the small control property.*

In order to prove statement (ii) of Theorem 2.4 we need the following lemma.

LEMMA 2.5. *Let* $\phi: R^n\to R^m$ *be a real map that satisfies a Lipschitz condition on a compact neighborhood* U *of* $0\in R^n$, *and* $\phi(0)=0$. *Then there exist a neighborhood* Q *of* $0\in R^n$, *a constant* $K>0$ *and a family of smooth mappings* $\phi_\varepsilon: Q\to R^m$, $\varepsilon>0$ *such that for every sufficiently small* ε *the following hold*:

$$\|\phi(x)-\phi_\varepsilon(x)\|<\varepsilon \quad \forall x\in Q-S(0,\varepsilon), \tag{2.14}$$

$$\phi_\varepsilon(0)=0, \tag{2.15}$$

$$\|D\phi_\varepsilon(x)\|<K \quad \forall x\in Q. \tag{2.16}$$

Moreover, for any sequences $\{\varepsilon_i\}\subset R^+$ *and* $\{x_i\}\subset Q$ *such that* $\varepsilon_i\to 0$ *and* $x_i\to x\in Q$, *as* $i\to+\infty$, *there exist subsequences* $\{\varepsilon_i'\}$ *and* $\{x_i'\}$ *of* $\{\varepsilon_i\}$ *and* $\{x_i\}$, *respectively, and a positive constant* $0\leqq\sigma\leqq 1$ *satisfying*

$$\phi_{\varepsilon_i'}(x_1')\to\sigma\phi(x). \tag{2.17}$$

Proof. Let Q be a compact neighborhood of zero, which is contained in the interior of U and let $p: R^n\to R$ be a smooth real map such that $p(x)=1$ for $x\in Q$ and $p(x)=0$ outside U. We define $\hat{\phi}=p\phi$ and consider its Sobolev's regularization

$$h_s(x)\overset{\text{def}}{=}\int a_s(x-u)\hat{\phi}(u)\,du=\int_{\|u\|<s} a_s(u)\hat{\phi}(x-u)\,du, \qquad 0<s<1,$$

where $a_s(x)=s^{-n}a(s^{-1}\|x\|)$, a being any positive smooth mapping such that $a(\|x\|)\leqq 1$, $a(\|x\|)=0$ for $\|x\|\geqq 1$ and $\int a(\|x\|)\,dx=1$. Using standard arguments (see, for instance, [25]), we can easily establish that, since $\hat{\phi}$ is continuous and has bounded support, the sequence h_s converges to $\hat{\phi}=p\phi=\phi$ as $s\to 0$ uniformly with respect to $x\in Q$, and further h_s is smooth for every s. Since p is smooth having bounded support in U and

ϕ is Lipschitz continuous on Q, it follows that $\hat{\phi}=p\phi$ also satisfies a Lipschitz condition in $S(Q,1)$, namely, there is a positive constant c such that

$$\|\hat{\phi}(v_1)-\hat{\phi}(v_2)\|<\frac{c}{2}\|v_1-v_2\| \quad \forall v_1, v_2\in S(Q,1).$$

For each $x_1, x_2\in Q$, $1>s>0$, and $\|u\|<s$ we have x_1-u, $x_2-u\in S(Q,1)$ and so

$$\|h_s(x_1)-h_s(x_2)\|\leqq\int_{\|u\|<s} a_s(u)\|\hat{\phi}(x_1-u)-\hat{\phi}(x_2-u)\|\,du$$

$$\leqq\frac{c}{2}\|x_1-x_2\|\int_{\|u\|<s} a_s(u)\,du=\frac{c}{2}\|x_1-x_2\|.$$

Smoothness of h_s and the previous inequality imply that

$$\|Dh_s(x)\|<c, \quad \text{and}$$

$$\|h_s(x)\|\leqq c\|x\|+\|h_s(0)\| \quad \forall x\in Q \text{ and } 0<s<1.$$

Consider, finally, a smooth real function ψ satisfying $\psi(x)=1$ for $\|x\|>1$, $\psi(x)=0$ for $\|x\|<\frac{1}{2}$, and $\psi(x)\leqq 1$ otherwise. Let $L>0$ such that $\|D\psi(x)\|<L$ for every $x\in R^n$, and let $s=s(\varepsilon)\leqq\varepsilon$ satisfying $\|\phi(x)-h_s(x)\|<\varepsilon$ for all $x\in Q$. We define

$$\phi_\varepsilon(x)=\psi\left(\frac{x}{\varepsilon}\right)h_{s(\varepsilon)}(x)$$

and $K=Lc+L+c$. Obviously $\phi_\varepsilon(x)=h_s(x)$ for each $x\in Q-S(0,\varepsilon)$ and $\phi_\varepsilon(0)=0$; hence, (2.14) and (2.15) are satisfied. Moreover,

$$D\phi_\varepsilon(x)=\frac{1}{\varepsilon}D\psi\left(\frac{x}{\varepsilon}\right)h_s(x)+\psi\left(\frac{x}{\varepsilon}\right)Dh_s(x);$$

therefore,

$$\|D\phi_\varepsilon(x)\|\leqq\begin{cases}\frac{L}{\varepsilon}(c\|x\|+\|h_s(0)\|)+c, & \frac{\varepsilon}{2}\leqq\|x\|<\varepsilon,\\ c \quad \text{otherwise}\end{cases}$$

and since $\|h_s(0)\|=\|\phi(0)-h_s(0)\|<\varepsilon$ the above inequality implies (2.16). Finally, for any sequences $\{\varepsilon_i\}\subset R^+$ and $\{x_i\}\subset Q$ with $\varepsilon_i\to 0$ and $x_i\to x$ it follows by the uniform convergence of $h_{s(\varepsilon_i)}$ to ϕ that $h_{s(\varepsilon_i)}(x_i)\to\phi(x)$. Since ψ is uniformly bounded on R^n, there exist subsequences $\{\varepsilon_i'\}\subset\{\varepsilon_i\}$ and $\{x_i'\}\subset\{x_i\}$ and a constant $0\leqq\sigma\leqq 1$ such that $\psi(x_i'/\varepsilon_i')\to\sigma$. Therefore $\phi_{\varepsilon_i'}(x_i')\to\sigma\phi(x)$ and so (2.17) is fulfilled. □

We are now in a position to prove Theorem 2.4. We shall establish only statement (ii). The proof of the first part of the theorem follows using similar arguments and is left to the reader.

Proof of Theorem 2.4 (ii). Suppose that the system (2.1) is stabilizable by means of the Lipschitzian feedback law $v=\phi(x_1)$ and $\phi(0)=0$. Then there is a smooth Lyapunov function V defined on a compact neighborhood U of R^{n_1} and a positive and strictly increasing continuous function $c: R^+\to R^+$ such that $c(0)=0$ and

$$f(V)(x_1,\phi(x_1))\leqq -c(\|x_1\|)$$

for any $x_1\in U$ [24]. Let $K>0$ and $Q\subset U$ as defined in Lemma 2.5, where ϕ is the above Lipschitzian stabilizer, which is defined on U and it takes values on R^{n_2}. Consider positive constants L_1 and L_2 such that $\|\phi(x_1)\| < L_1/2$ for $x_1 \in Q$ and $\|Df_1(x)\| < L_2$ for every x belonging to

$$N \overset{\text{def}}{=} \{x \in R^n \colon x_1 \in Q, \|x_2\| < L_1\}.$$

For any $r > 0$, such that the sphere $S(0, r)$ of radius r around $0 \in R^n$ is contained to N, consider a positive $l = l(r) < 1$ such that the region

$$N_l \overset{\text{def}}{=} \{x \in R^n \colon \|x_1\| \leqq l, \|x_2\| \leqq 2lK\}$$

is contained to $S(0, r)$. Let $\varepsilon = \varepsilon(r)$ with $\varepsilon < l$ and

$$\varepsilon < \frac{L_2^{-1}}{2} \min \{\|DV(x_1)\|^{-1} c(\|x_1\|) \colon x_1 \in Q, \|x_1\| \geqq l\}.$$

According to Lemma 2.5 there exists a smooth map ϕ_ε such that $\phi_\varepsilon(0) = 0$,

$$\|\phi(x_1) - \phi_\varepsilon(x_1)\| < \varepsilon \quad \forall x_1 \in Q, \quad \|x_1\| \geqq \varepsilon, \tag{2.18}$$

$$\|D\phi_\varepsilon(x_1)\| < K \quad \forall x_1 \in Q. \tag{2.19}$$

Then for any $x_1 \in Q$ with $\|x_1\| > l$ we get

$$\begin{aligned} f_1(V)(x_1, \phi_\varepsilon(x_1)) &\leqq |f_1(V)(x_1, \phi_\varepsilon(x_1)) - f_1(V)(x_1, \phi(x_1))| + f_1(V)(x_1, \phi(x_1)) \\ &\leqq L_2 \|DV(x_1)\| \, \|\phi(x_1) - \phi_\varepsilon(x_1)\| - c(\|x_1\|) \qquad (2.20) \\ &\leqq -\tfrac{1}{2} c(\|x_1\|) < 0. \end{aligned}$$

We define

$$\Phi_r(x) = V(x_1) + \tfrac{1}{2} \|x_2 - \phi_\varepsilon(x_1)\|^2 \quad (\varepsilon = \varepsilon(r)). \tag{2.21}$$

Obviously, Φ_r is continuously differentiable and positive definite for $x \in N$. Similar to Theorem 4 of [37], we consider smooth functions $h_1, \cdots, h_{n_2}$ of $x_1 \in R^{n_1}$, $\hat{x}_2, x_2 \in R^{n_2}$ such that

$$f_1(V)(x_1, \hat{x}_2) - f_1(V)(x_1, x_2) = \sum_{i=1}^{n_2} (\hat{x}_2 - x_2)_i h_i(x_1, \hat{x}_2, x_2)$$

and let $m_r \colon N \to R^{n_2}$ be a real map with components

$$(m_r(x))_i = \begin{cases} D(\phi_\varepsilon)_i f_1(x_1, x_2) - h_i(x_1, \phi_\varepsilon(x_1), x_2) - (x_2 - \phi_\varepsilon(x_1))_i & \text{for } x \notin N_l, \|x_1\| > l, \\ D(\phi_\varepsilon)_i f_1(x_1, x_2) - h_i(x_1, \phi_\varepsilon(x_1), x_2) - (x_2 - \phi_\varepsilon(x_1))_i & \\ \quad - \dfrac{f_1(V)(x_1, \phi_\varepsilon(x_1))}{\|x_2 - \phi_\varepsilon(x_1)\|^2} (x_2 - \phi_\varepsilon(x_1))_i & \text{for } x \notin N_l, \|x_1\| \leqq l, \\ 0 \quad \text{for } x \in N_l. \end{cases}$$

Note that for $x \in N - N_l$ and $\|x_1\| < l$ it holds that $\|x_2\| > 2Kl$ and by (2.19) that $\|\phi_\varepsilon(x_1)\| < Kl$; therefore,

$$\|x_2 - \phi_\varepsilon(x_1)\| \geqq \|x_2\| - K\|x_1\| > Kl \neq 0.$$

For each $x \in N - N_l$ we find

$$(f(\Phi_r) + g(\Phi_r) m_r)(x) = \begin{cases} f_1(V)(x_1, \phi_\varepsilon(x_1)) - \|x_2 - \phi_\varepsilon(x_1)\|^2, & \|x_1\| > l, \\ -\|x_2 - \phi_\varepsilon(x_1)\|^2, & \|x_1\| \leqq l. \end{cases}$$

Consequently, by (2.20) it follows that

$$(f(\Phi_r)+g(\Phi_r)m_r)(x)<0 \quad \forall x\in N-N_l.$$

Since f_1, h_i, and ϕ_ε are continuously differentiable, vanishing at zero, and because of (2.18) and (2.19), there is a positive constant M which is independent of r, satisfying

$$\|m_r(x)\|<M\|x\|+c_r, \quad \forall x\in N,$$

where

$$c_r=\sup\left\{\frac{|f_1(V)(x_1,\phi_\varepsilon(x_1))|}{\|x_2-\phi_\varepsilon(x_1)\|}, x\in N-N_l, \|x_1\|<l\right\} \qquad (\varepsilon=\varepsilon(r)).$$

Note that

$$\frac{|f_1(V)(x_1,\phi_\varepsilon(x_1))|}{\|x_2-\phi_\varepsilon(x_1)\|}\leqq\frac{L_2(1+K)\|DV(x_1)\|}{\|x_2\|-K\|x_1\|}\|x_1\|<L_2\left(1+\frac{1}{K}\right)\|DV(x_1)\|$$

for $x\in N-N_l$ and $\|x_1\|<l$. Since $DV(x_1)$ is continuously vanishing at zero and $\lim l(r)=\lim\varepsilon(r)=0$ as $r\to 0$ it follows that $c_r\to 0$ as $r\to 0$. Finally, for every sufficiently small r, condition (1.7a) holds. Indeed, otherwise there would exist sequences $\{x_{r_i}\}\subset\partial N$ and $\{y_{r_i}\}\subset S[0,r_i]$ such that $x_{r_i}\to x=(x_1',x_2')'\in\partial N$ and $\Phi_{r_i}(x_{r_i})\leqq\Phi_{r_i}(y_{r_i})$. Since $\varepsilon(r)\to 0$ it follows from (2.17) that there exist subsequences $\{x_{r_i}'\}\subset\{x_{r_i}\}$ and $\{y_{r_i}'\}\subset\{y_{r_i}\}$ and real constants σ_1 and σ_2 satisfying

$$V(x_1)+\tfrac{1}{2}\|x_2-\sigma_1\phi(x_1)\|^2=\lim\Phi_{r_i}(x_{r_i}')\leqq\lim\Phi_{r_i}(y_{r_i}')=V(0)+\tfrac{1}{2}\sigma_2^2\|\phi(0)\|^2=0,$$

and so $x_1=x_2=0$, a contradiction. Similarly, we can show (1.7b). We conclude that $\{\Phi_r\}$ as defined in (2.21) is a control Lyapunov family, which satisfies the small control property and so the proof of Theorem 2.4(ii) is completed. □

The following theorem is a consequence of the theory that we have developed and summarizes some useful properties concerning the stability behavior of (2.13).

THEOREM 2.6. *Consider the system* (2.13) *and suppose that* (2.1) *is stabilizable by means of the feedback law* $v=\phi(x_1)$, $\phi(0)=0$.

(i) *If* ϕ *is continuous, then* (2.13) *is practically stabilizable at zero.*

(ii) *Furthermore, if* ϕ *is Lipschitz continuous, then* (2.13) *is practically stabilizable at zero, where the corresponding family of the smooth stabilizers* $\{k_r\}$ *satisfies* (1.8).

(iii) *If, in addition,* ϕ *is continuously differentiable, then* (2.13) *is asymptotically stabilizable at zero, by means of a feedback law, which is smooth for* $x\neq 0$ *near zero and continuous at zero.*

3. Lyapunov functions and uncontrollable eigenvalues. In this section we examine the relationship between various types of Lyapunov conditions and the position on the complex field of the uncontrollable eigenvalues l_u of the linearization

$$(A,B)=(Df(0),g(0)) \tag{3.1}$$

of (1.1) at zero.

It is well known that a necessary condition for stabilization by means of a differentiable feedback is that the real parts of the uncontrollable eigenvalues of (3.1) are nonpositive:

$$\operatorname{Re} l_u\leqq 0. \tag{3.2}$$

If the differentiability assumptions for the stabilizing feedback are relaxed, the previous statement is no longer true [37], [38]. It turns out that, in general, the existence of a control Lyapunov function does not imply (3.2).

Next we establish that (3.2) is a necessary condition for the existence of a control Lyapunov function Φ satisfying the *small control property* and further there are positive constants k_1 and k_2 such that for any x near zero there holds

$$k_1\|x\|^2 \leqq \Phi(x) \leqq k_2\|x\|^2. \tag{3.3}$$

Similarly, condition (3.2) is necessary for the existence of a control Lyapunov family $\{\Phi_r\}$ satisfying the small control property and, in addition, there are constants k_1 and k_2 such that for any x near zero we have

$$k_1\|x\|^2 \leqq \Phi_r(x) \leqq k_2\|x\|^2, \qquad r>0. \tag{3.4}$$

Note that (3.3) is fulfilled, if for instance we assume that Φ is smooth and the matrix $D^2\Phi(0)$ is positive definite:

$$D^2\Phi(0)>0. \tag{3.5}$$

Indeed, since $0\in R^n$ is a local minimum for Φ, we have

$$\Phi(x)=x'D^2\Phi(0)x+O(x^2), \quad x \text{ near zero}$$

$$|O(x^2)|/\|x\|^2\to 0 \quad \text{as } x\to 0,$$

which in conjunction with (3.5) implies (3.3).

Moreover, we note that if there exists a control Lyapunov function, which satisfies (3.3), then (1.1) is strongly asymptotically stabilizable [38], namely, the solution $x(t, x_0)$ of (1.2) satisfies the additional property

$$\|x(t, x_0)\| \leqq m\|x_0\|, \quad m=\sqrt{k_2k_1^{-1}} \quad \forall t \geqq 0. \tag{3.6}$$

Similarly, the existence of a control Lyapunov family which satisfies (3.4) implies strong practical stabilization. That means there is a family of constants $\varepsilon_r>0$ with $\varepsilon_r\to 0$ as $r\to 0$ such that the trajectory $x_r(t, x_0)$ of (1.3) satisfies the additional property

$$\|x_r(t, x_0)\| \leqq m\|x_0\|+\varepsilon_r, \quad \forall t \geqq 0.$$

The following theorem generalizes Proposition 7 of [38].

THEOREM 3.1. *Assume that the system* (1.1) *is strongly asymptotic stabilizable by means of the feedback law* $u=k(x)$, *and there exists a strictly increasing continuous function* $c: R^+\to R^+$, $c(0)=0$ *such that*

$$\|(B-g(x))k(x)\| \leqq \|x\|c(\|x\|) \tag{3.7}$$

for x near zero. Then all the uncontrollable eigenvalues l_u *of* (A, B) *have nonpositive real parts. The same conclusion follows if we assume that* (1.1) *is strongly practical stabilizable by means of the family of feedback laws* $\{k_r\}$ *such that for almost all r and for x near zero there holds*

$$\|(B-g(x))k_r(x)\| \leqq \|x\|(c(\|x\|)+c_r),$$

where $c: R^+\to R^+$, $c(0)=0$ *is a strictly increasing continuous function and* $\{c_r\}$ *is a family of positive constants converging to zero as* $r\to 0$.

Outline of the proof. Suppose that (1.1) is strongly asymptotic stabilized by the feedback k, and let us, on the contrary, assume that the claim is not true. Then there is a linear change of coordinates such that the closed-loop system becomes

$$\begin{pmatrix}\dot{x}_1\\ \dot{x}_2\end{pmatrix}=\begin{pmatrix}A_1 & A_2\\ 0 & A_3\end{pmatrix}\begin{pmatrix}x_1\\ x_2\end{pmatrix}+\begin{pmatrix}B_1k(x)\\ 0\end{pmatrix}+\begin{pmatrix}F_1(x, k(x))\\ F_2(x, k(x))\end{pmatrix}, \tag{3.8}$$

where A_1, A_2, A_3, and B_1 are constant matrices, all the eigenvalues of A_3 have strictly positive real parts, and therefore there exist constants L and $p>0$ such that

$$\|e^{-A_3 t}\| \leqq L\, e^{-pt} \quad \forall t \geqq 0. \tag{3.9}$$

Furthermore, (3.7) is invariant under any linear change of coordinates; hence, there are positive constants M_1 and M_2 satisfying

$$\|F_2(x, k(x))\| < M_1(\|x\|^2 + \|x\| c(M_2\|x\|)). \tag{3.10}$$

The second equation of (3.8) is $\dot{x}_2 = A_3 x_2 + \hat{F}_2(x)$, $\hat{F}_2(x) = F_2(x, k(x))$ and its solution is written as

$$\begin{aligned} x_2(t, x_{20}) &= e^{A_3 t} x_{20} + \int_0^t e^{A_3(t-s)} \hat{F}_2(x(s, x_{20}))\, ds \\ &= e^{A_3 t}\left(x_{20} + \left(\int_0^{+\infty} - \int_t^{+\infty} \right) e^{-A_3 s} \hat{F}_2(x(s, x_{20}))\, ds \right). \end{aligned}$$

By (3.6) and (3.10) it follows that

$$\|\hat{F}_2(x(t, x_0))\| \leqq M_1(m^2\|x_0\|^2 + m\|x_0\| c(M_2 m\|x_0\|)) \tag{3.11}$$

and therefore it can be easily established that the integral

$$I(x_0) = \int_0^{+\infty} e^{-A_3 s} \hat{F}_2(x(s, x_0))\, ds$$

exists. In particular, (3.9), (3.11), and stability imply that there are positive C_1 and C_2 such that

$$\|I(x_0)\| \leqq C_1\|x_0\|^2 + C_2\|x_0\| \int_0^{+\infty} e^{-ps} c(M_2 m\|x_0\|)\, ds < +\infty.$$

Let

$$\theta(x_{20}) = x_{20} + \int_0^{+\infty} e^{-A_3 s} \hat{F}(x(s, x_0))\, ds|_{x_{10}=0}.$$

Then, similar to Proposition 7 of [38], condition (3.11) implies that $\theta(x_{20}) \neq 0$ for $x_{20} \neq 0$ near zero, but on the other hand by (3.9) and the fact that

$$0 \leftarrow x_2(t, x_{20}) = e^{A_3 t}\theta(x_{20}) - \int_t^{\infty} e^{-A_3 s} \hat{F}_2(x(sm\, x_0))\, ds \quad \text{as } t \to +\infty,$$

we have $\theta(x_{20}) = 0$, a contradiction. The rest of the theorem follows by applying a similar argument as before and as those given in Proposition 7 of [38]. □

The previous result leads to the following theorem.

THEOREM 3.2. *Assume that* (1.1) *satisfies the* L.C. (P.L.C.) *and the corresponding Lyapunov function* $\Phi(\Phi_r, r>0)$ *satisfies condition* (3.3) ((3.4), *respectively*). *Then all the uncontrollable eigenvalues* l_u *of* (A, B) *have nonpositive real parts provided that, in addition, one of the three following assumptions hold*:

(A_1) *The Lyapunov function* $\Phi(\Phi_r, r>0)$ *satisfies the small control property.*

(A_2) *The Lyapunov function* $\Phi(\Phi_r, r>0)$ *satisfies the bounded control property and there is a real constant* $c>0$ *such that* $\|B - g(x)\| < c\|x\|^2$, *for* x *near zero.*

(A_3) *The control term* g *is constant.*

Proof. Suppose that Φ is a control Lyapunov function and, in addition, one of the assumptions (A_1), (A_2), and (A_3) holds. Then by Theorem 1.2 there exists a stabilizer $k(x)$ which is smooth for $x \neq 0$ near zero and further $k(x) \to k(0) = 0$, if (A_1) holds, and $k(x)$ is bounded locally around zero, provided that (A_2) is satisfied. Then it is straightforward to see that there exists a nonnegative continuous real function $c_1 : R^n \to R$, $c_1(0) = 0$, such that $\|(B - g(x))k(x)\| < \|x\| c_1(x)$ for x near zero. Therefore (3.7) is fulfilled with $c : R^+ \to R^+$, $c(0) = 0$ being any strictly increasing continuous function such that $c_1(x) \leqq c(\|x\|)$ for x near zero. Hence by Theorem 3.1 all the uncontrollable eigenvalues of (A, B) have nonpositive real parts. □

Another important situation arises if we assume that there exists a control Lyapunov function satisfying the following strong type of L.C.

Assumption 3.3. Suppose that there exist a neighborhood N of $0 \in R^n$, a positive-definite smooth function $\Phi : N \to R$ and positive constants r_1 and r_2 such that for each $x \neq 0$ near zero there is a vector $u \in R^l$ satisfying the inequalities

$$\|u\| < r_1 \|x\|,$$
$$f(\Phi)(x) + g(\Phi)(x)u < -r_2 \|x\|^2.$$

THEOREM 3.4. *The following statements are equivalent*:

(i) *The system* (1.1) *satisfies Assumption* 3.3.

(ii) *All the uncontrollable eigenvalues of* (A, B) *have strictly negative real parts*: $\operatorname{Re} l_u < 0$.

(iii) *The system* (1.1) *is* (*locally*) *exponentially stabilizable by means of a linear feedback.*

Proof. (i)$\Rightarrow$(ii) Assumption 3.3 and smoothness of Φ, f, and g imply that for any $x \neq 0$ near zero there is a vector u such that $\|u\| < r_1 \|x\|$, which satisfies

$$\begin{aligned} D\Phi(x)(A + Bu) &= f(\Phi)(x) + g(\Phi)(x)u + D\Phi(x)(A - f(x)) + D\Phi(x)(B - g(x))u \\ &\leqq -r_2 \|x\|^2 + O(x^2) < 0; \end{aligned}$$

therefore, the pair (A, B) satisfies the L.C. Invoking Theorem 5 of [38] it follows that $\operatorname{Re} l_u < 0$. The implications (ii)$\Rightarrow$(iii) and (iii)$\Rightarrow$(i) are well-known consequences of the last inequality (see, for instance, [38], [18]). □

4. Numerical examples.

Example 4.1. Consider the system

$$\text{(4.1)} \qquad \begin{pmatrix} \dot w_1 \\ \dot w_2 \\ \dot w_3 \end{pmatrix} = \begin{pmatrix} w_1^3 - w_1^2(w_2 + w_3) \\ w_2 \\ 0 \end{pmatrix} + \begin{pmatrix} 0 \\ (w_1 - w_2)^3 \\ 0 \end{pmatrix} u_1 + \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} u_2.$$

The above system has the form (1.9), where $x_1 = w_1$, $x_2 = (w_2, w_3)'$, $x = (x_1, x_2')'$, $f_1(x) = w_1^3 - w_1^2(w_2 + w_3)$, $f_2(x) = (w_2, 0)'$, $u = (u_1, u_2)'$, and

$$g_2(x) = \begin{pmatrix} (w_1 - w_2)^3 & 0 \\ 0 & 1 \end{pmatrix}.$$

Let $r = (1, -w_3 + w_1)'$. Then the set

$$\text{(4.2)} \qquad M = \{x \in R^3, x_2 = \phi(x_1)\} \quad \text{where } \phi(x_1) = (x_1, x_1)'$$

is asymptotically stable with respect to (2.12). This follows easily by evaluating the time derivative $\dot W$ of the Lyapunov function

$$W(x) = \tfrac{1}{2} \|x_2 - \phi(x_1)\|^2$$

along the trajectories of (2.12). Indeed, we find

$$\dot{W}(x) = -(w_1 - w_2)^4 - (w_1 - w_3)^2 < 0 \quad \forall x \notin M.$$

Moreover, $W(x) = 0$ for $x \in M$ and $W(x) > 0$ otherwise; therefore, M is asymptotically stable with respect to (2.12). Finally the law $v = \phi(x_1)$, where ϕ is defined in (4.2), asymptotically stabilizes (2.1). Indeed, let $V(x_1) = \frac{1}{2}x_1^2$. Then we find

$$\dot{V}(x_1) = DV(x_1)f(x_1, \phi(x_1)) = -x_1^4 < 0 \quad \forall x_1 \neq 0.$$

Therefore (4.1) satisfies the assumptions of Theorem 2.2 and according to Theorem 1.2 it is asymptotically stabilizable at zero. Note that its linearization at the origin is uncontrollable and contains a positive eigenvalue; hence, it cannot be stabilized by a smooth law. Moreover, it is straightforward to see that according to Theorem 3.1 the system (4.1) cannot be strongly stabilized.

Example 4.2. Consider the planar system

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} x_1 + x_2^3 \\ 0 \end{pmatrix} + u \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{4.3}$$

which has the form (2.13) with $f_1(x_1, x_2) = x_1 + x_2^3$. Note that the system $\dot{x}_1 = f_1(x_1, v) = x_1 + v^3$ is stabilized by the continuous law $v = -(2x_1)^{1/3}$. Therefore, by statement (i) of Theorem 2.6 the system (4.3) is practically stabilizable at zero by means of a family of smooth feedback laws. The system cannot be locally stabilized by a smooth law since its linearization contains a positive eigenvalue. It cannot even be strongly stabilized, since its control term is constant (Theorem 3.1).

Example 4.3. Consider the system $\ddot{x} + \phi_1(x, \dot{x}) + u(\dot{x} + \phi_2(x)) = 0$, $x, u \in R$, or equivalently,

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} x_2 \\ \phi_1(x_1, x_2) \end{pmatrix} + u \begin{pmatrix} 0 \\ x_2 + \phi_2(x_1) \end{pmatrix}, \tag{4.4}$$

where we have assumed that $x_1 \phi_2(x_1) > 0$, for any $x_1 \neq 0$ near zero. Obviously, the system (4.4) has the form (1.9), and the function $\Phi(x_1, x_2) = x_1^2 + (x_2 + \phi_2(x_1))^2$ is a control Lyapunov function for (4.4), whereas the law $v = -\phi_2(x_1)$ asymptotically stabilizes (2.1) at zero. Therefore, by Theorems 1.2 and 2.1(i) the system (4.4) is asymptotically stabilizable by means of a feedback law which is smooth in a neighborhood of $0 \in R^2$, except possibly at zero. Note also that (2.3) is fulfilled with $a = 2$, $r = -1$, and $W = (x_2 + \phi_2(x_1))^2$; therefore, the function Φ satisfies the bounded control property provided that $D\phi_2(0) \neq 0$. In that case zero is exponentially stable with respect to (2.4), and according to Theorem 2.1(ii) the system (4.1) is asymptotically stabilized by a bounded feedback law.

Example 4.4. Consider the system

$$\begin{pmatrix} \dot{w}_1 \\ \dot{w}_2 \\ \dot{w}_3 \end{pmatrix} = \begin{pmatrix} -w_1^3 \\ w_2^3 + w_2 w_1(w_1 + w_2) + w_3(w_1^2 + w_2^2) \\ 0 \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} u. \tag{4.5}$$

The above system has the form (2.13), where $x_1 = (w_1, w_2)'$, $x_2 = w_3$, $x = (x_1', x_2)'$, and $f_1(x) = (-w_1^3, w_2^3 + w_1 w_2(w_1 + w_2) + w_3(w_1^2 + w_2^2))'$. Let

$$\phi(x_1) = \begin{cases} -2w_2 - \dfrac{w_1 w_2^2}{(w_1^2 + w_2^2)} & \text{for } x_1 \neq 0, \\ 0 & \text{for } x_1 = 0. \end{cases}$$

The map ϕ is differentiable for $x_1 \neq 0$ and, in addition, its derivative is uniformly bounded on R^2; hence, ϕ satisfies a Lipschitz condition on R^2. Furthermore, if we apply the feedback law $v = \phi$ in (2.1), the resulting system is

$$\begin{pmatrix} \dot{w}_1 \\ \dot{w}_2 \end{pmatrix} = \begin{pmatrix} -w_1^3 \\ -w_2^3 - w_2 w_1^2 \end{pmatrix}, \tag{4.6}$$

and obviously $0 \in R^2$ is asymptotically stable with respect to the above system. This follows easily if we compute the time derivative of the Lyapunov function $V(x) = w_1^2 + w_2^2$ along the trajectories of (4.6). Therefore, according to Theorem 2.6(ii) the system (4.7) is practically stabilizable at $0 \in R^3$ by means of a family of smooth feedback laws satisfying (1.8).

SECOND-ORDER HAMILTON-JACOBI EQUATIONS IN INFINITE DIMENSIONS*

PIERMARCO CANNARSA†§ AND GIUSEPPE DA PRATO‡§

Abstract. Some second-order Hamilton-Jacobi equations connected to stochastic optimal control problems for infinite-dimensional systems driven by a white noise are studied. A direct method to prove existence and uniqueness of mild solutions is developed. Then this solution is identified as the value function of the related stochastic control problem, and a feedback formula for optimal controls is derived.

Key words. Hamilton-Jacobi equations, stochastic optimal control, dynamic programming, viscosity solutions, white noise, infinite dimensions

AMS(MOS) subject classifications. 49C10, 49A60, 93E20

1. Introduction. Second-order Hamilton-Jacobi equations in infinite dimensions have been studied by several authors in connection with the stochastic optimal control of distributed parameter systems; see [Lecture Notes in Mathematics, Vol. 1390, Springer-Verlag, Berlin, 1989] and the references quoted therein. Most of the works on this subject concern systems governed by stochastic partial differential equations driven by a Hilbert space-valued Wiener process. In this paper, we focus our attention on the case of stochastic systems that are driven by a white noise. For such problems fewer results are available in the literature.

In order to explain the context we have in mind, let X be a separable Hilbert space, and consider the problem of minimizing:

$$J_\varepsilon(t,x;z)=\mathscr{E}\left\{\int_t^T\left[g(y_\varepsilon(s))+\frac{1}{2}|z(s)|^2\right]ds+\phi(y(T))\right\} \tag{1.1}$$

over all controls $z\in M_W^2(t,T;X)$ satisfying $|z(s)|\leqq R$ almost surely for all $s\in[t,T]$. Here ε, R, and T are given positive numbers and $g,\phi:X\to\mathbf{R}$ are bounded uniformly continuous functions. In (1.1), y_ε is the mild solution of the stochastic differential equation

$$\begin{aligned} &dy_\varepsilon(s)=(Ay_\varepsilon(s)+F(y_\varepsilon(s))+z(s))\,dt+\sqrt{\varepsilon}\,dW(s), \qquad t\leqq s\leqq T,\\ &y_\varepsilon(t)=x, \end{aligned} \tag{1.2}$$

where W is a cylindrical Wiener process (or *white noise*) on a probability space $(\Omega,\mathscr{F},P)$. Moreover, $M_W^2(t,T;X)$ denotes the space of the X-valued processes $x(s)$ that are adapted to W and satisfy

$$\mathscr{E}\left(\int_t^T|x(s)|^2\,ds\right)<\infty.$$

As is well known, the dynamic programming approach to problem (1.1), (1.2) consists of studying the *value function* V_ε, defined as

$$V_\varepsilon(t,x)=\inf\{J_\varepsilon(t,x;z): z\in M_W^2(t,T;X), |z(s)|\leqq R \text{ a.s. } \forall s\in[t,T]\}. \tag{1.3}$$

The function $u_\varepsilon(t, x) = V_\varepsilon(T-t, x)$ is related to the Hamilton-Jacobi-Bellman equation

$$\begin{aligned}&\frac{\partial u}{\partial t}=\frac{\varepsilon}{2}\operatorname{Tr}(u_{xx})+\langle Ax+F(x), u_x\rangle-H(u_x)+g(x) \quad \text{in }]0, T[\times X,\\ &u(0,x)=\phi(x),\end{aligned} \tag{1.4}$$

where

$$H(p)=\begin{cases}\frac{1}{2}|p|^2 & \text{if } |p|\leqq R,\\ R|p|-\frac{R^2}{2} & \text{if } |p|\geqq R.\end{cases} \tag{1.5}$$

The main goal of this paper is to develop a direct method of solution for equation (1.4). By "direct method" we mean a method that makes no use of the control theoretic interpretation of problem (1.4). More precisely, we will solve the above problem as an initial value problem for a semilinear parabolic equation. Then, after having identified the direct solution of (1.4) as the value function (1.3), we can transfer information from a partial differential equation context into a variational setting, by deriving a feedback formula for optimal controls.

We now explain the main ideas of our method. As in finite dimensions, we first consider the linear problem

$$\begin{aligned}&\frac{\partial u}{\partial t}=\frac{\varepsilon}{2}\operatorname{Tr}(u_{xx})+\langle Ax, u_x\rangle \quad \text{in }]0, T[\times X,\\ &u(0,x)=\phi(x)\end{aligned} \tag{1.6}$$

whose solution can be represented by the probabilistic formula

$$u(t,x)=\mathscr{E}\left[\phi\left(e^{tA}x+\sqrt{\varepsilon}\int_0^t e^{(t-s)A}\,dW(s)\right)\right]=:(T_t\phi)(x). \tag{1.7}$$

Indeed, when A is self-adjoint, strictly negative and A^{-1} is nuclear, it is shown in [7] that (1.7) is the unique *classical* solution of problem (1.6). This result is recalled and improved in § 3 of this paper, by proving the uniform convergence of some finite-dimensional approximations of (1.7).

Then, we define a *mild* solution of (1.4) as a solution of the integral equation

$$u(t,\cdot)=T_t\phi+\int_0^t T_{t-s}(\langle F, u_x(s,\cdot)\rangle-H(u_x(s,\cdot))+g)\,ds. \tag{1.8}$$

We solve (1.8) by fixed-point arguments in a space of functions which are C^1 in x for $t>0$ and satisfy a suitable blowup condition in zero, (see § 4).

In order to apply the above result to problem (1.1), (1.2) we have to identify the function $u(T-t, x)$ as the value function $V_\varepsilon(t, x)$. This could be done by standard verification techniques, computing the Itô differential $du(T-t, y_\varepsilon(t))$, if u were sufficiently smooth and the covariance of W had finite trace. To overcome this difficulty, we study a suitable finite-dimensional approximation of (1.4), for which the smoothness of the solution u_n is well known. We then apply the Itô formula to u_n and pass to the limit as $n\to\infty$. To make this procedure rigorous, it is essential to show that u_n converges to u, uniformly on the bounded sets of $[\tau, T]\times X$ for all $0<\tau<T$ (see Theorem 4.5).

The techniques of this paper could be easily arranged to study the equation

$$(1.9)\qquad \begin{aligned} &\frac{\partial u}{\partial t}=\frac{\varepsilon}{2}\operatorname{Tr}(Qu_{xx})+\langle Ax+F(x),u_x\rangle-H(u_x)+g(x)\quad \text{in }]0,T[\times X,\\ &u(0,x)=\phi(x),\end{aligned}$$

where Q is a self-adjoint positive nuclear operator in X. This problem is related to the optimal control of a system driven by a "genuine" Wiener process. Unlike (1.4), for which no other result seems available in the literature, equation (1.9) has been considered by several authors. In [1], problem (1.9) is studied with $F=0$ and assuming g and ϕ to be convex. In [9], the case of $A=0$ is treated by the theory of abstract Wiener spaces. Note that, even though the equation considered in [9] looks like (1.4), it is indeed equivalent to (1.9). The general equation (1.9) is solved in [5] by using a probabilistic formula like (1.7). In this case, however, we do not get C^1 regularity, but only differentiability in some special directions related to Q.

We conclude this Introduction by recalling that several results on viscosity solutions are available today for Hamilton–Jacobi equations in infinite dimensions (see [4] for first-order equations). Second-order equations have been treated by Lions in [10]–[12]. In this theory, the existence of solutions to (1.9), for weakly continuous data, is usually obtained by variational methods based on the representation formula (1.3).

2. Preliminaries. Let X be a separable Hilbert space, with norm $|\cdot|$. For any $R>0$, we set

$$B_R=\{x\in X;\ |x|\leqq R\}.$$

For any $x,y\in X$ we denote by $x\otimes y$ the operator defined by

$$x\otimes y\cdot z=\langle y,z\rangle x.$$

Let Y be another Hilbert space. We denote by $C_b(X,Y)$ the Banach space of all bounded uniformly continuous mappings $\phi:X\to Y$ endowed with the sup norm $\|\cdot\|_0$. Likewise, $C_b^h(X,Y)$, $h=0,1,2,\cdots$, endowed with the natural norm $\|\cdot\|_h$, is the set of all the mappings $\phi:X\to Y$ which are h times Fréchet differentiable and such that the kth derivative $\phi^{(k)}$ is uniformly continuous and bounded for all $k\leqq h$. Moreover, we set $C_b^h(X,\mathbf{R})=C_b^h(X)$.

For any $\phi\in C_b(X)$ we denote by ω_ϕ a continuity modulus of ϕ, i.e., continuous function $\omega_\phi:[0,\infty[\to[0,\infty[$ satisfying $\omega_\phi(0)=0$ and such that $|\phi(x)-\phi(y)|\leqq\omega_\phi(|x-y|)$ for all $x,y\in X$. It is well known that any function $\phi\in C_b(X)$ possesses a concave continuity modulus.[1]

Lip (X,Y) is the space of all Lipschitz continuous and bounded functions from X to Y, endowed with the norm

$$\|\phi\|_1=\sup\left\{\frac{|\phi(x)-\phi(y)|}{|x-y|};\ x,y\in X;\ x\neq y\right\}+\|\phi\|_0.$$

Throughout the whole paper we fix a complete orthonormal system in X, denoted by $\{e_k\}_{k\in N}$. We define the projection Π_n of X onto the span of $\{e_1,e_2,\cdots,e_n\}$ as follows:

$$(2.1)\qquad \Pi_n=\sum_{k=1}^{n}e_k\otimes e_k\quad\forall n\in\mathbf{N}.$$

[1] Indeed, set $\omega(t)=\sup\{|\phi(x)-\phi(y)|;\ |x-y|\leqq t\}$. Then ω is a nondecreasing subadditive continuity modulus for ϕ. So we can check that the concave envelope of ω has the required properties.

Now, let $\{\alpha_k\}$ be a sequence of positive real numbers. Then there exists a unique self-adjoint operator A in X such that $Ae_k = -\alpha_k e_k$. As is well known, A is densely defined and closed with domain

$$D(A) = \left\{x \in X : \sum_{k=1}^{\infty} \alpha_k^2 \langle x, e_k \rangle^2 < \infty\right\}.$$

Moreover, since A is negative, A generates an analytic semigroup e^{tA} in X and

$$e^{tA}x = \sum_{k=1}^{\infty} e^{-t\alpha_k} \langle x, e_k \rangle \tag{2.2}$$

for all $x \in X$.

Consider now a complete probability space $\{\Omega, \mathcal{F}, \mathbf{P}\}$ and a sequence $\{\beta_k\}$ of standard one-dimensional Brownian motions, mutually independent. We denote by $W^n(t)$ the n-dimensional Brownian motion given by

$$W^n(t) = \sum_{k=1}^{n} \beta_k(t) e_k \tag{2.3}$$

for all $t \geqq 0$. We set

$$W_A^n(t) = \sum_{k=1}^{n} e_k \int_0^t e^{-\alpha_k(t-s)}\, d\beta_k(s), \tag{2.4}$$

$$W_A(t) = \sum_{k=1}^{\infty} e_k \int_0^t e^{-\alpha_k(t-s)}\, d\beta_k(s). \tag{2.5}$$

We note that $W_A^n(t)$ is the stochastic convolution

$$W_A^n(t) = \int_0^t e^{(t-s)A}\, dW^n(s).$$

In general, (2.5) is meaningless since the series in the right-hand side may not converge. The following proposition shows that it becomes meaningful, under some restrictions on the sequence $\{\alpha_k\}$.

PROPOSITION 2.1. *Assume that*

$$\sum_{k=1}^{\infty} \frac{1}{\alpha_k} < \infty. \tag{2.6}$$

Then, the series in (2.5) *converges in* $L^2(\Omega, \mathcal{F}, \mathbf{P}; H)$ *for all* $t \geqq 0$. *Moreover,* $W_A(t)$ *is a Gaussian process with mean zero and covariance operator* Q_t *given by*

$$Q_t x = \sum_{k=1}^{\infty} \frac{1 - e^{-2\alpha_k t}}{2\alpha_k} \langle x, e_k \rangle e_k, \qquad x \in X. \tag{2.7}$$

Proof. For all $t \geqq 0$, we have

$$\sum_{k=1}^{\infty} \mathscr{E}\left[\int_0^t e^{-\alpha_k(t-s)}\, d\beta_k(s)\right]^2 = \sum_{k=1}^{\infty} \int_0^t e^{-2\alpha_k s}\, ds = \sum_{k=1}^{\infty} \frac{1 - e^{-2\alpha_k t}}{2\alpha_k},$$

which is finite in view of (2.6). Therefore, the series in (2.5) converges in X for all $t > 0$ almost surely to a Gaussian process $W_A(t)$. In order to prove (2.7) it suffices to remark that, for all $x, y \in X$, we have

$$\mathscr{E}\langle W_A(t), x \rangle \langle W_A(t), y \rangle = \sum_{k=1}^{\infty} \langle x, e_k \rangle \langle y, e_k \rangle \int_0^t e^{-2\alpha_k(t-s)}\, ds. \qquad \square$$

Remark 2.2. If (2.6) is fulfilled, we write the stochastic convolution (2.5) as follows:

$$W_A(t)=\int_0^t e^{(t-s)A}\,dW(s),$$

where $W(t)=\sum_{k=1}^{\infty} e_k\beta_k(t)$ is usually interpreted as a *white noise.*

In order to show that $W_A(t)$ has continuous trajectories, we will strengthen (2.6), assuming

$$\sum_{k=1}^{\infty} \alpha_k^{2\sigma-1}<\infty \tag{2.8}$$

for some $\sigma\in\,]0,\frac{1}{2}[$. We set

$$q(t)=\sum_{k=1}^{\infty}\frac{1-e^{-2\alpha_k t}}{2\alpha_k}.$$

We note that (2.8) yields

$$q(t)\leqq Mt^{2\sigma} \tag{2.9}$$

for all $t\geqq 0$ and some constant $M>0$.

PROPOSITION 2.3. *Assume* (2.8). *Then* $W_A(t)$ *has* α-*Hölder continuous trajectories for all* $\alpha\in\,]0,\sigma[$.

Proof. Since $\{\beta_k\}$ are independent, we have

$$\begin{aligned}\mathscr{E}|W_A(t)-W_A(s)|^2&=\sum_{k=1}^{\infty}\mathscr{E}\left[\int_0^t e^{-\alpha_k(t-\rho)}\,d\beta_k(\rho)\right]^2+\sum_{k=1}^{\infty}\mathscr{E}\left[\int_0^s e^{-\alpha_k(s-\rho)}\,d\beta_k(\rho)\right]^2\\&\quad-2\sum_{k=1}^{\infty}\mathscr{E}\left[\int_0^t e^{-\alpha_k(t-\rho)}\,d\beta_k(\rho)\int_0^s e^{-\alpha_k(s-\rho)}\,d\beta_k(\rho)\right]\\&=\sum_{k=1}^{\infty}\int_0^t e^{-2\alpha_k\rho}\,d\rho+\sum_{k=1}^{\infty}\int_0^s e^{-2\alpha_k\rho}\,d\rho-2\sum_{k=1}^{\infty}\int_0^s e^{-\alpha_k(t+s-2\rho)}\,d\rho\end{aligned}$$

for all $t\geqq s\geqq 0$. Now, by changing the variable ρ with $t+s-2\rho$, we obtain

$$\mathscr{E}|W_A(t)-W_A(s)|^2=q(t)+q(s)+2\left[q\left(\frac{t-s}{2}\right)-q\left(\frac{t+s}{2}\right)\right] \tag{2.10}$$

for all $t\geqq s\geqq 0$.

Next, note that, since $q(t)-q(s)\leqq q(t-s)$, (2.9) yields $q\in C^{2\sigma}([0,\infty[)$. Therefore, there exists $C>0$ such that

$$\left|q(t)+q(s)-2q\left(\frac{t+s}{2}\right)\right|\leqq C|t-s|^{2\sigma}.$$

From (2.10) it follows that

$$\mathscr{E}|W_A(t)-W_A(s)|^2\leqq C(1+2^{1-2\sigma})|t-s|^{2\sigma}.$$

Since $W_A(t)-W_A(s)$ is a Gaussian process, $\mathscr{E}|W_A(t)-W_A(s)|^{2m}\leqq C'|t-s|^{2m\sigma}$ for all $t,\ s\geqq 0$ and a suitable constant C'. The Kolmogorov test yields the conclusion. □

PROPOSITION 2.4. *Assume* (2.8). *Then, for all* $T>0$,

$$\mathscr{E}\left(\sup_{0\leqq t\leqq T}|W_A(t)|\right)<\infty, \tag{2.11}$$

$$\lim_{n\to\infty}\mathscr{E}\left(\sup_{0\leqq t\leqq T}|W_A^n(t)-W_A(t)|\right)=0. \tag{2.12}$$

Proof. We use the factorization method as in [6]. Set

$$Y(s)=\sum_{k=1}^{\infty} e_k \int_0^s (s-r)^{-\sigma}\, e^{-\alpha_k(s-r)}\, d\beta_k(r),$$

$$Y_n(s)=\Pi_n Y(s)$$

for all $s\geqq 0$. Then, by a straightforward computation,

$$W_A(t)=\frac{\sin \pi\sigma}{\sigma}\int_0^t (t-s)^{\sigma-1}\, e^{(t-s)A}\, Y(s)\, ds, \tag{2.13}$$

$$W_A^n(t)=\frac{\sin \pi\sigma}{\sigma}\int_0^t (t-s)^{\sigma-1}\, e^{(t-s)A_n}\, Y_n(s)\, ds, \tag{2.14}$$

where $A_n=A\Pi_n$. Therefore,

$$W_A(t)-W_A^n(t)=B_n(t)+C_n(t), \tag{2.15}$$

where

$$B_n(t)=\frac{\sin \pi\sigma}{\sigma}\int_0^t (t-s)^{\sigma-1}[e^{(t-s)A}-e^{(t-s)A_n}]\, Y(s)\, ds,$$

$$C_n(t)=\frac{\sin \pi\sigma}{\sigma}\int_0^t (t-s)^{\sigma-1}\, e^{(t-s)A_n}[Y(s)-Y_n(s)]\, ds.$$

We will estimate $B_n(t)$ and $C_n(t)$ separately. After some computations we obtain

$$\mathscr{E}|Y(s)|^2=\sum_{k=1}^{\infty}\int_0^s e^{-2\alpha_k(s-r)}(s-r)^{-2\sigma}\, dr \leqq k_0 \sum_{k=1}^{\infty}\frac{1}{\alpha_k^{1-2\sigma}}=:k_1 \tag{2.16}$$

for some constant $k_0>0$. Since $Y(s)$ is a Gaussian process, (2.16) implies that, for all $m\in \mathbf{N}$,

$$\mathscr{E}|Y(s)|^{2m}\leqq k_m \tag{2.17}$$

for some constant $k_m>0$. Now, by Hölder's inequality and (2.13) it follows that

$$\mathscr{E}\left(\sup_{0\leqq t\leqq T}|W_A(t)|^{2m}\right)\leqq\left(\frac{\sin \pi\sigma}{\sigma}\right)^{2m}\left(\int_0^T s^{2m(\sigma-1)/(2m-1)}\, ds\right)^{2m-1}\int_0^T \mathscr{E}|Y(s)|^{2m}\, ds.$$

Moreover, we conclude that

$$\mathscr{E}\left(\sup_{0\leqq t\leqq T}|B_n(t)|^{2m}\right)\leqq\left(\frac{\sin \pi\sigma}{\sigma}\right)^{2m}\left(\int_0^T s^{2m(\sigma-1)/(2m-1)}\|e^{sA}-e^{sA_n}\|^{2m/(2m-1)}\, ds\right)^{2m-1}$$
$$\cdot\int_0^T \mathscr{E}|Y(s)|^{2m}\, ds.$$

Now, since the semigroup e^{sA} is analytic, $\|e^{sA}-e^{sA_n}\|\to 0$ for all $s>0$ as $n\to\infty$. Thus, in view of (2.17), the dominated convergence theorem yields

$$\lim_{n\to\infty}\mathscr{E}\left(\sup_{0\leqq t\leqq T}|B_n(t)|^{2m}\right)=0 \tag{2.18}$$

provided that $(1-\sigma)2m/(2m-1)<1$. We will now estimate $C_n(t)$: we have

$$\begin{aligned}\mathscr{E}|Y(s)-Y_n(s)|^2&=\sum_{k=n+1}^{\infty}\int_0^s e^{-2\alpha_k(s-r)}(s-r)^{-2\sigma}\, dr\\ &\leqq k_0\sum_{k=n+1}^{\infty}\frac{1}{\alpha_k^{1-2\sigma}}:=k_{1n}\end{aligned} \tag{2.19}$$

for some constant $k_{1n}>0$ such that $\lim_{n\to\infty} k_{1n}=0$. Since $Y(s)-Y_n(s)$ is a Gaussian process, (2.19) implies that, for all $m\in\mathbf{N}$,

$$\mathscr{E}|Y(s)-Y_n(s)|^{2m}\leqq c_m(k_{1n})^m \tag{2.20}$$

for some constant $c_m>0$. Now, by Hölder's inequality we conclude that

$$\mathscr{E}\left(\sup_{0\leqq t\leqq T}|C_n(t)|^{2m}\right)\leqq\left(\frac{\sin\pi\sigma}{\sigma}\right)^{2m}\left(\int_0^T s^{2m(\sigma-1)/(2m-1)}\,ds\right)^{2m-1}$$
$$\cdot\int_0^T \mathscr{E}|Y(s)-Y_n(s)|^{2m}\,ds.$$

Hence

$$\lim_{n\to\infty}\mathscr{E}\left(\sup_{0\leqq t\leqq T}|C_n(t)|^{2m}\right)=0, \tag{2.21}$$

which, along with (2.18), gives the conclusion. □

3. Linear parabolic equations. In this section we study the linear problem:

$$\frac{\partial u}{\partial t}=\frac{\varepsilon}{2}\operatorname{Tr}(u_{xx})+\langle Ax, u_x\rangle \quad \text{in } [0, T]\times X, \qquad u(0,x)=\phi(x), \tag{3.1}$$

where ε is a given positive number and $\phi\in C_b(X)$. Here $A:D(A)\subset X\to X$ is a self-adjoint negative operator in X satisfying, for all $k\in\mathbf{N}$,

$$Ae_k=-\alpha_k e_k, \tag{3.2}$$

with $\alpha_k>0$. In (3.1) the subscript x represents Fréchet partial derivative with respect to x and Tr denotes the trace; i.e.,

$$\operatorname{Tr}(u_{xx})=\sum_{k=1}^{\infty}\langle u_{xx}e_k, e_k\rangle.$$

The following result, proved in [7], states that, for any $\phi\in C_b(X)$, problem (3.1) has a unique classical solution given by

$$u(t,x)=\mathscr{E}(\phi(e^{tA}x+\sqrt{\varepsilon}\;W_A(t)))=:(T_t\phi)(x), \tag{3.3}$$

where $W_A(t)$ is the process defined in (2.5). The method of [7], based on a procedure of Galerkin type, uses the following sequence of semigroups which is proved to converge pointwise to the semigroup defined in (3.3):

$$\mathscr{E}(\phi(e^{tA}\Pi_n x+\sqrt{\varepsilon}\;W_A^n(t)))=:(T_t^n\phi)(x) \tag{3.4}$$

for all $\phi\in C_b(X)$. In this paper we improve the result of [7], by showing that $(T_t^n\phi)(x)$ converges to $(T_t\phi)(x)$ uniformly. We will use this convergence result in § 5. In the following we denote by $\overline{e^{tA}Q_t^{-1}}$ the bounded operator defined by

$$\overline{e^{tA}Q_t^{-1}}\;e_k=\frac{2\alpha_k e^{-t\alpha_k}}{1-e^{-2t\alpha_k}}\,e_k,\qquad k\in\mathbf{N}. \tag{3.5}$$

PROPOSITION 3.1. *Assume* (3.2) *and* (2.6). *Then, for any* $\tau\in\,]0, T[$,

$$\text{(i)}\quad \lim_{n\to\infty}(T_t^n\phi)(x)=(T_t\phi)(x),$$
$$\text{(ii)}\quad \lim_{n\to\infty}(T_t^n\phi)_x(x)=(T_t\phi)_x(x) \tag{3.6}$$

uniformly on the bounded sets of $[\tau, T]\times X$. *Moreover, the function*

$$u:[0,\infty[\times X\to \mathbf{R},\ u(t,x)=(T_t\phi)(x)$$

is continuous. Furthermore, $u(t,\cdot)\in C_b^\infty(X)$ *for all* $t>0$, $u(\cdot,x)\in C^1(]0,\infty[)$ *for all* $x\in D(A)$ *and*

$$u_x(t,x)=\sqrt{\varepsilon}\ \mathscr{E}(\overline{e^{tA}Q_t^{-1}}W_A(t)\phi(e^{tA}x+\sqrt{\varepsilon}\ W_A(t))), \tag{3.7}$$

$$u_{xx}(t,x)=\varepsilon\mathscr{E}(\overline{e^{tA}Q_t^{-1}}\ W_A(t)\otimes\overline{e^{tA}Q_t^{-1}}\ W_A(t)\phi(e^{tA}x+\sqrt{\varepsilon}\ W_A(t))), \tag{3.8}$$

$$|u_x(t,x)|\leqq\sqrt{\varepsilon}\ \rho(t)\|\phi\|_0, \tag{3.9}$$

$$|\mathrm{Tr}\,[u_{xx}(t,x)]|\leqq\varepsilon\rho^2(t)\|\phi\|_0, \tag{3.10}$$

where

$$\rho^2(t)=\sum_{k=1}^{\infty}\frac{2\alpha_k e^{-2t\alpha_k}}{1-e^{-2t\alpha_k}}. \tag{3.11}$$

Finally, (3.1) *is fulfilled for all* $x\in D(A)$ *and* $t>0$.

Proof. First, we note that formulas (3.7) and (3.8) are derived in [7]. We will give a detailed proof of the uniform convergence in (3.6). The proofs of the remaining statements will be only sketched for the reader's convenience.

From (3.3) and (3.4) we obtain

$$\begin{aligned}|(T_t\phi)(x)-(T_t^n\phi)(x)|&\leqq\mathscr{E}|\phi(e^{tA}x+\sqrt{\varepsilon}\ W_A(t))-\phi(e^{tA}\Pi_nx+\sqrt{\varepsilon}\ W_A^n(t))|\\&\leqq\mathscr{E}\omega_\phi(|e^{tA}x-e^{tA}\Pi_nx|+\sqrt{\varepsilon}\ |W_A(t)-W_A^n(t)|)\\&\leqq\omega_\phi(|e^{tA}x-e^{tA}\Pi_nx|+\sqrt{\varepsilon}\ \mathscr{E}|W_A(t)-W_A^n(t)|),\end{aligned} \tag{3.12}$$

where ω_ϕ is a concave continuity modulus for ϕ. Now, since e^{tA} is compact for $t>0$,

$$\lim_{n\to\infty}|e^{tA}x-e^{tA}\Pi_nx|=0 \tag{3.13}$$

uniformly for $(t,x)\in[\tau,T]\times B_R$, $R>0$. Moreover,

$$\mathscr{E}|W_A(t)-W_A^n(t)|\leqq\sqrt{T}\sqrt{\mathscr{E}|W_A(t)-W_A^n(t)|^2}. \tag{3.14}$$

Thus, (3.6)(i) follows from (3.13) and (3.14), in light of Proposition 2.1. Equation (3.6)(ii) follows by a similar argument, using formula (3.7) for $u_x(t,x)$. Next, we have

$$\begin{aligned}|\langle u_x(t,x),e_k\rangle|^2&=\varepsilon\,e^{-2t\alpha_k}\left(\frac{2\alpha_k}{1-e^{-2t\alpha_k}}\right)^2\left|\mathscr{E}\int_0^t e^{-2(t-s)\alpha_k}\,d\beta_k(s)\phi(e^{tA}x+W_A(t))\right|^2\\&\leqq\varepsilon\,e^{-2t\alpha_k}\left(\frac{2\alpha_k}{1-e^{-2t\alpha_k}}\right)^2\mathscr{E}\left|\int_0^t e^{-2(t-s)\alpha_k}\,d\beta_k(s)\right|^2\|\phi\|_0^2\end{aligned} \tag{3.15}$$

and (3.9) follows taking the sum over k. Similarly, (3.8) yields

$$\begin{aligned}|\langle u_{xx}(t,x)e_k,e_k\rangle|&=\varepsilon\,e^{-2t\alpha_k}\left(\frac{2\alpha_k}{1-e^{-2t\alpha_k}}\right)^2\Bigg|\mathscr{E}\\&\quad\cdot\left\{\left[\int_0^t e^{-2(t-s)\alpha_k}\,d\beta_k(s)\right]^2\phi(e^{tA}x+W(t))\right\}\Bigg|\\&\leqq\varepsilon\,e^{-2t\alpha_k}\frac{2\alpha_k}{1-e^{-2t\alpha_k}}\|\phi\|_0,\end{aligned} \tag{3.16}$$

which in turn implies (3.10). □

Remark 3.2. Under the stronger condition (2.8), we have

$$\rho^2(t) \leqq \sup_k \left(\frac{2\alpha_k e^{-t\alpha_k}}{1-e^{-2t\alpha_k}} \right)^2 \cdot q(t) \leqq \frac{L}{t^2} q(t), \tag{3.17}$$

where

$$L = 4 \max_{\alpha \geqq 0} \frac{\alpha e^{-\alpha}}{1-e^{-2\alpha}}. \tag{3.18}$$

Hence, estimate (3.10) and (2.9) yield

$$|\mathrm{Tr}\,[u_{xx}(t,x)]| \leqq \frac{C\varepsilon}{t^{2-2\sigma}}. \tag{3.19}$$

4. Semilinear parabolic equations. Let $T > 0$ and consider the Cauchy problem

$$\begin{aligned} &\frac{\partial u}{\partial t} = \frac{\varepsilon}{2} \mathrm{Tr}\,(u_{xx}) + \langle Ax + F(x), u_x \rangle - H(u_x) + g(x) \quad \text{in } [0, T] \times X, \\ &u(0,x) = \phi(x), \end{aligned} \tag{4.1}$$

where we assume the following, in addition to (3.2) and (2.8),

$$\begin{aligned} &\text{(i)} \quad \phi, g \in C_b(X), \\ &\text{(ii)} \quad H \in \mathrm{Lip}\,(X), H(0) = 0, \\ &\text{(iii)} \quad F \in C_b(X; X). \end{aligned} \tag{4.2}$$

Obviously, the requirement $H(0) = 0$ implies no loss of generality, as we can replace g by $g - H(0)$. We will solve problem (4.1) in the Banach space

$$\Sigma = \{ v \in C_b([0, T] \times X) \colon v_x \in C(]0, T] \times X; X), t^{1-\sigma} v_x \in B(]0, T] \times X; X) \},$$

$$\|v\|_\Sigma = \sup \{ |v(t,x)| + |t^{1-\sigma} v_x(t,x)| \colon (t,x) \in]0, T] \times X \},$$

where σ is defined in (2.8) and $B(]0, T] \times X; X)$ denotes the space of all bounded X-valued functions defined in $]0, T] \times X$.

DEFINITION 4.1. A function $u \in \Sigma$ is called a mild solution of problem (4.1) if u is a solution of the integral equation

$$u(t,\cdot) = T_t\phi + \int_0^t T_{t-s}(\langle F, u_x(s,\cdot)\rangle - H(u_x(s,\cdot)) + g)\, ds \quad \forall t \in [0, T], \tag{4.3}$$

where T_t is the semigroup defined in (3.3).

LEMMA 4.2. *Assume* (2.8) *and let* $\psi :]0, T] \times X \to \mathbf{R}$ *be such that*

(i) $\psi \in C_b([\tau, T] \times X)$ *for all* $\tau \in]0, T]$,

(ii) $|t^{1-\sigma}\psi(t,x)| \leqq K$ *for all* $(t,x) \in]0, T] \times X$ *and some constant* $K > 0$.

Set

$$f(t,\cdot) = \int_0^t T_{t-s}(\psi(s,\cdot))\, ds \quad \forall t \in]0, T]. \tag{4.4}$$

Then $f \in \Sigma$.

Proof. Step 1. $f \in C_b([0, T] \times X)$. Fix $\varepsilon > 0$ and let $\tau \in]0, T]$ such that $K\tau^\sigma \leqq \sigma\varepsilon$. Let $(t,x), (t',x') \in [0, T] \times X$.

We shall consider two cases separately.

Case 1. $t, t' \in [0, \tau]$. Then we have, obviously,

$$|f(t,x)-f(t',x')| \leqq \int_0^t |T_{t-s}(s^{1-\sigma}\psi(s,\cdot))(x)|s^{\sigma-1}\,ds + \int_0^{t'} |T_{t-s}(s^{1-\sigma}\psi(s,\cdot))(x')|s^{\sigma-1}\,ds$$

$$\leqq 2K\int_0^\tau s^{\sigma-1}\,ds \leqq 2\varepsilon.$$

Case 2. $t \in]\tau/2, T[$, $t' \in [\tau, T]$. Then we have

$$|f(t,x)-f(t',x')| \leqq 2\varepsilon + \left|\int_{\tau/2}^t T_{t-s}(\psi(s,\cdot))(x)\,ds - \int_{\tau/2}^{t'} T_{t'-s}(\psi(s,\cdot))(x')\,ds\right|.$$

In view of (ii), standard continuity properties of the integral in the right-hand side imply that there exists $\delta > 0$ such that, if $|t-t'|+|x-x'|<\delta$, then

$$\left|\int_\tau^t T_{t-s}(\psi(s,\cdot))(x)\,ds - \int_\tau^{t'} T_{t'-s}(\psi(s,\cdot))(x')\,ds\right| < \varepsilon.$$

To conclude the reasoning, set $\delta' = \min\{\delta, \tau/2\}$. Then, from the above analysis it follows that $|f(t,x)-f(t',x')| \leqq 3\varepsilon$ provided $|t-t'|+|x-x'|<\delta$. This proves that $f \in C_b([0,T]\times X)$.

Step 2. $t^{1-\sigma}f_x(t,x)$ is bounded on $]0,T]\times X$. First, note that, by (3.9), (2.8), and Remark 3.2, we obtain

$$|(T_{t-s}\psi(s,\cdot))_x| \leqq \frac{C_0K}{(t-s)^{1-\sigma}s^{1-\sigma}}, \qquad 0<s<t, \tag{4.5}$$

where $C_0 = \sqrt{\varepsilon LM}$, L and M being defined in (3.17) and (2.9), respectively. Hence, $f_x(t,x)$ exists for all $t>0$ and $x \in X$. Moreover, by (ii),

$$|t^{1-\sigma}f_x(t,x)| \leqq t^{1-\sigma}C_0K\int_0^t (t-s)^{\sigma-1}s^{\sigma-1}\,ds. \tag{4.6}$$

On the other hand, (4.6) yields the conclusion of Step 2 since

$$\int_0^t (t-s)^{\sigma-1}s^{\sigma-1}\,ds = t^{2\sigma-1}\beta(\sigma,\sigma) \leqq \frac{2^{2(1-\sigma)}}{\sigma}t^{2\sigma-1}, \tag{4.7}$$

where β is the Euler beta function.

Step 3. $f_x \in C_b([t_0,T]\times X; X)$ for all $t_0 \in]0,T[$. Fix $t_0 \in]0,T[$ and $t_0 \leqq t \leqq t' \leqq T$, $x, x' \in X$. Then

$$\begin{aligned} &|f_x(t,x)-f_x(t',x')| \\ &\leqq \left|\int_0^t [(T_{t-s}\psi(s,\cdot))_x(x) - (T_{t'-s}\psi(s,\cdot))_x(x')]\,ds\right| \\ &\quad + \left|\int_t^{t'} (T_{t'-s}\psi(s,\cdot))_x(x)\,ds\right|. \end{aligned} \tag{4.8}$$

Moreover, recalling (4.6), we obtain

$$\left|\int_t^{t'} (T_{t'-s}\psi(s,\cdot))_x(x)\,ds\right| \leqq C_0K\int_t^{t'} (t'-s)^{\sigma-1}s^{\sigma-1}\,ds \leqq C_0\frac{K}{\sigma}t_0^{\sigma-1}(t'-t)^\sigma. \tag{4.9}$$

On the other hand, for all $\eta > 0$ there exists $\tau \in]0, t_0/2]$ such that

$$\begin{aligned}(4.10)\qquad &\left|\int_0^t [(T_{t-s}\psi(s,\cdot))_x(x) - (T_{t'-s}\psi(s,\cdot))_x(x')]\,ds\right| \\ &\leqq 2\eta + \left|\int_t^{t-\tau} [(T_{t-s}\psi(s,\cdot))_x(x) - (T_{t'-s}\psi(s,\cdot))_x(x')]\,ds\right|.\end{aligned}$$

Indeed, it suffices to take τ so that

$$(4.11)\qquad C_0 \frac{K}{\sigma}\left(\frac{t_0}{2}\right)^{\sigma-1} \tau^\sigma < \eta.$$

Finally, the conclusion follows from (4.8)-(4.10) and the uniform continuity of the mapping $(s, t, x) \to (T_{t-s}\psi(s,\cdot))_x(x)$ on $\{(s, t, x): t_0 \leqq t \leqq T,\ \tau \leqq s \leqq t-\tau,\ x \in X\}$. The proof of the lemma is thus complete. □

THEOREM 4.3. *Assume* (3.2), (2.8), *and* (4.2). *Then problem* (4.1) *has a unique mild solution.*

Proof. Suppose first that T is sufficiently small, i.e.,

$$(4.12)\qquad (1+2^{2(1-\sigma)}C_0)\frac{\|F\|_0 + \|H\|_1}{\sigma} T^\sigma \leqq \frac{1}{2},$$

where $C_0 = \sqrt{\varepsilon L M}$, L and M being defined in (3.17) and (2.9), respectively. Define a map Γ on Σ as follows:

$$(4.13)\qquad (\Gamma v)(t,\cdot) = T_t\phi + \int_0^t T_{t-s}(\langle F, v_x(s,\cdot)\rangle - H(v_x(s,\cdot)) + g)\,ds$$

for all $t \in [0, T]$. From Lemma 4.2, it follows that $\Gamma: \Sigma \to \Sigma$. Moreover,

$$(4.14)\qquad |(\Gamma v)(t,x) - (\Gamma z)(t,x)| \leqq \frac{\|F\|_0 + \|H\|_1}{\sigma} T^\sigma \|v-z\|_\Sigma,$$

$$(4.15)\qquad t^{1-\sigma}|(\Gamma v)_x(t,x) - (\Gamma z)_x(t,x)| \leqq C_0(\|F\|_0 + \|H\|_1)\beta(\sigma,\sigma)T^\sigma \|v-z\|_\Sigma,$$

where β is the Euler beta function. Since $\beta(\sigma,\sigma) \leqq 2^{2(1-\sigma)}/\sigma$, (4.13)-(4.15) imply that Γ is a contraction in Σ and the conclusion follows by the contraction mapping principle. Finally, condition (4.12) can be removed by a finite number of iterations of the previous fixed-point argument. □

In the sequel we will consider the following "finite-dimensional" approximation of (4.1):

$$(4.16)\qquad \begin{aligned}&\frac{\partial u_n}{\partial t} = \frac{\varepsilon}{2}\operatorname{Tr}(u_{n,xx}) + \langle A\Pi_n x + \Pi_n F(\Pi_n x), u_{n,x}\rangle - H(u_{n,x}) + g(\Pi_n x),\\ &u_n(0,x) = \phi(\Pi_n x),\end{aligned}$$

which has the integral form

$$(4.17)\quad u_n(t,\cdot) = T_t^n\phi\circ\Pi_n + \int_0^t T_{t-s}^n(\langle F\circ\Pi_n, u_{n,x}(s,\cdot)\rangle - H(u_{n,x}(s,\cdot)) + g\circ\Pi_n)\,ds.$$

THEOREM 4.5. *Assume* (3.2), (2.8), *and* (4.2) *and let* u *and* u_n *be the solutions of* (4.1) *and* (4.16), *respectively. Then, for all* $\tau \in]0, T[$,

$$(4.18)\quad \begin{aligned} &\text{(i)}\quad \lim_{n\to\infty} |u(t,x)-u_n(t,x)|=0,\\ &\text{(ii)}\quad \lim_{n\to\infty} |u_x(t,x)-u_{n,x}(t,x)|=0 \end{aligned}$$

uniformly for $t\in[\tau, T]$ *and* x *in bounded sets of* X.

We first prove the following lemma.

LEMMA 4.6. *Assume* (2.8) *and let* $\psi_n, \psi:]0, T]\times X \to \mathbf{R}$, $n\in N$, *be such that*

(i) $\psi_n, \psi \in C_b([\tau, T]\times X)$ *for all* $\tau\in]0, T]$

(ii) $|t^{1-\sigma}\psi_n(t,x)|\leqq K$, $|t^{1-\sigma}\psi(t,x)|\leqq K$ *for all* $(t,x)\in]0,T]\times X$ *and some constant* $K>0$.

(iii) $\lim_{n\to\infty}\sup\{|t^{1-\sigma}(\psi(t,x)-\psi_n(t,x))|: t\in[0,T], |x|\leqq R\}=0$ *for all* $R>0$.

Set

$$f_n(t,\cdot)=\int_0^t (T_{t-s}\psi_n)(s,\cdot)\,ds, \qquad f(t,\cdot)=\int_0^t (T_{t-s}\psi)(s,\cdot)\,ds.$$

Then, for all $R>0$

$$(4.19)\qquad \lim_{n\to\infty} |f_n(t,x)-f(t,x)|=0,$$

$$(4.20)\qquad \lim_{n\to\infty} t^{1-\sigma}|f_{n,x}(t,x)-f_x(t,x)|=0$$

uniformly for $t\in[0,T]$ *and* $|x|\leqq R$.

Proof. First, we note that $f_n, f\in\Sigma$ in view of Lemma 4.2. Now, fix $R>0$ and let $t\in[0,T]$, $|x|\leqq R$. We have

$$(4.21)\qquad \begin{aligned} |f(t,x)-f_n(t,x)|\leqq &\left|\int_0^t T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)]\,ds\right|\\ &+\left|\int_0^t [T_{t-s}-T^n_{t-s}]\psi(s,\cdot)\,ds\right|. \end{aligned}$$

We claim that

$$(4.22)\qquad \lim_{n\to\infty}\left|\int_0^t [T_{t-s}-T^n_{t-s}]\psi(s,\cdot)\,ds\right|=0$$

uniformly for $t\in[0,T]$, $|x|\leqq R$. Indeed, fix $\eta>0$ and let $\tau\in]0,T[$ be such that $(K/\sigma)\tau^\sigma<\eta$. Then, if $0\leqq t\leqq\tau$,

$$(4.23)\qquad \left|\int_0^t [T_{t-s}-T^n_{t-s}]\psi(s,\cdot)\,ds\right|\leqq 2\eta.$$

On the other hand, if $\tau<t\leqq T$, then

$$(4.24)\qquad \begin{aligned} \left|\int_0^t [T_{t-s}-T^n_{t-s}]\psi(s,\cdot)\,ds\right| &\leqq 2\eta+\left|\int_{\tau/2}^{t-\tau/2} [T_{t-s}-T^n_{t-s}]\psi(s,\cdot)\,ds\right|\\ &\quad+\left|\int_{t-\tau/2}^{t} [T_{t-s}-T^n_{t-s}]\psi(s,\cdot)\,ds\right|\\ &\leqq 4\eta+\left|\int_{\tau/2}^{t-\tau/2} [T_{t-s}-T^n_{t-s}]\psi(s,\cdot)\,ds\right| \end{aligned}$$

and (4.22) follows from (3.6). Next, let us show that

$$\lim_{n\to\infty}\left|\int_0^t T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)]\,ds\right|=0 \tag{4.25}$$

uniformly for $t\in[0,T]$, $|x|\leqq R$. Recalling (3.4), we obtain

$$\begin{aligned} T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)](x)=\mathscr{E}[\psi(s,e^{(t-s)A}\Pi_n x+\sqrt{\varepsilon}\;W^n_A(t-s))\\ -\psi_n(s,e^{(t-s)A}\Pi_n x+\sqrt{\varepsilon}\;W^n_A(t-s))].\end{aligned} \tag{4.26}$$

Moreover, Proposition 2.4 implies that there exists a random variable C, such that

$$|e^{(t-s)A}\Pi_n x+\sqrt{\varepsilon}\;W^n_A(t-s)|\leqq R+C \tag{4.27}$$

for $n\in\mathbf{N}$, $0\leqq s\leqq t\leqq T$ and $|x|\leqq R$. So, in light of hypothesis (iii),

$$\begin{aligned}\lim_{n\to\infty}\sup_{|x|\leqq R,\tau\leqq s\leqq t}|\psi(s,e^{(t-s)A}\Pi_n x+\sqrt{\varepsilon}\;W^n_A(t-s))\\ -\psi_n(s,e^{(t-s)A}\Pi_n x+\sqrt{\varepsilon}\;W^n_A(t-s))|=0\end{aligned} \tag{4.28}$$

almost surely for all $\tau\in]0,T]$. Hence, by the dominated convergence theorem, for all $\tau\in]0,T]$.

$$\lim_{n\to\infty}\left|\int_\tau^t T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)](x)\,ds\right|=0 \tag{4.29}$$

uniformly for $|x|\leqq R$ and $\tau\in]0,T]$. Now fix $\eta>0$ and choose τ so that $(K/\sigma)\tau^\sigma<\eta$. Then

$$\left|\int_0^t T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)](x)\,ds\right|\leqq 2\eta+\left|\int_\tau^t T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)](x)\,ds\right| \tag{4.30}$$

and (4.25) follows from (4.28). Finally, (4.21), (4.22), and (4.25) imply (4.19). Next, we prove (4.20). For all $t\in]0,T]$, $|x|\leqq R$ we have

$$\begin{aligned} t^{1-\sigma}|f_x(t,x)-f_{n,x}(t,x)|\leqq t^{1-\sigma}\left|\int_0^t (T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)])_x\,ds\right|\\ +t^{1-\sigma}\left|\int_0^t ([T_{t-s}-T^n_{t-s}]\psi)_x(s,\cdot)\,ds\right|.\end{aligned} \tag{4.31}$$

Now, fix $\eta>0$ and let $\tau\in]0,T[$ be such that $8C_0Kt^\sigma<\sigma\eta$, where $C_0=\sqrt{\varepsilon LM}$, L and M being defined in (3.17) and (2.9), respectively. Then, by (4.5) and (4.7) we conclude that, if $0\leqq t\leqq T$,

$$t^{1-\sigma}\left|\int_0^t ([T_{t-s}-T^n_{t-s}]\psi)_x(s,\cdot)\,ds\right|\leqq 2C_0Kt^{1-\sigma}\int_0^t (t-s)^{\sigma-1}s^{\sigma-1}\,ds\leqq\frac{8}{\sigma}\,C_0Kt^\sigma<\eta.$$

On the other hand, if $\tau<t\leqq T$, we obtain, as in (4.24),

$$\begin{aligned} t^{1-\sigma}\left|\int_0^t ([T_{t-s}-T^n_{t-s}]\psi)_x(s,\cdot)\,ds\right|\\ \leqq 2\eta+t^{1-\sigma}\left|\int_{\tau/2}^{t-\tau/2} ([T_{t-s}-T^n_{t-s}]\psi)_x(s,\cdot)\,ds\right|.\end{aligned} \tag{4.32}$$

So, by (3.6)(ii),

$$\lim_{n\to\infty} t^{1-\sigma}\left|\int_0^t ([T_{t-s}-T^n_{t-s}])_x\psi(s,\cdot)\,ds\right|=0 \tag{4.33}$$

uniformly for $t\in]0, T]$ and $|x|\leqq R$. Next we prove that

$$\lim_{n\to\infty} t^{1-\sigma}\left|\int_0^t (T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)])_x\,ds\right|=0 \tag{4.34}$$

uniformly for $t\in]0, T]$ and $|x|\leqq R$. From (3.7) it follows that

$$\begin{aligned}&(T^n_{t-s}[\psi(s,\cdot)-\psi_n(s,\cdot)])_x(x)\\ &\quad=\sqrt{\varepsilon}\ \mathscr{E}\{\overline{e^{(t-s)A}Q^{-1}_{t-s}}\,\Pi_n W_A(t-s)[\psi(s, e^{(t-s)A}\Pi_n x+\sqrt{\varepsilon}\ W^n_A(t-s))\\ &\qquad-\psi_n(s, e^{(t-s)A}\Pi_n x+\sqrt{\varepsilon}\ W^n_A(t-s))]\}.\end{aligned} \tag{4.35}$$

Recalling (4.28) and (2.11), we conclude that, if $t\geqq\tau$, then

$$\begin{aligned}\lim_{n\to\infty}\ \sup_{|x|\leqq R,\tau\leqq s\leqq t}\ &|\overline{e^{(t-s)A}Q^{-1}_{t-s}}\,\Pi_n W_A(t-s)[\psi-\psi_n]\\ &\cdot(s, e^{(t-s)A}\Pi_n x+\sqrt{\varepsilon}\ W^n_A(t-s))|=0\end{aligned} \tag{4.36}$$

almost surely for $|x|\leqq R$, $\tau/2\leqq s\leqq t-\tau/2$. Now, arguing as above, we can prove (4.34) and so (4.20). □

Proof of Theorem 4.5. Set

$$\begin{aligned}G_n(x,p)&=\langle F(\Pi_n x),p\rangle-H(p)+g(\Pi_n x),\\ G(x,p)&=\langle F(\Pi x),p\rangle-H(p)+g(\Pi x)\end{aligned} \tag{4.37}$$

for all x, $p\in X$ and

$$(\Gamma_n v)(t,\cdot)=T^n_t\phi+\int_0^t T^n_{t-s}G(\cdot, v_x(s,\cdot))\,ds\quad \forall v\in\Sigma. \tag{4.38}$$

From Lemma 4.2 it follows that Γ_n maps Σ into Σ. Arguing as in the proof of Theorem 4.3 it follows that

$$\|\Gamma_n v-\Gamma_n z\|_\Sigma\leqq\tfrac{1}{2}\|v-z\|_\Sigma \tag{4.39}$$

provided that T satisfies (4.12). Therefore, Γ_n has a unique fixed-point u_n, which is the unique mild solution of (4.16). Moreover,

$$\|u_n-\Gamma^\mu_n(0)\|_\Sigma\leqq 2^{1-\mu}(T\|g\|_0+\|\phi\|_0), \tag{4.40}$$

where Γ^μ_n denotes the μ-iterate of Γ_n. We claim that for all $\mu\in\mathbf{N}$ and all $R>0$,

$$\lim_{n\to\infty}\Gamma^\mu_n(0)(t,x)=\Gamma^\mu(0)(t,x) \tag{4.41}$$

uniformly for $t\in[\tau, T]$ and $|x|\leqq R$. In fact, (4.41) is true for $\mu=1$, in view of (3.6)(i). Now, suppose that (4.41) holds for $\mu\in\mathbf{N}$. Then the functions

$$\psi(t,x)=G(x,\Gamma^\mu(0))_x(t,x),\qquad \psi_n(t,x)=G(x,\Gamma^\mu_n(0))_x(t,x) \tag{4.42}$$

satisfy the assumptions of Lemma 4.6. Consequently, by (4.19)

$$\lim_{n\to\infty}\Gamma^{\mu+1}_n(0)(t,x)=\Gamma^{\mu+1}(0)(t,x) \tag{4.43}$$

uniformly for $t\in[0, T]$, $|x|\leqq R$. Therefore (4.41) holds for all $\mu\in\mathbf{N}$.

Finally, to prove (4.18)(i) note that for all μ, $n\in\mathbf{N}$

$$\begin{aligned}&|u(t,x)-u_n(t,x)|\\ &\quad\leqq|u(t,x)-\Gamma^\mu(0)(t,x)|+|\Gamma^\mu(0)(t,x)-\Gamma^\mu_n(0)(t,x)|+|\Gamma^\mu_n(0)(t,x)-u_n(t,x)|\\ &\quad\leqq 2^{2-\mu}(T\|g\|_0+\|\phi\|_0)+|\Gamma^\mu(0)(t,x)-\Gamma^\mu_n(0)(t,x)|.\end{aligned} \tag{4.44}$$

Fix $\eta > 0$ and let $\mu_\eta \in \mathbf{N}$ be such that $2^{2-\mu_\eta}(T\|g\|_0 + \|\phi\|_0) < \eta$. Then, (4.44) yields

$$|u(t,x) - u_n(t,x)| \leqq 2\eta + |\Gamma^{\mu_\eta}(0)(t,x) - \Gamma_n^{\mu_\eta}(0)(t,x)|. \tag{4.45}$$

Now, (4.18)(ii) can be easily derived by minor modifications of the above argument (using (3.6)(ii) instead of (3.6)(i) and (4.20) instead of (4.19)). Therefore, the proof is complete. □

5. Application to stochastic optimal control. Let $\{\Omega, \mathcal{F}, \mathbf{P}\}$ be a complete probability space and $\{\beta_k\}$ a sequence of standard one-dimensional Brownian motions, mutually independent. For any $s \geqq 0$ let $\mathcal{F}_t$ be the σ-algebra generated by $\{\beta_k(s)\colon k = 1, 2, \cdots;\ 0 \leqq s \leqq t\}$. Let $M_W^2(t, T; X)$ denote the space of the X-valued processes x such that $x(s)$ in $\mathcal{F}_s$-measurable for all $t \leqq s \leqq T$ and

$$\mathscr{E}\left(\int_t^T |x(s)|^2\, ds\right) < \infty.$$

Consider a stochastic system governed by the state equation

$$y(s) = e^{(s-t)A}x + \int_t^s e^{(s-r)A}[F(y(r)) + z(r)]\, dr + \sqrt{\varepsilon}\ W_A(t,s), \qquad s \geqq t \geqq 0, \tag{5.1}$$

where $x \in X$, A is a self-adjoint operator satisfying (3.2) and (2.8), $F \in \operatorname{Lip}(X, X)$, $z \in M_W^2(t, T; X)$, and $W_A(t,s)$ is defined by

$$W_A(t,s) = \sum_{k=1}^{\infty} e_k \int_t^s e^{-\alpha_k(s-r)}\, d\beta_k(r), \qquad s \geqq t \geqq 0. \tag{5.2}$$

Equation (5.1) can be regarded as the "mild" form of the stochastic differential equation

$$\begin{aligned} &dy(s) = \{Ay(s) + F(y(s)) + z(s)\}\, ds + \sqrt{\varepsilon}\, dW(s), \qquad t \leqq s \leqq T, \\ &y(t) = x, \end{aligned} \tag{5.3}$$

where $W(t)$ is a cylindrical Wiener process (see Remark 2.2).

We now prove the existence of solutions to (5.3) as well as a Galerkin approximation result.

PROPOSITION 5.1. *Assume* (3.2), (2.8) *and let* $F \in \operatorname{Lip}(X, X)$. *Then, for all* $z \in M_W^2(t, T; X)$, *equation* (5.1) *has a unique solution* $y_\varepsilon(\cdot\,; t, x, z)$, *which is continuous with probability one.*

Proof. Let $\Lambda = \{v \in M_W^2(t, T; X)\colon \mathscr{E}(\sup_{t \leqq s \leqq T} |v(s)|^2) < +\infty\}$ and define a map λ on Λ as follows:

$$\lambda(v)(s) = e^{(s-t)A}x + \int_t^s e^{(s-r)A}[F(v(r)) + z(r)]\, dr + \sqrt{\varepsilon}\ W_A(t,s), \qquad t \leqq s \leqq T. \tag{5.4}$$

From Proposition 2.4 it follows that $W_A(t, \cdot) \in \Lambda$. Hence, $\lambda : \Lambda \to \Lambda$. Moreover, λ is a contraction provided that $T - t < 1/\|F\|_1$ and the conclusion follows by standard fixed-point arguments. □

PROPOSITION 5.2. *Assume* (3.2), (2.8) *and let* $F \in \operatorname{Lip}(X, X)$. *Let* $y_{\varepsilon,n}(\cdot\,; t, x, z)$ *be the solution of*

$$\begin{aligned} &dy_{\varepsilon,n}(s) = \{A\Pi_n y_{\varepsilon,n}(s) + \Pi_n F(\Pi_n y_{\varepsilon,n}(s)) + \Pi_n z(s)\}\, ds + \sqrt{\varepsilon}\, dW^n(s), \\ &y_{\varepsilon,n}(t) = \Pi_n x, \qquad\qquad t \leqq s \leqq T, \end{aligned} \tag{5.5}$$

where $z \in M^2_W(t, T; X)$ *and* $W^n(t)$ *is defined in* (2.3). *Then,*

$$\lim_{n\to\infty} \mathscr{E}\left(\sup_{t\leqq s\leqq T} |y_\varepsilon(s; t, x, z) - y_{\varepsilon,n}(s; t, x, z)|\right) = 0 \tag{5.6}$$

for all $x \in X$.

Proof. Let Λ be the space defined in the previous proof and define a map $\lambda_n n$ on Λ as follows:

$$\lambda_n(v)(s) = e^{(s-t)A}\Pi_n x + \int_t^s e^{(s-r)A}\Pi_n[F(\Pi_n v(r)) + \Pi_n z(r)]\, dr + \sqrt{\varepsilon}\,\Pi_n W_A(t, s),$$

$$t \leqq s \leqq T.$$

Then, λ_n is a contraction in Λ uniformly with respect to $n \in \mathbf{N}$, provided that $T - t < 1/\|F\|_1$. Moreover, Proposition 2.4 implies that

$$\lim_{n\to\infty} \mathscr{E}\left(\sup_{t\leqq s\leqq T} |\lambda_n(v)(s) - \lambda(v)(s)|\right) = 0$$

for all $v \in M^2_W(t, T; X)$. The conclusion then follows by the contraction mapping theorem depending on a parameter. □

We will now study the following stochastic optimal control problem.

Given $R > 0$, minimize the cost functional

$$J_\varepsilon(t, x; z) = \mathscr{E}\left\{\int_t^T \left[g(y_\varepsilon(s; t, x, z)) + \frac{1}{2}|z(s)|^2\right] ds + \phi(y_\varepsilon(T; t, x, z))\right\} \tag{5.7}$$

over all controls $z \in M^2_W(t, T; X)$ satisfying $|z(s)| \leqq R$ almost surely for all $s \in [t, T]$.

The *value function* of problem (5.7) is given by

$$V_\varepsilon(t, x) = \inf\{J_\varepsilon(t, x; z) \colon z \in M^2_W(t, T; X), |z(s)| \leqq \mathbf{R}\}. \tag{5.8}$$

The corresponding Hamilton-Jacobi-Bellman equation reads as follows:

$$\begin{aligned} &\frac{\partial v}{\partial t} + \frac{\varepsilon}{2}\operatorname{Tr}(v_{xx}) + \langle Ax + F(x), v_x\rangle - H(v_x) + g(x) = 0 \quad \text{in } [0, T] \times X,\\ &v(T, x) = \phi(x), \end{aligned} \tag{5.9}$$

where H is defined by

$$H(p) = \begin{cases} \frac{1}{2}|p|^2 & \text{if } |p| \leqq R,\\ R|p| - \frac{R^2}{2} & \text{if } |p| \geqq R. \end{cases} \tag{5.10}$$

From Theorem 4.3 we obtain the result below.

THEOREM 5.3. *Assume* (2.1), (2.8), (4.2)(i) *and let* $F \in \operatorname{Lip}(X, X)$. *Then problem* (5.9) *has a unique mild solution, which coincides with the value function* V_ε. *Moreover, for any* $(t, x) \in [0, T] \times X$, *there exists an optimal control for problem* (5.7). *Furthermore, any optimal control* z^* *is related to the corresponding optimal state* y^* *by the feedback formula*

$$z^*(s) = -h\left(\frac{\partial V_\varepsilon}{\partial x}(s, y^*(s))\right), \qquad t \leqq s \leqq T, \tag{5.11}$$

where

$$h(p) = \begin{cases} p & \textit{if } |p| \leqq R,\\ \frac{pR}{|p|} & \textit{if } |p| \geqq R. \end{cases} \tag{5.12}$$

Proof. First, we note that the existence and uniqueness of a mild solution v to (5.9) follows from Theorem 4.3, since the function H defined in (5.10) fulfills (4.2)(ii).

Let us show that $v = V_\varepsilon$. We claim that v satisfies the dynamic programming principle below: for any $t \in]0, T[$, $x \in X$ and $z \in M^2_W(t, T; X)$ such that $|z(s)| \leqq R$ almost surely, we have

$$(5.13)\quad \begin{aligned} &v(t, x) + \frac{1}{2}\mathscr{E}\int_t^T \{|z(s) + v_x(s, y_\varepsilon(s; t, x, z))|^2 - \chi(v_x(s, y_\varepsilon(s; t, z, z)) - R)\}\, ds \\ &\qquad = \mathscr{E}\left\{\int_t^T \left[g(y_\varepsilon(s; t, x, z)) + \frac{1}{2}|z(s)|^2\right] ds + \phi(y_\varepsilon(T; t, x, z))\right\}, \end{aligned}$$

where $\chi(a) = 0$ if $a \leqq 0$ and $\chi(a) = a^2$ if $a \geqq 0$.

Indeed, let u_n be the solution of problem (4.16) with H given by (5.10) and set $v_n(t, x) = u_n(T - t, x)$. We claim that v_n is regular. To show this fact let $\zeta(t, x_1, \cdots, x_n)$ be defined as $\zeta(t, x_1, \cdots, x_n) = v_n(t, x_1 e_1 + \cdots + x_n e_n)$, for all $(t, x_1, \cdots, x_n) \in]0, T[\times \mathbf{R}^n$. Then ζ is a classical solution of the problem

$$\begin{aligned} &\frac{\partial \zeta}{\partial t} + \Delta\zeta - \sum_{i=1}^n [\alpha_i x_i - \langle F(x_1 e_1 + \cdots + x_n e_n), e_i\rangle] \frac{\partial \zeta}{\partial x_i} \\ &\qquad - H\left(\frac{\partial \zeta}{\partial x_1} e_1 + \cdots + \frac{\partial \zeta}{\partial x_n} e_n\right) + g(x_1 e_1 + \cdots + x_n e_n) = 0, \\ &\zeta(T, x_1, \cdots, x_n) = \phi(x_1 e_1 + \cdots + x_n e_n). \end{aligned}$$

So, we can use the Itô formula to differentiate $v_n(s, y_{\varepsilon,n}(s))$ where $y_{\varepsilon,n}(s) = y_{\varepsilon,n}(s; t, x, z)$. Thus, we obtain

$$dv_n(s, y_{\varepsilon,n}(s)) = \frac{\partial v_n}{\partial t}(s, y_{\varepsilon,n}(s))\, ds + \langle dy_{\varepsilon,n}(s), v_{n,x}(s, y_{\varepsilon,n}(s))\rangle + \frac{\varepsilon}{2}\operatorname{Tr}(v_{n,xx}(s, y_{\varepsilon,n}(s)))\, ds.$$

Now, recall (4.16) and (5.5), integrate on $[t, T]$ and take expectation to obtain

$$\begin{aligned} &v_n(t, x) + \frac{1}{2}\mathscr{E}\int_t^T \{|\Pi_n z(s) + v_{n,x}(s, y_{\varepsilon,n}(s))|^2 - \chi(|v_{n,x}(s, y_{\varepsilon,n}(s))| - R\}\, ds \\ &\qquad = \mathscr{E}\left\{\int_t^T \left[g(y_{\varepsilon,n}(s; t, x, z)) + \frac{1}{2}|\Pi_n z(s)|^2\right] ds + \phi(y_{\varepsilon,n}(T; t, x, z))\right\}. \end{aligned}$$

By Proposition 5.2 and Theorem 4.5, we obtain (5.13) in the limit as $n \to \infty$. Next, we note that the following inequality holds:

$$(5.14)\quad |z(s) + v_x(s, y_\varepsilon(s; t, x, z))|^2 - \chi(v_x(s, y_\varepsilon(s; t, x, z)) - R) \geqq 0.$$

Thus, from (5.13) and (5.14) it follows that $v(t, x) \leqq V_\varepsilon(t, x)$.

To prove the reverse inequality, let us consider the closed-loop equation

$$(5.15)\quad \begin{aligned} &y(s) = e^{(s-t)A}x + \int_t^s e^{(s-r)A}[F(y(r)) - h(v_x(r, y(r)))]\, dr + \sqrt{\varepsilon}\, W_A(t, s), \\ &\qquad\qquad T > s \geqq t \geqq 0, \end{aligned}$$

which can be solved by the Schauder fixed-point theorem (see, e.g., [13, Cor. 2.3]). Indeed, from (2.8) it follows that e^{tA} is compact for $t > 0$. Let y^* be a mild solution of (5.15). Taking

$$z(s) = -h(v_x(s, y^*(s))), \tag{5.16}$$

we have the equality in (5.14), and so $v(t, x) \geqq V_\varepsilon(t, x)$ for all $t < T$. Moreover, the choice (5.16) provides an optimal control at (t, x). Finally, the feedback formula (5.11) follows from (5.13) and the fact that $v(t, x) = V_\varepsilon(t, x)$. □

Example 5.4. Let $X = L^2(0, \pi)$ and define

$$\begin{aligned} &D(A) = H^2(0, \pi) \cap H_0^1(0, \pi), \\ &Ax = \frac{\partial^2 x}{\partial \xi^2} \quad \forall x \in D(A), \end{aligned} \tag{5.17}$$

$$F(x)(\xi) = f(x(\xi)), \quad g(x) = \int_0^\pi \alpha(x(\xi))\, d\xi, \quad \phi(x) = \int_0^\pi \beta(z(\xi))\, d\xi,$$

where $f \in C_b^1(\mathbf{R})$, $\alpha, \beta \in C_b(\mathbf{R})$. By inspection, F, g, and ϕ fulfill the hypotheses of Theorem 5.3. As for operator A, (3.2) is satisfied by $\alpha_k = k^2$, and so (2.8) holds true for any $\sigma \in]0, \frac{1}{2}[$. Therefore, the results of this section apply to the following stochastic optimal control problem.

Minimize

$$J_\varepsilon(t, x; z) = \mathscr{E}\left\{\int_t^T \int_0^\pi \left[\alpha(y(s, \xi)) + \frac{1}{2}|z(s, \xi)|^2\right] d\xi\, ds + \int_0^\pi \beta(y(T, \xi))\, d\xi\right\} \tag{5.18}$$

over all controls $z \in M_W^2([t, T]; L^2(0, \pi))$ satisfying $\int_0^\pi |z(s, \xi)|^2\, d\xi \leqq R^2$ almost surely for all $s \in [t, T]$, where the state y is subject to

$$\begin{aligned} &dy(s, \xi) = \left\{\frac{\partial^2}{\partial x^2} y(s, \xi) + f(y(s, \xi)) + z(s, \xi)\right\} ds + \sqrt{\varepsilon}\, dW(s), \\ &y(s, 0) = y(s, \pi) = 0, \qquad s \in [t, T], \\ &y(t, \xi) = x(\xi). \end{aligned} \tag{5.19}$$

Remark 5.5. Let us consider the same problem as in Example 5.4 for an N-dimensional parabolic state equation, i.e., taking $X = L^2([0, \pi]^N)$ and $Ax = \Delta x$, with Dirichlet or Neumann boundary conditions. Then, Theorem 5.3 does not apply. In fact, we can show that $q(t) = t^{1-N/2} o(t)$ (see [7]) and (2.6) is not satisfied. However, if we consider the iterated Laplace operator $A_1 x = (-1)^{m-1}(-\Delta)^m x$, (with Dirichlet boundary conditions), we have $q(t) = t^{1-N/2m} O(t)$ and Theorem 5.3 applies if $N < 2m$.

Remark 5.6. Using Theorem 5.3 and the variational technique of [8] we can characterize the value functions of deterministic optimal control problems as limits, as $\varepsilon \downarrow 0$, of the mild solutions u_ε of (4.1). For example, consider the following problem.

Given $R > 0$, minimize

$$J(t, x; z) = \int_t^T \left[g(y(s; t, x, z)) + \frac{1}{2}|z(s)|^2\right] ds + \phi(y(T; t, x, z)) \tag{5.20}$$

over all controls $z \in L^2(t, T; X)$ satisfying $|z(s)| \leqq R$.

Here $y(\cdot\,; t, x, z)$ is the mild solution of the state equation

$$\begin{aligned} &y'(s) = Ay(s) + F(y(s)) + z(s), \qquad t \leqq s \leqq T, \\ &y(t) = x. \end{aligned}$$

Define the value function of problem (5.20) as

$$V(t, x) = \inf\{J(t, x; z) : z \in L^2(t, T; H), |z(s)| \leqq R\}.$$

Then, for all $(t, x) \in [0, T] \times H$, we can show that

$$|u_\varepsilon(T-t, x) - V(t, x)| \leqq T\omega_g(C\sqrt{\varepsilon}) + \omega_\phi(C\sqrt{\varepsilon}), \tag{5.21}$$

where ω_g (respectively, ω_ϕ) denotes a concave modulus of continuity for g (respectively, ϕ) and

$$C = \sqrt{q(T) - q(t)}\, e^{T\|F\|_1}.$$

CALMNESS AND EXACT PENALIZATION*

J. V. BURKE‡

Abstract. The notion of calmness, which was introduced by Clarke and Rockafellar for constrained optimization, is considered. An equivalence to the technique of exact penalization due to Eremin and Zangwill is established. It is then shown that *calmness* is satisfied on a dense subset of the domain of the optimal value function.

Key words. exact penalization, calmness, constrained optimization

AMS(MOS) subject classifications.49A42, 49D30, 49D37, 90D30

1. Introduction. The notion of calmness was originally formulated by Rockafellar and first appears in the literature of Clarke [3]. Since its appearance it has been recognized as a fundamental concept in optimization theory and consequently many variations on the original definition have been proposed and studied (e.g., see Rockafellar [6]). In general terms, calmness can be described as a basic regularity condition under which we can study the sensitivity properties of certain variational systems. On the other hand, the term "exact penalization" refers to a reduction principle in constrained optimization wherein we replace a constrained optimization problem by an unconstrained optimization problem whose objective is finite-valued on the domain of the original objective function and which under various conditions possesses a common local minimum. The particular reduction technique for exact penalization discussed herein originates in the papers of Eremin [4] and Zangwill [8] (also see Pietrzykowski [5]). We shall establish an equivalence between the notion of calmness and the viability of the Eremin–Zangwill exact penalization procedure for the constrained optimization problem

$$(\mathcal{P}) \qquad \begin{array}{l} \text{minimize } f(x) \\ \text{subject to } g(x) \in C, \end{array}$$

where f is a mapping from the normed linear space X into $\mathbb{R} \cup \{+\infty\}$, g is a mapping from X into the normed linear space Y, and C is a nonempty closed subset of Y. In order to make this statement precise we give the following definitions.

DEFINITION 1.1. Let f, g, X, Y, and C be as in the statement of $\mathcal{P}$ and consider the perturbed problems

$$(\mathcal{P}_u) \qquad \begin{array}{l} \text{minimize } f(x) \\ \text{subject to } g(x) \in C + u, \end{array}$$

where $u \in Y$. Let $\overline{x} \in X$ and $\overline{u} \in Y$ be such that

$$g(\overline{x}) \in C + \overline{u} \text{ and } \overline{x} \in \operatorname{dom}(f) := \{x \in X : f(x) < +\infty\}.$$

*Received by the editors September 8, 1989; accepted for publication (in revised form) March 26, 1990.

‡Department of Mathematics, GN–50, University of Washington, Seattle, Washington 98195. This work was supported in part by National Science Foundation grants DMS–8602399 and DMS–8803206 and by Air Force Office of Scientific Research grant ISSA-860080.

The problem $\mathcal{P}_{\overline{u}}$ is said to be *calm* at $\overline{x}$ if there are constants $\overline{\alpha} \geq 0$ and $\varepsilon > 0$ such that for every pair $(x, u) \in X \times Y$ with $\|x - \overline{x}\| \leqq \varepsilon$ and $g(x) \in C + u$, we have

$$f(x) + \overline{\alpha}\|u - \overline{u}\| \geq f(\overline{x}). \tag{1.1}$$

Here we use the notation $\|z\|$ for the norm of z. The constants $\overline{\alpha}$ and ε are called the *modulus* and *radius* of calmness for $\mathcal{P}_{\overline{u}}$ at $\overline{x}$, respectively.

Remarks. (1) Definition 1.1 varies from the definition given by Clarke [2, Def. 6.4.1] in that the variable u is not required to satisfy $\|u - \overline{u}\| \leq \varepsilon$ in order for inequality (1.1) to hold. In §2, we show that the restriction on the perturbation u is redundant.

(2) Observe that if $\mathcal{P}_{\overline{u}}$ is calm at $\overline{x}$, then $\overline{x}$ is necessarily a local solution to $\mathcal{P}_{\overline{u}}$.

DEFINITION 1.2. Let f be a mapping from the normed linear space X into $\mathbb{R} \cup \{+\infty\}$ and let S be a subset of X. Let $\varepsilon > 0$. We say that $\overline{x} \in S$ is an *ε-local minimum* of f on S if

$$f(\overline{x}) \leq f(x)$$

for all $x \in S$ with $x \in \overline{x} + \varepsilon\mathbb{B}$ where $\mathbb{B}$ is the closed unit ball in X, i.e., $\mathbb{B} := \{v \in X : \|v\| \leqq 1\}$, and $\overline{x} + \varepsilon\mathbb{B} := \{\overline{x} + \varepsilon v : v \in \mathbb{B}\}$.

The main result of this paper can now be stated.

THEOREM 1.1. *Let $\overline{x} \in X$ and $\overline{u} \in Y$ be such that*

$$g(\overline{x}) \in C + \overline{u} \text{ and } \overline{x} \in \operatorname{dom}(f).$$

Then $\mathcal{P}_{\overline{u}}$ is calm at $\overline{x}$ with modulus $\overline{\alpha}$ and radius ε if and only if $\overline{x}$ is an ε-local minimum of

$$P_{\overline{u},\overline{\alpha}}(x) := f(x) + \alpha \operatorname{dom}(g(x)|C + \overline{u}),$$

where we define

$$\operatorname{dist}(z|C + \overline{u}) := \inf\{\|y + \overline{u} - z\| : y \in C\}.$$

Proof. ($\Longrightarrow$) Let $\delta > 0$. Given $x \in \overline{x} + \varepsilon\mathbb{B}$, set $u_x := g(x) - y_x$, where $y_x \in C$ satisfies

$$\|y_x + \overline{u} - g(x)\| \leq \operatorname{dist}(g(x)|C + \overline{u}) + \delta.$$

Note that $g(x) \in C + u_x$ and

$$\|\overline{u} - u_x\| \leq \operatorname{dist}(g(x)|C + \overline{u}) + \delta.$$

Thus, if $\alpha \geq \overline{\alpha}$, we obtain from the calmness hypothesis that

$$\begin{aligned} f(\overline{x}) + \alpha \operatorname{dist}(g(\overline{x})|C + \overline{u}) &= f(\overline{x}) \\ &\leq f(x) + \alpha\|\overline{u} - u_x\| \\ &\leq f(x) + \alpha \operatorname{dist}(g(x)|C + \overline{u}) + \alpha\delta. \end{aligned}$$

Since $\delta > 0$ was chosen arbitrarily the implication is established.

($\Longleftarrow$) Let $u \in Y$ and $x \in \overline{x} + \varepsilon\mathbb{B}$ be such that $g(x) \in C + u$ and $x \in \operatorname{dom}(f)$. Then

$$\begin{aligned} f(\overline{x}) &\leqq f(x) + \overline{\alpha} \operatorname{dist}(g(x)|C + \overline{u}) \\ &= f(x) + \overline{\alpha} \inf\{\|y + \overline{u} - g(x)\| : y \in C\} \\ &\leq f(x) + \overline{\alpha} \inf\{\|y + u - g(x)\| + \|u - \overline{u}\| : y \in C\} \\ &= f(x) + \overline{\alpha} \operatorname{dist}(g(x)|C + u) + \overline{\alpha}\|u - \overline{u}\| \\ &= f(x) + \overline{\alpha}\|u - \overline{u}\|. \end{aligned}$$

Hence $\mathcal{P}_{\overline{u}}$ is calm at $\overline{x}$. □

Remark. The function $P_{u,\alpha}$ defined above is a familiar tool in the mathematical programming literature [2],[4],[5],[8]. For example, in the case where $X := \mathbb{R}^n$, $C := \mathbb{R}^m_- \subset \mathbb{R}^m =: Y$, and Y is endowed with the l_1 norm, we have

$$P_{u,\alpha}(x) = f(x) + \alpha \sum_{i=1}^{m} (g_i(x) - u_i)_+,$$

where g_i and u_i are the ith components of g and u, respectively, and $z_+ := \max\{0, z\}$ for every $z \in \mathbb{R}$.

In the case where Y is finite-dimensional and $g(x)$ is Lipschitz continuous, Clarke [2, Prop. 6.4.3] has shown that the calmness of $\mathcal{P}_{\overline{u}}$ at $\overline{x}$ implies the existence of a constant $\overline{m} > 0$ such that $\overline{x}$ is a local minimum for the function $P_{\overline{u},m}(x)$ for all $m \geqq \overline{m}$. However Clarke's result does not reveal the full extent of the relationship between calmness and exact penalization. In particular, it does not describe the relationship between the parameters $\overline{m}$ and $\overline{\alpha}$ as given in Theorem 1.1.

As previously stated calmness is an important tool in the sensitivity analysis for $\mathcal{P}$. In this regard Theorem 1.1 can be used to study the sensitivity of $\mathcal{P}_u$ to changes in u and to establish multiplier rules for $\mathcal{P}$. These results and others are pursued in Burke [1]. In the remainder of this note we briefly explore two topics directly related to the definitions of calmness and exact penalization as they are employed in Theorem 1.1. In §2 we compare Definition 1.1 to the definition for calmness used by Clarke in [2, Def. 6.4.1]. We conclude in §3 by providing a result that is in the spirit of Clarke's generic calmness result [2, Prop. 6.4.5] indicating the robustness of the notion of calmness.

2. Another formulation of calmness. According to Clarke [2, Def. 6.4.1] in order for $\mathcal{P}_{\overline{u}}$ to be calm at $\overline{x}$ we require that inequality (1.1) be satisfied whenever $\|x - \overline{x}\| \leqq \varepsilon$ and $\|u - \overline{u}\| \leqq \varepsilon$. In the next proposition we show that if g is continuous at $\overline{x}$, then no advantage gained by placing this further restriction on the choice of perturbation u.

PROPOSITION 2.1. *Let f, g, C, X, and Y be as in the statement of problem $\mathcal{P}$. Let $(\overline{x}, \overline{u}) \in X \times Y$ be such that g is continuous at $\overline{x}$ and $g(\overline{x}) \in C + \overline{u}$. If there is an $\overline{\alpha} > 0$ and an $\varepsilon > 0$ such that*

$$f(x) + \overline{\alpha}\|u - \overline{u}\| \geq f(\overline{x})$$

for every pair $(x, u) \in X \times Y$ with $\|u - \overline{u}\| \leq \varepsilon$, $\|x - \overline{x}\| \leq \varepsilon$, and $g(x) \in C + u$, then there is an $\hat{\varepsilon}$ with $0 < \hat{\varepsilon} \leq \varepsilon$ such that $\overline{x}$ is an $\hat{\varepsilon}$-local minimum of $P_{\overline{u},\overline{\alpha}}(x)$, and consequently, $\mathcal{P}_{\overline{u}}$ is calm at $\overline{x}$ with modulus $\overline{\alpha}$ and radius $\hat{\varepsilon}$.

Proof. Let $\delta \in (0, \frac{1}{2})$ and $\alpha \geq \overline{\alpha}$. Since the function $\varphi(x) := \mathrm{dist}(g(x)|C + \overline{u})$ is continuous at $\overline{x}$, there is an $\hat{\varepsilon} \in (0, \varepsilon]$ such that $0 \leq \varphi(x) \leq \frac{\varepsilon}{2}$ whenever $\|x - \overline{x}\| \leq \hat{\varepsilon}$. Now given $x \in \overline{x} + \hat{\varepsilon}\mathbb{B}$, set $u_x := g(x) - y_x$ where $y_x \in C$ satisfies

$$\|y_x + \overline{u} - g(x)\| \leq \mathrm{dist}(g(x)|C) + \delta\varepsilon.$$

Then $g(x) \in C + u_x$ and $\|u_x - \overline{u}\| \leq \varepsilon$. Hence, by hypothesis,

$$\begin{aligned} \mathcal{P}_{\overline{u},\alpha}(\overline{x}) &= f(\overline{x}) \\ &\leq f(x) + \alpha\|u_x - \overline{u}\| \\ &\leq f(x) + \alpha \ \mathrm{dist}(g(x)|C) + \alpha\delta\varepsilon. \end{aligned}$$

Taking the limit as $\delta \downarrow 0$ yields the result. □

Calmness can also be defined independent of the existence of a solution to $\mathcal{P}_u$. This is done by considering the value function for $\mathcal{P}_u$, $V : X \to \mathbb{R} \cup \{\pm\infty\}$, given by

$$V(u) := \inf\{f(x) : g(x) \in C + u\}$$

if $\{x : g(x) \in C + u\} \neq \emptyset$ and $+\infty$ otherwise. $\mathcal{P}_u$ is then said to be calm at $\overline{u}$ if

$$\liminf_{u \to \overline{u}} \frac{V(u) - V(\overline{u})}{\|u - \overline{u}\|} > -\infty. \tag{2.1}$$

In this connection we have the following straightforward extension to Clarke [2, Prop. 6.4.2].

PROPOSITION 2.2. *Let $f, g.C, X$, and Y be as in the statement of $\mathcal{P}$, and let $\overline{u} \in Y$. If* (2.1) *holds at $\overline{u}$, then for any solution $\overline{x}$ to $\mathcal{P}_{\overline{u}}, \mathcal{P}_{\overline{u}}$ is calm at $\overline{x}$.*

3. Calmness is a dense property in finite dimensions. In the case where P_u has the representation

$$\begin{array}{ll} \text{minimize} & f_0(x) \\ \text{subject to} & f_i(x) \le u_i, \ i = 1, \cdots, m \\ & \text{and } x \in D, \end{array}$$

where $f_i : \mathbb{R}^n \to \mathbb{R}$ is locally Lipschitz for each $i = 0, 1, \cdots, m$ and $D \subset \mathbb{R}^n$ is a nonempty closed set, we can employ the results of Clarke [2, §6.4] to show that if $\mathcal{P}_u$ has a finite value for every u near some $\overline{u} \in \mathbb{R}^m$, then for almost every u near $\overline{u}$ (in the sense of Lebesgue measure) $\mathcal{P}_u$ is calm at u. In the spirit of this result we give the following proposition.

PROPOSITION 3.1. *Let f, g, C, X, and Y be as in $\mathcal{P}$. Furthermore, assume that Y is finite-dimensional, f is lower semicontinuous, and g is continuous. If $\overline{u} \in Y$ and $\gamma > 0$ are such that V is bounded on $\overline{u} + \gamma\mathbb{B}$, then $\mathcal{P}_u$ is calm on a dense subset of $\overline{u} + \gamma\mathbb{B}$.*

Proof. With no loss in generality we assume that $\overline{u} = 0$. Let $u \in Y$ be an element of the interior of $\gamma\mathbb{B}$ and $\varepsilon > 0$. We must show that there is a $u_0 \in u + \varepsilon\mathbb{B}$ such that $\mathcal{P}_{u_0}$ is calm. Define $\theta : [0, \gamma - \|u\|] \to \mathbb{R}$ by

$$\theta(\rho) := \inf\{f(x) : g(x) \in C + u + \rho\mathbb{B}\}.$$

The boundedness of $\theta(\rho)$ on $[0, \gamma - \|u\|]$ follows from that of V on $\gamma\mathbb{B}$. Since θ is nonincreasing on $[0, \gamma - \|u\|]$, θ is differentiable at almost every $\rho \in [0, \gamma - \|u\|]$ (in the sense of Lebesgue measure) by Ward [7]. Let ρ_0 be a point of differentiability for θ such that $0 < \rho_0 < \min\{\varepsilon, \gamma - \|u\|\}$. From the definition of θ there is for each $n \in \{1, 2, \cdots\}$ a $u_n \in u + \rho_0\mathbb{B}$ such that

$$V(u_n) - \frac{1}{n} \le \theta(\rho_0). \tag{3.1}$$

Let u_0 be a cluster point of the sequence $\{u_n\}$. Now since f is lower semi continuous and g is continuous, we have that V is also lower semicontinuous, hence, by (3.1), it must be that $V(u_0) = \theta(\rho_0)$. We now show that $\mathcal{P}_u$ is calm at u_0.

Since θ is differentiable at ρ_0, there is a $\delta \in (0, \gamma - \|u\| - \rho_0)$ and an $\alpha > 0$ such that

$$\theta(\rho) - \theta(\rho_0) \ge -\alpha|\rho - \rho_0|$$

whenever $|\rho - \rho_0| < \delta$. Let $\varepsilon_0 \in (0, \min\{\delta, \min\{\varepsilon, \gamma - \|u\|\} - \rho_0\})$, and let $w \in u_0 + \varepsilon_0\mathbb{B}$. Then

$$\begin{aligned} V(w) - V(u_0) &\geqq \theta(\|u - w\|) - \theta(\rho_0) \\ &\geqq -\alpha|\ \|u - w\| - \rho_0|. \end{aligned} \tag{3.2}$$

Now if $\|u - w\| \leq \rho_0$, then $\theta(\|u - w\|) \geq \theta(\rho_0)$ so that

$$V(w) - V(u_0) \geq 0 \geq -\alpha\|w - u_0\|.$$

On the other hand, if $\|u - w\| \geq \rho_0$, then

$$|\ \|u - w\| - \rho_0| \leq \|w - u_0\|,$$

and hence

$$V(w) - V(u_0) \geq -\alpha\|w - u_0\|$$

by (3.2). Therefore

$$V(w) + \alpha\|w - u_0\| \geq V(u_0)$$

for all $w \in u_0 + \varepsilon_0\mathbb{B}$. Consequently, $\mathcal{P}_u$ is calm at u_0. □

The conclusion of Proposition 3.1 is weaker than that of Clarke [2, §6.4] since we do not show that $\mathcal{P}_u$ is calm for almost all u near $\overline{u}$. On the other hand, our result is valid for more general constraints than those considered by Clarke.

Acknowledgment. Just before the final version of this article was sent to the Publisher, we became aware of an important reference on this topic. The reference is Thibault [9]. In this thesis, Thibault establishes certain equivalences between the notions of calmness and exact penalization. These results, although similar to our own, are somewhat different. The results of Thibault are complementary to those presented in this paper.

ERRATUM:

Controllability of Nonlinear Discrete-Time Systems: A Lie-Algebraic Approach*

BRONISLAW JAKUBCZYK† AND EDUARDO D. SONTAG‡

As stated, Corollary 5.3 is false. The indices are missing in the statement. The correct version is as follows.

COROLLARY 5.3. *If an analytic system with connected* $\mathbb{U}$ *is forward accessible from* x *in* k *steps* (*that is,* $\operatorname{int} A_k^+(x) \neq \emptyset$), *then*

$$\dim L_k^-(y) = n \quad \textit{for any } y \in A_k^+(x).$$

Similarly, if it is backward accessible from x *in* k *steps, then*

$$\dim L_k^+(y) = n \quad \textit{for any } y \in A_k^-(x).$$

Proof. The first statement follows directly from the first inclusion in Proposition 5.2 and the inclusion

$$\bigcup_{k>1} \mathrm{Orb}_{\Delta_k^+}(x) \subset \mathrm{Orb}_L(x).$$

The second statement follows analogously. □

A NUMERICAL ALGORITHM FOR OPTIMAL FEEDBACK GAINS IN HIGH DIMENSIONAL LINEAR QUADRATIC REGULATOR PROBLEMS*

H. T. BANKS† AND K. ITO†

Abstract. A hybrid method for computing the feedback gains in linear quadratic regulator problems is proposed. The method, which combines use of a Chandrasekhar type system with an iteration of the Newton–Kleinman form with variable acceleration parameter Smith schemes, is formulated to efficiently compute directly the feedback gains rather than solutions of an associated Riccati equation. The hybrid method is particularly appropirate when used with large dimensional systems such as those arising in approximating infinite-dimensional (distributed parameter) control systems (e.g., those governed by delay-differential and partial differential equations). Computational advantages of the proposed algorithm over the standard eigenvector (Potter, Laub–Schur) based techniques are discussed, and numerical evidence of the efficacy of these ideas is presented.

Key words. linear quadratic regulator (LQR) problems, feedback gains, distributed parameter systems, computational algorithm, Chandrasekhar system, Newton–Kleinman scheme, Smith method

AMS(MOS) subject classifications. 65H10, 93B40, 93C20

1. Introduction. A great deal of effort in recent years in control of distributed systems has focused on approximation techniques (for example, see [1]-[6], [8], [11]-[14], [16], [18], [21], [22], [24], [26], [32]) to reduce inherently infinite-dimensional problems to (large) finite-dimensional analogues. Relatively little attention has been given to the development of efficient computational methods for the resulting large but finite-dimensional control problems. In this paper we consider such questions for one classical formulation of the feedback control problem, the well-known linear quadratic regulator (LQR) problem.

There are several approaches we can take in such an endeavor. With the emergence of new computer architectures (vector and parallel), one exciting possibility involves the development of new algorithms to be used with nonsequential computers. While we are currently investigating ideas in this direction , our presentation here reports on some of our efforts to develop better algorithms for use with conventional serial computers.

As is well known, the LQR problem can be reduced to the solution of a matrix Riccati equation in order to construct the feedback gain matrix. The most widely available method for solution of the Riccati equation is the Potter method [30], which is based on obtaining the eigenvectors and eigenvalues of an associated $2n \times 2n$ Hamiltonian system when the underlying dynamical control system is of dimension n. A related, but improved, version involving computation of Schur vectors for the system was proposed by Laub in [27]. While both of these "eigenvector" methods can be used satisfactorily (for a discussion of real advantages offered by the Laub–Schur approach over Potter's method, see [27]) for systems with n relatively small, say

$n < 100$, the computational effort (and time) grows like $n^3$and becomes prohibitive for large systems. More recently, the idea of using Chandrasekhar systems ([9], [20], [33, p. 304–310], [36]) when the number of states is large compared to the number of control inputs (exactly the situation in a number of cases where one approximates a distributed system) has been suggested by a number of authors [33, p. 309], [7], [8], [17], [31]. However, as we shall discuss below, there can be numerical difficulties in using the Chandrasekhar approach. On the other hand, it is known that iterative methods such as the Newton algorithm as formulated by Kleinman in [23] can be quite efficiently implemented (even for some large systems) if good initial estimates are provided and if we can efficiently solve the resulting Lyapunov equations. In this presentation, we discuss the formulation and numerical testing of a hybrid method that represents an attempt to combine the good features of the Chandrasekhar approach (growth like n in computational effort) with those of the Newton–Kleinman (quadratic convergence when good initial estimates are provided) along with innovative use of the Smith algorithm for solution of Lyapunov equations.

We expect these ideas to be quite useful in design of control laws for some of the models currently being investigated in connection with large flexible structures as well as in some of the population dispersal and control studies that we are currently pursuing with biologists and ecologists. Some of the large flexible structures involve rather sophisticated distributed parameter models (e.g., see [4], [34]), especially when we wish to include complicated damping mechanisms involving time or spatially related hysteresis [6], [34] or nonlinear effects [19]. For such models, the computational tasks can be rather demanding whether one is carrying out parameter identification [3] or feedback control calculations with traditional eigenvector based methods (the authors of [6] have indicated experiences with runs requiring nine hours of VAX time when using the Potter method for an approximation system with dimension equivalent to $n = 238$).

Our intention is to introduce a problem-oriented algorithm that can be used for large-scale but structured problems within a conventional computational capability rather than to develop a general purpose method for solutions of LQR problems. More precisely, we are interested in computing solutions of the approximating LQR problems for systems governed by partial differential equations. In such a case the dimension n of the states tends to be large while the dimension m of the inputs is fixed under approximation, and moreover the resulting system matrices (A, B) are, in general, sparse. Our hybrid method can be most efficiently carried out for such cases. Of course, this does not imply that our algorithm does not work for general problems, but it simply may not be efficient in some situations.

For our presentation, we assume that one has used his or her favorite approximation scheme (finite-elements, spline, spectral, etc.) to reduce the problems of interest to an LQR problem with a finite-dimensional system. More precisely, throughout our discussions we consider the following LQR problem: minimize the cost functional

$$J(u) = \int_0^\infty \{|Cx(t)|^2 + |u(t)|^2\}\, dt \tag{1.1}$$

subject to the state dynamics

$$\dot{x}(t) = Ax(t) + Bu(t), \qquad x(0) = x_0.$$

Here $A \in R^{n\times n}$, $B \in R^{n\times m}$, and $C \in R^{p\times n}$. (We have, without loss of generality, for our discussions here normalized our problem so that the control term in the cost functional (1.1) appears with a weighting matrix I.) We will assume that (A, B) is stabilizable and (C, A) is detectable [25], [38]. Then the optimal feedback control for the LQR problem involving (1.1) is given by

$$u(t) = -B^T Px(t),$$

where P is the unique nonnegative symmetric solution of the algebraic Riccati equation

$$A^T P + PA - PBB^T P + C^T C = 0. \tag{1.2}$$

In this paper we propose an algorithm which leads to direct calculation of the feedback gain matrix $K = B^T P$ without computation of P. In addition to providing substantial savings in computational time over eigenvector methods, our algorithm requires much less storage and can easily be implemented to take advantage of special structures (e.g., sparsity) in the system matrix A.

To outline the steps in our algorithms, we first recall that the optimal feedback gain K is given by the limit $K = \lim K(t)$ as $t \to -\infty$ of solutions of the Chandrasekhar system [9], [20]

$$\begin{aligned} \dot{K}(t) &= -B^T L^T(t) L(t), \qquad K(0) = 0, \\ \dot{L}(t) &= -L(t)(A - BK(t)), \qquad L(0) = C, \end{aligned} \tag{1.3}$$

where $K \in R^{m \times n}$ and $L \in R^{p \times n}$. In fact (see [20], [37]) $P = \lim \int_t^0 L^T(s) L(s)\, ds$ as $t \to -\infty$. The first step in the proposed hybrid algorithm involves a numerical integration of (1.3) backward in time on an appropriate interval $[-t_f, 0]$. For the second step, the value $K(-t_f)$ obtained through this numerical integration of the Chandrasekhar system is then refined by use of the Newton–Kleinman algorithm [23], if we use $K(-t_f)$ as an initial value K_0 for the Newton method.

To motivate our effort in these two steps, we note that the convergence $K(t) \to K$ as $t \to -\infty$ can be very slow when the eigenvalues of $A - BK$ lie close to the imaginary axis. Moreover, $L = 0$, K_∞ arbitrary are solutions in the asymptotic limit sense to (1.3). That is, if we denote by $f(K, L)$ the right side of system (1.3), then K_∞ arbitrary and $L = 0$ are solutions of $f(K_\infty, L) = 0$. Hence $K(t) \to K_\infty$, $L(t) \to 0$ as $t \to -\infty$ does not, in general, have a unique limit *numerically*. Thus, as is pointed out in [33, p. 316–318], if we are to use the Chandrasekhar approach alone, we need a very accurate numerical solver for (1.3). This can be quite expensive computationally if we are dealing with a large system and/or a stiff system. Hence, we propose to use a second order semi-implicit scheme (described in § 2) for the Chandrasekhar component of our algorithm and take the resulting numerical solution $K(-t_f)$ as a start-up value for the Newton iterations. If this estimate from the Chandrasekhar step is a sufficiently good initial guess, then we can expect to meet the Newton–Kleinman requirements that $A - BK_0$ be a stability matrix and to obtain quadratic convergence in this second component of the algorithm. Thus, the role of the Chandrasekhar step is to provide a good start-up value for the Newton–Kleinman method, not to produce a very accurate solution.

The first step of our hybrid method requires the solution of $n(m+p)$ simultaneous equations, while each iteration of the usual Newton–Kleinman step requires the solution of a Lyapunov equation for the $n \times n$ symmetric estimates of P. However, as we will see below, we can use factorization ideas [20] and the Smith method [35] for Lyapunov equations to reformulate the Newton–Kleinman method as a direct iterative method for the $m \times n$ gain K, thereby providing additional computational advantages. To speed up our calculations and improve convergence in the Smith algorithm, we propose a variable stepsize Smith method to solve the Lyapunov equations as described in § 4 below. In § 2 we outline a numerical scheme for the Chandrasekhar system, while the reformulated Newton-Kleinman iterative procedure to compute directly the gain K is detailed in § 3. Finally, in § 5, we further discuss some advantages and disadvantages of the proposed algorithm and, to illustrate the feasibility of our hybrid approach, report on our experience with two of the several numerical examples on which we have tested the method.

2. Numerical solution of the Chandrasekhar system. We return to consider more closely the Chandrasekhar system

$$\dot{K}(t) = -B^T L^T(t) L(t), \qquad K(0) = 0, \tag{2.1}$$

$$\dot{L}(t) = -L(t)(A - BK(t)), \qquad L(0) = C, \tag{2.2}$$

where $A \in R^{n\times n}$, L, $C \in R^{p\times n}$, and K, $B^T \in R^{m\times n}$. We first observe that the second equation (2.2) is linear in L. In cases where A arises from a discretization or approximation of partial differential equations, equation (2.2) tends to be a stiff system and thus it is advisable to use an implicit numerical scheme. Here we propose the second order Adams-Moulton algorithm [10, p. 235]. A second observation is that the right-hand side of equation (2.1) is independent of K and thus an explicit scheme is appropriate; we propose the second order Adams-Bashforth algorithm [10, p. 226].

These observations leads us to propose the following algorithm for the Chandrasekhar system (2.1), (2.2): Given a step size $h > 0$, approximations K_i and L_i to $K(-ih)$ and $L(-ih)$ are generated by

$$K^{(0)}_{i+1} = K_i + h(\tfrac{3}{2} B^T L_i^T L_i - \tfrac{1}{2} B^T L_{i-1}^T L_{i-1}), \tag{2.3}$$

$$K^{(0)}_{i+1/2} = (K^{(0)}_{i+1} + K_i)/2, \tag{2.4}$$

$$L_{i+1} = L_i + \frac{h}{2}(L_{i+1} + L_i)(A - BK^{(0)}_{i+1/2}), \tag{2.5}$$

$$K_{i+1} = K_i + \frac{h}{2}(B^T L_{i+1}^T L_{i+1} + B^T L_i^T L_i), \tag{2.6}$$

where $K_0 = 0$ and $L_{-1} = L_0 = C$.

Several remarks may be useful at this point.

Remark 1. The stiffness of the matrix A dictates the choice of stepsize h.

Remark 2. Subtraction of the expression in (2.3) from that in (2.6) yields that the predicted values $K^{(0)}_{i+1}$ and the corrected values K_{i+1} satisfy

$$K_{i+1} - K^{(0)}_{i+1} = \frac{h}{2} B^T (L_{i+1}^T L_{i+1} - 2L_i^T L_i + L_{i-1}^T L_{i-1}) \approx \frac{h}{2} B^T \frac{d^2}{dt^2}(L^T L)$$

and this relationship can be used for stepsize refinement, i.e., to give local bounds depending on stepsize which can be used in error control.

Remark 3. The formula (2.5) can be rewritten as

$$\begin{aligned} L_{i+1} &= L_i\left(I + \frac{h}{2}A_i\right)\left(I - \frac{h}{2}A_i\right)^{-1} \\ &= 2L_i\left(I - \frac{h}{2}A_i\right)^{-1} - L_i, \end{aligned} \tag{2.7}$$

where $A_i \equiv A - BK^{(0)}_{i+1/2}$. Defining $H = I - (h/2)A$ we have that $I - (h/2)A_i = H + (h/2)BK^{(0)}_{i+1/2}$ where $B \in R^{n\times m}$ and $K^{(0)}_{i+1/2} \in R^{m\times n}$. Thus by the Sherman-Morrison-Woodbury formula [29, p. 50] (used frequently when updating an $n \times n$ matrix by rank

m matrices)

$$\left(I-\frac{h}{2}A_i\right)^{-1}=H^{-1}-\frac{h}{2}H^{-1}B\left(I+\frac{h}{2}K_{i+1/2}^{(0)}H^{-1}B\right)^{-1}K_{i+1/2}^{(0)}H^{-1}, \tag{2.8}$$

where $I+(h/2)K_{i+1/2}^{(0)}H^{-1}B\in R^{m\times m}$. The matrix $K_{i+1/2}^{(0)}H^{-1}$ in (2.8) can be computed by

$$\begin{aligned} K_{i+1/2}^{(0)}H^{-1}&=K_iH^{-1}+\frac{h}{2}\left(\frac{3}{2}B^TL_i^TL_iH^{-1}-\frac{1}{2}B^TL_{i-1}^TL_{i-1}H^{-1}\right),\\ K_{i+1}H^{-1}&=K_iH^{-1}+\frac{h}{2}(B^TL_{1+i}^TL_{1+i}H^{-1}+B^TL_i^TL_iH^{-1}). \end{aligned} \tag{2.9}$$

Hence we see from (2.7)-(2.9) that the step (2.5) only involves the operation L_iH^{-1} plus inversion of an $m\times m$ matrix $I+K_{i+1/2}^{(0)}H^{-1}B$. Thus the step (2.5) can be reformulated so that it requires only an $m\times m$ matrix inversion plus matrix-vector multiplications if the LU decomposition of $H=I-(h/2)A$ is computed a priori. This procedure can be most advantageous computationally when m and p are small compared to n.

Remark 4. For some problems we might wish to use a completely implicit scheme in place of (2.3)-(2.6) to enhance stability and reduce sensitivity to step size choice. Then we might consider iterations $K_{i+1}^{(j)}$, $L_{i+1}^{(j)}$ generated by

$$\begin{aligned} L_{i+1}^{(j)}&=L_i+\frac{h}{2}(L_{i+1}^{(j)}+L_i)(A-BK_{i+1/2}^{(j-1)}),\\ K_{i+1}^{(j)}&=K_i+\frac{h}{2}(B^TL_{i+1}^{(j)}L_{i+1}^{(j)}+B^TL_i^TL_i),\\ K_{i+1/2}^{(j)}&=(K_{i+1}^{(j)}+K_i)/2 \end{aligned} \tag{2.10}$$

and thus produce iterates with limits (as $j\to\infty$)K_{i+1}, L_{i+1} satisfying

$$\begin{aligned} L_{i+1}&=L_i+\frac{h}{2}(L_{i+1}+L_i)(A-B(K_{i+1}+K_i)/2),\\ K_{i+1}&=K_i+\frac{h}{2}(B^TL_{i+1}^TL_{i+1}+B^TL_i^TL_i). \end{aligned} \tag{2.11}$$

3. An iterative method for computing the optimal feedback gain K. A widely used iterative method for finding the nonnegative solution of the algebraic Riccati equation (1.2) is Newton's method as modified by Kleinman [23]. We show that this method can be reformulated so that, when combined with a factored form of the well-known Smith method [35], we can compute directly a sequence of iterates K_i for the feedback gain K.

First we recall the Newton iterative algorithm as formulated by Kleinman:

(1) Choose a gain matrix K_0 so that $A-BK_0$ is stability matrix (i.e., Re $\lambda<0$ for all eigenvalues of $A-BK_0$);

(2) Update K_i by $K_{i+1}=B^TP_i$ where P_i is the solution of the Lyapunov equation

$$(A-BK_i)^TP_i+P_i(A-BK_i)+K_i^TK_i+C^TC=0.$$

It has been shown in [23] that $0\leqq P_{i+1}\leqq P_i$ for any i, and $P=\lim P_i$ where the convergence is quadratic. This algorithm can be viewed as an iterative method for the gain K, i.e., $K=\lim K_i$ where $K_{i+1}=F(K_i)$ with $F(K)=B^TP$ and P is the solution of the Lyapunov equation

$$(A-BK)^TP+P(A-BK)+K^TK+C^TC=0. \tag{3.1}$$

Thus, in order to calculate $F(K)$ we must solve the Lyapunov equation (3.1) for the symmetric matrix P. However, we can form an alternative version that allows us to directly calculate $F(K)$ using the Smith method for a Lyapunov equation in X of the form

$$S^TX+XS+D^TD=0, \tag{3.2}$$

where $S\in R^{n\times n}$ is a stability matrix and $D\in R^{p\times n}$.

To this end, we replace step (2) in the Newton–Kleinman method by the following:

(2′) For $i\geqq 1$, update K_i by $K_{i+1}=K_i-B^TZ_i$ where $Z_i=P_{i-1}-P_i$ is the solution of the Lyapunov equation

$$(A-BK_i)^TZ_i+Z_i(A-BK_i)+D_i^TD_i=0 \tag{3.3}$$

with $D_i\equiv K_i-K_{i-1}$.

The method with (2′) offers several advantages over that using (2). The Lyapunov equation in (2′) has fewer inhomogeneous terms than does the one in (2) and the term D_i has rank m which depends only on the number of inputs (controls) to the system. In the proposed modified Smith method described below, we are able to compute directly the $m\times n$ update matrix $J^i=B^TZ_i$ without computing Z_i (see (3.12) below). Since $Z_i\to 0$ as $i\to\infty$ is expected, choosing the start-up value $J_0^i=0$ in the factored Smith algorithm (where $J^i=B^TZ_i$ is computed as the limit as $k\to\infty$ of a sequence J_k^i) is a natural as well as convenient choice.

Note that the step (2′) requires that we have $Z_1=P_0-P_1$ in hand and hence we must start this procedure with P_0, P_1 (and K_0, K_1) given whereas (2) requires only that we start with K_0 given. Then K_1 is computed by $K_1=B^TP_0$ with P_0 the solution of

$$(A-BK_0)^TP_0+P_0(A-BK_0)+K_0^TK_0+C^TC=0.$$

Since our Smith algorithm below is formulated to solve Lyapunov equations of the form (3.2), we can, to maintain this form, initially solve the equation twice. That is, if we solve for $\tilde{Z}_0$ the solution of

$$(A-BK_0)^T\tilde{Z}_0+\tilde{Z}_0(A-BK_0)+K_0^TK_0=0 \tag{3.4}$$

and for $\hat{Z}_0$ the solution of

$$(A-BK_0)^T\hat{Z}_0+\hat{Z}_0(A-BK_0)+C^TC=0, \tag{3.5}$$

then we can obtain K_1 by $K_1=B^T\tilde{Z}_0+B^TZ_0$. Since the Smith method as formulated here actually returns B^TX where X is the solution to (3.2), we thus will use this Smith algorithm twice (with $S=A-BK_0$), once with $D^TD=K_0^TK_0$, once with $D^TD=C^TC$, and then simply add the solutions to obtain K_1.

We turn next to the desired factored form of the Smith method as applied to equation (3.2). Let X_0 be an arbitrary $n\times n$ symmetric matrix and let a sequence $\{X_k\}$ of $n\times n$ symmetric matrices be generated by

$$X_{k+1}=U_r^TX_kU_r+Y_r, \tag{3.6}$$

where r is a positive constant (the Smith stepsize) and

$$U_r=(I-rS)^{-1}(I+rS), \tag{3.7}$$

$$Y_r=2r(I-rS^T)^{-1}D^TD(I-rS)^{-1}. \tag{3.8}$$

Then we can argue [33] that $\{X_k\}$ converges to X, the solution of (3.2). The method and its analysis is based on the observation that for any positive constant r, the equation (3.2) is equivalent to

$$X = U_r^T X U_r + Y_r$$

which can be used to define a contraction map in the obvious manner [33].

We modify this standard formulation of the Smith method to suit our particular needs here (computing $B^T X$ instead of X). From (3.6) we have

$$X_{k+1} - X_k = U_r^T (X_k - X_{k-1}) U_r, \ k \geqq 1.$$

Hence, if $X_k - X_{k-1} = M_k^T M_k$ (i.e., if we have a factorable difference), then

$$X_{k+1} - X_k = U_r^T M_k^T M_k U_r = (M_k U_r)^T (M_k U_r).$$

If the start-up value X_0 is zero, then we can write

$$X_1 - X_0 = 2r M_1^T M_1, \qquad M_1 \equiv D(I - rS)^{-1}. \tag{3.9}$$

By induction on k, (3.6) is then equivalent to

$$M_{k+1} = M_k U_r, \tag{3.10}$$

$$X_{k+1} = X_k + 2r M_{k+1}^T M_{k+1}. \tag{3.11}$$

In this manner $B^T X$ can be obtained as the limit of $J_k = B^T X_k$ where J_k is generated by

$$J_{k+1} = J_k + 2r B^T M_{k+1}^T M_{k+1}.$$

Thus, the update step (2′) is carried out by the following Smith algorithm:

(3.12) (i) Set $S_i = A - BK_i$ and $D = K_i - K_{i-1}$;

(3.12) (ii) Choose a positive constant r and form U_r and M_1 by (3.7) and (3.9) with $S = S_i$; put $J_0 = 0$ and $J_1 = J_0 + 2r B^T M_1^T M_1$;

(3.12) (iii) Iterate for $k = 1, 2, \cdots$, on

$$M_{k+1} = M_k U_r,$$

$$J_{k+1} = J_k + 2r B^T M_{k+1}^T M_{k+1}.$$

In summary, we have described in this section a Newton–Kleinman scheme combined with the Smith method for the resulting Lyapunov equation at each step in the Newton–Kleinman. We have reformulated the Newton–Kleinman iteration and factored the Smith algorithm so as to result in algebraic savings in computing directly the gain estimates K_i.

4. The Smith method and variable stepsize. As is well known, the rate of convergence in the Smith method discussed in the last section depends upon the choice of the acceleration or step parameter. (See [33, p. 291–297] for several discussions. Note that our parameter r is the negative reciprocal of the parameter in Russell's discussions.) To increase speed in convergence, we may employ the accelerated Smith method [33], [35] which can yield quadratic convergence as compared to the linear convergence obtained with (3.6). However, unlike (3.6), the accelerated Smith method is not self-correcting [33] and here we propose to speed up convergence in an alternative way which has proved both reliable and efficient in some of our numerical tests. Specifically, we propose to use a succession of acceleration parameter values r_i (much in the spirit of other well-known iterative methods such as alternating directions [15], [28]) to accelerate convergence in the basic Smith method. Our formulation of this "variable stepsize" Smith method is based upon the observation that for fixed $r>0$ and $k\geqq 1$, the Smith algorithm can be written as

$$S^TX_k+X_kS+D^TD=E_k,\qquad E_k\equiv(I+rS)^TM_k^TM_k(I+rS), \tag{4.1}$$

where M_k is defined by (3.9) and (3.10). To see this, we note that from (3.6) we have

$$(I-rS)^TX_k(I-rS)=(I+rS)^TX_{k-1}(I+rS)+2rD^TD$$

or

$$\begin{aligned}(I+rS^T)X_k(I+rS)-(I-rS)^TX_k(I-rS)+2rD^TD\\ =(I+rS)^T(X_k-X_{k-1})(I+rS).\end{aligned}$$

Hence, from (3.11) we obtain

$$2r(S^TX_k+X_kS+D^TD)=2r(I+rS)^TM_k^TM_k(I+rS),$$

which implies (4.1). Moreover, from (3.9) and (3.10) we have

$$E_k=(U_r^T)^kD^TD(U_r)^k,\qquad k\geqq 1. \tag{4.2}$$

Thus, if we use the iteration (3.6) with acceleration parameter r_1 for k_1 iterates, we obtain an iterate $X^{(1)}$ and equation error $E^{(1)}$ satisfying

$$S^TX^{(1)}+X^{(1)}S+D^TD=E^{(1)},\qquad E^{(1)}=(U_{r_1}^T)^{k_1}D^TD(U_{r_1})^{k_1}. \tag{4.3}$$

Let us define the difference $\Sigma^{(1)}=X-X^{(1)}$ where X is the sought-after solution of (3.2). Then it is readily seen that $\Sigma^{(1)}$ satisfies a Lyapunov equation similar to that of (3.2):

$$S^T\Sigma+\Sigma S+E^{(1)}=0. \tag{4.4}$$

If we next apply the iteration (3.6) k_2 times with acceleration parameter r_2 to the residual equation (4.4) we obtain

$$S^TX^{(2)}+X^{(2)}S+E^{(1)}=E^{(2)}, \tag{4.5}$$

where $X^{(2)}$ is the final iterate using r_2 and the equation error $E^{(2)}$ is given by

$$E^{(2)}=(U_{r_2}^T)^{k_2}E^{(1)}(U_{r_2})^{k_2}.$$

If we proceed to define the difference $\Sigma^{(2)}=X-(X^{(1)}+X^{(2)})$, then from (4.4) and (4.5) we see that $\Sigma^{(2)}$ satisfies a Lyapunov equation

$$S^T\Sigma+\Sigma S+E^{(2)}=0.$$

We continue this procedure, using a sequence of acceleration values $\{r_i\}$ along with corresponding iteration counts $\{k_i\}$ to produce a sequence $\{X^{(i)}\}$ of nonnegative, symmetric matrices. For $i\geqq 1$, we have

$$S^TX^{(i)}+X^{(i)}S+E^{(i-1)}=E^{(i)}, \tag{4.6}$$

$$E^{(i)}=(U_{r_i}^T)^{k_i}E^{(i-1)}(U_{r_i})^{k_i},\qquad E^{(0)}\equiv D^TD. \tag{4.7}$$

Thus, if $\bar{X}_j\equiv\sum_{i=1}^{j}X^{(i)}$, then $\bar{X}_j$ satisfies

$$S^T\bar{X}_j+\bar{X}_jS+D^TD=E^{(j)} \tag{4.8}$$

and hence $\bar{X}_j\leqq X$ and $\bar{X}_{j-1}\leqq\bar{X}_j$, $j\geqq 1$.

Using arguments similar to those in [33, p. 291-294] we can show that for $0<\underline{r}\leqq r\leqq R$, with $\underline{r}$, R positive constants, there exists a constant ω, $0<\omega<1$, depending only on $\underline{r}$ and R, such that for $\omega<\rho<1$,

$$|U_r^k|\leqq M(\rho)\rho^k,\qquad k=0,1,\cdots,$$

where $M(\rho)$ is independent of r. Thus, if $\underline{r} \leqq r_i \leqq R$, then for any $0 < \varepsilon < 1$, there exists an integer $k(\varepsilon)$ such that for $k_i \geqq k(\varepsilon)$, $i \geqq 1$,

$$|U_{r_i}^{k_i}| \leqq 1 - \varepsilon. \tag{4.9}$$

Hence, using (4.7) we have

$$|E^{(j)}| \leqq (1-\varepsilon)^{2j} |D|^2$$

so that $E^{(j)} \to 0$ as $j \to \infty$ and therefore $\bar{X}_j \to X$ as $j \to \infty$.

For the hybrid method proposed in this paper, we have combined the variable stepsize method just outlined with the reformulated Smith method of (3.12). We then obtain the following algorithm for solving for the feedback gain K_i:

ALGORITHM 4.10. Set $S_i = A - BK_i$, $D_1 = K_i - K_{i-1}$ and $J_0 = 0$. For given acceleration parameters $r_1, r_2, \cdots$, and iteration count indices $k_1, k_2, \cdots$, we iterate on $j = 1, 2, \cdots$, in the following steps:

(4.10a) Compute $U_{r_j} = (I - r_j S_i)^{-1}(I + r_j S_i)$ and

$$M_1 = D_j (I - r_j S_i)^{-1},$$
$$J_1 = J_0 + 2 r_j B^T M_1^T M_1.$$

(4.10b) Iterate for $k = 1, 2, \cdots, k_j - 1$ in

$$M_{k+1} = M_k U_{r_j}$$
$$J_{k+1} = J_k + 2 r_j B^T M_{k+1}^T M_{k+1}.$$

(4.10c) Compute $D_{j+1} = M_{k_j}(I + r_j S_i)$, set $J_0 = J_{k_j}$ and return to (4.10a) with $j = j+1$.

The steps in Algorithm (4.10) are to be repeated, i.e., iteration through $r_1, r_2, \cdots$, until some convergence criterion is met. In performing the steps in (4.10b), we can use the Sherman-Morrison-Woodbury formula in a procedure such as that outlined in (2.7)-(2.9) in § 2.

Remarks. (1) The convergence of our hybrid method is guaranteed if (i) $A - BK_0$ is stable where K_0 is obtained through a numerical integration of the Chandrasekhar equation by Algorithm (2.3)-(2.9), and (ii) the iteration counts k_i's in the variable stepsize algorithm Algorithm (4.10) are chosen sufficiently large. Condition (i) can be met if the stepsize h is chosen sufficiently small and the integration is carried out on a sufficiently large interval $[-t_f, 0]$ so that the norm of L at $-t_f$ is smaller than a given small constant, say $\varepsilon > 0$.

(2) The efficiency of the method may rely heavily on a choice of the acceleration parameters $r_1, r_2, \cdots, r_l$. If we follow the guide provided by ADI methods (see [15, p. 37]), we might choose a set of values r_j to be used in some cyclic order. The best choices of values for the r_j often depend on the eigenvalues of $S_i = A - BK_i$. For example, consider the case where S_i has only real eigenvalues λ_j, each with multiplicity m_j, $j = 1, 2, \cdots, m$. Then a choice of $r_j = -1/\lambda_j$ and $k_j = m_j$ in the algorithm produces convergence in a finite number (m) of steps. That is, this choice yields $E^{(m)} = 0$ in (4.8). Of course, the complete eigenstructure of S_i will not be known (nor do we suggest that any sophisticated analysis along these lines be included with each use of Algorithm (4.10) to obtain the gains K_i).

For the case where the problem is obtained from an approximation of an LQR-problem for systems governed by PDE's, a good approximation method preserves the property of solutions to the orignal LQR-problem; e.g., the distribution of closed-loop eigenvalues. Thus, depending on the type of PDE's we consider, we can have an a priori knowledge of bounds on the closed loop eigenvalues for the approximating system. For example, in Example 2 of § 5, we consider a boundary control problem for the one-dimensional heat equation. In this case, we know that the closed-loop eigenvalues are contained in a sector $S=\{\lambda \in C: |\arg(\lambda-\rho)| \leqq (\pi/2)+\theta, \rho \geqq 0 \text{ and } \theta>0\}$. Thus we can choose the parameters r_i systematically as shown in Table 5.3.

(3) For the full matrix case, the following are rough operation counts. For the Chandrasekhar step, we have

$$\frac{n^3}{3}+\frac{t_f}{h}(pn^2+4mpn),$$

where t_f is the terminal time and h is the stepsize. For the Newton–Kleinman step with variable stepsize Smith, we find

$$\frac{l}{3}n^3+c_1(k_1+k_2+\cdots+k_l)[pn^2+4mpn+c_2(mn^2+4m^2n)],$$

where l is the number of acceleration parameters r_i, c_1 is the number of cycles of Algorithm (4.10), and c_2 is the number of Newton iterations. When A is sparse, the operation counts $n^3/3$ for the LU-decomposition of $(I-rA)$ and pn^2 for computing $L(I-rA)^{-1}$ can be significantly reduced using a Gauss-elimination procedure for the matrix A.

In closing this section, we note that the analogies of our variable step Smith method with the ADI methods used to solve partial differential equations can be made a little more precise. Briefly, in ADI splitting methods [28, p. 146–148], we attempt to solve a discretization of the evolution equation

$$\dot{\Phi}=A\Phi+f$$

when $A \geqq 0$ can be written $A=A_1+A_2$ with $A_i \geqq 0$ (for example, factored into components corresponding to spatial discretizations in the x and y directions, respectively, for an equation in a two-dimensional spatial domain). This can be shown [28, p. 150] to lead to an iterative scheme

$$\left(I+\frac{h}{2}A_1\right)\left(I+\frac{h}{2}A_2\right)\Phi^{j+1}=\left(I-\frac{h}{2}A_1\right)\left(I-\frac{h}{2}A_2\right)\Phi^j+hf^j, \tag{4.11}$$

where the index j is related to time stepping. On the other hand, if we consider the Smith method (3.6)-(3.8) for

$$S^TX+XS=F$$

and choose $r=h/2$, we obtain the iteration

$$\left(I-\frac{h}{2}S^T\right)X^{j+1}\left(I-\frac{h}{2}S\right)=\left(I+\frac{h}{2}S^T\right)X^j\left(I+\frac{h}{2}S\right)+hF. \tag{4.12}$$

In these iterations we may identify the $n \times n$ matrix $X=[x_1,\cdots,x_n]$, $x_i \in R^n$ and the n^2 vector $\Phi=\text{column}[x_1,\cdots,x_n]$. If we then identify $A_1\Phi$ with $-S^TX$ (i.e., $A_1=-I\otimes S^T$) and $A_2\Phi$ with $-XS$ (i.e., $A_2=-S\otimes I$), we can immediately see the equivalence between (4.11) and (4.12).

5. Summary remarks and numerical examples. In the preceding sections we have presented an algorithm that offers some definite advantages in computing directly the feedback gains K for high dimensional LQR problems such as those arising in approximating partial or delay differential equation control problems. As we will see with several numerical examples in this section, it can substantially outperform standard eigenvector methods on such problems. As we have pointed out, a fundamental algebraic operation (in both the Chandrasekhar update (2.6), (2.7) and in the reformulated Smith methods (4.10b)) involves computation of

$$L(I-r(A-BK))^{-1}, \tag{5.1}$$

where L and K are $p\times n$ and $m\times n$ matrices, respectively. Our algorithm uses the Sherman–Morrison–Woodbury formula which can provide significant computational savings when m and p are small compared to n. For systems involving sparse matrices A (a frequent occurrence in many approximation schemes), the needed calculations can be carried out quite efficiently.

We further note that that Chandrasehkar and Newton–Kleinman–Smith components as formulated in our algorithm lead to ready estimates between the true gain K and the iterates K_i in terms of equation errors in the steps being performed.

One component (the variable step Smith) of the algorithm is most effectively carried out if we possess some a priori knowledge of bounds on the closed loop eigenvalues. If the closed loop eigenvalues lie close to the imaginary axis, then convergence in the Smith method can be very slow. Eigen or Schur vector methods [27], [30] are less sensitive in this regard. For low order systems, the Schur vector approach is more reliable and less expensive computationally than our algorithm. Our hybrid algorithm depends critically on a number of choices (e.g., stopping criteria in the Newton–Kleinman and Smith components, stepsize sequence $\{r_j\}$ and iteration count sequence $\{k_j\}$ in the variable step component) to be made by the user, and the "best" choices are heavily problem dependent. Hence we can expect our hybrid algorithm to require more experimentation and fine tuning than other more standard methods. However, as we will demonstrate with examples, for the case where n is large compared to m and p, it can offer considerable computational savings with no loss in accuracy over the methods mentioned above.

We have tested (and are continuing our efforts in this direction) our hybrid algorithm on several numerical examples. We will report on just two of these here to illustrate our findings.

In Example 1, our algorithm is tested for the ill-posed LQR-problem reported in [27].

In Example 2, we will demonstrate various aspects of the proposed algorithm, using the approximate LQR-problems via Galerkin approximation of a boundary control problem for the one-dimensional heat equation. All our computations were carried out in double precision on an IBM 3081 at Brown University. We gratefully acknowledge the assistance of Yun Wang in our carrying out of the extensive computational studies reported for the boundary flux control in the diffusion equation problem of Example 2 below.

Example 1. As one of our examples, we considered an example (Example 6 of [27]) which Laub used to test his Schur based methods. The system is the n-dimensional system of (1.1) with

$$A=\begin{bmatrix}0 & 1 & 0 & \cdots & 0\\ 0 & 0 & 1 & & 0\\ \vdots & & & & \\ \vdots & & & 0 & 1\\ 0 & \cdots & & \cdots & 0\end{bmatrix}\qquad B=\begin{bmatrix}0\\ \vdots\\ 0\\ 1\end{bmatrix}\qquad C=[1\quad 0\quad \cdots\quad 0],$$

which leads to an ill-conditioned Riccati equation. This problem corresponds to one in which n integrators are connected in a series with a feedback controller to be applied to the nth integrator in order to stabilize the system. Only deviations of x_1 from the origin are penalized in the cost functional. The true optimal gain is an n vector $K=(\bar{K}^1, \cdots, \bar{K}^n)$ and for this example we can argue that $\bar{K}^1=1$. In [27], Laub used his Schur techniques to study this example and reported difficulties with loss of accuracy at a relatively low value of n, $n=21$. We carried out runs with our hybrid algorithm and obtained quite favorable performance. Some of our findings included the following:

(a) For $n=40$, we used the Chandrasekhar component to integrate to $t_f=100$ and produce an initial estimate $K_0^1=.99041$, which, when used in the Newton-Kleinman (fixed step size $r=.5$ in the Smith), produced the estimate $K_5^1=1.0$—in a total of 2.93 seconds of CPU time. When we used a cruder solution in the Chandrasekhar component ($t_f=200$ but with step size twice that in the first run) to produce $K_0^1=.9394$, followed by the $N-K$ ($r_1=.5$, $r_2=1.0$ in the variable step Smith) we obtained $\mathrm{K}_6^1=1.0$—all in 2.39 seconds.

(b) For $n=50$, we produced $K_0^1=.9224745$ at $t_f=220$ and after the N-K-Smith (fixed step $r=.5$ in the Smith) obtained $K_5^1=1.0000000003820$ in a total of 4.44 CPU seconds. For the same runs with variable step ($r_1=.5$, $r_2=.7$) Smith we obtained a K_5^1 as above with 3820 replaced by 3817 in a total of 4.31 seconds.

(c) We compared runs with the Chandrasekhar component only against the Potter method for $n=10$, 21, 40. Obtaining essentially the same estimates for $n=10$ and 21 (at $n=40$, the Potter degenerates numerically to produce useless estimates) we had CPU times of $\mathrm{CH}_{n=10}=.753$ seconds, $\mathrm{POTT}_{n=10}=.188$ seconds, $\mathrm{CH}_{n=21}=1.52$ seconds, $\mathrm{POTT}_{n=21}=1.22$ seconds, $\mathrm{CH}_{n=40}=4.35$ seconds, $\mathrm{POTT}_{n=40}=6.81$ seconds.

We also implemented the Laub-Schur method using the HQR3 and EXCHNG routines of Stewart [37]. Our implementation was exactly the same as suggested in [27] except that the stable and unstable blocks are separated by their absolute values along the diagonal. For the two examples we considered here, we did not observe any significant difference between Potter's method and Laub's method, either in performance or CPU times.

We found for this example that the eigenvector methods are best for small n, but as n grows, the Chandrasekhar alone, and, even more so, the hybrid method will out perform the Eigen-Schur methods in both accuracy and CPU times. A more striking demonstration of this behavior will be given in the next example.

Example 2. We consider the following linear quadratic regulator problem: minimize the cost functional

$$J(u)=\int_0^\infty (|Cz(t)|^2+|u(t)|^2)\,dt \tag{5.2}$$

subject to the partial differential equation

$$\begin{aligned}\frac{\partial}{\partial t}z(t,x)&=\frac{\partial^2}{\partial x^2}z(t,x), \qquad x\in(0,1),\\ z(0,x)&=\Phi(x)\end{aligned} \tag{5.3}$$

with boundary conditions

$$\frac{\partial}{\partial x}z(t,0)=u(t) \quad \text{and} \quad \frac{\partial}{\partial x}z(t,1)=0 \tag{5.4}$$

and

$$Cz(t)=\int_0^1 c(x)z(t,x)\,dx,$$

where $c(\cdot)$ is square integrable on $[0,1]$.

We can discretize or approximate (5.3)-(5.4) using the standard Galerkin method [2]; i.e., the approximating solution $z^N(t,x)$ to (5.3)-(5.4) is given by

$$z^N(t,x)=\sum_{i=0}^{N} w_i(t)l_i(x), \qquad w_i(t)\in R^1, \tag{5.5}$$

where $l_i=l_i^N$ is the first-order spline defined by

$$l_i^N(x)=\begin{cases} N\left(x-\dfrac{i-1}{N}\right), & \dfrac{(i-1)}{N}\leqq x\leqq \dfrac{i}{N}\\ N\left(\dfrac{i+1}{N}-x\right), & \dfrac{i}{N}\leqq x\leqq \dfrac{(i+1)}{N}\\ 0 \quad \text{otherwise} & \end{cases}$$

and $z^N(t,x)$ satisfies

$$\int_0^1 \frac{\partial}{\partial t} z^N(t,x)\psi^N(x)\,dx=-\int_0^1 \frac{\partial}{\partial x} z^N \frac{\partial}{\partial x}\psi^N\,dx-u(t)\psi^N(0) \tag{5.6}$$

$$\text{for all } \psi^N\in Z^N=\text{span}\,\{l_0^N, l_1^N,\cdots,l_N^N\}.$$

Then, (5.6) leads to the nth-order $(n=N+1)$ ordinary differential equation for $w^N=\text{col}\,(w_0,\cdots,w_N)$;

$$Q^N\dot{w}^N(t)=-H^Nw^N(t)-B^Nu(t), \tag{5.7}$$

where

$$Q^N=\frac{1}{N}\begin{bmatrix} \frac13 & \frac16 & 0 & \cdots & & 0\\ \frac16 & \frac23 & \frac16 & & & \vdots\\ 0 & & & & & \vdots\\ \vdots & & & & & 0\\ \vdots & & & \frac16 & \frac23 & \frac16\\ 0 & \cdots & & 0 & \frac16 & \frac13 \end{bmatrix} \quad \text{with } Q_{ij}^N=\int_0^1 l_il_j\,dx,$$

$$H^N=N\begin{bmatrix} 1 & -1 & 0 & \cdots & & 0\\ -1 & 2 & -1 & & & \vdots\\ 0 & & & & & \vdots\\ \vdots & & & & & 0\\ \vdots & & & -1 & 2 & -1\\ 0 & \cdots & & 0 & -1 & 1 \end{bmatrix} \quad \text{with } H_{ij}^N=\int_0^1 \frac{d}{dx}l_i\frac{d}{dx}l_j\,dx,$$

and

$$B^N=\text{col}\,(1 \quad 0 \quad \cdots \quad 0).$$

For computational convenience, we change coordinates (for fixed N) in the system (5.7) by $x=Q^Nw^N$ to obtain the approximate system

$$\dot{x}=-H^N(Q^N)^{-1}x-B^Nu.$$

Thus, in (1.1) we have $A=-H^N(Q^N)^{-1}$, $B=-B^N$ and $C=C^N(Q^N)^{-1}$ where C^N is the vector with components $c_i^N=\int_0^1 c(x)l_i(x)\,dx$, $0\leqq i\leqq N$.

For the problem in this example, the approximating optimal feedback operator K^N is given [2] by

$$K^N z = \int_0^1 k^N(x) z(x)\, dx,$$

where $k^N(x) = \sum_{i=1}^N k_i l_i(x)$ and $K = (k_0, \cdots, k_N)$ is the optimal feedback solution in the problem for (1.1) with A, B, C chosen as indicated above. We note in this case that for any $N \geqq 1$, A has only one unstable eigenvalue (zero), (A, B) is stabilizable, and (A, C) is detectable.

For the special case when $c(x) = 1$, we find $C = (1, \cdots, 1) \in R^{1\times(N+1)}$ and hence $CA = 0$. It is thus easy to see that the desired solution $(K(t), L(t))$ to the Chandrasekhar system (1.3) is given by

$$K(t) = k(t)C, \qquad L(t) = l(t)C,$$

where k, l are scalar functions satisfying

$$\dot{k} = l^2, \qquad k(0) = 0,$$

$$\dot{l} = -lk, \qquad l(0) = 1.$$

Therefore we find $\dot{k}k + \dot{l}l = 0$ so that $k^2(t) + l^2(t) = 1$. We thus find in this case that $k(t) \to 1$ as $t \to -\infty$ and hence $K = \lim K(t) = C$. For this case, the Chandrasekhar system for the infinite dimensional LQR problem (5.2)-(5.4) can also be analyzed [17], [36] and exactly the same argument as above shows the optimal feedback gain operator is given by

$$Kz = \int_0^1 1 \cdot z(x)\, dx.$$

These analytic solutions can be used to test software packages and approximation schemes before more interesting, analytically intractable examples are considered.

Remark. The form (5.7) of system equations appears frequently in applications. Thus the critical computational factor (5.1) can be modified so that we can avoid computing A. For example, in this case it has the form

$$L(I - r(-HQ^{-1} - BK))^{-1} = LQ(Q + rH + rBKQ)^{-1}, \tag{5.8}$$

where $Q + rH$ is a symmetric, tridiagonal, positive matrix. Thus we can readily use the Cholesky decomposition algorithm for computing $LQ(Q + rH)^{-1}$ and combine this with the Sherman-Morrison-Woodbury formula (see Remark 3 of § 2) to efficiently compute the critical expression (5.8).

We carried out extensive computations for this example with $c(x) = 1 + x$. We compared our hybrid method to the Potter algorithm and to the use of the Chandrasekhar system alone. We also used the Laub-Schur method on this example but, as in Example 1 above, found essentially no significant difference between Potter's method and the Laub-Schur, either in performance or CPU times. (Analysis and computational experience indicate that the Potter method and the Laub-Schur method are both $O(N^3)$ with the latter method about twice as fast as the Potter method.) We required, whenever feasible, the same level of accuracy in computation of feedback gains and compared relative CPU times.

In studying our hybrid scheme, we tested numerous sets of Smith acceleration parameters $\{r_j\}$, $\{k_j\}$, stopping times t_f in the Chandrasekhar component and error stopping criteria in both the Chandrasekhar and Newton-Kleinman-Smith components. We summarize some of our findings to date.

In Table 5.1 we present comparative CPU times for the hybrid scheme versus Potter as we increase N. Recall that the corresponding finite-dimensional approximation scheme has system with dimension $n = N+1$. In all of the runs reported in Table 5.1, the feedback gains for the hybrid and Potter calculations agreed to nine decimal places so both schemes provided accurate solutions. In these runs, the hybrid scheme calculations used $t_f = 2.2$ (corresponding to $h = .1$) with $|L(-t_f)| \simeq 10^{-3}$ in the Chandrasekhar component. The Newton-Kleinman component converged after four iterations (i.e., at K_4) and we used acceleration steps $r_1 = 1$, $r_2 = 10^{-1}$, $r_3 = 10^{-3}$, $r_4 = 10^{-5}$. Each Smith iteration was allowed a maximum of $k_j = 50$ per value of r_j although in most cases the iteration satisfied a convergence criterion before this maximum was attained. Careful consideration of Table 5.1 reveals that the hybrid scheme is clearly $O(N)$ while the Potter is $O(N^3)$; both rates are to be expected from our earlier observations about the methods. Note that at $N = 80$ the hybrid scheme is more than 25 times faster than the Potter scheme (with comparable accuracy, of course).

We also ran the hybrid scheme with $N = 80$ and a number of different fixed acceleration values r in the Smith component. The same Chandrasekhar component parameters as reported above were used. Table 5.2 contains relative CPU times as well as an indication of the N-K iterate for which convergence was achieved.

In Table 5.3 we list some CPU times when different sets of acceleration parameters $\{r_j\}$ were used. Again these runs were for $N = 80$ with the same Chandrasekhar solution as above. All of the converged Newton-Kleinman iterates were after six steps (i.e., K_6).

Finally, we made runs (for $N = 80$) to find the best results that the Chandrasekhar algorithm alone (i.e., accurate integration until $K(t) \to K$, $L(t) \to 0$) could produce. The

TABLE 5.1

best results we were able to achieve yielded an accurate value of K for $K(-t_f)$ with $t_f = 3.22$ with $|L(t_f)| \simeq 10^{-6}$ obtained in 5.85 CPU seconds.

Based on our computational findings for the above two examples and our experience with several other examples for infinite-dimensional systems (e.g., beams with tip bodies, etc.), we are quite confident that the hybrid scheme we propose in this paper can be profitably used with a number of large scale LQR problems. We are currently developing a rather general software package that implements the hybrid scheme in a manner so that a broad range of problems can be treated in the context of the ideas presented here.

ON CONSTRUCTING NONLINEAR OBSERVERS*

ANDREW R. PHELPS†

Abstract. Two algorithmic approaches to constructing nonlinear observers currently exist. Here one of these is improved by finding an explicit solution to the partial differential equations describing the change of state coordinates, thereby avoiding expensive bracket computations. This simplifies the algorithm and has implications for system identification.

Key words. nonlinear observer, observer normal form, canonical form, linearized error dynamics, observer algorithm, Macsyma, coefficient compatibility

AMS(MOS) subject classifications. 93C10

1. Necessary and sufficient conditions for observer normal form. We consider an uncontrolled affine control system

$$\dot{\xi}=f(\xi), \qquad y=h(\xi), \tag{1}$$

where f is a given vector field and we are operating in the neighborhood of a point $\xi^0=\xi(0)$. The problem is to estimate the state $\xi \in \mathbf{R}^n$ based on the measurement $y \in \mathbf{R}^p$. If we move beyond the special case where f is linear, this estimation problem is not very well understood. This paper takes up one of the current approaches to this problem and solves a certain set of differential equations not hitherto known to be solvable. This yields some amelioration of the algorithmic problems for computation of some nonlinear observers.

The *observer normal form* approach to nonlinear observers involves nonlinear transformation of the state and output coordinates to provide for observer design with linearized error dynamics.

To do this, we introduce new observer (state estimator) dynamics

$$\dot{\zeta}=\hat{f}(\zeta).$$

In this expression $\zeta \in \mathbf{R}^n$ is the observer, where $\hat{f}$ "adjusts" f. We consider the error estimate $e=\xi-\zeta$, seeking to dampen the error exponentially as a function of time.

To get the observer, we separate the influence of the inputs and outputs so as to get a system of the form (1). We then employ two particular normal forms, observ*able* and observ*er* forms. Nonlinear observable form, generally speaking, will be attainable under a wide range of conditions, whereas nonlinear observer form is more problematic. Attaining observer form means that we have found a coordinate system for the system (1) which makes it possible to "read off" the dynamics of the observer. This is the practical motivation underlying the use of these normal forms.

In the linear case, these forms are:

$$\begin{array}{ll} \text{Observable form} & \dot{\xi}=A\xi-B\alpha\xi, \quad y=C\xi, \\ \text{Observer form} & \dot{x}=Ax-\alpha Cx, \quad \bar{y}=\gamma Cx. \end{array}$$

For clarity of notation, we use (ξ, y) for generic state coordinates and reserve $(x, \bar{y})$ for observer form state coordinates.

Here, A, B, and C represent Brunovský canonical form [2] matrices in prime form [16]. Thus, we assume we have *observability indices* $l_1 \leqq \cdots \leqq l_j \leqq \cdots \leqq l_p$, with $\sum_{j=1}^{p} l_j = n$. A is an $n \times n$ block diagonal matrix where the jth block is an $l_j \times l_j$ upper diagonal matrix made up of 1's. C is a $p \times n$ block diagonal matrix where the jth block is a $1 \times l_j$ matrix $[1\,0 \cdot \cdot\, 0]$. B is the $n \times p$ "pseudocontrol" matrix corresponding to C—block diagonal with the jth block being a $l_j \times 1$ matrix $[0 \cdots 0\; 1]^T$. For example, in the case where $n=3$ and $p=1$, Brunovský form would give us

$$A=\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}, \quad B=\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad C=[1 \quad 0 \quad 0].$$

Also, α and γ are constant matrices of the appropriate dimensions.

In the nonlinear case, locally we can define (nonlinear) observability indices: In a neighborhood of the operating point ξ^0, we have l_j's, $1 \leqq j \leqq p$, as above, such that

$$\dim \operatorname{span}\{L_f^{i-1} h_j(\xi)\colon 1 \leqq i \leqq l_j \text{ and } 1 \leqq j \leqq p\} = n.$$

Using the above, we have nonlinear normal forms

$$\text{(2)} \qquad \text{Observable form} \qquad \dot{\xi} = A\xi - B\alpha(\xi), \quad y = C\xi,$$

$$\text{(3)} \qquad \text{Observer form} \qquad \dot{x} = Ax - \alpha(Cx), \quad \bar{y} = \gamma(Cx).$$

Note that the α of nonlinear observable form is different than that of the corresponding observer form. See [12] for a more detailed exposition.

We can achieve nonlinear observable form generically. Two approaches, involving different sets of conditions, have been developed for putting a system in *nonlinear observer form.* See, for instance, [1], [4], [8]-[10], [12]-[15], [17], and [18]. We describe the computational implications of their algorithms.

For the following, we annotate systems as follows. We write l_j, $1 \leqq j \leqq p$, for the jth observability index, corresponding to the output y_j, and f_j for the (l_j)th derivative of y_j, as it appears in observable form. We label the state coordinates with double indices $j\colon k$, for $1 \leqq j \leqq p$ and $1 \leqq k \leqq l_j$. Thus, $\xi_{j:1} = y_j$ and $\xi_{j:k}$ is its $(k-1)$th derivative. The unit vector in the $\xi_{j:l_j}$ direction is B_j, from the prime B matrix above. We annotate observable form coordinates with a bar when the output $\bar{y}$ is the particular output associated with observer form (see § 2). These state coordinates are given by $\bar{\xi}$; their observable form polynomials are given by $\bar{f}_j$.

The approach adhered to in this paper was developed in [13] and [14]. This algorithm is determined by the conditions required for conversion of a system (1) to observer form (3). These conditions are:

Observable form. Must be able to convert system to observable form (2);

Output coordinate change. Must satisfy differential equation (d.e.) for $y = y(\bar{y})$;

Polynomial degree. Polynomials $f_j(\xi)$ (the entries of $-B\alpha(\xi)$ in observable form (2)) must have degree $\leqq l_j$, for $1 \leqq j \leqq p$;

Bracket vanishing. Brackets of elements in $\{ad_{-f}^{i-1} B_j\colon 1 \leqq i \leqq l_j\}$ must vanish.

Examining this algorithm computationally, we may break it down into the following steps:

Bracket Vanishing Algorithm (Krener-Isidori-Respondek).

- Transform to observable form.
- Verify degree condition.
- Solve differential equation for $\bar{y}(y)$.
- Change to observable form coordinates $\bar{\xi}$ corresponding to $\bar{y}$ output coordinates.

- Compute $\mathrm{ad}^{i}_{-\bar{f}}\, B_j$, $1 \leqq i \leqq l_j - 1$, $1 \leqq j \leqq p$.
- Check bracket vanishing condition.
- Find observer coordinates and injections.
- Compute Jacobian $\partial\xi/\partial x$.
- Find observer.

A distinct approach has been developed in [1], [4], and [15]. It has been developed only for the case where $p=1$ and does not address the problem of changing output coordinates. (It does, however, incorporate the time-varying case.) It calls for the existence of observable form (2), but not its computation, and replaces the last two conditions above with a single requirement, as follows:

Observable form. Must be able to convert control system to observable form;

Output coordinate change. Must satisfy differential equation for $y = y(\bar{y})$;[1]

Bracket spanning. We must have $d(\mathrm{ad}^{l}_{-f}B) \in \mathrm{span}\,\{dh\}$ (expressed in observer coordinates), modulo a slight technical adjustment on the last coordinate.

This algorithm breaks down computationally as follows:

Bracket Spanning Algorithm (Bestle–Zeitz–Li–Tao).

- Check observable form rank condition.
- Verify observable form has single output index.
- Compute $\mathrm{ad}^{k}_{-f}B$, $0 \leqq k \leqq l$.
- Get $d\alpha/dy$ in observer coordinates.
- Get differential expression $\lambda(\xi)$ (not described here), to adjust check for α_l.
- Check bracket spanning condition.
- Recursively compute $x = x(\xi)$.
- Backsolve for $\xi = \xi(x)$.
- Compute observer.

Experience shows that to solve a general system using the bracket vanishing or bracket spanning conditions appears to be somewhat difficult. The $n=2$ case was completely worked out independently by authors using each method, but the solution for dimension three, in the single output case, has been published incorrectly [14], while dimensions four, five, and further get increasingly complicated to compute. We initially tried to implement this computation as a *Macsyma* program. Our results suggested to us a way through this difficulty, which is described below and developed in the succeeding sections.

The particular difficulty of both these algorithms is their requirement of extensive Lie bracket calculations. In § 2, we develop a substitute for the bracket vanishing condtion which obviates the necessity for these calculations.

Coefficient compatibility. Observable form polynomials must evaluate to certain integrals of differential expressions in injection terms (the entries of $\alpha(Cx)$ in (3)).

In § 3, we further develop the coefficient compatibility condition algorithm by finding a direct formula for the integrals in general observable form coordinates. Section 4 is a summary with concluding remarks.

2. Polynomial coefficients in standard coordinates.

We seek to simplify the computations for nonlinear observer form.

[1] This condition improves this algorithm, which in its orginal form neglected the issue of change of output coordinates.

The polynomial degree condition means that the observable form functions $f_j(\xi)$ must be *polynomials* with coefficients being functions in the observed states $\xi_{j:1}$, $1 \leqq j \leqq p$.

The bracket vanishing condition and the bracket spanning condition provide processes for verifying the convertibility of an observable form polynomial into nonlinear observer form. They do not, however, give us a clear and explicit idea of the restrictions on the coefficients that are necessary and sufficient for the existence of this transformation. They give us enough machinery to arrive at a solution recursively, while leaving us subject to a "bewildering" complexity of computation in all but the simplest cases. We must compute iterated brackets and we end up with complicated and unsuggestive expressions. (See, however, the work of Grossman, e.g., [6], for one approach to improving this situation.)

Suppose we try to find a direct solution of the change of state coordinates $x = x(\xi)$. We compute the d.e.'s stemming from the relationship $\bar{y} = \bar{y}(y)$ and the successive Lie differentiations of the output terms.

So doing, we get

$$\begin{aligned}
\xi_1 &= y(\bar{y}) = y(x_1),\\
\xi_2 &= \dot{\xi}_1 = J(x_2 - \alpha_1),\\
\xi_3 &= \dot{\xi}_2 = J\left(x_3 - \alpha_2 - \frac{d\alpha_2}{d\bar{y}}(x_2 - \alpha_1)\right) + \frac{dJ}{d\bar{y}}(x_2 - \alpha_1),\\
f(\xi) &= \dot{\xi}_l = J\left(-\alpha_l - \frac{d\alpha_{l-1}}{d\bar{y}}(x_2 - \alpha_1) + \cdots\right) + \cdots,
\end{aligned} \tag{4}$$

where J is an abbreviation for $dy/d\bar{y}$. Note that the expressions on the right-hand side of (4) exhibit a cascading complexity of terms in higher derivatives of J's, recurring in repeated backsubstitutions of their lower order versions.

However, we might assume that $J = 1$, that y is actually the "correct" output coordinate function $\bar{y}$, given by the output ordinary differential equation (o.d.e.)[2]. In this case, the equations (4) do indeed become more tractable.

The assumption $J = 1$, or $J = I_p$ (the identity matrix) in the general case, means, in effect, that we are using the particular observable form for our system that is given by using the special output $\bar{y}$ gained from the output d.e. and repeated Lie differentiations of it. We call the coordinate system thus derived *standard coordinates*, annotated by $\bar{\xi}$.

In these coordinates, the d.e. expansion (4) becomes

$$\begin{aligned}
\bar{\xi}_1 &= \bar{y} = x_1,\\
\bar{\xi}_2 &= \dot{\bar{\xi}}_1 = x_2 - \alpha_1,\\
\bar{\xi}_3 &= \dot{\bar{\xi}}_2 = x_3 - L_{\bar{f}}\,\alpha_1 - \alpha_2,\\
&\vdots\\
\bar{\xi}_l &= \dot{\bar{\xi}}_{l-1} = x_l - \sum_{i=1}^{l-1} L_{\bar{f}}^{l-i-1}\alpha_i,\\
\bar{f}_1(\bar{\xi}) &= \dot{\bar{\xi}}_l = \sum_{i=1}^{l} L_{\bar{f}}^{l-i}\,\alpha_i.
\end{aligned} \tag{5}$$

[2] In the bracket spanning condition, this assumption is the starting place for the calculation. Here, however, we have reduced it to a *convenience* with which we will eventually dispense (§ 3).

First, we give some notation. We let

$$\xi^{\#} := \prod_{j=1}^{p} \prod_{k=1}^{r_j} \bar{\xi}_{j:i_{j:k}+1}^{e_{j:k}} \tag{6}$$

be a general monomial in $\bar{f}_m(\bar{\xi})$. Let

$$\bar{a}_{m:\cdots}(\bar{y}) := \bar{a}_{m:\cdots\underbrace{|\cdots\underbrace{i_{j:k}+1\cdots i_{j:k}+1}_{e_{j:k}\text{ times}}\cdots|}_{(j)}\cdots}(\bar{y})$$

denote the coefficient of $\xi^{\#}$. Here, $e_{j:k}$ is the *exponent* of this contribution to the term, r_j is the number of contributions by different time-derivatives of $\bar{\xi}_{j:1} = \bar{y}_j$, and $i_{j:k}$ is the *degree*. The $p-1$ *vertical bars* separate the contributions of each set of time derivatives, with "$\|$" showing an empty contribution from the corresponding $\bar{\xi}_{j:k}$'s, for $1 \leqq k \leqq r_j$. (Note that we use "$i_{j:k}+1$" instead of "$i_{j:k}$" because the degree $i_{j:k}$ is one less than the subscript.) We write $e_j = \sum_{k=1}^{r_j} e_{j:k}$, $e = \sum_{j=1}^{p} e_j$. We also need the *total degree* $w = \sum_{j=1}^{p} \sum_{k=1}^{r_j} i_{j:k}\, e_{j:k}$.

Now, it turns out that the differential equations (5) are readily solvable in standard coordinates, with the proof to be established by a simple induction. Here is a low-dimensional example of how these d.e.'s solve.

Example 2.1. Change of state coordinates, single output, dimension three. The differential equation for $\bar{y} = \bar{y}(y)$ is

$$\frac{d\bar{y}}{dy} = \exp\left(-\frac{1}{3}\int_{\nu^0}^{\nu} a_{23}\, d\nu\right).$$

It solves to

$$\bar{y} = \int_{y^0}^{y} \exp\left(-\frac{1}{3}\int_{\nu^0}^{\nu} a_{23}\, d\eta\right) d\nu.$$

To get the change of coordinates $\bar{\xi} = \bar{\xi}(\xi)$, we iteratively substitute our solutions for the first $j-1$ variables $\bar{\xi}_1, \cdots, \bar{\xi}_{j-1}$ in the equation for $\bar{\xi}_j$, etc. We get

$$\begin{aligned} \bar{\xi}_1 &= \int_{y^0}^{y} \exp\left(-\frac{1}{3}\int_{\nu^0}^{\nu} a_{23}\, d\eta\right) d\nu, \\ \bar{\xi}_2 &= \frac{d\bar{y}}{dy}\,\xi_2, \\ \bar{\xi}_3 &= \frac{d\bar{y}}{dy}\left(\xi_3 - \frac{1}{3}\,a_{23}\xi_2^2\right). \end{aligned} \tag{7}$$

The function $\bar{f}_1(\bar{\xi})$ is written as

$$\bar{a}_{23}\bar{\xi}_2\bar{\xi}_3 + \bar{a}_3\bar{\xi}_3 + \bar{a}_{222}\bar{\xi}_2^3 + \bar{a}_{22}\bar{\xi}_2^2 + \bar{a}_2\bar{\xi}_2 + \bar{a}_1, \tag{8}$$

applying the polynomial degree condition. The d.e.'s (5) then become

$$\bar{\xi}_1 = \bar{y} = x_1, \qquad \bar{\xi}_2 = \dot{\bar{\xi}}_1 = x_2 - \alpha_1,$$

$$\bar{\xi}_3 = \dot{\bar{\xi}}_2 = x_3 - \frac{d\alpha_1}{d\bar{y}}\,\bar{\xi}_2 - \alpha_2,$$

$$\bar{f}_1(\bar{\xi}) = \dot{\bar{\xi}}_3 = -\frac{d\alpha_1}{d\bar{y}}\,\bar{\xi}_3 - \frac{d^2\alpha_1}{d\bar{y}^2}\,\bar{\xi}_2^2 - \frac{d\alpha_2}{d\bar{y}}\,\bar{\xi}_2 - \alpha_3.$$

We see that we can read off the $\bar a$ coefficients and we have, in fact,

$$\bar a_1 = -\alpha_3, \quad \bar a_2 = -\frac{d\alpha_2}{d\bar y}, \quad \bar a_{22} = -\frac{d^2\alpha_1}{d\bar y^2},$$

$$\bar a_{222} = 0, \quad \bar a_{23} = 0, \quad \bar a_3 = -\frac{d\alpha_1}{d\bar y}.$$

Plainly, we can backsolve for the α's by integration. □

In general, and in fact whenever the observability indices are all identical, we can read off the solutions to the $\bar a$ polynomial coefficients in terms of the α injection functions. The coefficients are those that arise naturally from tree structures stemming from partitions in graded differential algebras [5]. We get Theorem 2.2.

THEOREM 2.2. *Suppose that all observability indices are equal, i.e., $l_m = l$ for $1 \leqq m \leqq p$. Then the polynomial coefficient $\bar a_{m:\dots}(\bar y)$ is given by*

$$-\left(\frac{w!}{\prod_{j=1}^{p}\prod_{k=1}^{r_j} e_{j:k}!\,i_{j:k}!^{e_{j:k}}}\right)\frac{\partial^e \alpha_{m:l-w}(\bar y)}{\partial \bar y_1^{e_1}\cdots\partial \bar y_p^{e_p}}. \tag{9}$$

Proof. Outline. We use induction on l. We make a counting argument with combinatorics to trace the typical coefficient of a monomial term.

Body of proof. Let m, $1 \leqq m \leqq p$, be fixed. First of all, if $l = 1$, then the system degenerates to $\dot{\bar\xi}_{m:1} = \bar f_m(\bar\xi) = \bar f_m(\bar y)$. Thus, $\bar a_{m:1} = \bar f_m(\bar y) = -\alpha_{m:1}(\bar y)$, where we take $\alpha_{m:1} := -\bar f_m$. But this matches formula (9).

Note that the result of Example 2.1 also corresponds with formula (9). The derivation shown there illustrates the pattern we use for our induction.

As induction hypothesis, we assume that formula (9) holds for $l = \mu$. We target the coefficients in the expansion for $\bar\xi_{m:\mu} - x_{m:\mu}$ in the case $l = \mu + 1$ that are the *source* via Lie differentiation of the coefficients of $\bar f_m$ we seek to evaluate.

But, when we examine the p.d.e. expansion (5), we find the same expression, $-\sum_{i=1}^{\mu} L_{\bar f}^{\mu-i}\alpha_{m:i}$, for $\bar\xi_{m:\mu} - x_{m:\mu}$ in the expansion with $l = \mu + 1$, as we find for $\bar f_m$ in the expansion with $l = \mu$. This means that the induction assumption will enable us to know those "target" coefficients, which, when Lie differentiated, give contributions to the expansion for $\bar f_m$ in the case when the multi-index l is $\mu + 1$. These coefficients evaluate to nothing but the coefficients of the terms of $\bar f_m$ in the case (given by induction assumption) that the multi-index l is μ.

An expression that under Lie differentiation by $\bar f$ can give a term such as (6), with coefficient $\bar a_{m:\dots}$, may have two forms.

Case 1. It may have no increment in the exponent $e_{j:1}$ of $\bar\xi_{j:2}$, for $1 \leqq j \leqq p$.

In this instance, it will come from Lie differentiation of a term of the form

$$\xi^{\#}\,\bar\xi_{\eta:\iota_{\eta:k}}\bar\xi^{-1}_{\eta:\iota_{\eta:k}+1}. \tag{10}$$

By induction assumption, (10) has a numerical coefficient that calculates back from our projected coefficient for (6) as

$$-\frac{\iota_{\eta:k}!\,e_{\eta:k}}{(\iota_{\eta:k}-1)!\,e^{\#}}\left(\frac{1}{w}\right)\left(\frac{w!}{\prod_{j=1}^{p}\prod_{k=1}^{r_j} e_{j:k}!\,i_{j:k}!^{e_{j:k}}}\right).$$

Here we take

$$e^{\#} := \begin{cases} e_{\eta:k-1}+1 & \text{if } \iota_{\eta:k-1} = \iota_{\eta:k}-1, \\ 1 & \text{otherwise.} \end{cases}$$

The differentiation process contributes an extra factor of $e^{\#}$. Thus, the partial numerical contribution from this term is

$$\iota_{\eta:k} e_{\eta:k}\left(\frac{1}{w}\right). \tag{11}$$

In this case, the "α" part of the coefficient is carried through unchanged. Moreover, it was already of the required form, since e_η has not been altered by adding and subtracting 1 in (10).

Case 2. It may have an increment in the coefficient of $\bar{\xi}_{j:2}$ for $j = \eta$.

The source of the terms of this type is partial differentiation of the "α" coefficient by $\bar{y}_\eta$. This will give an additional factor of $\bar{\xi}_{\eta:2}$, while not affecting the numerical coefficient. The prior exponent of $\bar{\xi}_{\eta:2}$ will have been $e_{\eta:1} - 1$.

Therefore, the monomial term prior to Lie differentiation was $\xi^{\#} \bar{\xi}_{\eta:2}^{-1}$. By induction assumption, its numerical contribution was

$$-\iota_{\eta:1}!\, e_{\eta:1}\left(\frac{1}{w}\right)\left(\frac{w!}{\prod_{j=1}^{p} \prod_{k=1}^{r_j} e_{j:k}!\, i_{j:k}!^{e_{j:k}}}\right).$$

Its partial numerical contribution is therefore

$$\iota_{\eta:1}\, e_{\eta:1}\left(\frac{1}{w}\right), \tag{12}$$

since $\iota_{j:1}! = 1 = \iota_{j:1}$ when $j = \eta$.

Note that in this case the e_η increments by 1, so that the "α" term adjusts as prescribed by formula (9).

These two cases exhaust the possibilities. The "α" coefficients are as required. And, combining (11) and (12), we get a total contribution to the numerical coefficient of a factor of

$$\left(\sum_{j=1}^{p} \sum_{k=1}^{r_j} \iota_{j:k}\, e_{j:k}\right)\left(\frac{1}{w}\right) = 1,$$

which is also as required. □

The case where not all the observability indices are equal occasions an additional computational process. In this case, we may successively extend the systems, by prolongation, to systems with more indices equal. Thus, if there are three unequal observability indices $l_1 < l_2 < l_3$, we prolong to a system with two observability indices equal to l_2 and one to l_3, of dimension $2l_2 + l_3$, and then to another system with three observability indices, all equal to l_3, of dimension $3l_3$. So doing, we may prolong a given system with arbitrary observability indices to a system with all observability indices equal that is, "equivalent" in the sense that the solutions for $y = y(\bar{y})$ and $\alpha(\cdot)$ can be pulled back trivially to the original, lower dimensional system. This amounts, in effect, to an algorithm for computing the relations between the $\bar{a}$ coefficients and the α injection functions.

The key to this process, is the following lemma. It was originally stated by [14], but the proof there is flawed. The version given here was first proved by Phelps in [17]. The proof is technical and somewhat tedious, and is left for the Appendix.

Note that the lemma is stated in superfluous generality for the purposes of this section. This is so it can also be used to sustain some results of § 3.

LEMMA 2.3. *Suppose an uncontrolled system S, given in observable form coordinates* (ξ, y) (2), *has two distinct multi-indices* l_1, l_2 *of multiplicities* p_1, p_2 *and, further, that S* *may be transformed by change of output coordinates $y = y(\bar{y})$ and change of state coordinates $\xi = \xi(x)$ to observer form coordinates $(x, \bar{y})$. Then S can be prolonged to a system S', also given in observable form* (2), *having multi-indices $\lambda_1 := l_1 + 1$ and $\lambda_2 := l_2$, of the above multiplicities. Furthermore, the transformation $y = y(\bar{y})$ and the function $\alpha(\cdot)$, as given in observer form coordinates, prolong trivially to functions which will take the prolonged system S' over into prolonged observer form.*

We now describe the recursive algorithm for computing polynomial coefficients from injection functions, in the case where the observability indices are not all identical. Lemma 2.3 enables us to prolong a system with two distinct multi-indices $l_1 < l_2$ to a system p_1 dimensions higher by increasing the dimensionality of each of the l_1-dimensional output subsystems to l_2 dimensions, using in the process $l_2 - l_1$ iterations. The algorithm assumes that this has been done, and computes its effect on the functions $\bar{f}_j(\bar{\xi})$ for $p_1 + 1 \leqq j \leqq p_1 + p_2$. If there are more than two distinct multi-indices, we do this process for the lowest two, then for them, taken together, plus the next lowest one, etc.

Arrange the p observability indices into r sets of distinct multi-indices, where $p_1 = k_1$ and $p_i = k_i - k_{i-1}$ for $2 \leqq i \leqq r$. We have Algorithm 2.4.

ALGORITHM 2.4 (Coefficient Prolongation Algorithm). When we have arbitrary observability indices $l_1, \cdots, l_p$, the following steps enable us to compute the coefficients of the polynomials $\bar{f}_j(\bar{\xi})$, for $1 \leqq j \leqq p$:

1 Compute the polynomials $\bar{f}_j(\bar{\xi})$ for 1 or $k_{i-1} + 1 \leqq j \leqq k_i$ and $1 \leqq i \leqq r$, according to the formula of Theorem 2.2, as applied to systems with k_i observability indices equal to l_{k_i}.

2 The first p_1 of the l_j's, those that are equal to l_1, correspond to valid $\bar{f}_j$'s.

3 Suppose that for the first k_i of these l_j's, we have adjusted to get valid $\bar{f}_j$'s, where $i \leqq r$. We adjust the next p_{i+1} of them.

4 Substitute $L_{\bar{f}}^{s-1} \bar{f}_j$ for $\bar{\xi}_{j:l_j+s}$, where $1 \leqq s \leqq l_{k_{i+1}} - l_j$ and $p_i + 1 \leqq j \leqq p_{i+1}$, eliminating the $\bar{\xi}$'s in $\bar{f}_j$, gained by prolongation.

5 Backsubstitute the solutions for the $\bar{f}_j$'s, where $1 \leqq j \leqq p_i$.

6 The coefficients of the monic monomials in $\bar{f}_j$, $k_i + 1 \leqq j \leqq k_{i+1}$ extend our coefficient solutions to cover the variables indexed by $1 \leqq j \leqq k_{i+1}$.

Proof. This is just a restatement of Lemma 2.3 as an algorithm. □

We formulate the Coefficient Prolongation Algorithm as a theorem, and establish that the relations thus given can be backsolved for the α injection functions.

THEOREM 2.5. *Suppose we have arbitrary observability indices $l_1, \cdots, l_p$. Then*

(i) *We may derive the coefficients $\bar{a}_{m:\dots}(\bar{y})$ in terms of the $\alpha(\bar{y})$ injection terms by application of the Coefficient Prolongation Algorithm.*

(ii) *We may solve these equations for the injection terms $\alpha_{m:*}(\bar{y})$ by integrating an expression in $\bar{a}_{k:1}$ and the coefficients $\bar{a}_{k:\dots}(\bar{y})$ of the "linear" monomials $\bar{\xi}_{k:j}$, $2 \leqq j \leqq l_k$, belonging to $\bar{f}_k(\bar{\xi})$, for $1 \leqq k \leqq m$.*

Proof. Outline. Part (ii) requires a somewhat extended argument. We employ the Coefficient Prolongation Algorithm 2.4 and use a double induction on the index l_m and the time derivative level j, $1 \leqq j \leqq l_m$. In each situation we keep track of the sources of the coefficients and their possible forms.

Body of proof. (i) This has already been done in Theorem 2.2 for the case where all observability indices are the same. The Coefficient Prolongation Algorithm enables us to extend this result inductively whenever $l_h < l_{h+1}$ for $1 \leqq h \leqq p - 1$.

(ii) This, too, is immediate from Theorem 2.2 when all observability indices are equal. The coefficient of the "linear" monomial $\bar{\xi}_{m:j}$ is matched to the injection term

$\alpha_{m:l_m-j+1}$, with $\bar{a}_{m:1}$ being matched to $\alpha_{m:l_m}$. The coefficients of the other monomials follow directly by differentiating and/or integrating and/or multiplication by an integer.

Suppose not all observability indices are equal. The $\alpha_{s:*}$'s for $l_1 = \cdots = l_s$ solve as in the one multi-index case.

Now suppose, by induction hypothesis, that we have successfully solved for $\alpha_{k:*}$ by integrating the $\bar{a}_{k:\ldots}$'s for $1 \leqq k \leqq m-1 < p$. If $l_{m-1} = l_m$, we may exploit the symmetry of the construction to integrate for the $\alpha_{m:*}$'s. Thus, we may assume we are in a prolongation-type situation, and develop the induction step for $k = m$.

Let us again inspect the partial differential equation (p.d.e.) expansion in (5), with $j = m$. Consider the expansion at the monomial $\bar{\xi}_{m:l_m-j+1}$, $1 \leqq j \leqq l_m - 1$, of $\bar{f}_m$. The coefficient $\bar{a}_{m:\cdots|l_m-j+1|\cdots}$ with (m) under the bars can be represented as an expression $\bar{e}_1(\bar{y})$. The Coefficient Prolongation Algorithm provides that this expression may involve (a) $\alpha_{m:*}$'s and their Lie derivatives and (b) expressions deriving from the $\bar{f}_k(\bar{\xi})$'s, for $1 \leqq k \leqq m-1$ and their Lie derivatives. By induction assumption, the type (b) expressions are of the form desired.

Now, we establish a second induction on j, where we solve the expressions $\bar{e}_1(\bar{y})$ for $\alpha_{m:j}$ by (at most) a simple integration of a derivative.

For $j = 1$, the coefficient of $\bar{\xi}_{m:l_m}$ is just $-\partial \alpha_{m:j}/\partial \bar{y}_m$, so that the solution is trivial.

For $j < l_m$, the expression $\bar{e}_1(\bar{y})$ is of the form

$$-\frac{\partial \alpha_{m:j}}{\partial \bar{y}_m} + \bar{e}_2(\bar{y}),$$

where $\bar{e}_2(\bar{y})$ is another expression involving only partials of $\alpha_{m:1}, \cdots, \alpha_{m:j-1}$ and expressions of type (b) above. Hence, it too may be solved by a simple integration of a derivative. Finally, $-\alpha_{m:l_m}$ is an isolated term in the expression for $\bar{a}_{m:1}$, so that we may solve for $\alpha_{m:l_m}$ trivially without benefit of integration, given the induction assumptions.

Hence, we may compute the α's as functions of the $\bar{a}$'s, as required. □

A consequence of Theorem 2.5 is that in standard coordinates $\bar{\xi}$, the polynomial $\bar{f}_m(\bar{\xi})$ will not actually achieve degree l_m. Thus, we will come to view the attainment of degree l_m to be "linked" to the transformation $\bar{\xi} = \bar{\xi}(\xi)$, and hence to $\bar{y} = \bar{y}(y)$ (see § 3). We have Corollary 2.6.

COROLLARY 2.6. *In the standard $\bar{\xi}$ coordinates, the polynomials $f_m(\bar{\xi})$, $1 \leqq m \leqq p$, are of degree at most $l_m - 1$.*

Proof. In the p.d.e. expansion (5) and the general expansion for $f_m(\bar{\xi})$, each of the $\alpha_{j:1}$'s, $1 \leqq j \leqq p$, undergoes the *most* Lie differentiations, at $l_m - 1$ times.

Successive Lie differentiations of any α will increase the degree of the resulting expression by (at most) one each time. Even if we have $l_j < l_m$, and we eventually hit a contribution from $f_j(\bar{\xi})$, it will only increase the degree by (at most) one. Hence, the (theoretically possible) coefficients of the monomials of degree l_m, in $f_m(\bar{\xi})$ must vanish, as required. □

The Coefficient Prolongation Algorithm 2.4 provides a process for computing coefficients in the general case. An explicit formula could surely be developed, but it would be quite complicated. The next corollary to Theorem 2.2 treats the simplest case where not all the observability indices are identical, viz., the generic case, with $n \not\equiv 0 \pmod p$.

COROLLARY 2.7. *For the generic case of two different multi-indices of size λ_1 and $\lambda_2 := \lambda_1 + 1$ and multiplicities p_1 and p_2, the coefficient $\bar{a}_{m:\ldots}(\bar{y})$ is given by*

$$\left(\frac{w!}{\prod_{j=1}^{p} \prod_{k=1}^{r_j} e_{j:k}!\, i_{j:k}!^{e_{j:k}}}\right)\left[\sum_{i=1}^{p_1}\left(\frac{\partial^e \alpha_{i:\lambda_1-w}(\bar{y})}{\partial \bar{y}_1^{e_1}\cdots\partial \bar{y}_p^{e_p}}\,\frac{\partial \alpha_{m:l_m-\lambda_1}(\bar{y})}{\partial \bar{y}_i}\right)-\frac{\partial^e \alpha_{m:\lambda_2-w}(\bar{y})}{\partial \bar{y}_1^{e_1}\cdots\partial \bar{y}_p^{e_p}}\right]. \tag{13}$$

In particular, $\bar{a}_{m:\ldots}(\bar{y})$ is given by Theorem 2.2 *for* $1 \leqq m \leqq p_1$ *and for degree* $\geqq \lambda_1$ *when* $p_1 + 1 \leqq m \leqq p$.

Proof. Again, consider the expansion (5). We need to do exactly one prolongation, where we substitute in effect $\bar{f}_1(\bar{\xi})$ for the "quasi variable" $\bar{\xi}_{1:l_2}$ in the prolonged version (which is identical to the expansion (5)).

That is, take

$$\bar{f}_j(\bar{\xi}) = -\sum_{i=1}^{l_j} L_f^{l_j-i} \alpha_{j:i} \tag{14}$$

in the multi-index (abusive) notation. The "quasi coefficient" of the "quasi variable" $\bar{\xi}_{1:l_2}$, gained from prolongation, satisfies the relation

$$\bar{a}_{2:l_2|} = -\frac{\partial \alpha_{2:1}}{\partial \bar{y}_1}. \tag{15}$$

Now, employ the substitution

$$\bar{\xi}_{1:l_2} = \bar{f}_1(\bar{\xi}). \tag{16}$$

The monomial $\bar{\xi}_{1:l_2}$ has degree $l_2 - 1$. By Corollary 2.6, this is the maximum degree possible permitting a term in $\bar{f}_2(\bar{\xi})$ to have a nonzero coefficient. Hence, this is the only monomial we must replace in the prolongation by a substitution.

Now, consider a monomial in $\bar{f}_2$. Its coefficient may receive contributions from (a) the substitution above for the "quasi variable" $\bar{\xi}_{1:l_2}$ and (b) directly from the expression in the right-hand side of formula (14). Thus, evaluating (14) using (15) and (16), we get that the contributions (a) and (b) correspond exactly to the first and second terms (respectively) in (13), as required. □

These results imply that we have a third way of formulating necessary and sufficient conditions for the existence of observer form coordinates for a system. That is, the necessary change of state coordinates $\bar{\xi} = \bar{\xi}(x)$ exists precisely when the relationship between the $\bar{a}$ coefficients and the α injection functions prescribed by Theorem 2.5 can be arranged. In other words, there are certain dependencies which must be obtained in order for the coefficients to be mutually compatible. We formulate *coefficient compatibility* below.

CONDITION 2.8. (Coefficient Compatibility Condition). The coefficients of the polynomials $\bar{f}_m(\bar{\xi})$, for $1 \leqq m \leqq p$, given in standard coordinates, satisfy the injection relations defined by Theorem 2.5. In particular, the coefficients must be compatible with the dependencies given by these relations.

Summing up, we have Theorem 2.9.

THEOREM 2.9. *The observable form, output coordinate change, and polynomial degree conditions, together with the Coefficient Compatibility Condition* 2.8, *are necessary and sufficient for an uncontrolled system to be transformable to nonlinear observer form.*

Proof. This is immediate, since if the first three conditions are satisfied, we can always convert to standard coordinates. □

Let us now examine various examples of the relations that arise from the Coefficient Compatibility Condition.

We express the $\bar{a}$'s in terms of the α's for simplicity's sake. Note that, according to Corollary 2.6, the coefficients of monic monomials of total degree l_m in $\bar{f}_m(\bar{\xi})$ vanish. Hence, they are omitted from these examples.

Example 2.10. Change of state coordinates, single output, dimension four. We have

$$\bar{a}_1 = -\alpha_4, \qquad \bar{a}_2 = -\frac{d\alpha_3}{d\bar{y}},$$

$$\bar{a}_{22} = -\frac{d^2\alpha_2}{d\bar{y}^2}, \qquad \bar{a}_{222} = -\frac{d^3\alpha_1}{d\bar{y}^3},$$

$$\bar{a}_{23} = -3\frac{d^2\alpha_1}{d\bar{y}^2}, \quad \bar{a}_3 = -\frac{d\alpha_2}{d\bar{y}}, \quad \bar{a}_4 = -\frac{d\alpha_1}{d\bar{y}}. \qquad \square$$

We exhibit the three examples where $p = 2$ and $l_2 = 3$.

Example 2.11. Change of state coordinates, $l_1 = l_2 = 3$. Here, the observability indices are equal, corresponding to Theorem 2.2. We have

$$\bar{a}_{1:1} = -\alpha_{1:3}, \qquad \bar{a}_{2:1} = -\alpha_{2:3},$$

$$\bar{a}_{1:22|} = -\frac{\partial^2\alpha_{1:1}}{\partial\bar{y}_1^2}, \qquad \bar{a}_{2:22|} = -\frac{\partial^2\alpha_{2:1}}{\partial\bar{y}_1^2},$$

$$\bar{a}_{1:|2} = -\frac{\partial\alpha_{1:2}}{\partial\bar{y}_2}, \qquad \bar{a}_{2:|2} = -\frac{\partial\alpha_{2:2}}{\partial\bar{y}_2},$$

$$\bar{a}_{1:|22} = -\frac{\partial^2\alpha_{1:1}}{\partial\bar{y}_2^2}, \qquad \bar{a}_{2:|22} = -\frac{\partial^2\alpha_{2:1}}{\partial\bar{y}_2^2},$$

$$\bar{a}_{1:2|} = -\frac{\partial\alpha_{1:2}}{\partial\bar{y}_1}, \qquad \bar{a}_{2:2|} = -\frac{\partial\alpha_{2:2}}{\partial\bar{y}_1},$$

$$\bar{a}_{1:3|} = -\frac{\partial\alpha_{1:1}}{\partial\bar{y}_1}, \qquad \bar{a}_{2:3|} = -\frac{\partial\alpha_{2:1}}{\partial\bar{y}_1},$$

$$\bar{a}_{1:2|2} = -2\frac{\partial^2\alpha_{1:1}}{\partial\bar{y}_1\partial\bar{y}_2}, \qquad \bar{a}_{2:2|2} = -2\frac{\partial^2\alpha_{2:1}}{\partial\bar{y}_1\partial\bar{y}_2},$$

$$\bar{a}_{1:|3} = -\frac{\partial\alpha_{1:1}}{\partial\bar{y}_2}, \qquad \bar{a}_{2:|3} = -\frac{\partial\alpha_{2:1}}{\partial\bar{y}_2}. \qquad \square$$

Example 2.12. Change of state coordinates, $l_1 = 2$, $l_2 = 3$. This is a generic case with two distinct observability indices, corresponding to Corollary 2.7. We have

$$\bar{a}_{1:1} = -\alpha_{1:2}, \qquad \bar{a}_{2:1} = \alpha_{1:2}\frac{\partial\alpha_{2:1}}{\partial\bar{y}_1} - \alpha_{2:3},$$

$$\bar{a}_{1:2|} = -\frac{\partial\alpha_{1:1}}{\partial\bar{y}_1}, \qquad \bar{a}_{2:2|} = \frac{\partial\alpha_{1:1}}{\partial\bar{y}_1}\frac{\partial\alpha_{2:1}}{\partial\bar{y}_1} - \frac{\partial\alpha_{2:2}}{\partial\bar{y}_1},$$

$$\bar{a}_{1:|2} = -\frac{\partial\alpha_{1:2}}{\partial\bar{y}_2}, \qquad \bar{a}_{2:|2} = \frac{\partial\alpha_{1:1}}{\partial\bar{y}_2}\frac{\partial\alpha_{2:1}}{\partial\bar{y}_1} - \frac{\partial\alpha_{2:2}}{\partial\bar{y}_2},$$

$$\bar{a}_{2:22|} = -\frac{\partial^2\alpha_{2:1}}{\partial\bar{y}_1^2}, \qquad \bar{a}_{2:2|2} = -2\frac{\partial^2\alpha_{2:1}}{\partial\bar{y}_1\partial\bar{y}_2},$$

$$\bar{a}_{2:|22} = \frac{\partial^2\alpha_{2:1}}{\partial\bar{y}_2^2}, \qquad \bar{a}_{2:|3} = -\frac{\partial\alpha_{2:1}}{\partial\bar{y}_2}. \qquad \square$$

Example 2.13. Change of state coordinates, $l_1 = 1$, $l_2 = 3$. This is the simplest nongeneric case, and corresponds to our general Theorem 2.5.

$$\bar{a}_{1:1} = -\alpha_{1:1},$$

$$\bar{a}_{2:1} = -\alpha_{1:1}^2 \frac{\partial^2 \alpha_{2:1}}{\partial \bar{y}_1^2} - \alpha_{1:} \frac{\partial \alpha_{1:1}}{\partial \bar{y}_1} \frac{\partial \alpha_{2:1}}{\partial \bar{y}_1} + \alpha_{1:1} \frac{\partial \alpha_{2:2}}{\partial \bar{y}_1} - \alpha_{2:3},$$

$$\bar{a}_{2:|2} = 2\alpha_{1:1} \frac{\partial^2 \alpha_{2:1}}{\partial \bar{y}_1 \partial \bar{y}_2} + \frac{\partial \alpha_{1:1}}{\partial \bar{y}_2} \frac{\partial \alpha_{2:1}}{\partial \bar{y}_1} - \frac{\partial \alpha_{2:2}}{\partial \bar{y}_2},$$

$$\bar{a}_{2:|22} = -\frac{\partial^2 \alpha_{2:1}}{\partial \bar{y}_2^2}, \qquad \bar{a}_{2:|3} = -\frac{\partial \alpha_{2:1}}{\partial \bar{y}_2}. \qquad \square$$

Space problems preclude the exposition of the controlled case (1). In general, we find that the expansion (4) extends naturally to this case. We use this to get results akin to Theorem 2.2, etc. (see [17]).

3. Polynomial coefficients given in observable form coordinates. We found explicit coefficient solutions in the case of standard coordinates. It would be preferable to get explicit solutions in the general observable form case, so that no change of state coordinates will be required. It turns out that this can be readily achieved.

The main adjustment will come from expressions in the parameters of the d.e.'s for change of output coordinates. We will have more degrees of freedom in the choice of polynomial coefficients available to us.

We can convert the results in standard coordinates $(\bar{\xi}, \bar{y})$ to observable form coordinates (ξ, y). For instance, when $p = 1$, we have the change of output coordinates formula

$$\bar{y} = \int_{y^0}^{y} \exp\left(-\frac{1}{l}\int_{y^0}^{\nu} a_{2l}(\eta)\, d\eta\right) d\nu. \tag{17}$$

Repeated Lie differentiations (with backsubstitutions) enable us to compute explicitly the relation $\bar{\xi} = \bar{\xi}(\xi)$.

Using *Macsyma*, this can be done economically for $l < 10$, or so. Let us consider the difficulties in this calculation. We again write J for the change of output coordinates function $dy/d\bar{y}$.

Example 3.1. $\bar{\xi} = \bar{\xi}(\xi)$ calculation, dimension three. We extend the calculation given in Example 2.1 to observable form coordinates ξ. Start with the expansion (7), time differentiate ξ_3, and substitute into (8). With some work, we get

$$a_1 = -J\alpha_3, \qquad a_2 = -J\frac{d\alpha_2}{dy},$$

$$a_{22} = -J\frac{d^2\alpha_1}{dy^2}, \qquad a_{222} = \frac{1}{3}\frac{da_{23}}{dy} - \frac{1}{9}a_{23}^2,$$

$$a_3 = -J\frac{d\alpha_1}{dy}.$$

Also, the x's solved for ξ's come out as

$$x_1 = \int_{y_0}^{y} \exp\left(-\frac{1}{3}\int_{\nu^0}^{\nu} a_{23}\, d\eta\right) d\nu,$$

$$x_2 = J^{-1}\xi_2 - \int_{y^0}^{y} a_3\, d\nu + \alpha_1^0,$$

$$x_3 = J^{-1}\left(\xi_3 - \frac{1}{3}a_{23}\xi_2^2 - a_3\xi_2\right) - \int_{y^0}^{y} a_2\, d\nu + \alpha_2^0. \qquad \square$$

However, it is also possible to find a formula for the a coefficients directly.

The expansion (4) is quite complicated, as expressed in the ξ coordinates. But, once we have worked out the expansion to the $(j-1)$th time derivative, we find that computing from there the jth time derivative is not so complicated. Thus, we have the following theorem.

THEOREM 3.2. *Suppose a single-output system is given in observable form coordinates* (ξ, y), *with index* l. *Then the polynomial* $f_1(\xi)$ *decomposes to*

$$q_l(\xi) - Jp_l(\xi), \tag{18}$$

where $p_l(\xi)$ *is (the negative of) the formal polynomial of degree* $l-1$ *in* ξ, *having the same coefficients as those of* $\bar{f}_1(\bar{\xi})$, *given by Theorem* 2.2, *and* $q_l(\xi)$ *derives from the recursion relations*

$$\begin{aligned} &q_1(\xi) = 0, \\ &q_j(\xi) = L_f q_{j-1}(\xi) + \frac{a_{2l}}{l}(\xi_2(\xi_j - q_{j-1})). \end{aligned} \tag{19}$$

Observe that $q_j(\xi)$ is an abuse of notation, since this polynomial depends formally on l also.

Proof. Outline. The right-hand sides of the expansions in (4) for $f_1(\xi)$ when $j = l$ and for $\xi_{j+1} = L_f\xi_j$ when $j < l$ differ only in the value of the constant l and in the presence, when $j < l$, of the term Jx_{j+1}. We do a simultaneous induction on these two expansions and perform the appropriate backsubstitution. The result matches the recursion relation given by (19).

Body of proof. Note that

$$L_f p_j(\xi) = p_{j+1}(\xi) - \alpha_{j+1}(y) \quad \text{for } j < l. \tag{20}$$

This construction is *formally* identical to the corresponding construction for $\bar{f}$ and $p_j(\bar{\xi})$ under these conditions. First, suppose $j = l = 2$. Direct calculation, using repeated Lie differentiation, gives us

$$\xi_1 = x_1, \qquad J^{-1}\xi_2 = x_2 - \alpha_1(y),$$
$$\xi_2 = J(x_2 - p_1(\xi)),$$

using $p_1(\xi) = \alpha_1(\xi_1) = \alpha_1(y)$. Moreover, using the o.d.e. for J and backsubstituting the previous relation, we continue and get

$$\begin{aligned} f_1(\xi) &= L_f J(x_2 - p_1(\xi)) + J(-\alpha_2(y) - p_2(\xi) + \alpha_2(y)) \\ &= \frac{a_{22}}{2}\xi_2(J(x_2 - p_1(\xi))) - Jp_2(\xi), \\ &= \frac{a_{22}}{2}\xi_2^2 - Jp_2(\xi). \end{aligned}$$

A similar calculation for the case $j = 2$ and $l > 2$ gives us, likewise,

$$\xi_3 = \frac{a_{2l}}{l}\xi_2^2 + J(x_3 - p_2(\xi)).$$

Thus, we evaluate

$$q_2(\xi) = \frac{a_{2l}}{l}\xi_2^2.$$

Since $q_1(\xi)=0$, we see that the relation (19) holds for the case $j=2$. Assume the expansions (4) evaluate to (18) for $j=l$ and simultaneously to

$$q_j(\xi)+J(x_{j+1}-p_l(\xi))$$

for $j<l$, where $q_j(\xi)$ satisfies the recursion relation (19).

We calculate (assuming, first, that $j=l-1$)

$$\begin{aligned}\xi_{j+1}&=q_j(\xi)+J(x_{j+1}-p_j(\xi)),\\ L_f\xi_{j+1}&=L_fq_j(\xi)+L_fJ(x_{j+1}-p_j(\xi))+J(L_fx_{j+1}-L_fp_j(\xi))\\ &=L_fq_j(\xi)+\frac{a_{2l}}{l}\xi_2(J(x_{j+1}-p_j(\xi)))+J(-\alpha_{j+1}(y)-p_{j+1}(\xi)+\alpha_{j+1}(y))\\ &=L_fq_j(\xi)+\frac{a_{2l}}{l}\xi_2(\xi_{j+1}-q_j(\xi))-Jp_{j+1}(\xi).\end{aligned}$$

From this we extract the homogeneous polynomial of degree l and get

$$q_{j+1}(\xi)=L_fq_j(\xi)+\frac{a_{2l}}{l}\xi_2(\xi_{j+1}-q_j(\xi)). \tag{21}$$

Finally, if $j<l-1$, an analogous calculation establishes the relation (21), as required. □

Along the lines of the notation used in § 2 above, we use i_k, e_k, r, e, and w to describe the monomials

$$\xi^{\#}:=\prod_{k=1}^{r}\bar{\xi}_{i_k+1}^{e_k}$$

of $f_1(\xi)$.

In addition, we write $P(m)$ for the partitions of the integer m. We write a partition of $e-1$ by

$$e-1=\sum_{j=1}^{s}c_jn_j,$$

where the n_j's are a set of natural numbers in strictly increasing order. We define $c:=\sum_{j=1}^{s}c_j$ to be the *number of pieces* of the partition. For notational convenience, we also write $d^0a_{2l}(y)/dy^0$ as a synonym for $a_{2l}(y)$.

COROLLARY 3.3. *For the case of a single index l,*

(i) *For monomials of degree less than l, the polynmial coefficient $a_{\dots}(y)$ of $\xi^{\#}$ is given by*

$$-\left(\frac{w!}{\prod_{k=1}^{r}e_k!\,i_k!^{e_k}}\right)\frac{d^e\alpha_{l-w}(y)}{dy^e}\frac{dy}{d\bar{y}}. \tag{22}$$

(ii) *For monomials of degree l, the polynomial coefficient $a_{\dots}(y)$ of $\xi^{\#}$ is given by*

$$-\sum_{\pi\in P(e-1)}\left(\frac{w!(e-1)!}{\prod_{k=1}^{r}e_k!\,i_k!^{e_k}\prod_{j=1}^{s}c_j!n_j!^{c_j}}\right)\left(\frac{-1}{l}\right)^{c}\prod_{j=1}^{s}\left(\frac{d^{n_j-1}a_{2l}(y)}{dy^{n_j-1}}\right)^{c_j}. \tag{23}$$

Proof. Part (i) is immediate from Theorem 3.2.

(ii) We apply the coefficient relation (19). □

Example 3.4. The homogenous polynomial $q_j(\xi)$, for $1\leqq j\leqq 4$, and $l\geqq j$. These are readily generated by direct computation using *Macsyma*, or from formula (23).

We have, writing a_{2l} for $a_{2l}(y)$, etc.,

$$q_1 = 0, \qquad q_2 = \frac{a_{2l}}{l}\xi_2^2,$$

$$q_3 = 3\frac{a_{2l}}{l}\xi_2\xi_3 + \left(\frac{da_{2l}}{dy} - \frac{1}{l^2}\frac{d^2a_{2l}}{dy^2}\right)\xi_2^3,$$

$$q_4 = 4\frac{a_{2l}}{l}\xi_2\xi_4 + 3\frac{a_{2l}}{l}\xi_3^2 + 6\left(\frac{1}{l}\frac{da_{2l}}{dy} - \frac{a_{2l}^2}{l^2}\right)\xi_2^2\xi_3$$

$$+\left(\frac{1}{l}\frac{d^2a_{2l}}{dy^2} - 3\frac{a_{2l}}{l^2}\frac{da_{2l}}{dy} + \frac{a_{2l}^3}{l^3}\right)\xi_2^4. \qquad \square$$

We conjecture that Theorem 3.2 can be readily extended to the case where $p > 1$.

4. Implications and conclusions. We do not have a comprehensive understanding of nonlinear observers. The normal form approach was improved on here and brought closer to effective computability. The primary implication of the coefficient formulas which govern change of state coordinates for nonlinear observers is that these calculations are more susceptible to numeric algorithms than heretofore supposed.

Let us go back and review the bracket vanishing and bracket spanning algorithms. Using the Jacobi identity enables us to reduce the calculation of brackets of elements in $\{\mathrm{ad}_{-f}^{i-1}q_j : 1 \leqq i \leqq l_j\}$ to the calculation of brackets of the form $[\mathrm{ad}_{-f}^{i-1}q_j, q_k]$, for $1 \leqq i \leqq 2l_k - 2$, with indices numbered so that $j \leqq k$. This is a massive saving, but it does not obviate the need for extensive bracket computations in the bracket vanishing case. Similarly, the bracket spanning case (if and when it is extended to the multi-index situation) will likely require bracket calculations to the order of the indices.

One solution would be to write algorithms for bracket calculation that will make these calculations faster. Grossman and Larson [6] have made some progress with this. Another solution to this is to provide the explicit solutions to the change of state coordinates differential equations, as provided here. For instance, the author has written a *Macsyma* program, "Nonlinear Observer," described in [17], which computes the observer *abstractly* and *in the general case* when $p = 1$ and is extendable to the multiple output case. A third approach (see [7], [11]) now being tried involves "approximate normal forms." All these advances indicate that numeric algorithms now seem to be more closely at hand.

Another point worthy of note is that the coefficient compatibility approach implies a corresponding parameter estimation problem [3]. Suppose we have a system which we presume can be put in nonlinear observable form (as is generically the case). Suppose it satisfies the degree condition (this depends on the type of system under consideration). Then the system can be estimated by estimating the $a(y)$ coefficients.

If the system admits nonlinear observer form, then Theorem 2.5, as postulated to extend to the general case for output coordinates, says that the polynomial coefficients for the observable form polynomials are all derivatives of the $\alpha(y)$ injection functions. That is, the injection functions may be found by integration of a certain subset of the $a(y)$ coefficients. Either way, the system is determined by a (small) finite set of parameters.

In the dimension three example (2.1), the system is determined by the parameters $a_1(y)$, $a_2(y)$, and $a_3(y)$, which are the coefficients of the *affine* terms. The incorporation of the change of outputs coordinates (Thm. 3.2) gives us one additional parameter, the $a_{23}(y)$ coefficient that determines the o.d.e. governing this coordinate change. (Note how the parameters in nonlinear observer form extend those of the linear case!)

The number of parameters is affected by increasing the number of output coordinates p, since then the a's become functions of more variables.

In short, there is room to develop a theory of parameter estimation and state identification for systems which may be put into observer normal form.

It is important to do research in and to develop a full account of nonlinear observers. We have not attempted to go that far, but hopefully this contribution will provide some new impetus and direction for pursuing this goal.

Appendix A. Proof of the prolongation lemma. We present the proof of Lemma 2.3. First, we require Proposition A1.

PROPOSITION A1. *For a system with arbitrary indices, it is necessary that* $\partial y_j/\partial \bar{y}_i =: J_i^j = 0$ *when* $l_j > l_i$.

Proof. The proof is immediate. See [14] or [17] for details. □

Proof of Lemma 2.3. *Outline.* Essentially, we add a new multidimension, by way of the coordinate $\check{x}_{1:\lambda_1}$. The solution to S is to be prolonged to the hyperplane

$$\check{x}_{1:\lambda_1} = 0. \tag{24}$$

We set up the prolongation relations and verify that S' may be attained.

Body of proof. We exhibit the prolonged system S' in observable and observer forms. By abuse of notation, we are using y_j, $j = 1, 2$, to represent p_j-vectors. We do likewise for the l_j's, $\xi_{j:*}$'s, $x_{j:*}$'s, $\alpha_{j:*}$'s, f_j's, the prolonged coordinates $(\check{\xi}, \check{\bar{y}})$, etc. We have

$$\begin{aligned} \check{y}_j &= \check{\xi}_{j:1}, & \check{\bar{y}}_j &= \check{x}_{j:1}, \\ \dot{\check{\xi}}_{j:k} &= \check{\xi}_{j:k+1}, & \dot{\check{x}}_{j:k} &= \check{x}_{j:k+1} - \alpha_{j:k}(\check{y}), \\ \dot{\check{\xi}}_{j:\lambda_j} &= \check{f}_j(\check{\xi}), & \dot{\check{x}}_{j:\lambda_j} &= -\alpha_{j:\lambda_j}(\check{y}), \end{aligned} \tag{25}$$

with $j = 1, 2$ and $1 \leqq k \leqq \lambda_j - 1$.

Here we are taking

$$\begin{aligned} &\check{\xi}_{j:k} := \xi_{j:k} \quad \text{when } j = 1, 2 \text{ and } 1 \leqq k \leqq \lambda_1 - 1, \\ &\alpha_{1:\lambda_1} := 0, \end{aligned} \tag{26}$$

so that

$$\dot{\check{x}}_{1:\lambda_1} = 0 \tag{27}$$

holds.

To set up the remainder of the prolongation relations, it is advisable to look at the defining p.d.e.'s for S and see how they must be "adjusted" for the prolongation to S'.

Thus, we continue the theme expressed in formula (4), extracting p.d.e.'s relating observable form (2) to observer form (3). We now exhibit that expansion for the two multi-index case under consideration. We arrange the dimensionalities of the "α," "f," "ξ," "x" and "J" notation appropriately and get

$$\begin{aligned} &\xi_{j:1} = y_j(\bar{y}) = y_j(x_1), \\ &\quad \xi_{j:2} = \dot{\xi}_{j:1} = J_j^1(x_{1:2} - \alpha_{1:1}) + J_j^2(x_{2:2} - \alpha_{2:1}), \\ &\quad \xi_{j:3} = \dot{\xi}_{j:2} = \sum_{k=1}^{2} J_j^k\left(x_{k:3} - \alpha_{k:2} - \sum_{r=1}^{2} \frac{\partial \alpha_{k:1}}{\partial \bar{y}_r}(x_{r:2} - \alpha_{r:1})\right) + \cdots, \\ &\qquad \vdots \\ &\xi_{j:l_1} = \dot{\xi}_{j:l_1-1} = \sum_{k=1}^{2} J_j^k\left(x_{k:l_1} - \alpha_{k:l_1-1} - \sum_{r=1}^{2} \frac{\partial \alpha_{k:l_1-2}}{\partial \bar{y}_r}(x_{r:2} - \alpha_{r:1}) + \cdots\right) + \cdots, \end{aligned} \tag{28}$$

with additional terms depending on j.

The completion of (26) for $j=1$ goes as follows.

CLAIM. We can prolong f_1 by the relations

$$\check{\xi}_{1:\lambda_1} := J_1^1 \check{x}_{1:\lambda_1} + f_1(\check{\xi}), \tag{29}$$

$$\check{f}_1(\check{\xi}) := \frac{\partial J_1^1}{\partial y_1} \check{\xi}_{1:2} (J_1^1)^{-1} (\check{\xi}_{1:\lambda_1} - f_1) + \sum_{j=1}^{2} \sum_{k=1}^{l_j} f_{1;j:k} \dot{\check{\xi}}_{j:k}. \tag{30}$$

We may match the continuation of (28) to its prolonged version. We have

$$f_1(\xi) = \dot{\xi}_{1:l_1} = J_1^1 \left(-\alpha_{1:l_1} - \sum_{r=1}^{2} \frac{\partial \alpha_{1:l_1-1}}{\partial \bar{y}_r} (x_{r:2} - \alpha_{r:1}) + \cdots \right) + \cdots, \tag{31}$$

and

$$\begin{aligned} \check{\xi}_{1:\lambda_1} &= \dot{\check{\xi}}_{1:\lambda_1-1} \\ &= J_1^1 \left(\check{x}_{1:\lambda_1} - \alpha_{1:\lambda_1-1} - \sum_{r=1}^{2} \frac{\partial \alpha_{1:\lambda_1-2}}{\partial \bar{y}_r} (\check{x}_{r:2} - \alpha_{r:1} + \cdots \right) + \cdots . \end{aligned} \tag{32}$$

Recall that Proposition $A1$ establishes that $J_1^2 = 0$.

Now, assuming the partial prolongation (26), we may compare (31) (using $\check{\xi}$ and $\check{x}$ for ξ and x) with the corresponding equation (32). We get

$$\check{\xi}_{1:\lambda_1} = J_1^1 \check{x}_{1:\lambda_1} + f_1(\check{\xi}),$$

whence (29).

For our prolongation to be possible, we must have $\dot{\check{\xi}}_{1:\lambda_1} = \check{f}_1(\check{\xi})$. Differentiating (29), and recalling that $\dot{\check{x}}_{1:\lambda_1} = 0$ (27) and $J_1^2 = 0$, we get

$$\dot{\check{\xi}}_{1:\lambda_1} = \frac{\partial J_1^1}{\partial y_1} \xi_{1:2} \check{x}_{1:\lambda_1} + \sum_{j=1}^{2} \sum_{k=1}^{l_j} f_{1;j:k} \dot{\check{\xi}}_{j:k}. \tag{33}$$

Finally, we take $\check{f}_1(\check{\xi}) := \dot{\check{\xi}}_{1:\lambda_1}$, and backsolve in (33) for $\check{f}_1(\check{\xi})$. Since J_1^1 does not vanish locally, we may do this, and the claim follows.

The completion of (26) for $j=2$ is somewhat more intricate. This is due to "twistings" induced in the p.d.e.'s for the higher time derivatives of y_2 by the (formal) introduction of $\check{\xi}_{1:\lambda_1}$.

Extending (28) for the $j=2$ case, we have

$$\begin{aligned} \xi_{2:l_1+1} &= \dot{\xi}_{2:l_1} \\ &= J_2^2 x_{2:l_1+1} + \sum_{k=1}^{2} J_2^k \left(-\alpha_{k:l_1} - \sum_{r=1}^{2} \frac{\partial \alpha_{k:l_1-1}}{\partial \bar{y}_r} (x_{r:2} - \alpha_{r:1}) + \cdots \right) + \cdots, \\ \xi_{2:l_1+2} &= \dot{\xi}_{2:l_1+1} \\ &= J_2^2 (x_{2:l_1+2} + \alpha_{2:l_1+1}) + \left(\sum_{r=1}^{2} \frac{\partial J_2^2}{\partial \bar{y}_r} (x_{r:2} - \alpha_{r:1}) \right) x_{2:l_1+1} \\ &\quad + \sum_{k=1}^{2} J_2^k \left(- \sum_{r=1}^{2} \frac{\partial \alpha_{k:l_1}}{\partial \bar{y}_r} (x_{r:2} - \alpha_{r:1}) + \cdots \right) + \cdots, \\ &\ \ \vdots \\ \xi_{2:l_2} &= \dot{\xi}_{2:l_2-1} = J_2^2 (x_{2:l_2} - \alpha_{2:l_2-1}) + \cdots \\ &\quad + \sum_{k=1}^{2} J_2^k \left(- \sum_{r=1}^{2} \frac{\partial \alpha_{k:l_2-2}}{\partial \bar{y}_r} (x_{r:2} - \alpha_{r:1}) + \cdots \right) + \cdots, \\ f_2(\xi) &= \dot{\xi}_{2:l_2} \\ &= -J_2^2 \alpha_{2:l_2} + \cdots + \sum_{k=1}^{2} J_2^k \left(- \sum_{r=1}^{2} \frac{\partial \alpha_{k:l_2-1}}{\partial \bar{y}_r} (x_{r:2} - \alpha_{r:1}) + \cdots \right) + \cdots . \end{aligned} \tag{34}$$

What occurs when we introduce the new variable $\check{x}_{1;\lambda}$ as in (25)? We redo (34), this time using "checked" coordinates $\check{\xi}$ and $\check{x}$. By abuse of notation, we write "$\xi_{2;j}$," $l_1+1\leqq j\leqq l_2$, to denote the expression given by the corresponding right-hand side in (34), with $\check{x}$'s replacing x's.

We may now take

$$\begin{aligned}\check{\xi}_{2:\lambda_1} &:= s_0\check{x}_{1:\lambda_1}+\xi_{2:l_1+1},\\ \check{\xi}_{2:\lambda_1+1} &:= (L_{\check{A}\check{x}-\alpha}s_0+s_1)\check{x}_{1:\lambda_1}+\xi_{2:l_1+2},\\ &\ \vdots\\ \check{\xi}_{2:\lambda_2} &:= \left(\sum_{\sigma=0}^{\lambda_2-\lambda_1} L_{\check{A}\check{x}-\alpha}^{\lambda_2-\lambda_1-\sigma}s_\sigma\right)\check{x}_{1:\lambda_1}+\xi_{2:l_2},\\ \check{f}_2(\check{\xi}) &:= \left(\sum_{\sigma=0}^{\lambda_2-\lambda_1+1} L_{\check{A}\check{x}-\alpha}^{\lambda_2-\lambda_1+1-\sigma}s_\sigma\right)\check{x}_{1:\lambda_1}+f_2(\check{\xi}).\end{aligned}\tag{35}$$

Here, $\check{A}\check{x}-\alpha$ is $\check{f}$ in the $\check{x}$ coordinates, with $\check{A}$ being in Brunovsky canonical form. α, by abuse of notation, represents the prolonged $(n+1)$-vector

$$\begin{bmatrix}\alpha_{1:1}\\ \vdots\\ \alpha_{1:\lambda_1-1}\\ 0\\ \alpha_{2:1}\\ \vdots\\ \alpha_{2:\lambda_2}\end{bmatrix}.$$

The s_σ's, $0\leqq\sigma\leqq\lambda_2-\lambda_1+1$, are polynomials in $\check{x}$ with functions in $\bar{y}$ for coefficients. (Note that the coefficients of $\check{x}_{1:\lambda_1}$ will be of degree $\geqq 1$ if $\sigma\geqq 2\lambda_1-1$.)

S' is now defined by formulas (26), (27), (29), (30), and (35).

Finally, consider the hyperplane (24) given by $\check{x}_{1:\lambda_1}=0$. Restricted to this hyperplane, the equations for S and S' are identical, with the *same* α's and transformation $y=y(\bar{y})$. Thus, the solutions are the same, and S' prolongs S, as required for the lemma. □

ASYMPTOTIC BEHAVIOR OF STOCHASTIC SYSTEMS POSSESSING MARKOVIAN REALIZATIONS*

S. P. MEYN† AND P. E. CAINES‡

Abstract. Markovian stochastic systems of the form $\Phi_{k+1} = F(\Phi_k, w_{k+1})$ are considered, where $\mathbf{w}$ is an independent and identically distributed process and $\mathbf{\Phi}$ is a Markov chain, both evolving in Euclidean space. A condition called weak stochastic controllability (w.s.c.) is introduced, which is a generalization of the concept of controllability in linear system theory. Two different formulations of stability (boundedness in probability and boundedness in probability on average) are presented, and it is shown that these conditions are equivalent under the w.s.c. condition. These results are related to the ergodic behavior of $\mathbf{\Phi}$ by a set of results that includes the following: if $\mathbf{\Phi}$ is bounded in probability and w.s.c., then (i) sample path averages of functions of the state process converge for every initial condition, and (ii) if the stability is uniform then state process probabilities converge to a periodic orbit of probabilities. Finally, if the origin of an undriven system is globally attracting, the linearized system is controllable, and some technical conditions hold, then it is shown that $\mathbf{\Phi}$ is w.s.c.

Key words. nonlinear systems, accessibility, stochastic systems, Markov chains.

AMS(MOS) subject classifications. 60J05, 93B05, 93E03, 93E15

1. Introduction. The ergodic theory of Markov chains is a natural tool to apply in the analysis of nonlinear stochastic systems under feedback control. Such techniques can be found in the pioneering studies of stochastic stability [Kushner, 1967], [Kushner, 1972], and [Wonham, 1966], and there has recently been a resurgence of interest in their application in such work as [Kushner and Schwartz, 1984], [Kumar, 1985], [Aloneftis, 1987], [Meyn and Caines, 1987], [Meyn and Guo, 1990], Chapter 11 of [Caines, 1988], [Fernandez-Gaucherand, Arapostathis, and Marcus, 1988], and [Arapostathis and Marcus, 1990]. This is partly because the complexity of the feedback systems arising in stochastic control (in particular in stochastic adaptive control) often makes exact analysis impossible, so we seek techniques that will give overall qualitative measures of behavior.

Ergodic theory provides one such approach for stochastic systems once a Markovian state process has been constructed for the controlled output process. In the case where an appropriate form of stability holds together with other technical conditions, we may deduce (i) the existence of an invariant measure π for the process, and (ii) the convergence almost surely of the sample averages of a function of the state process (and its expectation) to its conditional expectation with respect to the sub σ-algebra of invariant sets.

In the ergodic theory of Markov chains' most general setting, it is not possible to establish the desired ergodic properties unless the initial condition of the process lies in a set of full measure with respect to the invariant probability π. A central issue in this paper is generalizing such results to the case of arbitrary initial conditions.

An example. To motivate the discussion and definitions that follow, consider the Gaussian Markov process $\mathbf{\Phi}$ generated by the recursion

$$\Phi_{k+1} = A\Phi_k + Bw_{k+1}, \tag{1}$$

where $\mathbf{\Phi}$ and $\mathbf{w}$ evolve on $\mathbb{R}^n$ and $\mathbb{R}^p$, respectively; A and B are, respectively, $n \times n$ and $n \times p$ matrices; $\mathbf{w} = \{w_k : k \geqq 1\}$ is an independent and identically distributed Gaussian stochastic process on $\mathbb{R}^p$ with $w_k \sim N(0, I)$ for all k; and the deterministic initial condition $\Phi_0 \in \mathbb{R}^n$ is given.

Suppose that the eigenvalues of A fall strictly within the unit disk in $\mathbb{C}$. Then many of the asymptotic properties of (1) are determined by its unique invariant probability π. The probability π is the Gaussian distribution $N(0, F)$, where F is the unique solution to the Lyapunov equation

$$F = AFA^\top + BB^\top.$$

If the pair (A, B) is controllable then an analysis of the asymptotic properties of $\mathbf{\Phi}$ is straightforward. If f is any positive Borel function on $\mathbb{R}^n$, then by the Strong Law of Large Numbers for Markov chains [Doob, 1953], for almost every initial condition $\Phi_0 = x \in \mathbb{R}^n[\pi]$,

$$\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k) = \int f\, d\pi \quad \text{a.s. } [P_x], \tag{2}$$

and by a simple computation,

$$\lim_{k\to\infty} E_x[f(\Phi_k)] = \int f\, d\pi. \tag{3}$$

By conditioning at time n, where $n = \dim \mathbf{\Phi}$, (2) may be generalized to arbitrary initial conditions by using the fact that $P^n(x, \cdot)$ is absolutely continuous with respect to π, which is implied by the controllability assumption. Hence if (1) describes a stochastic system operating under feedback, and f is a loss function on the state process $\mathbf{\Phi}$, then by (2), (3) the infinite horizon performance is determined by the invariant probability π.

On the other hand, if (A, B) is not controllable then (2), (3) does not hold for such a general class of functions in general. Because the covariance matrix F is not full rank in this case, the invariant probability π is supported on the controllability subspace $L \subset \mathbb{R}^n$ whose dimension is strictly less than n. Hence (2), (3) may not hold unless f is continuous on L. (Take, for example, f to be the indicator function of the set L.) To establish (2), (3) even for continuous functions requires extensive exploitation of the linear structure of (1). Motivated by such considerations our objective in this paper is to generalize the notion of controllability to analyse nonlinear stochastic systems operating under feedback.

Methodology and previous results. The principal tools applied (such as Harris recurrence) come from the theory of irreducible Markov chains; see for example [Nummelin, 1984]. It turns out that some form of stochastic controllability condition is precisely what is needed to obtain irreducibility for the state process $\mathbf{\Phi}$, and then a crude stability hypothesis implies the ergodic theorems of interest. In general, when no controllability hypothesis is satisfied, it is natural to search for a restricted class of functions (say, continuous bounded functions) for which (2), (3) hold. However, with the exception of the results for the class of *regular* Markov chains as presented in [Feller, 1971] that are extremely difficult to apply since a general verifiable criterion for regularity is not available, and the theory presented in [Foguel, 1973] that concentrates on the structure of the state space rather than stability and ergodic theory, there is no alternative framework available that is suitable for the analysis of stochastic control systems.

The present paper may be compared to [Kliemann, 1987] (see also [Ichihara and Kunita, 1974]), where diffusions possessing hypoelliptic generators are considered. However, the so-called crucial use of continuity of the samples paths of the processes under consideration, and use of the resolvant operator of the process, make these results meaningless in a discrete time setting. The techniques of the present paper extend naturally to the nonsmooth case, and may also be used to considerably strengthen the results now available in the continuous time Markov process literature.

Generalizations of some of the results of this paper to the case of discontinuous dynamics, and to continuous time processes with discontinuous sample paths (including Hunt processes) has begun in [Meyn and Tweedie, 1990a,b].

Overview of results. The paper is organized as follows. In § 2 we begin with definitions of weak and local stochastic controllability, discuss further formulations of controllability for a freely evolving system, and present some stability criteria for Markovian systems including boundedness in probability, and an averaged formulation of this condition. The main results of the paper are then presented: if $\mathbf{\Phi}$ is bounded in probability and w.s.c., then (i) sample path averages of functions of the state process converge for every initial condition, and (ii) if the stability is uniform, then state process probabilities converge to a periodic orbit of probabilities. Finally, if the origin of an undriven system is globally attracting, the linearized system is controllable, and some technical conditions hold, then it is shown that $\mathbf{\Phi}$ is w.s.c.

In § 3 some general results concerning the topological structure of the state space are derived and then applied to establish limit theorems for weakly stochastically controllable systems and hence the proofs of the main results.

2. Markovian systems. In this paper we consider input-state stochastic systems possessing Markovian realizations (which we call Markovian systems) of the form

$$\Phi_{k+1}=F(\Phi_k, w_{k+1}), \qquad k\in\mathbb{Z}_+, \tag{4}$$

where for all k, $\Phi_k\in\mathbf{X}=$ an open subset of $\mathbb{R}^n$, $w_k\in\mathbb{R}^p$, and $F:\mathbf{X}\times\mathbb{R}^p\to\mathbf{X}$ is smooth (C^∞).

We assume that the initial condition Φ_0 and the distrubance process $\mathbf{w}$ satisfy

A1. $(\Phi_0, \mathbf{w})$ are random variables on the probability space $(\Omega, \mathcal{F}, P_{\Phi_0})$;

A2. Φ_0 is independent of $\mathbf{w}$;

A3. $\mathbf{w}$ is an independent and identically distributed process;

A4. The distribution μ_w of w_k, $k\in\mathbb{Z}_+$, possesses a density that is lower semicontinuous.

A function $f:\mathbb{R}^p\to\mathbb{R}$ is *lower semicontinuous* if the set $\{x\in\mathbb{R}^p: f(x)>t\}$ is open for each $t\in\mathbb{R}$. The Vitali-Carathéodory Theorem implies that any $f\in L^1(\mathbb{R}^p, \mathcal{B}(\mathbb{R}^p), dx)$ may be approximated in L^1 by lower semicontinuous functions, and hence any distribution that possesses a density may be approximated in total variation norm by distributions satisfying condition A4.

Condition A4 implies that μ_w possesses a density that is strictly positive on an open set $\mathcal{O}_w\subset\mathbb{R}^p$ and zero elsewhere.

Markovian systems will be obtained from input-state-output systems by the choice of time invariant feedback control laws. To obtain the ergodic properties of interest for $\mathbf{\Phi}$ it will, of course, be necessary to verify that each particular feedback law generates a system satisfying the appropriate hypotheses.

The crucial property of $\mathbf{\Phi}$ that permits us to obtain these ergodic properties is that it possesses stationary Markovian transition probabilities P^k, $k \in \mathbb{Z}_+$, satisfying the defining property

$$E[f(\Phi_{n+k}) \mid \Phi_n] = \int_{\mathbf{X}} P^k(\Phi_n, dy) f(y) \quad \text{a.s. } [P_{\Phi_0}]$$

for all bounded Borel measurable functions f on $\mathbf{X}$. Because F is a continuous function of its arguments, the Markov chain $\mathbf{\Phi}$ has the Feller property.

2.1. Controllability. The *extended transition map* $S_x^k : \mathbb{R}^{kp} \to \mathbf{X}$ of the Markovian system (4) is defined inductively for $k \in \mathbb{Z}_+$, $x \in \mathbf{X}$, and $\mathbf{z} = (z_1, \cdots, z_k)^\top \in \mathbb{R}^{pk}$ by

$$S_x^k(\mathbf{z}) = F(S_x^{k-1}(z_1, \cdots, z_{k-1}), z_k), \qquad k \geqq 1,$$

$$S_x^0 = x.$$

The extended transition map is so named because for all $k \in \mathbb{Z}_+$,

$$\Phi_k = S_x^k(w_1, \cdots, w_k) \quad \text{when } \Phi_0 = x.$$

Stochastic controllability. Here we introduce two useful formulations of stochastic controllability. Given two measures ν and μ on $\mathcal{B}(\mathbf{X})$ we say that ν is *absolutely continuous* with respect to μ (denoted $\nu < \mu$) if $\nu\{A\} = 0$ whenever $\mu\{A\} = 0$. The measures ν and μ are called *equivalent* (denoted $\nu \approx \mu$) if $\nu < \mu$ and $\mu < \nu$. Throughout this paper we let $\mathbf{1}_A \mu$ denote the measure defined for $B \in \mathcal{B}(\mathbf{X})$ by $(\mathbf{1}_A \mu)\{B\} \triangleq \mu\{A \cap B\}$.

DEFINITION. (i) The Markovian system (4) is called *locally stochastically controllable* (l.s.c.) if for each initial condition $x \in \mathbf{X}$ there exists $T = T(x) \in \mathbb{Z}_+$ and an open set $\mathcal{O}_x \subset \mathbf{X}$ such that $P^T(x, \cdot) \approx \mathbf{1}_{\mathcal{O}_x} \mu^{\text{Leb}}$.

(ii) The Markovian system (4) is called *weakly stochastically controllable* (w.s.c.) if for each initial condition $x \in \mathbf{X}$ there exists $T = T(x) \in \mathbb{Z}_+$ and an open set $\mathcal{O}_x \subset \mathbf{X}$ such that $P^T(x, \cdot) > \mathbf{1}_{\mathcal{O}_x} \mu^{\text{Leb}}$.

If (4) is l.s.c. then the probability $P^T(x, \cdot)$ possesses a density that is strictly positive on an open set $\mathcal{O}_x$ and zero elsewhere. Similarly, if (4) is w.s.c. then the Radon-Nikodym derivative of the probability $P^T(x, \cdot)$ (with respect to Lebesgue measure) is strictly positive on $\mathcal{O}_x$.

One consequence of these definitions may be roughly described as follows: If (4) is weakly or locally stochastically controllable, and if starting at a point $y \in \mathbf{X}$ it is possible to reach a point $z \in \mathcal{O}_y$ at time T, then at time T all points in some neighborhood of z are reachable from y. In fact, under assumptions A1-A4 and the smoothness condition made on F, it is easily verified that with the disturbance sequence $\mathbf{w}$ viewed as an input, the forward accessibility condition of [Jakubczyk and Sontag, 1989] is equivalent to weak stochastic controllability. The terminology may also be motivated by the fact that if $F : \mathbf{X} \times \mathbb{R}^p \to \mathbf{X}$ is linear then the notions of local stochastic controllability, weak stochastic controllability, and controllability in the usual sense are equivalent.

For $y \in \mathbf{X}$ and a sequence $\{z_k : z_k \in \mathbb{R}^p, k \in \mathbb{Z}_+\}$ let $\{A_k, B_k : k \in \mathbb{Z}_+\}$ denote the matrices

$$A_k = A_k(y, z_1, \cdots, z_{k+1}) \triangleq \left[\frac{\partial F}{\partial x}\right]_{(S_y^k, z_{k+1})}$$

$$B_k = B_k(y, z_1, \cdots, z_{k+1}) \triangleq \left[\frac{\partial F}{\partial z}\right]_{(S_y^k, z_{k+1})},$$

and let $C_y^k = C_y^k(z_1, \cdots, z_k)$ denote the *generalized controllability matrix* (along the sequence z_1^k)

$$C_y^k \triangleq [A_{k-1} \cdots A_1 B_0 | A_{k-1} \cdots A_2 B_1 | \cdots | A_{k-1} B_{k-2} | B_{k-1}]. \tag{5}$$

We remark that if F is of the form

$$F(y, z) = Ay + Bz,$$

then the generalized controllability matrix becomes the familiar controllability matrix

$$[A^{T-1}B | A^{T-2}B | \cdots | AB | B].$$

Note that all quantities in the matrix (5) are deterministic.

Here we give necessary and sufficient conditions for local and weak stochastic controllability in terms of the generalized controllability matrix defined above. Alternative conditions for weak stochastic controllability involving the dimension of a certain Lie algebra and substantially stronger conditions on the function F may be found in [Jakubczyk and Sontag, 1989].

Let $\mathcal{O}_w^T$ denote the T-fold Cartesian product of $\mathcal{O}_w$ (recall that $\mathcal{O}_w$ is the open set that supports μ_w, defined at the beginning of this section).

THEOREM 2.1. *Suppose that* $\mathbf{\Phi}$ *is of the form* (4) *and that conditions* A1–A4 *hold. Then*

(i) *The Markovian system* (4) *is l.s.c. if and only if for all initial conditions* $x \in \mathbf{X}$ *there exists* $T \geqq 1$ *such that*

$$\text{rank}\, C_x^T(\lambda) = n \quad \textit{for all } \lambda \in \mathcal{O}_w^T \backslash Z_x, \tag{6}$$

where $Z_x \cap \mathcal{O}_w^T$ *has zero Lebesgue measure.*

(ii) *The Markovian system* (4) *is w.s.c. if and only if for all initial conditions* $x \in \mathbf{X}$, *there exists* $T \geqq 1$ *and* $\lambda \in \mathcal{O}_w^T$ *such that*

$$\text{rank}\, C_x^T(\lambda) = n. \tag{7}$$

(iii) *If* rank $C_x^T(\lambda) = n$ *for some* $\lambda \in \mathcal{O}_w^T$, *then there exists* $c > 0$, *and open sets* $\mathcal{U}_x^\lambda$, $\mathcal{V}_x^\lambda$ *containing* x *and* $S_x^T(\lambda)$, *respectively, such that*

$$P^T(y, A) \geqq c\mu^{\text{Leb}}\{A \cap \mathcal{V}_x^\lambda\} \tag{8}$$

for all $A \in \mathcal{B}(\mathbf{X})$ *and* $y \in \mathcal{U}_x^\lambda$.

The proof of Theorem 2.1 is given in § 3. We remark that (6) is equivalent to the condition that the random matrix

$$C_x^T(w_1 \cdots w_T)$$

is full rank almost surely, and (since C_x^T is smooth) (7) is equivalent to the condition that this matrix is full rank with positive probability.

Equation (8) may be written in the symbolic form

$$P^T(\cdot, \cdot) \geqq c\mathbf{1}_{\mathcal{U}_x^\lambda}(\cdot)(\mathbf{1}_{\mathcal{V}_x^\lambda}\mu^{\text{Leb}})\{\cdot\}.$$

A set $\mathcal{U}$ and measure φ satisfying

$$P^T(\cdot, \cdot) \geqq c\mathbf{1}_{\mathcal{U}}(\cdot)\varphi\{\cdot\} \tag{9}$$

for some $c > 0$ are called, respectively, a small set and a small measure [Nummelin, 1984]. It is the existence of open small sets together with the Feller property that allows points of the state space to be connected together. Once it can be shown that the state process $\mathbf{\Phi}$ enters some small set infinitely often with positive probability, it follows that every trajectory of probabilities eventually dominates the small measure φ and Harris recurrence (or a generalization as in Theorems 2.2 and 2.3) follows easily. Most of the stability conditions introduced in this paper will be used to show that an open small set is attracting in this sense.

From the fact that the state space may be covered by open small sets we may deduce that a certain stochastic kernel possesses continuous components, allowing an application of the results of [Tuominen and Tweedie, 1979]. However these results are not needed in the present paper.

By Theorem 2.1 it follows that, in many problems encountered in signal processing and adaptive control problems, the notions of local and weak stochastic controllability are equivalent.

COROLLARY 2.1. *If conditions* A1–A4 *hold and the function F defined in* (4) *is a real-analytic function of its arguments, then* $\mathbf{\Phi}$ *is l.s.c. if and only if it is w.s.c.*

Controllability to a fixed state. Given a Markovian system of the form (4) and a point $w^\star \in \mathbb{R}^p$ we will call the deterministic system

$$d_{k+1} = F(d_k, w^\star), \qquad k \in \mathbb{Z}_+ \tag{10}$$

with initial condition $d_0 \in \mathbf{X}$ the *freely evolving system.*

A5. There exist $w^\star \in \mathbb{R}^p$ and $d^\star \in \mathbf{X}$ such that

$$d^\star \in \overline{\left\{ \bigcup_{k=0}^{\infty} S_x^k(w^\star, \cdots, w^\star) \right\}} \tag{11}$$

for every initial condition $x \in \mathbf{X}$.

Observe that if condition A5 is satisfied then in particular, (11) holds with initial condition $d_N = S_x^N(w^\star, \cdots, w^\star)$. Hence for all $x \in \mathbf{X}$ and $N \in \mathbb{Z}_+$,

$$d^\star \in \overline{\left\{ \bigcup_{k=0}^{\infty} S_{d_N}^k(w^\star, \cdots, w^\star) \right\}} = \overline{\left\{ \bigcup_{k=N}^{\infty} S_x^k(w^\star, \cdots, w^\star) \right\}}.$$

It immediately follows that

$$d^\star \in \bigcap_{N=0}^{\infty} \overline{\left\{ \bigcup_{k=N}^{\infty} S_x^k(w^\star, \cdots, w^\star) \right\}},$$

and hence condition A5 is equivalent to the condition that $d^\star$ is an ω-limit point of the system (10) for every initial condition (see [Saperstone, 1981]).

By replacing the function $F(\cdot,\cdot)$ used in (4) with $F(\cdot + d^\star, \cdot + w^\star) - d^\star$ and translating the state space $\mathbf{X}$ we may replace the constants $w^\star$ and $d^\star$ with zero. So, we henceforth assume that

$$0 \in \mathbf{X}, \quad w^\star = 0, \quad \text{and} \quad d^\star = 0.$$

We say the Markovian system (4) *satisfies condition* GA if 0 is globally attracting for the freely evolving system. That is:

GA. For each initial condition $x \in \mathbf{X}$,

$$\lim_{k\to\infty} d_k = \lim_{k\to\infty} S_x^k(0, \cdots, 0) = 0.$$

Hence if the disturbance sequence $\mathbf{w}$ is replaced by $(0, \cdots, 0, \cdots)$ in (4) then $\Phi_k \to 0$ as $k \to \infty$ for all initial conditions. It is easily verified that condition GA implies condition A5.

For example, the controlled random parameter $AR(p)$ system examined in [Meyn and Caines, 1987] satisfies condition GA when $\sigma_e^2 < 1$, and it is shown in [Meyn, 1989] that a linear system under nonlinear control satisfies condition GA under extremely general conditions.

The following result greatly simplifies the task of verifying weak stochastic controllability.

PROPOSITION 2.1. *Suppose conditions* A1–A5 *hold, and that* $0 \in \operatorname{supp} \mu_w$. *Then the following statements are equivalent*:

(i) $\mathbf{\Phi}$ *is w.s.c.*;

(ii) *the controllability matrix* $C_0^T(\lambda)$ *is full rank for some* $T \in \mathbb{Z}_+$ *and* $\lambda \in \mathcal{O}_w^T$;

(iii) *for open sets* $0 \in \mathcal{U}$ *and* $\mathcal{V}$, $T \in \mathbb{Z}_+$, *and a constant* $c > 0$,

$$P^T(x, A) \geqq c\mathbf{1}_{\mathcal{U}}(x)\mu^{\text{Leb}}\{A \cap \mathcal{V}\} \quad \textit{for all } x \in \mathbf{X} \textit{ and } A \in \mathcal{B}(\mathbf{X}).$$

The following corollary follows immediately.

COROLLARY 2.2. *If conditions* A1–A4 *and* GA *hold, and* $0 \in \operatorname{supp} \mu_w$ *then* $\mathbf{\Phi}$ *is w.s.c. if the pair* $(A_0(0), B_0(0))$ *is controllable in the usual sense.*

Proof of Corollary 2.2. Under the given assumptions 0 is a fixed point of the dynamical system (10). Hence if $(A, B) \triangleq (A_0(0), B_0(0))$ is controllable, it follows that

$$C_0^n(0) = [A^{n-1}B| \cdots |AB|B] \quad \text{is full rank.}$$

Since $0 \in \operatorname{supp} \mu_w = \bar{\mathcal{O}}_w$ and the matricial function $C_0^n(\cdot)$ is continuous, it follows that $C_0^n(\lambda)$ is full rank for some $\lambda \in \mathcal{O}_w$ sufficiently close to 0. Hence condition (ii) of Proposition 2.1 holds. □

Before proving Proposition 2.1 we must establish the following lemma.

LEMMA 2.1. *Suppose that the Markov chain* $\mathbf{\Phi}$ *is generated by the Markovian system* (4) *satisfying conditions* A1–A4, *and that* $0 \in \operatorname{supp} \mu_w$. *Then for each* $x \in \mathbf{X}$, *and every open set* $\mathcal{U} \subset \mathbf{X}$ *containing the origin,*

(i) *if condition* A5 *is satisfied then*

$$\sup_{k \geqq 0} P^k(x, \mathcal{U}) > 0;$$

(ii) *if condition* GA *is satisfied then*

$$P^k(x, \mathcal{U}) > 0 \quad \textit{for all sufficiently large } k \in \mathbb{Z}_+.$$

Proof. Fix $x \in \mathbf{X}$, and let $\mathcal{U}$ satisfy the hypotheses of the lemma. If condition A5 holds we may choose $k \in \mathbb{Z}_+$ such that

$$S_x^k(0, \cdots, 0) \in \mathcal{U}, \tag{12}$$

and by continuity there exists a $\delta > 0$ such that

$$S_x^k(z_1, \cdots, z_k) \in \mathcal{U},$$

for all $(z_1, \cdots, z_k) \in \{B_\delta(0)\}^k$, where $B_\delta(0)$ is the open rectangle of width δ centered at the origin. It follows that

$$\begin{aligned} P^k(x, \mathcal{U}) &> E[\mathbf{1}_{\|w_1\|<\delta} \cdots \mathbf{1}_{\|w_k\|<\delta}] \\ &= (\mu_w\{B_\delta(0)\})^k > 0. \end{aligned}$$

If condition GA holds then (12) is satisfied for all k sufficiently large, and so by the same argument as before, $P^k(x, \mathcal{U}) > 0$ for such k. □

Proof of Proposition 2.1. By Theorem 2.1, condition (i) of Proposition 2.1 implies condition (ii), which implies condition (iii). To complete the proof we will show that condition (iii) implies condition (i).

Suppose condition (iii) holds. Fix $x \in \mathbf{X}$ and choose an integer k for which $P^k(x, \mathscr{U}) > 0$. This is possible by condition (iii) and Lemma 2.1.

Then for any $A \in \mathscr{B}(\mathbf{X})$,

$$P^{k+T}(x, A) = \int P^k(x, dy) P^T(y, A) \geqq c P^k(x, \mathscr{U}) \mu^{\text{Leb}}\{A \cap \mathscr{V}\}.$$

Since $cP^k(x, \mathscr{U}) > 0$, we conclude that $\mathbf{1}\mathscr{V}\mu^{\text{Leb}} < P^{T+k}(x, \cdot)$, and hence $\mathbf{\Phi}$ is w.s.c. □

Remark. It is easy to see that condition A5 may be considerably relaxed. The following weaker condition (implied by asymptotic controllability—see [Sontag, 1983]) may be used to replace condition A5 in all of the results of this paper:

For each $x \in \mathbf{X}$ and $\varepsilon > 0$, there exists $N \in \mathbb{Z}_+$ and a deterministic sequence $\{w_k^\star : 1 \leqq k \leqq N\}$ lying in $\mathscr{O}_w^N$ such that

$$|S_x^N(w_1^\star \cdots w_N^\star)| < \varepsilon. \tag{13}$$

Hence conditions GA and A5 are useful because they imply that the *deterministic* system (4) (with the disturbance $\mathbf{w}$ considered as a deterministic input) is controllable to the origin.

2.2. Stability. Here we introduce some useful stability conditions, and then in Proposition 2.2 we give necessary and sufficient conditions for (4) to be bounded in probability on average.

DEFINITION. (i) The Markovian system (4) is called *bounded in probability* if for each deterministic initial condition $x \in \mathbf{X}$ and each $\varepsilon > 0$ there exists a compact subset $C \subset \mathbf{X}$ such that

$$\liminf_{k \to \infty} P^k(x, C) \geqq 1 - \varepsilon.$$

(ii) The Markovian system (4) is called *bounded in probability on average* if for each deterministic initial condition $x \in \mathbf{X}$ and each $\varepsilon > 0$ there exists a compact subset $C \subset \mathbf{X}$ such that

$$\liminf_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} P^k(x, C) \geqq 1 - \varepsilon.$$

(iii) The Markovian system (4) is called *uniformly bounded in probability* if for each $\varepsilon > 0$ there exists a compact subset $C \subset \mathbf{X}$ such that

$$\liminf_{k \to \infty} P^k(x, C) \geqq 1 - \varepsilon$$

for all $x \in \mathbf{X}$. □

For example, if $\mathbf{X} = \mathbb{R}^n$ and

$$\limsup_{k \to \infty} E_x[|\Phi_k|^2] < \infty \quad \text{for every } x \in \mathbf{X},$$

then $\mathbf{\Phi}$ is bounded in probability, and if for some fixed constant $J < \infty$,

$$\limsup_{k \to \infty} E_x[|\Phi_k|^2] \leqq J \quad \text{for every } x \in \mathbf{X},$$

then $\mathbf{\Phi}$ is uniformly bounded in probability.

In stochastic control theory we are often concerned with showing that the performance criteria

$$L_\infty \triangleq \limsup_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} y_k^2 + \rho u_k^2 \quad \text{and} \quad J_\infty \triangleq \limsup_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} E[y_k^2 + \rho u_k^2]$$

are uniformly bounded for all initial conditions. If this is the case, then it often follows that $\mathbf{\Phi}$ is bounded in probability on average but it does not necessarily follow that it is bounded in probability. However if (4) is w.s.c. we will find that the two notions of stability are equivalent. This is one of the main results to be presented below.

Here we state a necessary and sufficient condition for the second form of stability.

PROPOSITION 2.2. *The Markovian system* (4) *is bounded in probability on average if and only if for each deterministic* $x \in \mathbf{X}$ *there exists a nonempty, tight collection of invariant probabilities* Π_x *such that*

$$\frac{1}{N}\sum_{k=1}^{N} P^k(x, \cdot) \xrightarrow{\text{weakly}} \Pi_x. \tag{14}$$

Proof. Fix $x \in \mathbf{X}$, let $\mu_k = P^k(x, \cdot)$, and suppose (4) is bounded in probability on average. In this case the collection of probabilities $\{(1/N)\sum_{k=1}^{N} \mu_k,\ k \geqq 1\}$ is a precompact subset of the space of all probabilities on $\mathscr{B}(\mathbf{X})$, and it is a routine exercise to show that any weak limit point is invariant. For each initial condition $x \in \mathbf{X}$, the set of invariant probabilities obtained in this way is tight under the conditions of Proposition 2.2 because the set of limit points of a precompact set is compact. The proof of the converse is straightforward, and so we omit it. □

2.3. Main results. Here we state the main results of the paper. We begin by presenting some definitions from the theory of Markov chains on general state spaces.

Let $\Lambda : \mathbf{X} \times \mathscr{B}(\mathbf{X}) \to [0, 1]$ denote the function

$$\Lambda(x, A) \triangleq P_x\{\mathbf{\Phi} \text{ enters } A\} = P_x\left\{\bigcup_{k=0}^{\infty} \{\Phi_k \in A\}\right\}. \tag{15}$$

A set $A \in \mathscr{B}(\mathbf{X})$ is called *absorbing* if it is nonempty and $P(x, A) = 1$ for each $x \in A$. An absorbing set H is called a *Harris set* if there exists a probability μ such that $\Lambda(x, A) = 1$ for all $x \in H$ whenever $\mu\{A\} > 0$. If the state space $\mathbf{X}$ is a Harris set, then $\mathbf{\Phi}$ is called *Harris recurrent.*

If a Harris set H exists, then there exists a unique, up to constant multiples, invariant measure π that is supported on H. When π is finite, then H is called a positive Harris set, and in the case where $H = \mathbf{X}$, we call $\mathbf{\Phi}$ positive Harris recurrent.

We will only consider positive Harris sets in this paper, and to simplify the terminology we will henceforth drop the adjective "positive."

Harris sets are periodic: There exists a maximal integer λ called the period of H, and disjoint measurable sets $\{E_i : 1 \leqq i \leqq \lambda\}$ such that $H = \bigcup E_i$ and

$$P(x, E_{i+1}) = 1, \qquad x \in E_i \pmod{\lambda};$$

when $\lambda = 1$ we call H (or $\mathbf{\Phi}$ in the case where $\mathbf{X} = H$) *aperiodic.*

Our interest in Harris sets comes from the following result. Let $\|\cdot\|_{tv}$ denote the total variation norm, defined on the space of finite signed measures on $\mathscr{B}(\mathbf{X})$.

PROPOSITION 2.3. $\mathbf{\Phi}$ *is positive Harris recurrent if and only if there exists a unique invariant probability* π *and an integer* λ *such that the following limits hold*:

$$\lim_{N\to\infty} \frac{1}{N}\sum_{k=1}^{N} f(\Phi_k) = \int f\,d\pi \quad a.s.\ [P_x], \tag{16}$$

$$\lim_{k\to\infty} \left\| \frac{1}{\lambda}\sum_{i=1}^{\lambda} P^{k+i}(x, \cdot) - \pi \right\|_{tv} = 0 \tag{17}$$

for every initial condition $x \in \mathbf{X}$, *and every function* $f \in L^1(\mathbf{X}, \mathscr{B}(\mathbf{X}), \pi)$.

Proof. It is shown in [Athreya and Ney, 1980] that if $\mathbf{\Phi}$ is positive Harris recurrent with invariant probability π, then (16) holds for every initial distribution, and in fact a generalization of (16) holds even in the null recurrent case (when the invariant measure π is not finite).

Conversely, if (16) holds for every initial condition, then it is obvious that $\Lambda(x, A)=1$ for every set A of positive π-measure, and hence $\mathbf{\Phi}$ is positive Harris recurrent.

A proof of the equivalence between Harris recurrence and the limit (17) may be found in [Nummelin, 1984]. □

Stability, controllability, and ergodicity. The following result is a direct consequence of Theorem 8.2 and the corollary to Theorem 9.1 of [Orey, 1971]. The hypotheses of these theorems are satisfied since if $\mathbf{\Phi}$ is w.s.c. then for each $x \in \mathbf{X}$ the probability

$$\sum_{k=0}^{\infty} 2^{-k-1} P^k(x, \cdot)$$

is nonsingular with respect to Lebesgue measure.

We remark that Proposition 2.4 also follows from (9) and the Decomposition Theorem of [Tuominen and Tweedie, 1979] by constructing a suitable continuous component.

PROPOSITION 2.4. *Suppose conditions* A1–A4 *hold and that* $\mathbf{\Phi}$ *is w.s.c. Then there exists a countable (possibly empty) index set I, a collection of disjoint Harris sets* $\{H_i \colon i \in I\}$, *and corresponding invariant probabilities* $\{\pi^i \colon i \in I\}$. *Furthermore, there exists at least one finite invariant measure* μ *if and only if I is nonempty, and in this case it has the form* $\mu = \sum q_i \pi^i$ *for a summable sequence* $\{q_i \colon i \in I\} \subset \mathbb{R}_+$.

The following functions will be of great use in studying the asymptotic behavior of $\mathbf{\Phi}$ with arbitrary initial conditions. Recall from (15) that $\Lambda(x, A) = P_x\{\mathbf{\Phi} \text{ enters } A\}$. For $x \in \mathbf{X}$ and $i \in I$ let

$$\alpha_i(x) = \Lambda(x, H_i), \qquad \alpha(x) = \sum_{i \in I} \alpha_i(x). \tag{18}$$

Of course, if the index set I is empty, then we have $\alpha \equiv 0$.

Although there may be more than one Harris set associated with one of the invariant probabilities π^i, the definition above does not depend on the Harris set chosen. Since H_i and $\cup H_i$ are absorbing

$$\alpha_i(x) = \lim_{k \to \infty} P^k(x, H_i), \qquad \alpha(x) = \lim_{k \to \infty} P^k\left(x, \bigcup_{i \in I} H_i\right).$$

In the following result weak stochastic controllability is used to establish the equivalence of boundedness in probability and its averaged formulation, and the Strong Law of Large Numbers for Markov chains [Doob, 1953] is generalized to arbitrary initial conditions.

If $\alpha(x) > 0$ we define the invariant probability π_x by

$$\pi_x = \frac{1}{\alpha(x)} \sum_{i \in I} \alpha_i(x) \pi^i. \tag{19}$$

THEOREM 2.2. *Suppose that conditions* A1–A4 *hold. If* (4) *is w.s.c. then the following are equivalent*:

(i) (4) *is bounded in probability*;

(ii) (4) *is bounded in probability on average*;

(iii) $\alpha(x)=1$ *for all* $x\in\mathbf{X}$;

(iv) *for each* $x\in\mathbf{X}$ *and* $f\in L^1(\mathbf{X}^{\mathbb{Z}_+},\mathscr{B}(\mathbf{X}^{\mathbb{Z}_+}),P_{\pi_x})$ *there exists* $f_\infty\in L^1(\mathbf{X}^{\mathbb{Z}_+},\mathscr{B}(\mathbf{X}^{\mathbb{Z}_+}),P_x)$ such that

$$\lim_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N} f(\Phi_k,\Phi_{k+1},\cdots)=f_\infty(\Phi_0,\Phi_1,\cdots)\quad a.s.\ [P_x];$$

(v) *for each* $x\in\mathbf{X}$,

$$\left\|\frac{1}{N}\sum_{k=1}^{N} P^k(x,\cdot)-\pi_x\right\|_{tv}\to 0$$

as $N\to\infty$, *uniformly for x in compact subsets of* $\mathbf{X}$.

The precise form of the random variable f_∞ used in (iv) is easy to guess. On the event $\{\Phi$ enters $H_i\}$ the limiting behavior of $(1/N)\sum_{k=1}^{N}f(\Phi_k,\Phi_{k+1},\cdots)$ is determined by π^i with probability one. Hence

$$f_\infty=\mathbf{1}_{\{\tau<\infty\}}\sum_{k\in I}\mathbf{1}\{\Phi_\tau\in H_k\}E_{\pi^k}[f(\Phi_0,\Phi_1,\cdots)],\tag{20}$$

where τ is the first entrance time into the set $H=\bigcup_{i\in I}H_i$:

$$\tau=\min\{k\in\mathbb{Z}_+:\Phi_k\in H\}.$$

The relevance of (iii) is greater than might first appear. To see how Theorem 2.2 may be applied to a specific control problem, consider the controlled system of [Meyn and Caines, 1987]. A direct stability proof for the Markovian state process of that system is difficult, but the existence of an invariant probability π is relatively easy to establish and it is then obvious that the state process enters the open set that supports π almost surely. Hence by Theorem 2.2 the system is bounded in probability and in particular (iv) and (v) hold for that example.

The following corollary immediately follows.

COROLLARY 2.3. *Suppose that* (4) *is w.s.c. Then* $\mathbf{\Phi}$ *is positive Harris recurrent if and only if it is bounded in probability and possesses exactly one invariant probability.*

We now strengthen the stability hypothesis on $\mathbf{\Phi}$ to obtain correspondingly stronger limit theorems.

THEOREM 2.3. *Suppose that conditions* A1–A4 *hold, and that* $\mathbf{\Phi}$ *is w.s.c. Then* $\mathbf{\Phi}$ *is uniformly bounded in probability if and only if it is bounded in probability and the index set I is finite. If this is the case, then there exists* $\lambda\in\mathbb{Z}_+$ *such that*

$$\left\|\frac{1}{\lambda}\sum_{k=1}^{\lambda} P^{k+i}(x,\cdot)-\pi_x\{\cdot\}\right\|_{tv}\to 0\quad as\ i\to\infty$$

uniformly for x in compact subsets of $\mathbf{X}$.

THEOREM 2.4. *Suppose that conditions* A1–A4 *hold,* $0\in\operatorname{supp}\mu_w$, *and* $\mathbf{\Phi}$ *is w.s.c. and bounded in probability. Then*

(i) *if* A5 *is satisfied then a unique invariant probability π exists, and hence* $\mathbf{\Phi}$ *is positive Harris recurrent*;

(ii) *if* GA *is satisfied then* $\mathbf{\Phi}$ *is aperiodic and positive Harris recurrent, and in this case* $P^k(x,A)\to\pi$ *as* $k\to\infty$ *uniformly for* $A\in\mathscr{B}(\mathbf{X})$ *and x in compact subsets of* $\mathbf{X}$.

The proofs of these results will be given in § 3. We now show how these results may be related to Lyapunov function theory.

On the properties of Lyapunov functions. One of the difficulties in deterministic as well as stochastic stability studies is that stability is a property of the entire process, viewed from time 0 to ∞, while any useful test should make use of only a finite amount of data, e.g., values of the process at specific (finite) times, or the relationship between values of the process at different finite times.

Lyapunov's second method or its stochastic generalizations [Kushner, 1967], [Has'minskiĭ, 1980] are among the most successful approaches to this problem that meet these requirements.

One specific example of a stochastic generalization of Lyapunov's second method may be found in the stability proof of [Goodwin, Ramadge, and Caines, 1981]. The methodology of that paper may be very roughly described as follows. A positive adapted stochastic process $\{V_k\}$ is constructed satisfying the super martingale property

$$E[V_{k+1} \mid \mathscr{F}_k] \leqq V_k, \tag{21}$$

where $\mathscr{F}_k$ is the σ-algebra generated by past and present values of $\mathbf{\Phi}$,

$$\mathscr{F}_k \triangleq \sigma\{\Phi_0, \cdots, \Phi_k\}, \tag{22}$$

and $\mathbf{\Phi}$ denotes a state process for the closed-loop system under consideration.

From the fact that $\{V_k\}$ is a convergent super martingale and other specific properties of this process we may deduce mean-square stability and, in some sense, optimality of the performance of the closed-loop system.

This approach will fail in the case of a w.s.c. Markovian system in many cases of interest. For example, if $V_k = V(\Phi_k)$ for a continuous function $V: \mathbf{X} \to \mathbb{R}_+$, then $\mathbf{\Phi}$ converges to a level set of the function V. If $\mathbf{\Phi}$ is bounded in probability and w.s.c., then by Theorem 2.2 the set of limit points of the sequence $\{\Phi_k : k \in \mathbb{Z}_+\}$ is equal to $\sum_{i \in I} \mathbf{1}_{\{\mathbf{\Phi} \text{ enters } S_i\}} \operatorname{supp} \pi^i$ almost surely. By weak stochastic controllability, the support of any invariant probability has nonempty interior, which implies that the function V must be flat over suitably large regions of the state space. For example, this rules out real-analytic functions. Since in many examples the function V is in fact a rational function of its arguments, it may be seen that weak stochastic controllability rules out a large class of test functions of the form (21).

However the following alternative stability test has already been of great use in a number of examples (see [Guo and Meyn, 1989], [Meyn and Guo, 1990] and [Meyn, 1989]) and has great theoretical potential. As before, let $\{V_k\}$ be a positive adapted stochastic process, and suppose that for some $0 < \lambda < 1$, $L > 0$,

$$E[V_{k+1} \mid \mathscr{F}_k] \leqq \lambda V_k + L, \tag{23}$$

which in the degenerate case $\lambda = 1$, $L = 0$ becomes (21). Under this condition and certain technical assumptions that include weak stochastic controllability, it may be shown that the underlying distributions of $\mathbf{\Phi}$ converge to an invariant probability at a geometric rate, and that the central limit theorem holds for functions whose square is dominated by $\{V_k\}$. Some of these results may be found in [Meyn and Tweedie, 1990a,b], and in [Meyn, 1989] where processes that are not w.s.c. are also considered.

3. Proofs of the main results.

3.1. Proof of Theorem 2.1. To prove Theorem 2.1 we will need the following lemma. For $x \in \mathbb{R}^m$ and $\varepsilon > 0$, let $B_\varepsilon(x)$ denote the open rectangle

$$B_\varepsilon(x) \triangleq \{y \in \mathbb{R}^m : |x_i - y_i| < \varepsilon \text{ for } 1 \leqq i \leqq m\}.$$

LEMMA 3.0. *Let $\mathscr{W}_1 \subset \mathbb{R}^n$, $\mathscr{X}_1 \subset \mathbb{R}^m$, and $\mathscr{Y}_1 \subset \mathbb{R}^n$ be open and suppose $G: \mathscr{W}_1 \times \mathscr{X}_1 \times \mathscr{Y}_1 \to \mathbb{R}^n$, $(w, x, y) \to z$, is smooth, and that the matrix $\partial G / \partial y$ is full rank at some $(w_0, x_0, y_0) \in \mathscr{W}_1 \times \mathscr{X}_1 \times \mathscr{Y}_1$. Then*

(i) *there exists an open set*

$$\mathscr{W} \times \mathscr{X} \times \mathscr{Y} \subset \mathscr{W}_1 \times \mathscr{X}_1 \times \mathscr{Y}_1 \quad \textit{containing } (w_0, x_0, y_0)$$

such that the measure $\nu(w, \cdot)$ defined for $A \in \mathcal{B}(\mathbb{R}^n)$ and $w \in \mathcal{W}$ by

$$\nu(w, A) = \int_{\mathcal{X}} \int_{\mathcal{Y}} \mathbf{1}_{G(w,x,y) \in A} \, dx \, dy$$

is equivalent to Lebesgue measure on an open set $\mathcal{R}_w$;

(ii) *there exists $c > 0$ and open sets $\mathcal{U}$ and $\mathcal{V}$ containing w_0 and $G(w_0, x_0, y_0)$, respectively, such that*

$$\nu(w, \cdot) \geqq c\mathbf{1}_{\mathcal{U}}(w)(\mathbf{1}_{\mathcal{V}} \mu^{\mathrm{Leb}}) \quad \textit{for all } w.$$

Proof of Lemma 3.0. Consider the function $G^\star: \mathcal{W}_1 \times \mathcal{X}_1 \times \mathcal{Y}_1 \to \mathbb{R}^{n+m+n}$ defined for $(w, x, y) \in \mathcal{W}_1 \times \mathcal{X}_1 \times \mathcal{Y}_1$ by

$$G^\star(w, x, y) \triangleq \begin{pmatrix} w \\ x \\ G(w, x, y) \end{pmatrix}.$$

Under the conditions of Lemma 3.0 the function $G^\star$ is smooth, and its derivative is full rank at (w_0, x_0, y_0). By the implicit function theorem there exist open sets

$$\mathcal{R} \subset \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^n \quad \text{and} \quad \mathcal{W} \times \mathcal{X} \times \mathcal{Y} \subset \mathcal{W}_1 \times \mathcal{X}_1 \times \mathcal{Y}_1$$

with $(w_0, x_0, y_0) \in \mathcal{W} \times \mathcal{X} \times \mathcal{Y}$, and a smooth function $H^\star: \mathcal{R} \to \mathcal{W} \times \mathcal{X} \times \mathcal{Y}$ such that

$$\mathcal{R} = \left\{ \begin{pmatrix} w \\ x \\ G(w, x, y) \end{pmatrix} : w \in \mathcal{W},\ x \in \mathcal{X},\ y \in \mathcal{Y} \right\}$$

and

$$H^\star(G^\star(w, x, y)) = (w, x, y)$$

for $(w, x, y) \in \mathcal{W} \times \mathcal{X} \times \mathcal{Y}$. Applying a projection to the function $H^\star$ we may find a smooth function $H: \mathcal{R} \to \mathcal{Y}$ for which

$$H(w, x, G(w, x, y)) = H(G^\star(w, x, y)) = y$$

for $(w, x, y) \in \mathcal{W} \times \mathcal{X} \times \mathcal{Y}$.

Since H is smooth and

$$\left[\frac{\partial H}{\partial z}\right] = \left[\frac{\partial G}{\partial y}\right]^{-1}$$

is full rank, we may assume that

$$\left| \det \left[\frac{\partial H}{\partial z}\right] \right| \geqq h_0 \tag{24}$$

for all $(w, x, z) \in \mathcal{R}$.

We now construct a density for the kernel

$$\nu(w, A) = \int_{\mathcal{X}} \int_{\mathcal{Y}} \mathbf{1}_{G(w,x,y) \in A} \, dx \, dy, \qquad w \in \mathcal{W}, \quad A \in \mathcal{B}(\mathbb{R}^n)$$

by a change of variables and Fubini's theorem:

$$\begin{aligned} \nu(w, A) &= \int_{\mathcal{X}} \left\{ \int_{G(w,x,\mathcal{Y})} \mathbf{1}_A(z) \left| \det \frac{\partial H}{\partial z} \right| dz \right\} dx \\ &= \int_{\mathbb{R}^n} \mathbf{1}_A(z) \left\{ \int_{\mathbb{R}^m} \mathbf{1}_{\mathcal{R}}(w, x, z) \left| \det \frac{\partial H}{\partial z} \right| dx \right\} dz. \end{aligned}$$

Hence for fixed $w \in \mathcal{W}$, the function $p : \mathbb{R}^n \to \mathbb{R}_+$ defined for $z \in \mathbb{R}^n$ by

$$p(w, z) \triangleq \int_{\mathbb{R}^m} \mathbf{1}_{\mathcal{R}}(w, x, z) \left| \det \frac{\partial H}{\partial z} \right| dx \tag{25}$$

is a density for $\nu(w, \cdot)$.

Fix $w \in \mathcal{W}$, and let $\mathcal{R}_w \subset \mathbb{R}^n$ denote the open set

$$\mathcal{R}_w \triangleq \{z \colon (w, x, z) \in \mathcal{R} \text{ for some } x \in \mathcal{X}\}.$$

Then by (24) and (25) it is easy to show that $p(w, \cdot)$ is strictly positive on $\mathcal{R}_w$ and zero elsewhere. Hence $\nu(w, \cdot)$ is equivalent to Lebesgue measure on $\mathcal{R}_w$ and this proves (i).

Since $\mathcal{R}$ is an open neighborhood of (w_0, x_0, z_0), there exists a nonempty open rectangle

$$(w_0, x_0, z_0) \in \mathcal{W}_0 \times \mathcal{X}_0 \times \mathcal{Z}_0 \subset \mathcal{R}.$$

Hence by (24) and (25),

$$\begin{aligned} p(w, z) &\geqq h_0 \int_{\mathbb{R}^m} \mathbf{1}_{\mathcal{W}_0}(w) \mathbf{1}_{\mathcal{X}_0}(x) \mathbf{1}_{\mathcal{Z}_0}(z) \, dx \\ &= h_0 \mu^{\text{Leb}}\{\mathcal{X}_0\} \mathbf{1}_{\mathcal{W}_0}(w) \mathbf{1}_{\mathcal{Z}_0}(z). \end{aligned}$$

It follows that

$$\nu(w, A) \geqq (h_0 \mu^{\text{Leb}}\{\mathcal{X}_0\}) \mathbf{1}_{\mathcal{W}_0}(w) (\mathbf{1}_{\mathcal{Z}_0} \mu^{\text{Leb}})\{A\} \qquad w \in \mathbb{R}^n, \quad A \in \mathcal{B}(\mathbb{R}^n)$$

and this establishes (ii). □

Proof of Theorem 2.1. Fix a point $x \in \mathbf{X}$, $T \in \mathbb{Z}_+$, and let $Z_x = Z_x(T)$ denote the closed subset of $\mathbb{R}^{pT}$,

$$Z_x \triangleq \{\lambda \in \mathbb{R}^{pT} \colon \operatorname{rank} C_x^T(\lambda) \leqq n - 1\}.$$

Proof of (ii). Suppose that rank $C_x^T(\lambda) < n$ for all $\lambda \in \mathcal{O}_w^T$. By Sard's theorem, the set $S = \{S_x^T(\lambda) \colon \lambda \in \mathcal{O}_w^T\}$ has zero Lebesgue measure. Hence in this case $P^T(x, \cdot)$ is supported on S, and it is therefore singular with respect to Lebesgue measure. This shows that the rank condition (7) is necessary.

To prove sufficiency suppose (7) is satisfied for some $\lambda_0 \in \mathcal{O}_w^T \backslash Z_x$. Let p_w denote the density for μ_w, and p the density defined for $(z_1, \cdots, z_T) \in \mathbb{R}^{Tp}$ by

$$p(z_1, \cdots, z_T) \triangleq p_w(z_1) \cdots p_w(z_T).$$

Since $\lambda_0 \in \mathcal{O}_w^T$ and p_w is lower semicontinuous we may find $p_0 > 0$ and an open rectangle $B_\delta(\lambda_0)$ such that

$$p(\lambda) \geqq p_0 \quad \text{for all } \lambda \in B_\delta(\lambda_0).$$

Hence

$$\begin{aligned} P^T(y, \cdot) &= \int \mathbf{1}_{S_y^T \in} \cdot p(\lambda) \, d\lambda \\ &\geqq p_0 \int_{B_\delta(\lambda_0)} \mathbf{1}_{S_y^T \in \cdot} \, d\lambda \quad \text{for all } y \in \mathbf{X}. \end{aligned} \tag{26}$$

Using the rank condition on C_x^T we may find integers $\{i_1, \cdots, i_n\}$ for which

$$\det \left[\frac{\partial S_x^T}{\partial \lambda_{i_1}} \Big| \cdots \Big| \frac{\partial S_x^T}{\partial \lambda_{i_n}} \right]_{\lambda_0} \neq 0.$$

This allows us to apply Lemma 3.0. By defining the function G in terms of S_x^T appropriately, all the conditions of that lemma are satisfied, and by reducing the size of δ if necessary, open sets $\mathcal{U}_x^{\lambda_0}$ and $\mathcal{V}_x^{\lambda_0}$ containing x and $S_x^{\lambda_0}$, respectively, an open set $\mathcal{R}_{\lambda_0}$, and a constant $c>0$ exist such that

$$(27)\qquad \begin{aligned} &\text{(i)} & &\int_{B_\delta(\lambda_0)} \mathbf{1}\{S_x^T\in\cdot\}\,d\lambda \approx \mathbf{1}_{\mathcal{R}_{\lambda_0}}\mu^{\mathrm{Leb}} \\ &\text{(ii)} & &\int_{B_\delta(\lambda_0)} \mathbf{1}\{S_x^T\in\cdot\}\,d\lambda \geqq c\mathbf{1}_{\mathcal{U}_x^{\lambda_0}}(y)(\mathbf{1}_{\mathcal{V}_x^{\lambda_0}}\mu^{\mathrm{Leb}}) \quad \text{for all } y\in\mathbf{X}, \end{aligned}$$

and $B_\delta(\lambda_0)\subset\mathcal{O}_w^T\backslash Z_x$. Combining (26) and (27)(i) shows that $P^T(x,\cdot)\succ\mathbf{1}_{\mathcal{R}_{\lambda_0}}\mu^{\mathrm{Leb}}$ and this proves (ii) of the theorem.

To prove (iii) observe that under the given hypotheses (26) and (27) hold and hence

$$P^T(y,\cdot)\geqq cp_0\mathbf{1}_{\mathcal{U}_x^{\lambda_0}}(y)(\mathbf{1}_{\mathcal{V}_x^{\lambda_0}}\mu^{\mathrm{Leb}})$$

for all $y\in\mathbf{X}$.

Proof of (i). Suppose that $\mu^{\mathrm{Leb}}\{Z_x\cap\mathcal{O}_w^T\}>0$, where Z_x is the set on which the matrix C_x^T is not full rank. By Sard's theorem the set $S=\{S_x^T(\lambda)\colon \lambda\in\mathcal{O}_w^T\cap Z_x\}$ has zero Lebesgue measure. Furthermore,

$$P^T(x,S)\geqq\int_{Z_x}\mathbf{1}\{S_s^T\in S\}\,d\mu_w^T=\mu_w^T\{Z_x\}>0,$$

and it follows that $P^T(x,\cdot)$ is not absolutely continuous with respect to Lebesgue measure. This shows that the rank condition (6) is necessary.

Under (6) and proceeding as above we may find for each $\lambda\in\mathcal{O}_w^T\backslash Z_x$ an open set $\mathcal{R}_\lambda$, and $\delta>0$ such that (27)(i) holds. We may assume that δ is so small that for some $p_0>0$,

$$p(\eta)>p_0 \quad \text{for all } \eta\in B_\delta(\lambda) \quad \text{and} \quad B_\delta(\lambda)\subset\mathcal{O}_w^T\backslash Z_x,$$

where the constant p_0 may depend on λ.

Define the set $\mathcal{O}_x$ by

$$\mathcal{O}_x\triangleq\{S_x^T(\lambda)\colon \lambda\in\mathcal{O}_w^T\backslash Z_x\}.$$

This set is open since it may also be written

$$\mathcal{O}_x=\bigcup_{\lambda\in\mathcal{O}_w^T\backslash Z_x}\mathcal{R}_\lambda.$$

The union of a family of open sets in $\mathbb{R}^N$ is equal to the union of some countable subfamily, and hence for constants δ_i, and open sets $\mathcal{R}_i$ we have

$$\mathcal{O}_x=\bigcup_{i=0}^\infty\mathcal{R}_i,\qquad \mathcal{O}_w^T\backslash Z_x=\bigcup_{i=0}^\infty B_{\delta_i},$$

with (26) and (27)(i) holding for each $i\in\mathbb{Z}_+$.

Hence $\mathbf{1}_{\mathcal{R}_i}\mu^{\mathrm{Leb}}\prec P^T(x,\cdot)$ for all $i\in\mathbb{Z}_+$, and it follows that $\mathbf{1}_{\mathcal{O}_x}\mu^{\mathrm{Leb}}\prec P^T(x,\cdot)$.

On the other hand,

$$\begin{aligned} P^T(x,\cdot)&\leqq\sum_{i=0}^\infty\int_{B_{\delta_i}}\mathbf{1}\{S_x^T\in\cdot\}p(\lambda)\,d\lambda \\ &\approx\sum_{i=0}^\infty\int_{B_{\delta_i}}\mathbf{1}\{S_x^T\in\cdot\}\,d\lambda \end{aligned}$$

since p is strictly positive on B_{δ_i}

$$\approx \sum_{i=0}^{\infty} \mathbf{1}_{\mathcal{R}_i} \mu^{\text{Leb}}$$

$$\approx \mathbf{1}_{\mathcal{O}_x} \mu^{\text{Leb}}.$$

Thus $P^T(x, \cdot) \approx \mathbf{1}_{\mathcal{O}_x} \mu^{\text{Leb}}$. □

3.2. Some technical lemmas. In this section we describe basic topological properties of the state space of locally and weakly stochastically controllable systems. These results will be used to establish limit theorems for the state process and its underlying distributions, and then the proofs of the main results of the paper in § 3.3.

Throughout the remainder of this paper we assume that conditions A1–A4 *hold and that* $\mathbf{\Phi}$ *is w.s.c.*

Let S_i denote the support of π^i, $\mathcal{U}_x$ and $\mathcal{V}_x$ will denote open sets satisfying

$$(28) \qquad P^T(y, A) \geqq c_x \mu^{\text{Leb}}\{A \cap \mathcal{V}_x\} \qquad A \in \mathcal{B}(\mathbf{X}), \quad y \in \mathcal{U}_x,$$

with $x \in \mathcal{U}_x$, $c_x > 0$, and $\mathcal{U}_i$ and $\mathcal{V}_i$ will denote some particular choice of $\mathcal{U}_x$ and $\mathcal{V}_x$ with $x \in S_i$. When I is nonempty, the existence of these sets is guaranteed by Theorem 2.1.

LEMMA 3.1. *If A is closed and absorbing then $\mathcal{V}_x \subset A$ for all $x \in A$.*

Proof. Let $x \in A$. Since A is absorbing, $P(x, A) = 1$, and since A is closed it follows that

$$\operatorname{supp} P^T(x, \cdot) \subset A.$$

By weak stochastic controllability and (28) we have $P^T(x, \cdot) \geqq c_x(\mathbf{1}_{\mathcal{V}_x} \mu^{\text{Leb}})\{\cdot\}$, and it follows that $\mathcal{V}_x \subset \operatorname{supp} P^T(x, \cdot)$. This shows that $\mathcal{V}_x \subset A$. □

LEMMA 3.2. *For each $i \in I$, the set, $\Lambda_i^{-1}\{0\} \triangleq \{y \in \mathbf{X}: \Lambda(y, \mathcal{U}_i) = 0\}$ is closed and absorbing.*

Proof. Since $\mathcal{U}_i$ is open, the function $\Lambda(\cdot, \mathcal{U}_i)$ is lower semicontinuous [Cogburn, 1975] and it follows that $\Lambda_i^{-1}\{0\}$ is closed.

It is a standard fact and easy to prove that $\Lambda_i^{-1}\{0\}$ is absorbing [Nummelin, 1984]. □

LEMMA 3.3. *For each $i \in I$ and $x \in \mathbf{X}$,*

(i) $\mathbf{1}_{\mathcal{V}_i} \mu^{\text{Leb}} < \pi^i$;

(ii) *$\mathcal{U}_x \cap S_j = \emptyset$ for all but possibly one $j \in I$;*

(iii) *$S_i \cap S_j = \emptyset$ for all $j \neq i$.*

Proof. Result (i) follows from the fact that $\mathcal{U}_i$ is a small set of positive π^i-measure [Nummelin, 1984] (see the discussion below (9)).

Result (ii) also follows from (i) since if for some $x \in \mathbf{X}$,

$$\mathcal{U}_x \cap S_i \neq \emptyset \quad \text{and} \quad \mathcal{U}_x \cap S_j \neq \emptyset \quad \text{then } \mathbf{1}_{\mathcal{V}_x} \mu^{\text{Leb}} < \pi^i, \pi^j.$$

This is impossible since π^i and π^j are mutually singular.

Finally, by (ii) and since $x \in \mathcal{U}_x$, if $i \neq j$,

$$S_j \subset \left\{ \bigcup_{x \in S_i} \mathcal{U}_x \right\}^c \subset S_i^c,$$

and this proves (iii). □

LEMMA 3.4. *For each compact set $K \subset \mathbf{X}$, $S_i \cap K = \emptyset$ for all but a finite number of integers $i \in I$.*

Proof. The collection of open sets $\{\mathcal{U}_x : x \in K\}$ cover K. Let $\{\mathcal{U}^1, \cdots, \mathcal{U}^N\}$ be a finite subcover. By Lemma 3.3 each $\mathcal{U}^i$ intersects at most one of the sets $\{S_i : i \in I\}$ and so no more than N of these sets intersect K. □

LEMMA 3.5. *For each $i \in I$, S_i does not contain any proper closed absorbing subsets.*

Proof. First of all, if A is an absorbing subset of S_i, then the function $\mathbf{1}_{A^c}$ is super harmonic. That is, $\int P(x, dy)\mathbf{1}_{A^c}(y) \leqq \mathbf{1}_{A^c}(x)$ for all $x \in \mathbf{X}$. By Proposition 3.13 of [Nummelin, 1984] it follows that $\pi^i\{A\}$ is equal to zero or one.

If A is also closed then by Lemma 3.1, $\mathcal{V}_x \subset A$ for every $x \in A$ and hence

$$\pi^i\{A\} \geqq \pi^i\{\mathcal{V}_x\} > 0,$$

which shows that in fact $\pi^i\{A\} = 1$. Since S_i is the smallest closed set that has full π_i-measure, it follows that $S_i = A$. □

LEMMA 3.6. *For each $x \in \mathbf{X}$,*

$$\{\Phi \textit{ enters } H_i\} = \{\Phi \in \mathcal{U}_i \text{ i.o.}\} = \{\lim_{k\to\infty} \Lambda(\Phi_k, \mathcal{U}_i) = 1\}$$

modulo P_x-null sets.

Proof. By a result of [Orey, 1971],

$$\lim_{k\to\infty} \Lambda(\Phi_k, \mathcal{U}_i) = \mathbf{1}_{\{\Phi \in \mathcal{U}_i \text{ i.o.}\}} \quad \text{a.s. } [P_x] \tag{29}$$

and so only the first equality requires verification. However this follows from (9), which expresses the fact that $\mathcal{U}_i$ is a small set of positive π^i-measure [Nummelin, 1984]. □

3.3. Asymptotic behavior. We now investigate the sample path properties and the asymptotic behavior of the underlying distributions of (4) under the weak stochastic controllability condition.

The following two results concern the asymptotic behavior of the Markov chain Φ restricted to one of the absorbing sets S_i. They are interesting in themselves and will also be useful for establishing limit theorems for arbitrary initial conditions.

If a set $A \in \mathcal{B}(\mathbf{X})$ is absorbing then for every initial condition $x \in A$, almost every $[P_x]$ sample path lies in $A^{\mathbb{Z}_+}$. Hence we can replace the state space $\mathbf{X}$ with A if we are only interested in such initial conditions.

The Markov chain Φ restricted to an absorbing set A is called *positive recurrent* if a Harris set $H \subset A$ exists and for each $x \in A$,

$$P_x\{\Phi \text{ enters } H\} > 0.$$

PROPOSITION 3.1. *Suppose conditions* A1–A4 *hold and Φ is weakly stochastically controllable. Then for each $i \in I$, the restriction of Φ to S_i is positive recurrent. If in addition Φ is bounded in probability, then S_i is a Harris set.*

Proof. Let $\mathcal{U}_i$, $\mathcal{V}_i$, and $\Lambda_i^{-1}\{0\}$ be defined as in § 3.2, and observe that by Lemma 3.2, $\Lambda_i^{-1}\{0\} \cap S_i$ is closed and absorbing. Since $\pi^i\{\mathcal{U}_i\} > 0$ it follows that

$$P_x\{\Phi \text{ enters } \mathcal{U}_i\} = 1 \quad \text{for all } x \in H_i.$$

Hence $\Lambda_i^{-1}\{0\} \subset H_i^c$ and it follows that $\pi^i\{\Lambda_i^{-1}\{0\}\} = 0$. So by Lemma 3.5, $\Lambda_i^{-1}\{0\} \cap S_i = \phi$. This implies that for every $x \in S_i$,

$$P_x\{\Phi \text{ enters } \mathcal{U}_i\} > 0. \tag{30}$$

We have, since $\mathbf{1}_{\mathcal{V}_i} < \pi^i$,

$$P_x\{\Phi \text{ enters } H_i\} \geqq \sup_{k\in\mathbb{Z}_+} P^{k+T}(x, H_i) \geqq \sup_{k\in\mathbb{Z}_+} cP^k(x, \mathcal{U}_i)\mu^{\text{Leb}}\{\mathcal{V}_i\}, \tag{31}$$

and combining (30) and (31) gives

$$P_x\{\mathbf{\Phi} \text{ enters } H_i\} > 0 \quad \text{for all } x \in S_i,$$

which shows that $\mathbf{\Phi}$ restricted to S_i is positive recurrent.

Suppose now that $\mathbf{\Phi}$ is bounded in probability. By Lemma 3.6, $\mathbf{\Phi}$ restricted to S_i is positive Harris recurrent if and only if

$$\lim_{k\to\infty} \Lambda(\Phi_k, \mathcal{U}_i) = 1 \quad \text{a.s. } [P_x] \tag{32}$$

for all $x \in S_i$.

Let $C \subset S_i$ be compact. By (30) the open sets

$$\mathcal{W}_k = \{x \in \mathbf{X} \colon \Lambda(x, \mathcal{U}_i) > 1/k\} \qquad k \geqq 1$$

form an open cover of C, and by compactness it follows that there exists $k_0 \in \mathbb{Z}_+$ such that

$$\Lambda(x, \mathcal{U}_i) > 1/k_0 \quad \text{for all } x \in C. \tag{33}$$

If the limit in (29) is zero then $\mathbf{\Phi}$ enters C only a finite number of times by (33). Since C is arbitrary, $\mathbf{\Phi}$ eventually leaves every compact set in this case. By stability, this can only happen on a P_x-null set and hence (32) holds. □

LEMMA 3.7. *Suppose conditions* A1–A4 *hold and that* $\mathbf{\Phi}$ *is l.s.c. Then for each* $x \in S_i$,

$$P^T(x, \cdot) < \pi^i,$$

where $T = T(x)$ *is the integer used in the definition of local stochastic controllability.*

Proof. Let $T = T(x)$, $\mathcal{O}_x$, Z_x, $\mathcal{V}_x^\lambda$, and $\mathcal{U}_x^\lambda$ be as in the proof of Theorem 2.1, and recall from Theorem 2.1 that

$$\mathcal{O}_x \triangleq \bigcup_{\lambda \in \mathcal{O}_w^T \setminus Z_x} S_x^T(\lambda) = \bigcup_{\lambda \in \mathcal{O}_w^T \setminus Z_x} \mathcal{V}_x^\lambda. \tag{34}$$

By Lemma 3.3(i),

$$\mathbf{1}_{\mathcal{V}_x^\lambda} \mu^{\text{Leb}} < \pi^i \quad \text{for all } x \in S_i \quad \text{and} \quad \lambda \in \mathcal{O}_w^T \setminus Z_x.$$

Since the union of a family of open sets in $\mathbf{X}$ is equal to the union of a countable subfamily, it follows from this and (34) that

$$P^T(x, \cdot) \approx \mathbf{1}_{\mathcal{O}_x} \mu^{\text{Leb}} < \pi^i. \qquad □$$

The following result follows immediately.

PROPOSITION 3.2. *If conditions* A1–A4 *hold and* $\mathbf{\Phi}$ *is l.s.c. then* S_i *is a Harris set for each* $i \in I$.

Proof. By Lemma 3.7 and the fact that $\pi^i\{H_i\} = 1$, it follows that $P^T(x, H_i) = 1$ for all $x \in S_i$, which by conditioning at time T and using the Markov property implies the desired result. □

We now show how the underlying distributions of w.s.c. Markovian systems exhibit asymptotically periodic behavior.

PROPOSITION 3.3. *If* (4) *is w.s.c. then for each initial condition* $x \in \mathbf{X}$, *the resulting trajectory* $\{\mu_k = P^k(x, \cdot) \colon k \in \mathbb{Z}_+\}$ *may be written*

$$\mu_k = n_k + \sum_{i \in I} \alpha_i(x) \mu_k^i, \tag{35}$$

where $\{n_k \colon k \in \mathbb{Z}_+\}$ *is a sequence of subprobabilities for which*

$$\frac{1}{N} \sum_{k=1}^{N} n_k \xrightarrow{\textit{vaguely}} 0, \tag{36}$$

and for each $i \in I$, the sequence of subprobabilities $\{\mu_k^i\colon k \in \mathbb{Z}_+\}$ converges in total variation norm to a periodic orbit; that is, there exists a periodic orbit $\{\gamma_k^i\colon k \in \mathbb{Z}_+\}$ such that

$$\lim_{k\to\infty}\left(\sup_{A\in\mathscr{B}(\mathbf{X})}|\mu_k^i\{A\}-\gamma_k^i\{A\}|\right)=0.$$

Proof. The proof of Proposition 3.3 will be completed in two steps.

Step 1. We show that for each $i \in I$, the sequence of subprobabilities

$$\{\mu_k^i \triangleq (1/\alpha_i(x))\mathbf{1}_{H_i}\mu_k\colon k\in\mathbb{Z}_+\}$$

converges to a periodic orbit whenever $\alpha_i(x) \neq 0$.

Fix $i \in I$. The Harris set H_i may be written as a disjoint union

$$H_i = \bigcup_{j=1}^{\lambda} E_j \cup \Delta, \quad \text{where } \pi^i\{\Delta\}=0,$$

and the cycle $\{E_j\colon 1 \leqq j \leqq \lambda\}$ has the invariance properties

$$P(y, E_{j+1}) = 1 \text{ for } y \in E_j \text{ (mod } \lambda),$$

and

$$P^\lambda(y, E_j) = 1 \text{ for } y \in E_j.$$

So, defining $\beta_k \in \mathbb{R}_+$ by $\beta_k \triangleq \lim_{n\to\infty} P^{n\lambda}(x, E_k)$ we have $\alpha_i(x) = \sum_{k=1}^{\lambda} \beta_k$.

If we let $d_k = \lambda \mathbf{1}_{E_k}\pi^i$,

$$\gamma_0 = \frac{1}{\alpha_i(x)}\sum_{k=1}^{\lambda}\beta_k d_k, \quad \text{and} \quad \gamma_k = \gamma_0 P^k \tag{37}$$

then $\gamma = \{\gamma_k\colon k \in \mathbb{Z}_+\}$ is a periodic orbit.

Since E_j is an aperiodic Harris set for the λ-step Markov chain $\{\Phi_{k\lambda}\colon k \in \mathbb{Z}_+\}$ (Proposition 3.14 of [Nummelin, 1984]) we have by Proposition 2.3

$$\lim_{k\to\infty}\sup_{B\in\mathscr{B}(\mathbf{X})}|\mathbf{1}_{E_j}\mu_{k\lambda}\{B\}-\beta_j d_j\{B\}|=0.$$

It follows that

$$\lim_{k\to\infty}\sup_{B\in\mathscr{B}(\mathbf{X})}\left|\frac{1}{\alpha_i(x)}\mathbf{1}_{H_i}\mu_{k\lambda}\{B\}-\gamma_0\{B\}\right|=0,$$

and further that for each $j \in \mathbb{Z}_+$,

$$\lim_{k\to\infty}\sup_{B\in\mathscr{B}(\mathbf{X})}\left|\frac{1}{\alpha_i(x)}\mathbf{1}_{H_i}\mu_{k\lambda+j}\{B\}-\gamma_j\{B\}\right|=0.$$

Hence $\{\mu_k^i\colon k \in \mathbb{Z}_+\}$ converges in total variation norm to the periodic orbit γ.

Step 2. We are left to show that with $H = \bigcup_{i\in I} H_i$, and $n_k \triangleq \mathbf{1}_{H^c}\mu_k$,

$$\frac{1}{N}\sum_{k=1}^{N} n_k \xrightarrow{\text{vaguely}} 0. \tag{38}$$

The set of all subprobabilities on $\mathscr{B}(\mathbf{X})$ is sequentially compact with respect to vague convergence. Hence (38) will hold if every vague limit point of the set of subprobabilities

$$\left\{\frac{1}{N}\sum_{k=1}^{N} n_k\colon N \in \mathbb{Z}_+\right\} \tag{39}$$

is zero. Let n_∞ be a vague limit point of (39) so that for some subsequence $\{N_i\}$ of $\mathbb{Z}_+$,

$$\lim_{i\to\infty}\frac{1}{N_i}\sum_{k=1}^{N_i}\int f\,dn_k \triangleq \lim_{i\to\infty}\frac{1}{N_i}\sum_{k=1}^{N_i} E_x[f(\Phi_k)\mathbf{1}_{H^c}(\Phi_k)] \tag{40}$$
$$= \int f\,dn_\infty$$

whenever $f\in C_c$. By choosing a further subsequence if necessary, we may assume that a subprobability μ_∞ exists such that

$$\frac{1}{N_i}\sum_{k=1}^{N_i}\mu_k \xrightarrow{\text{vaguely}} \mu_\infty \quad \text{as } i\to\infty.$$

It is easy to show that $\mu_\infty \geqq n_\infty$ (it is obvious that $\int f\,dn_\infty \leqq \int f\,d\mu_\infty$ for all $f\in C_c$) and by a proof similar to the result in [Foguel, 1969] we may show that μ_∞ is invariant.

Since every finite invariant measure is supported on $\cup\, S_i$, it follows that

$$n_\infty\left\{\bigcap_{i\in I} S_i^c\right\} \leqq \mu_\infty\left\{\bigcap_{i\in I} S_i^c\right\} = 0. \tag{41}$$

We now show that $n_\infty\{\cup_{i\in I} S_i\}=0$. From (41) it will follow that $n_\infty = 0$, completing the proof.

Let $i\in I$, $x\in S_i$, and $\mathcal{U}_x$ as before. If $\mathbf{\Phi}$ does not enter H_i then from Lemma 3.6 it follows that $\mathbf{\Phi}$ enters $\mathcal{U}_x$ finitely often and so,

$$\lim_{k\to\infty} \mathbf{1}_{H^c}(\Phi_k) - \mathbf{1}_{H^c}(\Phi_k)\mathbf{1}_{\mathcal{U}_x^c}(\Phi_k) = 0 \quad \text{a.s. } [P_x]. \tag{42}$$

Let $f\in C_c$ be any function which vanishes on $\mathcal{U}_x^c$. By (40),

$$\int f\,dn_\infty = \lim_{i\to\infty}\frac{1}{N_i}\sum_{k=1}^{N_i} E_x[f(\Phi_k)\mathbf{1}_{H^c}(\Phi_k)]$$
$$= \lim_{i\to\infty}\frac{1}{N_i}\sum_{k=1}^{N_i} E_x[f(\Phi_k)\mathbf{1}_{\mathcal{U}_x^c}(\Phi_k)\mathbf{1}_{H^c}(\Phi_k)]$$

by (42) and the Dominated Convergence Theorem

$$=0.$$

Since the function $\mathbf{1}_{\mathcal{U}_x}$ is the pointwise limit of an increasing sequence of such functions f, it follows that $n_\infty\{\mathcal{U}_x\}=0$. Furthermore, since S_i is contained in the union of a sequence of sets from $\{\mathcal{U}_x\colon x\in S_i\}$ it follows that $n_\infty\{S_i\}=0$. We conclude that

$$n_\infty\{\mathbf{X}\} = n_\infty\{\cup\, S_i\} + n_\infty\{\cap\, S_i^c\} = 0. \qquad \square$$

Observe that by Proposition 3.3, if (4) is w.s.c. then for each $x\in\mathbf{X}$

$$\frac{1}{N}\sum_{k=1}^{N}\mu_k \xrightarrow{\text{vaguely}} \alpha(x)\pi_x, \tag{43}$$

where, for $\alpha(x)\neq 0$, the invariant probability π_x is defined in (19). If $\alpha(x)=0$ then (43) still holds with $\pi_x = 0$.

The following result illustrates the sample path properties of w.s.c. Markovian systems.

PROPOSITION 3.4. *Suppose that conditions* A1–A4 *hold and that* Φ *is w.s.c. Then for any* $x \in \mathbf{X}$ *and* $f \in L^1(\mathbf{X}^{\mathbb{Z}_+}, \mathscr{B}(\mathbf{X}^{\mathbb{Z}_+}), P_{\pi_x})$,

$$P_x\left\{\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k, \Phi_{k+1}, \cdots) = f_\infty(\Phi_0, \Phi_1, \cdots)\right\} \geqq \alpha(x),$$

where $f_\infty \in L^1(\mathbf{X}^{\mathbb{Z}_+}, \mathscr{B}(\mathbf{X}^{\mathbb{Z}_+}), P_x)$ *is defined in* (20).

Proof. As before, let τ denote the first entrance time to H, and let $\mathscr{F}_\tau$ denote the sigma algebra of events before time τ.

By Proposition 2.3, for each $n \in I$, and $f \in L^1(\mathbf{X}^{\mathbb{Z}_+}, \mathscr{B}(\mathbf{X}^{\mathbb{Z}_+}), P_{\pi^n})$,

$$P_{\mu_0}\left\{\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k, \Phi_{k+1}, \cdots) = E_{\pi^n}[f(\Phi_0, \Phi_1, \cdots)]\right\} = 1$$

for any initial condition distribution μ_0 for wich $\mu_0\{H_n\} = 1$. From this and the strong Markov property it follows that for any $x \in \mathbf{X}$,

$$\begin{aligned}
&E_x\left[P_x\left\{\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k, \Phi_{k+1}, \cdots) = f_\infty(\Phi_0, \Phi_1, \cdots) \mid \mathscr{F}_\tau\right\} \mathbf{1}_{\tau<\infty}\right] \\
&= E_x\left[P_x\left\{\lim_{N\to\infty} \frac{1}{N} \sum_{k=\tau+1}^{\tau+N} f(\Phi_k, \Phi_{k+1}, \cdots) = f_\infty(\Phi_0, \Phi_1, \cdots) \mid \mathscr{F}_\tau\right\} \mathbf{1}_{\tau<\infty}\right] \\
&= E_x\left[P_{\Phi_\tau}\left\{\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k, \Phi_{k+1}, \cdots) = f_\infty(\Phi_0, \Phi_1, \cdots)\right\} \mathbf{1}_{\tau<\infty}\right] \\
&= P_x\{\tau < \infty\} = \alpha(x).
\end{aligned}$$

Hence

$$P_x\left\{\lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} f(\Phi_k, \Phi_{k+1}, \cdots) = f_\infty(\Phi_0, \Phi_1, \cdots)\right\} \geqq \alpha(x). \qquad \square$$

3.4. Proofs of Theorems 2.2–2.3. We begin with the proof of Theorem 2.2.

Proof of Theorem 2.2. We will proceed by establishing that (ii) implies (iii), and that (iii) implies (i). This is sufficient since it is obvious that (i) implies (ii), Propositions 3.3 and 3.4 show that (iii) implies (iv) and (v), and it is easy to see that (iv) and (v) each imply (ii).

The proof that the convergence in (v) is uniform on compact sets will be given in Proposition 3.5 below.

(ii)⇒(iii)

Let $\varepsilon > 0$, $x \in \mathbf{X}$ and $C \subset \mathbf{X}$ be a compact set for which

$$\liminf_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} P^k(x, C) > 1 - \varepsilon.$$

By Proposition 3.3 we have

$$\alpha(x) \geqq \alpha(x)\pi_x\{C\} = \lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} P^k(x, C),$$

and since ε was chosen arbitrarily, this implies $\alpha(x) = 1$.

(iii)⇒(i)

Let $x \in \mathbf{X}$, $\varepsilon > 0$. Then by condition (iii) and Proposition 3.3

$$\mu_k = \sum_{i\in I} \alpha_i(x)\mu_k^i + n_k, \qquad \text{where } \alpha(x) = \sum_{i\in I} \alpha_i(x) = 1.$$

Choose $M \in \mathbb{Z}_+$ so large that $\sum_{i=0}^{M} \alpha_i > 1-\varepsilon$, and choose a compact set $C \subset \mathbf{X}$ such that

$$\gamma_k^i\{C\} > 1-\varepsilon, \quad \text{for } 0 \leqq i \leqq M, \quad \text{and} \quad 1 \leqq k \leqq \lambda^i.$$

Then by Proposition 3.3

$$\begin{aligned} \liminf_{k\to\infty} \mu_k\{C\} &\geqq \liminf_{k\to\infty} \sum_{i=1}^{M} \alpha_i \mu_k^i\{C\} + n_k\{C\} \\ &\geqq \sum_{i=1}^{M} \alpha_i \min_k \gamma_k^i\{C\} \qquad (44) \\ &\geqq (1-\varepsilon)^2. \end{aligned}$$

Hence (4) is bounded in probability. □

We now present a strengthening of Proposition 3.3 and show that the probabilities $\{\pi_x\}$ are continuous functions of $x \in \mathbf{X}$.

A set $A \in \mathcal{B}(\mathbf{X})$ will be called *uniform* if

$$\lim_{N\to\infty} \sup_{x\in A} \left\| \frac{1}{N} \sum_{k=1}^{N} P^k(x, \cdot) - \pi_x(\cdot) \right\|_{tv} = 0.$$

The following result is taken from [Cogburn, 1975].

LEMMA 3.8. *Suppose that conditions* A1–A4 *hold, and that* $\mathbf{\Phi}$ *is bounded in probability and w.s.c. Then for each* $i \in I$, *every compact subset of* S_i *is uniform.*

This will be used to obtain the following proposition.

PROPOSITION 3.5. *Suppose that conditions* A1–A4 *hold, and that* $\mathbf{\Phi}$ *is bounded in probability and w.s.c. Then every compact subset of* $\mathbf{X}$ *is uniform.*

Proof. Under the conditions of Proposition 3.5, $\alpha_i(x) = \Lambda(x, S_i)$, and since S_i is a Harris set and $\mathcal{V}_i \subset S_i$ has positive π_i-measure we have

$$\alpha_i(x) = \Lambda(x, \mathcal{V}_i). \qquad (45)$$

Let $C \subset \mathbf{X}$ be compact and $\varepsilon > 0$. Define the functions $h_N : \mathbf{X} \to \mathbb{R}_+$ for $N \in \mathbb{Z}_+$, and $x \in \mathbf{X}$ by

$$h_N(x) = P_x\left\{ \bigcup_{k=1}^{N} \bigcup_{i=0}^{N} \{\Phi_k \in \mathcal{V}_i\} \right\}.$$

By the Feller property, the function h_N is lower semicontinuous, and for each $x \in \mathbf{X}$, $h_N(x) \uparrow \alpha(x) = 1$ as $N \to \infty$ by (45). By Dini's theorem the convergence is uniform on compact subsets of $\mathbf{X}$.

Since the sets $\{S_i\}$ are absorbing, this implies that there exists an integer $N_0 \in \mathbb{Z}_+$ such that

$$P_x\left\{ \Phi_{N_0} \in \bigcup_{i=0}^{N_0} S_i \right\} \geqq h_{N_0}(x) > 1-\varepsilon$$

for all $x \in C$.

By the Feller property, the map $x \to P^{N_0}(x, \cdot)$ that takes $\mathbf{X}$ to $\mathcal{M}$, the space of probabilities on $\mathcal{B}(\mathbf{X})$, is continuous with respect to weak convergence on $\mathcal{M}$. Since the continuous image of a compact set is compact, the probabilities $\{P^{N_0}(x, \cdot) : x \in C\}$ are tight. Hence for some compact set $K \subset \mathbf{X}$,

$$P_x\left\{ \Phi_{N_0} \in \bigcup_{i=0}^{N_0} K \cap S_i \right\} > 1-\varepsilon \qquad (46)$$

for all $x \in C$.

For all $k\in\mathbb{Z}_+$, and $x\in\mathbf{X}$,

$$\left\|\frac{1}{N_0+k}\sum_{i=1}^{N_0+k} P^i(x,\cdot)-\pi_x(\cdot)\right\|_{tv}=\sup\left|\frac{1}{N_0+k}\sum_{i=1}^{N_0+k}\int P^i(x,dy)f(y)-\int\pi_x(dy)f(y)\right|,$$

where the supremum is taken over all measurable $f:\mathbf{X}\to[-1,1]$. Hence by (46) we have for all $x\in C$,

$$\begin{aligned}&\left\|\frac{1}{N_0+k}\sum_{i=1}^{N_0+k} P^i(x,\cdot)-\pi_x(\cdot)\right\|_{tv}\\
&\leqq\sup\int P^{N_0}(x,dz)\left|\frac{1}{k}\sum_{i=1}^{k}\int P^i(z,dy)f(y)-\int\pi_z(dy)f(y)\right|+\frac{N_0}{N_0+k}\\
&\leqq\sup\sum_{j=0}^{N_0}P^{N_0}(x,K\cap S_j)\sup_{z\in K\cap S_j}\left|\frac{1}{k}\sum_{i=1}^{k}\int P^i(z,dy)f(y)-\int\pi_z(dy)f(y)\right|\\
&\qquad+\frac{N_0}{N_0+k}+\varepsilon\\
&\leqq\sup\sum_{j=0}^{N_0}\sup_{z\in K\cap S_j}\left|\frac{1}{k}\sum_{i=1}^{k}\int P^i(z,dy)f(y)-\int\pi_z(dy)f(y)\right|+\frac{N_0}{N_0+k}+\varepsilon\\
&\leqq\sum_{j=0}^{N_0}\sup_{z\in K\cap S_j}\left\|\frac{1}{k}\sum_{i=1}^{k}P^i(z,\cdot)-\pi_z(\cdot)\right\|_{tv}+\frac{N_0}{N_0+k}+\varepsilon.\end{aligned}$$

Applying Lemma 3.8 to the inequality above shows that

$$\limsup_{N\to\infty}\sup_{x\in C}\left\|\frac{1}{N}\sum_{i=1}^{N}P^i(x,\cdot)-\pi_x(\cdot)\right\|_{tv}\leqq\varepsilon.$$

Since ε is arbitrary, this proves the proposition. □

The following result shows that when $\mathbf{\Phi}$ satisfies the conditions of Proposition 3.5, the map $x\to\pi_x$ that takes $\mathbf{X}$ to $\mathcal{M}$ is continuous in total variation norm. In particular, the kernel $\Pi=\pi_{(\cdot)}(\cdot)$ has the strong Feller property.

COROLLARY 3.1. *Suppose that conditions* A1–A4 *hold. If* $\mathbf{\Phi}$ *is bounded in probability and w.s.c. then for each* $i\in I$, *the function* $\alpha_i(x)$ *is a continuous function of* $x\in\mathbf{X}$.

Proof. Fix $i\in I$, and let f_i be a continuous function for which $0\leqq f_i\leqq 1$, and

$$f_i(x)=\begin{cases}1 & \text{if } x\in S_i;\\ 0 & \text{if } x\in S_j, \qquad j\neq i.\end{cases}$$

It follows from Theorem 2.2 and the definition of π_x that

$$\alpha_i(x)=\int f_i\,d\pi_x=\lim_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N}\int P^k(x,dy)f_i(y),$$

where the convergence is uniform for x in compact subsets of $\mathbf{X}$. The corollary follows from these facts since for each $N\in\mathbb{Z}_+$, the function

$$\frac{1}{N}\sum_{k=1}^{N}\int P^k(\cdot,dy)f_i(y)$$

is continuous. □

Proof of Theorem 2.3. Suppose that $\mathbf{\Phi}$ is uniformly bounded in probability, and let $C\subset\mathbf{X}$ be a compact set for which

$$\liminf_{k\to\infty} P^k(x, C)\geqq\tfrac{1}{2}\quad\text{for every } x\in\mathbf{X}.$$

By Proposition 3.3, for each $x\in\mathbf{X}$,

$$\lim_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N} P^k(x, C)=\pi_x\{C\},$$

and hence $\pi^i\{C\}\geqq\frac{1}{2}$ for each $i\in I$. However by Lemma 3.4

$$\pi^i\{C\}=\pi^i\{C\cap S_i\}=0$$

for all but a finite number of $i\in I$ and this shows that I is in fact finite.

Conversely, if I is finite and $\mathbf{\Phi}$ is bounded in probability then Proposition 3.3 shows that the distributions of $\mathbf{\Phi}$ converge cyclically. Since in this case the collection of probabilities $\{\pi_x\colon x\in\mathbf{X}\}$ is tight, it follows that $\mathbf{\Phi}$ is uniformly bounded in probability.

To prove that the distributions of $\mathbf{\Phi}$ converge uniformly on compact sets, use the proof of Proposition 3.5. □

Proof of Theorem 2.4. The main idea of the proof of Theorem 2.4 is that condition GA or A5 ensures that the support of every invariant probability contains the origin. Under the weak stochastic controllability hypothesis, the supports of distinct the invariant probabilities $\{\pi^i\}$ are disjoint, and hence Harris recurrence is an immediate consequence. The idea of replacing a random disturbance by a deterministic sequence lying in its support has previously been used to determine the support of a diffusion process (see [Stroock and Varadhan, 1972] and [Kunita, 1976]).

To prove (i) we observe that the conditions of Theorem 2.2 are satisfied and hence by Corollary 2.3 it is enough to show that there is exactly one invariant probability.

Let π be one of the invariant probabilities $\{\pi^i\}$, and $\mathcal{W}$ any open set that contains the origin. By Lemma 2.1, the sets

$$D_n=\{x\in\mathbf{X}\colon P^n(x,\mathcal{W})>0\}\qquad n\in\mathbb{Z}_+$$

cover $\mathbf{X}$, and hence for some $n\in\mathbb{Z}_+$, $\pi\{D_n\}>0$. This implies that $\pi\{\mathcal{W}\}\geqq\int_{D_n} P^n(y,\mathcal{W})\pi(dy)>0$, and since $\mathcal{W}$ is an arbitrary open set containing the origin, it follows that $0\in\operatorname{supp}\pi$. By Lemma 3.3 the supports of π^i and π^j are disjoint for $i\neq j$, and this proves (i) of the proposition.

To prove (ii) suppose that a cycle $\mathbf{E}$ exists with period λ, let π denote the unique invariant probability for $\mathbf{\Phi}$, and let $\mathcal{U}$ and $\mathcal{V}$ be open sets that satisfy condition (iii) of Proposition 2.1.

Let $d_k\triangleq\lambda\mathbf{1}_{E_k}\pi$. Since the sets in the cycle $\mathbf{E}$ are disjoint, d_k and d_j are mutually singular for $k\neq j\,(\operatorname{mod}\lambda)$. However by Lemma 2.1 we have $d_k\{\mathcal{U}\}=\int P^k(x,\mathcal{U})d_0(dx)>0$ for all k sufficiently large, and this implies that $d_k>\mathbf{1}_{\mathcal{V}}\mu^{\text{Leb}}$ for all large k. Since $\{d_k\colon 1\leqq k\leqq\lambda\}$ are mutually singular, this implies that $\lambda=1$. □

4. Conclusions. In this paper we have presented a stability theory for nonlinear stochastic systems operating under feedback. Among the consequences of this theory are the following:

(i) If a Markovian system of the form (4) is bounded in probability and w.s.c.

then the limits

$$\lim_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N} f(\Phi_k)=f_\infty \quad \text{a.s. } [P_x],$$
(47)
$$\lim_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N} P_x\{\Phi_k\in A\}=\pi_x\{A\}$$

exist for *every* initial condition $x\in\mathbf{X}$, every $A\in\mathscr{B}(\mathbf{X})$, and for a very large class of functions f that includes all positive Borel measurable functions. This result is sharp because in the case where $F(\cdot,\cdot)$ is linear but not controllable there may exist Borel sets A and bounded Borel functions f for which (47) does not hold.

(ii) If (4) is uniformly bounded in probability and w.s.c. then the probabilities $\{P^k\colon k\in\mathbb{Z}_+\}$ governing the state process converge cyclically for *any* initial condition. For example, this implies that there exists a $\lambda\in\mathbb{Z}_+$ such that

$$\lim_{k\to\infty} P\{\Phi_{k\lambda+i}\in A\}$$

exists for every Borel measurable set $A\subset\mathbf{X}$ and every $i\in\mathbb{Z}_+$.

(iii) Under a mild stability condition on the undriven system, periodicity is ruled out and a unique invariant probability π may be shown to exist. Hence, for example, the limit above holds with $\lambda=1$.

These results have significant implications in stochastic system theory and, in particular, to the control of stochastic systems that vary randomly in time.

To illustrate what can go wrong with stochastic controllability, consider a single input single output ARMAX system under the mean-square optimal control law

$$B(z)u(z)=[A(z)-C(z)]y(z),$$

and define

$$\Phi_{k+1}=(y_k,\cdots,y_{k-n_1},u_{k-d},\cdots,u_{k-n_2},w_k,\cdots,w_{k-n_3})^{\mathrm{T}}.$$

Suppose that the zeros of the polynomials B and C lie outside the unit disc in $\mathbb{C}$. It is easily shown that the closed loop system is bounded in probability in this case and that

$$\lim_{k\to\infty}(y_k-w_k)=0 \quad \text{a.s. } [P_{\Phi_0}] \tag{48}$$

for all initial conditions Φ_0.

By (48) we have $y_0=w_0$ almost surely $[P_\pi]$ for the (unique) invariant probability π, and hence π is supported on a hyperplane in $\mathbb{R}^n$. Consequently, this system is *not* w.s.c. because π is singular with respect to Lebesgue measure. Similarly, the stochastic gradient algorithm of [Goodwin, Ramadge, and Caines, 1981] does not give rise to a w.s.c. system because the gain r_k^{-1} converges to zero almost surely.

However one active research area in stochastic control theory today is the adaptive control of time varying stochastic systems (see for example [Chen and Caines, 1985]). It is in this area that the ideas introduced in this paper will be very useful. For example, the Markovian system of [Meyn and Caines, 1987] is l.s.c., and this fact was crucial in establishing many of the results in that paper. Furthermore, an ARMAX system controlled by a gradient type algorithm gives rise to a w.s.c. Markovian system under mild conditions [Meyn and Guo, 1990].

There is much room for future research. For example, the asymptotic behavior of Markovian systems that are not w.s.c. is not well understood. We have already noted that in the linear case, $\Phi_{k+1}=A\Phi_k+Bw_{k+1}$, there are two extreme cases when A is asymptotically stable and the disturbance $\mathbf{w}$ satisfies condition A4. If (A, B) is controllable then $\mathbf{\Phi}$ is positive Harris recurrent and hence the law of large number holds for every positive Borel function on the state space and every initial condition distribution. If (A, B) is not controllable then this is not the case except in trivial situations (when A and B are both zero, for instance). However the law of large numbers does hold for continuous functions with arbitrary initial distributions.

There is evidence to suspect that this result may be generalized to arbitrary Feller Markov chains that are bounded in probability and possess exactly one invariant probability: By Proposition 2.2, for any such Markov chain and any bounded and continuous function f on the state space $\mathbf{X}$ we have

$$\lim_{N\to\infty} E_x\left[\frac{1}{N}\sum_{k=1}^{N} f(\Phi_k)\right]=\int f\,d\pi.$$

This suggests that it may be possible to remove the expectation operator "E_x" to establish the law of large numbers for the class of bounded and continuous functions.

One approach to the problem is to search for stronger stability assumptions on $\mathbf{\Phi}$ that allow an approximation with a w.s.c. Markov chain $\mathbf{\Phi}^{\varepsilon}$.

Another possible approach is to use some nonlinear version of the controllable/uncontrollable decomposition theorem used in linear system theory. By applying the results of this paper to the controllable part of $\mathbf{\Phi}$, it may be possible to achieve the desired ergodic properties.

For example, a result of [Jakubczyk and Sontag, 1989] shows that if a fixed point exists (a state $x\in\mathbf{X}$ with the property that $F(x, w)=x$ for some $w\in \operatorname{supp}\mu_w$) then under general conditions an invariant submanifold $x\in\mathbf{Y}\subset\mathbf{X}$ exists on which the restricted system is w.s.c. Applying the results of this paper, it is easily shown that if such a system is bounded in probability then an aperiodic Harris set containing x exists. This allows an analysis of the asymptotic behavior of $\mathbf{\Phi}$, at least in the case when $\Phi_0=x$. Some ideas along these lines, and extensions to arbitrary initial conditions were begun in [Meyn, 1989].

EXTENDED ZEROS AND MODEL MATCHING*

MICHAEL K. SAIN†, BOSTWICK F. WYMAN‡, AND JOSEPH L. PECZKOWSKI§

Abstract. The model matching equation $T(z)=P(z)M(z)$ induces constraints upon the multivariate zero structures of $P(z)$ and $M(z)$; the nature of the constraint is best explained by extending the usual notion of zero. In particular, the extended Γ-zero module of $P(z)$ must contain as a submodule the module Z_Γ of matching Γ-zeros, which depends only upon $T(z)$ and $M(z)$; and the extended Ω-zero module of $M(z)$ must contain as a factor module the module Z_Ω of matching Ω-zeros, which depends only upon $T(z)$ and $P(z)$. Essential solutions, in which the constraint is by module isomorphism, are possible if and only if the nullity of $P(z)$ does not exceed the nullity of $T(z)$, on the one hand, or the co-nullity of $M(z)$ does not exceed the co-nullity of $T(z)$, on the other. Both the matching zero modules and their finitely generated, torsion parts—which have state-space interpretation—can be given concrete, intuitive interpretation in terms of short exact sequences, though the former is less involved than the latter. Moreover, in the case of the latter, a natural notion of essential solution is not available, in marked contrast to the situation for poles.

Key words. zeros, zero modules, extended zeros, model matching

1. Introduction.

We begin by considering the linear transfer function equation

$$T(z)=P(z)M(z), \tag{1.1}$$

over the field $k(z)$ of rational functions in z having coefficients in a base field k. If $R(z)$, $U(z)$, and $Y(z)$ are the vector spaces, then (1.1) may be seen either in terms of the commutative diagram of Fig. 1.1 or that of Fig. 1.2, depending upon whether $T(z)$ and $M(z)$ are given and $P(z)$ is sought, or $T(z)$ and $P(z)$ are given and $M(z)$ is sought.

The problems of Figs. 1.1 and 1.2 arise naturally in various applications. For example, in the theory of codes for reliable communication, $P(z)$ has to do with the decoding process, while $M(z)$ is associated with code design (see [1] for additional discussion). Again, in the theory of feedback control for solutions to servomechanism problems, $P(z)$ may represent the plant and $M(z)$ the open-loop equivalent of precompensation and feedback; or $M(z)$ may represent the plant and $P(z)$ the open-loop equivalent of post-compensation and feedback (for illustrations, see [2]).

In feedback theory, (1.1) has come to be known as the model matching equation. Accordingly, Figs. 1.1 and 1.2 represent two versions of the model matching problem. The model matching problem has been a central issue of abstract control theory at least since the seminal work [3] of Wang and Davison in 1973. For a sample of technically and historically important papers in this area, see also [4]-[6]. Unfortunately, the diversity of language and points of view in this area makes a useful survey and comparison of results very difficult, and we cannot undertake a thorough survey in this already long and technical paper. Nevertheless, later in this Introduction, we discuss briefly the differences in outlook between the present paper and some previous work.

If nothing is required of the unknown mappings $P(z)$ in Fig. 1.1 and $M(z)$ in Fig. 1.2 beyond their existence as $k(z)$-linear transformations, then almost trivial necessary and sufficient conditions are well known. In Fig. 1.1, given $T(z)$ and $M(z)$, then there exists a $k(z)$-linear map $P(z)$ completing the diagram if and only if the nullspace $\ker M(z)$ is a subspace of $\ker T(z)$. In Fig. 1.2, there exists a $k(z)$-linear map $M(z)$ completing the diagram if and only if the image $T(z)R(z)$ is a subspace of $P(z)U(z)$. If these basic conditions are satisfied, then in general the solutions are not unique, and the interesting problems center around constraints describing the set of possible solutions. In this Introduction we discuss the constraints which arise in Fig. 1.1, although both diagrams are discussed in the paper.

Given $T(z)$ and $M(z)$, assuming the kernel condition above, what mappings $P(z)$ can occur as solutions? We approach this problem by trying to find out what poles and what zeros are required in any solution mapping $P(z)$, and we call these minima the fixed poles and the fixed zeros.

The problem of fixed poles in this context was discussed by Conte, Perdon, and Wyman [7], building on earlier work in [8] and [9]. For a solution $P(z)$, we denote the pole module of $P(z)$ by $P(P(z))$. By this we mean that $P(P(z))$ is the state space of the minimal realization of $P(z)$ considered as a module over the polynomial ring $k[z]$ in the usual way. In [7] a new module

$$P(T, M) = M^{-1}U[z]/\{M^{-1}U[z] \cap T^{-1}Y[z]\} \tag{1.2}$$

was introduced, and the first basic result there established that $P(T, M)$ must appear as a submodule of $P(P(z))$ for any solution $P(z)$. Now the module $P(T, M)$ is a finite-dimensional vector space with a dynamics matrix arising from the module action, and the eigenvalues of that matrix give the numerical values of the poles, so we know numerically what poles must exist in $P(z)$. A module inclusion result gives substantially deeper additional information about multiplicities and Jordan structure of the space of poles. Furthermore, "essential solutions" satisfying exactly $P(P(z)) = P(T, M)$ can be constructed; and the module $P(T, M)$ can be given a precise and attractive description in terms of the pole and zero modules of $T(z)$ and $M(z)$. Finally, this method is not limited solely to the study of finite poles and zeros, but by replacing the polynomial ring by the ring of proper rational functions or suitable more complicated rings, conclusions can be drawn about causal or causal and stable solutions by considering poles and zeros at infinity. One of the chief dividends of the present algebraic approach is its ability to attack varying problems (such as causality and various kinds of stability) by simply changing the rings involved. The polynomial ring can be replaced by the ring of proper or proper and stable rational functions. Alternatively, a solution to the model matching problem is causal if it has no poles at infinity, and it is causal and stable if it has no poles at infinity or in the designated unstable region of the complex plane. For further discussion of this philosophy, see § 9 herein.

The present paper considers the problem of "fixed zeros" of the desired solution mappings $P(z)$. The goal is to construct a module, say $Z(T, M)$, which would appear as a submodule of the transmission zero module of any $P(z)$. However, the theory of zeros is much more complicated than the theory of poles; and the results obtained must be expressed in module language, having in general no adequate numerical version. The major source of the difficulties is in fact the nullspace of $T(z)$, which creates an infinite-dimensional space of "generic zeros" which can nevertheless affect the lumped or finite-dimensional zero spaces of $P(z)$.

At this point it will be helpful to discuss the differences in outlook between the present work and that part of the model matching tradition represented by the important paper [10] of Emre. Emre considers the problem $T(z)=P(z)M(z)$ as in Fig. 1.1 above, where $M(z)$ and $T(z)$ are given and $P(z)$ is sought. This problem is called the exact model matching problem (EMMP), and the "generalized EMMP" adds a causality requirement. The solution in [10] is quite explicit, supplying algorithms and parameterized families of solutions. On the other hand, [10] is primarily concerned with the pole structure of the solutions, generalizing [8] in a way different from the results in [7]. Work on zeros in this spirit can be found in [11] which, however, does not discuss model matching explicitly (see also the classic [12]). We are grateful to the referees for references to the closely related dynamic cover problem. See [10, p. 157] and Antoulas' paper [13]. We should point out that there is a close relationship between model matching, zeros, and the geometric control theory. This is evident, not only in [7]-[9], but also in [14], which gives an explicit map between the zero module and spaces of the form V^*/R^*. Finally, we mention that the zeros of a composition $P(z)M(z)$ of two given $k[z]$-linear maps received earlier attention in [15] and [16]. Neither of these, however, addresses model matching.

We hope that the present work makes a new contribution to the diversity of approaches to the model matching problem. The technical results on fixed zeros are new, but perhaps difficult to relate to earlier work. We hope that this paper motivates some reader to prepare a comprehensive survey of all these competing points of view.

Finally, we supply a "roadmap" to the results in this paper. Section 2 is a review of the basic ideas surrounding the pole module and the finite-dimensional zero module of a transfer function. In § 3 these ideas are generalized to ideas involving certain (possibly infinite-dimensional) extended zero modules which arise inevitably in the study of transfer functions which fail to be injective and surjective. In § 4, the heart of the paper, new modules describing the "matching zero structures" associated to Figs. 1.1 and 1.2 are introduced. For example, the relevant matching zero module for Fig. 1.1 (defined in (4.5) below) is

$$Z_\Gamma = T^{-1}Y[z]/\{T^{-1}Y[z]\cap M^{-1}U[z]\}. \tag{1.3}$$

Although this module appears very similar to the $P(T, M)$ defined above for the fixed pole problem, it is in fact much more complicated. If $T(z)$ is not one-to-one, the module Z_Γ may contain an infinite-dimensional part (which is actually a divisible module over $k[z]$) coming from the nullspace of $T(z)$. The results obtained in this paper indicate that this phenomenon cannot be ignored. The central result of § 4 states in this case (Theorem 3(2)) that Z_Γ appears as a submodule of the (possibly infinite-dimensional) extended zero module $Z_\Gamma(P(z))$, so that we must consider Z_Γ as the most natural module of "fixed zeros" for the problem. Section 5 contains an extensive analysis of Z_Γ in terms of more familiar and intuitive concepts. Section 6 investigates the problem of "essential solutions," seeking solutions $P(z)$ such that Z_Γ exactly equals $Z_\Gamma(P(z))$, concluding that they do not in general exist. Theorem 6 gives necessary and sufficient conditions for the existence of essential solutions. Sections 7 and 8 discuss the complications which arise when we try to prove a corresponding theorem for the finite-dimensional matching zero spaces and the finite-dimensional transmission zero module. Although elaborate and detailed results are obtained here, it is hard to imagine discovering and proving them directly in terms of matrix theory and finite-dimensional lumped zero theory. We are convinced more than ever that the module-theoretic approach to zeros, including now the infinite-dimensional part of the theory, gives the "correct" approach to problems of the type considered here.

Although this Introduction has considered only the form of the problem arising from Fig. 1.1 and leading to divisible modules of extended zeros, the problem formulation of Fig. 1.2 is also examined in the paper. This version requires infinite-dimensional free modules of extended zeros and a matching zero module with possibly a free part. We remark that it is in principle possible to handle Fig. 1.2 by a sophisticated dualization of Fig. 1.1. Our experience in looking at this approach leads us to conclude that it increases technicality without saving space in a comparable way. Moreover, it reduces the possibility of giving intuitive interpretations to the building blocks of these modules. We have therefore chosen a parallel treatment.

2. Finitely generated, torsion poles and zeros. We set the following conventions. For a field k, let $k[z]$ be the ring of polynomials in z with coefficients in k, and let $k(z)$ be the induced quotient field. Recall that a "transfer function" in $k(z)$ is an equivalence class, and note that the customary representative of a class is a pair $(n(z), d(z))$ of polynomials in $k[z]$, with $d(z)$ nonzero and the pair relatively prime. In applications, the ratio $n(0)/d(0)$ is also of interest, when it is defined, and is designated as the "gain" K of the associated class. More generally, we can represent a transfer function in the manner $(Kz^{\alpha}n(z), d(z))$ or $(Kn(z), z^{\beta}d(z))$, where there is the additional condition that $n(0)=d(0)=1$. For the purposes of the investigation in this paper, any unit in $k[z]$ will serve just as well as any other. With these understandings, we refer to elements in $k(z)$ as transfer functions.

For a discussion of poles and zeros in the multivariable sense, it is necessary to have in hand a concrete representation of polynomials and transfer functions in a vector sense. Intuitively, we do this by "multiplying" the scalar version of the quantity in question onto the vector of interest. More precisely, let R, U, and Y be finite-dimensional vector spaces over k; and note that $k[z]$ and $k(z)$ are also k-vector spaces. Then we employ the k-bilinear tensor product to form $k[z]$-modules

$$(2.1) \qquad R[z]=k[z]\otimes_k R, \quad U[z]=k[z]\otimes_k U, \quad Y[z]=k[z]\otimes_k Y,$$

and $k(z)$-vector spaces

$$(2.2) \qquad R(z)=k(z)\otimes_k R, \quad U(z)=k(z)\otimes_k U, \quad Y(z)=k(z)\otimes_k Y.$$

If $M(z): R(z)\rightarrow U(z)$ is a $k(z)$-linear map, we wish to describe its poles and zeros in a precise, technical sense. For the elementary class represented by $(n(z), d(z))$, this is done easily and intuitively with the $k[z]$-modules $k[z]/d(z)k[z]$ and $k[z]/n(z)k[z]$. For $M(z)$, greater elaboration is needed.

The pole module $P(M(z))$ associated with a $k(z)$-linear map $M(z)$ is defined to be the $k[z]$-factor module given by

$$(2.3) \qquad P(M(z))=R[z]/\{R[z]\cap M^{-1}U[z]\},$$

where M^{-1} is the inverse image function of $M(z)$, defined on $U[z]$ by

$$(2.4) \qquad M^{-1}U[z]=\{r(z): r(z)\in R(z) \text{ and } M(z)r(z)\in U[z]\}.$$

As a $k[z]$-module, $P(M(z))$ is finitely generated, because $R[z]$ is finitely generated; it is a torsion module because every element in $R[z]$, even if not in $M^{-1}U[z]$, can be made so by scaling with a suitable polynomial $p(z)$ in $k[z]$.

Finitely generated, torsion modules over $k[z]$, such as the pole module $P(M(z))$, can be understood as traditional state spaces of finite dimension over the field k. Considered as a k-vector space, $P(M(z))=X_P$, the usual state space of a minimal realization of $M(z)$; and the scalar module action $z:P(M(z))\rightarrow P(M(z))$ defines a k-linear dynamics map $A_P:X_P\rightarrow X_P$ in the realization. On the system level, it may be observed from the definition (2.3) that the input signals of interest are polynomial vectors in $R[z]$, but not those which produce output vectors which lie entirely in $U[z]$. In terms of classical realization theory [17], entries in $R[z]$ may be understood as finite sequences of inputs starting in the past and ending at the present. An output contained entirely in $U[z]$ corresponds to a sequence all of whose future values are zero. From an engineering point of view, we may think of exciting the system with inputs which do not have poles, but which lead to outputs which do have poles.

In a quite realistic sense, we may regard the pole module $P(M(z))$ as a generalization of the "denominator polynomial" $d(z)$. The use of a module such as (2.3) permits us to carry information about the poles of $M(z)$ in a capsule form. The module describes, simultaneously, the dimension of the state space and the spectral character of its associated dynamics.

It is sometimes convenient to make use of isomorphic forms for the pole module (2.3). For example, we can write

$$P(M(z))\approx MR[z]/\{U[z]\cap MR[z]\}, \tag{2.5}$$

as a $k[z]$-module. To develop such an isomorphism, we can begin with the commutative diagram of Fig. 2.1, in which rows are natural inclusions and columns are restrictions of $M(z)$. If $r(z)$ represents an element in (2.3), then column two of Fig. 2.1 induces the desired isomorphism by the action

$$r(z)\mapsto M(z)r(z) \bmod MR[z]\cap U[z]. \tag{2.6}$$

The pole module of $M(z)$ maintains its basic character, being finitely generated and torsion, even when the kernel, $\ker M(z)$, of $M(z)$, or the cokernel, $\operatorname{coker} M(z)$, of $M(z)$ is nonzero. It turns out that this is not the situation for $k[z]$-zeros of $M(z)$. However, there is a fundamental module containing the zeros of $M(z)$ which are finitely generated and torsion. These zeros, of course, will be the most familiar because they resemble poles.

The finitely generated, torsion zero module $Z(M(z))$ associated with a $k(z)$-linear map $M(z)$ was defined by Wyman and Sain [8] in 1981 to be the $k[z]$-factor module

$$Z(M(z))=\{M^{-1}U[z]+R[z]\}/\{\ker M(z)+R[z]\}. \tag{2.7}$$

$$\begin{tikzcd}
R[z]\cap M^{-1}U[z] \arrow[r] \arrow[d, "M(z)"'] & R[z] \arrow[d, "M(z)"] \\
MR[z]\cap U[z] \arrow[r] & MR[z]
\end{tikzcd}$$

FIG. 2.1

From the fact that $R[z]$ and $U[z]$ are finitely generated, together with the fact that elements are equivalent modulo $\ker M(z)$, we have that (2.7) is finitely generated. It is torsion because any element in $M^{-1}U[z]$ can be scaled by a polynomial $p(z)$ in $k[z]$ so that the result lies in $R[z]$. From the definition, it is clear that the module $Z(M(z))$ has to do with inputs in $R(z)$ which lead to outputs in $U[z]$, but not polynomial vector inputs in $R[z]$ and not inputs in $\ker M(z)$. Intuitively, then, we are talking about system excitations which contain poles, but which produce nonzero responses without poles. In the sequel, when we use the term zero module, we will have in mind the finitely generated, torsion module (2.7), or one of its isomorphic forms. Two such forms are given by

$$Z(M(z)) \approx M^{-1}U[z]/\{M^{-1}U[z] \cap (\ker M(z) + R[z])\} \tag{2.8}$$

$$\approx \{U[z] \cap MR(z)\}/\{U[z] \cap MR[z]\}; \tag{2.9}$$

and explicit isomorphisms corresponding to (2.8) and (2.9) can be determined from the commutative diagrams of Figs. 2.2 and 2.3, respectively.

In a manner analogous to poles, the zero module permits a state-space interpretation. As a k-vector space, $Z(M(z)) = X_Z$, which is of finite dimension. Also, the scalar module action $z : Z(M(z)) \to Z(M(z))$ defines a k-linear map $A_Z : X_Z \to X_Z$. The space X_Z is not the usual state space; and the map A_Z is not the usual dynamics map. In order to distinguish the cases, we can think of X_P as a space of pole-states and of X_Z as a space of zero-states. Then A_P becomes the pole-state dynamics map, while A_Z is the zero-state dynamics map. It should be noted that the terminology "zero-state" is not in reference to any initial conditions. Rather, we are speaking of two distinct state spaces which are associated with the same $k(z)$-linear map. One of these spaces is for poles, while the other is for zeros.

The module $Z(M(z))$ is a generalization of the elementary notion of "numerator polynomial" $n(z)$, even as the module $P(M(z))$ generalizes $d(z)$. The algebra of these modules is somewhat more intricate than that of the ring $k[z]$, however, and involves commutative diagrams and exact sequences. Moreover, for the study of the problem in this paper, other types of $k[z]$-zeros have an important role to play. Some of these zeros are of torsion type, but not finitely generated. Others are finitely generated, but

$$\begin{tikzcd}
M^{-1}U[z] \cap (\ker M(z) + R[z]) \arrow[r] \arrow[d] & M^{-1}U[z] \arrow[d] \\
\ker M(z) + R[z] \arrow[r] & M^{-1}U[z] + R[z]
\end{tikzcd}$$

FIG. 2.2

$$\begin{tikzcd}
M^{-1}U[z] \cap (\ker M(z) + R[z]) \arrow[r] \arrow[d, "M(z)"'] & M^{-1}U[z] \arrow[d, "M(z)"] \\
U[z] \cap MR[z] \arrow[r] & U[z] \cap MR(z)
\end{tikzcd}$$

FIG. 2.3

are not torsion. We have, therefore, to extend the notion of zero; and this is the content of § 3.

3. Extended zeros: divisible and free. In § 2, we discussed $k[z]$-zeros of a $k(z)$-linear map $M(z): R(z) \to U(z)$. These zeros were finitely generated and torsion; and, accordingly, they possess a natural interpretation of state-space type. Such zeros, which have received almost all the attention in the systems literature, are most familiar because of their resemblance to poles. For systems having one input and one output, this concept of zero is entirely adequate. When multiple inputs and multiple outputs are considered, however, zeros appear which are not of pole-type. Some of these are torsion zeros, but not finitely generated; in the context of realization theory, these may be classified as zeros of output type. Others are finitely generated, but free; and these have an analogous classification as zeros of input type. It is possible to extend the idea of zeros in such a way as to embrace both the zeros of pole-type, as in the previous section, and zeros of output or input type. The development of these notions, as well as their interrelationships, is the goal of this section.

3.1. The Γ-zero module. We begin our discussion of extended zeros in such a way as to address the zeros of output type. Consider the $k[z]$-factor module

$$Z_\Gamma(M(z)) = M^{-1}U[z]/\{R[z] \cap M^{-1}U[z]\}. \tag{3.1}$$

This module is torsion. Indeed, observe that $M^{-1}U[z]$ is a submodule of $R(z)$, from which we have for every representative $r(z)$ of a class in (3.1) a polynomial $p(z)$ in $k[z]$ such that $p(z)r(z)$ is in $R[z]$ and is therefore equivalent to zero. If $\ker M(z)$ is not equal to zero, however, (3.1) is not finitely generated. We shall call (3.1) the Γ-zero module of $M(z)$.

When $\ker M(z)$ is zero, $Z_\Gamma(M(z))$ is identical to the form (2.8) and so is isomorphic, as a $k[z]$-module, to the zero module $Z(M(z))$ of § 2. Note that this statement holds whether or not $M(z)$ has a nontrivial cokernel. When $\ker M(z)$ is not zero, the nature of the Γ-zero module can be studied by means of the commutative diagram in Fig. 3.1, where rows and columns are natural inclusions. By the action

$$r(z) \mapsto r(z) \bmod (\ker M(z) + R[z]) \cap M^{-1}U[z], \tag{3.2}$$

this diagram induces an epic, $k[z]$-linear map $\alpha(z)$ from $Z_\Gamma(M(z))$ onto the isomorphic copy (2.8) of $Z(M(z))$. The kernel of $\alpha(z)$ is isomorphic to

$$\Gamma(M(z)) = \ker M(z)/\{R[z] \cap \ker M(z)\}. \tag{3.3}$$

Thus we have the short exact sequence

$$0 \to \Gamma(M(z)) \to Z_\Gamma(M(z)) \xrightarrow{\alpha(z)} Z(M(z)) \to 0, \tag{3.4}$$

if we identify (2.8) with $Z(M(z))$.

The module (3.3) is both torsion and divisible. To see the latter, observe that scalar multiplication $p(z): \ker M(z) \to \ker M(z)$ is an epimorphism of $k[z]$-modules whenever $p(z)$ is nonzero in $k[z]$. Then $\Gamma(M(z))$ inherits this same property. As a divisible module over $k[z]$, $\Gamma(M(z))$ is injective; and so its image under injection into

$$\begin{tikzcd}
R[z] \cap M^{-1}U[z] \arrow[r] \arrow[d] & M^{-1}U[z] \arrow[d] \\
(\ker M(z) + R[z]) \cap M^{-1}U[z] \arrow[r] & M^{-1}U[z]
\end{tikzcd}$$

FIG. 3.1

$Z_\Gamma(M(z))$ is a direct summand. It follows that

$$Z_\Gamma(M(z)) \approx \Gamma(M(z)) \oplus Z(M(z)). \tag{3.5}$$

We will refer to $\Gamma(M(z))$ as the divisible zero module of $M(z)$, and to $Z_\Gamma(M(z))$, the Γ-zero module of $M(z)$, as an extended zero module. In view of (3.5), we see that the notion of Γ-extended zeros includes both $\Gamma(M(z))$ and $Z(M(z))$ as special cases.

Realization theory also makes use of a torsion, divisible module. Indeed, let

$$M^{\#}(z) = pM(z)i \tag{3.6}$$

be the $k[z]$-linear composition of the natural inclusion $i: R[z] \to R(z)$, $M(z)$, and the natural projection $p: U(z) \to U(z)/U[z]$. $M^{\#}(z)$ is the restricted input/output map corresponding to $M(z)$. The output module of $M^{\#}(z)$ is torsion divisible, and is often denoted by ΓU. From the commutative diagram of Fig. 3.2, of natural inclusions, we can induce a monic, $k[z]$-linear map on $Z_\Gamma(M(z))$ into ΓR. Then we can think of $Z_\Gamma(M(z))$ as a submodule of ΓR. Accordingly, we employ the subscript Γ and regard Γ-zeros as being of output type.

3.2. The Ω-zero module. Next we examine zeros of input type, by forming the $k[z]$-factor module

$$Z_\Omega(M(z)) = U[z]/\{U[z] \cap MR[z]\}. \tag{3.7}$$

Module (3.7) is finitely generated, because $U[z]$ is finitely generated. Not every equivalence class in (3.7) is torsion, however, because not every $u(z)$ in $U[z]$ can be brought into $MR[z]$ by means of scalar multiplication. If the image, im $M(z)$, of $M(z)$ is equal to $U(z)$ on the $k(z)$-level, then the isomorphic form (2.9) of $Z(M(z))$ is equal to (3.7); and so we see that $Z_\Omega(M(z))$ differs from $Z(M(z))$ when coker $M(z)$ is nonzero. We call (3.7) the Ω-zero module of $M(z)$.

$$\begin{tikzcd}
R[z] \cap M^{-1}U[z] \arrow[r] \arrow[d] & M^{-1}U[z] \arrow[d] \\
R[z] \arrow[r] & R(z)
\end{tikzcd}$$

FIG. 3.2

When coker $M(z)$ is nonzero, we observe that form (2.9) is a submodule of (3.7). Identifying (2.9) with $Z(M(z))$, we have a natural inclusion of $Z(M(z))$ into $Z_\Omega(M(z))$, with cokernel isomorphic as a $k[z]$-module to

$$\Omega(M(z)) = U[z]/\{U[z] \cap MR(z)\}. \tag{3.8}$$

Thus there is a short exact sequence

$$0 \to Z(M(z)) \to Z_\Omega(M(z)) \to \Omega(M(z)) \to 0 \tag{3.9}$$

of $k[z]$-modules and $k[z]$-linear maps. The module (3.8) is torsion-free. To determine this, suppose the contrary. Then there is a nonzero $u(z)$ in $U[z]$ and a nonzero $p(z)$ in $k[z]$ such that

$$p(z)u(z) = M(z)r(z), \qquad r(z) \in R(z). \tag{3.10}$$

But then it follows that $u(z)$ is in $M(z)R(z)$ and must be equivalent to zero in (3.8). As a finitely generated, torsion-free module over the principal ideal domain $k[z]$,

$\Omega(M(z))$ is a free module. From the exactness of (3.9) at $\Omega(M(z))$, it then follows that

$$Z_\Omega(M(z)) \approx \Omega(M(z)) \oplus Z(M(z)). \tag{3.11}$$

We will call $\Omega(M(z))$ the free zero module of $M(z)$. Like $Z_\Gamma(M(z))$, then, $Z_\Omega(M(z))$ is an extended zero module, this time of Ω-type. Note from (3.11) that extended Ω-zeros include $\Omega(M(z))$ and $Z(M(z))$ as particular cases.

From the viewpoint of realization theory, the inputs to $M^{\#}(z)$ lie in $R[z]$, which is often denoted ΩR. As a factor module of ΩU, $Z_\Omega(M(z))$ may be thought of in terms of zeros of input type; and this motivates the subscript Ω.

3.3. Relation between $Z_\Gamma(M(z))$ and $Z_\Omega(M(z))$. The presence of $Z(M(z))$ in both the Γ-zero module, as a factor module, and the Ω-zero module, as a submodule, suggests that there may exist a relationship between Γ-zeros and Ω-zeros. Indeed, this is the case; and a convenient way in which to state this relationship is provided in the following theorem.

THEOREM 1. *Let $Z_\Gamma(M(z))$ be the Γ-zero module of $M(z)$, and let $Z_\Omega(M(z))$ be its Ω-zero module. Then there exists an exact sequence*

$$0 \to \Gamma(M(z)) \to Z_\Gamma(M(z)) \to Z_\Omega(M(z)) \to \Omega(M(z)) \to 0 \tag{3.12}$$

of $k[z]$-modules and $k[z]$-linear maps.

Proof. We establish a $k[z]$-linear map from $Z_\Gamma(M(z))$ into $Z_\Omega(M(z))$ by inducing from the restriction of $M(z)$ to $M^{-1}U[z]$. The existence of the desired map is a consequence of the commutative diagram of Fig. 3.3, where rows are natural inclusions and columns are restrictions of $M(z)$. The kernel of the induced map is given by

$$M^{-1}(MR[z] \cap U[z])/\{R[z] \cap M^{-1}U[z]\}, \tag{3.13}$$

which is isomorphic as a $k[z]$-module to $\Gamma(M(z))$. The image of the induced map is form (2.9); and so the cokernel is $\Omega(M(z))$, as asserted.

$$\begin{tikzcd}
R[z] \cap M^{-1}U[z] \arrow[r] \arrow[d, "M(z)"'] & M^{-1}U[z] \arrow[d, "M(z)"] \\
MR[z] \cap U[z] \arrow[r] & U[z]
\end{tikzcd}$$

FIG. 3.3

Remark. It is interesting to consider what happens in Theorem 1, with respect to its exact sequence (3.12), when the $k(z)$-linear map $M(z)$ has special features. For example, when $\ker M(z)$ is zero, so that its matrix representation would have full column rank over $k(z)$, then (3.3) indicates that $\Gamma(M(z))$ is zero and (3.5) shows that $Z_\Gamma(M(z))$ is isomorphic as a $k[z]$-module to $Z(M(z))$. Thus this special case of (3.12) becomes identical to the corresponding special case of (3.9). In like fashion, if the matrix of $M(z)$ has full row rank over $k(z)$, then $\Omega(M(z))$ becomes zero; and the corresponding specialization of (3.12) is identical to the associated specialization of (3.4).

Remark. It should be noted that $Z_\Gamma(M(z))$ and $Z_\Omega(M(z))$ will not be isomorphic unless the matrix of $M(z)$ is both square and invertible. For instance, it is quite possible for $Z_\Omega(M(z))$ to have finite dimension as a vector space over k while $Z_\Gamma(M(z))$ is infinite-dimensional. This occurs when the matrix of $M(z)$ is right invertible over $k(z)$, but not invertible.

In this section, we have discussed extensions of the classical idea of zero to include divisible or free zeros. These extensions were expressed, respectively, in terms of the

Γ-zero module $Z_\Gamma(M(z))$ and the Ω-zero module $Z_\Omega(M(z))$ of a $k(z)$-linear map $M(z): R(z) \to U(z)$. The Γ-zero module has received prior study in [14], where it has been shown to be closely related to the concept of zero signal generation. The Ω-zero module does not seem to have received prior attention. Both Γ-zeros and Ω-zeros play a central role in studying fixed zeros in model matching problems. We call such fixed modules "matching zeros," and discuss them in the following section.

4. Matching zeros. Suppose that the dimensions of R, U, and Y are each equal to unity, and consider the scalar equation

$$t(z) = p(z)m(z), \tag{4.1}$$

with all entries in $k(z)$. If we express these transfer functions in relatively prime form

$$t(z) = (n_t(z), d_t(z)), p(z) = (n_p(z), d_p(z)), m(z) = (n_m(z), d_m(z)), \tag{4.2}$$

then we obtain

$$p(z) = (n_t(z)d_m(z), d_t(z)n_m(z)), \tag{4.3}$$

which is useful when $m(z)$ is given, and

$$m(z) = (n_t(z)d_p(z), d_t(z)n_p(z)), \tag{4.4}$$

which is useful when $p(z)$ is given. From (4.3), we see that the zeros of $p(z)$ consist of those zeros of $t(z)$ which are not zeros of $m(z)$, together with those poles of $m(z)$ which are not poles of $t(z)$. From (4.4), we have that the zeros of $m(z)$ are zeros of $t(z)$ which are not zeros of $p(z)$, together with poles of $p(z)$ which are not poles of $t(z)$. This idea for determining fixed zeros in solutions to (4.1) is direct and intuitive; and we may well inquire if there exists a suitable extension to the multivariable case. Unfortunately, as we will later demonstrate in detail, such a generalization is not really available when we restrict our attention to $k[z]$-zeros which are finitely generated and torsion. But, if we permit the use of extended zeros, as explained in § 3, then we can obtain statements which are quite close in spirit to those above.

In order to capture in a more precise way the intuitive ideas of the preceding paragraph, we introduce the notion of a matching zero module. The matching Γ-zero module is denoted by Z_Γ and defined to be the $k[z]$-factor module

$$Z_\Gamma = T^{-1}Y[z]/\{T^{-1}Y[z] \cap M^{-1}U[z]\}, \tag{4.5}$$

where $T(z): R(z) \to Y(z)$ is a $k(z)$-linear map. The matching Ω-zero module is denoted by Z_Ω and defined to be the $k[z]$-factor module

$$Z_\Omega = \{PU[z] + TR[z]\}/TR[z], \tag{4.6}$$

for $P(z): U(z) \to Y(z)$ a $k(z)$-linear map. The algebraic character of matching zero modules of Γ-type and of Ω-type is settled by the theorem which follows.

THEOREM 2. *Let Z_Γ and Z_Ω be the matching zero modules of Γ-type and Ω-type, respectively, for $k(z)$-linear maps $M(z): R(z) \to U(z)$, $P(z): U(z) \to Y(z)$, and $T(z): R(z) \to Y(z)$. Define $k[z]$-factor modules*

$$Z'_\Gamma = T^{-1}Y[z]/\{T^{-1}Y[z] \cap (\ker T(z) + M^{-1}U[z])\}, \tag{4.7}$$

$$\Gamma = \ker T(z)/\{\ker T(z) \cap M^{-1}U[z]\}, \tag{4.8}$$

$$Z'_\Omega = \{PU[z] \cap TR(z)\}/\{PU[z] \cap TR[z]\}, \tag{4.9}$$

$$\Omega = PU[z]/\{PU[z] \cap TR(z)\}. \tag{4.10}$$

Then

$$Z_\Gamma \approx \Gamma \oplus Z'_\Gamma, \tag{4.11}$$

where Γ *is torsion divisible and* Z'_Γ *is finitely generated and torsion*; *and*

$$Z_\Omega \approx \Omega \oplus Z'_\Omega, \tag{4.12}$$

where Ω *is finitely generated and free while* Z'_Ω *is finitely generated and torsion.*

Proof. We begin by discussing the matching Ω-zero module. Because $R[z]$ and $U[z]$ are finitely generated, we have also from (4.6) that Z_Ω bears the same property. However, not every element in Z_Ω is a torsion element. Consider the torsion submodule of Z_Ω. If $y(z)$ represents a torsion element, then there exists a nonzero polynomial $p(z)$ such that

$$p(z)y(z) = T(z)r(z), \qquad r(z) \in R[z]. \tag{4.13}$$

But (4.13) implies that $y(z) \in T(z)R(z)$. Conversely, if $y(z) \in T(z)R(z)$, then (4.13) can be satisfied for appropriate choices of $p(z)$ and $r(z)$. Thus the torsion submodule of Z_Ω is given by

$$[\{PU[z]+TR[z]\} \cap TR(z)]/TR[z] = \{PU[z] \cap TR(z) + TR[z]\}/TR[z] \tag{4.14a}$$

$$\approx \{PU[z] \cap TR(z)\}/\{PU[z] \cap TR[z]\} \tag{4.14b}$$

$$= Z'_\Omega. \tag{4.14c}$$

Using the isomorphic form (4.14a), we can insert Z'_Ω into Z_Ω and produce a cokernel which is isomorphic to

$$\begin{aligned}&\{PU[z]+TR[z]\}/\{PU[z] \cap TR(z) + TR[z]\}\\ &\quad\approx PU[z]/\{PU[z] \cap TR(z)\} = \Omega.\end{aligned} \tag{4.15}$$

We claim that Ω is a torsion-free module. To see this, suppose that $y(z)$ represents a torsion element; then

$$p(z)y(z) = T(z)r(z), \qquad r(z) \in R(z), \tag{4.16a}$$

for some nonzero polynomial $p(z)$. Consequently, there is a polynomial $q(z)$ such that

$$(q(z)p(z))y(z) = T(z)(q(z)r(z)), \qquad q(z)r(z) \in R[z]. \tag{4.16b}$$

But this means that $y(z)$ is equivalent to zero in Z_Ω, as desired. As a finitely generated module over a principal ideal domain, Ω is also free. We thus have a short exact sequence

$$0 \to Z'_\Omega \to Z_\Omega \to \Omega \to 0; \tag{4.17}$$

and, because Ω is free, and a factor module of Z_Ω, we obtain (4.12). Next we turn to the matching Γ-zero module. If $r(z)$ is an element of $T^{-1}Y[z]$, and if the equation $p(z)x(z) = r(z)$ has a solution $x(z)$ in $T^{-1}Y[z]$ for each $p(z)$ in $k[z]$, then

$$T(z)(r(z)/p(z)) \in Y[z] \tag{4.18}$$

for all nonzero $p(z)$. But this cannot be true unless $r(z) \in \ker T(z)$. It follows that $\ker T(z)$ is the divisible submodule of $T^{-1}Y[z]$. Consequently, Γ is divisible and is isomorphic to the divisible submodule of Z_Γ. There exists an epic, $k[z]$-linear map from Z_Γ onto Z'_Γ, with kernel isomorphic to Γ. Thus we can write a short exact sequence

$$0 \to \Gamma \to Z_\Gamma \to Z'_\Gamma \to 0, \tag{4.19}$$

and infer (4.11) from the exactness of (4.19) at Γ, together with the fact that Γ is divisible. The torsion character of Γ and Z'_Γ follows, of course, from that of Z_Γ; and the torsion character of Z_Γ is a result of the fact that

$$M(T^{-1}Y[z]) \subset U(z). \tag{4.20}$$

Remark. It is evident from Theorem 2 that Z_Γ is a module having the same character as a module of extended Γ-zeros. In the same way, Z_Ω has a structure of the same type as a module of extended Ω-zeros.

Remark. Observe that Γ in (4.8) vanishes when the matrix of $T(z)$ has full column rank over $k(z)$. In this case the matching zero module of Γ-type is finitely generated and torsion. In similar fashion, we can say that Ω in (4.10) becomes zero when the matrix of $T(z)$ has full row rank over $k(z)$. Then the matching zero module of Ω-type is finitely generated and torsion.

Remark. It is worth pointing out that a $k(z)$-linear map, such as $T(z)$, may be onto while its restriction to polynomial vectors may not. It is precisely this fact which makes the study of zero properties possible for matrices. Thus, when we speak of the row rank or the column rank of a matrix, it is important to make clear whether we are regarding it as a linear map over $k[z]$ or $k(z)$.

So as to justify the use of the term "matching zeros" in connection with the modules Z_Γ and Z_Ω, we will show that they appear naturally as submodules and factor modules of the appropriate extended zero modules associated with solutions $M(z)$ or $P(z)$ to the model matching equation of § 1.

THEOREM 3. *Suppose that Z_Γ and Z_Ω are the matching zero modules of Γ-type and Ω-type, respectively, and let $T(z): R(z) \to Y(z)$ be a $k(z)$-linear map.*

(1) *If $P(z): U(z) \to Y(z)$ is a $k(z)$-linear map whose image contains that of $T(z)$, and if $M(z): R(z) \to U(z)$ is a $k(z)$-linear map which satisfies the equation $T(z) = P(z)M(z)$, then there exists an epic, $k[z]$-linear map*

$$\beta_\Omega(z): Z_\Omega(M(z)) \to Z_\Omega, \tag{4.21a}$$

so that Z_Ω is isomorphic to a factor module of the Ω-zero module of $M(z)$.

(2) *If $M(z): R(z) \to U(z)$ is a $k(z)$-linear map whose kernel is contained in that of $T(z)$, and if $P(z): U(z) \to Y(z)$ is a $k(z)$-linear map which satisfies the equation $T(z) = P(z)M(z)$, then there exists a monic, $k[z]$-linear map*

$$\beta_\Gamma(z): Z_\Gamma \to Z_\Gamma(P(z)), \tag{4.21b}$$

so that Z_Γ is isomorphic to a submodule of the Γ-zero module of $P(z)$.

Discussion of Theorem 3. From (4.5), Z_Γ depends upon $T(z)$ and $M(z)$, but not upon $P(z)$; accordingly, the constraint indicated by (4.21b) holds for *all* solutions $P(z)$ to the model matching equation. Likewise, (4.6) shows that Z_Ω depends only upon $P(z)$ and $T(z)$; and so (4.21a) is a feature of *all* solutions $M(z)$.

Proof of Theorem 3. Recall from § 3.2 the definition (3.7) for the Ω-zero module of $M(z)$. From the commutative diagram of Fig. 4.1, which is made up of natural inclusions and restrictions of $P(z)$, we can induce the map $\beta_\Omega(z)$, which is epic because the restriction of column two is epic. We remark that row two of Fig. 4.1 induces an isomorphic copy of Z_Ω, which is employed for convenience. Next, consider the

$$\begin{tikzcd}
U[z] \cap MR[z] \arrow[r] \arrow[d, "P(z)"'] & U[z] \arrow[d, "P(z)"] \\
PU[z] \cap TR[z] \arrow[r] & PU[z]
\end{tikzcd}$$

FIG. 4.1

commutative diagram of Fig. 4.2. The second row of the diagram induces $Z_\Gamma(P(z))$, in accord with definition (3.1), § 3.1, while the first row induces Z_Γ, as given in (4.5). Columns one and two are restrictions of $M(z)$. Map $\beta_\Gamma(z)$ of the theorem can be induced from this diagram. The calculation of its kernel gives

$$\{M^{-1}(P^{-1}Y[z]\cap U[z])\cap T^{-1}Y[z]\}/\{T^{-1}Y[z]\cap M^{-1}U[z]\}, \tag{4.22}$$

which vanishes as desired.

Remark. Theorem 3 has a number of features which occur in special cases. From Theorem 2, for example, we know that Z_Ω becomes a finitely generated, torsion module when $T(z)$ is an epic $k(z)$-linear map. The question arises about whether the solution $M(z)$ of (4.21a) will have extended zeros of Ω-type. It is easy to see that any nonzero element of $Z_\Omega(M(z))$ must either be a torsion element or lie in the kernel of $\beta_\Omega(z)$. But we know that the module $\Omega(M(z))$ contains no nonzero torsion elements. Thus, the question of whether a solution $M(z)$ has zeros of Ω-type can be related to whether $\beta_\Omega(z)$ has a kernel. We will see in § 7 that this kernel can be made to vanish by requiring that the kernel of $P(z)$ be zero. Accordingly, if the matrices of $T(z)$ and $P(z)$, considered as $k(z)$-linear maps, are of full row rank and column rank, respectively, then the unique solution $M(z)$ has no extended zeros of Ω-type. Moreover, the finitely generated, torsion zeros of $M(z)$ arise from the resulting, finite-dimensional matching zero module Z_Ω. Related remarks can be made if $T(z)$ is a monic $k(z)$-linear map. In this case Z_Γ is finitely generated and torsion; and the center of attention is the cokernel of $\beta_\Gamma(z)$. The extended Γ-zero character of solutions $P(z)$ can be eliminated by assuming that $M(z)$ has zero cokernel. Thus, if the matrices of $T(z)$ and $M(z)$, considered as $k(z)$-linear maps, are of full column rank and row rank, respectively, then the unique solution $P(z)$ has no extended zeros of Γ-type. For brevity, we leave the details of this second argument to the reader.

The constructions of (4.3) and (4.4) constitute a direct and intuitive way to characterize the zeros of solutions $p(z)$ and $m(z)$ to the model matching equation (4.1). In a generalization of those ideas to cases in which the dimensions of R, U, and Y are not equal to unity, we have replaced the elementary notion of polynomial with that of the more powerful and versatile module. One basic reason why we advance this point of view has to do with the fact that solutions $P(z)$ or $M(z)$ need not be unique, as they are in (4.1). We have to deal, then, with the module of zeros which is somehow a part of the zero module of any possible solution. The matching zero modules Z_Γ and Z_Ω play this role, for the two possible cases; and containment has to be understood either in terms of a submodule or in terms of a factor module.

However, an even more fundamental reason for introducing the matching zero modules has to do with generalizing the interpretations of (4.3) and (4.4), which follow those equations. It turns out that the analogous statements for higher-dimensional R, U, and Y must be made in terms of extended zeros. Because extended zeros are transparent in the familiar polynomial-matrix theories, it becomes both necessary and

$$\begin{tikzcd}
T^{-1}Y[z]\cap M^{-1}U[z] \arrow[r] \arrow[d, "M(z)"'] & T^{-1}Y[z] \arrow[d, "M(z)"] \\
P^{-1}Y[z]\cap U[z] \arrow[r] & P^{-1}Y[z]
\end{tikzcd}$$

FIG. 4.2

prudent to make use of the module-theoretic method in order to give them a careful accounting. The section following provides further detail.

5. Significance of Z_Γ and Z_Ω. We have seen in § 4 that the matching zero module Z_Γ is isomorphic to a direct sum of divisible zeros with zeros of finitely generated, torsion type. From § 2, we see that the latter type of module appears both in representations of poles and in representation of zeros. The former type of module, however, has appeared in § 3, which deals with extended zeros. In an analogous way, the matching zero module Z_Ω is isomorphic to a direct sum of free zeros with zeros of finitely generated, torsion type. Once again, the second class of module appears also in descriptions of poles, while the first type has been employed to discuss extended zeros. If, therefore, we are to generalize the conclusions which follow (4.3) and (4.4), we may anticipate that the term "zeros" will be replaced by the term "extended zeros." We might also hope to represent Z_Γ in terms of Γ-zeros of $T(z)$ and of $M(z)$, together with poles of $T(z)$ and of $M(z)$, and to represent Z_Ω with Ω-zeros of $T(z)$ and of $P(z)$, as well as with poles of $T(z)$ and of $P(z)$. These intuitions turn out to be true in great part.

The difference which arises has to do with the treatment of $M(z)$, in a discussion of Z_Γ, and with $P(z)$, in a treatment of Z_Ω. Basically, we must pair these maps with $T(z)$, in place of letting them stand alone. Thus, for Z_Γ, we study $T(z)$ and the pair $(T(z), M(z))$; for Z_Ω, we take $T(z)$ and the pair $(T(z), P(z))$. This section shows just what conceptual modifications have to be made. The main result is Theorem 4, following.

THEOREM 4. *Let Z_Γ and Z_Ω be the matching zero modules of Γ-type and Ω-type, respectively, for $k(z)$-linear maps $M(z): R(z) \to U(z)$, $P(z): U(z) \to Y(z)$, and $T(z): R(z) \to Y(z)$.*

(1) *If $[T(z)\ P(z)]: R(z) \oplus U(z) \to Y(z)$ is the $k(z)$-linear map with action*

$$[T(z)\ P(z)](r(z), u(z)) = T(z)r(z) + P(z)u(z), \tag{5.1}$$

then there exist $k[z]$-modules Z_1 and P_1, together with appropriate $k[z]$-linear maps, such that the following three short sequences are exact:

$$0 \to P(T(z)) \to P([T(z)\ P(z)]) \to P_1 \to 0, \tag{5.2a}$$

$$0 \to Z_1 \to Z_\Omega(T(z)) \to Z_\Omega([T(z)\ P(z)]) \to 0, \tag{5.2b}$$

$$0 \to Z_1 \to Z_\Omega \to P_1 \to 0. \tag{5.2c}$$

(2) *If*

$$\begin{bmatrix} T(z) \\ M(z) \end{bmatrix} : R(z) \to Y(z) \oplus U(z) \tag{5.3a}$$

is the $k(z)$-linear map having action

$$\begin{bmatrix} T(z) \\ M(z) \end{bmatrix} (r(z)) = (T(z)r(z), M(z)r(z)), \tag{5.3b}$$

then there exist $k[z]$-modules Z_2 and P_2, together with appropriate $k[z]$-linear maps, such that the following three short sequences are exact:

$$0 \to P_2 \to P\left(\begin{bmatrix} T(z) \\ M(z) \end{bmatrix}\right) \to P(T(z)) \to 0, \tag{5.4a}$$

$$0 \to Z_\Gamma\left(\begin{bmatrix} T(z) \\ M(z) \end{bmatrix}\right) \to Z_\Gamma(T(z)) \to Z_2 \to 0, \tag{5.4b}$$

$$0 \to P_2 \to Z_\Gamma \to Z_2 \to 0. \tag{5.4c}$$

Discussion of Theorem 4. The module P_1 is described in (5.2a), on a module-theoretic level, as "the poles of $[T(z)\ P(z)]$ which are not poles of $T(z)$." Note that, in the case (4.4), this reduces to the poles of $P(z)$ which are not poles of $T(z)$, as desired. The pole module of $[T(z)\ P(z)]$ has generalized "the poles of $P(z)$" for this situation. In the same way, from (5.2b), we see that the Ω-zero module of $T(z)$ has generalized "the zeros of $T(z)$," while the Ω-zero module of $[T(z)\ P(z)]$ has generalized "the zeros of $P(z)$." Note that, in the situation (4.4), $Z_\Omega(T(z)) = Z(T(z))$, and $Z_\Omega([T(z)\ P(z)]) = Z([T(z)\ P(z)])$. With the nature of Z_1 and P_1 established, (5.2c) shows that Z_Ω has a submodule Z_1, and a factor module P_1 containing those zeros of Z_Ω which are not zeros of Z_1. The explanation of (5.4) proceeds in a corresponding manner. Relative to (4.3), the Γ-zero module of $T(z)$ replaces "the zeros of $T(z)$," while the Γ-zero module of (5.3) replaces "the zeros of $M(z)$." The pole modules of $T(z)$ and of (5.3) replace "the poles of $T(z)$" and "the poles of $M(z)$," respectively. Once again, in the case (4.3), $Z_\Gamma(T(z)) = Z(T(z))$, and so forth.

Remark. In (5.2b) and (5.2c), it is apparent that none of the modules in the sequence will be extended of Ω-type if we assume that $T(z)$ is epic as a $k(z)$-linear map. This has already been discussed for $Z_\Omega(T(z))$ and Z_Ω. It follows for the right member in (5.2b) because $[T(z)\ P(z)]$ is onto when $T(z)$ is onto, and for the left member in (5.2b) and (5.2c) because Z_1 is a submodule in each case. Similar comments follow in (5.4b) and (5.4c) when $T(z)$ is monic as a $k(z)$-linear map. For these cases, Theorem 4 is for zeros a result corresponding to that obtained for fixed poles by Conte, Perdon, and Wyman [7]. The work in [7], however, required only the concepts of finitely generated, torsion poles and zeros. As we will see in §§ 7 and 8, the intuitively pleasing character of Theorem 4 is not carried over to the features of finite-dimensional zeros.

Proof of Theorem 4. We begin with the first part of the theorem and form a commutative diagram of natural inclusions, as in Fig. 5.1. Observe that column two has a cokernel which is Z_Ω, as in (4.6). Next consider the $k(z)$-linear map

$$[T(z)\ P(z)]: R(z) \oplus U(z) \to Y(z), \tag{5.5}$$

with action (5.1). The pole module of the map (5.5) is given by the isomorphic form (2.5) to be

$$P([T(z)\ P(z)]) = \frac{[T\,P](R[z] \oplus U[z])}{Y[z] \cap [T\,P](R[z] \oplus U[z])}, \tag{5.6}$$

which we recognize as the quotient module induced from row two of Fig. 5.1. Row one, of the same diagram, on the other hand, induces a quotient module

$$\frac{TR[z]}{Y[z] \cap TR[z]} = P(T(z)), \tag{5.7}$$

the pole module of $T(z)$. The diagram, moreover, induces a monic $k[z]$-linear map on $P(T(z))$ into $P([T(z)\ P(z)])$, with a cokernel that we have denoted by P_1. Return

$$\begin{tikzcd}
Y[z] \cap TR[z] \arrow[r] \arrow[d] & TR[z] \arrow[d] \\
Y[z] \cap \{PU[z] + TR[z]\} \arrow[r] & PU[z] + TR[z]
\end{tikzcd}$$

FIG. 5.1

now to the composite map (5.5), and form the Ω-zero module

$$Z_\Omega([T(z)\ \ P(z)]) = \frac{Y[z]}{Y[z] \cap [T\ P](R[z] \oplus U[z])}. \tag{5.8}$$

Next calculate the Ω-zero module of $T(z)$ in the manner

$$Z_\Omega(T(z)) = \frac{Y[z]}{Y[z] \cap TR[z]}. \tag{5.9}$$

By the inclusion $TR[z] \subset TR[z] + PU[z]$, there is an epic, $k[z]$-linear map on $Z_\Omega(T(z))$ onto $Z_\Omega([T(z)\ \ P(z)])$, with kernel isomorphic to

$$\frac{Y[z] \cap (TR[z] + PU[z])}{Y[z] \cap TR[z]}. \tag{5.10}$$

In Fig. 5.1, however, see that (5.10) is just the cokernel of column one, which we have denoted by Z_1. Equation (5.2c) then follows. Next we consider the second part of the theorem. A useful beginning point is the commutative diagram of Fig. 5.2, in which once again both the rows and the columns are natural inclusions. From the second row, we can induce $Z_\Gamma(T(z))$, while from the first row we obtain

$$Z_\Gamma\left(\begin{bmatrix} T(z) \\ M(z) \end{bmatrix}\right) \tag{5.11}$$

by the analogous process. The diagram of Fig. 5.2 then induces a monic, $k[z]$-linear map on the module (5.11) into $Z_\Gamma(T(z))$, with cokernel Z_2 as in (5.4b). The cokernel of column two is Z_Γ, by the definition (4.5). Because the cokernels of columns one and two, together with that of the induced monomorphism, fit into a short exact sequence, we have (5.4c) if P_2 is defined to be the cokernel of column one. This last cokernel can be related to certain pole modules. Recall definition (2.3), and form the pair of pole modules

$$P\left(\begin{bmatrix} T(z) \\ M(z) \end{bmatrix}\right) = \frac{R[z]}{R[z] \cap T^{-1}Y[z] \cap M^{-1}U[z]}, \tag{5.12}$$

$$P(T(z)) = \frac{R[z]}{R[z] \cap T^{-1}Y[z]}. \tag{5.13}$$

Clearly, $R[z] \cap T^{-1}Y[z] \cap M^{-1}U[z]$ is a submodule of $R[z] \cap T^{-1}Y[z]$, and so there exists an epic, $k[z]$-linear map from the module of (5.12) onto the module of (5.13). The kernel of this epimorphism is isomorphic as a $k[z]$-module to

$$\frac{R[z] \cap T^{-1}Y[z]}{R[z] \cap T^{-1}Y[z] \cap M^{-1}U[z]}, \tag{5.14}$$

which is P_2 in (5.4a).

$$\begin{tikzcd}
T^{-1}Y[z] \cap M^{-1}U[z] \cap R[z] \arrow[r] \arrow[d] & T^{-1}Y[z] \cap M^{-1}U[z] \arrow[d] \\
T^{-1}Y[z] \cap R[z] \arrow[r] & T^{-1}Y[z]
\end{tikzcd}$$

FIG. 5.2

Because the pole modules of (5.3) and of (5.5) are finitely generated and torsion, we have from the exactness of (5.2a) at P_1 and from the exactness of (5.4a) at P_2 that these modules have the same character. On the other hand, Z_1 and Z_2 may display behavior which is in part free or divisible, respectively. We conclude this section by giving an explicit description of these features.

Consider the module Z_1, as given in (5.10). Finitely generated, Z_1 has a torsion submodule. Suppose that $y(z)$ in $Y[z]$ represents a torsion element. Then there is a nonzero polynomial $p(z)$ in $k[z]$ such that $p(z)y(z)$ is in $TR[z]$, which means that $y(z)$ lies in $TR(z)$. The converse is also true, and so

$$Y[z]\cap(TR[z]+PU[z])\cap TR(z)=Y[z]\cap\{TR[z]+TR(z)\cap PU[z]\} \tag{5.15}$$

represents the torsion submodule Z_1' of Z_1. We can then set up a short exact sequence

$$0\to Z_1'\to Z_1\to\Omega_1\to 0, \tag{5.16}$$

in which Ω_1 may be taken as

$$\frac{Y[z]\cap(TR[z]+PU[z])}{Y[z]\cap(TR[z]+PU[z])\cap TR(z)}. \tag{5.17}$$

Now Ω_1 is torsion-free, because any representative which can be annihilated by a polynomial must already stand for the zero element. It then follows that Z_1 is isomorphic to a direct sum of Ω_1 and Z_1'. Next, we refer back to Fig. 5.2, where the cokernel of the induced monomorphism has been defined to be Z_2. Note that the image of the monomorphism is

$$\frac{T^{-1}Y[z]\cap M^{-1}U[z]+T^{-1}Y[z]\cap R[z]}{T^{-1}Y[z]\cap R[z]}, \tag{5.18}$$

so that we have the form

$$T^{-1}Y[z]/\{T^{-1}Y[z]\cap M^{-1}U[z]+T^{-1}Y[z]\cap R[z]\} \tag{5.19}$$

for Z_2. A torsion module, (5.19) has a divisible submodule given by

$$\Gamma_2=\ker T(z)/\{\ker T(z)\cap\{T^{-1}Y[z]\cap M^{-1}U[z]+T^{-1}Y[z]\cap R[z]\}\}. \tag{5.20}$$

If we establish a short exact sequence

$$0\to\Gamma_2\to Z_2\to Z_2'\to 0, \tag{5.21}$$

then Z_2' can be taken to be

$$T^{-1}Y[z]/\{\ker T(z)+T^{-1}Y[z]\cap M^{-1}U[z]+T^{-1}Y[z]\cap R[z]\}, \tag{5.22}$$

which is finitely generated. We summarize the discussion in the next theorem.

THEOREM 5. *Let Z_1 be the extended zero module of Ω-zeros of $T(z)$ which are not Ω-zeros of* (5.5), *and let Z_2 be the extended zero module of Γ-zeros of $T(z)$ which are not Γ-zeros of* (5.3). *Then there exist $k[z]$-modules Ω_1 and Z_1', Γ_2, and Z_2', such that*

$$Z_1\approx\Omega_1\oplus Z_1', \tag{5.23a}$$

$$Z_2\approx\Gamma_2\oplus Z_2', \tag{5.23b}$$

where Z_i', $i=1,2$, are finitely generated, torsion modules, Ω_1 is finitely generated and free, and Γ_2 is torsion divisible.

Proof. The details have been provided in the prelude to the theorem. Z_1' and Z_2' were discussed in (5.15) and (5.22); Ω_1 and Γ_2 are given by (5.17) and (5.20).

Remark. As remarked after the preceding theorem, Ω_1 or Γ_2 vanish if $T(z)$, as a $k(z)$-linear map, is epic or monic, respectively.

6. Essential solutions. We have seen in Theorem 3 that the modules Z_Γ and Z_Ω of matching zeros represent zero constraints which must hold for all solutions to the model matching equations. In particular, suppose that $T(z): R(z) \rightarrow Y(z)$ is a $k(z)$-linear map. When $P(z): U(z) \rightarrow Y(z)$ is a $k(z)$-linear map whose image contains that of $T(z)$, then Z_Ω is a factor module of the Ω-zero module of every $k(z)$-linear solution $M(z): R(z) \rightarrow U(z)$ to the equation $T(z) = P(z)M(z)$. Or, if we regard $M(z)$ to be given, with kernel included in that of $T(z)$, then Z_Γ must be a submodule of the Γ-zero module of every solution $P(z)$. The mechanism for the constraint is embodied in the $k[z]$-linear maps $\beta_\Omega(z)$ and $\beta_\Gamma(z)$ of (4.21). In this section, we examine initially the conditions under which the solution may have an extended zero module isomorphic to a matching zero module. This question is, of course, fundamental because the solution zero structure then achieves its limiting constraint. When $Z_\Omega(M(z)) \approx Z_\Omega$, we refer to $M(z)$ as an essential solution to the model matching equation. Likewise, when $Z_\Gamma(P(z) \approx Z_\Gamma$, we call $P(z)$ an essential solution. Necessary and sufficient conditions are given for the existence of essential solutions. A number of other types of related behavior occur; some of these are discussed in the next section. It should be noted here that the situation for essential solutions in regard to zeros differs concretely from the corresponding scenario for poles. It has been shown by Conte, Perdon, and Wyman [7] that essential solutions for poles always exist in the model matching problem. We shall see momentarily, however, that for zeros they need not exist.

Refer once again to Fig. 4.1, which induces the $k[z]$-linear map $\beta_\Omega(z): Z_\Omega(M(z)) \rightarrow Z_\Omega$. The kernel of this map is given by

$$\ker \beta_\Omega(z) = \{U[z] \cap P^{-1}(PU[z] \cap TR[z])\}/\{U[z] \cap MR[z]\} \tag{6.1a}$$

$$= \{U[z] \cap (MR[z] + \ker P(z))\}/\{U[z] \cap MR[z]\}. \tag{6.1b}$$

A solution $M(z)$ is essential, therefore, when

$$U[z] \cap (MR[z] + \ker P(z)) = U[z] \cap MR[z]. \tag{6.2}$$

On the other hand, from Fig. 4.2, we may determine that the image of $\beta_\Gamma(z): Z_\Gamma \rightarrow Z_\Gamma(P(z))$ is

$$\operatorname{im} \beta_\Gamma(z) = \{M(T^{-1}Y[z]) + P^{-1}Y[z] \cap U[z]\}/\{P^{-1}Y[z] \cap U[z]\}, \tag{6.3a}$$

so that the cokernel is given by isomorphism as

$$\operatorname{coker} \beta_\Gamma(z) \approx P^{-1}Y[z]/\{M(T^{-1}Y[z]) + P^{-1}Y[z] \cap U[z]\}. \tag{6.3b}$$

In this context, then, a solution $P(z)$ is essential when

$$P^{-1}Y[z] = M(T^{-1}Y[z]) + P^{-1}Y[z] \cap U[z]. \tag{6.4}$$

With these preliminaries, we are ready to give the basic result on equalities (6.2) and (6.4).

THEOREM 6. *Let $T(z): R(z) \rightarrow Y(z)$ be a $k(z)$-linear map. If $P(z): U(z) \rightarrow Y(z)$ is a $k(z)$-linear map whose image contains that of $T(z)$, then there exists a $k(z)$-linear map $M(z): R(z) \rightarrow U(z)$ which satisfies the equation $T(z) = P(z)M(z)$ and which has an Ω-zero module*

$$Z_\Omega(M(z)) \approx Z_\Omega \tag{6.5a}$$

if and only if

$$\operatorname{rank} P(z) - \operatorname{rank} T(z) \geqq \dim U - \dim R. \tag{6.5b}$$

If $M(z):R(z)\to U(z)$ *is a* $k(z)$*-linear map whose kernel is contained in that of* $T(z)$*, then there exists a* $k(z)$*-linear map* $P(z):U(z)\to Y(z)$ *which satisfies the equation* $T(z)=P(z)M(z)$ *and which has a* Γ*-zero module*

(6.6a) $$Z_\Gamma(P(z))\approx Z_\Gamma$$

if and only if

(6.6b) $$\operatorname{rank} M(z)-\operatorname{rank} T(z)\geqq \dim U-\dim Y.$$

Proof. For the first part of the theorem, we refer to condition (6.2). If this condition is true, it is necessary that

(6.7) $$U[z]\cap MR[z]\supset U[z]\cap \ker P(z).$$

But the only elements of $MR[z]$ which can possibly be in $\ker P(z)$ are those arising from $\ker T(z)$. Accordingly, (6.7) holds when and only when

(6.8) $$U[z]\cap M(\ker T(z)\cap R[z])\supset U[z]\cap \ker P(z).$$

When considered as a free module, the right member of (6.8) satisfies

(6.9) $$\operatorname{rank}\{U[z]\cap \ker P(z)\}=\dim U-\operatorname{rank} P(z),$$

while the left member depends upon the constraint

(6.10) $$\operatorname{rank}\{\ker T(z)\cap R[z]\}=\dim R-\operatorname{rank} T(z).$$

Together, the preceding three equations imply that (6.5b) must be satisfied. Suppose next that condition (6.5b) is satisfied. We will demonstrate the existence of an $M(z)$ such that (6.2) holds. Observe that $\ker T(z)$ and $\ker P(z)$ are divisible modules, so that

(6.11) $$R(z)=\tilde{R}(z)\oplus \ker T(z),\qquad U(z)=\tilde{U}(z)\oplus \ker P(z),$$

for suitable $k[z]$-linear isomorphisms

(6.12) $$\tilde{R}(z)\approx R(z)/\ker T(z),\qquad \tilde{U}(z)\approx U(z)/\ker P(z).$$

Because $M(\ker T(z))\subset \ker P(z)$, each $M(z)$ satisfying the equation $T(z)=P(z)M(z)$ induces a unique, $k(z)$-linear monomorphism $\bar{M}(z):R(z)/\ker T(z)\to U(z)/\ker P(z)$. The fact that $\bar{M}(z)$ is unique can also be seen as a consequence of the feature that the map induced by $P(z)$ on $U(z)/\ker P(z)$ is monic. If we suppress explicit use of the isomorphisms (6.12), we can think of $\bar{M}(z)$ as a map on $\tilde{R}(z)$ into $\tilde{U}(z)$. Next, we define the action of $M(z)$ on $\ker T(z)$. Let $\hat{M}(z):\ker T(z)\cap R[z]\to \ker P(z)\cap U[z]$ be any $k[z]$-linear epimorphism. $\hat{M}(z)$ induces an epic, $k(z)$-linear map on $\ker T(z)$ onto $\ker P(z)$; and we employ the same notation for both. Together, $\bar{M}(z)$ and $\hat{M}(z)$ can be used to define a map

(6.13) $$\hat{M}(z)\oplus \bar{M}(z):R(z)\to U(z)$$

with the understandings (6.11). For (6.13), we have

$$(\hat{M}(z)\oplus \bar{M}(z))(\ker T(z)\cap R[z]\oplus \tilde{R}(z)\cap R[z])$$

(6.14a) $$=\hat{M}(\ker T(z)\cap R[z])\oplus \bar{M}(\tilde{R}(z)\cap R[z])$$

(6.14b) $$=\ker P(z)\cap U[z]\oplus \bar{M}(\tilde{R}(z)\cap R[z]).$$

Thus, we have

$$U[z]\cap (MR[z]+\ker P(z))$$

(6.14c) $$=U[z]\cap\{(\ker P(z)\cap U[z]+\ker P(z))\oplus \bar{M}(\tilde{R}(z)\cap R[z])\}$$

(6.14d) $$=\ker P(z)\cap U[z]\oplus U[z]\cap \bar{M}(\tilde{R}(z)\cap R[z])$$

(6.14e) $$=U[z]\cap MR[z],$$

as desired. Note that, for these steps to be valid, the formation of (6.11) and (6.12) must satisfy

(6.14f) $$R[z]=\tilde{R}(z)\cap R[z]\oplus\ker T(z)\cap R[z],$$

(6.14g) $$U[z]=\tilde{U}(z)\cap U[z]\oplus\ker P(z)\cap U[z].$$

This is always possible. For the second part of the theorem, we make use of the condition expressed by (6.4). Because im $M(z)$ and im $T(z)$ are divisible modules, we can write

(6.15) $$U(z)=\tilde{U}(z)\oplus\operatorname{im} M(z), \qquad Y(z)=\tilde{Y}(z)\oplus\operatorname{im} T(z),$$

for suitable, $k[z]$-linear, isomorphisms

(6.16a) $$\tilde{U}(z)\approx\operatorname{coker} M(z), \qquad \tilde{Y}(z)\approx\operatorname{coker} T(z),$$

satisfying the constraints

(6.16b) $$U[z]=\tilde{U}(z)\cap U[z]\oplus\operatorname{im} M(z)\cap U[z],$$

(6.16c) $$Y[z]=\tilde{Y}(z)\cap Y[z]\oplus\operatorname{im} T(z)\cap Y[z].$$

Restricted to im $M(z)$, $P(z)$ gives an epic, $k(z)$-linear map $\hat{P}(z)$ onto im $T(z)$. Moreover, the action of $\hat{P}(z)$ remains the same for any solution $P(z)$ of the equation $T(z)=P(z)M(z)$. The design freedom for $P(z)$ lies, therefore, in its action on the cokernel of $M(z)$, represented by $\tilde{U}(z)$. Observe that ker $T(z)$ is a divisible submodule of $T^{-1}Y[z]$. Accordingly,

(6.17a) $$T^{-1}Y[z]=\ker T(z)\oplus\hat{R}(z),$$

where $\hat{R}(z)$ satisfies

(6.17b) $$\hat{R}(z)\approx T^{-1}Y[z]/\ker T(z),$$

as a $k[z]$-module. Though $\hat{R}(z)$ is finitely generated, ker $T(z)$ is not; and so the only term in the right member of (6.4) which is not finitely generated is $M(\ker T(z))$. We have, then, the preliminary necessity of

(6.18) $$M(\ker T(z))\supset\ker P(z),$$

which implies that the $k[z]$-linear map $\bar{P}(z)$: coker $M(z)\to$ coker $T(z)$, induced by $P(z)$, is a monomorphism. But this means that

(6.19) $$\dim(\operatorname{coker} T(z))\geqq\dim(\operatorname{coker} M(z)),$$

from which we have the condition

(6.20) $$\dim Y-\operatorname{rank} T(z)\geqq\dim U-\operatorname{rank} M(z),$$

which gives (6.6b). Under (6.6b), we can construct an essential solution. Let $\bar{P}(z)$ be any $k(z)$-linear monomorphism on $\tilde{U}(z)$ into $\tilde{Y}(z)$ with the property that

(6.21) $$\bar{P}^{-1}(\tilde{Y}(z)\cap Y[z])\subset\tilde{U}(z)\cap U[z].$$

Together, $\hat{P}(z)$ and $\bar{P}(z)$ give the map

(6.22) $$\hat{P}(z)\oplus\bar{P}(z): U(z)\to Y(z),$$

for which

$$P^{-1}Y[z] = P^{-1}\{\tilde{Y}(z)\cap Y[z]\oplus \text{im } T(z)\cap Y[z]\} \tag{6.23a}$$

$$= \bar{P}^{-1}(\tilde{Y}(z)\cap Y[z])\oplus \hat{P}^{-1}(\text{im } T(z)\cap Y[z]) \tag{6.23b}$$

$$\subset P^{-1}Y[z]\cap U[z]+\text{im } M(z)\cap P^{-1}Y[z] \tag{6.23c}$$

$$= P^{-1}Y[z]\cap U[z]+M(T^{-1}Y[z]), \tag{6.23d}$$

as required.

Discussion of Theorem 6. The conditions of the theorem, of course, are not always satisfied. This means that essential solutions for model matching problems need not always exist with respect to zeros. As explained in the prologue to this section, such a situation differs from that in the case of poles. We might ask if, when attention is fixed upon finitely generated, torsion zeros, a result more like that for poles could be obtained. We will see in the next section that the answer to this question must be given as a negative. When $P(z)$ is given, the construction of the theorem has to do with designing $\hat{M}(z)$ in such a way that

$$Z_\Omega(\hat{M}(z)) = 0. \tag{6.24a}$$

In like fashion, when $M(z)$ is given, the goal is a design of $\bar{P}(z)$ so that

$$Z_\Gamma(\bar{P}(z)) = 0. \tag{6.24b}$$

In fact, for $M(z)$ of the form (6.13), we have

$$\ker \beta_\Omega(z) \approx Z_\Omega(\hat{M}(z)), \tag{6.25a}$$

while for $P(z)$ of the form (6.22) we find

$$\text{coker } \beta_\Gamma(z) \approx Z_\Gamma(\bar{P}(z)). \tag{6.25b}$$

For instance, (6.25a) can be seen from a construction

$$\{U[z]\cap(MR[z]+\ker P(z))\}/\{U[z]\cap MR[z]\}$$

$$= \{U[z]\cap(MR[z]+\ker P(z))+U[z]\cap MR[z]\}/\{U[z]\cap MR[z]\} \tag{6.26a}$$

$$= \{U[z]\cap(\hat{M}(\ker T(z)\cap R[z])+\ker P(z))+U[z]\cap MR[z]\}$$

$$/\{\text{U}[z]\cap MR[z]\} \tag{6.26b}$$

$$= \{U[z]\cap \ker P(z)+U[z]\cap MR[z]\}/\{U[z]\cap MR[z]\} \tag{6.26c}$$

$$\approx \{U[z]\cap \ker P(z)\}/\{U[z]\cap \ker P(z)\cap \hat{M}(\ker T(z)\cap R[z])\}. \tag{6.26d}$$

More generally, whenever $M(z)$ is a solution to the equation $T(z) = P(z)M(z)$, whether or not it takes the form (6.13), we have that $Z_\Omega(M(z)|\ker T(z))$ is a submodule of $Z_\Omega(M(z))$. In the same way, whenever $P(z)$ is a solution and $\bar{P}(z)$ is its induced map on coker $M(z)$, then $Z_\Gamma(\bar{P}(z))$ is a factor module of $Z_\Gamma(P(z))$, whether or not $P(z)$ takes the form (6.22). These facts may be deduced from Figs. 6.1 and 6.2, following. In the first, Fig. 6.1, both rows and columns are natural inclusions. In the second, Fig. 6.2, row one is an inclusion, while the columns are natural projections; row two is a monomorphism of $k[z]$-modules.

$$\begin{tikzcd}
U[z]\cap MR[z]\cap \ker P(z) \arrow[r] \arrow[d] & U[z]\cap \ker P(z) \arrow[d] \\
U[z]\cap MR[z] \arrow[r] & U[z]
\end{tikzcd}$$

FIG. 6.1

$$\begin{tikzcd}
P^{-1}Y[z]\cap U[z] \arrow[r] \arrow[d] & P^{-1}Y[z] \arrow[d] \\
\frac{P^{-1}Y[z]\cap U[z]}{M(T^{-1}Y[z])\cap U[z]} \arrow[r] & \frac{P^{-1}Y[z]}{M(T^{-1}Y[z])}
\end{tikzcd}$$

FIG. 6.2

Remark. In case ker $T(z)$ is equal to zero, the rank of $T(z)$ must equal the dimension of R. Thus (6.5b) leads to $P(z)$ having zero kernel as well. If coker $T(z)$ equals zero, then (6.6b) gives that $M(z)$ must have zero cokernel as well. Note that in these cases the solutions, when they exist, are unique. Moreover, the unique solution $M(z)$ in (6.5a) has no Γ-zeros; and the unique solution $P(z)$ in (6.6a) has no Ω-zeros. In fact, much more is true. See the remarks after Theorem 7, where it is shown in an alternative context that the vanishing of ker $P(z)$ or coker $M(z)$ is always sufficient to satisfy (6.5b) or (6.6b), respectively. This is true whether or not we take special cases of $T(z)$.

The existence of solutions to the model matching equation $T(z)=P(z)M(z)$ is controlled by the conditions im $T(z)\subset$ im $P(z)$ and ker $M(z)\subset$ ker $T(z)$, respectively. In practice, the marginal case of these conditions is of great interest.

COROLLARY 1. *Under the condition* im $T(z)=$ im $P(z)$, *there exists an essential solution $M(z)$ if and only if*

$$\dim R \geqq \dim U. \tag{6.27a}$$

Under the condition ker $M(z)=$ ker $T(z)$, *there exists an essential solution $P(z)$ if and only if*

$$\dim Y \geqq \dim U. \tag{6.27b}$$

Another case of special interest occurs when the domains of $T(z)$ and $P(z)$, or the codomains of $T(z)$ and $M(z)$, have equal dimensions. In feedback systems, for instance, this situation has strong physical meaning.

COROLLARY 2. *Let the dimensions of R and U be equal. Then, whenever a solution $M(z)$ exists, there exists an essential solution. Alternatively, let the dimensions of Y and U be equal. Then, whenever a solution $P(z)$ exists, there exists an essential solution.*

In the case of feedback control, $M(z)$ stands for an open loop pre-compensator which is equivalent at specified operating conditions to a given closed-loop strategy. The concept of an essential solution carries a pleasing connotation in this case. For a solution $M(z)$ which is not essential presents a certain deficiency in its image; and this in turn points out an inadequacy in manipulating the control inputs to the plant $P(z)$. One way to address this difficulty is to increase the dimension of R, which corresponds to adding additional reference inputs; however, this method is subject to a suitable re-interpretation of $T(z)$. Another way, which is more traditional, is to reduce the dimension of U, by deleting dependent columns of $P(z)$, which corresponds to using fewer controls. Before the concept of extended zeros, the effects of plant input selection have been seen only in terms of their influence upon finitely generated, torsion zeros. In view of the preceding results on matching modules of extended zeros, however, this traditional approach may need to be reconsidered.

The matching zero modules, and the extended zero modules of solutions to model matching equations, treat finitely generated, torsion zeros together with divisible or free zeros, as the case may be. It is sometimes desirable to have in hand an idea of what is happening in regard to these individual types of zeros. Not surprisingly, it turns out that these behaviors are interrelated, by a snake mapping; and this is the subject of the next section.

7. The fundamental diagrams. Sections 3-6 have placed a focus upon the extended zero modules of Γ-type and of Ω-type and their role in model matching problems. In this section, our goal is to relate these results to solution zeros of finitely generated, torsion type, as described in § 2, and to divisible or free zeros, as explained in § 3. The main ideas center upon a pair of commutative diagrams.

THEOREM 7. *Suppose that $T(z): R(z) \to Y(z)$ is a $k(z)$-linear map. If $P(z): U(z) \to Y(z)$ is a $k(z)$-linear map whose image contains that of $T(z)$, and if $M(z): R(z) \to U(z)$ is a $k(z)$-linear map satisfying $T(z) = P(z)M(z)$, then there exist $k[z]$-linear maps $\hat{\beta}_\Omega(z): Z(M(z)) \to Z'_\Omega$ and $\bar{\beta}_\Omega(z): \Omega(M(z)) \to \Omega$, the latter an epimorphism, such that the diagram Fig.* 7.1 *commutes and has rows which are short exact sequences. If $M(z): R(z) \to U(z)$ is a $k(z)$-linear map whose kernel is included in that of $T(z)$, and if $P(z): U(z) \to Y(z)$ is a $k(z)$-linear map satisfying $T(z) = P(z)M(z)$, then there exist $k[z]$-linear maps $\hat{\beta}_\Gamma(z): \Gamma \to \Gamma(P(z))$ and $\bar{\beta}_\Gamma(z): Z'_\Gamma \to Z(P(z))$, the former a monomorphism, such that the diagram Fig.* 7.2 *commutes and has rows which are short exact sequences.*

Proof. Consider Fig. 7.1, and note that column two is the map (4.21a). Row one is (3.9), constructed as in § 3.2; and row two is just (4.17). Because $\beta_\Omega Z(M(z)) \subset Z'_\Omega$, the map $\hat{\beta}_\Omega(z)$ exists uniquely; and, consequently, there is a unique $\bar{\beta}_\Omega(z)$ which completes the diagram. A construction for Fig. 7.2 can be accomplished in like manner, with the aid of (4.21b), (3.4), and (4.19).

Theorem 7 leads to a number of quite detailed consequences. The first of these is a pair of technical corollaries.

COROLLARY 3. *Under the assumptions of Theorem* 7, *there exist $k[z]$-linear maps such that the following pair of sequences is exact:*

(7.1) $$0 \to \ker \hat{\beta}_\Omega(z) \to \ker \beta_\Omega(z) \to \ker \bar{\beta}_\Omega(z) \to \operatorname{coker} \hat{\beta}_\Omega(z) \to 0,$$

(7.2) $$0 \to \ker \bar{\beta}_\Gamma(z) \to \operatorname{coker} \hat{\beta}_\Gamma(z) \to \operatorname{coker} \beta_\Gamma(z) \to \operatorname{coker} \bar{\beta}_\Gamma(z) \to 0.$$

$$\begin{tikzcd}
0 \arrow[r] & Z(M(z)) \arrow[r] \arrow[d, "\hat{\beta}_\Omega(z)"'] & Z_\Omega(M(z)) \arrow[r] \arrow[d, "\beta_\Omega(z)"'] & \Omega(M(z)) \arrow[r] \arrow[d, "\bar{\beta}_\Omega(z)"'] & 0 \\
0 \arrow[r] & Z'_\Omega \arrow[r] & Z_\Omega \arrow[r] \arrow[d] & \Omega \arrow[r] \arrow[d] & 0 \\
 & & 0 & 0 &
\end{tikzcd}$$

FIG. 7.1

$$\begin{tikzcd}
 & 0 \arrow[d] & 0 \arrow[d] & & \\
0 \arrow[r] & \Gamma \arrow[r] \arrow[d, "\hat{\beta}_\Gamma(z)"'] & Z_\Gamma \arrow[r] \arrow[d, "\beta_\Gamma(z)"'] & Z'_\Gamma \arrow[r] \arrow[d, "\bar{\beta}_\Gamma(z)"'] & 0 \\
0 \arrow[r] & \Gamma(P(z)) \arrow[r] & Z_\Gamma(P(z)) \arrow[r] & Z(P(z)) \arrow[r] & 0
\end{tikzcd}$$

FIG. 7.2

Proof. Sequences (7.1) and (7.2) are consequences of the Snake lemma, applied to the pair of diagrams, Figs. 7.1 and 7.2.

COROLLARY 4. *Under the assumptions of Theorem* 7, *the modules in sequences* (7.1) *and* (7.2) *are given, up to* $k[z]$*-linear isomorphism, by*

$$\ker \hat{\beta}_\Omega(z) = \{U[z] \cap (MR[z] + \ker P(z) \cap MR(z))\}/\{U[z] \cap MR[z]\}, \tag{7.3a}$$

$$\ker \beta_\Omega(z) = \{U[z] \cap (MR[z] + \ker P(z))\}/\{U[z] \cap MR[z]\}, \tag{7.3b}$$

$$\ker \bar{\beta}_\Omega(z) = \{U[z] \cap (MR(z) + \ker P(z))\}/\{U[z] \cap MR(z)\}, \tag{7.3c}$$

$$\operatorname{coker} \hat{\beta}_\Omega(z) = \{PU[z] \cap TR(z)\}/\{P[U[z] \cap MR(z)] + PU[z] \cap TR[z]\}, \tag{7.3d}$$

$$\begin{aligned}\ker \bar{\beta}_\Gamma(z) = M^{-1}\{&\ker P(z) + P^{-1}Y[z] \cap U[z]\}\\ &/\{\ker T(z) + T^{-1}Y[z] \cap M^{-1}U[z]\},\end{aligned} \tag{7.4a}$$

$$\operatorname{coker} \hat{\beta}_\Gamma(z) = \ker P(z)/\{M(\ker T(z)) + \ker P(z) \cap U[z]\}, \tag{7.4b}$$

$$\operatorname{coker} \beta_\Gamma(z) = P^{-1}Y[z]/\{M(T^{-1}Y[z]) + P^{-1}Y[z] \cap U[z]\}, \tag{7.4c}$$

$$\operatorname{coker} \bar{\beta}_\Gamma(z) = P^{-1}Y[z]/\{M(T^{-1}Y[z]) + \ker P(z) + P^{-1}Y[z] \cap U[z]\}. \tag{7.4d}$$

Proof. We have already discussed (7.3b) and (7.4c) in § 6. The remaining forms follow from standard diagram chases applied to (4.21) and the row maps in (3.4), (3.9), (4.17), and (4.19). For brevity, we omit the details.

Remark. Observe that, when $\ker P(z)$ is zero, (7.3a), (7.3b), and (7.3c) vanish. From Fig. 7.1, we then have that (7.3d) vanishes. In this case, $Z_\Omega(M(z))$ is isomorphic as a $k[z]$-module to Z_Ω. If a solution $M(z)$ exists, therefore, $Z_\Omega(M(z))$ can fail to achieve its bound only if there is the possibility of more than one solution. Similar statements can be made for $\operatorname{coker} M(z)$, in reference to (7.4a), (7.4b), (7.4c), and (7.4d), relative to Fig. 7.2.

THEOREM 8. *Suppose that* $T(z) = P(z)M(z)$ *is an equation of* $k(z)$*-linear maps. Then each of the following three statements implies the others*:

$$\Omega(M(z)) \approx \Omega, \tag{7.5a}$$

$$\Gamma(P(z)) \approx \Gamma, \tag{7.5b}$$

$$M(\ker T(z)) = \ker P(z). \tag{7.5c}$$

In the case where (7.5) *holds, then* Z'_Ω *is a factor module of* $Z(M(z))$ *and* Z'_Γ *is a submodule of* $Z(P(z))$.

Proof. Condition (7.5a) makes $\ker \bar{\beta}_\Omega(z)$ vanish, which by (7.1) makes $\operatorname{coker} \hat{\beta}_\Omega(z)$ vanish, which means that Z'_Ω is a factor module of $Z(M(z))$. A like argument establishes that Z'_Γ is a submodule of $Z(P(z))$. From (7.5c), we find that (7.4b) is zero, which implies (7.5b); again, (7.5c) gives (7.3c) equal to zero, which leads to (7.5a). Now consider (7.5b), which implies that (7.4b) must vanish. If (7.5c) does not hold, then (7.4b) cannot vanish because $\ker P(z) \cap U[z]$ is finitely generated, while $\ker P(z)$ is not. Thus (7.4b) equal to zero must give (7.5c). Finally, we look at (7.5a), for which (7.3c) must vanish. A necessary condition for (7.3c) equal to zero is that

$$U[z] \cap MR(z) \supset U[z] \cap \ker P(z), \tag{7.6a}$$

which holds only if

$$U[z] \cap M(\ker T(z)) \supset U[z] \cap \ker P(z), \tag{7.6b}$$

which requires

$$\dim M(\ker T(z)) \geqq \dim \ker P(z); \tag{7.6c}$$

and (7.5c) follows.

Discussion of Theorem 8. The coincidence of the three statements (7.5) suggests the possibility that a corresponding observation may relate (6.5a) to (6.6a) in Theorem 6. However, such is not the case. For a given $P(z)$, when (6.5b) is satisfied, we may construct an $M(z)$ that fulfills (6.5a). Now, for this $M(z)$, it is quite possible that the original $P(z)$ fails to satisfy (6.6a). To demonstrate this behavior, we present an example.

Example 1.

(7.7)
$$T(z)=\begin{bmatrix}1&0\\0&0\\0&0\end{bmatrix},\quad P(z)=\begin{bmatrix}1&0&0\\0&0&0\\0&z&0\end{bmatrix},\quad M(z)=\begin{bmatrix}1&0\\0&0\\0&1\end{bmatrix}.$$

In this example, $M(z)$ is an essential solution; but $P(z)$ is not. On the other hand, conditions (7.5) hold.

When conditions (7.5) are satisfied, we have that both (6.5b) and (6.6b) hold simultaneously. If $P(z)$ is given, with (6.5b) true, then we can design an $M(z)$ so that (7.5) occurs. One way to carry out such a construction is to proceed according to the discussion following (6.11) and (6.12); for this situation, however, $\hat{M}(z)$ can be any epic, $k(z)$-linear map from ker $T(z)$ onto ker $P(z)$. Again, if $M(z)$ is given, with (6.6b) true, we can design a $P(z)$ so that (7.5) takes place. The design may be executed along the lines established in the proof of Theorem 6, except that we do not need the condition (6.21). In a manner similar to that of (6.24), the basic constructive conditions for these solutions are

(7.8a)
$$\Omega(\hat{M}(z))=0,$$

(7.8b)
$$\Gamma(\bar{P}(z))=0.$$

These follow from the $k[z]$-linear isomorphisms

(7.8c)
$$\ker\bar{\beta}_{\Omega}(z)\approx\Omega(\hat{M}(z)),$$

(7.8d)
$$\operatorname{coker}\hat{\beta}_{\Gamma}(z)\approx\Gamma(\bar{P}(z)),$$

for an $M(z)$ of form (6.13) or a $P(z)$ of form (6.22). In fact, for more general types of solutions $M(z)$ or $P(z)$, and with the aid of diagrams analogous to Figs. 6.1 and 6.2, we can establish that $\Omega(M(z)|\ker T(z))$ is a submodule of $\Omega(M(z))$, while $\Gamma(\bar{P}(z))$ is a factor module of $\Gamma(P(z))$. Here we denote by $\bar{P}(z)$ the induced map on coker $M(z)$.

Next we turn to a study of the finitely generated, torsion zeros in solutions to the model matching equation. In general, these solutions have zeros arising from the finitely generated, torsion parts of Z_{Γ} or Z_{Ω}. They may also have zeros which occur through the design of the induced action of $P(z)$ on coker $M(z)$ or of the restricted action of $M(z)$ on ker $T(z)$. Additional effects can also occur.

$$\begin{tikzcd}
U[z]\cap M(\ker T(z)\cap R[z]) \arrow[r] \arrow[d] & U[z]\cap M(\ker T(z)) \arrow[d] \\
U[z]\cap MR[z] \arrow[r] & U[z]\cap(MR[z]+M(\ker T(z)))
\end{tikzcd}$$

FIG. 7.3

We begin by directing our attention to the commutative diagram of Fig. 7.3, wherein the rows and columns are natural inclusions. This diagram induces a $k[z]$-linear map on $Z(M(z)|\ker T(z))$ into $\ker\hat{\beta}_{\Omega}(z)$. The kernel of this map is given by

(7.9)
$$\{U[z]\cap MR[z]\cap M(\ker T(z))\}/\{U[z]\cap M(\ker T(z)\cap R[z])\}.$$

But this will vanish if

$$M(\ker T(z) \cap R[z]) = M \ker T(z) \cap MR[z], \tag{7.10a}$$

which occurs when

$$(\ker T(z) + R[z]) \cap \ker M(z) = \ker T(z) \cap \ker M(z) + R[z] \cap \ker M(z). \tag{7.10b}$$

Consider an element in the left member of (7.10b); and represent it by

$$r_t(z) + r(z) = r_m(z). \tag{7.10c}$$

Applying $T(z)$ to (7.10c) shows that $r(z) \in \ker T(z) \cap R[z]$; and so both members of (7.10b) are equal to $\ker M(z)$. The induced map is therefore monic; and $Z(M(z)|\ker T(z))$ is a submodule of $\ker \hat{\beta}_\Omega(z)$, which is itself a submodule of $Z(M(z))$. In this way, we can use $M(z)|\ker T(z)$ to design specified zero submodules for solutions $M(z)$. The cokernel of the induced map is

$$\{U[z] \cap (MR[z] + M(\ker T(z)))\}/\{U[z] \cap M(\ker T(z)) + U[z] \cap MR[z]\}. \tag{7.11}$$

If $M(z)$ may be regarded as a direct sum map on $\ker T(z) \oplus \tilde{R}(z)$ into $\ker P(z) \oplus \tilde{U}(z)$, for $\tilde{R}(z)$ and $\tilde{U}(z)$ defined as in (6.11) and (6.12), and satisfying the conditions (6.14), then

$$MR[z] + M(\ker T(z)) = M[\tilde{R}(z) \cap R[z]] + M(\ker T(z)), \tag{7.12}$$

and (7.11) is zero, with $\ker \hat{\beta}_\Omega(z) \approx Z(\hat{M}(z))$. However, if $M(z)$ is otherwise, (7.11) may not disappear; and the solution may display additional zeros. To illustrate, we give an example.

Example 2.

$$T(z) = [1 \;\; 0], \quad P(z) = [1 \;\; 0], \quad M(z) = \begin{bmatrix} 1 & 0 \\ 1/(z+1) & 1 \end{bmatrix}. \tag{7.13}$$

Here, we have $Z'_\Omega = 0$, $Z(M(z)|\ker T(z)) = 0$, and $Z(M(z)) \approx k[z]/(z+1)k[z]$. The solution zero arises entirely from (7.11).

Another key observation can be made. If im $M(z)$ includes $\ker P(z)$, then from Theorem 8 we know that

$$Z(M(z))/\ker \hat{\beta}_\Omega(z) \approx Z'_\Omega, \tag{7.14}$$

which means that the torsion part of Z_Ω is necessarily present in $Z(M(z))$ as a factor module.

Turning, then, to the possibility of removing some part of Z'_Ω from our solution, we see that decreasing the dimension of $M(\ker T(z))$ is to our advantage. The best we can achieve in this regard is to choose $M(z)|\ker T(z)$ equal to zero. In this case, $\ker \hat{\beta}_\Omega(z)$ vanishes, and $Z(M(z))$ is a submodule of Z'_Ω. If the number of nonunit invariant factors of Z'_Ω is no greater than the dimension of $\ker P(z)$, then a solution $M(z)$ with $Z(M(z)) = 0$ is possible. For instance, if the zeros of Z'_Ω are all distinct, then $Z(M(z)) = 0$ is possible whenever $M(z)$ is not unique. Thus there is a tradeoff between inserting into the solution zeros which are distinct from those in Z'_Ω and removing from the solution zeros which are part of Z'_Ω. We summarize in the next theorem.

THEOREM 9. *Suppose that $T(z): R(z) \to Y(z)$ is a $k(z)$-linear map. If $P(z): U(z) \to Y(z)$ is a $k(z)$-linear map whose image contains that of $T(z)$, then $Z(M(z)|\ker T(z))$ is a submodule of $Z(M(z))$ whenever a $k(z)$-linear map $M(z): R(z) \to U(z)$ satisfies the equation $T(z) = P(z)M(z)$. A maximum of*

$$\min(\dim \ker P(z), \dim \ker T(z)) \tag{7.15}$$

invariant factors of $Z(M(z))$ can be specified in this way. Alternatively, up to

$$\dim \ker P(z) - \operatorname{rank} M(z)|\ker T(z) \tag{7.16}$$

nonunit invariant factors of Z'_Ω can be made into units in $Z(M(z))$ by design of $M(z)$ off the kernel of $T(z)$. If $M(z): R(z) \to U(z)$ is a $k(z)$-linear map whose kernel is included in that of $T(z)$, and if $P(z)$ is a $k(z)$-linear solution to the equation $T(z) = P(z)M(z)$, then $Z(\bar{P}(z))$ is a factor module of $Z(P(z))$, where $\bar{P}(z)$ is the map induced on coker $M(z)$. *A maximum of*

$$\min(\dim \operatorname{coker} T(z), \dim \operatorname{coker} M(z)) \tag{7.17}$$

invariant factors of $Z(P(z))$ can be specified in this way. Alternatively, up to

$$\dim \operatorname{coker} M(z) - \operatorname{rank} \bar{P}(z) \tag{7.18}$$

nonunit invariant factors of Z'_Γ can be made into units in $Z(P(z))$ by design of $P(z)$ off the cokernel of $M(z)$.

Proof. The argument for the first part of the theorem has been presented in the prologue. In the interest of space, we omit the second half.

Discussion of Theorem 9. It should be noted that the statements in this result have a number of interesting modifications. For example, with reference to (7.16), we do not have to make the invariant factor of Z'_Ω into a unit; instead, we could make a more general adjustment to it. Again, in regard to (7.18), adjustment of invariant factors could replace their reduction to units.

From Theorem 9, we see that Z'_Ω and Z'_Γ play an important role in the character of $Z(M(z))$ and $Z(P(z))$, respectively. The next section inquires further into the nature of these modules.

8. Description of Z'_Ω and Z'_Γ. In § 4, we have shown that the matching zero module Z_Ω, defined in (4.6), appears as a factor module in the zero module $Z(M(z))$ of every solution $M(z)$ to the model matching equation. Moreover, it was shown that Z_Ω has a torsion submodule Z'_Ω as given in (4.9). From these two results, it is natural to inquire about the nature of Z'_Ω.

We begin with the commutative diagram of Fig. 8.1. In this diagram, both rows and columns are natural inclusions. Notice, in the figure, that the second column, when extended to a short exact sequence, has its factor module isomorphic to Z'_Ω. Observe also that the first row extends into a short exact sequence with factor module $P(T(z))$. From Fig. 8.1, we find a monic, $k[z]$-linear map from $P(T(z))$ into the module

$$_T X_P = \frac{PU[z] \cap TR(z) + TR[z]}{Y[z] \cap \{PU[z] \cap TR(z) + TR[z]\}}. \tag{8.1}$$

The cokernel of this map is denoted by X'_z. It is possible to relate the module (8.1) to the pole module of the composite map $[T(z) \ P(z)]: R(z) \oplus U(z) \to Y(z)$. The basic idea is shown in the commutative diagram of Fig. 8.2, where rows and columns are

$$\begin{tikzcd}
Y[z] \cap TR[z] \arrow[r] \arrow[d] & TR[z] \arrow[d] \\
Y[z] \cap \{P\dot{U}[z] \cap TR(z) + TR[z]\} \arrow[r] & PU[z] \cap TR(z) + TR[z]
\end{tikzcd}$$

FIG. 8.1

$$\begin{tikzcd}
Y[z] \cap \{PU[z] \cap TR(z) + TR[z]\} \arrow[r] \arrow[d] & PU[z] \cap TR(z) + TR[z] \arrow[d] \\
Y[z] \cap \{PU[z] + TR[z]\} \arrow[r] & PU[z] + TR[z]
\end{tikzcd}$$

FIG. 8.2

again natural inclusions. From this diagram, we induce a monic, $k[z]$-linear map on ${}_TX_P$ into $P([T(z)\ \ P(z)])$, with cokernel isomorphic to

$$X_k = \frac{PU[z] + TR[z]}{PU[z] \cap TR(z) + TR[z] + Y[z] \cap \{PU[z] + TR[z]\}}. \tag{8.2}$$

Returning now to Fig. 8.1, we define the factor module induced by column one to be Z'_z, and point out that it is a submodule of $Z(T(z))$ by the inclusion

$$PU[z] \cap TR(z) + TR[z] \subset TR(z). \tag{8.3}$$

A natural inclusion of Z'_z into $Z(T(z))$ induces a factor module isomorphic to

$${}_TZ_P = \frac{Y[z] \cap TR(z)}{Y[z] \cap \{PU[z] \cap TR(z) + TR[z]\}}. \tag{8.4}$$

Module (8.4) can be related to the zero module $Z([T(z)\ \ P(z)])$. Refer to the commutative diagram of Fig. 8.3 of natural inclusions. This diagram induces a monic, $k[z]$-linear map on ${}_TZ_P$ into $Z([T(z)\ \ P(z)])$, with cokernel isomorphic to

$$Z_k = \frac{Y[z] \cap PU(z)}{Y[z] \cap TR(z) + Y[z] \cap (TR[z] + PU[z])}. \tag{8.5}$$

We summarize these results.

THEOREM 10A. *Let* im $T(z) \subset$ im $P(z)$, *and let* Z'_Ω *be the torsion submodule of the matching zero module* Z_Ω. *Then there exist* $k[z]$*-modules* ${}_TZ_P$, Z_k, ${}_TX_P$, X_k, Z'_z, *and* X'_z, *together with appropriate* $k[z]$*-linear maps, such that the following five short sequences are exact*:

$$0 \to {}_TX_P \to P([T(z)\ \ P(z)]) \to X_k \to 0, \tag{8.6a}$$

$$0 \to P(T(z)) \to {}_TX_P \to X'_z \to 0, \tag{8.6b}$$

$$0 \to {}_TZ_P \to Z([T(z)\ \ P(z)]) \to Z_k \to 0, \tag{8.6c}$$

$$0 \to Z'_z \to Z(T(z)) \to {}_TZ_P \to 0, \tag{8.6d}$$

$$0 \to Z'_z \to Z'_\Omega \to X'_z \to 0. \tag{8.6e}$$

Proof. Sequences (8.6a)-(8.6d) have been established in the prelude to the theorem. Sequence (8.6e) is a consequence of the requirements on cokernels of columns in Fig. 8.1, including the induced column.

$$\begin{tikzcd}
Y[z] \cap \{PU[z] \cap TR(z) + TR[z]\} \arrow[r] \arrow[d] & Y[z] \cap TR(z) \arrow[d] \\
Y[z] \cap \{TR[z] + PU[z]\} \arrow[r] & Y[z] \cap \{TR(z) + PU(z)\} = Y[z] \cap PU(z)
\end{tikzcd}$$

FIG. 8.3

Discussion of Theorem 10A. The study of Z'_Ω then begins with the finitely generated, torsion poles and zeros of $T(z)$ and of $[T(z)\ P(z)]$. From the submodules ${}_TZ_P$ of $Z([T(z)\ P(z)])$ and ${}_TX_P$ of $P([T(z)\ P(z)])$, together with $Z(T(z))$ and $P(T(z))$, we can find Z'_z and X'_z, the building blocks of Z'_Ω. Note that, if $\operatorname{im} T(z) = \operatorname{im} P(z)$, both Z_k and X_k vanish. In that case, we obtain the sequences

$$0 \to P(T(z)) \to P([T(z)\ P(z)]) \to X'_z \to 0, \tag{8.7a}$$

$$0 \to Z'_z \to Z(T(z)) \to Z([T(z)\ P(z)]) \to 0, \tag{8.7b}$$

$$0 \to Z'_z \to Z'_\Omega \to X'_z \to 0, \tag{8.7c}$$

and this result then reduces to Theorem 4, because Ω is zero. In general, however, the description of Z'_Ω is more complicated than that of Z_Ω, with five sequences instead of three.

Consider next the commutative diagram of Fig. 8.4, where columns and rows are natural inclusions. It is clear that row two extends into a short exact sequence having $Z(T(z))$ as the factor module. The corresponding construction on row one produces a module

$$\frac{T^{-1}Y[z] \cap (\ker T(z) + M^{-1}U[z])}{T^{-1}Y[z] \cap (\ker T(z) + M^{-1}U[z]) \cap (\ker T(z) + R[z])} = Z_M^T, \tag{8.8}$$

which is finitely generated and torsion. Moreover, a brief diagram chase yields the existence of a monic $k[z]$-linear map on Z_M^T into $Z(T(z))$, with cokernel Z''_z. The character of Z_M^T follows from the calculation

$$\frac{T^{-1}Y[z] \cap (\ker T(z) + M^{-1}U[z])}{T^{-1}Y[z] \cap (\ker T(z) + M^{-1}U[z]) \cap (\ker T(z) + R[z])}$$

$$\approx \frac{T^{-1}Y[z] \cap (\ker T(z) + M^{-1}U[z]) + \ker T(z) + R[z]}{\ker T(z) + R[z]} \tag{8.9a}$$

$$= \frac{T^{-1}Y[z] \cap M^{-1}U[z] + \ker T(z) + R[z]}{\ker T(z) + R[z]} \tag{8.9b}$$

$$\approx \frac{T^{-1}Y[z] \cap M^{-1}U[z]}{T^{-1}Y[z] \cap M^{-1}U[z] \cap (\ker T(z) + R[z])}. \tag{8.9c}$$

Then, as a result of the inclusion

$$\begin{aligned} &T^{-1}Y[z] \cap M^{-1}U[z] \cap (\ker M(z) + R[z]) \\ &\qquad \subset T^{-1}Y[z] \cap M^{-1}U[z] \cap (\ker T(z) + R[z]), \end{aligned} \tag{8.10}$$

there exists a $k[z]$-linear epimorphism from

$$Z\left(\begin{bmatrix} T(z) \\ M(z) \end{bmatrix}\right) \tag{8.11}$$

$$\begin{tikzcd}
T^{-1}Y[z] \cap (\ker T(z) + M^{-1}U[z]) \cap (\ker T(z) + R[z]) \arrow[r] \arrow[d] & T^{-1}Y[z] \cap (\ker T(z) + M^{-1}U[z]) \arrow[d] \\
T^{-1}Y[z] \cap (\ker T(z) + R[z]) \arrow[r] & T^{-1}Y[z]
\end{tikzcd}$$

FIG. 8.4

onto Z_M^T, with kernel isomorphic to

$$Z'_k = \frac{(\ker T(z)+R[z]) \cap T^{-1}Y[z] \cap M^{-1}U[z]}{(\ker M(z)+R[z]) \cap T^{-1}Y[z] \cap M^{-1}U[z]}. \tag{8.12}$$

We turn now to column one of Fig. 8.4; and we wish to relate the cokernel to certain pole modules. Note that

$$P(T(z)) = \frac{R[z]}{T^{-1}Y[z] \cap R[z]} \approx \frac{R[z]+\ker T(z)}{T^{-1}Y[z] \cap (R[z]+\ker T(z))}; \tag{8.13}$$

and consider the module

$$\begin{aligned} &\frac{R[z]}{(\ker T(z)+T^{-1}Y[z] \cap M^{-1}U[z]) \cap R[z]} \\ &\approx \frac{\ker T(z)+R[z]}{T^{-1}Y[z] \cap (\ker T(z)+M^{-1}U[z]) \cap (\ker T(z)+R[z])}. \end{aligned} \tag{8.14}$$

By the inclusion of denominators in right members of (8.13) and (8.14), there is an epic $k[z]$-linear map from X_M^T, the right member of (8.14), onto $P(T(z))$. The kernel of that map is isomorphic to the cokernel of column one in Fig. 8.4, which we denote by X''_z. From the left member of (8.14), there is an epic $k[z]$-linear map from the pole module of (5.3) onto X_M^T, with kernel isomorphic to

$$\frac{(\ker T(z)+T^{-1}Y[z] \cap M^{-1}U[z]) \cap R[z]}{T^{-1}Y[z] \cap M^{-1}U[z] \cap R[z]} = X'_k. \tag{8.15}$$

With the aid of the foregoing pieces of information, we can state the analogue of Theorem 10A for the case of Z'_Γ.

THEOREM 10B. *Let* $\ker M(z) \subset \ker T(z)$, *and let* Z'_Γ *be the finitely generated factor module of the matching zero module* Z_Γ. *Then there exist* $k[z]$-*modules* Z_M^T, Z'_k, X_M^T, X'_k, Z''_z, *and* X''_z, *and appropriate* $k[z]$-*linear maps, such that the following five short sequences are exact*:

$$0 \to X'_k \to P\left(\begin{bmatrix} T(z) \\ M(z) \end{bmatrix}\right) \to X_M^T \to 0, \tag{8.16a}$$

$$0 \to X''_z \to X_M^T \to P(T(z)) \to 0, \tag{8.16b}$$

$$0 \to Z'_k \to Z\left(\begin{bmatrix} T(z) \\ M(z) \end{bmatrix}\right) \to Z_M^T \to 0, \tag{8.16c}$$

$$0 \to Z_M^T \to Z(T(z)) \to Z''_z \to 0, \tag{8.16d}$$

$$0 \to X''_z \to Z'_\Gamma \to Z''_z \to 0. \tag{8.16e}$$

Proof. Equations (8.16a)-(8.16d) have already been established. Equation (8.16e) follows from the fact that the cokernels of the columns, including the induced, in Fig. 8.4 must fit into an exact sequence.

Discussion of Theorem 10B. The known quantities in (8.16) are the pole and zero modules, finitely generated and torsion, of (5.3) and of $T(z)$, and the pair X'_k and Z'_k, from (8.15) and (8.12), respectively. From these, we obtain X_M^T and Z_M^T, together with X''_z and Z''_z, and finally Z'_Γ. If $\ker M(z) = \ker T(z)$, then X'_k and Z'_k vanish, with resulting simplifications.

Although the results of §§ 2–8, Theorems 1–10, are stated for the ring $k[z]$, they hold in much more general situations. Section 9 describes some of these generalizations.

9. Extensions of the theory. For readability, we have chosen the ring $k[z]$ and the quotient field $k(z)$ in which to state the results of §§ 2–8. However, all these results remain true in more general contexts, sometimes with a modest re-interpretation of physical meaning. As an example, we can replace the subring $k[z]$ of $k(z)$ with any subring O which contains the base field k, which has quotient field $k(z)$, and which is a principal ideal domain. Such rings include localizations of $k[z]$ and discrete valuation rings. An important instance of the latter is O_∞, the subring of proper transfer functions. More illustrations of rings which are useful in system theory arise from forming the intersection of discrete valuation rings. One illustration here is the ring O_{ps} of transfer functions which are proper and stable, when $k = R$, the real numbers.

When $k[z]$ is replaced by O, (2.1) must be changed to

$$\Omega_O R = O \otimes_k R, \tag{9.1}$$

$$\Omega_O U = O \otimes_k U, \tag{9.2}$$

$$\Omega_O Y = O \otimes_k Y. \tag{9.3}$$

Elsewhere, simply replace $U[z]$ by $\Omega_O U$, and so forth.

In fact, the ideas of the paper also extend to systems defined over more general rings, with appropriate assumptions [18].

10. Conclusions. We have studied the constraints imposed upon the zeros of $k(z)$-linear maps $P(z): U(z) \to Y(z)$ and $M(z): R(z) \to U(z)$ by reason of the fact that they satisfy the model matching equation $T(z) = P(z)M(z)$, in which $T(z): R(z) \to Y(z)$ is $k(z)$-linear as well. This study was inspired by the work of Conte, Perdon, and Wyman [7] on fixed poles in the solution to this same equation. Yet it turns out that the situation for zeros differs markedly from that for poles. Indeed, Theorem 7 indicates that the usual type of zero—which we may think of intuitively as a state-space zero—does not have an intrinsic constraint imposed upon it from its appearance in a solution $P(z)$ or $M(z)$ to the equation. Rather, it is the extended zero, embodying the classical notion of zero together with the novel constructs of divisible or free zeros, which undergoes such constraint. Moreover, essential solutions—in which the constraint is achieved with equality—need not always exist; and this constitutes yet another distinction from the case for poles.

Because of the centrality of the model matching equation in many constructions of feedback systems and communications, we conclude that extended zeros may be just as important as, or perhaps even more important than, the classical or state-space type zeros. Accordingly, they appear to represent a fruitful topic for future research.

Finally these results are a consequence of the systematic use of module theory, which presents a convenient and natural framework for study of poles and zeros. Indeed, the existence and role of extended zeros have been discovered only as a result of its use.

OPTIMAL DAMPING CONTROL AND NONLINEAR ELLIPTIC SYSTEMS*

SRDJAN STOJANOVIC†

Abstract. Optimal control for an elliptic equation when the control is the zero-order coefficient of the differential operator is considered and an optimality system is derived. Under certain assumptions, the problem is solved completely by giving the uniqueness and the constructive existence proof for the nonlinear optimality system. An extension to the case when the state equation is a particular elliptic system is considered as well.

Key words. optimal control, nonlinear optimality system, constructive existence proof

AMS(MOS) subject classifications. 49B22, 35J60

Introduction. We will consider an optimal control problem in which the state of the system is defined as the unique solution of an elliptic equation and where control is the zero-order coefficient of the differential operator (cf. [2], [9]). Also, an extension to a particular elliptic system is given.

After proving the existence of an optimal control, deriving the optimality system, and proving uniqueness for the optimality system (which happens to be a system of two nonlinear elliptic equations), we show how to solve that system; i.e., we give a *constructive* existence theorem.

When constructing a solution, the difficulty is that uniform estimates, i.e., compactness, i.e., convergence for a subsequence of some natural iteration, is not enough to solve the system (cf. [5]). We must invent a procedure with a property that the full sequence converges (see Theorem 4.1). Also, uniqueness for the optimality system is important not only because it provides uniqueness for the optimal control, and because it guarantees that the solution of the optimality system *is* an optimal control, but because the uniqueness for one closely related system (Lemma 4.1) guarantees the convergence of the approximating sequence (see § 4).

We present one computational example as well. It seems worth mentioning that numerical experiments suggest that somewhat restrictive assumptions of Theorem 4.1, which guarantee the convergence of the constructive scheme, could be relaxed (see Remark 5.1).

1. Optimal damping problem.

Let Ω be a bounded domain of $\mathbb{R}^n$ with $\mathbf{C}^{1,1}$ boundary. Let

$$f \in \mathbf{L}^q(\Omega), \quad q \geqq 2, \quad q > \frac{n}{2}, \tag{1.1}$$

and

$$\lambda \in \mathbb{R}_+ = \{\beta \mid \beta \in \mathbb{R}, \beta \geqq 0\} \tag{1.2}$$

be given. For any $s \geqq 1$, set

$$\mathbf{L}_+^s(\Omega) = \{c \mid c \in \mathbf{L}^s(\Omega), c \geqq 0 \text{ a.e. in } \Omega\}. \tag{1.3}$$

† Department of Mathematical Sciences, University of Cincinnati, Cincinnati, Ohio 45221-0025.

For any $c \in \mathbf{L}^2_+(\Omega)$, we define $y = y(c)$ as a solution of (see [3])

$$(1.4)\qquad \begin{aligned} &-\Delta y + \lambda y + cy = f \quad \text{a.e. in } \Omega,\\ &y \in \mathbf{W}^{2,2}(\Omega) \cap \mathbf{H}^1_0(\Omega) \cap \mathbf{L}^\infty(\Omega). \end{aligned}$$

Remark 1.1. Results of this paper can be formulated for a general elliptic operator (with appropriate assumptions imposed) instead of $-\Delta$.

We observe that

(1.5) $\quad \|y(c)\|_{\mathbf{L}^\infty(\Omega)} \leqq \text{const.}$ where const. does not depend on $c \in \mathbf{L}^2_+(\Omega)$ and $\lambda \in \mathbb{R}_+$.

Next, for (q as in (1.1)

$$(1.6)\qquad y_d \in \mathbf{L}^q(\Omega)$$

and $N > 0$ given, we define the cost functional $\mathbf{J}$ by

$$(1.7)\qquad \mathbf{J}(c) = \frac{1}{2}\int_\Omega (y(c) - y_d)^2\, dx + \frac{N}{2}\int_\Omega (c)^2\, dx,$$

and we ask the question:

(1.8) How do we find an optimal control?

That is, how do we find (if it exists) a (damping) control $c_0 \in \mathbf{L}^2_+(\Omega)$ such that

$$(1.9)\qquad \mathbf{J}(c_0) = \inf_{c \in \mathbf{L}^2_+(\Omega)} \mathbf{J}(c).$$

Under certain assumptions, we will give a reasonably complete answer to the question (1.8). To start with, we observe that an optimal control always exists.

LEMMA 1.1. *There exists an optimal control.*

Proof. The proof is standard. Take a minimizing sequence $\{(c_n, y(c_n))\}$. Then $\|c_n\|_{\mathbf{L}^2(\Omega)}$ and $\|y(c_n)\|_{\mathbf{L}^\infty(\Omega)}$ are bounded sequences; hence, by elliptic estimates (see [3]), $\|y(c_n)\|_{\mathbf{W}^{2,2}(\Omega)}$ is bounded. Then there exist $c_0 \in \mathbf{L}^2_+(\Omega)$ and $y_0 \in \mathbf{L}^\infty(\Omega) \cap \mathbf{W}^{2,2}(\Omega)$, such that, for a subsequence,

$$\begin{aligned} c_n &\to c_0 \quad \text{weakly in } \mathbf{L}^2(\Omega),\\ y(c_n) &\to y_0 \quad \text{strongly in } \mathbf{H}^1_0(\Omega). \end{aligned}$$

Also, for any n we have

$$\int \nabla y(c_n) \cdot \nabla \varphi + \lambda y(c_n)\varphi + c_n y(c_n)\varphi = \int f\varphi \quad \forall \varphi \in \mathbf{H}^1_0(\Omega) \cap \mathbf{L}^\infty(\Omega).$$

Hence, passing the limit we conclude that

$$y_0 = y(c_0).$$

Also, by the lower semicontinuity of the cost functional, (c_0, y_0) is an optimal pair. □

2. Derivation of the optimality system. In this section we derive the necessary conditions, i.e., the optimality system, for an optimal pair (c, y). Two results are given in the next theorem. The first result holds under the general conditions already introduced. The second result holds under the condition that

$$(2.1)\qquad f \geqq 0 \quad \text{a.e. in } \Omega,$$

and

$$(2.2)\qquad y_d \leqq 0 \quad \text{a.e. in } \Omega.$$

THEOREM 3.1. (a) *Under the assumptions* (1.1), (1.2), *and* (1.6), *for any optimal pair* (c, y), *there exists* p *satisfying the system*

$$\begin{aligned}
&-\Delta y+\lambda y+cy=f \quad \text{a.e. in } \Omega, \quad y\in \mathbf{W}^{2,2}(\Omega)\cap \mathbf{H}_0^1(\Omega)\cap \mathbf{L}^\infty(\Omega),\\
&-\Delta p+\lambda p+cp-y=-y_d \quad \text{a.e. in } \Omega, \quad p\in \mathbf{W}^{2,2}(\Omega)\cap \mathbf{H}_0^1(\Omega)\cap \mathbf{L}^\infty(\Omega),\\
&c=\frac{1}{N}py \quad \text{a.e. in } \Omega\cap\{c>0\}, \qquad py\leqq 0 \quad \text{a.e. in } \Omega\cap\{c=0\}.
\end{aligned}\tag{2.3}$$

(b) *Under the assumptions* (1.1), (1.2), (1.6), (2.1), *and* (2.2), *for any optimal pair* (c, y), *there exists* p *satisfying the following nonlinear elliptic system*:

$$\begin{aligned}
&-\Delta y+\lambda y+\frac{1}{N}py^2=f \quad \text{a.e. in } \Omega, y=0, \quad \text{at } \partial\Omega, \quad y\in \mathbf{W}^{2,q}(\Omega),\\
&-\Delta p+\lambda p+\frac{1}{N}yp^2-y=-y_d \quad \text{a.e. in } \Omega, p=0 \quad \text{at } \partial\Omega, \quad p\in \mathbf{W}^{2,q}(\Omega),
\end{aligned}\tag{2.4}$$

and $c=py/N$. *Moreover*, $y\geqq 0$ *and* $p\geqq 0$.

Proof. It is not difficult to see (using standard arguments (cf. [1], [6])) that the mapping $\mathbf{L}^2_+(\Omega)\ni c\mapsto y(c)\in \mathbf{L}^2(\Omega)$ is differentiable in the following sense:

$$\frac{y(c+\beta\bar{c})-y(c)}{\beta}\to z \quad \text{strongly in } \mathbf{L}^2(\Omega), \quad \text{as } \beta\to 0,\tag{2.5}$$

for any $c\in \mathbf{L}^2_+(\Omega)$ and $\bar{c}\in \mathbf{L}^\infty(\Omega)$, such that $c+\beta\bar{c}\in \mathbf{L}^2_+(\Omega)$ (for $\beta\to 0$), and z is the solution to the equation

$$\begin{aligned}
&-\Delta z+\lambda z+cz=-y(c)\bar{c} \quad \text{a.e. in } \Omega,\\
&z\in \mathbf{W}^{2,2}(\Omega)\cap \mathbf{H}_0^1(\Omega)\cap \mathbf{L}^\infty(\Omega).
\end{aligned}\tag{2.6}$$

Let c be an optimal control. For every $\bar{c}\in \mathbf{L}^\infty_+(\Omega)$ and $\beta>0$, we have $c+\beta\bar{c}\in \mathbf{L}^2_+(\Omega)$, and

$$\begin{aligned}
&\frac{1}{2}\int_\Omega (y(c+\beta\bar{c})-y_d)^2\,dx+\frac{N}{2}\int_\Omega (c+\beta\bar{c})^2\,dx\\
&\geqq\frac{1}{2}\int_\Omega (y(c)-y_d)^2\,dx+\frac{N}{2}\int_\Omega (c)^2\,dx.
\end{aligned}$$

Hence, dividing by β, and sending $\beta\downarrow 0$, we get

$$\int_\Omega [(y(c)-y_d)z+Nc\bar{c}]\geqq 0.\tag{2.7}$$

Let p be a solution to the equation

$$\begin{aligned}
&-\Delta p+\lambda p+cp=y(c)-y_d \quad \text{a.e. in } \Omega,\\
&p\in \mathbf{W}^{2,2}(\Omega)\cap \mathbf{H}_0^1(\Omega)\cap \mathbf{L}^\infty(\Omega).
\end{aligned}\tag{2.8}$$

From (2.7) and (2.8) we get

$$\int_\Omega [(-\Delta p+\lambda p+cp)z+Nc\bar{c}]\geqq 0.$$

Integrating by parts and using (2.6), we deduce $(y=y(c))$

$$\int_\Omega (Nc-py)\bar{c}\geqq 0 \quad \forall \bar{c}\in \mathbf{L}^\infty_+(\Omega).\tag{2.9}$$

More precisely, for $c \in \mathbf{L}^2_+(\Omega)$, consider a variation $\bar{c} \in \mathbf{L}^\infty(\Omega)$. Define $\bar{c}_\varepsilon$ by

$$\bar{c}_\varepsilon = \begin{cases} \bar{c} & \text{if } c > \varepsilon \|\bar{c}\|_{\mathbf{L}^\infty(\Omega)}, \\ 0 & \text{elsewhere.} \end{cases} \tag{2.10}$$

Then for any $\beta \in \mathbb{R}$, such that $|\beta| < \varepsilon$,

$$c + \beta \bar{c}_\varepsilon \in \mathbf{L}^2_+(\Omega),$$

and proceeding as before, we conclude that, now

$$\int_\Omega (Nc - py)\bar{c}_\varepsilon = 0. \tag{2.11}$$

Passing $\varepsilon \downarrow 0$, we conclude that

$$\int_{\Omega \cap \{c>0\}} (Nc - py)\bar{c} = 0 \quad \forall \bar{c} \in \mathbf{L}^\infty(\Omega). \tag{2.12}$$

Putting together (2.8), (2.9), and (2.12), we prove (a).

Now, if (2.1) and (2.2) hold, then we have that

$$p \geqq 0 \quad \text{in } \Omega, \qquad y \geqq 0 \quad \text{in } \Omega,$$

and using (a) we conclude that

$$py = 0 \quad \text{a.e. in } \Omega \cap \{c = 0\},$$

hence,

$$c = \frac{1}{N} py \quad \text{in } \Omega,$$

and the theorem is proved. □

3. Uniqueness for the optimality system. In addition to (2.1) and (2.2) we assume that

(3.1) λ is sufficiently large.

Remark 3.1. From (1.5), (1.6), and (2.4) we see that there is a uniform constant C_0, depending only on the data (moreover, independent of λ and N), such that, for any optimal pair (c, y) and any corresponding p, we have

$$\max\{\|y\|_{\mathbf{L}^\infty(\Omega)}, \|p\|_{\mathbf{L}^\infty(\Omega)}\} \leqq C_0. \tag{3.2}$$

Then, we can write (3.1) explicitly, for example, a.

$$\lambda \geqq \frac{1}{2}\left|\frac{2}{N}(C_0)^2 - 1\right|. \tag{3.1}^*$$

PROPOSITION 3.1. *Under the assumptions* (1.1), (1.6), (2.1), (2.2), *and* (3.1) *there can be only one positive solution of* (2.4).

Proof. Weak formulation of (2.4) reads as

$$\begin{aligned} &\int_\Omega \left[\nabla y \cdot \nabla \psi + \lambda y \psi + \frac{1}{N} p y^2 \psi + \nabla p \cdot \nabla \varphi + \lambda p \varphi + \frac{1}{N} y p^2 \varphi - y \varphi\right] \\ &\quad = \int_\Omega [f\psi - y_d \varphi] \quad \forall (\psi, \varphi) \in [\mathbf{H}^1_0(\Omega)]^2 \cap [\mathbf{L}^\infty(\Omega)]^2; \end{aligned} \tag{3.3}$$

hence,

$$-\int_\Omega \left[|\nabla(p-\bar{p})|^2+|\nabla(y-\bar{y})|^2+\lambda(p-\bar{p})^2+\lambda(y-\bar{y})^2 + \frac{1}{N}(p-\bar{p})^2 y(p+\bar{p})+\frac{1}{N}(y-\bar{y})^2 p(y+\bar{y})\right] + \int_\Omega (\bar{p}-p)(y-\bar{y})\left[\frac{1}{N}(\bar{p}^2+\bar{y}^2)-1\right]=0.$$

It follows, since $y(p+\bar{p})\geqq 0$ and $p(y+\bar{y})\geqq 0$, that $p=\bar{p}$ and $y=\bar{y}$, provided

$$(3.1)^{**} \qquad \left\|\frac{1}{N}(\bar{p}^2+\bar{y}^2)-1\right\|_{\mathbf{L}^\infty(\Omega)} \leqq 2\lambda. \qquad \square$$

4. Solution of the optimality system. The purpose of this section is to give a constructive proof of the existence of a positive solution of the optimality system (2.4). Of course, since the proof is constructive, it can be easily used as an *algorithm for numerical computations* of the unique solutions of (2.4), which provides us with the optimal control. An example is given in the subsequent section.

We start with a simple problem:

(4.1) Find $u\in\mathbf{W}^{2,q}(\Omega)$, $u\geqq 0$, such that $-\Delta u+\lambda u+bu^2=f$ a.e. in Ω, $u=0$ at $\partial\Omega$.

We assume that

$$(4.2) \qquad b\in\mathbf{L}^\infty_+(\Omega).$$

Then we have the following proposition.

PROPOSITION 4.1. *Under the assumptions* (1.1), (1.2), (2.1), *and* (4.2), *there exists a unique solution of the problem* (4.1).

Proof. We shall prove the existence first. Let us start from u_0, the solution of

$$(4.3) \qquad \begin{aligned} &-\Delta u_0+\lambda u_0=f \quad \text{a.e. in } \Omega,\\ &u_0=0 \quad \text{at } \partial\Omega. \end{aligned}$$

Observe that (2.1) implies that $u_0\geqq 0$. Now, choose constant $M\geqq 0$, such that

(4.4) $-\|b\|_{\mathbf{L}^\infty(\Omega)}v^2+Mv$ is an increasing function of v, for $v\in[0, \|u_0\|_{\mathbf{L}^\infty(\Omega)}]$.

Next, for $k\geqq 1$, assuming we already have u_{k-1}, we define u_k as a solution of

$$(4.5) \qquad \begin{aligned} &-\Delta u_k+(\lambda+M)u_k=f-b(u_{k-1})^2+Mu_{k-1} \quad \text{a.e. in } \Omega,\\ &u_k=0 \quad \text{at } \partial\Omega. \end{aligned}$$

Then, for example, when $k=1$,

$$-\Delta(u_0-u_1)+M(u_0-u_1)=b(u_0)^2\geqq 0 \quad \text{a.e. in } \Omega,$$

and, hence, $u_0\geqq u_1$. Similarly, using (4.4), we conclude that $u_{k-1}\geqq u_k$ for any $k\geqq 1$. We conclude that full sequence converges, i.e.,

$$(4.6) \qquad u_k(x)\to u(x) \quad \forall x\in\Omega.$$

Also, by elliptic estimates, we have

$$(4.7) \qquad \|u_k\|_{\mathbf{W}^{2,q}(\Omega)}\leqq \text{const}.$$

Using (4.6) and (4.7) we can easily pass to the limit in (4.5) to conclude that u is a solution of (4.1).

Uniqueness will follow from the following lemma. It is worth mentioning that the lemma is a consequence of the monotonicity of the operator in (4.1) on the set $\{u \geqq 0\}$.

LEMMA 4.1. *Under the previous assumptions the following comparison result holds for the problem* (4.1):

$$b^* \geqq b, \qquad f^* \leqq f \Rightarrow u^* \leqq u. \tag{4.8}$$

Proof. We have

$$-\Delta(u^* - u) + \lambda(u^* - u) + b^*(u^*)^2 - b(u)^2 = f^* - f \leqq 0;$$

hence,

$$-\Delta(u^* - u) + \lambda(u^* - u) + b[(u^*)^2 - (u)^2] \leqq 0,$$

i.e.,

$$-\Delta(u^* - u) + \lambda(u^* - u) + b(u^* + u)(u^* - u) \leqq 0,$$

and, since $b(u^* + u) \geqq 0$, we conclude that $u^* \leqq u$. □

Next, we study the following (intermediate) problem:

(4.9) Find $(y, p) \in [\mathbf{W}^{2,q}(\Omega)]^2$, $y \geqq 0$, $p \geqq 0$, such that

$$-\Delta y + \lambda y + \frac{1}{N} p y^2 = f \quad \text{a.e. in } \Omega, \quad y = 0, \quad \text{at } \partial\Omega,$$

$$-\Delta p + \lambda p + \frac{1}{N} y p^2 = g \quad \text{a.e. in } \Omega, \quad p = 0 \quad \text{at } \partial\Omega.$$

We will assume that (for q as in (1.1))

$$g \in \mathbf{L}_+^q(\Omega). \tag{4.10}$$

We have the following proposition.

PROPOSITION 4.2. *Under the assumptions* (1.1), (1.2), (2.1), *and* (4.10) *there exists a solution* (y, p) *of* (4.9), *with the following comparison property*:

$$g^* \leqq g \Rightarrow p^* \leqq p, \qquad y^* \geqq y. \tag{4.11}$$

Remark 4.1. We can prove uniqueness for problem (4.9) using the same argument as in the proof of Proposition 3.1. Nevertheless, for this, instead of (3.1)**, we would need

$$\left\| \frac{1}{N}(p^2 + y^2) \right\|_{\mathbf{L}^\infty(\Omega)} \leqq 2\lambda. \tag{4.12}$$

We confine ourselves to prove only the existence of a solution satisfying property (4.11). This will be enough for our purposes.

Proof of Proposition 4.2. We shall construct in parallel, solutions corresponding to g and g^*. Define y_1 and y_1^* as a solution of

$$-\Delta y + \lambda y = f \quad \text{a.e. in } \Omega, \quad y = 0 \quad \text{at } \partial\Omega. \tag{4.13}$$

Next, using Proposition 4.1, define p_1 and p_1^* as a solution of

$$\begin{aligned} &-\Delta p + \lambda p + \frac{1}{N} y_1 p^2 = g \qquad \text{a.e. in } \Omega, \quad p = 0 \quad \text{at } \partial\Omega, \\ &-\Delta p + \lambda p + \frac{1}{N} y_1^* p^2 = g^* \quad \text{a.e. in } \Omega, \quad p = 0, \quad \text{at } \partial\Omega, \end{aligned} \tag{4.14}$$

respectively. By Lemma 4.1 we know that $p_1 \geqq p_1^*$. Furthermore, define y_2 and y_2^* as a solution of

$$(4.15)\qquad \begin{aligned} &-\Delta y+\lambda y+\frac{1}{N}p_1 y^2=f \quad \text{a.e. in } \Omega, \quad y=0 \quad \text{at } \partial\Omega, \\ &-\Delta y+\lambda y+\frac{1}{N}p_1^* y^2=f \quad \text{a.e. in } \Omega, \quad y=0 \quad \text{at } \partial\Omega, \end{aligned}$$

respectively. By Lemma 4.1 we conclude that $y_2 \leqq y_1$, $y_2^* \leqq y_1^*$ and that $y_2 \leqq y_2^*$. Proceeding similarly, we construct two sequences $\{(y_k, p_k)\}$ and $\{(y_k^*, p_k^*)\}$ such that, for $k \geqq 1$,

$$y_k \leqq y_{k-1}, \quad p_k \geqq p_{k-1}, \quad y_k^* \leqq y_{k-1}^*, \quad p_k^* \geqq p_{k-1}^*, \quad y_k \leqq y_k^*, \qquad p_k \geqq p_k^*.$$

Since those two sequences are bounded in $\mathbf{L}^\infty(\Omega)$, we can pass to the limit obtaining pointwise limits y, p, y^*, p^* for the full sequences and, moreover,

$$y \leqq y^* \quad \text{and} \quad p \geqq p^*.$$

Finally, since we have also uniform $\mathbf{W}^{2,q}(\Omega)$-estimates, we can conclude easily that the limiting functions satisfy (4.9). □

Remark 4.2. $y \leqq y_1$, where y is from the preceding proposition, and y_1 is defined in (4.13).

We are ready now to solve the original problem. We consider the following iterative scheme.

Let y_0 be defined as a solution of

$$(4.16)\qquad -\Delta y_0+\lambda y_0=f \quad \text{a.e. in } \Omega, \quad y_0=0 \quad \text{at } \partial\Omega.$$

Define (y_k, p_k), for $k \leqq 1$, as a solution, constructed in Proposition 4.2, of

$$(4.17)\qquad \begin{aligned} &-\Delta y_k+\lambda y_k+\frac{1}{N}p_k y_k^2=f \quad \text{a.e. in } \Omega, \quad y_k=0 \quad \text{at } \partial\Omega, \\ &-\Delta p_k+\lambda p_k+\frac{1}{N}y_k p_k^2=y_{k-1}-y_d \quad \text{a.e. in } \Omega, \quad y_k=0 \quad \text{at } \partial\Omega. \end{aligned}$$

Then we have Theorem 4.1.

THEOREM 4.1. *Under the assumptions* (1.1), (1.6), (2.1), (2.2), *and* (3.1) (*or* (3.1)*), *the following holds*:

$$(4.18)\qquad y_k \to y, \quad p_k \to p, \quad \text{as } k \to \infty,$$

weakly in $\mathbf{W}^{2,q}(\Omega)$, *for a full sequence. Hence,* (y, p) *is the unique positive solution of* (2.4), *and* $c_0 \equiv py/N$ *is the unique optimal control. Moreover,*

$$(4.19)\qquad y_{2k} \searrow y, \quad y_{2k+1} \nearrow y, \quad p_{2k} \nearrow p, \quad p_{2k+1} \searrow p \quad \text{as } k \to \infty.$$

Proof. From (4.16), (4.17) and Remark 4.2, we conclude that

$$y_0 \geqq y_2.$$

Hence, by the Proposition 4.2, we have

$$p_1 \geqq p_3, \qquad y_1 \leqq y_3,$$

which implies, in the same manner, that

$$p_2 \leqq p_4, \quad y_2 \geqq y_4, \qquad p_3 \geqq p_5, \quad y_3 \leqq y_5,$$

and so on. We conclude that

$$y_0 \geqq y_2 \geqq y_4 \geqq \cdots, \qquad y_1 \leqq y_3 \leqq y_5 \leqq \cdots,$$
$$p_2 \leqq p_4 \leqq p_6 \leqq \cdots, \qquad p_1 \geqq p_3 \geqq p_5 \geqq \cdots.$$

Hence, there are functions $\bar{y}$, $\underline{y}$, $\bar{p}$, $\underline{p}$, such that

$$y_{2k} \searrow \bar{y}, \quad y_{2k+1} \nearrow \underline{y}, \quad p_{2k} \nearrow \underline{p}, \quad p_{2k+1} \searrow \bar{p}, \tag{4.20}$$

and also, by the elliptic estimates, weakly in $\mathbf{W}^{2,q}(\Omega)$. Furthermore, we have

$$-\Delta y_{2k} + \lambda y_{2k} + \frac{1}{N} p_{2k}(y_{2k})^2 = f \quad \text{a.e. in } \Omega,$$

$$-\Delta p_{2k} + \lambda p_{2k} + \frac{1}{N} y_{2k}(p_{2k})^2 = y_{2k-1} - y_d \quad \text{a.e. in } \Omega,$$

and

$$-\Delta y_{2k+1} + \lambda y_{2k+1} + \frac{1}{N} p_{2k+1}(y_{2k+1})^2 = f \quad \text{a.e. in } \Omega,$$

$$-\Delta p_{2k+1} + \lambda p_{2k+1} + \frac{1}{N} y_{2k+1}(p_{2k+1})^2 = y_{2k} - y_d \quad \text{a.e. in } \Omega.$$

Passing to the limit, we conclude that $(\bar{y}, \underline{p}, \underline{y}, \bar{p})$ is a solution of

$$\begin{aligned}
&-\Delta \bar{y} + \lambda \bar{y} + \frac{1}{N} \underline{p} \bar{y}^2 = f \quad \text{a.e. in } \Omega, \quad \bar{y} = 0 \quad \text{at } \partial\Omega,\\
&-\Delta \underline{p} + \lambda \underline{p} + \frac{1}{N} \bar{y} \underline{p}^2 - \underline{y} = -y_d \quad \text{a.e. in } \Omega, \quad \underline{p} = 0 \quad \text{at } \partial\Omega,\\
&-\Delta \underline{y} + \lambda \underline{y} + \frac{1}{N} \bar{p} \underline{y}^2 = f \quad \text{a.e. in } \Omega, \quad \underline{y} = 0 \quad \text{at } \partial\Omega,\\
&-\Delta \bar{p} + \lambda \bar{p} + \frac{1}{N} \underline{y} \bar{p}^2 - \bar{y} = -y_d \quad \text{a.e. in } \Omega, \quad \bar{p} = 0 \quad \text{at } \partial\Omega.
\end{aligned} \tag{4.21}$$

Then, by the inspection, we see that $(\underline{y}, \bar{p}, \bar{y}, \underline{p})$ is a solution of (4.21) as well. So, if we show that, in an appropriate class (in a class where $(\bar{y}, \underline{p}, \underline{y}, \bar{p})$ and $(\underline{y}, \bar{p}, \bar{y}, \underline{p})$ belong), the uniqueness holds for problem (4.21), we can conclude that

$$\underline{y} = \bar{y}, \qquad \underline{p} = \bar{p},$$

and the theorem is proved. The following lemma addresses this last question.

LEMMA 4.2. *Suppose* $(\bar{y}, \underline{p}, \underline{y}, \bar{p})$ *and* $(\bar{l}, \underline{s}, \underline{l}, \bar{s})$ *are two positive solutions of* (4.21), *and suppose that*

$$\left\| \frac{1}{N}(\bar{l}^2 + \underline{s}^2) - 1 \right\|_{\mathbf{L}^\infty(\Omega)} \leqq 2\lambda, \tag{4.22}$$

and that

$$\left\| \frac{1}{N}(\underline{l}^2 + \bar{s}^2) - 1 \right\|_{\mathbf{L}^\infty(\Omega)} \leqq 2\lambda. \tag{4.23}$$

Then,

$$(\bar{y}, \underline{p}, \underline{y}, \bar{p}) = (\bar{l}, \underline{s}, \underline{l}, \bar{s}).$$

Proof. The proof is similar to the proof of Proposition 3.1. The variational formulation of (4.21) reads as

$$\int_\Omega \Big[\nabla\bar{y}\cdot\nabla\varphi_1+\lambda\bar{y}\varphi_1+\frac{1}{N}\underline{p}\bar{y}^2\varphi_1+\nabla\underline{p}\cdot\nabla\varphi_2+\lambda\underline{p}\varphi_2+\frac{1}{N}\bar{y}\underline{p}^2\varphi_2-\underline{y}\varphi_2$$

$$+\nabla\underline{y}\cdot\nabla\varphi_3+\lambda\underline{y}\varphi_3+\frac{1}{N}\bar{p}\underline{y}^2\varphi_3+\nabla\bar{p}\cdot\nabla\varphi_4+\lambda\bar{p}\varphi_4+\frac{1}{N}\underline{y}\bar{p}^2\varphi_4-\bar{y}\varphi_4\Big] \tag{4.24}$$

$$=\int_\Omega [f\varphi_1-y_d\varphi_2+f\varphi_3-y_d\varphi_4] \quad \forall(\varphi_1,\varphi_2,\varphi_3,\varphi_4)\in[\mathbf{H}_0^1(\Omega)]^4\cap[\mathbf{L}^\infty(\Omega)]^4.$$

Hence,

$$-\int_\Omega \Big[|\nabla(\bar{y}-\bar{l})|^2+|\nabla(\underline{p}-\underline{s})|^2+|\nabla(\underline{y}-\underline{l})|^2+|\nabla(\bar{p}-\bar{s})|^2$$

$$+\lambda((\bar{y}-\bar{l})^2+(\underline{p}-\underline{s})^2+(\underline{y}-\underline{l})^2+(\bar{p}-\bar{s})^2)$$

$$+\frac{1}{N}((\bar{l}-\bar{y})^2\underline{p}(\bar{y}+\bar{l})+(\underline{s}-\underline{p})^2\bar{y}(\underline{s}+\underline{p})+(\underline{l}-\underline{y})^2\bar{p}(\underline{l}+\underline{y})$$

$$+(\bar{s}-\bar{p})^2\underline{y}(\bar{s}+\bar{p}))\Big]$$

$$+\int_\Omega\Big[\Big(1-\frac{1}{N}(\bar{l}^2+\underline{s}^2)\Big)(\bar{y}-\bar{l})(\underline{p}-\underline{s})+\Big(1-\frac{1}{N}(\underline{l}^2+\bar{s}^2)\Big)(\underline{y}-\underline{l})(\bar{p}-\bar{s})\Big]=0.$$

The lemma follows since $\underline{p}(\bar{y}+\bar{l})$, $\bar{y}(\underline{s}+\underline{p})$, $\bar{p}(\underline{l}+\underline{y})$ and $\underline{y}(\bar{s}+\bar{p})$ are $\geqq 0$. Here we also use the assumptions (4.22) and (4.23). □

5. An example. In this section we present some computations done by implementing the algorithm developed in § 4.

Consider the state equation

$$\begin{aligned}&-\Delta u+cu=20(\sin(2\pi x)+1)\quad \text{in } \Omega=(0,1)\times(0.1),\\ &u=0\quad \text{on } \partial\Omega.\end{aligned} \tag{5.1}$$

The problem is to choose c, such that

$$\mathbf{J}(c)=\frac{1}{2}\int_\Omega [u(c)]^2\,dx+\frac{0.0005}{2}\int_\Omega c^2\,dx, \tag{5.2}$$

is minimized. Observe that

$$\lambda=0. \tag{5.3}$$

The optimality system is

$$\begin{aligned}&-\Delta u+\frac{1}{N}pu^2=20(\sin(2\pi x)+1)\quad \text{in } \Omega,\\ &-\Delta p+\frac{1}{N}up^2-u=0\quad \text{in } \Omega,\\ &u,p=0\quad \text{on } \partial\Omega.\end{aligned} \tag{5.4}$$

The program consists of several subroutines and a main program. Subroutine 1 is a solver for the problem (4.5). This is a single linear elliptic equation; hence, standard methods apply. We used piecewise linear finite elements. Subroutine 2 is a solver for the problem (4.1). It iterates Subroutine 1, as described in (4.5). Subroutine 3 is a solver for problem (4.9), using iteration defined in (4.13)-(4.15). Finally, the Main Program is a solver for the problem (2.4), using iteration (4.17).

Computations are done on Sun 386i workstation; the results are presented in Figs. 1–3. In Fig. 1, the solution of the state equation without any damping, i.e., $u(0)$, is given. In Fig. 2, the solution corresponding to the optimal damping $u(c)$ is presented. In Fig. 3, the optimal damping c is given. We observe that the convergence is fast: it takes only four to five iterations of the Subroutine 3 in the Main Program.

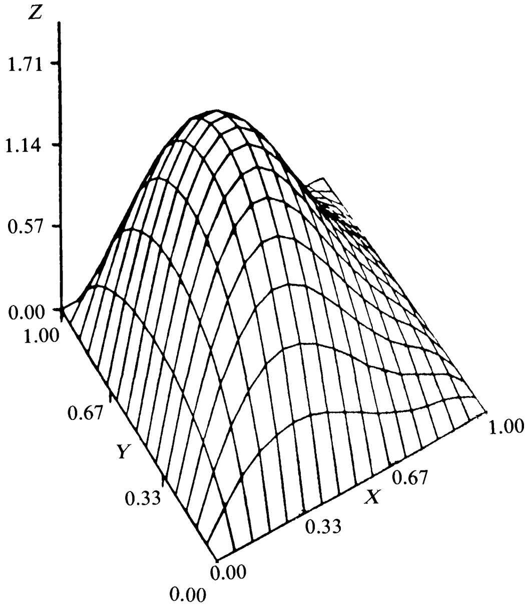

FIG. 1

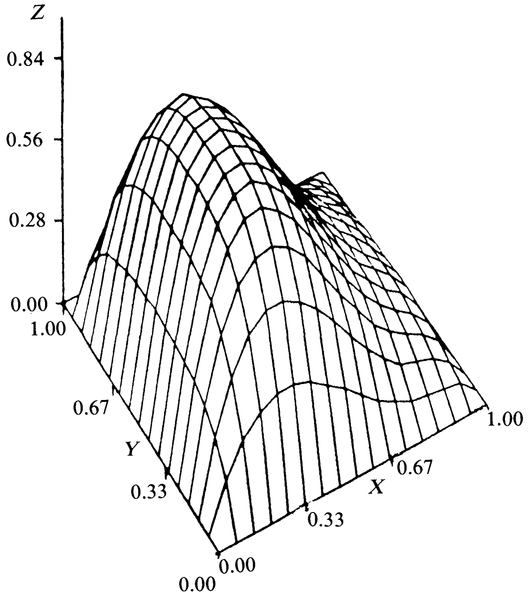

FIG. 2

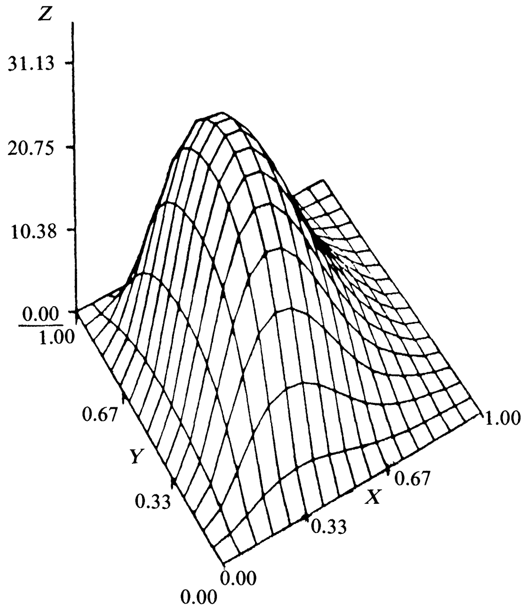

FIG. 3

Remark 5.1. In all numerical experiments that we have performed, the convergence has been recorded, even though λ was equal to zero. Hence, it seems reasonable to conjecture that Theorem 4.1 holds in that case as well. We observe that the largeness of λ was required to grant that

$$\underline{u} = \bar{u}, \qquad \underline{p} = \bar{p}.$$

6. An extension. Implicit damping control. Here we present, briefly, an extension to the case when the state equation is a particular elliptic system. Let

$$d \in \mathbf{L}^\infty_+(\Omega), \tag{6.1}$$

$$g \in \mathbf{L}^q(\Omega), \quad q \geqq 2, \quad q > \frac{n}{2}, \tag{6.2}$$

and

$$\lambda \in \mathbb{R}_+, \tag{6.3}$$

be given. For any $f \in \mathbf{L}^2_+(\Omega)$, we define $v = v(f)$ as a solution of the following equation:

$$\begin{gathered} -\Delta v + \lambda v + d[(-\Delta + \lambda)^{-1} f]v = g \quad \text{a.e. in } \Omega, \\ v \in \mathbf{W}^{2,2}(\Omega) \cap \mathbf{H}^1_0(\Omega) \cap \mathbf{L}^\infty(\Omega), \\ (-\Delta + \lambda)^{-1} f \in \mathbf{W}^{2,2}(\Omega) \cap \mathbf{H}^1_0(\Omega), \end{gathered} \tag{6.4}$$

or, more explicitly, we define $(u, v) = (u(f), v(f))$ as a solution of the following nonlinear system:

$$\begin{aligned} &-\Delta u + \lambda u = f \quad \text{a.e. in } \Omega, \\ &u \in \mathbf{W}^{2,2}(\Omega) \cap \mathbf{H}^1_0(\Omega), \\ &-\Delta v + \lambda v + duv = g \quad \text{a.e. in } \Omega, \\ &v \in \mathbf{W}^{2,2}(\Omega) \cap \mathbf{H}^1_0(\Omega) \cap \mathbf{L}^\infty(\Omega). \end{aligned} \tag{6.5}$$

Remark 6.1. Results of this section can be formulated for general elliptic operators, instead of $-\Delta$; more precisely, we can consider, instead of the state equation (1.5),

$$Av+\lambda v+d[(B+\lambda)^{-1}f]v=g,$$

where A and B are elliptic operators, with appropriate assumptions imposed.

Remark 6.2. When the first equation in (6.5) contains a zero-order term as in the second equation, it is natural to formulate, instead of the control problem considered here, a game problem. Then, the solution of the implicit damping problem can be viewed as a partial solution of the full game problem, which will be considered elsewhere (but under more restrictive assumptions).

It is easy to see that (6.5) has the unique solution. Also,

(6.6) $\|v(f)\|_{\mathbf{L}^{\infty}(\Omega)}\leqq$ const., const. does not depend on $\lambda\in\mathbb{R}_+$ and $f\in\mathbf{L}^2_+(\Omega)$.

Next, for (q as in (6.2))

$$v_d\in\mathbf{L}^q(\Omega) \tag{6.7}$$

and $N>0$ given, we define the cost functional $\mathbf{J}$ by

$$\mathbf{J}(f)=\frac{1}{2}\int_{\Omega}(v(f)-v_d)^2\,dx+\frac{N}{2}\int_{\Omega}f^2\,dx, \tag{6.8}$$

and, again, we look for an optimal control.

As before, it is not difficult to see that an optimal control always exists.

LEMMA 6.1. *There exists an optimal control.*

Again, we will need for the second part of the following theorem, the sign condition

$$g\geqq 0, \tag{6.9}$$

$$v_d\leqq 0. \tag{6.10}$$

THEOREM 6.1. (a) *Under the assumptions* (6.1), (6.2), (6.3), *and* (6.7), *for any optimal control f and associated solution to the state equation* (u, v), *there exists* (p_1, p_2) *satisfying the system*

$$\begin{aligned}
&-\Delta u+\lambda u=f \quad \textit{a.e. in } \Omega, \quad u\in\mathbf{W}^{2,2}(\Omega)\cap\mathbf{H}^1_0(\Omega),\\
&-\Delta v+\lambda v+duv=g \quad \textit{a.e. in } \Omega, \quad v\in\mathbf{W}^{2,2}(\Omega)\cap\mathbf{H}^1_0(\Omega)\cap\mathbf{L}^{\infty}(\Omega),\\
&-\Delta p_1+\lambda p_1-dvp_2=0 \quad \textit{a.e. in } \Omega, \quad p_1\in\mathbf{W}^{2,s}(\Omega), \quad p_1=0 \quad \textit{at } \partial\Omega,\\
&-\Delta p_2+\lambda p_2+dup_2-v=-v_d \quad \textit{a.e. in } \Omega, \quad p_2\in\mathbf{W}^{2,2}(\Omega)\cap\mathbf{H}^1_0(\Omega)\cap\mathbf{L}^{\infty}(\Omega),\\
&f=\frac{1}{N}p_1 \quad \textit{a.e. in } \Omega\cap\{f>0\}, \qquad p_1\leqq 0 \quad \textit{a.e. in } \Omega\cap\{f=0\},
\end{aligned} \tag{6.11}$$

for any $s<\infty$.

(b) *Under the assumptions* (6.1), (6.2), (6.3), (6.7), (6.9), *and* (6.10), *for any optimal control f and associated solution of the state equation* (u, v), *there exists* (p_1, p_2) *satisfying the following nonlinear elliptic system*:

$$\begin{aligned}
&-\Delta u+\lambda u-\frac{1}{N}p_1=0 \quad \textit{a.e. in } \Omega, \quad u\in\mathbf{W}^{2,s}(\Omega), \quad u=0 \quad \textit{at } \partial\Omega,\\
&-\Delta v+\lambda v+duv=g \quad \textit{a.e. in } \Omega, \quad v\in\mathbf{W}^{2,q}(\Omega), \quad v=0 \quad \textit{at } \partial\Omega,\\
&-\Delta p_1+\lambda p_1-dvp_2=0 \quad \textit{a.e. in } \Omega, \quad p_1\in\mathbf{W}^{2,s}(\Omega), \quad p_1=0 \quad \textit{at } \partial\Omega,\\
&-\Delta p_2+\lambda p_2+dup_2-v=-v_d \quad \textit{a.e. in } \Omega, \quad p_2\in\mathbf{W}^{2,q}(\Omega), \quad p_1=0 \quad \textit{at } \partial\Omega,
\end{aligned} \tag{6.12}$$

for any $s<\infty$, *and* $f=p_1/N$. *Moreover,* $u\geqq 0$, $v\geqq 0$, $p_1\geqq 0$, *and* $p_2\geqq 0$.

From (6.12), it is evident that there exists a constant C_0 depending only on data (moreover, independent of λ and N), such that

$$\|v\|_{L^\infty(\Omega)}, \|p_2\|_{L^\infty(\Omega)} \leqq C_0. \tag{6.13}$$

We assume that

$$\lambda \leqq \frac{1}{2} \max\left\{\frac{1}{N}, C_0\|d\|_{L^\infty(\Omega)}, 1\right\}. \tag{6.14}$$

LEMMA 6.2. *Under the assumptions* (6.1), (6.2), (6.3), (6.7), (6.9), (6.11), *and* (6.14), *there can be only one positive solution of* (6.12), *such that* (6.13) *holds.*

Finally, we construct solution of the optimality system. Consider the following auxiliary problem. Given $h \in L_+^\infty(\Omega)$, find $(u, v, p_1, p_2) \in W^{2,s}(\Omega) \times W^{2,q}(\Omega) \times W^{2,s}(\Omega) \times W^{2,q}(\Omega)$, for any $s < \infty$, such that

$$\begin{aligned} &-\Delta u + \lambda u = h \quad \text{a.e. in } \Omega, \quad u = 0 \quad \text{at } \partial\Omega,\\ &-\Delta v + \lambda v + duv = g \quad \text{a.e. in } \Omega, \quad v = 0 \quad \text{at } \partial\Omega,\\ &-\Delta p_1 + \lambda p_1 - dvp_2 = 0 \quad \text{a.e. in } \Omega, \quad p_1 = 0 \quad \text{at } \partial\Omega,\\ &-\Delta p_2 + \lambda p_2 + dup_2 - v = -v_d \quad \text{a.e. in } \Omega, \quad p_2 = 0 \quad \text{at } \partial\Omega. \end{aligned} \tag{6.15}$$

This is a trivial system. Indeed, $u \Rightarrow v \Rightarrow p_2 \Rightarrow p_1$. Also, we observe that

$$\bar{h} \geqq h \Rightarrow \bar{u} \geqq u \Rightarrow \bar{v} \leqq v \Rightarrow \bar{p}_2 \leqq p_2 \Rightarrow \bar{p}_1 \leqq p_1. \tag{6.16}$$

We are ready now to solve the original problem. Consider the following iterative scheme. Let $(u_0, v_0, p_{1,0}, p_{2,0})$ be a solution of

$$\begin{aligned} &u = 0 \quad \text{in } \Omega,\\ &-\Delta v + \lambda v = g \quad \text{a.e. in } \Omega, \quad v = 0 \quad \text{at } \partial\Omega,\\ &-\Delta p_1 + \lambda p_1 - dvp_2 = 0 \quad \text{a.e. in } \Omega, \quad p_1 = 0 \quad \text{at } \partial\Omega,\\ &-\Delta p_2 + \lambda p_2 + dup_2 - v = -v_d \quad \text{a.e. in } \Omega, \quad p_2 = 0 \quad \text{at } \partial\Omega. \end{aligned} \tag{6.17}$$

Define, by induction, for $k \geqq 1$, $(u_k, v_k, p_{1,k}, p_{2,k})$ as a solution of

$$\begin{aligned} &-\Delta u + \lambda u = \frac{1}{N} p_{1,k-1} \quad \text{a.e. in } \Omega, \quad u = 0 \quad \text{at } \partial\Omega,\\ &-\Delta v + \lambda v + duv = g \quad \text{a.e. in } \Omega, \quad v = 0 \quad \text{at } \partial\Omega,\\ &-\Delta p_1 + \lambda p_1 - dvp_2 = 0 \quad \text{a.e. in } \Omega, \quad p_1 = 0 \quad \text{at } \partial\Omega,\\ &-\Delta p_2 + \lambda p_2 + dup_2 - v = -v_d \quad \text{a.e. in } \Omega, \quad p_2 = 0 \quad \text{at } \partial\Omega. \end{aligned} \tag{6.18}$$

Then we have the following theorem.

THEOREM 6.2. *Under the assumptions* (6.1), (6.2), (6.3), (6.7), (6.9), (6.10), *and* (6.14), *the following holds*:

$$u_k \to u, \quad v_k \to v, \quad p_{1,k} \to p_1, \quad p_{2,k} \to p_2 \quad \text{as } k \to \infty, \tag{6.19}$$

weakly in $W^{2,q}(\Omega)$, *for a full sequence. Hence,* (u, v, p_1, p_2) *is the unique positive solution of* (6.12), *and* $f = p_1/N$ *is the unique optimal control. Moreover,*

$$\begin{aligned} &u_{2k} \nearrow u, \quad u_{2k+1} \searrow u, \quad v_{2k} \searrow v, \quad v_{2k+1} \nearrow v,\\ &p_{1,2k} \nearrow p_1, \quad p_{1,2k+1} \searrow p_1, \quad p_{2,2k} \searrow p_2, \quad p_{2,2k+1} \nearrow p_2, \end{aligned} \tag{6.20}$$

as $k \to \infty$.

Proof. It is not difficult to conclude from (6.16) that

$$u_{2k}\nearrow,\quad u_{2k+1}\searrow,\quad v_{2k}\searrow,\quad v_{2k+1}\nearrow,$$
$$p_{1,2k}\nearrow,\quad p_{1,2k+1}\searrow,\quad p_{2,2k}\searrow,\quad p_{2,2k+1}\nearrow. \tag{6.21}$$

Hence, there exists a $(\underline{u}, \bar{v}, \underline{p}_1, \bar{p}_2, \bar{u}, \underline{v}, \bar{p}_2, \underline{p}_2)$, such that

$$u_{2k}\nearrow \underline{u},\quad u_{2k+1}\searrow \bar{u},\quad v_{2k}\searrow \bar{v},\quad v_{2k+1}\nearrow \underline{v},$$
$$p_{1,2k}\nearrow \underline{p}_1,\quad p_{1,2k+1}\searrow \bar{p}_1,\quad p_{2,2k}\searrow \bar{p}_2,\quad p_{2,2k+1}\nearrow \underline{p}_2, \tag{6.22}$$

and also, by the elliptic estimates, weakly in $\mathbf{W}^{2,q}(\Omega)$ (actually, the u_i's and $p_{1,i}$'s converge weakly in $\mathbf{W}^{2,s}(\Omega)$, for any $s<\infty$). Furthermore, we have, for $k\geqq 1$,

$$-\Delta u_{2k}+\lambda u_{2k}-\frac{1}{N}p_{1,2k-1}=0 \quad \text{a.e. in } \Omega,\quad u_{2k}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta v_{2k}+\lambda v_{2k}+du_{2k}v_{2k}=g \quad \text{a.e. in } \Omega,\ v_{2k}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta p_{1,2k}+\lambda p_{1,2k}-dv_{2k}p_{2,2k}=0 \quad \text{a.e. in } \Omega,\quad p_{1,2k}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta p_{2,2k}+\lambda p_{2,2k}+dup_{2,2k}-v_{2k}=-v_d \quad \text{a.e. in } \Omega,\quad p_{2,2k}=0 \quad \text{at } \partial\Omega,$$

and

$$-\Delta u_{2k+1}+\lambda u_{2k+1}-\frac{1}{N}p_{1,2k}=0 \quad \text{a.e. in } \Omega,\quad u_{2k+1}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta v_{2k+1}+\lambda v_{2k+1}+du_{2k+1}v_{2k+1}=g \quad \text{a.e. in } \Omega,\quad v_{2k+1}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta p_{1,2k+1}+\lambda p_{1,2k+1}-dv_{2k+1}p_{2,2k+1}=0 \quad \text{a.e. in } \Omega,\quad p_{1,2k+1}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta p_{2,2k+1}+\lambda p_{2,2k+1}+dup_{2,2k+1}-v_{2k+1}=-v_d \quad \text{a.e. in } \Omega,\quad p_{2,2k+1}=0 \quad \text{at } \partial\Omega.$$

Passing to the limit, we conclude that $(\underline{u}, \bar{v}, \underline{p}_1, \bar{p}_2, \bar{u}, \underline{v}, \bar{p}_1, \underline{p}_2)$ is a solution of

$$-\Delta \underline{u}+\lambda \underline{u}-\frac{1}{N}\bar{p}_1=0 \quad \text{a.e. in } \Omega,\quad \underline{u}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta \bar{v}+\lambda \bar{v}+d\underline{u}\bar{v}=g \quad \text{a.e. in } \Omega,\quad \bar{v}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta \underline{p}_1+\lambda \underline{p}_1-d\bar{v}\bar{p}_2=0 \quad \text{a.e. in } \Omega,\quad \underline{p}_1=0 \quad \text{at } \partial\Omega,$$
$$-\Delta \bar{p}_2+\lambda \bar{p}_2+d\underline{u}\bar{p}_2-\bar{v}=-v_d \quad \text{a.e. in } \Omega,\quad \bar{p}_2=0 \quad \text{at } \partial\Omega.$$
$$-\Delta \bar{u}+\lambda \bar{u}-\frac{1}{N}\underline{p}_1=0 \quad \text{a.e. in } \Omega,\quad \bar{u}=0 \quad \text{at } \partial\Omega, \tag{6.23}$$
$$-\Delta \underline{v}+\lambda \underline{v}+d\bar{u}\underline{v}=g \quad \text{a.e. in } \Omega,\quad \underline{v}=0 \quad \text{at } \partial\Omega,$$
$$-\Delta \bar{p}_1+\lambda \bar{p}_1-d\bar{v}\underline{p}_2=0 \quad \text{a.e. in } \Omega,\quad \bar{p}_1=0 \quad \text{at } \partial\Omega,$$
$$-\Delta \underline{p}_2+\lambda \underline{p}_2+d\bar{u}\underline{p}_2-\underline{v}=-v_d \quad \text{a.e. in } \Omega,\quad \underline{p}_2=0 \quad \text{at } \partial\Omega.$$

Then, by the inspection, we see that $(\bar{u}, \underline{v}, \bar{p}_1, \underline{p}_2, \underline{u}, \bar{v}, \underline{p}_1, \bar{p}_2)$ is a solution, as well. But, quite similarly as in Lemma 4.2, we can show that, under the assumptions of the theorem, there can be only one solution of (6.23). Hence,

$$(\underline{u}, \bar{v}, \underline{p}_1, \bar{p}_2, \bar{u}, \underline{v}, \bar{p}_1, \underline{p}_2)=(\bar{u}, \underline{v}, \bar{p}_1, \underline{p}_2, \underline{u}, \bar{v}, \underline{p}_1, \bar{p}_2),$$

and we deduce (6.20). The theorem follows now easily. □

NONLINEAR NONINTERACTION WITH STABILITY BY DYNAMIC STATE FEEDBACK*

K. G. WAGNER†

Abstract. The dynamic feedback noninteraction with stability problem for square affine systems with a nonsingular decoupling matrix is investigated. First, a characterization of the class of dynamic feedbacks resulting in a noninteractive system is given. It is then shown that these feedbacks induce a certain subdynamic, which is determined by the given system alone and independent of the particular feedback used. The stability of this subdynamic is necessary for the achievement of noninteraction with stability. This condition extends an analogous result on the static feedback noninteraction with stability problem obtained recently by Isidori and Grizzle.

Key words. affine control systems, noninteraction with stability, dynamic noninteraction feedback, fixed dynamics

AMS(MOS) subject classifications. 93B10, 49E05

1. Introduction. Consider a square affine multi-input multi-output control system

$$(\Sigma)\qquad \begin{aligned} \dot{x} &= f(x) + \sum_{i=1}^{m} g_i(x)u_i, \\ y_i &= h_i(x), \qquad i = 1, \cdots, m, \quad m \geqq 2. \end{aligned}$$

Here the state x varies in $\mathbb{R}^n$, and the controls u_i and the outputs y_i are real-valued; f, g_i, h_i are assumed to be C^∞ mappings, defined on some open subset of $\mathbb{R}^n$. The following concepts are standard in control theory. (Σ) is called *noninteractive* if each output y_i is affected by the input u_i, but by no u_j, $j \neq i$. (Σ) is said to be *stable* at a reference point $\tilde{x}$ if $\tilde{x}$ is an asymptotically stable equilibrium point of the drift term $\dot{x} = f(x)$. The problem of the modification of (Σ) by feedback control such as to arrive at a noninteractive system is the *noninteracting control problem* [1], [2], [5], [7], [9]. If the feedback is also required to stabilize (Σ) locally at a given equilibrium of its drift term, we speak of the *noninteraction with stability problem* [3], [6], [9], [10]. The latter is the subject of the present paper. We discuss affine state feedbacks of the form

$$(\mathrm{F})\qquad \begin{aligned} \dot{\bar{x}} &= \bar{f}(x, \bar{x}) + \sum_{j=1}^{m} \bar{g}_j(x, \bar{x})v_j, \\ u_i &= \alpha_i(x, \bar{x}) + \sum_{j=1}^{m} \beta_{ij}(x, \bar{x})v_j, \qquad i = 1, \cdots, m, \end{aligned}$$

i.e., we include the possibility of a dynamic extension (state $\bar{x}$) and generally refer to (F) as a *dynamic feedback.* $v_1, \cdots, v_m$ are the new control variables. (F) contains the special case of a *static feedback* ($\dim \bar{x} = 0$).

In the discussion of the noninteraction with stability problem it is natural to consider only systems (Σ) that can be rendered separately noninteractive, respectively, stable by means of possibly different feedbacks. The question then is which further

† Mathematisches Institut der Universität Würzburg, 8700 Würzburg, Germany. Most of this research was done while visiting the Dipartimento di Informatica e Sistemistica, Università "La Sapienza," Rome, Italy.

conditions are needed in order to achieve both objectives simultaneously. For the case where only static feedback is allowed, the crucial condition has been found recently by Isidori and Grizzle [6]. It generalizes an analogous result for linear systems due to Gilbert [3] and amounts to the requirement that a certain invariant subsystem defined by (Σ), the so-called P^* *dynamics*, must be a priori stable (see § 3).

The knowledge about the dynamic feedback noninteraction with stability problem is less complete. For linear systems, Wonham and Morse showed the very satisfactory result that no additional conditions at all need to be imposed [9], [10]. In nonlinear systems theory, however, the problem remained open until, in [6], an example was presented that demonstrated that it may well be impossible to overcome the obstruction of an unstable P^* dynamics even by dynamic feedback, in contrast to the linear case.

In this paper we consider systems for which the static feedback noninteracting control problem is solvable. We show that a general genuinely nonlinear phenomenon underlies the cited example. It turns out that the P^* dynamics contains another, generally lower-dimensional subdynamic, called the Δ_{mix} *dynamics*, which is invariant even under dynamic feedbacks. If this dynamics is unstable, noninteraction with stability cannot be achieved. For linear systems, the Δ_{mix} dynamics reduces to dimension zero (i.e., does not appear), in accordance with the Wonham-Morse theory. An example shows that also in the nonlinear case a system with an unstable P^* dynamics may still be rendered both noninteractive and stable via a suitable dynamic feedback, provided the smaller Δ_{mix} dynamics is stable.

Throughout this paper we extensively use some standard methods of geometric control theory that by now are quite common in the field. All the necessary background material can be found in [5]. Also, our notation follows that of [5] and [6].

2. Regular noninteraction feedbacks. The following criterion will be used extensively: if (Σ) is noninteractive, then (see [5])

(H1) For $i=1,\cdots,m$ and for any product D of the differential operators L_f, L_{g_i} we have

$$L_{g_j}Dh_i \equiv 0 \quad \text{for all } j \neq i \tag{2.1}$$

(here L denotes the Lie derivative). Throughout this paper we consider the system (Σ) locally near the reference point $x=0$. We assume

(H2) Each output h_i has a well-defined (local) *characteristic number* ρ_i at $x=0$ with respect to (Σ), i.e., for $0 \leqq k < \rho_i$ and each j: $L_{g_j}L_f^k h_i \equiv 0$, and for some j: $L_{g_j}L_f^{\rho_i}h_i(0) \neq 0$,

$$\text{i.e., when (H1) holds: } L_{g_i}L_f^{\rho_i}h_i(0) \neq 0. \tag{2.2}$$

Given (H2), (H1) is also sufficient for noninteraction at least if f, g_i, h_i are analytic [4], [5]. So the following definition is natural.

DEFINITION 2.1. (i) A feedback (F) transforming (Σ) into the system

$$(\Sigma^e) \qquad \begin{aligned} \dot{x}^e &= F(x^e) + \sum_{j=1}^{m} G_j(x^e)v_j, \\ y_i &= H_i(x^e) = h_i(x), \qquad i=1,\cdots,m, \end{aligned}$$

where $x^e = \binom{x}{\bar{x}}$ and

$$F(x^e) = \begin{pmatrix} f(x) \\ \bar{f}(x^e) \end{pmatrix} + \sum_{i=1}^{m} \begin{pmatrix} g_i(x) \\ 0 \end{pmatrix} \alpha_i(x^e), \tag{2.3a}$$

$$G_j(x^e) = \begin{pmatrix} 0 \\ \bar{g}_j(x^e) \end{pmatrix} + \sum_{i=1}^{m} \begin{pmatrix} g_i(x) \\ 0 \end{pmatrix} \beta_{ij}(x^e), \qquad 1 \leqq j \leqq m, \tag{2.3b}$$

is called a *noninteraction feedback* (for (Σ)) if for any i and any product D^e of factors L_F, L_{G_i}

$$L_{G_j} D^e h_i \equiv 0 \quad \text{for all } j \neq i. \tag{2.4}$$

(ii) If, in addition, each output h_i has a characteristic number σ_i at the origin $x^e = 0$ with respect to (Σ^e), then (F) is called a *regular noninteraction feedback.*

(iii) When dealing with systems (Σ) with $f(0) = 0$ we say that the feedback (F) *preserves the equilibrium* if $\bar{f}(0, 0) = 0$ and $\alpha_i(0, 0) = 0$ for $i = 1, \cdots, m$ (so $F(0) = 0$).

The object of this preparatory section is a characterization of the class of regular noninteraction feedbacks for those systems (Σ) that are already noninteractive.

So assume that (H1), (H2) hold for (Σ) and consider a feedback (F) and the resulting system (Σ^e). For notational convenience from now on we will often omit the argument x^e when a mapping $H(x^e)$ is referred to. If H happens to depend only on the x part of $x^e = (x, \bar{x})$, we emphasize this by writing $H(x)$. The following formulas are easily deducted from the definitions:

$$\begin{aligned} &L_F^k h_i = L_f^k h_i(x), \qquad 0 \leqq k \leqq \rho_i, \\ &L_F^{\rho_i+1} h_i = L_f^{\rho_i+1} h_i(x) + L_{g_i} L_f^{\rho_i} h_i(x) \cdot \alpha_i, \\ &L_{G_j} L_F^k h_i = L_{g_i} L_f^k h_i(x) \cdot \beta_{ij}, \qquad 0 \leqq k \leqq \rho_i \qquad (=0 \text{ for } k < \rho_i). \end{aligned} \tag{2.5}$$

If (F) is a noninteraction feedback, then (2.5), (2.4), (2.2) imply $\beta_{ij} \equiv 0$ for $i \neq j$; thus, (2.3b) reduces to

$$G_j = \begin{pmatrix} 0 \\ \bar{g}_j \end{pmatrix} + \begin{pmatrix} g_j \\ 0 \end{pmatrix} (x) \cdot \beta_{jj}, \qquad j = 1, \cdots, m. \tag{2.6}$$

In addition, if $\beta_{ii}(x^e)$ is not identically zero on a neighborhood of $x^e = 0$, (2.5) implies that the characteristic number σ_i of h_i at $x^e = 0$ with respect to (Σ^e) exists if and only if $\beta_{ii}(0) \neq 0$ and in this case, $\sigma_i = \rho_i$. This is case (i) of the following claim (2).

PROPOSITION 2.2. *Assume that* (Σ) *satisfies* (H1) *and* (H2). *Claim*:

(1) *A feedback* (F) *is a noninteraction feedback if and only if its coefficients* α_i, β_{ij} *exhibit the following* decoupling property:

$$\beta_{ij} \equiv 0 \quad \text{if } j \neq i, \tag{2.7a}$$

$$L_{G_j} D^e \alpha_i \equiv 0, \qquad L_{G_j} D^e \beta_{ii} \equiv 0 \tag{2.7b}$$

for all $i = 1, \cdots, m$, *all* $j \neq i$ *and any product* D^e *of factors* L_F, L_{G_i}.

(2) (F) *is a regular noninteraction feedback if, in addition, for each* $i \in \{1, \cdots, m\}$ *one of the following statements holds*:

(i) $\beta_{ii}(0) \neq 0$, *or*

(ii) $\beta_{ii} \equiv 0$, *and* $\alpha_i(x^e)$ *has a characteristic number, say* $\tau_i - 1$ *at* $x^e = 0$ *with respect to* (Σ^e).

The characteristic number σ_i *of* h_i *at* $x^e = 0$ *with respect to* (Σ^e) *equals* ρ_i *in case* (i), *respectively,* $\rho_i + \tau_i$ *in case* (ii).

Sketch of proof. We may assume (2.7a). Let D^e be a product of factors L_F, L_{G_i}. The idea of the proof is to establish the following relations between the relevant Lie derivatives of h_i, β_{ii}, α_i (to prove by a straightforward induction on the number of factors of D^e, starting with (2.5)):

$$D^e L_{G_i} L_F^{\rho_i} h_i = L_{g_i} L_f^{\rho_i} h_i(x) \cdot D^e \beta_{ii} + \sum_{\text{finite}} \phi_{k,D^e}(x) \cdot B_{k,D^e}, \tag{2.8}$$

$$D^e L_F^{\rho_i+1} h_i = L_{g_i} L_f^{\rho_i} h_i(x) \cdot D^e \alpha_i + \sum_{\text{finite}} \psi_{k,D^e}(x) \cdot A_{k,D^e}. \tag{2.9}$$

Here k is a summation index. Each function ϕ_{k,D^e}, ψ_{k,D^e} is of the form $DL_{g_i}L_f^{\rho_i}h_i$ or $DL_f^{\rho_i+1}h_i$ for some product D of factors L_f, L_{g_i}. Each B_{k,D^e}, A_{k,D^e} is a product of functions of the form $\bar{D}^e\beta_{ii}$ or $\bar{D}^e\alpha_i$, the $\bar{D}^e$ being products of factors L_F, L_{G_i}. The total number of operators L_F, L_{G_i} appearing in B_{k,D^e}, respectively, A_{k,D^e} is strictly smaller than the number of factors of D^e (harmless exception: for $D^e =$ identity an $A_{k,D^e} \equiv 1$ appears, cf. (2.5)).

Claim (1) can now be derived from (2.8), (2.9) by a similar induction argument. The $\beta_{ii} \equiv 0$ case of claim (2) results from the following auxiliary claim: If $\beta_{ii} \equiv 0$, $\tau \geqq 1$ and $L_{G_i}L_F^t\alpha_i \equiv 0$, for $0 \leqq t < \tau - 1$, then $L_{G_i}L_F^{\rho_i+\tau}h_i = L_{g_i}L_f^{\rho_i}h_i(x) \cdot L_{G_i}L_F^{\tau-1}\alpha_i$. (To derive for $\tau = 1$ from (2.5) and, for $\tau > 1$, from (2.9): let $D^e = L_F^{\tau-1}$, then apply L_{G_i} and note (2.6).) □

Remark. The decoupling condition (2.7b) can also be expressed in terms of first-order differential operators involving Lie brackets. An elementary calculation using the rule $L_{[C,D]} = L_CL_D - L_DL_C$ shows the following well-known equivalence for a function $\alpha(x^e)$:

$$L_{G_j}D^e\alpha \equiv 0$$

$$\text{for all } j \neq i \text{ and all products } D^e \text{ of factors } L_F,\ L_{G_i}$$

if and only if

$$L_B\alpha \equiv 0$$

$$\text{for all Lie products } B \text{ of } F, G_1, \cdots, G_m \tag{2.10}$$

$$\text{containing a factor } G_j, j \neq i.$$

The form (2.10) for the decoupling condition will be useful later.

Proposition 2.2 may be compared with a similar characterization of the class of static regular noninteraction feedbacks due to Ha and Gilbert [4]. Its essential part is the decoupling property for α_i, β_{ii} with respect to the original system (Σ) instead of (Σ^e). In contrast, our condition refers to (Σ^e) and is thus only an implicit one. Nevertheless, it will serve as an essential tool for the proofs of our main results.

3. Review: the P^* decomposition. Let (H2) hold and let $A(x)$ be the so-called *decoupling matrix* of (Σ), defined by its entries

$$a_{ij}(x) = L_{g_j}L_f^{\rho_i}h_i(x), \qquad 1 \leqq i, j \leqq m.$$

Throughout the rest of this paper we assume that a static regular noninteraction feedback for (Σ) exists locally near $x = 0$. This is the case if and only if (see [5])

(H3) $A(x)$ is nonsingular near $x = 0$.

The starting point for the ensuing discussion is the main result of [6] on the static feedback noninteraction with stability problem which we briefly review here. Let R^* be the smallest distribution containing $g_1, \cdots, g_m$ and invariant under $f, g_1, \cdots, g_m$. Following [5] we denote this by

$$R^* = \langle f, g_1, \cdots, g_m | \operatorname{sp}\{g_1, \cdots, g_m\}\rangle.$$

R^* is the so-called strong accessibility distribution of (Σ) [8], [5, p. 38]. (H2) implies that, for $i = 1, \cdots, m$, the maximal controlled-invariant distribution Δ_i^* contained in $\ker dh_i$ is well-defined, nonsingular, and involutive [5, p. 145]. We need the following additional regularity assumption:

(H4) (i) Near $x = 0$, R^* is nonsingular and finitely computable (cf. [5, § I.6]).

(ii) Near $x = 0$, the largest controllability distribution P_i^* contained in Δ_i^* is defined, nonsingular, and finitely computable for $i = 1, \cdots, m$ [5, § IV.5].

Hypothesis (H4) is known to hold for an open and dense set of reference points. What we actually need is that $x=0$ belongs to this set.

THEOREM 3.1 [6]. *Let* (H2), (H3), (H4) *hold for* (Σ). *Then there exists a coordinate system* $x=(x_1,\cdots,x_{m+2})$ *locally around* $x=0$, *each* x_i *possibly vector-valued, with the following properties*:

(1) $P_i^* = \mathrm{sp}\,\{\partial/\partial x_j : 1 \leqq j \leqq m+1, j \neq i\}$,

$$P^* := \bigcap_{i=1}^{m} P_i^* = \mathrm{sp}\left\{\frac{\partial}{\partial x_{m+1}}\right\}. \tag{3.1}$$

(2) *In the coordinates* x, *each noninteractive system* ($\tilde{\Sigma}$) *obtained from* (Σ) *by means of a static regular noninteraction feedback displays the following* P^* decomposed form:

$$\begin{aligned} \dot{x}_1 &= \tilde{f}_1(x_1, x_{m+2}) + \tilde{g}_{11}(x_1, x_{m+2})v_1, && y_1 = h_1(x_1, x_{m+2}) \\ &\vdots \qquad\qquad \vdots && \vdots \\ \dot{x}_m &= \tilde{f}_m(x_m, x_{m+2}) + \tilde{g}_{mm}(x_m, x_{m+2})v_m, && y_m = h_m(x_m, x_{m+2}) \\ \dot{x}_{m+1} &= \tilde{f}_{m+1}(x) + \sum_{i=1}^{m} \tilde{g}_{i,m+1}(x)v_i \\ \dot{x}_{m+2} &= \tilde{f}_{m+2}(x_{m+2}). \end{aligned} \tag{3.2}$$

In addition we have in terms of ($\tilde{\Sigma}$):

$$P_i^* = \langle \tilde{f}, \tilde{g}_1, \cdots, \tilde{g}_m \,|\, \mathrm{sp}\,\{\tilde{g}_j : 1 \leqq j \leqq m, j \neq i\}\rangle. \tag{3.3}$$

(3) *Now suppose* $f(0)=0$ *and consider in* (2) *only feedbacks that preserve the equilibrium, so* $\tilde{f}(0)=0$ *in* (3.2). *Then the map* $\tilde{f}_{m+1}(0,\cdots,0,x_{m+1},0)$ *is determined by the given system* (Σ) *alone. The drift term of* ($\tilde{\Sigma}$) *can be asymptotically stable at* $x=0$ *only if the* P^* fixed dynamics

$$\dot{x}_{m+1} = \tilde{f}_{m+1}(0,\cdots,0,x_{m+1},0) \tag{3.4}$$

associated with (Σ) *is asymptotically stable at* $x_{m+1}=0$.

Remark. If dynamic feedback is considered, the stability of the P^* fixed dynamics is no longer necessary for noninteraction with stability. For linear systems, this is clear in view of the Wonham-Morse theory mentioned in the Introduction. A nonlinear example will be provided later in § 6.

4. The mixed brackets distribution and the corresponding subsystem. Invariance properties. The result just described indicates that the P^* dynamics constitutes the essential obstruction in the static feedback noninteraction with stability problem. It is natural to ask how far we can reduce this P^* dynamics if dynamic feedback is allowed. To motivate the following discussion a bit, suppose for the moment that (Σ) is already noninteractive and consider the case (Σ) = ($\tilde{\Sigma}$) in Theorem 3.1. By (3.3), (3.1) it is clear that all those Lie products of $f, g_1, \cdots, g_m$ that contain two factors g_i, g_j with $i \neq j$ belong "canonically" to P^*. We refer to these products in the sequel as *mixed brackets.* Of course, P^* may be bigger. For instance, if $[f, g_1]$ and $[f, g_2]$ happen to be nonzero and linearly dependent, then these nonmixed brackets also belong to P^*. However, the existence of such additional elements of P^* depends on the validity of certain nontrivial relations in the Lie algebra Lie $\{f, g_1, \cdots, g_m\}$ that might be destroyed by means of a suitable dynamic extension. Thus, it is reasonable to conjecture that P^* and, consequently, the P^* subsystem have a "core" determined by the mixed brackets and this intuition is indeed correct. So let

Δ_{mix}, the *mixed brackets distribution* be the distribution generated by all the mixed brackets. While Δ_i^*, P_i^*, P^* are invariant, at least under invertible static feedbacks, there is no obvious reason for expecting any kind of feedback invariance of the mixed brackets distribution. Yet our main result states that Δ_{mix} does exhibit invariance, in a sense, with respect to noninteraction feedbacks.

THEOREM 4.1 (invariant projection property of Δ_{mix}). *Suppose that* (Σ) *satisfies hypotheses* (H1) *and* (H2). *Let* (Σ^e) *be any system obtained from* (Σ) *by means of a* (*dynamic*) *regular noninteraction feedback. Let* Δ_{mix}^e *be the mixed brackets distribution of* (Σ^e) *and* π_x, *the canonical projection from the tangent bundle of the* x^e *space onto that of the* x *space. Then*

$$\pi_x(\Delta_{\text{mix}}^e) = \Delta_{\text{mix}}.$$

The proof of this theorem is given in the next section.

COROLLARY 4.2. *If in Theorem* 4.1 *the feedback applied to* (Σ) *is static, then* $\Delta_{\text{mix}}^e = \Delta_{\text{mix}}$.

Remark 4.3. As a consequence, if we start with a system (Σ') that satisfies (H2) and (H3) but is not itself noninteractive, then any two systems (Σ_1), (Σ_2) obtained from (Σ') by means of a static regular noninteraction feedback will result in the same mixed brackets distribution Δ_{mix} (for (Σ_1), (Σ_2) can be transformed into each other via static regular noninteraction feedbacks). That is, this Δ_{mix} is in fact determined by the given system (Σ') alone and does not depend on the particular choice of its noninteractive counterpart (Σ_i).

We now use the mixed brackets distribution to derive a refinement of the P^* decomposed form (3.2). Suppose that $f(0) = 0$ and that (Σ) also satisfies (H4) in addition to (H1) and (H2), so Theorem 3.1 can be applied for $(\tilde{\Sigma}) = (\Sigma)$ (accordingly, we omit $\tilde{}$ and write u_i instead of v_i when we refer to the P^* decomposed form (3.2) of (Σ) itself). Suppose further that

(H5) Δ_{mix} is of constant dimension locally around $x = 0$.

Given (H5) it follows by the very definition of Δ_{mix} that Δ_{mix} is an involutive subdistribution of P^* and is invariant under $f, g_1, \cdots, g_m$. In particular, the differentials of the components of the coordinates $x_1, \cdots, x_m, x_{m+2}$ used in Theorem 3.1 annihilate Δ_{mix}. Now recall that during the construction of the coordinate system x (see [6, Lemma 4.1]) the x_{m+1} part is required only to complete the previously constructed $x_1, \cdots, x_m, x_{m+2}$ to a full coordinate system. So we can, without affecting the statements of Theorem 3.1, choose new coordinates x_{m+1} as follows. First, choose x_{m+1}^{**} such that the components of $dx_1, \cdots, dx_m, dx_{m+1}^{**}, dx_{m+2}$ constitute a local base for the annihilator of Δ_{mix} (this is possible by the Frobenius theorem since Δ_{mix} is involutive and nonsingular). Then adjoin further coordinates x_{m+1}^* so as to obtain a full coordinate system. Then

$$\Delta_{\text{mix}} = \text{sp}\left\{\frac{\partial}{\partial x_{m+1}^*}\right\}, \tag{4.1}$$

and since Δ_{mix} is invariant under $f, g_1, \cdots, g_m$, the x_{m+1}^* coordinates appear in (3.2) nowhere but in the $\dot{x}_{m+1}^*$ equation (cf. [5, Lemma I.4.3]). Consequently, the P^* dynamics (3.4) splits:

$$\dot{x}_{m+1}^* = f_{m+1}^*(0, \cdots, 0, x_{m+1}^*, x_{m+1}^{**}, 0),$$

$$\dot{x}_{m+1}^{**} = f_{m+1}^{**}(0, \cdots, 0, x_{m+1}^{**}, 0).$$

For this dynamics, $x^{**}_{m+1}=0$ defines an invariant manifold and the restriction on this manifold is given by

$$\dot{x}^*_{m+1}=f^*_{m+1}(0,\cdots,0,x^*_{m+1},0,0). \tag{4.2}$$

This is (in coordinates) the restriction of the drift term of (Σ) to the integral manifold of Δ_{mix} passing through $x=0$; therefore, we call it the Δ_{mix} *dynamics.* Since P^*, Δ_{mix}, and the P^* dynamics are the same after any static regular noninteraction feedback, so is the Δ_{mix} dynamics. Accordingly, we can, in analogy to Remark 4.3, associate a well-defined Δ_{mix} dynamics also to systems (Σ') that satisfy only (H3) instead of (H1), simply by executing first an arbitrary static regular noninteraction feedback and then using the resulting system (Σ).

The most remarkable feature of the Δ_{mix} dynamics is that, unlike the P^* dynamics, it also survives dynamic noninteraction feedbacks. The following theorem constitutes an analogue to Theorem 3.1(3).

THEOREM 4.4 (invariant projection property of the Δ_{mix} dynamics). *Suppose that* $f(0)=0$ *and that* (Σ) *satisfies* (H1), (H2), (H4), (H5). *Let* (Σ^e) *be a system obtained from* (Σ) *by means of a (dynamic) regular noninteraction feedback which preserves the equilibrium. Assume that the mixed brackets distribution* Δ^e_{mix} *of* (Σ^e) *is also constant dimensional near* $x^e=0$. *Claim*:

(1) *The drift term of* (Σ^e) *admits the restriction on the integral manifold of* Δ^e_{mix} *passing through* $x^e=0$.

(2) *This restriction, called the* Δ^e_{mix} *dynamics of* (Σ^e), *has a well-defined projection into the x space, and this projection coincides with the* Δ_{mix} *dynamics of* (Σ). *Consequently,* (Σ^e) *can be asymptotically stable at* $x^e=0$ *only if* (Σ) *has an asymptotically stable* Δ_{mix} *dynamics.*

Proof. Since Δ^e_{mix} is nonsingular, it is involutive and so has an integral manifold I^e passing through the equilibrium point $x^e=0$ of the drift term

$$\dot{x}^e=F(x^e)=\begin{pmatrix} f(x) \\ \bar{f}(x^e) \end{pmatrix}+\sum_{i=1}^{m}\begin{pmatrix} g_i(x) \\ 0 \end{pmatrix}\cdot\alpha_i(x^e) \tag{4.3}$$

of (Σ^e). Δ^e_{mix} is also invariant under F, and this implies that I^e, containing an equilibrium of (4.3), is an invariant manifold for (4.3). This proves claim (1). Consider now the Δ^e_{mix} dynamics, i.e., the restriction of (4.3) to I^e. If B is an arbitrary mixed bracket of (Σ^e), then, by the decoupling property, $L_B\alpha_i\equiv 0$, $i=1,\cdots,m$. Since our feedback preserves the equilibrium, $\alpha_i(0)=0$, so $\alpha_i\equiv 0$ on I^e. Similarly, using the invariant projection property for Δ^e_{mix}, we deduce that $x_1\equiv 0,\cdots,x_m\equiv 0$, $x^{**}_{m+1}\equiv 0$, $x_{m+2}\equiv 0$ on I^e, whereas the coordinate functions x^*_{m+1} can be made part of a coordinate system $(x^*_{m+1},\bar{x}^*)$ on I^e. Here $\bar{x}^*$ is an appropriate selection of components of $\bar{x}$. In these coordinates the restriction of (4.3) to I^e reads

$$\dot{x}^*_{m+1}=f^*_{m+1}(0,\cdots,0,x^*_{m+1},0,0),$$

$$\dot{\bar{x}}^*=\bar{F}(x^*_{m+1},\bar{x}^*),\quad \bar{F}\text{ appropriate.}$$

Claim (2) is now obvious. □

Remark 4.5. The mixed brackets distribution and the corresponding subsystem are structural properties typical for nonlinear systems. In fact, for a linear system all mixed brackets vanish and so the obstructive Δ_{mix} dynamics does not appear. From the general viewpoint of nonlinear control theory, the success of the linear Wonham-Morse approach thus obtains an additional motivation.

Remark 4.6. If the assumption of nonsingularity of Δ_{mix}, Δ^e_{mix} in Theorem 4.4 is dropped, we nevertheless can show the invariance of certain dynamical characteristics. In fact, since $f(0)=0$, $F(0)=0$, we can conclude by the mere definitions and without invoking nonsingularity that the subspaces $\Delta_{\text{mix}}(0)$, $\Delta^e_{\text{mix}}(0)$ are invariant subspaces, respectively, for the differentials $f_x(0)$ and $F_{x^e}(0)$ which correspond to the linearized drift terms of (Σ) and (Σ^e). What we can show is the following inclusion for the spectra of the respective restrictions:

$$\sigma(f_x(0)|_{\Delta_{\text{mix}}(0)}) \subset \sigma(F_{x^e}(0)|_{\Delta^e_{\text{mix}}(0)}). \tag{4.4}$$

In particular, (Σ^e) is surely unstable if an eigenvalue of $f_x(0)|_{\Delta_{\text{mix}}(0)}$ has a positive real part.

Proof. We have $\alpha_i(0)=0$, and by the decoupling property the restrictions of the differentials $d\alpha_i(0)$ to $\Delta^e_{\text{mix}}(0)$ also vanish. It follows that the restrictions on $\Delta^e_{\text{mix}}(0)$ of the linear maps given by

$$F_{x^e}(0) \quad \text{and} \quad \frac{d}{dx^e}\bigg|_0 \begin{pmatrix} f \\ \bar{f} \end{pmatrix} = \begin{pmatrix} f_x(0) & 0 \\ * & * \end{pmatrix}$$

coincide (cf. (4.3)). Formula (4.4) follows from this by using the invariant projection property of Δ^e_{mix} and some standard arguments from linear algebra. □

This remark and proof constitute a direct generalization of the concluding reasoning in [6, § 5].

5. Proof of Theorem 4.1. The theorem is proved once we succeed in showing that the projection π_x maps all members of a set of generators of Δ^e_{mix} into Δ_{mix} and that the images thus obtained suffice to generate all of Δ_{mix}. So our first step is the selection of appropriate sets of generators. Consider first Δ_{mix}. Let $L_{r,s} \subset \Delta_{\text{mix}}$ be the $\mathbb{R}$-linear span of all those mixed brackets which contain exactly r factors f and s factors in all ($0 \leqq r \leqq s-2$). By repeated use of the skew symmetry of the Lie product and the Jacobi identity, we show successively that $L_{r,s}$ is linearly spanned by each of the following sets of more special mixed brackets:

(i) The mixed brackets in $L_{r,s}$ of the form

$$[b_s, [b_{s-1}, \cdots [b_2, b_1] \cdots]],$$
$$b_s, \cdots, b_1 \in \{f, g_1, \cdots, g_m\}.$$

(ii) The mixed brackets in $L_{r,s}$ of the form

$$\begin{gathered}[(\text{ad}^{r_q}f, g_{i_q}), [\cdots, [(\text{ad}^{r_2}f, g_{i_2}), (\text{ad}^{r_1}f, g_{i_1})] \cdots]], \\ q=s-r, \qquad r_q+\cdots+r_1=r, \qquad 1 \leqq i_1, \cdots, i_q \leqq m\end{gathered} \tag{5.1}$$

(to obtain from (i) by distributing all factors f, beginning from the left, through the products on their right via the Jacobi identity. The ad notation is defined by $(\text{ad}^0 f, g)=g$, $(\text{ad}^{k+1}f, g)=[f, (\text{ad}^k f, g)]$). Note that $i_j \neq i_1$ for some j.

(iii) $E_{r,s}$ = the set of the mixed brackets in $L_{r,s}$ of the form (5.1) with the additional property $i_2 \neq i_1$.

To see this, use (ii) and the fact that a formal Lie bracket $[B, [A_1, \cdots, [A_{q-1}, A_q] \cdots]]$, where $B, A_1, \cdots, A_q$ are indeterminates, can be linearly combined by the brackets $[C_1, [\cdots, [C_q, B] \cdots]]$, where the C's form permutations of the A's. (This fact can easily be proved by induction on q.)

Thus, Δ_{mix} is generated by the union of the sets $E_{r,s}$. The corresponding quantities of the system (Σ^e) are defined in an analogous way and, as usual, marked by the superscript e. Now let

$$\tau_i = \sigma_i - \rho_i, \qquad i = 1, \cdots, m,$$

where σ_i (respectively, ρ_i) is the characteristic number of the output h_i with respect to (Σ^e) (respectively, (Σ)). Recall from § 2 that, if $\tau_i = 0$, then $\beta_{ii}(x^e) \neq 0$ near $x^e = 0$; otherwise, $\beta_{ii}(x^e) \equiv 0$ near $x^e = 0$ and $\tau_i - 1$ is just the characteristic number of $\alpha_i(x^e)$ with respect to (Σ^e).

LEMMA 5.1. *For $i = 1, \cdots, m$ and $\rho = 0, 1, 2, \cdots$ an identity of the following form holds*:

$$(5.2) \qquad \pi_x((\operatorname{ad}^\rho F, G_i)) = \sum_k b^\rho_{k,i} \cdot \phi^\rho_{k,i}.$$

Here

$b^\rho_{k,i}$ = *product of the form*:

$$(5.3) \qquad \begin{aligned} &[g_{j_r}, [\cdots, [g_{j_1}, g_i] \cdots]], \qquad 0 \leqq r \leqq \rho - \tau_i \ , \\ &j_r, \cdots, j_1 \in \{0, \cdots, m\} \quad (\text{here we let } g_0 = f); \end{aligned}$$

$\phi^\rho_{k,i}$ = *"product" of one of the following two types*:

$$D_r(\cdots (D_1(\beta_{ii})) \cdots), \qquad 0 \leqq r \leqq \rho,$$

$$D_r(\cdots (D_1(-L_{(\operatorname{ad}^t F, G_i)}\alpha_i)) \cdots), \qquad 0 \leqq r + t < \rho,$$

where $D_r, \cdots, D_1 \in \{L_F, \alpha_1, \cdots, \alpha_m\}$.

In addition,

(i) *For each k we have the following alternatives*:

—*Either $\phi^\rho_{k,i}$ contains no α_j, $j \neq i$, and therefore has the same decoupling property as α_i, β_{ii} themselves,*

—*Or $b^\rho_{k,i}$ is mixed, i.e., $b^\rho_{k,i}$ contains a factor g_j, $j \neq 0$, i.*

(ii) *If $\rho < \tau_i$, then* (5.2) *vanishes. Otherwise, exactly one of the $b^\rho_{k,i}$, say $b^\rho_{k^*,i}$, contains a maximal number of factors f; namely, we have*

$$b^\rho_{k^*,i} \cdot \phi_{k^*,i} = \begin{cases} (\operatorname{ad}^{\rho-\tau_i} f, g_i) \cdot \beta_{ii} & \text{if } \tau_i = 0, \\ -(\operatorname{ad}^{\rho-\tau_i} f, g_i) \cdot L_{(\operatorname{ad}^{\tau_i - 1} F, G_i)}\alpha_i & \text{if } \tau_i > 0 \end{cases}$$

and here $\phi_{k^*,i}(x^e) \neq 0$ near $x^e = 0$.

Remark. $\phi_{k^*,i}$ does not depend on ρ; therefore, the superscript ρ is dropped here. Note also that if $\tau_i > 0$ we have by the definition of the characteristic number $\tau_i - 1$ of α_i

$$(5.4) \qquad L_{(\operatorname{ad}^\rho F, G_i)}\alpha_i = \begin{cases} 0 & \text{for } 0 \leqq \rho < \tau_i - 1, \\ (-1)^{\tau_i - 1} L_{G_i} L_F^{\tau_i - 1}\alpha_i \neq 0 & \text{for } \rho = \tau_i - 1. \end{cases}$$

Proof of Lemma 5.1. Fix $i \in \{1, \cdots, m\}$. The proof proceeds by induction on ρ. For $\rho = 0$ we have by (2.6)

$$\pi_x(G_i) = g_i \cdot \beta_{ii} \quad (= 0 \text{ if } \tau_i > 0)$$

as desired. Induction step $\rho \to \rho + 1$: by assumption and (2.3a) there are vector fields $\bar{X}$, $\bar{X}' \in \operatorname{sp}\{\partial/\partial \bar{x}\}$ such that

$$(5.5) \qquad F = f + \sum_{j=1}^m g_j \alpha_j + \bar{X}, \qquad (\operatorname{ad}^\rho F, G_i) = \sum_k b^\rho_{k,i} \cdot \phi^\rho_{k,i} + \bar{X}'$$

(for notational convenience we write here f, g_j instead of $\binom{f}{0}$, $\binom{g_j}{0}$)). Now remember the following product rule for vector fields X_i, Y_j and scalar functions γ_i, δ_j:

$$X=\sum_i X_i\cdot\gamma_i,\qquad Y=\sum_j Y_j\cdot\delta_j\ \Rightarrow$$

$$[X,Y]=\sum_j Y_j\cdot(L_X\delta_j)-\sum_i X_i\cdot(L_Y\gamma_i)+\sum_{i,j}[X_i,Y_j]\cdot\gamma_i\delta_j.$$

Thus, bracketing the vector fields (5.5) we obtain

$$\begin{aligned}(\mathrm{ad}^{\rho+1}F,G_i)&=\sum_k b^{\rho}_{k,i}\cdot L_F\phi^{\rho}_{k,i}-\sum_{j=1}^{m}g_j\cdot L_{(\mathrm{ad}^{\rho}F,G_i)}\alpha_j\\ &\quad+\sum_k[f,b^{\rho}_{k,i}]\cdot\phi^{\rho}_{k,i}+[f,\bar{X}']+\sum_k\sum_{j=1}^{m}[g_j,b^{\rho}_{k,i}]\cdot\alpha_j\phi^{\rho}_{k,i}\\ &\quad+\sum_{j=1}^{m}[g_j,\bar{X}']\cdot\alpha_j+\sum_k[\bar{X},b^{\rho}_{k,i}]\cdot\phi^{\rho}_{k,i}+[\bar{X},\bar{X}'].\end{aligned}\tag{5.6}$$

Because of the decoupling property we have here

$$L_{(\mathrm{ad}^{\rho}F,G_i)}\alpha_j=0\quad\text{for } j\neq i.$$

In addition, sp$\{\partial/\partial\bar{x}\}$ is, of course, involutive and (trivially) invariant under $f, g_1,\cdots,g_m$, even under each $b\in\mathrm{Lie}\{f,\cdots,g_m\}$. It follows that all those terms in (5.6) that contain $\bar{X}$ or $\bar{X}'$ belong to sp$\{\partial/\partial\bar{x}\}$. Summing up, the action of π_x on (5.6) results exactly in a representation (5.2) with ρ now replaced by $\rho+1$. The additional statements on (5.2) follows by direct inspection of (5.6) using the induction hypothesis and (5.4). □

LEMMA 5.2. *Let* $0\leqq r\leqq s-2$, $q:=s-r$, $i_1,\cdots,i_q\in\{1,\cdots,m\}$, $i_1\neq i_2$, $r_q,\cdots,r_1$ *nonnegative integers such that* $r_q+\cdots+r_1=r$, $R_j:=r_j+\tau_{i_j}$ *for* $j=1,\cdots,q$. *Claim*:

$$\begin{aligned}&\pi_x([(\mathrm{ad}^{R_q}F,G_{i_q}),[\cdots,[(\mathrm{ad}^{R_2}F,G_{i_2}),(\mathrm{ad}^{R_1}F,G_{i_1})]\cdots]])\\ &\quad=[(\mathrm{ad}^{r_q}f,g_{i_q}),[\cdots,[(\mathrm{ad}^{r_2}f,g_{i_2}),(\mathrm{ad}^{r_1}f,g_{i_1})]\cdots]]\\ &\qquad\cdot\phi_{k^*,i_q}\cdots\phi_{k^*,i_1}+\sum_j b_j\cdot\psi_j(x^e),\end{aligned}\tag{5.7}$$

where

$$b_j\in\bigcup_{\substack{r'<r\\ s'\leqq s}}E_{r',s'}\cup\bigcup_{\substack{r'\leqq r\\ s'<s}}E_{r',s'},\quad \psi_j(x^e)\ \textit{smooth}$$

(*note that the first summand on the right-hand side is a nonzero multiple of a typical element of* $E_{r,s}$).

Proof. The proof is by induction on q. First, let $q=2$. For notational convenience we may assume without loss of generality that $i_1=1$, $i_2=2$. From Lemma 5.1 we get, for $i=1,2$,

$$(\mathrm{ad}^{R_i}F,G_i)=(\mathrm{ad}^{r_i}f,g_i)\cdot\phi_{k^*,i}+\sum_{k\neq k^*}b^{R_i}_{k,i}\cdot\phi^{R_i}_{k,i}+\bar{X}_i\tag{5.8}$$

with certain vector fields $\bar{X}_i\in$ sp$\{\partial/\partial\bar{x}\}$ and all brackets $b^{R_i}_{k,i}$ of the form (5.3). Since $k\neq k^*$, these brackets contain fewer than r_i factors f and, besides the obligatory factor

g_i, at most r_i more factors in all. We now bracket the vector fields (5.8) and obtain, by means of a computation similar to that in the preceding proof,

$$
\begin{aligned}
&[(\mathrm{ad}^{R_2}F, G_2), (\mathrm{ad}^{R_1}F, G_1)] \\
&\quad \in \sum_k b_{k,1}^{R_1} \cdot L_{(\mathrm{ad}^{R_2}F, G_2)}\phi_{k,1}^{R_1} - \sum_k b_{k,2}^{R_2} \cdot L_{(\mathrm{ad}^{R_1}F, G_1)}\phi_{k,2}^{R_2} \\
&\qquad + [(\mathrm{ad}^{r_2}f, g_2), (\mathrm{ad}^{r_1}f, g_1)] \cdot \phi_{k^*,2}\phi_{k^*,1} \\
&\qquad + \sum_{(k,k')\neq(k^*,k^*)} [b_{k,2}^{R_2}, b_{k',1}^{R_1}] \cdot \phi_{k,2}^{R_2}\phi_{k',1}^{R_1} + \mathrm{sp}\left\{\frac{\partial}{\partial \bar{x}}\right\}.
\end{aligned}
\tag{5.9}
$$

Here, in the first two sums, if a bracket b is not mixed then its ϕ factor has the decoupling property (see Lemma 5.1), and therefore the Lie derivative of this ϕ appearing in (5.9) vanishes. So the π_x projection of (5.9) contains only mixed brackets. The special form (5.7) is now verified just by counting the factors of each bracket.

The induction step $q \to q+1$ proceeds in virtually the same way as the initial step just completed. We need only the additional observation that the argument of π_x in (5.7), denoted for the moment by B, is now a mixed bracket. Therefore, by the decoupling property, $L_B\bar{\phi}_{k,i}^{\rho}=0$ for *all* functions ϕ in (5.2) (where $i=i_{q+1}$, $\rho=R_{q+1}$). It is for this reason that the induction step does not give rise to nonmixed brackets on the right-hand side of the new (5.7) corresponding to $q+1$ instead of q. □

LEMMA 5.3. *Let* $0 \leqq r \leqq s-2$. *Then* $\pi_x(E_{r,s}^e) \subset \Delta_{\mathrm{mix}}$.

Proof. For those members (5.1) (replace f, g by F, G) of $E_{r,s}^e$ whose exponents $r_q, \cdots, r_1$ are all sufficiently large, i.e., $r_j \geqq \tau_{i_j}$ for $j=1, \cdots, q$, the statement is contained in Lemma 5.2. For the others, the procedure of the proof of Lemma 5.2 can be followed all the same. The only difference is that now some of the sums (5.2) used in this proof may be empty. On the other hand, there is now no more need to identify certain nonzero contributions, so this does not matter. □

Theorem 4.1 now follows easily from these lemmas. In fact, by Lemma 5.3, $\pi_x(\Delta_{\mathrm{mix}}^e)=\sum_{r,s}\pi_x(\mathrm{sp}\, E_{r,s}^e) \subset \Delta_{\mathrm{mix}}$. On the other hand, it follows from Lemma 5.2 by a combined induction on (r, s) that $\pi_x(\Delta_{\mathrm{mix}}^e)$ indeed contains each $E_{r,s}$; therefore,

$$\pi_x(\Delta_{\mathrm{mix}}^e) \supset \mathrm{sp}\left(\bigcup_{r,s} E_{r,s}\right) = \Delta_{\mathrm{mix}}.$$

6. Examples.

Example 6.1. Isidori and Grizzle [6] proved that a system of the form

$$
\begin{aligned}
\dot{x}_1 &= u_1, & y_1 &= x_1, \\
\dot{x}_2 &= u_2, & y_2 &= x_2, \\
\dot{x}_3 &= a_3(x_1, x_2, x_3), & &
\end{aligned}
\tag{6.1}
$$

where

$$
\begin{aligned}
&a_3(0)=0, \\
&(a_3)_{x_1}(0)\neq 0, \quad (a_3)_{x_2}(0)\neq 0, \quad (a_3)_{x_3}(0)>0, \\
&(a_3)_{x_1x_2}(0)\neq 0
\end{aligned}
$$

cannot be rendered both noninteractive and stable, although it is already noninteractive and could also easily be stablized by a simple linear feedback. This fact is now easily explained by the theory just presented. The system (6.1) is already in P^* decomposed form and we have

$$P_1^* = \mathrm{sp}\left\{\frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3}\right\}, \quad P_2^* = \mathrm{sp}\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_3}\right\}, \quad P^* = \mathrm{sp}\left\{\frac{\partial}{\partial x_3}\right\}.$$

Since

$$[g_2, [g_1, f]] = \begin{pmatrix} 0 \\ 0 \\ (a_3)_{x_1 x_2} \end{pmatrix} \in \Delta_{\mathrm{mix}},$$

we have here $\Delta_{\mathrm{mix}} = P^*$. So the Δ_{mix} dynamics equals the P^* dynamics

$$\dot{x}_3 = a_3(0, 0, x_3),$$

which is unstable because of $(a_3)_{x_3}(0) > 0$. The desired result now follows from our Remark 4.6. Its proof in [6] can be directly recognized as a special case of our preceding calculations.

Example 6.2. The next example demonstrates that a nonlinear system with an unstable P^* dynamics may nevertheless be rendered both noninteractive and stable if its Δ_{mix} dynamics is stable. Consider the following modification of the preceding example:

$$\text{(6.2)} \qquad \begin{aligned} &\dot{x}_1 = u_1, \qquad y_1 = x_1, \\ &\dot{x}_2 = u_2, \qquad y_2 = x_2, \\ &\dot{x}_3 = (x_1 + x_2)^2 - x_3, \\ &\dot{x}_4 = x_1 - x_2 + x_4. \end{aligned}$$

Obviously the linearization of (6.2), and hence (6.2) itself, are stabilizable at $x = 0$. Using (3.3) we compute

$$P_1^* = \mathrm{sp}\left\{\frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_4}\right\},$$

$$P_2^* = \mathrm{sp}\left\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_4}\right\},$$

$$P^* = \mathrm{sp}\left\{\frac{\partial}{\partial x_3}, \frac{\partial}{\partial x_4}\right\}, \qquad \Delta_{\mathrm{mix}} = \mathrm{sp}\left\{\frac{\partial}{\partial x_3}\right\}.$$

Thus, (6.2) is in refined P^* decomposed form. Its P^* dynamics

$$\dot{x}_3 = -x_3, \qquad \dot{x}_4 = x_4$$

is obviously unstable, whereas the Δ_{mix} dynamics

$$\dot{x}_3 = -x_3$$

is asymptotically stable. So no static feedback can render (6.2) noninteractive and stable; yet a suitable dynamic feedback may exist, and it does indeed. Adjoin to (6.2) the equation

$$\dot{x}_5 = -x_2 + x_5.$$

In the new coordinates

$$w_1 = x_1, \qquad w_3 = x_2,$$
$$w_2 = x_4 - x_5, \qquad w_4 = x_5,$$

the (x_1, x_2, x_4, x_5) part of the thus extended system reads

$$\begin{aligned} \dot{w}_1 &= u_1, \qquad y_1 = w_1, \\ \dot{w}_2 &= w_1 + w_2, \\ \dot{w}_3 &= u_2, \qquad y_2 = w_3, \\ \dot{w}_4 &= -w_3 + w_4. \end{aligned}$$

This pair of independent controllable single-input single-output systems can, of course, easily be stabilized without affecting the noninteraction. The final adjunction of the x_3 part

$$\dot{x}_3 = (w_1 + w_2)^2 - x_3$$

obviously does not change matters.

In view of this example it is natural to ask whether the stability of the Δ_{mix} dynamics is also sufficient for noninteraction with stability in our setup. However, up to now this question is unsettled. The above procedure is not general. For instance, changing x_1 to x_1^3 in the $\dot{x}_4$ equation of (6.2) does not affect P^* and Δ_{mix}, but the procedure now leads to a (w_1, w_2) subsystem which is no longer stabilizable. It is unknown to the author whether this modified system can at all be rendered noninteractive and stable. What can be done in general is to construct dynamic noninteraction feedbacks which reduce the distribution P^{*e} of the resulting system (Σ^e) to the smallest possible dimension, namely, that of Δ_{mix}. Hence, there is no fixed dynamics bigger than the Δ_{mix} dynamics. Unfortunately, the feedbacks known up to now generally destroy the stabilizability (even in the linear case), so they are of little practical interest, and we forego a more detailed discussion.

Acknowledgments. The author thanks A. Isidori for many fruitful and encouraging discussions on the subject. The financial support of the Deutsche Forschungsgemeinschaft and of the University of Rome is also gratefully acknowledged.

OPTIMAL DESIGN OF DOMAINS WITH FREE-BOUNDARY PROBLEMS*

VIOREL BARBU† AND AVNER FRIEDMAN‡

Abstract. A domain $\tilde{\Omega}_u$ depends upon a control variable u, and its boundary consists of three parts: Γ_0, Γ_u, and $\tilde{\Gamma}_u$. The part Γ_0 is prescribed independently of u. The part Γ_u is determined directly upon prescribing the control u. The remaining part $\tilde{\Gamma}_u$ is determined as the free boundary of a variational inequality with $\tilde{\Omega}_u$ as the noncoincidence set. The problem is to choose u so that $\tilde{\Gamma}_u$ will become "as close as possible" to a given surface. Properties of the optimal control u^* are derived.

Key words. optimal control, variational inequalities, optimal design

AMS(MOS) subject classifications. 49A15, 49A35, 49A35, 34H05

1. The physical problem. Let Q be a bounded domain in $\mathbb{R}^n$ with C^2 boundary and let a, b, H be constants satisfying $0 \leqq a < b < H$. Let

$$Q_H = \{(x, y);\ x \in Q, 0 < y < H\}.$$

We introduce the set U of control functions $u(x)$:

$$U = \{u \in \text{Lip}\,(\bar{Q}), |\nabla u| \leqq \rho \text{ a.e., } a \leqq u(x) \leqq b, \text{ and } u = u_0 \text{ on } \partial Q\},$$

where u_0 is a given C^1 function satisfying

$$a < u_0 < b,$$

and ρ is a given positive number; U is a compact subset in $L^2(Q)$.

For any $u \in U$ let

$$\Omega_u = \{(x, y);\ x \in Q, u(x) < y < H\}$$

and consider the variational inequality

$$\int_{\Omega_u} \nabla z \cdot \nabla(\zeta - z)\,dx\,dy \geqq -\int_{\Omega_u} f(\zeta - z)\,dx\,dy \quad \forall \zeta \in K_u, \quad z \in K_u, \tag{1.1}$$

where

$$K_u = \{z \in H^1(\Omega_u),\ z \geqq 0 \text{ in } \Omega_u,\ z = 1 \text{ on } \{y = u(x)\},\ z = 0 \text{ on } \{y = H\}\} \tag{1.2}$$

and f is a given function in $C^{0,1}(\bar{Q}_H)$ satisfying

$$0 \leqq f \leqq C^*, \quad f_y \geqq 0 \quad (C_* \text{ positive constant}); \tag{1.3}$$

the last two conditions in (1.2) are taken in the usual trace sense (recall [12, § 4.2]).

Formally, problem (1.1) is equivalent to the obstacle problem

$$\begin{aligned} &-\Delta z = -f \quad \text{in } \{z > 0\}, \quad z \geqq 0 \quad \text{in } \Omega_u, \quad -\Delta z \geqq -f \quad \text{in } \Omega_u, \\ &z = 1 \quad \text{on } \{y = u(x)\}, \qquad z = 0 \quad \text{on } \{y = H\}, \\ &\frac{\partial z}{\partial \nu} = 0 \quad \text{on the lateral boundary of } \Omega_u. \end{aligned} \tag{1.1a}$$

Let $y=\psi(x)$ be a given function satisfying

$$\psi\in C^2(\bar Q),\quad b<\psi(x)\leqq H\quad \text{if } x\in\bar Q. \tag{1.4}$$

We wish to find a control u such that the free boundary of the corresponding solution $z=z_u$ of (1.1), (1.2) will be "as close as possible" to $\{y=\psi\}$. This problem arises in electrochemical machinery [4, p. 177], [11] whereby we wish to achieve a specific shape of the surface of a metal workpiece (the anode) by electrochemical process; the control $\{y=u(x)\}$ plays the role of the cathode part of the outer boundary of the bath containing a chemical solution, and a fixed voltage is applied along this boundary. The function f represents a source term which we can introduce into the process.

In this paper we will adopt a weak formulation of the goal of achieving a shape close to $\{y=\psi(x)\}$ (see Remark 5.2), and we will establish necessary conditions on the optimal control u. In particular, the optimal control will be uniquely and explicitly determined for $u_0\equiv$ const., u_0 depending on the domain (see Corollary 5.2). At the end of the paper we will briefly consider other control sets.

2. The ε-problem. Let $X=(x,y)$, $dX=dx\,dy$.

Let $F(X,z)$ be a function satisfying

$$F\in C^1(\bar Q_H\times\mathbb{R}),\quad F\geqq -C_0\quad (C_0 \text{ const.}). \tag{2.1}$$

Introduce the functional

$$J(u)=\int_{\Omega_u}F(x,z_u)\,dX, \tag{2.2}$$

where z_u is the solution of (1.1), (1.2), and consider the following problem.

PROBLEM (P). Find u^* such that

$$u^*\in U,\quad J(u^*)=\min_{u\in U}J(u).$$

THEOREM 2.1. *There exists a solution u^* of Problem (P).*

Proof. Take a minimizing sequence u_m and denote the corresponding solution of (1.1), (1.2) by z_m. By standard estimates for variational inequalities [5], [9] we deduce that, for a subsequence, $u_m\to u^*$, $z_m\to z^*$ uniformly, and (u^*,z^*) is a solution of (1.1), (1.2). Clearly, u^* is then a solution of Problem (P).

From now on we will deal with a specific minimizer u^* and denote the corresponding solution of (1.1), (1.2) by z^*. We also set

$$\Omega^*=\Omega_{u^*}.$$

In order to derive necessary conditions on u^*, we wish to consider ε-approximate problems for which the cost function is differentiable; this procedure was used in [2] and [6].

Let $j\in C_0^\infty(\{|x|<1\})$, $j\geqq 0$, $\int j(x)\,dx=1$, $j_\varepsilon(x)=\varepsilon^{-n}j(x/\varepsilon)$ for any $\varepsilon>0$, and define the mollifier

$$\mu_\varepsilon(u)=\int_Q j_\varepsilon(x-\xi)u(\xi)\,d\xi.$$

Note that $\mu_\varepsilon(u)\to u$ in $C^\alpha(Q)$ for any $0<\alpha<1$.

Introduce functions $\beta_\varepsilon(z)\in C^\infty$ in z $(0<\varepsilon<1)$ such that

$$\begin{aligned}&\beta_\varepsilon(z)\to 0\quad \text{if } z>0,\quad \varepsilon\to 0,\qquad \beta_\varepsilon(z)\to-\infty\quad \text{if } z<0,\quad \varepsilon\to 0;\\ &\beta_\varepsilon'(z)\geqq 0\quad \text{for all } z,\quad \text{and}\quad \beta_\varepsilon(\varepsilon)=0,\quad \beta_\varepsilon(0)=-C_*\end{aligned} \tag{2.3}$$

with C_* as in (1.3). Consider the elliptic problem:

$$(2.4)\qquad -\Delta z+\beta_\varepsilon(z)=-f \quad \text{in } \Omega_{\mu_\varepsilon(u)},\quad 0\leqq\varepsilon<1,$$

$$z=1 \quad \text{on } \{y=\mu_\varepsilon(u)\},\qquad z=0 \quad \text{on } \{y=H\},$$

$$(2.5)\qquad \frac{\partial z}{\partial \nu}=0 \quad \text{on the lateral boundary of } \Omega_{\mu_\varepsilon(u)}.$$

We denote the solution by z_u^ε; note that z_u^ε belongs to $H^1(\Omega_{\mu_\varepsilon(u)})\cap C^{2,\alpha}(\Omega_{\mu_\varepsilon(u)})$. Consider the functional

$$J_\varepsilon(u)=\int_{\Omega_{\mu_\varepsilon(u)}} F(X,z_u^\varepsilon)\,dX+\frac{1}{2}\int_Q |u-u^*|^2\,dx.$$

PROBLEM (P_ε). Find $u_\varepsilon\in U$ such that

$$u_\varepsilon\in U,\qquad J_\varepsilon(u_\varepsilon)=\min_{u\in U} J_\varepsilon(u).$$

Proceeding as in the proof of Theorem 2.1 we can show that there exists a solution u_ε of Problem (P_ε); we denote the corresponding solution of (2.4), (2.5) by $z_{u_\varepsilon}^\varepsilon$. Furthermore, we have the following lemma.

LEMMA 2.2. *As* $\varepsilon\to 0$,

$$(2.6)\qquad u_\varepsilon\to u^* \quad \textit{weakly in } W^{1,p}(Q) \textit{ and strongly in } C^0(\bar{Q}),$$

$$(2.7)\qquad z_{u_\varepsilon}^\varepsilon\to z^* \quad \textit{weakly in } W^{2,p}_{\text{loc}}(\Omega_*)$$

for any $1<p<\infty$.

Proof. For any sequence $\varepsilon\to 0$ there is a subsequence such that

$$(2.8)\qquad u_\varepsilon\to u_1,\qquad z_{u_\varepsilon}^\varepsilon\to z_1$$

in the sense of (2.6), (2.7). Furthermore, taking $\varepsilon\to 0$ in the relation

$$J_\varepsilon(u_\varepsilon)\leqq J_\varepsilon(u^*),$$

we arrive at the inequality

$$\int_{\Omega_{u_1}} F(X,z_1)+\frac{1}{2}\limsup_{\varepsilon\to 0}\int_Q |u_\varepsilon-u^*|^2\leqq\int_{\Omega^*} F(X,z^*)\leqq J(u^*).$$

From the optimality of u^* it then follows that

$$\limsup_{\varepsilon\to 0}\int_Q |u_\varepsilon-u^*|^2=0$$

and therefore also $u_1=u^*$, $z_1=z^*$. Clearly, (2.6), (2.7) now follow from (2.8).

LEMMA 2.3. *For any* $u\in U$ *the corresponding solution* $z_\varepsilon\equiv z_{u_\varepsilon}^\varepsilon$ *of* (2.4), (2.5) *satisfies*

$$(2.9)\qquad 0\leqq z_\varepsilon\leqq 1,$$

$$(2.10)\qquad \frac{\partial z_\varepsilon}{\partial y}\leqq 0.$$

Proof. Suppose z_ε takes negative minimum at a point $X_0=(x_0,y_0)$ in $\Omega_{\mu_\varepsilon(u)}$. Then $\beta_\varepsilon(z_\varepsilon(X_0))<-C_*$ by (2.3). Since also $\Delta z_\varepsilon(X_0)\geqq 0$, (2.4) gives $f(X_0)>C_*$, a contradiction to (1.3). Thus the minimum of z_ε is achieved only on the boundary, and (by (2.5)) it is greater than or equal to zero.

Since $\beta_\varepsilon(1)=0$, $z\equiv 1$ is a supersolution of (2.4), (2.5); it follows (by comparison) that $z_\varepsilon \leqq 1$.

The function $w=\partial z_\varepsilon/\partial y$ satisfies

$$-\Delta w+\beta_\varepsilon'(z_\varepsilon)w=-f_y \quad \text{in } \Omega_{\mu_\varepsilon(u)},$$

and

$$\begin{aligned} &w\leqq 0 && \text{on } \{y=H\} \quad (\text{since } z_\varepsilon \geqq 0 \text{ in } \Omega_{\mu_\varepsilon(u)}),\\ &w\leqq 0 && \text{on } \{y=\mu_\varepsilon(u)\} \quad (\text{since } z_\varepsilon \leqq 1 \text{ in } \Omega_{\mu_\varepsilon(u)}),\\ &\frac{\partial w}{\partial \nu}=0 && \text{on the lateral boundary of } \Omega_{\mu_\varepsilon(u)}. \end{aligned}$$

Hence proceeding formally to use the maximum principle, we deduce that $w\leqq 0$, and (2.10) thus follows. Since w may not actually be continuous (or even bounded) at the corner points of $\Omega_{\mu_\varepsilon(u)}$, we should proceed to establish assertion (2.10) either by approximating $y=\mu_\varepsilon(u)$ so that it becomes horizontal near ∂Q (and then w is continuous in $\overline{\Omega_{\mu_\varepsilon(u)}}$) or else by working with the weak equation for w and applying the maximum principle for weak solutions.

3. The optimality conditions for (P_ε). We denote by u_ε a solution of Problem (P_ε) and by z_ε the corresponding solution of (1.1), (1.2); set $\Omega_\varepsilon=\Omega_{\mu_\varepsilon(u_\varepsilon)}$, $\Gamma=\{(x,H);\ x\in Q\}$, $\Gamma_\varepsilon=\{(x,y);\ y=\mu_\varepsilon(x), x\in Q\}$, $\Gamma_{1,\varepsilon}=$ the lateral boundary of Ω_ε.

Let v be any function such that $u_\varepsilon+\delta v\in U$ for all sufficiently small $\delta>0$, and introduce the quotient

$$q_{\varepsilon,\delta}=\frac{z^\varepsilon_{u_\varepsilon}+\delta v-z_\varepsilon}{\delta}.$$

LEMMA 3.1. *As* $\delta\to 0$,

$$q_{\varepsilon,\delta}\to w_\varepsilon \quad \textit{weakly in } W^{2,r}_{\text{loc}}(\Omega_\varepsilon) \tag{3.1}$$

for any $1<r<\infty$, *where* w_ε *is the weak solution in* $H^1(\Omega_\varepsilon)$ *of*

$$-\Delta w_\varepsilon+\beta_\varepsilon'(z_\varepsilon)w_\varepsilon=0 \quad \textit{in } \Omega_\varepsilon, \tag{3.2}$$

$$w_\varepsilon(x,y)=-\frac{\partial z_\varepsilon(x,y)}{\partial y}\mu_\varepsilon(v)(x) \quad \textit{on } \Gamma_\varepsilon, \tag{3.3}$$

$$w_\varepsilon=0 \quad \textit{on } \Gamma, \tag{3.4}$$

$$\frac{\partial w_\varepsilon}{\partial \nu}=0 \quad \textit{on the lateral boundary } \Gamma_{1,\varepsilon}. \tag{3.5}$$

Remark 3.1. Since w_ε is only in $H^1(\Omega_\varepsilon)$, it should be mentioned that $\partial w_\varepsilon/\partial\nu$ makes sense as an element of $H^{-1/2}(\Gamma_{1,\varepsilon})$, and the solution to (3.2)-(3.5) is defined in the sense that

$$\begin{aligned} &\int_{\Omega_\varepsilon} w_\varepsilon(x,y)[\zeta(x,y)\beta_\varepsilon'(z_\varepsilon)-\Delta\zeta(x,y)]\,dX\\ &\quad=\int_{\Gamma_\varepsilon}\frac{\partial z_\varepsilon(x,y)}{\partial y}\frac{\partial\zeta(x,y)}{\partial\nu}\mu_\varepsilon(v)(x)\,dS \end{aligned} \tag{3.6}$$

for all $\zeta\in H^2(\Omega_\varepsilon)$ such that $\zeta=0$ on $\Gamma\cup\Gamma_\varepsilon$ and $\partial\zeta/\partial\nu=0$ on $\Gamma_{1,\varepsilon}$.

Proof. Taking the difference of the elliptic equations for $z^\varepsilon_{u_\varepsilon+\delta v}$ and z_ε and applying L^p elliptic estimates, we find that

$$\|z^\varepsilon_{u_\varepsilon}+\delta v-z_\varepsilon\|_{W^{2,r}(\Omega^*)}\leqq\tilde{C}\delta$$

for any compact subdomain Ω^* of Ω_ε; $\tilde{C}$ depends on ε and Ω^*. It follows that for any sequence $\delta \to 0$ there is a subsequence for which (3.1) holds. Since (3.4) and (3.5) are rather obviously satisfied, it remains to establish (3.3). Using the fact that the boundaries $\{y = \mu_\varepsilon(u_\varepsilon)\}$ and $\{y = \mu_\varepsilon + \delta v)\}$ are smooth, we can compute $q_{\varepsilon,\delta}$ on $\{y = \mu_\varepsilon(u_\varepsilon) + C\delta\}$, for any $C > \sup v$. Setting $\theta_\delta(x) = \mu_\varepsilon(u_\varepsilon)(x) + C\delta$, we deduce that

$$q_{\varepsilon,\delta}(x, \theta_\delta(x)) = -\frac{\partial z^\varepsilon_{u_\varepsilon + \delta v}}{\partial y}(x, \theta_\delta(x))[\mu_\varepsilon(u_\varepsilon + \delta v)(x) - \theta_\delta(x)]$$

$$+\frac{\partial z_\varepsilon}{\partial y}(x, \theta_\delta(x))[\mu_\varepsilon(u_\varepsilon)(x) - \theta_\delta(x)] + o(1)$$

as $\delta \to 0$, from which (3.3), in the sense of (3.6), easily follows.

For any convex set U in a real Banach space X we define

$$h_U(u) = \begin{cases} 0 & \text{if } u \in U, \\ +\infty & \text{if } u \notin U. \end{cases}$$

Recall [1] that the subdifferential $\partial h_U(u)$ is defined as follows:

$w \in \partial h_U(u)$ if and only if $w \in X^*$ (the dual of X) and $h_U(u+v) - h_U(u) \geqq (w, v)$ $\forall v \in X$;

here (w, v) denotes the application of the bounded linear functional w to v. Recalling the definition of $h_U(u+v)$, we see that

$$\partial h_U(u) = \{w \in X;\ (w, u - v) \geqq 0\ \forall v \in U\}. \tag{3.7}$$

Since $u \to h_U(u)$ is a convex function, we easily find that

(3.8) $w \in \partial h_U(u)$ if and only if $\limsup_{\delta \downarrow 0} (h_U(u + \delta v) - h_U(u))/\delta \geqq (w, v)$, for all $v \in X$ such that $u + \delta v \in U$.

From the optimality of $(u_\varepsilon, z_\varepsilon)$ we have

$$\int_{\Omega_{\mu_\varepsilon}(u_\varepsilon + \delta v)} F(X, z^\varepsilon_{u_\varepsilon + \delta v)} - \int_{\Omega_\varepsilon} F(X, z_\varepsilon) + \int_Q \left[u_\varepsilon - u^* + \frac{\delta}{2} v\right] \delta v \geqq 0 \quad \text{if } u_\varepsilon + \delta v \in U. \tag{3.9}$$

Dividing by δ and letting $\delta \to 0$, we get

$$\begin{aligned} &\int_{\Omega_\varepsilon} F_z(X, z_\varepsilon) w_\varepsilon - \int_Q F(X, z_\varepsilon(x, \mu_\varepsilon(u_\varepsilon)(x))) \mu_\varepsilon(v)(x)\, dx \\ &\quad + \int_Q (u_\varepsilon - u^*) v \geqq 0 \quad \text{if } u_\varepsilon + \delta v \in U \quad \text{for all small } \delta > 0. \end{aligned} \tag{3.10}$$

We will rewrite this condition more effectively by introducing the "adjoint variable" p_ε, defined as the solution of the elliptic problem:

$$\begin{aligned} &-\Delta p_\varepsilon + \beta'_\varepsilon(z_\varepsilon) p_\varepsilon = -F_z(X, z_\varepsilon) \quad \text{in } \Omega_\varepsilon, \\ &p_\varepsilon = 0 \quad \text{on } \Gamma \cup \Gamma_\varepsilon, \\ &\frac{\partial p_\varepsilon}{\partial \nu} = 0 \quad \text{on } \Gamma_{1,\varepsilon}. \end{aligned} \tag{3.11}$$

Note that p_ε is smooth up the boundary $\{y = \mu_\varepsilon(u_\varepsilon)\}$; furthermore,

$$p_\varepsilon \in H^1(\Omega_\varepsilon) \cap H^2(\Omega^\delta_\varepsilon) \quad \forall \text{ small } \delta > 0,$$

where

$$\Omega_\varepsilon^\delta = \{(x, y);\ x \in Q, \operatorname{dist}(x, \partial Q) > \delta, \mu_\varepsilon(u_\varepsilon(x)) < y < H\}.$$

We can transform the first integral on the left-hand side of (3.10), formally as follows:

$$\begin{aligned}\int_{\Omega_\varepsilon} F_z(X, z_\varepsilon) w_\varepsilon &= \int_{\Omega_\varepsilon} [\Delta p_\varepsilon - \beta'_\varepsilon(z_\varepsilon) p_\varepsilon] w_\varepsilon \\ &= \int_{\partial\Omega_\varepsilon} \left(\frac{\partial p_\varepsilon}{\partial \nu} w_\varepsilon - p_\varepsilon \frac{\partial w_\varepsilon}{\partial \nu}\right) \quad \text{(by (3.2))} \\ &= -\int_Q \left[\frac{\partial z_\varepsilon}{\partial y} \cdot \frac{\partial p_\varepsilon}{\partial \nu}\right]_{y=\mu_\varepsilon(u_\varepsilon)} \mu_\varepsilon(v)[1+|\nabla \mu_\varepsilon(u_\varepsilon)|^2]^{1/2}\, dx \quad \text{(by (3.3)-(3.5))}.\end{aligned} \tag{3.12}$$

To proceed rigorously we take $\alpha_\delta \in C_0^\infty(\Omega_\varepsilon)$ such that $\alpha_\delta = 1$ in $\Omega_\varepsilon^\delta$ and $\alpha_\delta = 0$ in $\Omega_\varepsilon \backslash \Omega_\varepsilon^{\delta/2}$. We set $q_{\varepsilon,\delta} = p_\varepsilon \alpha_\delta$ and note that

$$q_{\varepsilon,\delta} \in H^2(\Omega_\varepsilon), \quad -\Delta q_{\varepsilon,\delta} + \beta'_\varepsilon(z_\varepsilon) q_{\varepsilon,\delta} = -\alpha_\delta F_z(X, z_\varepsilon) + \rho_{\varepsilon,\delta} \quad \text{in } \Omega_\varepsilon,$$

$$q_{\varepsilon,\delta} = 0 \quad \textit{on } \Gamma \cup \Gamma_\varepsilon, \qquad \frac{\partial q_{\varepsilon,\delta}}{\partial \nu} = 0 \quad \text{on } \Gamma_{1,\varepsilon},$$

where

$$\|\rho_{\varepsilon,\delta}\|_{L^2(\Omega_\varepsilon)} \leqq C\delta.$$

If we take $\zeta = q_{\varepsilon,\delta}$ in (3.6), we get the following precise (and modified) version of (3.12):

$$\begin{aligned}\int_{\Omega_\varepsilon} F_z(X, z_\varepsilon) w_\varepsilon = -\int_Q &\left[\frac{\partial z_\varepsilon}{\partial y} \cdot \frac{\partial q_{\varepsilon,\delta}}{\partial \nu}\right]_{y=\mu_\varepsilon(u_\varepsilon)} \mu_\varepsilon(v)[1+|\nabla \mu_\varepsilon(u_\varepsilon)|^2]^{1/2}\, dx \\ &+ \int_{\Omega_\varepsilon} [F_z(X, z_\varepsilon)(1-\alpha_\delta) - \rho_{\varepsilon,\delta}] w_\varepsilon.\end{aligned} \tag{3.13}$$

Substituting this into (3.10), we get

$$\begin{aligned}\int_Q \Bigg\{ -\mu_\varepsilon &\left\{\frac{\partial z_\varepsilon}{\partial y} \cdot \frac{\partial q_{\varepsilon,\delta}}{\partial \nu} [1+|\nabla \mu_\varepsilon(u_\varepsilon)|^2]^{1/2}\right\} \\ &- \mu_\varepsilon\{F(X, z_\varepsilon)\mu_\varepsilon(u_\varepsilon)\} + (u_\varepsilon - u^*) - \varphi_\delta \Bigg\} v \geqq 0\end{aligned} \tag{3.14}$$

if $u_\varepsilon + \delta v \in U$ for all small $\delta > 0$, where

$$\|\varphi_\delta\|_{L^2(\Omega)} \leqq C\delta.$$

Since $p_\varepsilon = q_{\varepsilon,\delta}$ in $\Omega_\varepsilon^\delta$, letting $\delta \to 0$ in (3.14) and recalling (3.8), we conclude that

$$\begin{aligned}\mu_\varepsilon &\left[\frac{\partial z_\varepsilon}{\partial y}(x, \mu_\varepsilon(u_\varepsilon)(x) \frac{\partial p_\varepsilon}{\partial \nu}(x, \mu_\varepsilon(u_\varepsilon)(x)(1+|\nabla \mu_\varepsilon(u_\varepsilon)|^2)^{1/2}\right] \\ &+ \mu_\varepsilon[F(X, z_\varepsilon(x, \mu_\varepsilon(u_\varepsilon)(x)))] \in \partial h_U(u_\varepsilon + (u_\varepsilon - u^*)),\end{aligned} \tag{3.15}$$

where U is the control set, considered as a subset of $L^2(Q)$. We summarize in Theorem 3.2.

THEOREM 3.2. *If* $(u_\varepsilon, z_\varepsilon, \Omega_\varepsilon)$ *is a solution of Problem* (P_ε), *then there exists a unique solution* p_ε *of* (3.11) *such that* (3.15) *holds.*

In order to apply this result we need to analyze the structure of $\partial h_U(u)$; this is done in the following section.

4. The structure of ∂h_U.

THEOREM 4.1. *Assume that there is a $g \in W^{1,\infty}(Q)$ such that $g = u_0$ in ∂Q and $\|\nabla g\|_{L^\infty(Q)} < \rho$. Then, for any $u \in U$, $w \in \partial h_U(u)$ is and only if w has the form*

$$w = -\text{div}\,\theta + \eta \quad \textit{in } Q, \tag{4.1}$$

where

$$\begin{aligned} &\theta \in (L^1(Q))^n, \\ &\theta(x) = 0 \quad \textit{a.e. in } \{x \in Q; |\nabla u(x)| < \rho\}, \\ &\theta(x) = \lambda(x)\nabla u(x) \quad \textit{a.e. in } \{x \in Q; |\nabla u(x)| = \rho\}, \\ &\textit{where } \lambda \in L^2(Q), \quad \lambda(x) \geqq 0 \quad \textit{a.e. } x \in Q \end{aligned} \tag{4.2}$$

and

$$\begin{aligned} &\eta \in L^2(Q), \\ &\eta(x) = 0 \quad \textit{a.e. in } \{x \in Q;\ a < u(x) < b\}, \\ &\eta(x) \leqq 0 \quad \textit{a.e. in } \{x \in Q;\ u(x) = a\}, \\ &\eta(x) \geqq 0 \quad \textit{a.e. in } \{x \in Q;\ u(x) = b\}. \end{aligned} \tag{4.3}$$

Proof. Observe first that if w is given by (4.1)-(4.3) then for any $v \in U$,

$$\begin{aligned} \int_Q w(x)(u(x) - v(x))\,dx &= -\int_Q \text{div}\,\theta(u - v)\,dx + \int_Q \eta(u - v)\,dx \\ &\geqq -\int_Q \text{div}\,\theta(u - v)\,dx = \int_Q (\theta, \nabla(u - v))\,dx \geqq 0; \end{aligned}$$

thus w belongs to $\partial h_U(u)$.

To prove the converse, write $U = U_0 \cap U_1$ where

$$U_0 = \{u \in W^{1,\infty}(Q); |\nabla u(x)| \leqq \rho \text{ a.e. in } Q;\ u = u_0 \text{ on } \partial Q\},$$
$$U_1 = \{u \in L^2(Q);\ a \leqq u(x) \leqq b \text{ a.e. in } \in Q\}$$

and set $h_i = h_{U_i}$, $i = 0, 1$.

It is easily seen that

$$\eta \in \partial h_1(u) \tag{4.4}$$

if and only if η satisfies (4.3).

Next we show that

$$w \in \partial h_0(u) \tag{4.5}$$

if and only if $w = -\text{div}\,\theta$ where θ satisfies (4.2). It is easily seen that if $w = -\text{div}\,\theta$ where θ satisfies (4.2) then w satisfies (4.5). To prove the converse, let $w \in \partial h_0(u) \subset L^2(Q)$. Since $w \in L^2(Q)$, there is $\xi \in (H^1(Q))^n$ such that $w(x) = -\text{div}\,\xi(x)$ almost everywhere in Q. By definition of $\partial h_0(u)$ we then find that $\xi \in \partial h_K(\nabla u)$ almost everywhere in Q where

$$K = \{\eta \in (L^\infty(Q))^n;\ \eta = \nabla v \text{ a.e. in } Q, v \in U_0\};$$

that is,

$$\int_Q (\xi, \nabla u - \eta)\,dx \geqq 0 \quad \forall \eta \in K. \tag{4.6}$$

We may represent K as $K=K_1\cap K_2$, where

$$K_1=\{\eta\in L^\infty(Q))^n;\ \eta=\nabla v,\ v\in W^{1,\infty}(Q),\ v=u_0 \text{ on } \partial Q\}.$$
$$K_2=\{\eta\in L^\infty(Q))^n;\ |\eta(x)|\leqq\rho \text{ a.e. in } Q\}.$$

Let us denote again $\partial h_K:(L^\infty(Q))^n\to((L^\infty))^n)^*$ the subdifferential of h_K viewed as function from $(L^\infty(Q))^n$ to $\bar{R}=(-\infty,+\infty]$. Then

$$\partial h_K(\eta)=\{\mu\in((L^\infty(Q))^n)^*;\ \mu(\eta-\nu)\geqq 0\ \forall\nu\in K\}$$

where $((L^\infty(Q))^n)^*$ is the dual space of $L^\infty(Q))^n$ and $\mu(\eta-\nu)$ is the value of measure μ in $\eta-\nu$. By assumption of the theorem we see that $g\in(\text{int } K_2)\cap K_1$ where int is taken in the $(L^\infty(Q))^n$ topology. Since $(\text{int } K_2)\cap K_1$ is nonempty, according to a well-known result due to Rockafellar [14] we have

$$\partial h_K=\partial h_{K_1}+\partial h_{K_2},$$

where $\partial h_{K_i}:(L^\infty(Q))^n\to((L^\infty(Q))^n)^*$ are subdifferentials of h_{K_i} viewed as functions from $(L^\infty(Q))^n$ into $\bar{R}$. Hence $\xi=\mu_1+\mu_2$ where $\mu_i\in\partial h_{K_i}(\nabla u)$. Let us denote by μ_i^a the absolutely continuous part of the measure μ_i. Then $\mu_i^a\in(L^1(Q))^n$ and, since $\xi\in(L^1(Q))^n$ (in fact ξ is even in $(H^1(Q))^n$), we must have that $\xi=\mu_1^a+\mu_2^a$.

We have

$$h_{K_2}(\eta)=\int_\Omega h(\eta(x))\,dx\quad\forall\eta\in(L^\infty(Q))^n,$$

where $h(\eta)=0$ if $|\eta|\leqq\rho$ and $h(\eta)=+\infty$ if $|\eta|>\rho$. But then, by Corollary 1.3 of [15],

$$\mu_2^a(x)\in\partial h(\nabla u(x))\quad\text{a.e. in } Q.$$

Since $\partial h(\eta)=0$ for $|\eta|<\rho$, $\partial h(\eta)=\{\lambda\eta,\ \lambda\geqq 0\}$ if $|\eta|=\rho$, we conclude that

$$\begin{aligned}&\mu_2^a(x)=0 &&\text{a.e. in } \{x\in Q;\ |\nabla u(x)|<\rho\},\\ &\mu_2^a(x)=\lambda\nabla u(x) &&\text{a.e. in } \{x\in Q;\ |\nabla u(x)|=\rho\},\end{aligned}\tag{4.7}$$

where $\lambda\in L^2(Q)$, $\lambda\geqq 0$ almost everywhere in Q.

Since $\partial h_{K_1}(\nabla u)$ is just the set of normals (in $((L^\infty(Q))^n)^*$) to the linear subspace $\{\eta\in(L^\infty(Q))^n;\ \eta=\nabla v,\ v\in W_0^{1,\infty}(Q)\}$ at ∇u, so is μ_1^a. Hence,

$$\int_Q \mu_1^a(x)\nabla v(x)\,dx=0\quad\forall v\in W_0^{1,\infty}(Q),\ v=0 \text{ on } \partial Q,$$

which yields

$$\operatorname{div}\mu_1^a=0\quad\text{a.e. in } Q.\tag{4.8}$$

Recalling that $\xi=\mu_1^a+\mu_2^a$ and using (4.7), (4.8) it follows that $w=-\operatorname{div}\xi=-\operatorname{div}\theta$ where $\theta=\xi-\mu_1^a$ satisfies (4.2).

To complete the proof of Theorem 4.1 we will need the following lemma [1, p. 28].

LEMMA 4.2. *Let A, B be maximal monotone operators in a real Hilbert space and assume that $D(A)\cap D(B)\neq 0$ and that*

$$(\xi,\eta)\geqq 0\quad\forall\xi\in Au,\quad\eta=B_\lambda u,\quad u\in D(A),\tag{4.9}$$

where $B_\lambda=\lambda^{-1}(1-(1+\lambda B^{-1}))$. Then $A+B$ is a maximal monotone operator.

We will apply this lemma with $A=\partial h_0$ and $B=\partial h_1$. We first observe that

$$(\xi,\eta)=0\quad\forall\xi\in Au,\quad\eta\in Bu,\quad u\in D(A)\cap D(B)\tag{4.10}$$

since by (4.4) and (4.5), $\xi=0$ almost everywhere in $\{x;\ \eta(x)\neq 0\}$. Next we note that $(1+\lambda B)^{-1}D(A)\subset D(A)$ for all $\lambda>0$. Indeed for any $u\in D(A)=U_0$,

$$(1+\lambda B)^{-1}u=\operatorname{Proj}\frac{u}{D(B)}=\begin{cases} u & \text{a.e. in } \{x;\ a\leqq u(x)\leqq b\},\\ a & \text{a.e. in } \{x;\ u(x)\leqq a\},\\ b & \text{a.e. in}\{x;\ u(x)\geqq b\}.\end{cases}$$

Thus since $\alpha\leqq u_0\leqq b$ the latter implies that $(1+\lambda B)^{-1}u\in U_0$. Also, by monotonicity of A,

$$(Au-A(1+\lambda B)^{-1}u,\ B_\lambda u)\geqq 0.$$

Since $B_\lambda u\in B(1+\lambda B)^{-1}u$, we conclude (using (4.10)) that

$$(Au,\ B_\lambda u)\geqq (A(1+\lambda B)^{-1}u,\ B(1+\lambda B)^{-1}u)\geqq 0$$

for any $u\in D(A)$.

We have thus verified the condition (4.9). It follows that the mapping $u\to \partial h_0(u)+\partial h_1(u)$ is maximal monotone. Since $\partial h_0+\partial h_1\subset \partial h_U$ we conclude that, in fact,

$$\partial h_0(u)+\partial h_1(u)=\partial h_U(u)$$

and Theorem 4.1 follows from the preceding characterizations of (4.4), (4.5).

5. Properties of the minimizer u^*. In this section we will apply Theorem 3.2 in order to deduce properties of the minimizer u^*. We take

$$F(X,z)=(z-z^0(X))^2, \tag{5.1}$$

where $z^0(x,y)$ satisfies

$$\Delta z^0\leqq f \quad \text{in } \bar{Q}_H, \tag{5.2}$$

$$z^0>1 \quad \text{in } \bar{Q}_H\cap\{a\leqq y\leqq b\}, \tag{5.3}$$

$$z^0>0 \quad \text{in } \overline{Q_H}, \tag{5.4}$$

$$\frac{\partial z^0}{\partial \nu}\geqq 0 \quad \text{on } \partial Q\times(0,H). \tag{5.5}$$

By comparison, $u^*<z^0$ in $\bar{Q}_H$ and, hence, if ε is sufficiently small,

$$z_\varepsilon-z^0\leqq -c_0<0 \quad \text{in } \Omega_\varepsilon, \tag{5.6}$$

where c_0 is a constant independent of ε. It follows that

$$-F_z(X,z_\varepsilon(X))=-2(z_\varepsilon-z^0)\geqq 2c_0>0 \quad \text{in } \Omega_\varepsilon.$$

Hence, we can apply the maximum principle to p_ε (in (3.11)) and deduce that

$$p_\varepsilon>0 \quad \text{in } \Omega_\varepsilon. \tag{5.7}$$

Since $p_\varepsilon=0$ on $\{y=\mu_\varepsilon(u_\varepsilon)\}$ we also get

$$\frac{\partial p_\varepsilon}{\partial \nu}<0 \quad \text{on } \{y=\mu_\varepsilon(u_\varepsilon)(x)\}. \tag{5.8}$$

Recalling (2.10) we conclude that the first term on the left-hand side of (3.15) is nonnegative. From (5.1), (5.6) we get

$$F(X, z_\varepsilon(X)) \geqq c_1 > 0 \quad \text{on } \Omega_\varepsilon,$$

where c_1 is a constant independent of ε. It follows that the left-hand side of (3.15) is strictly positive, independently of ε; i.e.,

$$w_\varepsilon + (u_\varepsilon - u^*) \geqq 2c > 0 \quad \text{for some } w_\varepsilon \in \partial h_U(u_\varepsilon), \tag{5.9}$$

where c is a constant independent of ε; in view of (2.6),

$$w_\varepsilon \geqq c > 0 \quad \text{for some } w_\varepsilon \in \partial h_U(u_\varepsilon) \tag{5.10}$$

if ε is sufficiently small. We will assume that

$$\|\nabla u_0\|_{L^\infty(Q)} < \rho. \tag{5.11}$$

Then, by Theorem 4.1 applied to w_ε,

$$-\text{div } \theta_\varepsilon + \eta_\varepsilon \geqq c > 0 \quad \text{a.e. in } Q, \tag{5.12}$$

where $\theta_\varepsilon \in (L^1(Q))^n$ and $\eta_\varepsilon \in L^2(Q)$ satisfy (4.2), (4.3); i.e.,

$$\nabla u_\varepsilon(x) = \rho \frac{\theta_\varepsilon(x)}{|\theta_\varepsilon(x)|} \quad \text{a.e. in } \{x \in Q;\ \theta_\varepsilon(x) \neq 0\}, \quad u_\varepsilon = u_0 \quad \text{on } \partial Q, \tag{5.13}$$

$$\begin{aligned} \eta_\varepsilon(x) &= 0 \quad \text{a.e. in } \{x;\ a < u_\varepsilon(x) < b\}, \\ \eta_\varepsilon(x) &\leqq 0 \quad \text{a.e. in } \{x;\ u_\varepsilon(x) = a\}, \\ \eta_\varepsilon(x) &\geqq 0 \quad \text{a.e. in } \{x;\ u_\varepsilon(x) = b\}. \end{aligned} \tag{5.14}$$

In particular, we see by (5.12) and (5.14) that $\theta_\varepsilon(x) \neq 0$ almost everywhere in $\{x \in Q;\ u_\varepsilon(x) < b\}$ and, therefore,

$$|\nabla u_\varepsilon(x)| = \rho \quad \text{a.e. in } Q_\varepsilon \equiv \{x \in Q;\ u_\varepsilon(x) < b\}. \tag{5.15}$$

In other words, $u_\varepsilon \in W^{1,\infty}(Q)$ is a weak solution in Q_ε of the eikonal equation

$$|\nabla u_\varepsilon| = \rho. \tag{5.16}$$

Since, in general, equation (5.16) with Dirichlet condition has an infinite number of weak solutions (i.e., solutions $u \in W^{1,\infty}(Q_\varepsilon)$ that satisfy almost everywhere the equation) it is not clear for the moment what u_ε looks like.

Recall [3] that $u \in C(G)$ (G an open subset of $\mathbb{R}^n$) is called a viscosity solution of (5.16) provided, for any $\phi \in C^1(G)$, if $u - \phi$ attains a local maximum at $x_0 \in G$ then $|\nabla \phi(x_0)| \leqq \rho$, and if $u - \phi$ attains a local minimum at $x_0 \in G$ then $|\nabla \phi(x_0)| \geqq \rho$.

An equivalent definition is the following (see [3]): Set

$$D^+u(x_0) = \{p \in \mathbb{R}^n;\ \limsup_{x \to x_0} [u(x) - u(x_0) - p \cdot (x - x_0)]|x - x_0|^{-1} \leqq 0\},$$

$$D^{-1}u(x_0) = \{p \in \mathbb{R}^n;\ \liminf_{x \to x_0} [u(x) - u(x_0) - p \cdot (x - x_0)]|x - x_0|^{-1} \geqq 0\}.$$

Then, $u \in C(G)$ is a viscosity solution if

$$|p| \leqq \rho \quad \text{for any } x_0 \in G, \quad p \in D^+u(x_0),$$

$$|p| \geqq \rho \quad \text{for any } x_0 \in G, \quad p \in D^-u(x_0).$$

From this definition it follows that if $u \in W^{1,\infty}(G)$ is a viscosity solution then it is also a weak solution; i.e., it satisfies the equation $|\nabla u| = \rho$ almost everywhere in G.

A function $u \in C(G)$ is said to be *semiconcave* if for any $\delta > 0$ there exist $C_\delta > 0$ such that $u(x) - C_\delta |x|^2$ is concave on every convex subset of

$$G_\delta \equiv \left\{ x \in G; |x| < \frac{1}{\delta}, \operatorname{dist}(x, \partial G) > \delta \right\}.$$

A function $u \in C(G)$ is said to be *semisuperharmonic* if for any $\delta > 0$ there exist $C_\delta > 0$ such that $\Delta u \leqq C_\delta$ in G_δ in the distribution sense.

Note that if u is semiconcave, then it is also semisuperharmonic.

THEOREM 5.1. *Under the assumptions* (5.1)-(5.5) *and* (5.11), u_ε *is a viscosity solution to the eikonal equation* (5.16) *in* Q_ε. *Moreover,* u_ε *is semiconcave and semisuperharmonic in any component* $\tilde{Q}_\varepsilon$ *of* Q_ε, *and it is given by*

$$u_\varepsilon(x) = \inf_{u \in \partial \tilde{Q}_\varepsilon} \{\phi(y) + L(x, y)\} \quad \forall x \in \tilde{Q}_\varepsilon, \tag{5.17}$$

where

$$\begin{aligned} L(x, y) = \inf \{ \rho T; \exists \xi \in \operatorname{Lip}[0, T], \xi(0) = x, \\ \xi(T) = y, \xi(t) \in \tilde{Q}_\varepsilon \ \forall t \in (0, T), |\xi'(t)| \leqq 1 \text{ a.e.}\} \end{aligned} \tag{5.18}$$

and

$$\phi(y) = \begin{cases} u_0(y) & \textit{if } u \in \partial \tilde{Q}_\varepsilon \cap \partial Q, \\ b & \textit{if } y \in \partial \tilde{Q}_\varepsilon \backslash \partial Q. \end{cases} \tag{5.19}$$

Proof. In view of Proposition 5.2 in Lions [10, p. 137] if suffices to show that u_ε is the maximum element of the set

$$S_\varepsilon = \{ v \in W^{1,\infty}(\tilde{Q}_\varepsilon), |\nabla v| \leqq \rho \text{ in } \tilde{Q}_\varepsilon, \ v \leqq u_\varepsilon \text{ on } \partial \tilde{Q}_\varepsilon \}.$$

Now, using (5.13) we have, for any $v \in S_\varepsilon$,

$$-\int_{\tilde{Q}_\varepsilon} \operatorname{div} \theta_\varepsilon (-u_\varepsilon + v)^+ \, dx = \int_{\tilde{Q}_\varepsilon} \theta_\varepsilon \nabla (-u_\varepsilon + v)^+ \, dx = \int_{\tilde{Q}_\varepsilon \cap \{-u_\varepsilon + v > 0\}} \theta_\varepsilon (-\nabla u_\varepsilon + \nabla v) \leqq 0.$$

Since, by (5.12), (5.14), $-\operatorname{div} \theta_\varepsilon \geqq c > 0$ on Q_ε, it follows that $(-u_\varepsilon + v)^+ = 0$. Thus $u_\varepsilon \geqq v$, which means that

$$u_\varepsilon(x) = \sup_{v \in S_\varepsilon} v(x) \quad \forall x \in \tilde{Q}_\varepsilon;$$

i.e., u_ε is the maximum element of S_ε.

Remark 5.1. By the proof of Theorem 1.4 in [3] and by Lemma 2.2, $u^* = \lim_{\varepsilon \to 0} u_\varepsilon$ is a viscosity solution of

$$|\nabla u| = \rho \quad \text{in } Q_0 = \{ x \in Q, u^*(x) < b \}.$$

If we knew that the boundaries $\partial \tilde{Q}_\varepsilon \backslash \partial Q$ are smooth (cf. [10, Remark 2.5, p. 70]) uniformly in ε, then we can apply Theorem 2.3 of [10, p. 66] to deduce $\Delta u_\varepsilon \leqq C'$ in compact subsets Q' of Q_0 with C' depending on Q' by not on ε (ε small enough). It follows that u^* is semisuperharmonic in every component $\tilde{Q}_0$ of Q_0. Hence, by uniqueness of semisuperharmonic viscosity solutions [10, p. 82] we conclude that u^* is the unique semisuperharmonic viscosity solution to (5.16) with Dirichlet data $u = u_0$ on $\partial Q \cap \partial \tilde{Q}_0$, $u = b$ on $\partial \tilde{Q}_0 \backslash \partial Q$; furthermore, the representation (5.17)-(5.19) extends to u^*. Note that this does not imply uniqueness of u^*, because Q_0 depends on u^*.

We will now use Theorem 5.1 to compute u^* in some simple cases.

Observe first that any component $\tilde{Q}_\varepsilon$ of Q_ε must satisfy

$$\partial \tilde{Q}_\varepsilon \cap \partial Q \neq \emptyset.$$

Indeed, otherwise we get from (5.17)-(5.19)

$$b > u_\varepsilon(x) = b + \inf_{y \in \tilde{Q}_\varepsilon} L(x, y) \quad \forall x \in \tilde{Q}_\varepsilon,$$

which is a contradiction. It follows that

(5.20) if ∂Q is connected, then Q_ε is connected.

Let $d(x) = \operatorname{dist}(x, \partial Q)$ for $x \in Q$. Set also

$$Q^* = \{x \in Q; \text{ there exists a unique point } y \in \partial Q \text{ such that } d(x) = |x - y|\},$$

$$d_0 = \min\{d(x); x \in \partial Q^* \backslash \partial Q\}, \qquad Q^*_\delta = \{x \in Q, d(x) < \delta\}.$$

We will assume for simplicity that ∂Q is connected and $u_0(x) = \text{const.} = u_0$. Since $u_\varepsilon(x) < b$ in Q_ε the "inf" in (5.17) cannot be attained for $y \in \partial \tilde{Q}_\varepsilon \backslash \partial Q$. Hence, recalling also (5.20),

$$u_\varepsilon(x) = u_0 + \inf_{y \in \partial Q} L(x, y) \quad \forall x \in Q_\varepsilon. \tag{5.21}$$

For small δ, $Q_\varepsilon \supset Q^*_\delta$ and, therefore,

$$\inf_{y \in \partial Q} L(x, y) = \rho d(x); \tag{5.22}$$

consequently,

$$u_\varepsilon(x) = u_0 + \rho d(x), \qquad d(x) < \delta. \tag{5.23}$$

As long as $u_0 + \rho\delta < b$ and $\delta < d_0$ we can continue to increase δ in small steps while proving that $Q_\varepsilon \supset Q^*_\delta$ and that (5.22), (5.23) hold. Consequently,

$$u_\varepsilon(x) = u_0 + \rho d(x) \quad \text{in } x \in Q^*_{\delta_0} \quad \text{where } \delta_0 = \min\left\{d_0, \frac{b - u_0}{\rho}\right\}.$$

Letting $\varepsilon \to 0$ we obtain Corollary 5.2.

COROLLARY 5.2. *Let* (5.1)-(5.5) *hold. Thus any optimal control* u^* *satisfies*

$$u^*(x) = u_0 + \rho d(x) \quad \textit{in } Q^*_\delta, \qquad \delta_0 = \min\left\{d_0, \frac{b - u_0}{\rho}\right\}. \tag{5.24}$$

If, in particular, $(b - u_0/)\rho \leqq d_0$ *then* $u^*(x) = b$ *in* $Q \backslash Q^*_{\delta_0}$ *and thus* u^* *is uniquely determined.*

In the case where $Q = \{x; |x| < R\}$, Corollary 5.2 implies that u^* is uniquely determined by

$$u^*(x) = \begin{cases} u_0 + \rho(R - |x|) & \text{if } |x| > R - \dfrac{b - u_0}{\rho}, \\ b & \text{if } |x| \leqq R - \dfrac{b - u_0}{\rho}. \end{cases} \tag{5.25}$$

To apply this theorem to the electrochemical machining problem (see Remark 5.2 below), we choose a function ψ satisfying

$$\psi \in C^2(\bar{Q}), \qquad \frac{\partial \psi}{\partial \nu} = 0 \quad \text{on } \partial Q, \tag{5.26}$$

$$b < \psi_0 \leqq \psi(x) \leqq H \quad \text{if } x \in \bar{Q} \quad (\psi_0 = \inf \psi),$$

and introduce the surface

$$\Gamma=\{y=\psi(x),\ x\in Q\}.$$

We take

$$z^0(x,y)=R(y-\psi(x)). \tag{5.27}$$

Then $\partial z^0/\partial\nu=0$ on $\partial Q\times(0,H)$, (5.2) reduces to

$$R''(y-\psi(x))[1+|\nabla\psi(x)|^2-R'(y-\psi(x))\Delta\psi(x)\leqq f, \tag{5.28}$$

and (5.3), (5.4) reduce to

$$R(y-\psi(x))>1 \quad \text{in } \bar{Q}_H\cap\{a\leqq y\leqq b\}, \tag{5.29}$$

$$R(y-\psi(x))>0 \quad \text{in } \bar{Q}_H. \tag{5.30}$$

The last two inequalities are satisfied if

$$R(b-\psi_0)>1, \qquad R(H)>0, \tag{5.31}$$

Remark 5.2. In the electrochemical machining problem we want to choose the control so that the free boundary $y=\mu(x)$ will be as close as possible to $y=\psi(x)$. This is hard to do. Suppose instead that we can choose in § 5

$$z^0=\begin{cases}0 & \text{if } y>\psi(x),\\ A & \text{if } y<\psi(x) \quad (A>0).\end{cases} \tag{5.32}$$

The solution z of the variational inequality satisfies

$$z=0 \quad \text{if } y>\mu(x),$$
$$z>0 \quad \text{if } y<\mu(x)$$

and thus the statement "$\|z-z^0\|$ is as small as possible" is a weak version of the statement "$\|\mu-\psi\|$ is as small as possible" (with suitable norms). This is the motivation for working with the functional (5.1). Next, for any small $\delta>0$ and $\varepsilon>0$, take a C^2 monotone function $R(s)$ satisfying

$$R(s)=\begin{cases}\varepsilon & \text{if } s>\delta,\\ A & \text{if } s<0 \quad (A>1).\end{cases} \tag{5.33}$$

If we choose $f\equiv C^*$ with C^* sufficiently large, then (5.28) and (5.31) are satisfied. Note that this choice of R yields a function $z^0(x,y)=R(y-\psi(x))$ which is very close (say, in L^1-norm) to the desired function in (5.32).

Remark 5.3. It is clear that the previous discussion and results remain valid if we take

$$F(X,z)=|z-z^0(X)|^p \tag{5.34}$$

where $p\geqq 2$ and z^0 satisfies (5.2)-(5.5). With F defined by (5.34) the cost functional (2.2) is a more accurate estimate of the "distance" between the coincidence set of z^* and the set $\{y\geqq\psi(x)\}$.

6. Generalizations. The results of §§ 2-5 extend to other control sets and functionals. We briefly mention one example whereby the control set is

$$U=\{u\in W^{1,p}(Q),\ a\leqq u(x)\leqq b\}, \qquad p>n, \tag{6.1}$$

and

$$J(u)=\int_{\Omega_u}F(X,z_u)\,dX+\lambda\int_Q|\nabla u|^p\,dx \qquad (\lambda>0); \tag{6.2}$$

since $p > n$, by Sobolev's inequality it follows that the control functions belong to $C^{\alpha}(\bar{Q})$ where $\alpha = (1/n) - (1/p)$. Here, in the ε-problem we replace $\partial h_U(u_\varepsilon)$ in (3.15) by

$$\partial h_1(u_\varepsilon) - \lambda p \Delta_p u_\varepsilon,$$

where Δ_p is the p-Laplacian

$$\Delta_p u = \operatorname{div}\,(|\nabla u|^{p-1} \nabla u)$$

taken in the distribution sense, and $\partial h_1(u_\varepsilon)$ is characterized by (4.4), (4.3). Thus (5.10) yields, as $\varepsilon \to 0$,

$$(6.3) \qquad -\Delta_p u^* \geqq c - \eta \quad c \text{ a positive constant and } \eta \text{ as in (4.3).}$$

We can therefore state the following result for Q in R^n, $n \geqq 1$.

THEOREM 6.1. *If* (5.1)-(5.5) *hold, then for any minimizer* u^* *of* (6.2), *in the class* (6.1), *the inequality* (6.3) *holds*; *in particular,*

$$(6.4) \qquad -\Delta_p u^* \geqq c > 0 \quad \textit{in the open set } \{u < b\}.$$

For $n = 1$, $p = 2$ we get that $u^*(x)$ is a convex function.

Remark 6.1. We recall (using (2.10)) that the free boundary for (1.1) is smooth (see [5, pp. 177-179]); if $f \in C^{m+\alpha}$ then the free boundary is given by $u = \varphi(x)$ with $\varphi \in C^{m+1+\alpha}$.

Remark 6.2. The method of this paper can be used, in principle, for other free boundary problems (see [6], [7]). However, in some cases it is difficult to derive meaningful properties of the optimal control from the optimality conditions for the ε-problem. We describe one such case which arises in contact problems for elastic bodies. In a rectangle

$$R = \{0 < x < 1, \, 0 < y < H\}$$

the control variable is a curve

$$\Gamma_u = \{y = u(x), \, 0 < x < 1\},$$

where u belongs to the control set

$$U = \{u \in \operatorname{Lip}[0, 1], |u'(x)| \leqq \rho, \, u(0) = u_0, \, u(1) = u_1, \, b \leqq u(x) \leqq H\} \qquad (0 < b < H)$$

and z is the solution of the Signorini problem (see, for instance, [5], [9]):

$$-\Delta z = f \quad \text{in } \Omega_u,$$

$$z \geqq 0, \quad \frac{\partial z}{\partial \nu} \geqq 0, \quad z \frac{\partial z}{\partial \nu} = 0 \quad \text{on } \Gamma_u,$$

$$z = 0 \quad \text{on } \partial\Omega_u \backslash \Gamma_u,$$

where $\Omega_u = R \cap \{y < u(x)\}$. The functional to be minimized is

$$J(u) = \int_{\Omega_u} (z_u - z^0(x, y))^2 \, dx \, dy,$$

where z^0 is a given function. This problem was studied by Hlaváček and Nečas [8], who proved the existence of an optimal control u^*. Using our method we define the

ε-problem whereby analogously to (2.4), (2.5) we take

$$-\Delta z = f \quad \text{in } \Omega_{\mu_\varepsilon(u)},$$

$$\frac{\partial z}{\partial \nu} + \beta_\varepsilon(z) = 0 \quad \text{on } \Gamma_{\mu_\varepsilon(u)},$$

$$z = 0 \quad \text{on } \partial\Omega_{\mu_\varepsilon(u)} \backslash \Gamma_{\mu_\varepsilon(u)}.$$

Proceeding as before, we arrive at the inequality

$$\begin{aligned} &\theta'_\varepsilon - \left[p \left(\frac{z_x}{(1+(u')^2)^{1/2}} + \frac{u'}{1+(u')^2} \frac{\partial z}{\partial \nu} \right) \right] \\ (6.5) \qquad &\geqq -p \frac{u' z_{xy} - z_{yy}}{(1+(u')^2)^{1/2}} + p\beta'_\varepsilon z_y + (u - u^*) + (z - z^0)^2 + \eta_\varepsilon \quad \text{on } \Gamma_{\mu_\varepsilon(u)} \cap [u_\varepsilon > b], \end{aligned}$$

where $u = u_\varepsilon$, $z = z_\varepsilon$, $\partial h_U(u_\varepsilon) - \theta'_\varepsilon + \eta_\varepsilon$, and where p_ε is the solution of

$$-\Delta p = z^0 - z_\varepsilon \quad \text{in } \Omega_{\mu_\varepsilon(u)},$$

$$\frac{\partial p_\varepsilon}{\partial \nu} + \beta'_\varepsilon(z_\varepsilon) p_\varepsilon = 0 \quad \text{on } \Gamma_{u_\varepsilon},$$

$$p_\varepsilon = 0 \quad \text{on } \partial\Omega_{\mu_\varepsilon(u)} \backslash \Gamma_{u_\varepsilon}.$$

Here Γ_{u_ε} is given by $\{y = \mu_\varepsilon(u_\varepsilon)(x)\}$.

Remark 6.3. For optimal design in elliptic variational inequalities, from the point of view of sensitivity analysis and numerical methods, see [13] and the references given there.

OPTIMAL CONSUMPTION BY A BOND INVESTOR: THE CASE OF RANDOM INTEREST RATE ADAPTED TO A POINT PROCESS*

PETER LAKNER† AND ERIC SLUD‡

Abstract. The problem of optimizing the expected total discounted utility of the rate of consumption by an agent with initial wealth x who, at each instant, can choose a rate of consumption and who invests all his unconsumed wealth in a bond (bank) is studied. The bond is assumed to have a randomly varying interest rate with known probabilistic behavior. A general martingale principle is formulated, according to which the optimal consumption rate is expressed in terms of a positive martingale, if one can be found, satisfying an almost sure integral condition. This martingale will be characterized in the case where the stochastic history of the interest rate is adapted to (i.e., expressible in terms of) an underlying counting process. The problem studied can be viewed as a special case of optimal consumption problems in "incomplete markets," a terminology introduced to the financial literature by Harrison and Pliska [*Stochastic Process. Appl.*, 11 (1981), pp. 215-260].

Key words. interest rate process, discounted utility, incomplete markets, counting process, martingale, minimal filtration, ordinary differential equation

AMS(MOS) subject classifications. 93E20, 49A60

Introduction. The present paper treats the problem of optimal consumption by an agent who invests his unconsumed wealth in a single bond (bank) with a stochastic interest rate, and who does not invest in the stock market.

Several authors discussed the optimization problem in the case where the agent invests in the stock market as well. The initial significant results were achieved by Merton in [11] and [12], and the more general, explicit solutions are presented in [2], [7]-[10] using the "martingale technique," instead of the method of dynamic programming. In [7]-[10], the financial market consists of several stocks and a bond. There is an agent who invests in the financial market and consumes on a finite time-horizon $[0, T]$, and defines his consumption preferences with a strictly concave, sufficiently smooth "utility function"

$$U:[0,\infty)\mapsto \mathcal{R}\cup\{-\infty\}.$$

The intuitive idea is that a rate of consumption $c(t)$ at time t gives our agent $e^{-\beta t}U(c(t))$ amount of "utility," where $\beta>0$ is a discount factor, and the agent strives to maximize the expected total discounted utility of consumption

$$E\int_0^T e^{-\beta t}U(c(t))\,dt,$$

subject to the restriction that he is not to be in debt at the terminal time.

In the above-mentioned papers there is a crucial assumption which is referred to as the "completeness of the market." This is a simple mathematical condition imposed on the vector of stock price processes, which guarantees the uniqueness of an auxiliary probability measure under which the vector of stock price processes, discounted by the current bond price, is a martingale. It also follows from the "complete market"

condition that under this auxiliary probability measure, every martingale can be represented as a stochastic integral with respect to the discounted stock price processes. Assuming that the market is complete, the optimization problem is solved explicitly in [7]-[10]. For more information about the notion of complete market, see [3] and [4], where it is defined and its use is illustrated in the theory of contingent claim pricing.

The question of contingent claim pricing and optimal consumption and investment remained open in the case where the market is *incomplete*. In the present paper we address the latter problem, assuming that our agent, whom we will call a consumer, does not invest in the stock market, only in the bond (bank). Since our market model has no stocks, and is therefore incomplete, our setting is a special case of the optimal consumption/investment problem in an incomplete market.

The "classical" approach of Merton to this problem (in [11] and [12]) would be to assume that the interest rate process is a diffusion, write down the corresponding Hamilton-Jacobi-Bellman equation of dynamic programming, and try to solve it for particular utility functions like $U(c)=\log c$, or $U(c)=c^{\delta}$ with a positive constant $0<\delta<1$. However, being unwilling to make the assumption that the interest rate is Markovian, we cannot follow this path. Instead, in § 2 we develop a general principle called the *martingale principle*, which is a sufficient condition for optimality. In the following part of the paper we present an application of this principle in the case where the underlying filtration, which models the flow of information, is generated by a counting process.

We can put our problem in a different framework, called the Hotelling problem [6], concerning the optimal rate of depletion of a resource which reproduces itself at a random exponential rate. Everything in the present paper can be applied to the Hotelling problem in continuous time by a change of terminology.

1. The optimization problem of a consumer. Let $(\Omega, \mathcal{F}, P)$ be a probability space and $[0, T]$ a bounded time-horizon, with positive terminal time $T<\infty$. The flow of information is represented by a filtration $\{\mathcal{F}_t: 0\leqq t\leqq T\}$ in $\mathcal{F}$. The σ-algebra $\mathcal{F}_t$ is generated by all the information available as of time t, including additional random data observed at time zero. The *interest rate* $\{r(t), \mathcal{F}_t: 0\leqq t\leqq T\}$ is assumed to be an adapted, measurable process, bounded above by a fixed positive constant K_0 and bounded below by -1.

We denote by $p(t)$ the price of the bond at time t, relative to its price at time zero. It evolves according to the equation

$$dp(t)=r(t)p(t)\,dt, \qquad p(0)=1. \tag{1.1}$$

The solution process

$$p(t)=\exp\left\{\int_0^t r(s)\,ds\right\}, \qquad 0\leqq t\leqq T \tag{1.2}$$

is positive, adapted to $\mathcal{F}_t$, bounded above, and bounded away from zero. Indeed, by the boundedness conditions imposed on the interest rate, the *discount process*

$$\gamma(t)\equiv\exp\left\{-\int_0^t r(s)\,ds\right\}=\frac{1}{p(t)} \tag{1.3}$$

satisfies

$$e^{-K_0T}\leqq\gamma(t)\leqq e^{T}, \qquad 0\leqq t\leqq T. \tag{1.4}$$

A *consumption process* $\{c(t), \mathcal{F}_t: 0 \leqq t \leqq T\}$ is a nonnegative, adapted process satisfying the integrability condition

$$\int_0^T c(s)\, ds < \infty \quad \text{a.s.} \tag{1.5}$$

The nonnegative, $\mathcal{F}_t$-measurable random variable $c(t)$ denotes the rate of consumption at time t. The condition that the consumption process $c(t)$ be adapted corresponds to the requirement that the consumption rate $c(t)$ depends only on the time t and on the available information at that time.

We will study the behavior of a consumer who has initial wealth $x > 0$ at time zero. Denote by $x(t)$ the value at time t of the consumer's wealth, which is assumed to be invested in the bond. If the consumption plan $c(t)$ is financed exclusively by the initial wealth and by the bank, then $x(t)$ satisfies

$$dx(t) = (r(t)x(t) - c(t))\, dt, \qquad x(0) = x, \tag{1.6}$$

where the factor $r(t)x(t)$ is the rate of gain or loss on the invested wealth. By (1.4) and (1.5), the unique solution of (1.6) is

$$x(t) = \frac{1}{\gamma(t)}\left(x - \int_0^t \gamma(s)c(s)\, ds\right). \tag{1.7}$$

A consumption process $\{c(t): 0 \leqq t \leqq T\}$ is said to be *admissible* if the corresponding terminal wealth is nonnegative, i.e., if

$$x(T) \geqq 0 \quad \text{a.s.} \tag{1.8}$$

By (1.7), a consumption process $\{c(t): 0 \leqq t \leqq T\}$ is admissible if and only if it satisfies the *budget inequality*

$$\int_0^T \gamma(t)c(t)\, dt \leqq x \quad \text{a.s.} \tag{1.9}$$

A *utility function* $U: (0, \infty) \mapsto \mathcal{R}$ will be a continuously differentiable, strictly increasing, strictly concave function, which satisfies the condition

$$\lim_{c \to \infty} U'(c) = 0. \tag{1.10}$$

It follows that the derivative function $U': (0, \infty) \mapsto (0, U'(0))$ is positive and strictly decreasing with $U'(0) \equiv U'(0+) \leqq \infty$ well defined, and therefore admits a strictly decreasing, continuous inverse $I: (0, U'(0)) \mapsto (0, \infty)$. If $U'(0) < \infty$, then we extend the inverse continuously on all of $(0, \infty)$ by defining $I(y) = 0$ for $y \geqq U'(0)$. For technical reasons (see Lemma A.1 in the Appendix), we also assume that for a sufficiently large positive constant $C < \infty$ to be fixed later (following condition (A3) in the Appendix) and for each $\delta > 0$, there is a constant $A = A(\delta)$ such that for all constants $1/C \leqq C_1$, $C_2 \leqq C$,

$$\left| U'\left(C_1 I\left(\frac{z}{C_2}\right)\right) - U'\left(C_1 I\left(\frac{z'}{C_2}\right)\right)\right| \leqq A|z - z'| \quad \text{for all } z, z' \geqq \delta, \tag{1.11}$$

and there is a constant A_1 not depending on δ for which

$$U'\left(C_1 I\left(\left(\frac{z}{C_2}\right)\right)\right) \leqq A_1 z \quad \text{for all } z > 0. \tag{1.12}$$

Extend the utility function $U(\cdot)$ to all of $[0, \infty)$ by

$$U(0) \equiv \lim_{c \to 0+} U(c) \geqq -\infty, \tag{1.13}$$

with the convention that the value of the function U at zero may be negatively infinite. In order to define his consumption preferences, our consumer chooses a utility function $U(\cdot)$ which satisfies the above conditions and a discount rate $\beta \in \mathcal{R}$, with the intuitive idea that rate of consumption $c(t)$ at time t gives him $e^{-\beta t}U(c(t))$ amount of "utility." In this paper we take the discount rate β to be a fixed constant. All of the results proved here extend easily to the case where β is replaced by a nonrandom function $\beta(\cdot)$ which is uniformly bounded away from 0 and ∞, and where all discount factors $e^{-\beta t}$ are replaced by $\exp(-\int_0^t \beta(s)\,ds)$.

The optimization problem of our consumer is to maximize the value of

$$E\int_0^T e^{-\beta t}U(c(t))\,dt \tag{1.14}$$

over all admissible consumption processes which satisfy the inequality

$$E\int_0^T e^{-\beta t}U^-(c(t))\,dt<\infty, \tag{1.15}$$

where $U^-(c)=-U(c)$ if $U(c)<0$, and $U^-(c)=0$ otherwise. Condition (1.15) guarantees that the expression in (1.14) is well defined. We denote by $\mathcal{A}(x)$ the class of admissible consumption policies that satisfy (1.15). The *value function* of this optimization problem is given by

$$V(x)\equiv\sup\left\{E\int_0^T e^{-\beta t}U(c(t))\,dt\colon \{c(t),0\leqq t\leqq T\}\in\mathcal{A}(x)\right\}. \tag{1.16}$$

Remark. The class $\mathcal{A}(x)$ is nonempty, since the constant consumption process

$$\bar{c}(t)=\bar{c}\equiv\frac{x}{T}e^{-T}$$

trivially satisfies (1.15), and (1.9) follows from (1.4).

For every admissible consumption process, (1.4) and (1.9) imply

$$\int_0^T c(t)\,dt\leqq x\,e^{K_0T},$$

and by Jensen's inequality

$$\int_0^T e^{-\beta t}U(c(t))\,dt\leqq\int_0^T U(c(t))\,dt\leqq TU\left(\int_0^T\frac{1}{T}c(t)\,dt\right)\leqq TU\left(\frac{x}{T}e^{K_0T}\right).$$

It follows that the value function of our optimization problem is finite: $V(x)<\infty$. Any consumption process $c(t)$ for which the expected discounted utility (1.14) achieves the value $V(x)$ is called *optimal.*

The following lemma shows that the optimal consumption process is unique.

LEMMA 1.1. *Let $c_1(t)$, $c_2(t)$ be two consumption processes in $\mathcal{A}(x)$, and assume that both are optimal. Then the Lebesgue $\times$ P measure of the set $\{(t,\omega)\in[0,T]\times\Omega\colon c_1(t,\omega)\neq c_2(t,\omega)\}$ is zero.*

Proof. Define

$$c_3(t)\equiv\tfrac{1}{2}(c_1(t)+c_2(t)).$$

By the convexity of the function $U^-(\cdot)$, the consumption process $c_3(t)$ satisfies (1.15). Obviously $c_3(t)$ satisfies (1.9), so it belongs to the class $\mathcal{A}(x)$. By the strict concavity of $U(\cdot)$ and the optimality of $c_1(t)$ and $c_2(t)$,

$$E\int_0^T e^{-\beta t}U(c_3(t))\,dt \geqq \frac{1}{2}\left(E\int_0^T e^{-\beta t}U(c_1(t))\,dt + E\int_0^T e^{-\beta t}U(c_2(t))\,dt\right) = V(x).$$

Since the last inequality cannot be strict, the lemma follows. □

2. A martingale principle. This section concerns a general principle of optimality for the optimization problem posed in § 1. The next result could be extended in an obvious way to the case $T=\infty$.

THEOREM 2.1. *Suppose that there exists a positive* $\mathcal{F}_t$*-martingale* $\{Y(t)\colon 0\leqq t\leqq T\}$ *which satisfies the identity*

$$\int_0^T \gamma(t)I(e^{\beta t}\gamma(t)Y(t))\,dt = x \quad a.s. \tag{2.1}$$

Then the consumption process

$$c^*(t) = I(e^{\beta t}\gamma(t)Y(t)) \tag{2.2}$$

belongs to the class $\mathcal{A}(x)$, *and is optimal for the consumer.*

Proof. The process $c^*(t)$ satisfies (1.9) trivially, since

$$E\int_0^T \gamma(t)c^*(t)\,dt = x \quad a.s. \tag{2.3}$$

Let $\{c(t)\colon 0\leqq t\leqq T\}$ be an arbitrary consumption process in the class $\mathcal{A}(x)$; by the remark following (1.16), such a process exists. Now we must show that $c^*(t)$ satisfies (1.15), and that

$$E\int_0^T e^{-\beta t}U(c^*(t))\,dt \geqq E\int_0^T e^{-\beta t}U(c(t))\,dt. \tag{2.4}$$

It follows from the concavity of $U(\cdot)$ that for all $c\geqq 0$ and $y>0$,

$$U(I(y)) \geqq U(c) + y(I(y)-c). \tag{2.5}$$

Substitute $y = e^{\beta t}\gamma(t)Y(t)$ and $c=c(t)$ in (2.5) to see that

$$U(c^*(t)) \geqq U(c(t)) + e^{\beta t}\gamma(t)Y(t)(c^*(t)-c(t)),$$

or, equivalently,

$$e^{-\beta t}U(c^*(t)) \geqq e^{-\beta t}U(c(t)) + \gamma(t)Y(t)(c^*(t)-c(t)). \tag{2.6}$$

In order to show that $c^*(t)$ satisfies (1.15) and (2.4), it suffices to show that

$$E\int_0^T \gamma(t)Y(t)c(t)\,dt \leqq E\int_0^T \gamma(t)Y(t)c^*(t)\,dt < \infty. \tag{2.7}$$

We define the new probability measure $\tilde{P}$ on $\mathcal{F}_T$ by

$$\tilde{P}(A) = \frac{1}{E[Y(0)]}E[1(A)Y(t)], \qquad A\in\mathcal{F}_t, \quad t\in(0,T]. \tag{2.8}$$

Since $Y(t)$ is a martingale, the above definition is consistent, and $\tilde{P}$ is a bona fide probability measure on $\mathcal{F}_T$, equivalent with P. We denote by $\tilde{E}$ the corresponding expectation operator. Using (2.3) and (1.9) we can write

$$\begin{aligned}E\left[\int_0^T \gamma(t)Y(t)c(t)\,dt\right] &= E[Y(0)]\tilde{E}\left[\int_0^T \gamma(t)c(t)\,dt\right] \leqq E[Y(0)]x\\ &= E[Y(0)]\tilde{E}\left[\int_0^T \gamma(t)c^*(t)\,dt\right]\\ &= E\left[\int_0^T \gamma(t)Y(t)c^*(t)\,dt\right] < \infty,\end{aligned}$$

which completes the proof of the theorem. □

The optimization problem has been reduced to finding a positive $\mathcal{F}_t$-martingale $Y(t)$ which satisfies (2.1).

3. Examples with history generated by a point process. We formulate the interest rate process in terms of a simple (nonexplosive, right-continuous, unit-jump) counting process $N(t)$, which counts the cumulative number up to time t of discrete events (such as changes in commercial-bank prime rate or federal reserve discount rate) related to major interest-rate changes. Let us generate the initial σ-algebra $\mathcal{F}_0$, which is generally not trivial, by information observed as of time zero, together with all negligible events in the probability space $(\Omega, \mathcal{F}, P)$. Then the interest rate process $r(t)$ and the corresponding discount process $\gamma(t)$ are adapted to

$$\mathcal{F}_t \equiv \mathcal{F}_0 \cup \mathcal{F}_t^N = \sigma(\mathcal{F}_0, \{N(u): 0 \leqq u \leqq t\}),$$

which is a "minimal right-continuous filtration" for the counting process $N(\cdot)$, and satisfies the "usual conditions" [1, Thm. T25, p. 304, and Thm. T35, p. 309].

Our primary assumptions are that $N(T)$ is bounded, i.e., that there exists a known constant n such that

$$N(T) \leqq n \tag{3.1}$$

and that $N(t)$ admits a predictable $\mathcal{F}_t$ intensity $\lambda(t)$ such that for some constants $0 < b < B < \infty$ and all $t \in [0, T]$,

$$b1_{\{N(t)<n\}} \leqq \lambda(t)1_{\{N(t)<n\}} \leqq B1_{\{N(t)<n\}}. \tag{3.2}$$

Let us assume first that we have a positive, $\mathcal{F}_t$-martingale $Y(t)$ satisfying (2.1), in order to derive necessary conditions. Then, by Theorem T20 of [1, p. 302], this martingale has a right-continuous modification, also denoted $Y(t)$, which is again a positive $\mathcal{F}_t$-martingale satisfying (2.1). The fundamental representation theorem for right-continuous $\mathcal{F}_t$-martingales [1, Thm. T9, p. 64] guarantees the existence of a predictable process $f(t)$ satisfying

$$\int_0^T |f(s)|\lambda(s)\,ds < \infty \quad \text{a.s.,} \tag{3.3}$$

such that

$$Y(t) = Y(0) + \int_0^t f(s)(dN(s) - \lambda(s)\,ds), \qquad 0 \leqq t \leqq T. \tag{3.4}$$

The integral on the right-hand side of (3.4) is a Riemann–Stieltjes integral.

Let $\tau_0=0$, and $\tau_1, \cdots, \tau_n$ denote the successive jump times of $N(t)$. Then every $\mathscr{F}_t$ adapted right-continuous process $\xi(t)$ can be represented almost surely on each event $\{\omega: \tau_k(\omega) \leqq t < \tau_{k+1}(\omega)\}$ for $k=0, \cdots, n-1$ as $\xi_k(t \mid \tau_1, \cdots, \tau_k)$ for some $\mathscr{F}_0$ measurable random element $\xi_k(\cdot \mid \cdot, \cdots, \cdot)$ of the space of measurable functions of $k+1$ arguments which are right-continuous in the first argument. For the rest of this paper, we adopt the notational convention that the ($\mathscr{F}_t$ predictable) processes $\gamma(t)$, $\lambda(t)$, $f(t)$, etc., are represented on random intervals $\tau_k(\omega) \leqq t < \tau_{k+1}(\omega)$ by functions denoted with the same letter written with subscripts and arguments ($\gamma_k(t \mid \tau_1, \cdots, \tau_k)$, $\lambda_k(t \mid \tau_1, \cdots, \tau_k)$, etc.).

3.1. The one-jump case. In this section, assume that $N(t)$ has at most one jump up to time T, i.e.,

$$N(T) \leqq 1 \quad \text{a.s.} \tag{3.5}$$

Then we have the following representations:

$$\lambda(t)=\lambda_0(t) 1_{\{t \leqq \tau_1\}}, \tag{3.6}$$

$$\gamma(t)=\gamma_0(t) 1_{\{t \leqq \tau_1\}}+\gamma_1(t \mid \tau_1) 1_{\{t>\tau_1\}}, \tag{3.7}$$

$$f(t)=f_0(t) 1_{\{t \leqq \tau_1\}}+f_1(t \mid \tau_1) 1_{\{t>\tau_1\}}. \tag{3.8}$$

It follows from (3.6)-(3.8) and (3.4) that on the event $\{t<\tau_1\}$

$$Y(t)=Y(0)-\int_0^t f_0(s) \lambda_0(s)\, ds, \tag{3.9}$$

whereas on the event $\{t \geqq \tau_1\}$

$$Y(t)=Y(0)+f_0(\tau_1)-\int_0^{\tau_1} f_0(s) \lambda_0(s)\, ds. \tag{3.10}$$

Since $f_1(\cdot)$ does not appear in (3.9) and (3.10), the only unknown function will be $f_0(\cdot)$. Consider the function

$$\alpha(t)=\int_0^t f_0(s) \lambda_0(s)\, ds, \qquad 0 \leqq t \leqq T. \tag{3.11}$$

By (2.1), almost surely on the event $\{\tau_1 \geqq T\}$

$$\int_0^T \gamma_0(t) I(e^{\beta t} \gamma_0(t)(Y(0)-\alpha(t)))\, dt=x, \tag{3.12}$$

whereas on $\{\tau_1<T\}$ almost surely

$$\begin{aligned} &\int_0^{\tau_1} \gamma_0(t) I(e^{\beta t} \gamma_0(t)(Y(0)-\alpha(t)))\, dt \\ &\quad+\int_{\tau_1}^T \gamma_1(t \mid \tau_1) I(e^{\beta t} \gamma_1(t \mid \tau_1)(Y(0)-\alpha(\tau_1)+f_0(\tau_1)))\, dt=x. \end{aligned} \tag{3.13}$$

By assumption (3.2), the support of τ_1 contains all of $[0, T]$, and the event $\{\tau_1 \geqq T\}$ has positive probability. Therefore, (3.12) and (3.13) must hold almost surely on $(\Omega, \mathscr{F}_0, P)$, the latter for Lebesgue-almost every $\tau_1 \in (0, T)$. Here, as throughout the rest of the paper, all equations involving functions $\lambda_k(t \mid \tau_1, \cdots, \tau_k)$, $\gamma_k(t \mid \tau_1, \cdots, \tau_k)$, etc., for $k \geqq 0$, should be understood as almost sure equalities among $\mathscr{F}_0$ measurable random variables or random elements of spaces of measurable functions (cf. the discussion immediately preceding § 3.1).

Define a function

$$Q(u\,|\,t,T)=\int_t^T \gamma_1(s\,|\,t)I(u\,e^{\beta s}\gamma_1(s\,|\,t))\,ds,\qquad 0<u<\infty,\quad 0\leqq t\leqq T. \tag{3.14}$$

It follows from the dominated convergence theorem, the monotone convergence theorem, and (1.4) that for each $t\in[0,T)$, the mapping $Q(\cdot\,|\,t,T)$ is continuous, strictly decreasing, and positive on an interval $(0,\Delta)$ for some constant $\Delta\equiv\Delta(t,T)\in(0,\infty)$; that $Q(u\,|\,t,T)=0$ if $\Delta<\infty$ and $u\geqq\Delta$; and that

$$\lim_{u\to\infty} Q(u\,|\,t,T)=0, \tag{3.15}$$

$$\lim_{u\to 0} Q(u\,|\,t,T)=\infty. \tag{3.16}$$

Therefore, $Q(\cdot\,|\,t,T)$ has a strictly decreasing, continuous pseudoinverse

$$\bar{Q}(v\,|\,t,T)=\inf\{u>0\colon Q(u\,|\,t,T)>v\}, \tag{3.17}$$

which satisfies

$$Q(\bar{Q}(v\,|\,t,T),t,T)=v,\qquad 0<v<\infty. \tag{3.18}$$

Rewrite (3.13) in the form

$$\int_0^t \gamma_0(s)I(e^{\beta s}\gamma_0(s)(Y(0)-\alpha(s)))\,ds+Q(Y(0)-\alpha(t)+f_0(t)\,|\,t,T)=x, \tag{3.19}$$

valid for almost every $t\in(0,T)$, and define for $t\in[0,T]$ the functions

$$h(t)=\exp\left\{-\int_0^t \lambda_0(s)\,ds\right\}, \tag{3.20}$$

$$Z_1(t)=h(t)(Y(0)-\alpha(t))>0, \tag{3.21}$$

and

$$Z_2(t)=x-\int_0^t \gamma_0(s)I\left(e^{\beta s}\gamma_0(s)\frac{Z_1(s)}{h(s)}\right)ds. \tag{3.22}$$

Then $h(\cdot)$ is differentiable for almost every $t\in(0,T)$, and

$$\dot{h}(t)=-\lambda_0(t)h(t)\quad\text{a.e. } t\in(0,T). \tag{3.23}$$

Now, by (3.21), (3.11), and (3.23), for almost every $t\in(0,T)$

$$\dot{Z}_1(t)=-\lambda_0(t)h(t)(Y(0)-\alpha(t)+f_0(t)), \tag{3.24}$$

and by (3.19), (3.21), (3.22), (3.24), for almost every $t\in(0,T)$

$$Q\left(-\frac{\dot{Z}_1(t)}{\lambda_0(t)h(t)}\,|\,t,T\right)=Z_2(t). \tag{3.25}$$

For Lebesgue almost every $t\in(0,T)$, (3.22) yields

$$\dot{Z}_2(t)=-\gamma_0(t)I\left(e^{\beta t}\gamma_0(t)\frac{Z_1(t)}{h(t)}\right) \tag{3.26}$$

and (3.21), (3.22), and (3.12) imply the boundary conditions

$$Z_1(0)=Y(0),\quad Z_2(0)=x,\quad Z_2(T)=0. \tag{3.27}$$

We summarize our results so far in the following theorem.

THEOREM 3.1. *Suppose that there exists a positive $\mathcal{F}_t$-martingale Y_t which satisfies* (2.1). *Then the functions $Z_1(\cdot)$, $Z_2(\cdot)$, given by* (3.21) *and* (3.22), *are absolutely continuous on* $[0, T]$ *and satisfy the differential equations* (3.25)-(3.26) *for almost every* $t \in (0, T)$, *with the boundary conditions* (3.27).

The converse of the preceding theorem is still more interesting for our purposes.

THEOREM 3.2. *Suppose that there exist two nonnegative, absolutely continuous functions $Z_1, Z_2 : [0, T] \mapsto [0, \infty)$, which for almost every $t \in (0, T)$ are positive and satisfy the* ODE *system*

$$(3.28)\qquad (\dot{Z}_1(t), \dot{Z}_2(t)) = \left(-\lambda_0(t)h(t)\bar{Q}(Z_2(t) \mid t, T), -\gamma_0(t)I\left(e^{\beta t}\frac{\gamma_0(t)}{h(t)} Z_1(t)\right)\right),$$

with the boundary conditions

$$(3.29)\qquad Z_1(0) < \infty, \quad Z_1(T) > 0, \quad Z_2(0) = x, \quad Z_2(T) = 0.$$

Then the process $\{Y(t) : 0 \leqq t \leqq T\}$ defined by

$$(3.30)\qquad Y(t) = \frac{Z_1(t)}{h(t)} \quad \text{on the event } \{0 < t < \tau_1\},$$

$$(3.31)\qquad Y(t) = \bar{Q}(Z_2(\tau_1) \mid \tau_1, T) \quad \text{on the event } \{\tau_1 \leqq t\} \cap \{\tau_1 < T\}$$

and defined arbitrarily on the null event $\{\tau_1 = T\}$, is a positive $\mathcal{F}_t$-martingale satisfying (2.1).

Proof. Since $Z_1(\cdot)$ and $Z_2(\cdot)$ must be strictly decreasing and positive on $(0, T)$, the process $Y(t)$ is well defined and positive. Define the function $f_0 : [0, T] \mapsto \mathcal{R}$ by $f_0(T) = 0$ and, for $0 \leqq t \leqq T$

$$(3.32)\qquad f_0(t) = -\frac{Z_1(t)}{h(t)} + \bar{Q}(Z_2(t) \mid t, T) = -\frac{1}{\lambda_0(t)}\frac{d}{dt}\left(\frac{Z_1(t)}{h(t)}\right)$$

and define the predictable process

$$(3.33)\qquad f(t) = f_0(t)1_{\{t \leqq \tau_1\}}, \qquad 0 \leqq t \leqq T.$$

Using (3.23) and the absolute continuity of the functions $Z_1(\cdot)$ and $h(\cdot)$, it is easy to show that (3.4) holds. Since $Z_1(\cdot)$ is strictly decreasing, and $\lambda_0(\cdot)$ and $1/h(\cdot)$ are bounded, it follows from (3.32) that

$$(3.34)\qquad E\int_0^T |f(t)|\lambda(t)\,dt \leqq e^{bT}\left\{Z_1(0)\int_0^{\min(\tau_1, T)} \lambda_0(t)\,dt + Z_1(0)\right\} < \infty$$

and $Y(t)$ is indeed a martingale [1, Thm. T8(β), p. 27]. By the absolute continuity of $Z_2(\cdot)$, together with (3.14) and (3.18), (2.1) follows immediately. □

The next step is to show that the ordinary differential equation system (3.28)-(3.29) does have a solution. Although we state the result here, its proof relies on the more general lemmas stated and proved in the Appendix.

THEOREM 3.3. *Under the assumptions of this section, the almost everywhere system* (3.28)-(3.29) *of ordinary differential equations in Theorem* 3.2 *has a unique solution, and this solution $\underline{Z}(t) = \binom{Z_1(t)}{Z_2(t)}$ is absolutely continuous as a function of t and satisfies the system for all $t \in [0, T]$.*

Proof. We verify the hypotheses of Lemma A.1 in the Appendix, where

$$F(z, t, T) \equiv -\dot{h}(t)\bar{Q}(z \mid t, T), \quad G_1(t) \equiv \gamma_0(t), \quad G_2(t) \equiv e^{\beta t}\frac{\gamma_0(t)}{h(t)}.$$

First, assumption (A1) on the function $I(\cdot)$ follows immediately from the assumptions on the utility function U made in the paragraph (1.10)-(1.13), and the uniform boundedness assumption (A3) on the functions $G_i(t)$ follows immediately for fixed $T<\infty$ from the bounds (1.4) on $\gamma(t)$ together with the definition of $h(t)$. We next check assumption (A2), that F is locally Lipschitz in $I^{-1}(z/(T-t))$. First, (3.14) says that

$$I^{-1}\left(\frac{Q(v\,|\,t,T)}{T-t}\right)-I^{-1}\left(\frac{Q(u\,|\,t,T)}{T-t}\right)=I^{-1}\left(\frac{1}{T-t}\int_t^T \gamma_1(s\,|\,t)I(v\,e^{\beta s}\gamma_1(s\,|\,t))\,ds\right)$$
$$-I^{-1}\left(\frac{1}{T-t}\int_t^T \gamma_1(s\,|\,t)I(u\,e^{\beta s}\gamma_1(s\,|\,t))\,ds\right).$$

By Lemma A.0 of Appendix A, with $G_1(s)=\gamma_1(s\,|\,t)$ and $G_2(s)=G_1(s)\,e^{\beta s}$, there exist s_1 and s_2 between t and T such that the last expression has the form

$$I^{-1}(\gamma_1(s_1\,|\,t)I(v\,e^{\beta s_2}\gamma_1(s_2\,|\,t)))-I^{-1}(\gamma_1(s_1\,|\,t)I(u\,e^{\beta s_2}\gamma_1(s_2\,|\,t))).$$

By (1.4) and then (A1.1) with $C\geqq\max(e^{K_0T}, e^{(\beta+1)T})$, we find that for all $u, v\geqq\delta^*\equiv I^{-1}(e^{(\beta+1)T}I(\delta\,e^{-K_0T}))$, the absolute value of the last displayed difference is at least $|u-v|/A(\delta)$. That is,

$$\left|I^{-1}\left(\frac{Q(v\,|\,t,T)}{T-t}\right)-I^{-1}\left(\frac{Q(u\,|\,t,T)}{T-t}\right)\right|\geqq\frac{|u-v|}{A(\delta)}.$$

Since $Q(u\,|\,t,T)\leqq e^{-K_0T}(T-t)I(\delta^*)$ implies that $u\geqq\delta^*$, we find that the inverse function $\bar{Q}(z\,|\,t,T)$ has the property

$$|\bar{Q}(z\,|\,t,T)-\bar{Q}(y\,|\,t,T)|\leqq A(\delta)\left|I^{-1}\left(\frac{z}{T-t}\right)-I^{-1}\left(\frac{y}{T-t}\right)\right|$$

for $y, z\leqq e^{-K_0T}(T-t)I(\delta^*)$. Similarly, it follows from (1.4) and (3.14) that $Q(u\,|\,t,T)\geqq e^{-K_0T}(T-t)I(u\,e^{(\beta+1)T})$, so that by (3.17)

$$\bar{Q}(z\,|\,t,T)\leqq e^{K_0T}I^{-1}\left(e^{-T}\frac{z}{T-t}\right)\quad\text{for all } z.$$

Thus, if we restrict T to lie in an interval $[0, T_*]$, then there exists a constant D $(=\exp(K_0T_*))$ such that for all positive z,

$$\bar{Q}(z\,|\,t,T)\leqq DI^{-1}\left(\frac{z}{(T-t)D}\right).$$

Since $|\dot{h}(t)|$ is uniformly bounded away from 0 and ∞, assumption (A2) of the Appendix holds for $F(z,t,T)$ as defined above. The conclusion of our Theorem is now part of Lemma A.1. □

3.2. The *n*-jump case. So far in this section, we have proved that a unique optimal consumption policy, determined by the "martingale principle" and an ordinary differential equation, exists under the very special assumption that the counting process $N(t)$ to which the interest-rate process is adapted has at most one jump in the bounded interval $[0, T]$. We now return to the case (3.1), where $N(T)$ is assumed bounded by the known integer n, and prove by a backward induction that the martingale $Y(t)$ determining an optimal policy is determined by recursively solving at most n ordinary differential equations.

Observe first that under (3.1), on the event $\{\omega\colon \tau_{n-1}(\omega) < T\}$, if the consumer has used the admissible policy $c(t)$ to guide his consumption on the time interval $[0, \tau_{n-1}]$, then his wealth as of time τ_{n-1} is $x_{n-1} \equiv x - \int_0^{\tau_{n-1}} c(t)\gamma(t)\,dt$. The restarted counting process $N(\tau_{n-1}+s) - N(\tau_{n-1})$ on the $\mathcal{F}_{\tau_{n-1}}$ measurable random time interval $[0, T-\tau_{n-1})$ has almost surely at most one jump. The problem of optimal consumption on the remaining interval $(\tau_{n-1}, T]$, posed conditionally given $\mathcal{F}_{\tau_{n-1}}$, is precisely the problem which we have just solved in the previous section, where initial wealth is replaced by x_{n-1}, the time horizon T by $T - \tau_{n-1}$, the time-variable t by $s = t - \tau_{n-1}$, the interest rate process by $\gamma(\tau_{n-1}+s)$, and the function $I(z)$ by $\tilde{I}(z) \equiv I(z\,e^{\beta\tau_{n-1}})$. In the present setting, Theorem 3.2 identifies the optimal consumption rate $c_{n-1}(t\,|\,\tau_1, \cdots, \tau_{n-1})$ for $\tau_{n-1} \leqq t \leqq T$, conditionally given $\mathcal{F}_{\tau_{n-1}}$, as follows.

Replace x by $x_{n-1} = x - \int_0^{\tau_{n-1}} c(t)\gamma(t)\,dt$ and T by $T-\tau_{n-1}$ in (A4), and define functions F and G_i $(i = 1, 2)$ in terms of the time-variable $s = t - \tau_{n-1}$ for $t \in [\tau_{n-1}, T]$ by

$$
\begin{aligned}
&F(z, t-\tau_{n-1}, T-\tau_{n-1})\\
&\quad = \lambda_{n-1}(t\,|\,\tau_1, \cdots, \tau_{n-1}) \exp\left(-\int_{\tau_{n-1}}^{t} \lambda_{n-1}(y\,|\,\tau_1, \cdots, \tau_{n-1})\,dy\right)\\
&\qquad \cdot \inf\left\{u > 0\colon \int_t^T \gamma_{n-1}(y\,|\,\tau_1, \cdots, \tau_{n-1}) I(u\,e^{\beta y}\gamma_{n-1}(y\,|\,\tau_1, \cdots, \tau_{n-1}))\,dy > z\right\},
\end{aligned}
$$

$$G_1(s) = \gamma_{n-1}(s+\tau_{n-1}\,|\,\tau_1, \cdots, \tau_{n-1}),$$

$$G_2(s) = G_1(s) \exp\left(\beta s + \int_{\tau_{n-1}}^{s+\tau_{n-1}} \lambda_{n-1}(y\,|\,\tau_1, \cdots, \tau_{n-1})\,dy\right).$$

The differential equation system (A4.0) defined in this way with initial and terminal conditions

$$Z_1^{(n)}(0\,|\,x_{n-1}) = x_{n-1} \quad \text{and} \quad Z_2^{(n)}((T-\tau_{n-1})-)|x_{n-1}) = 0$$

has a unique solution $\underline{Z}^{(n)}(s\,|\,x_{n-1})$ for $0 \leqq s \leqq T-\tau_{n-1}$, and $Z_1^{(n)}(s\,|\,x_{n-1})$ is monotonically decreasing in the parameter x_{n-1}. For $\tau_{n-1} \leqq t$, define the positive $\mathcal{F}_{\tau_{n-1}}$ measurable random function $Y_{n-1}(\cdot\,|\,\cdot, \cdots, \cdot) \equiv Y_{n-1}(\cdot\,|\,\cdot, \cdots, \cdot, x_{n-1})$ as in (3.30)-(3.31) by

$$
Y_{n-1}(t\,|\,\tau_1, \cdots, \tau_{n-1}, x_{n-1}) = \begin{cases} \exp\left(\int_0^t \lambda(v)\,dv\right) Z_1^{(n)}(t\,|\,x_{n-1}) & \text{if } t < \tau_n,\\[1ex] \exp\left(\int_0^{\tau_n} \lambda(v)\,dv\right) \dfrac{\dot{Z}_1^{(n)}(\tau_n\,|\,x_{n-1})}{\lambda(\tau_n)} & \text{if } t \geqq \tau_n. \end{cases}
$$

Then $Y_{n-1}(\tau_{n-1}+s\,|\,\tau_1, \cdots, \tau_{n-1}, x_{n-1})$ is a positive martingale in s, and the unique optimal consumption rate on $[\tau_{n-1}, T]$, after having used $c(\cdot)$ on $[0, \tau_{n-1})$, is

$$c_{n-1}(t\,|\,\tau_1, \cdots, \tau_{n-1}, x_{n-1}) = I(\gamma_{n-1}(t\,|\,\tau_1, \cdots, \tau_{n-1})\,e^{\beta t}\,Y_{n-1}(t\,|\,\tau_1, \cdots, \tau_{n-1}, x_{n-1})).$$

The only way in which the policy $c(\cdot)$ used on $[0, \tau_{n-1})$ enters into the expression for $c_{n-1}(t\,|\,\tau_1, \cdots, \tau_{n-1}, x_{n-1})$ is through the parameter $x_{n-1} = x - \int_0^{\tau_{n-1}} c(t)\gamma(t)\,dt$ denoting the consumer's wealth as of the random time τ_{n-1}. One of the immediate consequences of Lemma A.1 is that the function $Y_{n-1}(t\,|\,\tau_1, \cdots, \tau_{n-1}, x_{n-1})$ has a Lipschitz, nondecreasing dependence on the parameter $x_{n-1}/(T-\tau_{n-1})$ over bounded sets.

We next describe the backwards inductive step in solving for the martingale $Y(t)$ on $(\tau_{k-1}, \tau_k]$ after its trajectory on $(\tau_k, T]$ has been expressed as a nondecreasing locally Lipschitz function of $x_k/(T-\tau_k)$, where x_k denotes the consumer's wealth at random time τ_k.

THEOREM 3.4. *Suppose $1 \leqq k \leqq n$ is fixed and that the nonnegative $\mathscr{F}_t$ adapted random function $Y_k(t \mid \tau_1, \cdots, \tau_k, x_k)$ is nondecreasing and locally Lipschitz in $x_k/(T-\tau_k)$ on $(0, \infty)$, is uniformly bounded by $BI^{-1}(x_k/(T-\tau_k)B)$ for some constant B and, for $\tau_k \leqq t$, has the form*

$$\begin{aligned} Y_k(t \mid \tau_1, \cdots, \tau_k, x_k) \equiv {} & Y_k(\tau_k + \mid \tau_1, \cdots, \tau_k, x_k) \\ & - \int_{\tau_k}^{t \wedge \tau_{k+1}} f_k(y \mid \tau_1, \cdots, \tau_k, x_k) \lambda_k(y \mid \tau_1, \cdots, \tau_k)\, dy \\ & + 1_{\{\tau_{k+1} \leqq t\}} f_k(\tau_{k+1} \mid \tau_1, \cdots, \tau_k, x_k). \end{aligned} \tag{3.34$_k$}$$

Then there is a unique function $1_{\{\tau_{k-1} \leqq t\}} Y_{k-1}(t \mid \tau_1, \cdots, \tau_{k-1}, x_{k-1})$ satisfying the same properties and of the form (3.34_{k-1}), which is determined for $\tau_k = t \in (\tau_{k-1}, T]$ by

$$\begin{aligned} & Y_{k-1}(t \mid \tau_1, \cdots, \tau_{k-1}, x_{k-1}) \\ & \quad = Y_k\Bigg(t + \mid \tau_1, \cdots, \tau_{k-1}, t, x_{k-1} - \int_{\tau_{k-1}}^{t} \gamma_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}) \\ & \qquad \cdot I(e^{\beta s} \gamma_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}) Y_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}, x_{k-1}))\, ds \Bigg) \end{aligned} \tag{3.35}$$

and

$$\begin{aligned} x_{k-1} = \int_{\tau_{k-1}}^{T} & \gamma_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}) \\ & \cdot I(e^{\beta s} \gamma_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}) Y_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}, x_{k-1}))\, ds. \end{aligned} \tag{3.36}$$

Note. First, condition (3.34) says that the random functions $Y_j(t \mid \tau_1, \cdots, \tau_j, x_j)$ for $j = k$ and $k-1$ are nonrandom measurable functions of their arguments on the respective intervals $[\tau_k, \tau_{k+1})$ and $[\tau_{k-1}, \tau_k)$. In addition, (3.34) says that

$$\begin{aligned} & Y_j(\tau_{j+1} - \mid \tau_1, \cdots, \tau_j) - Y_j(\tau_{j+1} \mid \tau_1, \cdots, \tau_j) \\ & \quad = \frac{1}{\lambda(\tau_{j+1})} \frac{d}{dt} Y_j(t \mid \tau_1, \cdots, \tau_j) \big|_{t = \tau_{j+1}-}, \end{aligned} \tag{3.37}$$

where the displayed derivative makes sense for all $t < \tau_{j+1}$ and can be regarded as a left-derivative at τ_{j+1}. Next, since

$$\begin{aligned} x_k = x_{k-1} - \int_{\tau_{k-1}}^{t} & \gamma_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}) \\ & \cdot I(e^{\beta s} \gamma_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}) Y_{k-1}(s \mid \tau_1, \cdots, \tau_{k-1}, x_{k-1}))\, ds \end{aligned} \tag{3.38}$$

should denote the consumer's wealth as of time $\tau_k = t > \tau_{k-1}$, we recognize condition (3.35) simply as saying that the martingale $Y(\cdot)$ to be defined equal to $Y_{k-1}(\cdot \mid \tau_1, \cdots, \tau_{k-1}, x_{k-1})$ on $[\tau_{k-1}, \tau_k \wedge T]$ for $k = 1, 2, \cdots, n$, is right-continuous at each time τ_k which is less than T. Condition (3.36) recapitulates the requirement (2.1) for $Y(\cdot)$ on the event $[\tau_{k-1} < T \leqq \tau_k]$.

Proof. In order to characterize and solve for $Y_{k-1}(t \mid \tau_1, \cdots, \tau_{k-1})$ using (3.34)–(3.35), we will solve on $s = t - \tau_{k-1} \in [0, T - \tau_{k-1}]$ for $\underline{Z}^{(k)}(s)$ defined by

$$Z_1^{(k)}(t - \tau_{k-1}) = \exp\left(- \int_{\tau_{k-1}}^{t} \lambda_{k-1}(y \mid \tau_1, \cdots, \tau_{k-1})\, dy \right) Y_{k-1}(t \mid \tau_1, \cdots, \tau_{k-1}, x_{k-1}) 1_{\{\tau_k \geqq t\}}$$

$$\begin{aligned} & Z_2^{(k)}(t - \tau_{k-1}) \\ & \quad = x_{k-1} - \int_{\tau_{k-1}}^{t} I(e^{\beta y} \gamma_{k-1}(y \mid \tau_1, \cdots, \tau_{k-1}) Y_{k-1}(y)) \gamma_{k-1}(y \mid \tau_1, \cdots, \tau_{k-1})\, dy. \end{aligned}$$

According to (3.35)-(3.37) this vector function $\underset{\sim}{Z}^{(k)}(s)$ satisfies the almost-everywhere ordinary differential equation system (A4) in Lemma A.1 of Appendix A, where T in (A4) is replaced by $T-\tau_{k-1}$, x by x_{k-1}, and $I(z)$ by $\tilde{I}(z) \equiv I(z\, e^{\beta\tau_{k-1}})$, and where

$$\begin{aligned}F(z, s, T-\tau_{k-1}) = {} & \lambda_{k-1}(s+\tau_{k-1} \,|\, \tau_1, \cdots, \tau_{k-1}) \\ & \cdot \exp\left(-\int_{\tau_{k-1}}^{s+\tau_{k-1}} \lambda_{k-1}(y \,|\, \tau_1, \cdots, \tau_{k-1})\, dy\right) \\ & \cdot Y_k((s+\tau_{k-1})+ \,|\, \tau_1, \cdots, \tau_{k-1}, \tau_{k-1}+s, z), \\ G_1(s) = {} & \gamma_{k-1}(s+\tau_{k-1} | \tau_1, \cdots, \tau_{k-1}), \\ G_2(s) = {} & G_1(s) \exp\left(\beta s + \int_{\tau_{k-1}}^{\tau_{k-1}+s} \lambda_{k-1}(y \,|\, \tau_1, \cdots, \tau_{k-1})\, dy\right).\end{aligned}$$

The existence, uniqueness, and asserted regularity properties of the solution $\underset{\sim}{Z}^{(k)}(s)$ all follow immediately from Lemma A.1, the hypotheses of which hold by the assumptions of the present theorem. We note in conclusion that by the special form of (3.34), each of the random functions $Y_j(\tau_j+s \,|\, \tau_1, \cdots, \tau_j, x_j)$ is a martingale in $s \geqq 0$, and is a local martingale by [1, p. 27], with integrability verified exactly as in Theorem 3.2. □

It remains to tie together the construction of Y_{n-1} with the inductive step provided by Theorem 3.4. Note first that each of the systems of ordinary differential equations defining $\underset{\sim}{Z}^{(j)}(s)$ (and thereby defining Y_j) in the preceding proof involves only its own initial condition x_j and none of the other wealth-values x_k. Thus, after having obtained all the forms of $Y_j(t \,|\, \tau_1, \cdots, \tau_j, x_j)$ for $j = 0, \cdots, n-1$ as measurable functions of their arguments on $[\tau_j \leqq t < \tau_{j+1}]$, we proceed by *forward* induction as follows. First fix the total wealth $x_0 = x$, and define $Y(t) \equiv Y_0(t \,|\, x_0)$ for $0 \leqq t \leqq T$, $t < \tau_1$. Next, define inductively for $j = 1, 2, \cdots, n-1$, on the event $[\tau_j \leqq T]$,

$$\begin{aligned}x_j = x_{j-1} - \int_{\tau_{j-1}}^{\tau_j} & \gamma_{j-1}(s \,|\, \tau_1, \cdots, \tau_{j-1}) \\ & \cdot I(e^{\beta s}\gamma_{j-1}(s \,|\, \tau_1, \cdots, \tau_{j-1}) Y_{j-1}(s \,|\, \tau_1, \cdots, \tau_{j-1}, x_{j-1}))\, ds, \\ Y(t) = {} & Y_j(t \,|\, \tau_1, \cdots, \tau_j, x_j) \quad \text{for } \tau_j \leqq t \leqq T, \quad t < \tau_{j+1}.\end{aligned}$$

Use (3.37) to define $Y(t) = Y_{n-1}(\tau_n \,|\, \tau_1, \cdots, \tau_{n-1}, x_{n-1})$ for $\tau_n \leqq t \leqq T$ on the event $[\tau_n \leqq T]$. Then by construction and (3.37), $Y(\tau_j)$ agrees with $Y_{j-1}(\tau_j \,|\, \tau_1, \cdots, \tau_{j-1}, x_{j-1})$ for every τ_j which is less than or equal to T. The martingale property in s of each random function $Y_j(\tau_j+s \,|\, \tau_1, \cdots, \tau_j, x_j)$ implies immediately that the $\mathscr{F}_t$ adapted random function $Y(t)$ on $[0, T]$ is also a martingale (with respect to $\mathscr{F}_t$). Finally, the definition of x_j from x_{j-1}, together with the construction of the theorem, imply that $Y(t)$ satisfies (2.4) almost surely. The martingale principle of § 2 (Theorem 2.1) implies Theorem 3.5.

THEOREM 3.5. *Under assumptions* (3.1) *and* (3.2) *on the underlying counting process* $N(t)$, *for* $Y(t)$ *defined as in the present paragraph, the consumption rate* $c^*(t) \equiv I(e^{\beta t}\gamma(t) Y(t))$ *optimizes expected discounted utility* (1.13) *over all admissible consumption rates.*

4. Discussion and extensions. The main result of this paper, summarized in Theorem 3.5, says that under the condition (3.1) bounding a priori the number of jumps of $N(\cdot)$ on $[0, T]$, and under the regularity conditions assumed for the utility function, there exists a unique $\mathscr{F}_t$ adapted optimal consumption rate $c^*(t)$, which is constructed from the positive martingale $Y(t)$.

A number of possible interesting extensions of Theorem 3.5 are topics for further research. First, at least under some auxiliary assumption allowing one to prove a priori bounds on the optimal martingale $Y(t)$ or consumption rate $c^*(t)$, it seems likely that passage to limits as $n \to \infty$ should allow the bound n in (3.1) and (3.2) to be replaced by ∞. Second, it would be desirable to extend Theorem 3.5 to the case where the underlying process $N(t)$, to which both the interest rate and consumption rate processes are adapted, would be a multivariate or marked point process. If these first two extensions were accomplished, then the lower bound in (3.2) could be removed by replacing $N(t)$ by a multivariate counting process $N^*(t)$ with first component $N(t)$ and second component an independent Poisson process with intensity b. Other open problems connected with the martingale $Y(t)$ of this paper include: the relationship with the "value function," which plays such an important role in related treatments of interest rates adapted to diffusion processes, and the possibility of obtaining results for diffusion and more general interest-rate processes without jumps by passing to a high-intensity limit within the present framework.

Appendix A. Lemma on ordinary differential equations. The following summarizes the properties of equations (3.28)-(3.29) needed to show that each of these equations has in general a well-defined and unique solution. The results of this Appendix are self-contained, although for the applications in § 3, the function $I(\cdot)$ is the pseudo-inverse of the derivative $U'(\cdot)$ of the utility function $U(\cdot)$ of § 1.

(A1) For some positive ν which may be $+\infty$, $I:(0,\nu)\to(0,\infty)$ is a continuous and strictly decreasing function such that $I(0+)=\infty$ and $I(\nu)=0$. The function $I(\cdot)$ is defined $\equiv 0$ on $[\nu,\infty)$ if $\nu<\infty$. For some sufficiently large constant $C<\infty$ and each $\delta>0$, there are constants $A=A(\delta)$ such that for all constants $C^{-1}\leqq C_1, C_2 \leqq C$,

$$\left|I^{-1}\left(C_1 I\left(\frac{z}{C_2}\right)\right)-I^{-1}\left(C_1 I\left(\frac{z'}{C_2}\right)\right)\right|\leqq A|z-z'| \quad \text{for } z, z'\geqq\delta \tag{A1.1}$$

and there is a constant A_1 depending on C but not on δ for which

$$I^{-1}\left(C_1 I\left(\frac{z}{C_2}\right)\right)\leqq A_1 z \quad \text{for all } z>0. \tag{A1.2}$$

(A2) $F(z,t,T)$ is a nonnegative measurable function on $(0,\infty)\times\{(t,T): 0<t<T\leqq T_*\}$ for some $T_*<\infty$, which is nonincreasing in z with $F(0+,t,T)\leqq\infty$, and which is Lipschitz with respect to $I^{-1}(z/(T-t))$ on each set $\{(z,t,T): z/(T-t)\leqq\delta^{-1}\}$ for $\delta>0$. Moreover, there exists $D<\infty$ such that for all $z>0$ and $t<T$,

$$F(z,t,T)\leqq DI^{-1}\left(\frac{z}{(T-t)D}\right).$$

(A3) For $i=1,2$, $G_i(t)$ are positive continuous functions on $[0,T_*]$ such that for some $K_1<\infty$, $|\log G_i(t)|\leqq K_1$ for all $t\in[0,T_*]$.

In these three assumptions, T_* plays the role of a fixed upper bound on the time-horizon T, and the constant C in (A1.1) may and from now on will be fixed equal to $D\cdot\exp(K_1)$, with $D\geqq 1$.

LEMMA A.0. *For arbitrary $t<T$, there exist values s_1 and s_2 in $[t,T]$ such that*

$$\frac{1}{T-t}\int_t^T G_1(s)\binom{I(G_2(s)w)}{I(G_2(s)v)}\,ds = G_1(s_1)\binom{I(G_2(s_2)w)}{I(G_2(s_2)v)}.$$

Proof. Fix $t < T$, and let $v \leqq w$ be such that $I(G_2(s)v) > 0$ for some $s \in [t, T]$. Then the intermediate value theorem implies that there exists $s_2 \in [t, T]$ for which

$$\int_t^T G_1(s)\begin{pmatrix} I(G_2(s)w) \\ I(G_2(s)v) \end{pmatrix} ds \quad \text{is parallel to} \quad \begin{pmatrix} I(G_2(s_2)w)/I(G_2(s_2)v) \\ 1 \end{pmatrix},$$

i.e., for which

$$\frac{\int_t^T G_1(s) I(G_2(s)w)\, ds}{\int_t^T G_1(s)\{I(G_2(s)w) + I(G_2(s)v)\}\, ds} = \frac{I(G_2(s_2)w)}{I(G_2(s_2)w) + I(G_2(s_2)v)}.$$

Then the integral mean value theorem applied to

$$\frac{1}{T-t}\int_t^T G_1(s)\begin{pmatrix} I(G_2(s)w) \\ I(G_2(s)v) \end{pmatrix} \cdot \begin{pmatrix} I(G_2(s_2)w) \\ I(G_2(s_2)v) \end{pmatrix} ds$$

implies the existence of s_1. □

LEMMA A.1. *For each fixed* $T \leqq T_*$ *and* $x > 0$, *there exists a unique value* y_0 *such that the (unique) solution* $\underline{Z}(t) \equiv \binom{Z_1(t)}{Z_2(t)}$ *on* $(0, T)$ *in the almost-everywhere sense of the ordinary differential equation system*

$$\text{(A4.0)} \qquad \dot{\underline{Z}}(t) = \begin{pmatrix} -F(Z_2(t), t, t) \\ -G_1(t) I(G_2(t) Z_1(t)) \end{pmatrix}, \qquad \underline{Z}(0) = \begin{pmatrix} y_0 \\ x \end{pmatrix}$$

satisfies $Z_2(T-) = 0$, $Z_1(T-) > 0$. *Moreover,* $y_0 = y_0(T, x)$ *is continuous in both arguments, and is strictly decreasing and Lipschitz with respect to* x/T *on* $\{(t, x)\colon 0 \leqq T \leqq T_*, x/T \leqq \delta^{-1}\}$ *for each* $\delta > 0$. *In addition, there exists a finite positive constant* B *such that for all* z *and all* $T \leqq T_*$, $y_0(T, x) \leqq BI^{-1}(x/BT)$.

Proof. The main part of the proof consists in studying the existence and properties of the solution in almost-everywhere sense of

$$\text{(A4)} \qquad \dot{\underline{Z}}(t) = \begin{pmatrix} -F(Z_2(t), t, T) \\ -G_1(t) I(G_2(t) Z_1(t)) \end{pmatrix}, \qquad \underline{Z}(T-) = \begin{pmatrix} z \\ 0 \end{pmatrix}$$

as a function of $z > 0$. The strictly monotone dependence of each component of the right-hand side of (A4) will be used to establish the existence of a decreasing and absolutely continuous solution $Z_1(t)$. We omit the qualification "almost everywhere" in equalities and inequalities deduced from (A4).

The integrated form of (A4) tells that the function $W_1(t) \equiv Z_1(T-t) - z$ for $0 < t \leqq T$ must satisfy

$$\text{(A4}'\text{)} \quad W_1(t) = \int_{T-t}^T F\left(\int_s^T G_1(v) I(G_2(v)(W_1(T-v) + z))\, dv, s, T\right) ds, \qquad W_1(0) = 0.$$

Now fix $K = \exp(K_1) = k^{-1}$, and let $\mathscr{A}_T$ denote the set of nondecreasing functions $H(t)$ on $[0, T]$ such that $H(0) = 0$. Note that with our choice $C = D \exp(K_1)$, we have $C \geqq K$. For each $z > 0$, define the transformation R_z on $\mathscr{A}_T$ by

$$(R_z H)(t) \equiv \int_0^t F\left(\int_0^s G_1(T-v) I(G_2(T-v)(H(v) + z))\, dv, T-s, T\right) ds.$$

Then by (A1) and (A2), R_z is evidently monotone increasing in the sense that

$$H_1(t) \leqq H_2(t) \quad \text{for all } t \Rightarrow (R_z H_1)(t) \leqq (R_z H_2(t)) \quad \text{for all } t.$$

If $H_0(t) \equiv 0$, then $(R_z H_0)(t) \geqq H_0(t)$, and for each $_z$ and t, $R_z^j H_0(t)$ is a monotone increasing sequence in $j = 1, 2, \cdots$.

By assumptions (A1)-(A3), for all $t>0$ and all $z>0$,

$$
\begin{aligned}
(R_zH)(t) &\leqq \int_0^t DI^{-1}\left(\frac{1}{sD}\int_0^s G_1(T-v)I(G_2(T-v)(H(v)+z))\,dv\right) ds \\
\text{(A5)} \qquad &\leqq D\int_0^t I^{-1}\left(\frac{1}{KsD}\int_0^s I(K(H(v)+z))\,dv\right) ds \\
&\leqq D\int_0^t I^{-1}\left(\frac{k}{D} I(K(H(s)+z))\right) ds.
\end{aligned}
$$

But for each $z>0$, there exists by standard theorems and (A5) and (A1) with $C=KD$, a unique solution $\zeta(t,z)$ on $[0,T]$ of the equation

$$
\text{(A6)} \qquad \frac{d}{dt}\zeta(t)=DI^{-1}\left(\frac{k}{D}I(K(z+\zeta(t)))\right), \qquad \zeta(0)=0.
$$

The function $\zeta(\cdot)=\zeta(\cdot,z)$ evidently belongs to the domain $\mathscr{A}_T$ of R_z, and $H_0(t)\leqq(R_z\zeta)(t)$. In addition, $(R_z\zeta)(t)\leqq\zeta(t)$, by (A5) and (A6). Therefore $R_z^jH_0(t)\leqq\zeta(t)$ for all j and all $t\in[0,T]$, and $W_*(t)\equiv\lim_{j\to\infty}R_z^jH_0(t)$ exists and is an element of $\mathscr{A}_T$. Clearly, $W_*(t)=(R_zW_*)(t)$ is a minimal nonnegative solution of the integral fixed-point equation (A4′), and similarly $W^*(t)\equiv\lim_{j\to\infty}R_z^j\zeta(t)$ is a maximal solution since all solutions $W(t)$ of (A4′) are bounded by $\zeta(t)$, according to Theorem 4.1 of [5, pp. 25-26].

To show that the solution of (A4) or (A4′) is unique, we prove that the function $J(w)\equiv F(\int_t^T G_1(s)I(G_2(s)w)\,ds,t,T)$ is Lipschitz for $w\in[\delta',\infty)$ for each $\delta>0$, where $\delta'\equiv A_1kI^{-1}(k/\delta)$. Indeed, if $w\geqq v\geqq\delta'$, then both $I(v)$ and $I(w)$ are $\leqq\delta^{-1}$ by (A1.2), and by (A2)

$$
\begin{aligned}
|J(w)-J(v)|\leqq K_2\Bigg[&I^{-1}\left(\frac{1}{T-t}\int_t^T G_1(s)I(G_2(s)w)\,ds\right) \\
&-I^{-1}\left(\frac{1}{T-t}\int_t^T G_1(s)I(G_2(s)v)\,ds\right)\Bigg]
\end{aligned}
$$

for some constant K_2. By Lemma A.0

$$
\frac{1}{T-t}\int_t^T G_1(s)\begin{pmatrix} I(G_2(s)w) \\ I(G_2(s)v)\end{pmatrix} ds = G_1(s)\begin{pmatrix} I(G_2(s_2)w) \\ I(G_2(s_2)v)\end{pmatrix}
$$

for some values s_1 and s_2 in $[t,T]$ which depend on v and w. For fixed $t<T$, apply (A1) to deduce the Lipschitz property

$$
|J(w)-J(v)|\leqq K_2A(\delta)|w-v|.
$$

But all solution-functions W in $\mathscr{A}_T$ of the equation (A4′) are bounded between zero and the function $\zeta(\cdot,z)$ on $[0,T]$ by Theorem 4.1 of [5, pp. 25-26]. Thus all solutions W can be bounded uniformly on $[0,T]$ for each fixed $z>0$. It follows by standard arguments that the functions $W_*(t)$ and $W^*(t)$ coincide and that the solution $\underline{Z}(t,z)$ of (A4) or (A4′) is unique and depends continuously on z for $z\geqq\delta'$.

We know that $Z_1(0,z)\geqq z$ goes to ∞ as z does. Also, for each $z>0$, $Z_1(0,z)\leqq z+\zeta(T,z)$, and it is easy to see from (A6) and (A1.2) that $\zeta(T,0+)=0$. Thus $Z_1(0,z)$ goes to zero as z goes to zero. Therefore, the intermediate value theorem implies that for each $x>0$ there is a unique value of z for which the solution $\underline{Z}(\cdot,z)$ of (A4) satisfies $Z_2(0,z)=\int_0^T G_1(t)I(G_1(t)Z_1(t,z))\,dz=x$. Then $y_0=y_0(T,x)\equiv Z_1(0,z)$. Since $Z_1(t,z)$ increases with z for all t, it is easy to check that $Z_2(t,z)$ decreases with z, so that x decreases with increasing z, and y_0 is a decreasing function of x.

Next we check the upper bound for y_0 in terms of x/T. Since $Z_1(t, z) \leqq z + \zeta(T, z)$ for $0 \leqq t \leqq T$, we have for each s in $[0, T]$,

$$\frac{Z_2(s, z)}{T-s} = \frac{1}{T-s} \int_s^T G_1(t) I(G_2(t) Z_1(t, z))\, ds$$
$$\geqq \frac{1}{T-s} \int_0^T G_1(s) I(G_2(s)(z + \zeta(T, z)))\, ds \geqq kI(K(z + \zeta(T, z)))$$

by (A3) and the monotonic-decreasing property of $I(\cdot)$. Then by (A2),

$$y_0 = Z_1(0, z) = z + \int_0^T F(Z_2(s, z), s, T)\, ds$$
$$\leqq z + D \int_0^T I^{-1}\left(\frac{Z_2(s, z)}{(T-s)D}\right) ds$$
$$\leqq z + DTI^{-1}\left(\frac{k}{D} I(K(z + \zeta(T, z)))\right).$$

However, assumption (A1.2) for $C \geqq KD$ implies that

$$\frac{d}{dt} \zeta(t) \leqq DA_1(z + \zeta(t)), \qquad t \geqq 0$$

so that $\zeta(T, z) \leqq A_2 z$ for all $T \leqq T_*$ and some constant A_2 which will depend on T_*. Substituting in the upper bound for y_0, and applying (A1.2) once more, yields

$$y_0 \leqq (1 + DT_* A_1 A_2) z \equiv A_3 z.$$

Finally,

$$x = Z_2(0, z) = \int_0^T G_1(s) I(G_2(s) Z_1(s, z))\, ds \leqq KTI(kz) \leqq KTI(ky_0/A_3)$$

implies the desired upper bound $y_0 \leqq BI^{-1}(bx/T)$, where $B = A_3/k$, $b = 1/K$.

Clearly, y_0 is continuous with respect to x and T, and its Lipschitz dependence on x/T over compact intervals is obtained from (A2) and estimates like the preceding on the relations

$$y_0 = z + \int_0^T F(Z_2(t, z), t, T)\, dt, \qquad x = \int_0^T G_1(s) I(G_2(s) Z_1(s, z))\, ds.$$

The idea is to fix arbitrary $z, z' \geqq \delta'$, to define y_0' and x' from z' just as y_0 and x are defined from z, and then to bound difference quotients $(y_0' - y_0)/(z' - z)$ above and $(x' - x)/(T(z' - z))$ both above and below. Our proof is now complete. □

Acknowledgments. We are extremely grateful to Ioannis Karatzas for ideas that were very helpful in stimulating our proof of Lemma A.1 of the Appendix, and to the associate editor and an anonymous referee for suggesting numerous improvements in our presentation.

THE WAVE METHOD FOR DETERMINING THE ASYMPTOTIC DAMPING RATES OF EIGENMODES I: THE WAVE EQUATION ON A RECTANGULAR OR CIRCULAR DOMAIN*

JIANXIN ZHOU† AND GOONG CHEN†

Abstract. The uniform exponential decay property of the wave equation with viscous boundary damping has been studied by several people. The mathematical proofs used therein are commonly based on energy identities, which *cannot determine the actual decay rates* of the solution. In Quinn and Russell [*Proc. Roy. Soc. Edinburgh Sect. A*, 77 (1977), pp. 97-127] and Chen [Ph.D. thesis, University of Wisconsin, Madison, WI, May 1977], such damping rates have been calculated for rectangular and circular domains, respectively, using separation of variables and a perturbation approach good for *small* viscous damping parameters. In this paper, we extend some earlier *geometrical optics* and diffraction methods of Keller and Rubinow [*Ann. Phys.*, 9 (1960), pp. 24-75] to treat the eigenvalue problems with dissipative conditions. Such methods provide strong insights into the physical properties of the solutions. Asymptotic estimates of damping and wavenumber are shown to agree favorably with the earlier results of Quinn and Russell and Chen for small damping parameters, as well as with the numerical solutions computed herein for cases even when the damping parameters are not small.

1. Introduction.

Consider the wave equation

$$w_{tt}(x,t)-\Delta w(x,t)=0, \qquad x\in\Omega\subset\mathbb{R}^n, \quad t>0 \tag{1.1}$$

on a bounded domain Ω in $\mathbb{R}^n$. On the boundary $\partial\Omega$ of Ω, assume a dissipative condition

$$\frac{\partial w(x,t)}{\partial t}+\alpha\frac{\partial w(x,t)}{\partial n}=0, \qquad \alpha>0, \quad x\in\partial\Omega, \quad t>0, \tag{1.2}$$

where n is the unit outward normal on $\partial\Omega$. Condition (1.2) says that force $\partial w/\partial n$ is negatively proportional to the velocity, so a viscous damper is installed in effect everywhere on the boundary. We call α the viscous damping parameter. The initial conditions for the wave equation are

$$\left.\begin{aligned} w(x,0)&=w_0(x),\\ \frac{\partial w}{\partial t}(x,0)&=v_0(x),\end{aligned}\right\} \qquad x\in\Omega.$$

The energy of the system at time t is

$$E(t)=\int_\Omega [|\nabla w(x,t)|^2+w_t^2(x,t)]\,dx. \tag{1.3}$$

Several people (cf. [2], [8], [11], e.g.) have shown that if the domain Ω has certain geometries, then the energy of vibration will decay uniformly exponentially: there exist $M\geqq 1$, $\mu>0$ such that

$$E(t)\leqq Me^{-\mu t}E(0) \tag{1.4}$$

for all initial conditions $(w_0, v_0) \in H^1(\Omega) \oplus H^0(\Omega)$, where $H^k(\Omega)$ is the Sobolev space of order $k \geqq 0$. This uniform decay property is important in the design of linear-quadratic regulators for distributed parameter control systems. The larger μ is, the higher the performance of the regulator is commonly regarded. Thus, from the practical design viewpoint, it is useful to know the overall damping rate μ or the damping rates of individual eigenmodes of the controlled system. Nevertheless, except in [1] and [11], explicit information on such damping rates is not available because the mathematical proofs as given in [2] and [8] are based on energy identities, which cannot provide sharp estimates of decay in relation to the damping parameter α. Indeed, such sharp estimates are pretty hard to obtain for general domains. Therefore, the best hope is to look for some answers in the case of special domains: rectangles, circles, and ellipses, etc.

Quinn and Russell [11] studied the case of rectangular geometry, while Chen [1] did the circular geometry. Both works are based on the elementary separation of variables approach and a perturbation argument valid for a *small damping parameter* α, and provide certain useful estimates for the damping rates of eigenmodes. It is obvious that the perturbation argument used therein is also valid when the *damping parameter* α *is large*—we simply develop a perturbation series in terms of $1/\alpha$ in lieu of α. But when α is of medium size—neither too large, nor too small—then the perturbation argument in [1] and [11] would fail and no *explicit* damping rates of eigenmodes would be available. A more *general* approach is required in order to obtain such information.

In this series of papers, we plan to generalize the *wave propagation method* (WPM) developed by us in [3] and [4], and elsewhere, to study the problem. The WPM in [4] gives sharp asymptotic estimates of eigenfrequencies of vibration for equations in *one* space dimension, including the wave, beam, and Schrödinger equations. The extension of WPM to higher space dimensions, say $n=2$ in (1.1), is difficult because more complicated wave phenomena such as caustics, foci, grazing and gliding rays can happen. Fortunately, for simple geometries such as rectangles, circles, and ellipses, the fundamental work has been done in an important paper [7], wherein Keller and Rubinow used the general geometrical theory of optics (GTO) and the geometrical theory of diffraction (GTD) to estimate eigenvalues of the Laplacian subject to Dirichlet and Neumann boundary conditions. Their methods and results are still unsurpassed to this day, even though the paper is already three decades old. In this paper, we will incorporate our earlier ideas of WPM [4] into Keller and Rubinow's work [7] to obtain asymptotic eigenfrequency estimates for the Laplacian with dissipative boundary conditions. Our results agree with those in [1] and [11] when the damping parameter α is small, and agree sharply with the numerical results when the damping parameter is not small. Our analysis here is based on the physical postulates of wave propagation and optics, which have all been rigorously justified in the asymptotic sense by Maslov and Fedoriuk [10].

Our plan is as follows. In the present paper, Part I, we will study mainly the *circular and rectangular* cases in *two* space dimension. In the follow-up paper, Part II, we plan to study the case of a rectangular *plate*, generalizing Keller and Rubinow's work to the *biharmonic* operator Δ^2. There are additional interesting problems such as:

(i) The cases of elliptical and triangular geometries;
(ii) Overdamped modes (cf. Remark 4.2); and
(iii) Space dimension three.

If possible, we also wish to investigate them in subsequent parts of this series of papers.

2. Extending Keller and Rubinow's wave method to dissipative boundary conditions. Let Ω be a bounded domain in $\mathbb{R}^3$ or $\mathbb{R}^2$. We let the damping parameter α in (1.2) be complex:

$$\frac{\partial w(x,t)}{\partial t}+\alpha\frac{\partial w(x,t)}{\partial n}=0, \qquad x\in\partial\Omega, \quad \alpha\in\mathbb{C}, \quad \Re\alpha>0 \tag{2.1}$$

($\Re\alpha$ and $\Im\alpha$ denote, respectively, the real and imaginary parts of α). This condition is more general than (1.2) in that it also covers some acoustic and electromagnetic scattering problems wherein the impedance parameter α is complex in general.

We consider an eigenmode $\phi(x)$:

$$w(x,t)=e^{-ikt}\phi(x), \qquad x\in\Omega. \tag{2.2}$$

Substituting (2.2) into (1.1) and (2.1), we obtain a reduced wave (i.e., Helmholtz) equation with impedance boundary condition:

$$\begin{aligned}&(\Delta+k^2)\phi(x)=0, \qquad x\in\Omega,\\ &ik\phi(x)-\alpha\frac{\partial\phi(x)}{\partial n}=0, \qquad x\in\partial\Omega.\end{aligned} \tag{2.3}$$

Our task here is to derive estimates on the eigenfrequencies k.

To make our paper sufficiently self-contained, we first introduce the theory developed by Keller and Rubinow in [7], with suitable adaptations to our problem. (Not surprisingly, many passages and figures in this section are adopted from [7] without alteration.)

According to GTO [5], [6], when $|k|$ is large, ϕ can be represented by a geometrical optics expansion:

$$\begin{aligned}\phi(x)&=\sum_{j=1}^{N}e^{ikS_j(x)}\left[\sum_{p=0}^{\infty}\frac{A_{j,p}(x)}{(ik)^p}\right], \qquad x\in\Omega\\ &=\sum_{j=1}^{N}e^{ikS_j(x)}\left[A_{j,0}(x)+O\left(\frac{1}{k}\right)\right],\end{aligned} \tag{2.4}$$

where it is assumed there are N waves propagating in Ω. Each wave has phase S_j and (dominant) amplitude $A_{j,0}$. For simplicity, let us write $A_{j,0}$ as A_j. Substituting (2.4) into (2.3) and equating to zero the coefficients of k^2 and k, we obtain

$$|\nabla S_j|^2=1 \quad \text{(the eiconal equation)}, \tag{2.5}$$

$$2\nabla S_j\cdot\nabla A_j+A_j\Delta S_j=0 \quad \text{(the transport equation)} \tag{2.6}$$

for $j=1,2,\cdots,N$.

The surfaces $S_j=\text{constant}$ are called wavefronts, and the trajectories orthogonal to the wavefronts are called rays. The rays, as characteristic to (2.5), are easily seen to be straight lines. Let τ denote the arclength along a ray; then (2.6) implies that along the ray S_j is given by

$$S_j(\tau)=S_{j0}\pm\tau, \tag{2.7}$$

where S_{j0} is the value of S_j at the point from which τ is measured. The sign "±" in (2.7) can be chosen to be "+" or "−" depending on if τ is measured positively or negatively in the direction of increasing S_j.

The transport equation (2.6) is a linear ordinary differential equation along rays

$$2\frac{dA_j}{d\tau}+A_j(\Delta S_j)=0, \qquad j=1,2,\cdots,N,$$

which has solution

$$A_j(\tau)=A_j(0)\exp\left(-\frac{1}{2}\int_0^\tau \Delta S_j(\eta)\,d\eta\right)=A_j(0)\left[\frac{G_j(\tau)}{G_j(0)}\right]^{1/2}. \tag{2.8}$$

$G_j(\tau)$ is the Gaussian curvature of the wavefront $S_j=\text{const.}$ at τ. When $n=3$, (2.8) is further seen to be equal to

$$A_j(\tau)=A_j(0)\left[\frac{\rho_{j1}\rho_{j2}}{(\rho_{j1}+\tau)(\rho_{j2}+\tau)}\right]^{1/2} \quad (\text{in } \mathbb{R}^3), \tag{2.9}$$

where ρ_{j1} and ρ_{j2} denote the principal radii of curvature of the wave front at $\tau=0$. When $n=2$, we regard $\rho_{j2}=\infty$ in (2.9) (i.e., a cylindrical wavefront) so we can write

$$A_j(\tau)=A_j(0)\left(\frac{\rho_j}{\rho_j+\tau}\right)^{1/2} \quad (\text{in } \mathbb{R}^2). \tag{2.10}$$

We now apply the boundary conditions in (2.3) to the solution (2.4). We substitute and equate to zero the coefficient of k to obtain

$$\sum_{j=1}^{N}\left(A_j-\alpha A_j\frac{\partial S_j}{\partial n}\right)e^{ikS_j}=0. \tag{2.11}$$

As in [7], we now assume that at every point on the boundary the terms in (2.11) for which $A_j-\alpha A_j\,\partial S_j/\partial n\neq 0$ *vanish in pairs*. That is to say, for each such j wave, there is another j' wave, $j'\neq j$, such that

$$\left(A_j-\alpha A_j\frac{\partial S_j}{\partial n}\right)e^{ikS_j}+\left(A_{j'}-\alpha A_{j'}\frac{\partial S_{j'}}{\partial n}\right)e^{ikS_{j'}}=0 \quad \text{on } \Omega. \tag{2.12}$$

Physically, this assumption means that each wave hitting the boundary gives rise to a reflected wave. (The waves for which $A_j-\alpha A_j\,\partial S_j/\partial n=0$ are absorbed by the boundary and do not give rise to reflected waves.) Since (2.12) holds for a range of values of k, it follows that

$$S_j=S_{j'} \quad \text{on } \partial\Omega. \tag{2.13}$$

Therefore,

$$\frac{\partial S_j}{\partial s}=\frac{\partial S_{j'}}{\partial s} \quad \text{on } \partial\Omega, \tag{2.14}$$

where $s=(-n_2,n_1)$ is the unit tangent vector in the counterclockwise sense, with (n_1,n_2) being the components of the unit outward normal n. Since

$$\nabla S_k=\frac{\partial S_k}{\partial s}s+\frac{\partial S_k}{\partial n}n \quad \text{for } k=1,2,\cdots,N,$$

from (2.5) and (2.14), we obtain

$$\left\|\frac{\partial S_j}{\partial n}n\right\|^2=\left\|\frac{\partial S_{j'}}{\partial n}n\right\|^2.$$

Therefore,

$$\frac{\partial S_j}{\partial n}=\pm\frac{\partial S_{j'}}{\partial n} \quad \text{on } \partial\Omega. \tag{2.15}$$

Arguing along the same lines as in [7], we can show that the "+" sign in (2.15) is not admissible; thus,

$$\frac{\partial S_j}{\partial n} = -\frac{\partial S_{j'}}{\partial n} \quad \text{on } \partial\Omega. \tag{2.16}$$

Using (2.13) and (2.16), we obtain

$$A_{j'} = -\frac{1-\alpha(\partial S_j/\partial n)}{1+\alpha(\partial S_j/\partial n)} A_j \quad \text{on } \partial\Omega. \tag{2.17}$$

We call this the *reflection relation.* Note that if we choose $\alpha = 0$ and $\alpha = \infty$, then we obtain, respectively, the reflection relations for the Dirichlet and Neumann boundary conditions in [7].

Equation (2.9) for the amplitude A_j breaks down at points on a *caustic surface,* where $\tau = -\rho_{j1}$ or $\tau = -\rho_{j2}$ ($\rho_{j1} \neq \rho_{j2}$). (If $\tau = -\rho_{j1} = -\rho_{j2}$, such a point is called a *focal* point.) Indeed, near a caustic surface a more elaborate WKB approximation is necessary for a uniformly valid expansion of the field (cf. the book by Maslov and Fedoriuk [10] for a general treatment of wave optics on manifolds; cf. also Remark 4.2).

As in [7], we assume that

(i) Each wave converging to a caustic gives rise to another wave diverging from the caustic; and

(ii) The rays of the diverging wave (which are *gliding rays*) are assumed to be the continuations of those of the converging wave and the phase along these rays is assumed to be the continuation of the phase on the converging rays.

Thus,

$$S_j = S_{j'} \tag{2.18}$$

on a caustic. By passing a regular (i.e., nonfocal) point on a caustic, in (2.9), $\rho_{j1} + \tau$ (or $\rho_{j2} + \tau$) changes sign from "−" to "+." Thus

$$A_{j'} = e^{-i\pi/2} A_j. \tag{2.19}$$

(Passing a focal point, the relation is

$$A_{j'} = e^{-i\pi} A_j \tag{2.20}$$

because both $\rho_{j1} + \tau$ and $\rho_{j2} + \tau$ change signs from "−" to "+.")

Now let us trace a ray of any wave in the direction of increasing τ. We come to a caustic or boundary because Ω is a bounded domain. In either case, the ray continues as a ray of another wave. A sequence of waves is encountered in this manner. Since there are, by assumption, only a finite number N of waves in the solution, one of the waves in this sequence must *recur.* Therefore, a ray orthogonal to a given wavefront is ultimately orthogonal to this very same wave front again. But the value of S continually increases as a ray is traversed in the positive direction. Therefore, at the second point of intersection of the wavefront and the ray, the value of S_j is greater than its initial value by the length of the ray between intersections. Since S_j is constant on a wavefront, S_j must therefore be *multiple valued.* The corresponding amplitude A_j may also be *multiple valued* due to the change (2.19) or (2.20) on the ray paths.

To form an eigenmode ϕ, the solution to (2.3), *resonance must occur*; i.e., the wave that recurs must be *in phase with itself,* that is to say, the overall phase difference due to the changes of S_j and A_j must be an integral multiple of 2π. This is expressed by

$$k(\delta S_j) + \delta(\arg A_j) = 2\pi n_j, \qquad j = 1, \cdots, N, \ n_j \in \mathbb{Z}, \tag{2.21}$$

where δS_j and $\delta(\arg A_j)$ denote, respectively, the changes of S_j and the argument of the complex amplitude A_j.

In [7], Keller and Rubinow further used the important concept of a *covering space* to resolve the difficulty of the multivaluedness of S_j by regarding them as branches of a single function S. The covering space is *multisheeted*, just like a Riemann surface in complex analysis. The number of sheets is equal to the N distinct branches of ∇S. The various sheets are replicas of the domain Ω which may be bounded internally by caustics. The sheets corresponding to ∇S_{j1} and ∇S_{j2} are joined together along the part of the caustic or boundary where $S_{j1}=S_{j2}$, the places where the wave j_1 gives rise to the wave j_2 by reflection or by passing through a caustic. Similarly, we consider A_j to be branches of a single function A defined on the covering space.

Now assume that the fundamental group of the covering space (of ∇S) contains q linearly independent closed curves $C_j, j=1,2,\cdots,q$. Then the condition (2.21) can be rewritten as

$$k\oint_{C_j} \nabla S\cdot d\sigma+\sum \delta(\arg A)=2\pi n_j, \qquad j=1,2,\cdots,q. \tag{2.22}$$

We will incorporate the reflection condition (2.17) into the formula (2.22) to obtain the asymptotic damping rates and eigenfrequency estimates in the examples to be discussed in the next few sections.

3. Asymptotic damping rates and eigenfrequencies for a circular domain. Circular and elliptical domains seem to be the only domains where caustics are known to be constructible [7]. We consider a $(2-D)$ disk Ω with radius a. Let $C(a_0)$ be a circle with radius a_0 and centered at the origin. Any ray in Ω tangent to $C(a_0)$ will be tangential to it again after a reflection at $\partial\Omega$ (cf. Fig. 1). Thus $C(a_0)$ is a caustic to the family of rays generated by successive reflections at $\partial\Omega$.

To apply Keller and Rubinow's theory in § 2, we need to find a set of N normal congruences of rays that are closed under reflection. (A normal congruence of rays is a family of rays orthogonal to any given surface.) From the preceding paragraph, we can consider all those rays traveling inward from $\partial\Omega$ to the caustic $C(a_0)$ as one normal congruence (cf. Fig. 2) and all those traveling outward from $C(a_0)$ to $\partial\Omega$ as a second

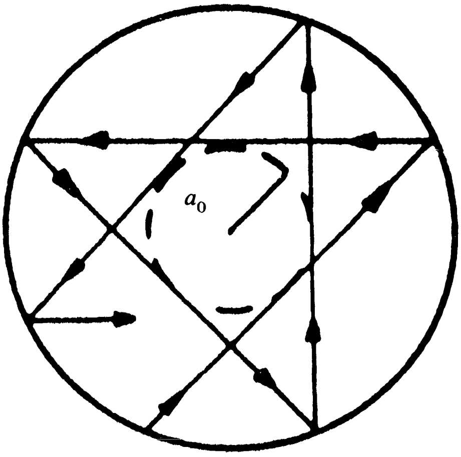

FIG. 1. *A ray inside a circular domain and some of the rays that arise from it after several reflections. All of these rays are tangential to a concentric circle of radius* a_0, *the caustic.* (*Reprinted from* [7], *with permission.*)

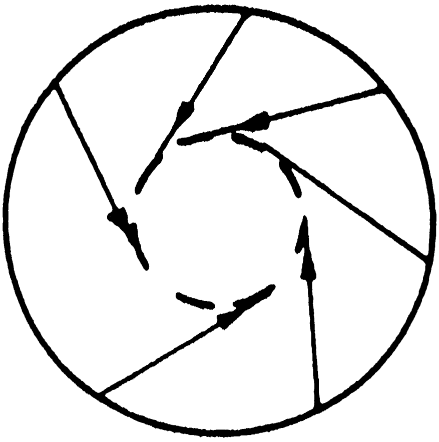

FIG. 2. *Normal congruence* I *of rays converging to the caustic.* (*Reprinted from* [7], *with permission.*)

congruence (cf. Fig. 3). Therefore, $N = 2$. The covering space for a disk is topologically homeomorphic to a torus [7]. There are only two linearly independent closed curves on a torus, so $q = 2$ in (2.22). From the way the covering space is constructed in [7], we can choose the first curve C_1 to be just $C(a_0)$, and choose C_2 to be shown as in Fig. 4.

We now apply (2.22) to C_1 and C_2. Along C_1, ∇S is tangent to it, and no ray crosses the caustic, so

$$\oint_{C(a_0)} \nabla S \cdot d\sigma = \text{arclength of } C(a_0) = 2\pi a_0,$$

$$\delta(\arg A) = 0,$$

and (2.22) gives

$$k(2\pi a_0) = 2\pi l, \qquad l = 0, 1, 2, \cdots. \tag{3.1}$$

Remark 3.1. It is well understood that for the eigenvalue problem (2.3), most of the true eigenvalues $\lambda = -k^2$ are *complex numbers.* This implies that (most of) the k themselves are complex numbers. So how can a complex number be equal to a real number in (3.1)? It turns out that k *in* (3.1) *should be regarded as a real number*, namely,

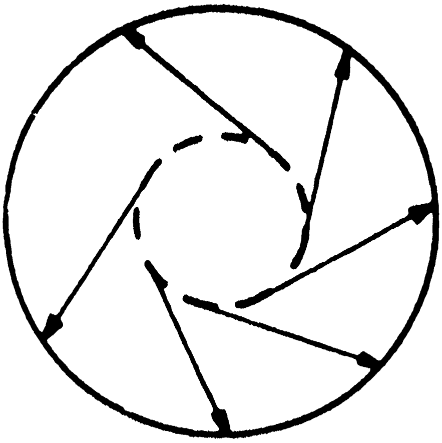

FIG. 3. *Normal congruence* II *of rays diverging from the caustic.* (*Reprinted from* [7], *with permission.*)

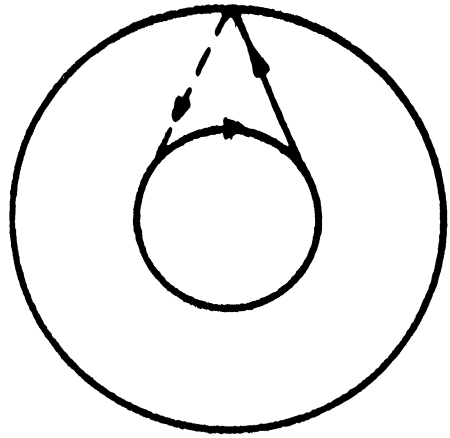

FIG. 4. *The closed path C_2 on the toroidal covering space.* (*Reprinted from* [7], *with permission.*)

the real part of the true eigenfrequence λ in Theorem 1 *later,* as k here is only an approximation to the real part of the true eigenfrequence λ. We can aptly call k the *wavenumber.* The rationale will become clear later on (see especially Remark 3.2 afterwards).

The curve C_2, as shown in Fig. 4, consists of two rays, each of length $(a^2-a_0^2)^{1/2}$, and an arc of the caustic of length $2a_0\cos^{-1}(a_0/a)$. Therefore,

$$\oint \nabla S\cdot d\sigma = 2\left(\sqrt{a^2-a_0^2}-a_0\cos^{-1}\frac{a_0}{a}\right). \tag{3.2}$$

Note the choice of "$-$" sign to conform to the counterclockwise sense on $C(a_0)$. Consider the change of arg A. This path crosses the caustic only once, so by (2.19) arg A is retarded by $\pi/2$. Also at the boundary, reflection occurs according to (2.17). Therefore, arg A changes by another angle

$$-\pi+\arg\frac{1-\alpha(\partial S/\partial n)}{1+\alpha(\partial S/\partial n)}. \tag{3.3}$$

Let us combine both changes of $\delta(\arg A)$. In consistency with the sign convention in [7], we actually have

$$\begin{aligned}\delta(\arg A)&=\left(-\frac{\pi}{2}\right)-\left[-\pi+\arg\left(\frac{1-\alpha(\partial S/\partial n)}{1+\alpha(\partial S/\partial n)}\right)\right]\\&=\frac{\pi}{2}-\arg\left(\frac{1-\alpha(\partial S/\partial n)}{1+\alpha(\partial S/\partial n)}\right)\end{aligned} \tag{3.4}$$

and using (3.1) in (3.2), we obtain

$$\begin{aligned}2k\left(\sqrt{a^2-a_0^2}-a_0\cos^{-1}\frac{a_0}{a}\right)&=2\pi m-\frac{\pi}{2}+\arg\left(\frac{1-\alpha(\partial S/\partial n)}{1+\alpha(\partial S/\partial n)}\right),\\ k\left(\sqrt{a^2-a_0^2}-a_0\cos^{-1}\frac{a_0}{a}\right)&=\pi\left[m-\frac{1}{4}+\frac{1}{2\pi}\arg\left(\frac{1-\alpha(\partial S/\partial n)}{1+\alpha(\partial S/\partial n)}\right)\right],\end{aligned} \tag{3.5}$$

$$m=1,2,3,\cdots.$$

We further simplify the above by noting from Fig. 5 (or cf. (32) of [7, p. 35]) that

$$S_1(r,\theta)=a_0\left[\theta-\cos^{-1}\left(\frac{a_0}{r}\right)\right]+(r^2-a_0^2)^{1/2}.$$

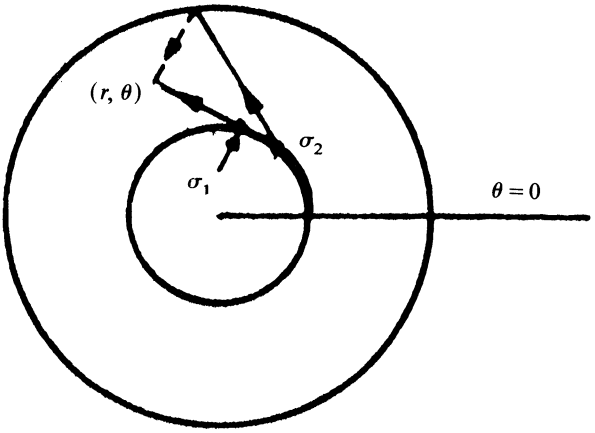

FIG. 5. *The two-ray paths from the caustic to the point* (r, θ). *One ray leaves the caustic at* $\sigma_1 = a_0[\theta - \cos^{-1})]$ *and travels a distance* $\tau_1 = (r^2 - a_0^2)^{1/2}$ *to the point. The other ray leaves the caustic at* $\sigma_2 = a_0[\theta + \cos^{-1}(a_0/r) - 2\cos^{-1}(a_0/a)]$, *is reflected from the boundary, and reaches the same point on the second sheet after traversing a distance* $\tau_2 = 2(a^2 - a_0^2)^{1/2} - (r^2 - a_0^2)^{1/2}$. (*Reprinted from* [7], *with permission.*)

Thus,

$$\left.\frac{\partial S_1}{\partial n}\right|_{\partial\Omega} = \left.\frac{\partial S_1}{\partial r}\right|_{r=a} = \frac{\sqrt{a^2 - a_0^2}}{a}$$

and (3.5) becomes

$$(3.6)\qquad k\left(\sqrt{a^2 - a_0^2} - a_0 \cos^{-1}\frac{a_0}{a}\right) = \pi\left[m + \frac{3}{4} + \frac{1}{2\pi}\arg\left(\frac{1 - \alpha\sqrt{a^2 - a_0^2}/a}{1 + \alpha\sqrt{a^2 - a_0^2}/a}\right)\right]$$

$$m = 0, 1, 2, \cdots.$$

Note that we have shifted m by one from (3.5).

Substituting a_0 from (3.1) into (3.6), we obtain

$$(3.7)\qquad [(ka)^2 - l^2]^{1/2} - l\cos^{-1}\left(\frac{l}{ka}\right) = \pi\left[m + \frac{3}{4} + \frac{1}{2\pi}\arg\left(\frac{1 - \alpha\sqrt{k^2a^2 - l^2}/ak}{1 + \alpha\sqrt{k^2a^2 - l^2}/ak}\right)\right]$$

$$m, l = 0, 1, 2, 3, \cdots.$$

This relation determines k, the (real) wavenumber, up to $O(1/k)$. Note that by choosing $\alpha = 0$ and $\alpha = +\infty$ in (3.6), we recover, respectively, formulas (26) and (25) of [7, pp. 33-34] for the Dirichlet and Neumann boundary conditions.

Next, we determine the damping rates of eigenmodes. We use the same idea as developed in [4]. The damping of wave motion is completely attributed to the *attenuation of the wave amplitude after reflection* at the boundary. According to the reflection relation (2.17), the amount of damping endured after each reflection is

$$\ln\left|-\frac{1 - \alpha(\partial S/\partial n)}{1 + \alpha(\partial S/\partial n)}\right| = \ln\left|\frac{1 - (\alpha/a)\sqrt{a^2 - a_0^2}}{1 + (\alpha/a)\sqrt{a^2 - a_0^2}}\right|.$$

Consider a *complete cycle* of wave motion; i.e., let a wave of normal congruence II reflect (at $\partial\Omega$) into a wave of normal congruence I, and then further transmit across the caustic to become a wave of normal congruence II (cf. Figs. 1, 2). Since the caustic is essentially a barrier against wave penetration, it can be regarded as a boundary surface (curve) also. As the wave propagates with speed one, and the round trip distance made by the wave from the circumference to the caustic is $2(a^2-a_0^2)^{1/2}$ (cf. Fig. 4) by using the very same arguments as in the one-dimensional wave propagation case in [4, § 2], we obtain

$$\text{rate of damping per unit time} = \frac{\text{total attenuation in a cycle of wave motion}}{\text{the round trip time duration}},$$

i.e.,

$$\mu(k) = \frac{1}{2\sqrt{a^2-a_0^2}} \ln \left| \frac{1-(\alpha/a)\sqrt{a^2-a_0^2}}{1+(\alpha/a)\sqrt{a^2-a_0^2}} \right| \left(= \frac{1}{2\sqrt{a^2-(l/k)^2}} \ln \left| \frac{ak-\alpha\sqrt{k^2a^2-l^2}}{ak+\alpha\sqrt{k^2a^2-l^2}} \right| \right). \tag{3.8}$$

We can now state Theorem 1.

THEOREM 1. *Let $\lambda \in \mathbb{C}$, $\Im\lambda \leqq 0$, satisfy*

$$\begin{aligned} &(\Delta+\lambda^2)\phi(x)=0, && x\in\Omega = \textit{the disk with radius } a,\\ &i\lambda\phi(x)-\alpha\frac{\partial\phi(x)}{\partial n}=0 && \textit{on } \partial\Omega. \end{aligned} \tag{3.9}$$

Then $k+i\mu(k)$ is an approximation to some λ such that

$$\lambda = k+i\mu(k)+O\left(\frac{1}{k}\right) \quad \textit{for large } k\in\mathbb{R}, \tag{3.10}$$

where k and $\mu(k)$ satisfy, respectively, (3.7) *and* (3.8) *for given integers l, $m=0,1,2,\cdots$.*

Remark 3.2. Our treatment in this section is based on the right *physics* of the problem. As the waves are propagating in the medium Ω, there is no loss of energy; therefore, *the wavenumber k should be real,* at least asymptotically. The only energy loss happens when the wave hits the boundary and makes the reflection. Therefore, nearly the entire damping rate can be attributed to the decrease of magnitude of the amplitude.

4. Comparison with existing results and numerical solutions. The case where Ω is the *unit disk* has been treated by Chen in his Ph.D. thesis [1]. Since those results have never been published elsewhere, we briefly summarize them below.

A direct approach of separation of variables in polar coordinates

$$\phi(x)=J_l(\lambda r)\,e^{\pm il\theta}, \quad J_l\text{: the Bessel function of order } l \tag{4.1}$$

for (3.9) leads to the transcendental equation

$$J_l(\lambda)+i\alpha J_l'(\lambda)=0, \qquad l=0,1,2,\cdots, \tag{4.2}$$

for the determination of the eigenfrequency λ. Let λ_{lm} denote the mth positive zero of the Bessel function J_l. We divide our discussion into the following cases:

(a) *Small α.* It has been shown in [1] that each λ_{lm} has a small neighborhood (uniform with respect to l, m) such that the solution λ of (4.2) is analytic with respect *to the damping parameter* α:

$$(4.3)\qquad \lambda = \lambda_{lm} + C_{lm1}\alpha + C_{lm2}\alpha^2 + \cdots + C_{lmj}\alpha^j + \cdots, \quad |\alpha| \text{ sufficiently small.}$$

We can actually compute a few coefficients by substituting (4.3) into (4.2) and using the Taylor expansion:

$$C_{lm1} = -i,$$

$$C_{lm2} = -\frac{3}{2}\frac{1}{\lambda_{lm}},$$

$$\vdots$$

(cf. [1, p. 114]). Thus for small α, the rate of damping is approximately equal to

$$(4.4)\qquad \Re(-i\lambda) = -\Re\alpha + O(\alpha^2).$$

We have computed a set of zeros of (4.2) for small α by using Newton's method, for $l = 0, 1, 4$. See Table 1. Using $\alpha = 0.01$, 0.015, 0.02, respectively, we have found from Table 1 that the damping rates are approximately equal to those in Table 2, in close agreement with (4.4).

To make comparisons, now we apply our formula (3.8) to the unit disk.

COROLLARY 1. *Consider the unit disk where* $a = 1$. *Then for* $\alpha \in \mathbb{C}$ *such that* $|\alpha|$ *is small and* $\Re\alpha > 0$, *we have*

$$\mu(k) = -\Re\alpha + O(\alpha^2).$$

Proof. Write

$$\alpha = \eta + i\xi, \qquad \eta, \xi \in \mathbb{R}.$$

We note that the caustic radius a_0 satisfies $0 < a_0 < 1$. By (3.8),

$$\begin{aligned}\mu(k) &= \frac{1}{2\sqrt{1-a_0^2}} \ln\left|\frac{[1-\eta\sqrt{1-a_0^2}]^2 + (\xi\sqrt{1-a_0^2})^2}{[1+\eta\sqrt{1-a_0^2}]^2 + (\xi\sqrt{1-a_0^2})^2}\right| \cdot \frac{1}{2} \\ &= \frac{1}{4\sqrt{1-a_0^2}} \ln\left|\frac{1-2\eta\sqrt{1-a_0^2} + |\alpha|^2\sqrt{1-a_0^2}}{1+2\eta\sqrt{1-a_0^2} + |\alpha|^2\sqrt{1-a_0^2}}\right| \\ &= \frac{1}{4\sqrt{1-a_0^2}}[-4\eta\sqrt{1-a_0^2} + O(|\alpha|^2)] \\ &= -\eta + O(|\alpha|^2) \\ &= -\Re\alpha + O(|\alpha|^2). \qquad \square\end{aligned}$$

Thus Corollary 1 is in full agreement with (4.4).

(b) *Medium size* α, $\alpha \neq 1$. Again, we use Newton's method to compute the zeros of (4.2), using $\alpha = 0.2$, 0.5, $0.6 + i \cdot 0.3$, 0.95, 1.5. Here we only tabulate the case $l = 4$. (For other integral values of l, the numerical data have manifested the same pattern.) Refer to Table 3.

TABLE 1

Zeros of $J_l(\lambda)+i\alpha J_l'(\lambda)=0$ for $l=0,1,4$ and small α. The number on the left denotes the real part of λ, while the number on the right denotes the imaginary part of λ.

10	36.806140, −1.770878	35.092441, −0.817906

We now compare the damping rates in Table 3 with the values obtained by applying formula (3.8). Using $a=1$, and noting that the radius a_0 of the caustic $C(a_0)$ shrinks to 0 as m becomes large, we obtain

(i) For $\alpha=0.2$

$$\frac{1}{2}\ln\left|\frac{1-0.2}{1+.02}\right|=-0.202733.$$

This is very close to the value −0.202695 at the bottom of the second column in Table 3.

(ii) For $\alpha=0.5$

$$\frac{1}{2}\ln\left|\frac{1-0.5}{1+0.5}\right|=-0.549306.$$

This is very close to the value −0.548514 at the bottom of the fourth column in Table 3.

(iii) For $\alpha=0.6+i0.3$,

$$\frac{1}{2}\ln\left|\frac{1-(06.+i\cdot 0.3)}{1+(0.6+i\cdot 0.3)}\right|=-0.581575,$$

which is close to −0.598217 at the bottom of the sixth column in Table 3. Note that the values in that column are increasing, contrasting the decreasing columns 2 and 4 in (i) and (ii).

(iv) For $\alpha = 0.95$,

$$\frac{1}{2}\ln\left|\frac{1-0.95}{1+0.95}\right| = -1.831781. \tag{4.5}$$

This deviates a little from the value 1.770878 at the bottom of column 8 in Table 3. The reason is that the damping parameter 0.95 is rather close to one. There is little question that those damping rates will still converge to the value in (4.5) if we let m become larger and larger.

(v) For $\alpha = 1.5$,

$$\frac{1}{2}\ln\left|\frac{1-1.5}{1+1.5}\right| = -0.804719. \tag{4.6}$$

(iv) This is close to the value -0.815787 at the bottom of column 10 in Table 3. We have checked that if more and more roots are computed (i.e., m is chosen large), then those damping rates will keep increasing and getting closer and closer to the value (4.6).

(c) *The characteristic impedance case*, $\alpha = 1$. When $\alpha = 1$, formula (3.8) gives

$$\frac{1}{2}\ln\left|\frac{1-1}{1+1}\right| = -\infty.$$

This infinitely large damping rate means that the amplitude of the reflected wave is zero; i.e., the incoming wave (here, the normal congruence II wave) would be *completely absorbed* by the boundary. In the *one-dimensional* case, such a complete wave absorption property is easy to confirm (see [3], e.g.; cf. also [9] for the higher-dimensional case). Let us look at the two-dimensional case here.

We have computed a large number of zeros of (4.2) for $l = 4$ again. These zeros are listed in Table 4. The reader can find that the rates of damping are steadily decreasing. For the 185th root, the damping rate is -3.881022. Since

$$2 \cdot e^{-3.881022} = 0.041259,$$

this means that at the wavenumber $k = 587.4475$ (i.e., the real part of the 185th zero of (4.2), when $l = 4$), the reflected wave (i.e., normal congruence I) has an amplitude that is only about 4.1 percent of the incoming wave.

We conjecture that the imaginary parts of the zeros of (4.2) for each l will decrease without bound, reaching $-\infty$.

From the stabilizer design point of view, choosing $\alpha = 1$ seems to suppress vibration most effectively.

We have observed that the damping rates listed in certain columns of various tables are steadily decreasing (see, e.g., columns 2, 4, and 8 in Table 3), whereas those listed elsewhere (e.g., columns 6 and 10 in Table 3) are steadily increasing.

This can be interpreted by Corollary 2.

COROLLARY 2. *Let $l \in \mathbb{Z}^+$ be fixed in* (3.8). *Then the rates of damping are decreasing if*

$$\frac{d}{da_0}\mu(k, a_0) < 0 \tag{4.7}$$

and increasing if

$$\frac{d}{da_0}\mu(k, a_0) > 0, \tag{4.8}$$

TABLE 4

Zeros of $J_4(\lambda)+i\alpha J_4(\lambda)=0$ *when* $\alpha=1$. *Note that the imaginary parts of* λ *all have negative signs as indicated by* $-\mathrm{Im}$.

where $\mu(k, a_0)$ is given by (3.8). *In particular, when $a=1$ and $0<\alpha<1$, we have*

$$\frac{d}{da_0}\mu(k, a_0)>0 \qquad (0<\alpha<1) \tag{4.9}$$

so the rates of damping are decreasing.

Proof. a_0 is the radius of the caustic, $0<a_0<1$. As m increases in (3.8), a_0 decreases monotonically to zero [7]. Therefore, (4.7) and (4.8) hold. To see (4.9), we note that from (3.8),

$$\mu(k, a_0)=-\left[1+\frac{1}{3}\alpha(1-a_0^2)+\frac{1}{5}\alpha^2(1-a_0^2)^2+\cdots+\frac{1}{2n+1}\alpha^n(1-a_0^2)^n+\cdots\right].$$

So $\mu(k, a_0)$ decreases as a_0 decreases on the interval $(0, 1)$. □

So far in this section we have only dealt with the damping rates of eigenmodes. How good is formula (3.7) in approximating the wavenumber k? In [7], Keller and Rubinow did some calculations (using $\alpha=0$ and $\alpha=\infty$ in (3.6)) and noted that the numerical solutions are extremely close to the tabulated values of zeros of Bessel functions and their derivatives. Here we list two sets of values of k computed from (3.7), using

$$l=4,\ \alpha=0.5, \quad \text{for Table 5,}$$

$$l=4,\ \alpha=0.6+i\cdot 0.3, \quad \text{for Table 6.}$$

The reader can compare those values against, columns 3 and 5 in Table 3, respectively, and find that they are rather agreeable, the more so when the wavenumber becomes large. Here our fractional errors are considerably larger than those reported in [7] (for the energy conserving cases) at all frequencies.

Remark 4.1. For each m, the smallest (positive) solution k of the transcendental equation (3.6) (corresponding to $m=0$ or 1) is known to have the strongest "whispering gallery" property. Such a whispering gallery mode has the largest radius a_0 for its

caustic. Since a whispering gallery mode is "essentially supported" only on an annulus with outer radius a and inner radius a_0, as shown in Fig. 1. Therefore, a whispering gallery wave propagates right adjacent to $\partial\Omega$. Since there is boundary damping present at $\partial\Omega$, *will the whispering gallery mode get damped with the largest damping rate* (in the same family of eigenmodes, i.e., given fixed l)? The answer is *negative* as evidenced by the damping rates data given in column 2, Table 3, for $l=4$, with $\alpha=0.5$. The reason is that the wave "slides" along the boundary; thus the energy loss from damping, being "the friction in the perpendicular direction," is not as large as expected.

Remark 4.2. By adapting the work in [7, pp. 35-39] to our problem, it is not difficult to show that the eigenmode $\phi(x)$ has the asymptotic representation

$$(4.10)\qquad \phi(x)=\phi(r,\theta)=\begin{cases} [(kr)^2-l^2]^{-1/4}\cos\left\{[(kr)^2-l^2]^{1/2}-l\cos^{-1}\dfrac{l}{kr}\right. \\ \qquad\left.-\left[\dfrac{3\pi}{4}+\dfrac{1}{2}\arg\left(\dfrac{ka-\alpha\sqrt{(ka)^2-l^2}}{ka+\alpha\sqrt{(ka)^2-l^2}}\right)\right]\right\} \\ \qquad\qquad\text{if } r\geqq a_0, \\ \dfrac{1}{2}[l^2-(kr)^2]^{-1/4}\exp\left\{il\theta-l\cos h^{-1}\left(\dfrac{l}{kr}\right)+[l^2-(kr)^2]\right\}, \\ \qquad\qquad\text{if } r\leqq a_0. \end{cases}$$

The second representation can be regarded as the analytic continuation of the first one. This function is easily seen to be exponentially small inside the caustic (i.e., $r\leqq a_0$) when l becomes large.

Remark 4.3. Let the damping parameter α be positive and small. It is known that the eigenmodes (4.1), where λ is a solution of (4.2) and λ is close to λ_{lm} (cf. (4.3)), do *not* constitute a *complete* set of eigenfunctions of $L^2(\Omega)$. Another family of eigenmodes must be added to make a complete set. This family is given by

$$I_l(\lambda r)\, e^{\pm il\theta},$$

where I_l is the modified Bessel function of order l, and λ is a (unique) real positive root of

$$I_l(\lambda)-\alpha I_l'(\lambda)=0.$$

Such an eigenmode decays exponentially in time *without oscillations*, i.e.,

$$w(x,t)=e^{-\lambda t}I_l(\lambda r)\,e^{\pm il\theta},\qquad \lambda>0,$$

satisfies (1.1) and (1.2). We will call such modes *overdamped* modes. Our wave method developed here *does not* cover such overdamped modes. Such eigenmodes seem to be intimately connected with the complex or imaginary rays [6], [7] and with the second representation formula in (4.10). We hope to be able to treat them in a separate article.

5. The case of rectangular geometry. Quinn and Russell [11] first studied the problem (1.1), (1.2) on a rectangular domain, which initiated a series of papers by Chen and others. We describe their setup of the problem and results. Let Ω be a rectangle:

$$\Omega=\{(x_1,x_2)|0<x_1<a,0<x_2<b\}$$

throughout the rest of this section. On $\partial\Omega$, the boundary conditions are prescribed as

$$(5.1)\qquad \begin{aligned} &w=0 && \text{on } \mathscr{S}_1\colon 0\leqq x\leqq a,\quad y=0,\quad t\geqq 0,\\ &\frac{\partial w}{\partial t}+\alpha\frac{\partial w}{\partial x}=0 && \text{on } \mathscr{S}_2\colon 0\leqq y\leqq b,\quad x=a,\quad t\geqq 0,\quad \Re\alpha\geqq 0,\\ &\frac{\partial w}{\partial t}+\beta\frac{\partial w}{\partial y}=0 && \text{on } \mathscr{S}_3\colon 0\leqq x\leqq a,\quad y=b,\quad t\geqq 0,\quad \Re\beta\geqq 0,\\ &w=0 && \text{on } \mathscr{S}_4\colon 0\leqq y\leqq b,\quad x=0,\quad t\geqq 0.\end{aligned}$$

In [11], Quinn and Russell let $a=b=\pi$, and α, β real and small. They showed that under such circumstances there exists a two-parameter family of eigenmodes:

$$w(x,t)=e^{-i\lambda t}\phi(x),$$

$$(5.2)\qquad \lambda=\sqrt{l^2+m^2}-\frac{i}{\pi}\left(\frac{\alpha l^2+\beta m^2}{l^2+m^2}\right)+O(\alpha^2+\beta^2),\qquad l,m=1,2,3,\cdots$$

and another one-parameter family of overdamped eigenmodes:

$$(5.3)\qquad \begin{gathered} w(x,t)=e^{-\lambda_j t}\phi(x),\\ 0<\lambda_1<\lambda_2<\cdots<\lambda_j<\cdots\to+\infty.\end{gathered}$$

We will leave out the study of overdamped modes in the present paper.

In [11], Quinn and Russell also gave explicit forms for the $\phi(x)$ in (5.3) in their paper. (They had an extra factor $\frac{1}{2}$ in their expression immediately before their Lemma 6.2, which has been corrected by us in (5.2).)

We now study the eigenfrequencies for the rectangular geometry and boundary conditions (5.1) by the wave method.

For the rectangle, Keller and Rubinow [7, pp. 57–59] pointed out that there are four normal congruences of waves, i.e., $N=4$, and the covering space is again topologically a torus. The four normal congruences of waves are depicted in Figs. 6–9.

Consider the family of rays in Fig. 6. The geometrical optics expansion in § 2 reduces to

$$(5.4)\qquad \phi(x)=A_1\exp\left(ik(\eta_1x_1+\eta_2x_1)\right),$$

where

$$(5.5)\qquad \begin{gathered}\eta_1=\cos\theta,\qquad \eta_2=\sin\theta\\ (\theta=\text{the angle formed between the ray and the } x_1 \text{ axis}).\end{gathered}$$

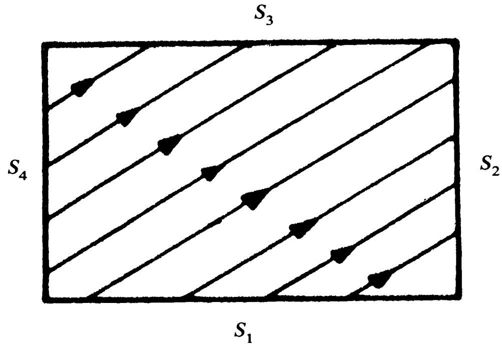

FIG. 6. *Rays of normal congruence* I. (*Reprinted from* [7], *with permission.*)

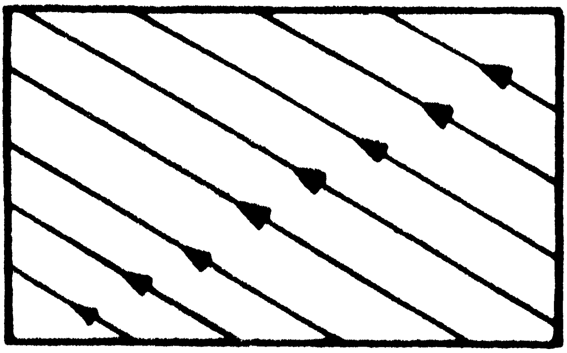

FIG. 7. *Rays of normal congruence* II. (*Reprinted from* [7], *with permission.*)

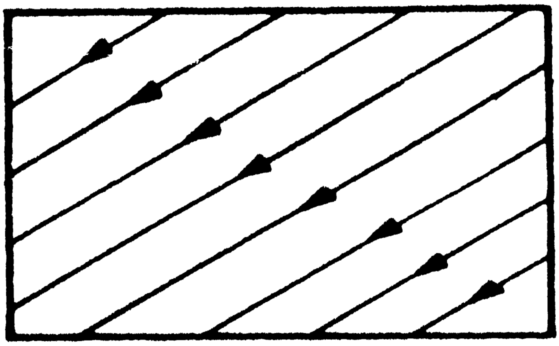

FIG. 8. *Rays of normal congruence* III. (*Reprinted from* [7], *with permission.*)

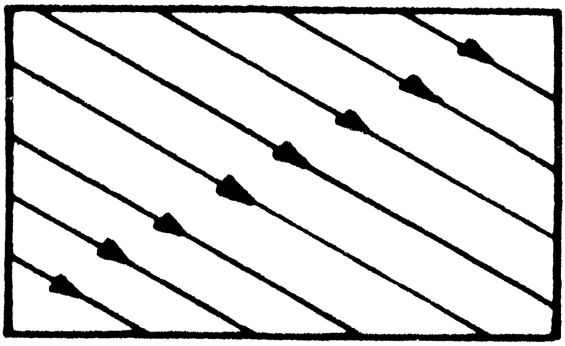

FIG. 9. *Rays of normal congruence* IV. (*Reprinted from* [7], *with permission.*)

Upon hitting side $\mathcal{S}_2$, reflection happens. Utilizing (2.17), we obtain the reflected wave of normal congruence II

$$\left[\frac{(-1+\alpha\eta_1)}{(1+\alpha\eta_1)}e^{ik\eta_1 a}A_1\right]\exp\left(ik[-\eta_1(x_1-a)+\eta_2x_2]\right), \tag{5.6}$$

the one as shown in Fig. 7. This wave moves left, hits side $\mathcal{S}_4$, makes a reflection there, and returns to the same direction as in Fig. 6. The reflection of wave (5.6), according to the last boundary condition in (5.1), gives rise to a wave of normal congruence I:

$$-\left[\frac{(-1+\alpha\eta_1)}{(1+\alpha\eta_1)}e^{2ik\eta_1 a}A_1\right]\exp(ik(\eta_1x_1+\eta_2x_2)). \tag{5.7}$$

In order for an eigenmode to form, resonance must happen so the two waves (5.4) and (5.7) must be in phase

$$\arg\left[-\frac{(-1+\alpha\eta_1)}{(1+\alpha\eta_1)}e^{2ik\eta_1 a}\right]=2l\pi, \qquad l\in\mathbb{Z},$$

$$\arg\left(\frac{1-\alpha\eta_1}{1+\alpha\eta_1}\right)+2k\eta_1 a=2l\pi, \qquad l\in\mathbb{Z}. \tag{5.8}$$

This is equivalent to applying (2.22) to a first closed path, $j=1$, on the torus, the covering space of wave motion.

Similarly, if we track the motions of normal congruences and III and II of rays as shown in Figs. 7 and 8, beginning from

$$\phi(x)=A_2\exp(ik[-\eta_1x_1-\eta_2(x_2-b)])$$

in Fig. 8, we see that after first reflection at $\mathcal{S}_1$ and second reflection at $\mathcal{S}_3$, this wave becomes

$$\left[\frac{(1-\beta\eta_2)}{(1+\beta\eta_2)}e^{2ik\eta_2 b}A_2\right]\exp(ik[-\eta_1x_1-\eta_2(x_2-b)]).$$

So, again, we deduce that

$$\arg\left(\frac{1-\beta\eta_2}{1+\beta\eta_2}\right)+2k\eta_2 b=2m\pi, \qquad m\in\mathbb{Z}^+. \tag{5.9}$$

This is equivalent to applying (2.22) to the second independent closed path, $j=2$, on the torus. From (5.5),

$$\eta_1^2+\eta_2^2=1; \tag{5.10}$$

therefore, the wavenumber k satisfies

$$k^2=\frac{1}{4a^2}\left[2l\pi-\arg\left(\frac{1-\alpha\eta_1}{1+\alpha\eta_1}\right)\right]^2+\frac{1}{4b^2}\left[2m\pi-\arg\left(\frac{1-\beta\eta_2}{1+\beta\eta_2}\right)\right]^2, \qquad l,m\in\mathbb{Z}, \tag{5.11}$$

subject to

$$\eta_1^2+\eta_2^2=1.$$

Note that once l and m are given, k is determinable from (5.8)-(5.10). So the solutions k form a two-parameter family.

A special case is where $\alpha=\beta=0$, then

$$\arg\frac{1-\alpha\eta_1}{1+\alpha\eta_1}=0, \qquad \arg\frac{1-\beta\eta_2}{1+\beta\eta_2}=0,$$

and we have

$$k^2=\left(\frac{l^2}{a^2}+\frac{m^2}{b^2}\right)\pi^2, \qquad l,m\in\mathbb{Z}. \tag{5.12}$$

This agrees entirely with the separation of variables approach because the boundary conditions (5.1) reduce to the Dirichlet condition, which is known to have eigenfrequencies k satisfying (5.12).

Similarly, if $\alpha=\beta=+\infty$, then

$$\arg\frac{1-\alpha\eta_1}{1+\alpha\eta_1}=\pm\pi, \qquad \arg\frac{1-\beta\eta_2}{1+\beta\eta_2}=\pm\pi$$

and (5.11) yields

$$k^2=\left[\frac{1}{4a^2}(2l+1)^2+\frac{1}{4b^2}(2m+1)^2\right]\pi^2, \qquad l, m\in\mathbb{Z}.$$

This determines the eigenfrequencies k for a mixed Dirichlet-Neumann boundary value problem which are also well understood.

Now let us compute the damping rates of eigenmodes. We note that for normal congruence I and II waves, *a complete cycle of wave motion* takes $2a/\eta_1$ units of time because $2a/\eta_1$ is the distance traveled by these waves. The total amount of damping that the waves have endured is

$$\ln\left|\frac{1-\alpha\eta_1}{1+\alpha\eta_1}\right|.$$

Therefore, the rate of damping per unit time for such a cycle of wave motion is

$$\frac{1}{(2a/\eta_1)}\ln\left|\frac{1-\alpha\eta_1}{1+\alpha\eta_1}\right|.$$

Similarly, the rate of damping per unit time for a cycle of wave motion as characterized by (5.9) is

$$\frac{1}{(2b/\eta_2)}\ln\left|\frac{1-\beta\eta_2}{1+\beta\eta_2}\right|.$$

Hence, the rate of damping per unit time for a wave to go through the complete sequence of motion

$$\text{waves (I, II)}\rightarrow\text{waves (II, III)}\rightarrow\text{waves (I, II)}$$

is

$$\left[\frac{1}{(2a/\eta_1)}\ln\left|\frac{1-\alpha\eta_1}{1+\alpha\eta_1}\right|+\frac{1}{(2b/\eta_2)}\ln\left|\frac{1-\beta\eta_2}{1+\beta\eta_2}\right|\right]. \tag{5.13}$$

This expression is obtained based upon the understanding that vertical and horizontal wave motions are independent of each other. Because of the amplitudes' multiplicative effect, the total rate of damping (as the logarithm of gain ratio) must be additive of damping rates in the separate horizontal and vertical directions. Also note that on a rectangle, there does not exist any caustics, so (5.13) will suffice to provide the damping rate per unit time, from the same ideas as in the circular geometry.

Any other complete sequences of wave motions (such as combinations of (III, II), (I, IV)) will also give the same damping rate as (5.13).

COROLLARY 3. *When α and β are real nonnegative and small, $a=b=\pi$, the damping rate per unit time* (5.13) *is*

$$-\frac{1}{\pi}\left(\frac{\alpha l^2+\beta m^2}{l^2+m^2}\right)+O(\alpha^2+\beta^2), \qquad l, m\in\mathbb{Z}. \tag{5.14}$$

Proof. When α and β are real and small

$$1-\alpha\eta_1>0, \qquad 1-\beta\eta_2>0$$

because $|\eta_1|\leqq 1$, $|\eta_2|\leqq 1$. Thus

$$\arg\left(\frac{1-\alpha\eta_1}{1+\alpha\eta_1}\right)=0, \qquad \arg\left(\frac{1-\beta\eta_2}{1+\beta\eta_2}\right)=0.$$

Therefore, from (5.8) and (5.9), we obtain

$$\eta_1=\frac{l}{k}, \qquad \eta_2=\frac{m}{k}. \tag{5.15}$$

Substituting (5.15) into (5.13), for small α and β, we have

$$\begin{aligned}(5.13)&=\frac{\eta_1}{2a}[-2\alpha\eta_1+O(\alpha^2\eta_1^2)]+\frac{\eta_2}{2b}[-2\beta\eta_2+O(\beta^2\eta_2^2)]\\ &=-\frac{1}{\pi}\{\alpha\eta_1^2+\beta\eta_2^2+O(\alpha^2+\beta^2)\}\\ &=-\frac{1}{\pi}\left(\frac{\alpha l^2+\beta m^2}{l^2+m^2}\right)+O(\alpha^2+\beta^2).\end{aligned}$$ □

Therefore, we see that the damping rate (5.14) agrees with (the dominant) imaginary part of λ in (5.2) given by Quinn and Russell, for small α and β. But our formulas (5.13) and (5.11) (subject to (5.8)-(5.10)) are more general because they apply to almost all range of values of α, β, $\Re\alpha\geqq 0$, $\Re\beta\geqq 0$.

There have been many physical arguments used by Keller and Rubinow in [7] and by us in this paper. These arguments are all based on the accepted standards of wave propagation and optics and have been rigorously established in [10] by Maslov and coworkers; therefore, they yield asymptotically accurate solutions.

NONSMOOTH PROBLEMS WITH CONFLICTING CONTROLS*

J. WARGA†

Abstract. This paper considers nonsmooth problems defined by ordinary differential equations and involving conflicting controls of two players. These problems differ from differential games in that the second player is informed of the first player's choice of control function before making his own choice. It attempts, with only partial success, to generalize the results obtained for C^1 problems in [J. Warga, *Optimal Control of Differential and Functional Equations*, Chaps. IX and X, Academic Press, 1972]. The results are in the form of a familiar alternative: either the problem is "strongly controllable" at a first player's relaxed control σ_0 or certain maximum principles and transversality conditions are valid. Two models are discussed in which the controls of the second player are relaxed controls, respectively, hyperrelaxed controls.

Key words. differential equations, conflicting controls, relaxed controls, hyperrelaxed controls, necessary conditions, derivate containers

AMS(MOS) subject classifications. 49B10, 49B40, 49E15

1. Introduction. We will consider problems with conflicting controls that bear some formal resemblance to differential games but provide the second player with a priori information about the first player's decisions. A special case of these problems are minimax problems of the form $\inf_u \sup_v$, where u and v are the controls of the first and second players. Specifically, consider functions y, $\tilde{y}$, and $\hat{y}=(y,\tilde{y})$ satisfying the differential equations

$$(1.1)\qquad \begin{aligned} y(t)&=\int_{t_0}^{t} f(s,y(s),u(s))\,ds,\\ \tilde{y}(t)&=\int_{t_0}^{t} \tilde{f}(s,\hat{y}(s),u(s),v(s))\,ds \quad \forall t\in T:=[t_0,t_1], \end{aligned}$$

in which R and R_P are compact metric spaces and $u:T\to R$ and $v:T\to R_P$ are (Lebesgue) measurable functions or, more generally, measurable selections of measurable set-valued mappings $t\to R^{\#}(t)$ and $t\to R_P^{\#}(t)$. For given functions

$$h=(h^1,\cdots,h^m):\mathbb{R}^n\to\mathbb{R}^m,\qquad \hat{h}:\mathbb{R}^n\times\mathbb{R}^p\to\mathbb{R}$$

(where $\mathbb{R}$ denotes the space of real numbers), we set

$$\varphi(u)=(\varphi^1,\cdots,\varphi^m)(u)=h(y(t_1)),\qquad \Phi(u)(v)=\hat{h}(\hat{y}(t_1))$$

and consider the restricted attainable set

$$(1.2)\qquad \mathcal{F}=\{\varphi(u)\mid\Phi(u)(v)\leqq 0\ \forall v\}.$$

If u_0 yields the minimum of $\varphi^1(u)$ subject to $\varphi^j(u)=0$ for $j=2,\cdots,m$ and $\Phi(u)(v)\leqq 0$ for all v, then clearly $\varphi(u_0)$ is on the boundary of $\mathcal{F}$. This cannot be the case if φ is either *controllable* at u_0, i.e., some neighborhood of $\varphi(u_0)$ is contained in $\mathcal{F}$, or a fortiori, if φ is *strongly controllable* at u_0, i.e., there exists $\beta>0$ such that some neighborhood of $\varphi(u_0)$ is contained in

$$(1.3)\qquad \mathcal{F}_\beta:=\{\varphi(u)\mid\Phi(u)(v)\leqq-\beta\ \forall v\}.$$

† Department of Mathematics, Northeastern University, Boston, Massachusetts 02115.

(We might mention, in passing, that the restriction $\hat{h}(\hat{y}(t_1)) \leqq 0$ is more general than it may appear. Thus, e.g., a restriction of the form $h^{\#}(\hat{y}(t_1)) \in A \subset \mathbb{R}^a$, with A a convex body, is equivalent to $\hat{h}(\hat{y}(t_1)) \leqq 0$ if we set $h = \phi \circ h^{\#}$, where ϕ is a gauge function of A. For a more detailed discussion, see [6, p. 29].)

A similar problem was studied in [4, Chaps. IX and X] under the assumption that the functions $f(t, \cdot, r)$, $\tilde{f}(t, \cdot, r, r_P)$, h and $\hat{h}$ are C^1. It was shown there—and the proof remains valid under the weaker assumptions of this paper—that there are two ways of compactifying the problem, corresponding to different "physical" models. The first of these ways replaces the conflicting ordinary controls u and v with relaxed controls σ and π so that (1.1) is replaced by

$$\text{(1.4)}\qquad \begin{aligned} \hat{y}(t) &= \int_{t_0}^{t} \hat{f}(s, \hat{y}(s), \sigma(s), \pi(s))\, ds \\ &= \int_{t_0}^{t} ds \int \hat{f}(s, \hat{y}(s), r, r_P)\sigma(s)(dr) \times \pi(s)(dr_P) \quad \forall t \in T, \end{aligned}$$

where $\hat{f} = (f, \tilde{f})$. This properly models two kinds of problems: problems with additively coupled (or separated) controls in which

$$\hat{f}(t, \hat{\mathbf{y}}, r, r_P) = \hat{f}_1(t, \hat{\mathbf{y}}, r) + \hat{f}_2(t, \hat{\mathbf{y}}, r_P)$$

(where the boldfaced letter $\hat{\mathbf{y}}$ represents a point in the space $\mathbb{R}^{n+p}$ to distinguish it from the function $\hat{y}$ with values in $\mathbb{R}^{n+p}$); and problems in which the adversary (who controls v) does not have perfect means of detecting the exact value of $u(t)$ but only detects the distribution of values of $u(\cdot)$ over short intervals of time. The second kind of compactification replaces $u(\cdot)$ with the corresponding relaxed controls $\sigma(\cdot)$ while replacing $v(\cdot)$ with the corresponding *hyperrelaxed* controls $\pi: T \times R \to \operatorname{rpm}(R_P)$, where $\operatorname{rpm}(R_P)$ represents the set of Radon probability measures on R_P. This latter type of compactification properly models problems with nonseparated controls and with perfect observation capabilities of the v-controller, and replaces the sets $\mathcal{F}$ and $\mathcal{F}_\beta$ of (1.2) and (1.3) with their closures.

In the present paper we primarily study, in Theorem 2.4, the controllability of the problem when it is subjected to the first kind of compactification involving relaxed controls of both opponents. However, we also derive a weaker result, Theorem 2.5, pertaining to problems with hyperrelaxed adverse controls. In both cases, we assume that $f(t, \cdot, r)$, $\hat{f}(t, \cdot, r, r_P)$, h, and $\hat{h}$ are Lipschitz continuous but not necessarily C^1. We also require the additional "semi-C^1" assumption (2.3.5)

$$\hat{f}(t, \hat{\mathbf{y}}, r, r_P) = \hat{f}_1(t, \hat{\mathbf{y}}, r) + \hat{f}_2(t, \hat{\mathbf{y}}, r, r_P),$$

where $\hat{f}_2(t, \cdot, r, r_P)$ is assumed to be C^1. Our results are in the form of an alternative: either the problem is strongly controllable or certain maximum principles and transversality conditions are valid. The maximum principles (or, more properly, minimum principles) appear in different forms. In Theorem 2.4, the "integral" form 2.4(b2.1) of the maximum principle is analogous to those obtained for many other nonsmooth problems. On the other hand, our first "pointwise" principle 2.4(b2.2) involves an integral of a function with values in L^2 provided with a "weak" norm, while each version of the second one, 2.4(b2.3), requires a special assumption (verifiable a priori). The maximum principle 2.4(b2.2) involves certain considerations about an interchange of the order of integration that bear a superficial resemblance to some aspects of stochastic integration [3, Thm. 3A, p. 79].

We define the framework of our problems and the corresponding results, Theorems 2.4 and 2.5, in § 2. In that section we also include an abstract result, Theorem 2.6, which we use in proving Theorems 2.4 and 2.5 and which we expect to have other applications in optimal control. In § 3 we comment on the maximum principles of Theorems 2.4 and 2.5 and on the "semi-C^1" assumption (2.3.5). The proofs appear in § 4.

2. Definitions and results.

2.1. Preliminary definitions and notation. We denote by $\bar{A}$ or cl A, A°, ∂A, co A, and $\overline{\text{co}}\, A$ the closure, interior, boundary, convex hull, and convex closure of A. We endow the spaces $\mathbb{R}^a$ with the Euclidean norm and the spaces $\mathscr{L}(\mathbb{R}^a, \mathbb{R}^b)$ (of $b \times a$ matrices) with the (strictly convex) norm $|(M_{ij})| := [\sum_{i,j} M_{ij}^2]^{1/2}$. We represent the elements of any $\mathbb{R}^a$ as column vectors and denote their transpose by the superscript T. We denote by $\bar{B}_{\mathscr{Y}}$ the closed unit ball in a normed vector space $\mathscr{Y}$ and by $\bar{B}_m$ the closed unit ball in $\mathbb{R}^m$. If ν is a Radon measure on a compact metric space X, $x \in X$, and $g: X \to \mathbb{R}^a$ continuous, we write supp(ν) for the support of ν, δ_x for the Dirac measure at x, and $g(\nu)$ for $\int g(x)\nu(dx)$.

We use some of the notation, definitions, and results of [4, Chaps. IX and X], which we summarize in the present context. Let $T := [t_0, t_1] \subset \mathbb{R}$, μ be the Lebesgue measure on T; R and R_P compact metric spaces, $\hat{R} := R \times R_P$; and $R^\#: T \to 2^R$ and $R_P^\#: T \to 2^{R_P}$ μ-measurable mappings whose values are nonempty closed sets. We write $C(T, \mathbb{R}^a)$ $[AC(T, \mathbb{R}^a)]$ for the spaces of all continuous (absolutely continuous) functions from T to $\mathbb{R}^a$ with the sup norm, and $L^q(\mu, \mathscr{X})$ for the Banach space of μ-measurable functions with values in a Banach space $\mathscr{X}$ and with the usual norm $|\cdot|_q < \infty$. We denote by frm (X) the vector space of all Radon measures on X, and by frm$^+$ (X) and rpm (X) its subsets consisting of nonnegative and probability measures, each with the weak* topology of $C(X)^*$ (the topological dual of $C(X) = C(X, \mathbb{R})$).

We denote by $\mathscr{S}^\#$ the collection of *relaxed controls*, i.e., μ-measurable mappings $\sigma: T \to \text{rpm}(R)$ with $\sigma(t)(R^\#(t)) = 1$ μ-almost everywhere and with the weak* topology of $L^1(\mu, C(R))^*$. We similarly define $\mathscr{S}_P^\#$, respectively $\hat{\mathscr{S}}^\#$, with R, $R^\#(t)$ replaced by R_P, $R_P^\#(t)$, respectively, $\hat{R}$, $R^\#(t) \times R_P^\#(t)$. The sets $\mathscr{S}^\#$, $\mathscr{S}_P^\#$, and $\hat{\mathscr{S}}^\#$ are compact and convex. We write $\mathscr{P}^\#$ for the collection of *hyperrelaxed controls*, i.e., Borel measurable mappings $\pi: T \times R \to \text{rpm}(R_P)$ with $\pi(t, r)(R_P^\#(t)) = 1$ for all $r \in R$ μ-almost everywhere. For each $\sigma \in \mathscr{S}^\#$ and $\pi \in \mathscr{P}^\#$, we write $\sigma \otimes \pi$ for the unique element of $\hat{\mathscr{S}}^\#$ such that

$$\int_{t_0}^{t_1} dt \int \varphi(t, r, r_P)\sigma \otimes \pi(t)(d(r, r_P)) = \int_{t_0}^{t_1} dt \int \sigma(t)(dr) \int \varphi(t, r, r_P)\pi(t, r)(dr_P)$$
$$\forall \varphi \in L^1(\mu, C(\hat{R})).$$

There appears to be no useful way of defining a compact metric topology for $\mathscr{P}^\#$ so as to render the mapping $\pi \to \sigma \otimes \pi : \mathscr{P}^\# \to \hat{\mathscr{S}}^\#$ continuous for every $\sigma \in \mathscr{S}^\#$. However, if we choose any denumerable subset $\mathscr{S}'$ of $\mathscr{S}^\#$, then we can define [4, Def. X.2.1]

(a) a set $\tilde{\mathscr{P}}$ of equivalence classes in $\mathscr{P}^\#$ such that

$$\sigma \otimes \pi_1(t) = \sigma \otimes \pi_2(t) \quad \mu\text{-a.e.} \quad \forall \sigma \in \text{co}\, \mathscr{S}'$$

if π_1 and π_2 belong to the same equivalence class, and

(b) a compact metric topology for $\tilde{\mathscr{P}}$ such that the mapping $\pi \to \sigma \otimes \pi : \tilde{\mathscr{P}} \to \hat{\mathscr{S}}^\#$ is continuous for every $\sigma \in \text{co}\, \mathscr{S}'$.

We will use the symbol $\mathscr{P}$ to denote either $\mathscr{S}_P^\#$ or $\tilde{\mathscr{P}}$ and, for $\sigma \in \mathscr{S}^\#$ and $\pi \in \mathscr{S}_P^\#$, we will write $\sigma \otimes \pi(t)$ for $\sigma(t) \times \pi(t)$. We observe that, with these definitions, the mapping $\pi \to \sigma \otimes \pi : \mathscr{P} \to \hat{\mathscr{S}}^{\#}$ is continuous for every choice of $\sigma \in \operatorname{co} \mathscr{S}'$, where $\mathscr{S}'$ is an arbitrary denumerable subset of $\mathscr{S}^{\#}$ and $\tilde{\mathscr{P}}$ is defined accordingly. If $g : R \times R_P \to \mathbb{R}^a$ is continuous, we write $g(\sigma \otimes \pi(t))$ or $g(\sigma(t), \pi(t))$ for $\int \sigma(t)(dr) \int g(r, r_P)\pi(t)(dr_P)$ if $\pi \in \mathscr{S}_P^{\#}$ and $g(\sigma \otimes \pi(t))$ for $\int \sigma(t)(dr) \int g(r, r_P)\pi(t, r)(dr_P)$ if $\pi \in \tilde{\mathscr{P}}$. We observe that for any continuous $g : R \to \mathbb{R}^a$ we have $g(\sigma \otimes \pi(t)) = g(\sigma(t))$ for all $\pi \in \mathscr{P}$. We also write $\int_w \varphi(\pi)\omega(d\pi)$ for the integral of a function $\varphi : \mathscr{P} \to (L^2(\mu, \mathbb{R}), |\cdot|_w)$, where $|\cdot|_w$ is a "weak" norm on $L^2(\mu, \mathbb{R})$ that can be defined as follows. Let $\{x_1, x_2, \cdots\}$ be a dense denumerable subset of $L^2(\mu, \mathbb{R})$ and

$$|\ell|_w := \sum_{i=1}^{\infty} \frac{2^{-i}}{1+|x_i|} |\langle \ell, x_i \rangle| \quad \forall \ell \in L^2(\mu, \mathbb{R}) = (L^2(\mu, \mathbb{R}))^*.$$

Then $|\cdot|_w$ is a norm on $L^2(\mu, \mathbb{R})$, and it induces the weak topology (=the weak* topology) on any bounded subset of $L^2(\mu, \mathbb{R}) = (L^2(\mu, \mathbb{R}))^*$ [4, Thm. I.3.11].

We will also use the concepts of a derivate container and of Clarke's generalized Jacobian [2, p. 70].

DEFINITION 2.2. Let $W \subset \mathbb{R}^a$ be open and $g : W \to \mathbb{R}^b$ locally Lipschitzian.

(2.2.1) We say that a collection $\{\Lambda^\varepsilon g(x)\} \mid \varepsilon > 0\}$, also denoted by $\Lambda^\varepsilon g(x)$, of closed bounded subsets of $\mathscr{L}(\mathbb{R}^a, \mathbb{R}^b)$ is a *derivate container* for g at x if

$$\Lambda^\varepsilon g(x) \subset \Lambda^{\varepsilon'} g(x) \quad \text{for } \varepsilon < \varepsilon'$$

and there exists a sequence $(g_i : W \to \mathbb{R}^b)$ of C^1 functions converging uniformly to g and such that

$$g_i'(y) \in \Lambda^\varepsilon g(x) \quad \text{if } y \in W, \quad |y - x| \leqq \varepsilon, \quad i \geqq 1/\varepsilon.$$

We set

$$\Lambda g(x) = \bigcap_{\varepsilon > 0} \Lambda^\varepsilon g(x)$$

for every derivate container $\Lambda^\varepsilon g(x)$, and refer to $\Lambda g(x)$, as well as to $\Lambda^\varepsilon g(x)$, as a derivate container. Since the sets

$$\Lambda_1^\varepsilon g(x) = \operatorname{cl}\{g_i'(y) \mid y \in W, |y - x| \leqq \varepsilon, i \geqq 1/\varepsilon\} \subset \Lambda^\varepsilon g(x)$$

also define a (better) derivate container, and the set-valued function $x \to \Lambda_1^\varepsilon g(x)$ is upper semicontinuous, we henceforth assume that the derivate containers that we use have this upper semicontinuity property.

(2.2.2) Let $D = \{y \in W \mid g'(y) \text{ exists}\}$,

$$\partial^\varepsilon g(x) = \overline{\operatorname{co}}\{g'(y) \mid y \in D, |y - x| \leqq \varepsilon\}, \quad \partial g(x) = \bigcap_{\varepsilon > 0} \partial^\varepsilon g(x).$$

Then $\partial g(x)$ coincides with Clarke's generalized Jacobian and, by [6, Thm. 2.5], $\partial^\varepsilon g$ is a derivate container that is upper semicontinuous.

Assumption 2.3. Let $V \subset \mathbb{R}^n$ and $\tilde{V} \subset \mathbb{R}^p$ be open, $\hat{V} = V \times \tilde{V}$, and the functions

$$f : T \times V \times R \to \mathbb{R}^n, \qquad \tilde{f} : T \times \hat{V} \times R \times R_P \to \mathbb{R}^p,$$

$$\hat{f} = (f, \tilde{f}) : T \times \hat{V} \times R \times R_P \to \mathbb{R}^{n+p}, \quad h : V \to \mathbb{R}^m, \quad \hat{h} : \hat{V} \to \mathbb{R}$$

such that

(2.3.1) $\hat{f}(\cdot, \hat{y}, r, r_P)$ are μ-measurable;

(2.3.2) $\hat{f}(t, \cdot, \cdot, \cdot)$ are continuous;

and there exist $c \geqq 0$ and a μ-integrable $\psi : T \to [0, \infty)$ such that

(2.3.3) $\hat{f}(t,\cdot,r,r_P)$ have $\psi(t)$, and h and $\hat{h}$ have c, as a common bound and a common Lipschitz constant;

(2.3.4) the differential equation

$$\hat{y}(t)=\int_{t_0}^{t}\hat{f}(s,\hat{y}(s),\sigma\otimes\pi(s))\,ds\quad\forall t\in T$$

has a unique solution $\hat{y}(\sigma\otimes\pi)(\cdot)=(y(\sigma),\tilde{y}(\sigma\otimes\pi))(\cdot)$ for every choice of $\sigma\in\mathcal{S}^{\#}$ and $\pi\in\mathcal{P}$;

(2.3.5) $\hat{f}(t,\hat{\mathrm{y}},r,r_P)=\hat{f}_1(t,\hat{\mathrm{y}},r)+\hat{f}_2(t,\hat{\mathrm{y}},r,r_P)$, where $\hat{f}_1$ and $\hat{f}_2$ satisfy the same conditions as $\hat{f}$ and, in addition, $\hat{f}_2$ has a partial derivative $\mathcal{D}_2\hat{f}_2$ with respect to the second argument of $\hat{f}_2$, and the function

$$(\hat{\mathrm{y}},r,r_P)\to\mathcal{D}_2\hat{f}_2(t,\hat{\mathrm{y}},r,r_P):\hat{V}\times R\times R_P\to\mathcal{L}(\mathbb{R}^{n+p},\mathbb{R}^{n+p})$$

is continuous for each $t\in T$.

We can now state our principal results. Theorem 2.4 deals with the case of adverse relaxed controls and Theorem 2.5 with the case of adverse hyperrelaxed controls. We write $\partial f(t,w,r)$ and $\partial\hat{f}(t,\hat{w},r,r_P)$ for the generalized Jacobians of $f(t,\cdot,r)$ at w and of $\hat{f}(t,\cdot,r,r_P)$ at $\hat{w}$.
