stable it implies almost immediately that the approximating semigroups are uniformly exponentially stable with a decay rate that can be made arbitrarily close (as $N \to \infty$) to the decay rate of the original equations. Second, and more important, this makes it possible to obtain convergence rates of the homogeneous solution. In [L1], precise statements of the optimal convergence estimates and their dependence on the initial data and system parameters were presented for the first time. Moreover, they showed that convergence of the approximating semigroups in the uniform operator topology can be obtained for sufficiently large time. The strong convergence of approximating semigroups has been proved via the Trotter–Kato approximation theorem in [B1].

A problem that has not yet been considered is whether analogous results can be developed for averaging approximation of RFDE with general delays in control and observation. In this paper we extend the results in Banks and Burns [B1] and Lasiecka and Manitius [L1] to retarded systems with unbounded input and output operators considered in the state space framework developed by Pritchard and Salamon [P2]. Moreover, convergence properties of the approximating output operators and the approximating state solution corresponding to the nonhomogeneous problem were also analyzed. The convergence results of the approximating output operators were obtained based on detailed analyses of the convergence and bounds of the composition of the unbounded input and output operators with the well-known operators characterizing the resolvents. Finally, we noted that the development presented in this paper gives a basis for numerical investigations of control problems, in particular using the operator Riccati equations. In particular, recently Ito and Tran [I3] have developed a general approximation framework for the numerical treatment of Riccati operators for a class of linear infinite-dimensional systems with unbounded input and output operators. As a simple application, the convergence theory was applied to the linear quadratic control problem for linear retarded systems with point delays in the controls. Later, Tran [T1] provided numerical evidence demonstrating the feasibility of the general approach in the context of feedback control of retarded systems with delay in the control using the averaging approximation scheme.

The organization of the paper is as follows. We first review in §2 a general setting for our system approximation problem in some appropriate Hilbert space. Much of the material in this section comes from a recent article by Pritchard and Salamon [P2] in which a unified theory of control systems with delays in state, control and observation based on C_0-semigroups is provided. Within the framework in §2, the averaging approximating scheme for linear RFDE with general delays in control and observation is developed in §3.1. Section 3.2 contains results on uniform differentiability of the approximating semigroups and uniform exponential stability of these semigroups when the original semigroup is exponentially stable. The main part of the paper is §4, where we give precise statements of convergence results as well as estimates of convergence rates with their proofs. Finally, §5 gives our concluding remarks.

2. Linear retarded systems with delays in input and output. In this section we define the type of hereditary systems to be considered in this paper and review some well-known results on the state space description of linear RFDE with general delays in input and output in terms of semigroups and evolution equations. Much of the material in this section comes from Pritchard and Salamon [P2] but must be presented to give a clear discussion of the developments in the subsequent sections.

We consider the linear RFDE of the form

$$\dot{x}(t) = Lx_t + \hat{B}u_t, \qquad t \geq 0, \tag{1a}$$

$$y(t) = \hat{C}x_t, \tag{1b}$$

where $x(t) \in R^n$, $u(t) \in R^m$, $y(t) \in R^p$ and x_t, u_t are defined by $x_t(\theta) = x(t+\theta)$, $u_t(\theta) = u(t+\theta)$ for $\theta \in [-h, 0]$, $0 < h < \infty$. The bounded linear operators $L, \hat{B}$, and $\hat{C}$ are mappings from spaces of real vector-valued continuous functions to real finite-dimensional spaces and are given by

$$\begin{aligned} L\phi &= \int_{-h}^{0} d\eta(\theta)\phi(\theta) + A_0\phi(0) \\ &= \sum_{i=0}^{q} A_i\phi(-h_i) + \int_{-h}^{0} A_{01}(\theta)\phi(\theta)d\theta, \\ \hat{C}\phi &= \int_{-h}^{0} d\gamma(\theta)\phi(\theta) + C_0\phi(0) \\ &= \sum_{i=0}^{q} C_i\phi(-h_i) + \int_{-h}^{0} C_{01}(\theta)\phi(\theta)d\theta, \qquad \phi \in C(-h, 0; R^n), \\ \hat{B}\xi &= \int_{-h}^{0} d\beta(\theta)\xi(\theta) + B_0\xi(0) \\ &= \sum_{i=0}^{q} B_i\xi(-h_i) + \int_{-h}^{0} B_{01}(\theta)\xi(\theta)d\theta, \qquad \xi \in C(-h, 0; R^m), \end{aligned}$$

where $0 = h_0 < h_1 < \cdots < h_q = h$, $A_i \in R^{n\times n}$, $B_i \in R^{n\times m}$, $C_i \in R^{p\times n}$, $i = 0, \ldots, q$, and $A_{01}(\cdot) \in L^2(-h, 0; R^{n\times n})$, $B_{01}(\cdot) \in L^2(-h, 0; R^{n\times m})$, $C_{01}(\cdot) \in L^2(-h, 0; R^{p\times n})$. It is clear that the matrix function $\eta : [-h, 0] \to R^{n\times n}$ of bounded variation is of the form

$$\eta(\theta) = -\sum_{i=1}^{q} A_i\chi_{(-\infty,-h_i]}(\theta) - \int_{\theta}^{0} A_{01}(s)ds, \qquad \theta \in [-h, 0],$$

where χ_I denotes the characteristic function of the interval I. Similarly, we can define the matrix functions β and γ. Let

$$X = R^n \times L^2(-h, 0; R^n) \times L^2(-h, 0; R^m)$$

Consider the solution of (1) with the initial data

$$x(0) = \phi^0, \quad x(\theta) = \phi^1(\theta), \quad u(\theta) = \phi^2(\theta), \quad \theta \in [-h, 0),$$

where $\phi = (\phi^0, \phi^1, \phi^2) \in X$, and $u(\cdot) \in L^2_{\text{loc}}(-h, \infty; R^m)$. Routine extensions of standard results (see, e.g., [D1], [P2], [S2]) guarantee existence, uniqueness, and continuous dependence of the solution on the initial data $\phi \in X$. This motivates the "natural" definition of the state of system (1) at time $t \geq 0$ to be the triple $z(t) = \big(x(t), x_t, u_t\big) \in X$, and thus justifies the choice of X as the state space for (1).

In problems involving Laplace and Fourier transforms and eigenvalue analysis of (1), we will need to use the natural complex extension of X, i.e., the space

$$\tilde{X} = \mathbf{C}^n \times L^2(-h, 0; \mathbf{C}^n) \times L^2(-h, 0; \mathbf{C}^m).$$

This being understood, we will use notation X for both the state space and its complex extension without an explicit mention each time.

To accomodate the effect of delays in the observation, we will also use the space

$$X^T = R^n \times L^2(-h, 0; R^n) \times L^2(-h, 0; R^p),$$

or its complex extension (the integer p is the dimension of the output vector).

The evolution of the state $z(t)$ in time is governed by the variation-of-constants formula [P2]

$$z(t) = S(t)\phi + \int_0^t S(t-\theta)Bu(\theta)d\theta, \qquad t \geq 0 \tag{2}$$

with the corresponding output $y(t)$ given by

$$y(t) = Cz(t), \qquad t \geq 0.$$

To allow for possible unboundedness of the input and output operators, B and C, we assume that $B \in L(R^m, V)$, $C \in L(W, R^p)$ where W and V are Hilbert spaces such that

$$W \subset X \subset V$$

with continuous dense injections $i : W \to X$ and $j : X \to V$. Moreover, the input operator $B : R^m \to V$ is given by [I1]

$$Bu = (B_0 u, 0, T_{\delta_0}(u)), \qquad u \in R^m,$$

where the generalized function T_{δ_0} is the Dirac distribution concentrated at the point $0 \in R^m$, and the output operator $C : W \to R^p$ is given by

$$C\phi = \hat{C}\phi^1, \qquad \phi \in W.$$

The C_0-semigroup $S(\cdot)$ corresponding to the free motion of the system, $u(t) = 0$ for $t \geq 0$, i.e., the bounded linear operator $S(t) : X \to X$ is defined by

$$S(t)\phi = (x(t), x_t, u_t), \qquad \phi \in X.$$

The infinitesimal generator A of $S(\cdot)$ is given by

$$\begin{aligned} \mathrm{dom}A = \Big\{ & \phi \in X / \phi^1 \in W^{1,2}(-h, 0; R^n), \\ & \phi^2 \in W^{1,2}(-h, 0; R^m), \quad \phi^1(0) = \phi^0, \quad \phi^2(0) = 0 \Big\} \\ A\phi = (L\phi^1 + \hat{B}\phi^2 - B_0\phi^2(0), \dot{\phi}^1, \dot{\phi}^2), & \qquad \phi \in \mathrm{dom}A, \end{aligned} \tag{3}$$

[P2]. To make (2) precise and to allow for trajectories in all three spaces W, X, and V, we assume that $S(\cdot)$ is also a strongly continuous semigroup on W and V and that the following hypotheses are satisfied.

Let $k = ji$ be the continuous dense injection from W into V.

(H1) For any $u(\cdot) \in L^2(0, T; R^m)$,

$$\int_0^T S(T-\theta)Bu(\theta)d\theta \in kW$$

and there exists a positive constant b such that

$$\left\| k^{-1} \int_0^T S(T-\theta)Bu(\theta)d\theta \right\|_W \leq b\|u\|_{L^2(0,T;R^m)}.$$

(H2) There exists a positive constant c such that

$$\left\| CS(\cdot)\phi \right\|_{L^2(0,T;R^p)} \leq c\|k\phi\|_V, \qquad \phi \in W.$$

The dual statements of (H1) and (H2) are as follows.

(H1*) For every $x \in V^*$,

$$\left\| B^*S^*(T-\cdot)x \right\|_{L^2(0,T;R^m)} \leq b\|k^*x\|_{W^*}.$$

(H2*) For every $y(\cdot) \in L^2(0,T;R^p)$

$$\int_0^T S^*(T-\theta)C^*y(\theta)d\theta \in k^*V^*$$

and

$$\left\| (k^*)^{-1} \int_0^T S^*(T-\theta)C^*y(\theta)d\theta \right\|_{V^*} \leq c\|y\|_{L^2(0,T;R^p)}.$$

The function $z(t)$ as defined in (2) is a mild solution of the abstract Cauchy problem

$$(\Sigma) \qquad \begin{aligned} \frac{d}{dt}z(t) &= Az(t) + Bu(t), \\ y(t) &= Cz(t) \end{aligned}$$

in the Hilbert spaces W, respectively, V [P2]. We note here that, if we consider the Cauchy problem (Σ) in the state space W, then the ouput operator C will be bounded but the input operator B may be unbounded. Nevertheless, the solution of (Σ) in W is well defined, since B satisfies hypothesis (H1). Conversely, if we consider the Cauchy problem (Σ) in the bigger state space V, then B is bounded but C may be unbounded. Nevertheless, the output is well defined, since C satisfies hypothesis (H2).

Before closing this section, we will describe the structural operator F associated with (1) and the resolvent operator $R(\lambda, A)$ of the generator A, both being generalizations of the operators F and $R(\lambda, A)$ described in [D2].

Let $F : X \to X^{T^*}$ be defined by

$$[F\phi]^0 = \phi^0, \qquad [F\phi]^1(\theta) = \int_{-h}^{\theta} d\eta(s)\phi^1(s-\theta) + \int_{-h}^{\theta} d\beta(s)\phi^2(s-\theta),$$
$$[F\phi]^2(\theta) = \int_{-h}^{\theta} d\gamma(s)\phi^1(s-\theta), \qquad \theta \in [-h, 0].$$

This definition corresponds to the results of [P2]. We note that in the work of Delfour and Karrakchou [D1] the definition of F does not include the term with $\beta(\cdot)$, which instead is added as an exogenous component of the system state. Both choices of the structural operator are valid; ours is more suitable to describe the duality between the original system (1) and the "transposed" system (with input $v(t)$ and output $q(t)$)

$$(4) \qquad \begin{aligned} \frac{d}{dt}w(t) &= L^T w_t + \hat{C}^T v_t, \\ q(t) &= \hat{B}^T w_t, \end{aligned}$$

and the resulting duality by transposition between the finite-dimensional approximations of (1) and (4). The structural operator F has the same basic properties as the one in [D2]. In particular, its dual operator $F^* : X^T \to X^*$ is

$$
\begin{aligned}
[F^*\psi]^0 = \psi^0, \qquad [F^*\psi]^1(\theta) &= \int_{-h}^{\theta} d\eta^T(s)\psi^1(s-\theta) + \int_{-h}^{\theta} d\gamma^T(s)\psi^2(s-\theta) \\
[F^*\psi]^2(\theta) &= \int_{-h}^{\theta} d\beta^T(s)\psi^1(s-\theta), \qquad \theta \in [-h, 0].
\end{aligned} \tag{5}
$$

Remark 2.1. The structural operator is extremely useful in numerical approximations for two reasons: (a) it plays a crucial role in the proof of convergence rates; see the proof of Theorem 4.3, estimate of $\|T_3\|$, and (b) it often enables us to make a dramatic reduction in the dimensionality of approximating systems (see [T1]).

In the remainder of this section, X and X^T will be their complex extensions. For $\lambda \in \mathbf{C}$, let the "exponential map" $E_\lambda : \mathbf{C}^n \to X$ be defined by

$$
[E_\lambda x]^0 = x, \quad [E_\lambda x]^1(\theta) = e^{\lambda\theta}x, \quad [E_\lambda x]^2(\theta) = 0, \qquad x \in \mathbf{C}^n.
$$

An analogous definition holds for $E_\lambda^T : \mathbf{C}^n \to X^T$. The dual operators $E_\lambda^* : X^* \to \mathbf{C}^n$ and $E_\lambda^{T^*} : X^{T^*} \to \mathbf{C}^n$ are given by

$$
\begin{aligned}
E_\lambda^*\phi &= \phi^0 + \int_{-h}^{0} e^{\bar\lambda\theta}\phi^1(\theta)d\theta, \\
E_\lambda^{T^*}\psi &= \psi^0 + \int_{-h}^{0} e^{\bar\lambda\theta}\psi^1(\theta)d\theta.
\end{aligned}
$$

Note that the composition of maps $E_\lambda^{T^*}F : X \to \mathbf{C}^n$ is well defined and does not depend on $\gamma(\cdot)$. That is,

$$
E_\lambda^{T^*}F\phi = \phi^0 + \int_{-h}^{0} e^{\bar\lambda\theta}(F\phi)^1(\theta)d\theta.
$$

The linear operator $T_\lambda : X \to X$ is defined by

$$
\begin{aligned}
[T_\lambda\phi]^0 = 0, \quad [T_\lambda\phi]^1(\theta) &= \int_{\theta}^{0} e^{\lambda(\theta-s)}\phi^1(s)ds, \\
[T_\lambda\phi]^2(\theta) &= \int_{\theta}^{0} e^{\lambda(\theta-s)}\phi^2(s)ds.
\end{aligned}
$$

Define $\Delta(\lambda) = \lambda I - L(e^{\lambda\cdot})$ and the resolvent set $\rho(A) = \{\lambda/\det\,\Delta(\lambda) \neq 0\}$. It is easy to see that the spectrum of A is $\sigma(A) = \{\lambda/\det\Delta(\lambda) = 0\}$. Moreover, by using the same arguments as in [D2] we can also show that the resolvent $R(\lambda, A) = (\lambda I - A)^{-1}$ is given by

$$
R(\lambda, A) = E_\lambda\Delta^{-1}(\lambda)E_{\bar\lambda}^{T^*}F + T_\lambda, \quad \lambda \in \rho(A).
$$

3. Finite-dimensional approximations for retarded systems with delays in input and output. The object of this section is the approximation of solutions of the RFDE (2.1) via use of approximate solutions of the abstract Cauchy problem (Σ). To approximate solutions of the abstract evolution equation in $X = R^n \times L^2 \times L^2$, we

will use subspaces $Z^N \subseteq L^2$ being sets of piecewise constant functions on the delay interval $[-h, 0]$ and thereby obtain the semidiscrete finite-difference scheme widely known in the literature as the averaging approximation scheme. Based on some careful analysis of the structure of the approximating systems, it will be shown in §3.2 that the approximating semigroups are all uniformly differentiable with respect to the index N determining the mesh size. These are extended results of Lasiecka and Manitius [L1] to the case when delays are included in the control and observation. A necessary condition for an approximation scheme to have the uniform differentiability characteristic is that the location of the spectrum must be contained in some logarithmic sector. Such a property is by no means obvious and not all approximation schemes have this property. For example, it is shown by numerical calculations [L1] that the spectra of approximating generators corresponding to linear splines contain eigenvalues of large modulus located arbitrarily close, as $N \to \infty$, to the imaginary axis. Thus we cannot hope to prove the same property for the spline approximation scheme in [B2].

3.1. Averaging approximation. For every positive integer N, we define the finite-dimensional linear subspace X^N of X by

$$X^N = \Big\{ \phi \in X / \phi^0 = z_0 \in R^n; \phi^1 = \sum_{j=1}^{N} z_j \chi_j, \quad z_j \in R^n; \\ \phi^2 = \sum_{j=1}^{N} v_j \chi_j, \quad v_j \in R^m \Big\},$$

where χ_j denote the characteristic function of $[t_j, t_{j-1})$ for $j = 1, 2, \ldots, N$ and $t_j = -jh/N, j = 0, 1, \ldots, N$. This subspace can be made isometrically isomorphic to the Euclidean space $R^{n(N+1)+mN}$ by means of the embedding $\wr^N : R^{n(N+1)+mN} \to X^N$, which associates with every $z = \operatorname{col}(z_0, \ldots, z_N, v_1, \ldots, v_N) \in R^{n(N+1)+mN}$, where $z_i \in R^n$ and $v_i \in R^m$, the triple

$$\begin{aligned} &[\wr^N z]^0 = z_0, \\ &[\wr^N z]^1(\theta) = z_i, \quad \theta \in [t_i, t_{i-1}), \qquad i = 1, \ldots, N, \\ &[\wr^N z]^2(\theta) = v_i, \quad \theta \in [t_i, t_{i-1}), \qquad i = 1, \ldots, N. \end{aligned}$$

On $R^{n(N+1)+mN}$, we define the induced inner product

$$\langle z, y \rangle_N = z^T Q^N y, \qquad z, y \in R^{n(N+1)+mN},$$

where $Q^N = \operatorname{diag}(Q_{11}^N, Q_{22}^N)$ is an $n(N+1)+mN \times n(N+1)+mN$ matrix and $Q_{11}^N = \operatorname{diag}(I_n, \frac{h}{N} I^n, \ldots, \frac{h}{N} I_n)$, $Q_{22}^N = \operatorname{diag}(\frac{h}{N} I_m, \ldots, \frac{h}{N} I_m)$, are $n(N+1) \times n(N+1)$ and $mN \times mN$ matrices, respectively. The corresponding vector and matrix norms will be denoted by $\| \cdot \|_N$. It can be shown that the map $\pi^N : X \to R^{n(N+1)+mN}$, an extension of the dual map of $\wr^N$, is given by

$$\pi^N \phi = \operatorname{col}(z_0, \ldots, z_N, v_1, \ldots, v_N),$$

where

$$z_0 = \phi^0, \quad z_j = \frac{N}{h} \int_{t_j}^{t_{j-1}} \phi^1(\theta) d\theta, \quad v_j = \frac{N}{h} \int_{t_j}^{t_{j-1}} \phi^2(\theta) d\theta, \qquad j = 1, \ldots, N.$$

It is clear that $\iota^N\pi^N = P^N$ is an orthogonal projection of X onto X^N and $\pi^N\iota^N = I$.

We now define the approximating formulas of the generator A, the input operator B, and the output operator C. First we introduce the following matrices:

$$A_j^N = \lim_{\theta \uparrow t_j} \left[\eta\left(\theta + \frac{h}{N}\right) - \eta(\theta)\right], \qquad j = 1, 2, \ldots, N,$$

$$B_j^N = \lim_{\theta \uparrow t_j} \left[\beta\left(\theta + \frac{h}{N}\right) - \beta(\theta)\right], \qquad j = 1, 2, \ldots, N,$$

$$C_j^N = \lim_{\theta \uparrow t_j} \left[\gamma\left(\theta + \frac{h}{N}\right) - \gamma(\theta)\right], \qquad j = 1, 2, \ldots, N.$$

For $\phi \in X$, let $\pi^N\phi = z = \operatorname{col}(z_0, \ldots, z_N, v_1, \ldots, v_N) \in R^{n(N+1)+mN}$ and define the linear maps

$$L_1^N\pi^N\phi = A_0 z_0 + \sum_{j=1}^{N} A_j^N z_j + \sum_{j=1}^{N} B_j^N v_j,$$

$$L_2^N\pi^N\phi = C_0 z_0 + \sum_{j=1}^{N} C_j^N z_j,$$

$$\nabla_1 P^N\phi = \sum_{j=1}^{N} \frac{N}{h}(z_{j-1} - z_j)\chi_j,$$

$$\nabla_2 P^N\phi = \sum_{j=1}^{N} \frac{N}{h}(v_{j-1} - v_j)\chi_j,$$

where we define $v_0 = 0$. The approximating operators $A^N : X \to X^N$ are then defined by

$$A^N\phi = (L_1^N\pi^N\phi, \nabla_1 P^N\phi, \nabla_2 P^N\phi).$$

The approximating input operators $B^N : R^m \to X^N$ are defined by

$$B^N u = (B_0 u, 0, \tfrac{N}{h}\chi_1 u).$$

Finally, the approximating output operators $C^N : X \to R^p$ are defined by

$$C^N\phi = L_2^N\pi^N\phi.$$

Let $S^N(t)$ denote the semigroups generated by A^N on X. The following theorem concerns the important question of stability of the averaging approximations for (1).

THEOREM 3.1. *There exists constants M and ω independent of N such that*

$$\|e^{\pi^N A^N \iota^N t}\|_N \leq M e^{\omega t}.$$

Proof. The proof is based on the well-known Gronwall's inequality and the use of weighting functions in L_2-type norms as suggested in [B1].

Let N be sufficiently large so that the points $-h_i$ (corresponding to the delays), $i = 1, \ldots, q$, lie in distinct intervals in the partition of $[-h, 0]$ by $\{t_j\}$. Let $J^N = \{j_1, j_2, \ldots, j_q\}$ be the subset of indices in $\{1, 2, \ldots, N\}$ such that $-h_i \in [t_{j_i}, t_{j_i - 1}), i = 1, \ldots, q$. Following the notation of Banks and Burns [B1], we define the piecewise constant function τ_N, for each fixed N, on $[-h, 0]$ by

$$\tau_N(\theta) = a_j^N, \quad \theta \in [t_j, t_{j-1}), \qquad j = 1, 2, \ldots, N,$$

where the a_j^N's are defined recursively by

$$a_{N+1}^N = 1,$$
$$a_j^N = \begin{cases} a_{j+1}^N + 1 & \text{if } j \in J^N \\ a_{j+1}^N & \text{if } j \notin J^N \end{cases}, \qquad j = N, N-1, \ldots, 1.$$

Let $\langle .,. \rangle_{\tau^N}$ and $\| \cdot \|_{\tau^N}$ denote the induced inner product and Euclidean norm on $R^{n(N+1)+mN}$ using the weighting function $\tau_N(\theta)$, i.e.,

$$\langle z, y \rangle_{\tau^N} = z^T Q_\tau^N y, \qquad z, y \in R^{n(N+1)+mN},$$

where $Q_\tau^N = \text{diag}\,(Q_{\tau_{11}}^N, Q_{\tau_{22}}^N)$ of dimension $n(N+1)+mN \times n(N+1)+mN$ and $Q_{\tau_{11}}^N = \text{diag}\,(I_n, \frac{h}{N} a_1^N I_n, \ldots, \frac{h}{N} a_N^N I_n), Q_{\tau_{22}}^N = \text{diag}\,(\frac{h}{N} a_1^N I_m, \ldots, \frac{h}{N} a_N^N I_m)$ of dimension $n(N+1) \times n(N+1)$ and $mN \times mN$, respectively.

For $z \in R^{n(N+1)+mN}$, let

$$e^{\pi^N A^N \wr^N t} z = z(t) = \text{col}\,(z_0(t), \ldots, z_N(t), v_1(t), \ldots, v_N(t)).$$

Then

$$\begin{aligned} \frac{d}{dt} \|z(t)\|_{\tau^N}^2 &= \frac{d}{dt}[z^T(t) Q_\tau^N z(t)] \\ &= 2 z^T(t) Q_\tau^N \pi^N A^N \wr^N z(t) \\ &= 2 z_0^T(t)[A_0 z_0(t) + \sum_{j=1}^N A_j^N z_j(t) + \sum_{j=1}^N B_j^N v_j(t)] \\ &\quad + 2 \sum_{j=1}^N z_j^T(t)[z_{j-1}(t) - z_j(t)] a_j^N - 2 v_1^T(t) v_1(t) a_1^N \\ &\quad + 2 \sum_{j=2}^N v_j^T(t)[v_{j-1}(t) - v_j(t)] a_j^N. \end{aligned}$$

We now obtain the following bounds for the right-hand side terms:

$$\begin{aligned} \text{(i)} \quad 2 \sum_{j=1}^N z_j^T(t)[z_{j-1}(t) - z_j(t)] a_j^N &\le -2 \sum_{j=1}^N |z_j(t)|^2 a_j^N \\ &\quad + \sum_{j=1}^N |z_j(t)|^2 a_j^N + \sum_{j=1}^N |z_{j-1}(t)|^2 a_j^N \\ &= -\sum_{j=1}^N |z_j(t)|^2 a_j^N + \sum_{j=0}^{N-1} |z_j(t)|^2 a_{j+1}^N \\ &\le |z_0(t)|^2 a_1^N + \sum_{j=1}^N (a_{j+1}^N - a_j^N) |z_j(t)|^2. \end{aligned}$$

Similarly,

$$\text{(ii)} \quad -2 v_1^T(t) v_1(t) a_1^N + 2 \sum_{j=2}^N v_j^T(t)[v_{j-1}(t) - v_j(t)] a_j^N \le \sum_{j=1}^N (a_{j+1}^N - a_j^N) |v_j(t)|^2.$$

(iii) Define $(A_{01})_i = \frac{N}{h}\int_{t_i}^{t_{i-1}} A_{01}(\theta)d\theta, i = 1,\dots,N$. Then

$$2z_0^T(t)[A_0z_0(t) + \sum_{j=1}^{N} A_j^N z_j(t)] = 2z_0^T(t)[A_0z_0(t) - \sum_{i=1}^{q} A_i z_{j_i}(t) + \sum_{i=1}^{N} \frac{h}{N}(A_{01})_i z_i(t)]$$

$$\leq (1 + \sum_{i=0}^{q} |A_i|^2)|z_0(t)|^2 + \sum_{i=1}^{q} |z_{j_i}(t)|^2 + \frac{h}{N}\sum_{i=1}^{N} |(A_{01})_i|^2|z_0(t)|^2$$

$$+ \frac{h}{N}\sum_{i=1}^{N} |z_i(t)|^2$$

$$\leq (1 + \sum_{i=0}^{q} |A_i|^2 + \|A_{01}\|_{L^2}^2)|z_0(t)|^2 + \frac{h}{N}\sum_{i=1}^{N} |z_i(t)|^2 + \sum_{i=1}^{q} |z_{j_i}(t)|^2,$$

where we have used Schwartz inequality. Similarly,

$$\text{(iv)} \qquad 2z_0^T(t)\sum_{j=1}^{N} B_j^N v_j(t) \leq \left(\sum_{i=1}^{q} |B_i|^2 + \|B_{01}\|_{L^2}^2\right)|z_0(t)|^2 + \frac{h}{N}\sum_{i=1}^{N} |v_i(t)|^2$$

$$+ \sum_{i=1}^{q} |v_{j_i}(t)|^2$$

Combining estimates (i)–(iv), and noting that

$$\sum_{i=1}^{N} (a_{i+1}^N - a_i^N)|z_i(t)|^2 + \sum_{i=1}^{q} |z_{j_i}(t)|^2 = 0,$$

and

$$\sum_{i=1}^{N} (a_{i+1}^N - a_i^N)|v_i(t)|^2 + \sum_{i=1}^{q} |v_{j_i}(t)|^2 = 0,$$

we have

$$\frac{d}{dt}\|z(t)\|_{\tau^N}^2 \leq \omega\left\{|z_0(t)|^2 + \frac{h}{\omega N}\sum_{i=1}^{N} |z_i(t)|^2 + \frac{h}{\omega N}\sum_{i=1}^{N} |v_i(t)|^2\right\},$$

where $\omega = 1 + a_1^N + \sum_{i=0}^{q} |A_i|^2 + \sum_{i=1}^{q} |B_i|^2 + \|A_{01}\|_{L^2}^2 + \|B_{01}\|_{L^2}^2$. Since $\omega > 1$, and $\|\cdot\|_N \leq \|\cdot\|_{\tau^N} \leq \gamma\|\cdot\|_N$ where γ is independent of N [B1], then

$$\frac{d}{dt}\|z(t)\|_{\tau^N}^2 \leq \omega\|z(t)\|_{\tau^N}^2.$$

Hence,

$$\|z(t)\|_{\tau^N}^2 \leq \|z\|_{\tau^N}^2 + \omega\int_0^t \|z(\theta)\|_{\tau^N}^2 d\theta,$$

where we used $z = z(0)$. By Gronwall's inequality, $\|z(t)\|_{\tau^N}^2 \leq \|z\|_{\tau^N}^2 e^{\omega t}$, which concludes our proof. □

For the remainder of this section we will characterize the approximating resolvent operators $(\lambda I - [A^N])^{-1}$ where $[A^N]$ is the matrix representation of A^N (see Remark

3.2 below). In doing so we will introduce several approximating operators that are similar to well-known operators introduced in §2.

Let $\Delta^N(\lambda)$ be an $n \times n$ complex matrix defined by

$$\Delta^N(\lambda) = \lambda I - L^N(\lambda),$$

where $L^N(\lambda) = \sum_{j=0}^{N} A_j^N(\lambda/(\lambda h + N))^j$, for $\lambda \neq -\frac{N}{h}$, and where $A_0^N = A_0$. For $\lambda \in \mathbf{C}$ and $\lambda \neq -\frac{N}{h}$, we define the following mappings. The approximating "exponential" map $E_\lambda^N : \mathbf{C}^n \to \mathbf{C}^{n(N+1)+mN}$,

$$E_\lambda^N x = z = \text{col } (z_0, \ldots, z_N, v_1, \ldots, v_N),$$

where $z_0 = x, z_i = (N/(\lambda h + N))^i x, v_i = 0, i = 1, 2, \ldots, N$. A similar definition holds for $(E_\lambda^T)^N : \mathbf{C}^n \to \mathbf{C}^{n(N+1)+pN}$. Using the induced inner product in X^N, the dual mappings $(E_\lambda^*)^N$ and $(E_\lambda^{T^*})^N$ are given by

$$(E_\lambda^*)^N z = z_0 + \frac{h}{N} \sum_{i=1}^{N} \left(\frac{N}{\lambda h + N} \right)^i z_i,$$

$$(E_\lambda^{T^*})^N \xi = \xi_0 + \frac{h}{N} \sum_{i=1}^{N} \left(\frac{N}{\lambda h + N} \right)^i \xi_i,$$

where $\xi = \text{col } (\xi_0, \ldots, \xi_N, \nu_1, \ldots, \nu_N) \in \mathbf{C}^{n(N+1)+pN}$. We also define the linear mapping T_λ^N on $\mathbf{C}^{n(N+1)+mN}$ to be

$$T_\lambda^N z = y = \text{col } (y_0, \ldots, y_N, w_1, \ldots, w_N),$$

where

$$y_0 = 0, \quad y_j = \frac{h}{N} \sum_{i=1}^{j} \left(\frac{N}{\lambda h + N} \right)^{j+1-i} z_i, \quad w_j = \frac{h}{N} \sum_{i=1}^{j} \left(\frac{N}{\lambda h + N} \right)^{j+1-i} v_i,$$

for $j = 1, \ldots, N$. Finally, we introduce the "extended" approximating structural mapping $F^N : \mathbf{C}^{n(N+1)+mN} \to \mathbf{C}^{n(N+1)+pN}$

$$F^N z = y,$$

where

$$y_0 = z_0, \quad y_i = \sum_{j=i}^{N} A_j^N z_{j+1-i} + \sum_{j=i}^{N} B_j^N v_{j+1-i}, \quad w_i = \sum_{j=i}^{N} C_j^N z_{j+1-i},$$

$$\text{for } i = 1, 2, \ldots, N.$$

Using the same arguments as in [S1], we can easily show that the resolvent $(\lambda I - [A^N])^{-1}$ is given by

$$(\lambda I - [A^N])^{-1} = E_\lambda^N \Delta^N(\lambda)^{-1} (E_\lambda^{T^*})^N F^N + T_\lambda^N$$

for $\lambda \neq -\frac{N}{h}$ and satisfies $\det \Delta^N(\lambda) \neq 0$. Furthermore, the spectrum of A^N is the set $\{\lambda \in \mathbf{C}/\lambda \neq -\frac{N}{h},\ \det \Delta^N(\lambda) = 0\}$.

Remark 3.1. From the above formulas and those in §2 of the operators characterizing the approximating resolvents $R(\lambda, A^N)$ and $R(\lambda, A)$, respectively, it follows immediately from [S1] that $\wp^N(\lambda I - [A^N])^{-1}\pi^N$ converges to $R(\lambda, A)$ uniformly in the operator topology as $N \to \infty$ on bounded subsets of the complex plane that are uniformly bounded away from the zeros of $\det \Delta(\lambda)$.

Remark 3.2. To implement the averaging scheme on the computer, we must calculate the matrix representations for the operators A^N, B^N, and C^N with respect to the basis $\{(1,0,0),(0,\chi_j,0),(0,0,\chi_j)\}$, $j = 1,\ldots,N$. The matrix representation $[A^N]$ of A^N is given by

$$[A^N] = \begin{bmatrix} A_{11}^N & A_{12}^N \\ 0 & A_{22}^N \end{bmatrix},$$

where

$$A_{11}^N = (Q_{11}^N)^{-1}H_{11}^N, \qquad H_{11}^N = \begin{bmatrix} A_0 & A_1^N & \cdots & A_N^N \\ I_n & -I_n & & \\ & \ddots & \ddots & \\ & & I_n & -I_n \end{bmatrix},$$

$$A_{12}^N = (Q_{11}^N)^{-1}H_{12}^N, \qquad H_{12}^N = \begin{bmatrix} B_1^N & B_2^N & \cdots & B_N^N \\ 0 & & & 0 \\ & & & \\ 0 & & & 0 \end{bmatrix},$$

$$A_{22}^N = (Q_{22}^N)^{-1}H_{22}^N, \qquad H_{22}^N = \begin{bmatrix} -I_m & & & \\ I_m & -I_m & & \\ & \ddots & \ddots & \\ & & I_m & -I_m \end{bmatrix}.$$

The matrix representation $[B^N]$ of B^N is given by

$$[B^N] = \operatorname{col}\left[B_0, 0, \ldots, 0, \frac{N}{h}I_m, 0, \ldots, 0\right].$$

The matrix representation $[C^N]$ of C^N as an operator $X^N \to R^p$ is given by

$$[C^N] = [C_0\ C_1^N\ C_2^N\ \ldots\ C_N^N\ 0 \ldots 0].$$

3.2. Uniform differentiability and stability of approximating semigroups. Using the same notation as in Lasiecka and Manitius [L1], let $a, b > h$ and μ be fixed real numbers and let us define the set

$$\Sigma_a = \{\lambda \in \mathbf{C}/|I_m\lambda| \geq e^{ab}e^{-b\mathrm{Re}\lambda}, \quad \mathrm{Re}\lambda \leq \mu\}.$$

Let Σ_a^1 be the complement of Σ_a, and define

$$\mathcal{L} = \Sigma_a^1 \cap \{\lambda/\mathrm{Re}\lambda < \mu\}.$$

We will now obtain the following two results, which are essential for establishing the uniform differentiability of the approximating semigroups $S^N(t)$. At this point, we note that the spectra of A^N, $\sigma(A^N)$, is the same as the spectra of A_0^N, $\sigma(A_0^N)$, for each N, where A_0^N is the Nth averaging approximating generator corresponding to the RFDE (2.1) with no delays in control. Hence from [L1], the spectra of the approximating generators A^N corresponding to the averaging approximations are all contained in the logarithmic sector $\mathcal{L}$ for a suitable choice of a, b and μ. For the remainder of the paper we will denote Var ζ to be the total variation of ζ on $[-h, 0]$.

LEMMA 3.2. *Let $\mathcal{L}$ be given as above with $\mu >$ Var $\eta_0, b > h$ and $a > \max(a_0, a_1)$ where*

$$a_0 = \frac{1}{b}\log\frac{1+\sqrt{2}}{b-h} \quad \text{and} \quad a_1 = \gamma + \frac{\log \text{Var } \eta_0}{b}.$$

The eigenvalues of the approximating generators A^N are contained in $\mathcal{L}$ for all $N \in \mathbf{N}$.

Our next lemma shows that outside the logarithmic sector $\mathcal{L}$ the resolvents of the generators A^N are uniformly bounded by $|\text{Im}\lambda|$.

LEMMA 3.3. *Let μ, a, and b be given as in Lemma 3.2. Then there exists a positive constant c, independent of N, such that*

$$\|R(\lambda, A^N)\| \le c|\text{Im}\lambda|,$$

for all $\lambda \in \Sigma_a$, for all $N \in \mathbf{N}$.

Proof. By the representation of $R(\lambda, A^N)$, we have

$$\begin{aligned}\|R(\lambda, A^N)P^N\|_N &= \|\wr^N (\lambda I - [A^N])^{-1}\pi^N\| \\ &\le \|E_\lambda^N\|\,\|\Delta^N(\lambda)^{-1}\|\,\|(E_\lambda^{T^*})^N\|\,\|F^N\| + \|T_\lambda^N\|.\end{aligned}$$

For all λ in Σ_a and all N in $\mathbf{N}$ we have the following estimates of these norms with respect to $\|\cdot\|_N$.

(i) $\|(E_\lambda^{T^*})^N\| = \|E_\lambda^N\| \le \sqrt{1+h}Ke^{-ab}|\text{Im}\lambda|$, where $K = e^{\gamma b}$ (see [L1]).

(ii) $\|\Delta^N(\lambda)^{-1}\| \le c_0\frac{1}{|\lambda|}$, $c_0 = (1 - K\text{Var } \eta_0 e^{-ab})^{-1}$ (see [L1]).

(iii) $\|F^N\| \le \max\{1, \sqrt{2}\text{Var}\eta + \text{Var}\gamma, \sqrt{2}\text{Var}\beta\} = c_1$, for every N in $\mathbf{N}$.

For $z = \text{col}(z_0, \dots, z_N, v_1, \dots, v_N) \in R^{n(N+1)+mN}$

$$\begin{aligned}\|F^N z\|_N^2 = |z_0|^2 &+ \frac{h}{N}\sum_{i=1}^N \Big|\sum_{j=i}^N A_j^N z_{j+1-i} + \sum_{j=i}^N B_j^N v_{j+1-i}\Big|^2 \\ &+ \frac{h}{N}\sum_{i=1}^N \Big|\sum_{j=i}^N C_j^N z_{j+1-i}\Big|^2.\end{aligned}$$

By the well-known convolution inequality, we have

$$\begin{aligned}\sum_{i=1}^N \Big|\sum_{j=i}^N C_j^N z_{j+1-i}\Big|^2 &\le \left\{\sum_{j=1}^N |C_j^N|\right\}^2 \sum_{j=1}^N |z_j|^2 \\ &\le \text{Var}^2\gamma \sum_{j=1}^N |z_j|^2.\end{aligned}$$

Using standard argument, we can show that

$$\sum_{i=1}^{N} |\sum_{j=i}^{N} A_j^N z_{j+1-i} + \sum_{j=i}^{N} B_j^N v_{j+1-i}|^2 \leq 2\sum_{i=1}^{N} |\sum_{j=i}^{N} A_j^N z_{j+1-i}|2.$$

$$+ 2\sum_{i=1}^{N} |\sum_{j=i}^{N} B_j^N v_{j+1-i}|2$$

$$\leq 2\mathrm{Var}^2\eta \sum_{j=1}^{N} |z_j|^2 + 2\mathrm{Var}^2\beta \sum_{j=1}^{N} |v_j|^2.$$

Also,

(iv) $\|T_\lambda^N\| \leq hKe^{-ab}|\mathrm{Im}\lambda|$ (see [L1]).

Combining estimates (i)–(iv)

$$\|R(\lambda, A^N)P^N\|_N \leq c_2|\mathrm{Im}\lambda|$$

where

$$c_2 = c_0c_1Ke^{-ab}(1+h)h\left(\frac{Ke^{-ab}}{h} + \frac{1}{c_0c_1(1+h)}\right).$$

From [L1, App.],

$$\|R(\lambda, A^N)\| \leq \frac{\|I - P^N\|}{|\lambda|} + \|R(\lambda, A^N)P^N\|$$

$$\leq \frac{2}{|\lambda|} + c_2|\mathrm{Im}\lambda|$$

$$\leq (c_2 + c_3)|\mathrm{Im}\lambda|$$

where we used the estimate $\frac{2}{|\lambda|} \leq c_3|\mathrm{Im}\lambda|$ for some constant c_3 since $\lambda \in \Sigma_a$. □

From [L1], the above two lemmas imply immediately that the approximating semigroups $S^N(t)$ are uniformly differentiable for sufficiently large time. More precisely, we have the following theorem, which has been proved in [L1].

THEOREM 3.4. *For all N in $\mathbf{N}$ the approximating semigroups $S^N(t)$ are uniformly differentiable in the sense that there exist constants $t_0 = 3h, \mu > \mathrm{Var}\ \eta_0$ such that*

$$\|A^N S^N(t)\| \leq Me^{\mu t} \quad \forall t > t_0, \quad \forall N \in \mathbf{N}.$$

Furthermore, for $b > h$ and all $k = 0, 1, 2, \ldots$, and for any $t_k > (2+k)b$ there exist positive constants M_k (dependent on t_k, but independent of N) such that

$$\|(A^N)^k S^N(t)\| \leq M_k e^{\mu t}, \quad \forall t \geq t_k, \forall N \in \mathbf{N}.$$

Remark 3.3. (i) An important consequence of this theorem is that by considering $\int e^{\lambda t}R(\lambda, A^N)d\lambda$ along a shifted path, we can easily prove the following: if the original semigroup is exponentially stable with decay rate ω_0, $\omega_0 = \sup\{\mathrm{Re}\lambda/\lambda \in \sigma(A)\} < 0$, then the approximating semigroups are uniformly exponentially stable with decay rate $\omega_0 + \epsilon$, $\epsilon > 0$ is arbitrarily small and $N \geq N_1(\epsilon)$. The preservation of exponential stability under approximation is very important in the convergence proof of the approximating solution of the algebraic Riccati equation associated with a retarded system. Gibson [G1] showed that for RFDE without delays in control and observation,

uniform exponential stability of approximating semigroups yields strong convergence of approximating algebraic Riccati operators.

(ii) Another important consequence of the above theorem is that now we can write

$$S^N(t) = \frac{1}{2\pi i}\int_\Gamma e^{\lambda t}R(\lambda, A^N)d\lambda, \qquad t > 2b$$

where Γ is the boundary of $\mathcal{L}$ oriented so that $\mathrm{Im}\lambda$ increases along Γ. This representation of $S^N(t)$ makes it possible to study convergence rates of approximating semigroups by studying convergence rates of approximating resolvent operators (see §4). Furthermore, as will be evident in the next section, this formulation allowed us to prove that the approximating semigroups converge in the uniform operator topology to the original semigroup for sufficiently large time.

4. Convergence results and convergence rates.

4.1. Homogeneous equations. Throughout this section we will restrict our discussion to the homogeneous systems, $u(t) = 0$ for $t \geq 0$,

$$\frac{d}{dt}z(t) = Az(t), \qquad z(0) = \phi,$$

$$y(t) = Cz(t)$$

in the Hilbert space X and

$$\frac{d}{dt}z^N(t) = A^N Z^N(t), \qquad z^N(0) = P^N\phi,$$

$$y^N(t) = C^N z^N(t)$$

in the finite-dimensional subspaces X^N of X. The operators A and C and their approximating operators A^N and C^N corresponding to the averaging scheme are defined in §§2 and 3, respectively.

We will first show that the approximating semigroups converge to the original semigroup strongly for all initial data in X and the convergence is uniform in t for t in bounded intervals. The underlying tool for this convergence proof is the Trotter–Kato semigroup approximation theorem. We will use here a version of this theorem given by Pazy [P1, Thm. 4.5, p. 88]), which is also used by Banks and Burns [B1] and Gibson [G1].

THEOREM 4.1. *Let A generate a C_0-semigroup $S(\cdot)$ on a Hilbert space X and A^N be a sequence of linear operators, each of which generates a C_0-semigroup $S^N(\cdot)$ on X. Assume the following*:

(a) *as $N \to \infty$, $A^N x \to Ax$ for every $x \in D$ where D is dense in X;*

(b) *there exist constants ω, M independent of N such that $\|S^N(t)\| \leq Me^{\omega t}$;*

(c) *there exists a λ_0 with $\lambda_0 > \omega$ for which $(\lambda_0 I - A)D$ is dense in X.*

Then $\lim_{N\to\infty} S^N(t)x = S(t)x$ for all $t \geq 0$, $x \in X$ and the limit is uniform in t for t in bounded intervals.

We extend the definition of A^N to all of X by $A^N x = A^N P^N x$ and define the C_0-semigroup $S^N(t)$, $t \geq 0$, on X by

$$S^N(t)\phi = S^N(t)P^N\phi + \phi - P^N\phi, \qquad t \geq 0, \quad \phi \in X.$$

The desired convergence $S^N(t)P^N\phi \to S(t)\phi$, $\phi \in X$, will then follow directly from the above theorem and the strong convergence of P^N to I. Let us now proceed to

prove that condition (a) holds for the approximating generators A^N constructed in §3.1. Note that the stability result, condition (c), has been obtained in §3.1 (Theorem 3.1) whereas condition (b) has been proved in [B1].

LEMMA 4.2. *Let*

$$D = \{(\phi^1(0), \phi^1, \phi^2)/\phi^1 \in C^1([-h,0]; R^n), \phi^2 \in C^1([-h,0]; R^m)\}.$$

Then D is dense in X and $\lim_{N\to\infty} A^N\phi = A\phi$ for every ϕ in D.

Proof. Let $\phi = (\phi^1(0), \phi^1, \phi^2) \in D$. The following result has been proved in [B1]:

$$\lim_{N\to\infty} \left\|\nabla_1 P^N\phi - \dot{\phi}^1\right\|_{L^2}^2 = \lim_{N\to\infty} \left\|\sum_{j=1}^N \frac{N}{h}(z_{j-1} - z_j)\chi_j - \dot{\phi}^1(\cdot)\right\|_{L^2}^2 = 0,$$

where $P^N\phi = \text{col}\,(z_0, \ldots, z_N, v_1, \ldots, v_N)$. Similarly,

$$\lim_{N\to\infty} \left\|\nabla_2 P^N\phi - \dot{\phi}^2\right\|_{L^2}^2 = \lim_{N\to\infty} \left\|\sum_{j=1}^N \frac{N}{h}(v_{j-1} - v_j)\chi_j - \dot{\phi}^2(\cdot)\right\|_{L^2}^2 = 0.$$

Hence it only remains to prove the following convergence of R^n-component,

$$\lim_{N\to\infty} \left\{\sum_{j=0}^N A_j^N z_j + \sum_{j=1}^N B_j^N v_j\right\} = L\phi^1 + \hat{B}\phi^2.$$

Let us define $\eta_0^N(t) = \lim_{\theta\uparrow t_j} \eta_0(\theta)$ and $\beta^N(t) = \lim_{\theta\uparrow t_j} \beta(\theta)$ for $t \in (t_{j+1}, t_j]$ and $j = 0, 1, \ldots, N-1$. Then

$$\begin{aligned}
\sum_{j=0}^N A_j^N z_j &= \sum_{j=0}^N \eta_0^N(t_{j-1})z_j - \sum_{j=0}^N \eta_0^N(t_j)z_j \\
&= \sum_{j=1}^N \eta_0^N(t_{j-1})z_j - \sum_{j=1}^{N+1} \eta_0^N(t_{j-1})z_{j-1} \\
&= -\eta_0(-h)z_N - \frac{h}{N}\sum_{j=1}^N \eta_0^N(t_{j-1})\frac{N}{h}(z_{j-1} - z_j) \\
&= -\eta_0(-h)z_N - \sum_{j=1}^N \int_{t_j}^{t_{j-1}} \eta_0^N(s)\frac{N}{h}(z_{j-1} - z_j)ds \\
&= -\eta_0(-h)z_N - \int_{-h}^0 \eta_0^N(s)\sum_{j=1}^N \frac{N}{h}(z_{j-1} - z_j)\chi_j(s)ds.
\end{aligned}$$

Similarly,

$$\sum_{j=1}^N B_j^N v_j = -\beta(-h)v_N - \int_{-h}^0 \beta^N(s)\sum_{j=1}^N \frac{N}{h}(v_{j-1} - v_j)\chi_j(s)ds.$$

By integration by parts,

$$L\phi^1 + \hat{B}\phi^2 = -\eta_0(-h)\phi^1(-h) - \int_{-h}^{0} \eta_0(s)\dot{\phi}^1(s)ds - \beta(-h)\phi^2(-h) - \int_{-h}^{0} \beta(s)\dot{\phi}^2(s)ds.$$

Hence,

$$\begin{aligned}
&|L\phi^1 + \hat{B}\phi^2 - (\sum_{j=0}^{N} A_j^N z_j + \sum_{j=1}^{N} B_j^N v_j)| \\
&\quad \le \|\eta_0(-h)\|\ |\phi^1(-h) - z_N| + \|\beta(-h)\|\ |\phi^2(-h) - v_N| \\
&\qquad + \left| \int_{-h}^{0} \eta_0(s)\dot{\phi}^1(s)ds - \int_{-h}^{0} \eta_0^N(s) \sum_{j=1}^{N} \frac{N}{h}(z_{j-1} - z_j)\chi_j(s)ds \right| \\
&\qquad + \left| \int_{-h}^{0} \beta(s)\dot{\phi}^2(s)ds - \int_{-h}^{0} \beta^N(s) \sum_{j=1}^{N} \frac{N}{h}(v_{j-1} - v_j)\chi_j(s)ds \right|.
\end{aligned}$$

Since

$$z_N = \frac{N}{h}\int_{-h}^{-(N-1)\frac{h}{N}} \phi^1(s)ds \quad \text{and} \quad v_N = \frac{N}{h}\int_{-h}^{-(N-1)\frac{h}{N}} \phi^2(s)ds,$$

it follows immediately that $z_N \to \phi^1(-h)$ and $v_N \to \phi^2(-h)$. Furthermore, we have

$$\begin{aligned}
&\left| \int_{-h}^{0} \eta_0(s)\dot{\phi}^1(s)ds - \int_{-h}^{0} \eta_0^N(s) \sum_{j=1}^{N} \frac{N}{h}(z_{j-1} - z_j)\chi_j(s)ds \right| \\
&\quad \le \left| \int_{-h}^{0} (\eta_0(s) - \eta_0^N(s))\dot{\phi}^1(s)ds \right| \\
&\qquad + \left| \int_{-h}^{0} \eta_0^N(s)\Big(\dot{\phi}^1(s) - \sum_{j=1}^{N} \frac{N}{h}(z_{j-1} - z_j)\chi_j(s)\Big)ds \right|
\end{aligned}$$

From [S1, Rem. 4.1(i)], we can show that the first term on the right-hand side is bounded by $\sup_{s\in[-h,0]} |\dot{\phi}^1(s)| \frac{h}{N}\mathrm{Var}\eta_0$. The second term is bounded by $\mathrm{Var}\eta_0\sqrt{h}\|\dot{\phi}^1 - \sum_{j=1}^{N} \frac{N}{h}(z_{j-1} - z_j)\chi_j\|_{L^2}$. Analogously, we can show that

$$\begin{aligned}
&\left| \int_{-h}^{0} \beta(s)\dot{\phi}^2(s)ds - \int_{-h}^{0} \beta^N(s) \sum_{j=1}^{N} \frac{N}{h}(v_{j-1} - v_j)\chi_j(s)ds \right| \\
&\quad \le \sup_{s\in[-h,0]} |\phi^2(s)| \frac{h}{N}\mathrm{Var}\beta + \sqrt{h}\mathrm{Var}\beta \left\| \dot{\phi}^2 - \sum_{j=1}^{N} \frac{N}{h}(v_{j-1} - v_j)\chi_j \right\|_{L^2}.
\end{aligned}$$

The statement of the lemma then follows by the convergence of the C^1-terms [B1]. □

In what follows we will establish convergence rates for the sequence of approximating semigroups in both the strong and uniform operator topology. By using the differentiability of $S(t)$ and $S^N(t)$, i.e., for $t > 2b$ we have

$$P^N S(t) - S^N(t)P^N = \int_\Gamma \frac{1}{2\pi i}[P^N R(\lambda, A) - R(\lambda, A^N)P^N]e^{\lambda t}d\lambda,$$

where Γ is the boundary of some logarithmic sector containing all eigenvalues of A^N, we compute these estimates through technical estimates of the convergence rates of the approximating resolvent operators. The following hypotheses will be considered in various combinations.

(H3)

$$\eta(\theta) = -\sum_{i=1}^{q} A_i \chi_{(-\infty,-h_i]}(\theta) - \int_\theta^0 A_{01}(s)ds,$$

$$\beta(\theta) = -\sum_{i=1}^{q} B_i \chi_{(-\infty,-h_i]}(\theta) - \int_\theta^0 B_{01}(s)ds.$$

(H4) The matrix functions η, β are normalized functions of bounded variation, left continuous of $[-h, 0)$ (in the same sense as in [P2]).

(H5) The delays h_i are commensurate, i.e. there is a positive real number r, and integers $k_j, j = 1, \ldots, q$, such that $h_j = k_j r, j = 1, \ldots, q$.

(H6) The interval $[-h, 0]$ is partitioned into N subintervals $[t_j, t_{j-1})$, where $j = 1, \ldots, N$, and $t_j = -\frac{jh}{N}$.

(H7) In the case where $q > 1$, the set of meshpoints t_j includes $\{h_0, \ldots, h_q\}$, i.e., we partition $[-h, 0]$ into $k_q N$ subintervals $[t_j, t_{j-1})$ where $t_j = -\frac{jr}{N}$, $j = 0, 1, \ldots, k_q N$.

In the results we will point out which assumptions guarantee which convergence rate.

THEOREM 4.3. *Let λ be a fixed real number, $\lambda > \mathrm{Var}\eta_0$. Then $\lambda \in \rho(A) \cap \rho(A^N)$ for all $N \in \mathbf{N}$. Let $N_0 \geq \lambda h$. Then for all $N \geq N_0$:*

(i) *if* (H4) *and* (H6) *hold, then*

$$\|P^N R(\lambda, A) - R(\lambda, A^N)P^N\| \leq D_1 \left(\frac{h}{N}\right)^{\frac{1}{2}};$$

(ii) *if* (H3) *and* (H6) *hold and the system has only one delay, $h_i = h$, then*

$$\|P^N R(\lambda, A) - R(\lambda, A^N)P^N\| \leq D_2 \frac{h}{N};$$

(iii) *if* (H3), (H5)–(H7) *hold, then*

$$\|P^N R(\lambda, A) - R(\lambda, A^N)P^N\| \leq D_3 \frac{r}{N};$$

(iv) *if only* (H4) *and* (H6) *hold, but $x \in R^n \times L^\infty([-h, 0]; R^n) \times L^\infty([-h, 0]; R^m)$, then*

$$\|P^N R(\lambda, A)x - R(\lambda, A^N)P^N x\|_{R^n \times L^\infty \times L^\infty} \leq D_4 \frac{h}{N} \|x\|_{R^n \times L^\infty \times L^\infty}.$$

Proof. From the structures of the resolvents,

$$P^N R(\lambda, A) - R(\lambda, A^N)P^N = T_1 + T_2 + T_3 + T_4,$$

where

$$T_1 = (P^N E_\lambda - \wr^N E_\lambda^N)\Delta^{-1}(\lambda)E_\lambda^{T^*}F,$$
$$T_2 = \wr^N E_\lambda^N(\Delta^{-1}(\lambda) - \Delta^N(\lambda)^{-1})E_\lambda^{T^*}F,$$
$$T_3 = \wr^N E_\lambda^N \Delta^N(\lambda)^{-1}(E_\lambda^{T^*}F - (E_\lambda^{T^*})^N F^N \pi^N),$$
$$T_4 = P^N T_\lambda - \wr^N T_\lambda^N \pi^N.$$

Let us first obtain the following estimates on $\|F\|$:

$$\|F\phi\|_X^2 \le |\phi^0|^2 + 2\left\|\int_{-h}^{\cdot} d\eta(\theta)\phi^1(\theta - \cdot)\right\|_{L^2}^2 + 2\left\|\int_{-h}^{\cdot} d\beta(\theta)\phi^2(\theta - \cdot)\right\|_{L^2}^2 + \left\|\int_{-h}^{t} d\gamma(\theta)\phi^1(\theta - t)\right\|_{L^2}^2.$$

From [D1]

$$\|F\| \le d_2 = \max(1, \sqrt{2}\mathrm{Var}\eta + \mathrm{Var}\gamma, \sqrt{2}\mathrm{Var}\beta).$$

Now by comparing the operators characterizing the resolvents corresponding to RFDE with delays in control and observation and those same operators corresponding to systems with no delays in input and output, it follows straightforwardly from [L1] that the following estimates on $\|T_i\|, i = 1, 2, 4$, still hold.

(i) $\|T_1\| \le d_1 d_2 d_4 d_5 \frac{h}{N}$, for $\lambda > d_3$, and $N \ge N_0$, where $d_1 = \sqrt{1+h}$, $d_3 = \sup_{\theta\in[-h,0]}\|\eta_0(\theta)\| \le \mathrm{Var}\eta_0$, $d_4 = (\lambda - d_3)^{-1}$, and $d_5 = 2\lambda\sqrt{h}(1+\lambda h)$.

(ii) $\|T_2\| \le d_1^2 d_2 d_4^2 d_6 \frac{h}{N}$ for $\lambda > d_3, N \ge N_0$, where $d_6 = 2d_3\lambda(1+\lambda h)^2 + \lambda h\mathrm{Var}\eta_0$.

(iii) $\|T_4\| \le d_7 \frac{h}{N}$, for $N \ge N_0$, where $d_7 = \sqrt{2}(\lambda\sqrt{h}+1) + d_5\sqrt{h}$.

(iv) For $\|T_3\|$ we have

$$\|T_3\| \le d_1 d_4 \|E_\lambda^{T^*}F - (E_\lambda^{T^*})^N F^N \pi^N\|, \qquad \lambda > d_3.$$

Now

$$\|E_\lambda^{T^*}F - (E_\lambda^{T^*})^N F^N \pi^N\| \le \|E_\lambda^{T^*}(F - \wr^N F^N \pi^N)\| + \|(E_\lambda^{T^*}\wr^N - (E_\lambda^{T^*})^N)F^N\pi^N\|.$$

The second term on the right-hand side is bounded above by $d_2 d_5 \frac{h}{N}$, for $N \ge N_0$. As pointed out in Lasiecka and Manitius [L1], it would seem very difficult to obtain the convergence rate of $\|F\phi - \wr^N F^N \pi^N \phi\|$ valid uniformly for all ϕ in X. However, since $\|E_\lambda^{T^*}(F - \wr^N F^N \pi^N)\| = \|(F^* - \wr^N (F^N)^* \pi^N)E_\lambda^T\|$, the rate of convergence of $\|T_3\|$ to zero depends on the rate with which the approximation $\wr^N (F^N)^* \pi^N$ converges to F^* on the exponential function $E_\lambda^T x$, where x is the unit vector in R^n. This is a crucial step in the proof of the theorem and it is this rate that depends on the particular hypotheses (H3)–(H7) chosen.

From the formula (2.5) for the dual operator F^*, it is easy to show that

$$[F^* E_\lambda^T]^0 - [\wr^N (F^N)^* \pi^N E_\lambda^T]^0 = 0$$

and

$$[F^* E_\lambda^T]^1(\theta) = \int_{-h}^{\theta} d\eta^T(s) e^{\lambda(s-\theta)}$$
$$= \eta^T(\theta) - \eta^T(-h)e^{-\lambda h} - \lambda\int_{-h}^{0}\eta^T(s+\theta)e^{\lambda s}ds,$$
$$[F^* E_\lambda^T]^2(\theta) = \int_{-h}^{\theta} d\beta^T(s) e^{\lambda(s-\theta)}$$
$$= \beta^T(\theta) - \beta^T(-h)e^{-\lambda h} - \lambda\int_{-h}^{0}\beta^T(s+\theta)e^{\lambda s}ds.$$

Let $(F^N)^*\pi^N E_\lambda^T = \operatorname{col}(z_0, \dots, z_N, v_1, \dots, v_N) \in R^{n(N+1)+mN}$ where by using the same arguments as in [S1, Thm. 4.4] we have

$$z_j = \frac{N}{h}\int_{-h}^{0} [\eta^{N^T}(s+t_{j-1}) - \eta^{N^T}(s+t_j)]e^{\lambda s}ds,$$
$$v_j = \frac{N}{h}\int_{-h}^{0} [\beta^{N^T}(s+t_{j-1}) - \beta^{N^T}(s+t_j)]e^{\lambda s}ds, \qquad j = 1, 2, \dots, N.$$

Now

$$z_j = \frac{N}{h}\int_{-h}^{0} \eta^{N^T}(s+t_{j-1})e^{\lambda s}ds - \frac{N}{h}\int_{-h-\frac{h}{N}}^{-\frac{h}{N}} \eta^{N^T}(s+t_{j-1})e^{\lambda(s+\frac{h}{N})}ds$$

and after some simple manipulations on the second term on the right-hand side, we obtain

$$z_j = \frac{N}{\lambda h}[e^{\lambda h/N} - 1]\left\{\eta^{N^T}(t_{j-1}) - \eta^T(-h)e^{-\lambda h} - \lambda\int_{-h}^{0} \eta^{N^T}(s+t_{j-1})e^{\lambda s}ds\right\}.$$

Similarly,

$$v_j = \frac{N}{\lambda h}[e^{\lambda h/N} - 1]\left\{\beta^{N^T}(t_{j-1}) - \beta^T(-h)e^{-\lambda h} - \lambda\int_{-h}^{0} \beta^{N^T}(s+t_{j-1})e^{\lambda s}ds\right\}.$$

Note that

$$\frac{N}{\lambda h}(e^{\lambda h/N} - 1) = \frac{N}{\lambda h}\left(1 + \frac{\lambda h}{N} + \frac{(\lambda h)^2}{2!N^2} + \cdots - 1\right)$$
$$= 1 + \epsilon_N,$$

where

$$\epsilon_N = \frac{\lambda h}{2N} + \frac{(\lambda h)^2}{6N^2} + \cdots,$$

and

$$\epsilon_N = \frac{\lambda h}{2N}\left(1 + \frac{\lambda h}{3N} + \frac{(\lambda h)^2}{12N^2} + \cdots\right)$$
$$\le \frac{\lambda h}{2N}\left(1 + \frac{\lambda h}{2N} + \left(\frac{\lambda h}{2N}\right)^2 + \cdots\right), \qquad N > \lambda h$$
$$= \frac{\lambda h}{2N}\frac{1}{1 - \frac{\lambda h}{2N}} \le \frac{\lambda h}{2N}\frac{1}{1 - \frac{1}{2}} = \frac{\lambda h}{N}.$$

Hence

$$\|(F^*E_\lambda^T - \wr^N(F^N)^*\pi^N E_\lambda^T)^1(\cdot)\|_{L^2} \le \|\eta^T - \eta^{N^T}\|_{L^2} + 3d_3\frac{\lambda}{N}$$
$$+ \lambda\left\|\int_{-h}^{0} [\eta^T(s+\cdot) - \eta^{N^T}(s+t_{j-1})]e^{\lambda s}ds\right\|_{L^2}.$$

From the well-known convolution theorem (see, e.g., Hewitt and Ross [H1]) the last term on the right-hand side is bounded by $\|\eta^T - \eta^{N^T}\|_{L^2}$. Therefore,

$$\|(F^*E_\lambda^T - \wr^N(F^N)^*\pi^N E_\lambda^T)^1(\cdot)\|_{L^2} \le 3\frac{\lambda h}{N}d_3 + 2\|\eta^T - \eta^{N^T}\|_{L^2}.$$

Similarly,

$$\|(F^*E_\lambda^T - \iota^N(F^N)^*\pi^N E_\lambda^T)^2(\cdot)\|_{L^2} \leq 3\frac{\lambda h}{N}d_8 + 2\|\beta^T - \beta^{N^T}\|_{L^2},$$

where $d_8 = \sup_{\theta\in[-h,0]}\|\beta(\theta)\| < \mathrm{Var}\beta$. Therefore,

$$\|T_3\| \leq d_1d_4d_2d_5\frac{h}{N} + d_1d_4\Big\{\Big[3\frac{\lambda h}{N}d_3 + 2\|\eta^T - \eta^{N^T}\|_{L^2}\Big]^2 + \Big[3\frac{\lambda h}{N}d_8 + 2\|\beta^T - \beta^{N^T}\|_{L^2}\Big]^2\Big\}^{1/2}.$$

The rate of convergence of $\|T_3\|$ depends on both $\|\eta^T - \eta^{N^T}\|_{L^2}$ and $\|\beta^T - \beta^{N^T}\|_{L^2}$. The rate of convergence of these bounded variation functions depend on the particular hypotheses (H3)–(H7) chosen. Using the same arguments as in [L1, pp. 41–42], the statements in the theorem then follow straightforwardly. □

We can now state the following theorem, which has been proved by Lasiecka and Manitius [L1].

THEOREM 4.4. *Let $\alpha = \frac{1}{2}$ if* (H4) *and* (H6) *hold and $\alpha = 1$ if* (H3), (H6) *hold and $q = 1$, or* (H3), (H5)–(H7) *hold and h is replaced by r. Then the following estimates are true.*

(i) *If $x \in \mathrm{dom}A^2$, then for each $T > 0$ there is a constant D_5 such that*

$$\|P^NS(t)x - S^N(t)P^Nx\| \leq D_5\left(\frac{h}{N}\right)^\alpha \|x\|_{H^2}$$

uniformly for $t \in [0,T]$.

(ii) *If $x \in \mathrm{dom}A$, then*

$$\|P^NS(t)x - S^N(t)P^Nx\| \leq D_6e^{\gamma t}\left(\frac{h}{N}\right)^\alpha \|x\|_{H^1}, \quad \forall N \in \mathbf{N}, \quad t > 4h.$$

(iii) *For $t > 5h$ and $\forall N > N_0$,*

$$\|P^NS(t) - S^N(t)P^N\| \leq D_7e^{\gamma t}\left(\frac{h}{N}\right)^\alpha.$$

Remark 4.1. By the Trotter–Kato theorem, we have $S^N(t)P^N$ converge to $S(t)$ strongly and uniformly in t for t in bounded interval. By using differentiability results of $S(t)$ and $S^N(t)$, part (iii) shows a stronger convergence result in the sense that the convergence is uniform in the uniform operator topology for sufficiently large time, $t > 5h$.

We conclude this section by focusing on the convergence of the output operators. In particular, we will show that $C^NS^N(\cdot)\pi^N\phi$ converges to $CS(\cdot)\phi$ strongly in $L^2(0,T;R^p)$ for all ϕ in X. This is not a trivial problem, since we are considering the averaging approximation scheme on linear subspaces X^N of X, and on X the output operator C is unbounded. Furthermore, the approximating operators C^N are bounded but not uniformly bounded on X. Before turning to our main result, we will need the following important preliminary result, which is the hypothesis (H2) corresponding to the approximating equations in X^N.

THEOREM 4.5. *For every $T > 0$, there exists a positive constant c, dependent on T but independent of N, such that*

$$\int_0^T |C^N e^{A^N t} x|_{R^p}^2 \, dt \leq c \|x\|_N^2,$$

for all $x \in R^{n(N+1)+mN}$ and for all N in $\mathbf{N}$.

Proof. The whole essence of this proof is the application of the Plancherel's theorem. To this end, let us consider the composition of C^N and $(\lambda I - A^N)^{-1}x$ where $x \in R^{n(N+1)+mN}$. From the characterization of the approximating resolvent operators, we have

$$C^N(\lambda I - A^N)^{-1}x = C^N E_\lambda^N \Delta^N(\lambda)^{-1}(E_\lambda^{T^*})^N F^N x + C^N T_\lambda^N x.$$

Let R_1 and R_2 be the first and second terms of the above right-hand terms. We now prove the statement of the theorem in three steps.

(i) There exist constants $\gamma > 0$ and $D_8 > 0$ such that

$$|R_1| \leq \frac{D_8}{|Im\lambda|} \|x\|_N$$

for all $\lambda \in C$ with $\mathrm{Re}\lambda = \gamma$ and for all N in $\mathbf{N}$. This statement holds from the following elementary estimates.

(i1) $|C^N E_\lambda^N| \leq \mathrm{Var}\,\gamma_0$, $\mathrm{Re}\lambda > 0$.

Let $y \in C^n$, then

$$\begin{aligned} |C^N E_\lambda^N y|_{R^p} &= \left| \sum_{i=0}^N \left(\frac{N}{\lambda h + N} \right)^i C_i^N y \right| \\ &\leq \sum_{i=0}^N \left| \frac{N}{\lambda h + N} \right|^i |C_i^N||y|. \end{aligned}$$

For

$$\mathrm{Re}\lambda > 0, \quad \left| \frac{N}{\lambda h + N} \right| \leq 1$$

and thus the estimate.

(i2) For $|\lambda| > 2\mathrm{Var}\eta_0$, $|\Delta^N(\lambda)^{-1}| \leq \frac{2}{|\mathrm{Im}\lambda|}$.

We have

$$\Delta^N(\lambda)^{-1} = \frac{1}{\lambda} \left(I - \frac{1}{\lambda} \sum_{j=1}^N A_j^N \left(\frac{N}{\lambda h + N} \right)^j \right)^{-1}$$

and for $|\lambda| > \mathrm{Var}\eta_0$,

$$\Delta^N(\lambda)^{-1} = \frac{1}{\lambda} \sum_{i=0}^\infty \frac{(\sum_{j=0}^N A_j^N (\frac{N}{\lambda h + N})^j)^i}{\lambda^i}.$$

Therefore,

$$\begin{aligned} \|\Delta^N(\lambda)^{-1}\| &\leq \frac{1}{|\lambda|} \sum_{i=0}^\infty \frac{\mathrm{Var}^i \eta_0}{|\lambda|^i} \\ &= \frac{1}{|\lambda| - \mathrm{Var}\eta_0} = \frac{1}{\frac{|\lambda|}{2} + \frac{|\lambda|}{2} - \mathrm{Var}\eta_0} \\ &\leq \frac{2}{|\lambda|}, \quad \text{for } |\lambda| > 2\mathrm{Var}\eta_0. \end{aligned}$$

(i3) $\|(E_\lambda^{T^*})^N\|_N \le \sqrt{1+h}$.

(i4) $\|F^N\|_N \le \max(1, \sqrt{2}\mathrm{Var}\eta + \mathrm{Var}\gamma, \sqrt{2}\mathrm{Var}\beta)$ (Lemma 3.3 (iii)).

Next we show that

(ii) $\int_{-\infty}^{\infty} |C^N T_{\alpha+i\omega}^N x|_{C^p}^2 d\omega \le D_9 \|x\|_N^2$, for $x \in R^{n(N+1)+mN}$.

Let $x = \mathrm{col}(x_0, \dots, x_N, v_1, \dots, v_N) \in R^{n(N+1)+mN}$, then the matrix representation of $C^N T_\lambda^N x$ is given by

$$C^N T_\lambda^N = [0\ C_1^N \dots C_N^N\ 0 \dots 0] \frac{h}{N} \begin{bmatrix} 0 & 0 & \cdots & 0 & 0 \\ 0 & \frac{N}{\lambda h+N} I_n & & & 0 \\ \vdots & \vdots & \ddots & & \vdots \\ 0 & (\frac{N}{\lambda h+N})^N I_n & \cdots & \frac{N}{\lambda h+N} I_n & 0 \\ 0 & & \cdots & 0 & 0 \end{bmatrix},$$

which can be rewritten equivalently as

$$= [0\ I_p\ 0 \dots 0] \begin{bmatrix} 0 & 0 & \cdots & 0 & 0 \\ 0 & C_1^N & \cdots & C_N^N & 0 \\ \vdots & \vdots & \ddots & & \vdots \\ 0 & C_N^N & & & \\ 0 & 0 & \cdots & 0 & 0 \end{bmatrix} \frac{h}{N}$$

$$\times \begin{bmatrix} 0 & 0 & \cdots & 0 & 0 \\ 0 & \frac{N}{\lambda h+N} I_n & & & 0 \\ \vdots & \vdots & \ddots & & \vdots \\ 0 & (\frac{N}{\lambda h+N})^N I_n & \cdots & \frac{N}{\lambda h+N} I_n & 0 \\ 0 & 0 & \cdots & 0 & 0 \end{bmatrix}.$$

Let us denote by N_1 the first row matrix on the right-hand side, N_2 the second matrix and N_3^λ the third matrix multiply by $\frac{h}{N}$. Then

(ii1) $\|N_1\|_N = 1$.

(ii2) $\|N_2\|_N \le \max(1, \mathrm{Var}\gamma)$, for all $N \in \mathbf{N}$.

Let $z = \mathrm{col}(z_0, \dots, z_N, u_1, \dots, u_N) \in R^{n(N+1)+mN}$, then by convolution inequality

$$\begin{aligned} \|N_2 z\|_N^2 &= \frac{h}{N} \sum_{i=1}^{N} \left| \sum_{j=1}^{N} C_j^N z_{j+1-i} \right|^2 \\ &\le \frac{h}{N} \mathrm{Var}^2\gamma \sum_{j=1}^{N} |z_j|^2 \\ &\le \max^2(1, \mathrm{Var}\gamma) \|z\|_N^2, \quad \forall N \in \mathbf{N}. \end{aligned}$$

(ii3) From Salamon [S1, Thm. 4.9, Steps 1–3], we can show that

$$\int_{-\infty}^{\infty} \|N_3^{\alpha+i\omega} x\|_N^2 \, d\omega \le \frac{\pi h}{N} \frac{\gamma_0^2}{\alpha+\epsilon_0} \sum_{i=1}^{N} |x_i|^2,$$

where $0 \le \gamma_0 \le 1$, $\epsilon_0 > \frac{1}{h}$. Hence

$$\int_{-\infty}^{\infty} \|N_3^{\alpha+i\omega} x\|_N^2 \, d\omega \le \max^2 \left(1, \sqrt{\frac{\pi}{\alpha+\epsilon_0}} \gamma_0\right) \|x\|_N^2.$$

Combining (ii1)–(ii3), we obtain

$$\int_{-\infty}^{\infty} |C^N T^N_{\alpha+i\omega} x|^2 d\omega \leq D_9 \|x\|^2_N,$$

where $D_9 = \max^2(1, \mathrm{Var}\gamma)\max^2(1, \sqrt{\pi/(\epsilon_0+\alpha)}\gamma_0)$.

(iii) Now by steps (i) and (ii),

$$\int_{-\infty}^{\infty} |C^N((\alpha+i\omega)I - A^N)^{-1}x|^2 d\omega \leq 2\int_{-\infty}^{\infty} \frac{D_8^2}{\omega^2}\|x\|^2_N d\omega + 2\int_{-\infty}^{\infty} |C^N T^N_{\alpha+i\omega}x|^2 d\omega$$
$$\leq 2D_9\|x\|^2_N.$$

Since the Fourier transform of $e^{-\alpha t}C^N e^{A^N t}x$ is

$$\frac{1}{\sqrt{2\pi}} C^N((\alpha+i\omega)I - A^N)^{-1}x,$$

by Plancherel's theorem,

$$\int_0^{\infty} e^{-2\alpha t}|C^N e^{A^N t}x|^2 dt \leq \frac{1}{2\pi} 2D_9\|x\|^2_N.$$

Since $e^{2\alpha(T-s)} \geq 1$ for $s \in [0,T]$,

$$\int_0^T |C^N e^{A^N t}x|^2 dt \leq \int_0^T e^{2\alpha(T-s)}|C^N e^{A^N s}x|^2 ds \leq e^{2\alpha T}\frac{D_9}{\pi}\|x\|^2_N. \qquad \square$$

THEOREM 4.6. $\lim_{N\to\infty} \int_0^T |C^N e^{A^N t}\pi^N\phi - CS(t)\phi|^2 dt = 0$, *for all* ϕ *in* X.

Proof. By Theorem 4.5, it suffices to prove this theorem for all ϕ in D where D is some dense subset in X. To this end, we consider the following subset in X:

$$D = \{(\phi^1(0), \phi^1, \phi^2)/\phi^1 \in C^1([-h,0]; R^n), \phi^2 \in C^1([-h,0]; R^m)\}.$$

First let us obtain the following preliminary result. Let

$$z^N(t) = \mathrm{col}(z_1^N(t), \ldots, z_N^N(t), v_1^N(t), \ldots, v_N^N(t)) = e^{A^N t}\pi^N\phi \in R^{n(N+1)+mN},$$

where $\phi \in D$. We have

$$\|\wr^N A^N e^{A^N t}\pi^N\phi - AS(t)\phi\|_X \leq \|\wr^N e^{A^N t}\pi^N\| \|\wr^N A^N\pi^N\phi - A\phi\|$$
$$+ \|\wr^N e^{A^N t}\pi^N A\phi - S(t)A\phi\|_X.$$

From the stability result, Theorem 3.1, Lemma 4.2, and the Trotter–Kato Theorem 4.1, it follows straightforwardly

$$\lim_{N\to\infty} \|\wr^N A^N e^{A^N t}\pi^N\phi - AS(t)\phi\|_X = 0,$$

and the limit is uniform in t for t in bounded interval $[0,T]$.

Now, we consider

$$C^N z^N(t) = \sum_{i=0}^{N} C_i^N z_i^N(t).$$

Using the same arguments as in the proof of Lemma 4.2, we have

$$C^N z^N(t) = -\gamma_0(-h) z_N^N(t) - \int_{-h}^{0} \gamma_0^N(s) \sum_{i=1}^{N} \frac{N}{h} (z_{i-1}^N(t) - z_i^N(t)) \chi_i(s) ds.$$

Also by integration by parts

$$CS(t)\phi = -\gamma_0(-h)x(t-h) - \int_{-h}^{0} \gamma_0(s) \frac{d}{ds} x(t+s) ds.$$

However,

$$\begin{aligned}
\lim_{N\to\infty} z_N^N(t) &= \lim_{N\to\infty} \left[z_0^N(t) - \sum_{j=1}^{N} (z_{j-1}^N(t) - z_j^N(t)) \right] \\
&= \lim_{N\to\infty} \left[z_0^N(t) - \sum_{j=1}^{N} \int_{t_j}^{t_{j-1}} \frac{N}{h} (z_{j-1}^N(t) - z_j^N(t)) ds \right] \\
&= \lim_{N\to\infty} \left[z_0^N(t) - \sum_{j=1}^{N} \int_{-h}^{0} \frac{N}{h} (z_{j-1}^N(t) - z_j^N(t) \chi_j ds \right] \\
&= x(t) - \int_{-h}^{0} [AS(t)\phi]^1(s) ds \\
&= x(t-h),
\end{aligned}$$

and this limit is uniform in t for t in $[0, T]$. Also,

$$\begin{aligned}
&\left| \int_{-h}^{0} \gamma_0^N(s) \sum_{i=1}^{N} \frac{N}{h} (z_{i-1}^N(t) - z_i^N(t)) \chi_i ds - \int_{-h}^{0} \gamma_0(s) \frac{d}{ds} x(t+s) ds \right| \\
&\quad \le \left| \int_{-h}^{0} [\gamma_0^N(s) - \gamma_0(s)] dx(t+s) \right| \\
&\qquad + \left| \int_{-h}^{0} \gamma_0^N(s) \left[\sum_{i=1}^{N} \frac{N}{h} (z_{i-1}^N(t) - z_i^N(t)) \chi_i ds - \frac{d}{ds} x(t+s) \right] ds \right| \\
&\quad \le \sup_{\theta \in [-h, T]} |\dot{x}(\theta)| \frac{h}{N} \mathrm{Var}\gamma_0 + \mathrm{Var}\gamma_0 \int_{-h}^{0} \left| [\lambda^N A^N z^N(t)]^1(s) - \frac{d}{ds} x(t+s) \right| ds,
\end{aligned}$$

where we use the inequality [S1]. From the preliminary result of this proof, the right-hand side converges to zero uniformly in t for $t \in [0, T]$. Therefore,

$$\lim_{N\to\infty} C^N e^{A^N t} \pi^N \phi = CS(t)\phi, \qquad \phi \in D$$

and the limit is uniform in t for t in bounded interval $[0, T]$. The statement in the theorem now follows easily. □

4.2. Nonhomogeneous equations. Having obtained convergence results and estimates of the convergence rate associated with the homogeneous equations we now pose the following question, if—and in what sense—the operators associated with the

nonhomogeneous equations $u \neq 0$ converge. This problem will be considered in this section.

First we will consider the convergence of the output associated with the nonhomogeneous equations. We will show that $C^N S^N(\cdot)B^N$ converges to $CS(\cdot)B$ as a function in $L^2(0,t;R^p)$, uniformly for all $t > 0$. The underlying tool for this convergence proof is the Plancherel's theorem. Before turning to this main result, we will prove the following two lemmas. The first lemma shows that the sequence of operators $C^N R(\lambda, A^N)B^N$ and $CR(\lambda, A)B$ decay on the infinite semi-axis $\alpha+i\omega$, $|\omega| > \beta_1$, where $\beta_1 > 0$. And in the second lemma, it is shown that the sequence $C^N R(\lambda, A^N)B^N$ converges uniformly to $CR(\lambda, A)B$ on some compact set in the complex plane of the form $\{\lambda \in \mathbf{C}/\mathrm{Re}\lambda = \alpha, |\mathrm{Im}\lambda| \leq \beta_1\}$.

LEMMA 4.7. *There exist positive constants* α, β_1, D_{10}, *and* D_{11} *such that*

(i) $|C^N R(\lambda, A^N)B^N| \leq \frac{D_{10}}{|\mathrm{Im}\lambda|}$,

(ii) $|CR(\lambda, A)B| \leq \frac{D_{11}}{|\mathrm{Im}\lambda|}$,

for all $\lambda \in \mathbf{C}$ *with* $\mathrm{Re}\lambda = \alpha, |\mathrm{Im}\lambda| > \beta_1$.

Proof. (i) Since $C^N R(\lambda, A^N)B^N = C^N E_\lambda^N \Delta^N(\lambda)^{-1}(E_\lambda^{T^*})^N F^N B^N$, part (i) follows from the following estimates.

From part (i1) and (i2) of Theorem 4.5,

$$|C^N E_\lambda^N| \leq \mathrm{Var}\gamma_0 \quad \text{for } \mathrm{Re}\lambda > 0$$

and

$$|\Delta^N(\lambda)^{-1}| \leq \frac{2}{|\mathrm{Im}\lambda|}, \qquad |\lambda| > 2\mathrm{Var}\,\eta_0.$$

For $u \in \mathbf{C}^m$,

$$(E_\lambda^{T^*})^N F^N B^N u = B_0 u + \frac{h}{N}\sum_{i=1}^{N}\left(\frac{N}{\lambda h + N}\right)^i B_i^N \frac{N}{h} u;$$

it follows that

$$|(E_\lambda^{T^*})^N F^N B^N u| \leq (|B_0| + \mathrm{Var}\beta)|u|, \quad \mathrm{Re}\lambda > 0.$$

(ii) Since $CR(\lambda, A)B = CE_\lambda \Delta^{-1}(\lambda) E_\lambda^{T^*} FB$, similarly part (ii) follows from the following estimates.

Let $x \in \mathbf{C}^n$, then

$$\begin{aligned} |CE_\lambda x| &= \left|\int_{-h}^{0} d\gamma_0(s) e^{\lambda s} x\right| \\ &\leq \max_{s\in[-h,0]} e^{sRe\lambda}\mathrm{Var}\gamma_0 |x| \leq \mathrm{Var}\gamma_0 |x|, \quad \mathrm{Re}\lambda > 0. \end{aligned}$$

Using the same arguments as part (i2) in Theorem 4.5, we can show that, for $|\lambda| > 2\mathrm{Var}\eta_0$

$$|\Delta^{-1}(\lambda)| \leq \frac{2}{|\mathrm{Im}\lambda|}.$$

Since $|E_\lambda^{T^*} FB| = |(FB)^* E_\lambda^T|$. By [S1, Prop. 5.12]

$$\begin{aligned} (FB)^* E_\lambda^T &= B^T E_\lambda^T \\ &= \int_{-h}^{0} d\beta_0^T(s) e^{\lambda s}, \qquad \beta_0 = -B_0 \chi_{(-\infty,0)}(\theta) + \beta(\theta). \end{aligned}$$

It is easy to show that for $x \in \mathbf{C}^n$, $|(FB)^* E_\lambda^T x| \leq \mathrm{Var}\beta^T |x|$. Hence $|E_\lambda^{T^*} FB| \leq \mathrm{Var}\beta_0^T$. □

LEMMA 4.8. *There exist positive constants α and β_1 such that*

$$\lim_{N\to\infty} C^N R(\lambda, A^N) B^N = CR(\lambda, A)B$$

uniformly on every compact set of the form $S = \{\lambda \in \mathbf{C}/\mathrm{Re}\lambda = \alpha, |\mathrm{Im}\lambda| \leq \beta_1\}$.

Proof. The statement in the lemma is a direct consequence of the following convergence results.

(i) $\lim_{N\to\infty} |CE_\lambda - C^N E_\lambda^N| = 0$ exists uniformly on S.

Let y be an arbitrary vector in C^N. By integration by parts

$$CE^\lambda y = -e^{-\lambda h}\gamma_0(-h)y - \lambda \int_{-h}^{0} e^{\lambda s}\gamma_0(s)ds.$$

Let e_λ^N denote the approximate exponential function given by

$$e_\lambda^N(t) = \left(\frac{N}{\lambda h + N}\right)^i, \qquad t \in [t_i, t_{i-1}).$$

From [S1, Lem. 4.2]

$$C^N E_\lambda^N y = -\gamma_0(-h)e_\lambda^N y - \lambda \int_{-h}^{0} e_\lambda^N(s)\gamma_0^N(s)yds.$$

Hence

$$\begin{aligned} |CE_\lambda y - C^N E_\lambda^N y \leq\ & |\gamma_0(-h)y(e_\lambda^N(-h) - e^{-\lambda h})| \\ & + |\lambda| \int_{-h}^{0} |e^{\lambda s}||\gamma_0^N(s) - \gamma_0(s)||y|ds \\ & + |\lambda| \int_{-h}^{0} |\gamma_0^N(s)||y||e^{\lambda s} - e_\lambda^N(s)|ds. \end{aligned}$$

From the inequality [S1],

$$\begin{aligned} \leq\ & \mathrm{Var}\gamma_0 |e_\lambda^N(-h) - e^{-\lambda h}||y| + |\lambda||y|\frac{h}{N}\mathrm{Var}\gamma_0 \\ & + |\lambda| h \mathrm{Var}\gamma_0 |y| \sup_{s\in[-h,0]} |e^{\lambda s} - e_\lambda^N(s)| \end{aligned}$$

From [S1, Rem. 4.1(ii)], given $\epsilon > 0$ there exists an $N_0 \in \mathbf{N}$ such that

$$\sup_{s\in[-h,0]} |e^{\lambda s} - e_\lambda^N(s)| < \epsilon,$$

for all $\lambda \in S$ and all $N > N_0$. Therefore given $\epsilon_0 > 0$ there exists some N_1 such that for all $N > N_1$,

$$|CE_\lambda y - C^N E_\lambda^N y| < \epsilon_1 |y|$$

or

$$|CE_\lambda - C^N E_\lambda^N| < \epsilon, \qquad \lambda \in S, \quad N > N_1.$$

(ii) $\Delta^N(\lambda)$ converges to $\Delta(\lambda)$ uniformly on every bounded subset of $\mathbf{C}$ ([S1, Lem. 4.2]).

(iii) $\lim_{N\to\infty} |(E_\lambda^{T^*})^N F^N B^N - E_\lambda^{T^*} FB| = 0$ exists uniformly on S.

Let y be an arbitrary vector in $\mathbf{C}^n$. Consider the following adjoint operators

$$(E_\lambda^{T^*} FB)^* y = \int_{-h}^{0} d\beta^T(s) e^{\lambda s} y$$

and after some simple manipulations

$$(B^N)^*(F^N)^*(E_\lambda^T)^N y = \sum_{j=0}^{N} (B_j^N)^T \left(\frac{N}{\lambda h + N}\right)^j y.$$

Hence by the same reasoning as in part (i)

$$\lim_{N\to\infty} |(B^N)^*(F^N)^*(E_\lambda^T)^N - (FB)^* E_\lambda^T| = 0$$

exists uniformly on S and thus completes our proof. □

Using the above two lemmas and the Fourier–Plancherel Theorem, we now obtain the following convergence result of the output corresponding to the nonhomogeneous equations.

THEOREM 4.9. $\lim_{N\to\infty} \int_0^t |C^N S^N(\theta) B^N - CS(\theta)B|^2 d\theta = 0$ *for all* $t > 0$.

Proof. Let denote $G(\lambda) = CR(\lambda, A)B$ and $G^N(\lambda) = C^N R(\lambda, A^N)B^N$. Let $\epsilon > 0$ be given and choose $\beta_1 > 9D_{12}^2/\epsilon$,where the constant $D_{12} = \max\{D_{10}, D_{11}\}$ and D_{10}, D_{11} are the bounds in Lemma 4.7. Then from Lemma 4.7,

$$\begin{aligned}
\int_{-\infty}^{\infty} |G(\alpha+i\omega) - G^N(\alpha+i\omega)|^2 d\omega &= \int_{-\infty}^{-\beta_1} |G(\alpha+i\omega) - G^N(\alpha+i\omega)|^2 d\omega \\
&\quad + \int_{-\beta_1}^{\beta_1} |G(\alpha+i\omega) - G^N(\alpha+i\omega)|^2 d\omega + \int_{\beta_1}^{\infty} |G(\alpha+i\omega) - G^N(\alpha+i\omega)|^2 d\omega \\
&\le \int_{-\beta_1}^{\beta_1} |G(\alpha+i\omega) - G^N(\alpha+i\omega)|^2 d\omega + 8\int_{\beta_1}^{\infty} \frac{D_{12}^2}{\omega^2} d\omega \\
&= \int_{-\beta_1}^{\beta_1} |G(\alpha+i\omega) - G^N(\alpha+i\omega)|^2 d\omega + \frac{8D_{12}^2}{\beta_1}.
\end{aligned}$$

From Lemma 4.8, $\lim_{N\to\infty} |G^N(\lambda) - G(\lambda)| = 0$ exists uniformly in S. Hence there exists an $N_0 \in \mathbf{N}$ such that for all $N \ge N_0$,

$$\int_{-\beta_1}^{\beta_1} |G(\alpha+i\omega) - G^N(\alpha+i\omega)|^2 d\omega < \frac{\epsilon}{9}.$$

Therefore,

$$\int_{-\infty}^{\infty} |G(\alpha+i\omega) - G^N(\alpha+i\omega)|^2 d\omega < \frac{\epsilon}{9} + \frac{8D_{12}^2}{\beta_1} < \epsilon.$$

Since the Fourier transform of $e^{-\alpha t} CS(t)B$ is $G(\alpha+i\omega)1/\sqrt{2\pi}$, by Plancherel's theorem

$$\int_0^{\infty} e^{-2\alpha t} |C^N S^N(t) B^N - CS(t)B|^2 dt < \frac{\epsilon}{2\pi}.$$

Now since $e^{2\alpha(t-s)} \geq 1$ for $s \in [0,t]$

$$\int_0^t |C^N S^N(\theta)B^N - CS(\theta)B|^2 d\theta \leq \int_0^t e^{2\alpha(t-\theta)}|C^N S^N(\theta)B^N - CS(\theta)B|^2 d\theta$$
$$\leq e^{2\alpha t}\frac{\epsilon}{2\pi}$$

for $N > N_0$. This completes our proof. □

For the remainder of this section, we will consider the convergence of

$$\int_0^t S^N(t-\theta)B^N u(\theta)d\theta \quad \text{to} \quad \int_0^t S(t-\theta)Bu(\theta)d\theta \ \text{ in } X,$$

where $u \in L^2_{\text{loc}}([0,\infty); R^m)$ and B is an unbounded operator in X.

Let us first recall that for any $u \in R^m$, $Bu = (B_0 u, 0, T_{\delta_0} u)$. After some simple manipulations, it is easily seen that

$$A^{-1}Bu = \left(\Delta^{-1}\left(B_0 u + \int_{-h}^0 d\beta(\theta)u\right), \Delta^{-1}\left(B_0 u + \int_{-h}^0 d\beta(\theta)u\right), -u\right) \tag{6}$$

provided $\Delta = \int_{-h}^0 d\eta_0(\theta)$ is invertible, i.e., 0 is not in the spectrum of A. If Δ is not invertible, we can choose any $\lambda \in \rho(A)$ and consider $x_\lambda(t) = e^{-\lambda t}x(t)$ where $x(t)$ is the solution to the initial-value problem (1). As shown in [I2], the corresponding generator A_λ has $0 \in \rho(A_\lambda)$. Therefore, without loss of generality, we can assume the above formulation (6) of $A^{-1}Bu$.

Since $Gu = A^{-1}Bu \in \text{dom } A$,

$$\int_0^t S(t-\theta)Bu(\theta)d\theta = \int_0^t AS(t-\theta)Gu(\theta)d\theta.$$

If u is continuously differentiable, i.e. $u \in C^1(0,t,R^m)$, then it follows from Kato ([K1, pp. 488–489]) that

$$\int_0^t S(t-\theta)Bu(\theta)d\theta = S(t)Gu(0) - Gu(t) + \int_0^t S(t-\theta)G\dot{u}(\theta)d\theta. \tag{7}$$

From the formulation of A^N and B^N (§3.1), it is straightforward to show that

$$(A^N)^{-1}B^N u = Gu.$$

Hence by applying the above arguments to

$$\int_0^t A^N S^N(t-\theta)Gu(\theta)d\theta$$

we get

$$\int_0^t A^N S^N(t-\theta)Gu(\theta)d\theta = S^N(t)Gu(0) - Gu(t) + \int_0^t S^N(t-\theta)G\dot{u}(\theta)d\theta. \tag{8}$$

From the Trotter–Kato Theorem 4.1,

$$\lim_{N\to\infty} S^N(t)Gu = S(t)Gu \quad \text{in } X$$

for all $t \geq 0$ and the limit is uniform in t for t in bounded intervals. Since $u \in R^m$, the linear map $S(t)G : R^m \to X$ is continuous. Hence

$$\lim_{N\to\infty} \|(S^N(t) - S(t))G\|_{L(R^m,X)} = 0.$$

Therefore, it is now clear that from (7) and (8), for $u \in C^1(0,t;R^m)$

$$\lim_{N\to\infty} \int_0^t S^N(t-\theta)B^N u(\theta)d\theta = \int_0^t S(t-\theta)Bu(\theta)d\theta$$

in X, and the limit is uniform in t for t in bounded intervals. To obtain our desired convergence result for all $u \in L^2_{\text{loc}}([0,\infty);R^m)$ we need the following result.

THEOREM 4.10. *There exists positive constant D_{12}, dependent on t but independent of N, such that for every $u(\cdot) \in L^2_{\text{loc}}(0,t;R^m)$ and all N in* $\mathbf{N}$,

$$\left\| \int_0^t S^N(t-\theta)B^N u(\theta)d\theta \right\|_{X^N} \leq D_{12}\|u\|_{L^2(0,t;R^m)}$$

for each $t \geq 0$.

Proof. The proof uses the same arguments as the stability proof of Theorem 3.1. To this end, we consider the following equation:

$$\langle \dot{z}^N(t), z^N(t)\rangle_{\tau^N} = \langle A^N z^N(t) + B^N u(t), z^N(t)\rangle_{\tau^N},$$

where $z^N(t) = \text{col}\,(z_0^N(t),\ldots,z_N^N(t),v_1^N(t),\ldots,v_N^N(t)) \in R^{n(N+1)+mN}$ is the solution to the approximating system

$$\dot{z}^N(t) = A^N z^N(t) + B^N u(t)$$

with zero initial condition. The right-hand side is equivalent to

$$\begin{aligned}
&\left(A_0 z_0(t) + \sum_{j=1}^N A_j^N z_j(t) + \sum_{j=1}^N B_j^N v_j(t) + B_0 u(t), z_0(t) \right) \\
&\quad + \sum_{i=1}^N (z_{i-1}(t) - z_i(t))^T z_i(t) a_i^N + \sum_{i=2}^N (v_{i-1}(t) - v_i(t))^T v_i(t) a_i^N \\
&\quad - |v_1(t)|^2 a_1^N + u^T(t) v_1(t) a_1^N.
\end{aligned}$$

From part (i)–(iv) of Theorem 3.1,

$$\langle \dot{z}^N(t), z^N(t)\rangle_{\tau^N} \leq \frac{1}{2}\beta\|z^N(t)\|_N^2 + |u(t)|^2,$$

where $\beta = 1 + a_1^N + \sum_{i=0}^q |A_i|^2 + \sum_{i=0}^q |B_i|^2 + \|A_{01}\|_{L^2}^2 + \|B_{01}\|_{L^2}^2$. Since the left-hand side is $\frac{1}{2}\frac{d}{dt}\|z^N(t)\|_{\tau^N}^2$ and $\|\cdot\|_N \leq \|\cdot\|_{\tau^N} \leq \gamma\|\cdot\|_N$,

$$\frac{d}{dt}\|z^N(t)\|_{\tau^N}^2 \leq \beta\|z^N(t)\|_{\tau^N}^2 + 2|u(t)|^2.$$

For zero initial condition

$$\|z^N(t)\|^2_{\tau^N} \leq \int_0^t (\beta \|z^N(s)\|^2_{\tau^N} + 2|u(s)|^2) ds.$$

By Gronwall's ineqaulity, $\|z^N(t)\|^2_{\tau^N} \leq 2e^{\beta t} \int_0^t |u(s)|^2 ds$. The result then follows from the equivalence of the norm in X^N and the weighting norm τ^N. □

5. Concluding Remarks. We have considered the averaging approximation scheme for linear retarded functional differential equations with delays in control and observation. We have shown that known results on averaging approximation of retarded systems with only delays in the state can be extended to include delays in input and output. These are the convergence results of the approximating semigroups in the strong operator topology in the context of Trotter–Kato approximation theorem [B1] and estimates of its rate of convergence using the concept of differentiable semigroups [L1]. In addition, we also gave new convergence results of the output and the state corresponding to both homogeneous and nonhomogeneous equations in the presence of unbounded input and output operators. Finally, the present development gives a basis for numerical investigations of control problems, in particular using the operator Riccati equations.

Acknowledgments. The second author is very pleased to acknowledge discussions with K. Ito of the Center for Applied Mathematical Sciences, University of Southern California (current address, Center for Research in Scientific Computation, North Carolina State University) for the proof of Theorem 4.10, and thanks D. Salamon of the Control Theory Centre, University of Warwick, for his invaluable help and suggestions.

ROOT-LOCUS AND BOUNDARY FEEDBACK DESIGN FOR A CLASS OF DISTRIBUTED PARAMETER SYSTEMS*

CHRISTOPHER I. BYRNES†, DAVID S. GILLIAM‡, AND JIANQIU HE‡

This paper is presented in memory of the short but promising mathematical career of Jagath Chandrawansa.

Abstract. In this paper, a fairly complete parallel of the finite-dimensional root locus theory is presented for quite general, nonconstant coefficient, even order ordinary differential operators on a finite interval with control and output boundary conditions representative of a choice of collocated point actuators and sensors. Root-locus design methods for linear distributed parameter systems have also been studied for some time and the primary difficulties in rigorously interpreting root-locus conclusions for distributed parameter systems are well known. First, the transfer function of a distributed parameter system may not be meromorphic at infinity so that many of the standard Rouche arguments, required even in the lumped case to determine the asymptotic behavior of the root loci, are not generally valid. Another difficulty is that the infinitesimal generator in the state-space model for a closed-loop system may not be selfadjoint, accretive or even satisfy the spectrum determined growth condition. Thus, regardless of whether the root loci—interpreted as closed-loop eigenvalues—lie in the open left half-plane, additional analysis would be required to conclude that the closed-loop system would be asymptotically stable. Formulating the systems in the classical format of a boundary control problem, the asymptotic analysis of the root loci can be based on the pioneering work by Birkhoff on eigenfunction expansions for boundary value problems, work that predated and indeed motivated the development of spectral theory in Hilbert space. Birkhoff's work also contains an asymptotic expansion of eigenfunctions in the spatial variable, generalizing the earlier Sturm–Liouville theory for second-order operators. By further extending this general asymptotic analysis to also include expansions in the gain parameter, a rigorous treatment of the open- and closed-loop transfer functions and of the corresponding return difference equation can be presented. The asymptotic analysis of the return difference equation forms the basis for both the rigorous formulation of the basic problem and its solution.

Key words. root locus, distributed parameter systems, boundary feedback, control and sensors, transfer function, impulse response, Riesz basis

AMS subject classification. 93

1. Introduction.

Root-locus plots were invented by Evans over forty years ago as a simple graphical tool for analyzing closed-loop stability properties for feedback systems. Based on a few simple rules, we can sketch the evolution of the closed-loop poles of certain feedback systems as the feedback gain is varied from zero to either plus or minus infinity. While originally derived for proportional error (PE) feedback systems, the root-locus methodology is also a useful tool for the design of stabilizing proportional rate (PD) controllers and more general dynamic compensators. The graphical appeal of this "back of the envelope" design tool, now available in standard control software packages, was responsible for the widespread and continued use of root-locus methods in industrial control system design.

Not surprisingly, root-locus design methods for linear distributed parameter systems have also been studied for some time. For example, motivated by the desire to control rigid spacecraft with flexible appendages, Bryson and several of his students (see, e.g., [4], [28], [42]) developed closed-loop root-locus plots for PE and PD bound-

ary controllers for various wave and beam equations. Pohjolainen [31], [32], [33] has also presented some root-locus arguments for distributed parameter systems. Even though there are infinitely many branches of the root loci for distributed parameter systems, such feedback analysis and design methods retain the relative simplicity and intuitive appeal of classical automatic control and no doubt lead to stabilizing, low-dimensional controllers when used correctly. Nonetheless, the rigorous analysis of the asymptotic behavior of the infinitely many branches of the root-locus and of the apparently resulting closed-loop stability properties for non-selfadjoint boundary value problems have been open problems. Moreover, because of the engineering appeal of root-locus plots as a graphical basis for feedback design, it is important to resolve these questions in a systematic fashion. In this paper, we present a fairly complete parallel of the finite-dimensional root-locus theory for quite general, nonconstant coefficient, even order ordinary differential operators on a finite interval with boundary conditions whose highest-order terms are separated (i.e., occur at one end point or the other, as in the case of colocated actuators and sensors).

The primary difficulties in rigorously interpreting root locus conclusions for distributed parameter systems are well known. First, the transfer function of a distributed parameter system may not be meromorphic at infinity so that many of the standard Rouche arguments, required even in the lumped case to determine the asymptotic behavior of the root loci, are not generally valid. Related to this, but also important in its own right, is the apparent difficulty of obtaining a well-defined notion of "high frequency" or "instantaneous" gain, the sign of which is crucial in determining the direction of the root locus as well as in a variety of stability considerations throughout classical automatic control. More explicitly, this response gain is classically computed either as the residue of the transfer function at infinity, which is an essential singularity for the systems considered here, or as the value of the impulse response at time zero, which can also be seen to be a singular point by an elementary Dirichlet series argument. Nonetheless, many physical examples suggest a preferred choice of the sign of the feedback gain, reflecting the existence of what should be an instantaneous gain—at least between colocated actuators and sensors. These examples also display closed-loop root loci with markedly different asymptotic behavior as the gain parameter goes to either plus or minus infinity, differences far more exotic than in finite dimensions. Thus, one important corollary to a reasonably complete root locus theory would be a rigorous formulation and treatment of a "high frequency" or "instantaneous" gain.

Another difficulty is, of course, that the infinitesimal generator in the state-space model for a closed-loop system may not be selfadjoint, accretive or even satisfy the spectrum determined growth condition. Thus, regardless of whether the root loci—interpreted as closed-loop eigenvalues—lie in the open left half-plane, additional analysis would be required to conclude that the closed-loop system would be asymptotically stable. Compounding this problem is the fact that, for systems arising from boundary value problems for partial differential equations, we are often interested in point actuators and sensors; i.e., input and output sources occurring at points in the spatial domain. The operators representing these sensors and actuators are seldom bounded (in fact, not even closable) in the standard Hilbert state space defined by the boundary conditions. Thus, to formulate such problems in the state-space form it is required to introduce auxiliary spaces as in [11], [15], [16], [18], [21], [22], [24], [38], [35], [39]–[41]. While such a state-space representation is esthetically appealing, it is nevertheless true that obtaining explicit formulas for the operators B and C can

generally be quite difficult and is in any case not explicitly required in the formulation of a rigorous root locus methodology for boundary feedback controller design.

In §2 we have formulated our systems in the more classical format of a boundary control problem but we also indicate how this class of problems can be cast in terms of abstract boundary control systems, as in [14], [21]. This choice of a classical formulation enables us to base our asymptotic analysis of the root loci on the pioneering work by Birkhoff [1], [2], which consisted essentially of the development of a spectral theory for not necessarily selfadjoint boundary value problems. Of course, Birkhoff's work on eigenfunction expansions for boundary value problems predated, and indeed motivated (see, e.g., [36]), the development of spectral theory in Hilbert space. In particular, with some work in the non-selfadjoint case, by viewing changes in the feedback gain as perturbations of the boundary conditions an alternative approach to root locus analysis could also be carried out by appealing to the modern perturbation theory of unbounded spectral operators, which, however, can lead to subtle technical problems even in the selfadjoint case (cf. Example 3.4). Birkhoff's work also contains an asymptotic expansion of eigenfunctions in the spatial variable, generalizing the earlier Sturm–Liouville theory for second-order operators. By further extending this general asymptotic analysis to also include expansions in the gain parameter, we are able to present a rigorous treatment of the open- and closed-loop transfer functions and of the corresponding return difference equation, all familiar objects in classical automatic control. We remark that, by emphasizing the analysis of the roots of the return difference equation rather than just the closed-loop poles, we avoid difficulties arising in pole-zero cancellations and are thereby able to ultimately obtain results on internal stability of the original boundary value problems. Thus, the asymptotic analysis of the return difference equation forms the basis for both our rigorous formulation of the basic problem and its solution, as described in §§2 and 3, respectively.

In §2, we introduce a hypothesis on the relative orders of the input and the output boundary operators. Informally, we have found it useful to think of this as a "causality" condition, asserting that the "relative degree" of the system is nonnegative. Indeed, we show that the transfer functions for this class of systems exist, lie in the Callier–Desoer class, are strictly proper, and thus are holomorphic and, in fact, vanish at infinity in a right half-plane. We then develop an asymptotic expansion of the transfer function, in a half-plane, in terms of a fractional power series with exponent depending on the orders of the differential operator and of the boundary conditions. One very important corollary of this analysis is the formulation of the concept of "high frequency" or "instantaneous" gain, defined as the leading coefficient in this asymptotic expansion. Moreover, a formula for the sign of the instantaneous gain can be given in terms of the boundary conditions. As shown in §3, the sign of the instantaneous gain plays the expected fundamental role in our subsequent analysis of the root loci and of the spectral properties of the closed-loop system, an analysis that also depends rather heavily on the asymptotics of the return difference equation.

As a preliminary to the statements of the main results on root locus plots and spectral properties for closed-loop distributed parameter systems (DPS), we begin §3 with a series of examples illustrating some of the important contrasts with root locus theory for lumped systems. These differences arise, of course, from the fact that for the systems we consider, the transfer function is not rational but rather always has an essential singularity at infinity. Example 3.1 illustrates the possibility, in the absence of our hypotheses, that the closed-loop infinitesimal generator can have, for various values of the feedback gain, either discrete spectrum, or a continuum (the entire

complex plane) of point spectrum, or empty spectrum. Examples 3.2 and 3.3 are more subtle and illustrate the effect of the essential singularity at infinity on the asymptotic behavior of the root-locus plot for DPS, a situation clarified by the definition of the instantaneous gain and the statement of our main results. Among these, we note in Theorem 3.1 that the closed-loop operators form a holomorphic family. However, as an example of Rellich (adapted to our setting in Example 3.4) shows, from this it can only be argued that finite systems of eigenvalues vary continuously. In this context, the real difficulty in establishing a root-locus theory for this class of distributed systems lies in showing that all branches of the root locus vary continuously as the gain is varied from zero to either plus or minus infinity. With our additional "causality" hypothesis on the relative orders of the input and output boundary conditions, our asymptotic analysis of the return difference equation allows us to prove more refined continuity results for the root loci (cf. Theorem 3.2, Corollary 3.3, and Theorem 3.4) by verifying that we have "separation of the spectrum" for the one-parameter family of operators.

We conclude §3 with an outline of the asymptotic analysis of the return difference equation. In §4 we provide a detailed asymptotic analysis of the return difference equation, except for the proof of Proposition 4.2, which is tedious and therefore appended as §6. Section 5, based on the previous section, contains the complete proofs of the results announced in §2 and the proof of Theorem 3.4. In general, we recommend first reading the outline provided in §3, then skipping to §5 after which the reader can return to the proofs of the asymptotics in §§4 and 6.

Finally, we wish to address the general scope of applicability of these methods. Our immediate goal is to demonstrate that it is possible to obtain a fairly complete analogue of the finite-dimensional root-locus theory—at least for proportional error feedback laws and for a class of parabolic boundary control problems. On the one hand, using standard variational methods, an extension of this analysis to higher-dimensional selfadjoint problems can be obtained [10]. However, as far as we are aware, general methods for spectral analysis for non-selfadjoint problems are available only in one spatial dimension (see, e.g., [20]) or for abstract operators that are either maximal dissipative or for which the eigenfunctions form a Riesz basis. For nth-order ordinary differential operators, the corresponding boundary conditions considered in [1], [2] are now known as "Birkhoff regular" boundary conditions and, parameterizing a system of boundary conditions by an n by $2n$ matrix of rank n, we see that Birkhoff regular boundary conditions are generic among all boundary conditions. In this paper, we consider the case of separated boundary conditions, corresponding to colocated actuators and sensors. Separated boundary conditions are automatically Birkhoff regular. In [23] general Birkhoff regular boundary conditions are considered for parabolic systems. We have also investigated the extension of these methods to the hyperbolic case (see [8]), where our preliminary analysis indicates that it is also possible to obtain a fairly complete analogue of the finite-dimensional root-locus theory. Moreover, as in the classical case, the "root-locus" plots developed for distributed parameter systems can be used to study a broader set of design problems, e.g., PD controller design (see [8]), than just that of stabilization by proportional error feedback gain.

2. Formulation of the problem in the time and frequency domains. In this section, we describe the interpretation of root loci in both the state space and the frequency domain. All proofs are deferred to §4. In what follows, we consider a

distributed parameter control system

$$\begin{aligned} \frac{\partial w}{\partial t}(x,t) &= \mathcal{A}w(x,t), \\ \mathcal{B}w(t) &= u(t), \\ w(x,0) &= f(x) \in L^2(0,1), \\ y(t) &= \mathcal{C}w(t), \end{aligned} \tag{2.1}$$

where $\mathcal{A}$ is an even order, $n = 2\mu$, ordinary differential operator, with $C^\infty[0,1]$, real coefficients, of the form

$$\begin{aligned} \mathcal{A} &= L_0 + L, \\ L_0 &= (-1)^{(\mu-1)}D^n, \qquad D = \frac{d}{dx} \\ L &= \sum_{j=0}^{n-2} p_j(x)D^j \end{aligned} \tag{2.2}$$

acting in the state space $L^2(0,1)$ with domain

$$\mathcal{D}(\mathcal{A}) = \{f \in H^{(n)}(0,1) : \mathcal{W}_i(f) = 0,\ i = 2,\ \ldots, n\}, \tag{2.3}$$

where $H^{(n)}$ is the usual Sobolev space and the operators $\{\mathcal{W}_i\}_{i=0}^n$ are boundary operators providing homogeneous boundary conditions defining $\mathcal{A}$ for $i = 2,\ldots,n$ and defining the output and input operators $\mathcal{C}$ and $\mathcal{B}$ for $i = 0$ and $i = 1$, respectively (cf. (2.5), (2.6) below). Acting on C^{n-1} functions f by these operators are given by

$$\begin{aligned} \mathcal{W}_i(f) &\equiv \alpha_i f^{(m_i)}(0) + \sum_{j=0}^{m_i-1} \left\{\alpha_{ij} f^{(j)}(0) + \beta_{ij} f^{(j)}(1)\right\}, \\ \mathcal{W}_{\mu+i}(f) &\equiv \beta_i f^{(m_{\mu+i})}(1) + \sum_{j=0}^{m_{\mu+i}-1} \left\{\alpha_{(\mu+i)j} f^{(j)}(0) + \beta_{(\mu+i)j} f^{(j)}(1)\right\}, \end{aligned} \tag{2.4}$$

where $i = 1,\ldots,\mu$, $\alpha_i \neq 0$, $\beta_i \neq 0$, α_{ij}, β_{ij} are real and

$$m_1,\ m_{\mu+1} \leq (n-1), \quad m_1 > \cdots > m_\mu, \quad m_{\mu+1} > \cdots > m_n$$

and $\mathcal{W}_0$ is defined in (2.6).

The input $u(t)$ is assumed to occur through the boundary as in [5] and is assumed to occur through the first boundary condition $\mathcal{W}_1$, i.e.,

$$\mathcal{B}w(t) \equiv \mathcal{W}_1(w)(t) = u(t). \tag{2.5}$$

It is further assumed that the output sensor has the form

$$\begin{aligned} y(t) &= \mathcal{C}(w)(t) \equiv \mathcal{W}_0(w)(t), \\ \mathcal{W}_0(w)(t) &= \alpha_0 w^{(m_0)}(0,t) + \sum_{j=0}^{m_0-1} \left\{\alpha_{0j} w^{(j)}(0,t) + \beta_{0j} w^{(j)}(1,t)\right\}. \end{aligned} \tag{2.6}$$

ASSUMPTION 2.1. *The order m_0 of $\mathcal{W}_0$ is not equal to the orders $\{m_i\}_{i=1}^\mu$ of $\{\mathcal{W}_i\}_{i=1}^\mu$ and $\ell = m_1 - m_0 > 0$.*

Remark 2.1. As illustrated in Example 3.3, the assumption $\ell > 0$ is a time domain analogue of strict properness of a transfer function representation. In the time domain, Assumption 2.1 is consistent with the situation found for admissible controls as described in [24], [27], where for the heat equation it is seen that Dirichlet boundary input leads to an inadmissible input operator (cf. Example 3.3).

Returning to (2.1)–(2.6), the uncontrolled system (i.e., $u = 0$ in (2.1)) has the form

$$\begin{aligned} \frac{\partial w}{\partial t}(x,t) &= A_0 w(x,t), \\ \mathcal{B}w(t) &= 0, \\ w(x,0) &= f(x) \in L^2(0,1), \\ y(t) &= \mathcal{C}w(t), \end{aligned} \tag{2.7}$$

where we have introduced the open-loop spatial operator $A_0 = \mathcal{A}$ with domain

$$\mathcal{D}(A_0) = \mathcal{D}(\mathcal{A}) \cap \ker(\mathcal{B}), \tag{2.8}$$

which we can write as

$$\mathcal{D}(A_0) = \{f \in H^{(n)}(0,1) : \mathcal{W}_i(f) = 0,\ i = 1,\dots,n\}. \tag{2.9}$$

Remark 2.2. The operator A_0 with domain $\mathcal{D}(A_0)$ is a special case of the class of Birkhoff regular operators considered in [1], [30]. It follows from [29] that in the special case of boundary conditions (2.4), which are separated in the highest-order terms, the operator (2.2) with domain (2.9) is always a discrete spectral operator whose eigenfunctions and associated functions form a Riesz basis in $L^2(0,1)$. In fact as will be seen in what follows, much more can be said in this case. Furthermore, with significant additional work, the analysis presented here can be applied to more general Birkhoff regular boundary conditions and also to conditions that are not regular (e.g., boundary conditions of the type (2.4) with an unequal number of conditions at the end points). The details are considerably more complicated and the results not as easily stated as in the present case.

DEFINITION 2.1. *The zero dynamics associated with the system* (2.1)–(2.6) *is the system obtained by constraining the output to zero*

$$\begin{aligned} \dot{w}(x,t) &= \mathcal{A}w(x,t), \\ \mathcal{W}_0(w)(t) \equiv \mathcal{C}w(t) &= 0, \\ w(x,0) &= f(x) \in L^2(0,1). \end{aligned} \tag{2.10}$$

The zero dynamics (2.10) can be expressed in terms of the notation introduced in (2.8) by defining the operator $A_\infty = \mathcal{A}$ with domain

$$\mathcal{D}(A_\infty) = \mathcal{D}(\mathcal{A}) \cap \ker(\mathcal{C}), \tag{2.11}$$

which we can write as

$$\mathcal{D}(A_\infty) = \{f \in H^{(n)}(0,1) : \mathcal{W}_i(f) = 0,\ i = 0,2,\dots,n\}. \tag{2.12}$$

A closed-loop system is obtained via a simple scalar boundary output feedback law of the form

$$u(t) = -ky(t). \tag{2.13}$$

Formulated in terms of perturbation of spectra of unbounded spectral operators, we would define a family of operators depending on the parameter k by introducing the spatial operator A_k as the operator $\mathcal{A}$ subject to perturbed boundary conditions obtained from the feedback law (2.13), i.e., $\mathcal{B}(w) + k\mathcal{C}(w) = 0$ or

$$\mathcal{W}_1(w) + k\,\mathcal{W}_0(w) = 0.$$

Thus we define

$$\begin{aligned} A_k &= A \\ D(A_k) &= \{f \in L^2(0,1) \,:\, f \in H^{(n)}(0,1), \\ &\qquad \mathcal{W}_i(f) = 0,\ i = 2,\ \ldots, n,\ \mathcal{W}_1(f) + k\,\mathcal{W}_0(f) = 0\} \end{aligned} \tag{2.14}$$

and the resulting closed-loop system has the form

$$\begin{aligned} \dot{w}(x,t) &= A_k w(x,t), \\ w(x,0) &= f(x). \end{aligned} \tag{2.15}$$

We could, of course, allow more general input and consider a closed-loop system corresponding to a feedback law of the form

$$u(t) = -ky(t) + v(t) \tag{2.16}$$

by defining a closed-loop system with additional input by

$$\begin{aligned} \dot{w}(x,t) &= \mathcal{A}w(x,t), \\ (B(w) + kC(w))(t) &= v(t), \\ y(t) &= C(w), \\ w(x,0) &= f(x). \end{aligned} \tag{2.17}$$

The stability of particular examples of system (2.17) for judicious choices of the gain parameter k has long been an object of study in the area of boundary feedback stabilization and control. The main problem that motivates the present work is the development of a systematic methodology, similar in scope to automatic control, for determining general dynamical properties of (2.17) as a function of the gain parameter. While such a methodology would include in its goals the capability of shaping the system response by tuning one or more gain parameters, for linear systems many problems of regulation and control repose upon the ability to design stabilizing feedback laws. In this context, one particular problem of interest would be to deduce stability properties of A_k for k sufficiently large, from stability properties of the zero dynamics. More generally, we would certainly like to know whether the solution semigroups would vary continuously as a function of the gain parameter in the extended real line.

To this end, it will be important to analyze the behavior of the family of semigroups defined by (2.17); hence our study of this problem incorporates a state space analysis of this class of systems. On the other hand, most of the graphical stability tests in classical automatic control were developed in the frequency domain. In this spirit, the present work provides the rigorous development of a graphical criterion for stability analysis based on a generalization of the finite-dimensional root-locus theory, which provides a simple set of rules for determining the evolution of the closed-loop

poles as functions of the gain parameter. This methodology reposes, of course, on the development of a transfer function description of the underlying distributed parameter system that is both rigorous and easy to relate to the time domain or state space representation.

By a transfer function for the system (2.1)–(2.6) we adopt the following definition, which is more restrictive than it need be but suffices for the systems considered here. First we define the Hilbert space of inputs

$$U_a = \{f : (0,\infty) \to \mathbb{C} : \exp(-a\cdot)f(\cdot) \in L_2(0,\infty),\ a \in \mathbb{R}\} \tag{2.18}$$

with inner product

$$< f, g >_a = \int_0^\infty f(t)g(t)e^{-2at}\,dt.$$

For the single input-single output systems considered in the present work, the space of outputs coincides with the space of inputs. In this context, one of our reasons for adopting Assumption 2.1 was to obtain a system transfer function that lies in $H^\infty(C_+^a)$ (where $C_+^a = \{\lambda \in C | \operatorname{Re}(\lambda) > a\}$) for some $a \in R$.

DEFINITION 2.2. *A transfer function for* (2.1)–(2.6) *is a function* $\mathcal{G}_0(\cdot) \in H^\infty(C_+^a)$ (*where* $C_+^a = \{\lambda \in C | \operatorname{Re}(\lambda) > a\}$) *such that for* $u \in U_a$ *there is a corresponding output* $y \in U_a$ *related via the Laplace transform by*

$$\hat{y}(\lambda) = \mathcal{G}_0(\lambda)\hat{u}(\lambda).$$

PROPOSITION 2.1. *The system* (2.1)–(2.6) *with* $w(x,0) = 0$ *has a transfer function with the form*

$$\mathcal{G}_0(\lambda) = \frac{\mathcal{N}(\lambda)}{\mathcal{D}(\lambda)}, \tag{2.19}$$

where $\mathcal{D}$, $\mathcal{N}$ *are entire functions of* λ *of order* $(1/n)$ *with infinitely many zeros diverging to infinity; these zeros are denoted by* $\lambda_j(0)$, *and* $\lambda_j(\infty)$, *respectively, and are here referred to as the open-loop poles and open-loop zeros. Moreover, the transfer function* $\mathcal{G}_0$ *is real, i.e.,*

$$\mathcal{G}_0(\bar{\lambda}) = \overline{\mathcal{G}_0(\lambda)},$$

from which we conclude that the complex poles and zeros occur in conjugate pairs.

The closed-loop transfer function, i.e., the transfer function for the system (2.17) *corresponding to the feedback law*

$$u = -ky + v$$

is

$$\mathcal{G}_k = \frac{\mathcal{N}(\lambda)}{\mathcal{D}(\lambda) + k\mathcal{N}(\lambda)}. \tag{2.20}$$

Furthermore, for every k *the solutions of the return difference equation*

$$\mathcal{D}(\lambda) + k\mathcal{N}(\lambda) = 0$$

correspond exactly to the spectrum of the closed-loop operator A_k *defined in* (2.14).

Remark 2.3. According to Proposition 2.1, the problem of showing that the spectra of the operators A_k varies continuously as k varies from $k = 0$ to $k = \infty$ is equivalent to showing that the roots of the return difference equation vary from the zeros of $\mathcal{D}$ to the zeros of $\mathcal{N}$. The root-locus theory we seek to develop would provide graphical information on the variation of either the eigenvalues or the roots of the return difference equation as functions of the gain parameter, as well as information on stability of the closed-loop system.

Remark 2.4. As in the open-loop case, we refer to the zeros of $\mathcal{N}$ as the closed-loop zeros and to the zeros of $\mathcal{D}+k\mathcal{N}$ as the closed-loop poles. This convention is potentially different from the zeros and poles of the transfer function $\mathcal{G}_k$ treated as a meromorphic function. Our convention is adopted from the point of view of internal stability relative to the realizations (2.17). For example, the assertion in Proposition 2.1 is potentially stronger and preferable to the corresponding assertion for the poles and zeros of the closed-loop transfer function. More precisely, the fact that for some k the poles of the closed-loop transfer function might lie in the open left half-plane would not imply that the spectrum of A_k would also lie in the open left half-plane if there were a pole-zero cancellation in $\mathcal{G}_k$. Internal stability relative to the realization (2.17) would require information on the full spectrum rather than on those poles (eigenvalues) that are not cancelled especially if the cancellation would occur in the closed right half-plane.

Remark 2.5. Pole-zero cancellation for this class of problems is, however, far from mysterious. First, from the asymptotic analysis developed in §4 it follows that all but a finite number of the solutions of the return difference equation vary with k. On the other hand, to say a pole-zero cancellation occurs in $\mathcal{G}_k$, for some k, is to say that both $\mathcal{N}$ and $\mathcal{D}+k\mathcal{N}$ vanish at some λ_0 in the complex plane. That is, both $\mathcal{N}$ and $\mathcal{D}$ vanish at λ_0 so that a pole-zero cancellation occurs at λ_0 for every k. In particular these already occur $k = 0$ and are finite in number counting multiplicity. We finally note that, in the light of this discussion, to say that the closed-loop poles tend to the open-loop zeros as k tends to infinity is to say that the poles of the closed-loop transfer function tend to the zeros of the open-loop transfer function, and conversely. The actual convergence of these poles will be discussed in the next section.

PROPOSITION 2.2. *For any system* (2.1)–(2.6), *the transfer function* $\mathcal{G}(\lambda)$ *is in* $H^\infty(C_+^a)$ (*where* $C_+^a = \{\lambda \in C | \operatorname{Re}(\lambda) > a\}$) *for some* $a \in R$ *and is strictly proper* (*cf.* [17]); *i.e.,*

$$\lim_{\lambda \to \infty} \mathcal{G}(\lambda) = 0$$

for $\lambda \in C_+^a$. *Furthermore, the impulse response satisfies*

$$h(t) = h_1(t) + h_2(t)$$

with $h_1 \in L^1_{loc}(0, \infty)$, $e^{-at}h_1 \in L^1(0, \infty)$ *and* $h_2 \in L^1(0, \infty)$. *Finally, the input-output map given by* $y(t) = (h * u)(t)$ *defines a bounded map on* U_a.

This result states in particular that the transfer function not only exists but lies in the Callier–Desoer class [17]. A particular consequence of this fact is of immense importance for developing a root-locus theory for this class of distributed parameter systems. More explicitly, one invariant of a rational transfer function that plays an important role in classical automatic control is its high frequency gain; i.e., its residue at infinity. This is also expressible in the time domain as the "instantaneous gain," which can be computed as the system response to a delta function at time zero. In

the classical case, the instantaneous gain can also be computed as the value of the impulse response function at time zero; namely, $h(0)$. Formally, it would appear that for this class of distributed parameter systems neither the high frequency gain nor the instantaneous gain would exist. Indeed, infinity is an essential singularity of the transfer function. In the time domain, we can only assert that h lies in $L^1_{\text{loc}}(0,\infty)$ and, in fact, a straightforward Dirichlet series argument shows that h is singular at $t = 0$. Nonetheless, physically motivated examples (cf. Example 3.2) indicate that, at the very least, there exists the analogue of the signum of the instantaneous gain, which is in fact the quantity used in classical control design. We can now describe this in the frequency domain in terms of an asymptotic expansion in C^a_+

PROPOSITION 2.3. *In C^a_+ we have*

$$\lim_{\lambda\to\infty} \lambda^{\ell/n}\, \mathcal{G}_0(\lambda) = \widehat{\tau}$$

for some nonzero real number $\widehat{\tau}$ where the limit is taken on the positive real axis.

DEFINITION 2.3. *For a system* (2.1)–(2.6) *satisfying Assumption* 2.1, *we refer to the number $\widehat{\tau}$ defined in Proposition* 2.3 *as the "instantaneous gain."*

As in the finite-dimensional case, it will be important for control system design to be able to compute the sign of $\widehat{\tau}$. To this end, we set the notation

$$\ell_0 = \min\{j : m_j < m_0, \quad j = 2, \dots, \mu\},$$

with the convention that ℓ_0 is taken to be zero if no such j exists. Note that in the case of second-order operators ℓ_0 is always zero.

The next result gives a formula for signum of $\widehat{\tau}$ in terms of the input and output boundary operators.

THEOREM 2.4. *Denote by $\mathcal{K}$ the signum of the instantaneous gain, $\widehat{\tau}$. Then $\mathcal{K}$ satisfies*

$$\mathcal{K} = (-1)^s,$$

where

$$s = \arg(\alpha_0/\alpha_1)/\pi + (\ell_0 + \ell), \tag{2.21}$$

with $\ell = m_1 - m_0 > 0$, and α_0, α_1 and m_0, m_1 are the coefficients of the highest-order terms and orders of the output and input operators, respectively.

The instantaneous gain also plays a fundamental role in the finite behavior of $\mathcal{G}_0(\lambda)$.

PROPOSITION 2.5. *For the system* (2.1)–(2.6) *we have the following facts concerning the transfer function.*

1. *The residues corresponding to poles of large modulus are real and of the same sign.*

2. *Suppose λ_j is a pole of large modulus of $\mathcal{G}_0(\lambda)$, $\lambda_j = i^n z_j^n$ where $n = 2\mu$ is the order of $\mathcal{A}$, $\ell > 0$ is the difference of the orders of the input and output operators, s is the integer determining the sign of the instantaneous gain* (*given in* (2.21)). *Then*

$$\text{Res}_{\lambda=\lambda_j}\, \mathcal{G}_0(\lambda) = (-1)^s n|\tau| \sin(\ell\pi/n)|z_j|^{n-\ell-1}[1],$$

where for a complex a, we use the notation $[a] = a + O(1/z)$ for large $|z|$.

3. *The inverse Laplace transform of $\mathcal{G}_0(\lambda)$ can be computed by the method of residues and produces an impulse response function as described in Proposition 2.2. Indeed, all but finitely many poles are real and simple; we denote the real simple poles by λ_j for $j > N+1$. Then we obtain a formula*

$$
\begin{aligned}
h(t) &\equiv \frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty} e^{st}\,\mathcal{G}_0(s)\,ds \\
&= \sum_{j=1}^{\infty} \mathrm{Res}_{\lambda=\lambda_j}\left(\mathcal{G}_0(\lambda)e^{\lambda t}\right) \qquad (2.22)\\
&= \left\{ \sum_{j=1}^{N} \mathrm{Res}_{\lambda=\lambda_j}\left(\mathcal{G}_0(\lambda)e^{\lambda t}\right) \right. \\
&\quad \left. + \sum_{j=N+1}^{\infty} (-i)^{n-\ell}(-1)^s n|\tau|\sin(\ell\pi/n)|\lambda_j|^{(n-\ell-1)/n} e^{\lambda_j t}[1] \right\} \\
&= \left\{ \sum_{j=1}^{N} \mathrm{Res}_{\lambda=\lambda_j}\left(\mathcal{G}_0(\lambda)e^{\lambda t}\right) + C\sum_{j=N+1}^{\infty} \lambda_j^{(n-\ell-1)/n} e^{\lambda_j t}[1] \right\} \\
&\equiv h_1(t) + h_2(t).
\end{aligned}
$$

Naturally, the derivation of the detailed results discussed above requires a fairly explicit representation of the system transfer function. However, the existence of a transfer function for this class of distributed parameter systems can also be deduced from general principles. We conclude this section with an outline of an existence proof in the context of abstract boundary control systems [21], [11], [14], illustrating the relationship between our approach and another common approach found in the literature. First note that the system (2.1)–(2.6) defines an abstract boundary control system in the sense of [21] since the operator $(-A_0)$ given in (2.8) can be shown to be an accretive operator and hence A_0 generates an analytic semigroup on $Z = L_2(0,1)$. Furthermore, we can construct a polynomial $b \in \mathcal{D}(\mathcal{A})$ that satisfies $\mathcal{W}_1(b) = 1$, $\mathcal{W}_j(b) = 0$, $j = 2,\dots,n$. In fact we can choose the degree of b to be at most $2p+1$ where $p = \max_{1\le j\le n}\{m_j\}$. In particular, we have the following result which is proved in §5.

PROPOSITION 2.6. *There exists a polynomial*

$$b(x) = \sum_{j=0}^{2p+1} a_j x^j$$

such that $b(x)$ satisfies

$$\mathcal{W}_1(b) = 1, \quad \mathcal{W}_j(b) = 0, \qquad j = 2,\dots,n,$$

where $p = \max_{1\le j\le n}\{m_j\}$.

Now define a bounded operator B from the input space U of complex numbers to Z, i.e., $B \in \mathcal{L}(U,Z)$, by multiplication by the function b. Note that

$$Bu \in \mathcal{D}(\mathcal{A}), \quad \mathcal{A}B \in \mathcal{L}(U,Z), \quad \mathcal{B}Bu = u, \quad \forall u \in U.$$

These constructions for the boundary control system (2.1)–(2.6) lead to the abstract Cauchy problem

$$\begin{aligned} \dot{v}(t) &= A_0 v(t) - B\dot{u}(t) + \mathcal{A}Bu(t), \\ v(0) &= v_0. \end{aligned} \tag{2.23}$$

Assume that $u \in C^2([0,\tau],U)$ for all $\tau > 0$. Then if $v_0 = f - Bu(0) \in \mathcal{D}(A_0)$, the classical solutions of (2.1)–(2.6) and (2.23) are related by

$$v(t) = z(t) - Bu(t).$$

Furthermore, the classical solution of (2.1)–(2.6) is unique. On the extended state-space $Z^e = U \oplus Z$, let

$$A^e = \begin{pmatrix} 0 & 0 \\ \mathcal{A}B & A_0 \end{pmatrix}, \quad B^e = \begin{pmatrix} 1 \\ -B \end{pmatrix}, \quad z^e = \begin{pmatrix} u \\ v \end{pmatrix}. \tag{2.24}$$

THEOREM 2.7. *Consider the extended system*

$$\begin{aligned} \dot{z^e}(t) &= A^e z^e(t) + B^e \tilde{u}(t), \\ z^e(0) &= \begin{pmatrix} u(0) \\ v_0 \end{pmatrix} = \begin{pmatrix} u(0) \\ f(x) - b(x)u(0) \end{pmatrix}. \end{aligned} \tag{2.25}$$

If $u \in C^2([0,\tau],U)$ and $v_0 \in \mathcal{D}(A_0)$, the system (2.25) with $\tilde{u} = \dot{u}$ has the unique classical solution

$$z^e(t) = \begin{pmatrix} u(t) \\ v(t) \end{pmatrix},$$

where $v(t)$ is the classical solution of (2.23). Furthermore, if $f = v_0 + Bu(0)$, then the classical solution of (2.1)–(2.6) is given by

$$z(t) = C^e z^e(t),$$

where $C^e = (B, 1)$ is bounded.

This result is well known and can be found, for example, in [14]. The importance of this result, in the present context, is that for "state linear systems" with bounded input and output operators of the form

$$\begin{aligned} \dot{w} &= Aw + Bu, \\ y &= Cw \end{aligned} \tag{2.26}$$

it is shown in [14] that the transfer function and impulse response function are well defined and in fact the transfer function has the explicit representation

$$G(s) = C(sI - A)^{-1}B, \qquad s \in \rho_\infty(A), \tag{2.27}$$

where $\rho_\infty(A)$ is the connected component of the resolvent set of A containing a semi-axis of the positive real line. Moreover, the impulse response function can be represented by

$$h(t) = CT(t)B, \tag{2.28}$$

where A is the infinitesimal generator of the C_0 semigroup $T(t)$.

More explicitly, it can be shown that if $u \in C^2([0,\infty], U)$ and $u(0) = 0$ then

$$\widehat{y}(s) = \mathcal{W}_0 \left\{ I - (sI - A_0)^{-1}(sI - \mathcal{A}) \right\} b(\cdot)\widehat{u}(s),$$

while our earlier calculations show that

$$\widehat{y}(s) = \frac{\mathcal{N}(s)}{\mathcal{D}(s)}\widehat{u}(s).$$

Thus for u in a dense set we obtain

$$\mathcal{W}_0 \left\{ I - (sI - A_0)^{-1}(sI - \mathcal{A}) \right\} b(\cdot)\widehat{u}(s) = \frac{\mathcal{N}(s)}{\mathcal{D}(s)}\widehat{u}(s). \tag{2.29}$$

It now follows from (2.29) and Proposition 2.1 that the transfer function defined in this way can be extended to all $u \in U_a$, yielding the alternative representation

$$\mathcal{W}_0 \left\{ I - (sI - A_0)^{-1}(sI - \mathcal{A}) \right\} b(\cdot) = \frac{\mathcal{N}(s)}{\mathcal{D}(s)},$$

and that, remarkably, this representation is independent of the choice of b.

As a final comment in this section we note that simple examples can be given (cf. Remark 2.1 and [27]) to show that if Assumption 2.1 does not hold then an L^2 boundary input can give rise to a solution with infinite energy at a finite time. In this case we say that the input operator is not admissible. We now present, without proof, a brief summary of the results in [9] regarding admissibility of the boundary control systems considered here. The proofs of these results, while considerably more complicated, exactly parallel those given in §5 for Propositions 2.1–2.5. First we consider a system (2.1)–(2.5) and replace the output operator (2.6) by a point evaluation sensor at a point $x_0 \in [0,1]$, i.e., let

$$y_{x_0}(t) = w(x_0, t). \tag{2.30}$$

Note that this corresponds to the boundary operator

$$\mathcal{W}_0(w)(t) = w(x_0, t)$$

so that in the notation of Assumption 2.1 the order of the output is $m_0 = 0$ and $\ell = m_1 - m_0 = m_1 > 0$. For a fixed x_0 it can be shown that the resulting system has a transfer function of the form

$$\mathcal{G}_{x_0}(\lambda) = \frac{\mathcal{N}_{x_0}(\lambda)}{\mathcal{D}(\lambda)},$$

where the denominator is exactly the same as in (2.19). The asymptotic form of the transfer function is very similar to that for a general open-loop transfer function given in (4.22). The main difference is that the terms $e^{\pm\omega_\mu z}$ are replaced by terms $e^{\pm\omega_\mu z(x_0-1)}$ and the asymptotic constants in the numerator are different. Thus for every x_0 the system has the same open-loop poles as described in Propositions 2.1 and 2.5. The main result of [9] concerning admissibility of the boundary control systems in (2.1)–(2.5) with Assumption 2.1 is that L^2 inputs produce finite energy outputs in $L^2(0,1)$.

PROPOSITION 2.8. *For the system* (2.1)–(2.5) *with Assumption* 2.1 *and for* $x_0 \in [0,1]$, *we have the following results.*

1. *There exist constants a and C such that for all* $\operatorname{Re}\lambda > a$

$$|\mathcal{G}_{x_0}(\lambda)| \le C|\lambda|^{-\ell/n} \exp\left(-x_0|\lambda|^{1/n} \sin\left(\frac{\pi}{2n}\right)\right).$$

In fact, there are constants N_{01}, N_{02}, D_1, D_{-1} so that for large modulus of $\lambda = i^n z^n$ the transfer function has the asymptotic representation (cf. (4.22))

$$\mathcal{G}_{x_0}(\lambda) = \frac{\mathcal{N}_{x_0}(\lambda)}{\mathcal{D}(\lambda)} = \frac{\left(-[N_{01}]e^{\omega_\mu z(x_0-1)} + [N_{02}]e^{-\omega_\mu z(x_0-1)}\right)}{z^\ell\left(-[D_1]e^{\omega_\mu z} + [D_{-1}]e^{-\omega_\mu z}\right)}. \tag{2.31}$$

Here ω_μ is a particular nth root of minus one (cf. Remark 4.1, *part* 6).

2. *Suppose λ_j is a pole of large modulus of $\mathcal{G}_{x_0}(\lambda)$, $\lambda_j = i^n z_j^n$ where $n = 2\mu$ is the order of $\mathcal{A}$, $\ell > 0$ is the order of the input operator. Then*

$$\operatorname{Res}_{\lambda=\lambda_j} \mathcal{G}_{x_0}(\lambda) = (-1)^{t_2-t_1} n|z_j|^{n-\ell-1} \left|\frac{N_{02}}{D_{-1}}\right| \sin\left(\frac{\pi((1-x_0)m - M)}{n}\right)[1],$$

where t_1, t_2 are determined from

$$\arg D_{-1} = t_1\pi - m\pi/n, \qquad \arg N_{02} = t_2\pi - M\pi/n$$

with

$$m = \sum_{j=1}^{n} m_j, \qquad M = \sum_{j=\mu+1}^{n} m_j.$$

3. *The inverse Laplace transform of $\mathcal{G}_{x_0}(\lambda)$ can be computed by the method of residues and as in Proposition* 2.5 *there is a constant C for which*

$$\begin{aligned} h(x_0,t) &\equiv \frac{1}{2\pi i}\int_{\sigma-i\infty}^{\sigma+i\infty} e^{st}\,\mathcal{G}_{x_0}(s)\,ds \\ &= \left\{\sum_{j=1}^{N} \operatorname{Res}_{\lambda=\lambda_j}\left(\mathcal{G}_{x_0}(\lambda)e^{\lambda t}\right)\right. \\ &\qquad \left. + C\sin\left(\frac{\pi((1-x_0)m-M)}{n}\right)\sum_{j=N+1}^{\infty} |\lambda_j|^{(n-\ell-1)/n} e^{\lambda_j t}[1]\right\}. \end{aligned}$$

4. *$w(x,t) = y_x(t) = (h(x,\cdot) * u(\cdot))(t) \in L^2(0,1)$ for every $t > 0$ and $u \in U_a$.*

3. Statement and illustration of the main results. Deferring the detailed proofs to §4, in this section we describe a fairly complete analogue of finite-dimensional root-locus theory for systems (2.1)–(2.6) satisfying Assumption 2.1. In particular, closed-loop poles tend to open-loop zeros, all but a finite number of which are simple and real. The familiar real axis loci results are established from which we deduce some stability results. With some effort, this analysis can be extended to more general inputs and outputs. However, even in the case considered here, where the highest-order derivatives in the boundary conditions are separated—i.e., the actuators and sensors are colocated in the highest-order derivatives—there are some important differences from the finite-dimensional case. These differences mainly stem from the fact that for systems (2.1)–(2.6) the transfer function is not rational but always has an essential

singularity at infinity, a phenomenon which we encountered in §2 in formulating the definition of the instantaneous gain.

The following simple examples are given to demonstrate some of the subtle differences that can occur in the infinite-dimensional case and to motivate assumptions that were made to eliminate some of these difficulties. Example 3.1 shows that for completely general boundary inputs and outputs not of the type given in (2.4) the situation is very different from the finite-dimensional case and underscores the importance of certain of our hypotheses.

Example 3.1. Consider the controlled heat equation

$$\dot{w} = Aw, \quad A = \frac{d^2}{dx^2}, \qquad x \in (0,1),$$

$$w(0,t) = u(t),$$

$$\frac{\partial w}{\partial x}(0,t) - \beta \frac{\partial w}{\partial x}(1,t) = 0, \qquad \beta \in \mathbb{R},$$

$$y(t) = w(1,t).$$

Using the change of variables $\lambda = -z^2$ the characteristic equation for the closed-loop operator $A_k = A$ with boundary conditions

$$f(0) + kf(1) = 0, \qquad f'(0) - \beta f'(1) = 0$$

can be written as

$$(k - \beta)\cos(z) = (k\beta - 1)$$

and a straightforward analysis provides the following possibilities:

1. For $k \neq \beta$, $\beta = \pm 1$, we have that A_k is a discrete spectral operator with all double eigenvalues.
2. If $k = \beta = \pm 1$, the point spectrum consists of the entire complex plane.
3. For $k = \beta \neq \pm 1$ the spectrum is empty.
4. When $k \neq \beta \neq \pm 1$ A_k is a discrete spectral operator with all simple eigenvalues.

The next two examples show that even for simple examples with boundary conditions of the type (2.4) the root loci exhibits somewhat different behavior than the finite-dimensional case. Namely, we should expect very different asymptotic limits, not just angles of approach, as the gain goes either to plus or to minus infinity.

Example 3.2. Consider the controlled heat equation

$$\begin{aligned}
\dot{w} = Aw, \quad A &= \frac{d^2}{dx^2}, \qquad x \in (0,1), \\
u(t) = B(w)(t) &= \mathcal{W}_1(w)(t) = -\frac{\partial w}{\partial x}(0,t), \\
y(t) = C(w)(t) &= \mathcal{W}_0(w)(t) = w(0,t), \\
\mathcal{W}_2(w)(t) &= \frac{\partial w}{\partial x}(1,t) = 0.
\end{aligned}$$

For this problem, of course, a good strategy to stabilize the temperature at zero would be to heat the rod if it is cold and to cool the rod if it is hot. This suggests employing the simple scalar boundary feedback control law

$$u(t) = -ky(t).$$

The open-loop transfer function is easily computed and given by

$$\mathcal{G}_0(\lambda) = \frac{\cosh(\sqrt{\lambda})}{\sqrt{\lambda}\sinh(\sqrt{\lambda})}$$

from which a straightforward calculation provides the open-loop poles $\lambda_j(0) = -j^2\pi^2$, $j = 0, 1, \cdots$ and open-loop zeros $\lambda_j(\infty) = -(j+1/2)^2\pi^2$, $j = 0, 1, \cdots$ which interlace on the negative real axis.

For the feedback law

$$u(t) = -ky(t) + v(t),$$

the closed-loop transfer function is

$$\mathcal{G}_k(\lambda) = \frac{\cosh(\sqrt{\lambda})}{\sqrt{\lambda}\sinh(\sqrt{\lambda}) + k\cosh(\sqrt{\lambda})}$$

and the return difference equation can be written as

$$1 + k\frac{\cosh(\sqrt{\lambda})}{\sqrt{\lambda}\sinh(\sqrt{\lambda})} = 0.$$

To more easily describe geometrically the behavior of the closed-loop poles, we introduce the change of variables $\lambda = -z^2$ so that the return difference equation can be written as

$$-\frac{1}{k} = g(z) \equiv \frac{\cos(z)}{-z\sin(z)},$$

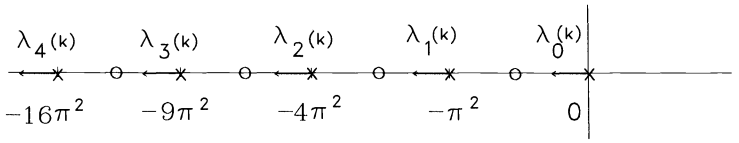
where

$$g(\bar{z}) = \overline{g(z)}.$$

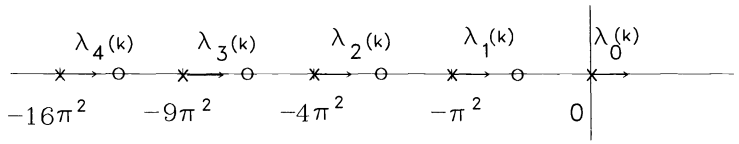
Since the operator A_k in this case is selfadjoint the closed-loop poles (i.e., points of the spectrum of A_k) are real and are given by $\{\lambda_j(k)\}_{j=0}^{\infty}$, which for $k > 0$, satisfy

$$-j^2\pi^2 = \lambda_j(0) > \lambda_j(k) \to \lambda_j(\infty) = -(j + 1/2)^2\pi^2, \qquad j = 0, 1 \ \ldots.$$

We can readily compute the instantaneous gain in this case. We have $\alpha_1 = -1$, $\alpha_0 = 1$, $m_1 = 1$, $m_0 = 0$ so that $\ell = m_1 - m_0 = 1 > 0$ and in Theorem 2.4 $\ell_0 = 0$ so that $s = 1 + 1 = 2$ and $\mathcal{K} = (-1)^s = 1$ and we would take $k > 0$. As k goes from zero to plus infinity the closed-loop poles move to left from the open-loop poles to the open-loop zeroes. All the branches of the root locus are bounded as k goes to plus infinity. For $k < 0$ we have the same functions $\{\lambda_j(k)\}_{j=0}^{\infty}$ defined as distinct branches of a single analytic function. As expected from finite-dimensional root locus the eigenvalues in this case move to the right. But in this case the eigenvalue $\lambda_0(k)$



(a) "x" *open-loop pole*, "o" *open-loop zero, gain* $k > 0$.



(b) "x" *open-loop pole*, "o" *open-loop zero, gain* $k < 0$.

FIG. 1

goes from zero to plus infinity. Thus in this case there is one unbounded branch of the root locus and again we find that unlike the finite-dimensional case the asymptotic behavior of the root loci is different as k goes to plus or minus infinity. (See Fig. 1.)

Example 3.3. In this example, originally due to Rellich [34], we illustrate the importance of Assumption 2.1 in constructing a system transfer function and in analyzing the behavior of the root loci. In particular, the candidate transfer function is unbounded in any right half-plane, the instantaneous gain formula no longer applies, and the conclusions we would draw about closed-loop stability are invalid for negative values of the gain.

Consider the controlled heat equation

$$\begin{aligned} \dot{w} &= Aw, \quad A = \frac{d^2}{dx^2}, \qquad x \in (0,1), \\ u(t) &= B(w)(t) = \mathcal{W}_1(w)(t) = w(0,t), \\ y(t) &= C(w)(t) = \mathcal{W}_0(w)(t) = -\frac{\partial w}{\partial x}(0,t), \\ \mathcal{W}_2(w)(t) &= w(1,t) = 0. \end{aligned}$$

Again we consider the scalar boundary feedback

$$u(t) = -ky(t) + v(t),$$

in which case the closed-loop transfer function is given by

$$\mathcal{G}_k(\lambda) = \frac{\sqrt{\lambda}\cosh(\sqrt{\lambda})}{\sinh(\sqrt{\lambda}) + k\sqrt{\lambda}\cosh(\sqrt{\lambda})}$$

and the open-loop poles are $\lambda_j(0) = -j^2\pi^2$, the open-loop zeros are $\lambda_j(\infty) = -(j - 1/2)^2\pi^2$, $j = 1, 2, \cdots$ and they interlace on the negative real axis.

On introducing the change of variables $\lambda = -z^2$, the return difference equation can be written as

$$-\frac{1}{k} = g(s) \equiv \frac{z\cos(z)}{\sin(z)},$$

where

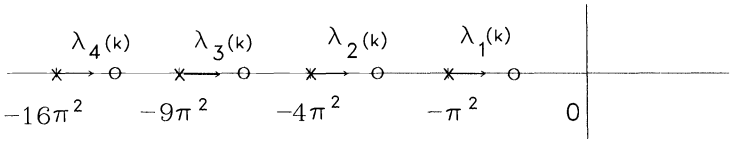
$$g(\bar{z}) = \overline{g(z)}.$$

Just as in the last example, the operator A_k is selfadjoint and it is easy to see that the closed-loop poles (i.e., the spectrum of A_k) given by $\{\lambda_j(k)\}_{j=1}^{\infty}$ is real and for $k \geq 0$, the poles move to the right and as k goes from zero to plus infinity the closed-loop poles move from the open-loop poles to the open-loop zeroes. For $k < 0$ we have the same branches $\{\lambda_j(k)\}_{j=1}^{\infty}$ that move to the left but in addition there is an unstable eigenvalue $\lambda_0(k)$ that begins at plus infinity, moves to zero as $k \to -1$ and as $k \to -\infty$ moves to the first open-loop zero. This eigenvalue satisfies

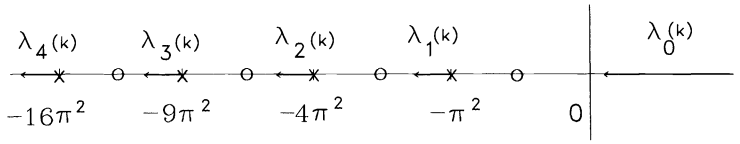
$$\tanh(\sqrt{\lambda_0}) = -k\sqrt{\lambda_0}.$$

Once again in this example, unlike the finite-dimensional case, we see a very different behavior for k positive and negative. (See Fig. 2.)

Note that for this example the "transfer function" is not bounded in the right half-plane. This is to be expected whenever the order of the input is less than the order of the output; this point will become clear once we establish the asymptotic form of the return difference equation.



(a) "x" *open-loop pole*, "o" *open-loop zero, gain* $k > 0$.



(b) "x" *open-loop pole*, "o" *open-loop zero, gain* $k < 0$.

FIG. 2

These examples indicate that some care must be taken in developing a root locus theory for distributed systems. For general boundary conditions the functions $\mathcal{N}$ and $\mathcal{D}$ are entire functions of λ and hence for each k the return difference equation either has a discrete set of zeros with no finite accumulation point, is identically zero (spectrum the entire complex plane) or does not vanish at all (spectrum empty). For the boundary conditions in (2.4) it can be shown that the first alternative always holds; i.e., the operator A_k is always a discrete spectral operator. This enables us to establish a root-locus theory much like the finite-dimensional case.

THEOREM 3.1. *The operators A_k of* (2.14) *are discrete* (*Riesz*) *spectral operators that generate analytic semigroups $T_k(t)$. Furthermore they form a holomorphic family in k* (*in the sense of norm resolvent convergence*), *which satisfies the "separation of the spectrum" condition uniformly in k and the "spectrum determined growth condition" for real k such that $k \cdot \mathcal{K} > 0$. In particular, the spectrum of A_k can be written as $\{\lambda_j(k)\}_{j=1}^{\infty}$ for which the eigenfunctions and associated functions form a Riesz basis in $L^2(0,1)$ for all $k \cdot \mathcal{K} > 0$ and all but finitely many of the eigenvalues are simple so that the associated projections have rank one.*

As stated in [25], [34] it is not so easy to conclude that an infinite set of eigenvalues (or closed-loop poles) vary continuously in k as is illustrated in Example 3.3. Nonetheless, under the additional hypothesis in Assumption 2.1 such an infinite-dimensional root locus result is valid.

THEOREM 3.2. *For the systems* (2.1)–(2.6), *which satisfy Assumption* 2.1, *all but a finite number of the open-loop poles $\{\lambda_j(0)\}_{j=1}^{\infty}$ and zeros $\{\lambda_j(\infty)\}_{j=1}^{\infty}$ are real, interlace on the negative real axis, and tend to minus infinity as $j \to \infty$. Choosing $k \cdot \mathcal{K} > 0$, the closed-loop poles $\{\lambda_j(k)\}_{j=1}^{\infty}$ vary continuously from the open-loop poles to the open-loop zeros. More specifically, the closed-loop poles corresponding to the infinitely many real open-loop poles and zeros $(\{\lambda_j(0)\}_{j=N+1}^{\infty}, \{\lambda_j(\infty)\}_{j=N+1}^{\infty})$ are real, simple, and move to the left from an open-loop pole to an open-loop zero. The remaining finitely many closed-loop poles lie inside a fixed simple closed curve that also contains an equal number of open-loop poles and zeros and these closed-loop poles vary continuously in k. Furthermore, all branches of the root locus are bounded. In general there are at most a fixed finite number of common open-loop poles and zeros that correspond to stationary eigenvalues in the spectrum of the operators A_k for $k \cdot \mathcal{K} \in [0, \infty]$.*

COROLLARY 3.3. *For the systems* (2.1)–(2.6) *satisfying Assumption* 2.1 *and an initial condition $f \in L^2(0,1)$, if $k \cdot \mathcal{K} > 0$ and $k_0 \cdot \mathcal{K} > 0$, then*

$$\|T_k(t)f - T_{k_0}(t)f\| \to 0, \quad \text{as} \quad k \to k_0$$

uniformly for t in compact subintervals of $(0, \infty)$.

From Theorem 3.2 and its proof follow a number of statements about the root loci that are similar to well-known rules in classical automatic control. As an example of our extension of finite-dimensional root locus theory, we show there is a version of the "real axis loci" test.

THEOREM 3.4. *For systems* (2.1)–(2.6) *satisfying Assumption* 2.1, *if $k \cdot \mathcal{K} > 0$, then a real point on the root locus always lies to the left of an odd number of poles and zeros.*

Remark 3.1. For both the case at hand and more general cases, it is interesting to analyze the finitely many "exceptional" branches of the root locus, which may be complex. To this end, we write

$$\mathcal{G}_0(\lambda) = \frac{n_1(\lambda)n_2(\lambda)}{d_1(\lambda)d_2(\lambda)},$$

where n_1, d_1 are polynomials of degree d, having all roots inside a fixed curve Γ and n_2, d_2 are entire functions having no zeros inside Γ. Then, from Rouche's theorem, Proposition 2.1, and Theorem 3.2 we may conclude that the branches of the root locus inside Γ coincide, for $k = 0$, with the roots of d_1, and converge, as $k \cdot \mathcal{K} \to \infty$, to the roots of n_1. Moreover, multiple arriving branches of the root-loci at a root λ_0 of n_1 form a Butterworth pattern having order determined by the rational transfer function

$n_1(\lambda)/d_1(\lambda)$. However, the angles of arrival may not coincide with those computed from $n_1(\lambda)/d_1(\lambda)$, nor will breakaway points for $\mathcal{G}_0(\lambda)$ coincide with those computed for $n_1(\lambda)/d_1(\lambda)$.

Choosing $k_0 = \infty$ in Corollary 3.3 we might expect that, if the zero dynamics is exponentially stable, then for $k \cdot \mathcal{K}$ sufficiently large the trajectories of the closed-loop system would tend to zero. Alternatively, exponential stability of the closed-loop system follows from Theorem 3.2 and the results in [13], [20] on discrete spectral operators, since the operators A_k generate analytic semigroups and are Riesz spectral operators. In particular, since the zero dynamics is exponentially stable we have an estimate for the growth constant

$$w_\infty = \sup_j \{\mathrm{Re}(\lambda_j(\infty))\} < 0.$$

Finally, using Theorem 3.2 and choosing $k_0 \cdot \mathcal{K} > 0$ sufficiently large we can find a positive σ so that for $k \cdot \mathcal{K} > k_0 \cdot \mathcal{K}$ we have

$$\|T_k(t)\| \leq Ce^{-\sigma t}.$$

COROLLARY 3.5. *For systems* (2.1)–(2.4) *satisfying Assumption* 2.1, *if the zero dynamics* (2.10) *is exponentially stable and the sign of the gain is chosen so that* $k \cdot \mathcal{K} > 0$, *then there exists a* k_0 *such that for* $k \cdot \mathcal{K} > k_0 \cdot \mathcal{K}$ *the closed-loop system is exponentially stable.*

Example 3.4. Consider the controlled heat equation

$$\begin{aligned} \dot{w} &= Aw, \quad A = \frac{d^2}{dx^2}, \qquad x \in (0,1), \\ u(t) &= B(w)(t) = \mathcal{W}_1(w)(t) = -\frac{\partial w}{\partial x}(0,t) - w(1,t), \\ y(t) &= C(w)(t) = w(0,t), \\ \mathcal{W}_2(w)(t) &= \frac{\partial w}{\partial x}(1,t) = 0. \end{aligned}$$

Again we consider the scalar boundary feedback

$$u(t) = -ky(t) + v(t).$$

On introducing the change of variables $\lambda = -z^2$, the return difference equation can be written as

$$\frac{1}{k} = g(s) \equiv \frac{\cos(z)}{1 + z\sin(z)}.$$

In this case the instantaneous gain is easily computed from $m_0 = 0$, $m_1 = 1$ and $\ell_0 = 0$, $\ell = 1$, which implies $s = 1 + \arg(-1)/\pi = 2$, so that

$$\mathcal{K} = (-1)^s = 1$$

so we take $k > 0$. It is easy to see that there are real open-loop poles $\{\lambda_j(0)\}_{j=1}^{\infty}$ that are asymptotic to the zeros of $\sin(z)$. In fact, the open-loop poles satisfy

$$-(2j\pi)^2 < \lambda_{2j}(0) < -((2j - 1/2)\pi)^2 < \lambda_{2j-1}(0) < -((2j-1)\pi)^2, \qquad j = 1, 2, \ldots,$$

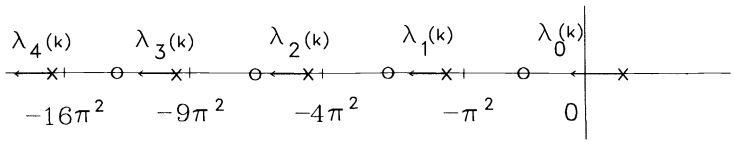


FIG. 3. "x" *open-loop pole*, "o" *open-loop zero, gain* $k > 0$.

where the open-loop zeros are

$$\lambda_j(\infty) = -((j - 1/2)\pi)^2$$

so the open-loop poles and zeros interlace.

In the region $S_0 = \{z : 0 \leq \arg(z) \leq \pi/2\}$ there is another root of the return difference equation having the form $\lambda_0(0) = r^2$, where r is the positive root of the equation

$$\tanh(r) = 1/r.$$

The corresponding branch of the root locus then moves to the first open-loop zero $\lambda_1(\infty) = -(\pi/2)^2$ as k goes from 0 to ∞. (See Fig. 3.)

We conclude this section with a brief outline of the proofs of Theorems 3.1 and 3.2, since the proofs are somewhat long and draw on a combination of methods from asymptotic analysis, complex analysis, and functional analysis. In effect, this combination of methods allows us to establish a spectral theory for certain non-selfadjoint boundary value problems.

More explicitly, the proofs of Theorems 3.1 and 3.2 are based on an analysis of the zeros $\lambda = \lambda(k)$ of the return difference equation

$$\mathcal{D}(\lambda) + k\mathcal{N}(\lambda) = 0,$$

which is also exactly the characteristic equation providing the spectra of the closed-loop operators A_k. In the proof of Proposition 2.1 given in §5, it is shown that the numerator and denominator of the open-loop transfer function are given explicitly by

$$\mathcal{N}(\lambda) = \det\left(\{\mathcal{W}_i(f_j(\cdot,\lambda))\}_{i=0,2,j=1}^{n,n}\right), \tag{3.1}$$

$$\mathcal{D}(\lambda) = \det\left(\{\mathcal{W}_i(f_j(\cdot,\lambda))\}_{i=1,j=1}^{n,n}\right),$$

where $\{f_j\}$ denotes a basis of solutions of the ordinary differential equation

$$Af - \lambda f = 0, \tag{3.2}$$

which are analytic functions of λ. The existence of such a basis is well known and is discussed in Proposition 5.1. Unfortunately it is extremely difficult in general to obtain this basis explicitly. So to obtain qualitative information concerning the zeros of the closed-loop transfer function, we employ the asymptotic techniques developed by Birkhoff in [1], [2] to obtain asymptotic formulas for a special basis of solutions

(given in Proposition 5.1 below) that are only analytic in the cut plane and have simple asymptotic representations for modulus of λ large. With this the analysis of the return difference equation is divided into two main parts. First an asymptotic development is employed to analyze the poles and zeros of large modulus. One important corollary of the analysis is that the operators A_k satisfy the separation of the spectrum condition of Kato [25] uniformly in $k \cdot \mathcal{K} > 0$. This then allows us to carry out the second part of the proof, which is to analyze the variation of the remaining finitely many closed-loop poles, not considered in the asymptotic development, based on classical perturbation techniques for finite systems of eigenvalues (cf. [25]). In particular we show that the operators A_k are holomorphic in k in the generalized sense of norm resolvent convergence.

To carry out the asymptotic analysis we employ techniques introduced by Birkhoff [1] for ordinary differential operators on a finite interval. This work predated the spectral theory for unbounded selfadjoint operators in Hilbert space by many years and, while his efforts were restricted to ordinary differential operators, the analysis is applicable to a wide variety of non-selfadjoint problems, providing in particular the basis of the present work. It is worth commenting that Birkhoff's work was followed by a lively literature related to his work as well as to generalizations. In 1912, Tamarkin [37] presented a paper questioning the validity of Birkhoff's work in the case of even order operators, evoking a paper [2] published by Birkhoff in response to these criticisms. In 1926, Stone [36] related the expansions of Birkhoff and Fourier. Birkhoff and Langer [3] later extended these results to systems of ordinary differential equations and Wilder [43] extended the analysis to problems with boundary conditions at points other than the end points (in the context of control theory this would correspond to interior point control problems). For a more complete reference to the many subsequent extensions and refinements we refer to the references contained in [20], [30].

For the asymptotic analysis, we first introduce a change of variables in the return difference equation by letting $\lambda = i^n z^n$ and then consider z in the region

$$S = \{z \in \mathbb{C} \mid -\pi/n \leq \arg(z) < /n\}.$$

In the region S of the z plane, the return difference equation can be written in the form (cf. (4.13))

$$\Delta(z,k) = h(z)\left(z^{\ell}\delta(z,0) + k\delta(z,\infty)\right), \tag{3.3}$$

where $h(z)$ described in (4.14) is not zero and $\delta(z,0)$ and $\delta(z,\infty)$ are given explicitly in (4.17) and (4.18), respectively. As is shown below, the cases in which $\mu = n/2$ is even or odd are somewhat different. Nevertheless, on introducing appropriate rotations, it is possible to treat both cases together. In particular, after considerable computation and simplification it is shown that the closed-loop poles of large modulus are the zeros of a function in the asymptotic form

$$F(z,k) = e^{-2iz} - [v]\left(\frac{z^{\ell} + k[\overline{\tau}]}{z^{\ell} + k[\tau]}\right).$$

Here the asymptotic notation $[a]$ introduced by Birkhoff [1] is used

$$[a] = a + O(1/z).$$

Moreover, $\tau \in \mathbb{C}$ satisfies

$$\arg(\tau) = \begin{cases} s\pi + \pi\ell/n, & \mu \text{ odd}, \\ s\pi + 2\pi\ell/n, & \mu \text{ even}, \end{cases}$$

where $s = \arg(\alpha_0/\alpha_1)/\pi + (\ell_0 + \ell)$ is defined in Theorem 2.4 and v satisfies

$$v = e^{2\pi m i/n}, \qquad m = \sum_{j=1}^{n} m_j.$$

The analysis proceeds by comparing the zeros of $F(z,k)$ with the zeros of the function

$$f(z,k) = e^{-2iz} - v\left(\frac{z^\ell + k\overline{\tau}}{z^\ell + k\tau}\right)$$

using Rouche's theorem.

It is first shown that for $z \in S$ and $k \cdot \mathcal{K} > 0$, there exists $M, y_0 > 0$ such that $F(z,k) \neq 0$ for $z \in S_{y_0,M}$

$$S_{y_0,M} = S \cap \{z \in \mathbb{C} \mid |\operatorname{Im}(z)| > y_0,\ |z| > M\}.$$

Next we show that the zeros of $f(z,k)$ are all real and simple and that the nonzero zeros of $f(z,0)$ and $f(z,\infty)$ interlace on the positive real axis. Indeed for $k = 0,\ \infty$ we obtain simple explicit formulas for the zeros of f.

Exploiting the periodicity of the factor $\exp(-2iz)$ in both F and f, we next decompose the complementary region $S \backslash S_{y_0,M}$ into rectangular regions $V_p = V + p\pi$ for $p \in \mathbb{Z}$ and

$$V = \{\tilde{z} \mid |\operatorname{Im}(\tilde{z})| < y_0,\ a_1 < \operatorname{Re}(\tilde{z}) < a_2,\ a_1 = \frac{\pi - \arg(v) + \pi\ell/n}{2},\ a_2 = a_1 + \pi\}.$$

This decomposition allows us to reduce the arguments for calculations on the regions V_p to the single region V. In particular, for a fixed p, we introduce the new gain parameter

$$g = \frac{k}{(p\pi)^\ell}$$

and the functions

$$F_p(\tilde{z},g) = e^{-2i\tilde{z}} - [v]\left(\frac{(1+\tilde{z}/(p\pi))^\ell + g[\overline{\tau}]}{(1+\tilde{z}/(p\pi))^\ell + g[\tau]}\right),$$

$$f_p(\tilde{z},g) = e^{-2i\tilde{z}} - v\left(\frac{(1+\tilde{z}/(p\pi))^\ell + g\overline{\tau}}{(1+\tilde{z}/(p\pi))^\ell + g\tau}\right),$$

and

$$h(\tilde{z},g) = e^{-2i\tilde{z}} - v\left(\frac{1+g\overline{\tau}}{1+g\tau}\right).$$

Using these functions defined on the single rectangle V, we show that for sufficiently large p, f_p has only one zero in $\overline{V}$ which, since the roots occur in conjugate pairs, must be real. To this end, we show that

$$|f_p(\tilde{z}, g) - h(\tilde{z}, g)|$$

goes to zero uniformly in g for $\tilde{z} \in \overline{V}$ as $p \to \infty$. Then we show that for $\tilde{z} \in \partial V$ (the boundary of V) and all g there is a $C > 0$ so that

$$|h(\tilde{z}, g)| > C,$$

which implies that there exists a P_1 such that for $p > P_1$

$$|f_p(\tilde{z}, g)| > C/2$$

for $\tilde{z} \in \partial V$ and all g.

Next we show, in a similar way, that

$$|F_p(\tilde{z}, g) - f_p(\tilde{z}, g)| = O(1/p)$$

uniformly for $\tilde{z} \in \overline{V}$ and $g \cdot \mathcal{K} > 0$. Hence there exists $P_2 > P_1$ such that for $p > P_2$

$$|F_p(\tilde{z}, g)| \geq C/3$$

for $\tilde{z} \in \partial V$ and $g \cdot \mathcal{K} > 0$. So for $p > P_2$, $\tilde{z} \in \partial V$ and $g \cdot \mathcal{K} > 0$,

$$|F_p(\tilde{z}, g) - f_p(\tilde{z}, g)| < |f_p(\tilde{z}, g)|$$

and we can apply Rouche's theorem to conclude that $F_p(\tilde{z}, g)$ has only one zero in V which again must be real since roots occur in conjugate pairs.

The next step is to show that for large $|z|$, the zeros of $F(z, k)$ are continuous monotone increasing functions of k for $|k| \to \infty$, $k \cdot \mathcal{K} > 0$. Once this is established we will know that the infinitely many real closed-loop poles of large modulus vary continuously from real open-loop zeros to real open-loop poles that interlace on the negative real axis and that the operators A_k satisfy the separation of the spectrum condition uniformly in k.

The remainder of the proof of Theorem 3.2 consists in establishing that the resolvent operator $R(\lambda, k) = (A_k - \lambda I)^{-1}$ is a holomorphic family in the generalized sense [25] for $k \cdot \mathcal{K} > 0$ and hence every finite system of eigenvalues vary continuously.

4. Asymptotic analysis of the return difference equation. In this section, we provide detailed information on the asymptotic behavior of the closed-loop systems described in §2. The essential ingredient for carrying out this analysis is an explicit asymptotic representation for a basis of solutions of the ordinary differential equation (3.2) that are analytic in λ. This analysis reposes heavily on work found in [1], [2], [30]. In particular, it can be shown (as in §5) that the spectra of A_0, A_∞, and A_k (open-loop zeros, open-loop poles, and closed-loop poles) are given, respectively (cf. the proof of Proposition 2.1 in §5 and (3.1)), by the zeros of the determinants

$$\mathcal{N}(\lambda) = \det\left(\{\mathcal{W}_i(f_j(\cdot, \lambda))\}_{i=0,2,j=1}^{n,n}\right), \tag{4.1}$$

$$\mathcal{D}(\lambda) = \det\left(\{\mathcal{W}_i(f_j(\cdot, \lambda))\}_{i=1,j=1}^{n,n}\right),$$

$$\mathcal{D}(\lambda) + k\mathcal{N}(\lambda),$$

where $\{f_j\}$ denotes a basis of solutions of (3.2).

As suggested by the examples in §3, it is convenient to introduce the change of variables in the complex parameter λ by

$$z^n = i^n \lambda, \qquad i = \sqrt{-1} \tag{4.2}$$

and consider the eigenvalue problem

$$f^{(n)} + i^{n-2} L_1 f + z^n f = 0 \tag{4.3}$$

$$\mathcal{W}_1(f) + k\,\mathcal{W}_0(f) = 0, \quad \mathcal{W}_i(f) = 0, \qquad i = 2, \ldots, n$$

in a suitable region of the z-plane. Namely for $n = 2\mu$ and for $0 \leq j \leq (2n-1)$ let

$$S_j = \{z \mid j\pi/n \leq \arg(z) < (j+1)\pi/n\} \tag{4.4}$$

and denote by ψ_j, $j = \pm 1, \pm 3, \cdots, \pm(n-1)$ the nth roots of (-1) given by

$$\psi_j = \exp(\pi i + j\pi i/n). \tag{4.5}$$

(See Fig. 4.)

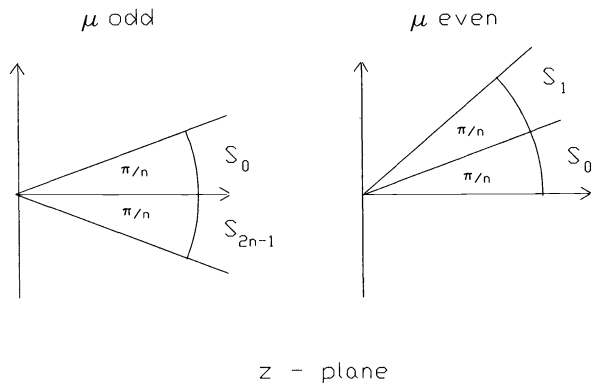

FIG. 4

Remark 4.1.

1. The entire complex λ-plane under the map (4.2) is covered by the image of two adjacent regions S_j from (4.4). In the following analysis it is important to know that the eigenvalues obtained are independent of the pair of regions chosen. This is proven in, for example, [1], [30].

2. Following [1], [30], for each region S_j we prescribe a particular ordering of the roots ψ_k, denoted by ω_k, $k = 1, 2, \ldots, n$. The ordering is chosen so that for all z in S_j, we have

$$\begin{aligned} &\operatorname{Re}(z\omega_1) \leq \operatorname{Re}(z\omega_2) \leq \cdots \leq \operatorname{Re}(z\omega_{\mu-1}) < 0, \\ &\operatorname{Re}(z\omega_\mu) \leq 0, \qquad \operatorname{Re}(z\omega_{\mu+1}) \geq 0, \\ &0 < \operatorname{Re}(z\omega_{\mu+2}) \leq \operatorname{Re}(z\omega_{\mu+3}) \leq \cdots \leq \operatorname{Re}(z\omega_n). \end{aligned} \tag{4.6}$$

In particular, for S_0, let

$$\omega_{2j-1} = \exp\left(\left(1 - \frac{2j-1}{n}\right)\pi i\right), \quad \omega_{2j} = \exp\left(\left(1 + \frac{2j-1}{n}\right)\pi i\right), \qquad j = 1, \ldots, \mu.$$

Then for S_{2n-1} let $\{\omega_j'\}$ denote the appropriate ordering. We have

$$\omega_j' = \overline{\omega_j}, \qquad j = 1, \ldots, n$$

and defining $\{\omega_j''\}$ as the ordering for S_1 we have

$$\omega_j'' = \omega_j' e^{-(2\pi i/n)} = \overline{\omega_j} e^{-(2\pi i/n)}, \qquad j = 1, \ldots, \mu.$$

3. A straightforward calculation based on the definition of ω_j shows that (see Fig. 5)

$$e^{-(2\pi i/n)}\omega_j = \begin{cases} \omega_1, & j = 2, \\ \omega_{j-2}, & j \neq 2 \text{ even}, \\ \omega_{j+2}, & j \neq n-1 \text{ odd}, \\ \omega_n, & j = n-1, \end{cases}$$

$$e^{2\pi i/n}\omega_j = \begin{cases} \omega_2, & j = 1, \\ \omega_{j-2}, & j \neq 1 \text{ odd}, \\ \omega_{j+2}, & j \neq n \text{ even}, \\ \omega_{n-1}, & j = n. \end{cases}$$

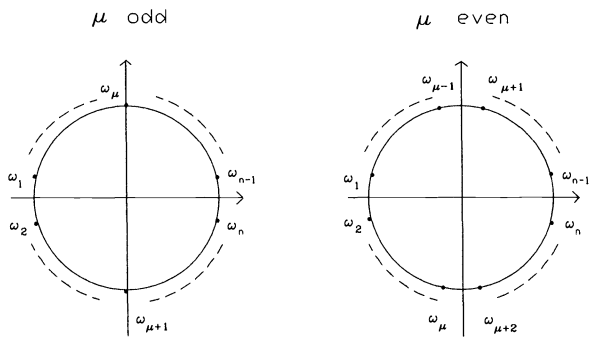

FIG. 5. *Roots of minus one for region* S_0.

4. For $c \in \mathbb{C}$ and $S = S_j$, for some j, we define $T_c = c + S$. With the ordering $\{\omega_j\}$ of the roots of minus one given above for a region S we have the estimates for $z \in T_c$

$$|e^{\omega_j z}| \leq \exp(\mathrm{Re}(z\omega_{\mu-1})) \to 0, \quad |z| \to \infty, \qquad j = 1, \ldots, \mu - 1,$$

$$|e^{\omega_j z}| \geq \exp(\mathrm{Re}(z\omega_{\mu+2})) \to \infty, \quad |z| \to \infty, \qquad j = \mu + 2, \ldots, n.$$

5. Recall the notation of Birkhoff [a] for $a \in \mathbb{C}$ to indicate an asymptotic expression of the form

$$[a] = a + O(1/z),$$

where by $O(1/z)$, as usual, we mean there exists a constant C so that

$$|O(1/z)| \leq C/|z|, \qquad |z| >> 1.$$

6. For $n = 2\mu$ we have
(a) For μ odd, $\omega_\mu = i$ for S_0.
(b) For μ even, $\omega_\mu = i\exp(-i\pi/n)$ for S_1.
For $z \in S_r$, $r = 0, \ldots, (2n-1)$, the functions

$$e^{z\omega_j x}, \qquad 1 \leq j \leq n, \tag{4.7}$$

form a basis of solutions for the equation

$$f^{(n)}(x) + z^n f(x) = 0. \tag{4.8}$$

It was shown by Birkhoff [1] that the asymptotic behavior of the eigenvectors and eigenvalues for the general problem are completely determined by the solutions (4.7) for (4.8). In particular, the following result can be found in [1], [30] regarding the asymptotic representation for a basis of solutions for (4.3).

THEOREM 4.1. *If the functions $p_2, \ldots, p_n$ are continuous in the interval* [0,1], *then the equation*

$$(-1)^{\mu-1}Af + z^n f = 0$$

has, for each region T_c (for any $c \in \mathbb{C}$) of the complex z-plane, n linearly independent solutions $f_1, \ldots, f_n$, that are regular for $z \in T_c$ for sufficiently large $|z|$, and which, with their derivatives, can be expressed in the form

$$\begin{aligned} f_j &= e^{z\omega_j x}[1], \\ \frac{df_j}{dx} &= (z\omega_j)e^{z\omega_j x}[1], \\ &\vdots \\ \frac{d^{n-1}f_j}{dx^{n-1}} &= (z\omega_j)^{n-1}e^{z\omega_j x}[1]. \end{aligned} \tag{4.9}$$

From this result and because of the special ordering chosen for the roots of minus one, we have for $j < \mu$, that the functions $e^{z\omega_j}$ decreases exponentially as $z \to \infty, z \in T_c$; hence

$$\mathcal{W}_i(f_j) = (z\omega_j)^{m_i}[\alpha_i] \quad \text{for } j < \mu. \tag{4.10}$$

Similarly we find that for $j > \mu + 1$

$$\mathcal{W}_i(f_j) = (z\omega_j)^{m_i}e^{z\omega_j}[\beta_i]. \tag{4.11}$$

Appealing to notation introduced in Propositions 5.1 and 5.2 of the proof of Proposition 2.1 in §5, we can use the simple asymptotic formulas (4.10), (4.11) to

obtain an explicit asymptotic form of the return difference equation in the z plane. To this end, again using the notation of §5, let the subscript g and f denote a quantity with respect to the basis of functions given in Proposition 5.1 and Theorem 4.1, respectively. Then for $|z| >> 0$, $z \in T_c$, $c \in \mathbb{C}$, $\lambda = i^n z^n$, the return difference equation can be written as in Proposition 5.2 as

$$\begin{aligned} \mathcal{D}(\lambda) + k\mathcal{N}(\lambda) &= \mathcal{D}_g(\lambda) + k\mathcal{N}_g(\lambda) \\ &= (\mathcal{D}_f(\lambda) + k\mathcal{N}_f(\lambda))\, W_f^{-1}(0,\lambda) \\ &\equiv \Delta(z,k). \end{aligned} \tag{4.12}$$

Substituting the asymptotic formulas in (4.10), (4.11) satisfied by the basis of solutions given in Theorem 4.1 into the formulas for the return difference equation in (4.12) and factoring out the common factors $z^{m_0}, z^{m_2}, \dots, z^{m_n}$ from the rows and also the common factors $e^{z\omega_{\mu+1}}, e^{z\omega_{\mu+2}}, \dots, e^{z\omega_n}$ from the last μ columns of the determinant $\Delta(z,k)$, the equation can be written in the form

$$\Delta(z,k) = h(z)\left(z^{\ell}\delta(z,0) + k\delta(z,\infty)\right), \tag{4.13}$$

where $\delta(z,0)$ and $\delta(z,\infty)$ are discussed in detail below,

$$h(z) = z^{m^0} e^{\omega z} W_f^{-1}(0,z) \tag{4.14}$$

and

$$\begin{aligned} m &= \sum_{j=1}^{n} m_j, \quad m^0 = \sum_{j=0,2}^{n} m_j, \\ \omega &= \sum_{j=1}^{\mu} \omega_{\mu+j}, \\ \ell &= m_1 - m_0 = m - m^0. \end{aligned} \tag{4.15}$$

A straightforward computation shows that $W_f(0,z)$ can be expressed asymptotically in terms of a simple Vandermonde determinant, namely,

$$W_f(0,z) = z^{\mu(n-1)} \det\left(\left\{\left[\omega_j^{i-1}\right]\right\}_{i=1,j=1}^{n,n}\right),$$

where

$$\det\left(\left\{\left[\omega_j^{i-1}\right]\right\}_{i=1,j=1}^{n,n}\right) = \det\left(\left\{\omega_j^{i-1}\right\}_{i=1,j=1}^{n,n}\right) + O(1/z)$$

and the absolute value of the determinant on the right hand side is

$$\left|\det\left(\left\{\omega_j^{i-1}\right\}_{i=1,j=1}^{n,n}\right)\right| = n^{\mu}.$$

Thus the nonzero roots of the return difference equation satisfy a much simpler equation, which we denote by

$$\delta(z,k) = z^{\ell}\delta(z,0) + k\delta(z,\infty) = 0, \tag{4.16}$$

where $\delta(z,0)$ is the determinant

$$\begin{vmatrix} [\alpha](U_1,\cdots,U_{\mu-1}), & \alpha]\, U_{\mu}, & [\alpha]e^{z\omega_{\mu}}\, U_{\mu+1}, & \left[0_{\mu\times(\mu-1)}\right] \\ \left[0_{\mu\times(\mu-1)}\right], & [\beta]e^{z\omega_{\mu}}\, V_{\mu}, & [\beta]V_{\mu+1}, & [\beta](V_{\mu+2},\cdots,V_n) \end{vmatrix} \tag{4.17}$$

and $\delta(z,\infty)$ is the determinant

$$(4.18)\quad \begin{vmatrix} [\alpha^0](U_1^0,\cdots,U_{\mu-1}^0), & [\alpha^0]\,U_\mu^0, & [\alpha^0]e^{z\omega_\mu}\,U_{\mu+1}^0, & [0_{\mu\times(\mu-1)}] \\ [0_{\mu\times(\mu-1)}], & [\beta]e^{z\omega_\mu}\,V_\mu, & [\beta]\,V_{\mu+1}, & [\beta](V_{\mu+2},\cdots,V_n) \end{vmatrix}$$

with

$$\begin{aligned} U_j &= [\omega_j^{m_1},\omega_j^{m_2},\ldots,\omega_j^{m_\mu}]^T, \\ U_j^0 &= [\omega_j^{m_0},\omega_j^{m_2},\ldots,\omega_j^{m_\mu}]^T, \\ V_j &= [\omega_j^{m_{\mu+1}},\omega_j^{m_{\mu+2}},\ldots,\omega_j^{m_n}]^T, \\ \alpha &= \operatorname{diag}(\alpha_1,\ldots,\alpha_\mu), \\ \alpha^0 &= \operatorname{diag}(\alpha_0,\alpha_2,\ldots,\alpha_\mu), \\ \beta &= \operatorname{diag}(\beta_1,\ldots,\beta_\mu). \end{aligned} \tag{4.19}$$

Expanding the determinants $\delta(z,0)$, $\delta(z,\infty)$ using Laplace's expansion method for $\mu\times\mu$ minors, we find that

$$\delta(z,0) = -[D_1]e^{2z\omega_\mu} + [D_{-1}], \tag{4.20}$$

$$\delta(z,\infty) = -[N_1]e^{2z\omega_\mu} + [N_{-1}], \tag{4.21}$$

where D_1, D_{-1}, N_1, N_{-1} are constants. In the notation in (4.19), these constants are given by the determinants

$$\begin{aligned} D_1 &= |\alpha||\beta|\,|U_1,\ldots,U_{\mu-1},U_{\mu+1}|\,|V_\mu,\ V_{\mu+2},\ldots,V_n|, \\ D_{-1} &= |\alpha||\beta|\,|U_1,\ldots,U_\mu|\,|V_{\mu+1},\ldots,V_n|, \\ N_1 &= |\alpha^0||\beta|\,\left|U_1^0,\ldots,U_{\mu-1}^0,U_{\mu+1}^0\right|\,|V_\mu,\ V_{\mu+2},\ldots,V_n|, \\ N_{-1} &= |\alpha^0||\beta|\,\left|U_1^0,\ldots,U_\mu^0\right|\,|V_{\mu+1},\ldots,V_n|. \end{aligned}$$

Remark 4.2. Recalling the form of the open-loop transfer function $\mathcal{G}_0(\lambda)$ in terms of $\mathcal{N}(\lambda)$, $\mathcal{D}(\lambda)$ together with the results in (4.12)–(4.21) and the relation $\lambda = i^n z^n$, we obtain a very useful asymptotic representation for the open-loop transfer function

$$\mathcal{G}_0(\lambda) = \frac{\mathcal{N}(\lambda)}{\mathcal{D}(\lambda)} = \frac{(-[N_1]e^{\omega_\mu z} + [N_{-1}]e^{-\omega_\mu z})}{z^\ell\,(-[D_1]e^{\omega_\mu z} + [D_{-1}]e^{-\omega_\mu z})}. \tag{4.22}$$

To investigate the poles and zeroes of the transfer functions, we need to establish several important properties of the determinants D_1, D_{-1}, N_1, N_{-1}. To this end we first introduce some notation and recall the definition of instantaneous gain given in Definition 2.3.

DEFINITION 4.1. *Let*

1. $\tau = N_{-1}/D_{-1}$, $\tau_1 = N_1/D_1$,

2. $v_d = D_{-1}/D_1$, $v_n = N_{-1}/N_1$.

With this we have the following proposition, whose proof is rather lengthy and technical and is provided in detail in §5.

PROPOSITION 4.2. *If the ordering of the nth roots of* (-1) *is chosen so that for* $z \in S_0$ *when* μ *is odd, for* $z \in S_1$ *when* μ *is even, then we obtain the inequalities in* (4.6) *so that the following relations hold:*

1. $$\overline{D_{-1}} = \begin{cases} D_1, & \mu \text{ odd}, \\ D_{-1}\exp\left(\frac{4m\pi i}{n}\right), & \mu \text{ even}. \end{cases}$$

2. $$\overline{N_{-1}} = \begin{cases} N_1, & \mu \text{ odd}, \\ N_{-1}\exp\left(\frac{4m^0\pi i}{n}\right), & \mu \text{ even}. \end{cases}$$

3. *For any* μ, $D_{-1} = D_1 \exp\left(\dfrac{-2m\pi i}{n}\right)$ *therefore* $v_d = \exp\left(\dfrac{-2m\pi i}{n}\right)$.

4. *For any* μ, $N_{-1} = N_1 \exp\left(\dfrac{-2m^0\pi i}{n}\right)$ *therefore* $v_n = \exp\left(\dfrac{-2m^0\pi i}{n}\right)$.

5. *From parts* 1 *and* 2 *we have*

   (a) $$\overline{\tau} = \begin{cases} \tau_1, & \mu \text{ odd} \\ \tau\exp\left(\frac{-4\ell\pi i}{n}\right), & \mu \text{ even} \end{cases} \quad \text{so for all } \mu\ \tau_1 = \tau\exp\left(-\frac{2\pi i\ell}{n}\right).$$

   (b) *The argument of* τ *is given in terms of* $s = \arg(\alpha_0/\alpha_1)/\pi + (\ell_0 + \ell)$ (*cf. Theorem* 2.4) *by*

$$\arg(\tau) = \begin{cases} s\pi + \frac{\ell\pi}{n}, & \mu \text{ odd}, \\ s\pi + \frac{2\ell\pi}{n}, & \mu \text{ even}. \end{cases}$$

It now follows from (4.13), (4.14) and (4.16)–(4.18), (4.20), (4.21), and Proposition 4.1 that the asymptotic behavior of the closed-loop poles is completely determined by the equation

$$e^{-2\omega_\mu z}\left(z^\ell[D_{-1}] + k[N_{-1}]\right) = \left(z^\ell[D_1] + k[N_1]\right),$$

which, for $\left(z^\ell[D_{-1}] + k[N_{-1}]\right) \neq 0$, is the same as

$$\begin{aligned} e^{-2\omega_\mu z} &= \left(\frac{z^\ell[D_1] + k[N_1]}{z^\ell[D_{-1}] + k[N_{-1}]}\right) \\ &= \frac{[D_1]}{[D_{-1}]}\left(\frac{z^\ell + k[N_1/D_1]}{z^\ell + k[N_{-1}/D_{-1}]}\right) \\ &= [v_d^{-1}]\left(\frac{z^\ell + k[\tau_1]}{z^\ell + k[\tau]}\right). \end{aligned} \tag{4.23}$$

Initially, the cases μ odd and even must be treated separately due to the asymptotic distribution of the roots z of $\delta(z,k)$. Namely, it is shown in [30] that when k is fixed, for μ odd the roots are asymptotic to the real axis (the bisector of S_0 and

S_{2n-1}) while for μ even the roots are asymptotic to the ray $\arg(z) = \pi/n$ (the bisector of the regions S_0 and S_1). Nevertheless the properties described in Proposition 4.2, together with the asymptotic form of the return difference equation, allow us to treat both cases at the same time once we introduce a change of variables (in the μ even case) corresponding to a rotation of the regions S_1, S_0 into S_0, S_{2n-1}, respectively.

First recall the relations

$$\omega_\mu = \begin{cases} i, & \mu \text{ odd}, \\ ie^{-i\pi/n}, & \mu \text{ even}; \end{cases}$$

$$\tau_1 = \begin{cases} \overline{\tau}, & \mu \text{ odd}, \\ \tau e^{-2\pi i\ell/n}, & \mu \text{ even}; \end{cases}$$

$$v_d = \begin{cases} e^{-2\pi mi/n}, & \mu \text{ odd}, \\ e^{-2\pi mi/n}, & \mu \text{ even}; \end{cases}$$

$$\arg(\tau) = \begin{cases} s\pi + \frac{\ell\pi}{n}, & \mu \text{ odd}, \\ s\pi + \frac{2\ell\pi}{n}, & \mu \text{ even}. \end{cases}$$

Now for μ odd, and z in S_0 we have

$$\begin{aligned} e^{-2iz} &= e^{-2\omega_\mu z} \\ &= [v_d^{-1}] \left(\frac{z^\ell + k[\overline{\tau}]}{z^\ell + k[\tau]} \right) \\ &= [e^{2\pi mi/n}] \left(\frac{z^\ell + k[\overline{\tau}]}{z^\ell + k[\tau]} \right). \end{aligned} \tag{4.24}$$

For μ even, and z in S_1 we have

$$\begin{aligned} e^{-2\omega_\mu z} &= \left(\frac{z^\ell [D_1] + k[N_1]}{z^\ell [D_{-1}] + k[N_{-1}]} \right) \\ &= \frac{[D_1]}{[D_{-1}]} \left(\frac{z^\ell + k[N_1/D_1]}{z^\ell + k[N_{-1}/D_{-1}]} \right) \\ &= [v_d^{-1}] \left(\frac{z^\ell + k[\tau_1]}{z^\ell + k[\tau]} \right) \\ &= [e^{2\pi mi/n}] \left(\frac{z^\ell + k[\tau_1]}{z^\ell + k[\tau_1 e^{2\pi i\ell/n}]} \right). \end{aligned} \tag{4.25}$$

If we make the change of variables $z = we^{i\pi/n}$, then $w \in S_0$ and

$$\omega_\mu z = ie^{-\pi i/n} we^{\pi i/n} = iw.$$

Hence the asymptotic form of the return difference equation in this case can again be written in the form

$$e^{-2iw} = e^{-2\omega_\mu z} = [e^{2\pi mi/n}]\left(\frac{w^\ell e^{\pi\ell i/n} + k[\tau_1]}{w^\ell e^{\pi\ell i/n} + k[\tau_1 e^{2\pi i\ell/n}]}\right)$$

$$= [e^{2\pi mi/n}]\left(\frac{w^\ell + k[\tau_1 e^{-\pi\ell i/n}]}{w^\ell + k[\tau_1 e^{\pi\ell i/n}]}\right)$$

$$= [e^{2\pi mi/n}]\left(\frac{w^\ell + k[\widetilde{\tau}]}{w^\ell + k[\widetilde{\tau}]}\right) \tag{4.26}$$

with

$$\widetilde{\tau} = \tau_1 e^{\pi i\ell/n},$$

and

$$\arg(\widetilde{\tau}) = \arg(\tau_1) + \frac{\pi\ell}{n} = s\pi + \pi\ell/n.$$

Therefore to carry out the asymptotic analysis for μ even or odd, we need only consider the asymptotic behavior for μ odd and $z \in T_c = c + S_0$ for an equation in the form

$$e^{-2iz} = [v]\left(\frac{z^\ell + k[\overline{\tau}]}{z^\ell + k[\tau]}\right), \qquad v = e^{2\pi mi/n}. \tag{4.27}$$

Remark 4.3. Recall that for μ odd, the argument of τ is $s\pi + \ell\pi/n$ where $1 \le \ell \le (n-1)$ and $s = \arg(\alpha_0/\alpha_1)/\pi + (\ell + \ell_0)$. Thus s is either an even or odd integer, so that $\tau \notin \mathbb{R}$. Similarly, for μ even we consider (4.26) with $\widetilde{\tau}$ having argument of the same form $\arg(\widetilde{\tau}) = s\pi + \ell\pi/n$ and exactly the same result follows.

The choice of k positive or negative is determined by the sign of $\mathcal{K}$ so that mod 2π, we have

$$\arg(k \cdot \tau) = \frac{\pi\ell}{n} \quad \text{for} \quad k \cdot \mathcal{K} > 0. \tag{4.28}$$

We see that there exists a positive constant c such that for all k satisfying $k \cdot \mathcal{K} > 0$

$$|z^\ell + k\tau| > c \tag{4.29}$$

for all $z \in S_0 \cap \{|z| > M\}$.

LEMMA 4.3. *There exists an $M > 0$ such that*

$$\left|[v]\frac{z^\ell + k[\overline{\tau}]}{z^\ell + k[\tau]}\right| \le 9/2$$

uniformly in k and z for $k \cdot \mathcal{K} > 0$ and $z \in S_0$ with $|z| > M$.

Proof. First we show that

$$\left|\frac{z^\ell + k\overline{\tau}}{z^\ell + k\tau}\right| \le 1 \tag{4.30}$$

for $k \cdot \mathcal{K} > 0$ uniformly in k and $z \in S_0$.

For $z \in S_0$, $z = re^{i\theta}$ the modulus squared of (4.30) is

$$\frac{r^{2\ell} + |k\tau|^2 + 2r^{\ell}|k\tau| \cos(\ell\theta + (\pi\ell/n))}{r^{2\ell} + |k\tau|^2 + 2r^{\ell}|k\tau| \cos(\ell\theta - (\pi\ell/n))}. \tag{4.31}$$

The expression (4.31) is less than or equal to one provided

$$\cos(\ell\theta + (\pi\ell/n)) \leq \cos(\ell\theta - (\pi\ell/n)),$$

which is true provided $0 \leq \theta \leq \pi/n$, $k \cdot \mathcal{K} > 0$.

To complete the proof of the lemma we note that our expression can be written as

$$(v + O(1/z)) \frac{z^{\ell} + k\overline{\tau} + kO(1/z)}{z^{\ell} + k\tau + kO(1/z)}.$$

Divide the numerator and denominator by $z^{\ell} + k\tau$ and define

$$T_1(z,k) = \frac{z^{\ell} + k\overline{\tau}}{z^{\ell} + k\tau},$$

$$T_2(z,k) = \frac{k}{z^{\ell} + k\tau}.$$

Recalling that $|v| = 1$, the modulus of the resulting expression can be written as

$$\left| [v] \frac{T_1(z,k) + T_2(z,k)O(1/z)}{1 + T_2(z,k)O(1/z)} \right|.$$

From (4.30), we see that

$$|T_1(z,k)| \leq 1$$

uniformly in z and k.

Note that for every $M > 0$, the map

$$(k,z) \mapsto \frac{z^{\ell}}{k}$$

takes $(0,\infty) \times \{S_0 \cap \{|z| > M\}\}$ onto $S_0^{\ell} = \{w : 0 \leq \arg(w) \leq \ell\pi/n\}$ and it maps $(-\infty,0) \times \{S_0 \cap \{|z| > M\}\}$ onto $-S_0^{\ell} = \{w : \pi \leq \arg(w) \leq \pi + \ell\pi/n\}$.

For $T_2(z,k)$ we define $w = z^{\ell}/k$ and consider the function

$$\frac{1}{w + \tau}$$

on S_0^{ℓ} or $-S_0^{\ell}$ depending on whether $k > 0$ or $k < 0$. By our assumption $k \cdot \mathcal{K} > 0$ we see that $w + \tau \neq 0$ and hence

$$\left| \frac{1}{w + \tau} \right| \leq C$$

for some constant C. Therefore

$$|T_2(z,k)| \leq C$$

uniformly in k and $z \in S_0$. With this we choose $M > 0$ so that for $|z| > M$ the term $|O(1/z)|$ satisfies

$$|O(1/z)| \leq \frac{1}{2C}$$

and

$$|[v]| \leq (1 + 1/2).$$

So finally we obtain

$$\left|[v]\frac{z^\ell + k[\overline{\tau}]}{z^\ell + k[\tau]}\right| \leq (1+1/2)\frac{1+1/2}{1-1/2} \leq \frac{9}{2}. \qquad \square$$

THEOREM 4.4. *There exists an $M > 0$ and $y_0 > 0$ such that*

$$e^{-2iz} = [v]\left(\frac{z^\ell + k[\overline{\tau}]}{z^\ell + k[\tau]}\right)$$

has no roots for $z \in (S_0 \cup S_{2n-1}) \cap \{z : |\operatorname{Im}(z)| \geq y_0,\ |z| > M\}$ and all k such that $k \cdot \mathcal{K} > 0$.

Proof. For $z \in S_0$, $z = x + iy$ we have

$$\left|e^{-2iz}\right| = e^{2y} > e^{2y_0}$$

for $y > y_0 > 0$ and we see that the modulus of the left side of our equation can be made as large as we like. From the previous lemma, we need only take $y_0 > 0$ so that

$$e^{2y_0} > \frac{9}{2}.$$

So for $|z| > M$ and $\operatorname{Im}(z) > y_0$ there are no roots for all k so that $k \cdot \mathcal{K} > 0$. The result for $\operatorname{Im}(z) < -y_0$ follows by conjugation. $\square$

Remark 4.4. Recall that we have reduced the general problem of the asymptotic behavior of the closed-loop poles to the case in which μ is odd. For μ odd, recall that the zeros of $\mathcal{D}(\lambda) + k\mathcal{N}(\lambda)$ of large modulus and $\pi \leq \arg(\lambda) < 2\pi$ are exactly the set of $\lambda = -z^n$ where z are the zeros of large modulus of $\Delta(z,k)$ (and hence $\delta(z,k)$) in S_0. Indeed, for any $c \in \mathbb{C}$ the zeros of $\Delta(z,k)$ and $\mathcal{D}(-z^n) + k\mathcal{N}(-z^n)$ agree for $z \in T_c$, $|z| >> 0$. The zeros of $\mathcal{D}(\lambda) + k\mathcal{N}(\lambda)$ occur in conjugate pairs and we have shown that for large modulus there are no zeros of $\delta(z,k)$ for $\operatorname{Im}(z) > y_0$ so there are no zeros of $\mathcal{D}(-z^n) + k\mathcal{N}(-z^n)$ for $\operatorname{Im}(z) > y_0$ and hence for $\operatorname{Im}(z) < -y_0$. From this we observe that there are no zeros of $\delta(z,k)$ or $\mathcal{D}(-z^n) + k\mathcal{N}(-z^n)$ for $|z|$ large, $|\operatorname{Im}(z)| > y_0$ in $S_0 \cup S_{2n-1}$.

We now proceed to show that for $|\lambda|$ large the closed-loop poles are real, negative, simple and move to the left for $k \cdot \mathcal{K} > 0$.

LEMMA 4.5. *If $k \cdot \mathcal{K} \geq 0$, then the roots of*

$$e^{-2iz} = (v)\left(\frac{z^\ell + k\overline{\tau}}{z^\ell + k\tau}\right)$$

are all real and simple for $z \in S_0 \cup S_{2n-1}$.

Proof. If $z = r\exp(i\theta) \in S_0$, then $0 \le \theta \le \pi/n$ and

$$e^{4r\sin\theta} = |e^{-2iz}|^2 = \left|\frac{(z^\ell + k\overline{\tau})}{(z^\ell + k\tau)}\right|^2 \le 1$$

by (4.30), from which it follows that $\theta = 0$ and hence a root z must be real.

To see that the roots are simple, let

$$h(z,k) = e^{-2iz} - (v)\left(\frac{z^\ell + k\overline{\tau}}{z^\ell + k\tau}\right).$$

Then for $z \in \mathbb{R}_+$, we have

$$\frac{\partial h}{\partial z}(z,k) = -2ie^{-2iz} - (v)\,\frac{\ell z^{\ell-1}(z^\ell + k\tau) - \ell z^{\ell-1}(z^\ell + k\overline{\tau})}{(z^\ell + k\tau)^2}$$

$$= -2ie^{-2iz} - (v)\,\frac{2i\ell z^{\ell-1} k\,\mathrm{Im}(\tau)}{(z^\ell + k\tau)^2}$$

$$= -2i\left((v)\,\frac{z^\ell + k\overline{\tau}}{z^\ell + k\tau} + (v)\,\frac{\ell z^{\ell-1} k\,\mathrm{Im}(\tau)}{(z^\ell + k\tau)^2}\right)$$

$$= \frac{-2i\,(v)}{(z^\ell + k\tau)^2}\left(|z^\ell + k\overline{\tau}|^2 + |\ell z^{\ell-1} k\,\mathrm{Im}(\tau)|\right) \neq 0.$$

Therefore the real positive roots are simple. □

Assume $k \cdot \mathcal{K} > 0$ which implies $\arg(k\tau) = \pi\ell/n$, and let

$$g = \frac{k}{(p\pi)^\ell}, \qquad p = 1, 2, \ldots,$$

$$a_1 = \frac{\pi - \arg(v) + \pi\ell/n}{2}, \qquad a_2 = \pi + a_1$$

and define

$$V = \{\tilde{z} \;:\; |\,\mathrm{Im}(\tilde{z})| < y_0,\ a_1 < \mathrm{Re}(\tilde{z}) < a_2\}.$$

With this, for any $z \in V + p\pi$ we have $z = \tilde{z} + p\pi$, $\tilde{z} \in V$ and (4.27) can be written as

$$e^{-2i\tilde{z}} = [v]\left(\frac{(\tilde{z} + p\pi)^\ell + k[\overline{\tau}]}{(\tilde{z} + p\pi)^\ell + k[\tau]}\right), \qquad v = e^{2\pi mi/n}. \tag{4.32}$$

Thus we let

$$F_p(\tilde{z}, g) = e^{-2i\tilde{z}} - [v]\left(\frac{(1 + \tilde{z}/(p\pi))^\ell + g[\overline{\tau}]}{(1 + \tilde{z}/(p\pi))^\ell + g[\tau]}\right),$$

$$f_p(\tilde{z}, g) = e^{-2i\tilde{z}} - v\left(\frac{(1 + \tilde{z}/(p\pi))^\ell + g\overline{\tau}}{(1 + \tilde{z}/(p\pi))^\ell + g\tau}\right),$$

$$h(\tilde{z}, g) = e^{-2i\tilde{z}} - v\frac{1+g\overline{\tau}}{1+g\tau},$$

for $\tilde{z}$ in a neighborhood of $\overline{V}$ (recall $[a] = a + O(1/p)$).

Our goal now is to show that for p sufficiently large, $F_p(\tilde{z}, g)$ has only one zero in $\overline{V}$ that, since the roots must occur in conjugate pairs, must be real. To this end we first show that

$$|f_p(\tilde{z}, g) - h(\tilde{z}, g)|$$

goes to zero uniformly in g for $\tilde{z} \in \overline{V}$ as p goes to infinity. We have

$$\begin{aligned}
|f_p(\tilde{z}, g) - h(\tilde{z}, g)| &= \left| \frac{(1+\tilde{z}/(p\pi))^{\ell} + g\overline{\tau}}{(1+\tilde{z}/(p\pi))^{\ell} + g\tau} - \frac{1+g\overline{\tau}}{1+g\tau} \right| \\
&= \left| \frac{2g\,\mathrm{Im}(\tau)\left\{1 - (1+\tilde{z}/(p\pi))^{\ell}\right\}}{\left\{(1+\tilde{z}/(p\pi))^{\ell} + g\tau\right\}(1+g\tau)} \right| \\
&\leq O(1/p),
\end{aligned}$$

where we have used the fact that

$$\left| \frac{2g\,\mathrm{Im}(\tau)}{\left\{(1+\tilde{z}/(p\pi))^{\ell} + g\tau\right\}(1+g\tau)} \right|$$

is uniformly bounded for $\tilde{z} \in \overline{V}$ and for $g \in \mathbb{R}_{\pm}$ (depending on the requirement that $g \cdot \mathcal{K} > 0$).

Now we define θ_g by

$$\frac{1+g\overline{\tau}}{1+g\tau} \equiv e^{-i\theta_g}$$

and by our choice of a_j, $j = 1, 2$ and hence V we see that $h(\tilde{z}, g)$ has exactly one real root in V that can be written in terms of θ_g as

$$\tilde{z}(g) = -\frac{\arg(v)}{2} + \frac{\theta_g}{2} + \pi$$

and we now show there exists a constant C such that

$$|h(\tilde{z}, g)| > C, \qquad \tilde{z} \in \partial V$$

for all g.

If $\tilde{z} = a_j + iy \in \partial V$, $j = 1, 2$ then

$$\begin{aligned}
|h(\tilde{z}, g)|^2 &= \left| \exp(-2ia_j + 2y) - v\frac{1+g\overline{\tau}}{1+g\tau} \right|^2 \\
&= |\exp(-i(\arg(g\tau) - \arg(v)) + 2y) + \exp(i(\arg(v) - 2\arg(1+g\tau)))|^2 \\
&= |\exp(2y - i\arg(g\tau)) + \exp(-2i\arg(1+g\tau))|^2 \\
&= |\exp(2y) + \exp(i\arg(g\tau) - 2i\arg(1+g\tau))|^2.
\end{aligned}$$

Now

$$\arg(g\tau) = \frac{\ell\pi}{n} \in \left[\frac{\pi}{n}, \frac{(n-1)\pi}{n}\right],$$

which implies that

$$\arg(g\tau) > \arg(1+g\tau) > 0.$$

This in turn implies

$$\begin{aligned} -\frac{(n-1)}{n}\pi \le -\arg(g\tau) &< -\arg(1+g\tau) \\ &< \arg(g\tau) - 2\arg(1+g\tau) < \arg(g\tau) \le \frac{(n-1)}{n}\pi; \end{aligned}$$

that is,

$$|\arg(g\tau) - 2\arg(1+g\tau)| \le \frac{(n-1)}{n}\pi.$$

Let $\theta = \arg(g\tau) - 2\arg(1+g\tau)$, so that $|\theta| \le \dfrac{(n-1)}{n}\pi$ and we have

$$\begin{aligned} |h(\tilde{z}, g)|^2 &= |e^{2y} + e^{i\theta}|^2 \\ &= e^{4y} + 1 + 2e^{2y}\cos(\theta) \\ &= e^{4y} - 2e^{2y} + 1 + 2e^{2y} + 2e^{2y}\cos(\theta) \\ &= (e^{2y}-1)^2 + 2e^{2y}(1+\cos(\theta)) \\ &\ge (e^{2y}-1)^2 + 2e^{2y}\left(1 + \cos\left(\frac{(n-1)}{n}\pi\right)\right) \\ &= (e^{2y}-1)^2 + 2e^{2y}\left(1 - \cos\left(\frac{\pi}{n}\right)\right) \\ &\ge 2e^{-2y_0}\left(1 - \cos\left(\frac{\pi}{n}\right)\right) > 0. \end{aligned}$$

If $\tilde{z} = x \pm iy_0 \in \partial V$, then

$$\begin{aligned} |h(\tilde{z}, g)| &= |e^{\pm 2y_0 - 2ix} - v\frac{1+g\overline{\tau}}{1+g\tau}| \\ &\ge \left| |e^{\pm 2y_0}| - |v\frac{1+g\overline{\tau}}{1+g\tau}| \right| \\ &= |e^{\pm 2y_0} - 1| > 0 \end{aligned}$$

for $y_0 \neq 0$. Therefore there exists a constant C such that

$$|h(\tilde{z}, g)| > C, \qquad \tilde{z} \in \partial V$$

for all g.

Let P_1 be a number such that for $p > P_1$

$$|h(\tilde{z}, g) - f_p(\tilde{z}, g)| < C/2$$

and hence for $\tilde{z} \in \partial V$ and all g we have

$$|f_p(\tilde{z}, g)| \geq |h(\tilde{z}, g)| - |h(\tilde{z}, g) - f_p(\tilde{z}, g)| > C/2.$$

In a similar manner we have

$$\begin{aligned}
|F_p(\tilde{z}, g) - f_p(\tilde{z}, g)| &= \left| [v] \frac{(1 + \tilde{z}/(p\pi))^{\ell} + g[\overline{\tau}]}{(1 + \tilde{z}/(p\pi))^{\ell} + g[\tau]} - (v) \frac{(1 + \tilde{z}/(p\pi))^{\ell} + g\overline{\tau}}{(1 + \tilde{z}/(p\pi))^{\ell} + g\tau} \right| \\
&\leq \left| \frac{(1 + \tilde{z}/(p\pi))^{\ell} + g[\overline{\tau}]}{(1 + \tilde{z}/(p\pi))^{\ell} + g[\tau]} - \frac{(1 + \tilde{z}/(p\pi))^{\ell} + g\overline{\tau}}{(1 + \tilde{z}/(p\pi))^{\ell} + g\tau} \right| \\
&\quad + \left| \frac{(1 + \tilde{z}/(p\pi))^{\ell} + g[\overline{\tau}]}{(1 + \tilde{z}/(p\pi))^{\ell} + g[\tau]} \right| |O(1/p)| \\
&= \left| \frac{g}{(1 + \tilde{z}/(p\pi))^{\ell} + g[\tau]} \right| |O(1/p)| + |O(1/p)| \\
&= O(1/p)
\end{aligned}$$

uniformly for $\tilde{z} \in \overline{V}$ and $g \cdot \mathcal{K} > 0$. Hence there exists a $P_2 > P_1$ such that for $p > P_2$

$$|F_p(\tilde{z}, g) - f_p(\tilde{z}, g)| \leq C/6$$

for $\tilde{z} \in \overline{V}$ and $g \cdot \mathcal{K} > 0$. Therefore

$$|F_p(\tilde{z}, g)| \geq |f_p(\tilde{z}, g)| - |f_p(\tilde{z}, g) - F_p(\tilde{z}, g)| > C/3$$

for $p > P_2$ and $\tilde{z} \in \partial V$, $g \cdot \mathcal{K} > 0$. The inequalities

$$|f_p| > C/2, \quad |F_p| > C/3$$

guarantee that f_p and F_p have no zeros on ∂V so that we can apply Rouche's theorem.

For P_2, we have

$$|F_p(\tilde{z}, g) - f_p(\tilde{z}, g)| \leq C/6 < C/2 < |f_p(\tilde{z}, g)|$$

for all $p > P_2$, $\tilde{z} \in \partial V$ and $g \cdot \mathcal{K} > 0$. Thus we can apply Rouche's theorem to F_p and f_p to conclude that $F_p(\tilde{z}, g)$ has only one zero in V, which must be real since the zeros of $f_p(\tilde{z}, g)$ occur in conjugate pairs. □

Remark 4.5. When $k = 0$, (4.27) reduces to

$$e^{-2iz} = [e^{2\pi mi/n}]$$

with zeros

$$\tilde{z}_j(0) = -m\pi/n + j\pi + O(1/j), \qquad j = 0, \pm 1, \ldots. \tag{4.33}$$

Similarly, for $k = \infty$ (4.27) reduces to

$$e^{-2iz} = [e^{2\pi m^0 i/n}]$$

with zeros

$$\tilde{z}_j(\infty) = -m^0\pi/n + j\pi + O(1/j),\ j = 0, \pm 1, \ldots. \tag{4.34}$$

THEOREM 4.6. *For $|z|$ large, the zeros of*

$$F(z,k) \equiv e^{-2iz} - \left[e^{2\pi mi/n}\right] \frac{z^\ell + k[\overline{\tau}]}{z^\ell + k[\tau]}$$

are continuous, monotone increasing functions of k for $|k| \to \infty$ with $k \cdot \mathcal{K} > 0$.

Proof. Because we have shown that the roots of large modulus are real and simple, we know that

$$\frac{\partial F}{\partial z}(z,k) \neq 0$$

at these real zeros of $F(z,k)$, and thus we can apply the implicit function theorem to show that these zeros $z(k)$ of $F(z,k)$ vary continuously in k.

To see that a real zero $z(k)$ is monotone in k, let us suppose that $F(z,k_1) = F(z,k_2)$ and hence

$$\frac{z^\ell + k_1[\overline{\tau}]}{z^\ell + k_1[\tau]} = \frac{z^\ell + k_2[\overline{\tau}]}{z^\ell + k_2[\tau]},$$

which implies

$$k_1[\overline{\tau}] + k_2[\tau] = k_1[\tau] + k_2[\overline{\tau}]$$

or

$$(k_1 - k_2)[\mathrm{Im}(\tau)] = 0, \qquad \Rightarrow k_1 = k_2,$$

and hence $z(k)$ is monotone.

To show that the roots move to the right, we first show that if $z_p(0)$, $z_q(\infty)$ are zeros for $k = 0$ and $k = \infty$, respectively, that lie in a region

$$j\pi + a_1 < z < j\pi + a_2 = (j+1)\pi + a_1$$

then

$$z_p(0) < z_q(\infty).$$

As shown above,

$$F(z,0) = e^{-2iz} - [v] = 0$$

implies

$$z_p(0) = p\pi - \frac{\arg(v)}{2} + o(1/p),$$

while

$$F(z,\infty) = e^{-2iz} - \left[v\frac{\overline{\tau}}{\tau}\right]$$

implies

$$z_q(\infty) = q\pi - \frac{\arg(v)}{2} + \ell\pi/n + o(1/q).$$

If

$$j\pi + a_1 < p\pi - \frac{\arg(v)}{2} + o(1/p) < (j+1)\pi + a_1,$$

then subtracting $j\pi$ and adding $\arg(v)/2$, we obtain

$$0 < \frac{\pi}{2} + \frac{\ell\pi}{2n} < (p-j)\pi + o(1/p) < \pi + \frac{\pi}{2} + \frac{\ell\pi}{2n} < 2\pi.$$

Hence, we see that $p = (j+1)$.

If

$$j\pi + a_1 < q\pi - \frac{\arg(v)}{2} + \frac{\ell\pi}{n} + o(1/q) < (j+1)\pi + a_1,$$

then

$$\frac{\pi}{2} + \frac{\ell\pi}{2n} < (q-j)\pi + \frac{\ell\pi}{n} + o(1/q) < \pi + \frac{\pi}{2} + \frac{\ell\pi}{2n}$$

and

$$\frac{\pi}{2} < (q-j)\pi + \frac{\ell\pi}{2n} + o(1/q) < \pi + \frac{\pi}{2}.$$

Hence, $q = (j+1) = p$ and

$$\begin{aligned} z_p(0) - z_p(\infty) &= -\frac{1}{2}\arg(v) + \frac{1}{2}\arg(v) - \frac{\ell\pi}{n} + o(1/p) \\ &= -\frac{\ell\pi}{n} + o(1/p) < 0. \end{aligned}$$

Thus the zero of $F(z,k)$ on a particular branch must lie to the right of the corresponding zero of $F(z,0)$ and to the left of the zero of $F(z,\infty)$. Since they are monotone, they must move to the right. □

Remark 4.6. Since these roots are simple, the corresponding eigenvalues are simple and must occur in conjugate pairs so they must be real for all k. Thus under the Assumption 2.1 on the order of inputs and outputs and sign of the gain chosen by the instantaneous gain formula, we see that there are no unbounded branches of the root locus; sufficiently large modulus open-loop poles and zeros are real and interlace on the negative real axis; for these open-loop poles and zeros, the closed-loop poles are real and vary from the open-loop poles to the open-loop zeros.

Finally, we consider the possible finite number of multiple and/or complex roots.

THEOREM 4.7. *The resolvent* $R(\lambda,k) = (A_k - \lambda I)^{-1}$ *is holomorphic in* k *in the norm resolvent sense and the spectrum of* A_k *is precisely the set* $\{\lambda_j(k)\}$ *of closed-loop poles for the system* (2.2)–(2.13). *Every finite system of eigenvalues of* A_k *vary continuously for* $k \cdot \mathcal{K} \geq 0$.

Proof. The proof consists of providing an explicit representation (following [30]) for the resolvent in the form

$$R(\lambda,k)f(x)=\int_0^1 G_k(x,\xi;\lambda)f(\xi)\,d\xi,$$

where $G_k(x,\xi;\lambda)$ is the resolvent kernel for A_k. The explicit form of the resolvent kernel will show that the resolvent is analytic.

Let $\{g_j(x,\lambda)\}_{j=1}^n$ denote the unique basis of solutions of $(A-\lambda)f=0$ given in Proposition 5.1 (we will also use the notation $g_j(x)\equiv g_j(x,\lambda)$ and in what follows we suppress the dependence on λ to simplify notation) that are entire functions of λ and satisfy

$$g_j^{(k-1)}(0,\lambda)=\delta_{jk}.$$

Furthermore, define

$$\widehat{W}(x)=\left(\{g_j^{(i-1)}(x)\}_{i=1,j=1}^{n,n}\right)$$

so that the Wronskian is given by

$$W(x)=\det\left(\widehat{W}(x)\right).$$

With this, we can define

$$g(x,\xi)=\frac{\pm 1}{2W(\xi)}\begin{vmatrix} g_1(x) & g_2(x) & \cdots & g_n(x)\\ g_1^{n-2}(\xi) & g_2^{n-2}(\xi) & \cdots & g_n^{n-2}(\xi)\\ \vdots & \vdots & \ddots & \vdots\\ g_1(\xi) & g_2(\xi) & \cdots & g_n(\xi)\end{vmatrix},$$

where the positive sign is taken if $x>\xi$ and the negative sign is taken if $x<\xi$. As in the formula for the closed-loop transfer function in (5.45), we let $\Delta(\lambda,k)=\mathcal{D}(\lambda)+k\mathcal{N}(\lambda)$. Then the resolvent kernel is given by

$$G_k(x,y;\lambda)=\frac{(-1)^n}{\Delta(\lambda,k)}H_k(x,y;\lambda),$$

where

$$H_k(x,\xi;\lambda)=\begin{vmatrix} g_1(x) & \cdots & g_n(x) & g(x,\xi)\\ \mathcal{W}_1(g_1)+k\mathcal{W}_0(g_1) & \cdots & \mathcal{W}_1(g_n)+k\mathcal{W}_0(g_n) & \mathcal{W}_1(g)+k\mathcal{W}_0(g)\\ \mathcal{W}_2(g_1) & \cdots & \mathcal{W}_2(g_n) & \mathcal{W}_2(g)\\ \vdots & \vdots & \ddots & \vdots\\ \mathcal{W}_n(g_1) & \cdots & \mathcal{W}_n(g_n) & \mathcal{W}_n(g)\end{vmatrix}.$$

From this we see that the spectrum of A_k coincides exactly with the closed-loop poles; namely, the zeros of the return difference equation,

$$\Delta(\lambda,k)=\mathcal{D}(\lambda)+k\mathcal{N}(\lambda)=0.$$

Thus the resolvent kernel is an analytic function of λ and k with singularities only at the closed-loop poles.

Since we have shown that there are no roots of Δ for all $k \cdot \mathcal{K} > 0$, $|z| > M$, $z \in S_0 \cup S_{2n-1}$, there is a complex number z_0 such for $\lambda_0 = -z_0^n$

$$\operatorname{dist}(\lambda_0, \sigma(A_k)) > (\text{constant}) > 0$$

for all k where $\sigma(A_k)$ denotes the spectrum of A_k. Thus the resolvent operator $R_k(\lambda_0) = (A_k - \lambda_0)^{-1}$ maps the entire Hilbert space onto the domain of A_k for every k. Therefore by Kato [25, Chap. VII, §1.2, Thm. 1.3] A_k is a holomorphic family for all k. From this we see that, in our case, if the boundary conditions are holomorphic in the parameter k, then the resulting family of operators A_k is holomorphic in the generalized sense of Kato [25].

A further result of the proof of Theorem 3.1 is that the operators A_k satisfy the separation of the spectrum condition (cf. [25, Chap. III, §6.4]). Namely, we can find a rectifiable curve Γ separating the spectrum of A_k into a finite part contained in the interior of Γ and the remainder of the spectrum that consists of an infinite set of real negative values $\lambda_j(k)$ that converge to minus infinity as j tends to infinity. In particular, for $z_j(k)$ a zero of $\delta(z,k)$ of large modulus, we have an integer p so that for all $j' > j$ and the closed-loop poles $z_{j'}(k)$ satisfy

$$a_1 + p\pi < z_j(0) \le z_j(k) \le z_j(\infty) < a_2 + p\pi < z_{j'}(k).$$

So it is easy to find such a curve Γ. Furthermore the decomposition for this curve Γ holds for all $k \cdot \mathcal{K} \ge 0$. Thus for $k \cdot \mathcal{K} \ge 0$, the spectrum of A_k satisfies the spectrum separation property described in Kato [25].

Appealing once again to results found in Kato [25, Chap. VII, §1.3, Thms. 1.7, 1.8] we see that the finite number of eigenvalues of A_k, $k \cdot \mathcal{K} \ge 0$, inside Γ vary continuously in k while the remainder of the spectrum of A_k for all $k \cdot \mathcal{K} \ge 0$ is real and has been shown to varies continuously on the negative real axis. □

5. Proofs of the results in §2 and Theorem 3.4. We begin this section with the proof of Proposition 2.1.

Proof of Proposition 2.1. The proof is based on the Laplace transform, straightforward calculations, and two propositions which are given below in Proposition 5.1 and 5.2. We first obtain a representation for the transfer function in terms of a special basis of solutions of a boundary value problem for an ordinary differential equation. Then we show that this representation is independent of the basis chosen.

Applying the Laplace transform to (2.2)–(2.6) with initial data $w_0 = 0$ we obtain the system

$$\begin{aligned} A\hat{w} &= \lambda\hat{w}, \\ \mathcal{W}_1(\hat{w}) &= \hat{u}, \\ \mathcal{W}_i(\hat{w}) &= 0, \qquad i = 2, \dots, n, \\ \hat{y} &= \mathcal{W}_0(\hat{w}). \end{aligned} \tag{5.35}$$

Computation of a candidate for the closed-loop transfer function can be carried out once we have sufficient knowledge of a basis of eigenfunctions and eigenvalues for the problem

$$Af = \lambda f \tag{5.36}$$

$$\mathcal{W}_1(f) + k\,\mathcal{W}_0(f) = 0, \quad \mathcal{W}_i(f) = 0, \qquad i = 2, \dots, n.$$

PROPOSITION 5.1. *There is a unique basis of solutions* $\{g_j(x,\lambda)\}_{j=1}^n$ *of*

$$g^{(n)} + (-1)^{(\mu-1)}\left(p_{n-2}(x)g^{(n-2)} + \cdots + p_1(x)g^{(1)} + p_0(x)g - \lambda g\right) = 0 \tag{5.37}$$

that are entire functions of λ *and satisfy*

$$g_j^{(k-1)}(0,\lambda) = \delta_{jk}. \tag{5.38}$$

Furthermore, these functions are real in the sense that

$$\overline{g(x,\lambda)} = g(x,\overline{\lambda})$$

under the assumption that the coefficients $\{p_{n-j}\}_{j=2}^n$ *are real.*

The proof of this result is classical; see, for example, [30].

Let $g_j \equiv g_j(x,\lambda)$ denote the basis of solutions of (5.36) given in Proposition 5.1. Then the solution to (5.35) is given by

$$\hat{w} = \sum_{j=1}^n a_j g_j$$

with $\{a_j\}$ determined from the system

$$\sum_{j=1}^n a_j \mathcal{W}_1(g_j) = \hat{u}, \tag{5.39}$$

$$\sum_{j=1}^n a_j \mathcal{W}_i(g_j) = 0, \qquad i = 2,\ldots,n.$$

Applying Cramer's rule we obtain

$$\hat{w} = \det\left(\{\mathcal{W}_i(g_j)\}_{i=1,j=1}^{n,n}\right)^{-1} \sum_{j=1}^n C_{1j} g_j \hat{u},$$

where C_{1j} is the $1j$th cofactor of $\{\mathcal{W}_i(g_j)\}_{i=1,j=1}^{n,n}$. Now apply the observation operator $C = \mathcal{W}_0$ to obtain

$$\hat{y} = \det\left(\{\mathcal{W}_i(g_j)\}_{i=1,j=1}^{n,n}\right)^{-1} \sum_{j=1}^n C_{1j}\, \mathcal{W}_0(g_j)\hat{u}.$$

The sum on the right is precisely $\det(\{\mathcal{W}_i(g_j)\}_{i=0,2,j=1}^{n,n})$ and so we have

$$\mathcal{G}_0 = \frac{\mathcal{N}}{\mathcal{D}}, \tag{5.40}$$

where

$$\mathcal{N}(\lambda) \equiv \det\left(\{\mathcal{W}_i(g_j)\}_{i=0,2,j=1}^{n,n}\right), \tag{5.41}$$

$$\mathcal{D}(\lambda) \equiv \det\left(\{\mathcal{W}_i(g_j)\}_{i=1,j=1}^{n,n}\right), \tag{5.42}$$

$$\hat{y} = \mathcal{G}_0 \hat{u}. \tag{5.43}$$

Now consider the feedback

$$u(t) = -ky(t) + v(t). \tag{5.44}$$

The closed-loop transfer function, denoted by $\mathcal{G}_k$, is obtained using exactly the same argument as above but with $\mathcal{W}_1$ replaced by $\mathcal{W}_1 + k\mathcal{W}_0$. In this case the expression (5.42) is replaced by an expression in which only the first row of the determinant is changed. In particular, $\mathcal{W}_1$ is replaced by $\mathcal{W}_1 + k\mathcal{W}_0$. Expanding this determinant using the first row gives

$$\hat{y} = \mathcal{G}_k \hat{v},$$

where

$$\mathcal{G}_k(\lambda) = \frac{\mathcal{N}(\lambda)}{\mathcal{D}(\lambda) + k\mathcal{N}(\lambda)}. \tag{5.45}$$

The functions $\mathcal{D}(\lambda)$, $\mathcal{N}(\lambda)$ are entire functions with discrete zeros (cf. [30])

$$\{\lambda_j(0)\}_{j=1}^{\infty},\ \{\lambda_j(\infty)\}_{j=1}^{\infty}$$

and provide the spectrum of A_0 and A_∞, respectively. The spectrum of A_k is obtained in the same way from the zeros of

$$\mathcal{D}(\lambda) + k\mathcal{N}(\lambda) = 0.$$

That $\mathcal{G}_k(\lambda)$ is real follows from Proposition 5.1 where it was observed that

$$\overline{g_j(x,\lambda)} = g_j(x,\overline{\lambda}).$$

So far, our calculations of $\mathcal{G}_0$ apparently depend on a choice of basis. In fact, this dependence is superfluous.

PROPOSITION 5.2. *Suppose that* $\{f_j\}$ *and* $\{g_j\}$ *are both bases for* (5.36) *where* $\{g_j\}$ *is the basis of Proposition* 5.1 *and we define*

$$\mathcal{D}_g(\lambda) = \det\left(\{\mathcal{W}_i(g_j)\}_{i=1,j=1}^{n,n}\right), \qquad \mathcal{N}_g(\lambda) = \det\left(\{\mathcal{W}_i(g_j)\}_{i=0,2,j=1}^{n,n}\right),$$

and

$$\mathcal{D}_f(\lambda) = \det\left(\{\mathcal{W}_i(f_j)\}_{i=1,j=1}^{n,n}\right), \qquad \mathcal{N}_f(\lambda) = \det\left(\{\mathcal{W}_i(g_j)\}_{i=0,2,j=1}^{n,n}\right).$$

Let

$$\widehat{W}_f(x) = \left(\{f_j^{(i-1)}(x)\}_{i=1,j=1}^{n,n}\right)$$

and denote the Wronskian for the basis $\{f_j\}$ *by*

$$W_f(x) = \det\left(\widehat{W}_f(x)\right).$$

Then

$$\mathcal{G}_0(\lambda) = \frac{\mathcal{N}_g(\lambda)}{\mathcal{D}_g(\lambda)} = \frac{\mathcal{N}_f(\lambda)W_f^{-1}(0)}{\mathcal{D}_f(\lambda)W_f^{-1}(0)} = \frac{\mathcal{N}_f(\lambda)}{\mathcal{D}_f(\lambda)} \tag{5.46}$$

from which it follows that the definition of our transfer function is invariant with respect to the basis chosen for (5.36).

Proof. We have

$$\widehat{W}_g(x,\lambda) = \widehat{W}_f(x,\lambda)\widehat{W}_f^{-1}(0,\lambda)$$

and from this it can be shown that

$$\mathcal{D}_g(\lambda) = W_f^{-1}(0,\lambda)\,\mathcal{D}_f(\lambda),$$

and

$$\mathcal{N}_g(\lambda) = W_f^{-1}(0,\lambda)\,\mathcal{N}_f(\lambda).$$

This follows from the relation

$$g_k(x) = \sum_{j=1}^{n} c_{kj} f_j(x),$$

which implies

$$\delta_{ik} = g_k^{(i-1)}(0) = \sum_{j=1}^{n} c_{kj} f_j^{(i-1)}(0)$$

and hence

$$C = \left(\{f_j^{(i-1)}(0)\}_{i=1,j=1}^{n,n}\right) = W_f^{(-1)}(0).$$

Let

$$a_{1i} = (\alpha_{i0}, \alpha_{i1}, \ldots, \alpha_{im_i-1}, \alpha_i, \overbrace{0, \ldots, 0}^{n-m_i}), \qquad i = 1, \ldots, \mu,$$

$$b_{1i} = (\beta_{i0}, \beta_{i1}, \ldots, \beta_{im_i-1}, \overbrace{0, \ldots, 0}^{n-m_i+1}), \qquad i = 1, \ldots, \mu,$$

$$a_{2i} = (\alpha_{i0}, \alpha_{i1}, \ldots, \alpha_{im_i-1}, \overbrace{0, \ldots, 0}^{n-m_i+1}), \qquad i = \mu+1, \ldots, n,$$

$$b_{2i} = (\beta_{i0}, \beta_{i1}, \ldots, \beta_{im_i-1}, \beta_i, \overbrace{0, \ldots, 0}^{n-m_i}), \qquad i = \mu+1, \ldots, n$$

and define the four $\mu \times n$ matrices

$$A_j = \begin{pmatrix} a_{j1} \\ a_{j2} \\ \vdots \\ a_{j\mu} \end{pmatrix}, \quad B_j = \begin{pmatrix} b_{j1} \\ b_{j2} \\ \vdots \\ b_{j\mu} \end{pmatrix}, \qquad j = 1, 2.$$

With this notation we have

$$\begin{aligned}\mathcal{D}_g(\lambda) &= \det\left(\begin{bmatrix} A_1 & B_1 \\ A_2 & B_2 \end{bmatrix}\begin{bmatrix} \widehat{W}_g(0) \\ \widehat{W}_g(1) \end{bmatrix}\right) \\ &= \det\left(\begin{bmatrix} A_1 & B_1 \\ A_2 & B_2 \end{bmatrix}\begin{bmatrix} \widehat{W}_f(0) \\ \widehat{W}_f(1) \end{bmatrix}\widehat{W}_f^{-1}(0)\right) \\ &= \det\left(\begin{bmatrix} A_1 & B_1 \\ A_2 & B_2 \end{bmatrix}\begin{bmatrix} \widehat{W}_f(0) \\ \widehat{W}_f(1) \end{bmatrix}\right) W_f^{-1}(0) \\ &= \mathcal{D}_f(\lambda)W_f^{-1}(0).\end{aligned}$$

The analogous result for $\mathcal{N}_g$ and $\mathcal{N}_f$ is exactly the same. □

The proof that $\mathcal{D}$ and $\mathcal{N}$ are entire functions of order $1/n$ is based on explicit information on the asymptotic form of the functions $\mathcal{N}(\lambda)$ and $\mathcal{D}(\lambda)$. From Propositions 5.1 and 5.2 it is clear that they are entire functions and simple estimates obtained from the asymptotic form of $\mathcal{N}$ and $\mathcal{D}$ in the z variable (recall that $\lambda = i^n z^n$) will show that these functions have the same order $\sigma = 1/n$. We consider only the case μ odd and note that the case μ even can be handled following the discussion in (4.23)–(4.26). In this case $\omega_\mu = i$ and from (4.13)–(4.22),

$$\begin{aligned}\mathcal{N}(\lambda) &= \frac{z^{m^0-\mu(n-1)}e^{\omega z}\delta(z,\infty)}{\det\left([\omega_j^{i-1}]\right)} \\ &= [C]z^{m^0-\mu(n-1)}e^{\omega z}\left\{-[N_1]e^{2z\omega_\mu} + [N_{-1}]\right\}.\end{aligned}$$

Factor out N_1 and recall that from Proposition 4.2, part 4, $N_{-1}/N_1 = \exp(-2m^0\pi i/n)$; also factor out $\exp(-m^0\pi i/n)$, $\exp(\omega_\mu z)$ and recall from (4.15) and $\omega_\mu = -\omega_{\mu+1}$ that

$$\omega + \omega_\mu \equiv \widehat{\omega} = \sum_{j=2}^{\mu}\omega_{\mu+j}.$$

From this we obtain

$$\mathcal{N}(\lambda) = [-2iN_1C]z^{m^0-\mu(n-1)}e^{-m^0\pi i/n}e^{\widehat{\omega}z}\left[\sin(z + m^0\pi/n)\right],$$

where $|C| = n^{-\mu}$.

Hence for $|z|$ large

$$\begin{aligned}|\mathcal{N}(\lambda)| &= |[2N_1C]|\,|z|^{m^0-\mu(n-1)}|e^{-m^0\pi i/n}||e^{\widehat{\omega}z}|\,\left|\left[\sin(z + m^0\pi/n)\right]\right| \\ &= |[2N_1C]|\,|\lambda|^{(m^0-\mu(n-1))/n}|e^{\widehat{\omega}\lambda^{1/n}}|\left|\left[\sin(i\lambda^{1/n} + m^0\pi/n)\right]\right|,\end{aligned}$$

from which it is easy to see that for large modulus of λ

$$\limsup_{|\lambda|\to\infty}\left(\frac{\log\log\max_{0\le\theta<2\pi}|\mathcal{N}(|\lambda|e^{i\theta})|}{\log(|\lambda|)}\right) = \frac{1}{n},$$

which, with the definition of order of an entire function, shows that the order of $\mathcal{N}$ is $1/n$. A completely analogous argument shows that the order of $\mathcal{D}$ is also $1/n$ and this concludes the proof of Proposition 2.1.

Proof of Proposition 2.3. For μ odd, $z \in S_0 \cup S_{2n-1}$, we have

$$\arg z \in [-\pi/n, \pi/n)$$

and for μ even, $z \in S_0 \cup S_1$ with

$$\arg z \in [0, 2\pi/n).$$

Thus by the relation $\lambda = i^n z^n$, we have for $\lambda \in \mathbb{R}_+$,

$$z^\ell = \begin{cases} \lambda^{\ell/n} e^{-\ell\pi i/n}, & \text{for } \mu \text{ odd}, \\ \lambda^{\ell/n} & \text{for } \mu \text{ even}. \end{cases}$$

Then by the asymptotic expression for the transfer function given in (4.22) we have

$$\lim_{\lambda \to +\infty} \lambda^{\ell/n} \mathcal{G}_0(\lambda) \equiv \widehat{\tau} = \begin{cases} \tau_1 e^{\ell\pi i/n}, & \text{for } \mu \text{ odd}, \\ \tau_1 & \text{for } \mu \text{ even}. \end{cases}$$

Finally using Proposition 4.2, part 5, we know that $\lim_{\lambda \to +\infty} \lambda^{\ell/n} \mathcal{G}_0(\lambda)$ is a real number. □

Proof of Theorem 2.4. From the proof of Propositions 2.3 and 4.2, we see that the signum of the instantaneous gain $\widehat{\tau}$ is given by $(-1)^s$ with s defined in (2.21) and computed in Proposition 4.2. □

Proof of Proposition 2.5. Part 1 of Proposition 2.5 proceeds as follows. Since by Proposition 2.1 both $\mathcal{D}(\lambda)$ and $\mathcal{D}(\lambda)$ are entire function of order $1/n$, by the Hadamard factorization theorem, there exists integers p and q and constants C_1, C_2 so that

$$\mathcal{N}(\lambda) = \lambda^p C_1 \prod_{n=p+1}^{\infty} \left(1 - \frac{\lambda}{\xi_n}\right),$$

$$\mathcal{D}(\lambda) = \lambda^q C_2 \prod_{n=q+1}^{\infty} \left(1 - \frac{\lambda}{p_n}\right),$$

where $\{\xi_n\}$, $\{p_n\}$ are the nonzero zeros of $\mathcal{N}(\lambda)$ and $\mathcal{D}(\lambda)$, respectively, i.e., the nonzero open-loop zeros and poles ordered so that

$$|\xi_n| \leq |\xi_{n+1}|,$$

$$|p_n| \leq |p_{n+1}|.$$

By Theorem 3.2, there is an $N > 0$ so that for $n \geq N$ the poles and zeros are simple and

$$\xi_n < p_n < \xi_{n-1} < p_{n-1} < 0.$$

Hence for $k \geq N$,

$$\text{Res}_{\lambda = p_k} = \lim_{\lambda \to p_k} (\lambda - p_k) \frac{\mathcal{N}(\lambda)}{\mathcal{D}(\lambda)} = \mathcal{N}(p_k) \left[\lim_{\lambda \to p_k} \frac{\mathcal{D}(\lambda)}{(\lambda - p_k)} \right]^{-1}$$

and we can assert

$$\lim_{\lambda\to p_k}\frac{\mathcal{D}(\lambda)}{(\lambda-p_k)} = C_2 p_k^q \prod_{n=q+1}^{k-1}\left(1-\frac{p_k}{p_n}\right)\left(-\frac{1}{p_k}\right)\prod_{n=k+1}^{\infty}\left(1-\frac{p_k}{p_n}\right)$$
$$= C_2(-1)^{k-1}|p_k|^{q-1}\prod_{\substack{n>q\\ n\neq k}}\left|1-\frac{p_k}{p_n}\right|,$$

where we note that some finite number of the terms in the infinite product may correspond to complex poles, which must occur in conjugate pairs, so that the absolute value is still correct.

Again by the Hadamard factorization theorem we have

$$\mathcal{N}(p_k) = C_1 p_k^p \prod_{n=p+1}^{\infty}\left(1-\frac{p_k}{\xi_n}\right)$$
$$= C_1(-1)^{k-1}|p_k|^p \prod_{n=p+1}^{\infty}\left|1-\frac{p_k}{\xi_n}\right|.$$

Here again there may be a finite number of terms corresponding to complex zeros but they occur in conjugate pairs.

Now recalling that $\mathcal{G}_0(\lambda) = \mathcal{N}(\lambda)/\mathcal{D}(\lambda)$ is real, the above calculations show that C_1/C_2 is real. Thus we have that $\operatorname{Res}_{\lambda=p_k}\mathcal{G}_0(\lambda)$ is real and has the same sign as C_1/C_2 and we have established the first part of the proof.

For the second part of the proof recall that $\lambda = i^n z^n$ and note that for any constant a, $d[a]/dz = [0]$ and also for any pole λ_k with k large

$$e^{2\omega_\mu z_k} = \left[\frac{D_{-1}}{D_1}\right] = \left[e^{-2m\pi i/n}\right].$$

With this and the asymptotic form of the transfer function in (4.22), we have

$$\operatorname{Res}_{\lambda=p_k}\mathcal{G}_0(\lambda) = \lim_{\lambda\to p_k}(\lambda-p_k)\,\mathcal{G}_0(\lambda)$$

$$= \lim_{\lambda\to p_k}\frac{\left(-[N_1]e^{2\omega_\mu z}+[N_{-1}]\right)(i^n z^n - i^n z_k^n)/(z-z_k)}{z^\ell\left(-[D_1]e^{2\omega_\mu z}+[D_{-1}]\right)/(z-z_k)}$$

$$= \frac{\left(-[N_1]e^{2\omega_\mu z_k}+[N_{-1}]\right)ni^n z_k^{n-1}}{z_k^\ell\left(-2\omega_\mu[D_1]e^{2\omega_\mu z_k}\right)}$$

$$= \frac{ni^n z_k^{n-\ell-1}}{-2\omega_\mu}\,\frac{-[N_1]\left[e^{-2m\pi i/n}\right]+[N_{-1}]}{[D_{-1}]}$$

$$= \frac{ni^n z_k^{n-\ell-1}}{-2\omega_\mu}\,\frac{N_{-1}}{D_{-1}}\,\frac{-\left[\left[e^{-2m^0\pi i/n}\right]e^{-2m\pi i/n}\right]+[1]}{[1]}$$

$$= \frac{ni^n z_k^{n-\ell-1}\tau}{-\omega_\mu}\,\frac{\left[e^{\ell\pi i/n}\right]-\left[e^{-\ell\pi i/n}\right]}{[2]}\,e^{-\ell\pi i/n}$$

$$= -\frac{ni^{n+1}z_k^{n-\ell-1}\tau}{\omega_\mu}e^{-\ell\pi i/n}\sin\left(\frac{\ell\pi}{n}\right)[1].$$

When μ is odd, $\omega_\mu = i$ and this reduces to

$$-\frac{ni^{n+1}|z_k|^{n-\ell-1}|\tau|}{i} e^{(s+2\ell/n)\pi i} e^{-\ell\pi i/n} \sin\left(\frac{\ell\pi}{n}\right)[1],$$

where s is given (2.21) and when μ is even, $\omega_\mu = ie^{-\pi i/n}$ and

$$-\frac{ni^{n+1}|z_k|^{n-\ell-1}e^{(n-\ell-1)\pi i/n}|\tau|}{ie^{-\pi i/n}} e^{(s+2\ell/n)\pi i} e^{-\ell\pi i/n} \sin\left(\frac{\ell\pi}{n}\right)[1].$$

Simplifying these expressions, we arrive at the conclusion of part 2, namely,

$$\operatorname{Res}_{\lambda=p_k} \mathcal{G}_0(\lambda) = (-1)^s n|z_k|^{n-\ell-1}|\tau| \sin\left(\frac{\ell\pi}{n}\right)[1].$$

For part 3 of the proof we first show that for

$$x_j = j\pi + \frac{\pi}{2} - \frac{m\pi}{n},$$

we have

$$|\mathcal{G}_0(s_j)| \le \frac{3|\tau|}{|\xi_j|^\ell},$$

where $s_j = i^n \xi_j^n$ and $\xi_j = x_j + iy \in S_0 \cup S_{2n-1}$.

Recall the asymptotic expression for $\mathcal{G}_0(s)$ in the z-plane

$$\begin{aligned}
\mathcal{G}_0(s)|_{s=i^n z^n} &= \left.\frac{\mathcal{N}(s)}{\mathcal{D}(s)}\right|_{s=i^n z^n} \\
&= \frac{[-2iN_1 n^{-\mu}]z^{m^0-\mu(n-1)}e^{-m^0\pi i/n}e^{\hat{w}z}[\sin(z+m^0\pi/n)]}{[-2iD_1 n^{-\mu}]z^{m-\mu(n-1)}e^{-m\pi i/n}e^{\hat{w}z}[\sin(z+m\pi/n)]} \\
&= \left[\tau_1 e^{\frac{\ell\pi i}{n}}\right] \frac{[\sin(z+m^0\pi/n)]}{z^\ell[\sin(z+m\pi/n)]}.
\end{aligned}$$

Since

$$\begin{aligned}
\left|\left[\sin\left(\xi_j + \frac{m\pi}{n}\right)\right]\right| &= \left|\left[\sin\left(j\pi + \frac{\pi}{2} + iy\right)\right]\right| \\
&= \left|[(-1)^j \cos(iy)]\right| \\
&= \left|[(-1)^j \cosh(y)]\right| \\
&\ge \cosh(y) - \frac{1}{2},
\end{aligned}$$

$$\begin{aligned}
\left|\left[\sin\left(\xi_j + \frac{m^0\pi}{n}\right)\right]\right| &= \left|\left[\sin\left(j\pi + \frac{\pi}{2} + iy - \frac{\ell\pi}{n}\right) -\right]\right| \\
&= \left|[(-1)^j \cos(iy - \frac{\ell\pi}{n})]\right| \\
&\le \cosh(y) + \frac{1}{2};
\end{aligned}$$

thus

$$|\mathcal{G}_0(s_j)| \le \left| \frac{\tau_1 \left(\cosh(y) + \frac{1}{2}\right)}{\xi_j^{\ell} \left(\cosh(y) - \frac{1}{2}\right)} \right|$$

$$\le \frac{|\tau|}{|\xi_j|^{\ell}} \left(1 + \frac{1}{\cosh(y) - \frac{1}{2}}\right)$$

$$\le \frac{3|\tau|}{|\xi_j|^{\ell}}$$

for j large. The assertion is established.

Note that the impulse response function is given by

$$h(t) = \frac{1}{2\pi i} \int_{\sigma - i\infty}^{\sigma + i\infty} e^{st}\, \mathcal{G}_0(s)\, ds$$

$$= \lim_{R \to \infty} \frac{1}{2\pi i} \int_{\sigma - iR}^{\sigma + iR} e^{st}\, \mathcal{G}_0(s)\, ds$$

$$= \lim_{j \to \infty} \frac{1}{2\pi i} \int_{\sigma - ir_j}^{\sigma + ir_j} e^{st}\, \mathcal{G}_0(s)\, ds.$$

To see that the inverse Laplace transform of $\mathcal{G}_0$ can be computed using the method of residues, we let

$$V = \{s : \operatorname{Re} s = \sigma\}$$

be a vertical line such that all poles of $\mathcal{G}_0(s)$ lie to the left of V. Let

$$L = \{z \in S_0 \cup S_{2n-1} : \operatorname{Re} z = x\},$$
$$W = \{s = -z^n : z \in L, \operatorname{Re} s \le \sigma\},$$
$$l = \{z \in L : -z^n \in W\}.$$

Then W is a simple rectifiable curve in the λ-plane that intersects V at two points, is symmetric with respect to the real axis, and extends to the left of the vertical line V. It is clear that when $x \to \infty$, the curve W contains the whole half-plane left of the vertical line V.

What we need to show now is

$$\left| \int_W e^{st} \mathcal{G}_0(s) ds \right| \to 0$$

as $x \to \infty$.

Let $y_x > 0$ be the end point of l in S_0. Let σ_x be the intersection of W and V corresponding to y_x; then σ_x is in quadrant IV if we assume $\sigma > 0$. Let α be the angle between the negative imaginary axis and σ_x in the λ-plane. Then since for $z = x + iy \in l, s = -z^n \in W$,

$$z = \sqrt{x^2 + y^2} e^{i \arctan(y/x)},$$

$$s = (x^2 + y^2)^{\frac{n}{2}} e^{i(\pi + n \arctan(y/x))},$$

we know

$$\alpha = \arcsin \frac{\sigma}{(x^2 + y_x^2)^{n/2}} \leq \arcsin \frac{\sigma}{x^n}.$$

Let

$$\beta = \arcsin \frac{\sigma}{x^n}.$$

From

$$\frac{\pi}{2} - \beta \leq \pi + n \arctan \frac{y}{x} \leq \frac{3\pi}{2} + \beta$$

we see that

$$-\frac{\pi + 2\beta}{2n} \leq \arctan \frac{y}{x} \leq \frac{\pi + 2\beta}{2n},$$

which implies

$$-x \tan \frac{\pi + 2\beta}{2n} \leq y \leq x \tan \frac{\pi + 2\beta}{2n}.$$

Now, for $C = 3|\tau|$, we have

$$\left| \int_W e^{st} \mathcal{G}_0(s) ds \right| = \left| \int_l e^{-z^n t} \left[\tau_1 e^{\frac{\ell \pi i}{n}} \right] \frac{[\sin(z + m^0 \pi/n)]}{z^\ell [\sin(z + m\pi/n)]} i^n n z^{n-1} dz \right|$$

$$\leq n \int_{-x \tan \frac{\pi+2\beta}{2n}}^{x \tan \frac{\pi+2\beta}{2n}} e^{-(x^2+y^2)^{n/2} t \cos(n \arctan(y/x))} \frac{C}{(x^2 + y^2)^{\ell/2}} (x^2 + y^2)^{(n-1)/2} dy$$

$$= 2Cn \int_0^{x \tan \frac{\pi+2\beta}{2n}} e^{-(x^2+y^2)^{n/2} t \cos(n \arctan(y/x))} (x^2 + y^2)^{(n-\ell-1)/2} dy.$$

Let $y = x \tan u$. Then

$$x^2 + y^2 = x^2 \sec^2 u, \qquad dy = x \sec^2 u du.$$

Therefore

$$\left| \int_W e^{st} \mathcal{G}_0(s) ds \right| \leq 2Cnx^{n-\ell} \int_0^{\frac{\pi+2\beta}{2n}} e^{-x^n t (\sec^n u) \cos(nu)} \sec^{n-\ell+1} u du$$

$$\equiv I_1 + I_2,$$

where

$$I_1 \equiv 2Cnx^{n-\ell} \int_0^{\frac{\pi}{2n}} e^{-x^n t (\sec^n u) \cos(nu)} \sec^{n-\ell+1} u du$$

$$\leq 2Cnx^{n-\ell} \int_0^{\frac{\pi}{2n}} e^{-x^n t (\sec^n 0) \cos(nu)} \left(\sec^{n-\ell+1} \frac{\pi}{2n} \right) du$$

$$\leq 2Cnx^{n-\ell}\left(\sec^{n-\ell+1}\frac{\pi}{2n}\right)\int_0^{\frac{\pi}{2n}} e^{x^n t\frac{2}{\pi}(nu-\frac{\pi}{2})}du$$

$$= C\pi x^{-\ell}t^{-1}\left(\sec^{n-\ell+1}\frac{\pi}{2n}\right)e^{x^n t\frac{2}{\pi}(nu-\frac{\pi}{2})}\Big|_0^{\frac{\pi}{2n}}$$

$$= C\pi x^{-\ell}t^{-1}\left(\sec^{n-\ell+1}\frac{\pi}{2n}\right)\left(1-e^{-x^n t}\right)\to 0$$

as $x\to\infty$, and

$$I_2 \equiv 2Cnx^{n-\ell}\int_{\frac{\pi}{2n}}^{\frac{\pi+2\beta}{2n}} e^{-x^n t(\sec^n u)\cos(nu)}\left(\sec^{n-\ell+1}u\right)du$$

$$\leq 2Cnx^{n-\ell}\int_{\frac{\pi}{2n}}^{\frac{\pi+2\beta}{2n}} e^{-x^n t\left(\sec^n\frac{\pi+2\beta}{2n}\right)\cos\frac{\pi+2\beta}{2}}\left(\sec^{n-\ell+1}\frac{\pi+2\beta}{2n}\right)du$$

$$= 2Cnx^{n-\ell}\left(\sec^{n-\ell+1}\frac{\pi+2\beta}{2n}\right)e^{x^n t\left(\sec^n\frac{\pi+2\beta}{2n}\right)\sin\beta}\left(\frac{\pi+2\beta}{2n}-\frac{\pi}{2n}\right)$$

$$= 2Cx^{-\ell}\left(\sec^{n-\ell+1}\frac{\pi+2\beta}{2n}\right)e^{t\sec^n\frac{\pi+2\beta}{2n}x^n\sin\beta}x^n\beta$$

$$= 2Cx^{-\ell}\left(\sec^{n-\ell+1}\frac{\pi+2\beta}{2n}\right)e^{t\sec^n\frac{\pi+2\beta}{2n}\sigma}\sigma\frac{\beta}{\sin\beta}\to 0$$

as $x\to\infty$. Here we have used the fact that

$$\sin\beta = \frac{\sigma}{x^n}$$

and

$$\lim_{\beta\to 0}\frac{\beta}{\sin\beta} = 1.$$

Also in the second inequality in the expression for I_1 we have used the estimate $-\cos(nu)\leq(2/\pi)(nu-\pi/2)$ for $u\in[0,\pi/(2n)]$. This inequality follows from the well-known estimate $\sin(x)\geq(2/\pi)x$ for $x\in[0,\pi/2]$. Namely, let $y=nu$ and consider $-\cos(y)\leq(2/\pi)(y-\pi/2)$, which is equivalent to $\cos(y)\leq(2/\pi)(\pi/2-y)$. Let $x=\pi/2-y$, then $x\in[0,\pi/2]$, $\sin(x)=\sin(\pi/2-y)=\cos(y)$ and the result follows.

Thus for $t>0$

$$\lim_{j\to\infty}\left|\int_W e^{st}\mathcal{G}_0(s)\,ds\right| = 0$$

and we are justified in evaluating the integral via residues. □

Proof of Proposition 2.2. The proof is similar to those given in Propositions 2.3 and 2.5 and relies heavily on the results of Proposition 2.5. From Theorem 3.2 we know that the poles of large modulus of $\mathcal{G}_0$ are all negative and exactly as in the proof of part 3 of Proposition 2.5 we can show that there exists a constant M so that

$$|\mathcal{G}_0(\lambda)|\leq\frac{M}{|\lambda|^{\ell/n}}$$

for all $\lambda \in \mathbb{C}_+^a$ for some $a \geq 0$ where a is chosen, by Theorem 3.2, so that $\mathcal{G}_0$ is analytic and has no zeros for $\mathrm{Re}(\lambda) > a$. Then clearly, $\mathcal{G}_0 \in H^\infty(\mathbb{C}_+^a)$ and $\mathcal{G}_0$ is strictly proper since it goes to zero as λ goes to infinity in this right half-plane.

Choosing N by Theorem 3.2 large enough so that for $n > N$ all the open-loop poles and zeros interlace and the closed-loop poles are real and simple. Then defining $h_1(t)$ and $h_2(t)$ through the expressions (cf. Proposition 2.5, part 3)

$$h_1(t) = \sum_{j=1}^{N} \mathrm{Res}_{\lambda=p_k} \left(\mathcal{G}_0(\lambda)e^{\lambda t}\right),$$

$$h_2(t) = C \sum_{j=N+1}^{\infty} |\lambda_j|^{(n-\ell-1)/n} e^{\lambda_j t}[1]$$

we have that the impulse response function is given by $h(t) = h_1(t) + h_2(t)$ with h_1 a continuous function of $t \in [0, \infty)$ and $e^{-at}h_1(t) \in L^p(0, \infty)$ for every $p \geq 1$. Also from the asymptotic distribution of the poles $\lambda_j \sim (j\pi)^n$ for large j we see that h_2 is integrable near $t = \infty$. The only real concern is whether the infinite sum is in L^1_{loc} at $t = 0$. It is obvious that this Dirichlet series is always singular at $t = 0$ but nevertheless we show that it is integrable on all of $(0, \infty)$. From the above definition of h_2 there is a constant $\widetilde{C}$ such that

$$|h_2(t)| \leq \widetilde{C} \sum_{j=N+1}^{\infty} |\lambda_j|^{(n-\ell-1)/n} e^{\lambda_j t}.$$

Thus for every $b > 0$, by Tonelli's Theorem,

$$\begin{aligned}
\int_0^b |h_2(t)|\, dt &\leq \widetilde{C} \sum_{j=N+1}^{\infty} |\lambda_j|^{(n-\ell-1)/n} \int_0^b e^{\lambda_j t}\, dt \\
&= \widetilde{C} \sum_{j=N+1}^{\infty} |\lambda_j|^{(n-\ell-1)/n} \frac{(1 - e^{\lambda_j b})}{\lambda_j} \\
&\leq \widetilde{C} \sum_{j=N+1}^{\infty} |\lambda_j|^{-(\ell+1)/n} < \infty
\end{aligned}$$

since by Assumption 2.1 $0 < \ell = m_1 - m_0 \leq (n-1)$ (recall that $0 \leq m_0 < m_1 \leq (n-1)$) and the final sum is finite from the asymptotic form of the open-loop poles.

Now we show that the map given by $y(t) = (h * u)(t)$ defines a bounded map on

$$U_a = \{f : (0, \infty) \to \mathbb{C} \,:\, \exp(-a\cdot)f(\cdot) \in L_2(0, \infty),\ a \in \mathbb{R}\}.$$

First note that

$$\begin{aligned}
\widehat{(e^{-a\cdot}y(\cdot))}(s) &= \widehat{y}(s + a) \\
&= \mathcal{G}_0(s + a)\widehat{u}(s + a) \\
&= \widehat{(e^{-a\cdot}h(\cdot))}(s)\widehat{(e^{-a\cdot}u(\cdot))}(s) \\
&= \widehat{(e^{-a\cdot}h(\cdot)) * (e^{-a\cdot}u(\cdot))}(s).
\end{aligned}$$

Hence

$$\begin{aligned} e^{-at}y(t) &= \left(e^{-a\cdot}h(\cdot)\right) * \left(e^{-a\cdot}u(\cdot)\right)(t) \\ &= \int_0^\infty e^{-a(t-s)}h(t-s)e^{-as}u(s)\,ds \\ &= e^{-at}\int_0^\infty h(t-s)u(s)\,ds \\ &= e^{-at}(h*u)(t) \end{aligned}$$

and we have $y(t) = (h*u)(t)$ and for $u \in U_a$

$$\begin{aligned} \int_0^\infty \left|e^{-at}y(t)\right|^2 dt &= \int_0^\infty \left|(e^{-a\cdot}h) * (e^{-a\cdot}u)\right|^2 dt \\ &\le \|e^{-a\cdot}h\|_1^2 \, \|e^{-a\cdot}u\|_2^2 < \infty. \qquad \square \end{aligned}$$

Proof of Proposition 2.6. Let $p = \max_{1\le j\le n}\{m_j\}$ and we seek a polynomial in the form

$$b(x) = \sum_{j=0}^{2p+1} a_j x^j.$$

For any given set of boundary operators $\{\mathcal{W}_j\}_{j=1}^n$ in (2.4) we can rewrite the operators in the form $(i = 1, \dots, n)$

$$\mathcal{W}_i(f) \equiv \sum_{j=0}^{p} \alpha_{ij} f^{(j)}(0) + \sum_{j=0}^{p} \beta_{ij} f^{(j)}(1)$$

by introducing zero coefficients as necessary.

Then the problem reduces to showing that given $2p+2$ pieces of data $\{\alpha_j,\ \beta_j\}_{j=0}^p$, we can find constants $\{a_j\}_{j=0}^{2p+1}$ such that the polynomial b satisfies

$$b^{(j)}(0) = \alpha_j, \quad b^{(j)}(1) = \beta_j, \qquad j = 0, 1, \dots, p.$$

Now since

$$b^{(k)}(x) = \sum_{j=k}^{2p+1} a_j[j(j-1)\cdots(j-k+1)]x^{(j-k)}, \qquad k = 0, 1, \dots, 2p+1,$$

we have

$$b^{(k)}(0) = a_k k!, \quad b^{(k)}(1) = \sum_{j=k}^{2p+1} a_j A_j^k, \qquad k = 0, 1, \dots, 2p+1,$$

where

$$A_j^k = \frac{j!}{(j-k)!} = j(j-1)\cdots(j-k+1), \qquad k \le j.$$

Hence

$$a_j = \frac{b^{(j)}(0)}{j!} = \frac{\alpha_j}{j!},$$

$$\beta_k = b^{(k)}(1) = \sum_{j=k}^{2p+1} a_j A_j^k = \sum_{j=k}^{p} a_j A_j^k + \sum_{j=p+1}^{2p+1} a_j A_j^k$$

$$= \sum_{j=k}^{p} \frac{\alpha_j}{j!} + \sum_{j=p+1}^{2p+1} a_j A_j^k,$$

which implies

$$\sum_{j=p+1}^{2p+1} a_j A_j^k = \beta_k - \sum_{j=k}^{p} \frac{\alpha_j}{(j-k)!} \equiv \gamma_k, \qquad k = 0, 1, \ldots, p.$$

Thus the remainder of the proof reduces to showing the solvability of the $(p+1)\times(p+1)$ linear system

$$Aa = \gamma,$$

where

$$A_{ij} = A_{p+j}^i, \qquad i = 0, 1, \ldots, p, \quad j = 1, 2, \ldots (p+1),$$

$$a = [a_{p+1}, a_{p+2}, \ldots, a_{2p+1}]^T, \qquad \gamma = [\gamma_0, \gamma_1, \ldots, \gamma_p]^T.$$

Thus we show that the determinant of A is not zero. To this end, we claim that for any integers ℓ and p, we have

$$I_{\ell,p} \equiv \det\left(\{A_{\ell+j}^i\}_{i=0,j=1}^{p-1,p}\right) = \prod_{k=1}^{p-1}(k!).$$

To establish this result we recall that $A_j^k = (j!/(j-k)!)$ so that the determinant $I_{\ell,p}$ can be written as

$$I_{\ell,p} = \begin{vmatrix} 1 & 1 & \cdots & 1 \\ (\ell+1) & (\ell+2) & \cdots & (\ell+p) \\ (\ell+1)\ell & (\ell+2)(\ell+1) & \cdots & (\ell+p)(\ell+p-1) \\ \vdots & \vdots & \ddots & \vdots \\ (\ell+1)\cdots(\ell-p+4) & (\ell+2)\cdots(\ell-p+5) & \cdots & (\ell+p)\cdots(\ell+3) \\ (\ell+1)\cdots(\ell-p+3) & (\ell+2)\cdots(\ell-p+4) & \cdots & (\ell+p)\cdots(\ell+2) \end{vmatrix}.$$

But by elementary column reduction used to reduce the first row to a 1 in the first position and zeros elsewhere and then on expanding by the first row we have

$$(p-1)! \begin{vmatrix} 1 & 1 & \cdots & 1 \\ (\ell+1) & (\ell+2) & \cdots & (\ell+p-1) \\ (\ell+1)\ell & (\ell+2)(\ell+1) & \cdots & (\ell+p)(\ell+p-1) \\ \vdots & \vdots & \ddots & \vdots \\ (\ell+1)\cdots(\ell-p+5) & (\ell+2)\cdots(\ell-p+6) & \cdots & (\ell+p-1)\cdots(\ell+3) \\ (\ell+1)\cdots(\ell-p+4) & (\ell+2)\cdots(\ell-p+5) & \cdots & (\ell+p-1)\cdots(\ell+2) \end{vmatrix}$$

and hence

$$I_{\ell,p} = (p-1)!\, I_{\ell,(p-1)}.$$

Thus by induction we have

$$I_{\ell,p} = (m-1)!(m-2)!\cdots 2!\, I_{\ell 2}.$$

Now

$$I_{\ell,2} = \begin{vmatrix} 1 & 1 \\ \ell+1 & \ell+2 \end{vmatrix} = 1 = 1!$$

and we have

$$I_{\ell,p} = \prod_{k=1}^{p-1} (k!)$$

and this completes the proof.

We note that in the case where the input occurs in the highest order, i.e., $m_1 > m_i$ for $i = 2, \ldots, n$, we may choose

$$b(x) = \frac{1}{\alpha_1 m_1!} x^{m_1}(1-x)^{m_1+1},$$

which satisfies

$$\mathcal{W}_1(b) = 1, \quad \mathcal{W}_i(b) = 0, \qquad i = 2, \ldots, n.$$

This can be checked by direct verification using the fact that

$$b^{(k)}(0) = \begin{cases} 0, & k < m_1, \\ \frac{1}{\alpha_1}, & k = m_1, \end{cases} \qquad b^{(k)}(1) = 0,\ k \le m_1. \qquad \square$$

Proof of Theorem 3.4. From the asymptotic form of the open-loop poles and zeros and the Hadamard factorization theorem, there exist integers p and q and constants C_1 and C_2 such that

$$\mathcal{N}(\lambda) = \lambda^p C_1 \prod_{n=p+1}^{\infty} \left(1 - \frac{\lambda}{z_n}\right),$$

$$\mathcal{D}(\lambda) = \lambda^q C_2 \prod_{n=q+1}^{\infty} \left(1 - \frac{\lambda}{p_n}\right),$$

where $\{z_n\}$, $\{p_n\}$ are the nonzero zeros of $\mathcal{N}(\lambda)$ and $\mathcal{D}(\lambda)$, respectively, i.e., the nonzero open-loop zeros and poles ordered so that

$$|z_n| \le |z_{n+1}|,$$

$$|p_n| \le |p_{n+1}|.$$

Now by the proof of the main theorem, every open-loop pole moves continuously to an open-loop zero as the gain parameter varies from 0 to $\pm\infty$ and z_n, p_n are real and interlace for n large. Thus there is an N and $\Lambda_N > 0$ so that for $n > N$

$$z_n < p_n < -\Lambda_N$$

and

$$\{z_n\}_{n=p+1}^{N-1} \cup \{p_n\}_{n=q+1}^{N-1} \subset B(0, \Lambda_N).$$

Now for $z_N < a < p_N$ we have

$$\arg\left(\prod_{n=N}^{\infty}(1 - a/z_n)\right) = \arg\left(\prod_{n=N+1}^{\infty}(1 - a/p_n)\right) = 0.$$

Throughout the remainder of the proof it will be assumed that all equalities related to arguments of complex numbers are congruent modulo 2π. Further we note that if $\operatorname{Im}(z_0) \neq 0$ and a is real, we have

$$\arg(1 - a/z_0) + \arg(1 - a/\overline{z_0}) = 0.$$

The return difference equation can be written as

$$k\frac{\mathcal{N}(\lambda)}{\mathcal{D}(\lambda)} = -1,$$

so that a number λ being on the root locus implies

$$\arg\left(k\frac{\mathcal{N}(\lambda)}{\mathcal{D}(\lambda)}\right) = \pi.$$

Now we have

$$\begin{aligned}
\arg\left(k\frac{\mathcal{N}(a)}{\mathcal{D}(a)}\right) &= \arg\left(ka^{p-q}\frac{C_1}{C_2}\right) + \arg\left(\prod_{n=p+1}^{\infty}(1 - a/z_n)\right) - \arg\left(\prod_{n=q+1}^{\infty}(1 - a/p_n)\right) \\
&= \arg\left(ka^{p-q}\frac{C_1}{C_2}\right) + \sum_{n=p+1}^{N-1}\arg(1 - a/z_n) + \sum_{n=q+1}^{N}\arg(1 - a/p_n) \\
&= \arg\left(ka^{p-q}\frac{C_1}{C_2}\right) + \sum_{n=p+1}^{N-1}\{\arg(a - z_n) + \arg(-z_n)\} \\
&\quad + \sum_{n=q+1}^{N}\{\arg(a - p_n) + \arg(-p_n)\} \\
&= \arg\left(ka^{p-q}\frac{C_1}{C_2}\right) + (N - 1 - p)\pi + (N - q)\pi + r\pi \\
&= \arg\left(k(-1)^r a^{p-q}\frac{C_1}{C_2}\right) + (p + q + 1)\pi,
\end{aligned}$$

where r is the number of positive zeros and poles.

By the fact that

$$z_N < a < p_N,$$

we know that a is on the root locus; hence

$$\arg\left(k(-1)^r a^{p-q}\frac{C_1}{C_2}\right) = \begin{cases} 0 & \text{if } p+q \text{ even,} \\ \pi & \text{if } p+q \text{ odd.} \end{cases}$$

Therefore, in general, for $a \in \mathbb{R}$

$$\arg\left(k(-1)^r a^{p-q}\frac{C_1}{C_2}\right) = \begin{cases} 0 & \text{if } p+q \text{ even,} \\ 0 & \text{if } p+q \text{ odd,} \qquad a > 0, \\ \pi & \text{if } p+q \text{ odd,} \qquad a < 0. \end{cases}$$

With this relation we are able to finish the proof.

Let S be the number of nonzero zeros and poles that lie on the right of $a > p_N$. Then we have

$$\begin{aligned} \arg\left(k\frac{\mathcal{N}(a)}{\mathcal{D}(a)}\right) &= \arg\left(ka^{p-q}\frac{C_1}{C_2}\right) + \sum_{n=p+1}^{N-1}\{\arg(a-z_n) + \arg(-z_n)\} \\ &\quad + \sum_{n=q+1}^{N-1}\{\arg(a-p_n) + \arg(-p_n)\} \\ &= \arg\left(ka^{p-q}\frac{C_1}{C_2}\right) + S\pi + r\pi \\ &= \arg\left(k(-1)^r a^{p-q}\frac{C_1}{C_2}\right) + S\pi. \end{aligned}$$

Thus a being on the root locus implies the following.

1. If $(p+q)$ is even, we have S odd. And if $a < 0$, then the number of zeros and poles on the right of a is $(S+p-q)$ or $(S-p+q)$ which is odd; if $a > 0$, then the number of zeros and poles is S which is odd again.

2. If $(p+q)$ is odd, we have

$$S \text{ is } \begin{cases} \text{odd} & \text{when } a > 0, \\ \text{even} & \text{when } a < 0. \end{cases}$$

Since the number of zeros and poles on the right of a is S when $a > 0$ and $(S+p-q)$ or $(S-p+q)$ when $a < 0$, we know that the number is always odd. □

6. Proof of Proposition 4.2. To establish the proposition, we introduce notation similar to that found in [26]. Namely, we let

$$x_j = \exp\left(\frac{2\pi i}{n}m_j\right), \quad y_j = \exp\left(\frac{2\pi i}{n}m_{\mu+j}\right), \qquad j = 1, \ldots, \mu$$

and

$$X(t) = \operatorname{diag}(x_1^t, \ldots, x_\mu^t),$$

$$Y(t) = \operatorname{diag}(y_1^t, \ldots, y_\mu^t),$$

$$V(x) = \left[x_i^{(j-1)}\right]_{i=1,j=1}^{\mu,\mu}, \qquad V(y) = \left[y_i^{(j-1)}\right]_{i=1,j=1}^{\mu,\mu},$$

$$E(k_1, k_2, \ldots, k_\mu) = [e_{k_1}, e_{k_2}, \ldots, e_{k_\mu}],$$

$$I_1 = [e_\mu, e_{\mu-1}, \ldots, e_1],$$

where e_{k_j} is the k_jth standard unit basis vector in $\mathbb{R}^\mu$. For μ odd, let

$$E_o = E\left(\frac{\mu-1}{2}+1, \frac{\mu-1}{2}+2, \frac{\mu-1}{2}, \frac{\mu-1}{2}+3, \ldots, \mu, 1\right),$$

$$F_o = E\left(\frac{\mu-1}{2}, \frac{\mu-1}{2}+1, \frac{\mu-1}{2}-1, \frac{\mu-1}{2}+2, \ldots, 1, \mu-1, \mu\right),$$

then we have

$$[U_1, \ldots, U_\mu] = X\left(\frac{\mu}{2}\right) V(x) E_o,$$

$$[V_{\mu+1}, \ldots, V_n] = Y\left(\frac{3\mu}{2}\right) V(y) E_o I_1,$$

$$[U_1, \ldots, U_{\mu-1}, U_{\mu+1}] = X\left(\frac{\mu}{2}+1\right) V(x) F_o,$$

$$[V_\mu, V_{\mu+2}, \ldots, V_n] = Y\left(\frac{3\mu}{2}+1\right) V(y) F_o I_1.$$

For μ even, let

$$E_e = E\left(\frac{\mu}{2}, \frac{\mu}{2}+1, \frac{\mu}{2}-1, \frac{\mu}{2}+2, \ldots, 1, \mu\right),$$

$$F_e = E\left(\frac{\mu}{2}+1, \frac{\mu}{2}+2, \frac{\mu}{2}, \frac{\mu}{2}+3, \ldots, \mu, 2, 1\right),$$

and we have

$$[U_1, \ldots, U_\mu] = X\left(\frac{\mu-1}{2}\right) V(x) I_1 E_e,$$

$$[V_{\mu+1}, \ldots, V_n] = Y\left(-\frac{\mu+1}{2}\right) V(y) I_1 E_e I_1,$$

$$[U_1, \ldots, U_{\mu-1}, U_{\mu+1}] = X\left(\frac{\mu+1}{2}\right) V(x) I_1 F_e,$$

$$[V_\mu, V_{\mu+2}, \ldots, V_n] = Y\left(-\frac{\mu-1}{2}\right) V(y) I_1 F_e I_1.$$

It is easy to establish that

$$|E_o| = \prod_{j=1}^{\frac{\mu-1}{2}} (-1)^{2j} = 1, \quad |F_o| = \prod_{j=1}^{\frac{\mu-1}{2}-1} (-1)^{2j} = 1,$$

$$|E_e| = \prod_{j=1}^{\frac{\mu}{2}-1} (-1)^{2j} = 1, \quad |F_e| = (-1)^{\mu-1} \prod_{j=1}^{\frac{\mu}{2}-1} (-1)^{2j} = -1,$$

$$|I_1| = \prod_{j=1}^{\mu-1} (-1)^j = (-1)^{\mu(\mu-1)/2}$$

which now implies that

$$D_{-1} = \begin{cases} \prod_{j=1}^{\mu} (\alpha_j \beta_j) (-1)^{\mu(\mu-1)/2} \prod_{j=1}^{\mu} \left(x_j^{\mu/2} y_j^{3\mu/2}\right) |V(x)|\, |V(y)|, & \mu \text{ odd}, \\ \prod_{j=1}^{\mu} (\alpha_j \beta_j) (-1)^{\mu(\mu-1)/2} \prod_{j=1}^{\mu} \left(x_j^{(\mu-1)/2} y_j^{-(\mu+1)/2}\right) |V(x)|\, |V(y)|, & \mu \text{ even}, \end{cases}$$

$$D_1 = \begin{cases} \prod_{j=1}^{\mu} (\alpha_j \beta_j) (-1)^{\mu(\mu-1)/2} \prod_{j=1}^{\mu} \left(x_j^{(\mu/2)+1} y_j^{(3\mu/2)+1}\right) |V(x)|\, |V(y)|, & \mu \text{ odd}, \\ \prod_{j=1}^{\mu} (\alpha_j \beta_j) (-1)^{\mu(\mu-1)/2} \prod_{j=1}^{\mu} \left(x_j^{(\mu+1)/2} y_j^{-(\mu-1)/2}\right) |V(x)|\, |V(y)|, & \mu \text{ even}, \end{cases}$$

and hence

$$\frac{D_{-1}}{D_1} = \begin{cases} \prod_{j=1}^{\mu} (x_j y_j)^{-1} = \exp\left(-\frac{2m\pi i}{n}\right), & \mu \text{ odd}, \\ \prod_{j=1}^{\mu} (x_j y_j)^{-1} = \exp\left(-\frac{2m\pi i}{n}\right), & \mu \text{ even}. \end{cases}$$

Similarly, for

$$x_0 = \exp\left(\frac{2\pi i}{n} m_0\right)$$

and

$$V^0(x) = \left[x_i^{(j-1)}\right]_{i=0,2,j=1}^{\mu,\mu},$$

we have

$$N_{-1} = \begin{cases} \alpha_0 \beta_1 \prod_{j=2}^{\mu} (\alpha_j \beta_j) (-1)^{\mu(\mu-1)/2} \\ \quad \times \prod_{j=0,2}^{\mu} \left(x_j^{\mu/2}\right) \prod_{j=1}^{\mu} \left(y_j^{3\mu/2}\right) |V^0(x)|\, |V(y)|, & \mu \text{ odd}, \\ \alpha_0 \beta_1 \prod_{j=2}^{\mu} (\alpha_j \beta_j) (-1)^{\mu(\mu-1)/2} \\ \quad \times \prod_{j=0,2}^{\mu} \left(x_j^{(\mu-1)/2}\right) \prod_{j=1}^{\mu} \left(y_j^{-(\mu+1)/2}\right) |V^0(x)|\, |V(y)|, & \mu \text{ even}, \end{cases}$$

$$N_1 = \begin{cases} \alpha_0\beta_1 \prod_{j=2}^{\mu}(\alpha_j\beta_j)(-1)^{\mu(\mu-1)/2} \\ \times \prod_{j=0,2}^{\mu}\left(x_j^{(\mu/2)+1}\right)\prod_{j=1}^{\mu}\left(y_j^{(3\mu/2)+1}\right)|V^0(x)|\,|V(y)|, & \mu \text{ odd}, \\ \alpha_0\beta_1 \prod_{j=2}^{\mu}(\alpha_j\beta_j)(-1)^{\mu(\mu-1)/2} \\ \times \prod_{j=0,2}^{\mu}\left(x_j^{(\mu+1)/2}\right)\prod_{j=1}^{\mu}\left(y_j^{-(\mu-1)/2}\right)|V^0(x)|\,|V(y)|, & \mu \text{ even}, \end{cases}$$

and hence

$$\frac{N_{-1}}{N_1} = \begin{cases} \prod_{j=0,2}^{\mu}(x_j)^{-1}\prod_{j=1}^{\mu}(y_j)^{-1} \\ \prod_{j=0,2}^{\mu}(x_j)^{-1}\prod_{j=1}^{\mu}(y_j)^{-1} \end{cases} = \begin{cases} \exp\left(-\frac{2m^0\pi i}{n}\right), & \mu \text{ odd}, \\ \exp\left(-\frac{2m^0\pi i}{n}\right), & \mu \text{ even}. \end{cases}$$

Furthermore, if we define

$$\gamma = \prod_{j=2}^{\mu}\frac{(x_j - x_0)}{(x_j - x_1)}$$

then

$$\tau = \frac{N_{-1}}{D_{-1}} = \begin{cases} \frac{\alpha_0}{\alpha_1}\frac{x_0^{\mu/2}}{x_1^{\mu/2}}\gamma = \frac{\alpha_0}{\alpha_1}\exp(-\frac{\pi i\ell}{2})\gamma, & \mu \text{ odd}, \\ \frac{\alpha_0}{\alpha_1}\frac{x_0^{(\mu-1)/2}}{x_1^{(\mu-1)/2}}\gamma = \frac{\alpha_0}{\alpha_1}\exp(-\frac{(\mu-1)\pi i\ell}{n})\gamma, & \mu \text{ even}, \end{cases} \tag{6.47}$$

$$\tau_1 = \frac{N_1}{D_1} = \begin{cases} \frac{\alpha_0}{\alpha_1}\frac{x_0^{\mu/2+1}}{x_1^{\mu/2+1}}\gamma = \frac{\alpha_0}{\alpha_1}\exp(-\frac{(\mu+2)\pi i\ell}{n})\gamma, & \mu \text{ odd}, \\ \frac{\alpha_0}{\alpha_1}\frac{x_0^{(\mu+1)/2}}{x_1^{(\mu+1)/2}}\gamma = \frac{\alpha_0}{\alpha_1}\exp(-\frac{(\mu+1)\pi i\ell}{n})\gamma, & \mu \text{ even}. \end{cases} \tag{6.48}$$

Using the facts that

$$x_j^n = y_j^n = 1, \quad \overline{x_j} = x_j^{-1}, \quad \overline{y_j} = y_j^{-1}, \qquad j = 1, \ldots, n,$$

we have

$$\overline{V(x)} = X(1-\mu)V(x)I_1, \qquad \overline{X(t)} = X(-t) = X(2\mu - t).$$

Hence

$$\overline{D_{-1}} = \begin{cases} \prod_{j=1}^{\mu}(\alpha_j\beta_j)(-1)^{\mu(\mu-1)/2}\prod_{j=1}^{\mu}\left(x_j^{1+(\mu/2)}y_j^{1+(3\mu/2)}\right)|V(x)|\,|V(y)|, \\ \prod_{j=1}^{\mu}(\alpha_j\beta_j)(-1)^{\mu(\mu-1)/2}\prod_{j=1}^{\mu}\left(x_j^{(\mu+3)/2}y_j^{(3\mu+3)/2}\right)|V(x)|\,|V(y)| \end{cases}$$

$$= \begin{cases} D_{-1}\prod_{j=1}^{\mu}(x_jy_j), & \mu \text{ odd}, \\ D_{-1}\prod_{j=1}^{\mu}(x_jy_j)^2, & \mu \text{ even}, \end{cases}$$

$$\overline{D_1} = \begin{cases} \prod_{j=1}^{\mu}(\alpha_j\beta_j)(-1)^{\mu(\mu-1)/2}\prod_{j=1}^{\mu}\left(x_j^{\mu/2}y_j^{3\mu/2}\right)|V(x)|\,|V(y)|, \\ \overline{D_{-1}}\exp\left\{-\frac{2m\pi i}{n}\right\} \end{cases}$$

$$= \begin{cases} D_1\prod_{j=1}^{\mu}(x_jy_j)^{-1} = D_{-1}, & \mu \text{ odd}, \\ D_{-1}\exp\left\{\frac{2m\pi i}{n}\right\} = D_1, & \mu \text{ even}, \end{cases}$$

and a similar computation shows

$$\overline{N_{-1}} = \begin{cases} N_{-1}\prod_{j=0,2}^{\mu}(x_j)\prod_{j=1}^{\mu}(y_j), & \mu \text{ odd}, \\ N_{-1}\prod_{j=0,2}^{\mu}(x_j)^2\prod_{j=1}^{\mu}(y_j)^2, & \mu \text{ even}, \end{cases}$$

$$\overline{N_1} = \begin{cases} N_1\prod_{j=0,2}^{\mu}(x_j^{-1})\prod_{j=1}^{\mu}(y_j^{-1}) \\ N_{-1}\exp\left\{\frac{2m^0\pi i}{n}\right\} \end{cases} = \begin{cases} N_{-1}, & \mu \text{ odd}, \\ N_1, & \mu \text{ even}. \end{cases}$$

To establish 5(b), let

$$T(z) = \frac{z - x_0}{z - x_1}.$$

Then T is a Möbius transformation with

$$T(x_0) = 0, \qquad T(x_1) = \infty.$$

Hence T maps the unit circle to a straight line L passing through the origin. Now $x_j = \exp(2\pi i m_j/n)$, $j = 1, \ldots, \mu$; therefore $T(x_j)$ is on L for each j.

Since $\arg(1 - e^{it}) = (1/2)(t - \pi)$ for $0 < t < 2\pi$,

$$\arg(T(1)) = \arg(1 - x_0) - \arg(1 - x_1) = -\frac{\pi\ell}{n}.$$

Hence by the fact that $T(x_0) = 0$,

$$\arg(T(x_j)) = \begin{cases} \pi - \frac{\pi\ell}{n}, & 2 \le j \le \ell_0 - 1, \\ -\frac{\pi\ell}{n}, & \ell_0 \le j \le \mu. \end{cases}$$

And then

$$\arg(\gamma) = (\ell_0 - 2)(\pi - \pi\ell/n) + (\mu - \ell_0 + 1)(-\pi\ell/n) = (\ell_0 - 2)\pi - (\mu - 1)(\pi\ell/n)$$

so that finally

$$\arg(\tau) = \begin{cases} \arg(\alpha_0/\alpha_1) - \frac{\pi\ell}{2} + (\ell_0 - 2)\pi - (\mu - 1)\frac{\pi\ell}{n}, \\ \arg(\alpha_0/\alpha_1) - \frac{\mu-1}{n}\pi\ell + (\ell_0 - 2)\pi - (\mu - 1)\frac{\pi\ell}{n}, \end{cases}$$

$$= \begin{cases} \arg(\alpha_0/\alpha_1) + (\ell_0 - \ell - 2)\pi + \frac{\pi\ell}{n}, & \mu \text{ odd}, \\ \arg(\alpha_0/\alpha_1) + (\ell_0 - \ell - 2)\pi + \frac{2\pi\ell}{n}, & \mu \text{ even}. \end{cases} \qquad \square$$

Acknowledgments. We thank the referees and the associate editor for very helpful and constructive advice leading to a much improved manuscript.

OPTIMAL CONTROLS OF NAVIER–STOKES EQUATIONS*

MIHIR DESAI† AND KAZUFUMI ITO†

Abstract. This paper studies optimal control problems of the fluid flow governed by the Navier–Stokes equations. Two control problems are formulated in the case of the driven cavity and flow through a channel with sudden expansion and solved successfully using a numerical optimization algorithm based on the augmented Lagrangian method. Existence and the first-order optimality condition of the optimal control are established. A convergence result on the augmented Lagrangian method for nonsmooth cost functional is obtained.

Key words. flow control, Navier–Stokes equation, augmented Lagrangian method

AMS subject classifications. 35Q10, 49B22, 49D29

1. Introduction.

Considerable progress has been made in mathematical analysis and computation of Navier–Stokes equations. However, very little attention has been given to the question of controlling the Navier–Stokes equations with the exception of experiments (e.g., Nagib, Reisenthal, and Koga [NRK]) and the problem of optimal shape design for drag minimization (e.g., Pironneau [Pi]). An abstract formulation of a control problem does exist in literature (e.g., [Li]). However (to our knowledge[1]) there has been very little effort toward mathematical formulation and computation in the context of control of physical flow situations. As a step in this direction we formulate and solve computationally the steady-state control problem for two flows that have been investigated extensively in numerical computations; i.e., the driven cavity and flow through a channel with sudden expansion. Finding a suitable cost functional that is relevant to the physics of the flow is a very important step in formulating control problems in both the driven cavity and channel flow. The control problems, which are formulated in §2, involve only one-dimensional control input acting through a part of the boundary as Drichlet boundary control. The influence of a one-parameter control input is limited (which can be seen in our numerical calculations) and thus our numerical calculations have been carried out for relatively low Reynolds number flow. Also, some of the hypotheses for our analysis can be verified only for relatively low Reynolds number flow. To improve the performance of our control law we must consider a full boundary control through a part of the boundary. Our analysis can be extended to treat such a problem and will be discussed in a forthcoming paper.

The paper is organized as follows. In §2 two optimal control problems are described. In §3 the basic theory of Navier–Stokes equation is given. In §4 the existence and first-order optimality condition for optimal control problems are established. In §5 a solution technique based on the augmented Lagrangian method is described. Convergence of the augmented Lagrangian method is obtained. Finally some of our numerical findings are reported in §6.

[1] Since this paper was submitted, there has been increasing interest in the study of control of the Navier–Stokes equations, e.g., [AT], [FS], [GHS], [DG], and the references therein.

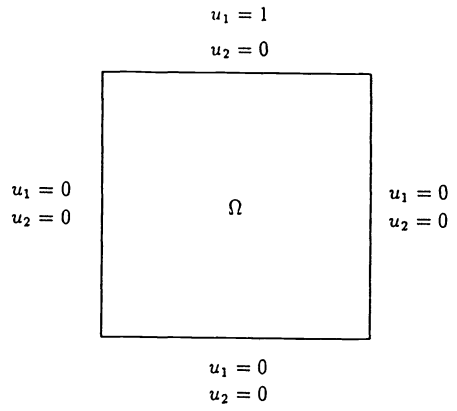

FIG. 1. *Driven cavity.*

2. Two flow problems. In this section two flow control problems will be formulated.

2.1. Driven cavity. Consider the two-dimensional motion of fluid modeled by the (stationary) Navier–Stokes equation,

$$-\nu \Delta u + (u \cdot \nabla)u + \nabla p = f \quad \text{in } \Omega \tag{2.1}$$

$$\nabla \cdot u = 0, \tag{2.2}$$

confined in a square cavity Ω, depicted in Fig. 1. Here $u = (u_1, u_2)$ is the velocity field, p the pressure, ν the kinematic viscosity of the fluid ($\nu = 1/\mathrm{Re}$, where Re is the Reynolds number), and f the density of external forces (in this example $f = 0$). The nonlinear term $(u \cdot \nabla)u$ in (2.1) (often called the convective term), is a symbolic notation for the vector

$$\left(u_1 \frac{\partial u_1}{\partial x_1} + u_2 \frac{\partial u_1}{\partial x_2}, \, u_1 \frac{\partial u_2}{\partial x_1} + u_2 \frac{\partial u_2}{\partial x_2} \right).$$

The divergence-free condition (2.2) is the equation for law of conservation of mass.

Conventionally, the problem has been treated with boundary conditions as in Fig. 1; i.e., only the top surface moving with velocity U_{top}. However we observe (numerically) that if both the top and bottom surfaces move in the same direction, the flow separates into two distinct regions as shown in Fig. 2 (where the top and bottom velocities are .5 and the viscosity $\nu = 1/50$ is used). Hence, the control problem we consider is as follows.

PROBLEM. *Given the bottom velocity U_{bot}, find the top velocity U_{top} such that the separation of flow occurs at a desired horizontal line location Γ_L.*

We cast the problem as a minimization of cost functional defined for U_{top}

$$J(U_{\text{top}}) = \int_{\Gamma_L} |u_2|^2 \, ds, \tag{2.3}$$

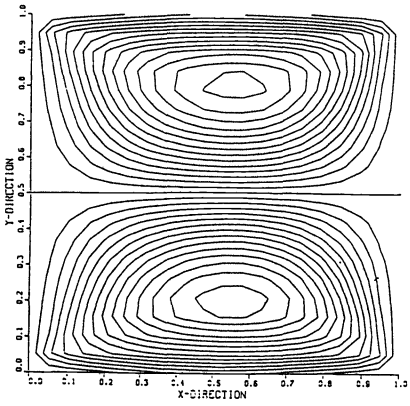

FIG. 2. *Seperation of flow in a cavity.*

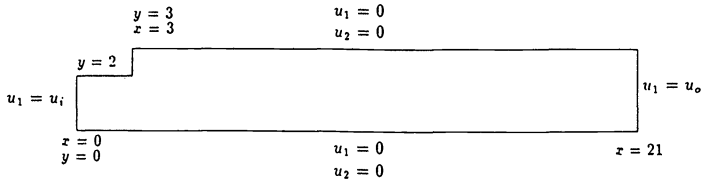

FIG. 3. *Channel with sudden expansion.*

subject to (2.1) and (2.2), where u_2 is the vertical component of the velocity field u and $u_2 = 0$ on Γ_L implies that no flow crosses the horizontal line Γ_L.

Remark 2.1. Note that the boundary condition in Fig. 1 is not in $H^{1/2}(\Gamma)$: i.e., it is not the trace of a function in $H^1(\Omega)$ on Γ. Thus, the existence theory (e.g., in [GR]; also see Theorem 3.5) cannot be applied in this case. However, we are able to show in [Di] that the Stokes equation (that is of the form (2.1), (2.2) without convective term) has a unique solution in $L^2(\Omega)^2$.

2.2. Channel flow. The second problem is a control of channel flow illustrated in Fig. 3. We assume that the inflow (at $x = 0$) and outflow (at $x = 21$) are parabolic (Poiseuille flow assumption) with $u_{\text{in}} = x_2(2 - x_2)$ and $u_{\text{out}} = cx_2(3 - x_2)$ where c is chosen such that $\int_\Gamma u \cdot n\, ds = 0$. There is a recirculation region in the corner whose size increases with the Reynolds number. Figure 4 qualitatively illustrate the flow in the corner with Re= 50. The objective is to shape the flow in the recirculation region to a desired configuration by means of controlled injection (suction) along a portion Γ of the vertical boundary facing the recirculation flow (see the shaded line in Fig. 4). The key question is then: What is a "*desirable*" *flow*? The answer to this question clearly depends on the applications in which the flow situation occurs. We consider the following two cost functionals. The first one corresponds to the total vorticity in the flow given by

$$\int_\Omega \left| \frac{\partial u_2}{\partial x_1} - \frac{\partial u_1}{\partial x_2} \right|^2 dx, \tag{2.4}$$

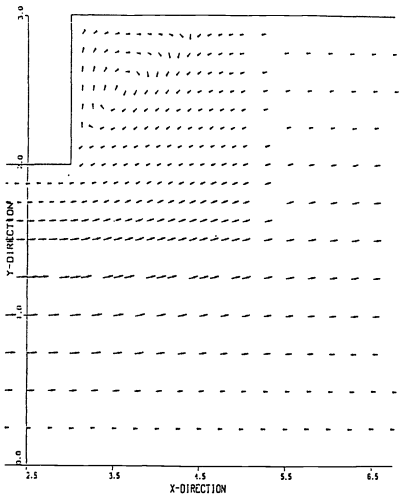

FIG. 4. *Channel flow for* Re = 20.

where the vorticity

$$\omega = \frac{\partial u_2}{\partial x_1} - \frac{\partial u_1}{\partial x_2}.$$

This cost is motivated by the fact that potential flows (zero vorticity) are frictionless and incur low energy dissipation. The second one is the "back flow" cost,

$$\int_\Omega (|\min(0, u_1)|^2 + |\min(0, u_2)|^2)\, dx, \tag{2.5}$$

which is motivated by the fact that if we do not have any recirculation, then $u_1 \geq 0$ and $u_2 \geq 0$ (i.e., fluid moving upward and to the right).

3. Basic theory for the Navier–Stokes equations. In this section we summarize the basic theory of the Navier–Stokes equation that we need for our discussions. We consider the boundary-value problems (2.1), (2.2) with the Dirichlet boundary condition $u|_\Gamma = g$ where $\int_\Gamma g \cdot n\, ds = 0$ since by Green's formula

$$\int_\Omega \nabla \cdot u\, dx = \int_\Gamma g \cdot n\, ds = 0. \tag{3.1}$$

Here n is the outward unit normal vector and it is assumed that Ω is bounded open set in R^n, $n = 2, 3$ and its boundary is at least Lipschitz continuous.

Define the function spaces and notation that will be used in what follows (our treatment and notation are along the lines presented in [GR] and [Te]):

$$V = \{u \in H_0^1(\Omega)^n \text{ with } \nabla \cdot u = 0\},$$

$$H = \{u \in L^2(\Omega)^n \text{ with } \nabla \cdot u = 0 \text{ and } u \cdot n = 0 \text{ on } \Gamma\}.$$

Let $a(u,v) : H^1(\Omega)^n \times H^1(\Omega)^n \to R$ be the symmetric sesquilinear form defined by

$$a(u,v) = \nu \int_\Omega \operatorname{grad} u \cdot \operatorname{grad} v \, dx \tag{3.2}$$

and define the bilinear form $c(u,p) : H^1(\Omega)^n \times L^2(\Omega) \to R$ by

$$c(u,p) = \int_\Omega (\nabla \cdot u) p \, dx \quad \text{for } u \in H^1(\Omega)^n \text{ and } p \in L^2(\Omega). \tag{3.3}$$

The trilinear form b on $H^1(\Omega)^n$ that corresponds to the convective term in (2.1) is defined by

$$b(u; v, w) = \int_\Omega \sum_{i,j=1}^{n} u_j \frac{\partial v_i}{\partial x_j} w_i \, dx. \tag{3.4}$$

Then the variational form for the Navier–Stokes equations (2.1), (2.2) with boundary condition $u|_\Gamma = g$ is given by

$$\begin{aligned} a(u,v) + b(u;u,v) - c(v,p) &= \langle f, v \rangle \quad \text{for all } v \in H_0^1(\Omega)^n, \\ c(u,q) &= 0 \quad \text{for all } q \in L^2(\Omega), \end{aligned} \tag{3.5}$$

where $\langle \cdot, \cdot \rangle$ denotes the dual product of $H^{-1}(\Omega)^n \times H_0^1(\Omega)^n$. Discarding the convective term in (2.1) results in the Stokes equation

$$-\nu \Delta u + \nabla p = f \quad \text{and} \quad \nabla u = 0 \tag{3.6}$$

with $u|_\Gamma = g$. Using our notation it can be written as

$$\begin{aligned} a(u,v) - c(v,p) &= \langle f, v \rangle \quad \text{for all } v \in H_0^1(\Omega)^n, \\ c(u,q) &= 0 \quad \text{for all } q \in L^2(\Omega). \end{aligned} \tag{3.7}$$

Note that (3.7) is the first-order necessary optimality condition for the following minimization problem:

$$\text{Minimize} \quad \tfrac{1}{2} a(u,u) - \langle f, u \rangle$$

$$\text{over } u \in H^1(\Omega)^n \text{ with } u|_\Gamma = g,$$

subject to $\nabla \cdot u = 0$. In fact, the Lagrangian corresponding to the constrained minimization stated above is

$$L(u,\lambda) = \tfrac{1}{2} a(u,u) - \langle f, u \rangle - c(u,\lambda),$$

where the Lagrange multiplier $\lambda \in L^2(\Omega)$ turns out to be the pressure p in (3.6). For the homogeneous boundary condition (i.e., $g = 0$) since

$$\operatorname{div} : H_0^1(\Omega) \to L_0^2(\Omega) = \left\{ \phi \in L^2(\Omega) : \int_\Omega \phi \, dx = 0 \right\}$$

is surjective, it follows from [GR] that there exists a unique solution $(u,p) \in V \times L_0^2(\Omega)$ of (3.7). Hence (3.7) is equivalently written as

$$a(u,\psi) = \langle f, \psi \rangle \quad \text{for all } \psi \in V. \tag{3.8}$$

We state the important property of the trilinear form b [GR].

LEMMA 3.1. *The trilinear form b defined by* (3.4) *is continuous on* $(H^1(\Omega)^n)^3$. *Let* $v,\ w \in H^1(\Omega)^n$ *and let* $u \in H^1(\Omega)^n$ *satisfy* $\nabla \cdot u = 0$ *and assume either* $n \cdot u|_\Gamma = 0$ *or* $w \cdot v|_\Gamma = 0$. *Then we have*

$$b(u; v, w) + b(u; w, v) = 0, \tag{3.9}$$

which implies in particular

$$b(u; v, v) = 0. \tag{3.10}$$

We now state the existence result and for the sake of completeness of our discussions we include a sketch of its proof.

THEOREM 3.2. *For* $f \in H^{-1}(\Omega)^n$ *and* $g = 0$ *there exists at least one solution* $(u, p) \in V \times L_0^2(\Omega)$ *of* (3.5).

Proof. It follows from (3.8) and [GR] that (3.5) is equivalent to an equation for $u \in V$:

$$a(u, \psi) + b(u; u, \psi) = \langle f, \psi \rangle \quad \text{for all } \psi \in V. \tag{3.11}$$

Thus, we argue the existence of solutions to (3.11). Define the map $T : V \to V$ by $z = T(u)$ where given $u \in V$, z is a unique solution to

$$a(z, \psi) + b(u; z, \psi) = \langle f, \psi \rangle \quad \text{for all } \psi \in V. \tag{3.12}$$

Existence and uniqueness of a solution to (3.12) can be shown by the Lax–Milgram theory [Yo] since the bilinear form $a(\phi, \psi) + b(u; \phi, \psi)$ defined on $V \times V$ is continuous and V-coercive by Lemma 3.1. The fixed points of T are the solutions of (3.11). Taking $\psi = z$ in (3.12) and from (3.10), we obtain $\|z\|_V \le \frac{1}{\nu} \|f\|_{V^*}$. Hence $T : C \to C$, where the set $C = \{w \in V : \|w\|_V \le \frac{1}{\nu} \|f\|_{V^*}\}$is a bounded, closed convex subset of V. Since V is a Hilbert space, every bounded set in V contains a weak convergent sequence, $u_n \to u$ in V. Since V is compactly embedded into $L^4(\Omega)^n$, the sequence converges strongly in $L^4(\Omega)^n$. However, since for $z_n = T(u_n)$ and $z = T(u)$

$$a(z_n - z, \psi) + b(u_n - u; z_n, \psi) + b(u; z_n - z, \psi) = 0 \quad \text{for all } \psi \in V,$$

and $|b(u; v, w)| \le M \|u\|_{L^4} \|v\|_{H^1} \|w\|_{H^1}$ for $u,\ v,\ w \in H^1(\Omega)^n$,

$$\nu \|z_n - z\|_V \le M \|z_n\|_V \|u_n - u\|_{L^4}.$$

Thus z_n converges strongly to z in V. Hence T is compact and therefore there exists a $u \in C$ such that $T(u) = u$ by the Shauder fixed point theorem [Is]. □

COROLLARY 3.3. *The solution* $u \in V$ *of* (3.11) *is unique provided that* $k \|f\|_{V^*} < \nu^2$ *where for a constant* $k > 0$

$$|b(u; v, w)| \le k \|u\|_V \|v\|_V \|w\|_V. \tag{3.13}$$

For the case of nonhomogeneous Dirichlet boundary conditions we need the following technical lemma due to Hopf [GR].

LEMMA 3.4. *Suppose* Ω *is a bounded open domain with Lipschtz continuous boundary. Then, given* $g \in H^{1/2}(\Gamma)^n$ *satisfying* $\int_\Gamma g \cdot n \, ds = 0$, *for any* $\varepsilon > 0$ *there exists a function* $u_\varepsilon \in H^1(\Omega)^n$ *such that* $\nabla \cdot u_\varepsilon = 0$, $u_\varepsilon|_\Gamma = g$ *and*

$$|b(\phi; u_\varepsilon, \phi)| \le \varepsilon |\phi|_V^2 \quad \textit{for all } \phi \in V. \tag{3.14}$$

Now, the nonhomogeneous boundary value problem can be transformed into the one with homogeneous boundary condition by using the transformation $u = w + u_\varepsilon$; substituting u into (3.5) we obtain the equation for $w \in V$:

$$a(w,\psi) + b(w;u_\varepsilon,\psi) + b(u_\varepsilon;w,\psi) + b(w;w,\psi) = \langle \bar{f},\ \psi\rangle \quad \text{for all } \psi \in V, \tag{3.15}$$

where $\bar{f} \in V^*$ is given by

$$\langle \bar{f},\ \psi\rangle = \langle f,\ \psi\rangle - a(u_\varepsilon,\psi) - b(u_\varepsilon;u_\varepsilon,\psi).$$

Define the sesquilinear form $\hat{a}$ on $V \times V$ by

$$\hat{a}(\phi,\psi) = a(\phi,\psi) + b(\phi;u_\varepsilon,\psi) + b(u_\varepsilon;\phi,\psi) \quad \text{for } \phi,\ \psi \in V.$$

Then, if $\varepsilon < \nu$ then $\hat{a}$ is V-coercive from (3.10) and (3.14). Thus, applying the Shauder fixed point theorem as in the proof of Theorem 3.2 to (3.15) we obtain the following result.

THEOREM 3.5. *Given $f \in H^{-1}(\Omega)$ and $g \in H^{1/2}(\Gamma)$ with $\int_\Gamma g \cdot n\, ds = 0$ there exists at least one pair $(u,p) \in H^1(\Omega)^n \times L_0^2(\Omega)$ satisfying* (3.5).

Remark. $u_\varepsilon \in H^1(\Omega)$ appearing in the Hopf's lemma is used to show the existence of a solution to the Navier–Stokes equations. However, it is not feasible to be used in computations. In our numerical calculations we use $\bar{u} \in H^1(\Omega)^n$ that satisfies the Stokes equation

$$a(\bar{u},v) - c(v,p) = 0 \quad \text{and} \quad c(\bar{u},q) = 0 \tag{3.16}$$

for all $(v,q) \in H_0^1(\Omega) \times L^2(\Omega)$ with boundary condition $\bar{u} = g$ on Γ. Note that $\bar{u}$ is unique [GR] but with $\bar{u}$, condition (3.14) is not necessarily satisfied for arbitrary $\varepsilon > 0$.

4. Existence and first-order necessary condition of optimal solutions. Two control problems described in §2 can be formulated as a constrained minimization in a Hilbert sapce using the notation of §3:

$$\begin{aligned} &\text{Minimize} && J(u) \\ &\text{subject to} && a(u,\psi) + b(u;u,\psi) = 0 \quad \text{for all } \psi \in V \\ &&& \nabla \cdot u = 0 \\ &&& u = g_0 + \sum_{i=1}^{m} f_i\, \chi_i \quad \text{on } \Gamma \\ &&& f \in U, \end{aligned} \tag{4.1}$$

where $g_0,\ \chi \in H^{1/2}(\Gamma)$ with $\int_\Gamma g \cdot n\, ds = \int_\Gamma \chi_i \cdot n\, ds = 0$ and U is a closed bounded set in R^m. We discuss the Dirichlet boundary control problem and thus the body force is discarded. The function $f \cdot \chi = \sum_{i=1}^m f_i\, \chi_i,\ f \in U$ is the control input and influences the equation only through a part of boundary Γ, and the functions χ_i represent

distribution functions of control input at Γ. The specific form of g_0 and χ $(m = 1)$ for the cavity and channel problems is as follows. For the cavity $g_0 = (U_{\text{bot}}, 0)$ at the bottom surface, zero otherwise and $\chi = (1, 0)$ at the top surface, zero otherwise. For the channel

$$g_0 = \begin{cases} x_2(2 - x_2) & \text{at } x_1 = 0, \\ c\,x_2(3 - x_2) & \text{at } x_1 = 21, \\ \text{zero} & \text{otherwise}, \end{cases}$$

and

$$\chi = \begin{cases} (x_2 - 2.375)(2.625 - x_2) & \text{at } x_1 = 3, \\ \hat{c}\,x_2(3 - x_2) & \text{at } x_1 = 21, \\ \text{zero} & \text{otherwise}, \end{cases}$$

where c, $\hat{c}$ are chosen such that $\int_\Gamma g_0 \cdot n\,ds = \int_\Gamma \chi \cdot n\,ds = 0$. As pointed out in Remark 2.1, for the driven cavity problem g_0, χ are not in $H^{1/2}(\Gamma)$. Hence in our discussion we consider the problem in which g_0 and χ are replaced by $C^\infty(\Gamma)$ function that approximates g_0 and χ in $L^\infty-$ norm, respectively.

Let $u = w + \bar{u}^{(0)} + \sum_{i=1}^m f_i\,\bar{u}^{(i)}$ with $w \in V$ where $\bar{u}^{(0)}$ and $\bar{u}^{(i)}$, $1 \le i \le m$ are the solution of the Stokes equation (3.16) with boundary condition g_0 and χ_i, $1 \le i \le m$, respectively. Let $\bar{u} = \text{col}(\bar{u}^{(1)}, \cdots, \bar{u}^{(m)})$. Then the problem (1.4) can be equivalently written as

$$\begin{aligned} &\text{Minimize} \quad J(u) \\ &\text{subject to} \quad a(w, \psi) + b(u; u, \psi) = 0 \quad \text{for all } \psi \in V, \end{aligned} \tag{4.2}$$

where $u = w + \bar{u}^{(0)} + \sum_{i=1}^m f_i\,\bar{u}^{(i)}$ and the cost functional J is minimized over $(w, f) \in V \times U$. Here not only is the boundary control problem transformed into the distributed control problem but also the control f appears directly in the cost functional J.

In our example without loss of generality we assume that $U = [-1, 1]$.

THEOREM 4.1. *The set S of solutions defined by*

$$S = \{u \in H^1(\Omega)^n : u = w + \bar{u}^{(0)} + \textstyle\sum_{i=1}^m f_i\,\bar{u}^i,\ w \in V\ f \in U \text{ and}$$

$$u \text{ satisfies } a(u, \psi) + b(u; u, \psi) = 0 \text{ for all } \psi \in V\ \},$$

is bounded in $H^1(\Omega)^n$.

Proof. Let $u^{(0)}$ and $u^{(i)}$, $1 \le i \le m$ are the Hopf's function (see Lemma 3.4) corresponding to g_0 and χ_i, $1 \le i \le m$, respectively. Then for any $f \in U$ we can write $u = w + u^{(0)} + \sum_{i=1}^m f_i\,u^{(i)}$ where $w \in V$ satisfies

$$a(w, \psi) + b(z; w, \psi) + b(w; z, \psi) + b(w; w, \psi) = -a(z, \psi) - b(z; z, \psi) \quad \text{for all } \psi \in V, \tag{4.3}$$

where $z = u^{(0)} + \sum_{i=1}^m f_i\,u^{(i)}$. It follows from Theorems 3.2 and 3.5 that there exists a solution $w \in V$ of (4.3) and taking $\psi = w$ in (4.3) and using Lemma 3.1, we obtain

$$(\nu - (m+1)\varepsilon)\|w\|_V \le \alpha\,\|z\|_{H^1} \quad \text{for some } \alpha > 0.$$

Thus, there exists a constant $\gamma > 0$ such that $\|u\|_{H^1} \leq \gamma$. □

THEOREM 4.2. *Suppose the cost functional J is weakly, sequentially lower semicontinuous. Then, the control problem* (4.2) *has at least one solution. In particular, each control problem described in* §2 *has at least one solution.*

Proof. Let (w_n, f_n) be a minimizing sequence. Since U is compact and the solution set S is bounded in $H^1(\Omega)^n$ there exists a subsequence (w_n, f_n) such that $f_n \to f^*$ in U and $w_n \to w^*$ weakly in V. Note that $(w_n, f_n) \in V \times U$ satisfies

$$a(u_n, \psi) + b(u_n; u_n, \psi) = 0 \quad \text{for all } \psi \in V$$

$$u_n = w_n + \bar{u}^{(0)} + f_n \cdot \bar{u}$$

and that $|b(w; u, \psi)| \leq M \|w\|_{L^4} \|u\|_{H^1} \|\psi\|_{H^1}$ for w, u, $\psi \in H^1(\Omega)^n$. Since $H^1(\Omega)$ is compactly embedded int $L^4(\Omega)$, $\|u_n - u^*\|_{L^4} \to 0$ and therefore it follows from (3.4) and Lemma 3.1 that $(w^*, f^*) \in S$. Hence if the cost functional $J : H^1(\Omega)^n \to R$ is weakly, sequentially lower semicontinuos, then (w^*, f^*) minimizes J. It is not difficult to show that each cost functional J is weakly, sequentially lower semicontinuous. In fact, for (2.3) the claim follows from the fact that the trace operator of $H^1(\Omega)$ on Γ_L is compact in $L^2(\Gamma_L)$. The cost functional (2.4) is the square of a norm on $H^1(\Omega)^2$. For (2.5) note that the cost functional is continuous on $L^2(\Omega)^2$. Hence each control problem has at least one solution. □

Remark. It is not difficult to extend Theorems 4.1 and 4.2 to the case when the control input g belongs to a compact subset of $H^{1/2}(\Gamma)^n$.

Next we discuss the first-order necessary optimality condition. Assume that $u^* = (w^*, f^*) \in V \times U$ is a local solution of (4.2) and that $f^* \in \text{int}(U)$. Let $G : V \times U \to V^*$ be defined by

$$\langle G(w, f), \psi \rangle = a(w, \psi) + b(u; u, \psi) \quad \text{for } \psi \in V$$

where $u = w + \bar{u}^{(0)} + \sum_{i=1}^m f_i \bar{u}^{(i)}$. In what follows we identify u with the pair (w, f) whenever $u = w + \bar{u}^{(0)} + \sum_{i=1}^m f_i \bar{u}^{(i)}$. It follows from [MZ] that if the Fréchet derivative of G at (w^*, f^*) is surjective, then the regular point condition is satisfied and hence there exists a Lagrange multiplier $\lambda \in V$ such that

$$J'(u^*)(v + h \cdot \bar{u}) + \langle G'(u^*)(v, h), \lambda \rangle = 0 \quad \text{for all } (v, h) \in V \times R^m.$$

LEMMA 4.3. *$G'(u^*)$ is given by*

$$\begin{aligned} \langle G'(u^*)(v, h), \psi \rangle = {} & a(v, \psi) + b(v; u^*, \psi) + b(u^*; v, \psi) \\ & + h \cdot (b(\bar{u}; u^*, \psi) + b(u^*, \bar{u}, \psi)) \quad \textit{for } \psi \in V \end{aligned} \tag{4.6}$$

and $G'(u^*)$ is surjective if and only if the equation for $\psi \in V$

$$a(v, \psi) + b(v, u^*, \psi) + b(u^*; v, \psi) = 0 \quad \textit{for all } v \in V \tag{4.7}$$

$$b(\bar{u}^{(i)}; u^*, \psi) + b(u^*; \bar{u}^{(i)}, \psi) = 0 \quad \textit{for all } 1 \leq i \leq m \tag{4.8}$$

implies $\psi = 0$.

Proof. It is easy to show that the Fréchet derivative G at (w^*, f^*) is given by (4.6). It thus follows from (4.6) that (4.7), (4.8) are equivalent to the fact that

$\ker(G'(u^*)^*) = \{0\}$. Note that $G'(u^*)$ is surjective if and only if there exists a $(v, h) \in V \times R^m$ such that

$$v + Cv + Bh = T_0 f \quad \text{for arbitrary } f \in V^*, \tag{4.9}$$

where $T_0 f = (-\nu \Delta_S)^{-1} f$, $f \in V^*$ is the unique solution to the Stokes equation (3.8), the linear operator $C : V \to V$, defined by $Cv = T_0((v \cdot \nabla)u^* + (u^* \cdot \nabla)v)$, and the linear operator $B : R^m \to V$ is defined by $Bh = h \cdot T_0((\bar{u} \cdot \nabla)u^* + (u^* \cdot \nabla)\bar{u})$. Then since $H^1(\Omega)$ is embedded compactly into $L^4(\Omega)$, C is compact. Since B is of finite rank, V admits the orthogonal decomposition $V = \text{range}(B) \oplus \ker(B^*)$. Let Q be the orthogonal projection onto $\ker(B^*)$. Then (4.9) is equivalent to

$$v + QCv = QT_0 f \quad v \in \ker(B^*).$$

Since QC is compact it follows from the Riesz–Schauder theory [Yo] that $\text{range}(I + QC)$ on $\ker(B^*)$ is closed, which implies that $\text{range}(T_0 G'(u^*))$ is closed. Since $T_0 : V^* \to V$ is isometric isomorphism it follows from the Banach closed range theory [Yo] that $G'(u^*)$ is surjective if and only if $\ker(G'(u^*)^*) = \{0\}$. □

Remark. Lemma 4.3 implies that if the only solution of $v + Cv = 0$ is the zero solution (i.e., -1 is not an eigenvalue of C) then the surjectivity of $G'(u^*)$ is satisfied. Such a case occurs when u^* satisfies

$$|b(\phi; u^*, \phi)| < \nu \|\phi\|_V^2. \tag{4.10}$$

This inequality is, for example, satisfied when ν is sufficiently large since from Theorem 4.1 $\|u^*\|_{H^1(\Omega)^n}$ is uniformly bounded in $\nu \geq \nu_0 > 0$. Moreover, if C has the eigenvalue -1 with multiplicity less than $m + 1$, then the assumption of Lemma 4.3 still holds when (4.8) has only trivial solution on the eigenmanifold corresponding to the eigenvalue -1 of C.

Under the condition in Lemma 4.3 we obtain the first-order necessary condition for optimality:

$$a(u^*, \psi) + b(u^*; u^*, \psi) = 0 \quad \text{for all } \psi \in V, \tag{4.11a}$$

$$a(\lambda, \phi) + b(u^*; \lambda, \phi) + b(\lambda; u^*, \phi) + J'(u^*)(\phi) = 0 \quad \text{for all } \phi \in V, \tag{4.11b}$$

$$b(u^*; \lambda, \bar{u}^{(i)}) + b(\lambda; u^*, \bar{u}^{(i)}) + J'(u^*)(\bar{u}^{(i)}) = 0 \quad \text{for } 1 \leq i \leq m. \tag{4.11c}$$

5. Augmented Lagrangian method and convergence analysis. We solve the constrained minimization problem (4.2) (or equivalently (4.1)) using the augmented Lagragian method [He], [Po]. In our approach the divergence free constraint is imposed explicitly (without augmentation) but the Navier–Stokes constraint $G(w, f) = 0$ in V^* will be treated by the augmented Lagrangian method. We consider the augmented Lagrange functional

$$L_c(u, \lambda) = J(u) + \langle \lambda, G(w, f) \rangle_{V, V^*} + \frac{c}{2} a(z, z) \tag{5.1}$$

where $z \in V$ satisfies

$$a(z, \psi) = a(u, \psi) + b(u; u, \psi) \quad \text{for all } \psi \in V. \tag{5.2}$$

Note that $a(z, z)$ represents the square of the norm $\|G(w, f)\|_{V^*}$. Then, the augmented Lagrangian method applied to (4.2) is the following iterative scheme.

AUGMENTED LAGRANGIAN METHOD

Step 1. Choose the starting $\lambda_0 \in V$, a nondecreasing sequence of positive numbers c_k and set $k = 0$.

Step 2. Given λ_k, c_k find $u_k = (w_k, f_k) \in V \times U$ by

$$L_{c_k}(u_k, \lambda_k) = \min\ L_{c_k}(u, \lambda_k) \quad \text{over } (w, f) \in V \times U.$$

Step 3. Update λ_k by $\lambda_{k+1} = \lambda_k + c_k z_k$ where $z_k \in V$ satisfies

$$a(z_k, \psi) = \langle G(w_k, f_k), \psi \rangle \quad \text{for all } \psi \in V. \tag{5.3}$$

Step 4. If convergence criterion is not satisfied then $k = k + 1$ and go to Step 2.

Let $u^* = (w^*, f^*)$ be a local solution of (4.2). Assume that the assumption in Lemma 4.3 is satisfied. Then there exists a Lagrange multiplier $\lambda^* \in V$ such that (4.5) holds, where J is assumed to be continuously Fréchet differentiable in a neighborhood of u^*. Augmentabilty defined as below is of central importance in showing the convergence of the augmented Lagrangian method [He], [IK1].

DEFINITION. *The problem* (4.2) *is augmentable at* u^* *if there exist a neighborhood* $\tilde{U}(u^*)$ *of* (w^*, f^*) *in* $V \times U$ *and positive constants* $\bar{\sigma}$, $\bar{c}$ *such that*

$$L_c(u, \lambda^*) - L_c(u^*, \lambda^*) \geq \bar{\sigma}\,(\|w - w^*\|_V^2 + |f - f^*|^2) \tag{5.4}$$

for all $(w, f) \in \tilde{U}$ *and* $c \geq \bar{c}$.

Then the following theorem follows from [IK1], [IK2].

THEOREM 5.1. *Assume that the augmentability* (5.4) *holds. Given* $\lambda_0 \in V$ *for each* k *assume that* (w_k, f_k) *in the neighborhood* $\tilde{U}$ *satisfies*

$$L_c(u_k, \lambda_k) \leq L_c(u^*, \lambda_k) = J(u^*) \tag{5.5}$$

and update $\lambda_{k+1} = \lambda_k + (c_k - \bar{c})\, z_k$ *with* z_k *satisfying* (5.3). *Then we have*

(1) $$\bar{\sigma}\,(\|w_k - w^*\|_V^2 + |f_k - f^*|^2) + (c_k - \bar{c})\,\|\lambda_k - \lambda^*\|_V^2 \leq (c_k - \bar{c})\,\|\lambda_{k-1} - \lambda^*\|_V^2,$$

(2) $$\bar{\sigma} \sum_{k-1}^{\infty} (\|w_k - w^*\|_V^2 + |f_k - f^*|^2) \leq \frac{1}{c_0 - \bar{c}}\,\|\lambda_0 - \lambda^*\|_V^2.$$

Remark. (i) The condition (w_k, f_k) being in the neighborhood of u^* can be satisfied either by taking c_0 sufficiently large or λ_0 sufficiently close to λ^*.

(ii) The statement (2) implies the strong convergence of u_k to u^* in $H^1(\Omega)^n$.

(ii) The condition (5.5) means the sufficient reduction of successive cost functional.

Next we discuss a sufficient condition for the augmentability of (4.2). Let L be the Lagrangian corresponding to (4.2) defined by

$$L(u, \lambda) = J(u) + \langle \lambda, G(w, f) \rangle.$$

Suppose $J : H^1(\Omega) \to R$ is twice continuously differentiable in a neighborhood of u^*. The second derivative of $L(u, \lambda^*)$ at $u^* = (w^*, f^*)$ is given by

$$L''(u^*, \lambda^*)((v, h), (v, h)) = J''(u^*)(\xi, \xi) + b(\xi; \xi, \lambda^*), \tag{5.6}$$

where $\xi = v + h \cdot \bar{u}$. Then it follows from [IK1] that the augmentability (5.4) is achieved if the following second-order sufficient optimality condition is satisfied.

$$
\begin{aligned}
&L''(u^*, \lambda^*)((v,h),(v,h)) \geq \sigma\,(\|v\|_V^2 + |h|^2) \\
&\text{for all } (v,h) \in V \times R^m \text{ satisfying } G'(u^*)(v,h) = 0,
\end{aligned}
\tag{5.7}
$$

where $\sigma > 0$. Moreover, it follows from [PT], [IK1] that $(u_k, \lambda_k) \in H^1(\Omega)^n \times V$ converges q-linearly to (u^*, λ^*); i.e.,

$$
\|\lambda_n - \lambda^*\|_V \leq \frac{K^n}{c_0 \cdots c_{n-1}} \|\lambda_0 - \lambda\|_V,
$$

$$
\|u_n - u^*\|_{H^1(\Omega)^n} \leq \frac{K^n}{c_0 \cdots c_{n-1}} \|\lambda_0 - \lambda\|_V
$$

for $n \geq 1$ and some constant K, provided that c_0 is sufficiently large or λ_0 sufficiently close to λ^*.

The following lemma gives an algebraic characterization of the second order sufficient optimality (5.7).

LEMMA 5.2. *Assume that for each i equation for V*

$$
a(v,\psi)+b(v;u^*,\psi)+b(u^*;v,\psi) = -b(u^*;\bar{u}^{(i)},\psi)-b(\bar{u}^{(i)};u^*,\psi)) \quad \text{for all } \psi \in V \tag{5.8}
$$

has a unique solution $v_i \in V$ Then the condition (5.7) *is satisfied if and only if the matrix M on R^m, defined by*

$$
M_{i,j} = J''(u^*)(\phi_i, \phi_j) + b(\phi_i; \phi_j, \lambda^*) \quad \text{with } \phi_i = v_i + \bar{u}^{(i)} \tag{5.9}
$$

is positive definite; i.e., $h^t M h \geq \alpha\,|h|^2$ for all $h \in R^m$ and some $\alpha > 0$.

Proof. Suppose $(v,h) \in V \times R^m$ satisfies $G'(u^*)(v,h) = 0$. Since for each i (5.8) has a unique solution v_i it thus follows from (4.6) and (5.8) that $v = \sum_{i=1}^m h_i v_i$ and therefore $\xi = \sum_{i=1}^m h_i(v_i + \bar{u}^{(i)})$ in (5.6). Then from (5.6) and (5.9) we have

$$
L''(u^*)((v,h),(v,h)) = h^t M h \quad \text{for } (v,h) \in \ker\,(G'(u^*)).
$$

Since $\|v\|_V \leq |h| \sqrt{\sum_{i=0}^m \|v_i\|_V^2}$ the positivity of the matrix M defined by (5.9) is equivalent to (5.7). □

COROLLARY 5.3. *Suppose the matrix $\bar{M}$ on R^m, defined by $\bar{M}_{i,j} = J''(\bar{u}^{(i)}, \bar{u}^{(j)})$, is positive definite. Then, if ν is sufficiently large then* (5.8) *has a unique solution and* (5.9) *holds.*

Proof. It follows from (3.16) and Theorem 4.1 that $\|u^*\|_{H^1(\Omega)^n}$, $\|\bar{u}^{(i)}\|_{H^1(\Omega)^n}$, $1 \leq i \leq m$ are uniformly bounded. Thus, if ν is sufficiently large then (4.10) holds and hence (5.8) has a unique solution $v_i \in V$ for each i. It follows from (4.11b) and (5.8) that

$$
\|v_i\|_V \leq \frac{M_1}{\nu} \|u^*\| \|\bar{u}^{(i)}\| \quad \text{and} \quad \|\lambda^*\|_V \leq \frac{M_2}{\nu} \|J'(u^*)\|_{V^*}
$$

for some constants M_1, M_2. Thus, from Lemma 3.1 and (5.9) if the matrix $\bar{M}$ is positive definite then the matrix M is positive definite provided that ν is sufficiently large. Hence, the corollary follows from Lemma 5.2. □

Note that the cost functional (2.5) is not twice Fréchet differentiable. Motivated by this example we consider the following minimization problem in a Hilbert space X:

$$\text{Minimize } f(x) \text{ subject to } g(x) = 0,$$

where $g : X \to Y$ and y is a Hilbert space. Assume the following standard hypotheses:

(H1) $x^* \in X$ is a local solution;

(H2) g is twice continuously F-differentiable and f is (only) continuously $F-$ differentiable in a convex neighborhood of x^*;

(H3) $g'(x^*) : X \to Y$ is surjective.

Then there exists a unique Lagrange multiplier $\lambda^* \in Y^*$ such that

$$f'(x^*)(h) + \langle \lambda^*, g'(x^*)(h) \rangle = 0 \quad \text{for all } h \in X. \tag{5.10}$$

Define the functional F_t defined on $X \times X$ for $t > 0$ by

$$F_t(x)(h,h) = \frac{1}{t^2}\,(f(x + t\,h) - f(x) - t\,f'(x)h). \tag{5.11}$$

We make the following hypotheses on F_t:

(H4) There exists $\delta > 0$ and $0 < c_1 < 1 < c_2$ such that for $h = h_1 + h_2,\ h_1,\ h_2 \in X$ and $0 < t < \delta$

$$F_t(x^*)(h,h) \geq c_1\, F_t(x^*)(h_1,h_1) - c_2\, \|h_2\|_X^2.$$

(H5) There exists a $\sigma > 0$ such that

$$c_1\, F_t(x^*)(h,h) + \tfrac{1}{2}\,\langle \lambda^*, g''(h,h) \rangle \geq \sigma\, \|h\|_X^2$$

for all $h \in X$ satisfying $g'(x^*)h = 0$ and t sufficiently small.

Remark. If is f is twice differentiable the hypothesis (H5) reduces to the second sufficient optimality condition (5.7). Moreover, assuming $f''(x^*)$ is nonnegative definite then (H4) holds with $c_1 = 1/2$ and $c_2 = \|f''(x^*)\|$.

We have the following result.

THEOREM 5.4. *Assuming* (H1)–(H5), *we have the augmentability*; *i.e., there exists a neighborhood* $\tilde{U}(x^*)$ *and* $\bar{\sigma},\ \bar{c} > 0$ *such that*

$$L_c(x, \lambda^*) - L_c(x^*, \lambda^*) \geq \bar{\sigma}\, \|x - x^*\|_X^2$$

for all $x \in \tilde{U}(x^*)$ *and* $c \geq \bar{c}$ *where for* $c \geq 0$ *and* $\lambda \in Y^*$

$$L_c(x, \lambda) = f(x) + \langle \lambda,\, g(x) \rangle_{Y^*,Y} + \tfrac{1}{2}\, \|g(x)\|_Y^2.$$

Proof. For each $h \in X$ with $\|h\| = 1$ we have

$$\begin{aligned} L_c(x + t\,h, \lambda^*) - L_c(x^*, \lambda^*) &= t\,(f'(x^*)h + \langle \lambda^*,\, g'(x^*)h\rangle) \\ &\quad + t^2\,(F_t(x^*)(h,h) + \frac{1}{2}\,\langle \lambda^*,\, g''(x^*)(h,h)\rangle) \\ &\quad + \frac{1}{2}t^2\,\langle \lambda^*,\, g''(\zeta(t))(h,h) - g''(x^*)(h,h)\rangle) \\ &\quad + \frac{c}{2}t^2\,\|g'(x^*)h + \frac{t}{2}\,g''(\zeta(t))(h,h)\|_Y^2, \end{aligned}$$

where $\zeta(t) = x^* + \hat{t}\,h$, $\hat{t} \in (0,t)$ (which depends upon $(t,h) \in R \times X$). Since $g'(x^*) : X \to Y$ is surjective there exists a constant $\beta > 0$ such that

$$\|g'(x^*)h\|_Y^2 \geq \beta\,\|h\|_X^2 \tag{5.12}$$

for $h \in \text{range}(g'(x^*)^*)$ where by the closed range theory [Yo] we have

$$X = \text{range}(g'(x^*)^*) \oplus \ker(g'(x^*)).$$

Thus, for each $h \in X$ we have a unique representation $h = h_1 + h_2$, $h_1 \in \ker(g'(x^*))$ and $h_2 \in \text{range}(g'(x^*)^*)$. It then follows from (5.10) – (5.12) and (H4) that for $x = x^* + t\,h$

$$\begin{aligned} I &= \frac{1}{t^2}\,(L_c(x, \lambda^*) - L_c(x^*, \lambda^*)) \\ &\geq c_1\,F_t(x^*)(h_1,h_1) + \frac{1}{2}\,\langle \lambda^*, g''(x^*)(h_1,h_1)\rangle + \left(\frac{c\beta}{4} - c_2\right)\beta\,\|h_2\|^2 \\ &\quad + \langle \lambda^*, g''(x^*)(h_1,h_2)\rangle + \frac{1}{2}\,\langle \lambda^*, g''(x^*)(h_2,h_2)\rangle - Mt(1+ct) \end{aligned}$$

for some $M > 0$, where we used the fact that g'' is Lipschitz continuous in a neighborhood of x^*. It then follows from (H5) that

$$\begin{aligned} I &\geq \sigma\,\|h_1\|^2 + \left(\frac{c\beta}{4} - c_2\right)\,\|h_2\|^2 - Mt(1+ct) - \frac{\varepsilon}{2}\,\|h_1\|^2 \\ &\quad - \frac{1}{2}\left(1 + \frac{\|\lambda^*\|\,\|g''(x^*)\|}{\varepsilon}\right)\,\|\lambda^*\|\,\|g''(x^*)\|\,\|h_2\|^2, \end{aligned}$$

for all $\varepsilon > 0$. Thus, for $t > 0$ sufficiently small (say, $0 < t < \delta$) we can choose $\bar{c} > 0$ such that

$$I \geq \bar{\sigma}\,\|h\|_X^2 \quad \text{with } \bar{\sigma} = \frac{\sigma}{2},$$

for all $c \geq \bar{c}$ and $h \in X$ satisfying $\|h\| = 1$ which completes the proof. □

Now we apply Theorems 5.1 and 5.4 to the control problem (2.5). An elementary calculation in [Di] shows that the function defined by

$$f_t(x,k) = \tfrac{1}{2}\,(|\min(0, x + tk)|^2 - |\min(0,x)|^2) - tk\,\min(0,x)$$

for $x,\ k \in R$, satisfies

$$f_t(x, k_1 + k_2) \geq \tfrac{1}{2} f_t(x, k_1) - t^2 |k_2|^2 \tag{5.14}$$

for $k_1,\ k_2 \in R$. Note that for the control problem (2.5), F_t defined by (5.11) is given by

$$F_t(u^*)(h,h) = \frac{1}{t^2} \int_\Omega (f_t(u_1^*(x), h_1(x)) + f_t(u_2^*(x), h_2(x)))\, dx, \tag{5.15}$$

where $u^* = (u_1^*, u_2^*)$ and $h = (h_1, h_2) \in L^2(\Omega)^2$. It thus follows from (5.14) and the dominated convergence theorem that

$$F_t(u^*)(\xi,\xi) \geq \tfrac{1}{2} F_t(\xi^{(1)}, \xi^{(1)}) - \|\xi^{(2)}\|_{L^2}^2, \tag{5.16}$$

where $h = v + k\bar{u}^{(1)}$, $(v,k) \in V \times R$ and $\xi = \xi^{(1)} + \xi^{(2)} \in H^1(\Omega)^2$. Assume henceforth that (5.8) has a unique solution $v_1 \in V$. Then, as argued in the proof of Lemma 5.2, the hypothesis (H5) is equivalent to the following condition:

$$F_t(u^*)(\phi,\phi) + b(\phi;\phi,\lambda^*) > 0,$$

where $\phi = v_1 + \bar{u}^{(1)}$, for the control (2.5). Let $\Omega^* = \{x \in \Omega : u_1^*(x) \leq 0$ and $u_2^*(x) \leq 0\}$. Then it follows from (5.14), (5.15) that

$$F_t(u^*)(\phi,\phi) \geq \frac{1}{t^2} \int_{\Omega^*} (f_t(u_1^*(x), h_1(x)) + f_t(u_2^*(x), h_2(x)))\, dx, \tag{5.17}$$

since the right-hand side of (5.17) is monotonically nonincreasing in t. Thus, assuming

$$\frac{1}{t^2} \int_{\Omega^*} (f_t(u_1^*(x), h_1(x)) + f_t(u_2^*(x), h_2(x)))\, dx$$

is positive for some $t > 0$, it can be shown as in the proof of Corollary 5.3 that for ν sufficiently large (5.16) holds. Hence Theorems 5.1 and 5.4 apply to the control problem (2.5).

6. Numerical results. In this section we discuss numerical solution of the optimal control problems formulated in §2. The solution to (4.2) (equivalently (4.1)) is determined using the augmented Lagrangian method described in §5. The method involves the successive minimization of the cost functional of form

$$L_c(u,\lambda) = J(u) + a(u,\lambda) + b(u;u,\lambda) + \frac{c}{2} a(z,z) \tag{6.1}$$

over $(w,f) \in V \times U$ where $c > 0$ and $\lambda \in V$ are given, $u = w + \bar{u}^{(0)} + h \cdot \bar{u}$ and $z \in v$ satisfies (5.2). We use the projected conjugate gradient method (e.g., see [Gl]) to solve the constrained (i.e., $w \in V$ involves the divergence free condition $\nabla \cdot w = 0$) minimization problem (6.1).

PROJECTED CONJUGATE GRADIENT METHOD

Step 1. Choose the start-up $(w_0, f_0) \in V \times R^m$ and set $k = 0$.

Step 2. Compute the gradient $(g_k, r_k) \in V^* \times R^m$ by

$$\langle g_k, \psi \rangle_{V^*,V} = J'(u_k)(\psi) + a(\psi, \tilde{\lambda}) + b(\psi; u_k, \tilde{\lambda}) + b(u_k; \psi, \tilde{\lambda}) \quad \text{for all } \psi \in V$$

$$r_k = b(u_k; \bar{u}, \tilde{\lambda}) + b(u_k; \bar{u}, \tilde{\lambda}),$$

where $\tilde{\lambda} = \lambda + c\, z_k$ and $z_k \in V$ satisfies (5.3).

Step 3. The gradient $g_k \in V^*$ is projected onto V by the Stokes projection [Gl]; i.e., the projection $h_k \in V$ of g_k is given by

$$a(h_k, \psi) = \langle g_k, \psi \rangle \quad \text{for all } \psi \in V. \tag{6.2}$$

Set $d_k = (h_k, r_k) \in V \times R^m$ as the search direction.

Step 4. Set $\eta_k = h_k + r_k \cdot \bar{u}$. Compute $a_k = \text{Argmin } L_c(u_k - \alpha\, \eta_k, \lambda)$ over $\alpha > 0$ (line search) and set

$$w_{k+1} = w_k - \alpha_k\, h_k,$$

$$f_{k+1} = f_k - \alpha_k\, r_k.$$

Step 5. Find gradients $(h_{k+1}, r_{k+1}) \in V \times R^m$ as in Step 2, 3 and compute

$$\beta_k = \frac{a(h_k, h_k) + |r_k|^2}{a(h_{k+1}, h_{k+1}) + |r_{k+1}|^2}$$

and set the search direction as

$$d_{k+1} = \begin{pmatrix} h_{k+1} \\ r_{k+1} \end{pmatrix} + \beta_k\, d_k.$$

Step 6. If the convergence criterion is not satisfied, then set $k = k + 1$ and go to Step 4.

Remark. Note that for $\alpha > 0$ if $z(\alpha) \in V$ satisfies

$$a(z(\alpha), \psi) = a(u(\alpha), \psi) + b(u(\alpha); u(\alpha), \psi) \quad \text{for all } \psi \in V$$

with $u(\alpha) = u_k - \alpha \eta_k$, then $z(\alpha)$ can be written as

$$z(\alpha) = z_k + \alpha\, z_k^{(1)} + \alpha^2\, z_k^{(2)},$$

where $z_k^{(1)}$, $z_k^{(2)} \in V$ satisfy

$$a(z_k^{(1)}, \psi) = -a(\eta_k, \psi) - b(\eta_k; u_k, \psi) - b(u_k; \eta_k, \psi) \tag{6.3}$$

$$a(z_k^{(2)}, \psi) = b(\eta_k; \eta_k, \psi) \tag{6.4}$$

for all $\psi \in V$. Thus, $L_c(u_k - \alpha\, \eta_k, \lambda)$ is the polynomial of degree four in α and one can carry out the line search in Step 4 exactly provided that J is quadratic in u. Moreover, once the value of α_k in Step 4 is determined, then $z_{k+1} \in V$ is given by

$$z_{k+1} = z_k + \alpha_k\, z_k^{(1)} + \alpha_k^2\, z_k^{(2)}.$$

Hence our algorithm is reduced to solving a series of Stokes problem. Each inner iteration of the augmented Lagrangian algorithm (Step 2) requires solution of three Stokes problems; two (i.e., (6.3), (6,4)) in the line search and one ((6.2)) for the projection of the gradient onto V.

To carry out the computation we discretized the problem using the mixed finite element method [GR], [Te]. In our calculations the quadrilateral element for the

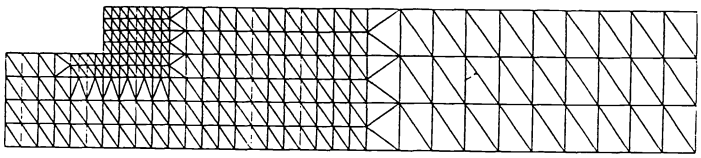

FIG. 5. *The triangulation for the channel*

velocity and the bilinear element for the pressure defined on the uniform rectangular grid with meshsize $h = .1$, are used in the cavity problem. The piecewise quadratic element for the velocity and the linear element for the pressure over the triangular grid shown Fig. 5 are used for the channel flow.

Let $\{\phi_h^i\}$, $\{\chi_h^i\}$ be the linearly independent basis functions of $H_h \subset H^1(\Omega)^2$ and $Q_h \subset L^2(\Omega)$ for velocity and pressure, respectively. Then, for example, the discretization of the Stokes equation (3.6) is given by

$$\begin{aligned} &a(u_h, \psi_h) - c(\psi_h, p_h) = \langle f, \psi_h \rangle \quad \text{for all } \psi_h \in H_h^0 \\ &c(u_h, \chi_h) = 0 \quad \text{for all } \chi_h \in Q_h \end{aligned} \tag{6.5}$$

where $u_h = \sum u_h^i \phi_h^i \in H_h$, $p_h = \sum p_h^i \chi_h^i \in Q_h$ and H_h^0 is the subspace of H_h that consists of all functions ψ_h in H_h satisfying $\psi_h \in H_0^1(\Omega)^2$. The solution $(u_h, p_h) \in H_h \times Q_h$ of (6.5) can be obtained by solving the following system of linear equations:

$$\begin{aligned} &A_h x + B_h^t y = f_h, \\ &B_h x = c_h \end{aligned} \tag{6.6}$$

where the (i,j)th element of the square matrix A_h is given by $a(\psi_h^i, \psi_h^j)$, ψ_h^i, $\psi_h^j \in H_h^0$ and the one of B_h is given by $c(\psi_h^i, \chi_h^j)$, $\chi_h^j \in Q_h$. We refer to [Di] for the detailed discussion of the discretization procedure and solution techniques for (6.6).

We now present numerical results for the control problems. For the problem (2.3) we take the Reynolds number to be 50 ($\nu = 1/50$) and Γ_L to be the horizontal line 0.4 units from the bottom. Given the bottom velocity as 0.5 we obtain the top velocity $U_{\text{top}}^{\text{opt}} = 1.16$ after four iterations of the augmented Lagrangian method with the value of c's equal to 20. The resulting flow field is shown in Fig. 6.

For the channel flow problem with Reynolds number 20 ($\nu = 1/20$) we obtain the following results. For the vorticity cost (2.4), using $c_k = 20$ in Step 2, the optimal control $f^{\text{opt}} = -.77$ (suction) and the optimal cost functional 23.13 are attained after five updates of the Lagrange multiplier. The resulting flow field is shown in Fig. 7. For the back flow cost (2.5), using $c_k = 0.05$ the optimal control $f^{\text{opt}} = 0.11$ (injection) is obtained and the optimal field flow is shown in Fig. 8. It must be noted, however, that a larger injection than f^{opt} decreases the size of the "bubble," but the strength (velocity of recirculation) is higher.

We also simulate the flow corresponding to the optimal control input using the ADI scheme (e.g., see [Gl]) with a finer discretization. Such simulations are in good agreement with the resulting flows we obtain in all three problems.

NECESSARY CONDITIONS FOR OPTIMAL CONTROL OF STOCHASTIC SYSTEMS WITH RANDOM JUMPS*

SHANJIAN TANG† AND XUNJING LI†

Abstract. A maximum principle is proved for optimal controls of stochastic systems with random jumps. The control is allowed to enter into both diffusion and jump terms. The form of the maximum principle turns out to be quite different from the one corresponding to the pure diffusion system (the word "pure" here means the absence of the jump term). In calculating the first-order coefficient for the cost variation, only a property for Lebesgue integrals of scalar-valued functions in the real number space $\mathcal{R}$ is used. This shows that there is no essential difference between deterministic and stochastic systems as far as the derivation of maximum principles is concerned.

Key words. maximum principle, optimal stochastic control, Poisson point process, Lebesgue integral

1. Introduction.

1.1. Basic notations. We write $\mathcal{R}^k$ for k-dimensional Euclidean space, $\mathcal{R}^{k\times l}$ for the space of matrices with order $k \times l$,and $\mathcal{Z}$ for some nonempty subset of $\mathcal{R}^l$. We denote by $L(\mathcal{R}^d, \mathcal{R}^{n\times n})$ the space of linear continuous operators from $\mathcal{R}^d$ to $\mathcal{R}^{n\times n}$. The element $B \in L(\mathcal{R}^d, \mathcal{R}^{n\times n})$ is represented as $B = \{B^i\}_1^d =: (B^1, B^2, \dots, B^d)$, with $B^i \in \mathcal{R}^{n\times n}$ $(i = 1, 2, \dots, d)$.

Let $(\Omega, \mathcal{F}, \nu)$ be a complete probability space with a ν-completed right-continuous filtration $\mathcal{F}_t$, let $w(\cdot)$ $(= (w^1(\cdot), w^2(\cdot), \dots, w^d(\cdot)))$ be an $\mathcal{R}^d$-valued standard Wiener process, and let $k(\cdot)$ be a stationary $(\mathcal{F}_t)$-Poisson point process on $\mathcal{Z}$ with the characteristic measure $\pi(dz)$ [16]. We denote by $N_k(dzdt)$ the counting measure induced by $k(\cdot)$ and set $\widetilde{N}_k(dzdt) = N_k(dzdt) - \pi(dz)dt$. We assume that

$$\mathcal{F}_t = \sigma\left[\iint_{A\times(0,s]} N_k(dzd\tau); s \le t, A \in \mathcal{B}(\mathcal{Z})\right] \bigvee \sigma[w(s); s \le t] \bigvee \mathcal{N},$$

where $\mathcal{N}$ denotes the totality of ν-null sets and $\sigma_1 \vee \sigma_2$ denotes the σ-field generated by $\sigma_1 \cup \sigma_2$.

Let $\mathcal{H}$ be a finite-dimensional vector space. We also denote by $L^2_{\mathcal{F}}[[0,1];\mathcal{H}]$ the space of $\mathcal{H}$-valued square integrable $(\mathcal{F}_t)$-adapted process, by $L^2_{\mathcal{F},p}[[0,1];\mathcal{H}]$ the space of $(\mathcal{F}_t)$-predictable versions of equivalent classes in $L^2_{\mathcal{F}}[[0,1];\mathcal{H}]$, by $F^2_\pi[\mathcal{Z};\mathcal{H}]$ the Hilbert space of the square integrable functions $\bar{f}(\cdot) : \mathcal{Z} \to \mathcal{H}$, and by $F^2_p[[0,1];\mathcal{H}]$ the space of $\mathcal{H}$-valued $(\mathcal{F}_t)$-predictable (see [16]) vector processes $\hat{f}(\cdot,\cdot,\cdot)$ defined on $\mathcal{Z} \times [0,1] \times \Omega$ such that

$$\int\int_{\mathcal{Z}\times[0,1]} E|\hat{f}(z,t,\cdot)|^2 \pi(dz)dt < \infty.$$

† Institute of Mathematics, Fudan University, Shanghai 200433, People's Republic of China.

For $\hat{f} \in F_p^2[[0,1];\mathcal{H}]$, we define the following stochastic integral

$$\int\int_{\mathcal{Z}\times(0,t]} \hat{f}(z,\tau,\cdot)\widetilde{N}_k(dzd\tau)$$

as in [16], and set

$$\int\int_{\mathcal{Z}\times(s,t]} \hat{f}(z,\tau,\omega)\widetilde{N}_k(dzd\tau) =: \int\int_{\mathcal{Z}\times(0,t]} \hat{f}(z,\tau,\omega)\widetilde{N}_k(dzd\tau) - \int\int_{\mathcal{Z}\times(0,s]} \hat{f}(z,\tau,\omega)\widetilde{N}_k(dzd\tau) \quad \text{for } s \le t.$$

Throughout this paper we adopt Einstein's notation on summation. That is, we use repeated scripts to stand for the summation over these scripts.

1.2. Formulation of the optimal control problem and basic assumptions. Consider the following stochastic control system:

$$\begin{aligned} x(t) = x_0 &+ \int_{(0,t]} a(x(s),v(s))ds + \int_{(0,t]} b^i(x(s),v(s))dw^i(s) \\ &+ \int\int_{\mathcal{Z}\times(0,t]} c(x(s-),v(s),z)\widetilde{N}_k(dzds). \end{aligned} \tag{1.1}$$

An admissible control $v(\cdot)$ is defined as a U-valued $(\mathcal{F}_t)$-predictable process such that

$$||v(\cdot)|| =: \sup_{0\le t\le 1} [E|v(t)|^8]^{1/8} < \infty, \tag{1.2}$$

with U being a nonempty subset of $\mathcal{R}^m$. The set of admissible controls $v(\cdot)$ is denoted by U_{ad}. When $U = \mathcal{R}^m$, we write $L^{\infty,8}_{\mathcal{F},p}[[0,1];\mathcal{R}^m]$ for U_{ad}. The terminal constraint is

$$Ef(x_0,x(1)) \in Q \subset \mathcal{R}^k. \tag{1.3}$$

The cost functional is

$$J(v(\cdot),x_0) = E\left[\int_0^1 g(x(s),v(s))ds + h(x_0,x(1))\right]. \tag{1.4}$$

In the above statement, $a(\cdot,\cdot) : \mathcal{R}^n \times U \to \mathcal{R}^n; b^i(\cdot,\cdot) : \mathcal{R}^n \times U \to \mathcal{R}^n, i = 1,\dots,d$; $c(\cdot,\cdot,\cdot) : \mathcal{R}^n \times U \times \mathcal{Z} \to \mathcal{R}^n; f(\cdot,\cdot) =: \{f^i(\cdot,\cdot)\}_1^k : \mathcal{R}^n \times \mathcal{R}^n \to \mathcal{R}^k; g(\cdot,\cdot) : \mathcal{R}^n \times U \to \mathcal{R}$; and $h(\cdot,\cdot) : \mathcal{R}^n \times \mathcal{R}^n \to \mathcal{R}$. The optimal control problem is to find a pair $(y_0,u(\cdot)) \in \mathcal{R}^n \times U_{\text{ad}}$ such that (1.1) and (1.3) are satisfied and (1.4) is minimized.

Throughout the paper we make the following assumptions.

Assumption 1. The vector functions $a(x,v), b(x,v) =: \{b^i(x,v)\}_{i=1}^d, c(x,v,z)$, $f(y,x), g(x,v)$, and $h(y,x)$ are twice differentiable in x, and $f(y,x), h(y,x)$ are differentiable in y. They and their derivatives in x or y are continuous in (x,v) or (y,x). The vector functions $a(x,v), b(x,v)$, $f_{y^i}(y,x)$, $f_{x^i}(y,x)$, $g_{x^i}(x,v), h_{y^i}(y,x)$, $h_{x^i}(y,x)$, and

$$\left[\int_{\mathcal{Z}} |c(x,v,z)|^{2k}\pi(dz)\right]^{1/2k}, \qquad k = 1,2$$

$(i = 1,\dots,n)$ are bounded by $(1+|x|+|y|+|v|)$. The vector functions $f(y,x)$, $g(x,v)$, $h(y,x)$ are bounded by $(1+|x|^2+|y|^2+|v|^2)$, $a_{x^i}(x,v), a_{x^ix^j}(x,v), b_{x^i}(x,v), b_{x^ix^j}(x,v)$,

$f_{x^ix^j}(y,x), g_{x^ix^j}(x,v))$, $h_{x^ix^j}(y,x)$, and

$$\int_{\mathcal{Z}} |c_{x^i}(x,v,z)|^{2k}\pi(dz), \quad k=1,2, \quad \int_{\mathcal{Z}} |c_{x^ix^j}(x,v,z)|^2\pi(dz)$$

$(i,j=1,\dots,n)$ are bounded. Here x^i, y^i $(i=1,\dots,n)$ stand for the ith coordinates of x and y, respectively.

Assumption 2. The set Q is closed and convex.

For the given $(x_0, v(\cdot)) \in \mathcal{R}^n \times U_{\text{ad}}$, an $\mathcal{R}^n$-valued process $x(\cdot)$ is called a solution of (1.1) if it is an $(\mathcal{F}_t)$-adapted cadlag (i.e., right-continuous with left-hand limits) process such that (1.1) holds. Under Assumption 1, (1.1) admits a unique solution for the given $x_0 \in \mathcal{R}^n$ and $v(\cdot) \in U_{\text{ad}}$ (cf.[16]), and the above formulation of optimal control problem is well defined.

1.3. Developments of optimal stochastic control and contributions of the paper. Since [11], a number of results have been obtained on optimal stochastic control problems, (cf., for example, [1], [2], [4], [12]–[15], [21], [23]). Two major advances have been made in the last two decades. One is the definition of the adjoint processes and its characterization by Itô-type equations. This was done by Kushner [17] and Bismut [4], and summarized by Bensoussan [2], [3] via functional analysis methods. The other advance, which is well-worth mentioning, was marked by the idea of second-order variation in calculating the variation of the cost functional caused by the spike variation of the given optimal control. This was motivated by the study of the nonconvex optimal stochastic control of diffusion processes with the control entering into the diffusion term, and was developed by Peng [21]. On nonconvex controls of diffusion processes, we refer the reader to Kushner [17], Haussmann [12], Bensoussan [2], Hu [14], Peng [21], and Zhou [24], [25]. In this paper we apply the idea of second-order variation to study the general optimal stochastic control with random jumps. Here, by the word "general" we mean the allowance of the control into both diffusion and jump terms and the nonconvexity property of the set U. We mention that optimal control of jump processes was first considered by Boel [5], Boel and Varaiya [6], Rishel [22], Davis and Elliott [7], and Situ [23]. In this paper, however, we need not assume $c(x,v) \equiv c(x)$. Our result (see Theorem 2.1, below) shows that the maximum principle with random jumps is different from the pure diffusion version.

It is well known that vector-valued measure theory (see [18, Cor. 1]) has been playing a fundamental role in studying maximum principles for deterministic optimal control problems (cf. [18], [19]). For the application of the theory to optimal stochastic control problems, the reader is referred to [14]. However, the context of [14] seems difficult for adaptation even to the case considered in [21]. We also provide in this paper an application of the vector-valued measure theory to general stochastic control problems. It is this application that enables us to obtain the stochastic maximum principle with random jumps (more precisely, this application will solve the "differentiability" problem in an elegant way). In fact, we use only the one-dimentional case of vector-valued measure theory. That is to say, we use only a property for Lebesgue integrals of scalar-valued functions in the real number space $\mathcal{R}$. We remark here that our situation does not use the finite dimensionality of the state space and therefore can be adapted without any essential difficulty to the infinite-dimensional case, which will be the subject of a forthcoming paper. All these results show that the proof of maximum principle is almost identical and can be completed by means of very elementary tools whether the control system is finite, infinite dimensional, deterministic, or stochastic.

In this paper we also consider the optimal stochastic control with a general terminal constraint.

The rest of the paper is organized as follows. Section 2 contains some preliminary lemmas and the main result, §3 contains the main proof, and §4 contains a conclusion.

2. Preliminary lemmas and the main result.

Notation. Let $(y_0, y(\cdot), u(\cdot))$ be an optimal triplet. For the given $(x_0, v(\cdot)) \in \mathcal{R}^n \times U_{\text{ad}}$, write $y(\cdot; v(\cdot), x_0)$ for the solution of (1.1). For $v, v_1, v_2 \in U$, denote

$$
\begin{aligned}
\Delta m(s; v_2, v_1) &=: m(y(s-), v_2) - m(y(s-), v_1),\\
\Delta m(s; v) &=: m(y(s-), v) - m(y(s-), u(s)),\\
m(s; v_1) &=: m(y(s), v_1),\\
m(s) &=: m(y(s), u(s)),\\
\Delta n(s, z; v_2, v_1) &=: n(y(s-), v_2, z) - n(y(s-), v_1, z),\\
\Delta n(s, z; v) &=: n(y(s-), v, z) - n(y(s-), u(s), z),\\
n(s, z; v_1) &=: n(y(s-), v_1, z),\\
n(s, z) &=: n(y(s-), u(s), z),
\end{aligned}
\tag{2.1}
$$

with m standing for a, b, g and all their (up to second-) derivatives in x, and n for c and its (up to second-) derivatives in x.

For $I_0 \subset [0,1]$, let $|I_0|$ denote the Lebesgue measure of the set I_0. Let $v(\cdot)$, $v_1(\cdot)$, $v_2(\cdot) \in U_{\text{ad}}$. Define

$$
\hat{d}(v_1(\cdot), v_2(\cdot)) =: |\{t \in [0,1]; E|v_1(t) - v_2(t)|^2 > 0\}|. \tag{2.2}
$$

For $\rho \in (0,1]$, $I_\rho \subset [0,1]$, and $v(\cdot) \in U_{\text{ad}}$, define

$$
\begin{aligned}
u^\rho(s) &=: u(s)\chi_{[0,1]\setminus I_\rho}(s) + v(s)\chi_{I_\rho}(s), \qquad s \in [0,1],\\
y_0^\rho &=: y_0 + |I_\rho|\eta, \qquad \eta \in \mathcal{R}^n,\\
y^\rho(\cdot) &= y(\cdot; u^\rho(\cdot), y_0^\rho),
\end{aligned}
\tag{2.3}
$$

with $\chi_A(\cdot)$ denoting the indicator function of some set A. Obviously, we have

$$
\hat{d}(u_\rho(\cdot), u(\cdot)) = |I_\rho|. \tag{2.4}
$$

We can prove that $u^\rho(\cdot) \in U_{\text{ad}}$.

Let the process $y_1(t; v_2(\cdot), v_1(\cdot))$ be the solution of

$$
\begin{aligned}
y_1(t) = &\int_{(0,t]} a_x(s; v_1(s)) y_1(s) ds\\
&+ \int_{(0,t]} [b_x^k(s; v_1(s)) y_1(s) + \Delta b^k(s; v_2(s), v_1(s))] dw^k(s)\\
&+ \int\int_{\mathcal{Z}\times(0,t]} [c_x(s, z; v_1(s)) y_1(s-) + \Delta c(s, z; v_2(s), v_1(s))] \widetilde{N}_k(dzds),
\end{aligned}
\tag{2.5}
$$

and the process $y_2(t; v_2(\cdot), v_1(\cdot))$ be the solution of

$$
\begin{aligned}
y_2(t) = {} & \hat{d}(v_2(\cdot), v_1(\cdot))\eta \\
& + \int_{(0,t]} \Big[a_x(s; v_1(s)) y_2(s) + \Delta a(s; v_2(s), v_1(s)) \\
& \qquad + \frac{1}{2} a_{x^i x^j}(s; v_1(s)) y_1^i(s) y_1^j(s) \Big] ds \\
& + \int_{(0,t]} \Big[b_x^k(s; v_1(s)) y_2(s) + \Delta b_x^k(s; v_2(s), v_1(s)) y_1(s) \\
& \qquad + \frac{1}{2} b_{x^i x^j}^k(s; v_1(s)) y_1^i(s) y_1^j(s) \Big] dw^k(s) \\
& + \int\int_{\mathcal{Z} \times (0,t]} \Big[c_x(s, z; v_1(s)) y_2(s-) + \Delta c_x(s, z; v_2(s), v_1(s)) y_1(s-) \\
& \qquad + \frac{1}{2} c_{x^i x^j}(s, z; v_1(s)) y_1^i(s-) y_1^j(s-) \Big] \tilde{N}_k(dz ds),
\end{aligned} \tag{2.6}
$$

where $y_1^i(\cdot)$ $(i = 1, \ldots, n)$ stand for the ith coordinate of vector $y_1(\cdot)(=: y_1(\cdot; v_1(\cdot), v_2(\cdot)))$. Write $y_i(t; v(\cdot))$ for $y_i(t; v(\cdot), u(\cdot))$, $i = 1, 2$.

Remark 2.1. The definitions of $y_1(t; v(\cdot))$ and $y_2(t; v(\cdot))$ are different from those in [21]. These changes have the following advantage: $y_1(t; v(\cdot))$ represents the half-order component and $y_2(t; v(\cdot))$ represents the first-order component of the variation for the state; when the control appears in neither diffusion nor jump terms, $y_1(t; v(\cdot))$ vanishes in an automatic way and $y_2(t; v(\cdot))$ is the usual first-order component of the variation.

We have the following estimates, which play a crucial role in calculating the variation of the cost.

LEMMA 2.1. *Assume that Assumption* 1 *is satisfied. Then for* $v(\cdot), v_i(\cdot) \in U_{\text{ad}}, i = 1, 2, x_0 \in \mathcal{R}^n$, *we have*

$$
\begin{aligned}
& \sup_{0 \le t \le 1} E|y(t; v(\cdot), x_0)|^8 = O((1 + ||v(\cdot)||)^8), \\
& \sup_{0 \le t \le 1} E|y(t; v_1(\cdot), x_0) - y(t; v_2(\cdot), x_0)|^4 = O(\hat{d}^2(v_2(\cdot), v_1(\cdot))(1 + ||v_1(\cdot)|| + ||v_2(\cdot)||)^4), \\
& \sup_{0 \le t \le 1} E|y_1(t; v_2(\cdot), v_1(\cdot))|^8 = O(\hat{d}^4(v_2(\cdot), v_1(\cdot))(1 + ||v_1(\cdot)|| + ||v_2(\cdot)||)^8), \\
& \sup_{0 \le t \le 1} E|y_2(t; v_2(\cdot), v_1(\cdot))|^4 = O(\hat{d}^4(v_2(\cdot), v_1(\cdot))(1 + ||v_1(\cdot)|| + ||v_2(\cdot)||)^8), \\
& \sup_{0 \le t \le 1} E|y(t; v_2, y_0 + \hat{d}(v_i, v_1)\eta) - y(t; v_1, y_0) - y_1(t; v_2, v_1) - y_2(t; v_2, v_1)|^2 \\
& \qquad = o(\hat{d}^2(v_2(\cdot), v_1(\cdot))(1 + ||v_1(\cdot)|| + ||v_2(\cdot)||)^8), \quad \text{as } \hat{d}(v_2(\cdot), v_1(\cdot)) \to 0.
\end{aligned} \tag{2.7}
$$

Remark 2.2. Assume that Assumption 1 is satisfied. Then for fixed $v(\cdot) \in U_{\text{ad}}$,

we have

$$\begin{aligned} &\sup_{0\le t\le 1} E|y_1(t)|^8 = O(|I_\rho|^4), \\ &\sup_{0\le t\le 1} E|y_2(t)|^4 = O(|I_\rho|^4), \\ &\sup_{0\le t\le 1} E|y^\rho(t) - y(t) - y_1(t) - y_2(t)|^2 = o(|I_\rho|^2), \quad \text{as } |I_\rho| \to 0. \end{aligned} \tag{2.8}$$

Here $y_i(t) =: y_i(t; u^\rho(\cdot)), i = 1, 2$.

Remark 2.3. When $I_\rho = [t, t+\rho] \subset [0,1]$ and $c \equiv 0$, Remark 2.2 is Lemma 1 of [21]. We point out that a misprint was made in the statement of Lemma 1 in [21]; however, our Remark 2.2 for the above-mentioned case is what was actually proved in [21].

Remark 2.4. Note that the first two estimates (2.7) are concerned with the boundedness and the continuity of the system state $y(\cdot; v(\cdot), x_0)$, as a functional (x_0 is fixed) on the metric space $(U_{\text{ad}}, \hat{d})$, and they depend on the upper bounds of $||v_1(\cdot)||+||v_2(\cdot)||$. When U_{ad} is bounded in $L^{\infty,8}_{\mathcal{F},p}[[0,1]; \mathcal{R}^m]$, they imply the boundedness and the continuity in $(U_{\text{ad}}, \hat{d})$ of $y(\cdot; v(\cdot), x_0)$ with respect to $v(\cdot)$; then the same boundedness and continuity is possessed by the cost functional since the cost can be viewed as a component of the state in the augmented system.

Proof. Without loss of generality, we assume that

$$\eta = 0, \quad v_1(\cdot) = u(\cdot), \quad v_2(\cdot) = u^\rho(\cdot). \tag{2.9}$$

Define

$$\begin{aligned} \int_{I_\rho} f_0(s)\, dw(s) &=: \int_0^1 \chi_{I_\rho}(s) f_0(s)\, dw(s), \\ \iint_{\mathcal{Z}\times I_\rho} g_0(s,z)\, \widetilde{N}_k(dz\, ds) &=: \iint_{\mathcal{Z}\times(0,1]} \chi_{I_\rho}(s) g_0(s,z)\, \widetilde{N}_k(dz\, ds). \end{aligned}$$

We have the following inequalities:

$$\begin{aligned} E\left|\int_{I_\rho} f_0(s)\, ds\right|^p &\le C_p |I_\rho|^{p-1} E \int_{I_\rho} |f_0(s)|^p\, ds, \\ E\left|\int_{I_\rho} f_0(s)\, dw(s)\right|^{2p} &\le C_p |I_\rho|^{p-1} E \int_{I_\rho} |f_0(s)|^{2p}\, ds, \\ E\left|\iint_{\mathcal{Z}\times I_\rho} g_0(s,z)\, \widetilde{N}_k(dz\, ds)\right|^{2p} &\le C_p |I_\rho|^{p-1} E \int_{I_\rho} \left|\int_{\mathcal{Z}} |g_0(s,z)|^2\, \pi(dz)\right|^p ds, \end{aligned} \tag{2.10}$$

with $p > 1$.

By virtue of the Assumption 1, we have

$$
\begin{aligned}
&\sup_{0\le t\le 1} E|y(t)|^8 = O((1+||v(\cdot)||+||u(\cdot)||)^8),\\
&\sup_{0\le t\le 1} E|\Delta a(t;u^\rho(s))|^4 = O((1+||v(\cdot)||+||u(\cdot)||)^4),\\
&\sup_{0\le t\le 1} E|\Delta b(t;u^\rho(s))|^8 = O((1+||v(\cdot)||+||u(\cdot)||)^8),\\
&\sup_{0\le t\le 1} E\left|\int_{\mathcal{Z}} |\Delta c(t,z;u^\rho(s))|^2\,\pi(dz)\right|^4 = O((1+||v(\cdot)||+||u(\cdot)||)^8).
\end{aligned}
\tag{2.11}
$$

Then we can obtain the following inequalities by using (2.10):

$$
\begin{aligned}
&E\left|\int_0^1 \Delta a(s;u^\rho(s))\,ds\right|^4 = O(|I_\rho|^4(1+||v(\cdot)||+||u(\cdot)||)^4),\\
&E\left|\int_0^1 \Delta b(s;u^\rho(s))\,dw(s)\right|^8 = O(|I_\rho|^4(1+||v(\cdot)||+||u(\cdot)||)^8),\\
&E\left|\iint_{\mathcal{Z}\times(0,1]} \Delta c(s,z;u^\rho(s))\,\tilde N_k(dz\,ds)\right|^8 = O(|I_\rho|^4(1+||v(\cdot)||+||u(\cdot)||)^8).
\end{aligned}
\tag{2.12}
$$

Then the first four estimates of (2.7) are easily proved by using the familiar elementary inequalities

$$(m_1+m_2+m_3)^i \le C(|m_1|^i+|m_2|^i+|m_3|^i), \qquad i=4,8,$$

and the well-known Gronwall's inequality.

The proof for the last estimate follows. Set $y_3 = y_1 + y_2$. We have

$$
\begin{aligned}
&\int_0^t a(y+y_3,u^\rho)ds + \int_0^t b^k(y+y_3,u^\rho)dw^k(s)\\
&\quad + \iint_{\mathcal{Z}\times(0,t]} c(y+y_3,u^\rho,z)\tilde N_k(dzds)\\
&= \int_0^t \left[a(y,u^\rho) + a_x(y,u^\rho)y_3 + \int_0^1\int_0^1 \lambda a_{x^ix^j}(y+\lambda\mu y_3,u^\rho)d\lambda\,d\mu y_3^i y_3^j\right] ds\\
&\quad + \int_0^t \Bigg[b^k(y,u^\rho) + b^k_x(y,u^\rho)y_3\\
&\qquad + \int_0^1\int_0^1 \lambda b^k_{x^ix^j}(y+\lambda\mu y_3,u^\rho)d\lambda\,d\mu y_3^i y_3^j\Bigg] dw^k(s)\\
&\quad + \iint_{\mathcal{Z}\times(0,t]} \Bigg[c(y,u^\rho,z) + c_x(y,u^\rho,z)y_3\\
&\qquad + \int_0^1\int_0^1 \lambda c_{x^ix^j}(y+\lambda\mu y_3,u^\rho,z)d\lambda\,d\mu y_3^i y_3^j\Bigg] \tilde N_k(dz\,ds)\\
&= y(t)+y_3(t)-y_0 + \int_0^t A(s;\rho)\,ds + \int_0^t B^k(s;\rho)\,dw^k(s)\\
&\quad + \iint_{\mathcal{Z}\times(0,t]} C(s,z;\rho)\,\tilde N_k(dz\,ds),
\end{aligned}
$$

where

$$\begin{aligned}A(s;\rho) =&\frac{1}{2}a_{x^ix^j}(s)(y_2^i(s)y_2^j(s)+2y_1^i(s)y_2^j(s))\\&+\Delta a_x(s;u^\rho(s))y_3(s)\\&+\int_0^1\int_0^1\lambda[a_{x^ix^j}(y+\lambda\mu y_3,u^\rho)-a_{x^ix^j}(s)]d\lambda\,d\mu\,y_3^i(s)y_3^j(s),\\B(s;\rho) =&\frac{1}{2}b_{x^ix^j}(s)(y_2^i(s)y_2^j(s)+2y_1^i(s)y_2^j(s))\\&+\Delta b_x(s;u^\rho(s))y_2(s)\\&+\int_0^1\int_0^1\lambda[b_{x^ix^j}(y+\lambda\mu y_3,u^\rho)-b_{x^ix^j}(s)]d\lambda\,d\mu\,y_3^i(s)y_3^j(s),\\C(s,z;\rho) =&\frac{1}{2}c_{x^ix^j}(s,z)(y_2^i(s)y_2^j(s)+2y_1^i(s)y_2^j(s))\\&+\Delta c_x(s,z;u^\rho(s))y_2(s)\\&+\int_0^1\int_0^1\lambda[c_{x^ix^j}(y+\lambda\mu y_3,u^\rho,z)-c_{x^ix^j}(s,z)]d\lambda\,d\mu\,y_3^i(s)y_3^j(s).\end{aligned}$$

We can derive that

$$\begin{aligned}(y^\rho-y-y_3)(t)=&\int_0^t[\widetilde{A}(s;\rho)(y^\rho-y-y_3)(s)+A(s;\rho)]\,ds\\&+\int_0^t[\widetilde{B}^k(s;\rho)(y^\rho-y-y_3)(s)+B^k(s;\rho)]\,dw^k(s)\\&+\iint_{\mathcal{Z}\times(0,t]}[\widetilde{C}(s,z;\rho)(y^\rho-y-y_3)(s)+C(s,z;\rho)]\,\widetilde{N}_k(dz\,ds),\end{aligned}$$

$$|\widetilde{A}(s;\rho)|+|\widetilde{B}^k(s;\rho)|+|\widetilde{C}(s,\cdot;\rho)|\le C,$$

$$\begin{aligned}&\sup_{0\le t\le 1}E\left(\left|\int_0^t A(s;\rho)ds\right|^2+\left|\int_0^t B^k(s;\rho)dw^k(s)\right|^2+\left|\iint_{\mathcal{Z}\times(0,t]}C(s,z;\rho)\widetilde{N}_k(dzds)\right|^2\right)\\&\quad=o(|I_\rho|^2(1+||v(\cdot)||+||u(\cdot)||^8).\end{aligned}$$

From these we can use Ito's formula and Gronwall's inequality to obtain the fifth estimate (2.7). □

LEMMA 2.2. *Assume that $l(\cdot)$ is a scalar-valued Lebesgue integrable function defined on $[0,1]$. Then for $\rho\in(0,1]$, there exists a measurable subset $I_\rho\subset[0,1]$ such that*

$$\begin{aligned}&|I_\rho|=\rho,\\&\int_{I_\rho}l(s)ds=\rho\int_{[0,1]}l(s)ds+o(\rho)\quad as\ \rho\to 0.\end{aligned}\tag{2.13}$$

The proof is quite elementary and the reader is referred to [18]. We would like to mention that a stronger statement (more precisely, this lemma with the term $o(\rho)$ vanishing) is available via an application of the well-known Liapunov convexity theorem to the $\mathcal{R}^2$-valued integrable vector function $(l(\cdot),1)$. However, this lemma is enough for our argument below.

LEMMA 2.3 (Martingale representation). *Let $\mathcal{H}$ be a finite-dimensional space and let $m(t)$ be an $\mathcal{H}$-valued $(\mathcal{F}_t)$-adapted square-integrable Martingale. Then there exist $q^i(\cdot) \in L^2_{\mathcal{F},p}[(0,1);\mathcal{H}]$ $(i = 1, \dots, d)$ and $r(\cdot,\cdot) \in F^2_p[(0,1);\mathcal{H}]$ such that*

$$m(t) = m(0) + \int_{(0,t]} q^i(s)dw^i(s) + \int\int_{\mathcal{Z}\times(0,t]} r(s,z)\widetilde{N}_k(dzds).$$

The lemma is a combination of [16, Chap. 2, Thms. 6.6–6.7], and its proof is given in the Appendix.

Consider the following Itô-type stochastic integral equation with terminal conditions

$$\begin{aligned} p(t) = p_1 &+ \int_{(t,1]} \hat{a}(s,\cdot,p(s),q(s),r_s(\cdot))ds - \int_{(t,1]} q(s)dw(s) \\ &- \int\int_{\mathcal{Z}\times(t,1]} r(s,z)\,\widetilde{N}_k(dz\,ds), \qquad 0 \le t \le 1. \end{aligned} \tag{2.14}$$

Here p_1 is an $\mathcal{H}$-valued square integrable random variable on $(\Omega,\mathcal{F}_1)$, and $\hat{a}(\cdot,\cdot,\cdot,\cdot,\cdot) : [0,1]\times\Omega\times\mathcal{H}\times L(\mathcal{R}^d,\mathcal{H})\times F^2_\pi[\mathcal{Z};\mathcal{H}] \to \mathcal{H}$ whose $a(t,\cdot,p,q,r)$ is $\mathcal{F}_t$-measurable for given $(t,p,q,r) \in [0,1]\times\mathcal{H}\times L(\mathcal{R}^d,\mathcal{H})\times F^2_\pi[\mathcal{Z};\mathcal{H}]$ and which satisfies the following:

$$\begin{aligned} &|\hat{a}(t,\omega,0,0,0)| \le C, \\ &|\hat{a}(t,\omega,p_1,q_1,r_1) - \hat{a}(t,\omega,p_2,q_2,r_2)| \le C(|p_1-p_2| + |q_1-q_2| + |r_1-r_2|), \end{aligned} \tag{2.15}$$

with the constant C being independent of $(t,\omega) \in [0,1]\times\Omega$. Based on Lemma 2.3, we have the following lemma.

LEMMA 2.4. *Let (2.15) hold. Then there exists unique*

$$(p(\cdot),q(\cdot),r(\cdot,\cdot)) \in L^2_{\mathcal{F}}[[0,1];\mathcal{H}]\times L^2_{\mathcal{F},p}[[0,1];L(\mathcal{R}^d,\mathcal{H})]\times F^2_p[[0,1];\mathcal{H}],$$

with $p(\cdot)$ being a cadlag process, which solves (2.14).

Proof. For each

$$(\bar{p}(\cdot),\bar{q}(\cdot),\bar{r}(\cdot,\cdot)) \in L^2_{\mathcal{F}}[[0,1];\mathcal{H}]\times L^2_{\mathcal{F},p}[[0,1];L(\mathcal{R}^d,\mathcal{H})]\times F^2_p[[0,1];\ \mathcal{H}],$$

we know from Lemma 2.3 that there exist $q(\cdot) \in L^2_{\mathcal{F},p}[[0,1];L(\mathcal{R}^d,\mathcal{H})]$, $r(\cdot,\cdot)) \in F^2_p[[0,1];\mathcal{H}]$, such that

$$\begin{aligned} &E^{\mathcal{F}_t}[p_1 + \int_{(0,1]} \hat{a}(s,\cdot,\bar{p}(s),\bar{q}(s),\bar{r}(s,\cdot))ds] \\ &\quad = X + \int_{(0,t]} q(s)dw(s) + \int\int_{\mathcal{Z}\times(0,t]} r(s,z)\,\widetilde{N}_k(dzds). \end{aligned}$$

This implies

$$\begin{aligned} X = p_1 &+ \int_{(0,1]} \hat{a}(s,\cdot,\bar{p}(s),\bar{q}(s),\bar{r}(s,\cdot))ds - \int_{(0,1]} q(s)dw(s) \\ &- \int\int_{\mathcal{Z}\times(0,1]} r(s,z)\widetilde{N}_k(dzds). \end{aligned}$$

Set

$$p(t) =: E^{\mathcal{F}_t}\left[p_1 + \int_{(t,1]} \hat{a}(s,\cdot,\bar{p}(s),\bar{q}(s),\bar{r}(s,\cdot))ds\right].$$

We verify that for given triplet $(\bar{p}(\cdot), \bar{q}(\cdot), \bar{r}(\cdot,\cdot))$, the corresponding triplet $(p(\cdot), q(\cdot), r(\cdot,\cdot))$ is characterized by the equation

$$\begin{aligned} p(t) = & p_1 + \int_{(t,1]} \hat{a}(s,\cdot,\bar{p}(s),\bar{q}(s),\bar{r}(s,\cdot))ds \\ & - \int_{(t,1]} q(s)dw(s) - \int\int_{\mathcal{Z}\times(t,1]} r(s,z)q(dzds). \end{aligned} \tag{2.16}$$

This implies

$$\begin{aligned} p(t) = & p(0) - \int_{(0,t]} \hat{a}(s,\cdot,\bar{p}(s),\bar{q}(s),\bar{r}(s,\cdot))ds \\ & + \int_{(0,t]} q(s)dw(s) + \int\int_{\mathcal{Z}\times(0,t]} r(s,z)\widetilde{N}_k(dzds). \end{aligned} \tag{2.17}$$

Equation (2.16) defines a map $\Lambda : (\bar{p}(\cdot), \bar{q}(\cdot), \bar{r}(\cdot,\cdot)) \to (p(\cdot), q(\cdot), r(\cdot,\cdot))$. Let $D^2_{\mathcal{F}}(0,1;\mathcal{H})$ be the Banach space of $\mathcal{H}$-valued $(\mathcal{F}_t)$-adapted cadlag processes $\hat{p}(t)$ such that

$$\sup_{0\le t\le 1} E|\hat{p}(t)|^2 < \infty.$$

We introduce, for $k =: (p(\cdot), q(\cdot), r(\cdot,\cdot)) \in D^2_{\mathcal{F}}(0,1;\mathcal{H}) \times L^2_{\mathcal{F},p}[[0,1]; L(\mathcal{R}^d,\mathcal{H})] \times F^2_p[[0,1];\mathcal{H}]$, the norm defined by

$$\begin{aligned} ||k|| =: & \sup_{0\le t\le 1} e^{bt} E|p(t)|^2 \\ & + \sup_{0\le t\le 1} e^{bt} \left[\int_t^1 E|q(s)|^2 ds + \int\int_{\mathcal{Z}\times(t,1]} E|r(s,z)|^2 \pi(dz)ds \right], \end{aligned} \tag{2.18}$$

with $b > 0$ to be determined later. To complete the proof, it is enough to show that Λ maps $D^2_{\mathcal{F}}(0,1;\mathcal{H}) \times L^2_{\mathcal{F},p}[[0,1]; L(\mathcal{R}^d,\mathcal{H})] \times F^2_p[[0,1];\mathcal{H}]$ into itself and is a contraction under the norm (2.18). For this purpose, let $(\bar{p}_i(\cdot), \bar{q}_i(\cdot), \bar{r}_i(\cdot,\cdot)) \in D^2_{\mathcal{F}}(0,1;\mathcal{H}) \times L^2_{\mathcal{F},p}[[0,1]; L(\mathcal{R}^d,\mathcal{H})] \times F^2_p[[0,1];\mathcal{H}]$ and $(p_i(\cdot), q_i(\cdot), r_i(\cdot,\cdot)) =: \Lambda(\bar{p}_i(\cdot), \bar{q}_i(\cdot), \bar{r}_i(\cdot,\cdot))$ for $i = 1, 2$. Then, using Itô's formula [10], we have from (2.14)–(2.16) that

(2.19)

$$\begin{aligned} & E|p_1(t) - p_2(t)|^2 + E\int_t^1 \sum_{i=1}^d |q_1^i(s) - q_2^i(s)|^2 ds \\ & \qquad + E\int\int_{\mathcal{Z}\times(t,1]} |r_1(s,z) - r_2(s,z)|^2 \pi(dz)ds \\ & \le \hat{\gamma} C^2 E \int_{(t,1]} |p_1(s) - p_2(s)|^2 ds + \frac{1}{\hat{\gamma}} \Bigg[E\int_{(t,1]} |\bar{p}_1(s) - \bar{p}_2(s)|^2 ds \\ & \qquad\qquad + E\int_{(t,1]} \sum_{i=1}^d |\bar{q}_1^i(s) - \bar{q}_2^i(s)|^2 ds \\ & \qquad\qquad + E\int\int_{\mathcal{Z}\times(t,1]} |\bar{r}_1(s,z) - \bar{r}_2(s,z)|^2 \pi(dz)ds \Bigg]. \end{aligned}$$

This implies from Gronwall's inequality that

$$
\begin{aligned}
&E|p_1(t)-p_2(t)|^2+E\int_t^1\sum_{i=1}^d|q_1^i(s)-q_2^i(s)|^2ds\\
&\qquad+E\int\int_{\mathcal{Z}\times(t,1]}|r_1(s,z)-r_2(s,z)|^2\pi(dz)ds\\
&\le\frac{1}{\hat\gamma}\Bigg[E\int_{(t,1]}|\bar p_1(s)-\bar p_2(s)|^2ds+E\int_{(t,1]}\sum_{i=1}^d|\bar q_1^i(s)-\bar q_2^i(s)|^2ds\\
&\qquad+E\int\int_{\mathcal{Z}\times(t,1]}|\bar r_1(s,z)-\bar r_2(s,z)|^2\pi(dz)ds\Bigg]\\
&\quad+C^2\int_t^1e^{\hat\gamma C^2(s-t)}\Bigg[E\int_{(s,1]}|\bar p_1(\tau)-\bar p_2(\tau)|^2d\tau\\
&\qquad+E\int_{(s,1]}\sum_{i=1}^d|\bar q_1^i(\tau)-\bar q_2^i(\tau)|^2d\tau\\
&\qquad+E\int\int_{\mathcal{Z}\times(s,1]}|\bar r_1(\tau,z)-\bar r_2(\tau,z)|^2\pi(dz)d\tau\Bigg]ds,
\end{aligned}
\tag{2.20}
$$

with $\hat\gamma$ being any positive real number. Noting (2.18), we conclude that

$$
\begin{aligned}
&||(p_1-p_2,q_1-q_2,r_1-r_2)||\\
&\quad\le\max\left\{\frac{2}{b\hat\gamma},\frac{2}{\hat\gamma},\frac{2C^2}{b(b-\hat\gamma C^2)},\frac{2C^2}{b-\hat\gamma C^2}\right\}||(\bar p_1-\bar p_2,\bar q_1-\bar q_2,\bar r_1-\bar r_2)||,
\end{aligned}
\tag{2.21}
$$

which completes the proof by choosing appropriate $\hat\gamma$ and b. □

Remark 2.5. We note that a special case of Lemma 2.4 is obtained in [20].

The Hamiltonian is defined as

$$
\begin{aligned}
H(x,v,\lambda,p,\{q^i\}_1^d,r(\cdot))=&\lambda g(x,v)+\langle p,a(x,v)\rangle+\langle q^i,b^i(x,v)\rangle\\
&+\int_{\mathcal{Z}}\langle r(z),c(x,v,z)\rangle\pi(dz);
\end{aligned}
$$

this is a map from $\mathcal{R}^n\times U\times\mathcal{R}\times\mathcal{R}^n\times\mathcal{R}^{n\times d}\times F_\pi^2[\mathcal{Z};\mathcal{R}^n]$ into $\mathcal{R}$. Here we have used $\langle,\rangle$ for the scalar product of Euclidean spaces.

From Lemma 2.3 and Assumption 1 we see for the given $p(1)\in L^2(\Omega,\mathcal{F}_1;\mathcal{R}^n)$, $P(1)\in L^2(\Omega,\mathcal{F};\mathcal{R}^{n\times n})$ that the Itô-type adjoint equations

$$
\begin{aligned}
p(t)=&p(1)+\int_{(t,1]}H_x(y(s),u(s),\lambda,p(s),\{q^i(s)\}_1^d,r(s,\cdot))\,ds\\
&-\int_{(t,1]}q^i(s)dw^i(s)-\int\int_{\mathcal{Z}\times(t,1]}r(s,z)\,\tilde N_k(dz\,ds)
\end{aligned}
\tag{2.22}
$$

and

$$
\begin{aligned}
P(t) = P(1) + \int_{(t,1]} \Big\{ & a_x^*(s)P(s) + P(s)a_x(s) \\
& + b_x^{i*}(s)P(s)b_x^i(s) + b_x^{i*}(s)Q^i(s) + Q^i(s)b_x^i(s) \\
& + \int_{\mathcal{Z}} c_x^*(s,z)P(s)c_x(s,z)\,\pi(dz) \\
& + \int_{\mathcal{Z}} [c_x^*(s,z)R(s,z)c_x(s,z) \\
& \qquad + c_x^*(s,z)R(s,z) + R(s,z)c_x(s,z)]\pi(dz) \\
& + H_{xx}(y(s),u(s),\lambda,p(s),\{q^i(s)\}_1^d,r(s,\cdot))\Big\}\,ds \\
& - \int_{(t,1]} Q^i(s)dw^i(s) - \int\int_{\mathcal{Z}\times(t,1]} R(s,z)\,\widetilde{N}_k(dz\,ds)
\end{aligned} \tag{2.23}
$$

admit unique solutions $(p(\cdot), \{q^i(\cdot)\}_{i=1}^d, r(\cdot,\cdot))$ and $(P(\cdot), \{Q^i(\cdot)\}_{i=1}^d, R(\cdot,\cdot))$, with $p(\cdot)$ and $P(\cdot)$ being cadlag processes.

Define the following function:

$$
\Phi(s,z;\varepsilon) =: \inf_{(\bar{z},t)\in Q\times(-\infty,J(u(\cdot),y_0)-\varepsilon]} \sqrt{|\bar{z}-z|^2 + |s-t|^2}. \tag{2.24}
$$

LEMMA 2.5. *For given $\varepsilon > 0$, the function $\Phi(s,z;\varepsilon)$ is continuously differentiable on the open set $\hat{Q} =: \{(s,z) : \Phi(s,z;\varepsilon) > 0\}$. Moreover, when $\Phi(s,z;\varepsilon) > 0$, we have*

$$
\begin{aligned}
\langle \Phi_z(s,z;\varepsilon), \hat{z} - z\rangle &\le 0, \qquad \forall\, \hat{z} \in Q, \\
\Phi_s(s,z;\varepsilon) &\ge 0, \\
|\Phi_s(s,z;\varepsilon)|^2 + |\Phi_z(s,z;\varepsilon)|^2 &= 1.
\end{aligned} \tag{2.25}
$$

Proof. We easily see that the distance function $\Phi(\cdot,\cdot;\varepsilon)$ is Lipschitz with Lipschitz constant 1 and we derive from Lemma 3.4 and Corollary 3.5 of [19] that $\Phi(s,z;\varepsilon)$ is continuously differentiable at (s,z), and further, that

$$
\partial\Phi(s,z;\varepsilon) = \{D\Phi(s,z;\varepsilon)\}, \tag{2.26}
$$

$$
|D\Phi(s,z;\varepsilon)|^2_{\mathcal{R}\times\mathcal{R}^k} = 1, \tag{2.27}
$$

whenever $\Phi(s,z;\varepsilon) > 0$. From the definition of $\partial\Phi(s,z;\varepsilon)$ (see [19]) and (2.24), we have

$$
\langle D\Phi(s,z;\varepsilon), (\hat{s},\hat{z}) - (s,z)\rangle \le 0, \qquad \forall (\hat{s},\hat{z}) \in (-\infty, J(u(\cdot),y_0) - \varepsilon] \times Q. \tag{2.28}
$$

This implies

$$
\langle \Phi_s(s,z;\varepsilon), \hat{s} - s\rangle \le 0, \qquad \forall \hat{s} \in (-\infty, J(u(\cdot),y_0) - \varepsilon] \tag{2.29}
$$

and

$$
\langle \Phi_z(s,z;\varepsilon), \hat{z} - z\rangle \le 0, \qquad \forall \hat{z} \in Q. \tag{2.30}
$$

The last two relations (2.25) follow from (2.29) and (2.27), respectively. □

We introduce the smooth function $\alpha(\cdot)$ defined by

$$\alpha(t,z) =: \begin{cases} C\exp(t^2+|z|^2-1)^{-1}, & t^2+|z|^2<1, \\ 0, & t^2+|z|^2 \geq 1. \end{cases}$$

Choose the constant C such that

$$\int_{\mathcal{R}\times\mathcal{R}^k} \alpha(t,z)dtdz = 1.$$

Set

$$\alpha_\delta(t,z) = \delta^{-(k+1)}\alpha\left(\frac{t}{\delta},\frac{z}{\delta}\right).$$

We define the smooth approximations $\Psi(\cdot,\cdot;\varepsilon,\delta)$ of $\Phi(\cdot,\cdot;\varepsilon)$ as follows:

$$\Psi(s,z;\varepsilon,\delta) =: \int_{\mathcal{R}\times\mathcal{R}^k} \Phi(s-\bar{s},z-\bar{z};\varepsilon)\alpha_\delta(\bar{s},\bar{z})d\bar{s}d\bar{z}. \tag{2.31}$$

Then we easily have

$$0 \leq \Psi(J(u(\cdot),y_0),Ef(y_0,y(1));\varepsilon,\delta) \leq \varepsilon+\sqrt{2}\delta. \tag{2.32}$$

Moreover, we have the following lemma.

LEMMA 2.6. *For $\hat{Q}$ defined in Lemma 2.5, we have for $(s,z) \in \hat{Q}$,*

$$\begin{aligned} &\lim_{\delta\to 0+} \Psi_s(s,z;\varepsilon,\delta) = \Phi_s(s,z;\varepsilon), \\ &\lim_{\delta\to 0+} \Psi_z(s,z;\varepsilon,\delta) = \Phi_z(s,z;\varepsilon). \end{aligned} \tag{2.33}$$

Our main result is the following theorem.

THEOREM 2.1. *Assume Assumptions 1 and 2 hold. Let $(y_0,y(\cdot),u(\cdot))$ be an optimal triplet. Then there exist $0 \leq \lambda \in \mathcal{R}, \mu =: \{\mu^i\}_1^k \in \mathcal{R}^k, p(\cdot) \in L^2_{\mathcal{F}}[[0,1];\mathcal{R}^n], \{q^i(\cdot)\}_1^d \in L^2_{\mathcal{F},p}[[0,1];\mathcal{R}^{n\times d}]$, $r(\cdot,\cdot) \in F^2_p[[0,1];\mathcal{R}^n]$, and $P(\cdot) \in L^2_{\mathcal{F}}[[0,1];\mathcal{R}^{n\times n}], \{Q^i(\cdot)\}_1^d \in L^2_{\mathcal{F},p}[[0,1]; L(\mathcal{R}^d,\mathcal{R}^{n\times n})]$, $R(\cdot,\cdot) \in F^2_p[[0,1];\mathcal{R}^{n\times n}]$ such that we have the following.*

1) *The nontrivial condition*

$$|\lambda|^2+|\mu|^2 = 1 \tag{2.34}$$

is satisfied.

2) *The Itô-type adjoint equations* (2.22), (2.23), *as well as*

$$\begin{aligned} p(1) =& \lambda h_x(y_0,y(1)) + \mu^j f^j_x(y_0,y(1)), \\ p(0) =& -\lambda Eh_y(y_0,y(1)) - \mu^j Ef^j_y(y_0,y(1)), \end{aligned} \tag{2.35}$$

and

$$P(1) = \lambda h_{xx}(y_0,y(1)) + \mu^j f^j_{xx}(y_0,y(1)), \tag{2.36}$$

are satisfied, with $p(\cdot)$ and $P(\cdot)$ being cadlag processes.

3) *The following maximum condition holds:*

(2.37)
$$H(y(s-),v,\lambda,p(s-),\{q^i(s)\}_1^d,r(s,\cdot))-H(y(s-),u(s),\lambda,p(s-),\{q^i(s)\}_1^d,r(s,\cdot))$$
$$+\frac{1}{2}\text{trace } P(s-)\left[\Delta b^i(s;v)\Delta b^{i*}(s;v)+\int_{\mathcal{Z}}\Delta c(s,z;v)\Delta c^*(s,z;v)\,\pi(dz)\right]$$
$$+\frac{1}{2}\text{trace}\int_{\mathcal{Z}}R(s,z)[\Delta c(s,z;v)\Delta c^*(s,z;v)]\,\pi(dz)\geq 0,\qquad \forall\, v\in U,\ a.e.\ a.s..$$

4) *The following transversality condition holds:*

$$\langle\mu,z-Ef(y_0,y(1))\rangle\leq 0,\qquad \forall\, z\in Q. \tag{2.38}$$

Remark 2.6. When $c(x,v,z)\equiv c(x,z), f(y,x)\equiv y, Q\equiv\{x_0\}$, Theorem 2.1 can be stated as follows. Let $(y(\cdot),u(\cdot))$ be an optimal pair; then there exist $p(\cdot)\in L^2_{\mathcal{F}}[[0,1];\mathcal{R}^n]$, $\{q^i(\cdot)\}_1^d\in L^2_{\mathcal{F},p}[[0,1];\mathcal{R}^{n\times d}]$, $r(\cdot,\cdot)\in F_p^2[[0,1];\mathcal{R}^n]$, and $P(\cdot)\in L^2_{\mathcal{F}}[[0,1];\mathcal{R}^{n\times n}]$, $\{Q^i(\cdot)\}_1^d\in L^2_{\mathcal{F},p}[[0,1];L(\mathcal{R}^d,\mathcal{R}^{n\times n})]$, $R(\cdot,\cdot)\in F_p^2[[0,1];\mathcal{R}^{n\times n}]$ such that

1) the Itô-type adjoint equations (2.22), (2.23) with

$$p(1)=h_x(y_0,y(1)),\qquad P(1)=h_{xx}(y_0,y(1))$$

are satisfied, with $p(\cdot)$ and $P(\cdot)$ being cadlag processes;

2) the following maximum condition holds:

$$H(y(s-),v,1,p(s-),\{q^i(s)\}_1^d,0)-H(y(s-),u(s),1,p(s-),\{q^i(s)\}_1^d,0)$$
$$+\frac{1}{2}\text{trace } P(s-)[\Delta b^i(s;v)\Delta b^{i*}(s;v)]\geq 0,\qquad \forall\, v\in U,\text{a.e. a.s..}$$

This is the result of Situ [23].

Remark 2.7. In [7], Davis and Elliott considered an optimal control problem for an elementary jump process $k(\cdot)$. Let the random jump time and the random jump position of $k(\cdot)$ be denoted by $T(\omega)$ and $Z(\omega)$, respectively. The problem of the case $T(\omega)\leq 1$ can be stated, under our framework, as follows. Minimize the following cost functional:

$$J(v)=E[x^1(1)x^2(1)] \tag{2.39}$$

subject to the system

$$\begin{cases} x^1(t)=1+\displaystyle\int_{\mathcal{Z}\times(0,t]}x^1(s-)[\alpha(s,v(s))\beta(s,v(s),z)-1]\,\widetilde{N}_k(dzds),\\ x^2(t)=\displaystyle\int_{\mathcal{Z}\times(0,t]}f(s,z,v(s))\alpha(s,v(s))\beta(s,v(s)z)\,\widehat{N}_k(dzds). \end{cases} \tag{2.40}$$

Here $\widehat{N}_k(dzds)$ denotes the predictable dual projection of $N_k(dzds)$. On one hand, (2.40) does not contain the diffusion term $b(x,v)$ and is linear in the state $x=(x^1,x^2)^*$, and also the cost is of a special quadratic form. On the other hand, however, the measure $\widehat{N}(dzds)=\lambda(dz,s)d\Lambda(s)$ in [7] is allowed to have atoms with respect to $s\in[0,1]$. In this paper, we have assumed $\widehat{N}_k(dzds)=\pi(dz)ds$; actually, however, we only need to assume that $\widehat{N}(dzds)$ is nonatomic with respect to $s\in[0,1]$. In the case of nonatomic $\widehat{N}(dzds)$, Theorem 2.1 holds for the above stated optimal control

problem. Moreover, we can check that

$$p(t) = (p^1(t), y^1(t))^*, \quad y^1(t) > 0, \quad q(t) = 0,$$
$$r(t,z) = (r^1(t,z), y^1(t-)[\alpha(t,u(t))\beta(t,u(t),z) - 1])^*,$$
$$P(t) = \begin{pmatrix} 0 & P^{12}(t) \\ P^{21}(t) & 0 \end{pmatrix}, \quad Q(t) = 0, \quad R(t,z) = \begin{pmatrix} 0 & R^{12}(t,z) \\ R^{21}(t,z) & 0 \end{pmatrix}.$$

Then the following minimum principle is true. Let $(y^1(\cdot), y^2(\cdot), u(\cdot))$ be optimal; then there exist $p^1(\cdot), r^1(\cdot,\cdot)$ satisfying the equation

$$\begin{aligned} p^1(t) = y^2(1) &+ \iint_{\mathcal{Z}\times(t,1]} r^1(s,z)[\alpha(s,u(s))\beta(s,u(s),z) - 1]\widehat{N}_k(dzds) \\ &- \iint_{\mathcal{Z}\times(t,1]} r^1(s,z)\widetilde{N}_k(dzds), \end{aligned} \tag{2.41}$$

such that $u(t)$ almost everywhere, almost surely, minimizes

$$\alpha(t,v)\int_{\mathcal{Z}} [f(t,z,v) + r^1(t,z)]\beta(t,v)\lambda(t,dz). \tag{2.42}$$

Next, we explain how to derive the related result of Davis and Elliott [7]. Equation (2.41) can be rewritten as

$$p_1(t) = y^2(1) - \iint_{\mathcal{Z}\times(t,1]} r^1(s,z)\widetilde{N}_k^{u(\cdot)}(dzds), \tag{2.43}$$

where $\widetilde{N}_k^{u(\cdot)}(dzdt)$ is the Martingale part of $N_k(dzdt)$ under the measure $\nu^{u(\cdot)}$ determined by the Lévy system $(\beta(t,u(t),z)\lambda(t,dz), \alpha(t,u(t))\Lambda(t))$. We have

$$J(u(\cdot)) = E^{u(\cdot)}[f(T,Z)], \tag{2.44}$$

where $E^{u(\cdot)}$ denotes the expectation relative to the measure $\nu^{u(\cdot)}$. According to the Martingale representation theorem, $E^{u(\cdot)}[f(T,Z)|\,\mathcal{F}_t]$ can be written as the following integral:

$$E^{u(\cdot)}[f(T,Z)|\,\mathcal{F}_t] = J(u(\cdot)) + \iint_{\mathcal{Z}\times(0,t]} g(s,z)\widetilde{N}_k^{u(\cdot)}(dzds) \tag{2.45}$$

for some g. Then from (2.43)–(2.45), we can show that

$$r^1(t,z) = g(t,z) - f(t,z,u(t)). \tag{2.46}$$

Putting (2.46) into (2.42), we obtain the necessary part of Theorem 5.1 of Davis and Elliott [7].

3. The proof of Theorem 2.1.

Step 1. *Applying Ekeland's variational principle.* We first consider the case that the set U_{ad} is bounded in $L^{\infty,8}_{\mathcal{F},p}[[0,1];\mathcal{R}^m]$; the unbounded case can be reduced to the bounded case (see step 5 below). Assume that

$$U_{\text{ad}} \text{ is bounded in } L^{\infty,8}_{\mathcal{F},p}[[0,1];\mathcal{R}^m].$$

An application of Ekeland's variational principle will lead to the reduction of a general end-constraint problem to a family of free end-constraint problems.

Define the following auxiliary function:

$$J(v(\cdot),x_0;\varepsilon,\delta)=\Psi(J(v(\cdot),x_0),Ef(x_0,x(1));\varepsilon,\delta), \tag{3.1}$$

with $\Psi(\cdot,\cdot;\varepsilon,\delta)$ being defined as in §2. Then consider the metric space $(\mathcal{R}^n\times U_{\rm ad},d)$, with the distance d defined by

$$d((x_1,v_1(\cdot)),(x_2,v_2(\cdot)))=\sqrt{|x_1-x_2|^2+\hat{d}^2(v_1(\cdot),v_2(\cdot))}. \tag{3.2}$$

We can verify that $(\mathcal{R}^n\times U_{\rm ad},d)$ is complete and $J(v(\cdot),x_0;\varepsilon,\delta)$ is continuous and bounded. In fact, since $U_{\rm ad}$ is bounded under the norm $||\cdot||$, the system state of (1.1), as a functional defined on $(\mathcal{R}^n\times U_{\rm ad},d)$, is bounded and continuous (note Remark 2.4); from this, we can check that $J(v(\cdot),x_0;\varepsilon,\delta)$ is bounded and continuous. To prove the completeness of $(\mathcal{R}^n\times U_{\rm ad},d)$, we only need to show the completeness of $(U_{\rm ad},\hat{d})$. For this purpose, we suppose that $\{v_i(\cdot)\}_{i=1}^{\infty}$ is a Cauchy sequence in $(U_{\rm ad},\hat{d})$. Then we can find a subsequence $\{v_{i_K}(\cdot)\}_{K=1}^{\infty}$ such that

$$\hat{d}(v_{i_{K+1}}(\cdot),v_{i_K}(\cdot))<\frac{1}{2^K}.$$

Set

$$I^j=:\bigcup_{K=j}^{\infty}\{t\in[0,1]|\,\hat{d}(v_{i_{K+1}}(\cdot),v_{i_K}(\cdot))>0\},\qquad j=1,2,\ldots.$$

Choose

$$v(t)=:\begin{cases}v_1(t), & \text{as } t\in[0,1]\setminus I^1,\\ v_j(t), & \text{as } t\in I^{j-1}\setminus I^j,\qquad j=2,3,\ldots.\end{cases}$$

Then we have

$$v(\cdot)\in U_{\rm ad},\quad \hat{d}(v_{i_K}(\cdot),v(\cdot))\to 0\quad\text{as } K\to\infty.$$

Since $\{v_i(\cdot)\}_{i=1}^{\infty}$ is a Cauchy sequence in $(U_{\rm ad},\hat{d})$, we also have

$$v_i(\cdot)\to v(\cdot)\,(\in U_{\rm ad})\quad\text{as } i\to\infty.$$

The completeness of $(U_{\rm ad},\hat{d})$ then follows.

Also, we have for any given $\varepsilon>0$,

$$\begin{aligned}&\Phi(J(v(\cdot),x_0),Ef(x_0,x(1));\varepsilon)>0,\qquad \forall\,(x_0,v(\cdot))\in\mathcal{R}^n\times U_{\rm ad};\\ &\Phi(J(u(\cdot),y_0),Ef(y_0,y(1));\varepsilon)=\varepsilon;\\ &J(v(\cdot),x_0;\varepsilon,\delta)>0,\qquad \forall\,(x_0,v(\cdot))\in\mathcal{R}^n\times U_{\rm ad}\\ &\qquad\qquad\qquad\qquad\qquad\qquad\text{for sufficiently small }\delta>0;\\ &J(u(\cdot),y_0;\varepsilon,\delta)\le\varepsilon+2\delta+\inf_{(x_0,v(\cdot))\in\mathcal{R}^n\times U_{\rm ad}}J(v(\cdot),x_0;\varepsilon,\delta).\end{aligned} \tag{3.3}$$

Therefore we can apply Ekeland's variational principle (cf. [8], [9]) and conclude that there exist $u^{\varepsilon\delta}(\cdot)\in U_{\rm ad}$ and $y_0^{\varepsilon\delta}\in\mathcal{R}^n$ such that

1) $J(u^{\varepsilon\delta}(\cdot),y_0^{\varepsilon\delta};\varepsilon,\delta)\le\varepsilon+2\delta$;

2) $d((y_0^{\varepsilon\delta},u^{\varepsilon\delta}(\cdot)),(y_0,u(\cdot)))\le\sqrt{\varepsilon+2\delta}$;

3) $\bar{J}(v(\cdot),x_0;\varepsilon,\delta)=:J(v(\cdot),x_0;\varepsilon,\delta)+\sqrt{\varepsilon+2\delta}d((x_0,v(\cdot)),(y_0^{\varepsilon\delta},u^{\varepsilon\delta}(\cdot)))$
$\ge J(u^{\varepsilon\delta}(\cdot),y_0^{\varepsilon\delta}),\ \ \forall\,(x_0,v(\cdot))\in\mathcal{R}^n\times U_{\rm ad}$.

Set

$$
\begin{aligned}
\lambda^{\varepsilon\delta} &=: \Psi_s(J(u^{\varepsilon\delta}(\cdot), y_0^{\varepsilon\delta}), Ef(y_0^{\varepsilon\delta}, y^{\varepsilon\delta}(1)); \varepsilon, \delta),\\
\mu^{\varepsilon\delta} &=: \Psi_z(J(u^{\varepsilon\delta}(\cdot), y_0^{\varepsilon\delta}), Ef(y_0^{\varepsilon\delta}, y^{\varepsilon\delta}(1)); \varepsilon, \delta),\\
\hat{\lambda}^{\varepsilon\delta} &=: \Phi_s(J(u^{\varepsilon\delta}(\cdot), y_0^{\varepsilon\delta}), Ef(y_0^{\varepsilon\delta}, y^{\varepsilon\delta}(1)); \varepsilon),\\
\hat{\mu}^{\varepsilon\delta} &=: \Phi_z(J(u^{\varepsilon\delta}(\cdot), y_0^{\varepsilon\delta}), Ef(y_0^{\varepsilon\delta}, y^{\varepsilon\delta}(1)); \varepsilon).
\end{aligned} \tag{3.4}
$$

From the first relation (3.3) and Lemmas (2.5) and (2.6), we have for each sufficiently small $\varepsilon > 0$,

$$
\lim_{\delta\to 0+}(\lambda^{\varepsilon\delta} - \hat{\lambda}^{\varepsilon\delta}) = 0,
$$

$$
\lim_{\delta\to 0+}(\mu^{\varepsilon\delta} - \hat{\mu}^{\varepsilon\delta}) = 0,
$$

$$
|\hat{\lambda}^{\varepsilon\delta}|^2 + |\hat{\mu}^{\varepsilon\delta}|^2 = 1.
$$

Therefore, for each sufficiently small $\varepsilon > 0$, we can choose $\delta(\varepsilon) > 0$ such that

$$
\begin{aligned}
&J(u^{\varepsilon\delta(\varepsilon)}(\cdot), y_0^{\varepsilon\delta(\varepsilon)}; \varepsilon, \delta(\varepsilon)) > 0,\\
&\delta(\varepsilon) \le \varepsilon,\\
&|\mu^{\varepsilon\delta(\varepsilon)}|^2 + |\mu^{\varepsilon\delta(\varepsilon)}|^2 = 1 + o(1), \quad \text{as } \varepsilon \to 0.
\end{aligned} \tag{3.5}
$$

Set

$$
\begin{aligned}
\lambda^{\varepsilon} &=: \lambda^{\varepsilon\delta(\varepsilon)}, \qquad \mu^{\varepsilon} =: \mu^{\varepsilon\delta(\varepsilon)},\\
y_0^{\varepsilon} &=: y_0^{\varepsilon\delta(\varepsilon)}, \qquad u^{\varepsilon}(\cdot) =: u^{\varepsilon\delta(\varepsilon)}(\cdot).
\end{aligned}
$$

Then we see (noting Lemma 2.5) that $\lambda^{\varepsilon} \ge 0$ and $\mu^{\varepsilon} \in \mathcal{R}^k$ satisfy the following:

$$
\begin{aligned}
&\lim_{\varepsilon\to 0+}(|\lambda^{\varepsilon}|^2 + |\mu^{\varepsilon}|^2) = 1,\\
&\langle \mu^{\varepsilon}, z - Ef(y_0^{\varepsilon}, y^{\varepsilon}(1))\rangle \le \delta(\varepsilon) \le \varepsilon.
\end{aligned} \tag{3.6}
$$

Step 2. *Computing the first-order component of the cost variation.* In this and the next steps,we look for the necessary conditions for the minimization of $\bar{J}(v(\cdot), x_0; \varepsilon, \delta)$ at $(y_0^{\varepsilon}, u^{\varepsilon}(\cdot))$.

For given $(\eta, v(\cdot)) \in \mathcal{R}^n \times U_{\text{ad}}$, set

$$
\begin{aligned}
u^{\varepsilon\rho}(t) &= u^{\varepsilon}(t)\chi_{[0,1]\setminus I_\rho}(t) + v(t)\chi_{I\rho}(t),\\
y_0^{\varepsilon\rho} &= y_0^{\varepsilon} + |I_\rho|\eta,\\
y^{\varepsilon\rho}(\cdot) &= y(\cdot; u^{\varepsilon\rho}(\cdot), y_0^{\varepsilon\rho}).
\end{aligned} \tag{3.7}
$$

We introduce, as in §2, the following simplified notations:

$$
\begin{aligned}
\Delta m^{\varepsilon}(s; v) &=: m(y^{\varepsilon}(s), v) - m(y^{\varepsilon}(s), u^{\varepsilon}(s)),\\
m^{\varepsilon}(s) &=: m(y^{\varepsilon}(s), u^{\varepsilon}(s)),\\
\Delta n^{\varepsilon}(s, z; v) &=: n(y^{\varepsilon}(s-), v, z) - n(y^{\varepsilon}(s-), u^{\varepsilon}(s), z),\\
n^{\varepsilon}(s, z) &=: n(y^{\varepsilon}(s-), u^{\varepsilon}(s), z),
\end{aligned} \tag{3.8}
$$

with m standing for a, b, g and all their (up to second-) derivatives in x, and n for c and its (up to second-) derivatives in x.

Let $y^{\varepsilon\rho}(\cdot)$ be the solution of (1.1) corresponding to $(y_0^{\varepsilon\rho}, u^{\varepsilon\rho}(\cdot))$. We define, as in §2, the half- and first-order processes $y_1^\varepsilon(\cdot), y_2^\varepsilon(\cdot)$, respectively, by

$$
\begin{aligned}
y_1^\varepsilon(t) = &\int_{(0,t]} a_x^\varepsilon(s) y_1^\varepsilon(s) ds + \int_{(0,t]} [b_x^{\varepsilon k}(s) y_1^\varepsilon(s) + \Delta b^{\varepsilon k}(s; u^{\varepsilon\rho}(s))] dw^k(s) \\
&+ \int\int_{\mathcal{Z}\times(0,t]} [c_x^\varepsilon(s,z) y_1^\varepsilon(s-) + \Delta c^\varepsilon(s,z; u^{\varepsilon\rho}(s))] \widetilde{N}_k(dzds)
\end{aligned} \tag{3.9}
$$

and

(3.10)

$$
\begin{aligned}
y_2^\varepsilon(t) = &|I_\rho|\eta + \int_{(0,t]} \left[a_x^\varepsilon(s) y_2^\varepsilon(s) + \Delta a^\varepsilon(s; u^{\varepsilon\rho}(s)) + \frac{1}{2} a_{x^i x^j}^\varepsilon(s) y_1^{\varepsilon i}(s) y_1^{\varepsilon j}(s) \right] ds \\
&+ \int_{(0,t]} \left[b_x^{\varepsilon k}(s) y_2^\varepsilon(s) + \Delta b_x^{\varepsilon k}(s; u^{\varepsilon\rho}(s)) y_1^\varepsilon(s) + \frac{1}{2} b_{x^i x^j}^{\varepsilon k}(s) y_1^{\varepsilon i}(s) y_1^{\varepsilon j}(s) \right] dw^k(s) \\
&+ \int\int_{\mathcal{Z}\times(0,t]} \Big[c_x^\varepsilon(s,z) y_2^\varepsilon(s-) + \Delta c_x^\varepsilon(s,z; u^{\varepsilon\rho}(s)) y_1^\varepsilon(s-) \\
&\qquad + \frac{1}{2} c_{x^i x^j}^\varepsilon(s,z) y_1^{\varepsilon i}(s-) y_1^{\varepsilon j}(s-) \Big] \widetilde{N}_k(dzds).
\end{aligned}
$$

From Remark 2.2, we see

$$
\begin{aligned}
&\sup_{0\le t\le 1} E|y_1^\varepsilon(t)|^8 = O(|I_\rho|^4), \\
&\sup_{0\le t\le 1} E|y_2^\varepsilon(t)|^4 = O(|I_\rho|^4), \\
&\sup_{0\le t\le 1} E|y^{\varepsilon\rho}(t) - y^\varepsilon(t) - y_1^\varepsilon(t) - y_2^\varepsilon(t)|^2 = o(|I_\rho|^2), \text{ as } |I_\rho| \to 0.
\end{aligned} \tag{3.11}
$$

In this step, we are to calculate the first-order component of the cost variation. From 3) of step 1,we have

$$
\begin{aligned}
-|I_\rho|\sqrt{\varepsilon + 2\delta}\sqrt{1+|\eta|^2} &\le J(u^{\varepsilon\rho}(\cdot), y^{\varepsilon\rho}(0); \varepsilon) - J(u^\varepsilon(\cdot), y_0^\varepsilon; \varepsilon) \\
&\le \lambda^\varepsilon [J(u^{\varepsilon\rho}(\cdot), y_0^\varepsilon + |I_\rho|\eta) - J(u^\varepsilon(\cdot), y_0^\varepsilon)] \\
&\quad + \mu^{\varepsilon j} [Ef^j(y_0^\varepsilon + |I_\rho|\eta, y^{\varepsilon\rho}(1)) - Ef^j(y_0^\varepsilon, y^\varepsilon(1))] \\
&\quad + O(|J(u^{\varepsilon\rho}(\cdot), y_0^\varepsilon + |I_\rho|\eta) - J(u^\varepsilon(\cdot), y_0^\varepsilon)|^2) \\
&\quad + O(|Ef(y_0^\varepsilon + |I_\rho|\eta, y^{\varepsilon\rho}(1)) - Ef(y_0^\varepsilon, y^\varepsilon(1))|^2).
\end{aligned} \tag{3.12}
$$

Using (3.11), we have

(3.13)

$$
\begin{aligned}
&J(u^{\varepsilon\rho}(\cdot), y_0^\varepsilon + |I_\rho|\eta) - J(u^\varepsilon(\cdot), y_0^\varepsilon) \\
&= E\int_0^1 [g(y^{\varepsilon\rho}(t), u^{\varepsilon\rho}(t)) - g(y^\varepsilon(t), u^\varepsilon(t))] dt + E[h(y_0^{\varepsilon\rho}, y^{\varepsilon\rho}(1)) - h(y_0^\varepsilon, y^\varepsilon(1))] \\
&= E\int_0^1 [g(y^\varepsilon(t) + y_1^\varepsilon(t) + y_2^\varepsilon(t), u^{\varepsilon\rho}(t)) - g(y^\varepsilon(t), u^\varepsilon(t))] dt \\
&\quad + E[h(y_0^{\varepsilon\rho}, y^\varepsilon(1) + y_1^\varepsilon(1) + y_2^\varepsilon(1)) - h(y_0^\varepsilon, y^\varepsilon(1))] + o(|I_\rho|) \\
&= E\int_0^1 [g(y^\varepsilon(t) + y_1^\varepsilon(t) + y_2^\varepsilon(t), u^\varepsilon(t)) - g(y^\varepsilon(t), u^\varepsilon(t))] dt
\end{aligned}
$$

$$
\begin{aligned}
&+ E[h(y_0^{\varepsilon\rho}, y^\varepsilon(1) + y_1^\varepsilon(1) + y_2^\varepsilon(1)) - h(y_0^\varepsilon, y^\varepsilon(1))] \\
&+ E\int_0^1 [g(y^\varepsilon(t) + y_1^\varepsilon(t) + y_2^\varepsilon(t), u^{\varepsilon\rho}(t)) - g(y^\varepsilon(t) + y_1^\varepsilon(t) + y_2^\varepsilon(t), u^\varepsilon(t))] + o(|I_\rho|) \\
&= |I_\rho|\langle Eh_y(y_0^\varepsilon, y^\varepsilon(1)), \eta\rangle + E\langle h_x(y_0^\varepsilon, y^\varepsilon(1)), y_1^\varepsilon(1) + y_2^\varepsilon(1)\rangle \\
&+ \frac{1}{2}Ey_1^{\varepsilon *}(1)h_{xx}(y_0^\varepsilon, y^\varepsilon(1))y_1^\varepsilon(1) + \\
&+ E\int_0^1 g_x^\varepsilon(s)[y_1^\varepsilon(s) + y_2^\varepsilon(s)]ds + \frac{1}{2}E\int_0^1 y_1^{\varepsilon *}(s)g_{xx}^\varepsilon(s)y_1^\varepsilon(s)ds \\
&+ E\int_0^1 \Delta g^\varepsilon(s; u^{\varepsilon\rho}(s))ds + o(|I_\rho|)
\end{aligned}
$$

and similarly,

$$
\begin{aligned}
Ef^j(y_0^\varepsilon + |I_\rho|\eta, y^{\varepsilon\rho}(1)) - Ef^j(y_0^\varepsilon, y^\varepsilon(1)) &= |I_\rho|\langle Ef_y^j(y_0^\varepsilon, y^\varepsilon(1)), \eta\rangle_n \\
&+ E\langle f_x^j(y_0^\varepsilon, y^\varepsilon(1)), y_1^\varepsilon(1) + y_2^\varepsilon(1)\rangle \\
&+ \frac{1}{2}Ey_1^{\varepsilon *}(1)f_{xx}^j(y_0^\varepsilon, y^\varepsilon(1))y_1^\varepsilon(1) + o(|I_\rho|).
\end{aligned} \tag{3.14}
$$

From Lemma 2.4, we see that

$$
\begin{cases}
p^\varepsilon(t) = p^\varepsilon(1) + \displaystyle\int_{(t,1]} H_x(y^\varepsilon(s), u^\varepsilon(s), \lambda^\varepsilon, p^\varepsilon(s), \{q^{\varepsilon i}(s)\}_1^d, r^\varepsilon(s,\cdot))ds \\
\qquad\qquad - \displaystyle\int_{(t,1]} q^{\varepsilon i}(s)dw^i(s) - \int\int_{\mathcal{Z}\times(t,1]} r^\varepsilon(s,z)\widetilde{N}_k(dzds), \\
p^\varepsilon(1) = \lambda^\varepsilon h_x(y_0^\varepsilon, y^\varepsilon(1)) + \mu^{\varepsilon j} f_x^j(y_0^\varepsilon, y^\varepsilon(1))
\end{cases} \tag{3.15}
$$

and

$$
\begin{cases}
P^\varepsilon(t) = P^\varepsilon(1) \\
\qquad + \displaystyle\int_{(t,1]} \Big\{ a_x^{\varepsilon *}(s)P^\varepsilon(s) + P^\varepsilon(s)a_x^\varepsilon(s) \\
\qquad\qquad + b_x^{\varepsilon i *}(s)P^\varepsilon(s)b_x^{\varepsilon i}(s) + (b_x^{\varepsilon i *}(s)Q^{\varepsilon i}(s) + Q^{\varepsilon i}(s)b_x^{\varepsilon i}(s) \\
\qquad\qquad + \displaystyle\int_{\mathcal{Z}} c_x^{\varepsilon *}(s,z)P(s)c_x^\varepsilon(s,z)\pi(dz) \\
\qquad\qquad + \displaystyle\int_{\mathcal{Z}} [c_x^{\varepsilon *}(s,z)R^\varepsilon(s,z)c_x^\varepsilon(s,z) + c_x^{\varepsilon *}(s,z)R^\varepsilon(s,z) \\
\qquad\qquad\qquad\qquad + R^\varepsilon(s,z)c_x^\varepsilon(s,z)]\pi(dz) \\
\qquad\qquad + H_{xx}(y^\varepsilon(s), u^\varepsilon(s), \lambda^\varepsilon, p^\varepsilon(s), \{q^{\varepsilon i}(s)\}_1^d, r^\varepsilon(s,\cdot)) \Big\} ds \\
\qquad - \displaystyle\int_{(t,1]} Q^{\varepsilon i}(s)dw^i(s) - \int\int_{\mathcal{Z}\times(t,1]} R^\varepsilon(s,z)\widetilde{N}_k(dzds), \\
P^\varepsilon(1) = \lambda^\varepsilon h_{xx}(y_0^\varepsilon, y^\varepsilon(1)) + \mu^{\varepsilon j} f_{xx}^j(y_0^\varepsilon, y^\varepsilon(1))
\end{cases} \tag{3.16}
$$

have unique solutions $(p^\varepsilon(\cdot), \{q^{\varepsilon i}(\cdot)\}_1^d, r^\varepsilon(\cdot,\cdot))$ and $(P^\varepsilon(\cdot), \{Q^{\varepsilon i}(\cdot)\}_1^d, R^\varepsilon(\cdot,\cdot))$, respectively, with $p^\varepsilon(\cdot)$ and $P^\varepsilon(\cdot)$ being cadlag processes.

Using Itô's formula, we have from (3.9), (3.15) and (3.16), that

$$
E\langle \lambda^\varepsilon h_x(y_0^\varepsilon, y^\varepsilon(1)) + \mu^{\varepsilon j} f_x^j(y_0^\varepsilon, y^\varepsilon(1)), y_1^\varepsilon(1) + y_2^\varepsilon(1)\rangle = E\langle p^\varepsilon(1), y_1^\varepsilon(1) + y_2^\varepsilon(1)\rangle
$$

$$
\begin{aligned}
&= \langle p^\varepsilon(0), \eta\rangle |I_\rho| + E\int_0^1 [H(y^\varepsilon(s), u^{\varepsilon\rho}(s), 0, p^\varepsilon(s), \{q^{\varepsilon i}(s)\}_1^d, r_s^\varepsilon(\cdot)) \\
&\qquad - H(y^\varepsilon(s), u^\varepsilon(s), 0, p^\varepsilon(s), \{q^{\varepsilon i}(s)\}_1^d, r_s^\varepsilon(\cdot))]ds \\
&\quad + \frac{1}{2}E\int_0^1 y_1^{\varepsilon *}(s) H_{xx}(y^\varepsilon(s), u^\varepsilon(s), 0, p^\varepsilon(s), \{q^{\varepsilon i}(s)\}_1^d, r_s^\varepsilon(\cdot)) y_1^\varepsilon(s) ds \qquad (3.17)\\
&\quad + E\int_0^1 \langle q^{\varepsilon i}, \Delta b_x^{\varepsilon i}(s; u^{\varepsilon\rho}(s)) y_1^\varepsilon(s)\rangle ds \\
&\quad + E\int\int_{\mathcal{Z}\times[0,1]} \langle r_s^\varepsilon(z), \Delta c_x^\varepsilon(s; u^{\varepsilon\rho}(s)) y_1^\varepsilon(s)\rangle \pi(dz)ds,
\end{aligned}
$$

$$
\begin{aligned}
y_1^\varepsilon(t) y_1^{\varepsilon *}(t) = &\int_{(0,t]} [a_x^\varepsilon(s) y_1^\varepsilon(s) y_1^{\varepsilon *}(s) + y_1^\varepsilon(s) y_1^{\varepsilon *}(s) a_x^{\varepsilon *}(s) \\
&+ b_x^{\varepsilon k}(s) y_1^\varepsilon(s) y_1^{\varepsilon *}(s) b_x^{\varepsilon k *}(s) + \int_{\mathcal{Z}} c_x^\varepsilon(s,z) y_1^\varepsilon(s) y_1^{\varepsilon *}(s) c_x^{\varepsilon *}(s,z)\pi(dz) \\
&+ b_x^{\varepsilon k}(s) y_1^\varepsilon(s) \Delta b^{\varepsilon k *}(s; u^{\varepsilon\rho}(s)) + \Delta b^{\varepsilon k}(s; u^{\varepsilon\rho}(s)) y_1^{\varepsilon *}(s) b_x^{\varepsilon k *}(s) \\
&+ \Delta b^{\varepsilon k}(s; u^{\varepsilon\rho}(s)) \Delta b^{\varepsilon k *}(s; u^{\varepsilon\rho}(s)) \\
&+ \int_{\mathcal{Z}} [c_x^\varepsilon(s,z) y_1^\varepsilon(s) \Delta c^{\varepsilon *}(s,z; u^{\varepsilon\rho}(s)) \\
&\qquad + \Delta c^\varepsilon(s,z; u^{\varepsilon\rho}(s)) y_1^{\varepsilon *}(s) c_x^{\varepsilon *}(s,z) \\
&\qquad + \Delta c^\varepsilon(s,z; u^{\varepsilon\rho}(s)) \Delta c^{\varepsilon *}(s,z; u^{\varepsilon\rho}(s))]\pi(dz)]ds \qquad (3.18)\\
&+ \int_{(0,t]} [b_x^{\varepsilon k}(s) y_1^\varepsilon(s) y_1^{\varepsilon *}(s) + y_1^\varepsilon(s) y_1^{\varepsilon *}(s) b_x^{\varepsilon k *}(s) \\
&\qquad + y_1^\varepsilon(s) \Delta b^{\varepsilon k *}(s; u^{\varepsilon\rho}(s)) + \Delta b^{\varepsilon k}(s; u^{\varepsilon\rho}(s)) y_1^{\varepsilon *}(s)] dw^k(s) \\
&+ \int\int_{\mathcal{Z}\times(0,t]} [c_x^\varepsilon(s,z) y_1^\varepsilon(s-) y_1^{\varepsilon *}(s-) + y_1^\varepsilon(s-) y_1^{\varepsilon *}(s-) c_x^{\varepsilon *}(s,z) \\
&\qquad + c_x^\varepsilon(s,z) y_1^\varepsilon(s-) y_1^{\varepsilon *}(s-) c_x^{\varepsilon *}(s,z) \\
&\qquad + c_x^\varepsilon(s,z) y_1^\varepsilon(s-) \Delta c^{\varepsilon *}(s,z; u^{\varepsilon\rho}(s)) \\
&\qquad + \Delta c^\varepsilon(s,z; u^{\varepsilon\rho}(s)) y_1^{\varepsilon *}(s-) c_x^{\varepsilon *}(s,z) \\
&\qquad + \Delta c^\varepsilon(s,z; u^{\varepsilon\rho}(s)) \Delta c^{\varepsilon *}(s,z; u^{\varepsilon\rho}(s)) \\
&\qquad + y_1^\varepsilon(s-) \Delta c^{\varepsilon *}(s,z; u^{\varepsilon\rho}(s)) \\
&\qquad + \Delta c^\varepsilon(s,z; u^{\varepsilon\rho}(s)) y_1^{\varepsilon *}(s-)] \widetilde{N}_k(dzds),
\end{aligned}
$$

and

$$
\begin{aligned}
&\lambda^\varepsilon E y_1^{\varepsilon *}(1) h_{xx}(y_0^\varepsilon, y^\varepsilon(1)) y_1^\varepsilon(1) + \mu^{\varepsilon j} E y_1^{\varepsilon *}(1) f_{xx}^j(y_0^\varepsilon, y^\varepsilon(1)) y_1^\varepsilon(1) \\
&\quad = \text{trace } E[P^\varepsilon(1) y_1^\varepsilon(1) y_1^{\varepsilon *}(1)] \\
&\quad = E\int_0^1 \Big\{ y_1^{\varepsilon *}(s) H_{xx}(y^\varepsilon(s), u^\varepsilon(s), \lambda^\varepsilon, p^\varepsilon(s), \{q^{\varepsilon i}(s)\}_1^d, r_s^\varepsilon(\cdot)) y_1^\varepsilon(s) ds \\
&\qquad + \text{trace } P^\varepsilon(s) \Big[\Delta b^{\varepsilon i}(s; u^{\varepsilon\rho}(s)) \Delta b^{\varepsilon i *}(s; u^{\varepsilon\rho}(s)) \\
&\qquad\qquad + \int_{\mathcal{Z}} \Delta c^\varepsilon(s,z; u^{\varepsilon\rho}(s)) \Delta c^{\varepsilon *}(s,z; u^{\varepsilon\rho}(s)) \pi(dz) \Big]
\end{aligned}
$$

(3.19)
$$
\begin{aligned}
&+\int_{\mathcal{Z}} \operatorname{trace}\,[R_s^\varepsilon(z)\Delta c^\varepsilon(s,z;u^{\varepsilon\rho}(s))\Delta c^{\varepsilon *}(s,z;u^{\varepsilon\rho}(s))]\pi(dz)\Big\}ds\\
&+2E\int_0^1 \Big\{\operatorname{trace} P^\varepsilon(s)\Big[b_x^{\varepsilon k}(s)y_1^\varepsilon(s)\Delta b^{\varepsilon k *}(s;u^{\varepsilon\rho}(s))\\
&\qquad\qquad +\int_{\mathcal{Z}} c_x^\varepsilon(s,z)y_1^\varepsilon(s)\Delta c^{\varepsilon *}(s,z;u^{\varepsilon\rho}(s))\pi(dz)\Big]\\
&\qquad +\operatorname{trace}[Q^\varepsilon(s)y_1^\varepsilon(s)\Delta b^{\varepsilon k *}(s;u^{\varepsilon\rho}(s))]\\
&\qquad +\int_{\mathcal{Z}} \operatorname{trace} R_s^\varepsilon(z)[c_x^\varepsilon(s,z)y_1^\varepsilon(s)\Delta c^{\varepsilon *}(s,z;u^{\varepsilon\rho}(s))\\
&\qquad\qquad +y_1^\varepsilon(s)\Delta c^{\varepsilon *}(s,z;u^{\varepsilon\rho}(s))]\pi(dz)\Big\}ds.
\end{aligned}
$$

Noting (3.11), we conclude from (3.12)–(3.14) and (3.17)–(3.19) that

$$
\begin{aligned}
&\langle \lambda^\varepsilon Eh_y(y_0^\varepsilon, y^\varepsilon(1)) + \mu^{\varepsilon j} Ef_y^j(y_0^\varepsilon, y^\varepsilon(1)) + p^\varepsilon(0), \eta\rangle |I_\rho|\\
&\quad +\int_0^1 l^\varepsilon(s;u^{\varepsilon\rho}(s))ds + o(|I_\rho|) \geq -|I_\rho|\sqrt{\varepsilon+2\delta(\varepsilon)}\sqrt{1+|\eta|^2},
\end{aligned}
\tag{3.20}
$$

where $l^\varepsilon(\cdot;v)$ is defined by

$$
\begin{aligned}
l^\varepsilon(s;v) =:\ & E\{H(y^\varepsilon(s),v,\lambda^\varepsilon,p^\varepsilon(s),\{q^{\varepsilon i}(s)\}_1^d,r_s^\varepsilon(\cdot))\\
&-H(y^\varepsilon(s),u^\varepsilon(s),\lambda^\varepsilon,p^\varepsilon(s),\{q^{\varepsilon i}(s)\}_1^d,r_s^\varepsilon(\cdot))\\
&+\frac{1}{2}\operatorname{trace} P^\varepsilon(s)\Big[\Delta b^{\varepsilon i}(s;v)\Delta b^{\varepsilon i *}(s;v)\\
&+\int_{\mathcal{Z}} \Delta c^\varepsilon(s,z;v)\Delta c^{\varepsilon *}(s,z;v)\pi(dz)\Big]\\
&+\frac{1}{2}\operatorname{trace}\int_{\mathcal{Z}} R_s(z)\Delta c^\varepsilon(s,z;v)\Delta c^{\varepsilon *}(s,z;v)\pi(dz)\}.
\end{aligned}
\tag{3.21}
$$

Step 3. *Differentiability.* For given $v(\cdot)\in U_{\text{ad}}$, applying Lemma 2.2 to the real valued Lebesgue integrable function, we know that there exists $I_\rho\subset[0,1]$ such that

$$
\begin{aligned}
&|I_\rho| = \rho,\\
&\int_{I_\rho} l^\varepsilon(s;v(s))ds = \rho\int_0^1 l^\varepsilon(s;v(s))ds + o(\rho), \quad \text{as } \rho\to 0.
\end{aligned}
\tag{3.22}
$$

Next choose the above I_ρ in (3.7), and we have

$$
\int_{I_\rho} l^\varepsilon(s;v(s))ds = \int_0^1 l^\varepsilon(s;u^{\varepsilon\rho}(s))ds. \tag{3.23}
$$

From (3.20)–(3.23), we conclude for given $v(\cdot)\in U_{\text{ad}}$ that

$$
\begin{aligned}
&\langle \lambda^\varepsilon Eh_y(y_0^\varepsilon, y^\varepsilon(1)) + \mu^{\varepsilon j} Ef_y^j(y_0^\varepsilon, y^\varepsilon(1)) + p^\varepsilon(0), \eta\rangle\rho + \rho\int_0^1 l^\varepsilon(s;v(s))ds\\
&\quad \geq -\rho\sqrt{\varepsilon+2\delta(\varepsilon)}\sqrt{1+|\eta|^2} + o(\rho), \quad \text{as } \rho\to 0.
\end{aligned}
\tag{3.24}
$$

Hence

$$\begin{aligned}(3.25)\qquad &\langle \lambda^\varepsilon E h_y(y_0^\varepsilon, y^\varepsilon(1)) + \mu^{\varepsilon j} E f_y^j(y_0^\varepsilon, y^\varepsilon(1)) + p^\varepsilon(0), \eta\rangle + \int_0^1 l^\varepsilon(s; v(s))ds \\ &\quad \geq -\sqrt{\varepsilon + 2\delta(\varepsilon)}\sqrt{1+|\eta|^2}, \quad \forall\, \eta \in \mathcal{R}^n \quad \text{and} \quad \forall\, v(\cdot) \in U_{\text{ad}}.\end{aligned}$$

This implies that

$$\begin{aligned}(3.26)\qquad &|p^\varepsilon(0) + \lambda^\varepsilon E h_y(y_0^\varepsilon, y^\varepsilon(1)) + \mu^{\varepsilon j} E f_y^j(y_0^\varepsilon, y^\varepsilon(1))| \leq C\sqrt{3\varepsilon}, \\ &\int_0^1 l^\varepsilon(s; v(s))ds \geq -\sqrt{\varepsilon + 2\delta(\varepsilon)}, \quad \forall\, v(\cdot) \in U_{\text{ad}}.\end{aligned}$$

Step 4. *Passing to the limit.* Without loss of generality, we assume that $\lambda^\varepsilon \to \lambda$, $\mu^\varepsilon \to \mu$, as $\varepsilon \to 0+$.

Let $\varepsilon \to 0+$. Equation $(3.6)_2$ gives the following:

$$\begin{aligned}(3.27)\qquad &E\int_0^1 \Big\{ H(y(s), v(s), \lambda, p(s), \{q^i(s)\}_1^d, r(s,\cdot)) - H(y(s), u(s), \lambda, p(s), \{q^i(s)\}_1^d, r(s,\cdot)) \\ &+ \frac{1}{2}\text{trace}\, P(s)\Big[\Delta b^i(s; v(s))\Delta b^{i*}(s; v(s)) + \int_{\mathcal{Z}} \Delta c(s,z; v(s))\Delta c^*(s,z; v(s))\pi(dz)\Big] \\ &+ \frac{1}{2}\text{trace}\int_{\mathcal{Z}} R(s,z)[\Delta c(s,z; v(s))\Delta c^*(s,z; v(s))]\,\pi(dz)\Big\} ds \geq 0, \qquad \forall v(\cdot) \in U_{\text{ad}};\end{aligned}$$

this implies (2.37). Furthermore, (2.34) is obtained from $(3.6)_1$, $(2.35)_2$ is obtained from $(3.26)_1$, and the rest of Theorem 2.1 is checked from (3.15)–(3.16).

Step 5. *The unbounded case of* U_{ad} *in* $L^{\infty,8}_{\mathcal{F},p}[[0,1];\mathcal{R}^m]$. This case can be treated via the bounded case. The details are as follows.

Set

$$(3.28)\qquad U_{\text{ad}}^K =: \{v(\cdot) \in U_{\text{ad}} |\, ||v(\cdot)|| \leq ||u(\cdot)|| + K\}, \quad K = 1, 2, \dots .$$

Obviously, we have

$$\begin{aligned}(3.29)\qquad &u(\cdot) \in U_{\text{ad}}^K \subset U_{\text{ad}}^{K+1}, \qquad K = 1, 2, \dots ; \\ &U_{\text{ad}} = \bigcup_{K=1}^{\infty} U_{\text{ad}}^K.\end{aligned}$$

Moreover, U_{ad}^K $(K = 1, 2, \dots)$ are bounded in $L^{\infty,8}_{\mathcal{F},p}[[0,1];\mathcal{R}^m]$, and the triplet $(y_0, y(\cdot), u(\cdot))$ is still optimal when the original admissible control set U_{ad} is replaced with U_{ad}^K $(K = 1, 2, \dots)$. Then, for each $K = 1, 2, \dots$, by steps 1–4, there exists

$$\{\lambda_K, \mu_K; p_K, \{q_K^i\}_{i=1}^d, r_K; P_K, \{Q_K^i\}_{i=1}^d, R_K\}$$

satisfying all the conditions of Theorem 2.1 except that the maximum condition (2.37) is replaced with the following (cf. (3.27)):

(3.30)
$$
\begin{aligned}
&E\int_0^1 \Big\{ H(y(s), v(s), \lambda_K, p_K(s), \{q_K^i(s)\}_1^d, r_K(s,\cdot)) \\
&- H(y(s), u(s), \lambda_K, p_K(s), \{q_K^i(s)\}_1^d, r_K(s,\cdot)) \\
&+ \frac{1}{2}\text{trace } P_K(s)\Big[\Delta b^i(s; v(s))\Delta b^{i*}(s; v(s)) + \int_{\mathcal{Z}} \Delta c(s,z; v(s))\Delta c^*(s,z; v(s))\pi(dz)\Big] \\
&+ \frac{1}{2}\text{trace}\int_{\mathcal{Z}} R_K(s,z)[\Delta c(s,z; v(s))\Delta c^*(s,z; v(s))]\,\pi(dz)\Big\}\,ds \geq 0, \qquad \forall v(\cdot) \in U_{\text{ad}}^K.
\end{aligned}
$$

Without loss of generality, we assume

$$\lambda_K \to \lambda, \quad \mu_K \to \mu \quad \text{as } K \to \infty.$$

Then we see that $\{p_K, \{q_K^i\}_{i=1}^d, r_K; P_K, \{Q_K^i\}_{i=1}^d, R_K\}_{K=1}^\infty$ is a Cauchy sequence. Let its limit be denoted by $\{p, \{q^i\}_{i=1}^d, r; P, \{Q^i\}_{i=1}^d, R\}$. By letting $K \to \infty$, we can obtain conditions 1), 2), and 4) of Theorem 2.1. The remainder is to prove the maximum condition 3).

For fixed $v(\cdot) \in U_{\text{ad}}$, we see from (3.29) and (3.30) that there exists K_0 such that

(3.31)
$$
\begin{aligned}
&E\int_0^1 \Big\{ H(y(s), v(s), \lambda_K, p_K(s), \{q_K^i(s)\}_1^d, r_K(s,\cdot)) \\
&- H(y(s), u(s), \lambda_K, p_K(s), \{q_K^i(s)\}_1^d, r_K(s,\cdot)) \\
&+ \frac{1}{2}\text{trace } P_K(s)\Big[\Delta b^i(s; v(s))\Delta b^{i*}(s; v(s)) + \int_{\mathcal{Z}} \Delta c(s,z; v(s))\Delta c^*(s,z; v(s))\pi(dz)\Big] \\
&+ \frac{1}{2}\text{trace}\int_{\mathcal{Z}} R_K(s,z)[\Delta c(s,z; v(s))\Delta c^*(s,z; v(s))]\,\pi(dz)\Big\}\,ds \geq 0, \qquad \text{as } K > K_0.
\end{aligned}
$$

Hence

(3.32)
$$
\begin{aligned}
&E\int_0^1 \Big\{ H(y(s), v(s), \lambda, p(s), \{q^i(s)\}_1^d, r(s,\cdot)) - H(y(s), u(s), \lambda, p(s), \{q^i(s)\}_1^d, r(s,\cdot)) \\
&+ \frac{1}{2}\text{trace } P(s)\Big[\Delta b^i(s; v(s))\Delta b^{i*}(s; v(s)) + \int_{\mathcal{Z}} \Delta c(s,z; v(s))\Delta c^*(s,z; v(s))\pi(dz)\Big] \\
&+ \frac{1}{2}\text{trace}\int_{\mathcal{Z}} R(s,z)[\Delta c(s,z; v(s))\Delta c^*(s,z; v(s))]\,\pi(dz)\Big\}\,ds \geq 0.
\end{aligned}
$$

Note that (3.31) holds for all $v(\cdot) \in U_{\text{ad}}$, and therefore the maximum condition 3) follows.

The proof of Theorem 2.1 is complete. □

Remark 3.1. In the proof of Theorem 2.1, I_ρ is chosen so that $\int_{I_\rho} l^\varepsilon(s; u^{\varepsilon\rho}(s))\,ds$ is differentiable with respect to $|I_\rho|$, and the derivative is $\int_0^1 l^\varepsilon(s; v(\cdot))\,ds$. When choosing $I_\rho = [t, t+\rho]$,$u^\rho(\cdot)$, defined by (2.1) is the so-called "spike-variation" control of the optimal control $u(\cdot)$. This is the approach in [17], [21] for the case $c \equiv 0$. When the control enters into neither diffusion nor jump terms, the spike-variation method is enough for the "differentiating" argument (step 3) to be rigorous; for this justification,

the reader is referred to [1], [10], [13], [17] for the case $c \equiv 0$. When the control appears in either diffusion or jump terms, however, the classical spike-variation method is not rigorous in the "differentiating" argument (because, even for the case of $c \equiv 0$, we are not sure that the stochastic process $q(\cdot)$ is continuous), and the I_ρ has to be carefully chosen as in step 3 so that the "differentiating" argument is rigorous.

4. Conclusion. The stochastic maximum principle with random jumps is quite different from that corresponding to the pure diffusion system. In calculating the first-order coefficient of the cost variation, we use only a property for Lebesgue integrals of scalar-valued functions in the real number space $\mathcal{R}$. This application can overcome the difficulty of "differentiation" caused by the appearence of the control in either diffusion or jump terms.

Appendix. The Proof of Lemma 2.3. In the Appendix, we provide the detailed proof of Lemma 2.3 concerning the Martingale representation result. The proof is an adaptation of that for Theorem 6.6 (see [16, p. 80]). Before starting the proof, we first give some lemmas.

Define

$$\begin{aligned} \mathcal{F}_t^w &=: \sigma[w(s); s \le t] \bigvee \mathcal{N}, \\ \mathcal{F}_t^k &=: \sigma[N_k(A, (0, s]); s \le t, A \in \mathcal{B}(\mathcal{Z})] \bigvee \mathcal{N}, \\ \mathcal{F}_t^* &=: \mathcal{F}_t^w \bigvee \mathcal{F}_t^k. \end{aligned} \tag{A1}$$

LEMMA A1. $\mathcal{F}_{t+0}^* = \mathcal{F}_t^*$.

Proof. We can check that $w(\cdot)$ is an $\mathcal{F}_t^*$-adapted Wiener process, and $k(\cdot)$ is an $\mathcal{F}_t^*$-adapted Poisson point process.

Let $0 \le t_1 < t_2 < \cdots < t_n$ and $f_1, f_2, \ldots, f_n \in C_0(\mathcal{R}^d)$,[1] $g_{ij} (i = 1, \ldots, n, j = 1, \ldots, m)$ be bounded functions from the positive integer set $\mathbb{N}$ to $\mathcal{R}$, and $U_1, \ldots, U_m \in \mathcal{B}(\mathcal{Z})$ be disjoint such that $\widehat{N}_k(U_j, (0, t]) =: \pi(U_j)t < \infty (j = 1, \ldots, m)$ for all $t > 0$. From the independence property of $\{w(t)\}$ and $\{N_k(U_j, (0, t])\}_{j=1}^m$ we have

$$\begin{aligned} &E\left[\prod_{i=1}^n f_i(w(t_i)) \prod_{i=1}^n \prod_{j=1}^m g_{ij}(N_k(U_j, (0, t_i]))| \mathcal{F}_t^*\right] \\ &= E\left[\prod_{i=1}^n f_i(w(t_i))| \mathcal{F}_t\right] \prod_{j=1}^m E\left[\prod_{i=1}^n g_{ij}(N_k(U_j, (0, t_i]))| \mathcal{F}_t^*\right]. \end{aligned}$$

Furthermore, if $t_{i^*-1} \le t < t_{i^*}$, we have

$$\begin{aligned} &E\left[\prod_{i=1}^n f_i(w(t_i))| \mathcal{F}_t^*\right] \\ &= \prod_{i=1}^{i^*-1} f_i(w(t_i)) H_{n-i^*+1}(t_{i^*} - t, t_{i^*+1} - t, \ldots, t_n - t; f_{i^*}, f_{i^*+1}, \ldots, f_n)(w(t)) \end{aligned}$$

[1] $C_0(\mathcal{R}^d)$ is the Banach space of all continuous functions on $\mathcal{R}^d$ such that $\lim_{|x| \to \infty} = 0$ with the maximum norm.

with

$$\begin{cases} H_1(t;f) =: H_t f, f \in C_0(\mathcal{R}^d), \\ H_t f(x) =: \int_{\mathcal{R}^d} p(t, x-y) f(y)\, dy, \ f \in C_0(\mathcal{R}^d), \\ p(t,x) =: (2\pi t)^{-d/2} \exp[-|x|^2/2t], \\ H_n(t_1, \dots, t_n; f_1, \dots, f_n) = H_{n-1}(t_1, \dots, t_{n-1}; f_1, \dots, f_{n-2}, f_{n-1} H_{t_n - t_{n-1}} f_n) \end{cases}$$

and

$$\begin{aligned} & E\left[\prod_{i=1}^{n} g_{ij}(N_k(U_j, (0,t_i]))| \mathcal{F}_t^*\right] \\ &= \prod_{i=1}^{i^*-1} g_{ji}(N_k(U_j, (0,t_i])) \\ &\quad \times \tilde{H}^j_{n-i^*+1}(t_{i^*} - t, t_{i^*+1} - t, \dots, t_n - t; g_{i^*}, g_{i^*+1}, \dots, g_n)(N_k(U_j, (0,t])) \end{aligned}$$

with

$$\tilde{H}_1^j(t;g) =: \tilde{H}_t^j g,$$

$$\begin{aligned} (\tilde{H}_t^j g)(m) &=: \prod_{n=1}^{\infty} g(n+m) \frac{[\hat{N}_k(U_j, (0,t])]^n e^{-\hat{N}_k(U_j,(0,t])}}{n!} \\ &=: \prod_{n=m}^{\infty} g(n) \frac{[\hat{N}_k(U_j, (0,t])]^{n-m} e^{-\hat{N}_k(U_j,(0,t])}}{(n-m)!} \\ &\quad \times \tilde{H}_n^j(t_1, t_2, \dots, t_n; g_1, g_2, \dots, g_n) \\ &=: \tilde{H}^j_{n-1}(t_1, t_2, \dots, t_{n-1}; g_1, g_2, \dots, g_{n-2}, g_{n-1} \tilde{H}^j_{t_n - t_{n-1}} g_n). \end{aligned}$$

Note that $H_{n-i^*+1}(t_{i^*} - \tau, t_{i^*+1} - \tau, \dots; f_{i^*}, f_{i^*+1}, \dots, f_n)(w(t))$ and $\tilde{H}^j_{n-i^*+1} \times (t_{i^*} - \tau, t_{i^*+1} - \tau, \dots; f_{i^*}, f_{i^*+1}, \dots, f_n)(m)$ are continuous at $\tau = t$ for fixed m. Paying attention to the right-continuity property with respect to τ of the Brownian motion $w(\tau)$ and the counting measure $N_k(U_j, (0,\tau])$, we have

$$\begin{aligned} E[\bullet\bullet\,|\mathcal{F}^*_{t+0}] &= \lim_{h\to 0+} E[E[\bullet\bullet\,|\mathcal{F}^*_{t+h}]|\mathcal{F}^*_{t+0}] \\ &= E[\lim_{h\to 0+} E[\bullet\bullet\,|\mathcal{F}^*_{t+h}]|\mathcal{F}^*_{t+0}] \\ &= E[E[\bullet\bullet\,|\mathcal{F}^*_t]|\mathcal{F}^*_{t+0}] \\ &= E[\bullet\bullet\,|\mathcal{F}^*_t], \end{aligned}$$

where $\bullet\bullet$ stands for $\prod_{i=1}^n f_i(w(t_i))$ or $\prod_{i=1}^n g_{ij}(N_k(U_j, (0,t_i])), j = 1, 2, \dots, m$. This proves the desired result. □

LEMMA A2. *For any increasing sequence $\{\sigma_n\}$ of $(\mathcal{F}_t^*)$-stopping times, we have*

$$\bigvee_n \mathcal{F}^*_{\sigma_n} = \mathcal{F}^*_\sigma,$$

where $\sigma = \lim_{n\to\infty} \sigma_n$. This property of $\mathcal{F}_t^*$ is called the quasi-left-continuous property.

Proof. Next we adopt the notations introduced in the proof of Lemma A1. The following is an adaptation of [16, p. 80]. Noting the independence property of the

Brownian motion and the Poisson point process as well as their strong Markov properties, we have

$$
\begin{aligned}
&E[\bullet\bullet|\mathcal{F}_\tau^*]\\
=&E\Big[\prod_{i=1}^n f_i(w(t_i))|\mathcal{F}_\tau^*\Big]\prod_{j=1}^m E\Big[\prod_{i=1}^n g_{ij}(N_k(U_j,(0,t_i]))|\mathcal{F}_\tau^*\Big]\\
=&\Big[\sum_{l=1}^n \chi_{\{t_{l-1}\le\tau<t_l\}}\prod_{i=1}^{l-1} f_i(w(t_i))H_{n-l+1}\\
&\times(t_l-\tau,t_{l+1}-\tau,\dots,t_n-\tau;f_l,f_{l+1},\dots,f_n)(w(\tau))\\
&+\prod_{i=1}^n f_i(w(t_i))\chi_{\{t_n\le\tau\}}\Big]\prod_{j=1}^m\Big[\sum_{l=1}^n\chi_{\{t_{l-1}\le\tau<t_l\}}\prod_{i=1}^{l-1}g_{ji}(N_k(U_j,(0,t_i]))\\
&\times\widetilde{H}_{n-l+1}^j(t_l-\tau,t_{l+1}-\tau,\dots,t_n-\tau;g_{jl},g_{j(l+1)},\dots,g_{jn})(N_k(U_j,(0,\tau]))\Big],
\end{aligned}
$$

for any $\mathcal{F}_t^*$-stopping time τ.

Paying attention to insure that the predictable dual projection $\widehat{N}_k(U_j,(0,t])$ of $\mathcal{F}_t^*$-Martingale $N_k(U_j,(0,t])$ is continuous with respect to t, we see that the $\mathcal{F}_t^*$-Martingale $N_k(U_j,(0,t])$ is quasi-left-continuous, almost surely,

$$\lim_{n\to\infty}N_k(U_j,(0,\sigma_n])=N_k(U_j,(0,\sigma]),\ \text{a.s.}$$

While obviously

$$\lim_{n\to\infty}w(\sigma_n)=w(\sigma),$$

by the continuity of the sample of $w(\cdot)$ with respect to t, we conclude the proof. □

Let $\mathcal{M}_2$ denote the space of $\mathcal{H}$-valued $\mathcal{F}_t^*$-adapted square-integrable Martingales $M(\cdot)$, satisfying $M(0)=0$. Write $L^2_{\mathcal{F}^*,p}$ for $L^2_{\mathcal{F}^*,p}[[0,1];\mathcal{H}]$, and F_p^2 for $F_p^2[[0,1];\mathcal{H}]$. Define

$$
\begin{aligned}
\mathcal{M}_2^*=:\Big\{&M(t)=\int_{(0,t]}q^i(s)dw^i(s)+\iint_{\mathcal{Z}\times(0,t]}r(s,z)\widetilde{N}_k(dzds)|\,q^i(\cdot)\in L^2_{\mathcal{F}^*,p},\\
&i=1,\dots,d;r(\cdot,\cdot)\in F_p^2.\Big\}
\end{aligned}
\tag{A2}
$$

LEMMA A3. *Let $M\in\mathcal{M}_2$ be bounded and suppose that $M\cdot N$ is $\mathcal{F}_t^*$-Martingale for every $N\in\mathcal{M}_2^*$. Then $M=0$.*

Proof. Let M^i denote the ith component of $M, i=1,\dots,n$, and $U_1\in\mathcal{B}(\mathcal{Z})$ satisfy $\hat{N}_k(U_1,(0,t])=:\pi(U_1)t<\infty$ for all $t>0$. Set $W(t)=w(t)\otimes q(U_1,(0,t]), t\in[0,1]$. We see that $M^iW, i=1,2,\dots,n$, are Martingales.

Assume $|M(t)|\le\alpha$, where α is a positive constant, and set $D^i(\omega)=:1+M^i(1,\omega)/2\alpha$, $i=1,2,\dots,n$. Then $D^i(\omega)\ge\frac{1}{2}$ and $E[D^i(\omega)]=1$. Define new probability measures $\widetilde{P}^i$ on $\mathcal{F}_1^*$ by

$$\widetilde{P}^i(B)=E[D^i(\omega)\chi_B(\omega)],\quad B\in\mathcal{F}_1^*;\quad i=1,2,\dots,n.$$

Then for every $\mathcal{F}_t^*$-stopping time $\sigma\in[0,1]$,

$$
\begin{aligned}
\widetilde{E}[W(\sigma)]&=E[D^i(\omega)W(\sigma)]=E[E[D^i(\omega)|\mathcal{F}_\sigma]W(\sigma)]\\
&=E[W(\sigma)]+\frac{1}{2\alpha}E[M^i(\sigma)W(\sigma)]=E[W(\sigma)]=0,
\end{aligned}
$$

because M^iW is an $\mathcal{F}_t^*$-Martingale, $i = 1, 2, \dots, n$.

Similarly, $\widetilde{E}[W(\sigma) \otimes W^j(\sigma) - \sigma[I \otimes \pi(U_1)] = 0$, because every component of the stochastic matrix process $W(\sigma) \otimes W^j(\sigma) - \sigma[I \otimes \pi(U_1)] = \int_0^t W(s) \otimes dW(s) + \int_0^t [dW(s)] \otimes W(s) + (0I) \otimes q(U_1, (0,t])$ belongs to $\mathcal{M}_2^*$,and hence $M^i\{W(\sigma) \otimes W^j(\sigma) - \sigma[I \otimes \pi(U_1)]\}$ is a matrix $\mathcal{F}_t^*$-Martingale, $i = 1, 2, \dots, n$. That is, both $t \mapsto W(t)$ and $t \mapsto W(\sigma) \otimes W^j(\sigma) - \sigma[I \otimes \pi(U_1)]$ are $\mathcal{F}_t^*$-Martingales with respect to the probabilities $\widetilde{P}^i, i = 1, 2, \dots, n$. By Theorem 6.3 of [16], $t \mapsto w(t)$ is an $\mathcal{F}_t^*$-Brownian motion and $t \mapsto k(t)$ is an $\mathcal{F}_t^*$-Poisson point process with respect to $\widetilde{P}^i, i = 1, 2, \dots, n$. This clearly implies that $P = \widetilde{P}^i$ on $\mathcal{F}_1^*, i = 1, 2, \dots, n$; hence we must have $D = 1$ almost surely, almost everywhere, $M = 0$ almost surely. The proof is finished. □

Proof of Lemma 2.3. Lemma 2.3 asserts that $\mathcal{M}_2 = \mathcal{M}_2^*$. To prove this, we first show that every $M \in \mathcal{M}_2$ can be expressed as

$$M(t) = M_1(t) + M_2(t), \tag{A3}$$

where $M_1 \in \mathcal{M}_2^*$ and $M_2 \in \mathcal{M}_2$ satisfies the following: $M_2 \cdot N$ is an $\mathcal{F}_t^*$-Martingale for all $N \in \mathcal{M}_2^*$. Clearly, such a decomposition is unique if it exists.

Let $\mathcal{H} = \{M_1(1) | M_1 \in \mathcal{M}_2^*\}$. It is easy to see that $\mathcal{H}$ is a closed subspace of $L_2(\Omega, P)$. Let $\mathcal{H}^\perp$ be the orthogonal complement of $\mathcal{H}$. Now, let $M \in \mathcal{M}_2$ be given. Then, since $M(1) \in L_2(\Omega, P)$, we have the orthogonal decomposition $M(1) = H_1 + H_2$, where $H_1 \in \mathcal{H}$ and $H_2 \in \mathcal{H}^\perp$. By definition, H_1 is of the form

$$H_1(\omega) = \int_0^1 \Phi(s)\, dw(s) + \iint_{\mathcal{Z} \times (0,1]} r(s,z)\, \widetilde{N}_k(dzds)$$

for some $\Phi \in L_2$ and $r \in F_p^2$. Let $M_2(t)$ be the right-continuous modification of $E[H_2 | \mathcal{F}_t^*]$. Then clearly

$$M(t) = M_1(t) + M_2(t), \qquad t \in [0,1],$$

where $M_1(t) = \int_0^t \Phi(s)\, dw(s) + \iint_{\mathcal{Z} \times (0,1]} r(s,z)\, \widetilde{N}_k(dzds)$. It remains to show that for every $N \in \mathcal{M}_2^*, t \mapsto M_2(t) \cdot N(t)$ is an $\mathcal{F}_t^*$-Martingale on $[0,1]$. For this it is sufficient to show that for every $\mathcal{F}_t^*$-stopping time σ such that $\sigma \le 1$, $E[M_2(\sigma) \cdot N(\sigma)] = 0$. However, if

$$N(t) = \int_0^t \Psi(s)\, dw(s) + \iint_{\mathcal{Z} \times (0,t]} r(s,z)\, \widetilde{N}_k(dzds),$$

then

$$\begin{aligned} N^\sigma(t) &=: N(t \wedge \sigma) \\ &= \int_0^t \Psi(s) \chi_{s \le \sigma} dw(s) + \iint_{\mathcal{Z} \times (0,t]} r(s,z) \chi_{s \le \sigma}\, \widetilde{N}_k(dzds) \in \mathcal{M}_2^*, \end{aligned}$$

and hence

$$\begin{aligned} E[N(\sigma) \cdot M_2(\sigma)] &= E[N(\sigma) \cdot E[M_2(1) | \mathcal{F}_\sigma^*]] \\ &= E[N(\sigma) \cdot M_2(1)] = E[N^\sigma(1) H_2] = 0. \end{aligned}$$

Thus far, we have completed the proof of the decomposition (A3).

Let $\widetilde{\mathcal{N}} =: \{M \in \mathcal{M}_2 | M \text{ is bounded}\}$. It is easy to see that $\widetilde{\mathcal{N}}$ is dense in $\mathcal{M}_2$. Let $M \in \widetilde{\mathcal{N}}$ and $M = M_1 + M_2$ be the decomposition of (A3). Since $M_1 \in \mathcal{M}_2^*$, we

can check that

$$E \sup_{0\le t\le 1} |M_1(t)| < \infty,$$

and then $M_1(t)$ are almost surely bounded in t. Thus there exists a sequence σ_n $(= \sigma_n(M_1))$ of $\mathcal{F}_t^*$-stopping times such that $\sigma_n \in [0,1], \sigma_n \uparrow 1$, and $M_1^{\sigma_n} = (M_1(t\wedge\sigma_n))$ is a bounded Martingale, $n = 1, 2, \ldots$. As we know, $M_1^{\sigma_n} \in \mathcal{M}_2^*$ and $M^{\sigma_n} = M_1^{\sigma_n} + M_2^{\sigma_n}$ is the decomposition of (A3) for M^{σ_n} since $M_2^{\sigma_n} \cdot N$ is an $\mathcal{F}_t^*$-Martingale for every $N \in \mathcal{M}_2^*$. Set $\widehat{\mathcal{N}} =: \{M^{\sigma_n} | n = 1, 2, \ldots, M \in \widehat{\mathcal{N}}\}$. Then by Lemma A2 it is easy to see that $\widehat{\mathcal{N}}$ is dense in $\mathcal{M}_2$. Furthermore, if $M = M_1 + M_2$ is the decomposition of (A3) for $M \in \widehat{\mathcal{N}}$, then both M_1 and M_2 are bounded. Hence $M_2 = 0$ by Lemma A3. This shows that $\widehat{\mathcal{N}} \subset \mathcal{M}_2^*$.

Since $\mathcal{M}_2^*$ is closed and $\widehat{\mathcal{N}}$ is dense in $\mathcal{M}_2$, we have $\mathcal{M}_2 \subset \mathcal{M}_2^*$. The proof is complete. □

Acknowledgments. The authors thank Professor Jiongmin Yong for helpful conversations related to this subject. The authors also thank the editor and the referees for their useful suggestions to improve the first version of the paper.

NONSMOOTH OPTIMUM PROBLEMS WITH CONSTRAINTS*

ZS. PÁLES† AND V. M. ZEIDAN‡

Abstract. This paper develops second-order necessary conditions for nonsmooth infinite-dimensional optimization problems with Banach space-valued equality and real-valued inequality constraints. Another constraint in the form of a closed convex set is also present. The objective function is the maximum over a parameter of functions $f(t,z)$ that are Lipschitz in z and upper semicontinuous in t. The inequality constraints $g(s,z)$ depend on a parameter s. The technique we use is a generalization of that of Dubovitskii and Milyutin. The second-order conditions obtained here are in terms of a certain function σ that disappears when the parameters and a certain set that derives from the given convex set are absent. The presence of the function σ and that set is due to the envelope-like effect discovered by Kawasaki.

Key words. nonsmooth analysis, second-order necessary conditions, Dubovitskii–Milyutin approach, inequality constraints with parameter, envelope-like effect

AMS subject classifications. 49B27, 49B36

1. Introduction.

The goal of this paper is to develop second-order necessary conditions for nonsmooth optimum problems with constraints. The prototype of such a problem arises in control theory, when state inequality constraints are to be satisfied, or when the objective functional is the maximum of smooth functionals depending on a parameter from a compact metric space (minimax problems).

A general discussion on second- and higher-order necessary conditions can be found in Levitin, Milyutin, and Osmolovskii [16]. The Dubovitskii–Milyutin scheme for second order necessary conditions was first presented in [7]. This method was applied by Ben-Tal and Zowe [4] to abstract infinite-dimensional programming problems. The inequality-like constraint $-g(x) \in K$ treated in [4] can be considered as infinitely many (real-valued) inequality constraints, and, as was discovered by Kawasaki [12]–[15], we must encounter an envelope-like effect caused by the constraints (see also Ioffe [9], [10]). The result of this effect is that the second-order necessary conditions involve terms different from the second derivatives of the data of the problem. These new terms are probably enough to fill the gap between necessary and sufficient conditions.

In §2 we consider abstract optimum problems. Generalizing the scheme of Dubovitskii and Milyutin ([6], [7]), we deduce necessary conditions that involve the concepts of descent, admissible, and tangent variations for a one-parameter family of directions. The suitable choice of the family of directions then leads to first-, second-, and higher-order necessary conditions. The method introduced here is applicable to Pareto optimum problems as well. We also recall the separation theorem of Dubovitskii and Milyutin for convex sets, which enables us to rewrite the necessary conditions, as an analytic form, in terms of affine functionals from the adjoint sets of descent, admissible, and tangent variations. The standard results of convex analysis are also recalled here.

The object of §3 is to introduce the first- and second-order Clarke's derivative and the function σ, which plays a key role in the determination of descent and admissible

variations. This function σ appears first in the Key Lemma, which gives necessary and sufficient conditions for a quadratic inequality with function coefficients. The connection of the function σ to the function E of Kawasaki (see [13]–[15]) is described after the proof of the Key Lemma.

There are several notions of first- and second-order differentiation that are used to investigate optimization problems. One recent technique is due to Rockafellar [18], who introduced the concept of second-order epidifferentiation. (See also Ioffe [10].) As we see in §4, for our purposes Clarke's first derivative and the induced second-order directional derivative fit the best.

In §4 we deal with second-order descent variations. The objective functional considered there is of the form

$$F(z) = \max_{t \in T} f(t, z), \qquad z \in D,$$

where T is a compact metric space and D is an open set of a Banach space Z. The set of descent variations is completely described with the help of the first- and second-order Clarke's derivative and the function σ introduced in the previous section. Section 5 contains similar results for second-order admissible variations of inequality constraints. In the same section we also treat admissible variations of convex set constraints that are of great importance to control problems. Here we derive another form of the set introduced by Kawasaki for the case of convex cones (see [12]).

Second-order tangent variations of constraints $H(z) = 0$ are considered in §6. Here H maps Z into another Banach space. Several regularity assumptions have to be assumed on H, in order that the theorem of Lyusternik [17] on the tangent space of differentiable manifolds can be applied.

Section 7 contains the main result of this paper, a second-order Lagrange multiplier rule. We can automatically specialize it to a first-order rule taking the identically zero family of directions. This rule turns out to be sufficient to handle minimax problems, Pareto optima, inequality constraints consisting of "compactly many" inequalities, convex set constraints, and also equality constraints with one Banach space-valued equality and a finite number of real-valued equalities. Therefore this result can be used effectively in control problems, as we will show in a forthcoming paper. The result generalizes most of the known versions of the existing multiplier rules. For instance, some recent results of Ben-Tal and Zowe [4] and the results of Kawasaki [12],[13] are generalized. In [12] Kawasaki makes use of the so called Mangasarian–Fromovitz condition. Since Kawasaki uses tangent cones in describing the envelope-like effect, this condition seems to be important. In our approach the convex set constraints are handled in another way; therefore the results obtained do not involve the Mangasarian–Fromovitz condition.

2. Statement of the problem—General theory of variations. In this section we treat the notions and results introduced by Dubovitskii and Milyutin [6], [7] in a unified form. The advantage of our approach is that we can deal with first-, second-, and higher-order necessary conditions using the same scheme. We also formulate a result for optimum problems in the sense of Pareto. The sets of admissible, descent, and tangent variations introduced below turn out to have a certain relation, i.e., each set can be expressed with the use of one notion only.

Let Z be a Banach space (over $\mathbf{R}$), $D \subset Z$ be open, $F : D \to \mathbf{R}$ and $Q_1, \ldots, Q_N$,

Q_{N+1} subsets of Z. The problem $(\mathcal{P})$ is to minimize $F(z)$ subject to

$$z \in \bigcap_{i=1}^{N+1} Q_i. \tag{1}$$

A point $\hat{z} \in D$ is called a (*local*) *solution of* $(\mathcal{P})$ if $\hat{z} \in \cap_{i=1}^{N+1} Q_i$ and there exists a neighbourhood U of $\hat{z}$ such that

$$F(z) \geq F(\hat{z}) \quad \text{for all} \quad z \in \left(\bigcap_{i=1}^{N+1} Q_i \right) \cap U \cap D.$$

If there are given M objective functions $F_1, \ldots, F_M : D \to \mathbf{R}$, then we can speak about Pareto optimality subject to the above constraint (1). Denote this problem by $(\mathcal{P})^*$. A point $\hat{z} \in D$ is called a (*local*) *solution* of $(\mathcal{P})^*$ if $\hat{z} \in \cap_{i=1}^{N} Q_i$ and there exists a neighbourhood U of $\hat{z}$ such that

$$\text{for all} \quad z \in \left(\bigcap_{i=1}^{N+1} Q_i \right) \cap U \cap D \quad \exists j \text{ such that} \quad F_j(z) \geq F_j(\hat{z}).$$

Defining F by $F(z) := \max\left(F_1(z) - F_1(\hat{z}), \ldots, F_M(z) - F_M(\hat{z})\right)$, one can see that $\hat{z}$ is a solution of $(\mathcal{P})^*$ if and only if it is a solution of $(\mathcal{P})$ with this function F.

A function $d : [0, \varepsilon_0] \to Z$ will be called a *one-parameter family of directions* if it is continuous at 0 with $d(0) = 0$. In what follows, we introduce several concepts of variations of order k with respect to a given one-parameter family of directions d. We note that k need not be an integer in the definitions and theorems below, although it is in the usual applications.

DEFINITION 1. *A vector* $\overline{w} \in Z$ *is a* kth-order descent variation of F at $\hat{z}$ in the direction d *if there exists an* $\overline{\varepsilon} > 0$ *such that* $\hat{z} + d(\varepsilon) + \varepsilon^k(\overline{w} + w) \in D$ *and*

$$F\left(\hat{z} + d(\varepsilon) + \varepsilon^k(\overline{w} + w)\right) < F(\hat{z}),$$

whenever $0 < \varepsilon < \overline{\varepsilon}$ *and* $||w|| < \overline{\varepsilon}$. *We denote by* $\mathcal{W}_\delta^{(k)} = \mathcal{W}_\delta^{(k)}(F; \hat{z}, d)$ *the set of all such variations* $\overline{w}$. *This set* $\mathcal{W}_\delta^{(k)}$ *is always open.*

DEFINITION 2. *A vector* $\overline{w} \in Z$ *is called a* kth-order admissible variation of $Q \subset Z$ at $\hat{z}$ in the direction d *if there exists an* $\overline{\varepsilon} > 0$ *such that*

$$\hat{z} + d(\varepsilon) + \varepsilon^k(\overline{w} + w) \in Q$$

for $0 < \varepsilon < \overline{\varepsilon}$ *and* $||w|| < \overline{\varepsilon}$. *We denote this set by* $\mathcal{W}_\alpha^{(k)} = \mathcal{W}_\alpha^{(k)}(Q; \hat{z}, d)$, *which is always open.*

DEFINITION 3. *A vector* $\overline{w} \in Z$ *is said to be a* kth-order tangent variation of $Q \subset Z$ at $\hat{z}$ in the direction d *if there exist sequences* $\varepsilon_n > 0$ *and* $w_n \in Z$ *with* $\varepsilon_n \to 0$ *and* $w_n \to 0$ *such that*

$$\hat{z} + d(\varepsilon_n) + {\varepsilon_n}^k(\overline{w} + w_n) \in Q \quad \textit{for all} \quad n \in \mathbf{N}.$$

This set will be denoted by $\mathcal{W}_\tau^{(k)} = \mathcal{W}_\tau^{(k)}(Q; \hat{z}, d)$.

Remarks. We can observe that Definitions 1 and 3 slightly differ from that of [6], [4], [8]. However, the changes here make possible the following unification: All the notions can be expressed in terms of the tangent variations.

Denote by $\rho_Q(z)$ the distance of $z \in Z$ from Q; then it is easy to check that

$$\mathcal{W}_\tau^{(k)}(Q;\hat{z},d) = \left\{ \overline{w} \mid \liminf_{\varepsilon \to 0+} \frac{\rho_Q(\hat{z} + d(\varepsilon) + \varepsilon^k \overline{w})}{\varepsilon^k} = 0 \right\}.$$

We can also write

$$\mathcal{W}_\tau^{(k)}(Q;\hat{z},d) = \operatorname*{Limsup}_{\varepsilon \to 0+} \frac{1}{\varepsilon^k}\big(Q - \hat{z} - d(\varepsilon)\big);$$

here Limsup denotes the upper set-limit introduced in [2]. The following duality relation between $\mathcal{W}_\tau^{(k)}$ and $\mathcal{W}_\alpha^{(k)}$ can be easily proved:

$$\mathcal{W}_\alpha^{(k)}(Z \setminus Q;\hat{z},d) = Z \setminus \mathcal{W}_\tau^{(k)}(Q;\hat{z},d)$$

for all $Q \subset Z$, $\hat{z} \in Z$. If Q denotes the level set $\{z \in D \mid F(z) < F(\hat{z})\}$, then we have

$$\mathcal{W}_\delta^{(k)}(F;\hat{z},d) = \mathcal{W}_\alpha^{(k)}(Q;\hat{z},d).$$

Therefore, using the concept of tangent variations, the sets of admissible and descent variations can be determined.

If $k = 1$ and $d \equiv 0$, then the above relations show that $\mathcal{W}_\tau^{(1)}$ is the contingent cone of Q at $\hat{z}$ (cf. [2, p. 121]). In this case the set $\mathcal{W}_\alpha^{(1)}$ becomes the Dubovitskii–Milyutin cone defined in [2, p. 126]. The duality relation between these two cones is stated there in Lemma 4.1.4. (See also [6] for the origin of these concepts.)

If $k = 2$ and $d(\varepsilon) \equiv \varepsilon\overline{d}$ for some constant vector $\overline{d}$, then we obtain the concept of second variations due to [7]. To obtain variations of order k, we must take $d(\varepsilon) = P(\varepsilon)$, where $P(\varepsilon)$ is a polynomial in ε of degree $k-1$ with $P(0) = 0$. This concept of higher-order tangent variations corresponds to the higher-order contingent set defined in [2, §4.7]. In [2] two other tangent sets, the adjacent and circatangent (Clarke's) sets, are also defined; however these concepts do not play any role in our approach.

We can easily check that $\mathcal{W}_\alpha^{(k)}$, $\mathcal{W}_\delta^{(k)}$ and $\mathcal{W}_\tau^{(k)}$ do not depend on the terms of d of order higher than k; i.e., if $d_1, d_2 : [0,\varepsilon_0] \to Z$ are two families of directions, such that $\|d_1(\varepsilon) - d_2(\varepsilon)\|/\varepsilon^k \to 0$ as $\varepsilon \to 0$, then

$$\mathcal{W}_\alpha^{(k)}(F;\hat{z},d_1) = \mathcal{W}_\alpha^{(k)}(F;\hat{z},d_2), \qquad \mathcal{W}_\delta^{(k)}(Q;\hat{z},d_1) = \mathcal{W}_\delta^{(k)}(Q;\hat{z},d_2),$$

and

$$\mathcal{W}_\tau^{(k)}(Q;\hat{z},d_1) = \mathcal{W}_\tau^{(k)}(Q;\hat{z},d_2).$$

Now we state a general necessary condition for optimality. This result contains that of [6] and [7] by the above remarks. Its proof follows the ideas in [4]. But it is so brief that we present it here only to render the presentation complete.

THEOREM 1. *If $\hat{z}$ is a local minimum for the problem $(\mathcal{P})$, then*

$$\mathcal{W}_\delta^{(k)}(F;\hat{z},d) \cap \left(\bigcap_{i=1}^{N} \mathcal{W}_\alpha^{(k)}(Q_i;\hat{z},d) \right) \cap \mathcal{W}_\tau^{(k)}(Q_{N+1};\hat{z},d) = \emptyset$$

for all one-parameter families of variations d and for all $k \in]0,\infty[$.

Proof. Let us proceed by contradiction. If there exist d and k so that there is an element $\overline{w}$ in the intersection above, then there exists $\overline{\varepsilon} > 0$ such that

$$\begin{aligned} \hat{z} + d(\varepsilon) + \varepsilon^k(\overline{w} + w) &\in D, \\ F\left(\hat{z} + d(\varepsilon) + \varepsilon^k(\overline{w} + w)\right) &< F(\hat{z}), \\ \hat{z} + d(\varepsilon) + \varepsilon^k(\overline{w} + w) &\in \bigcap_{i=1}^{N} Q_i \end{aligned}$$

hold for all $||w|| < \overline{\varepsilon}$ and $0 < \varepsilon < \overline{\varepsilon}$. Furthermore, there exist sequences $\varepsilon_n > 0$, $w_n \in Z$ converging to zero such that

$$\hat{z} + d(\varepsilon_n) + {\varepsilon_n}^k(\overline{w} + w_n) \in Q_{N+1}$$

for all $n \in \mathbf{N}$.

Choose n_0 such that $\varepsilon_n < \overline{\varepsilon}$ and $||w_n|| < \overline{\varepsilon}$ for all $n > n_0$. Then the sequence $z_n := \hat{z} + d(\varepsilon) + {\varepsilon_n}^k(\overline{w} + w_n)$ converges to $\hat{z}$ and

$$z_n \in \bigcap_{i=1}^{N+1} Q_i \quad \text{and} \quad F(z_n) < F(\hat{z}) \quad \text{for all} \quad n > n_0.$$

However, this is in contradiction with the optimality of $\hat{z}$. □

In a similar manner, we can obtain necessary conditions for Pareto optima using the following analogue of Theorem 1.

THEOREM 1*. *If $\hat{z}$ is a local minimum for the problem $(\mathcal{P})^*$, then*

$$\left(\bigcap_{j=1}^{M} \mathcal{W}_\delta^{(k)}(F_j; \hat{z}, d)\right) \cap \left(\bigcap_{i=1}^{N} \mathcal{W}_\alpha^{(k)}(Q_i; \hat{z}, d)\right) \cap \mathcal{W}_\tau^{(k)}(Q_{N+1}; \hat{z}, d) = \emptyset$$

for all one-parameter families of variations d and for all $k \in]0, \infty[$.

To extract useful information from the necessary condition of Theorem 1 (and Theorem 1*), the following separation theorem of Dubovitskii and Milyutin is a fundamental one.

LEMMA 1. *Let $C_0, C_1, \ldots, C_K$ be given nonempty convex sets in Z such that $C_1, \ldots, C_K$ are open. Then*

$$\bigcap_{i=0}^{K} C_i = \emptyset$$

if and only if there exist affine functions $\varphi_0, \ldots, \varphi_K : Z \to \mathbf{R}$ (not simultaneously identically constant) such that

$$\sum_{i=0}^{K} \varphi_i = 0 \quad \text{and} \quad \varphi_i|_{C_i} \geq 0, \qquad i = 0, \ldots, K.$$

Proof. For the proof see [7]. □

Remark. To apply this separation theorem to the problem involved in Theorem 1, we need conditions on the data and on the one-parameter family of directions d so that the nonemptiness and the convexity of the sets $\mathcal{W}_\alpha^{(k)}$, $\mathcal{W}_\delta^{(k)}$, and $\mathcal{W}_\tau^{(k)}$ are

assured. A one-parameter family of directions is called *critical* for the problem $(\mathcal{P})$ if all these sets are convex and nonempty.

For a nonempty convex set $C \subset Z$, we define the adjoint set of C by

$$C^+ := \{\varphi : Z \to \mathbf{R} \mid \varphi \text{ is affine and } \varphi|_C \geq 0\}.$$

Now we list some additional results from convex analysis that we use in what follows. The proofs of Lemmas 2 and 4 can be obtained by using standard arguments of convex analysis that can be found in [1] and [11]. Lemma 3 is derived from [12, Lem. 5.4].

When $C \subset Z$ is the solution set of "compactly many" convex inequalities, then its adjoint set is described in the following lemma.

LEMMA 2. *Let T be a compact metric space, D is an open set in Z and $\gamma : T \times D \to \mathbf{R}$ be an upper semicontinuous function such that it is convex and uniformly locally Lipschitz in the second variable. Denote*

$$C := \{ z \in Z \mid \gamma(t, z) < 0, \forall t \in T \}.$$

Then C is open and convex. If $C \neq \emptyset$, then

$$C^+ = \{ \varphi : Z \to \mathbf{R} \mid \varphi \text{ is affine } \exists \mu \in \mathcal{M}(T) : \varphi(z) \geq -\int_T \gamma(t, z) d\mu, \ (z \in Z) \},$$

where $\mathcal{M}(T)$ denotes the set of all nonnegative bounded Borel measures on the Borel measurable subsets of T.

If $C = \emptyset$, then there exists a nonzero $\mu \in \mathcal{M}(T)$ such that

$$\int_T \gamma(t, z) d\mu(t) \geq 0 \quad \text{for all} \quad z \in Z.$$

When C is the conical hull of a translate of $\operatorname{cone}(Q^\circ - \hat{z})$, where Q is a convex set, then the description of its adjoint set requires the following notion: A linear functional $z^* : Z \to \mathbf{R}$ is called a *supporting functional of the convex set Q at $\hat{z} \in Q$* if $z^*(z) \geq z^*(\hat{z})$ holds true for all $z \in Q$. We denote this set by $Q^*(\hat{z})$.

LEMMA 3. *Let $Q \subset Z$ be a closed convex set with nonempty interior, $\hat{z} \in Q$, $\overline{d} \in \overline{\operatorname{cone}}(Q - \hat{z})$ and*

$$C := \operatorname{cone}(\operatorname{cone}(Q^\circ - \hat{z}) - \overline{d}).$$

(Here "cone" and "$\overline{\text{cone}}$" stand for the conical and closed conical hull, respectively.) Then an affine function $\varphi(z) = z^*(z) + c$ (where $z^* \in Z^*$, $c \in \mathbf{R}$) is bounded below on C if and only if $z^* \in Q^*(\hat{z})$ and $z^*(\overline{d}) = 0$. Moreover

$$C^+ = \{ \varphi = z^* + c \mid z^* \in Q^*(\hat{z}), \ z^*(\overline{d}) = 0, \ c \geq 0 \}.$$

Define the *support function* of a set C by

$$\delta^*(z^*; C) := \sup\{z^*(c) : c \in C\}.$$

When C is the inverse image of a convex set by a surjective linear operator then the description of C^+ is contained in the following lemma.

LEMMA 4. *Let Z and Y be Banach spaces and $A : Z \to Y$ be a bounded linear operator that maps Z onto Y and let $K \subset Y$ be a nonempty convex set. Denote*

$$C := \{ z \in Z \mid Az \in K \}.$$

Then

$$C^+ = \{\, \varphi : Z \to \mathbf{R} \mid \varphi \text{ is affine and } \exists y^* \in Y^* : \varphi(z) \geq -y^* Az + \delta^*(y^*; K),\ z \in Z \,\}.$$

The subject of the following sections is the determination of second-order descent, admissible, and tangent variations and their adjoint sets.

3. Basic concepts of differentiations, auxiliary results. In this section we recall first the concept of *Clarke's generalized derivative* and introduce a more general notion for functions that are pointwise suprema of families of functions.

If F is a real-valued locally Lipschitzian functional on an open set D of Z, and $\hat{z} \in D$, then *Clarke's generalized derivative* of F at $\hat{z}$ is defined by

$$F^\circ(\hat{z}; d) := \limsup_{(z,\varepsilon)\to(\hat{z},0+)} \frac{F(z+\varepsilon d) - F(z)}{\varepsilon}, \qquad d \in Z$$

(cf. [5]). Using this notion, we introduce the second-order directional derivative

$$F^{\circ\circ}(\hat{z}; d) := \limsup_{\varepsilon\to 0+} 2\frac{F(\hat{z}+\varepsilon d) - F(\hat{z}) - \varepsilon F^\circ(\hat{z}; d)}{\varepsilon^2}.$$

If F is a Fréchet-differentiable function at $\hat{z}$ then $F^\circ(\hat{z}; d) = F'(\hat{z})d$; furthermore if F is two times differentiable at $\hat{z}$, then $F^{\circ\circ}(\hat{z}; d) = F''(\hat{z})(d, d)$.

Now we are going to deal with functionals $F : D \to \mathbf{R}$ represented in the form

$$F(z) = \sup_{t\in T} f(t, z), \tag{2}$$

where T is a compact metric space, $f : T \times D \to \mathbf{R}$ is an upper semicontinuous function in the first variable and uniformly locally Lipschitzian at $\hat{z}$ in the second variable. (This means that there exists $\varepsilon > 0$ and $K \in \mathbf{R}$ such that $\|f(t, z') - f(t, z'')\| \leq K\|z' - z''\|$ if $\|z' - \hat{z}\| < \varepsilon$ and $\|z'' - \hat{z}\| < \varepsilon$.) Note that these conditions imply the upper semicontinuity of $(t, z) \mapsto f(t, z)$. Since upper semicontinuous functions attain their suprema on compact spaces, "sup" can be changed to "max" in (2). We denote this class of functions by $\mathcal{F}(T, D)$.

The study of functionals of this form is sufficient to handle problems with very general objective functions, minimax problems, Pareto optima, and inequality constraints as well. Now we introduce the following generalization of Clarke's derivative: For functions $f : T \times D \to \mathbf{R}$ with $f \in \mathcal{F}(T, D)$, define

$$f^\circ_{[T]}(t, \hat{z}; d) := \limsup_{(\tau,z,\varepsilon)\to(t,\hat{z};0+)} \frac{f(\tau, z+\varepsilon d) - f(\tau, z)}{\varepsilon},$$

$$f^{\circ\circ}_{[T]}(t, \hat{z}; d) := \limsup_{(\tau,\varepsilon)\to(t,0+)} 2\frac{f(\tau, \hat{z}+\varepsilon d) - f(\tau, \hat{z}) - \varepsilon f^\circ_{[T]}(\tau, \hat{z}; d)}{\varepsilon^2}.$$

Clearly, $f^\circ_{[T]}$ is a real-valued and $f^{\circ\circ}_{[T]}$ is an extended real-valued function. We note that $f^\circ_{[T]}$ is usually not identical with f° (and the same is true for $f^{\circ\circ}_{[T]}$ and $f^{\circ\circ}$). If T is discrete, then $f^\circ_{[T]} = f^\circ$ and $f^{\circ\circ}_{[T]} = f^{\circ\circ}$ obviously holds. If f is Fréchet differentiable and $(t, z) \to f'(t, z)$ is continuous on $T \times Z$, then $f^\circ_{[T]}(t, \hat{z}, d) = f^\circ(t, \hat{z}, d) = f'(t, \hat{z})(d)$; moreover, if f is twice Fréchet differentiable with continuous $(t, z) \to f''(t, z)$ on $T \times Z$, then $f^{\circ\circ}_{[T]}(t, \hat{z}, d) = f^{\circ\circ}(t, \hat{z}, d) = f''(t, \hat{z})(d, d)$ can also be checked. The most important properties of $f^\circ_{[T]}$ and $f^{\circ\circ}_{[T]}$ are summarized in the following lemma.

LEMMA 5. *Let $f \in \mathcal{F}(T, D)$. Then the functions $f^\circ_{[T]}$ and $f^{\circ\circ}_{[T]}$ have the following properties:*

(i) $f^{\circ}_{[T]}$ *is upper semicontinuous on* $T \times D \times Z$.

(ii) *For fixed* $t \in T$ *and* $\hat{z} \in D$, $d \mapsto f^{\circ}_{[T]}(t, \hat{z}; d)$ *is a positively homogeneous, subadditive and (globally) Lipschitz function.*

(iii) *For fixed* $\hat{z} \in D$ *and* $d \in Z$, $t \mapsto f^{\circ\circ}_{[T]}(t, \hat{z}; d)$ *is an upper semicontinuous function on* T.

(iv) *For fixed* $t \in T$ *and* $\hat{z} \in D$, $d \mapsto f^{\circ\circ}_{[T]}(t, \hat{z}; d)$ *is a positively quadratically homogeneous function.*

Proof. The proof of properties (i), (ii) is analogous to that of [5, Thm. 2.1.1]. Property (iii) can be verified similarly to (i). Finally, the proof of (iv) is obvious. □

In what follows, we prove a result necessary for describing descent and admissible variations. We introduce the following notation: If $\mathcal{C}$ is a condition for the points of T, then $T_{\mathcal{C}}$ denotes the set of those points of T, where $\mathcal{C}$ is satisfied, e.g., $T_{f>0}$ denotes the set $\{t \in T | f(t) > 0\}$, where $f : T \to \mathbf{R}$ is an arbitrary function. If H is a subset of T, then ∂H stands for the boundary of H.

KEY LEMMA. *Let* (T, ρ) *be a compact metric space and* $a, b, c : T \to \mathbf{R}$ *be upper semicontinuous functions. Define* $\sigma : T \to [-\infty, 0]$ *by*

$$\sigma(t) := \sigma_{a,b}(t) := \begin{cases} \liminf\limits_{\substack{\tau \to t \\ a(\tau) < 0,\ b(\tau) > 0}} \dfrac{b^2(\tau)}{4a(\tau)}, & \text{if} \quad t \in T_{a=0,\, b=0} \cap \partial(T_{a<0,\, b>0}), \\ 0, & \text{otherwise.} \end{cases}$$

Then σ *is a lower semicontinuous function and* $T_{\sigma<0}$ *is nowhere dense in* T. *Furthermore, the following statements are equivalent to each other*

(i)

$$\begin{array}{rcll} a(t) & \leq & 0 & \text{for all} \quad t \in T, \\ b(t) & \leq & 0 & \text{for all} \quad t \in T_{a=0}, \\ c(t) & < & \sigma(t) & \text{for all} \quad t \in T_{a=0,\, b=0}. \end{array}$$

(ii) *There exists* $\delta > 0$ *such that for all* $t_0 \in T$, *for all sequences* $t_n \in T$ *with* $t_n \to t_0$ *and* $\varepsilon_n > 0$ *with* $\varepsilon_n \to 0$,

$$a(t_n) + \varepsilon_n b(t_n) + {\varepsilon_n}^2 (c(t_0) + \delta) \leq 0$$

holds true for sufficiently large values of $n \in \mathbf{N}$.

Proof. First we show the lower semicontinuity of σ. Let $t_0 \in T_{a=0,\, b=0}$ be arbitrary and assume that σ is not lower semicontinuous at t_0. Then there exist $\delta > 0$ and a sequence t_n such that

$$\sigma(t_n) < \sigma(t_0) - \delta \quad \text{and} \quad 0 < \rho(t_n, t_0) < 1/2n \quad \text{for} \quad n \in \mathbf{N}. \tag{3}$$

Clearly, $t_n \in T_{a=0,\, b=0} \cap \partial(T_{a<0,\, b>0})$; therefore there exists $s_n \in T_{a<0,\, b>0}$ such that $\rho(s_n, t_n) < 1/2n$ and

$$\frac{b^2(s_n)}{4a(s_n)} < \begin{cases} \sigma(t_n) + \dfrac{1}{n}, & \text{if } \sigma(t_n) > -\infty, \\ -n, & \text{if } \sigma(t_n) = -\infty. \end{cases}$$

Then $s_n \to t_0$ as $n \to \infty$ and we have

$$\liminf_{n \to \infty} \sigma(t_n) = \liminf_{n \to \infty} \frac{b^2(s_n)}{4a(s_n)} \geq \sigma(t_0).$$

This inequality contradicts (3); therefore σ must be lower semicontinuous at t_0.

By definition of σ, $T_{\sigma<0} \subset T^* := T_{a\geq 0} \cap \partial(T_{a<0})$. This set is closed, since a is upper semicontinuous. Assume that t_0 is in the interior of $T_{a\geq 0}$. Then $t_0 \notin \partial(T_{a<0})$; therefore the interior of T^* is empty, i.e., T^* is nowhere dense in T. Thus $T_{\sigma<0}$ must be nowhere dense as well.

The proof of (i) $\Rightarrow$ (ii). By the first two inequalities of (i), we have $T_{a=0,\,b=0} = T_{a\geq 0,\,b\geq 0}$, thus $T_{a=0,\,b=0}$ is a compact subset of T. By the third inequality of (i), $c - \sigma$ is negative and upper semicontinuous on $T_{a=0,\,b=0}$; therefore the least upper bound of $c - \sigma$ on this set is a negative number; denote it by -2δ. Then we have $c(t) - \sigma(t) + \delta < 0$ for $t \in T_{a=0,\,b=0}$. If (ii) is not true with this δ, then there exist $t_0 \in T$, sequences $t_n \in T$ with $t_n \to t_0$ and $\varepsilon_n > 0$ with $\varepsilon_n \to 0$ such that

$$a(t_n) + \varepsilon_n b(t_n) + {\varepsilon_n}^2(c(t_0) + \delta) > 0 \tag{4}$$

holds for infinitely many values of $n \in \mathbf{N}$. By taking subsequences if necessary, we may assume (4) for all n. Taking the limsup as $n \to \infty$ in (4), we get $a(t_0) \geq 0$; therefore $a(t_0) = 0$ by the first inequality of (i). It follows from (4) that

$$b(t_n) + \varepsilon_n(c(t_0) + \delta) > 0 \quad \text{for all} \quad n \in \mathbf{N}.$$

Taking $n \to \infty$ again, we get $b(t_0) \geq 0$. Now the second condition of (i) implies $b(t_0) = 0$. If $a(t_n)$ were 0 for some n, then (4) and $c(t_0) + \delta < \sigma(t_0) \leq 0$ would imply $b(t_n) > 0$, which contradicts the second inequality in (i), and therefore $a(t_n) < 0$ for $n \in \mathbf{N}$. Now (4) yields

$$0 < a(t_n) + (c(t_0) + \delta)\left({\varepsilon_n}^2 + \varepsilon_n \frac{b(t_n)}{c(t_0) + \delta}\right) \leq a(t_n) - \frac{b^2(t_n)}{4(c(t_0) + \delta)},$$

whence we get

$$c(t_0) + \delta > \frac{b^2(t_n)}{4a(t_n)} \quad \text{for all} \quad n \in \mathbf{N}.$$

Now taking the liminf as $n \to \infty$, we arrive at

$$c(t_0) + \delta \geq \sigma(t_0),$$

which contradicts the choice of δ.

The proof of (ii) $\Rightarrow$ (i). Assume that (ii) is valid and let t_0 in T be fixed arbitrarily. Letting $t_n = t_0$, $\varepsilon_n = 1/n$ and applying (ii), we easily the first and second inequalities of (i) and $c(t_0) + \delta \leq 0$ if $t_0 \in T_{a=0,\,b=0}$, whence we get $c(t_0) < 0$ for these values of t_0. Therefore we must show $c(t) < \sigma(t)$ only for values $t \in T_{a=0,\,b=0} \cap \partial(T_{a<0,\,b>0})$. If t_0 is in this set, then we can find a sequence $t_n \in T_{a<0,\,b>0}$ converging to t_0 and satisfying

$$\sigma(t_0) = \lim_{n\to\infty} \frac{b^2(t_n)}{4a(t_n)}.$$

Define

$$\varepsilon_n := -\frac{b(t_n)}{2c(t_0) + \delta}, \qquad n \in \mathbf{N}.$$

Since b is upper semicontinuous at t_0,

$$\limsup_{n\to\infty} b(t_n) \le b(t_0) = 0.$$

On the other hand, $b(t_n) > 0$, therefore $b(t_n) \to 0$ as $n \to \infty$. As we have proved, $c(t_0) + \delta/2 < 0$, thus $\varepsilon_n > 0$ for $n \in \mathbf{N}$ and $\varepsilon_n \to 0$ as $n \to \infty$. Applying now (ii) to these sequences $t = t_n$ and $\varepsilon = \varepsilon_n$, we obtain (for large n)

$$c(t_0) + \delta/2 < \frac{b^2(t_n)}{4a(t_n)}.$$

Taking the limit of both sides, we arrive at $c(t_0) < \sigma(t_0)$. □

Remark. In [13] Kawasaki introduced the function E defined below: Let u and v be continuous functions on T with

$$u(t) \ge 0 \quad \text{for} \quad t \in T \quad \text{and} \quad v(t) \ge 0 \quad \text{for} \quad t \in T_{u=0}.$$

Let T_0 be the set of all $t \in T$ for which there exists a sequence $\{t_n\} \in T$ with

$$u(t_n) > 0, \qquad t_n \to t \quad \text{and} \quad -v(t_n)/u(t_n) \to +\infty \quad \text{as} \quad n \to \infty.$$

Denote by $\mathcal{T}_t$ the set all those sequences. Define $E_{u,v} := E$ at $t \in T_0$ by

$$E(t) = \sup_{\{t_n\}\in\mathcal{T}_t} \limsup_{n\to\infty} v(t_n)^2/4u(t_n).$$

For $t \in T_{u=0,v=0}$, $t \notin T_0$ let $E(t) = 0$, and let $E(t) = -\infty$ otherwise.

Now we can observe that

$$\sigma_{-u,-v}(t) = -E_{u,v}(t) \quad \text{for} \quad t \in T_{u=0,v=0}.$$

Therefore the last inequality of (i) can be rewritten as

$$c(t) < -E_{-a,-b}(t) \quad \text{for all} \quad t \in T.$$

Thus the function σ could be changed to E throughout the paper. However we prefer to keep our function σ, since it takes only finite values in the regular cases.

Ioffe [10] also defines a function e that plays a similar role as E in [12]. This function is then used to investigate the second-order epidifferentiability of a function given in the form (2).

4. Second-order descent variations. In this section we deal with the determination of descent variations. We give conditions that are sufficient for vectors $\overline{w}$ to be a descent variation of a function F given by the form (2). These sufficient conditions turn out to be very close to necessary ones, e.g., in the case of $\mathcal{C}^2$ functions. This result is known in [4] for the special case where T is a singleton and f is C^2. However, when T is not a singleton a result, close in nature, is given in [11]–[13], where f is assumed C^2 in z with partial derivatives continuous in t, and the underlying space Z is of finite dimension.

THEOREM 2. *Let T be a compact metric space, $D \subset Z$ be an open set, $\hat{z} \in D$ and f be in $\mathcal{F}(T, D)$. Let $F : D \to \mathbf{R}$ be defined by (2), and $d(\varepsilon) := \varepsilon\overline{d}$, $\varepsilon > 0$. Assume that $f^{\circ\circ}_{[T]}(t, \hat{z}; \overline{d})$ is finite for $t \in T$ and denote*

$$a(t) := f(t, \hat{z}) - F(\hat{z}), \qquad b(t) := f^{\circ}_{[T]}(t, \hat{z}; \overline{d}).$$

(*Obviously,* $a(t) \le 0$, $(t \in T)$.) *If*

$$b(t) \le 0, \quad (t \in T_{a=0}) \tag{5}$$

and $\overline{w} \in Z$ *satisfies*

$$f^{\circ}_{[T]}(t, \hat{z}; \overline{w}) + \tfrac{1}{2} f^{\circ\circ}_{[T]}(t, \hat{z}; \overline{d}) < \sigma_{a,b}(t) \quad \text{for} \quad t \in T_{a=0,b=0}, \tag{6}$$

(*where* $\sigma_{a,b}$ *is the function introduced in the previous section*). *Then*

$$\overline{w} \in \mathcal{W}^{(2)}_{\delta}(F; \hat{z}, d). \tag{7}$$

Conversely, assume that $f^{\circ}_{[T]}$, $f^{\circ\circ}_{[T]}$, *and* $\overline{d}$ *satisfy*

$$f^{\circ}_{[T]}(t, \hat{z}; w) = \lim_{(\tau,z,\varepsilon)\to(t,\hat{z},0+)} \frac{f(\tau, z + \varepsilon w) - f(\tau, z)}{\varepsilon}, \qquad (t \in T,\ w \in Z),$$

$$f^{\circ\circ}_{[T]}(t, \hat{z}; \overline{d}) = \lim_{(\tau,\varepsilon)\to(t,0+)} 2\frac{f(\tau, \hat{z} + \varepsilon\overline{d}) - f(\tau, \hat{z}) - \varepsilon f^{\circ}_{[T]}(\tau, \hat{z}; \overline{d})}{\varepsilon^2}, \qquad (t \in T),$$

and there exists w^* *such that* $f^{\circ}_{[T]}(t, \hat{z}; w^*) < 0$ *for all* $t \in T_{a=0,\,b=0}$. *Then* (5) *and* (6) *are also necessary in order that* (7) *be valid.*

Proof. In the proof we apply the following identity twice:

$$\begin{aligned} f(t, \hat{z} + \varepsilon\overline{d} + \varepsilon^2 w) = f(t, \hat{z}) &+ \varepsilon f^{\circ}_{[T]}(t, \hat{z}; \overline{d}) \\ &+ \varepsilon^2 \left(\frac{f(t, \hat{z} + \varepsilon\overline{d} + \varepsilon^2 w) - f(t, \hat{z} + \varepsilon\overline{d})}{\varepsilon^2} \right) \\ &+ \varepsilon^2 \left(\frac{f(t, \hat{z} + \varepsilon\overline{d}) - f(t, \hat{z}) - \varepsilon f^{\circ}_{[T]}(t, \hat{z}; \overline{d})}{\varepsilon^2} \right). \end{aligned} \tag{8}$$

Assume that $\overline{d}, \overline{w}$ satisfy the assumptions of the theorem, and denote

$$c(t) := f^{\circ}_{[T]}(t, \hat{z}; \overline{w}) + \frac{1}{2} f^{\circ\circ}_{[T]}(t, \hat{z}; \overline{d}) \quad \text{for} \quad t \in T.$$

Then a, b, c satisfy the assumptions of the Key Lemma and statement (i) also holds. Therefore we have (ii) satisfied for a certain positive value of δ. Now we are going to show that there exists $\overline{\varepsilon} > 0$ such that

$$F(\hat{z}) \ge f(t, \hat{z} + \varepsilon\overline{d} + \varepsilon^2\overline{w}) + \varepsilon^2\delta/2, \qquad 0 < \varepsilon < \overline{\varepsilon},\ t \in T. \tag{9}$$

We proceed by contradiction. If this inequality were not true for any $\overline{\varepsilon} > 0$, then, taking $\overline{\varepsilon} = 1/n$, we can find sequences ε_n, t_n such that $\varepsilon_n \to 0$ and

$$F(\hat{z}) < f(t_n, \hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2\overline{w}) + {\varepsilon_n}^2\delta/2, \tag{10}$$

holds for all $n \in \mathbf{N}$. Taking subsequences if necessary, we may assume that t_n converges to a point $t_0 \in T$. Applying (8) and the definition of $f^{\circ}_{[T]}$, $f^{\circ\circ}_{[T]}$, it follows from (10) that

$$0 < f(t_n, \hat{z}) - F(\hat{z}) + \varepsilon_n f^{\circ}_{[T]}(t_n, \hat{z}; \overline{d}) + {\varepsilon_n}^2 \left(f^{\circ}_{[T]}(t_0, \hat{z}; \overline{w}) + \tfrac{1}{2} f^{\circ\circ}_{[T]}(t_0, \hat{z}; \overline{d}) + \delta \right)$$

for $n > n_0$. However this inequality contradicts (ii) of the Key Lemma; thus (9) must be valid. The local Lipschitz property of f at $\hat{z}$ and (9) then yields that

$$F(\hat{z}) > F(\hat{z} + \varepsilon\overline{d} + \varepsilon^2(\overline{w} + w))$$

for small ε and w. Therefore $\overline{w} \in \mathcal{W}_\delta^{(2)}(F, \hat{z}; d)$.

To prove the converse of the statement, assume that $f_{[T]}^\circ$ and $f_{[T]}^{\circ\circ}$ satisfy the conditions of the theorem. If $\overline{w}$ is a descent variation of F at $\hat{z}$ in the direction d, then

$$F(\hat{z}) > f(t, \hat{z} + \varepsilon\overline{d} + \varepsilon^2(\overline{w} + w)) \quad \text{for} \quad 0 < \varepsilon < \overline{\varepsilon},\ \|w\| < \overline{\varepsilon},\ t \in T. \tag{11}$$

Using the homogeneity of $f_{[T]}^\circ$, we can find w^* such that $f_{[T]}^\circ(t, \hat{z}; -w^*) < 0$ for $t \in T_{a=0,\, b=0}$ and $\|w^*\| < \overline{\varepsilon}$. Since $t \mapsto f_{[T]}^\circ(t, \hat{z}; -w^*)$ is upper semicontinuous, hence, for some positive δ,

$$f_{[T]}^\circ(t, \hat{z}; -w^*) \le -2\delta \quad \text{for all} \quad t \in T_{a=0,\, b=0}. \tag{12}$$

Let $t_n \in T$ and $\varepsilon_n > 0$ be arbitrary sequences with $t_n \to t_0 \in T$ and $\varepsilon_n \to 0$. By the assumptions of the necessity part of the theorem and (8), we get from (11)

$$0 > f(t_n, \hat{z}) - F(\hat{z}) + \varepsilon_n f_{[T]}^\circ(t_n, \hat{z}; \overline{d}) + {\varepsilon_n}^2 \left(f_{[T]}^\circ(t_0, \hat{z}; \overline{w} + w^*) + \tfrac{1}{2} f_{[T]}^{\circ\circ}(t_0, \hat{z}; \overline{d}) - \delta \right).$$

for $n \ge n_0$. We have proved that statement (ii) of the Key Lemma is now satisfied with a, b described above and

$$c(t) := f_{[T]}^\circ(t, \hat{z}; \overline{w} + w^*) + \tfrac{1}{2} f_{[T]}^{\circ\circ}(t, \hat{z}; \overline{d}) - 2\delta, \qquad (t \in T).$$

Therefore (5) and, for $t \in T_{a=0,\, b=0}$

$$f_{[T]}^\circ(t, \hat{z}; \overline{w} + w) + \tfrac{1}{2} f_{[T]}^{\circ\circ}(t, \hat{z}; \overline{d}) - 2\delta < \sigma_{a,b}(t)$$

must be valid. By (12) and the subadditivity of $f_{[T]}^\circ$, we have

$$f_{[T]}^\circ(t, \hat{z}; \overline{w}) \le f_{[T]}^\circ(t, \hat{z}; \overline{w} + w) + f_{[T]}^\circ(t, \hat{z}; -w) \le f_{[T]}^\circ(t, \hat{z}; \overline{w} + w) - 2\delta,$$

whence we get (6), which was to be proved. □

Remark. Introducing the notation

$$\mathcal{V}_\delta^{(2)}(F, \hat{z}; \overline{d}) := \{\, \overline{w} \in Z \mid f_{[T]}^\circ(t, \hat{z}; \overline{w}) + \tfrac{1}{2} f_{[T]}^{\circ\circ}(t, \hat{z}; \overline{d}) < \sigma_{a,b}(t),\ t \in T_{a=0,\, b=0} \,\},$$

the statement of the theorem says that

$$\mathcal{V}_\delta^{(2)}(F; \hat{z}, \overline{d}) \subset \mathcal{W}_\delta^{(2)}(F; \hat{z}, d). \tag{13}$$

Using the properties of $f_{[T]}^\circ$, we can see that $\mathcal{V}_\delta^{(2)} = \mathcal{V}_\delta^{(2)}(F; \hat{z}, \overline{d})$ is always an open convex set (that can be empty). In order that $\mathcal{V}_\delta^{(2)}$ be nonempty, it is enough to assume that $\sigma_{a,b}$ has only finite values and that there exists $w^* \in Z$ such that $f_{[T]}^\circ(t, \hat{z}; w^*) < 0$ for all $t \in T_{a=0,\, b=0}$. In this case, we can find a positive δ such that $f_{[T]}^\circ(t, \hat{z}; w^*) < -\delta$. On the other hand, $t \mapsto \sigma_{a,b}(t) - \frac{1}{2} f_{[T]}^{\circ\circ}(t, \hat{z}; \overline{d})$ is lower semicontinuous; therefore it is bounded below by a negative real constant r. Now we can check that the element $\overline{w} = \lambda w^*$ is in $\mathcal{V}_\delta^{(2)}$ if $\lambda > -r/\delta$.

Since $T_{a=0,\,b=0}$ is compact, the set $\mathcal{V}_\delta^{(2)}$ is a special case of the set C dealt with in Lemma 2. Therefore the adjoint set of $\mathcal{V}_\delta^{(2)}$ can be obtained by the help of that result. By (13), we have $\mathcal{W}_\delta^{(2)^+} \subset \mathcal{V}_\delta^{(2)^+}$, i.e., the affine functionals from the adjoint set of $\mathcal{W}_\delta^{(2)}$ can be described.

We note that in [12]–[14] Kawasaki obtained the closure of the above set $\mathcal{V}_\delta^{(2)}$, since he investigated descent directions in the tangential sense, not in the sense of Definition 1.

5. Second-order admissible variations. In this section we are going to investigate two types of constraints $z \in Q$ and their corresponding admissible variations. The first case is when Q is given by a family of inequalities

$$Q := \{\, z \in D \mid g(s,z) \le 0\,, \forall s \in S \,\}, \tag{14}$$

The second case to be considered below is when Q is a closed convex set with nonempty interior.

For inequality constraints we have the following theorem.

THEOREM 3. *Let S be a compact metric space, $D \subset Z$ be an open set, and $g \in \mathcal{F}(S,D)$. Let Q be defined by* (14), *$\hat{z} \in Q$, and $d(\varepsilon) := \varepsilon\overline{d}$, $\varepsilon > 0$. Assume that $g^{\circ\circ}_{[S]}(s,\hat{z};\overline{d})$ is finite for $s \in S$ and denote*

$$a(s) := g(s,\hat{z}), \qquad b(s) := g^{\circ}_{[S]}(s,\hat{z};\overline{d}).$$

(Obviously, $a(s) \le 0$, $(s \in S)$.) If $a(s) < 0$ for all $s \in S$, then $\mathcal{W}_\alpha^{(2)}(Q;\hat{z},d) = Z$. If $S_{a=0} \neq \emptyset$,

$$b(s) \le 0, \qquad (s \in S_{a=0}) \tag{15}$$

and $\overline{w} \in Z$ satisfies

$$g^{\circ}_{[S]}(s,\hat{z};\overline{w}) + \tfrac{1}{2} g^{\circ\circ}_{[S]}(s,\hat{z};\overline{d}) < \sigma_{a,b}(s), \quad \text{for} \quad s \in S_{a=0,b=0}, \tag{16}$$

(where $\sigma_{a,b}$ is the function introduced in §3). *Then*

$$\overline{w} \in \mathcal{W}_\alpha^{(2)}(Q;\hat{z},d). \tag{17}$$

Conversely, if $g^{\circ}_{[S]}$, $g^{\circ\circ}_{[S]}$ and $\overline{d}$ satisfy similar conditions as $f^{\circ}_{[T]}$ and $f^{\circ\circ}_{[T]}$ in the converse part of Theorem 2, *then* (15) *and* (16) *are also necessary for* (17) *to be valid.*

Proof. If $a(s) = g(s,\hat{z}) < 0$ for all $s \in S$, then using the Lipschitz property of g, we can find $\varepsilon^* > 0$ such that $g(s,z) < 0$ for all $s \in S$ if $||z - \hat{z}|| < \varepsilon^*$. In this case, $\overline{\varepsilon} > 0$ can be determined such that $\big|\big|(\hat{z} + \varepsilon\overline{d} + \varepsilon^2(\overline{w} + w)) - \hat{z}\big|\big| < \varepsilon^*$ if $0 < \varepsilon < \overline{\varepsilon}$, $||w|| < \overline{\varepsilon}$, whenever $\overline{d}$ and $\overline{w}$ are fixed vectors. Then $g(s, \hat{z} + \varepsilon\overline{d} + \varepsilon^2(\overline{w} + w)) < 0$ for $0 < \varepsilon < \overline{\varepsilon}$, $||w|| < \overline{\varepsilon}$; therefore we have $\overline{w} \in \mathcal{W}_\alpha^{(2)}(Q;\hat{z},d)$.

If $S_{a=0}$ is not empty, then using Theorem 2 with g instead f, we can check that (15) and (16) imply $\overline{w} \in \mathcal{W}_\delta^{(2)}(G;\hat{z},d)$, where G is defined by $G(z) := \sup_{s\in S} g(s,z)$, $z \in D$. It easy to see that $\mathcal{W}_\delta^{(2)}(G;\hat{z},d) \subset \mathcal{W}_\alpha^{(2)}(Q;\hat{z},d)$, therefore (17) holds. The converse statement can be proved on the line that was followed in the proof of Theorem 2. □

Remark. The set described by (16) turns out to be convex and open, and its adjoint set can be obtained with the help of Lemma 2. Therefore nonnegative affine functions on $\mathcal{W}_\alpha^{(2)}(Q;\hat{z},d)$ can also be determined.

If $Q \subset Z$ is an arbitrary closed set with nonempty interior then define the signed distance of $z \in Z$ from Q by

$$\rho_Q(z) := \begin{cases} \inf\{||w - z|| \,|w \in Q\}, & \text{if} \quad z \in Z \setminus Q, \\ -\inf\{||w - z|| \,|w \in Z \setminus Q\}, & \text{if} \quad z \in Q. \end{cases}$$

Then it is easy to check that ρ_Q is a Lipschitz function on Z with Lipschitz constant 1, and Q can be described as the level set of ρ_Q:

$$Q = \{z \in Z | \rho_Q(z) \leq 0\}.$$

Therefore Theorem 3 implies the following corollary.

COROLLARY. *Let $Q \subset Z$ be an arbitrary closed set with nonempty interior, $\hat{z} \in Q$, and $d(\varepsilon) := \varepsilon\overline{d}$, $\varepsilon > 0$. If either $z \in Q^\circ$, or $z \in \partial Q$ and $\rho_Q{}^\circ(\hat{z}; \overline{d}) < 0$, then $\mathcal{W}_\alpha^{(2)}(Q; \hat{z}, d) = Z$. If $z \in \partial Q$, $\rho_Q{}^\circ(\hat{z}; \overline{d}) = 0$, $\rho_Q{}^{\circ\circ}(\hat{z}; \overline{d})$ is finite and $\overline{w} \in Z$ satisfies*

$$\rho_Q{}^\circ(\hat{z}; \overline{w}) + \frac{1}{2}\rho_Q{}^{\circ\circ}(\hat{z}; \overline{d}) < 0,$$

then $\overline{w} \in \mathcal{W}_\alpha^{(2)}(Q; \hat{z}, d)$.

Proof. We must only deal with the case when $z \in \partial Q$, $\rho_Q{}^\circ(\hat{z}; \overline{d}) = 0$, $\rho_Q{}^{\circ\circ}(\hat{z}; \overline{d})$ is finite. Then let S be a one-element set, say $S := \{0\}$, and define $g(0, z) := \rho_Q(z)$. Now the conditions of Theorem 3 are satisfied, and clearly $\sigma_{a,b} = 0$, since the set where $\sigma < 0$ must be nowhere dense in S. Thus (16) reduces to the inequality of the theorem, and therefore Theorem 3 yields $\overline{w} \in \mathcal{W}_\alpha^{(2)}(Q; \hat{z}, d)$. □

As we have seen in the previous corollary, Theorem 3 could be used to obtain the description of admissible variations of convex sets. However, in this case, a direct approach is more convenient here; see below.

If $Q \subset Z$ is a closed convex set with nonempty interior and $\hat{z} \in Q$, $\overline{d} \in Z$, then we define the following two sets:

$$Q^\circ(\hat{z}, \overline{d}) := \bigcup_{\overline{\varepsilon} > 0} \bigcap_{\substack{\varepsilon < \overline{\varepsilon} \\ ||w|| < \overline{\varepsilon}}} \left[\frac{1}{\varepsilon^2}(Q - \hat{z} - \varepsilon\overline{d}) + w\right]$$

and

$$Q(\hat{z}, \overline{d}) := \bigcup_{\delta(\,.\,)} \bigcap_{\varepsilon > 0} \left[\frac{1}{\varepsilon^2}(Q - \hat{z} - \varepsilon\overline{d}) + \delta(\varepsilon)B\right]$$

where, in the latter, the union is taken over all function $\delta :]0, \infty[\to [0, \infty[$ with $\lim_{\varepsilon \to 0} \delta(\varepsilon) = 0$ and B denotes the closed unit ball.

The set $Q(\hat{z}, \overline{d})$, when $Q = K$, a convex cone, was introduced and investigated by Kawasaki [12]. This set turned out to be important in the description of the envelope-like effect for the constraint $z \in K$. We can observe that, taking $d(\varepsilon) \equiv \varepsilon\overline{d}$, the relation

$$Q(\hat{z}, \overline{d}) \subset \mathcal{W}_\tau^{(2)}(Q; \hat{z}, d)$$

holds. (Equality cannot be stated here in most of the cases.)

The set $Q^\circ(\hat{z};\overline{d})$ is in a stronger connection with admissible variations, namely, it follows directly from the definition that

$$Q^\circ(\hat{z},\overline{d}) = \mathcal{W}_\alpha^{(2)}(Q;\hat{z},d).$$

The determination of the set $Q(\hat{z},\overline{d})$ seems more difficult, since there we have to take the union over a class of functions, not over real numbers. In what follows we list the most important properties of these two sets and we clarify the relationship between them.

We can easily see that both sets are convex, $Q^\circ(\hat{z},\overline{d})$ is open (since it is the set of admissible variations), $Q(\hat{z},\overline{d})$ is closed (for the proof see [12, Lem. 3.4] when Q is convex cone). Furthermore,

$$Q^\circ(\hat{z},\overline{d}) \subset Q(\hat{z},\overline{d}).$$

This inclusion is proved in a much sharper form in Theorem 4 below. If one of these sets is not empty, then $\overline{d} \in \overline{\text{cone}}(Q-\hat{z})$. Therefore this relation is necessary in order that $\overline{d}$ be critical.

THEOREM 4. *Let $Q \subset Z$ be a closed convex set with nonempty interior, $\hat{z} \in Q$ and $\overline{d} \in Z$ arbitrary. Then*

(i) $Q(\hat{z},\overline{d}) + \text{cone}(\text{cone}(Q^\circ - \hat{z}) - \overline{d}) \subset Q^\circ(\hat{z},\overline{d})$;

(ii) $Q^\circ(\hat{z},\overline{d}) \subset \text{cone}(\text{cone}(Q^\circ - \hat{z}) - \overline{d})$; *moreover, if $\overline{d} \in \text{cone}(Q-\hat{z})$, then the inclusion can be replaced by equality here*;

(iii) $\overline{Q^\circ(\hat{z},\overline{d})} = Q(\hat{z},\overline{d})$.

Proof.

Proof of (i). When $Q(\hat{z},\overline{d}) = \emptyset$, then there is nothing to prove (since we adopt the convention $\emptyset + H = \emptyset$). Let $\overline{w} \in Q(\hat{z},\overline{d})$ and $w_0 \in K := \text{cone}(\text{cone}(Q^\circ - \hat{z}) - \overline{d})$. Then there exists a function $\Delta :]0,\infty[\to Z$ with $\lim_{\varepsilon\to 0}\Delta(\varepsilon) = 0$ and $\lambda,\mu,\delta > 0$ such that

$$\hat{z} + \varepsilon\overline{d} + \varepsilon^2(\overline{w} + \Delta(\varepsilon)) \in Q \quad \text{for} \quad \varepsilon > 0$$

and

$$\hat{z} + \lambda\overline{d} + \lambda\mu(w_0 + w) \in Q \quad \text{for} \quad ||w|| < \delta.$$

Taking the convex combination of these inclusions and $\hat{z} \in Q$ with the weights

$$\frac{\mu^2}{(\varepsilon+\mu)^2}, \quad \frac{\varepsilon^2\mu}{(\varepsilon+\mu)^2\lambda}, \quad 1 - \frac{\mu^2}{(\varepsilon+\mu)^2} - \frac{\varepsilon^2\mu}{(\varepsilon+\mu)^2\lambda}$$

(where ε is so small that $\varepsilon(\mu-\lambda) < 2\lambda\mu$), whence follows that all the weights are positive), then we obtain

$$\hat{z} + \frac{\varepsilon\mu}{\varepsilon+\mu}\overline{d} + \left(\frac{\varepsilon\mu}{\varepsilon+\mu}\right)^2(\overline{w} + w_0 + w + \Delta(\varepsilon)) \in Q \tag{18}$$

for $||w|| < \delta$ and small $\varepsilon > 0$. If ε is small, then we also have

$$\frac{\delta}{2}B \subset \{w + \Delta(\varepsilon) \mid ||w|| < \delta\}.$$

Introducing the new variable $\theta = \varepsilon\mu/(\varepsilon + \mu)$, we can see that (18) reduces to

$$\hat{z} + \theta\overline{d} + \theta^2(\overline{w} + w_0 + w) \in Q \quad \text{for} \quad 0 < \theta < \theta_0,\ ||w|| < \delta/2.$$

Thus we obtain $\overline{w} + w_0 \in Q^\circ(\hat{z}, \overline{d})$, which was to be proved.

Proof of (ii). If $\overline{w} \in Q^\circ(\hat{z}, \overline{d})$, then

$$\overline{w} \in \frac{1}{\varepsilon^2}(Q^\circ - \hat{z} - \varepsilon\overline{d}) = \frac{1}{\varepsilon}\left(\frac{1}{\varepsilon}(Q^\circ - \hat{z}) - \overline{d}\right) \subset K$$

for small $\varepsilon > 0$. To prove the reversed inclusion when $\overline{d} \in \operatorname{cone}(Q - \hat{z})$, observe that in this case, $0 \in Q(\hat{z}, \overline{d})$. (If $\hat{z} + \overline{\varepsilon}\overline{d} \in Q$, then the convexity of Q and $\hat{z} \in Q$ yields $\hat{z} + \varepsilon\overline{d} \in Q$ for $\varepsilon < \overline{\varepsilon}$, and hence $0 \in Q(\hat{z}, \overline{d})$ easily follows.) Taking out the zero element of $Q(\hat{z}, \overline{d})$, the inclusion stated in (i) implies the reversed inclusion in (ii).

Proof of (iii). Using the closure of the inclusion (i) and taking $0 \in \overline{K}$, we get $Q(\hat{z}, \overline{d}) \subset \overline{Q^\circ(\hat{z}, \overline{d})}$. The reversed inclusion is a consequence of the elementary properties listed earlier. □

Remarks. The (iii) statement of the theorem shows that the two sets $Q^\circ(\hat{z}, \overline{d})$ and $Q(\hat{z}, \overline{d})$ can be used equivalently in the description of admissible variations. It follows from (i), (ii) and (iii), that the following relations are also valid:

(iv) $Q(\hat{z}, \overline{d}) + \overline{\operatorname{cone}}(\operatorname{cone}(Q - \hat{z}) - \overline{d}) \subset Q(\hat{z}, \overline{d})$;

(v) $Q(\hat{z}, \overline{d}) \subset \overline{\operatorname{cone}}(\operatorname{cone}(Q - \hat{z}) - \overline{d})$, moreover, if $\overline{d} \in \operatorname{cone}(Q - \hat{z})$, then the inclusion can be replaced by equality here.

These inclusions (iv) and (v) were already proved by Kawasaki in the case when Q is a convex cone (see [12, Lems. 5.3, 5.7]).

When we must determine the adjoint set of $Q^\circ(\hat{z}, \overline{d})$, then Lemma 3 should be applied. The relation (i) of the theorem shows that an affine function from the adjoint set is necessarily bounded below on $\operatorname{cone}(\operatorname{cone}(Q - \hat{z}) - \overline{d})$, thus its linear part satisfies the conditions listed in Lemma 3.

6. Second-order tangent variations. In this section we deal with tangent variations of sets Q determined by Banach space valued equations

$$Q := \{\, z \in D \mid H(z) = 0 \,\}.$$

The main tool we have to apply here is the following result of Lyusternik [17] (see also [1]).

LEMMA 6. *Let Z and Y be Banach spaces, $D \subset Z$ be an open set, $\hat{z} \in D$ and $H : D \to Y$ be strictly Fréchet differentiable at $\hat{z}$. Assume that $H'(\hat{z})$ maps Z onto Y. Then there exists a neighbourhood of U of $\hat{z}$, a positive constant K and a function $h : U \to Z$ such that*

$$H(z + h(z)) = H(\hat{z}) \quad \text{and} \quad ||h(z)|| \le K\,||H(z) - H(\hat{z})|| \tag{19}$$

holds for $z \in U$.

We note that this result is in fact the same as Graves's implicit function theorem (cf. Aubin and Frankowska [2]).

The *strict Fréchet differentiability of H at $\hat{z}$* means the following: There exists a bounded linear operator $H'(\hat{z}) : Z \to Y$ such that for all $\varepsilon > 0$, there exists $\delta(\epsilon)$ with

$$||H(z') - H(z'') - H'(\hat{z})(z' - z'')|| \le \varepsilon\,||z' - z''||$$

whenever z' and z'' satisfy $||z' - \hat{z}|| < \delta(\varepsilon)$ and $||z'' - \hat{z}|| < \delta(\varepsilon)$. It is easy to see that

$$H'(\hat{z})\overline{d} = \lim_{(z,\varepsilon)\to(\hat{z},0+)} \frac{H(z+\varepsilon\overline{d}) - H(z)}{\varepsilon}$$

holds for $\overline{d} \in Z$.

If H is strictly Fréchet differentiable at $\hat{z}$, $\overline{d} \in Z$, then we introduce the second-order weak directional derivative of H by the formula

$$H''(\hat{z};\overline{d}) := \left\{ z \in Z \mid \liminf_{\varepsilon\to 0+} \left\| z - 2\frac{H(\hat{z}+\varepsilon\overline{d}) - H(\hat{z}) - \varepsilon H'(\hat{z})\overline{d}}{\varepsilon^2} \right\| = 0 \right\}.$$

In other words, using the concept of the upper set-limit of [2],

$$H''(\hat{z};\overline{d}) = \operatorname*{Limsup}_{\varepsilon\to 0+} \left\{ 2\frac{H(\hat{z}+\varepsilon\overline{d}) - H(\hat{z}) - \varepsilon H'(\hat{z})\overline{d}}{\varepsilon^2} \right\}.$$

This set is possibly empty. If it is not empty, then we say that H is *twice weakly directionally differentiable at $\hat{z}$ in the direction $\overline{d}$*. If the above relations hold with "limsup" and "Liminf," respectively, then we speak about strong directional differentiability. In that case $H''(\hat{z};\overline{d})$ clearly consists of one point. When H is $\mathcal{C}^2$ near $\hat{z}$ then we can see that $H''(\hat{z};\overline{d}) = \{H''(\hat{z})(\overline{d},\overline{d})\}$.

The statement of the following theorem is well known for twice continuously differentiable functions [4]. The proof follows the standard argument in an improved form, where the above notion of the second-order directional derivative is exploited.

THEOREM 5. *Let Z and Y be Banach spaces, $D \subset Z$ be an open set, $\hat{z} \in D$, $d(\varepsilon) := \varepsilon\overline{d}$, and $H : D \to Y$ be strictly Fréchet differentiable at $\hat{z}$. Assume that $H(\hat{z}) = 0$ and $H'(\hat{z})$ maps Z onto Y. Define the set Q by* (18). *Then $\overline{w} \in \mathcal{W}_T^{(2)}(Q;\hat{z},d)$ if and only if $H'(\hat{z})\overline{d} = 0$, H is twice weakly directionally differentiable at $\hat{z}$ in the direction $\overline{d}$ and*

$$0 \in H'(\hat{z})\overline{w} + \tfrac{1}{2}H''(\hat{z};\overline{d}). \tag{20}$$

Proof. Assume that $\overline{w}$ is a tangent variation of Q at $\hat{z}$. Then we have sequences $\varepsilon_n > 0$ and $w_n \in Z$ converging to 0 such that

$$H(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2(\overline{w} + w_n)) = 0 = H(\hat{z})$$

for $n \in \mathbf{N}$. Using the strict Fréchet differentiability of H, it follows from this equation that

$$\frac{H'(\hat{z})(\varepsilon_n\overline{d} + {\varepsilon_n}^2(\overline{w} + w_n))}{\varepsilon_n} \to 0 \qquad \text{as} \quad n \to \infty;$$

that is, $H'(\hat{z})\overline{d} = 0$. Then we have

$$\begin{aligned} 0 = {} & \frac{H(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2(\overline{w} + w_n)) - H(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2 w_n)}{{\varepsilon_n}^2} \\ & + \frac{H(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2 w_n) - H(\hat{z} + \varepsilon_n\overline{d})}{{\varepsilon_n}^2} + \frac{H(\hat{z} + \varepsilon_n\overline{d}) - H(\hat{z}) - \varepsilon_n H'(\hat{z})\overline{d}}{{\varepsilon_n}^2} \end{aligned}$$

for $n \in \mathbf{N}$. Now observe that the first term converges to $H'(\hat{z})\overline{w}$ and the second to zero as $n \to \infty$. Therefore the third term must have a limit as well, i.e., $H''(\hat{z};\overline{d})$ is not empty. Taking the limit, we get (20).

To prove the sufficiency of the conditions, assume $H'(\hat{z})\overline{d} = 0$ and (20). This latter means that there exists a sequence $\varepsilon_n > 0$ with $\varepsilon_n \to 0$ such that

$$\lim_{n\to\infty} \frac{H(\hat{z} + \varepsilon_n\overline{d}) - H(\hat{z}) - \varepsilon_n H'(\hat{z})\overline{d}}{{\varepsilon_n}^2} = -H'(\hat{z})\overline{w}.$$

By Lyusternik's theorem, we have a function h that satisfies (19). Define

$$w_n := \frac{1}{{\varepsilon_n}^2} h(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2\overline{w})$$

for large values of n. Then the first equation in (19) yields

$$H(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2(\overline{w} + w_n)) = H(\hat{z}) = 0,$$

i.e.,

$$\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2(\overline{w} + w_n) \in Q \quad \text{for} \quad n > n_0.$$

We have only to show that $w_n \to 0$ as $n \to \infty$. Applying the inequality of (19), we get

$$\begin{aligned} ||w_n|| &\le K \left|\left| \frac{H(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2\overline{w}) - H(\hat{z})}{{\varepsilon_n}^2} \right|\right| \\ &= K \left|\left| \frac{H(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2\overline{w}) - H(\hat{z} + \varepsilon_n\overline{d})}{{\varepsilon_n}^2} + \frac{H(\hat{z} + \varepsilon_n\overline{d}) - H(\hat{z})}{{\varepsilon_n}^2} \right|\right|. \end{aligned}$$

Taking the limit $n \to \infty$, we arrive at

$$\begin{aligned} &\limsup_{n\to\infty} ||w_n|| \\ &\quad \le K \left|\left| \lim_{n\to\infty} \frac{H(\hat{z} + \varepsilon_n\overline{d} + {\varepsilon_n}^2\overline{w}) - H(\hat{z} + \varepsilon_n\overline{d})}{{\varepsilon_n}^2} + \lim_{n\to\infty} \frac{H(\hat{z} + \varepsilon_n\overline{d}) - H(\hat{z})}{{\varepsilon_n}^2} \right|\right| \\ &\quad = K\,||H'(\hat{z})\overline{w} - H'(\hat{z})\overline{w}|| = 0, \end{aligned}$$

which was to be shown. □

The set of second-order tangent variations has turned out to be the set $(H'(\hat{z}))^{-1}(-\frac{1}{2}H''(\hat{z};\overline{d}))$. To guarantee the convexity of this set it is enough to assume that $H''(\hat{z};\overline{d})$ is convex. However, as we will see later, we can avoid this assumption if we take a convex subset of $-\frac{1}{2}H''(\hat{z};\overline{d})$ and form its inverse image by $H'(\hat{z})$. (In most of the applications the set $H''(\hat{z};\overline{d})$ consists of one point only.) In this way we usually do not obtain the whole set $\mathcal{W}_\tau^{(2)}$, but we obtain a big convex part of it that is still disjoint from the sets of descent and admissible variations. To describe the adjoint set of inverse images of nonempty convex sets, we must use Lemma 4 from the second section.

7. The Lagrange multiplier rule. In this section we give a multiplier rule for a large class of optimum problems. The general problem to be considered here is the following specification of $(\mathcal{P})$.

Assume that Z and Y are Banach spaces (over $\mathbf{R}$), $D \subset Z$ is nonempty and open, T and S are compact metric spaces, $f : T \times D \to \mathbf{R}$ and $g : S \times D \to \mathbf{R}$, $H : D \to Y$, furthermore, Q is a closed convex subset of Z with nonempty interior. Denote

$$F(z) = \sup_{t\in T} f(t, z).$$

The problem $(\overline{\mathcal{P}})$ is to minimize $F(z)$ subject to

$$z \in D: \quad g(s,z) \leq 0, \quad (s \in S), \quad z \in Q, \quad H(z) = 0.$$

Let $Q_1 := \{z \in D | g(s,z) \leq 0,\ s \in S\}$, $Q_2 := Q$ and $Q_3 := \{z \in D | H(z) = 0\}$. Then $(\overline{\mathcal{P}})$ is a special case of $(\mathcal{P})$ with $N = 2$.

Introducing the notation

$$G(z) = \sup_{s \in S} g(s,z),$$

the constraint $g(s,z) \leq 0$, $(s \in S)$ can be rephrased as $G(z) \leq 0$. However, as we will see later, the "pointwise" analysis of this constraint yields more effective necessary conditions than the analysis of the single inequality.

A point $\hat{z} \in D$ is called an *admissible point* for the problem $(\overline{\mathcal{P}})$ if $g(s,\hat{z}) \leq 0$, $(s \in S)$, $\hat{z} \in Q$ and $H(\hat{z}) = 0$.

A point $\hat{z} \in D$ is called a *regular point* for the problem $(\overline{\mathcal{P}})$ if

— $f \in \mathcal{F}(T,U)$ for some neighbourhood $U \subset D$ of $\hat{z}$;

— $g \in \mathcal{F}(S,U)$ for some neighbourhood $U \subset D$ of $\hat{z}$;

— H is strictly Fréchet differentiable at $\hat{z}$ and the range of the linear operator $H'(\hat{z})$ is a closed subspace of Y.

Let $\hat{z}$ be regular admissible point for the problem $(\overline{\mathcal{P}})$. Introduce the following notation: If $\overline{d}$ is an arbitrary direction then let

$$\sigma_{[f]}(t,\hat{z};\overline{d}) := \sigma_{a_f,b_f}(t), \quad \text{with } a_f(t) := f(t,\hat{z}) - F(\hat{z}), \qquad b_f(t) := f^{\circ}_{[T]}(t,\hat{z};\overline{d})$$

and

$$\sigma_{[g]}(s,\hat{z};\overline{d}) := \sigma_{a_g,b_g}(s), \quad \text{with } a_g(s) := g(s,\hat{z}), \qquad b_g(s) := g^{\circ}_{[S]}(s,\hat{z};\overline{d}).$$

A direction $\overline{d}$ is called a *regular direction* at $\hat{z}$ for our problem $(\overline{\mathcal{P}})$ if

— $f^{\circ\circ}_{[T]}(t,\hat{z};\overline{d})$ and $\sigma_{[f]}(t,\hat{z};\overline{d})$ are finite on T;

— $g^{\circ\circ}_{[S]}(s,\hat{z};\overline{d})$ and $\sigma_{[g]}(s,\hat{z};\overline{d})$ are finite on S;

— H is twice weakly directionally differentiable at $\hat{z}$ in the direction $\overline{d}$, that is $H''(\hat{z};\overline{d})$ is nonempty;

— $Q^{\circ}(\hat{z},\overline{d}) \neq \emptyset$.

A direction $\overline{d}$ is called a *critical direction* at $\hat{z}$ if

— $f^{\circ}_{[T]}(t,\hat{z};\overline{d}) \leq 0$ for $t \in T_{f(t,\hat{z})=F(\hat{z})}$;

— $g^{\circ}_{[S]}(s,\hat{z};\overline{d}) \leq 0$ for $s \in S_{g(s,\hat{z})=0}$;

— $H'(\hat{z};\overline{d}) = 0$;

— $\overline{d} \in \overline{\text{cone}}(Q - \hat{z})$.

We can see that zero is always a regular and critical direction at $\hat{z}$ for $(\overline{\mathcal{P}})$.

Our main result is the following theorem.

THEOREM 6. *Let $\hat{z}$ be a regular solution of the above problem $(\overline{\mathcal{P}})$. Then for all regular critical directions $\overline{d}$ and convex set $K \subset H''(\hat{z};\overline{d})$ there exist Lagrange multipliers $\mu \in \mathcal{M}(T)$, $\nu \in \mathcal{M}(S)$, $y^* \in Y^*$, and $z^* \in Z^*$ such that at least one of ν, μ, y^* is different from zero and the following relations hold:*

$$\text{supp } \mu \subset T_{f(t,\hat{z})=F(\hat{z})}, \qquad \text{supp } \nu \subset S_{g(s,\hat{z})=0}, \tag{21}$$

$$-z^* \in Q^*(\hat{z}) \quad \textit{and} \quad z^*(\overline{d}) = 0,$$

$$\int_T f^{\circ}_{[T]}(t,\hat{z};z)d\mu(t) + \int_S g^{\circ}_{[S]}(s,\hat{z};z)d\nu(s) + y^*(H'(\hat{z})z) + z^*(z) \geq 0 \tag{22}$$

for all $z \in Z$ *and*

$$\int_T \left(f^{\circ\circ}_{[T]} - 2\sigma_{[f]}\right)(t,\hat{z};\bar{d})d\mu(t) + \int_S \left(g^{\circ\circ}_{[S]} - 2\sigma_{[g]}\right)(s,\hat{z};\bar{d})d\nu(s) - d^*(-y^*;K) - 2\delta^*(z^*;Q^{\circ}(\hat{z},\bar{d})) \geq 0. \tag{23}$$

Proof. First we eliminate the trivial cases, when the existence of multipliers μ, ν, y^*, z^* is more or less obvious. Assume that $\bar{d}$ is a fixed regular critical direction, and $K \subset H''(\hat{z};\bar{d})$, then consider the following cases.

Case A. Define

$$a_f(t) := f(t,\hat{z}) - F(\hat{z}), \qquad b_f(t) := f^{\circ}_{[T]}(t,\hat{z};\bar{d})$$

and

$$V_f := \{\, w \in Z \mid f^{\circ}_{[T]}(t,\hat{z};w) + \tfrac{1}{2}f^{\circ\circ}_{[T]}(t,\hat{z};\bar{d}) < \sigma_{[f]}(t,\hat{z};\bar{d}),\ t \in T_{a_f=0,\,b_f=0} \,\}.$$

Now we show that if $V_f = \emptyset$ then there exists a nonzero μ such that the conditions of the theorem hold with this μ and $\nu = 0$, $y^* = 0$, $z^* = 0$.

Assume that $V_f = \emptyset$. With

$$\gamma(t,w) := f^{\circ}_{[T]}(t,\hat{z};w) + \tfrac{1}{2}f^{\circ\circ}_{[T]}(t,\hat{z};\bar{d}) - \sigma_{[f]}(t,\hat{z};\bar{d})$$

and $T_{a_f=0,\,b_f=0}$ instead of T, the last statement of Lemma 2 yields a nonzero measure $\mu \in \mathcal{M}(T)$ with supp $\mu \subset T_{a_f=0,\,b_f=0}$ such that

$$\int_T \left[f^{\circ}_{[T]}(t,\hat{z};w) + \frac{1}{2}f^{\circ\circ}_{[T]}(t,\hat{z};\bar{d}) - \sigma_{[f]}(t,\hat{z};\bar{d})\right] d\mu(t) \geq 0$$

for all $w \in Z$. Putting $w = 0$, we get (23). Substituting $w = \lambda z$, dividing by λ and taking the limit $\lambda \to \infty$ in the resulting inequality, we obtain (22).

Case B. Define

$$a_g(s) := g(s,\hat{z}), \qquad b_g(s) := g^{\circ}_{[S]}(s,\hat{z};\bar{d})$$

and

$$V_g := \{\, w \in Z \mid g^{\circ}_{[S]}(s,\hat{z};w) + \tfrac{1}{2}g^{\circ\circ}_{[S]}(s,\hat{z};\bar{d}) < \sigma_{[g]}(s,\hat{z};\bar{d}),\ s \in S_{a_g=0,\,b_g=0} \,\}.$$

If $V_g = \emptyset$ then an argument similar to Case A shows that there exists a nonzero measure $\nu \in \mathcal{M}(S)$ such that the conditions of the theorem are satisfied with $\mu = 0$, $y^* = 0$, $z^* = 0$ and this measure ν.

Case C. Assume that the range of $H'(\hat{z})$ is a proper subspace of Y. Then, since it is also closed by our regularity assumptions, there exists a nonzero linear functional $y_0 \in Y^*$ that is identically zero on the range of $H'(\hat{z})$. Then the requirements of the theorem can be satisfied with $\mu = 0$, $\nu = 0$, $z^* = 0$ and with $y^* = y_0$ or $y^* = -y_0$.

Summarizing our observations, the only case we have to deal with is when V_f and V_g are nonempty sets and the range of $H'(\hat{z})$ is the whole space Y.

Define

$$Q_1 := \{z \in D | g(s,z) \leq 0, \forall s \in S\}, \quad Q_2 := Q, \quad Q_3 := \{z \in D | H(z) = 0\}.$$

The point $\hat{z}$ is a solution of $(\overline{\mathcal{P}})$ if and only if it is a solution of $(\mathcal{P})$ with these sets Q_1, Q_2, and Q_3 and $N = 2$. Therefore, by Theorem 1, we have

$$\mathcal{W}_\delta^{(2)}(F;\hat{z},d) \cap \mathcal{W}_\alpha^{(2)}(Q_1;\hat{z},d) \cap \mathcal{W}_\alpha^{(2)}(Q_2;\hat{z},d) \cap \mathcal{W}_\tau^{(2)}(Q_3;\hat{z},d) = \emptyset.$$

On the other hand, Theorems 2–5 yield

$$V_f \subset \mathcal{W}_\delta^{(2)}(F;\hat{z},d), \qquad V_g \subset \mathcal{W}_\alpha^{(2)}(Q_1,\hat{z},d),$$

and

$$V_H := \{w \in Z | H'(\hat{z})w \in -\tfrac{1}{2}K\} \subset \mathcal{W}_\tau^{(2)}(Q_3;\hat{z},d),$$

since $\overline{d}$ is a critical direction. Let

$$V_Q := \mathcal{W}_\alpha^{(2)}(Q_2;\hat{z},d) = Q^\circ(\hat{z},\overline{d}) \neq \emptyset.$$

Thus

$$V_f \cap V_g \cap V_Q \cap V_H = \emptyset.$$

Since we have eliminated Cases A–C, these sets are nonempty; moreover, they are convex and the first three sets are open. Now Lemma 1, the Dubovitskii–Milyutin separation theorem, can be applied. Then there exist affine functions $\varphi_f, \varphi_g, \varphi_Q, \varphi_H : Z \to \mathbf{R}$ (not simultaneously identically constant) such that

$$\varphi_f \in V_f{}^+, \quad \varphi_g \in V_g{}^+, \quad \varphi_Q \in V_Q{}^+, \quad \varphi_H \in V_H{}^+,$$

and

$$\varphi_f + \varphi_g + \varphi_Q + \varphi_H = 0. \tag{24}$$

Applying Lemma 2, we can find measures $\mu \in \mathcal{M}(T)$ and $\nu \in \mathcal{M}(S)$ with $\operatorname{supp}\mu \subset T_{a_f=0,\,b_f=0}$ and $\operatorname{supp}\nu \subset S_{a_g=0,\,b_g=0}$ such that

$$\varphi_f(w) \geq -\int_T \left[f^\circ_{[T]}(t,\hat{z};w) + \frac{1}{2}f^{\circ\circ}_{[T]}(t,\hat{z};\overline{d}) - \sigma_{[f]}(t,\hat{z};\overline{d})\right] d\mu(t),$$

$$\varphi_g(w) \geq -\int_S \left[g^\circ_{[S]}(s,\hat{z};w) + \frac{1}{2}g^{\circ\circ}_{[S]}(s,\hat{z};\overline{d}) - \sigma_{[g]}(s,\hat{z};\overline{d})\right] d\nu(s).$$

Write the affine functional φ_Q into the form $\varphi_Q = -z^* + c$, where $z^* \in Z^*$ and $c \in \mathbf{R}$. Then, by Lemma 3 and Theorem 4, we have $-z^* \in Q^*(\hat{z})$ and $z^*(\overline{d}) = 0$. Since $\varphi_Q \in \big(Q^\circ(\hat{z},\overline{d})\big)^+$, we also have

$$\varphi_Q(w) = -z^*(w) + c \geq -z^*(w) + \delta^*(z^*;Q^\circ(\hat{z},\overline{d})).$$

It follows from Lemma 4 that there exist a linear functional $y^* \in Y^*$ such that

$$\varphi_H(w) \geq -y^*(H'(\hat{z})w) + \tfrac{1}{2}\delta^*(-y^*,K).$$

Then (24) yields

$$\begin{aligned} 0 \leq \quad & \int_T \left[f^\circ_{[T]}(t,\hat{z};w) + \frac{1}{2}f^{\circ\circ}_{[T]}(t,\hat{z};\overline{d}) - \sigma_{[f]}(t,\hat{z};\overline{d})\right] d\mu(t) \\ & + \int_S \left[g^\circ_{[S]}(s,\hat{z};w) + \frac{1}{2}g^{\circ\circ}_{[S]}(s,\hat{z};\overline{d}) - \sigma_{[g]}(s,\hat{z};\overline{d})\right] d\nu(s) \\ & + y^*(H'(\hat{z})w) - \frac{1}{2}\delta^*(-y^*;K) + z^*(w) - \delta^*(z^*;Q^\circ(\hat{z},\overline{d})) \end{aligned}$$

for all $w \in Z$.

Putting $w = 0$ into this equation, we obtain (23). To get (22), substitute $w = \lambda z$, divide by λ, and take the limit $\lambda \to \infty$.

To complete the proof of the theorem, we must show that μ, ν, y^* cannot be zero at the same time. In fact, if they were zero, then φ_f, φ_g, and φ_H would be nonnegative affine functions on Z. Then they must be constants, and by (24), φ_Q is then also a constant. However this contradicts the statement of the Dubovitskii–Milyutin separation theorem. □

Now we formulate two important corollaries of Theorem 6. In the first result the functions $\sigma_{[f]}$ and $\sigma_{[g]}$ and z^* do not play any role, but we have only a first-order necessary condition.

COROLLARY 1. *Let $\hat{z}$ be a regular solution of the above problem $(\overline{\mathcal{P}})$. Then there exist Lagrange multipliers $\mu \in \mathcal{M}(T)$, $\nu \in \mathcal{M}(S)$, and $y^* \in Y^*$ such that at least one of them is different from zero,* (21) *holds, and*

$$\int_T f^\circ_{[T]}(t, \hat{z}; w)d\mu(t) + \int_S g^\circ_{[S]}(s, \hat{z}; w)d\nu(s) + y^*(H'(\hat{z})w) \geq 0$$

for $w \in Q - \hat{z}$.

Proof. Let $\overline{d} = 0$. Then $\overline{d}$ is trivially a critical direction for the problem $(\overline{\mathcal{P}})$ at $\hat{z}$ and $H''(\hat{z}; \overline{d}) = \{0\}$; furthermore, $Q^\circ(\hat{z}, \overline{d}) = \operatorname{cone}(Q^\circ - \hat{z})$. Therefore $\overline{d} = 0$ is also regular for $(\overline{\mathcal{P}})$. Now, applying Theorem 6 for $\overline{d} = 0$ and $K = \{0\}$, we arrive at the above statement. □

The second corollary deals with the following generalization $(\hat{\mathcal{P}})$ of problem $(\overline{\mathcal{P}})$: Instead of the constraint $z \in Q$ we take $G(z) \in Q$, where Q is assumed to be a closed convex subset (with nonempty interior) of the Banach space W and $G : D \to W$. The notion of the admissibility of a point $\hat{z} \in D$ is defined analogously.

A point $\hat{z}$ is called regular if it is regular for problem $(\hat{\mathcal{P}})$ and, in addition, G is strictly Fréchet differentiable at $\hat{z}$.

A direction $\overline{d}$ is regular for $(\hat{\mathcal{P}})$ at $\hat{z}$ if it satisfies the first two conditions on regularity of directions to problem $(\overline{\mathcal{P}})$; furthermore, the mapping $(H, G) : D \to Y \times W$ is twice weakly differentiable at $\hat{z}$ in the direction $\overline{d}$ and $Q^\circ(G(\hat{z}), G'(\hat{z})\overline{d}) \neq \emptyset$. We can check that in order that the assumption on the second-order directional differentiability be satisfied it is necessary that both H and G be twice weakly differentiable, and it is sufficient that one of them be weakly and the other be strongly twice directionally differentiable at $\hat{z}$.

A direction $\overline{d}$ is called critical at $\hat{z}$ if the conditions of criticality for problem $(\overline{\mathcal{P}})$ are satisfied except the last one. Instead of the last one, we require now the following condition: $G'(\hat{z})\overline{d} \in \overline{\operatorname{cone}}(Q - G(\hat{z}))$.

Clearly, when $G(z) \equiv z$ then this problem $(\hat{\mathcal{P}})$ reduces to $(\overline{\mathcal{P}})$, and also the notions defined above reduce to that of $(\overline{\mathcal{P}})$, respectively.

COROLLARY 2. *Let $\hat{z}$ be a regular solution of the above problem $(\hat{\mathcal{P}})$. Then for all regular critical directions $\overline{d}$ and convex set $K \subset (H, G)''(\hat{z}; \overline{d})$ there exist Lagrange multipliers $\mu \in \mathcal{M}(T)$, $\nu \in \mathcal{M}(S)$, $y^* \in Y^*$, and $w^* \in W^*$ such that at least one of ν, μ, y^* is different from zero,* (21) *is valid, and the following relations hold:*

$$-w^* \in Q^*(G(\hat{z})) \quad \text{and} \quad w^*(G'(\hat{z})\overline{d}) = 0,$$

$$\int_T f^\circ_{[T]}(t, \hat{z}; z)d\mu(t) + \int_S g^\circ_{[S]}(s, \hat{z}; z)d\nu(s) + y^*(H'(\hat{z})z) + w^*(G'(\hat{z})z) \geq 0$$

for all $z \in Z$ *and*

$$\int_T \left(f^{\circ\circ}_{[T]} - 2\sigma_{[f]}\right)(t, \hat{z}; \overline{d})d\mu(t) + \int_S \left(g^{\circ\circ}_{[S]} - 2\sigma_{[g]}\right)(s, \hat{z}; \overline{d})d\nu(s)$$
$$-\delta^*(-(y^*, w^*); K) - 2\delta^*(w^*; Q^\circ(G(\hat{z}), G'(\hat{z})\overline{d})) \geq 0.$$

Proof. The proof of this corollary can be done with the following reduction trick: Introduce a new artificial variable $w \in W$, and write the constraint $G(z) \in Q$ as $G(z) - w = 0$ and $w \in Q$. Thus we obtain an optimum problem for the new variable (z, w). It is easy to check that the problem $(\hat{\mathcal{P}})$ rewritten in this form can be handled already with Theorem 6. The multipliers obtained for this new problem then exactly yield the statement of Corollary 2. □

Remarks. 1. Putting $z = \overline{d}$ in (22), we can see that the stronger relations

$$\operatorname{supp} \mu \subset T_{f(t,\hat{z})=F(\hat{z}),\, f^\circ_{[T]}(t,\hat{z};\overline{d})=0}, \qquad \operatorname{supp} \nu \subset S_{g(s,\hat{z})=0,\, g^\circ_{[S]}(s,\hat{z};\overline{d})=0},$$

are also valid instead of (21).

If the critical direction in problem $(\overline{\mathcal{P}})$ is taken from the smaller set $\operatorname{cone}(Q - \hat{z})$, then $Q^\circ(\hat{z}, \overline{d})$ turns out to be a cone (by Theorem 4); therefore the term containing z^* in the second-order necessary condition vanishes and the last condition for the regularity of $\overline{d}$, $Q^\circ(\hat{z}, d) \neq \emptyset$, holds. (An analogous statement is true for Corollary 2.)

When the multipliers are uniquely determined, then we can see that $\delta^*(-y^*;K)$ can be replaced by $\delta^*(-y^*; H''(\hat{z}, \overline{d}))$. This is important when H is twice weakly but not strongly directionally differentiable.

2. If there are given M objective functions $F_1, \ldots, F_M$ of the form

$$F_i(z) = \max_{t \in T_i} f_i(t, z), \qquad i = 1, \ldots, M;\ z \in D,$$

i.e., when the problem is a Pareto optimum problem, then introducing

$$T := \bigcup_{i=1}^{M} \{i\} \times T_i,$$
$$f((i,t), z) := f_i(t, z) - F_i(\hat{z}), \qquad (i,t) \in T,\ z \in D,$$

this Pareto optimum problem is equivalent to $(\overline{\mathcal{P}})$ with this set T and function f. Now the criticality and regularity of a direction $\overline{d}$ with respect to the objective function means that $\overline{d}$ is critical and regular with respect to $F_1, \ldots, F_M$. Applying Theorem 6, we obtain now that μ should be replaced by $\mu_1, \ldots, \mu_M$; f by f_i, T by T_i and the subformulae

$$\int_T f^\circ_{[T]}(t, \hat{z}; w)d\mu(t) \quad \text{and} \quad \int_T \left(f^{\circ\circ}_{[T]} - 2\sigma_{[f]}\right)(t, \hat{z}; \overline{d})d\mu(t)$$

should be replaced by

$$\sum_{i=1}^{M} \int_{T_i} f^\circ_{i\,[T_i]}(t, \hat{z}; w)d\mu_i(t) \quad \text{and} \quad \sum_{i=1}^{M} \int_{T_i} \left(f^{\circ\circ}_{i\,[T_i]} - 2\sigma_{[f_i]}\right)(t, \hat{z}; \overline{d})d\mu_i(t),$$

respectively, in the formulation of Theorem 6. If the sets $T_1, \ldots, T_M$ are singletons (one-element sets), then the measures μ_i can be interpreted simply as nonnegative

scalars, and the integration becomes multiplication by this scalar. In this case (since T_i is discrete) the functions $\sigma_{[f_i]}$ are zero and therefore do not occur in the formulation of the theorem.

3. A similar reasoning shows how Theorem 6 is transformed when, instead of $g(s,z) \leq 0$, there are given N inequalities:

$$g_i(s,z) \leq 0, \qquad i = 1,\dots,N.$$

4. If instead of $H(z) = 0$, we are given the following equality constraints:

$$H_0(z) = 0, \qquad h_1(z) = 0,\dots,h_N(z) = 0,$$

where $H_0 : D \to Y$ is strictly Fréchet differentiable at $\hat{z}$ with closed range $H_0'(\hat{z})(Z)$, and $h_i : D \to \mathbf{R}$ are also strictly differentiable functions at $\hat{z}$, then introduce

$$H(z) := (H_0(z), h_1(z),\dots,h_N(z)), \qquad z \in D.$$

Clearly $H : D \to Y \times \mathbf{R}^N$ is again strictly differentiable at $\hat{z}$ and it still satisfies the closed-range property by the closed image theorem of [1]. Now the equality constraints can equivalently be expressed as $H(z) = 0$; therefore Theorem 6 can be applied in this situation. To formulate the result that we can obtain now, $y \in H''(\hat{z};\overline{d})$ and $y^* \in Y^*$ should be replaced by $y_0 \in H_0''(\hat{z};\overline{d})$, $y_1 \in h_1''(\hat{z};\overline{d}),\dots,y_N \in h_N''(\hat{z};\overline{d})$, and $y^* \in Y^*$, $\lambda_1,\dots,\lambda_N \in \mathbf{R}$, respectively. The formulae

$$y^*(H'(\hat{z})w) \geq 0 \quad \text{and} \quad y^*(y)$$

should be replaced by

$$\sum_{i=1}^{N} \lambda_i h_i'(\hat{z})w + y^*(H_0'(\hat{z})w) \geq 0 \quad \text{and} \quad \sum_{i=1}^{N} \lambda_i y_i + y^*(y_0),$$

respectively, in the text of Theorem 6.

5. Using the above remarks, the results obtained in Theorem 6, or in Corollary 1, are more general than that of [5, Thm. 6.1.1], [1, Thm. 3.2.2], [11, Thm. 1, Chap. 1], [19, Thm. 48.B], and other known versions of the Lagrange multiplier rule. In [5], only the finite-dimensional case of equality constraints is considered; however the functions involved need not be strictly Fréchet differentiable, only locally Lipschitzian at $\hat{z}$. In our corollary we deal with infinite-dimensional equality constraints, but the strict Fréchet differentiability and the closed-range property is required. In [1, Thm. 3.4.2], second-order conditions are developed, where neither f in the objective function nor g in the inequality constraints is "time dependent." Furthermore, the set Q there is Z.

Theorem 6 and Corollary 2 include as a special case some recent results of Ben-Tal and Zowe [4] and Kawasaki [12]. Kawasaki already improved the result of Ben-Tal and Zowe, pointing out that when the constraint qualification $\overline{d} \in \operatorname{cone}(Q - \hat{z})$ is replaced by the less restrictive condition $\overline{d} \in \overline{\operatorname{cone}}(Q - \hat{z})$, then we must encounter an envelope-like effect, and as a result, a new term in the second-order necessary condition appears. However, Kawasaki could prove this result only assuming the twice continuous differentiability of the data and also the so-called Mangasarian–Fromovitz condition. The regularity conditions of our results are much weaker. Moreover, we did not need the Mangasarian–Fromovitz condition since we treated the convex set

constraint using admissible variations instead of tangent variations. The possibility of omitting this condition was already noted by Ioffe [9].

6. The first-order necessary conditions of Corollary 1 could also be expressed in the following subdifferential form:

$$0 \in \int_T \partial_{[T]} f(t, \hat{z}) d\mu(t) + \int_S \partial_{[S]} g(s, \hat{z}) d\nu(s) + y^* \circ H'(\hat{z}) - Q^*(\hat{z}),$$

where $\partial_{[T]} f(t, \hat{z})$ is the weak* convex hull of those linear functionals $z^* : Z \to \mathbf{R}$ for which there exists sequences $z_n \to \hat{z}$, $t_n \to t$ and $z_n{}^* \in \partial f(t_n, z_n)$ such that $z_n{}^*$ converges to z^* in the weak* topology. Here $\partial f(t_n, z_n)$ denotes the Clarke's subgradient of the function $z \to f(t_n, z)$ at $z = z_n$ (see [5, §2.1]). The set $\partial_{[S]} g(s, \hat{z})$ is defined analogously. These notions are introduced similarly in [5, §2.8]. It might happen that the second-order conditions of Theorem 6 can also be expressed in a subdifferential form if we define second-order subdifferentials in a suitable manner.

7. The question about the sufficiency of our necessary conditions is open. However in convex optimization problems or in smooth problems we can become convinced that they are close to sufficiency.

Now we present a simple example that shows that the presence of the function σ cannot be eliminated from the above multiplier rule.

Example. Let T be the closed unit ball in $\mathbf{R}^2$ and define

$$f(u, v, x, y) := (2u - 1)x + 2vy - u^2 - v^2, \qquad (u, v) \in T,\ (x, y) \in \mathbf{R}^2,$$
$$F(x, y) := \max_{(u,v) \in T} f(u, v, x, y), \qquad (x, y) \in \mathbf{R}^2.$$

It is easy to observe that $F(x, y) = x^2 + y^2 - x$ for $\|(x, y)\| < 1$; moreover, the maximum is then attained at $u = x$ and $v = y$. Let us consider the following optmization problem:

$$\text{Minimize } F(x, y) \quad \text{subject to } x - y^2 = 0.$$

For directions $(h, k) \in \mathbf{R}^2$ and (x, y), $(u, v) \in T$, we can easily obtain

$$f^{\circ}_{[T]}(u, v, x, y; h, k) = (2u - 1)h + 2vk, \quad \text{and} \quad f^{\circ\circ}_{[T]}(u, v, x, y; h, k) = 0.$$

Now we compute the function $\sigma_{[f]}$. Let x, y, h, and k be fixed as above and define

$$a(u, v) := f(u, v, x, y) - F(x, y) = -(x - u)^2 - (y - v)^2,$$
$$b(u, v) := f^{\circ}_{[T]}(u, v, x, y; h, k) = (2u - 1)h + 2vk.$$

for $(u, v) \in T$. Then $\sigma_{[f]}(u, v, x, y; h, k) = \sigma_{a,b}(u, v)$. By definition, we have that $\sigma_{a,b}(u, v) = 0$ if $(u, v) \notin T_{a=0,\, b=0}$. This latter set is nonempty if and only if $(2x - 1)h + 2yk = 0$ and then it is the singleton $\{(x, y)\}$. Let us determine $\sigma_{a,b}(x, y)$, when $(2x - 1)h + 2yk = 0$. By definition again,

$$\sigma_{a,b}(x, y) = \liminf_{\substack{(u,v) \to (x,y) \\ a(u,v) < 0,\ b(u,v) > 0}} \frac{b^2(u, v)}{4a(u, v)}$$
$$= \liminf_{\substack{(u,v) \to (x,y) \\ (2u-1)h + 2vk > 0}} \frac{((2u - 1)h + 2vk)^2}{-4[(x - u)^2 + (y - v)^2]}$$

$$= \liminf_{\substack{(u,v)\to(x,y)\\(2u-1)h+2vk>0}} \frac{(2(u-x)h+2(v-y)k)^2}{-4[(x-u)^2+(y-v)^2]}$$

$$= \liminf_{\substack{(u,v)\to(0,0)\\uh+vk>0}} \frac{(uh+vk)^2}{-[u^2+v^2]} = -\limsup_{\substack{(u,v)\to(0,0)\\uh+vk>0}} \frac{(uh+vk)^2}{[u^2+v^2]} = -(h^2+k^2).$$

(The last equality is a consequence of the Cauchy–Schwarz inequality.) Thus

$$\sigma_{[f]}(u,v,x,y;h,k) = -(h^2+k^2) \quad \text{for} \quad u=x,\ v=y, \quad \text{if } (2x-1)h+2yk=0$$

and is equal to zero otherwise.

Define $H(x,y) := x - y^2$. Then $H'(x,y)(h,k) = h - 2yk$ and $H''(x,y;h,k) = \{-2k^2\}$.

Now we can apply the multiplier rule of Theorem 6 to our problem. We are going to show that $(\hat{x},\hat{y}) = (0,0)$ is the only point where the necessary conditions of Theorem 6 are satisfied. Let $(\hat{x},\hat{y})$ be a solution of the above problem and (h,k) be a regular critical direction at $(\hat{x},\hat{y})$. Clearly, all directions (h,k) are regular now; therefore (h,k) is a critical direction if

$$(2\hat{x}-1)h + 2\hat{y}k \le 0 \quad \text{and} \quad h - 2\hat{y}k = 0.$$

By Theorem 6, there exists a measure μ and $\lambda := y^* \in \mathbf{R}$ (not all zero) such that

$$\int_T (2u-1)s + 2vtd\mu(u,v) + \lambda(s-2\hat{y}t) \ge 0, \quad \text{for} \quad (s,t)\in\mathbf{R}^2,$$

$$\int_T 2(h^2+k^2)d\mu(u,v) + \lambda(-2k^2) \ge 0$$

and the support of the measure μ is at most the one-element set $(\hat{x},\hat{y})$. Therefore integration on T by μ can be interpreted now as multiplication by a nonnegative scalar μ at the point $(u,v) = (\hat{x},\hat{y})$. Thus the above inequalities can be rewritten as

$$\mu[(2\hat{x}-1)s + 2\hat{y}t] + \lambda(s-2\hat{y}t) \ge 0, \quad \text{for} \quad (s,t)\in\mathbf{R}^2,$$
$$2\mu(h^2+k^2) + \lambda(-2k^2) \ge 0.$$

The first inequality yields

$$\mu(2\hat{x}-1) + \lambda = 0 \quad \text{and} \quad \mu\hat{y} = \lambda\hat{y}. \tag{25}$$

The multiplier μ must be different from zero, otherwise λ would also be zero (by the first equality in (25)). If $\hat{y}$ is not zero, then we get $\mu = \lambda$ from the second equation, and then the first yields $\mu\hat{x} = 0$. This means that $\hat{x}$ and also $\hat{y}$ must be zero. Then $\mu = \lambda = 1$ is a solution for the multipliers and the critical directions at $(0,0)$ are now of the form $(0,k)$, where $k\in\mathbf{R}$ is arbitrary. We can also see that the second-order inequality condition is satisfied with equality now. Therefore $(\hat{x},\hat{y}) = (0,0)$ is the only solution candidate of our problem. On the other hand, if $x = y^2$, then $F(x,y) = x^2 + y^2 - x = y^4 \ge 0$, thus $(0,0)$ is a solution.

Acknowledgment. We thank the referee, who called our attention to some recent works, especially those by Kawasaki.

ROBUST STABILITY OF LINEAR EVOLUTION OPERATORS ON BANACH SPACES*

D. HINRICHSEN† AND A. J. PRITCHARD‡

Abstract. This paper introduces a stability radius for a wide class of linear infinite-dimensional time-varying systems under structured time-varying perturbations. A framework is presented that allows the same degree of unboundedness in the perturbations as in the generator of the nominal model.

Key words. infinite-dimensional systems, time-varying, evolution operators, Cauchy problem, robust stability, structured perturbations

AMS subject classifications. 93D09, 93C73, 93G50, 93C25

Notation.

$X, \underline{X}, \overline{X}, U_i, Y_i, U, Y$	Banach spaces over $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$ with norms $\|\cdot\|_X$, etc.
$\mathcal{L}(X,Y)$ (respectively, $\mathcal{L}(X)$)	Banach space of bounded linear operators from X to Y (respectively, on X) provided with the operator norm $\|\cdot\|_{\mathcal{L}(X,Y)}$ (respectively, $\|\cdot\|_{\mathcal{L}(X)}$)
$\mathcal{U}(X)$	$\{L \in \mathcal{L}(X);\ L$ invertible in $\mathcal{L}(X)\}$, the set of invertible bounded linear operators on X provided with the operator norm
$C(s,t;X)$	The set of X-valued continuous functions on $[s,t]$, $s \le t \le \infty$
$PC(\mathbb{R}_+, \mathcal{L}(X,Y))$	The set of piecewise continuous $\mathcal{L}(X,Y)$-valued operator functions on $\mathbb{R}_+ = [0,\infty)$
$PC_b(\mathbb{R}_+, \mathcal{L}(X,Y))$	The set of bounded operator functions in $PC(\mathbb{R}_+, \mathcal{L}(X,Y))$
$PC^1(s,t;\mathcal{U}(X))$	The set of continuous piecewise continuously differentiable functions from $[s,t]$ into the set $\mathcal{U}(X)$ of invertible linear operators on X
$L^p(s,t;X)$	The set of strongly measurable p-integrable X-valued functions on $[s,t]$, $1 \le p < \infty$
$L^p_{loc}(s,\infty;X)$	The set of strongly measurable locally p-integrable X-valued functions on $[s,\infty)$
$L^\infty(s,t;X)$	The set of strongly measurable functions $h : [s,t] \to X$ such that $\sup_{\tau\in[s,t]} \|h(\tau)\|_X < \infty$, where sup denotes the essential supremum
$\underline{N}$	$= \{1, \dots, N\}$

1. Introduction. A systematic theory of infinite-dimensional time-varying differentiable equations

$$\dot{x}(t) = A(t)x(t), \qquad t \ge 0, \tag{1}$$

where the $A(t)$ are unbounded linear operators on a Banach space X, was initiated in the fifties by Kato [14]. He approximated the fundamental solution of (1) by fundamental solutions

corresponding to piecewise constant generators. Using the theory of holomorphic semigroups Tanabe [25] constructed a fundamental solution for (1) by representing the system generator as a time-varying perturbation of a time-invariant generator. For both approaches an essential assumption is that $A(t)$ generates a C_0-semigroup for each $t \geq 0$. This assumption, which we do not make, is also of basic importance in more recent treatments of evolution equations (see [26], [20, Chap. 4], [8, Chap. 7]). The fundamental questions concerning existence and uniqueness of solutions, construction of evolution operators, and the well-posedness of the Cauchy problem are still subjects of current research. In broad correspondence to the approaches of Kato and Tanabe, two sets of assumptions have evolved: one for hyperbolic-type equations and the other for parabolic-type equations (see [26], [20], [8]). A different approach has been developed by Lions [19], who assumed that $A(t)$ is defined via a time-varying bilinear form. In spite of these efforts the existence theory for solutions of time-varying equations (1) is by no means as well developed as that of time-invariant differential equations, where necessary and sufficient conditions for unique solvability are given by the Hille–Yosida theorem.

The first attempts to develop a *stability theory* for time-varying linear differential equations in Banach spaces go back to the late forties. In [16] Krein extended results of Liapunov on second-order systems with periodic coefficients to a Hilbert space setting. Over the next two decades the work on the stability of time-varying infinite-dimensional systems was mainly restricted to equations (1) with *bounded* $A(t) \in \mathcal{L}(X)$, $t \geq 0$ [4]. Early contributions to the stability theory of systems with *unbounded* operators $A(t)$ can be found in [5] and [26].

Our main objective is to investigate the *robustness* of exponentially stable systems (1) when the unbounded generator $A(\cdot)$ is subjected to various types of unbounded perturbations. A prerequisite for this is to secure the existence and uniqueness of solutions of the perturbed equation. However, we emphasize that in our analysis the question of existence and uniqueness is treated jointly with the problem of exponential stability. A separate treatment is possible (along the lines indicated in Remark 3.4, below) but is beyond the scope of the present paper. Clearly, such an analysis would be of independent interest and desirable from a systematic point of view.

Problems of robust stability rely for their solution on methods from both stability theory and perturbation theory. For the time-invariant case, there is a well-developed perturbation theory [9], [16], [20], although the effects of *large perturbations* on the system behaviour have not been so frequently studied in the literature [23], [24]. In comparison, the situation for time-varying systems is bleak. Phillips [21] has given an example where A generates a C_0-semigroup on X, $\Delta(\cdot) \in C(\mathbb{R}_+, \mathcal{L}(X))$, and for certain initial states $x \in D(A)$ there are no differentiable functions $x(\cdot)$ such that $\dot{x}(t) = (A + \Delta(t))x(t)$, $t \geq 0$, $x(0) = x$. Because we want to consider quite general perturbations, we cannot, therefore, insist that the perturbed system has differentiable solutions for every $x \in D(A)$.

We now proceed to specify the perturbation structures that we consider in this paper. Suppose that $A(t)$ is subjected to perturbations of the *output feedback type*, that is, there are Banach spaces $\underline{X}, \overline{X}, U, Y$ with

$$\underline{X} \subset X \subset \overline{X}, \tag{2}$$

such that the perturbed system equations are of the form

$$\dot{x}(t) = [A(t) + D(t)\Delta(t)E(t)]x(t), \qquad t \geq 0, \tag{3}$$

where $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y, U))$ is an unknown *bounded* time-varying disturbance operator and $D(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(U, \overline{X}))$, $E(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(\underline{X}, Y))$ are given operator-valued functions that describe the structure and unboundedness of the perturbation.

We assume that the inclusions in (2) are continuous with dense ranges so that $E(t) \in \mathcal{L}(\underline{X}, Y)$ may be viewed as an unbounded operator from X to Y and $D(t) \in \mathcal{L}(U, \overline{X})$ as an unbounded operator from U to X. Moreover, because $E(\cdot)$, $D(\cdot)$ are only assumed to be piecewise continuous, the perturbations may also be unbounded *in time*. The size of the disturbance operator $\Delta(\cdot)$ is measured by

$$\|\Delta(\cdot)\|_\infty = \operatorname*{ess\,sup}_{t\geq 0} \|\Delta(t)\|_{\mathcal{L}(Y,U)}.$$

The idea of a *stability radius* was introduced in [11] for time-invariant finite-dimensional systems. It is the size of the smallest perturbation Δ, which results in a time-invariant system (3) that is not exponentially stable. A fairly complete theory of the stability radius has been developed for both finite- and infinite-dimensional time-invariant systems over the complex field $\mathbb{C}$ [11], [24]. For time-varying systems the results are less satisfactory and there is no computable formula available for the stability radius. In the finite-dimensional case lower bounds have been obtained in terms of an associated input–output operator, and these have been improved by the use of scaling techniques [10], [13]. Here we extend this approach to infinite-dimensional time-varying systems.

The organization of the paper is as follows. To deal with uncertain parameters in the model we need a framework that allows for the same degree of unboundedness in the perturbations $D(t)\Delta(t)E(t)$ as in the generator $A(t)$. This is developed in §2 where we recall some notions from infinite-dimensional systems theory [3] and discuss various relationships between a generator $A(\cdot)$ and an associated evolution operator $\Phi(\cdot,\cdot)$. We have already seen that it would be overrestrictive to assume that the perturbed system (3) defines a well-posed Cauchy problem. Therefore, we renounce this requirement and introduce a mild version of the perturbed system equation. This leads us to the basic concept of a *mild evolution operator*. A disturbance Δ is called *admissible* if the mild version of the perturbed system equation defines a mild evolution operator. Based on this notion we introduce stability radii for a wide class of perturbed systems.

In the two subsequent sections we derive the main results of this paper. In §3 we specify conditions that enable us to determine a lower bound for the stability radius of an exponentially stable mild evolution operator $\Phi(\cdot,\cdot)$ under perturbations of a given structure (D, E). This lower bound is $\|\mathbb{L}_0\|^{-1}$, where $\mathbb{L}_0$ is the input–output operator of the system

$$\begin{aligned} x(t) &= \Phi(t,0)x(0) + \int_0^t \Phi(t,s)D(s)u(s)ds, \\ y(t) &= E(t)x(t), \qquad t \geq 0. \end{aligned}$$

The central problem here is to construct a perturbed mild evolution operator for every disturbance Δ satisfying $\|\Delta(\cdot)\|_\infty < \|\mathbb{L}_0\|^{-1}$. The conditions imposed in §3 are rather complicated, so we specialize them to time-invariant systems and compare them with ones that have been given in the literature. In particular, we see that if (A, D, E) is a regular system in the sense of Weiss [29], then our conditions hold. Moreover, under a slight additional assumption we are able to prove that the lower bound $\|\mathbb{L}_0\|^{-1}$ is in fact equal to the stability radius in a time-invariant setting *when the ground field* $\mathbb{K}$ *is complex*. This theorem considerably improves the result in [23]. We also show that a time-invariant system cannot be destabilized by smaller time-varying perturbations than by constant disturbances.

Because of its generality, a mild evolution operator is not necessarily representable as the fundamental solution of a time-varying differential equation, nor is it necessarily associated with a generator. Therefore, we introduce (in §2) the more restrictive notion of a *weak evolution operator*, which has a generator and is associated with a differential equation (although this

equation is not necessarily well posed). This class of models lies between the class of strong evolution operators defined by well-posed Cauchy problems and the general class of mild evolution operators. In §4 we investigate under which conditions the perturbed mild evolution operator that exists and is unique for Δ satisfying $\|\Delta(\cdot)\|_\infty < \|\mathbb{L}_0\|^{-1}$ is in fact a weak evolution operator. It turns out that the unboundedness of the perturbations has to be restricted to roughly "half of the unboundedness" of the weak generator. The precise result is given in Theorem 4.2. Specializing to time-invariant system, we show that if the system (A, D, E) is in the so-called Pritchard–Salamon class [22], then again our conditions hold. We also examine in some detail the case where the nominal model is an analytic semigroup.

In §5 the notion of a Bohl transformation is extended to an infinite-dimensional context and the behaviour of the stability radius under these transformations is investigated. We show that scalar Bohl transformations of the state may be used to improve the tightness of the lower bound. We also consider *multiperturbations* of the form

$$\dot{x} = A(t)x(t) + \sum_{i=1}^{N} D_i(t)\Delta_i(t)E_i(t)x(t), \qquad t \geq 0 \tag{4}$$

and introduce a stability radius for this wider class of structured perturbations. Equation (4) may be written in the form (3) where $\Delta(\cdot)$ has a diagonal structure. We are, therefore, able to apply the results of §§3 and 4 to obtain a lower bound for the stability radius of multiperturbation problems. Moreover, we show that scalar Bohl transformations of the state and arbitrary scalings of the inputs and outputs may be used to improve this lower bound.

In §6 the applicability of the abstract results and conditions are illustrated by three examples: an uncertain time-varying system (1) with $A(t) \in \mathcal{L}(X)$ unbounded in time, a perturbed distributed parameter system described by a three-dimensional heat equation with uncertain conductivity (space dependent), and an interconnected system with perturbed subsystems and uncertain couplings.

2. Definitions. We begin by introducing a number of concepts that enable us to define the meaning of the nominal equation (1) and the perturbed system equation (3). The concept of a weak evolution operator (Definition 2.4) is fundamental in §4, while the weaker concept of a mild evolution operator is basic in §3.

In the literature $A(\cdot)$ is usually supposed to be strongly continuous [17], [8], [26]. However, to allow for perturbations with jumps, we assume that $A(\cdot)$ is piecewise continuous. More precisely, the following is a standing assumption for the nominal model (1).

Assumption. For all $t \geq 0$, $A(t)$ is a linear operator on X, its domain $D(A)$ is dense in X and is independent of t. There exists a discrete subset $J \subset \mathbb{R}_+$ (set of jump points) such that, for all $x \in D(A)$, $A(\cdot)x$ is continuous on $\mathbb{R}_+\backslash J$ and the one-sided limits $\lim_{t\downarrow\tau} A(t)x$, $\lim_{t\uparrow\tau} A(t)x$ exist at each jump point $\tau \in J$.

Consider the Cauchy problem

$$\begin{aligned} \dot{x}(t) &= A(t)x(t), \qquad t \geq s, \\ x(s) &= x, \end{aligned} \tag{5}$$

where the initial state $x \in D(A)$ and the initial time $s \geq 0$ are given.

DEFINITION 2.1. *A function $x(\cdot) \in C(s, \infty; X)$ is said to be a* strong solution *of* (5) *on $[s, \infty)$ if $x(t) \in D(A)$ for all $t \geq s$, $x(\cdot)$ is strongly differentiable on $[s, \infty)\backslash J$ with right-sided derivative in s and satisfies* (5) *in the following sense*:

(i) (5) *holds for every $t \in (s, \infty)\backslash J$;*

(ii) $$\left.\begin{aligned} \frac{\partial_+ x}{\partial t}(\tau) &:= \lim_{h\downarrow 0} \frac{x(\tau+h)-x(\tau)}{h} = \lim_{t\downarrow\tau} A(t)x(t), \\ \frac{\partial_- x}{\partial t}(\tau) &:= \lim_{h\downarrow 0} \frac{x(\tau)-x(\tau-h)}{h} = \lim_{t\uparrow\tau} A(t)x(t), \end{aligned}\right\} \tau \in J\backslash\{s\};$$

(iii) $x(s) = x$ *and* $\frac{\partial_+ x}{\partial t}(s) = \lim_{t\downarrow s} A(t)x(t)$.

Note that a strong solution can only exist if $x \in D(A)$. It is not clear at this point whether such a solution of (5) exists and whether it is uniquely determined. Let $\Gamma = \{(t,s);\ 0 \le s \le t < \infty\}$.

DEFINITION 2.2. *The Cauchy problem* (5) *is said to be* well posed *on* Γ *if the following hold*:

(i) *For every* $s \ge 0$, $x \in D(A)$, (5) *has a unique strong solution* $x(\cdot, s)$ *on* $[s, \infty)$;

(ii) $x(t,s)$ *is continuous and* $(\partial x/\partial t)(t,s)$ *is piecewise continuous in* $t \in [s,\infty)$ *and in* $s \in [0,t]$ *with jump points only in* J;

(iii) *The solution* $x(t,s)$ *depends continuously on the initial value* x *locally uniformly in* s *and in* t, *that is, if* $x_n \in D(A)$ *and* $\lim_{n\to\infty} x_n = 0$, *then the corresponding solutions* $x_n(t,s)$ *converge to zero locally uniformly in* t *for fixed* s *and locally uniformly in* s *for fixed* t *as* $n \to \infty$.

This definition is slightly weaker than the definition of a well-posed Cauchy problem in the literature [17, II§2], [8].

PROPOSITION 2.3. *Suppose the Assumption holds and that the Cauchy problem* (5) *is well posed. Then there is a (unique) family* $\Phi = (\Phi(t,s))_{(t,s)\in\Gamma}$ *of bounded linear operators* $\Phi(t,s) \in \mathcal{L}(X)$ *such that the solutions of* (5) *are given by* $x(t,s) = \Phi(t,s)x$, *for all* $x \in D(A)$, $s \ge 0$. *Moreover,* Φ *has the following properties*:

(i) $\Phi(t,t) = I$, $t \in \mathbb{R}_+$;

(ii) $\Phi(t,\sigma)\Phi(\sigma,s) = \Phi(t,s)$, $0 \le s \le \sigma \le t < \infty$;

(iii) $D(A)$ *is* $\Phi(t,s)$*-invariant for all* $(t,s) \in \Gamma$, $t \mapsto A(t)\Phi(t,s)x$ *is piecewise continuous on* $[s,\infty)$ *with jump points only in* J *for all* $x \in D(A)$, *and*

$$\Phi(t,s)x - x = \int_s^t A(\rho)\Phi(\rho,s)x\,d\rho, \qquad (t,s) \in \Gamma; \tag{6}$$

(iv) *For all* $x \in D(A)$, $s \mapsto \Phi(t,s)A(s)x$ *is piecewise continuous on* $[0,t]$ *with jump points only in* J, *and*

$$\Phi(t,s)x - x = \int_s^t \Phi(t,\rho)A(\rho)x\,d\rho, \qquad (t,s) \in \Gamma; \tag{7}$$

(v) $\Phi(\cdot,s)$ *is strongly continuous on* $[s,\infty)$ *and* $\Phi(t,\cdot)$ *is strongly continuous on* $[0,t]$.

Proof. The existence and uniqueness of the family $(\Phi(t,s))_{(t,s)\in\Gamma}$ satisfying $x(t,s) = \Phi(t,s)x$ and (i), (ii) is easily established [17]. If (x_k) is a sequence in $D(A)$ converging to $x \in X$ in X, then $\Phi(\cdot,s)x_k$ converges to $\Phi(\cdot,s)x$ uniformly on every compact subset in $[s,\infty)$ by condition (iii) of Definition 2.2. Hence $\Phi(\cdot,s)x$ is continuous on $[s,\infty)$. Similarly, it can be shown that $\Phi(t,\cdot)$ is strongly continuous on $[0,t]$, whence (v).

As a consequence of (v), the sets $\{\Phi(t,s)x;\ s \in [0,t]\}$ and $\{\Phi(t,s)x;\ t \in [s,\tau]\}$ are bounded for arbitrary $t \ge 0$, respectively, $\tau \ge s$ and $x \in X$. By the theorem of Banach–Steinhaus it follows that the sets $\{\Phi(t,s);\ s \in [0,t]\}$ and $\{\Phi(t,s);\ t \in [s,\tau]\}$ are uniformly bounded in $\mathcal{L}(X)$. Using the same arguments as in [17, II§3] it can be shown that $\Phi(\cdot,s)x$ and $\Phi(t,\cdot)x$ are strongly differentiable on $[s,\infty)\backslash J$, $[0,t]\backslash J$, respectively, and

$$\frac{\partial\Phi(t,s)x}{\partial t} = A(t)\Phi(t,s)x, \qquad t \in [s,\infty)\backslash J,\ x \in D(A), \tag{8}$$

$$\frac{\partial \Phi(t,s)x}{\partial s} = -\Phi(t,s)A(s)x, \qquad s \in [0,t]\backslash J,\ x \in D(A). \tag{9}$$

The partial derivatives in (8), (9) are taken in the unilateral sense at $t = s$ and $s = 0$, $s = t$, respectively, and at all jump points $\tau \in J$ of $A(\cdot)$. Then the equations in (8), (9) are also satisfied at the jump points if their right-hand sides (RHS) are replaced by the corresponding unilateral limits. For $x \in D(A)$ the map $t \mapsto A(t)\Phi(t,s)x$ is piecewise continuous on $[s,\infty)$ and continuous on $[s,\infty)\backslash J$ by condition (ii) in Definition 2.2 and $s \mapsto \Phi(t,s)A(s)x$ is piecewise continuous on $[0,t]$ and continuous on $[0,t]\backslash J$ by the Assumption and the uniform boundedness of $\Phi(t,\cdot)$ on $[0,t]$. This proves (iii) and (iv). □

The operator family Φ in the previous proposition is called the *evolution operator* associated with the well-posed Cauchy problem (5).

DEFINITION 2.4. *Let $A = (A(t))_{t\geq 0}$ be a family of linear operators on X satisfying the Assumption and $\Phi = (\Phi(t,s))_{(t,s)\in\Gamma}$ be a family of bounded linear operators $\Phi(t,s) \in \mathcal{L}(X)$ such that conditions* (i)–(v) *of Proposition* 2.3 *are satisfied. Then we say that Φ is a* strong evolution operator *with generator $A(\cdot)$. If only conditions* (i), (ii), (iv), (v) *are satisfied, Φ is called a* weak evolution operator *with (weak) generator $A(\cdot)$.*

Note that the two equations (8), (9) hold if Φ is a strong evolution operator, whereas only (9) holds if Φ is a weak evolution operator. In both cases the generator $A(\cdot)$ is uniquely determined outside of J by the evolution operator via

$$A(t)x = -\frac{\partial_- \Phi(t,s)x}{\partial s}\bigg|_{s=t} = -\lim_{h\downarrow 0}\frac{x - \Phi(t,t-h)x}{h}, \qquad t \in \mathbb{R}_+\backslash J,\ x \in D(A).$$

However, observe that there is some arbitrariness in the definition of the domain $D(A)$. In fact, Definition 2.4 does not give a definition of a strong (weak) evolution operator that is separated from and independent of its generator and vice versa. For a systematic study of the relationship between these two objects (e.g., in the spirit of the Hille–Yosida theorem for semigroups, see [20]) this would be unsatisfactory. But such a study is not intended in this paper and for our purpose a joint definition of the two concepts is sufficient.

To see that any strong evolution operator is uniquely determined by its generator we need the following lemma.

LEMMA 2.5. *Suppose $\Phi = (\Phi(\rho))_{\rho\in[s,t]}$ is a family of operators in $\mathcal{L}(X)$ such that $\rho \mapsto \Phi(\rho)z$ is continuous on $[s,t]$ for all $z \in X$ and differentiable on (s,t) for all $z \in D \subset X$. Moreover, assume that $x(\cdot) : (s,t) \to X$ is differentiable and has values in D. Then $y(\rho) = \Phi(\rho)x(\rho)$ is differentiable on (s,t) and the following "product rule" holds:*

$$y'(\rho) = \Phi'(\rho)x(\rho) + \Phi(\rho)x'(\rho),$$

where $\Phi'(\rho)x(\rho)$ denotes the derivative of $\tau \mapsto \Phi(\tau)x(\rho)$ at $\tau = \rho$.

Proof. For any $\rho \in (s,t)$ and $h \neq 0$ such that $\rho + h \in (s,t)$, we have

$$\begin{aligned}\frac{1}{h}[y(\rho+h) - y(\rho)] = {} & \frac{1}{h}[\Phi(\rho+h)x(\rho+h) - \Phi(\rho+h)x(\rho)] \\ & + \frac{1}{h}[\Phi(\rho+h)x(\rho) - \Phi(\rho)x(\rho)].\end{aligned} \tag{10}$$

As $h \to 0$ the second term converges toward $\Phi'(\rho)x(\rho)$ by assumption. Setting $x_h(\rho) = \frac{1}{h}[x(\rho+h) - x(\rho)]$ the first term in (10) is

$$\Phi(\rho+h)[x_h(\rho) - x'(\rho)] + \Phi(\rho+h)x'(\rho)$$

and the first term tends toward zero as $h \to 0$ because of the uniform boundedness of $(\Phi(\rho))_{\rho\in[s,t]}$ in $\mathcal{L}(X)$ (by the theorem of Banach–Steinhaus), whilst the second term tends toward $\Phi(\rho)x'(\rho)$. This concludes the proof. □

If Φ is a weak evolution operator on X, it is not clear whether there exists a strong solution of the Cauchy problem (5) for every $x \in D(A)$. However, if one exists, then it is unique and it is given by the evolution operator.

PROPOSITION 2.6. *Suppose $(\Phi(t,s))_{(t,s)\in\Gamma}$ is a weak evolution operator on X with generator $A(\cdot)$ and $x(\cdot)$ solves (5) for given $s \geq 0$, $x \in D(A)$. Then $x(t) = \Phi(t,s)x$.*

Proof. For $[\bar{s},\bar{t}] \subset \mathbb{R}_+\backslash J$ by the previous lemma $y(\rho) = \Phi(\bar{t},\rho)x(\rho)$ is differentiable on $(\bar{s},\bar{t})$ with derivative

$$y'(\rho) = -\Phi(\bar{t},\rho)A(\rho)x(\rho) + \Phi(\bar{t},\rho)A(\rho)x(\rho) = 0.$$

Thus,

$$x(\bar{t}) - \Phi(\bar{t},\bar{s})x(\bar{s}) = \int_{\bar{s}}^{\bar{t}} \frac{\partial}{\partial\rho}[\Phi(\bar{t},\rho)x(\rho)]d\rho = 0.$$

Now let $J \cap [s,\infty) = \{t_k\}$, $t_1 < t_2 < \cdots$ and set $t_0 = s$. By continuity we obtain from the above that $x(\bar{t}) = \Phi(\bar{t},\bar{s})x(\bar{s})$ for any $\bar{s} \leq \bar{t}, \bar{s}, \bar{t} \in [t_k, t_{k+1}]$, $k \in \mathbb{N}$. Hence by induction, $x(t) = \Phi(t,s)x$ follows, using the properties (i) and (ii) of an evolution operator. □

PROPOSITION 2.7. *If Φ is a strong evolution operator on X with generator A, then the Cauchy problem (5) is well posed.*

Proof. By Definition 2.4 and (8), $x(t) = \Phi(t,s)x$ is a strong solution of (5) on $[s,\infty)$ for every $s \geq 0$, $x \in D(A)$, and this solution is uniquely determined by the previous proposition. This shows condition (i) in Definition 2.2. Condition (ii) follows from the Assumption and (iii), (iv), (v) in Proposition 2.3. Finally, by condition (v) in Proposition 2.3 and the theorem of Banach–Steinhaus, the sets $\{\Phi(t,s);\ 0 \leq s \leq t\}$ and $\{\Phi(t,s);\ s \leq t \leq \tau\}$ are bounded in $\mathcal{L}(X)$ for every $t \geq 0$, respectively $\tau \geq s$. This implies (iii) in Definition 2.2. □

COROLLARY 2.8. *If $(\Phi(t,s))_{(t,s)\in\Gamma}$ and $(\hat{\Phi}(t,s))_{(t,s)\in\Gamma}$ are two strong evolution operators with the same generator $A(\cdot)$, then they are equal.*

Various sufficient conditions under which a family $(A(t))_{t\in\mathbb{R}_+}$ of linear operators on X generates a strong evolution operator can be obtained from the results in [27].

We now turn to the perturbed system equation (3), that is, we consider the Cauchy problem

$$\begin{aligned} \dot{x}(t) &= (A(t) + D(t)\Delta(t)E(t))x(t), \qquad t \geq s, \\ x(s) &= x. \end{aligned} \tag{11}$$

In view of the above results it seems natural to assume that the nominal Cauchy problem (5) is well posed and to look for conditions on the perturbations Δ that guarantee that the perturbed Cauchy problem (11) is again well posed with an associated strong evolution operator Φ_Δ. However, even in the case where the nominal system is time-invariant and the time-varying perturbations $D(t)\Delta(t)E(t)$ are bounded ($\underline{X} = X = \overline{X}$), one cannot guarantee that (11) has strong solutions. More precisely, if a time-invariant closed operator A generates a strongly continuous semigroup $(S(t))_{t\geq 0}$ on X (hence a strong evolution operator $(S(t-s))_{(t,s)\in\Gamma}$), $D(t) = E(t) = I$, $t \geq 0$, and $\Delta(\cdot) \in C(\mathbb{R}_+;\mathcal{L}(X))$, then it is possible that (11) has no differentiable solutions for certain initial conditions $x(s) = x \in D(A)$ [21]. However, we can show [3] that $A + \Delta(\cdot)$ always generates a weak evolution operator with domain $D(A + \Delta) = D(A)$.

Our main aim in this paper is to define and examine a stability radius for (1) when subjected to a wide range of unbounded perturbations. If the perturbed Cauchy problem is required to

be well posed, we have just seen that the perturbation class needs to be restricted. Instead of following this path we consider a *mild* version of the perturbed Cauchy problem (11) that allows us to admit perturbations $D(t)\Delta(t)E(t)$ of the same degree of unboundedness as that of $A(t)$. In §4 we analyze the degree of unboundedness that can be admitted if we require the perturbed equation (11) to define a *weak* evolution operator.

To motivate the mild version of the perturbed Cauchy problem, suppose that (11) has a strong solution $x(\cdot)$ with values in $D(A)$, for some given $s \geq 0$, $x \in D(A)$. Applying Lemma 2.5, we obtain

$$\begin{aligned} x(t) - \Phi(t,s)x &= \int_s^t \frac{\partial}{\partial \rho}[\Phi(t,\rho)x(\rho)]d\rho \\ &= \int_s^t \Phi(t,\rho)[-A(\rho) + A(\rho) + D(\rho)\Delta(\rho)E(\rho)]x(\rho)d\rho \\ &= \int_s^t \Phi(t,\rho)D(\rho)\Delta(\rho)E(\rho)x(\rho)d\rho, \qquad (t,s) \in \Gamma. \end{aligned}$$

Or

$$x(t) = \Phi(t,s)x + \int_s^t \Phi(t,\rho)D(\rho)\Delta(\rho)E(\rho)x(\rho)d\rho, \qquad t \geq s. \tag{12}$$

This is the "mild" version of the perturbed Cauchy problem (11), and to make sense of it we specify some standing hypotheses. Because the generator $A(\cdot)$ does not appear in (12), this equation can be considered the perturbed system equation for a wider class of dynamical models described by *mild evolution operators*.

DEFINITION 2.9 (Mild evolution operator). $\Phi(\cdot,\cdot) : \Gamma \to \mathcal{L}(X)$ *is a* mild evolution operator *on* X *if the following hold*:

(i) $\Phi(t,t) = I$, $t \in \mathbb{R}_+$;

(ii) $\Phi(t,\sigma)\Phi(\sigma,s) = \Phi(t,s)$, $0 \leq s \leq \sigma \leq t < \infty$;

(iii) $\Phi(\cdot,s)$ *is strongly continuous on* $[s,\infty)$ *and* $\Phi(t,\cdot)$ *is strongly continuous on* $[0,t]$.

If there exist $M > 0$, $\omega > 0$ *such that*

$$\|\Phi(t,s)\| \leq Me^{-\omega(t-s)}, \qquad t \geq s \geq 0, \tag{13}$$

then the mild evolution operator $\Phi(\cdot,\cdot)$ *is said to be* exponentially stable.

Remark 2.10. By definition, every weak evolution operator is a mild one. A mild evolution operator Φ is said to be *time-invariant* if $\Phi(t,s) = \Phi(t-s,0)$, $(t,s) \in \Gamma$. But then $S(t) := \Phi(t,0)$ defines a strongly continuous semigroup on X, and as a consequence we see that the concepts of mild, weak, and strong evolution operators coincide in the time-invariant setting [3].

If Φ is a mild evolution operator, then the sets $\{\Phi(t,s);\ s \in [0,t]\}$ and $\{\Phi(t,s);\ t \in [s,\tau]\}$ are bounded in $\mathcal{L}(X)$ for every $t \geq 0$, respectively $\tau \geq s$. However, in contrast to the semigroup case, there may not exist exponential bounds for $\Phi(\cdot,s)$ on $[s,\infty)$. To capture this property, Bohl [1] introduced the concept of a Bohl exponent, which we now extend to an infinite-dimensional setting [4].

DEFINITION 2.11 (Bohl exponent). *The* (upper) Bohl exponent $\beta(\Phi)$ *of a mild evolution operator* $\Phi(t,s)$ *is given by*

$$\beta(\Phi) = \inf\{\omega \in \mathbb{R};\ \exists M_\omega > 0 : t \geq s \geq 0 \Rightarrow \|\Phi(t,s)\| \leq M_\omega e^{\omega(t-s)}\}.$$

It is possible that $\beta(\Phi) = \pm\infty$. If $\Phi(t,s) = S(t-s)$, where $(S(t))_{t\in\mathbb{R}_+}$ is an analytic semigroup on X with generator A, then

$$\beta(\Phi) = \sup_{\lambda\in\sigma(A)} \operatorname{Re}\lambda.$$

The following proposition collects some basic properties of Bohl exponents used throughout this paper.

PROPOSITION 2.12. *Suppose that Φ is a mild evolution operator on X. Then we have the following.*

(i) *The Bohl exponent of Φ is finite if and only if* $\sup_{0\le t-s\le 1}\|\Phi(t,s)\| < \infty$.

(ii) *If $\beta(\Phi) < \infty$, then*

$$\beta(\Phi) = \limsup_{s,t-s\to\infty} \frac{\ln\|\Phi(t,s)\|}{t-s}.$$

(iii) *If $\beta(\Phi) < \infty$, $1 \le p < \infty$ the following statements are equivalent:*

(a) *Φ is exponentially stable;*

(b) *$\beta(\Phi) < 0$;*

(c) *there exists a constant c such that*

$$\int_s^\infty \|\Phi(t,s)x\|^p\,dt \le c^p\|x\|^p \quad \text{for all } s \ge 0,\ x \in X.$$

Proof. (i), (ii), and the equivalence "(a) $\Leftrightarrow$ (b)" in (iii) can be proved in a similar manner to that in [4]. The implication "(a) $\Rightarrow$ (c)" being trivial, it only remains to show that (c) implies (a). This is proved in [4] for the case where Φ is generated by a bounded A and in [5] for the general case with $p = 2$. A slick proof for the case $p = 2$ is given in [3] and it is easy to see that this proof can be extended to any p, $1 \le p < \infty$. □

The Bohl exponent of (1) is said to be *strict* if "lim sup" can be replaced by "lim" in (ii).

Remark 2.13. Suppose that Φ is a mild evolution operator on X and $D(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(U,X))$, $E(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(X,Y))$. Then the triplet (Φ, D, E) defines a time-varying linear dynamical system with input space U, state space X, and output space Y. The state trajectory generated by an initial condition $x(s) = x \in X$ and a control function $u(\cdot) \in L^1(s,\tau;U), \tau > s$ is

$$\varphi(t,s,x,u(\cdot)) = \Phi(t,s)x + \int_s^t \Phi(t,\rho)D(\rho)u(\rho)d\rho, \qquad t \in [s,\tau], \tag{14}$$

with associated output function

$$\begin{aligned} y(t,s,x,u(\cdot)) &= E(t)\varphi(t,s,x,u(\cdot)) \\ &= E(t)\Phi(t,s)x + E(t)\int_s^t \Phi(t,\rho)D(\rho)u(\rho)d\rho, \qquad t \in [s,\tau]. \end{aligned} \tag{15}$$

It can be shown that if the Bohl exponent $\beta(\Phi) < \infty$, then $x(\cdot) = \varphi(\cdot,s,x,u(\cdot))$ is continuous on $[s,\tau]$. Indeed, if $s \le \hat{t} \le t \le \tau$, then

$$\begin{aligned} x(t) - x(\hat{t}) = [\Phi(t,s) - \Phi(\hat{t},s)]x &+ \int_s^{\hat{t}} [\Phi(t,\hat{t}) - I_X]\Phi(\hat{t},\rho)D(\rho)u(\rho)d\rho \\ &+ \int_{\hat{t}}^t \Phi(t,\rho)D(\rho)u(\rho)d\rho. \end{aligned} \tag{16}$$

If we fix $\hat{t}$, the first and the second term go to zero as $t \downarrow \hat{t}$ by the strong continuity of $\Phi(\cdot, s)$. Now because $\beta(\Phi) < \infty$, there exists M_τ such that $\|\Phi(t,\rho)\| \leq M_\tau, s \leq \rho \leq t \leq \tau$. Hence the last term goes to zero by the estimate

$$\left\| \int_{\hat{t}}^{t} \Phi(t,\rho)D(\rho)u(\rho)d\rho \right\| \leq M_\tau \int_{\hat{t}}^{t} \|D(\rho)u(\rho)\|d\rho \to 0 \quad \text{as } t \downarrow \hat{t}.$$

So $x(\cdot)$ is continuous from the right. Now fix t and let $\hat{t} \uparrow t$. The first and the last term in (16) go to zero by the same arguments as before. Extending the integrand of the second term by zero to the fixed interval $[s,t]$, it can be written in the form $\int_s^t f(\hat{t},\rho)d\rho$, where $f(\hat{t},\rho)$ tends pointwise (in ρ) to zero as $\hat{t} \uparrow t$ (by strong continuity of $\Phi(t,\cdot)$) and its norm is bounded by the integrable function $2M_\tau\|D(\rho)u(\rho)\|_X$. Therefore, $\int_s^t f(\hat{t},\rho)d\rho \to 0$ as $\hat{t} \uparrow t$. Hence $x(\cdot)$ is continuous from the left.

Because in our context the operators $D(t)$ and $E(t)$ are unbounded, the integral in (14) is not well defined without further assumptions. We introduce the following hypotheses (which will be supplemented later). Throughout this paper we suppose that p is given a real number with $1 \leq p \leq \infty$.

Hypothesis 1. $\underline{X}$, X, $\overline{X}$ are Banach spaces such that $\underline{X} \subset X \subset \overline{X}$ and the canonical injections $\underline{X} \hookrightarrow X$, $X \hookrightarrow \overline{X}$ are continuous with dense ranges. $D(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(U, \overline{X}))$, $E(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(\underline{X}, Y))$.

Hypothesis 2. $(\Phi(t,s))_{(t,s)\in\Gamma}$ is a mild evolution operator on X, and for all $t \geq s \geq 0$, $\Phi(t,s)$ can be extended to a bounded linear operator on $\overline{X}$ (again denoted by $\Phi(t,s)$).

Hypothesis 3. For every $u(\cdot) \in L^p(0,t;U)$, $t > 0$, the map $\Phi(t,\cdot)D(\cdot)u(\cdot)$ from $[0,t]$ to $\overline{X}$ is integrable in $\overline{X}$.

An important role will be played by the *input to state* operators $\mathbb{M}_s$, $s \geq 0$,

$$(\mathbb{M}_s u)(t) = \int_s^t \Phi(t,\rho)D(\rho)u(\rho)d\rho, \qquad t \geq s, \qquad u(\cdot) \in L^p(s,\infty;U). \tag{17}$$

Note that because of Hypothesis 3, the integral in (17) is well defined (in $\overline{X}$). The following hypothesis will be needed later and contains stronger assumptions than required for this section.

Hypothesis 4. For every $u(\cdot) \in L^p(s,\infty;U)$, $s \geq 0$, $(\mathbb{M}_s u)(t) \in \underline{X}$ for almost every $t \geq s$, $t \mapsto (\mathbb{M}_s u)(t)$ is continuous on $[s,\infty)$ with respect to the norm $\|\cdot\|_X$, and there exists an exponentially bounded $k(t) \geq 0$ such that

$$\|(\mathbb{M}_s u)(t)\|_X \leq k(t)\|u(\cdot)\|_{L^p(s,t;U)}, \qquad t \geq s \geq 0. \tag{18}$$

DEFINITION 2.14. *Given a perturbation $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U))$, a continuous function $x(\cdot) : [s,\infty) \to X$ is said to be a* mild solution *of* (12) *on $[s,\infty)$ if $x(t) \in \underline{X}$ for almost all $t \geq s$, $E(\cdot)x(\cdot)$ is L^p-integrable on every interval $[s,t]$ and* (12) *is satisfied for all $t \geq s$.*

Note that at this stage we cannot be sure that a mild solution $x(\cdot)$ of (12) exists and is unique, even if $x \in \underline{X}$.

Remark 2.15. Under Hypotheses 1 and 2, $(\Phi(t,s))_{(t,s)\in\Gamma}$ satisfies conditions (i), (ii) of Definition 2.9 on $\overline{X}$. Moreover, Φ is a mild evolution operator on $\overline{X}$ if and only if, in addition, $\{\Phi(t,s); s \in [0,t]\}$ and $\{\Phi(t,s); t \in [s,\tau]\}$ are bounded in $\mathcal{L}(\overline{X})$ for every $t \geq 0$, respectively, $s \geq 0$, $\tau \geq s$. The necessity is clear. Now assume that the above sets are bounded. For any $x \in \overline{X}$, let (x_k) be a sequence in X that converges to x in $\overline{X}$. Because

$$\|\Phi(t,s)x - \Phi(t,s)x_k\|_{\overline{X}} \leq \sup_{s\in[0,t]} \|\Phi(t,s)\|_{\mathcal{L}(\overline{X})}\|x - x_k\|_{\overline{X}}, \qquad s \in [0,t],$$

$\Phi(t,\cdot)x : [0,t] \to \overline{X}$ is a uniform limit of the continuous functions $\Phi(t,\cdot)x_k : [0,t] \to \overline{X}$; hence it is continuous. The continuity of $\Phi(\cdot,s)x$ on $[s,\infty)$ for $x \in \overline{X}$ is proved similarly.

Now suppose that there exists a mild evolution operator $\Phi_\Delta(\cdot,\cdot)$ on X such that for all $t \geq s \geq 0$,

$$\Phi_\Delta(\rho,s)x \in \underline{X}, \quad \text{for any } x \in \underline{X} \quad \text{and} \quad \text{a.e. } \rho \in [s,t], \tag{19}$$

$$\|E(\cdot)\Phi_\Delta(\cdot,s)x\|_{L^p(s,t;Y)} \leq k\|x\|_X, \qquad x \in \underline{X} \quad (k \geq 0 \text{ a constant}), \tag{20}$$

$$\Phi_\Delta(t,s)x = \Phi(t,s)x + \int_s^t \Phi(t,\rho)D(\rho)\Delta(\rho)E(\rho)\Phi_\Delta(\rho,s)x\,d\rho, \qquad x \in \underline{X}. \tag{21}$$

If $x \in X$, there exists a sequence (x_k) in $\underline{X}$ that converges to x in X. By (20) the corresponding sequence $(E(\cdot)\Phi_\Delta(\cdot,s)x_k|_{[s,t]})$ in $L^p(s,t;Y)$ is Cauchy for all $t > s$. We denote the limit in $L^p_{loc}(s,\infty;Y)$ by

$$E(\cdot)\Phi_\Delta(\cdot,s)x = \lim_{k\to\infty} E(\cdot)\Phi_\Delta(\cdot,s)x_k. \tag{22}$$

With this notation we conclude from Hypotheses 3 and 4 that $x(t) = \Phi_\Delta(\cdot,s)x$ is a mild solution of the perturbed equation (12) for all $x \in X$ (see Definition 2.14).

DEFINITION 2.16 (Perturbed mild evolution operator). *Suppose Hypotheses* 1–4 *hold and* $\Delta \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U))$. *If there exists a unique mild evolution operator* $\Phi_\Delta(\cdot,\cdot)$ *on* X *satisfying* (19)–(21) *for all* $t \geq s \geq 0$, *then* $\Delta(\cdot)$ *is called an* admissible *perturbation for* $\Phi(\cdot,\cdot)$ *under the perturbation structure* (D,E) *and* $\Phi_\Delta(\cdot,\cdot)$ *is called the perturbed mild evolution operator corresponding to the admissible perturbation* $\Delta(\cdot)$.

We are now in a position to introduce the stability radius as a measure of robust stability for exponentially stable mild evolution operators.

DEFINITION 2.17. *Suppose* Φ *is exponentially stable and Hypothesis* 1–4 *hold. The* stability radius *of* $\Phi(\cdot,\cdot)$ *with respect to the perturbation structure* (D,E) *is defined by*

$$r(\Phi;D,E) = \sup\{r \in \mathbb{R}_+;\ \forall \Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U)) : \|\Delta\|_\infty \leq r \Rightarrow \Delta \text{ is admissible and } \Phi_\Delta(\cdot,\cdot) \text{ is exponentially stable}\}.$$

3. A lower bound for the stability radius. Throughout this section we assume that $\Phi(\cdot,\cdot)$ is an exponentially stable mild evolution operator on X and $1 \leq p < \infty$, $\mathbb{M}_s$ defined by (17). In addition to Hypotheses 1–4 we also require the following.

Hypothesis 5. For all $s \geq 0$, $\mathbb{M}_s \in \mathcal{L}(L^p(s,\infty;U),\ L^p(s,\infty;X))$.

Hypothesis 6. $\Phi(t,s)x \in \underline{X}$, for any $x \in \underline{X}$ and almost every $t \geq s$, $s \geq 0$.

Hypothesis 7. For every $x \in \underline{X}$, $t > 0$,

$$\lim_{s\to t} \|E(\cdot)\Phi(\cdot,s)x\|_{L^p(s,t;Y)} = 0, \tag{23}$$

and there exists a constant $K > 0$ such that $E(\cdot)\Phi(\cdot,s)x : [s,\infty) \to Y$ is p-integrable and

$$\|E(\cdot)\Phi(\cdot,s)x\|_{L^p(s,\infty;Y)} \leq K\|x\|_X, \qquad x \in \underline{X}, \quad s \geq 0. \tag{24}$$

Then just as in (22), we define $y_0(\cdot,s,x) \in L^p(s,\infty;Y)$, for $x \in X$, by

$$y_0(\cdot,s,x) = E(\cdot)\Phi(\cdot,s)x = \lim_{k\to\infty} E(\cdot)\Phi(\cdot,s)x_k, \tag{25}$$

where (x_k) is some sequence in $\underline{X}$ converging to x in X. Using this definition it is easy to see that (23) holds for every $x \in X$, $t > 0$. In fact, for any $\varepsilon > 0$ there exists, by (24), $l \in \mathbb{N}$ such that $\|E(\cdot)\Phi(\cdot,s)x - E(\cdot)\Phi(\cdot,s)x_l\|_{L^p(s,t;Y)} < \varepsilon/2$ for all $s \in [0,t]$ and there exists $\delta \in (0,t)$ such that $\|E(\cdot)\Phi(\cdot,s)x_l\|_{L^p(s,t;Y)} < \varepsilon/2$ for $s \in [t-\delta, t]$, whence $\|E(\cdot)\Phi(\cdot,s)x\|_{L^p(s,t;Y)} < \varepsilon$ for $s \in [t-\delta, t]$.

Our final hypothesis concerns the input–output operator $\mathbb{L}_s$, where

$$(\mathbb{L}_s u)(t) = E(t)\int_s^t \Phi(t,\rho)D(\rho)u(\rho)d\rho, \qquad t \geq s \geq 0,\ u(\cdot) \in L^p(s,\infty;U). \tag{26}$$

Hypothesis 8. $\mathbb{L}_s \in \mathcal{L}(L^p(s,\infty;U),\ L^p(s,\infty;Y))$, $s \geq 0$.

Remark 3.1. (i) If $E(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(X,Y))$, $\underline{X} = X$, then Hypothesis 6 and (23) are automatically satisfied and (24) is a consequence of the exponential stability of $\Phi(\cdot,\cdot)$.

(ii) If $D(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(U,X))$, $\overline{X} = X$, then Hypotheses 2, 3, and 5, and all but the first statement in Hypothesis 4 are satisfied.

(iii) If the conditions in both (i) and (ii) are satisfied, then Hypotheses 1–8 hold.

We have the following result.

THEOREM 3.2. *Suppose Hypotheses* 1–8 *hold and* Φ *is exponentially stable on* X. *Then*

$$r(\Phi; D, E) \geq \|\mathbb{L}_0\|^{-1}. \tag{27}$$

Proof. Let $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U))$ be such that $\|\Delta\|_\infty < \|\mathbb{L}_0\|^{-1}$. We begin by constructing the operators $\Phi_\Delta(t,s)$, $(t,s) \in \Gamma$. Consider the equations

$$y_\Delta(\cdot,s,x) = y_0(\cdot,s,x) + (\mathbb{L}_s\Delta_s y_\Delta(\cdot,s,x))(\cdot), \tag{28}$$

where $s \geq 0$ and $y_0(\cdot,s,x)$ is defined by (25). Here $\Delta_s : L^p(s,\infty;Y) \to L^p(s,\infty;U)$ is the multiplication operator described by $\Delta(\cdot)$. It is not difficult to show that $\|\mathbb{L}_s\| \leq \|\mathbb{L}_{\hat{s}}\|$, $\|\mathbb{M}_s\| \leq \|\mathbb{M}_{\hat{s}}\|$, $\|\Delta_s\| \leq \|\Delta_{\hat{s}}\|$ for $s \geq \hat{s}$. Because $\|\Delta_s\|_\infty$ is the operator norm of the multiplication operator Δ_s, $\mathbb{L}_s\Delta_s$ is a contraction on $L^p(s,\infty;Y)$. Furthermore, because $y_0(\cdot,s,x) \in L^p(s,\infty;Y)$ by (25), there must exist a unique solution $y_\Delta(\cdot,s,x) \in L^p(s,\infty;Y)$ of (28) for each $s \geq 0$, $x \in X$. Moreover,

$$\begin{aligned}\|y_\Delta(\cdot,s,x)\|_{L^p(s,\infty;Y)} &= \|(I - \mathbb{L}_s\Delta_s)^{-1}y_0(\cdot,s,x)\|_{L^p(s,\infty;Y)} \\ &\leq (1 - \|\mathbb{L}_0\|\|\Delta_0\|)^{-1}\|y_0(\cdot,s,x)\|_{L^p(s,\infty;Y)}, \qquad x \in X.\end{aligned}$$

Hence by Hypothesis 7, there exists a $K_\Delta > 0$ such that

$$\|y_\Delta(\cdot,s,x)\|_{L^p(s,\infty;Y)} \leq K_\Delta\|x\|_X, \qquad s \geq 0, \qquad x \in X, \tag{29}$$

and $x \mapsto y_\Delta(\cdot,s,x)$ is bounded linear operator from X to $L^p(s,\infty;Y)$. Now define $x_\Delta(\cdot,s,x)$ by

$$x_\Delta(\cdot,s,x) = \Phi(\cdot,s)x + (\mathbb{M}_s\Delta_s y_\Delta(\cdot,s,x))(\cdot), \tag{30}$$

for $s \geq 0$, $x \in X$. Then Hypotheses 4 and 5 and the exponential stability of $\Phi(\cdot,\cdot)$ imply

$$\|x_\Delta(t,s,x)\|_X \leq k_\Delta(t)\|x\|_X, \qquad t \geq s \geq 0, \qquad x \in X, \tag{31}$$

$$\|x_\Delta(\cdot,s,x)\|_{L^p(s,\infty;X)} \leq c\|x\|_X, \qquad s \geq 0, \qquad x \in X \tag{32}$$

for some constant $c > 0$ (independent of t, s) and some exponentially bounded $k_\Delta(t)$. In particular, $\Phi_\Delta(t,s) : x \mapsto x_\Delta(t,s,x)$ is a bounded linear operator on X for all $t \geq s \geq 0$ and

$$\|\Phi_\Delta(t,s)\|_{\mathcal{L}(X)} \leq k_\Delta(t) \qquad t \geq s \geq 0. \tag{33}$$

Next, we show that Φ_Δ satisfies (19)–(21). It follows from Hypotheses 6 and 4 that $x_\Delta(t,s,x) \in \underline{X}$ for all $x \in \underline{X}$ and almost every $t \geq s$, $s \geq 0$, whence (19). By Hypotheses 7, 4, and 8, $E(\cdot)x_\Delta(\cdot,s,x) \in L^p(s,\infty;Y)$ is well defined for $x \in X$, $s \geq 0$ (making use of (25)), and we have, from (28),

$$E(\cdot)x_\Delta(\cdot,s,x) = y_0(\cdot,s,x) + (\mathbb{L}_s\Delta_s y_\Delta(\cdot,s,x))(\cdot) = y_\Delta(\cdot,s,x), \qquad x \in X, \qquad s \geq 0.$$

Thus,

$$E(\cdot)\Phi_\Delta(\cdot,s)x = (I - \mathbb{L}_s\Delta_s)^{-1}E(\cdot)\Phi(\cdot,s)x = y_\Delta(\cdot,s,x), \qquad x \in X, \qquad s \geq 0. \tag{34}$$

So (20) and (21) follow from (29) and (30).

Now we show that Φ_Δ is uniquely determined by the above properties. Suppose that $(\hat{\Phi}_\Delta(t,s))_{(t,s)\in\Gamma}$ is another mild evolution operator on X satisfying (19)–(21). Then $\hat{y}(\cdot,s,x) = E(\cdot)\hat{\Phi}_\Delta(\cdot,s)x \in L^p(s,\infty;Y)$ is well defined for every $x \in \underline{X}$, $s \geq 0$ and satisfies $\hat{y}(\cdot,s,x) = y_0(\cdot,s,x) + (\mathbb{L}_s\Delta_s\hat{y}(\cdot,s,x))(\cdot)$, so that $E(\cdot)\hat{\Phi}_\Delta(\cdot,s)x = y_\Delta(\cdot,s,x)$. Hence (21) implies

$$\hat{\Phi}_\Delta(t,s)x = \Phi(t,s)x + \int_s^t \Phi(t,\rho)D(\rho)\Delta(\rho)y_\Delta(\rho,s,x)d\rho = \Phi_\Delta(t,s)x, \qquad x \in \underline{X}.$$

It remains to be proven that Φ_Δ is an exponentially stable mild evolution operator. Clearly, property (i) of Definition 2.9 is satisfied. To prove the evolution property (ii), let $t \geq \hat{s} \geq s \geq 0$. Then

$$\begin{aligned}\Phi_\Delta(t,s)x = \Phi(t,\hat{s})\Phi(\hat{s},s)x \; &+ \int_{\hat{s}}^t \Phi(t,\rho)D(\rho)\Delta(\rho)y_\Delta(\rho,s,x)d\rho \\ &+ \int_s^{\hat{s}} \Phi(t,\rho)D(\rho)\Delta(\rho)y_\Delta(\rho,s,x)d\rho.\end{aligned} \tag{35}$$

Because $\Phi(t,\hat{s}) \in \mathcal{L}(\overline{X})$, we have

$$\int_s^{\hat{s}} \Phi(t,\rho)D(\rho)\Delta(\rho)y_\Delta(\rho,s,x)d\rho = \Phi(t,\hat{s})\int_s^{\hat{s}} \Phi(\hat{s},\rho)D(\rho)\Delta(\rho)y_\Delta(\rho,s,x)d\rho,$$

and therefore we obtain from (35) and (30)

$$\Phi_\Delta(t,s)x = \Phi(t,\hat{s})\Phi_\Delta(\hat{s},s)x + \int_{\hat{s}}^t \Phi(t,\rho)D(\rho)\Delta(\rho)y_\Delta(\rho,s,x)\,d\rho. \tag{36}$$

Thus, $y(\cdot) = y_\Delta(\cdot,s,x) = E(\cdot)\Phi_\Delta(\cdot,s)x$ satisfies

$$y(\cdot) = y_0(\cdot,\hat{s},\Phi_\Delta(\hat{s},s)x) + (\mathbb{L}_{\hat{s}}\Delta_{\hat{s}}y(\cdot))(\cdot).$$

Because this equation has a unique solution in $L^p(\hat{s},\infty;Y)$, we conclude that

$$y_\Delta(\cdot,s,x) = y_\Delta(\cdot,\hat{s},\Phi_\Delta(\hat{s},s)x) = E(\cdot)\Phi_\Delta(\cdot,\hat{s})\Phi_\Delta(\hat{s},s)x.$$

Substituting in (36) for $y_\Delta(\cdot, s, x)$ and applying (30), we obtain $\Phi_\Delta(t,s)x = \Phi_\Delta(t,\hat{s})\Phi_\Delta(\hat{s},s)x$.

We now show that $\Phi_\Delta(\cdot,s)x = x_\Delta(\cdot,s,x) \in C(s,\infty;X)$ for all $x \in X$, $s \geq 0$, and $\Phi_\Delta(t,\cdot)x = x_\Delta(t,\cdot,x) \in C(0,t;X)$ for all $x \in X$, $t > 0$. The former statement is immediate because the first term on the RHS of (30) is continuous by Hypothesis 2 and the second term is continuous by Hypothesis 4. To prove the latter statement, let $t \geq \hat{s} \geq s$, then

$$\begin{aligned} x_\Delta(t,s,x) - x_\Delta(t,\hat{s},x) &= \Phi(t,s)x - \Phi(t,\hat{s})x + \Phi(t,\hat{s})\int_s^{\hat{s}} \Phi(\hat{s},\rho)D(\rho)\Delta(\rho)y_\Delta(\rho,s,x)d\rho \\ &\quad + \int_{\hat{s}}^t \Phi(t,\rho)D(\rho)\Delta(\rho)[y_\Delta(\rho,s,x) - y_\Delta(\rho,\hat{s},x)]\,d\rho. \end{aligned}$$

So by Hypothesis 4,

$$\begin{aligned} \|x_\Delta(t,s,x) - x_\Delta(t,\hat{s},x)\|_X &\leq \|\Phi(t,s)x - \Phi(t,\hat{s})x\|_X \\ &\quad + M\left\| \int_s^{\hat{s}} \Phi(\hat{s},\rho)D(\rho)\Delta(\rho)y_\Delta(\rho,s,x)d\rho \right\|_X \\ &\quad + k(t)\|\Delta_0\|\|y_\Delta(\cdot,s,x) - y_\Delta(\cdot,\hat{s},x)\|_{L^p(\hat{s},t;Y)}, \end{aligned} \tag{37}$$

where M is taken from (13). Now

$$\begin{aligned} y_\Delta(\rho,s,x) - y_\Delta(\rho,\hat{s},x) &= E(\rho)[\Phi(\rho,s)x - \Phi(\rho,\hat{s})x] \\ &\quad + E(\rho)\Phi(\rho,\hat{s})\int_s^{\hat{s}} \Phi(\hat{s},\sigma)D(\sigma)\Delta(\sigma)y_\Delta(\sigma,s,x)d\sigma \\ &\quad + E(\rho)\int_{\hat{s}}^{\rho} \Phi(\rho,\sigma)D(\sigma)\Delta(\sigma)[y_\Delta(\sigma,s,x) - y_\Delta(\sigma,\hat{s},x)]d\sigma. \end{aligned}$$

By Hypothesis 7,

$$\begin{aligned} &\|y_\Delta(\cdot,s,x) - y_\Delta(\cdot,\hat{s},x)\|_{L^p(\hat{s},\infty;Y)} \\ &\leq K\left[\|(\Phi(\hat{s},s) - I_X)x\| + \left\| \int_s^{\hat{s}} \Phi(\hat{s},\sigma)D(\sigma)\Delta(\sigma)y_\Delta(\sigma,s,x)d\sigma \right\|\right] \\ &\quad + \|\mathbb{L}_{\hat{s}}\|\|\Delta_{\hat{s}}\|\|y_\Delta(\cdot,s,x) - y_\Delta(\cdot,\hat{s},x)\|_{L^p(\hat{s},\infty;Y)}. \end{aligned} \tag{38}$$

First we fix s. The first and second terms on the RHS of (37) go to zero as $\hat{s} \downarrow s$ by the strong continuity of $\Phi(t,\cdot)$ and by Hypothesis 4. By the same argument, the term in brackets on the RHS of (38) goes to zero as $\hat{s} \downarrow s$. Because $\|\mathbb{L}_{\hat{s}}\|\|\Delta_{\hat{s}}\| \leq \|\mathbb{L}_0\|\|\Delta_0\| < 1$, (38) implies $\|y_\Delta(\cdot,s,x) - y_\Delta(\cdot,\hat{s},x)\|_{L^p(\hat{s},\infty;Y)} \to 0$ as $\hat{s} \downarrow s$. Hence, the third term in (37) goes to zero as $\hat{s} \downarrow s$.

Now fix $\hat{s}$. By Hypothesis 4,

$$\begin{aligned} &\left\| \int_s^{\hat{s}} \Phi(\hat{s},\sigma)D(\sigma)\Delta(\sigma)y_\Delta(\sigma,s,x)d\sigma \right\|_X \\ &\quad \leq k(\hat{s})\|\Delta_0\|\|y_\Delta(\cdot,s,x)\|_{L^p(s,\hat{s};Y)} \\ &\quad \leq k(\hat{s})\|\Delta_0\|(1 - \|\mathbb{L}_0\|\,\|\Delta_0\|)^{-1}\|y_0(\cdot,s,x)\|_{L^p(s,\hat{s};Y)} \to 0 \end{aligned}$$

as $s \uparrow \hat{s}$ by Hypothesis 7. Hence the second term on the RHS of (37) and the term in brackets on the RHS of (38) tend to zero as $s \uparrow \hat{s}$. It follows as above that the third and the first term on the RHS of (37) go to zero as $s \uparrow \hat{s}$. This proves $x_\Delta(t,\cdot,x) \in C(0,t;X)$.

Altogether we see that $\Phi_\Delta(\cdot,\cdot)$ satisfies (i)–(iii) of Definition 2.9, that is, $\Phi_\Delta(\cdot,\cdot)$ is a mild evolution operator that is exponentially bounded on Γ because of (33). Hence $\beta(\Phi_\Delta) < \infty$ and from (32),

$$\int_s^\infty \|\Phi_\Delta(t,s)x\|^p dt \le c^p \|x\|_X^p, \qquad s \ge 0, \qquad x \in X. \tag{39}$$

Applying Proposition 2.12 it follows that $\Phi_\Delta(\cdot,\cdot)$ is exponentially stable on $[0,\infty)$ and this completes the proof. □

Remark 3.3. If we extend $y_\Delta(\cdot,s,x) = E(\cdot)\Phi_\Delta(\cdot,s)x \in L^p(s,\infty;Y)$ trivially to $\mathbb{R}_+$, for every $s \ge 0$ and $x \in X$,

$$\bar{y}(t,s,x) = \begin{cases} E(t)\Phi_\Delta(t,s)x & \text{a.e. } t \ge s, \\ 0 & t \in [0,s). \end{cases}$$

The above proof shows that the map $s \mapsto \bar{y}(\cdot,s,x)$ from $\mathbb{R}_+$ into $L^p(\mathbb{R}_+,Y)$ is continuous for every $x \in X$.

Remark 3.4. (i) All the previous definitions and results can be stated analogously for an arbitrary time interval $[t_0,\infty)$ instead of the fixed interval $[0,\infty)$. Thus, if we assume $\|\Delta\|_\infty < \|\mathbb{L}_{t_0}\|^{-1}$ for some $t_0 \ge 0$ in the previous proof, then the existence, uniqueness, and exponential stability of the perturbed mild evolution operator Φ_Δ *on the interval* $[t_0,\infty)$ follows. Contrary to the finite-dimensional case [10], however, we are not able to extend this evolution operator backward to the interval $[0,\infty)$. Therefore we cannot exclude the possibility that the stability radius may be increased by restricting the data (Φ,D,E) to intervals $[t_0,\infty)$, $t_0 > 0$.

(ii) We have analyzed the existence of a perturbed evolution operator and its properties in the context of robust stability. In so doing we have not separated the problem of existence from that of stability. Therefore, we assumed Φ to be exponentially stable and imposed conditions in Hypotheses 7, 5, and 8, which enabled us to first construct $y_\Delta(\cdot,s,x)$ via (28) and then $x_\Delta(\cdot,s,x)$ by (30) on an infinite interval $[s,\infty)$. Our basic method could also have been applied on finite time intervals without the assumption that Φ is exponentially stable. For example, we would seek $y_\Delta(\cdot,s,x)$ as a fixed point of (28) in $L^p(s,t;Y)$. Then $x_\Delta(\cdot,s,x)$ is determined on $[s,t]$ via (30). Proceeding stepwise on successive intervals—under suitable assumptions that ensure that the sums of the lengths of the intervals diverge—we construct $x_\Delta(\cdot,s,x)$ on $[s,\infty)$.

(iii) In the finite-dimensional case it has been shown [10] that if $p = 2$, then $\|\mathbb{L}_{t_0}\|^{-1}$ is the largest value of ρ for which the differential Riccati equation

$$\dot{P}(t) + A^*(t)P(t) + P(t)A(t) - \rho^2 E^*(t)E(t) - P(t)D(t)D^*(t)P(t) = 0, \quad t \ge t_0 \tag{40}$$

has a bounded Hermitian solution. We believe it should be possible to extend this result to systems satisfying the assumptions of Theorem 3.2, but the differential Riccati equation must be replaced by an integral Riccati equation

$$P(t)x = -\int_t^\infty \Phi^*(s,t)[\rho^2 E^*(s)E(s) + P(s)D(s)D^*(s)P(s)]\Phi(s,t)x\,ds, \qquad x \in \underline{X}, \quad t \ge t_0.$$

In the following we apply Theorem 3.2 to a time-invariant setting. Heretofore, our development is equally valid for the fields $\mathbb{R}$ or $\mathbb{C}$; however, for the second part of the next theorem it is essential that $\mathbb{K} = \mathbb{C}$, because our construction of a destabilizing perturbation $\Delta \in \mathcal{L}(Y,U)$ presupposes that U, Y are *complex* Hilbert spaces.

THEOREM 3.5. (i) *Suppose the system* $(S(\cdot), D, E)$ *satisfies the following conditions*:

(a) *Hypothesis* 1 *holds with* D, E *time-invariant*, $S(\cdot)$ *is an exponentially stable* C_0-*semigroup on* X, *and* $S(t)$ *can be extended to a bounded linear operator on* $\overline{X}$ *for every* $t \geq 0$, *such that* $S(t-\cdot)Du(\cdot)$ *is integrable in* $\overline{X}$ *on* $[0,t]$, *for every* $u(\cdot) \in L^p(0,\infty;U)$.

(b) *For every* $u(\cdot) \in L^p(0,\infty;U)$, *the input-state map* $\mathbb{M}_0$,

$$(\mathbb{M}_0 u)(t) = \int_0^t S(t-\rho)Du(\rho)d\rho, \qquad t \geq 0, \qquad u(\cdot) \in L^p(0,\infty;U)$$

satisfies $(\mathbb{M}_0 u)(t) \in \underline{X}$ *for almost every* $t \geq 0$, *and there exists* $\tau > 0$, $k > 0$ *such that*

$$\|(\mathbb{M}_0 u)(\tau)\|_X \leq k\|u(\cdot)\|_{L^p(0,\tau;U)}, \qquad u(\cdot) \in L^p(0,\infty;U). \tag{41}$$

(c) $S(t)x \in \underline{X}$ *for any* $x \in \underline{X}$ *and almost every* $t \geq 0$, $ES(\cdot)x : [0,\infty) \to Y$ *is* p-*integrable for every* $x \in \underline{X}$, *and there exists a constant* $K > 0$ *such that*

$$\|ES(\cdot)x\|_{L^p(0,\infty;Y)} \leq K\|x\|_X, \qquad x \in \underline{X}.$$

(d) *The input–output operator* $\mathbb{L}_0$,

$$(\mathbb{L}_0 u)(t) = E\int_0^t S(t-\rho)Du(\rho)d\rho, \qquad t \geq 0, \qquad u(\cdot) \in L^p(0,\infty;U),$$

satisfies $\mathbb{L}_0 \in \mathcal{L}(L^p(0,\infty;U),\ L^p(0,\infty;Y))$.

Then

$$r(S(\cdot);D,E) \geq \|\mathbb{L}_0\|^{-1}_{\mathcal{L}(L^p(0,\infty;U),L^p(0,\infty;Y))}. \tag{42}$$

(ii) *Suppose additionally that* $\mathbb{K} = \mathbb{C}$, U, Y *are Hilbert spaces*, $p = 2$, *and*

(e) S *extends to an exponentially stable semigroup on* $\overline{X}$ *with generator* $A^{\overline{X}}$ *such that* $D(A^{\overline{X}}) \subset \underline{X}$, *where the embedding is dense and continuous with respect to the graph norm on* $D(A^{\overline{X}})$. *Then*

$$r^c(S;D,E) = r(S;D,E) = \|\mathbb{L}_0\|^{-1}_{\mathcal{L}(L^2(0,\infty;U),L^2(0,\infty;Y))} = [\sup_{\omega\in\mathbb{R}}\|H(i\omega)\|_{\mathcal{L}(U,Y)}]^{-1}, \tag{43}$$

where $r^c(S;D,E)$ *is defined in the same way as* $r(S;D,E)$ *except the perturbations* Δ *are restricted to be constant and* $H(s) = E(sI - A^{\overline{X}})^{-1}D$, $s \in \mathbb{C}\backslash\sigma(A^{\overline{X}})$.

Proof. (i) It is shown in [27] that (a) and (b) imply that for every $u(\cdot) \in L^p(0,\infty;U)$ and $t \geq 0$, $(\mathbb{M}_0 u)(\cdot) \in C(0,t;X)$, and there exists a constant $k > 0$ such that

$$\|(\mathbb{M}_0 u)(t)\|_X \leq k\|u(\cdot)\|_{L^p(0,t;U)}, \qquad t \geq 0.$$

Moreover, it follows from the exponential stability of $S(\cdot)$ that $\mathbb{M}_0 \in \mathcal{L}(L^p(0,\infty;U), L^p(0,\infty;X))$ [29]. Also

$$\lim_{s\to t}\|ES(\cdot - s)x\|_{L^p(s,t;Y)} = \lim_{s\to t}\|ES(\cdot)x\|_{L^p(0,t-s;Y)} = 0, \qquad x \in \underline{X},\ t > 0.$$

So (a)–(d) imply Hypotheses 1–8 for the system $(S(\cdot), D, E)$, and hence we may apply Theorem 3.2 to obtain (42).

(ii) Now assume the hypotheses of the second part of the theorem. In [29] it is shown that under these assumptions,

$$\|\mathbb{L}_0\|_{\mathcal{L}(L^2(0,\infty;U),L^2(0,\infty;Y))} = \sup_{s\in\mathbb{C}_0}\|H(s)\|_{\mathcal{L}(U,Y)}, \tag{44}$$

where $\mathbb{C}_0 = \{s \in \mathbb{C};\ \mathrm{Re}\, s > 0\}$, $H(s) = E_L(sI - A^{\overline{X}})^{-1}D$, and E_L is the Lebesgue extension of E defined by

$$E_L x = \lim_{\tau \to 0} E\frac{1}{\tau}\int_0^\tau S(s)x\, ds,$$

with domain $D(E_L) = \{x \in X;$ the above lim exists$\}$. Suppose $x \in D(A^{\overline{X}}) \subset \underline{X}$, $(A^{\overline{X}})^{-1}x = y$, then $y \in D((A^{\overline{X}})^2)$, and because S is a semigroup on the Banach space $D(A^{\overline{X}})$ with generator $A^{\overline{X}}|D((A^{\overline{X}})^2)$, we have

$$\begin{aligned}
Ex &= E\, A^{\overline{X}} y,\\
&= E \lim_{\tau \to 0} \frac{1}{\tau}(S(\tau) - I)y \quad \text{(where the limit is taken in } D(A^{\overline{X}})),\\
&= \lim_{\tau \to 0} E\frac{1}{\tau}(S(\tau) - I)y \quad \text{(where the limit is taken in } Y),\\
&= \lim_{\tau \to 0} E\frac{1}{\tau}\int_0^\tau \frac{dS(s)y}{ds}\, ds = \lim_{\tau \to 0} E\frac{1}{\tau}\int_0^\tau S(s)A^{\overline{X}} y\, ds,\\
&= \lim_{\tau \to 0} E\frac{1}{\tau}\int_0^\tau S(s)x\, ds = E_L x.
\end{aligned}$$

Hence $D(A^{\overline{X}}) \subset D(E_L)$ and $Ex = E_L x$ for all $x \in D(A^{\overline{X}})$. By the exponential stability of S on $\overline{X}$, there exists $\delta > 0$ such that the resolvent $(sI - A^{\overline{X}})^{-1}$ is analytic on $\mathbb{C}_{-\delta} = \{s \in \mathbb{C};\ \mathrm{Re}\, s > -\delta\}$. Hence $(sI - A^{\overline{X}})^{-1}Du \in D(A^{\overline{X}})$ for all $s \in \mathbb{C}_{-\delta}$, $u \in U$ and

$$H(s) = E(sI - A^{\overline{X}})^{-1}D, \qquad s \in \mathbb{C}_{-\delta}$$

is analytic on $\mathbb{C}_{-\delta}$. It follows from the maximum principle and (44) that

$$\|\mathbb{L}_0\|_{\mathcal{L}(L^2(0,\infty;U),L^2(0,\infty;Y))} = \sup_{\omega \in \mathbb{R}} \|H(\imath\omega)\|_{\mathcal{L}(U,Y)}. \tag{45}$$

Now suppose, by way of contradiction, that $\|H(\imath\omega)\|^{-1}_{\mathcal{L}(U,Y)} < r^c(S; D, E)$ and choose $\varepsilon > 0$ small enough to satisfy $[\sup_{\omega \in \mathbb{R}} \|H(\imath\omega)\| - \varepsilon]^{-1} < r^c(S; D, E)$. There exist $\omega_0 \in \mathbb{R}$, $u \in U$ such that $\|u\| = 1$ and $\|H(\imath\omega_0)u\| \geq \sup_{\omega \in \mathbb{R}} \|H(\imath\omega)\| - \varepsilon$. Define $\Delta \in \mathcal{L}(Y, U)$ by

$$\Delta y = \frac{\langle y,\, H(\imath\omega_0)u\rangle u}{\|H(\imath\omega_0)u\|^2}, \qquad y \in Y.$$

Then $\|\Delta\| = \|H(\imath\omega_0)u\|^{-1}$, and so

$$\left[\sup_{\omega \in \mathbb{R}} \|H(\imath\omega)\|\right]^{-1} \leq \|\Delta\| \leq \left[\sup_{\omega \in \mathbb{R}} \|H(\imath\omega)\| - \varepsilon\right]^{-1}.$$

Setting $y(t) = e^{\imath\omega_0 t}H(\imath\omega_0)u$, we obtain $\Delta y(t) = e^{\imath\omega_0 t}u$ and

$$\int_0^t S(t - \rho)D\Delta y(\rho)d\rho = e^{\imath\omega_0 t}\int_0^t e^{-\imath\omega_0(t-\rho)}S(t - \rho)Du\, d\rho.$$

But $x = (\imath\omega_0 I - A^{\overline{X}})^{-1}\, Du \in D(A^{\overline{X}})$ satisfies

$$\frac{d}{d\rho}[e^{-\imath\omega_0(t-\rho)}S(t - \rho)x] = e^{-\imath\omega_0(t-\rho)}S(t - \rho)(\imath\omega_0 I - A^{\overline{X}})x = e^{-\imath\omega_0(t-\rho)}S(t - \rho)Du.$$

Hence

$$\int_0^t S(t-\rho)D\Delta y(\rho)d\rho = e^{i\omega_0 t}\int_0^t \frac{d}{d\rho}[e^{-i\omega_0(t-\rho)}S(t-\rho)x]d\rho$$
$$= e^{i\omega_0 t}x - S(t)x,$$

and $y(t) = e^{i\omega_0 t}Ex$. So $x(t) = e^{i\omega_0 t}x$ solves

$$x(t) = S(t)x + \int_0^t S(t-\rho)D\Delta Ex(\rho)d\rho.$$

But because $\|\Delta\| < r^c(S; D, E)$, the mild perturbed evolution operator Φ_Δ must be exponentially stable and $x(t) = \Phi_\Delta(t,0)x$. This is a contradiction and so $[\sup_{\omega\in\mathbb{R}}\|H(i\omega)\|]^{-1} \geq r^c(S; D, E)$. Equation (43) now follows from (45), (42), and the fact that, by definition, $r^c(S; D, E) \geq r(S; D, E)$. □

Remark 3.6. (i) Weiss has introduced the notion of a regular linear system for which the input and output functions are locally L^p, and on any finite interval, the final state and the output function depend continuously on the initial state and input function. These systems provide a unifying framework for a large class of phenomena usually described as linear, time-invariant, and well posed. If, with the notation in [29], we set

$$S(\cdot) = \mathbb{T}(\cdot), \qquad \overline{X} = X_{-1}, \qquad \underline{X} = D(C_L), \qquad E = C_L, \qquad D = B,$$

then for exponentially stable $\mathbb{T}(\cdot)$, the first part of the theorem applies to regular linear systems. In [28] Weiss considers time-invariant perturbations of regular linear systems without the stability constraint. He introduces a *well-posedness radius* with respect to output feedback and determines a lower bound that is exact when U and Y are finite-dimensional. Our lower bound (42) is, of course, a more conservative one for the well-posedness radius, but it does have the advantage that time-varying perturbations are allowed.

(ii) Even for semigroups $S(t) = e^{At}$ on finite-dimensional spaces it is well known [12] that in the *real* case ($\mathbb{K} = \mathbb{R}$) equality does not in general hold in (43).

(iii) A stability radius for complex time-invariant perturbations of infinite-dimensional systems was introduced in [23]. It was assumed that S restricts to an exponentially stable semigroup on $\underline{X}$; U, Y are Hilbert spaces; $p = 2$; and (b), (c), (e) hold. Instead of (d), the authors imposed the condition $\mathbb{M}_0 \in \mathcal{L}(L^2(0,\infty;U), L^2(0,\infty;\underline{X}))$. This clearly implies (d) because $\mathbb{L}_0 = E\mathbb{M}_0$, but splitting condition (d) in this way is in general much more restrictive. Under these stronger assumptions it was shown that the time-invariant complex stability radius equals $\|\mathbb{L}_0\|^{-1}$. So Theorem 3.5 considerably improves this result.

(iv) Of course, we cannot expect more than an inequality from Theorem 3.2 because it is concerned with time-varying systems and we know that equality does not hold even for scalar time-varying systems [10].

4. Perturbations of weak evolution operators. In this section we suppose that Φ is an exponentially stable *weak* evolution operator with generator A and we look for conditions under which the perturbed mild evolution operator $\Phi_\Delta(\cdot,\cdot)$ constructed in §3 is a weak evolution operator with generator $A(\cdot) + D(\cdot)\Delta(\cdot)E(\cdot)$. An immediate problem is that $D(t)\Delta(t)E(t)x$ may not be in X for any nonzero $x \in \underline{X}$, $t \geq 0$. Hence we cannot expect Φ_Δ to be a weak evolution operator on X. However, for $x \in \underline{X}$, $D(t)\Delta(t)E(t)x \in \overline{X}$, so it may be possible to impose conditions which ensure that Φ_Δ is a weak evolution operator on $\overline{X}$. If this is to be the case, an obvious first condition is that Φ_Δ is a mild evolution operator on $\overline{X}$. And because we want to apply Theorem 3.2, we have to set $\overline{X} = X$. So instead of the triple $(\underline{X}, X, \overline{X})$, in this

section we only consider the pair $(\underline{X}, X)$. As a consequence of setting $\overline{X} = X$, some of the hypotheses of Theorem 3.2 are automatically satisfied. For example, if Φ is a mild evolution operator on X, then necessarily Hypothesis 3 is satisfied (because $D(t) \in \mathcal{L}(U, X)$, $t \geq 0$). Also Hypothesis 4 is satisfied with the exception of the requirements that $k(t)$ be exponentially bounded and that $u(\cdot) \in L^p(s, t; U)$, $s \geq 0$ implies $(\mathbb{M}_s u)(t) \in \underline{X}$ for almost every $t \geq s$. We have, of course, paid the price for these advantages in that the unboundedness of the term $D(t)\Delta(t)E(t)$ has been severely reduced.

To prove that Φ_Δ is a weak evolution operator on X, we need to impose further conditions. Obviously, Φ must be a weak evolution operator on X. We recall that this means that for all $t \geq 0$, there is a linear operator $A(t)$ on X with a time-independent domain $D(A)$ dense in X, such that for all $x \in D(A)$, $A(\cdot)x$ is piecewise continuous in the sense of the Assumption and

$$\Phi(t, s)x - x = \int_s^t \Phi(t, \rho)A(\rho)x \, d\rho, \qquad (t, s) \in \Gamma.$$

The other additional hypotheses are as follows.

Hypothesis 9. For each $t > 0$ there exists $\gamma(t) \geq 0$ such that

$$\|(\mathbb{M}_s u)(t)\|_{\underline{X}} \leq \gamma(t)\|u(\cdot)\|_{L^p(s,t;U)}, \qquad u(\cdot) \in L^p(s, t; U). \tag{46}$$

Hypothesis 10. $D(A) \subset \underline{X}$ and for every $(t, s) \in \Gamma$, $x \in D(A)$, and $u(\cdot) \in L^p(s, t; U)$ we have

$$\int_s^t E(t)\Phi(t, \sigma)A(\sigma)x \, d\sigma = E(t) \int_s^t \Phi(t, \sigma)A(\sigma)x \, d\sigma \quad (= E(t)[\Phi(t, s)x - x]),$$

$$\int_s^t E(t)\Phi(t, \sigma)D(\sigma)u(\sigma)d\sigma = E(t) \int_s^t \Phi(t, \sigma)D(\sigma)u(\sigma)d\sigma \quad (= E(t)(\mathbb{M}_s u)(t)).$$

Remark 4.1. (i) If $\gamma(\cdot)$ is exponentially bounded, Hypothesis 9 can be viewed as a strengthening of Hypothesis 4. If, additionally, $\gamma(\cdot)$ is L^p-integrable on $[s, \infty)$, Hypothesis 9 then also implies Hypothesis 5.

(ii) It is not immediately clear that the integrals on the left-hand side (LHS) in Hypothesis 10 are well defined; however, we will see that this is a consequence of the ensuing lemmata.

Our main result is as follows.

THEOREM 4.2. *Suppose Hypotheses* 1–10 *hold with* $\overline{X} = X$, *and* Φ *is an exponentially stable weak evolution operator on* X *with generator* A. *If* $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y, U))$ *has norm* $\|\Delta(\cdot)\|_\infty < \|\mathbb{L}_0\|^{-1}$, *then the perturbed mild evolution operator* Φ_Δ (*which exists and is exponentially stable by Theorem* 3.2) *is a weak evolution operator on* X *with generator* $A_\Delta(t) = A(t) + D(t)\Delta(t)E(t)$, $t \geq 0$ *and domain* $D(A_\Delta) = D(A)$.

To prove this theorem we use the following lemmata. The first shows that Hypothesis 7 is inherited by the perturbed evolution operator Φ_Δ.

LEMMA 4.3. *Under Hypotheses* 1–8, *for every* $x \in \underline{X}$, $t > 0$,

$$\lim_{s \to t} \|E(\cdot)\Phi_\Delta(\cdot, s)x\|_{L^p s,t;Y)} = 0, \tag{47}$$

and there exists a constant $K_\Delta \geq 0$ *such that*

$$\|E(\cdot)\Phi_\Delta(\cdot, s)x\|_{L^p(s,\infty;Y)} \leq K_\Delta \|x\|_X, \qquad x \in \underline{X}, \qquad s \geq 0. \tag{48}$$

Proof. Suppose $s \geq 0$, $x \in \underline{X}$ and let $y_\Delta(\cdot, s, x) = E(\cdot)\Phi_\Delta(\cdot, s)x$. It was shown in the proof of Theorem 3.2 that $y_\Delta(\cdot, s, x) \in L^p(s, \infty; Y)$ and

$$y_\Delta(\cdot, s, x) = (I - \mathbb{L}_s\Delta_s)^{-1}E(\cdot)\Phi(\cdot, s)x$$

(see (34)). Hence by Hypothesis 7,

$$\|y_\Delta(\cdot,s,x)\|_{L^p(s,\infty;Y)} \le (1-\|\mathbb{L}_0\|\|\Delta_0\|)^{-1}K\|x\|_X.$$

Thus, (48) follows with $K_\Delta = K/(1-\|\mathbb{L}_0\|\|\Delta_0\|)$. By (28) we have for all $t > s$,

$$y_\Delta(\cdot,s,x)|_{[s,t]} = y_0(\cdot,s,x)|_{[s,t]} + (\mathbb{L}_{s,t}\Delta_{s,t}y_\Delta(\cdot,s,x)|_{[s,t]})(\cdot)|_{[s,t]},$$

where $\mathbb{L}_{s,t}$, $\Delta_{s,t}$ denote the restrictions of the operators $\mathbb{L}_s$, Δ_s to $L^p(s,t;U) \subset L^p(s,\infty;U)$ respectively, $L^p(s,t;Y) \subset L^p(s,\infty;Y)$. Because $(1-\|\mathbb{L}_{s,t}\|\|\Delta_{s,t}\|)^{-1} \le (1-\|\mathbb{L}_0\|\|\Delta_0\|)^{-1}$, we obtain

$$\|y_\Delta(\cdot,s,x)\|_{L^p(s,t;Y)} \le (1-\|\mathbb{L}_0\|\|\Delta_0\|)^{-1}\|E(\cdot)\Phi(\cdot,s)x\|_{L^p(s,t;Y)}, \qquad t > s,$$

whence (47) follows. □

By (48), $E(\cdot)\Phi_\Delta(\cdot,s)x \in L^p(s,\infty;Y)$ is well defined for every $x \in X$, namely

$$E(\cdot)\Phi_\Delta(\cdot,s)x = \lim_{k\to\infty} E(\cdot)\Phi_\Delta(\cdot,s)x_k,$$

where (x_k) is a sequence in $\underline{X}$ converging toward x in X. For $s \ge 0$, $x \in X$ we denote by $E(t)\Phi_\Delta(t,s)x$, $t \ge s$ the values of a representative of the function class $E(\cdot)\Phi_\Delta(\cdot,s)x \in L^p(s,\infty;Y)$.

LEMMA 4.4. *Under Hypotheses* 1–8, *let* $(s,t) \in \Gamma$, $z(\cdot) \in PC(s,t;X)$, *and* $\Gamma_{s,t} := \{(\tau,\sigma);\ s \le \sigma \le \tau \le t\}$. *Then the maps* $z^t(\cdot,\cdot) : \Gamma_{s,t} \to X$ *and* $y(\cdot,\cdot) : \Gamma_{s,t} \to Y$ *defined by*

$$y(\tau,\sigma) = E(\tau)\Phi_\Delta(\tau,\sigma)z(\sigma), \qquad (\tau,\sigma) \in \Gamma_{s,t}, \tag{49}$$

$$z^t(\tau,\sigma) = \Phi(t,\tau)D(\tau)\Delta(\tau)y(\tau,\sigma), \qquad (\tau,\sigma) \in \Gamma_{s,t} \tag{50}$$

are (Bochner) integrable with respect to the Lebesgue measure on $\Gamma_{s,t}$, $\tau \mapsto \int_s^\tau y(\tau,\sigma)d\sigma$ *is p-integrable on* $[s,t]$, *and*

$$\int_s^t \int_\sigma^t z^t(\tau,\sigma)d\tau\, d\sigma = \int_s^t \int_s^\tau z^t(\tau,\sigma)d\sigma\, d\tau. \tag{51}$$

Proof. First we prove the statements concerning $y(\cdot,\cdot)$. For $\sigma \in [s,t]$, define $F(\sigma) \in L^p(s,t;Y)$ by

$$F(\sigma)(\tau) = \begin{cases} y(\tau,\sigma) & \text{if } (\tau,\sigma) \in \Gamma_{s,t}, \\ 0 & \text{otherwise.} \end{cases} \tag{52}$$

By Lemma 4.3, $F(\cdot) : [s,t] \to L^p(s,t;Y)$ is bounded because $z(\cdot)$ is bounded. We now show that $F(\cdot)$ is continuous at all $\sigma \in [s,t]$, where $z(\cdot)$ does not jump. Let $y_\Delta(\cdot,\sigma,x) = E(\cdot)\Phi_\Delta(\cdot,\sigma)x$ for all $x \in X$ so that $y(\tau,\sigma) = y_\Delta(\tau,\sigma,z(\sigma))$, $\tau \in [\sigma,t]$, $\sigma \in [s,t]$. For all $\hat\sigma \ge \sigma$ in $[s,t]$,

$$\begin{aligned}
\|F(\sigma) - F(\hat\sigma)\|^p_{L^p(s,t;Y)} &= \int_\sigma^{\hat\sigma} \|y(\tau,\sigma)\|_Y^p\, d\tau \\
&\quad + \int_{\hat\sigma}^t \|y(\tau,\sigma) - y(\tau,\hat\sigma)\|_Y^p\, d\tau \\
&= \int_\sigma^{\hat\sigma} \|y_\Delta(\tau,\sigma,z(\sigma))\|_Y^p\, d\tau \\
&\quad + \int_{\hat\sigma}^t \|y_\Delta(\tau,\sigma,z(\sigma)) - y_\Delta(\tau,\hat\sigma,z(\hat\sigma))\|_Y^p\, d\tau.
\end{aligned}$$

However,

$$\begin{aligned}\|y_\Delta(\cdot,\sigma,z(\sigma))\|_{L^p(\sigma,\hat\sigma;Y)} &\le \|y_\Delta(\cdot,\sigma,z(\hat\sigma))\|_{L^p(\sigma,\hat\sigma;Y)} + \|y_\Delta(\cdot,\sigma,z(\sigma)-z(\hat\sigma))\|_{L^p(\sigma,\hat\sigma;Y)}\\ &\le \|y_\Delta(\cdot,\sigma,z(\hat\sigma))\|_{L^p(\sigma,\hat\sigma;Y)} + K_\Delta\|z(\sigma)-z(\hat\sigma)\|_X\end{aligned}$$

by (48). The LHS clearly tends to zero as $\hat\sigma \downarrow \sigma$, whereas the first term on the RHS tends to zero as $\sigma \uparrow \hat\sigma$ by (47) and the second term tends to zero if $z(\cdot)$ is continuous at $\hat\sigma$. Now

$$\begin{aligned}\|y_\Delta(\cdot,\sigma,z(\sigma)) - y_\Delta(\cdot,\hat\sigma,z(\hat\sigma))\|_{L^p(\hat\sigma,t;Y)} &\le \|y_\Delta(\cdot,\sigma,z(\sigma)) - y_\Delta(\cdot,\hat\sigma,z(\sigma))\|_{L^p(\hat\sigma,t;Y)}\\ &\quad + \|y_\Delta(\cdot,\hat\sigma,(z(\sigma)-z(\hat\sigma)))\|_{L^p(\hat\sigma,t;Y)}.\end{aligned}$$

The first term on the RHS tends to zero as $\sigma \uparrow \hat\sigma$ or $\hat\sigma \downarrow \sigma$ by Remark 3.3 and the second term is majorized by $K_\Delta\|z(\sigma)-z(\hat\sigma)\|_X$. Therefore, $F(\cdot):[s,t]\to L^p(s,t;Y)$ is bounded and continuous at all continuity points of $z(\cdot)$, hence integrable on $[s,t]$. By Theorem III.11.17 in [7] there exists a strongly Lebesgue measurable function $f:[s,t]^2\to Y$ such that

$$F(\sigma) = f(\cdot,\sigma), \quad \text{a.e. } \sigma\in[s,t].$$

Hence $y(\cdot,\cdot):\Gamma_{s,t}\to Y$ is strongly Lebesgue measurable because it coincides almost everywhere on $\Gamma_{s,t}$ with $f(\cdot,\cdot)$. Moreover, by the same theorem in [7], $f(\tau,\cdot)$ is integrable on $[s,t]$ for almost all $\tau\in[s,t]$ and the integral $\int_s^t f(\tau,\sigma)d\sigma = \int_s^\tau y_\Delta(\tau,\sigma,z(\sigma))d\sigma$, as a function of τ, is a representative of the function class $\int_s^t F(\sigma)d\sigma$ in $L^p(s,t;Y)$. This proves the statements concerning $y(\cdot,\cdot)$.

The statements concerning $z^t(\cdot,\cdot)$ are proved similarly. For $\sigma\in[s,t]$ define $G(\sigma)\in L^p(s,t;X)$ by

$$G(\sigma)(\tau) = \begin{cases} z^t(\tau,\sigma) & \text{if } (\tau,\sigma)\in\Gamma_{s,t},\\ 0 & \text{otherwise.}\end{cases}$$

By assumption, there exist M, $\omega>0$ such that $\|\Phi(t,\tau)\|_{\mathcal{L}(X)}\le Me^{-\omega(t-\tau)}$. Let

$$c^p = M^p \sup_{\tau\in[s,t]}\|D(\tau)\|^p_{\mathcal{L}(U,\overline{X})}\|\Delta(\tau)\|^p_{\mathcal{L}(Y,U)}.$$

Then, for all $\hat\sigma\ge\sigma$ in $[s,t]$:

$$\begin{aligned}\|G(\sigma)-G(\hat\sigma)\|^p_{L^p(s,t;X)} &= \int_\sigma^{\hat\sigma}\|z^t(\tau,\sigma)\|_X^p\,d\tau + \int_{\hat\sigma}^t\|z^t(\tau,\sigma)-z^t(\tau,\hat\sigma)\|_X^p\,d\tau\\ &\le c^p\Bigg[\int_\sigma^{\hat\sigma}\|y_\Delta(\tau,\sigma,z(\sigma))\|_Y^p\,d\tau\\ &\quad + \int_{\hat\sigma}^t\|y_\Delta(\tau,\sigma,z(\sigma)) - y_\Delta(\tau,\hat\sigma,z(\hat\sigma))\|_Y^p\,d\tau\Bigg]\\ &= c^p\|F(\sigma)-F(\hat\sigma)\|^p_{L^p(s,t;Y)}.\end{aligned}$$

Hence $G(\cdot):[s,t]\to L^p(s,t;X)$ is bounded and continuous at all continuity points of $z(\cdot)$. By the same reasoning as above, we conclude that $z(\cdot,\cdot):\Gamma_{s,t}\to X$ is strongly Lebesgue measurable. Moreover, we have

$$\begin{aligned}\int_s^t\int_\sigma^t\|z^t(\tau,\sigma)\|_X\,d\tau\,d\sigma &\le \int_s^t\int_\sigma^t Me^{-\omega(t-\tau)}\|D(\tau)\|\|\Delta(\tau)\|\|y_\Delta(\tau,\sigma,z(\sigma))\|_Y\,d\tau\,d\sigma\\ &\le c\int_s^t(t-\sigma)^{1/q}\|y_\Delta(\cdot,\sigma,z(\sigma))\|_{L^p(\sigma,t;Y)}\,d\sigma\\ &\le c(t-s)^{1/q}\int_s^t K_\Delta\|z(\sigma)\|_X\,d\sigma<\infty,\end{aligned}$$

where $1/p + 1/q = 1$. By Tonelli's theorem [7, Cor. III.11.15] it follows that $z^t(\cdot,\cdot)$ is (Bochner) integrable on $\Gamma_{s,t}$ (with respect to the induced Lebesgue measure) and so Fubini's theorem yields (51). □

As a consequence of this lemma, the map $\sigma \mapsto y(t,\sigma) = E(t)\Phi_\Delta(t,\sigma)z(\sigma)$ is integrable on $[0,t]$ for almost all $t > 0$, if $z(\cdot) \in PC(s,t;X)$. Setting $\Delta = 0$ we see that the same is true for $E(t)\Phi(t,\sigma)z(\sigma)$ and thus the LHS integrals in Hypothesis 10 are well defined.

LEMMA 4.5. *Under the assumptions of Theorem* 4.2, *suppose that for* $(t,s) \in \Gamma$, $z(\cdot) \in PC(s,t;X)$. *If* $z^t(\tau,\sigma)$ *is defined by* (50), *then* $Z^t(\cdot) : \sigma \mapsto \int_\sigma^t z^t(\tau,\sigma)d\tau$ *is a piecewise continuous map from* $[s,t]$ *into* $\underline{X}$. *In particular,*

$$\int_s^t E(t)\int_\sigma^t z^t(\tau,\sigma)d\tau\,d\sigma = E(t)\int_s^t\int_\sigma^t z^t(\tau,\sigma)d\tau\,d\sigma. \tag{53}$$

Proof. Let $t \geq \hat\sigma \geq \sigma \geq s$. Then

$$Z^t(\sigma) - Z^t(\hat\sigma) = \int_\sigma^{\hat\sigma} z^t(\tau,\sigma)d\tau + \int_{\hat\sigma}^t \Phi(t,\tau)D(\tau)\Delta(\tau)[y_\Delta(\tau,\sigma,z(\sigma)) - y_\Delta(\tau,\hat\sigma,z(\hat\sigma))]d\tau.$$

Setting $s = \sigma$ and $u(\tau) = 0$, $\tau \geq \hat\sigma$ in (46) yields

$$\left\| \int_\sigma^{\hat\sigma} \Phi(t,\tau)D(\tau)u(\tau)d\tau \right\|_{\underline{X}} \leq \gamma(t)\|u(\cdot)\|_{L^p(\sigma,\hat\sigma;U)}, \qquad u(\cdot) \in L^p(\sigma,\hat\sigma;U).$$

Hence by Hypothesis 9 and (49),

$$\begin{aligned}
&\|Z^t(\sigma) - Z^t(\hat\sigma)\|_{\underline{X}} \\
&\quad \leq \gamma(t)\|\Delta_0\|\,[\|y_\Delta(\cdot,\sigma,z(\sigma))\|_{L^p(\sigma,\hat\sigma,Y)} + \|y_\Delta(\cdot,\sigma,z(\sigma)) - y_\Delta(\cdot,\hat\sigma,z(\hat\sigma))\|_{L^p(\hat\sigma,t;Y)}] \\
&\quad \leq C(p)\gamma(t)\|\Delta_0\|\,\|F(\sigma) - F(\hat\sigma)\|_{L^p(s,t;Y)},
\end{aligned}$$

where $F(\cdot)$ is given by (52) and $C(p)$ is some constant depending on p. This shows that $Z^t(\cdot) : [s,t] \to X$ is piecewise continuous and (53) is a consequence of this fact. □

We now have all the tools necessary to establish the theorem.

Proof of Theorem 4.2. Suppose $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U))$ has norm $\|\Delta(\cdot)\|_\infty < \|\mathbb{L}_0\|^{-1}$ and let $s \geq 0$, $x \in D(A)$. Then $A_\Delta(\cdot)x \in PC(s,\infty;X)$ and from (21), we have

$$\Phi_\Delta(t,\sigma)A_\Delta(\sigma)x = \Phi(t,\sigma)A_\Delta(\sigma)x + \int_\sigma^t z^t(\tau,\sigma)d\tau, \tag{54}$$

where $z^t(\tau,\sigma)$ is defined as in (49) with $z(\sigma) = A_\Delta(\sigma)x$, namely

$$z^t(\tau,\sigma) = \Phi(t,\tau)D(\tau)\Delta(\tau)E(\tau)\Phi_\Delta(\tau,\sigma)A_\Delta(\sigma)x. \tag{55}$$

Hence, for every $t \geq s$,

$$\begin{aligned}
\int_s^t \Phi_\Delta(t,\sigma)A_\Delta(\sigma)x\,d\sigma = \int_s^t \Phi(t,\sigma)A(\sigma)x\,d\sigma + \int_s^t \Phi(t,\sigma)D(\sigma)\Delta(\sigma)E(\sigma)x\,d\sigma \\
+ \int_s^t\int_\sigma^t z^t(\tau,\sigma)d\tau\,d\sigma.
\end{aligned}$$

Using (51) and the fact that $\Phi(\cdot,\cdot)$ is a weak evolution operator in X with generator $A(\cdot)$, we have

$$\int_s^t \Phi_\Delta(t,\sigma)A_\Delta(\sigma)x\,d\sigma + x = \Phi(t,s)x + \int_s^t \Phi(t,\tau)D(\tau)\Delta(\tau)E(\tau)x\,d\tau + \int_s^t \int_s^\tau z^t(\tau,\sigma)d\sigma\,d\tau \qquad t \geq s. \tag{56}$$

By (55) this means

$$\int_s^t \Phi_\Delta(t,\sigma)A_\Delta(\sigma)x\,d\sigma + x = \Phi(t,s)x + \int_s^t \Phi(t,\tau)D(\tau)\Delta(\tau) \cdot \left[E(\tau)x + \int_s^\tau E(\tau)\Phi_\Delta(\tau,\sigma)A_\Delta(\sigma)x\,d\sigma\right] d\tau. \tag{57}$$

Now Hypothesis 10 implies

$$\int_s^\tau E(\tau)\Phi(\tau,\sigma)A_\Delta(\sigma)x\,d\sigma = \int_s^\tau E(\tau)\Phi(\tau,\sigma)[A(\sigma)x + D(\sigma)\Delta(\sigma)E(\sigma)x]d\sigma = E(\tau)\int_s^\tau \Phi(\tau,\sigma)A_\Delta(\sigma)x\,d\sigma.$$

Therefore, we obtain from Lemma 4.5 and (54), (55),

(58)

$$\int_s^\tau E(\tau)\Phi_\Delta(\tau,\sigma)A_\Delta(\sigma)x\,d\sigma = \int_s^\tau E(\tau)\left[\Phi(\tau,\sigma)A_\Delta(\sigma)x + \int_\sigma^\tau z^\tau(\rho,\sigma)d\rho\right] d\sigma = E(\tau)\int_s^\tau \Phi_\Delta(\tau,\sigma)A_\Delta(\sigma)x\,d\sigma.$$

From (57) we conclude

$$\int_s^t \Phi_\Delta(t,\sigma)A_\Delta(\sigma)x\,d\sigma + x = \Phi(t,s)x + \int_s^t \Phi(t,\tau)D(\tau)\Delta(\tau)E(\tau) \cdot \left[x + \int_s^\tau \Phi_\Delta(\tau,\sigma)A_\Delta(\sigma)x\,d\sigma\right] d\tau. \tag{59}$$

Hence $\Psi_\Delta(t,s)x := x + \int_s^t \Phi_\Delta(t,\sigma)A_\Delta(\sigma)x\,d\sigma$ satisfies the same equation (21) as $\Phi_\Delta(t,s)x$ on $[s,\infty)$. Now by (56),

$$\Psi_\Delta(t,s)x = \Phi(t,s)x + \int_s^t \Phi(t,\tau)D(\tau)\Delta(\tau)E(\tau)x\,d\tau + \int_s^t \int_\sigma^t z^t(\tau,\sigma)d\tau\,d\sigma.$$

For $x \in D(A)$, the RHS lies in $\underline{X}$. In fact, this is the case for the first term by Hypotheses 6 and 10, for the second term by Hypothesis 9, and it was proved to be so for the last term in Lemma 4.5. Thus,

$$\hat{y}(t,s,x) := E(t)\Psi_\Delta(t,s)x = E(t)x + E(t)\int_s^t \Phi_\Delta(t,\sigma)A_\Delta(\sigma)x\,d\sigma$$

is well defined for every $x \in D(A)$, $t \geq s$. It follows from Lemma 4.4 and (58) that

$$\hat{y}(\cdot,s,x)|_{[s,t]} = \left[E(\cdot)x + \int_s^\cdot E(\cdot)\Phi_\Delta(\cdot,\sigma)A_\Delta(\sigma)x\,d\sigma\right]\Big|_{[s,t]} \in L^p(s,t;Y)$$

for every $t > s$ and from (59) that

$$\hat{y}(\cdot, s, x)|_{[s,t]} = y_0(\cdot, s, x)|_{[s,t]} + (\mathbb{L}_{s,t}\Delta_{s,t}\hat{y}(\cdot, s, x)|_{[s,t]})(\cdot)|_{[s,t]}, \qquad t > s,$$

where $y_0(\cdot, s, x)$ is defined by (25). Hence,

$$E(\cdot)\Psi_\Delta(\cdot, s)x = y_\Delta(\cdot, s, x),$$

and (59) implies

$$\Psi_\Delta(t, s)x = \Phi(t, s)x + \int_s^t \Phi(t, \tau)D(\tau)\Delta(\tau)y_\Delta(\tau, s, x)d\tau = \Phi_\Delta(t, s)x,\ x \in D(A).$$

Or, equivalently,

$$\int_s^t \Phi_\Delta(t, \sigma)A_\Delta(\sigma)x\, d\sigma + x = \Phi_\Delta(t, s)x, \qquad x \in D(A).$$

This completes the proof. □

To illustrate the assumptions of the theorem, we discuss them in a time-invariant setting for the so called Pritchard–Salamon class of systems. This class was introduced in [22] to study linear quadratic optimal control for infinite-dimensional systems with unbounded input and output operators.

DEFINITION 4.6. *A system $\Sigma = (S(\cdot), D, E)$ is said to be in Pritchard–Salamon class ($\Sigma \in \mathbb{PS}$) if the following conditions hold.*

(a) *$\underline{X}, X, U, Y$ are Hilbert spaces; $\underline{X} \hookrightarrow X$ with a continuous dense injection; $D \in \mathcal{L}(U, X)$, $E \in \mathcal{L}(\underline{X}, Y)$.*

(b) *$S(\cdot)$ is a C_0-semigroup of operators on $\underline{X}$, which extends to a semigroup on X (denoted by the same symbol).*

(c) *There exists $t_1 > 0$ and $k_1 > 0$ such that $\int_0^{t_1} S(t_1 - \sigma)Du(\sigma)d\sigma \in \underline{X}$ for all $u(\cdot) \in L^2(0, t_1; U)$ and*

$$\left\| \int_0^{t_1} S(t_1 - \sigma)Du(\sigma)d\sigma \right\|_{\underline{X}} \le k_1\|u(\cdot)\|_{L^2(0,t_1;U)}, \qquad u(\cdot) \in L^2(0, t_1; U). \tag{60}$$

(d) *There exists $t_2 > 0$ and $k_2 > 0$ such that*

$$\|ES(\cdot)x\|_{L^2(0,t_2;Y)} \le k_2\|x\|_X, \qquad x \in \underline{X}. \tag{61}$$

Remark 4.7. (i) If (60) (respectively, (61)) hold for some $t_1 > 0\,(t_2 > 0)$, it can be shown that they hold for all $t_1\,(t_2)$, where k_1, (k_2) depend on t_1, (t_2). Moreover, if $S(t)$ is exponentially stable on $\underline{X}$ and X, then the $k_1(t_1)$ (respectively, $k_2(t_2)$) may be chosen to be independent of t_1 (respectively, t_2) [27].

(ii) Because $S(\cdot)$ is a strongly continuous semigroup on X, $\Phi(t, s) = S(t-s)$ is a strong (and therefore a weak) evolution operator.

The properties of the class $\mathbb{PS}$ are chosen to guarantee that (in spite of the unboundedness of the operators D, E) bounded linear output feedbacks generate a C_0-semigroup on X. More precisely, let $\Sigma = (S(\cdot), D, E) \in \mathbb{PS}$, let A be the generator of $S(\cdot)$ with domain $D(A)$, and consider, for any $\Delta \in \mathcal{L}(Y, U)$, the operator $A + D\Delta E$ with the same domain. If $D(A) \subset \underline{X}$, it is shown in [2] that A_Δ generates a strongly continuous semigroup $S_\Delta(\cdot)$ on X.

Using Remark 4.7 it is easily verified that if $(S(\cdot), D, E) \in \mathbb{PS}$ is exponentially stable, then all the assumptions of Theorem 3.2 (with $\overline{X} = X$, $p = 2$) are automatically satisfied

except Hypothesis 8. In fact, condition (a) of Definition 4.6 implies Hypothesis 1, (b) implies Hypotheses 2 and 6, (c) implies Hypotheses 4 and 5, and (d) implies Hypothesis 7 (for exponentially stable $S(\cdot)$). If Hypothesis 8 is not satisfied, that is, the operator

$$\mathbb{L}_0 : L^2(0,\infty;U) \to L^2(0,\infty;Y), \qquad u(\cdot) \mapsto E\int_0^{\cdot} S(\cdot-\sigma)Du(\sigma)d\sigma$$

is unbounded, then the statement of Theorem 3.2 is void ($\|\mathbb{L}_0\| = \infty$). If, however, $\mathbb{L}_0$ is bounded and $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U))$ is a perturbation with norm $\|\Delta(\cdot)\|_\infty < \|\mathbb{L}_0\|^{-1}$, then there exists by Theorem 3.2 a unique perturbed mild evolution operator $\Phi_\Delta(\cdot,\cdot)$ on X satisfying (19)–(21) and $\Phi_\Delta(\cdot,\cdot)$ is exponentially stable on X.

To relate Φ_Δ to the perturbed differential equation

$$\dot{x}(t) = [A + D\Delta(t)E]x(t), \qquad t \geq 0, \tag{62}$$

we have to consider the additional assumptions required for Theorem 4.2, that is, Hypotheses 9 and 10. Hypothesis 9 is a direct consequence of (c). Now if we assume the additional property that

$$D(A) \subset \underline{X}, \tag{63}$$

then the closed graph theorem implies that the canonical injection $i : D(A) \to \underline{X}$ is continuous, when $D(A)$ is provided with the graph norm. It was proved in [22] that the second equation in Hypothesis 10 holds, and more recently it has been shown in [2] that this is in fact the case for all systems in $\mathbb{PS}$ *without* the property (63). The following lemma shows that for any system in $\mathbb{PS}$ possessing the property (63), the first equation in Hypothesis 10 also holds.

LEMMA 4.8. *If* $(S(\cdot), D, E) \in \mathbb{PS}$ *satisfies* $D(A) \subset \underline{X}$, *then*

$$E\int_s^t S(t-\sigma)Ax\,d\sigma = \int_s^t ES(t-\sigma)Ax\,d\sigma, \qquad x \in D(A). \tag{64}$$

Proof. An easy argument shows that for every $x \in D(A)$ there exists a sequence (x_k) in $D(A)$ such that $Ax_k \in \underline{X}$, $\lim_{k\to\infty}\|x_k - x\|_{\underline{X}} = 0$ and $\lim_{k\to\infty}\|Ax_k - Ax\|_X = 0$. Because the restriction $S(\cdot)|_{\underline{X}}$ is a semigroup on $\underline{X}$, we have for all $k \in \mathbb{N}$

$$E\int_s^t S(t-\sigma)Ax_k\,d\sigma = \int_s^t ES(t-\sigma)Ax_k\,d\sigma$$

and

$$\begin{aligned}\lim_{k\to\infty} E\int_s^t S(t-\sigma)Ax_k\,d\sigma &= \lim_{k\to\infty} E[S(t-s)x_k - x_k] \\ &= E[S(t-s)x - x] = E\int_s^t S(t-\sigma)Ax\,d\sigma.\end{aligned}$$

On the other hand, we have by (61)

$$\begin{aligned}&\lim_{k\to\infty}\left\| \int_s^t ES(t-\sigma)Ax\,d\sigma - \int_s^t ES(t-\sigma)Ax_k\,d\sigma \right\|_Y \\ &\quad\leq (t-s)^{1/2}\lim_{k\to\infty}\|ES(\cdot)(Ax - Ax_k)\|_{L^2(0,t-s;Y)} \\ &\quad\leq (t-s)^{1/2}k_2\lim_{k\to\infty}\|Ax - Ax_k\|_X = 0.\end{aligned}$$

This proves (64). □

As a consequence we obtain the following corollary of Theorem 4.2.

COROLLARY 4.9. *Suppose* $(S(\cdot), D, E) \in \mathbb{PS}$ *is exponentially stable,* $D(A) \subset \underline{X}$, $\mathbb{L}_0$ *is bounded, and* $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U))$ *is a time-varying perturbation with norm* $\|\Delta(\cdot)\|_\infty < \|\mathbb{L}_0\|^{-1}$. *Then the unique mild evolution operator* $\Phi_\Delta(\cdot,\cdot)$ *satisfying* (19)–(21) *is an exponentially stable weak evolution operator on* X *with generator* $A_\Delta(\cdot)$. *Moreover, if* $\Delta \in \mathcal{L}(Y,U)$ *is constant, then the perturbed system operator* $A + D\Delta E$ *with domain* $D(A)$ *is the infinitesimal generator of a strongly continuous semigroup* $S_\Delta(\cdot)$ *on* X, *such that* $\Phi_\Delta(t,s) = S_\Delta(t-s)$ *and, for every* $x \in D(A)$, *the function* $x_\Delta(t) = S_\Delta(t)x$ *is a strong solution of the perturbed system equation* (62) *with* $x_\Delta(0) = x$. Φ_Δ *is a strong evolution operator and the Cauchy problem associated with* (62) *is well posed.*

Proof. It only remains to prove that the generator of $S_\Delta(\cdot)$ is $A + D\Delta E$ with domain $D(A)$ and this is carried out in [2]. □

Note that, by the counterexample of Phillips [21], we cannot, in general, expect to obtain a strong evolution operator Φ_Δ or strong solutions of the perturbed system equation if Δ is *time-varying*.

In [23], [24] the authors claim that if the conditions indicated in Remark 3.6 hold and if $\|\Delta\|_\infty < \|\mathbb{L}_0\|^{-1}$, then the perturbed semigroup $S_\Delta(\cdot)$ has the property that $x(t) = S_\Delta(t)x$, $x \in D(A)$ satisfies $\dot{x}(t) = (A + D\Delta E)x(t)$, $t \geq 0$. However, the proof is rather obscure and probably requires an additional condition like (60).

We now illustrate the restrictions imposed by the various hypotheses (in this and the previous section) with the following time-invariant example. In particular, we see that the assumptions that guarantee the perturbed evolution operator is exponentially stable and weak are far more restrictive than those that guarantee it is exponentially stable and mild.

Example 4.10. Suppose $-A$ generates an exponentially stable analytic semigroup $S(\cdot)$ on a Hilbert space H (with norm $\|\cdot\|$). Then for any $\gamma \in \mathbb{R}$, A^γ can be defined as in [20]. For α (respectively, β) $\in [0,1]$, we denote the domain of A^α by H_α and endow it with the associated graph norm, $\|\cdot\|_\alpha$ (respectively, the range of $A^{-\beta}$ by $H_{-\beta}$ and for $y = A^{-\beta}x$ we set $\|y\|_{-\beta} = \|x\|$). Then $S(\cdot)$ restricts (extends) to an exponentially stable strongly continuous semigroup on the Hilbert space H_α (respectively, $H_{-\beta}$). Moreover, there exist constants M, $\omega > 0$ such that for all $t > 0$ and $x \in H$ (respectively, $x \in H_{-\beta}$),

$$\|S(t)x\|_\alpha \leq \frac{Me^{-\omega t}}{t^\alpha}\|x\|, \qquad \left(\text{respectively, } \|S(t)x\| \leq \frac{Me^{-\omega t}}{t^\beta}\|x\|_{-\beta}\right),$$

where $\|\cdot\|$ is the norm on H [20]. (Note that for $t > 0$, $S(t)$ maps H into H_α and $H_{-\beta}$ into H.)

Now suppose that $E \in \mathcal{L}(H_{\alpha(E)}, H)$ and $D \in \mathcal{L}(H, H_{-\beta(D)})$ for some $\alpha(E), \beta(D) \in [0,1]$. Then, for arbitrary $\beta \in [0,1]$ and $x \in H_{\alpha(E)}$,

$$\begin{aligned}
\|ES(\cdot)x\|_{L^2(0,\infty;H)} &\leq \|E\|_{\mathcal{L}(H_{\alpha(E)},H)} \left[\int_0^\infty \|S(\rho/2)S(\rho/2)x\|^2_{\alpha(E)} d\rho\right]^{1/2} \\
&\leq \|E\|_{\mathcal{L}(H_{\alpha(E)},H)} \left[\int_0^\infty \frac{M^2 e^{-\omega\rho}}{(\rho/2)^{2\alpha(E)}}\|S(\rho/2)x\|^2 d\rho\right]^{1/2} \qquad (65) \\
&\leq \|E\|_{\mathcal{L}(H_{\alpha(E)},H)} M^2 \left[\int_0^\infty \frac{e^{-2\omega\rho}}{(\rho/2)^{2(\alpha(E)+\beta)}}\, d\rho\right]^{1/2} \|x\|_{-\beta}.
\end{aligned}$$

For arbitrary $\alpha \in [0,1]$, $u(\cdot) \in L^2(0,t;H)$,

$$\begin{aligned}\|(\mathbb{M}_0 u)(t)\|_\alpha &\le \int_0^t \|S((t-\rho)/2)S((t-\rho)/2)Du(\rho)\|_\alpha d\rho \\ &\le \int_0^t \frac{M^2 e^{-\omega(t-\rho)}}{((t-\rho)/2)^{\alpha+\beta(D)}}\|D\|_{\mathcal{L}(H,H_{-\beta(D)})}\|u(\rho)\|d\rho \qquad (66)\\ &\le M^2\|D\|_{\mathcal{L}(H,H_{-\beta(D)})}\left[\int_0^t \frac{e^{-2\omega\rho}}{(\rho/2)^{2(\alpha+\beta(D))}}\,d\rho\right]^{1/2}\|u(\cdot)\|_{L^2}.\end{aligned}$$

Finally, for arbitrary $\alpha \in [0,1]$, $u(\cdot) \in L^2(0,\infty;H)$,

$$\begin{aligned}\|(\mathbb{M}_0 u)(\cdot)\|^2_{L^2(0,\infty;H_\alpha)} &\le \int_0^\infty \left(\int_0^t \|S(t-\rho)Du(\rho)\|_\alpha\,d\rho\right)^2 dt \qquad (67)\\ &\le M^4\|D\|^2_{\mathcal{L}(H,H_{-\beta(D)})}\int_0^\infty\left(\int_0^t \frac{e^{-\omega(t-\rho)}\|u(\rho)\|d\rho}{((t-\rho)/2)^{\alpha+\beta(D)}}\right)^2 dt.\end{aligned}$$

To apply Theorem 3.5 we set

$$X = H, \quad \underline{X} = H_{\alpha(E)}, \quad \overline{X} = H_{-\beta(D)}, \quad U = Y = H.$$

Then (a) of Theorem 3.5 is automatically satisfied. If $\alpha(E) < \frac{1}{2}$, $\beta(D) < \frac{1}{2}$ and $p = 2$, we see from (66) (with $\alpha = 0$) that (b) is satisfied and from (65) (with $\beta = 0$) that (c) is satisfied. Using the convolution estimate $\|f*g\|_{L^2(0,\infty)} \le \|f\|_{L^1(0,\infty)}\|g\|_{L^2(0,\infty)}$ in (67) (with $\alpha = \alpha(E)$), we see that (d) holds provided $\alpha(E)+\beta(D) < 1$. Finally, $D(A^{H_{-\beta(D)}}) \subset H_{\alpha(E)}$ and hence (e) holds if $\alpha(E) + \beta(D) \le 1$ [20]. In summary, the conditions of Theorem 3.5 are satisfied with $p = 2$ provided $\alpha(E) < \frac{1}{2}$, $\beta(D) < \frac{1}{2}$. Hence, under these conditions, $r(S(\cdot); D, E) \ge \|\mathbb{L}_0\|^{-1}$ with equality in the case of a complex perturbation.

Now suppose

$$X = H_{-\beta(D)}, \quad \underline{X} = H_{\alpha(E)}, \quad U = Y = H.$$

Then (a) and (b) of Definition 4.6 are automatically satisfied. From (66) and (65) we see that (c) and (d) are satisfied if $\alpha(E) + \beta(D) < \frac{1}{2}$. Hence for $\alpha(E) + \beta(D) < \frac{1}{2}$ we may apply Corollary 4.9 to conclude that if $\|\Delta(\cdot)\|_\infty < \|\mathbb{L}_0\|^{-1}$, then there exists an exponentially stable weak evolution operator $\Phi_\Delta(\cdot,\cdot)$ on $H_{-\beta(D)}$ with generator $-A + D\Delta(\cdot)E$. Moreover, if $\Delta \in \mathcal{L}(H)$ is constant, $-A + D\Delta E$ with domain $D(A)$ is the infinitesimal generator of the C_0-semigroup $S_\Delta(\cdot) = \Phi_\Delta(\cdot, 0)$ on $H_{-\beta(D)}$.

5. Multiperturbations. In this section we extend the results of the previous sections from the single to the multiperturbation case. But before introducing the formal definitions, we briefly review the effect of time-varying state transformations $\hat{x}(t) = T(t)^{-1}x(t)$ on mild evolution operators and stability radii.

To derive a formula for the transformed evolution operator, let us assume for a moment that Φ is generated by a family $A(\cdot)$ of bounded linear operators on X and $T(\cdot) \in PC^1(\mathbb{R}_+, \mathcal{U}(X))$. Then the above transformation converts the system (1) into

$$\dot{\hat{x}}(t) = \hat{A}(t)\hat{x}(t), \qquad t \ge 0, \qquad (68)$$

where

$$\hat{A}(t) = T(t)^{-1}A(t)T(t) - T(t)^{-1}\dot{T}(t), \qquad t \ge 0.$$

The evolution operator of the system (68) is

$$\hat{\Phi}(t,s) = T(t)^{-1}\Phi(t,s)T(s), \qquad t \geq s \geq 0. \tag{69}$$

The RHS of (69) makes sense for arbitrary mild evolution operators $\Phi(t,s)$ on X and arbitrary time-varying transformations $T(\cdot) \in C(\mathbb{R}_+, \mathcal{U}(X))$. In this way (69) defines a right group action of $C(\mathbb{R}_+, \mathcal{U}(X))$ on the set of mild evolution operators on X. We say that the mild evolution operator $\hat{\Phi}(t,s)$ defined by (69) is obtained from the mild evolution operator $\Phi(t,s)$ by application of the time-varying similarity transformation $T = (T(t))_{t\in\mathbb{R}_+}$.

Because these transformations will not, in general, preserve stability properties, additional assumptions must be imposed if we want to use them in stability analysis. The following class of transformations preserves exponential stability.

DEFINITION 5.1 (Bohl transformation). *$T(\cdot) \in C(\mathbb{R}_+, \mathcal{U}(X))$ is said to be a* Bohl transformation *if*

$$\inf\{\varepsilon \in \mathbb{R};\ \exists M_\varepsilon > 0\ \forall t,s \geq 0 : \|T(t)^{-1}\|\|T(s)\| \leq M_\varepsilon e^{\varepsilon|t-s|}\} = 0.$$

The next example characterizes scalar Bohl transformations and shows that every time-varying scalar system can be made *time-invariant* via a Bohl transformation.

Example 5.2. Suppose $\theta(\cdot) \in PC^1(\mathbb{R}_+, \mathbb{C}^*)$, $\mathbb{C}^* = \mathbb{C}\backslash\{0\}$ and let $a(t) = \dot{\theta}(t)/\theta(t)$, $t \geq 0$, so that $\dot{\theta}(t) = a(t)\theta(t)$. The fundamental solution of this differential equation is

$$\Phi(t,s) = \theta(t)\theta(s)^{-1}, \qquad s,t \in \mathbb{R}_+.$$

By Definition 5.1, $\theta(\cdot)$ is a Bohl transformation if and only if for every $\varepsilon > 0$ there exists $M_\varepsilon > 0$ such that, for $t \geq s \geq 0$,

$$M_\varepsilon^{-1} e^{-\varepsilon(t-s)} \leq |\Phi(s,t)^{-1}| = |\Phi(t,s)| \leq M_\varepsilon e^{\varepsilon(t-s)}.$$

This condition holds if and only if $a(\cdot)$ has *strict* Bohl exponent 0, that is, $\lim_{s,t-s\to\infty} \ln|\theta(t)\theta(s)^{-1}|/(t-s) = 0$.

It is easily verified [10] that every *scalar* system $\dot{x}(t) = A(t)x(t)$ that has a strict Bohl exponent β can be transformed via the Bohl transformation

$$\theta(t) = \exp\left(\int_0^t [A(\rho) - \beta]d\rho\right), \qquad t \geq 0$$

into the *time-invariant* linear system $\dot{\hat{x}}(t) = \beta\hat{x}(t)$, $t \geq 0$.

The following proposition summarizes some elementary properties of Bohl transformations (compare [10]).

PROPOSITION 5.3. (i) *The Bohl transformations form a group with respect to (pointwise) multiplication.*

(ii) *The Bohl exponent is invariant with respect to Bohl transformations.*

(iii) *Let Φ be a mild evolution operator on X. If $T(\cdot) \in C(\mathbb{R}_+, \mathcal{U}(X))$ is a Bohl transformation and $\hat{\Phi}$ is defined by* (69), *then*

$$r(\hat{\Phi}; T^{-1}D,\ ET) = r(\Phi; D, E). \tag{70}$$

(iv) *If $\theta(\cdot) \in C(\mathbb{R}_+, \mathbb{C}^*)$ is a scalar Bohl transformation and Φ^θ is defined by $\Phi^\theta(t,s) = \theta(t)^{-1}\Phi(t,s)\theta(s)$, then*

$$r(\Phi^\theta; D, E) = r(\Phi; D, E). \tag{71}$$

We omit the proof, which is straightforward. Note that, contrary to (70), the structure operators D, E are not transformed in (71). In general, the stability radius may vary dramatically if a *non-scalar* Bohl transformation $T(\cdot)$ (or even a constant transformation $T \in \mathcal{U}(X)$) is applied to Φ alone and not to (D, E). Indeed, if $\Phi(t,s) = e^{A(t-s)}$, where $A \in \mathbb{C}^{n\times n}$ is exponentially stable, it has been shown in [11] that $r(T^{-1}\Phi T; I_n, I_n)$ varies from 0 to $\beta(\Phi) = -\sup_{\lambda\in\sigma(A)} \operatorname{Re}\lambda$ as T varies through $Gl_n(\mathbb{C})$.

Let us now turn to *multiperturbations*. On the level of system equations these are additive perturbations of the generator $A(\cdot) \rightsquigarrow A(\cdot) + \sum_{i=1}^N D_i(\cdot)\Delta_i(\cdot)E_i(\cdot)$, leading to the perturbed system equation

$$\dot{x}(t) = A(t)x(t) + \sum_{i=1}^{N} D_i(t)\Delta_i(t)E_i(t)x(t), \qquad t \geq 0. \tag{72}$$

Here $\Delta_i(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y_i, U_i))$, $i \in \underline{N}$ are unknown *bounded* time-varying disturbance operators; Y_i, U_i are Banach spaces over $\mathbb{K}$; and $D_i(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(U_i, \overline{X}))$, $E_i(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(\underline{X}, Y_i))$, $i \in \underline{N}$ are given operator-valued functions that describe the structure and unboundedness of the perturbation. In the previous sections, we only considered the *single perturbation* case $N = 1$. Setting $Y = \oplus_1^N Y_i$, $U = \oplus_1^N U_i$ (with norms $\|(y)\|_Y = (\sum_1^N \|y_i\|_{Y_i}^2)^{1/2}$, $\|(u)\|_U = (\sum_1^N \|u_i\|_{U_i}^2)^{1/2}$), the size of the overall disturbance operator

$$\Delta(\cdot) = \bigoplus_1^N \Delta_i(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U)) \tag{73}$$

is measured by

$$\|\Delta(\cdot)\|_\infty = \sup_{t\geq 0} \max_{i\in\underline{N}} \|\Delta_i(t)\|_{\mathcal{L}(Y_i,U_i)}. \tag{74}$$

The effect of multiperturbations on mild evolution operators is most easily described by writing multiperturbations in the form of a single perturbation. For this let

$$D(t) = [D_1(t), \dots, D_N(t)] : U \to \overline{X}; \quad (u_i)_{i=1}^N \mapsto \sum_{i=1}^N D_i(t)u_i, \quad (u_i) \in U,\ t \in \mathbb{R}_+;$$

$$E(t) = \begin{bmatrix} E_1(t) \\ \vdots \\ E_N(t) \end{bmatrix} : \underline{X} \to Y; \quad x \mapsto \begin{bmatrix} E_1(t)x \\ \vdots \\ E_N(t)x \end{bmatrix}, \quad x \in \underline{X}, \quad t \in \mathbb{R}_+. \tag{75}$$

Then $D(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(U, \overline{X}))$, $E(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(\underline{X}, Y))$, and the perturbed equation (72) takes the same form as (3), namely

$$\dot{x}(t) = [A(t) + D(t)\Delta(t)E(t)]x(t), \qquad t \geq 0.$$

As a consequence we can apply all the concepts introduced in §2 to multiperturbations. An adequate definition of stability radius for multiperturbations is obtained by restricting the perturbations in (23) to be of the form (73).

DEFINITION 5.4. *Suppose Φ is exponentially stable, $D(\cdot), E(\cdot)$ are given by* (75) *and Hypotheses* 1–4 *hold. The* stability radius *of $\Phi(\cdot,\cdot)$ with respect to the perturbation structure $(D_i, E_i)_{i\in\underline{N}}$ is defined by*

$$r(\Phi; (D_i, E_i)) = \sup\{r \in \mathbb{R}_+; \forall \Delta_i(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y_i, U_i)) :$$
$$\left\| \bigoplus_1^N \Delta_i \right\|_\infty \leq r \Rightarrow \Delta = \bigoplus_1^N \Delta_i \text{ is admissible and } \Phi_\Delta(\cdot,\cdot) \text{ is exponentially stable}\}. \tag{76}$$

In (76) only perturbations $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U))$ are considered, which have the block structure $\Delta(\cdot) = \oplus_1^N \Delta_i(\cdot)$ given by the families of Banach spaces $(U_i)_{i\in\underline{N}}$, $(Y_i)_{i\in\underline{N}}$. But the norm $\|\Delta(\cdot)\|_\infty$ defined in (74) is just the L^∞-norm of $\Delta(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y,U))$, where $\mathcal{L}(Y,U)$ is provided with the operator norm corresponding to the norms $\|(u)\|_U$, $\|(y)\|_Y$ defined above. Hence the perturbation norms applied in Definitions 5.4 and 2.17 are the same so that we obtain

$$r(\Phi; (D_i, E_i)) \geq r(\Phi; D, E), \tag{77}$$

where D, E are defined by (75).

We now examine the following effect of rescaling the structure operators D_i, E_i, $i \in \underline{N}$:

$$D_i(t) \rightsquigarrow D_i^\alpha(t) = \alpha_i^{-1}(t) D_i(t) \quad \text{and} \quad E_i(t) \rightsquigarrow E_i^\alpha(t) = \alpha_i(t) E_i(t), \qquad i \in \underline{N}, \tag{78}$$

where $\alpha_i(t) \in PC(\mathbb{R}_+, \mathbb{C}^*)$, $i \in \underline{N}$. Interpreting D_i, E_i, $i \in \underline{N}$ as input and output operators, the transformations (78) represent scalar input and output transformations of the system. We set

$$D^\alpha(t) = [D_1(t)\alpha_1^{-1}(t), \ldots, D_N(t)\alpha_N^{-1}(t)], \qquad E^\alpha(t) = \begin{bmatrix} \alpha_1(t)E_1(t) \\ \vdots \\ \alpha_N(t)E_N(t) \end{bmatrix}, \qquad t \geq 0, \tag{79}$$

where

$$\alpha(\cdot) = (\alpha_1(\cdot), \ldots, \alpha_N(\cdot)) \in \mathcal{D}_N := PC(\mathbb{R}_+, \mathbb{C}^*)^N.$$

Because

$$D(t)\Delta(t)E(t) = \sum_1^N D_i(t)\Delta_i(t)E_i(t) = \sum_1^N D_i^\alpha(t)\Delta_i(t)E_i^\alpha(t) = D^\alpha(t)\Delta(t)E^\alpha(t),$$

(72) and (21) have the same solution if D, E are replaced by D^α, E^α. As a consequence we obtain

$$r(\Phi, (D_i, E_i)) = r(\Phi, (D_i^\alpha, E_i^\alpha)), \qquad \alpha(\cdot) \in \mathcal{D}_N. \tag{80}$$

Now suppose that $\theta \in C(\mathbb{R}_+, \mathbb{C}^*)$ is a Bohl transformation, $\alpha(\cdot) = (\alpha_1(\cdot), \ldots, \alpha_N(\cdot)) \in \mathcal{D}_N$, D^α, E^α are defined by (79), and Φ^θ is as in Proposition 5.3. We denote by $\mathbb{L}_s^{\alpha,\theta}$, $\mathbb{M}_s^{\alpha,\theta}$ the operators given by (25), (16) with (Φ, D, E) replaced by $(\Phi^\theta, D^\alpha, E^\alpha)$, assuming that these operators are well defined. For example,

$$\begin{aligned} \mathbb{L}_s^{\alpha,\theta} &= \big((\mathbb{L}_s^{\alpha,\theta})_{ij}\big)_{i,j\in\underline{N}}, \\ \big((\mathbb{L}_s^{\alpha,\theta})_{ij}u\big)(t) &= \alpha_i(t)E_i(t)\int_s^t \theta(t)^{-1}\Phi(t,\rho)\theta(\rho)D_j(\rho)\alpha_j^{-1}(\rho)u(\rho)d\rho, \\ & \qquad\qquad t \geq s, \qquad i,j \in \underline{N}. \end{aligned} \tag{81}$$

As a consequence of Theorems 3.2, 4.2, and (71), (80), (77) we have the following corollaries.

COROLLARY 5.5. *Let $\theta \in C(\mathbb{R}_+, \mathbb{C}^*)$ be a Bohl transformation, $\alpha(\cdot) = (\alpha_1(\cdot), \ldots, \alpha_N(\cdot)) \in \mathcal{D}_N$. If Hypotheses 1–8 hold for $(\Phi^\theta, D^\alpha, E^\alpha)$ and Φ is exponentially stable, then*

$$r(\Phi; (D_i, E_i)) \geq \|\mathbb{L}_0^{\alpha,\theta}\|^{-1}, \tag{82}$$

where $\mathbb{L}_0^{\alpha,\theta}$ *is defined by* (81) *and* Φ^θ *is as in Proposition* 5.3.

COROLLARY 5.6. *Let* $\theta \in C(\mathbb{R}_+, \mathbb{C}^*)$ *be a Bohl transformation,* $\alpha(\cdot) = (\alpha_1(\cdot), \dots, \alpha_N(\cdot)) \in \mathcal{D}_N$. *If Hypotheses* 1–10 *hold for* $(\Phi^\theta, D^\alpha, E^\alpha)$ *with* $\overline{X} = X$, Φ *is an exponentially stable weak evolution operator on* X *with generator* A, *and* $\|\Delta(\cdot)\|_\infty < \|\mathbb{L}_0^{\alpha,\theta}\|^{-1}$, *then the perturbed mild evolution operator* Φ_Δ *is an exponentially stable weak evolution operator on* X *with generator* A_Δ.

Corollary 5.5 tightens the lower bound in (27) for the single perturbation case. Indeed, it has been shown in [10] for the scalar case that the lower bound (27) may not equal the stability radius, whereas if $a(\cdot)$ has a strict Bohl exponent it is always possible to find a Bohl transformation that increases the lower bound (82) to the stability radius. In the time-invariant finite-dimensional multiperturbation case, it is known that if $N \leq 3$, equality holds in (82); however, this may not be so if $N > 3$.

Because in (81) the effect of θ can be subsumed into the α_i's by means of the transformation $\alpha_i \mapsto \alpha_i\theta^{-1}$, $i \in \underline{N}$, it would seem that there is no loss in generality in setting $\theta(t) \equiv 1$, $t \geq 0$. But this is not the case because the transformation $\alpha_i \mapsto \alpha_i\theta^{-1}$ changes Hypotheses 5–7. For example, Hypothesis 5 for the operator $\mathbb{M}_s^{\alpha,\theta}$ is not equivalent to Hypothesis 5 for the operator $\mathbb{M}_s^{\alpha\theta^{-1},1}$. Indeed the scaling of the evolution operator Φ and the structure operators (D_i, E_i) does not only open up the possibility of tightening the lower bound in (27), but may also extend the applicability of Theorem 3.2 and Theorem 4.2. This is because if Hypotheses 1–10 do not hold for the original data, it may be their validity can be enforced by scaling (see Example 6.1). On the other hand, supposing that Hypotheses 1–10 are satisfied for (Φ, D, E), then they will also be satisfied for $(\Phi^\theta, D^\alpha, E^\alpha)$, if the scaling functions $\alpha_i(\cdot), \alpha_i(\cdot)^{-1}, \theta(\cdot), \theta(\cdot)^{-1}$ are all bounded on $\mathbb{R}_+$.

6. Examples. In this final section we consider three examples. The first one is time-varying and illustrates that scaling transformations can be used to extend the applicability of the results as well as (possibly) improving the lower bound.

Example 6.1. Consider the time-varying system

$$\dot{x}(t) = -tAx(t), \qquad t \geq 0, \tag{83}$$

where A is a bounded linear operator on a Hilbert space H. We assume that $-A$ is exponentially stable, that is, there exist constants $M, \omega_0 > 0$ such that $\|e^{-At}\| \leq Me^{-\omega_0 t}$, $t \geq 0$. The linear operators $A(t) = -tA \in \mathcal{L}(H)$ are bounded for each $t \geq 0$, but their norm $\|A(t)\|$ is unbounded in time. The strong evolution operator generated by $A(\cdot)$,

$$\Phi(t, s) = e^{-A(t^2-s^2)/2}, \qquad t \geq s \geq 0,$$

satisfies $\|\Phi(t, s)\| \leq Me^{-\omega_0(t^2-s^2)/2}$, $t \geq s \geq 0$.

We assume that (83) is a nominal model that is subjected to perturbations of the form $A(t) \rightsquigarrow A_\Delta(t) = -t(A + \Delta)$, where $\Delta \in \mathcal{L}(H)$. This can be catered for by the perturbed system (72) in a number of different ways, for example, setting $\underline{X} = X = \overline{X} = U = Y = H$ and

(i) $D(t) = t^{1/2}I$, $E(t) = t^{1/2}I$ or (ii) $D(t) = I$, $E(t) = tI$.

Clearly, Hypotheses 1–4 are satisfied for both of the above perturbation structures. Now in case (i),

$$\begin{aligned} \|E(\cdot)\Phi(\cdot, s)x\|_{L^2}^2 &= \int_s^\infty \rho\|e^{-A(\rho^2-s^2)/2}x\|_H^2 \, d\rho \\ &\leq M^2 \int_s^\infty \rho e^{-\omega_0(\rho^2-s^2)} \, d\rho \|x\|_H^2 = \frac{M^2\|x\|_H^2}{(2\omega_0)} \end{aligned} \tag{84}$$

and hence Hypothesis 7 holds with $p = 2$. For the second case,

$$\begin{aligned}\|E(\cdot)\Phi(\cdot,s)x\|_{L^2}^2 &= \int_s^\infty \rho^2 \|e^{-A(\rho^2-s^2)/2}x\|_H^2 \, d\rho \\ &\geq s\int_s^\infty \rho \|e^{-A(\rho^2-s^2)/2}x\|_H^2 \, d\rho = \frac{s}{2}\int_0^\infty \|e^{-A\sigma}x\|_H^2 \, d\sigma.\end{aligned} \tag{85}$$

So it is not possible to find a constant k such that Hypothesis 7 holds with $p = 2$. However, note that the scaling factor $\alpha(t) = t^{-1/2}$, $t > 0$ transforms the second structure into the first. This demonstrates the point made after Corollary 5.5—scaling can extend the applicability of Theorem 3.2. Another possibility would be to take $p = 1$. An easy calculation shows that Hypothesis 7 holds for $p = 1$ in case (ii). We do not pursue this but continue our development for the first case with $p = 2$. The associated input–output operator is given by

$$(\mathbb{L}_0 u)(t) = t^{1/2}\int_0^t e^{-A(t^2-s^2)/2} s^{1/2} u(s) ds. \tag{86}$$

It is easy to see that Hypothesis 5 is satisfied. To get a good estimate for $\|\mathbb{L}_0\|^{-1}$, we may use the Riccati equation (40) as described in Remark 3.4(iii). A short calculation yields $\|\mathbb{L}_0\| \leq \max_{\omega\in\mathbb{R}} \|(i\omega I + A)^{-1}\|$. Hence (83) will be exponentially stable if

$$\|\Delta\|_{\mathcal{L}(H)} < [\max_{\omega\in\mathbb{R}} \|(i\omega I + A)^{-1}\|]^{-1}.$$

Because $\dot{x}(t) = -t(A+\Delta)x(t)$ is exponentially stable if and only if the time-invariant system $\dot{x}(t) == -(A + \Delta)x(t)$ is exponentially stable, it follows easily that $[\max_{\omega\in\mathbb{R}} \|(i\omega I + A)^{-1}\|]^{-1}$ is in fact the stability radius of (83) with respect to time-varying perturbations with the structure $(t^{1/2}I, t^{1/2}I)$.

In concrete applications the general results contained in Example 4.10 can be sharpened. This is illustrated by the following example.

Example 6.2. Consider a thermal process modeled by an equation of the form

$$\begin{aligned}&\frac{\partial T}{\partial t}(\xi,t) = \sum_{i=1}^3 \frac{\partial}{\partial \xi_i}\left[k(\xi)\frac{\partial T}{\partial \xi_i}(\xi,t)\right], \qquad \xi \in \Omega,\ t \geq 0, \\ &T(\xi,t) = 0, \quad \xi \in \partial\Omega, \quad t \geq 0, \quad T(\xi,0) = T_0(\xi), \quad \xi \in \Omega, \quad T_0(\cdot) \in L^2(\Omega),\end{aligned} \tag{87}$$

where $\emptyset \neq \Omega \subset \mathbb{R}^3$ is a bounded connected open set with smooth boundary $\partial\Omega$. $T(\xi,t)$ is the temperature at point $\xi \in \Omega$ and time t, $k(\xi)$ is the conductivity. Lions [18] has developed a general existence theory for partial differential equations of the type given by (87). A bilinear form on the Hilbert space $V = H_0^1(\Omega)$ is associated with (87) and if $k(\cdot) \in L^\infty(\Omega)$, $k(\xi) \geq \underline{k} > 0$ almost everywhere, the form is used to obtain an operator $A \in \mathcal{L}(V, V^*)$, where $V^* = H^{-1}(\Omega)$. The operator A with domain $D(A) = H^2(\Omega) \cap H_0^1(\Omega)$ generates a strongly continuous semigroup $S(t)$ on $L^2(\Omega)$ and for sufficiently smooth initial data $T_0(\cdot)$, $T(\cdot,t) = S(t)T_0$ is a classical solution of (87). We will use Lions' framework throughout this example without further reference.

Now suppose that the conductivity $k(\xi)$ is uncertain with nominal value k_0 (a space-independent positive constant). The nominal system can be written in the form $\dot{x}(t) = k_0 A_0 x(t)$, $t \geq 0$, where $A_0 = \nabla^2$ (the Laplacian with zero boundary condition). For simplicity, we assume that on $X = L^2(\Omega)$, ∇^2 with zero Dirichlet boundary conditions has simple eigenvalues $-\lambda_1 > -\lambda_2 > \cdots$ with $\lambda_1 > 0$ and $\Psi_n \in H^2(\Omega) \cap H_0^1(\Omega)$, $n \in \mathbb{N}$ is an

orthonormal basis of eigenfunctions satisfying $\nabla^2\Psi_n = -\lambda_n\Psi_n$ in Ω. Then

$$A_0x = -\sum_{n=1}^{\infty}\lambda_n\Psi_n\langle\Psi_n, x\rangle,$$

$$D(A_0) = \left\{x \in L^2(\Omega); \sum_{n=1}^{\infty}\lambda_n^2\langle\Psi_n, x\rangle^2 < \infty\right\} = H^2(\Omega)\cap H_0^1(\Omega).$$

k_0A_0 generates an analytic semigroup $S_0(t)$ on $L^2(\Omega)$ where

$$S_0(t)x = \sum_{n=1}^{\infty}e^{-k_0\lambda_n t}\Psi_n\langle\Psi_n, x\rangle,$$

and hence

$$\|S_0(t)\| \le e^{-k_0\lambda_1 t}, \qquad t \ge 0.$$

The perturbations of the nominal system take the form

$$(B_kT)(\xi) = \sum_{i=1}^{3}\frac{\partial}{\partial\xi_i}\left[(k(\xi) - k_0)\frac{\partial T}{\partial\xi_i}(\xi)\right], \qquad \xi \in H^2(\Omega)\cap H_0^1(\Omega). \tag{88}$$

However, this specific perturbation structure cannot be catered for by our model (4). We have to consider a more general structure. A natural one is $D(t) = A_0^{1/2}$, $E(t) = A_0^{1/2}$, $Y = U = L^2(\Omega)$,

$$A_0^{1/2}x = \sum_{n=1}^{\infty}\lambda_n^{1/2}\Psi_n\langle\Psi_n, x\rangle,$$

$$\underline{X} = V = \left\{x \in L^2(\Omega); \sum_{n=1}^{\infty}\lambda_n\langle\Psi_n, x\rangle^2 < \infty\right\} = H_0^1(\Omega),$$

$$\overline{X} = V^* = \left\{x \in L^2(\Omega); \sum_{n=1}^{\infty}\lambda_n^{-1}\langle\Psi_n, x\rangle^2 < \infty\right\} = H^{-1}(\Omega).$$

Note that this structure corresponds, in the context of Example 4.10, to the case $\alpha(D) = \frac{1}{2}$, $\beta(E) = \frac{1}{2}$, which is not (quite) allowed in the result that establishes conditions $\alpha(D) < \frac{1}{2}$, $\beta(E) < \frac{1}{2}$ for the applicability of Theorem 3.5. Nevertheless, we see that the assumptions of this theorem are satisfied. Clearly, (a) holds. If $x \in L^2(\Omega)$, $x = \sum_{n=1}^{\infty}x_n\Psi_n$, $\|x\|_{L^2(\Omega)} = 1$,

$$\|ES_0(\cdot)x\|^2_{L^2(0,\infty;L^2(\Omega))} = \int_0^{\infty}\left\|\sum_{n=1}^{\infty}\lambda_n^{1/2}e^{-k_0\lambda_n t}x_n\Psi_n\right\|^2_{L^2(\Omega)}dt,$$

$$= \int_0^{\infty}\sum_{n=1}^{\infty}\lambda_n e^{-2k_0\lambda_n t}x_n^2\,dt = \frac{1}{2k_0}\sum_{n=1}^{\infty}x_n^2 = \frac{1}{2k_0}.$$

For $u(\cdot) \in L^2(0,\infty;L^2(\Omega))$, $\|u(\cdot)\|_{L^2} = 1$, let $u(t) = \sum_{n=1}^{\infty}u_n(t)\Psi_n$. Then

$$\left\|\int_0^t S_0(t-\rho)Du(\rho)d\rho\right\|^2_{L^2(\Omega)} = \sum_{n=1}^{\infty}\left(\int_0^t\lambda_n^{1/2}e^{-k_0\lambda_n(t-\rho)}u_n(\rho)d\rho\right)^2$$

$$\le \frac{1}{2k_0}\sum_{n=1}^{\infty}(1 - e^{-2k_0\lambda_n t})\int_0^t u_n^2(\rho)d\rho \le \frac{1}{2k_0}.$$

Also

$$\left\| \int_0^{\cdot} S_0(\cdot - \rho) Du(\rho) d\rho \right\|^2_{L^2(0,\infty;V)} = \sum_{n=1}^{\infty} \lambda_n^2 \int_0^{\infty} \left(\int_0^t e^{-k_0 \lambda_n (t-\rho)} u_n(\rho) d\rho \right)^2 dt.$$

But by a well-known convolution inequality [6],

$$\int_0^{\infty} \left(\int_0^t e^{-k_0 \lambda_n (t-\rho)} u_n(\rho) d\rho \right)^2 dt \le \frac{1}{k_0^2 \lambda_n^2} \int_0^{\infty} u_n^2(\rho) d\rho.$$

Hence,

$$\|\mathbb{L}_0 u(\cdot)\|^2_{L^2(0,\infty;L^2(\Omega))} = \|(\mathbb{M}_0 u)(\cdot)\|^2_{L^2(0,\infty;V)} \le \frac{1}{k_0^2} \sum_{n=1}^{\infty} \int_0^{\infty} u_n^2(\rho) d\rho = \frac{1}{k_0^2}.$$

The above estimates prove that (b)–(d) of Theorem 3.5 hold with $p = 2$ and $\|\mathbb{L}_0\| \le k_0^{-1}$. We are therefore able to conclude that $r(S_0(\cdot), D, E) \ge k_0$. For the time-invariant case we have proved that if $\Delta \in \mathcal{L}(L^2(\Omega))$, $\|\Delta\| < k_0$, then the perturbed semigroup $S_\Delta(\cdot)$ is exponentially stable. This is quite a strong result because for arbitrary $B \in \mathcal{L}(V, V^*)$, it is possible to find a $\Delta \in \mathcal{L}(L^2(\Omega))$ such that $B = A_0^{1/2} \Delta A_0^{1/2}$. Moreover, the result compares well with others in the literature. For example, in [19] it was shown that if A generates a contraction semigroup on a reflexive Banach space X, B is accretive, $D(B) \subset D(A)$ and for some $a \ge 0$,

$$\|Bx\|_X \le a\|x\|_X + \|Ax\|_X, \qquad x \in D(A). \tag{89}$$

Then the closure of $A - B$ generates a contraction semigroup. Equation (89) is slightly weaker than our requirement that $\|\Delta\| < k_0$. However, we do not assume that the perturbation is accretive, and our conclusion is different in that $S_\Delta(\cdot)$ is not necessarily a contraction semigroup but it is exponentially stable. Also our result is valid for time-varying $\Delta(\cdot)$.

It is easy to see that the operator in (88) satisfies $B_k \in \mathcal{L}(V, V^*)$ and $\|B_k\|_{\mathcal{L}(V,V^*)} \le \|k(\cdot) - k_0\|_{L^\infty(\Omega)}$. So the mild solution of (87) will be exponentially stable if we have $\|k(\cdot) - k_0\|_{L^\infty(\Omega)} < k_0$. This estimate is tight because if $k(\cdot) \equiv 0$, (87) is not exponentially stable. Hence, $r(S_0(\cdot), D, E) = r^c(S_0(\cdot), D, E) = \|\mathbb{L}_0\|^{-1} = k_0$. Note that the first two equalities could have been inferred directly from Theorem 3.5 because assumption (e) is also satisfied.

In the above examples we carefully matched the unboundedness in the structure operators with the unboundedness in $A(\cdot)$. Robust stability cannot be expected for structured perturbations whose unboundedness surpasses that of the nominal system generator. For example, it would not be sensible to introduce structure operators $D(t)$, $E(t)$ in Example 6.1, which are unbounded operators on H. Similarly, we should not introduce operators $D(t) \in \mathcal{L}(U, \overline{X})$, $E(t) \in \mathcal{L}(\underline{X}, Y)$ in Example 6.2, which are unbounded in time.

We conclude with an example of an interconnected system with uncertain couplings illustrating the effect of scaling in a multiperturbation problem.

Example 6.3. Suppose that we have two control systems both of which are uncertain, where the uncertainty can be modeled by a single perturbation structure. We write them formally as

$$\begin{aligned} \dot{x}_i(t) &= A_i(t)x_i(t) + D_i(t)\Delta_i(t)E_i(t)x_i(t) + B_i v_i(t), \qquad t \ge 0,\ i = 1, 2, \\ z_i(t) &= C_i(t)x_i(t), \end{aligned}$$

where $v_i(\cdot)$, $z_i(\cdot)$, $i = 1, 2$ represent the inputs and outputs. Now let us assume that the two systems are coupled via uncertain couplings $v_1(t) = K_1(t)z_2(t)$, $v_2(t) = K_2(t)z_1(t)$ so that the overall system takes the form

$$\text{(90)} \quad \begin{bmatrix} \dot{x}_1(t) \\ \dot{x}_2(t) \end{bmatrix} = \begin{bmatrix} A_1(t) + D_1(t)\Delta_1(t)E_1(t) & B_1(t)K_1(t)C_2(t) \\ B_2(t)K_2(t)C_1(t) & A_2(t) + D_2(t)\Delta_2(t)E_2(t) \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix}.$$

Or

$$\text{(91)} \quad \dot{x}(t) = A(t)x(t) + D(t)\Delta(t)E(t)x(t), \qquad t \geq 0,$$

where

$$x(t) = \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix}, \quad A(t) = \begin{bmatrix} A_1(t) & 0 \\ 0 & A_2(t) \end{bmatrix},$$

$$D(t) = \begin{bmatrix} D_1(t) & B_1(t) & 0 & 0 \\ 0 & 0 & B_2(t) & D_2(t) \end{bmatrix}, \quad E(t) = \begin{bmatrix} E_1(t) & 0 \\ 0 & C_2(t) \\ C_1(t) & 0 \\ 0 & E_2(t) \end{bmatrix},$$

$$\Delta(t) = \begin{bmatrix} \Delta_1(t) & 0 & 0 & 0 \\ 0 & K_1(t) & 0 & 0 \\ 0 & 0 & K_2(t) & 0 \\ 0 & 0 & 0 & \Delta_2(t) \end{bmatrix}.$$

The nominal models are assumed to be given by exponentially stable mild evolution operators $\Phi_i(\cdot, \cdot)$ on Banach spaces X_i, $i = 1, 2$. $D_i(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(U_i, \overline{X}_i))$, $E_i(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(\underline{X}_i, Y_i))$, $B_i(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(V_i, \overline{X}_i))$, $C_i(\cdot) \in PC(\mathbb{R}_+, \mathcal{L}(\underline{X}_i, Z_i))$, $\Delta_i(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Y_i, U_i))$, $i = 1, 2$, $K_1(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Z_2, V_1))$, $K_2(\cdot) \in PC_b(\mathbb{R}_+, \mathcal{L}(Z_1, V_2))$, where $\underline{X}_i$, $\overline{X}_i$, Y_i, U_i, V_i, Z_i, $i = 1, 2$ are Banach spaces satisfying $\underline{X}_i \subset X_i \subset \overline{X}_i$, with continuous dense injections.

The problem is to obtain joint bounds on each of the unknowns $\Delta_i(\cdot)$, $K_i(\cdot)$, $i = 1, 2$, which guarantee the overall coupled uncertain system is exponentially stable. The mild perturbed system associated with (91) is described by the equation

$$x(t) = \Phi(t, s)x + \int_s^t \Phi(t, \rho)D(\rho)\Delta(\rho)E(\rho)x(\rho)d\rho, \qquad t \geq s \geq 0,$$

where

$$\Phi(t, s) = \begin{bmatrix} \Phi_1(t, s) & 0 \\ 0 & \Phi_2(t, s) \end{bmatrix}, \qquad t \geq s \geq 0.$$

Suppose that $(\Phi(\cdot, \cdot), D(\cdot), E(\cdot))$ satisfy Hypotheses 1–8 for $p = 2$, then $r(\Phi, D, E) \geq \|\mathbb{L}_0\|^{-1}$, and we seek an estimate for this lower bound. Now

$$(\mathbb{L}_0 u)(t) = \begin{bmatrix} (L_{11}u_1)(t) & (L_{12}v_1)(t) & 0 & 0 \\ 0 & 0 & (L_{23}v_2)(t) & (L_{24}u_2)(t) \\ (L_{31}u_1)(t) & (L_{32}v_1)(t) & 0 & 0 \\ 0 & 0 & (L_{43}v_2)(t) & (L_{44}u_2)(t) \end{bmatrix},$$

where $u(t) = [u_1(t),\, v_1(t),\, v_2(t),\, u_2(t)]^\top$, $u_i(\cdot) \in L^2(0,\infty;U_i)$, $v_i(\cdot) \in L^2(0,\infty;V_i)$, $i = 1,2$, and

(92)

$$(L_{11}u_1)(t) = E_1(t)\int_0^t \Phi_1(t,\rho)D_1(\rho)u_1(\rho)d\rho, (L_{12}v_1)(t) = E_1(t)\int_0^t \Phi_1(t,\rho)B_1(\rho)v_1(\rho)d\rho,$$

$$(L_{23}v_2)(t) = C_2(t)\int_0^t \Phi_2(t,\rho)B_2(\rho)v_2(\rho)d\rho, (L_{24}u_2)(t) = C_2(t)\int_0^t \Phi_2(t,\rho)D_2(\rho)u_2(\rho)d\rho,$$

$$(L_{31}u_1)(t) = C_1(t)\int_0^t \Phi_1(t,\rho)D_1(\rho)u_1(\rho)d\rho, (L_{32}v_1)(t) = C_1(t)\int_0^t \Phi_1(t,\rho)B_1(\rho)v_1(\rho)d\rho,$$

$$(L_{43}v_2)(t) = E_2(t)\int_0^t \Phi_2(t,\rho)B_2(\rho)v_2(\rho)d\rho, (L_{44}u_2)(t) = E_2(t)\int_0^t \Phi_2(t,\rho)D_2(\rho)u_2(\rho)d\rho.$$

Hence

$$\|\mathbb{L}_0\| = \max\{\|{}^1\mathbb{L}_0\|, \|{}^2\mathbb{L}_0\|\} \quad \text{with } {}^1\mathbb{L}_0 = \begin{bmatrix} L_{11} & L_{12} \\ L_{31} & L_{32} \end{bmatrix}, \quad {}^2\mathbb{L}_0 = \begin{bmatrix} L_{23} & L_{24} \\ L_{43} & L_{44} \end{bmatrix}. \tag{93}$$

Introducing time-invariant positive scaling $\alpha_1, \ldots, \alpha_4$, we have

$$\|\mathbb{L}_0^\alpha\| = \max\{\|{}^1\mathbb{L}_0^\alpha\|, \|{}^2\mathbb{L}_0^\alpha\|\}, \tag{94}$$

where

$${}^1\mathbb{L}_0^\alpha = \begin{bmatrix} L_{11} & \frac{\alpha_1}{\alpha_2}L_{12} \\ \frac{\alpha_3}{\alpha_1}L_{31} & \frac{\alpha_3}{\alpha_2}L_{32} \end{bmatrix}, \qquad {}^2\mathbb{L}_0^\alpha = \begin{bmatrix} \frac{\alpha_2}{\alpha_3}L_{23} & \frac{\alpha_2}{\alpha_4}L_{24} \\ \frac{\alpha_4}{\alpha_3}L_{43} & L_{44} \end{bmatrix}.$$

Suppose l_{ij} are upper bounds for $\|\mathbb{L}_{ij}\|$, which we assume are non-zero $(i,j = 1,2)$, then

$$\|{}^1\mathbb{L}_0^\alpha\| \le \left\| \begin{bmatrix} l_{11} & \frac{\alpha_1}{\alpha_2}l_{12} \\ \frac{\alpha_3}{\alpha_1}l_{31} & \frac{\alpha_3}{\alpha_2}l_{32} \end{bmatrix} \right\|, \qquad \|{}^2\mathbb{L}_0^\alpha\| \le \left\| \begin{bmatrix} \frac{\alpha_2}{\alpha_3}l_{23} & \frac{\alpha_2}{\alpha_4}l_{24} \\ \frac{\alpha_4}{\alpha_3}l_{43} & l_{44} \end{bmatrix} \right\|. \tag{95}$$

LEMMA 6.4. *Given* $\beta_i > 0$, $i \in \underline{4}$, *then*

$$\left\| \begin{bmatrix} \beta_1 & \sqrt{\beta_2\beta_3} \\ \sqrt{\beta_2\beta_3} & \beta_4 \end{bmatrix} \right\| \le \left\| \begin{bmatrix} \beta_1 & \gamma\beta_2 \\ \beta_3/\gamma & \beta_4 \end{bmatrix} \right\| \quad \textit{for all } \gamma > 0. \tag{96}$$

Proof. The two matrices in (96) have the same eigenvalues. Because the matrix on the LHS is symmetric, its norm is equal to the spectral radius, whereas the norm of the matrix on the RHS is not less than this spectral radius. □

Setting $\alpha_3/\alpha_2 = \rho$ and choosing α_1, α_4 to optimise the estimates in (95), we see

$$\|{}^1\mathbb{L}_0^\alpha\| \le \left\| \begin{bmatrix} l_{11} & \sqrt{\rho l_{12}l_{31}} \\ \sqrt{\rho l_{12}l_{31}} & \rho l_{32} \end{bmatrix} \right\|, \qquad \|{}^2\mathbb{L}_0^\alpha\| \le \left\| \begin{bmatrix} l_{23}/\rho & \sqrt{l_{24}l_{43}/\rho} \\ \sqrt{l_{24}l_{43}/\rho} & l_{44} \end{bmatrix} \right\|. \tag{97}$$

PROPOSITION 6.5. *With the notations introduced above,* $\|\mathbb{L}_0^\alpha\| \leq \lambda_m$, *where* λ_m *is the spectral radius of the nonnegative matrix*

$$L = \begin{bmatrix} l_{11} & l_{12} & 0 & 0 \\ 0 & 0 & l_{23} & l_{24} \\ l_{31} & l_{32} & 0 & 0 \\ 0 & 0 & l_{43} & l_{44} \end{bmatrix}.$$

Proof. By the Frobenius theorem, λ_m is an eigenvalue of L; hence it satisfies the associated characteristic equation. A simple calculation yields

$$(\lambda_m^2 - l_{44}\lambda_m)(\lambda_m^2 - l_{11}\lambda_m) + (l_{23}l_{44} - l_{24}l_{43} - l_{23}\lambda_m)(l_{12}l_{31} - l_{11}l_{32} + l_{32}\lambda_m) = 0. \tag{98}$$

From (97) $\|\mathbb{L}_0^\alpha\| \leq \max\{\mu_1(\rho), \mu_2(\rho)\}$, where $\mu_1(\rho), \mu_2(\rho)$ are the maximum solutions of

$$\lambda^2 - (l_{11} + \rho l_{32})\lambda + \rho(l_{11}l_{32} - l_{12}l_{31}) = 0, \tag{99}$$

$$\lambda^2 - (l_{44} + l_{23}/\rho)\lambda + (l_{23}l_{44} - l_{24}l_{43})/\rho = 0, \tag{100}$$

respectively. It is not difficult to show that the continuous function $\mu_1(\cdot)$ is strictly increasing from l_{11} to ∞, whilst $\mu_2(\cdot)$ is strictly decreasing from ∞ to l_{44} as ρ varies from 0 to ∞. Hence there is a unique $\hat{\rho} \in (0, \infty)$ for which $\mu_1(\hat{\rho}) = \mu_2(\hat{\rho})$ and by (94), (97), $\|\mathbb{L}_0^\alpha\| \leq \mu_2(\hat{\rho})$. All that remains to be proved is $\mu_2(\hat{\rho}) = \lambda_m$. Now $\mu_2(\hat{\rho}) > l_{44}$ and $l_{23}\mu_2(\hat{\rho}) - l_{23}l_{44} + l_{24}l_{43} > 0$. Hence from (100),

$$\hat{\rho} = \frac{l_{23}\mu_2(\hat{\rho}) - l_{23}l_{44} + l_{24}l_{43}}{(\mu_2(\hat{\rho}))^2 - l_{44}\mu_2(\hat{\rho})},$$

and substituting in (99) we see that $\mu_2(\hat{\rho})$ satisfies (98). Suppose there exists a root $\tilde{\lambda}$ of (98) with $\tilde{\lambda} > \mu_2(\hat{\rho})$, then $\tilde{\lambda} > l_{44}$ and $l_{23}\tilde{\lambda} - l_{23}l_{44} + l_{24}l_{43} > 0$. Let

$$\rho = \frac{l_{23}\tilde{\lambda} - l_{23}l_{44} + l_{24}l_{43}}{\tilde{\lambda}^2 - l_{44}\tilde{\lambda}},$$

then by (98), $\tilde{\lambda}^2 - l_{11}\tilde{\lambda} - \rho(l_{11}l_{31} - l_{11}l_{32} + l_{32}\tilde{\lambda}) = 0$. Hence the pair $(\tilde{\lambda}, \rho)$ satisfies (99), (100), which is a contradiction. This completes the proof. □

Summarizing the above results we have the following.

PROPOSITION 6.6. *Suppose* $(\Phi(\cdot), D, E)$ *satisfies Hypotheses* 1–8 *and* λ_m *is the spectral radius of the matrix*

$$M_L = \begin{bmatrix} \|L_{11}\| & \|L_{12}\| & 0 & 0 \\ 0 & 0 & \|L_{23}\| & \|L_{24}\| \\ \|L_{31}\| & \|L_{32}\| & 0 & 0 \\ 0 & 0 & \|L_{43}\| & \|L_{44}\| \end{bmatrix},$$

where the operators L_{ij} *are defined by* (92). *If*

$$\|\Delta_i(\cdot)\|_\infty, \|K_i(\cdot)\|_\infty < \lambda_m^{-1}, \qquad i = 1, 2,$$

then the uncertain coupled system (90) *is exponentially stable. Moreover, the same conclusion holds if* λ_m *is the spectral radius of the matrix* M_l, *where the norms of the* L *operators are replaced by upper estimates.*

As an application of this result, let us assume that the two basic models and uncertainty structures are those considered in Examples 6.1 and 6.2. To illustrate the proposition rather than the (difficult) estimation of the norm of various operators, we assume that $B_1(t) = C_1(t) = D_1(t) = E_1(t) = t^{1/2}I$ and $B_2(t) = C_2(t) = D_2(t) = E_2(t) = A_0^{1/2}$, and $A_1(t) = tA$, $A_2(t) = A_0$, where A_1A_0 are as in Examples 6.1 and 6.2. Then each of the norms $\|L_{11}\|$, $\|L_{12}\|$, $\|L_{31}\|$, $\|L_{32}\|$ is bounded by $[\max_{\omega\in\mathbb{R}} \|(i\omega I + A)^{-1}\|]^{-1} =: \sigma$ and each of the norms $\|L_{23}\|$, $\|L_{24}\|$, $\|L_{43}\|$, $\|L_{44}\|$ is bounded by k_0^{-1}. So the matrix M_l is

$$M_l = \begin{bmatrix} \sigma & \sigma & 0 & 0 \\ 0 & 0 & k_0^{-1} & k_0^{-1} \\ \sigma & \sigma & 0 & 0 \\ 0 & 0 & k_0^{-1} & k_0^{-1} \end{bmatrix}$$

and the maximum eigenvalue is $k_0^{-1} + \sigma$. Note that the estimate (93) obtained without scaling gives $\|\mathbb{L}_0\| \le 2\max\{k_0^{-1}; \sigma\}$, which is inferior to $k_0^{-1} + \sigma$ for all $\sigma \ne k_0^{-1}$. In this very special case the perturbation can be written in the form

$$\begin{bmatrix} t^{1/2}I & 0 \\ 0 & A_0^{1/2} \end{bmatrix} \begin{bmatrix} \Delta_1 & K_1 \\ K_2 & \Delta_2 \end{bmatrix} \begin{bmatrix} t^{1/2}I & 0 \\ 0 & A_0^{1/2} \end{bmatrix}.$$

Applying Theorem 3.2 to this single perturbation structure, we see that the perturbed system is exponentially stable if

$$\left\| \begin{matrix} \Delta_1 & K_1 \\ K_2 & \Delta_2 \end{matrix} \right\| < \min\{k_0; 1/\sigma\}.$$

In the particular case that $H = L^2(\Omega)$ and $\Delta_1 = \Delta_2 = K_1 = K_2 = \delta I$, the above estimate requires $\delta < \min\{k_0/2;\ 1/(2\sigma)\}$, which is again inferior to the estimate $\delta < 1/(k_0^{-1} + \sigma)$ obtained from Proposition 6.6.

Acknowledgment. We thank the anonymous referee whose detailed comments helped us to improve the organization and content of the paper.

SOLUTION DIFFERENTIABILITY FOR NONLINEAR PARAMETRIC CONTROL PROBLEMS*

HELMUT MAURER† AND HANS JOSEF PESCH‡

Abstract. Perturbed nonlinear control problems with data depending on a vector parameter are considered. Using second-order sufficient optimality conditions, it is shown that the optimal solution and the adjoint multipliers are differentiable functions of the parameter. The proof exploits the close connections between solutions of a Riccati differential equation and shooting methods for solving the associated boundary value problem. Solution differentiability provides a firm theoretical basis for numerical feedback schemes that have been developed for computing neighbouring extremals. The results are illustrated by an example that admits two extremal solutions. Second-order sufficient conditions single out one optimal solution for which a sensitivity analysis is carried out.

Key words. parametric control problems, second-order sufficient conditions, solution differentiability, shooting methods, feedback controls

AMS subject classifications. 49K15, 49K40

1. Introduction.

This paper is concerned with parametric nonlinear control problems where all data depend on a vector parameter $p \in \mathbb{R}^k$. To make the main ideas more transparent, we restrict the discussion to the following basic control problem:

$$\text{(P(p))} \qquad \begin{aligned} &\text{Minimize} && J(x,u,p) = \int_a^b L(t,x,u,p)dt \\ &\text{subject to} && \dot{x} = f(t,x,u,p), \qquad a \le t \le b, \\ & && x(a) = \varphi(p), \qquad x(b) = \psi(p). \end{aligned}$$

Problem (P(p_0)) corresponding to a fixed parameter $p_0 \in \mathbb{R}^k$ is considered the *unperturbed* problem. It is assumed that a local minimum (optimal solution) x_0, u_0 exists for (P(p_0)). An important problem in sensitivity analysis is the following: Find conditions for the unperturbed optimal solution x_0, u_0 such that the perturbed problem (P(p)) admits an optimal solution $x(p)$, $u(p)$ near x_0, u_0 that is a differentiable function of the parameter p near p_0. Comparing sensitivity approaches in optimization and optimal control it is apparent that *second-order sufficient optimality conditions* (SSCs) are a crucial assumption for this type of sensitivity result. Let us briefly review some papers in this regard.

A survey of basic results on stability and sensitivity for *finite-dimensional* optimization problems can be found in Fiacco [15]. A direct generalization of the second-order sensitivity result to equality constrained *optimization problems in Hilbert spaces* is given in Wierzbicki and Kurcyusz [46, Thm. 8.6]. For *Hilbert-space* optimization problems with general cone constraints, Alt [1]–[3] and Malanowski [24]–[28] have shown that the optimal solution is directionally differentiable with respect to the parameter. These results have recently been extended by Colonius and Kunisch [10]. The setting in Hilbert spaces allows for applications to *convex* control problems. A direct treatment of convex control problems with control appearing linearly has been performed earlier by Dontchev [13] and Malanowski [24]–[26].

There is a second stream of papers dealing with the second-order sensitivity analysis for *nonlinear* control problems. These papers are mainly concerned with developing neighbouring feedback schemes for perturbed solutions. Here the main ideas go back as far as the ingenious papers of Breakwell and Ho [6], Breakwell et al. [7], and Kelley [17], [18]. This approach is

summarized in Bryson and Ho [8]. Similar ideas may be found in [11], [14], [22], [23], [36], [47]. Extensions to control problems with inequality constraints are treated in Bock [4], Bock and Krämer-Eis [5], Dillon and Tun [12], Krämer-Eis [19]. Kugelmann and Pesch [20], [21], and Pesch [37]–[41]. All these papers suffer from the fact that the theory developed therein is rather formal and nonrigorous. The work of these authors supports the fact that theory lags behind numerical implementation.

We may conclude that a second-order sensitivity result for *nonlinear* control problems is still lacking. It is the main purpose of this paper to provide such a result using SSCs. SSCs depend on the existence of a finite solution of a *Riccati* differential equation that is associated with the variational system for the underlying boundary value problem. In addition to SSCs, we require that the iteration matrix of the shooting method is nonsingular. The nonsingularity of this matrix allows for an application of the implicit function theorem that yields a family of neighbouring extremals. The implicit function theorem has been used by many authors to establish the existence of a family of extremals; cf. [4], [5], [19], [31], [37]–[41]. However, the proof of optimality remains incomplete unless one superimposes sufficient conditions.

Up to now, the two streams of papers described above have flown separately. We hope that the ideas of this paper provide some help for merging these two streams into one that carries theoretical and numerical methods as close partners. This paper is a slightly shortened version of the report [34]. After completing this report we became aware that Malanowski [29], [30] obtained results on directional differentiability of solutions to nonlinear parametric optimization and control problems. Malanowski develops a fully infinite-dimensional implicit function theorem based on the two-norm approach. Our approach uses more elementary methods and tries to interweave theory and numerical techniques.

2. Second-order sufficient conditions and shooting methods. We begin with the *unperturbed* problem (P(p_0)) and suppress the parameter p_0 in this section. We summarize the second-order sufficient conditions (SSCs) derived in [16], [32], [35], [44], [48]–[50] and establish the close connections between SSCs and shooting methods for solving the associated boundary value problem (BVP).

Let the following data be given: a fixed interval $[a, b] \subset \mathbb{R}$; end-points x_a, $x_b \in \mathbb{R}^n$; an open, convex, and bounded set $U \subset \mathbb{R}^m$; and functions $L : \mathbb{R} \times \mathbb{R}^n \times U \to \mathbb{R}$ and $f : \mathbb{R} \times \mathbb{R}^n \times U \to \mathbb{R}^n$. The control problem (P) is defined to be

$$\text{(P)} \qquad \text{minimize} \quad J(x,u) = \int_a^b L(t,x,u)dt$$

over all feasible pairs (x, u) of piecewise continuous functions $u : [a, b] \to \mathbb{R}^m$ and absolutely continuous functions $x : [a, b] \to \mathbb{R}^n$ such that

$$\dot{x} = f(t,x,u) \quad \text{for almost every } t \in [a,b], \tag{2.1}$$

$$x(a) = x_a, \qquad x(b) = x_b, \tag{2.2}$$

$$u(t) \in U. \tag{2.3}$$

The control constraint (2.3) with U *open* and bounded has been introduced for technical reasons; mainly it should allow for a practical verification of the regularity condition in Definition 2.1.

Let $C^n[a, b]$ denote the space of continuous functions $x : [a, b] \to \mathbb{R}^n$ equipped with the usual topology. For $x \in C^n[a, b]$ and $\varepsilon > 0$ we denote by $B(x; \varepsilon)$ the open ε-ball around x in $C^n[a, b]$. Similarly, the *tube* about $x \in C^n[a, b]$ in $\mathbb{R}^{n+1}$ is the set

$$T(x;\varepsilon) = \{(t,y) \in \mathbb{R}^{n+1} \mid t \in [a,b], \|y - x(t)\| < \varepsilon\}.$$

A feasible pair (x_0, u_0) is called a (*strong*) *local minimum* if for some $\varepsilon > 0$,

$$J(x, u) \geq J(x_0, u_0)$$

for all feasible pairs (x, u) with $x \in B(x_0; \varepsilon)$ and u satisfying (2.3).

We use hereafter the terminology $\varphi(t) = \varphi(t, x_0(t), u_0(t))$ for any function φ. Given a pair (x_0, u_0) we assume the following hypotheses.

Hypothesis 1. The functions L and f are of class C^k with $k \geq 2$ on $T(x_0; \varepsilon) \times U$.

Hypothesis 2. The linearized system $\dot{y} = f_x(t)y + f_u(t)v$ is completely controllable in $[a, b]$.

The controllability assumption (Hypothesis 2) is usually referred to as the *normality* condition.

The *Hamiltonian* of (P) is defined by

$$H(t, x, \lambda, u) = L(t, x, u) + \lambda^T f(t, x, u), \qquad \lambda \in \mathbb{R}^n, \tag{2.4}$$

where T denotes the transpose. Assuming normality (Hypothesis 2), the first-order necessary conditions for a strong local minimum (minimum principle of *Pontryagin*) are as follows. There exists an absolutely continuous function $\lambda_0 : [a, b] \to \mathbb{R}^n$ such that

$$\dot{\lambda}_0 = -H_x(t)^T \quad \text{for almost every } t \in [a, b], \tag{2.5}$$

$$u_0(t) \in \arg\min\{H(t, x_0(t), \lambda_0(t), u) \mid u \in U\} \quad \text{for all } t \in [a, b]. \tag{2.6}$$

The latter minimum condition yields because U is open

$$H_u(t) = 0, \qquad H_{uu}(t) \geq 0 \quad \text{(positive semidefinite)}.$$

One basic assumption for SSCs is that the following strengthened *Legendre* condition holds:

$$H_{uu}(t) > 0 \quad \text{positive definite for } t \in [a, b]. \tag{2.7}$$

This condition is not sufficient to guarantee the *continuity* of the control $u_0(t)$. The continuity and, in fact, the smoothness of $u_0(t)$ follows from the *regularity* of the *Hamiltonian*. In the following definition, $T(x_0, \lambda_0; \varepsilon)$ denotes the tube about (x_0, λ_0) which is defined in an obvious way.

DEFINITION 2.1. *Let $k \geq 1$. The Hamiltonian H is called C^k-regular (about (x_0, λ_0, u_0)) if there exists $\varepsilon > 0$ and a C^k-function*

$$u^* : T(x_0, \lambda_0; \varepsilon) \to U$$

such that

$$u^*(t, x, \lambda) = \arg\min\{H(t, x, \lambda, u) \mid u \in U\}$$

is the unique minimum for all $(t, x, \lambda) \in T(x_0, \lambda_0; \varepsilon)$.

This condition strengthens the regularity condition (1.2)‴ of Zeidan [49, p. 22]. Also, this regularity condition is tacitly underlying numerical methods for solving the BVP defined by (2.1), (2.2), (2.5), and (2.6). This can be seen as follows. The optimal solution (x_0, u_0) is obtained by solving the BVP

$$\begin{aligned} \dot{x} &= f(t, x, u^*(t, x, \lambda)), \\ \dot{\lambda} &= -H_x(t, x, \lambda, u^*(t, x, \lambda))^T \end{aligned} \tag{2.8}$$

with boundary values $x(a) = x_a$, $x(b) = x_b$. The solutions $x_0(t)$, $\lambda_0(t)$ of this BVP are C^k-functions because the right-hand side of (2.8) is a C^k-function. Hence the optimal control

$$u_0(t) = u^*(t, x_0(t), \lambda_0(t)) \tag{2.9}$$

is also a C^k-function.

Remark. The C^k-regularity of the Hamiltonian is not as restrictive as it may appear. The C^k-regularity holds for most practical examples where the control variable appears *nonlinearly*; compare, for example, the famous reentry problem in Stoer and Bulirsch [45]. Observe that the open and bounded control set U has been introduced to allow for a check of the uniqueness of the minimizing function $u^*(t, x, \lambda)$. Note also that the strict Legendre–Clebsch condition (2.7) alone does not guarantee the continuity or even the differentiability of the control $u(t)$ that is indispensable for the sensitivity result in Theorem 3.1. This can be seen by choosing $L(t, x, u) = (u^2 - 1)^2$, $U = \mathbb{R}$, $f(t, x, u) = u$. Here any control $u(t) = \pm 1$ is optimal with $H_{uu}(t) \equiv 8$, but H is not C^k-regular.

Next, we introduce the *variational system* corresponding to (2.8). The continuity of $u_0(t)$ and (2.7) imply that there exists $\varepsilon > 0$ such that the C^k-function $u^*(t, x, \lambda)$ in Definition 2.1 satisfies

$$\begin{aligned} H_u(t, x, \lambda, u^*(t, x, \lambda)) &= 0 \\ H_{uu}(t, x, \lambda, u^*(t, x, \lambda)) &> 0 \end{aligned} \qquad \text{for } (t, x, \lambda) \in T(x_0, \lambda_0; \varepsilon). \tag{2.10}$$

By differentiation of the first equation we obtain the identities

$$H_{ux} + H_{uu} u_x^* \equiv 0, \qquad H_{u\lambda} + H_{uu} u_\lambda^* \equiv 0$$

and hence in view of the second relation in (2.10) and $H_{u\lambda} = f_u^T$ we obtain

$$u_x^* = -H_{uu}^{-1} H_{ux}, \qquad u_\lambda^* = -H_{uu}^{-1} f_u^T. \tag{2.11}$$

Then the variational system for (2.8) about (x_0, u_0) becomes (see [8, (6.1.21)–(6.1.25)], [38], [51], [52])

$$\dot{y} = A(t)y + B(t)\eta, \qquad \dot{\eta} = C(t)y - A(t)^T \eta, \tag{2.12}$$

where

$$\begin{aligned} A(t) &= f_x(t) - f_u(t) H_{uu}(t)^{-1} H_{ux}(t), \\ B(t) &= -f_u(t) H_{uu}(t)^{-1} f_u(t)^T, \\ C(t) &= -H_{xx}(t) + H_{xu}(t) H_{uu}(t)^{-1} H_{ux}(t). \end{aligned} \tag{2.13}$$

We use the system with vector solutions $y(t), \eta(t)$ as well as with (n, n) matrix solutions $y(t), \eta(t)$.

Our aim now is to establish the connection between the variational system (2.12) and shooting methods for solving the BVP (2.2), (2.8). Consider solutions of the differential equation (2.8) with initial values depending on a shooting parameter $s \in \mathbb{R}^n$ (compare [9], [45]):

$$x(a) = x_a, \qquad \lambda(a) = s. \tag{2.14}$$

These solutions denoted by $x(t, s)$ and $\lambda(t, s)$ are C^k-functions for s near $s_0 := \lambda_0(a)$. We have to solve the nonlinear equation

$$F(s) := x(b, s) - x_b = 0, \tag{2.15}$$

where F is a C^k function for s near s_0. Newton's method for solving this equation requires the nonsingularity of the matrix

$$y(b) := \frac{\partial F}{\partial s}(s_0) = \frac{\partial x}{\partial s}(b, s_0). \tag{2.16}$$

The matrix $y(b)$ is computed by noting that the matrices

$$y(t) = \frac{\partial x}{\partial s}(t, s_0), \qquad \eta(t) = \frac{\partial \lambda}{\partial s}(t, s_0) \tag{2.17}$$

are solutions of the variational system (2.12) with initial conditions

$$y(a) = O_n, \qquad \eta(a) = I_n. \tag{2.18}$$

Now we consider the following matrix Riccati equation associated with the variational system (2.12) (compare Reid [43, Chap. III]):

$$\begin{aligned} \dot{Q} &= -QA(t) - A(t)^T Q - QB(t)Q + C(t) \\ &= -Qf_x(t) - f_x(t)^T Q - H_{xx}(t) \\ &\quad +(H_{xu}(t) + Qf_u(t))H_{uu}(t)^{-1}(H_{ux}(t) + f_u(t)^T Q). \end{aligned} \tag{2.19}$$

Here, $Q(t)$ is a symmetric $n \times n$ matrix. Based on the Riccati equation (2.19), the following SSCs are obtained in [32, Thm. 5.2], [35, Thm. 2.2], [44, Thm. 5.3], and [49, Thm. 2.2].

THEOREM 2.1. *Let (x_0, u_0) be a feasible pair for* (P) *such that Hypotheses* 1 *and* 2 *hold. Assume that there exists an absolutely continuous function $\lambda_0 : [a, b] \to \mathbb{R}^n$ such that the necessary conditions* (2.5), (2.6) *are satisfied and assume further that the following conditions hold*:

(a) $H_{uu}(t) > 0$, $\forall\, t \in [a, b]$;

(b) *the Hamiltonian H is C^k regular*;

(c) *there exists a symmetric C^1 solution $Q(t)$ of the Riccati equation* (2.19).

Then (x_0, u_0) provides a local minimum for (P) *and, moreover, u_0 is a C^k function.*

Note that conditions (a)–(c) are stable with respect to small C^k perturbations of the data. This property is crucial for the second-order sensitivity result in the next section.

3. Solution differentiability. The problem (P) considered in §2 is embedded into the following parametric control problem (P(p)) depending on a parameter $p \in \mathbb{R}^k$:

$$\text{Minimize} \quad J(x, u, p) = \int_a^b L(t, x, u, p)dt$$

subject to

$$\dot{x} = f(t, x, u, p), \qquad a \le t \le b, \tag{3.1}$$

$$x(a) = \varphi(p), \qquad x(b) = \psi(p), \tag{3.2}$$

$$u(t) \in U. \tag{3.3}$$

The unperturbed problem corresponding to $p = p_0 \in \mathbb{R}^k$ is identified with problem (P) of §2. Let (x_0, u_0) be a feasible pair for (P(p_0)). Hypothesis 1 is replaced by Hypothesis 1′.

Hypothesis 1′. The functions $L : \mathbb{R}\times\mathbb{R}^n\times U\times\mathbb{R}^k \to \mathbb{R}$ and $f : \mathbb{R}\times\mathbb{R}^n\times U\times\mathbb{R}^k \to \mathbb{R}^n$ are of class C^k ($k \geq 2$) on $T(x_0, u_0; \varepsilon) \times U \times B(p_0; \varepsilon)$ and the functions $\varphi, \psi : \mathbb{R}^k \to \mathbb{R}^n$ are of class C^k on $B(p_0; \varepsilon)$ for some $\varepsilon > 0$.

The Hamiltonian for problem (P(p)) is

$$H(t, x, \lambda, u, p) = L(t, x, u, p) + \lambda^T f(t, x, u, p), \qquad \lambda \in \mathbb{R}^n. \tag{3.4}$$

We assume that (x_0, u_0) satisfies the second-order sufficient conditions of Theorem 2.1 with a C^k function λ_0. The C^k regularity of the unperturbed *Hamiltonian* (2.4) carries over to the perturbed *Hamiltonian* (3.4): there exists $\varepsilon > 0$ and a C^k function

$$u^* : T(x_0, \lambda_0; \varepsilon) \times B(p_0; \varepsilon) \to U$$

such that the minimum of H is uniquely attained at

$$u^*(t, x, \lambda, p) = \arg\min\{H(t, x, \lambda, u, p) \mid u \in U\} \tag{3.5}$$

for all $(t, x, \lambda, p) \in T(x_0, \lambda_0; \varepsilon) \times B(p_0; \varepsilon)$. The uniqueness follows from the compactness of $\bar{U}$ combined with arguments used in Proposition 3.1 of Zeidan [49]. The smoothness property of u^* is a consequence of the implicit function theorem because u^* satisfies

$$H_u(t, x, \lambda, u^*(t, x, \lambda, p), p) = 0$$

and the strict *Legendre* condition (2.7) holds.

Now we can state the main result of this paper. A preliminary version for more general control problems has been announced in [40].

THEOREM 3.1 (Solution differentiability). *Let (x_0, u_0) be feasible for the unperturbed problem* (P(p_0)) *such that Hypothesis* 1′ *holds. Assume that (x_0, u_0) satisfies the second-order sufficient conditions of Theorem* 2.1 *and that the shooting matrix $y(b)$ in* (2.16) *is regular.*

Then there exists a neighbourhood $V \subset \mathbb{R}^k$ of $p = p_0$ and C^k functions

$$x, \lambda : [a, b] \times V \to \mathbb{R}^n, \qquad u : [a, b] \times V \to U$$

such that the following statements hold:

(1) $x(t, p_0) = x_0(t)$, $u(t, p_0) = u_0(t)$, $\lambda(t, p_0) = \lambda_0(t)$ *for all* $t \in [a, b]$;

(2) *The triple $x(\cdot, p)$, $u(\cdot, p)$, $\lambda(\cdot, p)$ satisfies the second-order sufficient conditions in Theorem* 2.1 *for all $p \in V$ and $x(\cdot, p)$, $u(\cdot, p)$ provide a strong local minimum for* (P(p)).

Proof. In a first step we construct functions $x(t, p)$, $u(t, p)$, $\lambda(t, p)$ satisfying the first order conditions (2.5), (2.6) for p near p_0. Using the minimizing function $u^*(t, x, \lambda, p)$ in (3.5), this amounts to solving the BVP

$$\begin{aligned} \dot{x} &= f(t, x, u^*(t, x, \lambda, p), p), \\ \dot{\lambda} &= -H_x(t, x, \lambda, u^*(t, x, \lambda, p), p)^T, \end{aligned} \tag{3.6}$$

$$x(a) = \varphi(p), \qquad x(b) = \psi(p). \tag{3.7}$$

The shooting procedure is a parametric version of (2.14)–(2.18). We consider the differential equation (3.6) with initial values depending on a shooting parameter $s \in \mathbb{R}^n$,

$$x(a) = \varphi(p), \qquad \lambda(a) = \lambda_0(a) + s.$$

Solutions $\tilde{x}(t,p,s)$, $\tilde{\lambda}(t,p,s)$ exist in $[a,b]$ for $\|s\|$ and $\|p-p_0\|$ small and are C^k functions with respect to all arguments (t,p,s). Then the mapping $F:\mathbb{R}^k\times\mathbb{R}^n\to\mathbb{R}^n$ defined by

$$F(p,s)=\tilde{x}(b,p,s)-\psi(p)$$

is a C^k function with $F(p_0,0)=0$. Solving the BVP (3.6), (3.7) is then equivalent to solving the nonlinear equation $F(p,s)=0$ for $s=s(p)$. To apply the implicit function theorem, we have to check the nonsingularity of the (n,n)-matrix

$$\frac{\partial F}{\partial s}(p_0,0)=\frac{\partial\tilde{x}}{\partial s}(b,p_0,0).$$

As we have already seen in (2.16) this matrix agrees with the matrix $y(b)$ where

$$y(t)=\frac{\partial\tilde{x}}{\partial s}(t,p_0,0),\qquad \eta(t)=\frac{\partial\tilde{\lambda}}{\partial s}(t,p_0,0)$$

are solutions of the variational system (2.12) with initial conditions

$$y(a)=O_n,\qquad \eta(a)=I_n.$$

Because $y(b)$ is assumed to be regular, the implicit function theorem yields a neighbourhood $V\subset\mathbb{R}^k$ of $p=p_0$ and a C^k function $s:V\to\mathbb{R}^n$ such that $s(p_0)=0$ and

$$F(p,s(p))=\tilde{x}(b,p,s(p))-\psi(p)=0\qquad\forall\, p\in V.$$

The conclusion to this point is that the functions

$$x(t,p):=\tilde{x}(t,p,s(p)),\qquad \lambda(t,p):=\tilde{\lambda}(t,p,s(p))$$

are C^k functions that solve the BVP (3.6) and (3.7) for $p\in V$. The associated control function

$$u(t,p):=u^*(t,x(t,p),\lambda(t,p),p)$$

is also of class C^k and satisfies the minimum principle in view of (3.5). Claim (1) of the theorem is immediate.

In a second step we have to show that, indeed, $x(t,p)$ and $u(t,p)$ are optimal for problem (P(p)). We can choose the neighbourhood V so small that the following two statements are true for all $p\in V$:

(a) The strict *Legendre* condition holds

$$H_{uu}(t,x(t,p),\lambda(t,p),u(t,p),p)>0\qquad\forall\, t\in[a,b];$$

(b) The *Riccati* equation

$$\dot{Q}=-Q\,A(t,p)-A(t,p)^TQ-Q\,B(t,p)Q+C(t,p)$$

has a symmetric C^1 solution $Q(t,p)$ on $[a,b]$ where $A(t,p)$, $B(t,p)$, $C(t,p)$ are the matrices (2.13) evaluated at $x(t,p)$, $\lambda(t,p)$, $u(t,p)$.

Statement (b) follows from the standard embedding theorem for differential equations. Applying Theorem 2.1 for each $p\in V$, we arrive at the desired conclusion that the pair $(x(\cdot,p),u(\cdot,p))$ is a local minimum for every $p\in V$. □

We now briefly illustrate the use of this sensitivity result when devising efficient numerical feedback schemes for neighbouring extremals. Because the functions $x(t,p)$, $\lambda(t,p)$, and $u(t,p)$ are of class C^k on $[a,b] \times V$ $(k \geq 2)$, the following *Taylor*-expansions exist:

$$x(t,p) = x_0(t) + \frac{\partial x}{\partial p}(t,p_0)(p-p_0) + 0(\|p-p_0\|^2),$$

$$\lambda(t,p) = \lambda_0(t) + \frac{\partial \lambda}{\partial p}(t,p_0)(p-p_0) + 0(\|p-p_0\|^2),$$

$$u(t,p) = u_0(t) + \frac{\partial u}{\partial p}(t,p_0)(p-p_0) + 0(\|p-p_0\|^2).$$

The variations

$$z(t) := \frac{\partial x}{\partial p}(t,p_0), \quad \mu(t) := \frac{\partial \lambda}{\partial p}(t,p_0), \quad v(t) := \frac{\partial u}{\partial p}(t,p_0)$$

are (n,p), respectively, (m,p), matrices of class C^1 that satisfy the *linear* inhomogeneous BVP

$$\begin{aligned} \dot{z} &= A^0(t)z + B^0(t)\mu + f_p^0(t) - f_u^0(t)H_{uu}^0(t)^{-1}H_{up}^0(t), \\ \dot{\mu} &= C^0(t)z - A^0(t)^T\mu + H_{xx}^0 H_{uu}^0(t)^{-1}H_p^0(t) - H_{xp}^0(t), \end{aligned} \tag{3.8}$$

$$z(a) = \varphi_p(p_0), \qquad z(b) = \psi_p(p_0). \tag{3.9}$$

Here the upper index zero denotes arguments evaluated at $p = p_0$. This result follows by differentiating (3.6) and (3.7) with respect to p. Moreover, differentiation of the identity

$$H_u(t, x(t,p), \lambda(t,p), u(t,p), p) = 0$$

yields

$$v(t) = -H_{uu}^0(t)^{-1}(H_{ux}^0(t)z(t) + f_u^0(t)^T\mu(t) + H_{up}^0(t)). \tag{3.10}$$

The linear BVP (3.8) and (3.9) can be solved by stable shooting techniques (see [4], [5], [19]–[21], [37]–[41] for special perturbations).

4. An illustrative example. We present an example that admits two kinds of extremal solutions, both with a nonsingular shooting matrix. The sufficient conditions single out only one solution as optimal. For this solution a sensitivity analysis is performed according to Theorem 3.1. Consider the following variational problem depending on a parameter $p \in \mathbb{R}$:

$$\begin{aligned} &\text{Minimize} \quad \frac{1}{2}\int_0^1 (px(t)^3 + \dot{x}(t)^2)dt \\ &\text{subject to} \quad x(0) = 4, \qquad x(1) = 1. \end{aligned}$$

The unperturbed problem corresponds to $p_0 = 1$. Defining as usual the control variable by $u := \dot{x}$, the *Hamiltonian* becomes

$$H(x,\lambda,u,p) = \frac{1}{2}(px^3 + u^2) + \lambda u. \tag{4.1}$$

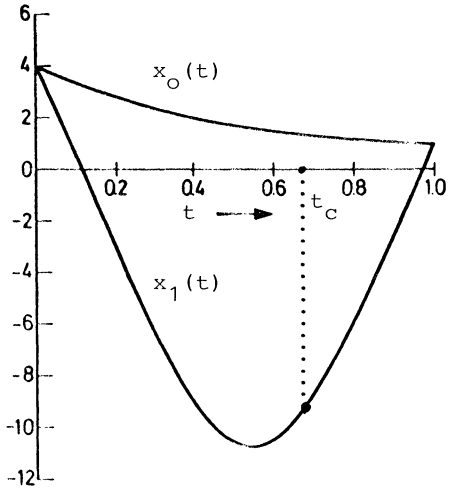

FIG. 1. *Solutions* $x_0(t)$ *and* $x_1(t)$ *of* BVP (4.2 with $p = 1$); *conjugate point* $t_c = 0.674437$ *for* $x_1(t)$.

The strict *Legendre* condition $H_{uu} = 1 > 0$ holds throughout. The function u^* in (3.5) minimizing the *Hamiltonian* is $u^*(x, \lambda, p) = -\lambda$. The *Hamiltonian* (4.1) is C^∞-regular. The BVP (3.6) and (3.7) leads to

$$\ddot{x} = \frac{3}{2} p x^2, \qquad x(0) = 4, \qquad x(1) = 1. \tag{4.2}$$

Unperturbed solution for $p_0 = 1$. Using shooting methods, Stoer and Bulirsch [45, p. 471], have shown that the BVP (4.2) with $p = 1$ has two solutions $x_0(t) = 4/(1 + t)^2$ and $x_1(t)$ characterized by

$$\dot{x}_0(0) = -8 \quad \text{and} \quad \dot{x}_1(0) = -35.85849. \tag{4.3}$$

The two solutions are shown in Fig. 1. To test $x_0(t)$ and $x_1(t)$ for optimality, we consider the following variational equation for (4.2) with respect to $x_0(t)$ or $x_1(t)$ (compare also (2.12) with initial conditions (2.18)):

$$\begin{aligned} \ddot{x}_i &= \frac{3}{2} x_i^2, \quad x_i(0) = 4, \quad \dot{x}_i(0) \quad \text{as in (4.3)}, \\ \ddot{y}_i &= 3x_i(t) y_i, \qquad y_i(0) = 0, \quad \dot{y}_i(0) = 1 \quad (i = 0, 1). \end{aligned} \tag{4.4}$$

It can be verified by numerical integration that the following classical *Jacobi* condition holds:

$$y_0(t) \neq 0 \quad \text{for } 0 < t \leq 1.$$

Hence $x_0(t)$ is optimal. Alternatively, optimality of $x_0(t)$ can be verified by invoking Theorem 2.1. The Riccati equation (2.19) becomes $\dot{Q} = -3x_0(t) + Q^2$. It is straightforward to compute a bounded solution Q in [0,1].

On the other hand, for the solution x_1 we find that

$$y_1(t_c) = 0 \quad \text{for } t_c = 0.674437.$$

Thus, there exists a point $t_c \in (0, 1)$ that is conjugate to $t = 0$. This violates the necessary condition of optimality in [51, Theorem 3.1]. Hence $x_1(t)$ is *nonoptimal*. We note that the

TABLE 1

0.5	0.051	0.20	0.011	0.086

exact value of the conjugate point t_c can be computed via the BVP (4.4) and $y_1(t_c) = 0$ treating t_c as a *free* variable.

Perturbed solutions and neighbouring extremals. By Theorem 3.1 there exists a neighbourhood $V \subset \mathbb{R}$ of $p_0 = 1$ and a C^∞ function $x(t,p)$ for $(t,p) \in [0,1] \times V$ such that $x(\cdot,p)$ is optimal for the variational problem and satisfies $x(t,p_0) = x_0(t) = 4/(1+t)^2$.

The function $x(t,p)$ solves the BVP (4.2) and admits a *Taylor* expansion

$$x(t,p) = x_0(t) + \frac{\partial x}{\partial p}(t,p_0)(p-p_0) + \frac{1}{2}\frac{\partial^2 x}{\partial p^2}(t,p_0)(p-p_0)^2 + O(|p-p_0|^3) \tag{4.5}$$

on $[0,1] \times V$. The variations

$$z_1(t) := \frac{\partial x}{\partial p}(t,p_0), \qquad z_2(t) = \frac{\partial^2 x}{\partial p^2}(t,p_0)$$

are solutions of the linear inhomogeneous BVP

$$\ddot{z}_1 = 3x_0(t)z_1 + \frac{3}{2}x_0(t)^2, \qquad z_1(0) = z_1(1) = 0,$$

respectively,

$$\ddot{z}_2 = 3x_0(t)z_2 + 3z_1(t)(2x_0(t) + z_1(t)), \qquad z_2(0) = z_2(1) = 0,$$

which can be obtained from (4.2) by formal differentiation; compare also (3.8) and (3.9). The solutions $z_1(t)$ and $z_2(t)$ are given by

$$\dot{z}_1(0) = -3.779528, \qquad \dot{z}_2(0) = 1.483277.$$

Table 1 presents some numerical results reflecting the error of the first- and second-order Taylor expansion in (4.5) where $p = 1 + \Delta p$, $k = 1, 2$, as follows:

$$e_k(\Delta p) := \max_{0 \le t \le 1} \left| x(t,p) - \sum_{i=0}^{k} \frac{1}{i!}\frac{\partial^i x}{\partial p^i}(t,p_0)(\Delta p)^i \right|.$$

5. Conclusion and extensions. The second-order sensitivity result derived in this paper states that the optimal solution of a nonlinear control problem is differentiable with respect to parameters provided that (1) second-order sufficient conditions (SSCs) hold for the unperturbed (nominal) problem and (2) the shooting matrix associated with the boundary value problem is nonsingular. Many authors have used the nonsingularity of the shooting matrix as the only tool to obtain a differentiable family of extremals. The example in §4 demonstrates that this alone does not suffice to find an optimal solution to which perturbation analysis can be applied.

Thus, the solution differentiability result in this paper gives a firm theoretical basis to existing numerical feedback schemes for computing neighbouring extremals.

It is desirable to extend the solution differentiability to perturbed nonlinear control problems with inequality constraints of the type

$$\begin{aligned} \text{mixed state-control constraints:} \quad & C(x,u,p) \le 0, \qquad C : \mathbb{R}^{n+1+k} \to \mathbb{R}, \\ \text{state constraints:} \quad & S(x,p) \le 0, \qquad S : \mathbb{R}^{n+k} \to \mathbb{R}. \end{aligned}$$

These general control constraints comprise the special case of a *closed* control set U that has not been treated in this paper. Boundary value problems for inequality constrained problems have been successfully solved by multiple shooting techniques. These techniques usually require that the structure of the solution, that is, the number and the type of junction points with the boundary, is known. Then one main obstacle to extending the techniques of this paper to inequality constraints is the fact that SSCs in [32], [44] are too strong and are not directly related to the variational system of the associated boundary value problem. SSCs that use a type of Riccati ODE related to this variational system have first been obtained by Orrell and Zeidan [35] for the state independent constraint $C(u) \le 0$. Recently, extensions of these SSCs to mixed constraints $C(x,u) \le 0$ have been derived in Maurer [33] and Pickenhain [42]. The SSCs in [33] are developed directly on the basis of the variational system to provide the ingredients for a sensitivity result along the lines of this paper. Results and examples will be reported in a future paper.

COMMENTS ON A STRUCTURAL APPROACH TO THE NONLINEAR MODEL MATCHING PROBLEM*

Ü. KOTTA†

Abstract. It is shown that, under certain regularity assumptions, the sufficient conditions for solvability of the model matching problem (MMP) in terms of structural invariants presented by Moog, Perdon, and Conte [*SIAM J. Control Optim.*, 29 (1991), pp. 769–785] are also necessary. The seeming controversy involving the example of Huijberts is resolved.

Key words. nonlinear system, model matching, structure algorithm, regularity, dynamic precompensation

AMS subject classifications. 93B50, 93C10, 93B52

1. Introduction.

In [3] the model matching problem (MMP) for affine nonlinear systems has been investigated using an approach based on the structure (inversion) algorithm [4]. Sufficient conditions for the solvability of the problem have been found in terms of the structural invariants: the MMP admits a solution if the structure at infinity of the system and that of the so-called extended system (i.e., a suitable composition of the system and the model) are equal. It has been claimed that the proposed conditions are not necessary and an example of Huijberts [1] has been presented to confirm the argument. Although not stated explicitly, to obtain the equations of the compensator, the authors of [3] had to work under certain regularity assumptions about the triplet (state, disturbance, output).

The purpose of the present paper is to show that under slightly stronger regularity assumptions, these conditions are also necessary and to resolve the seeming controversy with the example of Huijberts.

2. Main result.

Consider a nonlinear plant G, described by the equations

$$\begin{cases} \dot{z} = f_G(z) + g_G(z)v, & z(0) = z_0, \\ y_G = h_G(z), \end{cases} \tag{2.1}$$

where the state $z \in R^n$, the input $v \in R^m$, the output $y_G \in R^p$, $f_G(\cdot)$, and the columns of g_G and h_G are meromorphic functions of z.

Furthermore, let a nonlinear model T be given, which is described by the equations

$$\begin{cases} \dot{x} = f(x) + g(x)u, & x(0) = x_0, \\ y_T = h(x), \end{cases} \tag{2.2}$$

where the state $x \in R^{n_T}$, the input $u \in R^{m_T}$, the output $y_T \in R^p$, $f(\cdot)$, and the columns of $g(\cdot)$ and $h(\cdot)$ are meromorphic functions of x.

An extended system GT can be associated with the plant G and the model T as follows:

$$\begin{cases} \dot{x} = f(x) + g(x)u, \\ \dot{z} = f_G(z) + g_G(z)v, \\ y_{GT} = h(x) - h_G(z), \end{cases} \tag{2.3}$$

with the state $x_{GT} = (x^T, z^T)^T$, the control v, the measurable input disturbance u, and the output y_{GT}.

* Received by the editors May 28, 1992; accepted for publication (in revised form) June 21, 1993.
† Institute of Cybernetics, Akadeemia tee 21, Tallinn EE0026, Estonia.

The compensator H used to control G is a nonlinear system described by the equations of the form

$$\begin{cases} \dot{\xi} = f_H(\xi, z, u), & \xi(0) = \xi_0, \\ v = h_H(\xi, z, u), \end{cases} \tag{2.4}$$

with state $\xi \in R^q$.

The MMP in [3] has been formulated in the following way.

DEFINITION 1. *Given the plant* (2.1) *and model* (2.2), *find a compensator of the form* (2.4) *and a map* φ: $R^n \to R^q$ *such that the difference* $y_T(u, x_0) - y_{GH}(u, \varphi(x_0), z_0)$ *between the output of the model, viewed as a function of* u *and of the initial state* x_0, *and the output* y_{GT} *of the closed-loop system* (2.1), (2.4), *viewed as a function of* u *and of the initial states* z_0 *and* $\xi_0 = \varphi(x_0)$, *does not depend on* u.

The result of [3] on the MMP is based on the inversion (structure) algorithm. Actually, two versions of the inversion algorithm for systems with two types of inputs—controls and disturbances—are considered. In the first version (denoted by Singh), inversion is accomplished with regard to both types of inputs, controls and disturbances, whereas in the second version (denoted by Singh$_v$) the disturbances are considered as system parameters and inversion is accomplished with regard to control inputs only. We do not present the inversion algorithm here, and in the following, we borrow the notations for vectors, functions, etc., appearing in the inversion algorithm from [3].

Moog, Perdon, and Conte [3] presented sufficient conditions for the solvability of the MMP in terms of the structure at infinity ρ_k, $k \geq 1$ of the original system G and the extended system GT. They stated that the problem is solvable if the following structure at infinity of G and GT are equal:

$$\rho_k(GT) = \rho_k(G), \qquad k \geq 1.$$

In the sequel we need the two notions of regularity for GT associated with the two versions of the inversion algorithm, respectively.

Denote by T^nU_{GT} the nth-order tangent bundle of the input manifold $U_{GT} = R^{m_T}$ of the extended system GT, and denote by T^nY_{GT} the nth-order tangent bundle of the output manifold $Y_{GT} = R^P$ of the extended system GT.

DEFINITION 2. *Let a point* $x_{GT,0} = (x_0, z_0) \in R^{n_T} \times R^n$, *a point* $\tau_{GT,0} = (u_0, u_0^{(1)}, \ldots, u_0^{(n)}) \in T^nU_{GT}$, *and a point* $\gamma_{GT,0} = (y_{GT,0}, y_{GT,0}^{(1)}, \ldots, y_{GT,0}^{(n)}) \in T^nY_{GT}$ *be given. We call* $(x_{GT,0}, \tau_{GT,0}, \gamma_{GT,0})$ *a locally strongly regular triplet for* GT *with respect to Singh (Singh$_v$) if, for each application of the algorithm,* rank $G_k(\cdot)$ $1 \leq k \leq n + n_T$ *is constant around a triplet* $(x_{GT,0}, \tau_{GT,0}, \gamma_{GT,0})$.

Moog, Perdon, and Conte did not state explicitly that they work around a locally strongly regular triplet for the extended system GT with respect to Singh$_v$. However, implicitly they assumed it because otherwise it is not possible to solve the equations, obtained at the last step of the inversion algorithm, to find the compensator. Taking this observation into account, we can reformulate the result of [3] in the following way.

THEOREM 1. *Consider a nonlinear plant* G *and a nonlinear model* T. *Assume that* $(x_{GT,0}, \tau_{GT,0}, \gamma_{GT,0})$ *is a strongly regular triplet for the extended system* GT *with respect to Singh$_v$. The* MMP *is locally solvable around* $(x_{GT,0}, \tau_{GT,0}, \gamma_{GT,0})$ if

$$\rho_k(GT) = \rho_k(G), \qquad 1 \leq k \leq n + n_T. \tag{2.5}$$

Of course, if we do not work around a locally strongly regular triplet with respect to

Singh_v, then the conditions (2.5) are no longer sufficient. Take the extremely simple example

$$G = \begin{cases} \dot{x} = vz, \\ y_G = z, \end{cases} \qquad T = \begin{cases} \dot{x} = u, \\ y_T = x. \end{cases}$$

Condition (2.5) for G and T is clearly verified since $y_{GT} = vz - u$, and hence $\rho_i(GT) = \rho_i(G)$, $i = 1, 2$. Nevertheless, around the nonregular triplet defined by $z_0 = 0$, the MMP is not solvable.

Now we are going to prove that under slightly stronger regularity assumptions about the triplet, the conditions of (2.5) are also necessary for the solvability of the MMP.

THEOREM 2. *Consider a nonlinear plant G and a nonlinear model T. Assume that $(x_{GT,0}, \tau_{GT,0}, \gamma_{GT,0})$ is a strongly regular triplet for the extended system GT with respect to both versions of the inversion algorithm. The* MMP *is locally solvable around $(x_{GT,0}, \tau_{GT,0}, \gamma_{GT,0})$ only if*

$$\rho_k(GT) = \rho_k(G), \qquad 1 \le k \le n + n_T.$$

Proof. Let us assume that there exists a precompensator H of the form (2.4) for G and T that, around the strongly regular triplet $(x_{GT,0}, \tau_{GT,0}, \gamma_{GT,0})$, locally solves the MMP. Apply the first step of the inversion algorithm to GT with respect to control v only, considering disturbances u as parameters, to obtain

$$\begin{cases} \tilde{y}_1 = \tilde{f}_1(x, z, u) + \tilde{g}_1(x, z)v, \\ \hat{y}_1 = \hat{y}_1(x, z, u, \tilde{y}_1), \end{cases} \tag{2.6}$$

where $\operatorname{rank} \tilde{G}_1(x, z) := \operatorname{rank} \tilde{g}_1(x, z) = \rho_{1v}$.

If we plug the output of H in (2.6), the equations no longer depend on u, since H solves the MMP for G and T. In particular, this means that either

$$\frac{\partial \hat{y}_1}{\partial u} = \gamma(x, z, \tilde{y}_1) \equiv \dot{0} \tag{2.7}$$

everywhere around the triplet $(x_{GT,0}, \tau_{GT,0}, \gamma_{GT,0})$, or the compensator H will guarantee the equality (2.7). Note that around the regular triplet with respect to Singh, $\partial \hat{y}_1 / \partial u$ is everywhere either equal to zero or different from zero. This means that if $\partial \hat{y}_1 / \partial u \not\equiv 0$, we can never make it equal to zero by a suitable choice of the compensator. This implies that $\partial \hat{y}_1 / \partial u \equiv 0$, which gives us

$$\rho_1 = \operatorname{rank} \begin{bmatrix} \tilde{G}_1(\cdot) & \partial \tilde{f}_1 / \partial u \\ 0 & \partial \hat{y}_1 / \partial u \end{bmatrix} = \operatorname{rank} \tilde{G}_1(\cdot) = \rho_{1v}.$$

Applying this argument repeatedly, we finally obtain $\rho_k(GT) = \rho_{kv}(GT)$, $k \ge 1$. The conclusion of Theorem 2 follows using the fact that $\rho_k(G) = \rho_{kv}(GT)$, $k \ge 1$ [3].

Of course, around a nonregular triplet for the system GT with respect to Singh_v it is sometimes possible to make $\partial \hat{y}_1 / \partial u$ equal to zero by the proper choice of H. Such a choice will exploit the nonregularity of the triplet around which we work; namely, with this choice, we fall into a nonregular triplet. Note that $\rho_k(GT)$, evaluated at this point, is less than optimal, and exactly equal to $\rho_{kv}(GT)$.

Now we are ready to solve the seeming controversy of Theorem 2 with the example due to Huijberts [1] (and also presented in [3]),

$$G = \begin{cases} \dot{z} = (z_2 + z_2 v_2, v_1, v_2)^T, \\ y_G = (z_2, z_3, z_1)^T, \end{cases} \qquad T = \begin{cases} \dot{x} = (x_2, x_3 + u_1, u_2, x_4)^T, \\ y_T = (x_2, x_4, x_1)^T. \end{cases}$$

By applying the inversion algorithm to G, we obtain $\rho_1(G) = 2$, $\rho_2(G) = \rho_3(G) = 0$. The same procedure applied to GT gives

$$\left\{ \begin{array}{l} \dot{y}_{GT,1} = v_1 - x_3 - u_1, \\ \dot{y}_{GT,2} = v_2 - x_4, \\ \dot{y}_{GT,3} = z_2(1 + \dot{y}_{GT,2} + x_4) - x_2, \end{array} \right. \tag{2.8}$$

and thus

$$\ddot{y}_{GT,3} = u_1(\dot{y}_{GT,2} + x_4) + (\dot{y}_{GT,1} + x_3)(\dot{y}_{GT,2} + x_4) + z_2(\dot{y}_{GT,2} + x_4) + \dot{y}_{GT,1}.$$

So $\rho_1(GT) = s_1(GT) = 2$,

$$s_2(GT) = \operatorname{rank} \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & 0 \\ 0 & 0 & \dot{y}_{GT,2} + x_4 \end{pmatrix} = 3,$$

and $\rho_2(GT) = s_2(GT) - s_1(GT) = 1$.

In [1], [3] it has been claimed that the condition $\rho_2(GT) = \rho_2(G)$ is not satisfied, but the compensator

$$\left\{ \begin{array}{l} \dot{\xi} = (\xi_2, \xi_3 + u_1, u_2, -\xi_4)^T, \\ v = (\xi_3 + u_1, 0)^T \end{array} \right. \tag{2.9}$$

still solves the MMP. What actually happens with the choice of the compensator (2.9) is that we fall into the nonregular triplet (for the extended system GT with respect to Singh), defined by $\dot{y}_{GT,2} + x_4 = 0$ (see (2.8)). This triplet is nonregular, because $\rho_2(GT) = 1$ everywhere except for the case where $\dot{y}_{GT,2} + x_4 = 0$; in this case, $\rho_2(GT) = 0$. So Theorem 2 does not state anything about the solvability of the MMP around this triplet.

3. Conclusions. Around a regular triplet for the extended system with respect to both versions of the inversion algorithm, the conditions (2.5) are sufficient as well as necessary. Hence around a regular triplet, the necessary and sufficient conditions for solvability of the nonlinear MMP are in accordance with the corresponding conditions for linear systems [2], and a solution of the nonlinear MMP naturally extends the solution of the MMP for linear systems.

Of course, this similarity no longer holds around a nonregular triplet, where the conditions (2.5) are neither necessary (see the example by Huijberts) nor sufficient. In other words, around a nonregular triplet with respect to Singh_v, the nonlinear MMP is not solvable even if the condition $\rho_k(GT) = \rho_k(G)$, $1 \leq k \leq n + n_T$ holds. And in spite of this, that for some j, $\rho_j(GT) \neq \rho_j(G)$, the problem may still be solvable if we work around a nonregular triplet with respect to Singh.

RECURSIVE ALGORITHMS FOR SOLVING A CLASS OF NONLINEAR MATRIX EQUATIONS WITH APPLICATIONS TO CERTAIN SENSITIVITY OPTIMIZATION PROBLEMS*

WEI-YONG YAN†, JOHN B. MOORE‡, AND UWE HELMKE§

Abstract. This paper is concerned with solving a class of nonlinear algebraic matrix equations. Two recursive algorithms are proposed in terms of matrix *difference* equations and are studied. A set of initial values is characterized, from which the convergence of the algorithms can be guaranteed.

Based on the general results, several effective algorithms are presented to compute L^2-sensitivity optimal realizations, as well as Euclidean norm balancing realizations, of a given linear system. A locally exponential convergence property is proved for one of them. As is shown by simulation in this paper, these algorithms prove to be far more practical for digital computer implementation than the gradient flows previously proposed.

Key words. matrix equations, difference equations, linear systems, sensitivity, minimal realizations

AMS subject classifications. 93B40, 15A24, 39A10

1. Introduction.

Consider the algebraic matrix equation of the form

$$\mathcal{F}(X) - X\mathcal{G}(X)X = 0, \qquad X \in \mathcal{P}(n), \tag{1.1}$$

with $\mathcal{F}(\cdot)$ and $\mathcal{G}(\cdot)$ continuous operators from $\mathcal{P}(n)$ to itself, where $\mathcal{P}(n)$ denotes the set of all positive definite symmetric $n \times n$ matrices. In this paper we are interested in finding the solution to (1.1) under the following basic assumptions:

Assumption 1. $\mathcal{F}(\cdot)$ and $\mathcal{G}(\cdot)^{-1}$ are nondecreasing, that is, for any $X_1, X_2 \in \mathcal{P}(n)$ with $X_2 \geq X_1$, there hold $\mathcal{F}(X_2) \geq \mathcal{F}(X_1)$ and $\mathcal{G}(X_2) \leq \mathcal{G}(X_1)$, where the notation $X_2 \geq X_1$ ($X_2 > X_1$) means that $X_2 - X_1$ is positive semidefinite (definite).

Assumption 2. Equation (1.1) has a unique solution $\bar{X}$ in $\mathcal{P}(n)$.

This type of matrix equation often arises in systems and control. For example, it has been recently found [1], [3] that solving the problems of L^2-sensitivity minimization and Euclidean norm balancing can be reduced to solving certain highly nonlinear equations of the form (1.1). Unfortunately, there is no explicit formula for their unique solution to these algebraic equations. The only computation method available to date is to solve certain related nonlinear *differential* equations. For high-order problems, this method may be impractical or inefficient using conventional digital computers. Therefore, it is desirable to develop suitable iterative algorithms in terms of *difference* equations whose solution can converge to the required solution from appropriate initial conditions.

Of course, it is not always possible to relate (1.1) to some optimization problem or differential equation so that certain numerical methods such as Euler approximation and Newton–Raphson can be applied. Moreover, even if possible, the existing numerical methods may not always work well and may be inefficient because their success heavily depends on intricate step size adjustment, which is sometimes time consuming. In contrast, the method to be proposed in this paper for solving (1.1) does not require any step size adjustment, as will be seen soon.

§ Department of Mathematics, University of Regensburg, 8400 Regensburg, Germany.

To suggest a workable algorithm for (1.1), let us consider the trivial case where $\mathcal{F}(P) = F \in \mathcal{P}(n)$ and $\mathcal{G}(P) = G \in \mathcal{P}(n)$, that is, the operators $\mathcal{F}$ and $\mathcal{G}$ are constant. Quite obviously, Assumptions 1 and 2 are fulfilled in this case. Equation (1.1) then reduces to

$$F - XGX = 0, \tag{1.2}$$

which is apparently a very special form of the algebraic Riccati equation in continuous time. Thus, by the bilinear transformation given in [2], (1.2) is equivalent to the following algebraic Riccati equation in discrete time:

$$X = X - 2(X + F)(2X + F + G^{-1})^{-1}(X + F) + 2F. \tag{1.3}$$

It is known from [2] that the solution of the Riccati difference equation

$$X_{i+1} = X_i - 2(X_i + F)(2X_i + F + G^{-1})^{-1}(X_i + F) + 2F \tag{1.4}$$

converges to the solution of (1.2) or (1.3) from any initial condition $X_0 \in \mathcal{P}(n)$.

The above-mentioned fact inspires us to come up with the following difference equation for the general purpose:

$$X_{i+1} = X_i - 2[X_i + \mathcal{F}(X_i)][2X_i + \mathcal{F}(X_i) + \mathcal{G}(X_i)^{-1}]^{-1}[X_i + \mathcal{F}(X_i)] + 2\mathcal{F}(X_i), \tag{1.5}$$

which is obtained by respective substitution of the operators $\mathcal{F}$ and $\mathcal{G}$ for F and G into (1.4). A natural question arises as to whether the solution of (1.5) can still converge to the solution of (1.1) from any initial condition $X_0 \in \mathcal{P}(n)$ in the general case. In particular, can (1.5) serve as an iterative algorithm in the practical cases of interest?

Remark 1.1. It is worth emphasizing that the operators $\mathcal{F}$ and $\mathcal{G}$ will not be required to be smooth in the development to follow. We hope that this would widen the potential applications of the algorithms to be developed in the paper.

Remark 1.2. Note that computing the value of the operators $\mathcal{F}$ and $\mathcal{G}$ is required at each iteration of the algorithm (1.5), which may be undesirable or difficult in the situation where $\mathcal{F}$ and $\mathcal{G}$ are complicated or there are even no explicit expressions for them. As will be seen in the sequel, this difficulty can be overcome by way of incorporating two additional difference equations with (1.5).

Remark 1.3. If the operators $\mathcal{F}$ and $\mathcal{G}$ satisfy differentiability conditions, homotopy methods might be used to find the solution of (1.1). However, this kind of method eventually rests in solving a differential equation [4]. Moreover, its success crucially depends on the construction of a homotopy map satisfying certain requirements; otherwise, there is no guarantee that the method is globally convergent (see, e.g., [4]).

In the next section we prove some auxiliary results. Section 3 is devoted to studying the convergence properties of two types of general nonlinear difference equations including (1.5). Section 4 discusses specific iterative schemes for solving (1.1) in the cases of L^2-sensitivity minimization and Euclidean norm balancing. Section 5 proves that the convergence of the proposed algorithm for the L^2-sensitivity minimization problem is locally exponential, and §6 presents some simulation results. Conclusions appear in §7.

2. Preliminary results. Define

$$\mathcal{R}(X) \triangleq X - 2[X + \mathcal{F}(X)][2X + \mathcal{F}(X) + \mathcal{G}(X)^{-1}]^{-1}[X + \mathcal{F}(X)] + 2\mathcal{F}(X) \tag{2.1}$$

for $X \in \mathcal{P}(n)$, where $\mathcal{F}(\cdot), \mathcal{G}(\cdot) : \mathcal{P}(n) \mapsto \mathcal{P}(n)$. The following fundamental properties of $\mathcal{R}(\cdot)$ are instrumental in discussing the convergence of the algorithm $X_{i+1} = \mathcal{R}(X_i)$ subsequently.

LEMMA 2.1. *Suppose $\mathcal{F}(X)$ and $\mathcal{G}(X)^{-1}$ are nondecreasing with respect to $X \in \mathcal{P}(n)$. Then $\mathcal{R}(\cdot)$ maps $\mathcal{P}(n)$ to itself; moreover, for any $X, Y \in \mathcal{P}(n)$ there hold*

$$X \geq Y \Longrightarrow \mathcal{R}(X) \geq \mathcal{R}(Y), \tag{2.2}$$

$$\mathcal{R}(X) \geq X \Longleftrightarrow \mathcal{F}(X) \geq X\mathcal{G}(X)X, \tag{2.3}$$

$$\mathcal{R}(X) \leq X \Longleftrightarrow \mathcal{F}(X) \leq X\mathcal{G}(X)X, \tag{2.4}$$

$$\mathcal{R}(X) = X \Longleftrightarrow \mathcal{F}(X) = X\mathcal{G}(X)X. \tag{2.5}$$

Proof. Upon noting from the matrix inversion formula that

$$\mathcal{R}(X) = 2\{[X + \mathcal{F}(X)]^{-1} + [X + \mathcal{G}(X)^{-1}]^{-1}\}^{-1} - X, \tag{2.6}$$

it follows that $X \in \mathcal{P}(n)$ implies $\mathcal{R}(X) \in \mathcal{P}(n)$. Now assume $X \geq Y$. Because $\mathcal{F}(X)$ and $\mathcal{G}(X)^{-1}$ are nondecreasing, we obtain

$$\begin{aligned}
\mathcal{R}(X) &\geq 2\{[X + \mathcal{F}(Y)]^{-1} + [X + \mathcal{G}(Y)^{-1}]^{-1}\}^{-1} - X \\
&= X + 2\mathcal{F}(Y) - 2[X + \mathcal{F}(Y)][2X + \mathcal{F}(Y) + \mathcal{G}(Y)^{-1}]^{-1}[X + \mathcal{F}(Y)] \\
&= \mathcal{F}(Y) + [\mathcal{G}(Y)^{-1} - \mathcal{F}(Y)][2X + \mathcal{F}(Y) + \mathcal{G}(Y)^{-1}]^{-1}[X + \mathcal{F}(Y)] \\
&= \frac{1}{2}[\mathcal{F}(Y) + \mathcal{G}(Y)^{-1}] - \frac{1}{2}[\mathcal{G}(Y)^{-1} - \mathcal{F}(Y)] \\
&\quad \cdot [2X + \mathcal{F}(Y) + \mathcal{G}(Y)^{-1}]^{-1}[\mathcal{G}(Y)^{-1} - \mathcal{F}(Y)] \\
&\geq \frac{1}{2}[\mathcal{F}(Y) + \mathcal{G}(Y)^{-1}] - \frac{1}{2}[\mathcal{G}(Y)^{-1} - \mathcal{F}(Y)] \\
&\quad \cdot [2Y + \mathcal{F}(Y) + \mathcal{G}(Y)^{-1}]^{-1}[\mathcal{G}(Y)^{-1} - \mathcal{F}(Y)] \\
&= \mathcal{R}(Y),
\end{aligned}$$

implying that (2.2) holds. Further, from the identity

$$\mathcal{R}(X) = X + 2\mathcal{F}(X) - 2\{[X + \mathcal{F}(X)]^{-1} + [X + \mathcal{F}(X)]^{-1}[X + \mathcal{G}(X)^{-1}][X + \mathcal{F}(X)]^{-1}\}^{-1} \tag{2.7}$$

it can be seen that

$$\begin{aligned}
&\mathcal{R}(X) \geq X \\
&\quad \Longleftrightarrow \mathcal{F}(X)^{-1} \leq [X + \mathcal{F}(X)]^{-1} + [X + \mathcal{F}(X)]^{-1}[X + \mathcal{G}(X)^{-1}][X + \mathcal{F}(X)]^{-1} \\
&\quad \Longleftrightarrow [X + \mathcal{F}(X)]\mathcal{F}(X)^{-1}[X + \mathcal{F}(X)] \leq [X + \mathcal{F}(X)] + [X + \mathcal{G}(X)^{-1}] \\
&\quad \Longleftrightarrow X\mathcal{F}(X)^{-1}X \leq \mathcal{G}(X)^{-1} \\
&\quad \Longleftrightarrow \mathcal{F}(X) \geq X\mathcal{G}(X)X,
\end{aligned}$$

that is, (2.3) holds. In the same spirit, (2.4) can be proved and (2.5) is obtained as a direct result of (2.3) and (2.4). □

COROLLARY 2.1. *Let*

$$f(X, Y, Z) = X - 2(X + Y)(2X + Y + Z)^{-1}(X + Y) + 2Y \tag{2.8}$$

for $(X, Y, Z) \in \mathcal{P}(n) \times \mathcal{Q}(n) \times \mathcal{Q}(n)$, where $\mathcal{Q}(n)$ denotes the set of all $n \times n$ nonnegative definite symmetric matrices. Then

$$0 < X_1 \leq X_2, \quad 0 \leq Y_1 \leq Y_2, \quad 0 \leq Z_1 \leq Z_2 \tag{2.9}$$

imply

$$f(X_1, Y_1, Z_1) \leq f(X_2, Y_2, Z_2). \tag{2.10}$$

In particular, if $Y, Z \geq A$ for some $A \in \mathcal{P}(n)$, there holds

$$f(X, Y, Z) \geq A, \quad \forall X \in \mathcal{P}(n). \tag{2.11}$$

Proof. From (2.2) of Lemma 2.1 and (2.6) it follows that

$$\begin{aligned} f(X_1, Y_1, Z_1) &\leq f(X_2, Y_1, Z_1) \\ &= 2\{(X_2 + Y_1)^{-1} + (X_2 + Z_1)^{-1}\}^{-1} - X_2 \\ &\leq 2\{(X_2 + Y_2)^{-1} + (X_2 + Z_2)^{-1}\}^{-1} - X_2 \\ &= f(X_2, Y_2, Z_2), \end{aligned}$$

which gives (2.10). □

Remark 2.1. From (2.5), we can see that under Assumption 1 in §1 the equilibrium point of the difference equation $\mathcal{R}(X_{i+1}) = X_i$ exactly equals the solution of (1.1).

The next two results are only used in developing an efficient iterative scheme for finding L^2-sensitivity optimal realizations.

LEMMA 2.2. *Given a minimal realization (A, b, c) with the eigenvalues of A being in the open unit disk, let $U(\mu)$ be the solution of the following Lyapunov equation:*

$$Q = \begin{bmatrix} A' & c'b' \\ 0 & A' \end{bmatrix} Q \begin{bmatrix} A & 0 \\ bc & A \end{bmatrix} + \begin{bmatrix} c'c & 0 \\ 0 & \mu I \end{bmatrix}. \tag{2.12}$$

Then there holds

$$\lim_{\mu \to \infty} U(\mu)^{-1} = 0. \tag{2.13}$$

Proof. Let $V(\mu)$ be the solution of the Lyapunov equation

$$Q = \begin{bmatrix} A' & c'b' \\ 0 & A' \end{bmatrix} Q \begin{bmatrix} A & 0 \\ bc & A \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & \mu I \end{bmatrix}. \tag{2.14}$$

Then it is quite evident that $U(\mu) \geq V(\mu) = \mu V(1)$. Because the realization (A, b, c) is minimal, it follows that the pair

$$\left(\begin{bmatrix} A' & c'b' \\ 0 & A' \end{bmatrix}, \begin{bmatrix} 0 \\ I \end{bmatrix} \right)$$

is controllable. Thus, $V(1)$ is positive definite, leading to $\lim_{\mu \to \infty} U(\mu)^{-1} = 0$. □

LEMMA 2.3. *Given a minimal realization (A, b, c) with the eigenvalues of A being in the open unit disk, consider the difference equation*

(2.15)

$$Q_{i+1} \triangleq \begin{bmatrix} Q_{i+1}^{11} & Q_{i+1}^{12} \\ Q_{i+1}^{21} & Q_{i+1}^{22} \end{bmatrix} = \begin{bmatrix} A' & c'b' \\ 0 & A' \end{bmatrix} \begin{bmatrix} Q_i^{11} & Q_i^{12} \\ Q_i^{21} & Q_i^{22} \end{bmatrix} \begin{bmatrix} A & 0 \\ bc & A \end{bmatrix} + \begin{bmatrix} c'c & 0 \\ 0 & P_i \end{bmatrix}$$

with an initial symmetric matrix Q_0.

(i) *If* P_i *is nonnegative definite for all* $i = 0, 1, \ldots$, *then there exists a constant* $\beta > 0$ *and an integer* k *such that*

$$Q_i^{11} > \beta I, \quad \forall\, i \geq k. \tag{2.16}$$

(ii) *If there hold* $P_i \geq \mu I$, $i = 0, 1, \ldots$, *for some constant* $\mu > 0$, *then there exists an integer* k *such that*

$$Q_i > U(\mu/2), \quad \forall\, i \geq k, \tag{2.17}$$

where $U(\cdot)$ *is defined as in Lemma* 2.2.

Proof. By close inspection, it can be seen that $\lim_{i\to\infty} Q_i^{11} = \bar{Q}$, where $\bar{Q}$ is the unique positive definite solution to the Lyapunov equation

$$A'QA - c'c = Q. \tag{2.18}$$

From this, (i) immediately follows.

As for (ii), note that $Q_i \geq \tilde{Q}_i$ for all $i \geq 0$, where $\tilde{Q}_i$ is the solution to

$$\tilde{Q}_{i+1} = \begin{bmatrix} A' & c'b' \\ 0 & A' \end{bmatrix} \tilde{Q}_i \begin{bmatrix} A & 0 \\ bc & A \end{bmatrix} + \begin{bmatrix} c'c & 0 \\ 0 & \mu I \end{bmatrix},$$

with $\tilde{Q}_0 = Q_0$. Because

$$\lim_{i\to\infty} \tilde{Q}_i = U(\mu) > U(\mu/2),$$

(ii) is concluded. □

3. General convergence analysis. Recall that the main purpose of this paper is to solve the matrix equation

$$\mathcal{F}(X) - X\mathcal{G}(X)X = 0, \qquad X \in \mathcal{P}(n), \tag{3.1}$$

with $\mathcal{F}(\cdot), \mathcal{G}(\cdot) : \mathcal{P}(n) \mapsto \mathcal{P}(n)$ continuous operators. For this purpose, we propose the following difference equation:

$$\Phi_{i+1} = \mathcal{R}(\Phi_i), \tag{3.2}$$

with

$$\mathcal{R}(X) \triangleq X - 2[X + \mathcal{F}(X)][2X + \mathcal{F}(X) + \mathcal{G}(X)^{-1}]^{-1}[X + \mathcal{F}(X)] + 2\mathcal{F}(X). \tag{3.3}$$

Our first convergence result characterizes a set of initial values for which the solution of (3.2) will converge to the unique solution of (3.1).

THEOREM 3.1. *Adopt Assumptions* 1 *and* 2 *in* §1. *Suppose there exist* $X_1, X_2 \in \mathcal{P}(n)$ *with* $X_1 \leq X_2$ *such that*

$$\mathcal{F}(X_1) \geq X_1\mathcal{G}(X_1)X_1 \quad \textit{and} \quad \mathcal{F}(X_2) \leq X_2\mathcal{G}(X_2)X_2. \tag{3.4}$$

Then the solution Φ_i *of* (3.2) *converges to the solution* $\bar{X}$ *of* (3.1) *from any initial condition* Φ_0 *satisfying*

$$X_1 \le \Phi_0 \le X_2. \tag{3.5}$$

Proof. Let $\Phi_0^{(1)} = X_1$, $\Phi_0^{(2)} = X_2$, and Φ_0 satisfy (3.5). Then it follows from (2.3)–(2.4) in Lemma 2.1 that

$$\Phi_0^{(1)} \le \mathcal{R}(\Phi_0^{(1)}) = \Phi_1^{(1)} \quad \text{and} \quad \Phi_0^{(2)} \ge \mathcal{R}(\Phi_0^{(2)}) = \Phi_1^{(2)}.$$

Thus, making use of (2.2) in Lemma 2.1 leads to

$$\Phi_0^{(1)} \le \Phi_1^{(1)} \le \Phi_1^{(2)} \le \Phi_0^{(2)}.$$

By induction, the following relation is established

$$\Phi_0^{(1)} \le \Phi_1^{(1)} \le \cdots \le \Phi_k^{(1)} \le \Phi_k^{(2)} \le \cdots \le \Phi_1^{(2)} \le \Phi_0^{(2)} \quad \forall\, k \ge 1. \tag{3.6}$$

Therefore, $\lim_{k\to\infty} \Phi_k^{(1)}$ and $\lim_{k\to\infty} \Phi_k^{(2)}$ exist and are in $\mathcal{P}(n)$ because $\{\Phi_k^{(1)}\}$ and $\{\Phi_k^{(2)}\}$ are bounded above by $\Phi_0^{(2)}$ and below by $\Phi_0^{(1)}$, respectively. Consequently, these two limits satisfy $\mathcal{R}(X) = X$ and therefore are solutions of (3.1) because of (2.5) in Lemma 2.1. By Assumption 2, it turns out that

$$\lim_{k\to\infty} \Phi_k^{(1)} = \lim_{k\to\infty} \Phi_k^{(2)} = \bar{X}. \tag{3.7}$$

Further, note that $\Phi_0^{(1)} \le \Phi_0 \le \Phi_0^{(2)}$. Hence, again by induction and using (2.2) in Lemma 2.1, there results

$$\Phi_k^{(1)} \le \Phi_k \le \Phi_k^{(2)}, \quad \forall\, k \ge 0.$$

This together with (3.7) yields that $\lim_{k\to\infty} \Phi_k = \bar{X}$. □

Remark 3.1. It is worth mentioning that Theorem 3.1 is still valid if (3.5) is replaced with the existence of an integer $N \ge 0$ such that

$$X_1 \le \Phi_N \le X_2. \tag{3.8}$$

Remark 3.2. Observe that (3.1) is equivalent to

$$\mathcal{F}_\alpha(X) - X\mathcal{G}_\alpha(X)X = 0, \qquad X \in \mathcal{P}(n), \tag{3.9}$$

where $\mathcal{F}_\alpha(X) \triangleq \mathcal{F}(X)/\alpha$ and $\mathcal{G}_\alpha(X) \triangleq \mathcal{G}(X)/\alpha$ for any $\alpha > 0$. This suggests that an infinite number of algorithms can be generated for (3.1) by substituting $\mathcal{F}_\alpha$ and $\mathcal{G}_\alpha$ for $\mathcal{F}$ and $\mathcal{G}$ and setting different values to α. Naturally, we might expect α to play some role in achieving a satisfactory convergence rate. Later simulation results do demonstrate that a suitable choice of α can significantly speed up the convergence of the algorithm.

Because the equation

$$\mathcal{G}(Y^{-1}) - Y\mathcal{F}(Y^{-1})Y = 0, \qquad Y \in \mathcal{P}(n) \tag{3.10}$$

is equivalent to (3.1) with $Y = X^{-1}$, it follows from Theorem 3.1 that the solution of the difference equation

$$\begin{aligned} \Sigma_{i+1} = {} & \Sigma_i - 2[\Sigma_i + \mathcal{G}(\Sigma_i^{-1})] \\ & \times [2\Sigma_i + \mathcal{G}(\Sigma_i^{-1}) + \mathcal{F}(\Sigma_i^{-1})^{-1}]^{-1}[\Sigma_i + \mathcal{G}(\Sigma_i^{-1})] + 2\mathcal{G}(\Sigma_i^{-1}) \end{aligned} \tag{3.11}$$

converges to $\bar{X}$ from the initial condition $\Sigma_0 = \Phi_0^{-1}$, where Φ_0 satisfies (3.5). What is more interesting is the following result.

THEOREM 3.2 *With the same hypotheses and notation as in Theorem* 3.1, *let* Σ_i *denote the solution of the difference equation* (3.11) *with the initial condition* $\Sigma_0 = \Phi_0^{-1}$. *Then there holds*

$$\Phi_i \Sigma_i = I, \qquad i = 0, 1, \ldots. \tag{3.12}$$

Proof. Simple matrix manipulations yield

$$\begin{aligned} \Phi_{i+1} &= 2\{[\Phi_i + \mathcal{F}(\Phi_i)]^{-1} + [\Phi_i + \mathcal{G}(\Phi_i)^{-1}]^{-1}\}^{-1} - \Phi_i \\ &= \{2\{[I + \mathcal{F}(\Phi_i)\Phi_i^{-1}]^{-1} + [I + \mathcal{G}(\Phi_i)^{-1}\Phi_i^{-1}]^{-1}\}^{-1} - I\}\Phi_i \\ &= \{[I + \Phi_i \mathcal{F}(\Phi_i)^{-1}]^{-1} + [I + \Phi_i \mathcal{G}(\Phi_i)]^{-1}\} \end{aligned} \tag{3.13}$$

$$\times\{[I + \mathcal{F}(\Phi_i)\Phi_i^{-1}]^{-1} + [I + \mathcal{G}(\Phi_i)^{-1}\Phi_i^{-1}]^{-1}\}^{-1}\Phi_i. \tag{3.14}$$

Similarly, we have

$$\begin{aligned} \Sigma_{i+1} = \Sigma_i\{&[I + \mathcal{G}(\Sigma_i^{-1})^{-1}\Sigma_i]^{-1} + [I + \mathcal{F}(\Sigma_i^{-1})\Sigma_i]^{-1}\} \\ &\times\{[I + \Sigma_i^{-1}\mathcal{G}(\Sigma_i^{-1})]^{-1} + [I + \Sigma_i^{-1}\mathcal{F}(\Sigma_i^{-1})^{-1}]^{-1}\}^{-1}. \end{aligned} \tag{3.15}$$

Quite obviously, $\Phi_k \Sigma_k = I$ implies $\Phi_{k+1}\Sigma_{k+1} = I$. Thus, by induction, (3.12) is proved. □

Note that implementing (3.2) requires computation of the values of the operators $\mathcal{F}$ and $\mathcal{G}$ at each iteration. However, in some situations, the operators $\mathcal{F}$ and $\mathcal{G}$ may be so complicated that evaluating them is too time consuming if not impossible, which severely diminishes the efficiency of the algorithm. On the other hand, it is sometimes possible to approximate $\mathcal{F}$ and $\mathcal{G}$ by simpler operators somehow. In this case, it does not seem unreasonable to calculate the approximate values of $\mathcal{F}$ and $\mathcal{G}$ instead at each iteration. Let us now consider this strategy and address the related convergence issue in detail.

Assume that there exist two continuous operators

$$\mathcal{S} : \mathcal{Q}(k) \times \mathcal{P}(n) \mapsto \mathcal{Q}(k) \quad \text{and} \quad \mathcal{T} : \mathcal{Q}(l) \times \mathcal{P}(n) \mapsto \mathcal{Q}(l),$$

and two constant matrices $K \in \mathbb{R}^{k\times n}$, $L \in \mathbb{R}^{l\times n}$ such that we have the following assumptions.

Assumption 3. $\mathcal{S}$ is nondecreasing with respect to each of its arguments, and $\mathcal{T}$ is nondecreasing with respect to its first argument and nonincreasing with respect to its second argument.

Assumption 4. For any given $X \in \mathcal{P}(n)$, the equations

$$U = \mathcal{S}(U, X) \quad \text{and} \quad V = \mathcal{T}(V, X) \tag{3.16}$$

have unique solutions $U(X) \in \mathcal{Q}(k)$ and $V(X) \in \mathcal{Q}(l)$, which satisfy

$$\mathcal{F}(X) = K'U(X)K \quad \text{and} \quad \mathcal{G}(X) = L'V(X)L. \tag{3.17}$$

With these assumptions, we suggest the following modified algorithm for solving (3.1):

$$\begin{aligned} \Psi_{i+1} = \Psi_i &- 2(\Psi_i + K'U_iK) \times [2\Psi_i + K'U_iK + (L'V_iL)^{-1}]^{-1} \\ &\cdot(\Psi_i + K'U_iK) + 2K'U_iK, \end{aligned} \tag{3.18}$$

$$U_{i+1} = \mathcal{S}(U_i, \Psi_i), \tag{3.19}$$

$$V_{i+1} = \mathcal{T}(V_i, \Psi_i). \tag{3.20}$$

Its convergence property is stated below.

THEOREM 3.3. *Consider the system of difference equations* (3.18)–(3.20) *with the initial condition* $(P_0, U_0, V_0) \in \mathcal{P}(n) \times \mathcal{Q}(k) \times \mathcal{Q}(l)$. *Let Assumptions* 2–4 *be enforced. Suppose that there exist* X_1, $X_2 \in \mathcal{P}(n)$ *with* $X_1 \leq X_2$ *such that* (3.4) *is met. If there exists an integer* $N \geq 0$ *such that*

$$X_1 \leq \Psi_N \leq X_2, \quad U(X_1) \leq U_N \leq U(X_2), \quad V(X_2) \leq V_N \leq V(X_1), \tag{3.21}$$

there holds

$$\lim_{i \to \infty} (\Psi_i, U_i, V_i) = (\bar{X}, U(\bar{X}), V(\bar{X})). \tag{3.22}$$

Proof. Without loss of generality we assume $N = 0$. Put

$$(\Psi_0^{(1)}, U_0^{(1)}, V_0^{(1)}) \triangleq (X_1, U(X_1), V(X_1)) \text{ and } (\Psi_0^{(2)}, U_0^{(2)}, V_0^{(2)}) \triangleq (X_2, U(X_2), V(X_2)).$$

Then it is obvious that

$$U_0^{(2)} = \mathcal{S}(U_0^{(2)}, \Psi_0^{(2)}) = U_1^{(2)} \quad \text{and} \quad V_0^{(2)} = \mathcal{T}(V_0^{(2)}, \Psi_0^{(2)}) = V_1^{(2)}.$$

By (2.4) of Lemma 2.1, it follows from the second inequality of (3.4) that

$$\Psi_1^{(2)} = \mathcal{R}(\Psi_0^{(2)}) \leq \Psi_0^{(2)}.$$

Now assume that for some positive integer m,

$$\Psi_m^{(2)} \leq \Psi_{m-1}^{(2)}, \quad U_m^{(2)} \leq U_{m-1}^{(2)}, \quad V_m^{(2)} \geq V_{m-1}^{(2)}. \tag{3.23}$$

Then by Corollary 2.1, we have $\Psi_{m+1}^{(2)} \leq \Psi_m^{(2)}$. Moreover,

$$\begin{aligned} U_{m+1}^{(2)} &= \mathcal{S}(U_m^{(2)}, \Psi_m^{(2)}) \leq \mathcal{S}(U_{m-1}^{(2)}, \Psi_{m-1}^{(2)}) = U_m^{(2)}, \\ V_{m+1}^{(2)} &= \mathcal{T}(V_m^{(2)}, \Psi_m^{(2)}) \geq \mathcal{T}(V_{m-1}^{(2)}, \Psi_m^{(2)}) \geq V_m^{(2)}. \end{aligned}$$

Therefore by induction, (3.23) is valid for any integer $m \geq 0$. In the same manner, it can be shown that

$$\Psi_m^{(1)} \geq \Psi_{m-1}^{(1)}, \quad U_m^{(1)} \geq U_{m-1}^{(1)}, \quad V_m^{(1)} \leq V_{m-1}^{(1)}, \quad m = 1, 2, \ldots. \tag{3.24}$$

Again from Corollary 2.1 together with (3.21), it can be inductively established that

$$\Psi_i^{(1)} \leq \Psi_i \leq \Psi_i^{(2)}, \quad U_1^{(1)} \leq U_i \leq U_i^{(2)}, \quad V_i^{(2)} \leq V_i \leq V_i^{(1)}, \quad i = 0, 1, \ldots. \tag{3.25}$$

As a consequence of (3.23)–(3.25), it follows that

$$\Psi_0^{(1)} \leq \Psi_1^{(1)} \leq \cdots \leq \Psi_i^{(1)} \leq \Psi_i \leq \Psi_i^{(2)} \leq \cdots \leq \Psi_1^{(2)} \leq \Psi_0^{(2)}, \tag{3.26}$$

$$U_0^{(1)} \leq U_1^{(1)} \leq \cdots \leq U_i^{(1)} \leq U_i \leq U_i^{(2)} \leq \cdots \leq U_2^{(1)} \leq U_0^{(2)}, \tag{3.27}$$

$$V_0^{(2)} \leq V_1^{(2)} \leq \cdots \leq V_i^{(2)} \leq V_i \leq V_i^{(1)} \leq \cdots \leq V_1^{(1)} \leq V_0^{(1)}, \tag{3.28}$$

which imply that the limit

$$\lim_{i\to\infty}(\Psi_i^{(j)}, U_i^{(j)}, V_i^{(j)})$$

exists and is in $\mathcal{P}(n)\times\mathcal{Q}(k)\times\mathcal{Q}(l)$ for $j=1,2$. Let $(\Psi^{(j)}, U^{(j)}, V^{(j)})$ denote the limit. By continuity of the operators $\mathcal{S}$ and $\mathcal{T}$ and invertibility of $L'V^{(j)}L$, $(\Psi^{(j)}, U^{(j)}, V^{(j)})$ is a fixed point of the system of difference equations (3.18)–(3.20). In particular, we have

$$U^{(j)} = \mathcal{S}(U^{(j)}, \Psi^{(j)}) \quad \text{and} \quad V^{(j)} = \mathcal{T}(V^{(j)}, \Psi^{(j)}) \tag{3.29}$$

which, by Assumption 4, leads to

$$\mathcal{F}(\Psi^{(j)}) = K'U^{(j)}K \quad \text{and} \quad \mathcal{G}(\Psi^{(j)}) = L'V^{(j)}L.$$

It turns out that $\Psi^{(j)} = \mathcal{R}(\Psi^{(j)})$, that is, $\Psi^{(j)}$ satisfies (3.1). By Assumption 2, there results $\Psi^{(j)} = \bar{X}$. This together with (3.29) gives rise to

$$(\Psi^{(j)}, U^{(j)}, V^{(j)}) = (\bar{X}, U(\bar{X}), V(\bar{X})), \qquad j=1,2.$$

Therefore, again from (3.26)–(3.28), (3.22) follows. □

COROLLARY 3.1. *With the same hypotheses as in Theorem* 3.1, *the solution of the second-order difference equation*

(3.30)

$$\Phi_{i+1} = \Phi_i - 2[\Phi_i + \mathcal{F}(\Phi_{i-1})][2\Phi_i + \mathcal{F}(\Phi_{i-1}) + \mathcal{G}(\Phi_{i-1})^{-1}]^{-1}[\Phi_i + \mathcal{F}(\Phi_{i-1})] + 2\mathcal{F}(\Phi_{i-1})$$

converges to the solution $\bar{X}$ *of* (3.1) *from any initial condition* $(\Phi_{-1}, \Phi_0) \in \mathcal{P}(n)\times\mathcal{P}(n)$ *satisfying*

$$X_1 \le \Phi_{-1}, \qquad \Phi_0 \le X_2, \tag{3.31}$$

with X_1, X_2 *given as in Theorem* 3.1.

Proof. Consider the system of difference equations (3.18)–(3.20) with

$$(\Psi_0, U_0, V_0) = (\Phi_0, \mathcal{F}(\Phi_{-1}), \mathcal{G}(\Phi_{-1})) \tag{3.32}$$

and

$$S(U,X) \triangleq \mathcal{F}(X), \qquad \mathcal{T}(V,X) \triangleq \mathcal{G}(X), \qquad K = L = I. \tag{3.33}$$

Then it is straightforward to check that $\Psi_i = \Phi_i$ for all $i \ge 0$, where Ψ_i denotes the first component of the solution of (3.18)–(3.20) and Φ_i is the solution of (3.30). It is also trivial to see that the operators $\mathcal{S}$ and $\mathcal{T}$ fulfill Assumptions 3 and 4. Finally, note that

$$\mathcal{F}(X_1) \le U_0 \le \mathcal{F}(X_2) \quad \text{and} \quad \mathcal{G}(X_2) \le V_0 \le \mathcal{G}(X_1). \tag{3.34}$$

Thus, by Theorem 3.3, it is concluded that

$$\lim_{i\to\infty}\Phi_i = \lim_{i\to\infty}\Psi_i = \bar{X}. \qquad \square$$

Remark 3.3. By using a similar argument, Theorem 3.1 can also be proved as a consequence of Theorem 3.3.

4. Iterative computation of L^2-sensitivity optimal realizations and Euclidean norm-balancing realizations. In this section, we apply the established general results to two specific problems in system realization theory. One problem is to find L^2-sensitivity optimal realizations of a given system and the other is to find Euclidean norm-balancing realizations. Several iterative algorithms are proposed and proved to possess the convergence property.

Now consider a discrete-time, single-input–single-output, stable system with a transfer function $H(z)$ of order n. Assume that $H(z)$ has an initial minimal realization as follows:

$$\left[\begin{array}{c|c} A & b \\ \hline c & d \end{array}\right] \triangleq c(zI - A)^{-1}b + d. \tag{4.1}$$

The L^2-sensitivity index of the system $H(z)$ with respect to the realization (A, b, c, d) is defined by

$$\Gamma_1(A, b, c) \triangleq \left\| \frac{\partial H}{\partial A} \right\|_2^2 + \left\| \frac{\partial H}{\partial b} \right\|_2^2 + \left\| \frac{\partial H}{\partial c} \right\|_2^2 \tag{4.2}$$

$$= \frac{1}{2\pi i}\text{trace}\left\{ \oint [\mathcal{A}(z)\mathcal{A}(z)^* + \mathcal{B}(z)\mathcal{B}(z)^* + \mathcal{C}(z)^*\mathcal{C}(z)]\frac{dz}{z} \right\}, \tag{4.3}$$

where

$$\mathcal{A}(z) = \left[\begin{array}{cc|c} A & bc & 0 \\ 0 & A & I \\ \hline I & 0 & 0 \end{array}\right], \quad \mathcal{B}(z) = \left[\begin{array}{c|c} A & b \\ \hline I & 0 \end{array}\right], \quad \mathcal{C}(z) = \left[\begin{array}{c|c} A & I \\ \hline c & 0 \end{array}\right]. \tag{4.4}$$

The L^2-sensitivity minimization problem is to find a similarity transformation T so that the L^2-sensitivity index $\Gamma_1(TAT^{-1}, Tb, cT^{-1})$ of $H(z)$ with respect to the transformed realization is minimized. Regarding this problem, we summarize the main known facts from [1] as follows.

Fact 1. $\Gamma_1(TAT^{-1}, Tb, cT^{-1})$ achieves its minimum at $T = T_0$ if and only if $T_0'T_0$ is an equilibrium point of the differential equation

$$\begin{aligned} \dot{P}(t) = \frac{1}{2\pi i} \oint \{ & P(t)^{-1}[\mathcal{A}(z)^*P(t)\mathcal{A}(z) + \mathcal{C}(z)^*\mathcal{C}(z)]P(t)^{-1} \\ & - \mathcal{A}(z)P(t)^{-1}\mathcal{A}(z)^* - \mathcal{B}(z)\mathcal{B}(z)^*\}\frac{dz}{z}. \end{aligned} \tag{4.5}$$

Fact 2. Equation (4.5) has a unique equilibrium $\bar{P}$ in $\mathcal{P}(n)$.

Fact 3. The solution $P(t)$ of (4.5) exponentially converges to $\bar{P}$ from any initial value $P(0) \in \mathcal{P}(n)$.

Although Fact 3 suggests that the equilibrium $\bar{P}$ can be found by solving an initial value problem associated with (4.5), this method lacks computational efficiency and can be numerically ill conditioned, especially when the order n of the system is high.

A similar situation arises when we try to minimize the Euclidean norm defined by

$$\Gamma_2(A, b, c) \triangleq \text{trace}(AA' + bb' + c'c) \tag{4.6}$$

with respect to realizations of $H(z)$. There are three analogous facts [3], but here the relevant equation is

$$\dot{P}(t) = P(t)^{-1}[A'P(t)A + c'c]P(t)^{-1} - AP(t)^{-1}A' - bb'. \tag{4.7}$$

Although (4.7) looks much simpler than (4.5), likewise a computationally attractive method to find its unique equilibrium point has not been proposed.

We are in a position to present several iterative algorithms for finding the unique solution to the matrix equation

(4.8)

$$\frac{1}{2\pi i}\oint\{P^{-1}[\mathcal{A}(z)^*P\mathcal{A}(z)+\mathcal{C}(z)^*\mathcal{C}(z)]P^{-1}-\mathcal{A}(z)P^{-1}\mathcal{A}(z)^*-\mathcal{B}(z)\mathcal{B}(z)^*\}\frac{dz}{z}=0.$$

PROPOSITION 4.1. *Given the initial minimal realization of* $H(z)$ *as in* (4.1) *with* $\bar{P}$ *denoting the solution of* (4.8), *define*

$$W_c(P)\triangleq\frac{1}{2\pi i}\oint[\mathcal{A}(z)P^{-1}\mathcal{A}(z)^*+\mathcal{B}(z)\mathcal{B}(z)^*]\frac{dz}{z}, \tag{4.9}$$

$$W_o(P)\triangleq\frac{1}{2\pi i}\oint[\mathcal{A}(z)^*P\mathcal{A}(z)+\mathcal{C}(z)^*\mathcal{C}(z)]\frac{dz}{z}. \tag{4.10}$$

Let Φ_i *be the solution of the first-order difference equation*

$$\begin{aligned}\Phi_{i+1}&=\Phi_i-2[\Phi_i+W_o(\Phi_i)/\alpha]\\&\quad\times[2\Phi_i+W_o(\Phi_i)/\alpha+\alpha W_c(\Phi_i)^{-1}]^{-1}[\Phi_i+W_o(\Phi_i)/\alpha]+2W_o(\Phi_i)/\alpha\end{aligned} \tag{4.11}$$

from an initial condition $\Phi_0\in\mathcal{P}(n)$ *and* Π_i *the solution of the second-order difference equation*

(4.12)

$$\begin{aligned}\Pi_{i+1}&=\Pi_i-2[\Pi_i+W_o(\Pi_{i-1})/\alpha]\\&\quad\times[2\Pi_i+W_o(\Pi_{i-1})/\alpha+\alpha W_c(\Pi_{i-1})^{-1}]^{-1}[\Pi_i+W_o(\Pi_{i-1})/\alpha]+2W_o(\Pi_{i-1})/\alpha\end{aligned}$$

from $(\Pi_{-1},\Pi_0)\in\mathcal{P}(n)\times\mathcal{P}(n)$, *where* α *is any fixed positive constant. Then there holds*

$$\lim_{i\to\infty}\Phi_i=\lim_{i\to\infty}\Pi_i=\bar{P}. \tag{4.13}$$

Proof. Letting

$$\mathcal{F}(P)=W_o(P)/\alpha\quad\text{and}\quad\mathcal{G}(P)=W_c(P)/\alpha, \tag{4.14}$$

we can easily see that both $\mathcal{F}(P)$ and $\mathcal{G}(P)^{-1}$ are nondecreasing and continuous with respect to $P\in\mathcal{P}(n)$ and that $\bar{P}$ is the unique solution of $\mathcal{F}(P)=P\mathcal{G}(P)P$ in $\mathcal{P}(n)$. Because for any fixed $P\in\mathcal{P}(n)$ there hold

$$\lim_{\mu\to0^+}[\mathcal{F}(\mu P)-(\mu P)\mathcal{G}(\mu P)(\mu P)]=\frac{1}{2\pi\alpha i}\oint\mathcal{C}(z)^*\mathcal{C}(z)\frac{dz}{z}>0, \tag{4.15}$$

$$\lim_{\nu\to+\infty}[\mathcal{F}(\nu P)-(\nu P)\mathcal{G}(\nu P)(\nu P)]/\nu^2=-\frac{1}{2\pi\alpha i}\oint P\mathcal{B}(z)\mathcal{B}(z)^*P\frac{dz}{z}<0. \tag{4.16}$$

Thus, the theorem follows by directly applying Theorem 3.1 and Corollary 3.1. □

Remark 4.1. It is readily seen from Theorem 3.2 that the algorithm

(4.17)

$$\begin{aligned}\Sigma_{i+1} = \Sigma_i &- 2[\Sigma_i + W_c(\Sigma_i^{-1})/\alpha] \\ &\times [2\Sigma_i + W_c(\Sigma_i^{-1})/\alpha + \alpha W_o(\Sigma_i^{-1})^{-1}]^{-1}[\Sigma_i + W_c(\Sigma_i^{-1})/\alpha] + 2W_c(\Sigma_i^{-1})/\alpha\end{aligned}$$

with the initial value $\Sigma_0 \in \mathcal{P}(n)$ also provides an alternative way to compute the equilibrium $\bar{P}$.

Note that the calculation of $W_c(P)$ and $W_o(P)$ inevitably involves intensive iterations given a P. To overcome this drawback, we propose the following modified algorithm, which only needs to evaluate much simpler expressions than $W_c(P)$ and $W_o(P)$ at each iteration.

PROPOSITION 4.2. *Adopt the same hypotheses and notation as in Proposition* 4.1. *Then for any given* $\alpha > 0$ *and initial condition* $(\Psi_0, U_0, V_0) \in \mathcal{P}(n) \times \mathcal{P}(2n) \times \mathcal{P}(2n)$, *the solution* (Ψ_i, U_i, V_i) *of the system of difference equations*

(4.18)

$$\begin{aligned}\Psi_{i+1} = \Psi_i &- 2(\Psi_i + U_i^{11}/\alpha) \\ &\times [2\Psi_i + U_i^{11}/\alpha + \alpha(V_i^{11})^{-1}]^{-1}(\Psi_i + U_i^{11}/\alpha) + 2U_i^{11}/\alpha,\end{aligned}$$

(4.19)

$$U_{i+1} \triangleq \begin{bmatrix} U_{i+1}^{11} & U_{i+1}^{12} \\ U_{i+1}^{21} & U_{i+1}^{22} \end{bmatrix} = \begin{bmatrix} A' & c'b' \\ 0 & A' \end{bmatrix} \begin{bmatrix} U_i^{11} & U_i^{12} \\ U_i^{21} & U_i^{22} \end{bmatrix} \begin{bmatrix} A & 0 \\ bc & A \end{bmatrix} + \begin{bmatrix} c'c & 0 \\ 0 & \Psi_i \end{bmatrix},$$

(4.20)

$$V_{i+1} \triangleq \begin{bmatrix} V_{i+1}^{11} & V_{i+1}^{12} \\ V_{i+1}^{21} & V_{i+1}^{22} \end{bmatrix} = \begin{bmatrix} A & bc \\ 0 & A \end{bmatrix} \begin{bmatrix} V_i^{11} & V_i^{12} \\ V_i^{21} & V_i^{22} \end{bmatrix} \begin{bmatrix} A' & 0 \\ c'b' & A' \end{bmatrix} + \begin{bmatrix} bb' & 0 \\ 0 & \Psi_i^{-1} \end{bmatrix}$$

converges to its unique fixed point $(\bar{P}, \bar{U}, \bar{V}) \in \mathcal{P}(n) \times \mathcal{P}(2n) \times \mathcal{P}(2n)$.

Proof. Define the operators $\mathcal{S}$ and $\mathcal{T}$ on $\mathcal{Q}(2n) \times \mathcal{P}(n)$ by

(4.21)

$$\mathcal{S}(U, X) \triangleq \begin{bmatrix} A' & c'b' \\ 0 & A' \end{bmatrix} U \begin{bmatrix} A & 0 \\ bc & A \end{bmatrix} + \begin{bmatrix} c'c & 0 \\ 0 & X \end{bmatrix},$$

(4.22)

$$\mathcal{T}(V, X) \triangleq \begin{bmatrix} A & bc \\ 0 & A \end{bmatrix} V \begin{bmatrix} A' & 0 \\ c'b' & A' \end{bmatrix} + \begin{bmatrix} bb' & 0 \\ 0 & X^{-1} \end{bmatrix},$$

and let $L = K = \begin{bmatrix} I \\ 0 \end{bmatrix} \in \mathbb{R}^{2n \times n}$ with I an $n \times n$ identity matrix. Because (A, b, c) is minimal, the operators $\mathcal{S}$ and $\mathcal{T}$ continuously map $\mathcal{P}(2n) \times \mathcal{P}(n)$ into $\mathcal{P}(2n)$. Quite obviously, $\mathcal{S}$ and $\mathcal{T}$ meet Assumption 3 in the previous section. Moreover, it is clear that the Lyapunov equations

$$U = \mathcal{S}(U, X) \quad \text{and} \quad V = \mathcal{S}(V, X)$$

have unique solutions $U(X) \in \mathcal{P}(2n)$ and $V(X) \in \mathcal{P}(2n)$ for any $X \in \mathcal{P}(n)$. In addition to this, it is known from [5] that

$$\mathcal{F}(X) = K'U(X)K \quad \text{and} \quad \mathcal{G}(X) = L'V(X)L,$$

where $\mathcal{F}(\cdot)$ and $\mathcal{G}(\cdot)$ are defined as in (4.14). Thus, Assumption 4 is fulfilled.

Next, it is routine to check inductively that $\Psi_i > 0$ for all $i \geq 0$. Hence, from (i) of Lemma 2.3, there exists an integer k_1 such that

$$U_i^{11}, V_i^{11} > \beta I, \quad \forall\, i \geq k_1 \tag{4.23}$$

for some constant $\beta > 0$. By Corollary 2.1, this implies that $\Psi_i > (\beta/\alpha)I$ for all $i > k_1$. Making use of (ii) of Lemma 2.3 yields that there exists $k_2 > k_1$ such that

$$U_i > \tilde{U} \quad \text{and} \quad V_i > \tilde{V}, \quad \forall\, i \geq k_2, \tag{4.24}$$

where $\tilde{U}$ and $\tilde{V}$ are the solutions to the Lyapunov equations

$$U = \begin{bmatrix} A' & c'b' \\ 0 & A' \end{bmatrix} U \begin{bmatrix} A & 0 \\ bc & A \end{bmatrix} + \begin{bmatrix} c'c & 0 \\ 0 & 0 \end{bmatrix}, \tag{4.25}$$

$$V = \begin{bmatrix} A & bc \\ 0 & A \end{bmatrix} V \begin{bmatrix} A' & 0 \\ c'b' & A' \end{bmatrix} + \begin{bmatrix} bb' & 0 \\ 0 & 0 \end{bmatrix}, \tag{4.26}$$

respectively. Now by Lemma 2.2, for sufficiently small $\mu > 0$ and sufficiently large $\nu > 0$ there hold

$$U_{k_2} < U(\nu I) \quad \text{and} \quad V_{k_2} < V(\mu I). \tag{4.27}$$

Because

$$\lim_{\mu \to 0} U(\mu I) = \tilde{U} \quad \text{and} \quad \lim_{\nu \to \infty} V(\nu I) = \tilde{V}, \tag{4.28}$$

it is seen from (4.24) that for sufficiently small $\mu > 0$ and sufficiently large $\nu > 0$ there hold

$$U_{k_2} > U(\mu I) \quad \text{and} \quad V_{k_2} > V(\nu I). \tag{4.29}$$

Also, it is clear that

$$\mu I < \Psi_{k_2} < \nu I \tag{4.30}$$

for sufficiently small $\mu > 0$ and sufficiently large $\nu > 0$. In view of (4.15)–(4.16), a direct application of Theorem 3.3 leads to

$$\lim_{i \to \infty} (\Psi_i, U_i, V_i) = (\bar{P}, U(\bar{P}), V(\bar{P})). \qquad \square$$

Finally, regarding the Euclidean norm-balancing problem with an initial minimal realization (A, B, C), we claim that with the new definitions

$$W_o(P) \triangleq A'PA + C'C \quad \text{and} \quad W_c(P) \triangleq AP^{-1}A' + BB', \tag{4.31}$$

(4.11) and (4.12) are convergent to the unique solution $\mathbb{P}$ of

$$(A'PA + C'C) - P(AP^{-1}A' + BB')P = 0 \tag{4.32}$$

in $\mathcal{P}(n)$. In fact, it suffices to verify by Theorem 3.1 that for any $P \in \mathcal{P}(n)$ there exist P_1, $P_2 \in \mathcal{P}(n)$ with $P_1 \leq P \leq P_2$ such that

$$W_o(P_1) \geq P_1 W_c(P_1) P_1 \quad \text{and} \quad W_o(P_2) \leq P_2 W_c(P_2) P_2. \tag{4.33}$$

However, this is true upon noting that

$$\begin{aligned} W_o(\mu\mathbb{P}) - (\mu\mathbb{P})W_c(\mu\mathbb{P})(\mu\mathbb{P}) &= \mu A'\mathbb{P}A + C'C - \mu^2\mathbb{P}(\mu^{-1}A\mathbb{P}^{-1}A' + BB')\mathbb{P} \\ &= \mu(A'\mathbb{P}A - \mathbb{P}A\mathbb{P}^{-1}A'\mathbb{P}) + (C'C - \mu^2\mathbb{P}BB'\mathbb{P}) \\ &= \mu(\mathbb{P}BB'\mathbb{P} - C'C) + (C'C - \mu^2\mathbb{P}BB'\mathbb{P}) \\ &= (1-\mu)(C'C + \mu\mathbb{P}BB'\mathbb{P}). \end{aligned}$$

Hence, the claim is true.

5. A result on convergence rate. In this section we prove that the convergence of (4.11) is locally exponential by showing that their unique equilibrium is sink. In other words, the linearization of (4.11) at the equilibrium has all its eigenvalues in the open unit disk.

PROPOSITION 5.1. *The linearization of* (4.11) *is asymptotically stable at the fixed point* $\bar{P}$.

Proof. We might as well assume $\alpha = 1$. Now with

(5.1)

$$S_1(X) \triangleq [X + W_o(X)]^{-1}, \quad S_2(X) = [X + W_c(X)^{-1}]^{-1}, \quad T(X) = [S_1(X) + S_2(X)]^{-1},$$

(4.11) can be rewritten as

$$P_{i+1} = \mathcal{R}(P_i) \triangleq 2T(P_i) - P_i. \tag{5.2}$$

Note that $S_1(X), S_2(X), T(X)$ are defined for the realization (A, b, c). Accordingly, we can define $\mathbb{A}(z)$, $\mathbb{W}_o(X)$, and $\mathbb{S}_1$, and so on for the L^2-sensitivity optimal realization $(\bar{P}^{\frac{1}{2}}A\bar{P}^{-\frac{1}{2}}, \bar{P}^{\frac{1}{2}}b, c\bar{P}^{-\frac{1}{2}})$. Then it is routine to check the following relations:

$$\bar{P}^{\frac{1}{2}}S_1(\bar{P})\bar{P}^{\frac{1}{2}} = \mathbb{S}_1(I), \quad \bar{P}^{\frac{1}{2}}S_2(\bar{P})\bar{P}^{\frac{1}{2}} = \mathbb{S}_2(I), \quad \bar{P}^{-\frac{1}{2}}T(\bar{P})\bar{P}^{-\frac{1}{2}} = \mathbb{T}(I). \tag{5.3}$$

Because $\mathcal{R}(X)$ is an operator from $R^{n\times n}$ to $R^{n\times n}$, its Fréchet derivative at $X = \bar{P}$ is a linear operator from $R^{n\times n}$ to $R^{n\times n}$ given by

$$\begin{aligned} \mathcal{R}'(\bar{P})X = {} & 2T(\bar{P})\{S_1(\bar{P})[X + W_o'(\bar{P})X]S_1(\bar{P}) \\ & + S_2(\bar{P})[X - W_c(\bar{P})^{-1}W_c'(\bar{P})XW_c(\bar{P})^{-1}]S_2(\bar{P})\}T(\bar{P}) - X, \end{aligned} \tag{5.4}$$

with

(5.5)

$$W_o'(\bar{P})X = \frac{1}{2\pi i}\oint \mathcal{A}(z)^*X\mathcal{A}(z)\frac{dz}{z} \quad \text{and} \quad W_c'(\bar{P})X = -\frac{1}{2\pi i}\oint \mathcal{A}(z)\bar{P}^{-1}X\bar{P}^{-1}\mathcal{A}(z)^*\frac{dz}{z}.$$

Using (5.3), we have

(5.6)

$$\begin{aligned} & \bar{P}^{-\frac{1}{2}}[\mathcal{R}'(\bar{P})X]\bar{P}^{-\frac{1}{2}} \\ & \quad = 2\mathbb{T}(I)\{\mathbb{S}_1(I)\left[\bar{P}^{-\frac{1}{2}}X\bar{P}^{-\frac{1}{2}} + \frac{1}{2\pi i}\oint \mathcal{A}(z)^*(\bar{P}^{-\frac{1}{2}}X\bar{P}^{-\frac{1}{2}})\mathcal{A}(z)\frac{dz}{z}\right]\mathbb{S}_1(I) \\ & \qquad + \mathbb{S}_2(I)\left[\bar{P}^{-\frac{1}{2}}X\bar{P}^{-\frac{1}{2}} + \mathbb{W}_c(I)^{-1}\frac{1}{2\pi i}\oint \mathcal{A}(z)\bar{P}^{-\frac{1}{2}}X\bar{P}^{-\frac{1}{2}}\mathcal{A}(z)^*\frac{dz}{z}\mathbb{W}_c(I)^{-1}\right] \\ & \qquad \cdot \mathbb{S}_2(I)\}\mathbb{T}(I) - \bar{P}^{-\frac{1}{2}}X\bar{P}^{-\frac{1}{2}} \\ & \quad = \mathbb{R}'(I)(\bar{P}^{-\frac{1}{2}}X\bar{P}^{-\frac{1}{2}}), \end{aligned} \tag{5.6}$$

from which it is not hard to see that the linear operator $\mathcal{R}'(\bar{P})$ is asymptotically stable in the discrete time sense if and only if $\mathbb{R}'(I)$ is also. Because $\mathbb{W}_c(I) = \mathbb{W}_o(I)$, it follows that

$$\mathbb{R}'(I)X$$

$$= 2\mathbb{T}\mathbb{S}_1 \left[X + \mathbb{W}_o X \mathbb{W}_o + \frac{1}{2\pi i} \oint [\mathbb{A}(z)^* X \mathbb{A}(z) + \mathbb{A}(z) X \mathbb{A}(z)^*] \frac{dz}{z} \right] \mathbb{S}_1 \mathbb{T} - X \tag{5.7}$$

$$= 2\mathbb{S}_1 \left[X + \mathbb{W}_o X \mathbb{W}_o + \frac{1}{2\pi i} \oint [\mathbb{A}(z)^* X \mathbb{A}(z) + \mathbb{A}(z) X \mathbb{A}(z)^*] \frac{dz}{z} \right] \mathbb{S}_1 - X, \tag{5.8}$$

where $\mathbb{T}$ is understood to be $\mathbb{T}(I)$ and so on. Thus, the matrix representation of $\mathbb{R}'(I)$ is expressed by

$$2(\mathbb{S}_1 \otimes \mathbb{S}_1) \left\{ I + \mathbb{W}_o \otimes \mathbb{W}_o + \frac{1}{2\pi i} \oint [\mathbb{A}(z)^* \otimes \mathbb{A}(z)^\tau + \mathbb{A}(z) \otimes \mathbb{A}(\bar{z})] \frac{dz}{z} \right\} - I. \tag{5.9}$$

It remains to show that this matrix has all its eigenvalues in the open unit disk, which is equivalent to saying that so is the matrix

$$\Gamma \triangleq 2(\mathbb{S}_1^{1/2} \otimes \mathbb{S}_1^{1/2}) \left\{ I + \mathbb{W}_o \otimes \mathbb{W}_o + \frac{1}{2\pi i} \oint [\mathbb{A}(z)^* \otimes \mathbb{A}(z)^\tau + \mathbb{A}(z) \otimes \mathbb{A}(\bar{z})] \frac{dz}{z} \right\} \cdot (\mathbb{S}_1^{1/2} \otimes \mathbb{S}_1^{1/2}) - I.$$

Since Γ is symmetric and $\Gamma > -I$, it suffices to prove that $\Gamma < I$. To do this, note that

$$\begin{aligned}
&\Gamma < I \\
&\iff I + \mathbb{W}_o \otimes \mathbb{W}_o + \frac{1}{2\pi i} \oint [\mathbb{A}(z)^* \otimes \mathbb{A}(z)^\tau + \mathbb{A}(z) \otimes \mathbb{A}(\bar{z})] \frac{dz}{z} < \mathbb{S}_1^{-1} \otimes \mathbb{S}_1^{-1} \\
&\iff \frac{1}{2\pi i} \oint [\mathbb{A}(z)^* \otimes \mathbb{A}(z)^\tau + \mathbb{A}(z) \otimes \mathbb{A}(\bar{z})] \frac{dz}{z} < \mathbb{W}_o \otimes I + I \otimes \mathbb{W}_o \\
&\iff \frac{1}{2\pi i} \oint [\mathbb{A}(z)^* \otimes \mathbb{A}(z)^\tau + \mathbb{A}(z) \otimes \mathbb{A}(\bar{z})] \frac{dz}{z} \\
&\quad < \frac{1}{2\pi i} \oint [\mathbb{A}(z)^* \mathbb{A}(z) \otimes I^\tau + I \otimes \mathbb{A}(\bar{z}) \mathbb{A}(z)^\tau + \mathbb{C}(z)^* \mathbb{C}(z) \otimes I + I \otimes \mathbb{B}(z) \mathbb{B}(z)^*] \frac{dz}{z} \\
&\iff \frac{1}{2\pi i} \oint (\mathbb{A}(z) \otimes I - I \otimes \mathbb{A}(z)^\tau)^* (\mathbb{A}(z) \otimes I - I \otimes \mathbb{A}(z)^\tau) \frac{dz}{z} + \Sigma_o \otimes I + I \otimes \Sigma_c \\
&> 0,
\end{aligned}$$

where Σ_o and Σ_c denote the observability and controllability Gramians. Hence, it follows that $\Gamma < I$. □

6. Simulation results. The purpose of this section is to demonstrate the effectiveness of the algorithms proposed in the previous section by simulation on a SPARCstation. To do this, consider a specific minimal statespace realization (A, b, c) with

$$A = \begin{bmatrix} 0.5 & 0 & 1.0 \\ 0 & -0.25 & 0 \\ 0 & 0 & 0.1 \end{bmatrix}, \quad b - \begin{bmatrix} 0 \\ 1 \\ 2 \end{bmatrix}, \quad c = [1 \quad 5 \quad 10]. \tag{6.1}$$

Recall that there exists a unique positive definite matrix $\bar{P} \in \mathbb{R}^{3\times 3}$ such that the realization (TAT^{-1}, Tb, cT^{-1}) is L^2-sensitivity optimal for any similarity transformation T with $T'T =$

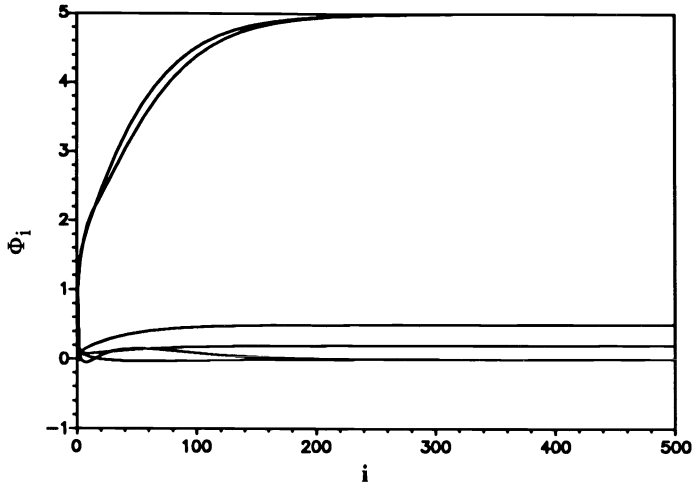

FIG. 6.1. *The trajectory of* Φ_i *of* (4.11) *with* $\alpha = 300$.

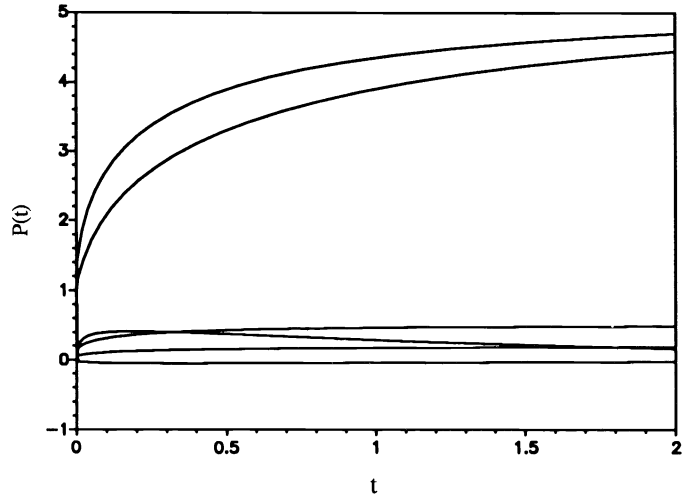

FIG. 6.2. *The trajectory of* $P(t)$ *of* (4.5).

$\bar{P}$. It turns out that $\bar{P}$ is exactly given by

$$\bar{P} = \begin{bmatrix} 0.2 & 0 & 0.5 \\ 0 & 5.0 & 0 \\ 0.5 & 0 & 5.0 \end{bmatrix}, \tag{6.2}$$

which indeed satisfies (4.8).

We first take (4.11) with $\alpha = 300$ and implement it starting from the identity matrix using MATLAB. The resulting trajectory Φ_i during the first 500 iterations is shown in Fig. 6.1 and is clearly seen to converge very fast to $\bar{P}$. The time taken for this implementation is less than three minutes. In contrast, if an ordinary differential equation (ODE) algorithm in MABLAB is used to solve (4.5) with the same initial condition, it is found that it takes about 45 minutes to compute the solution $P(t)$ on the time interval [0, 2], which is depicted in Fig. 6.2. In fact, more than 2,400 iterations are performed during that time interval. Even so, the solution does not appear to be close enough to $\bar{P}$ though it very slowly tends to $\bar{P}$.

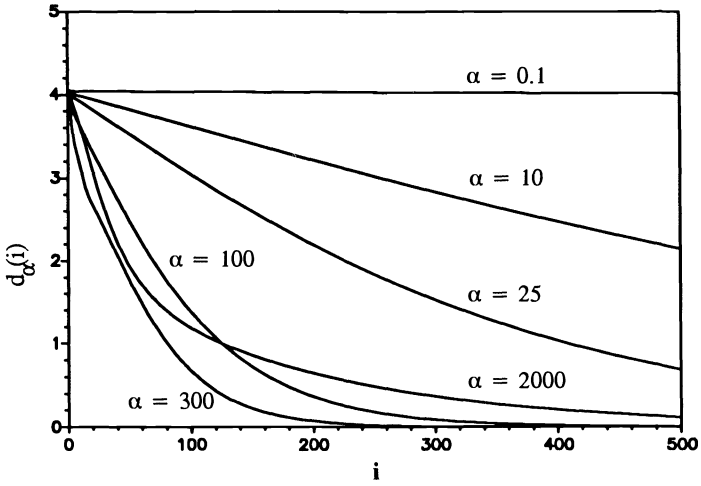

FIG. 6.3. *Effect of different* α *on the convergence rate of* (4.11).

Next, we examine the effect of α on the convergence rate (4.11). For this purpose, define the deviation between Φ_i and the true solution $\bar{P}$ in (6.2) as

$$d_\alpha(i) = \|\Phi_i - \bar{P}\|_2, \tag{6.3}$$

where $\|\cdot\|_2$ denotes the spectral norm of a matrix. Implement (4.11) with

$$\alpha = 0.1,\ 10,\ 25,\ 100,\ 300,\ 2000,$$

respectively, and depict the evolution of the associated deviation $d_\alpha(i)$ for each α in Fig. 6.3. Then we can see that $\alpha = 300$ is the best choice. In addition, as long as $\alpha \leq 300$, the larger α, the faster the convergence of the algorithm. On the other hand, it should be observed that a larger α is not always better than a smaller α and that too small an α can make the convergence extremely slow.

Finally, let us turn to two algorithms (4.12) and (4.18)–(4.20) with $\alpha = 300$. All the initial matrices required for the implementation are set to identity matrices of appropriate dimension. Define

$$f(i) = \|\Pi_i - \bar{P}\|_2 \quad \text{and} \quad g(i) = \|\Psi_i - \bar{P}\|_2$$

as the deviations from the true solution $\bar{P}$ for the two algorithms, respectively. Their evolutions are depicted in Fig. 6.4 and manifestly exhibit the convergence of the algorithms. Indeed, the algorithm (4.18)–(4.20) is fastest in terms of the execution time, but with the same number of iterations it does not produce a solution as satisfactory as (4.11) or (4.12).

Some concluding remarks are in order.

Remark 6.1. Adding a scalar factor to (4.5) does not help much in reducing the CPU time required for solving it on a digital computer.

Remark 6.2. Because α does play an important role in speeding up the algorithms, it is worthwhile to do further study to find some helpful guidelines for choosing a suitable α.

Remark 6.3. It appears that the proposed algorithms are quite robust against nonsymmetric or indefinite disturbances. This is demonstrated by implementing (4.11) with $\alpha = 300$ and the initial matrix

$$\Phi_0 = \begin{bmatrix} 1 & 10 & -10 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix},$$

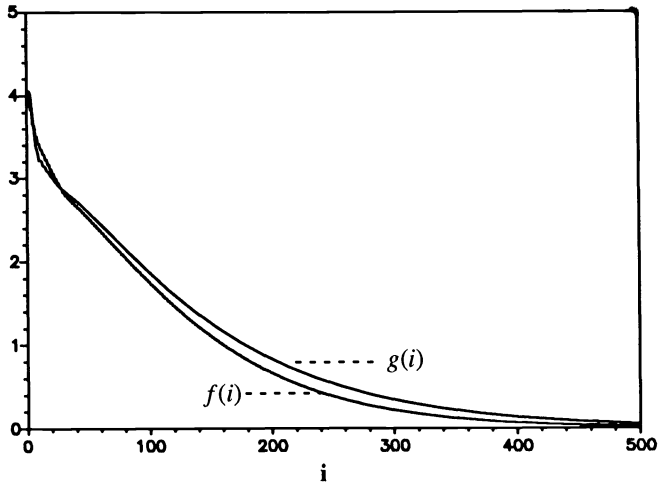

FIG. 6.4. *Convergence of algorithms* (4.12) *and* (4.18)–(4.20) *with* $\alpha = 300$.

which is obviously nonsymmetric and indefinite. It turns out that the effect of the nonsymmetry and indefiniteness almost completely vanishes after 30 iterations. Afterwards, the algorithm converges to $\bar{P}$ with no oscillatory behavior.

7. Conclusions. Two types of difference equation have been proposed and studied with the aim of solving a class of nonlinear matrix equations. The main contribution of this paper is twofold. First, we characterize a set of initial conditions from which the solution of the proposed difference equations is guaranteed to converge to the solution of the matrix equation of concern. Second, the general results have been successfully employed to derive a number of efficient iterative algorithms for finding L^2-sensitivity optimal realizations and Euclidean norm-balancing realizations. These algorithms are simple to implement without any requirement of step-size adjustment. Another feature of them is that their convergence rate can be significantly improved by proper choice of a constant scalar in advance. In addition, the convergence of one algorithm is locally exponential. The effectiveness of the algorithms are demonstrated by simulation.

OPTIMAL PROBLEMS FOR NONLINEAR PARABOLIC BOUNDARY CONTROL SYSTEMS*

H. O. FATTORINI† AND T. MURPHY†

Abstract. This paper considers optimal problems for boundary control systems with the control acting through a general nonlinear boundary condition. The problems include constraints on the control and target conditions. The final result is a version of Pontryagin's maximum principle. This setup covers such physical situations as Stefan–Boltzmann boundary conditions, and is based on an abstract theory of nonlinear programming problems.

Key words. boundary control systems, maximum principle, optimal control

AMS subject classifications. 93E20, 93E25

1. Introduction. Let Ω be a bounded domain with boundary $\partial\Omega$ in m-dimensional Euclidean space $\mathbb{R}^m$. We consider a boundary control system described by the heat equation in Ω,

$$y_t(t,x) = \Delta y(t,x) \qquad (x \in \Omega,\ 0 < t \leq T), \tag{1.1}$$

$$y(0,x) = \zeta(x), \qquad (x \in \Omega), \tag{1.2}$$

with a nonlinear boundary condition

$$\partial_\nu y(t,x) = g(t, y(t,x)) + u(t,x) \qquad (x \in \partial\Omega,\ 0 < t \leq T) \tag{1.3}$$

(∂_ν is the outer normal derivative at the boundary). Controls are taken in $L^\infty((0,T) \times \partial\Omega)$. The optimal control problem is that of minimizing a *cost functional* $y_0(t,u)$ among all controls satisfying a constraint

$$u(t,\cdot) \in U = \textit{ control set } \subseteq L^\infty(\partial\Omega) \qquad (0 \leq t \leq \bar{t}) \tag{1.4}$$

whose corresponding solutions $y(t,x,u)$ satisfy a *target condition*

$$y(\bar{t},\cdot,u) \in Y = \textit{target set } \subseteq C(\bar{\Omega}) \tag{1.5}$$

($C(\bar{\Omega})$ is the space of all continuous functions in $\bar{\Omega}$ endowed with the supremum norm). The time $\bar{t}$ at which the optimal process terminates may be fixed or free. A physically realistic instance is that where $m = 1$, 2, or 3 and the body Ω undergoes Stefan–Boltzmann cooling at the boundary,

$$\partial_\nu y(t,x) = -y(t,x)^4 + u(t,x) \qquad (x \in \partial\Omega,\ 0 < t \leq \bar{t}). \tag{1.6}$$

The term $u(t,x)$ represents heat applied at the boundary $\partial\Omega$ and satisfies constraints on $\partial\Omega$, for instance

$$0 \leq u(t,x) \leq 1 \qquad (x \in \partial\Omega,\ 0 \leq t \leq \bar{t}). \tag{1.7}$$

As a very particular case of the results in this paper, we obtain existence and necessary conditions for the time optimal problem under (1.6) and (1.7).

EXISTENCE THEOREM 1.1. *Assume that a control* $u(\cdot,\cdot) \in L^\infty((0,\bar{t})\times\Omega)$ *satisfying* (1.7) *almost everywhere and driving an initial state* $\zeta(\cdot) \in C(\bar{\Omega})$ *to a closed target set* $Y \subseteq C(\bar{\Omega})$ *exists. Then there exists a time optimal control* $\bar{u}(t,x)$.

THEOREM 1.2 (Pontryagin's maximum principle). *Let* $\bar{u}(\cdot,\cdot) \in L^\infty((0,\bar{t})\times\Omega)$ *be a time optimal control and* $y(t,x,\bar{u})$ *be the solution corresponding to* $\bar{u}$. *Let the target set* $Y \subseteq C(\bar{\Omega})$ *be defined by*

$$|y(x) - \bar{y}(x)| \le \varepsilon \quad (x \in \bar{\Omega}), \qquad y(x_j) = c_j \quad (j = 1,2,\dots,N),$$

where $\bar{y}(\cdot) \in C(\bar{\Omega})$, $\varepsilon > 0$, $x_j \in \bar{\Omega}$, *and the* c_j *are arbitrary constants. Then there exists a finite Borel measure* ν *in* $\bar{\Omega}$, $\nu \neq 0$, *such that*

$$\int_{\partial\Omega} z(t,x)\bar{u}(t,x)d\sigma = \max_{v\in L^\infty(\partial\Omega),0\le v(x)\le 1} \int_{\partial\Omega} z(t,x)v(x)d\sigma$$

almost everywhere in $0 \le t \le \bar{t}$ = *optimal time, where* $d\sigma$ *is the area differential in* $\partial\Omega$ *and* $z(t,x)$ *is the solution of the backwards problem*

$$z_t(t,x) = -\Delta z(t,x) \qquad (x \in \Omega,\ 0 \le t < \bar{t}), \tag{1.8}$$

$$z(\bar{t},\cdot) = \nu \qquad (x \in \bar{\Omega}), \tag{1.9}$$

$$z_\nu(t,x) = -4y(t,x,\bar{u})^3 z(t,x), \qquad (x \in \partial\Omega,\ 0 \le t < \bar{t}). \tag{1.10}$$

For a proof of (a more general version of) Theorem 1.2, see §6, where versions of Pontryagin's maximum principle are also given for other optimal problems; the proofs are based on an abstract theory of nonlinear programming problems in Banach spaces [10], [11], which generalizes some of the results in [16]. The earlier Hilbert space theory is in [7], [8], [14], [15]. Existence of optimal controls is treated in §4. We clarify in §§3 and 4 the definition of solutions of (1.1)–(1.3) and of other auxiliary equations (such as (1.8)–(1.10)), and compute in §5 the directional derivatives of the solution map $u \to y(t,y,u)$ needed to apply the abstract nonlinear programming theory. Finally, some open problems are pointed out in §6.

The method chosen to construct solutions of (1.1)–(1.3) is the classical one of integral equations with the Neumann function as kernel. It has been extensively used in boundary control problems for nonlinear parabolic equations, for instance in [30], [26], [28], [29], solutions taking instantaneous values in L^p or Sobolev spaces. The only novelty in our treatment may be that solutions take values in the space $C(\bar{\Omega})$. There are some advantages in this. The first is conceptual. If the equation describes a heat process, the supremum norm in $C(\bar{\Omega})$ is more natural than the $L^p(\Omega)$ norm—the latter allows for large temperature spikes possibly exceeding the melting point of the material and invalidating (1.1)–(1.3) as a model (of course, this could also be avoided via Sobolev norms). Also, the supremum norm allows us to use smaller target sets than L^p norms. The second advantage is one purely of convenience; the supremum norm allows easy treatment of continuous nonlinearities in the equation (no growth conditions needed), and trace theorems become trivial.

The reason the method of integral equations is preferred over others in this paper is that expressions for the solutions are formally similar to those for distributed parameter systems (see for instance [11]), so that proving continuity of the solution map and computing directional derivatives in §5 can be done in well-understood ways. On the other hand, the existence results that we obtain in this way for (1.1)–(1.3) are by no means the best available. For instance, much more general boundary conditions are dealt with in [1] and other papers of the same

author. Also, different approaches using monotonicity rather than Lipschitz continuity [2], [3] yield results for some nonsmooth nonlinearities.

A large number of recent papers examine boundary control problems for parabolic equations, and we have included some of them in the references. In the linear case, [5] deals with the time optimal problem with a point target (see comments at the end of §6). Optimal approximation in the supremum norm is studied in [18]; the results in [22] and [23] include target conditions as well as state constraints. In the nonlinear case, [26] deals with boundary conditions including (among many others) Stefan–Boltzmann; the problem is optimum approximation of a target. Similar problems in dimension ≥ 1 are considered in [27]. The integral equation approach is used in [30], [19], and (combined with semigroup methods) in [28]. Finally, many control problems, distributed parameter and boundary are outlined in [29] with a substantial bibliography.

In the one-dimensional case, the abstract nonlinear programming approach to optimal problems applied in this paper was outlined (but not carried out in detail) in [8].

2. The Neumann function. Because of hypoellipticity of the heat operator, any solution of

$$y_t(t,x) = \Delta y(t,x) \qquad ((t,x) \in \Omega \times (0,T]). \tag{2.1}$$

$$y(0,x) = \zeta(x) \qquad (x \in \Omega), \tag{2.2}$$

$$\partial_\nu y(t,x) = g(t,x) \qquad ((t,x) \in (0,T) \times \partial\Omega) \tag{2.3}$$

(∂_ν the outer normal derivative) is analytic in $(0,T] \times \Omega$. If $\zeta(\cdot)$ is continuous in $\bar{\Omega}$ and $g(\cdot,\cdot)$ is continuous in $[0,T] \times \partial\Omega$, a solution $y(t,x)$ is called *strong* or *classical* if it is continuous in $[0,T] \times \bar{\Omega}$, continuously differentiable in $((0,T] \times \bar{\Omega})$, and satisfies (2.1) in $(0,T] \times \Omega$, (2.2) in $\bar{\Omega}$, and (2.3) literally in $(0,T] \times \partial\Omega$; the normal derivative $\partial_\nu y(t,x)$ is assumed to be continuous in $[0,T] \times \partial\Omega$. A solution is *semistrong* if it is continuous in $[0,T] \times \bar{\Omega}$ and satisfies (2.1) in $(0,T] \times \Omega$ and (2.2) in $\bar{\Omega}$ where $\partial_\nu y(t,x)$ at a boundary point x is understood as the limit of $\partial_\nu y(t,\eta)$, where $\eta \to x$ in K, K any finite closed cone with vertex in x such that $K \subseteq \Omega$. Similar considerations apply to the initial-boundary value problem in an interval $\tau \leq t \leq T$.

We call $\Gamma(t,x;\,\tau,\xi)$ the *fundamental solution* of the heat equation in $\mathbb{R}^m$,

$$\Gamma(t,x;\,\tau,\xi) = \frac{\exp(-|x-\xi|^2/4(t-\tau))}{(4\pi)^{m/2}(t-\tau)^{m/2}},$$

$x, \xi \in \mathbb{R}^m$, $x \neq \xi$, $\tau < t$. The *Neumann function* $N(t,x;\,\tau,\xi)$ of the heat equation in $[0,T] \times \Omega$ is defined for $t \geq \tau$, $\xi \in \Omega$ by

$$N(t,x;\,\tau,\xi) = \Gamma(t,x;\,\tau,\xi) - V(t,x;\,\tau,\xi) \qquad ((t,x) \in [\tau,T] \times \Omega),$$

where $V(t,x;\,\tau,\xi)$ satisfies [17, p. 155]

$$V_t(t,x;\,\tau,\xi) = \Delta_x V(t,x;\,\tau,\xi), \qquad ((t,x) \in (\tau,T] \times \Omega)),$$

$$V(\tau,x;\,\tau,\xi) = 0, \qquad (x \in \Omega),$$

$$\partial_{\nu,x} V(t,x;\,\tau,\xi) = \partial_{\nu,x}\Gamma(t,x;\,\tau,\xi), \qquad ((t,x) \in (\tau,T] \times \partial\Omega).$$

A domain $\Omega \subseteq \mathbb{R}^m$ is said to be *of class* $C^{(2)}$ if, locally, its boundary $\partial\Omega$ can be represented in the form $x_j = h(x_1, \dots, x_{j-1}, x_{j+1}, \dots, x_m)$ with h twice continuously differentiable; if h is continuously differentiable with λ-Hölder continuous derivatives, Ω is *of class* $C^{(1+\lambda)}$. If $\xi \in \Omega$, $\partial_{\nu,x}\Gamma(t,x;\,\tau,\xi)$ is infinitely differentiable in the cylinder $[\tau,T]\times\bar{\Omega}$, thus [17, Thm. 2, p. 144] $V(t,x;\,\tau,\xi)$ exists; if Ω is of class $C^{(2)}$, $V(t,x;\,\tau,\xi)$, as a function of t, x is analytic in $(\tau,T]\times\Omega$, continuous in $[\tau,T]\times\bar{\Omega}$, and continuously differentiable in $(\tau,T]\times\bar{\Omega}$. The boundary condition is understood literally. Application of the maximum principle shows that

$$N(t,x;\,\tau,\xi) > 0, \qquad (t > \tau, x, \xi \in \Omega). \tag{2.4}$$

If $N^-(t,x;\,\tau,\xi)$ is the Neumann function of the backward heat equation $y_t = -\Delta y$ in $[0,T]\times\Omega$, then

$$N^-(t,x;\,\tau,\xi) = N(\tau,\xi,t,x) \qquad (t > \tau, x, \xi \in \Omega). \tag{2.5}$$

(The proof is similar to that for the Green function, see [17, p. 84].) Equality (2.5) translates to (τ,ξ) the (t,x)-dependence properties of the Neumann function. An application of the divergence theorem shows that if $y(t,x)$ is a strong solution of (2.1)–(2.3), then

$$\begin{aligned} y(t,x) = &\int_\Omega N(t,x;\,\tau,\xi)\zeta(\xi)d\xi \\ &+ \int_{(\tau,t)\times\partial\Omega} N(t,x;\,r,\xi)g(r,\xi)d\sigma_\xi\,dr \qquad (t > \tau,\ x \in \Omega), \end{aligned} \tag{2.6}$$

where $d\sigma_\xi$ is the area differential on $\partial\Omega$. On the other hand, if $g(t,\xi)$ is continuously differentiable in $[0,T]\times\partial\Omega$ and $\zeta(x)$ is continuously differentiable in $\bar{\Omega}$ with $\partial_\nu y(0,x) = g(0,x)$, a strong solution exists [21] and thus (2.6) provides a strong solution for such ζ and g. An approximation argument using the continuous dependence properties of the solution of (2.1)–(2.3) on ζ, and g [17, p. 146] shows that (2.6) extends to semistrong solutions. Formula (2.6) will be used in §3 to define weak solutions of (1.1)–(1.3) via suitable estimates for the Neumann function. Because $N(t,x,\tau,\xi)$ inherits the t-singularity of $\Gamma(t,x;\,\tau,\xi)$ at $(t,x) = (\tau,\xi)$, which is not integrable (except in dimension 1), we use the properties of the negative exponential to quench this singularity at the cost of introducing an "artificial singularity" in x in the estimations. Although the results below (in particular, Theorem 2.1) are apparently known to all specialists, we were unable to locate precise references and include a sketch of the proofs.

We construct $V(t,x;\,\tau,\xi)$ using a method in [17, p. 144] to solve the initial-boundary value problem (2.1)–(2.3). We try

$$V(t,x;\,\tau,\xi) = \int_{(\tau,t)\times\partial\Omega} \Gamma(t,x;\,r,\eta)\rho(r,\eta;\,\tau,\xi)d\sigma_\eta\,dr \tag{2.7}$$

with density $\rho(r,\eta;\,\tau,\xi)$ to be determined. Using formula (2.10) in [17, p. 137] for the derivative of single layer potentials and the boundary condition for V, we obtain the integral equation

$$\rho(t,x;\,\tau,\xi) = 2\partial_{\nu,x}\Gamma(t,x;\,\tau,\xi) - 2\int_{(\tau,t)\times\partial\Omega} \partial_{\nu,x}\Gamma(t,x;\,r,\eta)\rho(r,\eta;\,\tau,\xi)d\sigma_\eta\,dr \tag{2.8}$$

for $\rho(r,\eta;\,\tau,\xi)$ in x, $\xi \in \partial\Omega$. We solve this equation by the following iteration process:

$$\rho(t,x;\,\tau,\xi) = 2\partial_{\nu,x}\Gamma(t,x;\,\tau,\xi) - 2\int_{(\tau,t)\times\partial\Omega} \partial_{\nu,x}\Gamma(t,x;\,r,\eta)R(r,\eta;\,\tau,\xi)d\sigma_\eta\,dr \tag{2.9}$$

$$R(r,\eta;\,\tau,\xi)=\sum_{j=0}^{\infty}\rho_j(r,\eta;\,\tau,\xi), \tag{2.10}$$

the ρ_j defined inductively by $\rho_0(t,x;\,\tau,\xi)=2\partial_{\nu,\eta}\Gamma(t,x;\,\tau,\xi)$,

$$\rho_{j+1}(t,x;\,\tau,\xi)=-2\int_{(\tau,t)\times\partial\Omega}\partial_{\nu,x}\Gamma(t,x;\,r,\eta)\rho_j(r,\eta;\,\tau,\xi)d\sigma_\eta\,dr. \tag{2.11}$$

Estimation of the successive terms depends on the inequality

$$\int_\Sigma\frac{d\sigma_\eta}{|x-\eta|^\alpha|\eta-\xi|^\beta}\le\begin{cases}C|x-\xi|^{m-1-\alpha-\beta} & \text{if } \alpha+\beta>m-1,\\ C & \text{if } \alpha+\beta<m-1,\end{cases} \tag{2.12}$$

valid in a bounded $C^{(1)}$ hypersurface in $\mathbb{R}^m$ for arbitrary α, β and x, ξ in a bounded subset $A\subseteq\mathbb{R}^m$. If $x,\,\xi\notin\Sigma$, then α and β are arbitrary. If $x\in\Sigma$ (respectively, $\xi\in\Sigma$), we must have $\alpha<m-1$ (respectively, $\beta<m-1$); in all cases, the constant C only depends on A, α, β. For a proof, see [24]; a somewhat less general formula is in [17, p. 137].

The estimates for $\Gamma(t,x;\,\tau,\xi)$ are based on the inequality $e^{-x}\le Cx^{-\beta}$ ($\beta>0$, $0<x\le\infty$) and are detailed in [17, pp. 137–38]. The result for a domain of class $C^{(1+\lambda)}$, $0<\lambda<1$ is as follows. If $0<\mu<1$, then

$$|\partial_{\nu,x}\Gamma(t,x,\tau,\xi)|\le\frac{C}{(t-\tau)^\mu|x-\xi|^{m+1-2\mu-\lambda}}, \tag{2.13}$$

where $m+1-2\mu-\lambda<m-1$ if $\mu>1-\lambda/2$. We use this and (2.12) to estimate the η-integral in (2.11); to estimate the r-part, we use the gamma formula

$$\int_\tau^t(t-r)^{-\alpha}(r-\tau)^{-\mu}\,dr=\frac{\Gamma(1-\alpha)\Gamma(1-\mu)}{\Gamma(2-\alpha-\mu)}(t-\tau)^{1-\alpha-\mu}, \tag{2.14}$$

valid for $\alpha,\,\mu<1$. The η-part of the integrals is estimated using (2.12). In the first step the exponent is $m-1-(m+1-2\mu-\lambda)-(m+1-2\mu-\lambda)=-m-3+4\mu+2\lambda$; the second exponent is $-m-5+6\mu+3\lambda$ and, in general, the nth exponent is $-m-(2n+1)+(2n+2)\mu+(n+1)\lambda=-m-1+2\mu+\lambda+n(2\mu+\lambda-2)=a+bn$, where $b>0$ if $\mu>1-\lambda/2$. For the r-integral we use formula (2.14) inductively for $\alpha=-(n-1+n\mu)$, $n=1,2,\dots$. The integral equals $\{\Gamma(n(1-\mu))\Gamma(1-\mu)/\Gamma((n+1)(1-\mu))\}(t-\tau)^{n-(n+1)\mu}$. The final result is

$$|\rho_n(t,x;\,\tau,\xi)|\le\frac{\Gamma(1-\mu)^{n+1}}{\Gamma((n+1)(1-\mu))}M_n(t-\tau)^{n-(n+1)\mu}|x-\xi|^{a+bn},$$

where the constant M_n is the product of all constants C_n, $C_{n-1},\dots,C_1$ arising from the estimate (2.12) at each step. Obviously, it is enough to show that the M_n are bounded by the powers of an absolute constant C. This in turn follows from the fact that the power $|x-\xi|$ in (2.12) becomes positive after a finite number of iterations; precisely, (2.12) is used for $\alpha=m+1-2\mu-\lambda$ fixed and $\beta=-a-bn$. Accordingly, $|x-\xi|^{a+bn}$ can be uniformly bounded by a C^{a+bn} if $n\ge-a/b$, where C is the diameter of Σ. We have thus established estimates sufficient to ensure the uniform convergence of a tail of (2.10). Because the powers of $t-\tau$ and $|x-\xi|$ become higher with the index of ρ_j, the final estimate for R is the same as that for ρ_0,

$$|R(t,x,\tau,\xi)|\le\frac{C}{(t-\tau)^\mu|x-\xi|^{m+1-2\mu-\lambda}}, \tag{2.15}$$

which implies

$$|\rho(t,x,\tau,\xi)| \le \frac{C}{(t-\tau)^{\mu}|x-\xi|^{m+1-2\mu-\lambda}}. \tag{2.16}$$

THEOREM 2.1. *Let C be a bounded domain of class $C^{(2)}$, $\mu > 1/2$. The Neumann function $N(t,x;\tau,\xi)$ $(\xi \in \partial\Omega)$ can be extended to $t > \tau$, $x \in \bar{\Omega}$, $\xi \in \partial\Omega$, $x \neq \xi$, is continuous there and satisfies*

$$|N(t,x,\tau,\xi)| \le \frac{C}{(t-\tau)^{\mu}|x-\xi|^{m-2\mu}}. \tag{2.17}$$

Proof. The fundamental solution $\Gamma(t,x;\tau,\xi)$ satisfies (2.17) [17, p. 134]. Thus, we only have to estimate $V(t,x;\tau,\xi)$, which we do using (2.12) and (2.16), noting that $m-1-(m-2\mu)-(m+1-2\mu-\lambda) = -(m+2-4\mu-\lambda) > -(m-2\mu)$ if $\mu > 1-\lambda/2$. The fundamental solution $\Gamma(t,x;\tau,\xi)$ is infinitely differentiable for $t \ge \tau$, $x \neq \xi$, thus only continuity of $V(t,x;\tau,\xi)$ has to be proved, and it is enough to show continuity in sets Υ_δ defined by

$$(t,x,\tau,\xi) \in ([\tau,T]\times\bar{\Omega})\times([\tau,T]\times\partial\Omega), \qquad (t-\tau\ge\delta,\ |x-\xi|\ge\delta),$$

where $\delta > 0$. Continuity is obvious for $\rho_0(t,x;\tau,\xi)$. Assume it has been proved for $\rho_j(t,x;\tau,\xi)$, and consider the integral (2.11) defining $\rho_{j+1}(t,x;\tau,\xi)$. Extend all functions as zero in $t \le \tau$, so that we may integrate over $[\tau,T]\times\partial\Omega$ in (2.11). If $\rho_{j+1}(t,x;\tau,\xi)$ is not continuous in Υ_δ, there exist sequences $\{(t_n,x_n,\tau_n,\xi_n)\} \subset \Upsilon_\delta$ with $\{(t_n,x_n,\tau_n,\xi_n)\} \to (\bar{t},\bar{x},\bar{\tau},\bar{\xi}) \in \Upsilon_\delta$ and

$$|\rho_{j+1}(t_n,x_n,\tau_n,\xi_n) - \rho_{j+1}(\bar{t},\bar{x},\bar{\tau},\bar{\xi})| \ge \varepsilon > 0. \tag{2.18}$$

Continuity of $\rho_j(r,\eta;\tau,\xi)$ for $\eta \neq \xi$ implies

$$\partial_{\nu,\eta}\Gamma(t_n,x_n;r,\eta)\rho_j(r,\eta;\tau_n,\xi_n) \to \partial_{\nu,\eta}\Gamma(\bar{t},\bar{x};r,\eta)\rho_j(r,\eta;\bar{\tau},\bar{\xi}) \tag{2.19}$$

almost everywhere in $[0,T]\times\partial\Omega$. On the other hand, this function is bounded by

$$C(t_n-r)^{-\mu}(r-\tau_n)^{n-(n+1)\mu}|x_n-\eta|^{m+1-2\mu-\lambda}|\eta-\xi_n|^{a+\iota n}$$

(extended to zero if $r > t_n$ or $r < \tau_n$). Now, the integrals of these functions are equicontinuous in $[\tau,T]\times\partial\Omega$, so Vitali's theorem applies to show that $\rho_j(t_n,x_n,\tau_n,\xi_n) - \rho_j(\bar{t},\bar{x},\bar{\tau},\bar{\xi})$ as $n \to \infty$. This contradicts (2.18) and thus shows continuity of $\rho_j(t,x;\tau,\xi)$ in Υ_δ. Using the estimates for the terms of (2.10), we obtain continuity of $R(t,x;\tau,\xi)$ in $t > \tau$, $x \neq \xi$. Arguing in a similar way first with (2.8), then with (2.7), we show continuity of $\rho(t,x;\tau,\xi)$ and then of $V(t,x;\tau,\xi)$ in $t > \tau$, $x \neq \xi$. This ends the proof of Theorem 2.1. □

3. Solutions of the nonlinear initial-boundary value problem. We consider (1.1)–(1.3) in a domain of class $C^{(2)}$ with $g(t,y)$ defined and continuous in $[0,T]\times\mathbb{R}$ and the control $u(\cdot,\cdot)$ in $L^\infty((0,T)\times\partial\Omega)$. By definition, $y(t,x)$ is a *weak solution* of (1.1)–(1.3) for $\zeta(\cdot) \in C(\bar{\Omega})$ if and only if it is continuous in $[0,T]\times\bar{\Omega}$ and satisfies

$$\begin{aligned} y(t,x) = &\int_\Omega N(t,x;0,\xi)\zeta(\xi)\,d\xi \\ &+ \int_{(0,t)\times\partial\Omega} N(t,x;\tau,\xi)\{g(\tau,y(\tau,\xi)) + u(\tau,\xi)\}\,d\sigma_\xi\,d\tau, \end{aligned} \tag{3.1}$$

where $N(t,x;\tau,\xi)$ is the Neumann function of $[0,T]\times\Omega$. For $x\in\partial\Omega$, (3.1) is an integral equation for the restriction $\phi(t,x)$ of $y(t,x)$ to $\partial\Omega$. Once solved, we construct $y(t,x)$ from (3.1).

Consider the two parameter family of operators

$$(\mathbf{N}(t,\tau)\psi)(x)=\int_{\partial\Omega}N(t,x;\tau,\xi)\psi(\xi)d\sigma_\xi \qquad (\tau<t) \tag{3.2}$$

for $\psi\in L^\infty(\partial\Omega)$. Theorem 2.1 shows that $\mathbf{N}(t,\tau)$ is a bounded operator from $L^\infty(\partial\Omega)$ into $C(\bar\Omega)$; moreover, $\mathbf{N}(t,\tau)$ is continuous in $\tau<t$ in the norm of $L(L^\infty(\partial\Omega),\,C(\bar\Omega))$ in $0\le\tau<t\le T$ and

$$\|\mathbf{N}(t,\tau)\|_{L(L^\infty(\partial\Omega),C(\bar\Omega))}\le B(t-\tau)^{-\mu} \qquad (0\le\tau<t\le T), \tag{3.3}$$

with $1/2\le\mu<1$, where $L(X,Y)$ is the Banach space of all bounded operators from the Banach space X into the Banach space Y. Let $\mathbf{M}(t,\tau)=\Pi\circ\mathbf{N}(t,\tau)$, $\Pi: C(\bar\Omega)\to C(\partial\Omega)$ the restriction operator; $\mathbf{M}(t,\tau)$ is continuous in the norm of the space $L(L^\infty(\partial\Omega),\,C(\partial\Omega))$ and satisfies the companion of (3.3) in that norm. The *solution operator* $\mathbf{S}(t,\tau)$ of the heat equation in Ω (with Neumann boundary conditions) is given by the first term of (2.6), that is

$$\mathbf{S}(t,\tau)\zeta(x)=\int_\Omega N(t,x;\tau,\xi)\zeta(\xi)d\xi \tag{3.4}$$

and is a bounded operator from $C(\bar\Omega)$ into $C(\bar\Omega)$; moreover, $\mathbf{S}(t,\tau)$ is differentiable in the norm of $L(C(\bar\Omega),\,C(\bar\Omega))$ for $t>\tau$ and strongly continuous and uniformly bounded in $0\le\tau\le t\le T$, with $S(\tau,\tau)=I$. Finally, $\mathbf{T}(t,\tau)=\Pi\circ\mathbf{S}(t,\tau)$; $\mathbf{T}(t,\tau)$ is differentiable in the norm of $L(C(\bar\Omega),\,C(\partial\Omega))$ in $0\le\tau<t\le T$ and strongly continuous for $t\ge\tau$. All these operators depend on $t-\tau$, although we keep the present notation in view of the treatment of time-dependent equations (see §6). The function $g(t,y)$ produces an operator $\mathbf{g}:[0,T]\times C(\partial\Omega)\to C(\partial\Omega)$ defined by $\mathbf{g}(t,\boldsymbol{\phi})(x)=g(t,\phi(t,x))$ that is continuous in t in the norm of $(C(\partial\Omega),\,C(\partial\Omega))$. Using this operator jargon, the integral equation to be solved is

$$\begin{aligned}\boldsymbol{\phi}(t)&=\mathbf{T}(t,0)\zeta+\int_0^t\mathbf{M}(t,\tau)\mathbf{u}(\tau)d\tau+\int_0^t\mathbf{M}(t,\tau)\mathbf{g}(\tau,\boldsymbol{\phi}(\tau))d\tau\\&=\mathbf{f}(t)+\int_0^t\mathbf{M}(t,\tau)\mathbf{g}(\tau,\boldsymbol{\phi}(\tau))d\tau,\end{aligned} \tag{3.5}$$

where $\boldsymbol{\phi}(t)(x)=\phi(t,x)$, $\mathbf{u}(t)(x)=u(t,x)$; setting $\mathbf{y}(t)=y(t,x)$, formula (3.1) becomes

$$\mathbf{y}(t)=\mathbf{S}(t,0)\zeta+\int_0^t\mathbf{N}(t,\tau)\mathbf{u}(\tau)d\tau+\int_0^t\mathbf{N}(t,\tau)\mathbf{g}(\tau,\boldsymbol{\phi}(\tau))d\tau. \tag{3.6}$$

Note that $\boldsymbol{\phi}(\cdot)\in C([0,T];\,C(\partial\Omega))$ (respectively, $\mathbf{y}(\cdot)\in C([0,T];\,C(\bar\Omega))$ if and only if $\phi(\cdot,\cdot)\in C([0,T]\times\partial\Omega)$ (respectively, $y(\cdot,\cdot)\in C([0,T]\times\bar\Omega)$); here, if X is a Banach space, $C([0,T];\,X)$ denotes the space of continuous X-valued functions defined in $[0,T]$ endowed with the supremum norm. On the other hand, the first integrals on the right sides of (3.5) and (3.6) need explanation because the function $\mathbf{u}(\cdot)$ may not be strongly measurable as an $L^\infty(\partial\Omega)$-valued function. We use the fact that $L^\infty((0,T)\times\partial\Omega)$ can be identified (algebraically and metrically) with the space $L^\infty_W(0,T;\,L^\infty(\partial\Omega))$ of all $L^1(\Omega)$-weakly measurable $L^\infty(\partial\Omega)$-essentially bounded functions defined in $0\le t\le T$ endowed with the essential supremum norm (if $\mathbf{u}(\cdot)\in L^\infty_W(0,T;\,L^\infty(\partial\Omega))$, then $\|\mathbf{u}(t)\|=\sup\langle y_n,\mathbf{u}(t)\rangle$, where $\{y_n\}$ is any sequence dense in the unit ball of $L^1(\partial\Omega)$, so that $t\to\|\mathbf{u}(t)\|$ is measurable).

LEMMA 3.1. *Let* $\mathbf{u}(\cdot) \in L^\infty_W(0,T;\, L^\infty(\partial\Omega))$. *Then*

$$\tau \to \mathbf{M}(t,\tau)\mathbf{u}(\tau) \qquad (0 \le \tau < t) \tag{3.7}$$

is a strongly measurable $C(\bar\Omega)$*-valued function.*

Proof. Because the space $C(\bar\Omega)$ is separable, it is enough to show that (3.7) is $C(\bar\Omega)^*$-weakly measurable, where the dual $C(\bar\Omega)^*$ is the space $\Sigma(\bar\Omega)$ of all finite Borel measures on $\bar\Omega$ endowed with the total variation norm. Let $\nu \in \Sigma(\bar\Omega)$. Then

$$\langle \nu, \mathbf{N}(t,\tau)\mathbf{u}(\tau)\rangle = \int_{\bar\Omega}\int_{\partial\Omega} N(t,x;\,\tau,\xi)\nu(dx)u(\tau,\xi)d\sigma_\xi.$$

Using the continuity properties of $N(t,x;\,\tau,\xi)$, we check that $\tau \to \langle \nu, \mathbf{N}(t,\tau)\mathbf{u}(\tau)\rangle$ is continuous in $0 < \tau < t$, which is more than enough. □

THEOREM 3.2. *Assume* $g(t,y)$ *satisfies a local Lipschitz condition in* y*; for every* $C > 0$ *there exists* $K = K(C)$ *such that*

$$|g(t,y') - g(t,y)| \le K|y' - y| \qquad (0 \le t \le T,\ |y|,\ |y'| \le C). \tag{3.8}$$

Then a unique solution of (3.5) *exists in an interval* $0 \le t \le T_0$, $T_0 \le T$.

Proof. Inequality (3.8) implies a local Lipschitz condition for $\mathbf{g}$. Lemma 3.1 and the properties of the operator $\mathbf{M}(t,\tau)$ imply that $\mathbf{f}(t)$ in (3.5) belongs to $C([0,T];\, C(\partial\Omega))$. We consider the map

$$\mathbf{L}\boldsymbol{\phi}(t) = \mathbf{f}(t) + \int_0^t \mathbf{M}(t,\tau)\mathbf{g}(\tau,\boldsymbol{\phi}(\tau))d\tau$$

in a closed ball $B(\mathbf{f}(\cdot),\rho)$ of $C([0,T_0];\, C(\partial\Omega))$ (endowed with the supremum norm) where $\rho > 0$. Using the companion of (3.3) for $\mathbf{M}(t,\tau)$, local boundedness of $\mathbf{g}$, and the local Lipschitz condition, we show that $\mathbf{L}$ is a contraction for T_0 small enough. Thus a unique fixed point $\boldsymbol{\phi} = \mathbf{L}\boldsymbol{\phi}$ exists. The estimations are based on the *generalized Gronwall inequality* [20, p. 188]: if $b \ge 0$, $\beta > -1$, $a(\cdot)$, $b(\cdot) \in L^1_{\mathrm{loc}}(0,T)$, and

$$u(t) \le a(t) + b\int_\tau^t (t-r)^\beta u(r)dr \qquad (\tau \le t \le T), \tag{3.9}$$

then there exists a constant c depending only on β and T such that

$$u(t) \le a(t) + c\int_\tau^t (t-r)^\beta a(r)dr \qquad (\tau \le t \le T). \tag{3.10}$$

The solution $\boldsymbol{\phi}(t)$ of (3.5) is not necessarily defined in $0 \le t \le T$. If it is not, we can define a maximal interval of existence $0 \le t < T_m$ at the end of which $\boldsymbol{\phi}(t)$ must blow up.

LEMMA 3.3. *Let* $\boldsymbol{\phi}(t)$ *be a solution of* (3.5) *in* $0 \le t < \bar t$. *Assume that* $\|\boldsymbol{\phi}(t)\| \le C$. *Then* $\boldsymbol{\phi}(t)$ *can be continued as a solution in* $0 \le t \le \tilde t > \bar t$.

The proof is classical. We use the integral equation to show that $\{\boldsymbol{\phi}(t);\ \bar t - \delta \le t < \bar t\}$ is Cauchy as $t \to \bar t$, so that $\lim_{t\to\bar t}\boldsymbol{\phi}(t)$ exists and $\boldsymbol{\phi}(t)$ can be continued as a solution to $0 \le t \le \bar t$. Then we solve

$$\begin{aligned}\boldsymbol{\psi}(t) = \mathbf{T}(t,0)\zeta &+ \int_0^t \mathbf{M}(t,\tau)\mathbf{u}(\tau)d\tau \\ &+ \int_0^{\bar t} \mathbf{M}(t,\tau)\mathbf{g}(\tau,\boldsymbol{\phi}(\tau))d\tau + \int_{\bar t}^t \mathbf{M}(t,\tau)\mathbf{g}(\tau,\boldsymbol{\psi}(\tau))d\tau\end{aligned}$$

and extend $\boldsymbol{\phi}(t)$ with $\boldsymbol{\psi}(t)$. □

Consider the linear nonhomogeneous version of (1.1)–(1.3),

$$\xi_t(t,x) = \Delta\xi(t,x) \qquad (x \in \Omega,\ 0 < t < \bar{t}), \tag{3.11}$$

$$\xi(0,x) = \zeta(x) \qquad (x \in \Omega), \tag{3.12}$$

$$\partial_\nu \xi(t,x) = a(t,x)\xi(t,x) + \delta(t-s)v(x) \qquad (x \in \partial\Omega,\ 0 < t \le T), \tag{3.13}$$

where $0 < s < T$, $\zeta(\cdot) \in C(\bar{\Omega})$, $a(\cdot,\cdot) \in C([0,T] \times \partial\Omega)$, $v(\cdot) \in L^\infty(\partial\Omega)$, and $\delta(t)$ is the Dirac delta. This type of boundary condition is not covered by the preceding nonlinear theory, but we can stretch the treatment to accommodate (3.13). The equation for $\boldsymbol{\psi}(t) = \Pi \circ \boldsymbol{\xi}(t)$ is

$$\begin{aligned} \boldsymbol{\psi}(t) &= \mathbf{T}(t,0)\zeta + h(t-s)\mathbf{M}(t,s)v \\ &\quad + \int_0^t \mathbf{M}(t,\tau)\mathbf{a}(\tau)\boldsymbol{\psi}(\tau)d\tau \\ &= \mathbf{f}(t) + h(t-s)\int_s^t \mathbf{M}(t,\tau)\mathbf{a}(\tau)\boldsymbol{\psi}(\tau)d\tau, \end{aligned} \tag{3.14}$$

where $h(t) = 1$ for $t \ge 0$, $h(t) = 0$ for $t < 0$, and $\mathbf{a}(t)$ is the linear bounded operator defined by $(\mathbf{a}(t)\boldsymbol{\phi})(x) = a(t,x)\phi(t,x)$. By definition, the solution of (3.14) is given by

$$\begin{aligned} \boldsymbol{\xi}(t) &= \mathbf{S}(t,\tau)\zeta + h(t-s)\mathbf{N}(t,s)v \\ &\quad + \int_s^t \mathbf{N}(t,\tau)\mathbf{a}(\tau)\boldsymbol{\psi}(\tau)d\tau. \end{aligned} \tag{3.15}$$

In view of (3.3), $\mathbf{f}(t)$ is continuous in $t < s$ and $t > s$ with $\|\mathbf{f}(t)\| \le C(t-s)^{-\mu}$ $(t > s)$. Extending $\mathbf{f}(t)$ to $t = s$ by $\mathbf{f}(s) = \lim_{t \to s-} \mathbf{f}(t)$, we may actually consider $\mathbf{f}(t)$ continuous in $t \le s$. This time, we construct $\boldsymbol{\psi}(\cdot)$ in the space $C_{s,\mu}([0,T];\, C(\partial\Omega))$ of all $C(\partial\Omega)$-valued $\boldsymbol{\psi}(t)$ continuous in $0 \le t \le s$ and $s < t \le T$ endowed with the weighted supremum norm with weight $\omega(t,\mu) = 1$ $(t \le s)$, $\omega(t,\mu) = (t-s)^\mu$, $(t > s)$. Equation (3.14) may be directly solved by successive approximations in the interval $0 \le t \le T$ starting with $\boldsymbol{\psi}_0(t) = \mathbf{f}(t)$, estimations based on the gamma formula. The solution belongs to $C_{s,\mu}([0,T];\, C(\partial\Omega))$, thus

$$\|\boldsymbol{\psi}(t)\| \le C\omega(t,-\mu) \tag{3.16}$$

so that, in view of (3.6) and the gamma formula, the solution $\mathbf{z}(t)$ will satisfy a bound of the same form.

We will also have to stretch the (linear) theory to accommodate the backwards initial value (or final value) problem

$$z_t(t,x) = -\Delta z(t,x) - f(t,x) \qquad (x \in \Omega,\ 0 \le t \le \bar{t}), \tag{3.17}$$

$$z(\bar{t},\cdot) = \nu \qquad (x \in \Omega), \tag{3.18}$$

$$\partial_\nu \xi(t,x) = b(t,x)\xi(t,x) + v(t,x) \qquad (x \in \partial\Omega,\ 0 \le t \le \bar{t}), \tag{3.19}$$

with $\nu \in \Sigma(\bar{\Omega})$, $f(\cdot,\cdot) \in C([0,T] \times \bar{\Omega})$, $b(\cdot,\cdot) \in C([0,T] \times \partial\Omega)$, and $v(\cdot,\cdot) \in L^\infty((0,T) \times \partial\Omega)$. Because of the symmetry (2.5) of the Neumann function, if $\mathbf{S}^-(t,\tau)$, $\mathbf{N}^-(t,\tau)$, $\mathbf{M}^-(t,\tau)$ $(t < \tau)$ are the operators associated with (3.17)–(3.19), we have $\mathbf{S}^-(t,\tau) = \mathbf{S}(\tau,t)$, with

similar equalities for $\mathbf{N}$ and $\mathbf{M}$. Accordingly, the associated integral equation for $\boldsymbol{\psi}(t) = \Pi \circ \mathbf{z}(t)$ is

$$\begin{aligned}\boldsymbol{\psi}(t) &= \mathbf{T}(\bar{t}, t)\nu + \int_t^{\bar{t}} \mathbf{T}(\tau, t)\mathbf{f}(\tau)d\tau \\ &+ \int_t^{\bar{t}} \mathbf{M}(\tau, t)\mathbf{v}(\tau)d\tau + \int_t^{\bar{t}} \mathbf{M}(\tau, t)\mathbf{a}(\tau)\boldsymbol{\psi}(\tau)d\tau.\end{aligned} \tag{3.20}$$

As to the first term, we extend $\mathbf{S}(t, \tau)$ to $\Sigma(\bar{\Omega})$ by

$$(\mathbf{S}(t, \tau)\nu)(x) = \int_{\bar{\Omega}} N(t, \xi; \tau, x)\nu(d\xi) \tag{3.21}$$

because $N(t, x; \tau, \cdot)$ is continuous in $(x, \xi) \in \bar{\Omega} \times \bar{\Omega}$ for $t > \tau$. Moreover, $\mathbf{S}(t, \tau)\Sigma(\bar{\Omega}) \subseteq C(\bar{\Omega})$ and $\mathbf{S}(t, \tau)$ are continuous in the norm of $L(\Sigma(\bar{\Omega}), C(\bar{\Omega}))$ in $t > \tau$; again, $\mathbf{T}(t, \tau) = \Pi \circ \mathbf{S}(t, \tau)$ and $\mathbf{T}(t, \tau) : \Sigma(\bar{\Omega}) \to C(\partial\Omega)$. It can be shown by semigroup theoretic methods [4] that $\|\mathbf{S}(t, \tau)\|$ is uniformly bounded in $t > \tau$ and that $\mathbf{S}(t, \tau)\nu \to \nu$ $C(\bar{\Omega})$-weakly in $\Sigma(\bar{\Omega})$. We solve (3.20) by successive approximations in the space $C([0, \bar{t}); C(\partial\Omega))$ of all $C(\partial\Omega)$-valued functions $\boldsymbol{\psi}(t)$ bounded and continuous in $0 \leq t < \bar{t}$ endowed with the supremum norm and obtain the solution from the backwards analogue of (3.6).

4. Existence theory for the optimal control problem. We denote by $\mathbf{U}_{\text{ad}}(0, T; U)$ the *admissible control space*, that is, the set of all $\mathbf{u}(\cdot) \subseteq L^\infty_W(0, T; L^\infty(\partial\Omega))$ satisfying the control constraint (1.4) almost everywhere in $0 \leq t \leq T$; if $\mathbf{u}(\cdot) \in \mathbf{U}_{\text{ad}}(0, T; U)$ (or, more generally, if $\mathbf{u}(\cdot) \in L^\infty_W(0, T; L^\infty(\partial\Omega))$), $\boldsymbol{\phi}(t, \mathbf{u})$ is the $C(\partial\Omega)$-valued solution of the integral equation (3.5) corresponding to a the control $\mathbf{u}(\cdot) \in L^\infty_W(0, T; L^\infty(\partial\Omega))$. Likewise, $\mathbf{y}(t, \mathbf{u})$ is the $C(\bar{\Omega})$-valued solution defined by (3.6). Both functions need not be defined in the whole interval $0 \leq t \leq T$.

LEMMA 4.1. *The operators* $\mathbf{N}(t, \tau) : L^\infty(\partial\Omega) \to C(\bar{\Omega})$ *and* $\mathbf{M}(t, \tau) : L^\infty(\partial\Omega) \to C(\partial\Omega)$ *are compact.*

Proof. We only have to consider $\mathbf{N}(t, \tau)$. Let $\{u_n(\cdot)\} \subset L^\infty(\partial\Omega)$ be $L^1(\partial\Omega)$-weakly convergent to zero. If $\mathbf{N}(t, \tau)$ is not convergent to zero in $C(\bar{\Omega})$, there exists a sequence $\{x_n\} \subset \bar{\Omega}$ such that

$$|\mathbf{N}(t, \tau)u_n(x_n)| \geq \varepsilon > 0 \tag{4.1}$$

(we may assume $x_n \to \bar{x} \in \bar{\Omega}$). However, by (2.17) and Vitali's theorem, $N(t, x_n, \tau, \cdot) \to N(t, \bar{x}, \tau, \cdot)$ in $L^1(\partial\Omega)$, thus $\mathbf{N}(t, \tau)u_n(x_n) \to 0$, a contradiction. □

THEOREM 4.2. *The operator*

$$(\boldsymbol{\Delta}u)(t) = \int_0^t \mathbf{N}(t, \tau)\mathbf{u}(\tau)d\tau$$

from $L^\infty_W(0, T; L^\infty(\partial\Omega))$ *into* $C([0, T]; C(\bar{\Omega}))$ *is compact.*

The proof is essentially the same as that of Lemma 6.1 in [9] and is omitted; the result implies compactness of the operator $\boldsymbol{\Lambda} = \Pi \circ \boldsymbol{\Delta}$.

A cost functional $y_0(t, \mathbf{u})$ is *weakly lower semicontinuous* if

$$y_0(t, \bar{\mathbf{u}}) \leq \limsup_{n \to \infty} y_0(t_n, \mathbf{u}_n) \tag{4.2}$$

for every sequence $\{t_n\} \subseteq \mathbb{R}$ with $t_n \to \bar{t}$ and every sequence $\{\mathbf{u}_n\} \subseteq L^\infty_W(0, T; L^\infty(\partial\Omega))$ with $\mathbf{u}_n \to \bar{\mathbf{u}}$ $L^1(0, T; L^1(\partial\Omega))$-weakly.

Let m be the minimum of the cost functional $y_0(t, \mathbf{u})$ subject to the control constraint (1.4) and the target condition (1.5). Assuming that $-\infty < m < \infty$, a sequence $\{\mathbf{u}^n\}$, $\mathbf{u}^n \in \mathbf{U}_{\text{ad}}(0, t_n; U)$ is called a *minimizing sequence* if and only if

$$\limsup_{n\to\infty} y_0(t_n, \mathbf{u}^n) \le m, \qquad \lim_{n\to\infty} \operatorname{dist}(\mathbf{y}(t_n, \mathbf{u}^n), Y) \to 0. \tag{4.3}$$

THEOREM 4.3. *Let $\mathbf{U}_{\text{ad}}(0,T;U)$ be $L^1(0,T;L^1(\partial\Omega))$-weakly compact in $L^\infty_W(0,T;L^\infty(\partial\Omega))$, and assume $y_0(t,\mathbf{u})$ is weakly lower semicontinuous. Let $\{\mathbf{u}^n(\cdot)\}$, $\mathbf{u}^n(\cdot) \in \mathbf{U}_{\text{ad}}(0,t_n;U)$ be a minimizing sequence with $t_n \to \bar t$ and $\|\boldsymbol{\phi}(t,\mathbf{u}^n)\|_{C(\partial\Omega)} \le C$ $(0 \le t \le \bar t)$. Then (a subsequence of) $\{\mathbf{u}^n\}$ converges $L^1(0,\bar t;L^1(\partial\Omega))$-weakly to an optimal control $\bar{\mathbf{u}}(\cdot) \in \mathbf{U}_{\text{ad}}(0,\bar t;U)$.*

Proof. We write (3.5) for each t_n, u^n, $\boldsymbol{\phi}(t,\mathbf{u}^n)$ in the interval $0 \le t \le \bar t$; if $t_n < \bar t$, we define, say, $\mathbf{u}^n(t) = \mathbf{u}^n(t_n)$, $\boldsymbol{\phi}(t,\mathbf{u}^n) = \boldsymbol{\phi}(t_n,\mathbf{u}^n)$ in $t \ge t_n$. We then obtain

$$\tilde{\boldsymbol{\phi}}(t,\mathbf{u}^n) = \mathbf{T}(t,s)\zeta + \int_0^{\bar t} \mathbf{M}(t,\tau)\mathbf{u}^n(\tau)d\tau + \int_0^{\bar t} \mathbf{M}(t,\tau)g(\tau,\boldsymbol{\phi}(\tau,\mathbf{u}^n))d\tau \tag{4.4}$$

in $0 \le t \le \bar t$, where if $t_n \ge \bar t$, $\tilde{\boldsymbol{\phi}}(t,\mathbf{u}^n) = \boldsymbol{\phi}(t,\mathbf{u}^n)$. If $t_n \le \bar t$, $\tilde{\boldsymbol{\phi}}(t,\mathbf{u}^n)$ is defined by (4.4) in terms of the extended $\boldsymbol{\phi}$. Passing, if necessary, to a subsequence, we may assume that $\mathbf{u}^n(\cdot) \to \bar{\mathbf{u}}(\cdot) \in \mathbf{U}_{\text{ad}}(0,\bar t;U)$ $L^1(0,T;L^1(\partial\Omega))$-weakly. Using Theorem 4.2 and passing again to a subsequence, we deduce that $\tilde{\boldsymbol{\phi}}(\cdot,\mathbf{u}^n) \to \boldsymbol{\phi}(\cdot) \in C([0,\bar t];\partial\Omega)$ in the norm of $C([0,\bar t];\partial\Omega)$. Accordingly, the limit of (4.4) is the integral equation (3.5) for $\boldsymbol{\phi}(t)$ and $\bar{\mathbf{u}}(\cdot)$, which shows that $\boldsymbol{\phi}(t) = \boldsymbol{\phi}(t,\bar{\mathbf{u}})$ and ends the proof. □

The proof of Theorem 4.3 depends essentially on the fact that controls enter linearly into the boundary condition. If this is not the case (for instance, if the boundary condition is of the form $\partial_\nu y(t,x) = g(t,y(t,x),u(t,x))$, the infinite-dimensional theory of relaxed controls [12], [13] can be applied.

We examine global existence for (3.5). Lemma 4.4 below shows that it extends from a control $\bar{\mathbf{u}}$ to neighboring controls.

LEMMA 4.4. *Let $\bar{\mathbf{u}}(\cdot) \in L^\infty_W(0,\bar t;L^\infty(\partial\Omega))$ be such that $\boldsymbol{\phi}(t,\bar{\mathbf{u}})$ exists in $0 \le t \le \bar t$, and let $q > 1/(1-\mu)$, μ the constant in (3.3). Then, if $\|\mathbf{u}-\bar{\mathbf{u}}\|_{L^q(0,\bar t;L^q(\partial\Omega))} \le \rho$, the solution $\boldsymbol{\phi}(t,\mathbf{u}^n)$ of (3.5) exists in $0 \le t \le \bar t$. Moreover, if $\mathbf{v}(\cdot) \in L^\infty_W(0,\bar t;L^\infty(\partial\Omega))$ is such that $\|\mathbf{v}-\bar{\mathbf{u}}\|_{L^q(0,\bar t;L^q(\partial\Omega))} \le \rho$ as well, then*

$$\|\boldsymbol{\phi}(t,\mathbf{v}) \to \boldsymbol{\phi}(t,\mathbf{u})\| \le C\|\mathbf{v}-\mathbf{u}\|_{L^q(0,\bar t;L^q(\partial\Omega))}. \tag{4.5}$$

Proof. Let $[0,t_0]$ be the maximal interval where $\boldsymbol{\phi}(t,\mathbf{u})$ exists and satisfies $\|\boldsymbol{\phi}(t,\mathbf{u}) - \boldsymbol{\phi}(t,\bar{\mathbf{u}})\| \le 1$. Using (3.5) and estimating via Hölder's inequality in the first integral and local Lipschitz continuity of $q(t,y)$ in the second we obtain

$$\|\boldsymbol{\phi}(t,\mathbf{u}) - \boldsymbol{\phi}(t,\bar{\mathbf{u}})\| \le C\|\mathbf{u}-\bar{\mathbf{u}}\|_{L^q((0,T)\times\partial\Omega)} + C'\int_0^t (t-\tau)^{-\mu}\|\boldsymbol{\phi}(\tau,\mathbf{u}) - \boldsymbol{\phi}(\tau,\bar{\mathbf{u}})\|d\tau.$$

Taking ρ small enough and using the generalized Gronwall's inequality, we produce a contradiction unless $[0,t_0] = [0,\bar t]$ and prove (4.5) for $\mathbf{v} = \bar{\mathbf{u}}$. A similar argument deals with the general pair $\mathbf{v}, \mathbf{u}$. □

Formula (3.6) produces an estimate of the form of (4.5) for solutions $\mathbf{y}(t)$ and shows in particular (taking $\mathbf{v} \in C([0,T];\partial\Omega)$ and approximating with bounded $L^\infty_W(0,\bar t;L^\infty(\partial\Omega))$-norm) that the following corollary holds.

COROLLARY 4.5. *A weak solution $\mathbf{y}(t,\mathbf{u})$ of (1.1)–(1.3) can be uniformly approximated in $[0,\bar t]\times\bar\Omega$ by semistrong solutions $\mathbf{y}_n(t,\mathbf{u}_n)$ with $\mathbf{u}_n(\cdot) \in C([0,T]\times\partial\Omega)$ uniformly bounded. If $\mathbf{u}(t) \ge 0$ almost everywhere, the $\mathbf{u}_n(t)$ can be chosen such that $\mathbf{u}_n(t) > 0$.*

In the result below, $\mathbf{U}_{\text{ad}}(0,T;\,U)$ is equipped with the distance

$$d(\mathbf{u},\mathbf{v}) = \text{meas}\{t;\ \mathbf{u}(t) \neq \mathbf{v}(t)\}. \tag{4.6}$$

(Note that $\{t;\ \mathbf{u}(t) \neq \mathbf{v}(t)\}$ is the union of the countable family of measurable sets $\{t;\ \langle y_n, \mathbf{u}(t)\rangle \neq \langle y_n, \mathbf{v}(t)\rangle\}$, $\{y_n\}$ a countable dense set in $L^1(\partial\Omega)$, thus is measurable.)

COROLLARY 4.6. *Let $\bar{\mathbf{u}}(\cdot) \in \mathbf{U}_{\text{ad}}(0,\bar{t};\,U)$ be such that $\boldsymbol{\phi}(t,\bar{\mathbf{u}})$ exists in $0 \leq t \leq \bar{t}$. Then there exists $\rho > 0$ such that if $d(\mathbf{u},\bar{\mathbf{u}}) \leq \rho$ then $\boldsymbol{\phi}(t,\mathbf{u})$ also exists in $0 \leq t \leq \bar{t}$. Moreover,*

$$\|\boldsymbol{\phi}(t,\mathbf{v}) - \boldsymbol{\phi}(t,\mathbf{u})\| \leq C d(\mathbf{v},\mathbf{u})^{1-\mu} \qquad (0 \leq t \leq \bar{t}, \mathbf{u}, \mathbf{v} \in B(\bar{\mathbf{u}},\rho)). \tag{4.7}$$

Proof. Take $\mu > \mu' > 1/2$, $q = 1/(1-\mu) > 1/(1-\mu')$, and apply Lemma 4.4, noting that $\|\mathbf{v} - \mathbf{u}\|_{L^q(0,\bar{t};L^q(\partial\Omega))} \leq C d(\mathbf{v},\mathbf{u})^{1-\mu}$. □

LEMMA 4.7. *Assume $\zeta(x) \geq 0$, $g(t,0) = 0$, $g(t,y) < 0$ for $y \neq 0$, and let $\mathbf{u}(\cdot) \in L^\infty_W(0,\bar{t};\,L^\infty(\partial\Omega))$, $\mathbf{u}(t) \geq 0$ almost everywhere. Then the solution $\boldsymbol{\phi}(t,\mathbf{u})$ of* (3.5) *exists in $0 \leq t \leq \bar{t}$ and satisfies*

$$0 \leq \boldsymbol{\phi}(t,\mathbf{u}) \leq \|\zeta\| + Ct^{1-\mu}\|u\| \qquad (0 \leq t \leq \bar{t}). \tag{4.8}$$

Proof. We solve first with boundary condition $\partial_\nu y(t,\bar{x}) = g(t,y(t,x)\text{sign } y(t,x) + u(t,x)$ and show that the solution $y(t,x)$ is nonnegative. By Lemma 4.3 we may assume that $\mathbf{u}(\cdot) \in C([0,T]\times\partial\Omega)$ and thus that the solution is semistrong. Let $[0,t_0]$ be an interval where $\boldsymbol{\phi}(t,\mathbf{u})$ exists. By the maximum principle, $y(t,x,u)$ must attain its minimum at $\bar{\Omega} \cup ([0,T]\times\partial\Omega)$. If the minimum lies in $\bar{\Omega}$, it is nonnegative. If $y(t,x)$ attains a negative minimum $\bar{x}$ in $[0,T]\times\partial\Omega$, then $\partial_\nu y(t,\bar{x}) \leq 0$, which contradicts the boundary condition. It follows then that $y(t,x)$ must coincide with the (unique) solution with the original boundary condition $\partial_\nu y(t,x) = g(t,y(t,x)) + u(t,x)$. To show that $\boldsymbol{\phi}(t,\mathbf{u})$ exists in $0 \leq t \leq \bar{t}$ we use Lemma 3.3 in combination with a priori bound. This bound is obtained from (3.5); in fact, by positivity of the kernels, the third term is nonpositive so that we have $\|\boldsymbol{\phi}(t,\mathbf{u})\| \leq \|\zeta\| + Ct^{1-\mu}\|\mu\|$. This ends the proof. □

THEOREM 4.8. *Let $\xi(t,x)$ be a solution of* (3.11)–(3.13) *with $\zeta = 0$ and let $z(t,x)$ be a solution of* (3.17)–(3.19). *Then*

$$\begin{aligned}\int_{\bar{\Omega}} \xi(\bar{t},x)\nu(dx) &= \int_{\partial\Omega} v(x)z(s,x)d\sigma \\ &+ \int_{(s,\bar{t})\times\partial\Omega} \{\xi(\tau,x)a(\tau,x)z(\tau,x) - \xi(\tau,x)(b(\tau,x)z(\tau,x) + v(\tau,x))\}d\sigma\,d\tau \\ &- \int_{(s,\bar{t})\times\Omega} \xi(\tau,x)f(\tau,x)dx\,d\tau.\end{aligned}$$

The proof is a consequence of the divergence theorem for smooth solutions. For general solutions, an approximation argument is used [24].

5. Directional derivatives. Let V be a metric space, E be a Banach space, and $g : V \to E$. An element $\xi \in E$ is a (one-sided) *directional derivative* of g at $u \in V$ if and only if there exists $u : [0,\delta] \to V$ with $d(u(h),u) \leq h$ and

$$g(u(h)) = g(u) + h\xi + o(h) \quad \text{as } h \to 0+.$$

The set of all directional derivatives of g at u is denoted $\partial g(u)$; it is star-shaped and closed. We compute below certain directional derivatives of the function $\mathbf{f} : \mathbf{U}_{\text{ad}}(0,\bar{t};U) \to E$ defined by

$$\mathbf{f}(\mathbf{u}) = \mathbf{y}(\bar{t},\mathbf{u}) \in C(\bar{\Omega}), \tag{5.1}$$

where $\mathbf{u} \in \mathbf{U}_{\text{ad}}(0, \bar{t}; U)$ is such that $\boldsymbol{\phi}(t, \mathbf{u})$ (thus $\mathbf{y}(t, \mathbf{u})$) exists in $0 \le t \le \bar{t}$. The space $\mathbf{U}_{\text{ad}}(0, \bar{t}; U)$ is equipped with the distance (4.6). Derivatives are constructed by means of "multispike perturbations" $\mathbf{u}(h) = \mathbf{u}_{\mathbf{s},\mathbf{p},h,\mathbf{v}}(t)$ defined by

$$\mathbf{u}_{\mathbf{s},\mathbf{p},h,\mathbf{v}}(t) = \begin{cases} v_j & (s_j - p_j h \le t \le s_j,\ j = 1, 2, \dots, m), \\ \mathbf{u}(t) & \text{elsewhere}, \end{cases} \tag{5.2}$$

where $\mathbf{s} = (s_1, s_2, \dots, s_m)$, $0 < s_1 < s_2 < \cdots < s_m < \bar{t}$, $\mathbf{p}$ is a probability vector $(p_1, p_2, \dots, p_m)$, $p_j \ge 0$, $\sum p_j = 1$, and $\mathbf{v} = (v_1, v_2, \dots, v_m)$, $v_j \in U$. The number m of spikes is arbitrary.

THEOREM 5.1. *Assume that $g(t, y)$ is differentiable with respect to y and the partial $\partial_y g(t, y)$ is continuous in $[0, \bar{t}] \times \mathbb{R}$. Then there exists a set e of full measure in $0 \le s \le \bar{t}$ such that if $s_j \in e$ $(j = 1, 2, \dots, m)$, then*

$$\boldsymbol{\xi}(t, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v}) = \lim_{h \to 0+} \frac{\mathbf{y}(t, \mathbf{u}_{\mathbf{s},\mathbf{p},h,\mathbf{v}}) - \mathbf{y}(t, \mathbf{u})}{h} \tag{5.3}$$

exists in the norm of $C(\bar{\Omega})$, convergence being uniform outside of the intervals $|s - s_j| < \varepsilon$, $j = 1, 2, \dots, m$ for any $\varepsilon > 0$. We have

$$\boldsymbol{\xi}(t, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v}) = \sum_{j=1}^{m} p_j \boldsymbol{\xi}(t, s_j, \mathbf{u}, v_j), \tag{5.4}$$

where $\xi(t, x, s, u, v) = \boldsymbol{\xi}(t, s, \mathbf{u}, v)(x)$ $(0 \le s \le \bar{t},\ v \in U)$ is the solution of the linear initial value problem

$$\xi_t(t, x, s, u, v) = \Delta_x \xi(t, x, s, u, v) \qquad ((t, x) \in (0, \bar{t}] \times \Omega), \tag{5.5}$$

$$\xi(0, x, s, u, v) = 0 \qquad (x \in \Omega), \tag{5.6}$$

$$\begin{aligned} \partial_\nu \xi(t, x, s, u, v) &= \partial_y g(t, y(t, x, u)) \xi(t, x, s, u, v) \\ &\quad + \delta(t - s)(v(x) - u(s, x)) \qquad ((t, x) \in (0, \bar{t}] \times \partial\Omega). \end{aligned} \tag{5.7}$$

Moreover,

$$\|h^{-1}(\mathbf{y}(t, \mathbf{u}_{\mathbf{s},\mathbf{p},h,\mathbf{v}}) - \mathbf{y}(t, \mathbf{u})) - \boldsymbol{\xi}(t, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v})\|_{C(\bar{\Omega})} \le C \sum_{j=1}^{m} \kappa(t, s_j, h, 1 - 2\mu) \tag{5.8}$$

for sufficiently small h, with $\kappa(t, h, s, \beta) = h(t - (s - h))$ for $\beta \ge 0$; for $\beta < 0$,

$$\kappa(t, h, s, \beta) = \begin{cases} 0 & (0 \le t \le s - h), \\ (t - (s - h))^\beta & (s - h \le t \le s), \\ (t - s)^\beta & (s \le t \le \bar{t}). \end{cases} \tag{5.9}$$

We note that, in view of the representation (3.6) for solutions of the nonlinear problem and the corresponding formula (3.15) for the linear problem, it is enough to prove (5.3), (5.4), and (5.8) for $\boldsymbol{\phi}(t, \mathbf{u})$, $\boldsymbol{\phi}(t, \mathbf{u}_{\mathbf{s},\mathbf{p},h,\mathbf{v}})$, $\boldsymbol{\psi}(t, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v})$, where $\boldsymbol{\phi}(t, \mathbf{u})$ (respectively, $\boldsymbol{\phi}(t, \mathbf{u}_{\mathbf{s},\mathbf{p},h,\mathbf{v}})$) is the boundary restriction of $\mathbf{y}(t, u)$ (respectively, $\mathbf{y}(t, \mathbf{u}_{\mathbf{s},\mathbf{p},h,\mathbf{v}})$) and

$$\boldsymbol{\psi}(t, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v}) = \sum_{j=1}^{m} p_j \boldsymbol{\psi}(t, s_j, u, v_j),$$

$\boldsymbol{\psi}(t,s,\mathbf{u},v)$ is the solution of the integral equation

$$\begin{aligned}\boldsymbol{\psi}(t,s,\mathbf{u},v) &= h(t-s)\mathbf{M}(t,s)(v-\mathbf{u}(s))\\ &\quad+\int_0^t \mathbf{M}(t,\tau)\partial_y\mathbf{g}(\tau,\boldsymbol{\phi}(\tau,\mathbf{u}))\boldsymbol{\psi}(\tau,s,\mathbf{u},v)d\tau,\end{aligned}\tag{5.10}$$

where $\partial_y\mathbf{g}(t,\boldsymbol{\phi})(x) = \partial_y g(t,\phi(x))$ ($\partial_y\mathbf{g}$ is the Fréchet derivative of $\mathbf{g}$). Also, existence of $\boldsymbol{\phi}(t,\mathbf{u}_{\mathbf{s,p},h,\mathbf{v}})$ in $0\le t\le \bar t$ is covered by Lemma 4.6. The proof of Theorem 5.1 is very similar to that of [11, Thm. 5.2], thus we only sketch it. In particular, we only treat the case of a single spike $\mathbf{u}_{s,h,v}(t) = v\in U$ $(s-h\le t\le s)$, $\mathbf{u}_{s,h,v}(t) = \mathbf{u}(t)$ elsewhere (for justification of a similar simplification see [11, §5]).

Define a $C(\partial\Omega)$-valued function by

$$\boldsymbol{\eta}(t,s,h) = h^{-1}(\boldsymbol{\phi}(t,\mathbf{u}_{s,h,v}) - \boldsymbol{\phi}(t,\mathbf{u})) - \boldsymbol{\psi}(t,s,\mathbf{u},v)).$$

Obviously, $\boldsymbol{\eta}(t,s,h) = 0$ for $t < s-h$. For $t\ge s-h$,

$$\begin{aligned}\boldsymbol{\eta}(t,s,h) =& \int_0^t \mathbf{M}(t,\tau)\partial_y\mathbf{g}(\tau,\boldsymbol{\phi}(\tau,\mathbf{u}))\boldsymbol{\eta}(\tau,s,h)d\tau\\ &+\int_0^t \mathbf{M}(t,\tau)h^{-1}\boldsymbol{\rho}(\tau,\boldsymbol{\phi}(\tau,\mathbf{u}),\boldsymbol{\phi}(\tau,\mathbf{u}_{s,h,v}))d\tau\\ &+\frac{1}{h}\int_{s-h}^s \mathbf{M}(t,\tau)(v-\mathbf{u}(\tau))d\tau - \mathbf{M}(t,s)(v-\mathbf{u}(s)),\end{aligned}\tag{5.11}$$

where $\boldsymbol{\rho}(t,\boldsymbol{\phi},\boldsymbol{\phi}') = \mathbf{g}(t,\boldsymbol{\phi}') - \mathbf{g}(t,\boldsymbol{\phi}) - \partial_y\mathbf{g}(t,\boldsymbol{\phi})(\boldsymbol{\phi}'-\boldsymbol{\phi})$. Taking norms,

$$\begin{aligned}\|\boldsymbol{\eta}(t,s,h)\| \le C\int_{s-h}^t (t-\tau)^{-\alpha}\|\boldsymbol{\eta}(\tau,s,h)\|d\tau\\ +\|\boldsymbol{\delta}_1(t,s,h)\| + \|\boldsymbol{\delta}_2(t,s,h)\|,\end{aligned}\tag{5.12}$$

where $\boldsymbol{\delta}_1$ (respectively, $\boldsymbol{\delta}_2$) is the second integral on the right-hand side of (5.11) (respectively, the combination of the third integral and the nonintegral term). Writing $r(t,s,h) = \|\boldsymbol{\delta}_1(t,s,h)\| + \|\boldsymbol{\delta}_2(t,s,h)\|$, we obtain from the generalized Gronwall inequality that

$$\|\boldsymbol{\eta}(t,s,h)\| \le r(t,s,h) + C\int_0^t (t-\tau)^{-\alpha}r(\tau,s,h)d\tau.\tag{5.13}$$

Assume we can show that

$$r(t,s,h)\le C\kappa(t,s,-\mu)\qquad (0\le t\le\bar t,\ 0<h\le\delta)\tag{5.14}$$

and that for every $\varepsilon>0$ we have

$$r(t,s,h)\to 0\quad\text{uniformly in } s+\varepsilon\le t\le\bar t.\tag{5.15}$$

Then all the claimed properties of $\boldsymbol{\eta}(t,s,h)$ will be a consequence of the result below, where $\mu<1$, $\{r(t,s,h);\ 0\le h\le\delta\}$ is a family of nonnegative functions in $L^1(0,\bar t)$ with $\mu(t,s,h) = 0$ for $t\le s-h$, and $\nu(t,s,h)$ is defined by

$$\nu(t,s,h) = \int_0^t (t-\tau)^{-\mu}r(\tau,s,h)d\tau.\tag{5.16}$$

LEMMA 5.2. *Assume that* $\{r(t,s,h);\ 0<h\le\delta\}$ *satisfies* (5.14). *Then*

$$\nu(t,s,h)\le C'\kappa(t,s,h,\,1-2\mu)\qquad(0\le t\le\bar t,\ 0\le h\le\delta). \tag{5.17}$$

Moreover, if $\{r(t,s,h)\}$ *is uniformly bounded in* $s+\varepsilon\le t\le\bar t$ *for any* $\varepsilon>0$ *and* $r(t,s,h)\to 0$ *as* $h\to 0$ *almost everywhere in* $s\le t\le\bar t$, *then* $\nu(t,s,h)\to 0$ *as* $h\to 0$ *uniformly for* $s+\varepsilon\le t\le\bar t$ *for any* $\varepsilon>0$.

For a proof see [11, Lem. 5.3]. To show (5.15) we note that, because of the uniform boundedness of the $\boldsymbol{\phi}(t,\mathbf{u}_{s,h,v})$ and the local Lipschitz continuity of $g(t,y)$, we have

$$\begin{aligned}\|\boldsymbol{\phi}(t,\mathbf{u}_{s,h,v})-\boldsymbol{\phi}(t,\mathbf{u})\|&\le C\int_0^t(t-\tau)^{-\mu}\|\boldsymbol{\phi}(\tau,\mathbf{u}_{s,h,v})-\boldsymbol{\phi}(\tau,\mathbf{u})\|d\tau\\&\le C'\int_{(0,t)\cap(s-h,s)}(t-\tau)^{-\mu}d\tau\le Ch\kappa(t,s,h,-\mu)\end{aligned} \tag{5.18}$$

[11, §5] and use again the local Lipschitz continuity of $\mathbf{g}$. $\boldsymbol{\delta}_2(t,s,h)$ is estimated in the same way using (3.3) and the last inequality (5.18) in the integral term. To show (5.15) for $\boldsymbol{\delta}_1$, we use the fact that $h^{-1}\boldsymbol{\rho}(t,\boldsymbol{\phi}(t,\mathbf{u}),\boldsymbol{\phi}(t,\mathbf{u}_{s,h,v}))\to 0$ for $t>s$. To deal with $\boldsymbol{\delta}_2$, let $\{t_n\}$ be an enumeration of the rationals in $0\le t\le\bar t$, and let $e_n\subseteq[0,t_n]$ be the set of the (left) Lebesgue points of the function $\tau\to\mathbf{N}(t_n,\tau)u(\tau)$ (which is strongly measurable by Lemma 3.1). Define $e=\cap_{n\ge1}(e_n\cup[t_n,\bar t])$. Then e has full measure in $0\le t\le\bar t$ and if $s\in e$, then $\boldsymbol{\delta}_2(t_n,s,h)\to 0$ for each n. On the other hand, if $t>s$ and $t_n\ge t$,

$$\begin{aligned}\|\boldsymbol{\delta}_2(t_n,s,u)-\boldsymbol{\delta}_2(t,s,u)\|\le{}&\frac{C}{h}\int_{s-h}^{s}\{(t_n-\tau)^{-\mu}-(t-\tau)^{-\mu}\}d\tau\\&+C\{(t_n-s)^{-\mu}-(t-s)^{-\mu}\}\end{aligned}$$

that can be made arbitrarily small taking t_n-t small enough. Thus (5.15) holds for $\boldsymbol{\delta}_2$ as well. This ends the proof of Theorem 5.1.

We compute directional derivatives (for $t=\bar t$) of

$$\begin{aligned}\mathbf{f}_0(\mathbf{u})=y_0(t,\mathbf{u})={}&\int_{(0,t)\times\Omega}f_0(\tau,y(\tau,x,u))dx\,d\tau\\&+\int_{(0,t)\times\partial\Omega}g_0(\tau,y(\tau,x,u),\,u(\tau,x))d\sigma\,d\tau.\end{aligned} \tag{5.19}$$

THEOREM 5.3. *Assume that* $f_0(t,y)$ *and* $g_0(t,y,u)$ *are continuous in all variables and continuously differentiable with respect to* y. *Let* $\mathbf{u}\in\mathbf{U}_{\text{ad}}(0,\bar t;\,U)$, $\mathbf{s}$, $\mathbf{p}$, h, $\mathbf{v}$, *be as in Theorem* 5.1. *Then there exists a set* $e_0\subseteq e$ *of full measure in* $0\le t\le\bar t$ *such that if* $s_j\in e_0$, *then*

$$\xi_0(\bar t,\mathbf{s},\mathbf{p},\mathbf{u},\mathbf{v})=\lim_{h\to0+}\frac{y_0(\bar t,\mathbf{u}_{\mathbf{s},\mathbf{p},h,\mathbf{v}})-y_0(\bar t,\mathbf{u})}{h} \tag{5.20}$$

exists and equals

$$\xi_0(t,x,\mathbf{s},\mathbf{p},\mathbf{u},\mathbf{v})=\sum_{j=1}^{m}p_j\xi_0(t,x,s_j,\mathbf{u},v_j), \tag{5.21}$$

where

$$\xi_0(t,x,s,\mathbf{u},v) = \int_{(s,t)\times\Omega} \partial_y f_0(\tau, y(\tau,x,u))\xi(\tau,x,s,u,v)dx\,d\tau$$

$$+ \int_{(s,t)\times\partial\Omega} \partial_y g_0(\tau, y(\tau,x,u))\xi(\tau,x,s,u,v)d\sigma\,d\tau \tag{5.22}$$

$$+ \int_{\partial\Omega} g_0(s, y(s,x,u),\, v(x))d\sigma - \int_{\partial\Omega} g_0(s, y(s,x,u), u(s,x))d\sigma.$$

The proof is based on (5.3), (5.4), and (5.8). We omit the details.

6. The maximum principle. We apply the abstract nonlinear programming theory in [11, §2] to the optimal control problem written in the form

$$\text{minimize } \mathbf{f}_0(\mathbf{u}) \quad \text{subject to } \mathbf{f}(\mathbf{u}) \in Y, \tag{6.1}$$

where $\mathbf{f}$ (respectively, $\mathbf{f}_0$) is defined by (5.1) (respectively, (5.19)) in the space $\mathbf{U}_{\text{ad}}(0,\bar{t};\, U)$, equipped with the distance (4.6) that makes the space complete. The function $\mathbf{f}$ is (Hölder) continuous (Corollary 4.6).

LEMMA 6.1. *Let* $\bar{\mathbf{u}}$, ρ, μ *be as in Corollary* 4.6. *Then*

$$|y_0(t,\mathbf{v}) - y_0(t,\mathbf{u})| \le Cd(\mathbf{v},\mathbf{u})^{1-\mu} \qquad (\mathbf{u},\mathbf{v} \in B(\bar{\mathbf{u}},\rho)). \tag{6.2}$$

The estimation of the first integral in (5.19) is immediate from (4.7) and y-differentiability of f_0. In the second, we rewrite the integrand in the form $g_0(t, y(t,x,v), v(t,x)) - g_0(t, y(t,x,v), u(t,x)) + g_0(t, y(t,x,v), u(t,x)) - g_0(t, y(t,x,u), u(t,x))$. The second integral is estimated again using (4.7) and differentiability of g_0; the integrand in the first vanishes outside of $\{t;\, \mathbf{u}(t) \ne \mathbf{v}(t)\}$, so that the integral is $\le Cd(\mathbf{v},\mathbf{u})$.

Having checked (with excess) all hypotheses to apply Theorem 2.8 in [11], let $\bar{\mathbf{u}}$ be a solution of (6.1) (that is, an optimal control). Theorem 2.8 provides a sequence $\{\mathbf{u}^n\} \in \mathbf{U}_{\text{ad}}(0,\bar{t};\, U)$ with $\mathbf{u}^n \to \bar{\mathbf{u}}$ ($d(\mathbf{u}^n,\bar{\mathbf{u}}) \to 0$ as fast as we wish) such that, if $\{\mathbf{D}_n\}$ is a sequence of convex sets with $\mathbf{D}_n \subseteq \partial(\mathbf{f}_0,\mathbf{f})(\mathbf{u}^n)$, there exists a sequence $\{(\mu_n,\nu_n)\} \subseteq \mathbb{R} \times C(\bar{\Omega})^* = \mathbb{R} \times \Sigma(\bar{\Omega})$ such that

$$\mu_n^2 + \|\nu_n\|^2 = 1, \quad \mu_n \ge 0, \quad \mu_n\eta^n + \langle \nu_n, \xi^n\rangle \ge -\delta_n \tag{6.3}$$

for $(\eta^n,\xi^n) \in \mathbf{D}_n$, where $\delta_n \to 0$. If (μ,ν) is the $\mathbb{R} \times C(\bar{\Omega})$-weak limit of (a subsequence of) $\{(\mu_n,\nu_n)\}$, we obtain the Kuhn–Tucker inequality

$$\mu\eta + \langle \nu, \xi\rangle \ge 0 \tag{6.4}$$

for (η,ξ) in the set $\liminf_{n\to\infty} \mathbf{D}_n$ of all limits of sequences $\{(\eta^n,\xi^n)\}$, $(\eta^n,\xi^n) \in \mathbf{D}_n$. Here, $\mathbf{D}_n$ consists of all elements

$$(\xi_0(\bar{t},\mathbf{s},\mathbf{p},\mathbf{u},\mathbf{v}), \boldsymbol{\xi}(\bar{t},\mathbf{s},\mathbf{p},\mathbf{u},\mathbf{v})), \tag{6.5}$$

where $\mathbf{u} = \mathbf{u}^n$, $\boldsymbol{\xi}(\bar{t},\mathbf{s},\mathbf{p},\mathbf{u}^n,\mathbf{v})$ (respectively, $\xi_0(\bar{t},\mathbf{s},\mathbf{p},\mathbf{u}^n,\mathbf{v})$) is given by (5.4) (respectively, (5.21)). So that $\mathbf{D}_n$ is convex, we must allow for the possibility that two or more of the s_j in the vector $\mathbf{s}$ coincide.

LEMMA 6.2. *Let* $\mathbf{u} \in \mathbf{U}_{\text{ad}}(0,\bar{t};\, U)$. *Then there exists a set* e *of full measure in* $0 \le t \le \bar{t}$ *such that* (6.5) *belongs to* $\partial(\mathbf{f}_0,\mathbf{f})(\mathbf{u})$ *for* $\mathbf{s} = (s_1, s_2, \dots, s_m)$, $s \in e$, $0 < s_1 \le s_2 \le \cdots \le s_m < \bar{t}$.

Proof. We limit ourselves to the case $\mathbf{s} = (s, s)$ with $0 < s < \bar{t}$, which puts in evidence the general argument. We only have to construct two sequences $\{s_n^-\}$, $\{s_n^+\} \subset e$, e the set in Theorem 5.1 such that if $\mathbf{s}_n = (s_n^-, s_n^+)$, then $\boldsymbol{\xi}(\bar{t}, \mathbf{s}_n, \mathbf{p}, \mathbf{u}, \mathbf{v}) \to \boldsymbol{\xi}(\bar{t}, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v})$, $\boldsymbol{\xi}_0(\bar{t}, \mathbf{s}_n, \mathbf{p}, \mathbf{u}, \mathbf{v}) \to \boldsymbol{\xi}_0(\bar{t}, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v})$.

In view of the integral equation (3.15), the boundary projection $\boldsymbol{\psi}(t, s, \mathbf{u}, v) = \Pi \circ \boldsymbol{\xi}(t, s, \mathbf{u}, v)$ is

$$\boldsymbol{\psi}(t, s, \mathbf{u}, v) = \mathbf{U}(t, s, \mathbf{u})(v - \mathbf{u}(s)), \tag{6.6}$$

where the operator $\mathbf{U}(t, s, \mathbf{u})$ is given by the integral equation

$$\mathbf{U}(t, s, \mathbf{u}) = \mathbf{M}(t, s) + \int_0^t \mathbf{M}(t, \tau)\partial_y \mathbf{g}(\tau, \mathbf{y}(\tau, \mathbf{u}))\mathbf{U}(\tau, s, \mathbf{u})d\tau. \tag{6.7}$$

Solving by successive approximations and using the properties of $\mathbf{M}(t, s)$, we show that $\mathbf{U}(t, \tau, \mathbf{u}) \in L(L^\infty(\partial\Omega), C(\bar{\Omega}))$ and that $\mathbf{U}(t, \tau, \mathbf{u})$ is continuous in $t, \tau, \mathbf{u}$ for $0 \le \tau < t \le \bar{t}$, $\mathbf{u} \in \mathbf{U}_{\text{ad}}(0, \bar{t}; U)$ ($\mathbf{U}_{\text{ad}}(0, \bar{t}; U)$ endowed with the distance (4.6)) in the norm of $L(L^\infty(\partial\Omega), C(\bar{\Omega}))$. Moreover,

$$\|\mathbf{U}(t, \tau, \mathbf{u})\|_{L(L^\infty(\partial\Omega), C(\bar{\Omega}))} \le B(t - \tau)^{-\mu} \qquad (0 \le \tau < t \le \bar{t}). \tag{6.8}$$

Using the argument in Lemma 3.1, we show that $s \to \boldsymbol{\psi}(\bar{t}, s, \mathbf{u}, v) = \mathbf{U}(\bar{t}, s, \mathbf{u})(v - \mathbf{u}(s))$ is strongly measurable in $0 \le t \le \bar{t}$. Hence if s is a Lebesgue point of $\boldsymbol{\psi}(\bar{t}, \cdot, \mathbf{u}, v)$ and

$$e(s, h) = \{\sigma;\ s - h \le \sigma \le h;\ \|\boldsymbol{\psi}(\bar{t}, \sigma, \mathbf{u}, v) - \boldsymbol{\psi}(\bar{t}, s, \mathbf{u}, v)\| \ge h\},$$

then $\text{meas}\, e(s, h) = o(h)$. It follows that there exists a sequence $\{s_n^-\}$ in the set e of Theorem 5.1, $s_n < s$ such that $s_n^- \to s$, $\boldsymbol{\psi}(\bar{t}, s_n^-, \bar{\mathbf{u}}, v) \to \boldsymbol{\psi}(\bar{t}, s, \bar{\mathbf{u}}, v)$. A similar argument produces a corresponding sequence $\{s_n^+\}$ of similar properties with $s_n^+ > s$ and thus completes the proof. The treatment of $\xi_0(\bar{t}, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v})$ is similar. □

LEMMA 6.3. *Let $\{t_n\}$ be a sequence in $0 \le t \le \bar{t}$ with $t_n \to \bar{t}$ and $\{\mathbf{u}^n\}$ be a sequence in $\mathbf{U}_{\text{ad}}(0, t_n, U)$ such that $\sum d_n(\mathbf{u}^n, \bar{\mathbf{u}}) < \infty$. Then there exists a set e of full measure in $0 \le s \le \bar{t}$ such that if $s_j \in e$ and n is large enough, then the directional derivatives $\boldsymbol{\xi}(\bar{t}, \mathbf{s}, \mathbf{p}, \mathbf{u}^n, \mathbf{v})$, $\xi_0(\bar{t}, \mathbf{s}, \mathbf{p}, \mathbf{u}^n, \mathbf{v})$ exist and converge to* (6.5).

Proof. Let $e_n = \{t;\ 0 \le t \le t_n, \bar{\mathbf{u}}(t) \ne \mathbf{u}^n(t)\}$. Then $\sum_n \text{meas}(c_n) < \infty$, and if $e = \cap_{m \ge 1} \cup_{n \ge m} c_n$, $\text{meas}(e) = 0$; if $t \notin e$, $\mathbf{u}^n(t) = \bar{\mathbf{u}}(t)$ for sufficiently large n. We use formula (6.6) and $\mathbf{u}$-continuity of the operator $U(t, \tau, \mathbf{u})$. The argument for $\xi_0(\bar{t}, \mathbf{s}, \mathbf{p}, \mathbf{u}, \mathbf{v})$ is similar. □

Lemma 6.3 shows that there exists a set e of full measure in $0 \le t \le \bar{t}$ such that (6.5) belongs to $\liminf_{n \to \infty} \mathbf{D}_n$ if $s_j \in e$.

THEOREM 6.4. *Let $\bar{u}(t, x) \in L^\infty((0, T) \times \partial\Omega) = L_W^\infty(0, T; L^\infty(\partial\Omega))$ be an optimal control. Then there exists a set e of full measure in $0 \le t \le \bar{t}$ and $(\mu, \nu) \in \mathbb{R} \times \Sigma(\bar{\Omega})$, $\mu \ge 0$ such that, if $z(t, x)$ is the solution of the final value problem*

$$z_t(t, x) = -\Delta z(t, x) - \mu\partial_y f_0(t, y(t, x, \bar{u})) \qquad ((t, x) \in [0, \bar{t}] \times \Omega), \tag{6.9}$$

$$z(\bar{t}, \cdot) = \nu \qquad (x \in \bar{\Omega}), \tag{6.10}$$

$$\partial_\nu z(t, x) = \partial_y g(t, y(t, x, \bar{u}))z(t, x) - \mu\partial_y g_0(t, y(t, x, \bar{u}) \qquad (t, x) \in [0, \bar{t}] \times \partial\Omega, \tag{6.11}$$

then we have

$$\begin{aligned}&\int_{\partial\Omega}\{z(s,x)\bar{u}(s,x)+\mu g_0(s,y(s,y(s,x,\bar{u}),\bar{u}(s,x)))\}d\sigma\\&\quad=\min_{v\in U}\int_{\partial\Omega}\{z(s,x)v(x)+\mu g_0(s,y(s,x,\bar{u}),v(x))\}d\sigma\end{aligned}\tag{6.12}$$

almost everywhere in $0\le t\le\bar{t}$.

Proof. We use the Kuhn–Tucker inequality (6.4) for the elements (6.5) of $\liminf_{n\to\infty}\mathbf{D}_n$. For single spikes we obtain

$$\mu\xi_0(\bar{t},x,s,\bar{u},v)+\langle\nu,\xi(\bar{t},x,s,\bar{u},v)\rangle\ge 0$$

so that

$$\begin{aligned}&\mu\int_{(s,\bar{t})\times\Omega}\partial_y f_0(\tau,y(\tau,x,\bar{u}))\xi(\tau,x,s,\bar{u},v)dx\,d\tau\\&\quad+\mu\int_{(s,\bar{t})\times\partial\Omega}\partial_y g_0(\tau,y(\tau,x,\bar{u}))\xi(\tau,x,s,\bar{u},v)d\sigma\,d\tau\\&\quad+\mu\int_{\partial\Omega}\{g_0(s,y(t,x,\bar{u}),v(x))-g_0(s,y(t,x,\bar{u}),\bar{u}(s,x))\}d\sigma\\&\quad+\int_{\bar{\Omega}}\xi(\bar{t},x,s,\bar{u},v)\nu(dx)\ge 0.\end{aligned}\tag{6.13}$$

Using Theorem 4.8, (6.12) results. □

For the time optimal problem apply Theorem 2.4 in [11] to the sequence of functions $\mathbf{f}_n(\mathbf{u})=\mathbf{y}(t_n,\mathbf{u}),\mathbf{f}_n:\mathbf{U}_{\text{ad}}(0,t_n;U)\to C(\bar{\Omega})$, where $\{t_n\}$ is a sequence with $t_n<\bar{t}=$ optimal time, $t_n\to\bar{t}$ (see [11] for details). If $\bar{\mathbf{u}}$ is a time optimal control, Theorem 2.4 provides a sequence $\{\mathbf{u}^n\}$, $\mathbf{u}^n\in\mathbf{U}_{\text{ad}}(0,t_n;U)$ (with $d_n(\mathbf{u}^n,\bar{\mathbf{u}})\to 0$ as fast as we wish, d_n the distance (4.6)) such that, if $\{\mathbf{D}_n\}$ is a sequence of convex sets with $\mathbf{D}_n\subseteq\partial\mathbf{f}_n(\mathbf{u}^n)$, there exists a sequence $\{\nu_n\}\subseteq C(\bar{\Omega})^*=\Sigma(\bar{\Omega})$ such that

$$\|\nu_n\|^2=1,\qquad\langle\nu_n,\xi^n\rangle\ge-\delta_n\tag{6.14}$$

for every $\xi^n\in\mathbf{D}_n$, where $\delta_n\to 0$. Taking limits,

$$\langle\nu,\xi\rangle\ge 0.\tag{6.15}$$

For single-spike perturbations,

$$\int_{\bar{\Omega}}\xi(\bar{t},x,s,\bar{u},v)\nu(dx)\ge 0\tag{6.16}$$

for all s in a total set e and all $v\in e$. Operating as above, we obtain the following theorem.

THEOREM 6.5. *Let $\bar{u}(t,x)$ be an optimal control for the time optimal problem. Then there exists $\nu\in\Sigma(\bar{\Omega})$ such that, if $z(t,x)$ is the solution of*

$$z_t(t,x)=-\Delta z(t,x)\qquad(t,x)\in[0,\bar{t})\times\Omega,\tag{6.17}$$

$$z(\bar{t},\cdot)=\nu\qquad(x\in\bar{\Omega}),\tag{6.18}$$

$$\partial_\nu z(t,x)=\partial_y g(t,y(t,x,u))z(t,x)\qquad(t,x)\in[0,\bar{t})\times\partial\Omega,\tag{6.19}$$

then we have

$$\int_{\partial\Omega} z(s,x)\bar{u}(s,x)d\sigma = \min_{v\in U}\int_{\partial\Omega} z(s,x)v(x)d\sigma \quad \textit{almost everywhere in } 0\le t\le \bar{t}. \tag{6.20}$$

Without special assumptions, the multipliers (μ,ν) in Theorem 6.4 and ν in Theorem 6.5 may be trivial. Conditions for the abstract nonlinear programming problem that prevent this are given in [11, Lem. 2.5]. For the general problem, this result requires a compact set Q such that

$$\Delta = \bigcap_{n\ge 1}(\overline{\text{conv}}(\Delta_n)+Q) \tag{6.21}$$

contains an interior point, where $\Delta_n = \Pi(\mathbf{D}_n)-N_Y(\mathbf{y}^n)+Q$; $\{\mathbf{D}_n\}$, the sequence in provided by [15, Thm. 2.8]; Π, the canonical projection from $\mathbb{R}\times C(\bar{\Omega})$ into $C(\bar{\Omega})$; $\{\mathbf{y}_n\}$, a sequence in the target set Y with $\mathbf{y}^n\to\bar{\mathbf{y}}=\mathbf{y}(\bar{t},\bar{\mathbf{u}})$; and $N_Y(\bar{\mathbf{y}})$, the tangent cone to Y at $\bar{\mathbf{y}}$. It can be shown that, due to the smoothing properties of the heat equation, $\Pi(\mathbf{D}_n)+Q$ will never satisfy this condition by itself, thus we must rely on a "large" target set Y. A suitable target set is, for instance $Y=C\cap B(x,\varepsilon)$, where C is the variety in $C(\bar{\Omega})$ defined by $\phi_1(y)=\phi_2(y)=\cdots=\phi_p(y)=0$, the ϕ_j continuously differentiable functionals with $\{\partial_j\phi(y)\}$ linearly independent in $C(\bar{\Omega})^*=\Sigma(\bar{\Omega})$. In the time optimal case, $\Delta_n=\mathbf{D}_n-N_Y(\mathbf{y}^n)+Q$ and the same comments apply. (See [11] for a similar situation for distributed parameter systems.)

There are some indications that the point target case for the general control problem as well as for the time optimal problem could be treated in controllability subspaces such as those provided in [25]. This has been done in the linear case (using separation theorems) in [5], [6]. However, the nonlinear case seems to be open.

Acknowledgment. The authors are grateful to the referee for numerous bibliographical indications.

ON BROCKETT'S CONDITION FOR SMOOTH STABILIZABILITY AND ITS NECESSITY IN A CONTEXT OF NONSMOOTH FEEDBACK*

E. P. RYAN†

Abstract. The necessity of Brockett's condition for stabilizability of nonlinear systems by smooth feedback is shown, by an argument based on properties of a degree for set-valued maps, to persist when the class of controls is enlarged to include discontinuous feedback.

Key words. degree, discontinuous control, nonlinear systems, nonsmooth feedback, set-valued maps, stabilizability

AMS subject classifications. 34D99, 55M25, 93B55, 93D15

1. Introduction.

Consider the control system

$$\dot{x}(t) = f(x(t), u(t)), \quad x(0) = x^0 \in \mathbb{R}^N, \quad f(0,0) = 0, \tag{1}$$

with $f : \mathbb{R}^N \times \mathbb{R}^M \to \mathbb{R}^N$ continuous. In the case of linear f, it is well known that the system is (globally) asymptotically null controllable if and only if it is stabilizable by (linear) feedback. Brockett [2] has shown that an analogous equivalence of (local) asymptotic null controllability and (nonlinear) feedback stabilizability does not hold for smooth (by which we mean C^1) nonlinear systems. In particular, he proved a result that implies the following necessary condition for (local) smooth stabilizability—henceforth referred to as Brockett's condition.

BROCKETT'S CONDITION. *Let $f \in C^1$. If (1) is C^1 stabilizable (in the sense that there exists a time-invariant C^1 feedback that renders $\{0\}$ both Lyapunov stable and an attractor), then the image of f contains an open neighbourhood of 0.*

If f is linear, that is, if $f(x,u) = Ax + Bu$, then the necessary condition for stabilizability is simply the requirement that $[A : B]$ be of full rank, and this is implied by asymptotic null controllability of the linear system. However, for general $f \in C^1$, (local asymptotic) null controllability of (1) does not imply that f has the above property, a (now classic) illustration is the case

$$f : \mathbb{R}^3 \times \mathbb{R}^2 \to \mathbb{R}^3, \qquad (x,u) = (x_1, x_2, x_3, u_1, u_2) \mapsto (u_1, u_2, x_2u_1 - x_1u_2)$$

that defines a completely controllable bilinear system (1) for which $(0,0,\epsilon) \notin \mathrm{im}(f)$ for all $\epsilon \neq 0$, and so this system is not C^1 stabilizable.

Such examples are counterintuitive. It is tempting to conjecture that the "gap" between controllability and feedback stabilizability is due to the restriction to the class of smooth (C^1) time-invariant feedbacks. As in Sontag [11], the investigation readily extends to time-invariant feedbacks that are only locally Lipschitz (in fact, even this requirement is too strong, its consequence, *uniqueness of the solution* of the feedback-controlled initial-value problem, suffices as in [13]) and the gap is found to persist. Furthermore, Zabczyk [13] has shown that the necessity of Brockett's condition on f also persists when "stabilizability by time-invariant continuous feedback is interpreted in either of the following senses: (i) that of rendering $\{0\}$ a global attractor (which, of course, does not imply Lyapunov stability of $\{0\}$), or (ii) in the case of $n \leq 2$, that of rendering $\{0\}$ Lyapunov stable. Two possible avenues for further investigation suggest themselves naturally: (a) time-varying feedback and (b) discontinuous feedback. The former avenue has been followed by Coron [5]. In the case of $f(x,u) = \sum_{i=1}^{M} u_i f_i(x)$ with

$f_i \in C^\infty(\mathbb{R}^N)$, he has established that the accessibility rank condition, $\dim \mathrm{Lie}(\Phi)(x) = N$ for all $x \in \mathbb{R}^N \backslash \{0\}$ (where $\mathrm{Lie}(\Phi)$ denotes the Lie algebra of vector fields generated by $\Phi = (f_1, \ldots, f_M)$), is sufficient for the existence of T-periodic C^∞ feedbacks that globally asymptotically stabilize (1). In particular, this result applies to the example cited above. In the present paper, we take the second avenue and restrict to time-invariant feedbacks.

Discontinuous feedbacks arise naturally in many areas of control theory (see [7]) and practice (indeed, bang-bang or relay-type control actions permeate much of the early development of the field). It is not difficult to construct examples that fail to be locally asymptotically stabilizable by continuous feedback, but that are so stabilizable by discontinuous feedback. One such example is system (1) with $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$, $(x, u) \mapsto x + |x|u$. Therefore, the additional dynamic behaviours engendered by discontinuous feedbacks (that subsume the continuous case) raise the question of whether or not their adoption might close the controllability-stabilizability gap. Here this question is answered negatively. We show that with f only required to be continuous and to have property (2), below, and with the class of time-invariant feedbacks taken to be that of upper semicontinuous set-valued maps with nonempty convex and compact values (a class into which a wide variety of discontinuous strategies may be embedded and within which continuous feedbacks may be identified with the subclass of singleton-valued maps), the necessity of Brockett's condition on f again persists.

2. Class of systems and statement of main result. We study systems of form (1) and assume only that continuous f has the property (see also Remark 1, below)

$$K \subset \mathbb{R}^M \text{ convex} \Longrightarrow f(x, K) \subset \mathbb{R}^N \text{ convex}. \tag{2}$$

Evidently, (2) holds for systems that are linear in the control.

As *admissible feedback controls* for (1), we take the class $\mathcal{K}$ of upper semicontinuous maps $x \mapsto k(x) \subset \mathbb{R}^M$ on $\mathbb{R}^N$, with nonempty convex and compact values and with $0 \in k(0)$. For example, in the case $M = 1$, discontinuous feedbacks of the form $x \mapsto \gamma(x)\mathrm{sgn}(\xi(x))$, with γ and ξ continuous and such that the product $\gamma(0)\xi(0)$ is zero, fall within our framework if the signum function is interpreted as the upper semicontinuous set-valued map

$$v \mapsto \mathrm{sgn}(v) := \begin{cases} \{+1\}, & v > 0, \\ [-1, 1], & v = 0, \\ \{-1\}, & v < 0. \end{cases}$$

For every feedback $k \in \mathcal{K}$, the map $x \mapsto f(x, k(x))$ is also upper semicontinuous with nonempty convex and compact values. Therefore, for each $x^0 \in \mathbb{R}^N$, the initial-value problem

$$\dot{x}(t) \in f(x(t), k(x(t))), \qquad x(0) = x^0 \tag{3}$$

has at least one solution (see [1, Thm. 2.1.3]), that is, a function $x : [0, \omega) \to \mathbb{R}^N$, with $x(0) = x^0$, that is absolutely continuous on compact subintervals and that satisfies the differential inclusion in (3) almost everywhere. Moreover, every solution x can be maximally extended. Furthermore, if x is bounded on its maximal interval of existence $[0, \omega)$, then $\omega = \infty$ (see, for example, [10]). We say that $\{z\}$ is an equilibrium of (3) if $0 \in f(z, k(z))$. Note that, for each $k \in \mathcal{K}$, $\{0\}$ is an equilibrium of (3).

In contrast with the smooth case, the property of uniqueness of the solution for the initial-value problem (3) clearly does not hold in our general nonsmooth framework. Implicit in the following definition is a notion of local asymptotic stability wherein we impose "equi-attractivity" of the equilibrium $\{0\}$. In essence, attraction to this equilibrium is required to be uniform with respect to nonunique solutions.

DEFINITION 1. *A feedback control $k \in \mathcal{K}$ is said to be* equi-asymptotically stabilizing *for* (1) *if it renders the equilibrium* $\{0\}$ *of* (3) *equi-asymptotically stable in the sense that the following two properties hold.*

(i) Lyapunov stability of the equilibrium $\{0\}$: *for each* $\rho > 0$, *there exists* $\delta > 0$ *such that*

$$\|x^0\| \leq \delta \Longrightarrow \|x(t)\| < \rho \quad \text{for all } t \geq 0$$

for every maximal solution x *of the initial-value problem* (3).

(ii) Equi-attractivity of the equilibrium $\{0\}$: *there exists* $\delta > 0$ *and, to each* $\tau > 0$, *there corresponds* $T > 0$ *such that*

$$\|x^0\| \leq \delta \Longrightarrow \|x(t)\| < \tau \quad \text{for all } t \geq T$$

for every maximal solution x *of the initial-value problem* (3).

Although the above definition is intrinsic to the problem, the following weaker (but somewhat artificial) property of the feedback is all that is required in the analysis.

DEFINITION 2. *A feedback control $k \in \mathcal{K}$ is said to be* equi-constricting *for* (1) *if* (3) *has the following property. There exist scalars* $\rho > \delta > \tau > 0$ *and* $T > 0$ *such that*

$$\|x^0\| \leq \delta \Longrightarrow \|x(t)\| < \rho \quad \text{for all } t \geq 0 \quad \text{and} \quad \|x(t)\| < \tau \quad \text{for all } t \in [T, 2T]$$

for every maximal solution x *of* (3).

It is clear that, if $k \in \mathcal{K}$ is an equi-asymptotically stabilizing feedback for (1), then k is an equi-constricting feedback for (1). While the former concept is manifestly more natural from an applications viewpoint, the latter is considerably weaker. In particular, Definition 2 simply invokes the existence of *some* quadruple (ρ, δ, τ, T), assuring the requisite properties. In essence, solutions of (3) are required only to be bounded uniformly with respect to initial data in some closed ball (of radius δ) and, on an interval $[T, 2T]$, to take their values in some smaller ball (of radius $\tau < \delta$).

The main result we will prove is the following.

THEOREM 1. *Let f be continuous with property* (2). *If there exists an equi-constricting feedback control $k \in \mathcal{K}$ for* (1), *then the image of f contains an open neighbourhood of* 0.

A simple modification to the proof of Theorem 1 will yield the following generalization of Brockett's condition.

COROLLARY 1. *Let f be continuous with property* (2). *If there exists an equi-asymptotically stabilizing feedback control $k \in \mathcal{K}$ for* (1), *then, for each open neighbourhood $\mathcal{N}$ of $0 \in \mathbb{R}^N$, $f(\mathcal{N} \times \mathbb{R}^M)$ contains an open neighbourhood of* 0.

Remark 1. If $\mathcal{K}$ is replaced by the class of C^1 feedbacks and attention is restricted to functions $f \in C^1$, then condition (2), which plays its role only in assuring that the right hand side of (3) takes convex values, may be removed; furthermore, the qualifier "equi" in Definition 2 is redundant. In this manner, Brockett's original result for smooth systems may be recovered as a special case of the above. It is in this sense that we regard Corollary 1 as a generalization of Brockett's condition.

The proof of Theorem 1, which is given in §4, is degree-theoretic in nature and similar in concept to the approaches of [8, §52], [11, §4.8], and [13, §2]. However, in the present nonsmooth setting, we first require some appropriate notion of degree for set-valued maps. This has been investigated by Cellina and Lasota [3] (see also [9], [12], [6]), and a distillation of results pertinent to our application is given in the next section.

3. Degree for set-valued maps. Here the objective is to reiterate, within the framework of [3], [12] but tailored to our immediate purpose, some results pertaining to degree for set-valued maps. The approach to defining degree for a (suitably regular) set-valued map F is via the Brouwer degree for single-valued approximate selections for F. With this in mind, some basic definitions and properties of upper semicontinuous maps and approximate selections (for details, see [1], [6]) are initially assembled.

3.1. Upper semicontinuous maps and approximate selections. For notational convenience, write $X := \mathbb{R}^N$. The ball of radius $r > 0$, centred at $c \in X$, will be denoted $B_r(c)$; when $c = 0$, we simply write B_r. For nonempty subsets U, V of a Banach space Y, define

$$d(y, V) := \inf_{v \in V} \|y - v\| \quad \text{for all } y \in Y, \quad \text{and} \quad d^*(U, V) := \sup_{u \in U} d(u, V).$$

Let $x \mapsto F(x) \subset X$, with domain $\mathrm{dom}(F) = D \subset X$, have nonempty values. F is upper semicontinuous if it is upper semicontinuous at each $x \in D$: for each $\epsilon > 0$, there exists $\delta > 0$ such that

$$F(w) \subset F(x) + B_\epsilon \quad \text{for all } w \in D \cap B_\delta(x).$$

If $C \subset D$ is compact and F is upper semicontinuous with compact values, then $F(C)$ is compact.

THEOREM 2 (Approximate selection theorem). *Let F be an upper semicontinuous map with domain $D \subset X$ and taking nonempty convex compact values in X. For each $\epsilon > 0$, there exists a locally Lipschitz single-valued function $f_\epsilon : D \to \mathrm{co}(F(D))$ such that*

$$d^*(\mathrm{graph}(f_\epsilon), \mathrm{graph}(F)) < \epsilon.$$

(Any such f_ϵ will be referred to as an approximate selection for F.)

3.2. Construction and properties of degree. Initially, we recall *Brouwer degree* in the context of single-valued maps. As before, let $X := \mathbb{R}^N$. Henceforth, $\Omega \subset X$ is a bounded open set, with closure $\bar{\Omega}$ and boundary $\partial\Omega$. Let

$$\mathcal{M} = \{(f, \Omega, p) | X \supset \Omega \text{ open bounded}, f : \bar{\Omega} \to X \text{ continuous}, p \in X \backslash f(\partial\Omega)\},$$

then the Brouwer degree $\deg_B$ is the unique map $\mathcal{M} \to \mathbb{Z}$ with the following properties:

B-1. $\deg_B(I, \Omega, p) = 1$ for all $p \in \Omega$;

B-2. If $\deg_B(f, \Omega, p) \neq 0$, then $p = f(x)$ for some $x \in \Omega$;

B-3. (Homotopic invariance). If $h : [0, 1] \times \bar{\Omega} \to X$ and $q : [0, 1] \to X$ are continuous with $q(t) \notin h(t, \cdot)(\partial\Omega)$ for all $t \in [0, 1]$, then $\deg_B(h(t, \cdot), \Omega, q(t))$ is independent of $t \in [0, 1]$;

B-4. (Odd mappings). If Ω contains, and is symmetric about, the origin in X and $f(-x) = -f(x)$ for all $x \in \partial\Omega$, then $\deg_B(f, \Omega, 0)$ is odd (and so is nonzero).

The class of set-valued maps F, to which the ensuing construction [3], [12] of degree applies, are precisely those satisfying the hypotheses of Theorem 2: upper semicontinuous maps $x \mapsto F(x) \subset X$ from $\mathrm{dom}(F) \subset X$ to the nonempty convex compact subsets of X.

For every open bounded Ω, with closure $\bar{\Omega} \subset \mathrm{dom}(F) \subset X$, and every $p \in X \backslash F(\partial\Omega)$, we define an integer $\deg(F, \Omega, p)$, the degree of F (with respect to the set Ω and point p).

3.2.1. Construction. Let $p \in X \backslash F(\partial\Omega)$ and let $F^{(p)}$ denote the map defined on compact $\bar{\Omega}$ by $x \mapsto F(x) - \{p\} = \{v - p | v \in F(x)\}$. By Theorem 2, for each $\epsilon > 0$ there exists an approximate selection f_ϵ for $F^{(p)}$. We first show that, for all $\epsilon > 0$ sufficiently small, every such approximate selection f_ϵ has no zeros in $\partial\Omega$. Suppose otherwise. Then there

exist sequences (ϵ_n), (f_{ϵ_n}), and $(x_n) \subset \partial\Omega$, with $\epsilon_n \downarrow 0$, $0 = f_{\epsilon_n}(x_n) \in \text{co}(F^{(p)}(\bar{\Omega}))$, and $0 \in F^{(p)}(y_n) + B_{\epsilon_n}$ for some $y_n \in \bar{\Omega}$ with $\|x_n - y_n\| < \epsilon_n$. By compactness of $\bar{\Omega}$, (y_n) has a convergent subsequence (that we do not relabel), with limit z say, and so $x_n \to z \in \partial\Omega$ as $n \to \infty$. By upper semicontinuity of $F^{(p)}$, for each $\epsilon > 0$, $0 \in F^{(p)}(z) + B_{\epsilon_n+\epsilon}$ for all n sufficiently large. Therefore, $0 \in \overline{F^{(p)}(z)} = F^{(p)}(z)$ and so $p \in F(z)$ with $z \in \partial\Omega$, a contradiction. It follows that for all $\epsilon > 0$ sufficiently small, $\deg_B(f_\epsilon, \Omega, 0)$ is well defined for every approximate selection f_ϵ for $F^{(p)}$.

Let f_ϵ and g_ϵ be any two such approximate selections. Define the continuous function

$$h_\epsilon : [0,1] \times \bar{\Omega} \to X, \qquad (t,x) \mapsto tf_\epsilon(x) + (1-t)g_\epsilon(x).$$

For all $\epsilon > 0$ sufficiently small, $h_\epsilon(t,\cdot)$ has no zeros in $\partial\Omega$ for every $t \in [0,1]$. This can be argued (in a similar manner to above) by contradiction. Suppose otherwise; then there exist $t \in [0,1]$, a sequence (ϵ_n) with $\epsilon_n \downarrow 0$, and a sequence $(x_n) \subset \partial\Omega$ such that

$$0 = h_{\epsilon_n}(t,x_n) = tf_{\epsilon_n}(x_n) + (1-t)g_{\epsilon_n}(x_n) \in tF^{(p)}(y_n) + (1-t)F^{(p)}(z_n) + B_{\epsilon_n}$$

for some $y_n, z_n \in \bar{\Omega}$ with $\|x_n - y_n\|$, $\|x_n - z_n\| < \epsilon_n$. By compactness of $\bar{\Omega}$, without loss of generality we may assume that $z_n \to z$ and so $y_n \to z$ and $x_n \to z \in \partial\Omega$ as $n \to \infty$. By upper semicontinuity of $F^{(p)}$ and convexity of its values, for each $\epsilon > 0$, $0 \in F^{(p)}(z) + B_{\epsilon_n+\epsilon}$ for all n sufficiently large and so $0 \in F^{(p)}(z)$, contradicting the fact that $p \notin F(\partial\Omega)$. Therefore, for all $\epsilon > 0$, $0 \notin h_\epsilon(t,\cdot)(\partial\Omega)$ for all $t \in [0,1]$. Thus, by property B-3, $\deg_B(h_\epsilon(t,\cdot),\Omega,0)$ is independent of $t \in [0,1]$, and so we may conclude that, for all $\epsilon > 0$ sufficiently small,

$$\deg_B(f_\epsilon,\Omega,0) = \deg_B(h(1,\cdot),\Omega,0) = \deg_B(h(0,\cdot),\Omega,0) = \deg_B(g_\epsilon,\Omega,0).$$

Simply stated, for all $\epsilon > 0$ sufficiently small, $\deg_B(f_\epsilon,\Omega,0)$ is well defined for every approximate selection f_ϵ and is independent of the particular selection chosen.

In summary, the above construction ensures that the following concept of degree for the set-valued map F is well defined:

$$\deg(F,\Omega,p) := \lim_{\epsilon \downarrow 0} \deg_B(f_\epsilon,\Omega,0).$$

3.2.2. Properties.

THEOREM 3. *Let $x \mapsto F(x) \subset X$ be upper semicontinuous on compact $\bar{\Omega} \subset X$ with nonempty, convex, and compact values.*

(i) *If $q : [0,1] \to X \backslash F(\partial\Omega)$ is continuous, then $\deg(F,\Omega,q(t))$ is independent of $t \in [0,1]$.*

(ii) *If $p \in X \backslash F(\partial\Omega)$ is such that $\deg(F,\Omega,p) \neq 0$, then $p \in F(x)$ for some $x \in \Omega$.*

Proof. By the above construction, all degrees in the assertions of the theorem are well defined.

Assertion (i) is an immediate consequence of the construction together with B-3.

(ii) Because $\deg_B(F,\Omega,p) \neq 0$, there exists a sequence (ϵ_n), with $\epsilon_n \downarrow 0$, and an associated sequence (f_{ϵ_n}) of approximate selections for $F^{(p)}$ such that $\deg_B(f_{\epsilon_n},\Omega,0) \neq 0$ for all n sufficiently large. By B-2, for each n sufficiently large, there exists $x_n \in \Omega$ such that $0 = f_{\epsilon_n}(x_n)$. By compactness of $\bar{\Omega}$, without loss of generality we may assume that $x_n \to x \in \bar{\Omega}$. Moreover, because the functions f_{ϵ_n} are approximate selections, for each n there exists $y_n \in \bar{\Omega}$, with $\|x_n - y_n\| < \epsilon_n$, such that

$$0 = f_{\epsilon_n}(x_n) \in F^{(p)}(y_n) + B_{\epsilon_n}.$$

Arguing as before (using semicontinuity of F and compactness of its values), it follows that $0 \in F^{(p)}(x)$ and so $p \in F(x)$. This proves assertion (ii) of the theorem. □

4. Proof of the main result. We now turn attention to the proof of Theorem 1. Again write $X := \mathbb{R}^N$. Assume $k \in \mathcal{K}$ is an equi-constricting feedback for (1). Then there exist $\rho > \delta > \tau > 0$ and $T > 0$ such that

$$\|x^0\| \leq \delta \Longrightarrow \|x(t)\| < \rho \quad \text{for all } t \geq 0 \quad \text{and} \quad \|x(t)\| < \tau \quad \text{for all } t \in [T, 2T]$$

for every maximal solution $x(\cdot)$ of (3).

Define the set-valued map F on X as follows:

$$F : x \mapsto \begin{cases} f(x, k(x)), & \|x\| \leq \rho, \\ f(\rho\|x\|^{-1}x, k(\rho\|x\|^{-1}x)), & \|x\| > \rho. \end{cases} \tag{4}$$

It is evident that F is upper semicontinuous with nonempty convex and compact values, and so $F(\bar{B}_\rho) \equiv F(X)$ is compact. By the construction in §3.2.1, for every open bounded set $\Omega \subset X$ and every $p \in X \backslash F(\partial\Omega)$, $\deg(F, \Omega, p)$ is well defined.

Consider the initial-value problem

$$\dot{x}(t) \in F(x(t)), \qquad x(0) = x^0. \tag{5}$$

By compactness of $F(X)$ we may deduce that, for each $x^0 \in X$, every solution of (5) has maximal interval of existence $\mathbb{R}^+ := [0, \infty)$. Observe that, for each x^0 with $\|x^0\| \leq \delta$, the set of maximal solutions of (5) is precisely the set of maximal solutions of (3).

Write $\Omega^0 := B_\delta$, with closure $\overline{\Omega^0}$. By the equi-constricting property, the annulus $\overline{\Omega^0} \backslash B_\tau$ cannot contain an equilibrium of (5) (or, equivalently, a point x such that $0 \in F(x)$). Therefore, $0 \notin F(\partial\Omega^0)$ and $\deg(F, \Omega^0, 0)$ is well defined. Let $(f_n)_{n\in\mathbb{N}}$ be a sequence of locally Lipschitz approximate selections for F with

$$d^*(\text{graph}(f_n), \text{graph}(F)) \to 0 \quad \text{as } n \to \infty$$

and such that $\deg(F, \Omega^0, 0) = \deg_{\text{B}}(f_n, \Omega^0, 0)$ for all n.

Write $I := [0, 2T]$ and $Y := C(I; X)$ with the uniform norm. On $\overline{\Omega^0}$ we define the map

$$\mathcal{F} : x^0 \mapsto \{x \in Y | \dot{x}(t) \in F(x(t)) \text{ a.e., } x(0) = x^0\}.$$

For each n, define the map $\phi_n : \overline{\Omega^0} \to Y$ as follows: $\phi_n(x^0)$ is the unique element x of Y such that

$$\dot{x}(t) = f_n(x(t)) \quad \text{for all } t \in I, \quad \text{and} \quad x(0) = x^0.$$

By the classical theory of ordinary differential equations, the map $(t, x^0) \mapsto (\phi_n(x^0))(t)$ is continuous.

We claim that, for every $\epsilon > 0$,

$$d^*(\text{graph}(\phi_n), \text{graph}(\mathcal{F})) < \epsilon \quad \text{for some } n.$$

Suppose otherwise. Then there exist $\epsilon > 0$ and a sequence $(x_n^0) \subset \overline{\Omega^0}$ such that

$$d((x_n^0, \phi_n(x_n^0)), \text{graph}(\mathcal{F})) \geq \epsilon \quad \text{for all } n.$$

For notational convenience, we write $x_n = \phi_n(x_n^0)$. Arguing as in the first proof of Theorem 2.1.3 of [1] (see also [4, Thm 3.1.7]) and extracting a subsequence if necessary, we may assume that $(x_n) \subset Y$ converges uniformly to an absolutely continuous function $x : I \to X$, $x(0) =$

$x^0 \in \overline{\Omega^0}$, satisfying $\dot{x}(t) \in F(x(t))$ almost everywhere, whence the following contradiction: $(x_n^0, x_n) \to (x^0, x) \in \text{graph}(\mathcal{F})$ as $n \to \infty$.

Let $0 < \epsilon < \delta - \tau$ and let m be such that $d^*(\text{graph}(\phi_m), \text{graph}(\mathcal{F})) < \epsilon$. We assert that

$$\text{for all } x^0 \in \overline{\Omega^0}, \quad (\phi_m(x^0))(t) \in \Omega^0 \quad \text{for all } t \in [T, 2T]. \tag{6}$$

This may be shown as follows. Let $x^0 \in \overline{\Omega^0}$ be arbitrary. There exists $y^0 \in \overline{\Omega^0}$, with $\|x^0 - y^0\| < \epsilon$, and $y \in \mathcal{F}(y^0)$ such that $\|(\phi_m(x^0))(t) - y(t)\| < \epsilon$ for all $t \in I$. Because the set $\{y(t) | y \in \mathcal{F}(\overline{\Omega^0})\}$ lies in the ball B_τ for all $t \in [T, 2T]$, the assertion must hold.

Define a function $h : [0, 1] \times \overline{\Omega^0} \to X$ by

$$h(s, x^0) := \begin{cases} f_m(x^0), & s = 0, \\ \frac{1}{s}[(\phi_m(x^0))(sT) - x^0], & 0 < s \leq 1. \end{cases}$$

That h is continuous is readily verified. Furthermore, $h(s, x^0) \neq 0$ for all $(s, x^0) \in [0, 1] \times \partial\Omega^0$ by the following argument. Suppose $h(0, x^0) = f_m(x^0) = 0$ for some $x^0 \in \partial\Omega^0$. Then $(\phi_m(x^0))(t) = x^0 \in \partial\Omega^0$ for all $t \in I$, which contradicts (6). Now suppose $h(s, x^0) = 0$ for some $(s, x^0) \in (0, 1] \times \partial\Omega^0$. Then $(\phi_m(x^0))(nsT) = x^0 \in \partial\Omega^0$ for all $n \in \mathbb{N}$ with $ns \leq 2$.

In particular, there exists $n \in \mathbb{N}$ such that

$$1 \leq ns \leq 2 \quad \text{and} \quad (\phi_m(x^0))(nsT) = x^0 \in \partial\Omega^0.$$

This contradicts (6).

We have now established h as a homotopic connection of the functions f_m and

$$g_m : x^0 \mapsto (\phi_m(x^0))(T) - x^0.$$

It is evident that $h_0 : [0, 1] \times \overline{\Omega^0}$, $(s, x^0) \mapsto (1 - s)g_m(x^0) - sx^0$ defines a homotopic connection of g_m and the odd map $x^0 \mapsto -x^0$. By properties B-3 and B-4, we may conclude that

$$\deg(F, \Omega^0, 0) = \deg_B(f_m, \Omega^0, 0) = \deg_B(g_m, \Omega^0, 0) \neq 0.$$

Since $0 \notin F(\partial\Omega^0)$, $d(0, F(x)) > 0$ for all $x \in \partial\Omega^0$. Next, we show that $x \mapsto d(0, F(x))$ is lower semicontinuous on $\partial\Omega^0$. Let $x \in \partial\Omega^0$ be arbitrary and let $(x_n) \subset \partial\Omega^0$ be a convergent sequence with limit x. Let subsequence (x_{n_k}) be such that

$$\lim_{k \to \infty} d(0, F(x_{n_k})) = \liminf_{n \to \infty} d(0, F(x_n)).$$

For each k, let y_k be a minimizer of $\|\cdot\|$ over compact $F(x_{n_k})$, that is, $\|y_k\| = d(0, F(x_{n_k}))$. By upper semicontinuity of F, for each $\epsilon > 0$ we have $y_k \in F(x_{n_k}) \subset F(x) + B_\epsilon$ for all k sufficiently large. By compactness of $F(x)$, it follows that (y_k) has a convergent subsequence (that we do not relabel) with limit $y \in F(x)$, whence

$$d(0, F(x)) = \min_{v \in F(x)} \|v\| \leq \|y\| = \lim_{k \to \infty} \|y_k\| = \liminf_{n \to \infty} d(0, F(x_n)).$$

Thus, $x \mapsto d(0, F(x))$ is positive-valued and lower semicontinuous on compact $\partial\Omega^0$ and so attains a positive minimum value thereon. We may now conclude the existence of a scalar $\mu > 0$ such that $p \notin F(\partial\Omega^0)$ for all $p \in B_\mu$. By Theorem 3(i) we deduce that, for every such p,

$$\deg(F, \Omega^0, p) = \deg(F, \Omega^0, 0) \neq 0.$$

Therefore, by Theorem 3(ii), for each $p \in B_\mu$ there exists $x \in \Omega^0 = B_\delta$ such that $p \in F(x) = f(x, k(x))$. It immediately follows that each $p \in B_\mu$ is the image, under f, of some point $(x, u) \in B_\delta \times \mathbb{R}^M$. This completes the proof of Theorem 1.

It remains only to prove Corollary 1. Let $\mathcal{N}$ be any open neighbourhood of $0 \in X$ and let $\rho > 0$ be such that $B_\rho \subset \mathcal{N}$. Let $k \in \mathcal{K}$ be equi-asymptotically stabilizing. Then there exist scalars $T > 0$ and δ, τ, with $0 < \tau < \delta < \rho$, such that the equi-constricting property of Definition 2 holds. Now, arguing exactly as in the proof of Theorem 1, it follows that $f(B_\delta \times \mathbb{R}^M)$ (and so, a fortiori, $f(\mathcal{N} \times \mathbb{R}^M)$) contains an open neighbourhood of $0 \in X$.

Acknowledgment. The author is indebted to his colleague, J. F. Toland of the University of Bath, for many helpful discussions.

ABNORMAL MINIMIZERS*

RICHARD MONTGOMERY†

Abstract. This paper constructs the first example of a singular, abnormal minimizer for the Lagrange problem with linear velocity constraints and quadratic definite Lagrangian, or, equivalently, for an optimal control system of linear controls, with k controls, n states, and a running cost function that is quadratic positive-definite in the controls. In the example, $k = 2$, $n = 3$, and the system is completely controllable. The example is stable: if both the control law and cost are perturbed, the singular minimizer persists. Its importance is due, in part, to the fact that it is a counterexample to a theorem that has appeared several times in the differential geometry literature. There, the problem is called the problem of finding minimizing sub-Riemannian geodesics, and it has been claimed that all minimizers are normal Pontryagin extremals [*The Mathematical Theory of Optimal Processes*, Wiley-Interscience, New York, 1962]. (If the number of states equals the number of controls, then the problem is that of finding Riemannian geodesics.) The main difficulty is proving minimality. To do this, the length (cost) of the abnormal is compared with all competing normal extremals. A detailed asymptotic analysis of the differential equations governing the normals shows that they are all longer.

Key words. nonholonomic distributions, sub-Riemannian or singular geometry, geodesics, abnormal extremals

1. Introduction.

Consider a system

$$\dot{q} = \sum_{i=1}^{k} u_i X_i(q),$$

linear in the k controls u_i. Here the point q evolves on an n-manifold Q, and we assume $k < n$. If Q is connected and if the vector fields X_i are bracket generating, then according to Chow's theorem we can find piecewise continuous controls $u_i(t)$ that steer between any two points of Q. Consider the optimal control problem of finding controls $u_i(t), 0 \leq t \leq 1$ that steer between two given points in such a way as to minimize the L^2-norm $\frac{1}{2}\int_0^1 \sum_i u_i^2\, dt$ over all controls that steer between these points. If desired, this can be reformulated as a minimum time problem. Impose the bounds $\sum_i u_i^2 \leq 1$ and find the controls joining the two points in the minimum possible time.

This problem can be viewed as a generalization of the problem of finding geodesics on a Riemannian manifold. Let $D_q = \text{Span}\{X_i(q) : i = 1, 2, \ldots, k\}$. We assume that the X_i are everywhere linearly independent. Then $D = \cup_{q\in Q} D_q$ forms a *distribution*, that is, a linear subbundle of the tangent bundle TQ of Q. By declaring the X_i to be orthonormal, we define an inner product $\langle \cdot, \cdot \rangle$ on the k-planes D_q. The pair $(D, \langle \cdot, \cdot \rangle)$ is called a *sub-Riemannian metric* on Q. And the X_i form a *framing* of D.

Call an absolutely continuous path *horizontal*, *integrable*, or a *D-curve* if its derivative lies in D wherever it is defined. The *length* of such a path is $\int ds$, where $ds = \sqrt{\langle \dot{\gamma}, \dot{\gamma} \rangle}\, dt$. The *distance* between two points is the infimum of the lengths of all horizontal curves joining them. Our problem is to find a horizontal curve joining the two given points whose length realizes the distance between them. We call such a path a minimizing geodesic.

The Pontryagin maximum principle [19] provides necessary conditions for a curve to be a minimizing geodesic. The Hamiltonian equations that govern the normal Pontryagin extremals will be called the *geodesic equations*. They are similar to the geodesic equations

of Riemannian geometry, the principle difference being that the fiber-quadratic form defining the Hamiltonian has rank $k < n$. We will also say that a curve in Q satisfies the geodesic equations if it is the projection of a solution to the geodesic equations.

Our main result is the construction of a sub-Riemannian metric on $\mathbf{R}^3$ and a horizontal curve in this space that is a minimizing geodesic but does not satisfy the geodesic equations. This curve is necessarily the projection of an abnormal extremal. The distribution on $\mathbf{R}^3$ is bracket generating. The curve is smooth.

The assertion that every minimizer is the projection of a normal extremal, that is, that every minimizing geodesics satisfies the sub-Riemannian geodesic equations, has occurred numerous times in the literature (see, for example, Rayner [21], Strichartz [22], or Taylor [24]). Strichartz later retracted his claim [23]. Our result came out of attempts to understand this (false) assertion. Gaveau [7] proposed a counterexample to this assertion in 1977 but Brockett [4] found a fundamental flaw in his reasoning. For completeness we have included an appendix containing Gaveau's example and Brockett's refutation of it.

A basic property of our curve is that it is rigid in the sense it admits no piecewise-C^1 endpoint-preserving variations through D-curves. Having no variations, such a curve is automatically an extremal (in the C^1 topology) for any functional. Because this extremality has no relation to the function being minimized (length) there is no reason that the curve should solve its Euler–Lagrange equations, which are the sub-Riemannian geodesic equations. Our main difficulty will be to show that our curve is in fact a minimum.

One of our main tools is a partial dictionary between sub-Riemannian geometry and gauge theory begun in [16]. This dictionary tells us that the sub-Riemannian geodesic equations for our example are identical to the equations of a charged particle traveling in the plane under the influence of a magnetic field determined by the distribution.

The paper is organized as follows. Section 2 contains basic definitions and notation. Section 3 describes the counterexample and some of its properties. Section 4 gives a heuristic proof that it is a minimizing geodesic. Sections 5 and 6 contain the proof; the core of the proof is in §§5.3 and 5.4. In §7 we show that our example is stable.

Since this article was first written (1991), several other proofs of minimality have appeared. One is due to I. Kupka [13] of the University of Toronto and is similar in spirit to ours. Another is due to W.-S. Liu and H. Sussmann [14] and is based on an inequality.

2. Preliminaries. A sub-Riemannian (sR) structure on a smooth manifold Q consists of a nonintegrable distribution $\mathcal{D} \subset TQ$ together with a smoothly varying inner product $\langle \cdot, \cdot \rangle_q$ on the fibers $\mathcal{D}_q$ of this distribution. In this section we describe the basic notions and notations of sR geometry (for more detailed treatments, see Strichartz [22], Brockett [3], [4], Pansu [18], Hamenstädt [10], Rayner [21], Hermann [11], [12], or Vershik and Gershkovich [9]). Sub-Riemannian structures have also been called "Carnot–Caratheodory metrics," "singular Riemannian metrics," and "nonholonomic Riemannian metrics."

A path in Q is said to be horizontal if it is locally rectifiable (for example, piecewise differentiable) and if its derivatives, whenever defined, lie in $\mathcal{D}$. The *length* of a horizontal path γ is the integral over t of $\sqrt{\langle d\gamma/dt,\, d\gamma/dt \rangle_{\gamma(t)}}\, dt$. The *distance* $d(q_0, q_1)$ between two points q_0, q_1 in Q is the infimum of the lengths of the horizontal paths joining them.

DEFINITION 1. *A path $\gamma : [a, b] \to Q$ is called a minimizing geodesic if it is the shortest horizontal path joining its endpoints.*

DEFINITION 2. *A path $\gamma : I \subset \mathbf{R} \to Q$ is called a geodesic if it is locally a minimizing geodesic. In other words, each $t_0 \in I$ is contained in a nontrivial closed subinterval $J \subset I$ such that γ restricted to J is a minimizing geodesic. If, in addition, $d(\gamma(t_2), \gamma(t_1)) = |t_2 - t_1|$ whenever $|t_2 - t_1|$ is sufficiently small, then we say that γ is a unit speed geodesic.*

When do minimizing sub-Riemannian geodesics exist? The distribution is said to be

bracket generating (or to satisfy Hörmander's condition) if every point q in Q has a neighborhood on which there is a local frame field $X_i, i = 1, \ldots,$ rank$\mathcal{D}$ for $\mathcal{D}$ such that the X_i together with all of their iterated Lie brackets $[X_i, X_j], [X_i, [X_j, X_k]], \ldots$, span the tangent space at every point of this neighborhood. (This condition is independent of the choice of local frame.) A corollary to a classical theorem of Chow [6] and Rashevski [20] asserts that if $\mathcal{D}$ is bracket generating and Q is connected, then any two points of Q can be joined by a horizontal path. In particular, it follows from this and the Arzela–Ascoli theorem that if $\mathcal{D}$ is bracket generating and if the inner product on $\mathcal{D}$ is the restriction of a complete Riemannian metric, then any two points of Q can be joined by a minimizing sub-Riemannian geodesic.

A formal application of the method of Lagrange multipliers yields differential equations for the geodesics. They can also be derived from the Pontryagin maximum principle [19], in which case they are the equations for the normal extremals. We call them the sub-Riemannian geodesic equations. To define them, set $a_{ij}(q) = \langle X_i, X_j \rangle_q$, where X_i is a frame for $\mathcal{D}$ as before. Let a^{ij} be the inverse matrix. Then

$$g = \sum \alpha^{ij} X_i X_j$$

is independent of the choice of frame field and defines a fiber-quadratic form on the cotangent bundle T^*Q, that is, a symmetric covariant tensor of type (2,0). (We can define g intrinsically by saying that it is a vector bundle map $T^*Q \to TQ$ which satisfies $g(q)^* = g(q)$, image$(g) = \mathcal{D}$, and $p(w) = \langle g(q)(p), w \rangle$ whenever $p \in T_q^*Q$, and $w \in \mathcal{D}_q$.) The function $H : T^*Q \to \mathbf{R}$ defined by

$$H(q,p) = \frac{1}{2} g(q)(p,p)$$

is the Hamiltonian that defines the geodesic equations. (In the Riemannian case, $\mathcal{D}$ is the entire tangent bundle, and this is the usual kinetic energy that generates geodesic flow.) If we choose coordinates q^μ on Q and the corresponding induced coordinates q^μ, p_ν on T^*Q, then

$$H = \frac{1}{2} g^{\mu\nu}(q) p_\mu p_\mu,$$

where $g^{\mu\nu}(q)$ is a symmetric matrix of rank equal to the rank of $\mathcal{D}$ that represents the (2,0) tensor. And the sub-Reimannian geodesic equations are

$$\dot{q}^\mu = \sum g^{\mu\nu}(q) p_\nu; \qquad \dot{p}_\mu = -\frac{1}{2} \sum \frac{\partial g^{\alpha\beta}}{\partial q^\mu} p_\alpha p_\beta. \tag{1}$$

By a slight abuse of language, we call a curve $q(t)$ in Q a solution to the sub-Riemannian geodesic equations if it is the projection of a solution $(q(t), p(t))$ to this system of first-order ordinary differential equations on T^*Q.

LEMMA 1 (Rayner [21, Cor. 2.2], Hamenstädt [10, Cor. 5.9]). *Every solution to the sub-Riemannian geodesic equations,* (1) *above, is a geodesic.*

Our counterexample is to the converse of this lemma.

Remark 1. The lemma does not require any assumptions on the distribution. In particular, it need not be bracket generating. Rayner's proof proceeds by showing that in a neighborhood of any non-self-intersecting solution γ to the sR geodesic equation, there is an extension of the distribution's inner product to a Riemannian metric such that γ is a Riemannian geodesic relative to that extension.

3. The counterexample. Take Q to be $\mathbf{R}^3$ for our example. Let $\mathcal{D}$ be the distribution annihilated by a smooth one-form of the type

$$\Theta = dz + A(r)d\theta,$$

where (r, θ, z) are standard cylindrical coordinates on Q. This means that a vector $(\dot{r}, \dot{\theta}, \dot{z})$ is in $\mathcal{D}(r, \theta, z)$ if and only if $\dot{z} = -A(r)\dot{\theta}$. We require that A has a single nondegenerate maximum at $r = 1$. Thus, $dA/dr\,|_{r=1} = 0$ and $d^2A/dr^2\,|_{r=1} < 0$. For example,

$$A = \frac{1}{2}r^2 - \frac{1}{4}r^4 \tag{2}$$

is a good choice and defines a smooth one-form on all of $\mathbf{R}^3$. We refer to this choice as the "model case."

Let us check the bracket-generating condition for $\mathcal{D}$. $X_1 = \partial/\partial r$ and $X_2 = \partial/\partial\theta - A(r)(\partial/\partial z)$ form a local nonorthonormal frame field for $\mathcal{D}$. $[Y_1, Y_2] = -(dA/dr)(\partial/\partial z)$ so that $X_1, X_2, [X_1, X_2]$ span $\mathbf{R}^3$ everywhere except at points on the unit cylinder $r = 1$. But here $[X_1, [X_1, X_2]] = -(d^2A/dr^2)(\partial/\partial z) \neq 0$ and so $Y_1, Y_2, [Y_1, [Y_1, Y_2]]$ span $\mathbf{R}^3$, and the bracket-generating condition holds everywhere.

The fiber metric for our example is the restriction of the form $dx^2 + dy^2$ to $\mathcal{D}$. Here (x, y, z) are the usual Cartesian coordinates, so that $dx^2 + dy^2 = dr^2 + r^2d\theta^2$. In other words, the length of a horizontal curve is equal to the Euclidean length of its projection to the x, y plane.

The horizontal curves that provide the counterexample are any horizontal curves lying on the unit cylinder $r = 1$. Thus, they are helices with pitch $-A(1)$. One such curve is parameterized according to $(r, \theta, z) = (1, \theta, -A(1)\theta)$. We call this curve $\hat{C}$. Its projection to the xy plane is the unit circle C.

Our main result follows.

THEOREM 1. *The above-defined distribution $\mathcal{D}$ is bracket generating. The helix $\hat{C}$ or any subarc thereof is a geodesic. It does not satisfy the sub-Riemannian geodesic equations*, (1), *above. In particular, there are minimizing sub-Riemannian geodesics that do not satisfy the sub-Riemannian geodesic equations.*

Analytically speaking, this theorem says that for some sufficiently small positive number θ_0, the arc of the helix $\hat{C}$ from $\hat{C}(0)$ to $\hat{C}(\theta_0)$ is the shortest horizontal curve among all horizontal curves that join $\hat{C}(0)$ to $\hat{C}(\theta_0)$.

Remark 2. Bär [1] gives quite a different kind of a counterexample. His curve γ is also a geodesic that does not satisfy the geodesic equations. However, every sufficiently short arc of his geodesic does satisfy the geodesic equations, whereas *no* subarc of our geodesic satisfies the equations. In his example, normal extremals $\xi : I \to T^*Q$ that project to subarcs of γ can be found, but they cannot not be chosen consistently so as to be continous over all of γ. It follows from the maximum principle that his curve is not a minimizing geodesic.

4. The helix does not satisfy the geodesic equations. An orthonormal framing of D is provided by

$$X_1 = \frac{\partial}{\partial r}$$

and

$$X_2 = \frac{1}{r}\left\{\frac{\partial}{\partial\theta} - A(r)\frac{\partial}{\partial z}\right\}.$$

It follows that the normal Pontryagin Hamiltonian (cf. the equation immediately preceding (1)) is

$$H(r,\theta,z,p_r,p_\theta,p_z)=\frac{1}{2}\left\{p_r^2+\frac{1}{r^2}(p_\theta-p_zA(r))^2\right\}. \tag{3}$$

In Cartesian coordinates,

$$H(x,y,z,p_x,p_y,p_z)=\frac{1}{2}\{(p_x-p_zA_x(x,y))^2+(p_y-p_zA_y(x,y))^2\}.$$

Here $A_x\,dx+A_y\,dy=A(r)d\theta$ and the Cartesian p's are related to the cylindrical p's in the usual way, that is, through the formula $p_x\,dx+p_y\,dy=p_r\,dr+p_\theta\,d\theta$.

This is exactly the Hamiltonian for a particle with charge

$$e=p_z$$

traveling in the xy plane under the influence of a magnetic field normal to the plane and with strength

$$B=\frac{1}{r}\frac{dA}{dr}.$$

It is important in this regard that H is independent of z, for it follows from this that one of the geodesic equations is

$$\dot{p}_z=0$$

and thus the "charge" is constant along solutions.

To write these equations, let

$$\pi:\mathbf{R}^3\to\mathbf{R}^2;\qquad \pi(x,y,z)=(x,y)$$

be the map that projects out the vertical coordinate. If γ is a solution to the geodesic equations, write

$$c=\pi\circ\gamma$$

for its planar projection. Now write c in terms of complex variables $c=x+iy$. Then by straightforward calculation, c satisfies

$$\ddot{c}=-ieB(c)\dot{c}, \tag{4}$$

where $B(x,y)=d\Theta/dx\wedge dy=\partial A_y/\partial x-\partial A_x/\partial y$. In the particular case where A is a function of r alone, we easily calculate that B is given by the previous formula. If γ is parameterized by arclength, or what is the same, if $H=\frac{1}{2}$ along γ, then the above differential equation can be rewritten as

$$\kappa(s)=-eB(c(s)), \tag{5}$$

where κ is the curvature of the unit speed curve c. In our example, $B=0$ on the unit circle C. But C has curvature 1 and is the projection of our helix $\hat{C}$. Thus, $\hat{C}$ cannot satisfy the sub-Riemannian geodesic equations.

Remark 3. This connection between the equations of motion of a particle in a magnetic field and the sub-Riemannian geodesic equations was first pointed out in [16]. If the codimension of D is larger than one, then the equations are related to those of a "classical quark" in a non-Abelian gauge field. The relation only holds if the sub-Riemannian structure admits a Lie group of symmetries acting transversely to its distribution.

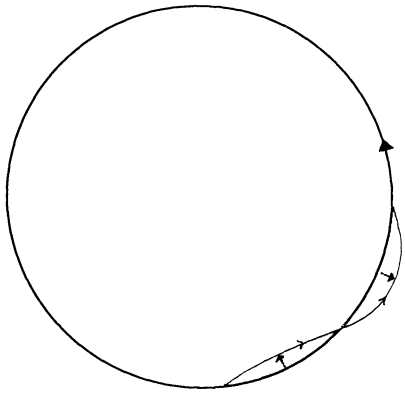

FIG. 1

5. Rigidity: A heuristic proof of the theorem. It remains to show that sufficiently small subarcs of $\hat{C}$ are minimizing geodesics. In this section we give an incomplete but illuminating argument in support of this fact.

Consider a horizontal curve γ in $\mathbf{R}^3$ that connects the point $(x_0, y_0, 0)$ to the point (x_0, y_0, z_1). Thus, the projected curve $c \subset \mathbf{R}^2$ is closed. By Stoke's theorem and the fact that $dz = -Ad\theta$ along γ,

$$z_1 = -\int\int d\Theta = -\int\int B(r) r\, dr\, d\theta, \tag{6}$$

where the last integral is over the (oriented) region in the plane enclosed by c. Following the theory of magnetism, we call the integral $\int\int B(r) r\, dr\, d\theta$ the *flux* enclosed by c. Recall that the (Euclidean) length of c is the same as the sub-Riemannian length of γ. It follows that γ is a minimizing geodesic if and only if its projection to the xy plane minimizes length among all loops based at (x_0, y_0) and enclosing an amount of flux equal to $-z_1$.

Now consider our helix $\hat{C}$. The flux enclosed by going once around $C = \pi \circ \hat{C}$ is $2\pi A(1) = \int\int_D B\, dx\, dy$, where D is the unit disc. Imagine perturbing $\hat{C}$ to form the horizontal curve γ and consequently perturbing its projection C to form c. If we push part of C into the interior of the unit disc, we have subtracted flux because B is positive in the interior. On the other hand, if we push part of C to the exterior of the disc, then we add negative flux, that is, we also subtract flux (Fig. 1). No matter how we perturb C, we decrease the flux and hence increase the height difference z_1 and thus violate the endpoint conditions. We conclude that there are no allowable variations of $\hat{C}$, and consequently it is a local minimum for our constrained variational problem. This heuristic argument can easily be turned into a rigorous proof of the following.

Assertion 1. There are no piecewise C^1 endpoint-preserving variations of $\hat{C}$ through horizontal curves except those whose variation field is tangential to $\hat{C}$.

This shows that $\hat{C}$ is an isolated point in the space of all horizontal piecewise C^1 unparameterized curves that join $\hat{C}(0)$ to $\hat{C}(2\pi)$ with the (piecewise) C^1 topology on this path space. Being an isolated point, it is automatically a local minimum for any function on this space and in particular for the length functional.

Remark 4. Extremals of this type have been a source of major difficulties to practitioners of "classical" (one independent variable) calculus of variations. Such extremals are called "rigid" by Young [26], "abnormal" by Bliss [2], and of "maximal class" by Carathéodory [5]. If the Pontryagin maximum principle [19] is applied to the problem of finding sub-Riemannian geodesics, we find that they are precisely the abnormal extremals and that these are also the

singular extremals in this case. We especially recommend the treatment in the beginning of volume 2 of Young's book regarding these extremals. Also of interest is the treatment of Morse and Mayers [17].

$\hat{C}$ is not isolated in the C^0 or even the Sobolev H^1 topology on the space of all horizontal curves with its endpoints. We can find arbitrarily C^0- or H^1-close curves to $\hat{C}$ that $\hat{C}$'s endpoints by making tiny kinks in chords to the circle C. One might then wonder whether it is possible to make sufficiently small kinks in C so as to shorten its length while keeping its flux the same. The theorem says that this is not possible, at least for small enough arcs of $\hat{C}$. Our work lies in showing this.

6. Proof.

6.1. The proof from two propositions. Theorem 1 follows immediately from the following two propositions.

PROPOSITION 1. *Any minimizer not lying in the cylinder must satisfy the sR geodesic equations.*

PROPOSITION 2. *There is a positive number θ_* such that for all $\theta \leq \theta_*$, every solution γ to the sub-Riemannian geodesic equations with endpoints $\hat{C}(0)$ and $\hat{C}(\theta)$ has length $(\gamma) > \theta$.*

Proof of Theorem 1. Combine the two propositions, recalling that θ is the sub-Riemannian arclength along $\hat{C}$. □

6.2. Proof of Proposition 1. The salient fact is that the unit cylinder is precisely where the distribution D fails to be a contact distribution.

DEFINITION 3. *A rank-two distribution on a three-manifold is said to be contact at a point q if for some (and hence any) frame field X_1, X_2 of D defined near q the vectors $X_1(q), X_2(q)$ together with their Lie bracket $[X_1, X_2](q)$ form a basis for the tangent space at q.*

With this in mind, we can find various proofs of Proposition 1 in the literature (see for example, Zhong [8], Hamenstädt [10], Strichartz [22], or Hermann [11]). We give another proof based on the maximum principle.

Proof of Proposition 1. According to that principle, every minimizer is a Pontryagin extremal and all such extremals can be divided into the abnormal and the normal ones. The normal ones satisfy, by definition, the sR geodesic equations. The proposition now follows from the following lemma.

LEMMA 2. *Every nonconstant abnormal Pontryagin extremal projects to a D-curve that lies on the locus of points where D fails to be contact.*

Proof of Lemma. Let X_1, X_2 be the frame for D used earlier and let X_3 be their Lie bracket. Let P_i be the corresponding "power functions" as above $P_i(q,p) = p(X_i(q))$. The maximum principle tells us to introduce the multipliers $(p(t), \lambda_0) \in (\mathbf{R}^2)^* \oplus \mathbf{R}$, $(p(t), \lambda_0) \neq (0,0)$. For fixed (q, p, λ_0), the controls $u(t)$ leading to an extremal must maximize

$$H(q, u, p, \lambda_0) = u_1 P_1 + u_2 P_2 - (\lambda_0)\frac{1}{2}(u_1^2 + u_2^2).$$

For an abnormal extremal $\lambda_0 = 0$ so the only possibility is that $P_1 = P_2 = 0$, $p \neq 0$ along the extremal. If $u(t)$ is the control inducing the abnormal extremal, then the extremal is an integral curve of the Hamiltonian flow of the time-dependent Hamiltonian $H_*(q,p,t) = u_1(t)P_1 + u_2(t)P_2$. Because $\{P_1, P_2\} = -P_3$, we find that $\dot{P}_1 = -u_2 P_3, \dot{P}_2 = u_1 P_3$. Thus, we require that $P_1 = P_2 = P_3 = 0$ along an abnormal. (The u_i cannot both be zero because the extremal is not a single point.) But these are the components of the covector p on the vectors X_1, X_2, X_3. Consequently, if these vectors form a basis at a point q we must have $p = 0$, which is not allowed. Therefore, the curve $q(t)$ must lie on the locus of points where X_1, X_2, and X_3 become linearly dependent, which is to say where D fails to be contact.

Remark 5. From the point of view of differential topology, Proposition 1 is a statement about the regularity of the endpoint map. This is the map that assigns to each D-path γ beginning at a point q_0 its endpoint $\text{end}(\gamma) = q(1)$. (Alternatively, end is the input-output map.) The proposition states that if D is contact at one point of the curve γ, then end is a submersion at γ. Hence, by the implicit function theorem the subset $\text{end}^{-1}(q_1)$ of D-paths that join q_0 to q_1 forms a smooth submanifold of the space of all horizontal paths based at q_0. It is then legitimate to use the standard method of Lagrange multipliers applied to the functional (length) $+\lambda$(end) to find the equations characterizing extremals. These are the sub-Riemannian geodesic equations.

7. Proof of Proposition 2. The proof is by contradiction. Suppose it is false. Then there must exist a sequence of lengths s_i decreasing to zero and a sequence $\gamma_i : [0, t_i] \to \mathbf{R}^3$ of minimal solutions to the sR geodesic equations, which have the same endpoints as $\hat{C}[0, s_i]$, are parameterized by arclength, and are shorter than s_i. Thus, $\gamma_i(0) = \hat{C}(0)$ and $\gamma_i(t_i) = \hat{C}(s_i)$. Also $\|dc_i/dt\| = 1$, where we write $c_i = \pi \circ \gamma_i$ and finally

$$\sin(s_i) \leq t_i \leq s_i.$$

The first inequality expresses the fact that the Euclidean distance between the endpoints of $C[0, s_i]$ is $\sin(s_i)$.

Let

$$m_{*i} = \max |1 - r_i(t)|,$$

where

$$\gamma_i(t) = (r_i(t), \theta_i(t), z_i(t))$$

is the expression for γ_i in cylindrical coordinates. Then we also must have

$$m_{*i} \leq s_i, \tag{7}$$

for otherwise the length of γ_i would be greater than s_i.

The proof is based on an analysis of the geodesic equations as $i \to \infty$. The salient fact is that the "charges" e_i must go to infinity as i does. To perform the analysis we need the equations in both their geometric form, $\kappa(s) = -eB(c(s))$, and their Hamiltonian form,

$$\dot{\theta} = \frac{1}{r^2}(p_\theta - eA(r)), \tag{8}$$

$$\dot{r} = p_r,$$

$$\dot{z} = -A(r)\dot{\theta},$$

$$\dot{p}_\theta = 0,$$

$$\dot{p}_z = 0.$$

The differential equation for p_r that we use is found by solving for $\dot{r}$ in the formula for the Hamiltonian

$$\frac{1}{2} = H = \frac{1}{2}\left\{\dot{r}^2 + \frac{1}{r^2}(p_\theta - eA(r))^2\right\}. \tag{9}$$

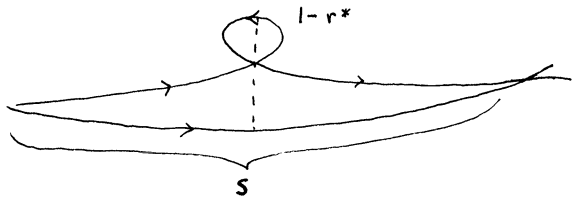

FIG. 2

The following facts regarding solutions will be needed.

Fact 1. p_θ and $p_z = e$ are constant along solutions.

Fact 2. Suppose that the projection $c = \pi \circ \gamma$ of a solution is tangent to a circle $r = \text{const}$ at some point $c_* = c(t_*)$. Then c is symmetric with respect to reflection about the radial line through this point. Analytically, this reads $c(t_* + s) = R(c(t_* - s))$, where R is the reflection about the line joining the origin to c_*.

These two facts follow directly from the equations and their invariance with respect to orthogonal transformations. The following facts are direct consequences of Facts 1 and 2 and the equations.

Fact 3. Let $\beta(n)$ denote the angle a projected solution c makes with the unit circle at its nth crossing. Then $\beta(n+1) = -\beta(n)$. In particular, because $\dot\theta(n) = \cos(\beta(n))$ at each crossing, we have $\dot\theta(n) = \dot\theta(n+1)$.

DEFINITION 4. *An arc of solution γ will mean that part lying between two consecutive intersections with the unit cylinder $r = 1$ or the projection to the xy plane of such an arc. Thus, if there are $n+1$ such intersections, then there are n arcs.*

An arc will be called "interior" or "exterior" depending on whether or not it is interior or exterior to the unit disc. By the "corresponding arc" of C we mean the shorter arc of C lying between the endpoints of such an arc. By the "height" or "vertical coordinate" of an arc we mean the difference between the z-coordinates of γ corresponding to the two endpoints of the arc. Thus, the height is $-\int_{\text{arc}} A d\theta$.

Fact 4. Extremals of $B(c(s))$ along any projected solution c coincide with points of tangency to some circle. Because the curve is symmetric, upon reflection about the line through such a point there is exactly one such extremal on any arc and it is a strict maximum for $|B|$ and for $|1 - r|$ along the arc.

Fact 5. For $e \neq 0$ and $r \neq 1$, the sign of the curvature κ is equal to $-\text{sgn}(e)\text{sgn}(1-r)$.

We begin our analysis by eliminating certain solution curves. Solutions with $e = 0$ can be eliminated because they project to straight line segments. If such a curve satisfies the xy endpoint conditions, its projection must be a chord of the circle. So, by the argument of §4 it cannot satisfy the z-endpoint condition. Solutions with $\dot\theta_0 = 0$ can be eliminated because they must remain exterior to the cylinder (see Fact 3). It follows from the convexity of the unit disc that their projections are always longer than the corresponding segment of the circle, and so they cannot be minimizing.

Solutions with $\dot\theta_0 > 0$ and $e > 0$, or with $\dot\theta_0 < 0$ and $e > 0$ can be eliminated because they can never satisfy the z-component of the endpoint conditions. To see this, observe that the projected arcs of such a curve can never have self-intersections. For example, if $0 < \beta_0 < \pi/2$ and $e > 0$, then by Fact 5 the curvature in the arc's interior is strictly negative. Coupled with Fact 2 this shows that the arc can have no self-intersection. (For example, viewed as a graph over its tangent at $t = 0$, it forms a concave function; see Fig. 2.) Upon crossing the cylinder, the sign of the curvature of the arc switches and the same argument applies again. (As a graph it becomes strictly convex.) Therefore, the Green's theorem argument of §4 (the heuristic

proof) is valid, and these curves can never satisfy the vertical (z) endpoint condition.

We are left with analyzing sequences of solutions $\gamma_i(t) = (x_i(t), y_i(t), z_i(t))$ with initial conditions $\dot\theta_{i,0} > 0, e_i < 0$, or $\dot\theta_{i,0} < 0,\ e_i > 0$. Set

$$h_i = z_i(t_i) - (-A(1)s_i)$$

so that our last endpoint condition is

$$h_i = 0.$$

We have

$$h_i = -\int_{c_i} A d\theta + A(1)s_i.$$

Now

$$A(r) = A(1) - \eta(r)^2,$$

where

$$\eta = \eta(r) = b(1-r) + O((1-r)^2); \qquad b > 0$$

is a smooth invertible function of $1 - r$ near $r = 1$. This follows from the fact that A has a nondegenerate maximum at $r = 1$. (For the model case (2), $A(r) = \frac{1}{2}r^2 - \frac{1}{4}r^4$, we find $A = \frac{1}{4} - \eta(r)^2$ with $\eta(r) = (1-r^2)/2 = (1-r) - \frac{1}{2}(1-r)^2$. Thus $b = 1$. We have chosen $b > 0$ so that $\eta > 0$ when $r < 1$. Then $b = +\sqrt{-\frac{1}{2}(d^2A(1)/dr^2)}$.) It follows that

$$h_i = \int_0^{t_i} \eta^2 \dot\theta \, dt. \tag{10}$$

Because η^2 is positive off of the unit cylinder, it follows that somewhere along the solution the sign of $\dot\theta$ must become opposite to its initial sign, $\dot\theta_0$.

We now fix attention on the particular arc for which this sign switch occurs. Later, we show that the sign switch must occur on every subarc of the solution. Most importantly, we show that the length of this solution arc (and all of these other subarcs) is longer than the corresponding subarc of the circle.

Without loss of generality we assume that $\dot\theta_0 > 0$, the argument for the contrary case being identical. The curvature and symmetry conditions guarantee that the sign switch occurs at the midpoint of the arc. The qualitative shape of the arc is indicated in Fig. 2. We use a subscript * to denote any variable evaluated at this midpoint; thus,

$$\dot r_* = 0.$$

Now $H = \frac{1}{2} = \frac{1}{2}\{\dot r^2 + r^2\dot\theta^2\}$ for any unit speed solution. Therefore

$$1 = r_*^2\dot\theta_*^2.$$

As we saw at the beginning of the proof of Proposition 2 (7), $m_* = |1 - r_*| \to 0$ so that

$$r_* \to 1, \qquad \eta_* \to 0,$$

and

$$\dot{\theta}_* \to -1$$

as $i \to \infty$.

Equation (8) at $r = 1$ tells us that the initial angular velocity is

$$\dot{\theta}_{0,i} = p_{\theta,i} - e_i A(1).$$

Because p_θ is constant, we can rewrite (8) as

$$\dot{\theta} = \frac{1}{r^2}\{\dot{\theta}_{0,i} + e_i \eta(r)^2\}. \tag{11}$$

Evaluating this equation at the midpoint and taking the limit as $i \to \infty$ and recalling that $\eta_* \to 0$, we see that for the limit just calculated for $\dot{\theta}_*$ to be valid we must have

$$e_i \to -\infty$$

as $i \to \infty$. More precisely,

$$e_i \eta_* \to -2. \tag{12}$$

Define the small parameter ε by

$$|e| = \frac{1}{\varepsilon^2}.$$

Define the rescaled variable Y through the relation

$$\eta = \varepsilon Y.$$

The above limit (12) becomes

$$Y_{*,i} \to \sqrt{2}. \tag{13}$$

(The +/sign occurs because the arc is interior to the unit disc.) Also, $A d\theta = A(1)d\theta - \varepsilon^2 Y^2\, d\theta$.

Remark 6. It follows from (7) above that

$$\varepsilon_i = O(s_i)$$

because

$$\eta_* = b m_* + O(\eta_*^2).$$

(A refinement of (7) shows that $m_* = o(s_i)$ and so, in fact, $\varepsilon = o(s_i)$.)

Now

$$\dot{\eta}^2 = R_i(Y), \tag{14}$$

where the function $R = R_i$ is obtained by solving (9) for $\dot{r}^2$ and then using our change of variables $r \to \eta \to Y$. We calculate

$$R_i(Y) = R(Y, \varepsilon_i, \dot{\theta}_{i,0}) = b^2[1 - (1 - Y^2)^2] + O(\varepsilon_i) + O(1 - \dot{\theta}_{i,0}).$$

Now η_* is the unique zero of R_i on its arc, because the midpoint of the arc is the only place where $\dot{\eta} = 0$ (see Fact 4 above). Because R_i and the right-hand side of the equation for $\dot{\theta}$ (11) do not depend on time, it follows that on every arc of our solution $\dot{\theta}$ is negative and close to -1 at that arc's midpoint and that the value of η, there, is η_*.

We complete the argument now by showing that for i large enough, each subarc of the solution is longer than the corresponding arc of the circle. (If the arc is exterior to the circle, this follows immediately from convexity. But this observation does not seem to lead to simplification of the proof. For we do not know that a single arc satisfies the endpoint condition $h_i = 0$ and so several may need to be concatenated to satisfy the vertical endpoint condition.) For this purpose, let us change the meaning of the original notation so that now our curves γ_i each consist of single arcs, with lengths t_i and subtending angles s_i: $\theta(t_i) = s_i$. But we do not insist on the vertical endpoint condition. By reflectional symmetry it suffices to show that $t_{*,i} - \theta_{*,i}$ is eventually positive. Now this quantity is the integral of $dt - d\theta$ over half an arc. Thus, we now show that

$$\int_0^{t_{*,i}} (1 - \dot{\theta}_i(t))dt > 0 \tag{15}$$

provided i is sufficiently large. To do this we change variables to Y. Now $dt = (dt/d\eta)d\eta = (1/\eta)(\varepsilon)dY$. It follows that

$$dt = \varepsilon \frac{dY}{\sqrt{R_i(Y)}}.$$

Hamilton's equation for $\dot{\theta}$ in terms of the scaled variable Y is

$$\dot{\theta} = \frac{1}{r^2}(\dot{\theta}_0 - Y^2).$$

Thus,

$$\begin{aligned} 1 - \dot{\theta} &= 1 - \frac{1}{r^2}(\dot{\theta}_o - Y^2) \\ &= (1 - Y^2) - \frac{1}{r^2}[1 - Y^2 + (\dot{\theta}_0 - 1)] + Y^2 \\ &= \left(1 - \frac{1}{r^2}\right)(1 - Y^2) + Y^2 + \frac{1 - \dot{\theta}_0}{r^2}. \end{aligned}$$

Now

$$1 - \frac{1}{r^2} = \frac{r^2 - 1}{r^2} = -\frac{2\varepsilon}{b} Y g(Y, \varepsilon_i),$$

where $g(Y, \varepsilon)$ is a smooth function converging uniformly to 1 on the interval of integration $[0, Y_*]$ as $\varepsilon \to 0$. This follows from the expansion $\eta = b(1 - r) + O(\eta^2)$. (For the special model we have $\eta = 1 - r^2/2 = (1 - r) - \frac{1}{2}(1 - r)^2$ exactly.) Thus, our integrand is

$$(1 - \dot{\theta})dt = \varepsilon_i[Y^2 + \varepsilon_i Y k_i(Y)] \frac{dY}{\sqrt{R_i(Y)}} + \frac{1 - \dot{\theta}_0}{r^2}\, dt.$$

Here $k_i(Y) = -2g(Y, \varepsilon_i)/b$, which is a smooth bounded function uniformly converging to a constant on the interval of integration. The last term in the integrand, the one involving dt,

is always nonnegative because $1 > \dot{\theta}_{0,i}$ for unit speed curves. (In fact, this term is strictly positive for interior arcs.) It follows that

$$\limsup \frac{t_{*,i} - \theta_{*.i}}{\varepsilon_i} \geq \limsup \int_0^{Y_*} [Y^2 + \varepsilon_i Y k_i(Y)] \frac{dY}{\sqrt{R_i(Y)}}. \tag{16}$$

Assuming the validity of interchanging limits and integration, we obtain

$$\limsup \frac{t_{*,i} - s_{*,i}}{\varepsilon_i} \geq \int_0^{\sqrt{2}} \frac{Y^2}{b\sqrt{1-(1-Y^2)^2}}\, dY = \frac{\sqrt{2}}{b} > 0.$$

This completes the proof, modulo showing that we may interchange the limit with the integration.

7.1. Interchange of limit and integration. The only difficulty is that the limiting denominator $\sqrt{R(Y,0,0)}$ has a simple zero at $Y = 0$ in the case of a self-intersecting arc. This pole cancels with a factor of Y in the limiting numerator, yielding an integrable function. However, we cannot blindly apply the dominated convergence theorem. (To see the difficulties, consider, for example, the function $Y^2/|Y - \varepsilon|$, which has a simple pole at ε and whose limiting denominator has a simple zero at zero. Its integral over the unit interval is $+\infty$ for $\varepsilon > 0$ but the integral of its limit is $\frac{1}{2}$.)

Recall that the tangent vector to any smooth planar curve c turns by a total amount $\int_c \kappa(s)ds$ upon traversing the curve. For our self-intersecting arcs c_i, this amount of turning is $2\pi + \theta_i - 2\beta_i$, where θ_i is the angle subtended by the arc and β_i is the angle the arc initially makes with the circle. (Thus, if the curve consists of one arc, we have $\theta_i = s_i$.)

Because our arcs solve the geodesic equations, they have curvature

$$\kappa(t) = eB(t) = \frac{1}{\varepsilon^2} 2\eta(s) b(1 + O(\varepsilon)) = \frac{1}{\varepsilon} 2Y(s) b K_i(Y),$$

where the function $K_i = K_i(Y) = 1 + O(\varepsilon_i)$ is a smooth function on the interval $[0, Y_{*,i}]$ and tends uniformly to 1. (For the model case, $b = 1$ and $K_i = 1$ exactly.) Changing variables from t to Y and using the reflectional symmetry of the arc we obtain

$$\int_0^{Y_{*,i}} \frac{Y b K_i(Y)}{\sqrt{R_i(Y)}}\, dY = \frac{\pi}{2} + \frac{\theta_i}{4} - \frac{\beta_i}{2}.$$

Let g_i denote the integrand

$$g_i = \frac{Y(bK_i(Y))}{\sqrt{R_i(Y)}} = \frac{Y b(1 + O(\varepsilon_i))}{b\sqrt{1-(1-Y^2)^2 + O(\varepsilon_i)}}.$$

Then

$$g_i \to g = \frac{1}{\sqrt{2 - Y^2}},$$

where the convergence is uniform on compact subsets of the open interval $(0, \sqrt{2})$. We calculate directly that

$$\int g(Y) dY = \frac{\pi}{2}$$

so that $\int g_i \to \int g$ as well.

Referring back to the integrand of the desired limit (16), set

$$f_i = Y(1 + \varepsilon_i k_i(Y)).$$

Then the integrand for the desired limit is $f_i g_i$. Also

$$f_i \to f = Y,$$

where the convergence is now uniform on the entire closed interval $[0, \sqrt{2}]$.

The following lemma now validates interchanging the limit with the integral sign.

LEMMA 3. *Let b_i be a sequence of numbers converging to a number b. Let g_i be a sequence of nonnegative continuous functions defined on the open intervals (a, b_i) that converge uniformly on every compact subset $[a + \delta, b - \delta]$, $\delta > 0$ of the limit interval (a, b) to the function g. Suppose that $\int_a^{b_i} g_i \to \int_a^b g$, this integral being finite. Let f_i be a sequence of continuous functions on a neighborhood of the* closed *interval $[a, b]$ that converge uniformly on that interval to a function f. Then $f_a^{b_i} f_i g_i \to \int_a^b fg$.*

The proof of this lemma is a straightforward exercise in real analysis. We do not give the proof, except to say that the only difficulty is that the g_i can have poles at the endpoints. The value of f at these endpoints together with the uniform convergence of the f_i and the boundedness of $\int g$ serve to control the sequence of integrals near the endpoints.

This completes the proof of Proposition 2 and hence Theorem 1.

8. Stability. The germ of a distribution at a point is called *stable* if any other distribution that is sufficiently (Whitney-) close to it is locally diffeomorphic to it. For example, the Darboux theorem states that any contact distribution is stable.

The distribution in our example is stable. To see this, we formalize some properties of that distribution. Suppose that $\mathcal{D}$ is a distribution on a three-manifold that is defined in a neighborhood of a point q by the vanishing of a nonzero one-form Θ. Define the function B by writing

$$\Theta \wedge d\Theta = B d^3x,$$

where d^3x is a locally defined volume form. Suppose that B has a transverse zero at q: $B(q) = 0$ and $dB(q) \neq 0$. These are precisely the properties of our example that we need.

DEFINITION 5. *A distribution with the above properties will be called a simply degenerate contact structure. The surface $\{B = 0\}$ is called the singular surface.*

By a theorem of Martinet [15], if Θ is any one form with the above properties, then there exists a smooth nonzero function g and coordinates x, y, z defined in a neighborhood of q such that

$$g\Theta = dz - y^2\, dx$$

(see also Zhitomirskii [26]). Because Θ and $g\Theta$ define the same distribution, this proves the following lemma.

LEMMA 4. *Distributions of simply degenerate contact type are stable.*

THEOREM 2 (Stable counterexample). *Suppose that Q is a three-dimensional sR manifold whose underlying distribution is a simply degenerate contact structure. Then every horizontal curve on the singular surface is a geodesic.*

For an open dense set of fiber inner products on the distribution, these geodesics do not satisfy the geodesic equations. In particular, the abnormal geodesics of Theorem 2 are stable under C^2 perturbations of the sR structure.

We do not prove this theorem. It follows the same lines as our proof of Theorem 1, but the algebra and analysis is considerably messier. There is now a simple proof due to Liu and Sussmann [14].

Remark 7. The fact that the result is purely differential-topological suggests that there is a differential-topological proof. We have not found one yet.

Acknowledgments. I thank Alan Weinstein for bringing Rayner's paper [21] to my attention and Stanislaw Janeczko for referring me to the papers of Martinet [15] and Zhitomirskii [26]. I also thank Ge Zhong and Danny Goroff for extended discussions while at Mathematics Science Research Institute, University of California, Berkeley. I thank the University of California, Berkeley, the National Science Foundation, and the University of California, Santa Cruz for support.

Note added in proof. Bryant and Hsu [R. Bryant and L. Hsu, *Rigidity of Integral Curves of Rank Two Distributions*, Invent. Math., 114 (1993), pp. 435–461.] used the term C^1*-rigid curve* for curves having the rigidity property of our abnormal curve. They showed how to find a large class of such curves for a typical two-plane field in a space of arbitrary dimension. Liu and Sussmann (already referenced) independently discovered this same class of curves and call them *regular abnormal extremals*. They prove that these curves are locally minimizing curves, independent of the choice of inner product on the two-plane fields.

INVERSE FUNCTION THEOREMS AND SHAPE OPTIMIZATION*

LUC DOYEN†

Abstract. In this paper the problem of shape optimization under shape constraints is investigated. Using the shape gradient and shape tangent cones, inverse function theorems are established. With these theorems, the existence of Lagrangian or Kuhn–Tucker multipliers for shape optimization problems with equality or inequality constraints is proved.

Key words. shape optimization, shape gradient, tangent cones, velocity cones, inverse function theorem, Fermat rule, Lagrangian multipliers, Kuhn–Tucker multipliers

AMS subject classification. 49A22

1. Introduction.

Shape analysis and shape optimization (see [14], [15], [6]) deal with problems where the variables are no longer vectors of parameters or functions, but the shape of a geometric domain K contained in a subset E of R^p.

We adapt to the metric space $\mathcal{P}(E)$ of all nonempty closed subsets of a given compact set E, Graves' inverse function theorem, and, more generally, some constrained inverse function theorems (see [1], [11]), which allow us to solve locally a constrained problem of the form

$$\text{Find } K \in \mathcal{K} \subset \mathcal{P}(E) \quad \text{such that } F(K) = y$$

for any right-hand side y in the neighbourhood of a fixed

$$y_0 = F(K_0) \in F(\mathcal{K}),$$

where F is a map from $\mathcal{P}(E)$ into a finite-dimensional space Y.

To do this, we first need to define the gradient $\overset{\circ}{J}(K)$ of a functional J on $\mathcal{P}(E)$; the framework of shape derivatives introduced by many authors (see [3], [16], [5]) is used.

We also propose extensions of the contingent and Clarke's tangent cones, hereafter referred to as the velocity cones, that are defined for a family $\mathcal{K}$ of nonempty closed subsets of E and denoted by $\mathcal{V}_{\mathcal{K}}(K)$ and $\mathcal{U}_{\mathcal{K}}(K)$, respectively.

Once inverse function theorems have been established, they are applied to the calculus of velocity cones of subsets, especially those defined by inequality and equality constraints. This, if a Fermat rule is used, naturally gives rise to the shape Lagrangian and Kuhn–Tucker multipliers for the class of shape optimization problems of the form

$$J(\widehat{K}) = \inf J(K).$$
$$\begin{cases} A_i(K) \le 0, & i = 1, \dots, r, \\ B_j(K) = 0, & j = 1, \dots, s, \\ K \in \mathcal{P}(E), \end{cases}$$

These multipliers $(\widehat{\beta}, \widehat{\lambda})$ satisfy the following equality:

$$\overset{\circ}{J}(\hat{K}) = \sum_{i=1}^{r} \widehat{\lambda}_i \overset{\circ}{A}_i(\widehat{K}) + \sum_{j=1}^{s} \widehat{\beta}_j \overset{\circ}{B}_j(\widehat{K}).$$

2. Shape gradient. Let E be a subset of R^p. The definition of the directional derivative has to be adapted to the family $\mathcal{P}(E)$ of all nonempty closed subsets of E. To do this, the velocity method is used. From [5], it is known that velocity and transformation approaches are equivalent (see [7], [8], [9], [10]).

2.1. Velocity method and shape-directional derivative. Let us consider the following differential equation in R^p:

$$\left\{ \begin{array}{l} x'(t) = f(x(t)), \\ x(0) = x, \end{array} \right. \tag{1}$$

where $f : R^p \to R^p$.

The solution map is denoted by $T_f(t, \cdot)$, namely

$$T_f(t, x) := x(t),$$

where $x(\cdot)$ denotes a fixed solution of (1).

Given an initial domain K, we introduce the set

$$K_t = T_f(t, K) = \{T_f(t, x) \,|\, x \in K\}$$

that represents the transformed domain at time t.

Now, let us consider a subset E of R^p. We denote by $d_E(y)$ the distance between a point $y \in R^p$ and the set E, that is,

$$d_E(y) = \inf_{x \in E} \|x - y\|.$$

Nagumo's theorem (see Appendix 7.1) gives Assumption 1 on f and E, which guarantees that, for any domain $K \subset E$, the transformed set K_t stays in E for any $t \geq 0$.

Assumption 1. The following hold:

$$\left\{ \begin{array}{ll} \text{(i)} & f \text{ is Lipschitzian on } \overline{E}, \\ \text{(ii)} & \forall\, x \in \overline{E}, \qquad f(x) \in T_E(x) \cap -T_E(x), \end{array} \right. \tag{2}$$

where the contingent (or Bouligand) cone $T_E(x)$ is defined for an element x of $\overline{E}$ by

$$v \in T_E(x) \Longleftrightarrow \liminf_{h \to 0^+} \frac{d_E(x + hv)}{h} = 0.$$

The following definition provides the adaptation of directional derivatives for a shape functional.

DEFINITION 2.1 (Shape-directional derivative). *Consider a subset E of R^p and a map $J : \mathcal{P}(E) \to R$. Given a domain K in $\mathcal{P}(E)$, and $f : R^p \to R^p$ satisfying Assumption* 1, *we say that J has an Eulerian semiderivative at K in the direction f, if*

$$\lim_{t \to 0^+} \frac{J(T_f(t, K)) - J(K)}{t}$$

exists and is finite. It is denoted by $DJ(K, f)$.

2.2. Shape gradient. To define the shape gradient, the following spaces of functions are used.

- $\mathcal{D}^l(E, R^p)$ is the space of l-times continuously differentiable functions from R^p into R^p having a compact support in E. As usual, $\mathcal{D}^\infty(E, R^p)$ is written as $\mathcal{D}(E, R^p)$.
- $\mathcal{F}_E^l = \begin{cases} \mathcal{D}^l(E, R^p) & \text{if } 1 \le l \le +\infty, \\ \mathcal{D}^0(E, R^p) \cap \mathrm{Lip}(E, R^p) & \text{if } l = 0, \end{cases}$

where $\mathrm{Lip}(E, R^p)$ denotes the space of Lipschitzian maps from E into R^p.

DEFINITION 2.2 (Shape gradient). *Consider a subset E of R^p, a domain K in $\mathcal{P}(E)$, and a map $J : \mathcal{P}(E) \to R$. The functional J is said to be shape differentiable at K, if the map from $\mathcal{D}(E, R^p)$ into R defined by*

$$f \mapsto DJ(K, f)$$

is linear and continuous on $\mathcal{D}(E, R^p)$. This map defines a vector distribution that is denoted by $\overset{\circ}{J}(K)$ and called the shape gradient of J at K. Furthermore, if this map is continuous for the topology $\mathcal{F}_E^l$, we say that the shape gradient $\overset{\circ}{J}(K)$ is of order l.

Remark. Note that (2) holds true for any function f in $\mathcal{D}^1(E, R^p)$ because for any $x \in \partial E$, we have $f(x) = 0 \in T_E(x)$.

We now extend the notion of shape gradient to a map from $\mathcal{P}(E)$ into R^n.

DEFINITION 2.3. *Let us consider a subset E of R^p, a domain K in $\mathcal{P}(E)$, and a map $J : \mathcal{P}(E) \to R^n$. We denote by $J_i(K)$ the ith coordinate of the vector $J(K)$. The map J is said to be shape differentiable of order l at K if the functionals J_i are shape differentiable of order l at K. We denote by $\overset{\circ}{J}(K)$ the sequence $(\overset{\circ}{J}_1(K), \dots, \overset{\circ}{J}_n(K))$.*

3. Velocity cones. Now we introduce two "velocity" cones that can be regarded as extensions to the metric space $\mathcal{P}(E)$ of the Bouligand and the Clarke tangent cones of normed spaces.

3.1. Tangent cones. Because the contingent cone $T_K(x)$ has already been defined, we now introduce Clarke's cone $C_K(x)$ and mention some properties of both cones. For details and proofs about these tangent cones, we refer to [1].

The Clarke cone of K at x is the set

$$C_K(x) = \left\{ v \in X \mid \lim_{h \to 0+, x' \to_K x} \frac{d_K(x' + hv)}{h} = 0 \right\},$$

where $x' \to_K x$ means that the convergence is in the set K.

PROPOSITION 3.1. *Let K be a subset of a normed space X, and x an element of K. We always have*

(i) $C_K(x) \subset T_K(x)$,
(ii) *$T_K(x)$ is a closed cone,*
(iii) *$C_K(x)$ is a closed convex cone,*
(iv) $C_K(x) = \liminf_{x_n \to_K x} T_K(x_n)$.

We say that K is sleek at x_0 if it is a closed subset and if the cone-valued map

$$K \ni x \rightsquigarrow T_K(x)$$

is lower semicontinuous at x_0. The domain K is called sleek if it is sleek at every point of K.

It can be proved that convex subsets are sleek and that, when K is a sleek subset of a Banach space, the contingent and the Clarke tangent cones to K coincide and, consequently, are convex.

3.2. Velocity cones. To construct tangent cones analogues in $\mathcal{P}(E)$, a distance between domains is needed. The Hausdorff distance between two compact subsets L and K in $\mathcal{P}(E)$ is defined as follows:

$$d\!\!\!/(K, L) = \sup_{x\in K} \inf_{y\in L} \|x - y\| + \sup_{y\in L} \inf_{x\in K} \|x - y\|.$$

We recall that if E is a compact subset of R^p, then $(\mathcal{P}(E), d\!\!\!/)$ is a compact metric space.

Notation. Consider a family $\mathcal{K}$ of compact sets in E, and a compact set L in E. The distance between the domain L and the family $\mathcal{K}$ is defined by

$$d_{\mathcal{K}}(L) = \inf_{K\in\mathcal{K}} d\!\!\!/(L, K).$$

We propose the following extensions of the tangent cones.

DEFINITION 3.2 (Velocity cones). *Let E be a subset of R^p, K an element of a family $\mathcal{K}$ of compact subsets of E, and l an integer satisfying $0 \le l \le \infty$.*

- *The velocity cone of order l to $\mathcal{K}$ at K is the set*

$$\mathcal{V}^l_{\mathcal{K}}(K) = \left\{ f \in \mathcal{F}^l_E \mid \liminf_{h\to 0^+} \frac{d_{\mathcal{K}}(T_f(h, K))}{h} = 0 \right\}.$$

- *The velocity convex cone of order l to $\mathcal{K}$ at K is the set*

$$\mathcal{U}^l_{\mathcal{K}}(K) = \left\{ f \in \mathcal{F}^l_E \mid \lim_{h\to 0^+, K'\to_{\mathcal{K}} K} \frac{d_{\mathcal{K}}(T_f(h, K'))}{h} = 0 \right\}.$$

Remark. We can see at once the characterizations of these two cones as follows.

- $f \in \mathcal{V}^l_{\mathcal{K}}(K)$ if and only if there exists a sequence of reals $t_n \to 0^+$ and there exists a sequence $\widetilde{K_n} \in \mathcal{K}$ satisfying $(1/t_n) d\!\!\!/(\widetilde{K_n}, T_f(t_n, K)) \to 0$.
- $f \in \mathcal{U}^l_{\mathcal{K}}(K)$ if and only if for any sequence $K_n \to_{\mathcal{K}} K$ (in the sense of Hausdorff) and for any sequence of reals $t_n \to 0^+$, there exists a sequence $\widetilde{K_n} \in \mathcal{K}$ satisfying $(1/t_n) d\!\!\!/(\widetilde{K_n}, T_f(t_n, K_n)) \to 0$.

The definition below provides a characterization of regularity of a family $\mathcal{K}$.

DEFINITION 3.3 (Well shaped). *Let E be a subset of R^p, l an integer satisfying $0 \le l \le \infty$, and K be in a closed family $\mathcal{K}$ of compact subsets of E. We say that $\mathcal{K}$ is well shaped at K if*

$$\mathcal{U}^l_{\mathcal{K}}(K) \subset \liminf_{K_n\to_{\mathcal{K}} K} \mathcal{V}^l_{\mathcal{K}}(K_n) \quad \textit{for the } \mathcal{D}^l(E, R^p) \textit{ topology.}$$

3.3. Properties of the velocity cones. The velocity cones (§3.2) verify properties similar to those of tangent cones.

PROPOSITION 3.4. *Let E be a subset of R^p, and K be in a family $\mathcal{K}$ of compact subsets of E. For any l satisfying $0 \le l \le \infty$, we have*

(i) $\mathcal{U}^l_{\mathcal{K}}(K) \subset \mathcal{V}^l_{\mathcal{K}}(K)$,
(ii) $\mathcal{V}^l_{\mathcal{K}}(K)$ *is a cone,*
(iii) $U^l_{\mathcal{K}}(K)$ *is a convex cone,*
(iv) $\mathcal{V}^l_{\mathcal{K}}(K)$ *and* $\mathcal{U}^l_{\mathcal{K}}(K)$ *are closed.*

Proof. (i) This can be easily checked.

(ii) Because $T_f(t, \cdot) = T_{\lambda f}(t/\lambda, \cdot)$, it is clear that $\mathcal{V}^l_{\mathcal{K}}(K)$ and $\mathcal{U}^l_{\mathcal{K}}(K)$ are cones.

(iii) Let f_1 and f_2 be elements of $\mathcal{U}^l_{\mathcal{K}}(K)$ and consider sequences

$$\text{(3)} \qquad \begin{cases} t_n \to 0^+, \\ \mathcal{K} \ni K_n \to K. \end{cases}$$

By definition, there exists $L_n^1 \in \mathcal{K}$ such that

$$\frac{d\!\!\!/(L_n^1, T_{f_1}(t_n, K_n))}{t_n} \to 0. \tag{4}$$

The triangular inequality yields

$$d\!\!\!/(L_n^1, K) \leq d\!\!\!/(L_n^1, T_{f_1}(t_n, K_n)) + d\!\!\!/(T_{f_1}(t_n, K_n), K_n) + d\!\!\!/(K_n, K).$$

Because f_1 is bounded as a continuous function on its compact support, it is easy to check that for any x_n in K_n,

$$\|T_{f_1}(t_n, x_n) - x_n\| \leq t_n \|f_1\|_\infty,$$

where $\|f\|_\infty = \sup_{x \in R^p} \|f(x)\|$ is the uniform norm of f.

Hence

$$d\!\!\!/(T_{f_1}(t_n, K_n), K_n) \to 0,$$

which leads to

$$d\!\!\!/(L_n^1, K) \to 0.$$

Consequently, because f_2 belongs to $\mathcal{U}_{\mathcal{K}}^l(K)$, there exists $L_n^2 \in \mathcal{K}$ such that

$$\frac{d\!\!\!/(L_n^2, T_{f_2}(t_n, L_n^1))}{t_n} \to 0. \tag{5}$$

Furthermore, the triangular inequality leads to

$$\begin{aligned} d\!\!\!/(L_n^2, T_{f_1+f_2}(t_n, K_n)) \leq\ & d\!\!\!/(L_n^2 T_{f_2}(t_n, L_n^1)) \\ & + d\!\!\!/(T_{f_2}(t_n, L_n^1), T_{f_2}(t_n, T_{f_1}(t_n, K_n)) \\ & + d\!\!\!/(T_{f_2}(t_n, T_{f_1}(t_n, K_n)), T_{f_1+f_2}(t_n, K_n)). \end{aligned} \tag{6}$$

In view of (4), (5), and Lemmas 7.4 and 7.5 (below), we can conclude that

$$\frac{1}{t_n} d\!\!\!/(L_n^2, T_{f_1+f_2}(t_n, K_n)) \to 0^+,$$

which implies that

$$f_1 + f_2 \in \mathcal{U}_{\mathcal{K}}^l(K).$$

Therefore $\mathcal{U}_{\mathcal{K}}^l(K)$ is convex.

(iv) Let us consider a sequence of functions f_n of $\mathcal{V}_{\mathcal{K}}^l(K)$ converging for the $\mathcal{F}_E^l$ topology to a function f. Recall that $d_{\mathcal{K}}$ is a 1-Lipschitz function, that is,

$$|d_{\mathcal{K}}(K_1) - d_{\mathcal{K}}(K_2)| \leq d\!\!\!/(K_1, K_2), \qquad \forall\, K_1, K_2.$$

From Lemma 7.6 we obtain that for any n,

$$\liminf_{h \to 0^+} \frac{1}{h} d_{\mathcal{K}}(T_f(h, K)) \leq \liminf_{h \to 0^+} \frac{1}{h} d_{\mathcal{K}}(T_{f_n}(h, K)) + 2\|f_n - f\|_\infty.$$

Because the convergence in $\mathcal{F}_E^l$ implies the uniform convergence, if we let n tend to ∞, we conclude that f belongs to $\mathcal{V}_{\mathcal{K}}^l(K)$. This implies that $\mathcal{V}_{\mathcal{K}}^l(K)$ is closed.

The same arguments are used to prove that $\mathcal{U}^l_K(K)$ is closed. □

PROPOSITION 3.5. *Let E be a compact subset of R^p and K be in $\mathcal{P}(E)$. We have*

$$\mathcal{U}^l_{\mathcal{P}(E)}(K) = \mathcal{V}^l_{\mathcal{P}(E)}(K) = \mathcal{F}^l_E.$$

Consequently, $\mathcal{P}(E)$ is well shaped at any K in $\mathcal{P}(E)$.

Proof. We already know that

$$\mathcal{U}^l_{\mathcal{P}(E)}(K) \subset \mathcal{V}^l_{\mathcal{P}(E)}(K) \subset \mathcal{F}^l_E.$$

It remains to check that

$$\mathcal{U}^l_{\mathcal{P}(E)}(K) \supset \mathcal{V}^l_{\mathcal{P}(E)}(K) \supset \mathcal{F}^l_E.$$

To do this, consider

$$\text{(7)} \qquad \begin{cases} f \in \mathcal{F}^l_E, \\ t_n \to 0^+, \\ K_n \to K \quad \text{in } \mathcal{P}(E). \end{cases}$$

Because $f \in \mathcal{F}^l_E$, Nagumo's theorem (Theorem 7.1) ensures that

$$\widetilde{K_n} = T_f(t_n, K_n) \subset E.$$

Consequently

$$\frac{d\!\!l(T_f(t_n, K_n), \widetilde{K_n})}{t_n} = 0.$$

Therefore, f belongs to $\mathcal{U}^l_{\mathcal{P}(E)}(K)$. □

3.4. Relations with tangent cones. Here we consider the case of a singleton $\{x\}$, and K is identified with the set $\{\{x\}\}_{x\in K} \subset \mathcal{P}(E)$. The following vector distribution $f \to f(x)$ is denoted δ_x.

PROPOSITION 3.6. *Let K be a closed subset of a set E in R^p, and let x be in K. We have*

$$\text{(8)} \qquad \begin{aligned} &\text{(i)} \quad f \in \mathcal{V}^l_K(\{x\}) \Rightarrow \delta_x f \in T_K(x), \\ &\text{(ii)} \quad f \in \mathcal{U}^l_K(\{x\}) \Rightarrow \delta_x f \in C_K(x). \end{aligned}$$

Proof. (i) Let us assume that the assertion $f \in \mathcal{V}^l_K(\{x\})$ is satisfied; thus

$$\text{(9)} \qquad \exists x_n \in K \quad \text{such that } \frac{1}{t_n} d\!\!l(x_n, T_f(t_n, x)) \to 0^+.$$

Hence

$$\frac{1}{t_n} d_K(T_f(t_n, x)) \to 0^+.$$

Moreover, we have

$$\text{(10)} \qquad \begin{aligned} |d_K(x + t_n f(x)) - d_K(T_f(t_n, x))| &\le \|x + t_n f(x) - T_f(t_n, x)\| \\ &\le t_n \varepsilon(t_n). \end{aligned}$$

Consequently,

$$\liminf_{t\to 0^+} \frac{1}{t} d_K(x + tf(x)) = 0,$$

which means that the assertion $\delta_x f \in T_K(x)$ is satisfied.

(ii) Let us assume that $f \in \mathcal{U}_K^l(\{x\})$. Consider a sequence x_n converging to x in K and a sequence of reals t_n converging to 0^+. This yields

$$\exists y_n \in K \quad \text{such that } \frac{1}{t_n} d(y_n, T_f(t_n, x_n)) \to 0^+. \tag{11}$$

Hence

$$\frac{1}{t_n} d_K(T_f(t_n, x_n)) \to 0^+.$$

Consequently, using (10) again, we obtain

$$\lim_{\substack{y \to_K x \\ t\to 0^+}} \frac{1}{t} d_K(y + tf(x)) = 0.$$

This proves that $\delta_x f \in C_K(x)$. □

4. Constrained inverse function theorem. Inverse function theorems are known to be efficient tools in analysis of a wide range of problems. Let us recall that Graves' theorem states that, if a continuously differentiably map $f : X \to Y$ between two Banach spaces has a surjective derivative $f'(\hat{x})$ at some $\hat{x} \in X$, then the inverse image $f^{-1}(\cdot)$ enjoys a Lipschitzian behaviour around $f(\hat{x})$.

Here, the constrained inverse function theorem and, consequently, Graves' inverse function theorem are extended to shape maps. More generally, the theorems are stated for maps where the variables are both vectors and domains.

4.1. Pseudo-Lipschitz set-valued map. First, let us make how we can characterize the Lipschitzian behaviour of a set-valued map precise.

DEFINITION 4.1 (Pseudo-Lipschitz). *When X and Y are metric spaces, we say that the set-valued map $F : X \rightsquigarrow Y$ is pseudo-Lipschitz around $(x, y) \in \mathrm{Graph}(F)$, if there exists a positive constant l and neighbourhoods $V_x \subset \mathrm{Dom}(F)$ of x and V_y of y, such that*

$$\forall x_1, x_2 \in V_x, \qquad \forall y_1 \in F(x_1) \cap V_y,$$

$$\exists y_2 \in F(x_2) \quad \textit{such that } d_Y(y_1, y_2) \le l d_X(x_1, x_2).$$

4.2. Constrained inverse function theorem. In what follows, we use the following notations.

- Consider two maps $F : \mathcal{P}(E) \to Y$ and $f : X \to Y$ where X, Y are normed spaces. The map $F \oplus f$ is defined by

$$(F \oplus f)(K, x) = F(K) + f(x),$$

where K belongs to $\mathcal{P}(E)$ and x belongs to X.

- The unit ball for the Euclidian norm on $Y = R^n$ is denoted B_Y and the unit ball of the space of bounded functions on R^p for the uniform norm is denoted by B_∞.

THEOREM 4.2 (Constrained inverse shape function). *Let X be a Banach space; Y, a finite-dimensional space; E, a compact set of R^p; $\mathcal{K}$, a closed subset of $\mathcal{P}(E)$; and K_0 be in $\mathcal{K}$. Let M be a closed subset of X and x_0 an element of M. Let us consider a shape function $F : \mathcal{P}(E) \to Y$ that is continuous (in the Hausdorff metric) on $\mathcal{K}$ and a continuous function $f : X \to Y$. Let us assume that the map F, in a neighbourhood of K_0, is Lipschitzian (in the Hausdorff metric) and shape differentiable of order l $(0 \leq l \leq \infty)$ and that the map f, in a neighbourhood of x_0, is differentiable. Furthermore, let us assume that the following transversality condition holds true:*

$$(12)\qquad \begin{cases} \exists c, c', \eta > 0, \qquad \exists \alpha \in [0,1[\quad \textit{satisfying}, \\ \forall K \in \mathcal{K} \cap B(K_0, \eta), \qquad \forall x \in M \cap B(x_0, \eta), \\ B_Y \subset \overset{\circ}{F}(K)(\mathcal{V}^l_{\mathcal{K}}(K) \cap cB_\infty) + f'(x)(C_M(x) \cap c'B_X) + \alpha B_Y. \end{cases}$$

Then the set-valued map $y \rightsquigarrow (F \oplus f)^{-1}(y) \cap (\mathcal{K} \times M)$ is pseudo-Lipschitz in a neighbourhood of $(F(K_0) + f(x_0), (K_0, x_0))$.

Remark. The above theorem still holds true with $T^\flat_M(x)$[1] instead of $C_M(x)$.

If f is taken to be 0, then the preceding theorem deals only with map of sets and becomes Theorem 4.3.

THEOREM 4.3. *Let Y be a finite-dimensional space; E, a compact set of R^p; $\mathcal{K}$, a closed subset of $\mathcal{P}(E)$; and K_0 be in $\mathcal{K}$. Let us consider a shape function $F : \mathcal{P}(E) \to Y$ continuous (in the Hausdorff metric) on $\mathcal{K}$. Let us assume that the map F, in a neighbourhood of K_0, is Lipschitzian (in the Hausdorff metric) and shape differentiable of order l $(0 \leq l \leq \infty)$. Furthermore, let us assume that*

$$(13)\qquad \begin{cases} \exists c, \eta > 0, \qquad \exists \alpha \in [0,1[\quad \textit{satisfying}, \\ \forall K \in \mathcal{K} \cap B(K_0, \eta), \qquad B_Y \subset \overset{\circ}{F}(K)(\mathcal{V}^l_{\mathcal{K}}(K) \cap cB_\infty) + \alpha B_Y \end{cases}$$

Then the set-valued map $y \rightsquigarrow F^{-1}(y) \cap \mathcal{K}$ is pseudo-Lipschitz in a neighbourhood of $(F(K_0), K_0)$.

Proof of Theorem 4.2. Let us consider

$$(14)\qquad \begin{cases} K \in \mathcal{K} & \text{such that } d(K, K_0) < \dfrac{\eta}{3}, \\ x \in M & \text{such that } \|x - x_0\| < \dfrac{\eta}{3}, \\ \rho > 0 & \text{such that } \dfrac{3\rho}{\eta} < \dfrac{1-\alpha}{2c+c'}, \\ y \in Y & \text{such that } \|y - F(K) - f(x)\| < \rho, \\ \varepsilon > 0 & \text{such that } \dfrac{3\rho}{\eta} < \varepsilon < \dfrac{1-\alpha}{2c+c'}, \end{cases}$$

and introduce the function

$$\mathcal{K} \times M \ni (K, x) \rightsquigarrow V(K, x) = \|y - F(K) - f(x)\|.$$

[1] The adjacent cone to K at x is the set defined by

$$T^\flat_K(x) = \left\{ v \in X \mid \lim_{h \to 0+} \frac{d_K(x + hv)}{h} = 0 \right\}.$$

Because E is a compact set of R^p, E is a complete metric space, which implies that $\mathcal{P}(E)$ is a complete metric space for the Hausdorff distance. Furthermore, $\mathcal{K}$ being closed, $\mathcal{K}$ is complete.

On the other hand, M is complete as a closed subset of the Banach space X. Consequently, the product set $\mathcal{K} \times M$ is complete for the distance $d((K,x),(H,y) = \|x-y\| + d\!\!\!l(K,H)$.

Because V is positive and lower semicontinuous, we can apply Ekeland's theorem[2] to V, that is,

(15)
$$\begin{cases} \exists(\widetilde{K},\tilde{x}) \in \mathcal{K}\times M, & V(\widetilde{K},\tilde{x}) + \varepsilon d\!\!\!l(\widetilde{K},K) + \varepsilon\|\tilde{x}-x\| \le V(K,x), \\ \forall (H,y) \neq (\widetilde{K},\tilde{x}), & V(\widetilde{K},\tilde{x}) < \varepsilon d\!\!\!l(H,\widetilde{K}) + \varepsilon\|\tilde{x}-y\|, (H,y) \in \mathcal{K}\times M + V(H,y). \end{cases}$$

It can be easily deduced that $d\!\!\!l(K_0,\widetilde{K}) \le 2\eta/3$, and that $\|x_0-\tilde{x}\| \le 2\eta/3$, which leads to

(16)
$$\begin{cases} \widetilde{K} \in B(K_0,\eta) \cap \mathcal{K}, \\ \tilde{x} \in B(x_0,\eta) \cap M. \end{cases}$$

Consequently, using the transversality condition (12), we have

$$B_Y \subset \overset{\circ}{F}(\widetilde{K})(\mathcal{V}^l_{\mathcal{K}}(\widetilde{K}) \cap cB_\infty) + f'(\tilde{x})(C_m(\tilde{x}) \cap c'B_X) + \alpha B_Y.$$

Therefore we have

(17)
$$y - F(\widetilde{K}) - f(\tilde{x}) = \overset{\circ}{F}(\widetilde{K})g + f'(\tilde{x})v + w,$$

where

(18)
$$\begin{cases} g \in \mathcal{V}^l_{\mathcal{K}}(\widetilde{K}), \qquad v \in C_M(\tilde{x}), \\ \|g\|_\infty \le c\|y - F(\widetilde{K}) - f(\tilde{x})\|, \\ \|w\| \le \alpha\|y - F(\widetilde{K}) - f(\tilde{x})\|, \\ \|v\| \le c'\|y - F(\widetilde{K}) - f(\tilde{x})\|. \end{cases}$$

Using the definition of $\mathcal{V}^l_{\mathcal{K}}(\widetilde{K})$, we know that there exist $t_n \to 0^+$ and $\widetilde{K_n} \in \mathcal{K}$ such that

(19)
$$\frac{1}{t_n} d\!\!\!l(\widetilde{K_n}, K_n) \to 0^+, \quad \text{where } K_n = T_g(t_n,\widetilde{K}).$$

Similarly, using the definition of $C_M(\tilde{x})$, we know that there exists a sequence $\widetilde{\varepsilon_n} \to 0$ such that

$$\widetilde{x_n} = \tilde{x} + t_n(v + \widetilde{\varepsilon_n}) \in M.$$

[2] See, for instance, [1] for details and proof.

EKELAND'S THEOREM. *Consider $V : E \to R \cup \{+\infty\}$ a strict, lower semicontinuous and positive function, where (E,d) is a complete metric space; then, given $\varepsilon > 0$ and $x_0 \in \mathrm{Dom}V$,*

$$\begin{cases} \exists \tilde{x} \in E & V(\tilde{x}) + \varepsilon d(\tilde{x},x_0) \le V(x_0), \\ \forall x \neq \tilde{x} & V(\tilde{x}) < \varepsilon d(x,\tilde{x}) + V(x). \end{cases}$$

From (15), we obtain that

$$\|y - F(\widetilde{K_n}) - f(\widetilde{x_n})\| + \varepsilon\|\widetilde{x_n} - \tilde{x}\| + \varepsilon d\!\!\!^{-}(\widetilde{K_n}, \widetilde{K}) \geq \|y - F(\widetilde{K}) - f(\tilde{x})\|. \tag{20}$$

Because F is Lipschitzian in a neighbourhood of K_0, we have

$$\|F(\widetilde{K_n}) - F(K_n)\| \leq k\, d\!\!\!^{-}(\widetilde{K_n}, K_n). \tag{21}$$

Hence, by virtue of (19),

$$F(\widetilde{K_n}) - F(K_n) = t_n\widehat{\varepsilon_n} \quad \text{with } \|\hat{\varepsilon}_n\| \to 0^+.$$

Using (21) and the definition of $\overset{\circ}{F}(\widetilde{K})$, we see that

$$F(\widetilde{K_n}) = F(\widetilde{K}) + t_n(\overset{\circ}{F}(\widetilde{K})g + \varepsilon_n^1).$$

Because f is differentiable around $\tilde{x}$, we can write

$$f(\widetilde{x_n}) = f(\tilde{x}) + t_n(f'(\tilde{x})v + \varepsilon_n^2).$$

We thus obtain

$$y - F(\widetilde{K_n}) - f(\widetilde{x_n}) = y - F(\widetilde{K}) - f(\tilde{x}) - t_n(\overset{\circ}{F}(\widetilde{K})g + f'(\tilde{x})v + \varepsilon_n^1 + \varepsilon_n^2).$$

In view of (17), we can write

$$y - F(\widetilde{K_n}) - f(\widetilde{x_n}) = (y - F(\widetilde{K}) - f(\tilde{x}))(1 - t_n) - t_n(\varepsilon_n^1 + \varepsilon_n^2 - w).$$

From (20), we obtain

$$\|y - F(\widetilde{K}) - f(\tilde{x})\| \leq \|\varepsilon_n\| + \|w\| + \frac{\varepsilon}{t_n}(d\!\!\!^{-}(\widetilde{K_n}, \widetilde{K}) + \|\widetilde{x_n} - \tilde{x}\|). \tag{22}$$

Moreover, we have

$$\begin{aligned} \sup_{z_n \in T_g(t_n, \tilde{K})} \inf_{z \in K} \|z_n - z\| &\leq \sup_{z \in \tilde{K}} \|T_g(t_n, z) - z\| \\ &\leq t_n\|g\|_\infty. \end{aligned} \tag{23}$$

Thus

$$\frac{d\!\!\!^{-}(K_n, \widetilde{K})}{t_n} \leq 2\|g\|_\infty. \tag{24}$$

Consequently, from (19) and the triangular inequality, we deduce that

$$\frac{d\!\!\!^{-}(\widetilde{K_n}, \widetilde{K})}{t_n} \leq 2\|g\|_\infty + \varepsilon_n. \tag{25}$$

Furthermore,

$$\frac{\|\widetilde{x_n} - \tilde{x}\|}{t_n} \leq \|v\| + \widetilde{\varepsilon_n}.$$

Consequently, using (18) and letting n tend to ∞, (22) becomes

$$\|y - F(\widetilde{K}) - f(\tilde{x})\| \leq (\varepsilon(2c + c') + \alpha)\|y - F(\widetilde{K}) - f(\tilde{x})\|.$$

Because $\varepsilon(2c+c')+\alpha<1$, it can be deduced that $\|y-F(\widetilde{K})-f(\tilde{x})\|=0$. Therefore

$$y=(F\oplus f)(\widetilde{K},\tilde{x}) \quad \text{with} \begin{cases} \widetilde{K}\in\mathcal{K}, \qquad \tilde{x}\in M, \\ d((K,x),(\widetilde{K},\tilde{x}))\le \dfrac{1}{\varepsilon}\|y-(F\oplus f)(K,x)\|. \end{cases}$$

This proves the theorem. □

Now we give a version of Theorem 4.2 using the convex cone $\mathcal{U}_{\mathcal{K}}(K)$ and stronger regularity assumptions on the maps and the family $\mathcal{K}$.

THEOREM 4.4. *Let X be a Banach space; Y, a finite-dimensional space; E, a compact set of R^p; and K_0 be in a subset $\mathcal{K}$ of $\mathcal{P}(E)$. Let x_0 be an element of a subset M of X. Consider a shape function $F:\mathcal{P}(E)\to Y$ that is continuous on $\mathcal{K}$ and a continuous function $f:X\to Y$. We assume that M is sleek at x_0, that $\mathcal{K}$ is well shaped at K_0, that the map F, in a neighbourhood of K_0, is Lipschitzian (in the Hausdorff metric) and continuously (weakly) shape differentiable of order l $(1\le l<\infty)$ and that the map f, in a neighbourhood of x_0, is continuously differentiable. Let us assume that*

$$\overset{\circ}{F}(K_0)\mathcal{U}^l_{\mathcal{K}}(K_0)+f'(x_0)C_M(x_0)=Y. \tag{26}$$

Then the set-valued map $y\rightsquigarrow(F\oplus f)^{-1}(y)\cap(\mathcal{K}\times M)$ is pseudo-Lipschitz in a neighbourhood of $((F\oplus f)(K_0,x_0),(K_0,x_0))$.

If f is taken to be 0, then the previous theorem deals only with maps of sets and becomes Theorem 4.5.

THEOREM 4.5. *Let Y be a finite-dimensional space; E, a compact set of R^p; $\mathcal{K}$, a closed subset of $\mathcal{P}(E)$; and let K_0 be in $\mathcal{K}$. Let us consider a shape function $F:\mathcal{P}(E)\to Y$ that is continuous on $\mathcal{K}$. Assume that the family $\mathcal{K}$ is well shaped at K_0, that the map F, in a neighbourhood of K_0, is Lipschitzian (in the Hausdorff metric) and continuously (weakly) shape differentiable of order l $(1\le l<\infty)$. Furthermore, let us assume that the following surjectivity assumption holds true:*

$$\overset{\circ}{F}(K_0)\mathcal{U}^l_{\mathcal{K}}(K_0)=Y. \tag{27}$$

Then the set-valued map $y\rightsquigarrow F^{-1}(y)\cap\mathcal{K}$ is pseudo-Lipschitz in a neighbourhood of $(F(K_0),K_0)$.

Proof of Theorem 4.4. We establish that the transversality requirement of Theorem 4.2 is satisfied. Let y_i be an element of S_Y, the unit sphere of Y. Because E is compact and $l<\infty$, $\mathcal{D}^l_E$ is a Banach space for the norm

$$\|f\|=\sum_{i=0}^{l}\|D^if\|_\infty.$$

Because $\mathcal{U}^l_{\mathcal{K}}(K_0)$ and $C_M(x_0)$ are closed $(l\ge1)$ and convex, we can apply the Robinson–Ursescu theorem[3] to the linear and continuous function

$$\mathcal{U}^l_{\mathcal{K}}(K_0)\times C_M(x_0)\ni(g,v)\mapsto\overset{\circ}{F}(K_0)g+f'(x_0)v.$$

[3] We refer, for instance, to [1] for the details and complete proof.

THE ROBINSON–URSESCU THEOREM. *Let X, Y be Banach spaces. Let us consider a continuous linear operator $A\in\mathcal{L}(X,Y)$ and a closed convex subset K of X. Suppose that Ax_0 belongs to the interior of the image of A. Then there exist positive constants l and β such that for any $y\in y_0+\beta B$, there exists a solution $x\in K$ to the equation $y=Ax$ satisfying*

$$\|x-x_0\|\le l\|y-Ax_0\|.$$

Hence there exists $c > 0$, g_0^i in $\mathcal{U}_{\mathcal{K}}(K_0)$ and v_0^i in $C_M(x_0)$ such that

$$\begin{cases} \overset{\circ}{F}(K_0)g_0^i + f'(x_0)v_0^i = y_i, \\ \|g_0^i\| + \|v_0^i\| \leq c\|y_i\| = c. \end{cases} \tag{28}$$

Let us consider $\varepsilon > 0$. From Proposition 3.1(iv), we know that, for every y^i, there exists $\eta_i > 0$ such that, for all $x \in B(x_0, \eta_i)$, we can find $v^i \in T_M(x)$ satisfying

$$\|v^i - v_0^i\| \leq c\varepsilon. \tag{29}$$

Because the family $\mathcal{K}$ is well shaped at K_0, we know that, for all y^i, there exists $\eta_i' > 0$ such that, for all $K \in B(K_0, \eta_i')$, there exists $g_i \in \mathcal{V}_{\mathcal{K}}(K)$ satisfying

$$\|g_i - g_i^0\|_\infty \leq c\varepsilon.$$

On the other hand, the continuity of $\overset{\circ}{F}$ and f' implies the existence of reals $\eta_0, \eta_0' > 0$ such that, for all $(K, x) \in B(K_0, \eta_0) \times B(x_0, \eta_0')$,

$$\begin{cases} \|\overset{\circ}{F}(K)\varphi - \overset{\circ}{F}(K_0)\varphi\| < \varepsilon \quad \text{for all } \varphi \in \mathcal{D}^l(E, R^p), \\ \|f'(x) - f'(x_0)\| < \varepsilon. \end{cases} \tag{30}$$

Let us now use the fact that S_Y is compact to claim that there exist p balls $B(y_i, \varepsilon)$ such that

$$S_Y \subset \bigcup_{i=1}^{p} B(y_i, \varepsilon). \tag{31}$$

Setting $\eta = \min(\min_{i=0,\dots,p} \eta_i, \min_{i=0,\dots,p} \eta_i')$, we have, for all $y \in S_Y$, for all $K \in B(K_0, \eta)$, and for all $x \in B(x_0, \eta)$,

$$\begin{cases} y &= \overset{\circ}{F}(K)g^i + f'(x)v^i + w_i, \\ w_i &= \overset{\circ}{F}(K_0)(g_0^i - g^i) + (\overset{\circ}{F}(K_0)g^i - \overset{\circ}{F}(K)g^i) \\ &\quad + f'(x_0)(v_0^i - v^i) + (f'(x_0) - f'(x))v^i + y - y_i. \end{cases} \tag{32}$$

In view of (30) and (31), we obtain

$$\|w_i\| \leq \varepsilon(2 + c\|f'(x_0)\| + c\|\overset{\circ}{F}(K_0)\| + c(1 + \varepsilon)) = \alpha. \tag{33}$$

Choosing ε such that $\alpha \in [0, 1[$ and setting $c' = c(1 + \varepsilon)$, we can conclude that

$$\exists c', \eta > 0, \qquad \exists \alpha \in [0, 1[\quad \text{satisfying}$$

$$\forall K \in \mathcal{K} \cap B(K_0, \eta), \qquad \forall x \in M \cap B(x_0, \eta), \tag{34}$$

$$B_Y \subset \overset{\circ}{F}(K)(\mathcal{V}_{\mathcal{K}}(K) \cap c'B_\infty) + f'(x)(C_M(x) \cap c'B_X) + \alpha B_Y.$$

This completes the proof of Theorem 4.5. □

4.3. Inverse function theorem. Using Theorem 4.5 and Proposition 3.5, we derive the following adaptation of Graves' theorem.

THEOREM 4.6 (Inverse shape function). *Let Y be a finite-dimensional space; E, a compact set of R^p; and K_0 be in $\mathcal{P}(E)$. Let us consider a continuous shape function $F : \mathcal{P}(E) \to Y$. Assume that the map F, in a neighbourhood of K_0, is Lipschitzian (in the Hausdorff metric) and continuously shape differentiable of order l $(1 \leq l < \infty)$, and that*

$$\overset{\circ}{F}(K_0) \quad \text{is surjective.} \tag{35}$$

Then the set-valued map $y \rightsquigarrow F^{-1}(y)$ is pseudo-Lipschitz in a neighbourhood of $(F(K_0), K_0)$.

5. Calculus of velocity cones. From Theorem 4.5, we can obtain a simple expression of the velocity cone when $\mathcal{K}$ is defined by equality and inequality constraints

$$\begin{cases} K \in \mathcal{P}(E), \\ A_i(K) \leq 0, \qquad i = 1, \ldots, r, \\ B_j(K) = 0, \qquad j = 1, \ldots, s, \end{cases} \tag{36}$$

where A_i, B_j are shape functionals.

5.1. Calculus of velocity cones of inverse image. More generally, we study the case of a family $\mathcal{K}$ defined as an inverse image of a set M in a finite-dimensional space Y, that is,

$$\mathcal{K} = F^{-1}(M).$$

PROPOSITION 5.1. *Let Y be a finite-dimensional space; E, a compact set of R^p; $\mathcal{L}$ a well shaped subset of $\mathcal{P}(E)$; and M, a sleek subset of Y. Let us consider a shape function $F : \mathcal{P}(E) \to Y$ that is continuous on $\mathcal{L}$. Assume that the map F, in a neighbourhood of $K \in \mathcal{L} \cap F^{-1}(M)$, is Lipschitzian (in the Hausdorff metric) and continuously shape differentiable of order l $(1 \leq l < \infty)$ and that the following transversality condition holds true:*

$$\overset{\circ}{F}(K)\mathcal{U}^l_{\mathcal{L}}(K) - C_M(F(K)) = Y. \tag{37}$$

Then

$$\mathcal{V}^l_{\mathcal{L}\cap F^{-1}(M)}(K) = \mathcal{V}^l_{\mathcal{L}}(K) \cap \overset{\circ}{F}(K)^{-1} T_M(F(K)).$$

If $\mathcal{L}$ is equal to the whole space $\mathcal{P}(E)$, we obtain Corollary 5.2.

COROLLARY 5.2. *Let E be a compact set of R^p, and M be a sleek subset of a finite-dimensional space Y. Let us consider a continuous map $F : \mathcal{P}(E) \to Y$. Consider a subset $K \in F^{-1}(M)$ and assume that the map F, in a neighbourhood of K, is Lipschitzian (in the Hausdorff metric) and continuously shape differentiable of order l $(1 \leq l < \infty)$. If the transversality condition*

$$\overset{\circ}{F}(K)\mathcal{D}^l(E, R^p) - C_M(F(K)) = Y \tag{38}$$

is satisfied, then

$$\mathcal{V}^l_{F^{-1}(M)}(K) = \overset{\circ}{F}(K)^{-1} T_M(F(K)).$$

Proof of 5.1. Let f be an element of $\mathcal{V}^l_{\mathcal{L}\cap F^{-1}(M)}(K)$. By definition, there exist $t_n \to 0^+$ and $K_n \in \mathcal{L} \cap F^{-1}(M)$ such that

$$\frac{1}{t_n} d\!\!\!l(K_n, T_f(t_n, K)) \to 0^+.$$

Obviously $f \in \mathcal{V}^l_{\mathcal{L}}(K)$.

Because F is shape differentiable of order l and Lipschitzian in a neighbourhood of K, we have

$$F(K_n) = F(K) + t_n(\overset{\circ}{F}(K)f + \varepsilon(t_n)). \tag{39}$$

Because $F(K_n)$ belongs to M, we have, by definition of the contingent cone,

$$\overset{\circ}{F}(K)f \in T_M(F(K)),$$

which states that

$$f \in \overset{\circ}{F}(K)^{-1}(T_M(F(K)).$$

Consequently,

$$\mathcal{V}^l_{\mathcal{L}\cap F^{-1}(M)}(K) \subset \mathcal{V}^l_{\mathcal{L}}(K) \cap \overset{\circ}{F}(K)^{-1} T_M(F(K)).$$

Conversely, let us consider $f \in \mathcal{V}^l_{\mathcal{L}}(K)$ such that $\overset{\circ}{F}(K)f \in T_M(F(K))$. Then, because M is sleek, there exist sequences $t_n \to 0^+$, $v_n \to \overset{\circ}{F}(K)f$, and $K_n \in \mathcal{L}$ such that

$$\begin{cases} \dfrac{1}{t_n} d\!\!\!l(K_n, T_f(t_n, K)) \to 0, \\ y_n = F(K) + t_n v_n \in M. \end{cases} \tag{40}$$

Let us introduce the map $F \ominus 1$ as follows:

$$\begin{aligned} F \ominus 1 : \mathcal{P}(E) \times Y &\to Y \\ (K, Y) &\mapsto F(K) - y. \end{aligned} \tag{41}$$

Theorem 4.4 and the assumption

$$\overset{\circ}{F}(K)\mathcal{U}^l_{\mathcal{L}}(K) - C_M(F(K)) = Y \tag{42}$$

imply that the map $\alpha \rightsquigarrow (F \ominus 1)^{-1}(\alpha) \cap (\mathcal{L} \times M)$ is pseudo-Lipschitz around $((K, F(K)), 0)$.

Because F is continuous, we have

$$(F \ominus 1)(K_n, y_n) = F(K_n) - F(K) - t_n(\overset{\circ}{F}(K)f + \varepsilon(t_n)) \to 0. \tag{43}$$

This yields

$$\exists \widehat{K_n} \in \mathcal{L}, \qquad \exists \widehat{y_n} \in M \quad \text{such that } (F \ominus 1)(\widehat{K_n}, \widehat{y_n}) = 0 \tag{44}$$

and

$$d\!\!\!l(\widehat{K_n}, K_n) \leq k \| F(K_n) - y_n - (F(\widehat{K_n}) - \widehat{y_n}) \|. \tag{45}$$

Using (39), it can be deduced that

$$\mathrm{dl}(\widehat{K_n}, K_n) \leq k t_n \|\varepsilon_n\|. \tag{46}$$

In view of (40), we obtain

$$\frac{1}{t_n} \mathrm{dl}(\widehat{K_n}, T_f(t_n, K)) \to 0. \tag{47}$$

Because $\widehat{K_n} \in \mathcal{L} \cap F^{-1}(M)$, we can conclude that $f \in \mathcal{V}^l_{\mathcal{L}\cap F^{-1}(M)}(K)$. □

5.2. The case of inequality and equality constraints. Let us consider the case of inequality and equality constraints. Namely,

$$\mathcal{K} = \left\{ K \in \mathcal{P}(E) \;\middle|\; \begin{array}{l} A_i(K) \geq 0, \ \forall i \in \{1, \ldots, r\} \\ B_j(K) = 0, \ \forall j \in \{1, \ldots, s\} \end{array} \right\}, \tag{48}$$

where B_i and A_j are functions from $\mathcal{P}(E)$ into R.

The maps A and B represent the vectors of shape functionals $(A_1, \ldots, A_r)$ and $(B_1, \ldots, B_s)$, respectively. We denote by $I(K) = \{i \mid A_i(K) = 0\}$ the set of active constraints.

PROPOSITION 5.3. *Let E be a compact subset of R^p. Let us assume that the shape functions A_i and B_j are continuous on $\mathcal{P}(E)$, Lipschitzian in the Hausdorff metric, and continuously shape differentiable of order l $(1 \leq l < \infty)$ in a neighbourhood of $K \in \mathcal{K}$ (defined in* (48)*) and that*

$$\left\{ \begin{array}{ll} \text{(i)} \ \overset{\circ}{B}(K)\mathcal{D}^l(E, R^p) = R^s, & \\ \text{(ii)} \ \exists g_0 \in \mathcal{D}^l(E, R^p) \quad \textit{such that} & \overset{\circ}{B}(K)(g_0) = 0, \\ & \overset{\circ}{A}_i(K)(g_0) > 0, \qquad \forall i \in I(K). \end{array} \right. \tag{49}$$

Then

$$\mathcal{V}^l_{\mathcal{K}}(K) = \{f \in \mathcal{F}^l_E \mid \overset{\circ}{B}(K)f = 0 \textit{ and } \overset{\circ}{A}_i(K)f \geq 0, \ \forall i \in I(K)\}.$$

Proof. It is only necessary to check that the transversality assumption of Corollary 5.2 holds true with $Y = R^{r+s}$, $F = (A, B)$, and $M = M^r_+ \times \{0\}^s$. Indeed, take $(y, z) \in R^r \times R^s$. From the first assumption, there exists $g \in \mathcal{D}^l(E, R^s)$ such that $\overset{\circ}{B}(K)g = z$. Fix

$$\alpha = \min_{i \in I(K)} \overset{\circ}{A}_i(K)g_0$$

and

$$\lambda = \max(0, y_1 - \overset{\circ}{A}_1(K)g, \ldots, y_r - \overset{\circ}{A}_r(K)g)/\alpha.$$

Let us set

$$v_i = \overset{\circ}{A}_i(K)(g + \lambda g_0) - y_i.$$

By construction, $v_i \neq 0$ for any $i \in I(K)$, so that $v = (v_1, \ldots, v_r)$ belongs to the tangent cone $C_{R^r}(A(K))$. Therefore $f = \lambda g_0 + g$ belongs to $\mathcal{D}^l(E, R^p)$ and satisfies

$$(y, z) = \overset{\circ}{F}(K)f - (v, 0).$$

Therefore

$$Y = \overset{\circ}{F}(K)\mathcal{D}^l(E, R^p) - C_M(F(K)),$$

and we can apply Corollary 5.2. □

5.3. Example. Let E be a compact set of R^p. Let $\mathcal{K}$ be the family of all closed connected subsets K of $\mathrm{Int}(E)$ satisfying the ε-cone property[4], with volume $V(K)$ equal to α, where

$$V(K) = \int_K dx.$$

We observe the following.

- V is shape differentiable of order 1 on any $K \in \mathcal{K}$ and for any $f \in \mathcal{D}^1_E$ and we have

$$\overset{\circ}{V}(K)f = \int_K \mathrm{div}(f(x))dx.$$

- It can be checked that V is continuous (Hausdorff) on $\mathcal{K}$, because it is continuous on $\mathcal{E} = \{K \subset E \text{ satisfying the } \varepsilon\text{-cone property}\}$.
- From the Steiner formula (see, for instance, [13]), we obtain, for any convex set $K \in \mathcal{K}$,

$$V(K \oplus B(0,r)) = V(K) + rM + r^2\varepsilon(r).$$

Thus, for any sequence K_n such that $d\!l(K_n, K) \to 0$, we have

$$V(K_n) \leq V(K \oplus B(0, d\!l(K_n, K))) = V(K) + M'd(K_n, K),$$

which implies that V is Lipschitzian in a neighbourhood of any convex set $K \in \mathcal{K}$.

- $\overset{\circ}{V}(K)$ is (weakly) continuous in a neighbourhood of any convex set $K \in \mathcal{K}$ because, for any $f \in \mathcal{D}^1(E, R^p)$,

$$|\overset{\circ}{V}(K_n)f - \overset{\circ}{V}(K)f| \leq \|\mathrm{div}(f)\|.|V(K_n) - V(K)|.$$

- We can write

$$\mathcal{K} = \mathcal{L} \cap V^{-1}(\alpha),$$

where $\mathcal{L}$ is the family of closed-connected subsets of $\mathrm{Int}(E)$ satisfying the ε-cone property. Note that

$$\mathcal{V}^1_{\mathcal{L}}(K) = \mathcal{D}^1_E(K)$$

because the image of a connected set by a continuous function is connected and because $T_f(t, \cdot)$ is Lipschitz.

- The transversality condition can be easily established by taking $f \in \mathcal{D}^1_E$ such that

$$\mathrm{div}(f)_{|K} = \frac{y}{\alpha}.$$

Thus we obtain, in the case when K is convex,

$$\mathcal{V}^1_{\mathcal{K}}(K) = \left\{ f \in \mathcal{D}^1_E \mid \int_K \mathrm{div}(f(x))dx = 0 \right\}.$$

[4] See [4]. Denote by $C(x, v, \varepsilon)$ the truncated cone of angle ε, direction v and vertex x intersected with the ball $B(x, \varepsilon)$. We say that K has the ε-cone property if, for any $x \in \partial K$, there exists a direction v such that

$$C(y, v, \varepsilon) \subset K, \quad \forall\, y \in B(x, \varepsilon) \cap \bar{K}.$$

6. Fermat rule and shape Lagrangian. We now consider the constrained optimization problem on $\mathcal{P}(E)$,

$$J(\widehat{K}) = \inf_{K \in \mathcal{K}} J(K), \tag{50}$$

where E is a subset of R^p, $\mathcal{K}$ a subset of $\mathcal{P}(E)$, and $J : \mathcal{P}(E) \to R$.

6.1. Fermat rule. First, let us recall the definition of the negative polar cone L^- of a subset L of a normed space X as follows:

$$p \in L^- \Longleftrightarrow \forall\, x \in L, \qquad \langle p, x \rangle \leq 0.$$

The Fermat rule is extended to the shape optimization case as follows.

THEOREM 6.1 (Fermat). *Let E be a subset of R^p and $\mathcal{K}$ be a family of compact subsets of E. Let us assume that the map $J : \mathcal{P}(E) \to R$ is Lipschitzian and shape differentiable of order l $(0 \leq l \leq \infty)$ in the neighbourhood of a solution $\widehat{K}$ of the constrained optimization problem* (50). *Then*

$$-\overset{\circ}{J}(\widehat{K}) \in \mathcal{V}_{\mathcal{K}}^{l}(\widehat{K})^-.$$

Proof. Let f be an element of $\mathcal{V}_{\mathcal{K}}^{l}(\widehat{K})$. Then

$$\begin{cases} \exists t_n \to 0^+, \\ \exists K_n \in \mathcal{K} \quad \text{such that } \varepsilon_n = \dfrac{1}{t_n} d(K_n, T_f(t_n, \widehat{K})) \to 0^+. \end{cases} \tag{51}$$

Because the functional J is Lipschitz, we have

$$\|J(K_n) - J(T_f(t_n, \widehat{K}))\| \leq c t_n \varepsilon_n.$$

Moreover, the definition of $\overset{\circ}{J}(\widehat{K})$ leads to

$$J(T_f(t_n, \widehat{K})) = J(\widehat{K}) + t_n(\overset{\circ}{J}(\widehat{K})(f) + \varepsilon(t_n)). \tag{52}$$

Consequently,

$$J(K_n) \leq J(\widehat{K}) + t_n \varepsilon_n + t_n(\overset{\circ}{J}(\widehat{K})(f) + \varepsilon(t_n)).$$

Because $J(K_n) \geq J(\widehat{K})$, dividing by t_n and letting n converge to ∞, we can conclude that

$$\overset{\circ}{J}(\widehat{K})(f) \geq 0. \qquad \square$$

The Euler's optimality condition then appears as a consequence of Fermat's rule (Theorem 6.1) and of Proposition 3.5.

THEOREM 6.2. *Let E be a compact subset of R^p. Let us assume that the shape map $J : \mathcal{P}(E) \to R$ is Lipschitzian and shape differentiable of order l $(0 \leq l \leq \infty)$ in the neighbourhood of a set solution $\widehat{K}$ of the constrained optimization problem* (50). *Then*

$$\overset{\circ}{J}(\widehat{K}) = 0.$$

6.2. Shape Lagrangian. Now let us consider the particular case of shape inequality and equality constraints, that is,

$$J(\widehat{K}) = \inf J(K). \quad \begin{cases} A_i(K) \le 0, & i = 1, \dots, r, \\ B_i(K) = 0, & i = 1, \dots, s, \\ K \in \mathcal{P}(E) \end{cases} \tag{53}$$

The Lagrangian of the shape optimization problem (53) is the map

$$\mathcal{P}(E) \times R^r \times R^s \to R$$
$$(K, \lambda, \beta) \mapsto L(K, \lambda, \beta) = J(K) - \langle \lambda, A(K) \rangle - \langle \beta, B(K) \rangle.$$

THEOREM 6.3. *Let E be a compact subset of R^p and $\widehat{K}$ be a solution of* (53). *Let us assume that $\widehat{K}, B, A$ satisfy* (49) *of Proposition* 5.3 *and that the map J verifies the assumptions of Theorem* 6.1. *Then*

$$\exists (\widehat{\lambda}, \widehat{\beta}) \in R^r_+ \times R^s \quad \textit{such that} \quad \begin{cases} \overset{\circ}{L}(\widehat{K}, \widehat{\lambda}, \widehat{\beta}) = 0, \\ \widehat{\lambda}_i A_i(\widehat{K}) = 0, \qquad \forall i \in \{1, \dots, r\}, \end{cases}$$

and $\widehat{\beta}$ and $\widehat{\lambda}$ are called the Lagrangian multipliers.

Proof. Set $F = (A, B)$ and $M = R^r_+ \times \{0\}^s$. We know from Proposition 5.1 that

$$\overset{\circ}{F}(\widehat{K}) \mathcal{V}^l_{F^{-1}(M)}(\widehat{K}) = T_M(F(\widehat{K})),$$

with $\overset{\circ}{F}(\widehat{K}) \in \mathcal{L}(\mathcal{D}^l(E, R^p), R^n)$.

Observing that $\mathcal{D}^l(E, R^p)$ is a Banach space (because E is compact and $k < \infty$), we use the bipolar theorem[5] to obtain

$$\mathcal{V}^l_{F^{-1}(M)}(\widehat{K})^- = \overset{\circ}{F}(\widehat{K})^* T_M(F(\widehat{K}))^-.$$

Because $T_{\{0\}}(0)^- = X$ and $T_{R^n_+}(x)^- = \{p \,|\, p_i \le 0, p_i = 0 \text{ if } x_i > 0\}$, we conclude the proof. □

6.3. Example. Consider the problem

$$\min \int_K h(x)dx \quad \begin{cases} K \in \mathcal{P}(E) \\ K \text{ connected}, \\ K \, \varepsilon\text{-cone}, \\ V(K) \ge 1, \end{cases} \tag{54}$$

[5] See [1].

BIPOLAR THEOREM. *Let X and Y be two Banach spaces; L, a subset of X; and F, a linear and continuous operator from X into Y. Then*

$$F(L)^- = (F^*)^{-1}(L^-).$$

where h is $\mathcal{C}^1(R^p, R)$ and E is a compact set of R^p. The solution domain $\widehat{K}$ is assumed to be convex.

As in the example in §5.3, the regularity assumptions on V can be checked. The transversality condition on V holds if g_0 is taken such that div $g_0 > 0$ on $\widehat{K}$. The functional $J(K) = \int_K h(x)dx$ is shape differentiable of order 1 and, for any $f \in \mathcal{D}^1_E$, we have

$$\overset{\circ}{J}(K)f = \int_K \operatorname{div}(h(x)f(x))dx.$$

Furthermore, J is Lipschitzian around the convex domain $\widehat{K}$ because

$$J(\widehat{K}) \leq V(\widehat{K}) \sup_{x\in E} \|h(x)\|$$

and because V is Lipschitzian in the neighbourhood of $\widehat{K}$ (see Proposition 5.3).

The Lagrangian optimality condition yields

$$\begin{cases} \widehat{\lambda}(V(\widehat{K}) - 1) = 0, \\ \displaystyle\int_{\widehat{K}} \operatorname{div}(h(x)f(x))dx - \widehat{\lambda}\int_{\widehat{K}} \operatorname{div}(f(x))dx = 0, \quad \forall f \in \mathcal{D}^1(E, R^p). \end{cases}$$

In particular, when $p = 1$, setting $E = [a, b]$ $(b \geq a + 1)$, the solutions of Theorem 6.3 are

$$\begin{cases} \widehat{K_1} = [a, a + 1], & \widehat{\lambda_1} = 1, \\ \widehat{K_2} = [b - 1, b], & \widehat{\lambda_2} = b - 1. \end{cases} \tag{55}$$

7. Appendix. We recall below Nagumo's theorem [2], whereby we can define shape directional derivatives and mention some properties of the solution map $T_f(t, \cdot)$.

THEOREM 7.1 (Nagumo). *Let E be a subset of R^p and f a map from R^p into R^p satisfying*

$$\begin{cases} \text{(i)} \ f \text{ is Lipschitzian on } \bar{E}, \\ \text{(ii)} \ \forall x \in \bar{E}, \qquad f(x) \in T_E(x) \cap -T_E(x). \end{cases} \tag{56}$$

Then, for all $t > 0$,

$$\begin{cases} \text{(a)} \ T_f(t, \cdot) \text{ is Lipschitzian on } \bar{E}, \\ \text{(b)} \ T_f(t, \cdot) \text{ is a bijection from } \bar{E} \text{ into } \bar{E}, \\ \text{(c)} \ T_f(t, \cdot)^{-1} \text{ is Lipschitzian on } \bar{E}. \end{cases} \tag{57}$$

LEMMA 7.2. *Let E be a subset of R^p and f be in $\mathcal{F}^k_E$ $(k \geq 0)$. Then there exists $T > 0$ such that*

$$\forall t \in]0, T[, \qquad \frac{1}{t}(T_f(t, \cdot) - I) \in \mathcal{D}^k(E, R^p). \tag{58}$$

Proof. By standard arguments (see, for example, [12]), we can establish that, for any $t > 0$,

$$T_f(t, \cdot) \in C^k(E, R^p).$$

Consequently, for any $t > 0$,

$$\frac{1}{t}(T_f(t, \cdot) - I) \in C^k(E, R^p).$$

Now let us consider $x \notin D = \text{Supp}(f) = \overline{\{y \in E \mid f(y) \neq 0\}} \subset E$. Because D is closed, there exists $\eta > 0$ such that $B(x, \eta) \cap D = \emptyset$. Consider a solution $x(\cdot)$ of (1). By continuity of $x(\cdot)$ around zero, we know that there exists $T > 0$ such that

$$|t| < T \Rightarrow \|x(t) - x\| < \eta.$$

Consequently, for any $t \in]0, T]$, we can write

$$(T_f(t, \cdot) - I)(x) = \int_0^t f(x(s))ds = 0.$$

Therefore, for any $t \in]0, T[$,

$$\text{Supp}(T_f(t, \cdot) - I) \subset \text{Supp}(f) \subset E,$$

which completes the proof. □

LEMMA 7.3. *Let K be a compact subset of $E \subset R^p$ and $f : E \to R^p$ be a function satisfying the assumptions* (56) *of Theorem* (7.1). *Then*

$$\forall\, t_n \to 0^+, \qquad \frac{T_f(t_n, \cdot) - I}{t_n} \to f \quad \textit{uniformly on } K.$$

Proof. First, we have that, for any t converging to 0^+ and for any x in K,

$$\frac{1}{t}(T_f(t, x) - x) = \frac{1}{t}\int_0^t f(x(s))ds \to f(x),$$

which implies the pointwise convergency.

Using Gronwall's lemma, we can establish that

$$\|(T_f(t, \cdot) - I)(x) - (T_f(t, \cdot) - I)(y)\| \leq (e^{kt} - 1)\|x - y\|,$$

where k is the Lipschitz constant of f.

Let us consider any sequence t_n converging to 0^+, and the function α defined by

$$\alpha(t) = \frac{1}{t}(e^{kt} - 1), \qquad \alpha(0) = k.$$

Because this sequence is bounded and α is continuous around zero, the sequence $\alpha(t_n)$ is bounded.

Therefore $\{(1/t_n)(T_f(t_n, \cdot) - I)\}_{n \in N}$ is an equicontinuous family of continuous and bounded functions on K.

Consequently, because K is compact, we can apply the Ascoli theorem and deduce that $\frac{1}{t}(T_f(t, \cdot) - I) \to f$ uniformly on K. □

LEMMA 7.4. *Let E be a subset of R^p and K be a compact subset of E. Let f and g be two applications belonging to $\mathcal{F}_E^0$. Then*

$$\lim_{h \to 0^+} \frac{1}{h} d(T_f(h, T_g(h, K)), T_{f+g}(h, K)) = 0.$$

Proof. For any $x \in K$, we have

$$\begin{aligned}\frac{1}{h}(T_f[h, T_g(h, x)] - T_{f+g}(h, x)) = &\left(\frac{T_f(h, T_g(h, x)) - T_g(h, x)}{h} - f(T_g(h, x))\right) \\ &+ \left(\frac{T_{f+g}(h, x) - x}{h} - (g + f)(x)\right) \\ &+ \left(\frac{T_g(h, x) - x}{h} - g(x)\right) + f(T_g(h, x)) - f(x).\end{aligned}$$

Now let us denote

$$\begin{cases} i_1^h = \dfrac{T_{f+g}(h,\cdot) - I}{h} - (f+g), \\ g_1^h = \dfrac{T_g(h,\cdot) - I}{h} - g, \\ g_1^h = \dfrac{T_f(h,\cdot) - I}{h} - f. \end{cases}$$

From Lemma 7.2 we can write

(59)

$$\frac{1}{h}\sup_{x\in K}\|T_f[h,T_g(h,x)] - T_{f+g}(h,x)\| \le \sup_{x\in \mathrm{Supp}(f_1)}\|f_1(x)\| + \sup_{x\in \mathrm{Supp}(g_1^h)}\|g_1^h(x)\| + \sup_{x\in \mathrm{Supp}(i_1^h)}\|i_1^h(x)\| + \sup_{x\in E}\|f(T_g(h,x)) - f(x)\|.$$

Because g is continuous on the compact set $\mathrm{Supp}(f)$, we have

$$\|g\| = \sup_{x\in E}\|g(x)\| \le M < \infty.$$

Thus, because f is Lipschitzian, we have

(60)

$$\begin{aligned} \|f(T_g(h,x)) - f(x)\| &\le c\|T_g(h,x) - x\| \\ &\le c\left\| \int_0^h g(x(s))ds \right\| \\ &\le hMc. \end{aligned}$$

By virtue of (60) and Theorem 7.3 we can conclude that

$$\frac{1}{h}d\!\!\!d(T_f[h,T_g(h,K)],T_{f+g}(h,K)) \to 0. \qquad \square$$

LEMMA 7.5. *Let E be a subset of R^p and K_1, K_2 be two compact subsets of E. Consider $f \in \mathcal{F}_E^0$. Then*

$$\exists T > 0, \quad \exists k > 0, \quad \forall h \in [0,T], \quad d\!\!\!d(T_f(h,K_1),T_f(h,K_2)) \le k d\!\!\!d(K_1,K_2).$$

Proof. Because f is Lipschitzian, we know from Theorem 7.1 that $T_f(h,\cdot)$ is also Lipschitzian. Thus

$$\sup_{x\in K_2}\inf_{y\in K_1}\|T_f(h,x) - T_f(h,y)\| \le k \sup_{x\in K_2}\inf_{y\in K_1}\|x-y\|,$$

and the lemma is established. $\square$

LEMMA 7.6. *Let f and g be two functions that belong to $\mathcal{F}_E^0$, and let K_1 be a compact subset of E. Then*

$$\lim_{h\to 0+}\frac{1}{h}d\!\!\!d(T_g(h,K_1),T_f(h,K_1)) \le 2\|f-g\|_\infty.$$

Proof. For any $x \in K_1$, we have

$$\|T_g(h,x) - T_f(h,x)\| \le h(\|g_1^h(x)\| + \|g(x) - f(x)\| + \|f_1^h(x)\|),$$

where

$$\begin{cases} g_1^h = \dfrac{T_g(h,\cdot) - I}{h} - g, \\ f_1^h = \dfrac{T_f(h,\cdot) - I}{h} - f. \end{cases}$$

We know from Lemma 7.2 that f_1^h and g_1^h belong to $\mathcal{D}^0(E, R^p)$. Consequently,

$$\sup_{x\in K_1} \|T_g(h,x) - T_f(h,x)\| \leq h\left(\sup_{x\in \mathrm{Supp}(g_1^h)} \|g_1^h(x)\| + \sup_{x\in E} \|g(x) - f(x)\| + \sup_{x\in \mathrm{Supp}(f_1^h)} \|f_1^h(x)\|\right).$$

Hence, using Lemma 7.3 and the fact that the supports of g_1^k and f_1^h are compact, we obtain

$$\frac{1}{h} d_H(T_g(h,K_1), T_f(h,K_1)) \leq \varepsilon_1(h) + 2\|f - g\|_\infty + \varepsilon_2(h).$$

This completes the proof of the lemma. □

ESTIMATION OF INTERFACES FROM BOUNDARY MEASUREMENTS*

KARL KUNISCH† AND XIAOSU PAN‡

Abstract. The determination of an interface in an elliptic differential equation from Dirichlet and Neumann boundary data is investigated. Uniqueness of the function characterizing the interface is proved. For numerical purposes the problem is formulated as an optimization problem involving constraints that are based on potential theory. An augmented Lagrangian formulation is used for the solution of the optimization problem. Its convergence is investigated and numerical experiments are described.

Key words. inverse problems, elliptic differential equation, augmented Lagrangian techniques, interface problem

AMS subject classifications. 35R30, 65M30, 31A25

1. Introduction.

The aim of this contribution is the study of the reconstruction of an interface from boundary measurements. We are given a domain Ω in $\mathbf{R}^2$ and a curve a connecting two points of the boundary of Ω and dividing Ω into two connected subdomains Ω_1 and Ω_2. The governing equation is given by

$$-\Delta u = f_a \quad \text{in } \Omega, \tag{1.1}$$

where

$$f_a(x,y) = \begin{cases} \rho_1 & \text{for } (x,y) \in \Omega_1, \\ \rho_2 & \text{for } (x,y) \in \Omega_2, \end{cases}$$

with ρ_1 and ρ_2 known constants. The problem consists of determining a from measurements (z_1, z_2) of the boundary data $(u|\Gamma, \partial u/\partial n|\Gamma)$, with Γ the boundary of Ω. We also address the question when the data are available only on part of the boundary.

The motivation for this study originates from problems in the geophysical sciences. The earth is a stratified body made of layers with high density contrasts. On a macroscopic scale one distinguishes between the earth's core, its mantle, and its crust. The interfaces between these layers are referred to as the core-mantle boundary and the Mohorovičić discontinuity, respectively. While the densities within these layers are fairly well known, the precise location of the layers is not. A similar situation occurs in the crust itself. Over wide areas it consists of distinct layers made of material with high density differences. The problem consists of determining the location of the interfaces. To achieve this goal one uses measurements of the earth's potential on the surface of the earth and its low order derivatives, both measured on the surface and eventually in space. Such measurements are available with high data density and with high precision. The mathematical model that combines the quantities density and potential is given by the potential equation

$$-\Delta u = f \quad \text{in } \Omega,$$

where u denotes potential and f stands for density. The density itself depends on the location of the layers. The domain Ω represents all or part of the solid earth. Data are available for the potential u and its normal derivative $\partial u/\partial n$ on the surface of the earth. Here n denotes the unit outer normal to the surface of the earth. In the case where Ω represents only part of the solid earth, data will at first only be available on a part of the boundary Γ of Ω. The remaining parts of the boundary lie inside the earth. As a specific case let Ω represents a mountain arising above the geoid (Fig. 1). In this case primary data are available on the surface of the mountain but not on the geoid. One can use geophysical continuation methods, supplemented by mass remove-restore procedures, to obtain secondary (derived) data on that part of the boundary of Ω which represents the bottom of the mountain. As references one may consult [L], [M]. In the mathematical analysis we consider the two dimensional cross section, which is again denoted by Ω.

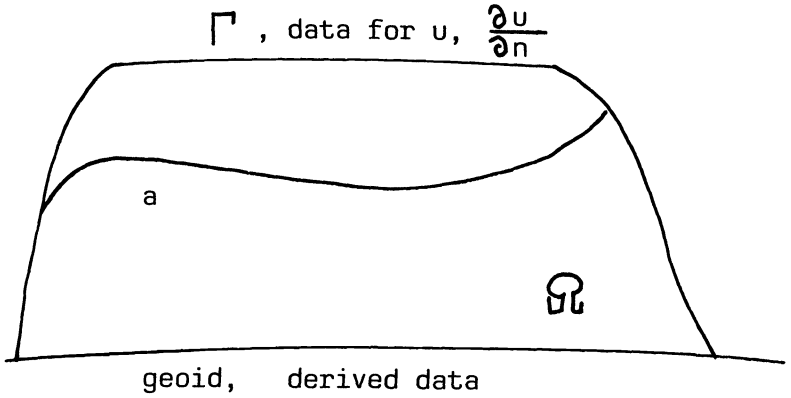

FIG. 1

We first establish conditions that ensure uniqueness of the function a from the measurements. Then Green's formula is used to establish certain compatibility conditions. These compatibility conditions play an essential part in the numerical solution of the estimation problem, which is based on an optimization theoretic formulation. We propose a least-squares formulation with the potential theoretic information in the form of the compatibility conditions as constraints. Numerically, the compatibility conditions also serve the purpose of providing a good start-up value for the unknown interface. During the iteration the cost functional combines a regularized least squares term, an equation error term, and the compatibility conditions. An additional distinct feature of our approach is that the unknown function a and the state variable u of (1.1) are both considered as independent variables related by the equation $\Delta u + f_a = 0$, which is also realized as a constraint. The optimization problem is solved by an augmented Lagrangian technique that is shown to converge provided that a second-order sufficient optimality condition holds. This second-order condition is investigated independently and can be shown to hold in specific cases. The paper ends with a description of numerical experience with the proposed algorithm. For the presentation of our results and specifically for the numerical code we chose Ω to be a rectangle. The choice of this specific domain allows certain simplifications, but it also implies some difficulties due to the lack of high smoothness of the boundary.

The contents of the following sections is best characterized by their titles.

1. Identifiability.
2. The compatibility conditions.

3. Formulation of the inverse problem as a constrained minimization problem.
4. Existence of Lagrange multiplier.
5. The augmented Lagrangian algorithm.
6. The augmentability condition.
7. A numerical example.
8. References.

2. Identifiability. In this section we prove the identifiability of the function a characterizing the interface from boundary measurements. For convenience we recall the problem under consideration as follows:

$$\begin{cases} -\Delta u = f_a & \text{in } \Omega, \\ u|\Gamma = z_1, \\ \partial u/\partial n|\Gamma = z_2, \end{cases} \tag{2.1}$$

where $\Omega = \{(x,y) \in \mathbf{R}^2 : 0 < x < 2, 0 < y < 1\}$; n; denotes the outward normal to Ω, Γ stands for the boundary of Ω;

$$f_a(x,y) = \begin{cases} \rho_1 & \text{if } y > a(x), \\ \rho_2 & \text{if } y < a(x), \end{cases}$$

with ρ_1 and ρ_2 fixed values in $\mathbf{R}$; and $a : [0,2] \to [0,1]$. The boundary data z_1 and z_2 are assumed to be known. If the function a was known as well, then (2.1) would be an overdetermined system.

However, a is unknown and we seek to determine it from knowledge of the boundary data z_1 and z_2. From Theorem 2.1 below it follows that the boundary data z_1 and z_2 determine a uniquely. For $a : [0,2] \to [0,1]$, we denote by $u(a)$ a solution of $-\Delta u = f_a$. Further, $\Gamma_i, i = 1, ..., 4$, denote the four edges of Ω, enumerated in a counterclockwise manner, starting with Γ_1 as the lower edge. The Dirichlet and Neuman trace operators on Γ are denoted by $\tau_0 u = u|\Gamma$ and $\tau_1 u = \partial u/\partial n|\Gamma$, respectively. In this and the following section we only require the restriction of τ_0 and τ_1 to elements $u \in H^2(\Omega)$. In this case $\tau_0 u \in H^{1/2}(\Gamma), \tau_1 u$ is interpreted as $\tau_1 u = \Pi_{j=1}^4 \partial u/\partial n|\Gamma_j$, and Green's formula holds (see Lemmas A.1 and A.3).

THEOREM 2.1. *Let a and $\tilde{a}$ be piecewise $C^{1,1}$-functions mapping $[0,2]$ into $[0,1]$, and let $u(a)$ and $u(\tilde{a})$ be solutions in $H^2(\Omega)$ of $-\Delta u = f_a$ and $-\Delta u = f_{\tilde{a}}$, respectively. Then $\rho_1 \neq \rho_2$ and*

$$(\tau_0 u(a), \tau_1 u(a)) = (\tau_0 u(\tilde{a}), \tau_1 u(\tilde{a})) \tag{2.2}$$

imply $a = \tilde{a}$.

Proof. Let us assume that $a \neq \tilde{a}$. Set $w = u(a) - u(\tilde{a})$ and note that $w \in H^2(\Omega) \subset C^{0,1}(\bar{\Omega})$ by Lemma A.4. The trace operators in (2.2) are well defined (see Lemma A.1). We denote by Ω_1 and Ω_2 the subdomains of Ω which lie above, respectively below, $a(x)$. More precisely,

$$\Omega_1 = \{(x,y) : 0 < x < 2, a(x) < y < 1\},$$

$$\Omega_2 = \{(x,y) : 0 < x < 2, 0 < y < a(x)\}.$$

The subdomains $\tilde{\Omega}_1$ and $\tilde{\Omega}_2$ are defined analogously with a replaced by $\tilde{a}$. Further we put

$$U = (\Omega_1 \cap \tilde{\Omega}_1) \cup (\Omega_2 \cap \tilde{\Omega}_2).$$

This is the union of the two domains which are above and below both a and $\tilde{a}$. We find that

$$-\Delta w = 0 \quad \text{in } U.$$

Since Δ is an analytic hypoelliptic operator [Tr], it follows that w is analytic in U. Due to (2.2), w satisfies homogeneous Cauchy data on Γ_3. The Cauchy–Kowalewsky theorem and analytic continuation [Mi] can now be used to argue that $w = 0$ on $\Omega_1 \cap \tilde{\Omega}_1$. An analogous argument implies that $w = 0$ on $\Omega_2 \cap \tilde{\Omega}_2$. Since $w \in C^{0,1}(\bar{\Omega})$ it follows that

$$w = 0 \quad \text{in } \bar{U}. \tag{2.3}$$

Next we turn to the region *between* a and $\tilde{a}$, and define

$$B = \{x \in [0,2] : a(x) = \tilde{a}(x), \text{ or } x = 0, \text{ or } x = 2\}.$$

Due to continuity of a and $\tilde{a}$, B is closed and $A := [0,2]\backslash B$ is open in $\mathbf{R}$. Since $a \neq \tilde{a}$, the set A is nonempty and it can be represented as $A = \cup_{i=1}^{\infty} I_i$, with I_i nonempty open pairwise disjoint intervals in $[0,2]$. (The union could of course be finite.) Denoting by α_i and β_i the left and right endpoints of I_i, we have α_i and $\beta_i \in B$ for all i. We further put

$$S_i = \{(x,y) : x \in I_i, m(x) < y < M(x)\},$$

where $m(x) = \min(a(x), \tilde{a}(x)), M(x) = \max(a(x), \tilde{a}(x))$. By construction, $m(x) < M(x)$ for all $x \in I_i$, and therefore

$$\text{meas}(S_i) = \iint_{S_i} dxdy = \int_{\alpha_i}^{\beta_i} (M(x) - m(x))dx > 0 \tag{2.4}$$

for every i. We now consider two cases. First, let $\alpha_i \neq 0$ and $\beta_i \neq 2$. Then

$$-\Delta w = \pm(\rho_1 - \rho_2) \quad \text{in } S_i, \tag{2.5}$$

and the transmissivity condition (see Lemma A.2) and (2.3) imply

$$\frac{\partial w}{\partial n}|\partial S_i = 0. \tag{2.6}$$

Here n denotes the unit normal to the boundary ∂S_i of S_i and points into the exterior of S_i. Due to the regularity assumptions on a and $\tilde{a}$, the boundary ∂S_i of S_i is piecewise $C^{1,1}$ and it is in this sense that (2.6) is well defined. Since S_i is a curvilinear polygon with a $C^{1,1}$ boundary, Green's formula (with $v = 1$, Lemma A.3) together with (2.5), (2.6) can be applied to induce

$$(\rho_1 - \rho_2)\ \text{meas}(S_i) = 0,$$

which contradicts $\rho_1 \neq \rho_2$ and meas $(S_i) > 0$. In the second case $\alpha_i = 0$ or $\beta_i = 2$, or both. We then find

$$\partial S_i \subset (\bar{S}_i \cap \overline{\Omega_1 \cap \tilde{\Omega}_1}) \cup (\bar{S}_i \cap \overline{\Omega_2 \cap \tilde{\Omega}_2}) \cup (\bar{S}_i \cap \Gamma).$$

As before, $\partial w/\partial n|(\bar{S}_i \cap \overline{\Omega_1 \cap \tilde{\Omega}_1}) = \partial w/\partial n|(\bar{S}_i \cap \overline{\Omega_2 \cap \tilde{\Omega}_2}) = 0$ and $\partial w/\partial n|(\bar{S}_i \cap \Gamma) = 0$. Again we can use Greens's formula to obtain a contradiction. Hence we have shown that $a = \tilde{a}$. □

Remark 2.2. From the proof it follows that the assumptions on knowledge of the boundary data can be weakened. In fact the conclusion of Theorem 2.1 remains correct, if (2.2) is replaced by

$$\left(u(a)\left|\gamma_1 \cup \gamma_3, \frac{\partial u(a)}{\partial n}\right|\tilde{\Gamma}\right) = \left(u(\tilde{a})\left|\gamma_1 \cup \gamma_3, \frac{\partial u(\tilde{a})}{\partial n}\right|\tilde{\Gamma}\right), \tag{2.7}$$

where $\tilde{\Gamma} = \Gamma_2 \cup \Gamma_4 \cup \gamma_1 \cup \gamma_3$ and γ_1, γ_3 are nonempty open subsets of Γ_1, Γ_3, respectively.

3. The compatibility properties. If, for a function a mapping $[0,2]$ into $[0,1]$, (2.1) has a solution $u = u(a) \in H^2(\Omega)$, then a must satisfy certain compatibility properties which we could refer to also as moment problems. We derive them next. They will be used for the formulation of determining the interface a numerically from knowledge of data z_1, z_2. The following assumptions will be used:

$$\rho_1 \neq \rho_2, \tag{3.1}$$

$$a : [0,2] \to [0,1] \quad \text{is measurable,} \tag{3.2}$$

$$u = u(a) \in H^2(\Omega) \quad \text{satisfies (2.1).} \tag{3.3}$$

We note that, due to trace theorems, (3.3) implies that $z_1 = \tau_0 u \in C(\Gamma) \cap \Pi_{i=1}^4 H^{3/2}(\Gamma_i)$ and $z_2 = \tau_1 u \in \Pi_{j=1}^4 H^{1/2}(\Gamma_j)$.

Let w be any harmonic function in Ω, i.e. $-\Delta w = 0$ in Ω. Due to Green's formula,

$$\iint_\Omega (u\Delta w - w\Delta u)d\Omega = \int_\Gamma \left(z_1 \frac{\partial w}{\partial n} - wz_2\right)d\Gamma,$$

and consequently

$$\iint_\Omega w f_a d\Omega = \int_\Gamma \left(z_1 \frac{\partial w}{\partial n} - wz_2\right)d\Gamma.$$

This further implies

$$\iint_{y<a(x)} w\, dxdy = \frac{1}{\rho_2 - \rho_1}\left[\int_\Gamma \left(z_1 \frac{\partial w}{\partial n} - wz_2\right)d\Gamma - \rho_1 \iint_\Omega w d\Omega\right]. \tag{3.4}$$

The boundary integrations along Γ have to be interpreted as the sum of the boundary integrations along the four edges Γ_j. Let χ_a be the characteristic function of the domain $\{(x,y) \in \Omega : y < a(x)\}$. Then (3.4) becomes

$$\langle w, \chi_a \rangle_{L^2(\Omega)} = A(w, z_1, z_2), \tag{3.5}$$

where

$$A(w, z_1, z_2) = \frac{1}{\rho_2 - \rho_1}\left[\int_\Gamma \left(z_1 \frac{\partial w}{\partial n} - wz_2\right)d\Gamma - \rho_1 \iint_\Gamma w d\Omega\right].$$

Note that A is independent of a. We point out that the compatibility properties (3.5) are well defined for $(z_1, z_2) \in H^{1/2}(\Gamma) \times H^{1/2}(\Gamma)^*$. Since (3.5) has to hold for any harmonic function, we have derived infinitely many compatibility conditions. In practice we use at most four. These are characterized by the functions

$$w_1(x,y) = 1, \quad w_2(x,y) = 2y, \quad w_3(x,y) = x, \quad w_4(x,y) = 2xy.$$

This leads to four basic compatibility properties which we abbreviate by

$$G_i(a) = A_i. \tag{3.6}$$

The following formulas for $G_i(a) = \langle w_i, \chi_a \rangle_{L^2(\Omega)}$ are given for later reference:

$$G_1(a) = \int_0^2 a \, dx, \qquad G_2(a) = \int_0^2 a^2 dx,$$

$$G_3(a) = \int_0^2 xa \, dx, \qquad G_4(a) = \int_0^2 xa^2 dx.$$

4. Formulation of the inverse problem as a constrained minimization problem. For the purpose of numerical determination of a from z_1 and z_2, the following optimization problem is introduced:

$$\min J(a,u) \text{ over } (a,u) \in Q_{ad} \times H^1(\Omega) \quad \text{with } e(a,u) = 0, \tag{4.1}$$

where

$$J(a,u) = \frac{1}{2}|\mathcal{D}(\tau_0 u - z_1)|^2_{H^1(\Omega)} + \frac{1}{2}|\mathcal{N}(\tau_1 u - z_2)|^2_{H^1(\Omega)} + \frac{1}{2}\beta |a_x|^2_{L^2(0,2)}, \tag{4.2}$$

$$e(a,u) = N(\Delta u + f_a), \tag{4.3}$$

and

$$Q_{ad} = \{a \in H^1(0,2) : a(x) \in [0,1], G_i(a) = A_i, i = 1, ..., 4\}. \tag{4.4}$$

In (4.2) the regularization parameter β is chosen in $[0, \infty)$. Throughout it is assumed that $(z_1, z_2) \in H^{1/2}(\Gamma) \times H^{1/2}(\Gamma)^*$ and that Q_{ad} is not empty. The operators $\mathcal{D} : H^{1/2}(\Gamma) \to H^1(\Omega)$, $\mathcal{N} : H^{1/2}(\Gamma)^* \to H^1(\Omega)$, and $N : H^1(\Omega)^* \to H^1(\Omega)$ are Dirichlet and Neumann solution operators given by

$$\mathcal{D}g = u \quad \text{with } -\Delta u = 0, \quad \tau_0 u = g,$$

$$\mathcal{N}g = u \quad \text{with } -\Delta u + u = 0, \quad \tau_1 u = g,$$

$$\begin{aligned} Nf &= u \quad \text{with } u \text{ the solution of } \langle \nabla u, \nabla v \rangle_{L^2} + \langle u, v \rangle_{L^2} \\ &= \langle f, v \rangle_{H^1, {}^*H^1} \quad \text{for all } v \in H^1(\Omega). \end{aligned}$$

They are all isomorphisms (see, e.g., [DL], [GR]).

The data $(z_1, z_2) \in H^{1/2}(\Gamma) \times H^{1/2}(\Gamma)^*$ are called *attainable* if there exists $(\hat{a}, \hat{u}) \in Q_{ad} \times H(\Delta, \Omega)$, such that

$$e(\hat{a}, \hat{u}) = 0, \quad \tau_0 \hat{u} = z_1 \quad \text{in } H^{1/2}(\Gamma) \quad \text{and} \quad \tau_1 \hat{u} = z_2 \quad \text{in } H^{1/2}(\Gamma)^*.$$

In this case $(\hat{a}, \hat{u})$ is a solution of the unregularized problem, i.e., $\beta = 0$ in (4.2), and $J(\hat{a}, \hat{u}) = 0$.

The equality constraints $G_i(a) = A_i$ are referred to as compatibility conditions. For attainable data they are automatically satisfied since they coincide with the compability properties derived in §3. The assumption of nonemptiness of Q_{ad} is not a severe one. In fact, a simple implicit function theorem argument implies that for every observation $(\hat{z}_1, \hat{z}_2)$ which is attainable by some pair $(\hat{a}, \hat{u})$, there exists a neighborhood $V(\hat{z}_1, \hat{z}_2)$ in $H^{1/2}(\Gamma) \times H^{1/2}(\Gamma)^*$ such that for every $(z_1, z_2) \in V(\hat{z}_1, \hat{z}_2)$, the set Q_{ad} is not empty, provided that $\hat{a}$ is not identically 0 or 1 and that $L := \{1, \hat{a}, x, \hat{a} \cdot x\}$ is not linearly dependent on some subintervall of $(0, 2)$. If only a subset of all four compatibility conditions is used for the definition of Q_{ad}, then the last statement remains correct if the set L is defined as the set of corresponding elements $1, \hat{a}, x$, or $\hat{a} \cdot x$.

Let us comment on (4.1)–(4.4). This is a least squares formulation with the equation $-\Delta u = f_a$ realized as an explicit constraint. The state variable u and the parameter a are both independent variables. If $\beta > 0$, then $\beta |a_x|^2_{L^2(0,2)}$ represents a Tikhonov regularization term. The specific choice of the operators $\mathcal{D}, \mathcal{N}$, and N guarantee that the Dirichlet as well as the Neumann boundary data residuals and the equation constraint $e(a, u) = 0$ are all uniformly represented as H^1-functions. The operators $\mathcal{D}$ and $\mathcal{N}$ in the definition of J can also be interpreted as preconditioning [IKK]. The use of a regularization term like $\beta |a_x|_{L^2}$ is well known for nonlinear inverse problems, we refer to [EKN], [IK2], [KS] and the literature cited there. We approach (4.1)–(4.4) by a Lagrangean framework, which requires the Hilbert space structure of Q_{ad}. The constraints $G_i(a) = A_i, i = 1, \ldots, 4$, in the definition of Q_{ad} were derived in §3. Numerically they play the role of providing good initial guesses and of stabilizing the algorithm. While we have used all four compatibility conditions in the formulation of problem (4.1)–(4.4), all the theoretical results—except for Theorem 4.1(ii), where $G_1(a) = A_1$ is used—remain correct without these conditions and their proofs become easier. To avoid index notation for subsets, we chose to put all four conditions as explicit constraints.

The cost functional $J(a, u)$ in (4.2) could equivalently be expressed as

$$J(a, u) = \frac{1}{2} |\tau_0 u - z_1|^2_{H^{1/2}(\Gamma)} + \frac{1}{2} |\tau_1 u - z_2|^2_{H^{1/2}(\Gamma)^*} + \frac{1}{2} \beta |a_x|^2_{L^2(0,2)}.$$

Here we chose the form given in (4.2) since it also describes the technique by which the $H^{1/2}(\Gamma)$ and the $H^{1/2}(\Gamma)^*$ norms were implemented numerically. The formulation (4.1)–(4.4) for the estimation of a from boundary measurements is motivated by previous work on the estimation of the coefficient a in $-\operatorname{div}(a \operatorname{grad} u) = f$ from data z corresponding to u (see [IK2], [IKK]) and from an optimization theoretic formulation of the impedance computed tomography problem [IJ]. There are several alternatives to formulating our estimation problem as an optimization problem. One of them is given by

$$\min_{\substack{a \in Q_{ad} \\ -\Delta u(a) = f_a \\ \tau_0 u(a) = z_1}} |\tau_1 u(a) - z_2|^2_{H^{1/2}(\Gamma)^*} + \beta |a_x|^2_{L^2(0,2)}. \tag{4.5}$$

This is a regularized least-squares formulation where u is treated as a dependent variable. The numerical success with (4.1)–(4.4) justifies giving priority to the more involved formulations over simpler ones like (4.5), which we expect to be less successful numerically. An alternative to (4.5) would be to enforce the Neumann boundary condition $\tau_1 u(a) = z_2$ and to use the Dirichlet condition in the cost functional. In either case the formulation would be asymetric and it would not be balanced with respect to errors in z_1 and z_2.

Before we commence our study of (4.1) it is necessary to address a technical issue that will have consequences throughout the remainder of this paper. We are referring to the fact that the Neumann boundary operator cannot be extended from the set of test functions $\mathcal{D}(\bar{\Omega})$ to a continuous linear operator from $H^1(\Omega)$ to $H^{1/2}(\Gamma)^*$. Additional regularity for the elements in the domain is required. One possibility is given by considering the space $H(\Delta, \Omega) = \{u \in H^1(\Omega) : \Delta u \in L^2(\Omega)\}$ [DL], [GR], where more precisely $\Delta u \in L^2(\Omega)$ means that the distribution $v \to \langle \Delta u, v \rangle_{L^2(\Omega)}$ for $v \in H_0^1(\Omega)$ can be indentified with an element of $L^2(\Omega)$. The regularity provided by $H(\Delta, \Omega)$ is sufficient but not necessary for a well-defined Neumann operator $H^{1/2}(\Gamma)^* \to H^1(\Omega)$. We shall return to this comment at the beginning of §5. For the moment it suffices to note that $\tau_1 u$ in (4.2) is well defined due to the fact that the constraint $e(a, u) = 0$ implies that $u \in H(\Delta, \Omega)$.

The existence problem for (4.1)–(4.4) is addressed next.

THEOREM 4.1. (i) *If $\beta > 0$, then* (4.1)–(4.4) *has a solution $(a^*, u^*) \in Q_{ad} \times H^1(\Gamma)$.*

(ii) *Any solution (a^*, u^*) of* (4.1)–(4.4) *satisfies*

$$\int_\Omega \mathcal{D}(\tau_0 u^*) d\Omega = \int_\Omega \mathcal{D} z_1 d\Omega$$

and

$$\begin{cases} |u^* - \tilde{u}|_{H^1(\Omega)} \le C|\tau_1 u^* - z_2|_{H^{1/2}(\Gamma)^*} \le c|\mathcal{D}(\tau_0 \tilde{u} - z_1)|_{H^1(\Omega)}, \\ J(a^*, u^*) \le \dfrac{1}{2}|\mathcal{D}(\tau_0 \tilde{u} - z_1)|^2_{H^1(\Omega)} + \dfrac{\beta}{2}|a_x^*|^2_{L^2(0,2)}, \end{cases}$$

where c and C are independent of (a^*, u^*) and $\tilde{u} = \int_\Omega \mathcal{D} z_1 d\Omega / \mathrm{meas}(\Omega) + \tilde{u}_2$, with $\tilde{u}_2$ the unique solution of

$$\begin{cases} -\Delta \tilde{u}_2 = f_{a^*}, \\ \tau_1 \tilde{u}_2 = z_2, \\ \int_\Omega \mathcal{D}(\tau_0 \tilde{u}_2) d\Omega = 0. \end{cases}$$

(iii) *If the data (z_1, z_2) are attainable and if in addition $z_1 \in C(\Gamma) \cap \Pi_{j=1}^4 H^{3/2}(\Gamma_j)$, then the solution (a^*, u^*) of* (4.1)–(4.4) *with $\beta = 0$ is unique in the class $(Q_{ad} \cap \{a$ piecewise $C^{1,1}\}) \times H^1(\Omega)$.*

To interpret the estimate involving u^* and $\tilde{u}$ in (ii), observe that the distance between u^* and $\tilde{u}$ is bounded by the amount that $\tau_1 u^*$ fails to match the data z_2, respectively, $\tau_0 \tilde{u}$ fails to match data z_1. The function $\tilde{u}$ satisfies the differential equation, the Neumann boundary condition, and the Dirichlet boundary condition in an averaged sense.

Proof. (i) Throughout, c denotes a generic constant which depends on embedding constants, Poincaré-type inequalities, and meas(Ω). Let (a_k, u_k) be a minimizing sequence for (4.1)–(4.4).

By Lemma A.6 there exists a constant c such that

$$\begin{cases} |\tau_0 u_k|_{H^{1/2}(\Gamma)} \le c, \\ |\tau_1 u_k|_{H^{1/2}(\Gamma)^*} \le c, \\ |a_k|_{H^1(0,2)} \le c, \end{cases} \tag{4.6}$$

for all k. Since $H^1(0,2)$ is compactly embedded in $C(0,2)$ it follows that there exists a subsequence of $\{a_k\}$ again denoted by the same symbol, and $a^* \in H^1(0,2)$ such that $\lim a_k = a^*$ strongly in $C(0,2)$. It is simple to argue that $a^* \in Q_{ad}$. Next it is shown that $\{u_k\}$ is a bounded subset of $H^1(\Omega)$. Consider the linear functional on H^1 given by

$$l(u) = \int_\Gamma u \, d\Gamma / \operatorname{meas}(\Gamma).$$

It determines a decomposition of $H^1(\Omega)$ as a direct sum of $\ker l = \{u : \int_\Gamma u \, d\Gamma = 0\}$ and $\{\lambda \cdot 1 : \lambda \in \mathbf{R}\}$, with 1 the constant function with value 1. Any $u \in H^1(\Omega)$ can be written as $u = u^{(1)} + u^{(2)}$, where $u^{(1)} = \int_\Gamma u d\Gamma / \operatorname{meas} \Gamma$ and $l(u_2) = 0$. Any u_k is decomposed as

$$u_k = u_k^{(1)} + u_k^{(2)},$$

where

$$u_k^{(1)} = \int_\Gamma u_k \, d\Gamma / \operatorname{meas}(\Gamma), \quad \int_\Gamma u_k^{(2)} \, d\Gamma = 0, \quad \tau_1 u_k = \tau_1 u_k^{(2)}.$$

Since $e(a_k, u_k) = 0$ for all k, we have

$$-\Delta u_k^{(2)} = f_{a_k} \quad \text{in } L^2(\Omega),$$

and therefore by Green's formula (Lemma A.3),

$$\langle f_{a_k}, v\rangle_{L^2(\Omega)} = \langle \nabla u_k^{(2)}, \nabla v\rangle_{L^2(\Omega)} - \langle \tau_1 u_k^{(2)}, v\rangle_{H^{1/2}(\Gamma)^*, H^{1/2}(\Gamma)} \quad \text{for all } v \in H^1. \tag{4.7}$$

Taking $v = u_k^{(2)}$ in (4.7) gives

$$|\nabla u_k^{(2)}|^2_{L^2(\Omega)} \le |\tau_1 u_k^{(2)}|_{H^{1/2}(\Gamma)^*} |u_k^{(2)}|_{H^{1/2}(\Gamma)} + |f_{a_k}|_{L^2(\Omega)} |u_k^{(2)}|_{L^2(\Omega)},$$

and Lemma A.6 and (4.6) imply the existence of c such that $|\nabla u_k^{(2)}|_{L^2(\Omega)} \le c$. From Lemma A.6(iv) we further have $|u_k|^2_{H^1(\Omega)} \le \sigma_3^2 [c^2 + |\int_\Gamma u_k d\Gamma|^2]$.

Applying (4.6) once again shows that $\{u_k\}$ is a bounded subset of $H(\Delta, \Omega)$. Hence there exists a subsequence, again denoted by $\{u_k\}$, and $u^* \in H(\Delta, \Omega)$, such that

$$\begin{cases} u_k \rightharpoonup u^* & \text{in } H^1(\Omega), \\ \tau_0 u_k \rightharpoonup \tau_0 u^* & \text{in } H^{1/2}(\Gamma), \\ \tau_1 u_k \rightharpoonup \tau_1 u^* & \text{in } H^{1/2}(\Gamma)^*. \end{cases} \tag{4.8}$$

For every $w \in H^1(\Omega)$ we find

$$\begin{aligned} \langle \Delta u^* + f_{a^*}, w\rangle_{L^2(\Omega)} &= \langle \Delta(u^* - u_k), w\rangle_{L^2(\Omega)} + \langle f_{a^*} - f_{a_k}, w\rangle_{L^2(\Omega)} \\ &= -\langle \nabla(u^* - u_k), \nabla w\rangle_{L^2(\Omega)} + \langle \tau_1(u^* - u_k), w\rangle_{H^{1/2}(\Gamma)^*, H^{1/2}(\Gamma)} \\ &\quad + \langle f_{a^*} - f_{a_k}, w\rangle_{L^2(\Omega)}. \end{aligned}$$

It is simple to argue that $\lim\langle f_{a_k} - f_{a^*}, w\rangle_{L^2(\Omega)} = 0$. This, together with (4.8), implies that $-\Delta u^* + f_{a^*} = 0$ in $H^1(\Omega)^*$, and therefore $e(a^*, u^*) = 0$. Weak lower semicontinuity of norms, the fact that bounded linear operators map weakly convergent sequences into weakly convergent sequences, and (4.8) finally imply that (a^*, u^*) is a minimizer of J. This proves (i).

(ii) Let k be the linear functional on $H(\Delta, \Omega)$ given by

$$k(u) = \int_\Omega \mathcal{D}(\tau_0 u)\, d\Omega \,/\mathrm{meas}(\Omega).$$

It determines a decomposition of $H(\Delta, \Omega)$ as the direct sum of $\ker k = \{u : \int_\Omega \mathcal{D}(\tau_0 u) d\Omega = 0\}$ and $\{\lambda \cdot 1 : \lambda \in \mathbf{R}\}$. Any $u \in H(\Delta, \Omega)$ can be represented as $u = u_1 + u_2$, where

$$u_1 = \int_\Omega \mathcal{D}(\tau_0 u) d\Omega / \mathrm{meas}(\Omega) \quad \text{and} \quad \int_\Omega \mathcal{D}(\tau_0 u_2) d\Omega = 0. \tag{4.9}$$

For any $u = u_1 + u_2$ we obtain,

$$\begin{aligned} |\mathcal{D}(\tau_0 u - z_1)|^2_{H^1(\Omega)} &= |\mathcal{D}(\tau_0 u_2 - z_1)|^2_{H^1(\Omega)} + |u_1|^2_{H^1(\Omega)} + 2\langle \mathcal{D}(\tau_0 u_2 - z_1), u_1\rangle_{L^2(\Omega)} \\ &= |\mathcal{D}(\tau_0 u_2 - z_1)|^2_{H^1(\Omega)} + |u_1|^2 \,\mathrm{meas}(\Omega) - |2u_1|\langle \mathcal{D}z_1, 1\rangle_{L^2(\Omega)}, \end{aligned}$$

where (4.9) was used. We find for $(a, u) \in H^1(0,2) \times H(\Delta, \Omega)$,

$$J(a, u) = J_1(a, u_1) + J_2(a, u_2),$$

where

$$J_1(a, u_1) = \frac{1}{2}|u_1|^2 \,\mathrm{meas}(\Omega) - u_1\langle \mathcal{D}z_1, 1\rangle_{L^2(\Omega)} + \frac{1}{2}\beta |a_x|_{L^2(0,2)},$$

and

$$J_2(a, u_2) = \frac{1}{2}|\mathcal{D}(\tau_0 u_2 - z_1)|^2_{H^1(\Omega)} + \frac{1}{2}|\mathcal{N}(\tau_1 u_2 - z_2)|^2_{H^1(\Omega)}.$$

Let (a^*, u^*) be a solution of (4.1)–(4.4). We decompose $u^* = u_1^* + u_2^*$, and claim that

$$J_1(a^*, u_1^*) = \min_{u_1 \in \mathbf{R}} J_1(a^*, u_1), \tag{4.10}$$

$$J_2(a^*, u_2^*) = \min_{u_2 \in \mathcal{J}} J_2(a^*, u_2), \tag{4.11}$$

where $\mathcal{J} = \{u_2 \in H^1(\Omega) : \int \mathcal{D}(\tau_0 u_2) d\Omega = 0, e(a^*, u_2) = 0\}$. If (4.10) were false, then $J_1(a^*, u_1^*) > \min_{u_1 \in \mathbf{R}} J_1(a^*, u_1)$, and further

$$\begin{aligned} J(a^*, u^*) = J_1(a^*, u_1^*) + J_2(a^*, u_2^*) &> \min_{u_1 \in \mathbf{R}} J_1(a^*, u_1) + \min_{u_1 \in \mathcal{J}} J_2(a^*, u_2) \\ &= \min_{\substack{u \in H^1 \\ e(a^*, u) = 0}} J(a^*, u) = J(a^*, u^*), \end{aligned}$$

which is a contradiction and proves (4.10). The verification of (4.11) is similar. From a short calculation using (4.10) we deduce that

$$u_1^* = \frac{< \mathcal{D}z_1, 1 >_{L^2(\Omega)}}{\mathrm{meas}(\Omega)},$$

and from (4.11) we have

$$J_2(a^*, u_2^*) \leq J_2(a^*, \tilde{u}_2),$$

where $\tilde{u}_2$ is the unique element in $\mathcal{J} \cap \{\tau_1 u_2 = z_2\}$. Equivalently, $\tilde{u}_2$ is the unique solution in $H^1(\Omega)$ of

$$\left\{ \begin{array}{r} -\Delta \tilde{u}_2 = f_{a^*}, \\ \tau_1 \tilde{u}_2 = z_2, \\ \int_\Omega \mathcal{D}(\tau_0 \tilde{u}_2) d\Omega = 0. \end{array} \right. \tag{4.12}$$

To argue the existence of a unique solution to (4.12), consider

$$\left\{ \begin{array}{r} -\Delta v = f_{a^*}, \\ \tau_1 v = z_2, \\ \int_\Omega v d\Omega = 0. \end{array} \right. \tag{4.13}$$

The constraint $G_1(a^*) = A_1$ implies $\langle 1, f_{a^*} \rangle_{L^2(\Omega)} = \langle 1, -z_2 \rangle_{L^2(\Gamma)}$, which is the compatibility condition for (4.13). It is now well known that (4.13) has a unique solution $v \in H^1(\Omega)$, and it follows that

$$\tilde{u}_2 = v + \gamma, \quad \text{where } \gamma = -\int_\Omega \mathcal{D}(\tau_0 v) d\Omega / \text{ meas}(\Omega)$$

is the desired unique solution in $H(\Delta, \Omega)$ of (4.12).

Let us define

$$\tilde{u} = u_1^* + \tilde{u}_2.$$

We derive the estimate of $u^* - \tilde{u}$ in terms of $\tau_1 u^* - z_2$ next. Let $w = u_2^* - \tilde{u}_2$ and $g = \tau_1 u^* - z_2$, and observe that $\tilde{u}_2 \in \mathcal{J}, u_2^* \in \mathcal{J}$, and $\tau_1 u_2^* = \tau_1 u^*$ in $H^{1/2}(\Gamma)^*$. We find that w is the unique solution in $H(\Delta, \Omega)$ of

$$\left\{ \begin{array}{r} -\Delta w = 0, \\ \tau_1 w = g, \\ \int_\Omega \mathcal{D}(\tau_0 w) d\Omega = 0, \end{array} \right. \tag{4.14}$$

and consequently

$$| \bigtriangledown w|^2_{L^2(\Omega)} \leq \sigma_1 |g|_{H^{1/2}(\Gamma)^*} |w|_{H^1(\Omega)},$$

with σ_1 from Lemma A.6. Moreover, we have the Poincaré-type inequality

$$|v|_{H^1(\Omega)} \leq C| \bigtriangledown v|_{L^2(\Omega)} \quad \text{for all } v \in H^1(\Omega) \quad \text{with } \int_\Omega \mathcal{D}(\tau_0 v) d\Omega = 0.$$

It follows that

$$|w|_{H^1(\Omega)} \leq c|g|_{H^{1/2}(\Gamma)^*},$$

and thus

$$|u^* - \tilde{u}|_{H^1(\Omega)} = |u_2^* - \tilde{u}_2|_{H^1(\Omega)} = |w|_{H^1(\Omega)} \leq c|\tau_1 u^* - z_2|_{H^{1/2}(\Gamma)^*}. \tag{4.15}$$

Finally, observe that

$$J(a^*,u^*) = \frac{1}{2}|\mathcal{D}(\tau_0 u^* - z_1)|^2_{H^1(\Omega)} + \frac{1}{2}|\mathcal{N}(\tau_1 u^* - z_2)|^2_{H^1(\Omega)} + \frac{\beta}{2}|a^*_x|^2_{L^2(0,2)}$$
$$\leq J(a^*,\tilde{u}) = \frac{1}{2}|\mathcal{D}(\tau_0 \tilde{u} - z_1)|^2_{H^1(\Omega)} + \frac{\beta}{2}|a^*_x|^2_{L^2(0,2)}.$$

Together with Lemma A.6 this inequality gives

$$|\tau_1 u^* - z_2|_{H^{1/2}(\Gamma)^*} \leq \sigma_1 |\mathcal{N}(\tau_1 u^* - z_2)|_{H^1(\Omega)} \leq \sigma_1 |\mathcal{D}(\tau_0 \tilde{u} - z_1)|_{H^1(\Omega)}.$$

The asserted bounds in (ii) follow from these estimates.

(iii) The attainability assumption implies the existence of $(\hat{a},\hat{u}) \in Q_{ad} \times H^1(\Omega)$, where $\hat{u}$ satisfies

$$\begin{aligned} -\Delta \hat{u} &= f_{\hat{a}} \quad \text{in } H^1(\Omega)^*, \\ \tau_0 \hat{u} &= z_1 \quad \text{in } H^{1/2}(\Gamma), \\ \tau_1 \hat{u} &= z_2 \quad \text{in } H^{1/2}(\Gamma)^*. \end{aligned} \tag{4.16}$$

Due to the regularity assumptions on the data z_1 and by Lemma A.5, it follows that $\hat{u} \in H^2(\Omega)$. If (4.1)–(4.4) with $\beta = 0$ has another solution (a^*,u^*), then (a^*,u^*) satisfies (4.16) with $(\hat{a},\hat{u})$ replaced by (a^*,u^*). If both a^* and $\hat{a}$ are piecewise $C^{1,1}$ functions, then Theorem 3.1 implies that $\hat{a} = a^*$, and $\hat{u} = u^*$ by (4.16). This is the desired uniqueness in the case of attainability. □

Remark 4.2. The conclusions of Theorem 4.1 (i) and (iii) remain correct without the compatibility conditions. In (ii) of Theorem 4.1, only the first compatibility condition $G_1(a) = A_1$ is used.

5. Existence of a Lagrange multiplier. In this section we discuss the existence and the properties of a Langrange multiplier associated with the constrained optimization problem (4.1)–(4.4). We start with the following lemma.

LEMMA 5.1. *The Fréchet derivative of* $a \to f_a$ *from* $H^1(0,2)$ *to* $H^1(\Omega)^*$ *at* a *in direction* h *is given by*

$$f'_a(a)h = (\rho_2 - \rho_1)(h\tau_a),$$

where $(h\tau_a) \in H^1(\Omega)^*$ *is defined by*

$$\langle h\tau_a, \phi\rangle_{H^1(\Omega)^*,H^1(\Omega)} = \int_0^2 \phi(x,a(x))h(x)dx.$$

Proof. Let $\phi \in H^1(\Omega), \alpha \in \mathbf{R}$, and a and h in $H^1(0,2)$. Then

$$\langle f_{a+\alpha h}, \phi\rangle_{L^2(\Omega)'} = \int_0^2 \left[\rho_2 \int_0^{a+\alpha h} \phi(x,y)dy + \rho_1 \int_{a+\alpha h}^1 \phi(x,y)dy\right]dx,$$

provided that it is well defined. The Gateaux derivative is now easily found to be

$$\begin{aligned} \frac{d}{d\alpha}\langle f_{a+\alpha h}, \phi\rangle|_{\alpha=0} &= (\rho_2 - \rho_1)\int_0^2 \phi(x,a(x))h(x)dx \\ &= \langle(\rho_2 - \rho_1)h\tau_a, \phi\rangle_{H^1(\Omega)^*,H^1(\Omega)}. \end{aligned} \tag{5.1}$$

The mapping $h \to (h\tau_a)$ for $a \in H^1(0,2)$ is an element of $\mathcal{L}(H^1(0,2), H^1(\Omega)^*)$. To verify that (5.1) gives in fact the Fréchet derivative of $a \to f_a$, we need to show the continuity of $a \to (h \to (h\tau_a))$ from $H^1(0,2)$ to $\mathcal{L}(H^1(0,2), H^1(\Omega)^*)$. Let a and $\bar{a}$ be in $H^1(0,2)$. Then

$$\begin{aligned}
\sup_{|h|_{H^1}=1} |(h\tau_a) - (h\tau_{\bar{a}})|_{H^1(\Omega)^*} &= \sup_{\substack{|h|_{H^1}=1 \\ |\phi|_{H^1}=1}} \Big| \int_0^2 [\phi(x,a(x)) - \phi(x,\bar{a}(x))]h(x)dx \Big| \\
&\le c \sup_{|\phi|_{H^1}=1} \int_0^2 \left| \int_{a(x)}^{\bar{a}(x)} \phi_y(x,s)ds \right| dx \\
&\le c \sup_{|\phi|_{H^1}=1} \int_0^2 |\bar{a}(x) - a(x)|^{1/2} \Big(\int_0^1 \phi_y^2(x,y)dy \Big)^{1/2} dx \\
&\le c^2 |\bar{a} - a|^{1/2}_{L^\infty(0,2)} \sqrt{2} \sup_{|\phi|_{H^1}=1} \left[\int_0^2 \int_0^1 \phi_y^2(x,y)dydx \right]^{1/2} \\
&\le \sqrt{2} c^2 |\bar{a} - a|^{1/2}_{L^\infty(0,2)},
\end{aligned}$$

where c is independent of h and ϕ. □

In the previous section the constraint $\Delta u + f_a = 0$ served two purposes: it induced additional regulariy for $u \in H^1(\Omega)$, namely $\Delta u \in L^2$, so that $\tau_1 u$ was well defined, and it enforced the equation itself. For iterative numerical methods, where at each step of the iteration the variables are not required to be feasible (i.e., they do not necessarily satisfy the equality constraint), u must be chosen in a smaller space than $H^1(\Omega)$, so that $\tau_1 u$ is well defined. We may be tempted to choose $H^1(0,2) \times H(\Delta, \Omega)$ as the space for the optimization problem. For the numerical implementation, however, we do not want to exclude using linear finite elements that are not contained in $H(\Delta, \Omega)$. Moreover, due to the fact that the Fréchet derivative of $a \to f_a$ is only in $H^1(\Omega)^*$, we cannot show the existence of a Lagrange multiplier associated with the constraint $e(a,u) = 0$ if u is chosen in $H(\Delta, \Omega)$. We therefore introduce the space $H(\Gamma, \Omega)$ as the closure of the space of all infinitely differentiable functions on Ω such that all the derivatives have continuous extension up to Γ in the norm

$$|u|^2_{H(\Gamma,\Omega)} = |u|^2_{H^1(\Omega)} + |\tau_1 u|^2_{H^{1/2}(\Gamma)^*}$$

(see, e.g., [Az]). Let us point out that due to Lemma A.3, we have $H(\Delta, \Omega) \subset H(\Gamma, \Omega)$ and hence any solution of (4.1)–(4.4) satisfies $(a^*, u^*) \in H^1(0,2) \times H(\Gamma, \Omega)$.

To obtain an understanding of the space $H(\Gamma, \Omega)$, we consider the mapping

$$S : H(\Gamma, \Omega) \to H^1(\Omega) \times H^{1/2}(\Gamma) \times H^{1/2}(\Gamma)^*,$$

defined for an infinitely differentiable function u on Ω with all derivatives having continuous extensions up to Γ by

$$S\ u = (u, \tau_0 u, \tau_1 u),$$

and extended by continuity to any $H(\Gamma, \Omega)$. Then

$$\begin{aligned}
SH(\Gamma,\Omega) = \{(u, u_0, u_1) : u \in H^1, u_0 = \tau_0 u \in H^{1/2}(\Gamma), \\
u_1 \in H^{1/2}(\Gamma)^* \text{ arbitrary}\}
\end{aligned} \tag{5.2}$$

[Az, p. 66]. Thus, to be precise, we should denote any element of $H(\Gamma,\Omega)$ by a pair of elements $(u,u_1)\in H^1(\Omega)\times H^{1/2}(\Gamma)^*$. To avoid additional notation we refrain from doing so, but we stress that for $u\in H(\Gamma,\Omega)$, $\tau_1 u$ is only a symbol denoting the element u_1.

Some additional notation will be used, as follows:

$$X = H^1(0,2)\times H(\Gamma,\Omega),$$

$$C = \{(a,u)\in X : a(x)\in[0,1]\},$$

$$Y = H^1(\Omega)\times \mathbf{R}^4,$$

$$g : X\to Y,$$

$$g(a,u) = \Big(e(a,u), G_1(a)-A_1, G_2(a)-A_2, G_3(a)-A_3, G_4(a)-A_4\Big),$$

where $e : X\to H^1(\Omega)$ is given by

$$e(a,u) = N(\Delta u + f_a).$$

Here $\Delta u\in H^1(\Omega)^*$ must be interpreted as

$$\langle \Delta u, v\rangle_{H^1(\Omega)^*,H^1(\Omega)} = -\langle \nabla u,\nabla v\rangle_{L^2(\Omega)} + \langle \tau_1 u,\tau_0 v\rangle_{L^2(\Gamma)}$$

for all $v\in H^1(\Omega)$. We note that C is a closed convex subset of X.

Problem (4.1)–(4.4) can be equivalently expressed as

$$(P^\beta)\quad \min_{\substack{(a,u)\in C\\ g(a,u)=0}} J(a,u) = \frac{1}{2}|\mathcal{D}(\tau_0 u - z_1)|^2_{H^1(\Omega)} + \frac{1}{2}|\mathcal{N}(\tau_1 u - z_2)|^2_{H^1(\Omega)} + \frac{\beta}{2}|a_x|^2_{L^2(0,2)}.$$

The Fréchet derivatives of J and g will be needed. The functional J is quadratic in a and u and hence the derivative is obvious. The Fréchet derivatives of G_i are simple to calculate and the Fréchet derivative of $a\to f_a$ from $H^1(0,2)$ to $H^1(\Omega)^*$ was calculated in Lemma 5.1.

Henceforth we fix a solution $x^* = (a^*,u^*)\in X$ of $(P^\beta), \beta\geq 0$. A functional $\Lambda^* = (\lambda^*,\mu_1^*,\dots,\mu_4^*)\in Y^*$ is called Lagrange multiplier if

$$J'(x^*) + \Lambda^* g'(x^*)\in C(x^*)^+, \tag{5.3}$$

where

$$C(x^*)^+ = \{\eta\in X^* :< \eta, x - x^* >_{X^*,X}\geq 0,\ \text{for all } x\in C(x^*)\}$$

and

$$C(x^*) = \{\lambda(x-x^*) : x\in C, \lambda\in \mathbf{R}^+\}.$$

Some comments are in order. The primes in (5.3) denote Fréchet derivatives with respect to $x=(a,u)$. Henceforth we identify the functional $\Lambda^*\in Y^*$ with its Riesz

representation $\Lambda^* \in Y$ and analogously for $\eta \in X$. Due to the special form of C and g, (5.3) is equivalent to

$$\begin{cases} J_a(a^*, u^*) + \Lambda^* g_a(a^*, u^*) \in C(a^*)^+, \\ J_u(a^*, u^*) + \Lambda^* g_u(a^*, u^*) = 0, \end{cases} \tag{5.4}$$

where

$$C(a^*)^+ = \{\eta_1 \in H^1(0,2) : \langle \eta_1, a \rangle_{H^1(0,2)} \geq 0 \text{ for all } a \in C(a^*)\}$$

and

$$C(a^*) = \{\lambda(a - a^*) : 0 \leq a(x) \leq 1, \lambda \in \mathbf{R}^+\},$$

and the subscripts with J and g denote partial Fréchet derivatives. If a^* satisfies $0 < a^*(x) < 1$ on $[0,2]$, then $C(a^*)^+ = \{0\}$ and the first equation in (5.4) becomes

$$J_a(a^*, u^*) + \Lambda^* g_a(a^*, u^*) = 0. \tag{5.5}$$

The existence of a Lagrange multiplier is implied by certain regular point conditions for the minimizer (a^*, u^*). Here we employ the condition

$$0 \in \operatorname{int}\{g'(a,u)(C - (a,u))\} \tag{5.6}$$

for $(a,u) \in C$, where the expression on the right-hand side of (5.6) denotes the interior of the set $\{g'(a,u)(c - (a,u)) : c \in C\}$. If (5.6) holds with $(a,u) = (a^*, u^*)$, then it is known to imply the existence of Λ^* satisfying (5.3) (see, e.g., [ZK]). To guarantee (5.6) an additional condition is necessary. To state this condition we first note that

$$(G_1'(a)h, \ldots, G_4'(a)h) = (\langle l_1, h \rangle_{L^2}, \ldots, \langle l_4, h \rangle) \quad \text{for } a \text{ and } h \in H^1(0,2),$$

where

$$l_1(x) = 1, \quad l_2(x) = 2a(x), \quad l_3(x) = x, \quad l_4(x) = 2xa(x).$$

For $a \in H^1$ with $0 \leq a \leq 1$, let

$$\vec{a} = \operatorname{col}(\langle l_1, a \rangle_{L^2}, \ldots, \langle l_4, a \rangle).$$

The condition announced above is given by

$$\begin{gathered} \text{there exist vectors } \{k_j\}_{j=1}^4 \text{ in } C(0,2), \\ \text{such that the matrix } M \in \mathbf{R}^{4\times 4} \text{ defined by} \\ M_{ij} = \langle l_i, k_j \rangle_{L^2(0,2)} \\ \text{is nonsingular and} \\ 0 < b = \sum_{i=1}^4 b_i k_i(x) < 1, \\ \text{with } \{b_i\}_{i=1}^4 \text{ the coordinates of } \vec{b} = M^{-1}\vec{a}. \end{gathered} \tag{5.7}$$

If a is not a linear function and satisfies $0 < a < 1$, then (5.7) is satisfied with $k_i = l_i$ and $b = a$. Further discussion of (5.7) follows after the next theorem.

THEOREM 5.2. *Condition* (5.7) *implies* (5.6). *In particular, if* (5.7) *holds for* a^*, *where* (a^*, u^*) *is a solution of* (P^β), *then there exists an associated Lagrange multiplier* Λ^*.

Proof. The assertion follows from the fact that there exists $\eta > 0$ such that

$$(5.8)\begin{pmatrix} w \\ \vec{r} \end{pmatrix} = \begin{pmatrix} N(\Delta v + (\rho_2 - \rho_1)(h\tau_{a^*})) \\ \langle l_1, h\rangle_{L^2} \\ \vdots \\ \langle l_4, h\rangle_{L^2} \end{pmatrix} - \begin{pmatrix} N(\Delta u^* + (\rho_2 - \rho_1)(a^*\tau_{a^*})) \\ \\ \vec{a}^* \\ \\ \end{pmatrix}$$

has a solution $(h, v) \in C$ for all $(w, \vec{r}) \in Y = H^1(\Omega) \times \mathbf{R}^4$, provided that $|\vec{r}|_{\mathbf{R}^4} \leq \eta$. We verify below the existence of a solution $h \in H^1(0, 2)$ to

$$(5.9) \qquad \vec{r} = \begin{pmatrix} \langle l_1, h\rangle_{L^2} \\ \vdots \\ \langle l_4, h\rangle_{L^2} \end{pmatrix} - \vec{a}^*$$

for all sufficiently small $\vec{r} \in \mathbf{R}^4$. Once h is determined, we turn to the first equation in (5.8), which has to be solved for $v \in H(\Gamma, \Omega)$.

This equation is equivalent to solving

$$(5.10) \qquad w - Nf = N(\Delta v)$$

for $v \in H(\Gamma, \Omega)$, where $f \in H^1(\Omega)^*$ is given by $f = (\rho_2 - \rho_1)(h - a^*)\tau_a^* - \Delta u^*$. Since N is an isomorphism from $H^1(\Omega)$ to $H^1(\Omega)^*$, there exists a unique $\tilde{v} \in H^1(\Omega)^*$ such that

$$w - Nf = N\tilde{v},$$

and it suffices to solve $\Delta v = \tilde{v}$ for $v \in H(\Gamma, \Omega)$. Let g be any element in $L^2(\Gamma)$ satisfying

$$\langle g, 1\rangle_{L^2(\Gamma)} = \langle \tilde{v}, 1\rangle_{H^1(\Omega)^*, H^1(\Omega)}.$$

Then there exists $v \in H(\Gamma, \Omega)$ satisfying

$$-\langle \nabla v, \nabla \varphi\rangle + \langle g, \varphi\rangle_{L^2(\Gamma)} = \langle \tilde{v}, \varphi\rangle_{H^1(\Omega)^*, H^1(\Omega)}$$

for all $\varphi \in H^1(\Omega)$ (c.f. [Az, p. 62]), and an element v satisfying the desired properties is found.

Returning to (5.9) we look for a solution of the form $h = \sum_{j=1}^4 h_j k_j$. Inserting this expression in (5.9) gives

$$\vec{h} = M^{-1}(\vec{a} + \vec{r}), \quad \text{with } \vec{h} = \operatorname{col}(h_1, \ldots, h_4).$$

Assumption (5.7) implies the existence of $\tilde{\eta} > 0$ such that $0 \leq h \leq 1$ for all $\vec{r} \in \mathbf{R}^4$ with $|\vec{r}|_{\mathbf{R}^4} \leq \eta$. □

The following result summarizes different situations in which (5.7) holds. Some of them require that not all compatibility conditions $G_i(a) = A_i$ are considered simultaneously. As a consequence the corresponding components in the definition of g and Λ^* have to be dropped. No additional notation will be introduced for these cases.

PROPOSITION 5.3. *Let* $a \in H^1(0, 1)$ *satisfy* $0 \leq a \leq 1$.

(i) *If only one of the constraints* $\{G_i(a) - A_i = 0\}_{i=1}^4$ *is considered, then* (5.7) *holds provided that* $a \not\equiv 0$ *and* $a \not\equiv 1$.

(ii) *If only the constraints* $G_i(a) - A_i = 0, i = 1, 3$ *are considered, then* (5.7) *holds if* $0 < \epsilon \leq P_2 a \leq 1 - \epsilon < 1$, *where* P_2 *is the orthogonal projector onto* $\operatorname{span}\{l_1, l_3\}$ *in the* L^2*-norm.*

(iii) *If only the constraints* $G_i(a) - A_i = 0, i = 2, 4$ *are present, then* $0 < \epsilon \leq a \leq 1 - \epsilon < 1$ *implies* (5.7).

(iv) *If all constraints* $\{G_i(a) - A_i = 0\}_{i=1}^4$ *are considered, then* (5.7) *holds if* $0 < \epsilon \leq a \leq 1 - \epsilon < 1$ *and* a *is such that* $\{1, a, x, a \cdot x\}$ *are not linearly dependent as elements in* $H^1(0, 2)$.

Proof. (i) In this case we choose $k_i = 1$. Then $b = \langle l_i, a\rangle_{L^2} / \langle l_i, 1\rangle_{L^2}$ and $M = \langle l_i, 1\rangle_{L^2}$. Since $a \not\equiv 0$ and $a \not\equiv 1$, it follows that $0 < b < 1$ as desired.

(ii) We choose $k_1 = l_1, k_3 = l_3$. Then

$$M = \begin{pmatrix} 2 & 2 \\ 2 & \frac{8}{3} \end{pmatrix}$$

is nonsingular and $b = P_2 a$, which satisfies $0 < \epsilon \leq b \leq 1 - \epsilon$, by assumption.

(iii) In this case we take $k_2 = l_2, k_4 = l_4$. Since $a \not\equiv 0$, the functions l_2 and l_4 are linearly independent and therefore

$$M = \begin{pmatrix} \langle l_2, l_2\rangle \langle l_2, l_4\rangle \\ \langle l_4, l_2\rangle \langle l_4, l_4\rangle \end{pmatrix}$$

is nonsingular. Since $a \in \operatorname{span}\{l_2, l_4\}$, it follows that $b = P_2 a = a$ and by assumption, $0 < \epsilon \leq b \leq 1 - \epsilon < 1$.

(iv) We take $k_i = l_i$ for $i = 1, \ldots, 4$. Due to the linear independence of $\{1, a, x, a \cdot x\}$, the matrix M with $(M)_{ij} = \langle l_i, l_j\rangle$ is nonsingular. Again we find $b = P_2 a = a$ and $0 < \epsilon \leq b \leq 1 - \epsilon < 1$, as desired. □

Remark 5.4. Proposition 5.3 does not cover the case when the first and second compatibility condition are present simultaneously, unless $0 < \epsilon \leq a \leq 1 - \epsilon < 1$. But this situation is not excluded by (5.7), as the following example shows. We consider the first two compatibilities $G_i(a) - A_i = 0, i = 1, 2$ with $a = x/2$. In this case we choose $k_1 = 1, k_2(x) = \cos(\pi/2)x$. We find

$$M = \begin{pmatrix} 2 & 0 \\ 2 & -\frac{8}{\pi^2} \end{pmatrix} \quad \text{and} \quad b = \frac{1}{2} - \frac{\pi^2}{24} \cos \frac{\pi}{2} x,$$

so that (5.7) clearly holds.

We turn to a discussion of the implications of (5.3) for the problem (P^β). The next result will be given under the assumption of existence of a Lagrange multiplier Λ^* for all four compatibility conditions. The modifications for the case where only a subset of these conditions is enforced are straightforward. For convenience of notation we put $G(a) = (G_1(a), \ldots, G_4(a))$.

THEOREM 5.5. *Let* (5.6) *hold and let* $(a^*, u^*) \in X$ *be a solution of* (P^β) *with Lagrange multiplier* $\Lambda^* = (\lambda^*, \mu_1^*, \ldots, \mu_4^*) \in Y$. *Then* λ^* *is the unique solution of*

$$\begin{aligned} \langle \nabla \lambda^*, \nabla v\rangle_{L^2(\Omega)} &= \langle \mathcal{D}(\tau_0 u^* - z_1), \mathcal{D}(\tau_0 v)\rangle_{H^1(\Omega)} \quad \text{for all } v \in H^1(\Omega) \\ \tau_0 \lambda^* &= \tau_0 \mathcal{N}(z_2 - \tau_1 u^*) \quad \text{in } H^{1/2}(\Gamma). \end{aligned} \tag{5.11}$$

Moreover, there exists $\eta^* \in C(a^*)^+$ *such that*

$$\begin{aligned} &\langle \mu^*, G'(a^*)h\rangle_{\mathbf{R}^4} + (\rho_2 - \rho_1)\langle h\tau_{a^*}, \lambda^*\rangle_{L^2(\Omega)} + \beta\langle a_x^*, h_x\rangle_{L^2(0,2)} \\ &\quad = \langle \eta^*, h\rangle_{H^1(0,2)} \quad \text{for all } h \in H^1(0, 2). \end{aligned} \tag{5.12}$$

If $\beta > 0$, and $\rho_2 \neq \rho_1$ or at least one of the compatibility conditions is present, this implies the regularity property $a^* \in H^2(I)$, where $I = \{x \in [0,2] : 0 < a^*(x) < 1\}$.

Proof. We employ the necessary optimality condition (5.4). It follows that there exists $\eta^* \in C(a^*)^+$ such that

$$\begin{aligned}\beta\langle a_x^*, h_x\rangle_{L^2(0,2)} + (\rho_2 - \rho_1)\langle h\tau_{a^*}, \lambda^*\rangle_{H^1(\Omega)^*,H^1(\Omega)} + \langle \mu^*, G'(a^*)h\rangle_{\mathbf{R}^4} \\ = \langle \eta^*, h\rangle_{H^1(0,2)} \quad \text{for all } h \in H^1(0,2) \quad \text{and}\end{aligned}$$

$$\begin{aligned}\langle \mathcal{D}(\tau_0 u^* - z_1), \mathcal{D}(\tau_0 v)\rangle_{H^1(\Omega)} + \langle \mathcal{N}(\tau_1 u^* - z_2), \mathcal{N}(\tau_1 v)\rangle_{H^1(\Omega)} \\ -\langle \nabla\lambda^*, \nabla v\rangle_{L^2(\Omega)} + \langle \tau_0\lambda^*, \tau_1 v\rangle_{H^{1/2}(\Gamma),H^{1/2}(\Gamma)^*} = 0\end{aligned} \tag{5.13}$$

for all $v \in H(\Gamma, \Omega)$. We remind the reader that in (5.13), $\tau_1 v$ is only the symbol for the second coordinate of $v \in H(\Gamma, \Omega)$, unless v has additional regularity. The first of these equation is (5.12). Using the definition of $\mathcal{N}$ in the second we obtain

$$\begin{aligned}\langle \mathcal{D}(\tau_0 u^* - z_1), \mathcal{D}(\tau_0 v)\rangle_{H^1(\Omega)} - \langle \nabla\lambda^*, \nabla v\rangle_{L^2(\Omega)} \\ + \langle \tau_0\lambda^* + \tau_0\mathcal{N}(\tau_1 u^* - z_2), \tau_1 v\rangle_{H^{1/2}(\Gamma),H^{1/2}(\Gamma)^*} = 0.\end{aligned} \tag{5.14}$$

Recalling (5.2) and evaluating (5.14) for v in the set $\{v \in H(\Gamma, \Omega) : \tau_1 v = 0\}$ we find

$$\langle \nabla\lambda^*, \nabla v\rangle_{L^2(\Omega)} = \langle \mathcal{D}(\tau_0 u^* - z_1), \mathcal{D}(\tau_0 v)\rangle_{H^1(\Omega)},$$

for all $v \in H^1(\Omega)$.

The first equality in (5.12) now follows. Reconsidering (5.14) we find $\langle \tau_0\lambda^* + \tau_0\mathcal{N}(\tau_1 u^* - z_1), \tau_1 v\rangle_{H^{1/2}(\Gamma),H^{1/2}(\Gamma)^*} = 0$ for all $\tau_1 v \in H^{1/2}(\Gamma)^*$ and thus (5.11) is verified.

We turn to the proof of the regularity property. Since I is open relative to [0,2], it can be expressed as $I = \bigcup_{j=1}^{\infty} I_j$, with I_j pairwise disjoint intervals open relative to $[0,2]$. On each I_j, the functional η^* is zero, i.e., $\langle \eta^*, h\rangle_{H^1(I_j)} = 0$ for all $h \in H^1(I_j)$. From (5.12) it follows that

$$\mu^* G'(a^*) + (\rho_2 - \rho_1)\lambda^*(\cdot, a^*(\cdot)) = \beta a_{xx}^* \quad \text{in } H^1(I_j)^*. \tag{5.15}$$

Since the left-hand side of (5.15) is in $L^2(I_j)$ and $\beta > 0$ by assumption, it follows that a_{xx}^* can be identified with an element in $L^2(I_j)$ and $a^* \in H^2(I_j)$. It follows that $a^* \in H^2(I)$ and the proof is finished. □

Remark 5.6. From (5.13) we deduce that $|\lambda^*|_{H^1}$ is small provided that $|\mathcal{D}(\tau_0 u^* - z_1)|_{H^1}$ and $|\mathcal{N}(\tau_1 u^* - z_2)|_{H^1}$ are small. Moreover $\lambda^* = 0$, if $\tau_0 u^* = z_1$ and $\tau_1 u^* = z_2$, which can be expected to hold only in the case that the data (z_1, z_2) are attainable and $\beta = 0$.

6. The augmented Lagrangian algorithm. In this section we describe the algorithm that we propose for the solution of (P^β). Conceptually we can distinguish three stages. In the first stage the equality constraint $g(a,u) = 0$ is eliminated from the set of explicit constraints and only the simple constraints $0 \leq a(x) \leq 1$ are left as explicit constraints. The second and third stages consist of discretizing the resulting infinite-dimensional optimization problem with only simple constraints and of choosing an appropriate algorithm to solve the finite-dimensional optimization problems. While the specific choices that are made in these last two stages as well as the order in which these two stages are carried out are important, we do not study these aspects

here. The focus in this and the following section is on the analysis of the first stage. An augmented Lagrangian functional is used to eliminate the constraint $g(a,u)=0$. The resulting optimization problems are quadratic in u for fixed a and "completely" nonlinear in a. A conjugate gradient algorithm is used to solve the optimization problems. The discretization of the variables (a,u) is carried out by finite elements.

The augmented Lagrangian function

$$\mathcal{L}_c : X \times Y = H^1(0,2) \times H(\Gamma,\Omega) \times H^1(\Omega) \times \mathbf{R}^4 \to \mathbf{R} \quad \text{is defined by}$$

$$\mathcal{L}_c(x,\Lambda) = J(x) + \langle \Lambda, g(x)\rangle_Y + \frac{c}{2}|g(x)|_Y^2,$$

where $c \in \mathbf{R}^+$. In this and the following section it is convenient to use interchangably the notation (a,u) and x to denote an element in X. Let us assume that x^* is a local solution of (P^β) with associated Lagrange multiplier Λ^*. The possibility of eliminating the constraint $g(x)=0$ from the explicit constraints in (P^β) relies on the following augmentability condition [H], [IK1].

(6.1)
$$\begin{cases} \text{There exist constants } \sigma > 0, r > 0, \text{ and } \bar{c} \geq 0 \text{ such that} \\ \mathcal{L}_c(x,\Lambda^*) - J(x^*) \geq \sigma |x - x^*|_X^2 \\ \text{for all } c \geq \bar{c}, \text{ and } x \in B(x^*,r) = \{x=(a,u) : |x-x^*|_X \leq r, \\ 0 \leq a(x) \leq 1\}. \end{cases}$$

Let us note that (6.1) implies that

$$J(x) \geq J(x^*) + \sigma |x - x^*|_X^2$$

for all $x \in B(x^*,r)$, which also satisfies $g(x)=0$. Thus x^* is a strict local minimum. Condition (6.1) will be analyzed in §7. If Λ^* was knwon, then based on (6.1) it would be natural to minimize $\mathcal{L}_c(x,\Lambda^*)$, subject to $0 \leq a \leq 1$. But since Λ^* is unknown it needs to be approximated as part of the numerical procedure to solve (P^β). This leads to the augmented Lagrangian algorithm, which we describe next.

Augmented Lagrangian algorithm.

(i) CHOOSE $\Lambda_0, \beta, \{c_n\}_{n=1}^\infty$ with $\bar{c} < c_1 \leq c_2, \ldots$

(ii) SET $n=1$

REPEAT

(iii) (P_n^β) minimize $\mathcal{L}_{c_n}(a,u,\Lambda_{n-1})$ subject to $(a,u) \in X$ and $0 \leq a \leq 1$ to obtain a solution (a_n,u_n).

(iv) UPDATE

$\Lambda_n = \Lambda_{n-1} + (c_n - \bar{c})g(a_n,u_n)$

(v) SET $n = n+1$.

Remark 6.1. (i) In our calculations we took $\Lambda_0 = (\lambda_0, \mu_{1,0}, \ldots, \mu_{4,0}) = 0$. The choice of $\lambda_0 = 0$ is suggested by (5.11), which implies that λ^* should be small if the data are almost attainable and if β is small.

(ii) For the computations in this paper we took $\{c_n\}$ to be a constant sequence and we chose β heuristically; compare, however, [IK3].

(iii) It is not difficult to argue that the problems (P_n^β) in step (iii) of the algorithm have a solution. To solve these problems numerically, a conjugate gradient algorithm

was used. In view of Lemma 5.1 it is simple to calculate the analytical gradient of $\mathcal{L}_{c_n}(a, u, \Lambda_{n-1})$ with respect to (a, u). Numerically, an alternate direction method was used. First the variable a was fixed and the quadratic problem was solved for u, then u was fixed at the value obtained and the nonlinear function was minimized with respect to a. We can repeat these steps several times before updating Λ.

(iv) As a startup value for the numerical solution of (P_n^β) the solution (a_{n-1}, u_{n-1}), $n = 2, 3, \ldots$ was taken. For $n = 1$ a very good choice for a startup value a_1^0 is given as a solution to the compatibility conditions $G_i(a) = A_i$.

(v) For some calculations the regularization term $\beta|a_x|^2_{L^2(0,2)}$ in (P_n^β) was replaced by $\beta|a_x - \tilde{a}_x|^2_{L^2(0,2)}$, where $\tilde{a}$ represents some a priori guess to a^*. A good choice for $\tilde{a}$ is again given by a function which satisfies the compatibility conditions.

(vi) The update rule in (iv) of the augmented Lagrangian algorithm realizes a steepest ascent rule for the dual optimization problem; compare [B], [IK1].

The convergence analysis is based on (6.1). A priori it is not guaranteed that the iterates x_n are contained in $B(x^*, r)$, which is the ball in which (6.1) is applicable. Therefore the auxilary constrained problems

$$(P_{n,c}^\beta) \text{ minimize } \mathcal{L}_{c_n}(a, u, \Lambda_{n-1}) \quad \text{subject to } (a, u) \in B(x^*, r)$$

are introduced. The following result guarantees that if in the augmented Lagrangian algorithm (P_n^β) is replaced by $(P_{n,c}^\beta)$, then the solutions $x_n \in \text{ int } B(x^*, r)$ either for all sufficiently large n, or for all n if $|\Lambda_0 - \Lambda^*|_Y$ is sufficiently small or c_1 is sufficiently large, i.e., the constraint $|x - x^*|_X \leq r$ is not active in these cases. Moreover it asserts convergence of $\{x_n\}$ and boundedness of the Lagrange multipliers $\{\lambda_n\}$.

THEOREM 6.2. *Let* (6.1) *hold. Then for every* $n = 1, 2, \ldots$, *there exists a solution* x_n *to* $(P_{n,c}^\beta)$. *Moreover, there exists* n_0 *such that* $x_n \in \text{ int } B(x^*, r)$ *for all* $n \geq n_0$. *Alternatively, if* $|\Lambda_0 - \Lambda^*|_Y$ *is sufficiently small or* c_n *are taken sufficiently large, then* x_n *is a solution to* (P_n^β) *in* int $B(x^*, r)$ *for every* $n = 1, 2, \ldots$. *Assuming that* x_n *are solutions of* (P_n^β) *in* $B(x^*, r)$ *we find for* $n = 1, 2, \ldots$,

$$\sigma|x_n - x^*|_X^2 + \frac{1}{2\sigma_n}|\Lambda_n - \Lambda^*|_Y^2 \leq \frac{1}{2\sigma_n}|\Lambda_{n-1} - \Lambda^*|_Y^2 \tag{6.2}$$

and

$$\sum_{n=1}^{\infty} \sigma_n |x_n - x^*|_X^2 \leq \frac{1}{2\sigma}|\Lambda^0 - \Lambda^*|_Y^2, \tag{6.3}$$

where $\sigma_n = c_n - \bar{c}$.

For the proof we refer to [IK1].

7. The augmentability condition. This section is devoted to the study of the augmentability condition (6.1) by means of a second-order analysis of $\mathcal{L}_c(x, \Lambda)$ at (x^*, Λ^*). The section is organized as follows. First a smoothing of the mapping $a \to f_a$ is introduced which will allow us to argue that a modified augmented Lagrangian functional which for convenience we again denote by $\mathcal{L}_c$, is twice continuously Fréchet differentiable with respect to x. Then Taylor's formula is used to verify the augmentability condition (6.1) under the assumption that the second Fréchet derivative $\mathcal{L}_c''(x^*, \Lambda^*)$ with respect to x at (x^*, Λ^*) is positive definite on the kernel of the linearized constraints. The latter condition is referred to as the second-order sufficient optimality condition, and is analyzed at the end of this section. At present

we cannot verify the augmentability condition for the original problem without the smoothing of $a \to f_a$.

The smoothing of $a \to f_a$ is defined next. The domain Ω and the right-hand side f_a are modified as follows:

$$\Omega = \left\{(x,y) : x \in [0,2], -\frac{\alpha}{2} \le y \le \frac{\alpha}{2} + 1\right\}, \tag{7.1}$$

where $\alpha > 0$ and

$$\tilde{f}_a(x,y) = \begin{cases} \rho_1 & \text{if } y > a(x) + \dfrac{\alpha}{2}, \\ \dfrac{\rho_1 - \rho_2}{\alpha}\left(y - a(x) + \dfrac{\alpha}{2}\right) + \rho_2 & \text{if } a(x) - \dfrac{\alpha}{2} \le y \le a(x) + \dfrac{\alpha}{2}, \\ \rho_2 & \text{if } y < a(x) - \dfrac{\alpha}{2}. \end{cases} \tag{7.2}$$

It is obvious that the results of the previous sections remain correct with f_a replaced by $\tilde{f}_a$.

Let us recall that

$$\mathcal{L}_c(x,\Lambda) = J(x) + \langle \Lambda, g(x)\rangle_Y + \frac{c}{2}|g(x)|_Y^2,$$

where g is understood with f_a replaced by $\tilde{f}_a$. Since $x \to J(x)$ is clearly twice continuously Fréchet differentiable we turn to the differentiability properties of

$$x \to \langle \Lambda, g(x)\rangle_Y + \frac{c}{2}|g(x)|_Y^2.$$

We note that $a \to \mu_i(G_i(a) - A_i) + (c/2)|G_i(a) - A_i|^2$ with $\mu_i \in \mathbf{R}$ is twice continuously Fréchet differentiable and therefore it suffices to consider

$$\tilde{G} : (a,u) = x \to \langle \lambda, N(\Delta u + \tilde{f}_a)\rangle_{H^1(\Omega)} + \frac{c}{2}|N(\Delta u + \tilde{f}_a)|_{H^1(\Omega)}^2, \tag{7.3}$$

where $\lambda \in H^1(\Omega)$.

Since $\tilde{G}$ is quadratic with respect to u, and since there are no mixed terms so that $\tilde{G}_{au} = 0$, we only specify the second Fréchet derivative of $\tilde{G}$ with respect to a. The first Fréchet derivative of $a \to \tilde{f}_a$ from $H^1(0,2)$ to $L^2(0,2)$ is given by

$$\tilde{f}'(a)h = \frac{\rho_2 - \rho_1}{\alpha}\tilde{\chi}_a h,$$

where $\tilde{\chi}_a$ is the characteristic function of the subdomain $\{(x,y) : 0 < x < 2, a(x) - \alpha/2 < y < a(x) + \alpha/2\}$. In view of Lemma 5.1 we put $\tilde{\tau}_a = (1/\alpha)\tilde{\chi}_a$ and we note that $(h\tau_a)$ is the limit of $h\tilde{\tau}_a$ as $\alpha \to 0$. In view of the proof of Lemma 5.1 we further find

$$\begin{aligned} \tilde{G}_{aa}(x)(h,\tilde{h}) &= \frac{\rho_2 - \rho_1}{\alpha}\langle h\tilde{h}(\tau_{a+\frac{\alpha}{2}} - \tau_{a-\frac{\alpha}{2}}), \lambda\rangle_{H^1(\Omega)^*, H^1\Omega)} \\ &\quad + c(\rho_2 - \rho_1)^2\langle N(h\tilde{\tau}_a), N(\tilde{h}\tilde{\tau}_a)\rangle_{H^1(\Omega)} \\ &= \frac{\rho_2 - \rho_1}{\alpha}\int_0^2 \left(\lambda\left(x, a(x) + \frac{\alpha}{2}\right) - \lambda\left(x, a(x) - \frac{\alpha}{2}\right)\right) h(x)\tilde{h}(x)dx \\ &\quad + c(\rho_2 - \rho_1)^2\langle N(h\tilde{\tau}_a), N(\tilde{h}\tilde{\tau}_a)\rangle_{H^1(\Omega)}, \end{aligned}$$

where $h, \tilde{h} \in H^1(0,2)$. We have thus shown that $\mathcal{L}_c(x,\lambda)$ is twice continuously Fréchet differentiable with respect to x if f_a is replaced by $\tilde{f}_a$.

Let us recall a lemma on positive definite bilinear forms. For a proof, see [H], for example.

LEMMA 7.1. *Let A be a bounded self-adjoint linear operator from a Hilbert space H into itself and let*

$$\langle Ax, x\rangle_H \geq m|x|_H^2 \quad \textit{for some } m > 0 \quad \textit{and all } x \in \ker C,$$

where C is a bounded linear operator from H onto a Hilbert space H_1. Then for every $\gamma \in (0, m)$ there exists $R > 0$ such that

$$\langle (A + KC^*C)x, x\rangle_H = \gamma|x|_H^2 \quad \textit{for all } x \in H \quad \textit{and } K \geq R.$$

Throughout this section $x^* = (a^*, u^*)$ denotes a solution of (P^β) with Lagrange multiplier Λ^*. It will be useful to observe that

$$\begin{aligned} \mathcal{L}_c''(x^*, \Lambda^*)(y, y) = J''(x^*)(y, y) + \langle \Lambda^*, g''(x^*)(y, y)\rangle_Y \\ + c|g'(x^*)y|_Y^2, \end{aligned} \tag{7.4}$$

where $y \in X$. The following second-order sufficient optimality condition will be used.

There exists a constant $K > 0$ such that

$$J''(x^*)(y, y) + \langle \Lambda^*, g''(x^*)(y, y)\rangle_Y \geq K|y|_X^2 \quad \text{for all } y \in \ker g'(x^*). \tag{7.5}$$

THEOREM 7.2. *Let* (7.5) *hold and assume that a^* is not a linear function. Then the augmentability condition* (6.1) *is satisfied.*

Proof. Due to Proposition 7.1, Taylor's theorem is applicable to $x \to \mathcal{L}_c(x, \Lambda^*)$. We find

$$\begin{aligned} \mathcal{L}_c(x, \Lambda^*) &= \mathcal{L}_c(x^*, \Lambda^*) + \mathcal{L}_c'(x^*, \Lambda^*)(x - x^*) + \mathcal{L}_c''(x^*, \Lambda^*)(x - x^*)^2 \\ &\quad + o(|x - x^*|_X^2) \\ &= J(x^*) + J'(x^*)(x - x^*) + < \Lambda^*, g'(x^*)(x - x^*) >_Y + \mathcal{L}_c''(x^*, \Lambda^*)(x - x^*)^2 \\ &\quad + o(|x - x^*|_X^2) \\ &\geq J(x^*) + \mathcal{L}_c''(x^*, \Lambda^*)(x - x^*)^2 + o(|x - x^*|_X^2), \end{aligned} \tag{7.6}$$

for all $x = (a, u)$ with $0 \leq a \leq 1$. In the last estimate we used (5.4). Lemma 7.1 will be employed next to argue positivity of $\mathcal{L}_c''(x^*, \Lambda^*)$. The operator $g'(x^*) : X \to Y \times \mathbf{R}^4$ is given by

$$g'(x^*)(h, v) = \begin{pmatrix} N(\Delta v + (\rho_2 - \rho_1)(h\tilde{\tau}_{a^*})) \\ \langle l_1, h\rangle_{L^2(0,2)} \\ \vdots \\ \langle l_4, h\rangle_{L^2(0,2)} \end{pmatrix}.$$

It is surjective since $\{l_i\}_{i=1}^4$ are linearely independent as a consequence of the assumption that a^* is not a linear function. In view of (7.4), $\mathcal{L}_c''(x^*, \Lambda^*)$ can be expressed as

$$\mathcal{L}_c''(x^*, \Lambda^*)(y, y) = \langle Ay, y\rangle_X + c|Cy|_Y^2, \qquad y \in X,$$

where $A \in \mathcal{L}(X), C \in \mathcal{L}(X,Y)$, are given by

$$\langle Ay, y\rangle_X = J''(x^*)(y,y) + \langle \Lambda^*, g''(x^*)(y,y)\rangle_Y$$

and $Cy = g'(x^*)y$ for $y \in X$. Let $\tilde{\sigma} \in (0,K)$, with K from (7.5). Then by Lemma 7.1 there exists $\bar{c}$ such that

$$\mathcal{L}''_{\bar{c}}(x^*,\Lambda^*)(y,y) \geq \tilde{\sigma}|y|_X^2 \quad \text{for all } y \in X.$$

Now (7.6) can be used to assert that for every $\sigma \in (0,\tilde{\sigma})$ there exists $r > 0$ such that

$$\mathcal{L}_c(x,\Lambda^*) \geq \mathcal{L}_{\bar{c}}(x,\Lambda^*) \geq J(x^*) + \sigma|x - x^*|_X^2$$

for all $c \geq \bar{c}$ and all $x \in B(x^*,r)$. This is the desired augmentability condition (6.1). □

Remark 7.3. The assumption that a^* is not a linear function is only required if the compatibility conditions $G_i(a) = A_i, i = 2,4$ are present. It can be replaced by the requirement that $\{l_i\}_{i\in I}$ are linearly independent, where I denotes the set of compatibility conditions which are considered.

Remark 7.4. The smoothing of f_a by $\tilde{f}_a$ guarantees the existence of the second Fréchet derivative of $\mathcal{L}_c(x,\Lambda)$ with respect to x. Let us briefly comment on the second derivative of $\mathcal{L}_c(x,\Lambda^*)$ with respect to x if f_a were not replaced by $\tilde{f}_a$. The only difference arises in the term $\tilde{G}$, which is then given by

$$\tilde{G} : x \to \langle \lambda^*, N(\Delta u + f_a)\rangle_{H^1} + \frac{c}{2}|N(\Delta u + f_a)|_{H^1}^2.$$

In this case, $\tilde{G}$ is not twice continuously differentiable in general, however, we can show that $\tilde{G}$ has a second Fréchet derivative at (x^*,Λ^*) provided that λ^* satisfies additional regularity properties, for instance $\lambda^*_{yy} \in L^p(\Omega)$ for some $p > 1$. In this case

$$\tilde{G}_{aa}(a^*)(h,\tilde{h}) = (\rho_2 - \rho_1)\int_0^2 \lambda^*_y(x,a^*(x))h(x)\tilde{h}(x)dx + c(\rho_2 - \rho_1)^2\langle N(h\tau_{a^*}), N(\tilde{h}\tau_{a^*})\rangle_{H^1(\Omega)}.$$

We now turn to the second order sufficient optimality condition (7.5), which will be verified to hold for various combinations of the compatibility conditions $G_i(a) = A_i$. The estimate will depend on the regularization parameter β, and to emphazise this fact we change the notation from (x^*,Λ^*,μ^*) to $(x^\beta,\Lambda^\beta,\mu^\beta)$. So let x^β denote a solution of $(P^\beta), \beta > 0$ and let $\Lambda^\beta = (\lambda^\beta,\mu_1^\beta,\dots,\mu_4^\beta)$ denote an associated Lagrange multiplier. If only a subset of all four compatibilities is considered, then the corresponding coordinates μ_i^β are deleted from Λ^β; see also the comment before Proposition 5.3 in this respect. We give some preparatory lemmas.

LEMMA 7.5. *There exists a constant σ_4 independent of β such that*

$$|\lambda^\beta|_{H^1} \leq \sigma_4(|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + |\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*}). \tag{7.7}$$

If, moreover,

$$\sigma_0 \leq a^\beta(x) \leq 1 - \sigma_0 \quad \text{for some constant } \sigma_0 > 0 \tag{7.8}$$

and only $G_2(a) = A_2$ *is present in* $g(a,u) = 0$, *then*

$$|\mu_2^\beta| \le \sigma_4(|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + |\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*}). \tag{7.9}$$

The same result holds with $G_2(a) = A_2$ *replaced by* $G_4(a) = A_4$.

Proof. We employ (5.11) of Theorem 5.5 and Lemma A.6. We find

$$|\nabla\lambda^\beta|^2_{L^2(\Omega)} \le \sigma_1\sigma_3^2|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)}|\lambda^\beta|_{H^1(\Omega)}$$

and

$$\begin{aligned}\left|\int_\Gamma \tau_0\lambda^\beta d\Gamma\right| &\le \text{ const}|\tau_0\mathcal{N}(z_2 - \tau_1 u^\beta)|_{H^{1/2}(\Gamma)} \\ &\le \text{ const } \sigma_1\sigma_3|\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*},\end{aligned}$$

where const is independent of β. From Lemma A.6 we find

$$\begin{aligned}|\lambda^\beta|^2_{H^1(\Omega)} &\le \sigma_2^2\left[|\nabla\lambda^\beta|^2_{L^2(\Omega)} + \left|\int_\Gamma \tau_0\lambda^\beta d\Gamma\right|^2\right] \\ &\le \sigma_1\sigma_2^2\sigma_3^2(|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)}|\lambda^\beta|_{H^1(\Omega)} \\ &\qquad + \text{ const}^2\cdot\sigma_1|\tau_1 u^\beta - z_2|^2_{H^{1/2}(\Gamma)^*}) \\ &\le \sigma_1\sigma_2^2\sigma_3^2\left[\frac{1}{2}\left(\tilde\alpha^2|\tau_0 u^\beta - z_1|^2_{H^{1/2}(\Gamma)} + \frac{1}{\tilde\alpha^2}|\lambda^\beta|^2_{H^1(\Omega)}\right)\right. \\ &\qquad \left. + \text{ const}^2\cdot\sigma_1|\tau_1 u^\beta - z_2|^2_{H^{1/2}(\Gamma)}\right]\end{aligned}$$

for every $\tilde\alpha > 0$. Take $\tilde\alpha^2 = \sigma_1\sigma_2^2\sigma_3^2$, then

$$|\lambda^\beta|^2_{H^1(\Omega)} \le \sigma_1^2\sigma_2^2\sigma_3^2[\sigma_2^2\sigma_3^2|\tau_0 u^\beta - z_1|^2_{H^{1/2}(\Gamma)} + 2\text{ const}^2\cdot|\tau_1 u^\beta - z_2|^2_{H^{1/2}(\Gamma)^*}]$$

and we obtain

$$|\lambda^\beta|_{H^1(\Omega)} \le \sigma_1\sigma_2\sigma_3(\sigma_2\sigma_3|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + \sqrt{2}\text{ const}^2\cdot|\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*}).$$

To verify the second part of the lemma, let (7.8) hold and let $G_2(a) = A_2$ be the only compatibility condition that is considered. In this case $\eta^\beta = 0$ and from (5.12) it follows that

$$2\mu_2^\beta\langle a^\beta, h\rangle_{L^2(0,2)} + (\rho_2 - \rho_1)\langle h\tilde\tau_{a^\beta}, \lambda^\beta\rangle_{L^2(\Omega)} + \beta\langle a_x^\beta, h_x\rangle_{L^2(0,2)} = 0$$

for all $h \in H^1(0,2)$. Coosing $h = 1$ we obtain

$$\mu_2^\beta = \frac{\rho_1 - \rho_2}{2\langle a^\beta, 1\rangle_{L^2(0,2)}}\langle\tilde\tau_{a^\beta}, \lambda^\beta\rangle_{L^2(\Omega)},$$

and therefore

$$|\mu_2^\beta| \le \frac{|\rho_1 - \rho_2|^2}{4\sigma_0\alpha}|\lambda^\beta|_{L^1(\Omega)}.$$

In view of (7.7), σ_4 can now be modified such that (7.7) and (7.9) hold simultanously. The proof for $G_4(a) = A_4$ is analogous. □

LEMMA 7.6. *There exists* $\sigma_5 > 0$ *such that*

$$|h|_{H^1(0,2)} \leq \sigma_5 |h_x|_{L^2(0,2)}$$

for all $h \in \ker G_i'(a^\beta)$, *where* $i \in \{1,3\}$. *If* $a^\beta(x) \geq \sigma_0 > 0$, *then* σ_5 *can be chosen independently of* β *such that*

$$|h|_{H^1(0,2)} \leq \sigma_5 |h_x|_{L^2(0,2)} \tag{7.10}$$

for all $h \in \ker G_i'(a^\beta)$, *where* $i \in \{2,4\}$.

The proof is left to the reader.

Remark 7.7. The condition $a^\beta(x) \geq \sigma_0 > 0$ is sufficient, but not necessary, for (7.10) to hold. If, for example, the data (z_1, z_2) are attainable by a unique pair $(\hat{a}, \hat{u})$, then $a^\beta \to \hat{a}$ in $H^1(0,2)$ (see [CK]) and there exists $\hat{\beta} > 0$ such that (7.10) holds for all $\beta \in [0, \hat{\beta}]$.

LEMMA 7.8. *An element* $(h, v) \in \ker(g'(x^\beta))$ *with* $x^\beta = (a^\beta, u^\beta)$ *is characterized by*

$$\begin{aligned} \langle \nabla v, \nabla \varphi \rangle_{L^2(\Omega)} &= \langle \tau_1 v, \tau_0 \varphi \rangle_{H^{1/2}(\Gamma)^*, H^{1/2}(\Gamma)} \\ &\quad + (\rho_2 - \rho_1) \langle h \tilde{\tau}_{a^\beta}, \varphi \rangle \quad \textit{for all } \varphi \in H^1(\Omega) \end{aligned} \tag{7.11}$$

and

$$\langle l_i(a^\beta), h \rangle_{L^2(0,2)} = 0 \quad \textit{for } i = 1, \ldots, 4.$$

There exists σ_6 *independent of* β *such that*

$$\begin{aligned} |v|^2_{H^1(\Omega)} &\leq \sigma_6 (|\mathcal{D}(\tau_0 v)|^2_{H^1(\Omega)} + |\mathcal{N}(\tau_1 v)|^2_{H^1(\Omega)} + |h|^2_{H^1(0,2)}) \\ &\qquad \textit{for every } (h, v) \in \ker(g'(x^\beta)). \end{aligned} \tag{7.12}$$

Proof. The first part of the lemma follows from a simple calculation and we therefore turn directly to (7.12). Using Lemma A.6(v) we can show that

$$|\tau_1 v|_{H^{1/2}(\Gamma)^*} \leq \sqrt{2} \sigma_3 |\mathcal{N}(\tau_1 v)|_{H^1(\Omega)}, \tag{7.13}$$

and with a similar proof as for Lemma A.6(iv) there exists $\hat{\sigma}_5$ such that

$$|\varphi|^2_{H^1(\Omega)} \leq \hat{\sigma}_5 (|\nabla \varphi|^2_{H^1(\Omega)} + |\mathcal{D}(\tau_0 \varphi)|^2_{H^1(\Omega)}) \tag{7.14}$$

for all $\varphi \in H^1(\Omega)$. From (7.11) we find, by (7.13) and Lemma A.6(i),

$$\begin{aligned} |\nabla v|^2_{L^2(\Omega)} &\leq |\tau_1 v|_{H^{1/2}(\Gamma)^*} |\tau_0 v|_{H^{1/2}(\Gamma)} + \frac{|\rho_2 - \rho_1|}{\alpha} \int_\Omega |\tilde{\chi}_{a^\beta} h v| d\Omega \\ &\leq \sigma_1 \sigma_3 \sqrt{2} |v|_{H^1(\Omega)} |\mathcal{N}(\tau_1 v)|_{H^1(\Omega)} + \tilde{\sigma}_6 |h|_{H^1(0,2)} |v|_{H^1(\Omega)}, \end{aligned}$$

where $\tilde{\sigma}_6$ is independent of β. This estimate together with (7.14) implies the desired estimate (7.12). □

THEOREM 7.9. *Assume that*

$$\rho(\beta) = \frac{\beta}{2\sigma_5^2} - \tilde{\sigma}_4 (|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + |\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*}) > 0, \tag{7.15}$$

where $\tilde{\sigma}_4$ and σ_5 are constants independent of β specified in the proof. If (i) *only $G_2(a) = A_2$ or $G_4(a) = A_4$ with $0 < \sigma_0 \le a^\beta(x) \le 1 - \sigma_0$ are considered, or* (ii) *$G_2(a) = A_2$ and $G_4(a) = A_4$ are not present but at least one of the other compatibilities are considered, then*

$$J''(x^\beta)(y,y) + \langle \Lambda^\beta, g''(x^\beta)(y,y)\rangle_Y \ge \eta \min\Big(\frac{1}{4\sigma_3}, \frac{1}{2\sigma_6}\Big)|v|^2_{H(\Gamma,\Omega)} + \rho(\beta)|h|^2_{H^1(0,2)} \quad \text{for all } y = (h,v) \in \ker g'(x^*),$$

where $\eta = \min\Big\{\beta/\sigma_5^2, 1\Big\}$, i.e. (7.5) *holds.*

Proof. We consider (i) with the compatibility condition $G_4(a) = A_4$. For $y = (h,v) \in \ker g'(x^*)$,

$$\begin{aligned} Q(y) &= J''(x^\beta)(y,y) + \langle \Lambda^\beta, g''(x^\beta)(y,y)\rangle_Y \\ &= |\mathcal{D}(\tau_0 v)|^2_{H^1(\Omega)} + |\mathcal{N}(\tau_1 v)|^2_{H^1(\Omega)} + \beta|h_x|^2_{L(0,2)} \\ &\quad + \frac{\rho_2 - \rho_1}{\alpha}\int_0^2 \int_{a^\beta - \alpha/2}^{a^\beta + \alpha/2} \lambda^\beta_y(x,s)h^2(x)dsdx + 2\mu_4^\beta \int_0^2 xh(x)^2dx. \end{aligned}$$

By (7.13), (7.10), and (7.12) we find for every $\eta \in [0,1]$,

$$\begin{aligned} Q(y) \ge{}& \frac{\eta}{4\sigma_3}|\tau_1 v|^2_{H^{1/2}(\Gamma)^*} + \frac{\eta}{2\sigma_6}|v|^2_{H^1(\Omega)} + \Big(\frac{\beta}{\sigma_5^2} - \frac{\eta}{2}\Big)|h|^2_{H^1(0,2)} \\ &- \frac{|\rho_1 - \rho_2|}{\alpha}|\lambda^\beta|_{H^1(\Omega)} \cdot |h|^2_{L^4(\Omega)} - 4|\mu_4^\beta||h|^2_{L^2(0,2)}. \end{aligned} \tag{7.16}$$

By Lemma 7.5 there exists $\tilde{\sigma}_4$ independent of β such that

$$\begin{aligned} Q(y) \ge{}& \eta \min\Big(\frac{1}{4\sigma_3}, \frac{1}{2\sigma_6}\Big)|v|^2_{H(\Gamma,\Omega)} \\ &+ \Big[\frac{\beta}{\sigma_5^2} - \frac{\eta}{2} - \tilde{\sigma}_4(|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + |\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*})\Big]|h|^2_{H^1(0,2)}. \end{aligned}$$

Choosing $\eta = \min\{\beta/\sigma_5^2, 1\}$ so that $\eta \in (0,1]$ we find

$$\begin{aligned} Q(y) &\ge \eta \min\Big(\frac{1}{4\sigma_3}, \frac{1}{2\sigma_6}\Big)|v|^2_{H(\Gamma,\Omega)} \\ &\quad + \Big[\frac{\beta}{2\sigma_5^2} - \tilde{\sigma}_4(|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + |\tau_1 u^* - z_2|_{H^{1/2}(\Gamma)^*})\Big]|h|^2_{H^1(0,2)} \\ &= \eta \min\Big(\frac{1}{4\sigma_3}, \frac{1}{2\sigma_6}\Big)|v|^2_{H(\Gamma,\Omega)} + \rho(\beta)|h|^2_{H^1(0,2)}, \end{aligned}$$

which is the desired estimate. For the compatibility condition $G_2(a) = A_2$, the proof is almost indentical. In case of (ii) where any nontrivial combination of the linear compatibilities $G_i(a) = A_i, i \in \{1,3\}$ is considered, the second derivative of the Lagrangian term involving μ_i with $i \in \{1,3\}$ vanishes and the estimate becomes simpler. □

Remark 7.10. Assumption (7.15) is the weakest condition that we could find so far to obtain the conclusion of Theorem 7.9. It is unsatisfactory from the point of

view that in general we can only show that $|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + |\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*} = o(\sqrt{\beta})$ if (z_1, z_2) are attainable. Additional regularity conditions are required to improve the rate of convergence $|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + |\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*}$ to zero as $\beta \to 0^+$ [EKN], [N]. We do not investigate these aspects in this paper. Of course, (7.15) holds for values of β that are sufficiently large, since the set $\{|\tau_0 u^\beta - z_1|_{H^{1/2}(\Gamma)} + |\tau_1 u^\beta - z_2|_{H^{1/2}(\Gamma)^*} : \beta > 0\}$ is bounded.

8. Numerical examples. For the construction of a test example we proceed as follows.

Let

$$f_a(x,y) = \begin{cases} \rho_1 & \text{for } y > a(x), \\ \rho_2 & \text{for } y < a(x), (x,y) \in \mathbf{R}^2, \end{cases}$$

where $a \in H^2(\mathbf{R})$ and $a(x) \in [0,1]$ for $x \in [0,2]$. Let us denote

$$\Omega_a = \{(x,y) : -1 < x < 3, a(x) - 2 < y < a(x) + 2\},$$

and note that $\Omega_a \supset \Omega = (0,2) \times (0,1)$. It is well known that the two-dimensional fundamental solution of $-\Delta$ is given by $E(x-\tilde{x}, y-\tilde{y}) = -(1/4\pi)\log[(x-\tilde{x})^2+(y-\tilde{y})^2]$. The function $\tilde{u}$ defined by

$$\tilde{u}(x,y) = \int_{\Omega_a} E(x-\tilde{x}, y-\tilde{y}) f_a(\tilde{x},\tilde{y}) d\tilde{x} d\tilde{y}$$

satisfies

$$-\Delta \tilde{u} = f_a \quad \text{in } \tilde{\Omega}.$$

A calculation shows that

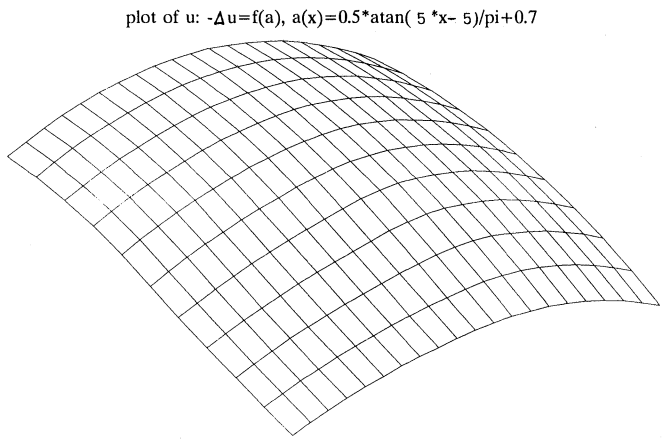
$$(8.1)\quad \begin{cases} \tilde{u}(x,y) &= -\dfrac{1}{4\pi}\displaystyle\int_{-1}^{3}\Big\{\rho_2\int_{-2}^{0}\log[(x-\tilde{x})^2+(y-\tilde{y}-a(x))^2]d\tilde{y} \\ &\qquad + \rho_1\displaystyle\int_{0}^{2}\log[(x-\tilde{x})^2+(y-\tilde{y}-a(x))^2]d\tilde{y}\Big\}d\tilde{x}, \\ \tilde{u}_x(x,y) &= -\dfrac{1}{2\pi}\displaystyle\int_{-1}^{3}\Big\{\rho_2\int_{-2}^{0}\frac{x-\tilde{x}}{(x-\tilde{x})^2+(y-\tilde{y}-a(x))^2}d\tilde{y} \\ &\qquad + \rho_1\displaystyle\int_{0}^{2}\frac{x-\tilde{x}}{(x-\tilde{x})^2+(y-\tilde{y}-a(x))^2}d\tilde{y}\Big\}d\tilde{x}, \\ \tilde{u}_y(x,y) &= -\dfrac{1}{2\pi}\displaystyle\int_{-1}^{3}\Big\{\rho_2\int_{-2}^{0}\frac{y-\tilde{y}-a(x)}{(x-\tilde{x})^2+(y-\tilde{y}-a(x))^2}d\tilde{y} \\ &\qquad + \rho_1\displaystyle\int_{0}^{2}\frac{y-\tilde{y}-a(x)}{(x-\tilde{x})^2+(y-\tilde{y}-a(x))^2}d\tilde{y}\Big\}d\tilde{x}. \end{cases}$$

Defining

$$z_1 = \tau_0 \tilde{u} \qquad \text{and} \qquad z_2 = \tau_1 \tilde{u}$$

provides exact data, which are attainable by the function a. For the test example we choose

$$a(x) = \frac{1}{2\pi}\arctan(5x-5) + 0.7.$$



N=10, meshdom: 20x10

FIG. 2.

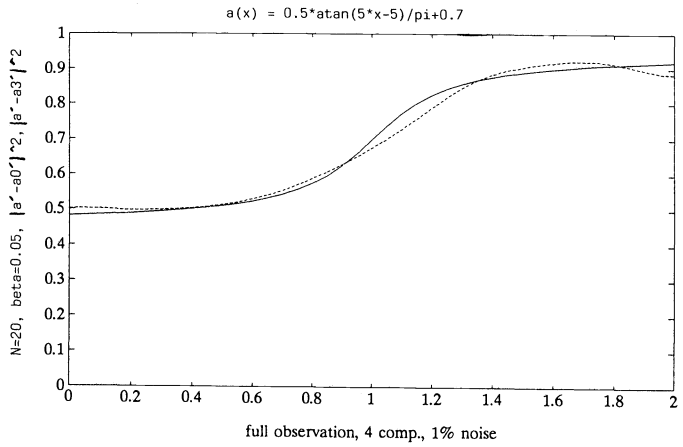


FIG. 3.

For the discretization of the variable $u \in H^1(\Omega)$ we use bilinear finite elements with respect to the grid $\{(i/N, j/N) : i = 0, \ldots, 2N; j = 0, \ldots N\}$, and the function $a \in H^1(0,2)$ was discretized by piecewise linear elements with respect to the grid $\{i/N, i = 0, \ldots, 2N\}$. A ten-point Gaussian-quadrature formula was used to calculate the exact data from (8.1). Further specifications for the numerical result of Fig. 3 to be presented below are as follows:

(i) $\rho_1 = 1, \rho_2 = 20$;

(ii) $N = 20$;

(iii) all four compatibilites are used;

(iv) observations are taken on all four sides of the rectangle;

(v) the regularization term has the form $\beta|a_x - a_x^0|^2$, with $\beta = 0.05$ and a^0 chosen such that the compatibility conditions hold;

(vi) the data are perturbed by adding 1% uniformly distributed relative noise at the nodal points of the observations (z_1, z_2).

Numerically, a^0 is calculated by solving (3.6) in the least-squares sense with start-up by a constant function with value .05. To illustrate the difficulty of the inverse

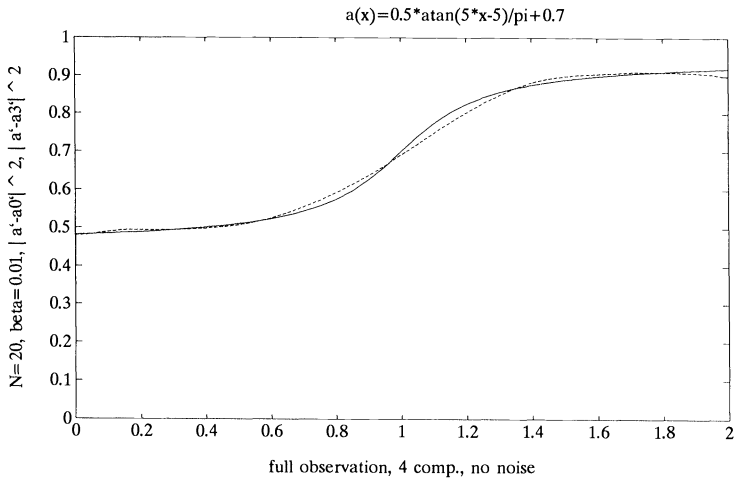

FIG. 4.

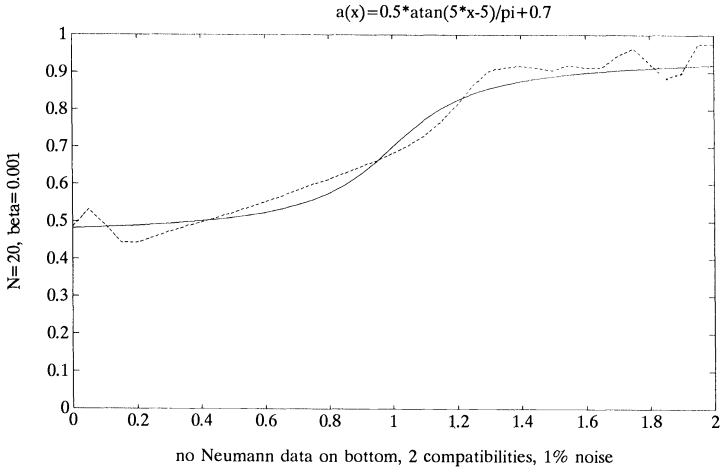

FIG. 5.

problem, a graph of $\tilde{u}$ on Ω is given in Fig. 2. The unperturbed data are obtained by evaluation of $\tilde{u}$ on the boundary Γ. Clearly, these data are extremely smooth thus making the inverse problem a difficult one. In Fig. 3 the solid line shows the exact function a and the dotted line gives the numerical result after three iterations. Observe that the scaling of the axis in the plot is not 1:1. It magnifies the error to our disadvantage.

For Fig. 4 all specifications are identical to those for Fig. 3, except for taking noise-free data and simultaneously decreasing the regularization parameter to $\beta = .01$. For the results of Fig. 5 only two compatibility conditions (the second and the fourth in (3.6)) and no Neumann data on the bottom are used. Moreover, the regularization term is changed to $\beta|a_x|^2$, which requires us to choose a smaller value for β. Here we take $\beta = .001$. As expected, the numerical reconstruction for a is now worse than in the two previous figures. Analyzing the effects of the changes between the specifications of the algorithm between Figs. 3 and 5 one at a time, it is found that

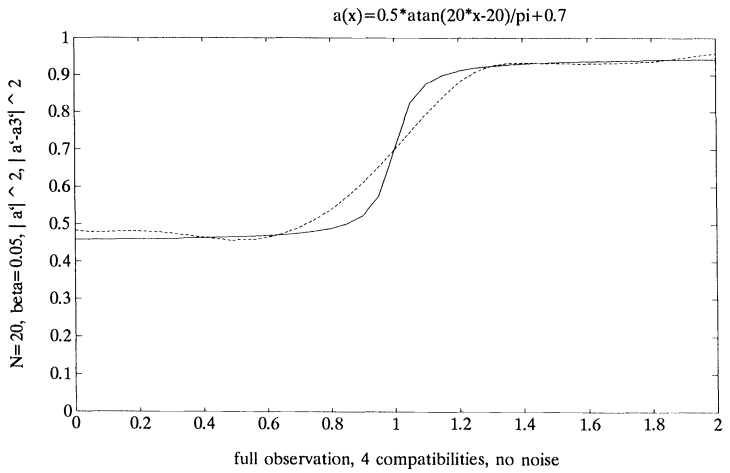

FIG. 6.

both changing the regularization term and using only two instead of four compatibility conditions contribute to the loss of accuracy. However, the former has less effect than the latter.

Returning once again to the result of Fig. 3, we recall that the compatibility conditions are used in three ways. First, they determine a very good start-up value for the first minimization with respect to a, as explained in Remark 6.1 (iii)–(iv).

Secondly, this start-up value is also used in the regularization term, and finally, the compatibility conditions are used as explicit constraints. We also tested the algorithm without the use of any compatibility condition, and using $a^\circ \equiv .5$ as a start-up value. The results (depending on various algorithmic parameters) vary from divergence to giving a qualitatively correct reconstruction of the unknown function, at best.

Figure 6 gives the numerical result in the case that the "true" inface function is given by

$$a(x) = \frac{1}{2\pi} \arctan(20x - 20) + 0.7,$$

which behaves almost like a discontinuity. The remaining specifications are those of Fig. 3 except that no noise is added.

Appendix. In this appendix we summarize facts on elliptic equations that are needed for this paper. For details we refer to [Ad], [G], [W]. Unless stated otherwise, Ω denotes an open subset of $\mathbf{R}^2$ whose boundary is a curvilinear polygon consisting of arcs $\Gamma_j, j = 1, \ldots, N$, [G], with outward normals w_j. We define $H(\Delta, \Omega) = \{u \in H^1(\Omega) : \Delta u \in L^2(\Omega)\}$.

LEMMA A.1 [G]. *Let Ω be a bounded open subset of $\mathbf{R}^2$ whose boundary is a curvilinear polygon of class $C^{1,1}$. Then for each j, the mapping*

$$u \to \left\{ u|\Gamma_j, \frac{\partial u}{\partial n}|\Gamma_j \right\},$$

which is well defined for $u \in \mathcal{D}(\bar{\Omega})$, has a unique continuous extension as an operator from $H^2(\Omega)$ into $\Pi_{i=0}^1 H^{3/2-i}(\Gamma_j)$. If, moreover, the boundary Γ of Ω is Lipschitzian, then $u \to u|\Gamma$ has an extension as a unique continuous operator from $H^2(\Omega)$ onto $H^{1/2}(\Gamma)$.

LEMMA A.2 [G]. *Let $u \in H^2(\Omega)$ and let Ω be divided into two regions Ω_1 and Ω_2 by a piecewise $C^{1,1}$ Jordan curve $\hat{\Gamma} = \bigcup_{j=1}^{p} \bar{\Gamma}_j$. Then for any smooth part of Γ the following transmissivity conditions hold:*

$$u^1|\Gamma_j = u^2|\Gamma_j \quad \text{and} \quad \frac{\partial u^1}{\partial n_j}\bigg|\Gamma_j = \frac{\partial u^2}{\partial n_j}\bigg|\Gamma_j, \quad j = 1, \dots, p,$$

where $u^1 = u|\Omega_1, u^2 = u|\Omega_2$, and n_j is normal to Γ_j and pointing into Ω.

LEMMA A.3 (Green's formula [DL], [G], [GR]). *For every $u \in H^2(\Omega)$ with Ω a polygonal domain we have*

$$\int_\Omega (\Delta u) v \, dx = -\int_\Omega \nabla u \cdot \nabla v \, dx + \sum_{j=1}^{N} \int_{\Gamma_j} \gamma_j \frac{\partial u}{\partial n_j} \gamma_j v \, dv,$$

where γ_j is the trace operator onto Γ_j. If the boundary Γ of Ω is Lipschitz continuous, then the Neumann boundary operator τ_1 has a unique continuous extension, again denoted by τ_1 from $H(\Delta, \Omega)$ to $H^{1/2}(\Gamma)^*$, and the generalized Green's formula

$$\langle \tau_1 u, v \rangle_{H^{1/2}(\Gamma)^*, H^{1/2}(\Gamma)} = \int_\Omega \Delta u \cdot v \, dx + \int_\Omega \nabla u \cdot \nabla v \, dx$$

holds for all $v \in H^1(\Omega)$.

LEMMA A.4. *The space $H^2(\Omega)$ is continuously embedded into $C^{0,1}(\bar{\Omega})$.*

LEMMA A.5. *Let Ω be a convex polygon $f \in L^2(\Omega)$ and $g \in C(\partial\Omega)$ with $g|\Gamma_j \in H^{3/2}(\Gamma_j)$. Then there exists a unique solution $u \in H^2(\Omega)$ of*

$$\begin{aligned} -\Delta u &= f \quad \text{in } \Omega, \\ u|\Gamma_j &= g|\Gamma_j, \qquad j = 1, \dots, N. \end{aligned} \tag{A.1}$$

Proof. By [G, p. 50] there exists an extension $\tilde{g} \in H^2(\Omega)$ of g such that $\tilde{g}|\Gamma_j = g|\Gamma_j$ for all j. Consider the equation

$$-\Delta w = f + \Delta \tilde{g} \qquad w|\partial\Omega = 0.$$

It has a unique solution $w \in H^2(\Omega)$ [G, p. 147], and $u = w + \tilde{g}$ is the desired solution of (A.1). □

LEMMA A.6. *Let $\Omega = \{(x, y) \in \mathbf{R}^2 : 0 < x < 2, 0 < y < 1\}, \Gamma = \partial\Omega$, and $\Gamma_a = \{(x, y) \in \Omega : y = a(x)\}$. Then there exist constants σ_i such that*

(i) $|\varphi|_{H^{1/2}(\Gamma)} \le \sigma_1 |\varphi|_{H^1(\Omega)}$ *for all* $\varphi \in H^1(\Omega)$;

(ii) $|\partial\varphi/\partial n|_{H^{1/2}(\Gamma)^*} \le \sigma_1 \Big(|\varphi|_{H^1(\Omega)} + |\Delta\varphi|^2_{L^2} \Big)^{1/2}$ *for all* $\varphi \in H(\Delta, \Omega)$;

(iii) *the embedding of $H^1(0, 2)$ into $C^0([0, 2])$ is compact*;

(iv) $|\varphi|^2_{H^1(\Omega)} \le \sigma_2^2 (|\nabla\varphi|^2_{L^2(\Omega)} + |\int_\Gamma \varphi \, d\Gamma|^2)$ *for all* $\varphi \in H^1(\Omega)$;

(v) $|\mathcal{D}\varphi|_{H^1(\Omega)} \le \sigma_3 |\varphi|_{H^{1/2}(\Omega)}$ *for all* $\varphi \in H^{1/2}(\Gamma)$, $|\mathcal{N}\varphi|_{H^1(\Omega)} \le \sigma_1 |\varphi|_{H^{-1/2}(\Gamma)}$ *for all* $\varphi \in H^{-1/2}(\Gamma)$.

Proof. (i)–(iii) are well-known trace and embedding properties (see [Ad], [DL, p. 380]). (iv) is a Poincaré type inequality (we refer to [DL, p. 127–133]). (v) can be verified with standard coercivity-type estimates. □

FEEDBACK STABILIZATION OVER COMMUTATIVE RINGS: THE MATRIX CASE*

V. R. SULE†

Abstract. This paper provides a solution of the feedback stabilization problem over commutative rings for *matrix transfer functions*. Stabilizability of a transfer matrix is realised as local stabilizability over the entire spectrum of the ring. For stabilizable plants, certain modules generated by its fractions and that of the stabilizing controller are shown to be projective compliments of each other. In the case of rings with irreducible spectrum, this geometric relationship shows that the plant is stabilizable if and only if the above modules of the plant are projective of ranks equal to the number of inputs and the outputs. If the maxspectrum of the ring is Noetherian and of zero (Krull) dimension, then this result shows that the stabilizable plants have doubly coprime fractions. Over unique factorization domains the above stabilizability condition is interpreted in terms of matrices formed by the fractions of the plant. Certain invariants of these matrices known as *elementary factors*, are defined and it is shown that the plant is stabilizable if and only if these elementary factors generate the whole ring. This condition thus provides a generalization of the coprime factorizability as a condition for stabilizabilty. A formula for the class of all stabilizing controllers is then developed that generalizes the previous well-known formula in factorization theory. For multidimensional transfer functions these results provide concrete conditions for stabilizabilty. Finally, it is shown that the class of polynomial rings over principal ideal domains is an additional class of rings over which stabilizable plants always have doubly coprime fractions.

Key words. feedback stabilization, coprime factorization, multidimensional systems

AMS subject classifications. 93D15, 93D25

1. Introduction.

The factorization approach to control systems over the past decade has provided important insights into the synthesis problems of linear control systems. The approach essentially emerged from the ring theoretic formulations of the feedback stabilization problem in [4] and [15] to obtain the algebraic characterization of the stabilizing controller on the lines of [16] and that of the achievable feedback system maps. However, this entire theory is founded on the coprime factorizability of transfer functions, a property always satisfied by transfer matrices over the fields of fractions of rings such as the principal ideal domain (PID) or the Bezout domain. This is the case, for example, in the stabilization of linear time-invariant transfer functions. This property fails for transfer functions having fractions over more general integral domains. In fact, in the well-known cases of n-dimensional systems and spatially distributed systems, the transfer functions belong to the fraction fields of unique factorization domains (UFDs), which do not always admit coprime fractions. Furthermore, some of the practically important problems, such as parametric scheduling of feedback controllers, involve transfer functions over several indeterminates for which coprime factorizability is not assured. For these reasons it seems worthwhile to develop a more general factorization theory of feedback systems which will encompass such examples. Thus, questions such as 1) *what are the necessary and sufficient conditions for stabilizability over a general commutative ring*? and 2) *if a plant is stabilizable, then what is the characterization of its stabilizing controllers*? need to be answered.

Recall that the coprime factorization theory (see [14]) which we refer to as the *standard factorization theory*, shows that the existence of doubly coprime fractions is

* Received by the editors October 7, 1991; accepted for publication (in revised form) April 30, 1993.

† Department of Electrical Engineering, Indian Institute of Technology, Kanpur 208 016, India.

sufficient for stabilization and characterization of the stabilizing controller. Moreover, one of the problems considered in this theory over general integral domains is to show existence of the doubly coprime fractions when any one, either left or right coprime fraction, exists. Hence for polynomial rings, an application of the celebrated Quillen–Suslin theorem shows that this is precisely true. See [14, Chap. 8] for details.

Our goal in this paper is, however, quite distinct from that of the above problems of the standard factorization theory. Primarily, our aim is to determine under what conditions a plant transfer matrix is stabilizable under the most natural fractional representation, so that these conditions also work even when coprime fractions do not exist. Next, we want to find a class of rings for which stabilizability will imply an existence of doubly coprime fractions. Thus for this class of rings, the parametrization of the controller and the achievable feedback maps will be identical to that of the standard factorization theory. Finally, we should also be able to determine the characterization of all stabilizing controllers in some concrete form in special cases of interest.

Although most rings of transfer functions needed thus far in feedback theory are integral domains, for the sake of generality, main results in this paper are developed for more general commutative rings with certain weak restrictions on the spectrum.

1.1. Previous background. The two-dimensional stabilization problem is considered in [2] for both the scalar as well as the matrix case. In [2] it is shown that the two-dimensional transfer matrices are stabilizable with the unit bidisc $\bar{U}^2$ as the domain of instability if and only if they have doubly coprime fractions. The standard coprime factorization theory of stabilization is also developed in [14, Chap. 8] for integral domains. Apart from [14, Chap. 8], the application of the Quillen–Suslin theorem is also considered in [5]. Formulation of the stabilization problem in [2] and [14] is purely in the input-output sense, where coprime factorizability of the transfer matrix plays a major role. In [8] relations between coprime factorizability and properties of split realizations are developed for rational transfer matrices over commutative rings.

For the case of scalar (i.e., single input, single output) plants, the stabilization problem over a general integral domain is solved in [13] and the conditions for stabilizability are developed in terms of coprimeness of ideals rather than in terms of fractions. Further, it is shown in [13] that the geometric interpretations for the n-dimensional case can be obtained for domains of instability that are *polynomially convex*. The purpose of this paper is to solve the corresponding matrix (i.e., multi input, multi output) case of the problem. This extension of the results of [13], which are primarily based on commutativity, to the matrix case should provide some insight into the noncommutative version of this problem.

1.2. Preview of results and organization of the paper. This section is devoted to the definition of the stabilization problem solved in the later sections as well as the relevant mathematical background and notations.

In §2 an algebraic formulation of the problem is developed. A linear system of equations is determined in Propositon 1 whose solution completely determines the solution of the stabilzation problem. Local solvability of this system of equations is then defined as local stabilizability, and it is shown in Proposition 2 that local stabilizability over the entire spectrum of the ring is equivalent to stabilizability. Analysis of these equations also reveals equivalence classes of plant transfer matrices whose stabilizability is determined by that of a given plant. Finally, an ideal theoretic interpretation of stabilizability of the plant is developed in Proposition 4, which generalizes the scalar result of [13].

Some of the main results are collected in §3. Lemma 2 shows that modules $\mathcal{T}$ and $\mathcal{W}$ determined by the fractions of the plant transfer matrix are projective complements of the similar modules of its stabilizing controller. Then it is shown that the plant has coprime fractions if and only if these modules of the plant are free. This observation, along with the local stabilizability, is then employed to show in Theorem 1 that if the spectrum of the ring is irreducible, then the plant is stabilizable if and only if the above modules are projective, of ranks equal to the number of inputs and outputs, respectively. This result is thus a geometrically necessary and sufficient condition for stabilizability over such rings. Finally, the problem of determining a class of rings for which these projective modules become free is addressd. A well-known theorem of Forster and Swan is used to show in Theorem 3 that these modules are free when the maxspectrum of the ring is Noetherian and has zero dimension. Thus, for this class of rings, stabilizability of a transfer matrix implies its coprime factorizability.

In §3.3 these results are developed further over unique factorization domains. A local-global characterization of projective modules is employed to determine a concrete interpretation of stabilizability in terms of certain invariants of the plant, called the *elementary factors*. Theorem 4 shows that the plant is stabilizable if and only if these elementary factors are coprime. A formula parametrizing all stabilizing controllers is then developed for this case.

Section 4 is devoted to the application of the above results for the problem of n-dimensional stabilization as well as for other classes of rings. Numerical examples are provided in which the stabilizability is checked by computing the elementary factors.

Next, an application of the well-known result of Quillen and Suslin is made to show that for polynomial rings over PIDs, stabilizable plants always have doubly coprime fractions. This result thus enlarges the class of rings for which the above modules are free, even when they may not have Noetherian and zero-dimensional maxspectrum. Finally, it is shown that the above theory specializes to the well-known standard factorization theory for PIDs and Bezout domains.

1.3. Stabilization problem. We begin by defining the stabilization problem for the standard feedback system considered in [14, Chap. 1, Fig. 1.2]. The reader is referred to [14] for all other details as these are well known. Let $\mathcal{A}$ be a commutative ring (with identity) denoting the ring of *stable causal* transfer functions and let $\mathcal{F}$ be its *total ring of fractions* (see notations below) denoting the class of all transfer functions. Let P, called the *plant transfer matrix*, belong to $\mathcal{F}^{n\times m}$, the set of $n \times m$ matrices over $\mathcal{F}$. Observe that P can always be represented in the form of a fraction $P = Nd^{-1}$, where N is an $n \times m$ matrix over $\mathcal{A}$ and d is a nonzero divisor. Let $\hat{F}$ denote the set $\mathcal{F}^{n\times m} \times \mathcal{F}^{m\times n}$ and consider $\hat{F}_{\text{ad}} \subset \hat{F}$ defined as

$$\hat{F}_{\text{ad}} = \{(X, Y) \in \hat{F} \mid \det(I + XY) \text{ is a unit of } \mathcal{F}\}.$$

Consider $(P, C) \in \hat{F}_{\text{ad}}$ and the map $H : \hat{F}_{\text{ad}} \longrightarrow \mathcal{F}^{(m+n)\times(m+n)}$ defined by

$$H(P,C) \triangleq \begin{pmatrix} (I+PC)^{-1} & -P(I+CP)^{-1} \\ C(I+PC)^{-1} & (I+CP)^{-1} \end{pmatrix}.$$

The stabilization problem. If the plant transfer matrix P belongs to $\mathcal{F}^{n\times m}$, when does there exist a *controller* C belonging to $\mathcal{F}^{m\times n}$ such that

1. $(P, C) \in \hat{F}_{\text{ad}}$, and
2. $H(P, C) \in \mathcal{A}^{(m+n)\times(m+n)}$?

Further, if such a C exists, what is the characterization of all such controllers? Call a plant *stabilizable* if, for its transfer function P, there exists such a C. Call C its *stabilizing controller.*

The significance of the above problem in the algebraic theory of linear feedback systems is by now quite well known and can be found in [2], [4], [14], and [15], as well as references therein. The above ring theoretic formulation of the problem of stabilizing the dynamics of a linear control system by means of a dynamic feedback was developed in [4] and [15], following its actual origin in [16]. When a controller C is a solution of the problem, the resulting feedback system is also called *externally stable* and produces bounded outputs from all the transfer functions for bounded external inputs. It is now well known that the external stability of such a feedback system also implies the stability of the dynamics, called *internal stability*, for a large class of linear systems. However, the ring theoretic stabilization problem in the above form is mathematically of a different variety and is more concerned with the structural aspects of the feedback system map $H(P, C)$, above. Its relevance to an internal state space realization (as dynamic system) has been shown in [8] for rational transfer matrices over rings. In this paper we restrict ourselves to the above form of the stabilization problem and do not attempt to relate it to state-space theoretic results.

Finally, for convenience, the problem defined above does not refer to the causality of the feedback controller C. However, following [2], [4], [15], causal transfer functions can be considerd in a ring of fractions that forms a subring of $\mathcal{F}$. In fact, since our primary goal in this paper is to study the stabilizability of a transfer matrix, causality of this matrix is not of much significance here, since it does not affect its stabilizability. We consider this condition in the following sections to show that all the solutions C of the above problem, when they exist, are causal if the plant P is strictly causal.

1.4. Notations and background results. The following notations and results are used throughout the paper. These are mentioned only briefly, as all are readily available in the standard texts indicated.

Total rings of fractions [1]. Let $\mathcal{A}$ be a commutative ring and $D \subset \mathcal{A}$ the set of all zero divisors of $\mathcal{A}$. The set $S = A - D$ is a *saturated multiplicatively closed* (MC) subset, and the *ring of fractions* $S^{-1}\mathcal{A}$ is called the *total ring of fractions* of $\mathcal{A}$. Total rings of fractions for our purpose are best, next to integral domains, for if $\mathcal{A}$ is an integral domain, then $\mathcal{F} = S^{-1}\mathcal{A}$ is its field of fractions. In the total ring of fractions $S^{-1}\mathcal{A}$, elements ab^{-1}, cd^{-1} are equal if and only if $ad - bc = 0$. The spectrum of $\mathcal{A}$ is denoted by spec $\mathcal{A}$ and its closed sets by $V(a)$ for an ideal $a \subset \mathcal{A}$. For $\mathrm{p} \in$ spec $\mathcal{A}$, the local ring at p is denoted by $\mathcal{A}_{\mathrm{p}}$. It is the ring of fractions $S^{-1}\mathcal{A}$ when the set $S = \mathcal{A} - \mathrm{p}$. Similarly, the localization of an $\mathcal{A}$-module M is denoted by M_{p}. If f in $\mathcal{A}$ is not nilpotent, then the ring of fractions with respect to the multiplicative subset $\{1, f, f^2, \ldots\}$ is denoted by $\mathcal{A}_f$. Its spectrum is homeomorphic to the open set $D(f) =$ spec $\mathcal{A} - V(f)$. Also, the maxspectrum of $\mathcal{A}$ is denoted by max $\mathcal{A}$. The *Jacobson's radical* of a commutative ring is the intersection of all its maximal ideals.

Matrix theory [12]. For a $p \times q$ matrix M with entries over a commutative ring $\mathcal{A}$, the ideal generated by the $k \times k$ minors of M is denoted by $I_k(M)$. By definition, $I_0 = \mathcal{A}$ and $I_t = 0$ for $t > \min(p, q)$. These ideals satisfy the chain $\mathcal{A} \supseteq I_1(M) \supseteq I_2(M) \supseteq \cdots \supseteq I_t(M) \supseteq 0$. A square matrix M is called *singular* if its determinant is a zero divisor of $\mathcal{A}$. For square M, the linear system of equations $Mx = 0$ over $\mathcal{A}$ has a nontrivial solution if and only if M is singular. We frequently refer to the Binet–Cauchy formula for the determinant of a product of matrices in terms of its maximal order minors. This formula is referred from [12, p. 21].

Matrix rings [11]. The ring of $n \times n$ matrices over a commutative ring $\mathcal{A}$ is denoted by $(\mathcal{A})_n$, while a_{R} and a_{L} denote its left and right ideals, respectively. Two-sided ideals are denoted without suffixes. For any right ideal $a_{\mathrm{R}} \subset (\mathcal{A})_n$, the *idealizer ring* of a_{R} is

$$\mathcal{I}(a_{\mathrm{R}}) = \{X \in (\mathcal{A})_n \mid Xa_{\mathrm{R}} \subseteq a_{\mathrm{R}}\}.$$

The center Z of $(\mathcal{A})_n$ belongs to $\mathcal{I}(a_{\mathrm{R}})$. Moreover $\mathcal{I}(a_{\mathrm{R}})$ is the largest subring of $(\mathcal{A})_n$ containing a_{R} as a two-sided ideal. Idealizer rings of left ideals are defined similarly.

Projective modules [9]. An $\mathcal{A}$-module M is called *projective* if it is a direct summand of a *free* $\mathcal{A}$-module, i.e., there is a module N such that $M \oplus N$ is free. The module N is then called its *projective complement*. For a *finitely generated* (or *finite*) projective module M, the projective complement N is also finite and $M \oplus N \simeq \mathcal{A}^n$ for some finite n. For a finite projective module M, the number of generators in a shortest system of generators (also called a *minimal generating system*) is denoted by $\mu(M)$. For a finite module M, $\mu_{\mathrm{p}}(M)$, for $\mathrm{p} \in \operatorname{spec} \mathcal{A}$, denotes the number of generators in a minimal generating system of the A_{p}-module M_{p} and is also called the *rank* of M at p. M is said to have a (constant) *rank* r if $\mu_{\mathrm{p}}(M) = r$ for all $\mathrm{p} \in \operatorname{spec} \mathcal{A}$. One of the standard results on projective modules used in the sequel is as follows (see [9, Chap. 4, §3] for details).

LEMMA 1. *If M is a finitely generated projective $\mathcal{A}$-module, then M_{p} is a free A_{p}-module, for all* p *in* spec $\mathcal{A}$.

2. Linear system of equations. In this section we develop a linear system of equations over the ring $\mathcal{A}$ whose solution determines the solution of the stabilization problem. However, observe that the stabilization problem defined above does not refer to the *causality* of the plant P or the controller C, which is an important physical constraint. In this respect we follow [2] and [15] and consider the set of causal transfer functions to be a ring of fractions contained in the ring $\mathcal{F}$ of all transfer functions. Thus consider a multiplicatively closed subset $R \subset S$ and let $R^{-1}\mathcal{A} \subset \mathcal{F}$ to be the ring of *causal* transfer functions. Observe that since $R \subset S$, it does not contain any zero divisors of $\mathcal{A}$. Next, we follow again [2], [15] and consider the set of strictly causal transfer functions as the Jacobson's radical of this ring of causal transfer functions. Hence let $\mathcal{J}$, the Jacobson's radical of $R^{-1}\mathcal{A}$, denote the set of *strictly causal* transfer functions. It is well known that this formulation of causal (strictly causal) transfer functions specializes to the familiar notion of proper (strictly proper) transfer functions of linear time-invariant systems. We extend these ideas for matrix transfer functions as follows.

DEFINITION 1. *A matrix M in $\mathcal{F}^{n\times m}$ is called causal if M has all entries in $R^{-1}\mathcal{A}$. A causal matrix M is called strictly causal if $I_t(M) \subseteq \mathcal{J}$, where $t = \min(n, m)$.*

Thus if $P = Nd^{-1}$ is strictly causal, then, since $d \in R$, the ideal $I_t(N)$ is contained in all maximal ideals of $\mathcal{A}$ which do not intersect R. Hence N treated as a matrix over $R^{-1}\mathcal{A}$ has $I_t(N) \subseteq \mathcal{J}$. Clearly, for 1×1 matrices we obtain a specialization of the above to familiar notions of causal and strictly causal transfer functions.

2.1. Linear system of equations and stabilizability. Consider an arbitrary fractional representation $P = Nd^{-1}$ for P. Any other fraction $P = Ab^{-1}$ satisfies $Ad - Nb = 0$. Fixing one fraction Nd^{-1} we have the following proposition.

PROPOSITION 1. *A strictly causal plant $P = Nd^{-1}$ is stabilizable if and only if there exists a solution $X \in (\mathcal{A})_n$, $U \in \mathcal{A}^{n\times m}$, $Y \in \mathcal{A}^{m\times n}$, and $W \in (\mathcal{A})_m$ for the*

equations

$$\begin{aligned} XN &= Ud, \\ YN &= Wd, \\ NY &= (I - X)d. \end{aligned} \tag{1}$$

Moreover, 1) *if* P *is stabilizable, then any stabilizing controller has the form* $C = YX^{-1}$, *where* Y, X *satisfy* (1), *and* 2) *conversely, if* (1) *has a solution* X, Y, *then* $\det X \in R$ *and* $C = YX^{-1}$ *is a stabilizing controller.*

Proof. First, the proof is by necessity and 1). Let an $m \times n$ matrix C over $\mathcal{F}$ be a stabilizing controller of P. Then $H(P, C)$ has all entries in $\mathcal{A}$. Call $(I + PC)^{-1} = X$, $C(I + PC)^{-1} = Y$, $P(I + CP)^{-1} = U$, and $(I + CP)^{-1} = I - W$. Clearly, since P is strictly causal, it follows that $\det (I + PC)^{-1}$ is a unit of $R^{-1}\mathcal{A}$. Hence $\det X \in R \subset S$. Also $C = Y(I + PC) = YX^{-1}$.

Now, $U = (I + PC)^{-1}P = XNd^{-1} \Leftrightarrow XN = Ud$.

Next, $I - W = I - C(I + PC)^{-1}P = I - YNd^{-1} \Leftrightarrow YN = Wd$.

Finally, $X = I - PC(I + PC)^{-1} \Leftrightarrow NY = (I - X)d$.

Second, the proof is by sufficiency and 2). Let (1) have a solution X. Consider the equation $NY = (I - X)d$ as an equation over $R^{-1}\mathcal{A}$ taking the denominator fractions as the identity. Since $I_t(N) \subseteq \mathcal{J}$, using the Binet–Cauchy formula it follows that $I_n(NY) = (\det (NY)) \subseteq \mathcal{J}$. Hence $\det (I - X)d$ is also in $\mathcal{J}$, which implies that $\det X \in R$ as d is a unit of $R^{-1}\mathcal{A}$. Hence $C = YX^{-1}$ is causal. For any such C, we have $(I + PC)^{-1} = Xd(dX + NY)^{-1} = dX(dX + (I - X)d)^{-1} = X$, i.e., $(I + PC)^{-1}$ belongs to $(\mathcal{A})_n$. Similarly it can be easily verified that all other entries of $H(P, C)$ belong to $\mathcal{A}$, which shows that C above stabilizes P. □

Thus the stabilizability of a strictly causal P by the above is equivalent to the solvability of (1). Moreover, every stabilizing controller is also causal. The result holds only for strictly causal P in this general case. Later, for integral domains, we relax this condition (see §4). At this stage it may be worthwhile to observe that if any other fractions $P = Ab^{-1}$ are used instead of Nd^{-1}, then $XN = Yd \Leftrightarrow XNb = Ydb \Leftrightarrow XA = Yb$ as both d and b are nonzero divisors if X, Y satisfy $XN = Yd$, since $Nb = Ad$ (identical arguments for $NX = Yd$). Thus solutions of (1) are invariant with respect to the choice of fractions of P. The above proposition is essentially just a reformulation of the well-known Q-parametrization in feedback stabilization.

2.1.1. Local stabilizability. The definition of stabilizability can be generalised as follows. Since $H(P, C)$ in the stable system has all entries in $\mathcal{A}$, we call the above notion $\mathcal{A}$-stabilizability. Hence for certain ring homomorphisms $f : \mathcal{A} \longrightarrow \mathcal{B}$, we can obtain $\mathcal{B}$-stabilizability. Using this idea, the following notion of stabilizability is obtained. Let $\mathcal{F}(\mathcal{B})$ denote the total ring of fractions of a ring $\mathcal{B}$. For the local ring $\mathcal{A}_{\mathrm{m}}$ at any maximal ideal m, it follows that a matrix P over $\mathcal{F}$ also belongs to $\mathcal{F}(\mathcal{A}_{\mathrm{m}})$.

DEFINITION 2 (Local stabilizability). *A matrix* P *belonging to* $\mathcal{F}^{n\times m}$ *is locally stabilizable at a maximal ideal* m *of* $\mathcal{A}$ *if there is a* C *in* $\mathcal{F}^{m\times n}$ *such that*

1. $\det H(P, C)$ *is a unit of* $\mathcal{F}(\mathcal{A}_{\mathrm{m}})$, *and*
2. *the matrix* $H(P, C)$ *has all entries in* $\mathcal{A}_{\mathrm{m}}$.

PROPOSITION 2. *A strictly causal* P *is stabilizable if and only if* P *is locally stabilizable at all maximal ideals of* $\mathcal{A}$.

Proof. First, the proof is by necessity. Let C be a stabilizing controller. Then $\det (I + PC)^{-1}$ is a nonzero divisor of $\mathcal{A}$ hence, treated as an element of $\mathcal{A}_{\mathrm{m}}$ also a nonzero divisor of $\mathcal{A}_{\mathrm{m}}$ and consequently a unit of $\mathcal{F}(\mathcal{A}_{\mathrm{m}})$ for any maximal ideal m.

Since all entries of $H(P,C)$ belong to $\mathcal{A}$ they also belong to $\mathcal{A}_{\mathrm{m}}$. Thus P is locally stabilizable at any m.

Second, the proof is by sufficiency. Imitating the steps of the necessity part of the proof of Proposition 1 with $\mathcal{A}$ replaced by $\mathcal{A}_{\mathrm{m}}$ and $\mathcal{F}$ replaced by $\mathcal{F}(\mathcal{A}_{\mathrm{m}})$, it follows that the linear system of equations is described over $\mathcal{A}_{\mathrm{m}}$ and has solutions of X, Y, U, W, with all entries in $\mathcal{A}_{\mathrm{m}}$.

Now we use a well-known result [12, p. 92] on linear systems of equations, which shows that a linear system of equations $Ax = b$ over a commutative ring $\mathcal{A}$ has a solution if and only if it has a solution over $\mathcal{A}_{\mathrm{m}}$ for every maximal ideal m.

Clearly, as (1) can be written in the form $Ax = b$ by choosing A and b from the entries of the fractions N and d, it follows from this lemma that (1) in fact has a solution over $\mathcal{A}$. Hence using the sufficiency part of the proof of Proposition 1, it follows that P is stabilizable. □

The notion of local stabilizability has also been useful in [6] and [7], though in the context of state feedback stabilization of systems over rings. In [7] the equivalence of local and global stabilizability is proved using analytic approaches. In comparison to these the approach developed above is purely algebraic.

2.1.2. Stabilizability and equivalence classes. We now show that stabilizability is in fact a property of much bigger equivalence classes of $\mathcal{A}^{n\times m} \times S$ than just those obtained by different choices of fractions of P. Two $n \times m$ matrices N, M over $\mathcal{A}$ are called *equivalent* (denoted $N \sim M$) if there exist *unimodular* (or invertible) matrices $A \in (\mathcal{A})_n$ and $B \in (\mathcal{A})_m$ such that $N = AMB$. Observe that two matrices P, Q in $\mathcal{F}^{n\times m}$ can always be written in terms of fractions having a common denominator. For if $P = Nd^{-1}$ and $Q = Ab^{-1}$, then we have $P = Nb(db)^{-1}$ and $Q = Ad(db)^{-1}$. Hence, call P, Q S-*equivalent* if $Nb \sim Ad$. It is easy to verify that this is an equivalent relation on $\mathcal{F}^{n\times m}$ and also on $\mathcal{A}^{n\times m} \times S$, where it defines bigger equivalence classes than those equivalent to elements in $\mathcal{F}^{n\times m}$.

PROPOSITION 3. *Let P be strictly causal. Then P is stabilizable if and only if Q is stabilizable for all Q that are S-equivalent to P.*

Proof. First, the proof is by sufficiency. P is S-equivalent to itself.

Second, the proof is by necessity. Let $P = Nd^{-1}$ and $Q = Mt^{-1}$ be S-equivalent to P. Thus there exist unimodular matrices A, B such that $ANtB = Md$. Since P is stabilizable, (1) has a solution X, Y, U, W for fractions Nt and dt. Define $\bar{X} = AXA^{-1}$, $\bar{Y} = B^{-1}YA^{-1}$, $\bar{U} = AUB$, and $\bar{W} = B^{-1}WB$. Then (1) in terms of these new matrices is as follows:

$$\begin{aligned}\bar{X}(ANBt) &= \bar{U}(dt),\\ \bar{Y}(ANBt) &= \bar{W}(dt),\\ (ANBt)\bar{Y} &= (I - \bar{X})(dt).\end{aligned}$$

Thus (1) is satisfied for Q as well. Since Q is also strictly causal, being S-equivalent to P, Q is stabilizable. □

The above proof shows that the stabilizing controllers of S-equivalent plants have fractions that are appropriately left and right associates.

2.1.3. Block diagonal plant. As another application of the linear equation formulation, consider a block decoupled transfer matrix

$$P = \begin{pmatrix} P_1 & 0 \\ 0 & P_2 \end{pmatrix},$$

where P_1 and P_2 are $n_1 \times m_1$ and $n_2 \times m_2$ matrices over $\mathcal{F}$, respectively. Clearly, P is strictly causal if and only if both P_1 and P_2 are strictly causal. For strictly causal P of this kind we have the following result. The proof follows from Proposition 1.

COROLLARY 1. *The block diagonal P is stabilizable if and only if both P_1 and P_2 are stabilizable. If C_1 and C_2 are stabilizing controllers of P_1 and P_2, then*

$$C = \begin{pmatrix} C_1 & 0 \\ 0 & C_2 \end{pmatrix}$$

is also a stabilizing controller of P.

2.2. Coprime ideals and stabilizability. In [13] stabilizability of a scalar plant $p = nd^{-1}$ is obtained as coprimeness of ideals $\hat{a} = (n : d)$ and $\hat{b} = (d : n)$. We now determine the corresponding ideals for stabilizability of a matrix P over $\mathcal{F}$. We treat the case of only the square plant matrix with $n = m$. Nonsquare cases can be developed on similar lines but require more complex notations. For $P = Nd^{-1}$ in $(\mathcal{F})_n$, consider the set

$$b_{\mathrm{L}} = \{X \in (\mathcal{A})_n \mid XN \in (d)_n\},$$

where $(d)_n \subset (\mathcal{A})_n$ is the principal ideal generated by dI. Clearly, b_{L} is a left ideal of $(\mathcal{A})_n$. Consider the set Nb_{L}, which consists of all matrices of the form NX where X belongs to b_{L}. Let $\mathcal{I}(b_{\mathrm{L}})$ be the idealizer ring of b_{L}. Recall that

$$\mathcal{I}(b_{\mathrm{L}}) = \{X \in (\mathcal{A})_n \mid b_{\mathrm{L}}\, X \subseteq b_{\mathrm{L}}\}.$$

Observe that $\mathcal{I}(b_{\mathrm{L}})$ contains the center Z of $(\mathcal{A})_n$ as well as the ring $C(N)$ of matrices that commute with N. Since b_{L} is a two-sided ideal of $\mathcal{I}(b_{\mathrm{L}})$, the set Nb_{L} is a right ideal of $\mathcal{I}(b_{\mathrm{L}})$. Consider

$$a_{\mathrm{R}} = \{Y \in \mathcal{I}(b_{\mathrm{L}}) \mid Yd \in Nb_{\mathrm{L}}\}.$$

Clearly, a_{R} is a right ideal of $\mathcal{I}(b_{\mathrm{L}})$. Thus the sum of ideals $b_{\mathrm{L}} + a_{\mathrm{R}}$ is also a right ideal of $\mathcal{I}(b_{\mathrm{L}})$. Finally, consider the following ideals of the center Z of $(\mathcal{A})_n$:

$$b = b_{\mathrm{L}} \cap Z, \qquad a = a_{\mathrm{R}} \cap Z.$$

Thus a and b are ideals of the commutative ring $\mathcal{A}$.

PROPOSITION 4. *A strictly causal $P = Nd^{-1}$ in $(\mathcal{F})_n$ is stabilizable if and only if $a + b = \mathcal{A}$.*

Proof. First, the proof is by necessity. Since (1) has a solution, there is X in b_{L} and $X' = I - X$ in a_{R}. As b_L is a left ideal of $(\mathcal{A})_n$, $\det X = (\mathrm{adj}\ X)X$ belongs to $b_{\mathrm{L}} \cap Z = b$. Further, $X + X' = I$ implies that $(\mathrm{adj}\ X')X + \det X' = \mathrm{adj}\ X'$. Hence as $(\mathrm{adj}\ X')X \in b_{\mathrm{L}} \subset \mathcal{I}(b_{\mathrm{L}})$ and $\det X' \in Z \subset \mathcal{I}(b_{\mathrm{L}})$, it follows that adj X' belongs to $\mathcal{I}(b_{\mathrm{L}})$.

Now, as X' belongs to the right ideal a_{R} of $\mathcal{I}(b_{\mathrm{L}})$, $\det X' = X'\mathrm{adj}\ X'$ also belongs to a_{R}, but then $\det X' \in a$. As $\det X + \det X' = 1$, $a + b = \mathcal{A}$.

Second, the proof is by sufficiency. Let $x \in a$ and $y \in b$ such that $x + y = 1$. Then $xI \in b_{\mathrm{L}}$, $yI \in a_{\mathrm{R}}$, and $I = xI + yI \in b_{\mathrm{L}} + a_{\mathrm{R}}$. Hence it follows from the definitions of ideals b_{L} and a_{R} that there is a solution to (1). Hence P is stabilizable. □

The above algebraic condition of coprimeness of ideals a and b is now immediately amenable to geometrical interpretation in terms of the closed sets of the spectrum of

the ring $\mathcal{A}$. Since two ideals are coprime if and only if there is no prime ideal containing both of them, it follows that P is stabilizable if and only if

$$V(a) \cap V(b) = \emptyset,$$

where $V(a)$ and $V(b)$ are closed sets in spec $\mathcal{A}$. Following [13] we call $V(a)$ the *generalized zero set* of P and $V(b)$ the *generalized pole set* of P.

For the scalar plant $p = nd^{-1}$, the above ideals are $b = (d : n)$ and $a = (nb : d)$. However, the ideals obtained in [13] are $\hat{b} = (d : n)$ and $\hat{a} = (n : d)$. Thus $\hat{b} = b$. We now show that $\hat{a}$ is also equal to a. For $a = (nb : d) \subseteq (n \cap b : d) = (n : d)$ as $(d) \subseteq b$. Thus $a \subseteq \hat{a}$. Conversely let $x \in \hat{a}$. Then for some y in $\mathcal{A}$,

$$\begin{array}{rrcl} & xd & = & yn, \\ \Rightarrow & y & \in & (d : n) = b, \\ \Rightarrow & yn & \in & (n)b, \\ \Rightarrow & x(d) & \subseteq & (n)b, \\ \Rightarrow & x & \in & (nb : d) = a. \end{array}$$

Thus the result above specializes to the scalar case of [13]. In fact the above result is valid for any commutative ring, not just for integral domains.

Although the results of this section resolve the stabilization problem algebraically, they do not reveal the geometric relationship between the plant and its stabilizing controller. This relationship is an important aspect of the feedback stabilization problem to which we now turn.

3. Geometric conditions for stabilizability. In this section we first investigate the geometric relationship between the plant and its stabilizing controller whenever one exists, and then develop the geometric necessary and sufficient conditon for stabilizability of the plant. In the standard factorization theory, this relationship is exhibited by the doubly coprime factorization. For convenience we reproduce the definition of this factorization.

DEFINITION 3 (Doubly coprime factorization). *Let P be an $n \times m$ matrix over $\mathcal{F}$. Then P is said to have a doubly coprime factorization* (DCF) *if there exist the following matrices*:

1. N, $\tilde{N}$ *in* $\mathcal{A}^{n\times m}$, $\tilde{D}$ *in* $(\mathcal{A})_n$, D *in* $(\mathcal{A})_m$;
2. X, $\tilde{X}$ *in* $\mathcal{A}^{m\times n}$, Y *in* $(\mathcal{A})_n$, $\tilde{Y}$ *in* $(\mathcal{A})_m$;
3. D, $\tilde{D}$, Y, $\tilde{Y}$ *are all nonsingular and satisfy*;
4. $P = ND^{-1} = \tilde{D}^{-1}\tilde{N}$ *and the identity*

$$\begin{bmatrix} \tilde{X} & \tilde{Y} \\ \tilde{N} & -\tilde{D} \end{bmatrix} \begin{bmatrix} D & Y \\ N & -X \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}.$$

In the standard factorization theory (i.e., over PIDs or Bezout domains) such a factorization exists for every plant. Moreover each such factorization gives rise to a stabilizing controller. Now consider some additional notations. For $P = Nd^{-1}$ and $C = N_c d_c^{-1}$, denote various matrices as follows:

$$T = \begin{bmatrix} N \\ dI \end{bmatrix}, \qquad T_c = \begin{bmatrix} N_c \\ d_c I \end{bmatrix},$$

$$W = \begin{bmatrix} N & dI \end{bmatrix}, \qquad W_c = \begin{bmatrix} N_c & d_c I \end{bmatrix},$$

$$Q_t = \begin{bmatrix} d_c I & N \\ -N_c & dI \end{bmatrix}, \qquad Q_w = \begin{bmatrix} dI & N \\ -N_c & d_c I \end{bmatrix},$$

$$\triangle_t = \begin{bmatrix} d_c I & 0 \\ 0 & dI \end{bmatrix}, \qquad \triangle_w = \begin{bmatrix} dI & 0 \\ 0 & d_c I \end{bmatrix}.$$

In the above matrices the dimension of the identity matrix I is made clear from the context. For example, in T the identity matrix is $m \times m$, while in W it is $n \times n$. Further, let $\mathcal{T}$ denote the $\mathcal{A}$-module generated by the rows of the matrix T, and let $\mathcal{T}_c$ denote the $\mathcal{A}$-module generated by the rows of the matrix T_c. Similarly let $\mathcal{W}$ denote the $\mathcal{A}$-module generated by the columns of the matrix W, while $\mathcal{W}_c$ denotes the module generated by the columns of the matrix W_c. In general, for a matrix X let $M_r(X)$ denote the module generated by the rows of X. Finally, let H denote the matrix $H(P, C)$ of the feedback system. The following lemma gives the relationship between P and C.

LEMMA 2. *Let $P = Nd^{-1}$ be stabilizable and $C = N_c d_c^{-1}$ be its stabilizing controller. Then*

$$\mathcal{T} \oplus \mathcal{T}_c \simeq \mathcal{A}^{n+m},$$
$$\mathcal{W} \oplus \mathcal{W}_c \simeq \mathcal{A}^{n+m}.$$

Proof. Recall that in the feedback system,

$$H = \begin{bmatrix} I & P \\ -C & I \end{bmatrix}^{-1}.$$

Hence $\det H = \det (I + PC)^{-1}$, which implies that both $\det H$ and $\det(\text{adj } H)$ are not zero divisors. As both d and d_c are also not zero divisors, from the above we obtain the following identities:

$$(\text{adj } H)\triangle_t = Q_t \det H, \tag{2}$$

$$\triangle_w(\text{adj } H) = Q_w \det H. \tag{3}$$

For (2) we obtain, upon padding the matrices on both sides by $\det H \triangle_t$,

$$\begin{bmatrix} (\text{adj } H)\triangle_t \\ \triangle_t \det H \end{bmatrix} = \begin{bmatrix} Q_t \\ \triangle_t \end{bmatrix} \det H,$$

which is equivalent to

$$\begin{bmatrix} I \\ H \end{bmatrix} (\text{adj } H)\triangle_t = \begin{bmatrix} Q_t \\ \triangle_t \end{bmatrix} \det H.$$

Now observe that the module generated by the rows of $[I\ H^T]^T$ is free of rank $m + n$. Hence as $\det((\text{adj } H)\triangle_t)$ is not a zero divisor, we obtain

$$M_r\left(\begin{bmatrix} I \\ H \end{bmatrix} (\text{adj } H)\triangle_t\right) \simeq M_r\left(\begin{bmatrix} I \\ H \end{bmatrix}\right) \simeq \mathcal{A}^{m+n}.$$

Using this fact and the fact that $\det H$ is not a zero divisor, it follows from the above equation that

$$M_r\left(\begin{bmatrix} Q_t \\ \triangle_t \end{bmatrix}\right) \simeq \mathcal{A}^{m+n}.$$

Now, a simple observation shows the equivalence of following matrices:

$$\begin{bmatrix} Q_t \\ \triangle_t \end{bmatrix} \sim \begin{bmatrix} T & 0 \\ 0 & T_c \end{bmatrix}.$$

Thus clearly,

$$M_r\left(\begin{bmatrix} T & 0 \\ 0 & T_c \end{bmatrix}\right) = \mathcal{T} \oplus \mathcal{T}_c \simeq \mathcal{A}^{m+n}.$$

An exactly similar computation starting from (3) shows that

$$\mathcal{W} \oplus \mathcal{W}_c \simeq \mathcal{A}^{m+n}$$

is also satisfied. □

Thus in a stable feedback system the modules $\mathcal{T}$ and $\mathcal{T}_c$ generated by the fractions of the plant and the controller, respectively, are projective complements of each other in $\mathcal{A}^{m+n}$. In the standard factorization theory, an algebraic characterization of the stabilizing controller is obtained once a DCF of P is computed. In contrast to this, the above result reveals a geometrical characteristic of all stabilizing controllers of P. However, this does not give a geometrical characterization of the controller since this is only a necessary condition that a controller must satisfy in order to be a stabilizing controller.

3.1. Doubly coprime factorization. We now give a necessary and sufficient condition under which a DCF exists for the plant P.

LEMMA 3. *$P = Nd^{-1}$ has a doubly coprime factorization if and only if both $\mathcal{T}$ and $\mathcal{W}$ are free $\mathcal{A}$-modules of ranks m and n, respectively.*

Proof. First, the proof is by sufficiency. Let $v_1, v_2, \ldots, v_m$, $v_i \in \mathcal{A}^m$ be a basis of $\mathcal{T}$ and $u_1, u_2, \ldots, u_n$, $u_j \in \mathcal{A}^n$ be a basis of $\mathcal{W}$. Cosider the matrix V in $(\mathcal{A})_m$ whose rows are v_i, and the matrix U in $(\mathcal{A})_n$ whose columns are u_j. Since $\{v_i\}$ and $\{u_j\}$ are both linearly independent sets, $\det V$ and $\det U$ are both nonzero divisors in $\mathcal{A}$. Thus we can write the matrices T and W in the form

$$T = \begin{bmatrix} A \\ B \end{bmatrix} V, \qquad W = U \begin{bmatrix} \tilde{A} & \tilde{B} \end{bmatrix},$$

by uniquely choosing the matrices A, $\tilde{A}$ in $\mathcal{A}^{n\times m}$, B in $(\mathcal{A})_m$, and $\tilde{B}$ in $(\mathcal{A})_n$. Clearly, as $d^m = \det(BV)$ and $d^n = \det(UB)$, both $\det B$ and $\det \tilde{B}$ are also nonzero divisors. Hence we also have $Nd^{-1} = AB^{-1} = \tilde{B}^{-1}\tilde{A}$. Now, since $v_i, i = 1, \ldots, m$ belong to $\mathcal{T}$ and $u_j, j = 1, \ldots, n$ belong to $\mathcal{W}$, we can obtain matrices $\tilde{Y}$, Y' in $\mathcal{A}^{m\times n}$, $\tilde{X}$ in $(\mathcal{A})_m$, and X' in $(\mathcal{A})_n$ such that

$$V = \begin{bmatrix} \tilde{Y}\tilde{X} \end{bmatrix} T = (\tilde{Y}A + \tilde{X}B)V,$$

$$U = W \begin{bmatrix} Y \\ X \end{bmatrix} = (\tilde{A}Y' + \tilde{B}X')U.$$

Hence, as $\det V$, $\det U$ are nonzero divisors, we obtain

$$\tilde{Y}A + \tilde{X}B = I, \qquad \tilde{A}Y' + \tilde{B}X' = I.$$

Now, by a well-known procedure [14], define $\tilde{Y}X' - \tilde{X}Y' = M$ and let $Y = BM + Y'$ and $X = X' - AM$. The doubly coprime factorization is then obtained as

$$\begin{bmatrix} \tilde{X} & \tilde{Y} \\ \tilde{A} & -\tilde{B} \end{bmatrix} \begin{bmatrix} B & Y \\ A & -X \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}.$$

Let this equation be denoted as $LR = I$, where L and R denote the unimodular matrices of the above DCF.

Second, the proof is by necessity. If P has a DCF $LR = I$ as above, then a small computation shows that there exist unimodular matrices E and F such that

$$ET = \begin{bmatrix} V \\ 0 \end{bmatrix} \quad \text{and} \quad WF = \begin{bmatrix} U & 0 \end{bmatrix},$$

where U and V are nonsingular. Hence, as E and F are unimodular, $\mathcal{T}$ is isomorphic to $M_r(V)$ which is free of rank m. Similarly, it follows that $\mathcal{W}$ is free of rank n. □

Remark. The matrix interpretation of the lemma, which is clear from the the proof above, is as follows. The modules $\mathcal{T}$ and $\mathcal{W}$ are free of ranks m and n, respectively, if and only if there exist unimodular matrices L and R such that

$$LT = \begin{bmatrix} V \\ 0 \end{bmatrix} \quad \text{and} \quad WR = \begin{bmatrix} U & 0 \end{bmatrix},$$

where V is $m \times m$, U is $n \times n$, and both are nonsingular.

It is well known that once the DCF is given as above then the plant P is stabilizable by the controller $C = \tilde{X}^{-1}\tilde{Y} = YX^{-1}$. We use this next to prove one of the central results of this paper.

3.2. Geometric necessary and sufficient condition. We now develop a necessary and sufficient condition for stabilizability of P purely in terms of the modules $\mathcal{T}$ and $\mathcal{W}$. Hence it is first necessary to establish the uniqueness of $\mathcal{T}$ and $\mathcal{W}$ with respect to fractions Nd^{-1} of P. Let $P = Ab^{-1}$ be another choice of fractions with $T' = [A^T\ bI]^T$. Then as $Nb = Ad$ and d and b are both nonzero divisors, we have $\mathcal{T} \simeq M_r(TbI) \simeq M_r(T'dI) \simeq M_r(T')$. Thus the module $\mathcal{T} = M_r(T)$ is obtained uniquely up to an isomorphism for any choice of fractions of P. Similarly, it follows that the module $\mathcal{W}$ is also obtained uniquely. In fact, it is easy to observe that if P and Q are S-equivalent, then the modules $\mathcal{T}$ of P and Q (similarly, $\mathcal{W}$) are isomorphic. Thus a stabilizability condition in terms of the modules $\mathcal{T}$ and $\mathcal{W}$ will be invariant, not only with respect to the choice of fractions, but also with respect to the S-equivalent class of fractions. We thus fix an arbitrary fraction $P = Nd^{-1}$.

Consider the class of rings $\mathcal{A}$ whose spectrum is an irreducible topological space. In such a space every nonempty open subset is dense. Hence any two nonempty open subsets have a nonempty intersection. A ring $\mathcal{A}$ has spec $\mathcal{A}$ irreducible if and only if its nilradical (the set of nilpotent elements) is a prime ideal. For this class of rings, which is sufficiently broad to cover applications of our interest, we obtain the necessary and sufficient conditon for stabilizability in the theorem below. We first need the following well-known lemma, which shows the semicontinuity of ranks of projective modules.

LEMMA 4. *If M is a finitely generated projective $\mathcal{A}$-module and r is a natural number, then the set of all prime ideals* p *in* spec $\mathcal{A}$, *for which* $\mu_{\mathrm{p}}(M) < r$, *is open.*

THEOREM 1. *Let* spec $\mathcal{A}$ *be irreducible. Then a strictly causal plant P is stabilizable if and only if $\mathcal{T}$ and $\mathcal{W}$ are both projective of ranks m and n, respectively.*

Proof. First, the proof is by necessity. From Lemma 2 there is a $C = N_c d_c^{-1}$ with $\mathcal{T} \oplus \mathcal{T}_c \simeq \mathcal{A}^{n+m}$. Hence, as projective modules are locally free (see Lemma 1) the localizations $\mathcal{T}_{\mathrm{p}}$ and $\mathcal{T}_{c\mathrm{p}}$ are free $\mathcal{A}_{\mathrm{p}}$-modules for all p $\in$ spec $\mathcal{A}$, and moreover, we have

$$\mathcal{T}_{\mathrm{p}} \oplus \mathcal{T}_{c\mathrm{p}} \simeq \mathcal{A}_{\mathrm{p}}^{n+m},$$

which implies that

$$\mu_{\mathrm{p}}(\mathcal{T}) + \mu_{\mathrm{p}}(\mathcal{T}_c) = n + m \quad \forall \mathrm{p} \in \text{spec } \mathcal{A},$$

where $\mu_{\mathrm{p}}(\mathcal{T})$ is the rank of $\mathcal{T}$ at p. Now, if d is not contained in a prime ideal p, then clearly $\mathcal{T}$ contains m linearly independent rows. Hence $\mu_{\mathrm{p}}(\mathcal{T}) = m$ for all p in the open set $D(d) =$ spec $\mathcal{A} - V(d)$. So let p be a prime ideal containing d. Thus p belongs to the closed set $V(d)$ in spec $\mathcal{A}$. Now if $\mu_{\mathrm{p}}(\mathcal{T}) < m$ at this p, then due to the semicontinuity property of the rank as given in the above lemma, there is an open set D' in spec $\mathcal{A}$ such that $\mu_{\mathrm{p}}(\mathcal{T}) < m$ for all p in D'. However, since spec $\mathcal{A}$ is irreducible, $D(d)$ and D' have a nonempty intersection which gives a contradiction. Hence rank of $\mathcal{T}_{\mathrm{p}}$ is equal to m for all p. On similar lines it can be proved that the rank of $\mathcal{W}_{\mathrm{p}}$ is equal to n over the entire spectrum.

Second, the proof is by sufficiency. By hypothesis, $\mathcal{T}_{\mathrm{m}}$ and $\mathcal{W}_{\mathrm{m}}$ are free of rank m and n, respectively, for all maximal ideals m. Hence from Lemma 3 it follows that P has a doubly coprime factorization over $\mathcal{A}_{\mathrm{m}}$ (i.e., all matrices in the DCF are obtained over $\mathcal{A}_{\mathrm{m}}$). Thus there is a $C = YX^{-1}$, with X, Y having all entries in $\mathcal{A}_{\mathrm{m}}$ and for which $\det(I + PC)$ is a unit of $\mathcal{F}(\mathcal{A}_{\mathrm{m}})$ as well as $H(P, C)$, that has all entries in $\mathcal{A}_{\mathrm{m}}$. Thus P is locally stabilizable for all maximal ideals m. Hence, by Proposition 2, P is stabilizable. □

In the proof of the above theorem we have used the results of Proposition 1 and the subsequent local-to-global implication of stabilizability of Proposition 2. This is because the only other sufficient condition for stabilizability available so far is via existence of DCF for which the modules $\mathcal{T}$ and $\mathcal{W}$ are required to be free, which is in general not the case. For this reason it will be useful to know when these modules are free because then, by Lemma 3, there will actually be a DCF available. We thus investigate the class of rings for which stabilizability will imply that the modules $\mathcal{T}$ and $\mathcal{W}$ are free of ranks m and n, respectively.

3.2.1. Number of generators and coprimeness. For convenience we reproduce below some standard definitions and results, see [9] for details. A topological space X is called *Noetherian* if every descending chain $V_1 \supset V_2 \supset \ldots$ of closed sets $V_i \subset X$ is stationary. The space X is called *irreducible* if, for any decomposition $X = V_1 \cup V_2$ with closed subsets $V_i \subset X$, we have either $X = V_1$ or $X = V_2$. A subset $Y \in X$ is called irreducible if Y is an irreducible space with the induced topology. The *Krull dimension* of X denoted as $\dim X$ is the supremum of the lengths n of all chains $V_0 \subset V_2 \subset \ldots V_n$, $V_{i+1} \neq V_i$, of nonempty closed irreducible subsets V_i of X.

Our above problem of determining when the modules $\mathcal{T}$ and $\mathcal{W}$ are free can be answered by calculating $\mu(\mathcal{T})$ and $\mu(\mathcal{W})$ the number of generators in any minimal generating systems of $\mathcal{T}$ and $\mathcal{W}$. In this respect the theorem of Forster and Swan (see

[9]) turns out to be of great importance. We reproduce below only the directly useful consequence of this theorem and refer the reader to [9] for other details.

THEOREM 2. *Let* $X = \max \mathcal{A}$ *be Noetherian and of finite Krull dimension, and let* M *be any finitely generated* $\mathcal{A}$*-module. Then*

$$\mu(M) \leq \dim X + \operatorname{Max} \{\mu_{\mathrm{m}}(M) \mid \mathrm{m} \in X \cap \operatorname{supp} M\}.$$

Hence, if M *is generated by* r *elements for each* m *in* $\max \mathcal{A}$*, then* M *is generated globally by* $r + \dim X$ *elements.*

The application of the above theorem to our problem is now quite obvious and is given in the following.

THEOREM 3. *Let* $\max \mathcal{A}$ *be Noetherian and* $\dim \max \mathcal{A} = 0$*. Then* P *is stabilizable if and only if* P *has a doubly coprime factorization.*

Proof. Only necessity need be proved. By Theorem 1, $\mathcal{T}$ and $\mathcal{W}$ are free of ranks m and n, respectively, at every maximal ideal m (hence also generated by m and n generators at each m). Hence by the theorem of Forster and Swan above, $\mathcal{T}$ and $\mathcal{W}$ are generated globally by m and n generators. But then all of these generators of $\mathcal{T}$, as well as $\mathcal{W}$, must be linearly independent, since $\mathcal{T}$ and $\mathcal{W}$ contain, respectively, m and n linearly independent elements, namely those of the m and n scalar matrices dI with d a nonzero divisor. Thus the modules $\mathcal{T}$ and $\mathcal{W}$ are free of ranks m and n. Consequently, we have DCF by Lemma 3. □

Remark. The above theorem shows that for the class of rings $\mathcal{A}$ that have a Noetherian and zero-dimensional maxspectrum, the stabilization theory is identical to that of the standard factorization theory, since it is only those plants that are stabilizable that have DCF. In the next section, we show that the class of polynomial rings over PIDs is also in another class for which this holds.

3.3. Stabilizability condition over UFDs. We now develop further geometrical interpretation of the condition of Theorem 1. This interpretation can in fact be developed for Noetherian rings with irreducible spectrum; however, to keep matters simple we restrict ourselves only to unique factorization domains (UFDs). Moreover, results over UFDs are directly relevant to our main application of multidimensional stabilization treated in the next section. To begin, consider the following local-global characterization of a projective module. This result is in fact valid for general rings. We refer the reader to [3, Thm. 1(d), p. 110] for the proof.

PROPOSITION 5. *The following statements are equivalent.*

1. *An* $\mathcal{A}$ *module* M *is finitely generated and projective.*

2. *There exists a finite family* $F = \{f_1 \dots f_r\}$ *of elements of* $\mathcal{A}$ *generating* $\mathcal{A}$*, i.e., the ideal* $(f_1 \dots f_r) = \mathcal{A}$ *and* M_f *is a free* A_f*-module of finite rank for all* f *in the finite set* F*.*

Observe that in our problem the modules $\mathcal{T}$ and $\mathcal{W}$ are finitely generated over $\mathcal{A}$ by the rows and columns of matrices T and W, respectively. Hence there already exist m (respectively, n) linearly independent generators of $\mathcal{T}$ (respectively, $\mathcal{W}$). It thus follows that the localizations $\mathcal{T}_{\mathrm{p}}$, respectively, $\mathcal{W}_{\mathrm{p}}$, over the zero prime ideal $\mathrm{p} = 0$ are free $\mathcal{A}_{\mathrm{p}}$-modules of rank m (respectively, n). Thus to prove that $\mathcal{T}$ and $\mathcal{W}$ are projective of ranks m and n it suffices to just prove that they are projective, since the rank is constant over the entire spectrum of an $\mathcal{A}$ a UFD.

From the above characterization of a projective module it follows that the problem of checking whether a plant is stabilizable can be solved, if we can identify the finite families corresponding to our modules $\mathcal{T}$ and $\mathcal{W}$ from the matrices T and W obtained from the fractions of the plant. A step in this direction is provided by the following.

PROPOSITION 6. *There exists a nonzero element h in $\mathcal{A}$ such that $\mathcal{T}_h$ and $\mathcal{W}_h$ are both free $\mathcal{A}_h$-modules of ranks m and n, respectively.*

Proof. Let T_1 be an $m \times m$ nonsingular submatrix of T. Recall that there is at least one. Consider the matrix $T_0 = TT_1^{-1}$ over the field of fractions $\mathcal{F}$ of $\mathcal{A}$. Let the entries of T_0 be considered in the reduced form, with the numerator and the denominator of each entry considered relatively prime after the greatest common denominator between the modulo units of $\mathcal{A}$ is cancelled. Let f be the radical of the least common multiple of all the denominators of T_0. Then for a sufficiently large integer k the matrix $K = f^k T_0$ has all entries in $\mathcal{A}$ and there is also an $m \times m$ submatrix of $f^{-k}K$ with row indices same as that of T_1 such that the determinant of this submatrix is a unit of $\mathcal{A}_f$. This implies a factorization of the form

$$T = f^{-k} K T_1,$$

where entries of $f^{-k}K$ are in $\mathcal{A}_f$ and the $m \times m$ minors of $f^{-k}K$ generate $\mathcal{A}_f$. Moreover, entries of T_1 are also in $\mathcal{A}_f$ and $\det T_1 \neq 0$. Thus it follows that $\mathcal{T}_f$ is a free $\mathcal{A}_f$ module. On similar lines we can construct a nonzero element g in $\mathcal{A}$ from the transposed matrix W^T, such that $\mathcal{W}_g$ is a free $\mathcal{A}_g$ module. Now set $h = \operatorname{rad}(fg)$. □

From the above proposition it follows that it would be useful to collect such elements f and g for the matrices T and W. Let $\{T_1, T_2 \dots T_r\}$ be the family of all nonsingular $m \times m$ submatrices of the matrix T, and for each index j, let f_j be the element corresponding to T_j (as constructed in the proof of the above proposition) with minimum number of irreducible factors such that $\mathcal{T}_{f_j}$ is a free $\mathcal{A}_{f_j}$ module. We call the family $F = \{f_1, f_2 \dots f_r\}$ the family of *elementary factors* of the matrix T. Similarly, let $G = \{g_1, g_2 \dots g_l\}$ denote the family of elementary factors of the matrix W^T. Now let the finite family $H = \{f_i g_j, i = 1 \dots r, j = 1 \dots l\}$ of rl elements be denoted by FG. We call H the *family of elementary factors of the transfer matrix* P. In fact, it can be shown that the closed sets $V(F)$, $V(G)$, and hence also $V(H)$, of the ideals (F), (G), and (H) generated by each of the above respective families of elementary factors remain invariant with respect to the choices of the generators of the modules $\mathcal{T}$ and $\mathcal{W}$. Moreover, two S-equivalent plants have the same $V(H)$. We omit these details as these are not needed further. However this observation shows that $V(H)$ is an invariant of the transfer matrix P.

Our main result now is as follows. We drop the strict causality condition on P as in Theorem 1 in view of the proof of Proposition 1 for integral domains given in §4.4.

THEOREM 4. *The plant transfer matrix P is stabilizable if and only if the family H of elementary factors of P satisfies*

$$\bigcap_{h \in H} V(h) = \emptyset$$

(i.e., the elementary factors of P are coprime).

Proof. We first establish the proof by necessity. By hypothesis, the modules $\mathcal{T}$ and $\mathcal{W}$ are projective of rank m and n, respectively. Hence by Proposition 5, there exist finite families F' and G' both generating $\mathcal{A}$ such that $\mathcal{T}_{f'}$ is a free $\mathcal{A}_{f'}$ module for all f' in F', and $\mathcal{W}_{g'}$ is a free $\mathcal{A}_{g'}$ module for all g' in G'. Let H' be the product family $F'G'$. Now consider the module $\mathcal{T}$ and a member f' of F'. It follows that there exist m linearly independet vectors of $\mathcal{T}$ forming a nonsingular $m \times m$ matrix $V_{f'}$, which extend to provide a basis of $\mathcal{T}_{f'}$ over $\mathcal{A}_{f'}$. Hence for a sufficiently large

integer ν there is a factorization

$$T = f'^{-\nu} K_{f'} V_{f'},$$

where the mth determinantal ideal $I_m(K_{f'})$ contains a unit of $\mathcal{A}_{f'}$. Now, let f in F be an elementary factor of T corresponding to a submatrix T_1. Also, let $K_{f'1}$ denote the corresponding submatrix of $K_{f'}$. Then, in the field of fractions $\mathcal{F}$ of $\mathcal{A}$ we obtain

$$TT_1^{-1} = K_{f'} K_{f'1}^{-1},$$

which shows that the elementary factor f is a factor of $\det K_{f'1}$. Hence the ideal $I_m(K_{f'})$ is contained in the ideal (F) generated by the elemetary factors of T. Since the family F' generates $\mathcal{A}$ and this inclusion holds for every f' in F' we have,

$$V(F) \subset V(F') = \emptyset.$$

On similar lines it can be shown that $V(G) = \emptyset$. Thus, it follows that

$$V(H) = V(F) \cup V(G) = \emptyset.$$

Now we establish the proof by sufficiency. Since $H = FG$, the ideal (H) generated by the family H is equal to the product of ideals $(F)(G)$. Hence $V(H) = V(F) \cup V(G)$ is empty implies that the families F and G both generate $\mathcal{A}$. Since F is the family of elementary factors of T, the module $\mathcal{T}_f$ is free $\mathcal{A}_f$-module for all f in F. Hence by Proposition 5 $\mathcal{T}$ is a projective $\mathcal{A}$-module. Its rank is thus clearly m. Similarly it can be shown that $\mathcal{W}$ is a projective $\mathcal{A}$-module of rank n. P is thus stabilizable by Theorem 1. □

The discussion preceding the above theorem clearly shows that when the family of elementary factors of P contains a unit, then both the modules $\mathcal{T}$ and $\mathcal{W}$ are free and the condition of the theorem is satisfied, which is a fact in confirmation of the standard factorization theory, i.e., the plant is stabilizable when it has a DCF. In general, stabilizabilty may not imply existence of DCF. It can be shown by similar reasoning as employed in the above proof that if P has DCF then the elementary factors of P generate $\mathcal{A}$. It has however not been possible to establish that the DCF may fail to exist for a stabilizable plant.

We now consider a necessary condition for stabilizability as a corollary of the above theorem, which should at times be a simpler check for stabilizabilty of P before we embark on the more exhaustive computation of the elementary factors of P. This is developed via some notation and a simplifying lemma below.

For the matrix T, let $t_i = a_i d_t$ for $i = 1 \ldots r$ denote the nonzero maximal order minors of T, where d_t is the greatest common divisor of t_i. Call $\{a_1 \ldots a_r\}$ the family of *reduced minors* of T. Similarly, let $\{b_1, b_2 \ldots b_l\}$ denote the family of reduced minors of the matrix W. The following lemma is stated without proof, which follows from a straightforward application of the determinant formula but is lengthy.

LEMMA 5. *For any transfer matrix P, the families of reduced minors of T and W are identical modulo units, i.e., $r = l$ and $a_i = b_i$ up to unit factors for $i = 1 \ldots r$.*

We now consider the corollary of Theorem 4.

COROLLARY 2. *If P is stabilizable, then the family of reduced minors of T (and also of W) generates $\mathcal{A}$, i.e.,*

$$(a_1, a_2, \ldots, a_r) = \mathcal{A}.$$

Proof. Stabilizabilty of P by Theorem 4 implies that the family H of elementary factors of P generates $\mathcal{A}$. Since $\mathcal{T}_h$ is a free $\mathcal{A}_h$-module for every h in H, we have a factorization $T = T_h D_h$, where $\det D_h$ is nonzero and the $m \times m$ minors of T_h generate $\mathcal{A}_h$. Thus $\det D_h$ is the greatest common divisor over $\mathcal{A}_h$ of the nonzero $m \times m$ minors of T. Hence these minors of T_h are of the form $u_i a_i$ for $i = 1 \ldots r$, where a_i are the reduced minors of T and u_i are units of $\mathcal{A}_h$. This implies that $\cap_{i=1}^{r} V(a_i) \subset V(h)$ for every h in H. Hence we have

$$\bigcap_{i=1}^{r} V(a_i) \subset \bigcap_{h \in H} V(h) = \emptyset.$$

From Lemma 5 above, a_i are also the reduced minors of W. □

Clearly, the above condition also becomes sufficient, and in that case also implies DCF of P if the reduced minors are also the minors of both the matrices T and W. Thus in this case the maximal minors of T and W are both coprime. Stabilization theory in such cases is thus trivial.

3.4. Formula for all stabilizing controllers. An important landmark of the standard factorization theory is its formula that characterizes all stabilizing controllers of the plant. The development above shows that the plant P always has DCFs over $\mathcal{A}_h$ for all its elementary factors h and becomes stabilizable if and only if these generate the whole ring $\mathcal{A}$. Thus we have the formula of stabilizing controllers for each elementary factor h and the ring $\mathcal{A}_h$. When P is stabilizable, we should thus be able to glue together these formulae to obtain all the stabilizing controllers of P. We carry out this construction in this section.

As before, let $H = \{h_1, h_2, \ldots, h_k\}$ denote the family of elementary factors of the plant P, which we now assume is stabilizable. Since P has a DCF over $\mathcal{A}_h$ for each h in H, it is stabilizable over $\mathcal{A}_h$ by standard factorization theory. Hence using Proposition 1, all its stabilizing controllers are of the form

$$C_h = Y_h X_h^{-1},$$

where the matrices Y_h and X_h have all entries in $\mathcal{A}_h$ and satisfy (1) for some other matrices U_h and W_h also over $\mathcal{A}_h$. Recall that all these matrices can be obtained from the controller formula of the standard factorization theory. Now, for a sufficiently large integer ν, (1), after multiplying by h^ν, becomes

$$\begin{aligned}(h^\nu X_h)N &= (h^\nu U_h)d,\\ (h^\nu Y_h)N &= (h^\nu W_h)d,\\ N(h^\nu Y_h) &= (h^\nu I - (h^\nu X_h))d,\end{aligned}$$

where all the matrices in the parentheses (.) have their entries in $\mathcal{A}$. For index $i = 1, \ldots, k$, let X_i, Y_i, U_i, and W_i be the quadruple of matrices over $\mathcal{A}_i = \mathcal{A}_{h_i}$ satisfying (1). Then for each of this index i there exist integers n_i such that the quadruple of matrices $h_i^{n_i} X_i$, $h_i^{n_i} Y_i$, $h_i^{n_i} U_i$, $h_i^{n_i} W_i$, all have entries in $\mathcal{A}$ and satisfy the above equations.

Now, since P is stabilizable, the elementary factors h_i generate $\mathcal{A}$. Hence there exist elements α_i such that

$$\sum_{i=1}^{k} \alpha_i h_i^{n_i} = 1.$$

Consider the quadruple

$$\begin{aligned} X &= \sum_{i=1}^{k} \alpha_i h_i^{n_i} X_i, \\ Y &= \sum_{i=1}^{k} \alpha_i h_i^{n_i} Y_i, \\ U &= \sum_{i=1}^{k} \alpha_i h_i^{n_i} U_i, \\ W &= \sum_{i=1}^{k} \alpha_i h_i^{n_i} W_i. \end{aligned}$$

Then these matrices satisfy (1) and hence YX^{-1} is a stabilizing controller. Moreover, by Proposition 1, every stabilizing controller can be obtained in this form. This formula thus clearly shows the gluing of the coprime fractions of the stabilizing controllers obtained over each ring $\mathcal{A}_h$ as h varies over the entire set of elementary factors H.

4. Applications. The purpose of this section is to apply the results of the previous sections to examples of integral domains. In particular, the problem of multidimensional stabilization is discussed and numerical examples are provided to illustrate the stabilizability conditions.

4.1. Multidimensional stabilization. One of the problems that motivates the present work is the problem of multidimensional or n-dimensional stabilization. In [2] the matrix problem is solved for the two-dimensional case, while in [13] the scalar problem is solved for the general n-dimensional case. Following [13], we now define the k-dimensional stabilization problem as follows. (Most of the definitions are well known and are given in [9]. Certain specific results are from [13]).

Let $\mathcal{B}$ denote the ring $\mathbf{R}[X_1 \dots X_k]$ of polynomials in k indeterminates over the real field $\mathbf{R}$, and let $V(f)$ (respectively, $V(I)$) denote the algebraic variety of an $f \in \mathcal{B}$ (respectively, an ideal $I \subset \mathcal{B}$) in the affine k-dimensional complex space $A^k(\mathbf{C})$. Let $\Gamma \subset \mathbf{C}^k$ be a *compact symmetric polynomially convex domain.* The domain Γ defines the saturated MC subset

$$S = \{f \in \mathcal{B} \mid V(f) \cap \Gamma = \emptyset\}.$$

The domain Γ is called the *domain of instability.* The polydisc $\bar{U}^n$ considered in [13] is, in fact, an example of such a domain. The following property of such domains, which immediately follows from the developments in [13], is relevant here.

LEMMA 6. *If Γ is a compact symmetric polynomially convex domain, then there is a bijective correspondence between the conjugate pairs of points of Γ and the maximal ideals of $S^{-1}\mathcal{B}$.*

Now returning to the k-dimensional stabilization problem, we consider $\mathcal{A} = S^{-1}\mathcal{B}$ as the ring of stable causal transfer functions and the k-dimensional plant P is an $n \times m$ matrix with entries in $\mathcal{F}$ the field of fractions of $\mathcal{A}$. Since this ring $\mathcal{A}$ is a UFD, the necessary and sufficient condition for stabilizability of such a plant is given by Theorem 4 in the previous section. We thus only consider some numerical examples for applying the condition of Theorem 4 to determine stabilizabilty. From the above lemma, the domain Γ now plays the role of spec $\mathcal{A}$, and the closed sets $V(I)$ for an ideal I are the zeros of generators of I in Γ. We thus denote the zeros in Γ of an element f of $\mathcal{A}$ again by $V(f)$.

Example 1. We have that

$$P = \frac{1}{1 + X_1 X_2} \begin{bmatrix} X_1 & X_2 \\ X_3 & X_4 \\ 1 & X_5 \end{bmatrix}.$$

The reduced minors of matrices T and W are obtained (modulo units) as $X_1X_4 - X_2X_3$, $X_1X_5 - X_2$, $X_2(1 + X_1X_2)$, $X_1(1 + X_1X_2)$, $X_3X_5 - X_4$, $X_3(1 + X_1X_2)$, $X_4(1 + X_1X_2)$, $X_5(1 + X_1X_2)$, $(1 + X_1X_2)$, $(1 + X_1X_2)^2$. Clearly, for $X_1 = 1$, $X_3 = X_5 = -1$ we can find a solution to the equation $X_4 + X_3 = 0$ such that the reduced minors above have a common zero in the polydisc $\bar{U}^5$. Thus this plant does not satisfy the necessary condition for stabilizabity of Corollary 2. Hence P is not stabilizable.

Example 2. We have that

$$P = \frac{1}{X_1^2 + X_2^2 + X_3^2 - 1} \begin{bmatrix} X_1X_2 \\ 1 \end{bmatrix}.$$

In this example, the minors of the matrix T have no common zero in the polydisc $\bar{U}^3$, hence T is free of rank 1. This is clearly observed since one of the elementary factors of T is a unit. The matrix W is obtained as

$$W = \begin{bmatrix} X_1X_2 & d & 0 \\ 1 & 0 & d \end{bmatrix},$$

where $d = X_1^2 + X_2^2 + X_3^2 - 1$. The submatrix $W(1,2)$ formed by the first two columns of W is nonsingular. The elementary factor of W with respect to $W(1,2)$ can be easily observed to be a unit again. Thus P has a unit elementary factor that shows that P has a DCF and is thus stabilizable.

Example 3. Let f and d be polynomials in three indeterminates each having zeros in the polydisc $\bar{U}^3$ but having no common zeros in this polydisc. Thus f and d are coprime in $\mathcal{A}$. Let d have irreducible factors $d = d_1d_2 = (X_1 - 1)(X_1X_2 - X_3)$. Then we have

$$P = \frac{1}{d} \begin{bmatrix} fX_1 & X_3 \\ f & X_2 \end{bmatrix}.$$

After a laborious computation, the elementary factors of both T and W become

$$f \quad d_1X_3 \quad fd_1X_1 \quad d_1X_2 \quad fd_1 \quad d.$$

Clearly, this is also the set of elementary factors of P. Since f and d are coprime, this set also generates $\mathcal{A}$. Thus P is stabilizable.

Above examples show that the condition of Theorem 4 allows a constructive procedure for checking stabilizabilty of multidimensional plants. However, this condition does not indicate whether DCFs exist for stabilizable plants as shown in [2] for the two-dimensional case.

4.2. Stabilization over polynomial rings. We now consider the stabilization problem over the polynomial ring $K[X_1, \ldots, X_k]$, where K is a PID. Thus our ring $\mathcal{A}$ of stable transfer functions is now this polynomial ring $K[X_1, \ldots, X_k]$.

Recall that the celebrated Quillen–Suslin resolution of the well-known Serre's conjecture [9, Thm. 3.15] shows that projective modules over the above class of polynomial rings are free. Hence for this class of rings the stabilizability conditions of Theorem 1 reduce to the following simpler form.

COROLLARY 3. *A strictly causal transfer matrix P over the field of fractions of $K[X_1, \ldots, X_k]$ is stabilizable if and only if the modules $\mathcal{T}$ and $\mathcal{W}$ are free.*

Proof. The proof follows by the Quillen–Suslin theorem [10] and Theorem 1. □

Clearly such transfer matrices also have DCFs. Thus it follows from the above result that for stabilization problems over this class of polynomial rings, the theorem of Forster and Swan and the zero dimensionality condition of Theorem 3 are not needed to show existence of DCF. It follows that, *for this class of rings, the parametrization of the stabilizing controllers is identical to that in the standard factorization theory.* In other words, existence of DCF is necessary for stabilization. Observe that this fact is not available from the standard factorization theory over the class of polynomial rings developed in [14, Chap. 8]. Thus the polynomial rings above are an additional class of rings for which DCFs exist for stabilizable plants apart from the class of rings satisfying conditions of Theorem 3. This is a reason for our motivation in considering the problem over polynomial rings.

The Serre's conjecture referred to above has been investigated for many other classes of rings. In particular, rings K that are not PIDs, but for which the polynomial rings satisfy the conjecture, have been investigated. The well-known reference [10] gives an excellent survey of results and developments on this problem. However, any discussion on the use of further results on the Quillen–Suslin theorem as well as Serre's conjecture are beyond the scope of this paper.

4.3. PID and Bezout domain. These integral domains are the main cases considered in the standard factorization theory. Now clearly, if $\mathcal{A}$ is a PID or a Bezout domain, then the modules $\mathcal{T}$ and $\mathcal{W}$ are automatically free. Hence every matrix P over $\mathcal{F}$ has a DCF and consequently is stabilizable. Thus our results above specialize to the well-known results of standard factorization theory.

4.4. Relaxing strict causality. We now show that when the ring $\mathcal{A}$ is an integral domain, Proposition 1 can be made stronger by relaxing the strict causality of P. Recall that the strict causality of P is required in the necessity part of the proof of Proposition 1.

Thus let (1) be satisfied. Then in the idealizer ring $\mathcal{I}(b_{\mathrm{L}})$, we have $b_{\mathrm{L}}+a_{\mathrm{R}} = \mathcal{I}(b_{\mathrm{L}})$. Now two cases arise.

Case 1. $a_{\mathrm{R}} \neq \mathcal{I}(b_{\mathrm{L}})$. We claim that there is $X \in b_{\mathrm{L}}$ with $\det X \neq 0$ for which $I - X$ belongs to a_{R}. Let $X \in b_{\mathrm{L}}$ and $Y \in a_{\mathrm{R}}$ be such that $X + Y = I$. Now if $\det X = 0$ then since $\det X = 1 - \det Y$, it follows that $\det Y = 1$. Thus a_{R} contains a unimodular matrix. Let Y^{-1} be the inverse of Y in $(\mathcal{A})_n$. Since $Y^{-1} = Y^{-1}X + I$ and as b_{L} is a left ideal of $(\mathcal{A})_n$ it follows that $Y^{-1}X$ belongs to b_{L} hence also in $\mathcal{I}(b_{\mathrm{L}})$. Hence Y^{-1} belongs to $\mathcal{I}(b_{\mathrm{L}})$. Thus as a_{R} is a right ideal of $\mathcal{I}(b_{\mathrm{L}})$, $I = YY^{-1}$ belongs to a_{R} which is a contradiction. Thus $\det X \neq 0$.

Case 2. $a_{\mathrm{R}} = \mathcal{I}(b_{\mathrm{L}})$. Since $d \neq 0$, the ideal $(d : I_1(N)) \neq 0$, where $I_1(N)$ is the ideal generated by all the entries of N, i.e., equal to $\sum(n_{ij})$. Now $(d : \sum(n_{ij})) = \cap_{i,j}(d : n_{ij}) \neq 0$. Choose $x \neq 0$ in this this ideal. Then clearly $xI \in b_{\mathrm{L}}$ and $\det xI = x^n \neq 0$. Thus $(I - xI) \in \mathcal{I}(b_{\mathrm{L}}) = a_{\mathrm{R}}$.

Thus what we have proved is that if (1) has a solution, then every solution X has $\det X \neq 0$. Now the remaining steps verifying that YX^{-1} is a stabilizing controller are identical to those in Proposition 1.

Although as shown above, stabilizability can be shown without using strict causality, it has not been possible to relax this condition for showing the causality of the stabilizing controller for general integral domains.

5. Conclusions. In this paper geometric stabilizability criteria are developed that are invariant with respect to fractions chosen for the transfer matrix. Next, a class of rings of stable transfer functions is determined for which stabilizability is

equivalent to existence of doubly coprime factorization. Thus for all such rings, the stabilization theory is identical to the standard factorization theory. Moreover, it is shown that the class of polynomial rings over PIDs is also an additional class of rings over which stabilizable transfer matrices have doubly coprime fractions. For general unique factorization domains, however, stabilizabilty is determined by the coprimeness of the elementary factors of the plant transfer matrix. The formula parametrizing all stabilizing controllers of a plant in this case also generalizes the well-known formula of the standard factorization theory. The question of whether stabilizable multidimensional plants have doubly coprime fractions remains unanswered in this development.

ROBUST INDIRECT ADAPTIVE CONTROL OF TIME-VARYING PLANTS WITH UNMODELED DYNAMICS AND DISTURBANCES*

SANJEEV M. NAIK† AND P. R. KUMAR†

Abstract. It is shown that indirect pole-zero placement adaptive controllers are robust for systems with time-varying parameters as well as unmodeled dynamics and disturbances. A parameter estimator with projection is used. No special signal normalization is employed to ensure robustness.

The nominal system parameters need only be bounded, and their variations need only be small in an average sense. This allows them to vary slowly with time, as well as to take large jumps occasionally. The adaptive controllers can also simultaneously tolerate small unmodeled dynamics, as well as bounded disturbances, with no restriction on the magnitude of the bound.

Key words. adaptive systems, disturbances, indirect adaptive control, robustness, robust performance, stability, time-varying plants, unmodeled dynamics

1. Introduction.

In [1] Åström and Wittenmark have proposed the use of indirect, certainty-equivalent self-tuning controllers based on pole-zero placement for the servo-problem. Thus, if the goal is to enforce a response

$$A^*(q^{-1})y_k = q^{-d}B^*(q^{-1})r_k \tag{1}$$

to a command signal $\{r_k\}$, then we first estimate system polynomials $\widehat{A}_{k-1}(q^{-1}) := 1 + \sum_{i=1}^{p} \hat{a}_{i,k-1}q^{-i}$ and $\widehat{B}_{k-1}(q^{-1}) := \sum_{i=0}^{\ell-1} \hat{b}_{i+1,k-1}q^{-i}$ at each time instant k by fitting a model

$$\widehat{A}_k(q^{-1})y_t = \widehat{B}_k(q^{-1})u_{t-d}$$

to the available data $\{y_t, u_{t-1} | 0 \le t \le k\}$ at time k. Then, the control input u_k is chosen such that

$$\widehat{R}_k(q^{-1})\widehat{B}_k(q^{-1})u_k = -\widehat{S}_k(q^{-1})y_k + B^*(q^{-1})r_k, \tag{2}$$

where the polynomials $\widehat{R}_k$ and $\widehat{S}_k$ are obtained by solving the Diophantine equation

$$\widehat{R}_k(q^{-1})\widehat{A}_k(q^{-1}) + q^{-d}\widehat{S}_k(q^{-1}) = A^*(q^{-1}) \tag{3}$$

at each time instant. To estimate the parameter vector $\widehat{\theta}_k := (-\hat{a}_{1,k}, \ldots, -\hat{a}_{p,k}, \hat{b}_{1,k}, \ldots, \hat{b}_{\ell,k})^T$, we may use a recursive algorithm of the form

$$\widehat{\theta}_k = \widehat{\theta}_{k-1} + \Gamma_{k-1}\phi_{k-1}(y_k - \phi_{k-1}^T\widehat{\theta}_{k-1}),$$

where

$$\phi_{k-1} = (y_{k-1}, \ldots, y_{k-p}, u_{k-d}, \ldots, u_{k-\ell-(d-1)})^T. \tag{4}$$

The choice of the "gain" matrix $\Gamma_k = \gamma_k I$ yields a gradient update law. Control schemes of this nature have proven popular in practice, and many successful implementations have been reported; see [2], [3], [4], [23]. Also, the model reference adaptive control method, the backbone of continuous-time adaptive control, is a "direct" version of such a pole-zero placement scheme.

Often, such adaptive control algorithms are employed to control plants that are subject to time-variations, for which there is consequently an ever-present need to adapt to the changing system characteristics. It is therefore important to develop a theory of robustness for such adaptive control algorithms for their use in the face of such system variations, as well as in the presence of uncertainties such as unmodeled dynamics and disturbances.

In this paper we consider an indirect adaptive control law, as above, with a parameter estimation scheme employing "projection" to keep the parameter estimates confined to a compact convex set. We establish that this simple modification is powerful enough to provide robustness simultaneously with respect to system time-variations, small unmodeled dynamics, and bounded disturbances. In particular, no special signal normalization is used.

Some background on the robustness problem for adaptive systems is in order. Much attention has been devoted over the past decade to the robustness problem caused by unmodeled dynamics and bounded disturbances, and an excellent unification of the work up to 1988 is provided by Ioannou and Sun [5]. Recently, in an important paper, Ydstie [6] has shown that just the simple mechanism of "projection," which confines the parameter estimates to a compact convex set, is sufficient for robustness with respect to bounded disturbances and some unmodeled dynamics. This paper is notable also for the introduction of a new proof technique involving a "switched signal." This work has been extended to continuous-time, while also enlarging the class of unmodeled dynamics, by Naik, Kumar, and Ydstie [7]. The net effect of these investigations is to show that many of the modifications, proposed in the 1980's to prove robustness with respect to unmodeled dynamics, are not necessary. The original simple "projection" modification, established by Egardt [8] to be robust with respect to bounded disturbances, is also robust with respect to small unmodeled dynamics.

Comparatively less attention has been devoted to the problem of robustness with respect to time-variations. Solo [9] established the boundedness of signals for a direct one-step-ahead adaptive control scheme using an a posteriori estimate-based gradient update law with leakage, when the parameters are slowly varying, while Kreisselmeier [10] has done so for an indirect adaptive control scheme with projection for slow-in-the-mean parameter variations, which allows occasional large parameter jumps. Tsakalis and Ioannou [11] obtained similar results for continuous-time plants, while Guo [12] and Meyn and Guo [13] have done so for discrete-time stochastic systems. In these works, while the plant is allowed to vary with time, the effect of unmodeled dynamics is not considered. In [14] de Larminat and Raynaud considered such robustness for a fairly general indirect adaptive control law that uses two parallel estimators as well as a specially constructed "normalization" signal. Middleton and Goodwin [15] also incorporated a normalization signal, and additionally assumed knowledge of the constant factor by which it overbounds the unmodeled dynamics. This constant is then used to set up a normalized dead-zone, for which they established robustness to slow-in-the-mean parameter variations and small unmodeled dynamics. Giri et al. [16] proved the robustness of an adaptive *regulator* for a

plant with small-in-the-mean parameter variations and unmodelled dynamics, using only the knowledge of the order of a nominal plant model. However, this is done using a complicated control law involving an identification–stabilization time-splitting, using a least-squares-based adaptation law that also employs a special normalization signal. Furthermore, arbitrarily large bounded disturbances cannot be handled, and the regulation objective is *not* achieved in the "ideal" case unless the algorithm is appropriately modified.

In all these works, the signals entering the adaptation law are normalized by a specially constructed normalization signal first proposed by Praly [17]. The effect of such normalization is to ensure that the modeling error entering the adaptation law is bounded or small in the mean. Construction of such a normalization signal requires a priori system knowledge and involves extra computation. In addition to these practical considerations, it is of theoretical interest to see if normalization is necessary for robustness.

The key point of this paper is that such normalization is not required to ensure the robustness of adaptive controllers to small unmodeled dynamics, bounded disturbances with arbitrarily large bound, and slow-in-the-mean parameter variations. We show that we obtain robust adaptive control by merely utilizing projection, together with "extended regressor" normalization, without recourse to any other modifications.

An indirect adaptive pole-zero placement controller is considered. The resulting necessity to cancel process zeros requires the nominal time-varying plant to be minimum phase at every instant. On the other hand, the problem of potential loss of estimated model controllability/stabilizability faced in adaptive pole placement is not an issue here. This itself results in a simpler adaptive control scheme than those in [14], [16], and [18], for instance. A result similar to ours has recently been reported by Wen [21] using a different proof technique developed earlier by Wen and Hill [22]. They consider a unit delay plant with the time-variations restricted to be slow. The true nominal time-varying parameter vector is assumed to lie in a convex compact set, which is assumed to have the property that the nominal system polynomials induced by any parameter vector in the set are uniformly coprime. This restrictive assumption is the consequence of choosing an indirect pole-placement controller design. A final point worth noting is that unlike the signal bounds derived in the present paper, those in [21] are not uniform in that they depend on the system initial condition.

Our main results are the following.

(i) A certainty equivalent adaptive controller, using a gradient based parameter estimator with projection and employing normalization based on an "extended regressor" ensures that all closed-loop signals are bounded, when applied to a nominally minimum phase discrete-time plant with slow-in-the-mean parameter variations with bounded disturbances and small unmodelled dynamics (Theorem 1).

(ii) In the absence of unmodeled dynamics and disturbances, and in case the parameter variations asymptotically tend to zero, i.e., in the nominal case, the error in tracking a reference trajectory converges to zero (Theorem 2). When unmodeled dynamics as well as bounded disturbances are present, the mean-squared output prediction error is linear in the magnitude of the unmodelled dynamics, bounded disturbances, and average rate of parameter variations (Theorem 3). Thus the adaptive controller provides robust performance in addition to robust boundedness.

2. System description. Consider a plant

$$y_k + \sum_{i=1}^{p} a_{i,k-1} y_{k-i} = \sum_{j=1}^{\ell} b_{j,k-1} u_{k-j+1-d} + v_k, \tag{5}$$

where u and y denote the input and output, while v represents the cumulative effect of unmodeled dynamics and disturbances. The coefficients $\{a_{i,k}, b_{i,k}\}$ may vary with time, and so the system is allowed to be time-varying. We wish to investigate the robustness of indirect adaptive control schemes for such systems that simultaneously consist of time-variations, unmodeled dynamics, and disturbances.

Let us suppose that the goal of adaptive control is to generate a closed-loop response to a command signal r_k, which satisfies (1), where q^{-1} denotes the usual backward-shift operator, i.e., $q^{-1}z_k := z_{k-1}$. If the plant in (5) were time-invariant and "ideal" without any unmodeled dynamics or disturbances, i.e., given by $A(q^{-1})y_k = q^{-d}B(q^{-1})u_k$, then the control law

$$R(q^{-1})B(q^{-1})u_k = -S(q^{-1})y_k + B^*(q^{-1})r_k,$$

where $R(q^{-1})$ and $S(q^{-1})$ satisfy the Diophantine equation

$$A(q^{-1})R(q^{-1}) + q^{-d}S(q^{-1}) = A^*(q^{-1}), \tag{6}$$

results in the cancellation of all original process zeros (hence necessitating some sort of minimum-phase condition) and a closed-loop transfer-function $q^{-d}B^*(q^{-1})/A^*(q^{-1})$ from r_k to y_k, as desired.

We consider here a certainty-equivalent indirect adaptive control scheme, which first forms parameter estimates

$$\widehat{\theta}_k = (-\hat{a}_{1,k}, \ldots, -\hat{a}_{p,k}, \hat{b}_{1,k}, \ldots, \hat{b}_{\ell,k})^T \tag{7}$$

at each time-step k, and then uses the resulting estimated polynomials $\widehat{A}_{k-1}(q^{-1}) := 1 + \sum_{i=1}^{p} \hat{a}_{i,k-1}q^{-i}$ and $\widehat{B}_{k-1}(q^{-1}) := \sum_{i=0}^{\ell-1} \hat{b}_{i+1,k-1}q^{-i}$ to solve the Diophantine equation

$$\widehat{R}_k(q^{-1})\widehat{A}_k(q^{-1}) + q^{-d}\widehat{S}_k(q^{-1}) = A^*(q^{-1}) \tag{8}$$

for $\widehat{R}_k$ and $\widehat{S}_k$.[1] We consider the minimum degree solution for $\widehat{R}_{k-1}$, so that it is monic and of degree $(d-1)$. We note that such a solution can be found through a $(d-1)$-step long division of the polynomial A^* by $\hat{A}$. Then we apply the input u_k, given by

$$\widehat{R}_k(q^{-1})\widehat{B}_k(q^{-1})u_k = -\widehat{S}_k(q^{-1})y_k + B^*(q^{-1})r_k. \tag{9}$$

It is well known in adaptive control (see Egardt [8]) that if we simply use a pure gradient-based parameter estimator, then the resulting adaptive system is destabilized by even a small bounded disturbance. It is therefore necessary to somehow modify

[1] Since we are dealing with time-varying polynomials in a shift-operator, we distinguish between the notations $C_k(q^{-1})D_k(q^{-1}) := \sum_{i=1}^{\ell}\sum_{j=1}^{\ell} c_{i,k}d_{j,k}q^{-(i+j)}$ and $C_k(q^{-1}) \circ D_k(q^{-1}) := \sum_{i=1}^{\ell}\sum_{j=1}^{\ell} c_{i,k}d_{j,k-i}q^{-(i+j)}$ when multiplying $C_k(q^{-1}) = \sum_{i=1}^{\ell} c_{i,k}q^{-i}$ and $D_k(q^{-1}) = \sum_{j=1}^{\ell} d_{j,k}q^{-j}$. For a signal x_k, $C_k(q^{-1})x_k \equiv C_k(q^{-1}) \circ x_k$ denotes $\sum_{i=1}^{\ell} c_{i,k}x_{k-i}$, as is usual.

the parameter estimator to secure robustness with respect to even just bounded disturbances.

We consider a parameter update law using parameter projection. This modification, motivated by the seminal work of Egardt [8], simply projects the parameter estimate vector onto a compact convex set $\mathcal{C}$ at each time step k. The set $\mathcal{C}$ is chosen such that

$$((p+1)\text{th component of } \theta) \geq b_{\min} > 0 \text{ for every } \theta \in \mathcal{C}.$$

(By thus ensuring that the estimated leading coefficient of $\widehat{B}_k(q^{-1})$ is positive, we also ensure that the control law (9) is well defined, since it does not involve division by zero.) The parameter estimates are recursively specified by

$$\widehat{\theta}'_k = \widehat{\theta}_{k-1} + \frac{\mu \phi_{k-1} e_k}{1 + \|\psi_{k-1}\|^2}, \tag{10}$$

$$e_k := y_k - \phi_{k-1}^T \widehat{\theta}_{k-1}, \tag{11}$$

and

$$\widehat{\theta}_k = \text{ Proj }_{\mathcal{C}}[\widehat{\theta}'_k], \tag{12}$$

where the regressor ϕ is given by (4). Here Proj $_{\mathcal{C}}[\cdot]$ denotes "orthogonal" projection onto the compact convex set $\mathcal{C}$, defined uniquely by Proj $_{\mathcal{C}}[x] \in \mathcal{C}$, and $\|$ Proj $_{\mathcal{C}}[x] - x\| \leq \|y - x\|, \forall y \in \mathcal{C}$. The vector ψ_k is an "extension" of the regression vector ϕ_k defined in (4)

$$\psi_{k-1} := (y_{k-1}, \ldots, y_{k-p'-d-m'+1}, u_{k-1}, \ldots, u_{k-\ell-2d-n'+2})^T, \tag{13}$$

where $p' := p, m' := 0, n' := 0$, if $d = 1$; and $p' := \max\{p, \deg(A^*)\}$, $m' := \max\{0, p - d\}$, $n' := \max\{0, p' - d + 1\}$, if $d > 1$.[2] Above, the constant μ in the step-size is chosen such that $0 < \mu < 2$, and the algorithm is initialized with $\hat{\theta}_0 \in \mathcal{C}$. We refer to this as the *parameter estimator with projection* (PEP).

Remarks. All the results of this paper can be extended to least-squares type parameter estimators, and also to "direct" pole-zero placement schemes. In fact, though we do not show it here, if we use a direct one-step-ahead adaptive control law, then robustness can be established easily through a similar analysis.

3. The assumptions. Our goal is to analyze the behavior of these adaptive controllers when they are applied to plants of the form shown in (5), which consist simultaneously of time-variations, unmodelled dynamics, and disturbances. We make the following assumptions on the plant (5) and the reference model (1).

Assumption 1. $\theta_k \in \mathcal{C}$ for all k, where $\mathcal{C}$ is a compact convex set such that the $(p+1)$th component of every vector in $\mathcal{C}$ is larger than or equal to $b_{\min} > 0$. Let K_θ be a constant that bounds $\|\theta\|$ for all $\theta \in \mathcal{C}$.

Assumption 2. The zeros of $B_k(q^{-1}) = \sum_{i=1}^{\ell} b_{i,k} q^{-i+1} = 0$ lie in the open disk $|q|^2 < \sigma < 1$, for all k.

[2] When the delay is unity, i.e., $d = 1$, then $\psi = \phi$, i.e., the extended regressor is identical to the regressor.

Assumption 3. $\sum_{k=t+1}^{t+T} \|\theta_k - \theta_{k-1}\| \leq K_\delta + k_\delta T$ for all $t, T \geq 0$, for some constants $K_\delta, k_\delta > 0$. Here $\theta_k := (a_{1,k}, \ldots, a_{p,k}, b_{1,k}, \ldots, b_{\ell,k})^T$ is the time-varying parameter vector.

Assumption 4. $v_k^2 \leq K_v m_{k-1} + k_v$ for all k, for some $K_v, k_v > 0$, where m_k satisfies a recursion

$$m_k = \sigma m_{k-1} + K_y y_k^2 + K_u u_k^2 + K_3, \qquad m_0 > 0, \tag{14}$$

and σ is as in Assumption 2.

Assumption 5. $A^*(q^{-1}) = 1 + \sum_1^{p'} a_i^* q^{-i}$ has all its zeros in the open disk $|q|^2 < \sigma < 1$, with σ as in Assumption 2.[3]

Assumptions 1 and 2 require that the time-varying parameter vector θ_k be bounded, have leading b_1-coefficient uniformly bounded away from zero, and be strictly minimum-phase, at every time-instant k. This latter restriction is necessitated by the requirement of canceling all process zeros. Assumption 3 allows slow-in-the-mean parameter time-variations, and thus occasional jumps too. Assumption 4 allows small unmodelled dynamics, and bounded disturbances with arbitrarily large bound. Finally, Assumption 5 simply requires the reference model to be stable with a prescribed margin of stability.

Remark. It is worthwhile to note that Assumption 4 includes the case of an incorrect assumption on the delay, since m_{k-1} includes input terms up to time $k-1$. Furthermore, the class of unmodeled dynamics covered by Assumption 4 allows the true plant to be nonminimum phase [19], [20].

In order to implement the above adaptive control schemes, we thus need to know upper bounds p and ℓ on the orders of the *nominal* time-varying portion of the plant, the nominal delay d, and the sign (say, positive) and a lower bound $b_{\min} > 0$ on the leading term in the polynomial $B_k(q^{-1})$ modeling the numerator of the nominal portion of the plant, for every k. In addition, since we must project the parameter estimates onto a compact convex set guaranteed to contain the true parameter θ_k for all k, we must know the bound K_θ on the norms of the time-varying parameters $\|\theta_k\|$ for all k. Finally, we must know the reference model given by $A^*(q^{-1})$, $B^*(q^{-1})$, and r_k.

Our central result in this paper is that under the above assumptions, the adaptive control laws are stable for all K_v and k_δ small enough, i.e., whenever the unmodeled dynamics are small enough, the parameter variations are small enough on the average, and the disturbances are bounded, though without any restriction on the magnitude of the bound.

4. Properties of the parameter estimators. We now derive some important properties of the parameter estimator PEP, which are independent of the control laws used. Let us denote by $\widetilde{\theta}_k := \widehat{\theta}_k - \theta_k$ the parameter estimation error. Using the definitions of ϕ_k and θ_k in (4) and Assumption 3, we can express the plant (5) as

$$y_k = \phi_{k-1}^T \theta_{k-1} + v_k. \tag{15}$$

Further, substituting (15) in (11) gives

$$e_k = -\phi_{k-1}^T \widetilde{\theta}_{k-1} + v_k. \tag{16}$$

LEMMA 1. *The following properties hold for the parameter estimator PEP.*

[3] Without loss of generality, if $\deg(A^*) < p'$, we set $a_i^* = 0$ for $i = \deg(A^*) + 1, \ldots, p'$.

(i) $\hat{b}_{k,1} \geq b_{\min} > 0, \forall k \geq 0$.

(ii) *The parameter estimation errors are uniformly bounded, i.e.,* $\|\widetilde{\theta}_k\| \leq K_{\widetilde{\theta}}$ *for all* k, *where*

$$K_{\widetilde{\theta}} := 2K_\theta.$$

(iii) *The parameter estimates* $\{\widehat{\theta}_k\}$ *are uniformly bounded also, with* $\|\widehat{\theta}_k\| \leq K_\theta$.

(iv) *Let* ϵ *satisfy* $0 < \epsilon < 2 - \mu$. *Then*

$$\sum_{k=t+1}^{t+T} \frac{e_k^2}{\rho_{k-1}} \leq K_{ev} \sum_{k=t+1}^{t+T} \frac{v_k^2}{\rho_{k-1}} + k_e T + K_e. \tag{17}$$

The quantity ρ_k *is defined as*

$$\rho_{k-1} := 1 + \|\psi_{k-1}\|^2, \tag{18}$$

and the constants are given by,

$$K_{ev} := \frac{\left(1 + \frac{1}{\epsilon}\right)}{2 - \mu - \epsilon}, \qquad k_e := \frac{2(K_\theta + K_{\widetilde{\theta}})(1+\mu)}{\mu(2-\mu-\epsilon)} k_\delta,$$

and

$$K_e := \frac{K_{\widetilde{\theta}}^2 + 2(K_\theta + K_{\widetilde{\theta}})(1+\mu)K_\delta}{\mu(2-\mu-\epsilon)}.$$

Proof. Define $\widetilde{\theta}'_k := \widehat{\theta}'_k - \theta_k$, $\overline{\phi}_{k-1} := \phi_{k-1}/\sqrt{\rho_{k-1}}$, $\bar{e}_k := e_k/\sqrt{\rho_{k-1}}$, and $\bar{v}_k := v_k/\sqrt{\rho_{k-1}}$.

(i) This is immediate from (12), and the property Assumption 1 of $\mathcal{C}$.

(ii) This is immediate from Assumption 1 and (12).

(iii) This follows from (ii) by Assumption 1.

(iv) Let us define $\delta_k := \theta_k - \theta_{k-1}$. By (10),

$$\widetilde{\theta}'_k = \widetilde{\theta}_{k-1} - \delta_k + \mu \overline{\phi}_{k-1} \bar{e}_k. \tag{19}$$

Using $\|\overline{\phi}_{k-1}\|^2 \leq 1$ and (16), we obtain

$$2\mu \overline{\phi}_{k-1}^T \widetilde{\theta}_{k-1} \bar{e}_k = 2\mu(\bar{v}_k - \bar{e}_k)\bar{e}_k \leq \frac{\mu \bar{v}_k^2}{\epsilon} + \mu\epsilon \bar{e}_k^2 - 2\mu \bar{e}_k^2.$$

Using (19) and noting that $\|\widetilde{\theta}'_k\| \leq \|\widetilde{\theta}_k\|$ due to projection, we obtain

(20)

$$\|\widetilde{\theta}_k\|^2 \leq \|\widetilde{\theta}_{k-1}\|^2 + \|\delta_k\|^2 + \mu^2 \bar{e}_k^2 - 2\widetilde{\theta}_{k-1}^T \delta_k - 2\mu \overline{\phi}_{k-1}^T \delta_k \bar{e}_k + \frac{\mu \bar{v}_k^2}{\epsilon} + \mu\epsilon \bar{e}_k^2 - 2\mu \bar{e}_k^2.$$

Thus, using (16) we obtain,

$$\begin{aligned}
\|\delta_k\|^2 - 2\delta_k^T(\widetilde{\theta}_{k-1} + \mu \overline{\phi}_{k-1} \bar{e}_k) &\leq \|\delta_k\|^2 + 2\|\delta_k\| \left(\|\widetilde{\theta}_{k-1}\| + \mu |\bar{e}_k| \right) \\
&\leq \|\delta_k\|^2 + 2\|\delta_k\| \left(K_{\widetilde{\theta}} + \mu |\bar{v}_k - \overline{\phi}_{k-1}^T \widetilde{\theta}_{k-1}| \right) \\
&\leq \|\delta_k\|^2 + 2\|\delta_k\| \left(K_{\widetilde{\theta}} + \mu |\bar{v}_k| + \mu \|\widetilde{\theta}_{k-1}\| \right) \\
&\leq \|\delta_k\|^2 + 2\|\delta_k\|(1+\mu)K_{\widetilde{\theta}} + \mu(\|\delta_k\|^2 + \bar{v}_k^2) \\
&\leq \mu \bar{v}_k^2 + (1+\mu)\|\delta_k\|(\|\delta_k\| + 2K_{\widetilde{\theta}}) \\
&\leq \mu \bar{v}_k^2 + 2(1+\mu)\|\delta_k\|(K_\theta + K_{\widetilde{\theta}}).
\end{aligned}$$

Substituting this into (20) gives

$$\mu(2-\mu-\epsilon)\bar{e}_k^2 \le \|\widetilde{\theta}_{k-1}\|^2 - \|\widetilde{\theta}_k\|^2 + \|\delta_k\|^2 + \frac{\mu}{\epsilon}\bar{v}_k^2 - 2\delta_k^T(\widetilde{\theta}_{k-1} + \mu\overline{\phi}_{k-1}\bar{e}_k)$$
$$\le \|\widetilde{\theta}_{k-1}\|^2 - \|\widetilde{\theta}_k\|^2 + \mu\left(1+\frac{1}{\epsilon}\right)\bar{v}_k^2 + 2(1+\mu)(K_\theta + K_{\widetilde{\theta}})\|\delta_k\|.$$

Summing from $t+1$ to $t+T$, telescoping, and using Assumption 3 as well as $\|\widetilde{\theta}_k\|^2 \le K_{\widetilde{\theta}}^2$ gives the desired result. □

The boundedness of parameter estimates yields the following important result that the controller parameters are Lipschitz functions of the plant parameters.

LEMMA 2. *Let $\theta^c :=$ (coefficients of $R(q^{-1})$, coefficients of $S(q^{-1}))^T$ denote the "controller" parameter vector, where R and S are functions of $\theta =$ (coefficients of $A(q^{-1};\theta)$, coefficients of $B(q^{-1};\theta))^T$ through (6). Let $\theta^{c,1}$ and $\theta^{c,2}$ denote the controller parameter vectors corresponding to two different plant parameter vectors θ^1 and θ^2, respectively. Then*

$$\|\theta^{c,1} - \theta^{c,2}\| \le K(C)\|\theta^1 - \theta^2\|$$

for all θ^1, $\theta^2 \in L_C := \{\theta \in R^{p+\ell} : \|\theta\| \le C\}$, where $K(C)$ is a constant that only depends on C.

Proof. Relation (6) can be rewritten as a system of linear equations

$$M(\theta^j)\theta^{c,j} = a^*, \qquad j = 1, 2,$$

where $M(\theta^j)$ denotes the Sylvester matrix corresponding to the polynomials $A(q^{-1})$ and q^{-d}, and a^* is formed from the coefficients of $A^*(q^{-1})$. Then, A being monic implies that there exists a positive ϵ such that, for all θ in L_C, $|\det(M(\theta^j))| \ge \epsilon$. We therefore obtain

$$\begin{aligned}\|\theta^{c,1} - \theta^{c,2}\| &\le \|M^{-1}(\theta^1) - M^{-1}(\theta^2)\| \cdot \|a^*\| \\ &\le \|M^{-1}(\theta^1)\| \cdot \|M(\theta^1) - M(\theta^2)\| \cdot \|M^{-1}(\theta^2)\| \cdot \|a^*\| \\ &\le \frac{(\|M(\theta^1)\| \cdot \|M(\theta^2)\|)^{p+\ell-1}}{|\det(M(\theta^1))\det(M(\theta^2))|}\|M(\theta^1) - M(\theta^2)\| \cdot \|a^*\| \\ &\le K(C)\|M(\theta^1) - M(\theta^2)\| \\ &\le K(C)\|\theta^1 - \theta^2\|,\end{aligned}$$

thereby concluding the proof. □

5. The switched system. We now introduce, for purposes of analysis only, the "switched" system,

(21)
$$z_k = I_{k-1}(\sigma z_{k-1} + K_y e_k^2 + K_u u_{k-1}^2 + K_3) + (1 - I_{k-1})(g z_{k-1} + 2K_3), \quad z_0 > 0,$$

where $0 < \sigma < g < 1$, and the indicator function I_{k-1} is defined as

$$I_{k-1} = \begin{cases} 1 & \text{if } \sigma z_{k-1} + K_y e_k^2 + K_u u_{k-1}^2 + K_3 \ge g z_{k-1} + 2K_3, \\ 0 & \text{otherwise.} \end{cases}$$

LEMMA 3. *For all k,*

(i) $\|\phi_k\|^2 \leq Km_k$, $\|\psi_k\|^2 \leq Km_k$;[4]
(ii) $m_k \leq K_{mz} z_k + k_{mz}$;
(iii) $z_k \leq K_z z_{k-1} + k_z$;
(iv) $v_k^2 \leq K_{vz} z_{k-1} + k_{vz}$;
(v) $u_k^2 \leq K\rho_{k-1} + K_{uz} z_{k-1} + K$;
(vi) $\rho_k \leq K\rho_{k-1} + K_{\rho z} z_{k-1} + K$;
(vii) $\rho_k \leq K_{zk} + K$.

Above, the constants K_{vz}, K_{uz}, and $K_{\rho z}$ can all be made as small as desired by choosing K_v small enough.

Proof. (i) These are obvious from (4), (13), and (14), where we also note that by choosing m_0 large, the constant K can be chosen independently of the initial conditions.

(ii) From

$$m_k = \sigma^k m_0 + \sum_{j=0}^{k} \sigma^{k-j}[K_y y_j^2 + K_u u_j^2 + K_3],$$

$$z_k \geq \sigma^k z_0 + \sum_{j=0}^{k} \sigma^{k-j}[K_y e_j^2 + K_u u_{j-1}^2 + K_3],$$

it is clear that it suffices to show that

$$\sum_{j=0}^{k} \sigma^{k-j} y_j^2 \leq K \sum_{j=0}^{k} \sigma^{k-j} e_j^2 + K \sum_{j=0}^{k} \sigma^{k-j} u_{j-1}^2 + K + K'\sigma^k, \quad \text{and} \tag{22}$$

$$\sum_{j=0}^{k} \sigma^{k-j} u_j^2 \leq K \sum_{j=0}^{k} \sigma^{k-j} y_j^2 + K \sum_{j=0}^{k} \sigma^{k-j} u_{j-1}^2 + K + K'\sigma^k, \tag{23}$$

where K' denotes a constant that may depend on the initial conditions, since the effects of the initial conditions can then be accounted for by making z_0 appropriately large, thus ensuring that K_{mz} and k_{mz} do not depend on the initial conditions.

For simplicity, let us first consider the case $d = 1$. In that case, $\widehat{R}_{k-1}(q^{-1}) = 1$ and $\widehat{S}_{k-1}(q^{-1}) = q(A^*(q^{-1}) - \widehat{A}_{k-1}(q^{-1}))$. Hence, dropping q^{-1} for brevity, and recalling the notation for multiplying time-varying polynomials in the shift operator, we obtain

$$\begin{aligned} A^* y_k &= (\widehat{R}_{k-1}\widehat{A}_{k-1} + q^{-1}\widehat{S}_{k-1}) y_k \\ &= \widehat{A}_{k-1} y_k - \widehat{R}_{k-1}\widehat{B}_{k-1} u_{k-1} + B^* r_{k-1} \quad \text{(from (9))} \\ &= q^{-1} B^* r_k + y_k - \phi_{k-1}^T \widehat{\theta}_{k-1} \quad (\text{since } \widehat{A}_{k-1} y_k - \widehat{B}_{k-1} u_{k-1} = y_k - \phi_{k-1}^T \widehat{\theta}_{k-1}) \\ &= q^{-1} B^* r_k + e_k. \end{aligned} \tag{24}$$

From Assumption 5 it follows that there exist constants $0 < \gamma, \delta < 1$ such that $|q|^2 < \gamma^2 < \gamma^{1+\delta} < \sigma < 1$ for every root q of $A^*(q^{-1}) = 0$. Using the boundedness of

[4] In the remainder of the paper, we use the symbol K to generically denote any positive constant that does not depend on either K_v or k_δ, and whose exact value is unimportant for the proofs which follow.

$\{r_k\}$ it follows from (24) that

$$\sum_{j=0}^{k} \sigma^{k-j} y_j^2 \le K + K'\sigma^k + K \sum_{i=0}^{k} \sigma^{k-i} e_i^2, \tag{25}$$

thus proving (22). For (23), recall from (9) that

$$u_k = \frac{1}{\hat{b}_{1,k}} \left[-\sum_{j=2}^{\ell} \hat{b}_{j,k} u_{k-j+1} - \sum_{j=0}^{\deg(\widehat{S})} \hat{s}_{j,k} y_{k-j} + B^*(q^{-1}) r_k \right]. \tag{26}$$

Since $\hat{b}_{1,k} > b_{\min} > 0$, $\widehat{\theta}_k$ is bounded, and the coefficients of $\widehat{S}_k(q^{-1})$ depend continuously on $\widehat{\theta}_k$, (23) follows from (26).

Now let us turn to the case $d > 1$. In that case,

$$\begin{aligned}
\widehat{A}_{k-1} y_k &= q^{-d} \widehat{B}_{k-1} u_k + (\widehat{A}_{k-1} - A_{k-1}) y_k + q^{-d}(B_{k-1} - \widehat{B}_{k-1}) u_k \\
&\quad + A_{k-1} y_k - q^{-d} B_{k-1} u_k \\
&= q^{-d} \widehat{B}_{k-1} u_k - \phi_{k-1}^T \tilde{\theta}_{k-1} + v_k \\
&= \widehat{B}_{k-1} u_{k-d} + e_k.
\end{aligned}$$

Hence operating on both sides by $\widehat{R}_{k-1}$, and keeping in mind the consequences of multiplying time-varying polynomials in the shift-operator and the associated notation, we have

$$\begin{aligned}
\widehat{R}_{k-1} e_k &= \widehat{R}_{k-1} \circ e_k = \widehat{R}_{k-1} \circ [\widehat{A}_{k-1} y_k - \widehat{B}_{k-1} u_{k-d}] \\
&= \widehat{R}_{k-1} \widehat{A}_{k-1} y_k - \widehat{R}_{k-1} \widehat{B}_{k-1} u_{k-d} - (\widehat{R}_{k-1} \widehat{A}_{k-1} - \widehat{R}_{k-1} \circ \widehat{A}_{k-1}) y_k \\
&\quad + (\widehat{R}_{k-1} \widehat{B}_{k-1} - \widehat{R}_{k-1} \circ \widehat{B}_{k-1}) u_{k-d} \\
&= (A^* - q^{-d} \widehat{S}_{k-1}) y_k - \widehat{R}_{k-d} \widehat{B}_{k-d} u_{k-d} + (\widehat{R}_{k-d} \widehat{B}_{k-d} - \widehat{R}_{k-1} \widehat{B}_{k-1}) u_{k-d} \\
&\quad - (\widehat{R}_{k-1} \widehat{A}_{k-1} - \widehat{R}_{k-1} \circ \widehat{A}_{k-1}) y_k + (\widehat{R}_{k-1} \widehat{B}_{k-1} - \widehat{R}_{k-1} \circ \widehat{B}_{k-1}) u_{k-d} \\
&= A^* y_k + (\widehat{S}_{k-d} - \widehat{S}_{k-1}) y_{k-d} - B^* r_{k-d} \\
&\quad + (\widehat{R}_{k-d} \widehat{B}_{k-d} - \widehat{R}_{k-1} \widehat{B}_{k-1}) u_{k-d} - (\widehat{R}_{k-1} \widehat{A}_{k-1} - \widehat{R}_{k-1} \circ \widehat{A}_{k-1}) y_k \\
&\quad + (\widehat{R}_{k-1} \widehat{B}_{k-1} - \widehat{R}_{k-1} \circ \widehat{B}_{k-1}) u_{k-d} \quad \text{(using (9))}.
\end{aligned}$$

Hence,

$$\begin{aligned}
A^* y_k &= q^{-d} B^* r_k + \widehat{R}_{k-1} e_k + (\widehat{R}_{k-1} \widehat{A}_{k-1} - \widehat{R}_{k-1} \circ \widehat{A}_{k-1}) y_k \\
&\quad + (\widehat{S}_{k-1} - \widehat{S}_{k-d}) y_{k-d} - (\widehat{R}_{k-1} \widehat{B}_{k-1} - \widehat{R}_{k-1} \circ \widehat{B}_{k-1}) u_{k-d} \qquad (27) \\
&\quad + (\widehat{R}_{k-1} \widehat{B}_{k-1} - \widehat{R}_{k-d} \widehat{B}_{k-d}) u_{k-d}. \qquad (28)
\end{aligned}$$

Now note that

$$\begin{aligned}
&|(\widehat{R}_{k-1} \widehat{A}_{k-1} - \widehat{R}_{k-1} \circ \widehat{A}_{k-1}) y_k - (\widehat{R}_{k-1} \widehat{B}_{k-1} - \widehat{R}_{k-1} \circ \widehat{B}_{k-1}) u_{k-d} \\
&\quad + (\widehat{R}_{k-1} \widehat{B}_{k-1} - \widehat{R}_{k-d} \widehat{B}_{k-d}) u_{k-d} + (\widehat{S}_{k-1} - \widehat{S}_{k-d}) y_{k-d}| \\
&\le \left| \sum_{i=1}^{d-1} \sum_{j=1}^{p} \hat{r}_{i,k-1} (\hat{a}_{j,k-1} - \hat{a}_{j,k-i-1}) y_{k-i-j} \right|
\end{aligned}$$

$$
\begin{aligned}
&+\left|\sum_{i=1}^{d-1}\sum_{j=1}^{\ell}\hat{r}_{i,k-1}(\hat{b}_{j,k-1}-\hat{b}_{j,k-i-1})u_{k-i-j-d+1}\right| \\
&+\left|\sum_{i=1}^{d-1}(\widehat{R}_{k-i}\widehat{B}_{k-i}-\widehat{R}_{k-i-1}\widehat{B}_{k-i-1})u_{k-d}\right|+\left|\sum_{i=1}^{d-1}(\widehat{S}_{k-i}-\widehat{S}_{k-i-1})y_{k-d}\right| \\
&\leq K\sum_{i=1}^{d-1}\sum_{j=1}^{p}\sum_{n=1}^{i}|\hat{a}_{j,k-n}-\hat{a}_{j,k-n-1}||y_{k-i-j}| \\
&+K\sum_{i=1}^{d-1}\sum_{j=1}^{\ell}\sum_{n=1}^{i}|\hat{b}_{j,k-n}-\hat{b}_{j,k-n-1}||u_{k-i-j-d+1}| \\
&+\left|\sum_{i=1}^{d-1}(\widehat{R}_{k-i}-\widehat{R}_{k-i-1})\widehat{B}_{k-i}u_{k-d}+(\widehat{B}_{k-i}-\widehat{B}_{k-i-1})\widehat{R}_{k-i-1}u_{k-d}\right| \\
&+\left|\sum_{i=1}^{d-1}\sum_{j=0}^{\deg(\widehat{S})}(\hat{s}_{j,k-i}-\hat{s}_{j,k-i-1})y_{k-d-j}\right| \\
&\leq K\sum_{i=1}^{d-1}\sum_{j=1}^{p}\sum_{n=1}^{i}\|\widehat{\theta}_{k-n}-\widehat{\theta}_{k-n-1}\|\|\psi_{k-1-n}\| \\
&+K\sum_{i=1}^{d-1}\sum_{j=1}^{\ell}\sum_{n=1}^{i}\|\widehat{\theta}_{k-n}-\widehat{\theta}_{k-n-1}\|\|\psi_{k-1-n}\| \\
&+\left|\sum_{i=1}^{d-1}\sum_{j=1}^{d-1}\sum_{m=1}^{\ell}(\hat{r}_{j,k-i}-\hat{r}_{j,k-i-1})\hat{b}_{m,k-i}u_{k-d-j-m+1}\right. \\
&\qquad\left.+\sum_{i=1}^{d-1}\sum_{m=1}^{\ell}\sum_{j=1}^{d-1}(\hat{b}_{m,k-i}-\hat{b}_{m,k-i-1})\hat{r}_{j,k-i-1}u_{k-d-j-m+1}\right| \\
&+K\sum_{i=1}^{d-1}\sum_{j=0}^{\deg(\widehat{S})}\|\widehat{\theta}_{k-i}-\widehat{\theta}_{k-i-1}\||y_{k-d-j}| \\
&\leq K\sum_{i=1}^{d-1}\sum_{j=1}^{p}\sum_{n=1}^{i}\|\widehat{\theta}'_{k-n}-\widehat{\theta}_{k-n-1}\|\|\psi_{k-1-n}\| \\
&+K\sum_{i=1}^{d-1}\sum_{j=1}^{\ell}\sum_{n=1}^{i}\|\widehat{\theta}'_{k-n}-\widehat{\theta}_{k-n-1}\|\|\psi_{k-1-n}\| \\
&+K\sum_{i=1}^{d-1}\sum_{j=1}^{d-1}\sum_{m=1}^{\ell}\|\widehat{\theta}'_{k-i}-\widehat{\theta}_{k-i-1}\|\|\psi_{k-i-1}\| \\
&+K\sum_{i=1}^{d-1}\sum_{j=0}^{\deg(\widehat{S})}\|\widehat{\theta}'_{k-i}-\widehat{\theta}_{k-i-1}\|\|\psi_{k-i-1}\| \\
&\leq K\sum_{n=1}^{d-1}\|\widehat{\theta}'_{k-n}-\widehat{\theta}_{k-n-1}\|\|\psi_{k-1-n}\|\leq K\sum_{n=1}^{d-1}|e_{k-n}|,
\end{aligned}
$$

where we have used Lemma 2. Now employing this bound in (27), we can establish (22) just as in the case of $d = 1$. Result (23) again follows from (22) by (26).

(iii) From (21), $z_k \le g z_{k-1} + K_y e_k^2 + K_u u_{k-1}^2 + 2K_3$. Thus we only need to bound e_k^2 and u_{k-1}^2 in terms of z_{k-1}. For the first, by Assumption 4 and (i), it follows from (16) that

$$\begin{aligned} e_k^2 &\le 2K_{\widetilde{\theta}}^2 \|\phi_{k-1}\|^2 + 2K_v m_{k-1} + 2k_v \le 2(K_{\widetilde{\theta}}^2 K + K_v) m_{k-1} + 2k_v \\ &\le 2K_{mz}(K_{\widetilde{\theta}}^2 K + K_v) z_{k-1} + 2(K_{\widetilde{\theta}}^2 K + K_v) k_{mz} + 2k_v. \end{aligned}$$

Also, from (14), $u_{k-1}^2 \le m_{k-1}/K_u \le (K_{mz} z_{k-1} + k_{mz})/K_u$.

(iv) From Assumption 4 and (ii), $v_k^2 \le K_v(K_{mz} z_{k-1} + k_{mz}) + k_v$.

(v) From the control law (26), and the boundedness of $\{r_k\}$,

$$u_k^2 \le K[\sum_{i=1}^{\ell-1} u_{k-i}^2 + \sum_{i=0}^{\deg(\widehat{S})} y_{k-i}^2 + 1].$$

Hence, $u_k^2 \le K\rho_{k-1} + K y_k^2 + K$. Since $y_k = \phi_{k-1}^T \theta_{k-1} + v_k$, we obtain

$$\begin{aligned} y_k^2 &\le K\rho_{k-1} + 2v_k^2 \\ &\le K\rho_{k-1} + KK_v z_{k-1} + K, \end{aligned} \tag{29}$$

and the required bound follows.

(vi) Clearly, $\rho_k \le K\rho_{k-1} + K y_k^2 + K u_k^2$. Hence, from (29) and (v), $\rho_k \le K\rho_{k-1} + K(K_{uz} + K_{vz}) z_{k-1} + K$.

(vii) Using (i) and (ii) of Lemma 3 gives $\|\psi_k\|^2 \le K z_k + K$. Hence $\rho_k \le K z_k + K$ for PEP. □

Now we examine the implications of the switching mechanism in more detail.

LEMMA 4. (i) *There exists a constant* $\epsilon_{\rho z} > 0$ *such that* $\rho_k \ge \epsilon_{\rho z} z_k - k_{\rho z}$, *whenever* $I_k = 1$.

(ii) *For every positive integer* N, *there exist positive constants* $L(N), \bar{k}(N)$, *and* $K_{v\max}(N)$ *with the following property. If* $K_v \in [0, K_{v\max}]$, $I_{t_1} = 1$, *and* $z_k \ge L$ *for all* $k \in [t_1 - N, t_1]$, *then* $\rho_k \ge \bar{k}(N) z_k$ *for all* $k \in [t_1 - N, t_1]$.

Proof. (i) Suppose $I_{k-1} = 1$. Then, from the definition of I_{k-1}, $K_y e_k^2 + K_u u_{k-1}^2 \ge (g - \sigma) z_{k-1} + K_3$. Hence, we have

$$K_y e_k^2 + K_u \rho_{k-1} \ge (g - \sigma) z_{k-1} + K_3. \tag{30}$$

Now, if $\rho_{k-1} \ge ((g - \sigma) z_{k-1} + K_3)/2K_u$, then the claim is true with $\epsilon_{\rho z} > 0$ chosen smaller than $(g - \sigma)/2K_u$. So let us consider only the interesting case, $\rho_{k-1} \le ((g - \sigma) z_{k-1} + K_3)/2K_u$. From (30) we then have $e_k^2 \ge ((g - \sigma) z_{k-1} + K_3)/2K_y$, while from (16), $e_k^2 \le 2K_{\widetilde{\theta}}^2 \|\phi_{k-1}\|^2 + 2v_k^2$, and so

$$2K_{\widetilde{\theta}}^2 \|\phi_{k-1}\|^2 \ge e_k^2 - 2v_k^2 \ge \frac{(g - \sigma) z_{k-1} + K_3}{2K_y} - 2K_{vz} z_{k-1} - 2k_{vz}.$$

Since $\rho_{k-1} \ge \|\phi_{k-1}\|^2$, the required result follows by choosing K_{vz} small enough, and $\epsilon_{\rho z} < (K_\phi / 2K_{\widetilde{\theta}}^2)((g - \sigma)/2K_y - 2K_{vz})$.

(ii) We bound the growth rate of ρ_k / z_k, and then use this in a reversed time argument. Consider $k \in [t_1 - N, t_1]$. Then

$$\frac{\rho_{k+1}}{z_{k+1}} \le \frac{K\rho_k + K_{\rho z 1} z_{k+1} + K_{\rho z} z_k + K}{z_{k+1}},$$

by Lemma 3(vi), where we set $K_{\rho z1} := 0$ in the case of PEP. Hence,

$$\begin{aligned}\frac{\rho_{k+1}}{z_{k+1}} &\le \frac{K}{\sigma}\frac{\rho_k}{z_k} + \left(K_{\rho z1} + \frac{K_{\rho z}}{\sigma}\right) + \frac{K}{\sigma L} \\ &= K_a \frac{\rho_k}{z_k} + K_b \quad (\text{since } z_{k+1} \ge \sigma z_k \text{ and } z_k \ge L),\end{aligned}$$

where K_a and K_b are appropriately chosen. So,

$$\begin{aligned}\frac{\rho_{t_1}}{z_{t_1}} &\le K_a^{t_1 - t}\left[\frac{\rho_t}{z_t} + \frac{K_b}{K_a - 1}\right], \qquad \forall t \in [t_1 - N, t_1], \\ \frac{\rho_{t_1}}{z_{t_1}} &\le K_a^{N}\left[\frac{\rho_t}{z_t} + \frac{K_b}{K_a - 1}\right], \qquad \forall t \in [t_1 - N, t_1].\end{aligned}$$

Hence,

$$\begin{aligned}\frac{\rho_t}{z_t} &\ge K_a^{-N}\frac{\rho_{t_1}}{z_{t_1}} - \frac{K_b}{K_a - 1} \\ &\ge K_a^{-N}\left(\epsilon_{\rho z} - \frac{k_{\rho z}}{L}\right) - \frac{K_b}{K_a - 1} \quad (\text{by (i) and since } z_{t_1} \ge L).\end{aligned}$$

Now we simply define

$$\bar{k}(N) := K_a^{-N}\left[\epsilon_{\rho z} - \frac{k_{\rho z}}{L}\right] - \frac{[K_{\rho z1} + \frac{K_{\rho z}}{\sigma} + \frac{K}{\sigma L}]}{K_a - 1},$$

noting that by choosing $L = L(N)$ large enough and $K_{\rho z1}, K_{\rho z}$ small enough (by choosing K_v small enough), we can ensure that $\bar{k}(N) > 0$. □

6. A representation of the closed-loop system. In this section, we obtain a nonminimal state space description of the closed-loop system consisting of a stable state-transition matrix, and driven by a composite input consisting of the output prediction error, the unmodelled dynamics and disturbances, the filtered reference input, and in the case of $d > 1$, also of "small" fractions of the input and output.

Consider first, for simplicity, the case $d = 1$. Then, using (24),

$$\begin{aligned}B_{k-1}(q^{-1})u_{k-1} &= A_{k-1}(q^{-1})y_k - v_k \\ &= A_{k-1}(q^{-1})y_k - v_k - [A^*(q^{-1})y_k - B^*(q^{-1})r_{k-1} - e_k] \\ &= [A_{k-1}(q^{-1}) - A^*(q^{-1})]y_k + e_k - v_k + B^*(q^{-1})r_{k-1}.\end{aligned}$$

Hence,

$$\begin{aligned}u_{k-1} &= \frac{1}{b_{1,k-1}}[A_{k-1}(q^{-1}) - A^*(q^{-1})]y_k + \frac{e_k - v_k}{b_{1,k-1}} \\ &\quad + \frac{B^*(q^{-1})r_{k-1}}{b_{1,k-1}} - \frac{(b_{2,k-1}u_{k-2} + \ldots + b_{\ell,k-1}u_{k-\ell})}{b_{1,k-1}} \\ &= -b'_{2,k-1}u_{k-2} - \cdots - b'_{\ell,k-1}u_{k-\ell} + a'_{1,k-1}y_{k-1} + \cdots + a'_{p',k-1}y_{k-p'} \\ &\quad + \frac{e_k - v_k}{b_{1,k-1}} + r'_{k-1},\end{aligned}$$

where b'_{k-1}, a'_{k-1} and r'_{k-1} are defined appropriately. Hence, defining the "state-vector"

$$x_k = [y_k, y_{k-1}, \ldots, y_{k-p'}, u_{k-1}, \ldots, u_{k-\ell+1}]^T,$$

we obtain the closed-loop system representation

$$x_k = F_k x_{k-1} + b_{e,k} e_k + b_{v,k} v_k + b_{r,k} r'_{k-1}, \tag{31}$$

where

$$F_k := \begin{bmatrix} J & 0 \\ G_k & H_k \end{bmatrix},$$

$$J = \begin{bmatrix} -a_1^* & \cdots & -a_{p'}^* \\ & & 0 \\ & \mathrm{I} & \vdots \\ & & 0 \end{bmatrix},$$

$$H_k = \begin{bmatrix} -b'_{2,k-1} & \cdots & -b'_{\ell,k-1} \\ & & 0 \\ & \mathrm{I} & \vdots \\ & & 0 \end{bmatrix},$$

$$G_k = \begin{bmatrix} a'_{1,k-1} & \cdots & a'_{p',k-1} \\ & & 0 \\ & 0 & \vdots \\ & & 0 \end{bmatrix},$$

$$b_{e,k} = [1\ 0\ \cdots\ 0\ 1/b_{1,k-1}\ 0\ \cdots\ 0]^T,$$
$$b_{v,k} = [0\ \cdots 0\ -1/b_{1,k-1}\ 0\ \cdots\ 0]^T,$$
$$b_{r,k} = [b_{1,k-1}\ 0\ \cdots\ 0\ 1\ 0\ \cdots\ 0]^T.$$

We note, for future use, that the eigenvalues of F_k, at each instant k, are the roots of $A^*(q^{-1})$ and $B_{k-1}(q^{-1})$. Hence, by Assumptions 2 and 5, F_k is a stable matrix with all eigenvalues λ_i lying in the disk $|\lambda_i|^2 < \sigma < 1$.

Now let us turn to the case of $d > 1$. First, recall that (27) gives

$$A^* y_k = q^{-d} B^* r_k + \widehat{R}_{k-1} e_k + \Delta_{1,k} u_{k-d} + \Delta_{2,k} u_{k-d} + \Delta_{3,k} y_k + \Delta_{4,k} y_{k-d}, \tag{32}$$

where $\Delta_{1,k} := -(\widehat{R}_{k-1}\widehat{B}_{k-1} - \widehat{R}_{k-1} \circ \widehat{B}_{k-1})$, $\Delta_{2,k} := \widehat{R}_{k-1}\widehat{B}_{k-1} - \widehat{R}_{k-d}\widehat{B}_{k-d}$, $\Delta_{3,k} := \widehat{R}_{k-1}\widehat{A}_{k-1} - \widehat{R}_{k-1} \circ \widehat{A}_{k-1}$, and $\Delta_{4,k} := \widehat{S}_{k-1} - \widehat{S}_{k-d}$.

Next, operating by $\widehat{A}_k$ on (9), adding $q^{-d}\widehat{S}_k\widehat{B}_k u_k$ to both sides, and then using (8) gives

$$A^* \widehat{B}_k u_k = (\widehat{A}_k \widehat{R}_k \widehat{B}_k - \widehat{A}_k \circ (\widehat{R}_k \widehat{B}_k)) u_k + q^{-d} \widehat{S}_k \widehat{B}_k u_k - \widehat{A}_k \circ \widehat{S}_k y_k + \widehat{A}_k B^* r_k.$$

This implies

$$\begin{aligned} A^* B_k u_k = {} & -A^* \widetilde{B}_{k-1+d} u_k + A^* (\widetilde{B}_{k-1+d} - \widetilde{B}_k) u_k + (\widehat{A}_k \widehat{R}_k \widehat{B}_k - \widehat{A}_k \circ (\widehat{R}_k \widehat{B}_k)) u_k \\ & + \widehat{A}_k B^* r_k + (\widehat{A}_k \widehat{S}_k - \widehat{A}_k \circ \widehat{S}_k) y_k + \widehat{S}_k (-\widehat{A}_{k-1} y_k + q^{-d} \widehat{B}_{k-1} u_k) \\ & + \widehat{S}_k (q^{-d} (\widehat{B}_k - \widehat{B}_{k-1}) u_k - (\widehat{A}_k - \widehat{A}_{k-1}) y_k), \end{aligned} \tag{33}$$

where $\widetilde{B}_k := \widehat{B}_k - B_k$. Next, note that by (4), (7), (15), and (16),

$$\begin{aligned} -\widehat{A}_{k-1} y_k + q^{-d} \widehat{B}_{k-1} u_k &= -y_k + \phi_{k-1}^T \widehat{\theta}_{k-1} \\ &= -e_k, \end{aligned} \tag{34}$$

and that by (34) and (5),

$$\begin{aligned} -\widetilde{B}_{k-1+d}u_k &= \widetilde{A}_{k-1+d}y_{k+d} - \widetilde{B}_{k-1+d}u_k - \widetilde{A}_{k-1+d}y_{k+d} \\ &= e_{k+d} - v_{k+d} - \widetilde{A}_{k-1+d}y_{k+d}, \end{aligned} \tag{35}$$

where $\widetilde{A}_k := \widehat{A}_k - A_k$. Using (34) and (35) in (33), and defining $\Delta_{5,k} := A^*(\widetilde{B}_{k-1} - \widetilde{B}_{k-d})$, $\Delta_{6,k} := (\widehat{A}_{k-d}\widehat{R}_{k-d}\widehat{B}_{k-d} - \widehat{A}_{k-d} \circ (\widehat{R}_{k-d}\widehat{B}_{k-d}))$, $\Delta_{7,k} := (\widehat{A}_{k-d}\widehat{S}_{k-d} - \widehat{A}_{k-d} \circ \widehat{S}_{k-d})$, $\Delta_{8,k} := \widehat{S}_{k-d}(\widehat{B}_{k-d} - \widehat{B}_{k-d-1})$, and $\Delta_{9,k} := \widehat{S}_{k-d}(\widehat{A}_{k-d} - \widehat{A}_{k-d-1})$, we thus obtain

$$\begin{aligned} A^*B_{k-d}u_{k-d} = &-A^*\widetilde{A}_{k-1}y_k + A^*(e_k - v_k) + \Delta_{5,k}u_{k-d} + \Delta_{6,k}u_{k-d} + \widehat{A}_{k-d}B^*r_{k-d} \\ &+\Delta_{7,k}y_{k-d} - \widehat{S}_{k-d}e_{k-d} + \Delta_{8,k}u_{k-2d} - \Delta_{9,k}y_{k-d}. \end{aligned} \tag{36}$$

We can now use (36) and (32) to obtain the required closed-loop system representation. Define

$$\begin{aligned} x_k &:= [y_k, \ldots, y_{k-p'-\max(p,d)+1}, u_{k-d}, \ldots, u_{k-p'-\ell-d+1}]^T, \\ l_{1,k} &:= q^{-d}B^*r_k + \widehat{R}_{k-1}e_k + \Delta_{1,k}u_{k-d} + \Delta_{2,k}u_{k-d} + \Delta_{3,k}y_k + \Delta_{4,k}y_{k-d}, \\ l_{2,k} &:= A^*(e_k - v_k) + \Delta_{5,k}u_{k-d} + \Delta_{6,k}u_{k-d} + \widehat{A}_{k-d}B^*r_{k-d} \\ &\quad + \Delta_{7,k}y_{k-d} - \widehat{S}_{k-d}e_{k-d} + \Delta_{8,k}u_{k-2d} - \Delta_{9,k}y_{k-d}, \quad \text{and} \\ C_k(q^{-1}) &:= A^*(q^{-1})B_k(q^{-1}) \\ &=: b_{1,k}(1 + c'_{2,k}q^{-1} + \cdots + c'_{p'+\ell+1,k}q^{-(p'+\ell)}). \end{aligned}$$

Note that by Assumptions 2 and 5, all roots of $C_k(q^{-1})$ lie in the open disk $|q|^2 < \sigma < 1$ for all $k \geq 1$.

Using the above definitions, we obtain the representation

$$x_k = F_k x_{k-1} + b_1 l_{1,k} + b_2 l_{2,k}, \tag{37}$$

where

$$F_k := \begin{bmatrix} J' & 0 \\ G'_k & H'_k \end{bmatrix},$$

$$J' = \begin{bmatrix} -a_1^* & \cdots & -a_{p'}^* & 0 & \cdots & 0 \\ & & & & & 0 \\ & & \mathrm{I} & & & \vdots \\ & & & & & 0 \end{bmatrix},$$

$$G'_k = \begin{bmatrix} \star & \cdots & \star \\ & & 0 \\ & 0 & \vdots \\ & & 0 \end{bmatrix},$$

$$H'_k = \begin{bmatrix} -c'_{2,k-1} & \cdots & -c'_{p'+\ell+1,k-1} \\ & & 0 \\ & \mathrm{I} & \vdots \\ & & 0 \end{bmatrix},$$

$$b_1 = [1, 0, \ldots, 0]^T,$$

$$b_2 = [0, \ldots, 0, 1, 0, \ldots, 0]^T,$$

and the $\star$'s represent nonzero scalars whose exact values are unimportant. Note that the eigenvalues of F_k are the zeros of $A^*(q^{-1})$ and the zeros of $B_{k-1}(q^{-1})$. One difference from (31) is that for the case $d > 1$, (37) is driven by terms involving the input and output. However, these occur only in products with the Δ_i terms, which are either parameter or parameter estimate differences or "swapping" terms.

7. The contraction property. We consider the "composite" Lyapunov function

$$W_k := k_F x_k^T P_k x_k + z_k,$$

where $k_F > 0$, and $P_k = P_k^T > 0$ satisfies the discrete-time Lyapunov equation

$$F_k^T P_k F_k - P_k = -I.$$

We note that since the F_k's lie in a compact set and each F_k has all its eigenvalues inside the disk of radius $\sigma^{1/2}$, we have $\|F_k^n\| \le \epsilon_F \gamma^n \le \epsilon_F \sigma^{n/2}$ for some $\epsilon_F > 0$, for all n, k. Hence, $P_k = \sum_{j=0}^{\infty} (F_k^T)^j (F_k)^j \le \lambda_m I$, where $\lambda_m := \epsilon_F^2/(1-\sigma)$.

In what follows, we first show that W_k has a bounded growth rate, and then that W_k has a certain "contraction" property, namely, $W_{k+T} < W_k$ for a certain T whenever W_k is large enough. These are then used to prove the boundedness of W_k, and hence of all signals in the closed-loop system, thus establishing "robust boundedness" of the adaptive system.

LEMMA 5 (Bounded Growth Rate of W). *There exist constants K_w and k_w such that*

$$W_k \le K_w W_{k-1} + k_w \quad \textit{for all } k.$$

Proof. First,

$$\begin{aligned} W_k &\le \frac{k_F \epsilon_F \|x_k\|^2}{1-\sigma} + z_k \\ &\le \frac{k_F \epsilon_F}{1-\sigma} \left(y_k^2 + \|\phi_{k-1}\|^2 + \sum_{j=p+1}^{p'+\max\{p,d\}-1} y_{k-j}^2 + \sum_{j=\ell+d}^{\ell+p'+d-1} u_{k-j}^2 \right) + z_k. \end{aligned}$$

Hence, for some K_{wz} and k_{wz},

$$W_k \le K_{wz} z_k + k_{wz} \le K_{wz}(K_z z_{k-1} + k_z) + k_{wz} \le K_{wz} K_z W_{k-1} + K_{wz} k_z + k_{wz}. \qquad \square$$

LEMMA 6 (the Key Lemma). *For every constant L large enough, whenever there is an interval $[a,b]$ with $W_k \ge 2K_{wz}L$ for all $k \in [a,b]$, the following properties hold.*

(i) $z_k \le W_k \le 2K_{wz} z_k$ *for all* $k \in [a,b]$.

(ii) $W_k \le K_{ww} W_{k-1}$ *for all* $k \in [a+1, b+1]$, *where* $K_{ww} := K_w + \frac{k_w}{2K_{wz}L}$.

(iii) *If* $I_{k-1} = 0$ *for all* $k \in [a,b]$, *then*

$$W_b \le 2K_{wz} \left(g^{b-a} + \frac{2K_3}{(1-g)L} \right) W_a.$$

(iv) *Let* $\overline{\gamma} \in (\max(1 - 1/\lambda_m, g), 1)$. *Let* $I_j = 1$ *for all* $j \in [a,b]$ *or, if* $I_j = 0$ *for any* $j \in [a,b]$, *then suppose there exists an* N *such that* $I_{j+n} = 1$ *for some* $n \in [0, N]$. *Then there exists* $0 < \lambda < 1$ *such that*

$$W_b \le K \exp[-(b-a)\lambda] \left[1 + \frac{K}{L\overline{\gamma}^{b-a}} \right] W_a.$$

Proof. (i) We already have $z_k \leq W_k$, by the definition of W_k. To show that $W_k \leq 2K_{wz}z_k$ for L large enough, we note that because $W_k \leq K_{wz}z_k + k_{wz}$ and $W_k \geq 2K_{wz}L$,

$$z_k \geq \frac{2K_{wz}L - k_{wz}}{K_{wz}} = 2L - \frac{k_{wz}}{K_{wz}}.$$

Hence if we choose L large enough that $k_{wz} \leq K_{wz}[2L - \frac{k_{wz}}{K_{wz}}]$, then $k_{wz} \leq K_{wz}z_k$, thus yielding $W_k \leq 2K_{wz}z_k$.

(ii) This follows easily from the lemma above.

(iii) Since $I_{k-1} = 0$, we have $z_k = gz_{k-1} + 2K_3$ for $a \leq k \leq b$. Hence,

$$\begin{aligned} z_b &= g^{b-a}z_a + 2K_3 \sum_{j=a+1}^{b} g^{b-j} \leq g^{b-a}W_a + \frac{2K_3}{(1-g)} \\ &\leq \left[g^{b-a} + \frac{2K_3}{L(1-g)}\right] W_a, \end{aligned} \tag{38}$$

since $2K_{wz} \geq 1$ implies $W_a \geq 2K_{wz}L \geq L$. Hence $W_b \leq 2K_{wz}z_b \leq 2K_{wz}[g^{b-a} + 2K_3/L(1-g)]W_a$.

(iv) First, let us consider the case $d = 1$ for simplicity. We note that

$$\begin{aligned} W_k &= k_F x_k^T P_k x_k + z_k \\ &\leq k_F(F_k x_{k-1} + b_{e,k}e_k + l_k)^T P_k(F_k x_{k-1} + b_{e,k}e_k + l_k) + gz_{k-1} \\ &\quad + K_y e_k^2 + K_u u_{k-1}^2 + 2K_3 \quad (\text{with } l_k := b_{v,k}v_k + b_{r,k}r'_{k-1}) \\ &\leq k_F x_{k-1}^T (P_k - I)x_{k-1} + 2k_F x_{k-1}^T F_k^T P_k b_{e,k}e_k + 2k_F x_{k-1}^T F_k^T P_k l_k \\ &\quad + 2k_F b_{e,k}^T P_k l_k e_k + k_F b_{e,k}^T P_k b_{e,k} e_k^2 + k_F l_k^T P_k l_k \\ &\quad + gz_{k-1} + K_y e_k^2 + K_u u_{k-1}^2 + 2K_3. \end{aligned} \tag{39}$$

Now defining $\gamma_1 := \sup_k \|F_k^T P_k b_{e,k}\|$, $\gamma_2 := \sup_k \|F_k^T P_k\|$, $\gamma_3 := \sup_k \|P_k b_{e,k}\|$, and since $P_k \leq \lambda_m I$, we have the following inequalities:

$$\left|2k_F x_{k-1}^T F_k^T P_k b_{e,k} e_k\right| \leq 2\gamma_1 k_F \|x_{k-1}\||e_k| \leq \gamma_1 k_F \left[\epsilon_5 \|x_{k-1}\|^2 + \frac{1}{\epsilon_5} e_k^2\right],$$

$$\left|2k_F x_{k-1}^T F_k^T P_k l_k\right| \leq \gamma_2 k_F \left(\epsilon_6 \|x_{k-1}\|^2 + \frac{1}{\epsilon_6}\|l_k\|^2\right),$$

$$\left|2k_F b_{e,k}^T P_k l_k e_k\right| \leq \gamma_3 k_F \left(\|l_k\|^2 + e_k^2\right),$$

and

$$u_{k-1}^2 \leq \frac{1}{b_{\min}^2}\left(K + K(K_\theta + K_{\widetilde{\theta}})^2 \|x_{k-1}\|^2\right) \quad (\text{from (26)}). \tag{40}$$

Hence,

$$\begin{aligned} W_k &\leq k_F x_{k-1}^T P_{k-1} x_{k-1} + gz_{k-1} + k_F\left[-1 + \epsilon_5\gamma_1 + \epsilon_6\gamma_2 + \frac{K_u K(K_\theta + K_{\widetilde{\theta}})}{b_{\min}^2 k_F}\right]\|x_{k-1}\|^2 \\ &\quad + k_F x_{k-1}^T (P_k - P_{k-1})x_{k-1} + \left[\frac{\gamma_1 k_F}{\epsilon_5} + \gamma_3 k_F + \left(1 + \frac{1}{b_{\min}^2}\right)k_F\lambda_m + K_y\right] e_k^2 \\ &\quad + \left[\frac{\gamma_2 k_F}{\epsilon_6} + \gamma_3 k_F + k_F\lambda_m\right]\|l_k\|^2 + 2K_3 + \frac{KK_u}{b_{\min}^u}. \end{aligned}$$

Now, choose $\overline{\gamma} \in (\max(1 - 1/\lambda_m, g), 1)$, k_F large enough, and $\epsilon_5, \epsilon_6 > 0$ small enough so that

$$-1 + \epsilon_5\gamma_1 + \epsilon_6\gamma_2 + \frac{K_u K(K_\theta + K_{\tilde{\theta}})^2}{b_{\min}^2 k_F} \leq -(1 - \overline{\gamma})\lambda_m, \tag{41}$$

and define $K_{ee} := \gamma_1 k_F/\epsilon_5 + \gamma_3 k_F + (1 + 1/b_{\min}^2)k_F\lambda_m + K_y$, $K_l := \gamma_2 k_F/\epsilon_6 + \gamma_3 k_F + k_F\lambda_m$ and $\overline{K}_3 := K_3 + KK_u/2b_{\min}^2$. This gives

$$\begin{aligned} W_k \leq\ & k_F x_{k-1}^T P_{k-1} x_{k-1} + g z_{k-1} - k_F(1 - \overline{\gamma})\lambda_m \|x_{k-1}\|^2 \\ & + k_F x_{k-1}^T (P_k - P_{k-1}) x_{k-1} + K_{ee} e_k^2 + K_l \|l_k\|^2 + 2\overline{K}_3. \end{aligned}$$

However,

$$\begin{aligned} k_F x_{k-1}^T P_{k-1} x_{k-1} + g z_{k-1} &= \overline{\gamma} W_{k-1} + k_F(1 - \overline{\gamma}) x_{k-1}^T P_{k-1} x_{k-1} + (g - \overline{\gamma}) z_{k-1} \\ &\leq \overline{\gamma} W_{k-1} + k_F(1 - \overline{\gamma})\lambda_m \|x_{k-1}\|^2, \end{aligned}$$

and so,

$$W_k \leq \overline{\gamma} W_{k-1} + k_F x_{k-1}^T (P_{k-1} - P_{k-1}) x_{k-1} + K_{ee} e_k^2 + K_l \|\ell_k\|^2 + 2\overline{K}_3.$$

Now focusing on $x_{k-1}^T (P_k - P_{k-1}) x_{k-1}$, we have

$$\begin{aligned} x_{k-1}^T (P_k - P_{k-1}) x_{k-1} &= x_{k-1}^T \left[\sum_{i=0}^{\infty} (F_k^T)^i F_k^i - \sum_{i=0}^{\infty} (F_{k-1}^T)^i F_{k-1}^i \right] x_{k-1} \\ &= \sum_{i=0}^{\infty} \left(\|F_k^i x_{k-1}\|^2 - \|F_{k-1}^i x_{k-1}\|^2 \right) \\ &= \sum_{i=0}^{\infty} (\|F_k^i x_{k-1}\| + \|F_{k-1}^i x_{k-1}\|)(\|F_k^i x_{k-1}\| - \|F_{k-1}^i x_{k-1}\|) \\ &\leq \sum_{i=0}^{\infty} 2\epsilon_F \sigma^{i/2} \|x_{k-1}\| (\|F_k^i x_{k-1}\| - \|F_{k-1}^i x_{k-1}\|). \end{aligned}$$

Now note that

$$\begin{aligned} \|F_k^i x_{k-1}\| - \|F_{k-1}^i x_{k-1}\| &\leq \|(F_k^i - F_{k-1}^i) x_{k-1}\| \leq \|F_k^i - F_{k-1}^i\| \|x_{k-1}\| \\ &= \|F_k^i - F_k^{i-1} F_{k-1} + F_k^{i-1} F_{k-1} - F_k^{i-2} F_{k-1}^2 \\ &\qquad + F_k^{i-2} F_{k-1}^2 \ldots - F_{k-1}^i\| \|x_{k-1}\| \\ &\leq \sum_{j=0}^{i-1} \|F_k^{i-j} F_{k-1}^j - F_k^{i-1-j} F_{k-1}^{j+1}\| \|x_{k-1}\| \\ &\leq \sum_{j=0}^{i-1} \|F_k^{i-1-j}\| \|F_{k-1}^j\| \|F_k - F_{k-1}\| \|x_{k-1}\| \\ &\leq \epsilon_F^2 \sum_{j=0}^{i-1} \sigma^{(i-1-j)/2} \sigma^{j/2} K \|\delta_k\| \|x_{k-1}\| \\ &= i\sigma^{(i-1)/2} \epsilon_F^2 K \|\delta_k\| \|x_{k-1}\|. \end{aligned}$$

Hence

$$x_{k-1}^T(P_k - P_{k-1})x_{k-1} \le K\epsilon_F^3 \sum_{i=0}^{\infty} 2i\sigma^{(2i-1)/2}\|\delta_k\|\|x_{k-1}\|^2 \le K\epsilon_F^3\|\delta_k\|\|x_{k-1}\|^2$$
$$\le K\epsilon_F^3\|\delta_k\|z_{k-1}.$$

Thus we have

$$W_k \le \overline{\gamma}W_{k-1} + Kk_F\epsilon_F^3\|\delta_k\|z_{k-1} + K_{ee}e_k^2 + K_l\|l_k\|^2 + 2\overline{K}_3$$
$$\le \left[\overline{\gamma} + Kk_F\epsilon_F^3\|\delta_k\| + K_{ee}\frac{e_k^2}{z_{k-1}} + K_l\frac{\|l_k\|^2}{z_{k-1}}\right]W_{k-1} + 2\overline{K}_3,$$

i.e., $W_k \le g_k W_{k-1} + 2\overline{K}_3$, where g_k is the term in the square brackets above.

From this recursive bound, we obtain

$$W_b \le \left(\prod_{j=a+1}^{b} g_j\right)W_a + 2\overline{K}_3\sum_{t=a+1}^{b}\left(\prod_{j=t+1}^{b} g_j\right),$$

and so

$$\frac{W_b}{W_a} \le \left(\prod_{j=a+1}^{b} g_j\right)\left[1 + \frac{2\overline{K}_3}{W_a}\sum_{t=a+1}^{b}\left(\prod_{j=a+1}^{t} g_j\right)^{-1}\right]$$
$$\le e^{\sum_{j=a+1}^{b}\ln g_j}\left[1 + \frac{\overline{K}_3}{K_{wz}L}\sum_{t=a+1}^{b}\left(\frac{1}{\overline{\gamma}}\right)^{t-a}\right] \tag{42}$$
$$\le e^{\sum_{j=a+1}^{b}\ln g_j}\left[1 + \frac{\overline{K}_3}{K_{wz}L}\frac{1}{\overline{\gamma}^{b-a}(1-\overline{\gamma})}\right].$$

Now, since $\log x \le x - 1$ for all $x > 0$,

$$\sum_{j=a+1}^{b}\ln g_j \le \sum_{j=a+1}^{b} g_j - (b-a)$$
$$\le (\overline{\gamma} - 1)(b-a) + Kk_F\epsilon_F^3\sum_{j=a+1}^{b}\|\delta_j\|$$
$$+K_{ee}\sum_{j=a+1}^{b}\frac{e_j^2}{z_{j-1}} + K_l\sum_{j=a+1}^{b}\frac{\|l_j\|^2}{z_{j-1}}.$$

Using (vii) of Lemma 3 and the fact that $z_{j-i} \ge L$, we obtain $z_{j-1} \ge K_\rho\rho_{j-1}$ for all $j \in [a+1, b]$. Now noting that $\sum_{j=a+1}^{b}\|\delta_j\| \le K_\delta + k_\delta(b-a)$, $z_{j-1} \ge K_\rho\rho_{j-1}$, and

$$\frac{\|l_j\|^2}{z_{j-1}} = \frac{\|b_{v,j}v_j + b_{r,j}r'_{j-1}\|^2}{z_{j-1}} \le 2\left[\frac{v_j^2}{b_{\min}^2 z_{j-1}} + \frac{\|b_{r,j}\|^2 r'^2_{j-1}}{z_{j-1}}\right]$$
$$\le 2\frac{K_{vz}}{b_{\min}^2} + \frac{2k_{vz}}{b_{\min}^2 L} + \frac{2K(1+K_\theta^2)}{L},$$

we obtain

$$\sum_{j=a+1}^{b} \ln g_j \le -(1-\overline{\gamma}-Kk_F\epsilon_F^3k_\delta)(b-a)+Kk_F\epsilon_F^3K_\delta+\frac{K_{ee}}{K_\rho}\sum_{j=a+1}^{b}\frac{e_j^2}{\rho_{j-1}}$$
$$+K_l\left[\frac{2K_{vz}}{b_{\min}^2}+\frac{2k_{vz}}{b_{\min}^2L}+\frac{2K(1+K_{\hat{\theta}}^2)}{L}\right](b-a).$$

From (17), using Lemma 4(ii), we obtain

$$\sum_{j=a+1}^{b}\frac{e_j^2}{\rho_{j-1}} \le K_{ev}\sum_{j=a+1}^{b}\frac{v_j^2}{\rho_{j-1}}+k_e(b-a)+K_e$$
$$\le \frac{K_{ev}}{\bar{k}(N)}(b-a)\left[K_{vz}+\frac{k_{vz}}{L}\right]+k_e(b-a)+K_e.$$

Hence,

$$\sum_{j=a+1}^{b}\ln g_j \le -(1-\overline{\gamma}-Kk_F\epsilon_F^3k_\delta)(b-a)+Kk_F\epsilon_F^3K_\delta$$
$$+\frac{K_{ee}}{K_\rho}\frac{K_{ev}}{\bar{k}(N)}\left[K_{vz}+\frac{k_{vz}}{L}\right](b-a)+\frac{K_{ee}}{K_\rho}k_e(b-a)$$
$$+\frac{K_{ee}K_e}{K_\rho}+K_l\left[\frac{2K_{vz}}{b_{\min}^2}+\frac{2k_{vz}}{b_{\min}^2L}+\frac{2K(1+K_{\hat{\theta}}^2)}{L}\right](b-a)$$
$$=-(b-a)\left(1-\overline{\gamma}-Kk_F\epsilon_F^3k_\delta-\frac{K_{ee}}{K_\rho}\frac{K_{ev}}{\bar{k}(N)}\left[K_{vz}+\frac{k_{vz}}{L}\right]\right.$$
$$\left.-\frac{K_{ee}k_e}{K_\rho}-K_l\left[\frac{2K_{vz}}{b_{\min}^2}+\frac{2k_{vz}}{b_{\min}^2L}+\frac{2K(1+K_{\hat{\theta}}^2)}{L}\right]\right)$$
$$+Kk_F\epsilon_F^3K_\delta+\frac{K_{ee}K_e}{K_\rho}$$
$$=-(b-a)\left[1-\overline{\gamma}-Kk_F\epsilon_F^3k_\delta-K_{vz}\left(\frac{K_{ee}}{K_\rho}\frac{K_{ev}}{\bar{k}(N)}+\frac{2K_l}{b_{\min}^2}\right)\right.$$
$$\left.-\frac{1}{L}\left(\frac{K_{ee}}{K_\rho}\frac{K_{ev}}{\bar{k}(N)}k_{vz}+\frac{2k_{vz}K_l}{b_{\min}^2}+\frac{2K(1+K_{\hat{\theta}}^2)K_l}{L}\right)-\frac{K_{ee}k_e}{K_\rho}\right]$$
$$+Kk_F\epsilon_F^3K_\delta+\frac{K_{ee}K_e}{K_\rho}.$$

By choosing K_v, k_δ small enough and L large enough, we obtain

$$\sum_{j=a+1}^{b}\ln g_j \le -(b-a)\lambda+\frac{K_eK_{ee}}{K_\rho}+Kk_F\epsilon_F^3K_\delta \tag{43}$$

for some $0<\lambda<1$.

We thus obtain

$$\frac{W_b}{W_a} \le e^{-(b-a)\lambda}\left[1+\frac{\overline{K}_3}{K_{wz}L(1-\overline{\gamma})\overline{\gamma}^{b-a}}\right]e^{\left(K_eK_{ee}/K_\rho+Kk_F\epsilon_F^3K_\delta\right)}.$$

Now we turn to the case $d > 1$. The essential difference between the cases $d = 1$ and $d > 1$ is that we replace $b_{e,k}e_k$ by $b_1 l_{1,k}$, and replace l_k by $b_{1,k-d}$ in (39). Hence we need to bound $l_{1,k}^2$ and $l_{2,k}^2$ in terms of $e_{(\cdot)}^2$, $v_{(\cdot)}^2$, and $\|\delta_{(\cdot)}\|$. This is done as in the proof of Lemma 3, except that $A^*(B_{k-1} - B_{k-d})u_{k-d}$, which is part of $\Delta_{5,k}u_{k-d}$ has to be handled differently. It gives rise to terms involving $\|\delta_j\|$.

Let us consider how we overbound $l_{1,k}^2$. As in the proof of Lemma 3(ii), we obtain

$$(\Delta_{1,k}u_{k-d})^2 \le K\sum_{j=1}^{d-1} e_{k-j}^2 + K,$$

$$(\Delta_{2,k}u_{k-d})^2 \le K\sum_{j=1}^{d-1} e_{k-j}^2 + K,$$

$$(\Delta_{3,k}y_k)^2 \le K\sum_{j=1}^{d-1} e_{k-j}^2 + K, \quad \text{and}$$

$$(\Delta_{4,k}y_{k-d})^2 \le K\sum_{j=1}^{d-1} e_{k-j}^2 + K.$$

Combining these yields $l_{1,k}^2 \le K\sum_{j=1}^{d-1} e_{k-j}^2 + K$.

Next, consider $l_{2,k}^2$. First, note that we have the following inequality, whose counterpart in the $d = 1$ case is (40):

$$u_{k-d}^2 \le K\|x_{k-1}\|^2 + K. \tag{44}$$

This is obtained by applying the control law (9), using the boundedness of the parameter estimates, and the boundedness from below, by $b_{\min} > 0$, of $\hat{b}_{1,k-d}$.

For the term $A^*(B_{k-1} - B_{k-d})u_{k-d}$, we have

$$\begin{aligned}
(A^*(B_{k-1} - B_{k-d})u_{k-d})^2 &= ((B_{k-1} - B_{k-d})A^*u_{k-d})^2 \\
&= \left(\sum_{j=1}^{d-1}(B_{k-j} - B_{k-j-1})A^*u_{k-d}\right)^2 \\
&= \left(\sum_{j=1}^{d-1}\sum_{i=0}^{\ell-1}\sum_{i'=1}^{p'}(b_{i+1,k-j} - b_{i+1,k-j-1})a_{i'}^*u_{k-d-i-i'}\right)^2 \\
&\le K\left(\sum_{j=1}^{d-1}\|\theta_{k-j} - \theta_{k-j-1}\|\sum_{i=0}^{p'+\ell-1}|u_{k-d-i}|\right)^2 \\
&\le K\sum_{j=1}^{d-1}\|\theta_{k-j} - \theta_{k-j-1}\|^2(u_{k-d}^2 + \cdots + u_{k-d-p'-\ell+1}^2) \\
&\le (K\|x_{k-1}\|^2 + K)\left(\sum_{j=1}^{d-1}\|\theta_{k-j} - \theta_{k-j-1}\|^2\right) \\
&\le (Kz_{k-1} + K)\left(\sum_{j=1}^{d-1}\|\theta_{k-j} - \theta_{k-j-1}\|^2\right),
\end{aligned}$$

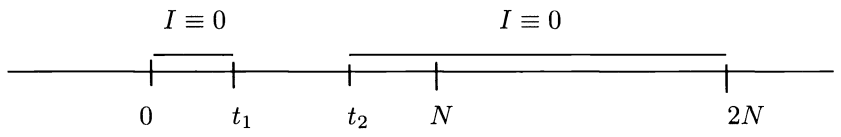

FIG. 1. *Illustration of Case* 2.

where the last two inequalities follow from (44) and the definition of $z(\cdot)$. The remaining terms can be handled similarly. □

LEMMA 7 (the Contraction Lemma). Consider $0 < \gamma^* < 1$. Then there exist N, L large enough, and $K_{v\max}, k_{\delta\max} > 0$ so that if $K_v \in [0, K_{v\max}]$ and $k_\delta \in [0, k_{\delta\max}]$, and

$$W_k \geq 2K_{wz}L \quad \text{for all } k \in [l-1, l+2N],$$

then

$$W_{l+2N} \leq \gamma^* W_{l-1}. \tag{45}$$

Proof. There are four cases to consider.

Case 1. Suppose $I_{t-1} = 0$ for all $t \in [l, l+2N]$. From part (iii) of Lemma 6,

$$W_{l+2N} \leq 2K_{wz}\left(g^{2N} + \frac{2\overline{K}_3}{(1-g)L}\right) W_l.$$

Hence, for N, L large enough, and $K_{v\max}$ and $k_{\delta\max}$ correspondingly small, we have (45).

Case 2. Suppose $0 \leq t_1 \leq t_2 \leq N$, where $t_1 = \min\{t \in [0, 2N] : I_{t+l-1} = 1\}$ and $t_2 = \max\{t \in [t_1, 2N] : I_{t+l-1} = 1\}$. (See Fig. 1.)

Note that this implies that $I_{k-1} = 0$ for all $k \in [l, l+t_1-1]$, and $I_{k-1} = 0$ for all $k \in [l+t_2+1, l+2N]$. First suppose $t_2 > 0$. Using parts (ii), (iii) and (iv) of Lemma 6, we have

$$\begin{aligned}
W_{l+2N} &\leq 2K_{wz}\left(g^{2N-t_2-1} + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l+t_2+1} \\
&\leq 2K_{wz}K_{ww}^2\left(g^{2N-t_2-1} + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l+t_2-1} \\
&\leq 2K_{wz}K_{ww}^2\left(g^{N-1} + \frac{2\overline{K}_3}{(1-g)L}\right) K\exp[-\lambda t_2]\left(1 + \frac{K}{L\overline{\gamma}^{t_2}}\right) W_{l-1} \\
&\leq 2K_{wz}K_{ww}^2 K\left(g^{N-1} + \frac{2\overline{K}_3}{(1-g)L}\right)\left(1 + \frac{K}{L\overline{\gamma}^N}\right) W_{l-1},
\end{aligned}$$

yielding (45) when N, L are large enough, and $K_{v\max}$ and $k_{\delta\max}$ appropriately small. If $t_2 = 0$, then by parts (ii) and (iii) of Lemma 6,

$$\begin{aligned}
W_{l+2N} &\leq 2K_{wz}\left(g^{2N-1} + \frac{2\overline{\overline{K}}_3}{(1-g)L}\right) W_{l+1} \\
&\leq 2K_{wz}K_{ww}^2\left(g^{2N-1} + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l-1},
\end{aligned}$$

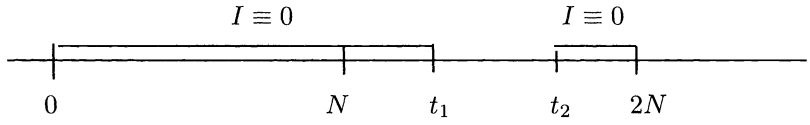

FIG. 2. *Illustration of Case* 3.

hence giving (45).

Case 3. Suppose $N < t_1 \leq t_2 \leq 2N$. First suppose $t_2 < 2N$. (See Fig. 2.)

Using parts (ii), (iii), and (iv) of Lemma 6, we have

$$W_{l+2N} \leq 2K_{wz}\left(g^{2N-t_2-1} + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l+t_2+1},$$

$$W_{l+t_2+1} \leq K_{ww}^2 W_{l+t_2-1},$$

$$W_{l+t_2-1} \leq K \exp\left[-\lambda(t_2 - 1 - N)\right]\left[1 + \frac{K}{L\overline{\gamma}^{t_2-1-N}}\right] W_{l+N},$$

and using parts (ii) and (iii) of Lemma 6 gives

$$W_{l+N} \leq 2K_{wz}K_{ww}\left(g^N + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l-1}.$$

This yields

$$W_{l+2N} \leq 4KK_{wz}^2K_{ww}^3\left(g^N + \frac{2\overline{K}_3}{(1-g)L}\right)\left(1 + \frac{2\overline{K}_3}{(1-g)L}\right)\left(1 + \frac{K}{L\overline{\gamma}^{N-1}}\right) W_{l-1},$$

and hence (45). If $t_2 = 2N$, the first two inequalities are replaced by

$$W_{l+2N} \leq K_{ww}W_{l+2N-1} = K_{ww}W_{l+t_2-1}.$$

This gives

$$W_{l+2N} \leq 2KK_{wz}K_{ww}^2\left(g^N + \frac{2\overline{K}_3}{(1-g)L}\right)\left(1 + \frac{K}{L\overline{\gamma}^{N-1}}\right) W_{l-1},$$

hence giving (45).

Case 4. Suppose $0 \leq t_1 \leq N < t_2 \leq 2N$. Define $t_3 := \min\{t \in [N, t_2] : I_{t+l-1} = 1\}$ and $t_4 := \max\{t \in [t_1, N] : I_{t+l-1} = 1\}$. Note that this implies that $I_{k-1} = 0$ for all $k \in [l + t_4 + 1, l + t_3 - 1]$. (See Fig. 3.)

Case 4a. Suppose $t_3 - t_4 < N$. First suppose $t_2 < 2N$. Using parts (ii), (iii), and (iv) of Lemma 6, we have

$$W_{l+2N} \leq 2K_{wz}\left(g^{2N-t_2-1} + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l+t_2+1},$$

$$W_{l+t_2+1} \leq K_{ww}^2 W_{l+t_2-1},$$

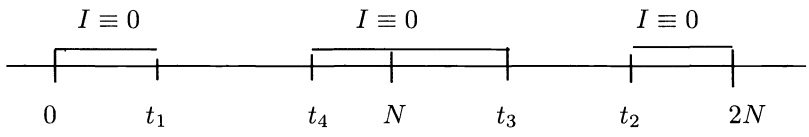

FIG. 3. *Illustration of Case* 4.

and

$$W_{l+t_2-1} \leq K \exp[-\lambda t_2] \left(1 + \frac{K}{L\bar{\gamma}^{t_2}}\right) W_{l-1},$$

which gives

$$W_{l+2N} \leq 2KK_{wz}K_{ww}^2 \left(1 + \frac{2\overline{K}_3}{(1-g)L}\right) \exp(-\lambda N) \left(1 + \frac{K}{L\bar{\gamma}^{2N}}\right) W_{l-1},$$

and hence (45). If $t_2 = 2N$, the first two inequalities are replaced by

$$W_{l+2N} \leq K_{ww} W_{l+2N-1} = K_{ww} W_{l+t_2-1}.$$

This gives

$$W_{l+2N} \leq KK_{ww} \exp(-2\lambda N) \left(1 + \frac{K}{L\bar{\gamma}^{2N}}\right) W_{l-1},$$

and hence (45).

Case 4b. Suppose $t_3 - t_4 \geq N$. Again, first suppose that $t_2 < 2N$. Using parts (ii), (iii), and (iv) of Lemma 6, we have

$$W_{l+2N} \leq 2K_{wz} \left(g^{2N-t_2-1} + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l+t_2+1},$$

$$W_{l+t_2+1} \leq K_{ww}^2 W_{l+t_2-1},$$

$$W_{l+t_2-1} \leq K \exp(-\lambda(t_2 - t_3)) \left(1 + \frac{K}{L\bar{\gamma}^{t_2-t_3}}\right) W_{l+t_3-1},$$

$$W_{l+t_3-1} \leq 2K_{wz} \left(g^{t_3-t_4-2} + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l+t_4+1},$$

$$W_{l+t_4+1} \leq K_{ww}^2 W_{l+t_4-1},$$

and

$$W_{l+t_4-1} \leq K \exp(-\lambda t_4) \left(1 + \frac{K}{L\bar{\gamma}^{t_4}}\right) W_{l-1},$$

which gives

$$W_{l+2N} \leq 4K^2 K_{wz}^2 K_{ww}^4 \left(g^{N-2} + \frac{2\overline{K}_3}{(1-g)L}\right) \left(1 + \frac{K}{L\bar{\gamma}^N}\right)^2 \left(1 + \frac{2\overline{K}_3}{(1-g)L}\right) W_{l-1},$$

and hence (45). If $t_2 = 2N$, the first two inequalities are replaced by

$$W_{l+2N} \leq K_{ww} W_{l+2N-1} = K_{ww} W_{l+t_2-1}.$$

This gives

$$W_{l+2N} \leq 2K^2 K_{wz} K_{ww}^3 \left(g^{N-2} + \frac{2\overline{K}_3}{(1-g)L} \right) \left(1 + \frac{K}{L\bar{\gamma}^N} \right)^2 W_{l-1},$$

thus establishing (45) in all cases. □

THEOREM 1 (Robust Boundedness Theorem). *Consider the adaptive control system, when the plant satisfies Assumptions 1–5. Then all signals in the closed-loop adaptive system are bounded, whenever K_v and k_δ are small enough.*

Proof. As a consequence of the Bounded Growth Rate Lemma (BGRL) and the Contraction Lemma (CL), W is bounded. To see this, note that by BGRL, W cannot have a finite escape time. Hence, it can only become infinite by growing over an unbounded length of time. However, CL disallows this by establishing that if W stays above a certain value ($2K_{wz}L$) for a certain time interval ($2N+1$ samples), it must contract. That is, W cannot continue to grow for more than $2N+1$ consecutive samples at a time, once it has grown larger that $2K_{wz}L$. Hence, W is bounded.

Since W bounds all other signals through z and x, we conclude that all closed-loop signals are bounded. □

Remark. These results extend easily to recursive least-squares-based schemes that keep the condition number of the covariance matrix bounded.

8. Performance for a nominal system. In this section we consider the performance that can be achieved in the absence of unmodeled dynamics, and when the parameter variations go to zero asymptotically, specifically when $\|\delta_k\| \in \ell_1$. We show that the desired objective is met.

THEOREM 2. *If $K_v = k_v = k_\delta = 0$, then*

(a) $\lim_{k\to\infty} e_k = 0$,

(b) $\lim_{k\to\infty} (A^*(q^{-1})y_k - q^{-d}B^*(q^{-1})r_k) = 0$.

Remark. Note that we *do not* need the nominal plant parameters to be time-invariant; we only require them to satisfy $\|\delta_k\| \in \ell_1$. That is,

$$\sum_{k=t+1}^{\infty} \|\theta_k - \theta_{k-1}\| \leq K_\delta, \qquad \forall t.$$

Proof. (a) Recall from Lemma 1(iii) that

$$\sum_{k=t+1}^{t+T} \frac{e_k^2}{\rho_{k-1}} \leq K_{ev} \sum_{k=t+1}^{t+T} \frac{v_k^2}{\rho_{k-1}} + k_e T + K_e.$$

Since $K_v = K_v = k_\delta = 0$, from Assumption 4 and Lemma 1(iii) we have $v_k \equiv 0$ and $k_e = 0$, which gives

$$\sum_{k=t+1}^{t+T} \frac{e_k^2}{\rho_{k-1}} \leq K_e \qquad \forall t, T.$$

Recalling that $\rho_{(\cdot)}$ is uniformly bounded by Theorem 1 and letting $\rho_{\max} := \max_{k\geq 0}\{\rho_k\}$, we obtain

$$\sum_{k=t+1}^{t+T} e_k^2 \leq K_e \rho_{\max} \qquad \forall t, T.$$

Fixing t and letting T go to infinity gives $e \in \ell_2$ and hence $e_k \to 0$ as $k \to \infty$.

(b) Recalling (10), the fact that $\|\widehat{\theta}_k - \widehat{\theta}_{k-1}\| \leq \|\widehat{\theta}'_k - \widehat{\theta}_{k-1}\|$ due to parameter projection and using the Cauchy–Schwarz inequality, we obtain

$$\|\widehat{\theta}_k - \widehat{\theta}_{k-j}\| \in \ell_2, \quad \text{for all finite } j.$$

Using this in (27), the closed-loop boundedness of all signals, and using (a) yields the desired result. □

9. Robust performance. We now show that the performance of the adaptive controller, as measured by the mean square output prediction error, is robust in that it is linear (hence also continuous) in the magnitude of the unmodeled dynamics, bounded disturbances, and average rate of parameter variations.

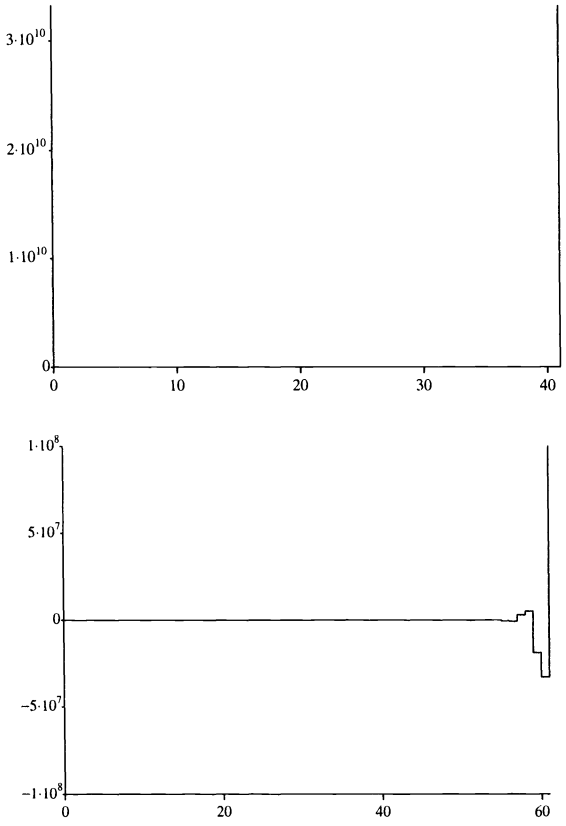

FIG. 4. (a) *Unmodified (LMS-type) gradient estimator: y blows up*; (b) *gradient estimator with parameter projection: y blows up.*

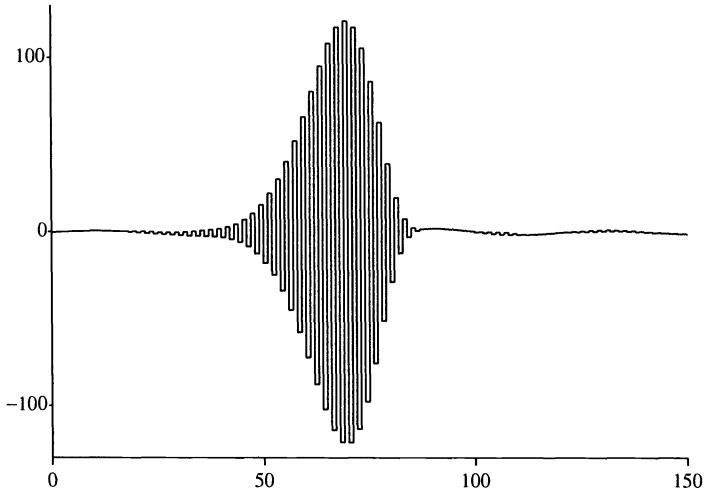

FIG. 5. *Normalized gradient estimator: y is not well behaved.*

THEOREM 3. *We have*

$$\limsup_{T\to\infty} \frac{1}{T} \sum_{k=t+1}^{t+T} e_k^2 \leq c_1 K_v + c_2 k_v + c_3 k_\delta,$$

where c_1, c_2, c_3 are generic constants that can only decrease (or remain constant) as K_v, k_v, k_δ decrease.

Proof. Using Assumption 4 and Lemma 1(iv), and recalling that $\{m_k\}$ and $\{\rho_k\}$ are uniformly bounded by Theorem 1, we obtain

$$\begin{aligned}\sum_{k=t+1}^{t+T} \frac{e_k^2}{\rho_{k-1}} &\leq K_{ev} \sum_{k=t+1}^{t+T} \frac{K_v m_{k-1} + k_v}{\rho_{k-1}} + k_e T + K_e, \qquad \forall t, T \\ &\leq K_{ev}(KK_v + Kk_v)T + k_e T + K_e, \qquad \forall T.\end{aligned}$$

This implies

$$\limsup_{T\to\infty} \frac{1}{T} \sum_{k=t+1}^{t+T} e_k^2 \leq KK_{ev}(KK_v + Kk_v) + Kk_e,$$

which yields the desired result after using Lemma 1(iv). □

10. Simulation example. We now demonstrate the advantage of the suggested adaptive control algorithm through a simulation example. The system is modelled as

$$y_k = a_k y_{k-1} + b_k u_{k-1},$$

where a_k and b_k are unknown, possibly time-varying parameters. The true unknown system is, however, given by the following:

$$y_k = 1.5 \sin\left(\frac{\pi k}{1000}\right) y_{k-1} + \left[1 + 0.4 \cos\left(\frac{\pi k}{1500}\right)\right] u_{k-1} + 0.2 \sum_{j=0}^{k-2} (0.5)^j y_{k-2-j} + d_k,$$

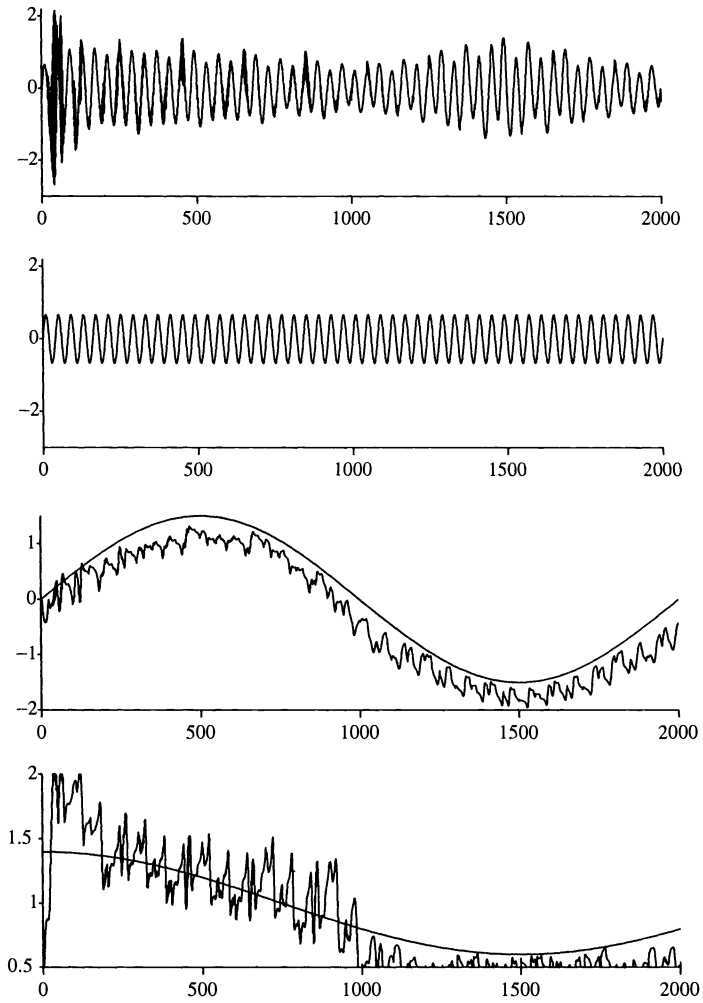

FIG. 6. *Proposed adaptive control algorithm*: (a) *system output*, y; (b) *model reference output*, y^*; (c) *true and estimated* a_k; (d) *true and estimated* b_k.

where d_k denotes a discrete square wave disturbance of period 100 and amplitude 0.15. The adaptive control is designed to track the following model reference trajectory:

$$y_k^* = -0.5y_{k-1}^* + r_k.$$

As Fig. 4 shows, using an unmodified LMS-type gradient estimator or an LMS-type gradient estimator with parameter projection causes the output to blow up. Figure 5 illustrates the undesirable behavior that results if we use a normalized gradient estimator, as used in the ideal case. Finally, Fig. 6 illustrates the results obtained if we use the adaptive control algorithm with parameter projection, as proposed in this paper. Figures 6(c) and 6(d) also exhibit the nice parameter tracking that is achieved.

11. Concluding remarks. We have presented an indirect adaptive pole-zero placement control law using a simple parameter estimator employing projection. We have shown that this is robust for plants that simultaneously feature unknown slow-

in-the-mean time-variations of the nominal parameters, as well as small unmodeled dynamics and bounded disturbances, without any restriction on the magnitude of the bound. The plant parameters may even make occasional jumps. No special normalization is used. Instead, the signals entering the parameter update law are normalized by the squared norm of an "extended" regressor, which requires neither any a priori system knowledge nor any additional computation.

It is straightforward to extend this analysis to recursive least-squares-based update laws that monitor, and keep bounded, the condition number of the covariance matrix.

Several issues still need to be explored. A major restriction is that we require the frozen nominal plant to be minimum phase at every instant. Transient performance, and the precise sizes of unmodeled dynamics and parameter variations tolerated, are issues that require deeper study.

INFORMATION STRUCTURES, CAUSALITY, AND NONSEQUENTIAL STOCHASTIC CONTROL II: DESIGN-DEPENDENT PROPERTIES*

MARK S. ANDERSLAND† AND DEMOSTHENIS TENEKETZIS‡

Abstract. In control theory, the usual notion of causality—that, at all times, a system's output (action) only depends on its past and present inputs (observations)—presupposes that all inputs and outputs can be ordered, a priori, in time. In reality, many distributed systems (those subject to deadlock, for instance), are not *sequential* in this sense.

In a previous paper (part I) [*SIAM J. Control Optim.*, 30 (1992), pp. 1447–1475], the relationship between a less restrictive notion of causality, *deadlock-freeness*, and the design-independent properties of a potentially *nonsequential* generic stochastic control problem formulated within the framework of Witsenhausen's intrinsic model was explored. In the present paper (part II) the properties of individual designs are examined. In particular, a property of a design's *information partition* that is necessary and sufficient to ensure its deadlock-freeness is identified and shown to be sufficient to ensure its possession of an expected reward. It is also shown, by example, that there exist nontrivial deadlock-free designs that cannot be associated with any deadlock-free information structure.

The first result provides an intuitive design-dependent characterization of the cause/effect notion of causality and suggests a framework for the optimization of constrained nonsequential stochastic control problems. The second implies that this characterization is finer than existing design-independent characterizations, including properties C (Witsenhausen) and CI (part I).

Key words. information structures, causality, deadlock-freeness, nonsequential stochastic control

1. Introduction.

In control theory the usual notion of causality—that, at all times a system's output (action) only depends on its past and present inputs (observations)—presupposes that all inputs and outputs can be ordered a priori in time. In reality, many controlled systems—including distributed data [5], communication [6], manufacturing [3], and detection networks [2]—need not be *sequential* [10] in this sense.

Consider, for example, a simple detection network in which three decentralized detectors D^1, D^2, and D^3 (perhaps radars or inspectors) each make a noisy observation of the same uncertain event (plane or product). Suppose that each detector forms and transmits a one-bit hypothesis concerning the event (e.g., friend/foe or pass/fail) to a silent coordinator. Moreover, suppose that each detector may elect to monitor the others' transmissions before forming its hypothesis. Then, depending on the detectors' control laws (termed the *design*) and the particular event that occurs, 64 different dependencies are possible, 39 of which deadlock.[1] For instance, D^3 may wait for D^1, and depending on D^1's transmission, perhaps D^2, but D^3 and D^1 may not wait for each other because then neither can act.

[1] Each of the three detectors may wait for: none, one, the other, or both detectors; hence there are 4^3 possibilities. By case analysis, 39 of these deadlock.

This example illustrates two key differences between sequential and *nonsequential* systems, namely: i) that the order in which a nonsequential system's actions occur may explicitly depend on the system's uncontrolled inputs and the actions taken, and ii) that when two or more of a nonsequential system's actions are interdependent, no "causal" ordering of the actions is possible. Due to i), deadlock-free designs that exploit a system's nonsequentiality can outperform those that do not (see [2], Appendix A). This should not be surprising; unlike sequential systems, the dependencies among a nonsequential system's actions can change dynamically. Due to ii), the problem of identifying these "good" designs is difficult to formulate as a well-defined stochastic control problem. In particular, a design that deadlocks need not possess an expected reward,[2] and when it does, it may be mathematically optimal despite the fact that it is "not causal." This raises the question: Under what conditions is it possible to pose well-defined nonsequential stochastic control problems?

In a previous paper [2] (part I), we addressed this question by defining a nonsequential system to be "causal" when, independent of its design, it is deadlock-free. We then identified a property of a potentially nonsequential generic stochastic control problem's *information structure* (property CI) that is necessary and sufficient to ensure deadlock-freeness, and sufficient to ensure that *all* of the problem's designs possess expected rewards. This result subsumes Witsenhausen's design-independent causality condition (property C, in [9], [11]) and provides a framework for the recursive optimization of *unconstrained* nonsequential stochastic control problems [1].

In the present paper (part II) we explore the relationship between deadlock-freeness and the properties of individual designs. Our work is motivated by the fact that when the observations available to a nonsequential system's decision-making agents (e.g., the detectors) are specified independently, the resulting information structure need not be causal in the C or CI sense, although many admissible designs may be deadlock-free. This presents systems designers with a dilemma. If the existence of noncausal designs is ignored, formal optimization may not be possible. On the other hand, if the agents' information is constrained to ensure design-independent causality—by forcing sequentiality, for instance—the designer may limit the system's possible performance.

An obvious alternative to either "fix" is to identify necessary and sufficient conditions for individual designs to be causal. Once again, Witsenhausen's intrinsic model [9], [11] provides the framework for our work. Within this framework, we identify design-dependent analogues of the causality properties C and CI. Specifically, we introduce properties of a design's *information partition* (properties C* and CI*) that are necessary and sufficient to ensure that the design is deadlock-free, and sufficient to ensure that it possesses an expected reward. Moreover, we show by example that there exist deadlock-free designs that cannot be associated with any deadlock-free information structure.

The first result provides an intuitive, design-dependent characterization of the cause/effect notion of causality, and suggests a framework for the optimization of *constrained* nonsequential stochastic control problems. The second implies that for $N > 2$ agents, this characterization is finer than existing design-independent characterizations, including properties C and CI. Because our conditions are based on what a nonsequential system's decision-making agents may know as opposed to what they may do, they are substantially different than those derived using event sequence-based

[2] To compute the reward we must break the deadlock, but the reward may vary depending on how this is done (see [2, §2.3]).

representations such as finite-state automata [7], or Petri nets [8].

The remainder of the paper is organized as follows. In §2 we briefly review the structure of Witsenhausen's intrinsic model and our generic stochastic control problem. In §3 we introduce the design-dependent analogues of the deadlock-freeness, well-posedness, and causality properties in [2] and [9], [11], and relate a design's possession of these properties to its deadlock-freeness and possession of an expected reward. In §4 we examine the relationship between the design-independent and dependent properties, and establish, by example, that the design-dependent properties are finer. Section 5 contains our conclusions.

2. Problem formulation. The generic stochastic control problem considered in this paper is identical to that in [2] (part I). As before, the problem is posed within the framework of Witsenhausen's intrinsic model [9], [11]. This model, which is interpreted in [2], has three components.

1. An *information structure* $\mathcal{I} := \{(\Omega, \mathcal{B}), (U^k, \mathcal{U}^k), \mathcal{J}^k : 1 \leq k \leq N\}$ specifies the system's allowable decisions and distinguishable events.

(a) $N \in \mathbb{N}$ denotes the number of control actions to be taken.

(b) $(\Omega, \mathcal{B})$ denotes the measurable space from which a random input ω is drawn.

(c) $(U^k, \mathcal{U}^k)$ denotes the measurable space from which u^k, the kth control action, is selected. $\mathrm{Card}(U^k)$ is assumed to be greater than one, and $\mathcal{U}^k$ is assumed to contain the singletons of U^k. The measurable product space containing the N-tuple of control actions, $u := (u^1, u^2, \ldots, u^N)$, is denoted by $(U, \mathcal{U}) := (\prod_{i=1}^N U^i, \bigotimes_{i=1}^N \mathcal{U}^i)$.

(d) $\mathcal{J}^k \subset \mathcal{B} \otimes \mathcal{U}$ characterizes the maximal information that can be used to select the kth control action.

2. A design constraint set Γ_C constrains N-tuples of control laws $\gamma := (\gamma^1, \gamma^2, \ldots, \gamma^N)$, $\gamma^k : (\Omega \times U, \mathcal{J}^k) \to (U^k, \mathcal{U}^k)$, $k = 1, 2, \ldots, N$, called *designs*, to a nonempty subset of $\Gamma := \prod_{i=1}^N \Gamma^i$, where Γ^k, $k = 1, 2, \ldots, N$, denotes the set of all $\mathcal{J}^k/\mathcal{U}^k$-measurable functions.

3. A probability measure P on $(\Omega, \mathcal{B})$ determines the statistics of the random input.

When posed within this framework the generic problem takes the following form [2].

(P). Given an information structure $\mathcal{I}$, a design constraint set Γ_C, a probability measure P, and a bounded, nonnegative $\mathcal{B} \otimes \mathcal{U}$-measurable reward function V, identify a design γ in Γ_C that achieves $\sup_{\gamma \in \Gamma_C} E_\omega[V(w, u_\omega^\gamma)]$ exactly, or within $\epsilon > 0$.[3]

3. Design-dependent properties. Problem (P) is well defined when it is: i) *causal*, i.e., every $\gamma \in \Gamma_C$ is deadlock-free; and ii) *well posed*, i.e., every $\gamma \in \Gamma_C$ possesses an expected reward. As in part I, our objective is to identify properties necessary and sufficient to ensure that (P) is causal and well-posed. Here, however, we permit the problem's design constraint set $\Gamma_C \subset \Gamma$ to be arbitrary, and focus on developing *design-dependent* properties (properties that may only hold for *specific* $\gamma \in \Gamma$), as opposed to *design-independent* properties (properties that hold for *all* $\gamma \in \Gamma$).

3.1. Deadlock-freeness, solvability, and solvability-measurability: properties DF*, S*, and SM*. The identification of the design-dependent analogues of the deadlock-freeness property DF [2], and the well-posedness properties S (solvability [9]) and SM (solvability-measurability [9]), is straightforward. To ensure the

[3] The notation u_ω^γ indicates that u depends on ω through γ (see Definitions 2 and 3).

deadlock-freeness of the control problem, it is necessary and sufficient to require that each $\gamma \in \Gamma_C$ possess property DF* (cf. [2, Def. 1]).

DEFINITION 1. *A design γ possesses* property DF* (deadlock-freeness) *when for every $\omega \in \Omega$ there exists an ordering of γ's N control laws, say $\gamma^{s_1(\omega)}$, $\gamma^{s_2(\omega)}$, ..., $\gamma^{s_N(\omega)}$, such that no control action depends on itself or the control actions that follow; i.e., $u^{s_i(\omega)}$ does not depend on $u^{s_j(\omega)}$ for $j \geq i$.*

When a design γ possesses property DF*, it is deadlock-free in the sense that, given ω, $u^{s_1(\omega)}$ can be determined; given ω and $u^{s_1(\omega)}$, $u^{s_2(\omega)}$ can be determined; and so on.

To ensure well-posedness, it suffices to require that each $\gamma \in \Gamma_C$ possess properties S* and SM* (cf. [9, §4]).

DEFINITION 2. *A design γ possesses* property S* (solvability) *when for every $\omega \in \Omega$ there exists a unique $u := (u^1, u^2, \ldots, u^N) \in U$ satisfying the system of equations $u^k = \gamma^k(\omega, u)$, $k = 1, 2, \ldots, N$.*

DEFINITION 3. *A design γ possesses* property SM* (solvability-measurability) *when γ possesses property S*, and the solution map $\Sigma^\gamma : \Omega \to U$ induced by the system of equations $u = \gamma(\omega, u)$ (i.e., $\Sigma^\gamma(\omega) = u^\gamma_\omega$, where $u^\gamma_\omega = \gamma(\omega, u^\gamma_\omega)$) is $\mathcal{B}/\mathcal{U}$-measurable.*

Properties S* and SM* ensure that γ's reward $V(\cdot, \Sigma^\gamma(\cdot))$ is $\mathcal{B}$-measurable, and consequently, that $E_\omega[V(w, \Sigma^\gamma(w))]$ is well defined.

3.2. Design-dependent causality: property C*. When all designs $\gamma \in \Gamma_C$ possess property SM*, (P) is well posed. However, just as property SM need not imply property C ([9, Thm. 2]), a design's possession of property SM* need not ensure that it is deadlock-free.

Example 1.[4] Suppose, for instance, that

$$\gamma^1(\omega, u^1, u^2, u^3) = \begin{cases} 1 & \omega \bar{u}^2 u^3 = 1, \\ 0 & \text{else}, \end{cases}$$

$$\gamma^2(\omega, u^1, u^2, u^3) = \begin{cases} 0 & \omega \bar{u}^3 u^1 = 1, \\ 1 & \text{else}, \end{cases} \tag{3.1}$$

and

$$\gamma^3(\omega, u^1, u^2, u^3) = \begin{cases} 1 & \omega \bar{u}^1 u^2 = 1, \\ 0 & \text{else},^5 \end{cases}$$

are the component control laws of an admissible design $\gamma := (\gamma^1, \gamma^2, \gamma^3)$ for a three-agent problem in which

$$\Omega = U^1 = U^2 = U^3 = \{0, 1\}, \tag{3.2}$$

and

$$\mathcal{B} = \mathcal{U}^1 = \mathcal{U}^2 = \mathcal{U}^3 = \{\emptyset, \{0\}, \{1\}, \{0, 1\}\}. \tag{3.3}$$

Because

$$\begin{aligned} \mathrm{G}^\gamma &:= \{(\omega, u) : \ \gamma(\omega, u) = u\} \\ &= \{(0, 0, 1, 0), (1, 0, 1, 1)\}, \end{aligned} \tag{3.4}$$

[4] This example is a variation of the example used to prove Theorem 2 of [9].

[5] $\bar{u}$ denotes the binary complement of $u \in \{0, 1\}$, i.e., $\bar{u} = 1 - u$.

γ possesses property SM*. Nonetheless, when $\omega = 1$, γ^1 depends on u^2 and u^3, γ^2 depends on u^3 and u^1, and γ^3 depends on u^1 and u^2. Accordingly, no agent can act without precognition.

Clearly, Witsenhausen's design-independent causality property C [9], [11] provides a condition sufficient to ensure that individual designs $\gamma \in \Gamma$ do not experience such deadlocks. This condition is not necessary, however, because it imposes constraints on all events that the agents can distinguish (i.e., the sets in the information fields $\mathcal{J}^k$, $k = 1, 2, \ldots, N$), not just those distinguishable given a particular design γ (i.e., those in the restriction of the *information partitions* $\mathcal{J}^{\gamma^k} := \{[\gamma^k]^{-1}(u^k) : u^k \in U^k\}$, $k = 1, 2, \ldots, N$, to the *graph* $\mathrm{G}^\gamma := \{(\omega, u) : \gamma(\omega, u) = u\}$ of γ).

These observations suggest that for fixed $\gamma \in \Gamma$, a design-dependent analogue to property C might be constructed by substituting $\mathcal{J}^{\gamma^k}$ for $\mathcal{J}^k$ and G^γ for $\Omega \times U$ in C (cf. [9, §5] or [11, §2]).

DEFINITION 4. *A design $\gamma \in \Gamma$ possesses* property c* *when $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \Omega$ and there exists at least one map $\psi : \mathrm{G}^\gamma \to S_N$ such that for all $s := (s_1, s_2, \ldots, s_k) \in S_k$ and $k = 1, 2, \ldots, N$,*

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [T_k^N \circ \psi]^{-1}(s) \subset \mathcal{F}(T_{k-1}^k(s)) \bigcap \mathrm{G}^\gamma. \tag{3.5}$$

Here, as in [2], S_k, $k = 1, 2, \ldots, N$, denotes the set of all k-action orderings (i.e., all injections of $\{1, 2, \ldots, k\}$ into $\{1, 2, \ldots, N\}$); $T_j^k : S_k \to S_j$, $j = 0, 1, \ldots, N$, $k = j, j+1, \ldots, N$, denotes a truncation map that returns the ordering of the first j agents of a k-action ordering (i.e., T_j^k restricts $s \in S_k$ to the domain $\{1, 2, \ldots, j\}$ or to $\emptyset$ when $j = 0$); $\mathcal{P}_s$, $s := (s_1, s_2, \ldots, s_k) \in S_k$, $k = 1, 2, \ldots, N$, denotes the projection of $\Omega \times (\prod_{i=1}^N U^i)$ onto $\Omega \times (\prod_{i=1}^k U^{s_i})$ (i.e.,

$$\mathcal{P}_s(\omega, u) := (\omega, u^{s_1}, u^{s_2}, \ldots, u^{s_k}), \tag{3.6}$$

when $s \neq \emptyset$ and (ω) when $s = \emptyset$); and

$$\mathcal{F}(s) := [\mathcal{P}_s]^{-1} \left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^k \mathcal{U}^{s_i} \right) \right), \tag{3.7}$$

$s := (s_1, s_2, \ldots, s_k) \in S_k$, $k = 1, 2, \ldots, N$, denotes the cylindrical extension of $\mathcal{B} \otimes (\bigotimes_{i=1}^k \mathcal{U}^{s_i})$ to $\Omega \times U$.

To interpret (3.5) note that

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [T_k^N \circ \psi]^{-1}(s) := \left\{ A \bigcap [T_k^N \circ \psi]^{-1}(s) : A \in \mathcal{J}^{\gamma^{s_k}} \right\} \tag{3.8}$$

is the restriction of the set of events distinguishable by agent s_k under γ to the subset of outcomes $(\omega, u) \in \mathrm{G}^\gamma$ that are mapped by ψ into action orders in which the order of the first k agents is $s \in S_k$. Similarly, $\mathcal{F}(T_{k-1}^k(s)) \bigcap \mathrm{G}^\gamma$ is the restriction, to G^γ, of the set of events that can be induced by ω and the actions of the first $k-1$ agents in s. Accordingly, (3.5) asserts that the set of events that agent s_k can distinguish under γ, for *known* G^γ, given that the ordering of the first k agents as determined by ψ is s, must be a subset of the events that can be induced on G^γ by ω and the actions of the first $k-1$ agents in s.

Consider, for instance, the design γ in Example 1. Because for all $k = 1, 2, 3$, and $s \in S_k$, $\mathcal{F}(T_{k-1}^k(s)) \bigcap \mathrm{G}^\gamma$ is the power set of G^γ, all events that can be distinguished by s_k under any $\psi : \mathrm{G}^\gamma \to S_3$ can be induced by $\omega, \ldots, u^{s_{k-1}}$. Hence γ satisfies property c*.

Although a design's possession of property c* implies that it possesses an expected reward (just as $\mathcal{I}$'s possession of property C implies that all designs $\gamma \in \Gamma$ possess expected rewards [9]), property c* does not imply deadlock-freeness.

LEMMA 1. *For fixed $\gamma \in \Gamma$, property c* implies property* SM*, *although property c* need not imply property* DF*.

Proof. See Appendix A. □

The proof that c* implies SM* parallels the proof that C implies SM in [9, Thm. 1]. Property c*'s failure to ensure deadlock-freeness can be explained as follows. Property C is too restrictive to characterize the deadlock-freeness of individual designs because it requires that there exist a causal ordering for all outcomes in $\Omega \times U$, not just those that can occur (i.e., the outcomes in G^γ). Property c* is not restrictive enough because, for fixed $s \in S_k$, it implicitly permits the s_kth agent to possess information about its own action and the actions of its successors in s—i.e., because the domain of ψ is G^γ, $\mathcal{J}^{\gamma^{s_k}} \bigcap [T_k^N \circ \psi]^{-1}(s)$ unavoidably constrains $\mathcal{J}^{\gamma^{s_k}}$ along axes corresponding to agents that are not among the first $k-1$ agents in s. For instance, as previously noted, the design in Example 1 trivially satisfies property c* although it is not deadlock-free.

One compromise between these extremes is to continue to restrict the domain of ψ to G^γ. However, another is to only require, for all $s \in S_k$ and $k = 1, 2, \ldots, N$, that the inclusion in (3.5) hold when $\mathcal{J}^{\gamma^{s_k}}$ and $\mathcal{F}(T_{k-1}^k(s))$ are restricted to, respectively,

$$[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \tag{3.9}$$

and

$$[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(G^\gamma)), \tag{3.10}$$

the smallest subsets of $\Omega \times U$ containing $[T_k^N \circ \psi]^{-1}(s)$ and G^γ that can be constructed without knowledge of the decisions of agents that are not among the first $k-1$ agents in s.

DEFINITION 5. *A design $\gamma \in \Gamma$ possesses* property C* (causality) *when $\mathcal{P}_\emptyset(G^\gamma) = \Omega$, and there exists at least one map $\psi : G^\gamma \to S_N$ such that for all $s := (s_1, s_2, \ldots, s_k) \in S_k$ and $k = 1, 2, \ldots, N$,*

$$\begin{aligned} &\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \\ &\qquad \subset \mathcal{F}(T_{k-1}^k(s)) \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(G^\gamma)). \end{aligned} \tag{3.11}$$

Because the restriction of $\mathcal{J}^{\gamma^{s_k}}$ to $[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s)))$ in (3.11) does not provide information to agent s_k concerning its action or the actions of its successors, in addition to ensuring that a design possesses an expected reward, property C* also implies deadlock-freeness.

THEOREM 1. *If a design $\gamma \in \Gamma$ possesses property* C*, *then*

(i) *γ possesses property* SM*, *and*

(ii) *γ possesses property* DF*.

Proof. See Appendix B. □

The proof of (i) follows from Lemma 1 and the fact that property C* implies property c*. Part (ii) is an immediate consequence of C*'s definition.

3.3. Design-dependent causality: property CI*. By Theorem 1, when all $\gamma \in \Gamma_C$ possess property C*, problem (P) is causal and well posed. It is not clear, however, that the converse implication holds. In particular, it would seem that the measurability constraints that property C* imposes on ψ are unnecessary to ensure deadlock-freeness. Regardless of ψ's measurability, γ should be deadlock-free if ψ orders the agents, for all outcomes $(\omega, u) \in \mathrm{G}^\gamma$, such that at (ω, u), each agent's action only depends on ω and its predecessors' actions. This suggests the following design-dependent analogue of property CI.

DEFINITION 6. *A design $\gamma \in \Gamma$ possesses* property CI* (causal implementability) *when $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \Omega$ and there exists at least one map $\psi : \mathrm{G}^\gamma \to S_N$ such that for all $k = 1, 2, \ldots, N$, and $(\omega, u) \in \mathrm{G}^\gamma$,*

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(\omega, u)) \subset \{\emptyset, [\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(\omega, u))\} \tag{3.12}$$

when $s := (s_1, s_2, \ldots, s_N) = \psi(\omega, u)$.

As in property C*, for fixed $\gamma \in \Gamma$, the ψ in property CI* is a function that maps every outcome in G^γ into an N-agent ordering. Unlike property C*, however, this ψ is not constrained to be measurable in any sense. Instead, for all outcomes $(\omega, u) \in \mathrm{G}^\gamma$, the cylinder set

$$[\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(\omega, u)) = [\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\omega, u^{s_1}, \ldots, u^{s_{k-1}}) \tag{3.13}$$

induced on $\Omega \times U$ by ω and the actions of the first $k-1$ agents in $s := (s_1, s_2, \ldots, s_N) = \psi(\omega, u)$ is constrained to be a subset of all events containing (ω, u) in the information partition $\mathcal{J}^{\gamma^{s_k}}$ induced by the s_kth agent's control law γ^{s_k}—i.e., no event in $\mathcal{J}^{\gamma^{s_k}}$ containing (ω, u), may depend on u^{s_k}, $u^{s_{k+1}}$, ..., or u^{s_N} (cf. [2, Def. 2]). Accordingly, property CI* ensures that for all outcomes $(\omega, u) \in \mathrm{G}^\gamma$, there exists an action order $s := (s_1, s_2, \ldots, s_N) = \psi(\omega, u)$ such that for all $k = 1, 2, \ldots, N$, the s_kth agent's action at the point (ω, u) does not depend on itself or the actions of its successors in s.

Clearly, the design in Example 1 does not satisfy this condition—when $\omega = 1$, all three agents' actions are interdependent. Such is not the case in the following three-agent example.

Example 2. Suppose that

$$\Omega = U^1 = U^2 = U^3 = [0, 1], \tag{3.14}$$

$$\mathcal{B} = \mathcal{U}^1 = \mathcal{U}^2 = \mathcal{U}^3 = \mathrm{Borel}[0, 1], \tag{3.15}$$

and

$$\gamma^1(\omega, u^1, u^2, u^3) = \begin{cases} 0 & \text{when } \omega \in [0, \frac{1}{2}), \\ \frac{1}{2} & \text{when } (\omega, u^2) \in [\frac{1}{2}, 1] \times [\frac{1}{2}, 1], \\ 1 & \text{else} \end{cases}$$

$$\gamma^2(\omega, u^1, u^2, u^3) = \begin{cases} 0 & \text{when } \omega \in [\frac{1}{2}, 1], \\ \frac{1}{2} & \text{when } (\omega, u^1) \in [0, \frac{1}{2}] \times [\frac{1}{2}, 1], \\ 1 & \text{else,} \end{cases} \tag{3.16}$$

$$\gamma^3(\omega, u^1, u^2, u^3) = \begin{cases} 0 & \text{when } \omega \in [0, \frac{1}{2}), \\ 1 & \text{else} \end{cases}$$

are the component policies of an admissible design $\gamma = (\gamma^1, \gamma^2, \gamma^3)$. It is straightforward to verify that

$$\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \mathcal{P}_\emptyset\left([0, \tfrac{1}{2}) \times \{(0, 1, 0)\} \bigcup [\tfrac{1}{2}, 1] \times \{(1, 0, 1)\}\right) = \Omega, \tag{3.17}$$

and that (3.12) is satisfied for all $k = 1, 2, 3$ and $(\omega, u) \in \mathrm{G}^\gamma$ when

$$\bar{\psi}(\omega, u^1, u^2, u^3) = \begin{cases} (1,2,3) & \text{when } \omega \in [0, \tfrac{1}{2}), \\ (2,1,3) & \text{else.} \end{cases} \tag{3.18}$$

Hence γ possesses property CI*.

Property CI* is of interest because it implies property SM* and provides a complete characterization of γ's deadlock-freeness.

THEOREM 2. *Let γ be an arbitrary design in Γ. Then*

(i) *γ possesses property* SM* *if γ possesses property* CI*, *and*

(ii) *γ possesses property* DF* *if and only if γ possesses property* CI*.

Proof. See Appendix C. □

Theorem 2 ensures that (P) is causal and well posed if and only if all designs $\gamma \in \Gamma_C$ possess property CI*. Its proof, like that of property CI [2], hinges on the following observation. When ψ is an order function such that γ possesses property CI*, for arbitrary but fixed $(\omega, u) \in \Omega \times U$, and $k = 1, 2, \ldots, N$, (3.12) and the fact that $\mathcal{U}^k$ contains the singletons of U^k imply that, at the point (ω, u), γ^{s_k}, $s = \psi(\omega, u)$, does not depend on the s_kth, s_{k+1}th, or s_Nth components of u. This suggests that for fixed $\gamma \in \Gamma$, a unique $\mathcal{B}$-measurable solution $\Sigma^\gamma : \Omega \to U$ to the closed-loop equation $u = \gamma(\omega, u)$ can be obtained by the following recursion.

Fix $\omega \in \mathcal{P}_\emptyset(\mathrm{G}^\gamma)$ and $u^\gamma_\omega \in \mathrm{G}^\gamma|_\omega$. Let $r \in U$ be an arbitrary reference element, let π_U and π_Ω denote the canonical projections of $\Omega \times U$ onto, respectively, U and Ω, let $L^\gamma : \Omega \times U \to \Omega \times U$ be defined as

$$L^\gamma(\omega, r) := (\omega, \gamma(\omega, r)), \tag{3.19}$$

and let $L^\gamma_k : \Omega \times U \to \Omega \times U$ be a k-fold composition of L^γ—i.e.,

$$L^\gamma_k(\omega, r) := (\underbrace{L^\gamma \circ \cdots \circ L^\gamma}_{k \text{ times}})(\omega, r). \tag{3.20}$$

Although (3.19) and (3.20) are nearly identical to (3.6) and (3.7) of [2], because the domain of ψ is G^γ (as opposed to $\Omega \times U$), the arguments following (3.7) in [2] no longer suffice to ensure $\pi_U \circ L^\gamma_N$ is the closed-loop solution map Σ^γ induced by γ. In particular, because $L^\gamma_k(\omega, r)$ need not belong to G^γ for all $r \in U$ and $k = 1, 2, \ldots, N$, a somewhat different argument is required to show that at least one agent's decision becomes invariant after every iteration. Formally, we have the following.

1. After one iteration, the components of $L^\gamma_1(\omega, r)$ corresponding to agents whose actions at the point (ω, r) do not depend on r become invariant to subsequent iterations. By property CI*, the set $\mathcal{A}_1(\omega) \subset \{1, 2, \ldots, N\}$ indexing (by agent) these components is nonempty since, at the point $(\omega, u^\gamma_\omega)$, at least agent $(\psi(\omega, u^\gamma_\omega))_1$'s action does not depend on r. Moreover, since r is arbitrary,

$$\mathcal{P}_i(L^\gamma_1(\omega, r)) = \mathcal{P}_i(L^\gamma_1(\omega, u^\gamma_\omega)) = \mathcal{P}_i(\omega, u^\gamma_\omega), \tag{3.21}$$

for all $i \in \mathcal{A}_1(\omega)$.

2. After two iterations, the components of $L^\gamma_2(\omega, r)$ corresponding to agents in $\{1, 2, \ldots, N\} \setminus \mathcal{A}_1(\omega)$ whose actions at the point $L^\gamma_1(\omega, r)$ do not depend on the components of agents in $\{1, 2, \ldots, N\} \setminus \mathcal{A}_1(\omega)$ become invariant to subsequent iterations.[6]

[6] For sets $A, B \subset X$, $A \setminus B := \{x \in A : x \notin B\}$, the complement of B relative to A.

By property CI*, the set $\mathcal{A}_2(\omega)$ indexing (by agent) these components is nonempty when $\text{card}(\mathcal{A}_1(\omega)) < N$ since, at the point $(\omega, u^\gamma_\omega)$, at least agent $(\psi(\omega, u^\gamma_\omega))_j$'s action,

$$j = \min\{m \in \{1,2,\dots,N\} : \ (\psi(\omega, u^\gamma_\omega))_m \notin \mathcal{A}_1(\omega)\}, \tag{3.22}$$

does not depend on the components of agents in $\{1,2,\dots,N\} \setminus \mathcal{A}_1(\omega)$, and by (3.21), the remaining components of $(\omega, u^\gamma_\omega)$ are identical to those of $L^\gamma_1(\omega, r)$. As before, since r is arbitrary,

$$\mathcal{P}_i(L^\gamma_2(\omega, r)) = \mathcal{P}_i(L^\gamma_2(\omega, u^\gamma_\omega)) = \mathcal{P}_i(\omega, u^\gamma_\omega) \tag{3.23}$$

for all $i \in \mathcal{A}_1(\omega) \cup \mathcal{A}_2(\omega)$.

$\vdots$

k. After k iterations, the components of $L^\gamma_k(\omega, r)$ corresponding to agents in $\{1,2,\dots,N\} \setminus \bigcup_{i=1}^{k-1} \mathcal{A}_i(\omega)$ whose decisions at the point $L^\gamma_{k-1}(\omega, r)$ do not depend on the components of agents in $\{1,2,\dots,N\} \setminus \bigcup_{i=1}^{k-1} \mathcal{A}_i(\omega)$ become invariant to subsequent iterations. By property CI*, the set $\mathcal{A}_k(\omega)$ indexing (by agent) these components is nonempty when $\text{card}(\bigcup_{i=1}^{k-1} \mathcal{A}_i(\omega)) < N$ since, at the point $(\omega, u^\gamma_\omega)$, at least agent $(\psi(\omega, u^\gamma_\omega))_j$'s action,

$$j = \min\left\{m \in \{1,2,\dots,N\} : \ (\psi(\omega, u^\gamma_\omega))_m \notin \bigcup_{i=1}^{k-1} \mathcal{A}_i(\omega)\right\}, \tag{3.24}$$

does not depend on the components of agents in $\{1,2,\dots,N\} \setminus \bigcup_{i=1}^{k-1} \mathcal{A}_i(\omega)$, and by the preceding iterations (e.g., (3.23)), the remaining components of $(\omega, u^\gamma_\omega)$ are identical to those of $L^\gamma_{k-1}(\omega, r)$. Once again, since r is arbitrary,

$$\mathcal{P}_i(L^\gamma_k(\omega, r)) = \mathcal{P}_i(L^\gamma_k(\omega, u^\gamma_\omega)) = \mathcal{P}_i(\omega, u^\gamma_\omega) \tag{3.25}$$

for all $i \in \bigcup_{i=1}^{k} \mathcal{A}_i(\omega)$.

$\vdots$

And so on....

Because property CI* ensures that, until all agents' components are invariant, at least one new component becomes invariant after every iteration, the recursive procedure must converge in, at most, N iterations—i.e., the unique solution to the closed-loop equation $u = \gamma(\omega, u)$ is $\pi_U(L^\gamma_N(\omega, r))$, where $r \in U$ is an arbitrary "seed" that starts the recursive solution process. Because π_Ω, π_U, and γ are, respectively, $\mathcal{B}\otimes\mathcal{U}/\mathcal{B}$-, $\mathcal{B}\otimes\mathcal{U}/\mathcal{U}$- and $\mathcal{B}\otimes\mathcal{U}/\mathcal{U}$-measurable, L^γ, and by composition, L^γ_k and $\pi_U \circ L^\gamma_N$, are, respectively, $\mathcal{B}\otimes\mathcal{U}/\mathcal{B}\otimes\mathcal{U}$-, $\mathcal{B}\otimes\mathcal{U}/\mathcal{B}\otimes\mathcal{U}$-, and $\mathcal{B}\otimes\mathcal{U}/\mathcal{U}$-measurable. It follows, because all u-sections of $\mathcal{B}\otimes\mathcal{U}/\mathcal{U}$-measurable functions are $\mathcal{B}/\mathcal{U}$-measurable, that the induced solution map $\Sigma^\gamma = \pi_U \circ L^\gamma_N|_r$ is necessarily $\mathcal{B}/\mathcal{U}$-measurable.

The preceding recursion has the same physical interpretation as the recursion in [2]. If for all k we ignore all components of $\pi_U(L^\gamma_k(\omega, r))$ except those corresponding to the agents indexed in $\mathcal{A}_k(\omega)$, the preceding recursion outlines the partial ordering

of agent actions that a passive observer would record, given ω, if the design γ were implemented in a "maximally" concurrent fashion. Although the recursion implicitly demonstrates that property CI* implies property DF*, it is far easier to establish sufficiency by a direct appeal to property CI*. For all $(\omega, u) \in \mathrm{G}^\gamma$ and $k = 1, 2, \ldots, N$, property CI* implies that at the point (ω, u), agent s_k's action does not depend on the s_kth, s_{k+1}th, ..., and s_Nth components of u. Consequently, no agent's action depends on its own action or the actions of its successors—i.e., γ must be deadlock-free.

The fact that γ must deadlock when property CI* fails to hold is also a direct consequence of property CI*'s definition. When $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) \neq \Omega$, for some $\omega \in \Omega$, the closed-loop equation has no solution; consequently, for that ω, γ has no implementation (let alone a deadlock-free implementation). Alternatively, suppose that there exists at least one outcome $(\omega, u) \in \mathrm{G}^\gamma$ such that for all N-agent orderings $s := (s_1, s_2, \ldots, s_N) \in S_N$, (3.12) fails for at least one $k \in \{1, 2, \ldots, N\}$, say k_s. Then, for all orderings $s \in S_N$, the s_{k_s}th agent's action, at the point (ω, u), always depends on itself and or the actions of its successors in s, and once again, γ is not deadlock-free.

3.4. Are properties C* and CI* equivalent? By Theorems 1(ii) and 2(ii), property C* implies DF*, which in turn implies property CI*. Consequently, we have the following.

COROLLARY 1. *Property* C* *implies property* CI*.

Proof. See Appendix D for a direct proof. □

Are properties C* and CI* equivalent? When $N = 1$, the answer is yes (this follows from Definition 7 and Theorem 3). When $N > 1$, it is not known (in general) whether property CI* implies property C*. In particular, attempts to establish a design-dependent analogue of Corollary 2 in [2] (i.e., that CI* implies C* when $N = 2$) are complicated by the fact that S* need not imply CI* (or C*) under any circumstances (cf. [9, Thm. 2]). Consider, for instance, the following one-agent example.

Example 3. Suppose that $\Omega = \{0, 1\}$ and $U = \{0, 1, 2\}$, and let

$$\gamma(\omega, u) = \begin{cases} 2 & \text{if } (\omega, u) \in \{(1,1), (1,2)\}, \\ 1 & \text{if } (\omega, u) = (1,0), \\ 0 & \text{else.} \end{cases} \tag{3.26}$$

Because

$$\begin{aligned} \mathrm{G}^\gamma &:= \{(\omega, u) : \gamma(\omega, u) = u\} \\ &= \{(0,0), (1,2)\}, \end{aligned} \tag{3.27}$$

γ possesses property S*. But $[\mathcal{P}_\emptyset]^{-1}(\mathcal{P}_\emptyset(1,2)) = \{(1,0), (1,1), (1,2)\}$ and $[\gamma]^{-1}(1) = \{(1,0)\}$; consequently,

$$[\gamma]^{-1}(1) \bigcap [\mathcal{P}_\emptyset]^{-1}(\mathcal{P}_\emptyset(1,2)) = \{(1,0)\} \notin \{\emptyset, \{(1,0), (1,1), (1,2)\}\}. \tag{3.28}$$

Hence γ does not process property CI*.

Properties CI* and C* are equivalent in at least two important cases: when γ is *sequential* (Theorem 3), and when the measurable structure underlying (P) is *discrete*, i.e., when $\mathcal{B} \otimes \mathcal{U}$ contains the singletons of $\Omega \times U$ and $\Omega \times U$ is a countable set (Theorem 4).

DEFINITION 7. *A design $\gamma \in \Gamma$ is said to be* sequential *when property* CI* *holds for some constant order function ψ.*

THEOREM 3. *All constant order functions ψ such that a design $\gamma \in \Gamma$ possesses property* CI* *are order functions such that γ possesses property* C*.

Proof. See Appendix E. □

THEOREM 4. *When Ω and U^k, $k = 1, 2, \ldots, N$, are countable sets, and $\mathcal{B}$ contains the singletons of Ω, all order functions ψ such that a design $\gamma \in \Gamma$ possesses property* CI* *are order functions such that γ possesses property* C*.

Proof. See Appendix F. □

When $\gamma \in \Gamma$ is nonsequential and (P)'s measurable structure is not discrete, it is far more difficult to prove that property CI* implies property C* because, even if γ possesses property C*, order functions for which γ possesses property CI* need not be order functions for which γ possesses property C*.

Example 4. Consider again the three-agent design of Example 2. Although the design γ defined in (3.16) possesses properties CI* and C*, when A is any nonmeasurable subset of $[0, \frac{1}{2})$ (such a set always exists [4]),

$$\psi(\omega, u^1, u^2, u^3) = \begin{cases} (1,2,3) & \text{when } \omega \in [0, \tfrac{1}{2})/A, \\ (3,1,2) & \text{when } \omega \in A, \\ (2,1,3) & \text{else} \end{cases} \tag{3.29}$$

is an order function such that γ possesses property CI*, but not property C*. To see this, note that (3.12) holds for all $k = 1, 2, 3$, and $s \in S_k$, whereas (3.11) fails, for instance, when $k = 1$ and $s = 3 \in S_1$, since

$$\begin{aligned} [\mathcal{P}_\emptyset]^{-1}(\mathcal{P}_\emptyset([T_1^3 \circ \psi]^{-1}(3))) &= A \times U \\ &\notin \mathcal{F}(\emptyset) \bigcap [\mathcal{P}_\emptyset]^{-1}(\mathcal{P}_\emptyset(\mathrm{G}^\gamma)) \\ &= \mathcal{B} \otimes \{\emptyset, U\}. \end{aligned} \tag{3.30}$$

The fact that there exist nonsequential designs $\gamma \in \Gamma$ and order functions ψ such that γ possesses property CI*, but not property C*, implies that general proofs that property CI* implies property C* (if such exist) must be constructive—i.e., to prove that property CI* implies property C*, given a ψ such that γ possesses property CI*, but not property C*, we must be able to construct a new order function $\widehat{\psi}$ (obviously distinct from ψ), such that γ possesses property C*. To date, no such constructions are known.

4. Design-independence vs. design-dependence. In this section we briefly examine the relationships between the design-independent properties introduced in [2] (part I) and the design-dependent properties introduced here (part II).

4.1. Basic relationships.

THEOREM 5. *Let $\mathcal{I}$ be an arbitrary information structure. Then*

(i) *all $\gamma \in \Gamma$ possess property* S* *if and only if $\mathcal{I}$ possesses property* S,

(ii) *all $\gamma \in \Gamma$ possess property* SM* *if and only if $\mathcal{I}$ possesses property* SM,

(iii) *all $\gamma \in \Gamma$ possess property* CI* *if and only if $\mathcal{I}$ possesses property* CI, *and*

(iv) *all $\gamma \in \Gamma$ possess property* C* *if $\mathcal{I}$ possesses property* C.

Proof. See Appendix G. □

Parts (i) and (ii) are immediate consequences of the definitions of properties S, SM, S*, and SM*. Part (iii) follows from the fact that properties CI and CI* are

necessary and sufficient conditions for, respectively, all designs $\gamma \in \Gamma$ and particular designs $\gamma \in \Gamma$, to be deadlock-free. If properties C and C* were known to provide necessary and sufficient conditions for, respectively, all designs and particular designs to be deadlock-free (as is the case, for instance, when Ω and U are countable sets and $\mathcal{B}$ contains the singletons of Ω), the proof of part (iv), with the *if* replaced by *if and only if*, would also be immediate. In the absence of such knowledge it is necessary to prove (iv)—and if possible, the converse of (iv)—constructively. The forward construction is straightforward. Given a ψ such that $\mathcal{I}$ possesses property C, simply let $\psi^\gamma = \psi|_{G^\gamma}$ (the restriction of ψ to G^γ) for each $\gamma \in \Gamma$. The reverse construction (if such exists) is not obvious since there does not seem to be any way of relating the set of order functions

$$\bigcup_{\gamma\in\Gamma}\{\psi^\gamma : \gamma \text{ possesses property C* given } \psi^\gamma\} \tag{4.1}$$

to an order function ψ such that $\mathcal{I}$ possesses property C.

4.2. Design-dependent characterizations are finer. By Theorem 5, an information structure $\mathcal{I}$ cannot possess the design-independent property CI (respectively, C, SM, or S) if any one of its designs $\gamma \in \Gamma$ fails to possess the design-dependent property CI* (respectively, C*, SM*, or S*). This suggests that the design-dependent properties provide a finer characterization of a design's closed-loop solvability and deadlock-freeness, than the design-independent properties.

THEOREM 6. *For $N > 2$, there exist designs possessing property* C* (*and consequently, properties* CI*, SM*, *and* S*) *that cannot be associated with any deadlock-free information structure possessing property* S, *let alone properties* SM, CI, *or* C.

Proof. Since C* $\Rightarrow$ CI* $\Rightarrow$ SM* $\Rightarrow$ S* (by Corollary 1, Theorem 2, and Definition 3), and since C $\Rightarrow$ CI $\Rightarrow$ SM $\Rightarrow$ S (by [2, Cor. 1 and Thm. 2] and [9, §4]), it suffices to construct a design possessing property C* that cannot be associated with any information structure possessing property S.

Example 5. Consider a nonsequential $\mathcal{I}$ of the following form:

$$\begin{aligned}
&N = 3,\\
&\Omega = U^1 = U^2 = U^3 = \{0,1\},\\
&\mathcal{B} = \mathcal{U}^1 = \mathcal{U}^2 = \mathcal{U}^3 = \Big\{\emptyset, \{0\}, \{1\}, \{0,1\}\Big\},\\
&\mathcal{J}^1 = \Big\{\emptyset, \{(\omega,u) : \omega = 0\}, \{(\omega,u) : \omega = 1\}, \Omega \times U\Big\},\\
&\mathcal{J}^2 = \Big\{\emptyset, \{(\omega,u) : \max(\bar{\omega}\bar{u}^1\bar{u}^3, u^1u^3) = 0\},\\
&\qquad\qquad \{(\omega,u) : \max(\bar{\omega}\bar{u}^1\bar{u}^3, u^1u^3) = 1\}, \Omega \times U\Big\},
\end{aligned} \tag{4.2}$$

(4.3)

and

$$\mathcal{J}^3 = \Big\{\emptyset, \{(\omega,u) : \omega u^2 = 0\}, \{(\omega,u) : \omega u^2 = 1\}, \Omega \times U\Big\}.$$

Since the closed-loop equations for the design $\hat{\gamma} = (\hat{\gamma}^1, \hat{\gamma}^2, \hat{\gamma}^3)$,

$$\begin{aligned}
\hat{\gamma}^1(\omega, u^1, u^2, u^3) &= \begin{cases} 1 & \omega = 1,\\ 0 & \text{else,}\end{cases}\\
\hat{\gamma}^2(\omega, u^1, u^2, u^3) &= \begin{cases} 1 & \max(\bar{\omega}\bar{u}^1\bar{u}^3, u^1u^3) = 1,\\ 0 & \text{else,}\end{cases}
\end{aligned} \tag{4.4}$$

$$\widehat{\gamma}^3(\omega, u^1, u^2, u^3) = \begin{cases} 1 & \omega u^2 = 1, \\ 0 & \text{else}, \end{cases}$$

exhibit two distinct outcomes when $\omega = 1$—i.e.,

$$\begin{aligned} \mathrm{G}^{\widehat{\gamma}} &:= \{(\omega, u) : \ \widehat{\gamma}(\omega, u) = u\} \\ &= \{(0,0,1,0), (1,1,0,0), (1,1,1,1)\} \end{aligned} \tag{4.5}$$

—$\widehat{\gamma}$ does not possess property S*. Consequently, no information structure (including $\mathcal{I}$) that can be associated with $\widehat{\gamma}$ can possess property S (Theorem 5)—i.e., no information structure

$$\widehat{\mathcal{I}} := \{(\Omega, \mathcal{B}), (U^k, \mathcal{U}^k), \widehat{\mathcal{J}}^k : \ 1 \leq k \leq 3\} \tag{4.6}$$

such that

$$[\widehat{\gamma}^k]^{-1}(\mathcal{U}^k) = \mathcal{J}^k \subset \widehat{\mathcal{J}}^k, \qquad 1 \leq k \leq 3 \tag{4.7}$$

can possess property S.

Consider, however, the design $\gamma = (\gamma^1, \gamma^2, \gamma^3)$,

$$\begin{aligned} \gamma^1(\omega, u^1, u^2, u^3) &= \begin{cases} 0 & \omega = 1, \\ 1 & \text{else}, \end{cases} \\ \gamma^2(\omega, u^1, u^2, u^3) &= \widehat{\gamma}^2(\omega, u^1, u^2, u^3), \\ \gamma^3(\omega, u^1, u^2, u^3) &= \widehat{\gamma}^3(\omega, u^1, u^2, u^3). \end{aligned} \tag{4.8}$$

This design possesses property S*—i.e.,

$$\begin{aligned} \mathrm{G}^{\gamma} &:= \{(\omega, u) : \ \gamma(\omega, u) = u\} \\ &= \{(0,1,0,0), (1,0,0,0)\}. \end{aligned} \tag{4.9}$$

Moreover, when

$$\psi(\omega, u^1, u^2, u^3) = \begin{cases} (1,3,2) & (\omega, u^1, u^2, u^3) = (0,1,0,0), \\ (1,2,3) & (\omega, u^1, u^2, u^3) = (1,0,0,0), \end{cases} \tag{4.10}$$

it can also be shown to possess property C*.[7] But for all $k = 1,2,3$, γ^k and $\widehat{\gamma}^k$ both induce the same information subfield $\mathcal{J}^k$ (i.e., $\mathcal{J}^k = [\gamma^k]^{-1}(\mathcal{U}^k) = [\widehat{\gamma}^k]^{-1}(\mathcal{U}^k)$, for all $k = 1,2,3$). Accordingly, even though γ possesses property C*, it cannot be associated with any information structure possessing property S. This proves the theorem. □

Heuristically, the three-agent information structure that appears in the preceding example can be viewed as a synthesis, parameterized by agent 1's $\mathcal{F}(\emptyset)$-measurable decision[8] of two different two-agent information structures for agents 2 and 3. The first of these structures, $\mathcal{I}^C$, corresponds to the restriction of agent 2 and agent 3's information subfields to the u^1-sections of $\mathcal{J}^2$ and $\mathcal{J}^3$ induced when $u^1 = 0$—i.e.,

$$\mathcal{I}^C := \left\{(\Omega, \mathcal{B}), \ (U^i, \mathcal{U}^i), \mathcal{J}^i|_{u^1=0} : \ 2 \leq i \leq 3\right\}, \tag{4.11}$$

[7] In this case it is somewhat easier to check property CI* and then apply Theorem 4.

[8] By (4.2), $\mathcal{J}^1 \subset \mathcal{F}(\emptyset) := \{\emptyset, \{0\} \times U, \{1\} \times U, \Omega \times U\}$.

where

$$\mathcal{J}^2|_{u^1=0} = \Big\{\emptyset, \{(\omega, u^2, u^3) : \ \bar{\omega}\bar{u}^3 = 0\}, \{(\omega, u^2, u^3) : \ \bar{\omega}\bar{u}^3 = 1\}, \Omega \times U^2 \times U^3\Big\} \tag{4.12}$$

and

$$\mathcal{J}^3|_{u^1=0} = \Big\{\emptyset, \{(\omega, u^2, u^3) : \ \omega u^2 = 0\}, \{(\omega, u^2, u^3) : \ \omega u^2 = 1\}, \Omega \times U^2 \times U^3\Big\}. \tag{4.13}$$

The second of these structures, $\mathcal{I}^{NS}$, corresponds to the restriction of agent 2 and agent 3's information subfields to the u^1-sections of $\mathcal{J}^2$ and $\mathcal{J}^3$ induced when $u^1 = 1$—i.e.,

$$\mathcal{I}^{NS} := \Big\{(\Omega, \mathcal{B}), (U^i, \mathcal{U}^i), \mathcal{J}^i|_{u^1=1} : \ 2 \leq i \leq 3\Big\}, \tag{4.14}$$

where

$$\mathcal{J}^2|_{u^1=1} = \Big\{\emptyset, \{(\omega, u^2, u^3) : \ u^3 = 0\}, \{(\omega, u^2, u^3) : \ u^3 = 1\}, \Omega \times U^2 \times U^3\Big\} \tag{4.15}$$

and

$$\mathcal{J}^3|_{u^1=1} = \Big\{\emptyset, \{(\omega, u^2, u^3) : \ \omega u^2 = 0\}, \{(\omega, u^2, u^3) : \ \omega u^2 = 1\}, \Omega \times U^2 \times U^3\Big\}. \tag{4.16}$$

It is not difficult to verify that $\mathcal{I}^C$ possesses property C when

$$\psi(\omega, u^2, u^3) = \begin{cases} (3,2) & \omega = 0, \\ (2,3) & \text{else.} \end{cases} \tag{4.17}$$

To see this note that

$$\mathcal{J}^2|_{u^1=0} \bigcap [T_1^2 \circ \psi]^{-1}(2) = \Big\{\emptyset, \{0\} \times U^2 \times U^3\Big\} \subset \mathcal{F}(\emptyset)|_{u^1=0} \tag{4.18}$$

and

$$\mathcal{J}^3\big|_{u^1=0} \bigcap [T_1^2 \circ \psi]^{-1}(3) = \Big\{\emptyset, \{1\} \times U^2 \times U^3\Big\} \subset \mathcal{F}(\emptyset)|_{u^1=0}\,. \tag{4.19}$$

$\mathcal{I}^{NS}$, however, does not even possess property S. For instance,

$$\begin{aligned} \mathrm{G}^\gamma &:= \{(\omega, u^2, u^3) : \ \gamma(\omega, u^2, u^3) = (u^2, u^3)\} \\ &= \{(0,0,0), (1,0,0), (1,1,1)\} \end{aligned} \tag{4.20}$$

when

$$\begin{aligned} \gamma^2(\omega, u^2, u^3) &= \begin{cases} 1 & u^3 = 1, \\ 0 & \text{else,} \end{cases} \\ \gamma^3(\omega, u^2, u^3) &= \begin{cases} 1 & \omega u^2 = 1, \\ 0 & \text{else.} \end{cases} \end{aligned} \tag{4.21}$$

It follows, because agent 1's decision determines whether agent 2 and agent 3's interdependence is characterized by $\mathcal{I}^C$ $(u^1 = 0)$ or $\mathcal{I}^{NS}(u^1 = 1)$, that agent 1's control law determines whether nontrivial designs for the synthesized system (4.4) possess property C* or do not possess property S*. Specifically, all designs such that

$$\gamma^1(\omega, u^1, u^2, u^3) = 1 \tag{4.22}$$

or

$$\gamma^1(\omega, u^1, u^2, u^3) = \begin{cases} 1 & \omega = 1, \\ 0 & \text{else}, \end{cases} \tag{4.23}$$

and neither γ^2 nor γ^3 is a constant policy (there are 8 such designs since $\text{card}(\mathcal{J}^k) > 2$ and $\text{card}(U^k) = 2$ for $k = 2, 3$), do not possess property S*. All remaining designs (there are 56) possess property C*.

Clearly, the preceding heuristic can be used to synthesize far more complicated information structures that fail to possess property S, but nonetheless admit nontrivial designs possessing property C*. For instance, noncausal and causal 2-agent information structures can be combined, when parameterized by two additional agents' decisions, to form a 4-agent information structure that fails to possess property S but admits nontrivial designs possessing property C*; similarly, this 4-agent information structure and a second 4-agent information structure can be combined, when parameterized by three additional agents' decisions, to form a 7-agent information structure that fails to possess property S but admits nontrivial designs possessing property C*; and so on. It follows that there exist a myriad of designs whose deadlock-freeness and closed-loop solvability can not be characterized using any design-independent property.

5. Conclusions. In this paper we have introduced conditions (properties C* and CI*) necessary and sufficient to ensure the deadlock-freeness (property DF*) and measurable closed-loop solvability (property SM*) of a nonsequential design γ represented within the framework of Witsenhausen's intrinsic model. We have also shown, by example, that there exist nontrivial, deadlock-free designs that cannot be associated with any deadlock-free information structure.

Our conditions, which are the design-dependent analogues of conditions in [2] and [9] (properties CI and C), provide an intuitive characterization of the cause/effect notion of causality in terms of the events that a system's decision-making agents can distinguish, and suggest a framework for the optimization of constrained nonsequential stochastic control problems.

The existence of deadlock-free designs that cannot be associated with any deadlock-free information structure is not surprising. Many network routing, flow, and concurrency control systems are seen to be deadlock-free under some designs and deadlock-prone under others. In fact, unless the specification of a nonsequential system's agents' information subfields is coordinated (in practice physical constraints, complexity and/or cost may preclude such coordination) it is unlikely that the system's information structure will possess any design-independent property. Moreover, as illustrated by Example 5, the deadlock-freeness and closed-loop solvability of the admissible designs for such systems may hinge on the control laws of a small fraction of the agents. The only difference between the designs $\widehat{\gamma}$ and γ of Example 5, for instance, is that $\widehat{\gamma}^1$'s decision is the binary complement of γ^1's decision. Nonetheless, although $\widehat{\gamma}$ does not possess any design-dependent property, γ possesses all of the

known design-dependent properties. Simply put, the inappropriate use of information by a single agent can give rise to deadlocks.

One final note. In [9, p. 159] it is remarked that the "physical interpretation" of information structures possessing property SM, but not property C, "appears difficult" (the difficulty being the host of paradoxes that arise when effects precede their causes). In light of Example 5, it would seem, rather, that it is the physical interpretation of *designs* possessing property SM* but not property CI* that may be difficult.

Appendix A.

Proof of Lemma 1. Fix $\gamma \in \Gamma$ and suppose that $\psi : \mathrm{G}^\gamma \to S_N$ is an order function such that γ possesses property c*. Except for the restriction of ψ's domain to G^γ, the proof that c* implies SM* parallels the proof that C implies SM in [9, Thm. 1]. Note, however, that unlike Witsenhausen's kth umpire update map [9, §7], the analogous update map, $M_k^\gamma : \mathrm{G}^\gamma \to \mathrm{G}^\gamma$ with

$$\text{(A.1)}\quad \mathcal{P}_\alpha(M_k^\gamma(\omega,u)) := \begin{cases} (\omega, \gamma^\alpha(\omega,u)) & \text{when } \alpha = (\psi(\omega,u))_k, \\ \mathcal{P}_\alpha(\omega, u_\omega^\gamma) & \text{when } \alpha = (\psi(\omega,u))_j, \quad j = k+1,\dots,N, \\ \mathcal{P}_\alpha(\omega,u) & \text{otherwise} \end{cases}$$

for all $\alpha \in \{\emptyset, 1, \dots, N\}$, cannot be used to establish γ's deadlock-freeness because the restriction of M_k^γ to G^γ permits the umpire to know the actions of agents before they have acted.

To see that c* need not imply property DF*, note that although the design in Example 1 is not deadlock-free, for all $\psi : \mathrm{G}^\gamma \to S_3$, it trivially satisfies property c* because, as pointed out in §3.2, for all $k = 1, 2, 3$, and $s \in S_k$, $\mathcal{F}(T_{k-1}^k(s)) \bigcap \mathrm{G}^\gamma$ is the power set of G^γ (see (3.4)). □

Appendix B. Proof of Theorem 1. To prove Theorem 1 we need the following facts.

FACT 1. *For all $s \in S_k$, $k = 1, 2, \dots, N$, if $\mathcal{P}_s(\omega,u) = \mathcal{P}_s(\bar\omega,\bar u)$ for some (ω,u) and $(\bar\omega,\bar u) \in \mathrm{G}^\gamma$, then no set in $\mathcal{F}(s) \bigcap \mathrm{G}^\gamma$ contains (ω,u) but not $(\bar\omega,\bar u)$.*

Proof of Fact 1. Suppose that the fact fails for some $s \in S_k$, $(\omega,u) \in \mathrm{G}^\gamma$, and $(\bar\omega,\bar u) \in \mathrm{G}^\gamma$. Then because

$$\text{(B.1)}\qquad \mathcal{F}(s) := [\mathcal{P}_s]^{-1}\left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^k \mathcal{U}^{s_i}\right)\right),$$

there exists a set $A \in \mathcal{B} \otimes (\bigotimes_{i=1}^k \mathcal{U}^{s_i})$ such that

$$\text{(B.2)}\qquad (\omega,u) \in [\mathcal{P}_s]^{-1}(A) \bigcap \mathrm{G}^\gamma$$

and

$$\text{(B.3)}\qquad (\bar\omega,\bar u) \notin [\mathcal{P}_s]^{-1}(A) \bigcap \mathrm{G}^\gamma.$$

It follows that ω and $\bar\omega$, or least one of the s_1th through s_kth components of u and $\bar u$, must differ. But $\mathcal{P}_s(\omega,u) = \mathcal{P}_s(\bar\omega,\bar u)$, a contradiction. Accordingly, the fact holds. □

FACT 2. *Property* C* *implies property* c*.

Proof of Fact 2. Fix $\gamma \in \Gamma$ and suppose that ψ is an order function such that γ possesses property C*. Because property C* ensures that $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \Omega$, it suffices to show that ψ is also an order function such that γ possesses property c*.

The restriction of (3.11) to G^γ yields the desired result—(3.5) of property c*—if, for all $k = 1, 2, \ldots, N$, and $s \in S_k$,

$$[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \bigcap G^\gamma = [T_k^N \circ \psi]^{-1}(s). \tag{B.4}$$

By construction, the right side of (B.4) is a subset of the left. Suppose that the converse inclusion fails for some $k \in \{1, 2, \ldots, N\}$ and $s \in S_k$. Then there exists an outcome

$$(\bar{\omega}, \bar{u}) \in [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \bigcap G^\gamma \tag{B.5}$$

that is not in $[T_k^N \circ \psi]^{-1}(s)$. Moreover,

$$\mathcal{P}_{T_{k-1}^k(s)}(\bar{\omega}, \bar{u}) \in \mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s)). \tag{B.6}$$

It follows from (B.6) that there exists an outcome $(\omega, u) \in [T_k^N \circ \psi]^{-1}(s)$ such that

$$\mathcal{P}_{T_{k-1}^k(s)}(\omega, u) = \mathcal{P}_{T_{k-1}^k(s)}(\bar{\omega}, \bar{u}), \tag{B.7}$$

and (ω, u) and $(\bar{\omega}, \bar{u})$ differ in one or more of the components of u not indexed in $T_{k-1}^k(s)$.

But this is impossible. By property C*, the sets

$$[\gamma^{s_k}]^{-1}(\bar{u}^{s_k}) \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \bigcap G^\gamma \tag{B.8}$$

and

$$[\gamma^{s_k}]^{-1}(u^{s_k}) \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \bigcap G^\gamma \tag{B.9}$$

are elements of $\mathcal{F}(T_{k-1}^k(s)) \bigcap G^\gamma$. If $\bar{u}^{s_k} \neq u^{s_k}$, $[\gamma^{s_k}]^{-1}(\bar{u}^{s_k})$ and $[\gamma^{s_k}]^{-1}(u^{s_k})$, and consequently the sets in (B.8) and (B.9), are disjoint. Since $(\bar{\omega}, \bar{u})$ and (ω, u) satisfy (B.7), this contradicts Fact 1.

Similarly, if, for $\bar{s} = T_j^N(\psi(\omega, u))$, $j > k$,

$$\mathcal{P}_{T_{j-1}^j(\bar{s})}(\omega, u) = \mathcal{P}_{T_{j-1}^j(\bar{s})}(\bar{\omega}, \bar{u}), \tag{B.10}$$

and $\bar{u}^{\bar{s}_j} \neq u^{\bar{s}_j}$, then by property C*,

$$[\gamma^{\bar{s}_j}]^{-1}(\bar{u}^{\bar{s}_j}) \bigcap [\mathcal{P}_{T_{j-1}^j(\bar{s})}]^{-1}(\mathcal{P}_{T_{j-1}^j(\bar{s})}([T_j^N \circ \psi]^{-1}(\bar{s}))) \bigcap G^\gamma \tag{B.11}$$

and

$$[\gamma^{\bar{s}_j}]^{-1}(u^{\bar{s}_j}) \bigcap [\mathcal{P}_{T_{j-1}^j(\bar{s})}]^{-1}(\mathcal{P}_{T_{j-1}^j(\bar{s})}([T_j^N \circ \psi]^{-1}(\bar{s}))) \bigcap G^\gamma \tag{B.12}$$

are disjoint sets in $\mathcal{F}(T_{j-1}^j(\bar{s})) \bigcap G^\gamma$. Since $(\bar{\omega}, \bar{u})$ and (ω, u) satisfy (B.10), Fact 1 is once again contradicted. It follows, by induction, that $(\omega, u) = (\bar{\omega}, \bar{u})$. Hence, Fact 2 is proved. □

Proof of Theorem 1. Fix $\gamma \in \Gamma$ and suppose that $\psi : G^\gamma \to S_N$ is an order function such that γ possesses property C*. The proof of (i) follows from Lemma 1 and Fact 2.

To prove (ii) it suffices to show that all agents can act without precognition for all outcomes in G^γ. Fix $(\omega, u) \in \mathrm{G}^\gamma$. The first agent to act under ψ is agent $s_1 = T_1^N(\psi(\omega, u))$. Since $T_0^1(s_1) = \emptyset$, property C* implies that

$$\mathcal{J}^{\gamma^{s_1}} \bigcap [\mathcal{P}_\emptyset]^{-1}(\mathcal{P}_\emptyset([T_1^N \circ \psi]^{-1}(s_1))) \subset \mathcal{F}(\emptyset) \bigcap [\mathcal{P}_\emptyset]^{-1}(\mathcal{P}_\emptyset(\mathrm{G}^\gamma)). \tag{B.13}$$

Because

$$\{\omega\} \times U \in [\mathcal{P}_\emptyset]^{-1}(\mathcal{P}_\emptyset([T_1^N \circ \psi]^{-1}(s_1))) \subset [\mathcal{P}_\emptyset]^{-1}(\mathcal{P}_\emptyset(\mathrm{G}^\gamma)), \tag{B.14}$$

and

$$\begin{aligned} \mathcal{F}(\emptyset) \bigcap (\{\omega\} \times U) &= (\mathcal{B} \otimes \{\emptyset, U\}) \bigcap (\{\omega\} \times U) \\ &= \{\emptyset, \{\omega\} \times U\}, \end{aligned} \tag{B.15}$$

the restriction of (B.13) to $\{\omega\} \times U$ can be rewritten as

$$\mathcal{J}^{\gamma^{s_1}} \bigcap (\{\omega\} \times U) \subset \{\emptyset, \{\omega\} \times U\}. \tag{B.16}$$

But (B.16) implies that at the point (ω, u), γ^{s_1} does not depend on u (recall that $\mathcal{J}^{\gamma^{s_1}} := [\gamma^{s_1}]^{-1}(U^{s_1})$); consequently, given ω, agent s_1 acts without precognition.

Now, suppose that $k-1$ agents (agents $s_1, s_2, \ldots, s_{k-1}$) have acted without precognition and in accordance with ψ (i.e., $s = T_{k-1}^N(\psi(\omega, u))$). The kth agent to act under ψ is agent $s_k = (T_k^N(\psi(\omega, u)))_k$. Since $T_{k-1}^k(s, s_k) = s$, property C* implies that

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_s]^{-1}(\mathcal{P}_s([T_k^N \circ \psi]^{-1}(s, s_k))) \subset \mathcal{F}(s) \bigcap [\mathcal{P}_s]^{-1}(\mathcal{P}_s(\mathrm{G}^\gamma)). \tag{B.17}$$

Because

$$\begin{aligned} [\mathcal{P}_s]^{-1}(\omega, u^{s_1}, \ldots, u^{s_{k-1}}) &\in [\mathcal{P}_s]^{-1}(\mathcal{P}_s([T_k^N \circ \psi]^{-1}(s, s_k))) \\ &\subset [\mathcal{P}_s]^{-1}(\mathcal{P}_s(\mathrm{G}^\gamma)) \end{aligned} \tag{B.18}$$

and

$$\begin{aligned} &\mathcal{F}(s) \bigcap [\mathcal{P}_s]^{-1}(\omega, u^{s_1}, \ldots, u^{s_{k-1}}) \\ &\quad = [\mathcal{P}_s]^{-1}\left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^{k-1} \mathcal{U}^{s_i}\right)\right) \bigcap [\mathcal{P}_s]^{-1}(\omega, u^{s_1}, \ldots, u^{s_{k-1}}) \\ &\quad = \{\emptyset, [\mathcal{P}_s]^{-1}(\omega, u^{s_1}, \ldots, u^{s_{k-1}})\}, \end{aligned} \tag{B.19}$$

the restriction of (B.17) to $[\mathcal{P}_s]^{-1}(\omega, u^{s_1}, \ldots, u^{s_{k-1}})$ can be rewritten as

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_s]^{-1}(\omega, u^{s_1}, \ldots, u^{s_{k-1}}) \subset \{\emptyset, [\mathcal{P}_s]^{-1}(\omega, u^{s_1}, \ldots, u^{s_{k-1}})\}. \tag{B.20}$$

But (B.20) implies that at the point (ω, u), γ^{s_k} does not depend on the s_kth, s_{k+1}th, ..., or s_Nth components of u; consequently, when nature and agents $s_1, s_2, \ldots, s_{k-1}$'s actions are $(\omega, u^{s_1}, \ldots, u^{s_{k-1}})$, agent s_k acts without precognition. It follows, by induction, that all agents act without precognition. Thus γ possesses property DF* and the theorem is proved. □

Appendix C.

Proof of Theorem 2. (i). Fix $\gamma \in \Gamma$, let $\mathrm{G}^\gamma := \{(\omega, u) \in \Omega \times U : \gamma(\omega, u) = u\}$, and suppose that ψ is an order function such that γ possesses property CI*. By assumption, the closed-loop equation $\gamma(\omega, u) = u$ admits at least one solution $u_\omega^\gamma \in \mathrm{G}^\gamma|_\omega := \{u \in U : \gamma(\omega, u) = u\}$ for all $\omega \in \Omega$ (i.e., $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \Omega$); hence, to prove that γ possesses property SM*, it suffices to show, for each $\omega \in \Omega$, that this solution is unique, and that the mapping $\Sigma^\gamma : \Omega \to U$ induced by these solutions (i.e., $\Sigma^\gamma(\omega) = u_\omega^\gamma$) is $\mathcal{B}/\mathcal{U}$-measurable (cf. Definitions 2 and 3).

Uniqueness. Fix $\omega \in \Omega$ and $u_\omega^\gamma \in \mathrm{G}^\gamma|_\omega$, and let $s := (s_1, s_2, \ldots, s_N) = \psi(\omega, u_\omega^\gamma)$. Let π_U denote the canonical projection of $\Omega \times U$ onto U, let $L^\gamma : \Omega \times U \to \Omega \times U$ be defined as in (3.19) and (3.20). Clearly, $u = \pi_U(L_N^\gamma(\omega, u))$ for all $u \in \mathrm{G}^\gamma|_\omega$, including u_ω^γ. Accordingly, to establish the uniqueness of u_ω^γ, it suffices to show that

$$(\omega, u_\omega^\gamma) = L_N^\gamma(\omega, r) \tag{C.1}$$

for all $r \in U$ (since $\mathrm{G}^\gamma|_\omega \subset U$), or equivalently, that

$$\mathcal{P}_{T_{k-1}^N(s)}(\omega, u_\omega^\gamma) = \mathcal{P}_{T_{k-1}^N(s)}(L_N^\gamma(\omega, r)) \tag{C.2}$$

when $k = N + 1$.

Fix $r \in U$. When $k = 1$, $T_{k-1}^N(s) = \emptyset$ and

$$\begin{aligned} \mathcal{P}_\emptyset(\omega, u_\omega^\gamma) &= (\omega) \\ &= \mathcal{P}_\emptyset(\omega, \gamma(L_{N-1}^\gamma(\omega, r))) \\ &= \mathcal{P}_\emptyset(L_N^\gamma(\omega, r)). \end{aligned} \tag{C.3}$$

Suppose, for $k > 1$, that (C.2) holds. Since property CI* holds with order function ψ,

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega, u_\omega^\gamma)) \subset \{\emptyset, [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega, u_\omega^\gamma))\}. \tag{C.4}$$

Equation (C.4) and the fact that $\mathcal{U}^{s_k}$ contains the singletons of U^{s_k} (§2, 1(c)), implies that at the point $(\omega, u_\omega^\gamma) \in \Omega \times U$, γ^{s_k} does not depend on the s_kth, s_{k+1}th, ..., or s_Nth components of u_ω^γ (recall that $\mathcal{J}^{\gamma^{s_k}} := [\gamma^{s_k}]^{-1}(U^{s_k})$). Accordingly, (C.2) implies that

$$\gamma^{s_k}(\omega, u_\omega^\gamma) = \gamma^{s_k}(L_N^\gamma(\omega, r)), \tag{C.5}$$

and consequently, that

$$\begin{aligned} \mathcal{P}_{T_k^N(s)}(\omega, u_\omega^\gamma) &= (\mathcal{P}_{T_{k-1}^N(s)}(\omega, u_\omega^\gamma), \gamma^{s_k}(\omega, u_\omega^\gamma)) \\ &= (\mathcal{P}_{T_{k-1}^N(s)}(L_N^\gamma(\omega, r)), \gamma^{s_k}(L_N^\gamma(\omega, r))) \\ &= \mathcal{P}_{T_k^N(s)}(L_N^\gamma(\omega, r)). \end{aligned} \tag{C.6}$$

It follows, by induction, that (C.2) holds for all $k = 1, 2, \ldots, N + 1$; hence, $(\omega, u_\omega^\gamma) = L_N^\gamma(\omega, r)$ for all $r \in U$, and consequently, the unique solution u_ω^γ to the closed-loop equation $u = \gamma(\omega, u)$ is $\pi_U(L_N^\gamma(\omega, r))$, where $r \in U$ is the (arbitrary) "seed" that starts the recursive solution process.

Measurability. Fix $r \in U$ and let π_U and π_Ω denote, respectively, the canonical projections of $\Omega \times U$ onto U and Ω. To establish the $\mathcal{B}/\mathcal{U}$-measurability of the induced closed-loop solution map $\Sigma^\gamma : \Omega \to U$, it suffices to show that the u-section of $\pi_U \circ L_N^\gamma$, $\pi_U \circ L_N^\gamma|_r$, is $\mathcal{B}/\mathcal{U}$-measurable because, for fixed r,

$$\Sigma^\gamma(\omega) = (\pi_U \circ L_N^\gamma|_r)(\omega) := (\pi_U \circ L_N^\gamma)(\omega, r). \tag{C.7}$$

To begin, note that (3.19) implies that

$$L^\gamma(\omega, r) = (\pi_\Omega(\omega, u), \gamma(\omega, r)). \tag{C.8}$$

By definition, π_Ω and π_U are, respectively, $\mathcal{B} \otimes \mathcal{U}/B$- and $\mathcal{B} \otimes \mathcal{U}/\mathcal{U}$-measurable. Likewise, γ^k, $k = 1, 2, \ldots, N$, is $\mathcal{J}^k/\mathcal{U}^k$-measurable. Accordingly, $\gamma := (\gamma^1, \gamma^2, \ldots, \gamma^N)$ is $\mathcal{B} \otimes \mathcal{U}/\mathcal{U}$-measurable (since $\mathcal{J}^k \subset \mathcal{B} \otimes \mathcal{U}$ for all k). It follows that L^γ and, by composition [4, Thm. 13.1], L_k^γ and $\pi_U \circ L_N^\gamma$ are, respectively, $\mathcal{B} \otimes \mathcal{U}/\mathcal{B} \otimes \mathcal{U}$-, $\mathcal{B} \otimes \mathcal{U}/\mathcal{B} \otimes \mathcal{U}$-, and $\mathcal{B} \otimes \mathcal{U}/\mathcal{U}$-measurable. But all u-sections of $\mathcal{B} \otimes \mathcal{U}/\mathcal{U}$-measurable functions are $\mathcal{B}/\mathcal{U}$-measurable [4, Thm. 18.1]; consequently, $\Sigma^\gamma = \pi_U \circ L_N^\gamma|_r$ is $\mathcal{B}/\mathcal{U}$-measurable.

(ii). *Sufficiency.* Fix $\gamma \in \Gamma$, and suppose that ψ is an order function such that γ possesses property CI*. To prove that γ is deadlock-free it suffices to show that for each $\omega \in \Omega$, the agents can be ordered such that no agent's action depends on itself, or actions of its successors.

Fix $\omega \in \Omega$. By (i), the closed-loop equation $u = \gamma(\omega, u)$ possesses a unique solution $u_\omega^\gamma \in U$. Let

$$s := (s_1, s_2, \ldots, s_N) = \psi(\omega, u_\omega^\gamma). \tag{C.9}$$

Since property CI* holds with order function ψ, for all $k = 1, 2, \ldots N$,

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega, u_\omega^\gamma)) \subset \{\emptyset, [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega, u_\omega^\gamma))\}. \tag{C.10}$$

But (C.10) implies that at the point $(\omega, u_\omega^\gamma) \in \mathrm{G}^\gamma$, γ^{s_k} does not depend on the s_kth, s_{k+1}th, ..., or s_Nth components of $(\omega, u_\omega^\gamma)$ (recall that $\mathcal{J}^{\gamma^{s_k}} := [\gamma^{s_k}]^{-1}(U^{s_k})$); consequently, for all $k = 1, 2, \ldots, N$, the s_kth agent's action does not depend on the actions of agents $s_k, s_{k+1}, \ldots,$ and s_N. This proves sufficiency.

Necessity. Fix $\gamma \in \Gamma$, and suppose that γ does not possess property CI* for any order function ψ. Then $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) \neq \Omega$, or there exists at least one outcome in G^γ, say (ω^*, u^*), such that for all N-agent orderings $s := (s_1, s_2, \ldots, s_N) \in S_N$, the inclusion

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega^*, u^*)) \subset \{\emptyset, [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega^*, u^*))\} \tag{C.11}$$

fails for at least one $k \in \{1, 2, \ldots, N\}$. To prove necessity, it suffices to demonstrate that γ is not deadlock-free in either case.

When $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) \neq \Omega$, for some $\omega \in \Omega$, the closed-loop equation $\gamma(\omega, u) = u$ has no solution; consequently, for that ω, γ has no implementation (let alone a deadlock-free implementation). When there exists an outcome $(\omega^*, u^*) \in \mathrm{G}^\gamma$ such that for every N-agent ordering $s \in S_N$, (C.11) fails for at least one $k \in \{1, 2, \ldots, N\}$ for fixed $s \in S_N$,

$$\begin{aligned} &\mathcal{J}^{\gamma^{s_{k^*}}} \bigcap [\mathcal{P}_{T_{k^*-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k^*-1}^N(s)}(\omega^*, u^*)) \\ &\qquad \not\subset \{\emptyset, [\mathcal{P}_{T_{k^*-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k^*-1}^N(s)}(\omega^*, u^*))\} \end{aligned} \tag{C.12}$$

for some $k^* \in \{1,2,\ldots,N\}$. But (C.12) implies that at the point (ω^*, u^*), $\gamma^{s_{k^*}}$ depends on the actions of agents that have yet to act under s; consequently, agent s_{k^*} cannot act without precognition under s. Since the same argument applies for all $s \in S_N$, γ must deadlock. This proves necessity. □

Appendix D.

Proof of Corollary 1. Although this corollary is an immediate consequence of Theorems 1(ii) and 2(ii) (property C* ⇒ property DF* ⇒ property CI*), it is instructive to prove it directly.

Fix $\gamma \in \Gamma$ and suppose that ψ is an order function such that γ possesses property C*. Since property C* ensures that $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \Omega$, it suffices to show that ψ is also an order function such that γ possesses property CI*—i.e., that (3.11) of property C* (with $s = T_k^N(\psi(\omega,u)) \in S_k$), implies (3.12) of property CI* (with $s = \psi(\omega,u) \in S_N$) for all $(\omega,u) \in \mathrm{G}^\gamma$ and $k = 1,2,\ldots,N$.

Fix $(\omega,u) \in \mathrm{G}^\gamma$ and $k \in \{1,2,\ldots,N\}$, and let

$$s := (s_1, s_2, \ldots, s_N) = \psi(\omega,u). \tag{D.1}$$

Since $T_k^N(s) \in S_k$ and $T_{k-1}^N = T_{k-1}^k \circ T_k^N$, (3.11) of property C* implies that

$$\begin{aligned} &\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}([T_k^N \circ \psi]^{-1}(T_k^N(s)))) \\ &\qquad \subset \mathcal{F}(T_{k-1}^N(s)) \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\mathrm{G}^\gamma)). \end{aligned} \tag{D.2}$$

Restricting both sides of (D.2) to

$$[\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega,u)) \tag{D.3}$$

yields the desired result—(3.12) of property CI*—if

$$\begin{aligned} &[\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}([T_k^N \circ \psi]^{-1}(T_k^N(s)))) \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega,u)) \\ &\qquad = [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega,u)) \end{aligned} \tag{D.4}$$

and

$$\begin{aligned} &\mathcal{F}(T_{k-1}^N(s)) \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\mathrm{G}^\gamma)) \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega,u)) \\ &\qquad = \{\emptyset, [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega,u))\}. \end{aligned} \tag{D.5}$$

Equation (D.5) follows from the definition of $\mathcal{F}(T_{k-1}^N(s))$,

$$\mathcal{F}(T_{k-1}^N(s)) := [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}\left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^{k-1} \mathcal{U}^{s_i}\right)\right), \tag{D.6}$$

the fact that inverse images preserve intersections—i.e.,

$$\begin{aligned} &[\mathcal{P}_{T_{k-1}^N(s)}]^{-1}\left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^{k-1} \mathcal{U}^{s_i}\right)\right) \bigcap [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega,u)) \\ &\qquad = \{\emptyset, [\mathcal{P}_{T_{k-1}^N(s)}]^{-1}(\mathcal{P}_{T_{k-1}^N(s)}(\omega,u))\} \end{aligned} \tag{D.7}$$

—and the fact that

$$[\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(\mathrm{G}^\gamma)) \bigcap [\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(\omega,u)) = [\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(\omega,u)) \tag{D.8}$$

since

$$[\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(\omega,u)) \in [\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(\mathrm{G}^\gamma)) \tag{D.9}$$

when $(\omega,u) \in \mathrm{G}^\gamma$.

Equation (D.4) follows from the observation that

$$[\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}(w,u)) \subset [\mathcal{P}_{T^N_{k-1}(s)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s)}([T^N_k \circ \psi]^{-1}(T^N_k(s)))) \tag{D.10}$$

by (D.1). □

Appendix E.

Proof of Theorem 3. Fix $\gamma \in \Gamma$ and suppose that γ is sequential. Then there exists a *constant* order function ψ such that γ possesses property CI*. Since property CI* ensures that $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \Omega$, it suffices to show that ψ is also an order function such that γ possesses property C*—i.e., that for all $k = 1, 2, \ldots, N$, the fact that (3.12) of property CI* holds for all $(\omega,u) \in \mathrm{G}^\gamma$ with $s = s^* \in S_N$ constant implies that (3.11) of property C* holds for all $s \in S_k$.

Fix $k \in \{1, 2, \ldots, N\}$ and let

$$s^* := (s^*_1, s^*_2, \ldots, s^*_N) \tag{E.1}$$

denote the constant order induced by ψ. Since $T^N_{k-1} = T^k_{k-1} \circ T^N_k$, and since for all $s \in S_k$,

$$[\mathcal{P}_{T^k_{k-1}(s)}]^{-1}(\mathcal{P}_{T^k_{k-1}(s)}([T^N_k \circ \psi]^{-1}(s))) = \begin{cases} [\mathcal{P}_{T^N_{k-1}(s*)}]^{-1}(\mathcal{P}_{T^N_{k-1}(s*)}(\mathrm{G}^\gamma)) & \text{when } s = T^N_k(s^*), \\ \emptyset & \text{else,} \end{cases} \tag{E.2}$$

it suffices to show that

$$\mathcal{J}^{\gamma^{s^*_k}} \subset \mathcal{F}(T^N_{k-1}(s^*)) \tag{E.3}$$

for all $k = 1, 2, \ldots, N$.

By definition (§2, 1(d)), $\mathcal{J}^{\gamma^{s^*_k}} \subset \mathcal{J}^{s^*_k}$ is a subset of

$$\mathcal{B} \otimes \mathcal{U} = [\mathcal{P}_{T^N_N(s^*)}]^{-1}\left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^N \mathcal{U}^{s^*_i}\right)\right). \tag{E.4}$$

Since (3.12) holds for all $(\omega,u) \in \mathrm{G}^\gamma$ when $s = s^*$, all events in $\mathcal{J}^{\gamma^{s^*_k}}$ must be of the form

$$[\mathcal{P}_{T^N_N(s^*)}]^{-1}\left(A \times \left(\prod_{i=k}^N U^{s^*_i}\right)\right), \tag{E.5}$$

where $A \subset \Omega \times (\Pi_{i=1}^{k-1} U^{s_i^*})$; accordingly, $\mathcal{J}^{\gamma^{s_k^*}}$ is also a subset of

$$\mathcal{C}_{s^*} := \sigma\left([\mathcal{P}_{T_N^N(s^*)}]^{-1}\left(A \times \left(\prod_{i=k}^{N} U^{s_i^*} \right) \right) : \; A \subset \Omega \times \left(\prod_{i=1}^{k-1} U^{s_1^*} \right) \right)$$

$$= \sigma\left([\mathcal{P}_{T_{k-1}^N(s^*)}]^{-1}(A) : \; A \subset \Omega \times \left(\prod_{i=1}^{k-1} U^{s_1^*} \right) \right) \tag{E.6}$$

—the cylindrical extension of the power set of $\Omega \times (\prod_{i=1}^{k-1} U^{s_i^*})$ to $\Omega \times U$. But

$$(\mathcal{B} \otimes \mathcal{U}) \bigcap \mathcal{C}_{s^*} = [\mathcal{P}_{T_{k-1}^N(s^*)}]^{-1}\left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^{k-1} \mathcal{U}^{s_i^*} \right) \right)$$

$$:= \mathcal{F}(T_{k-1}^N(s^*)). \tag{E.7}$$

Consequently, $\mathcal{J}^{\gamma^{s_k^*}} \subset \mathcal{F}(T_{k-1}^N(s^*))$. □

Appendix F.

Proof of Theorem 4. Fix $\gamma \in \Gamma$ and suppose that ψ is an order function such that γ possesses property CI*. Since property CI* ensures that $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \Omega$, it suffices to show that ψ is also an order function such that γ possesses property C*—i.e., that for all $k = 1, 2, \ldots, N$, the fact that (3.12) holds for all $(\omega, u) \in \mathrm{G}^\gamma$ with order function ψ implies that (3.11) holds for all $s \in S_k$ with order function ψ.

By assumption, the σ-fields $\mathcal{B}$ and $\mathcal{U}^k$, $k = 1, 2, \ldots, N$, contain, respectively, the singletons of the countable sets Ω and U^k, $k = 1, 2, \ldots, N$ ($\mathcal{U}^k$ contains the singletons of U^k due to (§2, 1(c)). Accordingly, for all $s := (s_1, s_2, \ldots, s_k) \in S_k$, $k = 1, 2, \ldots, N$, the product field $\mathcal{B} \otimes (\bigotimes_{i=1}^{k} \mathcal{U}^{s_i})$ contains the singletons of the countable set $\Omega \times (\Pi_{i=1}^{k} U^{s_i})$, implying that $\mathcal{B} \otimes (\bigotimes_{i=1}^{k} \mathcal{U}^{s_1})$ is the power set of $\Omega \times (\Pi_{i=1}^{k} U^{s_i})$. It follows, for all $s \in S_k$, $k = 1, 2, \ldots, N$, that

$$\mathcal{F}(T_{k-1}^k(s)) := [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}\left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^{k-1} \mathcal{U}^{s_i} \right) \right)$$

$$= \sigma\left([\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(A) : \; A \subset \Omega \times \left(\prod_{i=1}^{k-1} U^{s_i} \right) \right) \tag{F.1}$$

—i.e., that $\mathcal{F}(T_{k-1}^k(s))$ is the cylindrical extension of the power set of $\Omega \times (\Pi_{i=1}^{k-1} U^{s_i})$ to $\Omega \times U$.

Fix $k \in \{1, 2, \ldots, N\}$ and $s \in S_k$. Since property CI* holds with order function ψ, (3.12) and (F.1) imply that for all $(\omega, u) \in [T_k^N \circ \psi]^{-1}(s)$ and $A \in \mathcal{J}^{\gamma^{s_k}}$,

$$A \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\omega, u)) \in \{\emptyset, [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\omega, u))\}$$

$$\subset \mathcal{F}(T_{k-1}^k(s)). \tag{F.2}$$

Since $[T_k^N \circ \psi]^{-1}(s) \in \mathrm{G}^\gamma$ is a countable set, and since inverse and direct images preserve unions, it follows by (F.2) that

$$A \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s)))$$

$$= A \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}\left(\mathcal{P}_{T_{k-1}^k(s)}\left(\bigcup_{(\omega,u)\in[T_k^N\circ\psi]^{-1}(s)}(\omega,u)\right)\right)$$

$$= \bigcup_{(\omega,u)\in[T_k^N\circ\psi]^{-1}(s)} (A \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\omega,u))) \tag{F.3}$$

$$\in \mathcal{F}(T_{k-1}^k(s)).$$

But because $[T_k^N \circ \psi]^{-1}(s) \subset \mathrm{G}^\gamma$,

$$[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \subset [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\mathrm{G}^\gamma)); \tag{F.4}$$

hence (F.3) implies that

$$A \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s)))$$

$$\in \mathcal{F}(T_{k-1}^k(s)) \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\mathrm{G}^\gamma)). \tag{F.5}$$

Since (F.5) holds for all $A \in \mathcal{J}^{\gamma^{s_k}}$,

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s)))$$

$$\subset \mathcal{F}(T_{k-1}^k(s)) \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\mathrm{G}^\gamma)). \tag{F.6}$$

This proves the theorem. □

Appendix G.

Proof of Theorem 5. (i) and (ii). Properties S and SM are, by definition, specializations of properties S* and SM* to all $\gamma \in \Gamma$ (cf. Definitions 1 and 2, and [9, §4, Definitions]). Accordingly, all $\gamma \in \Gamma$ possess property S* (respectively SM*) if and only if $\mathcal{I}$ possesses property S (respectively SM).

(iii). By Theorem 1(ii) of [2], $\mathcal{I}$'s possession of property CI is a necessary and sufficient condition for all $\gamma \in \Gamma$ to possess property DF*. By Theorem 2(ii), $\gamma \in \Gamma$ possesses property DF* if and only if γ possesses property CI*. Accordingly, all $\gamma \in \Gamma$ possess property CI* if and only if $\mathcal{I}$ possesses property CI.

(iv). To prove that all $\gamma \in \Gamma$ possess property C* when $\mathcal{I}$ possesses property C, let $\psi : \Omega \times U \to S_N$ be an order function for which $\mathcal{I}$ possesses property C, fix $\gamma \in \Gamma$, and let ψ^γ denote the restriction of ψ to G^γ. Since γ induces a unique $\mathcal{B}/\mathcal{U}$-measurable mapping $\Sigma^\gamma : \Omega \to U$ with graph G^γ [9, Thm. 1], $\mathcal{P}_\emptyset(\mathrm{G}^\gamma) = \Omega$; accordingly, to establish that γ possesses property C*, it suffices to show that (3.11) of property C* holds with order function ψ^γ for all $s := (s_1, s_2, \ldots, s_k) \in S_k$ and $k = 1, 2, \ldots, N$.

Since $\Omega \times U \in \mathcal{J}^{s_k}$, property C [9, Lem. 1] implies that

$$[T_k^N \circ \psi]^{-1}(s) \in \mathcal{F}(T_{k-1}^k(s)) := [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}\left(\mathcal{B} \otimes \left(\bigotimes_{i=1}^{k-1} \mathcal{U}^{s_i}\right)\right). \tag{G.1}$$

Consequently,

$$[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) = [T_k^N \circ \psi]^{-1}(s). \tag{G.2}$$

Since $\mathcal{J}^{\gamma^{s_k}} \subset \mathcal{J}^{s_k}$, property C [9] also implies that

$$\mathcal{J}^{\gamma^{s_k}} \bigcap [T_k^N \circ \psi]^{-1}(s) \subset \mathcal{F}(T_{k-1}^k(s)). \tag{G.3}$$

Substitute (G.2) into (G.3), and restrict both sides of the result to

$$[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\mathrm{G}^\gamma)). \tag{G.4}$$

The desired result—(3.11) of property C*—follows if

$$\begin{aligned}&[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \bigcap [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\mathrm{G}^\gamma))\\ &\quad = [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi^\gamma]^{-1}(s))).\end{aligned} \tag{G.5}$$

To verify (G.5), note that

$$\begin{aligned}[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\mathrm{G}^\gamma)) &= \bigcup_{(\omega,u)\in \mathrm{G}^\gamma} [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}(\omega,u))\\ &= \bigcup_{s'\in S_k} [\mathcal{P}_{T_{k-1}^k(s')}]^{-1}(\mathcal{P}_{T_{k-1}^k(s')}([T_k^N \circ \psi^\gamma]^{-1}(s'))).\end{aligned} \tag{G.6}$$

Since ψ^γ is the restriction of ψ to G^γ, and since direct and inverse images preserve inclusions,

$$\begin{aligned}&[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi^\gamma]^{-1}(s)))\\ &\quad \subset [\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))).\end{aligned} \tag{G.7}$$

But

$$\begin{aligned}&\{[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) : s \in S_k\}\\ &\quad = \{[T_k^N \circ \psi]^{-1}(s) : s \in S_k\}\end{aligned} \tag{G.8}$$

partitions $\Omega \times U$ (cf. (G.2)). Hence, by (G.7), the restriction of (G.6) to

$$[\mathcal{P}_{T_{k-1}^k(s)}]^{-1}(\mathcal{P}_{T_{k-1}^k(s)}([T_k^N \circ \psi]^{-1}(s))) \tag{G.9}$$

is (G.5), and thus γ possesses property C*. □

ON CONVERGENCE OF ITERATED RANDOM MAPS*

JOHN R. LIUKKONEN† AND ARNOLD LEVINE†

Abstract. Let K be a compact subset of $\mathbf{R}^N$ consisting of an open subset of $\mathbf{R}^N$ and smooth boundary. Many stochastic optimization algorithms can be viewed as iterations of independent and identically distributed random elements of the continuous self-maps of such a K. In case the target of the algorithm is a single point $\mathbf{p}$, a near dichotomy for the convergence to $\mathbf{p}$ is given; roughly, if $\mathbf{M}_1$ is one of the random elements, then there will be no convergence in probability if $E(\log \|\mathbf{M}_1'(\mathbf{p})\|) > 0$, but there will be almost sure convergence if $E(\log \|M_1'(\mathbf{p})\|) < 0$ and an accessibility condition holds. Similar conclusions are reached if the algorithm has an entire closed set of target points. Illustrative applications of these algorithms to the analysis of algorithms are given, and stochastic order of convergence and expected number of steps to stopping are discussed.

Key words. stochastic optimization, iterated random maps, almost sure convergence, convergence in probability

AMS subject classifications. 93E20, 93E23, 60J20, 62L20

1. Introduction.

Numerical optimization or root finding for functions $g : \mathbf{R}^N \to \mathbf{R}^m$ is accomplished commonly through the following iterative algorithm:

$$x_n = M_n(x_{n-1}, \ldots, x_1), \qquad n = 1, 2, \ldots, \tag{1.1}$$

where $\{x_n\}, \{M_n\}$ are a sequence of solution estimates and operators on the estimates. Major problems faced by such algorithms include unacceptably slow convergence or failure to converge at all. Adding noise in a controlled fashion to such algorithms can yield solutions to problems intractable by the classical deterministic methods. Much work has been published on simulated annealing (see Hajek [3], most notably), but the technique of randomizing classical algorithms in Euclidean space is also available. In Joseph, Levine, and Liukkonen [5] and [6], for example, it is shown that by adding noise in a controlled fashion to Newton–Raphson we can obtain convergence in probability to a minimum or root for a wider class of functions and initial guesses than that for which usual deterministic Newton–Raphson works.

In this paper we develop general conditions for almost sure convergence for a wide class of such randomized algorithms. We also develop companion conditions for instances when these algorithms will not converge even in probability. We also discuss the stochastic order of convergence and the expected time to solution. We restrict attention to time-homogeneous Markov algorithms: the random solution estimate x_{n+1} is to depend solely on the previous estimate x_n and in particular not on the time variable n. Our rationale for this is the following: For some types of stochastic optimization, such as simulated annealing, one tacitly assumes that local minima are easy to come by but one does not know when one has arrived at the global minimum; the fear is that one will settle prematurely for a local minimum that, on a global scale, is in fact not very good. One guards against this by requiring the noise level to decrease slowly enough with time. By contrast, in other situations there may be few local minima and one may know immediately when one has arrived at a correct answer,

*Received by the editors October 7, 1992; accepted for publication (in revised form) May 21, 1993.

†Department of Mathematics, Tulane University, New Orleans, Louisiana 70118.

but there may be difficulty even getting near a local minimum through traditional means. To deal with these situations, we want the random part of the algorithm to be prominent during the first phase, during which we search through an uninformative wilderness for a neighborhood of a minimum, and during which we must avoid traps and cycles. But we also want the random part of the algorithm to get out of the way when we finally arrive in a region where the traditional algorithm is effective. For algorithms aimed at these latter situations we tie the noise level to current performance and not to time.

In this introductory section we set out our mathematical framework. In §2 we give conditions for almost sure convergence and conditions for the failure even of convergence in probability of our random algorithms. Section 3 is devoted to examples illustrating how these results can be used in the analysis of a random algorithm, and in §4 we take up the issues of order of convergence and expected stopping time for algorithms that meet our convergence criteria.

A simple motivating example for our mathematical setup is the following: Our starting value x_0 is given, and then for each n we define $X_{n+1} = f(x_n) + e_{n+1}(x_n)$, where the nth state x_n is a realization of the random variable X_n, f is a deterministic function, and $e_1(x_0), e_2(x_1), \ldots$, is the sequence of controlled noise terms. Each $e_{n+1}(x_n)$ depends continuously on the previous state. Moreover, as function-valued random variables the noise terms $e_1(\cdot), e_2(\cdot), \ldots$, are to be independent and identically distributed. For example the sequence $\{e_n(x_{n-1})\}$ might be obtained from a sequence $\{V_n\}$ of independent and identically distributed random variables by a continuous scale funtion ϕ : for each n, $e_{n+1}(x_n) = \phi(x_n)V_{n+1}$. In any case, our basic object of study is the map-valued random variable M given by $M(t) = f(t) + e(t)$.

In general we assume that we have a compact set K in $\mathbf{R}^N$ consisting of an open subset of $\mathbf{R}^N$ and a smooth boundary. We let $T \subset K$ be the set of target points of the algorithm; we assume T is closed. We consider the space $C(K, K)$ of continuous maps $M : K \to K$, equipped with the uniform topology and the resulting Borel structure. Let $C_T(K, K)$ denote the closed subspace of $C(K, K)$ consisting of those maps leaving all target points fixed. Letting $M_1 \circ M_2$ denote the composition of the maps M_1 and M_2 we have that the maps $(M_1, M_2) \to M_1 \circ M_2 : C_T(K, K) \times C_T(K, K) \to C_T(K, K)$ and $(M, \mathbf{t}) \to M(\mathbf{t}) : C_T(K, K) \times K \to K$ are continuous.

Any probability measure P on $C_T(K, K)$ defines a random element of $C_T(K, K)$. If we have two independent random elements M_1, M_2 of $C_T(K, K)$ defined, say, by the probability measures P_1, P_2, respectively, then their composition may be defined as a random element of $C_T(K, K)$ based on $(C_T(K, K) \times C_T(K, K), P_1 \times P_2)$. The probability measure on $C_T(K, K)$ giving the distribution of this composition is the convolution of probability measures on the topological semigroup (under composition) $C_T(K, K)$. We can similarly obtain the random element $M(k)$ of K, given independent random elements $M \in C_T(K, K)$ and $k \in K$, and a probability measure on K serving as the distribution of $M(k)$.

DEFINITION 1.1. *Let $\mathbf{p} \in T$ and let M be a random element of $C_T(K, K)$. We say $M'(\mathbf{p})$ exists in probability if there is a random $N \times N$ matrix $M'(\mathbf{p})$ such that*

$$M(\mathbf{t}) = \mathbf{p} + M'(\mathbf{p})(\mathbf{t} - \mathbf{p}) + o_P(\mathbf{t} - \mathbf{p}). \tag{1.2}$$

We say that $M'(\mathbf{p})$ exists in power if for some $\beta > 0$ and some random $N \times N$ matrix $M'(\mathbf{p})$ we have $\|M'(\mathbf{p})\| \in L^\beta$ and

$$M(\mathbf{t}) = \mathbf{p} + M'(\mathbf{p})(\mathbf{t} - \mathbf{p}) + o_\beta(\mathbf{t} - \mathbf{p}). \tag{1.3}$$

Here $o_\beta(\mathbf{t}-\mathbf{p})$ *denotes a random term such that* $E(\|o_\beta(\mathbf{t}-\mathbf{p})\|^\beta/\|\mathbf{t}-\mathbf{p}\|^\beta) \to 0$ *as* $\mathbf{t} \to \mathbf{p}$. *Note that if* (1.3) *holds for* $\beta > 0$ *and if* $0 < \beta' < \beta$, *then* (1.3) *also holds for* β'.

Given a problem with a single target point $\mathbf{p}$, an iterative algorithm based on a sequence of independent copies of M, and reasonable accessibility to neighborhoods of $\mathbf{p}$ we show that convergence to $\mathbf{p}$ depends essentially on whether $E(\log\|M'(\mathbf{p})\|) < 0$ or > 0. For problems with multiple target points we establish similar conditions guaranteeing convergence to the target set as a whole and further conditions guaranteeing convergence to a single unspecified point in the target set.

2. Convergence theorems. In this section we discuss several kinds of convergence, and we must distinguish among them carefully. We are given an independent and identically distributed sequence $\{M_n\}$ of random elements of $C_T(K,K)$. For each initial distribution ν on K we write the corresponding Markov random variables $X_n(\nu) = M_n \circ \cdots \circ M_1(\nu)$; letting $\delta_\mathbf{t}$ be point mass at $\mathbf{t}$ we write $X_n(\mathbf{t})$ for $X_n(\delta_\mathbf{t})$. For any closed subset S of T and $\mathbf{t} \in K$ we let $d_S(\mathbf{t})$ be the distance from $\mathbf{t}$ to S; we write $d(\mathbf{t})$ for $d_T(\mathbf{t})$. We say $X_n(\mathbf{t})$ converges in probability to S if $d_S(X_n(\mathbf{t})) \to 0$ in probability. We say $X_n(\mathbf{t})$ converges almost surely to S if $d_S(X_n(\mathbf{t})) \to 0$ almost surely. This leaves open the possibility of an oscillatory approach to S, and so we need two further definitions. We say $X_n(\mathbf{t})$ converges almost surely to some element $\mathbf{p} \in S$ if $X_n(\mathbf{t}) \to \mathbf{p}$ almost surely. We say $X_n(\mathbf{t})$ almost surely has a limit in S if $P(\exists\, \mathbf{p} \in S : X_n(\mathbf{t}) \to \mathbf{p}) = 1$.

We first develop a simple condition guaranteeing that the algorithm will not converge in probability to a given subset $S \subset T$. We place a mild restriction on our random map M : we assume that $\log[d_S(M(\mathbf{t}))/d_S(\mathbf{t})] \geq -Y$ for all $\mathbf{t}$, for some integrable nonnegative random variable Y. Then we say that the (scalar-valued) random variable L is a lower derivate in probability for M at S if

$$d_S(M(\mathbf{t})) \geq L d_S(\mathbf{t}) + o_P(d_S(\mathbf{t})) \quad \text{as } d_S(\mathbf{t}) \to 0. \tag{2.1}$$

Now we assume that we have an independent and identically distributed sequence $\{L_n\}$ of such lower derivates. To be precise we view $\{M_n\}$ as coordinate maps of the countable product of copies of a probability space $(C(K,K),\mu_0)$, and for each n, L_n is based on the same factor as M_n. Our first basic question is when will these sequences fail to converge to S in probability for all starting values $\mathbf{t}$?

THEOREM 2.1 (Negative convergence theorem). *Assume we have an independent and identically distributed sequence* $\{M_n\}$ *of random elements of* $C_T(K,K)$ *with independent and identically distributed lower derivates* $\{L_n\}$ *in probability at* S. *Suppose*

(i) $E(\log(L_1)) > 0$, *and*

(ii) *there is a nonnegative random variable* Y *with* $E(Y) < \infty$ *and* $\log[d_S(M_1(\mathbf{t}))/d_S(\mathbf{t})] \geq -Y$ *for all* $\mathbf{t}$.

Then for any $\mathbf{t} \notin S$, $X_n(\mathbf{t})$ *does not converge to* S *in probability.*

Proof. By (ii) we have for each $\mathbf{t}$,

$$E[\log d_S(M_n(\mathbf{t})) - \log d_S(\mathbf{t})] \geq -E(Y) > -\infty. \tag{2.2}$$

It follows that $E(\log d_S(X_{n+1})) - E(\log d_S(X_n)) > -\infty$ for all n, so that $E(\log d_S(X_n)) > -\infty$ for all n. However, also by condition (ii) and the convergence in probability version of Fatou's lemma

$$\liminf_{\mathbf{t}\to\mathbf{p}} E(\log d_S(M_n(\mathbf{t}))) - \log d(\mathbf{t}) \geq E(\log(L_1)). \tag{2.3}$$

By (i), this last expected value is positive, and so for $d_S(\mathbf{t})$ small we have $E[\log d_S(M_n(\mathbf{t}))] - \log d_S(\mathbf{t}) > a$ for some $a > 0$. It follows that for some $r_0 > 0$, we have

$$E(\log d_S(X_{n+1}) - \log d_S(X_n) \mid d_S(X_n) \leq r_0) > a \tag{2.4}$$

for every n. Now

(2.5)

$$\begin{aligned} E(\log d_S(X_{n+1}) - \log d_S(X_n)) =& E([\log d_S(X_{n+1}) - \log d_S(X_n)]I_{[d_S(X_n)\leq r_0]}) \\ &+ E([\log d_S(X_{n+1}) - \log d_S(X_n)]I_{[d_S(X_n)>r_0]}). \end{aligned}$$

By (ii), the negative part of $\log d_S(X_{n+1}) - \log d_S(X_n)$ is uniformly integrable. Therefore if $P(d_S(X_n) > r_0) \to 0$, then the negative part of the second summand in (2.5) also tends to 0, and we have all together

$$E(\log d_S(X_{n+1}) - \log d_S(X_n)) > aP(d_S(X_n) \leq r_0) - \psi(P(d_S(X_n) > r_0)), \tag{2.6}$$

where ψ is a function tending to 0 at 0.

Now assume that X_n converges to S in probability. Then $P(d_S(X_n) \leq r_0) \to 1$ and we have from (2.6) that $E(\log d_S(X_n))$ cannot converge to $-\infty$. But if $X_n \to S$ in probability we must have $E(\log d_S(X_n)) \to -\infty$. □

We now establish sufficient conditions for the almost sure convergence of our algorithm. To develop our conditions we impose a different mild restriction on the random map M: We assume $d(M(\mathbf{t}))/d(\mathbf{t}) \leq Y$ for all $\mathbf{t}$, where Y is some scalar-valued random variable whose βth moment exists for some $\beta > 0$. Note that this implies that $E(d(M(\mathbf{t}))^\beta) < \infty$ for each $\mathbf{t}$.

DEFINITION 2.2. *Let M be a random element of $C_T(K, K)$, let $S \subset T$ be a closed subset, and let U be a nonnegative scalar-valued random variable. We say that U is an upper derivate at S for M in power if for some $\beta > 0$,*

(i) $E(U^\beta) < \infty$ *and*

(ii) $d_S(M(\mathbf{t})) \leq U d_S(\mathbf{t}) + o_\beta(d_S(\mathbf{t}))$.

Observe that an upper derivate in power is also an upper derivate in probability.

PROPOSITION 2.3. *Suppose we have q independent random elements $M_1, \ldots, M_q$ in $C_T(K, K)$ with independent and identically distributed upper derivates $\{U_j\}$ in power at S. Then the composition $M_q \circ \cdots \circ M_1$ has upper derivate $U_q \cdot \cdots \cdot U_1$ in power at S.*

Proof. This is a straightforward real analysis argument using the Hölder inequality and the fact that for $0 < \beta \leq 1$ and nonnegative random variables Y_1, Y_2, $E([Y_1 + Y_2]^\beta) \leq E(Y_1^\beta) + E(Y_2^\beta)$. □

PROPOSITION 2.4. *Let M be a random element of $C_T(K, K)$ with upper derivate U in power at S. Suppose $E(\log U) < 0$. Then for some sufficiently small $\beta > 0$, some $r_0 > 0$, and some $C < 1$, we have*

$$E(d_S(M(\mathbf{t}))^\beta) \leq C d_S(\mathbf{t})^\beta \tag{2.7}$$

whenever $d_S(\mathbf{t}) \leq r_0$.

Proof. Let us observe that

$$\limsup_{d(\mathbf{t})\to 0} E(d(M(\mathbf{t}))^\beta)/d(\mathbf{t})^\beta \leq E(U^\beta) < \infty \tag{2.8}$$

for sufficiently small $\beta > 0$. Choose $B > 0$ such that $E(\log U\, I_{[-B \le \log U]}) < 0$. Then by the dominated convergence theorem we may differentiate $g_B(\beta) = E(U^\beta I_{[-B \le \log U]})$ through the expectation to obtain $g'_B(0) = E(\log U\, I_{[-B \le \log U]}) < 0$. It follows that for small positive β we have $g_B(\beta) < g_B(0) = P(-B \le \log U)$. Since $E(U^\beta I_{[-B > \log U]}) \le e^{-\beta B} P(-B > \log U)$, we obtain $E(U^\beta) < 1$ for $\beta > 0$ sufficiently small. □

THEOREM 2.5 (Positive convergence theorem). *Suppose given a sequence $\{M_n\}$ of independent and identically distributed random elements of $C_T(K, K)$ with independent and identically distributed upper derivates $\{U_n\}$ in power at T. Suppose there is a nonnegative random variable Y such that $d(M_1(\mathbf{t}))/d(\mathbf{t}) \le Y$ for all $\mathbf{t}$ and such that for some $\beta > 0$ the β moment of Y exists. Suppose also that*

(i) *for every $\mathbf{t} \in K$ and every neighborhood V of T there is an n such that $P(X_n(\mathbf{t}) \in V) > 0$, and*

(ii) $E(\log U_1) < 0$.

Then for any Markov chain generated by the sequence $\{M_n\}$, the invariant probability measures are precisely the probability measures supported on T. Moreover, for each $\mathbf{t} \in K$, $X_n(\mathbf{t})) \to T$ almost surely.

Proof. Let $PM(K)$ denote the probability measures on K. Using the common probability distribution μ_0 of $M_1, M_2, \ldots$, on $C_T(K, K)$, the Markov transition $L : PM(K) \to PM(K)$ may be defined by

$$L(\mu)(f) = \int \int f(M(\mathbf{t}))\, d\mu(\mathbf{t})\, d\mu_0(M) \tag{2.9}$$

for all $f \in C(K, \mathbf{R})$. Then L is continuous in the weak topology, and it is standard (see [8, Chap. 6]) that given any $\mu \in PM(K)$, a subsequence of $\{\Sigma_{k=1}^n L^n(\mu)/n\}$ converges weakly to an invariant probability measure ν on K. We claim that such a ν must be supported on T.

To prove the claim, consider a Markov chain $\{Z_n\}$ on K with initial distribution ν and defined by iterates of independent copies of M. Then every Z_n has distribution ν. By Proposition 2.4 we get $\beta > 0, r_0 > 0$, and $C < 1$ such that

$$E(d(M(\mathbf{t}))^\beta) \le C d(\mathbf{t})^\beta \tag{2.10}$$

whenever $d(\mathbf{t}) \le r_0$. For every n let $Y_n = d(Z_n)^\beta \wedge r_0^\beta$. Observe that the $\{Y_n\}$ are identically distributed and $P(Y_{n+1} = 0 \mid Y_n = 0) = 1$. From (2.10) we get $P(0 < Y_n < r_0^\beta) = 0$ for all n. Assume that $P(Y_n = r_0^\beta) > 0$. Then using assumption (i) we can find a positive integer k such that $P(Y_{n+k} < r_0^\beta \mid Y_n = r_0^\beta) > 0$. But then we get $P(Y_{n+k} < r_0^\beta) > P(Y_n < r_0^\beta)$, which is impossible. Thus $P(Y_n = 0) = 1$ for all n, and ν must be supported on T. The claim is proved.

Fix $\mathbf{t} \in K$, and let $X_n = X_n(\mathbf{t})$ for all n. We can now say that given $\epsilon > 0$ and $r_1 > 0$ there is an arbitrarily large n_1 with $(1/n_1)\Sigma_{k=1}^{n_1} P(d(X_k) \le r_1) > 1 - \epsilon$. Hence for at least one $n_0, P(d(X_{n_0}) \le r_1) > 1 - \epsilon$. Now choose $r_0 > 0$ and an upper derivate W for M at T in power such that $E(\log W) < 0$ and $d(M(\mathbf{t}))/d(\mathbf{t}) \le W$ whenever $d(\mathbf{t}) \le r_0$. Let $S_n(r_1)$ denote the random walk starting at $\log r_1$ with step $\log W$. Since $E(\log W) < 0$, we can show by [1, Thm. 8.3.4] that if we choose r_1 small enough, then $P(S_n(r_1) < \log r_0$ for all $n) > 1 - \epsilon$. Comparing $\log X_n$ stochastically with $S_n(r_1)$ for all n, we get $P(d(X_n) < r_0$ for all $n \ge n_0 \mid d(X_{n_0}) < r_1) > 1 - \epsilon$. Moreover, given $d(X_n) < r_0$ for all $n \ge n_0$, we get $E(d(X_{n+1})^\beta) < CE(d(X_n)^\beta)$ for all $n \ge n_0$, for some $C < 1$. A standard application of the Borel–Cantelli lemma (see for example [1, §4.2]) shows that given $d(X_n) \le r_0$ for all $n \ge n_0$, $d(X_n) \to 0$ almost surely. So given

an event with probability $> 1 - 2\epsilon$, the conditional probability that $d(X_n) \to 0$ is 1. Since $\epsilon > 0$ is arbitrary, $d(X_n) \to 0$ almost surely. □

COROLLARY 2.6. *Assume the hypotheses of Theorem* 2.5, *and in addition that there is a random variable* V *with*

$$\limsup_{d(\mathbf{t})\to 0} \frac{\|\mathbf{t} - M(\mathbf{t})\|}{d(\mathbf{t})} \leq V \tag{2.11}$$

in power and $E(V^\beta) < \infty$ *for some* $\beta > 0$. *Then for each* $\mathbf{t} \in K, X_n(\mathbf{t})$ *almost surely has a limit in* T.

Proof. The hypotheses of this corollary imply that for some $\beta > 0$ and $r_0 > 0$ sufficiently small,

$$E\left(\frac{\|\mathbf{t} - M(\mathbf{t})\|^\beta}{d(\mathbf{t})^\beta}\right) \leq D, \tag{2.12}$$

whenever $d(\mathbf{t}) \leq r_0$, for some finite D. From Theorem 2.5, $d(X_n) \leq r_0$ eventually, with probability 1. Moreover, for r_0 small enough, conditioned on $d(X_n) \leq r_0$, we have $E(d(X_{m+1})^\beta) \leq CE(d(X_m)^\beta)$ for all $m \geq n$, for some $C < 1$. Thus with probability 1, $\Sigma_{n=1}^\infty E(d(X_n)^\beta) < \infty$. But then also with probability 1,

$$E(\Sigma_{n=1}^\infty \|X_{n-1} - X_n\|^\beta) = \Sigma_{n=1}^\infty E(\|X_{n-1} - X_n\|^\beta) < \infty \tag{2.13}$$

by comparison with $\Sigma E(d(X_n)^\beta)$. Thus with probability 1, $\Sigma_{n=1}^\infty \|X_{n-1} - X_n\|^\beta < \infty$, and X_n converges to some $\mathbf{p} \in T$. □

COROLLARY 2.7. *Assume condition* (i) *of Theorem* 2.5, *and in addition that* $T = \{\mathbf{p_1}, \ldots, \mathbf{p_m}\}$ *is finite. Assume further that for each* $i = 1, \ldots, m$ *there is an upper derivate* U_i *at* p_i *for* M *in power, with* $E(\log U_i) < 0$. *Then for each* $\mathbf{t} \in K, X_n(\mathbf{t})$ *almost surely has a limit in* T.

Proof. We sketch a proof parallel to that of Theorem 2.5. Let $d_i(\mathbf{t}) = \|\mathbf{t} - \mathbf{p_i}\|$ for each $i = 1, \ldots, m$. By the hypotheses on the U_i's and Proposition 2.4 we get some $\beta > 0, r_0 > 0$, and $C < 1$ such that $E(d_i(M(\mathbf{t}))^\beta) \leq Cd_i(\mathbf{t})^\beta$ whenever $d_i(\mathbf{t}) \leq r_0$, for each i. Reduce r_0 if necessary so that $r_0 < \|p_i - p_j\|/2$ whenever $i \neq j$. Then for this same β, r_0, and C, (2.10) holds whenever $d(\mathbf{t}) \leq r_0$. We check the proof of Theorem 2.5 to see that the main steps go through. First, from condition (i) of Theorem 2.5 and (2.10), we have that the invariant measures are supported on T. Next we see that given $\epsilon > 0$ there is with probability at least $1 - \epsilon$ an n_0 and an i such that $d_i(X_{n_0}) < s$, where $s > 0$ is chosen so that for each i, the random walk starting at $\log s$ with step $\log W_i$ never exceeds $\log r_0$ except with probability $< \epsilon$. Given a fixed i and the event $d_i(X_n) \leq r_0$ for all $n \geq n_0$ for some n_0, we apply the fact that $d_i(X_{n+1})^\beta \leq Cd_i(X_n)^\beta$ for all $n \geq n_0$ to conclude via the Borel–Cantelli lemma that given this event, $X_n \to p_i$ almost surely. All together we have that given an event of probability $> 1 - 2\epsilon$, the conditional probability is 1 that for some $i, X_n \to p_i$. Since $\epsilon > 0$ is arbitrary this proves the corollary. □

3. Illustrative applications. In this section we illustrate the application of our theorems to the analysis of algorithms. The first example is patterned after the motivating example in the Introduction. It assumes complete information about the algorithm. In that sense it is not a realistic example of the analysis of a stochastic optimization algorithm, but it is a good introduction to the use of our theorems. The second example assumes only information typically available and so is a true-to-life analysis of a stochastic optimization algorithm.

Example A. For our first illustrative example let K be the closed unit ball in $\mathbf{R}^N$. Consider a fixed $f \in C(K, K)$ such that $f(\mathbf{0}) = \mathbf{0}$ and $f(\mathbf{t}) = o(\mathbf{t})$ as $\mathbf{t} \to \mathbf{0}$. Let X be an $\mathbf{R}^N$-valued random variable with bounded density and some finite β moment. Define the random map M by $M(\mathbf{t}) = f(\mathbf{t}) + \phi(\|\mathbf{t}\|)X$, where $\phi : [0,1] \to [0,1]$ is a continuous scale factor with sole root 0 and whose right-hand derivative at 0 exists (we allow $+\infty$ as a possible value for this derivative). Of course this definition must be adjusted to cope with the possibility that for some $\mathbf{t}$, $M(\mathbf{t})$ lands outside K with positive probability. Two common remedies are (i) reset (we project back onto the nearest point of K) and (ii) restart (we take $M(\mathbf{t})$ to be a randomly chosen point of K). We will adopt remedy (i) (reset).

From these assumptions we can verify the following: (a) the nonnegative integrable Y required for the positive convergence theorem exists provided $\phi'(0) < \infty$; (b) condition (ii) of the negative convergence theorem holds provided $\phi'(0) > 0$. A simple way to guarantee condition (i) of the positive convergence theorem is to require that the support of the density of X be all of $\mathbf{R}^N$; however condition (i) of that theorem might easily hold without this requirement.

Now $M'(\mathbf{0}) = \phi'(0)X$, in any sense that we choose. In case $\phi'(0) = +\infty$ we have a lower derivate in the sense we choose. To apply the positive and negative convergence theorems above we observe that

$$E(\log \|M'(0)\|) = \log \phi'(0) + E(\log \|X\|), \tag{3.1}$$

so that for a sequence of random variables generated by iterating independent copies of the map M, we obtain convergence almost surely starting from any nonzero element of K if $\phi'(0) < \exp\{-E(\log \|X\|)\}$, and we fail to have convergence in probability starting from any nonzero element of K if this last inequality is reversed. By Jensen's inequality, $E(\log \|X\|) < \log E(\|X\|)$, so it is enough to have $\phi'(0) < E(\|X\|)^{-1}$ in order to have convergence.

When the distribution of X is known we can say more. For example, if X is uniform on the ball of radius R centered at the origin in $\mathbf{R}^N$ we get $E(\log \|X\|) = \log R - 1/N$, with convergence when $\phi'(0) < \exp(1/N)/R$. In this case the accessibility condition is fulfilled provided that for some $C < 1$, $\|f(\mathbf{t}) + \phi(\|\mathbf{t}\|)X\|/\|\mathbf{t}\| \le C$ with positive probability for each $\mathbf{t} \in K$, and this holds if and only if

$$\sup_{\mathbf{t}} \frac{\|f(\mathbf{t})\|}{\|\mathbf{t}\|} - R\frac{\phi(\|\mathbf{t}\|)}{\|\mathbf{t}\|} < 1. \tag{3.2}$$

If on the other hand X is multivariate normal with mean $\vec{0}$ and covariance matrix I, then accessibility is automatic and $E(\log \|X\|) = \frac{1}{2}E(\log \|X\|^2)$. Now $\|X\|^2$ has the chi-squared distribution with N degrees of freedom and so $E(\log \|X\|^2) = \log 2 - \gamma + [1 + \frac{1}{2} + \cdots + 1/(\frac{N}{2} - 1)]$ for N even and $= -\gamma - \log 2 + 2 + 2/3 + \cdots + 2/(N-2)$ for N odd. (See [4, Chap. 16].)

Let us extend this example. Suppose we have a closed submanifold T of the unit ball K, and $h \in C(K, K)$ such that $h(\mathbf{t}) = \mathbf{t}$ for all $\mathbf{t} \in T$ and $d(h(\mathbf{t})) = o(d(\mathbf{t}))$ as $d(\mathbf{t}) \to 0$. Suppose further that (as might happen in a descent algorithm) $\|h(\mathbf{t}) - \mathbf{t}\| \le Rd(\mathbf{t})$ for all $\mathbf{t} \in K$, for some constant R. Let $M(\mathbf{t}) = h(\mathbf{t}) + [\phi(d(\mathbf{t})) + o(d(\mathbf{t}))]X$, where $\phi : [0,1] \to [0,1]$ is as above, X is an $\mathbf{R}^N$-valued random variable with distribution to be assigned, and we adopt the reset remedy as needed. Then (2.11) of Corollary 2.6 holds, and

$$\lim_{d(\mathbf{t}) \to 0} \frac{d(M(\mathbf{t}))}{d(\mathbf{t})} = \phi'(0)X. \tag{3.3}$$

Our discussion above carries over, and for the algorithm generated by independent copies of M, from Corollary 2.6 we almost surely have a limit in T if $\log \phi'(0) + E(\log \|X\|) < 0$, and from Theorem 2.1 we fail to have convergence in probability to T if $\log \phi'(0) + E(\log \|X\|) > 0$.

Example B. For our second example let us suppose that an optimization problem leads us to seek roots of a continuously differentiable function g on $[-1, 1]$, and that we decide to devise a randomized version of Newton–Raphson. Suppose that g has finitely many roots $p_1, \ldots, p_m$, and that root p_i has order k_i for each i. To cope with obstructions that arise but also to allow Newton–Raphson to proceed when we do make progress, we allow for varying combinations of "signal" and "noise" in our algorithm, depending on the current state. Thus we might base our algorithm on iterates of independent copies of the following map:

$$M(t) = t - \lambda(t)\frac{g(t)}{g'(t)} + (1 - \lambda(t))X, \tag{3.4}$$

where X is a random variable with distribution symmetric about 0 , and $\lambda : [-1, 1] \to [0, 1]$ is a function yet to be specified. Again we adopt the reset remedy when this algorithm jumps out of $[-1, 1]$.

First we want $\lambda(p_i) = 1$ for $i = 1, \ldots, k$, and $\lambda(x) = 0$ whenever x is a root of g' other than $p_1, \ldots, p_m$. One way to accomplish this is to set $\lambda(x) = \psi(|g(x)|/|g'(x)|)$ for some function $\psi : [0, \infty] \to [0, 1]$ such that $\psi(0) = 1$ and $\psi(\infty) = 0$. Then for each $i = 1, \ldots, m$ we have

$$\lim_{t \to p_i} \frac{|M(t) - p_i|}{|t - p_i|} = \left|1 - \frac{1}{k_i} - \frac{1}{k_i}\psi'(0)X\right|. \tag{3.5}$$

The accessibility condition (i) of the positive convergence theorem will hold provided we take X to have density with support all of $\mathbf{R}$. We must also deal with the local convergence condition (ii). We can take $\psi(x) = \exp(-cx)$ for all $x \in [0, \infty]$, for some $c > 0$. Then the right-hand side of (3.3) becomes $|a + bX|$, where $a = 1 - 1/k_i$ and $b = c/k_i$. Corollary 2.7 now gives convergence to some root of g provided

$$E(\log |a + bX|) < 0. \tag{3.6}$$

Since we control the density of X we can find a and b for which (3.4) holds.

If X is standard normal, then $2E(\log |a + bX|) = 2 \log b + E(\log(\eta + X)^2)$, where $(\eta + X)^2$ has the noncentral chi-squared distribution with one degree of freedom and noncentrality parameter $\eta = a/b$. If we assume only simple roots, then $\eta = 0$ and

$$2E(\log |a + bX|) = 2 \log b - \gamma - \log 2, \tag{3.7}$$

where $\gamma = .5772157\ldots$ is the Euler constant. So in this case we need $b < \exp((\gamma + \log 2)/2) = 1.89$. To handle roots of any order, we set $a = 1$ to cover all cases, and by reference to [4, Chap. 28] (see also [2, p. 15], for special functions background), we find

(3.8)

$$2E(\log |1 + bX|) = 2 \log b - \gamma - \log 2 + \exp\left(-\frac{1}{2b}\right) \sum_{j=1}^{\infty} \frac{(2b)^{-j}}{j!} \left[2 + \frac{2}{3} + \cdots + \frac{2}{2j - 1}\right],$$

from which we determine that we need $b < 1.36$.

On the other hand, we may want a heavier tailed distribution for X. If X has the Cauchy density $(\pi(1+x^2))^{-1}$, $-\infty < x < \infty$, then we see that $E(\log|a+bX|) = \log\sqrt{a^2+b^2}$. Thus if simple roots are our only concern we can take $b < 1$, but otherwise we must judge the maximum order k of root that will occur, set $a = 1 - 1/k$, and choose $b < \sqrt{1-a^2}$.

If we redefine ψ to be 0 whenever $|g/g'| \geq M$ and 1 whenever $|g/g'| \leq m$, and the latter condition is inside the region where Newton–Raphson is working, then we could take X to be uniform on an interval symmetric about 0 and determined so that

$$\psi\left(\frac{|g|}{|g'|}\right)\frac{g}{g'} + \left(1 - \psi\left(\frac{|g|}{|g'|}\right)\right)X \tag{3.9}$$

always has support containing $[-\epsilon, \epsilon]$ for some $\epsilon > 0$. This last definition, if successful, has the virtue that the final stages of convergence will be pure Newton–Raphson, and hence optimally fast.

Finally, we remark that if we wish to exclude a known root p_i from our target set, we simply modify λ so that $\lambda(p_i) = 0$, and this has the effect of removing p_i from our fixed point set almost surely.

4. On order of convergence and expected time to the stopping set. Our results have interpretations in terms of order of convergence. Suppose that the hypotheses of Theorem 2.5 hold; then $X_n \to T$ almost surely and by Proposition 2.4

$$\limsup_{d(\mathbf{t})\to 0} \frac{E(d(M(\mathbf{t}))^\beta)}{d(\mathbf{t})^\beta} < 1 \quad \text{for some } \beta > 0. \tag{4.1}$$

Let $\delta > 0$ and $C < 1$ such that $E(d(M(\mathbf{t}))^\beta) < Cd(\mathbf{t})^\beta$ whenever $d(\mathbf{t}) \leq \delta$. Let J be the (random) minimum integer such that $d(X_n) \leq \delta$ for all $n \geq J$; then $J < \infty$ almost surely. Also,

$$E(d(X_{J+k+1})^\beta) < CE(d(X_{J+k})^\beta) \tag{4.2}$$

for all k. If we now put a new metric on K so that the distance from $\mathbf{x}$ to $\mathbf{p}$ in the new metric is just $\|\mathbf{x}-\mathbf{p}\|^\beta$, then almost surely we have eventual mean C-linear convergence to $\mathbf{p}$.

Now suppose again that the hypotheses in our positive convergence theorem hold, and in addition $E(\log M_\eta) < 0$ for some $\eta > 0$, where

$$M_\eta = \limsup_{d(\mathbf{t})\to 0} \frac{d(M(\mathbf{t}))}{d(\mathbf{t})^\eta}. \tag{4.3}$$

Then we again have that $X_n \to T$ almost surely and the same arguments as in Proposition 2.4 can be used to show

$$E(d(X_{n+1})^\beta) < CE(d(X_n)^{\beta\eta}) \tag{4.4}$$

for large n, for some positive $\beta \leq 1$, and some $C < \infty$. Recoordinatizing K as above we have in this case almost sure eventual mean order η convergence.

To obtain realistic estimates of the expected number of steps to a stopping set we must first realize that a successful Markov algorithm will have two broad phases

of convergence. The first stage will be more or less random searching for the zone of rapid convergence. Let us first assume that for some positive integer q such that the probability of reaching this zone in q steps starting from any $x \in K$ has the lower bound $b > 0$ uniformly in x; then replacing the original Markov algorithm by q-fold iterates, we may assume the probability of reaching the zone of rapid convergence in one step has the uniform lower bound b over K. Then the expected number of steps to this zone is bounded above by the expected value of a geometric random variable whose stopping probability on a single trial is b. We finally obtain q/b as an upper bound for the expected number of steps of the original algorithm to the zone of rapid convergence. We should note that the more uniform in x the probability of reaching the zone of rapid convergence is, the more realistic will be this estimate.

The second stage of convergence is that which occurs after the random variable enters the zone of rapid convergence. First assume eventual linear mean convergence, and (possibly as a worst case) that

$$\frac{d(M(\mathbf{t}))}{d(\mathbf{t})} \simeq U, \tag{4.5}$$

a nondegenerate random variable independent of $\mathbf{t}$. It follows that $\log d(X_{n+1}) - \log d(X_n) \simeq \log U_{n+1}$ is approximately a sequence of independent and identically distributed random variables and that we are essentially dealing with a general random walk, familiar from the theory of sequential analysis. By assumption, $E(\log U_n) = a < 0$. Taking the stopping set to be of the form $\log d(X_n) < -C$, then as a consequence of Wald's identity we have that the expected number of steps to stopping is $\simeq C/a$, provided we are willing as usual to neglect the excess probability over boundary. (See [7, Prop. 2.18].)

Finally let us consider the case of eventual mean convergence of order $\eta > 1$. Assume

$$\frac{d(M(\mathbf{t}))}{d(\mathbf{t})^{\eta}} \simeq U, \tag{4.6}$$

a nondegenerate random variable independent of $\mathbf{t}$. Then $\log d(X_{n+1}) - \eta \log d(X_n) \simeq \log U_{n+1}$ defines an approximately independent and identically distributed sequence of random variables. For each n, let $Y_n = -\log U_n$ and $W_n = -\log d(X_n)$. Then $Y_1, \ldots, Y_n, \ldots$, are independent and identically distributed, $E(Y_n) > 0$, and $W_{n+1} = Y_{n+1} + \eta W_n = Y_{n+1} + \eta Y_n + \cdots + \eta^{n+1} Y_0$ for each n. The Wald analysis does not seem to apply immediately to this situation, but with additional reasonable assumptions we can still get an upper bound for the expected number of steps to stopping. We assume that we are far enough into rapid convergence that $Y_n \geq 0$ for each n, and also that we have a uniform upper bound B for the density of Y_n. Let $W_n \geq C$ be the stopping criterion and let J be the stopping time. Then $J = 1 + \Sigma_{n=1}^{\infty} I_{[W_1, \ldots, W_n < C]}$, so that

$$E(J) = 1 + \Sigma_{n=1}^{\infty} P(W_1, \ldots, W_n < C) = 1 + \Sigma_{n=1}^{\infty} P(W_n < C). \tag{4.7}$$

However,

$$P(W_n < C) = P(Y_0 + \cdots + \eta^{-n} Y_n < C\eta^{-n}). \tag{4.8}$$

Now we have three upper bounds for $P(W_n < C)$:

(a) $P(W_n < C) \leq 1$;
(b) $P(W_n < C) \leq P(Y_0 < C\eta^{-n}) \leq BC\eta^{-n}$; and
(c) $P(W_n < C) < B^{n+1}C^{n+1}[\eta^{n(n+1)/2}(n+1)!]^{-1}$.

To see (c) we first observe that the density for each $\eta^{-k}Y_k$ is bounded above by $B\eta^k$ and so

(4.9)
$$P(Y_0 + \cdots + \eta^{-n}Y_n < C\eta^{-n}) \leq \frac{B^{n+1}\eta^{n(n+1)/2}(C\eta^{-n})^{n+1}}{(n+1)!} = \frac{B^{n+1}C^{n+1}\eta^{-n(n+1)/2}}{(n+1)!}.$$

For each n let $B_n = 1 \wedge BC\eta^{-n} \wedge B^{n+1}C^{n+1}\eta^{-n(n+1)/2}/(n+1)!$. Then $E(J) \leq 1 + \Sigma_{n=1}^{\infty} B_n$. This series converges quickly: for example, if $B = 1, C = 10$, and $\eta = 2$, we get $E(J) \leq 4.67$.

Acknowledgment. We would like to thank Ian Dinwoodie for many helpful suggestions and discussions about this work.

MINIMIZING THE EUCLIDEAN CONDITION NUMBER*

RICHARD D. BRAATZ† AND MANFRED MORARI‡

Abstract. This paper considers the problem of determining the row and/or column scaling of a matrix A that minimizes the condition number of the scaled matrix. This problem has been studied by many authors. For the cases of the ∞-norm and the 1-norm, the scaling problem was completely solved in the 1960s. It is the Euclidean norm case that has widespread application in robust control analyses. For example, it is used for integral controllability tests based on steady-state information, for the selection of sensors and actuators based on dynamic information, and for studying the sensitivity of stability to uncertainty in control systems.

Minimizing the scaled Euclidean condition number has been an open question—researchers proposed approaches to solving the problem numerically, but none of the proposed numerical approaches guaranteed convergence to the true minimum. This paper provides a convex optimization procedure to determine the scalings that minimize the Euclidean condition number. This optimization can be solved in polynomial-time with off-the-shelf software.

1. Introduction.

Let $V_1 = \mathbf{C}^n$ be the normed complex vector space with Hölder p-norm $\|\cdot\|_p$, $\|x\|_p = (\sum |x_j|^p)^{1/p}$. For an $n \times n$ matrix $A : V_1 \to V_1$, the following induced matrix norm is defined:

$$\|A\|_{ip} = \max_{x \neq 0} \frac{\|Ax\|_p}{\|x\|_p}. \tag{1}$$

If the inverse A^{-1} exists, then the condition number subordinate to the norm $\|\cdot\|_p$ is defined by

$$\kappa_p(A) = \|A\|_{ip}\|A^{-1}\|_{ip}. \tag{2}$$

Define $\mathbf{C}^{n\times n}$ to be the set of complex $n \times n$ matrices. Let $\mathbf{D}^{n\times n}$ be the set of all diagonal invertible matrices in $\mathbf{C}^{n\times n}$. If $A \in \mathbf{C}^{n\times n}$ is the matrix defining a system of linear equations $Ax = b$, scaling the rows of this system is equivalent to premultiplying A by a diagonal matrix $D_1 \in \mathbf{D}^{n\times n}$. Scaling the unknowns is equivalent to postmultiplying A by a diagonal matrix $D_2 \in \mathbf{D}^{n\times n}$. The quality of numerical computations is generally better when the condition number of A is small. Since diagonal scalings of A are trivial modifications, researchers in the 1960s–1970s were led to investigate the following minimizations in order to obtain optimal scalings of a matrix:

$$\begin{aligned} &\text{(i)} && \kappa_p^l(A) = \inf_{D_1 \in \mathbf{D}^{n\times n}} \kappa_p(D_1 A), \\ &\text{(ii)} && \kappa_p^r(A) = \inf_{D_2 \in \mathbf{D}^{n\times n}} \kappa_p(A D_2), \\ &\text{(iii)} && \kappa_p^{lr}(A) = \inf_{D_1, D_2 \in \mathbf{D}^{n\times n}} \kappa_p(D_1 A D_2). \end{aligned} \tag{3}$$

TABLE 1

Minimized condition numbers. The matrix whose elements are the moduli of the corresponding elements of A is denoted by $|A|$. The spectral radius of A is denoted by $\rho(A)$. The maximum singular value $\overline{\sigma}(A)$ refers to $\|A\|_{i2}$.

	$p = 1, \infty$	$p = 2$
$\inf_{D_1} \kappa_p(D_1 A)$	$\overline{\sigma}\left(\lvert A^{-1}\rvert \cdot \lvert A\rvert\right)$	?
$\inf_{D_2} \kappa_p(A D_2)$	$\overline{\sigma}\left(\lvert A\rvert \cdot \lvert A^{-1}\rvert\right)$	?
$\inf_{D_1, D_2} \kappa_p(D_1 A D_2)$	$\rho(\lvert A\rvert \cdot \lvert A^{-1}\rvert)$	?

Problem (3(i)) was present for example in the error analysis of direct methods for the solution of linear equations [34], [2]. Problem (3(ii)) is important for obtaining the best possible bounds for eigenvalue inclusion theorems [3], and is a natural measure of the linear independence of the column vectors that form A [2]. Problem (3(iii)) was used for decreasing the error in calculation of the matrix inverse A^{-1} [14].

Later, it was realized that the appropriate scalings depend on the error in the matrix, not the elements of the matrix itself [10], [31]. This implied, for example, that the scalings solving problem (3(iii)) are not necessarily the best scalings of A to decrease the error in the calculation of A^{-1}. However, problems (3(i))–(3(iii)) still have widespread application in robust control analyses. For example, the minimized condition number (3(iii)) is used for integral controllability tests based on steady-state information [13], [18], and for the selection of sensors and actuators using dynamic information [24], [19], [20]. The sensitivity of stability to uncertainty in control systems is given in terms of the minimized condition number in [29], [30].

Without loss of generality, for each of these problems we need only consider the infimum over the set of real positive diagonal invertible matrices $\mathbf{D}_+^{n\times n}$. This is because any matrix in $\mathbf{D}^{n\times n}$ can be decomposed into a matrix in $\mathbf{D}_+^{n\times n}$ and a unitary diagonal matrix. The unitary diagonal matrix does not affect the value of the condition number in (2) (see [2] for a simple proof). Conditions for the existence of scaling matrices that achieve the infimum are given by Businger [6].

The minimizations were solved for $p = 1$ and $p = \infty$ by Bauer [2] (the results are in Table 1). Many researchers consider the 2-norm as most important for applications [2], [14], [17]. Solving (3(i))–(3(iii)) for the 2-norm has been an open question [28], [35]. In this paper we solve the minimizations for the 2-norm by transforming the minimizations (3(i))–(3(iii)) so that they can be solved via convex programming.

Nonsquare A [33], block diagonal scalings [12], [27], [9], [11], [35], and cross-condition numbers (with B replacing A^{-1} in (2), see [8], [16], [15]) have also received attention. For ease of notation, the results are derived for square matrices with fully diagonal scalings. The results (and proofs) hold for these other cases with the modifications given after the lemmas.

2. Results. The induced matrix norm for the vector 2-norm is commonly referred to as the maximum singular value, $\overline{\sigma}(A) = \|A\|_{i2}$. To simplify notation, drop the subscript on κ_2, i.e., $\kappa_2 = \kappa$. Let $\mathbf{R}_+$ be the set of real positive scalars. Let I be the $n \times n$ identity matrix.

LEMMA 2.1. *The following equality holds*:

$$\kappa(A) = \inf_{d_1, d_2 \in \mathbf{R}_+} \overline{\sigma}^2 \left(\begin{bmatrix} d_1 I & 0 \\ 0 & d_2 I \end{bmatrix} \begin{bmatrix} 0 & A^{-1} \\ A & 0 \end{bmatrix} \begin{bmatrix} (d_1)^{-1} I & 0 \\ 0 & (d_2)^{-1} I \end{bmatrix} \right). \tag{4}$$

Proof.

$$\inf_{d_1,d_2\in\mathbf{R}_+} \overline{\sigma}^2\left(\begin{bmatrix} d_1 I & 0 \\ 0 & d_2 I \end{bmatrix}\begin{bmatrix} 0 & A^{-1} \\ A & 0 \end{bmatrix}\begin{bmatrix} (d_1)^{-1} I & 0 \\ 0 & (d_2)^{-1} I \end{bmatrix}\right) \tag{5}$$

$$= \inf_{d_1,d_2\in\mathbf{R}_+} \overline{\sigma}^2\left(\begin{bmatrix} 0 & \frac{d_1}{d_2}A^{-1} \\ \frac{d_2}{d_1}A & 0 \end{bmatrix}\right) \tag{6}$$

$$= \inf_{d_1,d_2\in\mathbf{R}_+} \max\left\{\overline{\sigma}^2\left(\frac{d_1}{d_2}A^{-1}\right), \overline{\sigma}^2\left(\frac{d_2}{d_1}A\right)\right\} \tag{7}$$

$$= \inf_{d_1,d_2\in\mathbf{R}_+} \max\left\{\frac{d_1^2}{d_2^2}\frac{\overline{\sigma}\left(A^{-1}\right)}{\overline{\sigma}\left(A\right)}, \frac{d_2^2}{d_1^2}\frac{\overline{\sigma}\left(A\right)}{\overline{\sigma}\left(A^{-1}\right)}\right\} \cdot \overline{\sigma}\left(A\right)\overline{\sigma}\left(A^{-1}\right) \tag{8}$$

$$= \inf_{x\in\mathbf{R}_+} \max\left\{x, x^{-1}\right\} \cdot \overline{\sigma}\left(A\right)\overline{\sigma}\left(A^{-1}\right) \tag{9}$$

$$= \overline{\sigma}\left(A\right)\overline{\sigma}\left(A^{-1}\right) = \kappa(A). \tag{10}$$

Note that this proof is similar to a proof in [21]. □

The following lemma gives similar expressions as in (4) for $\kappa^l(A)$, $\kappa^r(A)$, and $\kappa^{lr}(A)$.

LEMMA 2.2. *The following equalities hold:*

$$\kappa^l(A) = \inf_{D_1\in\mathbf{D}_+^{n\times n}} \overline{\sigma}^2\left(\begin{bmatrix} I & 0 \\ 0 & D_1 \end{bmatrix}\begin{bmatrix} 0 & A^{-1} \\ A & 0 \end{bmatrix}\begin{bmatrix} I & 0 \\ 0 & D_1^{-1} \end{bmatrix}\right). \tag{11}$$

$$\kappa^r(A) = \inf_{D_2\in\mathbf{D}_+^{n\times n}} \overline{\sigma}^2\left(\begin{bmatrix} D_2^{-1} & 0 \\ 0 & I \end{bmatrix}\begin{bmatrix} 0 & A^{-1} \\ A & 0 \end{bmatrix}\begin{bmatrix} D_2 & 0 \\ 0 & I \end{bmatrix}\right). \tag{12}$$

$$\kappa^{lr}(A) = \inf_{D\in\mathbf{D}_+^{2n\times 2n}} \overline{\sigma}^2\left(D\begin{bmatrix} 0 & A^{-1} \\ A & 0 \end{bmatrix}D^{-1}\right). \tag{13}$$

Proof. Substituting D_1AD_2 for A in Lemma 2.1 and rearranging gives

$$\kappa(D_1AD_2) = \inf_{d_1,d_2\in\mathbf{R}_+} \overline{\sigma}^2\left(\begin{bmatrix} d_1D_2^{-1} & 0 \\ 0 & d_2D_1 \end{bmatrix}\begin{bmatrix} 0 & A^{-1} \\ A & 0 \end{bmatrix}\begin{bmatrix} (d_1D_2^{-1})^{-1} & 0 \\ 0 & (d_2D_1)^{-1} \end{bmatrix}\right), \tag{14}$$

where d_1 and d_2 are real positive scalars.

Take the infimum over D_1 and D_2 on both sides to give

$$\kappa^{lr}(A) = \inf_{D_1,D_2\in\mathbf{D}_+^{n\times n}} \inf_{d_1,d_2\in\mathbf{R}_+} \overline{\sigma}^2\left(\begin{bmatrix} d_1D_2^{-1} & 0 \\ 0 & d_2D_1 \end{bmatrix}\begin{bmatrix} 0 & A^{-1} \\ A & 0 \end{bmatrix}\begin{bmatrix} (d_1D_2^{-1})^{-1} & 0 \\ 0 & (d_2D_1)^{-1} \end{bmatrix}\right) \tag{15}$$

$$= \inf_{D_1,D_2\in\mathbf{D}_+^{n\times n}} \overline{\sigma}^2\left(\begin{bmatrix} D_2^{-1} & 0 \\ 0 & D_1 \end{bmatrix}\begin{bmatrix} 0 & A^{-1} \\ A & 0 \end{bmatrix}\begin{bmatrix} D_2 & 0 \\ 0 & D_1^{-1} \end{bmatrix}\right). \tag{16}$$

Letting $D = \operatorname{diag}\left\{D_2^{-1}, D_1\right\}$ gives (13). Expressions (11) and (12) are proved similarly. □

Let I_r be the $r \times r$ identity matrix. Let $\mathcal{D}^{2n\times 2n} = \operatorname{diag}\{[d_1 I_{r_1}, \ldots, d_m I_{r_m}] : d_j \in \mathbf{R}, r_1 + \cdots + r_m = 2n\}$, and $M \in \mathcal{C}^{2n\times 2n}$. Consider the following lemma.

LEMMA 2.3. *The following optimization is convex:*

$$\inf_{D\in\mathbf{D}^{2n\times 2n}} \overline{\sigma}^2\left(e^D M e^{-D}\right). \tag{17}$$

Proof. See [25]. □

Because $\left\{e^D : D \in \mathcal{D}\right\} = \{D : D \in \mathcal{D}_+\}$, the optimizations in Lemmas 2.1 and 2.2 are equivalent to the optimization in Lemma 2.3. This means that the condition number κ and minimized condition numbers κ^l, κ^r, κ^{lr} can all be calculated through convex programming. Since the optimization (17) is convex, it can have only one minimum.

The optimization (17) has been studied extensively [22], [32], [23], [25], and off-the-shelf software is available for solving these polynomial-time problems (for example, see the program *mu* in [1]). The calculation of the minimized condition numbers is slow, however, since the minimization (17) requires repeated maximum singular value calculations.

The parallelism between expressions (4), (11), (12), and (13) for κ, κ^l, κ^r, and κ^{lr} is interesting. The same optimization can be used for the condition number calculations—the optimizations are just over different "scaling matrices." This is nice theoretically, since κ^l, κ^r, and κ^{lr} are just the *scaled* condition numbers.

Remark 2.4. Conditions for the existence of scaling matrices that achieve the infimum are given by Businger [6]. When the infinum is achieved, any algorithm that solves (17) provides the minimizing scaling matrices for the condition number. When the infinum is not achieved, the algorithm provides scaling matrices such that the infinum is approached with arbitrary closeness.

Remark 2.5. To generalize to nonsquare A, replace every occurrence of A^{-1} with the respective right or left inverse. More specifically, if $A \in \mathbf{C}^{m\times n}$ and has full row rank with $m < n$, then replace A^{-1} with $A^T(AA^T)^{-1}$ in all proofs and lemmas. For $m > n$ with A having full column rank, replace A^{-1} with $(A^TA)^{-1}A^T$.

Remark 2.6. The Euclidean cross-condition number is defined by

$$\hat{\kappa}(A, B) := \overline{\sigma}(A)\,\overline{\sigma}(B). \tag{18}$$

Minimized cross-condition numbers can be defined similarly as in (3), for example,

$$\hat{\kappa}^{lr}(A, B) := \inf_{D_1, D_2\in\mathbf{D}^{n\times n}} \hat{\kappa}(D_1 A D_2, D_2^{-1} B D_1^{-1}). \tag{19}$$

Lemmas 2.1 and 2.2 follow with B, replacing A^{-1}. This problem is important for testing stability of systems with element-by-element uncertainty [7], [8], [16], [15].

Remark 2.7. For block-diagonal scaling matrices, without loss of generality we can take each block to be positive definite Hermitian. This is because any nonsingular complex matrix can be decomposed into a positive definite Hermitian matrix and a unitary matrix [4], and the unitary matrix does not affect the value of the Euclidean condition number. The proofs of Lemmas 2.1 and 2.2 follow exactly as for the fully diagonal case. Lemma 2.3 does not hold for block-diagonal scalings. For block-diagonal scalings it is better to convert the singular value minimizations in Lemma 2.2

into generalized eigenvalue minimizations, as follows:

$$\inf_{D\in\mathbf{D}_+} \overline{\sigma}(DMD^{-1}) = \inf_{D^2\in\mathbf{D}_+} \left\{\beta \,\middle|\, M^*D^2M - \beta D^2 < 0\right\}. \tag{20}$$

The condition $M^*D^2M - \beta D^2 < 0$ is convex in D^2, so any local minimum is global, and off-the-shelf software is available [1]. Many researchers are working to develop improved computational approaches for these polynomial-time problems (for example, see [5] and the literature cited therein).

3. Conclusions. We have completed Table 1 in the sense that all values in the table can now be calculated with arbitrary precision.

All entries in the table, including the now-filled entries, require the inverse of A to calculate the minimizing scalings and the minimized condition numbers. There are algorithms for numerically determining the minimized condition numbers without predetermining the matrix inverse [26], [35], but these methods are not guaranteed to converge to the true minima.

CONTINUITY OF BEST HANKEL APPROXIMATION AND CONVERGENCE OF NEAR-BEST APPROXIMANTS*

CHARLES K. CHUI† AND XIN LI‡

Abstract. Consider a bounded Hankel operator Γ with s-numbers $s_0 \geq s_1 \geq \cdots$ and a sequence of bounded Hankel operators Γ_n converging to Γ in the operator norm. In this paper, it is shown that for each k with $s_{k-1} > s_k \geq s_{k+1} \geq \cdots$, the rational symbols of the best rank-k Hankel approximants of Γ_n converge uniformly to the corresponding rational symbol of the best rank-k Hankel approximant of Γ. Based on this continuity result, the convergence of the near-best Hankel approximants corresponding to a fairly general class of truncated Hankel operators is discussed.

Key words. Hankel operators; Adamjun, Arov, and Krein (AAK); rational approximation; near-best approximation; continuity of best approximation

AMS subject classifications. primary 47B05, 41A35; secondary 41A20

1. Introduction.

Studies of Hankel operators and Hankel-type approximation date back to the original work of Carathéodory and Fejér [4], Schur [28], Takagi [29], and Achiezer [3]. A more recent fundamental approach, which may be regarded as a complete extension of the celebrated theorem of Nehari [22], was given by Adamjan, Arov, and Krein [1], [2], and for this reason, it is commonly called the AAK theory. Applications of Hankel operators to signal processing, H^∞-control, and approximation theory can be found in [8], [10], [12], [14], [21].

The objective of this paper is to give a complete answer to the question of "continuity" of best Hankel approximation. This result has important applications to systems theory and H^∞-control, and we also discuss the convergence of near-best Hankel approximants that correspond to a fairly large class of truncated Hankel operators. Similar problems have been studied in the literature. We only mention Helton and Schwartz [20], Hayashi, Trefethen, and Gutknecht [19], and Peller [26] (also cf. [32]).

Let R_k denote the class of all strictly proper rational functions with at most k poles (counting multiplicities), all of which lie inside the unit circle. As usual, we denote by L^∞ the Banach space of all essentially bounded measurable functions on the unit circle $|z| = 1$, and by H^∞, its Hardy subspace of bounded analytic functions in $|z| < 1$. We consider approximation of functions in L^∞ from

$$\widetilde{R}_k := R_k + H^\infty. \tag{1.1}$$

It is well known (cf. [2]) that, for each integer $k \geq 0$ and function $f \in L^\infty$, there exists a unique $g_k \in \widetilde{R}_k$ such that

$$\|f - g_k\|_\infty = \inf_{g \in \widetilde{R}_k} \|f - g\|_\infty. \tag{1.2}$$

The (nonlinear) operator

$$A_k\colon\ L^\infty \to \widetilde{R}_k, \tag{1.3}$$

defined by $A_k(f) = g_k$ as in (1.2), is called the operator of best approximation (see [19], [26]). Hence, the problem of continuity of this operator is to study conditions under which we have

$$\|f_n - f\|_\infty \to 0 \Rightarrow \|A_k(f_n) - A_k(f)\|_\infty \to 0, \quad \text{as } n \to \infty. \tag{1.4}$$

The problem of best approximation in (1.2) happens to be intimately related to the problem of best approximation of bounded Hankel operators by those with (specified) finite ranks. This is the so-called AAK theory, and we give a very brief review of this topic in the next section. For the time being, we only note that corresponding to any $f \in L^\infty$, there corresponds a unique bounded Hankel operator Γ_f, and that the measurement of error of best approximation in (1.2) is given by the singular values (better known as s-numbers in the AAK theory) $s_k\ (\Gamma_f)$ of Γ_f. These values are arranged in nonincreasing order, with $s_0(\Gamma)$ being the largest one.

Returning to the discussion of the continuity of the operator A_k as described by (1.4), we first mention a result in [20] which says that if the largest s-number $s_0(\Gamma_f)$ is simple and $f, f_n \in C^\infty$, then (1.4) holds for $k = 0$.

The Wiener class W of functions

$$f(z) = \sum_{-\infty}^{\infty} c_n z^n, \qquad |z| = 1,$$

defined by $\sum |c_n| < \infty$, was considered in [19]. Using the norm $\|f\|_W := \sum |c_n|$, and considering some extension of $\widetilde{R}_k$ (see [19, pp. 198–199]), the continuity result in [19] is that $A_k\colon\ W \to W$ is continuous at $f \in W$ relative to the norm $\|\ \|_W$, if and only if the s-number $s_k\ (\Gamma_f)$ is simple. This result is a consequence of the theorems of Wiener and AAK (cf. [19] for further discussions).

Some larger classes of functions, such as VMO and Besov classes, were considered in [26] (see properties $(A_1)-(A_4)$ in [26, pp. 143–144]). Let X be such a function space with norm $\|\ \|_X$ and $f \in X$. Then again under the assumption that the s-number $s_k\ (\Gamma_f)$ is simple, it was shown in [26] that the operator A_k is continuous at f relative to the norm $\|\ \|_X$.

In all the papers [19], [20], [26] mentioned above, the continuity of the operator A_k depends on the basic assumption that the s-number $s_k\ (\Gamma_k)$ is simple, namely that

$$s_{k-1}(\Gamma_f) > s_k(\Gamma_f) > s_{k+1}(f) \geq \cdots, \tag{1.5}$$

with $s_{-1}(f) := +\infty$. In fact, some counterexamples and negative results were given in [19], [20] and [26], respectively, to show that the results there do not hold otherwise.

In this paper, we attack the continuity problem by considering the intimate relationship between the approximation problem (1.2) and that of best approximation of bounded Hankel operators by those with (specified) finite ranks. In doing so, we are able to remove the requirement on the simpleness of the s-numbers. That is, the requirement (1.5) can be relaxed to

$$s_{k-1}(\Gamma_f) > s_k(\Gamma_k) \geq s_{k+1}(f) \geq \cdots\ . \tag{1.6}$$

More precisely, let $\mathcal{H}$ denote the Banach space of all bounded Hankel operators with norm $\|\ \|$, and $G^{[k]}$ the class of those operators in $\mathcal{H}$ with rank at most k. Note that to each $f \in L^\infty$ corresponds a unique $\Gamma = \Gamma_f \in \mathcal{H}$. Then the (best) Hankel approximation problem corresponding to the best approximation problem (1.2) is given by

$$\|\Gamma - \Lambda_k\| = \inf_{\Lambda \in G^{[k]}} \|\Gamma - \Lambda\|, \quad \Lambda_k \in G^{[k]}. \tag{1.7}$$

It is well known that Λ_k is unique, and similar to (1.3), we consider the operator

$$B_k\colon\ \mathcal{H} \to G^{[k]} \tag{1.8}$$

defined by $B_k(\Gamma) = \Lambda_k$. Then the continuity problem of this operator corresponding to (1.4) for A_k is to study conditions under which we have

$$\|\Gamma_n - \Gamma\| \to 0 \Rightarrow \|B_k(\Gamma_n) - B_k(\Gamma)\| \to 0, \quad \text{as } n \to \infty. \tag{1.9}$$

The main result in this paper is that (1.9) holds for all $\Gamma \in \mathcal{H}$ and for each k for which (1.6) is satisfied. That is, we don't require $s_k(\Gamma)$ to be simple, but only k to be the smallest index of the (possibly multiple) s-number. We also give a simple example to demonstrate the sharpness of this result in the case of multiple s-numbers, namely, if $s_k(\Gamma) = s_{k+1}(\Gamma)$, then (1.9) does not hold for $k+1$.

The relation between the continuity considerations (1.4) and (1.9) is governed by the AAK theory (to be discussed in §2). It is important to note that if r_k and $r_{n,k}$ are the rational (symbol) functions corresponding to $B_k(\Gamma)$ and $B_k(\Gamma_n)$, respectively, then the continuity result (1.9) yields

$$\|r_{n,k} - r_k\|_\infty \to 0 \quad \text{as } n \to \infty. \tag{1.10}$$

This is seen in §3. Hence, in parallel to the convergence of near-best "rational" approximants,

$$\|g_{n,k} - g_k\|_\infty = \|A_k(f_n) - A_k(f)\|_\infty \to 0, \quad n \to \infty,$$

as given in (1.4), and we have the convergence of near-best rational approximants as described in (1.10). A discussion of the construction of such approximants via "truncations" of the Hankel operator Γ is discussed in §4.

2. A review of Hankel approximation. In this section, we state some well-known results on Hankel operators that are used in the following sections. For any given function $f(z) = \sum_{n=-\infty}^{\infty} h_n z^{-n}$ in L^∞, the Hankel operator Γ_f associated with f is defined by

$$\Gamma_f g = P(fg), \quad g \in H^2. \tag{2.1}$$

Here and throughout, H^2 denotes the hardy Hilbert space of analytic functions in the unit disc and P denotes the orthogonal projection from L^2 onto $H^2_- := L^2 \ominus H^2$, the subspace of the space L^2 of square-integrable functions on $|z| = 1$, complementary to H^2. Let $e_i = (0, \ldots, 0, 1, 0, \ldots)^T$, $1 \le i < \infty$, whose entries are all zeros except the ith one, which is 1, be the standard basis of ℓ^2. Considering the isometric isomorphisms among ℓ^2, H^2, and H^2_-, we can easily verify that Γ_f has an infinite matrix representation Γ on ℓ^2, with respect to the basis e_i, $1 \le i < \infty$, given by

$$\Gamma = \begin{pmatrix} h_1 & h_2 & h_3 & \cdots \\ h_2 & h_3 & \cdots & \\ h_3 & \vdots & & \\ \vdots & & & \end{pmatrix}. \tag{2.2}$$

We call f the symbol function of the Hankel operator Γ_f. For simplicity, we also denote by $\Gamma = \{h_{i+j-1}\}_{1\le i,j<\infty}$ the Hankel matrix in (2.2). The intimate relations between Hankel operators and their symbol functions are well known. In particular, the following classical result due to Kronecker (see, for example, [13, p. 207]) is instrumental to our discussions.

THEOREM A (Kronecker). *The infinite matrix* $\Gamma = \{h_{i+j-1}\}_{1\le i,j<\infty}$ *has finite rank if and only if the symbol function*

$$\sum_{n=1}^{\infty} h_n z^{-n}$$

is a strictly proper rational function in z; *that is,*

$$\sum_{n=1}^{\infty} h_n z^{-n} = \frac{c(z)}{d(z)},$$

where $c(z)$ *and* $d(z)$ *are relatively prime polynomials in* z *with* $\text{degree}(c) < \text{degree}(d)$. *Furthermore, in this situation*

$$\text{rank}(\Gamma) = \text{degree}(d).$$

If $\text{rank}(\Gamma) \le k$ and we write $c(z) = c_1 z^{k-1} + \cdots + c_k$, $d(z) = z^k + d_1 z^{k-1} + \cdots + d_k$, then it can be shown that Γ has finite rank k if and only if

$$\begin{pmatrix} h_1 & \dots & h_k \\ \vdots & \ddots & \vdots \\ h_k & \dots & h_{2k-1} \end{pmatrix}, \tag{2.3}$$

called the principle minor of order k in Γ, is nonsingular. Moreover, the following relations hold:

$$\begin{pmatrix} h_1 & \dots & h_k \\ \vdots & \ddots & \vdots \\ h_k & \dots & h_{2k-1} \end{pmatrix} \begin{pmatrix} -d_k \\ \vdots \\ -d_1 \end{pmatrix} = \begin{pmatrix} h_{k+1} \\ \vdots \\ h_{2k} \end{pmatrix} \tag{2.4}$$

and

$$\begin{pmatrix} c_1 \\ \vdots \\ c_k \end{pmatrix} = \begin{pmatrix} h_1 & 0 & \dots & 0 \\ h_2 & h_1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ h_k & h_{k-1} & \dots & h_1 \end{pmatrix} \begin{pmatrix} 1 \\ d_1 \\ \vdots \\ d_{k-1} \end{pmatrix}. \tag{2.5}$$

The following theorem due to Nehari [22] is fundamental to H^∞-control (cf. [12]).

THEOREM B (Nehari). Γ *is a bounded Hankel operator on* ℓ^2 *if and only if there is a function* $f \in L^\infty$ *such that* $\Gamma = \Gamma_f$; *moreover,* f *can be so chosen that* $\|\Gamma\| = \|f\|_\infty$.

We now give some notations in order to introduce the main result of AAK in [1], [2]. For a given Hankel operator Γ on ℓ^2, let $\overline{\Gamma}$ denote its adjoint (or complex conjugate). Let $\sigma(|\Gamma|)$ represent the spectrum of $|\Gamma| := (\overline{\Gamma}\Gamma)^{1/2}$, and write $\sigma(|\Gamma|) =$

$\sigma_1 \cup \sigma_2$, where σ_2 is the (possibly empty) set of isolated eigenvalues $s_k := s_k(\Gamma)$ with finite multiplicities and $\sigma_1 = \sigma(|\Gamma|)\backslash\sigma_2$. Set

$$s_\infty = s_\infty(\Gamma) := \sup\{s:\ s \in \sigma_1\},$$

and order the elements in σ_2, listed according to their multiplicities, as follows:

$$s_0 \geq s_1 \geq \cdots \geq s_\infty.$$

If σ_2 contains $m(< \infty)$ members, then we set $s_{m+1} = s_{m+2} = \cdots = s_\infty$. These numbers s_k, $k = 0, 1, \ldots$, are called the s-numbers of Γ. In the case that $s_{k-1} > s_k = \cdots = s_{k+r} > s_{k+r+1}$ for some integers k and $r \geq 0$, there is, associated with k, an $(r+1)$-dimensional linear manifold of Schmidt pairs $\{\xi, \eta\}$, ξ, $\eta \in \ell^2$, such that

$$\Gamma\xi = s_k\eta \quad \text{and} \quad \overline{\Gamma}\eta = s_k\xi.$$

If we write $\xi = (\xi_1, \xi_2, \ldots)^T \in \ell^2$, $\eta = (\eta_1, \eta_2, \ldots)^T \in \ell^2$ and define

$$\xi_+(z) := \sum_{n=1}^{\infty} \xi_n z^{n-1} \quad \text{and} \quad \eta_-(z) := \sum_{n=1}^{\infty} \eta_n z^{-n},$$

then it follows that

$$|\eta_-(z)/\xi_+(z)| = 1, \qquad |z| = 1,$$

and the function $\eta_-(z)/\xi_+(z)$ does not depend on the choice of the Schmidt pairs $\{\xi, \eta\}$ (cf. [1], [2]). Corresponding to the function $\eta_-(z)/\xi_+(z)$, we consider the Hankel operator

$$\Gamma_{s_k} := s_k\Gamma_{\eta_-/\xi_+}. \tag{2.6}$$

The following theorem is the main result of AAK in [1], [2].

THEOREM C (AAK). *Let s_k be an s-number of Γ and suppose that $s_{k-1} > s_k = \cdots = s_{k+r}$ for some $r \geq 0$. Then there exists a unique bounded Hankel operator Λ_k in $G^{[k+r]}$ such that*

$$s_k = \|\Gamma - \Lambda_k\| = \inf_{\Lambda \in G^{[k+r]}} \|\Gamma - \Lambda\|. \tag{2.7}$$

Moreover, Λ_k is given by $\Gamma - \Gamma_{s_k}$ (cf. (2.6)) and has rank k.

A simple observation, by applying Theorem C, is that if $s_{k-1} > s_k = \cdots = s_{k+r}$, then the best approximants of Γ from $G^{[k]}$, $G^{[k+1]}, \ldots, G^{[k+r]}$, respectively, are identical, and are given by $\Lambda_k = \Gamma - \Gamma_{s_k}$ with $\operatorname{rank}(\Lambda_k) = k$. According to Theorems A and B, the result in Theorem C can be described in the L^∞ sense as follows. Suppose that a bounded Hankel operator Γ is generated by some $f \in L^\infty$ and $s_{k-1} > s_k = \cdots = s_{k+r}$. Then

$$s_k = \inf_{g \in \widetilde{R}_{k+r}} \|f - g\|_\infty, \tag{2.8}$$

and moreover, the infimum is attained at $f(z) - s_k \frac{\eta_-(z)}{\xi_+(z)}$. This result (particularly assertions (2.7) and (2.8)) describes the intimate relationship between the two approximation problems (1.2) and (1.7).

3. Continuity of best Hankel approximation. From Theorem C, we see that corresponding to any bounded Hankel operator Γ there exists a unique best approximant Λ_k from $G^{[k]}$ to Γ. The problem we are concerned with in this paper is the feasibility of replacing Λ_k, and consequently its rational function symbol $r_k(z)$, by $\Lambda_{n,k}$, which best approximates a more realistic model Γ_n (in terms of computational implementations) instead of Γ. More precisely, if $\|\Gamma_n - \Gamma\| \to 0$ and $\Lambda_{n,k}$, with rational function symbol $r_{n,k}(z)$ and best approximates Γ_n, we are interested in studying the possibility of $\|\Lambda_{n,k} - \Lambda_k\| \to 0$ and $\|r_{n,k} - r_k\|_\infty \to 0$ as $n \to \infty$. For instance, for computational purposes, if Γ has infinite rank, we choose $\{\Gamma_n\}$ to be a sequence of finite-rank approximants of Γ, by truncations, say. This is called the problem of "continuity of best Hankel approximation." The main result in this paper is the following theorem.

THEOREM 3.1. *Let Γ be a bounded Hankel operator with s-numbers $s_0 \geq s_1 \geq \cdots$. Suppose that $s_{k-1} > s_k \geq \cdots$ and Γ_n are bounded Hankel operators satisfying*

$$\|\Gamma_n - \Gamma\| \to 0.$$

Let $\Lambda_{n,k}$ and Λ_k denote the best approximants from $G^{[k]}$ to Γ_n and Γ, respectively. Also, let $r_{n,k}(z)$ and $r_k(z)$ be their corresponding (strictly proper) rational symbol functions. Then

$$\|\Lambda_{n,k} - \Lambda_k\| \to 0 \quad \textit{and} \quad \|r_{n,k} - r_k\|_\infty \to 0, \quad \textit{as } n \to \infty.$$

Proof. Assume that the conclusion is false, and assume, without loss of generality, by taking a subsequence, if necessary, that $\|\Gamma_n - \Gamma\| \to 0$ but

$$\|\Lambda_{n,k} - \Lambda_k\| \geq \epsilon_0 > 0 \tag{3.1}$$

for all n, where $\Lambda_{n,k}$ and Λ_k are the best approximants from $G^{[k]}$ to Γ_n and Γ, respectively. Write

$$\Lambda_{n,k} = \begin{pmatrix} l_{n,1} & l_{n,2} & l_{n,3} & \cdots \\ l_{n,2} & l_{n,3} & \cdots & \\ l_{n,3} & \vdots & & \\ \vdots & & & \end{pmatrix}.$$

Then

$$\Lambda_{n,k}(e_1) = (l_{n,1}, l_{n,2}, \cdots)^T \in \ell^2.$$

Let $s_{n,0} \geq s_{n,1} \geq \cdots$ denote the s-numbers of Γ_n. For each $j, 0 \leq j < \infty$, we have

$$\begin{cases} \|\Gamma_n - \Lambda_{n,k}\| = s_{n,k}, & \text{and} \\ |s_{n,j} - s_j| \leq \|\Gamma - \Gamma_n\| \to 0, \end{cases}$$

where the second inequality can be found in [17, p. 30], and from this inequality, it follows that, for all sufficiently large n,

$$s_{n,k-1} > s_{n,k} \geq \cdots,$$

so that $\operatorname{rank}(\Lambda_{n,k}) = k$. Since each $\Lambda_{n,k}(e_1)$ is a bounded sequence in ℓ^2, it has a weakly convergent subsequence. Without loss of generality, suppose that $\Lambda_{n,k}(e_1)$ itself converges weakly to $(l_1, l_2, \ldots)^T \in \ell^2$. Then

$$l_{n,m} \to l_m, \quad \text{as } n \to \infty, \tag{3.2}$$

for each $m = 1, 2, \ldots$. Set

$$\tilde{\Lambda} := \begin{pmatrix} l_1 & l_2 & l_3 & \cdots \\ l_2 & l_3 & \cdots & \\ l_3 & \vdots & & \\ \vdots & & & \end{pmatrix}. \tag{3.3}$$

Since the minors of $\Lambda_{n,k}$ converge to the corresponding minor of $\tilde{\Lambda}$, we have $\operatorname{rank}(\tilde{\Lambda}) \leq k$. Furthermore, for any $y, z \in \ell^2$, we have

$$((\Gamma - \tilde{\Lambda})y, z) = ((\Gamma - \Gamma_n)y, z) + ((\Gamma_n - \Lambda_{n,k})y, z) + ((\Lambda_{n,k} - \tilde{\Lambda})y, z),$$

and thus,

$$\|\Gamma - \tilde{\Lambda}\| \leq \overline{\lim_{n\to\infty}} \|\Gamma_n - \Lambda_{n,k}\| = s_k.$$

It now follows from Theorem C that $\tilde{\Lambda} = \Lambda_k$ is the best approximant from $G^{[k]}$ to Γ with $\operatorname{rank}(\Lambda_k) = k$. By Theorem A, we also have

$$r_{n,k}(z) = \sum_{j=1}^{\infty} l_{n,j} z^{-j} = \frac{c_n(z)}{d_n(z)} = \frac{c_{n,1}z^{k-1} + c_{n,2}z^{k-2} + \cdots + c_{n,k}}{z^k + d_{n,1}z^{k-1} + \cdots + d_{n,k}}$$

and

$$r_k(z) = \sum_{j=1}^{\infty} l_j z^{-j} = \frac{c(z)}{d(z)} = \frac{c_1 z^{k-1} + c_2 z^{k-2} + \cdots + c_k}{z^k + d_1 z^{k-1} + \cdots + d_k}.$$

We may now apply (2.4) to both $r_{n,k}(z)$ and $r_k(z)$, noting that the coefficient matrices in (2.4) for both situations are nonsingular. Thus, it follows from (3.2) that

$$d_{n,m} \to d_m, \quad \text{as } n \to \infty,$$

for $1 \leq m \leq k$. So, applying (2.5) to both $r_{n,k}(z)$ and $r_k(z)$, we also have

$$c_{n,m} \to c_m, \quad \text{as } n \to \infty,$$

for $1 \leq m \leq k$. This immediately gives

$$\|r_{n,k} - r_k\|_\infty \to 0,$$

and hence,

$$\|\Lambda_{n,k} - \Lambda_k\| \leq \|r_{n,k} - r_k\|_\infty \to 0,$$

which contradicts (3.1) and completes the proof of the theorem. □

In the following, we give an example to demonstrate the sharpness of Theorem 3.1, in the sense that if the s-number s_k is not simple, then the best Hankel approximation from $G^{[k+1]}$ is not necessarily continuous. This example is a modification of the one given in [19].

Example 3.1. Let $f(z) = z^{-1} - z^{-4}$. Then we have

$$\Gamma_f = \begin{pmatrix} 1 & 0 & 0 & -1 & 0 & \cdots \\ 0 & 0 & -1 & 0 & \cdots & \\ 0 & -1 & 0 & & & \\ -1 & 0 & & & & \\ 0 & \vdots & & & & \\ \vdots & & & & & \end{pmatrix},$$

and the s-numbers of Γ_f are given by

$$s_0 = \frac{\sqrt{5}+1}{2}, \quad s_1 = s_2 = 1, \quad s_3 = \frac{\sqrt{5}-1}{2}, \quad s_k = 0 \quad \text{for } k \geq 4.$$

So, for $k = 1$ or $k+1 = 2$, the best Hankel approximant of Γ_f from $G^{[2]}$ is

$$\Lambda_2 = \begin{pmatrix} 1 & 0 & 0 & \cdots \\ 0 & 0 & & \\ 0 & & & \\ \vdots & & & \end{pmatrix}$$

and its rational symbol is given by $r_2(z) = z^{-1}$. Now, if we consider

$$b_\alpha(z) := \frac{\alpha z - 1}{z - \alpha} = 1 + (\alpha - 1)\frac{z+1}{z-\alpha}$$

and $f_\alpha(z) := f(z)b_\alpha(z)$, we have

$$\lim_{\alpha \uparrow 1} \|\Gamma_f - \Gamma_{f_\alpha}\| \leq \lim_{\alpha \uparrow 1} \|f - f_\alpha\|_\infty = 0.$$

On the other hand, it is easy to verify that the best Hankel approximant of Γ_{f_α} from $G^{[2]}$ is $\Lambda_{\alpha,2} = \Gamma_{r_{\alpha,2}}$, where

$$r_{\alpha,2}(z) := r_2(z)b_\alpha(z).$$

Observe, however, that

$$\begin{aligned} \|\Lambda_2 - \Lambda_{\alpha,2}\| &= \|\Gamma_{(b_\alpha(z)-1)/z}\| \\ &\geq \|\Gamma_{b_\alpha - 1}\| \\ &= \|\Gamma_{b_\alpha}\| = 1. \end{aligned}$$

Hence, best Hankel approximation from $G^{[2]}$ is not continuous at f. It is also obvious that

$$\|r_{\alpha,2} - r_2\|_\infty = 2 \not\to 0 \quad \text{as } \alpha \uparrow 1.$$

4. Near-best Hankel approximants via truncations. Results on Hankel operators and Hankel-type approximation have been widely used in dealing with many problems in engineering such as systems reduction, systems identification, robust stability, and H^∞-control [9], [14], [12], [25], [21], [5]. When the Hankel operators associated with the systems have infinite rank, it is generally quite difficult to compute the best Hankel approximants. The only exceptions are systems of special types such as those with delays, etc., as discussed in [11], [8], [25]. Hence, some kinds of truncations, such as truncations of a balanced realization, are considered an intermediate step to finding the best approximation (cf. [15], [16], [24], [27]). In this section we give a general study of truncated Hankel operators, through which near-best Hankel approximants can be computed.

Let Γ_n be a sequence of bounded Hankel operators that converge to a given Hankel operator Γ, and let $\Lambda_{n,k}$, Λ_k be their corresponding best Hankel approximants from $G^{[k]}$. Then we have

$$\begin{aligned} (4.1) \quad s_k(\Gamma) &\leq \|\Gamma - \Lambda_{n,k}\| \leq \|\Gamma - \Gamma_n\| + \|\Gamma_n - \Lambda_{n,k}\| \leq s_{n,k}(\Gamma_n) + \|\Gamma - \Gamma_n\| \\ &\leq s_k(\Gamma) + 2\|\Gamma - \Gamma_n\|. \end{aligned}$$

Moreover, if $s_{k-1}(\Gamma) > s_k(\Gamma) \geq \cdots$, it follows from Theorem 3.1 that

$$\|\Lambda_{n,k} - \Lambda_k\| \to 0.$$

Therefore, we may call $\Lambda_{n,k}$ a near-best Hankel approximant of Γ.

In the following discussion, we assume that Γ is compact. It is then well known that its s-numbers $s_k(\Gamma)$ converge to 0. Hence, a sequence of Hankel operators Γ_n with finite rank can be chosen so that Γ_n converges to Γ. An application of the Carathéodory-Fejér (CF) algorithm to Γ_n yields its near-best Hankel approximant $\Lambda_{n,k}$. A discussion of the computation of $\Lambda_{n,k}$ from finite rank Γ_n is given in [30, §3], where the CF theorem is used to study the near-best rational Chebyshev approximation. In the following, we discuss the convergence of near-best approximants through a fairly general class of truncations.

Let Γ be given as in (2.2) and set

$$\gamma_n := (h_1, h_2, \ldots, h_n)^T.$$

Suppose that a sequence $\mathcal{M}$ of $n \times n$ matrices M_n, $n = 1, 2, \ldots$, is chosen. We consider the column vectors

$$\gamma_{n,n} := M_n \gamma_n = (h_{n,1}, h_{n,2}, \ldots, h_{n,n})^T \tag{4.2}$$

and the corresponding Hankel matrix

$$\Gamma_{n,\mathcal{M}} = \begin{pmatrix} h_{n,1} & h_{n,2} & \ldots & h_{n,n} & 0 & \ldots \\ h_{n,2} & & \iddots & \iddots & & \\ \vdots & \iddots & \iddots & & & \\ h_{n,n} & & & & & \\ 0 & & & & & \\ \vdots & & & & & \end{pmatrix}. \tag{4.3}$$

We call $\Gamma_{n,\mathcal{M}}$ the truncated Hankel operators of Γ relative to $\mathcal{M}$. It is obvious that different choices of $\mathcal{M}$ give different sequences of truncated Hankel operators $\Gamma_{n,\mathcal{M}}$. In the following, we discuss three kinds of truncations that are useful for computational purposes.

Example 4.1. Denote by $\mathcal{I}$ the sequence of identity matrices $I_{n\times n}$. Then the truncated Hankel operators $\Gamma_{n,\mathcal{I}}$ of Γ relative $\mathcal{I}$ are the truncated matrices

$$\Gamma_{n,\mathcal{I}} = \begin{pmatrix} h_1 & \ldots & h_n & 0 & \ldots \\ \vdots & & \iddots & \iddots & \\ h_n & \iddots & \iddots & & \\ 0 & \iddots & & & \\ \vdots & & & & \end{pmatrix}$$

considered in our earlier work [5] and [6].

Example 4.2. Let $0 < r < 1$ and $\mathcal{B}_r$ be the sequence of matrices

$$\mathcal{B}_{n,r} = \begin{pmatrix} 1 & 0 & \ldots & 0 \\ 0 & r & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & r^{n-1} \end{pmatrix}.$$

Then the truncated Hankel operators $\Gamma_{n,\mathcal{B}_r}$ associated with Γ are the infinite matrices

$$\Gamma_{n,\mathcal{B}_r} = \begin{pmatrix} h_1 & rh_2 & \dots & r^{n-1}h_n & 0 & \dots \\ rh_2 & & \iddots & \iddots & & \\ \vdots & \iddots & \iddots & & & \\ r^{n-1}h_n & \iddots & & & & \\ 0 & & & & & \\ \vdots & & & & & \end{pmatrix}.$$

As we will see, the importance of this type of truncation is that for some suitable choices of r_k and $n = n_k$, $\Gamma^n_{\mathcal{B}_{r_k}}$ always converge to the compact Hankel operator Γ.

Example 4.3. Consider the sequence $\mathcal{C}$ of matrices

$$C_n = \begin{pmatrix} 1 & 0 & \dots & 0 \\ 0 & 1-\frac{1}{n} & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1-\frac{n-1}{n} \end{pmatrix}.$$

Then the truncated Hankel operators $\Gamma_{n,\mathcal{C}}$ associated with Γ is

$$\Gamma_{n,\mathcal{C}} = \begin{pmatrix} h_1 & \left(1-\frac{1}{n}\right)h_2 & \dots & \left(1-\frac{n-1}{n}\right)h_n & 0 & \dots \\ \left(1-\frac{1}{n}\right)h_2 & & \iddots & \iddots & & \\ \vdots & \iddots & \iddots & & & \\ \left(1-\frac{n-1}{n}\right)h_n & \iddots & & & & \\ 0 & & & & & \\ \vdots & & & & & \end{pmatrix}.$$

By an application of Theorem B, it is easy to see that $\Gamma_{n,\mathcal{C}}$ converges to Γ.

In the following, we give some sufficient conditions on Γ under which the truncated Hankel operators discussed above converge to Γ.

PROPOSITION 4.1. *Suppose that the symbol function* $\sum_{i=1}^{\infty} h_i z^{-i}$ *of the Hankel operator* $\Gamma = \{h_{i+j-1}\}_{1\le i,j<\infty}$ *is in the Wiener class* W. *Then*

$$\|\Gamma - \Gamma_{n,\mathcal{I}}\| \to 0.$$

Proof. By Theorem B, we have

$$\|\Gamma - \Gamma_{n,\mathcal{I}}\| \le \left\| \sum_{i=1}^{\infty} h_i z^{-i} - \sum_{i=1}^{n} h_i z^{-i} \right\|_{\infty} \le \sum_{i=n+1}^{\infty} |h_i|,$$

which converges to 0. □

PROPOSITION 4.2. *Let* Γ *be compact. Then there exists a sequence* $r_k \uparrow 1$ *as* $k \to \infty$ *and a sequence of positive integers* n_k *such that*

$$\|\Gamma - \Gamma_{n_k,\mathcal{B}_{r_k}}\| \to 0.$$

Proof. Since $\Gamma = \{h_{i+j-1}\}_{1\le i,j<\infty}$ of compact, it is known (cf. [18]) that the Hankel operators $\Gamma_r := \{r^{i+j-2}h_{i+j-1}\}_{1\le i,j<\infty}$ converge to Γ as $r \to 1^-$. For each fixed r, $0 < r < 1$, we have

$$\begin{aligned}
\|\Gamma_r - \Gamma_{n,\mathcal{B}_r}\| &\le \left\| \sum_{k=1}^{\infty} r^{k-1}h_k z^{-k} - \sum_{k=1}^{n} r^{k-1}h_k z^{-k} \right\|_\infty \\
&= \left\| \sum_{k=n+1}^{\infty} r^{k-1}h_k z^{-k} \right\|_\infty \\
&\le \sup_{|z|=1} \left| \sum_{k=n+1}^{\infty} r^{k-1}h_k z^{-k} \right| \\
&\le \left(\sum_{k=n+1}^{\infty} r^{2(k-1)} \right)^{1/2} \left(\sum_{k=n+1}^{\infty} |h_k|^2 \right)^{1/2} \\
&\le \|\Gamma\| \frac{r^n}{\sqrt{1-r^2}},
\end{aligned}$$

so that

$$\lim_{n\to\infty} \|\Gamma_r - \Gamma_{n,\mathcal{B}_r}\| \to 0.$$

Therefore, we can choose a sequence $r_k \to 1^-$ and integers of n_k such that

$$\|\Gamma - \Gamma_{n_k,\mathcal{B}_{r_k}}\| \to 0. \qquad \square$$

PROPOSITION 4.3. *If the symbol function* $f(z) = \sum_{i=1}^{\infty} h_i z^{-i}$ *of* Γ *is continuous on the unit circle, then*

$$\|\Gamma - \Gamma_{n,\mathcal{C}}\| \to 0.$$

Proof. The Fejér sequence of functions $G_n(z)$ associated with $f(z)$ is given by

$$\begin{aligned}
G_n(z) &= \frac{1}{n} \left(\sum_{k=1}^{n} \left(\sum_{i=1}^{k} h_i z^{-i} \right) \right) \\
&= h_1 z^{-1} + \left(1 - \frac{1}{n}\right) h_2 z^{-2} + \cdots + \left(1 - \frac{n-1}{n}\right) h_n z^{-n}.
\end{aligned}$$

Since $f(z)$ is continuous, we have

$$\|f - G_n\|_\infty \to 0, \quad \text{as } n \to \infty.$$

Moreover, from the fact that $\Gamma_{n,\mathcal{C}} = \Gamma_{G_n}$, we have

$$\|\Gamma - \Gamma_{n,\mathcal{C}}\| \le \|f - G_n\|_\infty \to 0, \quad \text{as } n \to \infty.$$

This completes the proof of the proposition. $\square$

If Γ already has finite rank, then the precise rate of convergence of $\Gamma_{n,\mathcal{I}}$ to Γ is given in [5]. However, one cannot say too much about the convergence rate in general. Indeed, for any sequence $\varepsilon_k \downarrow 0$, there exists a Hankel operator Γ that satisfies $s_k(\Gamma) \ge \varepsilon_k$ for all k (cf. [23], [31]). Moreover, an explicit formulation of such a Γ is

given in [7]. Consequently, for any sequence $\varepsilon_n \downarrow 0$, there is a compact Hankel operator Γ such that

$$\|\Gamma - \Gamma_{n,\mathcal{M}}\| \geq \varepsilon_n, \qquad n \geq 1,$$

for any sequence $\mathcal{M}$ of $n \times n$ matrices M_n. A very important problem is, therefore, how to select an appropriate truncation so as to give a sufficiently good rate of convergence. Once the truncations $\Gamma_{n,\mathcal{M}}$ are determined, the CF algorithm or Kung's algorithm [21] can be applied to find the near-best Hankel approximants $\Lambda_{n,k}$.

ON ONE IDENTIFICATION PROBLEM FOR DISTRIBUTED CONTROLLABLE SYSTEMS*

BENZION SHKLYAR† AND VICTOR BAKHMUTSKY‡

Abstract. An identification problem for distributed control systems in the class of approximate null-controllable systems is considered. A criterion of identifiability of linear autonomous distributed systems has been proved, and is illustrated by an example of a system with small nonlinearity. Further development and generalization of the obtained results are discussed.

Key words. linear systems, distributed systems, systems with delays, identifiability, observability, controllability

AMS subject classifications. 93C25, 93D15

1. Introduction.

The main purpose of identification of control systems is to determine a mathematical model of a control object by using measured experimental data. The real control objects are described, as a rule, by nonlinear distributed-parameter systems. In the first approximation these objects can be modeled by the linear autonomous systems with distributed parameters.

This paper is devoted to the problem of determining the input parameters for a class of controllable systems. Controllability is a fundamental property of dynamic systems [1], therefore it is natural to use controllable systems for identification. In this paper we will use the class of approximately null-controllable systems. The obtained general results are used in an illustrative example of an electro-mechanical control system described by Minorsky's equation.

2. Problem statement.

Let X, Y, Z be Banach space. Consider the equation

$$\dot{x}(t) = Ax(t) + Gbu(t), \tag{1}$$

$$x(0) = x_0, \tag{2}$$

$$y(t) = Cx(t), \qquad 0 \le t \le t_1, \tag{3}$$

where $x(t)$ is the current state; x_0 is the initial state; $u(t)$ is the piecewise continuous control, $0 \le t \le t_1$; A is a linear operator whose domain $D(A)$ is dense in X; $G : Z \to X$ is a linear bounded operator; $b \in Z$; $C : X \to Y$ is a linear bounded operator; $x, x_0 \in X, y \in Y, u \in R^1$. We assume that problem (1)–(2) is uniformly well posed [2]. It follows from this assumption that A generates a strongly continuous semigroup $S(t)$ of operators in the class C_0 [2]. We consider only weak solutions of the above equation.

We assume A to have an additional property:

(i) there exists a number $T \ge 0$ such that the attainability set $K(t)$ of (1)-(2) is independent of t if $t > T$ $\forall b \in Z$.

If $x \in X$ and $f \in X^*$, we write (x, f) instead of $f(x)$.

We assume that operators A, G and the initial state x_0 are known and b is unknown. The main purpose of the given identification problem is to determine b using experimental data. If b can be uniquely determined, (1)–(3) is said to be identifiable.

The identification problem of this kind was investigated in [3] for an important particular case: when X is a Hilbert space, A is a symmetric coercive operator with domain $D(A) = V \subset X \subset V^*$($V$ is also Hilbert space, V is dense in X), $Z = X, G = I, b \in V^*, Y = R^m, m \geq 1$, and some additional assumptions (see [3, pp. 474–475]). It is proved in [4] that under assumptions of [3], property (i) holds for $T = 0$.

In the present paper the criterion of identifiability for (1)–(2) has been established. We can find the unknown b by the least square fit. If (1) with the determined b is not approximately null-controllable, it is possible to approximate b by a b_ϵ such that (1) with b replaced by b_ϵ is approximately null-controllable.

3. Necessary and sufficient identifiability conditions.

DEFINITION 3.1. *Equation* (1)–(3) *is said to be identifiable on* $[0, t_1]$ *if* b *is uniquely determined by output* (3), $0 \leq t \leq t_1$.

Consider the equation

$$\dot{x}(t) = Ax(t), \tag{4}$$

$$y(t) = Cx(t), \qquad 0 \leq t \leq t_1. \tag{5}$$

DEFINITION 3.2. *Equation* (4)–(5) *is said to be observable on* $[0, t_1]$ *with respect to* G *if* z_0 *is uniquely determined by output* (5), $0 \leq t \leq t_1$.

We consider $t_1 > T$ and denote by σ the spectrum of the operator A. The identifiability criterion of equation (1)–(3) will be proved in this paragraph.

THEOREM 3.3. *Equation* (1)–(3) *is identifiable on* $[0, t_1]$ *if and only if:*

1. *equation* (4)–(5) *is observable on* $[0, t_1]$ *with respect to* G;
2. $u(t) \not\equiv 0$ *on the* $[0, t_1]$.

Proof. We first prove the sufficiency. The weak solution of (1)–(2) is given by the following formula [2]:

$$x(t) = S(t)x_0 + \int_0^{t_1} S(t-\tau)Gbu(\tau)d\tau. \tag{6}$$

By the problem statement, $S(t), G$, and x_0 are assumed to be known. Hence from (3) and (6) it follows that (1)–(3) is identifiable on $[0, t_1]$ if and only if the identity

$$C\int_0^{t_1} S(t\tau)Gbu(\tau)d\tau \equiv 0, \qquad 0 \leq t \leq t_1 \tag{7}$$

implies that the b is equal to 0. Denote by $R(\xi) = (\xi I - A)^{-1}$ the resolvent of operator A [2], $\xi \notin \sigma$, $U(\xi) = \int_0^{t_1} u(t)\exp(-\xi t)dt$. By the independence of the attainable set of (1)–(3) of t for $t > T$, we obtain the identity

$$C\int_0^{t_1} S(t-\tau)Gbu(\tau)d\tau \equiv 0, \qquad 0 \leq t < \infty \tag{8}$$

from (8) [4]. Applying to (8) the Laplace transform, we obtain

$$CR(\xi)GbU(\xi) \equiv 0 \tag{9}$$

for any complex $\xi \notin \sigma$. Since $u(t) \not\equiv 0$ on $[0, t_1]$, from the last identity we obtain

$$CR(\xi)Gb \equiv 0, \qquad \forall \xi \notin \sigma. \tag{10}$$

Applying the inverse Laplace transform to (10), we obtain

$$CS(t)Gb \equiv 0, \qquad 0 \leq t \leq t_1. \tag{11}$$

From (11), by the observability of (4)–(6) on $[0, t_1]$ with respect to G, we have $b = 0$. The sufficiency has been proved.

Now we prove the necessity. The necessity of the second condition of the theorem is obvious. Now assume that the first condition of the theorem does not hold, i.e., there exists a $b, b \neq 0$, such that (11) holds. Then (8) follows from (11) and this fact contradicts the identifiability of (1)-(3) on $[0, t_1]$. □

The explicit observability conditions for various particular cases of (4)–(6) are given in many publications (see, for instance, [6]–[10]). We give below a sufficient condition of observability with respect to G for (4)–(6).

We assume that operator A has the following additional properties:

(ii) the operator A has a purely point spectrum σ that is either finite or has no finite limit points and each $\lambda \in \sigma$ has a finite multiplicity;

(iii) there is a time $T \geq 0$ such that for each $x_0 \in X$ and $t > T$ the function $x(t) = S(t)x_0$ is expanded in a series of eigenfunctions and associated functions of A converging uniformly with respect to t on an arbitrary interval $[T_1, T_2], T_2 > T_1 > T$ for a certain grouping of terms.

THEOREM 3.4. *Equation* (4)–(6) *is observable on* $[0, t_1]$ *with respect to* G *if*

1. *the system of equations*

$$Ax - \lambda x = 0, \qquad Cx = 0 \tag{12}$$

has only the trivial solution for each $\lambda \in \sigma$;

2. *the system of eigenvectors and associated vectors of operator* A^* *is complete*;

3. *the equation* $Gx = 0$ *has only the trivial solution.*

Proof. We assume that identity

$$CS(t)Gz \equiv 0, \quad 0 \leq t \leq t_1, \quad z \in Z \tag{13}$$

is true.

In virtue of independence of the attainable set of (1)–(3) of t when $t > T$ we obtain from (13) [4] the identity

$$CS(t)Gz \equiv 0, \qquad 0 \leq t < \infty. \tag{14}$$

Applying the Laplace transform to (14) we obtain

$$CR(\xi)Gz \equiv 0, \qquad \forall \xi \notin \sigma. \tag{15}$$

It is known [5] that each $\lambda_j \in \sigma, j = 1, 2, \ldots$ is a pole of the resolvent $R(\xi)$ and the function $R(\xi)Gz$ has the Laurent expansion

$$R(\xi)Gz = \gamma_{j1}(\xi - \lambda_1)^{-\beta_j} + \cdots + \gamma_{j\beta_j}(\xi - \lambda_1)^{-1} + R_j(\xi) \tag{16}$$

in a neighborhood of λ_j, where the operator-valued function $R_j(\xi)$ is holomorphic in this neighborhood.

Let φ_{ij} and ψ_{ij} be the eigenvectors and associated vectors of A and A^*, respectively, corresponding to an eigenvalue $\lambda_i \in \sigma$ such that

$$(17) \quad (\varphi_{ij}, \psi_{kl}) = \delta_{ik}\delta_{jl}, \quad i,k = 1,2,\ldots, \quad j = 1,2,\ldots,\beta_i, \quad l = 1,2,\ldots,\beta_k.$$

By assumption (iii) and (17) we obtain [4]

$$(18) \quad \gamma_{jl} = \sum_{k=\beta_j-l+1}^{\beta_j} (Gz, \psi_{jk})\varphi_{jk+l-\beta_j}, \quad l = 1,2,\ldots,\beta_j, \quad j = 1,2,\ldots.$$

It follows from (15)–(18) (see [4, p. 329]), that

$$(19) \quad \sum_{l=1}^{\beta_j-p} (Gz, \psi_{jl+p})C\varphi_{jl} = 0, \quad p = 0,1,\ldots,\beta_j - 1, \quad j = 1,2,\ldots.$$

Since (12) has only the trivial solution (condition 1 of Theorem 3.4) we obtain from (19) that

$$(20) \quad (Gz, \psi_{jl}) = 0, \quad j = 1,2,\ldots, \quad l = 1,2,\ldots,\beta_j,$$

and using completeness of vectors ψ_{jl} (condition 2 of Theorem 3.4) we obtain from (20) that $Gz = 0$. Hence $z = 0$ (see condition 3 of Theorem 3.4). □

Note. If X, Y are Hilbert spaces, A is a self-adjoint operator, $Z = X, G = I$ and A has the properties given in [3, pp. 474–475], the trivial solvability of (12) is the criterion of observability for (1)–(3) and coincides with condition (i) of Theorem 4 from [3, p. 475].

4. Identifiability of delay systems. Now we consider an important class of (1)–(3), to which results of [3] cannot be applied.

Consider the differential-difference system

$$(21) \quad \dot{v}(t) = A_0 v(t) + A_1 v(t-h) + cu(t),$$

$$(22) \quad v(0) = x_0, \quad v(\tau) = \varphi(\tau) \quad \text{a.e. on } [-h,0],$$

$$(23) \quad w(t) = Kv(t), \qquad 0 \le t \le t_1,$$

where $v, v_0 \in R^n, u \in R^1, A_j, j = 0,1$ are constant nxn-matrices, $c \in R^n, 0 < h, \varphi(.) \in L_2^n[-h,0]; y \in R^p, K$ is pxn-matrix. System (21)–(23) is an important particular case of (1)–(3) [2], [4], [11], [12]. Denote $x(t) = \{v(t), v_t(.)\}$, where $v_t(.) = v(t+\tau), -h \le \tau \le 0, t \ge 0, X = M_2^n[-h,0] = R^n X L_2^n[-h,0]$. It is known [11], [12] that if $v(t)$ is the solution of (21)–(22), then $x(t) \in M_2^n[-h,0]$ for all $t \ge 0$ and $x(t)$ is the solution of (1)–(2), where

$$X = M_2^n[-h,0] = R^n X L_2^n[-h,0], \quad Y = R^p, \quad Z = R^n;$$

$$(24) \quad Ax = \{A_0\varphi(0) + A_1\varphi(-h), \dot{\varphi}(.)\}$$

with the domain

$$D(A) = \{x = \{v_0, \varphi(.)\} : v_0 = \varphi(0), \dot{\varphi}(0) = A_0\varphi(0) + A_1\varphi(-h)\}$$

and with the spectrum

$$\sigma = \{z \in \mathbf{C} : zI - A_0 - A_1 xp(-zh) = 0\},$$

where $\mathbf{C}$ is the complex plane. For each $v_0 \in R^n$,

$$Gv_0 = \{v_0, 0\} \tag{25}$$

and operator $C : M_2^n[-h, 0] \to R^p$ is given by the formula

$$Cx = Kv_0, \quad \forall x = v_0, \quad \varphi(.) \in M_2^n[-h, 0]. \tag{26}$$

The operator A in this case is not self-adjoint and does not posses the properties described in [3], therefore it is impossible to apply results of [3] to this case, but we can apply Theorem 3.3 of the present paper.

DEFINITION 4.1. *System* (21)–(23) *is said to be identifiable on* $[0, t_1]$ *if* c *is uniquely determined by output* (33), $0 \le t \le t_1$.

DEFINITION 4.2. *System* (21)–(23) *with* $u(\tau) \equiv 0$ *is said to be relatively observable on* $[0, t_1]$ *if* $v(0)$ *is uniquely determined by output* (23), $0 \le t \le t_1$, *and by known function* $\varphi(.) \in L_2^n[-h, 0]$.

The criterion of relative observability for system (21)–(23) with $u(\tau) \equiv 0$ was proved in [6].

The relative observability of (21)–(23) with $u(\tau) \equiv 0$ is equivalent to observability of (4)–(6) with respect to operator G, where operators A, C, and G are defined by (24)–(26). The corresponding initial problem is uniformly well posed on $[0, t_1]$ and the attainable set for this system is independent of t if $t > nh$ [13].

It is well known that the solution of (21)–(22) is given by the formula [14]

$$v(t) = F(t)v_0 + \int_0^t F(t-\tau)A_1\varphi(\tau - h)d\tau + \int_0^t F(t-\tau)cu(\tau)d\tau, \tag{27}$$

where $F(t)$ is the fundamental matrix of (21) [14].

For (21) we consider its defining equation [15] as follows:

$$\begin{aligned} Q_{i+1j} &= A_0 Q_{ij} + A_1 Q_{i-1,j}, \qquad i, j = 0, 1, \ldots; \\ Q_{00} &= I, \quad Q_{ij} = 0, \quad i < 0, \quad j < 0; \\ X_{ij} &= Q_{ij}^T K^T, \qquad i, j = 0, 1, \ldots. \end{aligned} \tag{28}$$

It follows from Theorem 3.3 and the results of [6] that the following theorem is valid.

THEOREM 4.3. *For* (21)–(23) *to be identifiable on* $[0, t_1]$ *it is necessary and sufficient for* $t_1 > nh$, *that*

$$\operatorname{rank}\{X_{ij}, i, j = 0, 1, \ldots, n-1\} = n; \tag{29}$$

$$u(t) \not\equiv 0 \quad \text{on } [0, t_1].$$

Using (27) we consider a functional

$$J(c) = \int_0^{t_1} \|z(t) - q(t)\|^2 dt, \tag{30}$$

where

$$q(t) = \int_0^t KF(t-\tau)cu(\tau)d\tau,$$

$$z(t) = w(t) - K\left(F(t)v_0 - \int_0^t F(t-\tau)A_1\varphi(\tau-h)d\tau\right),$$

where $w(t), 0 \le t \le t_1$ is a known function obtained as a result of measurements, v_0 and $\varphi(\tau)$ are known initial conditions. The identification problem formulated in this section is to minimize functional (30) with respect to c.

To solve this problem we should find the derivative (gradient) $J'(c)$. We denote

$$P(t)c = \int_0^t KF(t-\tau)cu(\tau)d\tau, \qquad 0 \le t < \infty. \tag{31}$$

Calculating the derivative, we obtain the following from $J'(b) = 0$:

$$\left(\int_0^{t_1} P^T(t)P(t)dt\right)c = \int_0^{t_1} P^T(t)z(t)dt.$$

It follows from identifiability of system (21)–(23) that matrix

$$W = \int_0^{t_1} P^T(t)P(t)dt$$

is positive. Hence there exists W^{-1} and we have

$$\begin{aligned} c &= \left(\int_0^{t_1} P^T(t)P(t)dt\right)^{-1} \int_0^{t_1} P^T(t)z(t)dt \\ &= \left(\int_0^{t_1}\int_0^t F^T(t-\tau)K^TKF(t-\tau)u^2(\tau)d\tau dt\right)^{-1} \\ &\quad \cdot \int_0^{t_1}\int_0^t F^T(t-\tau)K^Tu(\tau)d\tau z(t)dt. \end{aligned} \tag{32}$$

It is possible to use the formula [16]

$$F(t) = \sum_{i=0}^{\infty}\sum_{j=0}^{k} Q_{ij}\frac{(t-jh)^i}{i!}, \quad t \in [kh,(k+1)h), \quad k = 0,1,\ldots \tag{33}$$

for calculating the fundamental matrix $F(t)$.

The criterion of approximate null-controllability on $[0,t_1]$ for (21)–(22) is [4], [17] (this criterion was first obtained in [17] for neutral systems):

$$\operatorname{rank}\{zI - A_0 - A_1\exp(-zh), c\} = n \quad \text{for all } z \in \sigma. \tag{34}$$

If vector c obtained by (32) does not satisfy (34), then for each $\delta > 0$ we can find a vector c_δ such that $\| c - c_\delta \| < \delta$ and (21)–(23) with vector c_δ, respectively, is approximate null-controllable on $[0,t_1]$.

Note. In this case c depends continuously on the initial state (22). It is well known [3] that when a space of unknown vectors c is an infinite-dimensional one, the identifiability does not ensure that vector c depends continuously on the initial state.

4.1. Example. Consider, for instance, Minorsky's equation [18]

$$\kappa^{(2)}(t) + 2r\dot{\kappa}(t) + \omega^2\kappa(t) + 2q\dot{\kappa}(t-1) = \epsilon\dot{\kappa}^3(t) + bu(t), \tag{35}$$

where r, q, w, b, and ϵ are constants and ϵ is small value,

$$\kappa(0) = \kappa_0, \quad \dot{\kappa}(0) = \dot{\kappa}_0; \quad \kappa(\tau) = \varphi(\tau), \quad \dot{\kappa}(t) = \dot{\varphi}(\tau) \quad \text{a.e. on } [-1, 0].$$

This equation describes the behavior of some electro-mechanical control systems. Linearizing (35), we obtain the linear time-invariant equation with delay

$$\kappa^{(2)}(t) + 2r\kappa(t) + \omega^2\kappa(t) + 2q\dot{\kappa}(t-1) = bu(t). \tag{36}$$

This equation is reduced to system (21)–(23), where

$$A_0 = \begin{bmatrix} 0 & 1 \\ -\omega^2 & -2r \end{bmatrix}, \quad A_1 = \begin{bmatrix} 0 & 0 \\ 0 & -2q \end{bmatrix}, \quad c = \begin{bmatrix} 0 \\ b \end{bmatrix}, \quad v = \begin{bmatrix} \kappa \\ \dot{\kappa} \end{bmatrix},$$

$$\sigma = \{z \in \mathbf{C} : z^2 - 2rz - \omega^2 - 2qz\exp(-z) = 0\}.$$

We denote by $f_0(t)$ the solution of (36) on the interval $[0, \infty)$ when $u(t) \equiv 0$ with initial data $f_0(0) = 1, f_0^{(1)}(0) = 0$, and we denote by $f_1(t)$ the solution of (36) with initial data $f_1(0) = 0, f_1^{(1)}(0) = 1$ on interval $[0, \infty)$. It follows from (27) that the solution $x(t)$ of equation (36) is given by the formula

$$\kappa(t) = f_0(t)\kappa(0) + f_1(t)\dot{\kappa}(0) - 2q\int_0^t f_1(t-\tau)\varphi(t-\tau)d\tau + \int_0^t f_1(t-\tau)bu(\tau)d\tau. \tag{37}$$

Let $z(t)$ be a function observed on the output of the electro-mechanical system described by (35) with known parameters r, ω, q, ϵ, and an unknown parameter b. The identification problem in this case is the selection of parameters b such that the deviation

$$J(b) = \int_0^{t_1} \|(z(t) - x(t)\|^2 dt$$

is minimal. Here $x(t)$ is the solution of (36) defined by (37). Computing $X_{ij}, i, j = 0, 1, \ldots$ by means of (28) we obtain

$$X_{00} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \qquad X_{10} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

Hence (29) holds, and if $u(t) \not\equiv 0$ on the $[0, t_1]$ and $t_1 > 2$, then by virtue of Theorem 4.3, (36) is identifiable on $[0, t_1]$. So

$$\int_0^{t_1}\int_0^t f_1^2(t-\tau)u^2(\tau)d\tau \neq 0.$$

Using the method of the last section we obtain

$$b = \left(\int_0^{t_1}\int_0^t f_1^2(t-\tau)u^2(\tau)d\tau\right)^{-1}\int_0^{t_1}\int_0^t f_1(t-\tau)y(\tau)d\tau, \tag{38}$$

where $y(t)$ is the known function defined by the formula

$$y(t) = z(t) - f_0(t)\kappa(0) - f_1(t)\dot{\kappa}(0) + 2q\int_0^t f_1(t-\tau)\varphi(t-\tau)d\tau.$$

Note. We can calculate functions $f_0(t)$ and $f_1(t)$ for any $t \in [j, j+1), j = 0, 1, 2, \ldots$ by (33) or by means of the step method. We have

$$f_0(t+j) = f_0(t)f_0(j) + f_1(t)\dot{f}_0(j)\int_0^t f_1(t-\tau)2qf_0(\tau+j-1)d\tau,$$

$$f_1(t+j) = f_0(t)f_0(j) + f_1(t)\dot{f}_1(j)\int_0^t f_1(t-\tau)2qf_1(\tau+j-1)d\tau, \qquad 0 \le t < 1,$$

and, for instance, if $\mu^2 = r^2 - \omega^2 > 0$, then

$$f_0(t) = \frac{\exp(-rt)}{\mu} r\mathrm{sh}(\mu t) + \mu\mathrm{ch}(\mu t), \qquad f_1(t) = \frac{\exp(-rt)}{\mu}\mathrm{sh}(\mu t).$$

We can easily calculate $f_0(t)$ and $f_1(t), 0 \le t < 1$, when $r \le \omega$. It follows from (34) that (35) is approximately null-controllable on the $[0, t_1], t_1 > 2$, if and only if

$$\operatorname{rank}\begin{bmatrix} \lambda & 1 & 0 \\ \omega + 2q\exp(-\lambda) + 2r & 0 & b \end{bmatrix} = 2.$$

Hence (36) is approximately null-controllable on the $[0, t_1], t_1 > 2$ if and only if $b \neq 0$. If we have obtained $b = 0$, we can take $b = \gamma$, where γ is an arbitrary small, and (36) with $b = \gamma$ will be approximately null-controllable on $[0, t_1]$, for all $t_1 > 2$. Since the theorem on approximate null-controllability by the linear approximation holds [19], (it is possible to prove this statement by applying the results of [19] to (35) and using the equivalence of approximate null-controllability and exact null-controllability for hereditary systems [20], [21]) (35) with b, obtained from (37), will be approximately (locally) null-controllable on $[0, t_1]$ for all $t_1 > 2$. We consider the obtained equation as the approximate solution of the identification problem. The solution of the obtained equation can differ little from that of (35) due to the smallness value of the ϵ in (35).

5. Conclusion. In the present paper we have investigated and proved an identifiability criterion represented by the observability concept for the distributed parameter system (1)–(3), where the operator A is not necessarily self-adjoint and the solution of this system is not necessarily expanded into a series for $t \ge 0$. The system with delays is investigated as an example of a distributed system where the operator A is not self-adjoint and the solution of this equation can be expanded into a series only for $t \ge nh$. We obtained an explicit formula for the solution of the formulated identification problem.

In the present paper, as well as in [3], only the case $u(t) \in R^1$ is considered. This restricts the application of Theorems 3.3, 3.4, and 4.3. However, it is possible to apply these theorems for multi-input equations (1)–(3).

Let us consider term $GBu(t)$ instead of term $Gbu(t)$ in (1)–(3), where $u(t) \in R^r, r > 1$, and $B : R^r \to Z$ is the linear bounded operator; that is, $Bu = \sum_{j=1}^r b_j u_j$ for all $u = \mathrm{col}(u_1, u_2, \ldots, u_r), b_j \in Z, j = 1, 2, \ldots, r$. Since the control object acts with the different control functions $u(t)$, for each natural $k, 1 \le k \le r$, it is possible to

set $u_k(t) \not\equiv 0, u_j(t) \equiv 0$ on $[0, t_1], j = 1, \ldots, r, j \neq k$ and to measure a corresponding output $y(t)$. Using Theorems 3.3, 3.4, and 4.3, we can find each vector $b_k, k = 1, 2, \ldots, r$.

The identification problem for operator A is not investigated in the present paper. This problem is essentially more general and it was considered for a linear one-dimensional parabolic partial differential equation [22].

The illustrative example concerning the electro-mechanical nonlinear control system described by Minorsky's equation is investigated. In this problem we really found the linear approximation of Minorsky's equation, which solves the formulated identification problem.

Formula (37) is the main tool for the above purpose. In the authors' opinions, it is interesting to obtain the solutions of nonlinear systems with small nonlinearity, like Minorsky's equation, as an expansion into a series with respect to a small parameter. One method of such expansion is called Poincare's method and it is developed and applied to obtain stationary and transient solutions of ordinary differential equations [23], [24]. This expansion may be used instead of (37) in the identification problem.
